3. Errata Details

3.1 Incorrect 32 mV and 64 mV Hysteresis Operation with ACMPH

3.1.1. Effect

ACMPH

3.1.2. Conditions

$V_{DD} > 4.6$ V, with hysteresis 32 mV at V_{REF} range 1.344 V to 2.016 V.

$V_{DD} > 3.6$ V, with hysteresis 32 mV at V_{REF} range 1.344 V to 1.504 V.

$V_{DD} > 4.6$ V, with hysteresis 64 mV at V_{REF} range 1.376 V to 1.664 V.

3.6 V $< V_{DD} < 4.6$ V, with hysteresis 64 mV only when V_{REF} is set to 1.376 V.

3.1.3. Technical Description

If using ACMPH with 32 mV or 64 mV hysteresis, ACMPH output could be glitching when ACMPH positive input (IN+) is close to the negative input (IN-). It can happen when V_{DD} is higher than 4.6 V, V_{REF} is in a range from 1.344 V to 2.016 V for 32 mV hysteresis, and V_{REF} is in a range from 1.376 V to 1.664 V for 64 mV hysteresis.

2. Waveform at $V_{REF} = 1504 \text{ mV}$, hysteresis is equal to 32 mV (zoomed rising edge).

Figure 3. Zoomed ACMPH Output during Glitching

3.1.4. Workaround

Use the deglitch filter connected to the ACMPH output.

Avoid conditions described in paragraph 3.1.2.

Decrease the reference to avoid conditions described in paragraph 3.1.2 at $IN-$ and add the $IN+$ gain to keep the needed threshold.

3.2 ACMPH Erroneous Behavior when Used with Wake-Sleep Controller for Certain V_{REF} Selection

3.2.1. Effect

ACMPH

3.2.2. Conditions

ACMPH is used with the macrocell CNT0 configured as a wake-sleep controller (WS Ctrl).

WS Ctrl Short wake time mode is selected, for V_{REF} range 1.312 V to 1.440 V.

WS Ctrl Normal wake time is selected, for two V_{REF} ranges 0.832 V to 0.896 V and 1.312 V to 1.440 V.

3.2.3. Technical Description

When WS Ctrl is used for controlling the power ON/OFF of the analog macrocell ACMP for power saving, ACMPH shows erroneous behavior for certain V_{REF} selections. V_{REF} transient settling error is observed for both WS Ctrl Wake time modes, Short wake time, and Normal wake time (selections under CNT0 settings).

Channel 3 (magenta /3rd line) - PIN#14 (ACMPH OUT)

1. Waveform at $V_{REF} = 1312$ mV, hysteresis is equal to 32 mV.

2. Waveform at Short wake time mode, $V_{REF} = 1312$ mV, hysteresis is equal to 32 mV (zoomed rising edge).

3. Waveform at Normal wake time mode, $V_{REF} = 1312 \text{ mV}$, hysteresis is equal to 32 mV (zoomed rising edge).

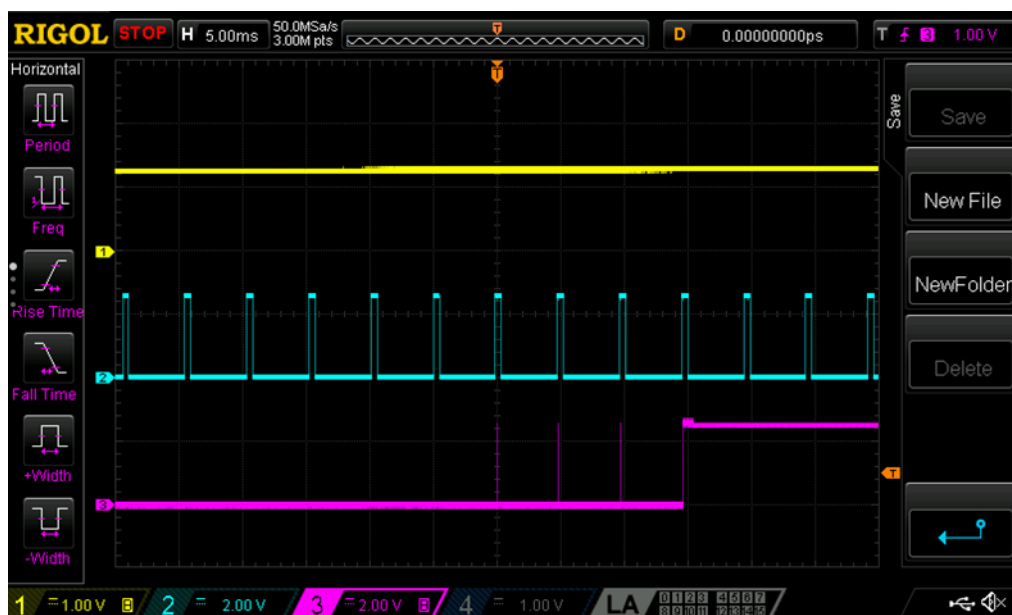

Figure 7. Zoomed ACMPH Output during Glitching at Normal Wake Time Mode

3.2.4. Workaround

1. If ACMPH is used with WS Ctrl counter, CNT0, avoid conditions described in paragraph 3.2.2.
2. Decrease the reference to avoid conditions described in paragraph 3.2.2 at IN- and add the IN+ gain to keep the needed threshold.

3.3 Abnormal ACMPH Behavior

3.3.1. Effect

GPIO5, ACMPH

3.3.2. Conditions

The ACMPH IN+ source is set to VDD and GPIO5 is set to Analog IO or 3-State Output

3.3.3. Technical Description

When GPIO5 is configured as “Analog Input/Output”, “Digital Input/Output in Analog In Mode”, or “3-State Output” mode, ACMPH behavior may be abnormal when the ACMPH IN+ source is set to VDD.

ACMPH has an input MUX which selects the IN+ source for the comparator. The MUX Options are shown in [Table 1](#).

Table 1. ACMPH Input Options

ACMPH IN+ MUX Options	
ACMPH	GPIO5 VDD

In Go Configure GreenPAK design software, the input source is selected by the IN+ source dropdown within the ACMP's properties window. When the input source is selected and ACMP is enabled, the analog switch connects the source to the ACMP's IN+ port.

GPIO5 can be repurposed as Digital IO if the ACMP is disabled or if another input source is selected for the ACMP by the IN+ input MUX. Whenever GPIO5 input mode is configured as an “Analog IO” in accordance with the register definition below, then the ACMP behavior may be abnormal if the ACMP is enabled and connected to another input source.

Table 2. GPIO5 Input/Output Mode Configurations

Byte	Register Bit	Signal Function	Register Bit Definition
GPIO5			
0x6A	849:848	Input Mode Configuration	00: Digital without Schmitt Trigger 01: Digital with Schmitt Trigger 10: Low Voltage Digital In 11: Analog IO
	851:850	Output Mode Configuration	00: Push-Pull 1x / 3-State Output 1x 01: Push-Pull 2x / 3-State Output 2x 10: Open-Drain 1x 11: Open-Drain 2x

There are 3 standard GPIO5 settings that use the “Analog IO” configuration: Analog input/output, Digital input/output (with “Input mode” set to Analog input), and Digital output (with “Output mode” set to 1x/2x 3-State Output). The first setting is reserved for use with the ACMP, but the other two settings use the “Analog IO” configuration as a high-impedance input.

For example, Figure 8 shows the GreenPAK configured with GPIO5 as a Digital Input/Output (with “Input mode” set to Analog input and “Output mode” set to 1x Push Pull) with a 1M pull-down resistor. GPIO is being used as a digital input and is connected to the OE input of GPIO5. This is used to determine the input/output mode:

1. when OE Input is LOW, then GPIO5 is acting as Analog Input.
2. when OE Input is HIGH, then GPIO5 is acting as 1x Push Pull Output.

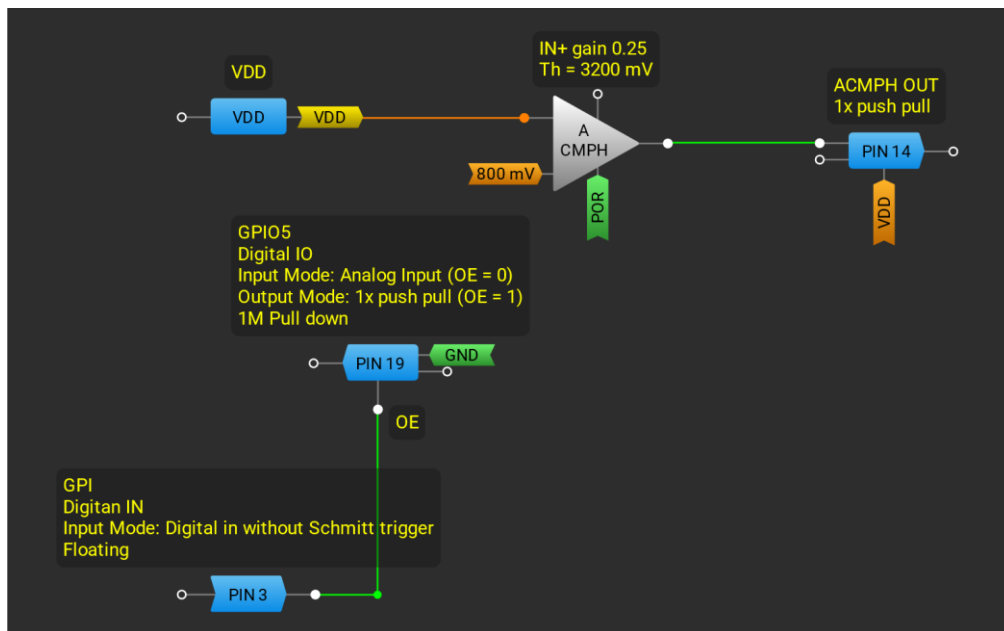

Figure 8. Testing Design

Figure 9 shows that when GPIO5 is in Analog input mode then abnormal ACMPH behavior.

D10 – PIN#3 (GPI)

D11 – PIN#14 (ACMPH OUT)

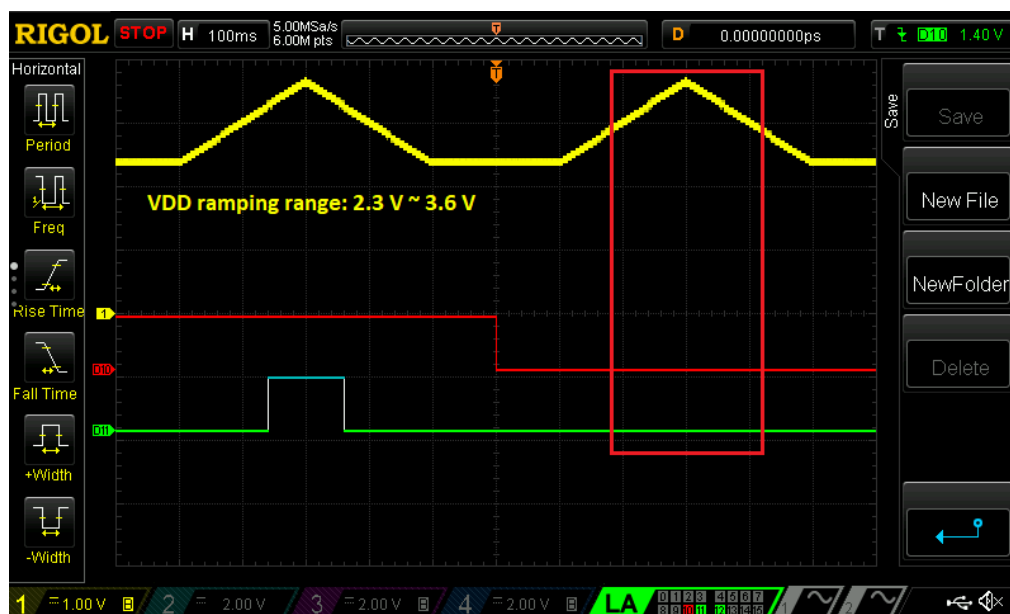

Figure 9. ACMP Output Behavior

3.3.4. Workaround

There is no workaround for this behavior. With this in mind, the GPIO5 should not be used as Digital IO (with “Input mode” set to Analog input) or as digital outputs (with “Output mode” set to 1x/2x 3-State Output) if the ACMPH is enabled and connected to another input source.
