In device controller mode, a resume interrupt is generated when the device state is the Suspend state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the Suspend state is detected by means of the resume interrupt.

In host controller mode, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

### 26.3.3.9 OVRCCR interrupt

An OVRCCR interrupt is generated when the USB\_OVRCURA pin level has changed. The levels of the USB\_OVRCURA pins can be checked in the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent is detected using the OVRCCR interrupt.

### 26.3.3.10 BCHG interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether a peripheral device is connected and can also be used to detect a remote wakeup in host controller mode. The BCHG interrupt is generated in both host and device controller modes.

### 26.3.3.11 DTCH interrupt

A DTCH interrupt occurs when a USB bus disconnect is detected in host controller mode. The USBFS detects bus disconnects in compliance with the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software. The pipes enter the wait state for a bus connection to the port, waiting for an ATTCH interrupt to occur. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt is detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

### 26.3.3.12 SACK interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet is received from the peripheral device in host controller mode. The SACK interrupt can be used to confirm that the setup transaction is successfully complete.

### 26.3.3.13 SIGN interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet is not correctly received from the peripheral device three consecutive times in host controller mode. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

### 26.3.3.14 ATTCH interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5  $\mu$ s in host controller mode. To be more specific, an ATTCH interrupt is detected on any of the following conditions:

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5  $\mu$ s
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5  $\mu$ s

### 26.3.3.15 EOFERR interrupt

An EOFERR interrupt occurs when the USBFS detects that communication is not complete at the EOF2 timing defined in the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software, and the port must be re-enumerated. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt is detected to 0
- Puts the port in which the EOFERR interrupt is generated into the idle state

### 26.3.3.16 Portable Device Detection Interrupt

The USBFS sets the INTSTS1.PDDETINT flag to 1 on detecting a portable device and generates the portable device detection interrupt. When the portable device detection interrupt is generated, use software to repeat reading the BCCTRL1.PDDETSTS flag until the same value is read three or more times, and perform debounce processing.

### 26.3.4 Pipe Control

[Table 26.19](#) lists the pipe settings for the USBFS. USB data transfer is performed through logical pipes that the software associates with endpoints. The USBFS provides 10 pipes that are used for data transfer. Set up the pipes based on your system specifications.

**Table 26.19 Pipe settings**

| Register name       | Bit name | Setting                                            | Notes                                                                                                                                           |
|---------------------|----------|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| DCPCFG<br>PIPECFG   | TYPE     | Transfer type                                      | Pipes 1 to 9: Settable                                                                                                                          |
|                     | BFRE     | BRDY interrupt mode                                | Pipes 1 to 5: Settable                                                                                                                          |
|                     | DBLB     | Double buffer select                               | Pipes 1 to 5: Settable                                                                                                                          |
|                     | DIR      | Transfer direction select                          | IN or OUT settable                                                                                                                              |
|                     | EPNUM    | Endpoint number                                    | Pipes 1 to 9: Settable<br>A value other than 0000b must be set when the pipe is used.                                                           |
|                     | SHTNAK   | Selects disabled state for pipe when transfer ends | Pipes 1 and 2: Settable only for bulk transfers<br>Pipes 3 to 5: Settable                                                                       |

| PIPEnTRN            | TRNCNT   | Transaction counter                                | Pipes 1 to 5: Settable                                                                                                                          |

### 26.3.4.1 Pipe control register switching procedures

The following bits in the pipe control registers can be changed only when USB communication is prohibited (PID = NAK).

Do not change the following registers and bits when USB communication is enabled (PID = BUF):

- Bits in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Bits in PIPECFG, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPEnCTR
- Bits in PIPEnTRE and PIPEnTRN

To set these bits when USB communication is enabled (PID = BUF):

1. A request to change the bits in the pipe control register occurs.
2. Set the PID[1:0] bits associated with the pipe to NAK.
3. Wait until the associated PBUSY bit clears to 0.
4. Set the bits in the pipe control register.

The following bits in the pipe control registers can be changed only when the selected pipe information is not set in the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Do not set the following registers when the CURPIPE[3:0] bits are set:

- Bits in DCPCFG and DCPMAXP
- Bits in PIPECFG, PIPEMAXP and PIPEPERI

To change pipe information, you must set the CURPIPE[3:0] bits in the port select registers to a pipe other than the one to be changed. For the DCP, the buffer must be cleared using the BCLR bit in the Port Control Register after the pipe information is changed.

### 26.3.4.2 Transfer types

The PIPECFG.TYPE[1:0] bits specify the following transfer types for each pipe:

- DCP: No setting is necessary (fixed at control transfer)
- Pipes 1 and 2: Set to bulk or isochronous transfer
- Pipes 3 to 5: Set to bulk transfer
- Pipes 6 to 9: Set to interrupt transfer

### 26.3.4.3 Endpoint number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to 15.

- DCP: No setting is necessary (fixed at endpoint 0)
- Pipes 1 to 9: Select and set the endpoint numbers from 1 to 15 so that the combination of the PIPECFG.DIR and EPNUM[3:0] bits is unique

### 26.3.4.4 Maximum packet size setting

Specify the maximum packet size for each pipe in the DCPMAXP.MXPS[6:0] and PIPEMAXP.MXPS[9:0] bits. The DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined in the USB 2.0 specification. For pipes 6 to 9, the maximum packet size is 64 bytes. Set the maximum packet size as follows before starting a transfer (PID = BUF):

- DCP: Set to 8, 16, 32, or 64
- Pipes 1 to 5: Set to 8, 16, 32, or 64 for bulk transfers
- Pipes 1 and 2: Set between 1 and 256 for isochronous transfers
- Pipes 6 to 9: Set between 1 and 64

### 26.3.4.5 Transaction counter for pipes 1 to 5 in the receiving direction

When the specified number of transactions is complete in the data packet receiving direction, the USBFS recognizes that the transfer ended. Two transaction counters are provided: one is the PIPEnTRN register, which specifies the number of transactions to be executed, and the other is the current counter, which internally counts the number of executed transactions. If the PIPECFG.SHTNAK bit is set to 1, when the current counter value matches the specified number of transactions, the associated PIPEnCTR.PID[1:0] bits are set to NAK and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The data read from PIPEnTRN differs depending on the PIPEnTRE.TRENB setting as follows:

- The TRENB bit = 0: Specified transaction counter value can be read
- The TRENB bit = 1: Current counter value indicating the internally counted number of executed transactions can be read

The following constraints apply when working with the TRCLR bit:

- If the transactions are being counted and PID = BUF, the current counter cannot be cleared
- If there is any data left in the buffer, the current counter cannot be cleared

### 26.3.4.6 Response PID

Specify the response PID for each pipe in the PID[1:0] bits in DCPCTR and PIPEnCTR. This section describes the USBFS operation with different response PID settings.

#### (1) Software response PID settings in host controller mode

Select the response PID to specify the execution of transactions as follows:

- NAK setting: Using pipes is disabled and no transactions are executed
- BUF setting: Transactions are executed based on the FIFO buffer state:
  - OUT direction: An OUT token is issued if the FIFO buffer contains transmit data.
  - IN direction: An IN token is issued if the FIFO buffer is not full and can receive data.
- STALL setting: Using pipes is disabled and no transactions are executed

Note: Use the DCPCTR.SUREQ bit to execute setup transactions for the DCP.

#### (2) Software response PID settings in device controller mode

Select the response PID to respond as follows to transactions from the host:

- NAK setting: A NAK response is returned to all generated transactions
- BUF setting: A response is returned to transactions based on the FIFO buffer
- STALL setting: A STALL response is returned to all generated transactions

Note: For setup transactions, an ACK response is always returned, regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

Sections (3) and (4) describe situations in which the USBFS writes to the PID[1:0] bits because of specific transaction results.

#### (3) Hardware response PID settings in host controller mode

- NAK setting: PID = NAK is set in the following cases, and issuing of tokens is automatically stopped:
  - When a non-isochronous transfer is performed and an NRDY interrupt is generated  
(For details, see [section 26.3.3.2. NRDY interrupt](#).)
  - If a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
  - If transaction counting ends when the SHTNAK bit is set to 1 for bulk transfers
- BUF setting: The USBFS does not write this setting.

- STALL setting: PID = STALL is set in the following cases, and issuing of tokens is automatically stopped:
  - When STALL is received in response to a transmitted token
  - When a received data packet exceeds the maximum packet size

#### (4) Hardware response PID settings in device controller mode

- NAK setting: PID = NAK is set in the following cases, and a NAK response is returned to transactions:
  - When the setup token is received normally (DCP only)
  - If transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
- BUF setting: There is no BUF writing by the USBFS.
- STALL setting: PID = STALL is set in the following cases, and a STALL response is returned to transactions:
  - When a received data packet exceeds the maximum packet size
  - When a control transfer sequence error is detected (DCP only)

#### 26.3.4.7 Data PID sequence bit

The USBFS automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON bit in DCPCTR and PIPEnCTR. When data is transmitted, the sequence bit toggles on ACK handshake reception. When data is received, the sequence bit toggles on ACK handshake transmission. The SQCLR bit in DCPCTR and the SQSET bit in PIPEnCTR can be used to change the data PID sequence bit.

In device controller mode when control transfers are used, the USBFS automatically sets the sequence bit for stage transitions. DATA1 is returned when the setup stage ends. The sequence bit is not referenced and PID = DATA1 is returned in the status stage. Therefore, no software settings are required. However, in host controller mode when control transfers are used, the sequence bit must be set by software for the stage transitions.

For ClearFeature requests for transmission or reception, the data PID sequence bit must be set by software in both host and device controller modes.

#### 26.3.4.8 Response PID = NAK function

The USBFS provides a function for disabling pipe operation (PID response = NAK) when the final data packet of a transaction is received. The USBFS automatically distinguishes this based on reception of a short packet or the transaction counter. Enable this function by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation is disabled, the software must enable the pipe again (PID response = BUF).

The response PID = NAK function can be used only for bulk transfers.

#### 26.3.4.9 Auto response mode

For bulk transfer pipes (1 to 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (PIPECFG.DIR = 0), OUT-NAK mode is invoked, and during an IN transfer (DIR = 1), null auto response mode is invoked.

#### 26.3.4.10 OUT-NAK mode

For bulk OUT transfer pipes, NAK is returned in response to an OUT token, and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To transition from normal mode to OUT-NAK mode, specify OUT-NAK mode while pipe operation is disabled (PID[1:0] = 00b for NAK response). Next enable pipe operation (PID[1:0] = 01b for BUF response), on which OUT-NAK mode becomes valid. If an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To transition from OUT-NAK mode to normal mode, cancel OUT-NAK mode while pipe operation is disabled (NAK). Next enable pipe operation (BUF). In normal mode, reception of OUT data is enabled.

### 26.3.4.11 Null auto response mode

For bulk IN transfer pipes, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To transition from normal mode to null auto response mode, specify null auto response mode while pipe operation is disabled (response PID = NAK). Next enable pipe operation (response PID = BUF) on which null auto response mode becomes valid. Before setting null auto response mode, check that PIPEnCTR.INBUFM = 0, because the mode can be set only when the buffer is empty. If the INBUFM bit is 1, empty the buffer using the PIPEnCTR.ACLRM bit. Do not write data from the FIFO port while a transition to null auto response mode is being made.

To transition from null auto response mode to normal mode, keep pipe operation disabled (response PID = NAK) for the period of the zero-length packet transmission (about 10  $\mu$ s) before canceling the null auto response mode. In normal mode, data can be written from the FIFO port, so packet transmission to the host is enabled by enabling pipe operation (response PID = BUF).

### 26.3.5 FIFO Buffer

The USBFS provides a FIFO buffer for data transfers, and it manages the memory area used for each pipe. The FIFO buffer has two states depending on whether the access right is assigned to the system (CPU side) or the USBFS (SIE side).

#### (1) Buffer status

Table 26.20 and Table 26.21 show the buffer status in the USBFS. The FIFO buffer status can be confirmed using the DCPCTR.BSTS and PIPEnCTR.INBUFM bits. The transfer direction for the FIFO buffer can be specified in either the PIPECFG.DIR or CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM bit is valid for pipes 1 to 5 in the transmitting direction.

When a transmitting pipe uses double buffering, the software can read the BSTS bit to monitor the FIFO buffer status on the CPU side and the INBUFM bit to monitor the FIFO buffer status on the SIE side. When write access to the FIFO port by the CPU or DMA/DTC is slow and the buffer empty status cannot be determined using the BEMP interrupt, the software can use the INBUFM bit to confirm the end of transmission.

**Table 26.20 Buffer status indicated in the BSTS bit**

| ISEL or DIR                | BSTS | FIFO buffer status                                                                                                                                                                                       |
|----------------------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 (receiving direction)    | 0    | There is no received data, or data is being received.<br>Reading from the FIFO port is disabled.                                                                                                         |
| 0 (receiving direction)    | 1    | There is received data, or a zero-length packet is received.<br>Reading from the FIFO port is allowed.<br>When a zero-length packet is received, reading is not possible and the buffer must be cleared. |
| 1 (transmitting direction) | 0    | Transmission has not completed.<br>Writing to the FIFO port is disabled.                                                                                                                                 |
| 1 (transmitting direction) | 1    | Transmission is complete.<br>CPU write is allowed.                                                                                                                                                       |

**Table 26.21 Buffer status indicated in the INBUFM bit**

| DIR                        | INBUFM  | FIFO buffer status                                                                |
|----------------------------|---------|-----------------------------------------------------------------------------------|
| 0 (receiving direction)    | Invalid | Invalid                                                                           |
| 1 (transmitting direction) | 0       | Transmission is complete.<br>There is no data waiting to be transmitted.          |
| 1 (transmitting direction) | 1       | The FIFO port has written data to the buffer.<br>There is data to be transmitted. |

### 26.3.6 FIFO Buffer Clearing

Table 26.22 shows the methods for clearing the FIFO buffer. The FIFO buffer can be cleared using BCLR bit in the port control register, DnFIFOSEL.DCLRM, or the PIPEnCTR.ACLRM bit.

Single or double buffering can be selected for pipes 1 to 5 in the PIPECFG.DBLB bit.

**Table 26.22 Buffer clearing methods**

| FIFO buffer clearing mode | Clearing FIFO buffer on the CPU side | Mode for automatically clearing the FIFO buffer after reading the specified pipe data | Auto buffer clear mode for discarding all received packets |
|---------------------------|--------------------------------------|---------------------------------------------------------------------------------------|------------------------------------------------------------|
| Register used             | CFIFOCTR<br>DnFIFOCTR                | DnFIFOSEL                                                                             | PIPEnCTR                                                   |
| Bit used                  | BCLR                                 | DCLRM                                                                                 | ACLRM                                                      |
| Clearing condition        | Cleared by writing 1                 | 1: Mode valid<br>0: Mode invalid                                                      | 1: Mode valid<br>0: Mode invalid                           |

### (1) Auto buffer clear mode function

The USBFS discards all received data packets if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet is received, the ACK response is returned to the host controller. The auto buffer clear mode function can only be set in the FIFO buffer reading direction.

Setting the ACLRM bit to 1 and then to 0 clears the FIFO buffer of the selected pipe regardless of the access direction. An access cycle of at least 100 ns is required for the internal hardware sequence processing between ACLRM = 1 and ACLRM = 0.

## 26.3.7 FIFO Port Functions

Table 26.23 shows the settings for the FIFO port functions. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, set the BVAL flag in the port control register to end writing. To send a zero-length packet, use the BCLR bit to clear the buffer, and then set the BVAL flag to end writing.

In reading, reception of new packets is automatically enabled when all data is read. Data cannot be read when a zero-length packet is received (DTLN[8:0] = 0), so the buffer must be cleared with the BCLR bit. The length of the receive data can be confirmed in the DTLN[8:0] bits in the port control register.

**Table 26.23 FIFO port function settings**

| Register name                        | Bit name | Description                                                                                     |
|--------------------------------------|----------|-------------------------------------------------------------------------------------------------|
| CFIFOSEL,<br>DnFIFOSEL<br>(n = 0, 1) | RCNT     | Selects DTLN[11:0] read mode                                                                    |
|                                      | REW      | FIFO buffer rewind (re-read, rewrite)                                                           |
|                                      | DCLRM    | Automatically clears receive data for a specified pipe after the data is read (only for DnFIFO) |
|                                      | DREQE    | Enables DMA/DTC transfers (only for DnFIFO)                                                     |
|                                      | MBW      | FIFO port access bit width                                                                      |
|                                      | BIGEND   | Selects FIFO port endian                                                                        |
|                                      | ISEL     | FIFO port access direction (only for DCP)                                                       |
|                                      | CURPIPE  | Selects the current pipe                                                                        |
| CFIFOCTR,<br>DnFIFOCTR<br>(n = 0, 1) | BVAL     | Ends writing to the FIFO buffer                                                                 |
|                                      | BCLR     | Clears the FIFO buffer on the CPU side                                                          |
|                                      | DTLN     | Checks the length of receive data                                                               |

### (1) FIFO port selection

Table 26.24 shows the pipes that can be selected with the different FIFO ports. The pipe to be accessed must be selected in the CURPIPE[3:0] bits in the port select register. After the pipe is selected, the software must check whether the written value can be read correctly from the CURPIPE[3:0] bits. (If the previous pipe number is read, it indicates that the USBFS is modifying the pipe.) Next, the software checks that the FRDY bit in the port control register is 1.

In addition, the software must specify the bus width to be accessed in the MBW bit in the port select register. The FIFO buffer access direction conforms to the PIPECFG.DIR setting. For the DCP only, the ISEL bit in the port select register determines the direction.

**Table 26.24** FIFO port access by pipe

| Pipe         | Access method  | Ports that can be used                                                                                         |
|--------------|----------------|----------------------------------------------------------------------------------------------------------------|
| DCP          | CPU access     | CFIFO port register                                                                                            |
| Pipes 1 to 9 | CPU access     | <ul style="list-style-type: none"> <li>• CFIFO port register</li> <li>• D0FIFO/D1FIFO port register</li> </ul> |
|              | DMA/DTC access | D0FIFO/D1FIFO port register                                                                                    |

## (2) REW bit

It is possible to temporarily stop access to a pipe currently being accessed, access a different pipe, and then continue processing for the first pipe again. The REW bit in the port select register is used for this processing.

If a pipe is selected in the CURPIPE[3:0] bits in the port select register with the REW bit set to 1, the pointer used for reading from and writing to the FIFO buffer is reset, and reading or writing can be carried out from the first byte. If a pipe is selected with 0 set for the REW bit, data can be read and written in continuation from the previous selection, without the pointer being reset.

To access the FIFO port, the software must check that the FRDY bit in the port control register is 1 after selecting a pipe.

## 26.3.8 DMA Transfers (D0FIFO and D1FIFO Ports)

### (1) Overview of DMA transfers

For pipes 1 to 9, the FIFO port can be accessed using the DMAC. When buffer access for a pipe targeted for DMA transfer is enabled, a DMA transfer request is issued.

Select the unit of transfer to the FIFO port in the DnFIFOSEL.MBW bit, and select the pipe targeted for the DMA transfer in the DnFIFOSEL.CURPIPE[3:0] bits. Do not change the selected pipe during the DMA transfer.

### (2) DnFIFO auto clear mode (D0FIFO and D1FIFO port reading direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USBFS automatically clears the FIFO buffer of the selected pipe when reading of data from the FIFO buffer is complete.

Table 26.25 shows the packet reception and FIFO buffer clearing processing by software for each of the settings. As shown in the table, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA transfers without involving software.

The DnFIFO auto clear mode can only be set in the FIFO buffer reading direction.

**Table 26.25** Packet reception and FIFO buffer clearing processing by software

| Buffer status when packet is received | Register setting     |                      |                      |                      |
|---------------------------------------|----------------------|----------------------|----------------------|----------------------|
|                                       | DCLRM = 0            |                      | DCLRM = 1            |                      |
|                                       | BFRE = 0             | BFRE = 1             | BFRE = 0             | BFRE = 1             |
| Buffer full                           | No clearing required | No clearing required | No clearing required | No clearing required |
| Zero-length packet reception          | Clearing required    | Clearing required    | No clearing required | No clearing required |
| Normal short packet reception         | No clearing required | Clearing required    | No clearing required | No clearing required |
| Transaction count end                 | No clearing required | Clearing required    | No clearing required | No clearing required |

## 26.3.9 Control Transfers Using the DCP

The DCP is used for data transfers in the control transfer data stage. The FIFO buffer of the DCP is a 64-byte single buffer with a fixed area for both control reads and control writes. The FIFO buffer can be accessed only through the CFIFO port.

### 26.3.9.1 Control transfers in host controller mode

#### (1) Setup stage

The USQREQ, USBVAL, USBINDEX, and USBLENG registers are used to transmit USB requests for setup transactions. Writing the setup packet data to the registers and then writing 1 to the DCPCTR.SUREQ bit transmits the specified data for the setup transaction. On completion of the transaction, the SUREQ bit clears to 0. Do not change these USB request registers while SUREQ = 1.

When an attached function device is detected, the software must issue the first setup transaction for the device using this sequence with the DCPMAXP.DEVSEL[3:0] bits cleared to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.

When an attached function device is shifted to the Address state, the software must issue setup transactions using this sequence with the assigned USB address set in the DEVSEL[3:0] bits and the bits in DEVADDn corresponding to the specified USB address set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in DEVADD2. When PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in DEVADD5.

When the setup transaction data is sent, an interrupt request is generated based on the response from the peripheral device (SIGN or SACK bit in INTSTS1). This interrupt request allows the software to check the setup transaction result.

A DATA0 data packet (USB request) for the setup transaction is always transmitted regardless of the status of the DCPCTR.SQMON bit.

#### (2) Data stage

The data stage is used to transfer data using the DCP FIFO buffer.

Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit. Specify the transfer direction in the DCPCFG.DIR bit.

For the first data packet of the data stage, the data PID must be transferred as DATA1. Set data PID = DATA1 in the DCPCTR.SQSET bit and set the PID bits = BUF. Completion of data transfer is detected using the BRDY or BEMP interrupt.

For control write transfers, when the number of data bytes to be sent is an integer multiple of the maximum packet size, the software must send a zero-length packet at the end.

#### (3) Status stage

The status stage is used for zero-length packet data transfers in the reverse direction of the data stage. As in the data stage, data is transferred using the DCP FIFO buffer. Transactions are executed using the same procedure as the data stage.

Data packets in the status stage must be transmitted and received with the data PID set to DATA1 using the DCPCTR.SQSET bit.

When a zero-length packet is received, check the receive-data length in the CFIFOCTR.DTLN[8:0] bits after a BRDY interrupt is generated, and then clear the FIFO buffer using the BCLR bit.

### 26.3.9.2 Control transfers in device controller mode

#### (1) Setup stage

The USBFS sends an ACK response to a normal setup packet for the USBFS. The USBFS operates in the setup stage as follows:

On receiving a new setup packet, the USBFS sets the following bits:

- Sets the INTSTS0.VALID bit to 1
- Sets the DCPCTR.PID[1:0] bits to NAK
- Sets the DCPCTR.CCPL bit to 0

When the USBFS receives a data packet following a setup packet, it stores the USB request parameters in USBREQ, USBVAL, USBINDEX, and USBLENG.

Before performing the response processing for a control transfer, set the VALID flag to 0. When the VALID bit = 1, PID = BUF cannot be set, and the data stage cannot be terminated.

Using the VALID bit function, the USBFS can suspend a request being processed when it receives a new USB request during a control transfer and return a response to the latest request.

In addition, the USBFS automatically detects the direction bit (bmRequestType bit [8]) and the request data length (wLength) in the received USB request. It distinguishes between control read transfers, control write transfers, and no-data control transfers, and it controls stage transitions. For an incorrect sequence, a sequence error occurs in the control transfer stage transition interrupt, and the interrupt is reported to the software. For a diagram of the stage control by the USBFS, see [Figure 26.14](#).

## (2) Data stage

The DCP must be used to execute data transfers for received USB requests. Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit.

If the transfer data is larger than the size of the DCP FIFO buffer, execute the data transfer using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

## (3) Status stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to BUF.

After this setting is made, the USBFS automatically executes the status stage based on the data transfer direction determined at the setup stage. The procedure is as follows:

- For control read transfers
  - The USBFS receives a zero-length packet from the USB host and transmits an ACK response.
- For control write transfers and no-data control transfers
  - The USBFS transmits a zero-length packet and receives an ACK response from the USB host.

## (4) Control transfer auto response function

The USBFS automatically responds to a correct SET\_ADDRESS request. If any of the following errors occurs in the SET\_ADDRESS request, a response from the software is necessary.

- bmRequestType is not 0x00: Any transfer other than a control write transfer
- wIndex is not 0x00: Request error
- wLength is not 0x00: Any transfer other than a no-data control transfer
- wValue is larger than 0x7F: Request error
- INTSTS0.DVSQ[2:0] are 011b (Configured state): Control transfer of a device state error

For all requests other than the SET\_ADDRESS request, a response is required from the corresponding software.

### 26.3.10 Bulk Transfers (Pipes 1 to 5)

The FIFO buffer usage (single/double buffer setting) is configurable for bulk transfers. The USBFS provides the following functions for bulk transfers:

- BRDY interrupt function (PIPECFG.BFRE bit), see [section 26.3.3.1. BRDY interrupt](#)
- Transaction count function (PIPEnTRE.TRENB, TRCLR, and PIPEnTRN.TRNCNT[15:0] bits), see [section 26.3.4.5. Transaction counter for pipes 1 to 5 in the receiving direction](#)
- Response PID = NAK function (PIPECFG.SHTNAK bit), see [section 26.3.4.8. Response PID = NAK function](#)
- Auto response mode (PIPEnCTR.ATREPM bit), see [section 26.3.4.9. Auto response mode](#)

### 26.3.11 Interrupt Transfers (Pipes 6 to 9)

In device controller mode, the USBFS performs interrupt transfers based on the timing dictated by the host controller.

In host controller mode, the software can set the timing for issuing tokens using the interval counter.

### 26.3.11.1 Interval counter for interrupt transfers in host controller mode

Specify the transaction interval for interrupt transfers in the PIPEPERI.IITV[2:0] bits. The USBFS issues interrupt transfer tokens based on this interval.

#### (1) Counter initialization

The USBFS initializes the interval counter under the following conditions:

- Power-on reset  
This initializes the IITV[2:0] bits.
- FIFO buffer initialization using the PIPEnCTR.ACLRM bit:  
This does not initialize the IITV[2:0] bits, but does initialize the count value. Setting the PIPEnCTR.ACLRM bit to 0 starts counting from the value set in IITV[2:0].

The interval counter is not initialized in the following case:

- USB bus reset or USB suspended  
The IITV[2:0] bits are not initialized. Setting 1 to the DVSTCTR0.UACT bit starts counting from the value saved before entering the USB bus reset state or USB suspend state.

#### (2) Operation when tokens cannot be transmitted or received even on token generation

No token is generated in the following cases even at token generation time. In these cases, the USBFS tries to execute the transaction in the next interval.

- When the PID is set to NAK or STALL
- When the FIFO buffer is full at token transmit time in the receiving (IN) direction
- When there is no data to be transmitted in the FIFO buffer at token transmit time in the transmitting (OUT) direction

### 26.3.12 Isochronous Transfers (Pipes 1 and 2)

The USBFS provides the following functions for isochronous transfers:

- Notification of isochronous transfer error
- Interval counter specified in the PIPEPERI.IITV[2:0] bits
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function specified in the PIPEPERI.IFIS bit

#### 26.3.12.1 Error detection in isochronous transfers

The USBFS provides a function for detecting the errors described in this section, so that when errors occur in isochronous transfers, they can be controlled by software. [Table 26.26](#) and [Table 26.27](#) show the priority order for errors detected by the USBFS and the associated interrupts.

##### **PID errors**

- The PID value of the received packet is invalid.

##### **CRC errors and bit stuffing errors**

- A CRC error is found in a received packet or the bit stuffing is illegal.

##### **Maximum packet size exceeded**

- The data size of the received packet exceeds the specified maximum packet size.

##### **Overrun and underrun errors**

In host controller mode:

- The FIFO buffer is full at token transmit time in the IN (receiving) direction
- There is no data to be sent in the FIFO buffer at token transmit time in the OUT (transmitting) direction

In device controller mode:

- There is no data to be sent in the FIFO buffer at token receive time in the IN (transmitting) direction
- The FIFO buffer is full at token receive time in the OUT (receiving) direction

### Interval errors

In device controller mode, the following cases are treated as an interval error:

- Failure to receive an IN token in the interval frame during an isochronous IN transfer
- Failure to receive an OUT token in the interval frame during an isochronous OUT transfer

**Table 26.26 Error detection for token transmission and reception**

| Detection priority | Error                       | Generated interrupt and status                                                                                                                                                                                                                                |
|--------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                  | PID error                   | No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)                                                                                                                                                          |
| 2                  | CRC or bit stuffing error   | No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)                                                                                                                                                          |
| 3                  | Overflow or underflow error | An NRDY interrupt is generated to set the FRMNUM.OVRN bit to 1 in both host and device controller modes.<br>In device controller mode, a zero-length packet is transmitted in response to an IN token. No data packets are received in response to OUT token. |
| 4                  | Interval error              | An NRDY interrupt is generated in device controller mode. No interrupt is generated in host controller mode.                                                                                                                                                  |

**Table 26.27 Error detection for data packet reception**

| Detection priority | Error                              | Generated interrupt and status                                                                            |
|--------------------|------------------------------------|-----------------------------------------------------------------------------------------------------------|
| 1                  | PID error                          | No interrupts are generated (ignored as a corrupted packet)                                               |
| 2                  | CRC or bit stuffing error          | An NRDY interrupt is generated and the FRMNUM.CRCE bit sets to 1 in both host and device controller modes |
| 3                  | Maximum packet size exceeded error | A BEMP interrupt is generated and the PID[1:0] bits set to STALL in both host and device controller modes |

### 26.3.12.2 DATA-PID

In device controller mode, the USBFS responds to a received PID as follows:

#### (1) IN direction

- DATA0: Transmitted as data packet PID
- DATA1: Not transmitted
- DATA2: Not transmitted
- mData: Not transmitted

#### (2) OUT direction

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets ignored
- mData: Packets ignored

### 26.3.12.3 Interval counter

The isochronous transfer interval can be set in the PIPEPERI.IITV[2:0] bits. In device controller mode, the interval counter enables the functions as shown in [Table 26.28](#). In host controller mode, the USBFS generates the token issuance timing, and the interval counter operation is the same as that for interrupt transfers.

**Table 26.28 Interval counter functions in device controller mode**

| Transfer direction | Function                              | Conditions for detection                                                                               |
|--------------------|---------------------------------------|--------------------------------------------------------------------------------------------------------|
| IN                 | Transmit buffer flush                 | Failure to receive an IN token successfully in the interval frame during an isochronous IN transfer.   |
| OUT                | Notification of no reception of token | Failure to receive an OUT token successfully in the interval frame during an isochronous OUT transfer. |

The interval count is performed when an SOF is received or for interpolated SOFs, so the isochronism can be maintained even if an SOF is corrupt. The frame interval can be set to  $2^{IITV}$  frames.

**(1) Counter initialization in device controller mode**

The USBFS initializes the interval counter under the following conditions:

- Power-on reset  
This initializes the PIPEPERI.IITV[2:0] bits.
- FIFO buffer initialization using the ACLRM bit  
This does not initialize the IITV[2:0] bits, but does initialize the count value.

After the interval counter is initialized, the interval count starts under one of the following conditions when a packet is transferred successfully:

- An SOF is received after data is transmitted in response to an IN token when PID = BUF
- An SOF is received after data is received in response to an OUT token when PID = BUF

The interval counter is not initialized in the following conditions:

- When the PID[1:0] bits are set to NAK or STALL  
This does not stop the interval timer. The USBFS attempts the transaction in the next interval.
- When the USB bus is reset or USBFS is suspended  
This does not initialize the IITV[2:0] bits. When an SOF is received, the interval counter starts counting from the value set before SOF was received.

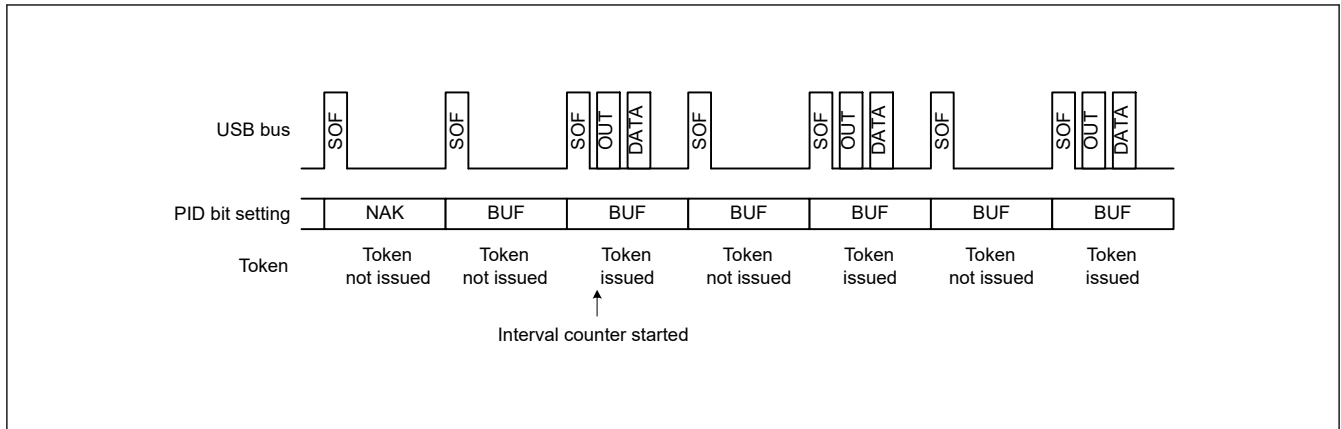

**(2) Interval counting and transfer control in host controller mode**

The USBFS controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bits settings. Specifically, the USBFS issues a token for a selected pipe once every  $2^{IITV}$  frames.

The USBFS starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits are set to BUF by software.

**Figure 26.15 Token issuance when IITV[2:0] = 0**

**Figure 26.16** Token issuance when IITV[2:0] = 1

When the selected pipe is set for isochronous transfers, the USBFS performs the following operation in addition to controlling the token issuance interval. The USBFS issues a token even when the NRDY interrupt generation condition is satisfied.

#### When the selected pipe is for isochronous IN transfers

The USBFS generates an NRDY interrupt when the USBFS issues an IN token but does not successfully receive a packet from a peripheral device (no response or packet error).

The USBFS sets the FRMNUM.OVRN bit to 1, generating an NRDY interrupt, when the time to issue an IN token occurs while the USBFS cannot receive data because the FIFO buffer is full, because the CPU or DMAC/DTC is too slow in reading data from the FIFO buffer.

#### When the selected pipe is for isochronous OUT transfers

The USBFS sets the OVRN bit to 1, generating an NRDY interrupt and transmitting a zero-length packet, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer, or because the CPU or DMAC/DTC is too slow in writing data to the FIFO buffer.

The token issuance interval is reset on any of the following conditions:

- When the USBFS is reset through a reset pin  
This initializes the IITV[2:0] bits.
- When the PIPEnCTR.ACLRM bit is set to 1 by software

### (3) Interval counting and transfer control in device controller mode

#### When the selected pipe is for isochronous OUT transfers

The USBFS generates an NRDY interrupt when it fails to receive a data packet within the interval set in the PIPEPERI.IITV[2:0] bits.

The USBFS also generates an NRDY interrupt when it fails to receive data because of a CRC error or other errors contained in the data packet or because the FIFO buffer is full.

The NRDY interrupt is generated on SOF packet reception. Even if the SOF packet is corrupted, internal interpolation allows the interrupt to be generated when the SOF packet is received. However, when the IITV[2:0] bits are set to a value other than 0, the USBFS generates an NRDY interrupt on receiving an SOF packet for every interval after interval counting starts.

When the PID[1:0] bits are set to NAK by software after starting the interval timer, the USBFS does not generate an NRDY interrupt on receiving an SOF packet.

The timing for starting interval counting depend on the IITV[2:0] setting as follows:

- When the IITV[2:0] bits = 0:  
Interval counting starts at the next frame after the software changes the PID[1:0] bits of the selected pipe to BUF.
- When the IITV[2:0] bits  $\neq$  0:

Interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe are changed to BUF.

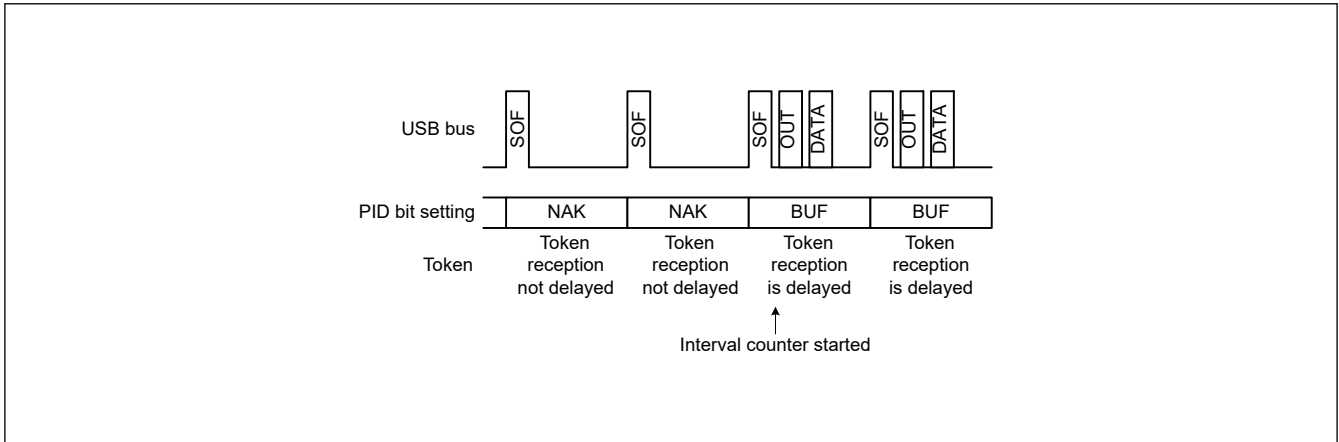

Figure 26.17 Relationship between frames and expected token reception when IITV[2:0] = 0

Figure 26.18 Relationship between frames and expected token reception when IITV[2:0] ≠ 0

**When the selected pipe is for isochronous IN transfers**

The PIPEPERL.IFIS bit must be 1 for this use case. When IFIS = 0, the USBFS transmits a data packet in response to a received IN token regardless of the PIPEPERL.IITV[2:0] setting.

When IFIS is 1 and there is data to be transmitted in the FIFO buffer, the USBFS clears the FIFO buffer when it fails to receive an IN token in the frame at the interval set in the IITV[2:0] bits.

The USBFS also clears the FIFO buffer when it fails to receive an IN token successfully because of a bus error, such as a CRC error, contained in the IN token.

The FIFO buffer is cleared on SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the FIFO buffer to be cleared when the SOF packet is received.

The timing to start interval counting depends on the IITV[2:0] setting, as with OUT transfers.

The interval is counted on any of the following conditions in device controller mode:

- When a hardware reset is applied to the USBFS (which also sets the IITV[2:0] bits to 000b)
- When the PIPEnCTR.ACLRm bit is set to 1 by software
- When the USBFS detects a USB bus reset

**(4) Transmit data setup for isochronous transfers in device controller mode**

With isochronous data transmission using the USBFS in device controller mode, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This isochronous transfer transmit data setup function can identify the frame that started transmission.

When the double buffering is used, transmission is only enabled for the buffer where data writing was completed first, even after the data write to both buffers is complete. Accordingly, even if multiple IN tokens are received, only the one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transferred and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 26.19 shows an example transmission using the isochronous transfer transmission data setup function when IITV[2:0] = 0 (every frame) is set.

Figure 26.19 Example data setup operation

(5) Transmit buffer flush for isochronous transfers in device controller mode

In device controller mode during isochronous data transmission, if the USBFS receives an SOF packet for the next frame without receiving an IN token in the interval frame, it operates as if the IN token is corrupt and clears the buffer that is enabled for transmission, putting that buffer in the writing enabled state.

When double buffering is used and writing to both buffers is complete, the cleared FIFO buffer is assumed to be the one where the data was transmitted in the interval frame, and transmission is enabled for the FIFO buffer that was not cleared on SOF packet reception.

The timing of the buffer flush function depends on the PIPEPERI.IITV[2:0] setting as follows:

- When IITV[2:0] = 0:
  - The buffer flush operation starts from the first frame after the pipe is enabled.
- When IITV[2:0] ≠ 0:
  - The buffer flush operation starts after the first normal transaction.

Figure 26.20 shows an example buffer flush. When an unanticipated token is received before the interval frame, the USBFS sends the write data or a zero-length packet as an underrun error, depending on the data setup status.

**Figure 26.20 Example buffer flush operation**

Figure 26.21 shows an example interval error occurrence. There are five types of interval errors, as shown in the figure. An interval error occurs at timing (A), and the buffer flush function is activated.

If an interval error occurs during an IN transfer, the buffer flush function is activated. If it occurs during an OUT transfer, an NRDY interrupt is generated. Use the FRMNUM.OVRN bit to distinguish between this and NRDY interrupts triggered by received packet errors and overrun errors.

For tokens that are shaded in the figure, responses are returned based on the FIFO buffer status.

- IN direction:
  - If the buffer is ready to transfer data, the data is transferred and a normal response is returned
  - If the buffer is not ready to transfer data, a zero-length packet is transmitted and an underrun error occurs
- OUT direction:
  - If the buffer is ready to receive data, the data is received and a normal response is returned
  - If the buffer is not ready to receive data, the received data is discarded and an overrun error occurs

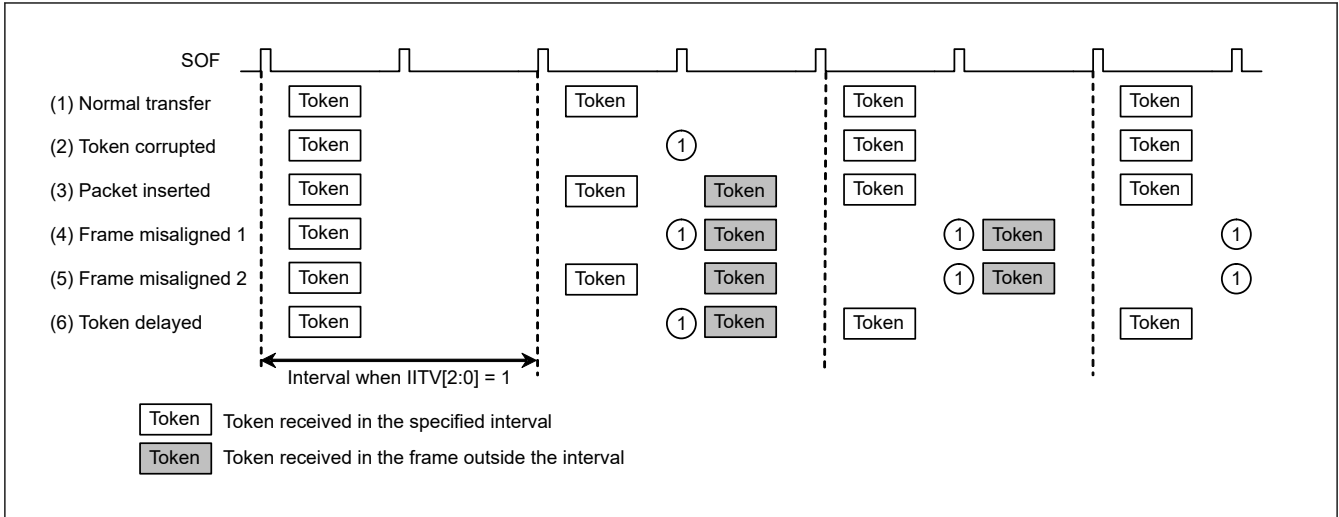

Figure 26.21 Example interval error occurrence when IITV[2:0] = 1

### 26.3.13 SOF Interpolation Function

In device controller mode, if packet reception is disabled at intervals of 1 ms because the SOF packet is corrupted or missing, the USBFS interpolates the SOF. SOF interpolation begins when the USBE and SCKE bits in SYSCFG are set to 1 and an SOF packet is received.

The interpolation function is initialized under the following conditions:

- MCU reset
- USB bus reset
- Suspend state detection

The SOF interpolation operates as follows:

- The interpolation function is not activated until an SOF packet is received
- When the first SOF packet is received, interpolation is performed by counting 1 ms on the 48-MHz internal clock
- When the second and subsequent SOF packets are received, interpolation is performed at the previous reception interval
- Interpolation is not performed in the Suspend state or on reception of a USB bus reset

The USBFS supports the following functions controlled by SOF packet reception. These functions operate normally with SOF interpolation if the SOF packet is missing:

- Updating of the frame number
- SOFR interrupt timing
- Isochronous transfer interval count

If an SOF packet is missing during full-speed operation, the FRMNUM.FRNM[10:0] bits are not updated.

### 26.3.14 Pipe Schedule

#### 26.3.14.1 Conditions for generating transactions

In host controller mode and when the DVSTCTR0.UACT bit is set to 1, the USBFS generates transactions under the conditions shown in Table 26.29.

Table 26.29 Conditions for generating transactions (1 of 2)

| Transaction | Conditions for generation |      |       |              |           |
|-------------|---------------------------|------|-------|--------------|-----------|
|             | DIR                       | PID  | IITV0 | Buffer state | SUREQ     |
| Setup       | __*1                      | __*1 | __*1  | __*1         | 1 setting |

**Table 26.29 Conditions for generating transactions (2 of 2)**

| Transaction                                              | Conditions for generation |     |         |                      |       |
|----------------------------------------------------------|---------------------------|-----|---------|----------------------|-------|
|                                                          | DIR                       | PID | IITV0   | Buffer state         | SUREQ |
| Control transfer data stage, status stage, bulk transfer | IN                        | BUF | Invalid | Receive area exists  | —*1   |
|                                                          | OUT                       | BUF | Invalid | Transmit data exists | —*1   |
| Interrupt transfer                                       | IN                        | BUF | Valid   | Receive area exists  | —*1   |
|                                                          | OUT                       | BUF | Valid   | Transmit data exists | —*1   |
| Isochronous transfer                                     | IN                        | BUF | Valid   | *2                   | —*1   |
|                                                          | OUT                       | BUF | Valid   | *3                   | —*1   |

Note 1. An em dash (—) in the table indicates that the condition is unrelated to the generating of tokens. "Valid" indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. "Invalid" indicates that a transaction is generated regardless of the interval counter.

Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.

Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

### 26.3.14.2 Transfer schedule

This section describes the transfer scheduling within a frame of the USBFS. After the USBFS sends an SOF, the transfer is carried out in the following sequence:

1. Execution of periodic transfers:

A pipe is searched for in the order of pipe 1 → pipe 2 → pipe 6 → pipe 7 → pipe 8 → pipe 9, and then if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.

2. Setup transactions for control transfers:

The DCP is checked, and if a setup transaction is possible, it is sent.

3. Execution of bulk transfers, control transfer data stages, and control transfer status stages:

A pipe is searched for in the order of DCP → pipe 1 → pipe 2 → pipe 3 → pipe 4 → pipe 5, and then if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.

When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

### 26.3.14.3 Enabling USB communication

Setting the DVSTCTR0.UACT bit to 1 initiates an SOF transmission, and transaction generation is enabled. Setting the UACT bit to 0 stops SOF transmission and the Suspend state is invoked. If the UACT setting is changed from 1 to 0, processing stops after the next SOF is sent.

## 26.3.15 Battery Charging Detection Processing

The USBFS provides control over the data contact detection processing (D+ line contact checking), primary detection processing (charger detection processing), and secondary detection processing (charger determination processing) as defined in the Battery Charging Specification.

### 26.3.15.1 Processing in device controller mode

To operate a function device as a battery charging portable device:

1. Start primary detection processing after detecting contact with the D+ and D- lines. The Battery Charging Specification describes two processing methods for Data Contact Detection. The USBFS supports both methods as follows:
  - Software processing

After a VBINT interrupt or polling of the VBSTS flag indicates a change in the state of the USBFS\_VBUS input pin, software controls a wait from 300 to 900 ms. The BCCTRL1.VDPSRCE and CHGDETE bits are then both set to 1 to start primary detection processing.

- Hardware Processing

Apply 7 to 13  $\mu$ A of current to the D+ line to hold the D+ line at the logical high level. This is done to detect the D+ and D- lines going to the logical low level because of pull-down resistors on the host device side when the D+ and D- lines come in contact with those of the host. Monitor the SYSSTS0.LNST[1:0] flags while the PHYSECTRL.CNEN bit, BCCTRL1.RPDME and IDPSRCE bit are set to 1 to see when the level on the D+ line changes from high to low. After detecting a low level on the D+ line, clear the PHYSECTRL.CNEN bit, BCCTRL1.RPDME and IDPSRCE bit to 0 and set both the BCCTRL1.VDPSRCE and CHGDETE bits to 1 to start primary detection processing. The VDPSRCE and CHGDETE bits must be set to 1 simultaneously.

2. After the start of primary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL1.CHGDETSTS flag. A value of 1 indicates detection of a charger, and secondary detection processing starts.\*1
3. To start secondary detection processing, clear the BCCTRL1.VDPSRCE bit to 0, then clear the BCCTRL1.CHGDETE bits to 0 after a software-controlled wait of 20 ms. Next, set both the BCCTRL1.VDMSRCE and PDDETE bits to 1.
4. After the start of secondary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL1.PDDETSTS flag, and determine the result of the secondary detection processing.

Note 1. In primary detection processing, detection of a voltage above the range from 0.25 to 0.4 V and below the range from 0.8 to 2.0 V on the D-Line indicates that the other device is a host device that supports battery charging (charging downstream port). The BCCTRL1.CHGDETSTS flag in the PHY block only indicates whether the voltage on the D-line is higher than the range from 0.25 to 0.4 V, so add processing as required to read the SYSSTS0.LNST[1:0] flags and confirm that the voltage on the D- line is also below the range from 0.8 to 2.0 V.

Figure 26.22 shows the process flow.

Figure 26.22 Processing flow as portable device

### 26.3.15.2 Processing in host controller mode

In host controller mode, driving the D- line is required for a portable device to perform primary detection. The USBFS supports the following two primary detection methods:

#### When using the Portable Device detection function

The D- line is driven when a Portable Device is detected.

1. Start driving the VBUS.
2. Set the BCCTRL1.PDDETE bit to 1 to enable the portable device detection circuit.
3. Monitor the portable device detection signal and start driving the D- line when the level of the portable device detection signal is high.\*<sup>1</sup>
4. Stop driving the D- line when the portable device detection signal is at the low level.\*<sup>1</sup>

Note 1. The PDDETINT interrupt indicates a change in the level of the portable device detection signal, and the current level can be obtained by reading the PDDETSTS flag.

#### When not using the Portable Device detection function

Regardless of whether or not a Portable Device was detected, drive the D- line after device disconnection is detected, and leave the D- line open after connection is detected. Software handles the timing of a and b.

- a. After disconnection is detected, start driving the D- line within 200 ms.
- b. After connection is detected, stop driving the D- line within 10 ms.

[Figure 26.23](#) shows the process flow for steps 1. to 4. and [Figure 26.24](#) shows the process flow for steps a. and b., respectively.

Figure 26.23 Processing flow when using the Portable Device detection function (steps 1. to 4.)

**Figure 26.24** Processing flow when not using Portable Device detection function (steps a. and b.)

## 26.4 Usage Notes

### 26.4.1 Settings for the Module-Stop State

USBFS operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The USBFS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

### 26.4.2 Clearing the Interrupt Status Register on Canceling Software Standby Mode

Because the input buffer is always enabled in Software Standby mode, an unexpected interrupt might occur under the following conditions:

- When the interrupt is enabled in Normal mode
- When the interrupt is disabled in Software Standby mode
- When the input level of the pin that cancels software standby mode is changed in Software Standby mode

These conditions might cause the associated interrupt flag in the Interrupt Status Register to set unexpectedly. After the MCU cancels the Software Standby mode, the unexpected interrupt might be sent to the interrupt controller. To avoid this, always clear the INTSTS0 and INTSTS1 registers in the canceling sequence.

### 26.4.3 Clearing the Interrupt Status Register after Setting Up the Port Function

The input buffer is disabled before the PmnPFS.PSEL and PmnPFS.PMR port is set up, so the internal signal is fixed high or low. The input buffer is enabled after the port is set so that the external pin state is propagated to the MCU. An unexpected interrupt might occur at this time, causing the VBINT and OVRCR bits in INTSTS0 and INTSTS1, or other

interrupt status flags to set to 1. To avoid a malfunction, always clear the INTSTS0 and INTSTS1 registers after setting up the port.

## 27. Serial Communications Interface (SCI)

### 27.1 Overview

The Serial Communications Interface (SCI) × 4 channels have asynchronous and synchronous serial interfaces:

- Asynchronous interfaces (UART and Asynchronous Communications Interface Adapter (ACIA))
- 8-bit clock synchronous interface
- Simple IIC (master-only)
- Simple SPI
- Smart card interface
- Manchester interface

The smart card interface complies with the ISO/IEC 7816-3 standard for electronic signals and transmission protocol. SCIn (n = 0, 3, 4, 9) has FIFO buffers to enable continuous and full-duplex communication, and the data transfer speed can be configured independently using an on-chip baud rate generator.

In this section, PCLK refers to PCLKA.

Table 27.1 lists the SCI specifications, Figure 27.1 shows a block diagram of SCI, and Table 27.3 lists the I/O pins.

**Table 27.1 SCI specifications (1 of 3)**

| Parameter                                         |                                       | Specifications                                                                                                                                                                                                              |
|---------------------------------------------------|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Number of modules                                 |                                       | 4 (SCIn (n = 0, 3, 4, 9))                                                                                                                                                                                                   |
| Serial communication modes                        |                                       | <ul style="list-style-type: none"> <li>• Asynchronous</li> <li>• Clock synchronous</li> <li>• Simple IIC</li> <li>• Simple SPI</li> <li>• Smart card interface</li> <li>• Manchester interface (SCIn (n = 3, 4))</li> </ul> |
| Transfer speed                                    |                                       | Bit rate specifiable with the on-chip baud rate generator                                                                                                                                                                   |
| Full-duplex communications                        |                                       | <ul style="list-style-type: none"> <li>• Transmitter: Continuous transmission possible using double-buffering</li> <li>• Receiver: Continuous reception possible using double-buffering</li> </ul>                          |
| Data transfer                                     |                                       | Selectable as LSB-first or MSB-first transfer                                                                                                                                                                               |
| Inverter for communication terminals (RXDn, TXDn) |                                       | Selectable inverter for each terminals (RXDn, TXDn)                                                                                                                                                                         |
| Interrupt sources                                 |                                       | Transmit end, transmit data empty, receive data full, receive error, receive data ready, address match.<br>Completion of generation of a start condition, restart condition, or stop condition. (for simple IIC mode)       |
| Module-stop function                              |                                       | Module-stop state can be set for each channel                                                                                                                                                                               |
| Snooze end request                                |                                       | SCI0 address mismatch (SCI0_DCUF)                                                                                                                                                                                           |
| Clock synchronous mode                            | Data length                           | 8 bits                                                                                                                                                                                                                      |
|                                                   | Receive error detection               | Overrun error                                                                                                                                                                                                               |
|                                                   | Clock source                          | Selectable to internal clock (master mode) or external clock (slave mode)                                                                                                                                                   |
|                                                   | Hardware flow control                 | Transmission and reception controllable with CTSn_RTsn pins                                                                                                                                                                 |
|                                                   | Transmission and reception            | Selectable to 1-stage register or 16-stage FIFO                                                                                                                                                                             |
| Asynchronous mode                                 | Data length                           | 7, 8, or 9 bits                                                                                                                                                                                                             |
|                                                   | Transmission stop bit                 | 1 or 2 bits                                                                                                                                                                                                                 |
|                                                   | Adjustment of receive sampling timing | Adjustable receive sampling timing before/after the default timing                                                                                                                                                          |
|                                                   | Adjustment of transmit timing         | Adjustable edge timing of transmit waveform controlled by the setting value of registers.                                                                                                                                   |

Table 27.1 SCI specifications (2 of 3)

| Parameter                 |                                           | Specifications                                                                                                                                                |
|---------------------------|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           | Parity                                    | Even parity, odd parity, or no parity                                                                                                                         |
|                           | Receive error detection                   | <ul style="list-style-type: none"> <li>Parity error</li> <li>Overrun error</li> <li>Framing error</li> </ul>                                                  |
|                           | Hardware flow control                     | Transmission and reception controllable with CTSn_RTSn pins                                                                                                   |
|                           | Transmission and reception                | Selectable to 1-stage register or 16-stage FIFO                                                                                                               |
|                           | Address match                             | Interrupt request/event output can be issued upon detecting a match between received data and the value in the compare match register                         |
|                           | Address mismatch (SCIO only) receive data | Snooze end request can be issued when detecting a mismatch between the received data and the value in the compare match register                              |
|                           | Start-bit detection                       | Selectable to low level or falling edge detection                                                                                                             |
|                           | Break detection                           | Breaks from framing errors detectable by read from SPTR register                                                                                              |
|                           | Clock source                              | Selectable to internal or external clock                                                                                                                      |
|                           | Double-speed mode                         | Baud rate generator double-speed mode is selectable                                                                                                           |
|                           | Multi-processor communications function   | Serial communication enabled among multiple processors                                                                                                        |
|                           | Noise cancellation                        | Digital noise filters included on signal paths from the RXDn pin inputs                                                                                       |
| Smart card interface mode | Error processing                          | Error signal can be automatically transmitted upon detecting a parity error during reception                                                                  |
|                           |                                           | Data can be automatically retransmitted upon receiving an error signal during transmission                                                                    |
|                           | Data type                                 | Both direct and inverse convention supported                                                                                                                  |
| Manchester mode           | Communication format                      | Manchester code with the preface and the Start Bit added                                                                                                      |
|                           | Data length                               | 7,8, or 9 bits                                                                                                                                                |
|                           | Transmission stop bit                     | 1 or 2 bits                                                                                                                                                   |
|                           | Parity function                           | Even parity, odd parity, or no parity                                                                                                                         |

## 27.2 Register Descriptions

### 27.2.1 RSR : Receive Shift Register

RSR is a shift register that receives serial data input from the RxD<sub>n</sub> pin and converts it into parallel data. When one frame of data is received, the data is automatically transferred to the RDR, RDRHL, or the receive FIFO register. The RSR register cannot be directly accessed by the CPU.

### 27.2.2 RDR : Receive Data Register

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x05

RDR is an 8-bit register that stores received data. When one frame of serial data is received, it is transferred from RSR to RDR, and the RSR register can receive more data. Because RSR and RDR function as a double buffer, continuous received operations can be performed.

Read the RDR only once after a receive data full interrupt (SCIn\_RXI) occurs.

Note: If the next frame of data is received before reading the received data from RDR, an overrun error occurs. The CPU cannot write to the RDR.

### 27.2.3 RDRHL : Receive Data Register for Non-Manchester mode (MMR.MANEN = 0)

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x10

| Bit  | Symbol    | Function                  | R/W |
|------|-----------|---------------------------|-----|
| 8:0  | RDAT[8:0] | Serial Receive Data       | R   |
| 15:9 | —         | These bits are read as 0. | R   |

RDRHL is a 16-bit register that stores received data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of RDRHL are the shadow register of RDR, so access to RDRHL affects the RDR register. Access to the RDRHL register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDR/RDRHL registers, allowing the RSR register to receive more data.

The RSR and RDRHL registers form a double-buffered structure to enable continuous reception. RDRHL should be read only when a receive data full interrupt (SCIn\_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from RDRHL. The CPU cannot write to the RDRHL register.

### 27.2.4 RDRHL\_MAN : Receive Data Register for Manchester mode (MMR.MANEN = 1)

Base address: SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x10

| Bit   | Symbol    | Function                                                                                                                                                                                        | R/W |
|-------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 8:0   | RDAT[8:0] | Serial receive data<br>It can read serial receive data                                                                                                                                          | R   |
| 9     | MPB       | Multi-processor bit<br>It can read multi-processor bit corresponded to serial receive data (RDATA[8:0])<br>0: Data transmission cycles<br>1: ID transmission cycles                             | R   |
| 11:10 | —         | These bits are read as 0. The write value should be 0.                                                                                                                                          | R   |
| 12    | RSYNC     | Receive SYNC data bit<br>It is valid when MMR.SBSEL = 1 in Manchester mode, 0 is read otherwise.<br>0: The received the Start Bit is DATA SYNC<br>1: The received the Start Bit is COMMAND SYNC | R   |
| 15:13 | —         | These bits are read as 0. The write value should be 0.                                                                                                                                          | R   |

RDRHL\_MAN is a 16-bit register that stores received data. Use this register when asynchronous mode and 9-bit data length are selected. The lower 8 bits of RDRHL\_MAN are the shadow register of RDR, so access to RDRHL\_MAN affects the RDR register. Access to the RDRHL\_MAN register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDR/RDRHL\_MAN registers, allowing the RSR register to receive more data.

The RSR and RDRHL\_MAN registers form a double-buffered structure to enable continuous reception.

RDRHL\_MAN should be read only when a receive data full interrupt (SCIn\_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from RDRHL\_MAN.

The CPU cannot write to the RDRHL\_MAN register.

#### RDAT[8:0] bit (Serial receive data)

It can read serial receive data.

#### MPB bit (Multi-processor bit)

Holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

#### RSYNC bit (Receive SYNC data bit)

When Manchester mode and MMR.SBSEL = 1, this bit indicates the type of SYNC of the received the Start Bit. For other settings, it is fixed to 0.

### 27.2.5 FRDRHL/FRDRH/FRDRL : Receive FIFO Data Register

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x10 (FRDRHL/FRDRH)  
0x11 (FRDRL)

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

| 15  | —      | This bit is read as 0.                                                                                                                                                                                                                                                                                                 | R   |

Note 1. If this flag is read, it indicates the same value as that read from the SSR\_FIFO register. Write 0 to the SSR\_FIFO register to clear the flag.

FRDRHL is a 16-bit register that consists of the 8-bit FRDRH and FRDRL registers. FRDRH is assigned to the FRDRHL[15:8] bits, and allocated to the same address as FRDRHL. FRDRL is assigned to the FRDRHL[7:0] bits, and allocated to (the address of FRDRHL + 1) address.

FRDRH and FRDRL constitute a 16-stage FIFO register that stores serial receive data and related status information readable by software. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

The SCI completes reception of one frame of serial data by transferring the received data from the Receive Shift Register (RSR) into FRDRH and FRDRL for storage. Continuous reception is executed until 16 stages are stored. If data is read when there is no received data in FRDRH and FRDRL, the value is undefined. When FRDRH and FRDRL are full, subsequent serial receive data is lost. The CPU can read from the FRDRH and FRDRL registers but cannot write to them.

Reading 1 from the RDF, ORER, or DR flags of the FRDRH register is the same as reading from those bits in the SSR\_FIFO register. When writing 0 to clear a flag in the SSR\_FIFO register after reading the FRDRH register, write 0 only to the flag that is to be cleared and write 1 to the other flags.

When reading both the FRDRH and FRDRL registers, read in order from FRDRH to FRDRL. The FRDRHL register can be accessed in 16-bit units.

### 27.2.6 TDR : Transmit Data Register

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x03

Bit position: 7 6 5 4 3 2 1 0

Bit field: 

|  |  |  |  |  |  |  |  |
|--|--|--|--|--|--|--|--|
|  |  |  |  |  |  |  |  |
|--|--|--|--|--|--|--|--|

Value after reset: 1 1 1 1 1 1 1 1

| Bit | Symbol | Function             | R/W |
|-----|--------|----------------------|-----|
| 7:0 | n/a    | Serial Transmit Data | R/W |

TDR is an 8-bit register that stores transmit data.

When the SCI detects that the TSR register is empty, it transfers the transmit data written in the TDR register to the TSR register and starts transmission.

The double-buffered structure of the TDR and TSR registers enables continuous serial transmission. If the next transmit data is already written to TDR when one frame of data is transmitted, the SCI transfers the written data to the TSR register to continue transmission.

The CPU can read from or write to TDR at any time. Only write transmit data to TDR once after each instance of the transmit data empty interrupt (SCIn\_TXI).

### 27.2.7 TDRHL : Transmit Data Register for Non-Manchester mode (MMR.MANEN = 0)

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x0E

| Bit  | Symbol    | Function                                            | R/W |
|------|-----------|-----------------------------------------------------|-----|
| 8:0  | TDAT[8:0] | Serial Transmit Data                                | R/W |
| 15:9 | —         | This bit is read as 1. The write value should be 1. | R/W |

TDRHL is a 16-bit register that stores transmit data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of TDRHL are the shadow register of TDR, so access to TDRHL affects the TDR register. Access to the TDRHL register is prohibited if 7-bit or 8-bit data length is selected.

When empty space is detected in the TSR register, the transmit data stored in the TDRHL registers is transferred to TSR and transmission starts.

The TSR and TDRHL registers have a double-buffered structure to support continuous transmission. When the next data to be transmitted is stored in TDRHL after one frame of data is transmitted, the transmitting operation continues by transferring the data to the TSR register.

The CPU can read and write to the TDRHL register. Bits [15:9] in TDRHL are fixed to 1. These bits are read as 1. The write value should be 1.

Write transmit data to the TDRHL register only once when a transmit data empty interrupt (SCIn\_TXI) request is issued.

### 27.2.8 TDRHL\_MAN : Transmit Data Register for Manchester mode (MMR.MANEN = 1)

Base address: SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x0E

| Bit | Symbol    | Function                                                | R/W |
|-----|-----------|---------------------------------------------------------|-----|
| 8:0 | TDAT[8:0] | Serial transmit data<br>It can set serial transmit data | R/W |

| Bit   | Symbol | Function                                                                                                                                                                                             | R/W |
|-------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 9     | MPBT   | Multi-processor transfer bit flag<br>Value of the multi-processor bit in the transmission frame<br>0: Data transmission cycles<br>1: ID transmission cycles                                          | R/W |
| 11:10 | —      | The write value should be 1.                                                                                                                                                                         | R   |
| 12    | TSYNC  | Transmit SYNC data bit<br>It is valid when MMR.SBSEL = 1 and MMR.SYNSEL = 1 in Manchester mode.<br>0: The Start Bit is transmitted as DATA SYNC.<br>1: The Start Bit is transmitted as COMMAND SYNC. | R/W |
| 15:13 | —      | The write value should be 1.                                                                                                                                                                         | R   |

TDRHL\_MAN is a 16-bit register that stores transmit data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of TDRHL\_MAN are the shadow register of TDR, so access to TDRHL\_MAN affects the TDR register. Access to the TDRHL\_MAN register is prohibited if 7-bit or 8-bit data length is selected.

When empty space is detected in the TSR register, the transmit data stored in the TDRHL\_MAN registers is transferred to TSR and transmission starts.

The TSR and TDRHL\_MAN registers have a double-buffered structure to support continuous transmission. When the next data to be transmitted is stored in TDRHL\_MAN after one frame of data is transmitted, the transmitting operation continues by transferring the data to the TSR register.

Write transmit data to the TDRHL\_MAN register only once when a transmit data empty interrupt (SCIn\_TXI) request is issued.

**TDAT[8:0] bit (Serial transmit data)**

This register sets serial transmission data.

**MPBT bit (Multi-processor transfer bit flag)**

Selects the multi-processor bit of transmit frame.

**TSYNC bit (Transmit SYNC data bit)**

When Manchester mode and MMR.SBSEL = "1" and MMR.SYNSEL = "1", the type of SYNC selected according to this bit becomes the Start Bit of the transmission frame.

**27.2.9 FTDRHL/FTDRH/FTDRL : Transmit FIFO Data Register**

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x0E (FTDRHL/FTDRH)  
0x0F (FTDRL)

| Bit | Symbol    | Function                                                                                                                                                                            | R/W |

| 15:10 | —      | The write value should be 1.                                                                                                                                                                                                                                                                                                                             | W   |

FTDRHL is a 16-bit register that consists of the 8-bit FTDRH and FTDL registers. FTDRH is assigned to the FTDRHL[15:8] bits, and allocated to the same address as FTDRHL. FTDL is assigned to the FTDRHL[7:0] bits, and allocated to (the address of FTDRHL + 1) address.

FTDRH and FTDL constitute a 16-stage FIFO register that stores data for serial transmission and a multi-processor transfer bit. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

When the SCI detects that the Transmit Shift Register (TSR) is empty, it transfers data written in the FTDRH and FTDL registers to the TSR register and starts serial transmission. Continuous serial transmission is executed until no transmit data is left in FTDRH and FTDL. When FTDRHL is full of transmit data, no more data can be written. If writing new data is attempted, the data is ignored. The CPU can write to the FTDRH and FTDL registers but cannot read them.

When writing to both the FTDRH and FTDL registers, write in order from FTDRH to FTDL.

#### TDAT[8:0] bits (Serial transmit data)

The TDAT[8:0] bits set the serial transmission data. This is valid only when FIFO is selected in asynchronous mode (including multiprocessor) or clock synchronous mode.

#### MPBT flag (Multi-Processor Transfer Bit Flag)

The MPBT flag specifies the value of the multi-processor bit of the transmit frame. When FCR.FM = 1, SSR.MPBT is invalid.

### 27.2.10 TSR : Transmit Shift Register

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first automatically transfers transmit data from TDR, TDRHL, or transmit FIFO to TSR, then sends the data to the TXDn pin. The CPU cannot directly access the TSR.

### 27.2.11 SMR : Serial Mode Register for Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Note 1. n is the decimal notation of the value of n in the BRR register. See [section 27.2.20. BRR : Bit Rate Register](#).

Note 2. In any mode other than asynchronous mode, this bit setting is invalid and a fixed data length of 8 bits is used.

Note 3. LSB-first is fixed and the MSB (bit [7]) in the TDR register is not transmitted in transmit mode.

Note 4. Writable only when SCR.TE = 0 and SCR.RE = 0 (both serial transmission and reception are disabled).

The SMR register sets the communication format and clock source for the on-chip baud rate generator.

### CKS[1:0] bits (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator. For the relationship between the settings of these bits and the baud rate, see [section 27.2.20. BRR : Bit Rate Register](#).

### MP bit (Multi-Processor Mode)

The MP bit disables or enables the multi-processor communications function. The PE and PM bit settings are invalid in multi-processor mode.

### STOP bit (Stop Bit Length)

The STOP bit selects the stop bit length in transmission.

In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

### PM bit (Parity Mode)

The PM bit selects the parity mode (even or odd) for transmission and reception. The PM bit setting is invalid in multiprocessor mode.

### PE bit (Parity Enable)

When the PE bit is set to 1, the parity bit is added to transmit data, and the parity bit is checked in reception. Regardless of the PE bit setting, the parity bit is not added or checked in multi-processor format.

### CHR bit (Character Length)

The CHR bit selects the data length for transmission and reception in combination with the SCMR.CHR1 bit. In modes other than asynchronous, a fixed data length of 8 bits is used.

### CM bit (Communication Mode)

The CM bit selects the communication mode:

- Asynchronous mode or simple IIC mode
- Clock synchronous mode or simple SPI mode

### 27.2.12 SMR\_SMCI : Serial Mode Register for Smart Card Interface Mode (SCMR.SMIF = 1)

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x00

|                    |    |     |    |    |          |          |   |   |
|--------------------|----|-----|----|----|----------|----------|---|---|

| 4   | PM       | Parity Mode<br>Valid only when the PE bit is 1.<br>0: Even parity<br>1: Odd parity                                                                                                           | R/W <sup>2</sup> |
| 5   | PE       | Parity Enable<br>When this bit is set to 1, a parity bit is added to transmit data, and the parity of received data is checked. Set this bit to 1 in smart card interface mode.              | R/W <sup>2</sup> |
| 6   | BLK      | Block Transfer Mode<br>0: Normal mode operation<br>1: Block transfer mode operation                                                                                                          | R/W <sup>2</sup> |
| 7   | GM       | GSM Mode<br>0: Normal mode operation<br>1: GSM mode operation                                                                                                                                | R/W <sup>2</sup> |

Note 1. n is the decimal notation of the value of n in the BRR register. See [section 27.2.20. BRR : Bit Rate Register](#).

Note 2. Writable only when SCR\_SMCI.TE = 0 and SCR\_SMCI.RE = 0 (both serial transmission and reception are disabled).

The SMR\_SMCI register sets the communication format and clock source for the on-chip baud rate generator.

#### CKS[1:0] bits (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator. For the relationship between the settings of these bits and the baud rate, see [section 27.2.20. BRR : Bit Rate Register](#).

#### BCP[1:0] bits (Base Clock Pulse)

The BCP[1:0] bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set these bits in combination with the SCMR.BCP2 bit.

For details, see [section 27.7.4. Receive Data Sampling Timing and Reception Margin](#).

**Table 27.4** Combinations of SCMR.BCP2 and SMR\_SMCI.BCP[1:0] bits (1 of 2)

| SCMR.BCP2 bit | SMR_SMCI.BCP[1:0] bits | Number of base clock cycles for 1-bit transfer period <sup>*1</sup> |
|---------------|------------------------|---------------------------------------------------------------------|
| 0             | 00b                    | 93 clock cycles (S = 93)                                            |
| 0             | 01b                    | 128 clock cycles (S = 128)                                          |
| 0             | 10b                    | 186 clock cycles (S = 186)                                          |

**Table 27.4 Combinations of SCMR.BCP2 and SMR\_SMCI.BCP[1:0] bits (2 of 2)**

| SCMR.BCP2 bit | SMR_SMCI.BCP[1:0] bits | Number of base clock cycles for 1-bit transfer period*1 |
|---------------|------------------------|---------------------------------------------------------|
| 0             | 11b                    | 512 clock cycles (S = 512)                              |
| 1             | 00b                    | 32 clock cycles (S = 32) (initial value)                |
| 1             | 01b                    | 64 clock cycles (S = 64)                                |
| 1             | 10b                    | 372 clock cycles (S = 372)                              |
| 1             | 11b                    | 256 clock cycles (S = 256)                              |

Note 1. S is the value of S in BRR (see section 27.2.20. BRR : Bit Rate Register).

**PM bit (Parity Mode)**

The PM bit selects the parity mode for transmission and reception (even or odd). For details on the usage of this bit in smart card interface mode, see section 27.7.2. Data Format (Except in Block Transfer Mode).

**PE bit (Parity Enable)**

Set the PE bit to 1. The parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

**BLK bit (Block Transfer Mode)**

Setting the BLK bit to 1 enables block transfer mode operation. For details, see section 27.7.3. Block Transfer Mode.

**GM bit (GSM Mode)**

Setting the GM bit to 1 enables GSM mode operation. In GSM mode, the SSR\_SMCI.TEND flag set timing is moved forward to 11.0 etus (elementary time unit = 1-bit transfer time) from the start bit, and clock output control is added. For details, see section 27.7.6. Serial Data Transmission (Except in Block Transfer Mode) and section 27.7.8. Clock Output Control.

**27.2.13 SCR : Serial Control Register for Non-Smart Card Interface Mode (SCMR.SMIF = 0)**

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x02

| Bit | Symbol   | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | R/W   |

| 7   | TIE    | Transmit Interrupt Enable<br>0: Disable SCIn_TXI interrupt requests<br>1: Enable SCIn_TXI interrupt requests                                                                                                                                                                                                                                                                                                                                                          | R/W              |

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. 1 can be written only when TE = 0 and RE = 0, when the SMR.CM bit is 1. After setting TE or RE to 1, only 0 can be written to TE and RE. When the SMR.CM bit is 0 and the SIMR1.IICM bit is 0, writing is enabled under any condition.

Note 3. When writing a new value to a bit other than the MPIE bit of this register in multi-processor mode (SMR.MP bit = 1), write 0 to the MPIE bit using the store instruction to avoid accidentally setting the MPIE bit to 1 by a read-modify-write operation when using a bit manipulation instruction.

The SCR register controls operation and clock source selection for transmission and reception.

### CKE[1:0] bits (Clock Enable)

The CKE[1:0] bits select the clock source and the SCKn pin function.

### TEIE bit (Transmit End Interrupt Enable)

The TEIE bit enables or disables SCIn\_TEI interrupt requests. Set TEIE to 0 to disable an SCIn\_TEI interrupt request.

In simple IIC mode, SCIn\_TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STIn).

In this case, the TEIE bit can be used to enable or disable the STI.

### MPIE bit (Multi-Processor Interrupt Enable)

When the MPIE bit is set to 1 and data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags RDRF, ORER, FER, RDF, and DR in SSR/SSR\_FIFO to 1 is disabled. When data with the multi-processor bit set to 1 is received, the MPIE bit is automatically set to 0, and normal reception resumes. For details, see [section 27.4. Multi-Processor Communication Function](#).

When the MPB bit in the SSR register is 0, the receive data is not transferred from the RSR register to the RDR register, a receive error is not detected, and setting the flags ORER and FER to 1 is disabled.

When the MPB bit is set to 1, the MPIE bit is automatically set to 0, SCIn\_RXI and SCIn\_ERI interrupt requests are enabled (if the RIE bit in SCR is set to 1), and setting of the ORER and FER flags to 1 is enabled.

Set MPIE to 0 if the multi-processor communications function is not used.

### RE bit (Receive Enable)

The RE bit enables or disables serial reception. When the RE bit is set to 1, serial reception starts by detecting the start bit in asynchronous mode or the synchronous clock input in clock synchronous mode. Set the reception format in the SMR register before setting the RE bit to 1.

In non-FIFO operation, when reception is halted by setting the RE bit to 0, the RDRF, ORER, FER, and PER flags in the SSR register are not affected, and the previous values are retained.

When FIFO operation is selected and reception is halted by setting the RE bit to 0, the RDF, ORER, FER, PER, and DR flags in SSR\_FIFO are not affected and the previous values are retained.

**TE bit (Transmit Enable)**

The TE bit enables or disables serial transmission.

When the TE bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Set the transmission format in the SMR register before setting the TE bit to 1.

**RIE bit (Receive Interrupt Enable)**

The RIE bit enables or disables SCIn\_RXI and SCIn\_ERI interrupt requests.

SCIn\_RXI and SCIn\_ERI interrupt requests are disabled by setting the RIE bit to 0.

An SCIn\_ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in SSR/SSR\_FIFO then setting the flag to 0, or by setting the RIE bit to 0.

**TIE bit (Transmit Interrupt Enable)**

The TIE bit enables or disables SCIn\_TXI interrupt requests. SCIn\_TXI interrupt requests are disabled by setting the TIE bit to 0.

Note: To switch the TIE bit value from 0 to 1 in FIFO mode, set the TIE and TE bits to 1 simultaneously or set the TIE bit to 1 when TE = 1. When TE = 0 in FIFO mode, setting the TIE bit to 1 is prohibited.

### 27.2.14 SCR\_SMCI : Serial Control Register for Smart Card Interface Mode (SCMR.SMIF = 1)

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x02

| 7   | TIE      | Transmit Interrupt Enable<br>0: Disable SCIn_TXI interrupt requests<br>1: Enable SCIn_TXI interrupt requests                                                                                                                                                                                                                                                                                                                                               | R/W              |

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written to TE and RE.

The SCR\_SMCI register sets transmission and reception control, interrupt control, and clock source selection for transmission and reception.

For details on interrupt requests, see [section 27.11. Interrupt Sources](#).

### CKE[1:0] bits (Clock Enable)

The CKE[1:0] bits control the clock output from the SCKn pin. In GSM mode, clock output can be dynamically switched. For details, see [section 27.7.8. Clock Output Control](#).

### TEIE bit (Transmit End Interrupt Enable)

Set the TEIE bit to 0 in smart card interface mode.

### MPIE bit (Multi-Processor Interrupt Enable)

Set the MPIE bit to 0 in smart card interface mode.

### RE bit (Receive Enable)

The RE bit enables or disables serial reception. When the RE bit is set to 1, serial reception starts by detecting the start bit. Set the reception format in the SMR\_SMCI register before setting the RE bit to 1.

If reception is halted by setting the RE bit to 0, the ORER, FER, and PER flags in SSR\_SMCI are not affected and the previous values are retained.

### TE bit (Transmit Enable)

The TE bit enables or disables serial transmission. When the TE bit is set to 1, serial transmission is started by writing transmit data to TDR. Set the transmission format in the SMR\_SMCI register before setting the TE bit to 1.

### RIE bit (Receive Interrupt Enable)

The RIE bit enables or disables SCIn\_RXI and SCIn\_ERI interrupt requests.

SCIn\_RXI and SCIn\_ERI interrupt requests are disabled by setting the RIE bit to 0.

An SCIn\_ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in the SSR\_SMCI register, and then setting the flag to 0, or by setting the RIE bit to 0.

### TIE bit (Transmit Interrupt Enable)

The TIE bit enables or disables SCIn\_TXI interrupt requests. SCIn\_TXI interrupt requests are disabled by setting the TIE bit to 0.

## 27.2.15 SSR : Serial Status Register for Non-Smart Card Interface and Non-FIFO Mode (SCMR.SMIF = 0, FCR.FM = 0, and MMR.MANEN = 0)

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x04

Bit position: 7 6 5 4 3 2 1 0

| 5   | ORER   | Overrun Error Flag<br>0: No overrun error occurred<br>1: Overrun error occurred                                                       | R/(W) <sup>1</sup> |
| 6   | RDRF   | Receive Data Full Flag<br>0: No received data in RDR register<br>1: Received data in RDR register                                     | R/(W) <sup>1</sup> |
| 7   | TDRE   | Transmit Data Empty Flag<br>0: Transmit data in TDR register<br>1: No transmit data in TDR register                                   | R/(W) <sup>1</sup> |

Note 1. Only 0 can be written to clear the flag after reading 1.

The SSR register provides SCI status flags and transmission and reception multi-processor bits.

#### MPBT bit (Multi-Processor Bit Transfer)

The MPBT bit sets the value of the multi-processor bit in the transmit frame.

#### MPB bit (Multi-Processor)

The MPB bit holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

#### TEND flag (Transmit End Flag)

The TEND flag indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled) and the FCR.FM bit is set to 0 (non-FIFO selected).  
When the SCR.TE bit is set to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated on transmission of the tail-end bit of a character being transmitted.

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR.TE bit is 1
- When 0 is written to TDRE after reading TDRE = 1 while the SCR.TE bit is 1

#### PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).  
Although receive data is transferred to the RDR register when the parity error occurs, no SCIn\_RXI interrupt request occurs. When the PER flag is set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to PER after reading PER = 1. After writing 0 to the PER flag, read the PER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

### FER flag (Framing Error Flag)

The FER flag indicates that a framing error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When 0 is sampled as the stop bit during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

In 2-stop-bit mode, only the first stop bit is checked. The second stop bit is not checked. Although receive data is transferred to the RDR register when the framing error occurs, no SCIn\_RXI interrupt request occurs. When the FER flag is to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to FER after reading FER = 1. After writing 0 to the FER flag, read the FER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

### ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error and a framing error is read from the RDR register.

The data received before an overrun error occurred is saved in the RDR register, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register. In clock synchronous mode, serial transmission and reception are stopped.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1. After writing 0 to the ORER flag, read the ORER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

### RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

- When 0 is written to RDRF after reading RDRF = 1
- When data is forwarded from the RDR register

### TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR.TE bit is 0
- When data is transmitted from the TDR register to the TSR register

[Clearing conditions]

- When 0 is written to TDRE after reading TDRE = 1
- When the SCR.TE bit is 1 and data is written to the TDR register

### 27.2.16 SSR\_FIFO : Serial Status Register for Non-Smart Card Interface and FIFO Mode (SCMR.SMIF = 0, FCR.FM = 1, and MMR.MANEN = 0)

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x04

|               |      |     |      |     |     |      |   |    |
|---------------|------|-----|------|-----|-----|------|---|----|
| Bit position: | 7    | 6   | 5    | 4   | 3   | 2    | 1 | 0  |
| Bit field:    | TDFE | RDF | ORER | FER | PER | TEND | — | DR |

Value after reset: 1 0 0 0 0 0 x 0

| Bit | Symbol | Function                                                                                                                                                                                                                                                                                                                                             | R/W              |
|-----|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 0   | DR     | Receive Data Ready Flag<br>0: Receiving is in progress, or no received data remains in FRDRHL after successfully completed reception (receive FIFO empty)<br>1: Next receive data is not received for a period after normal receiving is complete, when the amount of data stored in the FIFO is equal to or less than the receive triggering number | R/W <sup>1</sup> |
| 1   | —      | The read value is undefined. The write value should be 1.                                                                                                                                                                                                                                                                                            | R/W              |
| 2   | TEND   | Transmit End Flag<br>0: A character is being transmitted<br>1: Character transfer is complete                                                                                                                                                                                                                                                        | R/W <sup>1</sup> |
| 3   | PER    | Parity Error Flag<br>0: No parity error occurred<br>1: Parity error occurred                                                                                                                                                                                                                                                                         | R/W <sup>1</sup> |
| 4   | FER    | Framing Error Flag<br>0: No framing error occurred<br>1: Framing error occurred                                                                                                                                                                                                                                                                      | R/W <sup>1</sup> |
| 5   | ORER   | Overrun Error Flag<br>0: No overrun error occurred<br>1: Overrun error occurred                                                                                                                                                                                                                                                                      | R/W <sup>1</sup> |
| 6   | RDF    | Receive FIFO Data Full Flag<br>0: The amount of receive data written in FRDRHL is less than the specified receive triggering number<br>1: The amount of receive data written in FRDRHL is equal to or greater than the specified receive triggering number                                                                                           | R/W <sup>1</sup> |
| 7   | TDFE   | Transmit FIFO Data Empty Flag<br>0: The amount of transmit data written in FTDRHL exceeds the specified transmit triggering number<br>1: The amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number                                                                                             | R/W <sup>1</sup> |

Note 1. Only 0 can be written, to clear the flag after reading 1.

The SSR\_FIFO register provides the SCI with FIFO mode status flags.

#### DR flag (Receive Data Ready Flag)

The DR flag indicates that the amount of data stored in the Receive FIFO Data Register (FRDRHL) falls below the specified receive triggering number, and that no next data is received after 15 etus (elementary time units) from the last stop bit in asynchronous mode. This flag is valid only in asynchronous mode, including multi-processor mode, when FIFO operation is selected.

In clock synchronous mode, the DR flag is not set to 1.

[Setting condition]

- When FRDRHL contains less data than the specified receive triggering number, and no next data is received after 15  $\mu\text{s}$ <sup>\*1</sup> from the last stop bit, and the SSR\_FIFO.FER and SSR\_FIFO.PER flags are 0.

[Clearing conditions]

- When 1 is read from DR, after all received data is read
- When the FCR.FM bit is changed from 0 to 1

Note 1. This is equivalent to 1.5 frames in the 8-bit format with one stop bit.

The DR flag is only set to 1 when FIFO is selected in asynchronous mode, including multi-processor mode. It is not set to 1 in other operation modes.

### TEND flag (Transmit End Flag)

The TEND flag indicates that FTDRHL does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- When FTDRHL does not contain transmit data when the last bit of a 1-byte serial character is transmitted.

[Clearing conditions]

- When transmit data is written to FTDRHL<sup>\*1</sup> while the SCR.TE bit is 1
- When 0 is written to TEND after 1 is read from TEND, when the SCR.TE bit is 1
- When the FCR.FM bit is changed from 0 to 1

Note 1. Do not use the TEND bit as a transmit end flag when the DTC writes data to FTDRHL in response to an SCIn\_TXI interrupt request.

### PER flag (Parity Error Flag)

The PER flag indicates whether there is a parity error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When data is received and a parity error is detected, when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to PER after reading PER = 1.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a parity error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

### FER flag (Framing Error Flag)

The FER flag indicates whether there is a framing error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When 0 is sampled as the stop bit during reception when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to FER after reading FER = 1.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a framing error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

### ORER flag (Overrun Error Flag)

The ORER flag indicates that the receive operation stopped abnormally because an overrun error occurred.

[Setting condition]

- When the next serial reception completes while the receive FIFO is full with 16-byte receive data.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

### RDF flag (Receive FIFO Data Full Flag)

The RDF flag indicates that receive data was transferred to the FRDRHL register, and the amount of data in FRDRHL is equal to or exceeds the specified receive triggering number. When RTRG is set to 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0.

[Setting condition]

- When the amount of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL,<sup>\*1</sup> and the FIFO is not empty.

[Clearing conditions]

- When 0 is written to RDF after reading RDF = 1
- When FRDRHL is read by the DTC, but only when the block transfer is the last transmission
- When the setting and clearing conditions occur at the same time, the RDF bit is set to 0. After that, when the amount of data stored in the FRDRHL register is the same as or greater than the RTRG value, RDF is set to 1 after 1 PCLK.

Note 1. Because FRDRHL is a 16-stage FIFO register, the maximum amount of data that can be read when RDF is 1 is equivalent to the specified receive triggering number. If an attempt is made to read after all the data in FRDRHL is read, the data is undefined.

### TDFE flag (Transmit FIFO Data Empty Flag)

The TDFE flag indicates that data is transferred from the FTDRHL register into the TSR register, the amount of data in FTDRHL is below the specified transmit triggering number, and writing of transmit data to FTDRHL is enabled.

[Setting conditions]

- When the TE bit in SCR is 0
- When the amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number<sup>\*1</sup>

[Clearing conditions]

- When writing to FTDRHL is executed on the last transmission while the DTC is activated
- When 0 is written to the TDFE flag after reading TDFE = 1.<sup>\*2</sup>  
The setting conditions are given priority when TE = 0. When the setting condition and clearing condition occur at the same time, the TDFE flag is set to 0. After that, when the amount of data stored in the FTDRHL register is equal to or less than the TTRG value, TDFE is set to 1 after 1 PCLK.

Note 1. Because the FTDRHL register is a 16-stage FIFO register, when the TDFE flag is 1, the maximum amount of data that can be written to the FTDRHL register is 16 minus FDR.T[4:0] bytes. If more data is written, data is discarded.

Note 2. Do not clear the TDFE flag during block transfer processing by the DTC.

### 27.2.17 SSR\_SMCI : Serial Status Register for Smart Card Interface Mode (SCMR.SMIF = 1, and MMR.MANEN = 0)

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x04

|               |      |      |      |     |     |      |     |      |
|---------------|------|------|------|-----|-----|------|-----|------|
| Bit position: | 7    | 6    | 5    | 4   | 3   | 2    | 1   | 0    |
| Bit field:    | TDRE | RDRF | ORER | ERS | PER | TEND | MPB | MPBT |

Value after reset: 1 0 0 0 0 1 0 0

| Bit | Symbol | Function                                                                                             | R/W              |
|-----|--------|------------------------------------------------------------------------------------------------------|------------------|
| 0   | MPBT   | Multi-Processor Bit Transfer<br>Set this bit to 0 in smart card interface mode                       | R/W              |
| 1   | MPB    | Multi-Processor<br>Set this bit to 0 in smart card interface mode                                    | R                |
| 2   | TEND   | Transmit End Flag<br>0: A character is being transmitted<br>1: Character transfer is complete        | R                |
| 3   | PER    | Parity Error Flag<br>0: No parity error occurred<br>1: Parity error occurred                         | R/W <sup>1</sup> |
| 4   | ERS    | Error Signal Status Flag<br>0: No low error signal response<br>1: Low error signal response occurred | R/W <sup>1</sup> |
| 5   | ORER   | Overrun Error Flag<br>0: No overrun error occurred<br>1: Overrun error occurred                      | R/W <sup>1</sup> |
| 6   | RDRF   | Receive Data Full Flag<br>0: No received data in RDR register<br>1: Received data in RDR register    | R/W <sup>1</sup> |
| 7   | TDRE   | Transmit Data Empty Flag<br>0: Transmit data in TDR register<br>1: No transmit data in TDR register  | R/W <sup>1</sup> |

Note 1. Only 0 can be written, to clear the flag after reading 1.

The SSR\_SMCI register provides the SCI with smart card interface mode status flags.

#### TEND flag (Transmit End Flag)

When there is no error signal from the receiving side, the TEND flag is set to 1 when more data for transfer is ready to be transferred to the TDR register.

[Setting conditions]

- When the SCR\_SMCI.TE bit = 0 (serial transmission is disabled).  
When the SCR\_SMCI.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period elapses after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated.

The set timing is determined by the following register settings:

- When SMR\_SMCI.GM = 0 and SMR\_SMCI.BLK = 0, 12.5 etus after the start of transmission
- When SMR\_SMCI.GM = 0 and SMR\_SMCI.BLK = 1, 11.5 etus after the start of transmission
- When SMR\_SMCI.GM = 1 and SMR\_SMCI.BLK = 0, 11.0 etus after the start of transmission
- When SMR\_SMCI.GM = 1 and SMR\_SMCI.BLK = 1, 11.0 etus after the start of transmission

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR\_SMCI.TE bit is 1
- When 0 is written to TDRE after reading TDRE = 1 while the SCR\_SMCI.TE bit is 1

### PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception. Although receive data is transferred to RDR when a parity error occurs, no SCIn\_RXI interrupt request occurs. After the PER flag is set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after reading PER = 1. After writing 0 to the PER flag, read the flag to check that it is actually set to 0.

When the RE bit in SCR\_SMCI is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

### ERS flag (Error Signal Status Flag)

[Setting condition]

- When a low error signal is sampled.

[Clearing condition]

- When 0 is written to ERS after reading ERS = 1.

### ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error is read from the RDR register. The data received before an overrun error occurred is saved in the RDR, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1. After writing 0 to the ORER flag, read the flag to check that it is actually set to 0.

When the RE bit in SCR\_SMCI is set to 0, the ORER flag is not affected and retains its previous value.

### RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

- When 0 is written to RDRF after reading RDRF = 1
- When data is forwarded from the RDR register

### TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR\_SMCI.TE bit is 0
- When data is transmitted from the TDR register to the TSR register

[Clearing conditions]

- When 0 is written to TDRE after reading TDRE = 1
- When the SCR\_SMCI.TE bit is 1 and data is written to the TDR register

### 27.2.18 SSR\_MANC : Serial Status Register for Manchester Mode (SCMR.SMIF = 0, and MMR.MANEN = 1)

Base address: SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x04

|                    |      |      |      |     |     |      |     |     |
|--------------------|------|------|------|-----|-----|------|-----|-----|
| Bit position:      | 7    | 6    | 5    | 4   | 3   | 2    | 1   | 0   |
| Bit field:         | TDRE | RDRF | ORER | FER | PER | TEND | MPB | MER |

| Bit | Symbol | Function                                                                                                                               | R/W                |
|-----|--------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| 0   | MER    | Manchester Error Flag<br>Valid for Manchester mode only<br>0: No Manchester error occurred<br>1: Manchester error has occurred         | R/(W) <sup>1</sup> |
| 1   | MPB    | Multi-Processor<br>Value of the multi-processor bit in the reception frame<br>0: Data transmission cycles<br>1: ID transmission cycles | R                  |
| 2   | TEND   | Transmit End Flag<br>0: A character is being transmitted<br>1: Character transfer has been completed.                                  | R                  |
| 3   | PER    | Parity Error Flag<br>0: No parity error occurred<br>1: A parity error has occurred                                                     | R/(W) <sup>1</sup> |
| 4   | FER    | Framing Error Flag<br>0: No framing error occurred<br>1: A framing error has occurred                                                  | R/(W) <sup>1</sup> |
| 5   | ORER   | Overrun Error Flag<br>0: No overrun error occurred<br>1: An overrun error has occurred                                                 | R/(W) <sup>1</sup> |
| 6   | RDRF   | Receive Data Full Flag<br>0: No received data is in RDR register<br>1: Received data is in RDR register                                | R/(W) <sup>1</sup> |
| 7   | TDRE   | Transmit Data Empty Flag<br>0: Transmit data is in TDR register<br>1: No transmit data is in TDR register                              | R/(W) <sup>1</sup> |

Note 1. Only 0 can be written to this bit, to clear the flag after confirmed(read) the flag is set to 1.

SSR is constructed in the status flag of SCI and reception multi processor bits.

#### MER flag (Manchester Error Flag)

When data is received in Manchester mode, Manchester error is detected and it is displayed.

[Setting conditions]

- When receiving in Manchester mode and detecting Manchester code error in data area of received frame.  
Received data when an error occurs is transferred to the RDR register, but the RXI interrupt request is not generated and the ERI interrupt request is generated.  
When the Manchester error flag is set to “1”, subsequent receive data is not transferred to the RDR register.  
For details on Manchester error, see [section 27.5.11. Errors in Manchester Mode](#).

[Clearing conditions]

- When 0 is written to MER after 1 is read (after writing 0 to it, read the MER flag to check that it is actually set to 0.) Even when the RE bit in SCR is set to 0 (serial reception is disabled), the MER flag is not affected and retains its previous value.

### MPB flag (Multi-Processor)

Holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

### TEND flag (Transmit End Flag)

Indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled) and FCR.FM bit is set to 0 (non-FIFO selected). When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted

[Clearing conditions]

- When transmit data are written to the TDR register while the SCR.TE bit is 1.
- When 0 is written to TDRE after 1 is read while the SCR.TE bit is 1.

### PER flag (Parity Error Flag)

Indicates that a parity error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When a parity error is detected during reception in Asynchronous Mode and the state of Address Match function invalidity (DCCR.DCME = 0). Although receive data when the parity error occurs is transferred to RDR, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after 1 is read (after writing 0 to it, read the PER flag to check that it is actually set to 0.)

Even when the RE bit in SCR is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

### FER flag (Framing Error Flag)

Indicates that a framing error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When 0 is sampled as the stop bit during reception in Asynchronous Mode and the state of Address Match function invalidity (DCCR.DCME = 0). In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. Note that although receive data when the framing error occurs is transferred to RDR, no RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to FER after 1 is read (after writing 0 to it, read the FER flag to check that it is actually set to 0.)

Even when the RE bit in SCR is set to 0, the FER flag is not affected and retains its previous value.

### ORER flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from RDR which don't have any valid reception error. In RDR, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, reception data isn't forwarded to RDR register. Note that, in clock synchronous mode, serial transmission and reception are stopped.

[Clearing condition]

- When 0 is written to ORER after 1 is read (after writing 0 to it, read the ORER flag to check that it is actually set to 0.)

Even when the RE bit in SCR is set to 0, the ORER flag is not affected and retains its previous value.

### RDRF flag (Receive Data Full Flag)

Indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register

[Clearing conditions]

- When 0 is written to RDRF after 1 is read
- When it reads the data from the RDR register

### TDRE flag (Transmit Data Empty Flag)

Indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR.TE bit is 0
- When data is transmitted from the TDR register to the TSR register

[Clearing conditions]

- When 0 is written to TDRE after 1 is read
- When the SCR.TE bit is 1, it is written to the TDR register

Note: RDRF and TDRE should not be cleared by SSR register access unless communication is interrupted.

## 27.2.19 SCMR : Smart Card Mode Register

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x06

| 7   | BCP2   | Base Clock Pulse 2<br>Selects the number of base clock cycles in combination with the SMR_SMCI.BCP[1:0] bits.<br><a href="#">Table 27.5</a> lists the combinations of the SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | R/W <sup>1</sup> |

Note 1. Writable only when the TE and RE bits in SCR/SCR\_SMCI are 0 (both serial transmission and reception are disabled).

Note 2. The setting is invalid and a fixed data length of 8 bits is used in modes other than asynchronous mode.

Note 3. LSB-first must be selected and the value of the MSB (bit [7]) in TDR cannot be transmitted.

The SCMR register selects the smart card interface and communication format.

### SMIF bit (Smart Card Interface Mode Select)

Setting the SMIF bit to 1 selects smart card interface mode. Setting it to 0 selects all other modes:

- Asynchronous mode, including multi-processor mode
- Clock synchronous mode
- Simple SPI mode
- Simple IIC mode

### SINV bit (Transmitted/Received Data Invert)

The SINV bit inverts the transmit and receive data logic level. It does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in SMR or SMR\_SMCI.

### CHR1 bit (Character Length 1)

The CHR1 bit selects the data length of transmit and receive data in combination with the CHR bit in the SMR register. A fixed data length of 8 bits is used in modes other than asynchronous mode.

### BCP2 bit (Base Clock Pulse 2)

The BCP2 bit selects the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set this bit in combination with the SMR\_SMCI.BCP[1:0] bits.

**Table 27.5 Combinations of the SCMR.BCP2 and SMR\_SMCI.BCP[1:0] bits**

| SCMR.BCP2 bit | SMR_SMCI.BCP[1:0] bits | Number of base clock cycles for 1-bit transfer period  |
|---------------|------------------------|--------------------------------------------------------|
| 0             | 00b                    | 93 clock cycles (S = 93) <sup>*1</sup>                 |
| 0             | 01b                    | 128 clock cycles (S = 128) <sup>*1</sup>               |
| 0             | 10b                    | 186 clock cycles (S = 186) <sup>*1</sup>               |
| 0             | 11b                    | 512 clock cycles (S = 512) <sup>*1</sup>               |
| 1             | 00b                    | 32 clock cycles (S = 32) (Initial Value) <sup>*1</sup> |
| 1             | 01b                    | 64 clock cycles (S = 64) <sup>*1</sup>                 |
| 1             | 10b                    | 372 clock cycles (S = 372) <sup>*1</sup>               |
| 1             | 11b                    | 256 clock cycles (S = 256) <sup>*1</sup>               |

Note 1. S is the value of S in [section 27.2.20. BRR : Bit Rate Register](#).

### 27.2.20 BRR : Bit Rate Register

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x01

BRR is an 8-bit register that adjusts the bit rate.

As each SCI channel has independent baud rate generator control, different bit rates can be set for each channel. [Table 27.6](#) shows the relationship between the setting (N) in the BRR and the bit rate (B) for normal asynchronous mode, multi-processor transfer, clock synchronous mode, smart card interface mode, simple SPI mode, and simple IIC mode.

The initial value of the BRR register is 0xFF. The BRR register can be read by the CPU, but it can be written to only when the TE and RE bits in SCR/SCR\_SMCI are 0.

**Table 27.6 Relationship between N setting in BRR and bit rate B**

| Mode                                   | SEMR settings |          |            | BRR setting                                                    | Error                                                                                                            |
|----------------------------------------|---------------|----------|------------|----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|

Note: B: Bit rate (bps)  
 N: BRR setting for on-chip baud rate generator ( $0 \leq N \leq 255$ )  
 PCLK: Operating frequency (MHz)  
 n and S: Determined by the SMR/SMR\_SMCI and SCMR register settings as listed in [Table 27.8](#) and [Table 27.9](#).  
 Note 1. Adjust the bit rate so that the widths of high and low level of the SCLn output in simple IIC mode satisfy the I<sup>2</sup>C bus standard.

**Table 27.7 Calculating widths of SCLn high and low levels**

| Mode | SCLn                                | Formula (result in seconds)                                                   |
|------|-------------------------------------|-------------------------------------------------------------------------------|
| IIC  | Width at high level (minimum value) | $(N + 1) \times 4 \times 2^{2n-1} \times 7 \times \frac{1}{PCLK \times 10^6}$ |
|      | Width at low level (minimum value)  | $(N + 1) \times 4 \times 2^{2n-1} \times 8 \times \frac{1}{PCLK \times 10^6}$ |

**Table 27.8 Clock source settings**

| SMR or SMR_SMCI.CKS[1:0] bits setting |               |   |
|---------------------------------------|---------------|---|
| CKS[1:0] bits                         | Clock source  | n |
| 00b                                   | PCLK clock    | 0 |

| 10b                                   | PCLK/16 clock | 2 |
| 11b                                   | PCLK/64 clock | 3 |

**Table 27.9 Base clock settings in smart card interface mode**

| SCMR.BCP2 bit setting | SMR_SMCI.BCP[1:0] bits setting | Base clock cycles for 1-bit period | S   |
|-----------------------|--------------------------------|------------------------------------|-----|
| BCP2 bit              | BCP[1:0] bits                  |                                    |     |
| 0                     | 00b                            | 93 clock cycles                    | 93  |
| 0                     | 01b                            | 128 clock cycles                   | 128 |
| 0                     | 10b                            | 186 clock cycles                   | 186 |
| 0                     | 11b                            | 512 clock cycles                   | 512 |
| 1                     | 00b                            | 32 clock cycles                    | 32  |
| 1                     | 01b                            | 64 clock cycles                    | 64  |
| 1                     | 10b                            | 372 clock cycles                   | 372 |
| 1                     | 11b                            | 256 clock cycles                   | 256 |

[Table 27.10](#) and [Table 27.11](#) list examples of BRR (N) settings in normal asynchronous mode. [Table 27.12](#) lists the maximum bit rate settable for each operating frequency. [Table 27.16](#) lists examples of BRR (N) settings in smart card interface mode.

In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, see [section 27.7.4. Receive Data Sampling Timing and Reception Margin](#). [Table 27.13](#) and [Table 27.15](#) list the maximum bit rates with external clock input.

When either the Asynchronous Mode Base Clock Select bit (ABCS) or the Baud Rate Generator Double-speed Mode Select bit (BGDM) in the Serial Extended Mode Register (SEMR) is set to 1 in asynchronous mode, the bit rate becomes twice the value listed in [Table 27.17](#). When both of those registers are set to 1, the bit rate becomes four times the listed value.

**Table 27.10 Examples of BRR settings for different bit rates in asynchronous mode (1) (1 of 3)**

| Bit rate (bps) | Operating frequency PCLK (MHz) |     |           |        |     |           |    |     |           |    |     |           |        |     |           |  |

| 31250          | 0                              | 13  | 0.00      | 0  | 15  | 0.00      | 0       | 16  | 1.20      | 0  | 17  | 0.00      | 0       | 19  | -1.70     |
| 38400          | —                              | —   | —         | 0  | 12  | 0.16      | 0       | 13  | 0.00      | 0  | 14  | -2.34     | 0       | 15  | 0.00      |

Note: In this example, SEMR.ABCS = 0, SEMR.ABCSE = 0, and SEMR.BGDM = 0.  
 When either the ABCS or BGDM bit is set to 1, the bit rate doubles.  
 When both ABCS and BGDM are set to 1, the bit rate increases four times.

**Table 27.11 Examples of BRR settings for different bit rates in asynchronous mode (2) (1 of 3)**

| 4800           | 1                              | 80  | 0.47      | 1  | 97  | -0.35     | 1   | 162 | -0.15     |
| 9600           | 0                              | 162 | -0.15     | 1  | 48  | -0.35     | 1   | 80  | 0.47      |
| 19200          | 0                              | 80  | 0.47      | 0  | 97  | -0.35     | 0   | 162 | -0.15     |
| 31250          | 0                              | 49  | 0.00      | 0  | 59  | 0.00      | 1   | 24  | 0.00      |
| 38400          | 0                              | 40  | -0.76     | 0  | 48  | -0.35     | 0   | 80  | 0.47      |

Note: In this example, SEMR.ABCS = 0, SEMR.ABCSE = 0, and SEMR.BGDM = 0.  
 When either the ABCS or BGDM bit is set to 1, the bit rate doubles.  
 When both ABCS = 1 and BGDM = 1, the bit rate quadruples.

**Table 27.12 Maximum bit rate for each operating frequency in asynchronous mode (1 of 2)**

| PCLK (MHz) | SEMR settings |          |           |   |   | Maximum bit rate (bps) | PCLK (MHz) | SEMR settings |            |           |   |   | Maximum bit rate (bps) |

Note: Space: Setting prohibited.

—: Can be set, but an error occurs.

Note 1. Continuous transmission or reception is not possible. After transmitting or receiving one frame of data, a 1-bit period elapses before starting to transmit or receive the next frame of data. The output of the synchronization clock is stopped for a 1-bit period. Therefore, it takes 9 bits worth of time to transfer one frame (8 bits) of data, and the average transfer rate is 8/9 times the bit rate. When the FIFO is selected, this setting (BRR = 0x00 and SMR.CKS[1:0] = 00b) is not available.

**Table 27.15 Maximum bit rate with external clock input in clock synchronous and simple SPI modes**

| PCLK (MHz) | External input clock (MHz) | Maximum bit rate (Mbps) |
|------------|----------------------------|-------------------------|
| 8          | 1.3333                     | 1.3333333               |

### 27.2.21 MDDR : Modulation Duty Register

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x12

MDDR corrects the bit rate adjusted by the BRR register.

When the BRME bit in SEMR is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected using the settings in MDDR (M/256). Table 27.20 shows the relationship between the MDDR setting (M) and the bit rate (B).

The initial value of MDDR is 0xFF. Bit [7] in this register is fixed to 1.

The CPU can read the MDDR register, but this register is only writable when the TE and RE bits in SCR/SCR\_SMCI are 0.

**Table 27.20 Relationship between MDDR setting (M) and bit rate (B) when bit rate modulation function is used (1 of 2)**

B: Bit rate (bps)  
 M: MDDR setting (128 ≤ MDDR ≤ 256)  
 N: BRR setting for baud rate generator (0 ≤ N ≤ 255)  
 PCLK: Operating frequency (MHz)  
 n and S: Determined by the SMR/SMR\_SMCI and SCMR register settings as listed in Table 27.8 and Table 27.9 in section 27.2.20. BRR : Bit Rate Register.

| Mode                                 | SEMR settings |          |           | BRR setting                                                                   | Error                                                                                                                          |

**Table 27.20 Relationship between MDDR setting (M) and bit rate (B) when bit rate modulation function is used (2 of 2)**

B: Bit rate (bps)

M: MDDR setting (128 ≤ MDDR ≤ 256)

N: BRR setting for baud rate generator (0 ≤ N ≤ 255)

PCLK: Operating frequency (MHz)

n and S: Determined by the SMR/SMR\_SMCI and SCMR register settings as listed in Table 27.8 and Table 27.9 in section 27.2.20. BRR : Bit Rate Register.

| Mode                                        | SEMR settings |          |           | BRR setting                                                                                      | Error                                                                                                                                                   |
|---------------------------------------------|---------------|----------|-----------|--------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                             | BGDM bit      | ABCS bit | ABCSE bit |                                                                                                  |                                                                                                                                                         |

| Smart card interface                        |               |          |           | $N = \frac{PCLK \times 10^6}{S \times 2^{2n+1} \times \left(\frac{256}{M}\right) \times B} - 1$  | $\text{Error}(\%) = \left\{ \frac{PCLK \times 10^6}{B \times S \times 2^{2n+1} \times \left(\frac{256}{M}\right) \times (N+1)} - 1 \right\} \times 100$ |
| Simple IIC <sup>*2</sup>                    |               |          |           | $N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times \left(\frac{256}{M}\right) \times B} - 1$ | —                                                                                                                                                       |

Note 1. Do not use this function in clock synchronous mode or in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

Note 2. Adjust the bit rate so that the widths at high and low level of the SCLn output in simple IIC mode satisfy the IIC standard.

Table 27.21 and Table 27.22 list examples of N settings in BRR and M settings in MDDR in normal asynchronous mode.

**Table 27.21 Examples of the BRR and MDDR settings for different bit rates in asynchronous mode (1) (1 of 3)**

Note 1. Writable only when the TE and RE bits in SCR/SCR\_SMCI are 0 (both serial transmission and reception are disabled).

The SEMR register selects the clock source for the 1-bit period in asynchronous mode.

### PADIS bit (Preamble function Disable)

In asynchronous mode, select enable / disable of preamble function. In Manchester mode, preamble is not output regardless of this bit setting

### BRME bit (Bit Rate Modulation Enable)

The BRME bit enables or disables the bit rate modulation function. The bit rate generated by the on-chip baud rate generator is evenly corrected when this function is enabled. Set to 0 in Manchester mode.

**ABCSE bit (Asynchronous Mode Extended Base Clock Select 1)**

The ABCSE bit sets the pulse number for the base clock in a 1-bit period to 6, and the double-frequency clock is output from the baud rate generator. When the bit rate is set to 6 while dividing the bus clock frequency, use this bit and set  $SMR.CKS[1:0] = 00b$  and  $BRR = 0$ .

Set it to 0 in modes other than asynchronous mode. Even in asynchronous mode, set it to 0 when using external clock.

**ABCS bit (Asynchronous Mode Base Clock Select)**

The ABCS bit selects the number of clock cycles for a 1-bit period.

Set it to 0 in modes other than asynchronous mode and Manchester mode.

**NFEN bit (Digital Noise Filter Function Enable)**

The NFEN bit enables or disables the digital noise filter function.

When the digital noise filter function is enabled:

- Noise cancellation is applied to the RXDn input signal in asynchronous mode
- Noise cancellation is applied to the SDA<sub>n</sub> and SCL<sub>n</sub> input signals in simple I<sup>2</sup>C mode

In all other modes, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as received.

**BGDM bit (Baud Rate Generator Double-Speed Mode Select)**

The BGDM bit selects whether or not to double the base clock frequency output from the baud rate generator.

The BGDM bit is valid when the on-chip baud rate generator is selected as the clock source ( $SCR.CKE[1] = 0$ ) in asynchronous mode ( $SMR.CM = 0$ ) or Manchester mode ( $MMR.MANEN = 1$ ). When external clock is selected ( $SCR.CKE[1] = 1$ ), set it to 0. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.

Set this bit to 0 in modes other than asynchronous mode or Manchester mode.

**RXDESEL bit (Asynchronous Start Bit Edge Detection Select)**

The RXDESEL bit selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data reception operation depends on the setting of this bit. Set this bit to 1 when reception must be stopped while a break occurs or when reception must be started without keeping the RXDn pin input at the high level for the period of one data frame or longer after completion of the break.

Set this bit to 0 in modes other than asynchronous mode.

**27.2.23 SNFR : Noise Filter Setting Register**

Base address:  $SCI_n = 0x4011\_8000 + 0x0100 \times n$  ( $n = 0, 9$ )  
 $SCI_k = 0x4011\_8000 + 0x0100 \times k$  ( $k = 3, 4$ )

Offset address: 0x08

| 7:3 | —         | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | R/W               |

Note 1. Writing to these bits is only possible when the RE and TE bits in SCR/SCR\_SMCI are 0 (serial reception and transmission disabled).

The SNFR register sets the digital noise filter clock.

### NFCS[2:0] bits (Noise Filter Clock Select)

The NFCS[2:0] bits select the sampling clock for the digital noise filter. To use the noise filter in asynchronous mode, set these bits to 000b. In simple I<sup>2</sup>C mode, when 32 clocks are selected as one bit period in the basic clock selection bits of the SEMR register, set the NFCS [2: 0] bits in the range from 001b to 100b. When any other value is selected for the basic clock selection bit, set the NFCS bit to 001b.

## 27.2.24 SIMR1 : IIC Mode Register 1

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x09

Value after reset: 0 0 0 0 0 0 0 0 0

| Bit | Symbol     | Function                                                                                                                                                                                                                                                         | R/W               |

| 2:1 | —          | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                           | R/W               |
| 7:3 | IICDL[4:0] | SDAn Delay Output Select<br>SDAn signal output delay in cycles of the clock signal from the on-chip baud rate generator.<br>0x00: No output delay<br>Others: (IICDL - 1) to (IICDL) cycles                                                                       | R/W <sup>*1</sup> |

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).

SIMR1 selects simple IIC mode and the number of delay stages for the SDAn output.

### IICM bit (Simple IIC Mode Select)

In combination with the SCMR.SMIF bit, the IICM bit selects the operating mode.

**IICDL[4:0] bits (SDAn Delay Output Select)**

The IICDL[4:0] bits specify an output delay on the SDAn pin relative to the falling edge of the output on the SCLn pin.

The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generator as the base. The signal obtained by frequency-dividing PCLK by the divisor set in SMR.CKS[1:0] is supplied as the clock signal from the on-chip baud rate generator. Set 00000b to IICDL[4:0] bits unless operation is in simple IIC mode. In simple IIC mode, set the bits to a value in the range from 00001b to 11111b.

**Table 27.23 Settable value of IICDL[4: 0] bits in each communication mode**

| Communication mode         | ABCS       | Settable value of IICDL[4:0] bits |
|----------------------------|------------|-----------------------------------|
| Other than simple IIC mode | Don't care | 00000b                            |
| Simple IIC mode            | 0          | 00001b to 11111b                  |
|                            | 1          | 00001b to 00100b                  |

**27.2.25 SIMR2 : IIC Mode Register 2**

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x0A

| 1   | IICCS C | Clock Synchronization<br>0: Do not synchronize with clock signal<br>1: Synchronize with clock signal    | R/W <sup>1</sup> |
| 4:2 | —       | These bits are read as 0. The write value should be 0.                                                  | R/W              |
| 5   | IICACKT | ACK Transmission Data<br>0: ACK transmission<br>1: NACK transmission and ACK/NACK reception             | R/W              |
| 7:6 | —       | These bits are read as 0. The write value should be 0.                                                  | R/W              |

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (serial reception and transmission disabled).

SIMR2 selects how reception and transmission are controlled in simple IIC mode.

**IICINTM bit (IIC Interrupt Mode Select)**

The IICINTM bit selects the sources of interrupt requests in simple IIC mode.

**IICCS C bit (Clock Synchronization)**

Set the IICCS C bit to 1 if the internally generated SCLn clock signal is to be synchronized when the SCLn pin is driven low because a wait was inserted by another other device.

The SCLn clock signal is not synchronized if the IICCS C bit is 0. The SCLn clock signal is generated according to the rate selected in the BRR register regardless of the level being input on the SCLn pin.

Set the IICCS C bit to 1 except during debugging.

**IICACKT bit (ACK Transmission Data)**

Transmitted data contains ACK bits. Set the IICACKT bit to 1 when ACK and NACK bits are received.

## 27.2.26 SIMR3 : IIC Mode Register 3

Base address: SCLn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCLk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x0B

| 2   | IICSTPREQ    | Stop Condition Generation<br>0: Do not generate stop condition<br>1: Generate stop condition*2 *3 *5 *6                                                                                                                                                                        | R/W   |
| 3   | IICSTIF      | Issuing of Start, Restart, or Stop Condition Completed Flag<br>0: No requests are being made for generating conditions, or a condition is being generated<br>1: Generation of start, restart, or stop condition is complete.<br>When 0 is written to IICSTIF, it is set to 0*4 | R/W*4 |
| 5:4 | IICSDAS[1:0] | SDAn Output Select<br>0 0: Output serial data<br>0 1: Generate start, restart, or stop condition<br>1 0: Output low on SDAn pin<br>1 1: Drive SDAn pin to high-impedance state                                                                                                 | R/W   |
| 7:6 | IICSCLS[1:0] | SCLn Output Select<br>0 0: Output serial clock<br>0 1: Generate start, restart, or stop condition<br>1 0: Output low on SCLn pin<br>1 1: Drive SCLn pin to high-impedance state                                                                                                | R/W   |

Note 1. Only generate a start condition after checking the bus state and confirming that the bus is free.

Note 2. Generate a restart or stop condition after checking the bus state and confirming that the bus is busy.

Note 3. Do not set more than one of the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.

Note 4. Write only 0. When 1 is written, the value is ignored.

Note 5. Execute the generation of a condition after the value of the IICSTIF flag is 0.

Note 6. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

The SIMR3 register is used to control the start, restart, and stop conditions in the simple I<sup>2</sup>C mode, and to hold the SSDAn and SSCLn pins at fixed levels.

**IICSTAREQ bit (Start Condition Generation)**

When a start condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of start condition generation.

**IICRSTAREQ bit (Restart Condition Generation)**

When a restart condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICRSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of restart condition generation.

### IICSTPREQ bit (Stop Condition Generation)

When a stop condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTPREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of stop condition generation.

### IICSTIF flag (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, the IICSTIF flag indicates that the condition generation is complete. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR.TEIE bit, an STI request is output.

[Setting condition]

- On completion of a start, restart, or stop condition generation.

If the setting condition conflicts with any of the clearing conditions for the flag, the clearing condition takes precedence.

[Clearing conditions]

- On writing 0 to the bit. After writing 0 to the IICSTIF bit, read the bit to check that it is actually set to 0.
- On writing 0 to the SIMR1.IICM bit when operation is not in simple IIC mode.
- On writing 0 to the SCR.TE bit.

### IICSDAS[1:0] bits (SDAn Output Select)

The IICSDAS[1:0] bits control output from the SDAn pin. Set IICSDAS[1:0] and IICSCLS[1:0] to the same value during normal operations.

### IICSCLS[1:0] bits (SCLn Output Select)

The IICSCLS[1:0] bits control output from the SCLn pin. Set IICSDAS[1:0] and IICSCLS[1:0] to the same value during normal operations.

## 27.2.27 SISR : IIC Status Register

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x0C

| 7:6 | —      | These bits are read as 0.    | R   |

SISR monitors the state in simple IIC mode.

### IICACKR flag (ACK Reception Data Flag)

Received ACK and NACK bits can be read from the IICACKR flag. The IICACKR flag is updated on the rising edge of the SCLn clock for the received ACK/NACK bit.

## 27.2.28 SPMR : SPI Mode Register

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x0D

| 7   | CKPH   | Clock Phase Select<br>0: Do not delay clock<br>1: Delay clock                                                                                                                                                                                                             | R/W <sup>1</sup> |

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).

Note 2. Only 0 can be written to this bit, to clear the flag.

SPMR selects the extension settings in asynchronous and clock synchronous modes.

### SSE bit (SSn Pin Function Enable)

Set the SSE bit to 1 to use the SSn pin to control transmission and reception in simple SPI mode. Set this bit to 0 in all other modes. In simple SPI mode, when master mode is selected (SCR.CKE[1:0] = 00b and SPMR.MSS = 0) and there is a single master, the SSn pin on the master side is not required to control reception and transmission. In such a case, set the SSE bit to

0. Do not set both the SSE and CTSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

**CTSE bit (CTS Enable)**

Set the CTSE bit to 1 if the SSn pin is to be used for inputting the CTS control signal to control transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, and simple IIC mode. Do not set both the CTSE and SSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

**MSS bit (Master Slave Select)**

The MSS bit selects master or slave operation in simple SPI mode. The functions of the TXDn and RXDn pins are reversed when this bit is set to 1, so that data is received through the TXDn pin and transmitted through the RXDn pin.

Set this bit to 0 in modes other than simple SPI mode.

**CTSPEN bit (CTS external pin Enable)**

Select the terminals usage method when using the CTS and RTS functions.

**MFF flag (Mode Fault Flag)**

The MFF flag indicates mode fault errors. In a multi-master configuration, determine the mode fault error occurrence by reading this flag.

[Setting condition]

- When input on the SSn pin is low during master operation in simple SPI mode (SSE bit = 1 and MSS bit = 0).

[Clearing condition]

- On writing 0 to the bit after it is read as 1.

**CKPOL bit (Clock Polarity Select)**

The CKPOL bit selects the polarity of the clock signal output through the SCKn pin. See [Figure 27.96](#) for details. Set the CKPOL bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

**CKPH bit (Clock Phase Select)**

The CKPH bit selects the phase of the clock signal output through the SCKn pin. See [Figure 27.96](#) for details. Set the CKPH bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

**27.2.29 FCR : FIFO Control Register**

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x14

| 2     | TFRST      | Transmit FIFO Data Register Reset<br>Valid only when FCR.FM = 1.<br>0: Do not reset FTDRHL<br>1: Reset FTDRHL                                                                                                                                       | R/W |
| 3     | DRES       | Receive Data Ready Error Select<br>Selects the interrupt requested when detecting receive data ready.<br>0: Receive data full interrupt (SCIn_RXI)<br>1: Receive error interrupt (SCIn_ERI)                                                         | R/W |
| 7:4   | TTRG[3:0]  | Transmit FIFO Data Trigger Number<br>Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode.<br>The trigger number is specified in the TTRG[3:0] bits.                                                          | R/W |
| 11:8  | RTRG[3:0]  | Receive FIFO Data Trigger Number<br>Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode.<br>The trigger number is specified in the RTRG[3:0] bits.                                                           | R/W |
| 15:12 | RSTRG[3:0] | RTS Output Active Trigger Number Select<br>Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, when FCR.FM = 1, SPMR.CTSE = 0, and SPMR.SSE = 0.<br>The trigger number is specified in the RSTRG[3:0] bits. | R/W |

Note 1. Writable only when TE = 0 and RE = 0.

FCR selects FIFO mode, resets FTDRHL and FRDRHL, selects the FIFO data trigger number for transmission or reception, and selects the RTS output active trigger number.

#### FM bit (FIFO Mode Select)

When the FM bit is set to 1, FTDRHL and FRDRHL are selected for communication. When the FM bit is set to 0, TDR and RDR, or TDRHL and RDRHL are selected for communication.

#### RFRST bit (Receive FIFO Data Register Reset)

When the RFRST bit is set to 1, the FRDRHL register is reset and the received data count resets to 0. When 1 is written to the RFRST bit, it clears to 0 after 1 PCLK.

#### TFRST bit (Transmit FIFO Data Register Reset)

When the TFRST bit is set to 1, the FTDRHL register is reset and the transmit data count resets to 0. When 1 is written to the TFRST bit, it clears to 0 after 1 PCLK.

#### DRES bit (Receive Data Ready Error Select)

When detecting a receive data ready error, the selection can be made from an SCIn\_RXI interrupt request or an SCIn\_ERI interrupt request.

#### TTRG[3:0] bits (Transmit FIFO Data Trigger Number)

The TDFE flag is set to 1 when the amount of transmit data in FTDRHL is equal to or less than the transmit triggering number specified in the TTRG[3:0] bits, and software can write data to FTDRHL. If SCR.TIE = 1, an SCIn\_TXI interrupt request occurs.

#### RTRG[3:0] bits (Receive FIFO Data Trigger Number)

The RDF flag is set to 1 when the amount of receive data in FRDRHL is equal to or greater than the receive triggering number specified in the RTRG[3:0] bits, and software can read data from FRDRHL. If SCR.RIE = 1, an SCIn\_RXI interrupt request occurs.

When RTRG[3:0] is 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0, and an SCIn\_RXI interrupt does not occur.

**RSTRG[3:0] bits (RTS Output Active Trigger Number Select)**

When the amount of receive data stored in FRDRHL is equal to or greater than the receive triggering number specified in the RSTRG[3:0] bits, the RTS signal goes high.

When RSTRG[3:0] is 0, the RTS signal does not go high even when the amount of data in FRDRHL is equal to 0.

**27.2.30 FDR : FIFO Data Count Register**

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x16

| 4:0   | R[4:0] | Receive FIFO Data Count<br>Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, when FCR.FM = 1.<br>Indicates the amount of receive data stored in FRDRHL.          | R   |
| 7:5   | —      | These bits are read as 0.                                                                                                                                                                                  | R   |
| 12:8  | T[4:0] | Transmit FIFO Data Count<br>Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, when FCR.FM = 1.<br>Indicates the amount of non-transmitted data stored in FTDRHL. | R   |
| 15:13 | —      | These bits are read as 0.                                                                                                                                                                                  | R   |

The FDR register indicates the amount of data stored in FRDRHL and FTDRHL.

**R[4:0] bits (Receive FIFO Data Count)**

The R[4:0] bits indicate the amount of receive data stored in FRDRHL. 0x00 means no receive data, and 0x10 means that the maximum received data is stored in FRDRHL.

**T[4:0] bits (Transmit FIFO Data Count)**

The T[4:0] bits indicate the amount of non-transmitted data stored in FTDRHL. 0x00 means no transmit data, and 0x10 means that all (maximum amount) of the data to be transmitted is stored in FTDRHL.

**27.2.31 LSR : Line Status Register**

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)

| 7     | —         | This bit is read as 0.                                                                                         | R   |
| 12:8  | PNUM[4:0] | Parity Error Count<br>Indicates the amount of data with a parity error in the receive data stored in FRDRHL.   | R   |
| 15:13 | —         | These bits are read as 0.                                                                                      | R   |

Note 1. Write 0 to SSR\_FIFO.ORER to clear the flag.

The LSR register indicates the receive error status.

### ORER flag (Overflow Error Flag)

The ORER flag reflects the value in SSR\_FIFO.ORER.

### FNUM[4:0] bits (Framing Error Count)

The FNUM[4:0] value indicates the amount of data with a framing error stored in the FRDRHL register.

### PNUM[4:0] bits (Parity Error Count)

The PNUM[4:0] value indicates the amount of data with a parity error stored in the FRDRHL register.

## 27.2.32 CDR : Compare Match Data Register

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x1A

| Bit position:      | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8         | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------------------|----|----|----|----|----|----|---|-----------|---|---|---|---|---|---|---|---|
| Bit field:         | —  | —  | —  | —  | —  | —  | — | CMPD[8:0] |   |   |   |   |   |   |   |   |
| Value after reset: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0         | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit  | Symbol    | Function                                                                            | R/W |
|------|-----------|-------------------------------------------------------------------------------------|-----|
| 8:0  | CMPD[8:0] | Compare Match Data<br>Holds compare data pattern for address match wakeup function. | R/W |
| 15:9 | —         | These bits are read as 0. The write value should be 0.                              | R/W |

The CDR register sets the compare data for the address match function.

### CMPD[8:0] bits (Compare Match Data)

The CMPD[8:0] bits set the data to be compared to receive data for the address match function, when the address match function is enabled (DCCR.DCME = 1).

Three bit lengths are available:

- CMPD[6:0] with 7-bit length
- CMPD[7:0] with 8-bit length
- CMPD[8:0] with 9-bit length

### 27.2.33 DCCR : Data Compare Match Control Register

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
 SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x13

|                    |      |       |   |      |      |   |   |      |

| 4   | DFER   | Data Compare Match Framing Error Flag<br>0: No framing error occurred<br>1: Framing error occurred                                                                                                | R/(W) <sup>1</sup> |
| 5   | —      | This bit is read as 0. The write value should be 0.                                                                                                                                               | R/W                |
| 6   | IDSEL  | ID Frame Select<br>Valid only in asynchronous mode, including multi-processor mode.<br>0: Always compare data regardless of the MPB bit value<br>1: Only compare data when MPB bit = 1 (ID frame) | R/W                |
| 7   | DCME   | Data Compare Match Enable<br>Valid only in asynchronous mode, including multi-processor mode.<br>0: Disable address match function<br>1: Enable address match function                            | R/W                |

Note 1. Only 0 can be written, to clear the flag after reading 1.

The DCCR register controls the address match function.

#### DCMF flag (Data Compare Match Flag)

The DCMF flag indicates that the SCI detected a receive data match with the comparison data (CDR.CMPD).

[Setting condition]

- On match of the comparison data (CDR.CMPD) with the receive data when DCCR.DCME = 1.

[Clearing condition]

- When 0 is written after 1 is read from DCMF.

Clearing the SCR.RE bit to 0 does not affect the DCMF flag, which retains its previous value.

#### DPER flag (Data Compare Match Parity Error Flag)

The DPER flag indicates that a parity error occurred on address match detection (receive data match detection).

[Setting condition]

- When a parity error is detected in a frame in which an address match is detected.

[Clearing conditions]

- When 0 is written after 1 is read from DPER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DPER flag is not affected and retains its previous value.

**DFER flag (Data Compare Match Framing Error Flag)**

The DFER flag indicates that a framing error occurred on address match detection (receive data match detection).

[Setting conditions]

- When a stop bit of a frame in which an address match is detected is 0.  
When in 2-stop-bit mode, only the first bit of the stop bits is checked for a value of 1 (the second stop bit is not checked).

[Clearing conditions]

- When 0 is written after 1 is read from DFER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DFER flag is not affected and retains its previous value.

**IDSEL bit (ID Frame Select)**

The IDSEL bit selects whether to compare data regardless of the MPB bit value or to compare data only when MPB = 1 (ID frame), when the address match function is enabled.

**DCME bit (Data Compare Match Enable)**

The DCME bit enables or disables the address match function (data compare match function).

If the SCI detects a match to the comparison data (CDR.CMPD) with the receive data, the DCME bit clears automatically, after which SCI operation mode is in normal receive mode. See [section 27.3.6. Address Match \(Receive Data Match Detection\) Function](#).

The write value must be 0 for all modes other than asynchronous mode.

**27.2.34 SPTR : Serial Port Register**

Base address: SCIn = 0x4011\_8000 + 0x0100 × n (n = 0, 9)  
SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x1C

|                    |      |      |      |      |   |        |        |        |

| 6   | ASEN   | Adjust receive sampling timing enable<br>(This bit enables in asynchronous mode using internal clock)<br>This function can adjust the receive sampling timing.<br>In asynchronous mode using internal clock, see <a href="#">section 27.3.10. The function of adjust receive sampling timing (Asynchronous Mode)</a> for details.<br>0: Adjust sampling timing disable.<br>1: Adjust sampling timing enable. | R/W <sup>3</sup> |
| 7   | ATEN   | Adjust transmit timing enable<br>(This bit enables in asynchronous mode using internal clock)<br>This function can adjust the transmit edge of TXDn waveform. See <a href="#">section 27.3.11. The function of adjust transmit timing (Asynchronous Mode)</a> for details.<br>0: Adjust transmit timing disable.<br>1: Adjust transmit timing enable.                                                        | R/W <sup>3</sup> |

Note 1. Please use this bit in asynchronous mode and manchester mode. Movement by other mode isn't guaranteed.

Note 2. RINV/TINV should be set to 0 in smart card interface mode and simple I2C mode.

Note 3. Change the value of these bits only at SCR.TE = SCR.RE = 0.

The SPTR register provides confirmation of the serial reception pin (RXDn pin) status and sets the transmission and receive pin status.

And SPTR register has enable bits for adjust functions of receive sampling timing and transmit timing.

The TXDn pin status is determined by the combination of SCR.TE, SPTR.SPB2IO, and SPTR.SPB2DT settings, as shown in [Table 27.24](#).

The data of RDR is controlled by RINV and SCMR.SINV. And the data from TXDn terminal is controlled by TINV and SCMR.SINV. The control by RINV/TINV are done to communication terminals (RXDn/TXDn), so they can control not only data-bits but also other bits (start bit, stop bit, parity bit). For details, see [Figure 27.2](#).

**Table 27.24 TXDn pin status**

| Value of SCR.TE | Value of SPTR.SPB2IO | Value of SPTR.SPB2DT | TXDn pin status                |
|-----------------|----------------------|----------------------|--------------------------------|
| 0               | 0                    | —                    | Hi-Z (initial value)           |
| 0               | 1                    | 0                    | Low level output               |
| 0               | 1                    | 1                    | High level output              |
| 1               | —                    | —                    | Serial transmit data is output |

Note: —: Do not care.

Note: Use the SPTR register in asynchronous mode only. Using this register in any other mode is not guaranteed.

The receive/transmit data control (Data size=8bits, Even parity, MSB first)

The transmit data is controlled by SPTR.TINV and SCMR.SINV.

| SCMR.SINV | SPTR.TINV | TDR  | TSR  | Prity (even) | TXDn waveform |   |    |    |    |    |    |    |    |    |    |    |    |  |  |

|-----|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 2:0 | AST    | Adjustment value for receive Sampling Timing<br>The sampling timing of RXD terminal is adjusted from the middle of bit by the following formula.<br>Adjustment sampling timing = base clock × the setting value of AST[2:0].<br>This bit is effective only at SPTR.ASEN = 1. This setting timing is limited by setting the base clock cycles. For details, see <a href="#">section 27.3.10. The function of adjust receive sampling timing (Asynchronous Mode)</a> . | R/W <sup>1</sup> |
| 3   | AJD    | Adjustment Direction for receive sampling timing<br>Adjustment direction for RXD receive sampling timing is determined by this bit.<br>0: The sampling timing is adjusted backward to the middle of bit.<br>1: The sampling timing is adjusted forward to the middle of bit.<br>This bit is effective only at SPTR.ASEN = 1. For details, see <a href="#">section 27.3.10. The function of adjust receive sampling timing (Asynchronous Mode)</a> .                  | R/W <sup>1</sup> |
| 6:4 | ATT    | Adjustment value for Transmit timing<br>The selected edge timing of TXD is adjusted by the following formula.<br>Adjustment edge timing = base clock × the setting value of ATT[2:0].<br>This bit is effective only at SPTR.ATEN = 1. This setting timing is limited by setting the base clock cycles. For details, see <a href="#">section 27.3.11. The function of adjust transmit timing (Asynchronous Mode)</a> .                                                | R/W <sup>2</sup> |
| 7   | AET    | Adjustment edge for transmit timing<br>The adjustable edge is set by this bit.<br>When SPTR.TINV is 0,<br>0: Adjust the rising edge timing.<br>1: Adjust the falling edge timing.<br>When SPTR.TINV is 1,<br>0: Adjust the falling edge timing.<br>1: Adjust the rising edge timing.<br>This bit is effective only at SPTR.ATEN = 1. For details, see <a href="#">section 27.3.11. The function of adjust transmit timing (Asynchronous Mode)</a> .                  | R/W <sup>2</sup> |

Note 1. Write this bit only when SPTR.ASEN = 0.

Note 2. Write this bit only when SPTR.ATEN = 0.

This register controls adjustment of receive sampling timing and transmit timing. This register is effective only when asynchronous mode using internal clock.

For details of adjustment receive sampling timing by this register, see [section 27.3.10. The function of adjust receive sampling timing \(Asynchronous Mode\)](#).

For details of adjustment transmit timing by this register, see [section 27.3.11. The function of adjust transmit timing \(Asynchronous Mode\)](#).

Note: Sentences and a timing chart of the IP operation explanation (except [section 27.1. Overview](#), [section 27.2. Register Descriptions](#), [section 27.3.10. The function of adjust receive sampling timing \(Asynchronous Mode\)](#) and [section 27.3.11. The function of adjust transmit timing \(Asynchronous Mode\)](#)) are mentioned by the condition that the receive sampling timing and transmit timing adjustments are disabled (SPTR.ASEN = 0, SPTR.ATEN = 0).

Note: Bits 6 to 0 in this register are valid only when the Manchester mode is enabled.(MANEN = "1") in bit 7.

Note 1. Writing to these bits is only possible when the RE and TE bits in SCR are 0 (both serial transmission and reception are disabled).

This register is used to enable or disable the Manchester mode, set the start bit area, and set the logic polarity.

#### RMPOL bit (Polarity of Received Manchester Code)

This bit sets the polarity of the received Manchester code. For details, see [section 27.5.7. Serial Data Reception in Manchester Mode](#).

#### TMPOL bit (Polarity of Transmit Manchester Code)

This bit sets the polarity of the transmit Manchester code. For details, see [section 27.5.6. Serial data transmission in Manchester mode](#).

#### ERTEN bit (Manchester Edge Retiming Enable)

This bit sets the receive retiming function in Manchester mode.

For information on the receive retiming function, see [section 27.5.9. Receive Retiming](#).

### SYNVAL bit (SYNC value Setting)

This bit is valid when the SYNSEL bit of this register is set to 0.

The SYNC type can be set by combining this bit and the SBSEL bit.

For the start bit area determined by the combination of this bit and the SBSEL bit, see [Figure 27.49](#) and [Figure 27.50](#).

### SYNSEL bit (SYNC Select)

This bit is valid when the SBSEL bit of this register is set to 1. This bit determines the destination to be referred to for setting the SYNC type of the start bit area added to Manchester frames.

When this bit is set to 0, the SYNVAL bit of this register is referred to.

When this bit is set to 1, the TSYNC bit in the TDRH register is referred to.

For detail, see the bit table in [section 27.2.36. MMR : Manchester Mode Register](#).

### SBSEL bit (Start Bit Select)

This bit sets the start bit area in Manchester frames.

When this bit is set to 1, the start bit area added to each frame consists of three bits, and the SYNSEL and SYNVAL bits in this register are valid.

When this bit is set to 0, the start bit area added to each frame consists of one bit.

### MANEN bit (Manchester Mode Enable)

This bit sets the Manchester mode.

When this bit is set to 0, the Manchester mode is disabled.

When this bit is set to 1, the Manchester mode is enabled.

## 27.2.37 TMPR : Transmit Manchester Preface Setting Register

Base address: SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x22

Note: This register is valid only when the Manchester mode is enabled (MMR.MANEN = 1).

Note 1. Writing to these bits is only possible when the RE and TE bits in SCR are 0 (both serial transmission and reception are disabled).

This register is used to set the preface length and preface pattern of the transmit data in Manchester mode.

### TPLEN bit (Transmit preface length)

These bits set the preface bit length of the transmit data in Manchester mode.

The settable range is 0x0 to 0xF (0 to 15). 0x0 disables the transmit preface, which is not added.

### TPPAT bit (Transmit preface pattern)

These bits set one of the four preface patterns in Manchester mode.

When these bits are set to 00b, the preface area is set to all zeros.

When these bits are set to 01b, the preface area is set to the zero-one-zero-one pattern.

When these bits are set to 10b, the preface area is set to the one-zero-one-zero pattern.

When these bits are set to 11b, the preface area is set to all ones.

Note: For the transmit and receive data when the TPPAT bits are set, see [Figure 27.48](#).

## 27.2.38 RMPR : Receive Manchester Preface Setting Register

Base address: SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x23

|                    |   |   |            |   |            |   |   |   |
|--------------------|---|---|------------|---|------------|---|---|---|
| Bit position:      | 7 | 6 | 5          | 4 | 3          | 2 | 1 | 0 |
| Bit field:         | — | — | RPPAT[1:0] |   | RPLEN[3:0] |   |   |   |
| Value after reset: | 0 | 0 | 0          | 0 | 0          | 0 | 0 | 0 |

| Bit | Symbol | Function                                                                                                                                                                                         | R/W              |
|-----|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 3:0 | RPLEN  | Receive Preface Length<br>Set the preface length in received frames when Manchester mode is enabled<br>0: Disables the receive preface generation<br>Others: Receive preface length (bit length) | R/W <sup>1</sup> |
| 5:4 | RPPAT  | Receive Preface Pattern<br>Set the preface pattern of received frames<br>0 0: ALL ZERO<br>0 1: ZERO ONE<br>1 0: ONE ZERO<br>1 1: ALL ONE                                                         | R/W <sup>1</sup> |
| 7:6 | —      | These bits are read as 0. The write value should be 0.                                                                                                                                           | R                |

Note: This register is valid only when the Manchester mode is enabled (MMR.MANEN = 1).

Note 1. Writing to these bits is only possible when the RE and TE bits in SCR are 0 (both serial transmission and reception are disabled).

This register is used to set the preface length and preface pattern of the received frames in Manchester mode.

### RPLEN bit (Receive Preface Length)

These bits set the preface bit length of the received frames in Manchester mode.

The settable range is 0x0 to 0xF (0 to 15). 0x0 disables the receive preface, which is not added. When 0x1 to 0xF is set, the set value is handled as the receive preface bit length.

### RPPAT bit (Receive Preface Pattern)

These bits set one of the four preface patterns in Manchester mode.

When these bits are set to 00b, the preface area is handled as all zeros.

When these bits are set to 01b, the preface area is handled as the zero-one-zero-one pattern.

When these bits are set to 10b, the preface area is handled as the one-zero-one-zero pattern.

When these bits are set to 11b, the preface area is handled as all ones.

Note: For the transmit and receive data when the RPPAT bits are set, see [Figure 27.48](#).

### 27.2.39 MESR : Manchester Extended Error Status Register

Base address: SCIk = 0x4011\_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x24

|                    |   |   |   |   |   |      |      |      |
|--------------------|---|---|---|---|---|------|------|------|
| Bit position:      | 7 | 6 | 5 | 4 | 3 | 2    | 1    | 0    |
| Bit field:         | — | — | — | — | — | SBER | SYER | PFER |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0    | 0    | 0    |

| Bit | Symbol | Function                                                                                                                                                                           | R/W                |
|-----|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| 0   | PFER   | Preface Error flag<br>This bit is set when a preface error (pattern mismatch) is detected<br>0: No preface error detected<br>1: Preface error detected                             | R/(W) <sup>1</sup> |
| 1   | SYER   | SYNC Error flag<br>This bit is set when no edge is detected in the adjustable range during receive retiming<br>0: No receive SYNC error detected<br>1: Receive SYNC error detected | R/(W) <sup>1</sup> |
| 2   | SBER   | Start Bit Error flag<br>This bit is set when a pattern mismatch in the start bit area is detected<br>0: No start bit error detected<br>1: Start bit error detected                 | R/(W) <sup>1</sup> |
| 7:3 | —      | These bits are read as 0. The write value should be 0.                                                                                                                             | R                  |

Note: This register is valid only when the Manchester mode is enabled (MMR.MANEN = 1).

Note 1. Only 0 can be written to this bit, to clear the flag. To clear the flag, confirm that the flag is 1 before setting it to 0.

This register indicates an error status when receiving frames in Manchester mode.

A preface error, receive SYNC error or start bit error was detected.

#### PFER bit (Preface Error flag)

This bit indicates that a preface error was detected when receiving frames in Manchester mode.

[Setting condition]

- When detecting a preface error when receiving frames in Manchester mode  
The following operations are performed when a preface error occurs.  
When MECR.PFEREN = 1  
The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the PFER flag is being set to 1, the subsequently received data is not transferred to the RDR register.  
When MECR.PFEREN = 0  
The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the PFER flag being set to 1.

[Clearing condition]

- When 0 is written to the bit after it was read as 1

Even if the SCR.RE bit is cleared, the PFER flag is not affected, and the previous state is retained.

#### SYER bit (SYNC Error flag)

This bit indicates that a receive SYNC error was detected when receiving frames in Manchester mode with MMR.ERTEN = 1 (Manchester edge retiming enabled).

[Setting condition]

- When detecting a receive SYNC error when receiving frames in Manchester mode  
The following operations are performed when a receive SYNC error occurs.  
When MECR.SYEREN = 1

Although the received data is transferred to the RDR register, no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the SYER flag is being set to 1, the subsequently received data is not transferred to the RDR register.

When `MECR.SYEREN = 0`

The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SYER flag being set to 1.

[Clearing condition]

- When 0 is written to the bit after it was read as 1

Even if the `SCR.RE` bit is cleared, the SYER flag is not affected, and the previous state is retained.

### SBER bit (Start Bit Error flag)

This bit indicates that a start bit error was detected when receiving frames in Manchester mode.

[Setting condition]

- When detecting a start bit error when receiving frames in Manchester mode

The following operations are performed when a start bit error occurs.

When `MECR.SBEREN = 1`

The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the SBER flag is being set to 1, the subsequently received data is not transferred to the RDR register.

When `MECR.SBEREN = 0`

The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SBER flag being set to 1.

[Clearing condition]

- When 0 is written to the bit after it was read as 1

Even if the `SCR.RE` bit is cleared, the SBER flag is not affected, and the previous state is retained.

## 27.2.40 MECR : Manchester Extended Error Control Register

Base address: `SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)`

Offset address: `0x25`

|                    |   |   |   |   |   |            |            |            |
|--------------------|---|---|---|---|---|------------|------------|------------|
| Bit position:      | 7 | 6 | 5 | 4 | 3 | 2          | 1          | 0          |

| Bit | Symbol | Function                                                                                                                                                                                                                         | R/W |
|-----|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 0   | PFEREN | Preface Error Enable<br>Specifies whether to handle a preface error as an interrupt source<br>0: Does not handle a preface error as an interrupt source<br>1: Handles a preface error as an interrupt source                     | R/W |
| 1   | SYEREN | Receive SYNC Error Enable<br>Specifies whether to handle a receive SYNC error as an interrupt source<br>0: Does not handle a receive SYNC error as an interrupt source<br>1: Handles a receive SYNC error as an interrupt source | R/W |
| 2   | SBEREN | Start Bit Error Enable<br>Specifies whether to handle a start bit error as an interrupt source<br>0: Does not handle a start bit error as an interrupt source<br>1: Handles a start bit error as an interrupt source             | R/W |
| 7:3 | —      | These bits are read as 0. The write value should be 0.                                                                                                                                                                           | R   |

Note: This register is valid only when the Manchester mode is enabled (`MMR.MANEN = 1`).

This register is used to specify whether to handle a preface error, receive SYNC error, or a start bit error as an interrupt source in Manchester mode. If those errors are handled as interrupt sources, interrupt requests and event requests are generated at the occurrence of each error, and the next reception is not performed until the corresponding error flag is cleared.

Set this register when MMR.MANEN = 0. However, do not change this register during communication.

#### PFEREN bit (Preface Error Enable)

This bit specifies whether to handle a preface error as an interrupt source.

When it is set to 0, a preface error is not handled as an interrupt source. When it is set to 1, a preface error is handled as an interrupt source.

#### SYEREN bit (Receive SYNC Error Enable)

This bit specifies whether to handle a receive SYNC error as an interrupt source.

When it is set to 0, a receive SYNC error is not handled as an interrupt source. When it is set to 1, a receive SYNC error is handled as an interrupt source.

#### SBEREN bit (Start Bit Error Enable)

This bit specifies whether to handle a start bit error as an interrupt source.

When it is set to 0, a start bit error is not handled as an interrupt source. When it is set to 1, a start bit error is handled as an interrupt source.

## 27.3 Operation in Asynchronous Mode

Figure 27.3 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit or receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communications line is usually held in the mark state (high level).

The SCI monitors the communications line. When the SCI detects a low, it regards that as a start bit and starts serial communication.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and receiver have a double-buffered structure in addition to FIFO mode, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

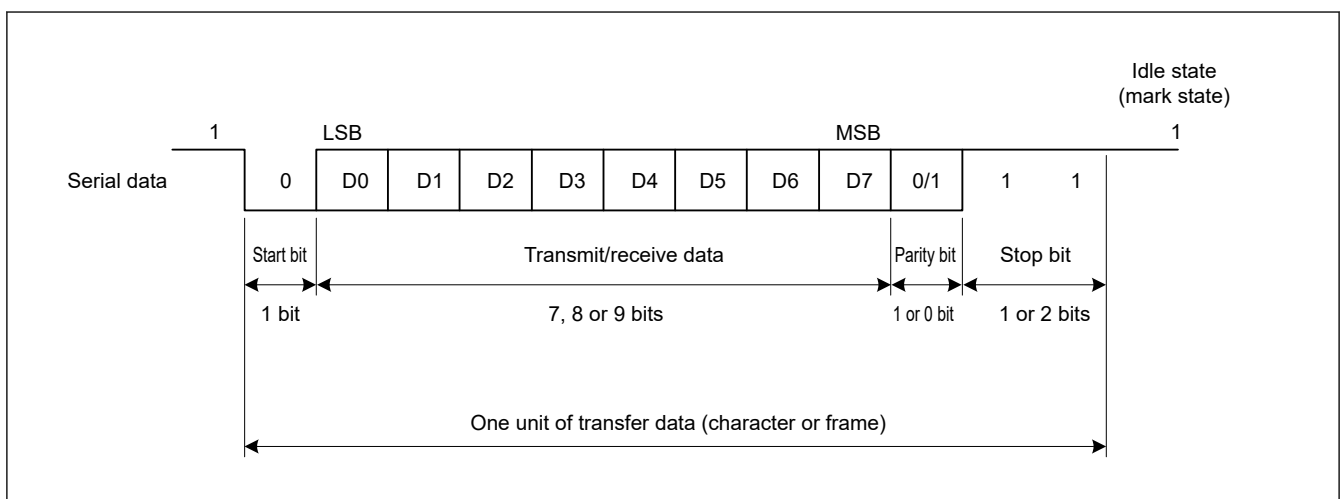

Figure 27.3 Data format in asynchronous serial communications with 8-bit data, parity bit, and 2 stop bits

### 27.3.1 Serial Data Transfer Format

Table 27.25 lists the serial data transfer formats that can be used in asynchronous mode. Any of 18 transfer formats can be selected with the SMR and SCMR settings. For details on the multi-processor function, see section 27.4. Multi-Processor Communication Function.

**Table 27.25 Serial transfer formats in asynchronous mode**

| SCMR setting | SMR setting |     |    |    | Serial transfer format and frame length |               |   |   |   |   |   |   |     |     |     |    |    |    |  |  |
|--------------|-------------|-----|----|----|-----------------------------------------|---------------|---|---|---|---|---|---|-----|-----|-----|----|----|----|--|--|
|              | CHR1        | CHR | PE | MP | STOP                                    | 1             | 2 | 3 | 4 | 5 | 6 | 7 | 8   | 9   | 10  | 11 | 12 | 13 |  |  |
| 0            | 0           | 0   | 0  | 0  | 0                                       | ST 9-bit data |   |   |   |   |   |   |     |     | SP  |    |    |    |  |  |
| 0            | 0           | 0   | 0  | 1  | 1                                       | ST 9-bit data |   |   |   |   |   |   |     |     | SP  |    | SP |    |  |  |

### 27.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times<sup>\*1</sup> the bit rate.

In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization.<sup>\*2</sup>

Because receive data is sampled on the rising edge of the 8th pulse\*1 of the base clock, data is latched at the middle of each bit (when sampling timing does not adjust (SPTR.ASEN = 0)), as shown in Figure 27.4 The reception margin in asynchronous mode is determined by the following formula (1):

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100 \text{ [%]} \quad \dots \text{ Formula (1)}$$

- Note: M: Reception margin  
 N: Ratio of bit rate to clock  
 (N = 16 when SEMR.ABCSE = 0 and SEMR.ABCS = 0,  
 N = 8 when SEMR.ABCS = 1,  
 N = 6 when SEMR.ABCSE = 1)  
 D: Duty cycle of clock (D = 0.5 to 1.0)  
 L: Frame length (L = 9 to 13)  
 F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined using the following formula:  
 $M = \{0.5 - 1/(2 \times 16)\} \times 100 \text{ (%) = 46.875 \%}$

This represents the computed value. Renesas recommends a margin of 20% to 30% in system design.

Note 1. In this example, the SEMR.ABCS bit is 0 and the SEMR.ABCSE is 0. When the ABCS bit is 1 and the ABCSE bit is 0, a frequency of 8 times the bit rate is used as a base clock, and receive data is sampled on the rising edge of the 4th pulse of the base clock.

When the ABCSE bit is 1, a sextuple frequency of a bit rate is used as a base clock, and receive data is sampled on the rising edge of the 3rd pulse of the base clock.

Note 2. The determination condition of the start bit is as follows.

The function of adjust sampling timing is OFF (ASEN = 0):

The determination condition of a start bit is that Low beyond half bit length continues. It is same as the sampling timing. In Figure 27.4, Low period should be kept over 8-cycles to detect a start bit. If Low period does not keep over 8-cycles, the IP judges this as a noise. So, the IP does not start reception and wait start bit.

The function of adjust sampling timing is ON (ASEN = 1):

The determination condition of a start bit is that Low keeps up until the sampling timing. Adjusting the sampling timing forward (AJD = 1) increases the possibility of erroneously determining a noise as the start bit.

Figure 27.4 Receive data sampling timing in asynchronous mode

### 27.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the transfer clock of the SCI, based on the SMR.CM and SCR.CKE[1:0] settings.

When an external clock is input to the SCKn pin, the clock frequency must be 16 times the bit rate (when SEMR.ABCS = 0) or 8 times the bit rate (when SEMR.ABCS = 1).

When the SCI uses its internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is configured so that the rising edge of the clock is in the middle of the transmit data, as shown in [Figure 27.5](#).

When clock output is enabled, the clock is output after setting the SCR.TE or SCR.RE bit to 1.

**Figure 27.5** Phase relationship between output clock and transmit data in asynchronous mode when SMR.CHR = 0, PE = 1, MP = 0, and STOP = 1

### 27.3.4 Double-Speed Operation and Frequency of 6 Times the Bit Rate

When the SEMR.ABCS bit is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0. When the SEMR.BGDM bit is set to 1, the cycle of the base clock is half and the bit rate is double that of when BGDM is set to 0. When the SCR.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the SCI to operate at a bit rate four times that when the ABCS and BGDM bits are set to 0.

When the SEMR.ABCSE bit is set to 1, the number of base clock pulses is 6 during a period of 1 bit, and the SCI operates at a bit rate 16/3 times that when SEMR.ABCS = 0, SEMR.BGDM = 0, and SEMR.ABCSE = 0.

As shown by Formula (1) in [section 27.3.2. Receive Data Sampling Timing and Reception Margin in Asynchronous Mode](#), the reception margin decreases when the SEMR.ABCS or SEMR.ABCSE bit is set to 1. Therefore, if the target bit rate can be obtained with ABCS or ABCSE set to 0, it is recommended that you use the SCI with ABCS and ABCSE set to 0.

### 27.3.5 CTS and RTS Functions

The CTS function uses input on the CTSn\_RTSn pin in transmission control. Setting the SPMR.CTSE bit to 1 enables the CTS function. For the functions of CTS and RTS, you can select the alternate setting that uses either function with one terminal and the dedicated setting that uses each function independently with two terminals. This setting is done with the SPMR.CTSPEN bit.

When the CTS function is enabled, placing a low level on the CTSn\_RTSn pin causes transmission to start.

Driving the CTSn\_RTSn pin high while transmission is in progress does not affect transmission of the current frame.

In the RTS function, which uses output on the CTSn\_RTSn pin, a low level is output when reception becomes possible. Conditions for output of the low and high levels are shown in this section.

[Conditions for low level output]

Satisfaction of all conditions are listed in this section.

#### Non-FIFO selected

- The value of the SCR.RE bit is 1
- Reception is not in progress
- There is no received data yet to be read

- The ORER, FER, and PER flags in the SSR register are all 0

#### FIFO selected

- The value of the SCR.RE bit is 1
- The amount of receive data written in FRDRHL is equal to or less than the setting value of FCRH.RSTRG[3:0]
- The ORER flag in the SSR\_FIFO register (ORER in FRDRH) is 0

[Condition for high level output]

- The conditions for low-level output are not satisfied

### 27.3.6 Address Match (Receive Data Match Detection) Function

The address match function can be used only in asynchronous mode.

If the DCCR.DCME bit is set to 1, when one frame of data is received, the SCI compares that received data with the data set in CDR.CMPD. If the SCI detects a match to the comparison data (CDR.CMPD<sup>\*1</sup>) with the received data, the SCI can issue the SCIn\_RXI interrupt request.

If the SMR.MP bit is set to 0, comparison occurs only for valid data in receive format. In multi-processor mode (SMR.MP bit = 1), if the DCCR.IDSEL bit is set to 1, receive data where the MPB bit is 1 is subject to comparison for address match and receive data where the MPB bit is 0 is always treated as a non-match.

If the DCCR.IDSEL bit is set to 0, SCI performs address match detection regardless of the MPB bit value of the received data.

Until SCI detects a match to the comparison data (CDR.CMPD<sup>\*1</sup>) with receive data, received data is skipped (discarded), and the SCI cannot detect a parity error or framing error.

When SCI detects a match, the DCCR.DCME bit is automatically cleared, and the DCCR.DCMF flag is set to 1. If the DCCR.IDSEL bit is set to 1, the SCR.MPIE bit is automatically cleared. If DCCR.IDSEL is set to 0, the value of the SCR.MPIE bit is retained. If the SCR.RIE bit is set to 1, the SCI issues an SCIn\_RXI interrupt request.

If the SCI detects a framing error in the receive data for which a match is detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag is set to 1. The compared receive data is not stored in the RDR register, and SSR.RDRF remains 0. When FCR.FM = 1, the RDR register indicates the FRDRHL register, and the SSR.RDRF flag indicates the SSR\_FIFO.RDF flag.

After the SCI detects a match, and DCCR.DCME is automatically cleared, the SCI receives the next data continuously based on the current register setting.

When the DCCR.DFER or DCCR.DPER flag is set, the address match is not performed. Before enabling the address match function, set the DCCR.DFER and DCCR.DPER flags to 0.

Examples of the address match function are shown in [Figure 27.6](#) and [Figure 27.7](#).

Note 1. This comparative target can select one length of 3 types: CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.

Figure 27.6 Example of address match (1) normal mode

Figure 27.7 Example of address match (2) multi-processor mode

### 27.3.7 SCI Initialization in Asynchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the SCR register, then continue through the SCI initialization procedure (select non-FIFO or FIFO) shown in Table 27.26 and Table 27.27. Whenever the operating mode or transfer format is to be changed, the SCR register must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied during initialization.

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, RDRF, RDF, PER, and DR flags in SSR/SSR\_FIFO nor RDR and RDRHL. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: In non-FIFO mode, switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of an SCIn\_TXI interrupt request.

**Table 27.26 Example flow of SCI initialization in asynchronous mode with non-FIFO selected**

| No. | Step Name                                                              | Description                                                                                                                                                   |

### 27.3.8 Serial Data Transmission in Asynchronous Mode

(1) Non-FIFO selected

[Figure 27.8](#), [Figure 27.9](#), and [Figure 27.10](#) show examples of serial transmission in asynchronous mode.

In serial transmission, the SCI operates as described in this section. When the SCR.TE bit is set to 1, the high level is output to TXDn for one frame. However, when SEMR.PADIS is set to "1", this preamble will not be output. An example of operation when preamble is not output is shown in [Figure 27.11](#).

- The SCI transfers data from the TDR<sup>\*1</sup> register to the TSR register when data is written to TDR<sup>\*1</sup> in the SCIn\_TXI interrupt handling routine.  
The SCIn\_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
- Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn\_RTsn pin causes data transfer from the TDR<sup>\*1</sup> register to the TSR register. If the SCR.TIE bit is 1, an SCIn\_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to the TDR<sup>\*1</sup> register in the SCIn\_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn\_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn\_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn\_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR<sup>\*1</sup> register from the handling routine for SCIn\_TXI requests.
- Data is sent from the TXDn pin in the following order:
  - Start bit
  - Transmit data
  - Parity bit or multi-processor bit (can be omitted depending on the format)
  - Stop bit
- The SCI checks for update of the TDR register on output of the stop bit.
- When the TDR register is updated, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn\_RTsn pin causes transfer of the next transmit data from the TDR<sup>\*1</sup> register to the TSR register and transmission of the stop bit, after which serial transmission of the next frame starts.
- If the TDR register is not updated, the SSR.TEND flag is set to 1, the stop bit is sent, and the mark state is entered, in which 1 is output. If the SCR.TEIE bit is 1, the SSR.TEND flag is set to 1 and an SCIn\_TEI interrupt request is generated.

Note 1. The TDRHL register when 9-bit data length is selected.

[Figure 27.8](#), [Figure 27.9](#), and [Figure 27.10](#) show examples of serial transmission in asynchronous mode.

**Figure 27.8** Example operation for serial transmission in asynchronous mode (1) with 8-bit data, parity bit, 1 stop bit, CTS function not used, and at the beginning of transmission

**Figure 27.9** Example operation for serial transmission in asynchronous mode (2) with 8-bit data, parity bit, one stop bit, CTS function used, and at the beginning of transmission

**Figure 27.10 Example operation for serial transmission in asynchronous mode (3) with 8-bit data, parity bit, one stop bit, CTS function not used, and from the middle of transmission until transmission completion**

**Figure 27.11 Example of Operation for Serial Transmission in Asynchronous Mode (4)(with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, from the Middle of Transmission until Transmission Completion, stop preamble)**

Figure 27.12 Example flow of serial transmission in asynchronous mode with non-FIFO selected

(2) FIFO selected

Figure 27.13 shows an example of a data format that is written to FTDRH and FTDRL register in asynchronous mode.

Data corresponding to the data length is set to FTDRH and FTDRL. Write 0 for unused bits. Write in order from FTDRH to FTDRL.

| Data Length | Register Setting |             | Transmit data in FTDRH, FTDRL |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |                     |
|-------------|------------------|-------------|-------------------------------|----|----|----|----|----|----|----|-------|----|----|----|----|----|----|----|---------------------|
|             | SCMR.<br>CHR1    | SMR.<br>CHR | FTDRHL                        |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |                     |
|             |                  |             | FTDRH                         |    |    |    |    |    |    |    | FTDRL |    |    |    |    |    |    |    |                     |
|             |                  |             | b7                            | b6 | b5 | b4 | b3 | b2 | b1 | b0 | b7    | b6 | b5 | b4 | b3 | b2 | b1 | b0 |                     |
| 7 bits      | 1                | 0           | -                             | -  | -  | -  | -  | -  | -  | -  | -     | -  | -  | -  | -  | -  | -  | -  | 7-bit transmit data |

Note: —: Invalid. The write value should be 0.

**Figure 27.13 Data format written to FTDRH and FTDRL with FIFO selected**

In serial transmission, the SCI operates as described in this section. When the TE bit is set to 1, the high level is output to TXDn for one frame (preamble).

1. The SCI transfers data from the FTDRL<sup>\*1</sup> register to the TSR register when data is written to FTDRL<sup>\*1</sup> in the SCIn\_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn\_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn\_RTSn pin causes data transfer from the FTDRL<sup>\*1</sup> register to the TSR register. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, SSR\_FIFO.TDFE is set to 1. If the SCR.TIE bit is 1, an SCIn\_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to FTDRL<sup>\*1</sup> in the SCIn\_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn\_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn\_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn\_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the FTDRL<sup>\*1\*2</sup> register from the handling routine for SCIn\_TXI requests.
3. Data is sent from the TXDn pin in the following order:
  - Start bit
  - Transmit data
  - Parity bit or multi-processor bit (can be omitted depending on the format)
  - Stop bit
4. On output of the stop bit, the SCI checks whether non-transmitted data remains in the FTDRL<sup>\*3</sup> register.
5. When data is set to FTDRL<sup>\*3</sup>, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn\_RTSn pin causes transfer of the next transmit data from FTDRL<sup>\*1</sup> to TSR and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set in FTDRL<sup>\*3</sup>, the TEND flag in SSR\_FIFO is set to 1, the stop bit is sent, and the mark state is entered in which 1 is output. If the SCR.TEIE bit is 1, the SSR\_FIFO.TEND flag is set to 1 and an SCIn\_TEI interrupt request is generated.

Note 1. Write data not to FTDRL but to the FTDRH and FTDRL registers.

Note 2. Write data in order from FTDRH to FTDRL when 9-bit data length is selected.

Note 3. The SCI only checks for update to the FTDRL register and not the FTDRH register when 9-bit data length is selected.

Figure 27.14 shows an example flow of serial transmission in asynchronous mode with FIFO selected.

Figure 27.14 Example flow of serial transmission in asynchronous mode with FIFO selected

### 27.3.9 Serial Data Reception in Asynchronous Mode

(1) Non-FIFO selected

Figure 27.15 and Figure 27.16 show an example of the operation for serial data reception in asynchronous mode.

In serial data reception, the SCI operates as follows:

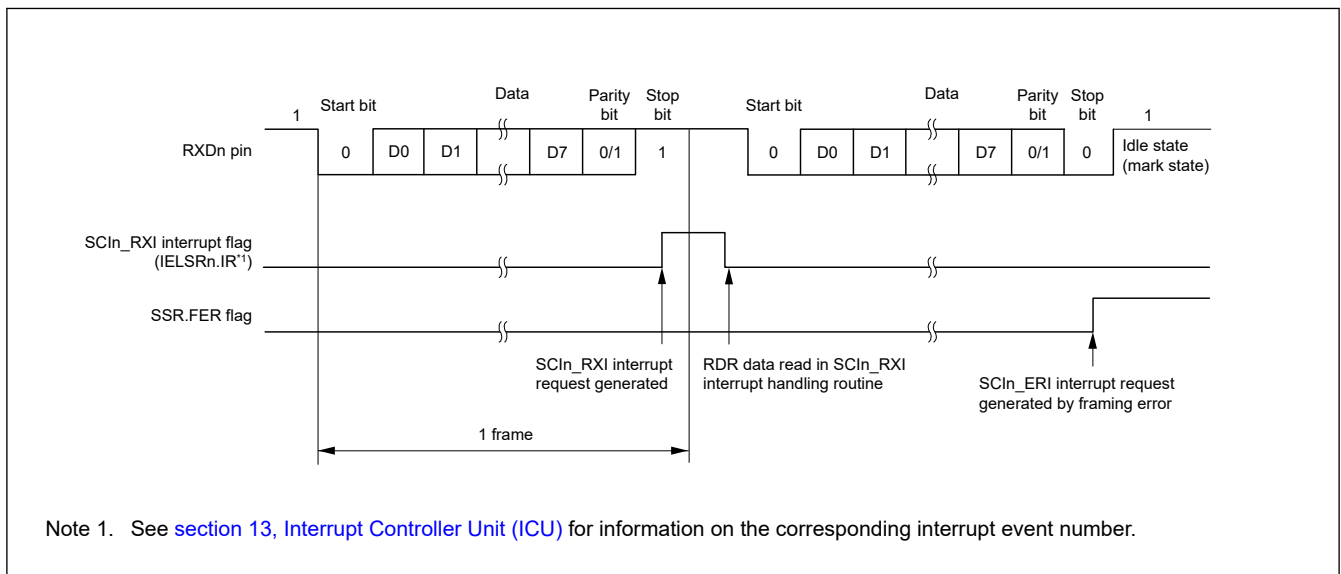

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn\_RTSn pin goes low.
2. The SCI monitors the communications line and when it detects a start bit, the SCI performs internal synchronization, stores receive data in RSR.
3. If the multi-processor communication function is enabled (SMR.MP = 1), see section 27.4.2. Multi-Processor Serial Data Reception. If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and comparison data (CDR.CMPD<sup>\*1</sup>).

4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn\_AM interrupt<sup>\*2</sup> request is generated. To enable the generation of an SCIn\_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register<sup>\*3</sup>. The SSR.RDRF flag remains 0.
5. If the SCI detects a framing error in the receive data for which an address match is detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn\_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn\_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are both 0), set the DCCR.DCMF flag to 0. See [Figure 27.6](#).
7. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn\_ERI interrupt request is generated. Receive data is not transferred to the RDR<sup>\*3</sup> register.
8. If a parity error is detected, the SSR.PER flag is set to 1 and receive data is transferred to the RDR<sup>\*3</sup> register. If the SCR.RIE bit is 1, an SCIn\_ERI interrupt request is generated.
9. If a framing error is detected, the SSR.FER flag is set to 1 and receive data is transferred to the RDR<sup>\*3</sup> register. If the SCR.RIE bit is 1, an SCIn\_ERI interrupt request is generated.
10. When reception finishes successfully, receive data is transferred to the RDR<sup>\*3</sup> register. If the SCR.RIE bit is 1, an SCIn\_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn\_RXI interrupt handling routine before reception of the next receive data is complete. Reading the received data that was transferred to the RDR register causes the CTSn\_RTSn pin to output low.

Note 1. This scope of comparison is selectable as one of three lengths: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.

Note 2. As no interrupt enable bit is assigned to the SCIn\_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.

Note 3. Only read data in the RDRHL register when 9-bit data length is selected.

**Figure 27.15 Example of SCI operation for serial reception in asynchronous mode (1) when the RTS function is not used, and with 8-bit data, parity bit, and 1 stop bit**

**Figure 27.16 Example of SCI operation for serial reception in asynchronous mode (2) when RTS function is used, and with 8-bit data, parity bit, and 1 stop bit**

Table 27.28 lists the states of the flags in the SSR register and receive data handling when a receive error is detected.

If a receive error is detected, an SCIIn\_ERI interrupt request is generated but an SCIIn\_RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. In addition, be sure to read the RDR or RDRHL register during overrun error processing. When a reception is forced to terminate by setting the SCR.RE bit to 0 during operation, read the RDR or RDRHL register because received data that is not yet read might be left in the RDR or RDRHL.

Figure 27.17 and Figure 27.18 show example flows of serial data reception.

**Table 27.28 Flags in SSR Status Register and receive data handling**

| Flags in the SSR Status Register |     |     | Receive data                     | Receive error type                           |
|----------------------------------|-----|-----|----------------------------------|----------------------------------------------|
| ORER                             | FER | PER |                                  |                                              |
| 1                                | 0   | 0   | Lost                             | Overrun error                                |
| 0                                | 1   | 0   | Transferred to RDR <sup>*1</sup> | Framing error                                |
| 0                                | 0   | 1   | Transferred to RDR <sup>*1</sup> | Parity error                                 |
| 1                                | 1   | 0   | Lost                             | Overrun error + framing error                |
| 1                                | 0   | 1   | Lost                             | Overrun error + parity error                 |
| 0                                | 1   | 1   | Transferred to RDR <sup>*1</sup> | Framing error + parity error                 |
| 1                                | 1   | 1   | Lost                             | Overrun error + framing error + parity error |

Note 1. Only read data in the RDRHL register when 9-bit data length is selected.

**Figure 27.17 Example flow of serial reception in asynchronous mode with non-FIFO selected and Address Matching Disabled (1)**

Figure 27.18 Example flow of serial reception in asynchronous mode with non-FIFO selected and Address Matching Disabled (2)

**Figure 27.19 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO not Selected and Address Matching Enabled) (1)**

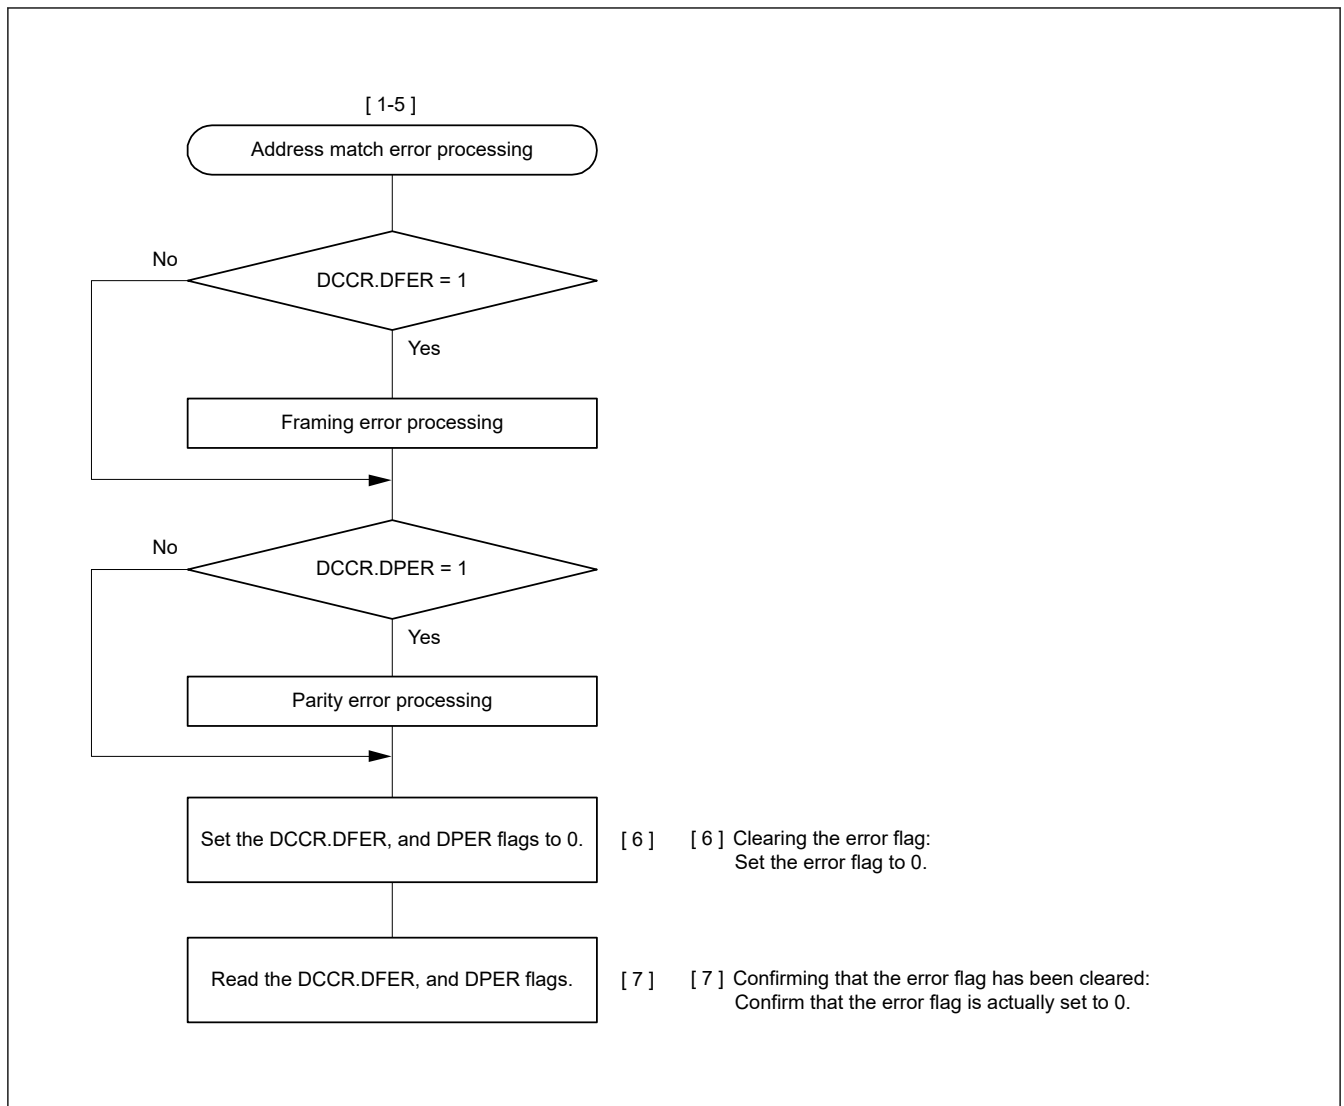

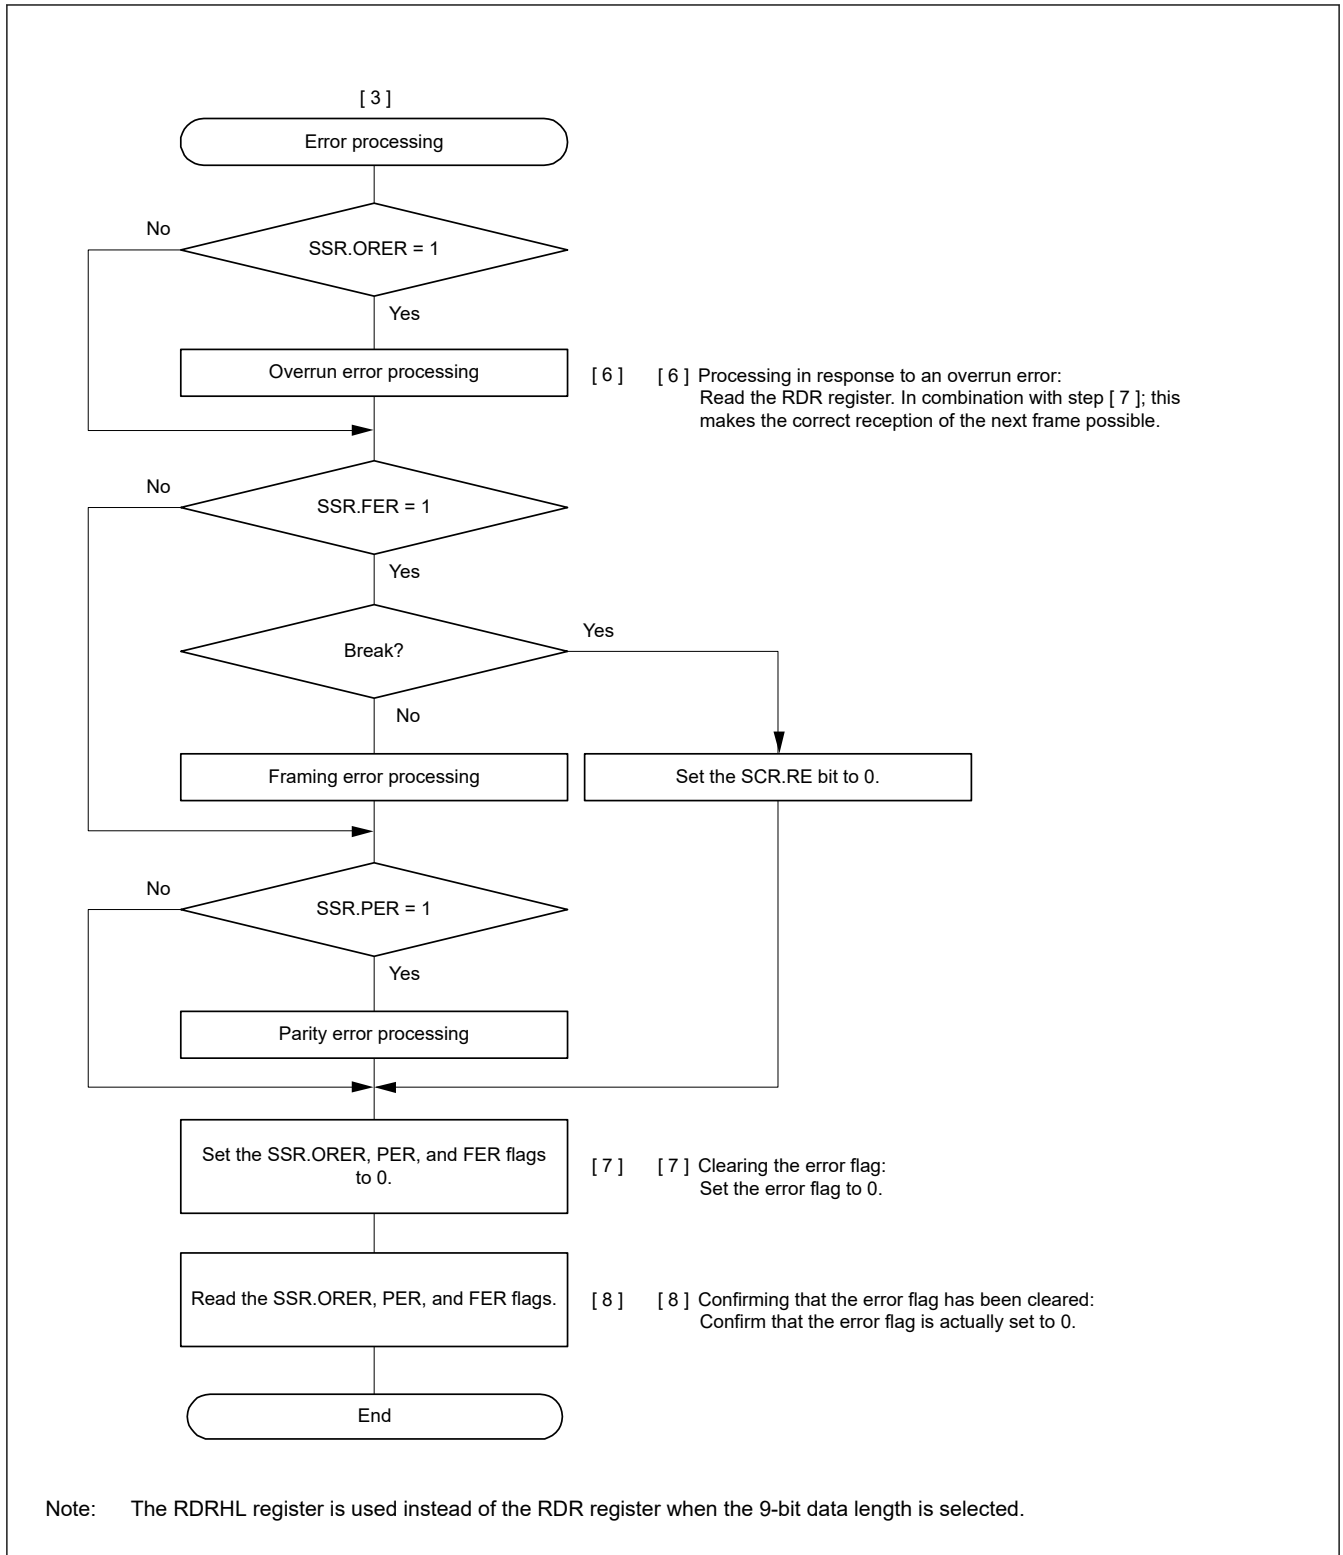

Figure 27.20 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO not Selected and Address Matching Enabled) (2)

**Figure 27.21 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO not Selected and Address Matching Enabled) (3)**

(2) FIFO selected

Figure 27.22 shows an example of a data format that is written to FRDRH register and FRDRL register in asynchronous mode.

In asynchronous mode, 0 is written to the MPB bit in the FRDRH register. Data that corresponds to the data length is written to FRDRH and FRDRL. Unused bits are written as 0. Read in order from FRDRH to FRDRL. If software reads FRDRL, the

SCI updates FER, PER, and receive data (RDAT[8:0]) in the FRDRL register with the next data. The flags RDF, ORER, and DR in the FRDRH register always reflect the associated flags in the SSR\_FIFO register.

| Data Length | Register Setting |             | Receive data in FRDRH, FRDRL |     |      |     |     |     |    |                    |                    |                    |    |       |    |    |
|-------------|------------------|-------------|------------------------------|-----|------|-----|-----|-----|----|--------------------|--------------------|--------------------|----|-------|----|----|
|             | SCMR.<br>CHR1    | SMR.<br>CHR | FRDRH                        |     |      |     |     |     |    |                    |                    |                    |    | FRDRL |    |    |
|             |                  |             | b15                          | b14 | b13  | b12 | b11 | b10 | b9 | b8                 | b7                 | b6                 | b5 | b4    | b3 | b2 |
| 7 bits      | 1                | 0           | -                            | RDF | ORER | FER | PER | DR  | 0  | 0                  | 0                  | 7-bit receive data |    |       |    |    |
| 8 bits      | 1                | 1           | -                            | RDF | ORER | FER | PER | DR  | 0  | 0                  | 8-bit receive data |                    |    |       |    |    |
| 9 bits      | 0                | Don't care  | -                            | RDF | ORER | FER | PER | DR  | 0  | 9-bit receive data |                    |                    |    |       |    |    |

Note: 0 is always read for MPB bit (FRDRH[1])  
 When data length is 7 bits, 0 is always read for FRDRH[0] and FRDRL[7]  
 When data length is 8 bits, 0 is always read for FRDRH[0]  
 FRDRH[7] bit is read as an indefinite value

**Figure 27.22 Data format stored in FRDRH and FRDRL with FIFO selected**

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn\_RTsn pin goes low.
2. The SCI monitors the communications line and, when it detects a start bit, the SCI performs internal synchronization, stores receive data in the RSR register.
3. If the multi-processor communications function is enabled (SMR.MP = 1), see [section 27.4.2. Multi-Processor Serial Data Reception](#). If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and the data for comparison (CDR.CMPD\*<sup>1</sup>).
4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn\_AM interrupt\*<sup>2</sup> request is generated. To enable the generation of an SCIn\_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register\*<sup>3</sup>. The SSR.RDRF flag remains 0.
5. If the SCI detects a framing error in the receive data for which an address match was detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn\_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn\_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are 0), set the DCCR.DCMF flag to 0. See [Figure 27.6](#).
7. If an overrun error occurs during normal communications, the SSR\_FIFO.ORER flag is set to 1. If the SCR.RIE bit in SCR is 1, an SCIn\_ERI interrupt request is generated. Receive data is not transferred to the FRDRL\*<sup>3</sup> register.
8. If a parity error is detected, the PER flag and receive data are transferred to the FRDRL\*<sup>3</sup> register. If the SCR.RIE bit is set to 1, an SCIn\_ERI interrupt request is generated.
9. If a framing error is detected, the FER flag and receive data are transferred to the FRDRL\*<sup>3</sup> register. If the SCR.RIE bit is set to 1, an SCIn\_ERI interrupt request is generated.
10. After a framing error is detected and when SCI detects that the continuous receive data is zero for one frame, reception stops.
11. When the amount of data stored in the FRDRL register falls below the specified receive triggering number, and the next data is not received after 15 etus from the last stop bit in asynchronous mode, the SSR\_FIFO.DR flag is set to 1. When the SCR.RIE bit is 1 and the FCR.DRES bit is 0, the SCI generates an SCIn\_RXI interrupt request. When the FCR.DRES bit is 1, SCI generates an SCIn\_ERI interrupt request.

12. When reception finishes successfully, receive data is transferred to the FRDRL<sup>\*3</sup> register. The RDF bit is set to 1 when the amount of receive data written to FRDRHL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit in SCR is 1, an SCIn\_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the FRDRL<sup>\*4</sup> register in the SCIn\_RXI interrupt handling routine, before an overrun error occurs. If the received data that is transferred to FRDRL<sup>\*5</sup> is less than the RTS trigger number, the CTSn\_RTSn pin outputs low.

- Note 1. One of three lengths is selected for the target for comparison: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.
- Note 2. As no interrupt enable bit is assigned to the SCIn\_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.
- Note 3. Only read data in the FRDRH and FRDRL registers when 9-bit data length is selected.
- Note 4. Read data in order from FRDRH to FRDRL when 9-bit data length is selected.
- Note 5. The SCI only checks for update to the FRDRL register and not to the FRDRH register when 9-bit data length is selected.

27.3.10 The function of adjust receive sampling timing (Asynchronous Mode)

When there is the difference between the rising transfer time and the falling transfer time through a photo coupler, the receive sampling timing at middle of bit affects the reception margin. In this case, the receive sampling timing is able to adjust from the middle of bit to the optimum timing by using this function.

The receive sampling timing is adjusted from the middle of bit by following formula. The adjustable direction is set by ACTR.AJD. When adjusting backward (ACTR.AJD = 0), substitute AJD = +1 and substitute AJD = -1 when adjusting forward (ACTR.AJD = 1).

$$\text{Adjusted sampling timing} = \text{the middle of bit} + \text{AJD} \times (\text{base clock} \times \text{the setting value of ACTR.AST}[2:0])$$

The setting timing is limited by base clock cycles per 1 bit. For details, see Table 27.29.

An overview of reception operation of the communication through a photo coupler with this function is shown in Figure 27.28, Figure 27.29 and Figure 27.30, the explanation of operation with this function is shown in Figure 27.31.

Do not use this function when there is no difference between the rising transfer time and the falling transfer time, because there is a possibility of deteriorating the reception margin.

**Table 27.29 The acceptable value of ACTR register (asynchronous mode using internal clock)**

| SEMR.ABCSE | SEMR.ABCS | The number of base clock cycles/1bit | The acceptable value of ACTR |                           |
|------------|-----------|--------------------------------------|------------------------------|---------------------------|
|            |           |                                      | ACTR.AJD                     | ACTR.AST                  |
| 1          | x         | 6                                    | 0                            | 000b – 010b <sup>*1</sup> |
|            |           |                                      | 1                            |                           |
| 0          | 1         | 8                                    | 0                            | 000b – 011b <sup>*1</sup> |
|            |           |                                      | 1                            |                           |
| 0          | 0         | 16                                   | 0                            | 000b – 111b               |
|            |           |                                      | 1                            |                           |

Note: x: Don't care

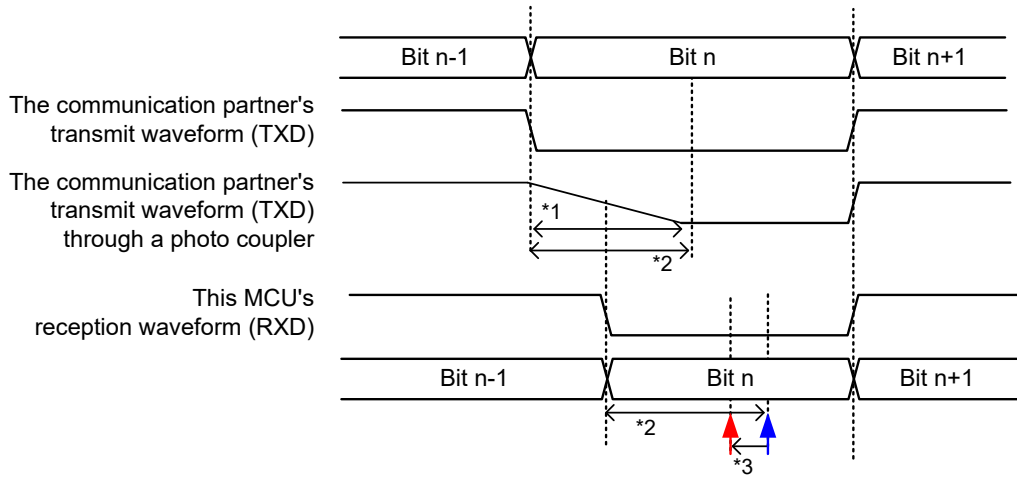

Note 1. When the value of ACTR.AST exceeds the acceptable value, sampling is done at default timing. (Adjustment of sampling is not done.)

**Figure 27.28 Block diagram image of the reception through a photo coupler**

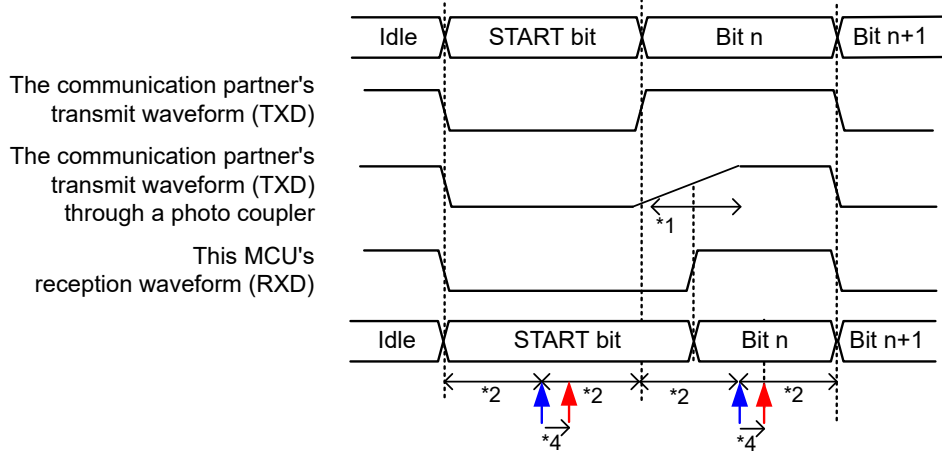

(a) In the case of the falling transfer time >> rising transfer time

The falling edge of reception waveform is made dull like following chart.  
 In this case, you can sampling at the middle of bit if you adjust the receive sampling timing to forward (AJD = 1).

(b) In the case of the falling transfer time << rising transfer time

The rising edge of reception waveform is made dull like following chart.  
 Thus, the reception margin of communications partner will be bad. In this case, you can improve the reception margin if you adjust the receive sampling timing to back.

- ▲ The receive sampling timing when unadjusted (middle of bit)
- ▲ The adjusted receive sampling timing

- Note: This waveform shows the operation image of adjustment in reception sampling timing.
- Note 1. The dull period by a photo coupler
  - Note 2. Bit center timing at set communication rate
  - Note 3. When ACTR.AJD is 1, the receive sampling timing is shifted to forward by the setting value of ACTR.AST[2:0].
  - Note 4. When ACTR.AJD is 0, the Receive sampling timing is shifted to backward by the setting value of ACTR.AST[2:0].

**Figure 27.29 Overview of reception operation of the communication through a photo coupler**

**Figure 27.30** Example of improvement in reception margin by the reception sampling timing adjustment function

**Figure 27.31 Overview of the adjustment operation for the reception sampling timing (asynchronous mode using internal clock)**

### 27.3.11 The function of adjust transmit timing (Asynchronous Mode)

In communication via a photo coupler or the like, when either the rising or falling transition time of the TXDn output signal is long, then a communication partner receive dulled waveform. In this case, the reception margin may be affected.

In these cases, make a communication partner to be sampling at middle of bit using the function of adjust transmit timing.

When SPTR.ATEN is 1, this function can adjust the edge timing at the timing calculated by the following formula for the edge set with ACTR.AET.

$$\text{The adjustment edge timing} = \text{the base clock} \times \text{ACTR.ATT}[2:0]$$

In addition, the upper limit of the adjustment edge timing is limited by setting the base clock cycles. For details, see [Table 27.30](#).

A transmission movement image figure of the communication through a photo coupler with this function is shown in [Figure 27.32](#), [Figure 27.33](#) and [Figure 27.34](#), the overview of operation with this function is shown in [Figure 27.35](#) and [Figure 27.36](#).

Do not use this function when there is not the difference between the rising transfer time and the falling transfer time, there is a possibility of deteriorating the reception margin of a communication partner.

**Table 27.30 The acceptable value of ACTR.AET and ACTR.ATT (asynchronous mode using internal clock) (1 of 2)**

| ABCSE | ABCS | The number of base clock cycles/1bit | The acceptable value of ACTR |             |
|-------|------|--------------------------------------|------------------------------|-------------|
|       |      |                                      | AET                          | ATT[2:0]    |
| 1     | x    | 6                                    | 0                            | 000b – 101b |
|       |      |                                      | 1                            |             |
| 0     | 1    | 8                                    | 0                            | 000b – 111b |
|       |      |                                      | 1                            |             |

**Table 27.30** The acceptable value of ACTR.AET and ACTR.ATT (asynchronous mode using internal clock) (2 of 2)

| ABCSE | ABCS | The number of base clock cycles/1bit | The acceptable value of ACTR |             |
|-------|------|--------------------------------------|------------------------------|-------------|
|       |      |                                      | AET                          | ATT[2:0]    |
| 0     | 0    | 16                                   | 0                            | 000b – 111b |
|       |      |                                      | 1                            |             |

Note: x: Don't care

Note: When the value of ACTR.AET/ATT is out of the acceptable value, this SCI module does not adjust transmit timing.

**Figure 27.32** block diagram image of the transmission through a photo coupler

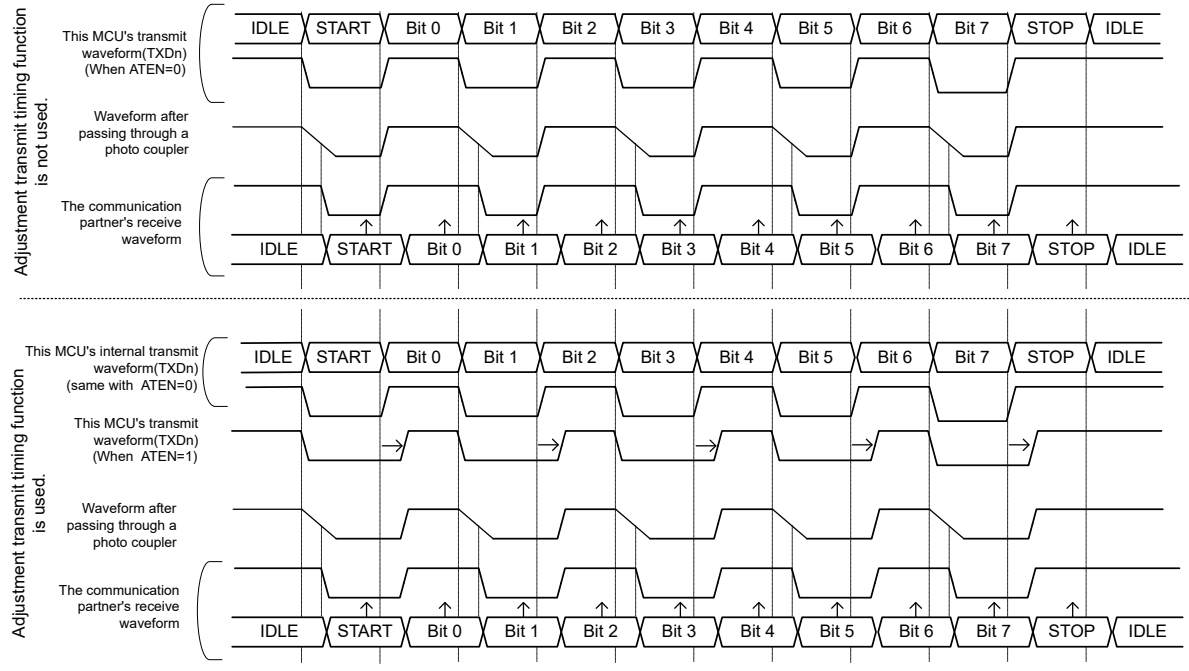

**Figure 27.33 The overview of transmission operation in the communication through a photo coupler**

The explanation of transmit waveforms of the communication through a photo coupler using adjust transmit timing function

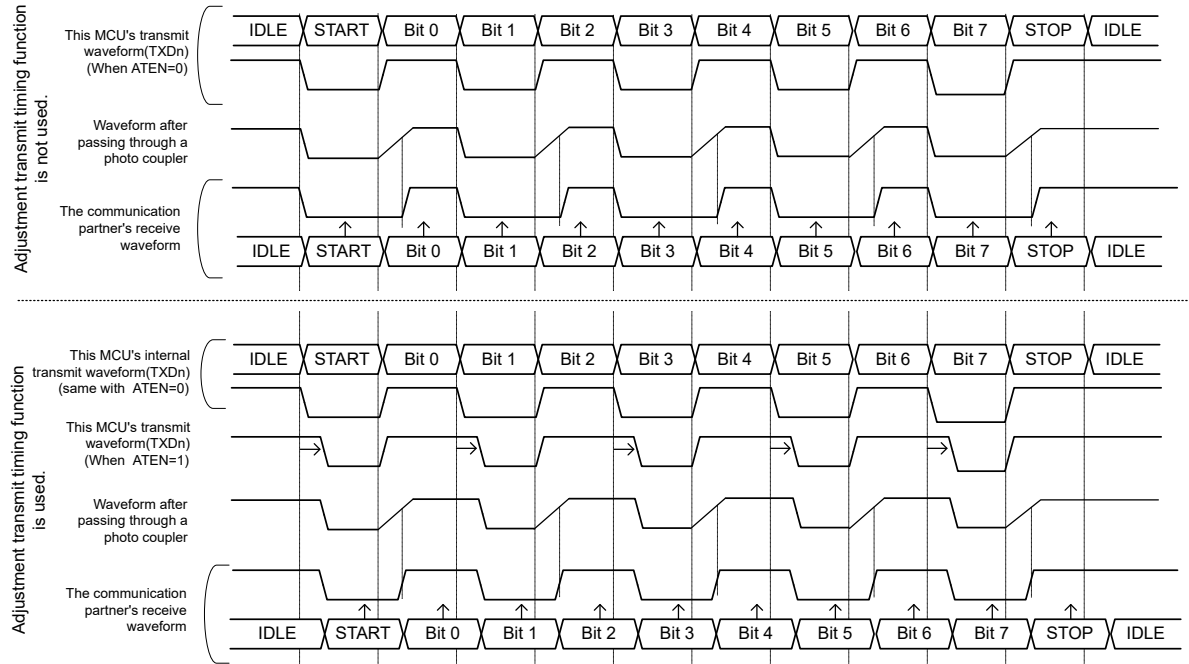

When using the transmission timing adjustment function, adjust the edge timing of the transmission waveform and correct the reception waveform of the communication partner

The following example is 8 bit long data.

(a) In the case of the falling edge transfer time >> the rising transfer time

(b) In the case of the falling edge transfer time << the rising transfer time

→ : The adjustment edge timing using this function    ↑ : A communication partner's sampling timing

Figure 27.34 The explanation for the transmit waveform through a photo coupler

The operation explanation of adjustment the transmit timing

(a) In the case of the falling transfer time >> rising transfer time.

In this case, the high period of a communication partner's reception waveform is made long, and the low period is made short. Therefore, this MCU transmits the waveform with the edge relatively brought forward by adjusting the falling edge timing. Then adjust value (ATT[2:0]) should be set to make equal the low-period/1 bit and high-period/1 bit for a communication partner. This function's operation is explained as an example of 6 cycles/1 bit.

Note 1. The rising edge of transmit timing is shifted to back by the setting value of ACTR.ATT[2:0].

Figure 27.35 The adjustment operation explanation for the transmit timing when AET is 0

Figure 27.36 The adjustment operation explanation for the transmit timing when AET is 1

### 27.4 Multi-Processor Communication Function

The multi-processor communication function enables the SCI to transmit and receive data between multiple processors by sharing an asynchronous serial communication line that has an added multi-processor bit. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station.

The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle:

- When the multi-processor bit is set to 1, the transmission cycle is the ID transmission cycle
- When the multi-processor bit is set to 0, the transmission cycle is the data transmission cycle

Figure 27.37 shows an example of communication between processors using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits communication data in which the multi-processor bit set to 0 is added to the transmit data. After receiving communication data with the multi-processor bit set to 1, the receiving station compares the received ID with the ID of the receiving station itself. If the two match, the receiving station receives communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until it receives data in which the multi-processor bit is set to 1.

#### (1) Non-FIFO selected

To support this function, the SCI provides the SCR.MPIE bit. When the MPIE bit is set to 1, the following operations are disabled until the reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR register (the RDRHL register when 9-bit data length is selected)
- Detection of a receive error
- Setting of the respective RDRF, ORER, and FER status flags in the SSR register

When the SCI receives a character in which the multi-processor bit is set to 1, the SSR.MPBT bit is set to 1 and the SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIIn\_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode. The clock used for the multi-processor communication is the same as the clock used in normal asynchronous mode.

**Figure 27.37 Example of communication using multi-processor format with transmission of data 0xAA to receiving station A**

#### (2) FIFO selected

For data transmission, software must write data to FTDRHL.MPBT that corresponds to transmit data in FTDRHL.TDAT. For data reception, the multi-processor bit that is part of the receive data is written to FTDRHL.MPB and receive data is written to FRDRL.

When the MPIE bit is set to 1, the following operations are disabled until reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the FRDRHL register
- Detection of a receive error
- Break
- Setting of the respective RDF, ORER, and FER status flags in the SSR\_FIFO register

When the SCI receives an 8-bit character in which the multi-processor bit is set to 1, the FTDRHL.MPB bit is set to 1 and receive data is written to FRDRHL.RDAT. The SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIIn\_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode with FIFO selected.

### 27.4.1 Multi-Processor Serial Data Transmission

#### (1) Non-FIFO selected

Figure 27.38 shows an example flow of multi-processor data transmission. In the ID transmission cycle, the ID must be transmitted with the SSR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode. Write the values in the order of the FTDRH register then the FTDRL register.

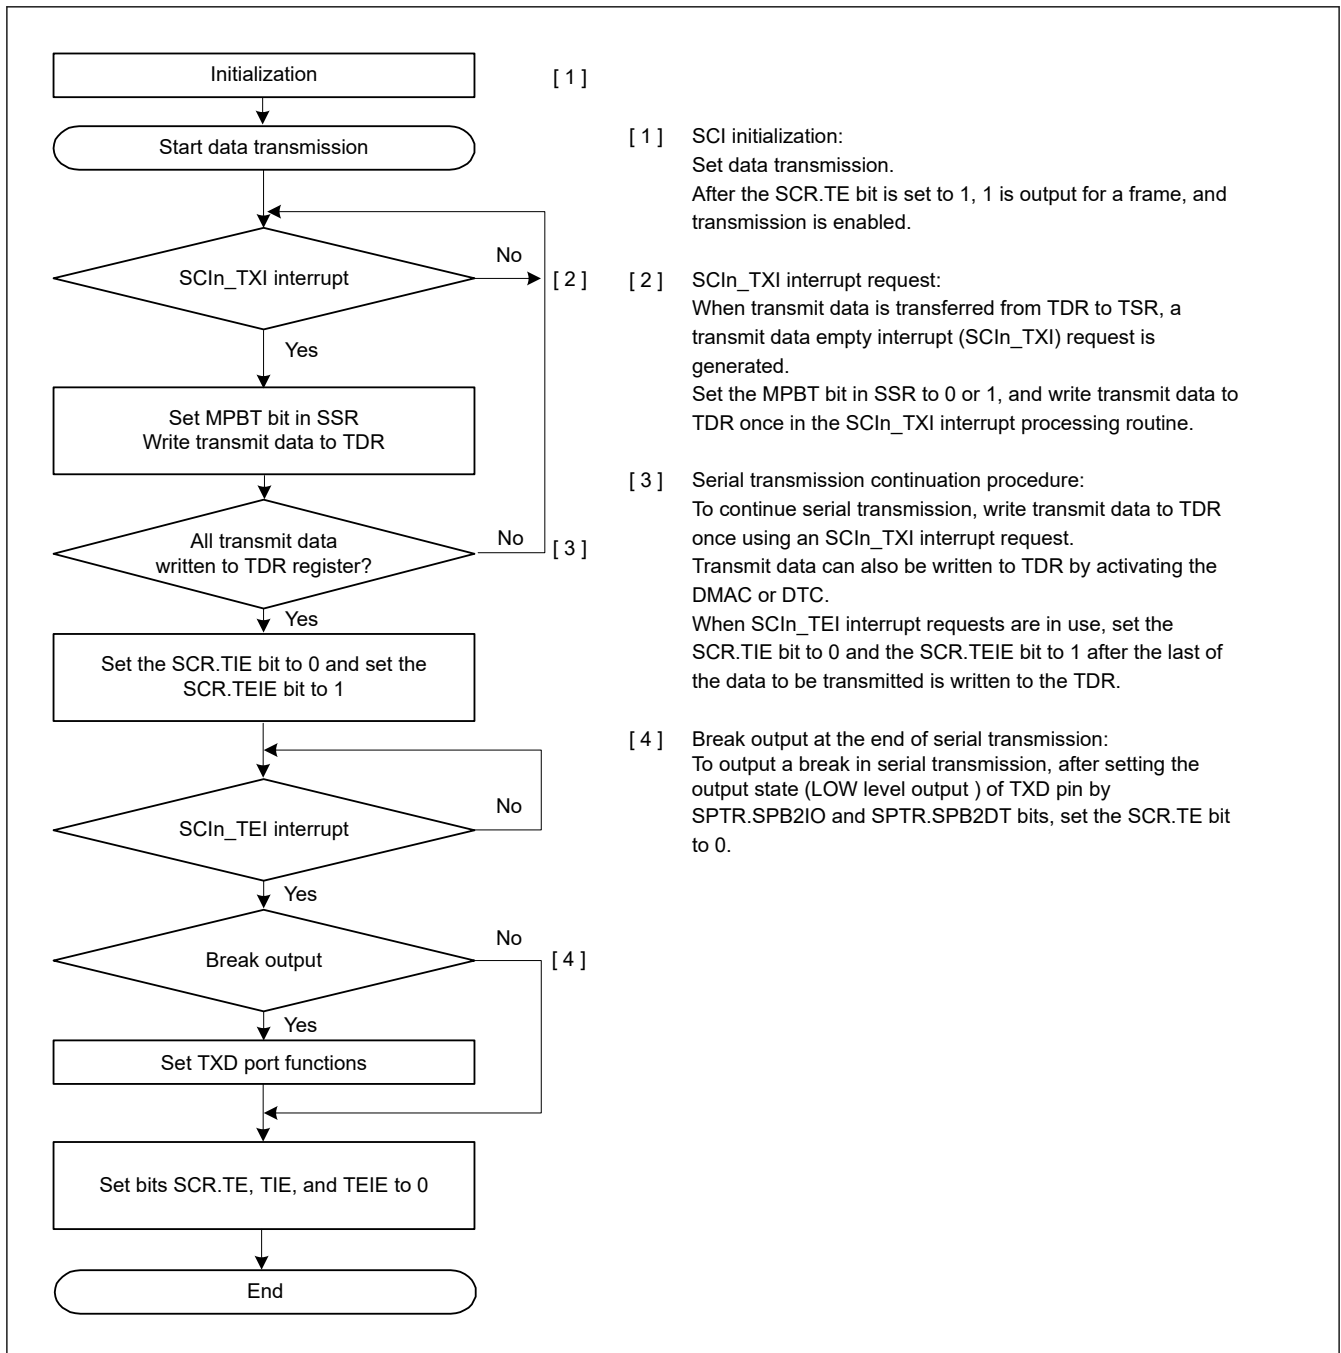

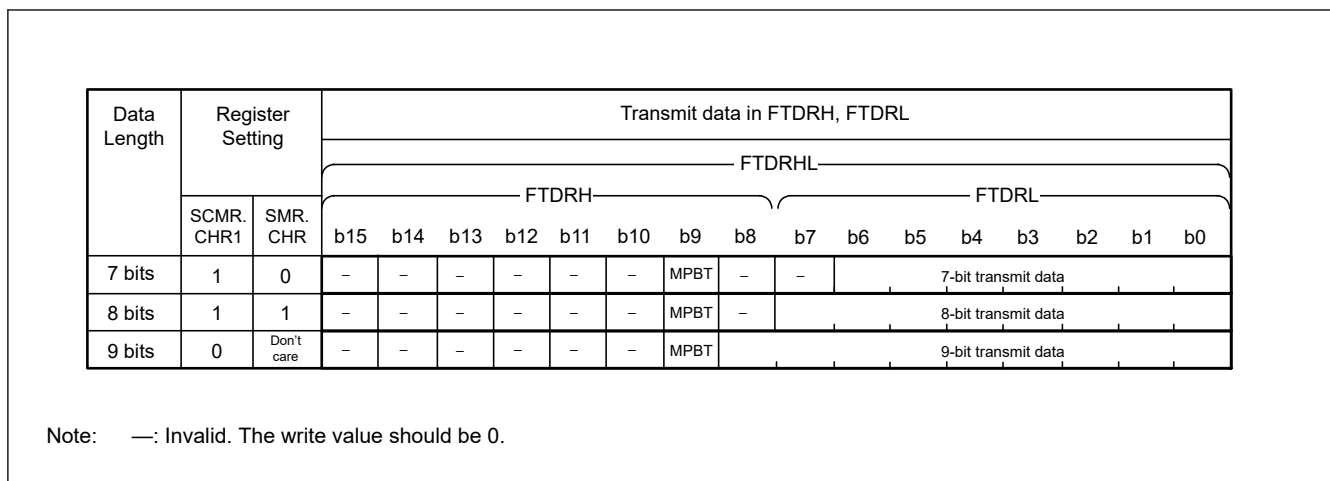

Figure 27.38 Example flow of multi-processor serial transmission with non-FIFO selected

(2) FIFO selected

Figure 27.39 shows an example of data format that is written to FTDRH and FTDRL in multi-processor mode. The FTDRH.MPBT bit is set to 1. Data is set to FTDRH and FTDRL with the correct data length. Write 0 for unused bits. Write in order from FTDRH to FTDRL.

**Figure 27.39 Data format written to FTDRH and FTDRL in multi-processor mode with FIFO selected**

Figure 27.40 shows an example flow of multi-processor serial transmission with FIFO selected. In the ID transmission cycle, the ID must be transmitted with the FTDRH.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode with FIFO selected.

Figure 27.40 Example flow of serial transmission in multi-processor mode with FIFO selected

### 27.4.2 Multi-Processor Serial Data Reception

#### (1) Non-FIFO selected

Figure 27.42 and Figure 27.43 are example flows of multi-processor serial reception. When the SCR.MPIE bit is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to the RDR register (the RDRHL register when 9-bit data length is selected), and the SCIn\_RXI interrupt request is generated. The rest of the operations are the same as operations in asynchronous mode. Read the order from FRDRH to FRDRL.

Figure 27.41 shows an example operation for data reception.

Figure 27.41 Example of SCI reception with 8-bit data, multi-processor bit, and 1 stop bit

Figure 27.42 Example flow of multi-processor serial reception with non-FIFO selected (1)

Figure 27.43 Example flow of multi-processor serial reception with non-FIFO selected (2)

(2) FIFO selected

Figure 27.44 shows an example of a data format that is written to FRDRH and FRDRL in multi-processor mode.

In multi-processor mode, the MPB value that is a part of the receive data is written to the FRDRH.MPB bit. A value of 0 is written to the FRDRH.PER flag. Data is written to FRDRH and FRDRL with the correct data length. Unused bits are written with 0. Read in order from FRDRH to FRDRL. When software reads the FRDRL register, the SCI updates FER, MPB, and receive data (RDAT[8:0]) in FRDRL with the next data. The RDF, ORER and DR flags in the FRDRH register always reflect the associated flags in the SSR\_FIFO register.

| Data Length | Register Setting |            | Receive data in FRDRH, FRDRL |     |      |     |     |     |     |                    |                    |                    |    |    |    |    |    |    |
|-------------|------------------|------------|------------------------------|-----|------|-----|-----|-----|-----|--------------------|--------------------|--------------------|----|----|----|----|----|----|
|             |                  |            | FRDRHL                       |     |      |     |     |     |     |                    |                    |                    |    |    |    |    |    |    |
|             | SCMR. CHR1       | SMR. CHR   | FRDRH                        |     |      |     |     |     |     |                    |                    | FRDRL              |    |    |    |    |    |    |
|             |                  |            | b15                          | b14 | b13  | b12 | b11 | b10 | b9  | b8                 | b7                 | b6                 | b5 | b4 | b3 | b2 | b1 | b0 |
| 7 bits      | 1                | 0          | -                            | RDF | ORER | FER | 0   | DR  | MPB | 0                  | 0                  | 7-bit receive data |    |    |    |    |    |    |
| 8 bits      | 1                | 1          | -                            | RDF | ORER | FER | 0   | DR  | MPB | 0                  | 8-bit receive data |                    |    |    |    |    |    |    |
| 9 bits      | 0                | Don't care | -                            | RDF | ORER | FER | 0   | DR  | MPB | 9-bit receive data |                    |                    |    |    |    |    |    |    |

Note: When data length is 7 bits, 0 is always read for FRDRH[0] and FRDRL[7]  
 When data length is 8 bits, 0 is always read for FRDRH[0]  
 FRDRHL[15] bit is read as an indefinite value

**Figure 27.44 Data format stored in FRDRH and FRDRL in multi-processor mode with FIFO selected**

Figure 27.45 shows an example flow of multi-processor data reception with FIFO selected. When the SCR.MPIE is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data, MPB and associated errors are transferred to the FRDRHL register. The SCR.MPIE bit is automatically cleared and normal reception continues. If a framing error occurs and the SSR\_FIFO.FER flag is set to 1, the SCI continues data reception. The rest of the operations are the same as operations in asynchronous mode with FIFO selected.

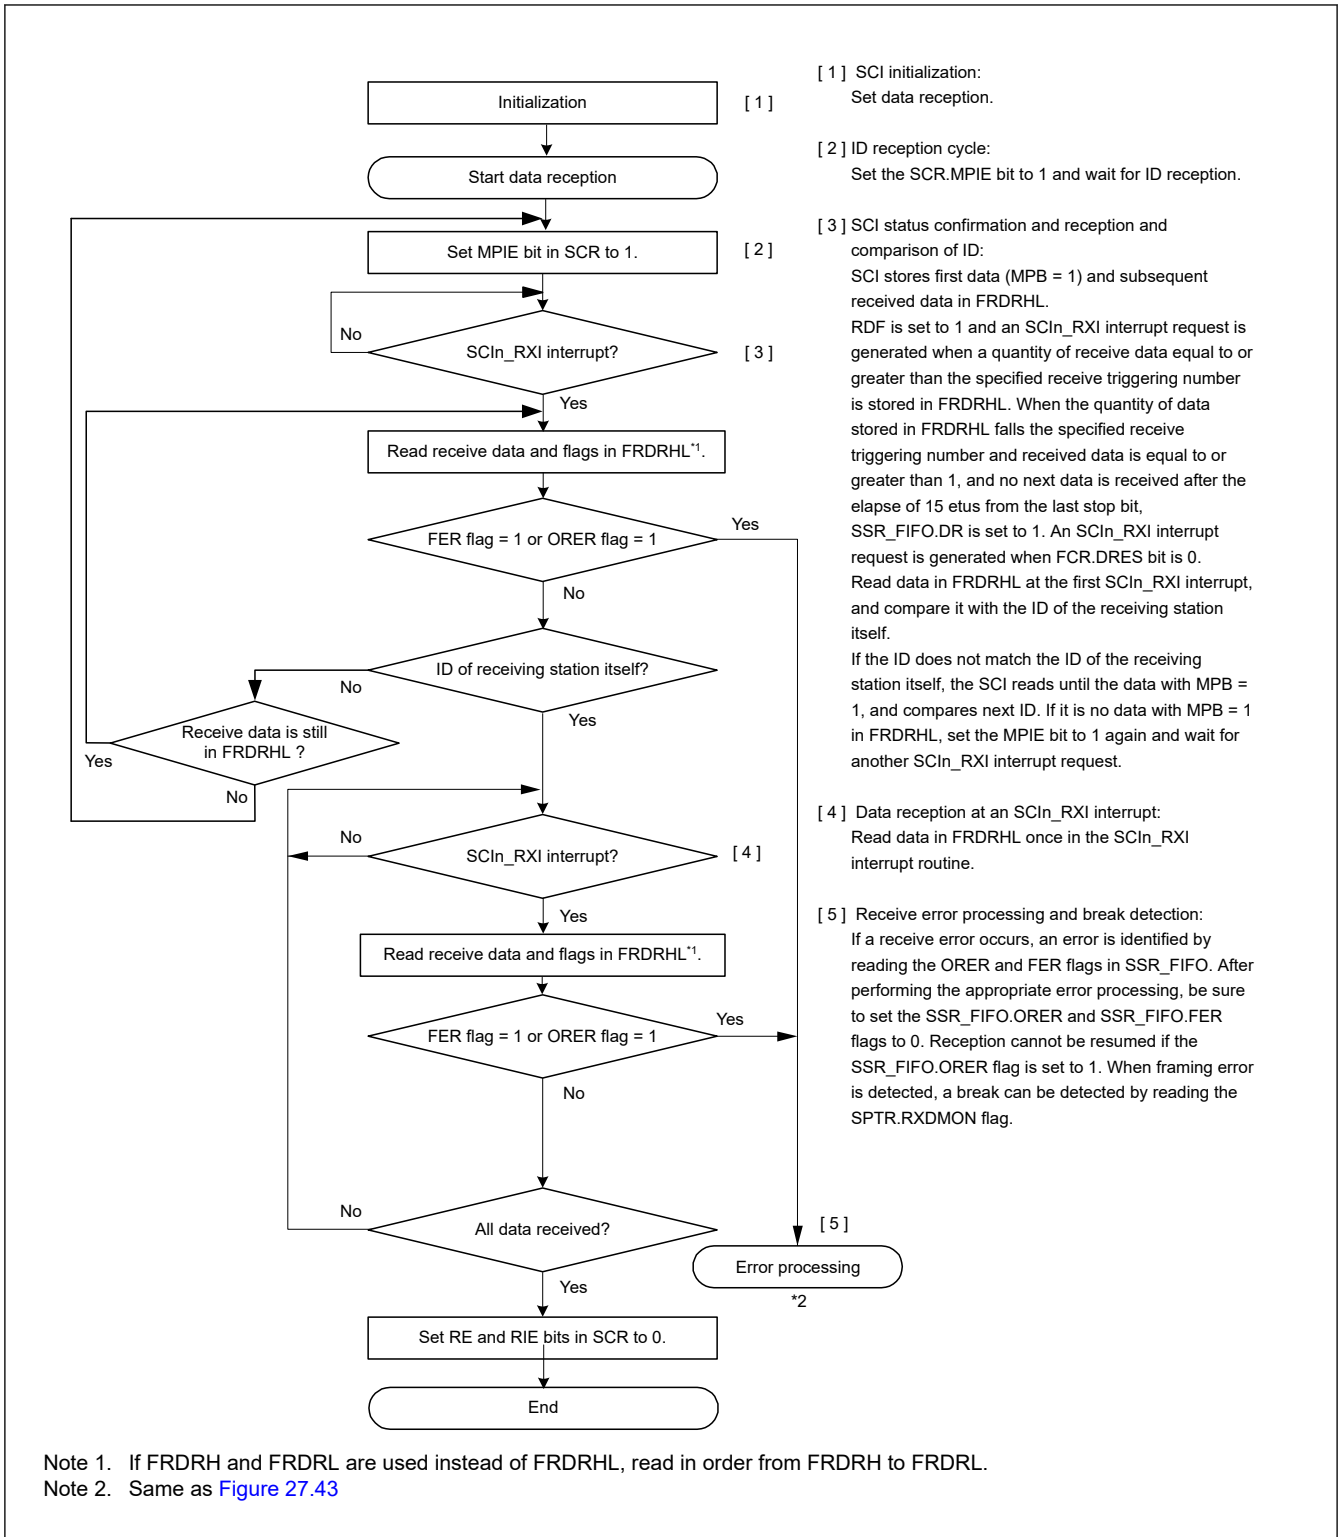

Figure 27.45 Example flow of serial reception in multi-processor mode with FIFO selected

### 27.5 Operation in Manchester mode

In Manchester mode, the transmit or receive serial data is coded in Manchester encoding.

Figure 27.46 shows the conceptual image of Manchester encoding.

**Figure 27.46 Example of Manchester Encoding**

In Manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.

For details on the frame format, see [section 27.5.1. Frame Format](#).

### 27.5.1 Frame Format

[Figure 27.47](#) shows the frame format in Manchester mode.

In the upper half of the figure, relevant setting registers are shown.

The preface area and the data area are encoded in Manchester encoding.

**Figure 27.47 Frame Format in Manchester Mode**

#### (1) Preface area

This is a fixed pattern area located at the beginning of each frame.

Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting TMRP.TPLEN[3:0] for transmission. It is determined by setting RMPR.RPLEN[3:0] for reception.

If it is set to 0, the transmit preface is disabled and is not added.

If it is set to 1d to 15d, a preface whose length is determined by this setting is added.

(For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)

The preface pattern is set with TMRP.TPPAT[1:0] for transmission and RMPR.RPPAT[1:0] for reception, and is selected from four types of patterns.

[Figure 27.48](#) shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

Figure 27.48 Preface Pattern Setting Example

(2) Start bit area

This is an area indicating the start of valid data in a frame. It is added after the preface area.

The start bit length is determined by MMR.SBSEL setting. When MMR.SBSEL = 0, the start bit length is 1 bit.

When MMR.SBSEL = 1, the start bit length is 3 bits.

When MMR.SBSEL = 1, the SYNC type can be selected from command SYNC and data SYNC.

Command SYNC means the three start bits are added as a one-to-zero transition.

Data SYNC means the three start bits are added as a zero-to-one transition.

The SYNC type is determined by the MMR.SYNSEL, MMR.SYNVAL and TDRH\_MAN.TSYNC settings.

(When receiving, the received result is applied to RDRH\_MAN.RSYNC.)

When MMR.SBSEL = 0, the start bit is added as a zero-to-one or one-to-zero transition.

The selection is determined by the MMR.SYNVAL setting.

The MMR.SYNSEL bit specifies the destination to be referred to when setting for transmission.

When the MMR.SYNSEL bit is set to 1, the MMR.SYNVAL setting is referred to. When the MMR.SYNSEL bit is set to 0, the TDRH\_MAN.TSYNC setting is referred to.

Figure 27.49 shows the state of the start bit area according to the settings in the MMR.SYNSEL, MMR.SYNVAL and TDRH\_MAN.TSYNC registers in the case of transmission. Figure 27.50 shows that in the case of reception.

The start bit(s) is not affected by the MMR.TMPOL or MMR.RMPOL setting.

Figure 27.49 Settings Related to and Format of the Start Bit Area at Transmission

When the start bit area is 3 bits long, SYNVAL is not referenced.

d.c. = don't care, Preface = Preface area, START = Start bit area, Data = Data area  
 P = Parity bit, MP = Multi-processor bit, STOP = Stop bit

| Register setting |        |        |           | Input signal        | Start bit detection result <sup>1</sup>     | Register indication |
|------------------|--------|--------|-----------|---------------------|---------------------------------------------|---------------------|
| MMR              |        |        | TDRHL_MAN | RXDn input waveform |                                             | RDRHL_MAN.R SYNC    |
| SBSEL            | SYNSEL | SYNVAL | TSYNC     |                     |                                             |                     |
| 0                | d.c.   | 0      | d.c.      |                     | Normal start bit (1 bit: 0-to-1 transition) | 0                   |
|                  |        |        |           |                     | Start bit error                             | 0                   |
|                  |        |        |           |                     | Start bit error                             | 0                   |
|                  |        |        |           |                     | Start bit error                             | 0                   |
| 0                | d.c.   | 1      | d.c.      |                     | Start bit error                             | 0                   |
|                  |        |        |           |                     | Normal start bit (1 bit: 1-to-0 transition) | 0                   |
|                  |        |        |           |                     | Start bit error                             | 0                   |
|                  |        |        |           |                     | Start bit error                             | 0                   |
| 1                | d.c.   | d.c.   | d.c.      |                     | Start bit error                             | 0                   |
|                  |        |        |           |                     | Start bit error                             | 0                   |
|                  |        |        |           |                     | Data SYNC                                   | 0                   |
|                  |        |        |           |                     | Command SYNC                                | 1                   |

Note 1. Data other than the start bit is assumed to be normal.

Figure 27.50 Settings Related to and Judgment of the Start Bit Area at Reception

### (3) DATA

Since the format of the data area is the same as that of the asynchronous mode, see [section 27.3.1. Serial Data Transfer Format](#).

As shown in [Figure 27.46](#), Frame Format in Manchester Mode, the stop bit is not included in the Manchester encoding range.

#### 27.5.2 Clock

As the transfer clock in Manchester mode, the clock generated by the on-chip baud rate generator is used by setting the SMR.CKS[1:0] bit.

Also it is possible to set the oversampling (transfer rate of one-bit period) by SEMR.ABCS bit.

When the SMER.ABCS bit is set to 0, oversampling x16 is selected with the one-bit period being 16 cycles of the base clock. When the SMER.ABCS bit is set to 1, oversampling x8 is selected with the one-bit period being 8 cycles of the base clock.

#### 27.5.3 Initialization of the SCI in Manchester Mode

Before transferring data, write the initial value (0x00) to the SCR register and initialize the SCI following the example of flowchart shown in [Figure 27.51](#).

Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.

Note that setting the SCR.RE bit to 0 initializes none of the ORER, FER, PER, MER, and RDRF flags in the SSR\_MANC register, the SYER, PFER and SBER flags in the MESR register, and the RDR, RDRHL\_MAN registers.

Note also that switching the value of SCR.TE from 0 to 1 when SCR.TIE is 1 generates a SCIn\_TXI interrupt request.

Figure 27.51 SCI Initialization Flow in Manchester Mode

### 27.5.4 Double-speed operation

When the ABCS bit in SEMR is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the BGDM bit in SEMR is set to 1, the cycle of the base clock is reduced to half and the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the ABCS and the BGDM bits in SEMR are set to 1, the SCI operates on the bit rate four times that of when the ABCS and the BGDM bits in SEMR are set to 0.

### 27.5.5 CTS and RTS functions

The CTS function uses input on the CTSn\_RTSn pin in transmission control. Setting the CTSE bit in SPMR to 1 enables the CTS function. The CTSn\_RTSn pin can be set as a multiplexed pin which allows one pin to be used for either function, or as dedicated pins with each pin for a single function. Use the CTSPEN bit in SPMR for this setting.

When the CTS function is enabled, reception starts only when the CTSn\_RTSn pin is at the low level.

Applying a high level to the CTSn\_RTSn pin after transmission starts does not affect transmission of the current frame, which continues.

The RTS function uses output on the CTSn\_RTSn pin to request transmission. When the SCI is ready to receive, it outputs a low level to the CTSn\_RTSn pin. Conditions for output of the low level and high level are as follows:

[Conditions for low-level output]

When all conditions listed below are satisfied:

- The value of the RE bit in SCR is 1.
- The SCI is ready to receive.
- There is no received data yet to be read.
- All of the following flags are set to 0: SSR\_MANC.ORER, FER, PER and MER flags, and MESR.SYER (when SYEREN = 1), PFER (when PFEREN = 1) and SBER flags (when SBEREN = 1).

[Conditions for high-level output]

- When the conditions for low output are not satisfied

### 27.5.6 Serial data transmission in Manchester mode

The SCI encodes data in Manchester encoding and sends the resultant data in Manchester mode.

When the polarity setting (MMR.TMPOL) set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.

When the polarity setting (MMR.TMPOL) set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.

For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See [Figure 27.46](#)).

The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.

For details on the frame format, see [section 27.5.1. Frame Format](#).

[Figure 27.52](#) shows the flowchart in transmission. [Figure 27.53](#), [Figure 27.54](#), and [Figure 27.55](#) show examples of the operation for serial transmission in Manchester mode.

Figure 27.52 Example of Serial Transmission Flowchart in Manchester Mode

**Figure 27.53 Example of Start-of-Transmission Operation for Serial Transmission in Manchester mode (with Preface but Without the CTS Function)**

**Figure 27.54 Example of Start-of-Transmission Operation for Serial Transmission in Manchester Mode (Without Preface but with the CTS Function)**

**Figure 27.55 Example of End-of-Transmission Operation for Serial Transmission in Manchester Mode (with Preface but Without the CTS Function)**

### 27.5.7 Serial Data Reception in Manchester Mode

In Manchester mode, the SCI operates on a base clock with a frequency of 16 times<sup>\*1</sup> the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in [Figure 27.56](#), reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the SCI judges it as an error and waits for a falling edge again.

If a high level is expected in the first half of a bit in the received data, the SCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when SEMR.ABCS = 0. When SEMR.ABCS = 1, the SCI operates on a base clock with a frequency of 8 times the bit rate.

**Figure 27.56 Data Reception Sampling Timing in Manchester Mode**

In Manchester mode, data reception starts with detection of a preface and start bit area.

The SCI checks the input from the RXDn pin to see whether a preface is added based on the value of RMPR.RPLEN.

If the preface is disabled ( $RMPR.RPLEN = 0$ ), it moves on to the detection of a start bit area without detecting a preface. When a preface is enabled, it identifies a preface pattern setting according to the set value in  $RMPR.RPPAT$ , and compares it with the  $RXDn$  input for a pattern match to detect a preface pattern.

Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.

If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).

For start bit detection, the SCI selects an expected value based on the register settings ( $MMR.SBSEL$  and  $SYNVAL$ ), compares it with the  $RXDn$  input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.

Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.

Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).

In data processing, the SCI shifts the data by the expected received data length based on the register settings ( $SCMR.CHR1$  and  $SMR.CHR$ ) through the RSR register. If two sampling points in a bit of the received data are identical, the SCI judges this as a Manchester code error.

For details, see [section 27.5.11. Errors in Manchester Mode](#) (4).

When the parity function is disabled ( $SMR.PE = 0$ ), the SCI moves on to the next phase of stop bit detection. When the parity function is enabled ( $SMR.PE = 1$ ), the SCI performs parity checking. If detecting a parity error, it asserts a parity error flag (PER), and then moves on to stop bit detection.

In stop bit detection, the SCI checks the following in the stop bit area of the received frame:

It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (FER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.

[Figure 27.57](#) shows an example of the operation for serial data reception in Manchester mode.

**Figure 27.57 Example of Operation for Serial Data Reception in Manchester mode (with a Preface)**

For the state of each status flag in the  $SSR\_MANC$  register and  $RXDn$  input processing when a receive error is detected, see [section 27.5.11. Errors in Manchester Mode](#).

If a receive error is detected, an  $SCIn\_ERI$  interrupt request is generated but an  $SCIn\_RXI$  interrupt request is not generated.

Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the  $ORER$ ,  $FER$ ,  $PER$ ,  $MER$ ,  $SYER^{*1}$ ,  $PFER^{*1}$ , and  $SBER^{*1}$  flags to 0 before resuming reception. Also, be sure to read the RDR (or  $RDRHL\_MAN$ ) register during overrun error processing. When a reception is forcibly terminated by setting the  $SCR.RE$  bit to 0 during operation, read the RDR (or the  $RDRHL\_MAN$ ) register because received data which has not yet been read may be left in the RDR (or the  $RDRHL\_MAN$ ) register.

Figure 27.58 and Figure 27.59 show examples of serial data reception flowchart in Manchester mode.

Note 1. Effective when the corresponding bit is enabled.

Figure 27.58 Example of Serial Data Reception Flowchart in Manchester Mode (Normal Reception)

Figure 27.59 Example of Serial Reception Flowchart in Manchester Mode (Error Processing)

### 27.5.8 Operation When Multi-Processor Bit Is Used

See [section 27.4. Multi-Processor Communication Function](#) (1) for the operation in Manchester mode when using multi-processor mode because the operation is the same.

A preface and a start bit area are added to the frame format in Manchester mode. See [Figure 27.59](#) for error processing in Manchester mode for the reception flowchart ([Figure 27.43](#)). See [Table 27.33](#) for the operation status when detecting various errors.

### 27.5.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.

The receive retiming function can be turned on or off by setting the ERTEN bit in the MMR register.

When the receive retiming function is turned off (MMR.ERTEN = 0), retiming is not performed, causing misalignment between the internal clock and the RXDn input to be accumulated and the receive margin to be reduced.

When the receive retiming function is turned on (MMR.ERTEN = 1), retiming is performed for the preface area, the start bit area<sup>\*1</sup>, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling x16 is selected is shown below.

When detecting an RXDn input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.

When detecting a RXDn input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.

(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)

[Figure 27.60](#) shows the conceptual image of receive retiming range.

When detecting an edge in the tolerance area in the figure, data is received as is without making correction.

When detecting an edge in the SyncJump area in the figure, data is corrected for reception.

When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.

For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the SCI reports a code error.

Figure 27.60 Conceptual Image of Reception Retiming Range

### 27.5.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Mode Register (MMR).

It can be set separately for transmission and reception. Use the MMR.TMPOL bit to set the polarity for transmission and the MMR.RMPOL bit to set the polarity for reception.

The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.

When the initial settings (TMPOL/RMPOL = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code. If the settings are changed to TMPOL/RMPOL = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 27.61 shows the conceptual image of the settings and operation.

Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (SCMR.SINV). Since the polarity of Manchester code (MMR.TMPOL/RMPOL) can be set separately from the transmitted/received data invert function (SCMR.SINV), if both are set to inversion (MMR.TMPOL/RMPOL = 1 and SCMR.SINV = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).

The polarity of the start bit area can be set by a register different from the ones mentioned above.

Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.

For details on the setting for the start bit area, see section 27.5.1. Frame Format (2).

Figure 27.61 Valid Range of the Manchester Code Polarity Setting

### 27.5.11 Errors in Manchester Mode

There are the following errors in Manchester mode:

1. Parity error
2. Over run error
3. Framing error
4. Manchester error
5. Preface error
6. Start Bit error
7. Receive SYNC error

For errors (1) to (3), see [section 27.3.9. Serial Data Reception in Asynchronous Mode \(1\)](#) because they are the same as in asynchronous mode.

Each errors are judged in each area, but they are reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.

[Table 27.31](#) lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR.

[Table 27.32](#) lists the errors that can be detected in each area of a Manchester frame.

If a Preface error or Start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous frame, data will not be received, but errors in the pre-face area and start bit area will update that flag. [Table 27.33](#) shows the flags and actions in this case.

## (4) Manchester error

A Manchester error is generated when a Manchester code error is detected.

In Manchester code, there must be an edge (transition) in the center of the bit.

In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values match.

If a Manchester code error is detected, the Manchester error flag (SSR\_MANC.MER) is asserted.

If a Manchester error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

## (5) Preface error

A preface error is generated when the preface pattern does not match or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (SSR\_MANC.PFER) is asserted.

It is possible to set whether to use this error flag as an interrupt source with the setting of the MECR register.

When MECR.PFEREN = 1, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.PFEREN = 0, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MESR.PFER.

## (6) Start bit error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MESR.SBER) is asserted.

It is possible to set whether to use the start bit error as an interrupt source with the setting of the MECR register.

When MECR.SBEREN = 1, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SBEREN = 0, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MESR.SBER.

## (7) Receive SYNC error

When the receive retiming function described in [section 27.5.9. Receive Retiming](#) is enabled, the receive retiming operation is performed.

If no edges are detected within the receive retiming range (SyncError area in [Figure 27.60](#)) when receive timing operation is being performed, a receive SYNC error is generated. Upon detection of a receive SYNC error, a receive SYNC error flag (MESR.SYER) is asserted. In areas not subject to retiming, receive SYNC errors are not detected.

The preface area<sup>\*1</sup>, the start bit area<sup>\*1,\*2</sup>, and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.

It is possible to set whether to use the receive SYNC error as an interrupt source with the setting of the MECR register.

When MECR.SYEREN = 1, a receive SYNC error is handled as an interrupt source or event source. If a receive SYNC error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SYEREN = 0, a receive SYNC error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive SYNC error is notified to MESR.SYER.

Note 1. In the case of a frame that starts with a pattern that expects the first half of the bit to be High, it is excluded from retiming.

Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming.

Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

**Table 27.31 Flags in the SSR\_MANC Register and Receive Data Handling in Manchester Mode (1 of 2)**

| Flag in the SSR_MANC register |     |     |     | Flag in the MESR register |                    |      | received data   | Received error status (ERI interrupt / event generation) |
|-------------------------------|-----|-----|-----|---------------------------|--------------------|------|-----------------|----------------------------------------------------------|
| ORE                           | FER | PER | MER | SBER <sup>*1</sup>        | PFER <sup>*1</sup> | SYER |                 |                                                          |
| 0                             | 0   | 0   | 0   | 0                         | 0                  | 0    | transfer to RDR | No error                                                 |

**Table 27.31** Flags in the SSR\_MANC Register and Receive Data Handling in Manchester Mode (2 of 2)

| Flag in the SSR_MANC register |                      |      |      | Flag in the MESR register |                    |      | received data   | Received error status (ERI interrupt / event generation)         |
|-------------------------------|----------------------|------|------|---------------------------|--------------------|------|-----------------|------------------------------------------------------------------|
| ORER                          | FER                  | PER  | MER  | SBER <sup>*1</sup>        | PFER <sup>*1</sup> | SYER |                 |                                                                  |
| 0                             | 1                    | 0    | 0    | 0                         | 0                  | 0    | transfer to RDR | Framing error                                                    |
| 0                             | 0                    | 1    | 0    | 0                         | 0                  | 0    | transfer to RDR | Parity error                                                     |
| 0                             | 1                    | 1    | 0    | 0                         | 0                  | 0    | transfer to RDR | Framing error + Parity error                                     |
| 0                             | 0                    | 0    | 1    | 0                         | 0                  | 0    | transfer to RDR | Manchester error                                                 |
| 0                             | 1                    | 0    | 1    | 0                         | 0                  | 0    | transfer to RDR | Framing error + Manchester error                                 |
| 0                             | 0                    | 1    | 1    | 0                         | 0                  | 0    | transfer to RDR | Parity error + Manchester error                                  |
| 0                             | 1                    | 1    | 1    | 0                         | 0                  | 0    | transfer to RDR | Framing error + Parity error + Manchester error                  |
| 1                             | 0                    | 0    | 0    | 0                         | 0                  | 0    | Lost            | Overrun error                                                    |
| 1                             | 1                    | 0    | 0    | 0                         | 0                  | 0    | Lost            | Overrun error + Framing error                                    |
| 1                             | 0                    | 1    | 0    | 0                         | 0                  | 0    | Lost            | Overrun error + Parity error                                     |
| 1                             | 1                    | 1    | 0    | 0                         | 0                  | 0    | Lost            | Overrun error + Framing error + Parity error                     |
| 1                             | 0                    | 0    | 1    | 0                         | 0                  | 0    | Lost            | Overrun error + Manchester error                                 |
| 1                             | 1                    | 0    | 1    | 0                         | 0                  | 0    | Lost            | Overrun error + Framing error + Manchester error                 |
| 1                             | 0                    | 1    | 1    | 0                         | 0                  | 0    | Lost            | Overrun error + Parity error + Manchester error                  |

| hold                          | hold                 | hold | hold | 1                         | 0                  | 0    | Lost            | Start bit error <sup>*3</sup>                                    |
| hold                          | hold                 | hold | hold | 0                         | 1                  | 1    | Lost            | Preface error <sup>*3</sup> + Receive SYNC error <sup>*2</sup>   |
| hold                          | hold                 | hold | hold | 1                         | 0                  | 1    | Lost            | Start bit error <sup>*3</sup> + Receive SYNC error <sup>*2</sup> |

Note 1. Start bit error and Preface error never become 1 at the same time.

Note 2. When MECR.SYEREN = 1, SCI<sub>n</sub>\_ERI interrupt / event is generated by SYER factor.

Note 3. If MECR.PFEREN = 1 or MECR.SBEREN = 1, an SCI<sub>n</sub>\_ERI interrupt / event is generated when the corresponding flag is set.

**Table 27.32** Errors Detectable in Each Area

|                      | Preface error (PFER) | Start Bit error (SBER) | Manchester error (MER) | Receive SYNC error (SYER) | Parity error (PER) | Framing error (FER) |

Note: ✓: Detected, —: Not detected

Note 1. When an Manchester code error occurs in the preface area, it is defined as a preface error.

Note 2. It may not be subject to Receive SYNC error detection. For details see the text [section 27.5.11. Errors in Manchester Mode \(7\)](#)

| There is some error<br>ORER |                               |                               |            |                  | Don't Care | Don't Care | Don't Care |            |               |                        |                      |                          |
| No Error                    | No Error                      | No Error                      | No Error   | No Error<br>ORER | Don't Care | Don't Care | Don't Care |            |               |                        |                      |                          |

- Note 1. If SYER is detected, the SYER flag is also set. Other operations are as shown in this table.
- Note 2. Other detected error flags including ORER are also set.
- Note 3. If all the error flags are cleared before the STOP bit is judged, the operation will be the same as the case where there is no error in the previous frame of this table.
- Note 4. Since the SCIn\_ERI interrupt request is level output, it remains active due to errors in the previous frame regardless of the presence or absence of error in the relevant frame.
- Note 5. Since the error cause is continuously detected, the SCIn\_ERI event is not newly output regardless of the presence or absence of errors in the relevant frame.
- Note 6. For PFER, SBER, and SYER, when each enable bit is set to disable, it is treated as no error.

**Table 27.34 Operation when MPIE = 1 in multi-processor mode (MPIE = 0)**

| MPB <sup>*1</sup> | Each area of the frame |                    |            |            |            | PFER N     | SBERE N    | SYERE N    | received data   | Error flag          | Interrupt request    | Event signal         |

| 1                 | No Error               | No Error           | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | transfer to RDR | set some flags      | output <sup>*2</sup> | output <sup>*2</sup> |
|                   |                        |                    |            |            |            |            |            |            |                 |                     |                      |                      |
|                   | SYER <sup>*3</sup>     | SYER <sup>*3</sup> | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | Lost            | don't set any flags | not output           | not output           |
|                   | PFER                   | No Error           |            |            |            |            |            |            |                 |                     |                      |                      |
|                   | No Error               | SBER               | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care | Don't Care |                 |                     |                      |                      |

- Note 1. If the received MPB bit is 0, it is not received the frame, and the operation is the same as lost of the reception data of this table.
- Note 2. If no error is detected, SCIn\_RXI interrupt request or event is output, and if it is detected, SCIn\_ERI interrupt request or event is output.

Note 3. When SYER is detected in the preface area or the start bit area, the behavior of handling as an error depending on the SYEREN bit changes.

## 27.6 Operation in Clock Synchronous Mode

Figure 27.62 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. For single-character data transfer, data consists of 8-bit. In clock synchronous mode, no parity bit can be added.

In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next falling edge. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit as output state. When the SPMR.CKPH bit is 1 in slave mode, the transmission line holds the first bit output state.

Within the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by using a shared clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

However, it is not possible to perform continuous transfer in the fastest bit rate setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b). Therefore, when the FIFO is selected, this setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b) is not available.

Figure 27.62 Data format in clock synchronous serial communications with LSB-first order

### 27.6.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected based on the SCR.CKE[1:0] setting.

When the SCI operates on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character. When no transfer is performed, the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output starts when the SCR.RE bit set to 1. The synchronization clock stops when it goes high\*1 and an overrun error occurs or the SCR.RE bit is set to 0.

When only data reception is performed and the CTS function is enabled, the clock output does not start when the SCR.RE bit set to 1 and the CTSn\_RTSn pin input is high. The synchronization clock output starts when the SCR.RE bit is set to 1 and the CTSn\_RTSn pin input is low. Following that, when the CTSn\_RTSn pin input is high on completion of the frame reception, the synchronization clock output stops when it goes high. If the CTSn\_RTSn pin input continues to be low, the synchronization clock stops when it goes high\*1 and an overrun error occurs or the SCR.RE bit is set to 0.

Note 1. The signal is held high while (SPMR.CKPH = 0 and SPMR.CKPOL = 1) or (SPMR.CKPH = 1 and SPMR.CKPOL = 1). It is held low while (SPMR.CKPH = 0 and SPMR.CKPOL = 0) or (SPMR.CKPH = 1 and SPMR.CKPOL = 0).

### 27.6.2 CTS and RTS Functions

In the CTS function, the CTSn\_RTSn pin input controls the start of data reception or transmission when the clock source is the internal clock. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, setting the CTSn\_RTSn pin low causes data reception or transmission to start.

Setting the CTSn\_RTSn pin high while the data transmission or reception is in progress does not affect transmission or reception of the current frame.

In the RTS function, the CTSn\_RTSn pin output is used to request the start of data reception or transmission when the clock source is an external synchronizing clock. The CTSn\_RTSn output goes low when serial communication is enabled. Conditions for output of the CTSn\_RTSn low and high are shown as follows:

[Conditions for low output]

Satisfaction of all the following conditions:

#### Non-FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- There is no received data available to be read when the SCR.RE bit is 1
- Transmit data is written when the SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR.ORER flag is 0

#### FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- The amount of receive data written in FRDRHL is less than the setting value of FCRH.RSTRG[3:0] when SCR.RE = 1
- Data that has not been transmitted is available in FTDRHL when SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR\_FIFO.ORER flag is 0

[Condition for high output]

- The conditions for low output are not satisfied

### 27.6.3 SCI Initialization in Clock Synchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the SCR register, then continue through the SCI initialization procedure given in the sections describing non-FIFO and FIFO selection in [section 27.6.2. CTS and RTS Functions](#). Anytime the operating mode or transfer format is to be changed, the SCR register must be initialized before the change can be made.

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in SSR/SSR\_FIFO nor the RDR register. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: In non-FIFO mode, switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 when the SCR.TIE bit is 1 generates an SCIn\_TXI interrupt request.

**Table 27.35 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (1 of 2)**

| No. | Step Name                                                      | Description                                                                                                                                       |
|-----|----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Start initialization                                           |                                                                                                                                                   |

| 7   | Set a value in SPTR                                                                                   | Set the communication terminals status in SPTR.                                                                                                               |
| 8   | Set a value in BRR                                                                                    | Write a value corresponding to the bit rate to BRR.<br>This step is not necessary if an external clock is used.                                               |
| 9   | Set a value in MDDR                                                                                   | Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is set to 0 or an external clock is used. |
| 10  | Set the FCR.TFRST and RFRST bits to 0                                                                 | Set the FCR.TFRST and RFRST bits to 0.                                                                                                                        |
| 11  | Set the I/O port functions                                                                            | Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.                                                        |
| 12  | Set the SCR.TE or RE bit to 1, and set the SCR.TIE and RIE bits                                       | Set the SCR.TE or RE bit to 1. Also set the SCR.TIE and RIE bits.<br>Setting the TE and RE bits allows TXDn and RXDn pins to be used.                         |
| 13  | Initialization completion                                                                             |                                                                                                                                                               |

Note: In simultaneous transmit and receive operations, the TE and RE bits in SCR must both be set to 0 or set to 1 simultaneously.

## 27.6.4 Serial Data Transmission in Clock Synchronous Mode

### (1) Non-FIFO selected

Figure 27.63, Figure 27.64, and Figure 27.65 show examples of serial transmission in clock synchronous mode.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn\_TXI interrupt handling routine. The SCIn\_TXI interrupt request at the beginning of transmission is generated when the TE bit is set to 1 but only after the TIE bit in the SCR is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the SCR.TIE bit is set to 1, an SCIn\_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in the SCIn\_TXI interrupt handling routine before transmission of the current transmit data finishes. When SCIn\_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn\_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks for update to the TDR register on output of the last bit.
5. When the TDR register is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame starts.
6. If TDR is not updated, the SSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn\_TEI interrupt request is generated and the SCKn pin is held high.

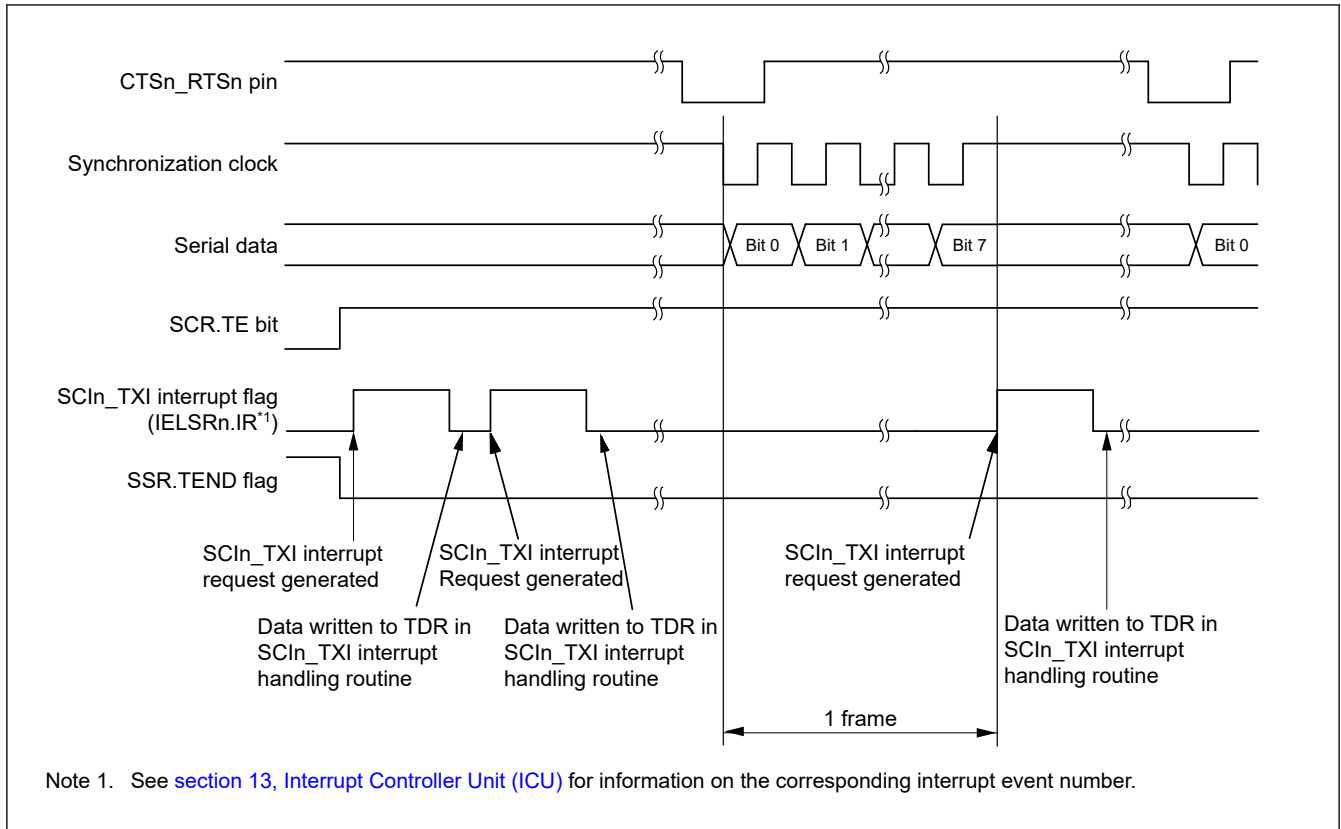

Figure 27.63, Figure 27.64, and Figure 27.65 show examples of serial data transmission.

Transmission does not start while a receive error flag (ORER, FER, or PER in SSR) is set to 1. Always set the receive error flags to 0 before starting transmission.

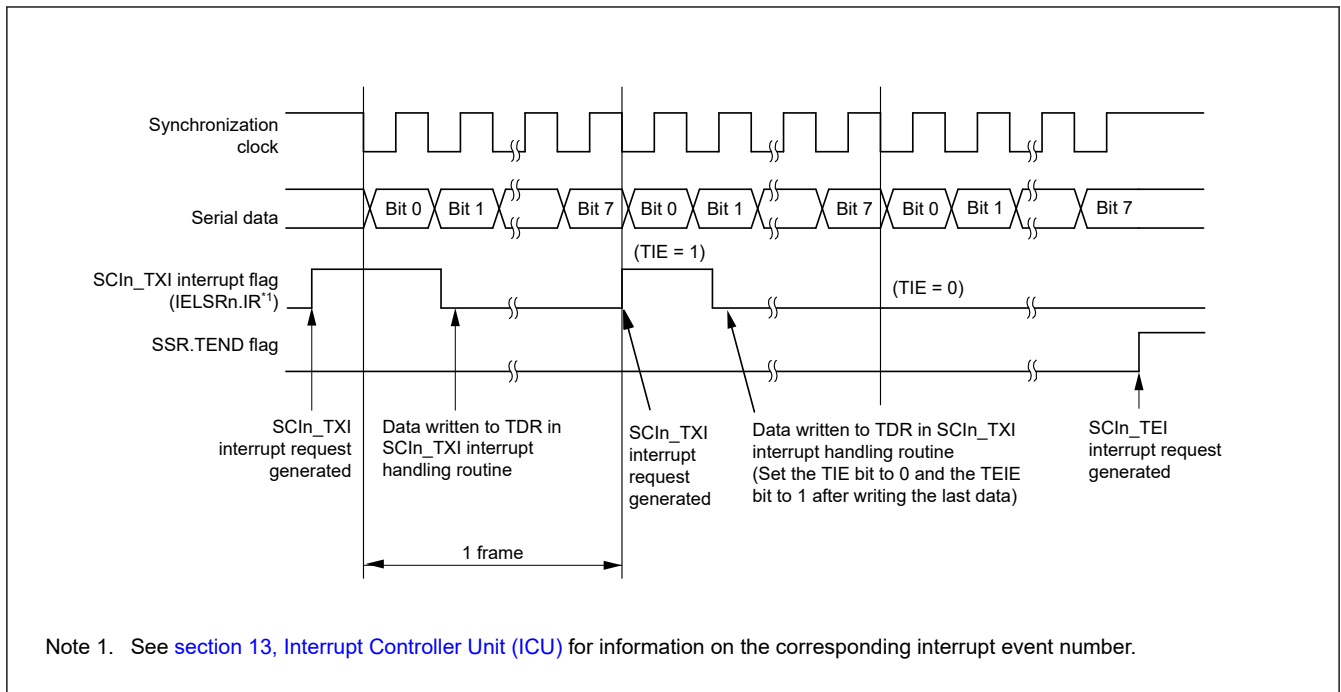

Note: Setting the SCR.RE bit to 0 does not clear the receive error flags.

**Figure 27.63 Example of serial data transmission in clock synchronous mode when the CTS function is not used at the beginning of transmission**

**Figure 27.64** Example of serial data transmission in clock synchronous mode when the CTS function is used at the beginning of transmission

**Figure 27.65** Example of serial data transmission in clock synchronous mode from the middle of transmission until transmission completion

**Figure 27.66 Example flow of serial transmission in clock synchronous mode with non-FIFO selected**

(2) FIFO selected

Figure 27.67 shows an example of serial transmission in clock synchronous mode with FIFO selected.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the FTDR<sup>\*1</sup> register to the TSR register when data is written to FTDR<sup>\*1</sup> in the SCIn\_TXI interrupt handling routine. The amount of data that can be written to FTDR is 16 minus FDR.T[4:0] bytes. The SCIn\_TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 but only after the SCR.TIE bit is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from FTDR to TSR, the SCI starts transmission. When the amount of transmit data written in FTDR is equal to or less than the specified transmit triggering number, the SSR\_FIFO.TDFE is set to 1. When the SCR.TIE bit is set to 1, an SCIn\_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to FTDR in the SCIn\_TXI interrupt handling routine before transmission of the current transmit data has finished. When SCIn\_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDR from the handling routine for SCIn\_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks whether non-transmitted data remains in FTDR on output of the stop bit.

- When FTDRL is updated, the next transmit data is transferred from FTDRL to TSR and serial transmission of the next frame starts.
- If FTDRL is not updated, the SSR\_FIFO.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn\_TEI interrupt request is generated and the SCKn pin is held high.

Note 1. In clock synchronous mode, FTDRH is not used.

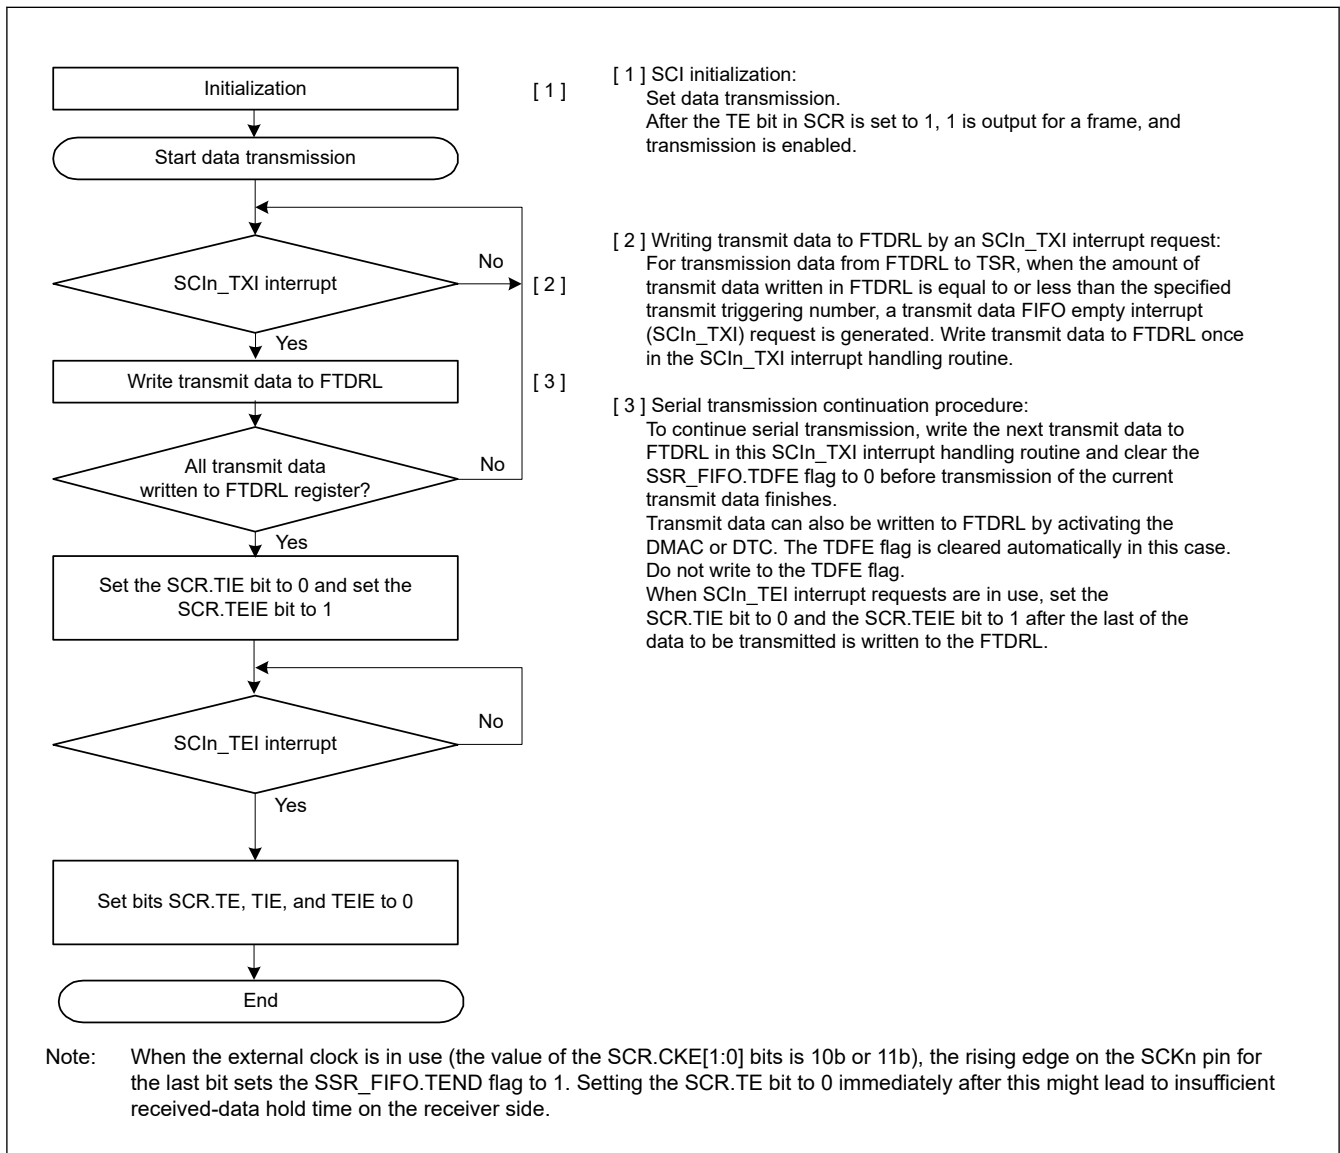

Figure 27.67 Example flow of serial transmission in clock synchronous mode with FIFO selected

### 27.6.5 Serial Data Reception in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 27.68 and Figure 27.69 show examples of SCI operation for serial reception in clock synchronous mode.

In serial data reception, the SCI operates as follows:

- When the value of the SCR.RE bit becomes 1, the CTSn\_RTsn pin goes low.
- The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
- If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn\_ERI interrupt request is generated. Receive data is not transferred to the RDR register.

- When reception completes successfully, receive data is transferred to the RDR register. If the SCR.RIE bit is 1, an SCIn\_RXI interrupt request is generated. Continuous reception is enabled by reading the received data transferred to the RDR register in the SCIn\_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that is transferred to RDR causes the CTSn\_RTSn pin to output low.

**Figure 27.68 Example operation for serial reception in clock synchronous mode (1) when the RTS function is not used**

**Figure 27.69 Example operation for serial reception in clock synchronous mode (2) when RTS function is used**

Data transfer cannot resume while the receive error flag is 1. Therefore, clear the ORER, FER, and PER flags in the SSR register to 0 before resuming data reception. Additionally, always read the RDR register during overrun error processing. When a data reception is forced to terminate by a 0 write to the SCR.RE bit during operation, read the RDR register because received data that is not yet read might be left in the RDR register.

Figure 27.70 shows an example flow of serial data reception.

Figure 27.70 Example flow of serial reception in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 27.71 shows an example of serial reception in clock synchronous mode with FIFO selected.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn\_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.

3. If an overrun error occurs, the SSR\_FIFO.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn\_ERI interrupt request is generated. Received data is not transferred to the FRDRL<sup>\*1</sup> register.
4. When data reception completes successfully, the receive data is transferred to the FRDRL<sup>\*1</sup> register. The RDF flag is set to 1 when the amount of the receive data stored in FRDRL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit is 1, an SCIn\_RXI interrupt request is generated. Continuous data reception is enabled by reading the receive data transferred to FRDRL<sup>\*2</sup> in the SCIn\_RXI interrupt handling routine before an overrun error occurs. If the amount of received data that is transferred to FRDRL is less than the specified receive triggering number, the CTSn\_RTSn pin goes low.

Note 1. In clock synchronous mode, FRDRH is not used.

Note 2. Read data in order from FRDRH to FRDRL when RDF and OREER are read with receive data.

Figure 27.71 Example flow of serial reception in clock synchronous mode with FIFO selected

## 27.6.6 Simultaneous Serial Data Transmission and Reception in Clock Synchronous Mode

### (1) Non-FIFO selected

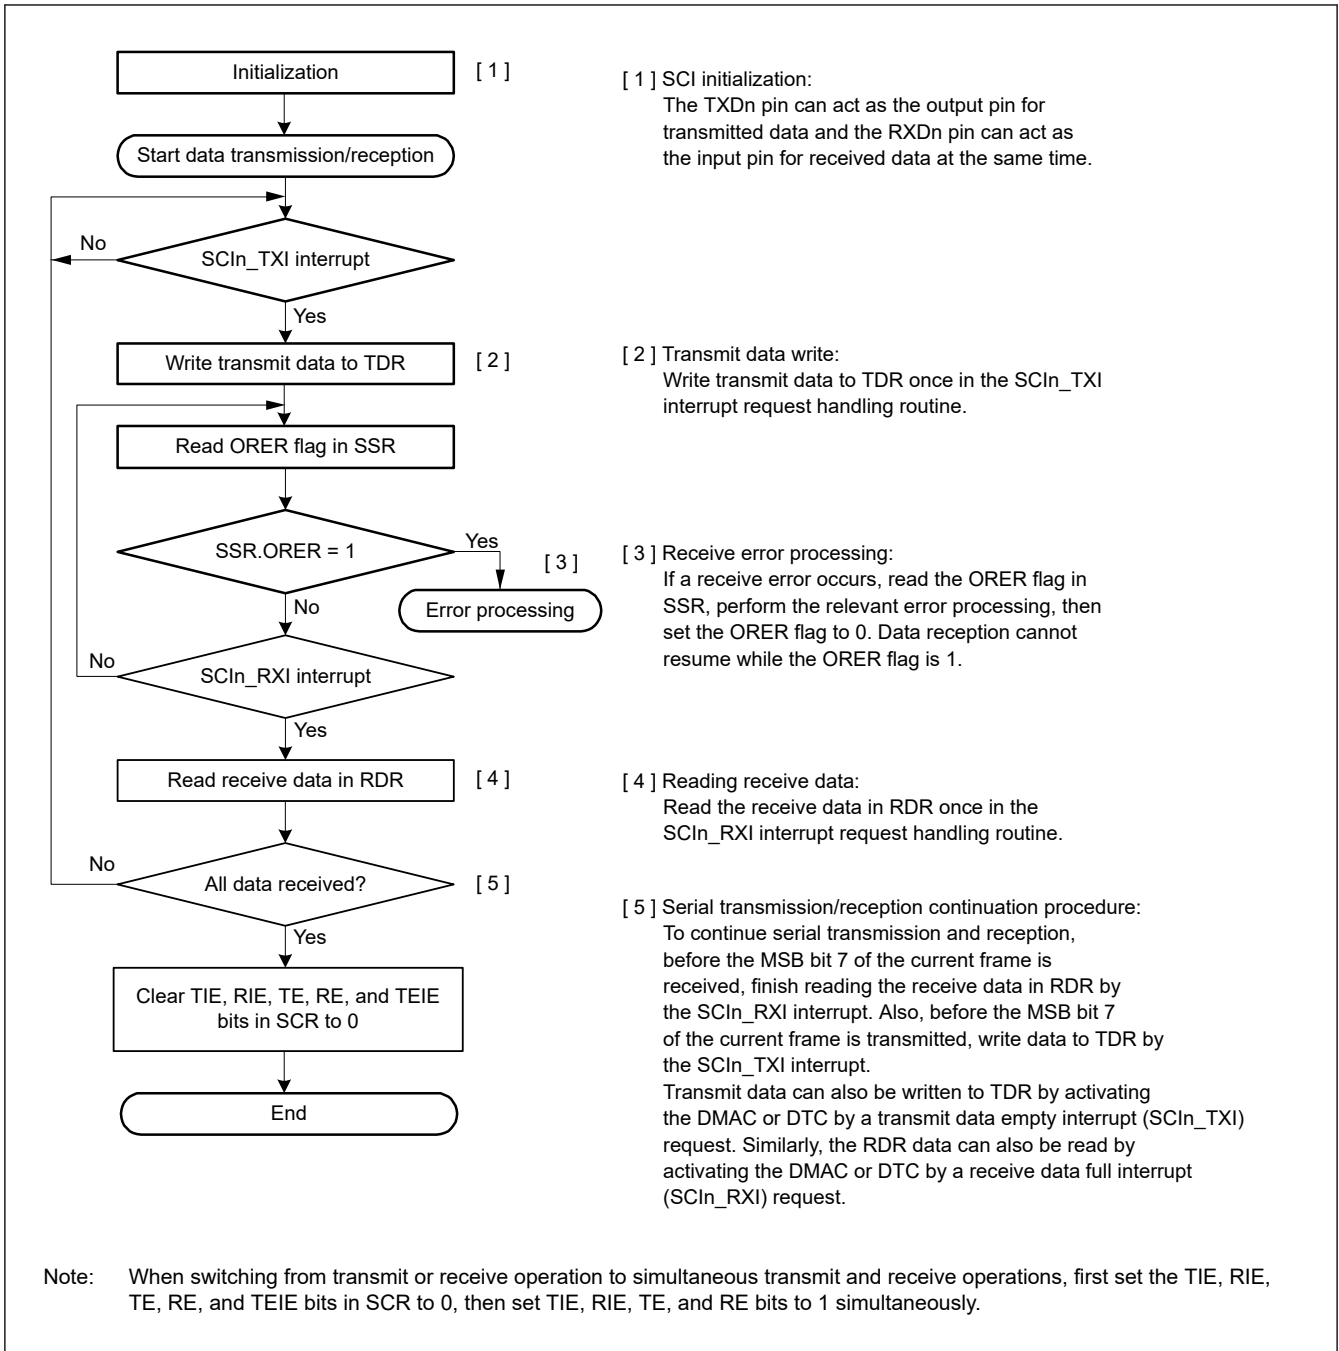

Figure 27.72 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode. After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data transmission by verifying that the SSR.TEND flag is set to 1.
2. Initialize the SCR register, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data reception.
2. Set the RIE and RE bits to 0, and then check that the receive error flag ORER in the SSR register is 0.
3. Set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

**Figure 27.72 Example flow of simultaneous serial transmission and reception in clock synchronous mode with non-FIFO selected**

**(2) FIFO selected**

Figure 27.73 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode with FIFO selected.

After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

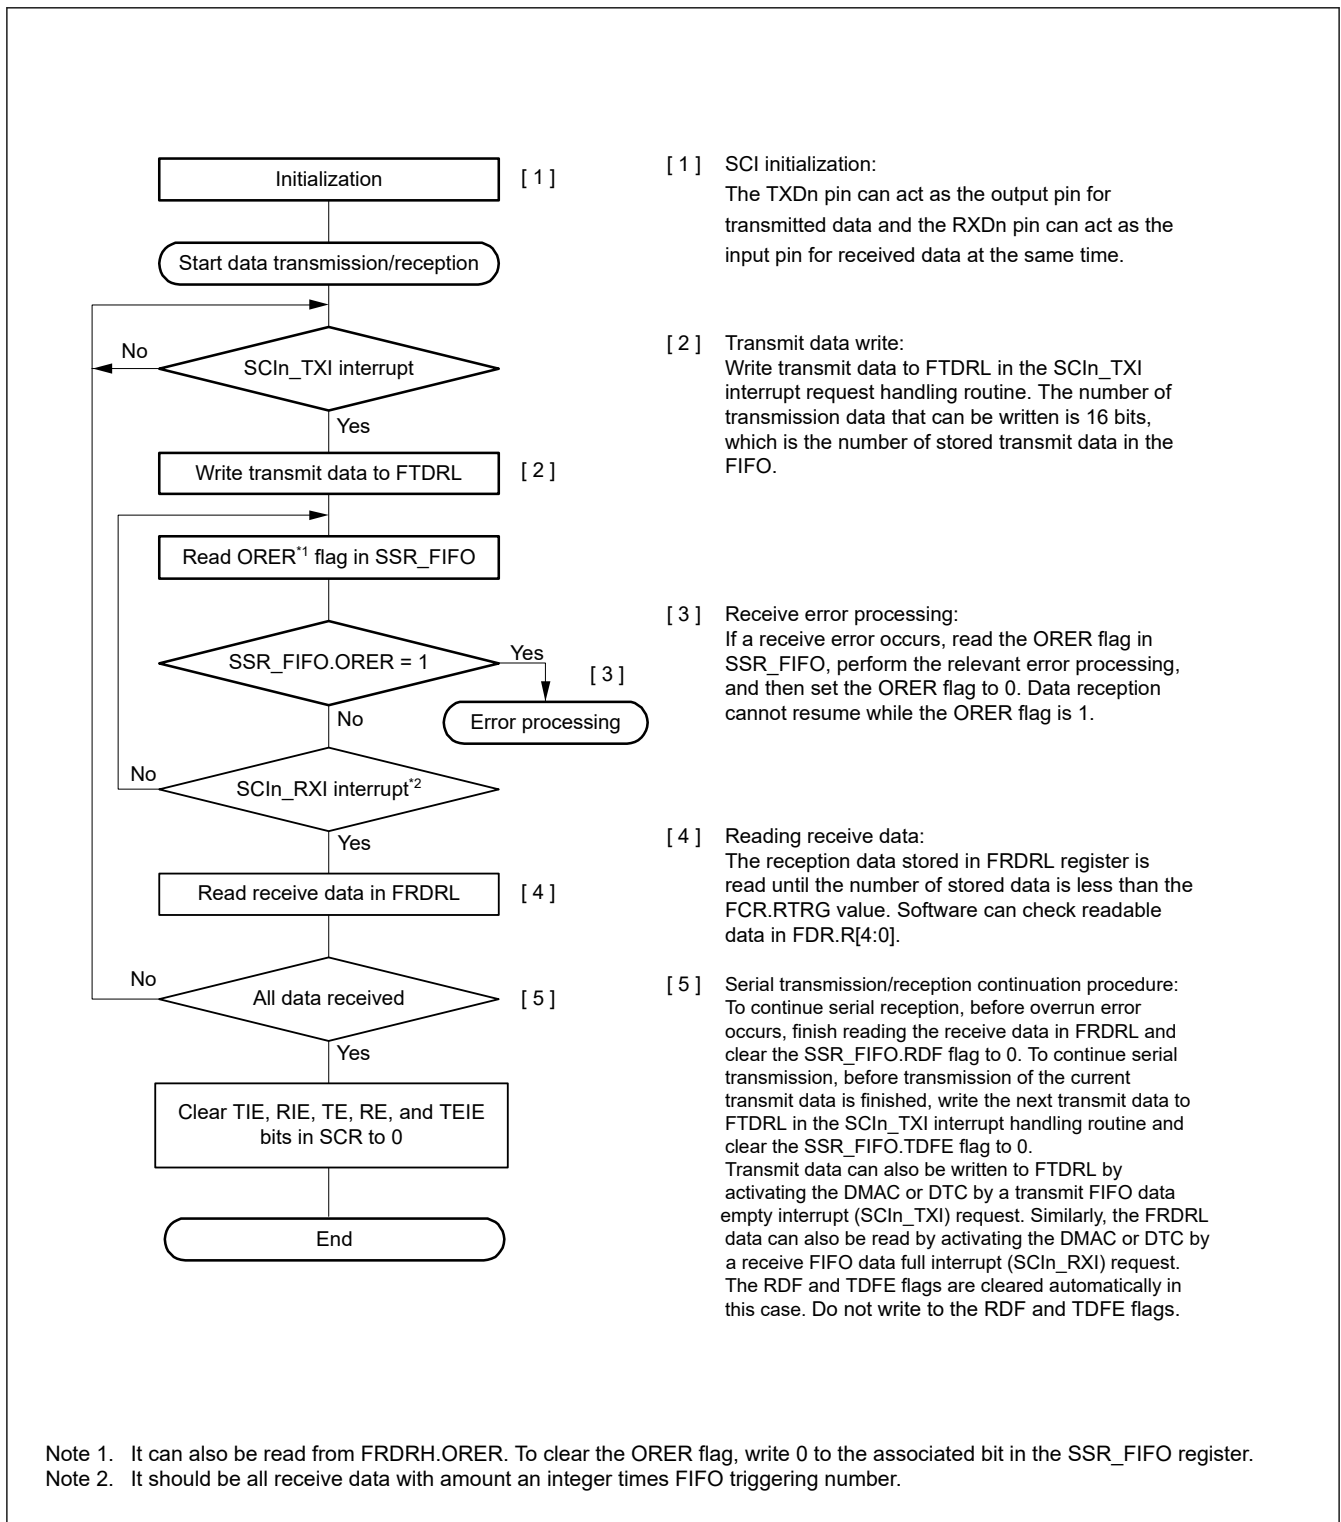

To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the transmission by verifying that the SSR\_FIFO.TEND flag is set to 1.
2. Initialize the SCR register, then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the reception.

2. Set the RIE and RE bits to 0.
3. Check that the receive error flags ORER in the SSR\_FIFO register are 0, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

**Figure 27.73 Example flow of simultaneous serial transmission and reception in clock synchronous mode with FIFO selected**

## 27.7 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

### 27.7.1 Example Connection

Figure 27.74 shows an example connection between a smart card (IC card) and the MCU. As shown in Figure 27.74, because the MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the SCR\_SMCI.TE and SCR\_SMCI.RE bits to 1 with an IC card disconnected enables closed-loop transmission or reception, allowing self-diagnosis. To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

An output port of the MCU can be used to output a reset signal.

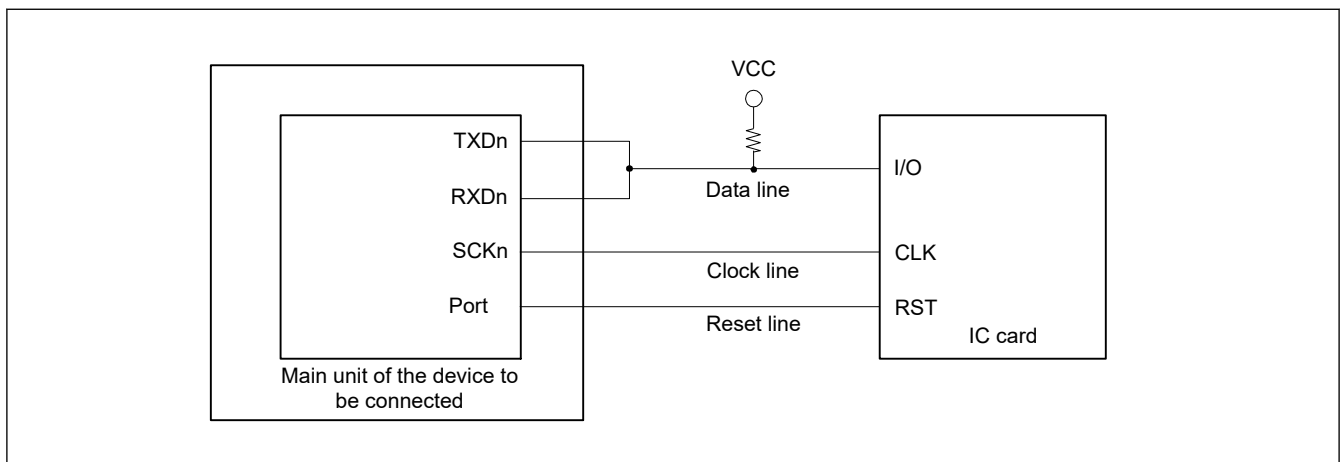

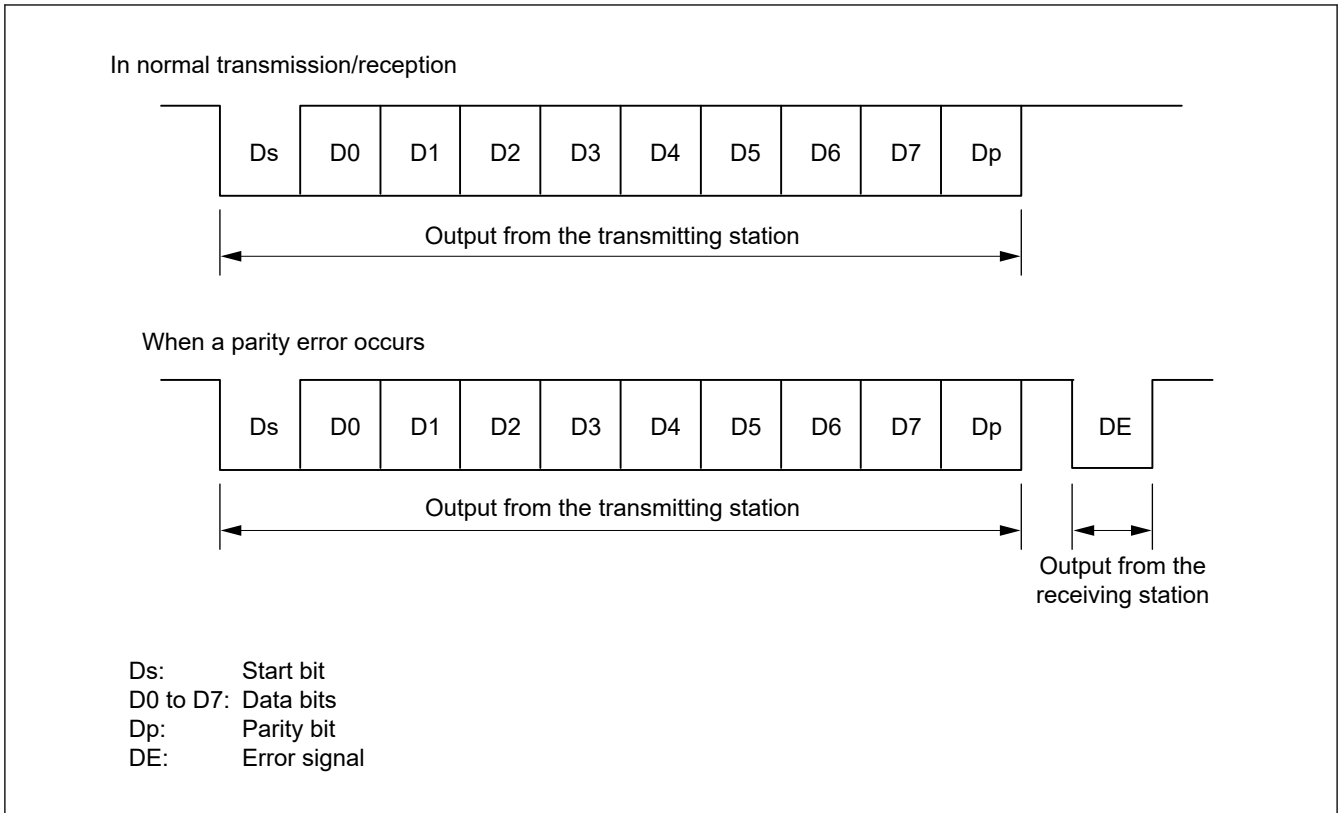

Figure 27.74 Example connection with a smart card (IC card)

### 27.7.2 Data Format (Except in Block Transfer Mode)

Figure 27.75 shows the data transfer formats in smart card interface mode:

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etus (elementary time unit – the time required for transferring 1 bit) is set as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low error signal is output for 1 etu after 10.5 etus elapse from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etus.

**Figure 27.75 Data formats in smart card interface mode**

For communications with IC cards of the direct convention type and inverse convention type, follow the procedures in this section.

**(1) Direct Convention Type**

For the direct convention type, logic levels 1 and 0 indicate the Z and A states, respectively, and data is transferred with LSB-first for the start character, as shown in Figure 27.76. Therefore, data in the start character in the figure is 0x3B.

When using the direct convention type, write 0 to both the SCMR.SDIR and SCMR.SINV bits. Write 0 to the SMR\_SMCI.PM bit to use even parity, which is prescribed by the smart card standard.

**Figure 27.76 Direct convention with SDIR in SCMR = 0, SINV in SCMR = 0, and PM in SMR\_SMCI = 0**

**(2) Inverse Convention Type**

For the inverse convention type, logic levels 1 and 0 indicate the A and Z states, respectively, and data is transferred with MSB-first for the start character, as shown in Figure 27.77. Therefore, data in the start character in the figure is 0x3F.

When using the inverse convention type, write 1 to both the SCMR.SDIR and SCMR.SINV bits. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to the Z state. Because the SINV bit of the MCU only inverts data bits D7 to D0, write 1 to the PM bit in SMR\_SMCI to invert the parity bit for both transmission and reception.

Figure 27.77 Inverse convention with **SDIR** in **SCMR** = 1, **SINV** in **SCMR** = 1, and **PM** in **SMR\_SMCI** = 1

### 27.7.3 Block Transfer Mode

Block transfer mode differs from normal smart card interface mode as follows:

- Even if a parity error is detected during reception, no error signal is output. Because the PER flag in SSR\_SMCI is set by error detection, clear the PER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is set as a guard time from the end of the parity bit until the start of the next frame
- Because the same data is not retransmitted, the TEND flag in SSR\_SMCI is set to 11.5 etus after transmission starts
- In block transfer mode, the ERS flag in SSR\_SMCI indicates the error signal status as in normal smart card interface mode, but the flag is read as 0 because no error signal is transferred

### 27.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate set up in the SCMR.BCP2 and the SMR\_SMCI.BCP[1:0] bits. The frequency is always 16 times the bit rate in normal asynchronous mode.

For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization.

Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 27.78. The reception margin is determined by the following formula:

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100 \text{ [%]}$$

M: Reception margin (%)

N: Ratio of bit rate to clock (N = 32, 64, 372, 256)

D: Duty cycle of clock (D = 0 to 1.0)

L: Frame length (L = 10)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the specified formula, the reception margin is determined using the following formula:

$$M = \{0.5 - 1/(2 \times 372)\} \times 100 \text{ [%]} = 49.866 \text{ %}$$

**Figure 27.78** Receive data sampling timing in smart card interface mode when the clock frequency is 372 times the bit rate

### 27.7.5 SCI Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, write the initial value 0x00 in the SCR\_SMCI register and initialize the SCI following the example flow shown in Table 27.37.

Always set the initial value in the TIE, RIE, TE, RE, TEIE bits in the SCR\_SMCI register before switching from transmission to reception mode or from reception to transmission mode. When SCR\_SMCI.RE is set to 0, the RDR register is not initialized.

To change from reception mode to transmission mode, first check that reception has completed, then initialize the SCI. At the end of initialization, set SCR\_SMCI.TE = 1 and SCR\_SMCI.RE = 0. Reception completion can be verified by reading the SCIn\_RXI request, ORER, or PER flag in SSR\_SMCI.

To change transmission mode to reception mode, first check that transmission has completed, then initialize the SCI. At the end of initialization, set SCR\_SMCI.TE = 0 and SCR\_SMCI.RE = 1. Transmission completion can be verified by reading the TEND flag in SSR\_SMCI.

**Table 27.37** Example flow of SCI initialization in smart card interface mode (1 of 2)

| No. | Step Name                                                              | Description                                                                  |
|-----|------------------------------------------------------------------------|------------------------------------------------------------------------------|
| 1   | Start initialization                                                   |                                                                              |
| 2   | Set SCR_SMCI.TIE, RIE, TE, RE, TEIE, and CKE[1:0] to 0                 | Stop the communication and initialize SKE[1:0].                              |
| 3   | Set SIMR1.IICM bit to 0.<br>Set SCMR.SMIF to 1.                        | Set to smart card interface mode.                                            |
| 4   | Set SSR_SMCI.ORER, ERS, PER to 0                                       | Write to SSR_SMCI after reading SSR_SMCI.                                    |
| 5   | Set SPMR.CKPH, CKPOL                                                   | Set the transmission or reception format in SPMR.                            |
| 6   | Set SMR_SMCI.GM, BLK, PM, BCP[1:0], CKS[1:0], and set SMR_SMCI.PE to 1 | Set the operation mode and the transmission or reception format in SMR_SMCI. |
| 7   | Set SCMR.BCP2, SDIR, SINV                                              | Set the transmission or reception format in SCMR.                            |
| 8   | Set SPTR to the initial value.                                         | Set the Initial value to SPTR.                                               |

**Table 27.37 Example flow of SCI initialization in smart card interface mode (2 of 2)**

| No. | Step Name                                             | Description                                                                                                                                                        |
|-----|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9   | Set SEMR.BRME and SEMR.RXDESEL to 0                   | Set SEMR.BRME and SEMR.RXDESEL to 0.                                                                                                                               |
| 10  | Set a value in BRR                                    | Write the value for the bit rate in BRR.                                                                                                                           |
| 11  | Set the I/O port functions                            | Set the I/O port functions for TXDn, RXDn, and SCKn.                                                                                                               |
| 12  | Set a value in SCR_SMCI.CKE[1:0]                      | Set the SCR_SMCI.CKE[1:0]. Even though the function depends on SMR_SMCI.GM, when the CKE[0] bit is set to 1, the clock is output from the SCKn pin.                |
| 13  | Set SCR_SMCI.TE or RE to 1, and set SCR_SMCI.TIE, RIE | Set the TE or RE bit in SCR_SMCI to 1, then set the TIE and RIE bits in SCR_SMCI. Do not simultaneously set the TE and RE bits to 1 if self-diagnosis is not used. |
| 14  | Initialization completed                              |                                                                                                                                                                    |

### 27.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode) is different from that in non-smart card interface mode, in that an error signal is sampled and data can be re-transmitted in smart card mode. [Figure 27.79](#) shows the data re-transfer operation during transmission.

1. When an error signal from the receiver end is sampled after 1-frame data is transmitted, the SSR\_SMCI.ERS flag is set to 1. If the SCR\_SMCI.RIE bit is 1, an SCIn\_ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
2. For a frame in which an error signal is received, the SSR\_SMCI.TEND flag is not set. Data is re-transferred from TDR to TSR, allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI determines that transmission of 1-frame data, including the re-transfer, is complete, and the TEND flag is set. If the SCR\_SMCI.TIE bit is 1, an SCIn\_TXI interrupt request is generated. Write transmit data to the TDR to start transmission of the next data.

[Figure 27.81](#) shows an example flow of serial transmission. All the processing steps are automatically performed using an SCIn\_TXI interrupt request to activate the DTC or DMAC.

When the SSR\_SMCI.TEND flag is set to 1 in transmission and when the SCR\_SMCI.TIE bit is 1, an SCIn\_TXI interrupt request is generated.

The DTC or DMAC is activated by an SCIn\_TXI interrupt request if the SCIn\_TXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission when an error occurs. Because the ERS flag is not automatically cleared, set the RIE bit to 1 before enabling an SCIn\_ERI interrupt request to be generated if an error occurs, and clear the ERS flag to 0.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings.

For DTC or DMAC settings, see [section 17, Data Transfer Controller \(DTC\)](#), [section 16, DMA Controller \(DMAC\)](#).

**Figure 27.79 Data re-transfer operation in smart card interface transmission mode**

The SSR\_SMCI.TEND flag is set at different timings depending on the SMR\_SMCI.GM bit setting. Figure 27.80 shows the TEND flag generation timing.

**Figure 27.80 SSR.TEND flag generation timing during transmission**

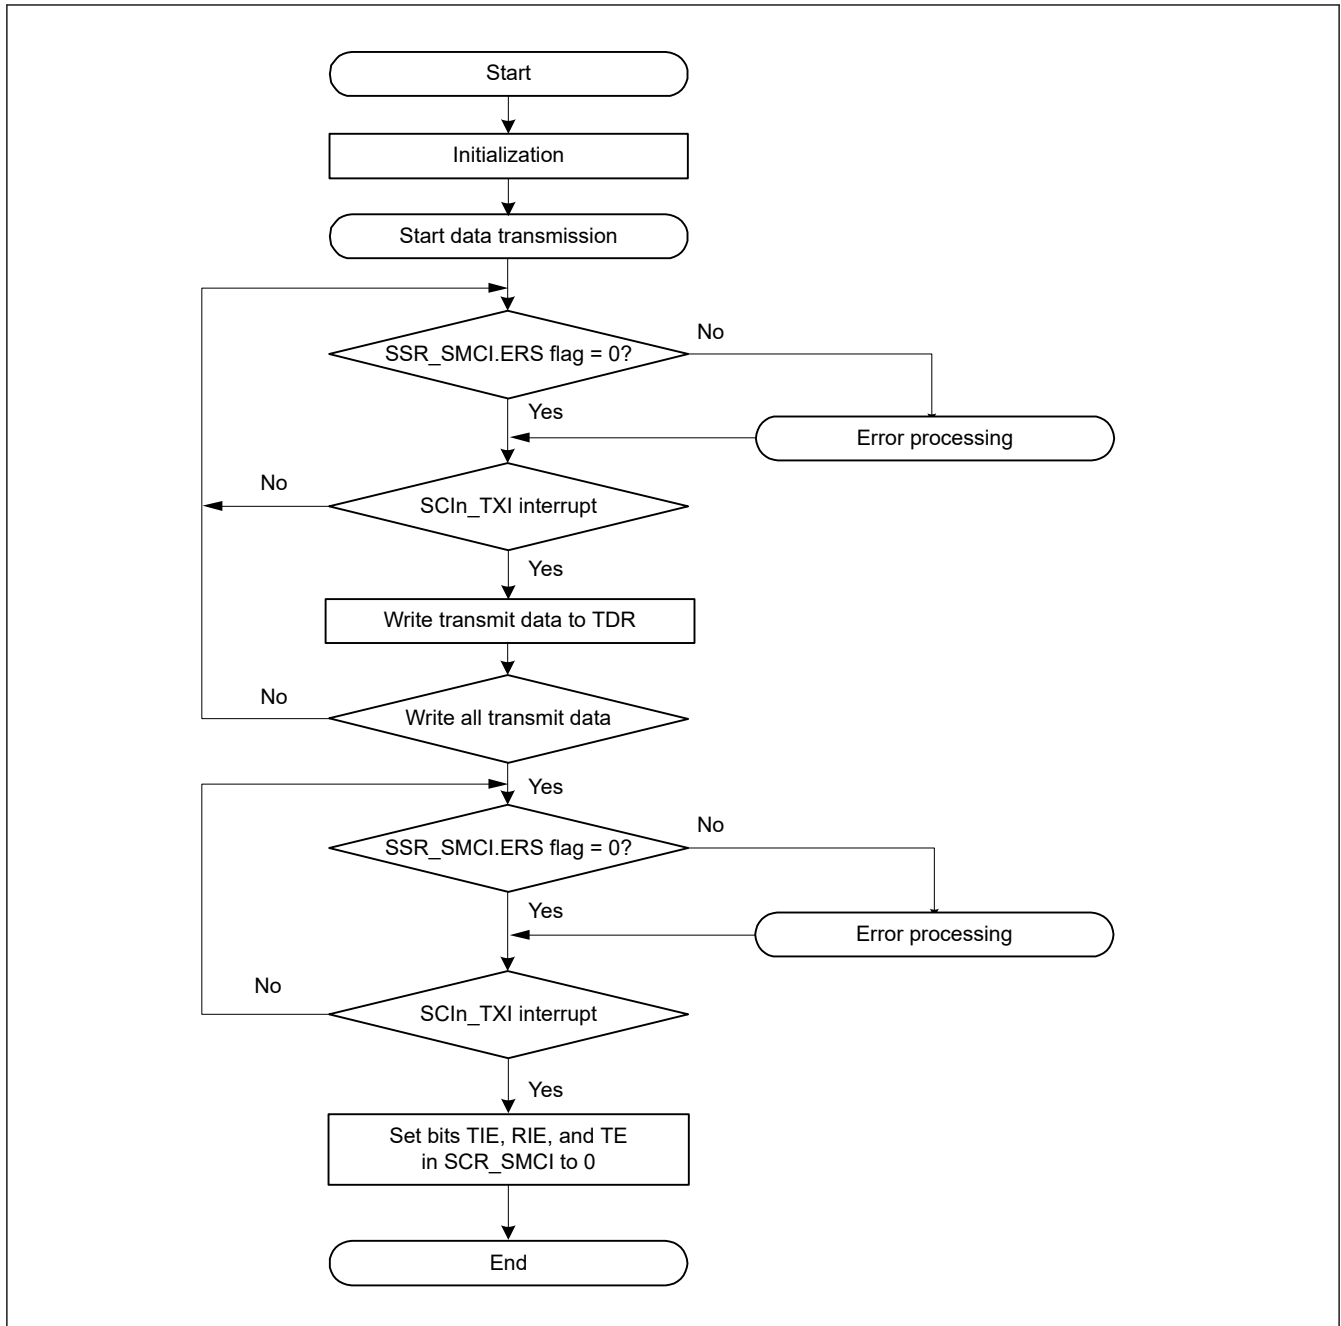

Figure 27.81 Example flow of smart card interface transmission

### 27.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 27.82 shows the data re-transfer operation in reception mode.

1. If a parity error is detected in the receive data, the SSR\_SMCI.PER flag is set to 1. When the SCR\_SMCI.RIE bit is 1, an SCIn\_ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no SCIn\_RXI interrupt is generated.
3. When no parity error is detected, the SCR\_SMCI.PER flag is not set to 1.
4. In this case, data is determined to be received successfully. When the SCR\_SMCI.RIE bit is 1, an SCIn\_RXI interrupt request is generated.

Figure 27.83 shows an example flow of serial data reception. All the processing steps are automatically performed using an SCIn\_RXI interrupt request to activate the DTC or DMAC.

In reception, setting the RIE bit to 1 allows an SCIn\_RXI interrupt request to be generated. The DTC or DMAC is activated by an SCIn\_RXI interrupt request if the SCIn\_RXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in SSR\_SMCI is set to 1, a receive error interrupt (SCIn\_ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

If a parity error occurs and the PER flag is set to 1 during reception, the receive data is transferred to RDR, allowing the data to be read.

When a reception is forced to terminate by setting SCR\_SMCI.RE to 0 during operation, read the RDR register because the received data that is not yet read might be left in the RDR.

Note: For operations in block transfer mode, see [section 27.3.9. Serial Data Reception in Asynchronous Mode](#).

Figure 27.82 Data re-transfer operation in smart card interface reception mode

Figure 27.83 Example flow of smart card interface reception

### 27.7.8 Clock Output Control

When the GM bit in SMR\_SMCI is set to 1, the clock output can be controlled by the CKE[1:0] bits in SCR\_SMCI. For details on the CKE[1:0] bits, see [section 27.2.14. SCR\\_SMCI : Serial Control Register for Smart Card Interface Mode \(SCMR.SMIF = 1\)](#). When setting the clock output, the base clock described in [section 27.7.4. Receive Data Sampling Timing and Reception Margin](#) is applied.

[Figure 27.84](#) shows an example timing for the clock output control when the CKE[1] bit in SCR\_SMCI is set to 0 and the CKE[0] bit in SCR\_SMCI is controlled.

When the GM bit in SMR\_SMCI is 0, output control by the CKE[0] bit in SCR\_SMCI is immediately reflected on the SCKn pin, so there is a possibility that pulses with an unintended width may be output from the SCKn pin.

When the GM bit in SMR\_SMCI is 1, the clock with the same pulse width as the base clock is output even if the CKE[0] bit in SCR\_SMCI is changed.

Figure 27.84 Clock Output timing

### 27.8 Operation in Simple IIC Mode

Simple IIC mode format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device can specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The I<sup>2</sup>C bus format and timing of the I<sup>2</sup>C bus are shown in Figure 27.85 and Figure 27.86.

Figure 27.85 I<sup>2</sup>C bus format

**Figure 27.86** I<sup>2</sup>C bus timing when SLA is 7 bits

- S: Indicates a start condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high
- SLA: Indicates a slave address, by which the master device selects a slave device
- R/W#: Indicates the direction of transfer (reception or transmission). The value 1 indicates transfer from the slave device to the master device and 0 indicates transfer from the master device to the slave device.
- A/A#: Indicates an acknowledge bit. This is returned by the slave device for master transmission and by the master device for master reception. Return low indicates ACK and return high indicates NACK.
- Sr: Indicates a restart condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high and after the setup time elapses
- DATA: Indicates the data being received or transmitted
- P: Indicates a stop condition, when the master device changes the level on the SDAn line from low to high while the SCLn line is high

### 27.8.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the SIMR3.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state
- The hold time for the start condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the IICSTAREQ bit in SIMR3 is set to 0, and a start-condition generated interrupt is output

Writing 1 to the IICRSTAREQ bit in SIMR3 causes the generation of a restart condition. The generation of a restart condition proceeds through the following operations:

- The SDAn line is released and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SDAn line falls (from the high level to the low level)
- The hold time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the SIMR3.IICRSTAREQ bit is set to 0, and a restart-condition generated interrupt is output

Writing 1 to the SIMR3.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)

- When a high level is detected on the SCLn line, the setup time for the stop condition is set as half of a bit period at the bit rate determined by the BRR setting
- The SDAn line is released (transition from the low to the high level), the SIMR3.IICSTPREQ bit is set to 0, and a stop-condition generated interrupt is output

Figure 27.87 shows the timing of operations in the generation of start, restart, and stop conditions.

Figure 27.87 Timing of operations in generation of start, restart, and stop conditions

## 27.8.2 Clock Synchronization

The SCLn line can be driven low if a wait is inserted by a slave device at the other side of the transfer. Setting the SIMR2.IICCSC bit to 1 applies control to obtain synchronization when a difference arises between the levels of the internal SCLn clock signal and the level being input on the SCLn pin.

When the SIMR2.IICCSC bit is set to 1, the level of the internal SCLn clock signal changes from low to high. Counting to determine the period at a high level stops while the low level is being input on the SCLn pin. Counting to determine the period at a high level starts after the transition of the input on the SCLn pin to the high level.

The interval from this time until counting to determine the period at high level starts on the transition of the SCLn pin to the high level, is the total of the delay of SCLn output, delay for noise filtering of the input on the SCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SCLn clock is extended even when other devices do not place the low level on the SCLn line.

If the SIMR2.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the SIMR2.IICCSC bit is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a wait period into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a wait period after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the waiting period, generation of the condition itself is not guaranteed.

Figure 27.88 shows an example operation for synchronizing the clocks.

Figure 27.88 Example operations for clock synchronization

### 27.8.3 SDAn Output Delay

The SIMR1.IICDL[4:0] bits can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. Delay settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, PCLK, by the divisor selected in the SMR.CKS[1:0] bits). A delay for output on the SDAn pin applies to the start condition/restart condition/stop condition signal, 8-bit transmit data, and acknowledge bit.

If the SDAn output delay is shorter than the time for the level on the SCLn pin to fall, the change of the output on the SDAn pin starts while the output level on the SCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SDAn pin specify times greater than the time output on the SCLn pin takes to fall (300 ns for IIC in normal mode and fast mode).

Figure 27.89 shows the timing of delays in SDAn output.

Figure 27.89 Timing of delays in SDAn output

### 27.8.4 SCI Initialization in Simple IIC Mode

Before transferring data, write the initial value 0x00 to SCR and initialize the interface following the example shown in Table 27.38.

Before making any changes to the operating mode or transfer format, be sure to set SCR to its initial value. In simple IIC mode, the open-drain setting for the communication ports should be made on the port side.

**Table 27.38 Example flow of SCI initialization in simple IIC mode**

| No. | Step Name                                                             | Description                                                                                                                                                                                                                                                                                                       |
|-----|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | Start of initialization                                               |                                                                                                                                                                                                                                                                                                                   |
| 2   | Set the TIE, RIE, TE, RE, TEIE and CKE[1:0] bits in SCR to 0          |                                                                                                                                                                                                                                                                                                                   |
| 3   | Set the I/O port functions                                            | Set the I/O port to allow use (on N-channel open-drain output pins) of the SSCLn and SSDAn pin functions.                                                                                                                                                                                                         |
| 4   | Set the IICSDAS[1:0] and IICSCLS[1:0] bits in SIMR3 to 11b            | Place the SSCLn and SSDAn pins in the high-impedance state until a start condition is to be generated.                                                                                                                                                                                                            |
| 5   | Set up the transfer or reception format in SMR and SCMR               | Set the format for transmission and reception in SMR and SCMR. In SMR, set the CKS[1:0] bits to the target value and set the other bits to 0. In SCMR, set the SDIR bit to 1 and the SINV and SMIF bits to 0.                                                                                                     |
| 6   | Set the initial value to SPTR.                                        | Set the Initial value to SPTR.                                                                                                                                                                                                                                                                                    |
| 7   | Set the value in BRR                                                  | Write the value for the targeted bit rate to BRR.                                                                                                                                                                                                                                                                 |
| 8   | Set a value in MDDR                                                   | Write the value obtained by correcting a bit rate error in MDDR. This step is not required if the BRME bit in SEMR is set to 0.                                                                                                                                                                                   |
| 9   | Set the values in SEMR, SNFR, SIMR1, SIMR2, and SPMR                  | Set the values in SEMR, SNFR, SIMR1, SIMR2, and SPMR. Set the NFEN and BRME bits in SEMR. In SNFR, set the NFCS[2:0] bits. In SIMR1, set the IICM bit to 1 and the IICDL[4:0] bits as required. In SIMR2, set the IICACKT and IICCCSC bits to 1 and the IICINTM bits as required. In SPMR, set all the bits to 0. |
| 10  | Set the SCR.RE and TE bit to 1 and set the SCR.TIE, RIE and TEIE bits | Set the RE and TE bits in the SCR to 1. Then, set the SCR.TIE, RIE, and TEIE bits (for transmission and when the SIMR2.IICINTM bit is 1, set the RIE bit to 0). Setting the TE and RE bits to 1 enables the SSCLn and SSDAn pin functions.                                                                        |
| 11  | Start of transmission or reception                                    |                                                                                                                                                                                                                                                                                                                   |

### 27.8.5 Operation in Master Transmission in Simple IIC Mode

Figure 27.90 and Figure 27.91 show examples of master transmission and Figure 27.92 shows an example flow of data transmission.

Figure 27.90 shows the operation example when SIMR2.IICINTM bit is 1 (use reception and transmission interrupts) and the value of the SCR.RIE bit is assumed to be 0 (SCIn\_RXI and SCIn\_ERI interrupt requests are disabled).

See Table 27.43 for more information on the STI interrupt.

Figure 27.92 shows a flow chart in the case of SIMR2.IICINTM is 1 and address transmission by CPU and data transmission by DTC or DMAC. When 10-bit slave addresses are in use, steps [3] and [4] are repeated twice.

In simple IIC mode, the transmit data empty interrupt (SCIn\_TXI) is generated when communication of one frame is complete, unlike the SCIn\_TXI interrupt request generation timing during clock synchronous transmission.

**Figure 27.90 Example 1 of operations for master transmission in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts**

When the SIMR2.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and required number of data bytes are transmitted. When the NACK is received, error processing such as transmission stop and retransmission is performed using the NACK interrupt as the trigger.

To restart communication for some reason after writing data in the TDR register, use the following procedure:

1. Set the TE and RE bits in the SCR register to 0 to stop communication.
2. Set 0xF0 in the SIMR3 register, release the I<sup>2</sup>C bus, and clear the generation of a condition.
3. If the RDRF flag in the SSR register is set to 1, clear it.
4. Set the TE and RE bits in the SCR register to 1 and start the next communication.

**Figure 27.91 Example 2 of operations for master transmission in simple IIC mode with 7-bit slave addresses, ACK interrupts, and NACK interrupts**

Figure 27.92 Example flow of master transmission in simple IIC mode with transmission interrupts and reception interrupts

### 27.8.6 Master Reception in Simple IIC Mode

Figure 27.93 shows an example operation in simple IIC mode master reception and Figure 27.94 shows an example flow of master reception.

The value of the SIMR2.IICINTM bit is assumed to be 1 (use reception and transmission interrupts).

In simple IIC mode, the transmit data empty interrupt (SCIn\_TXI) is generated when communication of one frame is complete, unlike the SCIn\_TXI interrupt request generation timing during clock synchronous transmission.

**Figure 27.93 Example operations for master reception in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts**

**Figure 27.94 Example flow of master reception in simple IIC mode with transmission interrupts and reception interrupts**

### 27.9 Operation in Simple SPI Mode

As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Using the settings for clock synchronous mode (SCMR.SMIF = 0, SIMR1.IICM = 0, SMR.CM = 1) and setting the SPMR.SSE bit to 1 place the SCI in simple SPI mode. However, the SSn pin function on the master side is not required for connection of the device used as the master in simple SPI mode when the configuration only has a single master. Therefore, set the SPMR.SSE bit to 0 in such cases.

Figure 27.95 shows an example of connections for simple SPI mode. Control a general port pin to produce the SSn output signal from the master.

In simple SPI mode, data is transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended. The data can be inverted by setting the SCMR.SINV bit to 1.

Because the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a shared clock signal. Additionally, because both the transmitter and receiver have a buffered structure, writing the next transmit data while transmission is in progress and reading previously received data while reception is in progress are both possible. This enables continuous transfer.

Figure 27.95 Example connections using simple SPI mode in single master mode with SPMR.SSE bit = 0

### 27.9.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (SCR.CKE[1:0] = 00b or 01b and SPMR.MSS = 0) or slave (SCR.CKE[1:0] = 10b or 11b and SPMR.MSS = 1).

Table 27.39 lists the relationship between the pin states, mode, and level on the SSn pin.

Table 27.39 States of pins by mode and input level on SSn pin (1 of 2)

| Mode          | Input on SSn pin                    | State of MOSIn pin             | State of MISOn pin                     | State of SCKn pin |
|---------------|-------------------------------------|--------------------------------|----------------------------------------|-------------------|
| Master mode*1 | High level (transfer can proceed)   | Output for data transmission*2 | Input for received data                | Clock output*3    |
|               | Low level (transfer cannot proceed) | High-impedance                 | Input for received data (but disabled) | High-impedance    |

**Table 27.39 States of pins by mode and input level on SSn pin (2 of 2)**

| Mode       | Input on SSn pin                     | State of MOSIn pin                     | State of MISO pin            | State of SCKn pin          |
|------------|--------------------------------------|----------------------------------------|------------------------------|----------------------------|
| Slave mode | High level (transfer cannot proceed) | Input for received data (but disabled) | High-impedance               | Clock input (but disabled) |
|            | Low level (transfer can proceed)     | Input for received data                | Output for data transmission | Clock input                |

Note 1. When there is only a single master (SPMR.SSE = 0), transfer is possible regardless of the input level on the SSn pin. This is equivalent to input of a high level on the SSn pin.

Note 2. The MOSIn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit = 0).

Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE = 0 and SCR.RE = 0) in a multi-master configuration (SPMR.SSE = 1).

## 27.9.2 SS Function in Master Mode

Setting the CKE[1:0] bits in the SCR to 00b or 01b and the MSS bit in the SPMR to 0 selects master mode operation. The SSn pin is not used in single-master configurations (SPMR.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn pin.

When the level on the SSn pin is high in a multi-master configuration (SPMR.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission.

When the level on the SSn pin is low in a multi-master configuration (SPMR.SSE = 1), there are other masters, and a transmission or reception is in progress. The MOSIn output and SCKn pins are placed in the high-impedance state and starting transmission or reception is not possible. In addition, the value of the SPMR.MFF bit is 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading SPMR.MFF flag. If a mode fault error occurs while transmission or reception is in progress, transmission or reception does not stop, but the MOSIn and SCKn outputs are in the high-impedance state after completion of the transfer.

Use a general port pin to produce the SS output signal from the master.

## 27.9.3 SS Function in Slave Mode

Setting the SCR.CKE[1:0] bits to 10b or 11b and the SPMR.MSS bit to 1 selects slave operation. When the SSn pin is high, the MISO output pin is in the high-impedance state and clock input through the SCKn pin is ignored. When the SSn pin is low, clock input through the SCKn pin is valid and transmission or reception can proceed.

If the input on the SSn pin changes from low to high during transmission or reception, the MISO output pin is placed in the high-impedance state. Meanwhile, the internal processing for transmission or reception continues at the rate of the clock input through the SCKn pin until processing for the character being transmitted or received is complete, after which it stops, and the appropriate interrupt (SCIn\_TXI, SCIn\_RXI, or SCIn\_TEI) is generated.

## 27.9.4 Relationship between Clock and Transmit/Receive Data

The CKPOL and CKPH bits in the SPMR register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in [Figure 27.96](#). The relation is the same for both master and slave operation. This is the same as when the level on the SSn pin is high.

**Figure 27.96** Relation between clock signal and transmit or receive data in simple SPI mode

### 27.9.5 SCI Initialization in Simple SPI Mode

Initialization in simple SPI mode is the same as in clock synchronous mode. See [section 27.6.3. SCI Initialization in Clock Synchronous Mode](#) for an example initialization flow. The CKPOL and CKPH bits in the SPMR register must be set to ensure that the clock signal is suitable for both master and slave devices.

Always initialize the SCR register before making any changes to the operating mode or transfer format.

**Note:** Only the RE bit is set to 0. The SSR.ORER, FER, PER, and RDR flags are not initialized.

Changing the value of the TE bit from 1 to 0 or from 0 to 1 when the TIE bit in the SCR register is 1 at the same time, leads to the generation of a transmit data empty interrupt (SCIn\_TXI).

### 27.9.6 Transmission and Reception of Serial Data in Simple SPI Mode

In master operation, ensure that the SSn pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. Otherwise, the procedures are the same as in clock synchronous mode.

### 27.10 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be evenly corrected using the number specified in the MDDR register among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in SMR/SMR\_SMCI.

Figure 27.97 shows an example where the PCLK is selected in the CKS[1:0] bits in SMR/SMR\_SMCI, the BRR bit is set to 0, and the MDDR is set to 160 in asynchronous mode. In this example, the cycle of the base clock is evenly corrected ( $256/160$ ) and the bit rate is also corrected ( $160/256$ ).

Note: Enabling an internal clock causes bias, and expansion and contraction are generated in the pulse width of the internal base clock.

Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

Figure 27.97 Example internal base clock when bit rate modulation function is used

## 27.11 Interrupt Sources

### 27.11.1 Buffer Operation for SCIn\_TXI and SCIn\_RXI Interrupts (Non-FIFO Selected)

If the conditions for an SCIn\_TXI and SCIn\_RXI interrupt are satisfied while the interrupt status flag in the ICU is 1, the ICU does not output the interrupt request but saves it internally with a capacity for retention of one request per source.

When the interrupt status flag in the ICU is set to 0, the interrupt request retained within the ICU is output. The internally retained interrupt request is automatically discarded when the actual interrupt is output. Clearing of the associated interrupt enable bit (the TIE or RIE bit in the SCR/SCR\_SMCI) can also be used to discard an internally retained interrupt request.

### 27.11.2 Buffer Operation for SCIn\_TXI and SCIn\_RXI Interrupts (FIFO Selected)

When an interrupt status flag in the ICU is set to 1, the SCIn\_TXI and SCIn\_RXI interrupts do not output interrupt requests to the ICU. When an interrupt status flag of the ICU is set to 0, and if the conditions for an SCIn\_TXI and SCIn\_RXI interrupts are satisfied, an interrupt request is generated.

### 27.11.3 Interrupts in Asynchronous, Manchester, Clock Synchronous, and Simple SPI Modes

#### (1) Non-FIFO selected

Table 27.40 lists interrupt sources in asynchronous mode, Manchester mode, clock synchronous mode, and simple SPI mode.

A different interrupt vector can be assigned to each interrupt source. Individual interrupt sources can be enabled or disabled with the enable bits in the SCR register.

If the SCR.TIE bit is 1, an SCIn\_TXI interrupt request is generated when transmit data is transferred from the TDR or TDRHL register<sup>\*1</sup> to the TSR register. An SCIn\_TXI interrupt request can also be generated by using a single instruction to set the SCR.TE and SCR.TIE bits to 1 at the same time. An SCIn\_TXI interrupt request can activate the DTC or DMAC to handle data transfer.

An SCIn\_TXI interrupt request is not generated by setting the SCR.TE bit to 1 when SCR.TIE is 0 or by setting the SCR.TIE bit to 1 when the SCR.TE is 1.<sup>\*2</sup>

When new data is not written by the time of transmission of the last bit of the current transmit data and SCR.TEIE is 1, the SSR.TEND flag is set to 1 and an SCIn\_TEI interrupt request is generated. Additionally, when SCR.TE is 1, the SSR.TEND flag retains the value 1 until more transmit data is written to the TDR or TDRHL register<sup>\*1</sup>, and setting SCR.TEIE to 1 leads to the generation of an SCIn\_TEI interrupt request.

Writing data to the TDR or TDRHL register<sup>\*1</sup> leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the SCIn\_TEI interrupt request.

If the SCR.RIE bit is 1, an SCIn\_RXI interrupt request is generated when received data is stored in the RDR register. An SCIn\_RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting any of the SSR.ORER, FER, PER and MER<sup>\*3</sup> flags to 1 when the SCR.RIE bit is 1 leads to the generation of an SCIn\_ERI interrupt request.

An SCIn\_RXI interrupt request is not generated in this case. Clearing all these flags (ORER, FER, PER, MER<sup>\*3</sup>, SYER<sup>\*3</sup>, PFER<sup>\*3</sup> and SBER<sup>\*3</sup>) leads to discarding of the SCIn\_ERI interrupt request.

Note 1. When asynchronous mode and 9-bit data length are selected.

Note 2. To temporarily prohibit SCIn\_TXI interrupts on transmission of the last of the data when a new round of transmission is to be started, after handling the transmission-completed interrupt, control activation of the interrupt by using the interrupt request enable bit in the ICU rather than using the SCR.TIE bit. This approach can prevent the suppression of SCIn\_TXI interrupt requests in the transfer of new data.

Note 3. MER, SYER, PFER, and SBER work as a factor of SCIn\_ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECCR) are set to "1".

## (2) FIFO selected

Table 27.41 lists interrupt sources in FIFO selected mode.

If the SCR.TIE bit is 1, an SCIn\_TXI interrupt request is generated when the stored amount of data in the FTDR register becomes the threshold value indicated in FCR.TTRG or below. An SCIn\_TXI interrupt request can also be generated by using a single instruction to set the SCR.TIE and SCR.TE bits to 1 simultaneously or by setting SCR.TIE to 1 when SCR.TE is 1.

An SCIn\_TXI interrupt request is not generated by setting SCR.TE to 1 when SCR.TIE is 0.

If SCR.TEIE is 1 and if the next data is not written to the FTDR register by the time the last bit of the transmit data is sent, the SSR\_FIFO.TEND flag is set to 1 and the SCIn\_TEI interrupt request is generated.

If SCR.RIE is 1, the SCIn\_RXI interrupt request is generated when the stored amount of data in the FRDRL register is equal to or greater than the threshold value indicated in FCR.RTRG. When RTRG is 0, an SCIn\_RXI interrupt does not occur even when the amount of data in the receive FIFO is equal to 0.

If the SCR.RIE bit is 1, when the SSR\_FIFO.ORER flag is set to 1 or data with a framing error or a parity error is stored in the FRDRL register, the SCIn\_ERI interrupt request is generated. When the amount of data stored in the FRDRL register is at the threshold value or above, the SCIn\_RXI interrupt request is also generated. The SCIn\_ERI interrupt request can be canceled, in which case SSR\_FIFO.ORER, FER, and PER flags are all cleared.

**Table 27.40 SCI interrupt sources with non-FIFO selected (1 of 2)**

| Name                      | Interrupt source            | Interrupt flag                                                                                             | Interrupt enable | DTC or DMAC activation |
|---------------------------|-----------------------------|------------------------------------------------------------------------------------------------------------|------------------|------------------------|
| SCIn_ERI (n = 0, 3, 4, 9) | Receive error <sup>*1</sup> | SSR.ORER, SSR.FER, SSR.PER, DCCR.DFER, DCCR.DPER, (SSR.MER, MESR.SYER, MESR.PFER, MESR.SBER) <sup>*2</sup> | SCR.RIE          | Not possible           |

**Table 27.40 SCI interrupt sources with non-FIFO selected (2 of 2)**

| Name                      | Interrupt source    | Interrupt flag | Interrupt enable | DTC or DMAC activation |
|---------------------------|---------------------|----------------|------------------|------------------------|
| SCIn_RXI (n = 0, 3, 4, 9) | Receive data full   | SSR.RDRF       | SCR.RIE          | Possible               |
|                           | Address match       | DCCR.DCMF      | SCR.RIE          | Possible               |
| SCIn_AM (n = 0, 3, 4, 9)  | Address match       | DCCR.DCMF      | —                | Not possible           |
| SCIn_TXI (n = 0, 3, 4, 9) | Transmit data empty | SSR.TDRE       | SCR.TIE          | Possible               |
| SCIn_TEI (n = 0, 3, 4, 9) | Transmit end        | SSR.TEND       | SCR.TEIE         | Not possible           |

Note 1. The interrupt flag is only ORER when in clock synchronous and simple SPI mode.

Note 2. MER, SYER, PFER, and SBER work as a factor of ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECCR) are set to 1.

**Table 27.41 SCI interrupt sources with FIFO selected**

| Name                      | Interrupt source    | Interrupt flag                                                  | Interrupt enable | DTC or DMAC activation |
|---------------------------|---------------------|-----------------------------------------------------------------|------------------|------------------------|
| SCIn_ERI (n = 0, 3, 4, 9) | Receive error*1     | SSR_FIFO.ORER, SSR_FIFO.FER, SSR_FIFO.PER, DCCR.DFER, DCCR.DPER | SCR.RIE          | Not possible           |
|                           |                     | SSR_FIFO.DR (when FCR.DRES = 1)                                 | SCR.RIE          | Not possible           |
| SCIn_RXI (n = 0, 3, 4, 9) | Receive data full   | SSR_FIFO.RDF                                                    | SCR.RIE          | Possible               |
|                           | Receive data ready  | SSR_FIFO.DR (when FCR.DRES = 0)                                 | SCR.RIE          | Possible               |
|                           | Address match       | DCCR.DCMF                                                       | SCR.RIE          | Possible               |
| SCIn_AM (n = 0, 3, 4, 9)  | Address match       | DCCR.DCMF                                                       | —                | Not possible           |
| SCIn_TXI (n = 0, 3, 4, 9) | Transmit data empty | SSR_FIFO.TDFE                                                   | SCR.TIE          | Possible               |
| SCIn_TEI (n = 0, 3, 4, 9) | Transmit end        | SSR_FIFO.TEND                                                   | SCR.TEIE         | Not possible           |

Note 1. The interrupt flag is only ORER when in clock synchronous and simple SPI mode.

## 27.11.4 Interrupts in Smart Card Interface Mode

Table 27.42 lists interrupt sources in smart card interface mode. A transmit end interrupt (SCIn\_TEI) request and an address match (SCIn\_AM) request cannot be used in this mode.

**Table 27.42 SCI Interrupt sources**

| Name                      | Interrupt source                        | Interrupt flag                            | Interrupt enable | DTC or DMAC activation |
|---------------------------|-----------------------------------------|-------------------------------------------|------------------|------------------------|
| SCIn_ERI (n = 0, 3, 4, 9) | Receive error or error signal detection | SSR_SMCI.ORER, SSR_SMCI.PER, SSR_SMCI.ERS | SCR_SMCI.RIE     | Not possible           |
| SCIn_RXI (n = 0, 3, 4, 9) | Receive data full                       | SSR_SMCI.RDRF                             | SCR_SMCI.RIE     | Possible               |
| SCIn_TXI (n = 0, 3, 4, 9) | Transmit data empty                     | SSR_SMCI.TEND                             | SCR_SMCI.TIE     | Possible               |

Data transmission or reception using the DTC or DMAC is also possible in smart card interface mode, similar to normal SCI mode. In transmission, when the SSR\_SMCI.TEND flag is set to 1, an SCIn\_TXI interrupt request is generated. This SCIn\_TXI interrupt request activates the DTC or DMAC, allowing transfer of transmit data if the SCIn\_TXI request is previously specified as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission after an error occurrence. However, the SSR\_SMCI.ERS flag is not automatically set to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR\_SMCI.RIE bit to 1 to enable an SCIn\_ERI interrupt request to be generated at error occurrence.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings. For DTC or DMAC settings, see [section 17, Data Transfer Controller \(DTC\)](#), [section 16, DMA Controller \(DMAC\)](#).

In reception, an SCIn\_RXI interrupt request is generated when receive data is set to the RDR register. This SCIn\_RXI interrupt request activates the DTC or DMAC, allowing transfer of the receive data if the SCIn\_RXI request is previously specified as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an SCIn\_ERI interrupt request is issued to the CPU instead. The error flag must be cleared.

### 27.11.5 Interrupts in Simple IIC Mode

[Table 27.43](#) lists the interrupt sources in simple IIC mode. The STI interrupt is allocated to the transmit end interrupt (SCIn\_TEI) request. The receive error interrupt (SCIn\_ERI) and the address match (SCIn\_AM) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple IIC mode.

When the SIMR2.IICINTM bit is 1:

- An SCIn\_RXI request is generated on the falling edge of the SCLn signal for the 8<sup>th</sup> bit. If SCIn\_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn\_RXI request activates the DTC or DMAC to handle transfer of the received data.
- An SCIn\_TXI request is generated on the falling edge of the SCLn signal for the 9<sup>th</sup> bit (acknowledge bit). If SCIn\_TXI is previously set up as an activation source for the DTC or DMAC, the SCIn\_TXI request activates the DTC or DMAC to handle transfer of the transmit data.

When the SIMR2.IICINTM bit is 0:

- An SCIn\_RXI request (ACK detection) is generated if the input on the SDAn pin is low on the rising edge of the SCLn signal for the 9<sup>th</sup> bit (acknowledge bit)
- An SCIn\_TXI request (NACK detection) is generated if the input on the SDAn pin is high on the rising edge of the SCLn signal for the 9<sup>th</sup> bit (acknowledge bit)
- If SCIn\_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn\_RXI request activates the DTC or DMAC to handle transfer of the received data.

If the DTC or DMAC is used for data transfer in reception or transmission, always set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in SIMR3 are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

**Table 27.43 SCI interrupt sources**

| Name                            | Interrupt source                                                | Interrupt flag | Interrupt enable | DTC or DMAC activation |
|---------------------------------|-----------------------------------------------------------------|----------------|------------------|------------------------|
| SCIn_RXI (n = 0, 3, 4, 9)       | Reception, ACK detection                                        | —              | SCMR.RIE         | Possible*1             |
| SCIn_TXI (n = 0, 3, 4, 9)       | Transmission, NACK detection                                    | —              | SCMR.TIE         | Possible               |
| SCIn_TEI(STIn) (n = 0, 3, 4, 9) | Completion of generation of a start, restart, or stop condition | SIMR3.IICSTIF  | SCMR.TEIE        | Not possible           |

Note 1. Activation of the DTC or DMAC is only possible when the SIMR2.IICINTM bit is 1 (use reception and transmission interrupts)

## 27.12 Event Linking

By using interrupt request signals as event signals, the SCIn can provide linked operation through the ELC for modules selected in advance.

Event signals can be output regardless of the values of the associated interrupt request enable bits.

(1) Error event output (receive error or error signal detected) (SCIn\_ERI, n = 0, 3, 4, 9)

- Indicates abnormal termination because of a parity error during reception in asynchronous mode
- Indicates abnormal termination because of a framing error during reception in asynchronous mode
- Indicates abnormal termination because of an overrun error during reception
- Indicates detection of the error signal during transmission in smart card interface mode
- The SSR\_FIFO.FER and PER flags are 0, and receive data less than the receive FIFO data trigger number is set in a reception FIFO buffer, and it indicates that 15 etus elapse when FIFO is selected and the FCR.DRES bit is 1

(2) Receive data full event output (SCIn\_RXI, n = 0, 3, 4, 9)

- Indicates that ACK is detected if the SIMR2.IICINTM bit is 0 in simple IIC mode
- Indicates that the 8th-bit SCLn falling edge is detected if the SIMR2.IICINTM bit is 1 in simple IIC mode
- When the SIMR2.IICINTM bit is 1 during master transmission in simple IIC mode, set the ELC so that receive data full events are not used

**Non-FIFO selected**

- Indicates that received data is set in the Receive Data Register (RDR or RDRHL).

**FIFO selected**

- Using this event output is prohibited.

(3) Transmit data empty event output (SCIn\_TXI, n = 0, 3, 4, 9)

- Indicates that the SCR/SCR\_SMCI.TE bit is changed from 0 to 1
- Indicates that transmission is complete in smart card interface mode
- Indicates that NACK is detected if the SIMR2.IICINTM bit is 0 in simple IIC mode
- Indicates that the 9th-bit SCLn falling edge is detected if the SIMR2.IICINTM bit is 1 in simple IIC mode

**Non-FIFO selected**

- Indicates that transmit data is transferred from the Transmit Data Register (TDR or TDRHL) to the Transmit Shift Register (TSR).

**FIFO selected**

- Using this event output is prohibited.

(4) Transmit end event output (SCIn\_TEI, n = 0, 3, 4, 9)

- Indicates the completion of transmission
- Indicates that the starting condition, resumption condition, or termination condition is generated in simple IIC mode

Note: When FIFO is selected, using this event output is prohibited

(5) Address match event output (SCIn\_AM, n = 0, 3, 4, 9)

- Indicates a match of the comparison data (CDR.CMPD) with one frame of receive data when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode.

## 27.13 Address Non-match Event Output (SCI0\_DCUF)

SCI0\_DCUF indicates the non-match of comparison data (CDR.CMPD) with receive data that is one frame of the data that is received when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode. This event can be used for Snooze end request only. For details, see [section 10, Low Power Modes](#).

## 27.14 Noise Cancellation Function

Figure 27.98 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a 2-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the 2-stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. When the same level is retained for 3 cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for 3 cycles or shorter is considered as noise, not as a receive signal.

In asynchronous mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The receive level of the RXDn is taken in the flip-flop circuit of the noise filter on the base clock of asynchronous mode.

- When SEMR.ABCS = 0 and SEMR.ABCSE = 0, the cycle is 1/16 of a 1-bit period.
- When SEMR.ABCS = 1 and SEMR.ABCSE = 0, the cycle is 1/8 of a 1-bit period.
- When SEMR.ABCSE = 1, the cycle is 1/6 of a 1-bit period.

In simple IIC mode, this function can be used for each input on SDA<sub>n</sub> and SCL<sub>n</sub>. The sampling clock is selected from divided clock of baud rate generator settings SNFR.NFCS[2:0].

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, the function determines that a level match is detected and the result is conveyed as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

Figure 27.98 Digital noise filter circuit block diagram

## 27.15 Usage Notes

### 27.15.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SCI operation. The SCI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

## 27.15.2 SCI Operation during Low Power State

### (1) Transmission

When setting the module to the stopped state or in transitions to Software Standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR/SCR\_SMCI to 0) after switching the TXDn pin to the general I/O port pin function. When setting I/O port as an SCI connection, the SPTR register can control the state of the TXDn pin. Setting the TE bit to 0 initializes the TSR register and the TEND bit in the SSR/SSR\_SMCI is initialized to 1 with non-FIFO selected, and the value is retained, with FIFO selected. Depending on the port settings and SPTR register settings, output pins might output the level before a transition to the low-power state is made after release from the module-stopped state or Software Standby mode. When transitions to these states are made during transmission, the transmitted data becomes indeterminate.

To transmit data in the same transmission mode after cancellation of the low-power state:

1. Set the TE bit to 1.
2. Read SSR/SSR\_FIFO/SSR\_SMCI.
3. Write data to TDR sequentially to start data transmission.

To transmit data with a different transmission mode, initialize the SCI first.

[Figure 27.99](#) shows an example flow of transition to Software Standby mode during transmission. [Figure 27.100](#) and [Figure 27.101](#) show the port pin states during transition to Software Standby mode.

Before specifying the module-stop state or transitioning to Software Standby mode from the transmission mode using DTC or DMAC transfer, stop the transmit operations (TE = 0). To start transmission after cancellation using the DTC or DMAC, set the TE bit to 1. The SCIn\_TXI interrupt flag is set to 1 and transmission starts using the DTC or DMAC.

### (2) Reception

#### When address match function is not used as wakeup condition

Before specifying the module-stop state or transitioning to Software Standby mode, stop the receive operations (RE = 0 in SCR/SCR\_SMCI). If transition is made during data reception, the received data is invalid.

[Figure 27.102](#) shows an example flow of transition to Software Standby mode during reception.

#### When address match function is used as wakeup condition

Before specifying the module-stop state or transitioning to Software Standby mode:

1. Set the operations after cancellation of the low power state.
2. Set CDR.CMPD and DCCR.DCME to 1.
3. Set the receive operations (RE = 1 in SCR/SCR\_SMCI).
4. Set the module-stop state or Software Standby mode.

When SCI transfers to low power mode, if the receive data pin (RXD) is at the low level, set SEMR.RXDESEL = 0.

When setting SEMR.RXDESEL = 1, there is a possibility that a start bit (falling edge of RXD pin) cannot be detected on release of the low power mode.

[Figure 27.103](#) shows an example flow of transition to Software Standby mode during reception with address match.

#### When using SCI0 in Snooze mode

When using SCI0 in Snooze mode, some restrictions apply, including maximum bit rates. For details, see [section 10, Low Power Modes](#).

Figure 27.99 Example flow of transition to Software Standby mode during transmission

**Figure 27.100** Port pin states during transition to Software Standby mode with internal clock and asynchronous transmission

**Figure 27.101** Port pin states during transition to Software Standby mode with internal clock and clock synchronous transmission

Figure 27.102 Example flow of transition to Software Standby mode during reception

Figure 27.103 Example flow of transition to Software Standby mode during reception with address match

### 27.15.3 Break Detection and Processing

#### (1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading the RXDn pin value directly. In a break, the input from the RXDn pin becomes all 0s, and the SSR.FER flag is set to 1 to indicate a framing error, and the SSR.PER flag might also be set to 1 to indicate a parity error. The SCI continues the receive operation even after a break is received. Therefore, even if the FER flag is 0, indicating that no framing error occurred, it is set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operations until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0, the SSR.FER flag retains 0 during the break.

When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit on the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

#### (2) FIFO selected

After a framing error is detected and when the SCI detects that continuous receive data is 0 for 1 frame, reception stops. When a framing error is detected, a break can be detected by reading the SPTR.RXDMON flag value. After the RXDn signal is in high and the break is finished, data reception to the FRDRHL register resumes.

### 27.15.4 Mark State and Production of Breaks

When the SCR/SCR\_SMCI.TE bit is 0, disabling serial transmission, the state of the TXDn pin can be set using the SPTR.SPB2IO and SPTR.SPB2DT bits. With this approach, a TXDn pin can be placed in the mark state to transmit a break.

Before setting the SCR/SCR\_SMCI.TE bit to 1, enabling serial transmission, set the SPB2IO and SPB2DT bits to put the communication line in the mark state (the state of 1), and change the TXDn pin using I/O port function. To output a break on data transmission, after setting the TXDn pin to output 0 by setting the SPB2IO and SPB2DT bits, change the TXDn pin using the I/O port function and set the SCR/SCR\_SMCI.TE bit to 0. When the SCR/SCR\_SMCI.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

### 27.15.5 Receive Error Flags and Transmit Operation in Clock Synchronous Mode and Simple SPI Mode

Transmission cannot start when a receive error flag (ORER) in SSR/SSR\_FIFO is set to 1, even when data is written to TDR or FTDR<sup>\*1</sup>. Always set the receive error flags to 0 before starting transmission.

Note: The receive error flags cannot be set to 0 when the RE bit in SCR/SCR\_SMCI is set to 0 (serial reception is disabled).

Note 1. Do not use the FTDRH register in simple SPI mode.

### 27.15.6 Restrictions on Clock Synchronous Transmission in Clock Synchronous Mode and Simple SPI Mode

When the external clock source is used as a synchronization clock, the following restrictions apply.

#### (1) Start of transmission

Wait at least the following time from writing transmit data to TDR to the start of the external clock input:

1 PCLK cycle + data output delay time for the slave ( $t_{DO}$ ) + setup time for the master ( $t_{SU}$ ). See [Figure 27.104](#).

#### (2) Continuous transmission

Write the next transmit data to TDR or TDRHL before the falling edge of the transmit clock for bit [7]. See [Figure 27.104](#).

When updating TDR after bit [7] has started to transmit, update TDR while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit [7]) to 4 PCLK cycles or longer. See [Figure 27.104](#).

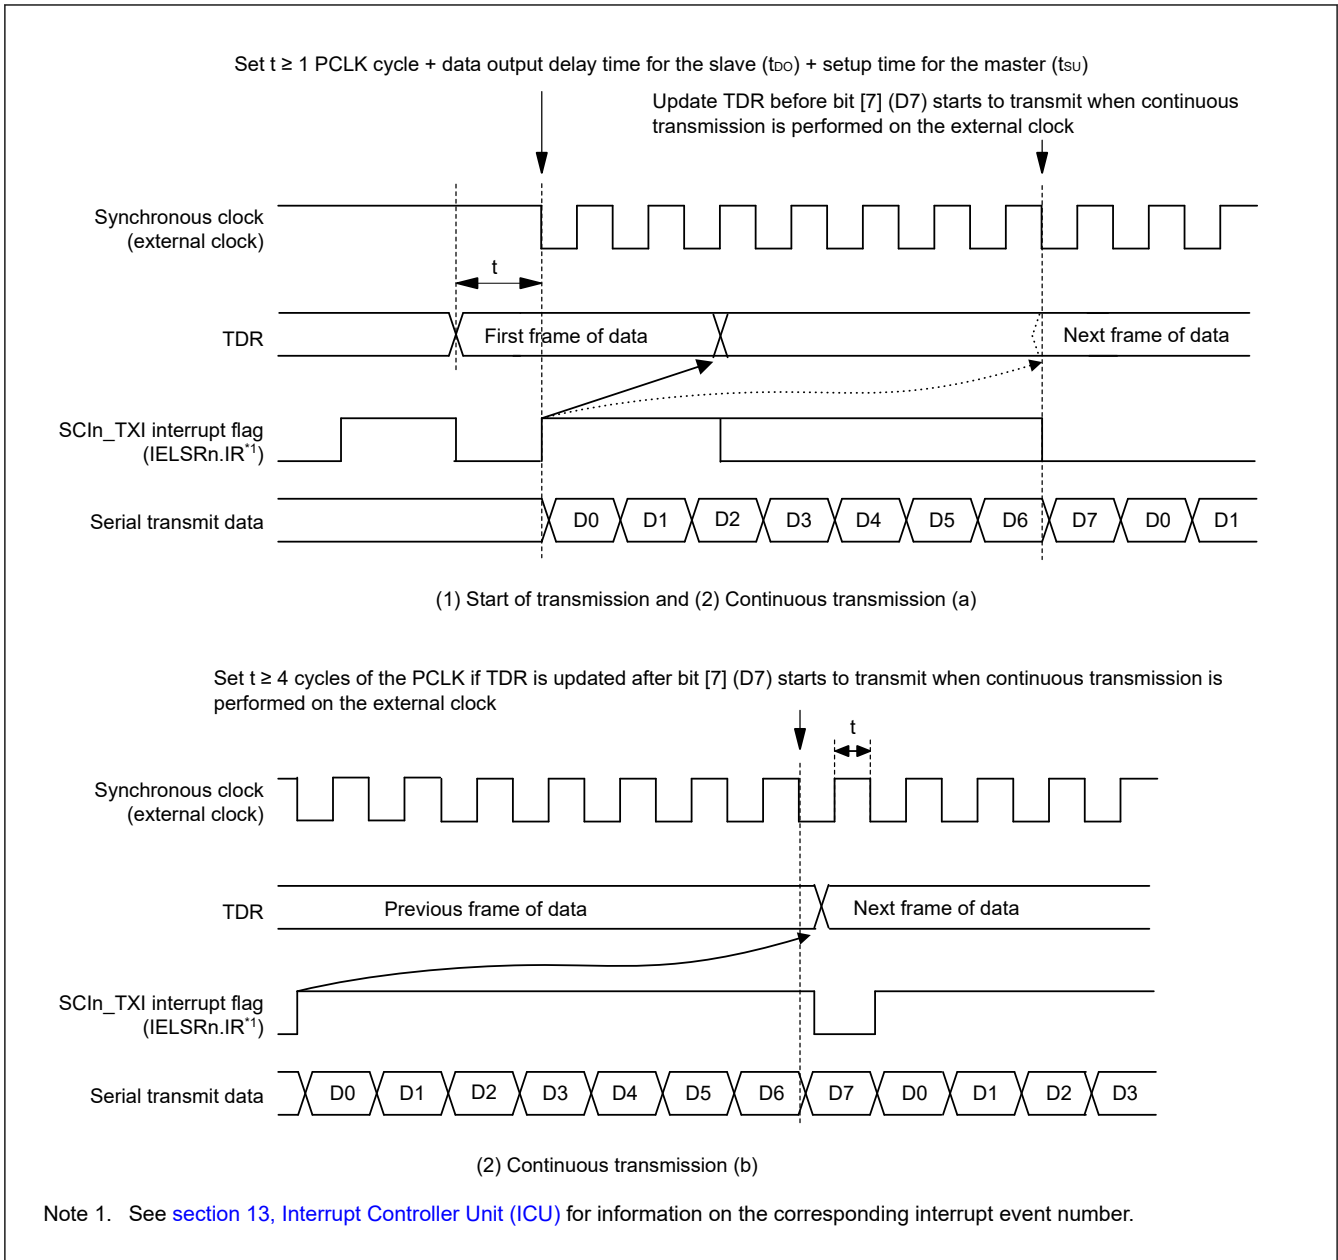

Figure 27.104 Restraints on use of external clock in clock synchronous transmission

### 27.15.7 Restrictions on Using DTC or DMAC

During transmission or reception operations using the DTC or DMAC, do not set transfer data for the DTC or DMAC.

#### (1) Writing data to TDR (FTDRHL)

##### Non-FIFO selected

Data can be written to TDR and TDRHL. However, if new data is written to TDR or TDRHL when transmit data remains in TDR or TDRHL, the previous data in TDR and TDRHL is lost because it was not transferred to TSR yet. When using DTC or DMAC, always write transmit data to TDR or TDRHL in the SCIn\_TXI interrupt request handling routine.

##### FIFO selected

It is possible to write data to the FTDRH and FTDRL registers when SCR.TE is 1. Confirm the amount of writable data using the FDR.T[4:0] bits.

## (2) Reading data from RDR (FRDRHL)

When using the DTC or DMAC to read RDR and RDRHL, always set the receive data full interrupt (SCI<sub>n</sub>\_RXI) as the activation source of the relevant SCI.

### 27.15.8 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IELSR<sub>n</sub>.IR flag) in the ICU is 1, follow the procedure in this section to clear interrupt requests before permitting operations (by setting the SCR/SCR\_SMCI.TE or SCR/SCR\_SMCI.RE bit to 1). For details on the interrupt status flag, see [section 13, Interrupt Controller Unit \(ICU\)](#).

1. Confirm that transfer has stopped (the SCR/SCR\_SMCI.TE or SCR/SCR\_SMCI.RE bit is 0)
2. Set the associated interrupt enable bit (SCR/SCR\_SMCI.TIE or SCR/SCR\_SMCI.RIE bit) to 0
3. Read the associated interrupt enable bit (SCR/SCR\_SMCI.TIE or SCR/SCR\_SMCI.RIE bit) to check that it actually becomes 0
4. Set the interrupt status flag, IELSR<sub>n</sub>.IR, in the ICU to 0

### 27.15.9 External Clock Input in Clock Synchronous Mode and Simple SPI Mode

In clock synchronous mode and simple SPI mode, the external clock SCK<sub>n</sub> must be input as follows:

High-pulse period, low-pulse period = 2 PCLK cycles or more, period = 6 PCLK cycles or more.

### 27.15.10 Limitations on Simple SPI Mode

#### (1) Master mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set in the SPMR.CKPH and CKPOL bits when the SPMR.SSE bit is 1.

This prevents the clock line from being placed in the high-impedance state when the SCR.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR.TE bit changes from 0 to 1. When the SPMR.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not required because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.

- For the clock delay setting (SPMR.CKPH bit is 1), the receive data full interrupt (SCI<sub>n</sub>\_RXI) is generated before the final clock edge on the SCK<sub>n</sub> pin as indicated in [Figure 27.105](#). If the TE and RE bits in the SCR register become 0 before the final edge of the clock signal on the SCK<sub>n</sub> pin, the SCK<sub>n</sub> pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Additionally, an SCI<sub>n</sub>\_RXI interrupt might lead to the input signal on the SS<sub>n</sub> pin of a connected slave going to the high level before the final edge of the clock signal on the SCK<sub>n</sub> pin, leading to incorrect operation of the slave.
- In a multi-master configuration, the SCK<sub>n</sub> pin output goes to high-impedance while the input on the SS<sub>n</sub> pin is at the low level if a mode fault error occurs while a character is being transferred, stopping supply of the clock signal to the connected slave. Reset the connected slave to avoid misaligned bits when transfer is restarted.

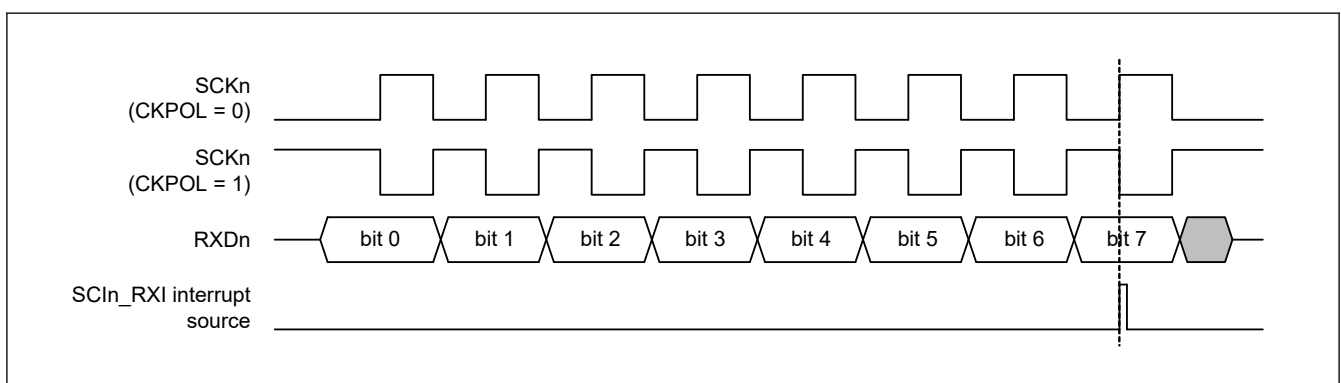

Figure 27.105 Timing of SCI<sub>n</sub>\_RXI interrupt in simple SPI mode with clock delay

## (2) Slave mode

- Wait at least the following time from writing transmit data in the TDR register to the start of the external clock input.  
1 PCLK cycle + data output delay for the slave ( $t_{DO}$ ) + setup time for the master ( $t_{SU}$ )  
Also wait at least 5 PCLK cycles from the input of the low level on the SSn pin to the start of the external clock input.
- Provide an external clock signal to the master the same as the data length for transfer
- Control the input on the SSn pin before the start and after the end of data transfer
- When the input level on the SSn pin is to be changed from low to high while a character is being transferred, set the TE and RE bits in the SCR register to 0 and, after restoring the settings, restart transfer of the first byte

### 27.15.11 Notes on Transmit Enable Bit (SCR.TE)

In initial register value, when SCR.TE = 0, the state of the TXDn pin is high impedance. The TXDn line should not be high impedance by the following one of ways.

1. The pull-up resistance is connected to the TXDn line.
2. Before setting the SCR.TE bit to 0, the function of the pin should be changed to a general-purpose output port. After that, set the SCR.TE bit to 1, and then change the function of the pin to TXDn.
3. In asynchronous mode, set SPTR and decided level of TXDn pin during SCR.TE = 0.

In the Simple SPI mode slave operation, the MISO pin operates in the same way as the above TXDn pin. The MISO pin, the same as TXDn pin, should not be high impedance by the above list number 1 or list number 2.

### 27.15.12 Note on Stopping Reception When Using the RTS Function in Asynchronous Mode

One clock cycle of PCLK is required for the time from setting the SCR.RE bit to 0 to stopping the RTS signal generator in asynchronous mode.

When reading the RDR (or RDRHL) register after setting the SCR.RE bit to 0, confirm that the SCR.RE bit has been set to 0 before reading the RDR (or RDRHL) register to prevent these two processes from being performed consecutively.

## 28. I<sup>2</sup>C Bus Interface (IIC)

### 28.1 Overview

The I<sup>2</sup>C bus interface (IIC) has 1 channel. The IIC module conforms with and provides a subset of the NXP I<sup>2</sup>C (Inter-Integrated Circuit) bus interface functions.

Table 28.1 lists the IIC specifications, Figure 28.1 shows a block diagram, and Figure 28.2 shows an example of I/O pin connections to external circuits, with an I<sup>2</sup>C bus configuration. Table 28.2 lists the I/O pins.

**Table 28.1 IIC specifications (1 of 2)**

| Parameter                        | Specifications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### SDAO bit (SDA Output Control/Monitor) and SCLO bit (SCL Output Control/Monitor)

The SDAO and SCLO bits directly control the SDA0 and SCL0 signals output from the IIC. When writing to these bits, also write 0 to the SOWP bit. Setting these bits results in input to the IIC by the input buffer. When slave mode is selected, a start condition might be detected and the bus might be released, depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, transmission, or reception. Operation after rewriting under these conditions is not guaranteed. When reading these bits, the state of signals output from the IIC can be read.

### CLO bit (Extra SCL Clock Cycle Output)

The CLO bit allows output of an extra SCL clock cycle for debugging or error processing. Normally, set this bit to 0. Setting the bit to 1 in a normal communication state causes a communication error. For details on this function, see [section 28.12.2. Extra SCL Clock Cycle Output Function](#).

### IICRST bit (I<sup>2</sup>C Bus Interface Internal Reset)

The IICRST bit initiates an internal state reset of the IIC. Setting this bit to 1 initiates an IIC reset or internal reset. Whether an IIC reset or internal reset is initiated is determined by the settings of this bit in combination with the ICE bit. [Table 28.3](#) lists the IIC resets.

The IIC reset initializes all registers except ICCR1.ICE and ICCR1.IICRST bits and internal states of the IIC. In addition to the internal states of the IIC, the internal reset initializes the following:

- Bit counter (ICMR1.BC[2:0] bits)
- I<sup>2</sup>C Bus Shift Register (ICDRS)
- I<sup>2</sup>C Bus Status Registers (ICSR1 and ICSR2)
- SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits)

- I<sup>2</sup>C Bus Control Register 2 (except ICCR2.BBSY bit)

For the reset conditions for each register, see [section 28.15. State of Registers When Issuing Each Condition](#).

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the IIC without initializing the port settings and the control and setting registers of the IIC. If the IIC hangs in a low-level output state, resetting the internal states cancels the low-level output state and releases the bus with the SCL0 pin and SDA0 pin at high impedance.

**Note:** If an internal reset is initiated using the IICRST bit for a bus hang-up that occurs during communication with the master device in slave mode, the slave and master devices might enter different states, because the bit counter information differs. For this reason, do not initiate an internal reset in slave mode. Initiate recovery processing from the master device. If an internal reset is required because the IIC hangs with the SCL0 line in a low-level output state in slave mode, initiate an internal reset, then issue a restart condition from the master device, or issue a stop condition and resume communication from the start condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start or restart condition from the master device, synchronization is lost because the master and slave devices operate asynchronously.

**Table 28.3 IIC resets**

| IICRST | ICE | State          | Specifications                                                                                                                                                                                                                                                                                                                       |

| 1      | 0   | IIC reset      | Resets all registers except ICCR1.IICRST and ICCR1.ICE bits, and the internal states of the IIC                                                                                                                                                                                                                                      |
|        | 1   | Internal reset | Reset the following: <ul style="list-style-type: none"> <li>• ICMR1.BC[2:0] bits</li> <li>• ICSR1, ICSR2, ICDRS registers</li> <li>• SDA0 and SCLO Output Control/Monitor (ICCR1.SDA0 and ICCR1.SCLO bits)</li> <li>• I<sup>2</sup>C Bus Control Register 2 (except ICCR2.BBSY bit)</li> <li>• Internal states of the IIC</li> </ul> |

### ICE bit (I<sup>2</sup>C Bus Interface Enable)

The ICE bit selects the active or inactive state of the SCL0 and SDA0 pins. It can also be combined with the IICRST bit to initiate two types of resets. See [Table 28.3](#) for the reset descriptions.

Set the ICE bit to 1 when using the IIC. The SCL0 and SDA0 pins are placed in the active state when the ICE bit is set to 1. Set the ICE bit to 0 when the IIC is not used. The SCL0 and SDA0 pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCL0 or SDA0 pin to the IIC when setting up the pin function control. Slave address comparison is performed if the pins are assigned to the IIC.

## 28.2.2 ICCR2 : I<sup>2</sup>C Bus Control Register 2

Base address: IIC0 = 0x4009\_F000

Offset address: 0x01

| 4   | —      | This bit is read as 0. The write value should be 0.                                                                               | R/W              |
| 5   | TRS    | Transmit/Receive Mode<br>0: Receive mode<br>1: Transmit mode                                                                      | R/W <sup>1</sup> |
| 6   | MST    | Master/Slave Mode<br>0: Slave mode<br>1: Master mode                                                                              | R/W <sup>1</sup> |
| 7   | BBSY   | Bus Busy Detection Flag<br>0: I <sup>2</sup> C bus released (bus free state)<br>1: I <sup>2</sup> C bus occupied (bus busy state) | R                |

Note 1. The MST and TRS bits can be written to when the ICMR1.MTWP bit is set to 1.

### ST bit (Start Condition Issuance Request)

The ST bit requests transition to master mode and triggers a start condition. When this bit is set to 1, a start condition is issued when the BBSY flag is set to 0 (bus free state). For details on this function, see [section 28.11. Start, Restart, and Stop Condition Issuing Function](#).

[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Only set the ST bit to 1 (start condition request) when the BBSY flag is set to 0 (bus free state). Arbitration might be lost if the ST bit is set to 1 (start condition request) when the BBSY flag is 1 (bus busy state).

### RS bit (Restart Condition Issuance Request)

The RS bit requests that a restart condition be issued in master mode. When this bit is set to 1 to request a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see [section 28.11. Start, Restart, and Stop Condition Issuing Function](#).

[Setting condition]

- When 1 is written to the RS bit with the BBSY flag in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Do not set the RS bit to 1 while issuing a stop condition.

Note: If 1 (restart condition request) is written to the RS bit in slave mode, the restart condition is not issued, but the RS bit remains set to 1. If the operating mode changes to master mode without the bit being cleared, a restart condition might be issued.

**SP bit (Stop Condition Issuance Request)**

The SP bit requests that a stop condition be issued in master mode. When this bit is set to 1, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see [section 28.11. Start, Restart, and Stop Condition Issuing Function](#).

[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition is issued (a stop condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Writing to the SP bit is not possible while the BBSY flag is 0 (bus free state).

Note: Do not set the SP bit to 1 while a restart condition is being issued.

**TRS bit (Transmit/Receive Mode)**

The TRS bit indicates transmit or receive mode. The IIC is in receive mode when the TRS bit is 0 and in transmit mode when the bit is 1. The combination of this bit and the MST bit indicates the IIC operating mode.

The value of the TRS bit automatically changes to 1 for transmit mode or 0 for receive mode when a start condition is issued or detected and the R/W# bit is set. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is issued normally because of a restart condition request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit appended to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in ICSEER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When the R/W# bit appended to the slave address is set to 1 in master mode
- In slave mode, on a match between the received address and the address enabled in ICSEER when the value of the received R/W# bit is 0, including when the received address is the general call address
- In slave mode, when a restart condition is detected (a restart condition is detected with ICCR2.BBSY = 1 and ICCR2.MST = 0)
- When 0 is written to the TRS bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

**MST bit (Master/Slave Mode)**

The MST bit indicates master or slave mode. The IIC is in slave mode when the MST bit is 0 and is in master mode when the bit is 1. The combination of this bit and the TRS bit indicates the IIC operating mode.

The value of the MST bit automatically changes to 1 for master mode or 0 for slave mode when a start condition is issued or a stop condition is issued or detected. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

## [Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the MTWP bit in ICMR1 set to 1.

## [Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 0 is written to the MST bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

**BBSY flag (Bus Busy Detection Flag)**

The BBSY flag indicates whether the I<sup>2</sup>C bus is occupied (bus busy state) or released (bus free state). The flag is set to 1 when the SDA0 line changes from high to low when the SCL0 line is high, assuming that a start condition was issued. The flag is set to 0 if a start condition is not detected for the bus free time (ICBRL setting), assuming that a stop condition was issued.

## [Setting condition]

- When a start condition is detected.

## [Clearing conditions]

- When a start condition is not detected for the bus free time (ICBRL setting) after detecting a stop condition
- When 1 is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0 (IIC reset).

**28.2.3 ICMR1 : I<sup>2</sup>C Bus Mode Register 1**

Base address: IIC0 = 0x4009\_F000

Offset address: 0x02

|                    |      |          |   |      |         |   |   |   |
|--------------------|------|----------|---|------|---------|---|---|---|

| 6:4 | CKS[2:0] | Internal Reference Clock Select<br>Select the internal reference clock source (IIC $\phi$ ) for the IIC.<br>IIC $\phi$ = (PCLKB / 2 <sup>CKS[2:0]</sup> ) clock | R/W               |
| 7   | MTWP     | MST/TRS Write Protect<br>0: Write protect MST and TRS bits in ICCR2<br>1: Write enable MST and TRS bits in ICCR2                                                | R/W               |

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

**BC[2:0] bits (Bit Counter)**

The BC[2:0] bits function as a counter indicating the number of bits remaining to be transferred on detection of a rising edge on the SCL0 line. Although BC[2:0] are read/write bits, it is not required to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one, for an additional acknowledge bit, between transferred frames when the SCL0 line is at a low level. The value in the BC[2:0] bits returns to 000b at the end of a data transfer, including the acknowledge bit, or when a start or restart condition is detected.

Note 1. The setting DLCS = 1 (IIC $\phi$ /2) is only valid when SCL is low. When SCL is high, the DLCS = 1 setting becomes invalid and the clock source becomes the internal reference clock (IIC $\phi$ ).

**TMOS bit (Timeout Detection Time Select)**

The TMOS bit selects long or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE = 1). When this bit is set to 0, long mode is selected. When it is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14-bit counter. While the SCL0 line is in the state that enables this counter as specified in the TMOH and TMOL bits, the counter counts up in synchronization with the internal reference clock (IIC $\phi$ ) as a count source. For details on this function, see [section 28.12.1. Timeout Function](#).

**TMOL bit (Timeout L Count Control)**

The TMOL bit enables or disables up-counting on the internal counter of the timeout function while the SCL0 line is held low and the timeout function is enabled (ICFER.TMOE = 1).

**TMOH bit (Timeout H Count Control)**

The TMOH bit enables or disables up-counting on the internal counter of the timeout function while the SCL0 line is held high and the timeout function is enabled (ICFER.TMOE = 1).

**SDDL[2:0] bits (SDA Output Delay Counter)**

The SDDL[2:0] bits can be used to delay the SDA output. This counter works with the clock source selected in the DLCS bit. This setting can be used for all types of SDA output, including transmission of the acknowledge bit.

Set the SDA output delay to meet the I<sup>2</sup>C bus standard for the data enable time/acknowledge enable time,<sup>\*1</sup> or the SMBus standard, within [data hold time (300 ns or more + the SCL clock low-level period) - the data setup time (250 ns)]. If a value outside the standard is set, communication between devices might malfunction or falsely indicate a start or stop condition, depending on the bus state.

For details on this function, see [section 28.5. SDA Output Delay Function](#).

Note 1. Data enable time/acknowledge enable time.

3,450 ns for up to 100 kbps: Standard mode (Sm)

900 ns for up to 400 kbps: Fast mode (Fm)

450 ns for up to 1 Mbps: Fast-mode Plus (Fm+)

|-----|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 6   | WAIT   | Low-hold is released by reading ICDDR.<br>0: No wait (The SCLn line is not held low during the period between the 9th clock cycle and the 1st clock cycle.)<br>1: Wait (The SCLn line is held low during the period between the 9th clock cycle and the 1st clock cycle.) | R/W <sup>2</sup> |
| 7   | SMBS   | SMBus/I <sup>2</sup> C Bus Select<br>0: Select I <sup>2</sup> C Bus<br>1: Select SMBus                                                                                                                                                                                    | R/W              |

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If the application writes 1 to the ACKWP and ACKBT bits at the same time, the ACKBT bit is not set to 1.

Note 2. The WAIT and RDRFS bits are only valid in receive mode (invalid in transmit mode).

### NF[1:0] bits (Noise Filter Stage Select)

The NF[1:0] bits select the number of stages in the digital noise filter. For details on this function, see [section 28.6. Digital Noise Filter Circuits](#)

Note: Set the noise range to be filtered within a range less than the SCL0 line high- or low-level period. If the noise range is set to a value of [SCL clock width: high- or low-level period, whichever is shorter] - [1.5 internal reference clock (IICp) cycles + analog noise filter: 120 ns (reference values)] or more, the SCL clock is regarded as noise, which might prevent the IIC from operating normally.

### ACKBR bit (Receive Acknowledge)

The ACKBR bit stores the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

### ACKBT bit (Transmit Acknowledge)

The ACKBT bit sets the acknowledge bit to be sent in receive mode

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1.

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition request is detected with the SP bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

### ACKWP bit (ACKBT Write Protect)

The ACKWP bit controls write enabling of the ACKBT bit.

### RDRFS bit (RDRF Flag Set Timing Select)

The RDRFS bit selects the RDRF flag set timing in receive mode and also selects whether to hold the SCL0 line low on the falling edge of the 8th SCL clock cycle.

When the RDRFS bit is 0, the SCL0 line is not held low on the falling edge of the 8th SCL clock cycle, and the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 on the rising edge of the 8th SCL clock cycle, and the SCL0 line is held low on the falling edge of the 8th SCL clock cycle. The low-hold of the SCL0 line is released by a write to the ACKBT bit.

After data is received with this setting, the SCL0 line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1), based on the receive data.

**WAIT bit (WAIT)**

The WAIT bit controls whether to force a low-hold between the ninth SCL clock cycle and the first SCL clock cycle, until the receive data buffer (ICDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation continues without a low-hold between the ninth and the first SCL clock cycle. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCL0 line is held low from the falling edge of the ninth clock cycle until the ICDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, always read ICDRR first.

**SMBS bit (SMBus/I<sup>2</sup>C Bus Select)**

Setting the SMBS bit to 1 selects the SMBus and enables the HOAE bit in ICSESR.

| 7   | FMPE <sup>*1</sup> | Fast-Mode Plus Enable<br>0: Do not use the Fm+ slope control circuit for the SCLn and SDAn pins<br>1: Use the Fm+ slope control circuit for the SCLn and SDAn pins.                                                                                                                                                                  | R/W |

Note 1. The Fast-mode Plus enable bit (FMPE) is supported by IIC0 (SCL0\_A, SDA0\_A). Bit [7] is the reserved bit in the not supported channel.

**TMOE bit (Timeout Function Enable)**

The TMOE bit enables or disables the timeout function. For details on this function, see [section 28.12.1. Timeout Function](#).

**MALE bit (Master Arbitration-Lost Detection Enable)**

The MALE bit specifies whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

**NALE bit (NACK Transmission Arbitration-Lost Detection Enable)**

The NALE bit specifies whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode, for example when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with a different number of receive bytes.

**SALE bit (Slave Arbitration-Lost Detection Enable)**

The SALE bit specifies whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode, for example when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs because of noise.

**NACKE bit (NACK Reception Transfer Suspension Enable)**

The NACKE bit specifies whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended. When the NACKE bit is 0, the next transfer operation continues regardless of the received acknowledge content.

For details, see [section 28.9.2. NACK Reception Transfer Suspension Function](#).

**SCLE bit (SCL Synchronous Circuit Enable)**

The SCLE bit specifies whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is set to 0 (no SCL synchronous circuit used), the IIC does not synchronize the SCL clock with the SCL input clock. With this setting, the IIC outputs the SCL clock at the transfer rate set in ICBRH and ICBRL, regardless of the SCL0 line state. For this reason, if the bus load of the I<sup>2</sup>C bus line is much larger than the specification value, or if the SCL clock output overlaps in multiple masters, a short-cycle SCL clock that does not meet the specification might be output. When no SCL synchronous circuit is used, it also affects the issuing of the start, restart, and stop conditions, and the continuous output of extra SCL clock cycles.

Do not set this bit to 0 except when checking the output of the set transfer rate.

**FMPE bit (Fast-Mode Plus Enable)**

The FMPE bit specifies whether to use a slope control circuit for Fast-mode Plus (Fm+).

When this bit is set to 1, a slope control circuit conforming to the I<sup>2</sup>C bus Fast-mode Plus (Fm+) standard (tof) is selected. When this bit is set to 0, a slope control circuit conforming to the I<sup>2</sup>C bus Standard-mode (Sm) and Fast-mode (Fm) standards (tof) is selected.

Set this bit to 1 when using transmission rates up to 1 Mbps (Fast-mode Plus (Fm+) standard). Set it to 0 when using other transmission rates (up to 100 kbps (Sm) or up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps).

| 4   | —      | This bit is read as 0. The write value should be 0.                                                                          | R/W |
| 5   | DIDE   | Device-ID Address Detection Enable<br>0: Disable device-ID address detection<br>1: Enable device-ID address detection        | R/W |
| 6   | —      | This bit is read as 0. The write value should be 0.                                                                          | R/W |
| 7   | HOAE   | Host Address Enable<br>0: Disable host address detection<br>1: Enable host address detection                                 | R/W |

### SARyE bit (Slave Address Register y Enable) (y = 0 to 2)

The SARyE bit enables or disables the received slave address and the slave address set in SARLy and SARUy.

When this bit is set to 1, the slave address set in SARLy and SARUy is enabled and is compared with the received slave address. When this bit is set to 0, the slave address set in SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

### GCAE bit (General Call Address Enable)

The GCAE bit specifies whether to ignore the general call address (0000 000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the IIC recognizes the received slave address as the general call address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the data receive operation. When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

### DIDE bit (Device-ID Address Detection Enable)

The DIDE bit specifies whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first frame after a start or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the IIC recognizes that the device-ID address was received. When the next R/W# bit is 0 (W), the IIC recognizes the second and the subsequent frames as slave addresses and continues the receive operation. When this bit is set to 0, the IIC ignores the received first frame even if it matches the device-ID address, and it recognizes the first frame as a normal slave address.

For details on this function, see [section 28.7.3. Device-ID Address Detection](#).

### HOAE bit (Host Address Enable)

The HOAE bit specifies whether to ignore the received host address (0001 000b) when the SMBS bit in ICMR3 is 1.

When this bit is set to 1 while the SMBS bit in ICMR3 is 1, if the received slave address matches the host address, the IIC recognizes the received slave address as the host address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the receive operation.

When the SMBS bit in ICMR3 or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

## 28.2.8 ICIER : I<sup>2</sup>C Bus Interrupt Enable Register

Base address: IIC0 = 0x4009\_F000 (n = 0)

Offset address: 0x07

|               |     |      |     |       |      |      |      |       |

| 7   | TIE    | Transmit Data Empty Interrupt Request Enable<br>0: Disable transmit data empty interrupt (IIC0_TXI) request<br>1: Enable transmit data empty interrupt (IIC0_TXI) request         | R/W |

### TMOIE bit (Timeout Interrupt Request Enable)

The TMOIE bit enables or disables timeout interrupt (TMOI) requests when the TMOF flag in ICSR2 is 1. To cancel a TMOI interrupt request, set the TMOF flag or the TMOIE bit to 0.

### ALIE bit (Arbitration-Lost Interrupt Request Enable)

The ALIE bit enables or disables arbitration-lost interrupt (ALI) requests when the AL flag in ICSR2 is 1. To cancel an ALI interrupt request, set the AL flag or the ALIE bit to 0.

### STIE bit (Start Condition Detection Interrupt Request Enable)

The STIE bit enables or disables start condition detection interrupt (STI) requests when the START flag in ICSR2 is 1. To cancel an STI interrupt request, set the START flag or the STIE bit to 0.

### SPIE bit (Stop Condition Detection Interrupt Request Enable)

The SPIE bit enables or disables stop condition detection interrupt (SPI) requests when the STOP flag in ICSR2 is 1. To cancel an SPI interrupt request, set the STOP flag or the SPIE bit to 0.

### NAKIE bit (NACK Reception Interrupt Request Enable)

The NAKIE bit enables or disables NACK reception interrupt (NAKI) requests when the NACKF flag in ICSR2 is 1. To cancel an NAKI interrupt request, set the NACKF flag or the NAKIE bit to 0.

**RIE bit (Receive Data Full Interrupt Request Enable)**

The RIE bit enables or disables receive data full interrupt (IIC0\_RXI) requests when the RDRF flag in ICSR2 is 1.

**TEIE bit (Transmit End Interrupt Request Enable)**

The TEIE bit enables or disables transmit end interrupt (IIC0\_TEI) requests when the TEND flag in ICSR2 is 1. To cancel an IIC0\_TEI interrupt request, set the TEND flag or the TEIE bit to 0.

**TIE bit (Transmit Data Empty Interrupt Request Enable)**

The TIE bit enables or disables transmit data empty interrupt (IIC0\_TXI) requests when the TDRE flag in ICSR2 is 1.

**28.2.9 ICSR1 : I<sup>2</sup>C Bus Status Register 1**

Base address: IIC0 = 0x4009\_F000

Offset address: 0x08

| 4   | —      | This bit is read as 0. The write value should be 0.                                                                                                                                                                                                             | R/W                |
| 5   | DID    | Device-ID Address Detection Flag<br>This bit is set to 1 when the first frame received immediately after a start condition is detected matches a value of (device ID (1111 100b) + 0[W]).<br>0: Device-ID command not detected<br>1: Device-ID command detected | R/(W) <sup>1</sup> |
| 6   | —      | This bit is read as 0. The write value should be 0.                                                                                                                                                                                                             | R/W                |
| 7   | HOA    | Host Address Detection Flag<br>This bit is set to 1 when the received slave address matches the host address (0001 000b).<br>0: Host address not detected<br>1: Host address detected                                                                           | R/(W) <sup>1</sup> |

Note 1. Only 0 can be written to clear the flag.

**AASy flag (Slave Address y Detection flag) (y = 0 to 2)**

The AASy flag indicates whether slave address y was detected.

[Setting conditions]

For 7-bit address format (SARUy.FS = 0):

- When the received slave address matches the SVA[6:0] value in SARLy, with the SARyE bit in ICSEr set to 1 (slave address y detection enabled).  
The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format: (SARUy.FS = 1):

- When the received slave address matches a value of  $(11110b + SVA[1:0]$  in SARUy), and the subsequent address matches the SARLy value, with the SARyE bit in IC SER set to 1 (slave address y detection enabled). The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

## [Clearing conditions]

- When 0 is written to the AASy flag after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

## For 7-bit address format (SARUy.FS = 0):

- When the received slave address does not match the SVA[6:0] value in SARLy, with the SARyE bit in IC SER set to 1 (slave address y detection enabled). The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

## For 10-bit address format (SARUy.FS = 1):

- When the received slave address does not match a value of  $(11110b + SVA[1:0]$  in SARUy), with the SARyE bit in IC SER set to 1 (slave address y detection enabled). The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of  $(11110b + SVA[1:0]$  in SARUy), and the subsequent address does not match the SARLy value, with the SARyE bit in IC SER set to 1 (slave address y detection enabled). The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

**GCA flag (General Call Address Detection Flag)**

The GCA flag indicates whether the general call address was detected.

## [Setting condition]

- When the received slave address matches the general call address  $(0000\ 000b + 0 [W])$ , with the GCAE bit in IC SER set to 1 (general call address detection enabled). The GCA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

## [Clearing conditions]

- When 0 is written to the GCA flag after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address  $(0000\ 000b + 0 [W])$ , with the GCAE bit in IC SER set to 1 (general call address detection enabled). The GCA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

**DID flag (Device-ID Address Detection Flag)**

The DID flag indicates whether the device-ID address was detected.

## [Setting condition]

- When the first frame received immediately after a start or restart condition is detected matches a value of  $(device\ ID\ (1111\ 100b) + 0 [W])$ , with the DIDE bit in IC SER set to 1 (device-ID address detection enabled). The DID flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

## [Clearing conditions]

- When 0 is written to the DID flag after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start or restart condition is detected does not match a value of  $(device\ ID\ (1111\ 100b))$ , with the DIDE bit in IC SER set to 1 (device-ID address detection enabled). The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), and the second frame does not match any slave address from 0 to 2, with the DIDE bit in ICSER set to 1 (device-ID address detection enabled)  
The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

### HOA flag (Host Address Detection Flag)

The HOA flag indicates whether the host address was detected.

[Setting condition]

- When the received slave address matches the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled).  
The HOA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the HOA flag after reading HOA = 1
- When a stop condition is detected
- When the received slave address does not match the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled)  
The HOA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

## 28.2.10 ICSR2 : I<sup>2</sup>C Bus Status Register 2

Base address: IIC0 = 0x4009\_F000

Offset address: 0x09

|                    |      |      |      |           |      |       |    |      |

| 6   | TEND   | Transmit End Flag<br>0: Data being transmitted<br>1: Data transmit complete                      | R/(W) <sup>*1</sup> |

| Bit | Symbol | Function                                                                                          | R/W |
|-----|--------|---------------------------------------------------------------------------------------------------|-----|
| 7   | TDRE   | Transmit Data Empty Flag<br>0: ICDRT contains transmit data<br>1: ICDRT contains no transmit data | R   |

Note 1. Only 0 can be written, to clear the flag.

### TMOF flag (Timeout Detection Flag)

The TMOF flag is set to 1 when the IIC detects a timeout because the SCL0 line state remains unchanged for the set period.

[Setting condition]

- When the SCL0 line state remains unchanged for the period specified in the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1 (timeout function enabled) in master or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF flag after reading TMOF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

### AL flag (Arbitration-Lost Flag)

The AL flag indicates that bus mastership was lost in arbitration because of a bus conflict or some other reason when a start condition was issued or an address and data was transmitted. The IIC monitors the level on the SDA0 line during transmission and, if the level on the line does not match the value of the bit being output, is set the value of the AL flag to 1 to indicate that the bus is occupied by another device.

The IIC can also set the AL flag to indicate the detection of arbitration loss during NACK transmission or during data transmission.

[Setting conditions]

When master arbitration-lost detection is enabled (ICFER.MALE = 1):

- When the internal SDA output state does not match the SDA0 line level on the rising edge of the SCL clock except for the ACK period during data transmission in master transmit mode
- When a start condition is detected while the ST bit in ICCR2 is 1 (start condition requested) or the internal SDA output state does not match the SDA0 line level
- When the ST bit in ICCR2 is 1 (start condition requested), with the BBSY flag in ICCR2 set to 1.

When NACK arbitration-lost detection is enabled (ICFER.NALE = 1):

- When the internal SDA output state does not match the SDA<sub>n</sub> line level on the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICFER.SALE = 1):

- When the internal SDA output state does not match the SDA0 line level on the rising edge of the SCL clock, except for the ACK period during data transmission in slave transmit mode.

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

**Table 28.4 Relationship between arbitration-lost generation sources and arbitration-lost enable functions**

| ICFER |      |      | ICSR2 | Error                          | Arbitration-lost generation source                                                                                               |
|-------|------|------|-------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| MALE  | NALE | SALE | AL    |                                |                                                                                                                                  |
| 1     | x    | x    | 1     | Start condition issuance error | When internal SDA output state does not match SDA0 line level when a start condition is detected, while the ST bit in ICCR2 is 1 |
|       |      |      | 1     |                                | When ST in ICCR2 is set to 1 while BBSY in ICCR2 is 1                                                                            |
| x     | 1    | x    | 1     | NACK transmission mismatch     | When ACK is detected during transmission of NACK in master or slave receive mode                                                 |
| x     | x    | 1    | 1     | Transmit data mismatch         | When transmit data does not match the bus state in slave transmit mode                                                           |

x: Don't care

### START flag (Start Condition Detection Flag)

The START flag indicates whether a start or restart condition was detected.

[Setting condition]

- When a start or restart condition is detected.

[Clearing conditions]

- When 0 is written to the START flag after reading START = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

### STOP flag (Stop Condition Detection Flag)

The STOP flag indicates whether a stop condition was detected.

[Setting condition]

- When a stop condition is detected.

[Clearing conditions]

- When 0 is written to the STOP flag after reading STOP = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

### NACKF flag (NACK Detection Flag)

The NACKF flag indicates whether a NACK was detected.

[Setting condition]

- When acknowledge is not received (NACK received) from the receive device in transmit mode, with the NACKE bit in ICFER set to 1 (transfer suspension enabled).

[Clearing conditions]

- When 0 is written to the NACKF flag after reading NACKF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1, the IIC suspends data transmission and reception. Writing to ICDRT in transmit mode or reading from ICDRR in receive mode with the NACKF flag set to 1 does not enable data transmit or receive operation. To restart data transmission or reception, set the NACKF flag to 0.

### RDRF flag (Receive Data Full Flag)

The RDRF flag indicates whether the ICDRR contains receive data.

## [Setting conditions]

- When receive data is transferred from ICDRS to ICDRR  
The RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL clock cycle (selected in the RDRFS bit in ICMR3).
- When the received slave address matches after a start or restart condition is detected with the TRS bit in ICCR2 set to 0.

## [Clearing conditions]

- When 0 is written to the RDRF flag after reading RDRF = 1
- When data is read from ICDRR
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

**TEND flag (Transmit End Flag)**

The TEND flag indicates completion of transmission.

## [Setting condition]

- On the rising edge of the ninth SCL clock cycle while the TDRE flag is 1.

## [Clearing conditions]

- When 0 is written to the TEND flag after reading TEND = 1
- When data is written to ICDRT
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

**TDRE flag (Transmit Data Empty Flag)**

The TDRE flag indicates whether the ICDRT contains transmit data.

## [Setting conditions]

- When data is transferred from ICDRT to ICDRS and ICDRT becomes empty
- When the TRS bit in ICCR2 is set to 1
- When the received slave address matches while the TRS bit is 1.

## [Clearing conditions]

- When data is written to ICDRT
- When the TRS bit in ICCR2 is set to 0
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1 while the NACKE bit in ICFER is 1, the IIC suspends data transmission and reception. In this case, if the TDRE flag is 0 (next transmit data written), data is transferred to the ICDRS register and the ICDRT register becomes empty on the rising edge of the 9th clock cycle, but the TDRE flag does not set to 1.

**WUF flag (Wakeup Event Occurrence Flag)**

The WUF flag indicates whether the slave address is matching during wakeup.

[Setting condition]

- When PCLKB is supplied after a slave-address match in the first 8th SCL low during wakeup mode.

[Clearing conditions]

- When 0 is written to the WUF flag after reading WUF = 1
- When ICE = 0 and IICRST = 1.

| 7:3 | —      | These bits are read as 1. The write value should be 1.                                                                                           | R/W |

### WUSEN bit (Wakeup Function Synchronous Enable)

The WUSEN bit is used in combination with the WUASYF flag (or WUSYF flag) to switch between the PCLKB synchronous and asynchronous operation, when the wakeup effective function is enabled (ICWUR.WUE = 1).

The PCLKB operation switches from synchronous to asynchronous operation:

When the ICCR2.BBSY flag is 0, if 0 is written to the WUSEN bit while the WUASYF flag is 0, the reception occurs independently of the operation of PCLKB (with PCLKB stopped) after it switches to the PCLKB asynchronous operation, on wakeup event detection.

The PCLKB operation switches from asynchronous to synchronous operation:

- When 1 is written to the WUSEN bit, with the WUASYF flag at 1, when a wakeup event is detected. After writing 1, the WUASYF flag immediately becomes 0.
- When the stop condition is detected with a wakeup event undetected.

### WUASYF flag (Wakeup Function Asynchronous Operation Status Flag)

The WUASYF flag can place the IIC in PCLKB asynchronous operation when the wakeup effective function is enabled (ICWUR.WUE = 1).

[Setting condition]

- When the ICCR2.BBSY flag is 0, and the WUSEN bit is set to 0 with the ICWUR.WUE bit set to 1.

[Clearing conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUASYF flag set to 1 with ICWUR.WUE bit set to 1.
- When you write 1 in the WUSEN bit with the WUASYF flag detected 1 and the wake-up event in the state of ICWUR.WUE = 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

### WUSYF flag (Wakeup Function Synchronous Operation Status Flag)

It is shown that IIC is in the PCLKB synchronous operation at wake-up effective function (ICWUR.WUE = 1). This flag is a value in which the WUASYF flag is always reserved.

[Setting conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1 with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

[Clearing condition]

- When the ICCR2.BBSY flag is 0 with the ICWUR.WUE bit set to 1 after writing 0 to the WUSEN bit.

### 28.2.13 SARLy : Slave Address Register L y (y = 0 to 2)

Base address: IIC0 = 0x4009\_F000

Offset address: 0x0A + 0x02 × y

|                    |          |   |   |   |   |   |   |      |
|--------------------|----------|---|---|---|---|---|---|------|
| Bit position:      | 7        | 6 | 5 | 4 | 3 | 2 | 1 | 0    |
| Bit field:         | SVA[6:0] |   |   |   |   |   |   | SVA0 |
| Value after reset: | 0        | 0 | 0 | 0 | 0 | 0 | 0 | 0    |

| Bit | Symbol   | Function                                                          | R/W |
|-----|----------|-------------------------------------------------------------------|-----|
| 0   | SVA0     | 10-bit Address LSB<br>Slave address setting.                      | R/W |
| 7:1 | SVA[6:0] | 7-bit Address/10-bit Address Lower Bits<br>Slave address setting. | R/W |

#### SVA0 bit (10-bit Address LSB)

When the 10-bit address format is selected (SARUy.FS = 1), the SVA0 bit functions as the LSB of a 10-bit address and is combined with the SVA[6:0] bits to form the lower 8 bits of a 10-bit address.

This bit is valid when the SARyE bit in ICSEr is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in this bit is ignored.

#### SVA[6:0] bits (7-bit Address/10-bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS = 0), the SVA[6:0] bits function as a 7-bit address. When the 10-bit address format is selected (SARUy.FS = 1), these bits combine with the SVA0 bit to form the lower 8 bits of a 10-bit address.

When the SARyE bit in ICSEr is 0, the setting in these bits is ignored.

### 28.2.14 SARUy : Slave Address Register U y (y = 0 to 2)

Base address: IIC0 = 0x4009\_F000

Offset address: 0x0B + 0x02 × y

|                    |   |   |   |   |   |          |    |   |
|--------------------|---|---|---|---|---|----------|----|---|
| Bit position:      | 7 | 6 | 5 | 4 | 3 | 2        | 1  | 0 |
| Bit field:         | — | — | — | — | — | SVA[1:0] | FS |   |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0        | 0  | 0 |

| Bit | Symbol   | Function                                                                                                | R/W |
|-----|----------|---------------------------------------------------------------------------------------------------------|-----|
| 0   | FS       | 7-bit/10-bit Address Format Select<br>0: Select 7-bit address format<br>1: Select 10-bit address format | R/W |
| 2:1 | SVA[1:0] | 10-bit Address Upper Bits<br>Slave address setting.                                                     | R/W |
| 7:3 | —        | These bits are read as 0. The write value should be 0.                                                  | R/W |

#### FS bit (7-bit/10-bit Address Format Select)

The FS bit selects 7- or 10-bit format for slave address y (in SARLy and SARUy).

When the SARyE bit in ICSEr is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SVA[6:0] setting in SARLy is valid, and the SVA[1:0] and SVA0 settings in SARLy are ignored.

When the SARyE bit in ICSEr is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the SVA[1:0] and SARLy settings are valid.

When the SARyE bit in ICSEr is 0 (SARLy and SARUy disabled), the SARUy.FS setting is invalid.

**SVA[1:0] bits (10-bit Address Upper Bits)**

When the 10-bit address format is selected (FS = 1), the SVA[1:0] bits function as the upper 2 bits of a 10-bit address.

These bits are valid when the SARyE bit in ICSEr is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in these bits is ignored.

**28.2.15 ICBRL : I<sup>2</sup>C Bus Bit Rate Low-Level Register**

Base address: IIC0 = 0x4009\_F000

Offset address: 0x10

Value after reset: 1 1 1 1 1 1 1 1

| Bit | Symbol   | Function                                                    | R/W |
|-----|----------|-------------------------------------------------------------|-----|
| 4:0 | BRL[4:0] | Bit Rate Low-Level Period<br>Low-level period of SCL clock. | R/W |
| 7:5 | —        | These bits are read as 1. The write value should be 1.      | R/W |

**BRL[4:0] bits (Bit Rate Low-Level Period)**

The BRL[4:0] bits set the low-level period of the SCL clock. ICBRL counts the low-level period with the internal reference clock source (IIC $\phi$ ) specified by the CKS[2:0] bits in ICMR1. ICBRL also generates the data setup time for automatic SCL low-hold operation, see [section 28.9. Automatic Low-Hold Function for SCL](#). When the IIC is used in slave mode, the BRL[4:0] bits must be set to a value longer than the data setup time<sup>\*1</sup>.

If the digital noise filter is enabled (NFE bit in ICFER is 1), set the BRL[4:0] bits to a value at least one greater than the number of stages in the noise filter. For details on the number of stages, see the description of the NF[1:0] bits in [section 28.2.5. ICMR3 : I<sup>2</sup>C Bus Mode Register 3](#).

Note 1. Data setup time (t<sub>SU</sub>: DAT)

250 ns for up to 100 kbps: Standard-mode (Sm)

100 ns for up to 400 kbps: Fast-mode (Fm)

50 ns for up to 1 Mbps: Fast-mode Plus (Fm+)

**28.2.16 ICBRH : I<sup>2</sup>C Bus Bit Rate High-Level Register**

Base address: IIC0 = 0x4009\_F000

Offset address: 0x11

Value after reset: 1 1 1 1 1 1 1 1

| Bit | Symbol   | Function                                                      | R/W |
|-----|----------|---------------------------------------------------------------|-----|
| 4:0 | BRH[4:0] | Bit Rate High-Level Period<br>High-level period of SCL clock. | R/W |
| 7:5 | —        | These bits are read as 1. The write value should be 1.        | R/W |

**BRH[4:0] bits (Bit Rate High-Level Period)**

The BRH[4:0] bits set the high-level period of SCL clock. BRH[4:0] bits are valid in master mode. If the IIC is used only in slave mode, do not set the BRH[4:0] bits.

ICBRH counts the high-level period with the internal reference clock source (IIC $\phi$ ) specified in the CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the NFE bit in ICFER is 1), set these bits to a value at least one greater than the number of stages in the noise filter. For the number of stages in the noise filter, see the description of the NF[1:0] bits in [section 28.2.5. ICMR3 : I<sup>2</sup>C Bus Mode Register 3](#).

The IIC transfer rate and the SCL clock duty are calculated using the following expressions (1) to (5):

1. ICFER.SCLE = 0  
 Transfer rate =  $1 / [\{(BRH + 1) + (BRL + 1)\} / IIC\phi^{*1} + tr^{*2} + tf^{*2}]$   
 Duty cycle =  $[tr + \{(BRH + 1) / IIC\phi\}] / [tr + tf + \{(BRH + 1) + (BRL + 1)\} / IIC\phi]$
2. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] = 000b (IIC $\phi$  = PCLKB)  
 Transfer rate =  $1 / [\{(BRH + 3) + (BRL + 3)\} / IIC\phi + tr + tf]$   
 Duty cycle =  $[tr + \{(BRH + 3) / IIC\phi\}] / [tr + tf + \{(BRH + 3) + (BRL + 3)\} / IIC\phi]$
3. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] = 000b (IIC $\phi$  = PCLKB)  
 Transfer rate =  $1 / [\{(BRH + 3 + nf^{*3}) + (BRL + 3 + nf)\} / IIC\phi + tr + tf]$   
 Duty cycle =  $[tr + \{(BRH + 3 + nf) / IIC\phi\}] / [tr + tf + \{(BRH + 3 + nf) + (BRL + 3 + nf)\} / IIC\phi]$
4. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0]  $\neq$  000b  
 Transfer rate =  $1 / [\{(BRH + 2) + (BRL + 2)\} / IIC\phi + tr + tf]$   
 Duty cycle =  $[tr + \{(BRH + 2) / IIC\phi\}] / [tr + tf + \{(BRH + 2) + (BRL + 2)\} / IIC\phi]$
5. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0]  $\neq$  000b  
 Transfer rate =  $1 / [\{(BRH + 2 + nf) + (BRL + 2 + nf)\} / IIC\phi + tr + tf]$   
 Duty cycle =  $[tr + \{(BRH + 2 + nf) / IIC\phi\}] / [tr + tf + \{(BRH + 2 + nf) + (BRL + 2 + nf)\} / IIC\phi]$

Note 1. IIC $\phi$  = PCLKB  $\times$  division ratio

Note 2. The SCLn line rise time (tr) and SCLn line fall time (tf) depend on the total bus line capacitance (Cb) and the pull-up resistor (Rp). For details, see the I<sup>2</sup>C bus standard from NXP Semiconductors.

Note 3. nf = Number of digital noise filters selected in the ICMR3.NF bit.

**Table 28.6 Example of ICBRH/ICBRL Settings for Transfer Rate IIC when SCLE = 0**

| Transfer rate (kbps) | CKS[2:0] (ICMR1) | BRH[4:0] (ICBRH) | BRL[4:0] (ICBRL) | PCLKB (MHz) | NF[1:0] | Computation expression |
|----------------------|------------------|------------------|------------------|-------------|---------|------------------------|
| 100                  | 011b             | 24 (0xF8)        | 30 (0xFE)        | 50          | —       | (1)                    |

**Table 28.8 Example of ICBRH/ICBRL Settings for Transfer Rate when SCLE = 1 and NFE = 1**

| Transfer rate (kbps) | CKS[2:0] (ICMR1) | BRH[4:0] (ICBRH) | BRL[4:0] (ICBRL) | PCLKB (MHz) | NF[1:0] | Computation expression |
|----------------------|------------------|------------------|------------------|-------------|---------|------------------------|
| 100                  | 011b             | 21 (0xF5)        | 26 (0xFA)        | 50          | 01b     | (5)                    |
| 400                  | 001b             | 11 (0xEB)        | 29 (0xFD)        | 50          | 01b     | (5)                    |
| 1000                 | 000b             | 8 (0xE8)         | 20 (0xF4)        | 50          | 01b     | (3)                    |

### 28.2.17 ICDRT : I<sup>2</sup>C Bus Transmit Data Register

Base address: IIC0 = 0x4009\_F000

Offset address: 0x12

|                    |   |   |   |   |   |   |   |   |
|--------------------|---|---|---|---|---|---|---|---|
| Bit position:      | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Bit field:         |   |   |   |   |   |   |   |   |
| Value after reset: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

When ICDRT detects a space in the I<sup>2</sup>C Bus Shift Register (ICDRS), it transfers the transmit data that was written to ICDRT to ICDRS and starts transmitting data in transmit mode. The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data is written to ICDRT while the ICDRS data is being transmitted.

ICDRT can always be read and written to. Write transmit data to ICDRT once when a transmit data empty interrupt (IIC0\_TXI) request is generated.

### 28.2.18 ICDRR : I<sup>2</sup>C Bus Receive Data Register

Base address: IIC0 = 0x4009\_F000

Offset address: 0x13

|                    |   |   |   |   |   |   |   |   |
|--------------------|---|---|---|---|---|---|---|---|
| Bit position:      | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Bit field:         |   |   |   |   |   |   |   |   |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

When 1 byte of data is received, the received data is transferred from the I<sup>2</sup>C Bus Shift Register (ICDRS) to ICDRR to enable the next data to be received. The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data is read from ICDRR while ICDRS is receiving data. ICDRR cannot be written to. Read data from ICDRR once when a receive data full interrupt (IIC0\_RXI) request is generated.

If ICDRR receives the next receive data before the current data is read from ICDRR (while the RDRF flag in ICSR2 is 1), the IIC automatically holds the SCL clock low 1 cycle before the RDRF flag is set to 1 next.

### 28.2.19 ICDRS : I<sup>2</sup>C Bus Shift Register

Base address: n/a

Offset address: n/a

|                    |   |   |   |   |   |   |   |   |
|--------------------|---|---|---|---|---|---|---|---|
| Bit position:      | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Bit field:         |   |   |   |   |   |   |   |   |
| Value after reset: | — | — | — | — | — | — | — | — |

ICDRS is an 8-bit shift register for data transmit and receive. During transmission, transmit data is transferred from ICDRT to ICDRS and is transmitted from the SDA0 pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data is received. ICDRS cannot be accessed directly.

## 28.3 Operation

### 28.3.1 Communication Data Format

The I<sup>2</sup>C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start or restart condition is an address frame that specifies a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 28.3 shows the I<sup>2</sup>C bus format, and Figure 28.4 shows the I<sup>2</sup>C bus timing.

Figure 28.3 I2C bus format

Figure 28.4 I2C bus timing when the SLA setting = 7 bits

- S: Start condition. The master device drives the SDAn line low from high while the SCLn line is high.
- SLA: Slave address, by which the master device selects a slave device.
- R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W# is 1, or from the master device to the slave device when R/W# is 0.
- A: Acknowledge. The receive device drives the SDAn line low. In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.
- A#: Not Acknowledge. The receive device drives the SDAn line high.
- Sr: Restart condition. The master device drives the SDAn line low from the high level after the setup time has elapsed with the SCLn line high.
- DATA: Transmitted or received data.
- P: Stop condition. The master device drives the SDAn line high from low while the SCLn line is high.

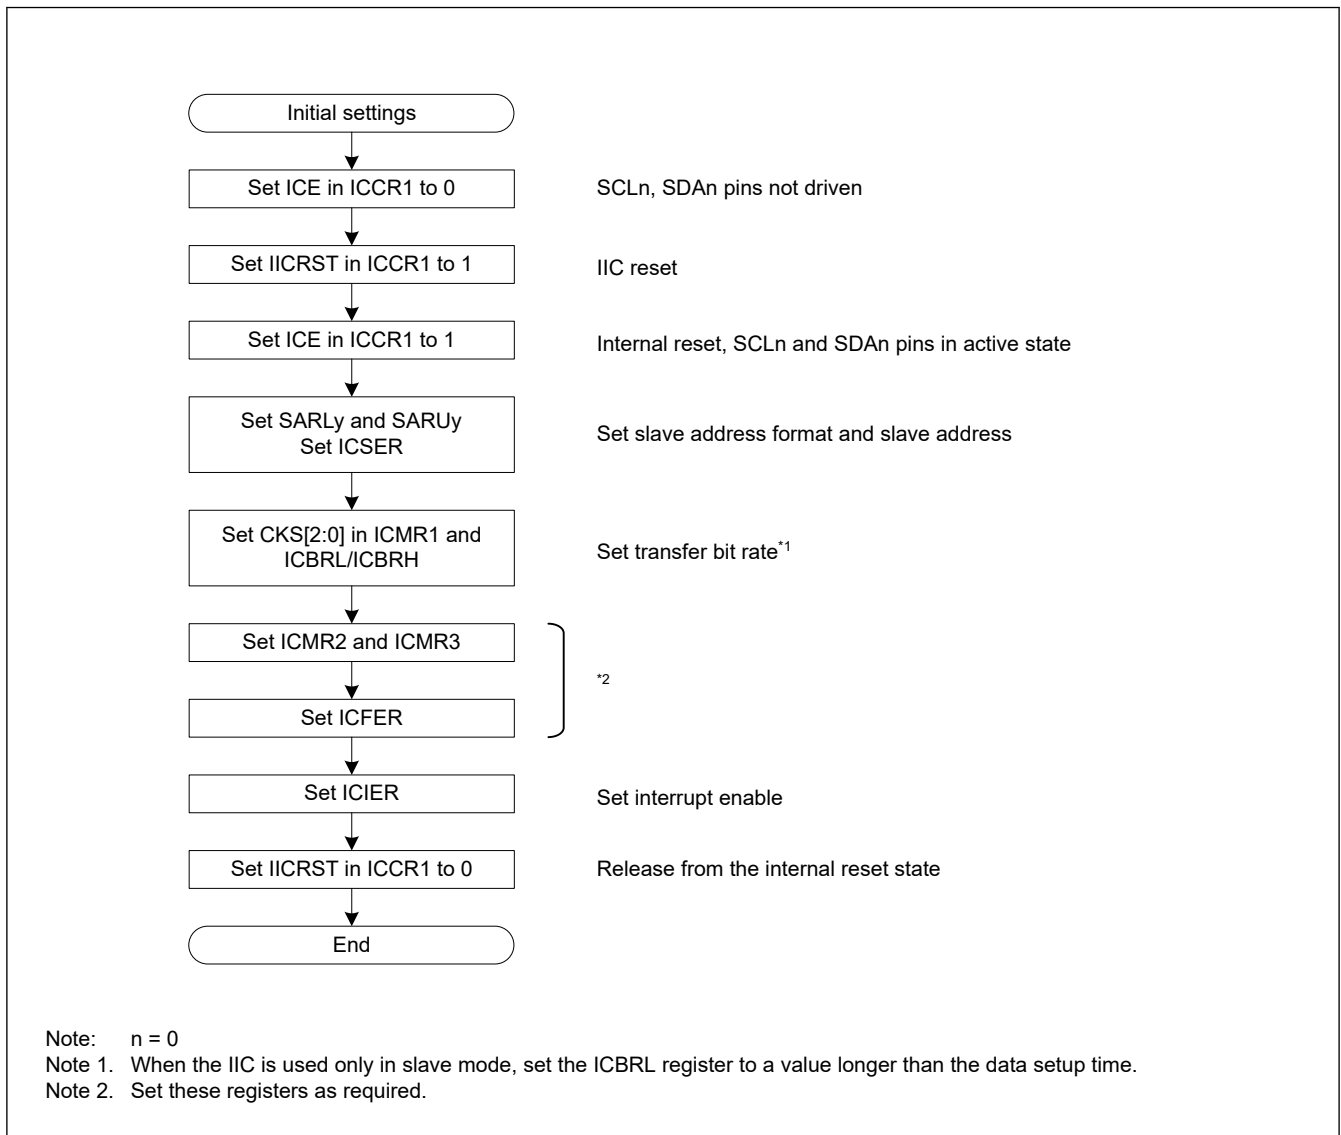

### 28.3.2 Initial Settings

Before starting data transmission or reception, initialize the IIC using the procedure shown in [Figure 28.5](#).

1. Set the ICCR1.ICE bit to 0 to set the SCLn and SDAn pins to the inactive state.
2. Set the ICCR1.IICRST bit to 1 to initiate IIC reset.
3. Set the ICCR1.ICE bit to 1 to initiate internal reset.

4. Set the SARLy, SARUy, ICSEr, ICMR1, ICBRH, and ICBRL registers ( $y = 0$  to  $2$ ), and set the other registers as required. For initial settings of the IIC, see [Figure 28.5](#).
5. When the required register settings are complete, set the ICCR1.IICRST bit to  $0$  to release the IIC reset.

This procedure is not required if the IIC initialization is already complete.

**Figure 28.5** Example IIC initialization flow

### 28.3.3 Master Transmit Operation

In master transmit operation, the IIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. [Figure 28.6](#) shows an example of master transmission, and [Figure 28.7](#) to [Figure 28.9](#) show the operation timing in master transmission.

To set up and perform master transmission:

1. Process initial settings. For details, see [section 28.3.2. Initial Settings](#).
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to  $1$  (start condition request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and START flags in ICSR2 automatically set to  $1$  and the ST bit automatically is set to  $0$ . At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is  $1$ , the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and

TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.

3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. After the byte containing the slave address and R/W# bit is transmitted, the value of the TRS bit automatically updates to select master transmit or master receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the IIC continues in master transmit mode. Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.  
For data transmission with an address in the 10-bit format, start by writing 11110b, the 2 higher-order bits of the slave address, and W to ICDRT as the first address transmission. For the second address transmission, write the 8 lower-order bits of the slave address to ICDRT.
4. Check that the TDRE flag in ICSR2 is 1, and then write the transmit data to the ICDRT register. The IIC automatically holds the SCLn line low until the transmit data is ready or a stop condition is issued.
5. After all bytes of transmit data are written to the ICDRT register, wait until the value in the TEND flag in ICSR2 returns to 1, and then set the SP bit in ICCR2 to 1 (stop condition requested). On receiving a stop condition request, the IIC issues the stop condition. Regarding issuing a stop condition, see [section 28.11.3. Issuing a Stop Condition](#).
6. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, it automatically sets the TDRE and TEND flags to 0, and sets the STOP flag in ICSR2 to 1.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

Figure 28.6 Example master transmission flow

Figure 28.7 Master transmit operation timing (1) with 7-bit address format

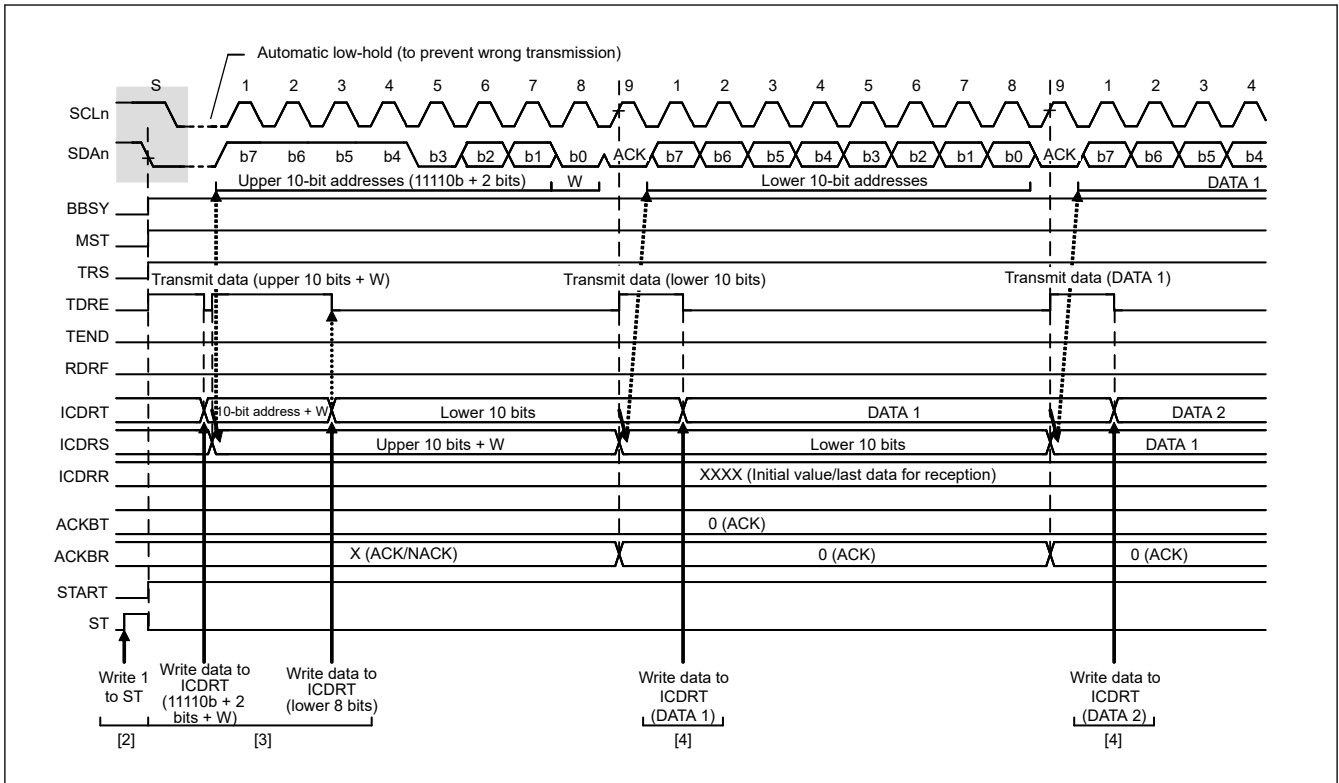

Figure 28.8 Master transmit operation timing (2) with 10-bit address format

Figure 28.9 Master transmit operation timing (3)

### 28.3.4 Master Receive Operation

In master receive operation, the IIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the IIC must start by sending a slave address to the associated slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 28.10 and Figure 28.11 show examples of master reception (7-bit address format), and Figure 28.12 to Figure 28.14 show the operation timing in master reception.

To set up and perform master reception:

1. Process initial settings. For details, see [section 28.3.2. Initial Settings](#).
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. When the IIC detects the start condition, the BBSY and START flags in ICSR2 automatically set to 1, and the ST bit automatically is set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDA line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. When the byte containing the slave address and R/W# bit is transmitted, the value of the ICCR2.TRS bit automatically updates to select transmit or receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 1, the TRS bit is set to 0 on the rising edge of the ninth cycle of the SCL clock, placing the IIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag automatically is set to 1. Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition. For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 11110b, the two higher-order bits of the slave address, and the R bit places the IIC in master receive mode.
4. Dummy read ICDRR after confirming that the RDRF flag in ICSR2 is 1. This makes the IIC start output of the SCL clock and start data reception.

5. After 1 byte of data is received, the RDRF flag in ICSR2 is set to 1 on the rising edge of the 8th or 9th cycle of the SCL clock, as selected in the RDRFS bit in ICMR3. Reading ICDRR at this time produces the received data, and the RDRF flag is automatically set to 0 at the same time. Additionally, the value of the acknowledgment field received during the ninth cycle of the SCL clock is returned as the value set in the ICMR3.ACKBT bit. If the next byte to be received is the second-to-last byte, set the ICMR3.WAIT bit to 1 for wait insertion before reading ICDRR, containing the second-to-last byte. In addition to enabling NACK output, even when interrupts or other operations result in delays in setting the ICMR3.ACKBT bit to 1 (NACK) in step (6), this fixes the SCLn line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, which enables the issuing of a stop condition.
6. When the ICMR3.RDRFS bit is 0, and the slave device must be notified that it is to end transfer for data reception after transfer of the next and final byte, set the ICMR3.ACKBT bit to 1 (NACK).
7. After reading the second-to-last byte from the ICDRR register, if the value of the ICSR2.RDRF flag is 1, write 1 to the SP bit in ICCR2 (stop condition requested), and then read the last byte from ICDRR. When ICDRR is read, the IIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is complete or the SCLn line is released from the low-hold state.
8. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, detection of the stop condition sets the ICSR2.STOP flag to 1.
9. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

Figure 28.13 Master receive operation timing (2) with 10-bit address format when RDRFS = 0

Figure 28.14 Master receive operation timing (3) when RDRFS = 0

### 28.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the IIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 28.15 shows an example of slave transmission, and Figure 28.16 and Figure 28.17 show the operation timing in slave transmission.

To set up and perform slave transmission:

1. Initialize the IIC using the procedure in [section 28.3.2. Initial Settings](#).  
After initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit is 1, the IIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.
3. Check that the ICSR2.TDRE flag is 1, then write the transmit data to the ICDRT register. If the IIC receives no acknowledge from the master device (receives an NACK signal) while the ICFER.NACKF bit is 1, the IIC suspends transfer of the next data.
4. Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the IIC drives the SCLn line low on the ninth falling edge of the SCL clock.
5. When the ICSR2.NACKF or ICSR2.TEND flag is 1, dummy read ICDRR to complete the processing. This releases the SCLn line.
6. On detecting the stop condition, the IIC automatically sets the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2), the ICSR2.TDRE and TEND flags, and the ICCR2.TRS bit to 0, and enters slave receive mode.
7. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

Figure 28.15 Example slave transmission flow

Figure 28.16 Slave transmit operation timing (1) with 7-bit address format

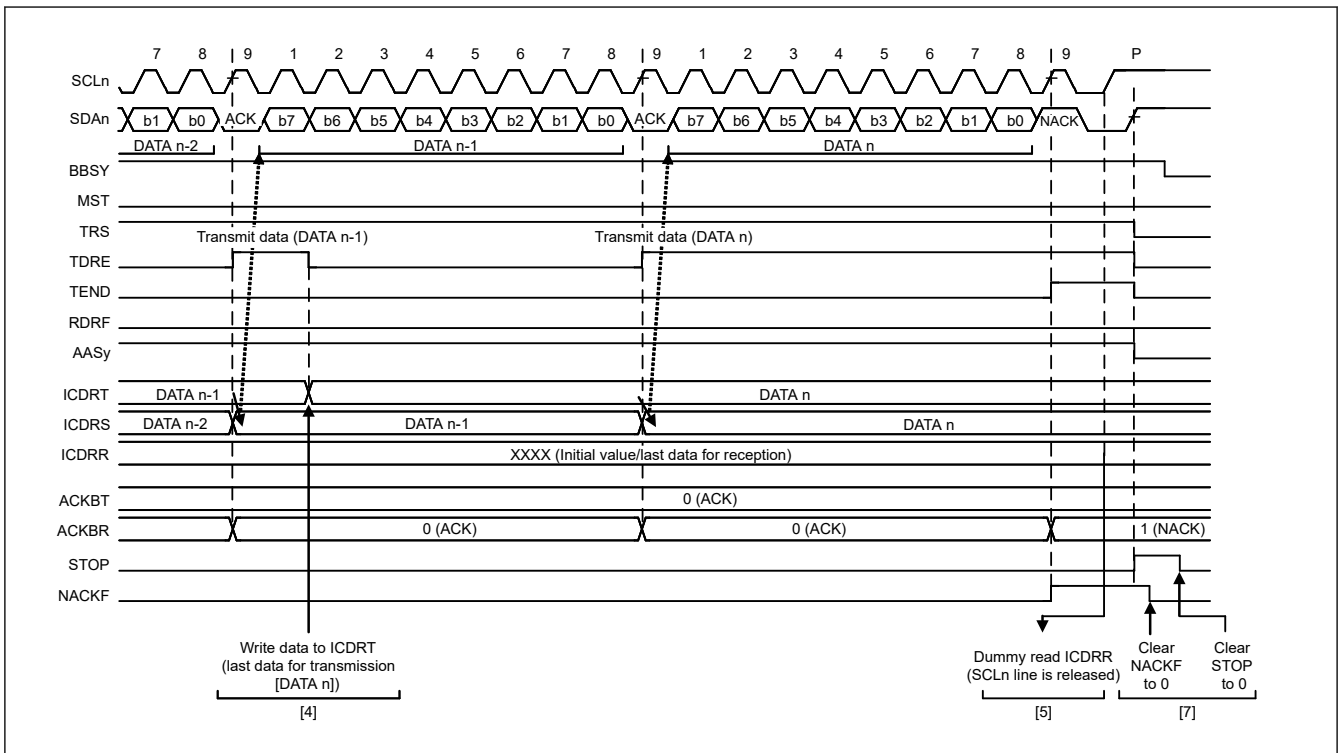

Figure 28.17 Slave transmit operation timing (2)

### 28.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the IIC returns acknowledgments as a slave device.

Figure 28.18 shows an example of slave reception, and Figure 28.19 and Figure 28.20 show the operation timing in slave reception.

To set up and perform slave reception:

1. Initialize the IIC using the procedure in [section 28.3.2. Initial Settings](#).  
After initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags ( $y = 0$  to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit is 0, the IIC continues to place itself in slave receive mode and sets the RDRF flag in ICSR2 to 1.
3. Check that the ICSR2.STOP flag is 0 and the ICSR2.RDRF flag is 1, then dummy read ICDRR. The dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected.
4. When ICDRR is read, the IIC automatically sets the ICSR2.RDRF flag to 0. If reading of ICDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the IIC holds the SCLn line low at the SCL clock one cycle before the point where the RDRF is set. In this case, reading ICDRR releases the SCLn line from being held low.  
When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1, read ICDRR until all the data is completely received.
5. On detecting the stop condition, the IIC automatically clears the ICSR1.HOA, GCA, and AASy flags ( $y = 0$  to 2) to 0.
6. Check that the ICSR2.STOP flag is 1, then set the ICSR2.STOP flag to 0 for the next transfer operation.

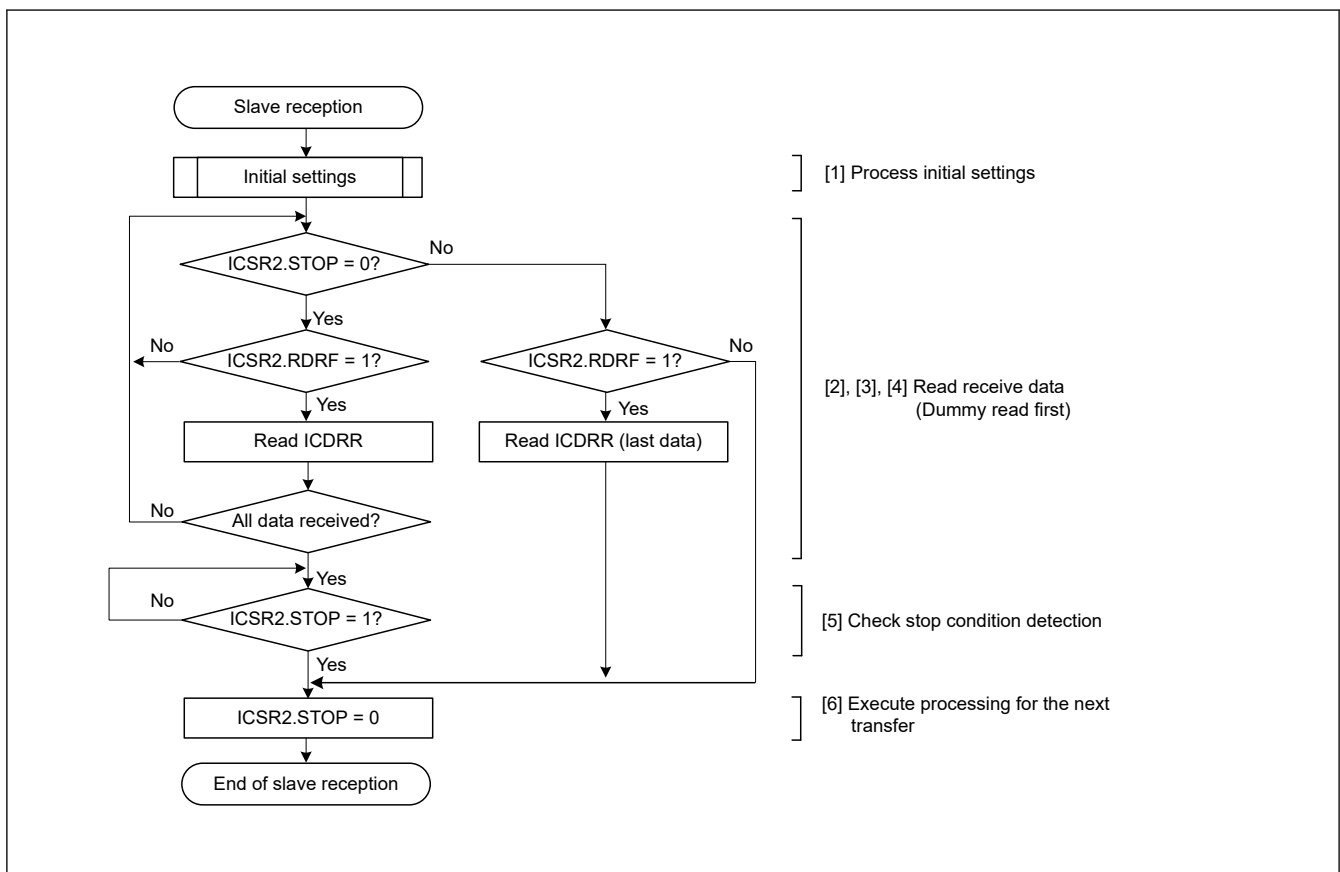

Figure 28.18 Example slave reception flow

Figure 28.19 Slave receive operation timing (1) with 7-bit address format when RDRFS = 0

Figure 28.20 Slave receive operation timing (2) when RDRFS = 0

### 28.4 SCL Synchronization Circuit

For generation of the SCL clock, the IIC starts counting the value for the high-level period specified in ICBRH when it detects a rising edge on the SCLn line, and it drives the SCLn line low when it completes counting. When the IIC detects

the falling edge of the SCLn line, it starts counting the value for the low-level period specified in ICBRL, and then it stops driving the SCLn line, releasing the line, when it completes counting. The IIC repeats this process to generate the SCL clock.

If multiple master devices are connected to the I<sup>2</sup>C bus, a collision of SCL signals might arise because of contention with another master device. In such cases, the master devices must synchronize their SCL signals. Because this synchronization of SCL signals must be bit-by-bit, the IIC is equipped with an SCL synchronization circuit to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When the IIC detects a rising edge on the SCLn line and starts counting the high-level period specified in ICBRH.BRH[4:0], and the level on the SCLn line falls because an SCL signal is being generated by another master device, the IIC performs the following:

1. Stops counting when it detects the falling edge.
2. Drives the level on the SCLn line low.
3. Starts counting the low-level period specified in ICBRL.BRL[4:0].

When the IIC finishes counting the low-level period, it stops driving the SCLn line low to release the line. If the low-level period of the SCL clock signal from the other master device is longer than the low-level period set in the IIC, the low-level period of the SCL signal is extended. When the low-level period for the other master device ends, the SCL signal rises because the SCLn line is released.

When the IIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, when SCL signals from more than one master are contending, the high-level period of the SCL signal is synchronized with that of the clock with the narrower period, and the low-level period of the SCL signal is synchronized with that of the clock with the broader period. However, such synchronization of the SCL signal is only enabled when the SCLE bit in ICFER is set to 1.

Figure 28.21 Generation and synchronization of SCL signal from IIC

## 28.5 SDA Output Delay Function

The IIC module incorporates a function for delaying output on the SDA line. The delay can be applied to all output on the SDA line, including issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals.

With this function, SDA output is delayed from the detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval during which the SCL clock is low. This approach helps prevent erroneous operation of communications devices, with the aim of satisfying the 300-ns minimum data-hold time requirement of the SMBus specification. The output delay function is enabled by setting the SDDL[2:0] bits in ICMR2 to a value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled, for example, the DLCS bit in ICMR2 selects the clock source for the SDA output delay counter, either as the internal base clock (IICφ) for the IIC module or as the internal base clock divided by 2 (IICφ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in ICMR2. When the delay cycles count is reached, the IIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.

Figure 28.22 SDA output delay function

## 28.6 Digital Noise Filter Circuits

The internal circuitry sees the states of the SCLn and SDAn pins through analog and digital noise-filter circuits. Figure 28.23 shows a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the IIC consists of four flip-flop circuit stages connected in series and a match-detection circuit. The number of valid stages in the digital noise filter is selected in the NF[1:0] bits in ICMR3. The selected number of valid stages determines the noise-filtering capability as a period from 1 to 4 IICφ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on falling edges of the IICφ signal. When the input signal level matches the output level of the number of valid flip-flop circuit stages as selected in the NF[1:0] bits in ICMR3, the signal level is seen in the subsequent stage. If the signal levels do not match, the previous value is saved.

If the ratio between the frequency of the internal operating clock (PCLKB) and the transfer rate is small, for example, if data transfer is 400 kbps with PCLKB = 4 MHz, the characteristics of the digital noise filter might lead to the elimination of

required signals as noise. In such cases, it is possible to disable the digital noise-filter circuit by setting the ICFER.NFE bit to 0, and use only the analog noise filter circuit.

**Figure 28.23** Digital noise filter circuit block diagram

## 28.7 Address Match Detection

The IIC can set three unique slave addresses in addition to the general call address and host address. The slave addresses can be 7-bit or 10-bit slave addresses.

### 28.7.1 Slave-Address Match Detection

The IIC can set three unique slave addresses and has a slave address detection function for each unique slave address. When the SARyE bit ( $y = 0$  to  $2$ ) in ICSER is set to 1, the slave addresses set in SARU $y$  and SARL $y$  ( $y = 0$  to  $2$ ) can be detected.

When the IIC detects a match of the set slave address, the associated AAS $y$  flag ( $y = 0$  to  $2$ ) in ICSR1 is set to 1 on the rising edge of the ninth SCL clock cycle, and the RDRF flag in ICSR2 or the TDRE flag in ICSR2 is set to 1 by the subsequent R/W# bit. This causes a receive data full interrupt (IIC $n$ \_RXI) or transmit data empty interrupt (IIC $n$ \_TXI) to be generated. The AAS $y$  flag identifies which slave address is specified.

Figure 28.24 to Figure 28.26 show the AAS $y$  flag set timing in three cases.

Figure 28.24 AASy flag set timing with 7-bit address format

Figure 28.25 AASy flag set timing with 10-bit address format

Figure 28.26 AASy flag set and clear timing with mixed 7-bit and 10-bit address formats

### 28.7.2 Detection of General Call Address

The IIC provides detection of the general call address (0000 000b + 0 [W]). This is enabled by setting the GCAE bit in IC SER to 1.

If the address received after a start or restart condition is issued is 0000 000b + 1 [R] (start byte), the IIC recognizes this as the address of a slave device with an all-zero address, but not as the general call address.

When the IIC detects the general call address, both the GCA flag in IC SR1 and the RDRF flag in IC SR2 set to 1 on the rising edge of the ninth cycle of the SCL clock. This leads to the generation of a receive data full interrupt (IICn\_RXI). The value of the GCA flag can be checked to confirm that the general call address was transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

**Figure 28.27** Timing of GCA flag setting during reception of general call address

### 28.7.3 Device-ID Address Detection

The IIC module provides detection of device-ID address compliant with the I<sup>2</sup>C bus specification (revision 03). When the IIC receives 1111 100b as the first byte after a start or restart condition is issued with the DIDE bit in ICSER set to 1, it recognizes the address as a device ID, sets the DID flag in ICSR1 to 1 on the rising edge of the ninth SCL clock cycle when the subsequent R/W# bit is 0, then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the IIC sets the associated AASy flag (y = 0 to 2) in ICSR1 to 1.

When the first byte received after the issue of a start or restart condition matches the device ID address (1111 100b) again and the subsequent R/W# bit is 1, the IIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device ID address detection function, the IIC sets the DID flag to 0 if a match with the IIC slave address is not obtained or a match with the device ID address is not obtained after a match with the IIC slave address and a restart condition is not detected. If the first byte after detection of a start or restart condition matches the device ID address (1111 100b), and the R/W# bit is 0, the IIC sets the DID flag to 1 and compares the second and subsequent bytes with the slave address of the IIC. If the R/W# bit is 1, the DID flag holds the previous value and the IIC does not compare the second and subsequent bytes. Therefore, the reception of a device ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Additionally, prepare the device ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal transmit data. For details on the information that must be included in device ID fields, contact NXP Semiconductors.

Figure 28.28 AASy and DID flag set and clear timing during reception of device ID

### 28.7.4 Host Address Detection

The IIC provides host address detection when operating in SMBus. When the HOAE bit in ICSER is set to 1 while the SMBS bit in ICMR3 is 1, the IIC can detect the host address (0001 000b) in slave receive mode (MST and TRS bits = 00b in ICCR2).

When the IIC detects the host address, the HOA flag in ICSR1 is set to 1 on the rising edge of the 9th SCL clock cycle, and at the same time, the RDRF flag in ICSR2 is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (IICn\_RXI) to be generated. The HOA flag indicates that the host address was sent from another device.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit = 1), the IIC can also detect the host address. After the host address is detected, the IIC operates in the same manner as in normal slave operation.

Figure 28.29 HOA flag set timing during reception of host address

### 28.8 Wakeup Function

The IIC provides a wakeup function that causes the MCU to transition from Software Standby mode or Snooze mode to normal operation. The wakeup function enables the reception of data when the system clock (PCLKB) is stopped, and generates a wakeup interrupt signal on a match of the slave address of the received data. This wakeup interrupt signal triggers the return to normal operation. After the wakeup interrupt occurs, switch the IIC to PCLKB synchronous operation so that communication can continue.

The wakeup function has four operation modes:

- Normal wakeup mode 1
- Normal wakeup mode 2
- Command recovery mode
- EEP response mode

Table 28.9 describes the behavior in these modes.

Table 28.9 Wakeup operation modes

| Operation mode        | ACK response timing                                          | ACK response before wakeup to PCLKB synchronous operation                      | SCL state during wakeup to PCLKB synchronous operation |
|-----------------------|--------------------------------------------------------------|--------------------------------------------------------------------------------|--------------------------------------------------------|
| Normal wakeup mode 1  | Before wakeup to PCLKB synchronous operation <sup>*1</sup>   | ACK                                                                            | Fixed low                                              |
| Normal wakeup mode 2  | After wakeup to PCLKB synchronous operation <sup>*2</sup>    | Before wakeup: no response (NACK level retained)<br>After wakeup: ACK response | Fixed low                                              |
| Command recovery mode | Before wakeup to PCLKB synchronous operation <sup>*1</sup>   | ACK                                                                            | Open                                                   |
| EEP response mode     | Before recovery to PCLKB synchronous operation <sup>*1</sup> | NACK                                                                           | Open                                                   |

Note 1. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 9th clock of the SCL.

Note 2. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 8th clock of the SCL.

The following can be selected as wakeup interrupt sources:

- Host address detection (valid when IC SER.HOAE = 1)
- General call address detection (valid when IC SER.GCAE = 1)
- Slave address 0<sup>\*1</sup> detection (valid when IC SER.SAR0E = 1)

- Slave address 1\*1 detection (valid when IC SER.SAR1E = 1)
- Slave address 2\*1 detection (valid when IC SER.SAR2E = 1)

Note 1. Only 7-bit address can be set. Set the FS bit in SARU<sub>y</sub> (y = 0 to 2) to 0.

### Precautions on the use of the wakeup function

- Do not change the content of the IIC registers except the ICIER register and WUSEN bit in ICWUR2 while the WUASYF flag in ICWUR2 is 1 (during PCLKB asynchronous operation).
- Set ICWUR.WUE and ICWUR.WUIE to 1, and ICCR2.MST and ICCR2.TRS to 0 (slave reception mode) before switching to PCLKB asynchronous mode.
- The device ID and the 10-bit slave address cannot be selected for the wakeup interrupt source. Set the DIDE bit in IC SER and FS bit in SARU<sub>y</sub> (y = 0 to 2) to 0.
- Set bits TIE, TEIE, RIE, NAKIE, SPIE, STIE, ALIE, and TMOIE in the ICIER register to 0 (interrupt disabled) after switching to PCLKB asynchronous operation (ICWUR2.WUASYF = 1).
- When the wakeup function is enabled, do not use the timeout function (ICWUR.WUE = 1)
- Even when a wakeup interrupt is generated during PCLKB asynchronous operation (when ICWUR2.WUASYF = 1), if the slave addresses match in PCLKB synchronous mode (ICWUR2.WUASYF = 0), the wakeup interrupt does not occur and the WUF flag is not set.
- If the timing of writing 0 to the ICWUR2.WUSEN bit and the timing of detecting a start condition conflict, the IIC might start the next reception in PCLKB synchronous operation mode. In this case, ICWUR2.WUASYF flag becomes 1 (switch to PCLKB asynchronous mode) when data communication is complete, a stop condition is detected, and detection of a wakeup event starts.
- After writing 0 to the WUSEN bit in ICWUR2, do not change registers relate to the IIC operation mode setting (ICMR3, IC SER, and SARL<sub>y</sub>) until the mode is switched to PCLKB asynchronous operation from PCLKB synchronous operation (while the ICWUR2.WUASYF flag is 1). If the register value changes during this period by an interrupt handling or another factor, the IIC might malfunction before switching to the asynchronous operation.

### 28.8.1 Normal Wakeup Mode 1

This section describes the behavior, the timing, and an example operation of normal wakeup mode 1.

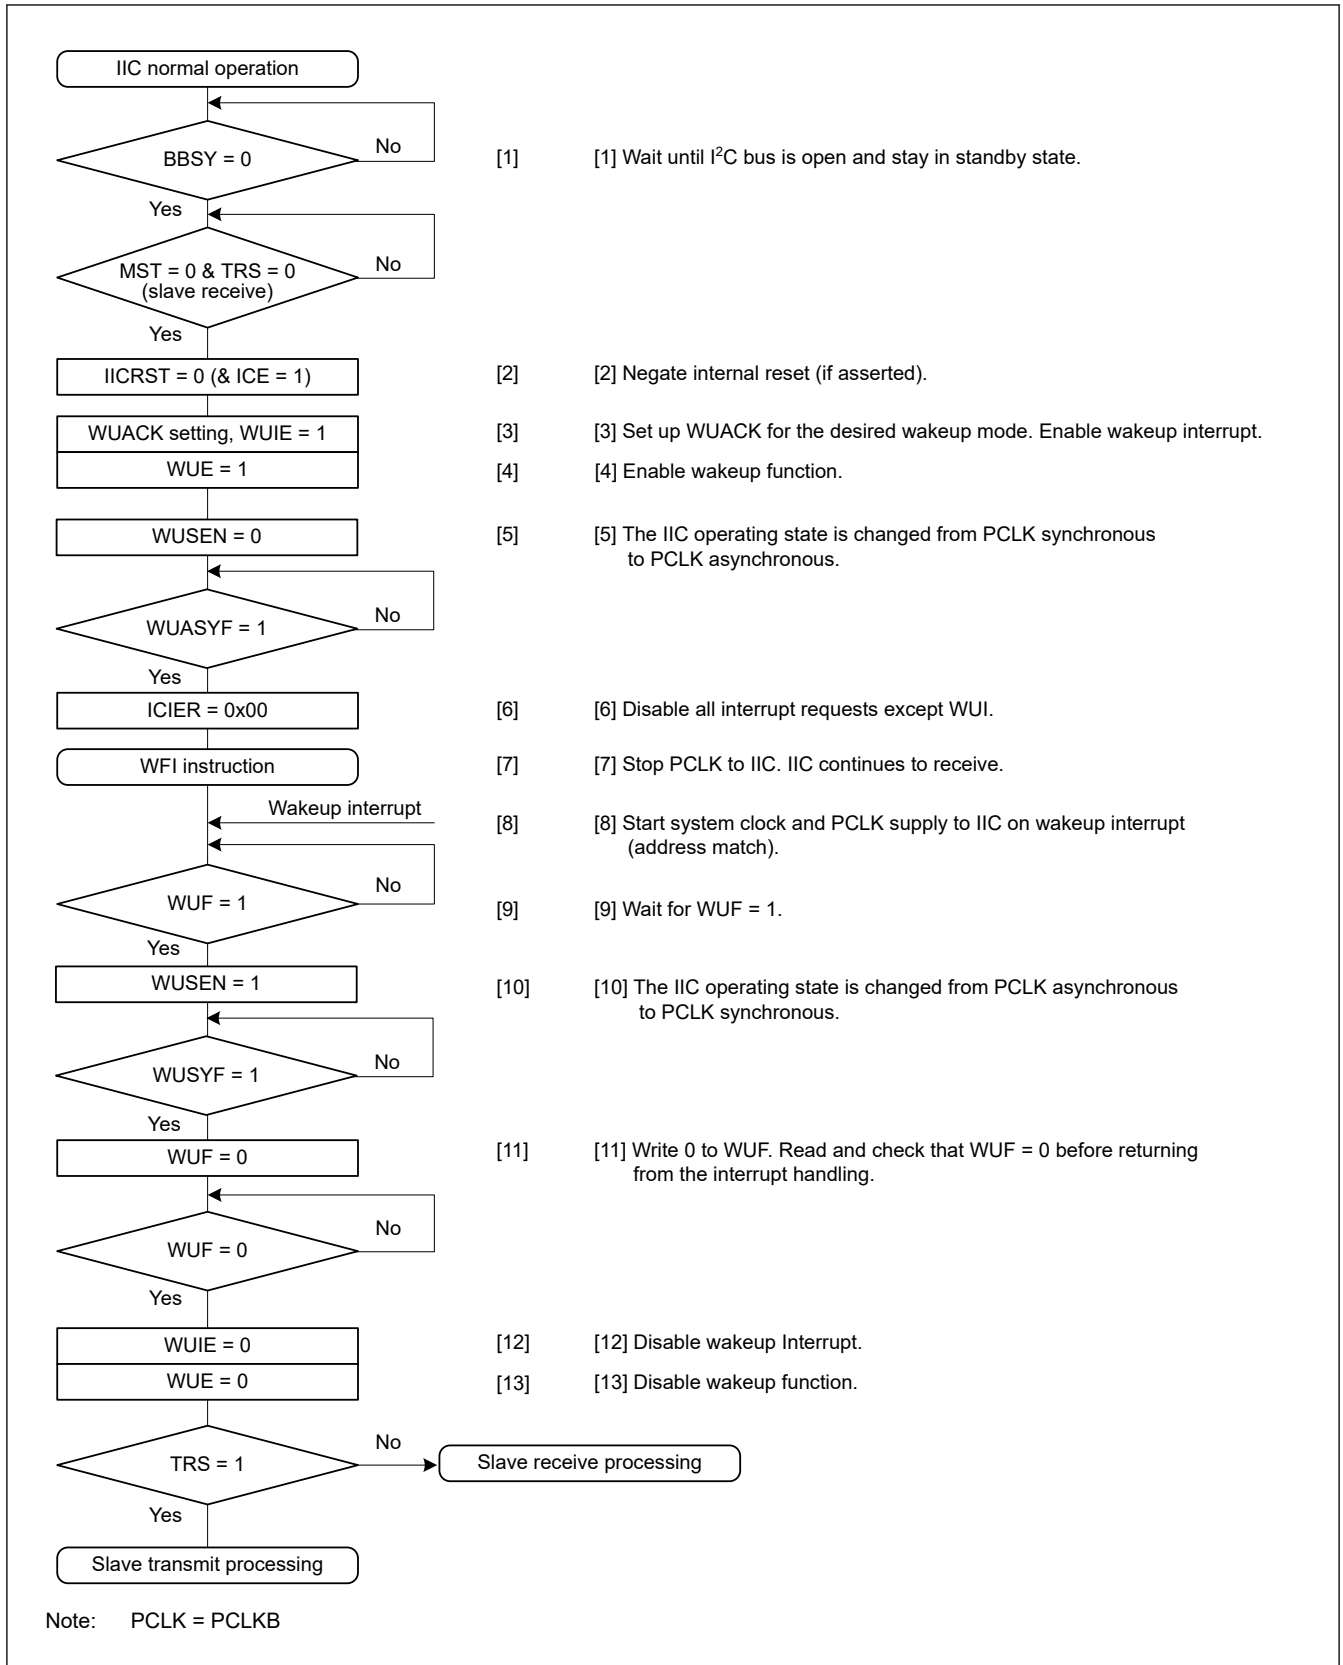

In normal wakeup mode 1, a wakeup interrupt triggered by the match of the slave address initiates the transition to normal operation as follows:

- Before wakeup: ACK is sent in response to the data received with its own slave address of the IIC.
- During wakeup: ACK response is made on the 9th clock cycle of SCL, after which SCL is held low\*1.
- After wakeup: Normal operation continues.

Note 1. Between the 9th clock cycle and 1st clock cycle during wakeup, WAIT = 1 is invalid.

If the slave address does not match, the SCL line is not held low after the 9th clock cycle of SCL, and the slave operation continues. [Figure 28.30](#) shows an operation example, and [Figure 28.32](#) shows the detailed timing.

If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, for example the IRQ<sub>n</sub>, the WUF flag is not set to 1. [Figure 28.31](#) shows an operation example.

**Figure 28.30** Example operation of normal wakeup mode 1 when wakeup is triggered by a wakeup interrupt on match of the slave address

Note: See [Precautions on the use of the wakeup function](#).

**Figure 28.31 Example operation of normal wakeup modes 1 and 2 when wakeup is triggered by an interrupt other than IIC wakeup interrupt, for example, the IRQn**

Note: For details on the IIC initial settings, see [section 28.3.2. Initial Settings](#).

Figure 28.32 Timing of normal wakeup mode 1

### 28.8.2 Normal Wakeup Mode 2

This section describes the behavior, the timing, and an example operation of normal wakeup mode 2.

In normal wakeup mode 2, a wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

- Before wakeup: No response to data received with its own slave address until the end of the 8th SCL cycle.
- During wakeup: SCL line held low during the 8th and 9th clock cycles.
- After wakeup: ACK returns on the 9th clock cycle of SCL, and normal operation continues.

If the slave address does not match, the SCL line is not held low after the 8th SCL clock cycle, and the slave operation continues. [Figure 28.33](#) shows an example operation, and [Figure 28.34](#) shows the detailed timing.

If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, such as the IRQn, for example, the WUF flag is not set to 1. [Figure 28.31](#) shows an operation example.

**Figure 28.33** Example operation of normal wakeup mode 2 when wakeup is triggered by a wakeup interrupt on match of the slave address

Note: See [Precautions on the use of the wakeup function.](#)

Figure 28.34 Timing of normal wakeup mode 2

### 28.8.3 Command Recovery Mode and EEP Response Mode (Special Wakeup Modes)

This section describes the behavior, the timing, and example operations of the command recovery and EEP response modes. In the command recovery and EEP response modes, the SCL line is not held low during the wakeup period (after the rise of the 9th clock cycle of SCL). Therefore, other I2C devices can use the I<sup>2</sup>C bus during this period.

A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

- Before wakeup: In response to the data received with its own slave address, the IIC returns ACK (command recovery mode) or NACK (EEP response mode).
- During wakeup: The SCL line is not held low.
- After wakeup: Normal operation continues after IIC initialization.

If the slave address does not match, the slave operation continues.

Note: Because the SCL line is not held low during wakeup, transmission or reception of the data that follows the slave address is not possible.

Note: The command recovery and EEP response modes are internal reset states (ICE = IICRST = 1). Therefore, the match of the slave address does not set the flags, HOA, GCA, ASS0, ASS1, and ASS2 in the ICSR1 register.

Figure 28.35 shows an example operation in recovery and EEP response modes. Figure 28.37 shows the detailed timing.

If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, such as IRQn for example, the WUF flag is not set to 1. Follow the processing shown in Figure 28.36.

**Figure 28.35 Example operation of command recovery mode and EEP response mode when wakeup is triggered by a wakeup interrupt on match of the slave address**

Note: See [Precautions on the use of the wakeup function](#).

**Figure 28.36** Example operation of command recovery and EEP response modes when wakeup is triggered by an interrupt other than IIC wakeup interrupt, for example, the IRQn

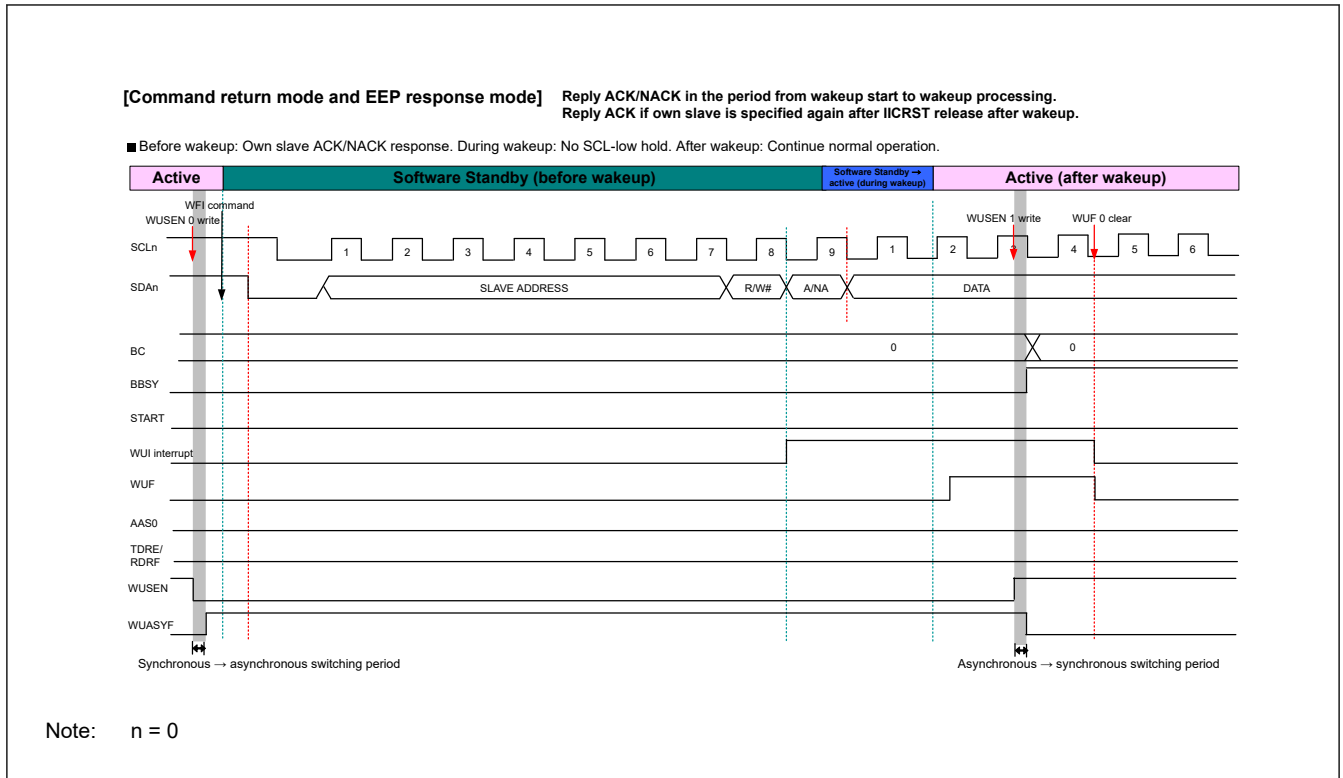

Figure 28.37 Timing of command recovery and EEP response modes

## 28.9 Automatic Low-Hold Function for SCL

### 28.9.1 Function to Prevent Wrong Transmission of Transmit Data

If the I<sup>2</sup>C Bus Shift Register (ICDRS) is empty and data has not been written to the I<sup>2</sup>C Bus Transmit Data Register (ICDRT) with the IIC in transmission mode (TRS bit = 1 in ICCR2), the SCLn line is automatically held low over the subsequent intervals. This low-hold period is extended until the transmit data is written, which prevents the unintended transmission of erroneous data.

Master transmit mode:

- Low-level interval after a start or restart condition is issued
- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

Slave transmit mode:

- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

Figure 28.38 Automatic low-hold operation in transmit mode

### 28.9.2 NACK Reception Transfer Suspension Function

This function suspends transfer operation when NACK is received in transmit mode (TRs bit = 1 in ICCR2). This function is enabled when the NACKEN bit in ICFER is set to 1. If the next transmit data is already written (TDRE flag = 0 in ICSR2) when NACK is received, the next data transmission on the falling edge of the 9th SCL clock cycle is automatically suspended. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (NACKF flag = 1 in ICSR2), transmit and receive operations are discontinued. To restore transmit or receive operation, after issuing the restart condition, you need to set the NACKF flag to 0 and try again, or set the NACKF flag to 0 after issuing the stop condition and then start again from issuing the start condition.

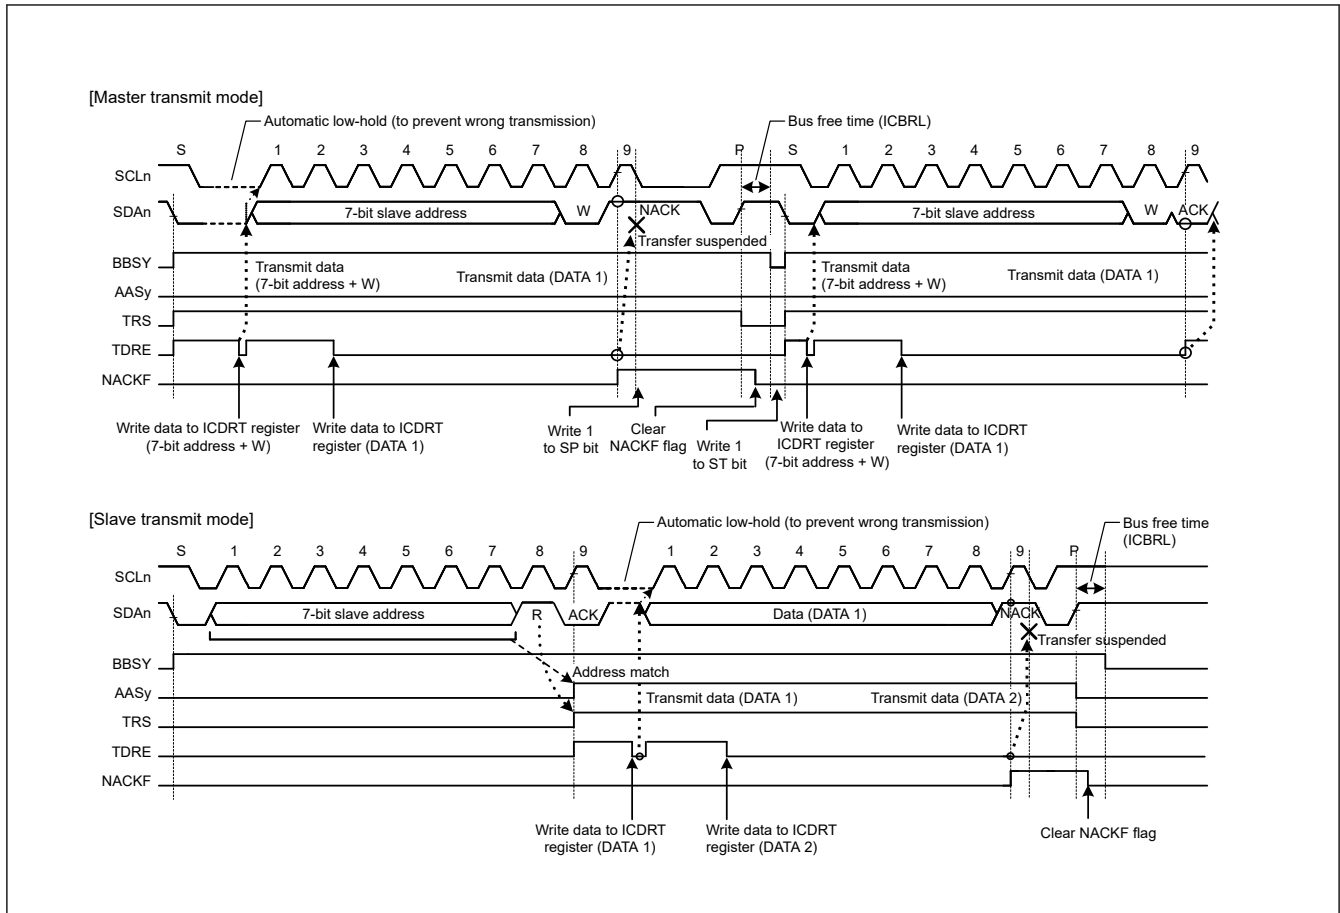

Figure 28.39 Suspension of data transfer when NACK is received, when NACK = 1

### 28.9.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer frame or more with receive data full (RDRF flag = 1 in ICSR2) in receive mode (TRS = 0 in ICCR2), the IIC holds the SCLn line low automatically immediately before the next data is received to prevent a failure to receive data.

This function is enabled even if the read processing of the final receive data is delayed and, in the meantime, the IIC slave address is designated after a stop condition is issued. This function does not interfere with other communication because the IIC does not hold the SCLn line low when a mismatch with its own slave address occurs after a stop condition is issued.

Periods in which the SCLn line is held low can be selected with a combination of the WAIT and RDRFS bits in ICMR3.

#### (1) 1-byte receive operation and automatic low-hold function using the WAIT bit

When the WAIT bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the WAIT bit function. Additionally, when the ICMR3.RDRFS bit is 0, the IIC automatically sends the ACKBT bit value in ICMR3 for the acknowledge bit in the period from the falling edge of the 8th SCL clock cycle to the falling edge of the 9th SCL clock cycle, and automatically holds the SCLn line low on the falling edge of the 9th SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from ICDRR, which enables byte-wise receive operation.

The WAIT bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

#### (2) 1-byte receive operation (ACK/NACK transmission control) and automatic low-hold function using the RDRFS bit

When the RDRFS bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the RDRFS bit function. When the RDRFS bit is set to 1, the RDRF flag in ICSR2 is set to 1 (receive data full) on the rising edge of the eighth SCL clock cycle, and the SCLn line is automatically held low on the falling edge of the eighth SCL clock cycle. This low-hold is released by writing a value to the ACKBT bit in ICMR3, but cannot be released by reading data from ICDRR, which enables receive operation through the ACK or NACK transmission control based on the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

Figure 28.40 Automatic low-hold operation in receive mode using the RDRFS and WAIT bits

## 28.10 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I<sup>2</sup>C bus standard, the IIC provides functions to prevent double-issue of a start condition, detect arbitration-lost during transmission of NACK, and detect arbitration-lost in slave transmit mode.

### 28.10.1 Master Arbitration-Lost Detection (MALE Bit)

The IIC drives the SDAn line low to issue a start condition. However, if the SDAn line was already driven low by another master device issuing a start condition, the IIC regards its own start condition as an error and considers this a loss in arbitration. Priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the ST bit in ICCR2 to 1 while the bus is busy (BBSY flag = 1 in ICCR2), the IIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration. This prevents a failure of transfer resulting from a start condition being issued while transfer is in progress.

When a start condition is issued successfully, if the transmit data including the address bits (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state and a low level is detected on the SDAn line), the IIC loses in arbitration.

After a loss in arbitration of mastership, the IIC immediately enters slave receive mode. If a slave address, including the general call address, matches its own address at this time, the IIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the MALE bit in ICFER is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Mismatching of the internal level for output on SDA and the level on the SDA<sub>n</sub> line after a start condition was issued by setting the ST bit in ICCR2 to 1 while the BBSY flag in ICCR2 is set to 0 (erroneous issuing of a start condition)
- Setting of the ST bit in ICCR2 to 1 (start condition double-issue error) while the BBSY flag is 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDA<sub>n</sub> line in master transmit mode (MST and TRS bits = 11b in ICCR2).

Figure 28.41 Examples of master arbitration-lost detection when MALE = 1

Figure 28.42 Arbitration-lost when start condition is issued when MALE = 1

28.10.2 Function to Detect Loss of Arbitration During NACK Transmission (NALE Bit)

This function causes arbitration to be lost if the internal SDA output level does not match the level on the SDAn line (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state and the low level is detected on the SDAn line) during transmission of NACK in receive mode. Arbitration is lost because of a conflict between NACK and ACK transmissions when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such a conflict occurs when multiple master devices send or receive the same information through a single slave device. Figure 28.43 shows an example of arbitration-lost detection during transmission of NACK.

Figure 28.43 Example of arbitration-lost detection during transmission of NACK when NALE = 1

The following explains arbitration-lost detection using an example in which two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in either master A or master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the required 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like

this occurs, master A cannot detect the ACK transmitted by master B and issues a stop condition. The stop condition issue conflicts with the SCL clock output of master B, which disrupts communication.

When the IIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost. If arbitration is lost during transmission of NACK, the IIC immediately cancels the slave match condition and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing, such as 0xFF transmission processing, which is required if the UDID (Unique Device Identifier) of the assigned address does not match in the Get UDID general processing after the Assign Address command.

The IIC detects arbitration-lost during transmission of NACK when the following condition is met with the NALE bit in ICFER set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ACKBT bit = 1 in ICMR3).

### 28.10.3 Slave Arbitration-Lost Detection (SALE Bit)

This function causes arbitration to be lost if the transmit data (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state and a low level is detected on the SDAn line) in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When the IIC loses slave arbitration, the IIC is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates subsequent redundant processing for the transmission of 0xFF.

The IIC detects slave arbitration-lost when the following condition is met with the SALE bit in ICFER set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When transmit data excluding acknowledge (internal SDA output level) does not match the SDAn line in slave transmit mode (MST and TRS bits = 01b in ICCR2).

Figure 28.44 Example of slave arbitration-lost detection when SALE = 1

## 28.11 Start, Restart, and Stop Condition Issuing Function

### 28.11.1 Issuing a Start Condition

The IIC issues a start condition when the ST bit in ICCR2 is set to 1. When the ST bit is set to 1, a start condition request is made, and the IIC issues a start condition when the BBSY flag in ICCR2 is 0 (bus free state). When a start condition is issued normally, the IIC automatically shifts to the master transmit mode.

To issue a start condition:

1. Drive the SDA<sub>n</sub> line low (high level to low level).
2. Ensure that the time set in ICBRH and the start condition hold time elapse.
3. Drive the SCL<sub>n</sub> line low (high level to low level).
4. Detect low level on the SCL<sub>n</sub> line and ensure the low-level period of the SCL<sub>n</sub> line set in ICBRL elapses.

### 28.11.2 Issuing a Restart Condition

The IIC issues a restart condition when the RS bit in ICCR2 is set to 1. When the RS bit is set to 1, a restart condition request is made, and the IIC issues a restart condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a restart condition:

1. Release the SDA<sub>n</sub> line.
2. Ensure the low-level period of the SCL<sub>n</sub> line set in ICBRL elapses.
3. Release the SCL<sub>n</sub> line (low level to high level).
4. Detect a high level on the SCL<sub>n</sub> line and ensure the time set in ICBRL and the restart condition setup time elapse.
5. Drive the SDA<sub>n</sub> line low (high level to low level).
6. Ensure the time set in ICBRH and the restart condition hold time elapse.
7. Drive the SCL<sub>n</sub> line low (high level to low level).
8. Detect a low level on the SCL<sub>n</sub> line and ensure the low-level period of the SCL<sub>n</sub> line set in ICBRL elapses.

**Note:** When issuing restart condition requests, write the slave address to ICDRT after confirming that ICCR2.RS = 0. Data written while ICCR2.RS = 1 is not forwarded because of the retransmission condition before the occurrence.

**Figure 28.45 Start and restart condition issue timing using the ST and RS bits**

Figure 28.46 shows the operation timing when a restart condition is issued after the master transmission.

[To issue a restart condition after the master transmission:]

1. Initialize the IIC using the procedure in [section 28.3.2. Initial Settings](#).
2. Read the BBSY flag in ICCR2 to check that the bus is open, then set the ST bit in ICCR2 to 1 (start condition issuance request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and the START flags in ICSR2 are automatically set to 1 and the ST bit is automatically set to 0. If the start condition is detected and the internal levels for the SDA output state and the levels on the SDA<sub>n</sub> line match while the ST bit is 1, the IIC recognizes that a start condition is successfully issued as requested by the ST bit has been successfully completed. The MST and TRS bits in ICCR2 are automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 is also automatically set to 1 when the TRS bit is set to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. After the data for transmission is written to ICDRT, the TDRE flag is automatically set to 0, data is transferred from ICDRT to ICDRS, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode according to the value of the transmitted R/W# bit. If the value of the R/W# bit is 0, the IIC continues in master transmit mode. If the ICSR2.NACKF flag is 1 at this time, indicating that no slave device recognized the address or that there was an error in communications, write 1 to ICCR2.SP bit to issue a stop condition. To transmit data with an address in the 10-bit format, start by writing 1111 0b, the 2 upper bits of the slave address, and W to ICDRT as the first address transmission. Then, as the second address transmission, write the 8 lower bits of the slave address to ICDRT.
4. After confirming that the TDRE flag in ICSR2 is 1, write data for transmission to the ICDRT register. The IIC automatically holds the SCL<sub>n</sub> line low until data for transmission is ready, a restart condition is issued or a stop condition is issued.
5. After all bytes of data for transmission are written to the ICDRT register, wait until the value of the TEND flag in ICSR2 returns to 1. Then after checking that the START flag in ICSR2 is 1, set the START flag in ICSR2 to 0.
6. Set the RS bit in ICCR2 to 1 (restart condition issue request). On receiving the request, the IIC issues a restart condition.
7. After checking that the START flag in ICSR2 is 1, write the value for transmission (the slave address and the R/W# bit) to ICDRT.

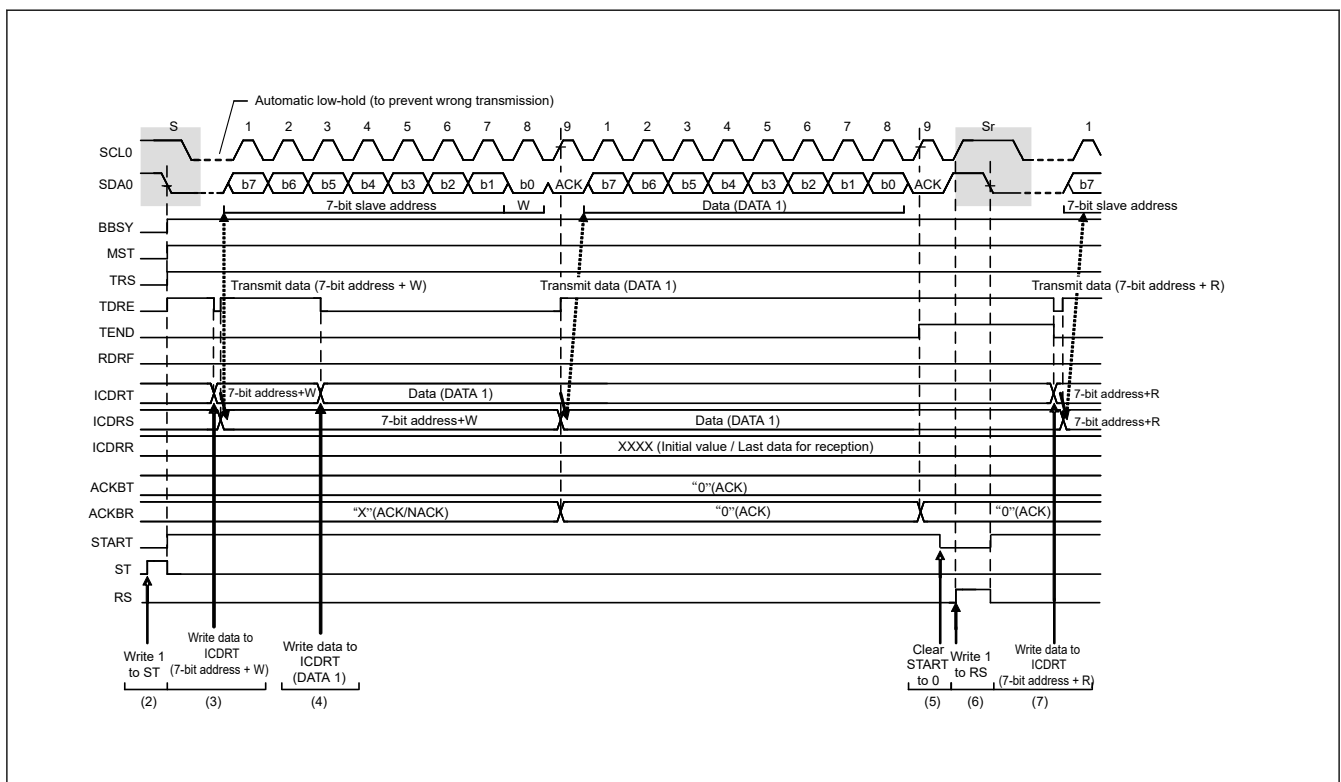

Figure 28.46 Restart condition issue timing after master transmission.

### 28.11.3 Issuing a Stop Condition

The IIC issues a stop condition when the SP bit in ICCR2 is set to 1. When the SP bit is set to 1, a stop condition request is made, and the IIC issues a stop condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a stop condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRH and the stop condition setup time elapse.
5. Release the SDAn line (low level to high level).
6. Ensure the time set in ICBRL and the bus free time elapse.
7. Clear the BBSY flag to 0 to release the bus mastership.

Figure 28.47 Stop condition issue timing using the SP bit

## 28.12 Bus Hanging

If the clock signals from the master and slave devices are out of synchronization because of noise or other factors, the I<sup>2</sup>C bus might hang with a fixed level on the SCLn line or SDAn line.

To manage bus hanging, the IIC has a timeout function to detect hanging by monitoring the SCLn line, and a function for outputting an extra SCL clock cycle to release the bus from:

- A timeout function to detect hanging by monitoring the SCLn line
- The IIC reset function
- An internal reset function.

By checking the SCLO, SDAO, SCLI, and SDAI bits in ICCR1, it is possible to see whether the IIC or its communicating partner is placing the low level on the SCLn or SDAn line.

### 28.12.1 Timeout Function

The timeout function can detect when the SCLn line is stuck longer than the predetermined time. The IIC can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.

The timeout function monitors the SCLn line state and counts the low- or high-level period using the internal counter. The timeout function resets the internal counter each time the SCLn line changes (rises or falls), but continues to count unless the SCLn line changes. If the internal counter overflows because no SCLn line changes, the IIC can detect the timeout and report the bus hung state.

This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state when the SCLn line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1)
- The IIC slave address is detected (ICSR1 register is not 0x00) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0)
- The bus is open (ICCR2.BBSY flag is 0) while a start condition is requested (ICCR2.ST bit is 1).

The internal counter of the timeout function uses the internal reference clock (IICφ) set in the CKS[2:0] bits in ICMR1 as a count source. It functions as a 16-bit counter when long mode is selected (TMOS bit = 0 in ICMR2) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCLn line level (low, high, or both levels) during which this counter is activated can be selected in the TMOH and TMOL bits in ICMR2. If both TMOL and TMOH bits are set to 0, the internal counter is disabled.

Figure 28.48 Timeout function using the TMOE, TMOS, TMOH, and TMOL bits

### 28.12.2 Extra SCL Clock Cycle Output Function

In master mode, this function outputs extra SCL clock cycles to release the SDA<sub>n</sub> line of the slave device from being held low because the master is out of synchronization with the slave device. This function is mainly used in master mode to release the SDA<sub>n</sub> line of the slave device from being fixed low by including extra cycles of SCL output from the IIC. It uses single cycles of the SCL clock for a bus error where the IIC cannot issue a stop condition because the slave device is holding the SDA<sub>n</sub> line at the low level. Do not use this function in normal situations. Using it when communications are proceeding correctly leads to malfunctions.

When the CLO bit in ICCR1 is set to 1 in master mode, a single cycle of the SCL clock at the frequency specified in the CKS[2:0] bits in ICMR1, and in the ICBRH and ICBRL registers, is output as an extra clock cycle. After output of this

single cycle of the SCL clock, the CLO bit is automatically set to 0. At this time, if ICCR2.BBSY = 1, the SCL pin goes low, and when ICCR2.BBSY = 0, the SCL pin goes high. After confirming that the CLO bit is 0 by software, write 1 to the CLO bit to output the additional clock continuously.

When the IIC module is in master mode and the slave device is holding the SDAn line low because synchronization with the slave device is lost because of effects like noise, the output of a stop condition is not possible. This function can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held low, and so recover the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the SDAI bit in ICCR1. After confirming the release of the SDAn line by the slave device, complete communications by reissuing the stop condition.

[Output conditions for using the CLO bit in ICCR1]

- When the bus is open (BBSY flag in ICCR2 = 0) or in master mode (MST bit = 1 and BBSY flag = 1 in ICCR2)
- When the communication device does not hold the SCLn line low.

Figure 28.49 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

Figure 28.49 Extra SCL clock cycle output function using the CLO bit

### 28.12.3 IIC Reset and Internal Reset

The IIC module incorporates a function for resetting itself. It uses two types of resets:

- An IIC reset, which initializes all registers, including the BBSY flag in ICCR2.
- An internal reset, which releases the IIC from the slave-address matched state and initializes the internal counter while saving other settings.

After issuing a reset, always set the IICRST bit in ICCR1 to 0. Both types of resets are valid for release from bus-hung states, because both restore the output state of the SCLn and SDAn pins to the high-impedance state.

Issuing a reset during slave operation might lead to a loss of synchronization between the master device clock and the slave device clock, so avoid this when possible. In addition, monitoring of the bus state, such as for the presence of a start condition, is not possible during an IIC reset (ICE and IICRST bits = 01b in ICCR1).

For a detailed description of the IIC and internal resets, see [section 28.15. State of Registers When Issuing Each Condition](#).

## 28.13 SMBus Operation

The IIC supports data communication conforming to the SMBus Specification (version 2.0). To perform SMBus communication, set the SMBS bit in ICMR3 to 1. To use the transfer rate within a range of 10 to 100 kbps of the SMBus standard, set the CKS[2:0] bits in ICMR1, the ICBRH, and ICBRL registers. In addition, specify the values in the DLCS bit in ICMR2 and the SDDL[2:0] bits in ICMR2 to meet the data hold time specification of 300 ns or more. When the IIC is used only as a slave device, the transfer rate setting is not required, but ICBRL must be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001b), use one of the slave address registers L0 to L2 (SARL0, SARL1, and SARL2), and set the associated FS bit (7- or 10-bit address format select) in SARUy (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the SALE bit in ICFER to 1 to enable the slave arbitration-lost detection function.

### 28.13.1 SMBus Timeout Measurement

#### (1) Measuring slave device timeout

The following period (timeout interval:  $T_{\text{LOW:SEXT}}$ ) must be measured for slave devices in SMBus communication:

- From start condition to stop condition.

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the GPT using the IIC start condition detection interrupt (STIn) and stop condition detection interrupt (SPIn). The measured timeout period must be within the total clock low-level period [slave device]  $T_{\text{LOW:SEXT}}$ : 25 ms (maximum) of the SMBus standard.

If the time measured with the GPT exceeds the clock low-level detection timeout  $T_{\text{TIMEOUT}}$ : 25 ms (minimum) of the SMBus standard, the slave device must release the bus by writing 1 to the IICRST bit in ICCR1 to issue an internal reset of the IIC. When an internal reset is issued, the IIC stops driving the bus for the SCLn and SDAn pins, making them output high-impedance, which releases the bus.

#### (2) Measuring master device timeout

The following periods (timeout interval:  $T_{\text{LOW:MEXT}}$ ) must be measured for master devices in SMBus communication:

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition.

To measure timeout for master devices, measure these periods with the GPT using the IIC start condition detection interrupt (STIn), stop condition detection interrupt (SPIn), transmit end interrupt (IICn\_TEI), or receive data full interrupt (IICn\_RXI). The measured timeout period must be within the total clock low-level extended period (master device)  $T_{\text{LOW:MEXT}}$ : 10 ms (maximum) of the SMBus standard, and the total of all  $T_{\text{LOW:MEXT}}$  values from start condition to stop condition must be within  $T_{\text{LOW:SEXT}}$ : 25 ms (maximum).

For the ACK receive timing (rising edge of the 9th SCL clock cycle), monitor the TEND flag in ICSR2 in master transmit mode (master transmitter) and the RDRF flag in ICSR2 in master receive mode (master receiver). Perform byte-wise transmit operations in master transmit mode, and hold the RDRFS bit in ICMR3 at 0 until the byte immediately before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device)  $T_{\text{LOW:MEXT}}$ : 10 ms (maximum) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout  $T_{\text{TIMEOUT}}$ : 25 ms (minimum) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (stop writing data to ICDRT).

Figure 28.50 SMBus timeout measurement

### 28.13.2 Packet Error Code (PEC)

The MCU provides a CRC calculator that enables transmission of a Packet Error Code (PEC) or allows checking of the received data in SMBus data communication for the IIC. For the CRC-generating polynomials of the CRC calculator, see [section 32, Cyclic Redundancy Check \(CRC\)](#).

In master transmit mode, the PEC data can be generated by writing all transmit data to the CRC Data Input Register (CRCDIR) in the CRC calculator.

In master receive mode, the PEC data can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC Data Output Register (CRCDOR) with the received PEC data.

To send ACK or NACK based on the match or mismatch result when the final byte is received as a result of the PEC code check, set the RDRFS bit in ICMR3 to 1 before the rising edge of the 8th SCL clock cycle during reception of the final byte, and hold the SCLn line low on the falling edge of the 8th clock cycle.

### 28.13.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communicating over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address, or to request its own slave address from the SMBus host.

For a product using the MCU to operate as an SMBus host or ARP master, the host address (0001 000b) sent from the slave device must be detected as a slave address, and so the IIC provides a function for detecting the host address. To detect the host address as a slave address, set the SMBS bit in ICMR3 and the HOAE bit in ICSE to 1. Operation after the host address is detected is the same as normal slave operation.

## 28.14 Interrupt Sources

The IIC issues five types of interrupt requests:

- Transfer error or event generation (arbitration-lost, NACK detection, timeout detection, start condition detection, and stop condition detection)
- Receive data full
- Transmit data empty
- Transmit end
- Address match during wakeup function

[Table 28.10](#) lists details about the interrupt requests. The receive data full and transmit data empty interrupts can activate data transfer by the DTC or DMAC.

**Table 28.10** Interrupt sources

| Symbol                                | Interrupt source                           | Interrupt flag | DTC or DMAC activation | Interrupt condition                                                                  |
|---------------------------------------|--------------------------------------------|----------------|------------------------|--------------------------------------------------------------------------------------|
| IICn_EEI* <sup>5</sup>                | Transfer error or event occurrence         | AL             | Not possible           | AL = 1, ALIE = 1                                                                     |
|                                       |                                            | NACKF          |                        | NACKF = 1, NAKIE = 1                                                                 |
|                                       |                                            | TMOF           |                        | TMOF = 1, TMOIE = 1                                                                  |
|                                       |                                            | START          |                        | START = 1, STIE = 1                                                                  |
|                                       |                                            | STOP           |                        | STOP = 1, SPIE = 1                                                                   |
| IICn_RXI* <sup>2</sup> * <sup>5</sup> | Receive data full                          | RDRF           | Possible               | RDRF = 1, RIE = 1                                                                    |
| IICn_TXI* <sup>1</sup> * <sup>5</sup> | Transmit data empty                        | TDRE           | Possible               | TDRE = 1, TIE = 1                                                                    |
| IICn_TEI* <sup>3</sup> * <sup>5</sup> | Transmit end                               | TEND           | Not possible           | TEND = 1, TEIE = 1                                                                   |
| IIC0_WUI* <sup>4</sup>                | Slave address match during wakeup function | WUF            | Not possible           | Slave address match<br>Slave receive complete<br>RWAK operation ASY0 = 1<br>WUIE = 1 |

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and the actual writing to the module. When an interrupt flag is cleared or masked, read the relevant flag again to check whether clearing or masking is complete, then return from interrupt handling. Not doing so creates the possibility of repeated processing of the same interrupt.

Note 1. Because IICn\_TXI is edge-detected, it does not require clearing. Additionally, the TDRE flag in ICSR2 (condition for IICn\_TXI) is automatically set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).

Note 2. Because IICn\_RXI is edge-detected, it does not require clearing. Additionally, the RDRF flag in ICSR2 (condition for IICn\_RXI) is automatically set to 0 when data is read from ICDRR.

Note 3. When using the IICn\_TEI interrupt, clear the TEND flag in ICSR2 in the IICn\_TEI interrupt handling. The TEND flag in ICSR2 automatically is set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).

Note 4. Only channel 0 has a wakeup function, so IIC0\_WUI is for channel 0 only.

Note 5. Channel number (n = 0).

Clear or mask each flag during interrupt handling.

### 28.14.1 Buffer Operation for IICn\_TXI and IICn\_RXI Interrupts

If the conditions for generating an IICn\_TXI or IICn\_RXI interrupt are satisfied while the associated IR flag is 1, the interrupt request is not output for the ICU but is saved internally. One request per source can be saved internally.

An interrupt request that is saved in the ICU is output when the ICU.IELSRn.IR flag becomes 0. Internally saved interrupt requests are automatically cleared under normal conditions. They can also be cleared by writing 0 to the interrupt enable bit within the associated peripheral module.

## 28.15 State of Registers When Issuing Each Condition

The IIC has two dedicated resets, IIC reset and Internal reset. [Table 28.11](#) lists the registers states when issuing each condition.

**Table 28.11** Register states when issuing each condition (1 of 2)

| Registers |             | Reset    | IIC reset<br>(ICE = 0, IICRST = 1) | Internal reset<br>(ICE = 1, IICRST = 1) | Start or restart<br>condition detection | Stop condition<br>detection |
|-----------|-------------|----------|------------------------------------|-----------------------------------------|-----------------------------------------|-----------------------------|
| ICCR1     | ICE, IICRST | In reset | Saved                              | Saved                                   | Saved                                   | Saved                       |
|           | SCLO, SDAO  |          | In reset                           | In reset                                |                                         |                             |
|           | Others      |          |                                    | Saved                                   |                                         |                             |
| ICCR2     | BBSY        | In reset | In reset                           | Saved                                   | Set                                     | In reset                    |
|           | ST, RS      |          |                                    | In reset                                | In reset                                | Saved                       |
|           | SP          |          |                                    |                                         |                                         | In reset                    |
|           | TRS         |          |                                    |                                         |                                         | Set or saved                |
|           | MST         |          |                                    |                                         |                                         |                             |

**Table 28.11 Register states when issuing each condition (2 of 2)**

| Registers                                  |         | Reset    | IIC reset<br>(ICE = 0, IICRST = 1) | Internal reset<br>(ICE = 1, IICRST = 1) | Start or restart<br>condition detection | Stop condition<br>detection |

## 28.16 Event Link Output

The IIC0 module handles the event output for the Event Link Controller (ELC) for the following sources:

### (1) Transfer error event

When a transfer error event occurs, the associated event signal can be output to another module by the ELC.

### (2) Receive data full

When a receive data register becomes full, the associated event signal can be output to another module by the ELC.

### (3) Transmit data empty

When a transmit data register becomes empty, the associated event signal can be output to another module by the ELC.

### (4) Transmit end

On completion of the transfer, the associated event signal can be output to another module by the ELC.

## 28.16.1 Interrupt Handling and Event Linking

Each of the IIC interrupt types (see [Table 28.10](#)) has an enable bit to control enabling and disabling of the associated interrupt signal. An interrupt request signal is output to the CPU when an interrupt source condition is satisfied while the associated enable bit is set.

The associated event link output signals are sent to other modules as event signals by the ELC when the interrupt source conditions are satisfied, regardless of the interrupt enable bit settings. For details on interrupt sources, see [Table 28.10](#).

## 28.17 Usage Notes

### 28.17.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable IIC operation. The IIC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

### 28.17.2 Notes on Starting Transfer

If the IR flag associated with the IIC interrupt is 1 when transfer is started (ICCR1.ICE bit = 1), follow the procedure in this section to clear the interrupts before enabling operations. Starting transfer with the IR flag set to 1 while the ICCR1.ICE bit is 1 leads to an interrupt request being internally saved after transfer starts, and this can lead to unexpected behavior of the IR flag.

To clear interrupts before starting transfer operation:

1. Confirm that the ICCR1.ICE bit is 0.
2. Set the relevant interrupt enable bits, such as ICIER.TIE to 0.
3. Read the relevant interrupt enable bits, such as ICIER.TIE, and confirm that the value is 0.
4. Set the IR flag to 0.

## 29. Controller Area Network (CAN) Module

### 29.1 Overview

The Controller Area Network (CAN) module uses a message-based protocol to receive and transmit data between multiple slaves and masters in electromagnetically noisy applications. The module complies with the ISO 11898-1 (CAN 2.0A/CAN 2.0B) standard and supports up to 32 mailboxes, which can be configured for transmission or reception in normal mailbox and FIFO modes. Both standard (11-bit) and extended (29-bit) messaging formats are supported. The CAN module requires an additional external CAN transceiver.

Table 29.1 lists the CAN specifications and Figure 29.1 shows a block diagram.

**Table 29.1 CAN specifications (1 of 2)**

| Parameter                            | Specifications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Figure 29.1 CAN module block diagram**

The CAN module includes the following blocks:

- CAN input and output pins  
CRXi and CTXi (i = 0)
- Protocol controller  
Handles CAN protocol processing such as bus arbitration, bit timing during transmission and reception, stuffing, and error handling.
- Mailboxes  
Consists of 32 mailboxes, which can be configured as either transmit or receive. Each mailbox has an individual ID, data length code (DLC), data field (8 bytes), and a time stamp.

- Acceptance filter  
Performs filtering of received messages. MKR0 to MKR7 are used for the filtering process.
- Timer  
Used for the time stamp function. The timer value when a message is stored in the mailbox is written as the time stamp value.
- Interrupt generator for five types of interrupts:
  - CANi reception complete interrupt
  - CANi transmission complete interrupt
  - CANi receive FIFO interrupt
  - CANi transmit FIFO interrupt
  - CANi error interrupt

Table 29.2 lists the CAN module pins. These pins are multiplexed with other signals on the MCU. For details, see [section 19, I/O Ports](#).

**Table 29.2 CAN module I/O pins (i = 0)**

| Pin name | I/O    | Function      |
|----------|--------|---------------|
| CRXi     | Input  | Data receive  |
| CTXi     | Output | Data transmit |

| 15:14 | —         | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                         | R/W |

Note 1. Write to the BOM[1:0], TSPS[1:0], TPM, MLM, IDFM[1:0], and MBM bits in CAN reset mode.

Note 2. Set the RBOC bit to 1 in the bus-off state.

Note 3. This bit is automatically set to 0 after being set to 1. It should read as 0.

Note 4. Set the TSRC bit to 1 in CAN operation mode.

Note 5. When the CANM[1:0] and SLPM bits are changed, check STR to ensure that the mode is switched. Do not change the CANM[1:0] bits or SLPM bit until the mode is switched.

Note 6. Write to the SLPM bit in CAN reset mode or CAN halt mode. When changing the SLPM bit, write 0 or 1 only to the SLPM bit.

### MBM bit (CAN Mailbox Mode Select)

When the MBM bit is 0 (normal mailbox mode), mailboxes 0 to 31 are configured as transmit or receive mailboxes. When the MBM bit is 1 (FIFO mailbox mode):

- Mailboxes 0 to 23 are configured as transmit or receive mailboxes
- Mailboxes 24 to 27 are configured as transmit FIFO
- Mailboxes 28 to 31 are configured as receive FIFO

Transmit data is written into mailbox 24, a window mailbox for the transmit FIFO. Receive data is read from mailbox 28, a window mailbox for the receive FIFO.

Table 29.3 lists the mailbox configuration.

### IDFM[1:0] bits (ID Format Mode Select)

The IDFM[1:0] bits specify the ID format.

### MLM bit (Message Lost Mode Select)

The MLM bit specifies the operation when a new message is captured in an unread mailbox. Overwrite mode or overrun mode can be selected. In both cases, the mode applies to all mailboxes, including the receive FIFO.

When the MLM bit is 0, all mailboxes are set to overwrite mode. Any new message received overwrites the pre-existing message.

When the MLM bit is 1, all mailboxes are set to overrun mode. Any new message received does not overwrite the pre-existing message, and it is discarded.

#### **TPM bit (Transmission Priority Mode Select)**

The TPM bit specifies the priority when transmitting messages. ID priority transmit mode or mailbox number transmit mode can be selected. All mailboxes are set for either ID priority transmission or mailbox number priority transmission.

When TPM is 0, ID priority transmit mode is selected and transmission priority is arbitrated as defined in the ISO11898-1 CAN specification. In ID priority transmit mode, mailboxes 0 to 31 (in normal mailbox mode), and mailboxes 0 to 23 (in FIFO mailbox mode), and the transmit FIFO are compared for the IDs of mailboxes configured for transmission. If two or more mailbox IDs are the same, the mailbox with the smaller number has higher priority.

Only the next message to be transmitted from the transmit FIFO is included in the transmission arbitration. If a FIFO message is being transmitted, the next pending message within the transmit FIFO is included in the transmission arbitration.

When TPM is 1, mailbox number transmit mode is selected and the transmit mailbox with the smallest mailbox number has the highest priority. In FIFO mailbox mode, the transmit FIFO has lower priority than normal mailboxes (0 to 23).

#### **TSRC bit (Time Stamp Counter Reset Command)**

The TSRC bit resets the time stamp counter. When it is set to 1, TSR is set to 0x0000. TSRC is set to 0 automatically.

#### **TSPS[1:0] bits (Time Stamp Prescaler Select)**

The TSPS[1:0] bits select the prescaler for the time stamp. The reference clock for the time stamp can be selected to 1-bit, 2-bit, 4-bit, or 8-bit time periods.

#### **CANM[1:0] bits (CAN Operating Mode Select)**

The CANM[1:0] bits select one of the following modes for the CAN module:

- CAN operation mode
- CAN reset mode
- CAN halt mode

The CAN sleep mode is set in the SLPM bit. For details, see [section 29.3. Operation Modes](#).

When the CAN module enters CAN halt mode based on the BOM[1:0] setting, the CANM[1:0] bits are automatically set to 10b.

#### **SLPM bit (CAN Sleep Mode)**

When the SLPM bit is set to 1, the CAN module enters CAN sleep mode. When the SLPM bit is set to 0, the CAN module exits CAN sleep mode. For details, see [section 29.3. Operation Modes](#).

#### **BOM[1:0] bits (Bus-Off Recovery Mode)**

The BOM[1:0] bits select bus-off recovery mode for the CAN module.

When the BOM[1:0] bits are 00b, the recovery from bus-off is compliant with the ISO11898-1 CAN specification. The CAN module recovers CAN communication (error-active state) after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request occurs when recovering from bus-off.

When the BOM[1:0] bits are 01b and the CAN module reaches the bus-off state, the CANM[1:0] bits in CTRL are set to 10b to enter CAN halt mode. No bus-off recovery interrupt request occurs when recovering from bus-off, and TECR and RECR are set to 0x00.

When the BOM[1:0] bits are 10b, the CANM[1:0] bits are set to 10b as soon as the CAN module reaches the bus-off state. The CAN module enters CAN halt mode after the recovery from the bus-off state, and after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request occurs when recovering from bus-off, and TECR and RECR are set to 0x00.

When the BOM[1:0] bits are 11b, the CAN module enters CAN halt mode by setting the CANM[1:0] bits to 10b while the CAN module is still in the bus-off state. No bus-off recovery interrupt request occurs when recovering from bus-off, and TECR and RECR are set to 0x00. However, if the CAN module recovers from bus-off after detecting 11 consecutive recessive bits 128 times before the CANM[1:0] bits are set to 10b, a bus-off recovery interrupt request is generated.

If the CPU requests an entry to CAN reset mode at the same time as the CAN module attempts to enter CAN halt mode (at bus-off entry when the BOM[1:0] bits are 01b, or at bus-off end when the BOM[1:0] bits are 10b), then the CPU request has higher priority.

**RBOC bit (Forcible Return from Bus-Off)**

When the RBOC bit is set to 1 in the bus-off state, the CAN module forcibly exits the bus-off state. It is set to 0 automatically, and the error state changes from bus-off to error-active. When the RBOC bit is set to 1, RECR and TECR are set to 0x00 and the BOST bit in STR is set to 0, indicating that the CAN module is not in bus-off state. The other registers remain unchanged when RBOC is set to 1. No bus-off recovery interrupt request occurs by this recovery from the bus-off state. Use the RBOC bit only when the BOM[1:0] bits are 00b (normal mode).

**Table 29.3 Mailbox configuration**

| Mailbox            | MBM bit = 0 (normal mailbox mode) | MBM bit = 1 (FIFO mailbox mode)*1 *2 *3 *4 *5 |
|--------------------|-----------------------------------|-----------------------------------------------|
| Mailboxes 0 to 23  | Normal mailbox                    | Normal mailbox                                |
| Mailboxes 24 to 27 |                                   | Transmit FIFO                                 |
| Mailboxes 28 to 31 |                                   | Receive FIFO                                  |

- Note 1. The transmit FIFO is controlled by TFCR. The MCTL\_TX[j] registers associated with mailboxes 24 to 27 are disabled. MCTL\_TX[24] to MCTL\_TX[27] cannot be used by the transmit FIFO.
- Note 2. The receive FIFO is controlled by RFCR. The MCTL\_RX[j] registers associated with mailboxes 28 to 31 are disabled. MCTL\_RX[28] to MCTL\_RX[31] cannot be used by the receive FIFO.
- Note 3. See the MIER\_FIFO description for information on the FIFO interrupts.
- Note 4. The bits in MKIVLR associated with mailboxes 24 to 31 are disabled. Set these bits to 0.
- Note 5. The transmit and receive FIFOs can be used for both data frames and remote frames.

**29.2.2 BCR : Bit Configuration Register**

Base address: CAN0 = 0x400A\_8000

Offset address: 0x844

| Bit  | Symbol     | Function                                                                                                                                                     | R/W |

| 15:14 | —          | These bits are read as 0. The write value should be 0.                                                                                                                                                                               | R/W |
| 25:16 | BRP[9:0]   | Baud Rate Prescaler Select* <sup>1</sup><br>These bits set the frequency of the CAN communication clock (fCANCLK).                                                                                                                   | R/W |
| 27:26 | —          | These bits are read as 0. The write value should be 0.                                                                                                                                                                               | R/W |
| 31:28 | TSEG1[3:0] | Time Segment 1 Control<br>0x3: 4 Tq<br>0x4: 5 Tq<br>0x5: 6 Tq<br>0x6: 7 Tq<br>0x7: 8 Tq<br>0x8: 9 Tq<br>0x9: 10 Tq<br>0xA: 11 Tq<br>0xB: 12 Tq<br>0xC: 13 Tq<br>0xD: 14 Tq<br>0xE: 15 Tq<br>0xF: 16 Tq<br>Others: Setting prohibited | R/W |

Note: Tq: Time Quantum

Note 1. Do not select a value less than or equal to 1 while the SCKSCR.CKSEL[2:0] bits are 011b (selecting the main clock oscillator).

For details about setting the bit timing, see [section 29.4. Data Transfer Rate Configuration](#). Set BCR before entering CAN halt or CAN operation mode from CAN reset mode. After the setting is made once, this register can be written to in CAN reset or CAN halt mode. A 32-bit read/write accesses must be performed carefully so as not to change bits [7:0].

### CCLKS bit (CAN Clock Source Selection)

The CCLKS bit selects CAN clock source. When the CCLKS bit is 0, the peripheral module clock (PCLKB) produced by the PLL frequency synthesizer is used as the CAN clock source (fCAN). When the CCLKS bit is 1, CANMCLK produced externally by the EXTAL pins is used as the CAN clock source (fCAN).

### TSEG2[2:0] bits (Time Segment 2 Control)

The TSEG2[2:0] bits specify the length of the phase buffer segment 2 (PHASE\_SEG2) with a Tq value. A value from 2 to 8 Tq can be set. Set a value smaller than that in the TSEG1[3:0] bits.

### SJW[1:0] bits (Synchronization Jump Width Control)

The SJW[1:0] bits specify the synchronization jump width with a Tq value. A value from 1 to 4 Tq can be set. Set a value smaller than or equal to that in the TSEG2[2:0] bits.

### BRP[9:0] bits (Baud Rate Prescaler Select)

The BRP[9:0] bits set the frequency of the CAN communication clock (fCANCLK). The fCANCLK cycle is 1 Tq. If the setting is P (0 to 1023), the baud rate prescaler divides fCAN by P + 1.

### TSEG1[3:0] bits (Time Segment 1 Control)

The TSEG1[3:0] bits specify the total length of the propagation time segment (PROP\_SEG) and phase buffer segment 1 (PHASE\_SEG1) with a time quantum (Tq) value. A value from 4 to 16 Tq can be set.

### 29.2.3 MKR[k] : Mask Register k (k = 0 to 7)

Base address: CAN0 = 0x400A\_8000

Offset address: 0x400 + 0x04 × k

| Bit   | Symbol    | Function                                                                                           | R/W |
|-------|-----------|----------------------------------------------------------------------------------------------------|-----|
| 17:0  | EID[17:0] | Extended ID<br>0: Do not compare associated EID[17:0] bits<br>1: Compare associated EID[17:0] bits | R/W |
| 28:18 | SID[10:0] | Standard ID<br>0: Do not compare associated SID[10:0] bits<br>1: Compare associated SID[10:0] bits | R/W |
| 31:29 | —         | The read values are undefined. The write value should be 0.                                        | R/W |

For the mask function in FIFO mailbox mode, see [section 29.6. Acceptance Filtering and Masking Functions](#).

Write to MKR0 to MKR7 in CAN reset mode or CAN halt mode.

#### EID[17:0] bits (Extended ID)

The EID[17:0] bits are the filter mask bits associated with the CAN extended ID bits. They are used to receive extended ID messages. When an EID[17:0] bit is set to 0, the received ID is not compared with the associated mailbox ID. When an EID[17:0] bit is set to 1, the received ID is compared with the associated mailbox ID.

#### SID[10:0] bits (Standard ID)

The SID[10:0] bits are the filter mask bits associated with the CAN standard ID bits. They are used to receive both standard ID and extended ID messages. When an SID[10:0] bit is set to 0, the received ID is not compared with the associated mailbox ID. When an SID[10:0] bit is set to 1, the received ID is compared with the associated mailbox ID.

### 29.2.4 FIDCRk : FIFO Received ID Compare Register k (k = 0, 1)

Base address: CAN0 = 0x400A\_8000

Offset address: 0x420 + 0x04 × k

| Bit   | Symbol    | Function                                                        | R/W |
|-------|-----------|-----------------------------------------------------------------|-----|
| 17:0  | EID[17:0] | Extended ID of data and remote frames                           | R/W |
| 28:18 | SID[10:0] | Standard ID of data and remote frames                           | R/W |
| 29    | —         | The read value is undefined. The write value should be 0.       | R/W |
| 30    | RTR       | Remote Transmission Request<br>0: Data frame<br>1: Remote frame | R/W |
| 31    | IDE       | ID Extension*1<br>0: Standard ID<br>1: Extended ID              | R/W |

Note 1. The IDE bit is enabled when the CTLR.IDFM[1:0] bits are 10b (mixed ID mode). When the IDFM[1:0] bits are not 10b, only write 0 to IDE. It reads as 0.

FIDCR0 and FIDCR1 are enabled when the MBM bit in CTRL is set to 1 (FIFO mailbox mode). In this mode, the EID[17:0], SID[10:0], RTR, and IDE bits in mailboxes 28 to 31 are disabled. Write to FIDCR0 and FIDCR1 in CAN reset mode or CAN halt mode. For information on using FIDCR0 and FIDCR1, see [section 29.6. Acceptance Filtering and Masking Functions](#).

### EID[17:0] bits (Extended ID of data and remote frames)

The EID[17:0] bits set the extended ID of data frames and remote frames. These bits are used to receive extended ID messages.

### SID[10:0] bits (Standard ID of data and remote frames)

The SID[10:0] bits set the standard ID of data frames and remote frames. These bits are used to receive both standard ID and extended ID messages.

### RTR bit (Remote Transmission Request)

The RTR bit sets the frame format to data frames or remote frames:

- When the RTR bits in both FIDCR0 and FIDCR1 registers are set to 0, only data frames are received
- When the RTR bits in both FIDCR0 and FIDCR1 registers are set to 1, only remote frames are received
- When the RTR bits in both FIDCR0 and FIDCR1 registers are set to different values, both data frames and remote frames are received

### IDE bit (ID Extension)

The IDE bit sets the ID format to standard ID or extended ID. The IDE bit is enabled when the IDFM[1:0] bits in CTRL are 10b (mixed ID mode):

- When the IDE bits in both FIDCR0 and FIDCR1 registers are set to 0, only standard ID frames are received
- When the IDE bits in both FIDCR0 and FIDCR1 registers are set to 1, only extended ID frames are received
- When the IDE bits in both FIDCR0 and FIDCR1 registers are set to different values, both standard ID and extended ID frames are received

## 29.2.5 MKIVLR : Mask Invalid Register

Base address: CAN0 = 0x400A\_8000

Offset address: 0x428

|                    |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|--------------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| Bit position:      | 31   | 30   | 29   | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Bit field:         | MB31 | MB30 | MB29 | MB28 | MB27 | MB26 | MB25 | MB24 | MB23 | MB22 | MB21 | MB20 | MB19 | MB18 | MB17 | MB16 |
| Value after reset: | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    |
| Bit position:      | 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Bit field:         | MB15 | MB14 | MB13 | MB12 | MB11 | MB10 | MB9  | MB8  | MB7  | MB6  | MB5  | MB4  | MB3  | MB2  | MB1  | MB0  |
| Value after reset: | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    |

| Bit  | Symbol      | Function                                         | R/W |
|------|-------------|--------------------------------------------------|-----|
| 31:0 | MB31 to MB0 | Mask Invalid<br>0: Mask valid<br>1: Mask invalid | R/W |

Each bit in MKIVLR is associated with a mailbox of the same number. Bit [0] in MKIVLR corresponds to mailbox 0 (MB0), and bit [31] corresponds to mailbox 31 (MB31).<sup>\*1</sup>

When a bit is set to 1, the associated acceptance mask register becomes invalid for the associated mailbox. When a mask invalid bit is set to 1, a message is received by the associated mailbox only if the receive message ID matches the mailbox ID exactly.

Write to MKIVLR in CAN reset or halt mode.

Note 1. Set bits [31:24] to 0 in FIFO mailbox mode.

### 29.2.6 Mailbox Registers

Table 29.4 lists the CANi mailbox memory mapping, and Table 29.5 lists the CAN data frame configuration.

The value of the CANi mailbox after reset is undefined.

Write to MBj\_ID, MBj\_DL, MBj\_Dm, and MBj\_TS only when the related MCTL\_TX[j] or MCTL\_RX[j] register (j = 0 to 31) is 0x00 and the associated mailbox is not processing an abort request.

See Table 29.4 for detailed on register addresses.

**Table 29.4 CANi mailbox memory mapping (i = 0)**

| Address                              | Message content             |
|--------------------------------------|-----------------------------|
| <b>CANn (n = 0)</b>                  | <b>Memory mapping</b>       |
| 0x4005_0200 + 1000 × n + 16 × j + 0  | IDE, RTR, SID10 to SID6     |
| 0x4005_0200 + 1000 × n + 16 × j + 1  | SID5 to SID0, EID17, EID16  |

The previous value of each mailbox is retained unless a new message is received.

#### 29.2.6.1 MBj\_ID : Mailbox ID Register j (j = 0 to 31)

Base address: CAN0 = 0x400A\_8000

Offset address: 0x200 + 0x10 × j

|                    |           |     |    |           |    |    |    |    |    |    |    |    |    |           |    |    |
|--------------------|-----------|-----|----|-----------|----|----|----|----|----|----|----|----|----|-----------|----|----|
| Bit position:      | 31        | 30  | 29 | 28        | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18        | 17 | 16 |
| Bit field:         | IDE       | RTR | —  | SID[10:0] |    |    |    |    |    |    |    |    |    | EID[17:0] |    |    |
| Value after reset: | x         | x   | x  | x         | x  | x  | x  | x  | x  | x  | x  | x  | x  | x         | x  | x  |
| Bit position:      | 15        | 14  | 13 | 12        | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2         | 1  | 0  |
| Bit field:         | EID[17:0] |     |    |           |    |    |    |    |    |    |    |    |    |           |    |    |
| Value after reset: | x         | x   | x  | x         | x  | x  | x  | x  | x  | x  | x  | x  | x  | x         | x  | 0  |

| Bit   | Symbol    | Function                                                        | R/W |
|-------|-----------|-----------------------------------------------------------------|-----|
| 17:0  | EID[17:0] | Extended ID of data and remote frames*1                         | R/W |
| 28:18 | SID[10:0] | Standard ID of data and remote frames                           | R/W |
| 29    | —         | The read value is undefined. The write value should be 0.       | R/W |
| 30    | RTR       | Remote Transmission Request<br>0: Data frame<br>1: Remote frame | R/W |
| 31    | IDE       | ID Extension*2<br>0: Standard ID<br>1: Extended ID              | R/W |

Note 1. If the mailbox receives a standard ID message, the EID bits in the mailbox are undefined.

Note 2. The IDE bit is enabled when the CTLR.IDFM[1:0] bits are 10b (mixed ID mode). When the IDFM[1:0] bits are not 10b, only write 0 to IDE. It reads as 0.

### EID[17:0] bits (Extended ID of data and remote frames)

The EID[17:0] bits set the extended ID of data frames and remote frames. They are used to transmit or receive extended ID messages.

### SID[10:0] bits (Standard ID of data and remote frames)

The SID[10:0] bits set the standard ID of data frames and remote frames. They are used to transmit or receive both standard ID and extended ID messages.

### RTR bit (Remote Transmission Request)

The RTR bit sets the frame format of data frames or remote frames.

- The receive mailbox only receives frames with the format specified in the RTR bit
- The transmit mailbox transmits with the frame format specified in the RTR bit
- The receive FIFO mailbox receives the data frame, remote frame, or both frames specified in the RTR bit in FIDCR0 and FIDCR1
- The transmit FIFO mailbox transmits the data frame or remote frame specified in the RTR bit in the transmit message

### IDE bit (ID Extension)

The IDE bit sets the ID format to standard IDs or extended IDs. The IDE bit is enabled when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode).

- The receive mailbox only receives the ID format specified in the IDE bit
- The transmit mailbox transmits with the ID format specified in the IDE bit
- The receive FIFO mailbox receives messages with the standard ID and extended ID settings specified in the IDE bit in FIDCR0 and FIDCR1
- The transmit FIFO mailbox transmits messages with the standard ID or extended ID settings specified in the IDE bit in the transmit message

## 29.2.6.2 MBj\_DL : Mailbox Data Length Register j (j = 0 to 31)

Base address: CAN0 = 0x400A\_8000

Offset address: 0x204 + 0x10 × j

| Bit position:      | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3        | 2 | 1 | 0 |
|--------------------|----|----|----|----|----|----|---|---|---|---|---|---|----------|---|---|---|
| Bit field:         | —  | —  | —  | —  | —  | —  | — | — | — | — | — | — | DLC[3:0] |   |   |   |
| Value after reset: | x  | x  | x  | x  | x  | x  | x | x | x | x | x | x | x        | x | x | x |

| Bit  | Symbol   | Function                                                                                                                                                                                                                                                                                          | R/W |
|------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 3:0  | DLC[3:0] | Data Length Code*1<br>0x0: Data length = 0 byte<br>0x1: Data length = 1 byte<br>0x2: Data length = 2 bytes<br>0x3: Data length = 3 bytes<br>0x4: Data length = 4 bytes<br>0x5: Data length = 5 bytes<br>0x6: Data length = 6 bytes<br>0x7: Data length = 7 bytes<br>Others: Data length = 8 bytes | R/W |
| 15:4 | —        | The read values are undefined. The write value should be 0.                                                                                                                                                                                                                                       | R/W |

Note 1. If the mailbox receives a message with data length (set in DLC[3:0]) of n bytes, where n is less than 8, the data in DATA<sub>n</sub> to DATA<sub>7</sub> registers in the mailbox is undefined. DATA<sub>0</sub> to DATA<sub>7</sub> are data registers for this mailbox. For example, if data length is 6 bytes (DLC[3:0] = 0x6), the data in DATA<sub>6</sub> and DATA<sub>7</sub> registers is undefined.

### DLC[3:0] bits (Data Length Code)

The DLC[3:0] bits specify the data length to be transmitted in data frames. When a remote frame is used to request data, this field specifies the requested data length.

When a data frame is received, the received data length is stored in this field. When a remote frame is received, this field stores the requested data length.

#### 29.2.6.3 MB<sub>j</sub>\_D<sub>m</sub> : Mailbox Data Register j (j = 0 to 31, m = 0 to 7)

Base address: CAN0 = 0x400A\_8000

Offset address: (0x206 + m) + 0x10 × j

Bit position: 7 6 5 4 3 2 1 0

Value after reset: x x x x x x x x

| Bit | Symbol                                 | Function                                                                                                                                                                                                                                                                     | R/W |
|-----|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 7:0 | DATA <sub>0</sub> to DATA <sub>7</sub> | Data Bytes 0 to 7*1 *2<br>DATA <sub>0</sub> to DATA <sub>7</sub> store the transmitted or received CAN message data. Transmission or reception starts from DATA <sub>0</sub> . The bit order on the CAN bus is MSB-first, and transmission or reception starts from bit [7]. | R/W |

Note 1. If the mailbox receives a message with n bytes, where n is less than 8 bytes, the values of DATA<sub>n</sub> to DATA<sub>7</sub> in the mailbox are undefined.

Note 2. If the mailbox receives a remote frame, the previous values of DATA<sub>0</sub> to DATA<sub>7</sub> in the mailbox are saved.

#### 29.2.6.4 MB<sub>j</sub>\_TS : Mailbox Time Stamp Register j (j = 0 to 31)

Base address: CAN0 = 0x400A\_8000

Offset address: 0x20E + 0x10 × j

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Value after reset: x x x x x x x x x x x x x x x x

| Bit | Symbol   | Function                                                                                                                                            | R/W |
|-----|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 7:0 | TSL[7:0] | Time Stamp Lower Byte<br>The TSH[7:0] and TSL[7:0] bits store the counter value of the time stamp when received messages are stored in the mailbox. | R/W |

| Bit  | Symbol   | Function                                                                                                                                             | R/W |

| Value after reset: | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    | x    |

| Bit  | Symbol      | Function                                                                                                                                            | R/W |
|------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 31:0 | MB31 to MB0 | Interrupt Enable<br>Bit [31] is associated with mailbox 31 (MB31), and bit [0] with mailbox 0 (MB0).<br>0: Disable interrupt<br>1: Enable interrupt | R/W |

MIER can enable interrupts for each mailbox independently. This register is available in normal mailbox mode. Do not access this register in FIFO mailbox mode.

Each bit is associated with the mailbox having the same number. These bits enable or disable transmission and reception complete interrupts for the associated mailboxes as follows:

- Bit [0] in MIER corresponds to mailbox 0 (MB0)
- Bit [31] in MIER corresponds to mailbox 31 (MB31)

Write to MIER only when the associated MCTL\_TX[j] or MCTL\_RX[j] register (j = 0 to 31) is 0x00 and the associated mailbox is not processing a transmission or reception abort request.

### 29.2.8 MIER\_FIFO : Mailbox Interrupt Enable Register for FIFO Mailbox Mode

Base address: CAN0 = 0x400A\_8000

Offset address: 0x42C

| 27:26 | —      | The read values are undefined. The write value should be 0.                                                                                                                                                      | R/W |
| 28    | MB28   | Receive FIFO Interrupt Enable<br>0: Disable interrupt<br>1: Enable interrupt                                                                                                                                     | R/W |
| 29    | MB29   | Receive FIFO Interrupt Generation Timing Control* <sup>1</sup><br>0: Generate every time reception completes<br>1: Generate when the receive FIFO becomes a buffer warning* <sup>2</sup> on reception completion | R/W |
| 31:30 | —      | The read values are undefined. The write value should be 0.                                                                                                                                                      | R/W |

Note 1. No interrupt request occurs when the receive FIFO becomes buffer warning because it is full.

Note 2. Buffer warning indicates a state in which the third message is stored in the receive FIFO.

MIER\_FIFO can independently enable interrupts for each mailbox and FIFO. This register is available in FIFO mailbox mode. Do not access it in normal mailbox mode.

The MB0 to MB23 bits are associated with the mailbox of the same number. These bits enable or disable transmission and reception complete interrupts for the associated mailboxes:

- Bit [0] in MIER\_FIFO is associated with mailbox 0 (MB0)
- Bit [23] in MIER\_FIFO is associated with mailbox 23 (MB23)

MB24, MB25, MB28, and MB29 specify whether transmit and receive FIFO interrupts are enabled or disabled, and the timing of interrupt requests.

Write to MIER\_FIFO only when the associated MCTL\_TX[j] or MCTL\_RX[j] register (j = 0 to 31) is 0x00 and the associated mailbox is not processing a transmission or reception abort request. In addition, change the bits in MIER\_FIFO for the associated FIFO only when all of the following conditions are true:

- The TFE bit in TFCR is 0 and the TFEST bit is 1.
- The RFE bit in RFCR is 0 and the RFEST bit in RFCR is 1.

### 29.2.9 MCTL\_TX[j] : Message Control Register for Transmit (j = 0 to 31)

Base address: CAN0 = 0x400A\_8000

Offset address: 0x820 + 0x01 × j

|                    |            |            |   |             |   |            |               |              |
|--------------------|------------|------------|---|-------------|---|------------|---------------|--------------|
| Bit position:      | 7          | 6          | 5 | 4           | 3 | 2          | 1             | 0            |
| Bit field:         | TRMR<br>EQ | RECR<br>EQ | — | ONES<br>HOT | — | TRMA<br>BT | TRMA<br>CTIVE | SENT<br>DATA |
| Value after reset: | 0          | 0          | 0 | 0           | 0 | 0          | 0             | 0            |

| Bit | Symbol    | Function                                                                                                                                                                                                                     | R/W |
|-----|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 0   | SENTDATA  | Transmission Complete Flag* <sup>1</sup> * <sup>2</sup><br>0: Transmission not complete<br>1: Transmission complete                                                                                                          | R/W |
| 1   | TRMACTIVE | Transmission-in-Progress Status Flag<br>0: Transmission pending or not requested<br>1: Transmission in progress                                                                                                              | R   |
| 2   | TRMABT    | Transmission Abort Complete Flag* <sup>1</sup> * <sup>2</sup><br>0: Transmission started, transmission abort failed because transmission completed,<br>or transmission abort not requested<br>1: Transmission abort complete | R/W |

| Bit | Symbol  | Function                                                                                               | R/W |
|-----|---------|--------------------------------------------------------------------------------------------------------|-----|
| 3   | —       | This bit is read as 0. The write value should be 0.                                                    | R/W |
| 4   | ONESHOT | One-Shot Enable*2 *3<br>0: Disable one-shot transmission<br>1: Enable one-shot transmission            | R/W |
| 5   | —       | This bit is read as 0. The write value should be 0.                                                    | R/W |
| 6   | RECREQ  | Receive Mailbox Request*2 *3 *4 *5<br>0: Do not configure for reception<br>1: Configure for reception  | R/W |
| 7   | TRMREQ  | Transmit Mailbox Request*2 *4<br>0: Do not configure for transmission<br>1: Configure for transmission | R/W |

Note 1. Write 0 only. Writing 1 has no effect.

Note 2. When writing to bits of this register, write 1 to SENTDATA and TRMABT flags if these bits are not the write target.

Note 3. To enter one-shot transmit mode, write 1 to the ONESHOT bit at the same time as setting the TRMREQ bit to 1. To exit one-shot transmit mode, write 0 to the ONESHOT bit after the message is transmitted or aborted.

Note 4. Do not set both the RECREQ and TRMREQ bits to 1.

Note 5. When setting the RECREQ bit to 0, set the SENTDATA, TRMACTIVE, and TRMABT flags to 0 simultaneously.

MCTL\_TX[j] sets mailbox j to transmit mode or receive mode. In transmit mode, MCTL\_TX[j] also controls and indicates the transmission status. Do not access MCTL\_TX[j] if mailbox j is in receive mode. Only write to MCTL\_TX[j] in CAN operation or halt mode. Do not use MCTL\_TX24 to MCTL\_TX31 in FIFO mailbox mode.

### SENTDATA flag (Transmission Complete Flag)

The SENTDATA flag is set to 1 when data transmission from the associated mailbox is complete. This flag is set to 0 through a software write. To set this flag to 0, first set the TRMREQ bit to 0. The SENTDATA flag and the TRMREQ bit cannot be set to 0 simultaneously. To transmit a new message from the associated mailbox, set the SENTDATA flag to 0.

### TRMACTIVE flag (Transmission-in-Progress Status Flag)

The TRMACTIVE flag is set to 1 when the associated mailbox of the CAN module begins to transmit a message. It is set to 0 when the CAN module loses the CAN bus arbitration, when a CAN bus error occurs, or when data transmission completes.

### TRMABT flag (Transmission Abort Complete Flag)

The TRMABT flag is set to 1 in the following cases:

- Following a transmission abort request, when the transmission abort is complete before starting transmission
- Following a transmission abort request, when the CAN module detects CAN bus arbitration-lost or a CAN bus error
- In one-shot transmission mode (RECREQ = 0, TRMREQ = 1, and ONESHOT = 1), when the CAN module detects a CAN bus arbitration-lost or a CAN bus error.

The TRMABT flag is not set to 1 when data transmission is complete. The SENTDATA flag is set to 1, and the TRMABT flag is set to 0 through a software write.

### ONESHOT bit (One-Shot Enable)

When the ONESHOT bit is set to 1 in transmit mode (RECREQ = 0 and TRMREQ = 1), the CAN module transmits a message only one time. The CAN module does not transmit the message again if a CAN bus error or CAN bus arbitration-lost occurs. When transmission is complete, the SENTDATA flag is set to 1. If transmission does not complete because of a CAN bus error or CAN bus arbitration-lost error, the TRMABT flag is set to 1. Set the ONESHOT bit to 0 after the SENTDATA or TRMABT flag is set to 1.

### RECREQ bit (Receive Mailbox Request)

The RECREQ bit selects the receive modes listed in [Table 29.10](#).

When the RECREQ bit is set to 1, the associated mailbox is configured for reception of a data or remote frame.

When the RECREQ bit is set to 0, the associated mailbox is not configured for reception of a data or remote frame.

Due to hardware protection, the RECREQ bit cannot be set to 0 through a software write during the following period:

- Hardware protection is started from the acceptance filter processing (the beginning of the CRC field)
- Hardware protection is released:
  - For the mailbox that is specified to receive the incoming message, after the received data is stored in the mailbox or a CAN bus error occurs. This means that the maximum period of hardware protection is from the beginning of CRC field to the end of the 7th bit of EOF.
  - For the other mailboxes, after acceptance filter processing
  - If no mailbox is specified to receive the message, after acceptance filter processing.

When setting the RECREQ bit to 1, do not set the TRMREQ bit to 1. To change the configuration of a mailbox from transmission to reception, first abort the transmission, then set the SENTDATA and TRMABT flags to 0 before changing to reception.

Note: MCTL\_TX[j].RECREQ is the mirror bit of MCTL\_RX[j].RECREQ.

### TRMREQ bit (Transmit Mailbox Request)

The TRMREQ bit selects the transmit modes listed in [Table 29.10](#).

When the TRMREQ bit is set to 1, the associated mailbox is configured for transmission of a data or remote frame.

When the TRMREQ bit is set to 0, the associated mailbox is not configured for transmission of a data or remote frame.

If the TRMREQ bit is changed from 1 to 0 to cancel the associated transmission request, either the TRMABT or SENTDATA flag is set to 1. When setting the TRMREQ bit to 1, do not set the RECREQ bit to 1. To change the configuration of a mailbox from reception to transmission, first abort the reception, then set the NEWDATA and MSGLOST flags to 0 before changing to transmission.

Note: MCTL\_TX[j].TRMREQ is the mirror bit of MCTL\_RX[j].TRMREQ.

## 29.2.10 MCTL\_RX[j] : Message Control Register for Receive (j = 0 to 31)

Base address: CAN0 = 0x400A\_8000

Offset address: 0x820 + 0x01 × j

|               |            |            |   |             |   |             |               |             |
|---------------|------------|------------|---|-------------|---|-------------|---------------|-------------|
| Bit position: | 7          | 6          | 5 | 4           | 3 | 2           | 1             | 0           |
| Bit field:    | TRMR<br>EQ | RECR<br>EQ | — | ONES<br>HOT | — | MSGL<br>OST | INVAL<br>DATA | NEWD<br>ATA |

Value after reset: 0 0 0 0 0 0 0 0 0

| Bit | Symbol    | Function                                                                                                                                                  | R/W |
|-----|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 0   | NEWDATA   | Reception Complete Flag <sup>*1 *2</sup><br>0: No data received, or 0 was written to the flag<br>1: New message being stored or was stored in the mailbox | R/W |
| 1   | INVALDATA | Reception-in-Progress Status Flag<br>0: Message valid<br>1: Message being updated                                                                         | R   |
| 2   | MSGLOST   | Message Lost Flag <sup>*1 *2</sup><br>0: Message not overwritten or overrun<br>1: Message overwritten or overrun                                          | R/W |
| 3   | —         | This bit is read as 0. The write value should be 0.                                                                                                       | R/W |
| 4   | ONESHOT   | One-Shot Enable <sup>*2 *3</sup><br>0: Disable one-shot reception<br>1: Enable one-shot reception                                                         | R/W |
| 5   | —         | This bit is read as 0. The write value should be 0.                                                                                                       | R/W |
| 6   | RECREQ    | Receive Mailbox Request <sup>*2 *3 *4 *5</sup><br>0: Do not configure for reception<br>1: Configure for reception                                         | R/W |

| Bit | Symbol | Function                                                                                               | R/W |
|-----|--------|--------------------------------------------------------------------------------------------------------|-----|
| 7   | TRMREQ | Transmit Mailbox Request*2 *4<br>0: Do not configure for transmission<br>1: Configure for transmission | R/W |

Note 1. Write 0 only. Writing 1 has no effect.

Note 2. When writing to bits of this register, write 1 to the NEWDATA and MSGLOST flags if they are not the write target.

Note 3. To enter one-shot receive mode, write 1 to the ONESHOT bit at the same time as setting the RECREQ bit to 1. To exit one-shot receive mode, write 0 to the ONESHOT bit after writing 0 to the RECREQ bit and confirming that it is 0.

Note 4. Do not set both the RECREQ and TRMREQ bits to 1.

Note 5. When setting the RECREQ bit to 0, set MSGLOST, NEWDATA, and RECREQ to 0 simultaneously.

MCTL\_RX[j] sets mailbox j to transmit or receive mode. In receive mode, MCTL\_RX[j] also controls and indicates the reception status. Do not access MCTL\_RX[j] if mailbox j is in transmit mode. Only write to the MCTL\_RX[j] in CAN operation or halt mode. Do not use MCTL\_RX24 to MCTL\_RX31 in FIFO mailbox mode.

### NEWDATA flag (Reception Complete Flag)

The NEWDATA flag is set to 1 when a new message is being stored or was stored in the mailbox. Always set this bit to 1 simultaneously with the INVALIDDATA flag. The NEWDATA flag is set to 0 through a software write. The NEWDATA flag cannot be set to 0 through a software write while the associated INVALIDDATA flag is 1.

### INVALIDDATA flag (Reception-in-Progress Status Flag)

After the completion of a message reception, the INVALIDDATA flag is set to 1 while the received message is updated in the associated mailbox. The INVALIDDATA flag is set to 0 immediately after the message is stored. If the mailbox is read while the INVALIDDATA flag is 1, the data is undefined.

### MSGLOST flag (Message Lost Flag)

The MSGLOST flag is set to 1 when the mailbox is overwritten or overrun by a new received message while the NEWDATA flag is 1. The MSGLOST flag is set to 1 at the end of the 6th bit of EOF. The MSGLOST flag is set to 0 through a software write.

In both overwrite and overrun modes, the MSGLOST flag cannot be set to 0 through a software write during the 5 PCLKB cycles following the 6th bit of EOF.

### ONESHOT bit (One-Shot Enable)

When the ONESHOT bit is set to 1 in receive mode (RECREQ = 1 and TRMREQ = 0), the mailbox receives a message only one time. The mailbox does not behave as a receive mailbox after having received a message one time. The behavior of the NEWDATA and INVALIDDATA flags is the same as in normal receive mode. In one-shot receive mode, the MSGLOST flag is not set to 1. To set the ONESHOT bit to 0, first write 0 to the RECREQ bit and ensure that it is 0.

### RECREQ bit (Receive Mailbox Request)

The RECREQ bit selects receive modes listed in [Table 29.10](#).

When the RECREQ bit is set to 1, the associated mailbox is configured for reception of a data or remote frame.

When the RECREQ bit is set to 0, the associated mailbox is not configured for reception of a data or remote frame.

Due to hardware protection, the RECREQ bit cannot be set to 0 through a software write during the following period:

- Hardware protection is started from the acceptance filter processing (the beginning of the CRC field)
- Hardware protection is released:
  - For the mailbox that is specified to receive the incoming message, after the received data is stored in the mailbox or a CAN bus error occurs. This means that the maximum period of hardware protection is from the beginning of the CRC field to the end of the 7th bit of EOF.
  - For the other mailboxes, after acceptance filter processing
  - If no mailbox is specified to receive the message, after acceptance filter processing.

When setting the RECREQ bit to 1, do not set the TRMREQ bit to 1. To change the configuration of a mailbox from transmission to reception, first abort the transmission, then set the SENTDATA and TRMABT flags to 0 before changing to reception.

Note: MCTL\_RX[j].RECREQ is the mirror bit of MCTL\_TX[j].RECREQ.

### TRMREQ bit (Transmit Mailbox Request)

The TRMREQ bit selects the transmit modes listed in [Table 29.10](#).

When the TRMREQ bit is set to 1, the associated mailbox is configured for transmission of a data or remote frame.

When the TRMREQ bit is set to 0, the associated mailbox is not configured for transmission of a data or remote frame.

If the TRMREQ bit is changed from 1 to 0 to cancel the associated transmission request, either the TRMABT or SENTDATA flag is set to 1. When setting the TRMREQ bit to 1, do not set the RECREQ bit to 1. To change the configuration of a mailbox from reception to transmission, first abort the reception, then set the NEWDATA and MSGLOST flags to 0 before changing to transmission.

Note: MCTL\_RX[j].TRMREQ is the mirror bit of MCTL\_TX[j].TRMREQ.

## 29.2.11 RFCR : Receive FIFO Control Register

Base address: CAN0 = 0x400A\_8000

Offset address: 0x848

|                    |           |           |           |           |            |   |     |   |

| 6   | RFWST      | Receive FIFO Buffer Warning Status Flag<br>0: Receive FIFO is not buffer warning<br>1: Receive FIFO is buffer warning (3 unread messages)                                                                                                     | R   |
| 7   | RFEST      | Receive FIFO Empty Status Flag<br>0: Unread message in receive FIFO<br>1: No unread message in receive FIFO                                                                                                                                   | R   |

Write to RFCR in CAN operation or halt mode.

### RFE bit (Receive FIFO Enable)

When the RFE bit is set to 1, the receive FIFO is enabled.

When the RFE bit is set to 0, the receive FIFO is disabled for reception and becomes empty (RFEST bit = 1). Write 0 to the RFE bit simultaneously with the RFMLF flag setting.

Do not set this bit to 1 in normal mailbox mode (MBM bit in CTRLR = 0). Due to hardware protection, the RFE bit cannot be set to 0 through a software write during the following period:

- Hardware protection is started from acceptance filter processing (the beginning of the CRC field)
- When hardware protection is released:
  - If the receive FIFO is specified to receive the incoming message, after the received data is stored in the receive FIFO or a CAN bus error occurs. This means that the maximum period of hardware protection is from the beginning of the CRC field to the end of the 7th bit of EOF.
  - If the receive FIFO is not specified to receive the message, after acceptance filter processing.

#### **RFUST[2:0] bits (Receive FIFO Unread Message Number Status)**

The RFUST[2:0] bits indicate the number of unread messages in the receive FIFO. The value of the RFUST[2:0] bits are initialized to 000b when the RFE bit is set to 0.

#### **RFMLF flag (Receive FIFO Message Lost Flag)**

The RFMLF flag is set to 1 (receive FIFO message lost) when the receive FIFO receives a new message and is full. It is set to 1 at the end of the 6th bit of EOF.

The RFMLF flag is set to 0 through a software write. Writing 1 has no effect. In both overwrite and overrun modes, if the receive FIFO is full and determined to have received a message, the RFMLF flag cannot be set to 0 (no receive FIFO message lost) through a software write during the 5 PCLKB cycles following the 6th bit of EOF.

#### **RFFST flag (Receive FIFO Full Status Flag)**

The RFFST flag is set to 1 (receive FIFO is full) when the number of unread messages in the receive FIFO is 4. The flag is 0 (receive FIFO is not full) when the number of unread messages in the receive FIFO is less than 4. The flag is set to 0 when the RFE bit is 0.

#### **RFWST flag (Receive FIFO Buffer Warning Status Flag)**

The RFWST flag is set to 1 (receive FIFO is a buffer warning) when the number of unread messages in the receive FIFO is 3. The flag is 0 (receive FIFO is not a buffer warning) when the number of unread messages in the receive FIFO is less than 3 or equal to 4. The RFWST flag is set to 0 when the RFE bit is 0.

#### **RFEST flag (Receive FIFO Empty Status Flag)**

The RFEST flag is set to 1 (no unread message in receive FIFO) when the number of unread messages in the receive FIFO is 0. The flag is set to 1 when the RFE bit is set to 0. The flag is set to 0 (unread message in receive FIFO) when the number of unread messages in the receive FIFO is one or more.

Figure 29.2 shows the receive FIFO mailbox operation.

**Figure 29.2** Receive FIFO mailbox operation when bits [29] and [28] in MIER\_FIFO = 01b or 11b

**29.2.12 RFPCR : Receive FIFO Pointer Control Register**

Base address: CAN0 = 0x400A\_8000

Offset address: 0x849

Value after reset: x x x x x x x x

| Bit | Symbol | Function                                                                      | R/W |
|-----|--------|-------------------------------------------------------------------------------|-----|
| 7:0 | n/a    | The CPU pointer for the receive FIFO is incremented by writing 0xFF to RFPCR. | W   |

When the receive FIFO is not empty, write 0xFF to RFPCR through software to increment the CPU pointer to the next mailbox location. Do not write to RFPCR when the RFE bit in RFCR is 0 (receive FIFO disabled).

Both the CAN and CPU pointers are incremented when a new message is received and the RFFST flag is 1 (receive FIFO is full) in overwrite mode. When the RFMLF flag is 1 in this condition, the CPU pointer does not increment on a software write to RFPCR.

### 29.2.13 TFCR : Transmit FIFO Control Register

| 5:4 | —          | These bits are read as 0. The write value should be 0.                                                                                                                                                                                         | R/W |
| 6   | TFFST      | Transmit FIFO Full Status<br>0: Transmit FIFO not full<br>1: Transmit FIFO full (4 unsent messages)                                                                                                                                            | R   |
| 7   | TFEST      | Transmit FIFO Empty Status<br>0: Unsent message in transmit FIFO<br>1: No unsent message in transmit FIFO                                                                                                                                      | R   |

Write to TFCR in CAN operation or halt mode.

#### TFE bit (Transmit FIFO Enable)

Setting the TFE bit set to 1 enables the transmit FIFO. Setting the TFE bit to 0 empties the transmit FIFO (TFEST bit = 1), and unsent messages in the transmit FIFO are lost in the following ways:

- Immediately if a message from the transmit FIFO is not scheduled for the next transmission or is already in transmission
- On completion of transmission, on a CAN bus error, CAN bus arbitration-lost, or entry to CAN halt mode, if a message from the transmit FIFO is scheduled for the next transmission or is already in transmission.

Before setting the TFE bit to 1 again, ensure that the TFEST bit is set to 1. After setting the TFE bit to 1, write transmit data to mailbox 24.

Do not set the TFE bit to 1 in normal mailbox mode (MBM bit in CTRL = 0).

#### TFUST[2:0] bits (Transmit FIFO Unsent Message Number Status)

The TFUST[2:0] bits indicate the number of unsent messages in the transmit FIFO. These bits are set to 000b after the TFE bit is set to 0 and transmission is aborted or completes.

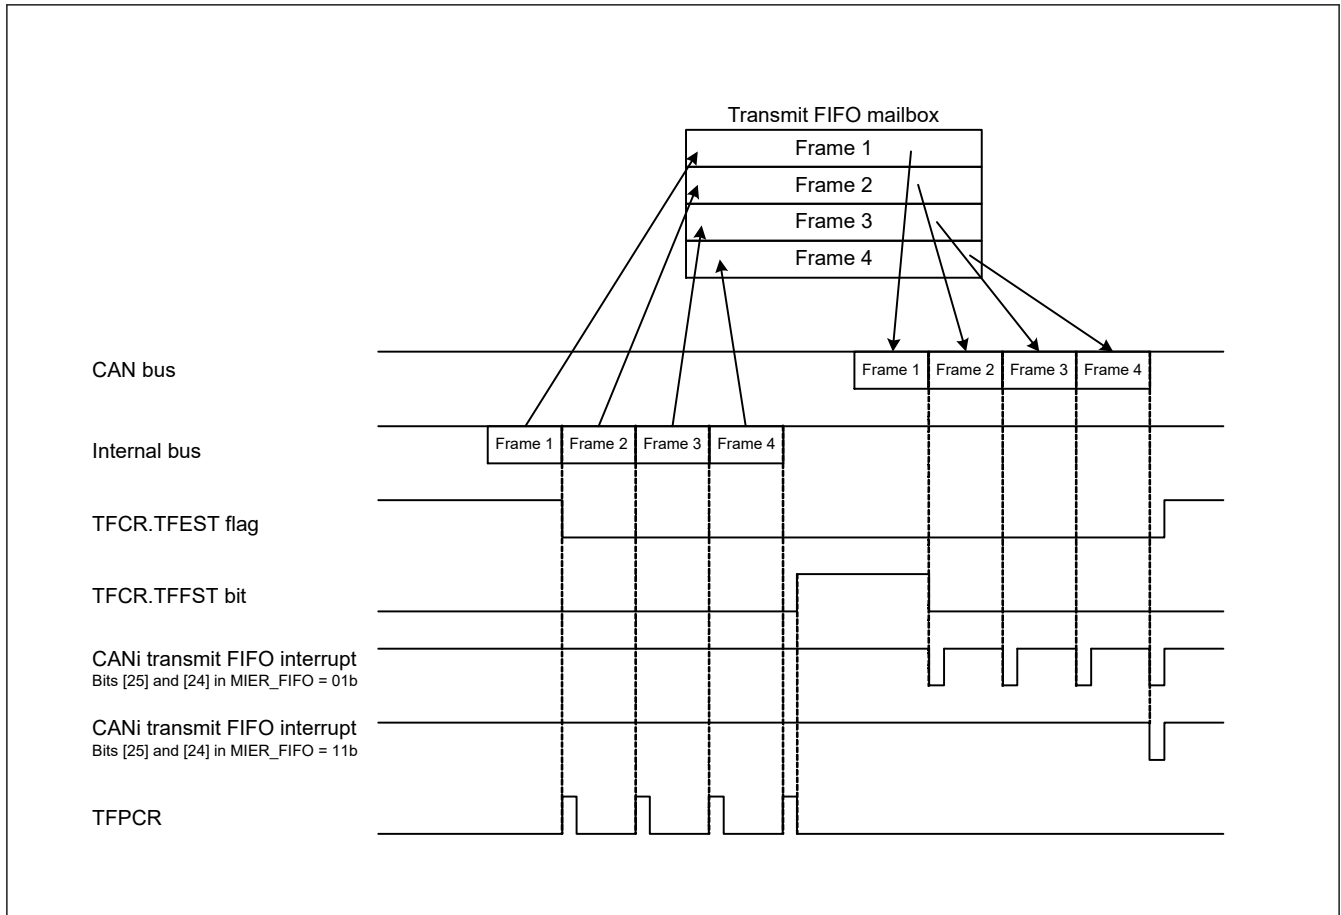

#### TFFST bit (Transmit FIFO Full Status)

The TFFST bit is set to 1 (transmit FIFO is full) when the number of unsent messages in the transmit FIFO is 4. The TFFST bit is set to 0 (transmit FIFO is not full) when the number of unsent messages in the transmit FIFO is less than 4. The TFFST bit is set to 0 when transmission from the transmit FIFO is aborted.

**TFEST bit (Transmit FIFO Empty Status)**

The TFEST bit is set to 1 (no message in transmit FIFO) when the number of unsend messages in the transmit FIFO is 0. The TFEST bit is set to 1 when transmission from the transmit FIFO is aborted. The TFEST bit is set to 0 (message in transmit FIFO) when the number of unsend messages in the transmit FIFO is not 0.

Figure 29.3 shows the transmit FIFO mailbox operation.

**Figure 29.3** Transmit FIFO mailbox operation when bits [25] and [24] in MIER\_FIFO = 01b or 11b

**29.2.14 TFPCR : Transmit FIFO Pointer Control Register**

Base address: CAN0 = 0x400A\_8000

Offset address: 0x84B

|                    |             |   |   |   |   |   |   |   |
|--------------------|-------------|---|---|---|---|---|---|---|
| Bit position:      | 7           | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Bit field:         | [Empty Box] |   |   |   |   |   |   |   |
| Value after reset: | x           | x | x | x | x | x | x | x |

| Bit | Symbol | Function                                                                       | R/W |
|-----|--------|--------------------------------------------------------------------------------|-----|
| 7:0 | n/a    | The CPU pointer for the transmit FIFO is incremented by writing 0xFF to TFPCR. | W   |

When the transmit FIFO is not full, write 0xFF to TFPCR through software to increment the CPU pointer for the transmit FIFO to the next mailbox location.

Do not write to TFPCR when the TFE bit in TFCR is 0 (transmit FIFO disabled).

| Bit | Symbol | Function               | R/W |
|-----|--------|------------------------|-----|
| 15  | —      | This bit is read as 0. | R   |

**NDST flag (NEWDATA Status Flag)**

The NDST flag is set to 1 when at least one NEWDATA flag in MCTL\_RX[j] (j = 0 to 31) is 1, regardless of the value of MIER or MIER\_FIFO. The NDST flag is set to 0 when all NEWDATA flags are 0.

**SDST flag (SENTDATA Status Flag)**

The SDST flag is set to 1 when at least one SENTDATA flag in MCTL\_TX[j] (j = 0 to 31) is 1, regardless of the value of MIER or MIER\_FIFO. The SDST flag is set to 0 when all SENTDATA flags are 0.

**RFST flag (Receive FIFO Status Flag)**

The RFST flag is set to 1 when the receive FIFO is not empty. The RFST flag is set to 0 when the receive FIFO is empty or normal mailbox mode is selected.

**TFST flag (Transmit FIFO Status Flag)**

The TFST flag is set to 1 when the transmit FIFO is not full. The TFST flag is set to 0 when the transmit FIFO is full or normal mailbox mode is selected.

**NMLST flag (Normal Mailbox Message Lost Status Flag)**

The NMLST flag is set to 1 when at least one MSGLOST flag in MCTL\_RX[j] (j = 0 to 31) is 1, regardless of the value of MIER or MIER\_FIFO. The NMLST flag is set to 0 when all MSGLOST flags are 0.

**FMLST flag (FIFO Mailbox Message Lost Status Flag)**

The FMLST flag is set to 1 when the RFMLF flag in RFCR is 1, regardless of the value of MIER\_FIFO. The FMLST flag is set to 0 when the RFMLF flag is 0.

**TABST flag (Transmission Abort Status Flag)**

The TABST flag is set to 1 when at least one TRMABT flag in MCTL\_TX[j] (j = 0 to 31) is 1, regardless of the value of MIER or MIER\_FIFO. The TABST flag is set to 0 when all TRMABT flags are 0.

**EST flag (Error Status Flag)**

The EST flag is set to 1 when at least one error is detected by EIFR, regardless of the value of EIER. The EST flag is set to 0 when no error is detected by EIFR.

**RSTST flag (CAN Reset Status Flag)**

The RSTST flag is set to 1 when the CAN module is in CAN reset mode. The RSTST flag is 0 when the CAN module is not in CAN reset mode. Even when the state changes from CAN reset mode to CAN sleep mode, the flag remains 1.

**HLTST flag (CAN Halt Status Flag)**

The HLTST flag is set to 1 when the CAN module is in CAN halt mode. The HLTST is set to 0 when the CAN module is not in CAN halt mode. Even when the state changes from CAN halt mode to CAN sleep mode, the flag remains 1.

**SLPST flag (CAN Sleep Status Flag)**

The SLPST flag is set to 1 when the CAN module is in CAN sleep mode. The SLPST flag is set to 0 when the CAN module is not in CAN sleep mode.

**EPST flag (Error-Passive Status Flag)**

The EPST flag is set to 1 when the value of TECR or RECR exceeds 127 and the CAN module is in the error-passive state ( $128 \leq \text{TEC} < 256$  or  $128 \leq \text{REC} < 256$ ). The EPST flag is set to 0 when the CAN module is not in the error-passive state.

**BOST flag (Bus-Off Status Flag)**

The BOST flag is set to 1 when the value of TECR exceeds 255 and the CAN module is in the bus-off state ( $\text{TEC} \geq 256$ ). The BOST flag is set to 0 when the CAN module is not in the bus-off state.

**TRMST flag (Transmit Status Flag)**

The TRMST flag is set to 1 when the CAN module performs as a transmitter node or is in the bus-off state. The TRMST flag is set to 0 when the CAN module performs as a receiver node or is in the bus-idle state.

**RECST flag (Receive Status Flag)**

The RECST flag is set to 1 when the CAN module performs as a receiver node. The RECST flag is set to 0 when the CAN module performs as a transmitter node or is in the bus-idle state.

**29.2.16 MSMR : Mailbox Search Mode Register**

Base address: CAN0 = 0x400A\_8000

Offset address: 0x853

| 7:2 | —         | These bits are read as 0. The write value should be 0.                                                                                                           | R/W |

Write to MSMR in CAN operation or halt mode.

**MBSM[1:0] bits (Mailbox Search Mode Select)**

The MBSM[1:0] bits select the search mode for the mailbox search function.

When the MBSM[1:0] bits are 00b, receive mailbox search mode is selected. In this mode, the search targets are the NEWDATA flag in MCTL\_RX[j] (j = 0 to 31) for the normal mailbox and the RFEST flag in RFCR.

When the MBSM[1:0] bits are 01b, transmit mailbox search mode is selected. In this mode, the search target is the SENTDATA flag in MCTL\_TX[j].

When the MBSM[1:0] bits are 10b, message lost search mode is selected. In this mode, the search targets are the MSGLOST flag in MCTL\_RX[j] for the normal mailbox and the RFMLF flag in RFCR.

When the MBSM[1:0] bits are 11b, channel search mode is selected. In this mode, the search target is CSSR. See [section 29.2.18. CSSR : Channel Search Support Register](#).

| 6:5 | —          | These bits are read as 0.                                                                                                                    | R   |

| Bit | Symbol | Function                                                              | R/W |
|-----|--------|-----------------------------------------------------------------------|-----|
| 7   | SEST   | Search Result Status<br>0: Search result found<br>1: No search result | R   |

### MBNST[4:0] bits (Search Result Mailbox Number Status)

In all mailbox search modes, the MBNST[4:0] bits output the smallest found mailbox number. In receive mailbox search mode, transmit mailbox search mode, and message lost search mode, the value of the mailbox (the search result to be output) is updated under the following conditions:

- When the associated NEWDATA, SENTDATA, or MSGLOST flag is set to 0 for a mailbox output by MBNST[4:0]
- When the associated NEWDATA, SENTDATA, or MSGLOST flag is set to 1 for a mailbox with a smaller number than that in MBNST[4:0]

If the MBSM[1:0] bits are set to 00b (receive mailbox search mode) or 10b (message lost search mode), the receive FIFO (mailbox 28) is output when it is not empty and there are no unread received messages and no lost messages in any of the normal mailboxes 0 to 23. If the MBSM[1:0] bits are set to 01b (transmit mailbox search mode), the transmit FIFO (mailbox 24) is not output. Table 29.6 lists the behavior of the MBNST[4:0] bits in FIFO mailbox mode.

In channel search mode, the MBNST[4:0] bits output the associated channel number. After MSSR is read by software, the next target channel number is output.

### SEST bit (Search Result Status)

The SEST bit is set to 1 (no search result) when no associated mailbox is found after searching all mailboxes. For example, in transmit mailbox search mode, the SEST bit is set to 1 when no SENTDATA flag is 1 for any mailbox. The SEST bit is set to 0 when at least one SENTDATA flag is 1. When the SEST bit is 1, the value of the MBNST[4:0] bits is undefined.

**Table 29.6 Behavior of MBNST[4:0] bits in FIFO mailbox mode**

| MBSM[1:0] bits | Mailbox 24 (transmit FIFO) | Mailbox 28 (receive FIFO)                                                                                                                                                                                          |
|----------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00b            | Mailbox 24 is not output.  | Mailbox 28 is output when no MCTL_RX[j].NEWDATA flag for the normal mailboxes is set to 1 (new message is being stored or was stored in the mailbox) and the receive FIFO is not empty.                            |
| 01b            |                            | Mailbox 28 is not output.                                                                                                                                                                                          |
| 10b            |                            | Mailbox 28 is output when no MCTL_RX[j].MSGLOST flag for the normal mailboxes is set to 1 (message is overwritten or overrun) and the RFCR.RFMLF flag is set to 1 (receive FIFO message lost) in the receive FIFO. |
| 11b            |                            | Mailbox 28 is not output.                                                                                                                                                                                          |

## 29.2.18 CSSR : Channel Search Support Register

Base address: CAN0 = 0x400A\_8000

Offset address: 0x851

Bit position: 7 6 5 4 3 2 1 0

Bit field:

Value after reset: x x x x x x x x

| Bit | Symbol | Function                                                                              | R/W |
|-----|--------|---------------------------------------------------------------------------------------|-----|
| 7:0 | n/a    | When the value for the channel search is input, the channel number is output to MSSR. | R/W |

The bits that are set to 1 in CSSR, are encoded by an 8/3 encoder (the LSB position has the higher priority) and output to the MBNST[4:0] bits in MSSR. MSSR outputs the updated value whenever it is read by software.

Write to CSSR only when the MSMR.MBSM[1:0] bits are 11b (channel search mode). Write to CSSR in CAN operation mode or CAN halt mode.

Figure 29.4 shows the write and read operations of the CSSR and MSSR registers.

**Figure 29.4 Write and read operations of the CSSR and MSSR registers**

The value of CSSR is also updated whenever MSSR is read. On this read, the value prior to conversion by the 8/3 encoder can be read.

### 29.2.19 AFSR : Acceptance Filter Support Register

Base address: CAN0 = 0x400A\_8000

Offset address: 0x856

| Bit  | Symbol | Function                                                                                                       | R/W |
|------|--------|----------------------------------------------------------------------------------------------------------------|-----|
| 15:0 | n/a    | After the standard ID of a received message is written, the value converted for data table search can be read. | R/W |

Note: Write to AFSR in CAN operation mode or CAN halt mode.

The acceptance filter support unit (ASU) can be used for data table (8 bits × 256) searches. In the data table, all standard IDs that are created are set as valid or invalid in bit units. When AFSR is written with data in 16-bit units including the SID[10:0] bits in MB<sub>j</sub>\_ID (j = 0 to 31), in which a received standard ID is stored, a decoded row (byte offset) position and column (bit) position for data table search can be read. The ASU can be used for standard (11-bit) IDs only.

The ASU is enabled in the following cases:

- When the ID to be received cannot be masked by the acceptance filter. For example, if IDs to be received are 0x078, 0x087, and 0x111.
- When there are too many IDs to receive, and the software filtering time is expected to be shortened.

Note: AFSR cannot be set in CAN reset mode.

Figure 29.5 shows the write and read operations in the AFSR register.

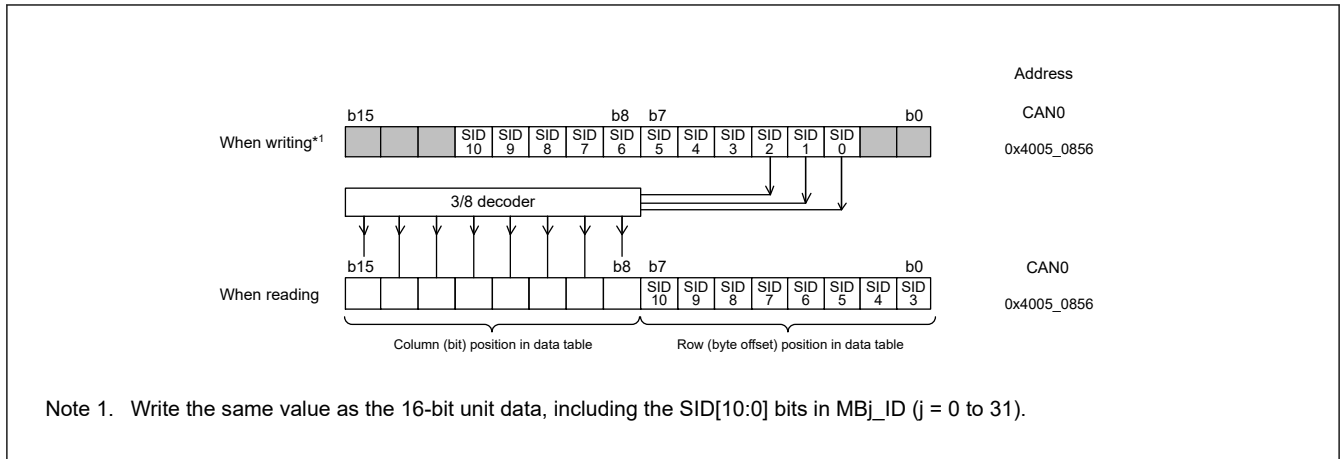

Figure 29.5 Write and read operations in the AFSR register

### 29.2.20 EIER : Error Interrupt Enable Register

Base address: CAN0 = 0x400A\_8000

Offset address: 0x84C

|                    |      |      |      |       |       |      |      |      |
|--------------------|------|------|------|-------|-------|------|------|------|
| Bit position:      | 7    | 6    | 5    | 4     | 3     | 2    | 1    | 0    |
| Bit field:         | BLIE | OLIE | ORIE | BORIE | BOEIE | EPIE | EWIE | BEIE |
| Value after reset: | 0    | 0    | 0    | 0     | 0     | 0    | 0    | 0    |

| Bit | Symbol | Function                                                                                | R/W |
|-----|--------|-----------------------------------------------------------------------------------------|-----|
| 0   | BEIE   | Bus Error Interrupt Enable<br>0: Disable interrupt<br>1: Enable interrupt               | R/W |
| 1   | EWIE   | Error-Warning Interrupt Enable<br>0: Disable interrupt<br>1: Enable interrupt           | R/W |
| 2   | EPIE   | Error-Passive Interrupt Enable<br>0: Disable interrupt<br>1: Enable interrupt           | R/W |
| 3   | BOEIE  | Bus-Off Entry Interrupt Enable<br>0: Disable interrupt<br>1: Enable interrupt           | R/W |
| 4   | BORIE  | Bus-Off Recovery Interrupt Enable<br>0: Disable interrupt<br>1: Enable interrupt        | R/W |
| 5   | ORIE   | Overrun Interrupt Enable<br>0: Disable interrupt<br>1: Enable interrupt                 | R/W |
| 6   | OLIE   | Overload Frame Transmit Interrupt Enable<br>0: Disable interrupt<br>1: Enable interrupt | R/W |
| 7   | BLIE   | Bus Lock Interrupt Enable<br>0: Disable interrupt<br>1: Enable interrupt                | R/W |

The EIER register enables or disables each error interrupt source independently in EIFR. Write to EIER in CAN reset mode.

#### BEIE bit (Bus Error Interrupt Enable)

When the BEIE bit is 0, no error interrupt request occurs even if the BEIF flag in EIFR is 1. When the BEIE bit is 1, an error interrupt request occurs if the BEIF flag is set to 1.

**EWIE bit (Error-Warning Interrupt Enable)**

When the EWIE bit is 0, no error interrupt request occurs even if the EWIF flag in EIFR is 1. When the EWIE bit is 1, an error interrupt request is generated if the EWIF flag is set to 1.

**EPIE bit (Error-Passive Interrupt Enable)**

When the EPIE bit is 0, no error interrupt request occurs even if the EPIF flag in EIFR is 1. When the EPIE bit is 1, an error interrupt request occurs if the EPIF flag is set to 1.

**BOEIE bit (Bus-Off Entry Interrupt Enable)**

When the BOEIE bit is 0, no error interrupt request occurs even if the BOEIF flag in EIFR is 1. When the BOEIE bit is 1, an error interrupt request occurs if the BOEIF flag is set to 1.

**BORIE bit (Bus-Off Recovery Interrupt Enable)**

When the BORIE bit is 0, no error interrupt request occurs even if the BORIF flag in EIFR is 1. When the BORIE bit is 1, an error interrupt request occurs if the BORIF flag is set to 1.

**ORIE bit (Overrun Interrupt Enable)**

When the ORIE bit is 0, no error interrupt request occurs even if the ORIF flag in EIFR is 1. When the ORIE bit is 1, an error interrupt request occurs if the ORIF flag is set to 1.

**OLIE bit (Overload Frame Transmit Interrupt Enable)**

When the OLIE bit is 0, no error interrupt request occurs even if the OLIF flag in EIFR is 1. When the OLIE bit is 1, an error interrupt request occurs if the OLIF flag is set to 1.

**BLIE bit (Bus Lock Interrupt Enable)**

When the BLIE bit is 0, no error interrupt request occurs even if the BLIF flag in EIFR is 1. When the BLIE bit is 1, an error interrupt request occurs if the BLIF flag is set to 1.

**29.2.21 EIFR : Error Interrupt Factor Judge Register**

Base address: CAN0 = 0x400A\_8000

Offset address: 0x84D

|                    |      |      |      |       |       |      |      |      |
|--------------------|------|------|------|-------|-------|------|------|------|

| Bit | Symbol | Function                                                                                                                         | R/W |
|-----|--------|----------------------------------------------------------------------------------------------------------------------------------|-----|
| 5   | ORIF   | Receive Overrun Detect Flag<br>0: No receive overrun detected<br>1: Receive overrun detected                                     | R/W |
| 6   | OLIF   | Overload Frame Transmission Detect Flag<br>0: No overload frame transmission detected<br>1: Overload frame transmission detected | R/W |
| 7   | BLIF   | Bus Lock Detect Flag<br>0: No bus lock detected<br>1: Bus lock detected                                                          | R/W |

If an event associated with an EIFR flag occurs, the associated bit in EIFR is set to 1, regardless of the setting of EIER.

Clear the bits to 0 through a software write. If a bit is set to 1 at the same time that the software clears it, it becomes 1. When setting a single bit to 0 in software, use the transfer instruction (MOV) to ensure that only the specified bit is set to 0 and the other bits are set to 1. Writing 1 has no effect to these bit values.

### BEIF flag (Bus Error Detect Flag)

The BEIF flag is set to 1 when a bus error is detected.

### EWIF flag (Error-Warning Detect Flag)

The EWIF flag is set to 1 when the value of the receive error counter (REC) or transmit error counter (TEC) exceeds 95. The EWIF flag is set to 1 only when REC or TEC initially exceeds 95. If software writes 0 to this flag while the REC or TEC value remains greater than 95, the EWIF flag does not set to 1 until the REC or TEC value goes below 95, and then exceeds 95 again.

### EPIF flag (Error-Passive Detect Flag)

The EPIF flag is set to 1 when the CAN error state becomes error-passive, when the REC or TEC value exceeds 127. The EPIF flag is set to 1 only when the REC or TEC value initially exceeds 127. If software writes 0 to this flag while REC or TEC remains greater than 127, the EPIF flag is not set to 1 until REC or TEC goes below 127, and then exceeds 127 again.

### BOEIF flag (Bus-Off Entry Detect Flag)

The BOEIF flag is set to 1 when the CAN error state becomes bus-off, when the TEC value exceeds 255. The BOEIF flag is also set to 1 when the BOM[1:0] bits in CTLR are 01b (automatic entry to CAN halt mode on bus-off entry) and the CAN module becomes the bus-off state.

### BORIF flag (Bus-Off Recovery Detect Flag)

The BORIF flag is set to 1 when the CAN module recovers from the bus-off state normally by detecting 11 consecutive bits 128 times in the following conditions:

- When the BOM[1:0] bits in CTLR are 00b
- When the BOM[1:0] bits in CTLR are 10b
- When the BOM[1:0] bits in CTLR are 11b

The BORIF flag is not set to 1 if the CAN module recovers from the bus-off state in the following conditions:

- When the CANM[1:0] bits in CTLR are set to 01b or 11b (CAN reset mode)
- When the RBOC bit in CTLR is set to 1 (forced return from bus-off)
- When the BOM[1:0] bits in CTLR are set to 01b
- When the BOM[1:0] bits in CTLR are set to 11b and the CANM[1:0] bits in CTLR are set to 10b (CAN halt mode) before normal recovery occurs

Table 29.7 lists the behavior of the BOEIF and BORIF flags for each CTLR.BOM[1:0] bits setting.

**Table 29.7 Behavior of BOEIF and BORIF flags for each CTRL.BOM[1:0] setting**

| BOM[1:0] bits | BOEIF flag                             | BORIF flag                                                                                          |
|---------------|----------------------------------------|-----------------------------------------------------------------------------------------------------|
| 00b           | Set to 1 on entry to the bus-off state | Sets to 1 on exit from the bus-off state                                                            |
| 01b           |                                        | Do not set to 1                                                                                     |
| 10b           |                                        | Set to 1 on exit from the bus-off state                                                             |
| 11b           |                                        | Set to 1 if normal bus-off recovery occurs before the CANM[1:0] bits are set to 10b (CAN halt mode) |

**ORIF flag (Receive Overrun Detect Flag)**

The ORIF flag is set to 1 when a receive overrun occurs. This flag is not set to 1 in overwrite mode.

In overwrite mode, a reception complete interrupt request occurs if an overwrite condition occurs and the ORIF flag is not set to 1.

In overrun mode with normal mailbox mode, if an overrun occurs in any of mailboxes 0 to 31, the ORIF flag is set to 1. In overrun mode with FIFO mailbox mode, if an overrun occurs in any of mailboxes 0 to 23 or the receive FIFO, this flag is set to 1.

**OLIF flag (Overload Frame Transmission Detect Flag)**

The OLIF flag is set to 1 if the transmitting condition of an overload frame is detected when the CAN module is transmitting or receiving.

**BLIF flag (Bus Lock Detect Flag)**

The BLIF flag is set to 1 if 32 consecutive dominant bits are detected on the CAN bus while the CAN module is in CAN operation mode. After the BLIF flag is set to 1, 32 consecutive dominant bits are detected again in either of the following conditions:

- Recessive bits are detected after the BLIF flag changes to 0 from 1
- The CAN module enters CAN reset or halt mode and then enters CAN operation mode again after the BLIF flag changes to 0 from 1

**29.2.22 RECR : Receive Error Count Register**

Base address: CAN0 = 0x400A\_8000

Offset address: 0x84E

Bit position: 7 6 5 4 3 2 1 0

Bit field:

Value after reset: 0 0 0 0 0 0 0 0

| Bit | Symbol | Function                                                                                                                                    | R/W |
|-----|--------|---------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 7:0 | n/a    | Receive error count function. RECR increments or decrements the counter value based on the error status of the CAN module during reception. | R   |

RECR indicates the value of the receive error counter. See the CAN specification (ISO11898-1) for information on the increment and decrement conditions of the receive error counter.

The value of RECR in the bus-off state is undefined.

### 29.2.23 TECR : Transmit Error Count Register

Base address: CAN0 = 0x400A\_8000

Offset address: 0x84F

| Bit | Symbol | Function                                                                                                                                        | R/W |
|-----|--------|-------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 7:0 | n/a    | Transmit error count function. TECR increments or decrements the counter value based on the error status of the CAN module during transmission. | R   |

TECR indicates the value of the transmit error counter. See the CAN specification (ISO11898-1) for information on the increment and decrement conditions of the transmit error counter.

The value of TECR in the bus-off state is undefined.

### 29.2.24 ECSR : Error Code Store Register

Base address: CAN0 = 0x400A\_8000

Offset address: 0x850

| Bit | Symbol | Function                                                                                                                 | R/W |
|-----|--------|--------------------------------------------------------------------------------------------------------------------------|-----|
| 0   | SEF    | Stuff Error Flag <sup>*1 *2</sup><br>0: No stuff error detected<br>1: Stuff error detected                               | R/W |
| 1   | FEF    | Form Error Flag <sup>*1 *2</sup><br>0: No form error detected<br>1: Form error detected                                  | R/W |
| 2   | AEF    | ACK Error Flag <sup>*1 *2</sup><br>0: No ACK error detected<br>1: ACK error detected                                     | R/W |
| 3   | CEF    | CRC Error Flag <sup>*1 *2</sup><br>0: No CRC error detected<br>1: CRC error detected                                     | R/W |
| 4   | BE1F   | Bit Error (recessive) Flag <sup>*1 *2</sup><br>0: No bit error (recessive) detected<br>1: Bit error (recessive) detected | R/W |
| 5   | BE0F   | Bit Error (dominant) Flag <sup>*1 *2</sup><br>0: No bit error (dominant) detected<br>1: Bit error (dominant) detected    | R/W |
| 6   | ADEF   | ACK Delimiter Error Flag <sup>*1 *2</sup><br>0: No ACK delimiter error detected<br>1: ACK delimiter error detected       | R/W |
| 7   | EDPM   | Error Display Mode Select <sup>*3 *4</sup><br>0: Output first detected error code<br>1: Output accumulated error code    | R/W |

Note 1. Writing 1 has no effect on these bit values.

Note 2. To write 0 to the SEF, FEF, AEF, CEF, BE1F, BE0F, and ADEF bits, use the transfer (MOV) instruction to ensure that only the specified bit is set to 0 and the other bits are set to 1.

Note 3. Write to the EDPM bit in CAN reset or halt mode.

Note 4. If more than one error condition is detected simultaneously, all related bits are set to 1.

ECSR indicates whether an error occurs on the CAN bus. See the CAN specification (ISO11898-1) for the conditions when each error occurs.

Clear all of the bits, except for the EDPM bit, to 0 through a software write. If the ECSR bit is set to 1 at the same time that software writes 0 to it, the bit becomes 1.

**SEF flag (Stuff Error Flag)**

The SEF flag is set to 1 when a stuff error is detected.

**FEF flag (Form Error Flag)**

The FEF flag is set to 1 when a form error is detected.

**AEF flag (ACK Error Flag)**

The AEF flag is set to 1 when an ACK error is detected.

**CEF flag (CRC Error Flag)**

The CEF flag is set to 1 when a CRC error is detected.

**BE1F flag (Bit Error (recessive) Flag)**

The BE1F flag is set to 1 when a recessive bit error is detected.

**BE0F flag (Bit Error (dominant) Flag)**

The BE0F flag is set to 1 when a dominant bit error is detected.

**ADEF flag (ACK Delimiter Error Flag)**

The ADEF flag is set to 1 when a form error is detected with the ACK delimiter during transmission.

**EDPM bit (Error Display Mode Select)**

The EDPM bit selects the output mode of ECSR. When the EDPM bit is set to 0, ECSR outputs the first error code. When the EDPM bit is set to 1, ECSR outputs the accumulated error code.

**29.2.25 TSR : Time Stamp Register**

Base address: CAN0 = 0x400A\_8000

Offset address: 0x854

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field:

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

| Bit  | Symbol | Function                                               | R/W |
|------|--------|--------------------------------------------------------|-----|
| 15:0 | n/a    | Free-running counter value for the time stamp function | R   |

Note: Read TSR in 16-bit units.

Reading the TSR register returns the current value of the 16-bit free-running time stamp counter. The time stamp counter reference clock is configured in the TSPS[1:0] bits in CTLR. The counter stops in CAN sleep mode and CAN halt mode, and is initialized in CAN reset mode. The time stamp counter value is stored in the TSL[7:0] and TSH[7:0] bits in MBj\_TS when a received message is stored in a receive mailbox.

### 29.2.26 TCR : Test Control Register

Base address: CAN0 = 0x400A\_8000

Offset address: 0x858

| Bit | Symbol    | Function                                                                                                                                                          | R/W |
|-----|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 0   | TSTE      | CAN Test Mode Enable<br>0: Disable CAN test mode<br>1: Enable CAN test mode                                                                                       | R/W |
| 2:1 | TSTM[1:0] | CAN Test Mode Select<br>0 0: Not CAN test mode<br>0 1: Listen-only mode<br>1 0: Self-test mode 0 (external loopback)<br>1 1: Self-test mode 1 (internal loopback) | R/W |
| 7:3 | —         | These bits are read as 0. The write value should be 0.                                                                                                            | R/W |

TCR controls the CAN test mode. Write to TCR in CAN halt mode only.

#### (1) Listen-only mode

The CAN specification (ISO11898-1) recommends an optional bus monitoring mode. In listen-only mode, valid data frames and valid remote frames can be received. However, only recessive bits can be sent on the CAN bus. The ACK bit, overload flag, and active error flag cannot be sent.

Listen-only mode can be used for baud rate detection. Do not request transmission from any mailboxes in listen-only mode.

Figure 29.6 shows the connection when listen-only mode is selected.

Figure 29.6 Connection when listen-only mode is selected (i = 0)

#### (2) Self-test mode 0 (external loopback)

Self-test mode 0 is provided for CAN transceiver tests. In this mode, the protocol module treats its own transmitted messages as those received by the CAN transceiver and stores them into the receive mailbox. To be independent from external stimulation, the protocol module generates the ACK bit. Connect the CTXi and CRXi pins to the transceiver.

Figure 29.7 shows the connection when self-test mode 0 is selected.

**Figure 29.7** Connection when self-test mode 0 is selected ( $i = 0$ )

### (3) Self-test mode 1 (internal loopback)

Self-test mode 1 is provided for self-test functions. In this mode, the protocol controller treats its transmitted messages as received messages and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

In self-test mode 1, the protocol controller performs an internal feedback from the internal CTXi pin to the internal CRXi pin. The input value of the external CRXi pin is ignored. The external CTXi pin outputs only recessive bits. The CTXi and CRXi pins are not required to be connected to the CAN bus or any external device.

Figure 29.8 shows the connection when self-test mode 1 is selected.

**Figure 29.8** Connection when self-test mode 1 is selected ( $i = 0$ )

## 29.3 Operation Modes

The CAN module operation includes the following modes:

- CAN reset mode
- CAN halt mode
- CAN operation mode
- CAN sleep mode

Figure 29.9 shows the transitions between different operation modes.

**Figure 29.9 Transition between different operation modes**

### 29.3.1 CAN Reset Mode

CAN reset mode is provided for CAN communication configuration. When the CTLR.CANM[1:0] bits are set to 01b or 11b, the CAN module enters CAN reset mode. The STR.RSTST bit is then set to 1. Do not change the CTLR.CANM[1:0] bits until the RSTST flag is 1. Set BCR before exiting CAN reset mode to enter any other modes.

The following registers are initialized to their reset values after entering CAN reset mode, and their initial values are saved during CAN reset mode:

- MCTL\_TX[j] and MCTL\_RX[j]
- STR (except for the SLPST and TFST bits)
- EIFR
- RECR
- TECR
- TSR
- MSSR
- MSMR
- RFCR
- TFCR
- TCR
- ECSR (except for the EDPM bit)

The following registers retain their previous values even after entering CAN reset mode:

- CTLR
- STR (only the SLPST and TFST bits)

- MIER and MIER\_FIFO
- EIER
- BCR
- CSSR
- ECSR (only the EDPM bit)
- MBj\_ID, MBj\_DL, MBj\_Dm and MBj\_TS
- MKRk
- FIDCR0 and FIDCR1
- MKIVLR
- AFSR
- RFPCR
- TFPCR

### 29.3.2 CAN Halt Mode

CAN halt mode is used for mailbox configuration and test mode setting.

When the CTLR.CANM[1:0] bits are set to 10b, CAN halt mode is selected, and the STR.HLTST bit is set to 1. Do not change the CTLR.CANM[1:0] bits until the HLTST bit is 1.

See [Table 29.8](#) for the state transition conditions when transmitting or receiving.

All registers except for the RSTST, HLTST, and SLPST bits in STR remain unchanged when the CAN enters CAN halt mode. Do not change CTLR (except for the CANM[1:0] and SLPM bits) and EIER in CAN halt mode. BCR can be changed in CAN halt mode only when listen-only mode is selected for automatic baud rate detection.

**Table 29.8 Operation in CAN reset mode and CAN halt mode**

| Operation mode                                        | Receiver                                                                             | Transmitter                                                                              | Bus-off                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------|--------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CAN reset mode (forced transition)<br>CANM[1:0] = 11b | CAN module enters CAN reset mode without waiting for the end of message reception.   | CAN module enters CAN reset mode without waiting for the end of message transmission.    | CAN module enters CAN reset mode without waiting for the end of bus-off recovery.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| CAN reset mode<br>CANM[1:0] = 01b                     | CAN module enters CAN reset mode without waiting for the end of message reception.   | CAN module enters CAN reset mode after waiting for the end of message transmission.*1 *4 | CAN module enters CAN reset mode without waiting for the end of bus-off recovery.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| CAN halt mode                                         | CAN module enters CAN halt mode after waiting for the end of message reception.*2 *3 | CAN module enters CAN halt mode after waiting for the end of message transmission.*1 *4  | <ul style="list-style-type: none"> <li>• When the BOM[1:0] bits are 00b: A halt request from software is accepted only after bus-off recovery.</li> <li>• When the BOM[1:0] bits are 01b: CAN module automatically enters CAN halt mode without waiting for the end of bus-off recovery, regardless of a halt request from the software.</li> <li>• When the BOM[1:0] bits are 10b: CAN module automatically enters CAN halt mode after waiting for the end of bus-off recovery, regardless of a halt request from software.</li> <li>• When the BOM[1:0] bits are 11b: CAN module enters CAN halt mode without waiting for the end of bus-off recovery, if a halt is requested by software during bus-off.</li> </ul> |

Note: BOM[1:0] bits: Bits in CTLR.

Note 1. If transmission of multiple messages is requested, a mode transition occurs on completion of the first transmission. If the CAN reset mode is being requested during suspend transmission, mode transition occurs when the bus is idle, the next transmission ends, or the CAN module becomes a receiver.

Note 2. If the CAN bus is locked at the dominant level, the program can detect this state by monitoring the BLIF flag in EIFR.

Note 3. If a CAN bus error occurs during reception after CAN halt mode is requested, the CAN module transitions to CAN halt mode.

Note 4. If a CAN bus error or arbitration-lost occurs during transmission after CAN reset mode or CAN halt mode is requested, the CAN module transitions to the requested CAN mode.

### 29.3.3 CAN Sleep Mode

CAN sleep mode reduces power consumption by stopping the clock supply to the CAN module. After a reset from an MCU pin or a software reset, the CAN module starts from CAN sleep mode.

When the SLPM bit in CTRL is set to 1, the CAN module enters CAN sleep mode, and the SLPST bit in STR is set to 1. Do not change the value of the SLPM bit until the SLPST bit is 1. The other registers remain unchanged when the CAN module enters CAN sleep mode.

Write to the SLPM bit in CAN reset mode and CAN halt mode. Do not change any registers (except for the SLPM bit) during CAN sleep mode. Read operation is still allowed.

When the SLPM bit is set to 0, the CAN module is released from CAN sleep mode. When the CAN module exits CAN sleep mode, the other registers remain unchanged.

### 29.3.4 CAN Operation Mode (Excluding Bus-Off State)

CAN operation mode is used for CAN communication.

When the CANM[1:0] bits in CTRL are set to 00b, the CAN module enters CAN operation mode. The RSTST and HLTST bits in STR are set to 0. Do not change the value of the CANM[1:0] bits until the RSTST and HLTST bits are 0.

If 11 consecutive recessive bits are detected after entering CAN operation mode:

- The CAN module becomes an active node on the network, which enables transmission and reception of CAN messages.
- Error monitoring of the CAN bus, such as receive and transmit error counters, is performed.

During CAN operation mode, the CAN module might be in one of the following three sub-modes, depending on the status of the CAN bus:

- Idle mode: No transmission or reception occurs.
- Receive mode: A CAN message sent by another node is being received.
- Transmit mode: A CAN message is being transmitted. The CAN module receives a message transmitted by the local node simultaneously when self-test mode 0 (TSTM[1:0] bits in TCR = 10b) or self-test mode 1 (TSTM[1:0] bits = 11b) is selected.

Figure 29.10 shows the sub-modes of CAN operation mode.

Figure 29.10 Sub-modes of CAN operation mode

### 29.3.5 CAN Operation Mode (Bus-Off State)

The CAN module enters the bus-off state based on the incrementing or decrementing rules for the transmit and error counters defined in the CAN specifications.

The following cases apply when the CAN module is recovering from the bus-off state. When the CAN module is in the bus-off state, the values of the CAN module registers remain unchanged, except for those in STR, EIFR, RECR, TECR, and TSR.

#### (1) When CTLR.BOM[1:0] = 00b (normal mode)

The CAN module enters the error-active state after it completes recovery from the bus-off state and CAN communication is enabled. The BORIF flag in EIFR is set to 1 (bus-off recovery detected).

#### (2) When CTLR.RBOC = 1 (forced return from bus-off)

The CAN module enters the error-active state when it is in the bus-off state and the RBOC bit is 1. CAN communication is enabled again after 11b consecutive recessive bits are detected. The BORIF flag is not set to 1.

#### (3) When CTLR.BOM[1:0] = 01b (automatic transition to CAN halt mode on bus-off entry)

The CAN module enters CAN halt mode when it reaches the bus-off state. The BORIF flag is not set to 1.

#### (4) When CTLR.BOM[1:0] = 10b (automatic transition to CAN halt mode on bus-off end)

The CAN module enters CAN halt mode when it completes recovery from bus-off. The BORIF flag is set to 1.

#### (5) When CTLR.BOM[1:0] = 11b (automatic transition to CAN halt mode through software) and CTLR.CANM[1:0] = 10b (CAN halt mode) during bus-off state

The CAN module enters CAN halt mode when it is in the bus-off state and the CANM[1:0] bits are set to 10b (CAN halt mode). The BORIF flag is not set to 1.

If the CANM[1:0] bits are not set to 10b during bus-off, the same behavior as (1) applies.

## 29.4 Data Transfer Rate Configuration

This section describes how to configure the data transfer rate.

### 29.4.1 Clock Setting

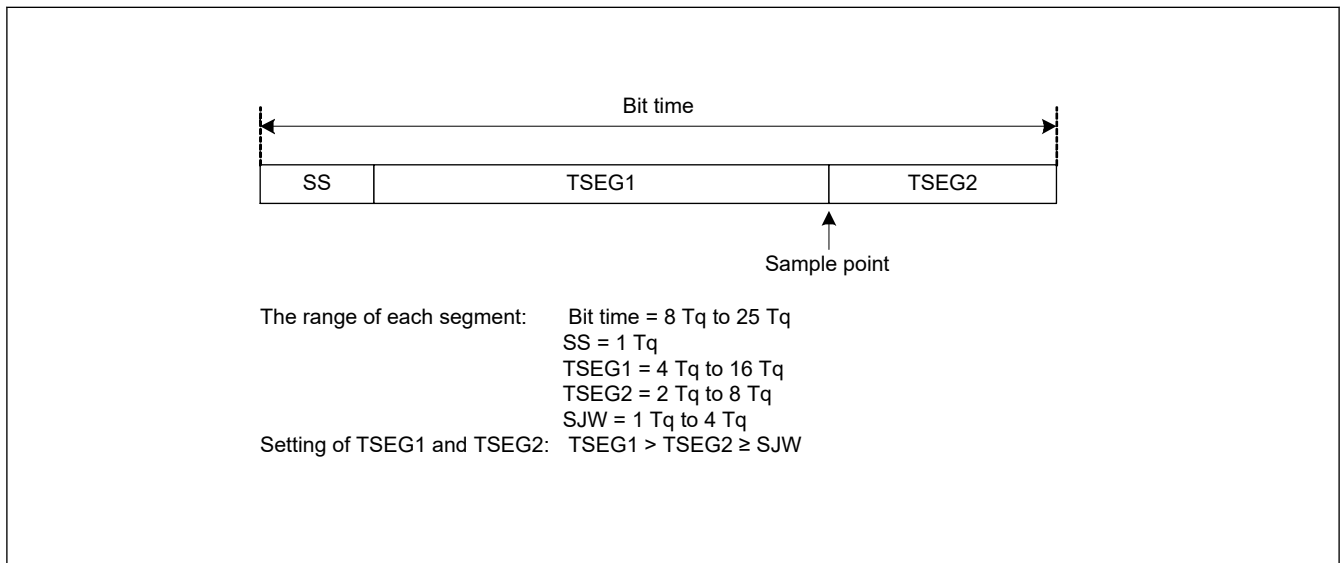

The CAN module provides a CAN clock generator. The CAN clock can be set in the CCLKS and BRP[9:0] bits in BCR. [Figure 29.11](#) shows a block diagram of the CAN clock generator.

**Figure 29.11** Block diagram of CAN clock generator

### 29.4.2 Bit Timing Setting

The bit timing consists of three segments as shown in [Figure 29.12](#).

**Figure 29.12 Bit timing**

### 29.4.3 Data Transfer Rate

The data transfer rate depends on the division value of fCAN (CAN system clock), the division value of the baud rate prescaler, and the Tq count for 1 bit time.

The division value of baud rate prescaler = P + 1 (P: 0 to 1023), where P is the BRP[9:0] setting in BCR.

$$\text{Data transfer rate (bps)} = \frac{f_{CAN}}{\text{Baud rate prescaler division value} \times \text{Tq count for 1 bit time}} = \frac{f_{CANCLK}}{\text{Tq count for 1 bit time}}$$

[Table 29.9](#) lists data transfer rate examples.

**Table 29.9 Data transfer rate examples**

| fCAN               | 20 MHz   |       |
|--------------------|----------|-------|
| Data transfer rate | Tq count | P + 1 |
| 1 Mbps             | 5 Tq     | 4     |
|                    | 10 Tq    | 2     |
| 500 kbps           | 5 Tq     | 8     |
|                    | 10 Tq    | 4     |
| 250 kbps           | 5 Tq     | 16    |
|                    | 10 Tq    | 8     |
| 125 kbps           | 5 Tq     | 32    |
|                    | 10 Tq    | 16    |
| 83.3 kbps          | 5 Tq     | 48    |
|                    | 10 Tq    | 24    |
| 33.3 kbps          | 5 Tq     | 120   |
|                    | 8 Tq     | 75    |
|                    | 10 Tq    | 60    |

### 29.5 Mailbox and Mask Register Structure

[Figure 29.13](#) shows the structure of the 32 mailbox registers: MBj\_ID, MBj\_DL, MBj\_Dm, and MBj\_TS.

Figure 29.13 Structure of the mailbox registers (j = 0 to 31)

Figure 29.14 shows the structure of the eight mask registers MKRk.

Figure 29.14 Structure of the MKRk registers (k = 0 to 7)

Figure 29.15 shows the structure of the two FIFO receive ID compare registers FIDCR0 and FIDCR1.

**Figure 29.15** Structure of the FIDCRn registers (n = 0)

## 29.6 Acceptance Filtering and Masking Functions

The acceptance filtering and masking functions allow you to select and receive messages with multiple IDs for mailboxes within a specified range.

The MKRk registers can mask the standard ID and the extended ID of 29 bits.

- MKR0 controls mailboxes 0 to 3
- MKR1 controls mailboxes 4 to 7
- MKR2 controls mailboxes 8 to 11
- MKR3 controls mailboxes 12 to 15
- MKR4 controls mailboxes 16 to 19
- MKR5 controls mailboxes 20 to 23
- MKR6 controls mailboxes 24 to 27 in normal mailbox mode and the receive FIFO mailboxes 28 to 31 in FIFO mailbox mode
- MKR7 controls mailboxes 28 to 31 in normal mailbox mode and the receive FIFO mailboxes 28 to 31 in FIFO mailbox mode

MKIVLR disables acceptance filtering independently for each mailbox.

The IDE bit in MBj\_ID is valid when the IDFM[1:0] bits in CTRLR are 10b (mixed ID mode).

The RTR bit in MBj\_ID selects a data or remote frame.

In FIFO mailbox mode, normal mailboxes 0 to 23 use one associated register from MKR0 to MKR5 for acceptance filtering. The receive FIFO mailboxes 28 to 31 use two registers, MKR6 and MKR7, for acceptance filtering.

The receive FIFO also uses two registers, FIDCR0 and FIDCR1, for ID comparison. The EID[17:0], SID[10:0], RTR, and IDE bits in MB28 to MB31 for the receive FIFO are disabled. As acceptance filtering depends on the result of two logic AND operations, two ranges of IDs can be received into the receive FIFO. MKIVLR is disabled for the receive FIFO.

If different standard ID and extended ID values are set in the IDE bits in FIDCR0 and FIDCR1, both ID formats are received.

If different data frame and remote frame values are set in the RTR bits in FIDCR0 and FIDCR1, both data and remote frames are received.

When a combination of two ranges of IDs is not required, set the same mask value and the same ID into both the FIFO ID and mask registers.

Figure 29.16 shows the associations between the mask registers and mailboxes. Figure 29.17 shows the acceptance filtering.

## 29.7 Reception and Transmission

Table 29.10 lists the CAN communication mode settings.

**Table 29.10 Settings for CAN receive and transmit modes**

| MCTL_TX[j].TRMREQ<br>and<br>MCTL_RX[j].TRMREQ | MCTL_TX[j].RECREQ<br>and<br>MCTL_RX[j].RECREQ | MCTL_TX[j].ONESHOT<br>and<br>MCTL_RX[j].ONESHOT | Mailbox communication mode                                                                                  |
|-----------------------------------------------|-----------------------------------------------|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| 0                                             | 0                                             | 0                                               | Mailbox disabled or transmission being aborted                                                              |
| 0                                             | 0                                             | 1                                               | Can be configured only when transmission or reception from a mailbox programmed in one-shot mode is aborted |
| 0                                             | 1                                             | 0                                               | Configured as a receive mailbox for a data or remote frame                                                  |
| 0                                             | 1                                             | 1                                               | Configured as a one-shot receive mailbox for a data or remote frame.                                        |
| 1                                             | 0                                             | 0                                               | Configured as a transmit mailbox for a data or remote frame.                                                |
| 1                                             | 0                                             | 1                                               | Configured as a one-shot transmit mailbox for a data or remote frame.                                       |
| 1                                             | 1                                             | 0                                               | Do not set.                                                                                                 |
| 1                                             | 1                                             | 1                                               | Do not set.                                                                                                 |

Note: j = 0 to 31

When a mailbox is configured as a receive mailbox or a one-shot receive mailbox, the following restrictions apply:

- Before configuring the mailbox, set MCTL\_RX[j] to 0x00.
- A received message is stored in the first mailbox that matches the condition resulting from the receive mode settings and acceptance filtering. The matching mailbox with the smallest number takes priority for storing the received message.
- In CAN operation mode, the CAN module does not receive its own transmitted data even when the ID is a match. In self-test mode, however, the CAN module receives its own transmitted data and returns ACK.

When configuring a mailbox as a transmit mailbox or a one-shot transmit mailbox, the following constraint applies:

- Before configuring a mailbox, ensure that MCTL\_TX[j] is 0x00 and that there is no pending abort process.

### 29.7.1 Reception

Figure 29.18 shows an operation example of data frame reception in overwrite mode. The example shows the overwriting of the first message when the CAN module receives two consecutive CAN messages that match the receiving conditions in MCTL\_RX[j] (j = 0 to 31).

**Figure 29.18 Operation example of data frame reception in overwrite mode**

1. When an SOF is detected on the CAN bus, the RECST bit in STR is set to 1 (reception in progress) if the CAN module has no message ready to start transmission.
2. Acceptance filtering starts at the beginning of the CRC field to select the receive mailbox.
3. After a message is received, the NEWDATA flag in MCTL\_RX[j] for the receive mailbox is set to 1 (new message is being stored or was stored in the mailbox). The INVALIDDATA flag in MCTL\_RX[j] is set to 1 (message is being updated) at the same time, and then the INVALIDDATA flag is set to 0 (message valid) again after the complete message is transferred to the mailbox.
4. When the interrupt enable bit in MIER for the receive mailbox is 1 (interrupt enabled), the INVALIDDATA flag is set to 0, which triggers a CAN0 reception complete interrupt request.
5. After reading the message from the mailbox, the NEWDATA flag must be set to 0 by software.
6. In overwrite mode, if the next CAN message is received before the NEWDATA flag in MCTL\_RX[j] is set to 1, the MSGLOST flag in MCTL\_RX[j] is set to 1 (message was overwritten). The new received message is transferred to the mailbox. The CAN0 reception complete interrupt request occurs the same as in step 4.

Figure 29.19 shows an operation example of data frame reception in overrun mode. The example shows the overrunning of the second message when the CAN module receives two consecutive CAN messages that match the receiving conditions in MCTL\_RX[j] (j = 0 to 31).

**Figure 29.19 Operation example of data frame reception in overrun mode**

1. When an SOF is detected on the CAN bus, the RECST bit in STR is set to 1 (reception in progress) if the CAN module has no message ready to start transmission.
2. Acceptance filtering starts at the beginning of the CRC field to select the receive mailbox.
3. After a message is received, the NEWDATA flag in MCTL\_RX[j] for the receive mailbox is set to 1 (new message is being stored or was stored in the mailbox). The INVALIDDATA flag in MCTL\_RX[j] is set to 1 (message is being updated) at the same time, and then the INVALIDDATA flag is set to 0 (message valid) again after the complete message is transferred to the mailbox.
4. When the interrupt enable bit in MIER for the receive mailbox is 1 (interrupt enabled), the INVALIDDATA flag is set to 0, which triggers a CAN0 reception complete interrupt request.
5. After reading the message from the mailbox, the NEWDATA flag must be set to 0 by software.
6. In overrun mode, if the next CAN message is received before the NEWDATA flag in MCTL\_RX[j] is set to 0, the MSGLOST flag in MCTL\_RX[j] is set to 1 (message was saved). The new received message is discarded and a CANi error interrupt request occurs if the associated interrupt enable bit in EIER is set to 1 (interrupt enabled).

### 29.7.2 Transmission

Figure 29.20 shows an operation example of data frame transmission.

**Figure 29.20 Operation example of data frame transmission**

1. When a TRMREQ bit in MCTL\_TX[j] ( $j = 0$  to 31) is set to 1 (transmit mailbox) in the bus-idle state, mailbox scanning starts to decide the highest-priority mailbox for transmission. When the transmit mailbox is decided, the TRMACTIVE flag in MCTL\_TX[j] is set to 1 (from acceptance of transmission request to completion of transmission, or error or arbitration-lost), the TRMST bit in STR is set to 1 (transmission in progress), and the CAN module starts transmission.<sup>\*1</sup>
2. If other TRMREQ bits are set, the transmission scanning starts with the CRC delimiter for the next transmission.
3. If transmission is complete without losing arbitration, the SENTDATA flag in MCTL\_TX[j] is set to 1 (transmission complete) and the TRMACTIVE flag is set to 0 (transmission is pending or transmission is not requested). If the interrupt enable bit in MIER is 1 (interrupt enabled), the CANi transmission complete interrupt request is generated.
4. When requesting the next transmission from the same mailbox, set the SENTDATA flag and TRMREQ bit to 0, and then set the TRMREQ bit to 1 after checking that the SENTDATA flag and TRMREQ bit are set to 0.

Note 1. If arbitration is lost after the CAN module starts transmission, the TRMACTIVE flag is set to 0. Transmission scanning is performed again to search for the highest-priority transmit mailbox from the beginning of the CRC delimiter. If an error occurs either during transmission or following arbitration-lost, transmission scanning is performed again to search for the highest-priority transmit mailbox from the start of the error delimiter.

## 29.8 Interrupts

The CAN module provides the following interrupts for each channel. [Table 29.11](#) lists the CAN interrupts.

- CANi reception complete interrupt for mailboxes 0 to 31 (CANi\_RXM)
- CANi transmission complete interrupt for mailboxes 0 to 31 (CANi\_TXM)
- CANi receive FIFO interrupt (CANi\_RXF)
- CANi transmit FIFO interrupt (CANi\_TXF)
- CANi error interrupt (CANi\_ERS)

Eight interrupt sources are available for CANi error interrupts. Check EIFR to determine the interrupt sources:

- Bus error
- Error-warning
- Error-passive
- Bus-off entry
- Bus-off recovery
- Receive overrun
- Overload frame transmission
- Bus lock

**Table 29.11 CAN interrupts**

| Module       | Interrupt name | Interrupt source                                                  | Source flag                             |
|--------------|----------------|-------------------------------------------------------------------|-----------------------------------------|
| CANi (i = 0) | CANi_ERS       | Bus lock detected                                                 | EIFR.BLIF                               |
|              |                | Overload frame transmission detected                              | EIFR.OLIF                               |
|              |                | Overrun detected                                                  | EIFR.ORIF                               |
|              |                | Bus-off recovery detected                                         | EIFR.BORIF                              |
|              |                | Bus-off entry detected                                            | EIFR.BOEIF                              |
|              |                | Error-passive detected                                            | EIFR.EPIF                               |
|              |                | Error-warning detected                                            | EIFR.EWIF                               |
|              |                | Bus error detected                                                | EIFR.BEIF                               |
|              | CANi_RXF       | Receive FIFO message received (MIER_FIFO.MB29 = 0)                | RFCR.RFUST[2:0]                         |
|              |                | Receive FIFO warning (MIER_FIFO.MB29 = 1)                         |                                         |
|              | CANi_TXF       | Transmit FIFO message transmission completed (MIER_FIFO.MB25 = 0) | TFCR.TFUST[2:0]                         |
|              |                | FIFO last message transmission completed (MIER_FIFO.MB25 = 1)     |                                         |
|              | CANi_RXM       | Mailbox 0 to 31 message received                                  | MCTL_RX0.NEWDATA to MCTL_RX31.NEWDATA   |
|              | CANi_TXM       | Mailbox 0 to 31 message transmission completed                    | MCTL_TX0.SENTDATA to MCTL_TX31.SENTDATA |

## 29.9 Usage Notes

### 29.9.1 Settings for the Module-Stop State

The MSTPCRB can enable or disable CAN operation. The CAN module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

### 29.9.2 Settings for the Operating Clock

The settings for the operating clock can be made as follows:

- The following clock constraint must be satisfied for the CAN module:

$$PCLKB \geq CANMCLK$$

- The peripheral module clock source must be PLL for the CAN module when the CCLKS bit is 0.

## 30. Serial Peripheral Interface (SPI)

### 30.1 Overview

The Serial Peripheral Interface (SPI) has 1 channel. The SPI provides high-speed full-duplex synchronous serial communications with multiple processors and peripheral devices. [Table 30.1](#) lists the SPI specifications, [Figure 30.1](#) shows a block diagram, and [Table 30.2](#) lists the I/O pins.

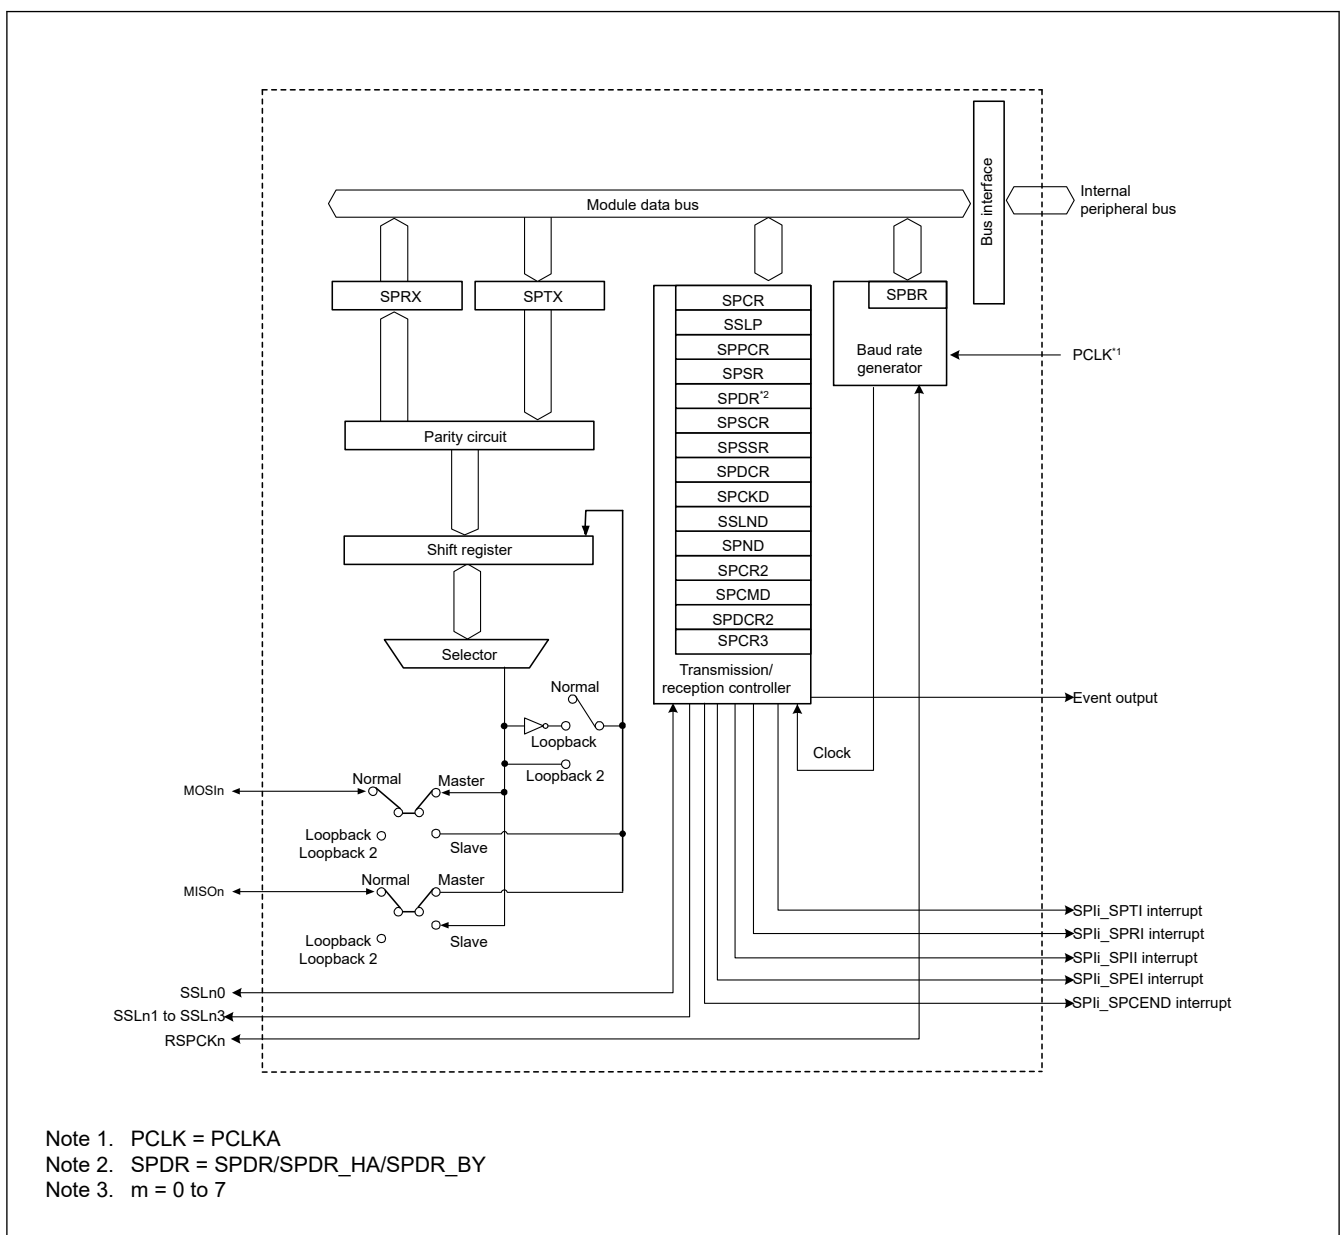

**Table 30.1 SPI specifications (1 of 2)**

| Parameter                  | Specifications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table 30.1 SPI specifications (2 of 2)**

| Parameter            | Specifications                                                                                                                                                                                                                                                                                                                |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Event link function  | The following events can be output to the Event Link Controller (ELC): <ul style="list-style-type: none"> <li>• Receive buffer full signal</li> <li>• Transmit buffer empty signal</li> <li>• Mode fault, underrun, overrun, or parity error signal</li> <li>• SPI idle signal</li> <li>• Communication end signal</li> </ul> |
| Other functions      | <ul style="list-style-type: none"> <li>• Switching between CMOS output and open-drain output</li> <li>• SPI initialization function</li> <li>• Loopback mode</li> </ul>                                                                                                                                                       |
| Module-stop function | Module-stop state can be set to reduce power consumption.                                                                                                                                                                                                                                                                     |
| TrustZone Filter     | Security attribution can be set                                                                                                                                                                                                                                                                                               |

Note 1. In master reception and when the RSPCK auto-stop function is enabled, an overrun error does not occur because the transfer clock is stopped on overrun error detection.

**Figure 30.1 SPI block diagram**

The SPI automatically switches the I/O direction of the SSLn0 pin. SSLn0 is set as an output when the SPI is a single master, and as an input when the SPI is a multi-master or a slave. The RSPCKn, MOSIn, and MISOn pins are automatically set as inputs or outputs based on the master or slave setting and the level input on the SSLn0 pin. For details, see [section 30.3.2. Controlling the SPI Pins](#).

**Table 30.2 SPI I/O pins**

| Channel | Pin name       | I/O    | Description                       |
|---------|----------------|--------|-----------------------------------|
| SPI0    | RSPCKA         | I/O    | Clock input/output pin            |
|         | SSLA0          | I/O    | Slave selection input/output      |
|         | SSLA1 to SSLA3 | Output | Slave selection output            |
|         | MOSIA          | I/O    | Master transmit data input/output |
|         | MISOA          | I/O    | Slave transmit data input/output  |

## 30.2 Register Descriptions

| 7   | SPRIE  | SPI Receive Buffer Full Interrupt Enable<br>0: Disable SPI receive buffer full interrupt requests<br>1: Enable SPI receive buffer full interrupt requests | R/W |

#### SPMS bit (SPI Mode Select)

The SPMS bit selects SPI operation (4-wire method) or clock synchronous operation (3-wire method).

The SSLn0 to SSLn3 pins are not used in clock synchronous operation. The RSPCKn, MOSIn, and MISO<sub>n</sub> pins handle communications. For clock synchronous operation in master mode (MSTR = 1), the SPCMDm.CPHA bit can be set to either 0 or 1. For clock synchronous operation in slave mode (MSTR = 0), always set the CPHA bit to 1. Do not perform operations if the CPHA bit is set to 0 for clock synchronous operation in slave mode (MSTR = 0).

#### **TXMD bit (Communications Operating Mode Select)**

The TXMD bit selects full-duplex synchronous serial communications or transmit-only operations. When this bit is set to 1, the SPI only performs transmit operations and does not perform receive operations (see [section 30.3.6. Data Transfer Modes](#)), and receive buffer full interrupt requests cannot be used.

TXMD setting is invalid in receive only slave mode.

#### **MODFEN bit (Mode Fault Error Detection Enable)**

The MODFEN bit enables or disables the detection of mode fault errors (see [section 30.3.9. Error Detection](#)). In addition, the SPI determines the I/O direction of the SSLni pins based on combination of the MODFEN and MSTR bits (see [section 30.3.2. Controlling the SPI Pins](#)).

#### **MSTR bit (SPI Master/Slave Mode Select)**

The MSTR bit selects master or slave mode for the SPI. Based on the MSTR bit settings, the SPI determines the direction of the RSPCKn, MOSIn, MISO<sub>n</sub>, and SSLni pins.

#### **SPEIE bit (SPI Error Interrupt Enable)**

The SPEIE bit enables or disables the generation of SPI error interrupt requests when one of the following occurs:

- The SPI detects a mode fault error or underrun error and sets the SPSR.MODF flag to 1
- The SPI detects an overrun error and sets the SPSR.OVRF flag to 1
- The SPI detects a parity error and sets the SPSR.PERF flag to 1

For details, see [section 30.3.9. Error Detection](#).

#### **SPTIE bit (Transmit Buffer Empty Interrupt Enable)**

The SPTIE bit enables or disables the generation of transmit buffer empty interrupt requests when the SPI detects that the transmit buffer is empty. To generate a transmit buffer empty interrupt request when transmission starts, set the SPE and SPTIE bits to 1 at the same time or set the SPE bit to 1 after setting the SPTIE bit to 1.

When the SPTIE bit is 1, transmit buffer interrupts are generated even when the SPI function is disabled (when the SPE bit is changed to 0).

#### **SPE bit (SPI Function Enable)**

The SPE bit enables or disables the SPI function. The SPE bit cannot be set to 1 when the SPSR.MODF flag is 1. For details, see [section 30.3.9. Error Detection](#).

Setting the SPE bit to 0 disables the SPI function and initializes a part of the module function. For details, see [section 30.3.10. Initializing the SPI](#). In addition, a transmit buffer empty interrupt request is generated when the SPE bit is changed from 0 to 1 or from 1 to 0.

#### **SPRIE bit (SPI Receive Buffer Full Interrupt Enable)**

The SPRIE bit enables or disables the generation of an SPI receive buffer full interrupt request when the SPI detects a receive buffer full write after completion of a serial transfer.

### 30.2.2 SSLP : SPI Slave Select Polarity Register

Base address: SPI0 = 0x4011\_A000

Offset address: 0x01

|                    |   |   |   |   |       |       |       |       |

| 0   | SPLP   | SPI Loopback<br>0: Normal mode<br>1: Loopback mode (receive data = inverted transmit data)                                                                           | R/W |
| 1   | SPLP2  | SPI Loopback 2<br>0: Normal mode<br>1: Loopback mode (receive data = transmit data)                                                                                  | R/W |
| 3:2 | —      | These bits are read as 0. The write value should be 0.                                                                                                               | R/W |
| 4   | MOIFV  | MOSI Idle Fixed Value<br>0: Set level output on MOSIn pin during MOSI idling to low<br>1: Set level output on MOSIn pin during MOSI idling to high                   | R/W |
| 5   | MOIFE  | MOSI Idle Value Fixing Enable<br>0: Set MOSI output value to equal final data from previous transfer<br>1: Set MOSI output value to equal value set in the MOIFV bit | R/W |
| 7:6 | —      | These bits are read as 0. The write value should be 0.                                                                                                               | R/W |

#### SPLP bit (SPI Loopback)

The SPLP bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISO pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0. The SPI then inverts the value of the input path for the shift register and connects it to the output path (loopback mode). For more information, see [section 30.3.13. Loopback Mode](#).

**SPLP2 bit (SPI Loopback 2)**

The SPLP2 bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISO pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0. The SPI then connects the value of the input path for the shift register to the output path (loopback mode) without inverting the value. For more information, see [section 30.3.13. Loopback Mode](#).

**MOIFV bit (MOSI Idle Fixed Value)**

The MOIFV bit determines the MOSIn pin output value during the SSL negation period (including the SSL retention period during a burst transfer) when the MOIFE bit is 1 in master mode.

**MOIFE bit (MOSI Idle Value Fixing Enable)**

The MOIFE bit fixes the MOSIn output value when the SPI is in master mode and in an SSL negation period (including the SSL retention period during a burst transfer). When the MOIFE bit is 0, the SPI outputs the last data from the previous serial transfer during the SSL negation period to the MOSIn pin. When the MOIFE bit is 1, the SPI outputs the fixed value set in the MOIFV bit to the MOSIn pin.

**30.2.4 SPSR : SPI Status Register**

Base address: SPI0 = 0x4011\_A000

Offset address: 0x03

|                    |      |           |           |      |      |      |       |      |

Note 1. Only 0 can be written to clear the flag after reading 1.

Note 2. Clear the UDRF flag at the same time as the MODF flag.

Note 3. The write value should be 1.

**OVRF flag (Overrun Error Flag)**

The OVRF flag indicates the occurrence of an overrun error. In master mode (SPCR.MSTR bit = 1) and when the RSPCK clock auto-stop function is enabled (SPCR1.SCKASE bit = 1), overrun errors do not occur. This flag does not set to 1. For details, see [section 30.3.9.1. Overrun errors](#).

[Setting condition]

When the next serial transfer ends and the receive buffer is full, and satisfy one of following.

- The SPCR.TXMD bit = 0. (transmit-receive master mode or transmit-receive slave mode or receive only slave mode)
- The SPCR.MSTR bit = 0, and the SPCR3.ETXMD bit = 1. (receive only slave mode)

[Clearing condition]

- When 0 is written to the OVRF flag after the OVRF flag is confirmed to be 1 by a read of SPSR.

**IDLNF flag (SPI Idle Flag)**

The IDLNF flag indicates the transfer status of the SPI.

[Setting conditions]

Master mode

- When none of the conditions in the master mode [Clearing condition] is met.

Slave mode

- When the SPE bit in SPCR is 1, enabling the SPI function.

[Clearing conditions]

Master mode

When condition 1 or all other conditions are satisfied.

Condition 1: The SPE bit in SPCR is 0, indicating that the SPI is initialized.

Condition 2: The transmit buffer (SPTX) is empty, indicating that data for the next transfer is not set.

Condition 3: The SPI internal sequencer is in the idle state, indicating that operation up to next-access delay is complete.

Condition 4: The SPCP[2:0] bits in SPSSR are 000 (at the beginning of sequence control)

Slave mode

- When condition 1 is satisfied.

**MODF flag (Mode Fault Error Flag)**

The MODF flag indicates the occurrence of a mode fault error or an underrun error. The UDRF flag indicates which error occurred.

[Setting conditions]

Multi-master mode

- When the input level of the SSLni pin changes to the active level while the SPCR.MSTR bit is 1 (master mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), triggering a mode fault error.

Slave mode

- When condition 1 or 2 is satisfied.

Condition 1: The SSLni pin is negated before the RSPCK cycle required for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), triggering a mode fault error.

Condition 2: The serial transfer begins with the SPCR.MSTR bit is set to 0 (slave mode), the SPCR.SPE bit is set to 1, and the transmission data not prepared, triggering an underrun error.

The active level of the SSLni signal is determined by the SSLP.SSLiP bit (SSLi signal polarity setting).

[Clearing condition]

- When SPSR is read while this flag is 1, and then 0 is written to this flag.

### PERF flag (Parity Error Flag)

The PERF flag indicates the occurrence of a parity error.

[Setting condition]

When a serial transfer ends while the SPCR2.SPPE bit is 1, triggering a parity error, and satisfy one of following.

- The SPCR.TXMD bit = 0. (transmit-receive master mode or transmit-receive slave mode or receive only slave mode)
- The SPCR.MSTR bit = 0, and the SPCR3.ETXMD bit = 1. (receive only slave mode)

[Clearing condition]

- When SPSR is read while this flag is 1, and then 0 is written to this flag.

### UDRF flag (Underrun Error Flag)

The UDRF flag indicates the occurrence of an underrun error.

[Setting condition]

- When the serial transfer begins if the SPCR.MSTR bit is set to 0 (slave mode), the SPCR3.ETXMD bit is set to 0 (transmit-receive slave mode or transmit slave mode), the SPCR.SPE bit is set to 1, and the transmission data is not prepared, triggering an underrun error.

[Clearing condition]

- When SPSR is read while this flag is 1, and then 0 is written to this flag.

### SPTEF flag (SPI Transmit Buffer Empty Flag)

The SPTEF flag indicates the status of the transmit buffer for the SPI Data Register (SPDR/SPDR\_HA).

[Setting conditions]

- When condition 1. or 2. is satisfied.
  1. The SPCR.SPE bit is 0, indicating that the SPI is initialized.
  2. Transmit data (the frame size specified by the SPDCR.SPFC[1:0]) is transferred from the transmit buffer to the shift register.

[Clearing condition]

- When data written to SPDR/SPDR\_HA/SPDR\_BY equals the number of frames set in the SPFC[1:0] bits in the SPI Data Control Register (SPDCR).

Data can only be written to SPDR/SPDR\_HA/SPDR\_BY when the SPTEF flag is 1. If data is written to the transmit buffer of SPDR/SPDR\_HA when the SPTEF flag is 0, data in the transmit buffer is not updated.

### CENDF flag (Communication End Flag)

This flag indicates communication end status of SPI. It turns 1 at communication end, and turns 0 at starting next communication.

[Setting condition]

#### Master mode

The following 3 conditions are met.

- The transmit buffer(SPTX) is empty. (There is no next transmission data.)
- The SPSSR.SPCC[2:0] are 000b. (It means the head of the sequential control.)
- The state of SPI internal sequencer transferred to the idle state. (It means the next access delay has been completed.)

#### Transmit-receive / transmit only slave mode in SPI serial communication (4-wire: the SPCR.SPMS bit is 0)

The following 3 conditions are met.

- The transmit buffer(SPTX) is empty. (There is no next transmission data.)

- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- SSL0 was negated.

Transmit-receive / transmit only slave mode in clock synchronous (3-wire: the SPCR.SPMS bit is 1)

The following 3 conditions are met.

- The transmit buffer(SPTX) is empty. (There is no next transmission data.)
- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- The last even edge of RSPCK of the last data was detected. (When the SPCMD.CPHA bit is "1".)

Receive only slave mode in SPI serial communication (4-wire: the SPCR.SPMS bit is 0)

The following condition is met.

- SSL0 was negated after the last data was written in the received buffer.

Receive only slave mode in clock synchronous (3-wire: the SPCR.SPMS bit is 1)

The following condition is met.

- The last even edge of RSPCK of the last data was detected. (When the SPCMD.CPHA bit is 1.)

[Clearing condition]

Master mode

Satisfy one of following.

- The next transmit data was written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1

Transmit-receive / transmit only slave mode

Satisfy one of following.

- The next transmit data was written to the transmit buffer(SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Receive only slave mode in SPI serial communication (4-wire: the SPCR.SPMS bit is 0)

Satisfy one of following.

- SSL0 assertion of next data was detected.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Receive only slave mode in clock synchronous (3-wire: the SPCR.SPMS bit is 1)

Satisfy one of following.

- The first edge of RSPCK of the next data was detected.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

**SPRF flag (SPI Receive Buffer Full Flag)**

The SPRF flag indicates the status of the receive buffer for the SPI Data Register (SPDR/SPDR\_HA).

[Setting condition]

- Received data with the frame size specified by the SPDCR.SPFC[1:0] bits have been transferred to the SPDR from the shift register while the SPRF flag is 0. And satisfy one of following. However, the SPRF flag does not change from 0 to 1 while the OVRF flag = 1.
  - The SPCR.TXMD bit is 0 (transmit-receive master mode, transmit-receive slave mode, or receive only slave mode)
  - The SPCR.MSTR bit is 0 and the SPCR3.ETXMD bit is 1 (receive only slave mode)

[Clearing condition]

- When received data is read from the SPDR/SPDR\_HA.

### 30.2.5 SPDR/SPDR\_HA/SPDR\_BY : SPI Data Register

Base address: SPI0 = 0x4011\_A000

Offset address: 0x04

Bit position: 31

0

Bit field:

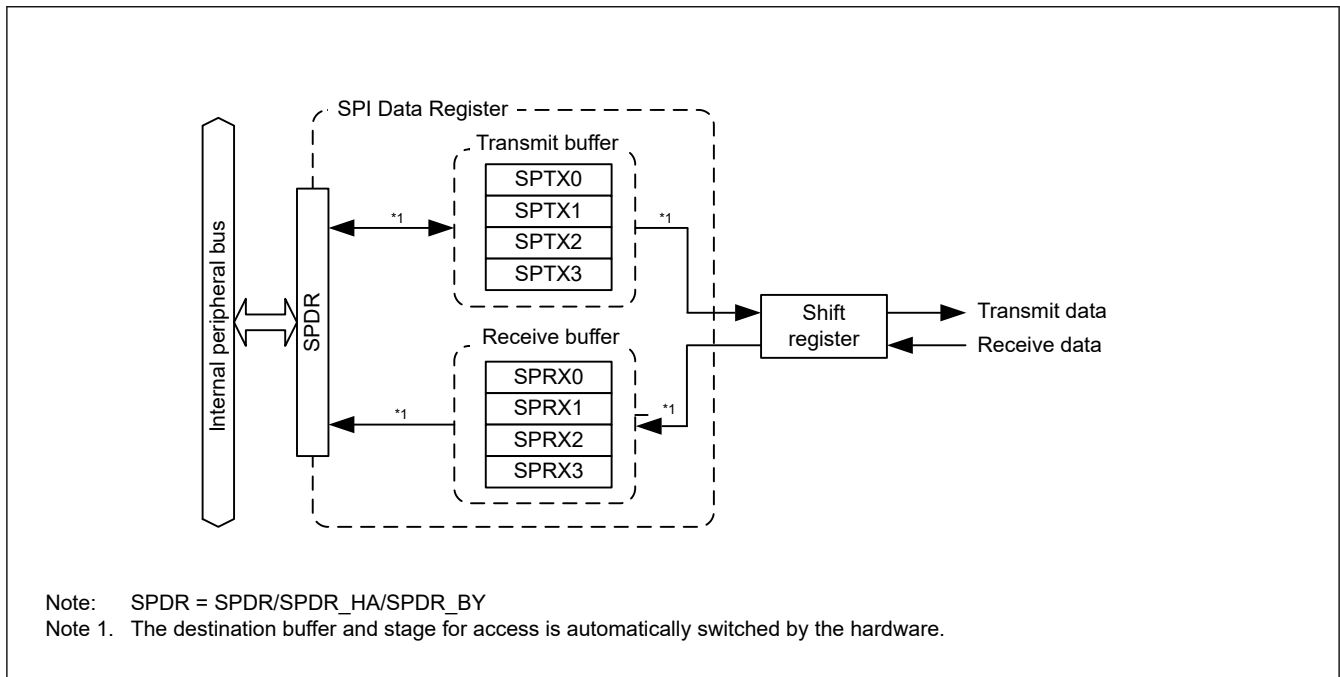

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

| Bit  | Symbol | Function | R/W |
|------|--------|----------|-----|
| 31:0 | n/a    | SPI Data | R/W |

SPDR/SPDR\_HA/SPDR\_BY is the interface with the buffers that hold data for transmission and reception by the SPI. When accessing this register in words (the SPDCR.SPLW bit is 1), access SPDR. When accessing it in halfwords (the SPLW bit is 0), access SPDR\_HA. When accessing it in byte (the SPDCR.SPBYT bit is 1), access SPDR\_BY.

The transmit buffer (SPTX) and receive buffer (SPRX) are independent but are both mapped to SPDR/SPDR\_HA. Figure 30.2 shows the configuration of the SPDR/SPDR\_HA register.

**Figure 30.2 Configuration of SPDR/SPDR\_HA/SPDR\_BY**

The transmit and receive buffers each have four stages. The eight stages of the buffer are all mapped to the single address of SPDR/SPDR\_HA/SPDR\_BY.

Data written to SPDR/SPDR\_HA/SPDR\_BY is written to a transmit-buffer stage (SPTX<sub>n</sub>) (n = 0 to 3), and then transmitted from the buffer. The receive buffer holds received data on completion of reception. The receive buffer is not updated if an overrun is generated.

Additionally, if the data length is not 32 bits, bits not referred to in SPTX<sub>n</sub> (n = 0 to 3) are stored in the associated bits in SPRX<sub>n</sub> (n = 0 to 3). For example, if the data length is 9 bits, the received data is stored in the SPRX<sub>n</sub>[8:0] bits, and the SPTX<sub>n</sub>[31:9] bits are stored in the SPRX<sub>n</sub>[31:9] bits.

#### (1) Bus interface

SPDR/SPDR\_HA/SPDR\_BY is an interface with 32-bit wide transmit and receive buffers, each of which has one stages, for a total of 32 bytes. The 32 bytes are mapped to the 4-byte address space for SPDR/SPDR\_HA/SPDR\_BY. Additionally, the unit of access for SPDR/SPDR\_HA/SPDR\_BY is selected by the SPI Word Access/Halfword Access Specification bit in

the SPI Data Control Register (SPDCR.SPLW). SPDR can also be accessed with the access size specified by the SPI Byte Access bit in the SPI Data Control Register (SPDCR.SPBYP).

Flush the transmission data at the LSB end of the register, and store the received data at the LSB end.

The following sections describe the operations involved in writing to and reading from SPDR/SPDR\_HA/SPDR\_BY.

### Writing

Data written to SPDR/SPDR\_HA/SPDR\_BY is written to a transmit buffer (SPTX<sub>n</sub>). This is not affected by the value of the SPDCR.SPRDTD bit, unlike when reading from SPDR/SPDR\_HA/SPDR\_BY. The transmit buffer includes a transmit buffer write pointer that is automatically updated to reference the next stage each time data is written to SPDR/SPDR\_HA/SPDR\_BY.

Figure 30.3 shows the configuration of the bus interface with the transmit buffer when writing to SPDR/SPDR\_HA/SPDR\_BY.

**Figure 30.3 Configuration of SPDR/SPDR\_HA/SPDR\_BY for write access**

The sequence for switching the transmit buffer write pointer differs with the setting of the number of frames specification bits in the SPI Data Control Register (SPDCR.SPFC[1:0]). The relationship of the SPFC[1:0] setting and the sequence of pointer switching from SPTX0 to SPTX3 is as follows:

- When SPFC[1:0] = 00b: SPTX0 → SPTX0 → SPTX0 → ...
- When SPFC[1:0] = 01b: SPTX0 → SPTX1 → SPTX0 → SPTX1 → ...
- When SPFC[1:0] = 10b: SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 → ...
- When SPFC[1:0] = 11b: SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → ...

When 1 is written to the SPI Function Enable bit in the SPI Control Register (SPCR.SPE) while the bit is 0, SPTX0 is the destination for the next write.

When writing to the transmit buffer (SPTX<sub>n</sub>) after generating the transmit buffer empty interrupt (when SPSR.SPTEF is 1), write the number of frames set in SPFC[1:0] in the SPI Data Control Register (SPDCR). Even when the specified number of frames is written to the transmit buffer (SPTX<sub>n</sub>), the value of the buffer is not updated after completion of the writing and before generation of the next transmit buffer empty interrupt (when SPTEF is 0).

### Reading

SPDR/SPDR\_HA/SPDR\_BY can be accessed to read the value of a receive buffer (SPRX<sub>n</sub>) or a transmit buffer (SPTX<sub>n</sub>). The setting in the SPI Receive/Transmit Data Select bit in the SPI Data Control Register (SPDCR.SPRDTD) selects whether reading is of the receive or transmit buffer. The sequence of reading the SPDR/SPDR\_HA/SPDR\_BY register is controlled by the independent receive buffer and transmit buffer read pointers.

Figure 30.4 shows the configuration of the bus interface with the receive and transmit buffers for reading from SPDR/SPDR\_HA/SPDR\_BY.

**Figure 30.4 Configuration of SPDR/SPDR\_HA/SPDR\_BY for read access**

Reading the receive buffer switches the receive buffer read pointer to the next buffer automatically. The switching sequence for the receive buffer read pointer is the same as that for the transmit buffer write pointer. However, when 1 is written to the SPI Function Enable bit in the SPI Control Register (SPCR.SPE) while the value of the bit is 1, SPRX0 is referenced by the buffer read pointer for the next read.

The transmit buffer read pointer is updated when writing to SPDR/SPDR\_HA/SPDR\_BY, but not updated when reading from the transmit buffer. When reading from the transmit buffer, the value most recently written to SPDR/SPDR\_HA/SPDR\_BY is read.

After a transmit buffer empty interrupt is generated, reading from the transmit buffer returns all 0s after the completion of writing the number of frames of data specified in the SPDCR.SPFC[1:0] bits, until the next buffer empty interrupt is generated (when SPTEF is 0).

### 30.2.6 SPSCR : SPI Sequence Control Register

Base address: SPI0 = 0x4011\_A000

Offset address: 0x08

SPSCR specifies the sequence length when the SPI operates in master mode. Before changing the SPSLN[2:0] bits while both the SPCR.MSTR and SPCR.SPE bits are 1, check that the SPSR.IDLNF flag is 0.

### SPSLN[2:0] bits (SPI Sequence Length Specification)

The SPSLN[2:0] bits specify the sequence length when the SPI in master mode performs sequential operations. The SPI in master mode changes the SPCMD0 to SPCMD7 registers to be referenced, and the order in which they are referenced is based on this sequence length setting. In slave mode, SPCMD0 is referenced.

### 30.2.7 SPSSR : SPI Sequence Status Register

SPSSR indicates the sequence control status when the SPI operates in master mode. Any writes to SPSSR are ignored.

**SPCP[2:0] bits (SPI Command Pointer)**

The SPCP[2:0] bits indicate the SPCMDm register that is referenced to by the pointer during sequence control by the SPI. For the SPI sequence control, see [section 30.3.11.1. Master mode operation](#).

**SPECM[2:0] bits (SPI Error Command)**

The SPECM[2:0] bits indicate the SPCMDm register that is specified in the SPCP[2:0] bits when an error is detected during sequence control by the SPI. The SPI updates the SPECM[2:0] bits only when an error is detected. If both the SPSR.OVRF and SPSR.MODF flags are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning.

For the SPI error detection function, see [section 30.3.9. Error Detection](#). For the SPI sequence control, see [section 30.3.11.1. Master mode operation](#).

**30.2.8 SPBR : SPI Bit Rate Register**

Base address: SPI0 = 0x4011\_A000

Offset address: 0x0A

| Bit | Symbol | Function | R/W |
|-----|--------|----------|-----|
| 7:0 | n/a    | Bit rate | R/W |

SPBR sets the bit rate in master mode.

When the SPI is in slave mode, the bit rate depends on the bit rate of the input clock, regardless of the settings in SPBR and the SPCMDm.BRDV[1:0] bits (bit rate division setting). Use bit rates that satisfy the electrical characteristics of the device.

The bit rate is determined by combinations of the SPBR and SPCMDm.BRDV[1:0] settings in the SPI Command Register. The equation for calculating the bit rate is given as follows:

$$\text{Bit rate} = \frac{f(\text{PCLK})}{2 \times (n + 1) \times 2^N}$$

( PCLK = PCLKA )

In the equation, n denotes an SPBR setting (0, 1, 2, ..., 255), and N denotes a BRDV[1:0] setting (0, 1, 2, 3).

[Table 30.3](#) lists examples of the relationship between the SPBR settings, the BRDV[1:0] settings, and bit rates.

**Table 30.3 Relationship between SPBR settings, BRDV[1:0] settings, and bit rates**

| SPBR(n) | BRDV[1:0] bits (N) | Division ratio | Bit rate       |
|---------|--------------------|----------------|----------------|
|         |                    |                | PCLKA = 32 MHz |
| 0       | 0                  | 2              | 16.0 Mbps      |
| 1       | 0                  | 4              | 8.00 Mbps      |
| 2       | 0                  | 6              | 5.33 Mbps      |

| 7   | —         | This bit is read as 0. The write value should be 0.                                                                                                                               | R/W |

The SPI Data Control Register (SPDCR) is used to read the number of frames that can be stored in the SPDR register, read the SPDR register, and to set the access width for the SPDR register to word access, halfword access, or byte access. Up to four frames can be transmitted or received in one round of transmission or reception. The amount of data in each transfer is controlled by the combination of the SPCMDm.SPB[3:0] bits, the SPCR.SPSSLN[2:0] bits, and the SPFC[1:0] bits.

When changing the SPFC[1:0] bits while the SPCR.SPE bit is 1, check that the SPSR.IDLNF flag is 0.

#### SPFC[1:0] bits (Number of Frames Specification)

The SPFC[1:0] bits specify the number of frames that can be stored in SPDR/SPDR\_HA per transfer activation. Up to four frames can be transmitted or received in one round of transmission or reception.

When the number of transmission data frames specified in the SPFC[1:0] bits is written to the SPDR/SPDR\_HA register, SPI clears the SPSR.SPTEF flag to 0 and begins transmitting. After that, when the number of transmission data frames specified in the SPFC[1:0] bits is transmitted to the shift register, the SPI generates the transmit buffer empty interrupt (SPSR.SPTEF sets to 1).

When the number of data frames specified in the SPFC[1:0] bits is received, the SPI generates the receive buffer full interrupt (SPSR.SPRF sets to 1).

**Table 30.4 Settable combinations of the SPSSLN[2:0] and SPFC[1:0] bits (1 of 2)**

| Setting | SPSSLN[2:0] | SPFC[1:0] | Number of frames in a single sequence | Number of frames at which transmission or receive buffer is filled |
|---------|-------------|-----------|---------------------------------------|--------------------------------------------------------------------|
| 1-1     | 000b        | 00b       | 1                                     | 1                                                                  |
| 1-2     | 000b        | 01b       | 2                                     | 2                                                                  |
| 1-3     | 000b        | 10b       | 3                                     | 3                                                                  |

**Table 30.4** Settable combinations of the SPSLN[2:0] and SPFC[1:0] bits (2 of 2)

| Setting | SPSLN[2:0] | SPFC[1:0] | Number of frames in a single sequence | Number of frames at which transmission or receive buffer is filled |
|---------|------------|-----------|---------------------------------------|--------------------------------------------------------------------|
| 2-2     | 001b       | 11b       | 4                                     | 4                                                                  |
| 3       | 010b       | 10b       | 3                                     | 3                                                                  |
| 4       | 011b       | 11b       | 4                                     | 4                                                                  |
| 5       | 100b       | 00b       | 5                                     | 1                                                                  |
| 6       | 101b       | 00b       | 6                                     | 1                                                                  |
| 7       | 110b       | 00b       | 7                                     | 1                                                                  |
| 8       | 111b       | 00b       | 8                                     | 1                                                                  |

**SPRDTD bit (SPI Receive/Transmit Data Select)**

The SPRDTD bit selects whether the SPDR/SPDR\_HA reads values from the receive buffer or from the transmit buffer. If reading is from the transmit buffer, the last value written to SPDR/SPDR\_HA register is read. Read the transmit buffer after an SPI transmit buffer empty interrupt is generated until data of frames specified by SPFC[1:0] has been written (while the SPSR.SPTEF flag is 1).

For details, see [section 30.2.5. SPDR/SPDR\\_HA/SPDR\\_BY : SPI Data Register](#).

**SPLW bit (SPI Word Access/Halfword Access Specification)**

The SPLW bit specifies the access width for SPDR. Access to SPDR\_HA in halfwords is valid when the SPLW bit is 0 and access to SPDR in words is valid when the SPLW bit is 1. Also, when this bit is 0, set the SPI data length setting bits, SPCMDm.SPB[3:0], from 8 to 16 bits. Do not perform any operations when a data length of 20, 24, or 32 bits is specified.

**SPBYT bit (SPI Byte Access Specification)**

The SPBYT bit is used to set the data width of access to the SPI Data Register (SPDR). When SPBYT = 0, use word or half word access to SPDR/SPDR\_HA. When SPBYT = 1 (in that case, SPLW is invalid), use byte access to SPDR\_BY.

When SPBYT = 1, set the SPI data length bits (SPB[3:0]) in the SPI Command Register m (SPCMDm) to 8 bits. If SPB[3:0] are set to 9 to 16, 20, 24, or 32 bits, subsequent operation is not guaranteed.

**30.2.10 SPCKD : SPI Clock Delay Register**

Base address: SPI0 = 0x4011\_A000

Offset address: 0x0C

Bit position: 7 6 5 4 3 2 1 0

| 7:3 | —          | These bits are read as 0. The write value should be 0.                                                                                                              | R/W |

SPCKD specifies the RSPCK delay, the period from the beginning of SSLni signal assertion to RSPCK oscillation, when the SPCMDm.SCKDEN bit is 1.

**SCKDL[2:0] bits (RSPCK Delay Setting)**

The SCKDL[2:0] bits specify an RSPCK delay value when the SPCMDm.SCKDEN bit is 1. When using the SPI in slave mode, set the SCKDL[2:0] bits to 000b.

**30.2.11 SSLND : SPI Slave Select Negation Delay Register**

Base address: SPI0 = 0x4011\_A000

Offset address: 0x0D

|                    |   |   |   |   |   |             |   |   |
|--------------------|---|---|---|---|---|-------------|---|---|

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0           | 0 | 0 |

| Bit | Symbol      | Function                                                                                                                                                                   | R/W |
|-----|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 2:0 | SSLNDL[2:0] | SSL Negation Delay Setting<br>0 0 0: 1 RSPCK<br>0 0 1: 2 RSPCK<br>0 1 0: 3 RSPCK<br>0 1 1: 4 RSPCK<br>1 0 0: 5 RSPCK<br>1 0 1: 6 RSPCK<br>1 1 0: 7 RSPCK<br>1 1 1: 8 RSPCK | R/W |
| 7:3 | —           | These bits are read as 0. The write value should be 0.                                                                                                                     | R/W |

SSLND specifies the SSL negation delay, the period from the transmission of a final RSPCK edge to the negation of the SSLni signal during a serial transfer by the SPI in master mode. If the contents of SSLND are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, do not perform subsequent operations.

**SSLNDL[2:0] bits (SSL Negation Delay Setting)**

The SSLNDL[2:0] bits specify an SSL negation delay value when the SLNDEN bit in SPCMDn is 1 and the SPI is in master mode. When using the SPI in slave mode, set the SSLNDL[2:0] bits to 000b.

**30.2.12 SPND : SPI Next-Access Delay Register**

Base address: SPI0 = 0x4011\_A000

Offset address: 0x0E

|                    |   |   |   |   |   |            |   |   |

| 7:3 | —          | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                        | R/W |

SPND specifies the next-access delay, the non-active period of the SSLni signal after termination of a serial transfer, when the SPCMDm.SPNDEN bit is 1.

**SPNDL[2:0] bits (SPI Next-Access Delay Setting)**

The SPNDL[2:0] bits specify a next-access delay when the SPCMDm.SPNDEN bit is 1. When using the SPI in slave mode, set the SPNDL[2:0] bits to 000b.

**30.2.13 SPCR2 : SPI Control Register 2**

Base address: SPI0 = 0x4011\_A000

Offset address: 0x0F

|                    |   |   |   |            |     |       |      |      |

| 4   | SCKASE | RSPCK Auto-Stop Function Enable<br>0: Disable RSPCK auto-stop function<br>1: Enable RSPCK auto-stop function                                                                                                                                                                                             | R/W |
| 7:5 | —      | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                   | R/W |

**SPPE bit (Parity Enable)**

The SPPE bit enables or disables the parity function.

When the SPCR.TXMD bit is 0 and this bit is 1, the parity bit is added to transmit data and parity checking is performed for receive data.

When the SPCR.TXMD bit is 1 and this bit is 1, the parity bit is added to transmit data but parity checking is not performed for receive data.

**SPOE bit (Parity Mode)**

The SPOE bit specifies odd or even parity.

When even parity is set, parity bit addition is performed so that the total number of bits whose value is 1 in the transmit or receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit addition is performed so that the total number of bits whose value is 1 in the transmit or receive character plus the parity bit is odd.

The SPOE bit is only valid when the SPPE bit is 1.

**SPIIE bit (SPI Idle Interrupt Enable)**

The SPIIE bit enables or disables the generation of SPI idle interrupt requests when an idle state is detected in the SPI and the SPSR.IDLNF flag clears is set to 0.

**PTE bit (Parity Self-Testing)**

The PTE bit enables self-diagnosis of the parity circuit to check whether the parity function is operating correctly.

**SCKASE bit (RSPCK Auto-Stop Function Enable)**

The SCKASE bit enables or disables the RSPCK auto-stop function. When this function is enabled, the RSPCK clock is stopped before an overrun error occurs, when data is received in master mode. For details, see [section 30.3.9.1. Overrun errors](#).

**30.2.14 SPCMDm : SPI Command Register m (m = 0 to 7)**

Base address: SPI0 = 0x4011\_A000

Offset address: 0x10 + 0x02 × m

|-----|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 14  | SLNDEN | SSL Negation Delay Setting Enable<br>0: Select SSL negation delay of 1 RSPCK<br>1: Select SSL negation delay equal to the setting in the SPI Slave Select Negation Delay Register (SSLND) | R/W |
| 15  | SCKDEN | RSPCK Delay Setting Enable<br>0: Select RSPCK delay of 1 RSPCK<br>1: Select RSPCK delay equal to the setting in the SPI Clock Delay Register (SPCKD)                                      | R/W |

The SPCMDm registers specify the transfer format for the SPI in master mode. Each channel has eight SPCMDm (m = 0 to 7). Some of the bits in the SPCMD0 registers are used to set the transfer mode for the SPI in slave mode. The SPI in master mode sequentially references the SPCMDm registers based on the settings in the SPSCR.SPSSLN[2:0] bits and executes the serial transfer that is set in the referenced SPCMDm registers.

Set the SPCMDm registers while the transmit buffer is empty (SPSR.SPTEF is 1 and data for the next transfer is not set) and before the setting of the data to be transmitted when that SPCMDm registers is referenced.

The SPCMDm registers referenced by the SPI in master mode can be checked by means of the SPSSR.SPCP[2:0] bits.

#### CPHA bit (RSPCK Phase Setting)

The CPHA bit selects the RSPCK phase of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK phase setting between the modules.

#### CPOL bit (RSPCK Polarity Setting)

The CPOL bit selects the RSPCK polarity of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK polarity setting between the modules.

#### BRDV[1:0] bits (Bit Rate Division Setting)

The BRDV[1:0] bits determine the bit rate in combination with the settings in the SPBR register. (see [section 30.2.8. SPBR : SPI Bit Rate Register](#)). The SPBR settings determine the base bit rate. The BRDV[1:0] setting selects the bit rate obtained by dividing the base bit rate by 1, 2, 4, or 8. Different BRDV[1:0] bit settings can be specified in the SPCMD0 register. This enables execution of serial transfers at different bit rates for each command.

#### SSLA[2:0] bits (SSL Signal Assertion Setting)

The SSLA[2:0] bits control the SSLni signal assertion when the SPI performs serial transfers in master mode. When an SSLni signal is asserted, its polarity is determined by the value set in the associated SSLP. When the SSLA[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSLn0 pin acts as input).

When using the SPI in slave mode, set the SSLA[2:0] bits to 000b.

#### SSLKP bit (SSL Signal Level Keeping)

When the SPI in master mode performs a serial transfer, the SSLKP bit specifies whether the SSLni signal level for the current command is to be kept or negated between the SSL negation associated with the current command and the SSL assertion associated with the next command. Setting the SSLKP bit to 1 enables a burst transfer. For details, see [section 30.3.11.1. Master mode operation](#). When using the SPI in slave mode, set the SSLKP bit to 0.

#### SPB[3:0] bits (SPI Data Length Setting)

The SPB[3:0] bits specify the transfer data length for the SPI in master or slave mode.

#### LSBF bit (SPI LSB First)

The LSBF bit specifies the data format of the SPI in master or slave mode to MSB-first or LSB-first.

#### SPNDEN bit (SPI Next-Access Delay Enable)

The SPNDEN bit specifies the next-access delay, the period from the time the SPI in master mode terminates a serial transfer and sets the SSLni signal inactive until the SPI enables the SSLni signal assertion for the next access. If the SPNDEN bit is 0, the SPI sets the next-access delay to 1 RSPCK + 2 PCLKA. If the SPNDEN bit is 1, the SPI inserts a next-access delay according to the SPND setting.

When using the SPI in slave mode, set the SPNDEN bit to 0.

### SLNDEN bit (SSL Negation Delay Setting Enable)

The SLNDEN bit specifies the SSL negation delay, the period from the time the SPI in master mode stops RSPCK oscillation until the SPI sets the SSL<sub>ni</sub> signal to inactive. If the SLNDEN bit is 0, the SPI sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the SPI negates the SSL signal at the SSL negation delay according to the SSLND setting.

When using the SPI in slave mode, set the SLNDEN bit to 0.

### SCKDEN bit (RSPCK Delay Setting Enable)

The SCKDEN bit specifies the SPI clock delay, the period from the point when the SPI in master mode asserts the SSL<sub>ni</sub> signal until the RSPCK starts oscillation. If the SCKDEN bit is 0, the SPI sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the SPI starts the oscillation of RSPCK at an RSPCK delay according to the SPCKD setting.

When using the SPI in slave mode, set the SCKDEN bit to 0.

## 30.2.15 SPDCR2 : SPI Data Control Register 2

Base address: SPI0 = 0x4011\_A000

Offset address: 0x20

|                    |   |   |   |   |   |   |      |      |
|--------------------|---|---|---|---|---|---|------|------|
| Bit position:      | 7 | 6 | 5 | 4 | 3 | 2 | 1    | 0    |
| Bit field:         | — | — | — | — | — | — | SINV | BYSW |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0    | 0    |

| Bit | Symbol | Function                                                                     | R/W |
|-----|--------|------------------------------------------------------------------------------|-----|
| 0   | BYSW   | Byte Swap Operating Mode Select<br>0: Byte Swap OFF<br>1: Byte Swap ON       | R/W |
| 1   | SINV   | Serial Data Invert Bit<br>0: Not invert serial data<br>1: Invert serial data | R/W |
| 7:2 | —      | These bits are read as 0. The write value should be 0.                       | R/W |

SPI Data Control Register 2 (SPDCR2) is the setting register, that is to swap a transmit/receive data in byte units and to invert serial data. If these bits are modified while the SPI in slave mode is enabled (SPCR.SPE = 1), subsequent operation is not guaranteed.

### BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. When byte access is valid (SPDCR.SPBYT = 1), byte swap is invalid. When byte swap is valid, parity function must be invalid (SPCR2.SPPE bit = 0). Setting change of BYSW bit must be SPCR.SPE bit = 0.

A data after byte swap is different by a data length (setting of SPCMD.SPB[3:0]).

When byte swap, A data length (setting of SPB[3:0]) must be set to 32 bit or 16bit. Other case of data length (that is 8 to 15, 20, 24 bit length), byte swap is not guaranteed. Before swap and after swap are shown below (length data (32 bit/16 bit)).

- Length data 32 bits (SPB[3:0] = 0010b or 0011b)
  - Before swap: [31:24] [23:16] [15:8] [7:0]
  - After swap: [7:0] [15:8] [23:16] [31:24]
- Length data 16 bit (SPB[3:0] = 1111b)
  - Before swap: [31:24] [23:16]
  - After swap: [23:16] [31:24]

When byte access mode (SPDCR.SPBT = 1), byte swap setting is invalid.

When byte swap is valid, set parity function to invalid (SPCR2.SPPE = 0). When the parity function set to valid, the behavior is not guaranteed.

### SINV bit (Serial Data Invert Bit)

This bit is used to invert transmit data and receive data.

When the SINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/reception data.

### 30.2.16 SPCR3 : SPI Control Register 3

Base address: SPI0 = 0x4011\_A000

Offset address: 0x21

|                    |   |   |   |            |   |   |      |            |
|--------------------|---|---|---|------------|---|---|------|------------|
| Bit position:      | 7 | 6 | 5 | 4          | 3 | 2 | 1    | 0          |

| 3:2 | —      | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                 | R/W |
| 4   | CENDIE | SPI Communication End Interrupt Enable<br>0: Communication end interrupt request is disabled.<br>1: Communication end interrupt request is enabled.                                                                                                                                                                    | R/W |
| 7:5 | —      | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                 | R/W |

SPI control register 3 (SPCR3) is control register for operation mode. If you change the value of ETXMD and BFDS when the SPCR.SPE bit is 1, the SPI operation does not guarantee.

### ETXMD bit (Extended Communication Mode Select)

This bit is valid on slave mode only (the SPCR.MSTR bit is 0). This bit select receive only operation. When the ETXMD bit is 1 on slave mode, the communication is only received not transmit (see [section 30.3.6. Data Transfer Modes](#)). When the ETXMD is 1, transmit data empty interrupt can not be used.

The communication state by each mode (master mode, slave mode) is shown as below. It is controlled by the ETXMD bit, the SPCR.MSTR bit and the TXMD bit.

**Table 30.5 SPI communication state (master/slave mode)**

| SPCR.MSTR bit | SPCR3.ETXMD bit | SPCR.TXMD bit | Communication state                   |
|---------------|-----------------|---------------|---------------------------------------|
| 1             | 0               | 0             | Transmit-receive master mode          |
| 1             | 0               | 1             | Transmit master mode                  |
| 0             | 0               | 0             | Transmit-receive slave mode (default) |
| 0             | 0               | 1             | Transmit slave mode                   |
| 0             | 1               | —             | Receive slave mode                    |

**BFDS bit (Between Burst Transfer Frames Delay Select)**

This bit controls whether insert the delay time between the burst transfer frames.

This bit is valid when the SPCMD.SSLKP bit is 1 in master mode (the SPCR.MSTR bit is 1).

This bit should be set to 0 in slave mode. The usage of SSL delay control between transfer frames is shown as below. For details, see (4) [Burst transfers](#).

**Table 30.6 Usage of SSL delay control between transfer frames (Master mode)**

| Transmit                                    |                                               | SPCMD.SSLKP bit | SPCR3.BFDS bit | SSL delay control register*1<br>(RSPCK clock delay, SSL negation delay, next access delay)                                                                                                                  |
|---------------------------------------------|-----------------------------------------------|-----------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Non-burst transmit                          |                                               | 0               | 0              | Any given value. You can control each delay value according to setting for RSPCK clock delay, SSL negation delay and next access delay.                                                                     |
| Burst transmit with delay between frames    | From the 1st frame to the last previous frame | 1               | 0              |                                                                                                                                                                                                             |
|                                             | The last frame                                | 0               | 0              |                                                                                                                                                                                                             |
| Burst transmit with no delay between frames | From the 1st frame to the last previous frame | 1               | 1              | Any given value. But delay is inserted only below. <ul style="list-style-type: none"> <li>RSPCK clock delay of the 1st frame</li> <li>SSL negation delay and next access delay of the last frame</li> </ul> |
|                                             | The last frame                                | 0               | 1              |                                                                                                                                                                                                             |

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit (see [section 30.2.14. SPCMDm : SPI Command Register m \(m = 0 to 7\)](#)).

The SPCKD.SCKDL[2:0] bits: RSPCK delay  
The SSLND.SLNDL[2:0] bits: SSL negate delay  
The SPND.SPNDL[2:0] bits: Next access delay

**CENDIE bit (SPI Communication End Interrupt Enable)**

This bit controls generation of a communication end interrupt request.

**30.3 Operation**

In this section, the serial transfer period refers to the period from the beginning of driving valid data to the fetching of the final valid data.

**30.3.1 Overview of SPI Operation**

The SPI is capable of synchronous serial transfers in the following modes:

- Slave mode (SPI operation)
- Single master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

The SPI mode can be selected by using the MSTR, MODFEN, and SPMS bits in SPCR. [Table 30.7](#) lists the relationship between SPI modes and SPCR settings, and a description of each mode.

**Table 30.7 Relationship between SPCR settings and SPI modes (1 of 2)**

| Mode               | Slave (SPI operation) | Single-master (SPI operation) | Multi-master (SPI operation) | Slave (clock synchronous operation) | Master (clock synchronous operation) |
|--------------------|-----------------------|-------------------------------|------------------------------|-------------------------------------|--------------------------------------|
| MSTR bit setting   | 0                     | 1                             | 1                            | 0                                   | 1                                    |
| MODFEN bit setting | 0 or 1                | 0                             | 1                            | 0                                   | 0                                    |
| SPMS bit setting   | 0                     | 0                             | 0                            | 1                                   | 1                                    |
| RSPCKn pins        | Input                 | Output                        | Output/Hi-Z                  | Input                               | Output                               |
| MOSIn pin          | Input                 | Output                        | Output/Hi-Z                  | Input                               | Output                               |
| MISOn pin          | Output/Hi-Z           | Input                         | Input                        | Output                              | Input                                |

**Table 30.7 Relationship between SPCR settings and SPI modes (2 of 2)**

| Mode                            | Slave (SPI operation)                 | Single-master (SPI operation)                                                                 | Multi-master (SPI operation)                                                                  | Slave (clock synchronous operation) | Master (clock synchronous operation)                                                          |

| Underrun error detection        | Supported <sup>*5</sup>               | Not supported                                                                                 | Not supported                                                                                 | Supported <sup>*5</sup>             | Not supported                                                                                 |

Note 1. This function is not supported in this mode.

Note 2. When the SPCR.TXMD bit is 1, detection of receiver buffer full, overrun error, and parity error are not performed.

Note 3. When the SPCR2.SPPE bit is 0, parity error detection is not performed.

Note 4. When the SPCR2.SCKASE bit is 1, overrun error detection does not proceed.

Note 5. When SPI is receive only slave mode, none of transmit buffer empty and underrun error is detected.

### 30.3.2 Controlling the SPI Pins

Based on the settings of the MSTR, MODFEN, and SPMS bits in SPCR and the PmnPFS.NCODR bit for I/O Ports, the SPI can switch pin states. [Table 30.8](#) lists the relationship between pin states and bit settings. Setting the PmnPFS.NCODR bit for an I/O port to 0 selects the CMOS output. Setting it to 1 selects the open-drain output. The I/O port settings must follow this relationship.

**Table 30.8 Relationship between pin states and bit settings**

| Mode                                                                             | Pin                            | Pin state <sup>2</sup>             |                                    |
|----------------------------------------------------------------------------------|--------------------------------|------------------------------------|------------------------------------|
|                                                                                  |                                | PmnPFS.NCODR bit for I/O ports = 0 | PmnPFS.NCODR bit for I/O ports = 1 |
| Single-master mode (SPI operation)<br>(MSTR = 1, MODFEN = 0, SPMS = 0)           | RSPCKn                         | CMOS output                        | Open-drain output                  |
|                                                                                  | SSLn0 to SSLn3                 | CMOS output                        | Open-drain output                  |
|                                                                                  | MOSIn                          | CMOS output                        | Open-drain output                  |
|                                                                                  | MISO <sub>n</sub>              | Input                              | Input                              |

|                                                                                  | MISO <sub>n</sub>              | Input                              | Input                              |
| Slave mode<br>(clock synchronous operation)<br>(MSTR = 0, SPMS = 1)              | RSPCKn                         | Input                              | Input                              |
|                                                                                  | SSLn0 to SSLn3 <sup>5</sup>    | Hi-Z <sup>1</sup>                  | Hi-Z <sup>1</sup>                  |
|                                                                                  | MOSIn                          | Input                              | Input                              |
|                                                                                  | MISO <sub>n</sub>              | CMOS output                        | Open-drain output                  |

Note 1. This function is not supported in this mode.

Note 2. SPI settings are not reflected in multiplexed pins for which the SPI function is not selected.

Note 3. When SSLn0 is at the active level, the pin state is Hi-Z. Whether the input signal is at the active level determines the setting of the SSLP.SSL0P bit.

Note 4. When SSLn0 is at the non-active level or the SPCR.SPE bit is 0, the pin state is Hi-Z. Whether the input signal is at the active level determines the setting of the SSLP.SSL0P bit.

Note 5. These pins are available for use as I/O port pins.

The SPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) based on the MOIFE and MOIFV bit settings in SPPCR, as listed in [Table 30.9](#).

**Table 30.9 MOSI signal value determination during SSL negation**

| MOIFE bit | MOIFV bit | MOSIn signal value during SSL negation |
|-----------|-----------|----------------------------------------|
| 0         | 0, 1      | Final data from previous transfer      |
| 1         | 0         | Low                                    |
| 1         | 1         | High                                   |

### 30.3.3 SPI System Configuration Examples

### 30.3.3.1 Single-master/single-slave with the MCU as a master

Figure 30.5 shows a single-master/single-slave SPI system configuration example where the MCU is used as a master. In the single-master/single-slave configuration, the SSLn outputs of the MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in the selected state.\*1

Note 1. In the transfer format configured when the SPCMDm.CPHA bit is 0, the SSL signal for some slave devices cannot be fixed to an active level. In this case, always connect the SSLn output of the MCU to the SSL input of the slave device.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

Figure 30.5 Single-master/single-slave configuration example with the MCU as a master

### 30.3.3.2 Single-master/single-slave with the MCU as a slave

Figure 30.6 shows a single-master/single-slave SPI system configuration example where the MCU is used as a slave. When the MCU operates as a slave, the SSLn0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI signals. The MCU (slave) drives the MISO signal.\*1

Note 1. When SSLn0 is at a non-active level, the pin state is Hi-Z.

In the single-slave configuration when the SPCMDm.CPHA bit is set to 1, the SSLn0 input of the MCU (slave) is fixed to the low level and the MCU (slave) is maintained in the selected state. This enables serial transfer execution (Figure 30.7). However, the communication end interrupt does not output when SSL0 input is fixed as Figure 30.7.

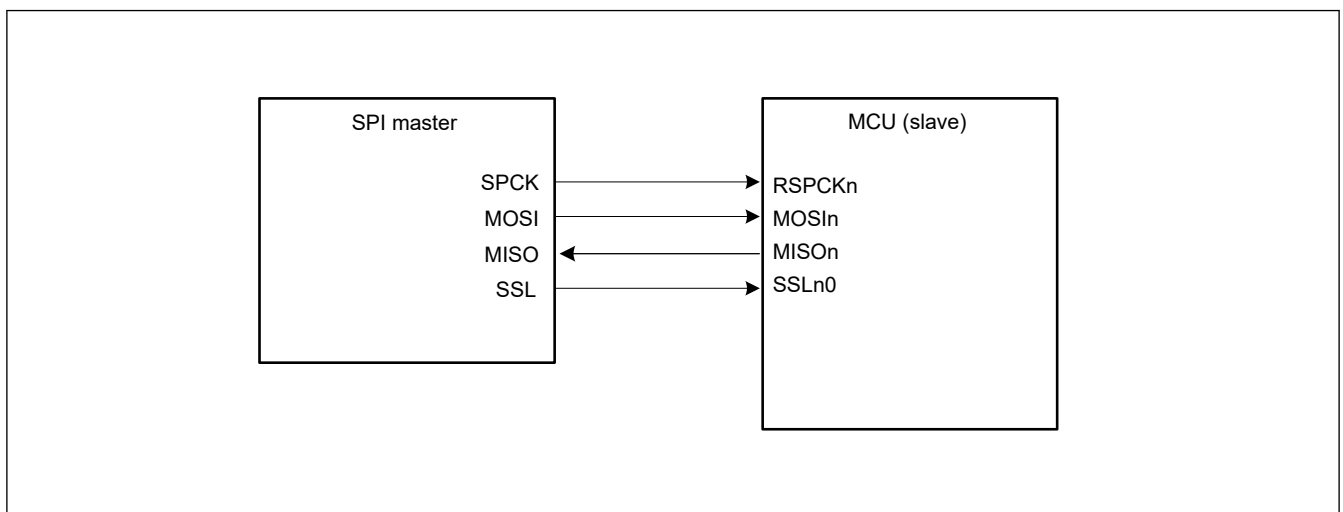

Figure 30.6 Single-master/single-slave configuration example with the MCU as a slave and CPHA = 0

**Figure 30.7** Single-master/single-slave configuration example with the MCU as a slave and CPHA = 1

### 30.3.3.3 Single-master/Multi-slave with the MCU as a Master

Figure 30.8 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes the MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKn and MOSIn outputs of the MCU (master) are connected to the RSPCK and MOSI inputs of SPI slaves 0 to 3. The MISO outputs of SPI slaves 0 to 3 are all connected to the MISOOn input of the MCU (master). The SSLn0 to SSLn3 outputs of the MCU (master) are connected to the SSL inputs of SPI slaves 0 to 3, respectively.

The MCU (master) drives the RSPCKn, MOSIn, and SSLn0 to SSLn3 signals. Out of the SPI slaves 0 to 3, the slave that receives low-level input into the SSL input drives the MISO signal.

**Figure 30.8 Single-master/multi-slave configuration example with the MCU as a master**

### 30.3.3.4 Single-master/Multi-slave with the MCU as a Slave

Figure 30.9 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a slave. In this example, the SPI system includes an SPI master and two MCUs (slaves X and Y).

The SPCK and MOSI outputs of the SPI master are connected to the RSPCKn and MOSIn inputs of the MCUs (slaves X and Y). The MISO outputs of the MCUs (slaves X and Y) are all connected to the MISO input of the SPI master. The SSLX and SSLY outputs of the SPI master are connected to the SSLn0 inputs of the MCUs (slaves X and Y, respectively).

The SPI master drives the SPCK, MOSI, SSLX, and SSLY signals. Of the MCUs (slaves X and Y), the slave that receives low-level input into the SSLn0 input drives the MISO signal.

**Figure 30.9** Single-master/multi-slave configuration example with the MCU as a slave

### 30.3.3.5 Multi-master/multi-slave with the MCU as a master

[Figure 30.10](#) shows a multi-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes two MCUs (masters X and Y) and two SPI slaves (SPI slaves 1 and 2).

The RSPCKn and MOSIn outputs of the MCUs (masters X and Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOOn inputs of the MCUs (masters X and Y). Any generic port Y output from the MCU (master X) is connected to the SSLn0 input of the MCU (master Y). Any generic port X output of the MCU (master Y) is connected to the SSLn0 input of the MCU (master X). The SSLn1 and SSLn2 outputs of the MCUs (masters X and Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, because the system can be comprised solely of SSLn0 input, and SSLn1 and SSLn2 outputs for slave connections, the SSLn3 output of the MCU is not required.

The MCU drives the RSPCKn, MOSIn, SSLn1, and SSLn2 signals when the SSLn0 input level is high. When the SSLn0 input level is low, the MCU detects a mode fault error, sets RSPCKn, MOSIn, SSLn1, and SSLn2 to Hi-Z, and releases the SPI bus directly to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives the MISO signal.

**Figure 30.10 Multi-master/multi-slave configuration example with the MCU as a master**

### 30.3.3.6 Master and slave in clock synchronous mode with the MCU configured as a master

Figure 30.11 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a master. In this configuration, SSLni of the MCU (master) are not used.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

Figure 30.11 Clock synchronous master/slave configuration example with the MCU as a master

### 30.3.3.7 Master and slave in clock synchronous mode with the MCU as a slave

Figure 30.12 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a slave. When the MCU operates as a slave (clock synchronous operation), the MCU (slave) drives the MISOOn signal and the SPI master drives the SPCK and MOSI signals. In addition, SSLn0 to SSLn3 of the MCU (slave) are not used.

The MCU (slave) can only execute serial transfers in the single-slave configuration when the SPCMDm.CPHA bit is set to 1.

Figure 30.12 Clock synchronous master/slave configuration example with the MCU as a slave and CPHA = 1

### 30.3.4 Data Formats

The data format of the SPI depends on the settings in SPI Command Register *m* (SPCMDm) and the parity enable bit in SPI Control Register 2 (SPCR2.SPPE). Regardless of whether the MSB or LSB is first, the SPI treats the range from the LSB bit in the SPI Data Register (SPDR/SPDR\_HA) to the bit associated with the selected data length, as transfer data.

This section shows the format of one frame of data before or after transfer.

#### Data format with parity disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register *m* (SPCMDm.SPB[3:0]).

### Data format with parity enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register  $m$  (SPCMD $m$ .SPB[3:0]). In this case, however, the last bit is a parity bit.

Figure 30.13 Data format with parity disabled and enabled

#### 30.3.4.1 Operation when parity is disabled (SPCR2.SPPE = 0)

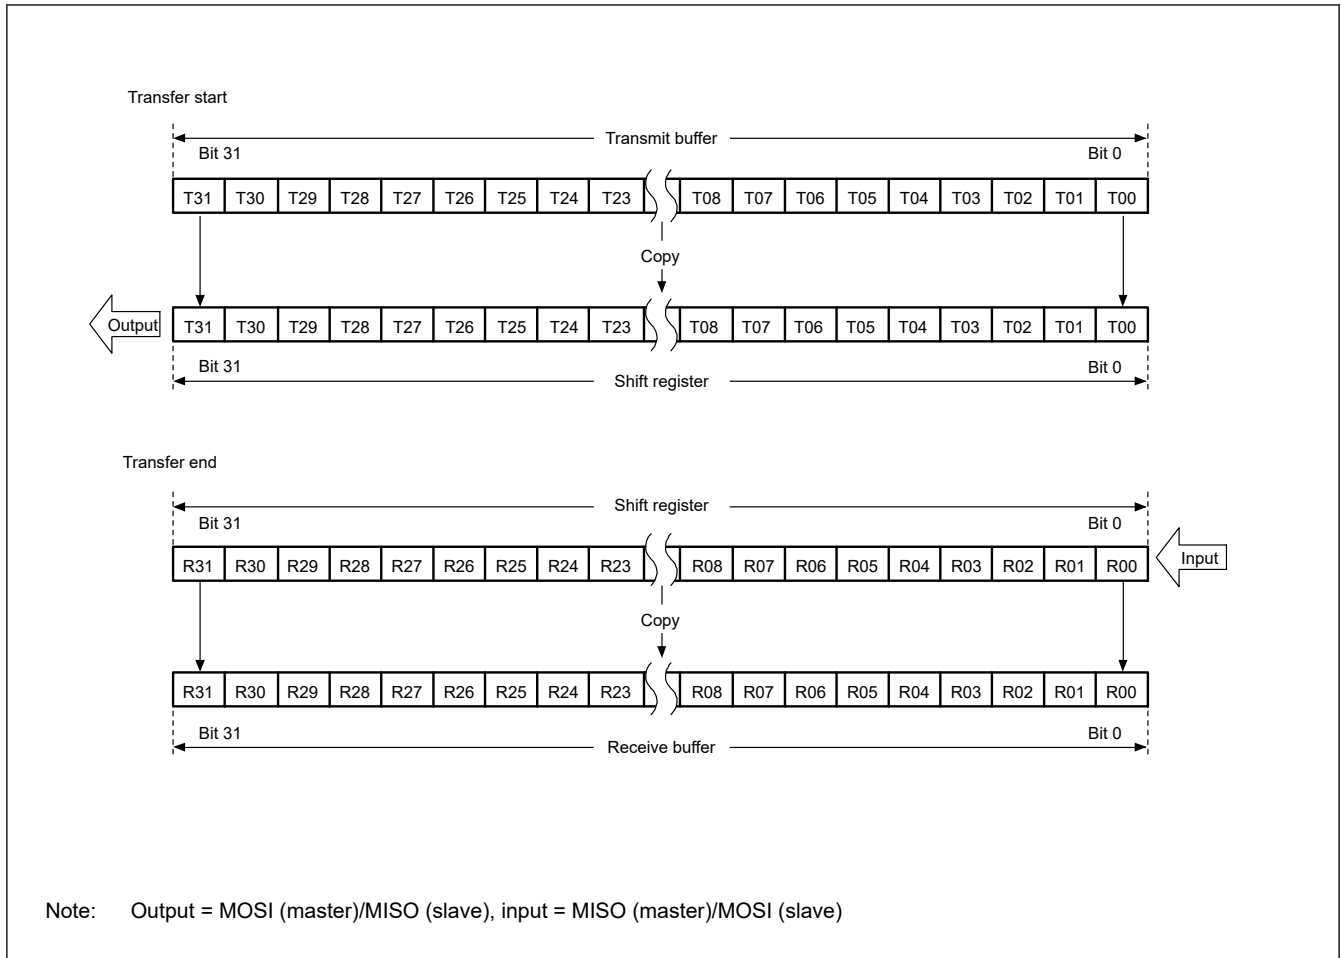

When parity is disabled, data for transmission is copied to the shift register with no pre-processing. This section describes the connection between the SPI Data Register (SPDR/SPDR\_HA) and the shift register in terms of the combination of MSB- or LSB-first order and data length.

##### (1) MSB-first transfer with 32-bit data

Figure 30.14 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 32 bits, and MSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T31 to T30, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

**Figure 30.14 MSB-first transfer with 32-bit data and parity disabled**

(2) MSB-first transfer with 24-bit data

Figure 30.15 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 24 bits for an example that is not 32 bits, and MSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T23 to T22, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to bits T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.

**Figure 30.15 MSB-first transfer with 24-bit data and parity disabled**

(3) LSB-first transfer with 32-bit data

Figure 30.16 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission is shifted out from the shift register in order from T00 to T01, and continuing to T31.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to R31 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

**Figure 30.16 LSB-first transfer with 32-bit data and parity disabled**

(4) LSB-first transfer with 24-bit data

Figure 30.17 shows the operation of the SPI Data Register (SPDR) and the shift register in transfers with parity disabled, an SPI data length of 24 bits for an example that is not 32, and LSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission is shifted out from the shift register from T00 to T01, and continuing to T23.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to R23 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.

Figure 30.17 LSB-first transfer with 24-bit data and parity disabled

### 30.3.4.2 Operation when parity is enabled (SPCR2.SPPE = 1)

When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

#### (1) MSB-first transfer with 32-bit data

Figure 30.18 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T31, T30, ..., T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R31 to P is checked for parity.

**Figure 30.18 MSB-first transfer with 32-bit data and parity enabled**

(2) MSB-first transfer with 24-bit data

Figure 30.19 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 24 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T23, T22, ..., T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R23 to P is checked for parity. The upper 8 bits of the transmit buffer is stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.

**Figure 30.19 MSB-first transfer with 24-bit data and parity enabled**

(3) LSB-first transfer with 32-bit data

Figure 30.20 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, ..., T30, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity.

**Figure 30.20** LSB-first transfer with 32-bit data and parity enabled

(4) LSB-first transfer with 24-bit data

Figure 30.21 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 24 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T22 to T0. This replaces the final bit, T23, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, ..., T22, and P.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity. The upper 8 bits of the transmit buffer is stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.

Figure 30.21 LSB-first transfer with 24-bit data and parity enabled

### 30.3.4.3 Byte Swap Transmission

(1) MSB-first transfer. (When the byte swap is disabled.)

Data (Byte0 [T31 to T24] to Byte3 [T07 to T00]) in the transmit buffer are copied to the shift register.

Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → ... → T00 as transmit data.

(2) MSB-first transfer. (When the byte swap is enabled.)

Byte values of the transmit buffer (Byte0 [T31 to T24] to Byte3 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte3 [T07 to T00] to Byte0 [T31 to T24].

Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → ... → T00 → T15 → T14 → ... → T08 → T23 → T22 → ... → T16 → T31 → T30 → ... → T24 as transmit data.

(3) LSB-first transfer. (When the byte swap is disabled.)

Bit values of the transmit buffer (Byte0 [T31 to T24] to Byte3 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte3 [T00 to T07] to Byte0 [T24 to T31].

Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → ... → T31 as transmit data.

(4) LSB-first transfer. (When the byte swap is enabled.)

Bit values of each byte of the transmit buffer (Byte0 [T31 to T24] to Byte3 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T24 to T31] to Byte3 [T00 to T07].

Bit values in the shift register are shifted and transmitted in the order of T24 → T25 → ... → T31 → T16 → T17 → ... → T23 → T08 → T09 → ... → T15 → T00 → T01 → ... → T07 as transmit data.

Figure 30.22 Byte swap with MSB/LSB transfer

### 30.3.4.4 Byte Swap Reception

#### (1) MSB-first transfer. (When the byte swap is disabled.)

The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → ... → R00.

When necessary RSPCK cycles are input and data is stored from Byte0 [R31 to R24] to Byte3 [R07 to R00], the shift register value is copied to the receive buffer.

#### (2) MSB-first transfer. (When the byte swap is enabled.)

The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → ... → R00 → R15 → R14 → ... → R08 → R23 → R22 → ... → R16 → R31 → R30 → ... → R24.

When necessary RSPCK cycles are input and data is stored from Byte3 [R07 to R00] to Byte0 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte0 [R31 to R24] to Byte3 [R07 to R00].

#### (3) LSB-first transfer. (When the byte swap is disabled.)

The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00 → R01 → ... → R31.

When necessary RSPCK cycles are input and data is stored from Byte3 [R00 to R07] to Byte0 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte0 [R31 to R24] to Byte3 [R07 to R00].

(4) LSB-first transfer. (When the byte swap is enabled.)

The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24 → R25 → ... → R31 → R16 → R17 → ... → R23 → R08 → R09 → ... → R15 → R00 → R01 → ... → R07.

When necessary RSPCK cycles are input and data is stored from Byte0 [R24 to R31] to Byte3 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte0 [R31 to R24] to Byte3 [R07 to R00].

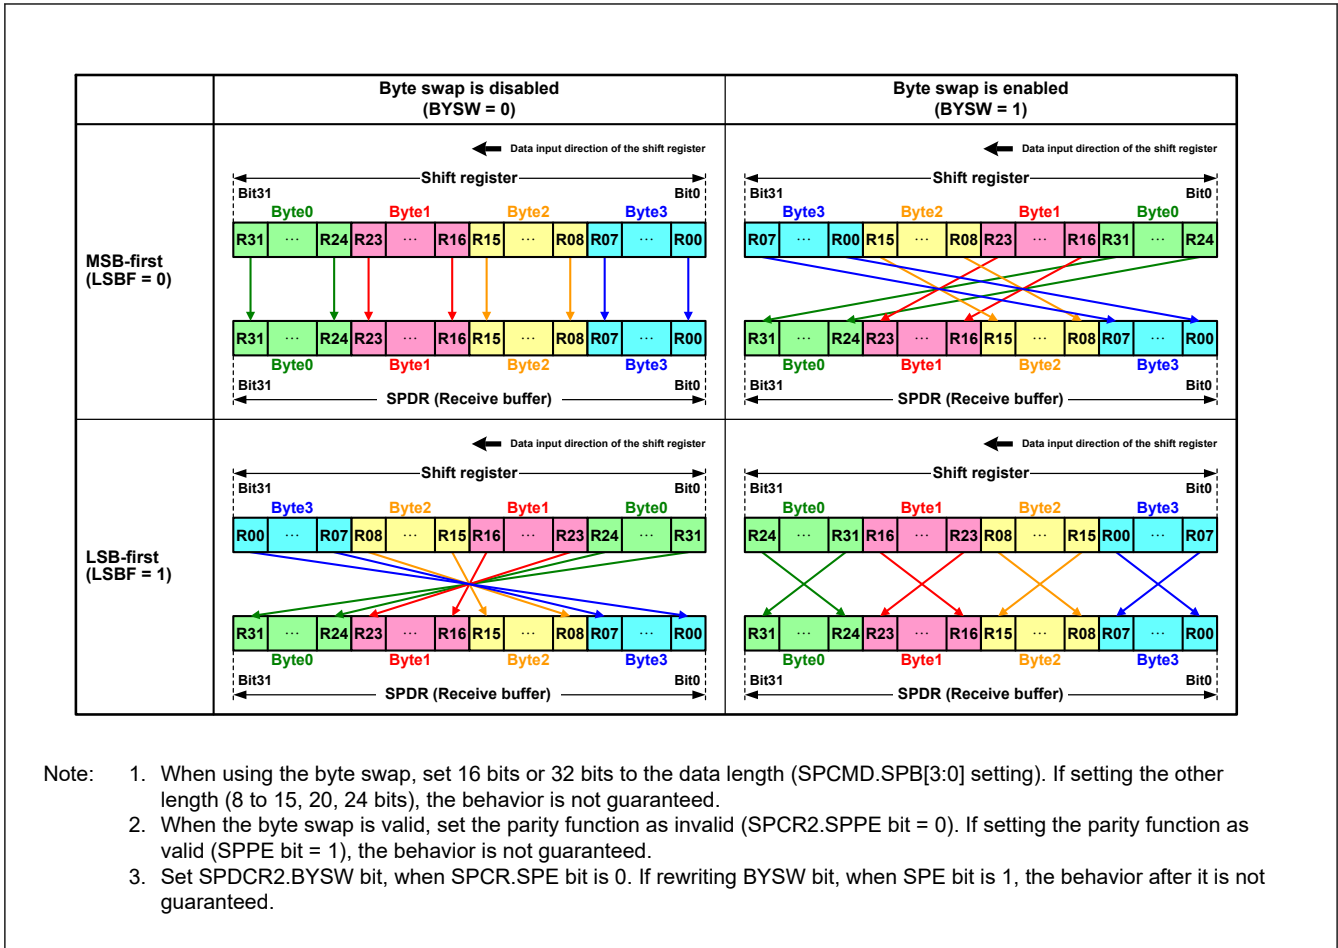

Figure 30.23 Byte swap with MSB/LSB transfer

30.3.5 Transfer Formats

30.3.5.1 When CPHA = 0

Figure 30.24 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Do not perform clock synchronous operation (SPCR.SPMS = 1) when the SPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 30.24, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0, and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI settings. For details, see section 30.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIn and MISOOn signals begins at an SSLni signal assertion. The first RSPCKn signal change that occurs after the SSLni signal assertion becomes the first transfer data fetch. After this, data is sampled every 1 RSPCKn cycle. The change timing for MOSIn and MISOOn signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCK signal operation timing as it only affects the signal polarity.

t1 denotes the RSPCK delay, the period from an SSLni signal assertion to RSPCKn oscillation. t2 denotes the SSL negation delay, the period from the termination of RSPCKn oscillation to an SSLni signal negation. t3 denotes the next-access delay,

the period in which SSLni signal assertion is suppressed for the next transfer after the end of serial transfer. t1, t2, and t3 are controlled by a master device running on the SPI system. For a description of t1, t2, and t3 when the SPI is in master mode, see [section 30.3.11.1. Master mode operation](#).

Figure 30.24 SPI transfer format when CPHA = 0

### 30.3.5.2 When CPHA = 1

Figure 30.25 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLni signals are not used, and only the three signals RSPCKn, MOSIn, and MISOOn handle communications. In Figure 30.25, RSPCK (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0 and RSPCK (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI mode (master or slave mode). For details, see [section 30.3.2. Controlling the SPI Pins](#).

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOOn signal begins at an SSLni signal assertion. The output of valid data to the MOSIn and MISOOn signals begins at the first RSPCKn signal change that occurs after the SSLni signal assertion. After this, data is updated every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKn signal operation timing. It only affects the signal polarity.

t1, t2, and t3 are the same as those when CPHA = 0. For a description of t1, t2, and t3 when the SPI of the MCU is in master mode, see [section 30.3.11.1. Master mode operation](#).

Figure 30.25 SPI transfer format when CPHA = 1

### 30.3.6 Data Transfer Modes

Full-duplex synchronous serial communications or transmit operations can only be selected in the Communications Operating Mode Select bit (SPCR.TXMD) when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is 0. The SPI operation is receive only in slave mode (SPCR.MSTR = 0) when the SPCR3.ETXMD bit is 1, because SPCR.TXMD bit does not affect the SPI operation. The register accesses shown in Figure 30.26, Figure 30.27, and Figure 30.28 indicate the condition of access to the SPDR/SPDR\_HA register, where W denotes a write cycle.

#### 30.3.6.1 Full-duplex synchronous serial communications (SPCR3.ETXMD = 0, SPCR.TXMD = 0)

Figure 30.26 shows an example of operation when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 0 and the Communications Operating Mode Select bit (SPCR.TXMD) is set to 0. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

**Figure 30.26** Operation example when SPCR3.ETXMD = 0 and SPCR.TXMD = 0

The operation of the flags at timings (1) and (2) in Figure 30.26 is as follows:

1. When a serial transfer ends with the receive buffer of SPDR\_HA empty, the SPI generates a receive buffer full interrupt request (SPIi\_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer.
2. When a serial transfer ends with the receive buffer of SPDR\_HA holding data that was received in the previous serial transfer, the SPI sets the SPSR.OVRF flag to 1, and discards the received data in the shift register. For details about the operation of the SPSR.OVRF flag, see section 30.3.9.1. [Overrun errors](#).

### 30.3.6.2 Transmit-Only Serial Communications (SPCR3.ETXMD = 0, SPCR.TXMD = 1)

Figure 30.27 shows an example of operation when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 0 and the Communications Operating Mode Select bit (SPCR.TXMD) is set to 1. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

**Figure 30.27** Operation example when SPCR3.ETXMD = 0 and SPCR.TXMD = 1

The operation of the flags at timings (1) to (3) in [Figure 30.27](#) is as follows:

1. Make sure there is no data left in the receive buffer (the SPSR.SPRF flag is 0) and the SPSR.OVRF flag is 0 before entering transmit-only mode (SPCR3.ETXMD = 0, SPCR.TXMD = 1).
2. When a serial transfer ends with the receive buffer of SPDR\_HA empty, if the transmit-only mode is selected (SPCR3.ETXMD = 0, SPCR.TXMD = 1), the SPSR.SPRF flag retains the value of 0, and the SPI does not copy the data in the shift register to the receive buffer.
3. Because the receive buffer of SPDR\_HA does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

In transmit-only mode (SPCR3.ETXMD = 0, SPCR.TXMD = 1), the SPI transmits data but does not receive data. Therefore, the SPSR.SPRF and SPSR.OVRF flags remain 0 at timings (1) to (3).

### 30.3.6.3 Receive-Only Serial Communication (MSTR = 0, ETXMD = 1)

[Figure 30.28](#) shows an example of operation when the SPI master/slave mode select bit (MSTR) in the SPI control register (SPCR) is set to 0 and the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 1. In the example in [Figure 30.28](#), the SPI performs 8-bit data serial transfer with the settings of SPFC[1:0] in the SPI data control register (SPDCR) = 00b, CPHA in the SPI command register (SPCMD) = 1, and CPOL in SPCMD = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

**Figure 30.28** Example of Operation when MSTR = 0 and ETXMD = 1

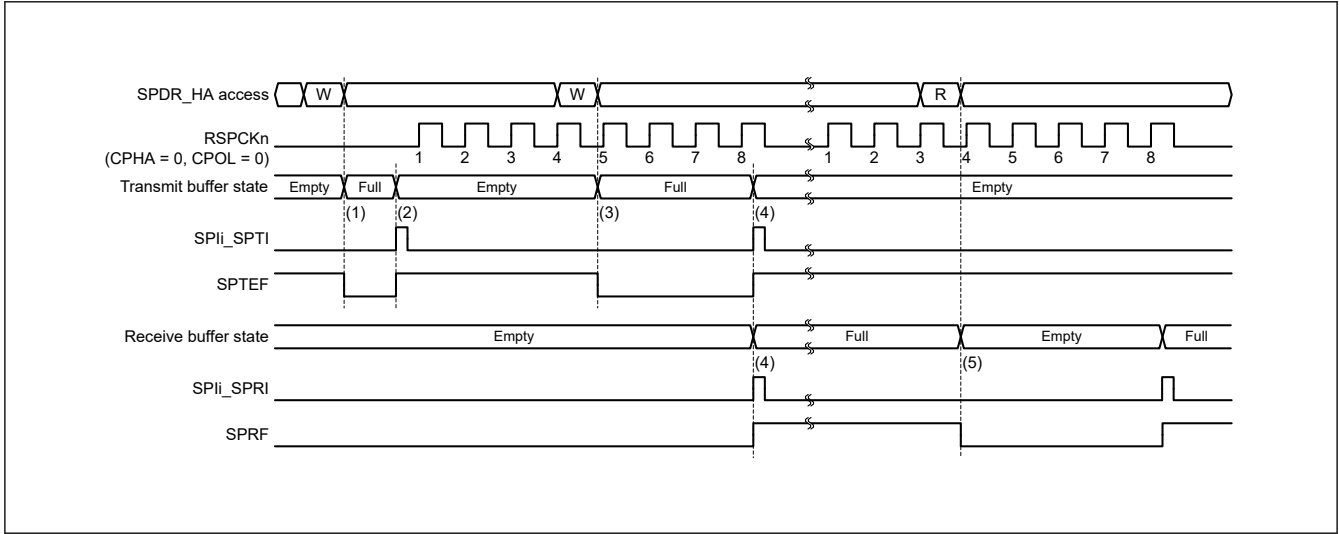

The following describes operation of flags at timings (1) and (2) in the figure above.

- (1) When serial transfer ends while the SPDR's receive buffer is empty, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer
- (2) When serial transfer ends while previously received data is remaining in the SPDR's receive buffer, the SPI sets the OVRF flag in the SPI status register (SPSR) to 1 and discards the received data in the shift register.

### 30.3.7 Transmit Buffer Empty and Receive Buffer Full Interrupts

[Figure 30.29](#) and [Figure 30.30](#) show examples of operation of the transmit buffer empty interrupt (SPIi\_SPTI) and the receive buffer full interrupt (SPIi\_SPRI). The SPDR\_HA register accesses shown in these figures indicate the conditions of access to the register, where W denotes a write cycle and R denotes a read cycle. In [Figure 30.29](#), the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 0, and the SPCMDm.CPOL bit is 0. In [Figure 30.30](#), the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the

SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

**Figure 30.29** Operation example of the SPIi\_SPTI and SPIi\_SPRI interrupts when CPHA = 0 and CPOL = 0 in master mode

**Figure 30.30** Operation example of the SPIi\_SPTI and SPIi\_SPRI interrupts when CPHA = 1 and CPOL = 0 in master mode

The operation of the SPI at timings (1) to (5) in [Figure 30.29](#) and [Figure 30.30](#) is as follows:

1. When transmit data is written to SPDR\_HA with the transmit buffer of SPDR\_HA is empty and data for the next transfer is not set, the SPI writes data to the transmit buffer and clears the SPSR.SPTEF flag to 0.
2. If the shift register is empty, the SPI copies the data in the transmit buffer to the shift register, generates a transmit buffer empty interrupt request (SPIi\_SPTI), and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the SPI mode. For details, see [section 30.3. Operation](#), and [section 30.3.12. Clock Synchronous Operation](#).
3. When transmit data is written to SPDR\_HA either by the transmit buffer empty interrupt routine, or by the processing of the transmit buffer empty using the SPTEF flag, the SPI writes data to the transmit buffer and clears the SPTEF flag to 0. Because the data being transferred serially is stored in the shift register, the SPI does not copy the data in the transmit buffer to the shift register.
4. When the serial transfer ends with the receive buffer of SPDR\_HA empty, the SPI copies the receive data in the shift register to the receive buffer, generates a receive buffer full interrupt request (SPIi\_SPRI), and sets the SPRF flag to 1. Because the shift register becomes empty on completion of the serial transfer, if the transmit buffer is full before the serial transfer ended, the SPI sets the SPTEF flag to 1 and copies data in the transmit buffer to the shift register. Even

when received data is not copied from the shift register to the receive buffer in an overrun error status, on completion of the serial transfer, the SPI determines that the shift register is empty, so data transfer from the transmit buffer to the shift register is enabled.

5. When SPDR\_HA is read either by the receive buffer full interrupt routine or processing of the receive buffer full interrupt using the SPRF flag, the receive data can be read.

If SPDR\_HA is written to when the transmit buffer holds data that is not yet transmitted (the SPTEF flag is 0), the SPI does not update data in the transmit buffer. When writing to SPDR\_HA, always use either a transmit buffer empty interrupt request or processing of the transmit buffer empty interrupt using the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1. If the SPI function is disabled (the SPCR.SPE bit is 0), set the SPTIE bit to 0.

When serial transfer ends and the receive buffer is full (the SPRF flag is 1), the SPI does not copy data from the shift register to the receive buffer, and it detects an overrun error (see [section 30.3.9. Error Detection](#)). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an SPI receive buffer full interrupt, set the SPCR.SPRIE bit to 1.

Transmission and reception interrupts or the associated IELSRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers.

Similarly, the SPTEF and SPRF flags can be used to confirm the states of the transmit and receive buffers. See [section 13, Interrupt Controller Unit \(ICU\)](#) for the interrupt vector numbers.

### 30.3.8 Communication End Interrupt

#### 30.3.8.1 Transmit-Receive/Transmit in Master Mode

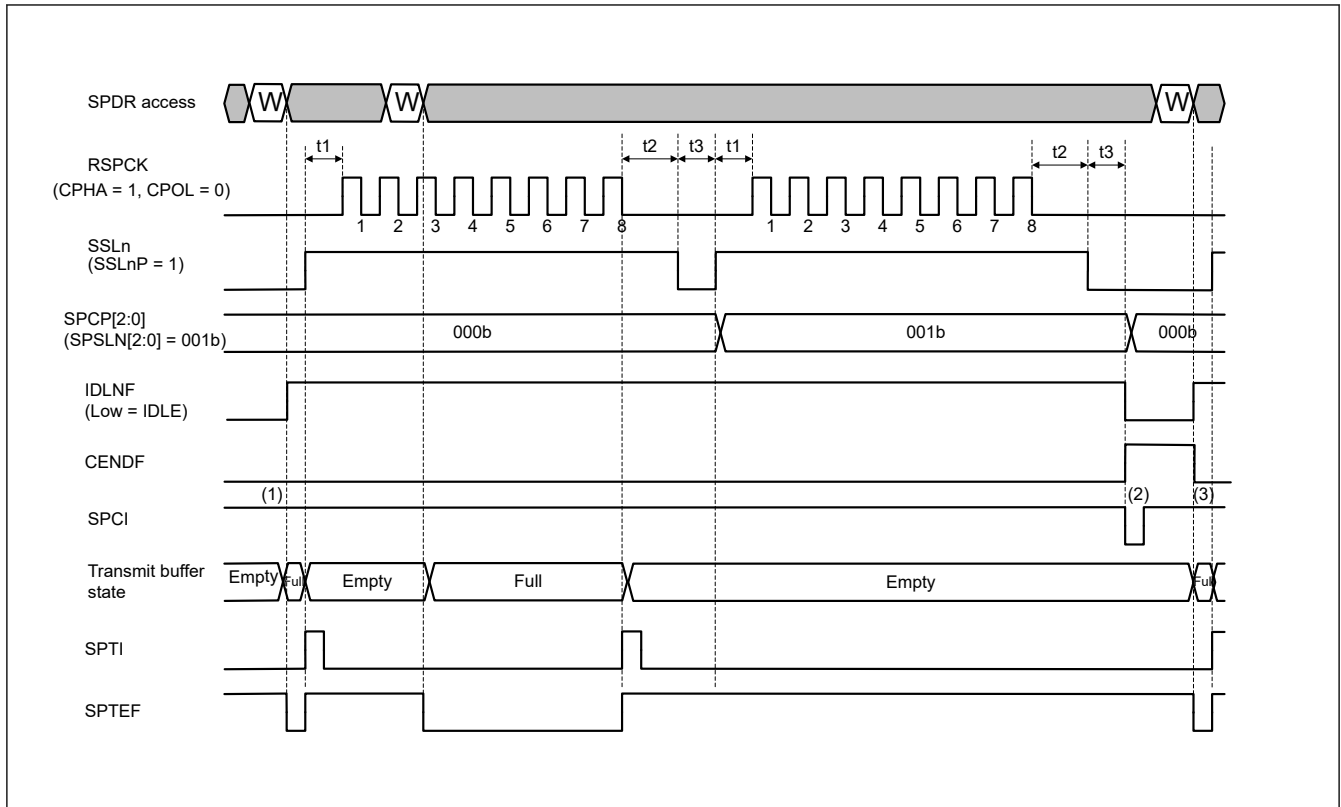

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1, when following conditions are satisfied in transmit-receive master mode and transmit master mode. The set timing of the CENDF flag is same as IDLNF flag. The communication end interrupt (SPCI) is one PCLKA width and low active.

- When the value of the SPSSR.SPCP[2:0] bits are same as the SPSCR.SPSSLN[2:0] bits.
- When there is no next transmission data.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of the following two conditions.

- When the next transmission data is written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

[Figure 30.31](#) shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

**Figure 30.31 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Master mode)**

1. The CENDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle, because the next command is 000b and there is no next transmit data, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

In slave mode operation, the output timing of the communication end interrupt is different due to the value of the SPCR.SPMS bit (SPI mode select bit), and the clear timing of the communication end interrupt is different due to the communication mode (transmit-receive or transmit-only or receive-only).

### 30.3.8.2 Transmit-Receive/Transmit in Slave Mode on SPI Operation (4-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1, when both SPTX buffer and transmit shift buffer are empty in transmit-receive/transmit slave mode on SPI Operation (4-wire). The set timing of the CENDF flag is same as SSL0 negate timing. The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of the following two conditions.

- When the next transmission data is written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 30.32 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on SPI operation.

**Figure 30.32 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on SPI Operation)**

1. The CENDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the timing of SSL0 negate, when both SPTX buffer and transmit shift buffer are empty, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

### 30.3.8.3 Receive Only in Slave Mode on SPI Operation (4-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 at the SSL0 negate timing in receive only slave mode on SPI operation (4-wire). The number of transmission frame is set by the SPDCR.SPFC[1:0]. Then the SSL0 is negated at the last frame transmission end. The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of the following two conditions.

- The SSL0 assert timing of next transmission.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 30.33 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

**Figure 30.33 Example of Communication End Interrupt Operation (Receive only Slave mode on SPI Operation)**

1. The CENDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the timing of SSL0 negate, when the last frame transmission ends, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared at the SSL0 assert when the next transmission start. Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

#### 30.3.8.4 Transmit-Receive/Transmit in Slave Mode on Clock Synchronous Operation (3-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 when both SPTX buffer and transmit shift register are empty in transmit-receive/transmit slave mode on clock synchronous operation (3-wire). The set timing of CENDF flag is same as the last data sampling of the RSPCK (the last odd edge of RSPCK when the SPCMD0.CPHA bit is 0, the last even edge of RSPCK when the SPCMD0.CPHA bit is 1). The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of the following two conditions.

- The SSL0 assert timing of next transmission.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 30.34 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on clock synchronous operation (3-wire).

**Figure 30.34 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on Clock Synchronous Operation)**

1. The CENDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the last data sampling timing of RSPCK, when both SPTX buffer and transmit shift buffer are empty, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

### 30.3.8.5 Receive Only in Slave Mode on Clock Synchronous Operation (3-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 at the last data sampling of the last transmission frame in receive only slave mode on clock synchronous operation (3-wire). The sampling timing is the last odd edge of RSPCK when the SPCMD0.CPHA bit is 0, the last even edge of RSPCK when the SPCMD0.CPHA bit is 1. The number of transmission frame is set by the SPDCR.SPFC[1:0]. The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of the following two conditions.

- The first edge of RSPCK for next transmission.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 30.35 shows an example of communication end interrupt operation during receive only slave mode on clock synchronous operation.

**Figure 30.35 Example of Communication End Interrupt Operation (Receive-only Slave mode on Clock Synchronous Operation)**

1. The CENDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the last data sampling timing of RSPCK, when the last frame transmission end. The number of transmission frame is set by the SPDCR.SPFC[1:0]. And then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared at the first edge of RSPCK for the next transmission. Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

### 30.3.8.6 Common Operation

In this chapter, the operation common to each mode / area option communication in [section 30.3.8.1. Transmit-Receive/ Transmit in Master Mode](#) to [section 30.3.8.5. Receive Only in Slave Mode on Clock Synchronous Operation \(3-wire\)](#) is explained. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set and an event of communication end (sp\_elccend) is output, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of SPI function (SPE) is 1, the communication end interrupt is output.

**Figure 30.36 Example of Communication End Interrupt Operation (Enable control)**

1. When the enable of SPI communication end interrupt (CENDIE) is 1, at the time of communication completion, the following three are the same timing.
  - A flag of communication end (CENDF)
  - An event of communication end (sp\_elccend)
  - The communication end interrupt

2. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following two are the same timing, but no interrupt.
  - A flag of communication end (CENDF)
  - An event of communication end (sp\_elccend)
3. After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt is output after 1 PCLKA.
4. After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt is not output.

### 30.3.9 Error Detection

In normal SPI serial transfers, data written to the transmit buffer of SPDR/SPDR\_HA is transmitted, and received data can be read from the receive buffer of SPDR/SPDR\_HA. If access is made to SPDR/SPDR\_HA, an abnormal transfer might occur, depending on the status of the transmit or receive buffer or the status of the SPI at the beginning or end of serial transfer.

If an abnormal transfer occurs, the SPI detects the event as an underrun error, overrun error, parity error, or mode fault error. [Table 30.10](#) lists the relationship between non-normal transfer operations and the SPI error detection function.

**Table 30.10 Relationship between non-normal transfer operations and SPI error detection**

| Operation | Occurrence condition                                                                                                                                                                                                                                                                                   | SPI operation                                                                                                                                                                                                                                                                                     | Error detection  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 1         | SPDR/SPDR_HA is written when the transmit buffer is full.                                                                                                                                                                                                                                              | <ul style="list-style-type: none"> <li>• The contents of the transmit buffer are kept</li> <li>• Write data is missing</li> </ul>                                                                                                                                                                 | None             |
| 2         | SPDR/SPDR_HA is read when the receive buffer is empty.                                                                                                                                                                                                                                                 | The contents of the receive buffer and previously received data are output.                                                                                                                                                                                                                       | None             |
| 3         | Serial transfer is started in slave mode when the SPI is not able to transmit data.                                                                                                                                                                                                                    | <ul style="list-style-type: none"> <li>• Serial transfer is suspended</li> <li>• Transmit or receive data is missing</li> <li>• Driving of the MISO<sub>n</sub> output signal is stopped</li> <li>• SPI function is disabled</li> </ul>                                                           | Underrun error   |
| 4         | Serial transfer terminates when the receive buffer is full.                                                                                                                                                                                                                                            | <ul style="list-style-type: none"> <li>• Keeps the contents of the receive buffer</li> <li>• Missing receive data</li> </ul>                                                                                                                                                                      | Overrun error    |
| 5         | An incorrect parity bit is received during full-duplex synchronous serial communication with the parity function enabled in following mode: <ul style="list-style-type: none"> <li>• Transmit-receive master mode</li> <li>• Transmit-receive slave mode</li> <li>• Receive-only slave mode</li> </ul> | The parity error flag is asserted                                                                                                                                                                                                                                                                 | Parity error     |
| 6         | The SSL <sub>n</sub> 0 input signal is asserted when the serial transfer is idle in multi-master mode.                                                                                                                                                                                                 | <ul style="list-style-type: none"> <li>• Driving of the RSPCK<sub>n</sub>, MOSI<sub>n</sub>, SSL<sub>n</sub>1 to SSL<sub>n</sub>3 output signals is stopped</li> <li>• SPI function is disabled</li> </ul>                                                                                        | Mode fault error |
| 7         | The SSL <sub>n</sub> 0 input signal is asserted during serial transfer in multi-master mode.                                                                                                                                                                                                           | <ul style="list-style-type: none"> <li>• Serial transfer is suspended</li> <li>• Transmit or receive data is missing</li> <li>• Driving of the RSPCK<sub>n</sub>, MOSI<sub>n</sub>, SSL<sub>n</sub>1 to SSL<sub>n</sub>3 output signals is stopped</li> <li>• SPI function is disabled</li> </ul> | Mode fault error |
| 8         | The SSL <sub>n</sub> 0 input signal is negated during serial transfer in slave mode.                                                                                                                                                                                                                   | <ul style="list-style-type: none"> <li>• Serial transfer is suspended</li> <li>• Transmit or receive data is missing</li> <li>• Driving of the MISO<sub>n</sub> output signal is stopped</li> <li>• SPI function is disabled</li> </ul>                                                           | Mode fault error |

In operation 1 described in [Table 30.10](#), the SPI does not detect an error. To prevent data omission during writes to SPDR/SPDR\_HA, the writes to SPDR/SPDR\_HA must be executed using a transmit buffer empty interrupt request (when the SPSR.SPTEF flag is 1).

Similarly, the SPI does not detect an error in operation 2. To prevent extraneous data from being read, SPDR/SPDR\_HA read must be executed with an SPI receive buffer full interrupt request (when the SPSR.SPRF flag is 1).

For information on the other errors, see the following sections:

- Underrun error, indicated in operation 3, see [section 30.3.9.4. Underrun errors](#)
- Overrun error, indicated in operation 4, see [section 30.3.9.1. Overrun errors](#)
- Parity error, indicated in operation 5, see [section 30.3.9.2. Parity errors](#)
- Mode fault error, indicated in operations 6 to 8, see [section 30.3.9.3. Mode fault errors](#)
- For the transmit and receive interrupts, see [section 30.3.7. Transmit Buffer Empty and Receive Buffer Full Interrupts](#).

### 30.3.9.1 Overrun errors

If a serial transfer ends when the receive buffer of SPDR/SPDR\_HA is full, the SPI detects an overrun error and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the SPI does not copy data from the shift register to the receive buffer, so the data prior to the error occurrence is retained in the receive buffer. To set the OVRF flag to 0, write 0 to the OVRF flag after the CPU reads SPSR with the OVRF flag set to 1.

[Figure 30.37](#) shows an example of operation of the OVRF and SPRF flags. The SPSR and SPDR\_HA accesses shown in [Figure 30.37](#) indicate the condition of accesses to the SPSR and SPDR\_HA register, where W denotes a write cycle, and R a read cycle. In this example, the SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

**Figure 30.37 Operation example of the OVRF and SPRF flags**

The operation of the flags at timings (1) to (4) in [Figure 30.37](#) is as follows:

1. If a serial transfer terminates with the SPRF flag set to 1 (receive buffer full), the SPI detects an overrun error, and sets the OVRF flag to 1. The SPI does not copy the data in the shift register to the receive buffer. Even when the SPPE bit is 1, parity errors are not detected.
2. When SPDR/SPDR\_HA is read, the SPI outputs the data in the receive buffer. The SPRF flag is then set to 0. The receive buffer becoming empty does not set the OVRF flag to 0.
3. If the serial transfer ends with the OVRF flag set to 1 (overrun error occurred), the SPI does not copy data in the shift register to the receive buffer (the SPRF flag does not set to 1). A receive buffer full interrupt is not generated. Even when the SPPE bit is 1, parity errors are not detected. In an overrun error state when the SPI does not copy the received data from the shift register to the receive buffer, on termination of the serial transfer, the SPI determines that the shift register is empty. This enables data transfer from the transmit buffer to the shift register.
4. If 0 is written to the OVRF flag after SPSR is read when the OVRF flag is 1, the OVRF flag clears is set to 0.

The occurrence of an overrun can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. When executing a serial transfer, you must ensure that overrun errors are detected early, for example by reading SPSR immediately after SPDR/SPDR\_HA/SPDR\_BY is read.

If an overrun error occurs and the OVRF flag sets to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled (SPCR2.SCKASE = 1) in master mode, an overrun error does not occur. Figure 30.38 and Figure 30.39 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

**Figure 30.38** Clock stop waveform when serial transfer continues while receive buffer is full in master mode (CPHA = 1)

**Figure 30.39** Clock stop waveform when serial transfer continues while receive buffer is full in master mode (CPHA = 0)

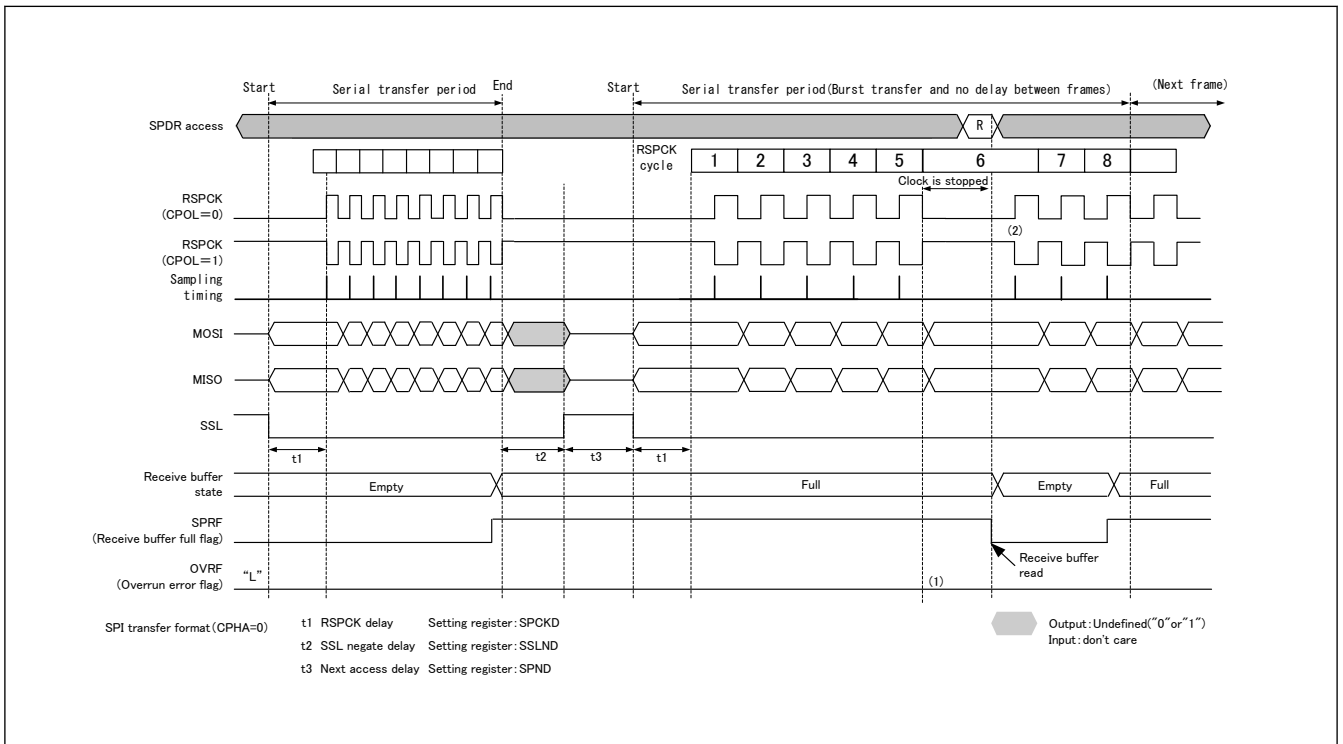

The operation of the flags at timings (1) and (2) in Figure 30.38 and Figure 30.39 is as follows:

1. When the receive buffer is full, an overrun error does not occur because the RSPCK clock is stopped.
2. If SPDR/SPDR\_HA is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts after reading the receive buffer (after the SPSR.SPRF flag is set to 0).

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. Figure 30.40 and Figure 30.41 show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the reception buffer full state.

**Figure 30.40 Clock stop waveform when serial transfer continues in the receive buffer full in master mode (at burst transfer and no delay between frames CPHA = 1)**

**Figure 30.41 Clock stop waveform when serial transfer continues in the receive buffer full in master mode (at burst transfer and no delay between frames CPHA = 0)**

The following describes operation of flags at timings (1) and (2) in the figure above.

1. While the receive buffer is full, the RSPCK clock is deactivated and no overrun error occurs.
2. Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read (after the SPSR.SPRF flag has been cleared to 0), the RSPCK clock restarts.

### 30.3.9.2 Parity errors

When full-duplex synchronous serial communications is performed with the SPCR.TXMD bit set to 0 and the SPCR2.SPPE bit set to 1, when serial transfer ends, the SPI checks whether there are parity errors. On detecting a parity error in the received data, the SPI sets the SPSR.PERF flag to 1. Because the SPI does not copy data in the shift register to the receive buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, write 0 to the PERF flag after the SPSR register is read with the PERF flag set to 1.

Figure 30.42 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 30.42 indicates the condition of access to the register, where W denotes a write cycle, and R a read cycle. In this example, full-duplex serial communication is performed while the SPCR2.SPPE bit is 1. The SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

**Figure 30.42 Operation example of the OVRF and PERF flags**

The operation of the flags at timings (1) to (3) in Figure 30.42 is as follows:

1. If a serial transfer terminates with the SPI not detecting an overrun error, the SPI copies the data in the shift register to the receive buffer. The SPI checks the received data at this time and sets the PERF flag to 1 if a parity error is detected.
2. If 0 is written to the PERF flag after the SPSR register is read when the PERF flag is 1, the PERF flag is set to 0.
3. When the SPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The SPI does not perform parity error detection at this time.

Parity errors can be checked for by either reading the SPSR register or using an SPI error interrupt and reading the SPSR register. When executing a serial transfer, such checks are required to ensure early detection of parity errors. When the SPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSR.SPECM[2:0] bits (Only SPI0).

### 30.3.9.3 Mode fault errors

The SPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input for the SSLn0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of the status of the serial transfer, and sets the SPSR.MODF flag to 1. On detecting the mode fault error, the SPI copies the value of the pointer to SPCMDm to the SPDCR.SPFC[1:0] bits. The active level of the SSLn0 signal is determined by the SSLP.SSLOP bit.

When the MSTR bit is 0, the SPI operates in slave mode. The SPI detects a mode fault error if the MODFEN bit of the SPI in slave mode is 1, and the SPMS bit is 0, and if the SSLn0 input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

On detecting a mode fault error, the SPI stops the driving of the output signals and clears the SPCR.SPE bit to 0 (see [section 30.3.10. Initializing the SPI](#)). For multi-master configuration, detection of a mode fault error is used to stop the driving of output signals and the SPI function, which allows the master to be released.

The occurrence of a mode fault error can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting mode-fault errors without using the SPI error interrupt requires polling of SPSR. When using the SPI in master mode, the value of the pointer to the SPCMDm register at the occurrence of the error can be checked by reading the SPSR.SPECM[2:0] bits.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of a mode fault error, the MODF flag must be set to 0.

#### 30.3.9.4 Underrun errors

While the SPI is operating in slave mode (SPCR.MSTR bit = 0) and the Extended Communication Mode Select bit (ETXMD) in the SPI Control Register 3 (SPCR3) is set to 0, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1 (SPI function enabled), the SPI detects an underrun error and sets the SPSR.MODF and SPSR.UDRF flags to 1.

On detecting an underrun error, the SPI stops the driving of output signals and clears the SPCR.SPE bit to 0 (see [section 30.3.10. Initializing the SPI](#)).

The occurrence of underrun errors can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting underrun errors without using the SPI error interrupt requires polling of SPSR.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of an underrun error, the MODF flag must be set to 0.

### 30.3.10 Initializing the SPI

If 0 is written to the SPCR.SPE bit or if the SPI sets the SPE bit to 0 because it detected a mode fault error or an underrun error, the SPI disables the SPI function and initializes some of the module functions. When a system reset is generated, the SPI initializes all the module functions. This section describes initialization by clearing of the SPCR.SPE bit and by a system reset.

#### 30.3.10.1 Initialization by clearing of the SPCR.SPE bit

When the SPCR.SPE bit is set to 0, the SPI initializes by:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the SPI
- Initializing the transmit buffer of the SPI (the SPSR.SPTEF flag sets to 1)

Initialization by clearing of the SPE bit does not initialize the control bits of the SPI. For this reason, the SPI can be started in the same transfer mode in use prior to initialization when the SPE bit is set to 1 again.

The SPSR.CENDF, SPSR.SPRF, SPSR.OVRF, SPSR.MODF, SPSR.PERF, and SPSR.UDRF flags are not initialized, and the value of the SPI Sequence Status Register (SPSSR) is not initialized. Therefore, even after the SPI is initialized, data from the receive buffer can be read to check the communication completion status and the error status during an SPI transfer.

The transmit buffer is initialized to an empty state (the SPSR.SPTEF flag sets to 1). Therefore, if the SPCR.SPTIE bit is set to 1 after SPI initialization, a transmit buffer empty interrupt is generated. To disable any transmit buffer empty interrupts when the SPI is initialized, write 0 to the SPTIE bit simultaneously while writing 0 to the SPE bit.

#### 30.3.10.2 Initialization by system reset

A system reset completely initializes the SPI by initializing all SPI control bits, status bits, and data registers, in addition to meeting the requirements described in [section 30.3.10.1. Initialization by clearing of the SPCR.SPE bit](#).

### 30.3.11 SPI Operation

#### 30.3.11.1 Master mode operation

The only difference between single- and multi-master mode operation is the use of mode fault error detection (see [section 30.3.9. Error Detection](#)). In single-master mode, the SPI does not detect mode fault errors whereas in multi-master mode, it does. This section explains operations that are common to both modes.

##### (1) Starting a serial transfer

The SPI updates the data in the transmit buffer (SPTX) when data is written to the SPI Data Register (SPDR/SPDR\_HA) with the SPI transmit buffer empty, data for the next transfer is not set, and the SPSR.SPTEF flag is 0. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR\_HA/SPDR\_BY, the SPI copies data from the transmit buffer to the shift register and starts serial transfer. On copying transmit data to the shift register, the SPI changes the status of the shift register to full. On termination of the serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

The polarity of the SSLn output pins depends on the SSLP register settings. For details on the SPI transfer format, see [section 30.3.5. Transfer Formats](#).

##### (2) Terminating a serial transfer

Regardless of the SPCMDm.CPHA bit setting, the SPI terminates the serial transfer after transmitting an RSPCKn edge associated with the final sampling timing. If free space is available in the receive buffer (SPRX) (the SPSR.SPRF flag is 0), on termination of the serial transfer, the SPI copies data from the shift register to the receive buffer of the SPDR/SPDR\_HA register.

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bit settings. The polarity of the SSLn output pin depends on the SSLP register settings. For details on the SPI transfer format, see [section 30.3.5. Transfer Formats](#).

##### (3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following items are set in the SPCMDm register:

- SSLn pin output signal value
- MSB- or LSB-first
- Data length
- Some of the bit rate settings
- RSPCK polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced

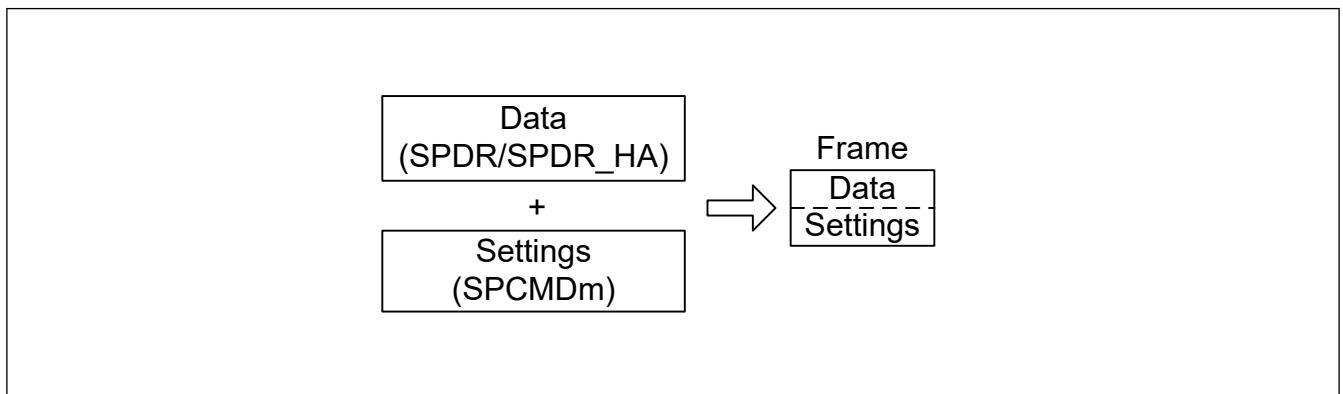

SPBR holds some of the bit rate settings, including SPCKD (SPI clock delay), SSLND (SSL negation delay), and SPND (next-access delay).

Based on the sequence length assigned in SPSCR, the SPI makes up a sequence comprised of a part or all of the SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command in the sequence, the SPI sets the pointer to SPCMD0, and in this way the sequence is executed repeatedly.

**Figure 30.43 Procedure for determining the form of a serial transfer in master mode**

In this section, a frame is the combination of the data in SPDR/SPDR\_HA and the settings in SPCMDm.

**Figure 30.44 Conceptual diagram of frames**

Figure 30.45 shows the correspondence between the commands and the transmit and receive buffers in the sequence of operations specified by the settings in Table 30.4.

**Figure 30.45 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations**

**(4) Burst transfers**

If the SPCMDm.SSLKP bit that the SPI references during the current serial transfer is 1, the SPI maintains the SSLni signal level during the serial transfer until the beginning of the SSLni signal assertion for the next serial transfer. If the SSLni

signal level for the next serial transfer is the same as the SSLni signal level for the current serial transfer, the SPI can execute continuous serial transfers while keeping the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register 3 (SPCR3) is 0.

Figure 30.46 shows an example of an SSLni signal operation for a burst transfer that is implemented using the SPCMD0 and SPCMD1 register settings. This section describes SPI operations (1) to (8) shown in Figure 30.46.

Note: The polarity of the SSLni output signal depends on the SSLP register settings.

**Figure 30.46 Example of burst transfer operation using the SSLKP bit (BFDS = 0)**

The SPI operation at times (1) to (8) in the figure is as follows:

1. Based on the SPCMD0 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
2. The SPI executes serial transfers in accordance with the SPCMD0 settings.
3. The SPI inserts an SSL negation delay.
4. Because the SPCMD0.SSLKP bit is 1, the SPI keeps the SSLni signal value specified in SPCMD0. This period is sustained at a minimum for a period equal to the next-access delay in SPCMD0. If the shift register is empty after the passage of the minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
5. Based on the SPCMD1 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
6. The SPI executes serial transfers in accordance with the SPCMD1 settings.
7. Insert SSL negate delay.
8. Because the SPCMD1.SSLKP bit is 0, the SPI negates the SSLni signal. In addition, a next-access delay is inserted in accordance with SPCMD1.

If the SSLni signal output settings in the SPCMDm register where 1 is assigned to the SSLKP bit are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the SPI switches the SSLni signal status to SSLni signal assertion as shown in (5) in Figure 30.46. This corresponds to the command for the next transfer.

Note: If such an SSLni signal switching occurs, the slaves that drive the MISO signal compete, and collision of signal levels might occur.

The SPI in master mode references the SSLni signal operation within the module when the SSLKP bit is not used. When the SPCMDm.CPHA bit is 0, the SPI can accurately start serial transfers by using the SSLni signal assertion for the next transfer that is detected internally.

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register 3 (SPCR3) is 1.

Figure 30.47 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 30.47. The SSL output signal polarity depends on the set SPI slave select polarity register (SSLP) value.

**Figure 30.47 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1)**

1. Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
3. The value of SSL signal according to SPCMD0 was hold, because the SPCMD0.SSLKP bit is 1. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.
4. Perform serial transfer according to SPCMD1.
5. Insert SSL negate delay for the last frame.
6. The SSL signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

**(5) RSPCK delay (t1)**

The RSPCK delay value of the SPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD.SCKDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during a serial transfer by pointer control, and determines an RSPCK delay using the SPCMDm.SCKDEN bit and SPCKD.SCKDL[2:0] bits, as listed in [Table 30.11](#). For a definition of RSPCK delay, see [section 30.3.5. Transfer Formats](#).

RSPCK delay insert to only the first frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay”. (The SPCMD.SSLKP bit is 1 and the SPCR3.BFDS bit is 1.)

**Table 30.11 Relationship between the SPCMDm.SCKDEN bit, SPCKD.SCKDL[2:0] bits, and RSPCK delay**

| SPCMDm.SCKDEN bit | SPCKD.SCKDL[2:0] bits | RSPCK delay |
|-------------------|-----------------------|-------------|
| 0                 | 000b to 111b          | 1 RSPCK     |
| 1                 | 000b                  | 1 RSPCK     |
|                   | 001b                  | 2 RSPCK     |
|                   | 010b                  | 3 RSPCK     |
|                   | 011b                  | 4 RSPCK     |
|                   | 100b                  | 5 RSPCK     |
|                   | 101b                  | 6 RSPCK     |
|                   | 110b                  | 7 RSPCK     |
|                   | 111b                  | 8 RSPCK     |

**(6) SSL negation delay (t2)**

The SSL negation delay value of the SPI in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND.SLNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced by pointer control during a serial transfer, and determines an SSL negation delay using the SPCMDm.SLNDEN bit and SSLND.SLNDL[2:0] bits, as listed in [Table 30.12](#). For a definition of SSL negation delay, see [section 30.3.5. Transfer Formats](#).

An SSL negation delay is inserted to only the last frame of the burst transmission, that is, transmit without “between burst transfer frames delay”. (SPCMD.SSLKP bit is 1 and SPCR3.BFDS bit is 1).

**Table 30.12 Relationship between the SPCMDm.SLN DEN bit, SSLND.SLNDL[2:0] bits, and SSL negation delay**

| SPCMDm.SLN DEN bit | SSLND.SLNDL[2:0] bits | SSL negation delay |
|--------------------|-----------------------|--------------------|
| 0                  | 000b to 111b          | 1 RSPCK            |
| 1                  | 000b                  | 1 RSPCK            |
|                    | 001b                  | 2 RSPCK            |
|                    | 010b                  | 3 RSPCK            |
|                    | 011b                  | 4 RSPCK            |
|                    | 100b                  | 5 RSPCK            |
|                    | 101b                  | 6 RSPCK            |
|                    | 110b                  | 7 RSPCK            |
|                    | 111b                  | 8 RSPCK            |

### (7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND.SPNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and then determines a next-access delay during serial transfer using the SPCMDm.SPNDEN bit and SPND.SPNDL[2:0] bits, as listed in [Table 30.13](#). For a definition of next-access delay, see [section 30.3.5. Transfer Formats](#).

A next-Access delay is inserted to only the last frame of the burst transmission, that is, transmit without “between burst transfer frames delay”. (SPCMD.SSLKP bit is 1 and SPCR3.BFDS bit is 1).

**Table 30.13 Relationship between the SPCMDm.SPNDEN bit, SPND.SPNDL[2:0] bits, and next-access delay**

| SPCMDm.SPNDEN bit | SPND.SPNDL[2:0] bits | Next-access delay |
|-------------------|----------------------|-------------------|
| 0                 | 000b to 111b         | 1 RSPCK + 2 PCLKA |
| 1                 | 000b                 | 1 RSPCK + 2 PCLKA |
|                   | 001b                 | 2 RSPCK + 2 PCLKA |
|                   | 010b                 | 3 RSPCK + 2 PCLKA |
|                   | 011b                 | 4 RSPCK + 2 PCLKA |
|                   | 100b                 | 5 RSPCK + 2 PCLKA |
|                   | 101b                 | 6 RSPCK + 2 PCLKA |
|                   | 110b                 | 7 RSPCK + 2 PCLKA |
|                   | 111b                 | 8 RSPCK + 2 PCLKA |

### (8) Initialization flow

[Figure 30.48](#) shows an example of SPI initialization flow when the SPI is in master mode. For information on how to set up the Interrupt Controller Unit (ICU), DMAC and I/O ports, see the descriptions given in the individual blocks.

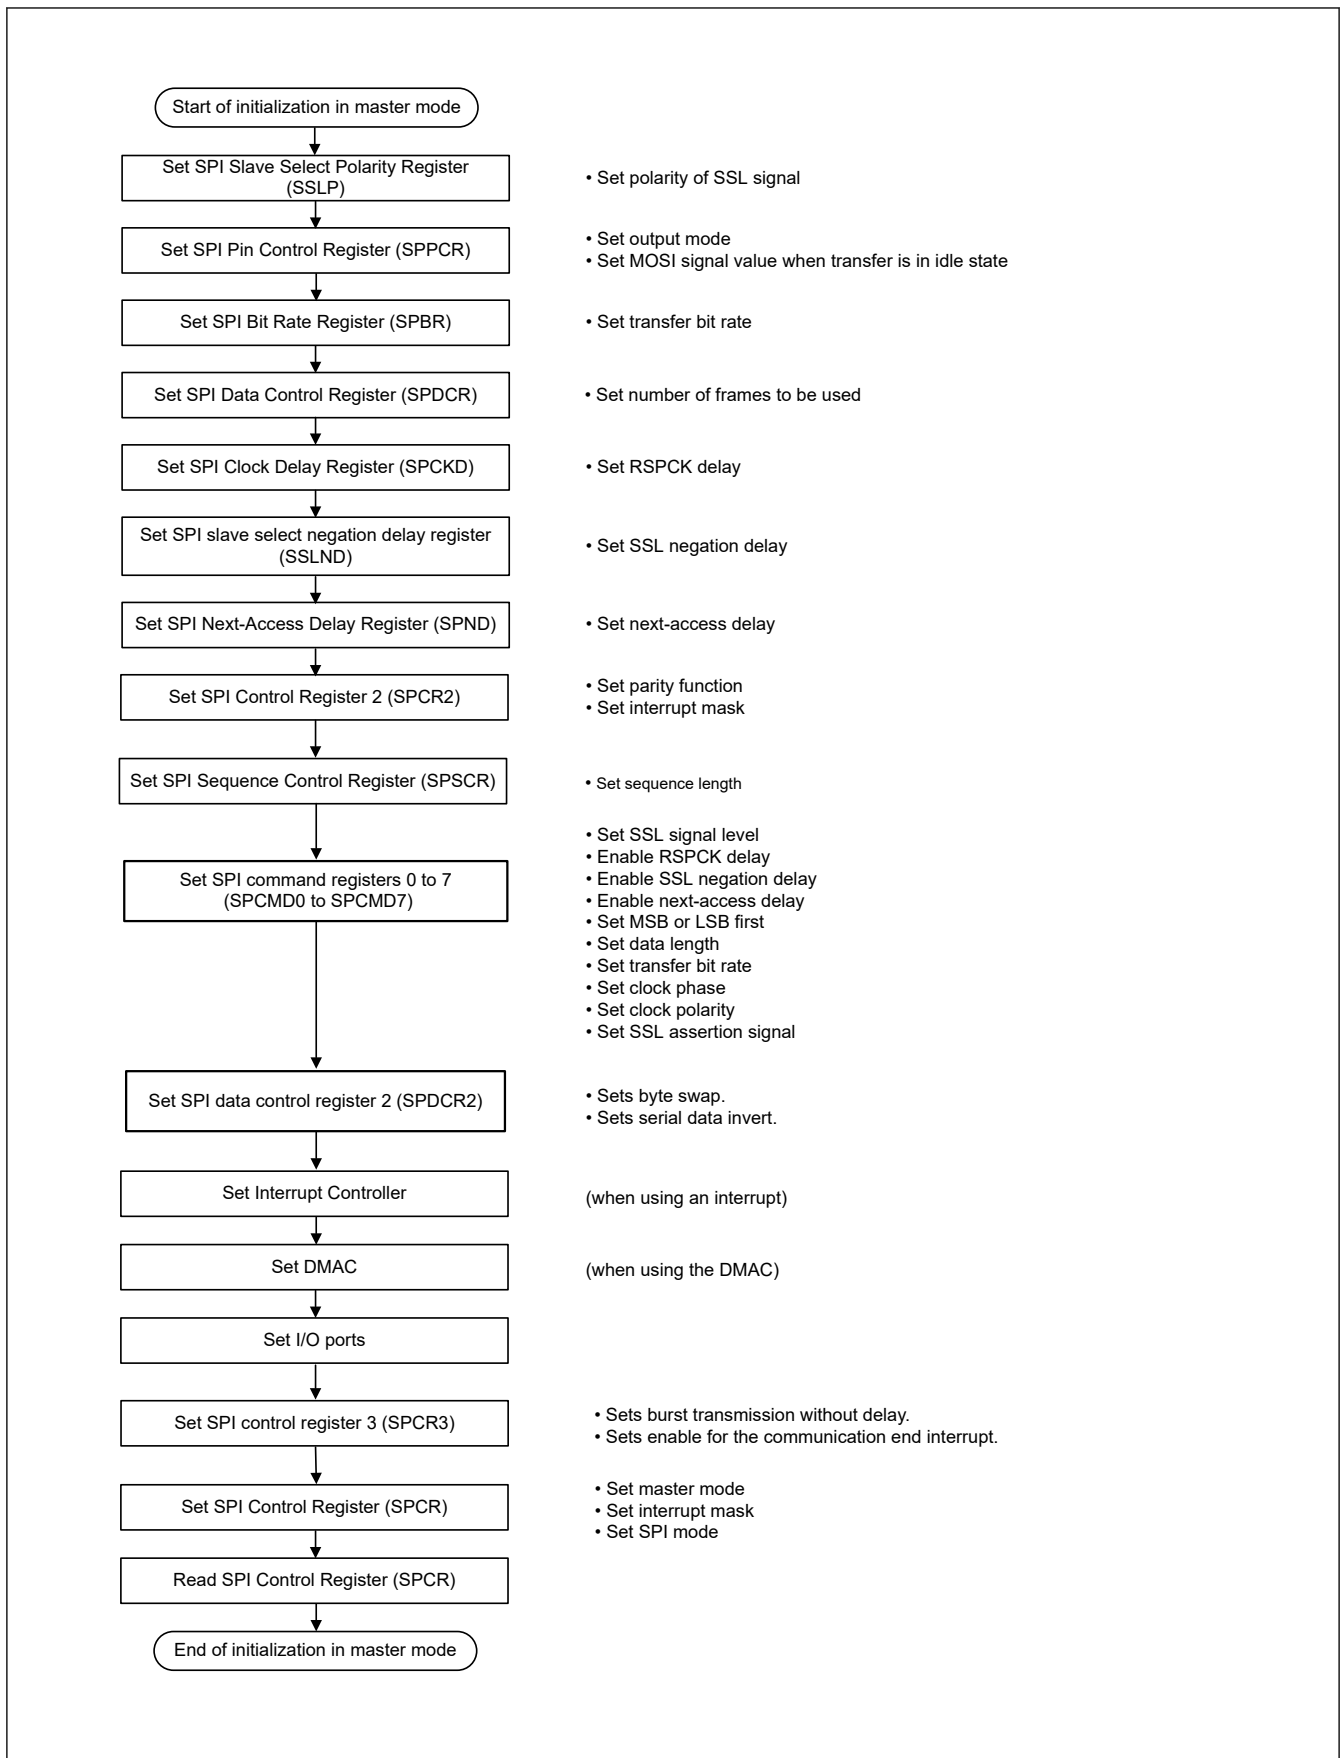

Figure 30.48 Example of initialization flow in master mode for SPI operation

(9) Software processing flow

Figure 30.49 to Figure 30.51 show examples of the software processing flow.

**Transmit processing flow**

When transmitting data, with the SPIi\_SPII interrupt enabled, the CPU is notified of the completion of data transmission after the last data write for transmission.

Figure 30.49 Transmission flow in master mode

**Receive processing flow**

The SPI has receive only operation in slave mode.

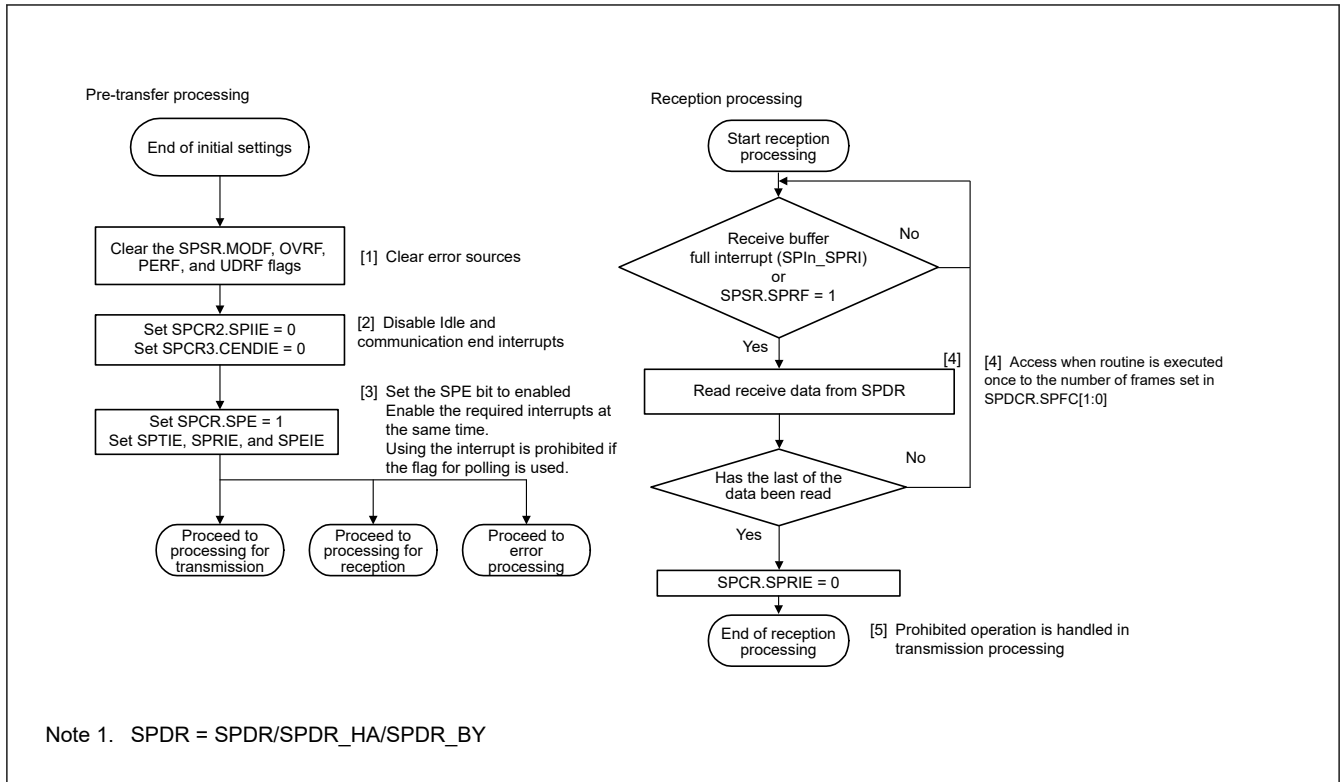

Figure 30.50 Reception flow in master mode

### Error processing flow

The SPI detects the following errors:

- Mode fault error
- Underrun error
- Overrun error
- Parity error

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, the SPCR.SPE bit is not cleared and operations for transmission and reception continue. Therefore, Renesas recommends clearing the SPCR.SPE bit to stop operations for errors other than mode fault errors. Not doing so leads to updating of the SPSR.SPECM[2:0] bits.

When an error is detected using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi\_SPTI or SPIi\_SPRI interrupt request. If the SPIi\_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

Figure 30.51 Error processing flow in master mode

### 30.3.11.2 Slave mode operation

#### (1) Starting a serial transfer

When the SPCMD0.CPHA bit is 0, if the SPI detects an SSLn0 input signal assertion, it must drive valid data to the MISO<sub>n</sub> output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLn0 input signal triggers the start of a serial transfer.

When the CPHA bit is 1, if the SPI detects the first RSPCK<sub>n</sub> edge in an SSLn0 signal asserted condition, it must drive valid data to the MISO<sub>n</sub> output signal. For this reason, when the CPHA bit is 1, the first RSPCK<sub>n</sub> edge in an SSLn0 signal asserted condition triggers the start of a serial transfer.

Regardless of the CPHA bit setting, the SPI drives the MISO<sub>n</sub> output signal on SSLn0 signal assertion. The data that is output by the SPI is either valid or invalid, depending on the CPHA bit setting.

For details on the SPI transfer format, see [section 30.3.5. Transfer Formats](#). The polarity of the SSLn0 input signal depends on the SSLP.SSL0P setting.

#### (2) Terminating a serial transfer

Regardless of the SPCMD0.CPHA bit setting, the SPI terminates the serial transfer after detecting an RSPCK<sub>n</sub> edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR/SPDR\_HA register. On termination of a serial transfer, the SPI changes the status of the shift register to empty, regardless of the receive buffer state. A mode fault error occurs if the SPI detects an SSLn0 input signal negation from the beginning of serial transfer to the end of serial transfer (see [section 30.3.9. Error Detection](#)).

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length is determined by the SPCMD0.SPB[3:0] bits setting. The polarity of the SSLn0 input signal is determined by the SSLP.SSL0P bit setting. For details on the SPI transfer format, see [section 30.3.5. Transfer Formats](#).

### (3) Notes on single-slave operations

If the SPCMD0.CPHA bit is 0, the SPI starts serial transfers when it detects the assertion edge for an SSLn0 input signal. In the configuration shown in [Figure 30.7](#), if the SPI is used in single-slave mode, the SSLn0 signal is fixed at an active state. Therefore, when the CPHA bit is set to 0, the SPI cannot correctly start a serial transfer. For the SPI to correctly execute transmit and receive operations in slave mode when the SSLn0 input signal is fixed at an active state, the CPHA bit must be set to 1. Do not fix the SSLn0 input signal if there is a requirement for setting the CPHA bit to 0.

### (4) Burst transfer

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLn0 input signal. When the CPHA bit is 1, the serial transfer period is the period from the first RSPCKn edge to the sampling timing for the reception of the final bit in an SSLn0 signal active state. Even when the SSLn0 input signal remains at the active level, the SPI can accommodate burst transfers, because it can detect the start of access.

When the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

### (5) Initialization flow

[Figure 30.52](#) shows an example of initialization flow for SPI operation when the SPI is in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.

**Figure 30.52 Example initialization flow in slave mode for SPI operation**

(6) Software processing flow

Figure 30.53 to Figure 30.55 show examples of the flow of software processing.

**Transmit processing flow**

**Figure 30.53 Transmission flow in slave mode**

**Receive processing flow**

The SPI does not handle receive-only operation, so processing for transmission is required.

**Figure 30.54 Reception flow in slave mode**

**Error processing flow**

In slave mode operation, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the state of the SSLn0 pin.

When an error is detected by using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi\_SPTI or SPIi\_SPRI interrupt request. If the SPIi\_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

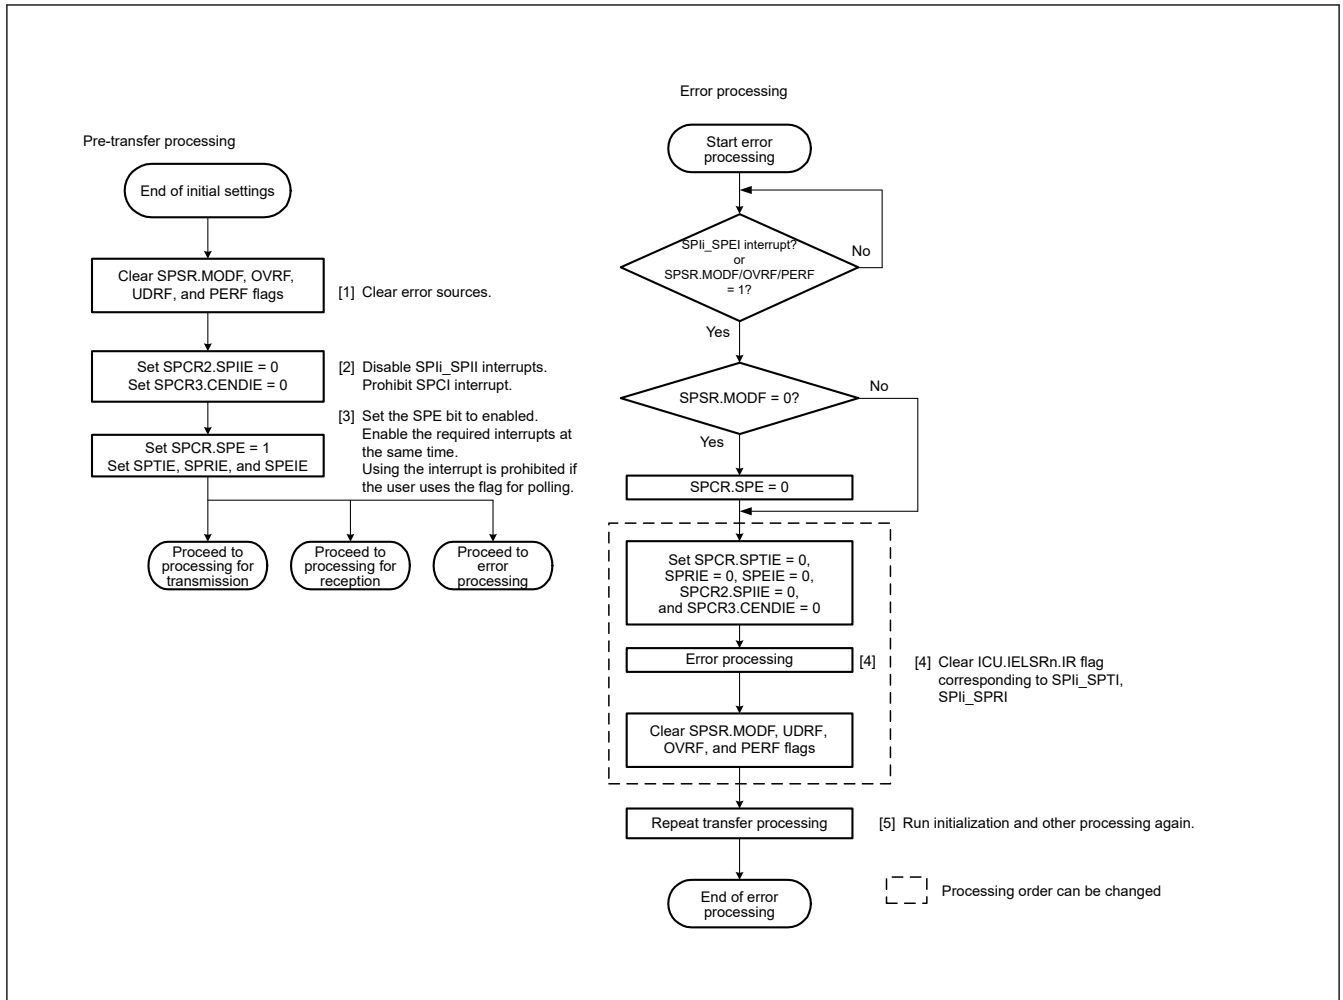

Figure 30.55 Error processing flow for slave mode

### 30.3.12 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the SPI. In clock synchronous operation, the SSLni pin is not used, and the RSPCKn, MOSIn, and MISON pins handle communications. All SSLni pins are available as I/O port pins.

Although clock synchronous operation does not require the use of the SSLni pin, operation of the module is the same as in SPI operation. In both master mode and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected, because the SSLni pin is not used.

Additionally, do not perform operation if clock synchronous operation is enabled when the SPCMDm.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

#### 30.3.12.1 Master mode operation

##### (1) Starting serial transfer

The SPI updates the data in the transmit buffer (SPTX) of SPDR/SPDR\_HA when data is written to the SPDR/SPDR\_HA register with the transmit buffer empty, the data for the next transfer not set and the SPSR.SPTEF flag is 1. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR\_HA, the SPI copies data from the transmit buffer to the shift register and starts serial transmission. On copying transmit data to the shift register, the SPI changes the status of the shift register to full, and on termination of serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see [section 30.3.5. Transfer Formats](#).

## (2) Terminating serial transfer

The SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the sampling timing. If free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies data from the shift register to the receive buffer of the SPI Data Register (SPDR/SPDR\_HA).

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bits setting. Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see [section 30.3.5. Transfer Formats](#).

## (3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers. Although the SSLni signals are not output in clock synchronous operation, these settings are valid.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following parameters are specified in the SPCMDm register:

- SSLni output signal value
- MSB or LSB first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced

SPBR holds some of the bit rate settings such as SPCKD, an SPI clock delay value, SSLND, an SSL negation delay, and SPND, a next-access delay value.

Based on the sequence length that is assigned to SPSCR, the SPI makes up a sequence comprised of a part or all of SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command comprising the sequence, the SPI sets the pointer to the SPCMD0 register, and in this manner the sequence is executed repeatedly.

Figure 30.56 Procedure for determining the form of serial transmission in master mode

In this section, a frame is the combination of the data (SPDR/SPDR\_HA) and the settings (SPCMDm).

**Figure 30.57 Conceptual diagram of frames**

[Figure 30.58](#) shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings in [Table 30.4](#).

**Figure 30.58 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations**

**(4) Initialization flow**

Figure 30.59 shows an example of initialization flow for clock synchronous operation when the SPI is used in master mode. For information on how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

Figure 30.59 Example of initialization flow in master mode for clock synchronous operation

### (5) Software processing flow

Software processing during clock synchronous master operation is the same as that for SPI master operation. For details, see (9) Software processing flow in [section 30.3.11.1. Master mode operation](#). Mode fault errors do not occur in clock synchronous operation.

## 30.3.12.2 Slave mode operation

### (1) Starting serial transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the SPI, and the SPI drives the MISO<sub>n</sub> output signal. The SSL0 input signal is not used in clock synchronous operation. For details on the SPI transfer format, see [section 30.3.5. Transfer Formats](#).

### (2) Terminating serial transfer

The SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR/SPDR\_HA register. On termination of a serial transfer, the SPI changes the status of the shift register to empty regardless of the receive buffer.

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length depends on the SPCMD0.SPB[3:0] bits setting. For details on the SPI transfer format, see [section 30.3.5. Transfer Formats](#).

### (3) Initialization flow

[Figure 30.60](#) shows an example of initialization flow for clock synchronous operation when the SPI is used in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.

**Figure 30.60 Example of initialization flow in slave mode for clock synchronous operation**

#### (4) Software processing flow

Software processing during clock synchronous slave operation is the same as that for SPI slave operation. For details, see [\(6\) Software processing flow](#). Mode fault errors do not occur in clock synchronous mode.

### 30.3.13 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the SPI shuts off the path between the MISO<sub>n</sub> pin and the shift register if the SPCR.MSTR bit is 1, or between the MOSI<sub>n</sub> pin and the shift register if the SPCR.MSTR bit is 0, and connects the input and output paths of the shift register, establishing a loopback mode. The SPI does not shut off the path between the MOSI<sub>n</sub> pin and the shift register if the SPCR.MSTR bit is 1, or between the MISO<sub>n</sub> pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the SPI or the reversed transmit data becomes the received data for the SPI.

Table 30.14 lists the relationship between the SPLP2 and SPLP bits and the received data. Figure 30.61 shows the configuration of the shift register I/O paths when the SPI in master mode is set to loopback mode (SPPCR.SPLP2 = 0, SPPCR.SPLP = 1).

**Table 30.14 SPLP2 and SPLP bit settings and received data**

| SPPCR.SPLP2 bit | SPPCR.SPLP bit | Received data                             |
|-----------------|----------------|-------------------------------------------|
| 0               | 0              | Input data from the MOSIn pin or MISO pin |
| 0               | 1              | Inverted transmit data                    |
| 1               | 0              | Transmit data                             |
| 1               | 1              | Transmit data                             |

**Figure 30.61 Configuration of shift register I/O paths in loopback mode for master mode**

### 30.3.14 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. To detect defects in the parity bit adding unit and error detecting unit, the parity circuit performs self-diagnosis as shown in Figure 30.62.

Figure 30.62 Self-diagnosis flow for parity circuit

### 30.3.15 Interrupt Sources

The SPI has the following interrupt sources:

- Receive buffer full
- Transmit buffer empty
- SPI error (mode-fault, underrun, overrun, or parity error)
- SPI idle
- Communication-end

The DMAC or DTC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Because the vector address for the SPIi\_SPEI (SPI error interrupt) is allocated to interrupt requests on mode-fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the SPI are listed in Table 30.15. An interrupt is generated on satisfaction of one of the interrupt conditions in Table 30.15. Clear the receive buffer full and transmit buffer empty sources through a data transfer.

When using the DMAC or DTC to perform data transmission and reception, you must first set up the DMAC or DTC to be in a transfer-enabled status before setting the SPI. For information on setting up the DMAC or DTC, see section 16, DMA Controller (DMAC) and section 17, Data Transfer Controller (DTC).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt occur while the ICU.IELSRn.IR flag is 1, the interrupt is not output as a request for the ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IELSRn.IR flag becomes 0. A retained interrupt request is automatically discarded when it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be set to 0.

**Table 30.15 SPI interrupt sources**

| Interrupt source                                           | Symbol    | Interrupt condition                                                                    | DTC/DMAC activation |
|------------------------------------------------------------|-----------|----------------------------------------------------------------------------------------|---------------------|
| Receive buffer full                                        | SPIi_SPRI | The receive buffer becomes full (SPSR.SPRF flag is 1) while the SPCR.SPRIE bit is 1    | Possible            |
| Transmit buffer empty                                      | SPIi_SPTI | The transmit buffer becomes empty (SPSR.SPTEF flag is 1) while the SPCR.SPTIE bit is 1 | Possible            |
| SPI error (mode-fault, underrun, overrun, or parity error) | SPIi_SPEI | The SPSR.MODF, OVRF, UDRF or PERF flag sets to 1 while the SPCR.SPEIE bit is 1         | Impossible          |
| SPI idle                                                   | SPIi_SPII | The SPSR.IDLNF flag sets to 0 while the SPCR2.SPIIE bit is 1                           | Impossible          |
| Communication-end                                          | SPIi_SPCI | CENDIE = 1 and CENDF = 1                                                               | Impossible          |

## 30.4 Event Link Controller Event Output

The Event Link Controller (ELC) can produce the following event output signals:

- Receive buffer full event output
- Transmit buffer empty event output
- Mode-fault, underrun, overrun, or parity error event output
- SPI idle event output
- Transmission-completed event output

The event link output signal is output regardless of the interrupt enable bit setting.

### 30.4.1 Receive Buffer Full Event Output

This event signal is output when received data is transferred from the shift register to the SPDR/SPDR\_HA on completion of serial transfer.

### 30.4.2 Transmit Buffer Empty Event Output

This event signal is output when data for transmission is transferred from the transmit buffer to the shift register and when the value of the SPE bit changes from 0 to 1.

### 30.4.3 Mode-Fault, Underrun, Overrun, or Parity Error Event Output

This event signal is output when mode-fault, underrun, overrun, or parity error is detected. See [section 30.5.4. Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output](#) if using this event signal.

#### (1) Mode-fault

[Table 30.16](#) lists the conditions for occurrence of a mode-fault event.

**Table 30.16 Conditions for mode-fault occurrence**

| SPI mode                                          | SPCR.MODFEN bit | SSLn0 pin  | Remarks                                                                    |
|---------------------------------------------------|-----------------|------------|----------------------------------------------------------------------------|
| SPI operation (SPMS = 0)<br>Slave (SPCR.MSTR = 0) | 1               | Not active | Event is output only when the SSLn0 pin is deactivated during transmission |

#### (2) Underrun

This event signal is output in response to an underrun when a serial transfer starts while the transmission data is not ready, and the value of the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1. Under these conditions, the MODF and UDRF flags are set to 1.

#### (3) Overrun

This event signal is output in response to an overrun when a serial transfer completes while the receive buffer contains unread data and the value of the SPCR.TXMD bit is 0. Under these conditions, the OVRF flag is set to 1.

#### (4) Parity error

This event signal is output in response to a parity error detected on completion of a serial transfer while the value of the TXMD bit in SPCR is 0 and the value of the SPPE bit in SPCR2 is 1.

### 30.4.4 SPI Idle Event Output

#### (1) In master mode

In master mode, an event is output when the condition for setting the IDLNF flag (SPI idle flag) to 0 is satisfied.

#### (2) In slave mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (SPI is initialized).

### 30.4.5 Communication End Event Output

In master mode, an event is output when the IDLNF flag (SPI idle flag) changes from 1 to 0. In slave mode, an event occurs with conditions shown in [Table 30.17](#) and [Table 30.18](#)

**Table 30.17 Communication End Event Generating Conditions (transmit-receive/transmit slave mode)**

|                                        | Transmit Buffer Status | Shift Register Status | Others                                                           |
|----------------------------------------|------------------------|-----------------------|------------------------------------------------------------------|
| SPI operation (SPMS = 0)               | Empty                  | Empty                 | SSL0 input is negated                                            |
| Clock synchronous operation (SPMS = 1) | Empty                  | Empty                 | The last even edge of RSPCK of last data was detected (CPHA = 1) |

**Table 30.18 Communication End Event Generating Conditions (receive only slave mode)**

|                                        | Others                                                           |
|----------------------------------------|------------------------------------------------------------------|
| SPI operation (SPMS = 0)               | SSL0 input is negated                                            |
| Clock synchronous operation (SPMS = 1) | The last even edge of RSPCK of last data was detected (CPHA = 1) |

Regardless of master mode or slave mode, no event is output when 0 is written to the SPCR.SPE bit during transmission or when the SPCR.SPE bit is cleared due to a mode fault error or an underrun error.

A communication end event is output at the following timing. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

Figure 30.63 Communication End Event Output Timing (Transmit slave mode, SPI Operation)

Figure 30.64 Communication End Event Output Timing (Transmit slave mode, Clock Synchronous Operation)

Figure 30.65 Communication End Event Output Timing (Receive only slave mode, SPI Operation)

**Figure 30.66** Communication End Event Output Timing (Receive only slave mode, Clock Synchronous Operation)

## 30.5 Usage Notes

### 30.5.1 Settings for the Module-Stop State

The Module Stop Control Register B (MSTPCRB) can enable or disable the SPI operation. The SPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details on the Module Stop Control Register B, see [section 10, Low Power Modes](#).

### 30.5.2 Constraint on Low-Power Functions

When using the module-stop function and entering a low-power mode other than Sleep mode, set the SPCR.SPE bit to 0 before completing communication.

### 30.5.3 Constraints on Starting Transfer

If the ICU.IELSRn.IR flag is 1 when transfer starts, the interrupt request is internally retained, which can lead to unanticipated behavior of the ICU.IELSRn.IR flag.

To prevent this, use the following procedure to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1):

1. Confirm that transfer stopped (the SPCR.SPE bit is 0).
2. Set the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IELSRn.IR flag to 0.

### 30.5.4 Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output

Using the mode-fault, underrun, overrun, or parity error event is prohibited if the SPI is in multi-master mode (when the SPCR.SPMS bit is 0, the SPCR.MSTR bit is 1, and the SPCR.MODFEN bit is 1).

### 30.5.5 Constraints on the SPSR.SPRF and SPSR.SPTEF Flags

If the polling flags, SPRF and SPTEF, are used, using the interrupts is prohibited, and you must set the SPCR.SPRIE and SPCR.SPTIE bits to 0. Either the interrupts or the flags can be used, but not both.

## 31. Quad Serial Peripheral Interface (QSPI)

### 31.1 Overview

The QSPI is a memory controller for connecting a serial ROM (nonvolatile memory such as a serial flash memory, serial EEPROM, or serial FeRAM) that has an SPI-compatible interface.

Table 31.1 lists the QSPI specifications, Figure 31.1 shows a block diagram, and Table 31.2 lists the I/O pins.

**Table 31.1 QSPI specifications**

| Parameter                      | Specifications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 31:16 | —          | These bits are read as 0. The write value should be 0.                                                                                                                                                                                   | R/W |

Note 1. The QSPI outputs additional one clock without accompanying data reception. For details, see [section 31.5.9. Serial Data Receiving Latency](#).

Note 2. When QSPI accesses serial flash memory, the instruction code is based on the SFMSAC register and SFMSMD register settings. See [section 31.6.1. SPI Instructions That Are Automatically Generated](#).

| 31:16 | —          | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | R/W |

Note 1. To avoid a conflict with the input/output switch of the serial flash memory pin connected to QIO0 pin, select more than four cycles of QSPCLK as the number of dummy cycles for the fast read instruction when the output enable signal is extended by setting the SFMOEX bit in the SFMSMD register to 1.

Note 2. As the mode data for serial flash memory, specify the XIP mode setting data set in actual serial flash memory.

## 31.3 Memory Map

### 31.3.1 External Bus Space

The locations of a serial flash memory and control register on the address space are determined by the address range of the area set in the configuration.

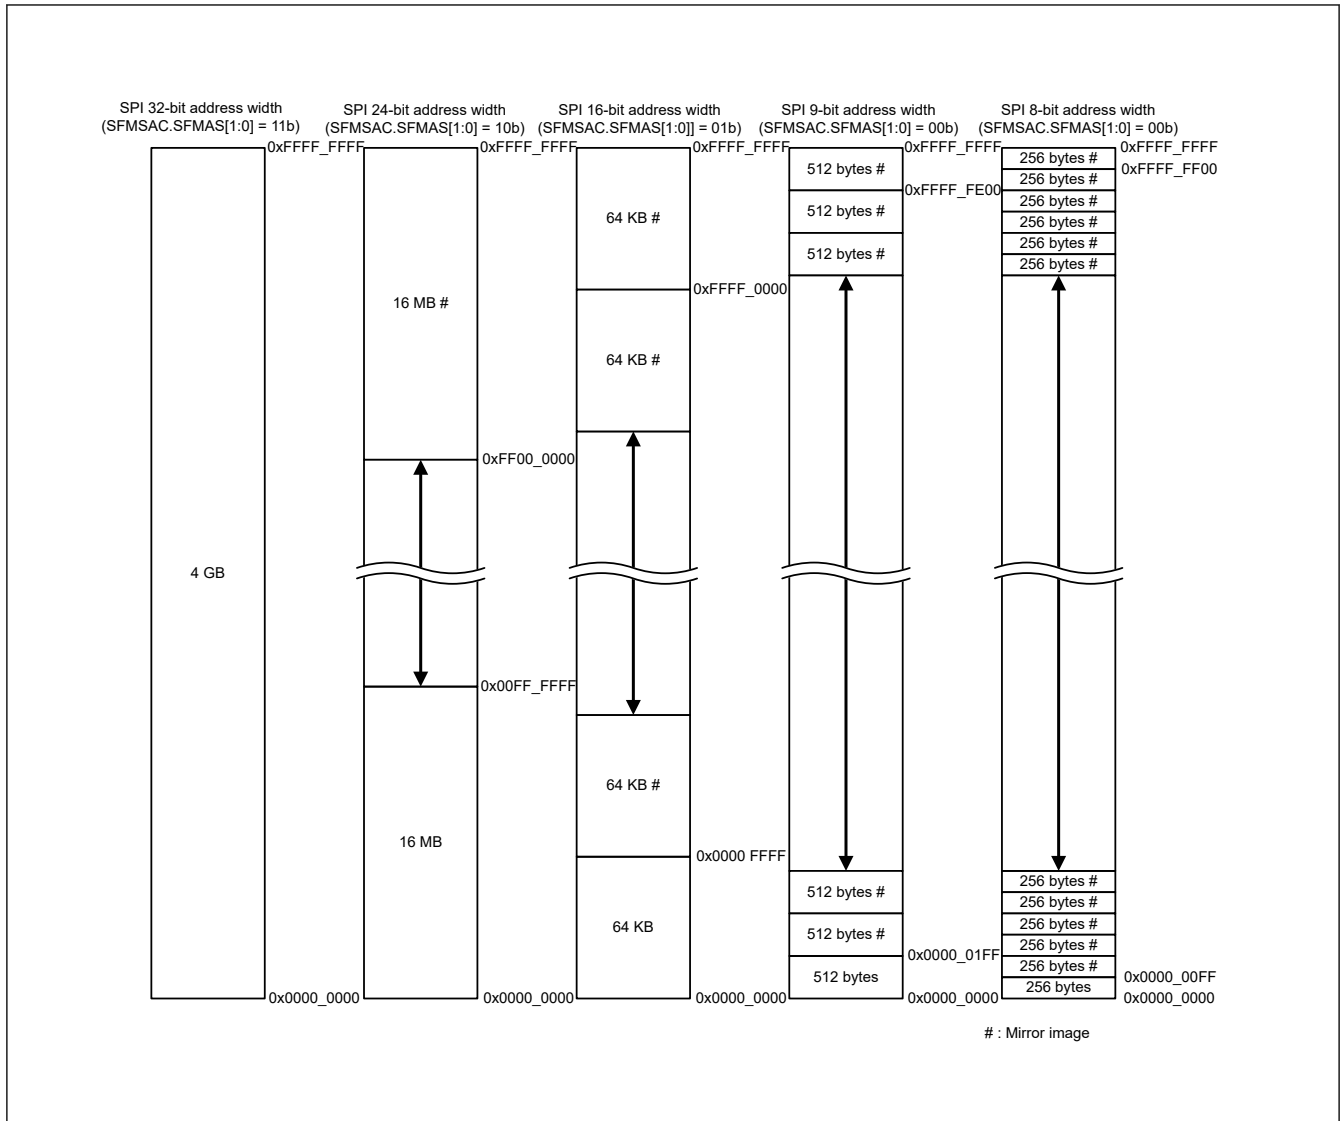

**Figure 31.2** Default area setting and memory map

### 31.3.2 Address Width of the SPI Space and SPI Bus

The SPI space has a 32-bit address width for referencing the serial flash memory. When the SPI space is accessed for a read, an SPI bus cycle starts automatically, and data read from the serial flash is returned.

The address width of the SPI space is fixed at 32 bits. However, the address width of the SPI bus is selectable to 8, 16, 24, or 32 bits in the SFMAS[1:0] bits in the Address Mode Control Register (SFMSAC) register. If 8, 16, or 24 bits is selected as the address width of the SPI bus, only the lower part of the address used to access the SPI space is posted to the serial flash memory through the SPI bus. As a result, the mirror image of the serial flash corresponding to the address width of the SPI bus repeatedly appears in the SPI space.

**Figure 31.3** Memory map of SPI space

Note: The SPI bus address width is selectable to 8, 16, 24, or 32 bits in the SFMAS[1:0] bits in the SFMSAC register (cases 1 to 3 and 5 in the figure correspond to the respective address widths). When an 8-bit address width is selected, the address information of the ninth bit can be embedded in the Read instruction code. The memory map in case 4 in the figure is for the 9-bit address width. For details on the Read instruction, see [section 31.6.2. Standard Read Instruction](#).

## 31.4 SPI Bus

### 31.4.1 SPI Protocol

Single SPI, extended SPI, dual SPI, and quad SPI are supported in addition to the SPI protocol used for serial flash memory connection.

The initial state of the SPI protocol is Single SPI, extended SPI and can be changed with the SFMSPI[1:0] bits in the SPI Protocol Control Register (SFMSPC) register.

The address and data pins used in the Single SPI, extended SPI protocol change depending on the setting of the serial interface read mode select bits SFMRM[2:0] in Transfer Mode Control Register (SFMSMD). [Table 31.3](#) and [Table 31.4](#) list the pins used for instruction code, addresses, and data in each of the SPI protocols.

Note: In read operation, the QSPI outputs additional one clock without accompanying data reception per one SPI bus cycle. For details, see [section 31.5.9. Serial Data Receiving Latency](#).

**Table 31.3 List of SPI Protocols (1)**

| SPI Protocol (SFMSPC.SFMSPi[1:0])                     | Single SPI Protocol, Extended SPI Protocol |                          |                          |                          |                                      |                                      |
|-------------------------------------------------------|--------------------------------------------|--------------------------|--------------------------|--------------------------|--------------------------------------|--------------------------------------|
| Serial interface read mode select (SFMSMD.SFMRM[2:0]) | Standard read                              | Fast read                | Fast read dual output    | Fast read dual I/O       | Fast read quad output                | Fast read quad I/O                   |
| All pins used                                         | QSPCLK, QSSL, QIO0, QIO1                   | QSPCLK, QSSL, QIO0, QIO1 | QSPCLK, QSSL, QIO0, QIO1 | QSPCLK, QSSL, QIO0, QIO1 | QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3 | QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3 |
| Pins used for instruction code                        | QIO0                                       | QIO0                     | QIO0                     | QIO0                     | QIO0                                 | QIO0                                 |
| Pins used for addresses                               | QIO0                                       | QIO0                     | QIO0                     | QIO0, QIO1               | QIO0                                 | QIO0, QIO1, QIO2, QIO3               |
| Pins used for data                                    | QIO0/QIO1                                  | QIO0/QIO1                | QIO0, QIO1               | QIO0, QIO1               | QIO0, QIO1, QIO2, QIO3               | QIO0, QIO1, QIO2, QIO3               |

Note: Single SPI protocol operation is for standard read and fast read. Extended SPI protocol operation is fast read dual output, fast read dual I/O, fast read quad output, and fast read quad I/O.

**Table 31.4 List of SPI Protocols (2)**

| SPI Protocol (SFMSPC.SFMSPi[1:0])                     | Dual-SPI Protocol        |                          | Quad-SPI Protocol                    |                                      |
|-------------------------------------------------------|--------------------------|--------------------------|--------------------------------------|--------------------------------------|
| Serial interface read mode select (SFMSMD.SFMRM[2:0]) | Fast read dual output    | Fast read dual I/O       | Fast read quad output                | Fast read quad I/O                   |
| All pins used                                         | QSPCLK, QSSL, QIO0, QIO1 | QSPCLK, QSSL, QIO0, QIO1 | QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3 | QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3 |
| Pins used for instruction code                        | QIO0, QIO1               | QIO0, QIO1               | QIO0, QIO1, QIO2, QIO3               | QIO0, QIO1, QIO2, QIO3               |
| Pins used for addresses                               | QIO0, QIO1               | QIO0, QIO1               | QIO0, QIO1, QIO2, QIO3               | QIO0, QIO1, QIO2, QIO3               |
| Pins used for data                                    | QIO0, QIO1               | QIO0, QIO1               | QIO0, QIO1, QIO2, QIO3               | QIO0, QIO1, QIO2, QIO3               |

In single SPI protocol and extended SPI protocol, the instruction code is always output from the QIO0 pin. Address and data input/output operations are performed according to the settings in SFMSMD.SFMRM[2:0].

**Figure 31.4 Single SPI Protocol example for Fast Read**

**Figure 31.5** Extended SPI Protocol example for Fast Read Quad I/O

The Dual SPI protocol performs I/O operation of all signals such as instruction codes, addresses, and data using two pins, QIO0 and QIO1.

**Figure 31.6** Dual SPI protocol example for Fast Read Dual I/O

The Quad SPI protocol performs I/O operation of all signals such as instruction codes, addresses, and data using four pins, QIO0, QIO1, QIO2, and QIO3.

Figure 31.7 Quad SPI protocol example for Fast Read Quad I/O

### 31.4.2 SPI Mode

Either SPI mode 0 or SPI mode 3 can be selected as the SPI mode by the SFMSMD.SFMMD3 bit. This can be switched by changing the register setting during operation. The difference between SPI modes 0 and 3 is the state of the QSPCLK signal when it is inactive. The standby level of the QSPCLK signal in SPI mode 0 is low, and high in SPI mode 3.

Serial data is output from the QSPI on a falling edge of the serial clock and is read into the serial flash memory on a rising edge of the serial clock. Serial data is output from the serial flash memory on a falling edge of the serial clock and is read into the QSPI on the next falling edge of the serial clock.

Figure 31.8 Basic serial interface timing (SPI mode 0)

Figure 31.9 Basic serial interface timing (SPI mode 3)

### 31.5 SPI Bus Timing Adjustment

The timing of the SPI bus signal can be adjusted in the registers. The configured timing is applied to all SPI bus accesses, for both ROM access and direct communication.

#### 31.5.1 SPI Bus Reference Cycles

The SPI bus operates on reference cycles obtained by multiplying PCLKA by an integer. The reference cycles are selectable within the range of PCLKA multiplied by 2 to 48 in the SFMDV[4:0] bits in the Transfer Mode Control Register (SFMSKC) register.

Table 31.5 Relationship among SFMDV[4:0] bits, cycle multiplier, and serial clock frequencies (1 of 2)

| SFMDV[4:0] | Cycle multiplier | PCLKA = 100 [MHz] |
|------------|------------------|-------------------|
| 11111b     | 48               | 2.08              |
| 11110b     | 46               | 2.17              |
| 11101b     | 44               | 2.27              |
| 11100b     | 42               | 2.38              |
| 11011b     | 40               | 2.50              |
| 11010b     | 38               | 2.63              |
| 11001b     | 36               | 2.78              |
| 11000b     | 34               | 2.94              |
| 10111b     | 32               | 3.13              |
| 10110b     | 30               | 3.33              |
| 10101b     | 28               | 3.57              |
| 10100b     | 26               | 3.85              |
| 10011b     | 24               | 4.17              |
| 10010b     | 22               | 4.55              |
| 10001b     | 20               | 5.00              |
| 10000b     | 18               | 5.56              |
| 01111b     | 17               | 5.88              |
| 01110b     | 16               | 6.25              |
| 01101b     | 15               | 6.67              |

**Table 31.5 Relationship among SFMDV[4:0] bits, cycle multiplier, and serial clock frequencies (2 of 2)**

| SFMDV[4:0] | Cycle multiplier | PCLKA = 100 [MHz] |
|------------|------------------|-------------------|
| 01100b     | 14               | 7.14              |
| 01011b     | 13               | 7.69              |
| 01010b     | 12               | 8.33              |
| 01001b     | 11               | 9.09              |
| 01000b     | 10               | 10.00             |
| 00111b     | 9                | 11.11             |
| 00110b     | 8                | 12.50             |
| 00101b     | 7                | 14.29             |
| 00100b     | 6                | 16.67             |
| 00011b     | 5                | 20.00             |
| 00010b     | 4                | 25.00             |
| 00001b     | 3                | 33.33             |
| 00000b     | 2                | 50.00             |

### 31.5.2 QSPCLK Signal Duty Ratio

When the reference clock is configured as PCLKA divided by an odd number without duty ratio correction, the duty ratio of the QSPCLK signal will not be 50%. When the reference clock is PCLKA divided by an odd number, be sure to enable the duty ratio correction function (SFMSKC.SFMDTY = 1).

When the reference clock is PCLKA divided by an even number, the SFMDTY setting in the SFMSKC register is ignored.

**Figure 31.10 Example correction of the QSPCLK signal duty ratio using the SFMDTY bit, when PCLKA is multiplied by 3**

### 31.5.3 Minimum High-Level Width for the QSSL Signal

Between adjacent SPI bus cycles, the QSSL signal must be held high (inactive) for a sufficient time to satisfy the deselect time required by the serial flash memory. The minimum high-level width of the QSSL output signal is selectable as the reference cycle multiplied by an integer from 1 to 16 in the SFMSW[3:0] bits in the Instruction Code Register (SFMSSC) register.

### 31.5.4 QSSL Signal Setup Time

The QSSL signal setup time that the serial flash memory requires after the QSSL signal is driven active low until the first rising edge of the QSPCLK signal can be configured. The setup time can be selected as 0.5 or 1.5 cycles of QSPCLK in the SFMSLD bit of the SFMSSC register.

Set a value that meets the most constrained timing condition for your application.

Figure 31.11 Setup time adjustment for the QSSL signal using the SFMSLD bit

### 31.5.5 QSSL Signal Hold Time

The QSSL signal hold time that the serial flash memory requires until the QSSL signal is driven high after the last rising edge of the QSPCLK signal can be configured. The hold time can be selected as 0.5 or 1.5 cycles of QSPCLK in the SFMSHD bit of the SFMSSC register.

Figure 31.12 Hold time adjustment for the QSSL signal using the SFMSHD bit

### 31.5.6 Hold Time of the Serial Data Output Enable

The buffer output enable of the QIO0, QIO1, QIO2, or QIO3 pin can be extended by 1 QSPCLK using the SFMOEX bit in the SFMSMD register.

For a standard read instruction, it is extended immediately after an address code. For other read instructions, it is extended after two cycles of mode data (XIP mode control) of the serial flash memory in dummy cycles.

Figure 31.13 Hold time adjustment for output enable using the SFMOEX bit (Standard Read)

Figure 31.14 Hold Time Adjustment of Output Enabling Using the SFMOEX Bit (Fast Read)

### 31.5.7 Setup Time for Serial Data Output

When a command or address is transmitted to the serial flash memory, the setup time begins on serial data output and ends when the QSPCLK signal rises. If this setup time is insufficient, it can be extended by 1 PCLKA using the SFMOSW bit in the SFMSMD register. When SFMOSW is 1, the low-level width of QSPCLK during serial data transmission is extended by 1 PCLKA while data is being output from the QSPI. This function has no effect on serial data reception.

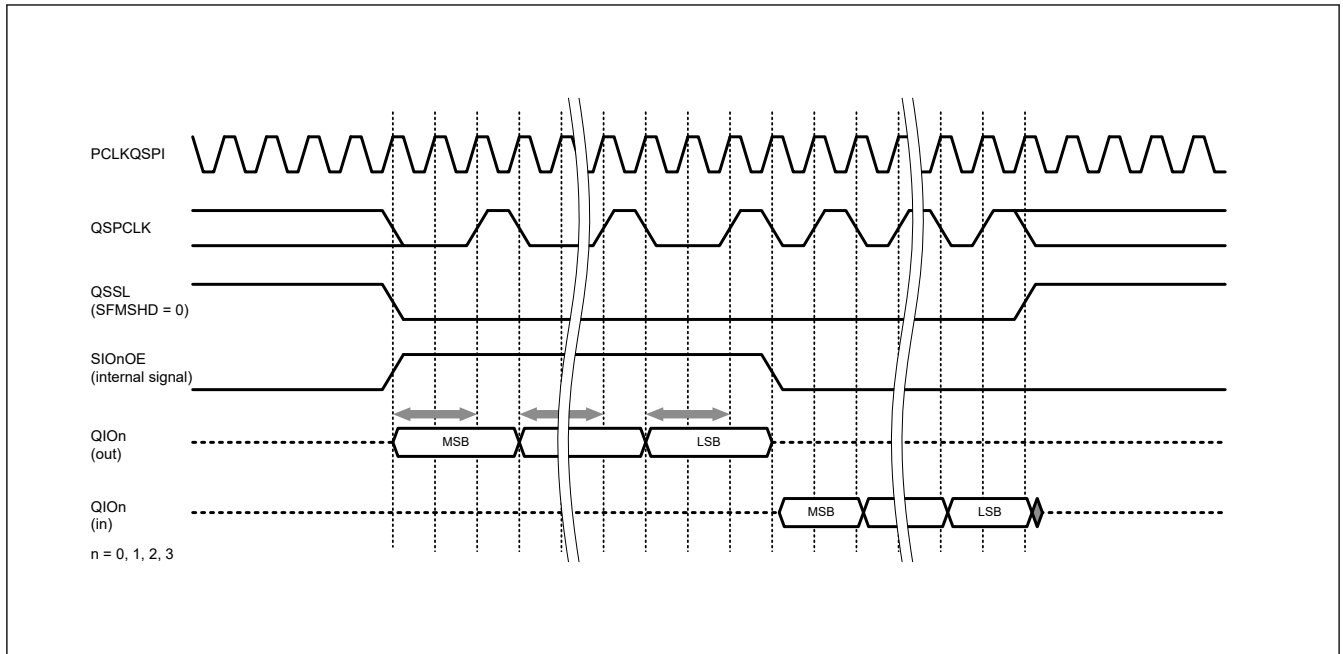

Figure 31.15 Setup time adjustment for serial data output using the SFMOSW bit

### 31.5.8 Hold Time for Serial Data Output

When a command or address is transmitted to the serial flash memory, the hold time begins on the rising edge of QSPCLK and ends when the serial data makes another transmission. If this hold time is insufficient, it can be extended by 1 PCLKA using the SFMOHW bit in the SFMSMD register. When SFMOHW is 1, the high-level width of QSPCLK during serial data transmission is extended by 1 PCLKA while data is being output from the QSPI. This function has no effect on serial data reception.

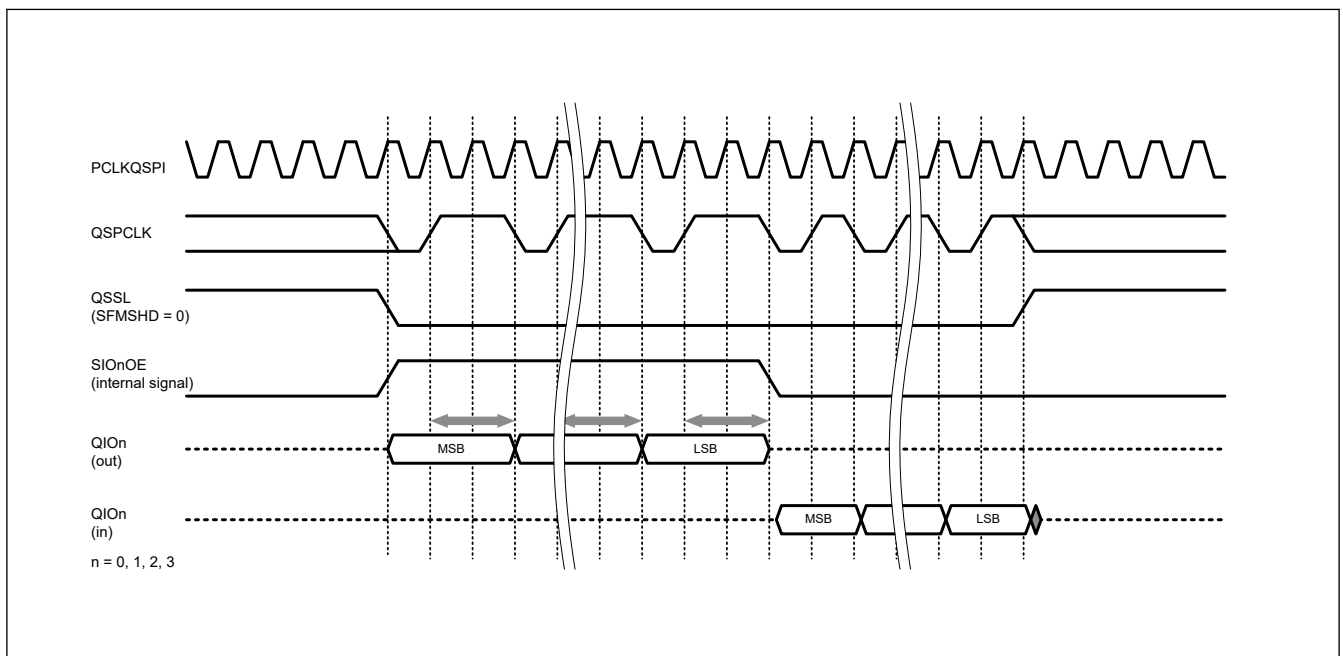

Figure 31.16 Hold time adjustment for serial data output using the SFMOHW bit

### 31.5.9 Serial Data Receiving Latency

The serial flash outputs data in synchronization with the falling edge of the QSPCLK signal. The QSPI receives that data in synchronization with the falling edge of the subsequent QSPCLK signal. The delay from when the serial flash starts outputting data until the QSPI receives that data is called the receiving latency. The QSPI adds a latency adjustment cycle

immediately before the first data reception cycle in the SPI bus cycle. From the serial flash side, this is seen as an increase in the number of data reception cycles. This added latency adjustment cycle is not generated in the SPI bus cycle without accompanying data reception.

Figure 31.17 Receiving latency

### 31.6 SPI Instruction Set Used for Serial Flash Memory Access

#### 31.6.1 SPI Instructions That Are Automatically Generated

When the serial flash memory is accessed, an SPI bus cycle using the instructions described in Table 31.6 to Table 31.10 is automatically generated based on the settings in the SFMSAC register and in the SFMSMD register.

Table 31.6 SPI instructions automatically generated when SFMAS[1:0] = 00b

| SPI instruction | Instruction code   | Address bytes | Dummy cycles | Data bytes | Remarks                   |
|-----------------|--------------------|---------------|--------------|------------|---------------------------|
| Standard Read   | 0x03 <sup>*1</sup> | 1             | —            | 1 to ∞     | SFMRM[2:0] = 000b, A8 = 0 |
|                 | 0x0B <sup>*1</sup> | 1             | —            | 1 to ∞     | SFMRM[2:0] = 000b, A8 = 1 |

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMCIC[7:0] bits in the Instruction Code Register (SFMSIC) setting is used as an instruction code.

Table 31.7 SPI instructions automatically generated when SFMAS[1:0] = 01b

| SPI instruction | Instruction code   | Address bytes | Dummy cycles | Data bytes | Remarks           |
|-----------------|--------------------|---------------|--------------|------------|-------------------|
| Standard Read   | 0x03 <sup>*1</sup> | 2             | —            | 1 to ∞     | SFMRM[2:0] = 000b |

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.

Table 31.8 SPI instructions automatically generated when SFMAS[1:0] = 10b (1 of 2)

| SPI instruction       | Instruction code   | Address bytes | Dummy cycles    | Data bytes | Remarks                       |
|-----------------------|--------------------|---------------|-----------------|------------|-------------------------------|
| Standard Read         | 0x03 <sup>*1</sup> | 3             | —               | 1 to ∞     | SFMRM[2:0] = 000b             |
| Fast Read             | 0x0B <sup>*1</sup> | 3             | 8 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 001b |
| Fast Read Dual Output | 0x3B <sup>*1</sup> | 3             | 8 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 010b |
| Fast Read Dual I/O    | 0xBB <sup>*1</sup> | 3             | 4 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 011b |

**Table 31.8 SPI instructions automatically generated when SFMAS[1:0] = 10b (2 of 2)**

| SPI instruction       | Instruction code   | Address bytes | Dummy cycles    | Data bytes | Remarks                       |
|-----------------------|--------------------|---------------|-----------------|------------|-------------------------------|
| Fast Read Quad Output | 0x6B <sup>*1</sup> | 3             | 8 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 100b |
| Fast Read Quad I/O    | 0xEB <sup>*1</sup> | 3             | 6 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 101b |

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.

Note 2. The number of dummy cycles is configurable by using SFMDN[3:0] bits in the Dummy Cycle Control Register (SFMSDC).

**Table 31.9 SPI instructions automatically generated when SFMAS[1:0] = 11b and SFM4BC = 0**

| SPI instruction       | Instruction code   | Address bytes | Dummy cycles    | Data bytes | Remarks                       |
|-----------------------|--------------------|---------------|-----------------|------------|-------------------------------|
| Standard Read         | 0x03 <sup>*1</sup> | 4             | —               | 1 to ∞     | SFMRM[2:0] = 000b             |
| Fast Read             | 0x0B <sup>*1</sup> | 4             | 8 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 001b |
| Fast Read Dual Output | 0x3B <sup>*1</sup> | 4             | 8 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 010b |
| Fast Read Dual I/O    | 0xBB <sup>*1</sup> | 4             | 4 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 011b |
| Fast Read Quad Output | 0x6B <sup>*1</sup> | 4             | 8 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 100b |
| Fast Read Quad I/O    | 0xEB <sup>*1</sup> | 4             | 6 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 101b |

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.

Note 2. The number of dummy cycles is configurable by using the SFMSDC.SFMDN[3:0] bits.

**Table 31.10 SPI instructions automatically generated when SFMAS[1:0] = 11b and SFM4BC = 1**

| SPI instruction       | Instruction code   | Address bytes | Dummy cycles    | Data bytes | Remarks                       |
|-----------------------|--------------------|---------------|-----------------|------------|-------------------------------|
| Standard Read         | 0x13 <sup>*1</sup> | 4             | —               | 1 to ∞     | SFMRM[2:0] = 000b             |
| Fast Read             | 0x0C <sup>*1</sup> | 4             | 8 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 001b |
| Fast Read Dual Output | 0x3C <sup>*1</sup> | 4             | 8 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 010b |
| Fast Read Dual I/O    | 0xBC <sup>*1</sup> | 4             | 4 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 011b |
| Fast Read Quad Output | 0x6C <sup>*1</sup> | 4             | 8 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 100b |
| Fast Read Quad I/O    | 0xEC <sup>*1</sup> | 4             | 6 <sup>*2</sup> | 1 to ∞     | Selectable: SFMRM[2:0] = 101b |

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.

Note 2. The number of dummy cycles is configurable by using the SFMSDC.SFMDN[3:0] bits..

### 31.6.2 Standard Read Instruction

The standard Read instruction is a common read instruction supported by most serial flash memory. When an SPI bus cycle starts, the QSSL signal (serial flash memory select) is asserted, and the instruction code (0x03 or 0x13)<sup>\*1</sup> is output. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted. Data is then received.

This standard Read instruction is selected in the initial QSPI settings.

Note 1. Many 4-KB serial flash memory devices have an address field not larger than 1 byte (A7-A0) to minimize the overhead and to receive A8 information from bit 3 of the Read instruction code. To support these devices, the QSPI only outputs A8 (address bit 8) to bit [3] of the standard Read instruction code when an address width of 1 byte is specified (SFMAS[1:0] = 00). This means that 0x0B might be output instead of 0x03 as the standard Read instruction code. This code duplicates the Fast Read instruction code. However, for most of the 2-KB or smaller serial flash memory, with an address width of 1 byte, bit 3 of a command is designed to be excluded from decoding as a don't-care bit, so such a Read instruction code is recognized correctly as the standard Read instruction code. In rare cases, some serial flash memory allow bit 3 to be decoded. When such a serial flash memory is connected, configure your application to avoid access resulting in A8 = 1.

Figure 31.18 Standard Read bus cycle

### 31.6.3 Fast Read Instruction

The Fast Read instruction is a read instruction that supports a higher communication clock speed than the standard Read instruction. When an SPI bus cycle starts, the QSSL signal is asserted, and the instruction code (0x0B or 0x0C) is output. Next, an address with a width of 3 to 4 bytes specified by the SFMSAC.SFMAS [1: 0] bits is transmitted, a dummy cycle specified by the SFMSDC register is generated, then the data is received.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see [section 31.8. XIP Control](#).

Switching to the Fast Read instruction is controlled in the SFMSMD register.

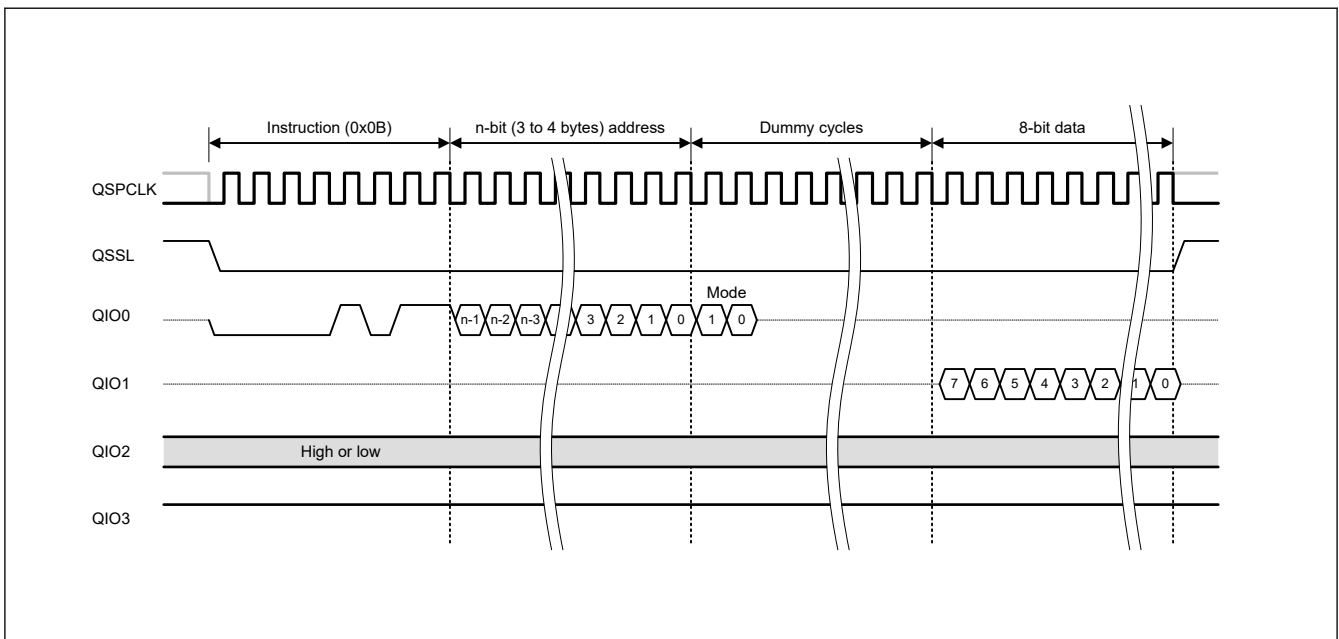

Figure 31.19 Fast Read bus cycle

**Figure 31.20 Fast Read bus cycle in XIP mode**

Note: To use the Fast Read instruction, a serial flash memory that supports Fast Read transfers is required.

### 31.6.4 Fast Read Dual Output Instruction

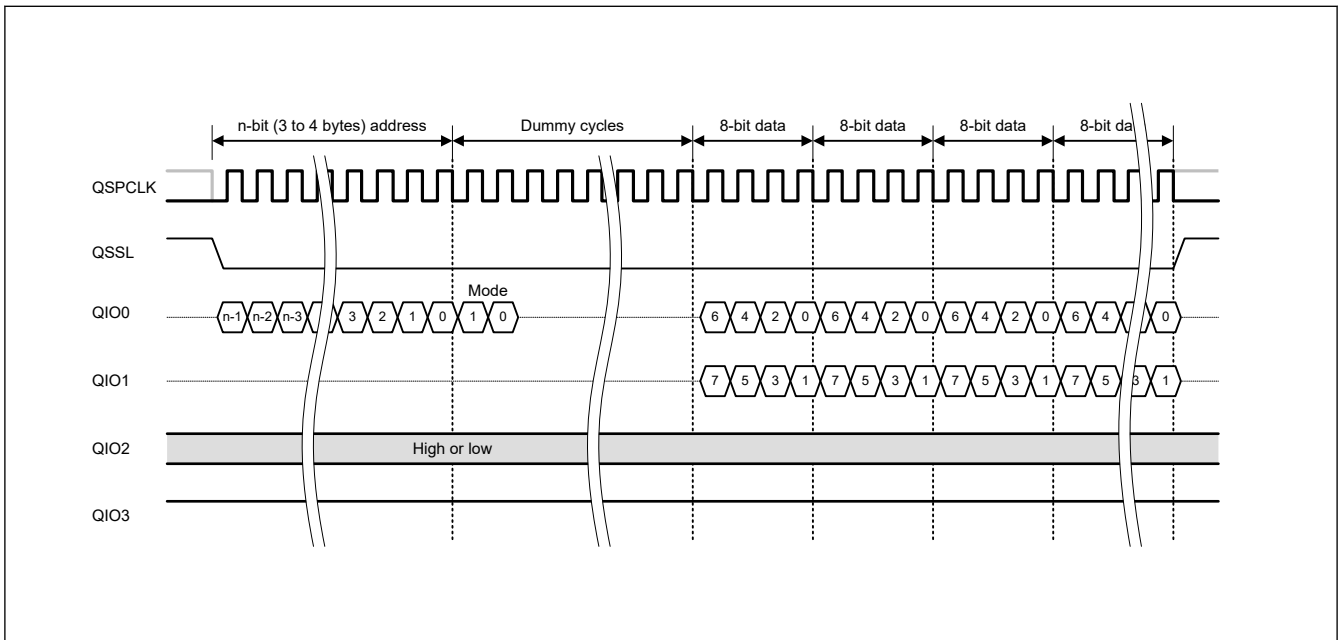

The Fast Read Dual Output instruction is a read instruction that uses two signal lines to receive data. When the SPI bus cycle starts, the QSSL signal is asserted. The instruction code (0x3B or 0x3C) and an address with a width of 3 to 4 bytes, specified by the SFMSAC.SFMAS [1: 0] bits are transmitted from the QIO0 pin in the extended SPI protocol, and transmitted from the QIO0 and QIO1 pins in the Dual-SPI protocol. Next, a certain number of dummy cycles, specified in the SFMSDC register, is generated. Data is then received through the QIO0 and QIO1 pins. Even bit data is received from the QIO0 pin and odd bit data is received from the QIO1 pin.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see [section 31.8. XIP Control](#).

Switching to Fast Read Dual Output is controlled in the SFMSMD register.

**Figure 31.21 Fast Read Dual Output bus cycle (with extended SPI protocol)**

**Figure 31.22 Fast Read Dual Output bus cycle in XIP mode (with extended SPI protocol)**

**Note:** To use the Fast Read Dual Output instruction, a serial flash memory that supports Fast Read Dual Output transfers is required.

### 31.6.5 Fast Read Dual I/O Instruction

The Fast Read Dual I/O instruction is a read instruction that uses two signal lines to transmit an address and receive data. When the SPI bus cycle starts, the QSSL signal is asserted, and the instruction code (0xBB / 0xBC) is transmitted from QIO0 pin in the extended SPI protocol and from QIO0, and QIO1 pins in the Dual SPI protocol. Next, an address with a width of 3 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted through the QIO0 and QIO1 pins, and a certain number of dummy cycles, specified in the SFMSDC register, is generated. Data is then received through the QIO0 and QIO1 pins. Address and dummy cycle transmission and data reception are performed through the QIO0 pin for even bits and through the QIO1 pin for odd bits.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see [section 31.8. XIP Control](#).

Switching to Fast Read Dual I/O is controlled in the SFMSMD register.

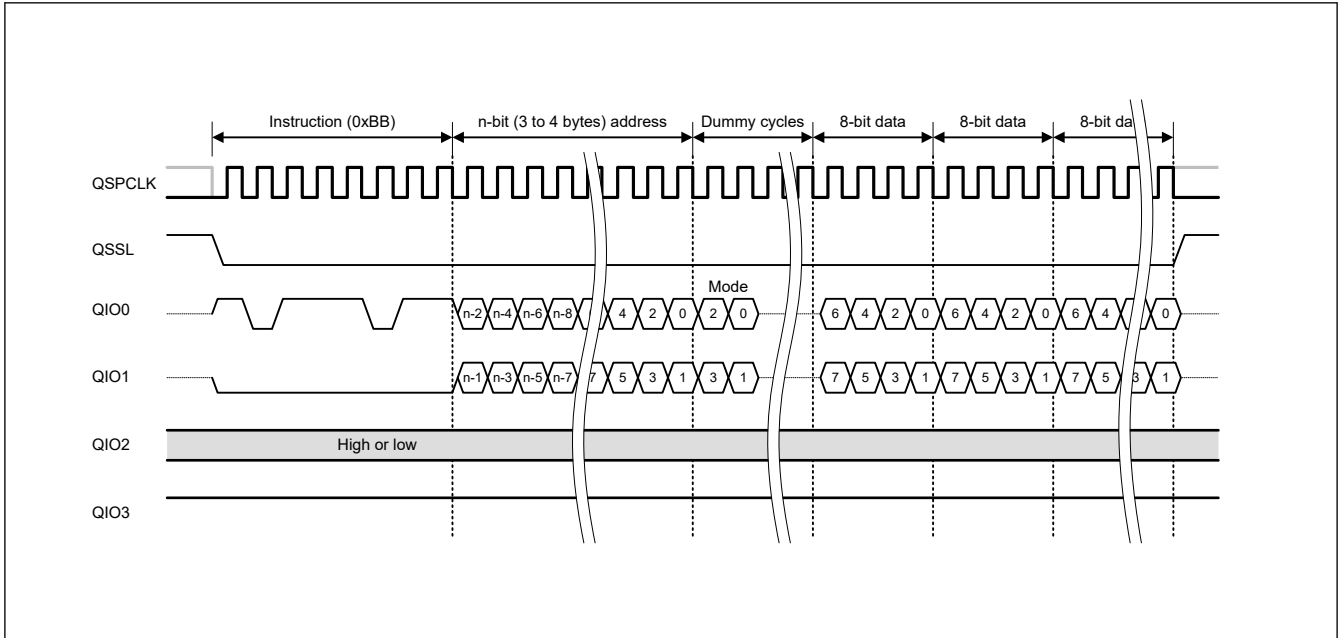

Figure 31.23 Fast Read Dual I/O bus cycle (with extended SPI protocol)

Figure 31.24 Fast Read Dual I/O bus cycle in XIP mode

Note: To use the Fast Read Dual I/O instruction, a serial flash memory that supports Fast Read Dual I/O transfers is required.

### 31.6.6 Fast Read Quad Output Instruction

The Fast Read Quad Output instruction is a read instruction that uses four signal lines to receive data. When the SPI bus cycle starts, the QSSL signal is asserted. The instruction code (0x6B or 0x6C) and an address with a width of 3 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, are output from the QIO0 pin. Next, a certain number of dummy

cycles, specified in the SFMDN[3:0] bits in the SFMSDC register, are generated. Data is then received through the QIO0, QIO1, QIO2, and QIO3 pins.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see [section 31.8. XIP Control](#).

Switching to Fast Read Quad Output is controlled in the SFMSMD register.

**Figure 31.25 Fast Read Quad Output bus cycle (with extended SPI protocol)**

**Figure 31.26 Fast Read Quad Output bus cycle in XIP mode (with extended SPI protocol)**

Note: To use Fast Read Quad Output, a serial flash memory that supports Fast Read Quad Output transfer is required.

### 31.6.7 Fast Read Quad I/O Instruction

The Fast Read Quad I/O instruction is a read instruction that uses four signal lines to transmit an address and receive data. When the SPI bus cycle starts, the QSSL signal is asserted, and the instruction code (0xEB / 0xEC) is transmitted from

QIO0 pin in the extended SPI protocol and from QIO0, QIO1, QIO2, and QIO3 pins in the Quad-SPI protocol. Next, an address with a width of 3 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted through the QIO0, QIO1, QIO2, and QIO3 pins, and a certain number of dummy cycles, specified in the SFMDN[3:0] bits in the SFMSDC register, is generated. Data is then received through the QIO0, QIO1, QIO2, and QIO3 pins.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see [section 31.8. XIP Control](#).

Switching to Fast Read Quad I/O is controlled in the SFMSMD register.

Figure 31.27 Fast Read Quad I/O bus cycle

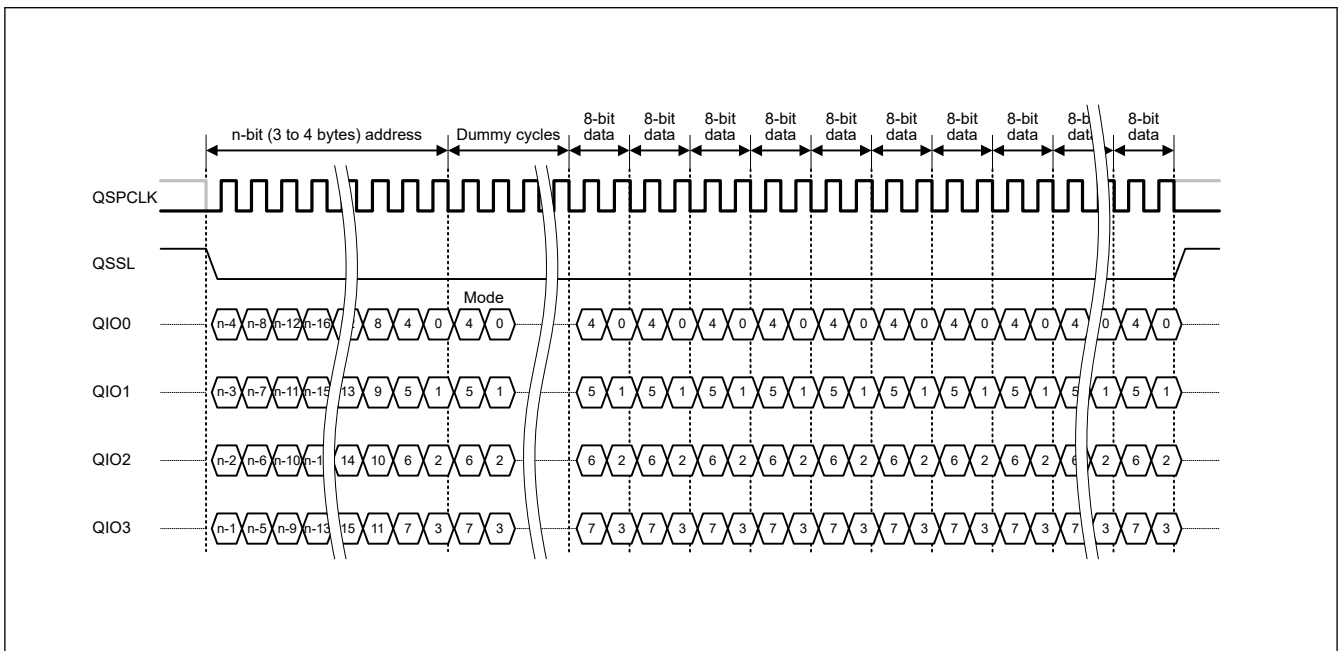

Figure 31.28 Fast Read Quad I/O bus cycle in XIP mode

Note: To use the Fast Read Quad I/O instruction, a serial flash memory that supports Fast Read Quad I/O transfers is required.

### 31.6.8 Enter 4-Byte Mode Instruction

The Enter 4-Byte Mode instruction sets the serial flash address width to 4 bytes. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (0xB7) is output.

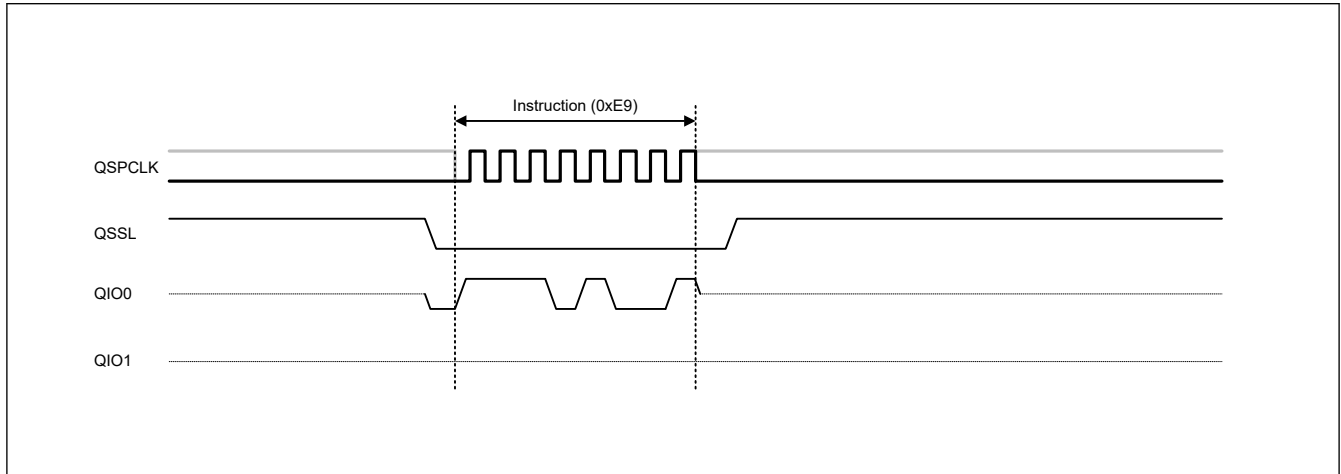

**Figure 31.29** Enter 4-Byte Mode bus cycle

Note: The Enter 4-Byte Mode instruction is issued regardless of whether the serial flash is in 3- or 4-byte mode.

### 31.6.9 Exit 4-Byte Mode Instruction

The Exit 4-Byte Mode instruction sets the serial flash address width to 3 bytes. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (0xE9) is output.

**Figure 31.30** Exit 4-Byte Mode bus cycle

Note: The Exit 4-Byte Mode instruction is issued regardless of whether the serial flash is in 3- or 4-byte mode.

### 31.6.10 Write Enable Instruction

The Write Enable instruction enables changing of the serial flash address width. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (0x06) is output.

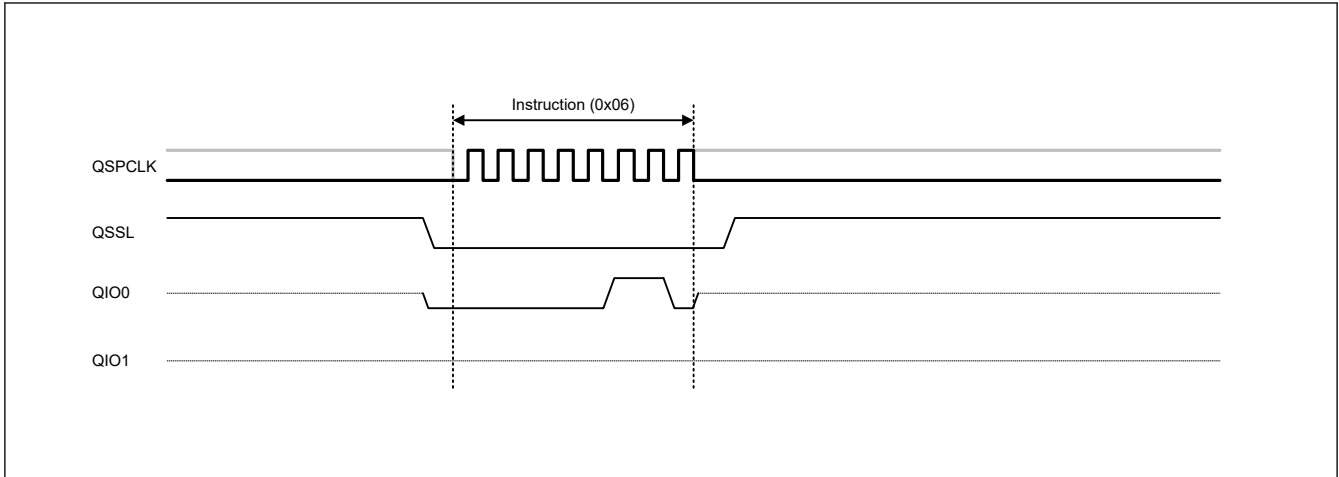

Figure 31.31 Write Enable bus cycle

### 31.7 SPI Bus Cycle Arrangement

#### 31.7.1 Serial Flash Memory Read Based on Individual Conversion

ROM read bus cycles are individually converted to SPI bus cycles on a one-to-one basis. When a ROM read bus cycle is detected, the QSSL signal is asserted, and an SPI bus cycle starts. When the data receiving is finished from the serial flash memory, the QSSL signal is negated and the SPI bus cycle is complete.

When the next ROM read bus cycle is detected, the QSSL signal set by the SFMSSC.SFMSW[3: 0] bits is asserted again, then the next SPI bus cycle starts.

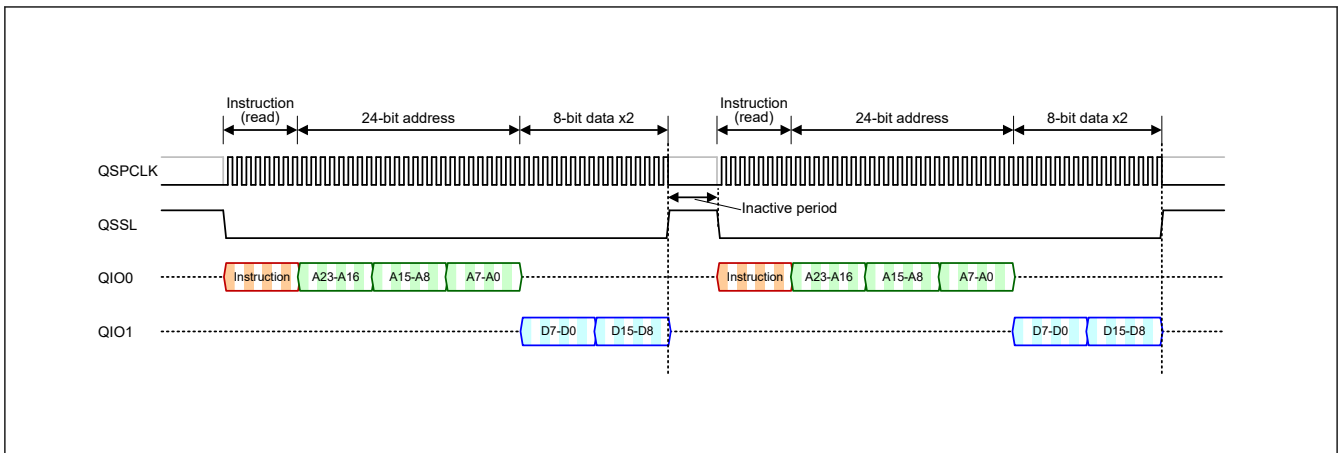

Figure 31.32 Successive data read operations based on individual conversion

#### 31.7.2 Serial Flash Memory Read Using the Prefetch Function

In operations such as CPU instruction execution and block data transfer, data is often read in ascending order from contiguous addresses. Serial flash memory provides the ability to repeat data reception without reissuing an instruction code and address. To work with this function, the QSPI has a prefetch function for continuous data reception. However, if the CPU issues a flash read request for discontinuous flash addresses, SPI bus cycles are separated from each other, disabling the prefetch function.

To enable the prefetch function of the QSPI, set the SFMPFE bit in the SFMSMD register to 1. When the prefetch function is enabled, data is received continuously and stored in the prefetch buffer of the QSPI, without waiting for another flash read request. When the CPU issues a flash read request, an address check is made. If an address match is confirmed, the data in the buffer is passed to the CPU. If an address mismatch is detected, the data in the buffer is discarded and a new SPI bus cycle is issued.

The buffer for prefetching is 18 bytes long. When this buffer is full, the SPI bus cycle is ended. When the buffer data is read to create free space, a new SPI bus cycle is automatically started to resume prefetching.

The prefetch function allows for efficient transfer operations when data is read in ascending order from contiguous addresses, as in instruction fetch and block data transfer.

**Figure 31.33** Successive data read operations using the prefetch function

### 31.7.3 Halt of Prefetching

If a serial flash memory read request for discontinuous addresses is issued when continuous data is being received by the prefetch function, the transfer of continuous data being made is halted and a new SPI bus cycle is started. Usually, such a halt of serial transfer occurs on data reception byte boundaries. However, if the SFMPAE bit in the SFMSMD register is set to 1, the halt can occur on locations other than byte boundaries.

### 31.7.4 Direct Specification of Prefetch Destination

When the prefetch function is enabled (SFMSMD.SFMPFE = 1), when writing to the QSPI window area occurs, after the writing is completed, prefetching starts from the write start address. Writes to serial flash memory cannot be performed.

Combining this function with described in [section 31.7.5. Prefetch State Polling](#), can reduce the load on the internal bus when data is read from a low-speed serial flash memory.

Note: Writing to the QSPI window area with a data size of 2 bytes or more causes a hardfault.

### 31.7.5 Prefetch State Polling

A read by CPU from a low-speed serial flash memory causes the CPU system bus to be occupied until completion of the SPI reception bus cycle. The prefetch state polling function is provided to reduce this load.

The PFOFF bit in the Status Register (SFMSST) register indicates the state of the prefetch function, and the PFCNT[4:0] bits in the SFMSST register indicate the number of data bytes already prefetched. Place the polling program in the SRAM of this device.

```
//
// copy 1K byte (32bit x 256 word) data from serial flash to internal SRAM
//
unsigned long *sptr; // pointer for the serial flash
unsigned long *dptr; // pointer for the destination
int i;

SFMSMD |= 0x0040; // set SFMPFE bit to enable prefetch
*((volatile unsigned char *) sptr) = 0; // make the TAG valid to start prefetch

for (i = 0 ; i < 256 ; i++){
while ((SFMSST & 0x00FF) < 0x04){}; // waiting for 4-byte data to be received
*(dptr++) = *(sptr++);
}
}
```

Note: When executing a polling program, place the program outside of the serial flash memory. If the polling program is executed when the program is placed on the serial flash memory, the prefetch target frequently switches to an instruction code. This eliminates the effect of polling, and an infinite loop can result because the prefetch buffer is not filled.

### 31.7.6 SPI Bus Cycle Extension Function

If the SFMSE[1:0] bits in the SFMSMD register are set to a value other than 00b, the QSPI waits for the next flash read. At this time, the QSPCLK signal stops, the QSSL signal is kept active low even after data is obtained from the serial flash memory, and the SPI bus cycle is suspended.

If the address of the next flash read is contiguous in ascending order, the toggling of the QSPCLK signal is restarted to continue reception of subsequent data. If the address of the next flash read is not contiguous in ascending order, the QSSL signal is driven high once to end the SPI bus cycle being suspended. A new SPI bus cycle is then started.

When data is read intermittently from ascending order contiguous addresses, this function enables an efficient transfer operation to be performed by reducing the overhead for instruction code and address transmission.

The SPI bus cycle extension time is selectable in the SFMSE[1:0] bits in the SFMSMD register. When the specified extension time elapses, the QSSL signal returns to the high level to automatically end the SPI bus cycle being suspended. If the SFMSE[1:0] bits are set to 11b, QSSL is extended infinitely. This increases the power consumption of the serial flash memory.

Figure 31.34 Successive data read operations using the SPI bus cycle extension

### 31.8 XIP Control

Some serial flash memory devices allow latencies to be reduced by skipping instruction code reception for flash reads. This instruction code skip function is selected in mode data received during the dummy cycle period of the previous serial bus cycle.

In the dummy cycle of the Fast Read instructions, the QSPI controls the XIP mode of the serial flash memory by using the serial data signal to send the mode data set in the SFMXD[7:0] bits in the SFMSDC register during the first 2 cycles, as shown in Figure 31.35.

The mode data to enable the XIP mode differs for each serial flash memory. Accordingly, set the appropriate mode data in the SFMXD[7:0] bits.

Figure 31.35 XIP mode control data

### 31.8.1 Setting XIP Mode

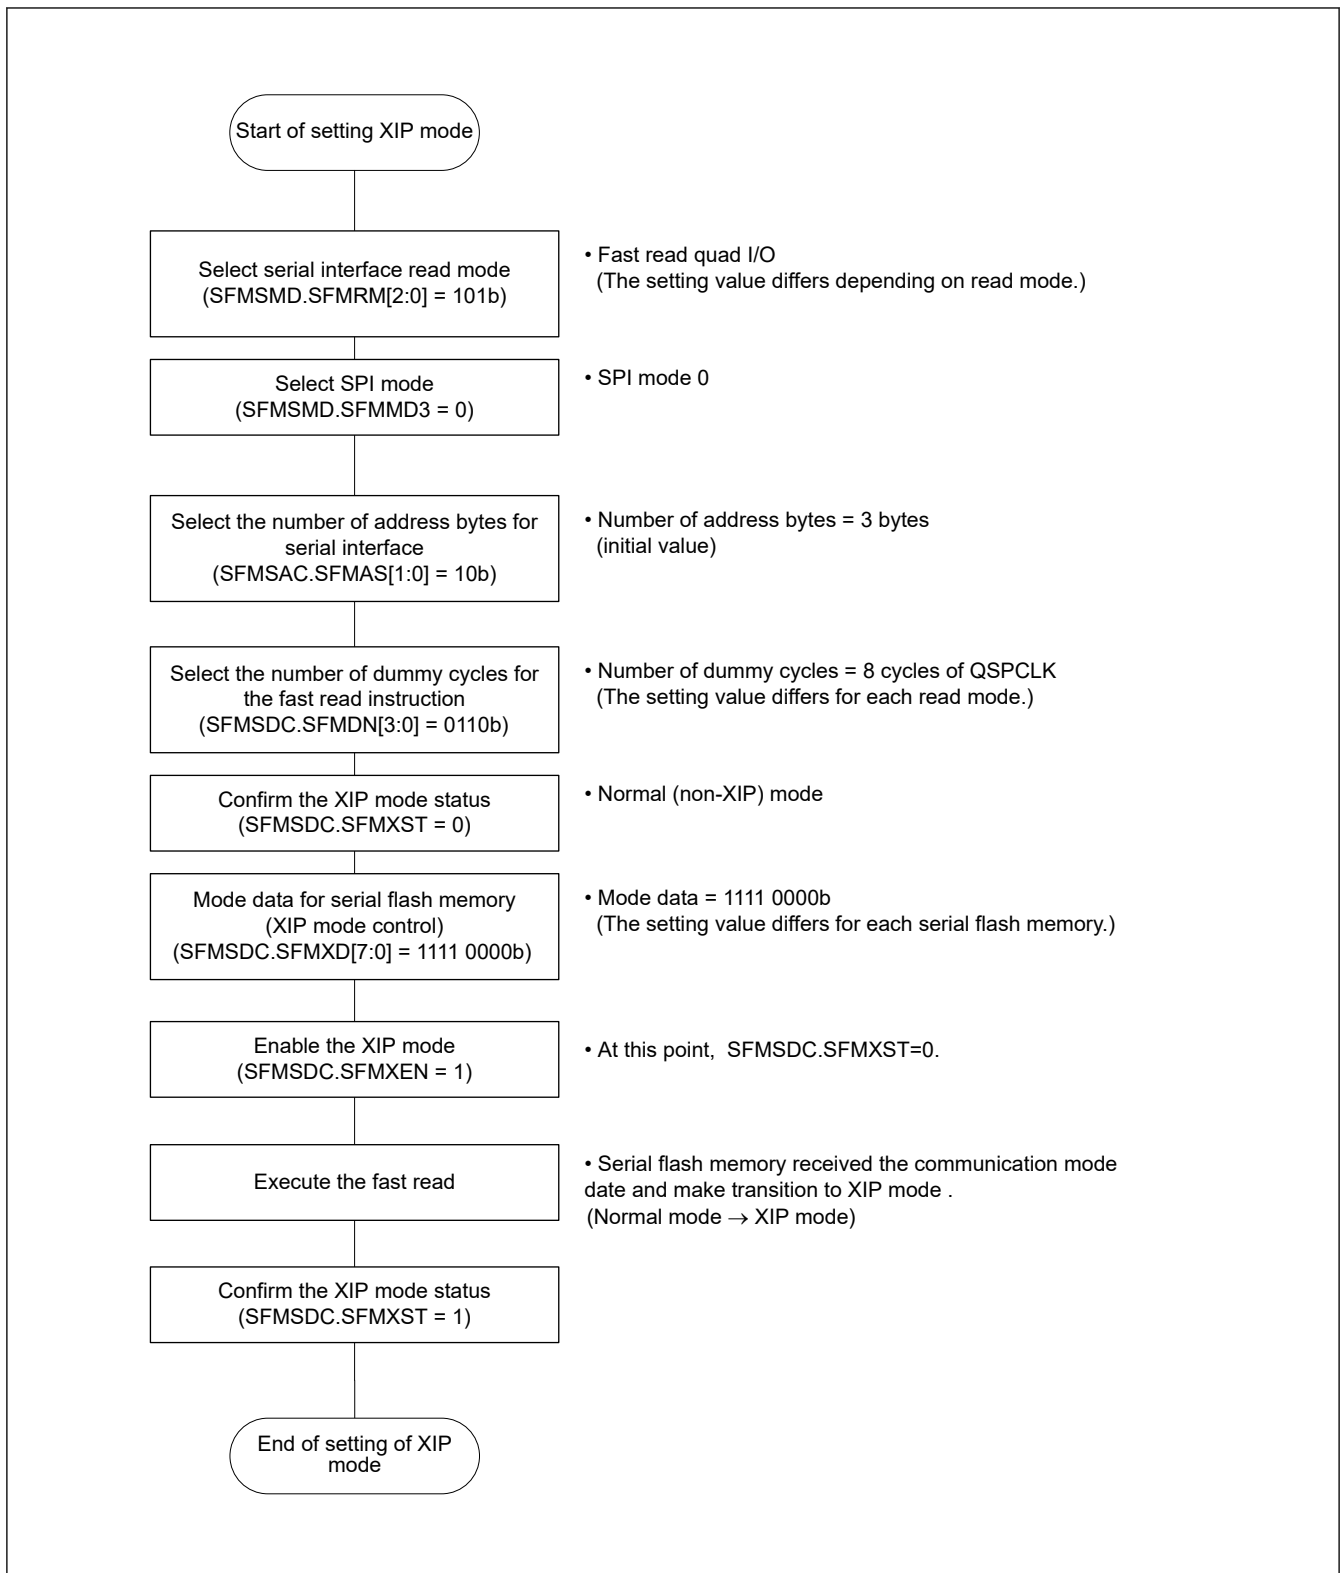

To start XIP mode in serial flash memory, perform the following register settings:

- Set a mode data value in the SFMXD[7:0] bits in the SFMSDC register.\*1
- Set the SFMXEN bit in the SFMSDC register to 1.

In the dummy cycle of the first fast read cycle after these registers are set, the mode data value set in the register is transferred. From that point, XIP mode is enabled in the serial flash memory. To confirm the current XIP mode status, read the SFMXST flag in the SFMSDC register.

Note 1. In the SFMXD[7:0] bits in the SFMSDC register, set the mode data that follows the specifications for the actual serial flash memory.

The following figure shows an example of the XIP mode setting procedure.

**Figure 31.36 Flowchart of XIP Mode**

### 31.8.2 Releasing the XIP Mode

To release XIP mode in serial flash memory, perform the following register setting:

- Set the mode data value to disable XIP mode in SFMSDC.SFMXD [7: 0] bits\*<sup>1</sup>
- Set the SFMXEN bit in the SFMSDC register to 0.

In the dummy cycle of the first fast read cycle after this register is set, The mode data value that disables the XIP mode set in the register is transferred. From that point, XIP mode is disabled in the serial flash memory. To confirm the current XIP mode status, read the SFMXST flag in the SFMSDC register.

Note 1. Set the mode data in the SFMSDC.SFMXD [7: 0] bits according to the specifications of the serial flash memory.

Figure 31.37 shows an example of the procedure for releasing XIP mode.

Figure 31.37 Releasing XIP mode (flowchart)

### 31.9 QIO2 and QIO3 Pin States

The QIO2 and QIO3 pin states depend on the serial interface read mode specified in the SFMRM[2:0] bits in the SFMSMD register.

Table 31.11 QIO2 and QIO3 pin states (1 of 2)

| SFMSMD.SFMRM[2:0] bits | QIO2 pin state*1                                                                          | QIO3 pin state*2                                                                          | Remarks               |
|------------------------|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|-----------------------|
| 111                    | Setting prohibited                                                                        |                                                                                           |                       |
| 110                    |                                                                                           |                                                                                           |                       |
| 101                    | Input or output as serial data signal (The pin is in the Hi-Z state when it is inactive.) | Input or output as serial data signal (The pin is in the Hi-Z state when it is inactive.) | Fast Read Quad I/O    |
| 100                    |                                                                                           |                                                                                           | Fast Read Quad Output |

**Table 31.11 QIO2 and QIO3 pin states (2 of 2)**

| SFMSMD.SFMRM[2:0] bits | QIO2 pin state <sup>*1</sup>                                                                  | QIO3 pin state <sup>*2</sup> | Remarks                       |
|------------------------|-----------------------------------------------------------------------------------------------|------------------------------|-------------------------------|
| 011                    | Output SFMWPL bit variable of the Port Control Register (SFMPMD) (initial value is low level) | Output high level            | Fast Read Dual I/O            |
| 010                    |                                                                                               |                              | Fast Read Dual Output         |
| 001                    |                                                                                               |                              | Fast Read                     |
| 000                    |                                                                                               |                              | Standard Read (Initial State) |

Note 1. The serial flash memory can also use the QIO2 pin for the write protect (WP) function. The WP function prohibits writes to the status registers. (The function is available in mode other than Quad-SPI mode.)

Note 2. The serial flash memory can also use the QIO3 pin for the HOLD or RESET function.

The hold function places the I/O pin in an inactive state without deselecting the chip. (The function is available in mode other than Quad-SPI mode.)

The reset function resets the serial flash memory. (The function is available when the QSSL pin function is disabled or in a mode in which the QIO3 pin is not used.)

## 31.10 Direct Communication Mode

### 31.10.1 About Direct Communication

The QSPI can read the serial flash memory contents by automatically converting from reading the QSPI window area to SPI bus cycles. However, serial flash memory have many different functions in addition to memory data read, including ID information read, erase, programming, and status information read. There is no standardized instruction set for using these functions, and more functions are being added rapidly by different vendors to different devices. Therefore, to support these functions, the software can create any required SPI bus cycle by communicating directly with serial flash memory.

### 31.10.2 Using Direct Communication Mode

To communicate directly with serial flash memory, transition to direct communication mode by setting the DCOM bit in the Communication Mode Control Register (SFMCMMD) register to 1. While direct communications mode is selected, the read operation to the serial flash memory by the QSPI window is invalid.

Note: If the QSPI is set to the XIP mode, you must terminate the XIP mode before starting direct communication mode.

### 31.10.3 Generating the SPI Bus Cycle during Direct Communication

The SPI bus cycle in direct communications starts on the first access to the SFMCOM register, and after a series of input / output operations are executed via the SFMCOM register, the bus cycle ends when 1 is written to the SFMCMMD register. At that point, writing to the SFMCOM port is converted to a one-byte transmission to the SPI bus, and reading from the SFMCOM register is converted to a one-byte reception from the SPI bus.

During the period from the first access to the SFMCOM register to the last write operation to the SFMCMMD register, the QSSL signal is held active to notify the serial flash memory that a series of SPI bus cycles is in progress.

Note: In direct communication mode, all writes to registers other than SFMCMMD and SFMCOM (including SFMSMD, SFMSSC, SFMSKC, SFMSST, SFMCST, SFMSIC, SFMSAC, SFMSDC, SFMSPC, and SFMPMD) are disabled.

Figure 31.38 to Figure 31.40 show direct communication program examples, and Figure 31.41 shows ID read direct communication timing examples.

Figure 31.38 Flowchart of Device ID Acquisition

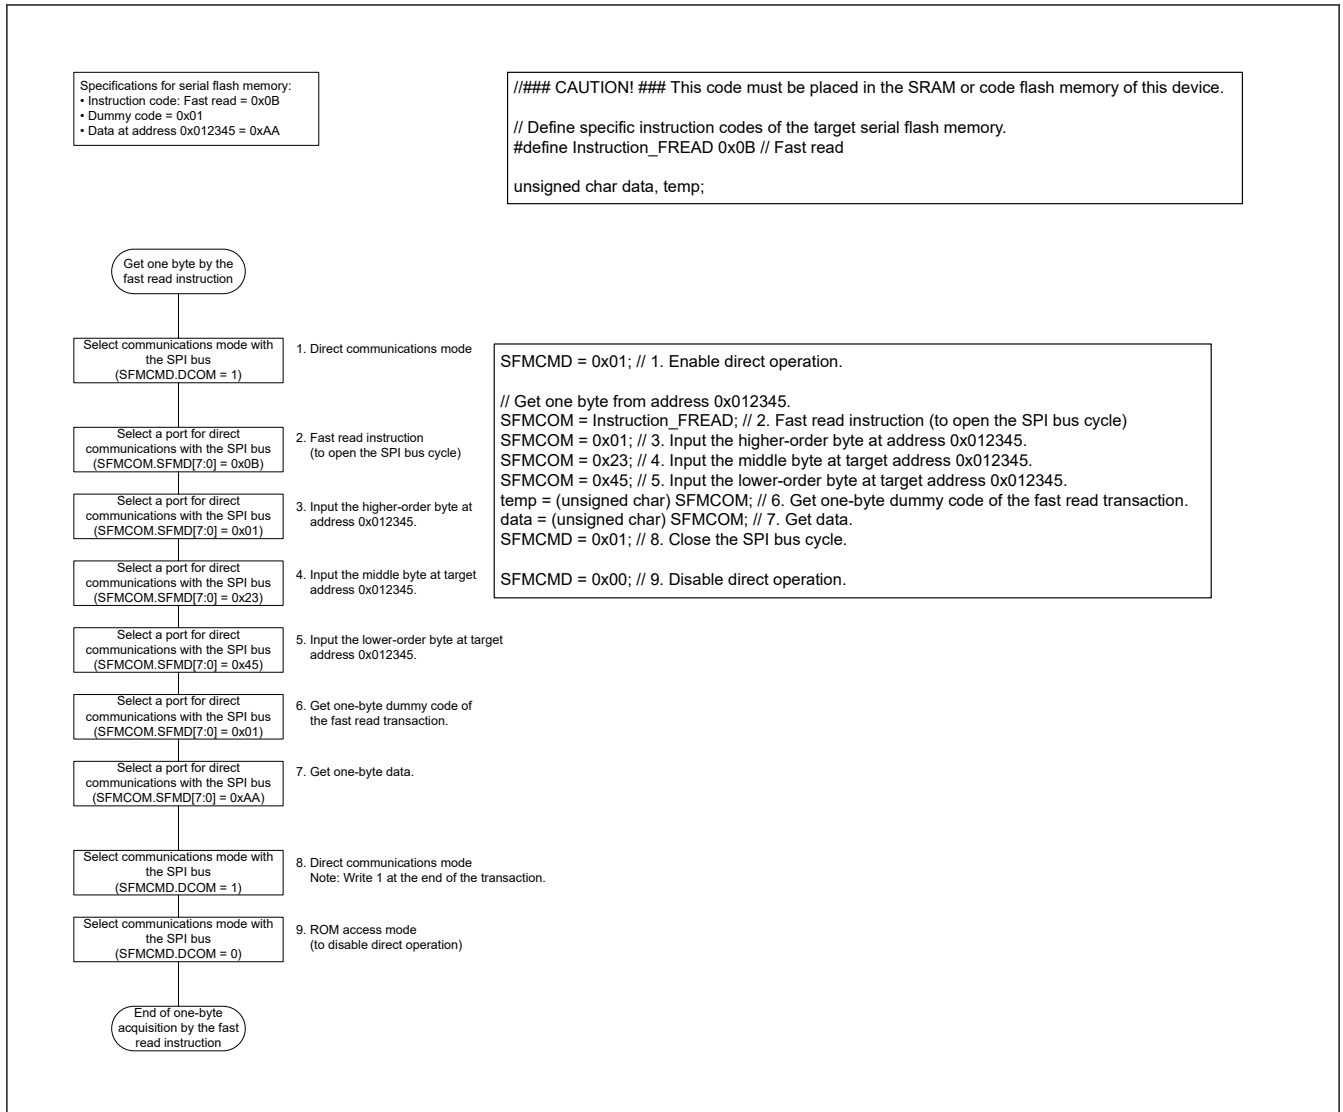

Figure 31.39 Flowchart of One-byte Acquisition by the Fast Read Instruction

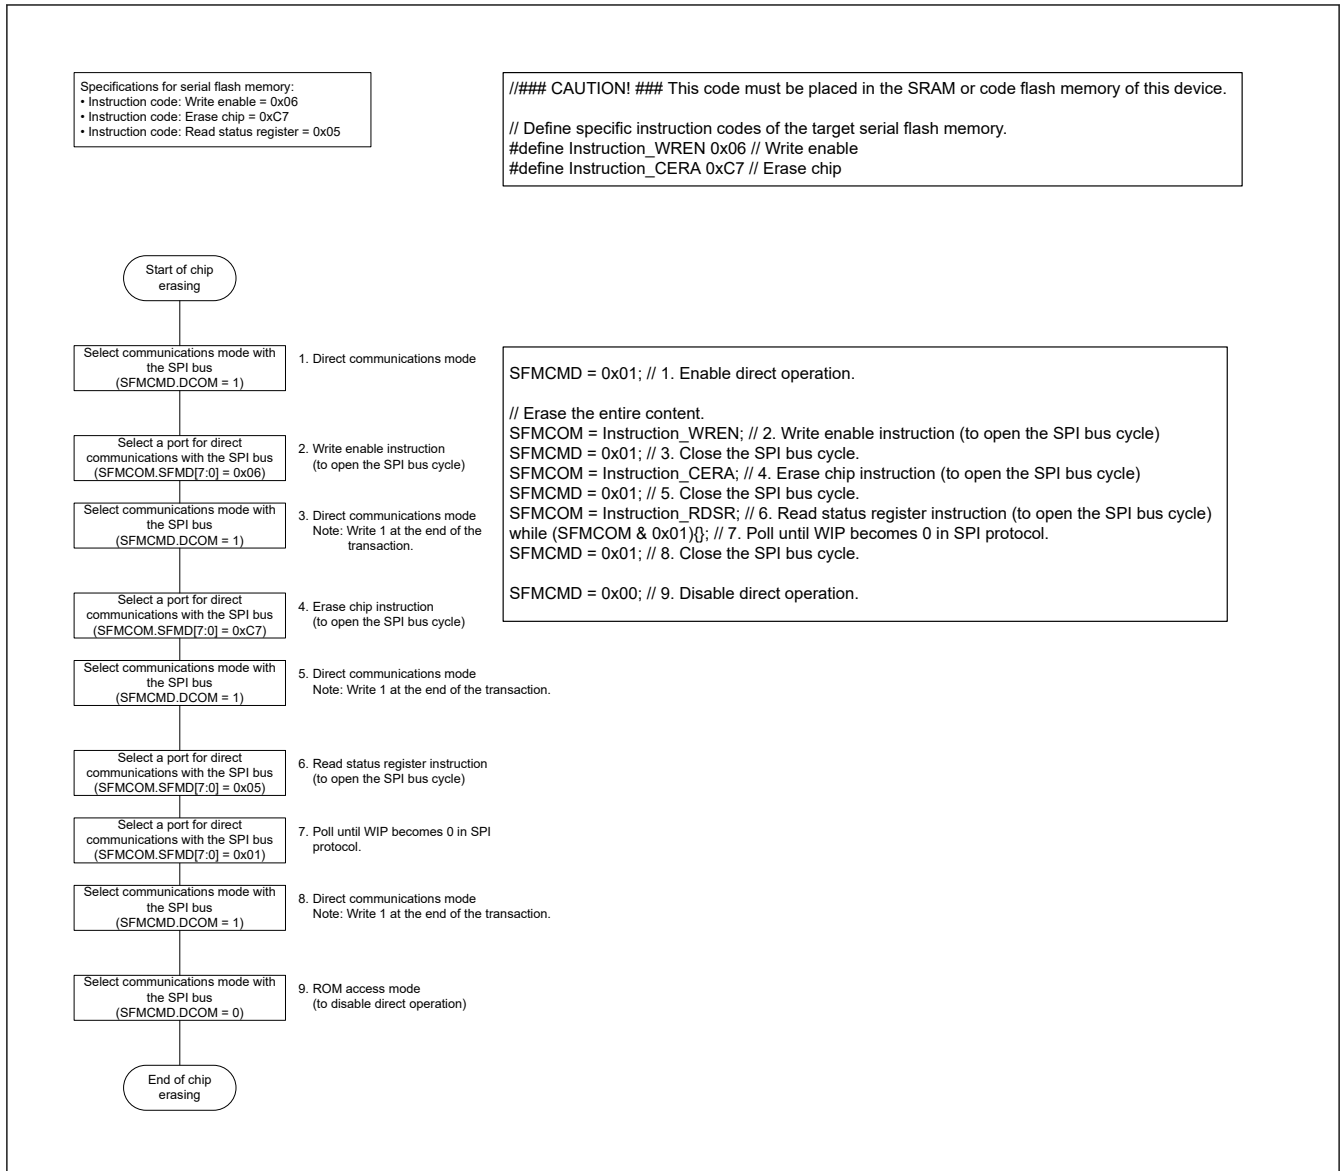

Figure 31.40 Flowchart of Chip Erasing

**Figure 31.41 Example of direct communication timing for ID read**

**Note:** When the Single SPI Protocol, Extended SPI Protocol is used in direct communication mode, the standard Read or Fast Read instruction must be used to reference the contents of the serial flash memory. The QSPI does not support Fast Read Dual Output, Fast Read Dual I/O, Fast Read Quad Output, or Fast Read Quad I/O transfers in this configuration. When these Fast Read operations are required, use ROM access memory.

## 31.11 Interrupts

When ROM read access is detected in direct communication mode, the SFMCST.EROMR flag is set to 1 and QSPI generates an interrupt request. Interrupt requests are retained until the EROMR flag is cleared by a 0 write. For details, see [section 13, Interrupt Controller Unit \(ICU\)](#).

## 31.12 Usage Note

### 31.12.1 Settings for the Module-Stop Function

QSPI operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The QSPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

### 31.12.2 Procedure for Changing Settings in Multiple Control Registers

The settings of the QSPI control registers can be modified dynamically during system operation. However, when the settings of multiple control registers are changed sequentially, an SPI bus cycle might occur before all the registers are updated. The register setting sequence must be designed so that the SPI bus timing specifications are satisfied at all stages of register setting modification.

Figure 31.42 Flowchart of Making QSPCLK Faster and Slower

## 32. Cyclic Redundancy Check (CRC)

### 32.1 Overview

The Cyclic Redundancy Check (CRC) generates CRC codes to detect errors in the data. The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication. Additionally, various CRC-generation polynomials are available.

Table 32.1 lists the CRC calculator specifications and Figure 32.1 shows a block diagram.

**Table 32.1 CRC calculator specifications**

| Item                       | Description                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data size                  | 8-bit                                                                                                                                                                                                                                                                                                                                             | 32-bit                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Data for CRC calculation*1 | CRC code generated for data in 8n-bit units (where n is a natural number)                                                                                                                                                                                                                                                                         | CRC code generated for data in 32n-bit units (where n is a natural number)                                                                                                                                                                                                                                                                                                                                                                      |
| CRC processor unit         | Operation executed on 8 bits in parallel                                                                                                                                                                                                                                                                                                          | Operation executed on 32 bits in parallel                                                                                                                                                                                                                                                                                                                                                                                                       |
| CRC generating polynomial  | One of three generating polynomials that is selectable:<br>[8-bit CRC]<br><ul style="list-style-type: none"> <li><math>X^8 + X^2 + X + 1</math> (CRC-8)</li> </ul> [16-bit CRC]<br><ul style="list-style-type: none"> <li><math>X^{16} + X^{15} + X^2 + 1</math> (CRC-16)</li> <li><math>X^{16} + X^{12} + X^5 + 1</math> (CRC-CCITT).</li> </ul> | One of two generating polynomials that is selectable:<br>[32-bit CRC]<br><ul style="list-style-type: none"> <li><math>X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1</math> (CRC-32)</li> <li><math>X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1</math> (CRC-32C).</li> </ul> |
| CRC calculation switching  | The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Module-stop function       | Module-stop state can be set to reduce power consumption                                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| TrustZone Filter           | Security attribution can be set                                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Note 1. This function cannot divide data used in CRC calculations. Write data in 8-bit or 32-bit units.

### 32.2.3 CRCDOR/CRCDOR\_HA/CRCDOR\_BY : CRC Data Output Register

Base address: CRC = 0x4010\_8000

Offset address: 0x08

Bit position: 31 0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

| Bit  | Symbol | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | R/W |
|------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 31:0 | n/a    | CRC output data<br>The CRCDOR register is a 32-bit read/write register for CRC-32 or CRC-32C calculation. The CRCDOR_HA (CRCDOR[31:16]) register is a 16-bit read/write register for CRC-16 or CRC-CCITT calculation. The CRCDOR_BY (CRCDOR[31:24]) register is an 8-bit read/write register for CRC-8 calculation. Because its initial value is 0x00000000, rewrite the CRCDOR/CRCDOR_HA/CRCDOR_BY register to perform the calculations using a value other than the initial value. Data written to the CRCDIR/CRCDIR_BY register is CRC calculated and the result is stored in the CRCDOR/CRCDOR_HA/CRCDOR_BY register. If the CRC code is calculated following the transferred data and the result is 0x00000000, there is no CRC error. | R/W |

## 32.3 Operation

### 32.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB-first or MSB-first transfer.

The following examples show CRC code generation for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ( $X^{16} + X^{12} + X^5 + 1$ ). In these examples, the value of the CRC Data Output Register (CRCDOR\_HA) is cleared before CRC calculation.

When an 8-bit CRC (with the polynomial  $X^8 + X^2 + X + 1$ ) is in use, the valid bits of the CRC code are obtained in CRCDOR\_BY. When a 32-bit CRC is in use, the valid bits of the CRC code are obtained in CRCDOR.

Figure 32.2 and Figure 32.3 show the LSB-first and MSB-first data transmission examples respectively. Figure 32.4 and Figure 32.5 show the LSB-first and MSB-first data reception examples.

Figure 32.2 LSB-first data transmission

Figure 32.3 MSB-first data transmission

Figure 32.4 LSB-first data reception

Figure 32.5 MSB-first data reception

## 32.4 Usage Notes

### 32.4.1 Settings for the Module-Stop State

The Module Stop Control Register C (MSTPCRC) can enable or disable CRC calculator operation. The CRC calculator is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see [section 10](#), [Low Power Modes](#).

### 32.4.2 Note on Transmission

The transmission sequence for the CRC code differs based on whether the transmission is LSB-first or MSB-first. [Figure 32.6](#) shows an LSB-first and MSB-first data transmission.

When transmitting 32-bit data (for operation executed on 8 bits in parallel)

1. CRC code

After specifying the method for generation calculation, write data to CRCDIR in order of (1), (2), (3), and (4).

2. Transmit data

(i) When transmission is LSB-first

(ii) When transmission is MSB-first

Figure 32.6 LSB-first and MSB-first data transmission

## 33. Boundary Scan

### 33.1 Overview

The boundary scan function provides a serial I/O interface based on the JTAG (Joint Test Action Group), IEEE Std.1149.1, and IEEE Standard Test Access Port and Boundary Scan Architecture. [Table 33.1](#) lists the boundary scan specifications, [Figure 33.1](#) shows a block diagram, and [Table 33.2](#) lists the I/O pins.

**Table 33.1 Boundary scan specifications**

| Parameter           | Specifications                                                                                                                                                                           |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Execution condition | Boundary scan must be executed when the RES pin is driven low.                                                                                                                           |

**Figure 33.1 Boundary scan function block diagram**

**Table 33.2 Boundary scan I/O pins**

| Pin name | I/O    | Description                                                                                                                        |
|----------|--------|------------------------------------------------------------------------------------------------------------------------------------|
| TCK      | Input  | Test clock input pin<br>Clock signal for boundary scan. The input clock duty cycle is 50% when the boundary scan function is used. |
| TMS      | Input  | Test mode select pin                                                                                                               |
| TDI      | Input  | Test data input pin                                                                                                                |
| TDO      | Output | Test data output pin                                                                                                               |

Note: This device does not support the TRST pin for the JTAG interface.

### 33.2 Register Descriptions

[Table 33.3](#) lists the boundary scan registers.

**Table 33.3** Boundary scan registers

| Register name          | Symbol | Value after reset |
|------------------------|--------|-------------------|
| Instruction Register   | JTIR   | 0xE               |
| ID Code Register       | JTIDR  | 0x0840_E447       |
| Bypass Register        | JTBPR  | Undefined         |
| Boundary Scan Register | JTBSR  | Undefined         |

Usage notes for the boundary scan registers:

- Instructions can be input to the Instruction Register (JTIR) through the TDI pin by serial transfer.
- The Bypass Register (JTBPR), which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.
- The Boundary Scan Register (JTBSR), which is configured according to the BSDL description, is connected between the TDI and TDO pins when test data is being shifted in.

Table 33.4 shows the availability of serial transfer for the registers.

**Table 33.4** Serial transfer for registers

| Register name                  | Serial input | Serial output |
|--------------------------------|--------------|---------------|
| Instruction Register (JTIR)    | Available    | Available     |
| ID Code Register (JTIDR)       | Available    | Available     |
| Bypass Register (JTBPR)        | Available    | Available     |
| Boundary Scan Register (JTBSR) | Available    | Available     |

### 33.2.1 JTIR : Instruction Register

| Bit     | Symbol                | Function                                                                                                                                                                                                                                                                                                                                                                                                                         | R/W     |             |     |        |     |                |     |                       |     |       |     |       |     |        |        |          |  |

| 0xF     | BYPASS                |                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |             |     |        |     |                |     |                       |     |       |     |       |     |        |        |          |  |
| Others  | Reserved              |                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |             |     |        |     |                |     |                       |     |       |     |       |     |        |        |          |  |

JTAG instructions can be transferred to the JTIR register by serial input from the TDI pin. The JTIR register is initialized when a power-on reset occurs, or when the TAP controller is in the Test-Logic-Reset state.

### 33.2.2 JTIDR : ID Code Register

| Bit  | Symbol    | Function                                                                                      | R/W |
|------|-----------|-----------------------------------------------------------------------------------------------|-----|
| 31:0 | DID[31:0] | Device ID<br>These bits store the fixed value that indicates the device IDCODE (0x0840_E447). | —   |

The JTIDR register data is output from the TDO pin when the IDCODE instruction is executed. After a reset release, the DID[31:0] of JTIDR changes into the Arm® debug code. See the *Arm® CoreSight™ SoC-400 Technical Reference Manual* (ARM DDI 0480F).

### 33.2.3 JTBPR : Bypass Register

The JTBPR register is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode. The JTBPR register cannot be read from or written to by the CPU.

### 33.2.4 JTBSR : Boundary Scan Register

The JTBSR register is a shift register for controlling the external input and output pins of this device, and is distributed across the pads. To apply the JTBSR register in boundary-scan testing, issue the EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ instructions. The BSDL file describes the associations between the JTBSR register bits and the pins of this device. The value after reset is undefined.

## 33.3 Operation

During a reset, the JTAG ports, TCK, TMS, TDI, and TDO, are assigned as default pin functions. The TCK, TMS, and TDI pins are pulled up by the pull-up resistors. Boundary scan testing can be executed after the setup time elapses when POR is negated and RES is driven low.

### 33.3.1 TAP Controller

[Figure 33.2](#) shows the state transition diagram of the TAP controller. All transitions are controlled by the TMS signal.

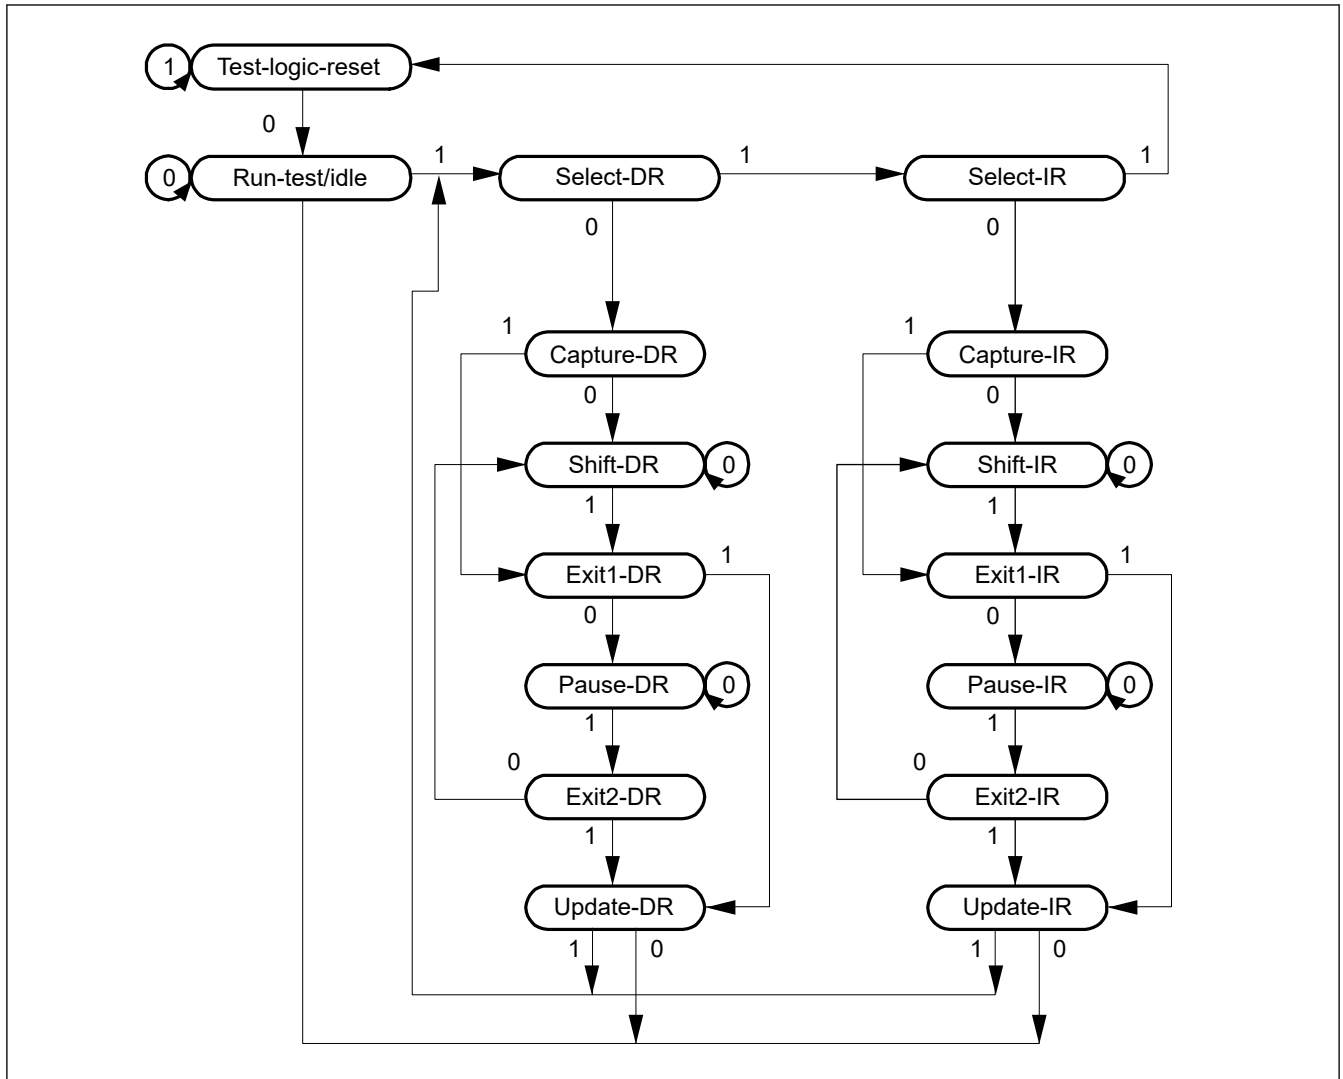

Figure 33.2 State transition diagram of TAP controller

### 33.3.2 Commands

#### (1) BYPASS

The BYPASS instruction drives the Bypass Register (JTBPB). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.

The JTBPB register is connected between the TDI and TDO pins. Bypass operation is initiated from the Shift-DR operation. The TDO is low in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, values input to the TDI pin are output from the TDO pin.

#### (2) EXTEST

The EXTEST instruction is used to test external circuits when this device is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified in the SAMPLE/PRELOAD instruction) from the Boundary Scan Register (JTBSR) to the other devices, and input pins are used to input the test result.

#### (3) SAMPLE/PRELOAD

The SAMPLE/PRELOAD instruction is used to input data from the internal circuits of this device to the JTBSR register, output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to this device and output signals are also directly output to the external circuits. This device system circuit is not affected by this instruction.

In SAMPLE operation, the JTBSR register latches a snapshot of the data transferred from the input pins to the internal circuit or data transferred from the internal circuit to the output pins. The latched data is read from the scan path. The JTBSR register latches the data snapshot on the rising edge of the TCK pin in the Capture-DR state. The data snapshot is only transferred from the internal circuit to the output pins during a reset.

In PRELOAD operation, the initial value is written from the scan path to the parallel output latch of the JTBSR register prior to the EXTEST instruction execution. If EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In the EXTEST instruction, output parallel latches are always output to the output pins.)

#### (4) IDCODE

When the IDCODE instruction is selected, the ID Code Register (JTIDR) value is output to the TDO pin in the Shift-DR state of the TAP controller. In this case, the JTIDR register value is output LSB-first. During this instruction execution, the test circuit does not affect the system circuit.

#### (5) CLAMP

When the CLAMP instruction is selected, output pins output the JTBSR register value that was specified in the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the JTBSR register is maintained regardless of the TAP controller state.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

#### (6) HIGHZ

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the JTBSR register is maintained regardless of the state of the TAP controller.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

### 33.4 Usage Notes

The boundary scan function is subject to the following constraints:

- The boundary scan must be executed when the RES pin is driven low
- Serial data input/output is in LSB order, as shown in [Figure 33.3](#)

**Figure 33.3 Serial data input/output**

The following pins cannot be boundary-scanned:

- Power supply pins (VCC, VCL, VSS, VBATT, AVCC0, AVSS0, VCC\_USB, and VSS\_USB)
- Analog reference pins (VREFH0, VREFL0, VREFH, VREFL)
- Clock pins (EXTAL, XTAL, XCIN, and XCOU)
- Reset pin (RES)
- USB-dedicated pins (USB\_DP, USB\_DM)
- The boundary-scan pins (TCK, TMS, TDI, and TDO).

## 34. Secure Cryptographic Engine (SCE9)

### 34.1 Overview

The Secure Cryptographic Engine (SCE9) consists of the access management circuit, encryption engine, and random number generation circuit. In combination with the SCE9 library, the SCE9 can prevent eavesdropping (to maintain confidentiality), falsification of information (to ensure integrity), and impersonation (to verify authenticity).

Because key information required for encryption and decryption is stored only in the SCE9 and all accesses from the outside can be blocked, SCE9 enables building a more robust security system.

Only access control circuit, random number generation circuit, and unique ID are supported. The operation of other circuits is not guaranteed.

Table 34.1 lists the SCE9 specifications. Figure 34.1 shows the SCE9 block diagram.

**Table 34.1 SCE9 specifications**

| Parameter                             | Specifications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Low power consumption                 | Setting of the module-stop state is possible                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Note 1. This does not include the overhead of calling SCE9 library functions.

Figure 34.1 SCE9 block diagram

## 34.2 Operation

### 34.2.1 Encryption Engine

Figure 34.2 shows conceptual diagram of the encryption engine installed in the SCE9.

The encryption engine uses the key generation information, and converts the plaintext data to ciphertext or ciphertext data to plaintext through the hardware.

The encryption/decryption process can be completed without exposing the key data and the process's intermediate data to the outside of the SCE9.

Figure 34.2 Conceptual diagram of the encryption engine

### 34.2.2 Encryption and Decryption

Follow the procedure below to encrypt and decrypt the data:

1. Enter the key generation information to the SCE9 and restore the key data.
2. Enter the target data to the SCE9. Plaintext data is converted to ciphertext and ciphertext data to plaintext.
3. Read the converted data.

The encryption engine has input and output buffers, and can perform encryption/decryption in parallel with data input/output. Figure 34.3 shows the encryption engine timing.

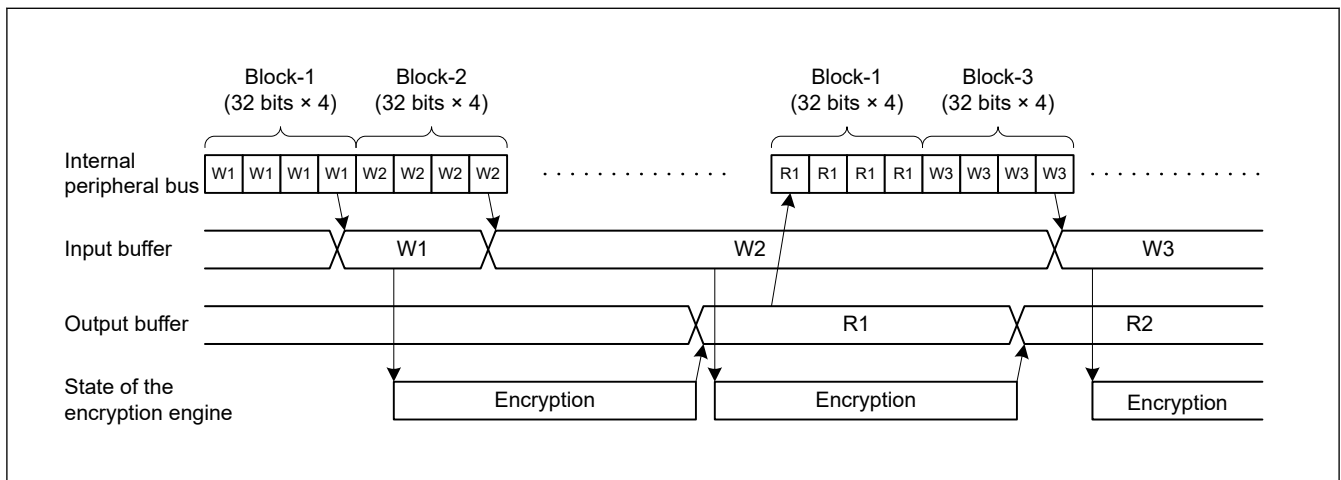

Figure 34.3 Encryption and decryption timing (AES)

### 34.3 Usage Notes

#### 34.3.1 Software Standby Mode

When Software Standby mode is entered while the encryption engine is in process, proper processing cannot be resumed after cancelling Software Standby mode. Software Standby mode should therefore be entered while the encryption engine is not running.

#### 34.3.2 Module-Stop Function Setting

SCE9 operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The SCE9 module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

## 35. 12-Bit A/D Converter (ADC12)

### 35.1 Overview

The MCU includes 12-bit successive approximation A/D converter (ADC12) unit. Analog input channels are selectable up to 9, and an internal reference voltage are selectable for conversion.

The A/D conversion accuracy is selectable from 12-bit, 10-bit, 8-bit conversion, making it possible to optimize the trade-off between speed and resolution in generating a digital value.

The ADC12 supports the following operating modes:

- Single scan mode to convert analog inputs of selected channels in ascending order of channel number
- Continuous scan mode to convert analog inputs of selected channels continuously in ascending order of channel number
- Group scan mode to divide analog inputs of channels into two groups (group A and B) and convert the analog inputs of selected channels for each group in ascending order of channel number.

In group scan mode, select two groups (group A and B). You can individually select the scan start conditions for each group (group A, B) and start scanning of each group at different times. In addition, when group A priority control operation is set, the ADC12 accepts group A scan start during group B A/D conversion, suspending group B conversion. This allows you to assign higher priority to A/D conversion start for group A.

In double trigger mode, the analog input of a selected channel is converted in single scan mode or group scan mode (group A), and data converted by the first and second A/D conversion start triggers are stored in different registers, providing duplexing of A/D converted data.

Self-diagnosis is performed once at the beginning of each scan, and one of the three reference voltage values generated in ADC12 is A/D converted.

The internal reference voltage is selectable at the same time as the analog input of the channel. First A/D conversion is performed for the analog input of the channel, and then for the internal reference voltage.

The ADC12 also provides a compare function (window A and window B). The compare function specifies the upper reference value for window A and lower reference value for window B, and outputs an interrupt when the A/D converted value of the selected channel meets the comparison conditions.

The A/D data storage buffer is a ring buffer consisting of 16 buffers to sequentially store A/D converted data.

[Table 35.1](#) lists the ADC12 specifications and [Table 35.2](#) list the functions. [Figure 35.1](#) shows a block diagram of ADC12 and [Table 35.3](#) lists the I/O pins.

Note 1. Changing the A/D conversion accuracy also changes the A/D conversion time. For details, see [section 35.3.6. Analog Input Sampling and Scan Conversion Time](#).

Note 2. When selecting the internal reference voltage, do not use continuous scan mode or group scan mode.

Note 3. For details, see [section 10, Low Power Modes](#).

| AVSS0                                 | Input | Analog block power supply ground pin<br>(Connect to VSS when ADC12/DAC12 is not used.) |
| VREFH0                                | Input | Analog reference voltage supply pin                                                    |
| VREFL0                                | Input | Analog reference ground pin                                                            |
| AN000 to AN004, AN011 to AN013, AN016 | Input | Analog input pins 0 to 4, 11 to 13, 16                                                 |
| ADTRG0                                | Input | External trigger input pin for starting A/D conversion                                 |

## 35.2 Register Descriptions

### 35.2.1 ADDRn : A/D Data Registers n (n = 0 to 4, 11 to 13, 16)

Base address: ADC120 = 0x4017\_0000

Offset address: 0x020 + 0x2 × n (n = 0 to 4, 11 to 13, 16)

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field: ADDR [15:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

| Bit  | Symbol      | Function                                                                                                                                               | R/W |
|------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 15:0 | ADDR [15:0] | Converted Value 15 to 0<br>Functions vary depending on the selected mode and accuracy. See <a href="#">Table 35.4</a> and <a href="#">Table 35.5</a> . | R   |

ADDRn registers are 16-bit read-only registers to store A/D conversion results.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

### (1) When A/D-converted value addition/average mode is not selected

[Table 35.4](#) shows the example of bit assignment for 12-bit accuracy.

**Table 35.4 Example of bit assignment for 12-bit accuracy**

| Accuracy                                  | b15                                                    | b14 | b13 | b12 | b11                                                    | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3                        | b2 | b1 | b0 |
|-------------------------------------------|--------------------------------------------------------|-----|-----|-----|--------------------------------------------------------|-----|----|----|----|----|----|----|---------------------------|----|----|----|
| Right-justified data with 12-bit accuracy | These bits are read as 0.                              |     |     |     | Converted Value 11 to 0:<br>12-bit A/D-converted value |     |    |    |    |    |    |    |                           |    |    |    |
| Left-justified data with 12-bit accuracy  | Converted Value 11 to 0:<br>12-bit A/D-converted value |     |     |     |                                                        |     |    |    |    |    |    |    | These bits are read as 0. |    |    |    |

### (2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

### (3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

[Table 35.5](#) shows example of the bit assignment for 12-bit accuracy.

**Table 35.5 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected (1 of 2)**

| Accuracy                                  | b15                                              | b14 | b13                                                          | b12 | b11                                                          | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|-------------------------------------------|--------------------------------------------------|-----|--------------------------------------------------------------|-----|--------------------------------------------------------------|-----|----|----|----|----|----|----|----|----|----|----|
| Right-justified data with 12-bit accuracy | When 16 conversion times is specified            |     | Added Value 15 to 0:<br>16-bit sum of A/D conversion results |     |                                                              |     |    |    |    |    |    |    |    |    |    |    |
|                                           | When 1, 2, 3, or 4 conversion times is specified |     | These bits are read as 0.                                    |     | Added Value 13 to 0:<br>14-bit sum of A/D conversion results |     |    |    |    |    |    |    |    |    |    |    |

**Table 35.5 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected (2 of 2)**

| Accuracy                                 |                                                  | b15                                                          | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1                        | b0 |
|------------------------------------------|--------------------------------------------------|--------------------------------------------------------------|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|---------------------------|----|
| Left-justified data with 12-bit accuracy | When 1, 2, 3, or 4 conversion times is specified | Added Value 15 to 0:<br>16-bit sum of A/D conversion results |     |     |     |     |     |    |    |    |    |    |    |    |    |                           |    |
|                                          | When 16 conversion times is specified            | Added Value 13 to 0:<br>14-bit sum of A/D conversion results |     |     |     |     |     |    |    |    |    |    |    |    |    | These bits are read as 0. |    |

### 35.2.2 ADDBLDR : A/D Data Duplexing Register

Base address: ADC120 = 0x4017\_0000

Offset address: 0x018

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field: ADDBLDR [15:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

| Bit  | Symbol         | Function                                                                                                                                               | R/W |
|------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 15:0 | ADDBLDR [15:0] | Converted Value 15 to 0<br>Functions vary depending on the selected mode and accuracy. See <a href="#">Table 35.6</a> and <a href="#">Table 35.7</a> . | R   |

ADDBLDR register is a 16-bit read-only register to store A/D conversion results in response to a second trigger in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

#### (1) When A/D-converted value addition/average mode is not selected

[Table 35.6](#) shows the example of bit assignment for 12-bit accuracy.

**Table 35.6 Example of bit assignment for 12-bit accuracy**

| Accuracy                                  | b15                                                    | b14 | b13 | b12 | b11                                                    | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3                        | b2 | b1 | b0 |
|-------------------------------------------|--------------------------------------------------------|-----|-----|-----|--------------------------------------------------------|-----|----|----|----|----|----|----|---------------------------|----|----|----|
| Right-justified data with 12-bit accuracy | These bits are read as 0.                              |     |     |     | Converted Value 11 to 0:<br>12-bit A/D-converted value |     |    |    |    |    |    |    |                           |    |    |    |
| Left-justified data with 12-bit accuracy  | Converted Value 11 to 0:<br>12-bit A/D-converted value |     |     |     |                                                        |     |    |    |    |    |    |    | These bits are read as 0. |    |    |    |

#### (2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

#### (3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 35.7 shows example of the bit assignment for 12-bit accuracy.

**Table 35.7 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected**

| Accuracy                                  |                                                  | b15                                                          | b14 | b13                                                          | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1                        | b0 |
|-------------------------------------------|--------------------------------------------------|--------------------------------------------------------------|-----|--------------------------------------------------------------|-----|-----|-----|----|----|----|----|----|----|----|----|---------------------------|----|
| Right-justified data with 12-bit accuracy | When 16 conversion times is specified            | Added Value 15 to 0:<br>16-bit sum of A/D conversion results |     |                                                              |     |     |     |    |    |    |    |    |    |    |    |                           |    |
|                                           | When 1, 2, 3, or 4 conversion times is specified | These bits are read as 0.                                    |     | Added Value 13 to 0:<br>14-bit sum of A/D conversion results |     |     |     |    |    |    |    |    |    |    |    |                           |    |
| Left-justified data with 12-bit accuracy  | When 1, 2, 3, or 4 conversion times is specified | Added Value 15 to 0:<br>16-bit sum of A/D conversion results |     |                                                              |     |     |     |    |    |    |    |    |    |    |    |                           |    |
|                                           | When 16 conversion times is specified            | Added Value 13 to 0:<br>14-bit sum of A/D conversion results |     |                                                              |     |     |     |    |    |    |    |    |    |    |    | These bits are read as 0. |    |

### 35.2.3 ADDBLDRn : A/D Data Duplexing Register n (n = A, B)

Base address: ADC120 = 0x4017\_0000

Offset address: 0x084 (n = A)  
0x086 (n = B)

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field: ADDBLDR [15:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

| Bit  | Symbol         | Function                                                                                                                                                   | R/W |
|------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 15:0 | ADDBLDR [15:0] | Converted Value 15 to 0<br><br>Functions vary depending on the selected mode and accuracy. See <a href="#">Table 35.8</a> and <a href="#">Table 35.9</a> . | R   |

ADDBLDRn registers are 16-bit read-only registers to store A/D conversion results in response to respective triggers during extended operation in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

#### (1) When A/D-converted value addition/average mode is not selected

Table 35.8 shows the example of bit assignment for 12-bit accuracy.

**Table 35.8 Example of bit assignment for 12-bit accuracy**

| Accuracy                                  | b15                                                    | b14 | b13 | b12 | b11                                                    | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3                        | b2 | b1 | b0 |
|-------------------------------------------|--------------------------------------------------------|-----|-----|-----|--------------------------------------------------------|-----|----|----|----|----|----|----|---------------------------|----|----|----|
| Right-justified data with 12-bit accuracy | These bits are read as 0.                              |     |     |     | Converted Value 11 to 0:<br>12-bit A/D-converted value |     |    |    |    |    |    |    |                           |    |    |    |
| Left-justified data with 12-bit accuracy  | Converted Value 11 to 0:<br>12-bit A/D-converted value |     |     |     |                                                        |     |    |    |    |    |    |    | These bits are read as 0. |    |    |    |

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 35.9 shows example of the bit assignment for 12-bit accuracy.

**Table 35.9 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected**

| Accuracy                                  | b15                                              | b14 | b13                                                          | b12 | b11                                                          | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0                        |
|-------------------------------------------|--------------------------------------------------|-----|--------------------------------------------------------------|-----|--------------------------------------------------------------|-----|----|----|----|----|----|----|----|----|----|---------------------------|

35.2.4 ADOCDR : A/D Internal Reference Voltage Data Register

Base address: ADC120 = 0x4017\_0000

Offset address: 0x01C

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

| Bit  | Symbol        | Function                                                                                                                | R/W |
|------|---------------|-------------------------------------------------------------------------------------------------------------------------|-----|
| 15:0 | ADOCDR [15:0] | Converted Value 15 to 0<br>Functions vary depending on the selected mode and accuracy. See Table 35.10 and Table 35.11. | R   |

ADOCDR register is a 16-bit read-only register to store A/D conversion result of the internal reference voltage.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 35.10 shows the example of bit assignment for 12-bit accuracy.

**Table 35.10 Example of bit assignment for 12-bit accuracy**

| Accuracy                                  | b15                                                    | b14 | b13 | b12 | b11                                                    | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3                        | b2 | b1 | b0 |
|-------------------------------------------|--------------------------------------------------------|-----|-----|-----|--------------------------------------------------------|-----|----|----|----|----|----|----|---------------------------|----|----|----|
| Right-justified data with 12-bit accuracy | These bits are read as 0.                              |     |     |     | Converted Value 11 to 0:<br>12-bit A/D-converted value |     |    |    |    |    |    |    |                           |    |    |    |
| Left-justified data with 12-bit accuracy  | Converted Value 11 to 0:<br>12-bit A/D-converted value |     |     |     |                                                        |     |    |    |    |    |    |    | These bits are read as 0. |    |    |    |

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 35.11 shows example of the bit assignment for 12-bit accuracy.

**Table 35.11 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected**

| Accuracy                                  |                                                  | b15                                                          | b14 | b13 | b12                                                          | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1                        | b0 |
|-------------------------------------------|--------------------------------------------------|--------------------------------------------------------------|-----|-----|--------------------------------------------------------------|-----|-----|----|----|----|----|----|----|----|----|---------------------------|----|
| Right-justified data with 12-bit accuracy | When 16 conversion times is specified            | Added Value 15 to 0:<br>16-bit sum of A/D conversion results |     |     |                                                              |     |     |    |    |    |    |    |    |    |    |                           |    |
|                                           | When 1, 2, 3, or 4 conversion times is specified | These bits are read as 0.                                    |     |     | Added Value 13 to 0:<br>14-bit sum of A/D conversion results |     |     |    |    |    |    |    |    |    |    |                           |    |
| Left-justified data with 12-bit accuracy  | When 1, 2, 3, or 4 conversion times is specified | Added Value 15 to 0:<br>16-bit sum of A/D conversion results |     |     |                                                              |     |     |    |    |    |    |    |    |    |    |                           |    |
|                                           | When 16 conversion times is specified            | Added Value 13 to 0:<br>14-bit sum of A/D conversion results |     |     |                                                              |     |     |    |    |    |    |    |    |    |    | These bits are read as 0. |    |

### 35.2.5 ADRD : A/D Self-Diagnosis Data Register

Base address: ADC120 = 0x4017\_0000

Offset address: 0x01E

| Bit   | Symbol      | Function                                                                                                                                                                                                                                                                                                                                                                                                                 | R/W |
|-------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 11:0  | AD[11:0]    | Converted Value 11 to 0<br>12-bit A/D-converted value                                                                                                                                                                                                                                                                                                                                                                    | R   |
| 13:12 | —           | These bits are read as 0.                                                                                                                                                                                                                                                                                                                                                                                                | R   |
| 15:14 | DIAGST[1:0] | Self-Diagnosis Status<br>For details on self-diagnosis, see <a href="#">section 35.2.14. ADCER : A/D Control Extended Register</a> .<br>0 0: Self-diagnosis not executed after power-on.<br>0 1: Self-diagnosis was executed using the 0 V voltage.<br>1 0: Self-diagnosis was executed using the reference voltage <sup>*1</sup> × 1/2.<br>1 1: Self-diagnosis was executed using the reference voltage <sup>*1</sup> . | R   |

Note: The example of the bit assignment for the right-justified data with 12-bit accuracy is indicated.

Note 1. The reference voltage refers to VREFH0.

ADRD is a 16-bit read-only register that holds the A/D conversion results based on the self-diagnosis of the ADC12. In addition to the AD[11:0] bits indicating the A/D-converted value, it includes the Self-Diagnosis Status bit (DIAGST[1:0]).

The settings of the A/D data register format and the A/D conversion accuracy determines the formats for data in this register.

The A/D-converted value addition and average modes cannot be applied to the A/D self-diagnosis function. For details on self-diagnosis, see [section 35.2.14. ADCER : A/D Control Extended Register](#).

This section describes the data formats for each condition. The register diagram and the register bit table shown in this section indicate example of the bit assignment for the left and right-justified data with 12-bit accuracy.

**Table 35.12 Bit assignment for each right-justified accuracy**

| Accuracy                                  | b15         | b14 | b13 | b12      | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|-------------------------------------------|-------------|-----|-----|----------|-----|-----|----|----|----|----|----|----|----|----|----|----|
| Right-justified data with 12-bit accuracy | DIAGST[1:0] |     | —   | AD[11:0] |     |     |    |    |    |    |    |    |    |    |    |    |

**Table 35.13 Bit assignment for each left-justified accuracy**

| Accuracy                                 | b15      | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2          | b1 | b0 |
|------------------------------------------|----------|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|-------------|----|----|
| Left-justified data with 12-bit accuracy | AD[11:0] |     |     |     |     |     |    |    |    |    |    |    | —  | DIAGST[1:0] |    |    |

### 35.2.6 ADCSR : A/D Control Register

Base address: ADC120 = 0x4017\_0000

Offset address: 0x000

| Bit   | Symbol      | Function                                                                                                                                                                                                                                              | R/W |
|-------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|

| 15    | ADST        | A/D Conversion Start<br>0: Stop A/D conversion process.<br>1: Start A/D conversion process.                                                                                                                                                           | R/W |

Note 1. To start A/D conversion using an external pin (asynchronous trigger):

After a high-level signal is input to the external pin (ADTRG0), write 1 to both the TRGE and EXTRG bits in the ADCSR register and drive the ADTRG0 pin low. With these settings, the scan conversion process starts on detection of the falling edge of ADTRG0. The pulse width of the low-level input must be at least PCLKA 1.5 clock cycles.

The ADCSR register sets double-trigger mode and A/D conversion start trigger, enables or disables scan end interrupt, selects the scan mode, and starts or stops A/D conversion.

#### DBLANS[4:0] bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one channel for A/D conversion data duplication in double-trigger mode. This can be selected by setting the binary value of the channel number to be duplicated. The A/D conversion results of the analog input of the channel selected in the DBLANS[4:0] bits are stored in A/D Data Register y when conversion is started by the first trigger, and in the A/D Data Duplexing Register when conversion is started by the second trigger.

In double-trigger mode, the channels selected in the ADANSA0 and ADANSA1 registers, are invalid, and the channel selected in the DBLANS[4:0] bits is A/D converted instead.

When double-trigger mode is used in group scan mode, double-trigger control is only applied to group A and not to group B. Therefore, multiple channel analog input can be selected for group B even in double-trigger mode.

Only set the DBLANS[4:0] bits when the ADST bit is 0. Do not set the DBLANS[4:0] bits at the same time that you write 1 to the ADST bit.

To enter A/D-converted value addition/average mode when in double-trigger mode, select the channel using the DBLANS[4:0] bits in the ADADS0 and ADADS1 registers.

A/D-converted data from the self-diagnosis function and internal reference voltage cannot be used in double-trigger mode.

#### GBADIE bit (Group B Scan End Interrupt and ELC Event Enable)

The GBADIE bit enables or disables group B scan end interrupt (ADC120\_GBADI) in group scan mode.

**DBLE bit (Double Trigger Mode Select)**

The DBLE bit selects or deselects double-trigger mode. Double-trigger mode can only be operated by the synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits.

Double-trigger operation is as follows:

1. The ADC120\_ADI interrupt is not output on completion of the first conversion but on completion of the second conversion.
2. The A/D conversion results from the duplication channel (selected in DBLANS[4:0]) started by the first trigger are stored in A/D Data Register y and those started by the second trigger are stored in the A/D Data Duplexing Register.

When the DBLE bit is set (double-trigger mode is selected), the channels specified in the ADANSA0 and ADANSA1 registers are invalid. Double-trigger mode is deselected by setting DBLE to 0. Setting DBLE to 1 again enables the same double-trigger operation described in 1. and 2. for first time scanning with the first trigger.

Do not select double-trigger mode in continuous scan mode. Software triggering cannot be used in double-trigger mode. Always set the ADST bit to 0 before setting the DBLE bit. Do not set the DBLE bit at that same time as writing 1 to the ADST bit.

**EXTRG bit (Trigger Select)**

The EXTRG bit selects the synchronous or asynchronous trigger as the trigger for starting A/D conversion.

In group scan mode, the setting of this bit takes effect on the trigger selected for group A. For group B, A/D conversion is started by the selected synchronous trigger regardless of this bit setting.

**TRGE bit (Trigger Start Enable)**

The TRGE bit enables or disables A/D conversion by the synchronous and asynchronous triggers. In group scan mode, set this bit to 1.

**ADCS[1:0] bits (Scan Mode Select)**

The ADCS[1:0] bits select the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, the scan conversion stops.

In continuous scan mode, when the ADCSR.ADST bit is 1, A/D conversion is performed for the analog inputs of the channels selected with the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion repeats from the first channel. If the ADCSR.ADST bit is set to 0 during continuous scan, A/D conversion stops even if scanning is in progress.

In group scan mode:

- Group A scanning is started by the synchronous trigger (ELC) selected in the TRSA[5:0] bits in the ADSTRGR register. A/D conversion is performed on group A analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.
- Group B scanning is started by the synchronous trigger (ELC) selected in the ADSTRGR.TRSB[5:0] bits. A/D conversion is performed on group B analog inputs of the channels selected in the ADANSB0 and ADANSB1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.

If the conversion processes in group A and group B occur at the same time, those conversions cannot be controlled separately. In this case, set group A Priority Control Setting bit (ADGSPCR.PGS) in the A/D Group Scan Priority Control Register (ADGSPCR) to 1 to assign a priority to group A conversion.

In group scan mode, select different channels and triggers for group A and group B.

Only set the ADCS[1:0] bits when the ADST bit is 0. Do not set the ADCS[1:0] bits at the same time that you write 1 to the ADST bit.

**Table 35.14 Selectable targets for A/D conversion depending on scan and double-trigger mode settings**

| Scan mode setting | Double-trigger mode setting | Targets for A/D conversion |                        |                        |                            |
|-------------------|-----------------------------|----------------------------|------------------------|------------------------|----------------------------|
|                   |                             | Self-diagnosis             | Analog input (group A) | Analog input (group B) | Internal reference voltage |

|                   | DBLE = 1                    | —                          | —                      | —                      | —                          |
| Group scan        | DBLE = 0                    | ✓                          | ✓                      | ✓                      | ✓                          |
|                   | DBLE = 1                    | —                          | ✓ (1 ch only)          | ✓                      | ✓                          |

Note: ✓: Selectable, —: Not selectable

**ADST bit (A/D Conversion Start)**

The ADST bit starts or stops the A/D conversion process. Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and the conversion target analog input.

[Setting conditions]

- 1 is written.
- The synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits is detected when ADCSR.EXTRG is 0 and ADCSR.TRGE is 1.
- The synchronous trigger (ELC) selected in the ADSTRGR.TRSB[5:0] bits is detected when ADCSR.TRGE is set to 1 in group scan mode.
- The asynchronous trigger is detected when the ADCSR.TRGE and ADCSR.EXTRG bits are set to 1 and the ADSTRGR.TRSA[5:0] bits are set to 0x00.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRP bit is set to 1, and each time A/D conversion on the group with the lowest priority is started.

[Clearing conditions]

- 0 is written.
- The A/D conversion of all the selected channels, the internal reference voltage completes in single scan mode.
- Group A scan completes in group scan mode.
- Group B scan completes in group scan mode.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRSCN bit is set to 1, and A/D conversion on the group with the lowest priority started by trigger completes.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 1.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 0. When forcing A/D conversion to terminate, follow the procedure for clearing the ADST bit.

ADANSA0 register selects analog input channels for A/D conversion. In group scan mode, this register selects group A channels.

Only set the ADANSA0 register when the ADCSR.ADST bit is 0.

### ANSAn bits (A/D Conversion Channels Select n) (n = 0 to 4, 11 to 13)

The ANSAn bits select any combination of analog input channels for A/D conversion. The channels and the number of channels can be arbitrarily set.

In double trigger mode, the channels selected in the ADANSA0 register are invalid, and the channel selected in the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in A/D Channel Select Register B0 (ADANSB0) and A/D Channel Select Register B1 (ADANSB1).

### 35.2.8 ADANSA1 : A/D Channel Select Register A1

| 15:1 | —      | These bits are read as 0. The write value should be 0.                                                                                                             | R/W |

ADANSA1 register selects analog input channels for A/D conversion. In group scan mode, this register selects group A channels.

Only set the ADANSA1 register when the ADCSR.ADST bit is 0.

### ANSA16 bit (A/D Conversion Channels Select 16)

The ANSA16 bit selects any combination of analog input channels for A/D conversion. The channels and the number of channels can be arbitrarily set.

In double trigger mode, the channels selected in the ADANSA1 register are invalid, and the channel selected in the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in A/D Channel Select Register B0 (ADANSB0) and A/D Channel Select Register B1 (ADANSB1).

### 35.2.9 ADANSB0 : A/D Channel Select Register B0

| 15:14 | —                | These bits are read as 0. The write value should be 0.                                                                                                                                                          | R/W |

ADANSB0 selects analog input channels for A/D conversion in group B when group scan mode is selected. The ADANSB0 register is not used in any scan mode other than group scan mode.

Only set the ADANSB0 register when the ADCSR.ADST bit is 0.

#### ANSBn bits (A/D Conversion Channels Select n) (n = 0 to 4, 11 to 13)

The ANSBn bits select any combination of analog input channels in group B for A/D conversion when group scan mode is selected.

Do not select channels specified in group A as selected in the ADANSA0 and ADANSA1 registers or the ADCSR.DBLANS[4:0] bits in double-trigger mode.

### 35.2.10 ADANSB1 : A/D Channel Select Register B1

ADANSB1 selects analog input channels for A/D conversion in group B when group scan mode is selected. The ADANSB1 register is not used in any scan mode other than group scan mode.

Only set the ADANSB1 register when the ADCSR.ADST bit is 0.

#### ANSB16 bit (A/D Conversion Channels Select 16)

The ANSB16 bit selects any combination of analog input channels in group B for A/D conversion when group scan mode is selected.

Do not select channels specified in group A as selected in the ADANSA0 and ADANSA1 registers or the ADCSR.DBLANS[4:0] bits in double-trigger mode.

### 35.2.11 ADADS0 : A/D-Converted Value Addition/Average Channel Select Register 0

#### ADS<sub>n</sub> bits (A/D-Converted Value Addition/Average Channel Select n) (n = 0 to 4, 11 to 13)

The ADS<sub>n</sub> bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADS<sub>n</sub> bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADS<sub>n</sub> bits apply only to channels that are selected for A/D conversion in:

- The ANSA<sub>n</sub> bits in the ADANSA0 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSB<sub>n</sub> bits in the ADANSB0 register

For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS0 register bits when the ADCSR.ADST bit is 0.

Figure 35.2 shows a scanning operation sequence in which the ADADS0 register bits (channel c and g) are set to 1. In this figure:

- Addition mode is selected (ADADC.AVEE = 0)
- The number of conversions is set to 4 (ADADC.ADC[1:0] = 11b)
- The analog input channels (a to h) are selected by ADANSA0 register in continuous scan mode (ADCSR.ADCS[1:0] = 10b).

The conversion process begins with analog input A (channel a). The analog input C (channel c) conversion is performed successively 4 times and the added value is returned to A/D Data Register c (ADDR<sub>c</sub>). Next, the analog input D (channel d) conversion process is started. The analog input G (channel g) is performed successively 4 times and the added value is returned to A/D Data Register g (ADDR<sub>g</sub>). After conversion of analog input H (channel h), the conversion operation repeats in the same sequence starting with analog input A (channel a).

**Figure 35.2** Scan conversion sequence with ADADC.ADC[2:0] = 011b, set 1 for analog inputs C and G by ADADS0/1

### 35.2.12 ADADS1 : A/D-Converted Value Addition/Average Channel Select Register 1

Base address: ADC120 = 0x4017\_0000

Offset address: 0x00A

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

| Bit  | Symbol | Function                                                                                                                                                                               | R/W |
|------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 0    | ADS16  | A/D-Converted Value Addition/Average Channel Select 16<br>Bit 0 (ADS16) is associated with AN016.<br>0: Do not select associated input channel.<br>1: Select associated input channel. | R/W |
| 15:1 | —      | These bits are read as 0. The write value should be 0.                                                                                                                                 | R/W |

#### ADS16 bit (A/D-Converted Value Addition/Average Channel Select 16)

The ADS16 bit determines which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADS16 bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADS16 bit applies only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA1 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB1 register.

For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS1 register when the ADCSR.ADST bit is 0.

Note: ✓: Selectable, —: Not selectable

#### ADC[2:0] bits (Addition/Average Count Select)

The ADC[2:0] bits set the addition count in all channels for which A/D conversion and addition/average mode are selected, including the channel selected in double trigger mode with the ADCSR.DBLANS[4:0] bits. The count also applies to A/D conversion of the internal reference voltage.

When self-diagnosis is executed (ADCER.DIAGM = 1), do not set the ADC[2:0] bits to any value other than 000b.

#### AVEE bit (Average Mode Select)

The AVEE bit selects addition or average mode in all channels for which A/D conversion and addition/average mode are selected, including the channels selected in double-trigger mode in the ADCSR.DBLANS[4:0] bits, internal reference voltage.

Note 1. The reference voltage refers to VREFH0.

#### ADPRC[1:0] bit (A/D Conversion Accuracy Specify)

The ADPRC[1:0] bits set the A/D conversion accuracy. Changing the A/D conversion accuracy also changes the bit width of valid data stored in the result register and the A/D conversion time. For details, see [section 35.3.6. Analog Input Sampling and Scan Conversion Time](#) and section 45.3.6, Analog Input Sampling and Scan Conversion Time. Only set the ADPRC[1:0] bits while the ADCSR.ADST bit is 0.

#### ACE bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of the ADDRy, ADDR, ADDBLDR, ADDBLDRA, ADDBLDRB, or ADOCDR register after any of these registers is read by the CPU or DTC. Automatic clearing of the A/D data registers enables detection of failures that are not updated in the A/D data registers. For details, see [section 35.3.7. Usage Example of A/D Data Register Automatic Clearing Function](#).

#### DIAGVAL[1:0] bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis fixed voltage mode. For details, see the DIAGLD bit description.

Do not execute self-diagnosis by setting the DIAGLD bit to 1 when the DIAGVAL[1:0] bits are set to 00b.

**DIAGLD bit (Self-Diagnosis Mode Select)**

The DIAGLD bit selects whether the three voltage values are rotated, or the fixed voltage is used in self-diagnosis.

Setting the DIAGLD bit to 0 selects conversion of the voltages in rotation mode, where 0 V, the reference voltage  $\times 1/2$ , and the reference voltage are converted, in that order. After reset and when self-diagnosis voltage rotation mode is selected, self-diagnosis is executed from 0 V. The self-diagnosis voltage value does not return to 0 V when scan conversion completes. When scan conversion is restarted, rotation starts at the voltage value following the previous value.

Setting the DIAGLD bit to 1 selects fixed voltage, in which the fixed voltage specified in the ADCER.DIAGVAL[1:0] bits is converted. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

Only set the DIAGLD bit when the ADCSR.ADST bit is 0.

**DIAGM bit (Self-Diagnosis Enable)**

The DIAGM bit enables or disables self-diagnosis.

Self-diagnosis is used to detect a failure of the ADC12. In self-diagnosis mode, one of the three voltage values (0 V, the reference voltage  $\times 1/2$ , or the reference voltage) is converted. When conversion completes, information on the converted voltage and the conversion result is stored into the A/D Self-Diagnosis Data Register (ADRD). The ADRD register can be read to determine whether the conversion result falls within the normal or abnormal range.

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. In double trigger mode (ADCSR.DBLE = 1), self-diagnosis (DIAGM = 0) is deselected. When self-diagnosis is selected in group scan mode, self-diagnosis is executed separately for group A and group B.

Only set the DIAGM bit when the ADCSR.ADST bit is 0.

**ADRFMT bit (A/D Data Register Format Select)**

The ADRFMT bit specifies flush-right or flush-left for data to be stored in the ADDR<sub>y</sub>, ADDBLDR, ADDBLDRA, ADDBLDRB, ADOCDR, ADCMPDR0/1, ADWINLLB, ADWINULB, or ADRD register.

Only set the ADRFMT bit when the ADCSR.ADST bit is 0.

**35.2.15 ADSTRGR : A/D Conversion Start Trigger Select Register**

| 7:6   | —         | These bits are read as 0. The write value should be 0.                                                                                                                                                     | R/W |
| 13:8  | TRSA[5:0] | A/D Conversion Start Trigger Select<br>Select the A/D conversion start trigger in single scan mode and continuous scan mode. In group scan mode, the A/D conversion start trigger for group A is selected. | R/W |
| 15:14 | —         | These bits are read as 0. The write value should be 0.                                                                                                                                                     | R/W |

**TRSB[5:0] bits (A/D Conversion Start Trigger Select for Group B)**

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits must only be set in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. In group scan mode, set the TRSB[5:0] bits to a value other than 0x00 and set the ADCSR.TRGE bit to 1.

When group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 0x3F. The issuance

period for a conversion trigger must be more than or equal to the actual scan conversion time ( $t_{SCAN}$ ). If the issuance period is less than  $t_{SCAN}$ , A/D conversion by the trigger might have no effect.

Table 35.16 lists the A/D conversion startup sources selected in the TRSB[5:0] bits.

**Table 35.16 Selection of A/D conversion start sources in the TRSB[5:0] bits**

| Source                          | Remarks | TRSB[5] | TRSB[4] | TRSB[3] | TRSB[2] | TRSB[1] | TRSB[0] |
|---------------------------------|---------|---------|---------|---------|---------|---------|---------|
| Trigger source deselected state | —       | 1       | 1       | 1       | 1       | 1       | 1       |

| ELC_AD00, ELC_AD01              | ELC     | 0       | 0       | 1       | 0       | 1       | 1       |

### TRSA[5:0] bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode, or the trigger to start scanning of group A analog inputs in group scan mode. When scanning is executed in group scan mode or double trigger mode, software trigger or asynchronous trigger is prohibited.

- When using a synchronous trigger (ELC), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 0.
- When using the asynchronous trigger (ADTRG0), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, or the TRSA[5:0] bits.

The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time ( $t_{SCAN}$ ). If the issuance period is less than  $t_{SCAN}$ , A/D conversion by a trigger might have no effect.

Table 35.17 lists the A/D conversion start sources selected in the TRSA[5:0] bits.

**Table 35.17 Selection of A/D activation sources in the TRSA[5:0] bits**

| Source                          | Remarks                   | TRSA[5] | TRSA[4] | TRSA[3] | TRSA[2] | TRSA[1] | TRSA[0] |
|---------------------------------|---------------------------|---------|---------|---------|---------|---------|---------|
| Trigger source deselected state | —                         | 1       | 1       | 1       | 1       | 1       | 1       |

| 10    | —      | These bits are read as 0. The write value should be 0.                                                                                                                                                                   | R/W |
| 11    | OCSB   | Internal Reference Voltage A/D Conversion Select for Group B<br>0: Disable A/D conversion of internal reference voltage<br>1: Enable A/D conversion of internal reference voltage                                        | R/W |
| 15:12 | —      | These bits are read as 0. The write value should be 0.                                                                                                                                                                   | R/W |

### OCSAD bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Internal Reference Voltage Data Register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADOCDR.

Only set the OCSAD bit while the ADCSR.ADST bit is 0.

### OCSA bit (Internal Reference Voltage A/D Conversion Select)

The OCSA bit selects A/D conversion of the internal reference voltage for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the internal reference voltage is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the OCSA bit while the ADCSR.ADST bit is 0. In addition, wait for 400 ns or more after the OCSA bit is set to 1 before starting A/D conversion.

### OCSB bit (Internal Reference Voltage A/D Conversion Select for Group B)

The OCSB bit selects A/D conversion of the internal reference voltage for group B in group scan mode. Only set the OCSB bit while the ADCSR.ADST bit is 0. Do not set the OCSB bit to 1 while the OCSA bit is 1. Moreover, start the A/D conversion after waiting for 400 ns or more after the OCSB bit is set to 1.

## 35.2.17 ADSSTRn/ADSSTRL/ADSSTRO : A/D Sampling State Register (n = 0 to 4, 11 to 13)

Base address: ADC120 = 0x4017\_0000

Offset address: 0x0E0 + 0x1 × n (n = 0 to 4, 11 to 13)  
0x0DD (ADSSTRL)  
0x0DF (ADSSTRO)

Bit position: 7 6 5 4 3 2 1 0

Bit field: 

|          |
|----------|
| SST[7:0] |
|----------|

Value after reset: 0 0 0 0 1 0 1 1

| Bit | Symbol   | Function                                                                                     | R/W |
|-----|----------|----------------------------------------------------------------------------------------------|-----|
| 7:0 | SST[7:0] | Sampling Time Setting<br>These bits set the sampling time in the range from 5 to 255 states. | R/W |

The ADSSTRn register sets the sampling time for analog input.

The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow. The set value indicates the time for one ADCLK cycle, and the required sampling time is specified by the voltage conditions. For details, see [section 43.5. ADC12 Characteristics](#).

The lower limit of the sampling time setting depends on the frequency ratio:

- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:1, 2:1, 4:1, or 8:1 the sampling time must be set to a value of more than 5 states
- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:2 or 1:4, the sampling time must be set to a value of more than 6 states.

[Table 35.18](#) shows the relationship between the A/D Sampling State Register and the associated channels. For details, see [section 35.3.6. Analog Input Sampling and Scan Conversion Time](#).

Only set the SST[7:0] bits when the ADCSR.ADST bit is 0.

**Table 35.18 Relationship between A/D sampling state register and associated channels**

| Bit name                                                   | Associated channels            |
|------------------------------------------------------------|--------------------------------|
| ADSSTRn.SST[7:0] bits (n = 0 to 4, 11 to 13)* <sup>1</sup> | AN000 to AN004, AN011 to AN013 |
| ADSSTRL.SST[7:0] bits                                      | AN016                          |
| ADSSTRO.SST[7:0] bits                                      | Internal reference voltage     |

Note 1. When the self-diagnosis function is selected, the sampling time set in the ADSSTRO.SST[7:0] bits is applied.

### 35.2.18 ADDISCR : A/D Disconnection Detection Control Register

Base address: ADC120 = 0x4017\_0000

Offset address: 0x07A

|                    |   |   |   |      |             |   |   |   |
|--------------------|---|---|---|------|-------------|---|---|---|
| Bit position:      | 7 | 6 | 5 | 4    | 3           | 2 | 1 | 0 |
| Bit field:         | — | — | — | PCHG | ADNDIS[3:0] |   |   |   |
| Value after reset: | 0 | 0 | 0 | 0    | 0           | 0 | 0 | 0 |

| Bit | Symbol      | Function                                                                                                                                                                                                 | R/W |
|-----|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 3:0 | ADNDIS[3:0] | Disconnection Detection Assist Setting<br>0x0: The disconnection detection assist function is disabled<br>0x1: Setting prohibited<br>Others: The number of states for the discharge or precharge period. | R/W |
| 4   | PCHG        | Precharge/discharge select<br>0: Discharge<br>1: Precharge                                                                                                                                               | R/W |
| 7:5 | —           | These bits are read as 0. The write value should be 0.                                                                                                                                                   | R/W |

The ADDISCR register selects either precharge or discharge, and the period of precharge or discharge for the A/D disconnection detection assist function. Only set the ADDISCR register when the ADCSR.ADST bit is 0. When the internal reference voltage is converted, the A/D converter executes discharge automatically.

Disable the disconnection detection assist function if any of the following functions are used:

- The internal reference voltage
- A/D self-diagnosis

#### ADNDIS[3:0] bits (Disconnection Detection Assist Setting)

The ADNDIS[3:0] bits specify the period of precharge or discharge. When ADNDIS[3:0] = 0000b, the disconnection detection assist function is disabled. Setting the ADNDIS[3:0] bits to 0001b is prohibited. Except when ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge or discharge. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, the disconnection detection assistance function is enabled.

**PCHG bit (Precharge/discharge select)**

The PCHG bit selects either precharge or discharge.

| 13:2 | —      | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                               | R/W |
| 14   | LGRRS  | Restart Channel Select<br>Enabled only when PGS = 1 and GBRSCN = 1.<br>0: Start rescanning from the first channel for scanning<br>1: Start rescanning from the channel for which A/D conversion is not completed.                                                    | R/W |
| 15   | GBRP   | Single Scan Continuous Start* <sup>2</sup><br>(enabled only when PGS = 1 and reserved when PGS = 0.)<br>0: Single scan is not continuously activated.<br>1: Single scan for the group with the lower-priority is continuously activated.                             | R/W |

Note 1. The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting PGS to 1. Operation is not guaranteed if these bits are set to any other value.

Note 2. When the GBRP bit is set to 1, single scan is performed continuously for the group with the lower-priority regardless of the setting in the GBRSCN bit.

**PGS bit (Group Priority Operation Setting)**

The PGS bit controls group priority operation in group scan mode. Set the PGS bit to 1 to enable group priority operation.

The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting the PGS bit to 1. Operation is not guaranteed if the bits are set to any other value.

When the PGS bit is set to 0, a clear operation must be performed by software as described in [section 35.6.3. Constraints on Stopping A/D Conversion](#). When the PGS bit is set to 1, use the settings described in [section 35.3.4.3. Group Priority Operation](#).

**GBRSCN bit (Lower-Priority Group Restart Setting)**

The GBRSCN bit controls the restarting of scan operation in group priority operation.

When the GBRSCN bit is set to 1, if the scan operation of a lower-priority group is stopped by a trigger input of a priority group, the lower-priority group scanning is restarted on completion of the priority group scanning. If a trigger of a lower-priority group is input during scanning of the priority group, the lower-priority group scanning is started on completion of the priority group scanning.

When the GBRSCN bit is set to 0, triggers input during scanning are ignored. Set the GBRSCN bit while the ADCSR.ADST bit is 0.

**LGRRS bit (Restart Channel Select)**

This bit sets the channel from which rescanning is to be started in group priority operation. The setting of the LGRRS bit is valid when the PGS and GBRSCN bits are 1.

If the LGRRS bit is 0, scanning of a lower-priority group that was stopped in group priority operation is restarted from the first channel after scanning of the priority group completes.

If the LGRRS bit is 1, scanning of a lower-priority group that was stopped in group priority operation is restarted (upon completion of scanning of the priority group) from the channel for which A/D conversion is not complete. If A/D conversion of the addition setting channel was not completed the specified number of times when scanning stopped, A/D conversion of the addition setting channel is performed again the specified number of times when scanning restarts.

Set the LGRRS bit while the ADCSR.ADST bit is 0.

**GBRP bit (Single Scan Continuous Start)**

The GBRP bit is set when a single scan operation is to be performed continuously on the group with the lower-priority.

Setting the GBRP bit to 1 starts a single scan of the group with the lower-priority. On completion of the scan, another single scan of the group with the lower-priority is started automatically. If scanning has been stopped during group priority operation, single scan of the group with the lower-priority is automatically restarted on completion of the A/D conversion of the priority group.

Before setting the GBRP bit to 1, disable input of a trigger for the lower-priority group. If the GBRP bit is set to 1, rescanning is performed only on the group with the lower-priority even if the GBRSCN bit is set to 0.

### CMPAB[1:0] bits (Window A/B Composite Conditions Setting)

The CMPAB[1:0] bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1) in single scan mode. These bits specify the compare function match/mismatch event output conditions and monitoring conditions of ADWINMON.MONCOMB. Only set the CMPAB[1:0] bits while the ADCSR.ADST bit is 0.

### CMPBE bit (Compare Window B Operation Enable)

The CMPBE bit enables or disables the compare window B operation. Set the CMPBE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- OCSB or OCSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- CMPCHB[5:0] bits in the Window B Channel Select Register (ADCMPBNSR)

### CMPAE bit (Compare Window A Operation Enable)

The CMPAE bit enables or disables the compare window A operation. Set the CMPAE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- OCSB or OCSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- Window A Channel Select Registers 0 and 1 (ADCMPANSR0 and ADCMPANSR1)
- Window A Extended Input Select Register (ADCMPANSER)

### CMPBIE bit (Compare B Interrupt Enable)

The CMPBIE bit enables or disables the ADC120\_CMPBI interrupt output when the comparison conditions (window B) are met.

### WCMPE bit (Window Function Setting)

The WCMPE bit enables or disables the window function. Set the WCMPE bit while the ADCSR.ADST bit is 0.

### CMPAIE bit (Compare A Interrupt Enable)

The CMPAIE bit enables or disables the ADC120\_CMPAI interrupt output when the comparison conditions (window A) are met.

**CMPCHAN bits (Compare Window A Channel Select n) (n = 0 to 4, 11 to 13)**

The compare function is enabled by writing 1 to the CMPCHAN bits with the same number as the A/D conversion channel selected in the ADANSA0.ANSAn bits and the ADANSB0.ANSBn bits.

Set the CMPCHAN bits while the ADCSR.ADST bit is 0.

**CMPLCHAN bits (Compare Window A Comparison Condition Select n)**

The CMPLCHAN bits specify the comparison conditions for channels to which Window A comparison conditions are applied. These bits can be set for each analog input to be compared. When the comparison result of each analog input meets the set condition, the ADCMPSR0.CMPSTCHAN flag sets to 1 and a compare interrupt (ADC120\_CMPAI) is generated.

**CMPLCHA16 bit (Compare Window A Comparison Condition Select 16)**

The CMPLCHA16 bit specifies the comparison conditions for analog channels to which window A comparison conditions are applied. This bit can be set for each analog input to be compared. When the comparison result of each analog input meets the set condition, the ADCMPSR1.CMPSTCHA16 bit is set to 1 and a compare interrupt (ADC120\_CMPAI) is generated.

**35.2.26 ADCMPLER : A/D Compare Function Window A Extended Input Comparison Condition Setting Register**

Base address: ADC120 = 0x4017\_0000

Offset address: 0x093

**CMPLOCA bit (Compare Window A Internal Reference Voltage Comparison Condition Select)**

The CMPLOCA bit specifies comparison conditions when the internal reference voltage is the target for the Window A comparison condition. When the internal reference voltage comparison result meets the set condition, the ADCMPSER.CMPSTOCA flag sets to 1 and a compare interrupt (ADC120\_CMPAI) is generated.

### 35.2.27 ADCMPDRn : A/D Compare Function Window A Lower-Side/Upper-Side Level Setting Register (n = 0, 1)

Base address: ADC120 = 0x4017\_0000

Offset address: 0x09C + (0x2 × n)

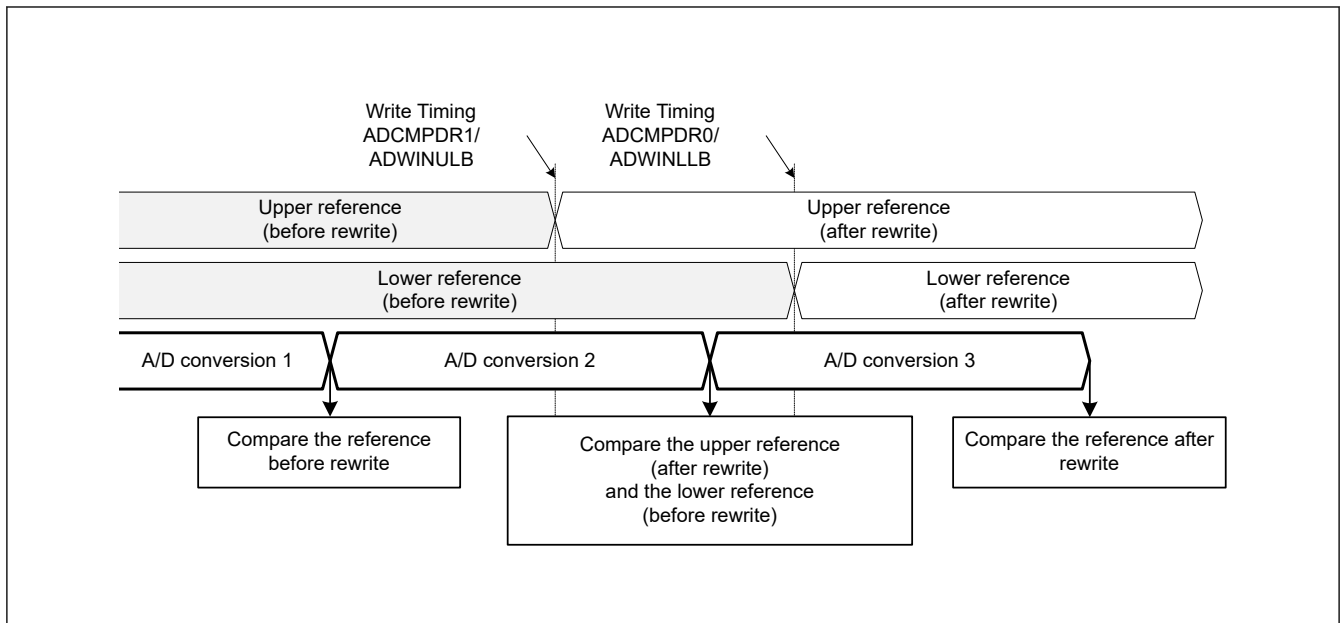

The ADCMPDRy (y = 0, 1) register specifies the reference data when the compare window A function is used. ADCMPDR0 sets the lower reference for window A, and ADCMPDR1 sets the upper reference for window A.

ADCMPDRy are read/write registers.

ADCMPDRy are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion\*1.

Set these registers so that the upper reference is not less than the lower reference (ADCMPDR1 ≥ ADCMPDR0). ADCMPDR1 are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See [Figure 35.4](#). If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPDR.CMPAE or ADCMPDR.CMPBE) are 0.

**Figure 35.4 Comparison between upper and lower references before and after a rewrite**

The ADCMPDRy registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected

- Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
  - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
  - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
  - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
  - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
  - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected
- Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) or 16 bits ([15:0]) are valid
  - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
  - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
  - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) or 16 bits ([15:0]) are valid
  - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
  - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

**Note:** The number of extended bits for addition varies with the A/D conversion accuracy and the number of addition times. A 2-bit extension is up to 4 times conversion (3 times addition) when the A/D conversion accuracy is 8, 10, or 12 bits. A 4-bit extension is 16 times conversion (15 times addition) when the A/D conversion accuracy is 12 bits.

### 35.2.28 ADWINnLB : A/D Compare Function Window B Lower-Side/Upper-Side Level Setting Register (n = L, U)

Base address: ADC120 = 0x4017\_0000

Offset address: 0x0A8 (n = L)  
0x0AA (n = U)

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field:

|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

The ADWINULB and ADWINLLB registers specify the reference data when the compare window B function is used. ADWINLLB sets the lower reference for window B, and ADWINULB sets the upper reference for window B.

ADWINnLB are read/write registers.

ADWINnLB are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion<sup>\*1</sup>.

Set these registers so that the upper reference is not less than the lower reference ( $ADWINULB \geq ADWINLLB$ ). ADWINULB are not used when the window function is disabled.

**Note 1.** The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See [Figure 35.5](#). If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

**Figure 35.5 Comparison between upper and lower references before and after a rewrite**

The ADWINnLB registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
  - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
  - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
  - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
  - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
  - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
  - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected
  - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) or 16 bits ([15:0]) are valid
  - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
  - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
  - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) or 16 bits ([15:0]) are valid
  - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
  - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

**Note:** The number of extended bits for addition varies with the A/D conversion accuracy and the number of addition times. A 2-bit extension is up to 4 times conversion (3 times addition) when the A/D conversion accuracy is 8, 10, or 12 bits. A 4-bit extension is 16 times conversion (15 times addition) when the A/D conversion accuracy is 12 bits.

#### CMPSTCHAN flags (Compare Window A Flag n) (n = 0 to 4, 11 to 13)

The CMPSTCHAN flags indicate the comparison results for channels to which Window A comparison conditions are applied. When a comparison condition set in ADCMPLR0.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAN flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC120\_CMPAI) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAN flags is invalid.

[Setting condition]

- The condition set in ADCMPLR0.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

### CMPSTCHA16 flag (Compare Window A Flag 16)

The CMPSTCHA16 flag indicates the comparison results for channels to which Window A comparison condition is applied. When the comparison condition set in ADCMPLR1.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHA16 flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC120\_CMPAI) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHA16 flag is invalid.

[Setting condition]

- The condition set in ADCMPLR1.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

| 1   | CMPSTOCA | Compare Window A Internal Reference Voltage Compare Flag<br>When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the internal reference voltage comparison result.<br>0: Comparison conditions are not met.<br>1: Comparison conditions are met. | R/W |
| 7:2 | —        | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                 | R/W |

The ADCMPSER register stores compare results of compare function window A.

### CMPSTOCA flag (Compare Window A Internal Reference Voltage Compare Flag)

The CMPSTOCA flag indicates the internal reference voltage comparison result. When the comparison condition set in ADCMPLR1.CMPLOCA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC120\_CMPAI) is generated when this flag sets to 1.

Writing 1 to the CMPSTOCA flag is invalid.

[Setting condition]

- The condition set in ADCMPLR1.CMPLOCA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

#### CMPCHB[5:0] bits (Compare Window B Channel Select)

The CMPCHB[5:0] bits specify the channels to be compared with the compare Window B conditions from AN000 to AN004, AN011 to AN013, AN016, the internal reference voltage. The compare Window B function is enabled by specifying the hexadecimal number of the A/D conversion channel selected in the ADANSA0, ADANSA1, ADANSB0, ADANSB1 registers.

Set the CMPCHB[5:0] bits while the ADCSR.ADST bit is 0.

#### CMPLB bit (Compare Window B Comparison Condition Setting)

The CMPLB bit specifies the comparison conditions for channels for Window B. When the comparison result of an analog input meets the set condition, the associated ADCMPBSR.CMPSTB flag sets to 1 and a compare interrupt request (ADC120\_CMPBI) is generated.

|-----|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 0   | CMPSTB | Compare Window B Flag<br>When Window B operation is enabled (ADCMPPCR.CMPBE = 1), this bit indicates the comparison result of channels to which Window B comparison conditions are applied, internal reference voltage.<br>0: Comparison conditions are not met.<br>1: Comparison conditions are met. | R/W |
| 7:1 | —      | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                | R/W |

#### CMPSTB flag (Compare Window B Flag)

The CMPSTB flag indicates the comparison result of channels to which Window B comparison conditions are applied, the internal reference voltage. When the comparison condition set in ADCMPBSR.CMPLB is met at the end of A/D

conversion, this flag sets to 1. When the ADCMPCR.CMPBIE bit is 1, a compare interrupt request (ADC120\_CMPBI) is generated when this flag sets to 1.

Writing 1 to the CMPSTB flag is invalid.

[Setting condition]

- The condition set in ADCMPBNSR.CMPLB is met when ADCMPCR.CMPBE = 1.

[Clearing condition]

- Writing 0 after reading 1.

### 35.2.34 ADWINMON : A/D Compare Function Window A/B Status Monitor Register

Base address: ADC120 = 0x4017\_0000

Offset address: 0x08C

|                    |   |   |             |             |   |   |   |             |
|--------------------|---|---|-------------|-------------|---|---|---|-------------|

| 3:1 | —       | These bits are read as 0.                                                                                                                                                                                                                            | R   |
| 4   | MONCMPA | Comparison Result Monitor A<br>0: Window A comparison conditions are not met.<br>1: Window A comparison conditions are met.                                                                                                                          | R   |
| 5   | MONCMPB | Comparison Result Monitor B<br>0: Window B comparison conditions are not met.<br>1: Window B comparison conditions are met.                                                                                                                          | R   |
| 7:6 | —       | These bits are read as 0.                                                                                                                                                                                                                            | R   |

#### MONCOMB bit (Combination Result Monitor)

The read-only MONCOMB bit indicates the combined result of comparison condition results A and B based on the combination condition set in the ADCMPCR.CMPAB[1:0] bits.

[Setting condition]

- The combined result meets the combination condition set in the ADCMPCR.CMPAB[1:0] bits when ADCMPCR.CMPAE = 1 and ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The combined result does not meet the combination condition set in the ADCMPCR.CMPAB[1:0] bits.
- ADCMPCR.CMPAE = 0 or ADCMPCR.CMPBE = 0.

#### MONCMPA bit (Comparison Result Monitor A)

The read-only MONCMPA bit is read as 1 when the A/D-converted value of the Window A target channel meets the condition set in ADCMPLR0/ADCMPLR1 and ADCMPLER. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPCR.CMPAE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPPCR.CMPAE = 1.
- ADCMPPCR.CMPAE = 0 (automatically cleared when the ADCMPPCR.CMPAE value changes from 1 to 0).

### MONCMPB bit (Comparison Result Monitor B)

The read-only MONCMPB bit is read as 1 when the A/D-converted value of the Window B target channel meets the condition set in the ADCMPBNSR.CMPLB bit. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in ADCMPBNSR.CMPLB when ADCMPPCR.CMPBE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in ADCMPBNSR.CMPLB when ADCMPPCR.CMPBE = 1.
- ADCMPPCR.CMPBE = 0 (automatically cleared when the ADCMPPCR.CMPBE value changes from 1 to 0).

### 35.2.35 ADBUFEN : A/D Data Buffer Enable Register

Base address: ADC120 = 0x4017\_0000

Offset address: 0x0D0

|                    |   |   |   |   |   |   |   |       |
|--------------------|---|---|---|---|---|---|---|-------|
| Bit position:      | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0     |
| Bit field:         | — | — | — | — | — | — | — | BUFEN |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0     |

| Bit | Symbol | Function                                                                             | R/W |
|-----|--------|--------------------------------------------------------------------------------------|-----|
| 0   | BUFEN  | Data Buffer Enable<br>0: The data buffer is not used.<br>1: The data buffer is used. | R/W |
| 7:1 | —      | These bits are read as 0. The write value should be 0.                               | R/W |

The ADBUFEN register sets whether to enable the data buffer.

#### BUFEN bit (Data Buffer Enable)

This bit enables the use of the data buffer.

When BUFEN = 1b, A/D conversion result (addition result) other than self-diagnosis result is stored in ADBUFn.

Disable the data storage operation (BUFEN = 0b) before reading ADBUFPTR.

Do not use the data buffer for data duplexing, or group scan.

### 35.2.36 ADBUFPTR : A/D Data Buffer Pointer Register

Base address: ADC120 = 0x4017\_0000

Offset address: 0x0D2

|                    |   |   |   |            |             |   |   |   |
|--------------------|---|---|---|------------|-------------|---|---|---|
| Bit position:      | 7 | 6 | 5 | 4          | 3           | 2 | 1 | 0 |
| Bit field:         | — | — | — | PTRO<br>VF | BUFPTR[3:0] |   |   |   |
| Value after reset: | 0 | 0 | 0 | 0          | 0           | 0 | 0 | 0 |

| Bit | Symbol      | Function                                                                                                                  | R/W |
|-----|-------------|---------------------------------------------------------------------------------------------------------------------------|-----|
| 3:0 | BUFPTR[3:0] | Data Buffer Pointer<br>These bits indicate the number of data buffer to which the next A/D converted data is transferred. | R/W |

| Bit | Symbol | Function                                                                                                              | R/W |
|-----|--------|-----------------------------------------------------------------------------------------------------------------------|-----|
| 4   | PTROVF | Pointer Overflow Flag<br>0: The data buffer pointer has not overflowed.<br>1: The data buffer pointer has overflowed. | R/W |
| 7:5 | —      | These bits are read as 0. The write value should be 0.                                                                | R/W |

ADBUFPtr is a register that indicates the data buffer pointer and overflow status.

**BUFPtr[3:0] bit (Data Buffer Pointer)**

These bits indicate the number of data buffer to which the next A/D converted data is transferred.

When data has been transferred to data buffer 15, the pointer value becomes 0000b and the PTROVF bit is set to 1.

When the next data has been transferred, the data in data buffer 0 is overwritten.

Writing 0x00 to this register clears the value of these bits. Writing a value other than 0x00 is disabled.

**PTROVF bit (Pointer Overflow Flag)**

This bit indicates whether the data buffer pointer has overflowed. This bit is set to 1 when the pointer value becomes 0000b (overflow).

Writing 0x00 to this register clears this bit value. Writing a value other than 0x00 is disabled.

**35.2.37 ADBUFn : A/D Data Buffer Registers n (n = 0 to 15)**

Base address: ADC120 = 0x4017\_0000

Offset address: 0x0B0 + 0x2 × n (n = 0 to 15)

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field:

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

| Bit  | Symbol | Function                                                                                                                                                 | R/W |
|------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 15:0 | n/a    | Converted Value 15 to 0<br>Functions vary depending on the selected mode and accuracy. See <a href="#">Table 35.19</a> and <a href="#">Table 35.20</a> . | R   |

ADBUFn registers are 16-bit read-only registers that sequentially store all A/D conversion results. The automatic clear function is not applied to these registers.

ADBUFn settings are the same as the A/D data register format settings. about details see section 1.2.1 ADDRn : A/D Data Registers n.

The following conditions determine the formats for data in the ADBUFn registers:

- Setting of the Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

[Table 35.19](#) shows the bit assignment for each accuracy.

**Table 35.19 Bit assignment for each accuracy (1 of 2)**

| Accuracy                                  | b15                       | b14 | b13 | b12 | b11                                                    | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|-------------------------------------------|---------------------------|-----|-----|-----|--------------------------------------------------------|-----|----|----|----|----|----|----|----|----|----|----|
| Right-justified data with 12-bit accuracy | These bits are read as 0. |     |     |     | Converted Value 11 to 0:<br>12-bit A/D-converted value |     |    |    |    |    |    |    |    |    |    |    |

**Table 35.19 Bit assignment for each accuracy (2 of 2)**

| Accuracy                                 | b15                                                    | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3                        | b2 | b1 | b0 |
|------------------------------------------|--------------------------------------------------------|-----|-----|-----|-----|-----|----|----|----|----|----|----|---------------------------|----|----|----|
| Left-justified data with 12-bit accuracy | Converted Value 11 to 0:<br>12-bit A/D-converted value |     |     |     |     |     |    |    |    |    |    |    | These bits are read as 0. |    |    |    |

**(2) When A/D-converted value average mode is selected**

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, These registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

**(3) When A/D-converted value addition mode is selected**

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 35.20 shows the bit assignment for each accuracy.

**Table 35.20 Bit assignment for each accuracy when A/D-converted value addition mode is selected**

| Accuracy                                  |                                                  | b15                                                          | b14 | b13 | b12                                                          | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1                        | b0 |

## 35.3 Operation

### 35.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

Scan conversion is performed in any of the three operating modes:

- Single scan mode
- Continuous scan mode
- Group scan mode

In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until software sets the ADCSR.ADST bit to 0. In group scan mode, the selected channels in group A, B are scanned once after scan starts in response to the respective synchronous trigger.

In single scan mode and continuous scan mode, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for the ANn channels in group A selected in the ADANSA0 and ADANSA1 registers, and for the

ANn channels in group B selected in the ADANSB0 and ADANSB1 registers, starting from the channel with the smallest number n.

When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three reference voltages is converted.

The internal reference voltage can be selected at the same time as the analog input of the channels, and A/D conversion is performed on the analog input of channels, and internal reference voltage, in that order.

Double trigger mode can be used with single scan mode or group scan mode. With double trigger mode enabled (ADCSR.DBLE = 1), A/D conversion data of a channel selected in the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use double trigger mode.

In the extended operation of double trigger mode, the A/D conversion operation is generated from the synchronous trigger combination selected in the ADSTRGR.TRSA[5:0] bits. In addition to normal double trigger mode operation, A/D conversion data with odd number trigger (ELC\_AD00) is stored in A/D Data Duplexing Register A (ADDBLDRA), and A/D conversion data with even number trigger (ELC\_AD01) is stored in A/D Data Duplexing Register B (ADDBLDRB). In the extended operation of double trigger mode, when one of the trigger combinations occurs at the same time, the data duplexing register settings for the specified triggers do not work, and A/D conversion data is stored in A/D Data Duplexing Register B (ADDBLDRB).

The ADC12 ignores a synchronous trigger that occurs during the A/D conversion started by another synchronous trigger.

## 35.3.2 Single Scan Mode

### 35.3.2.1 Basic Operation

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (ELC), or an asynchronous trigger input, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC120\_ADI interrupt request is generated .
4. The ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.

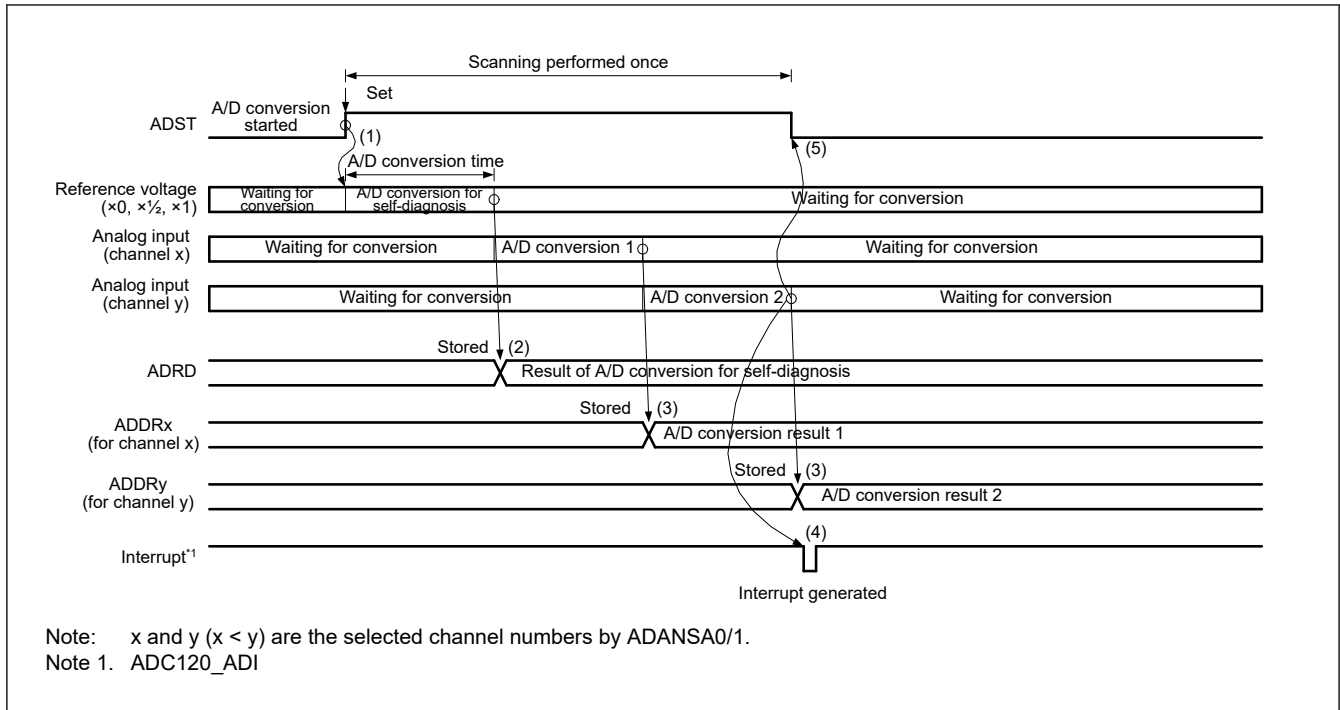

**Figure 35.7** Example basic operation in single scan mode when the analog inputs (channel x to z) are selected

### 35.3.2.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage ( $\times 0$ ,  $\times 1/2$ , or  $\times 1$ ), then A/D conversion is performed once on the analog input of the selected channels as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADDRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC120\_ADI interrupt request is generated.
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.

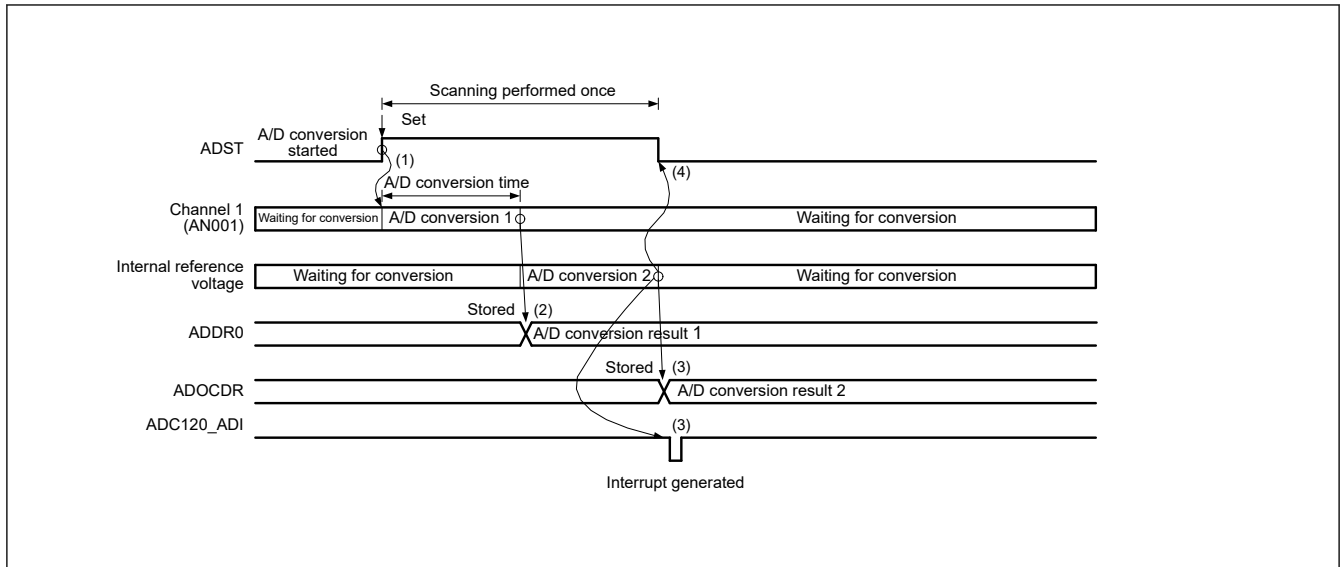

**Figure 35.8** Example basic operation in single scan mode when the analog inputs (channel x and y) are selected with self- diagnosis

### 35.3.2.3 A/D Conversion of Internal Reference Voltage

When the channels and internal reference voltage are selected at the same time, A/D conversion is performed first on the analog input of the selected channels, and once on the internal reference voltage. With the channels deselected, selecting only the internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of the internal reference voltage starts.
3. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC120\_ADI interrupt request is generated (no register setting).
4. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 on completion of A/D conversion. Then, the ADC12 enters a wait state.

**Figure 35.9** Example basic operation in single scan mode when AN000 and internal reference voltage are selected

### 35.3.2.4 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in single scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed in sequence.

Deselect self-diagnosis and set the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In double trigger mode, select a synchronous trigger (ELC) with the ADSTRGR.TRSA[5:0] bits. Additionally, set the ADCSR.EXTRG bit to 0 and the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC120\_ADI interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion is completed, the result is stored in the A/D Data Duplexing Register (ADDBLDR), which is exclusively used in double-trigger mode.
6. An ADC120\_ADI interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion is completed. Then the ADC12 enters a wait state.

**Figure 35.10 Example operation in single scan mode when double-trigger mode is selected and the analog input (channel x) is duplicated**

### 35.3.2.5 Extended Operations When Double-Trigger Mode Is Selected

When double trigger mode is selected in single scan mode, and a synchronous trigger (ELC\_AD00/ELC\_AD01) is selected as the trigger for the start of A/D conversion, two rounds of single scan operation are performed.

Deselect self-diagnosis and set the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In extended double trigger mode, select a synchronous trigger combination ELC\_AD00/ELC\_AD01 by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, set the ADCSR.EXTRG bit to 0, and set the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC\_AD00/ELC\_AD01), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. When A/D conversion completes, the A/D conversion result is stored in the associated A/D Data Register (ADDRy) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC\_ADi0 or ELC\_ADi1 trigger is input respectively (i = 0).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC120\_ADI interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger (ELC\_AD00/ELC\_AD01), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion completes, the A/D conversion result is stored in the A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC\_ADi0 or ELC\_ADi1 trigger is input respectively (i = 0).
6. An ADC120\_ADI interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion completes. The ADC12 then enters a wait state.

**Figure 35.11 Example extended operation in double trigger mode with duplication selected for the analog input (channel x) and ELC\_AD00/ELC\_AD01**

### 35.3.3 Continuous Scan Mode

#### 35.3.3.1 Basic Operation

In continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (ELC), or an asynchronous trigger input, A/D conversion is performed for ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC120\_ADI interrupt request is generated. The ADC12 sequentially starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. The ADCSR.ADST bit is not automatically cleared, and steps 2. and 3. are repeated as long as ADCSR.ADST remains 1 (A/D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADCSR.ADST bit is later set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.

**Figure 35.12 Example basic operation in continuous scan mode when the analog inputs (channel x to z) are selected**

### 35.3.3.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage ( $\times 0$ ,  $\times 1/2$ , or  $\times 1$ ) supplied to the ADC12, and A/D conversion is performed on the analog input of the selected channels. This sequence is repeated as described in the section that follows.

The operation is as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADDRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the corresponding A/D Data Register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC120\_ADI interrupt request is generated. At the same time, the ADC12 starts A/D conversion for self-diagnosis and then on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. The ADCSR.ADST bit is not automatically cleared, and steps 2. to 4. are repeated as long as the ADCSR.ADST bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is later set to 1 (A/D conversion start), the A/D conversion for self-diagnosis is started again.

**Figure 35.13 Example basic operation in continuous scan mode when the analog inputs (channel x and y) are selected with self-diagnosis**

### 35.3.3.3 A/D Conversion of Internal Reference Voltage

When the channels and internal reference voltage are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then the A/D conversion of the internal reference voltage is repeated.

With the channels deselected, selecting only the internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of internal reference voltage starts.
3. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC120\_ADI interrupt request is generated. In addition, the ADC12 continuously starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.
4. The ADCSR.ADST bit is not cleared automatically, and steps 2 to 4 are repeated as long as this bit remains set to 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.

**Figure 35.14** Example basic operation in continuous scan mode when AN000 and internal reference voltage are selected

### 35.3.4 Group Scan Mode

#### 35.3.4.1 Basic Operation

In group scan mode, A/D conversion is performed once on the analog input of all the specified channels in group A and B after scanning is started by a synchronous trigger (ELC). The scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A and B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger.

The group A channels to be A/D-converted are selected using the ADANSA0 and ADANSA1 registers and the ADEXICR.OCSA bit. The group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers and the ADEXICR.OCSB bit. Group A and B cannot use the same channels.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for Group A and B.

The following sequence describes operation in group scan mode using a synchronous trigger from the ELC. In this example, the ELC\_AD00 trigger from the ELC is used to start conversion of group A and the ELC\_AD01 trigger from the ELC is used to start conversion of group B. In addition, ELC\_AD00 and ELC\_AD01 are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group A is started by ELC\_AD00.
2. When group A scanning completes, an ADC120\_ADI interrupt is generated (no register setting).
3. Scanning of group B is started by ELC\_AD01.
4. When group B scanning completes, an ADC120\_GBADI interrupt is generated if the ADCSR.GBADIE bit is 1 (ADC120\_GBADI interrupt when scanning completion is enabled).

**Figure 35.15** Example basic operation in group scan mode when synchronous triggers from the ELC are used

### 35.3.4.2 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed as a sequence for group A. For group B, single scan operation started by a synchronous trigger (ELC) is performed once.

In group scan mode, the synchronous trigger can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A, B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger or an asynchronous trigger.

When an ELC\_AD00/ELC\_AD01 is selected as group A synchronous triggers by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, operation proceeds in extended double trigger mode.

The group A channel to be A/D-converted is selected using the DBLANS[4:0] bits in the ADCSR register, while the group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers. Group A, B cannot use the same channels.

When double-trigger mode is selected in group scan mode, set the A/D conversion select bits for the internal reference voltage (ADEXICR.OCSA) to 0 (deselected).

Self-diagnosis cannot be selected when double trigger mode is selected in group scan mode.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following sequence describes operation in group scan mode with double trigger mode selected and using a synchronous trigger from the ELC. In this example, the ELC\_AD00 trigger is used to start conversion of group A and the ELC\_AD01 trigger is used to start conversion of group B. In addition, ELC\_AD00 and ELC\_AD01 are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group B is started by the ELC\_AD00 trigger from the ELC.
2. When group B scanning completes, an ADC120\_GBADI interrupt is generated if the GBADIE bit in ADCSR is 1 (ADC120\_GBADI interrupt when scanning completion is enabled).
3. The first scan of group A is started by the first ELC\_AD01 trigger.

4. When the first scan of group A completes, the conversion result is stored in the associated A/D Data Register  $y$  (ADDR $y$ ); an ADC120\_ADI interrupt request is not generated.
5. The second scan of group A is started by the second ELC\_AD01 trigger.
6. When the second scan of group A completes, the conversion result is stored in ADDBLDR. An ADC120\_ADI interrupt is generated.

**Figure 35.16** Example basic operation in group scan mode with double-trigger mode when synchronous triggers from the ELC are used

### 35.3.4.3 Group Priority Operation

Group priority operation is performed by setting the ADGSPCR.PGS bit to 1 in group-scan mode. The priority of groups is group A > group B.

When setting the PGS bit in the ADGSPCR register to 1, follow the procedure described in [Figure 35.17](#). If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

As the basic operation in group-scan mode, a trigger input generated during A/D conversion of group A, B is ignored, and the A/D conversion operation of each group is similar to the operation in single-scan mode.

In group priority operation, if a trigger for a priority group is input during scanning of a lower-priority group, A/D conversion for the lower-priority group is stopped and A/D conversion for the priority group is performed.

If the setting of the ADGSPCR.GBRSCN bit is 0, the lower-priority group enters a wait state when A/D conversion for the priority group completes. A trigger input of the lower-priority group generated during A/D conversion is ignored.

If the setting of the ADGSPCR.GBRSCN bit is 1, A/D conversion for the lower-priority group automatically restarts upon completion of A/D conversion for the priority group. A trigger input of the lower-priority group generated during A/D conversion on the priority group takes effect, and A/D conversion for the lower-priority group is automatically performed upon completion of A/D conversion on the priority group.

If the ADGSPCR.GBRSCN bit is 1 and the ADGSPCR.LGRRS bit is 0, A/D conversion for the lower-priority group is restarted from the first channel. If the setting of the ADGSPCR.LGRRS bit is 1, A/D conversion for the lower-priority group is restarted from the channel for which the conversion stopped. However, if the self-diagnosis function is used, the A/D conversion is restarted from the channel for which the conversion stopped after self-diagnosis completed.

[Table 35.21](#) summarizes operations in response to the input of a trigger during A/D conversion with the settings of the ADGSPCR.GBRSCN bit.

If the setting of the ADGSPCR.GBRP bit is 1, A/D conversion operation for the lowest-priority group is to continuously perform single scans.

For the trigger settings in group-scan mode, select a synchronous trigger for group A by using the ADSTRGR.TRSA[5:0] bits, a synchronous trigger for group B by using the ADSTRGR.TRSB[5:0] bits. Each trigger must be different from each other. Set the ADSTRGR.TRSB[5:0] bits to 0x3F when setting the ADGSPCR.GBRP bit to 1.

The channels to be scanned must be selected in the registers shown in [section 35.3.4. Group Scan Mode](#).

Figure 35.17 Flowchart for ADGSPCR.PGS bit setting

**Table 35.21 Control of A/D conversion operations according to ADGSPCR.GBRSCN bit setting**

| A/D conversion operation                       | Trigger input                | ADGSPCR.GBRSCN = 0                                                                | ADGSPCR.GBRSCN = 1                                                                                                                                                                                                         |
|------------------------------------------------|------------------------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| When A/D conversion for group A is in progress | Input of trigger for group A | Trigger input is ineffective.                                                     | Trigger input is ineffective.                                                                                                                                                                                              |
|                                                | Input of trigger for group B | Trigger input is ineffective.                                                     | A/D conversion for group B is performed after A/D conversion for group A completes.                                                                                                                                        |
| When A/D conversion for group B is in progress | Input of trigger for group A | A/D conversion for group B is discontinued and A/D conversion for group A starts. | <ul style="list-style-type: none"> <li>A/D conversion for group B is discontinued and A/D conversion for group A starts.</li> <li>A/D conversion for group B starts after A/D conversion for group A completes.</li> </ul> |
|                                                | Input of trigger for group B | Trigger input is ineffective.                                                     | Trigger input is ineffective.                                                                                                                                                                                              |

To use group priority operation mode, select the operation mode to be implemented and set the registers according to the following table.

**Table 35.22 Group priority operation setting and operation mode for two groups (ADGSPCR.PGS = 1)**

| ADGSPCR |       |      | Operation category                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------|-------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GBRSCN  | LGRRS | GBRP |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Note: x: Don't care.

Note 1. When the self-diagnosis function is enabled (ADCER.DIAGM = 1), A/D conversion for the channel that has been stopped is started after self-diagnosis is performed.

### (1) Group priority operation for two groups (when ADGSPCR.PGS = 1)

Operation examples 1-1 to 1-3 show group priority operations in group-scan mode (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

#### Operation example 1-1: "Group A trigger input during group B scan" when rescanning is enabled

- When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
- On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
- When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1. Then A/D conversion for the group A analog input channels selected in the ADANSA0

and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).

4. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. An ADC120\_ADI interrupt request is generated.
6. If the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1.
7. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.

**Figure 35.18 Example of group priority operation 1-1: Group A trigger input during group B scanning when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)**

**Operation example 1-2: “Group A trigger input during rescanning of group B” when rescanning is enabled**

Figure 35.19 shows the operation when a group A trigger is input during rescanning operation for group B.

Even during rescanning operation, when a trigger for group A is input, A/D conversion on group B stops and A/D conversion for group A starts. A/D conversion for group B starts after A/D conversion for group A completes.

Operations for setting the ADCSR.ADST bit, storing the A/D conversion result in the corresponding A/D Data Register y (ADDRy), and generating interrupt requests are the same as those in operation example 1-1.

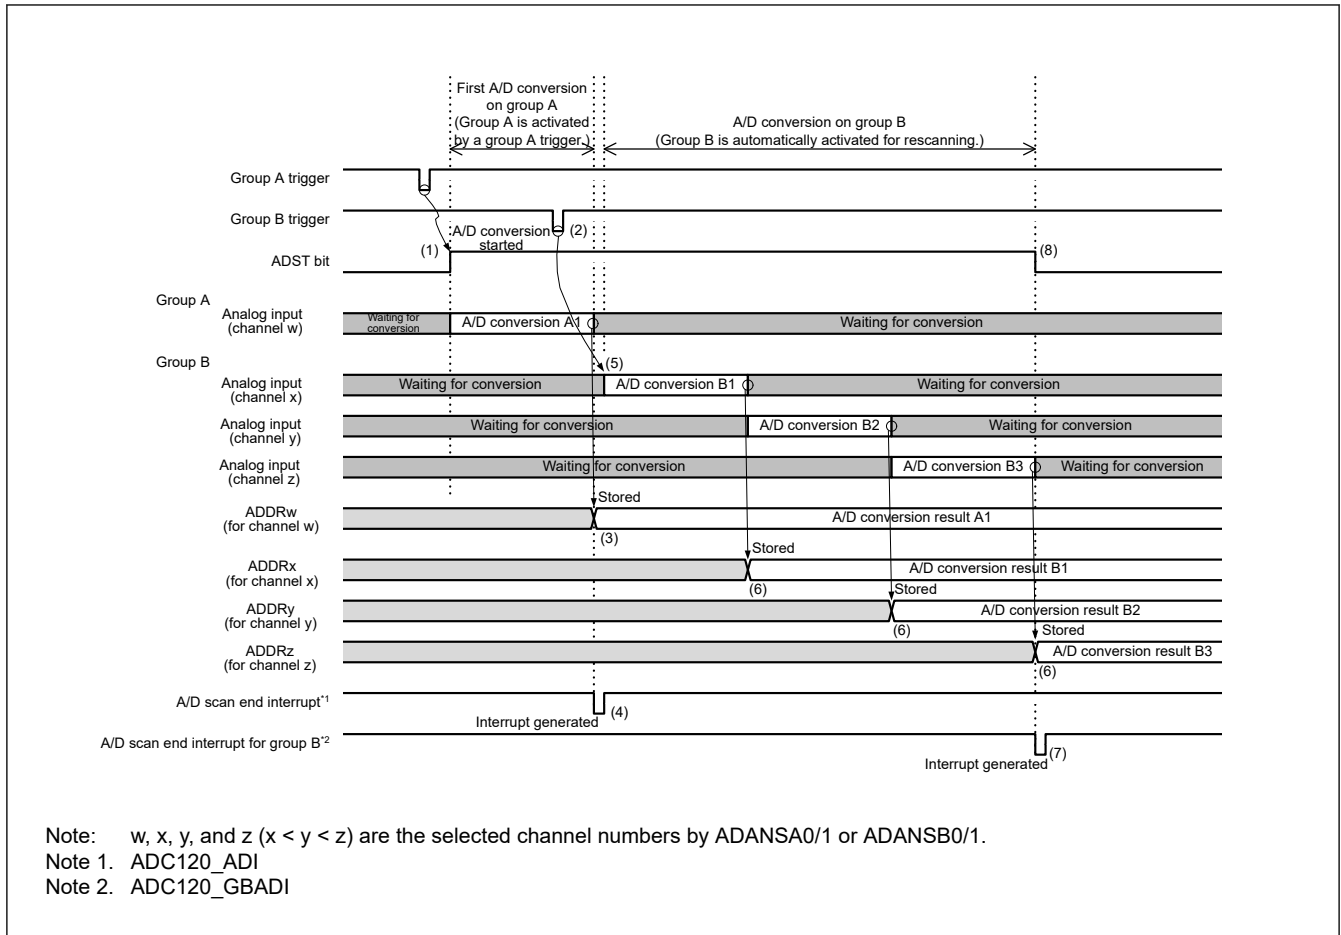

**Figure 35.19 Example of group priority operation 1-2: Group A trigger input during rescanning of group B when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)**

**Operation example 1-3: “Group B trigger input during group A scan” when rescanning is enabled**

The following describes the operation when the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation) and a trigger for group B is input during scanning operation for group A. If the setting of the ADGSPCR.GBRSCN bit is 0, any trigger for group B that is input during scanning operation for group A is invalid.

1. When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n.
2. When a trigger for group B is input during A/D conversion for group A, group B is ready for A/D conversion.
3. On completion of A/D conversion for each channel in group A, the result is stored in the corresponding A/D Data Register y (ADDRy).
4. An ADC120\_ADI interrupt request is generated.
5. When A/D conversion for group A completes, while the ADCSR.ADST bit remains 1, A/D conversion for the group B analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n.  
 (As with the case of operation example 1-1, if a trigger for group A is input during A/D conversion for group B, A/D conversion for group A starts. Then A/D conversion for group B starts upon completion of A/D conversion for group A.)
6. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
7. Upon completion of A/D conversion for group B, a group B scan end interrupt request is generated if the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan).
8. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.

**Figure 35.20 Example of group priority operation 1-3: Group B trigger input during group A scan when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)**

Operation example 1-4 shows the group priority operation in group-scan mode (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

**Operation example 1-4: “Group A trigger input during group B scan” when rescanning is disabled**

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120\_ADI interrupt request is generated.
6. When A/D conversion for group A completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state. A/D conversion for group B is not performed until a trigger for group B is input the next time.

**Figure 35.21 Group priority operation example 1-4: “Group A trigger is input during group B scan” when rescanning is disabled (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)**

Operation example 1-5 shows the group priority operation in group-scan mode (when ADGSPCR.GBRP = 1, and ADGSPCR.LGRRS = 0).

**Operation example 1-5: Continuously activating single-scan operation for group B**

1. When ADGSPCR.GBRP = 1 is set, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120\_ADI interrupt request is generated.
6. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).
7. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).

8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSA0 and ADANSA1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).

Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit remains 1. Do not clear the ADCSR.ADST bit as long as the ADGSPCR.GBRP bit is 1. To forcibly stop A/D conversion while ADGSPCR.GBRP = 1, follow the procedure shown in Figure 35.33.

**Figure 35.22 Group priority operation example 1-5: Continuously activating single scan for group B (when ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 0)**

Note: To continuously activate single-scan operation for group B, disable group B trigger input.

### 35.3.5 Compare Function for Windows A and B

#### 35.3.5.1 Compare Function Windows A and B

The compare function compares a reference value with the A/D conversion result. The reference value can be set for Window A and Window B independently. When the compare function is in use, the self-diagnosis function and double trigger mode cannot be used. The main differences between Window A and Window B are their different interrupt output signals and the constraint on Window B of only one selectable channel.

This section provides an example operation that combines continuous scan mode and the compare function.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, a synchronous trigger (ELC) or an asynchronous trigger, A/D conversion starts in the order of the selected channels and internal reference voltage.
2. On completion of A/D conversion, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy, or ADOCDR). When ADCMPCR.CMPAE = 1, if bits in the ADCMPANSRy register or the ADCMPANSER register are set for Window A, the A/D conversion result is compared with the set ADCMPDR0/1 register value. When ADCMPCR.CMPBE = 1, if bits in the ADCMPBNSR register are set for Window B, the A/D conversion result is compared with the ADWINULB/ADWINLLB register setting.

3. As a result of the comparison, when Window A meets the condition set in ADCMPLR0/1 or ADCMPLER, the Compare Window A Flag (ADCMPSTR0.CMPSTCHAn, ADCMPSTR1.CMPSTCHAn, or ADCMPSTR.CMPSTOCA) sets 1. At this time, if the ADCMPSTR.CMPAIE bit is 1, an ADC120\_CMPAI interrupt request is generated. In the same way, when Window B meets the condition set in ADCMPBSR.CMPLB, the Compare Window B Flag (ADCMPBSR.CMPSTB) sets to 1. At this time, if the ADCMPSTR.CMPBIE bit is 1, an ADC120\_CMPBI interrupt request is generated.
4. On completion of all selected A/D conversions and comparisons, scan restarts.
5. After the ADC120\_CMPAI and ADC120\_CMPBI interrupts are accepted, the ADCSR.ADST bit is set to 0 (A/D conversion stop) and processing is performed for channels for which the compare flag is set to 1.
6. When all compare flags of Window A are cleared, the ADC120\_CMPAI interrupt request is canceled. In the same way, when all compare flags of Window B are cleared, the ADC120\_CMPBI interrupt request is reset. To perform comparison again, restart the A/D conversion.

**Figure 35.23 Example of compare function operation, when the analog inputs (channel w to z) are compared**

### 35.3.5.2 Event Output of Compare Function

The event output of the compare function specifies the upper-side reference voltage value and the lower-side reference voltage value for window A and window B, respectively. The output compares the A/D converted value of the selected channel with the upper and lower side reference voltage value and outputs events (ADC120\_WCMPPM/ADC120\_WCMPUM) based on event conditions (A or B, A and B, A xor B) and comparison result of window A and window B.

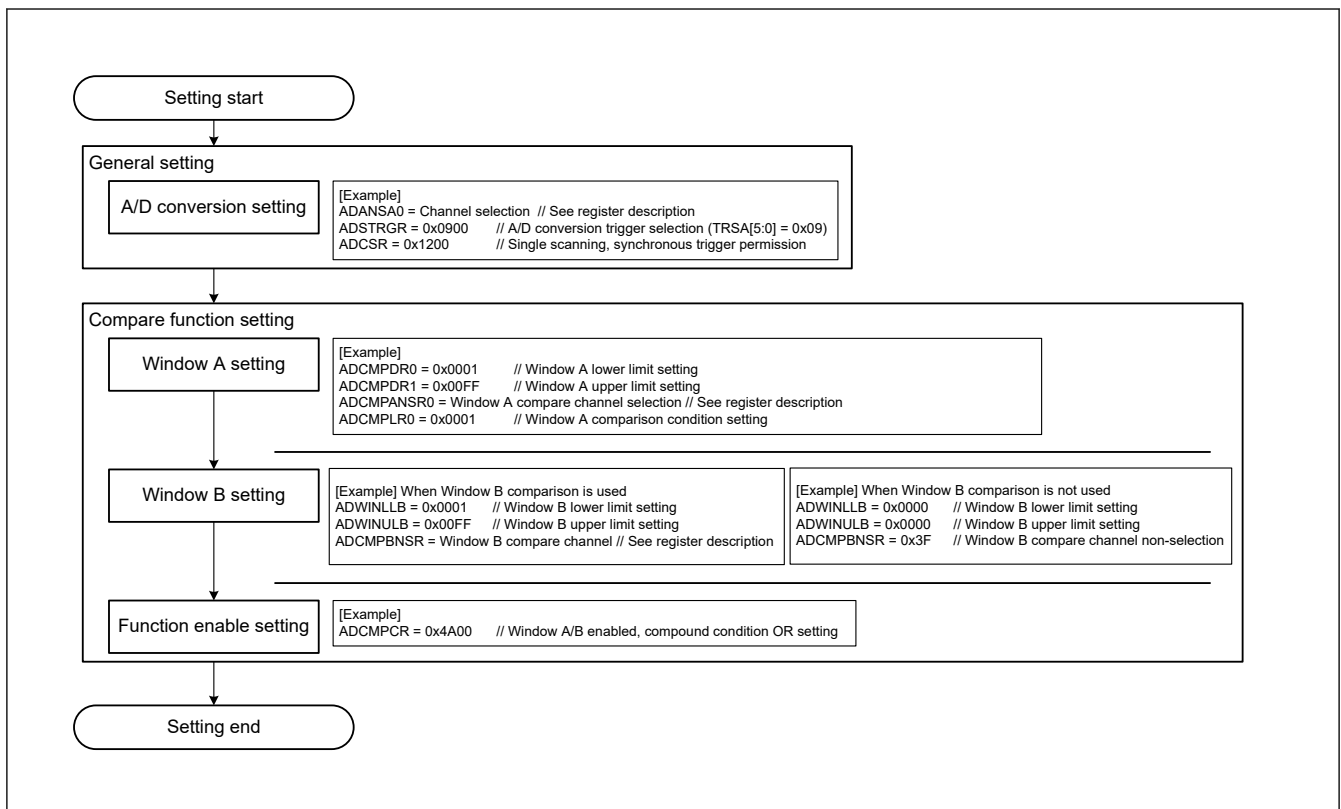

If more than one channel is selected for window A, and even when one channel in window A meets the comparison condition, the comparison result of window A is met. When using this function, perform A/D conversion in single scan mode.

Any channels from analog input and internal reference voltage are selectable for window A.

One channel from analog input and internal reference voltage is selectable for window B.

The following sequence is an example of how to set up and use the event output of the compare function:

1. Confirm that the value in the ADCSR.ADCS bits is 00b (single scan mode).
2. Select the channel for window A in the ADCMPANSR0/1 and ADCMPANSER registers. Set the window comparison conditions in the ADCMPLR0/1 and ADCMPLER registers. Set the upper-side and lower-side reference values in the ADCMPDR0/1 registers.
3. Select the channel and comparison conditions for Window B in the ADCMPBNSR register, and set the upper and lower reference values in the ADWINULB and ADWINLLB registers.
4. Set the composite conditions for window A/B, window A/B operation enable, and interrupt output enable in the ADCMPCR register.

**Figure 35.24** Setting example when using the event output of the compare function

For event output usage when using only window A for the compare function, note the following:

- Enable both Window A and Window B (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition of Window A and Window B to “OR condition” (ADCMPCR.CMPAB[1:0] = 00b)
- Set the compared channel of Window B to “No selection” (ADCMPBNSR.CMPCHB[5:0] = 0x3F)
- Set the compare condition of Window B to “0 < results < 0 always means mismatch”. (ADCMPCR.WCMPE = 1, ADWINLLB[15:0] = ADWINULB[15:0] = 0x0000, and ADCMPBNSR.CMPLB = 1)

Figure 35.25 shows the event output operation example of compare function.

A scan end event (ADC120\_ADI) is output with the same timing as single scan completion. A match or mismatch event (ADC120\_WCMPM/ADC120\_WCMPUM) is output with 1 PCLKA cycle delay depending on the ADCMPCR.CMPAB[1:0] settings.

Note: The match and mismatch events are exclusive, so both events are never output simultaneously.

**Figure 35.25 Example operation of the compare function event output, when the analog inputs (channel x and y) are compared**

Note: Event output of compare function outputs match/mismatch from the comparison results of Window A and Window B, based on the ADCMPCR.CMPAB[1:0] settings.

Note: The comparison result of Window A is the logical addition of the comparison results of the comparison target channels of Window A. The comparison results of Window A and Window B are updated by each A/D conversion, and are kept even when single scan ends. Set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0 to clear the comparison results to 0.

### 35.3.5.3 Restrictions on Compare Function

The following constraints apply for the compare function:

- The compare function cannot be used together with the self-diagnosis function or double-trigger mode. (The compare function is not available for ADRD, ADDBLDR, ADDBLDRA, and ADDBLDRB.)
- Specify single scan mode when using match/mismatch event outputs.
- When the internal reference voltage is selected for Window A, Window B operations are prohibited.
- When the internal reference voltage is selected for Window B, Window A operations are prohibited.
- Setting the same channel for Window A and Window B is prohibited.
- Set the reference voltage values so that the high-potential reference voltage value is equal to or larger than the low potential reference voltage value.

### 35.3.6 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger, a synchronous trigger (ELC), or an asynchronous trigger (ADTRG0). After the start-of-scanning-delay time ( $t_D$ ) has elapsed, processing for disconnection detection assistance, and processing of conversion for self-diagnosis all proceed, followed by processing for A/D conversion.

Figure 35.26 shows the scan conversion timing, in which scan conversion is activated by a software trigger or a synchronous trigger (ELC). Figure 35.27 shows the scan conversion timing, in which scan conversion is activated by an asynchronous trigger (ADTRG0). The scan conversion time ( $t_{SCAN}$ ) includes the start-of-scanning-delay time ( $t_D$ ), disconnection detection assistance processing time ( $t_{DIS}$ )<sup>\*1</sup>, self-diagnosis A/D conversion processing time ( $t_{DIAG}$  and  $t_{DSD}$ )<sup>\*2</sup>, A/D conversion processing time ( $t_{CONV}$ ), and end-of-scanning-delay time ( $t_{ED}$ ).

The A/D conversion processing time ( $t_{CONV}$ ) consists of input sampling time ( $t_{SPL}$ ) and time for conversion by successive approximation ( $t_{SAM}$ ). The sampling time ( $t_{SPL}$ ) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTRn register.

The time for conversion by successive approximation ( $t_{SAM}$ ) is the following

- 13 ADCLK states with 12-bit accuracy selected.
- 11 ADCLK states with 10-bit accuracy selected.
- 9 ADCLK states with 8-bit accuracy selected.

Table 35.23 shows the time for conversion by successive approximation ( $t_{SAM}$ ).

The scan conversion time ( $t_{SCAN}$ ) in single scan mode for which the number of selected channels is  $n$  can be determined as follows:

$$t_{SCAN} = t_D + (t_{DIS} \times n) + t_{DIAG} + t_{ED} + (t_{CONV} \times n) \text{ } ^{*3}$$

The scan conversion time for the first cycle in continuous scan mode is  $t_{SCAN}$  for single scan minus  $t_{ED}$ . The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed in the following:

$$(t_{DIS} \times n) + t_{DIAG} + t_{DSD} + (t_{CONV} \times n) \text{ } ^{*3}$$

Note 1. When disconnection detection assistance is not selected,  $t_{DIS} = 0$ .

Note 2. When the self-diagnosis function is not used,  $t_{DIAG} = 0$ ,  $t_{DSD} = 0$ .

Note 3. When input sampling times ( $t_{SPL}$ ) of all selected channels are the same, this element equals  $t_{CONV} \times n$ . If each channel has a different sampling time, this element equals that of  $t_{SPL}$  and  $t_{SAM}$  set to each selected channel.

Table 35.23 shows the times for conversion during scanning.

**Table 35.23 Conversion times during scanning (in numbers of cycles of ADCLK and PCLKA)**

| Item                                                                                                     |                                                                                    |                                                                                                                       | Symbol     | Type/Conditions                                      |                                                                                            |                  | Unit   |

| Scan end processing time <sup>*1</sup>                                                                   |                                                                                    |                                                                                                                       | $t_{ED}$   | 1 PCLKA + 3 ADCLK<br>2 PCLKA + 3 ADCLK <sup>*5</sup> |                                                                                            |                  |        |

Note 1. See [Figure 35.26](#) and [Figure 35.27](#) for an illustration of times  $t_D$ ,  $t_{SPLSH}$ ,  $t_{DIAG}$ ,  $t_{CONV}$ , and  $t_{ED}$ .

Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.

Note 3. The sampling time setting must satisfy the electrical characteristics.

Note 4. This does not include the time consumed in the path from timer output to trigger input.

Note 5. If ADCLK is faster than PCLKA (PCLKA to ADCLK frequency ratio = 1:2 or 1:4), the scan end processing time changes.

Figure 35.27 Scan conversion timing when activated by an asynchronous trigger input (ADTRG0)

### 35.3.7 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADOCDR) to 0x0000 when the A/D data registers are read by the CPU or DTC or DMAC.

This function enables detection of update failures of the A/D data registers (ADDRy, ADDR, ADDBLDR, ADDBLDRA, ADDBLDRB, ADOCDR). This section describes examples in which the function to automatically clear the ADDRy register is enabled and disabled.

- If the ADCER.ACE bit is 0 (automatic clearing is disabled) and for some reason, if the A/D conversion result (0x0222) is not written to the ADDRy register, the ADDRy value retains the old data (0x0111). In addition, if this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, the old data (0x0111) can be saved in the general-purpose register. When checking whether there is an update failure, it is necessary to frequently save the old data in SRAM or in a general-purpose register.
- If the ADCER.ACE bit is 1 (automatic clearing is enabled), when ADDRy = 0x0111 is read by the CPU or DTC or DMAC, ADDRy is automatically set to 0x0000. Next, if the A/D conversion result of 0x0222 cannot be transferred to ADDRy for some reason, the cleared data (0x0000) remains as the ADDRy value. If this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, 0x0000 is saved in the general-purpose register. Occurrence of an ADDRy update failure can be determined by checking that the read data value is 0x0000.

### 35.3.8 A/D-Converted Value Addition/Average Mode

A/D-converted value addition/average mode can be used when A/D conversion of the analog input of the selected channels, the internal reference voltage is selected.

In A/D-converted value addition mode, the same channel is A/D-converted 1, 2, 3, 4, or 16 consecutive times, and the sum of the converted values is stored in the data register. The conversion count of the addition function can be set to 16 only when 12-bit accuracy is selected. In A/D-converted value average mode, the same channel is A/D-converted 2 or 4 consecutive times, and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average function can be used when A/D conversion of the analog inputs of the selected channels or A/D conversion of the internal reference voltage is selected. The A/D-converted value addition/average function can also be used for channels for which the double-trigger function is selected.

The addition function for self-diagnosis is not provided.

### 35.3.9 Disconnection Detection Assist Function

The ADC12 incorporates a function to fix the charge for sampling capacitance to the specified state VREFH0 or VREFL0 before the start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

Figure 35.28 shows the A/D conversion operation when the disconnection detection assist function is used. Figure 35.29 shows an example of disconnection detection when precharge is selected. Figure 35.30 shows an example of disconnection detection when discharge is selected.

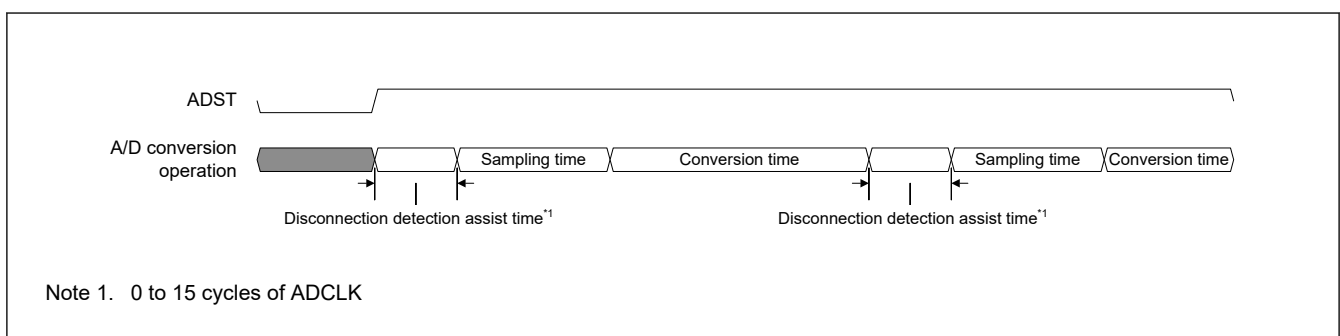

Figure 35.28 Operation of A/D conversion when disconnection detection assist function is used

**Figure 35.29** Example of disconnection detection when precharge is selected

**Figure 35.30 Example of disconnection detection when discharge is selected**

### 35.3.10 Starting A/D Conversion with an Asynchronous Trigger

A/D conversion can be started by the input of an asynchronous trigger. To start A/D conversion by an asynchronous trigger, set the pin function in the  $PmnPFS$  register, set the A/D Conversion Start Trigger Select bits ( $ADSTRGR.TRSA[5:0]$ ) to  $0x00$ , then input a high-level signal to the asynchronous trigger ( $ADTRG0$  pin). Finally, set both the  $ADCSR.TRGE$  and  $ADCSR.EXTRG$  bits to 1. **Figure 35.31** shows timing of the asynchronous trigger input.

An asynchronous trigger cannot be selected in the A/D conversion start trigger for group B used in group scan mode. For details on setting the pin function, see [section 19, I/O Ports](#).

**Figure 35.31 Asynchronous trigger input timing**

### 35.3.11 Starting A/D Conversion with a Synchronous Trigger from a Peripheral Module

A/D conversion can be started by a synchronous trigger (ELC). To do this, set the ADCSR.TRGE bit to 1 and the ADCSR.EXTRG bit to 0, and select the relevant sources in the ADSTRGR.TRSA[5:0] bits and ADSTRGR.TRSB[5:0] bits.

### 35.3.12 Using Data Buffers

This IP is provided with a ring buffer function consisting of 16 A/D data buffers. This function sequentially stores A/D conversion results other than self-diagnosis result (including addition/average results) in data buffers (ADBUF<sub>n</sub>, n = 0 to 15).

Each conversion result is stored at the timing when the A/D conversion result is stored in the data register, and most recent 16 conversion result data are retained.

The figure-below shows the schematic of data buffers, pointer, and overflow flag operations. When the BUFEN bit is set to 1, the A/D conversion result is transferred at each end of A/D conversion. The pointer indicates the number of data buffer to which the next transferred data is to be written. When data is written to up to buffer 15, the pointer is reset to 0000b and the overflow flag is set to 1. Subsequently transferred data overwrites the previously written data.

The overflow flag is reset to the initial value by writing 0x00 to the ADBUFPTR register.

Figure 35.32 Data Buffers, Pointer, and Overflow Flag Operations

### 35.4 Interrupt Sources and DTC, DMAC Transfer Requests

#### 35.4.1 Interrupt Requests

The ADC12 can send scan end interrupt requests ADC120\_ADI and ADC120\_GBADI to the CPU. The ADC12 also generates the ADC120\_CMPAI/ADC120\_CMPBI interrupt for the CPU in response to matches with a condition for comparison.

An ADC120\_ADI interrupt is always generated. An ADC120\_GBADI interrupt can be generated by setting the ADCSR.GBADI bit to 1. Similarly, ADC120\_CMPAI and ADC120\_CMPBI interrupts can be generated by setting the ADCMPCR.CMPAIE and ADCMPCR.CMPBIE bit to 1.

In addition, the DTC or DMAC can be started when an ADC120\_ADI or an ADC120\_GBADI interrupt is generated. Using an ADC120\_ADI or ADC120\_GBADI interrupt to activate the DTC or DMAC to read the converted data enables continuous conversion without a burden on software.

Table 35.24 describes the interrupt sources and ELC events available for the ADC12.

Table 35.24 The interrupt source and ELC event of ADC12 (1 of 2)

| Operation            |                     |                             | Interrupt request or ELC event | Interrupt request | DTC or DMAC activation | ELC event request | Function                                                                           |

Note: ✓ available  
—: unavailable

For details on DTC settings, see [section 17, Data Transfer Controller \(DTC\)](#).

## 35.5 Event Link Function

### 35.5.1 Event Output to the ELC

The ELC uses the ADC120\_ADI interrupt request signal as an event signal ADC120\_ADI, enabling link operation for the preset module. The ADC120\_GBADI interrupt and ADC120\_CMPAI/ADC120\_CMPBI interrupts cannot be used as an event signal. For details, see [Table 35.24](#).

An event signal can be output regardless of the settings of the corresponding interrupt request enable bits. For the scan end event(ADC120\_ADI), a high-level pulse for one PCLKA cycle is output at the same output timing as the interrupt output (ADC120\_ADI) shown in [Table 35.24](#). For a compare function match (ADC120\_WCMPPM) and mismatch event (ADC120\_WCMPUM) to the ELC, a high-level pulse for one PCLKA cycle is output at the timing delayed by one cycle (PCLKA) from the interrupt output (ADC120\_ADI) shown in [Table 35.24](#).

To use compare function match (ADC120\_WCMPPM) or mismatch event (ADC120\_WCMPUM) to the ELC, specify single-scan mode.

### 35.5.2 ADC12 Operation through an Event from the ELC

The ADC12 can start A/D conversion by the preset event specified in the ELSRn settings for the ELC as follows:

- Select the ELC\_AD00 signal in the ELC.ELSR8 register
- Select the ELC\_AD01 signal in the ELC.ELSR9 register

If an ELC event occurs during A/D conversion, the event is disabled.

## 35.6 Usage Notes

### 35.6.1 Constraints on Setting the Registers

Set each register while the ADCSR.ADST bit is 0.

### 35.6.2 Constraints on Reading the Data Registers

The following registers must be read in halfword units:

- A/D Data Registers
- A/D Data Duplexing Register
- A/D Data Duplexing Register A
- A/D Data Duplexing Register B
- A/D Internal Reference Voltage Register
- A/D Self-Diagnosis Data Register
- A/D Data Buffer Registers n (N = 0 to 15)

If a register is read twice in byte units, that is, the upper byte and lower byte are read separately, the A/D-converted value read initially might disagree with the A/D-converted value read subsequently. To prevent this, never read the data registers in byte units.

### 35.6.3 Constraints on Stopping A/D Conversion

#### (1) A/D Conversion Stop Procedure

To stop A/D conversion when an asynchronous trigger or a synchronous trigger is selected as the condition for starting A/D conversion, follow the procedure shown in [Figure 35.33](#).

**Figure 35.33** Procedures for clearing the ADCSR.ADST bit by software

To specify the following settings after performing the clear operation by software, provide a wait period for at least two ADCLK cycles.

- Enabling scan end interrupts
- Enabling scan end events for the event link controller
- Starting A/D conversion by software
- Enabling trigger input

## (2) Notes on Modes and Status Bits

If necessary, individually initialize or set again the voltage status for self-diagnosis, the judgment of the even number or odd number specified for double-trigger mode, and the monitor flags of the compare function.

- To set again the voltage status for self-diagnosis, set the ADCER.DIAGLD bit to 1 and then set a desired value in the ADCER.DIAGVAL[1:0] bits.
- If the setting of the ADCSR.DBLE bit is changed from 0 to 1, the double-trigger mode operation starts from the first scanning.
- To initialize the monitor flags of the compare function (MONCMPA, MONCMPB, and MONCOMB), set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0.

### 35.6.4 A/D Conversion Restart and Termination Timing

A maximum of 6 ADCLK cycles is required for the idle analog unit of the ADC12 to restart on setting the ADCSR.ADST bit to 1. A maximum of 2 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0.

### 35.6.5 Constraints on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data. This occurs when the CPU does not complete the reading of the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

### 35.6.6 Settings for the Module-Stop Function

The Module Stop Control Register can enable or disable ADC12 operation. The ADC12 is initially stopped after a reset. The registers become accessible on release from the module-stop state. After release from the module-stop state, wait for at least 1  $\mu$ s before starting A/D conversion. For details, see [section 10, Low Power Modes](#).

### 35.6.7 Notes on Entering the Low-Power States

Before entering the module-stop state or Software Standby mode, be sure to stop A/D conversion. Set the ADCSR.ADST bit in ADCSR to 0 and secure certain period until the analog unit of the ADC12 stops. Follow the procedure shown in [Figure 35.33](#) to clear the ADCSR.ADST bit with software. Then, wait for 2 clock cycles of ADCLK before entering the module-stop state or Software Standby mode.

### 35.6.8 Error in Absolute Accuracy When Disconnection Detection Assistance Is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the ADC12. This error arises because an erroneous voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull-down resistor ( $R_p$ ) and the resistance of the signal source ( $R_s$ ). This error in absolute accuracy is calculated from the following formula:

$$\text{Maximum error in absolute accuracy (LSB)} = (2^{\text{Resolution}} - 1) \times R_s / (R_s + R_p)$$

Only use disconnection detection assistance after thorough evaluation.

### 35.6.9 Constraints on Operating Modes and Status Bits

Initialize or set again individually, if necessary, the voltage values in self-diagnosis, the value of the first scan or second scan in double trigger mode, the data buffer pointer, and status monitor in the compare function.

- Select the voltage values in self-diagnosis (ADCER.DIAGVAL[1:0]) after setting ADCER.DIAGLD to 1.
- Double-trigger mode operates as the first scan after setting ADCSR.DBLE from 0 to 1.
- The status monitor bits (MONCMPA, MONCMPB, MONCOMB) in the compare function are initialized after setting ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

### 35.6.10 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or be placed near each other. If these rules are not followed, noise can occur on analog signals and A/D conversion accuracy is affected. The analog input pins, reference power supply pin (VREFH0), reference ground pin (VREFL0), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0). The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

### 35.6.11 Constraints on Noise Prevention

To prevent the analog input pins from being destroyed by abnormal voltage such as excessive surge, insert a capacitor between AVCC0 and AVSS0 and between VREFH0 and VREFL0. Additionally, connect a protection circuit to protect the analog input pins as shown in [Figure 35.34](#).

**Figure 35.34** Example protection circuit for analog inputs

### 35.6.12 Port Settings When Using the ADC12 Input

When using the high-precision channels, do not use PORT0 as digital output ports. Renesas recommends that you do not use the digital output that is also used as the AD analog input if normal-precision channel is used. If the digital output that is also used as the AD analog input is used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

### 35.6.13 Notes on Canceling Software Standby Mode

After software standby mode is canceled, wait at least 1  $\mu$ s after the stabilization time for the oscillator elapses and before starting A/D conversion. For details, see [section 10, Low Power Modes](#)

### 35.6.14 Calculation for Sampling Time

The sampling time can be easily estimated by the following figure and formula. This is the time to reach the voltage within 1/4 LSB.

$$t_{SPL} = (R_{EXT} + R_{AD}) \times (C_{EXT} + C_{AD}) \times \ln(C_{AD} / (C_{EXT} + C_{AD}) \times 2^{N+2})$$

$R_{EXT}$  shows external signal source impedance

$C_{EXT}$  shows external capacitance (pin capacitance\*1 + PCB parasitic capacitance)

$N = 12, 10$  or  $8$  (conversion resolution)

$C_{AD} = 5$  pF (internal capacitance)

$R_{AD} = 1.0$  k $\Omega$  (internal resistance, case of high-speed channels)

$R_{AD} = 2.0$  k $\Omega$  (internal resistance, case of normal-speed channels)

Note 1. Typical value of analog input pin is 5 pF

For example, if  $R_{EXT}$  is 1 k $\Omega$ ,  $C_{EXT}$  is 10 pF and  $N$  is 12 bits,  $t_{SPL}$  of high-speed channel is 258 ns.

This formula simplifies the general use case. This formula is not guaranteed and should be used only for estimation.

## 36. 12-Bit D/A Converter (DAC12)

### 36.1 Overview

The MCU provides a 12-bit D/A Converter (DAC12) with an output amplifier. [Table 36.1](#) lists the DAC12 specifications, [Figure 36.1](#) shows a block diagram, and [Table 36.2](#) lists the I/O pins.

**Table 36.1 DAC12 specifications**

| Parameter                                     | Specifications                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Resolution                                    | 12 bits                                                                                                                                                                                                                                                                                                                                                                                                                 |

## 36.2 Register Descriptions

### 36.2.1 DADRn : D/A Data Register n (n = 0)

Base address: DAC12 = 0x4017\_1000

Offset address: 0x00

Bit position: 15 0

Bit field:

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

DADRn register is 16-bit read/write registers that store data for D/A conversion. When an analog output is enabled, the values in DADRn are converted and output to the analog output pins.

12-bit data can be formatted as left- or right-justified in the DADPR.DPSEL bit setting. In right-justified format (DADPR.DPSEL = 0), the lower 12 bits, [11:0], are valid. In left-justified format (DADPR.DPSEL = 1), the upper 12 bits, [15:4], are valid.

### 36.2.2 DACR : D/A Control Register

Base address: DAC12 = 0x4017\_1000

Offset address: 0x04

Bit position: 7 6 5 4 3 2 1 0

Bit field:

Value after reset: 0 0 0 1 1 1 1 1

| Bit | Symbol            | Function                                                                                                                                               | R/W |
|-----|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 4:0 | —                 | These bits are read as 1. The write value should be 1.                                                                                                 | R/W |
| 5   | DAE <sup>*1</sup> | D/A Enable<br>0: Control D/A conversion of channels 0 and 1 individually<br>1: Control D/A conversion of channels 0 and 1 collectively                 | R/W |
| 6   | DAOE0             | D/A Output Enable 0<br>0: Disable D/A conversion and analog output of channel 0 (DA0)<br>1: Enable D/A conversion and analog output of channel 0 (DA0) | R/W |
| 7   | —                 | This bit is read as 0. The write value should be 0.                                                                                                    | R/W |

Note 1. This bit controls D/A conversion and analog output in combination with the DAOEi bit (i = 0), which controls the output of the conversion results. For details, see [Table 36.3](#)

**Table 36.3 D/A conversion controls**

| DAE | DAOE0 | Description                                                                                                                                        |
|-----|-------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | 0     | Disable D/A conversion and analog output pins (DA0) <sup>*1</sup>                                                                                  |
|     | 1     | <ul style="list-style-type: none"> <li>Enable D/A conversion of channel 0</li> <li>Enable analog output of channel 0 (DA0)<sup>*1</sup></li> </ul> |
| 1   | x     | <ul style="list-style-type: none"> <li>Enable D/A conversion of channels 0</li> <li>Collective enable analog output of channels 0 (DA0)</li> </ul> |

Note: x: Don't care

Note 1. When analog output is disabled, the analog output signal is placed in the Hi-Z state.

Only set this register while the ADC12 is halted when the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled). Only set DACR while the ADCSR.ADST bit is 0 and after selecting the software trigger, for the ADC12 trigger to securely stop the ADC12.

**DAE bit (D/A Enable)**

The DAE bit controls D/A conversion, amplifier operation, and analog output in combination with the DAOEi bit (i = 0) and the DAAMPCR.DAAMPi bit (i = 0). See Table 36.4.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the ADCSR.ADST bit of the ADC12 to 0. Then, select the software trigger for the ADC12 trigger to securely stop the ADC12.

**DAOE0 bit (D/A Output Enable 0 )**

The DAOE0 bit controls D/A conversion, amplifier operation, and analog output in combination with the DAE bit and DAAMPCR.DAAMPi bit (i = 0). See Table 36.4.

When both the DAOE0 bit and DAE bit are 0, D/A conversion of channel i (i = 0) is not processed, and no conversion result is output.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOE0 bit while the ADCSR.ADST bit of the ADC12 is set to 0. Then, select the software trigger for the ADC12 trigger to securely stop the ADC12.

The event link function can be used to set the DAOE0 bit to 1. The DAOE0 bit is set to 1 when the event specified in the ELSR12 register of the ELC (ELC\_DA0 event) occurs, and output of the D/A conversion results starts.

**Table 36.4 D/A conversion and analog output control**

| DACR |       | DAAMPCR | Channel i operation | Amplifier operation of channel i | Analog output of channel i |
|------|-------|---------|---------------------|----------------------------------|----------------------------|
| DAE  | DAOEi | DAAMPi  |                     |                                  |                            |
| 0    | 0     | 0       | Stop                | Stop                             | Hi-Z                       |
|      |       | 1       | Stop                | Stop                             | Hi-Z                       |
|      | 1     | 0       | Run                 | Stop                             | Amplifier-through          |
|      |       | 1       | Run                 | Run                              | Amplifier output           |
| 1    | 0     | 0       | Run                 | Stop                             | Amplifier-through          |
|      |       | 1       | Run                 | Run                              | Amplifier output           |
|      | 1     | 0       | Run                 | Stop                             | Amplifier-through          |
|      |       | 1       | Run                 | Run                              | Amplifier output           |

Note: i = 0

| Bit | Symbol | Function                                                                                                                                                                                                                                                         | R/W |
|-----|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 6:0 | —      | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                           | R/W |
| 7   | DAADST | D/A A/D Synchronous Conversion<br>0: Do not synchronize DAC12 with ADC12 operation (disable interference reduction between D/A and A/D conversion).<br>1: Synchronize DAC12 with ADC12 operation (enable interference reduction between D/A and A/D conversion). | R/W |

To minimize interference between D/A and A/D conversion, the DAADSCR register enables synchronization of the start timing of D/A conversion with the ADC12 synchronous D/A conversion enable input signal.

Only set this register while the ADC12 is halted, that is, while the ADCSR.ADST bit is 0 after selecting the software trigger as the ADC12 trigger.

Select the target ADC12 unit before setting the DAADST bit to 1. Set DAADUSR[0] bit to 1 to select unit 0.

#### DAADST bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the register value to be converted into analog data at any time. Setting the DAADST bit to 1 allows synchronization of D/A conversion with the synchronous D/A conversion enable input signal from the ADC12. With this bit set, D/A conversion does not start until the ADC12 completes A/D conversion, even when the register is changed.

Set this bit while the ADCSR.ADST bit is set to 0. Then, select the software trigger for the ADC12 trigger to securely stop the ADC12. Set the DAADUSR.AMADSEL0 bit to 1 before setting the DAADST bit to 1.

The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR12 register of the ELC.

### 36.2.5 DAAMPCR : D/A Output Amplifier Control Register

Base address: DAC12 = 0x4017\_1000

Offset address: 0x08

|                    |   |            |   |   |   |   |   |   |
|--------------------|---|------------|---|---|---|---|---|---|
| Bit position:      | 7 | 6          | 5 | 4 | 3 | 2 | 1 | 0 |
| Bit field:         | — | DAAM<br>P0 | — | — | — | — | — | — |
| Value after reset: | 0 | 0          | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function                                                                                             | R/W |
|-----|--------|------------------------------------------------------------------------------------------------------|-----|
| 5:0 | —      | These bits are read as 0. The write value should be 0.                                               | R/W |
| 6   | DAAMP0 | Amplifier Control 0<br>0: Do not use channel 0 output amplifier<br>1: Use channel 0 output amplifier | R/W |
| 7   | —      | This bit is read as 0. The write value should be 0.                                                  | R/W |

The DAAMPCR register selects D/A output with or without using the amplifier.

**DAAMP0 bit (Amplifier Control 0)**

When the DAAMP0 bit is 0, analog values are output for D/A output of channel 0 without using the amplifier. When the DAAMP0 bit is 1, analog values are output for D/A output of channel 0 through the amplifier.

When the DACR.DAOE0 bit is 0, the amplifier is not used regardless of the setting of the DAAMP0 bit. See [Table 36.4](#) for details.

**36.2.6 DAASWCR : D/A Amplifier Stabilization Wait Control Register**

Base address: DAC12 = 0x4017\_1000

Offset address: 0x1C

|                    |   |        |   |   |   |   |   |   |
|--------------------|---|--------|---|---|---|---|---|---|
| Bit position:      | 7 | 6      | 5 | 4 | 3 | 2 | 1 | 0 |
| Bit field:         | — | DAASW0 | — | — | — | — | — | — |
| Value after reset: | 0 | 0      | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Function                                                                                                                                                      | R/W |
|-----|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 5:0 | —      | These bits are read as 0. The write value should be 0.                                                                                                        | R/W |
| 6   | DAASW0 | D/A Amplifier Stabilization Wait 0<br>0: Amplifier stabilization wait off (output) for channel 0<br>1: Amplifier stabilization wait on (high-Z) for channel 0 | R/W |
| 7   | —      | This bit is read as 0. The write value should be 0.                                                                                                           | R/W |

The DAASWCR register controls D/A output with the output amplifier. This register is used in the initialization procedure to wait for stabilization of the D/A output amplifier. Each bit in DAASWCR should be set to 1 when the DACR.DAOE<sub>i</sub> (i = 0) bit is 0. See [section 36.6.5. Initialization Procedure with the Output Amplifier](#).

**DAASW0 bit (D/A Amplifier Stabilization Wait 0)**

Set the DAASW0 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 0 output amplifier. When DAASW0 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 0. When the DAASW0 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 0 is output through the output amplifier.

**36.2.7 DAADUSR : D/A A/D Synchronous Unit Select Register**

Base address: DAC12 = 0x4017\_1000

Offset address: 0x10C0

|                    |   |   |   |   |   |   |   |          |
|--------------------|---|---|---|---|---|---|---|----------|
| Bit position:      | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0        |
| Bit field:         | — | — | — | — | — | — | — | AMADSELO |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0        |

| Bit | Symbol   | Function                                                         | R/W |
|-----|----------|------------------------------------------------------------------|-----|
| 0   | AMADSELO | A/D Unit 0 Select<br>0: Do not select unit 0<br>1: Select unit 0 | R/W |
| 1   | —        | This bit is read as 0. The write value should be 0.              | R/W |
| 7:2 | —        | These bits are read as 0. The write value should be 0.           | R/W |

The DAADUSR register selects the target ADC12 unit for D/A and A/D synchronous conversions. Set the AMADSELO bit to 1 to select unit 0 as the target synchronous unit for the MCU. When setting the DAADSCR.DAADST bit to 1 for synchronous conversions, select the target unit in this register in advance.

Only set the DAADUSR register while the ADCSR.ADST bit of the ADC12 is set to 0 and the DAADSCR.DAADST bit is set to 0.

### 36.3 Operation

The DAC12 includes D/A conversion circuits for one channel. When the DAOEn bit (n = 0) in DACR is set to 1, DAC12 is enabled and the conversion result is output.

The following example shows D/A conversion on channel 0. Figure 36.2 shows the timing of this operation.

To process D/A conversion on channel 0:

1. Set the data for D/A conversion in the DADR0 register and the data format in the DADPR.DPSEL bit.
2. Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time  $t_{\text{DCONV}}$  elapses. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is set to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Setting in DADR0}}{4096} \times \text{VREFH}$$

3. To start conversion again, write another value to DADR0. The conversion result is output after the conversion time  $t_{\text{DCONV}}$  elapses.

When the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled), a maximum of one A/D conversion time is required for D/A conversion to start. When ADCLK is faster than the peripheral clock, a longer time might be required.

4. To disable analog output, set the DAOE0 bit to 0.

Figure 36.2 Example of DAC12 operation

#### 36.3.1 Reducing Interference between D/A and A/D Conversion

When D/A conversion starts, the DAC12 generates inrush current. Because the DAC12 and ADC12 share the same analog power supply, the generated inrush current can interfere with ADC12 operation.

While the DAADSCR.DAADST bit is 1, D/A conversion does not start immediately on updating the DADRm register. Instead:

- If the DADRm register data is modified while the ADC12 is halted, D/A conversion starts in 1 PCLKA cycle.
- If the DADRm register data is modified while the ADC12 is performing a 12-bit A/D conversion, D/A conversion starts on A/D conversion completion. Therefore, it takes up to one A/D conversion time period for the DADRm register data update to be reflected as the D/A conversion circuit output. Until the D/A conversion completes, the DADRm register value does not correspond to the analog output value.

When the DAADSCR.DAADST bit is 1, it is not possible to check through software whether the register value was D/A-converted.

The following sequence provides an example of D/A conversion, in which the DAC12 is synchronized with the ADC12. [Figure 36.3](#) shows the timing of this operation.

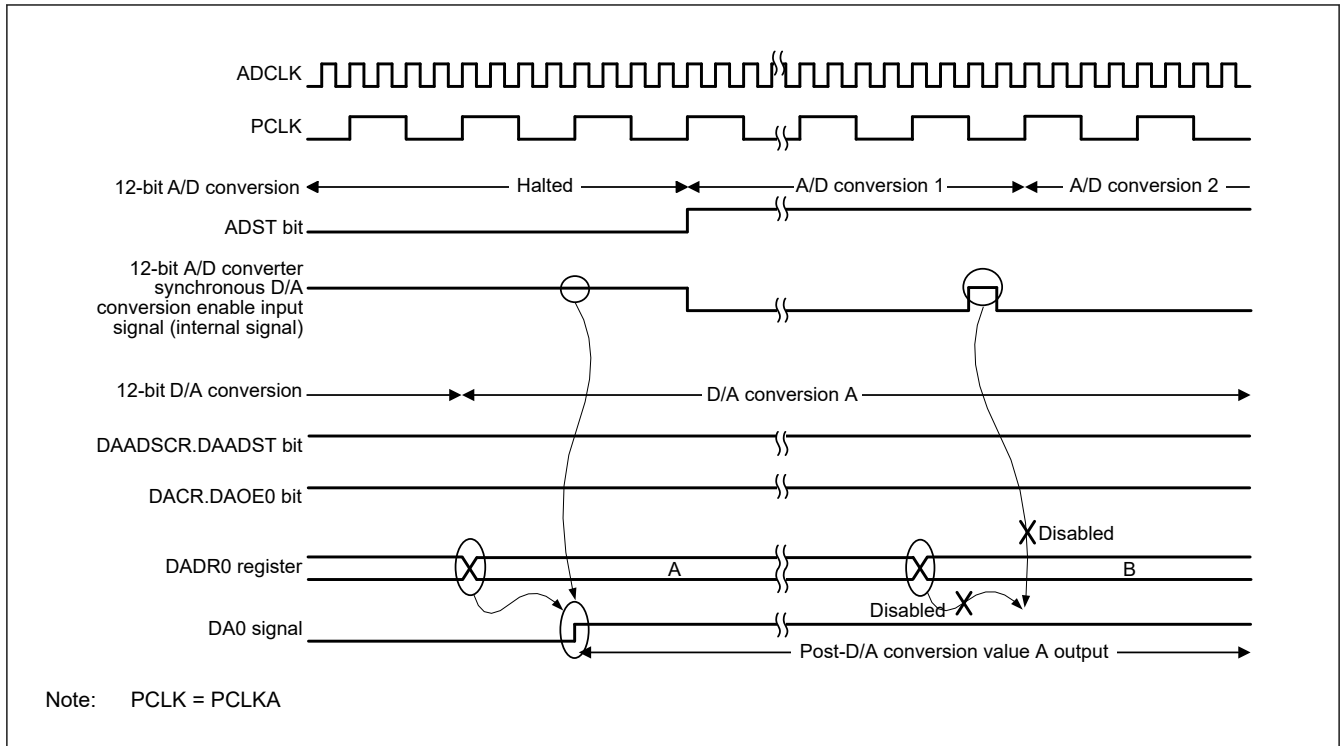

To perform D/A conversion in synchronization with the ADC12:

1. Confirm that the ADC12 is halted and set the DAADSCR.DAADST bit to 0.
2. Confirm that the ADC12 is halted and set the DAADUSR.AMAADSEL1 bit to 1.
3. Confirm that the ADC12 is halted and set the DAADSCR.DAADST bit to 1.
4. Confirm that the ADC12 (unit 1) is halted and set the DACR.DAOE0 bit to 1.
5. Set the DADR0 register. If ADCLK is faster than the peripheral clock, D/A conversion might be delayed for longer than one A/D conversion time.
  - If the ADC12 is halted (ADCSR.ADST = 0) when the DADR0 register is modified, D/A conversion starts in 1 PCLKA cycle.
  - If the 12-bit A/D conversion is in progress (ADCSR.ADST = 1) when the DADR0 register is modified, D/A conversion starts on A/D conversion completion. If the DADR0 register is modified twice during A/D conversion, the first update might not be converted.

**Figure 36.3 Example conversion when DAC12 is synchronized with ADC12**

When ADCLK is faster than PCLKA, the DAC12 might not be able to capture the synchronous D/A conversion enable input signal from the ADC12 during the 1 ADCLK cycle that is output between A/D conversion 1 and A/D conversion 2, as shown in [Figure 36.4](#). In this case, post-D/A conversion value A is continuously output as the DA0 signal.

**Figure 36.4** Example when the DAC12 cannot capture the synchronous D/A conversion enable input signal from the ADC12

## 36.4 Event Link Operation Setting Procedure

This section describes the procedures used in event link operation.

### 36.4.1 DA0 Event Link Operation Setting Procedure

To set up DA0 event link operation:

1. Set the DADPR.DPSEL bit and the data for D/A conversion in the DADR0 register.
2. Set the ELC\_DA0 event signal to be linked to each peripheral module in the ELSR12 register.
3. Set the ELCR.ELCON bit to 1. This enables event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion starts on channel 0.
5. Set the ELSR12 register to 0x0000 to stop event link operation of DAC12 channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

## 36.5 Usage Notes on Event Link Operation

- When the event link function is used, do not use the amplifier output function.
- When the event link function is used, set the DACR.DAE bit to 0.
- When the event specified for the ELC\_DA0 event signal is generated while a write to the DACR.DAOE0 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 to reduce interference between D/A and A/D conversions.

## 36.6 Usage Notes

### 36.6.1 Settings for the Module-Stop Function

DAC12 operation can be disabled or enabled using the Module Stop Control Register. The DAC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

### 36.6.2 DAC12 Operation in the Module-Stop State

When the MCU enters the module-stop state with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in the module-stop state, disable D/A conversion by setting the DACR.DAOE0, and DAE bits to 0.

### 36.6.3 DAC12 Operation in Software Standby Mode

When the MCU enters Software Standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in Software Standby mode, disable D/A conversion by setting the DACR.DAOE0, and DAE bits to 0.

### 36.6.4 Constraint on Entering Deep Software Standby Mode

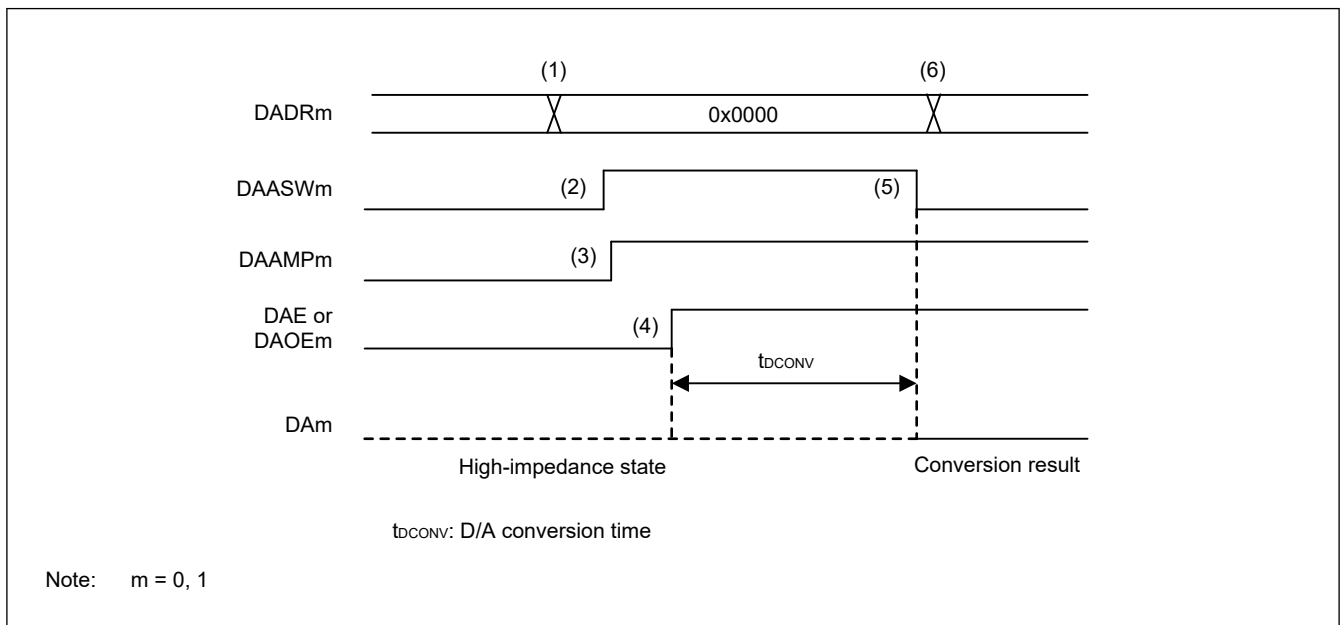

When the MCU enters Deep Software Standby mode with D/A conversion enabled, the outputs of the DAC12 are placed in a high impedance state.

### 36.6.5 Initialization Procedure with the Output Amplifier

Use the following initialization procedures with the output amplifier. The example shows the case for channel 0.

To initialize the DAC12 with the output amplifier:

1. Write 0x0000 to the DADR0 register.
2. Set the DAASWCR.DAASW0 bit to 1.
3. Set the DAAMPCR.DAAMP0 bit to 1.
4. Set the DACR.DAOE0 bit to 1 to start operation of the amplifier.
5. Clear the DAASWCR.DAASW0 bit to 0 after waiting for the duration of D/A conversion time  $t_{DCONV}$ .
6. Write the value to be converted in the DADR0 register.

**Figure 36.5 Example of the initial flow with the output amplifier in DAC12**

While the amplifier is running, clearing the DACR.DAE and DACR.DAOE0 bits to 0 allows the amplifier to stop operation. To use the amplifier again, repeat steps 1 to 6.

### 36.6.6 Constraint on Usage When Interference Reduction between D/A and A/D Conversion Is Enabled

When the DAADSCR.DAADST bit is 1, enabling interference reduction between D/A and A/D conversion, do not place the ADC12 in the module-stop state. Doing so can halt D/A conversion in addition to A/D conversion.

## 37. Data Operation Circuit (DOC)

### 37.1 Overview

The Data Operation Circuit (DOC) compares, adds, and subtracts 16-bit data. When a selected condition applies, 16-bit data is compared and an interrupt can be generated. [Table 37.1](#) lists the DOC specifications and [Figure 37.1](#) shows a block diagram.

**Table 37.1 DOC specifications**

| Item                                           | Description                                                                                                                                                                                                                                                                   |

| 5   | DOPCF               | DOC Flag<br>Indicates the result of an operation.                                                                                      | R   |
| 6   | DOPCFCL             | DOPCF Clear<br>0: Retain DOPCF flag state<br>1: Clear DOPCF flag                                                                       | R/W |
| 7   | —                   | These bits are read as 0. The write value should be 0.                                                                                 | R/W |

Note 1. Only valid when data comparison mode is selected.

### OMS[1:0] bits (Operating Mode Select)

The OMS[1:0] bits select the operating mode of the DOC.

### DCSEL bit (Detection Condition Select)

The DCSEL bit selects the detection condition in data comparison mode. This bit is only valid when data comparison mode is selected.

### DOPCF flag (DOC Flag)

The DOPCF flag indicates the result of an operation.

[Setting conditions]

- The result of data comparison matches the condition selected in the DCSEL bit
- A data addition result is greater than 0xFFFF
- A data subtraction result is less than 0x0000

[Clearing condition]

- Writing 1 to the DOPCFCL bit

### DOPCFCL bit (DOPCF Clear)

Setting the DOPCFCL bit to 1 clears the DOPCF flag. This bit is read as 0.

## 37.2.2 DODIR : DOC Data Input Register

Base address: DOC = 0x4010\_9000

Offset address: 0x02

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field:

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

| Bit  | Symbol | Function                                      | R/W |
|------|--------|-----------------------------------------------|-----|
| 15:0 | n/a    | It stores 16-bit data used in the operations. | R/W |

### 37.2.3 DODSR : DOC Data Setting Register

Base address: DOC = 0x4010\_9000

Offset address: 0x04

| Bit  | Symbol | Function                                                                                                                                                       | R/W |
|------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 15:0 | n/a    | It stores 16-bit data used as a reference in data comparison mode. This register also stores the results of operations in data addition and subtraction modes. | R/W |

## 37.3 Operation

### 37.3.1 Data Comparison Mode

Figure 37.2 shows an example operation in data comparison mode operation by the DOC. The following sequence is an example operation when DCSEL is set to 0 (data mismatch is detected as a result of data comparison):

1. Write 00b to the DOCR.OMS[1:0] bits to select data comparison mode.
2. Set 16-bit reference data in DODSR.
3. Write the 16-bit data for comparison to DODIR.
4. Continue writing the 16-bit data until all data for comparison is written to DODIR.
5. If a value written to DODIR does not match that in DODSR, the DOCR.DOPCF flag is set to 1.

Figure 37.2 Example of operation in data comparison mode

### 37.3.2 Data Addition Mode

Figure 37.3 shows an example operation in data addition mode. The steps are as follows:

1. Write 01b to the DOCR.OMS[1:0] bits to select data addition mode.
2. Set 16-bit data as the initial value in the DODSR register.
3. Write the 16-bit data to be added to the DODIR register. The result of the operation is stored in the DODSR register.
4. Continue writing the 16-bit data until all data to be added is written to the DODIR.
5. If the result of an operation is greater than 0xFFFF, the DOCR.DOPCF flag is set to 1.

Figure 37.3 Example of operation in data addition mode

### 37.3.3 Data Subtraction Mode

Figure 37.4 shows an example operation in data subtraction mode. The steps are as follows:

1. Write 10b to the DOCSR.OMS[1:0] bits to select data subtraction mode.
2. Set 16-bit data as the initial value in the DODSR register.
3. Write the 16-bit data to be subtracted to the DODIR register. The result of the operation is stored in DODSR.
4. Continue writing the 16-bit data to the DODIR register until all data to be subtracted is written.
5. If the result of an operation is less than 0x0000, the DOCSR.DOPCF flag is set to 1.

Figure 37.4 Example of operation in data subtraction mode

## 37.4 Interrupt Source

The DOC generates the DOC interrupt (DOC\_DOPCI) as an interrupt request. Table 37.2 describes the DOC interrupt request.

**Table 37.2** Interrupt request from DOC

| Interrupt request | Status flag | Interrupt source                                                                                                                                                                                                                                                |
|-------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DOC interrupt     | DOPCF       | <ul style="list-style-type: none"> <li>The result of data comparison matches the condition selected in the DOCR.DCSEL bit.</li> <li>The result of data addition is greater than 0xFFFF.</li> <li>The result of data subtraction is less than 0x0000.</li> </ul> |

### 37.5 Output of an Event Signal to the Event Link Controller (ELC)

The DOC outputs an event signal for the ELC under the following conditions:

- The compared values either match or mismatch
- The data addition result is greater than 0xFFFF
- The data subtraction result is less than 0x0000

This signal can be used to initiate operations by other modules selected in advance and can also be used as an interrupt request. When an event signal is generated, the DOC Flag (DOCR.DOPCF) is set to 1.

### 37.6 Usage Notes

#### 37.6.1 Settings for the Module-Stop State

The module Stop Control Register C (MSTPCRC) can enable or disable DOC operation. The DOC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

## 38. SRAM

### 38.1 Overview

The MCU provides an on-chip, high-density SRAM module with parity-bit checking. The first 64 KB area of the SRAM0 is the Non-parity. Parity check is performed on the other areas.

Table 38.1 lists the SRAM specifications.

**Table 38.1 SRAM specifications**

| Parameter               | With Parity                                                                                                                                                                                                                                                                                               | Without Parity                    |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| SRAM capacity           | SRAM0: 64 KB                                                                                                                                                                                                                                                                                              | SRAM0: 64 KB                      |
| SRAM address            | SRAM0: 0x2001_0000 to 0x2001_FFFF                                                                                                                                                                                                                                                                         | SRAM0: 0x2000_0000 to 0x2000_FFFF |
| Access                  | Can access with no wait. One wait access is set at initial state.<br>For details, see <a href="#">section 38.3.6. Access Cycle</a>                                                                                                                                                                        |                                   |
| Data retention function | Not available in Deep Software Standby mode                                                                                                                                                                                                                                                               |                                   |
| Module-stop function    | Module-stop state can be set to reduce power consumption                                                                                                                                                                                                                                                  |                                   |
| Parity                  | Even parity with 8-bit data and 1-bit parity                                                                                                                                                                                                                                                              | No parity                         |
| Error checking          | even-parity (Data:8bit, parity:1bit)                                                                                                                                                                                                                                                                      | No error checking                 |
| Security                | TrustZone Filter is integrated for memory access and SFR access. Access to the memory space is controlled by setting the memory Security Attribution (SA). And, access to I/O space (SFR) space is controlled by setting the register SA. See <a href="#">section 38.3.3. TrustZone Filter function</a> . |                                   |

## 38.2 Register Descriptions

### 38.2.1 SRAMSAR : SRAM Security Attribution Register

Base address: CPSCU = 0x4000\_8000

Offset address: 0x10

|                    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |          |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----------|
| Bit position:      | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17       | 16       |
| Bit field:         | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —        | —        |
| Value after reset: | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1        | 1        |
| Bit position:      | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1        | 0        |
| Bit field:         | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | SRAM SA1 | SRAM SA0 |
| Value after reset: | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1        | 1        |

| Bit  | Symbol  | Function                                                                             | R/W |
|------|---------|--------------------------------------------------------------------------------------|-----|
| 0    | SRAMSA0 | Security attributes of registers for SRAM Protection<br>0: Secure<br>1: Non-secure   | R/W |
| 1    | SRAMSA1 | Security attributes of registers for SRAM Protection 2<br>0: Secure<br>1: Non-secure | R/W |
| 2    | —       | This bit is read as 1. The write value should be 1.                                  | R/W |
| 31:3 | —       | These bits are read as 1. The write value should be 1.                               | R/W |

Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR register.

#### SRAMSA0 bit (Security attributes of registers for SRAM Protection)

Security attributes of registers for SRAM Protection. The target registers are as follows.

- PARIOAD
- SRAMPRCR

**SRAMSA1 bit (Security attributes of registers for SRAM Protection 2)**

Security attributes of registers for SRAM Protection 2. The target registers are as follows.

- SRAMWTSC
- SRAMPRCR2

**38.2.2 PARIOAD : SRAM Parity Error Operation After Detection Register**

Base address: SRAM = 0x4000\_2000

Offset address: 0x00

| Bit | Symbol | Function                                                           | R/W |
|-----|--------|--------------------------------------------------------------------|-----|
| 0   | OAD    | Operation After Detection<br>0: Non-maskable interrupt<br>1: Reset | R/W |
| 7:1 | —      | These bits are read as 0. The write value should be 0.             | R/W |

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

The PARIOAD register controls the operation on detection of a parity error. The SRAM Protection Register (SRAMPRCR) protects this register against writes. Always set the SRAMPRCR bit in SRAMPRCR to 1 before writing to this bit. Do not write to the PARIOAD register while accessing the SRAM.

**OAD bit (Operation After Detection)**

The OAD bit specifies the generation of either a reset or non-maskable interrupt when a parity error is detected. The OAD bit is commonly used for SRAM0(with Parity)/Standby SRAM.

**38.2.3 SRAMPRCR : SRAM Protection Register**

Base address: SRAM = 0x4000\_2000

Offset address: 0x04

| Bit | Symbol   | Function                                                                                                      | R/W |
|-----|----------|---------------------------------------------------------------------------------------------------------------|-----|
| 0   | SRAMPRCR | Register Write Control<br>0: Disable writes to protected registers<br>1: Enable writes to protected registers | R/W |
| 7:1 | KW[6:0]  | Write Key Code<br>These bits enable or disable writes to the SRAMPRCR bit                                     | W   |

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

### SRAMPRCR bit (Register Write Control)

The SRAMPRCR bit controls the write mode of the PARIOD register. Setting the bit to 1 enables writes to the PARIOD register. When you write to this bit, always write 0x78 to KW[6:0] bits simultaneously.

### KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the SRAMPRCR bit. When you write to the SRAMPRCR bit, always write 0x78 to these bits simultaneously. When a value other than 0x78 is written to KW[6:0], the SRAMPRCR bit is not updated. The KW[6:0] bits are always read as 0x00.

## 38.2.4 SRAMWTSC : SRAM Wait State Control Register

Base address: SRAM = 0x4000\_2000

Offset address: 0x08

|                    |   |   |   |   |   |   |   |                   |
|--------------------|---|---|---|---|---|---|---|-------------------|
| Bit position:      | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0                 |
| Bit field:         | — | — | — | — | — | — | — | SRAM<br>0WTE<br>N |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1                 |

| Bit | Symbol    | Function                                                                           | R/W |
|-----|-----------|------------------------------------------------------------------------------------|-----|
| 0   | SRAM0WTEN | SRAM0 wait enable<br>0: No wait<br>1: Add wait state in read access cycle to SRAM0 | R/W |
| 7:1 | —         | These bits are read as 0. The write value should be 0.                             | R/W |

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

This register can be rewritten only when the SRAMPRCR2 bit in the SRAMPRCR2 register is 1.

The protection register (SRAMPRCR2) protects this register against writing. Change the effective bit in the protection register (SRAMPRCR2) to write in this register.

Do not write to SRAMWTSC while access to SRAM is in progress.

### SRAM0WTEN bit (SRAM0 wait enable)

This bit sets the wait cycle to the operation region in SRAM0. When it is set 1 in the SRAM0WTEN bit, 1 wait cycle is inserted into the read cycle of operation region in SRAM0. And 1 wait cycle is also inserted between the “write to read/write” sequential cycle in the same region of SRAM0.

## 38.2.5 SRAMPRCR2 : SRAM Protection Register 2

Base address: SRAM = 0x4000\_2000

Offset address: 0x0C

|                    |         |   |   |   |   |   |   |                   |
|--------------------|---------|---|---|---|---|---|---|-------------------|
| Bit position:      | 7       | 6 | 5 | 4 | 3 | 2 | 1 | 0                 |
| Bit field:         | KW[6:0] |   |   |   |   |   |   | SRAM<br>PRCR<br>2 |
| Value after reset: | 0       | 0 | 0 | 0 | 0 | 0 | 0 | 0                 |

| Bit | Symbol    | Function                                                                                                              | R/W |
|-----|-----------|-----------------------------------------------------------------------------------------------------------------------|-----|
| 0   | SRAMPRCR2 | Register Write Control<br>0: Disable writes to the protected registers<br>1: Enable writes to the protected registers | R/W |

| Bit | Symbol  | Function                                                                   | R/W |
|-----|---------|----------------------------------------------------------------------------|-----|
| 7:1 | KW[6:0] | Write Key Code<br>These bits enable or disable writes to the SRAMPRCR2 bit | W   |

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

### SRAMPRCR2 bit (Register Write Control)

The SRAMPRCR2 bit controls the write mode of the SRAMWTSC register. Setting the bit to 1 enables writes to the SRAMWTSC register. When you write to this bit, always write 0x78 to KW[6:0] at the same time.

### KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the SRAMPRCR2 bit. When you write to SRAMPRCR2 bit, always write 0x78 to these bits at the same time. When a value other than 0x78 is written to KW[6:0], the SRAMPRCR2 bit is not updated. The KW[6:0] bits are always read as 0x00.

## 38.3 Operation

### 38.3.1 Module Stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

SRAM0 is controlled by SRAM0 bit in MSTPCRA register and, in the case of 1, SRAM0 becomes the clock stop state.

The SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The SRAM operates after a reset.

SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to SRAM is in progress.

Access to the SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see [section 10, Low Power Modes](#).

### 38.3.2 Parity Calculation Function

The IEC60730 standard requires the checking of SRAM data. When data is written, a parity bit is added to every 8-bit data in the SRAM which has 32-bit data width, and when data is read, the parity is checked. When a parity error occurs, a parity-error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the PARIOAD register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

Parity errors can be occasionally caused by noise. To confirm whether the cause of the parity error is noise or corruption, follow the parity check flows shown in [Figure 38.1](#) and [Figure 38.2](#).

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.

Figure 38.1 Flow of SRAM parity check when SRAM parity reset is enabled

Figure 38.2 Flow of SRAM parity check when SRAM parity interrupt is enabled

### 38.3.3 TrustZone Filter function

There are two types of TrustZone Filter function for SRAM.

- TrustZone Filter for SRAM register protection
- TrustZone Filter for SRAM memory protection

#### 38.3.3.1 TrustZone Filter for SRAM register protection

SRAM registers can be protected with a Security Attribution (SA) from Non-secure access. When SA indicates that SRAM registers are secure status, non-secure access cannot overwrite them because TrustZone Filter detects finds an error and protects the write access. SA for SRAM registers is just one to be used commonly among SRAM registers.

Table 38.2 Register protection (1 of 2)

| SA     | Access status | Write access                     | Read access |
|--------|---------------|----------------------------------|-------------|
| Secure | Secure        | Permit                           | Permit      |
|        | Non-secure    | TrustZone Filter error Protected | Permit      |

**Table 38.2 Register protection (2 of 2)**

| SA         | Access status | Write access | Read access |
|------------|---------------|--------------|-------------|
| Non-secure | Secure        | Permit       | Permit      |
|            | Non-secure    | Permit       | Permit      |

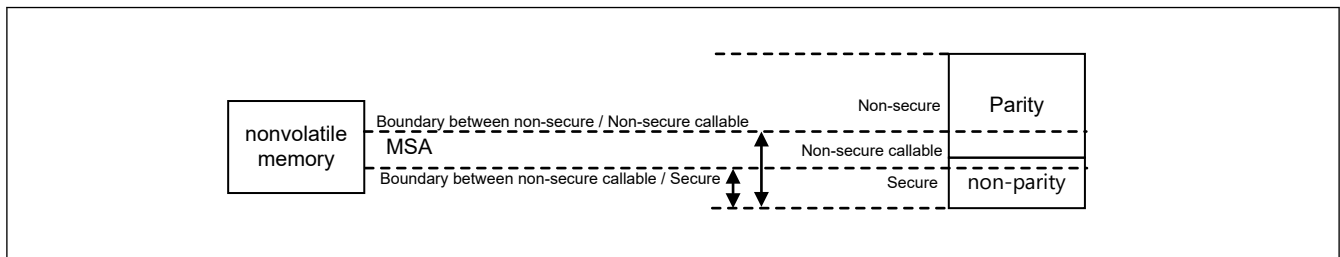

When TrustZone Filter error for SRAM register access occurs, no error notification and no error response occurs.

### 38.3.3.2 TrustZone Filter for SRAM memory protection

SRAM memory, e.g. SRAM0 include Non-parity region and Parity can be divided into Secure/Non-secure callable/Non-secure status with Memory Security Attribution (MSA) and can be protected from Non-secure access. When MSA indicates that SRAM memory region are Secure or Non-secure callable status, Non-secure access can't overwrite them.

**Table 38.3 Memory protection**

| SA                           | Access status | Write access                                                                                                      | Read access                                                                                                            |
|------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| Secure / Non-secure callable | Secure        | Permit                                                                                                            | Permit                                                                                                                 |
|                              | Non-secure    | TrustZone Filter error <ul style="list-style-type: none"> <li>Protected</li> <li>Error response occurs</li> </ul> | TrustZone Filter error <ul style="list-style-type: none"> <li>Read data is 0</li> <li>Error response occurs</li> </ul> |
| Non-secure                   | Secure        | Permit                                                                                                            | Permit                                                                                                                 |
|                              | Non-secure    | Permit                                                                                                            | Permit                                                                                                                 |

**Figure 38.3 TrustZone Filter for SRAM memory**

When TrustZone Filter error for SRAM memory access occurs, an error notification which become Reset request or NMI request occurs. See [section 42.2. Arm TrustZone Security](#) .

### 38.3.4 Interrupt Source

The SRAM interrupt source includes a Parity error and TrustZone filter error. Parity error can choose non-maskable interrupt or reset by OAD bit. When the debugger is connected, reset and non-maskable interrupt are maskable. For details on the debug mode, see [section 2, CPU](#).

**Table 38.4 SRAM Interrupt Source**

| Name      | Interrupt Source       | DTC Activation | DMAC Activation |
|-----------|------------------------|----------------|-----------------|
| PARITYERR | Parity error           | Not possible   | Not possible    |
| TZFLT     | TrustZone filter error | Not possible   | Not possible    |

### 38.3.5 Wait state

Depending on the operating frequency of ICLK, the WAIT setting for SRAM access has the following conditions.

[ICLK frequency] (SRAM0):

- $100 \text{ MHz} \geq \text{ICLK} = \text{No-wait}$

### 38.3.6 Access Cycle

- Number of cycles from the CPU

**Table 38.5 SRAM0**

| Register Setting | Read (cycles) |                       | Write (cycles) |                       |
|------------------|---------------|-----------------------|----------------|-----------------------|
|                  | Word access   | Half-word/Byte access | Word access    | Half-word/Byte access |
| SRAM0WTEN = 0    |               | 1                     |                | 1 <sup>*1</sup>       |
| SRAM0WTEN = 1    |               | 2                     |                | 1 <sup>*1</sup>       |

Note 1. For efficiency of the access, when read access occurs to the same memory after write, memory write by the precedent write command delays it until for the next idle cycle or the next write access. When read continues, it is given priority to read.

## 39. Standby SRAM

### 39.1 Overview

An on-chip SRAM is provided to retain data in Deep Software Standby mode. [Table 39.1](#) lists the Standby SRAM specifications.

**Table 39.1 Standby SRAM specifications**

| Item                    | Description                                                                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SRAM capacity           | 1 KB                                                                                                                                                                 |
| SRAM address            | 0x2800_0000 to 0x2800_03FF                                                                                                                                           |
| Access                  | Standby SRAM clock is the same clock as the PCLKB. See <a href="#">section 39.3.5. Access Cycle</a> for details.                                                     |
| Data retention function | Data can be retained in Deep Software Standby mode. See <a href="#">section 39.3.1. Data Retention</a> for details.                                                  |
| parity                  | Even parity (data: 8 bits, parity: 1 bit)                                                                                                                            |
| Module-stop function    | Module-stop state can be set to reduce power consumption. See <a href="#">section 39.3.2. Setting for the Module-stop Function</a> for details.                      |
| Security                | Permits the read and write operations to Standby RAM following TrustZone Filter function. See <a href="#">section 39.3.4. TrustZone Filter function</a> for details. |

### 39.2 Register Descriptions

#### 39.2.1 STBRAMSAR : Standby RAM memory Security Attribution Register

Base address: CPSCU = 0x4000\_8000

Offset address: 0x014

|                    |    |    |    |    |    |    |    |    |    |    |    |    |              |    |    |    |

| 31:4 | —            | This bit is read as 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | R   |

Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR register.

#### NSBSTBR[3:0] bit (Security attributes of each region for Standby RAM)

Standby RAM is divided into 8 regions. Each region can be set as Secure or Non-secure state with NSBSTBR[3:0]

Figure 39.1 Standby RAM regions

## 39.3 Operation

### 39.3.1 Data Retention

The power supply to the Standby SRAM in Deep Software Standby mode is enabled by the `DPSBYCR.DEEPCUT[1:0]` bits. If the `DPSBYCR.DEEPCUT[1:0]` bits are set to 00b, data in the Standby SRAM is retained in Deep Software Standby mode. For details on the `DPSBYCR.DEEPCUT[1:0]` bits, see [section 10, Low Power Modes](#).

### 39.3.2 Setting for the Module-stop Function

Power consumption can be reduced by setting module stop control register A (`MSTPCRA`) to stop supply of the clock signal to SRAM.

If the Standby SRAM bit in `MSTPCRA` is set to 1, supply of the clock signal to the Standby SRAM is stopped.

The Standby SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The Standby SRAM operates after a reset.

The Standby SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to the standby SRAM is in progress.

For details on the `MSTPCRA` register, see [section 10, Low Power Modes](#).

### 39.3.3 Parity Calculation Function

The parity calculation Function for Standby SRAM is as same as SRAM with Parity.

See [section 38.3.2. Parity Calculation Function](#) and [section 38.3.4. Interrupt Source](#).

OAD bit in `PARIOAD` register is commonly used for SRAM0 (with Parity) / Standby SRAM.

### 39.3.4 TrustZone Filter function

There is only one type of TrustZone Filter function for Standby SRAM and that is, TrustZone Filter for SRAM memory protection

#### 39.3.4.1 TrustZone Filter for Standby SRAM Memory Protection

Standby SRAM memory can be divided into 8 regions, 128 bytes each with a Security Attribution (SA) to be protected from Non-secure access. When SA indicates that the region in Standby SRAM is secure status, non-secure access cannot overwrite them because TrustZone Filter detects finds an error and protects the write access.

**Table 39.2 Security Attribution and Access status**

| SA         | Access status | Write access                          | Read access                                |
|------------|---------------|---------------------------------------|--------------------------------------------|
| Secure     | Secure        | Permit                                | Permit                                     |
|            | Non-secure    | TrustZone Filter error<br>- Protected | TrustZone Filter error<br>- Read data is 0 |
| Non-secure | Secure        | Permit                                | Permit                                     |
|            | Non-secure    | Permit                                | Permit                                     |

When TrustZone Filter error for Standby SRAM access occurs, no error notification and no error response occurs.

### 39.3.5 Access Cycle

Number of cycles from the CPU.

**Table 39.3 Standby SRAM (parity area 0x2800\_0000 to 0x2800\_03FF)**

|              | Read cycle                                    |                      | Write cycle                                   |                      |
|--------------|-----------------------------------------------|----------------------|-----------------------------------------------|----------------------|
|              | Word access                                   | Halfword/Byte access | Word access                                   | Halfword/Byte access |
| ICLK ≥ PCLKB | Min.: 2 PCLKB<br>Max.: (n - 1) ICLK + 2 PCLKB |                      | Min.: 1 PCLKB<br>Max.: (n - 1) ICLK + 1 PCLKB |                      |

Note: When the frequency ratio of ICLK : PCLKB is n : 1.

## 39.4 Usage Notes

### 39.4.1 Instruction Fetch from the Standby SRAM Area

When using Standby SRAM to operate a program, initialize the Standby SRAM area so that the CPU can correctly prefetch data. A parity error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 4-byte boundary. Renesas recommends using the NOP instruction for data initialization.

## 40. Flash Memory

This MCU incorporates code flash memory, data flash memory, and option-setting memory. The code flash memory stores instructions and operands, and the data flash memory stores data. For option-setting memory, see [section 6, Option-Setting Memory](#).

### 40.1 Overview

[Table 40.1](#) lists the specifications of the flash memory, and [Figure 40.1](#) is block diagrams of the flash memory related modules.

The I/O pins used in boot mode, see [Table 40.27](#).

The FCU (flash control unit) controls programming and erasure of the flash memory. The FACI (flash application command interface) controls the FCU according to the specified FACI commands.

Regarding the configuration of the code flash memory, see [Figure 40.2](#), and for the configuration of the data flash memory, see [Figure 40.3](#).

**Table 40.1 Specifications of flash memory (1 of 2)**

| Item                              | Code flash memory                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Data flash memory                                                                                                                                                                                                 |

Note 1. Limitations apply to the combinations of the address ranges for programming/erasure process and reading process: see [Table 40.29](#).

[Figure 40.1](#) shows how modules related to flash memory can be configured. The flash sequencer is configured with the FCU and FCI. The FCU executes basic control for rewriting of the flash memory. The FCI receives FCI commands using peripheral bus, and controls FCU operations accordingly.

In response to a reset, the FCI transfers data from the flash memory to the option byte storage registers.

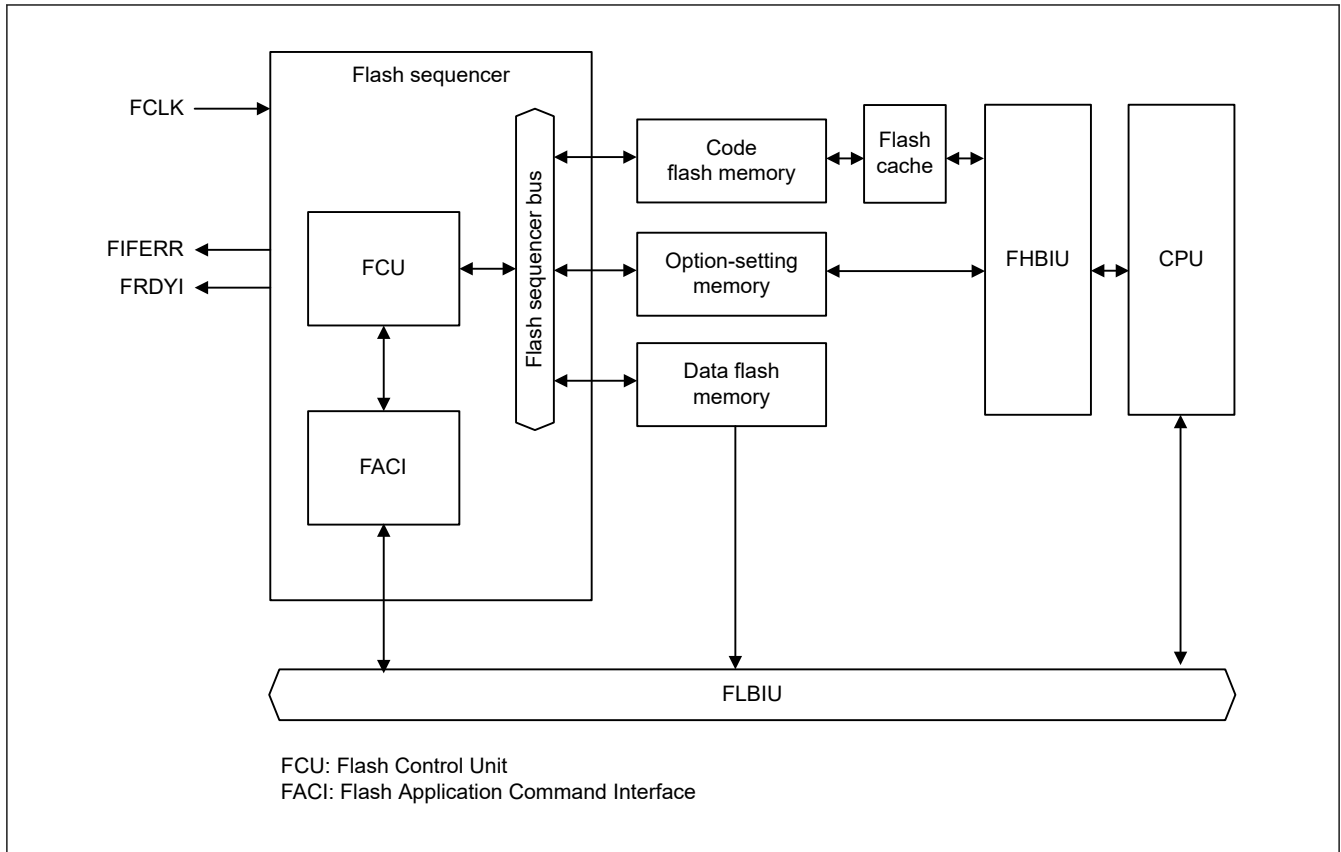

Figure 40.1 Block diagram of flash memory-related modules

## 40.2 Structure of Memory

Figure 40.2 shows the memory map of code flash memory.

The user area of the code flash memory in this MCU is divided into 8- and 32-Kbyte blocks, which serve as the units of erasure.

Figure 40.2 Map of the Code Flash Memory

Table 40.2 Read and programming/erasure address by product for the code flash memory

| Product            | Address                    | Number of blocks |
|--------------------|----------------------------|------------------|
| 512 Kbytes product | 0x0000_0000 to 0x0007_FFFF | 0 to 21          |
| 256 Kbytes product | 0x0000_0000 to 0x0003_FFFF | 0 to 13          |

The data area of the data flash memory in this MCU is divided into 64-byte blocks, with each being a unit for erasure. Figure 40.3 shows the mapping of the data flash memory.

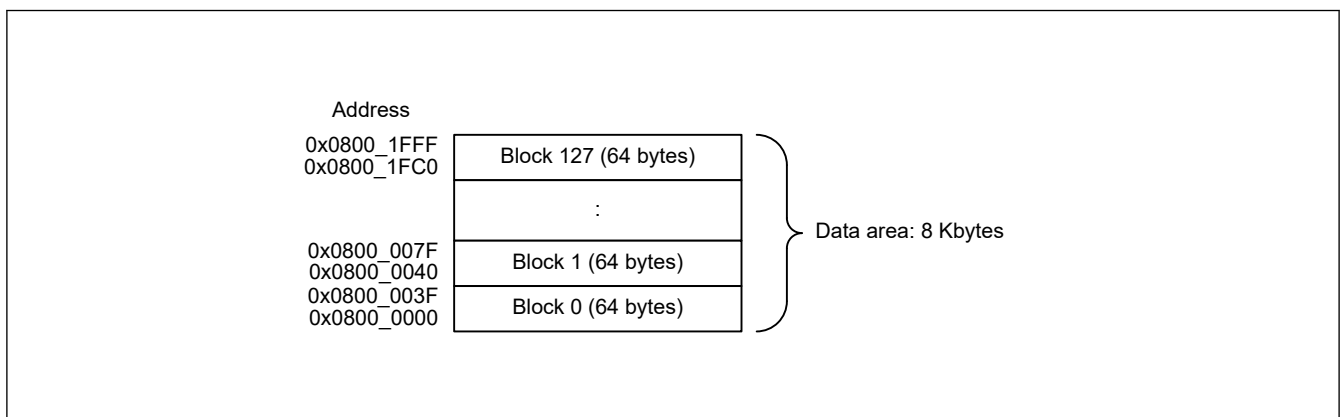

Figure 40.3 Map of the Data Flash Memory

### 40.3 Address Space

Using the hardware interface with flash memory requires access to all registers of the hardware, which is for issuing FACL commands. Table 40.3 provides information about the hardware interface.

**Table 40.3 Information on the hardware interface area**

| Area                                              | Address                                                   | Capacity                                                  |
|---------------------------------------------------|-----------------------------------------------------------|-----------------------------------------------------------|
| Area containing various registers of the hardware | See <a href="#">section 40.4. Register Descriptions</a> . | See <a href="#">section 40.4. Register Descriptions</a> . |
| FACI command-issuing area                         | 0x407E_0000                                               | 4 bytes                                                   |

For the address information of the flash memory, see [Figure 40.2](#).

## 40.4 Register Descriptions

### 40.4.1 FCACHEE : Flash Cache Enable Register

Base address: FCACHE = 0x4001\_C100

Offset address: 0x000

|                    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |          |
|--------------------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|----------|
| Bit position:      | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0        |
| Bit field:         | —  | —  | —  | —  | —  | —  | — | — | — | — | — | — | — | — | — | FCACHEEN |
| Value after reset: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0        |

| Bit  | Symbol   | Function                                                            | R/W |
|------|----------|---------------------------------------------------------------------|-----|
| 0    | FCACHEEN | Flash Cache Enable<br>0: FCACHE is disabled<br>1: FCACHE is enabled | R/W |
| 15:1 | —        | These bits are read as 0. The write value should be 0.              | R/W |

This register is not controlled by any security attribute register.

#### FCACHEEN bit (Flash Cache Enable)

FCACHEE.FCACHEEN bit enable and disables the function of Flash Cache of FCACHE1, FCACHE2 and FLPF.

FCACHEE.FCACHEEN bit dose not influence for FCACHEIV.FCACHEIV.

When FCACHE is enabled, it works for accesses marked as cacheable.

It is prohibited to disable FCACHE after enabling.

### 40.4.2 FCACHEIV : Flash Cache Invalidate Register

Base address: FCACHE = 0x4001\_C100

Offset address: 0x004

|                    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |          |
|--------------------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|----------|
| Bit position:      | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0        |
| Bit field:         | —  | —  | —  | —  | —  | —  | — | — | — | — | — | — | — | — | — | FCACHEIV |
| Value after reset: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0        |

| Bit  | Symbol   | Function                                                                                                                           | R/W |
|------|----------|------------------------------------------------------------------------------------------------------------------------------------|-----|
| 0    | FCACHEIV | Flash Cache Invalidate<br>0: Read: Do not invalidate.<br>Write: The setting is ignored.<br>1: Invalidate<br>FCACHE is invalidated. | R/W |
| 15:1 | —        | These bits are read as 0. The write value should be 0.                                                                             | R/W |

This register is not controlled by any security attribute register.

### FCACHEIV bit (Flash Cache Invalidate)

When 1 is written to FCACHEIV.FCACHEIV bit, the Flash cache data of FCACHE1, FCACHE2 and FLPF is invalidated. Invalidate FCACHE with keeping FCACHE enabled after programming or erasing the code flash or the option setting memory.

#### 40.4.3 FLWT : Flash Wait Cycle Register

Base address: FCACHE = 0x4001\_C100

Offset address: 0x01C

|               |   |   |   |   |   |           |   |   |
|---------------|---|---|---|---|---|-----------|---|---|
| Bit position: | 7 | 6 | 5 | 4 | 3 | 2         | 1 | 0 |
| Bit field:    | — | — | — | — | — | FLWT[2:0] |   |   |

Value after reset: 0 0 0 0 0 0 0 0 0

| Bit | Symbol    | Function                                                                                                                                                                       | R/W |
|-----|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 2:0 | FLWT[2:0] | Flash Wait Cycle<br>0 0 0: 0 wait (ICLK ≤ 50 MHz)<br>0 0 1: 1 wait (ICLK > 50 MHz)<br>0 1 0: 2 wait Not specified<br>0 1 1: 3 wait Not specified<br>Others: Setting prohibited | R/W |
| 7:3 | —         | These bits are read as 0. The write value should be 0.                                                                                                                         | R/W |

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

### FLWT[2:0] bits (Flash Wait Cycle)

The Flash Wait Cycle Register (FLWT) sets the access wait count for the flash memory.

For faster clock frequencies, set FLWT.FLWT before changing the clock frequency. For slower clock frequencies, set FLWT.FLWT after changing the clock frequency.

For information on the frequency setting, see [section 8, Clock Generation Circuit](#).

#### 40.4.4 FSAR : Flash Security Attribution Register

Base address: FCACHE = 0x4001\_C100

Offset address: 0x040

|               |    |    |    |    |    |    |   |             |   |   |   |   |   |   |   |            |
|---------------|----|----|----|----|----|----|---|-------------|---|---|---|---|---|---|---|------------|
| Bit position: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8           | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0          |
| Bit field:    | —  | —  | —  | —  | —  | —  | — | FKM<br>HZSA | — | — | — | — | — | — | — | FLWT<br>SA |

Value after reset: 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1

| Bit | Symbol | Function                                                                          | R/W |
|-----|--------|-----------------------------------------------------------------------------------|-----|
| 0   | FLWTSA | FLWT Security Attribution<br>Target register : FLWT<br>0: Secure<br>1: Non-secure | R/W |
| 7:1 | —      | These bits are read as 1. The write value should be 1.                            | R/W |

| Bit  | Symbol   | Function                                                                              | R/W |
|------|----------|---------------------------------------------------------------------------------------|-----|
| 8    | FCKMHZSA | FCKMHZ Security Attribution<br>Target register : FCKMHZ<br>0: Secure<br>1: Non-secure | R/W |
| 15:9 | —        | These bits are read as 1. The write value should be 1.                                | R/W |

Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR register.

Write access is invalid when PRCR.PRC4 bit is 0. See [section 12, Register Write Protection](#).

#### FLWTSA bit (FLWT Security Attribution)

This bit sets the security attribute of FLWT.

#### FCKMHZSA bit (FCKMHZ Security Attribution)

This bit sets the security attribute of FCKMHZ.

### 40.4.5 UIDRn : Unique ID Registers n (n = 0 to 3)

Address:  $0x0100\_8190 + n \times 4$

| Bit  | Symbol | Function  | R/W |
|------|--------|-----------|-----|
| 31:0 | UID    | Unique ID | R   |

The UIDRn is a read-only register that stores a 16-byte ID code (unique ID) for identifying the individual MCU. The UIDRn register should be read in 32-bit units. When reading by the signature request command of the serial programming interface, the data is read in order from the data with the large address. That is, the data in  $0x0100\_819F$  is read first, and in  $0x0100\_8190$  is read last.

### 40.4.6 PNRn : Part Numbering Register n (n = 0 to 3)

Address:  $0x0100\_80F0 + n \times 4$

| Bit  | Symbol | Function    | R/W |
|------|--------|-------------|-----|
| 31:0 | PNR    | Part Number | R   |

The PNRn is a read-only register that stores a 16-byte part numbering. The PNRn register should be read in 32-bit units. Each byte corresponds to the ASCII code representation of the product part number as detailed in [Table 1.13](#). The first character ("R",  $0x52$  in ASCII code) of the part number is stored in the byte with the smallest address ( $0x0100\_80F0$ ). When reading by the signature request command of the serial programming interface, the data is read in order from the data with the small address. That is, the data in  $0x0100\_80F0$  is read first, and in  $0x0100\_80FF$  is read last.

### 40.4.7 MCOVER : MCU Version Register

Address: 0x0100\_81B0

Value after reset: Value depend on the chip

| Bit | Symbol | Function    | R/W |
|-----|--------|-------------|-----|
| 7:0 | MCUVE  | MCU Version | R   |

The MCOVER is a read-only register that stores a MCU version. The MCOVER register should be read in 8-bit units.

### 40.4.8 FWEPROR : Flash P/E Protect Register

Base address: SYSC = 0x4001\_E000

Offset address: 0x416

Value after reset: 0 0 0 0 0 0 1 0

| Bit | Symbol    | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | R/W |
|-----|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 1:0 | FLWE[1:0] | Flash Programming and Erasure<br>0 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing.<br>0 1: Permits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing.<br>1 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing.<br>1 1: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. | R/W |
| 7:2 | —         | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                              | R/W |

It is possible that Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing are prohibited by software.

The FWEPROR register is initialized by a reset from the following:

- All reset source
- Transition to Deep Software Standby mode
- Transition to Software Standby mode.

#### FLWE[1:0] bits (Flash Programming and Erasure)

The FLWE[1:0] bits are used to set the flash P/E protection. The value after reset is 10b.

If these bits are set to other than 01b that does not allow programming and erasure of the flash memory, the following commands cannot be executed. Issuing any of the following commands leads to setting of the FLWEERR bit in the FSTATR register to 1.

Program / Block Erase / Multi Block Erase / Blank Check / Configuration set command

### 40.4.9 FASTAT : Flash Access Status Register

Base address: FACL = 0x407F\_E000

Offset address: 0x10

|                    |      |   |   |           |      |   |   |   |
|--------------------|------|---|---|-----------|------|---|---|---|
| Bit position:      | 7    | 6 | 5 | 4         | 3    | 2 | 1 | 0 |
| Bit field:         | CFAE | — | — | CMDL<br>K | DFAE | — | — | — |
| Value after reset: | 0    | 0 | 0 | 0         | 0    | 0 | 0 | 0 |

| Bit | Symbol | Function                                                                                                                                                  | R/W              |
|-----|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 2:0 | —      | These bits are read as 0. The write value should be 0.                                                                                                    | R/W              |
| 3   | DFAE   | Data Flash Memory Access Violation Flag<br>0: No data flash memory access violation has occurred<br>1: A data flash memory access violation has occurred. | R/W <sup>1</sup> |
| 4   | CMDLK  | Command Lock Flag<br>0: The flash sequencer is not in the command-locked state<br>1: The flash sequencer is in the command-locked state.                  | R                |
| 6:5 | —      | These bits are read as 0. The write value should be 0.                                                                                                    | R/W              |
| 7   | CFAE   | Code Flash Memory Access Violation Flag<br>0: No code flash memory access violation has occurred<br>1: A code flash memory access violation has occurred. | R/W <sup>1</sup> |

Note 1. Only 0 can be written to clear the flag after 1 is read.

The FASTAT register indicates whether a code flash or data flash memory access violation has occurred. If any of the CFAE, CMDLK, and DFAE bits is set to 1, the flash sequencer enters the command-locked state (see [section 40.11.2. Error Protection](#)). To release it from the command-locked state, issue a status clear command or Forced Stop command to the flash sequencer.

#### DFAE bit (Data Flash Memory Access Violation Flag)

The DFAE bit indicates whether a data flash memory access violation occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the data flash P/E mode are as follows:

- The setting of the FSADDR or FEADDR register is the reserved portion of the data area
- FACI commands of non-secure access are issued while the setting of the FSADDR or FEADDR register is the secure region address.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

#### CMDLK bit (Command Lock Flag)

The CMDLK bit indicates that the flash sequencer is in the command-locked state.

[Setting conditions]

- The flash sequencer detects an error and enters the command-locked state.

[Clearing conditions]

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

#### CFAE bit (Code Flash Memory Access Violation Flag)

The CFAE bit indicates whether a code flash memory access violation has occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the code flash P/E mode are as follows:

- The setting of the FSADDR register is the reserved portion of the user area
- The Configuration set command is issued while the setting of the FSADDR register is from 0x0000A100 to 0x0000A2F0 in self-programming mode
- FACI commands of non-secure access are issued while the setting of the FSADDR register is the secure region address.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

#### 40.4.10 FAEINT : Flash Access Error Interrupt Enable Register

Base address: FACI = 0x407F\_E000

Offset address: 0x14

|                    |        |   |   |         |        |   |   |   |
|--------------------|--------|---|---|---------|--------|---|---|---|
| Bit position:      | 7      | 6 | 5 | 4       | 3      | 2 | 1 | 0 |
| Bit field:         | CFAEIE | — | — | CMDLKIE | DFAEIE | — | — | — |
| Value after reset: | 1      | 0 | 0 | 1       | 1      | 0 | 0 | 0 |

| Bit | Symbol  | Function                                                                                                                                                                                                                              | R/W |
|-----|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 2:0 | —       | These bits are read as 0. The write value should be 0.                                                                                                                                                                                | R/W |
| 3   | DFAEIE  | Data Flash Memory Access Violation Interrupt Enable<br>0: Generation of an FIFERR interrupt request is disabled when FASTAT.DFAE is set to 1<br>1: Generation of an FIFERR interrupt request is enabled when FASTAT.DFAE is set to 1. | R/W |
| 4   | CMDLKIE | Command Lock Interrupt Enable<br>0: Generation of an FIFERR interrupt request is disabled when FASTAT.CMDLK is set to 1<br>1: Generation of an FIFERR interrupt request is enabled when FASTAT.CMDLK is set to 1.                     | R/W |
| 6:5 | —       | These bits are read as 0. The write value should be 0.                                                                                                                                                                                | R/W |
| 7   | CFAEIE  | Code Flash Memory Access Violation Interrupt Enable<br>0: Generation of an FIFERR interrupt request is disabled when FASTAT.CFAE is set to 1<br>1: Generation of an FIFERR interrupt request is enabled when FASTAT.CFAE is set to 1. | R/W |

The FAEINT register enables or disables generation of a flash access error (FIFERR) interrupt request.

##### DFAEIE bit (Data Flash Memory Access Violation Interrupt Enable)

The DFAEIE bit enables or disables generation of an FIFERR interrupt request when a data flash memory access violation occurs, setting the DFAE bit in the FASTAT register to 1.

##### CMDLKIE bit (Command Lock Interrupt Enable)

The CMDLKIE bit enables or disables generation of an FIFERR interrupt request when the flash sequencer enters the command-locked state, setting the CMDLK bit in the FASTAT register to 1.

##### CFAEIE bit (Code Flash Memory Access Violation Interrupt Enable)

The CFAEIE bit enables or disables generation of an FIFERR interrupt request when a code flash memory access violation occurs, setting the CFAE bit in the FASTAT register to 1.

### FSADDR[31:0] bits (Start Address for FACI Command Processing)

The FSADDR[31:0] bits specify the start address for FACI command processing. Bits [31:24] are ignored in FACI command processing for the code flash memory. Bits [31:17] are ignored in FACI command processing for the data flash memory. Bits associated with the address bits of lower order than the address boundary listed in Table 40.4 are also ignored.

For information on the addresses of the code flash memory and the data flash memory, see section 40.2. Structure of Memory.

For information on the addresses of the configuration setting, see section 40.9.3.15. Configuration Set Command.

#### 40.4.13 FEADDR : FACI Command End Address Register

Base address: FACI = 0x407F\_E000

Offset address: 0x34

Bit position: 31 0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

| Bit  | Symbol       | Function                                | R/W               |
|------|--------------|-----------------------------------------|-------------------|
| 31:0 | FEADDR[31:0] | End Address for FACI Command Processing | R/W <sup>*1</sup> |

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that bit [0] and bit [1] are read-only.

The FEADDR register specifies the end address of the target area for Multi Block Erase and Blank Check command processing. When incremental mode is selected as the addressing mode for Blank Checking (when FBCCNT.BCDIR = 0), the address specified in the FSADDR register should be equal to or smaller than the address in the FEADDR register. Conversely, the address in the FSADDR register should be equal to or larger than the address in the FEADDR register when decremental mode is selected as the addressing mode for Blank Check (i.e. when FBCCNT.BCDIR = 1). If the BCDIR, FSADDR, and FEADDR bit settings are inconsistent with the specified rules, the flash sequencer enters the command-locked state (see section 40.11.2. Error Protection).

The FEADDR value is initialized when the SUNIT bit in the FSUNITR register is set to 1. It is also initialized by a reset.

### FEADDR[31:0] bits (End Address for FACI Command Processing)

The FEADDR[31:0] bits specify the end address for Multi Block Erase and Blank Check command processing. In command processing, bits 31 to 17 and any bits that do not reach the address boundaries listed in the section 40.4.12. FSADDR : FACI Command Start Address Register are ignored.

For information on the addresses of the flash memory, see section 40.2. Structure of Memory.

#### 40.4.14 FMEPROT : Flash P/E Mode Entry Protection Register

Base address: FACI = 0x407F\_E000

Offset address: 0x44

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1

| Bit  | Symbol   | Function                                                                                                | R/W                        |
|------|----------|---------------------------------------------------------------------------------------------------------|----------------------------|
| 0    | CEPROT   | Code Flash P/E Mode Entry Protection<br>0: FENTRYC bit is not protected<br>1: FENTRYC bit is protected. | R/W <sup>*1</sup> *2<br>*4 |
| 7:1  | —        | These bits are read as 0. The write value should be 0.                                                  | R/W                        |
| 15:8 | KEY[7:0] | Key Code                                                                                                | W <sup>*3</sup>            |

- Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while the FRDY bit = 0 is ignored.
- Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY bits is 0xD9.
- Note 3. Written values are not retained by these bits (always read as 0x00).
- Note 4. Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

### CEPROT bit (Code Flash P/E Mode Entry Protection)

The CEPROT bit specifies the protection setting of the FRNTRYC bit in the FENTRYR register.

[Setting condition]

- 1 being written to the CEPROT bit while writing to FMEPROT is enabled.

[Clearing condition]

- 0 being written to the CEPROT bit while writing to FMEPROT is enabled.

### 40.4.15 FBPROT0 : Flash Block Protection Register

Base address: FACL = 0x407F\_E000

Offset address: 0x78

|                    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |           |
|--------------------|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|-----------|
| Bit position:      | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0         |
| Bit field:         | KEY[7:0] |    |    |    |    |    |   |   | — | — | — | — | — | — | — | BPCN<br>0 |
| Value after reset: | 0        | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0         |

| Bit  | Symbol   | Function                                                                                                     | R/W                  |
|------|----------|--------------------------------------------------------------------------------------------------------------|----------------------|
| 0    | BPCN0    | Block Protection for Non-secure Cancel<br>0: Block protection is enabled<br>1: Block protection is disabled. | R/W <sup>*1</sup> *2 |
| 7:1  | —        | These bits are read as 0. The write value should be 0.                                                       | R/W                  |
| 15:8 | KEY[7:0] | Key Code                                                                                                     | W <sup>*3</sup>      |

- Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
- Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x78.
- Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT0 register is used to disable the block protect function for non-secure. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT0 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

### BPCN0 bit (Block Protection for Non-secure Cancel)

The BPCN0 bit disables the block protect setting for non-secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to this bit.

[Clearing conditions]

- 8 bits being written to FBPROT0 while the FRDY bit is 1.
- A value other than 0x78 specified in the KEY bits and 16 bits are written to FBPROT0 while the FRDY bit is 1.
- 0 being written to the BPCN0 bit while writing to FBPROT0 is enabled.
- The FENTRYR register value is 0x0000.

### 40.4.16 FBPROT1 : Flash Block Protection for Secure Register

Base address: FACL = 0x407F\_E000

Offset address: 0x7C

|                    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |           |
|--------------------|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|-----------|
| Bit position:      | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0         |
| Bit field:         | KEY[7:0] |    |    |    |    |    |   |   | — | — | — | — | — | — | — | BPCN<br>1 |
| Value after reset: | 0        | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0         |

| Bit  | Symbol   | Function                                                                                                 | R/W                  |
|------|----------|----------------------------------------------------------------------------------------------------------|----------------------|
| 0    | BPCN1    | Block Protection for Secure Cancel<br>0: Block protection is enabled<br>1: Block protection is disabled. | R/W <sup>*1 *2</sup> |
| 7:1  | —        | These bits are read as 0. The write value should be 0.                                                   | R/W                  |
| 15:8 | KEY[7:0] | Key Code                                                                                                 | W <sup>*3</sup>      |

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while FRDY bit = 0 is ignored.

Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xB1.

Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT1 register is used to disable the block protect function for secure developer. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT1 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

#### BPCN1 bit (Block Protection for Secure Cancel)

The BPCN1 bit disables the block protect setting for secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to BPCN1.

[Clearing conditions]

- 8 bits being written to FBPROT1 while the FRDY bit is 1.
- A value other than 0xB1 specified in the KEY bits and 16 bits are written to FBPROT1 while the FRDY bit is 1.
- 0 being written to the BPCN1 bit while writing to FBPROT1 is enabled.
- The FENTRYR register value is 0x0000.

### 40.4.17 FSTATR : Flash Status Register

| 23    | ILGCOMERR | Illegal Command Error<br>0: A status clear or forced stop command processing is complete<br>1: An error has occurred.                                                                                                                                      | R   |
| 31:24 | —         | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                     | R/W |

The FSTATR register indicates the state of the flash sequencer.

#### FLWEERR flag (Flash Write/Erase Protect Error Flag)

The FLWEERR flag indicates a violation of the flash memory overwrite protection setting in the FWEPROR register. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The flash sequencer starts processing the Forced Stop command.

### **PRGSPD flag (Programming Suspend Status Flag)**

The PRGSPD flag indicates that the flash sequencer is in the programming suspension processing state or programming suspended state.

[Setting condition]

- The flash sequencer starts processing in response to the programming suspend command.

[Clearing conditions]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing the Forced Stop command.

### **ERSSPD flag (Erasure Suspend Status Flag)**

The ERSSPD flag indicates that the flash sequencer is in the erasure suspension processing state or erasure suspended state.

[Setting condition]

- The flash sequencer starts processing in response to an erasure suspend command.

[Clearing condition]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing of the Forced Stop command.

### **DBFULL flag (Data Buffer Full Flag)**

The DBFULL flag indicates the state of the data buffer when the program command is issued. The flash sequencer incorporates a buffer for write data (data buffer). When data for writing to the flash memory are written to the FACI command-issuing area while the data buffer is full, the flash sequencer inserts a wait cycle in the peripheral bus.

[Setting condition]

- The data buffer becomes full while program commands are issued.

[Clearing condition]

- The data buffer becomes empty.

### **SUSRDY flag (Suspend Ready Flag)**

The SUSRDY flag indicates whether the flash sequencer can receive a P/E suspend command.

[Setting condition]

- After starting programming/erasure processing, the flash sequencer enters a state in which P/E suspend commands can be received.

[Clearing conditions]

- Reception of the P/E suspend command or Forced Stop command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- During programming or erasure, the flash sequencer enters the command-locked state
- Programming or erasure has completed.

### **PRGERR flag (Programming Error Flag)**

The PRGERR flag indicates the result of programming of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during programming.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

### **ERSERR flag (Erasure Error Flag)**

The ERSERR flag indicates the result of erasure of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during erasure.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

### **ILGLERR flag (Illegal Command Error Flag)**

The ILGLERR flag indicates that the flash sequencer has detected an illegal FACI command or flash memory access. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting conditions]

- See [section 40.11.2. Error Protection](#).

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

### **FRDY flag (Flash Ready Flag)**

The FRDY flag indicates the command processing state of the flash sequencer.

[Setting conditions]

- The flash sequencer completes command processing
- The flash sequencer receives a P/E suspend command and suspends programming of the flash memory
- The flash sequencer received the Forced Stop command and ended command processing.

Note: In the case of program command processing, the FRDY flag might be set to 1 even if the flash sequencer does not complete command processing. For details, see [section 40.9.3.7. Program Command](#).

[Clearing conditions]

- The flash sequencer received an FACI command
- For Program and Configuration setting, the first write access to the FACI command-issuing area
- For other commands, the last write access to the FACI command-issuing area.

### **OTERR flag (Other Error)**

See [Table 40.21](#). When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

### **SECERR flag (Security Error)**

See [Table 40.21](#). When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

#### FESETERR flag (FENTRY Setting Error)

See Table 40.21. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

#### ILGCOMERR flag (Illegal Command Error)

See Table 40.21. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

### 40.4.18 FENTRYR : Flash P/E Mode Entry Register

Base address: FACL = 0x407F\_E000

Offset address: 0x84

|                    |          |    |    |    |    |    |   |   |         |   |   |   |   |   |   |         |
|--------------------|----------|----|----|----|----|----|---|---|---------|---|---|---|---|---|---|---------|
| Bit position:      | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7       | 6 | 5 | 4 | 3 | 2 | 1 | 0       |
| Bit field:         | KEY[7:0] |    |    |    |    |    |   |   | FENTRYD | — | — | — | — | — | — | FENTRYC |
| Value after reset: | 0        | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0       | 0 | 0 | 0 | 0 | 0 | 0 | 0       |

| Bit  | Symbol   | Function                                                                                    | R/W                |
|------|----------|---------------------------------------------------------------------------------------------|--------------------|
| 0    | FENTRYC  | Code Flash P/E Mode Entry<br>0: Code flash is in read mode<br>1: Code flash is in P/E mode. | R/W <sup>1*2</sup> |
| 6:1  | —        | These bits are read as 0. The write value should be 0.                                      | R/W                |
| 7    | FENTRYD  | Data Flash P/E Mode Entry<br>0: Data flash is in read mode<br>1: Data flash is in P/E mode. | R/W <sup>1*2</sup> |
| 15:8 | KEY[7:0] | Key Code                                                                                    | W <sup>3</sup>     |

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0.

Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xAA.

Note 3. Written values are not retained by these bits (always read 0x00).

FENTRYR is used to specify code flash P/E mode or data flash P/E mode. To specify the code flash P/E mode or data flash P/E mode so that the flash sequencer can receive FACL commands, set either the FENTRYD or FENTRYC bit to 1 to place the flash sequencer in P/E mode.

FENTRYR is initialized when the SUNIT bit in FSUINTR is set to 1. It is also initialized by a reset.

Note: Writing a value of 0XAA81 to this register causes the ILGLERR bit in the FSTATR register to be set to 1, resulting in the flash sequencer being placed in the command-locked state.

#### FENTRYC bit (Code Flash P/E Mode Entry)

The FENTRYC bit specifies P/E mode for the code flash memory.

[Setting condition]

- Write 1 to the FENTRYC bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- A value other than 0xAA is specified in the KEY[7:0] bits and 16 bits are written to FENTRYR while the FRDY bit is 1
- Write 0 to the FENTRYC bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000
- The protection of FMEPROT register is enabled.

### FENTRYD bit (Data Flash P/E Mode Entry)

The FENTRYD bit specifies P/E mode for the data flash memory.

[Setting condition]

- Write 1 to the FENTRYD bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- Writing of 16 bits to FENTRYR with a value other than 0xAA specified for the KEY[7:0] bits while the FRDY bit is 1
- Write 0 to the FENTRYD bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000.

### KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the FENTRYD or FENTRYC bits.

## 40.4.19 FSUINTR : Flash Sequencer Setup Initialization Register

Base address: FACL = 0x407F\_E000

Offset address: 0x8C

|                    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |        |
|--------------------|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|--------|
| Bit position:      | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0      |
| Bit field:         | KEY[7:0] |    |    |    |    |    |   |   | — | — | — | — | — | — | — | SUINIT |
| Value after reset: | 0        | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0      |

| Bit  | Symbol   | Function                                                                                                                                                                                                                                                                       | R/W                |
|------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| 0    | SUINIT   | Set-Up Initialization<br>0: The FSADDR, FEADDR, FBPROT0, FBPROT1, FENTRYR, FBCCNT, and FCPSR flash sequencer setup registers keep their current values<br>1: The FSADDR, FEADDR, FBPROT0, FBPROT1, FENTRYR, FBCCNT, and FCPSR flash sequencer setup registers are initialized. | R/W <sup>1,2</sup> |
| 7:1  | —        | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                         | R/W                |
| 15:8 | KEY[7:0] | Key Code                                                                                                                                                                                                                                                                       | W <sup>3</sup>     |

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x2D.

Note 3. Written values are not retained by these bits (always read 0x00).

FSUINTR is used for initialization of the flash sequencer setup.

### SUINIT bit (Set-Up Initialization)

The SUINIT bit initializes the following flash sequencer setup registers:

- FSADDR
- FEADDR

- FBPROT0
- FBPROT1
- FENTRYR
- FBCCNT
- FCPSR.

**KEY[7:0] bits (Key Code)**

The KEY[7:0] bits control writing permission to the SUNIT bit.

**40.4.20 FCMDR : FACL Command Register**

Base address: FACL = 0x407F\_E000

Offset address: 0xA0

| Bit  | Symbol     | Function                                                                  | R/W |
|------|------------|---------------------------------------------------------------------------|-----|
| 7:0  | PCMDR[7:0] | Pre-command Flag<br>The command just before the latest command is stored. | R   |
| 15:8 | CMDR[7:0]  | Command Flag<br>The latest command is stored.                             | R   |

FCMDR records the two most recent commands accepted by the flash sequencer.

**PCMDR[7:0] bits (Pre-command Flag)**

The PCMDR[7:0] bits indicate the command received immediately before the latest command received by the flash sequencer.

**CMDR[7:0] bits (Command Flag)**

The CMDR[7:0] bits indicate the latest command received by the flash sequencer.

**Table 40.5 States of FCMDR after receiving commands**

| Command           | CMDR | PCMDR            |
|-------------------|------|------------------|
| Program           | 0xE8 | Previous command |
| Block erase       | 0xD0 | 0x20             |
| Multi block erase | 0xD0 | 0x21             |
| P/E suspend       | 0xB0 | Previous command |
| P/E resume        | 0xD0 | Previous command |
| Status Clear      | 0x50 | Previous command |
| Forced Stop       | 0xB3 | Previous command |
| Blank Check       | 0xD0 | 0x71             |
| Configuration set | 0x40 | Previous command |

| Bit   | Symbol      | Function                                                                  | R/W |
|-------|-------------|---------------------------------------------------------------------------|-----|
| 16:0  | PSADR[16:0] | Programmed Area Start Address<br>The address of the first programmed area | R   |
| 31:17 | —           | These bits are read as 0. The write value should be 0.                    | R/W |

FPSADDR indicates the address of the first programmed area found in processing of the Blank Check command.

#### PSADR[16:0] bits (Programmed Area Start Address)

The PSADR[16:0] bits indicate the address of the first programmed area found in processing of the Blank Check command. The address is an offset from the address where the data flash memory starts. The setting of these bits is only valid if the BCST bit in the FBCSTAT register is 1 and while the FRDY bit in the FSTATR register is 1. When the BCST bit in the FBCSTAT register is 0, the PSADR[16:0] bits hold the address produced by the previous check.

#### 40.4.24 FSUASMON : Flash Startup Area Select Monitor Register

Base address: FACI = 0x407F\_E000

Offset address: 0xDC

|                    |       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------------|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit position:      | 31    | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Bit field:         | BTFLG | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  |
| Value after reset: | 0/1   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| Bit position:      | 15    | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Bit field:         | FSPR  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  |
| Value after reset: | 0/1   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

| Bit   | Symbol | Function                                                                                                                                                 | R/W |
|-------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 14:0  | —      | These bits are read as 0. The write value should be 0.                                                                                                   | R   |
| 15    | FSPR   | Protection Programming Flag to set Boot Flag and Startup Area Control<br>0: Protected state<br>1: Non-protected state.                                   | R   |
| 30:16 | —      | These bits are read as 0. The write value should be 0.                                                                                                   | R   |
| 31    | BTFLG  | Flag of Startup Area Select for Boot Swap<br>0: The startup area is the alternate block (block 1)<br>1: The startup area is the default block (block 0). | R   |

#### FSPR bit (Protection Programming Flag to set Boot Flag and Startup Area Control)

The FSPR bit indicates the protection state against the configuration set command for the BTFLG bit, and FSUACR Register.

In response to a reset or configuration set command, the FACI transfers data from flash memory to this register.

#### BTFLG bit (Flag of Startup Area Select for Boot Swap)

The BTFLG bit indicates whether the address of the startup area is exchanged for the boot swap function or not.

In response to a reset or configuration set command, the FACI transfers data from flash memory to this register.

### 40.4.25 FCPSR : Flash Sequencer Processing Switching Register

Base address: FACL = 0x407F\_E000

Offset address: 0xE0

|                    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |             |
|--------------------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|-------------|
| Bit position:      | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0           |
| Bit field:         | —  | —  | —  | —  | —  | —  | — | — | — | — | — | — | — | — | — | ESUS<br>PMD |
| Value after reset: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0           |

| Bit  | Symbol  | Function                                                                       | R/W |
|------|---------|--------------------------------------------------------------------------------|-----|
| 0    | ESUSPMD | Erase Suspend Mode<br>0: Suspension priority mode<br>1: Erasure priority mode. | R/W |
| 15:1 | —       | These bits are read as 0. The write value should be 0.                         | R/W |

FCPSR selects the erasure suspension mode. FCPSR is initialized when the SUNIT bit in FSUNITR is set to 1. It is also initialized by a reset.

#### ESUSPMD bit (Erase Suspend Mode)

The ESUSPMD bit selects the erasure suspension mode when a P/E suspend command is issued while the flash sequencer is executing erasure processing (see [section 40.9.3.10. P/E Suspend Command](#)). This bit should be set before issuing Block Erase or Multi Block Erase command.

### 40.4.26 FPCKAR : Flash Sequencer Processing Clock Notification Register

Base address: FACL = 0x407F\_E000

Offset address: 0xE4

|                    |          |    |    |    |    |    |   |           |   |   |   |   |   |   |   |   |
|--------------------|----------|----|----|----|----|----|---|-----------|---|---|---|---|---|---|---|---|
| Bit position:      | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8         | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Bit field:         | KEY[7:0] |    |    |    |    |    |   | PCKA[7:0] |   |   |   |   |   |   |   |   |
| Value after reset: | 0        | 0  | 0  | 0  | 0  | 0  | 0 | 0         | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 |

| Bit  | Symbol    | Function                                                                                                                                                  | R/W                |
|------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| 7:0  | PCKA[7:0] | Flash Sequencer Operating Clock Notification<br>These bits are used to set the operating frequency of the flash sequencer while processing FACL commands. | R/W <sup>1,2</sup> |
| 15:8 | KEY[7:0]  | Key Code                                                                                                                                                  | W <sup>3</sup>     |

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x1E.

Note 3. Written values are not retained by these bits (always read 0x00).

FPCKAR specifies the operating frequency of the flash sequencer while processing FACL commands. The highest operating frequency for the given product is set as the initial value.

#### PCKA[7:0] bits (Flash Sequencer Operating Clock Notification)

The PCKA[7:0] bits specify the operating frequency of the flash sequencer while processing FACL commands. Set the desired frequency for these bits before issuing an FACL command. Specifically, convert the frequency in MHz to a binary number and set it for these bits.

Example:

Frequency is 35.9 MHz (PCKA = 0x24)

Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics cannot be guaranteed. If the value set in these bits is greater than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics can be guaranteed but the FACL

command processing time such as the time programming/erasure takes will increase. The minimum FACL command processing time is obtained when the operating frequency of the flash sequencer is the same as the PCKA value.

### KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the PCKA bit.

#### 40.4.27 FSUACR : Flash Startup Area Control Register

Base address: FACL = 0x407F\_E000

Offset address: 0xE8

|                    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |          |   |
|--------------------|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|----------|---|
| Bit position:      | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1        | 0 |
| Bit field:         | KEY[7:0] |    |    |    |    |    |   |   |   |   |   | — | — | — | SAS[1:0] |   |
| Value after reset: | 0        | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0        | 0 |

| Bit  | Symbol   | Function                                                                                                                                                                                                                                                                 | R/W                  |
|------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| 1:0  | SAS[1:0] | Startup Area Select<br>0 0: Startup area is selected by BTFLG bit<br>0 1: Startup area is selected by BTFLG bit<br>1 0: Startup area is temporarily switched to the default area (block 0)<br>1 1: Startup area is temporarily switched to the alternate area (block 1). | R/W <sup>*1 *3</sup> |
| 7:2  | —        | These bits are read as 0. The write value should be 0.                                                                                                                                                                                                                   | R/W                  |
| 15:8 | KEY[7:0] | Key Code                                                                                                                                                                                                                                                                 | W <sup>*2</sup>      |

Note 1. Following described the write condition of these bits (these conditions are required at the same time).

1. Access size to this register is 16 bits
2. The value of KEY[7:0] is 0x66
3. The FSPR bit is 1.

Note 2. Written values are not retained by these bits (always read 0x00).

Note 3. Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

FSUACR sets the startup area for the boot swap function.

### SAS[1:0] bits (Startup Area Select)

The SAS[1:0] bits select the startup area. Three methods are available for changing the startup area.

### KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SAS [1:0] bits.

#### 40.4.28 FCKMHZ : Data Flash Access Frequency Register

Base address: FLAD = 0x407F\_C000

Offset address: 0x40

|                    |             |   |   |   |   |   |   |   |
|--------------------|-------------|---|---|---|---|---|---|---|
| Bit position:      | 7           | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Bit field:         | FCKMHZ[7:0] |   |   |   |   |   |   |   |
| Value after reset: | 0           | 0 | 1 | 1 | 1 | 1 | 0 | 0 |

| Bit | Symbol      | Function                                                                                                | R/W |
|-----|-------------|---------------------------------------------------------------------------------------------------------|-----|
| 7:0 | FCKMHZ[7:0] | Data Flash Access Frequency Register<br>These bits optimize the speed of reading the data flash memory. | R/W |

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

This register optimizes the speed of reading the data flash memory.

Set the frequency of the peripheral module clock (FCLK) of internal peripheral bus which is the clock for access to the data flash memory, in MHz units. For example, 35.9 MHz should be rounded up and set the frequency to 36. Number of cycles required for access to the data flash memory are inserted according to the frequency. When changing the frequency of the FCLK, follow the procedure below to modify the value of the data flash access frequency register (FCKMHZ) in either of the following ways according to whether operation is at a lower frequency before or after the change.

- When changing the speed from low to high: Modify FCKMHZ. After confirming the change by reading FCKMHZ, change the frequency.
- When changing the speed from high to low: Change the frequency. After the frequency is changed, modify FCKMHZ.

## 40.5 Flash Cache

### 40.5.1 Feature of flash cache

The FCACHE (Flash Cache) speeds up read access from bus master to the flash memory. The FCACHE includes:

- FCACHE1, for CPU instruction fetches
- FCACHE2, for CPU operand access
- FLPF, for the prefetch access in CPU instruction fetches

**Table 40.6 Flash Cache 1 (FCACHE1) overview**

|                     |                                                                              |
|---------------------|------------------------------------------------------------------------------|
| Cache Target Region | 0x0000_0000 - 0x007F_FFFF                                                    |
| Target Bus Master   | CPU instruction Fetch                                                        |
| Capacity            | 256 Bytes                                                                    |
| Associativity       | 8WAY set associative<br>128 bits/entry (128 bit aligned data), 2 entries/way |
| Access Cycle        | Cache Hit : 0 wait<br>Cache Miss : wait number of Flash Wait Cycle Register  |

## 40.7 Overview of Functions

By using a dedicated flash-memory programmer to program the flash memory through a serial interface (serial programming) or JTAG/SWD interface (on-chip debug mode), the device can be rewritten regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties.

Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations. [Table 40.10](#) lists the overview of the methods of programming and the corresponding operating modes.

**Table 40.10 Programming methods**

| Programming method      | Functional overview                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Operating mode          |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| Serial programming      | A dedicated flash-memory programmer through the SCI or USBFS interface enables on-board programming of the flash memory after the device is mounted on the target system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Serial programming mode |
|                         | A dedicated flash-memory programmer through the SCI or USBFS interface and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                         |
| Self-programming        | A user program written to memory in advance of serial programming execution can also program the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data from the code flash memory while the data flash memory is programmed. As a result, a program resident in the code flash memory is able to program the data flash memory. For background operations that are not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while the code flash memory is being programmed by self-programming. In such cases, a program for programming from the internal SRAM must be transferred in advance and executed. | Normal operating mode   |
| JTAG or SWD programming | A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD enables on-board programming of the flash memory after the device is mounted on the target system. A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.                                                                                                                                                                                                                                                                     | On-chip debug mode      |

[Table 40.11](#) lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.

**Table 40.11 Basic Functions**

| Function                              | Functional overview                                                                                                                                                                                                                                                               | Availability       |                                                                   |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|-------------------------------------------------------------------|
|                                       |                                                                                                                                                                                                                                                                                   | Serial programming | Self-programming                                                  |
| Blank check                           | Checks a specified block to ensure that writing to it has not already proceeded. Results of reading from data flash memory to which nothing is written after erasure are not guaranteed, so use blank checking to confirm that writing to memory has not proceeded after erasure. | Not supported      | Supported (data flash programming only)                           |
| Block erasure                         | Erases the memory contents in the specified block                                                                                                                                                                                                                                 | Supported          | Supported                                                         |
| Programming                           | Writes to the specified address                                                                                                                                                                                                                                                   | Supported          | Supported                                                         |
| CRC                                   | Calculates the CRC in the specified range of the flash memory and transfers it to the flash programmer                                                                                                                                                                            | Supported          | Non supported                                                     |
| Read                                  | Reads data programmed in the flash memory                                                                                                                                                                                                                                         | Supported          | Not supported (read by user program is possible)                  |
| Start-up program protection functions | Configures the start-up program protection functions                                                                                                                                                                                                                              | Supported          | Supported                                                         |
| Option function selection             | Selects the option function, and modifies the initial setting of this MCU                                                                                                                                                                                                         | Supported          | Supported                                                         |
| Block protection                      | Setting block protection                                                                                                                                                                                                                                                          | Supported          | Supported                                                         |
| Device lifecycle transition           | Transitions the device lifecycle                                                                                                                                                                                                                                                  | Supported          | Not supported                                                     |
| Memory security attribution           | Setting the memory security attribution                                                                                                                                                                                                                                           | Supported          | Not supported                                                     |
| Key                                   | Injects key                                                                                                                                                                                                                                                                       | Supported          | Supported (except the key related to device lifecycle transition) |
| All erasure                           | Erase the flash memory to the state after shipment                                                                                                                                                                                                                                | Supported          | Not supported                                                     |

The flash memory supports various security functions.

[Table 40.12](#) lists the security functions supported by the flash memory.

**Table 40.12 Lists of Security Functions**

| Function                               | Description                                                                                                                      |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Security flag for Start-up area select | Start-up area selection can be protected by setting of security flag (FSPR).                                                     |
| Permanently block protection           | Programming or erasure of each block of code flash memory can be protected permanently.                                          |
| Protection for TrustZone               | Programming or erasure area, readable area, register access, and FACI command operation are protected by ARM TrustZone security. |
| Programming or erasure mode protection | Only secure developer can enter the programming or erasure mode for code flash.                                                  |

## 40.8 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in [Figure 40.6](#). Transitions between modes are initiated by changing the value of the FENTRYR register.

When the value of the FENTRYR register is 0x0000, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are both readable.

When the value of the FENTRYR register is 0x0001, the flash sequencer is in code flash P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is readable.

When the value of the FENTRYR register is 0x0080, the flash sequencer is in data flash P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

Figure 40.6 Modes of the flash sequencer

## 40.9 FACI Commands

### 40.9.1 List of FACI Commands

The FACI controls the FCU according to the specified FACI commands.

This section describes information about the FACI commands and [Table 40.13](#) lists the FACI commands.

Table 40.13 FACI commands

| FACI command      | Function                                                                                                                                                                                                                           |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Program           | Programs the user area and data area. Units of programming are 128 bytes for the user area and 4, 8, or 16 bytes for the data area.                                                                                                |
| Block erase       | Erases user area and data area. The erase unit is 8 KB or 32 KB for user area, and 64 bytes for data flash.                                                                                                                        |
| Multi block erase | Erases data area. The erase unit is 64, 128, 256 bytes for data flash.                                                                                                                                                             |
| P/E suspend       | Suspends programming or erasure processing.                                                                                                                                                                                        |
| P/E resume        | Resumes suspended programming or erasure processing.                                                                                                                                                                               |
| Status clear      | Initializes the ILGLERR, ERSERR, PRGERR, ILGCOMERR, FESETERR, SECERR, and OTERR bits in the FSTATR register and the CMDLK, CFAE, and DFAE bits in the FASTAT register, and the flash sequencer released from command-locked state. |
| Forced stop       | Forcibly stops processing of FACI commands and initializes the FSTATR and FASTAT registers.                                                                                                                                        |
| Blank check       | Checks if data areas are blank. Units of Blank Check: 4 bytes to data flash memory capacity (specified in 4-byte units).                                                                                                           |
| Configuration set | Sets the option-setting memory. Units of setting: 16 bytes.                                                                                                                                                                        |

The FACI commands are issued by writing to the FACI command-issuing area (see [Table 40.3](#)). When write access as shown in [Table 40.14](#) proceeds in the specified state, the flash sequencer executes the processing associated with the given command (see [section 40.9.2. Relationship between the Flash Sequencer State and FACI Commands](#)).

**Table 40.14 FACI command formats**

| FACI commands                                                                                               | Number of write access | Write data to the FACI command-issuing area |                                     |                       |                |
|-------------------------------------------------------------------------------------------------------------|------------------------|---------------------------------------------|-------------------------------------|-----------------------|----------------|
|                                                                                                             |                        | 1st access                                  | 2nd access                          | 3rd to (N+2)th access | (N+3)th access |

Note: WDN (N = 1, 2, ...): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY bit to 0 at the start of a command processing other than the Status Clear command, and sets this bit to 1 on completion.

If the FRDYIE.FRDYIE bit setting is 1, a flash ready (FRDY) interrupt is generated when the FSTATR.FRDY bit is set to 1.

## 40.9.2 Relationship between the Flash Sequencer State and FACI Commands

The FACI commands are accepted according to the mode/state of the flash sequencer. FACI commands should be issued after transitioning of the flash sequencer to the code flash P/E mode or data flash P/E mode and after checking the state of the flash sequencer.

Use the FSTATR and FASTAT registers to check the state of the flash sequencer. In addition, the occurrence of errors in general can be checked by reading the CMDLK bit in the FASTAT register. The value of the CMDLK bit is the logical OR of the following bits in the FSTATR register:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR
- FLWEERR.

[Table 40.15](#) lists the available FACI commands in each operating mode.

**Table 40.15 Operating mode and available FACI commands**

| Operating mode      | FENTRYR | Available FACI commands                                                                                                |
|---------------------|---------|------------------------------------------------------------------------------------------------------------------------|
| Read mode           | 0x0000  | None                                                                                                                   |
| Code flash P/E mode | 0x0001  | Program<br>Block erase<br>P/E suspend<br>P/E resume<br>Status Clear<br>Forced Stop<br>Configuration set                |
| Data flash P/E mode | 0x0080  | Program<br>Block erase<br>Multi block erase<br>P/E suspend<br>P/E resume<br>Status Clear<br>Forced Stop<br>Blank Check |

Table 40.16 shows the state of the flash sequencer and acceptable FACI commands. An appropriate mode is assumed to have been set before the commands are executed.

**Table 40.16 Acceptable FACI commands and state of the flash sequencer**

|                                  | Program, block erase or multi block erase command processing | Configuration set command processing | Program, block erase or multi block erase command suspension processing | Blank check command processing | Programming suspended | Erasure suspended | Programming while erasure is suspended | Command-locked state (FRDY = 1) | Command-locked state (FRDY = 0) | Processing of forced stop command | Other state    |
|----------------------------------|--------------------------------------------------------------|--------------------------------------|-------------------------------------------------------------------------|--------------------------------|-----------------------|-------------------|----------------------------------------|---------------------------------|---------------------------------|-----------------------------------|----------------|

| Status clear                     | X                                                            | X <sup>4</sup>                       | X                                                                       | X                              | O                     | O                 | X                                      | O                               | X                               | X                                 | O              |
| Forced stop                      | O                                                            | O <sup>4</sup>                       | O                                                                       | O                              | O                     | O                 | O                                      | O                               | O                               | O                                 | O              |
| Blank check                      | X                                                            | X <sup>4</sup>                       | X                                                                       | X                              | O <sup>1</sup>        | O <sup>1</sup>    | X                                      | X                               | X                               | X                                 | O <sup>1</sup> |
| Configuration set                | X                                                            | X <sup>4</sup>                       | X                                                                       | X                              | X                     | X                 | X                                      | X                               | X                               | X                                 | O <sup>2</sup> |

Note: O: Acceptable

X: Not acceptable (places the sequencer in the command-locked state)

—: Ignored

Note 1. Only acceptable in data flash P/E mode.

Note 2. Only acceptable in code flash P/E mode

Note 3. Acceptable when programming area is other than erase suspending block.

Note 4. When configuration set is processing and when FSTATR.DBFULL bit is 1, do not issue this command.

### 40.9.3 Usage of FACI Commands

#### 40.9.3.1 Overview of Command Usage in Code Flash P/E Mode

Figure 40.7 show an overview of FACI command usage in code flash P/E mode. For the available commands in code flash P/E mode, see Table 40.15.

Figure 40.7 Overview of command usage in code flash P/E mode

#### 40.9.3.2 Overview of Command Usage in Data Flash P/E Mode

Figure 40.8 shows an overview of FACI command usage in data flash P/E and Table 40.15 lists the available commands in data flash P/E mode.

**Figure 40.8 Overview of command usage in data flash P/E mode**

### 40.9.3.3 Transition to Code Flash P/E Mode

To issue FACL commands for the code flash memory, a transition to code flash P/E mode is required by setting the FENTRYC bit in the FENTRYR register to 1.

[Figure 40.9](#) shows the procedure to transition to code flash P/E mode.

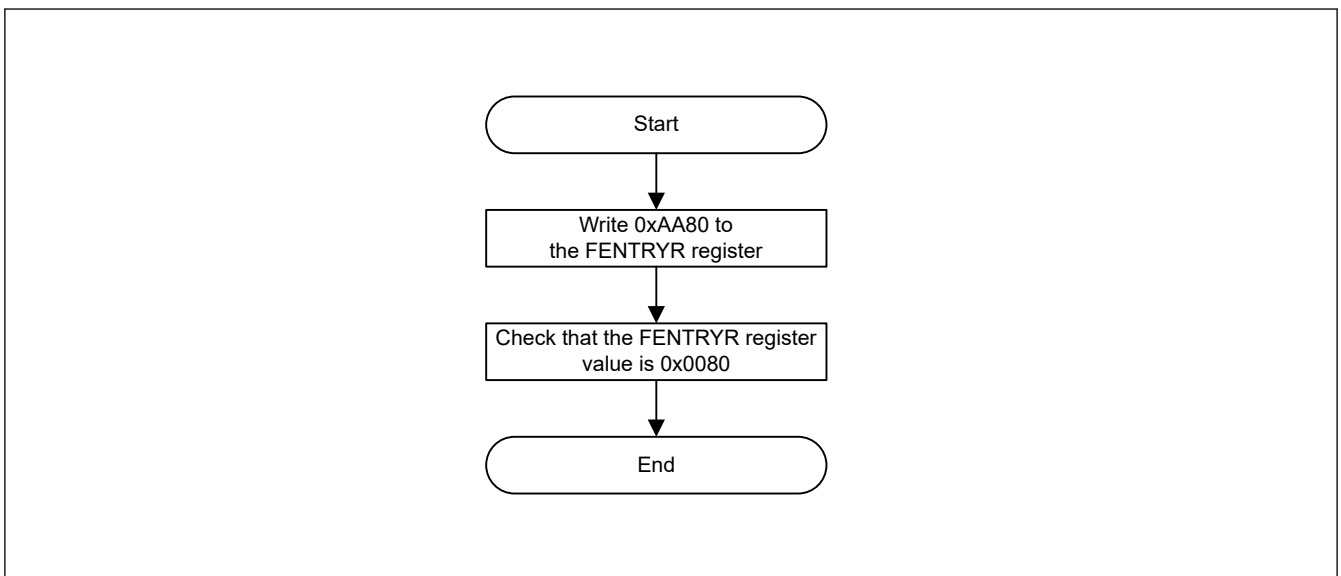

**Figure 40.9** Procedure to transition to code flash P/E mode

#### 40.9.3.4 Transition to Data Flash P/E Mode

To issue FACY commands for the data flash memory, a transition to data flash P/E mode is required by setting the FENTRYD bit in the FENTRYR register to 1.

Figure 40.10 shows the procedure to transition to data flash P/E mode.

**Figure 40.10** Procedure to transition to data flash P/E mode

#### 40.9.3.5 Transition to Read Mode

To read the flash memory, a transition to read mode is required by setting the FENTRYR register to 0x0000. The transition to read mode should be made after the flash sequencer completes the processing and while operation is not in the command-locked state.

Figure 40.11 shows the procedure to transition to read mode.

**Figure 40.11 Procedure to transition to read mode**

#### 40.9.3.6 Recovery from the Command-Locked State

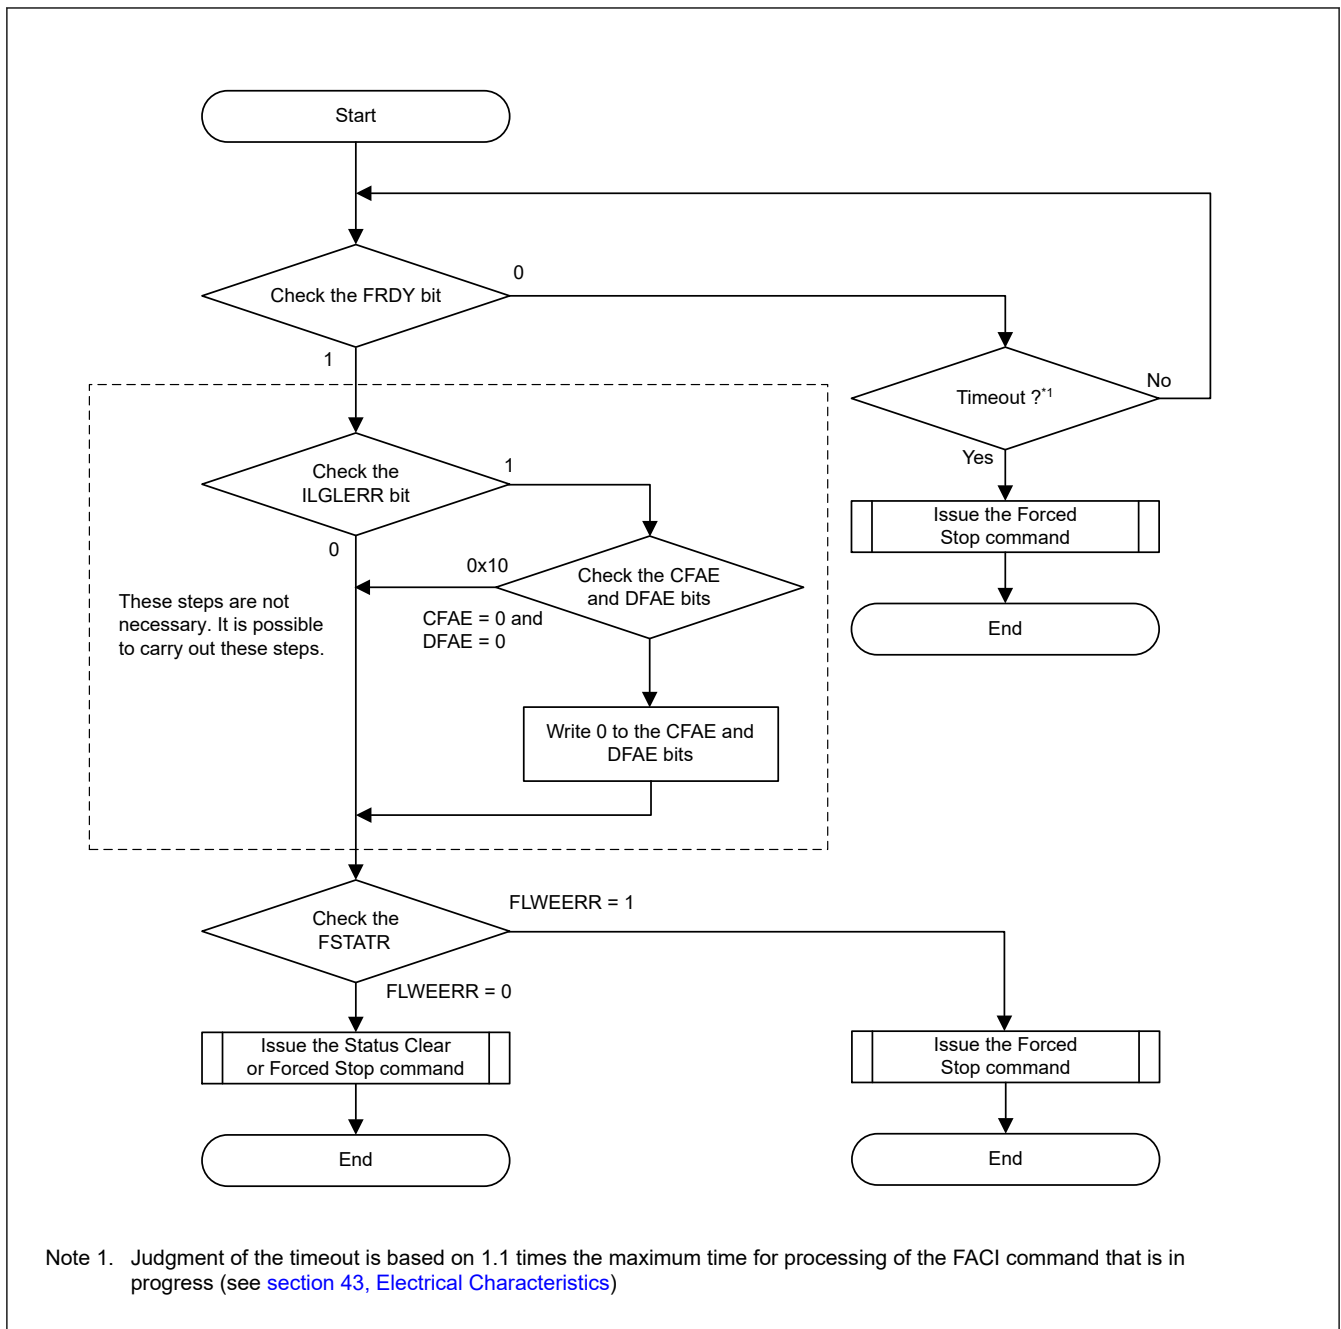

When the flash sequencer enters the command-locked state, FACL commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, forced stop command, or FASTAT register.

When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FRDY bit in the FSTATR register might be 0 even though command processing has not completed. If processing is not complete by the maximum programming/erasure time specified in the electrical characteristics, this is a timeout and the flash sequencer must be stopped with the forced stop command.

The FLWEERR bit in the FSTATR register does not change from 1 to 0 with the status clear command. When these bits are set to 1, use the forced stop command to release from the command-locked state. Bits other than FRDY and FLWEERR in FSTATR register that indicate the command-locked state can be changed from 1 to 0 with the status clear or forced stop command.

[Figure 40.12](#) shows the recovery flow from the command-locked state.

**Figure 40.12 Recovery flow from the command-locked state**

### 40.9.3.7 Program Command

Program commands are used to write to the user and data areas. Before issuing the FACI program command, set the first address of the target block in the FSADDR register.

Program processing is started by writing the last 16 bits of program data (WD64 for code flash and WD2, WD4, and WD8 for data flash in [Table 40.14](#)) to the FACI command-issuing area before 0xD0, the final value of the FACI command, is written. Therefore, if it takes time from writing the last 16 bits of program data to writing the final FACI command value 0xD0 (for example, due to interrupt processing), the FSTATR.FRDIY bit is set to 1 when program processing is completed even if 0xD0 has not been written. In this case, the program processing has been completed, but the FACI command reception has not been completed. If a subsequent FACI command is issued in this state, an illegal command error will occur. To avoid illegal command errors, disable interrupts with processing that issues FACI commands while program commands are issued (from writing 0xE8 to writing 0xD0).

If the target area for program command processing includes an area that is not for writing, write 0xFFFF to the corresponding area. If a program command is issued while the FACI internal data buffer is full, a wait period may occur on

the peripheral bus, which may affect the communication performance of other peripheral modules. To avoid the occurrence of a waiting period, set the DBFULL bit in the FSTATR register to 0 when issuing a FOCI command. Writing to the data area will not cause the data buffer to become full.

[Figure 40.13](#) shows the usage of the program command.

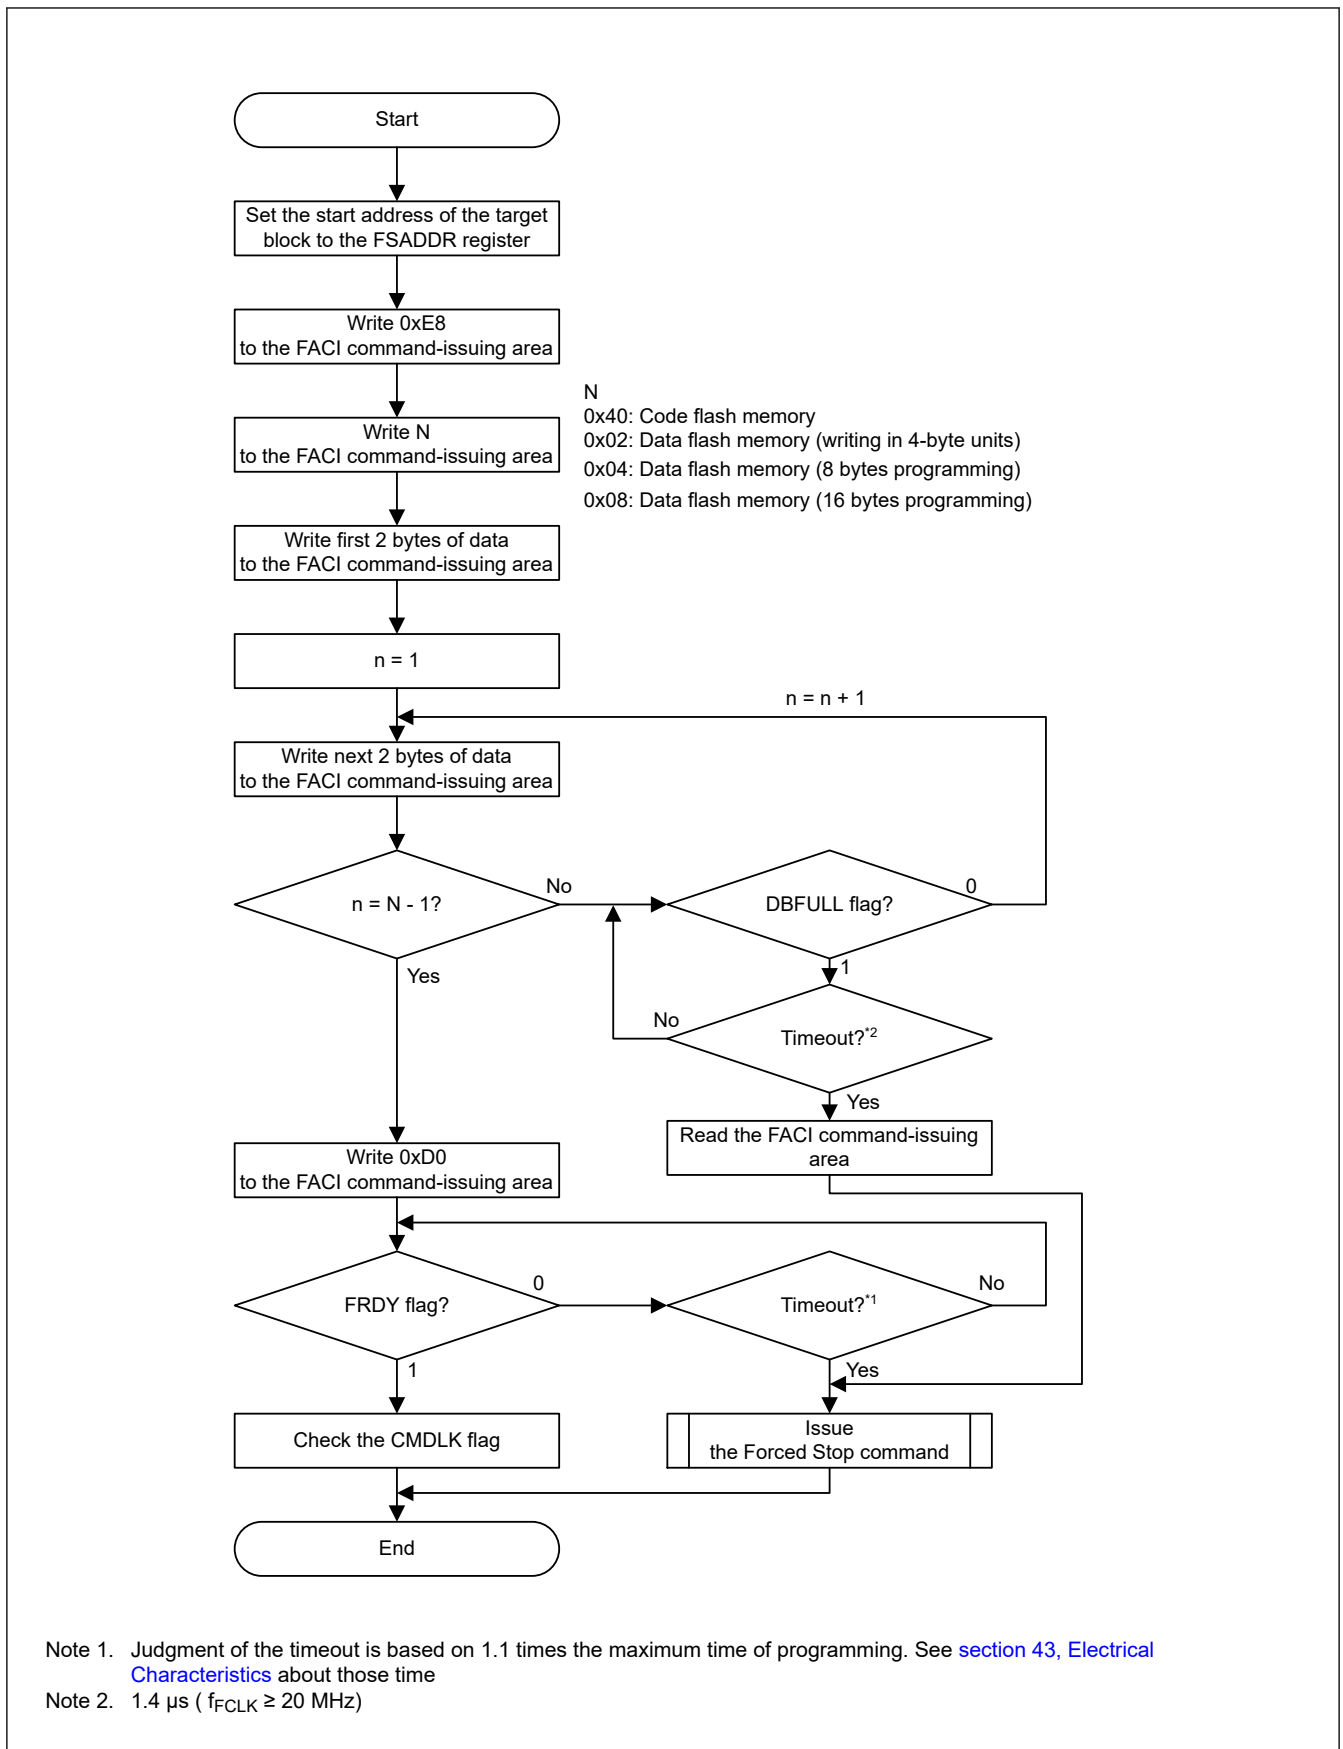

Figure 40.13 Usage flow of the program command

### 40.9.3.8 Block Erase Command

The block erase command is used for erasing user area or data area. The erase unit is one block. Before issuing a block erase command, set the first address of the target block to FSADDR register. Writing 0xD0 at the second write access of the FACL command triggers the FACL to start the block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

Figure 40.14 shows the usage of the block erase command.

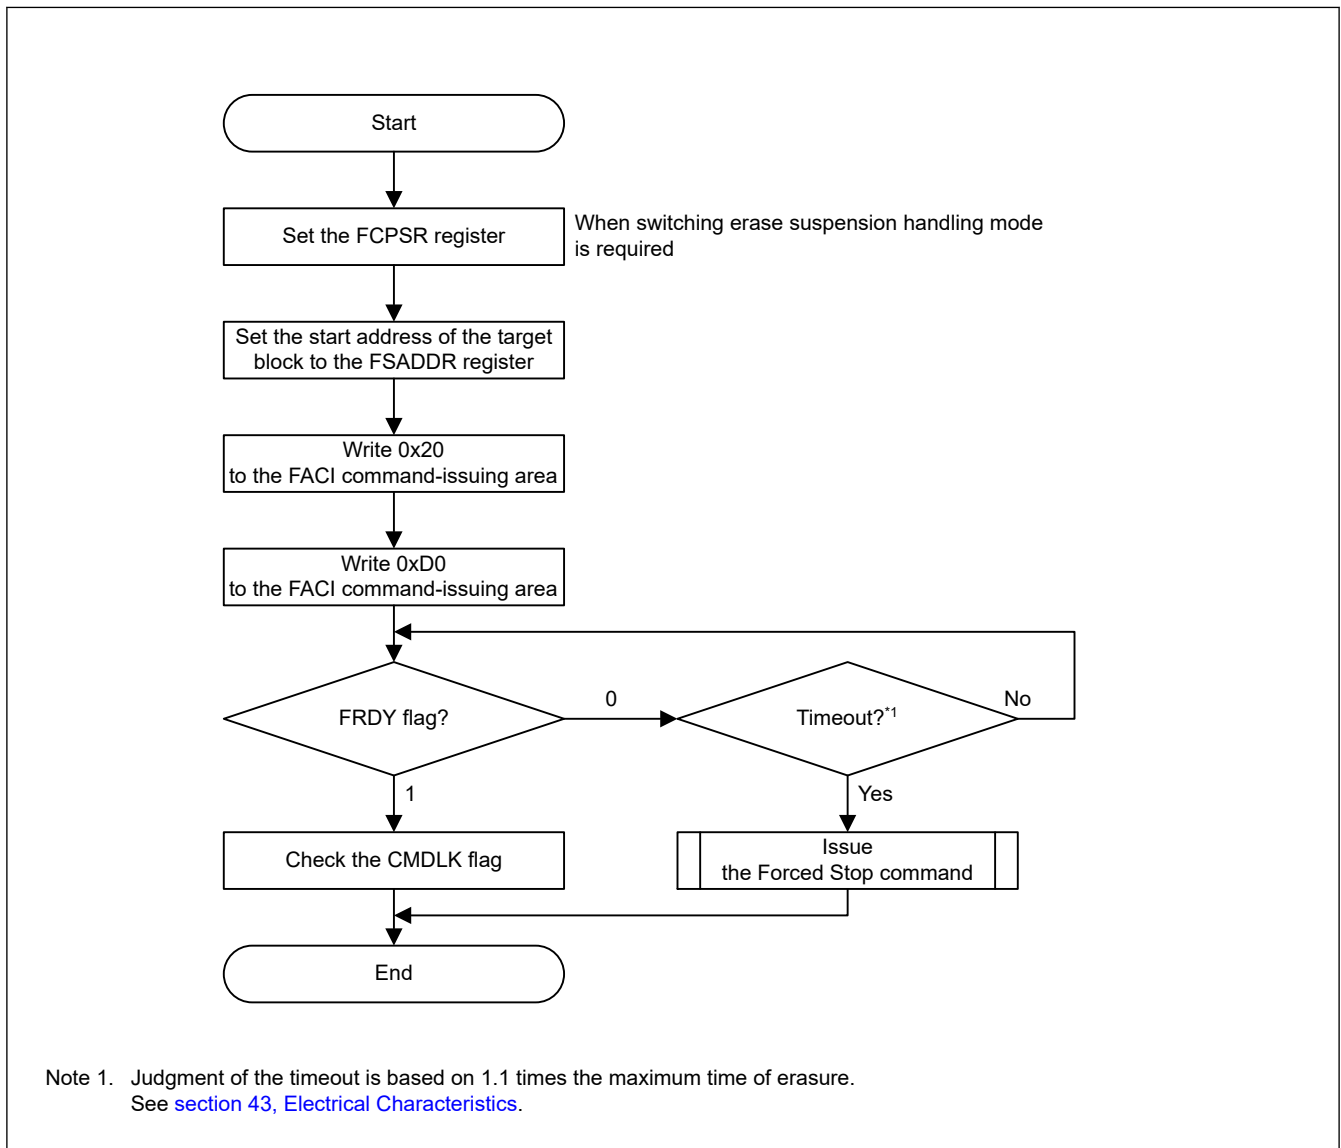

Figure 40.14 Usage flow of the block erase command

### 40.9.3.9 Multi Block Erase Command

The multi block erase command is used for erasing data area. The erase unit is 64, 128, or 256 bytes. Before issuing the multi block erase command, set the start address to FSADDR register and the end address to FEADDR register. Writing 0xD0 at the second write access of the FACL command triggers FACL to start the multi block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the multi block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

The erase size is specified by both the FSADDR and FEADDR settings. [Table 40.17](#) describes how to set the FSADDR and FEADDR.

**Table 40.17 Settings for the erase size**

| Erase size | FSADDR                               | FEADDR        |
|------------|--------------------------------------|---------------|
| 64 bytes   | FSA0 to FSA5 = 0 (64 byte-boundary)  | FSADDR + 0x3C |
| 128 bytes  | FSA0 to FSA6 = 0 (128 byte-boundary) | FSADDR + 0x7C |
| 256 bytes  | FSA0 to FSA7 = 0 (256 byte-boundary) | FSADDR + 0xFC |

**Figure 40.15 Usage flow of the multi block command**

### 40.9.3.10 P/E Suspend Command

The P/E suspend command is used to suspend programming/erasure. Before issuing a P/E suspend command, check that the CMDLK bit in the FASTAT register is 0, and that the execution of programming/erasure is performed normally. To confirm that the P/E suspend command can be received, check that the SUSRDY bit in the FSTATR register is 1. After issuing a P/E suspend command, read the CMDLK bit to confirm that no error occurs.

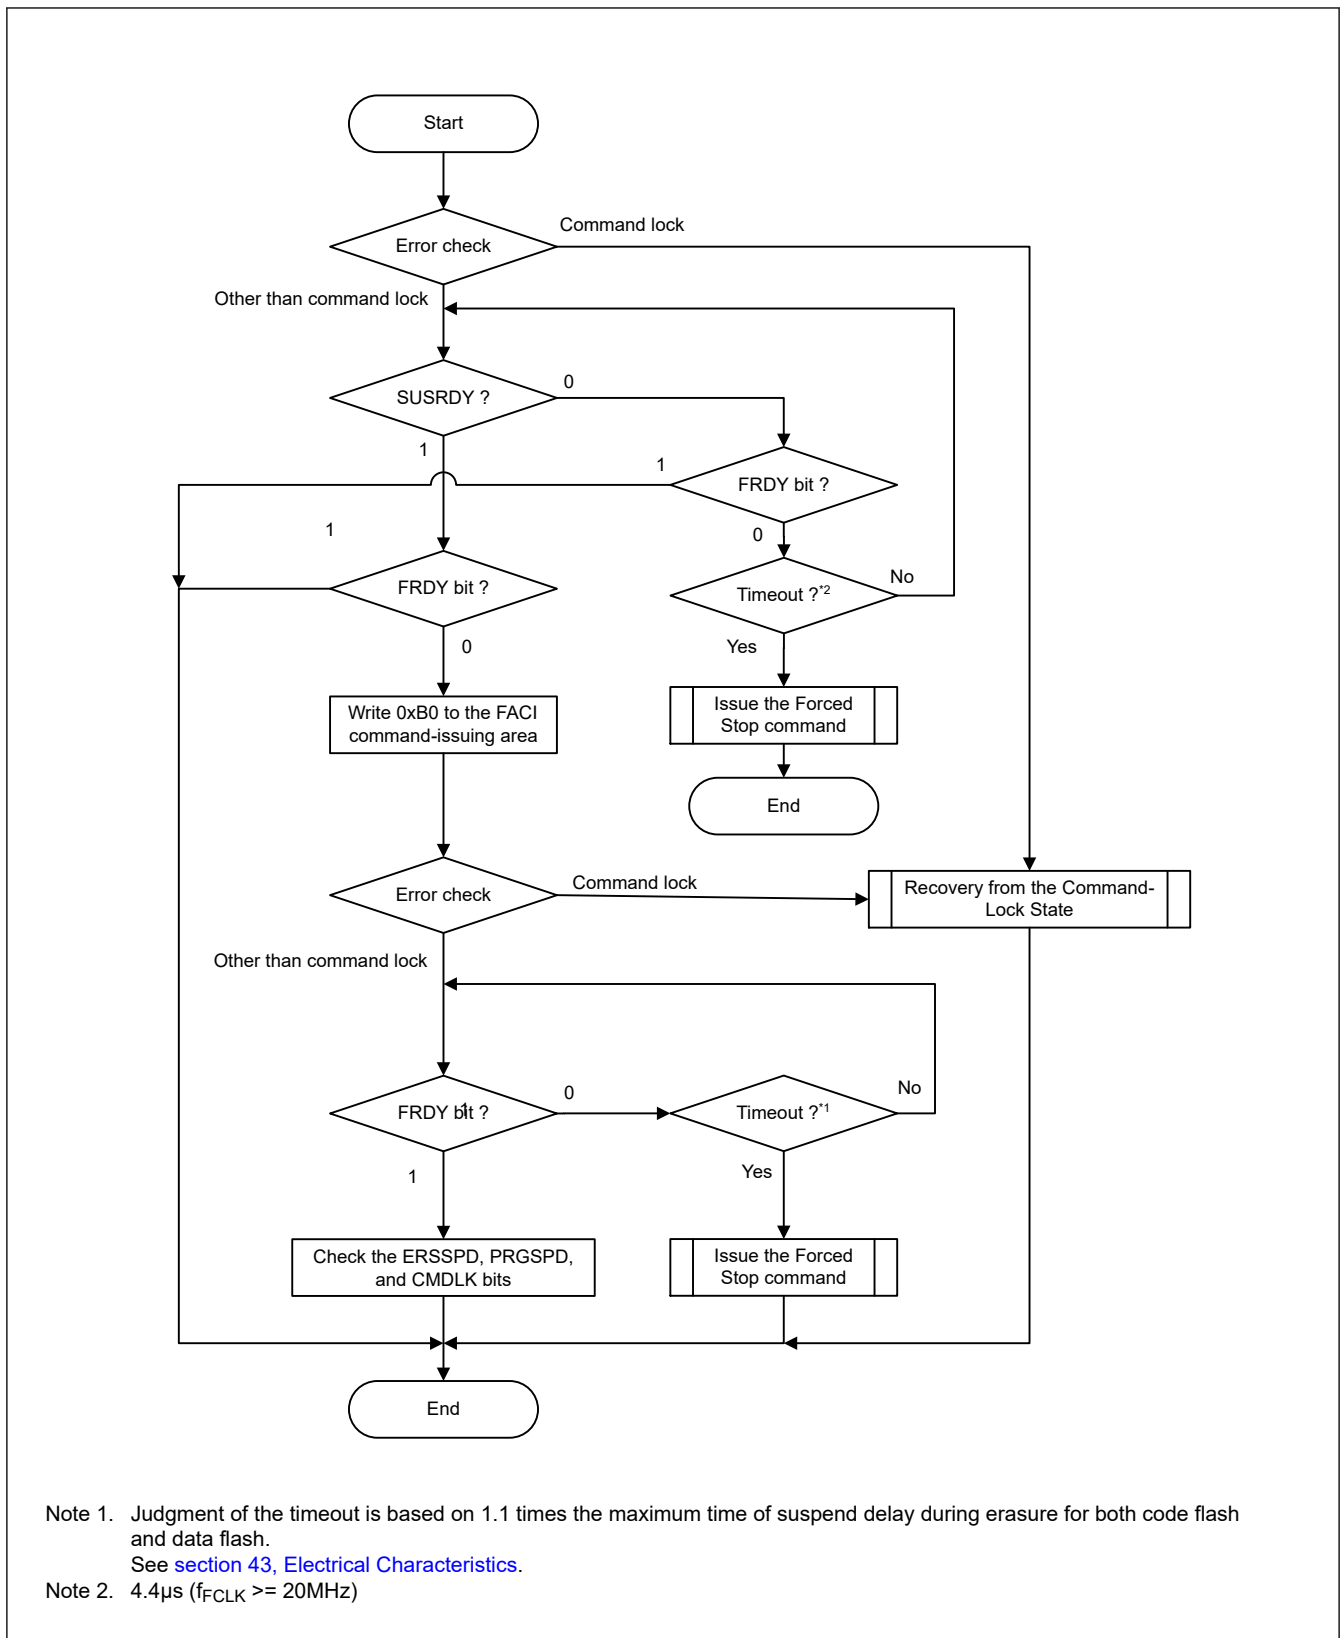

If an error occurs during programming/erasure, the CMDLK bit is set to 1. When programming/erasure processing has finished from the time when the SUSRDY bit is 1 to when the P/E suspend command is received, no error occurs and the

suspended state is not entered (the FRDY bit in the FSTATR register is 1 and the ERSSPD and PRGSPD bits in FSTATR are 0).

When a P/E suspend command is received and the programming/erasure suspend processing finishes normally, the flash sequencer enters the suspended state, the FRDY bit is set to 1, and the ERSSPD or PRGSPD bit is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD bit is 1 and the suspended state is entered, then proceed with the subsequent flow. If a P/E resume command is issued in the subsequent flow even when the suspended state is not entered, an illegal command error occurs and the flash sequencer shifts to the command-locked state (see [section 40.11.2. Error Protection](#)).

If the erasure suspended state is entered, programming to blocks other than an erasure target block can be performed. Additionally, the programming and erasure suspended states can shift to read mode by clearing the FENTRYR register.

[Figure 40.16](#) shows the usage of the P/E suspend command.

**Figure 40.16 Usage flow of the P/E suspend command**

**(1) Suspension during Programming**

When issuing a P/E suspend command during flash memory programming, the flash sequencer suspends programming processing. [Figure 40.17](#) shows the suspend programming operation. When receiving programming-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start programming. If the flash sequencer enters the

state in which the P/E suspend command can be received after programming starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0. If the flash sequencer receives a P/E suspend command while a programming pulse is applied, the flash sequencer continues with the pulse. After the specified pulse application time, the flash sequencer finishes pulse application, starts the programming suspend processing, and sets the PRGSPD bit in the FSTATR register to 1.

When a suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the programming suspended state. When receiving a P/E resume command in the programming suspended state, the flash sequencer clears the FRDY and PRGSPD bits to 0 and resumes programming.

Figure 40.17 shows the timing for suspension during programming.

**Figure 40.17** Suspension during programming

## (2) Suspension during Erasure (Suspension Priority Mode)

The flash sequencer has a suspension priority mode for the suspension of erasure. Figure 40.18 shows the suspend operation of erasure when the erasure suspend mode is set to the suspension priority mode (the ESUSPMD bit in the FCPSR register is 0).

When receiving an erasure-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start erasure. If the flash sequencer enters the state in which the P/E suspend command can be received after erasure starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0.

When receiving a suspend command during erasure, the flash sequencer starts the suspend processing and sets the ERSSPD bit in the FSTATR register to 1 even when it is applying an erasure pulse. When the suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the erasure suspended state. When receiving a P/E resume command in the erasure suspended state, the flash sequencer clears the FRDY and ERSSPD bits to 0 and resumes erasure. Operations of the FRDY, SUSRDY, and ERSSPD bits at the suspension and resumption of erasure are the same, regardless of the erasure suspend mode.

The setting of the erasure suspend mode affects the control method of erasure pulses. In suspension priority mode, when receiving a P/E suspend command while erasure pulse A that has not been previously suspended is being applied, the flash sequencer suspends the application of erasure pulse A and enters the erasure suspended state. When receiving a P/E suspend command while reapplying erasure pulse A after erasure is resumed with a P/E resume command, the flash sequencer

continues to apply erasure pulse A. After the specified pulse application time, the flash sequencer finishes erasure pulse application and enters the erasure suspended state.

When the flash sequencer receives a P/E resume command next and erasure pulse B is being applied, the flash sequencer receives a P/E suspend command again, and the application of erasure pulse B is then suspended. In suspension priority mode, delays due to suspension can be minimized because the application of an erasure pulse is suspended once per pulse, and priority is given to the suspend processing.

If the interval of suspension after resume is longer than  $t_{REST1}$  (Resume time: priority on suspension, resume after the 1st suspend for the same pulse), suspend delay will be always  $t_{SESD1}$  (Suspend delay: priority on suspension, the 1st suspend for the same pulse).

If the interval of suspension after resume is shorter than  $t_{REST1}$ , suspend delay becomes either  $t_{SESD1}$  or  $t_{SESD2}$  (Suspend delay: priority on suspension, the 2nd suspend for the same pulse).

(The value of  $t_{REST1}$  /  $t_{SESD1}$  /  $t_{SESD2}$ , see [section 43, Electrical Characteristics](#).)

**Figure 40.18 Suspension during erasure (suspension priority mode)**

### (3) Suspension during Erasure (Erasure Priority Mode)

The flash sequencer has an erasure priority mode for the suspension of erasure. [Figure 40.19](#) shows the suspend operation of erasure when the erasure suspend mode is set to the erasure priority mode (the ESUSPMD bit in the FCPSR register is 1). The control method of erasure pulses in erasure priority mode is the same as that of programming pulses for the programming suspend processing.

If the flash sequencer receives a P/E suspend command while an erasure pulse is applied, the flash sequencer continues to apply the pulse. In this mode, the required time for the erasure processing can be reduced compared to the suspension priority mode because the re-application of erasure pulses does not occur when a P/E resume command is issued.

**Figure 40.19** Suspension during erasure (erasure priority mode)

#### 40.9.3.11 P/E Resume Command

The P/E resume command is used to resume suspended programming or erasure. If the FENTRYR setting has been modified during suspension, issue a P/E resume command only after resetting FENTRYR to the previous value that was held before the P/E suspend command was issued. [Figure 40.20](#) shows usage of the P/E resume command.

**Figure 40.20** Usage flow of the P/E resume command

### 40.9.3.12 Status Clear Command

The status clear command is used to clear the command-locked state (see [section 40.9.3.6. Recovery from the Command-Locked State](#)).

You can use the status clear command to clear the following bits in the FSTATR register in the command-locked state:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR

[Figure 40.21](#) shows usage of the status clear command.

**Figure 40.21** Usage flow of the status clear command

### 40.9.3.13 Forced Stop Command

The forced stop command is used to forcibly end command processing by the flash sequencer. Although this command halts command processing more quickly than the P/E suspension command, values from the programming or erasure that are in progress are not guaranteed. Additionally, resumption of processing is not possible. Processing of programming or erasure that is halted by the forced stop command is also defined as one programming round.

Executing the forced stop command also initializes part of the FACL, the whole FCU, the FSTATR and FASTAT registers. This command can be used in the procedure for recovery from the command-locked state and for processing in response to a timeout of the flash sequencer (see [section 40.9.3.6. Recovery from the Command-Locked State](#)).

[Figure 40.22](#) shows usage of the forced stop command.

**Figure 40.22 Usage flow of the forced stop command**

#### (1) Notes on Using the Forced Stop Command during Command Issue

When using the forced stop command at the timeout occurrence by DBFULL bit of the program command, writing in the FACI command-issuing area is sometimes processed as writing in data of the program command. See [Table 40.3](#) in [section 40.3. Address Space](#) for information on the FACI command-issuing area to force a command lock. Then issue a forced stop command with return method from the command lock status (see [Figure 40.13](#)). Locking commands is possible in any case where the unit for reading the FACI command issuing area is 8, 16, or 32 bits.

#### 40.9.3.14 Blank Check Command

The blank check command is used to confirm that an area is in the non-programmed state. Values read from the data flash memory that have been erased but not yet programmed again that is in the non-programmed state, are undefined.

Before issuing the Blank Check command, set addressing mode, start address, and end address of the target area for Blank Check to the FBCCNT, FSADDR, and FEADDR registers. When Blank Check addressing mode is set to decremental mode (i.e. FBCCNT.BCDIR = 1), address specified in FSADDR should be equal to or larger than address in FEADDR.

On the other hand, the address in FSADDR should be equal to or smaller than address in FEADDR when Blank Check addressing mode is set to incremental mode (i.e. FBCCNT.BCDIR = 0).

If the settings of the BCDIR bit, FSADDR, and FEADDR are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for Blank Check is in the range from 4 bytes to the data flash memory capacity and is set in units of 4 bytes.

Write 0x71 and 0xD0 to the FACI command-issuing area to start Blank Check. Completion of processing can be confirmed by the FRDY bit of the FSTATR register. At the end of processing, the result of Blank Check is stored in the BCST bit in the FBCSTAT register. If non-programmed data exists within the target area for Blank Check, flash sequencer stops Blank Check command operation. In this case, address of non-programmed data is indicated to FPSADDR register.

[Figure 40.23](#) shows usage of the blank check command.

**Figure 40.23 Usage flow of the blank check command**

### 40.9.3.15 Configuration Set Command

The Configuration set command is used to set option-setting memory. Before issuing the Configuration set command, set the specified address (shown in [Table 40.18](#)) in the FSADDR register. Writing 0xD0 to the FSCI command-issuing area in the final access for issuing the FSCI command starts FSCI processing of the Configuration set command.

[Figure 40.24](#) shows usage of the configuration set command.

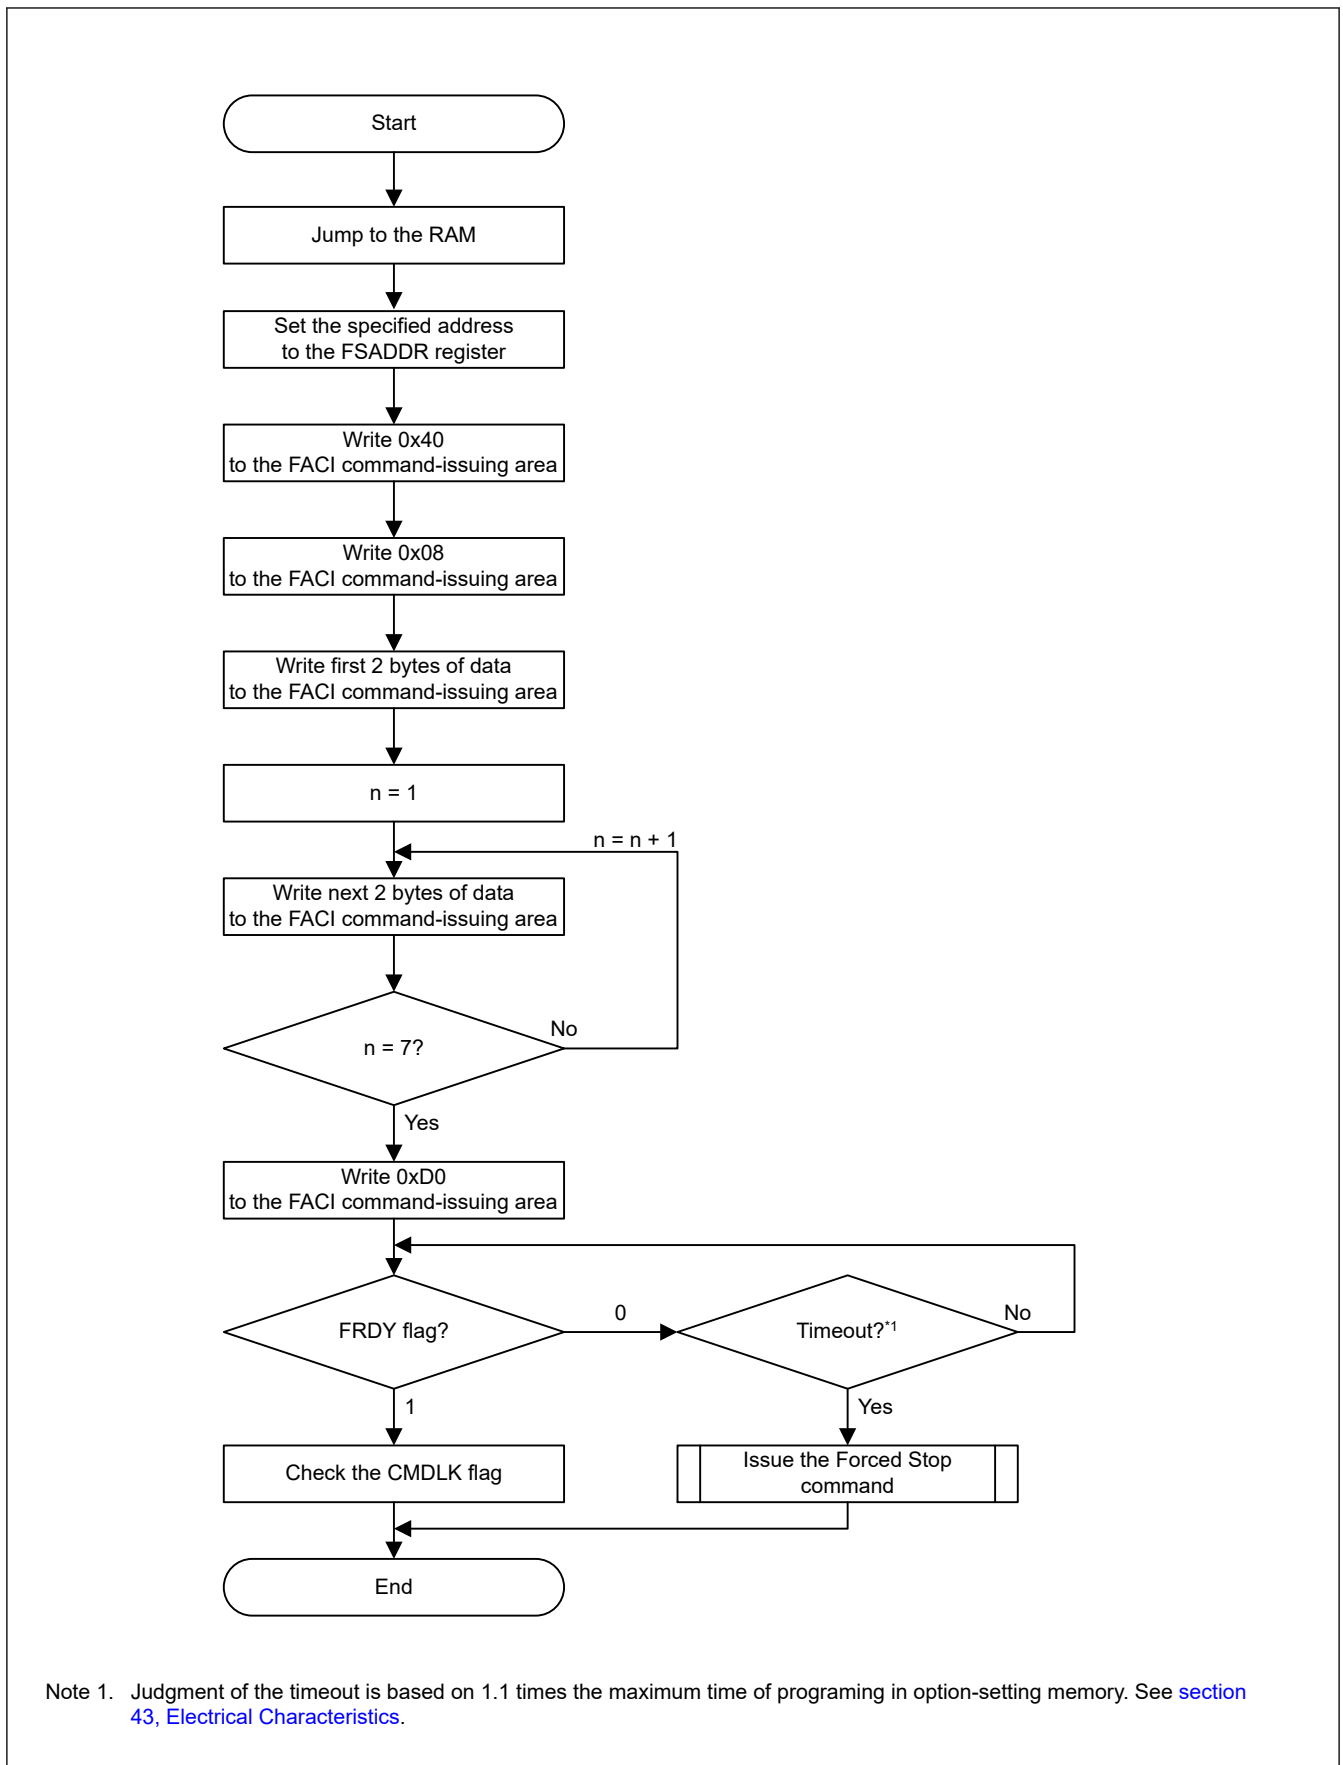

Figure 40.24 Usage flow of the configuration set command

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in [Table 40.18](#). For details, see [section 40.4.12. FSADDR : FOCI Command Start Address Register](#).

**Table 40.18 Address Used by Configuration Set Command**

| Address     | FSADDR Register Value | Setting Data                                               | Operation of additional writing  |                                  | Timing when the Setting is Enabled  |
|-------------|-----------------------|------------------------------------------------------------|----------------------------------|----------------------------------|-------------------------------------|
|             |                       |                                                            | SAS.FSPR bit is 1                | SAS.FSPR bit is 0                |                                     |
| 0x0100_A100 | 0x0100_A100           | Option Function Select Register 0 (OFS0)                   | Writable                         | Writable                         | At a reset                          |
| 0x0100_A134 | 0x0100_A130           | Start-up Area Setting Register (SAS)                       | Writable                         | Not writable*1                   | When a reset or command is executed |
| 0x0100_A180 | 0x0100_A180           | Option Function Select Register 1 (OFS1)                   | Writable                         | Writable                         | At a reset                          |
| 0x0100_A1C0 | 0x0100_A1C0           | Block Protect Setting Register (BPS)                       | Writable*2                       | Writable*2                       | When a reset or command is executed |
| 0x0100_A1E0 | 0x0100_A1E0           | Permanent Block Protect Setting Register (PBPS)            | Writable*3<br>(from 1 to 0 only) | Writable*3<br>(from 1 to 0 only) | When a reset or command is executed |
| 0x0100_A200 | 0x0100_A200           | Option Function Select Register 1 Secure (OFS1_SEC)        | Writable                         | Writable                         | At a reset                          |
| 0x0100_A240 | 0x0100_A240           | Block Protect Setting Register Secure (BPS_SEC)            | Writable*4                       | Writable*4                       | When a reset or command is executed |
| 0x0100_A260 | 0x0100_A260           | Permanent Block Protect Setting Register Secure (PBPS_SEC) | Writable*5<br>(from 1 to 0 only) | Writable*5<br>(from 1 to 0 only) | When a reset or command is executed |
| 0x0100_A280 | 0x0100_A280           | Option Function Select Register 1 Select (OFS1_SEL)        | Writable                         | Writable                         | At a reset                          |
| 0x0100_A2C0 | 0x0100_A2C0           | Block Protect Setting Register Select (BPS_SEL)            | Writable                         | Writable                         | At a reset                          |

- Note 1. The SAS.FSPR bit cannot be restored to 1 by using the Configuration set command once it is set to 0. Therefore, setting the start-up area select flags again becomes impossible. (when the Configuration set command is issued to the address of 0x0100A134, the command is locked.) Exercise extra caution when handling the SAS.FSPR bit.
- Note 2. Once PBPS[n] bit is set to 0, the BPS[n] bit cannot be restored to 1 by using the Configuration set command.
- Note 3. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS[n] bit cannot be set to 0 by using the Configuration set command when the BPS[n] bit is 1.
- Note 4. Once PBPS\_SEC[n] bit is set to 0, the BPS\_SEC[n] bit cannot be restored to 1 by using the Configuration set command.
- Note 5. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS\_SEC[n] bit cannot be set to 0 by using the Configuration set command when the BPS\_SEC[n] bit is 1.

## 40.10 Suspend Operation

Reading from the flash memory is not possible during programming or erasure if the conditions for background operation given in [Table 40.29](#) are not satisfied. When a P/E suspend command is issued to suspend the programming or erasure of the flash memory, reading from the flash memory is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available. For details on the suspend operation, see [Figure 40.16](#).

## 40.11 Protection Function

### 40.11.1 Software Protection

Software protection disables programming and erasure of the code flash memory through the settings of control registers and block protect setting in the user area. If an attempt is made to issue an FOCI command against software protection, the flash sequencer enters the command-locked state.

#### 40.11.1.1 Protection through FWEPROR

Unless the FWEPROR.FLWE[1:0] bits are set to 01b, programming cannot proceed in any mode.

### 40.11.1.2 Protection by FENTRYR

When the FENTRYR register is set to 0x0000, the flash sequencer enters read mode. In read mode, FACI commands cannot be accepted. If an attempt is made to issue an FACI command in read mode, the flash sequencer enters the command-locked state.

### 40.11.1.3 Protection by Block Protect Setting

Each block in user area has the block protect setting (BPS or BPS\_SEC). When the FBPROT0 or FBPROT1 register is 0x0000 and the block protect bit is 0, issuing the Program or Block Erase command to user area of the code flash causes the command-locked state. To program or erase the block whose block protect bit is 0, set the FBPROT0 or FBPROT1 register to 0x0001.

The block protect setting can be locked by the permanent block protect setting (PBPS or PBPS\_SEC). When the permanent block protect setting and the block protect setting are 0, issuing a Program or Block erase command to user area of the code flash causes the flash sequencer to enter the command-locked state regardless of the FBPROT0 and FBPROT1 register settings.

Valid block protect setting (BPS or BPS\_SEC) depends on the Block Protect Select bit (BPS\_SEL).

See [section 40.12.2. Permanent Block Protect Setting](#) for details of the block protect setting and permanent block protect setting. See [section 40.4.15. FBPROT0 : Flash Block Protection Register](#) and [section 40.4.16. FBPROT1 : Flash Block Protection for Secure Register](#) for more information.

For details of block protect setting (BPS or BPS\_SEC) and block protect select (BPS\_SEL), see [section 6, Option-Setting Memory](#).

The protected area by the block protect setting is always determined by the address of the FSADDR register setting regardless of the address swapping function setting (the startup area select). [Table 40.19](#) to [Table 40.20](#) show the relation of user area and the block protect setting in each function setting.

- BPS[0] to BPS[n] or BPS\_SEC[0] to BPS\_SEC[n] are assigned to the block of user area (for example, address is 0x00\_0000 to the last block address).
- BPS[0]/BPS\_SEC[0] and BPS[1]/BPS\_SEC[1] are assigned to the block of user area depending on the startup area select setting (SAS.BTFLG bit). (See [section 40.11.3. Start-Up Program Protection](#)).

[Table 40.19](#) shows the block protect setting when the startup area select is disabled (not swapping).

[Table 40.20](#) show example of the block protect setting when the address conversion function is used.

**Table 40.19 Example of Block Protect setting when SAS.BTFLG is 1**

| FSADDR[23:0]           | Block size | Block protect setting | User area block number | Notes                                                            |
|------------------------|------------|-----------------------|------------------------|------------------------------------------------------------------|
| The last block address | 32 KB      | BPS[n] or BPS_SEC[n]  | Block n                | —                                                                |
| ⋮                      | ⋮          | ⋮                     | ⋮                      | —                                                                |
| 0x01_8000 to 0x01_FFFF | 32 KB      | BPS[9] or BPS_SEC[9]  | Block 9                | —                                                                |
| 0x01_0000 to 0x01_7FFF | 32 KB      | BPS[8] or BPS_SEC[8]  | Block 8                | —                                                                |
| 0x00_E000 to 0x00_FFFF | 8 KB       | BPS[7] or BPS_SEC[7]  | Block 7                | —                                                                |
| 0x00_C000 to 0x00_DFFF | 8 KB       | BPS[6] or BPS_SEC[6]  | Block 6                | —                                                                |
| ⋮                      | ⋮          | ⋮                     | ⋮                      | —                                                                |
| 0x00_2000 to 0x00_3FFF | 8 KB       | BPS[1] or BPS_SEC[1]  | Block 1                | Not swap block 0 and block 1 in this startup area select setting |
| 0x00_0000 to 0x00_1FFF | 8 KB       | BPS[0] or BPS_SEC[0]  | Block 0                | Not swap block 0 and block 1 in this startup area select setting |

**Table 40.20 Example of Block Protect setting when SAS.BTFLG is 0**

| FSADDR[23:0]           | Block size | Block protect setting | User area block number | Notes                                                        |
|------------------------|------------|-----------------------|------------------------|--------------------------------------------------------------|
| The last block address | 32 KB      | BPS[n] or BPS_SEC[n]  | Block n                | —                                                            |

| 0x00_2000 to 0x00_3FFF | 8 KB       | BPS[1] or BPS_SEC[1]  | Block 0                | Swap block 0 and block 1 in this startup area select setting |
| 0x00_0000 to 0x00_1FFF | 8 KB       | BPS[0] or BPS_SEC[0]  | Block 1                | Swap block 0 and block 1 in this startup area select setting |

### 40.11.2 Error Protection

Error protection detects the issuing of illegal FACI commands, illegal access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue the Status Clear or Forced Stop command. The Status Clear command can only be used while the FRDY bit in the FSTATR register is 1. The Forced Stop command can be used regardless of the value of the FRDY bit. While the CMDLKIE bit in the FAEINT register is 1, a flash access error (FIFERR) interrupt is generated if the flash sequencer enters the command-locked state (the CMDLK bit in the FFASTAT register is set to 1).

If the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during programming or erasure processing, the flash sequencer continues the processing for programming or erasure. In this state, the P/E suspend command cannot be used to suspend the processing for programming or erasure. If a command is issued in the command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set from previous error detection.

Table 40.21 shows the error protection types and status bit values after error detections.

**Table 40.21 Error protection type (1 of 3)**

| Error type            | Description                                                            | ILGOMERR | FESETERR | SECERR | OTERR | ILGLERR | ERSERR | PRGERR | FLWEERR | CFAE | DFAE |
|-----------------------|------------------------------------------------------------------------|----------|----------|--------|-------|---------|--------|--------|---------|------|------|
| FENTRYR setting error | The value set in FENTRYR is not 0x0000, 0x0001, or 0x0080              | 0        | 1        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 0    |
|                       | The FENTRYR setting at suspension is different from that at resumption | 0        | 1        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 0    |

Table 40.21 Error protection type (2 of 3)

| Error type                         | Description                                                                                                                                                                                       | ILGOMERR | FESETERR | SECERR | OTERR | ILGLERR | ERSERR | PRGERR | FLWEERR | CFAE | DFAE  |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|----------|--------|-------|---------|--------|--------|---------|------|-------|
| Illegal command error              | An undefined size is specified in the first cycle of the command. (not byte-write)                                                                                                                | 1        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 0     |
|                                    | An undefined code is written in the first access of the FACL command                                                                                                                              | 1        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 0     |
|                                    | The value specified in the last access of the multiple-access FACL command is not 0xD0                                                                                                            | 1        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 0     |
|                                    | The value (N) specified in the second write access of the FACL command in the program or configuration set command is wrong                                                                       | 1        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 0     |
|                                    | Blank Check command is issued with inconsistent BCDIR, FSADDR, and FEADDR settings (see <a href="#">section 40.4.13. FEADDR : FACL Command End Address Register</a> )                             | 1        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 0/1*1 |
|                                    | A multi block erase command is issued with inconsistent FSADDR and FEADDR settings. <ul style="list-style-type: none"> <li>FSADDR &gt; FEADDR</li> <li>FEADDR is set to reserved area.</li> </ul> | 1        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 0/1*1 |
|                                    | An FACL command not acceptable in each mode is issued (see <a href="#">Table 40.15</a> )                                                                                                          | 1        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 0     |
|                                    | An FACL command is issued when command acceptance conditions are not satisfied (see <a href="#">Table 40.16</a> )                                                                                 | 0/1      | 0/1      | 0/1    | 0/1   | 1       | 0/1    | 0/1    | 0/1     | 0/1  | 0/1   |
|                                    | A program or block erase command is issued against the area protected by the block protect setting (see <a href="#">section 40.11.1.3. Protection by Block Protect Setting</a> )                  | 1        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 0     |
|                                    | A program command is issued against the erase area in erase suspend                                                                                                                               | 1        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 0     |
| Erasure error                      | An error occurs during erasure                                                                                                                                                                    | 0        | 0        | 0      | 0     | 0       | 1      | 0      | 0       | 0    | 0     |
| Programming error                  | An error occurs during programming                                                                                                                                                                | 0        | 0        | 0      | 0     | 0       | 0      | 1      | 0       | 0    | 0     |
| Code flash memory access violation | An FACL command is issued to the reserved portion of the user area in code flash P/E mode                                                                                                         | 0        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 1    | 0     |
|                                    | Configuration set command is issued to the reserved option-setting memory                                                                                                                         | 0        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 1    | 0     |
|                                    | Configuration set command of non-secure access is issued to the secure region of TrustZone in the code flash                                                                                      | 0        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 1    | 0     |
|                                    | Program or block erase command of non-secure access is issued to the secure region of user area.                                                                                                  | 0        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 1    | 0     |

**Table 40.21 Error protection type (3 of 3)**

| Error type                         | Description                                                                                                                                                      | ILGOMERR | FESETERR | SECERR | OTERR | ILGLERR | ERSERR | PRGERR | FLWEERR | CFAE | DFAE |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|----------|--------|-------|---------|--------|--------|---------|------|------|
| Data flash memory access violation | A program or block erase command is issued to the reserved data area in data flash P/E mode                                                                      | 0        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 1    |
|                                    | A multi block erase command is issued to the reserved data area in data flash P/E mode. (FSADDR is set to reserved data area).                                   | 1        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 1    |
|                                    | Blank Check command is issued to reserved data area in data flash P/E mode. (FSADDR is set to reserved data area ).                                              | 1        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 1    |
|                                    | A program, block erase, multi block erase, or blank check command of non-secure access is issued to the secure region of data area.                              | 0        | 0        | 0      | 0     | 1       | 0      | 0      | 0       | 0    | 1    |
| Security error                     | Configuration set command for the SAS.BTFLG bit setting is issued when the SAS.FSPR bit is 0 (see <a href="#">section 40.9.3.15. Configuration Set Command</a> ) | 0        | 0        | 1      | 0     | 1       | 0      | 0      | 0       | 0    | 0    |
| Others                             | An FACI command-issuing area is accessed in read mode                                                                                                            | 0        | 0        | 0      | 1     | 1       | 0      | 0      | 0       | 0    | 0    |
|                                    | An FACI command-issuing area is read in code flash P/E mode or data flash P/E mode                                                                               | 0        | 0        | 0      | 1     | 1       | 0      | 0      | 0       | 0    | 0    |
| Flash write erase protection error | A flash memory write protection error is detected by the FWEPROR register setting <sup>2</sup> during command processing by the flash sequencer                  | 0        | 0        | 0      | 0     | 0       | 0/1    | 0/1    | 1       | 0    | 0    |

Note 1. DFAE value depends on the FSADDR setting.

Note 2. For details on the FWEPROR register, see [section 40.4.8. FWEPROR : Flash P/E Protect Register](#).

### 40.11.3 Start-Up Program Protection

Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.

The startup area is 8 Kbytes in size and is assigned to the user area in the code flash memory. This function uses the values of the SAS.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see [Figure 40.25](#) to [Figure 40.28](#)).

In protection of the startup program, the state of the selection of the startup area can be fixed by the FSPR bit. However, the SAS.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the SAS.FSPR bit.

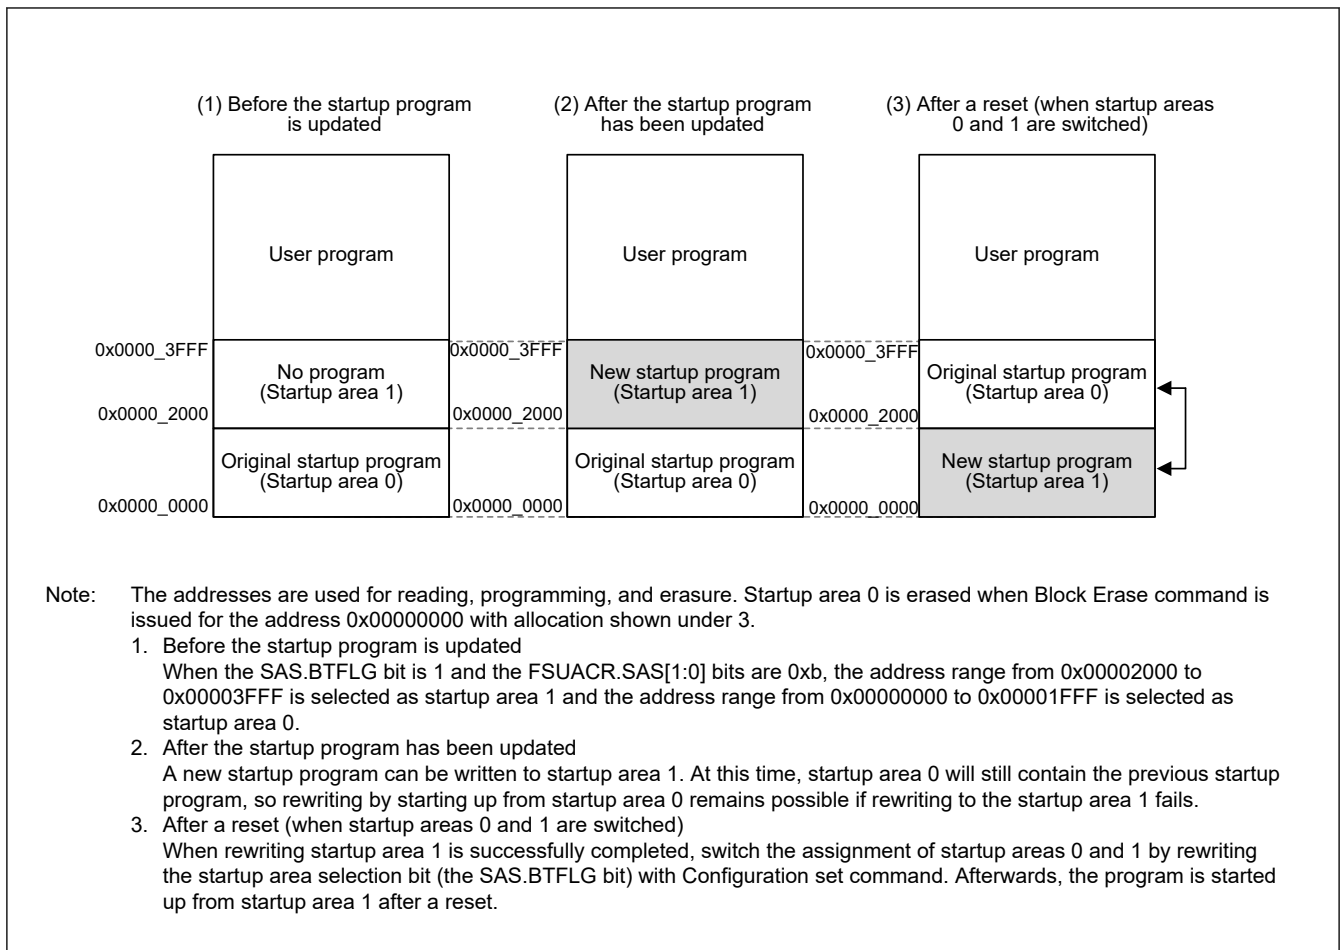

Figure 40.25 Concept of Protection of the Startup Program

Figure 40.26 Example 1 of Transitions for Startup Program Protection Settings

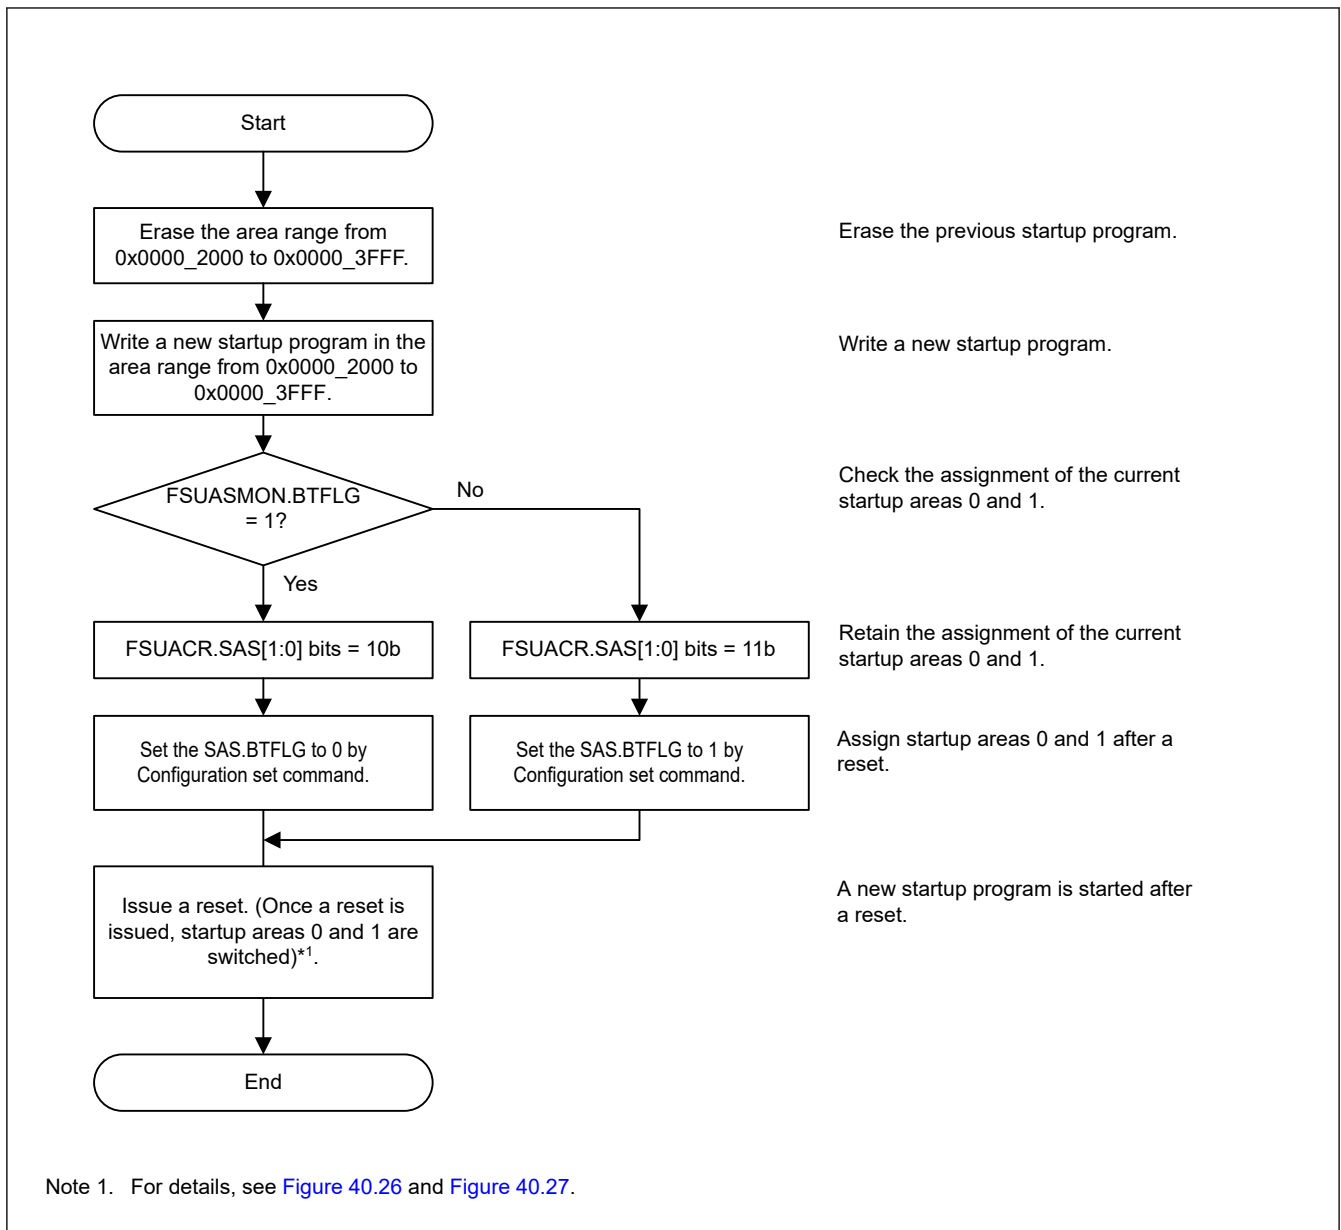

Figure 40.27 Example 2 of Transitions for Startup Program Protection Settings

**Figure 40.28** Concept of Protection of the Startup Program

## 40.12 Security Function

The flash sequencer supports the following security functions:

- Security flag for startup area
- Permanent block protect setting
- Flash memory protection for TrustZone

### 40.12.1 Security Flag for Startup Area Select

The security flag (SAS.FSPR) for the startup area is located in the option-setting memory.

When the SAS.FSPR bit is 0, issuing the configuration set command to change the SAS.BTFLG bit causes the flash sequencer to be in the command-locked state. Also, when the SAS.FSPR bit is 0, it is invalid to write to the Startup Area Select bits SAS[1:0] in the FSUACR register. The SAS.FSPR bit enables protection.

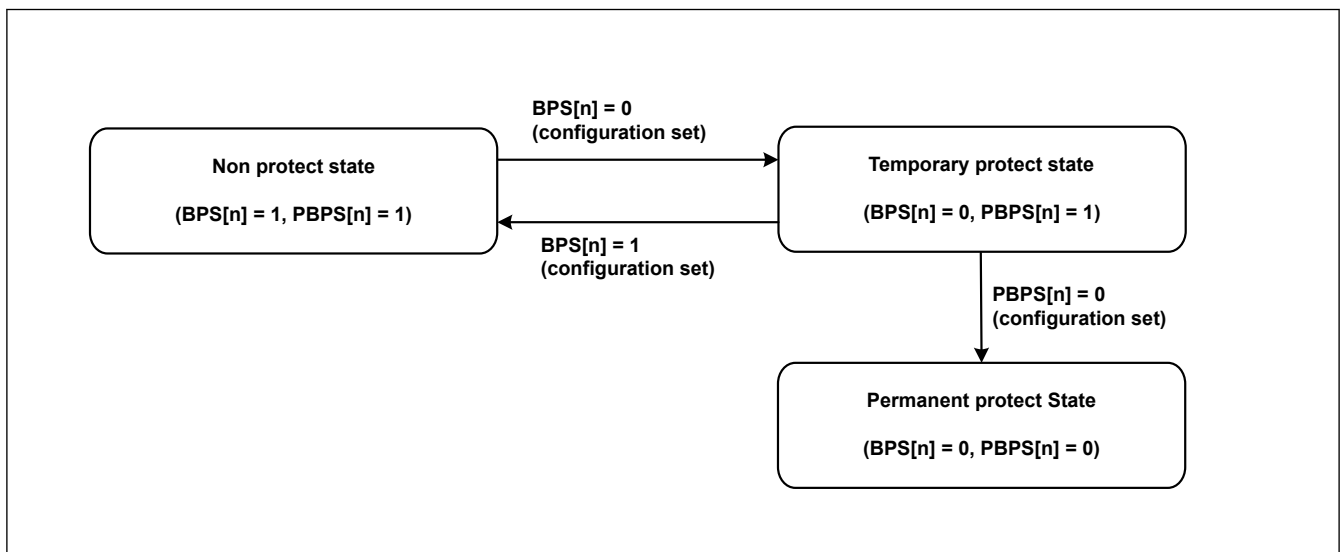

### 40.12.2 Permanent Block Protect Setting

The permanent block protect setting is the clear protection for the block protection setting. User area cannot be permanently updated by the FACI command when the permanent block protect setting is enabled. See [section 40.11.1.3. Protection by Block Protect Setting](#) for more details.

The block protect setting and the permanent block protect setting have the write/clear protection against the configuration set command. The flash sequencer does not detect an error when the configuration set command is issued to the write/clear protected settings.

[Figure 40.29](#) and [Table 40.22](#) show the write/clear protection against the block protect setting (BPS[n]) and the permanent protect setting (PBPS[n]). [Figure 40.30](#) and [Table 40.23](#) show the write/clear protection against the block protect setting for secure (BPS\_SEC[n]) and permanent protect setting for secure (PBPS\_SEC[n]).

Effective permanent block protect setting (PBPS or PBPS\_SEC) depends on block protect select (BPS\_SEL). For details of permanent block protect setting (PBPS or PBPS\_SEC) and block protect select (BPS\_SEL), see [section 6, Option-Setting Memory](#).

**Figure 40.29** Status transition of flash sequencer by BPS[n] and PBPS[n]

**Table 40.22** Write/clear protection of BPS[n] and PBPS[n]

| Current state |         | Updatable state by configuration set command |            |             |             |
|---------------|---------|----------------------------------------------|------------|-------------|-------------|
| BPS[n]        | PBPS[n] | BPS[n] = 1                                   | BPS[n] = 0 | PBPS[n] = 1 | PBPS[n] = 0 |
| 1             | 1       | ✓                                            | ✓          | ✓           | X           |
| 1             | 0       | —                                            | —          | —           | —           |
| 0             | 1       | ✓                                            | ✓          | ✓           | ✓           |
| 0             | 0       | X                                            | ✓          | X           | ✓           |

Note:

- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- — indicates not reaching to this state.

Figure 40.30 Status transition of flash sequencer by BPS\_SEC[n] and PBPS\_SEC[n]

Table 40.23 Write/clear protection of BPS\_SEC[n] and PBPS\_SEC[n]

| Current state |             | Updatable state by configuration set command |                |                 |                 |
|---------------|-------------|----------------------------------------------|----------------|-----------------|-----------------|
| BPS_SEC[n]    | PBPS_SEC[n] | BPS_SEC[n] = 1                               | BPS_SEC[n] = 0 | PBPS_SEC[n] = 1 | PBPS_SEC[n] = 0 |
| 1             | 1           | ✓                                            | ✓              | ✓               | X               |
| 1             | 0           | —                                            | —              | —               | —               |
| 0             | 1           | ✓                                            | ✓              | ✓               | ✓               |
| 0             | 0           | X                                            | ✓              | X               | ✓               |

Note:

- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- — indicates not reaching to this state.

### 40.12.3 Flash Memory Protection for TrustZone

Information in this section focuses on the flash sequencer operation.

The flash memory provides the following types of protect function against non-secure access:

- Protection for flash memory area (P/E)
- Protection for flash memory area (read)
- Protection for registers
- Protection during FACI command operation
- Code flash P/E mode entry protection

#### 40.12.3.1 Protection for Flash Memory Area (P/E)

This function protects the secure region of the code flash and data flash from FACI commands of non-secure access. The condition of protection depends on the FACI command, the access attribution, and the memory boundary setting.

For details of secure region, see [section 42, Security Features](#) .

See [Table 40.24](#) for information on protection of the flash memory area (P/E).

**Table 40.24 Protection for the flash memory area (P/E)**

| FACI command                  | Target area       |                                         | Issuing of FACI command by non-secure access | Issuing of FACI command by secure access |
|-------------------------------|-------------------|-----------------------------------------|----------------------------------------------|------------------------------------------|
| Program Block erase           | Code flash memory | User area (non-secure area)             | ✓                                            | ✓                                        |
|                               |                   | User area (secure area)                 | X                                            | ✓                                        |
|                               | Data flash memory | Data area (non-secure area)             | ✓                                            | ✓                                        |
|                               |                   | Data area (secure area)                 | X                                            | ✓                                        |
| Multi block erase Blank check | Data flash memory | Data area (non-secure area)             | ✓                                            | ✓                                        |
|                               |                   | Data area (secure area)                 | X                                            | ✓                                        |
| Configuration set             | Code flash memory | option-setting memory (non-secure area) | ✓                                            | ✓                                        |
|                               |                   | option-setting memory (secure area)     | X                                            | ✓                                        |

Note:

- ✓ indicates FACI command operation is not prohibited.
- X indicates FACI command operation is prohibited. Error occurs when the area is selected, and the FACI command is executed.

When the target area of FACI command is the user area of code flash, the flash sequencer compares the FSADDR register setting with the memory boundary setting of the code flash and determines whether the target area is in the secure region.

The memory boundary can be set to 0x0000\_0000 to 0x00FF\_8000 in 32 KB unit.

Figure 40.31 shows details of the non-secure/secure attribute of user area in the code flash.

**Figure 40.31 Secure/non-secure region in user area**

When the target area of the issuing FACI command is the data area of data flash, the flash sequencer compares the FSADDR/FEADDR register setting with the memory boundary setting of the data flash and determines whether the target area is in secure region. The memory boundary can be set to 0x0800\_0000 to 0x0800\_FC00 in 1 KB unit. Figure 40.32 shows details of the non-secure/secure attribute of data area in the data flash.

**Figure 40.32 Secure/non-secure region in data area**

See [Figure 40.33](#) for details of non-secure/secure region of option-setting memory. The flash sequencer judges that target area is secure region from the FSADDR register setting.

**Figure 40.33 Secure/non-secure region in option-setting memory**

### 40.12.3.2 Protection for Flash Memory Area (Read)

This function protects the secure region of code flash and data flash from non-secure bus access.

For details of secure region, see [section 42, Security Features](#) .

### 40.12.3.3 Protection for Register

The flash sequencer registers have write-access protection against non-secure access. [Table 40.25](#) shows details of the protected registers of the flash sequencer.

**Table 40.25 Protected registers of the flash sequencer for TrustZone (1 of 2)**

| Protection target register | Security attribute setting                            | Notes                                                                                   |

| FSUACR                                                                                          | Always secure                                   | See <a href="#">section 40.4.27. FSUACR : Flash Startup Area Control Register</a>         |
| FACI command-issuing area and all registers of FACI (Base address is FACI) and FWEPROR register | During FACI command processing by secure access | See <a href="#">section 40.12.3.4. Protection during FACI Command Operation</a>           |

### 40.12.3.4 Protection during FACI Command Operation

This function protects read/write access to the FACI command-issuing area, including all registers of FACI (Base address is FACI) and FWEPROR register by the non-secure access during the FACI command processing of the secure access. The protect condition includes the suspending period of the program, block erase, or multi block erase command by the P/E suspend command of the secure access. See [Figure 40.34](#) and [Table 40.26](#) for details of the protection during the FACI command operation.

**Figure 40.34 State of protection during FACI command operation**

**Table 40.26 Protection during FACL command operation**

|                        | Flash sequencer is not operating | Program, Block erase, Multi block erase, Blank check, or Configuration set command processing |    | Command lock state |    | Forced stop command processing |     | While suspend Program, Block erase, or Multi block erase command |     | Program command processing while suspend Block erase or Multi block erase command by secure access |                  | Program command processing while suspend Block erase or Multi block erase command by non-secure access |    | P/E resume command processing while suspend Program, Block erase, or Multi block erase command by secure access |                  | P/E Resume command processing while suspend Program, Block erase, or Multi block erase command by non-secure access |    |

| PRGSPD or ERSSPD bit   | 0                                | 0                                                                                             | 0  | 0                  | 0  | 0                              | 0   | 1                                                                | 1   | 1                                                                                                  | 1                | 1                                                                                                      | 1  | 0                                                                                                               | 0                | 0                                                                                                                   | 0  |
| CMDLK bit              | 0                                | 0                                                                                             | 0  | 1                  | 1  | 1/0                            | 1/0 | 1/0                                                              | 1/0 | 0                                                                                                  | 0                | 0                                                                                                      | 0  | 0                                                                                                               | 0                | 0                                                                                                                   | 0  |
| Non-secure access      | ✓                                | X                                                                                             | ✓  | ✓                  | ✓  | X                              | ✓   | X                                                                | ✓   | X                                                                                                  | ✓                | X                                                                                                      | ✓  | X                                                                                                               | ✓                | X                                                                                                                   | ✓  |

- Note:
- S indicates the FACL command by the secure access.
  - NS indicates the FACL command by the non-secure access.
  - ✓ indicates read/write access is possible by the non-secure access.
  - X indicates read/write access is not possible by the non-secure access. Write data is ignored and read data is always 0.
- Note 1. The FACL command issued by the non-secure access is not allowed.

Code flash programming/erasure can be protected by the FMEPROT register of secure function. Therefore, it does not assume that secure function issues P/E suspend command during code flash programming/erasure of non-secure function.

Data flash programming/erasure of non-secure can be suspended by secure function. If secure function issues P/E suspend command during data flash programming/erasure of non-secure function, secure function should issue P/E resume command. When secure function issues P/E resume command, secure function should notify non-secure function that data flash programming/erasure is complete and return to non-secure function. See [Figure 40.35](#) and [Figure 40.36](#) in example of issuing P/E suspend of secure function during programming/erasure of non-secure function.

Figure 40.35 Data Flash P/E suspend of secure function Example (Check FRDY bit to detect P/E end)

Figure 40.36 Data Flash P/E suspend of secure function Example (Check interrupt request to detect P/E end)

#### 40.12.3.5 Code Flash P/E Mode Entry Protection

The flash sequencer has protection function of code flash P/E by the FMEPROT register for the secure developer. Secure function can prevent disturbance of reading code flash memory by this protection function. See [section 40.4.14. FMEPROT : Flash P/E Mode Entry Protection Register](#).

For applications that do not require non-secure region programming/erasure other than from secure function, it is recommended to always disable non-secure function of code flash programming/erasure by enabling the protection function of FMEPROT register.

For details, see [Figure 40.37](#) of the code flash P/E sequence example by non-secure function.

Figure 40.37 Code Flash P/E Sequence Example by non-secure function (Using secure function for code flash P/E)

### 40.13 Boot Mode

There are two serial programming modes; the boot mode (for the SCI interface) with SCI9 and the boot mode (for the USB interface) with USBFS. The available interfaces and connection times to the tool vary depending on the clock source connected to the MCU. Table 40.27 lists the I/O pins used in boot mode. Table 40.28 lists the available communication interface and the connection time depending on the clock sources in the boot mode.

**Table 40.27 I/O pins used in boot mode**

| Pin name       | I/O    | Mode to be used                                                              | Use                                                     |
|----------------|--------|------------------------------------------------------------------------------|---------------------------------------------------------|
| MD             | Input  | Boot mode<br>(for the SCI interface)<br>Boot mode<br>(for the USB interface) | Selection of operating mode                             |
| P110/RXD9      | Input  | Boot mode<br>(for the SCI interface)                                         | For host communication (to receive data through SCI)    |
| P109/TXD9      | Output |                                                                              | For host communication (to transmit data through SCI)   |
| USB_DP, USB_DM | I/O    | Boot mode<br>(for the USB interface)                                         | Data input/output of USB                                |
| USB_VBUS       | Input  |                                                                              | Detection of connection and disconnection of USB cables |

**Table 40.28 Tool connection time depending on the clock source**

| Main clock oscillator | Sub-clock oscillator | Available interface | Tool connection time*2 |
|-----------------------|----------------------|---------------------|------------------------|
| Connected             | Don't care           | SCI/USB             | Up to 1 second         |
| Unconnected           | Connected*1          | SCI/USB             | Up to 2 seconds        |
| Unconnected           | Unconnected          | SCI                 | Up to 3 seconds        |

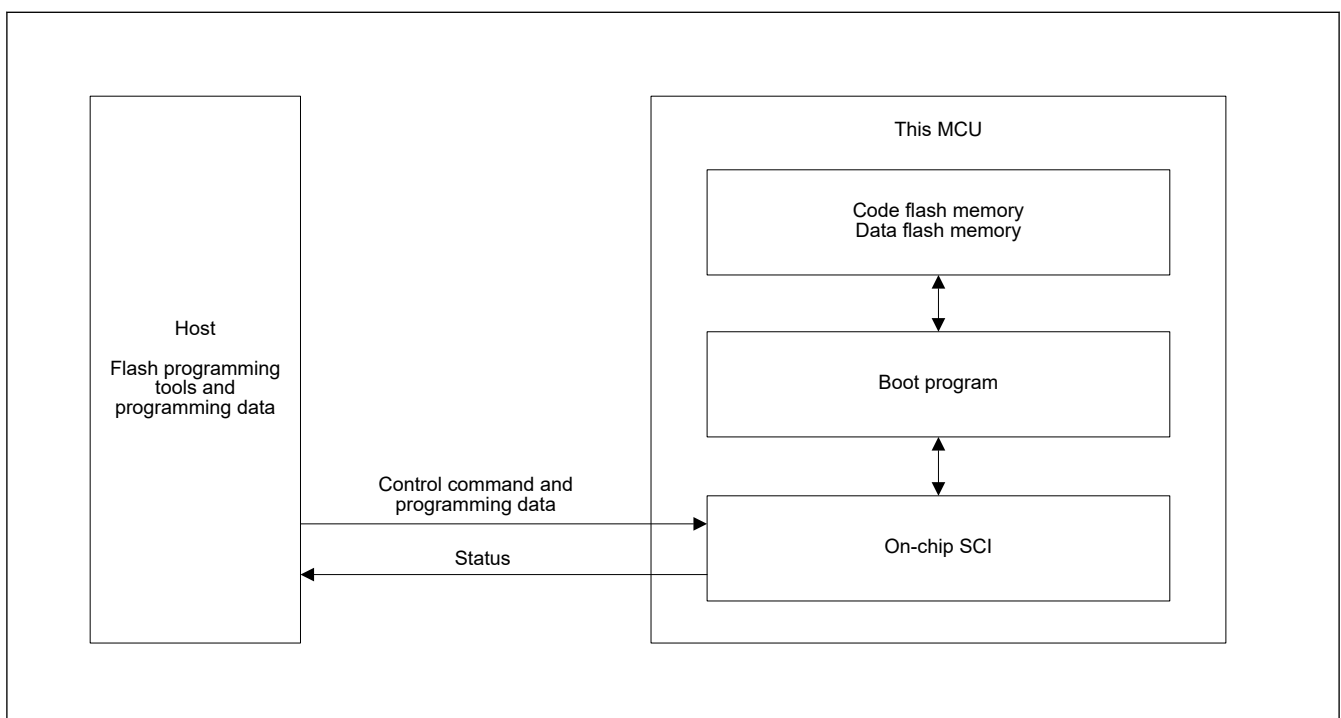

Note 1. The drive capability of the sub-clock oscillator is set to standard by SOMCR.SODRV bit. Note that if you use the crystal resonator corresponding to the low drive capability on your board, the crystal resonator may not oscillate in the boot mode.  
 Note 2. Tool connection time means that it takes for communication to be established between MCU and the host. For details, see the boot firmware application note.

### 40.13.1 Boot Mode (for the SCI Interface)

In boot mode (for the SCI interface), the host sends control commands and data for programming, and the flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (for the SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 40.38 shows the system configuration for operations in boot mode (for the SCI interface).

**Figure 40.38 System Configuration for Operations in Boot Mode (for the SCI Interface)**

### 40.13.2 Boot Mode (for the USB Interface)

In boot mode (with the USB interface), the flash memory can be programmed or erased by sending control commands and program data from the host. An on-chip USB is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 40.39 shows the configuration of a system for use in boot mode (for the USB interface). The USB cable must be connected on reset release.

**Figure 40.39 System Configuration in Boot Mode (for the USB Interface)**

## 40.14 Using the Serial Programmer for Rewriting

A serial programmer can be used to rewrite flash memory in boot mode.

### (1) Serial Programming

This MCU is mounted on the system board at the time of serial programming. Providing a connector to the board enables rewriting of this MCU by the serial programmer to proceed.

#### 40.14.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU with data are described below.

**Figure 40.40** Environments for Rewriting the Flash Memory

## 40.15 Programming through Self-Programming

### 40.15.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACL commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

The program for rewriting must be transferred to the internal RAM in advance when the BGO is not available or when rewriting the option-setting memory.

**Figure 40.41 Schematic View of Self-Programming**

For comprehensive information on the self-programming, see [section 40.9. FACL Commands](#).

### 40.15.2 Background Operation

The background operation (BGO) can be used to execute the flash rewrite routine on the code flash memory when the data flash memory is rewritten.

Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

**Table 40.29 Conditions under which Background Operation is Usable**

|        | Range for rewriting | Range for reading |
|--------|---------------------|-------------------|
| Common | Code flash memory   | Data flash memory |
|        | Data flash memory   | Code flash memory |

## 40.16 Reading Flash Memory

### 40.16.1 Reading Code Flash Memory

Special settings are not required to read code flash memory after release from the reset state. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

### 40.16.2 Reading Data Flash Memory

Special settings are not required to read data flash memory after release from the reset state. Data can simply be read out through access to addresses in the data flash memory.

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

### 40.16.3 Access Cycle

**Table 40.30 Code Flash Memory (1 of 2)**

| Flash Cache Operation | FLWT Register Setting | Read cycle (ICLK) |
|-----------------------|-----------------------|-------------------|
| enable and hit        | —                     | 1                 |

**Table 40.30 Code Flash Memory (2 of 2)**

| Flash Cache Operation | FLWT Register Setting | Read cycle (ICLK) |
|-----------------------|-----------------------|-------------------|
| disable or miss       | 0x00                  | 1                 |
|                       | 0x01                  | 2                 |

**Table 40.31 Data Flash Memory**

| FCKMHZ Register Setting | Read cycle                                |
|-------------------------|-------------------------------------------|
| 0x00 to 0x09            | Min: 3 FCLK<br>Max: (n - 1) ICLK + 3 FCLK |
| 0x0A to 0x13            | Min: 4 FCLK<br>Max: (n - 1) ICLK + 4 FCLK |
| 0x14 to 0x1D            | Min: 5 FCLK<br>Max: (n - 1) ICLK + 5 FCLK |
| 0x1E to 0x27            | Min: 6 FCLK<br>Max: (n - 1) ICLK + 6 FCLK |
| 0x28 to 0x31            | Min: 7 FCLK<br>Max: (n - 1) ICLK + 7 FCLK |
| 0x32                    | Min: 8 FCLK<br>Max: (n - 1) ICLK + 8 FCLK |

Note: When the frequency ratio of ICLK : FCLK is n : 1

## 40.17 Usage Notes

### (1) Reading Area Where Programming/Erase was Interrupted and Area Targeted for Suspension

The data stored in the area where programming or erasure has been suspended or the area where programming or erasure has been suspended by using the suspend command are undefined. To avoid faulty operation caused by reading undefined data, take care not to fetch instructions or read data from areas where programming or erasure was suspended and where programming or erasure was suspended by using the suspend command.

### (2) Suspension During Programming/Erase

When processing of programming/erasure is stopped by issuing the P/E suspend command, the programming/erasure processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area

### (3) Prohibition of Additional Programming

Programming a given area of the code flash memory or data flash memory twice is not possible. To program the code flash memory or data flash memory where has been programmed, erase the target area. Programming can be added to the option-setting memory.

### (4) Resets During Programming/Erase, or Blank Checking

In the case of a reset due to the signal on the RES pin during programming/erasure, or blank checking of the flash memory, wait for at least  $t_{RESW}$  (see [section 43, Electrical Characteristics](#)) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

### (5) Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erase

Generation of an interrupt or other exception during programming/erasure may lead to fetching of the vector from the code flash memory. Under conditions where BGO cannot be used, set the address of the vector to an address that is not in the code flash memory. Alternatively, make sure that no handling of interrupts or exceptions proceeds during programming/erasure.

## (6) Items Prohibited During Programming/Erase, or Blank Checking

High voltage is applied to the flash memory during programming/erase, or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0]bits.
- Change the OPCCR.OPCM[2:0] and SOPCCR.SOPCM bits.
- Change the SCKDIVCR.FCK[2:0]bits.
- Change the SCKSCR.CKSEL[2:0]bits.
- Transition to the software standby mode, or Deep Software Standby mode.

## (7) Programming/Erase in Low-Speed Modes and Subosc-Speed Mode

Do not programming/erase the flash memory when low-speed mode or subosc-speed mode is selected with the operating power control register (OPCCR or SOPCCR).

## (8) Emulator Connection

Renesas provides the emulator which supports both debugging using SWD or JTAG communication and serial programming using SCI communication. This emulator makes it easy to switch between debugging and serial programming.

Table 40.32 shows the pinout of 10 pin or 20 pin socket pinouts when using this emulator. The pinout of SWD and JTAG is ARM standard, and MD, TXD, RXD pins are added for the serial programming using SCI communication.

The serial programming interface must be used to program the TrustZone IDAU boundary register settings.

It is recommended to connect P300/SWCLK/TCK and P201/MD pins using wired OR circuit on the board to use both debugging and serial programming

**Table 40.32 Pin assign for emulator**

| Pin No.          | SWD                                 | JTAG                              | Serial Programming using SCI |
|------------------|-------------------------------------|-----------------------------------|------------------------------|
| 1                | VCC                                 | VCC                               | VCC                          |
| 2                | P108/SWDIO                          | P108/TMS                          | NC                           |
| 4                | P300/SWCLK<br>Wired OR with P201/MD | P300/TCK<br>Wired OR with P201/MD | P201/MD                      |
| 6                | P109/SWO/TXD9                       | P109/TDO/TXD9                     | P109/TXD9                    |
| 8                | P110/RXD9                           | P110/TDI/RXD9                     | P110/RXD9                    |
| 9                | GNDdetect                           | GNDdetect                         | GNDdetect                    |

## 41. Internal Voltage Regulator

### 41.1 Overview

The MCU includes one internal voltage regulator:

- Linear regulator (LDO)

This regulator supplies voltage to all internal circuits and memory except for I/O, analog, USB, and battery backup power domains.

### 41.2 Operation

Table 41.1 lists the LDO mode pin settings, and Figure 41.1 shows the LDO mode settings. In LDO mode, the internal voltage is generated from VCC.

**Table 41.1 LDO mode pin**

| Pins    | Setting descriptions                                                                                                                                                                                                                    |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| All VCC | <ul style="list-style-type: none"> <li>• Connect each pin to the system power supply.</li> <li>• Connect each pin to VSS through a 0.1-<math>\mu</math>F multilayer ceramic capacitor. Place the capacitor close to the pin.</li> </ul> |
| VCL     | Connect the each pin to VSS through a 0.22- $\mu$ F multilayer ceramic capacitor. Place the capacitor close to the pin.                                                                                                                 |

**Figure 41.1 LDO mode settings**

## 42. Security Features

### 42.1 Features

- ARMv8-M TrustZone security
  - Eight regions IDAU for memory space
    - Up to three regions for the code flash
    - Up to two regions for the data flash
    - Up to three regions for the SRAM
    - IDAU setting is common for the CPU, DMAC, and DTC
  - SAU is not implemented
  - Secure or Non-secure region for the Standby SRAM
  - Secure or Non-secure region for the VBATT backup registers
  - Individual Secure or Non-secure security attribution for each peripheral
  - Some peripherals support both Secure and Non-secure security attributions
- Device lifecycle management
- Three debug access levels
  - DBG2: The debugger connection is allowed, and no restriction to access memories and peripherals
  - DBG1: The debugger connection is allowed, and restricted to access only non-secure memory regions and peripherals
  - DBG0: The debugger connection is not allowed
- Key injection
- Cryptographic accelerator
  - See [section 34, Secure Cryptographic Engine \(SCE9\)](#)
- Secure pin multiplexing
  - All I/O port pins can be configured individually as secure or non-secure
  - Pin functions of SCI3, SPI0, IIC0, GPT321 and GPT165 can be configured as secure pin
  - See [section 19, I/O Ports](#)

### 42.2 Arm TrustZone Security

#### 42.2.1 Arm TrustZone Technology

Arm TrustZone technology divides the system and the application into Secure and Non-secure domains. Secure application can access both Secure and Non-secure memory and resources. Non-secure application can only access Non-secure memory and resources.

The system starts up in Secure state by default. The security state of CPU can be either Secure or Non-secure.

#### 42.2.2 Memory Security Attribution

The code flash, the data flash, and the SRAM are divided into Secure (S), Non-secure (NS) and Non-secure callable (NSC) regions. These memory security attributions are set into the nonvolatile memory by the serial programming command when the device lifecycle is SSD state. These memory security attributions are loaded into the IDAU and the memory controller before application execution. These memory security attributions cannot be updated by application but can be through the dedicated registers.

The code flash can be divided in up to three regions. The data flash can be divided in up to two regions. The SRAM can be divided in up to three regions. [Figure 42.1](#) shows the memory mapping. [Table 42.1](#) shows the size of memory region.

Figure 42.1 Memory mapping

Table 42.1 Memory Region Size

| Memory Region                  | Start Address            | Size                           |
|--------------------------------|--------------------------|--------------------------------|
| Code flash secure              | 0x0000_0000              | CFS1 × 1 KB                    |
| Code flash non-secure callable | CFS1 × 1 KB              | CFS2 × 32 KB - CFS1 × 1 KB     |
| Code flash non-secure          | CFS2 × 32 KB             | Code flash size - CFS2 × 32 KB |
| Data flash secure              | 0x0800_0000              | DFS × 1 KB                     |
| Data flash non-secure          | 0x0800_0000 + DFS × 1 KB | Data flash size - DFS × 1 KB   |
| SRAM secure                    | 0x2000_0000              | SS1 × 1 KB                     |
| SRAM non-secure callable       | 0x2000_0000 + SS1 × 1 KB | SS2 × 8 KB - SS1 × 1 KB        |
| SRAM non-secure                | 0x2000_0000 + SS2 × 8 KB | SRAM size - SS2 × 8 KB         |

The Standby SRAM is divided 8 regions. Security attribution can be set for each region, but both secure region and non-secure region must be contiguous. In other words, the Standby SRAM can have one contiguous secure region and one contiguous non-secure region. The Standby SRAM security attribution is set to the dedicated register by the secure application. See [section 39, Standby SRAM](#) for the details.

The VBATT backup register is divided 8 regions. Security attribution can be set for each region, but both secure region and non-secure region must be contiguous. In other words, the VBATT backup register can have one contiguous Secure region and one contiguous Non-secure region. The VBATT backup register security attribution is set to the dedicated register by the secure application. See [section 11, Battery Backup Function](#) for the details.

[Table 42.2](#) shows the access permission of the memory.

**Table 42.2 Access Permission of Memory**

| Memory                                                                   | Secure access | Non-secure access                                                    |
|--------------------------------------------------------------------------|---------------|----------------------------------------------------------------------|
| Code flash, Data flash, SRAM configured as Secure or Non-secure callable | allowed       | Write ignored / Read ignored<br>TrustZone Access error is generated  |
| Code flash, Data flash, SRAM configured as non-secure                    | allowed       | allowed                                                              |
| Standby SRAM, VBATT backup register configured as Secure                 | allowed       | Write ignored / Read 0x00<br>TrustZone Access error is not generated |
| Standby SRAM, VBATT backup register configured as Non-secure             | allowed       | allowed                                                              |

### 42.2.3 Peripheral Security Attribution

Each peripheral can be configured to be Secure or Non-secure.

Peripherals are divided into two types.

Type-1 peripherals has the one security attribution. Access to all registers is controlled by one security attribution. Type-1 peripheral security attribution is set to the PSARx (x = B to E) register by the secure application.

Type-2 peripherals has the security attribution for each register or for each bit. Access to each register or bit field is controlled according to these security attributions. Type-2 peripheral security attribution is set to the Security Attribution register in each module by the secure application. For the Security Attribution register, see sections in the user manual for each peripheral.

Table 42.3 shows the classification of peripheral type.

**Table 42.3 Peripheral Type Classification**

| Type              | Peripheral                                                                                                                                                                                 |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Type-1            | SCI, SPI, USBFS, CAN, IIC, SCE9, DOC, CRC, CAC, ADC12, DAC12, POEG, AGT, GPT, RTC, IWDT, WDT                                                                                               |
| Type-2            | System control (Resets, LVD, Clock Generation Circuit, Low Power Modes, Battery Backup Function), FLASH CACHE, SRAM controller, DMAC, DTC, ICU, MPU, BUS, Security setting, ELC, I/O ports |
| Always Non-secure | QSPI                                                                                                                                                                                       |

Table 42.4 shows the access permission of type-1 peripherals. The access permission of type-2 peripherals is different by peripherals. See section Register Description of each peripheral.

**Table 42.4 The access permission of type-1 peripherals**

| Permission                          | Secure access | Non-secure access                                                   |
|-------------------------------------|---------------|---------------------------------------------------------------------|
| Peripheral configured as secure     | allowed       | Write ignored / Read ignored<br>TrustZone Access error is generated |
| Peripheral configured as non-secure | allowed       | allowed                                                             |

### 42.2.4 Flash Sequencer Security Attribution

The flash sequencer is used to program or erase the flash.

The flash sequencer has the special security attribution. Table 42.5 shows the access permission of flash sequencer.

**Table 42.5 Access Permissions of Flash Sequencer (1 of 2)**

|                           | Secure access | Non-secure access                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FACI command issuing area | allowed       | When the FACI command is issued to the secure region of code flash, data flash and option-setting memory <ul style="list-style-type: none"> <li>Issued FACI command is invalid</li> <li>Flash sequencer error is generated</li> </ul> When the FACI command is issued to the non-secure region of code flash, data flash and option-setting memory <ul style="list-style-type: none"> <li>Issued FACI command is valid</li> </ul> |

**Table 42.5 Access Permissions of Flash Sequencer (2 of 2)**

|                                    | Secure access | Non-secure access                                                                                                                                                                                                                                                                                          |
|------------------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FBPROT1, FSUACR, FMEPROT registers | allowed       | Write ignored / Readable<br>TrustZone Access error is not generated                                                                                                                                                                                                                                        |
| FCKMHZ register                    | allowed       | Configured by Flash Security Attribution register<br>When configured as Secure, <ul style="list-style-type: none"> <li>• Write ignored / Readable</li> <li>• TrustZone Access error is not generated.</li> </ul> When configured as Non-secure <ul style="list-style-type: none"> <li>• allowed</li> </ul> |
| Other registers                    | allowed       | During programming/erasure or during suspend programming/erasure by secure application <ul style="list-style-type: none"> <li>• Write ignored / Read 0x00</li> <li>• TrustZone Access error is not generated</li> </ul> In other state <ul style="list-style-type: none"> <li>• allowed</li> </ul>         |

### 42.2.5 Address Space Security Attribution

Table 42.6 shows the security attribution of the address space.

**Table 42.6 Address Space Security Attribution**

| Region                         | Attribution         |
|--------------------------------|---------------------|
| Code flash secure              | Secure              |
| Code flash non-secure callable | Non-secure callable |
| Code flash non-secure          | Non-secure          |
| Data flash secure              | Secure              |
| Data flash non-secure          | Non-secure          |
| SRAM secure                    | Secure              |
| SRAM non-secure callable       | Non-secure callable |
| SRAM non-secure                | Non-secure          |
| Peripherals                    | Exempt              |
| Other area                     | Exempt              |

Note: Exempt: No check will be done. All bus transactions are propagated.

### 42.2.6 TrustZone Access Error

Table 42.7 shows the behavior when TrustZone access error. The behavior varies depending on the master or slave area to be accessed.

**Table 42.7 The Behavior When TrustZone Access Error**

| Area                         | CPU                                                                                                                     | DMAC/DTC                                                                                                                                              |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Code flash, Data flash, SRAM | Detect SecureFault exception*2                                                                                          | <ul style="list-style-type: none"> <li>• Transfer does not start</li> <li>• Occur NMI or reset*1</li> <li>• Occur interrupt (DMA_TRANSERR)</li> </ul> |
| Other area                   | <ul style="list-style-type: none"> <li>• Detect BusFault exception*2 *3</li> <li>• Occur NMI or reset*1*2 *3</li> </ul> | <ul style="list-style-type: none"> <li>• Stop transfer*4</li> <li>• Occur NMI or reset *1 *4</li> <li>• Occur interrupt (DMA_TRANSERR)*4</li> </ul>   |

Note 1. NMI or reset is selected with TZFOAD.OAD bit.

Note 2. When TrustZone access error occurs by the debugger access, exception, NMI, or reset does not occur. Only the error response is returned.

Note 3. These error behaviors does not occur for write access to the PHBIU or PLBIU address space which memory attribute is set to "Early Write Acknowledgment" by the ARM MPU.

Note 4. These error behaviors does not occur for write access from DMAC to the PHBIU or PLBIU address space when the bufferable write is enabled by DMBWR.BWE.

### 42.3 Device Lifecycle Management

Device lifecycle identifies the current phase of the device and controls the capabilities of the debug interface, the serial programming interface and Renesas test mode. Figure 42.2 is the illustration of the device lifecycle. Table 42.8 shows the lifecycle definition and capability in each lifecycle.

Figure 42.2 The illustration of the device lifecycle

Table 42.8 The lifecycle definition and the capability can be used in each lifecycle (1 of 2)

| Lifecycle | Definition                                                                                                              | Debug level | Serial programming                                                       | Renesas test mode |
|-----------|-------------------------------------------------------------------------------------------------------------------------|-------------|--------------------------------------------------------------------------|-------------------|
| CM        | “Chip Manufacturing”                                                                                                    | DBG2        | Available<br>cannot access code/data flash area                          | Not available     |
| SSD       | “Secure Software Development”<br>The secure part of application is being developed.                                     | DBG2        | Available<br>can program/erase/read all code/data flash area             | Not available     |
| NSECSD    | “Non-SECure Software Development”<br>The non-secure part of application is being developed.                             | DBG1        | Available<br>can program/erase/read only non-secure code/data flash area | Not available     |
| DPL       | “DePLoyed”<br>The device is in-field.                                                                                   | DBG0        | Available<br>cannot access code/data flash area                          | Not available     |

| LCK_BOOT  | “LoCKed BOOT interface”<br>The debug interface and the serial programming interface are permanently disabled.           | DBG0        | Not available                                                            | Not available     |
| RMA_REQ   | “Return Material Authorization REQuest”<br>Request for RMA. The customer must send the device to Renesas in this state. | DBG0        | Available<br>cannot access code/data flash area                          | Not available     |

**Table 42.8 The lifecycle definition and the capability can be used in each lifecycle (2 of 2)**

| Lifecycle | Definition                                                                  | Debug level | Serial programming                              | Renesas test mode |
|-----------|-----------------------------------------------------------------------------|-------------|-------------------------------------------------|-------------------|
| RMA_ACK   | “Return Material Authorization ACKnowledged”<br>Failure analysis in Renesas | DBG2        | Available<br>cannot access code/data flash area | Available         |

Note: The customer receives the device in either CM or SSD state.

### 42.3.1 Changing the Lifecycle State

Use the serial programming commands to change the device lifecycle state. See the boot firmware application note for the detail of command. The lifecycle cannot be updated by application but can read through the dedicated registers.

As shown in [Figure 42.2](#), there are three types lifecycle transition.

The first one is to change to lower debug access level or restrict the serial programming mode. This change can be done with no restriction.

Note: The debug interface is permanently disabled in LCK\_DBG. After changed to LCK\_DBG, the debug interface cannot be used forever.

Note: The debug interface and serial programming interface are permanently disabled in LCK\_BOOT. After changed to LCK\_BOOT, the debug interface and the serial programming interface cannot be used forever.

The second one is to change to higher debug access level or request for RMA. This change needs key authentication. The key length is 128 bits. The secure developer needs to inject two keys when the lifecycle is SSD state. One is “SECDBG\_KEY” which is used to authentication to change the lifecycle from NSECSD to SSD. Other one is “RMA\_KEY” which is used to authentication to change the lifecycle from SSD or DPL to RMA\_REQ. The non-secure developer needs to inject one key when the lifecycle is NSECSD state. This is “NONSECDBG\_KEY” which is used to authentication to change the lifecycle from DPL to NSECSD. See [section 42.4. Key Injection](#) for the detail of how to inject the key. The key authentication uses a challenge and response authentication or authentication using the unique ID. The authentication using the unique ID is available only transition to RMA\_REQ. The following is the process of how to calculate the response, challenge and response authentication, or the authentication code using unique ID.

Response = HMAC-SHA256 (KEY, 128bits challenge || fixed value (256bits))

Authentication code = HMAC-SHA256 (KEY, 128bits unique ID || fixed value (256 bits))

fixed value = 9e56dc41 cf0c9648 1b811141 f8f9ba1e 4dd77746 6d403593 17f46d64 fe64fdf6

Note: That “||” represents concatenation, not logical or.

Note: In case the key is not injected, these lifecycle changes cannot be done.

Note: In the lifecycle transition from NSECSD to SSD or form DPL to NSECSD, the contents on the flash memory are not erased.

Note: MCU does not respond after changing to higher debug access level or RMA\_REQ. If you continue to use the serial programming commands, need to re-enter the boot mode after a reset. See the boot firmware application note for the detail.

Note: In the lifecycle transition to RMA\_REQ, the contents on the flash memory except permanently locked block or setting or BPS\_SEL register are erased. The contents in the permanently locked block or register can be read by Renesas at failure analysis. Permanently locked block means the block which programming and erasure is disabled permanently by PBPS, PBPS\_SEC and BPS\_SEL register. Permanently locked register means SAS register which programming and erasure is disabled permanently by FSPR bit.

The third one is all erase. This is done by an initialize command unless an initialize command itself is disabled. The lifecycle is back to SSD and the contents on the flash memory is erased. If there is permanently locked block or register, an initialize command does not execute. In case of the all bits of PBPS and PBPS\_SEC register are 1 and FSPR bit is 1, an initialize command is executable.

Note: The initialize command can be issued by everyone, so contents on the flash memory are easily erased. Developers who do not want this can invalidate the initialize command permanently by parameter setting command.

- Note: MCU does not respond after executing the initialize command. If you continue to use the serial programming commands, need to re-enter the boot mode after a reset. See the boot firmware application note for the detail.
- Note: For proper DLM state management, it is required to issue an initial DLM state transition command to SSD in case of receiving in CM state.
- Note: Use the serial programming in boot mode (SCI interface) or boot mode (USB interface) to change the device lifecycle state. A serial programming connection is also required even if debugging using SWD or JTAG communication.

### 42.3.2 Debug access level

There are three debug access levels, and the debug access level changes according to the lifecycle state.

- DBG2: The debugger connection is allowed, and no restriction to access memories and peripherals
- DBG1: The debugger connection is allowed, and restricted to access only non-secure memory regions and peripherals
- DBG0: The debugger connection is not allowed

### 42.3.3 Serial Programming

Whether a serial programmer can be connected and the range of flash memory that can be accessed depends on the lifecycle state as shown in [Table 42.8](#). And the accepted serial programming command differs depending on the lifecycle state. See the boot firmware application note for the detail of command.

### 42.3.4 Lifecycle changing example

The following is a typical lifecycle changing example.

#### Secure developer

- Change the lifecycle from CM to SSD by using the serial programming command.
- Set the memory security attribution of the code flash, data flash and SRAM by using the serial programming command.
- Program the secure application by using the serial programming interface and debug the secure application. Debug is possible if the lifecycle is CM, but it is impossible to set the memory security attribution in CM state. If the memory security attribution is not set, all area of the code flash, data flash and SRAM is Secure.

Note: Need to configure the registers listed in [Table 42.10](#) as Non-secure only in NSECSD state. See [section 42.6.1. Restrictions on setting the security attribution](#) for details.

- Inject “SECDBG\_KEY” and “RMA\_KEY” by using the serial programming command (if need).
- Inject AES, RSA, ECC, HMAC keys listed in [Table 42.9](#) (if need).
- Disable the all erase by using the serial programming command (if need).
- Change the lifecycle from SSD to NSECSD by using the serial programming command.

#### Non-secure developer

- Program the Non-secure application by using the serial programming interface and debug the Non-secure application.
- Inject “NONSECDBG\_KEY” by using the serial programming command (if need).
- Inject AES, RSA, ECC, HMAC keys listed in [Table 42.9](#) (if need).
- Disable the all erase by using the serial programming command (if need).
- Change the lifecycle to DPL by using the serial programming command.

### 42.3.5 Failure analysis

If the customer requests the failure analysis to Renesas, it is necessary to send the device after changing the lifecycle to RMA\_REQ. If the lifecycle is not RMA\_REQ, Renesas cannot do the failure analysis. Because RMA\_REQ is permanent state, it cannot back to the another state after changing to RMA\_REQ. It is assumed to change to SSD or NSECSD and analyze before changing to RMA\_REQ.

Devices sent to Renesas will not be returned to customers. The device will be discarded.

Note: As described in the [section 42.3.1. Changing the Lifecycle State](#), RMA\_KEY is needed to change the lifecycle to RMA\_REQ. If the customer forgets the RMA\_KEY, Renesas cannot do the failure analysis.

## 42.4 Key Injection

There are three steps required to inject a user key into the MCU.

First, the customer needs to create the 256 bits installation key. This key is called User Factory Programming Key (UFPK) and used to encrypt a user key. The customer gets the key of the wrapped version (W-UFPK) through the Renesas Key Wrapping Service.

Second the customer encrypts the user key using UFPK as the AES key.

Last the customer sends W-UFPK and the encrypted user key to the MCU by using serial programming interface. The sent user key is decrypted, wrapped with the hardware unique key, and then stored in the nonvolatile memory.

[Figure 42.3](#) is the illustration of key injection. [Table 42.9](#) shows the keys that can be injected by serial programming interface.

User Key is used for authentication during the life cycle transition.

Figure 42.3 Key Injection

Table 42.9 The keys that can be injected by serial programming

| 29  | PSARB29 | SCI2 and the MSTPCRB.MSTPB29 bit security attribution<br>0: Secure<br>1: Non-secure | R/W |
| 30  | PSARB30 | SCI1 and the MSTPCRB.MSTPB30 bit security attribution<br>0: Secure<br>1: Non-secure | R/W |
| 31  | PSARB31 | SCI0 and the MSTPCRB.MSTPB31 bit security attribution<br>0: Secure<br>1: Non-secure | R/W |

Note: A bit undefined in this table is reserved bit. The reserved bit should be kept the initial value.

Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR register.

The PSARB specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

### 42.5.2 PSARC : Peripheral Security Attribution Register C

|------|--------|-------------------------------------------------------------------------------------|-----|
| 0    | TZFSA0 | Security attributes of registers for TrustZone Filter<br>0: Secure<br>1: Non-secure | R/W |
| 31:1 | —      | These bits are read as 1.                                                           | R   |

Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR register.

#### TZFSA0 bit (Security attributes of registers for TrustZone Filter)

Security attributes of register for TZFOAD and TZFPT registers.

### 42.5.13 TZFOAD : TrustZone Filter Operation After Detection Register

Base address: TZF = 0x4000\_0E00

Offset address: 0x00

|                    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |     |
|--------------------|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|-----|
| Bit position:      | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0   |
| Bit field:         | KEY[7:0] |    |    |    |    |    |   |   | — | — | — | — | — | — | — | OAD |
| Value after reset: | 0        | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0   |

| Bit  | Symbol   | Function                                                                 | R/W |
|------|----------|--------------------------------------------------------------------------|-----|
| 0    | OAD      | Operation after detection<br>0: Non-maskable interrupt<br>1: Reset       | R/W |
| 7:1  | —        | These bits are read as 0. The write value should be 0.                   | R/W |
| 15:8 | KEY[7:0] | KeyCode<br>This bit is used to enable or disable writing of the OAD bit. | W   |

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

#### OAD bit (Operation after detection)

The OAD bit is specified to generate either reset or non-maskable interrupt when the access to the protect region is detected by the TrustZone Filter.

When the OAD bit is set, write 0xA5 in the KEY[7:0] bits at the same time.

#### KEY[7:0] bits (KeyCode)

The KEY[7:0] bits are used to enable or disable writing of the OAD bit. When writing the OAD bit, write 0xA5 in the KEY[7:0] bits at the same time.

When the KEY[7:0] bits value except 0xA5 is written in, the OAD bit is not updated.

The KEY[7:0] bits are read always as 0x00.

### 42.5.14 TZFPT : TrustZone Filter Protect Register

Base address: TZF = 0x4000\_0E00

Offset address: 0x04

|                    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |         |
|--------------------|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---------|
| Bit position:      | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0       |
| Bit field:         | KEY[7:0] |    |    |    |    |    |   |   | — | — | — | — | — | — | — | PROTECT |
| Value after reset: | 0        | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0       |

| Bit  | Symbol   | Function                                                                                                                                                            | R/W |
|------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| 0    | PROTECT  | Protection of register<br>0: All Bus TrustZone Filter register writing is protected. Read is possible.<br>1: All Bus TrustZone Filter register writing is possible. | R/W |
| 7:1  | —        | These bits are read as 0. The write value should be 0.                                                                                                              | R/W |
| 15:8 | KEY[7:0] | KeyCode<br>This bit is used to enable or disable writing of the PROTECT bit.                                                                                        | W   |

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

### PROTECT bit (Protection of register)

The PROTECT bit controls enable or disable writing to the corresponding registers to be protected. TZFOAD register is protected by PROTECT.

When the PROTECT bit is set, write 0xA5 in the KEY[7:0] bits at the same time.

### KEY[7:0] bits (KeyCode)

The KEY[7:0] bits are used to enable or disable writing of the PROTECT bit. When writing the PROTECT bit, write 0xA5 in the KEY[7:0] bits at the same time.

When the KEY[7:0] bits value except 0xA5 is written in, the PROTECT bit is not updated.

The KEY[7:0] bits are read always as 0x00.

## 42.6 Usage Notes

### 42.6.1 Restrictions on setting the security attribution

To set the software breakpoint, the debugger need to re-program the flash. [Table 42.10](#) shows the registers that the debugger sets to re-program the flash. If the security attribution of the register listed in [Table 42.10](#) is configured as secure, the debugger cannot set the software breakpoint in NSECSD state because the debugger cannot change the register setting. Secure developer need to configure the registers listed in [Table 42.10](#) as non-secure only in NSECSD state.

**Table 42.10** The registers that the debugger sets to re-program the flash

| Function name            | Register name                                    |
|--------------------------|--------------------------------------------------|
| Clock Generation Circuit | SCKDIVCR, SCKCR, PLLCCR, PLLCR, HOCOCCR, MOCOCCR |
| Low-Power modes          | OPCCR, SOPCCR                                    |

### 42.6.2 SAU setting

After reset, all of address space is marked as Secure by SAU default setting. SAU\_CTRL register should be set to 0x2 to enable the IDAU security attribution. That is, after setting SAU\_CTRL register to 0x2, the address space security attribution becomes as shown in [Table 42.6](#).

### 42.6.3 Non-secure exception during the setting of FACI registers

As shown in [Table 42.5](#), the registers related to FACI are protected from non-secure access only during programming/erasure or during suspend programming/erasure. Outside of this state, the access from non-secure region is not protected. For example, when programming by the secure user, the non-secure user can rewrite the FSADDR if a non-secure exception occurs immediately after “Set the start address of the target block to the FSADDR register” flow in [Figure 40.13](#). If the FACI command is issued after the non-secure exception processing is completed and the CPU state returns to the secure state, data will be programmed to an address not intended by the secure user.

To prevent such a thing, secure user needs to set not to accept the non-secure exception during the following period.

- Set not to accept the non-secure exception before setting FWEPROR to 0x01 or setting FENTRYR to other than 0x0000, that is before releasing the protection of FWEPROR or FENTRYR.
- Set to accept the non-secure exception after all write access to the FACI command-issuing area is completed.

### 42.6.4 FCU interrupt usage

It is recommended that secure users do not use the FCU interrupts, but rather use the register polling. Because non-secure users can program/erase the data flash without calling the secure gateway, if secure user uses FCU interrupts, the unintentional exception handling may be executed when data flash is programmed/erased by a non-secure user.

## 43. Electrical Characteristics

Supported peripheral functions and pins differ from one product name to another.

Unless otherwise specified, the electrical characteristics of the MCU are defined under the following conditions:

- $VCC = AVCC0 = VCC\_USB = VBATT = 2.7$  to  $3.6$  V
- $2.7 \leq VREFH0/VREFH \leq AVCC0$
- $VSS = AVSS0 = VREFL0/VREFL = VSS\_USB = 0$  V
- $T_a = T_{opr}$

Figure 43.1 shows the timing conditions.

**Figure 43.1** Input or output timing measurement conditions

The recommended measurement conditions for the timing specification of each peripheral provided are for the best peripheral operation. Make sure to adjust the driving abilities of each pin to meet your conditions.

### 43.1 Absolute Maximum Ratings

**Table 43.1** Absolute maximum ratings

| Parameter                                                    | Symbol                     | Value                          | Unit |
|--------------------------------------------------------------|----------------------------|--------------------------------|------|
| Power supply voltage                                         | VCC, VCC_USB <sup>*2</sup> | -0.3 to +4.0                   | V    |
| VBATT power supply voltage                                   | VBATT                      | -0.3 to +4.0                   | V    |
| Input voltage (except for 5 V-tolerant ports <sup>*1</sup> ) | V <sub>in</sub>            | -0.3 to VCC + 0.3              | V    |
| Input voltage (5 V-tolerant ports <sup>*1</sup> )            | V <sub>in</sub>            | -0.3 to + VCC + 4.0 (max. 5.8) | V    |
| Reference power supply voltage                               | VREFH/VREFH0               | -0.3 to VCC + 0.3              | V    |
| Analog power supply voltage                                  | AVCC0 <sup>*2</sup>        | -0.3 to +4.0                   | V    |
| Analog input voltage                                         | V <sub>AN</sub>            | -0.3 to AVCC0 + 0.3            | V    |
| Operating temperature <sup>*3 *4</sup>                       | T <sub>opr</sub>           | -40 to +85                     | °C   |
| Storage temperature                                          | T <sub>stg</sub>           | -55 to +125                    | °C   |

Note 1. Ports P205, P206, P400, P401, and P407 to P411 are 5 V tolerant.

Note 2. Connect AVCC0 and VCC\_USB to VCC.

Note 3. See [section 43.2.1. Tj/Ta Definition](#).

Note 4. Contact a Renesas Electronics sales office for information on derating operation when  $T_a = +85^\circ\text{C}$ . Derating is the systematic reduction of load for improved reliability.

**Caution:** Permanent damage to the MCU might result if absolute maximum ratings are exceeded.

**Table 43.2 Recommended operating conditions**

| Parameter                    | Symbol              | Value                | Min | Typ | Max | Unit |
|------------------------------|---------------------|----------------------|-----|-----|-----|------|
| Power supply voltages        | VCC                 | When USB is not used | 2.7 | —   | 3.6 | V    |
|                              |                     | When USB is used     | 3.0 | —   | 3.6 | V    |
|                              | VSS                 | —                    | 0   | —   | V   |      |
| USB power supply voltages    | VCC_USB             | —                    | VCC | —   | V   |      |
|                              | VSS_USB             | —                    | 0   | —   | V   |      |
| VBATT power supply voltage   | VBATT               | 1.65 <sup>*2</sup>   | —   | 3.6 | V   |      |
| Analog power supply voltages | AVCC0 <sup>*1</sup> | —                    | VCC | —   | V   |      |
|                              | AVSS0               | —                    | 0   | —   | V   |      |

Note 1. Connect AVCC0 to VCC. When the A/D converter and the D/A converter are not in use, do not leave the AVCC0, VREFH/VREFH0, AVSS0, and VREFL/VREFL0 pins open. Connect the AVCC0 and VREFH/VREFH0 pins to VCC, and the AVSS0 and VREFL/VREFL0 pins to VSS, respectively.

Note 2. Low CL crystal cannot be used below VBATT = 1.8V.

## 43.2 DC Characteristics

### 43.2.1 T<sub>j</sub>/T<sub>a</sub> Definition

**Table 43.3 DC characteristics**

Conditions: Products with operating temperature (T<sub>a</sub>) -40 to +85°C

| Parameter                        | Symbol         | Typ | Max | Unit | Test conditions                                        |
|----------------------------------|----------------|-----|-----|------|--------------------------------------------------------|
| Permissible junction temperature | T <sub>j</sub> | —   | 105 | °C   | High-speed mode<br>Low-speed mode<br>Subosc-speed mode |

Note: Make sure that  $T_j = T_a + \theta_{ja} \times \text{total power consumption (W)}$ , where total power consumption =  $(V_{CC} - V_{OH}) \times \Sigma I_{OH} + V_{OL} \times \Sigma I_{OL} + I_{CCmax} \times V_{CC}$ .

### 43.2.2 I/O V<sub>IH</sub>, V<sub>IL</sub>

**Table 43.4 I/O V<sub>IH</sub>, V<sub>IL</sub> (1 of 2)**

| Parameter                                             | Symbol                  | Min                                              | Typ             | Max       | Unit                |   |
|-------------------------------------------------------|-------------------------|--------------------------------------------------|-----------------|-----------|---------------------|---|
| Input voltage (except for Schmitt trigger input pins) | Peripheral function pin | EXTAL (external clock input), SPI (except RSPCK) | V <sub>IH</sub> | VCC × 0.8 | —                   | V |
|                                                       |                         |                                                  | V <sub>IL</sub> | —         | —                   |   |
|                                                       | IIC (SMBus)             | V <sub>IH</sub>                                  | 2.1             | —         | VCC + 3.6 (max 5.8) |   |
|                                                       |                         | V <sub>IL</sub>                                  | —               | —         | 0.8                 |   |

**Table 43.4 I/O  $V_{IH}$ ,  $V_{IL}$  (2 of 2)**

| Parameter                     |                                            |                         | Symbol                                 | Min                                 | Typ               | Max                    | Unit                     |   |                                                           |
|-------------------------------|--------------------------------------------|-------------------------|----------------------------------------|-------------------------------------|-------------------|------------------------|--------------------------|---|-----------------------------------------------------------|
| Schmitt trigger input voltage | Peripheral function pin                    | IIC (except for SMBus)  |                                        | $V_{IH}$                            | $VCC \times 0.7$  | —                      | $VCC + 3.6$<br>(max 5.8) | V |                                                           |

Note 1. RES and peripheral function pins associated with Ports P205, P206, P400, P401, and P407 to P411 (total 10 pins).  
 Note 2. All input pins except for the peripheral function pins already described in the table.  
 Note 3. Ports P205, P206, P400, P401, and P407 to P411 (total 9 pins).  
 Note 4. All input pins except for the ports already described in the table.  
 Note 5. When VCC is less than 2.7 V, the input voltage of 5 V-tolerant ports should be less than 3.6 V, otherwise breakdown may occur because 5 V-tolerant ports are electrically controlled so as not to violate the break down voltage.

Note 1. This is the value when low driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.

Note 2. This is the value when middle driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.

Note 3. This is the value when high driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.

Note 4. Except for P200, which is an input port.

**Caution:** To protect the reliability of the MCU, the output current values should not exceed the values in this table. The average output current indicates the average value of current measured during 100  $\mu$ s.

| Reference power supply current (VREFH)             | During D/A conversion             | Without AMP output      | —   | 0.1  | 0.4  | mA   | —               |
|                                                    |                                   | With AMP output         | —   | 0.1  | 0.4  | mA   | —               |
|                                                    | Waiting for D/A conversion        | AI <sub>REFH</sub>      | —   | 0.07 | 0.8  | μA   | —               |
| USB operating current                              | Low speed                         | USB                     | —   | 3.5  | 6.5  | mA   | VCC_USB         |
|                                                    | Full speed                        | USB                     | —   | 4.0  | 10.0 | mA   | VCC_USB         |
| LDO on operating current (per unit) <sup>*15</sup> |                                   | I <sub>CC</sub> LDO     | —   | 0.18 | —    | mA   | —               |
| PLL2-LDO operating current                         |                                   | I <sub>CC</sub> PLL2LDO | —   | 0.21 | —    | mA   | —               |

- Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
- Note 2. Measured with clocks supplied to the peripheral functions. This does not include the BGO operation.
- Note 3. I<sub>CC</sub> depends on f (ICLK) as follows.  
 I<sub>CC</sub> Max. = 0.53 × f + 12 (max. operation in high-speed mode)  
 I<sub>CC</sub> Typ. = 0.05 × f + 1.85 (normal operation in high-speed mode, all peripheral clocks disabled)  
 I<sub>CC</sub> Typ. = 0.12 × f + 0.69 (low-speed mode)  
 I<sub>CC</sub> Max. = 0.13 × f + 12 (sleep mode)
- Note 4. This does not include the BGO operation.
- Note 5. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
- Note 6. FCLK, PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (1.563 MHz).
- Note 7. FCLK, PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (3.125 MHz).
- Note 8. Reference value
- Note 9. When the MCU is in Software Standby mode or the MSTPCRD.MSTPD16 (12-Bit A/D Converter 0 Module Stop bit) and MSTPCRD.MSTPD20 (12-bit D/A converter module stop bit) are in the module-stop state.
- Note 10. FCLK, PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (15.6 kHz).
- Note 11. PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (512 Hz). FCLK is the same frequency as that of ICLK.
- Note 12. PLL output frequency = 100MHz.
- Note 13. PLL output frequency = 200MHz.
- Note 14. PLL2-LDO disabled.
- Note 15. n = 0, 1

|                              | Normal mode                  | All peripheral clocks disabled, cache on, while (1) code executing from flash <sup>*2 *3 *4</sup>  |                 | 60  |        |                                                                   |
|                              |                              | All peripheral clocks disabled, cache off, while (1) code executing from flash <sup>*2 *3 *4</sup> |                 | 118 |        |                                                                   |

- Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
- Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
- Note 3. PLL output frequency = 100MHz.
- Note 4. PLL2-LDO disabled.

### 43.2.6 VCC Rise and Fall Gradient and Ripple Frequency

**Table 43.9** Rise and fall gradient characteristics

| Parameter              |                                             | Symbol | Min    | Typ | Max | Unit | Test conditions |
|------------------------|---------------------------------------------|--------|--------|-----|-----|------|-----------------|
| VCC rising gradient    | Voltage monitor 0 reset disabled at startup | SrVCC  | 0.0084 | —   | 20  | ms/V | —               |
|                        | Voltage monitor 0 reset enabled at startup  |        | 0.0084 | —   | —   |      | —               |
|                        | SCI/USB boot mode*1                         |        | 0.0084 | —   | 20  |      | —               |
| VCC falling gradient*2 |                                             | SrVCC  | 0.0084 | —   | —   | ms/V | —               |

Note 1. At boot mode, the reset from voltage monitor 0 is disabled regardless of the value of the OFS1.LVDAS bit.

Note 2. This applies when VBATT is used.

**Table 43.10 Rising and falling gradient and ripple frequency characteristics**

The ripple voltage must meet the allowable ripple frequency  $f_r(V_{CC})$  within the range between the VCC upper limit (3.6 V) and lower limit (2.7 V). When the VCC change exceeds  $V_{CC} \pm 10\%$ , the allowable voltage change rising and falling gradient  $dt/dV_{CC}$  must be met.

| Parameter                                            | Symbol        | Min | Typ | Max | Unit | Test conditions                                      |
|------------------------------------------------------|---------------|-----|-----|-----|------|------------------------------------------------------|
| Allowable ripple frequency                           | $f_r(V_{CC})$ | —   | —   | 10  | kHz  | Figure 43.6<br>$V_r(V_{CC}) \leq V_{CC} \times 0.2$  |
|                                                      |               | —   | —   | 1   | MHz  | Figure 43.6<br>$V_r(V_{CC}) \leq V_{CC} \times 0.08$ |
|                                                      |               | —   | —   | 10  | MHz  | Figure 43.6<br>$V_r(V_{CC}) \leq V_{CC} \times 0.06$ |
| Allowable voltage change rising and falling gradient | $dt/dV_{CC}$  | 1.0 | —   | —   | ms/V | When VCC change exceeds $V_{CC} \pm 10\%$            |

**Figure 43.6 Ripple waveform**

### 43.2.7 Thermal Characteristics

Maximum value of junction temperature ( $T_j$ ) must not exceed the value of “[section 43.2.1.  \$T\_j/T\_a\$  Definition](#)”.

$T_j$  is calculated by either of the following equations.

- $T_j = T_a + \theta_{ja} \times \text{Total power consumption}$
- $T_j = T_t + \Psi_{jt} \times \text{Total power consumption}$ 
  - $T_j$  : Junction Temperature ( $^{\circ}\text{C}$ )
  - $T_a$  : Ambient Temperature ( $^{\circ}\text{C}$ )
  - $T_t$  : Top Center Case Temperature ( $^{\circ}\text{C}$ )
  - $\theta_{ja}$  : Thermal Resistance of “Junction”-to-“Ambient” ( $^{\circ}\text{C}/\text{W}$ )
  - $\Psi_{jt}$  : Thermal Resistance of “Junction”-to-“Top Center Case” ( $^{\circ}\text{C}/\text{W}$ )
- Total power consumption = Voltage  $\times$  (Leakage current + Dynamic current)
- Leakage current of IO =  $\sum (I_{OL} \times V_{OL}) / \text{Voltage} + \sum (|I_{OH}| \times |V_{CC} - V_{OH}|) / \text{Voltage}$
- Dynamic current of IO =  $\sum IO (C_{in} + C_{load}) \times IO \text{ switching frequency} \times \text{Voltage}$ 
  - $C_{in}$ : Input capacitance
  - $C_{load}$ : Output capacitance

Regarding  $\theta_{ja}$  and  $\Psi_{jt}$ , refer to [Table 43.11](#).

**Table 43.11 Thermal Resistance**

| Parameter          | Package                    | Symbol        | Value*1 | Unit | Test conditions              |
|--------------------|----------------------------|---------------|---------|------|------------------------------|
| Thermal Resistance | 48-pin QFN (PWQN0048KC-A)  | $\theta_{ja}$ | 23.9    | °C/W | JESD 51-2 and 51-7 compliant |
|                    | 64-pin LQFP (PLQP0064KB-C) |               | 54.6    |      |                              |
|                    | 48-pin QFN (PWQN0048KC-A)  | $\Psi_{jt}$   | 0.28    | °C/W |                              |
|                    | 64-pin LQFP (PLQP0064KB-C) |               | 1.90    |      |                              |

Note 1. The values are reference values when the 4-layer board is used. Thermal resistance depends on the number of layers or size of the board. For details, refer to the JEDEC standards.

### 43.2.7.1 Calculation guide of $I_{CCmax}$

Table 43.12 shows the power consumption of each unit.

**Table 43.12 Power consumption of each unit**

| Dynamic current/<br>Leakage current | MCU Domain               | Category                      | Item            | Frequency [MHz] | Current [ $\mu$ A/MHz] | Current*1 [mA] |
|-------------------------------------|--------------------------|-------------------------------|-----------------|-----------------|------------------------|----------------|
| Leakage current                     | Analog                   | LDO and Leak*2                | Ta = 75 °C*3    | —               | —                      | 7.82           |
|                                     |                          |                               | Ta = 85 °C*3    | —               | —                      | 9.13           |
| Dynamic current                     | CPU                      | Operation with Flash and SRAM | Coremark        | 100             | 55.556                 | 5.56           |
|                                     |                          |                               | Peripheral Unit | Timer           | GPT16 (2ch)*4          | 100            |

Note 1. The values are guaranteed by design.

Note 2. LDO and Leak are internal voltage regulator's current and MCU's leakage current.

It is selected according to the temperature of Ta.

Note 3.  $\Delta(T_j - T_a) = 20$  °C is considered to measure the current.

Note 4. To determine the current consumption per channel, group or unit, divide Current [mA] by the number of channels, groups or units.

Table 43.13 shows the outline of operation for each unit.

**Table 43.13 Outline of operation for each unit**

| Peripheral | Outline of operation                                                                                                                                                  |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GPT        | Operating modes is set to saw-wave PWM mode.<br>GPT is operating with PCLKD.                                                                                          |
| POEG       | Only clear module stop bit.                                                                                                                                           |
| AGT        | AGT is operating with PCLKB.                                                                                                                                          |
| RTC        | RTC is operating with LOCO.                                                                                                                                           |
| WDT        | WDT is operating with PCLKB.                                                                                                                                          |
| IWDT       | IWDT is operating with IWDTCLK.                                                                                                                                       |
| USBFS      | Transfer types is set to bulk transfer.<br>USBFS is operating using Full-speed transfer (12 Mbps).                                                                    |
| SCI        | SCI is transmitting data in clock synchronous mode.                                                                                                                   |
| IIC        | Communication format is set to I2C-bus format.<br>IIC is transmitting data in master mode.                                                                            |
| CAN        | CAN is transmitting and receiving data in self-test mode 1.                                                                                                           |
| SPI        | SPI mode is set to SPI operation (4-wire method).<br>SPI master/slave mode is set to master mode.<br>SPI is transmitting 8-bit width data.                            |
| QSPI       | QSPI is issuing Fast Read Quad I/O Instruction.                                                                                                                       |
| ADC12      | Resolution is set to 12-bit accuracy.<br>Data registers is set to A/D-converted value addition mode.<br>ADC12 is converting the analog input in continuous scan mode. |
| DAC12      | DAC12 is outputting the conversion result while updating the value of data register.                                                                                  |

| DMAC       | Bit length of transfer data is set to 32 bits.<br>Transfer mode is set to block transfer mode.<br>DMAC is transferring data from SRAM0 to SRAM0.                      |
| DTC        | Bit length of transfer data is set to 32 bits.<br>Transfer mode is set to block transfer mode.<br>DTC is transferring data from SRAM0 to SRAM0.                       |

### 43.2.7.2 Example of $T_j$ calculation

Assumption :

- Package 64-pin LQFP :  $\theta_{ja} = 54.6 \text{ } ^\circ\text{C/W}$
- $T_a = 80 \text{ } ^\circ\text{C}$
- $I_{CCmax} = 40 \text{ mA}$
- $V_{CC} = 3.5 \text{ V}$  ( $V_{CC} = AV_{CC} = V_{CC\_USB}$ )
- $I_{OH} = 1 \text{ mA}$ ,  $V_{OH} = V_{CC} - 0.5 \text{ V}$ , 12 Outputs
- $I_{OL} = 20 \text{ mA}$ ,  $V_{OL} = 1.0 \text{ V}$ , 8 Outputs
- $I_{OL} = 1 \text{ mA}$ ,  $V_{OL} = 0.5 \text{ V}$ , 12 Outputs
- $C_{in} = 8 \text{ pF}$ , 16 pins, Input frequency = 10 MHz
- $C_{load} = 30 \text{ pF}$ , 16 pins, Output frequency = 10 MHz

$$\begin{aligned}
 \text{Leakage current of IO} &= \Sigma (V_{OL} \times I_{OL}) / \text{Voltage} + \Sigma ((VCC - V_{OH}) \times I_{OH}) / \text{Voltage} \\
 &= (20 \text{ mA} \times 1 \text{ V}) \times 8 / 3.5 \text{ V} + (1 \text{ mA} \times 0.5 \text{ V}) \times 12 / 3.5 \text{ V} + ((VCC - (VCC - 0.5 \text{ V})) \times 1 \text{ mA}) \times 12 / 3.5 \text{ V} \\
 &= 45.7 \text{ mA} + 1.71 \text{ mA} + 1.71 \text{ mA} \\
 &= 49.1 \text{ mA}
 \end{aligned}$$

$$\begin{aligned}
 \text{Dynamic current of IO} &= \Sigma IO (C_{in} + C_{load}) \times \text{IO switching frequency} \times \text{Voltage} \\
 &= ((8 \text{ pF} \times 16) \times 10 \text{ MHz} + (30 \text{ pF} \times 16) \times 10 \text{ MHz}) \times 3.5 \text{ V} \\
 &= 21.3 \text{ mA}
 \end{aligned}$$

$$\begin{aligned}
 \text{Total power consumption} &= (I_{CCmax} \times \text{Voltage}) + (\text{Leakage current of IO} + \text{Dynamic current of IO}) \times \text{Voltage} \\
 &= (40 \text{ mA} \times 3.5 \text{ V}) + (49.1 \text{ mA} + 21.3 \text{ mA}) \times 3.5 \text{ V} \\
 &= 386 \text{ mW} (0.386 \text{ W})
 \end{aligned}$$

$$\begin{aligned}
 T_j &= T_a + \theta_{ja} \times \text{Total power consumption} \\
 &= 80 \text{ }^\circ\text{C} + 54.6 \text{ }^\circ\text{C/W} \times 0.386 \text{ W} \\
 &= 101.1 \text{ }^\circ\text{C}
 \end{aligned}$$

### 43.3 AC Characteristics

#### 43.3.1 Frequency

**Table 43.14 Operation frequency value in high-speed mode**

| Parameter           | Symbol                                        | Min             | Typ | Max | Unit |
|---------------------|-----------------------------------------------|-----------------|-----|-----|------|
| Operation frequency | System clock (ICLK) <sup>*2</sup>             | —               | —   | 100 | MHz  |
|                     | Peripheral module clock (PCLKA) <sup>*2</sup> | —               | —   | 100 |      |
|                     | Peripheral module clock (PCLKB) <sup>*2</sup> | —               | —   | 50  |      |
|                     | Peripheral module clock (PCLKC) <sup>*2</sup> | — <sup>*3</sup> | —   | 50  |      |
|                     | Peripheral module clock (PCLKD) <sup>*2</sup> | —               | —   | 100 |      |
|                     | Flash interface clock (FCLK) <sup>*2</sup>    | — <sup>*1</sup> | —   | 50  |      |

Note 1. FCLK must run at a frequency of at least 4 MHz when programming or erasing the flash memory.

Note 2. See [section 8, Clock Generation Circuit](#) for the relationship between the ICLK, PCLKA, PCLKB, PCLKC, PCLKD, and FCLK frequencies.

Note 3. When the ADC12 is used, the PCLKC frequency must be at least 1 MHz.

**Table 43.15 Operation frequency value in low-speed mode**

| Parameter           | Symbol                                           | Min             | Typ | Max | Unit |
|---------------------|--------------------------------------------------|-----------------|-----|-----|------|
| Operation frequency | System clock (ICLK) <sup>*2</sup>                | —               | —   | 1   | MHz  |
|                     | Peripheral module clock (PCLKA) <sup>*2</sup>    | —               | —   | 1   |      |
|                     | Peripheral module clock (PCLKB) <sup>*2</sup>    | —               | —   | 1   |      |
|                     | Peripheral module clock (PCLKC) <sup>*2 *3</sup> | — <sup>*3</sup> | —   | 1   |      |
|                     | Peripheral module clock (PCLKD) <sup>*2</sup>    | —               | —   | 1   |      |
|                     | Flash interface clock (FCLK) <sup>*1 *2</sup>    | —               | —   | 1   |      |

Note 1. Programming or erasing the flash memory is disabled in low-speed mode.

Note 2. See [section 8, Clock Generation Circuit](#) for the relationship between the ICLK, PCLKA, PCLKB, PCLKC, PCLKD, and FCLK frequencies.

Note 3. When the ADC12 is used, the PCLKC frequency must be set to at least 1 MHz.

**Table 43.16 Operation frequency value in Subosc-speed mode**

| Parameter           | Symbol                                           | Min  | Typ  | Max  | Unit |     |
|---------------------|--------------------------------------------------|------|------|------|------|-----|
| Operation frequency | System clock (ICLK) <sup>*2</sup>                | f    | 29.4 | —    | 36.1 | kHz |
|                     | Peripheral module clock (PCLKA) <sup>*2</sup>    | —    | —    | 36.1 |      |     |
|                     | Peripheral module clock (PCLKB) <sup>*2</sup>    | —    | —    | 36.1 |      |     |
|                     | Peripheral module clock (PCLKC) <sup>*2 *3</sup> | —    | —    | 36.1 |      |     |
|                     | Peripheral module clock (PCLKD) <sup>*2</sup>    | —    | —    | 36.1 |      |     |
|                     | Flash interface clock (FCLK) <sup>*1 *2</sup>    | 29.4 | —    | 36.1 |      |     |

Note 1. Programming or erasing the flash memory is disabled in Subosc-speed mode.

Note 2. See [section 8, Clock Generation Circuit](#) for the relationship between the ICLK, PCLKA, PCLKB, PCLKC, PCLKD, and FCLK frequencies.

Note 3. The ADC12 cannot be used.

### 43.3.2 Clock Timing

**Table 43.17 Clock timing except for sub-clock oscillator (1 of 2)**

| Parameter                                                              | Symbol                 | Min                 | Typ    | Max             | Unit   | Test conditions                                             |                  |
|------------------------------------------------------------------------|------------------------|---------------------|--------|-----------------|--------|-------------------------------------------------------------|------------------|
| EXTAL external clock input cycle time                                  | t <sub>EXcyc</sub>     | 41.66               | —      | —               | ns     | <a href="#">Figure 43.7</a>                                 |                  |

**Table 43.17 Clock timing except for sub-clock oscillator (2 of 2)**

| Parameter                 | Symbol                                 | Min | Typ       | Max       | Unit | Test conditions                          |
|---------------------------|----------------------------------------|-----|-----------|-----------|------|------------------------------------------|
| PLL/PLL2 period jitter    | $f_{PLL}, f_{PLL2} \geq 120\text{MHz}$ | —   | —         | $\pm 100$ | ps   | —                                        |
|                           | $f_{PLL}, f_{PLL2} < 120\text{MHz}$    | —   | —         | $\pm 120$ | ps   | —                                        |
| PLL/PLL2 long term jitter | —                                      | —   | $\pm 300$ | —         | ps   | Term: 1 $\mu\text{s}$ , 10 $\mu\text{s}$ |

Note 1. When setting up the main clock oscillator, ask the oscillator manufacturer for an oscillation evaluation, and use the results as the recommended oscillation stabilization time. Set the MOSCWTCR register to a value equal to or greater than the recommended value.  
 After changing the setting in the MOSCCR.MOSTP bit to start main clock operation, read the OSCSF.MOSCSF flag to confirm that it is 1, and then start using the main clock oscillator.

Note 2. This is the time from release from reset state until the HOCO oscillation frequency ( $f_{HOCO}$ ) reaches the range for guaranteed operation.

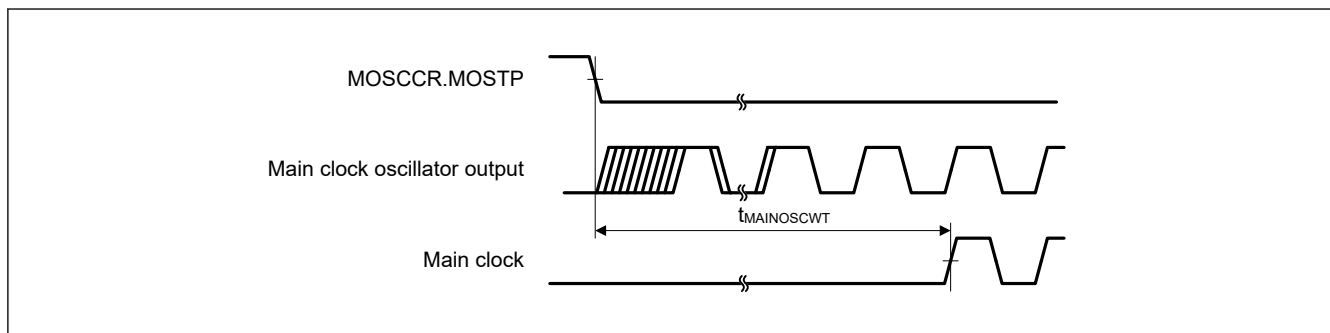

**Table 43.18 Clock timing for the sub-clock oscillator**

| Parameter                                     | Symbol         | Min | Typ    | Max | Unit | Test conditions |
|-----------------------------------------------|----------------|-----|--------|-----|------|-----------------|
| Sub-clock frequency                           | $f_{SUB}$      | —   | 32.768 | —   | kHz  | —               |
| Sub-clock oscillation stabilization wait time | $t_{SUBOSCWT}$ | —   | —      | —*1 | s    | Figure 43.11    |

Note 1. When setting up the sub-clock oscillator, ask the oscillator manufacturer for an oscillation evaluation and use the results as the recommended oscillation stabilization time.  
 After changing the setting in the SOSCCR.SOSTP bit to start sub-clock operation, only start using the sub-clock oscillator after the sub-clock oscillation stabilization time elapses with an adequate margin. A value that is two times the value shown is recommended.

**Table 43.20 Timing of recovery from low power modes (2 of 2)**

| Parameter                                                  | Symbol                                                    | Min               | Typ | Max   | Unit             | Test conditions |              |
|------------------------------------------------------------|-----------------------------------------------------------|-------------------|-----|-------|------------------|-----------------|--------------|
| Recovery time from Deep Software Standby mode              | DPSBYCR.DEEPCUT[1] = 0 and DPSWCR.WTSTS[5:0] = 0x0E       | t <sub>DSBY</sub> | —   | 0.38  | 0.54             | ms              | Figure 43.15 |
|                                                            | DPSBYCR.DEEPCUT[1] = 1 and DPSWCR.WTSTS[5:0] = 0x19       | t <sub>DSBY</sub> | —   | 0.55  | 0.73             | ms              |              |
| Wait time after cancellation of Deep Software Standby mode | t <sub>DSBYWT</sub>                                       | 56                | —   | 57    | t <sub>cyc</sub> |                 |              |
| Recovery time from Software Standby mode to Snooze mode    | High-speed mode when system clock source is HOCO (20 MHz) | t <sub>SNZ</sub>  | —   | 35*12 | 70*12            | μs              | Figure 43.16 |
|                                                            | High-speed mode when system clock source is MOCO (8 MHz)  | t <sub>SNZ</sub>  | —   | 11*12 | 14*12            | μs              |              |

Note 1. The recovery time is determined by the system clock source. When multiple oscillators are active, the recovery time can be determined with the following equation:

Total recovery time = recovery time for an oscillator as the system clock source + the longest t<sub>SBYOSCWT</sub> in the active oscillators - t<sub>SBYOSCWT</sub> for the system clock + 2 LOCO cycles (when LOCO is operating) + Subosc is oscillating and MSTPC0 = 0 (CAC module stop)

- Note 2. When the frequency of the crystal is 24 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 1.
- Note 3. When the frequency of PLL is 200 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 4.
- Note 4. When the frequency of the external clock is 24 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 1.
- Note 5. When the frequency of PLL is 200 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 4.
- Note 6. The Sub-clock oscillator frequency is 32.768 kHz and the greatest value of the internal clock division setting is 1.
- Note 7. The LOCO frequency is 32.768 kHz and the greatest value of the internal clock division setting is 1.
- Note 8. The HOCO frequency is 20 MHz and the greatest value of the internal clock division setting is 1.
- Note 9. The PLL frequency is 200 MHz and the greatest value of the internal clock division setting is 4.
- Note 10. The MOCO frequency is 8 MHz and the greatest value of the internal clock division setting is 1.
- Note 11. In Subosc-speed mode, the sub-clock oscillator or LOCO continues oscillating in Software Standby mode.
- Note 12. When the SNZCR.RXDREQEN bit is set to 0, the following time is added as the power supply recovery time: 16 μs (typical), 48 μs (maximum).
- Note 13. The recovery time can be calculated with the equation of t<sub>SBYOSCWT</sub> + t<sub>SBYSEQ</sub>. And they can be determined with the following value and equation. For n, the greatest value is selected from among the internal clock division settings.

| Wakeup time        | TYP                         |                                                        | MAX                         |                                                        | Unit |
|--------------------|-----------------------------|--------------------------------------------------------|-----------------------------|--------------------------------------------------------|------|
|                    | t <sub>SBYOSCWT</sub>       | t <sub>SBYSEQ</sub>                                    | t <sub>SBYOSCWT</sub>       | t <sub>SBYSEQ</sub>                                    |      |
| t <sub>SBYMC</sub> | (MSTS[7:0]*32 + 3) / 0.262  | 35 + 18 / f <sub>ICLK</sub> + 4n / f <sub>MAIN</sub>   | (MSTS[7:0]*32 + 14) / 0.236 | 62 + 18 / f <sub>ICLK</sub> + 4n / f <sub>MAIN</sub>   | μs   |
| t <sub>SBYPC</sub> | (MSTS[7:0]*32 + 34) / 0.262 | 35 + 18 / f <sub>ICLK</sub> + 4n / f <sub>PLL</sub>    | (MSTS[7:0]*32 + 45) / 0.236 | 62 + 18 / f <sub>ICLK</sub> + 4n / f <sub>PLL</sub>    | μs   |
| t <sub>SBYEX</sub> | 10                          | 35 + 18 / f <sub>ICLK</sub> + 4n / f <sub>EXMAIN</sub> | 62                          | 62 + 18 / f <sub>ICLK</sub> + 4n / f <sub>EXMAIN</sub> | μs   |
| t <sub>SBYPE</sub> | 135                         | 35 + 18 / f <sub>ICLK</sub> + 4n / f <sub>PLL</sub>    | 192                         | 62 + 18 / f <sub>ICLK</sub> + 4n / f <sub>PLL</sub>    | μs   |
| t <sub>SBYSC</sub> | 0                           | 35 + 18 / f <sub>ICLK</sub> + 4n / f <sub>SUB</sub>    | 0                           | 62 + 18 / f <sub>ICLK</sub> + 4n / f <sub>SUB</sub>    | μs   |
| t <sub>SBYLO</sub> | 0                           | 35 + 18 / f <sub>ICLK</sub> + 4n / f <sub>LOCO</sub>   | 0                           | 62 + 18 / f <sub>ICLK</sub> + 4n / f <sub>LOCO</sub>   | μs   |
| t <sub>SBYHO</sub> | 20                          | 35 + 18 / f <sub>ICLK</sub> + 4n / f <sub>HOCO</sub>   | 67                          | 62 + 18 / f <sub>ICLK</sub> + 4n / f <sub>HOCO</sub>   | μs   |
| t <sub>SBYPH</sub> | 140                         | 35 + 18 / f <sub>ICLK</sub> + 4n / f <sub>PLL</sub>    | 202                         | 62 + 18 / f <sub>ICLK</sub> + 4n / f <sub>PLL</sub>    | μs   |
| t <sub>SBYMO</sub> | 0                           | 35 + 18 / f <sub>ICLK</sub> + 4n / f <sub>MOCO</sub>   | 0                           | 62 + 18 / f <sub>ICLK</sub> + 4n / f <sub>MOCO</sub>   | μs   |

### 43.3.5 NMI and IRQ Noise Filter

Table 43.21 NMI and IRQ noise filter

| Parameter       | Symbol     | Min                         | Typ | Max | Unit | Test conditions             |                                  |
|-----------------|------------|-----------------------------|-----|-----|------|-----------------------------|----------------------------------|
| NMI pulse width | $t_{NMIW}$ | 200                         | —   | —   | ns   | NMI digital filter disabled | $t_{Pcyc} \times 2 \leq 200$ ns  |
|                 |            | $t_{Pcyc} \times 2^{*1}$    | —   | —   |      |                             | $t_{Pcyc} \times 2 > 200$ ns     |
|                 |            | 200                         | —   | —   |      | NMI digital filter enabled  | $t_{NMICK} \times 3 \leq 200$ ns |
|                 |            | $t_{NMICK} \times 3.5^{*2}$ | —   | —   |      |                             | $t_{NMICK} \times 3 > 200$ ns    |
| IRQ pulse width | $t_{IRQW}$ | 200                         | —   | —   | ns   | IRQ digital filter disabled | $t_{Pcyc} \times 2 \leq 200$ ns  |
|                 |            | $t_{Pcyc} \times 2^{*1}$    | —   | —   |      |                             | $t_{Pcyc} \times 2 > 200$ ns     |
|                 |            | 200                         | —   | —   |      | IRQ digital filter enabled  | $t_{IRQCK} \times 3 \leq 200$ ns |
|                 |            | $t_{IRQCK} \times 3.5^{*3}$ | —   | —   |      |                             | $t_{IRQCK} \times 3 > 200$ ns    |

- Note: 200 ns minimum in Software Standby mode.
- Note: If the clock source is switched, add 4 clock cycles of the switched source.
- Note 1.  $t_{Pcyc}$  indicates the PCLKB cycle.
- Note 2.  $t_{NMICK}$  indicates the cycle of the NMI digital filter sampling clock.
- Note 3.  $t_{IRQCK}$  indicates the cycle of the IRQi digital filter sampling clock.

| GTIOCxY output skew (x = 1, 2, 4, 5, Y = A or B) | Middle drive buffer                        | —                      |                  | 6    |                                         |                                          |
|                                                  | High drive buffer                          | —                      |                  | 6    |                                         |                                          |
| AGT                                              | AGTIO, AGTEE input cycle                   | $t_{ACYC}^{*2}$        | 100              | —    | ns <a href="#">Figure 43.23</a>         |                                          |
|                                                  | AGTIO, AGTEE input high width, low width   | $t_{ACKWH}, t_{ACKWL}$ | 40               | —    |                                         |                                          |
|                                                  | AGTIO, AGTO, AGTOA, AGTOB output cycle     | $t_{ACYC2}$            | 62.5             | —    |                                         |                                          |
| ADC12                                            | ADC12 trigger input pulse width            | $t_{TRGW}$             | 1.5              | —    | $t_{Pcyc}$ <a href="#">Figure 43.24</a> |                                          |

- Note:  $t_{Pcyc}$ : PCLKB cycle,  $t_{PDcyc}$ : PCLKD cycle.
- Note 1. This skew applies when the same driver I/O is used. If the I/O of the middle and high drivers is mixed, operation is not guaranteed.
- Note 2. Constraints on input cycle:  
 When not switching the source clock:  $t_{Pcyc} \times 2 < t_{ACYC}$  should be satisfied.  
 When switching the source clock:  $t_{Pcyc} \times 6 < t_{ACYC}$  should be satisfied.

|                          | Data input setup time                                            | $t_{SDAS}$ | $t_{IICcyc} + 50$                                      | —                         | ns   |                 |
|                          | Data input hold time                                             | $t_{SDAH}$ | 0                                                      | —                         | ns   |                 |
| SCL, SDA capacitive load | $C_b^{*2}$                                                       | —          | 400                                                    | pF                        |      |                 |

Note:  $t_{IICcyc}$ : IIC internal reference clock (IIC $\phi$ ) cycle,  $t_{Pcyc}$ : PCLKB cycle.

Note: Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.

Note: Must use pins that have a letter appended to their name, for instance "\_A", "\_B", to indicate group membership. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Note 1. Only supported for SCL0\_A and SDA0\_A.

Note 2.  $C_b$  indicates the total capacity of the bus line.

**Table 43.30 IIC timing (2)**

Setting of the SCL0\_A, SDA0\_A pins is not required with the Port Drive Capability bit in the PmnPFS register.

|                                                                        | INL integral nonlinearity error                                |                                                 | —                         | ±1.0 | ±5.5 | LSB  | —                                                                            |

Note: These specification values apply when there is no access to the external memory during A/D conversion. If access occurs during A/D conversion, values might not fall within the indicated ranges.

The use of PORT0 as digital outputs is not allowed when the 12-Bit A/D converter is used.

The characteristics apply when AVCC0, AVSS0, VREFH0, VREFL0, and 12-bit A/D converter input voltage are stable.

Note 1. The conversion time includes the sampling and comparison times. The number of sampling states is indicated for the test conditions.

Note 2. Values in parentheses indicate the sampling time.

**Table 43.35 A/D internal reference voltage characteristics**

| Parameter                      | Min  | Typ  | Max  | Unit | Test conditions |
|--------------------------------|------|------|------|------|-----------------|
| A/D internal reference voltage | 1.13 | 1.18 | 1.23 | V    | —               |
| Sampling time                  | 4.15 | —    | —    | μs   | —               |

Figure 43.47 Illustration of ADC12 characteristic terms

### Absolute accuracy

Absolute accuracy is the difference between output code based on the theoretical A/D conversion characteristics, and the actual A/D conversion result. When measuring absolute accuracy, the voltage at the midpoint of the width of the analog input voltage (1-LSB width), which can meet the expectation of outputting an equal code based on the theoretical A/D conversion characteristics, is used as an analog input voltage. For example, if 12-bit resolution is used and the reference voltage  $V_{REFH0} = 3.072$  V, then the 1-LSB width becomes 0.75 mV, and 0 mV, 0.75 mV, and 1.5 mV are used as the analog input voltages. If the analog input voltage is 6 mV, an absolute accuracy of  $\pm 5$  LSB means that the actual A/D conversion result is in the range of 0x003 to 0x00D, though an output code of 0x008 can be expected from the theoretical A/D conversion characteristics.

### Integral nonlinearity error (INL)

Integral nonlinearity error is the maximum deviation between the ideal line when the measured offset and full-scale errors are zeroed, and the actual output code.

### Differential nonlinearity error (DNL)

Differential nonlinearity error is the difference between the 1-LSB width based on the ideal A/D conversion characteristics and the width of the actual output code.

### Offset error

Offset error is the difference between the transition point of the ideal first output code and the actual first output code.

**Full-scale error**

Full-scale error is the difference between the transition point of the ideal last output code and the actual last output code.

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.

Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.

Note 3. This result is obtained from reliability testing.

Note 4. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 10,000), erasing can be performed n times for each block. For example, when 128-byte programming is performed 64 times for different addresses in 8-KB blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. Overwriting is prohibited.

Note 5. Time for resumption includes time for reapplying the erasing pulse (up to one full pulse) that was cut off at the time of suspension.

Note 6. The reference value at VCC = 3.3V and room temperature.

- Note 1. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 125,000), erasing can be performed n times for each block. For example, when 4-byte programming is performed 16 times for different addresses in 64-byte blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. Overwriting is prohibited.
- Note 2. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.
- Note 3. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.
- Note 4. This result is obtained from reliability testing.
- Note 5. Time for resumption includes time for reapplying the erasing pulse (up to one full pulse) that was cut off at the time of suspension.
- Note 6. The reference value at VCC = 3.3 V and room temperature.

### 43.10.3 Option Setting Memory Characteristics

**Table 43.42 Option setting memory characteristics**

Conditions: Program: FCLK = 4 to 50 MHz  
Read: FCLK ≤ 50 MHz

| Parameter                                        | Symbol           | FCLK = 4 MHz |       |     | 20 MHz ≤ FCLK ≤ 50 MHz |       |     | Unit  | Test conditions |
|--------------------------------------------------|------------------|--------------|-------|-----|------------------------|-------|-----|-------|-----------------|
|                                                  |                  | Min          | Typ*4 | Max | Min                    | Typ*4 | Max |       |                 |
| Programming time<br>N <sub>OPC</sub> ≤ 100 times | t <sub>OP</sub>  | —            | 83    | 309 | —                      | 45    | 162 | ms    |                 |
| Programming time<br>N <sub>OPC</sub> > 100 times | t <sub>OP</sub>  | —            | 100   | 371 | —                      | 55    | 195 | ms    |                 |
| Reprogramming cycle                              | N <sub>OPC</sub> | 20000*1      | —     | —   | 20000*1                | —     | —   | Times |                 |
| Data hold time*2                                 | t <sub>DRP</sub> | 10*2*3       | —     | —   | 10*2*3                 | —     | —   | Years |                 |

- Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.
- Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.
- Note 3. This result is obtained from reliability testing.
- Note 4. The reference value at VCC = 3.3 V and room temperature.

### 43.11 Boundary Scan

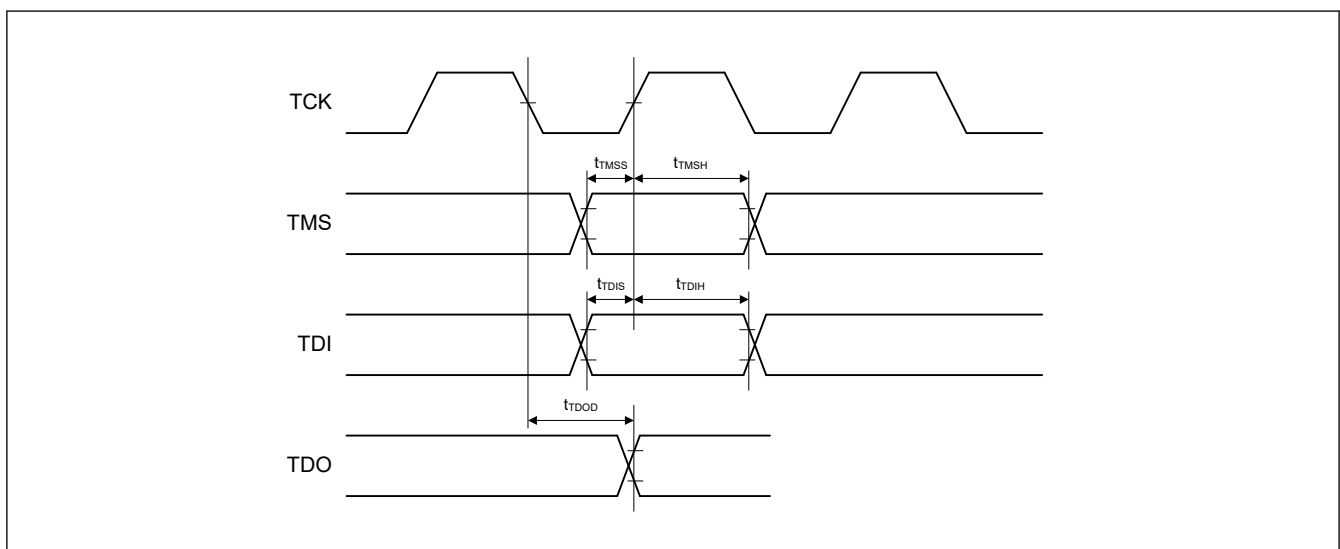

**Table 43.43** Boundary scan characteristics

| Parameter                            | Symbol       | Min         | Typ | Max | Unit | Test conditions |
|--------------------------------------|--------------|-------------|-----|-----|------|-----------------|
| TCK clock cycle time                 | $t_{TCKcyc}$ | 100         | —   | —   | ns   | Figure 43.56    |
| TCK clock high pulse width           | $t_{TCKH}$   | 45          | —   | —   | ns   |                 |
| TCK clock low pulse width            | $t_{TCKL}$   | 45          | —   | —   | ns   |                 |
| TCK clock rise time                  | $t_{TCKr}$   | —           | —   | 5   | ns   |                 |
| TCK clock fall time                  | $t_{TCKf}$   | —           | —   | 5   | ns   |                 |
| TMS setup time                       | $t_{TMSS}$   | 20          | —   | —   | ns   | Figure 43.57    |
| TMS hold time                        | $t_{TMSh}$   | 20          | —   | —   | ns   |                 |
| TDI setup time                       | $t_{TDis}$   | 20          | —   | —   | ns   |                 |
| TDI hold time                        | $t_{TDIH}$   | 20          | —   | —   | ns   |                 |
| TDO data delay                       | $t_{TDOD}$   | —           | —   | 40  | ns   |                 |
| Boundary scan circuit startup time*1 | $T_{BSSTUP}$ | $t_{RESWP}$ | —   | —   | —    | Figure 43.58    |

Note 1. Boundary scan does not function until the power-on reset becomes negative.

**Figure 43.56** Boundary scan TCK timing

**Figure 43.57** Boundary scan input/output timing

Figure 43.58 Boundary scan circuit startup timing

### 43.12 Joint Test Action Group (JTAG)

Table 43.44 JTAG

| Parameter                  | Symbol       | Min | Typ | Max | Unit | Test conditions |
|----------------------------|--------------|-----|-----|-----|------|-----------------|
| TCK clock cycle time       | $t_{TCKcyc}$ | 40  | —   | —   | ns   | Figure 43.59    |
| TCK clock high pulse width | $t_{TCKH}$   | 15  | —   | —   | ns   |                 |
| TCK clock low pulse width  | $t_{TCKL}$   | 15  | —   | —   | ns   |                 |
| TCK clock rise time        | $t_{TCKr}$   | —   | —   | 5   | ns   |                 |
| TCK clock fall time        | $t_{TCKf}$   | —   | —   | 5   | ns   |                 |
| TMS setup time             | $t_{TMSS}$   | 8   | —   | —   | ns   | Figure 43.60    |

| Others   | —                                        | Hi-Z    | Keep-O                                                  | Keep                       | Hi-Z                                                                  | Keep                     |

Note: H: High-level

L: Low-level

Hi-Z: High-impedance

Keep-O: Output pins retain their previous values. Input pins go to high-impedance.

Keep: Pin states are retained during periods in Software Standby mode.

Note 1. Retains the I/O port state until the DPSBYCR.IOKEEP bit is cleared to 0.

Note 2. Input is enabled if the pin is specified as the Software Standby canceling source while it is used as an external interrupt pin.

Note 3. Input is enabled if the pin is specified as the Deep Software Standby canceling source.

Note 4. Input is enabled while the pin is used as an input pin.

## Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings is displayed in “Packages” on the Renesas Electronics Corporation website.

Figure A2.1 LQFP 64-pin

|                     |              |               |

## Appendix 3. I/O Registers

This appendix describes I/O register address and access cycles by function.

### 3.1 Peripheral Base Addresses

This section provides the base addresses for peripherals described in this manual. [Table A3.1](#) shows the name, description, and the base address of each peripheral.

**Table A3.1 Peripheral base address (1 of 2)**

| Name   | Description                                  | Base address |
|--------|----------------------------------------------|--------------|
| RMPU   | Renesas Memory Protection Unit               | 0x4000_0000  |
| TZF    | TrustZone Filter                             | 0x4000_0E00  |
| SRAM   | SRAM Control                                 | 0x4000_2000  |
| BUS    | BUS Control                                  | 0x4000_3000  |
| DMAC0  | Direct memory access controller 0            | 0x4000_5000  |
| DMAC1  | Direct memory access controller 1            | 0x4000_5040  |
| DMAC2  | Direct memory access controller 2            | 0x4000_5080  |
| DMAC3  | Direct memory access controller 3            | 0x4000_50C0  |
| DMAC4  | Direct memory access controller 4            | 0x4000_5100  |
| DMAC5  | Direct memory access controller 5            | 0x4000_5140  |

Note: Name = Peripheral name  
Description = Peripheral functionality  
Base address = Lowest reserved address or address used by the peripheral

## 3.2 Access Cycles

This section provides access cycle information for the I/O registers described in this manual.

- Registers are grouped by associated module.
- The number of access cycles indicates the number of cycles based on the specified reference clock.
- In the internal I/O area, reserved addresses that are not allocated to registers must not be accessed, otherwise operations cannot be guaranteed.
- The number of I/O access cycles depends on bus cycles of the internal peripheral bus, divided clock synchronization cycles, and wait cycles of each module. Divided clock synchronization cycles differ depending on the frequency ratio between ICLK and PCLK.
- When the frequency of ICLK is equal to that of PCLK, the number of divided clock synchronization cycles is always constant.
- When the frequency of ICLK is greater than that of PCLK, at least 1 PCLK cycle is added to the number of divided clock synchronization cycles.
- The number of write access cycles indicates the number of cycles obtained by non-bufferable write access.

Note: This applies to the number of cycles when access from the CPU does not conflict with the instruction fetching to the external memory or bus access from other bus masters such as DTC or DMAC.

Table A3.2 Access cycles (1 of 3)

| Peripherals                                | Address     |             | Number of access cycles |                 |                           |                      | Cycle Unit | Related function                                                                                                                                                                   |
|--------------------------------------------|-------------|-------------|-------------------------|-----------------|---------------------------|----------------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| QSPI        | 0x6400_0804 | 0x6400_0807 | 4                       | 3        | 1 to 4                    | 1 to 3   | PCLKA      | Quad-SPI         |

**Table A3.2 Access cycles (3 of 3)**

| Peripherals | Address     |             | Number of access cycles |       |                           |        | Cycle Unit | Related function                                |
|-------------|-------------|-------------|-------------------------|-------|---------------------------|--------|------------|-------------------------------------------------|
|             |             |             | ICLK = FCLK             |       | ICLK > FCLK* <sup>1</sup> |        |            |                                                 |
|             | From        | To          | Read                    | Write | Read                      | Write  |            |                                                 |
| FLAD, FACL  | 0x407F_C000 | 0x407F_EFFF | 3                       | 3     | 2 to 3                    | 2 to 3 | FCLK       | Data Flash, Flash Application Command Interface |

- Note 1. If the number of PCLK or FCLK cycles is non-integer (for example 1.5), the minimum value is without the decimal point, and the maximum value is rounded up to the decimal point. For example, 1.5 to 2.5 is 1 to 3.
- Note 2. When accessing a 16-bit register (FTDRHL, FRDRHL, FCR, FDR, LSR, and CDR), access is 2 cycles more than the value shown in [Table A3.2](#). When accessing an 8-bit register (including FTDRH, FTDRL, FRDRH, and FRDRL), the access cycles are as shown in [Table A3.2](#).
- Note 3. When accessing the 32-bit register (SPDR), access is 2 cycles more than the value in [Table A3.2](#). When accessing an 8-bit or 16-bit register (SPDR\_HA), the access cycles are as shown in [Table A3.2](#).
- Note 4. The access cycles depend on the QSPI bus cycles.

## Revision History

### Revision 1.00 — September 15, 2021

First edition, issued

### Revision 1.10 — February 4, 2022

#### 1. Overview:

- Added the introduction to 1.1 Function Outline.
- Removed the sentence on brushless DC motors from GPT functional description in Table 1.7 Timers.
- Fixed the note in Table 1.11 Security.
- Added Table 1.12 I/O ports to 1.1 Function Outline.
- Fixed the note 1 in Figure 1.1 Block diagram.
- Fixed the row of QSPI in Table 1.14 Function Comparison.
- Added the row of I/O ports to Table 1.14 Function Comparison.
- Fixed the note 2 in Table 1.14 Function Comparison.

#### 10. Low Power Modes:

- Fixed Low Power Asynchronous General Purpose Timer in Table 10.2 Operating conditions of each low power mode.

#### 18. Event Link Controller:

- Added the row of ELSR9 in Table 18.2 Association between the ELSRn registers and peripheral functions.

#### 19. I/O Ports:

- Fixed Table 19.5 Register settings for input/output pin function (PORT0).
- Fixed Table 19.7 Register settings for input/output pin function (PORT2).

#### 20. Port Output Enable for GPT:

- Removed the phrases on the 3-phase PWM output for BLDC motor control pins in 20.3 Output-Disable Control Operation.

#### 21. General PWM Timer:

- Removed the sentence on brushless DC motors in 21.1 Overview.
- Removed the phrases on brushless DC motors and input UVW in Table 21.1 GPT specifications.
- Removed the row of brushless DC motor control function in Table 21.2 GPT functions.
- Changed GPT0 to GPT1 in Figure 21.1 GPT block diagram.
- Changed GPT0 to GPTn, and GPT1 to GPTn+1 in 21.2.27 GTSECR.

#### 34. Secure Cryptographic Engine:

- Added the sentence in 34.1 Overview.
- Removed the note in Table 34.1 SCE9 specifications.

### Revision 1.20 — October 31, 2024

#### 14. Buses:

- Added the note in 14.3.3 BUSSCNT<slave>

#### 34. Secure Cryptographic Engine (SCE9):

- Updated 39.1 Overview.

### Revision 1.30 — June 6, 2025

#### 1. Overview:

- Updated Figure 1.2 Part numbering scheme.

#### 2. CPU:

- Updated Table 2.7 Peripheral address map.

#### 4. Address Space:

- Updated Figure 4.1 Memory map.

#### 8. Clock Generation Circuit:

- Updated 8.2.23 LOCOUTCR : LOCO User Trimming Control Register.
- Updated 8.2.24 MOCOUTCR : MOCO User Trimming Control Register.

#### 11. Battery Backup Function:

- Updated 11.4 Usage Notes.

#### 14. Buses:

- Updated 14.3.3 BUSSCNT<slave> : Slave Bus Control Register (<slave> = FHBIU, FLBIU, S0BIU, EQBIU).

#### 21. General PWM Timer:

- Updated 21.2.12 GTCR : General PWM Timer Control Register.
- Updated 21.3.4 Automatic Dead Time Setting Function.

**Revision 1.30 — June 6, 2025****22. Low Power Asynchronous General Purpose Timer:**

- Updated 22.1 Overview.
- Updated 22.2.5 AGTMR1 : AGT Mode Register 1.
- Updated 22.3.10 Standby Mode.
- Updated 22.4.8 When Selecting AGTn (n = 0, 2) Underflow as the Count Source.

**24. Watchdog Timer:**

- Updated 24.3.3 Refresh Operation.

**25. Independent Watchdog Timer:**

- Updated 25.3.2 Refresh Operation.

**26. USB 2.0 Full-Speed Module:**

- Updated 26.2.30 DCPCTR : DCP Control Register.
- Updated 26.2.34 PIPEPERI : Pipe Cycle Control Register.

**28. I2C Bus Interface:**

- Updated 28.8 Wakeup Function.
- Updated Table 28.10 Interrupt sources.

**30. Serial Peripheral Interface:**

- Updated Figure 30.49 Transmission flow in master mode.

**35. 12-Bit A/D Converter:**

- Updated 35.3.6 Analog Input Sampling and Scan Conversion Time.
- Updated 35.6.12 Port Settings When Using the ADC12 Input.

**42. Security Features:**

- Updated Table 42.8 The lifecycle definition and the capability can be used in each lifecycle.
- Updated 42.3.1 Changing the Lifecycle State.
- Updated 42.5.6 CFSAMONA : Code Flash Security Attribution Monitor Register A.
- Updated 42.5.7 CFSAMONB : Code Flash Security Attribution Monitor Register B.
- Updated 42.5.8 DFSAMON : Data Flash Security Attribution Monitor Register.
- Updated 42.5.9 SSAMONA : SRAM Security Attribution Monitor Register A.
- Updated 42.5.10 SSAMONB : SRAM Security Attribution Monitor Register B.
