Absolute Maximum Ratings

Stresses above the ratings listed below can cause permanent damage to the 932S890C. These ratings, which are standard values for IDT commercially rated parts, are stress ratings only. Functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods can affect product reliability. Electrical parameters are guaranteed only over the recommended operating temperature range.

[2] Single-ended measurement at crossing point. Value is maximum – minimum over all time. DC value of common mode is not important due to the blocking cap.

[3] Minimum Frequency is a result of 0.5% down spread spectrum

[4] Differential measurement through the range of ±100 mV, differential signal must remain monotonic and within slew rate spec when crossing through this region.

[5] Defined as the total variation of all crossing voltages of CLK rising and CLK# falling. Matching applies to rising edge rate of CLK and falling edge of CLK#. It is measured using a +/-75mV window centered on the average cross point where CLK meets CLK#.

[6] Max difference of t_{CYCLE} between any two adjacent cycles.

[7] Accumulated tjc over a 10 µs time period, measured with JIT2 TIE at 50ps interval.

[8] VD(PK-PK) is the overall magnitude of the differential signal.

[9] VD(min) is the amplitude of the ring-back differential measurement, guaranteed by design, that ring-back will not cross 0V VD. VD(max) is the largest amplitude allowed.

[10] The difference in magnitude of two adjacent VD_DC measurements. VD_DC is the stable post overshoot and ring-back part of the signal.

[11] All Long Term Accuracy and Clock Period specifications are guaranteed assuming that REFOUT is at 14.31818MHz

[3] Vxabs is defined as the voltage where CLK = CLK#

[4] Only applies to the differential rising edge (CLK rising and CLK# falling)

[5] Defined as the total variation of all crossing voltages of CLK rising and CLK# falling. Matching applies to rising edge rate of CLK and falling edge of CLK#. It is measured using a +/-75mV window centered on the average cross point where CLK meets CLK#.

[6] All Long Term Accuracy and Clock Period specifications are guaranteed assuming that REFOUT is at 14.31818MHz

[7] Applicable to all SRC outputs. See http://www.pcisig.com for complete specs. Guaranteed by design and characterization, not tested in production.

[8] SRC outputs are divided into two banks, odd and even. The odd bank skew window is 200 ps. The even bank skew window is 200ps. The skew between the even and odd banks is intentionally set at 1375ps.
