Figure 22.64 Example of Compare Match Generation Sequence Operation in Complementary PWM Mode (Complementary PWM mode 3 single buffer operation, GTIOCnA pin = Low / GTIOCnB pin = High at GTCCRA register compare match during up-counting, GTIOCnA pin = High / GTIOCnB pin = Low at GTCCRA register compare match during down-counting, the dead time value is 0x0000 2000, compare match generation order: a' → (b', c) → d) (n = 4, 7)

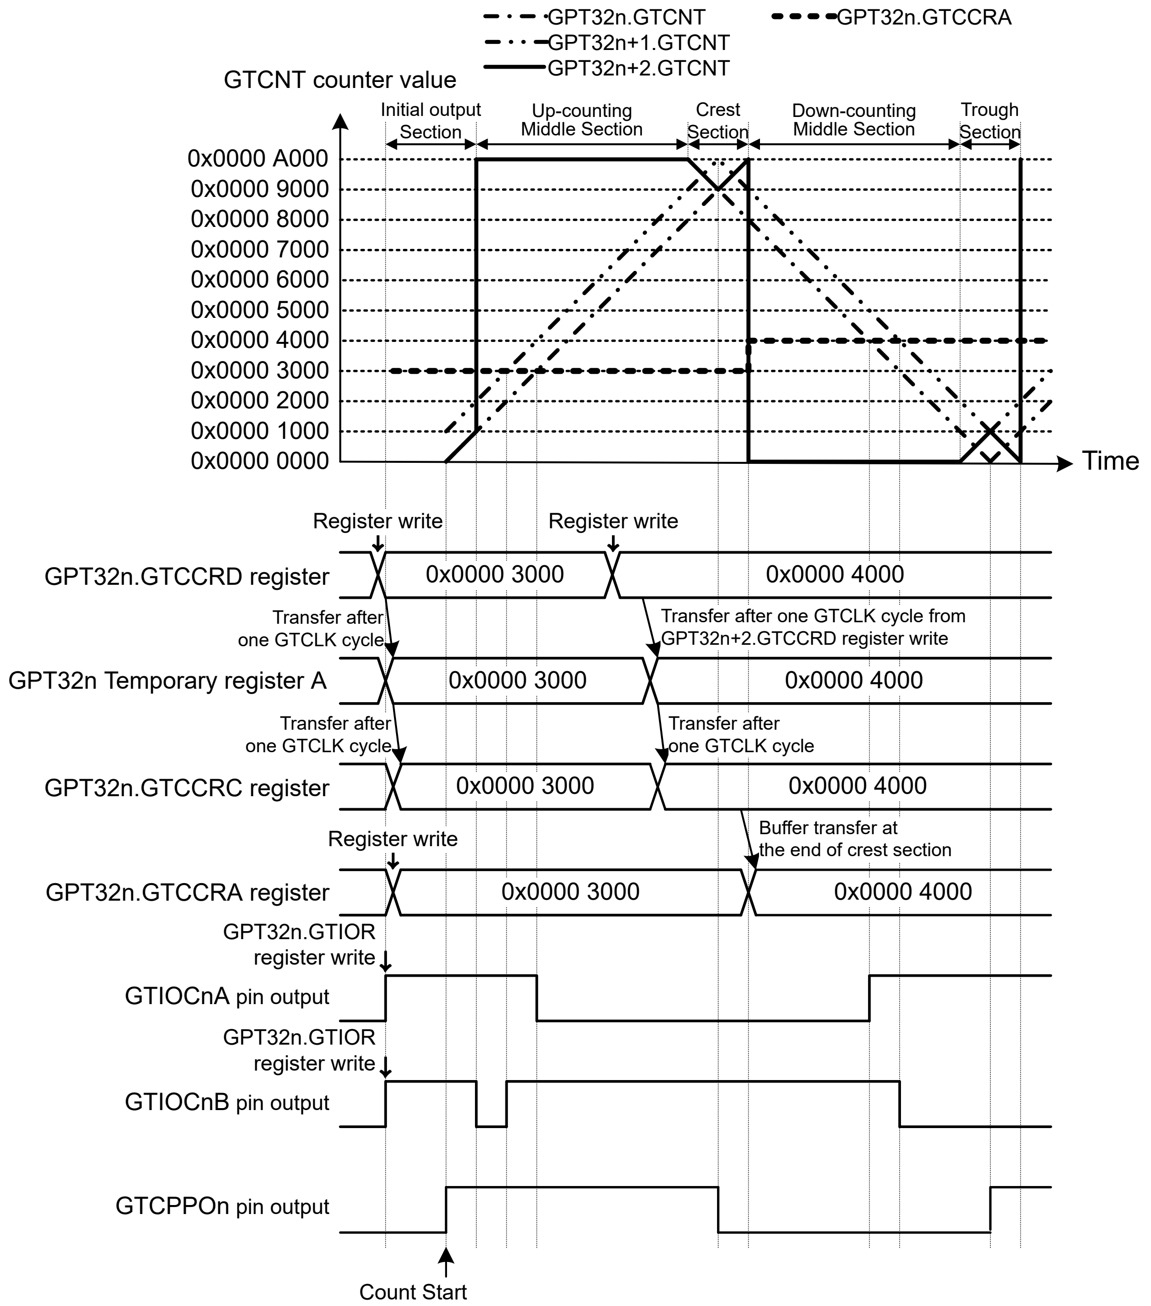

Figure 22.65 **Example of Complementary PWM Mode Initial Output Operation (Complementary PWM mode 1 operation, GTIOCnA pin = Low / GTIOCnB pin = High at GTCCRA register compare match during up-counting, GTIOCnA pin = High / GTIOCnB pin = Low at GTCCRA register compare match during down-counting, the dead time value is 0x0000 1000, in the case that the initial GTCCRA register value is larger than the dead time value) (n = 4, 7)**

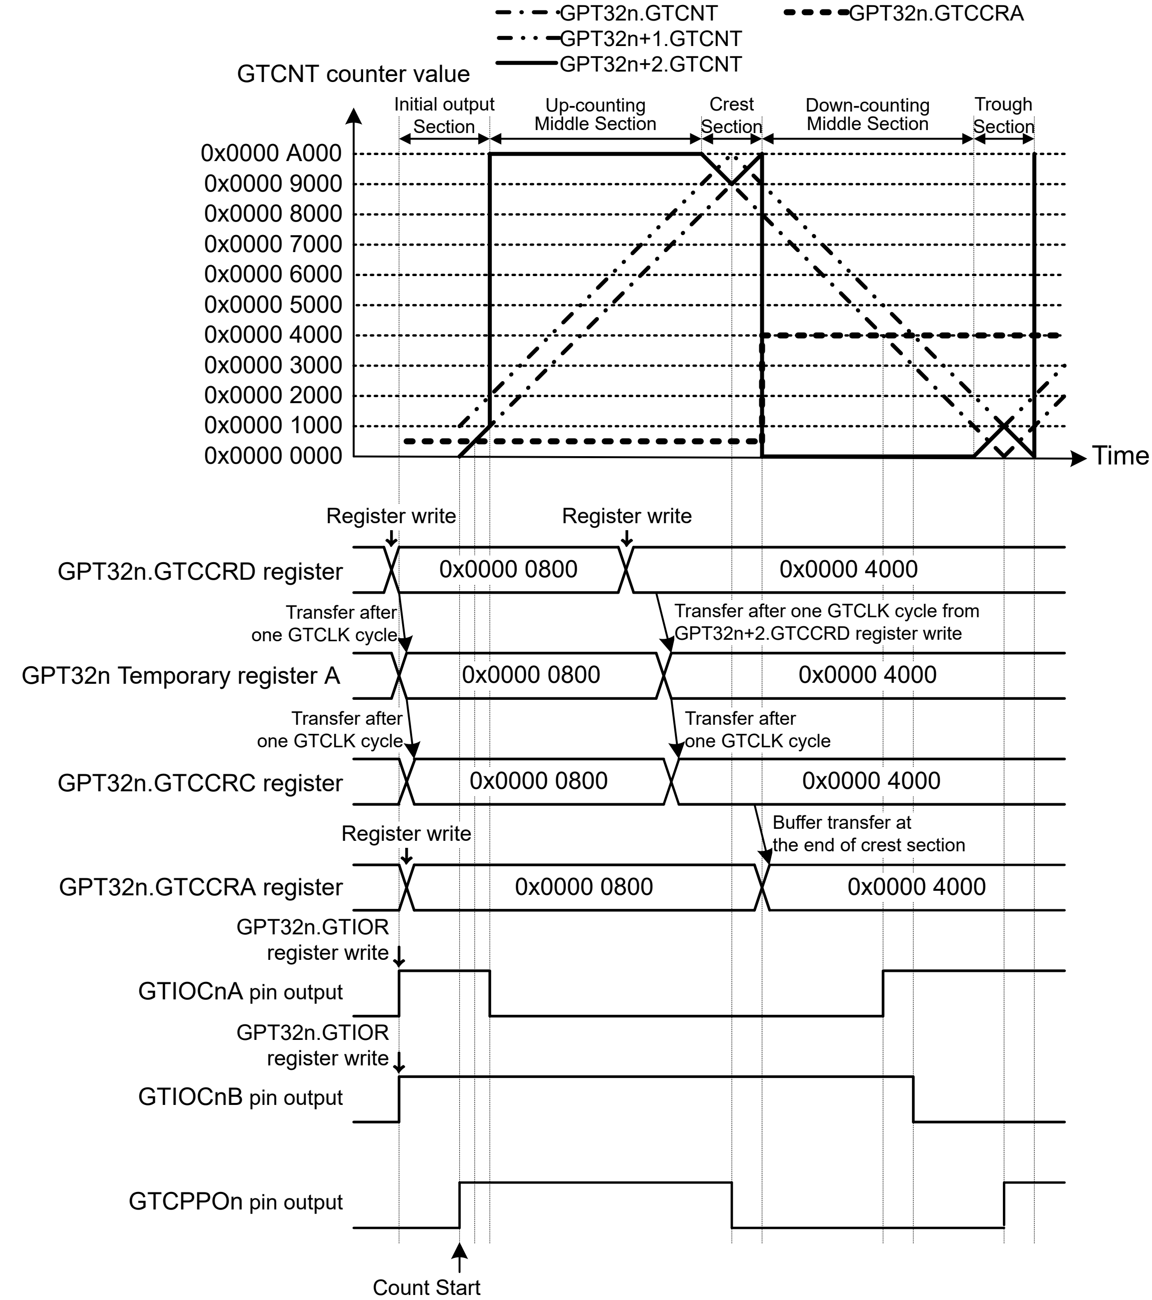

Figure 22.66 Example of Complementary PWM Mode Initial Output Operation (Complementary PWM mode 1 operation, GTIOCnA pin = Low / GTIOCnB pin = High at GTCCRA register compare match during up-counting, GTIOCnA pin = High / GTIOCnB pin = Low at GTCCRA register compare match during down-counting, the dead time value is 0x0000 1000, in the case that the initial GTCCRA register value is equal to or less than the dead time value) (n = 4, 7)

Table 22.35 Example for Setting Complementary PWM Mode 1, 2, 3 (1 of 2)

No.	Step Name	Description
1	Set operating mode	Set the operating mode with GTCR.MD[3:0] bits of GTP32n channel.
2	Select count clock	Select the count clock with GTCR.TPCS[3:0] bits of GPT32n channel.
3	Set cycle	Set the cycle in the GPTWn.GTPR, GPTWn.GTPBR and GPTWn.GTPDBR register.

Table 22.35 Example for Setting Complementary PWM Mode 1, 2, 3 (2 of 2)

No.	Step Name	Description
4	Set GTIOCnm /GTIOCn+1m / GTIOCn+2m pin function	Set the function of the GTIOCnm, GTIOCn+1m, and GTIOCn+2m pins with GTIOA[4:0] and GTIOB[4:0] bits in the GTIOR register of the GPT32n, GPT32n+1, and GPT32n+2 channels.
5	Enable GTCPPOn pin output	Set to enable or disable PWM synchronous output from the GTCPPOn pin with the PSYE bit in the GTIOR register of the GPT32n channel.
6	Enable GTIOCnm / GTIOCn+1m /GTIOCn+2m pin output	Set to enable the output from the GTIOCnm, GTIOCn+1m, and GTIOCn+2m pins with the OAE and OBE bits in the GTIOR register of the GPT32n, GPT32n+1, and GPT32n+2 channels.
7	Set buffer operation	In complementary PWM mode 3, set buffer operation with the GTBER2.CP3DB bit of the GPT32n, GPT32n+1, and GPT32n+2 channels.
8	Set compare match value	Set the output pin changing point during up-counting after count start in the GTCCRA register of the GPT32n, GPT32n+1, and GPT32n+2 channels.
9	Set buffer value	For single buffer operation, set data (to be transferred for the first buffer transfer to the GTCCRA register after count start) in the GTCCRD register. For buffer operation in complementary PWM mode 2, set the same value as the GTCCRA register in the GTCCRD register because the first buffer transfer does not take place. For double buffer operation in complementary PWM mode 3, set data to be transferred at the first end of crest in the GTCCRD register and set data to be transferred at the first end of trough in the GTCCRF register.
10	Set dead time value	Set the dead time value in GTDVU of GTP32n channel.
11	Start count operation	Set GTCR.CST of GPT32n channel to 1 to start count operation.
12	Set buffer value for each cycle	For single buffer operation, set data (to be transferred for the next buffer transfer to the GTCCRA register) in the GTCCRD register. For double buffer operation in complementary PWM mode 3, set data to be transferred for the next buffer transfer in the GTCCRF register. Make settings for the GPT32n+2.GTCCRD register finally. (Data is transferred to the temporary register.)

Note: n = 4, 7
m = A, B

22.3.3.8 Complementary PWM mode 4

In complementary PWM mode 4, the value written to the GTCCRD and GTCCRF registers is immediately applied to compare match operation by transferring data also to the GTCCRA register during buffer transfer to a temporary register before crest or trough transfer timing.

Figure 22.67 shows the block diagram in complementary PWM mode 4.

In the configuration of complementary PWM mode 4, a buffer transfer path from the GTCCRD register to the GTCCRC and GTCCRA registers and a buffer transfer path from the GTCCRF register to the GTCCRE and GTCCRA registers are added to other complementary PWM modes shown in Table 22.35.

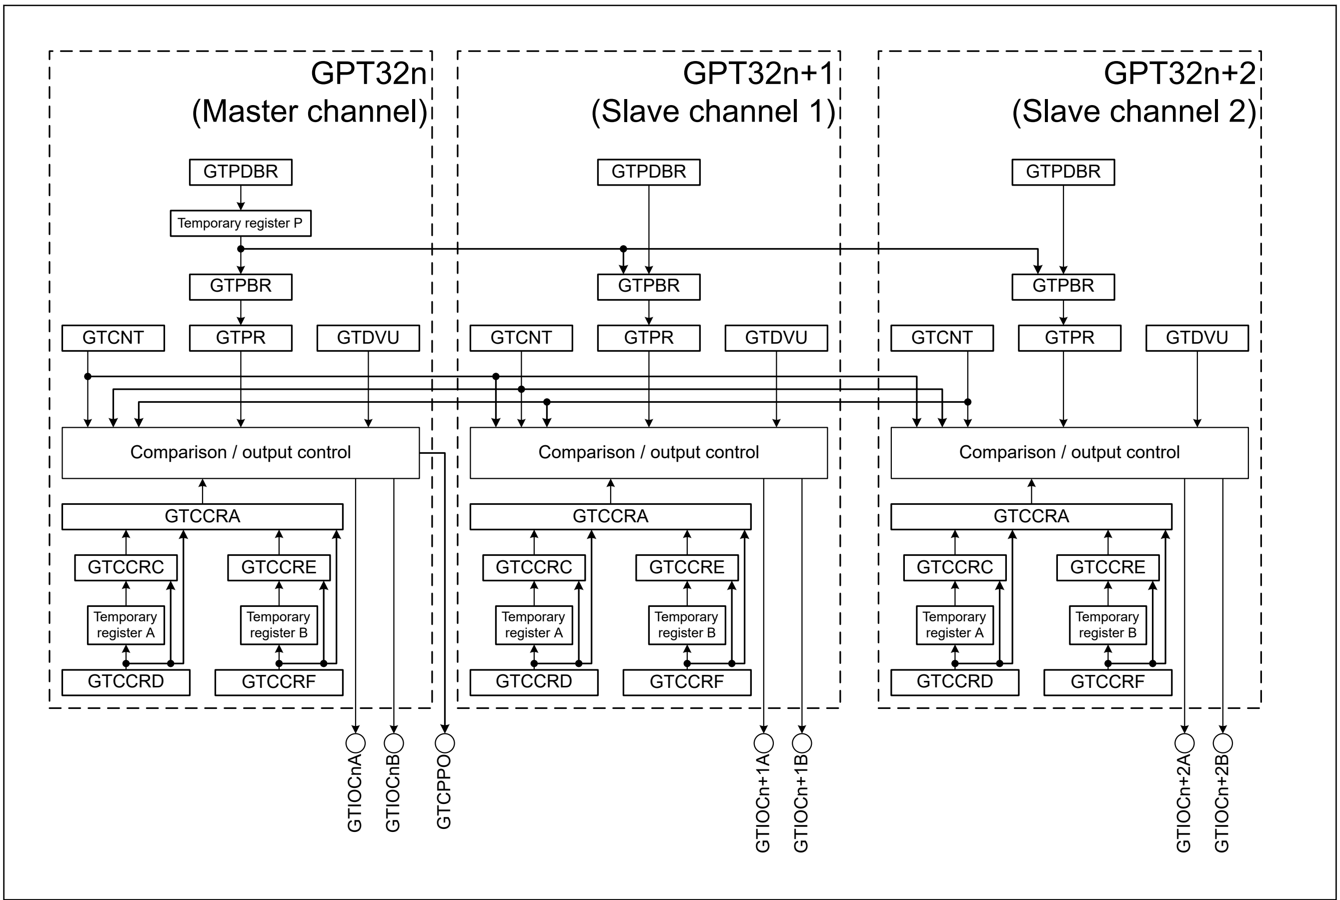

Figure 22.67 Block Diagram in Complementary PWM Mode 4 (n = 4, 7)

Count operation is performed in the same way as complementary PWM modes 1 to 3. See Table 22.30 and Table 22.31.

With respect to buffer operation and PWM waveform changes in complementary PWM mode 4, buffer transfer (shown in Figure 22.67) from the GTCCRD and GTCCRF registers is added based on the complementary PWM mode 3 operation. Buffer transfer and PWM waveform are controlled according to operation section, state of comparison with the GTCCRA register, and write value.

The double buffer function by writing to the GTCCRF register can be enabled or disabled with the GTBER2.CP3DB bit. In double buffer operation, the value written to the GTCCRD register is used as a compare match value for positive-phase OFF (negative-phase ON) during down-counting, and the value written to the GTCCRF register is used as a compare match value for negative-phase OFF (positive-phase ON) during up-counting. Transfer register, transfer value, and PWM output changes are controlled by operation section (where the value is written), state of comparison with the GTCCRA register, and write value.

Double buffer operation is guaranteed only in the up-counting middle section and down-counting middle section. Setting a value not larger than the dead time value and not less than the count cycle is prohibited.

In single buffer operation, a compare match value is written only to the GTCCRD register, and transfer register, transfer value, and PWM output changes are controlled by operation section (where the value is written), state of comparison with the GTCCRA register, and write value.

Transfer from the GTCCRD register to the temporary register A and transfer from the GTCCRF register to the temporary register B are performed in the same way as other complementary PWM modes. Transfers are concurrently performed in three channels by writing a value to the GPT32n+2.GTCCRD register. Transfer from the GTCCRD register to the GTCCRC register, GTCCRA register, temporary register B, and GTCCRE register and transfer from the GTCCRF register to the GTCCRE register and the GTCCRA register are performed at the same time as the above-mentioned transfer to the temporary register.

Table 22.36 and Table 22.37 show immediate buffer transfer (for transfer to the temporary register by writing a value to the GPT32n+2.GTCCRD register) to the GTCCRC and GTCCRA registers by writing a value to the GTCCRD register during single buffer operation in complementary PWM mode 4 for each compare match state in each operation section. Transfers (from the GTCCRD register to the temporary register A, from the temporary register A to the GTCCRC register, and from the GTCCRC register to the GTCCRA register) other than those shown in Table 22.36 and Table 22.37 are the same as single buffer transfer in complementary PWM mode 3 shown in Table 22.32.

Table 22.38 and Table 22.39 show immediate buffer transfer (for transfer to the temporary register by writing a value to the GPT32n+2.GTCCRD register) to each register by writing a value to the GTCCRD and GTCCRF registers during double buffer operation in complementary PWM mode 4 for each compare match state in each operation section. Transfers (from the GTCCRD register to the temporary register A, from the GTCCRF register to the temporary register B, from the temporary register A to the GTCCRC register, from the temporary register B to the GTCCRE register, and from the GTCCRC and GTCCRE registers to the GTCCRA register) other than those shown in Table 22.38 and Table 22.39 are the same as double buffer transfer in complementary PWM mode 3 shown in Table 22.33.

Table 22.40 Example for Setting Complementary PWM Mode 4 (1 of 2)

No.	Step Name	Description
1	Set operating mode	Set the operating mode (1111b) with GTCR.MD[3:0] of GTP32n channel.
2	Select count clock	Select the count clock with GTCR.TPCS[3:0] bits of GPT32n channel.
3	Set cycle	Set the cycle in the GPTWn.GTPR, GPTWn.GTPBR and GPTWn.GTPDBR register.
4	Set GTIOCnm /GTIOCn+1m / GTIOCn+2m pin function	Set the function of the GTIOCnm, GTIOCn+1m, and GTIOCn+2m pins with GTIOA[4:0] and GTIOB[4:0] bits in the GTIOR register of the GPT32n, GPT32n+1, and GPT32n+2 channels.
5	Enable GTCPPOn pin output	Set to enable or disable PWM synchronous output from the GTCPPOn pin with the PSYE bit in the GTIOR register of the GPTWn channel.
6	Enable GTIOCnm / GTIOCn+1m /GTIOCn+2m pin output	Set to enable the output from the GTIOCnm, GTIOCn+1m, and GTIOCn+2m pins with the OAE and OBE bits in the GTIOR register of the GPT32n, GPT32n+1, and GPT32n+2 channels.
7	Set buffer operation	Set buffer operation with the GTBER2.CP3DB bit of the GPT32n, GPT32n+1, and GPT32n+2 channels.

Table 22.40 Example for Setting Complementary PWM Mode 4 (2 of 2)

No.	Step Name	Description
8	Set compare match value	Set the output pin changing point during up-counting after count start in the GTCCRA register of the GPT32n, GPT32n+1, and GPT32n+2 channels.
9	Set buffer value	For single buffer operation, set data (to be transferred for the first buffer transfer to the GTCCRA register after count start) in the GTCCRD register. For double buffer operation, set data to be transferred at the first end of crest in the GTCCRD register and set data to be transferred at the first end of trough in the GTCCRF register.
10	Set dead time value	Set the dead time value in GTDVU of GTP32n channel.
11	Start count operation	Set GTCR.CST of GPT32n channel to 1 to start count operation.
12	Set compare match value to be transferred immediately	For single buffer operation, set data (to be transferred immediately to the GTCCRA register) in the GTCCRD register. For double buffer operation, set the compare match value for down-counting to be transferred immediately in the GTCCRD register and the compare match value for up-counting in the GTCCRF register. Make settings for the GPT32n+2.GTCCRD register finally. (Data is transferred to the temporary register.)

Note: n = 4, 7
m = A, B

22.3.4 Automatic Dead Time Setting Function

By setting GTDTCR, a compare match value for a negative waveform with dead time obtained by a compare match value for a positive waveform (GTCCRA value) and specified dead time value (GTDVU and GTDVD value) can automatically be set to GTCCRB.

The automatic dead time setting function can be used in saw-wave one-shot pulse mode and all the triangle PWM modes.

Dead time can be separately set for the first half and second half of a waveform. Dead time for the changing point in the first half of a negative waveform is set in the GTDVU register and that in the second half is set in GTDVD register. The same dead time can also be set for the first and second halves by setting the GTDTCR.TDFER bit to 1.

The GTDBU register can be used as a buffer register of the GTDVU register, and the GTDBD register can be used as a buffer register of the GTDVD registers. Buffer transfer is performed at the end of the cycle (in saw-wave mode: either of an overflow of the GTCNT counter (up-counting), an underflow (down-counting), or the GTCNT counter clearing; in triangle-wave mode: a trough).

The change point of the negative-phase waveform, which is automatically calculated, is obtained by reading the GTCCRB register. Writing to GTCCRB is prohibited when the automatic dead time setting function is used.

Do not set the dead time that makes the change point of the waveform exceeding the count period. When any dead-time setting which would generate a dead-time error is made, adjust the change points of the positive- and negative-phase waveforms to generate waveforms with secured dead-time as shown in Table 22.41. The adjusted change point of the negative-phase waveform is automatically set in the GTCCRB register. An internal signal is used to judge the change point of the positive-phase waveform, thus the value of the GTCCRA register is not updated by the adjusted value.

In saw-wave one-shot pulse mode, if the order of the change point becomes inconsistent by adjustment of the waveform change point due to occurrence of dead time errors, or if the change point exceeds the count period even after the adjustment, the complementary relation between the positive- and negative-phases cannot be guaranteed.

In triangle-wave PWM mode, if dead time exceeds the count period by setting 0x00000000 or a value greater than or equal to the setting value of the GTPR register is set in the GTCCRA register, output change is controlled by the output protection function (see section 22.8.4. Output Protection Function for GTIOCnm Pin Output (n = 0 to 13; m = A, B)). When the GTCCRA register is greater than or equal to [GTPR register + GTDVm (m = U, D) register], [GTPR register - 1] is set in the GTCCRB register as the upper limit.

Automatic setting for a dead time value to the GTCCRB register is performed at the next count clock after the register value for calculating the automatic setting value is updated. In triangle-wave mode, it also can be done at the next count clock from the current crest.

Table 22.41 Adjustment of the Waveform Change Point When a Dead-Time Error Occurs

PWM Output Operating Mode	Count Direction	Period	Condition for Dead Time Error	Change Point of the Positive-Phase Waveform after Adjustment	Change Point of the Negative-Phase Waveform after Adjustment
Saw-wave one-shot pulse mode	Up-counting	First half	GTCCRA - GTDVU < 0	GTDVU	0
		Second half	GTCCRA + GTDVD > GTPR (GTCCRA + GTDVU > GTPR)*1	GTPR - GTDVD (GTPR - GTDVU)*1	GTPR
	Down-counting	First half	GTCCRA + GTDVU > GTPR	GTPR - GTDVU	GTPR
		Second half	GTCCRA - GTDVD < 0 (GTCCRA - GTDVU < 0)*1	GTDVD (GTDVU)*1	0
Triangle-wave PWM mode 1/2/3	Up-counting	(First half)	GTCCRA - GTDVU ≤ 0	GTDVU + 1	1
	Down-counting	(Second half)	GTCCRA - GTDVD < 0 (GTCCRA - GTDVU < 0)*1	GTDVD (GTDVU)*1	0

Note 1. In the case of GTDTCR.TDFER = 1.

Figure 22.77 to Figure 22.80 show examples of automatic dead time setting function operation. Table 22.42 and Table 22.43 show the setting examples.

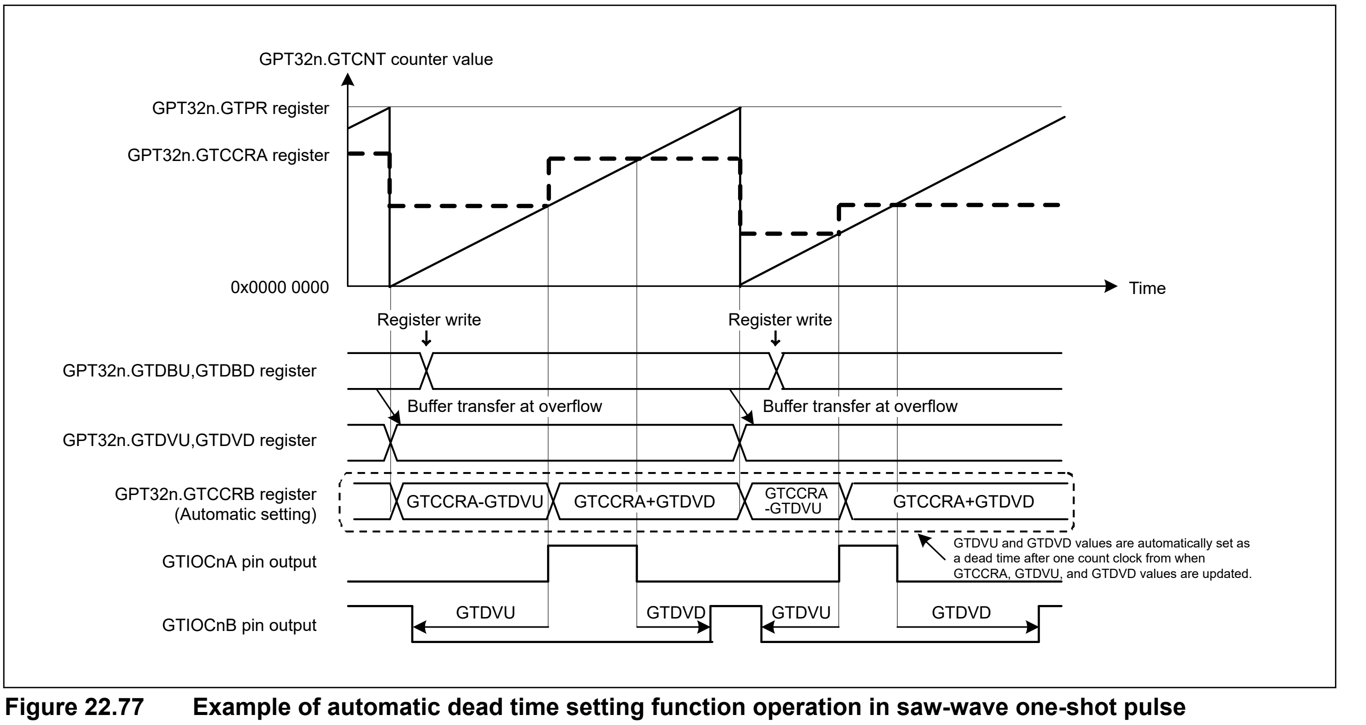

Figure 22.77 Example of automatic dead time setting function operation in saw-wave one-shot pulse mode, up-counting, GTDVU and GTDVD set to buffer operation, and active-high

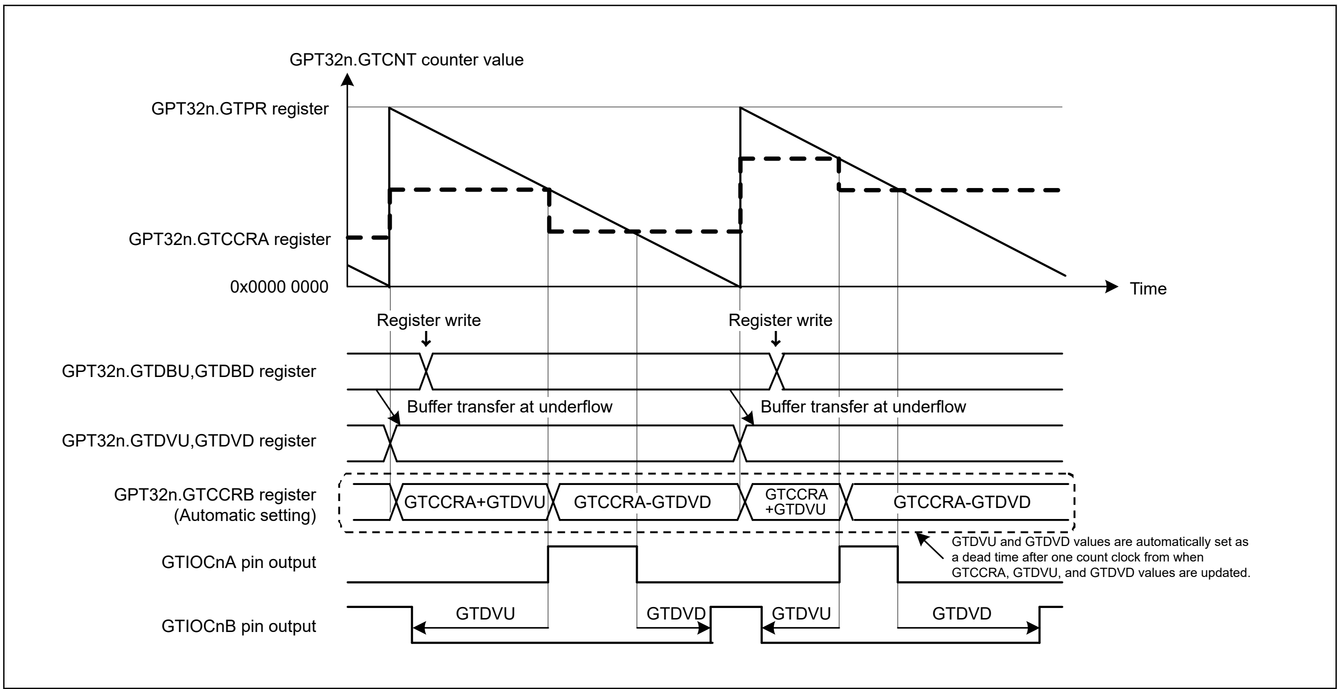

Figure 22.78 Example of automatic dead time setting function operation in saw-wave one-shot pulse mode, down-counting, GTDVU and GTDVD set to buffer operation, and active-high

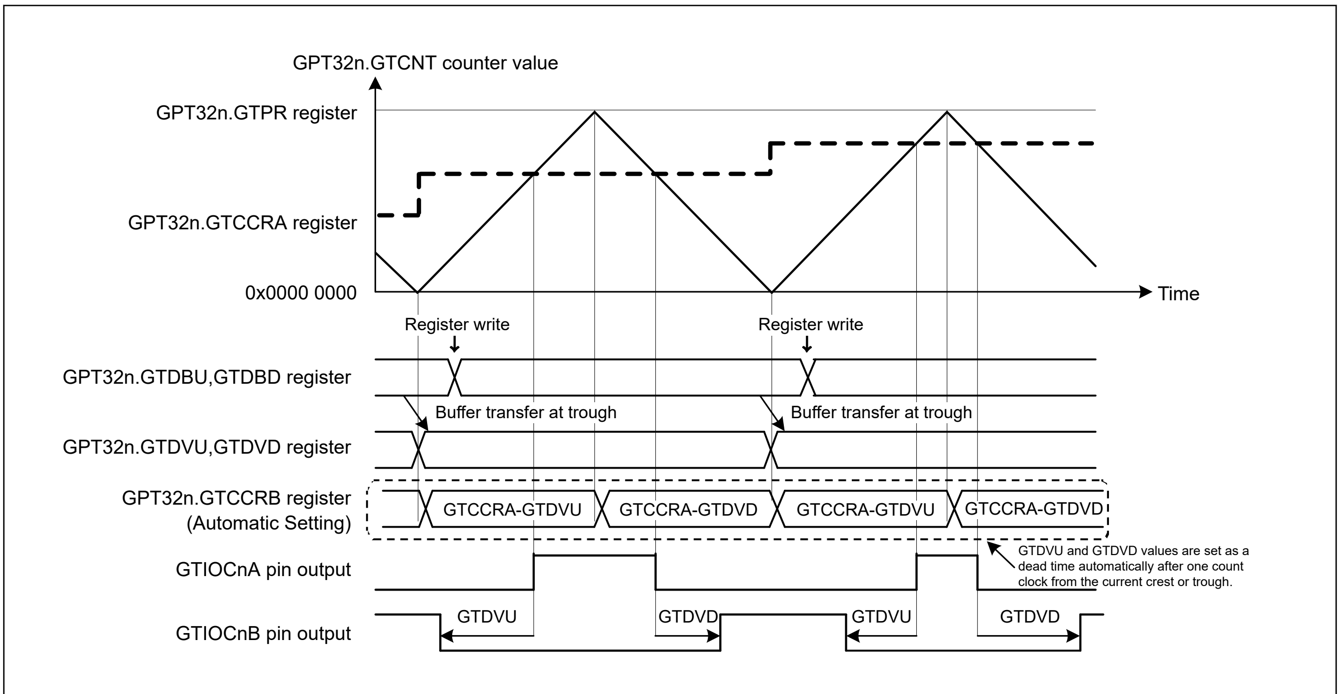

Figure 22.79 Example of automatic compare-match value setting function with dead time in triangle-wave PWM mode 1, GTDVU and GTDVD set to buffer operation, and active-high

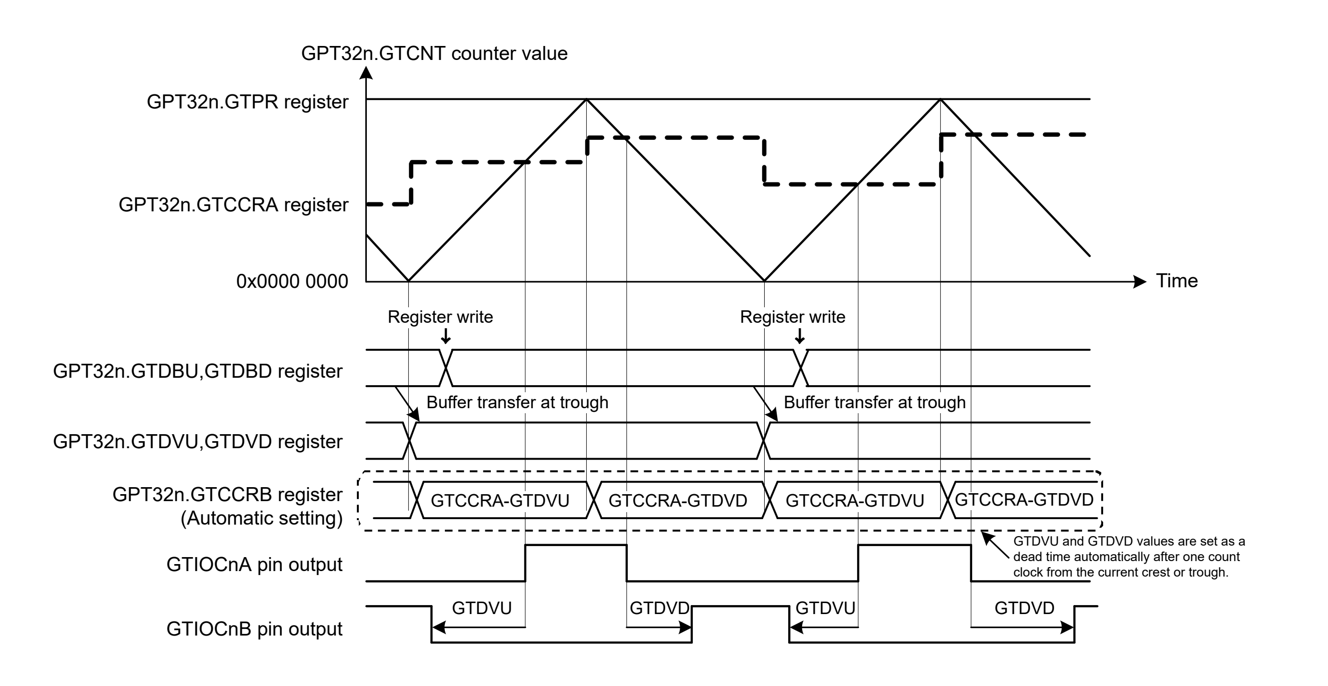

Figure 22.80 Example of automatic compare-match value setting function with dead time in triangle-wave PWM mode 2 or 3, GTDVU and GTDVD set to buffer operation, and active-high

Table 22.42 Example setting for automatic dead time setting function in saw-wave one-shot pulse mode, and triangle-wave PWM mode 3 (1 of 2)

No.	Step Name	Description
1	Set operating mode	Set the operating mode with GTCR.MD[2:0] or GTCR.MD[3:0]. In Figure 22.77 and Figure 22.78, 001b or 0001b (saw-wave one-shot pulse mode) is set. In Figure 22.80, 110b or 0110b (triangle-wave PWM mode 3) is set.
2	Set count direction	Select the count direction (up or down) with the GTUDDTYC register. In Figure 22.77, 01b is set after 11b is set in GTUDDTYC[1:0] (up count). In Figure 22.78, 00b is set after 10b is set in GTUDDTYC[1:0] (down count).
3	Select count clock	Select the count clock with GTCR.TPCS[3:0].
4	Set cycle	Set the cycle in GTPR.
5	Set initial value for counter	Set the initial value in the GTCNT counter.
6	Set GTIOCnm pin function	Set the GTIOCnm pin function with GTIOA[4:0] and GTIOB[4:0] in GTIOR. In Figure 22.77, Figure 22.78, and Figure 22.80, GTIOA[4:0] = 00011b and GTIOB[4:0] = 10011b.
7	Enable GTIOCnm pin output*1	Set to enable the GTIOCnm pin output with OAE and OBE in GTIOR.
8	Set buffer value for compare match*1	Set the GTIOCnA pin transition immediately after the count start in GTCCRC and GTCCRD.
9	Set forcible buffer transfer for compare match*1	Set GTBER.CCRSWT to 1 to transfer buffer register data forcibly to GTCCRA.
10	Set buffer value for compare match	Set the GTIOCnA pin transition in 1 cycle after the current cycle in GTCCRC and GTCCRD.
11	Set automatic dead time setting function	Set GTDTCR.TDE to 1 to enable the automatic dead time setting function.
12	Set buffer operation for dead time setting	Set buffer operation with TDBUE and TDBDE bits in GTDTCR.
13	Set dead time value	Set the first half dead time value in GTDVU and the second half dead time in GTDVD. When GTDVU is set with GTDTCR.TDFER bit set to 1, the same value is also set to GTDVD, the same dead time value can be set for the first and second halves.
14	Set buffer value for dead time	For buffer operation, set the first half dead time in one cycle after the current cycle in GTDBU and the second half dead time in GTDBD.

Table 22.42 Example setting for automatic dead time setting function in saw-wave one-shot pulse mode, and triangle-wave PWM mode 3 (2 of 2)

No.	Step Name	Description
15	Start count operation	Set GTCR.CST to 1 to start count operation.
16	Set buffer value for each cycle	Set the GTIOCnA pin transition in 1 cycle after the current cycle in GTCCRC and GTCCRD. When the dead time register is used for buffer operation, set the dead time value in the first half of the next cycle from the current cycle to GTDBU and the dead time value in the second half to GTDBD.

Note: n: 0 to 13
m: A, B

Note 1. When using PWM Delay Generation circuit, change the order of setting for Enable GTIOCnm pin output and setting for Set buffer value for compare match + Set forcible buffer transfer for compare match.

Table 22.43 Example setting for automatic dead time setting function in triangle-wave PWM mode 1 or 2

No.	Step Name	Description
1	Set operating mode	Set the operating mode with GTCR.MD[2:0] or GTCR.MD[3:0]. In Figure 22.79, 100b or 0100b (triangle-wave PWM mode 1) is set. In Figure 22.80, 101b or 0101b (triangle-wave PWM mode 2) is set.
2	Select count clock	Select the count clock with GTCR.TPCS[3:0].
3	Set cycle	Set the cycle in GTPR.
4	Set initial value for counter	Set the initial value in the GTCNT counter.
5	Set GTIOCnm pin function	Set the GTIOCnm pin function with GTIOA[4:0] and GTIOB[4:0] in GTIOR. In Figure 22.79 and Figure 22.80, GTIOA[4:0] = 00011b and GTIOB[4:0] = 10011b.
6	Enable GTIOCnm pin output*1	Set to enable the GTIOCnm pin output with OAE and OBE in GTIOR.
7	Set buffer operation for compare match	Set buffer operation with CCRA in GTBER.
8	Set compare match value*1	Set the GTIOCnA pin transition in GTCCRA.
9	Set buffer value for compare match	For buffer operation, set the GTIOCnA pin transition in 1 cycle after the current cycle (in triangle-wave PWM mode 1) or half cycle after the current cycle (in triangle-wave PWM mode 2) in GTCCRC. For double buffer operation, also set the GTIOCnA pin transition in 2 cycles after the current cycle (in triangle-wave PWM mode 1) or 1 cycle after the current cycle (in triangle-wave PWM mode 2) in GTCCRD.
10	Set automatic dead time setting function	Set GTDTCR.TDE to 1 to enable the automatic dead time setting function.
11	Set buffer operation for dead time setting	Set buffer operation with TDBUE and TDBDE bits in GTDTCR.
12	Set dead time value	Set the first half dead time value in GTDVU and the second half dead time in GTDVD. When GTDVU is set with GTDTCR.TDFER bit set to 1, the same value is also set to GTDVD, the same dead time value can be set for the first and second halves.
13	Set buffer value for dead time	For buffer operation, set the first half dead time in one cycle after the current cycle in GTDBU and the second half dead time in GTDBD.
14	Start count operation	Set GTCR.CST to 1 to start count operation.
15	Set buffer value for each cycle	When the compare match register is used for buffer operation, set the GTIOCnA pin transition in 1 cycle after the current cycle (in triangle-wave PWM mode 1) or half cycle after the current cycle (in triangle-wave PWM mode 2) in GTCCRC. When the compare match register is used for double-buffered operation, set the GTIOCnA pin changing point in two cycles after the current cycle (in triangle-wave PWM mode 1) or one cycle after the current cycle (in triangle-wave PWM mode 2) in GTCCRD. In the same way, set the dead time value in the first half of the cycle after current cycle in GTDBU and the dead time in the second half in GTDBD.

Note: n: 0 to 13
m: A, B

Note 1. When using PWM Delay Generation circuit, change the order of setting for the GTIOCnm pin output enable and setting for a compare match value.

22.3.5 Count Direction Changing Function

The count direction of the GTCNT counter can be changed by modifying the UD bit in GTUDDTYC.

In saw-wave mode, if the UD bit in GTUDDTYC is modified during count operation, the count direction is changed at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the GTUDDTYC.UD bit is modified while the count operation stops and the GTUDDTYC.UDF bit is 0, the GTUDDTYC.UD bit modification is not reflected at the start of counting and the count direction is changed at an overflow or an underflow. If the UDF bit is set to 1 while the count operation stops, the GTUDDTYC.UD bit value at that time is reflected at the start of counting.

In triangle-wave mode, the count direction does not change even though the UD bit in GTUDDTYC is modified during the count operation. When the GTUDDTYC.OABDTYT bit is 0, the output duty setting changed when underflow occurs is reflected, and when the GTUDDTYC.OABDTYT bit is 1, the output duty setting changed when underflow occurs and at the top of the triangle-wave is reflected. Similarly, even though the GTUDDTYC.UD bit is modified while the count operation stops and GTUDDTYC.UDF bit is 0, the GTUDDTYC.UD bit value is not reflected to the count operation. If the GTUDDTYC.UDF bit is set to 1 while the count operation is stopped, the GTUDDTYC.UD bit value at that time is reflected at the start of counting.

If the count direction changes during a saw-wave count operation, the GTPR value after the start of up-counting is reflected in the count cycle during up-counting and the GTPR value after the start of down-counting is reflected in the count cycle during down-counting.

Figure 22.81 shows an example of count direction changing function operation.

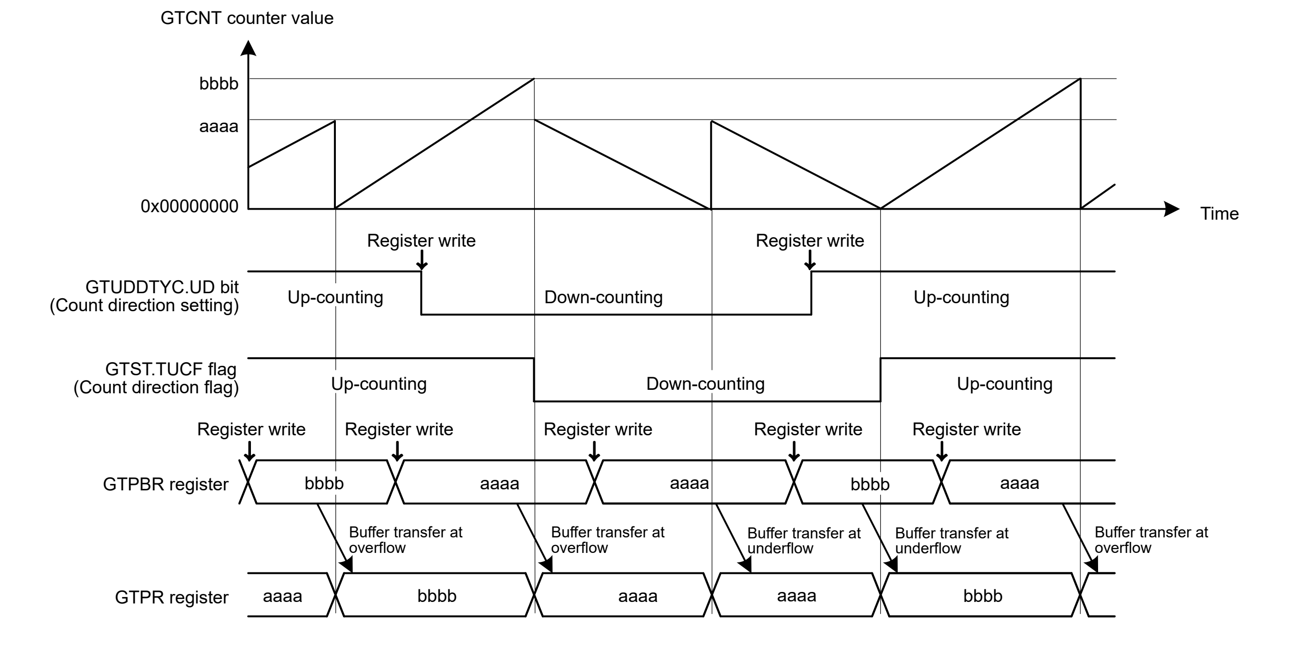

Figure 22.81 Example of a count direction changing function operation during buffer operation

22.3.6 Function of Output Duty 0% and 100%

The output duty of the GTIOCnA pin and the GTIOCnB pin (n = 0 to 13) are set to 0% or 100% by changing the GTUDDTYC.OADTY bit or GTUDDTYC.OBDTY bit.

This function is invalid in saw-wave PWM mode 2 or complementary PWM mode.

In saw-wave mode, if the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified during the count operation, the output duty setting is reflected at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is 0, the output duty modification is not reflected at the start of counting. The output duty changes at an overflow or an underflow. If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the

GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is 1, the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit value at that time is reflected at the start of counting.

In triangle-wave mode, if the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified during the count operation, when the GTUDDTYC.OABDTYT bit is 0, the output duty setting changed when underflow occurs is reflected, and when the GTUDDTYC.OABDTYT bit is 1, the output duty setting changed when underflow occurs and at the top of the triangle-wave is reflected.

If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is 0, the output duty modification is not reflected at the start of counting. The output duty changes at an underflow. If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation stops and the GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is 1, the output duty modification is reflected at the start of counting.

In performing 0% or 100% duty operation, GPT internally continues to:

- Perform compare match operation
- Set compare match flag
- Output interrupt
- Perform buffer operation.

When the control is changed from 0% or 100% duty setting to compare match, the output value of GTIOCnA pin at cycle end is decided by GTIOR.GTIOA[3:2] and GTUDDTYC.OADTYR. The output value of GTIOCnB pin at cycle end is decided by GTIOR.GTIOB[3:2] and GTUDDTYC.OBDTYR.

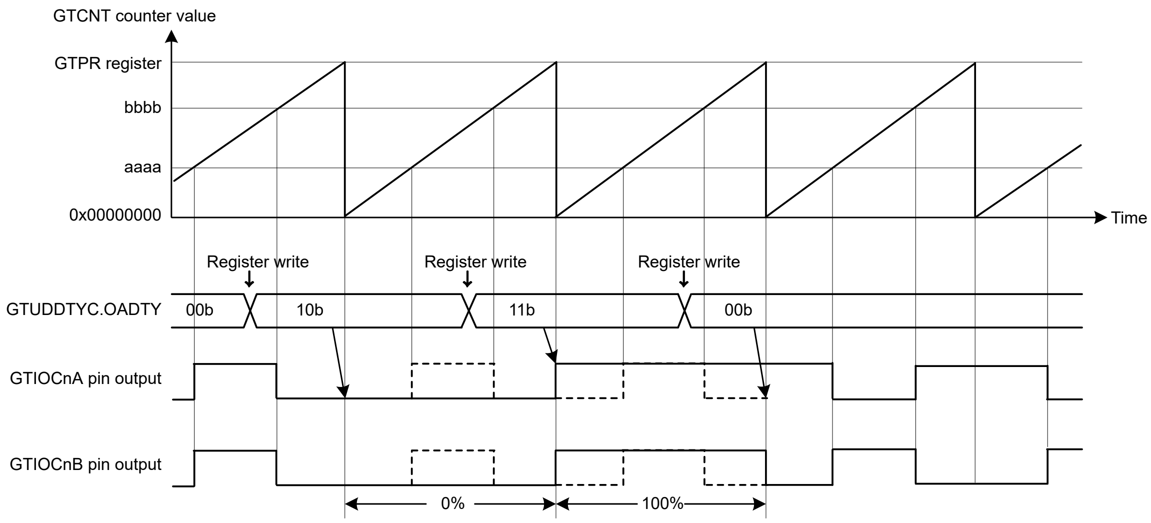
When GTIOR.GTIOA[3:2] and GTIOR.GTIOB[3:2] are set to 01b, the output pins output low at cycle end. When GTIOR.GTIOA[3:2] and GTIOR.GTIOB[3:2] are set to 10b, the output pins output high at cycle end.

GTUDDTYC.OADTYR selects the value that is the object of output retained/toggled at cycle end, when GTIOR.GTIOm[3:2] are set to 00b (output retained at cycle end) or when GTIOR.GTIOm[3:2] are set to 11b (output toggled at cycle end). Table 22.44 shows the values of GTIOCnA and GTIOCnB pin output at cycle end.

Table 22.44 Output values after releasing 0% or 100% duty setting (m = A, B)

GTIOR.GTIOm[3:2]	Compare match value at cycle end masked by 0% or 100% duty setting	GTUDDTYC.OmDTYR in duty 0% setting		GTUDDTYC.OmDTYR in duty 100% setting	
		0	1	0	1
00 (output retained at cycle end)	0	0	0	1	0
	1	0	1	1	1
01 (low output at cycle end)	—	0	0	0	0
10 (high output at cycle end)	—	1	1	1	1
11 (output toggled at cycle end)	0	1	1	0	1
	1	1	0	0	0

Figure 22.82 shows an example of output duty 0% and 100% function.



Note: The base address of registers are the same.

Note: [Setting examples]

GTIOR.GTIOA[4:0] bits:	00011b Initial low output, output toggled at compare match, output retained at cycle end
GTUDDTYC.OADTYR bit:	0b The function selected by GTIOA[3:2] is applied to the output value when the duty cycle is set after release from 0 or 100% duty-cycle setting.
GTIOR.GTIOB[4:0] bits:	00011b Initial low output, output toggled at compare match, output retained at cycle end
GTUDDTYC.OBDTYR bit:	1 The function of GTIOB[3:2] is applied to the compare match output value which is masked after 0 or 100% duty setting release.

Figure 22.82 Example of output duty 0% and 100% function

22.3.7 Hardware Count Start/Count Stop and Clear Operation

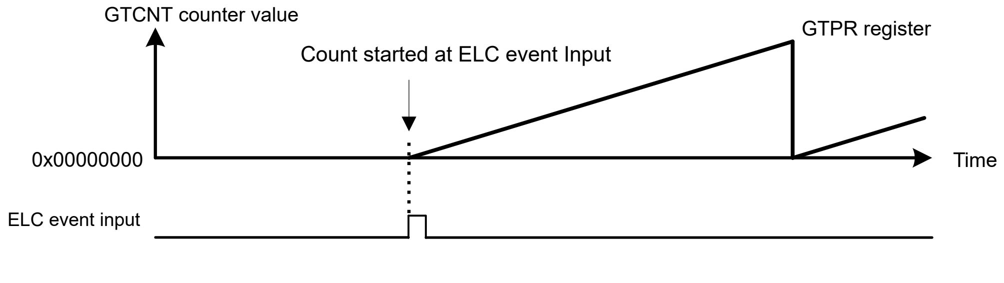
The GTCNT counter can be started, stopped, or cleared by the following hardware sources:

- External trigger input
- ELC event input
- GTIOCnA and GTIOCnB pin input (n = 0 to 13).

22.3.7.1 Hardware Start Operation

The GTCNT counter can be started by selecting a hardware source using GTSSR.

Figure 22.83 shows an example of a count start operation by a hardware source. Table 22.45 shows the setting example.



Note: ELC event input: ELCA event input

Figure 22.83 Example of count start operation by a hardware source started at the input of the signal from the ELCA event

Table 22.45 Example setting for count start operation by a hardware source

No.	Step Name	Description
1	Set operating mode	Set the operating mode with the GTCR.MD[2:0] bits or GTCR.MD[3:0] bits. In Figure 22.83, 000b or 0000b (saw-wave PWM mode 1) is set.
2	Set count direction	Select the count direction (up or down) with the GTUDDTYC register. In Figure 22.83, after 11b is set in the GTUDDTYC[1:0] bits, 01b is set in the GTUDDTYC[1:0] bits (up-counting).
3	Select count clock	Select the count clock with the GTCR.TPCS[3:0] bits.
4	Set cycle	Set the cycle in the GTPR register.
5	Set initial value for counter	Set the initial value in the GTCNT counter. In Figure 22.83, 0x00000000 is set.
6	Set hardware count start	Select a hardware source for starting count operation in the GTSSR register. In Figure 22.83, GTSSR.SSELCA = 1
7	Set hardware source operation	Set operation of the hardware source selected by the GTSSR register and start counting. In Figure 22.83, the ELCA event input operation is set.

Figure 22.84 shows an example of the timing of operations to start counting in response to ELC_GPTA event input.

This is an example of operations to start counting by the GPT321.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPT320.GTCCRA register. This is selected as a trigger for output to the GPT321 by the ELC as ELC_GPTA.

ELC passes the event signal output from GPT320 without delay to GPT321.

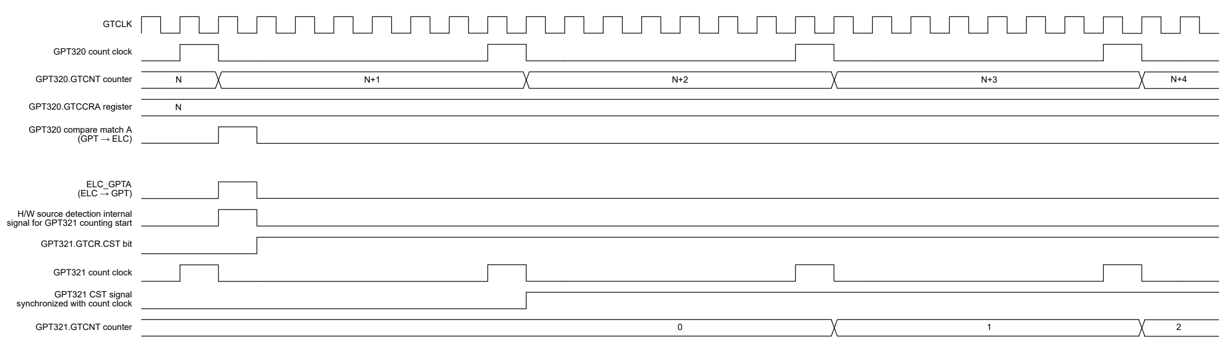


Figure 22.84 Example of Timing of Operations to Start Counting in Response to Event Input from ELC_GPTA

22.3.7.2 Hardware Stop Operation

The GTCNT counter can be stopped by selecting a hardware source using GTPSR.

Figure 22.85 shows an example of a count stop operation by a hardware source. Table 22.46 shows the setting example. In this example, the count operation stops at the ELCA event input and restarts at the ELCB event input.

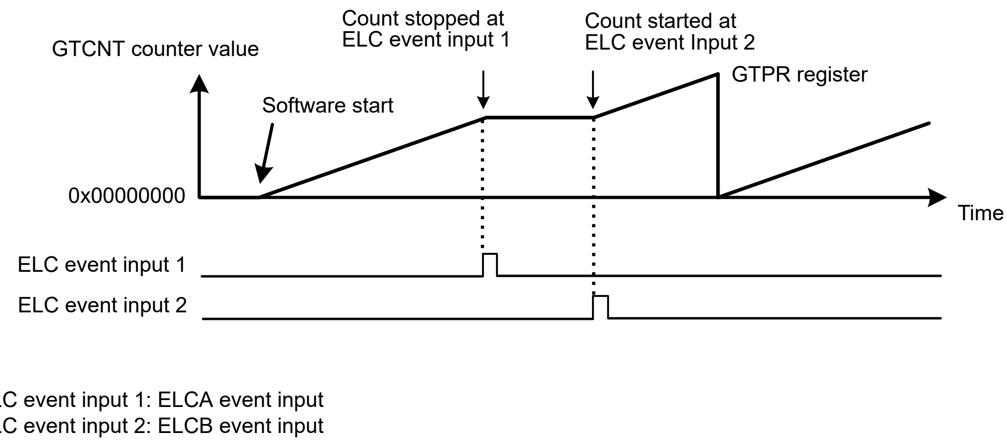

Figure 22.85 Example of count stop operation by hardware source started by software, stopped at ELCA input, and restarted at ELCB input

Table 22.46 Example setting for count stop operation by a hardware source

No.	Step Name	Description
1	Set operating mode	Set the operating mode with GTCR.MD[2:0] or GTCR.MD[3:0] bits. In Figure 22.85, 000b or 0000b (saw-wave PWM mode 1) is set.
2	Set count direction	Select the count direction (up or down) with the GTUDDTYC register. In Figure 22.85, after 11b is set in GTUDDTYC[1:0], 01b is set in GTUDDTYC[1:0] (up-counting).
3	Select count clock	Select the count clock with GTCR.TPCS[3:0].
4	Set cycle	Set the cycle in GTPR.
5	Set initial value for counter	Set the initial value in the GTCNT counter. In Figure 22.85, 0x00000000 is set.
6	Set hardware count start	Select a hardware source for starting count operation in GTSSR register, and wait for count start by the hardware source. In Figure 22.85, GTSSR.SSELCB = 1.
7	Set hardware count stop	Select a hardware source for stopping count operation in GTPSR register and wait for count stop by the hardware source. In Figure 22.85, GTPSR.PSELCA = 1.
8	Set hardware source operation	Set operation of the hardware source selected in GTSSR register or GTPSR register, and start or stop counting. In Figure 22.85, ELCA input operation and ELCB input operation are set.

Figure 22.86 shows an example of a count start/stop operation by a hardware source. Table 22.47 shows the setting example. In this example, the counter operates during the high-level periods of the external trigger input GTETRGA.

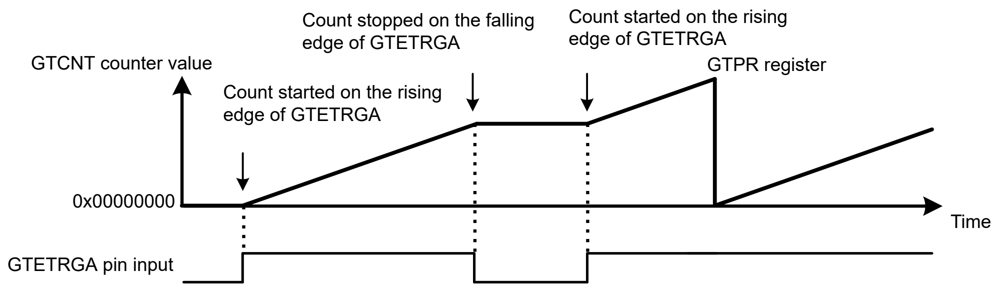

Figure 22.86 Example of count start/stop operation by a hardware source started on the rising edge of GTETRGA pin input, and stopped on the falling edge of GTETRGA pin input

Table 22.47 Example setting for count start/stop operation by a hardware source

No.	Step Name	Description
1	Set operating mode	Set the operating mode with the GTCR.MD[2:0] bits or GTCR.MD[3:0] bits. In Figure 22.86, 000b or 0000b (saw-wave PWM mode 1) is set.
2	Set count direction	Select the count direction (up or down) with the GTUDDTYC register. In Figure 22.86, after 11b is set in the GTUDDTYC[1:0] bits, 01b is set in the GTUDDTYC[1:0] bits (up-counting).
3	Select count clock	Select the count clock with the GTCR.TPCS[3:0] bits.
4	Set cycle	Set the cycle in the GTPR register.
5	Set initial value for counter	Set the initial value in the GTCNT counter. In Figure 22.86, 0x00000000 is set.
6	Set hardware count start	Select a hardware source for starting count operation with the GTSSR register, and wait for count start by the hardware source. In Figure 22.86, GTSSR.SSGTRGAR = 1.
7	Set hardware count stop	Select a hardware source for stopping count operation with the GTPSR register, and wait for count stop by the hardware source. In Figure 22.86, GTPSR.PSGTRGAF = 1.
8	Set hardware source operation	Set operation of the hardware source selected in the GTSSR register or GTPSR register and start or stop counting. In Figure 22.86, the GTETRGA pin operation is set.

Figure 22.87 shows an example of timing of operations to stop counting in response to event input from ELC_GPTA.

This is an example of operations to stop counting by the GPT321.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPT320.GTCCRA register. This is selected as a trigger for output to the GPT321 by the ELC as ELC_GPTA.

ELC passes the event signal output from GPT320 without delay to GPT321.

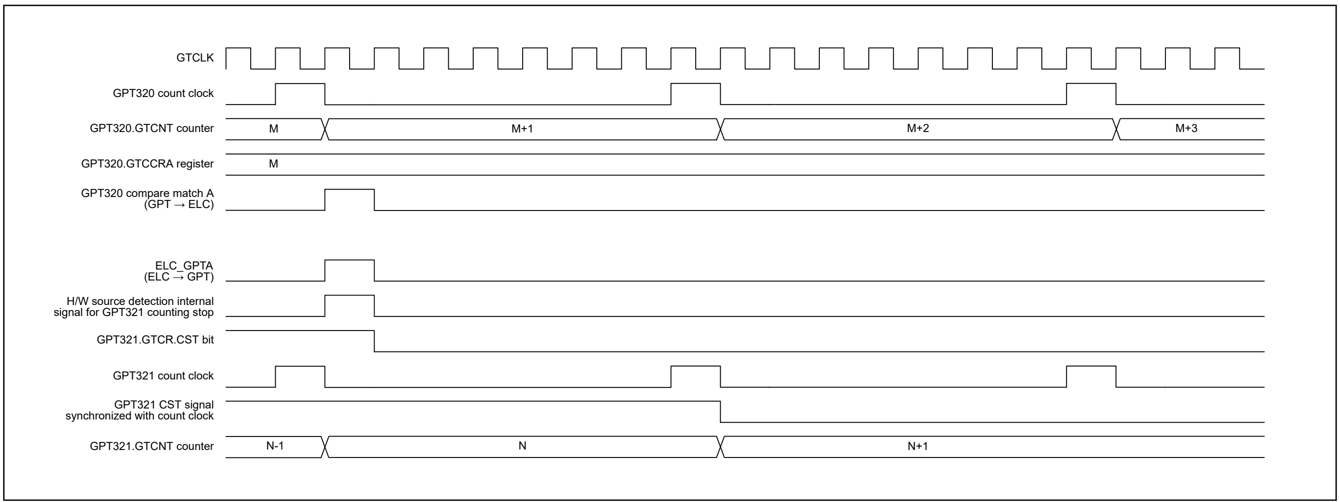

Figure 22.87 Example of Timing of Operations to Stop Counting in Response to Event Input from ELC_GPTA

22.3.7.3 Hardware Clear Operation

The GTCNT counter can be cleared by selecting a hardware source using GTCSR. The GPTn_OVF/GPTn_UDF (n = 0 to 13) interrupt (overflow/underflow interrupt) is not generated when the GTCNT counter is cleared by a hardware source or by software.

Figure 22.88 and Figure 22.89 show examples of the GTCNT counter clearing operation by a hardware source. Table 22.48 shows the setting example. In this example, the GTCNT counter starts at the ELCA input, and the counter stops and clears at the ELCB input.

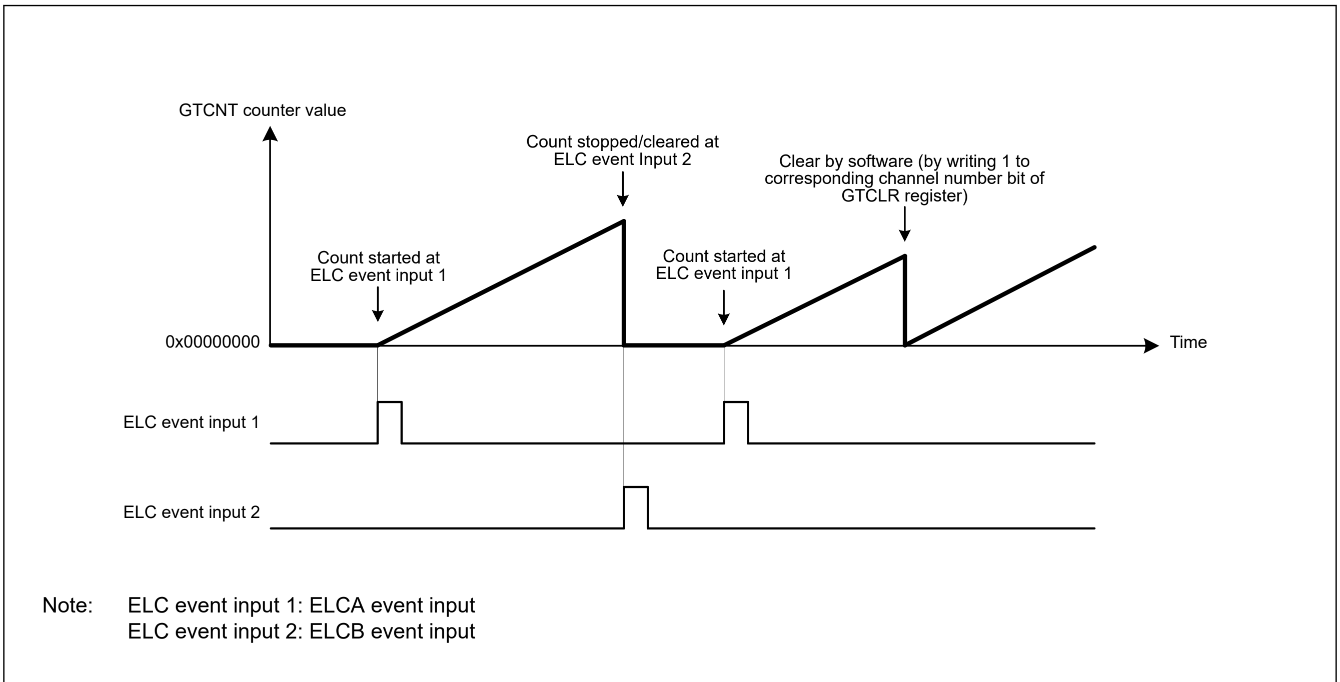

Figure 22.88 Examples of count clearing operation by hardware source in saw wave up-counting, started at ELCA input, and stopped/cleared at ELCB input

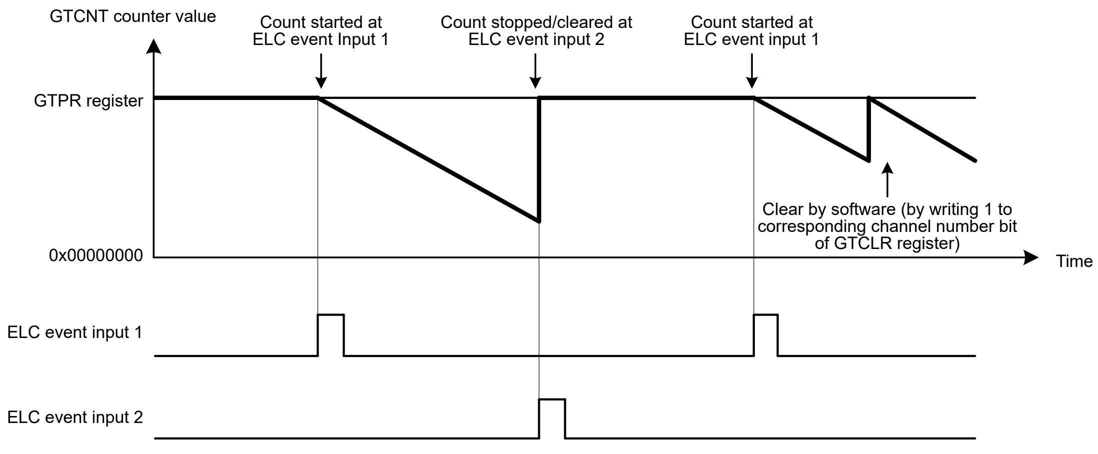

Note: ELC event input 1: ELCA event input
ELC event input 2: ELCB event input

Figure 22.89 Examples of count clearing operation by hardware source in saw wave down-counting, started at ELCA input, and stopped/cleared at ELCB input

Table 22.48 Example setting for count clearing operation by a hardware source

No.	Step Name	Description
1	Set operating mode	Set the operating mode with the GTCR.MD[2:0] bits or GTCR.MD[3:0] bits. In Figure 22.88 and Figure 22.89, 000b or 0000b (saw-wave PWM mode 1) is set.
2	Set count direction	Select the count direction (up or down) with the GTUDDTYC register. In Figure 22.88, after 11b is set in the GTUDDTYC[1:0] bits, 01b is set in the GTUDDTYC[1:0] bits (up-counting). In Figure 22.89, after 10b is set in the GTUDDTYC[1:0] bits, 00b is set in the GTUDDTYC[1:0] bits (down-counting).
3	Select count clock	Select the count clock with the GTCR.TPCS[3:0] bits.
4	Set cycle	Set the cycle in the GTPR register.
5	Set initial value for counter	Set the initial value in the GTCNT counter. In Figure 22.88, 0x00000000 is set. In Figure 22.89, the GTPR register value is set.
6	Set hardware count start	Select a hardware source for starting count operation in the GTSSR register, and wait for count start by the hardware source. In Figure 22.88 and Figure 22.89, GTSSR.SSELCA = 1.
7	Set hardware count stop	Select a hardware source for stopping count operation in the GTPSR register, and wait for count stop by the hardware source. In Figure 22.88 and Figure 22.89, GTPSR.PSELCB = 1.
8	Set hardware count clear	Select a hardware source for clearing count operation in the GTCSR register, and wait for count clear by the hardware source. In Figure 22.88 and Figure 22.89, GTCSR.CSELCB = 1.
9	Set hardware source operation	Set operation of the hardware source selected in the GTSSR register, GTPSR register or GTCSR register and start, stop or clear counting. In Figure 22.88 and Figure 22.89, the ELCA input and ELCB input are set.

The GPTn_OVF/GPTn_UDF (n = 0 to 13) interrupt (overflow/underflow interrupt) is not generated when the counter is cleared by a hardware source or by software.

Figure 22.90 shows the relationship between the counter clearing by a hardware source and the GPTn_OVF (n = 0 to 13) interrupt.

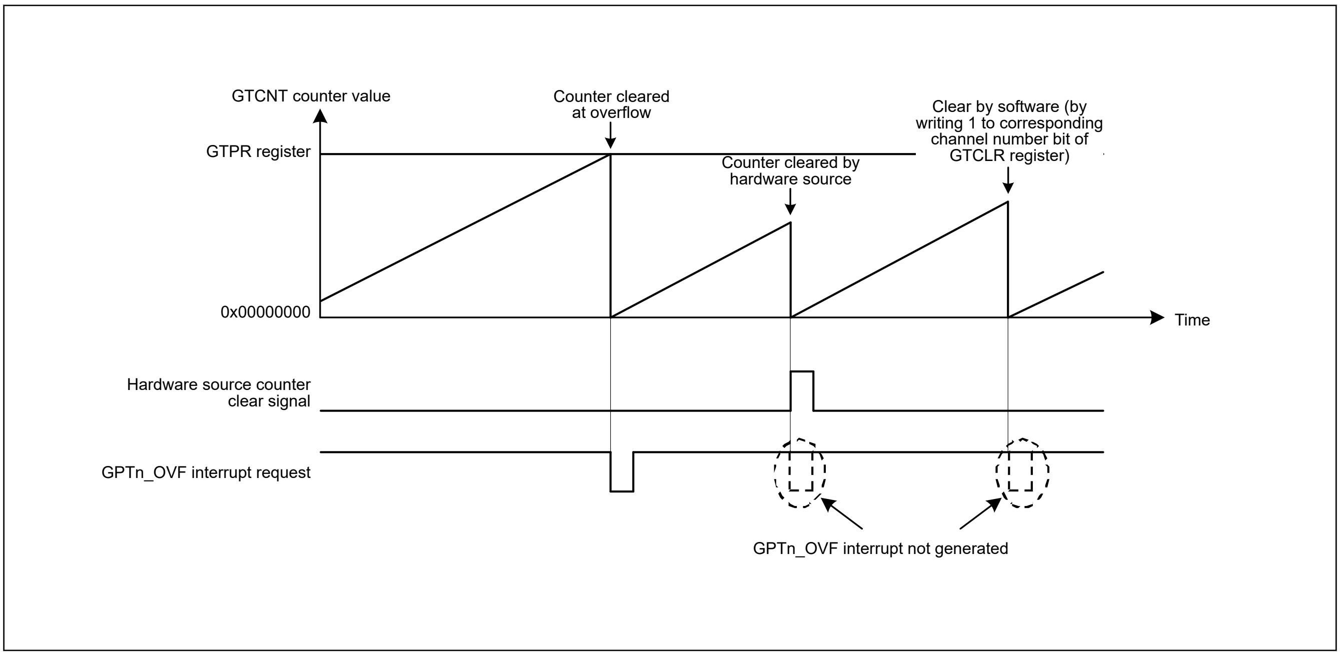

Figure 22.90 Relationship between counter clearing by hardware source and GPTn_OVF (n = 0 to 13) interrupt

Figure 22.91 shows an example of the timing of operations to clear the counter in response to event input from ELC_GPTA when a clock signal produced by frequency-dividing the GTCLK signal is used as the counter clock for the GTCNT counter.

This is an example of operations to clear counting by the GPT321.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPT320.GTCCRA register. This is selected as a trigger for output to the GPT321 by the ELC as ELC_GPTA.

ELC passes the event signal output from GPT320 without delay to GPT321.

The GTCNT counter is cleared when counting is in progress after the GPT32 has detected the internal clearing signal.

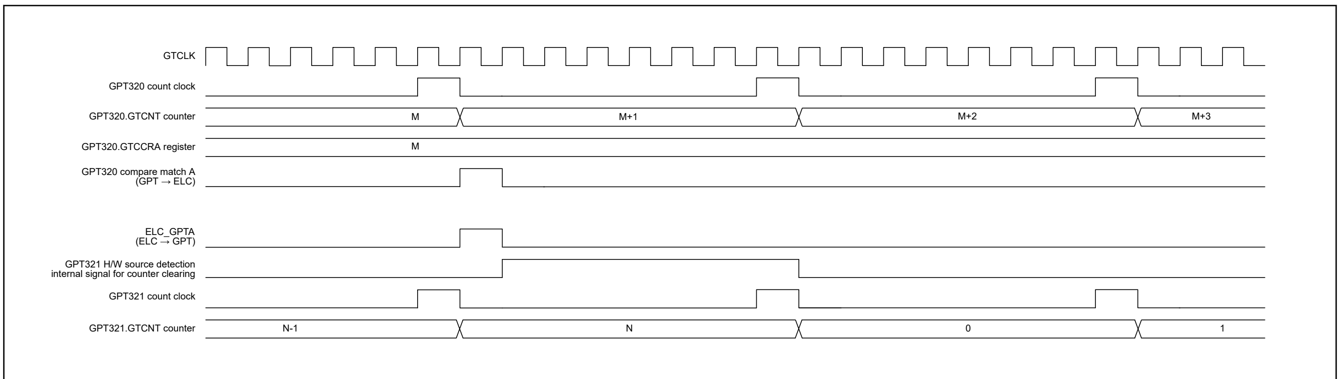

Figure 22.91 Examples of Timing of Operations for Counter Clearing in Response to Event Input from the ELC_GPTA (During the Counting of Cycles of Clock Signal Produced by Dividing the GTCLK Frequency)

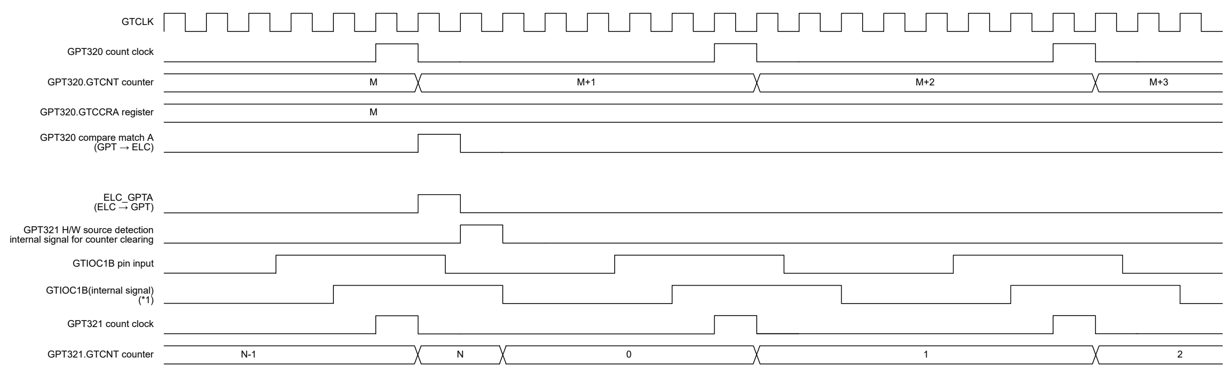
Figure 22.92 shows an example of the timing of operations for clearing the counter in response to the input of an event signal from the ELC_GPTA when counting is triggered by a hardware source.

This is an example of operations to clear counting by the GPT321.GTCNT counter in response to a signal. An event signal is output to the ELC after matches in comparison with the GPT320.GTCCRA register. This is selected as a trigger for output to the GPT321 by the ELC as ELC_GPTA.

ELC passes the event signal output from GPT320 without delay to GPT321.

The GTCNT counter is cleared in synchronization with GTCLK after the GPT32 has detected the internal clearing signal.



Note 1. This is the case when the digital noise filter is not in use.

Figure 22.92 Examples of the Timing of Operations for Counter Clearing in Response to Event Input from the ELC_GPTA (During Counting Triggered by Hardware Source)

22.3.8 Synchronized Operation

Synchronized operation on channels such as a synchronized start, stop, and clear operation can be performed.

22.3.8.1 Synchronized Operation by Software

The GTCNT counters can be started, stopped, and cleared on multiple channels by setting the associated GTSTR, GTSTP, or GTCLR bits simultaneously to 1.

Count start with a phase difference is possible by setting the initial value in the GTCNT counter and setting the associated GTSTR bits simultaneously to 1.

When the GTCNT synchronous set/clear function is enabled on the GTCR.SSCEN bit, the GTCNT registers of the channel set in same group on the GTCR.SSCGRP [1:0] bits can be written at the same time.

The synchronous GTCNT write is invalid in complementary PWM mode.

When either the SSCE bit or the SSCD bit of the GTSECR register is set to 1, the GTCR.SSCEN bits of the channels that selected on the GTSECSR register are set to 0 or 1 and the GTCNT synchronous set/clear function of multiple channels are enabled or disabled at the same time.

Because the clock of count operation is selected by GTCR.TPCS[3:0] bits in respective channels, if the clock period of each channel that performs synchronous operation (count start/stop/clear) is different from others, the synchronous operation timings of every channel are not exact same.

Figure 22.93 shows an example of a simultaneous start, stop, and clear by software. Figure 22.94 shows an example of phase start operation by software. Figure 22.95, Figure 22.96, Figure 22.97 show an example of simultaneous start/stop/clearing with different count period.

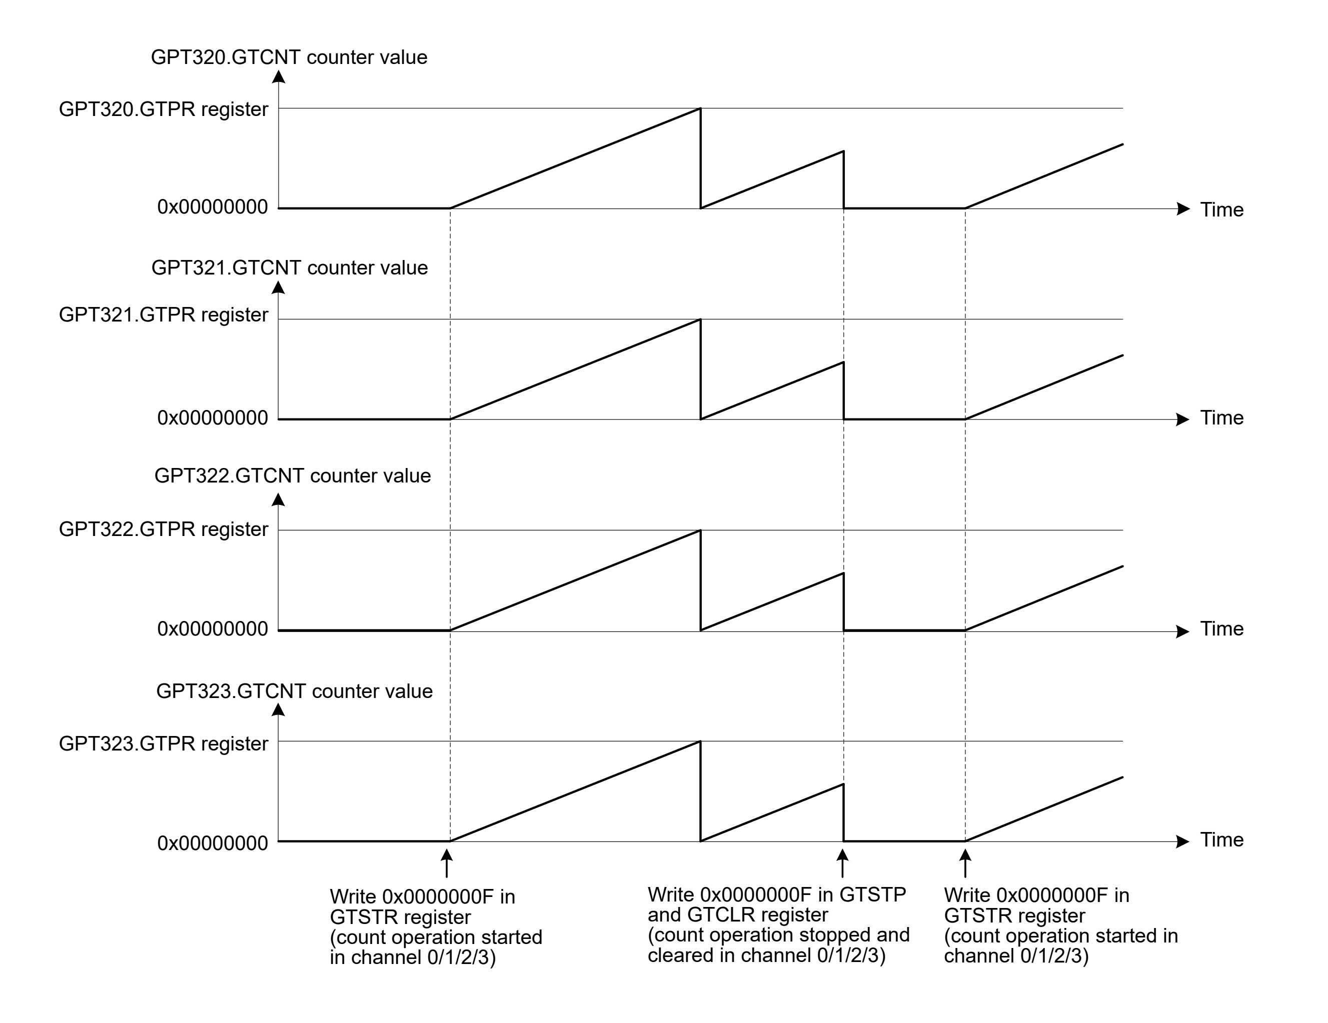


Figure 22.93 Example of a simultaneous start, stop, and clear by software with the same count cycle (GTPR register value)

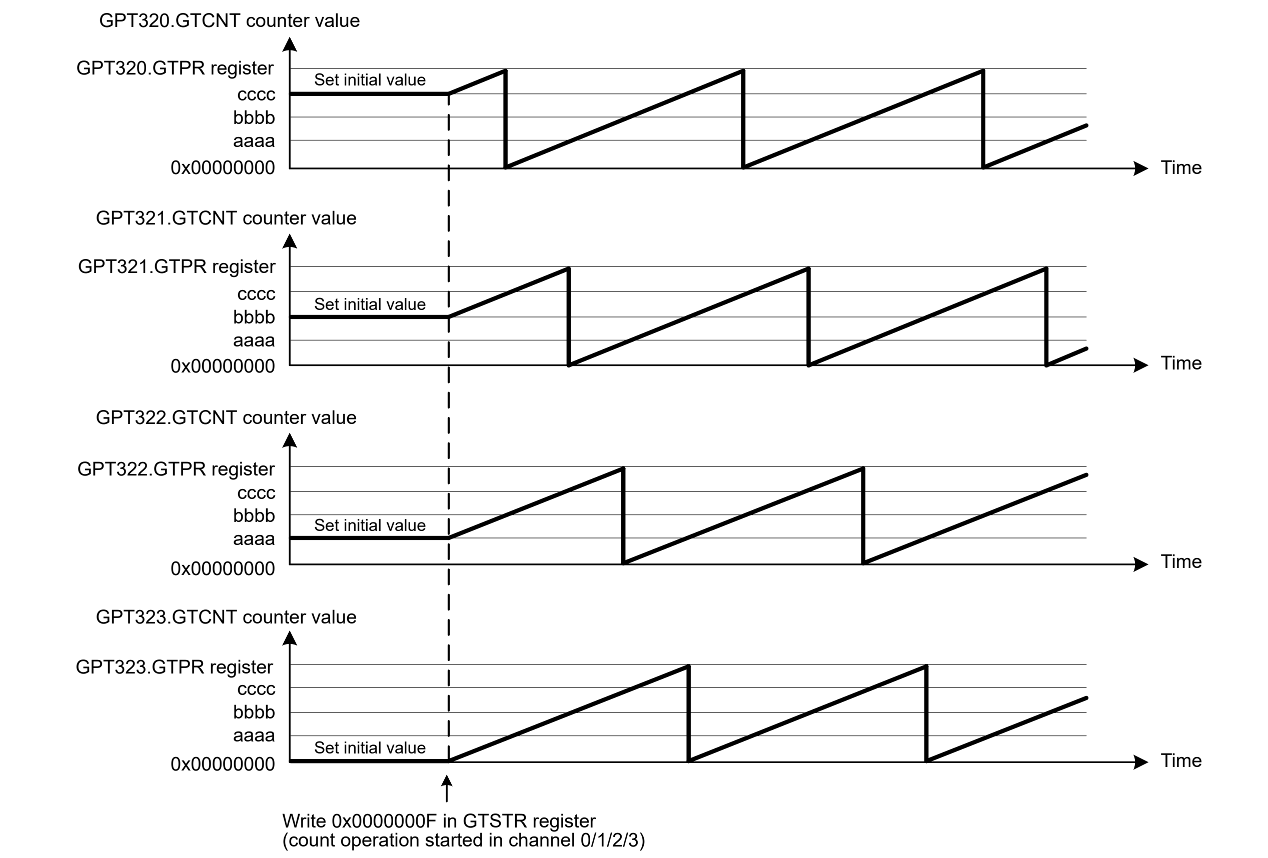

Figure 22.94 Example of software phase start with the same count cycle (GTPR register value)

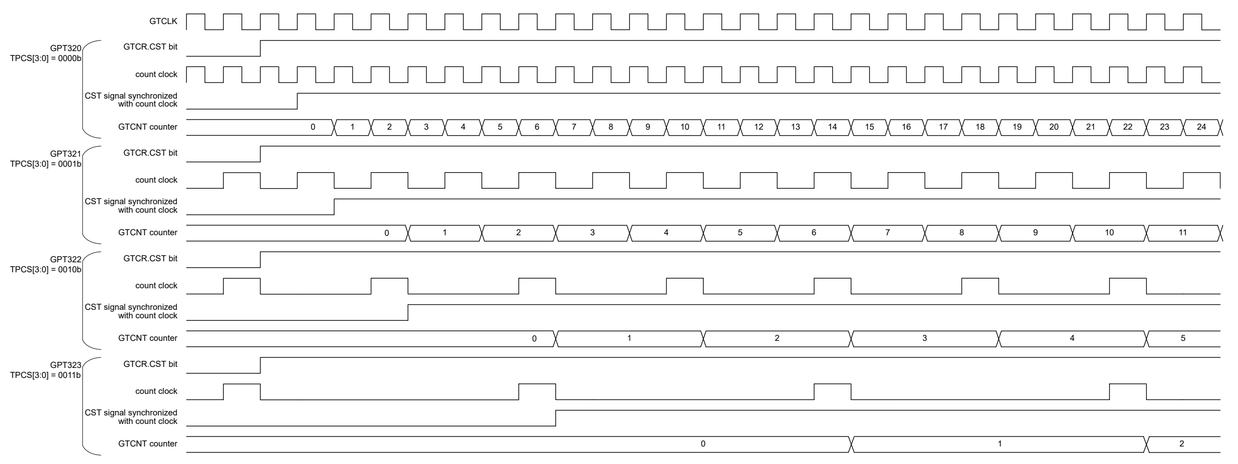

Figure 22.95 Example of Simultaneous Start Operation by Software (with Different Count Period)

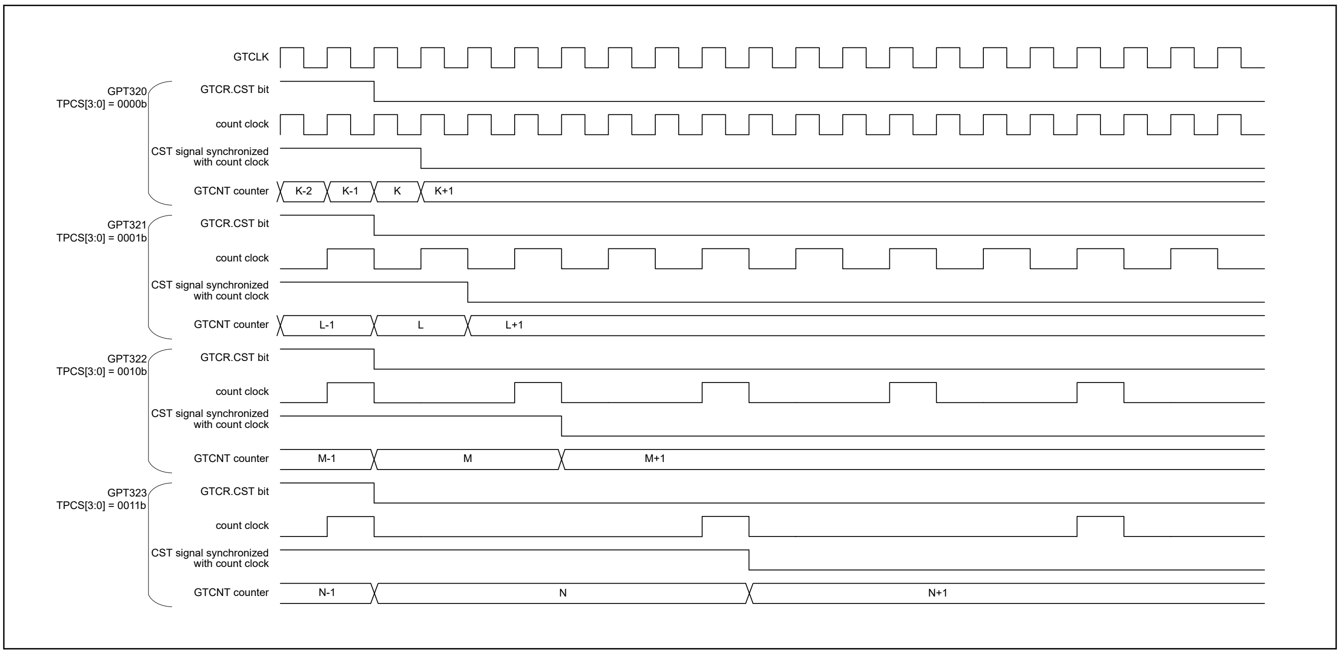

Figure 22.96 Example of Simultaneous Stop Operation by Software (with Different Count Period)

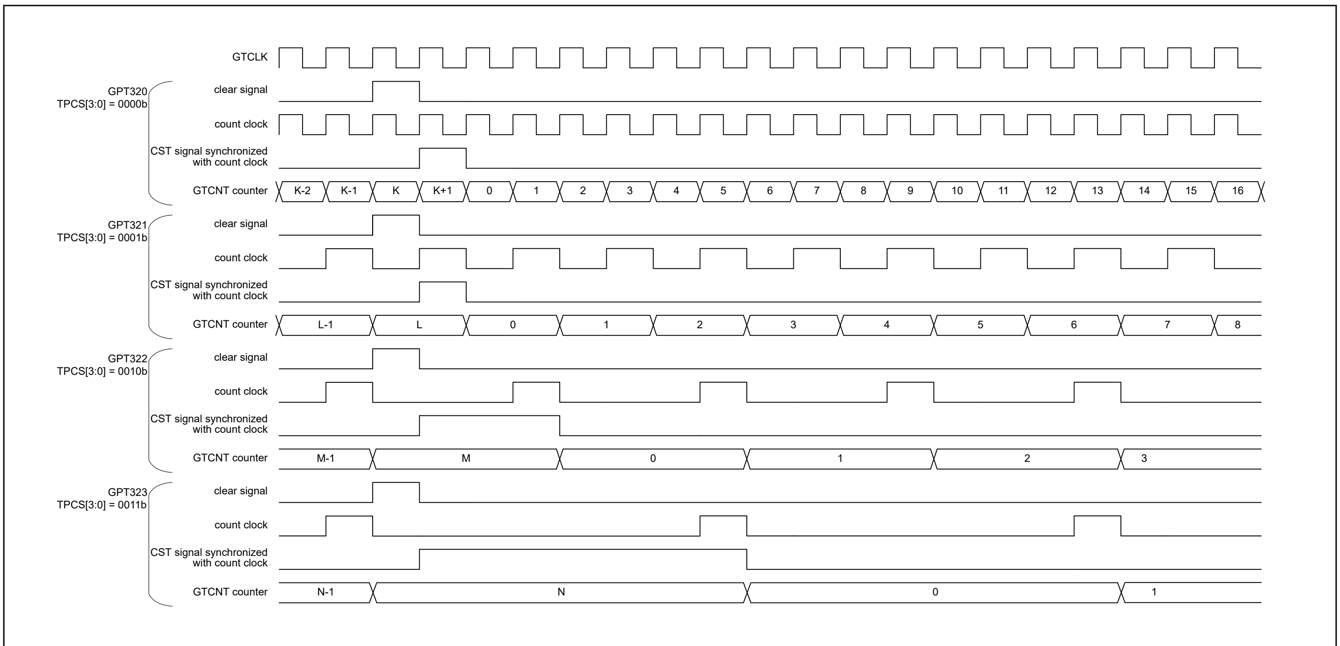

Figure 22.97 Example of Simultaneous Clearing Operation by Software (with Different Count Period)

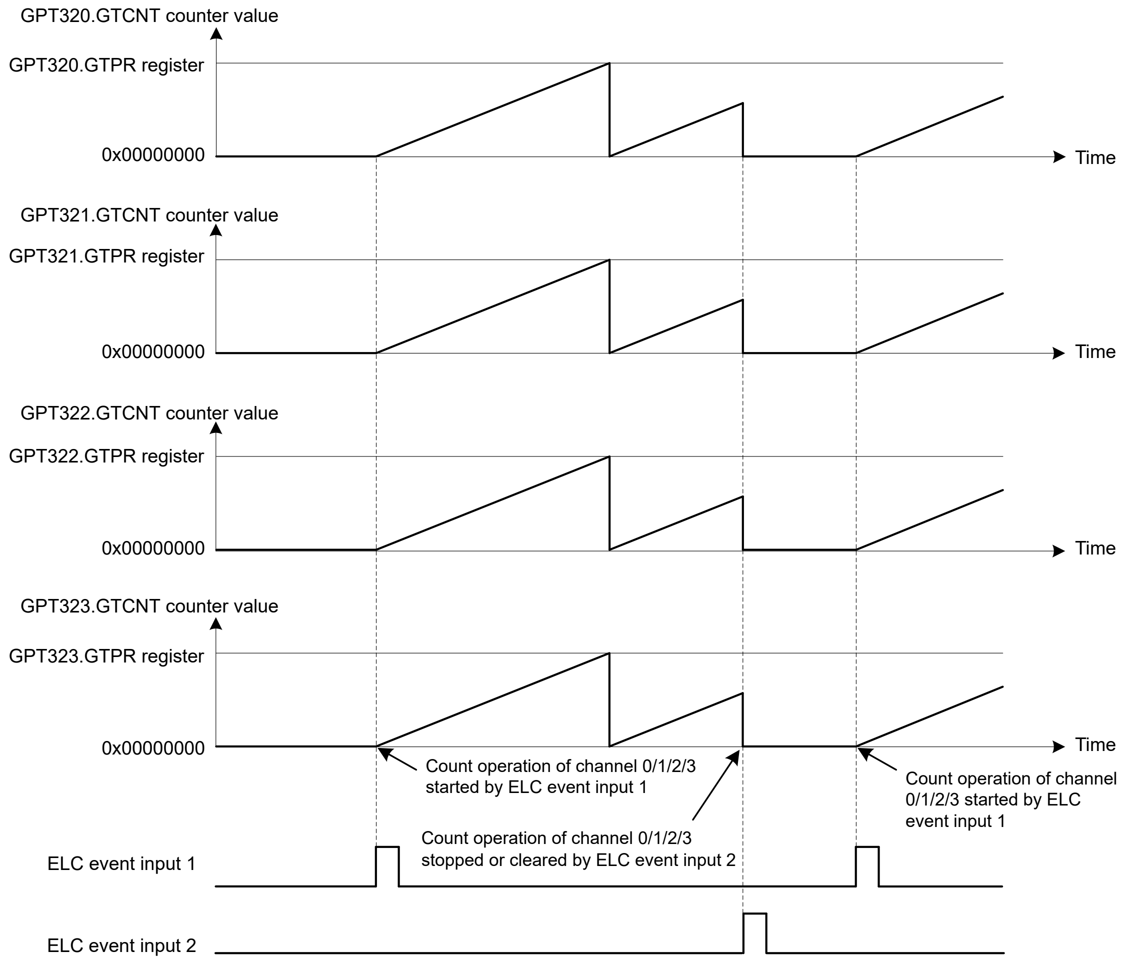
22.3.8.2 Synchronized Operation by Hardware

The counters for multiple channels can be started, stopped, and cleared simultaneously by ELC event input.

Figure 22.98 shows an example of a simultaneous start, stop, and clear operation by a hardware source. Table 22.49 shows the setting example.



Note: ELC event input 1: ELCA event input
ELC event input 2: ELCB event input

Figure 22.98 Example of a simultaneous start, stop, and clear by a hardware source with the same count cycle (GTPR register value)

Table 22.49 Example setting for simultaneous start by a hardware source (1 of 2)

No.	Step Name	Description
1	Set operating mode	Set the operating mode with the GTCR.MD[2:0] bits or GTCR.MD[3:0] bits. In Figure 22.98, 000b or 0000b (saw-wave PWM mode 1) is set.
2	Set count direction	Select the count direction (up or down) with the GTUDDTYC register. In Figure 22.98, after 11b is set in the GTUDDTYC[1:0] bits, 01b is set in the GTUDDTYC[1:0] bits (up-counting).
3	Select count clock	Select the count clock with the GTCR.TPCS[3:0] bits.
4	Set cycle	Set the cycle in the GTPR register.
5	Set initial value for counter	Set the initial value in the GTCNT counter. In Figure 22.98, 0x00000000 is set.
6	Set hardware count start	Select a hardware source for starting count operation with the GTSSR register, and wait for count start by the hardware source. In Figure 22.98, GTSSR.SSELCA = 1.

Table 22.49 Example setting for simultaneous start by a hardware source (2 of 2)

No.	Step Name	Description
7	Set hardware count stop	Select a hardware source for stopping count operation with the GTPSR register, and wait for count stop by the hardware source. In Figure 22.98, GTPSR.PSELCB = 1.
8	Set hardware count clear	Select a hardware source for clearing count operation with the GTCSR register, and wait for count clear by the hardware source. In Figure 22.98, GTCSR.CSELCB = 1.
9	Set hardware source operation	Set operation of the hardware source selected in the GTSSR, GTPSR, or GTCSR registers, and start, stop, or clear counting. In Figure 22.98, ELCA input and ELCB input are set.

22.3.8.3 Input Capture Operation by Inter Channel Cooperation

The events of compare match, input capture, sawtooth wave up-count overflow, sawtooth wave down-count underflow, the crest and trough of triangle wave and complementary PWM mode and the count clock can be used as the input capture factor for the GTCCRm register (m = A or B) of other channels. The input capture factors by inter channel cooperation can be set by the GTICCR register of the channel that generates the input capture factor. Input capture by other channel factors can be enabled by GTICmSR.mSOC bit (m = A or B) in the captured channels. The channels that generate input capture factors and the channels that are captured are set to the same input capture group by GTICCR.ICmGRP[1:0] bits (m = A or B).

Figure 22.99 shows an example of input capture operation by inter channel cooperation and Table 22.50 shows an example for setting input capture operation by inter channel cooperation.

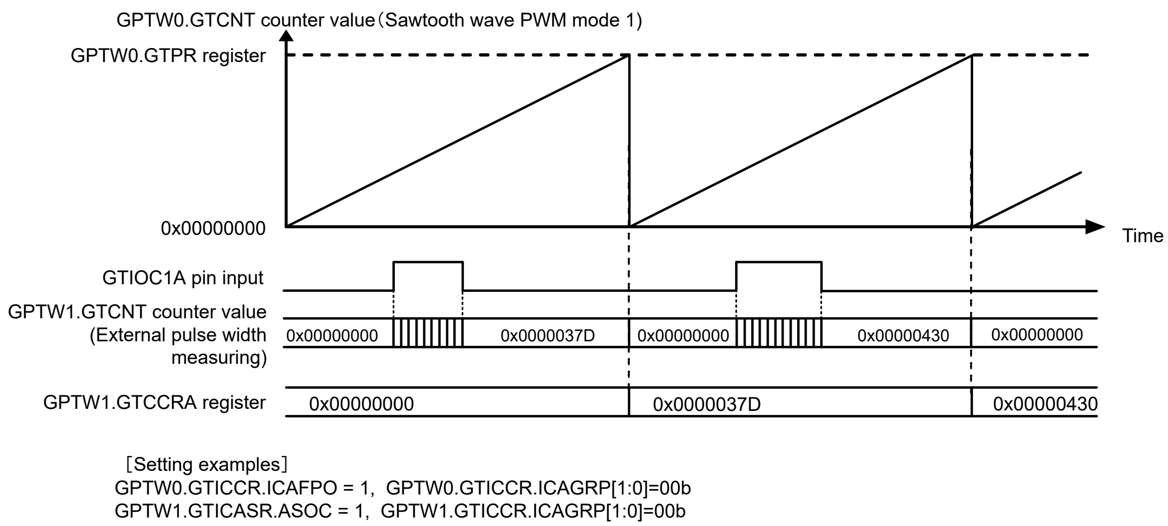


Figure 22.99 Example of input capture operation by inter channel cooperation (channel 1 is captured by the overflow of channel 0)

Table 22.50 Example for setting input capture operation by inter channel cooperation (1 of 2)

Step name	Description
(1) Set operating mode	Set the operating mode with the GTCR.MD[2:0] or the GTCR.MD [3:0] bits. In Figure 22.99,GTCR.MD[2:0] = 000b or GTCR.MD[3:0] = 0000b (sawtooth-wave PWM mode 1) is set to GPTW0.

Table 22.50 Example for setting input capture operation by inter channel cooperation (2 of 2)

Step name	Description
(2) Set external pulse width measuring function	Enable external pulse width measuring function with the GTUPSR.USILVL [3: 0] bits for up-counting operation and the GTDNSR.DSILVL [3: 0] bits for down-counting operation and select the input pin and level to measure. In Figure 22.99, GTUPSR.USILVL[3:0] = 0011b (count up when GTIOCnA pin is 1).
(3) Set count direction	Select the count direction (up or down) with the GTUDDTYC register. In Figure 22.99, for GPTW0, lower 2 bits of the GTUDDTYC register is set to 11b, and then lower 2 bits of the GTUDDTYC register is set to 01b (up-counting).
(4) Select count clock	Select the count clock with GTCR.TPCS[2:0] bits or GTCR.TPCS [3:0] bits of the corresponding channel.
(5) Period setting	Set a period in the GTPR register of the corresponding channel.
(6) Set initial value for counter	Set the initial value in the GTCNT counter of the corresponding channel.
(7) Set counter clear factor to the inter channel cooperation Input capture (cleared channels)	Set the GTCSR.CSCMSC[2:0] bits in the channel to be cleared by input capture by inter channel cooperation to 001b, 010b, and select input capture as counter clear factor. In Figure 22.99, GPTW1.GTCSR.CSCMSC[2:0] bits are 001b.
(8) Inter channel cooperation input capture setting (source channel)	Set the input capture factor using the GTICCR register in the source channels of inter channel cooperation input capture. In Figure 22.99, GPTW0.GTICCR.ICAFPO bit is 1b.
(9) Inter channel cooperation input capture setting (captured channels)	Set the GTICmSR.mSOC bit (m = A or B) in the captured channels to allow input capture to the GTCCRm register (m = A or B) by other channel factors. In Figure 22.99, GPTW1.GTICASR.ASOC bit is 1b.
(10) Set group of inter channel cooperation input capture	Set the same value to the GTICCR.ICmGRP[1:0] bits (m = A or B) in the source channels and cleared channels of inter channel cooperation input capture and set them in the same input capture group.

22.3.8.4 Synchronous Clear Operation by Inter Channel Cooperation

The counters of other channels can be cleared at the same time with the counter clear of some channel caused by the compare match, input capture, saw wave up-count overflow, saw wave down-count underflow, and the GTIOCnA / GTIOCnB pin input selected in the GTCSR register.

The counter clear caused by GTCLR register, external trigger input and the ELC input can perform as synchronous clear when the same counter clear factor is set to target channels of synchronous clear. Therefore, these factors are not prepared for the synchronous clear operation by inter channel cooperation.

Set the channel that generates the synchronization clear source and the channel that is synchronized clear in the same synchronous set/clear group with the GTCR.SSCGRP[1:0] bits.

Similar to the synchronous operation in section 22.3.8.1. Synchronized Operation by Software, if the count clock selected by the GTCR.TPCS [3:0] bits is different for each channel, the synchronous clear operation cannot be performed at exact same timing. Similar to the example of simultaneous clearing operation by software in Figure 22.97, if the count clock is different for each channel, the synchronous clear factor is synchronized with the count clock of each channel before counter clearing.

When either the SSCE bit or the SSCD bit of the GTSECR register is set to 1, the GTCR.SSCEN bits of the channels that selected on the GTSECSR register are set to 0 or 1 and the GTCNT synchronous set/clear function of multiple channels are enabled or disabled at the same time.

Table 22.51 shows synchronous clear factor register setting and Figure 22.100 shows an example of synchronous clear operation by inter channel cooperation and Table 22.52 shows an example for setting synchronous clear operation by inter channel cooperation.

Table 22.51 Synchronous clear factor register setting

Synchronous clear factor by inter channel cooperation	Setting register	Setting value
GTCCRA register compare match/input capture	GTINTAD.SCFA	1b
	GTCSR.CSCMSC[2:0]	001b
GTCCRB register compare match/input capture	GTINTAD.SCFB	1b
	GTCSR.CSCMSC[2:0]	010b
GTCCRC register compare match	GTINTAD.SCFC	1b
	GTCSR.CSCMSC[2:0]	011b
GTCCRD register compare match	GTINTAD.SCFD	1b
	GTCSR.CSCMSC[2:0]	100b
GTCCRE register compare match	GTINTAD.SCFE	1b
	GTCSR.CSCMSC[2:0]	101b
GTCCRF register compare match	GTINTAD.SCFF	1b
	GTCSR.CSCMSC[2:0]	110b
Overflow of Sawtooth-Wave up-count	GTINTAD.SCFPO	1b
Underflow of Sawtooth-Wave down-count	GTINTAD.SCFPU	1b
Clear caused by GTIOCnA/GTIOCnB pin	GTCR.SCGTIOC	1b

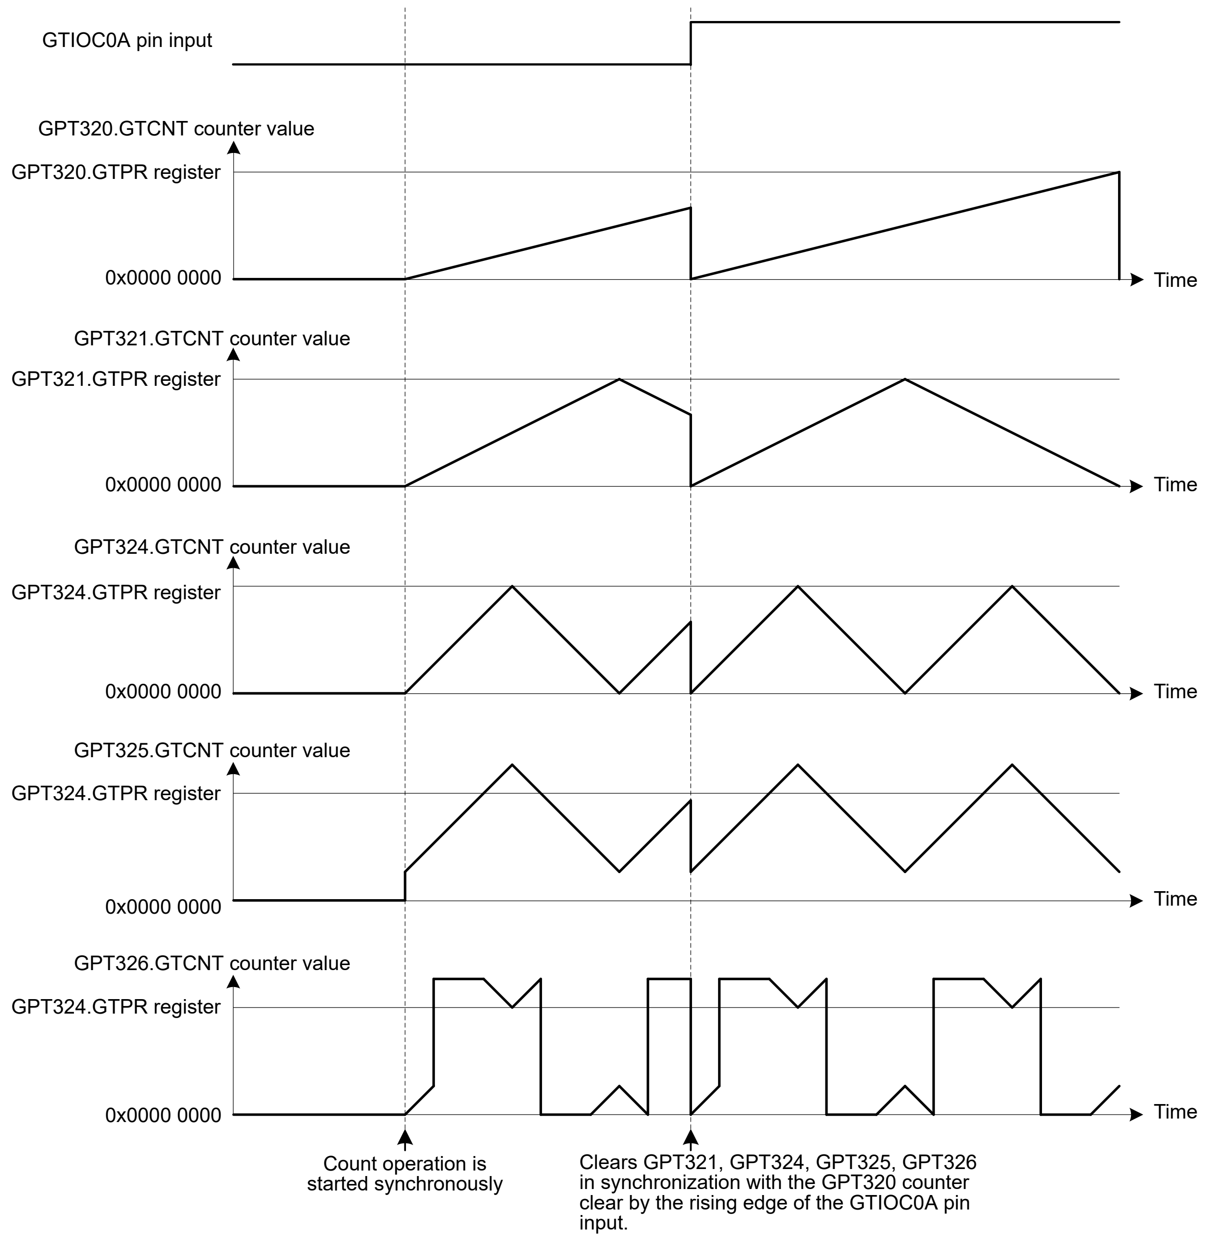

Figure 22.100 Example of Synchronous Clear Operation by Inter Channel Cooperation (GPT320 is saw-wave and counter is cleared by the rising edge of the GTIOC0A, GPT321 is triangle wave, GPT324,5,6 are complementary PWM mode. GPT320,1,4,5,6 are the same synchronous set/ clear group)

Table 22.52 Example for Setting Synchronous Clear Operation by Inter Channel Cooperation (1 of 2)

No.	Step Name	Description
1	Set operating mode	Set the operating mode with GTCR.MD[2:0] or GTCR.MD[3:0]. In Figure 22.100, 000b (saw-wave PWM mode 1) is set to GPT320. 100b (triangle-wave PWM mode 1) is set to GPT321. 1100b (complementary PWM mode 1) is set to GPT324(GPT325,6).
2	Set count direction	Select the count direction (up or down) with GTUDDTYC. In Figure 22.100, for GPT320 and GPT321, lower 2 bits of GTUDDTYC is set to 11b, and then lower 2 bits of GTUDDTYC is set to 01b (up-counting).
3	Select count clock	Select the count clock with GTCR.TPCS[3:0] bits of the corresponding channel.

Table 22.52 Example for Setting Synchronous Clear Operation by Inter Channel Cooperation (2 of 2)

No.	Step Name	Description
4	Set cycle	Set the cycle in GTPR of the corresponding channel. When complementary PWM mode, set the cycle in GTPR of the master channel.
5	Set initial value for counter	Set the initial value in the GTCNT counter of the corresponding channel.
6	Inter channel cooperation synchronous clear setting (Source channel)	Set the GTINTAD register and GTCR.SCGTIOC bit in the source channel of inter channel cooperation synchronous clear to enable synchronous clear. When complementary PWM mode, set GTINTAD of the master channel. In Figure 22.100, GPT320.GTCR.SCGTIOC bit is 1.
7	Inter channel cooperation synchronous clear setting (Cleared channels)	Set GTCSR.CSCMSC[2:0] bits in the cleared channels of inter channel cooperation synchronous clear to select the counter clear by synchronous counter clearing group. When complementary PWM mode, set GTCSR of the master channel. In Figure 22.100, GTCSR.CSCMSC[2:0] bits of GPT321, GPT324, GPT325 and GPT326 is 111b.
8	Set group of inter channel cooperation synchronous clear	Set the same value to GTCR.SSCGRP[1:0] bits in the source channel and cleared channels of inter channel cooperation synchronous clear and set them in the same synchronous set/clear group. When complementary PWM mode, set GTCR of the master channel.
9	Enable inter channel cooperation synchronous clear	Set GTCR.SSCEN bits in the source channel and cleared channels of inter channel cooperation synchronous clear to enable synchronous clear.

Table 22.53 Example for Setting Synchronous Clear Operation by Inter Channel Cooperation (Clear caused by the GTCCRA input capture using the GTIOCnA/GTIOCnB pin)

Set operating mode	Set the operating mode with the GTCR.MD[2:0] bits or the GTCR.MD[3:0] bits.
Set count direction	Select the count direction (up or down) with the GTUDDTYC register.
Select count clock	Select the count clock with GTCR.TPCS[2:0] bits of the corresponding channel, or Select the count clock with GTCR.TPCS [3:0] bits of the corresponding channel
Period setting	Set a period in the GTPR register of the corresponding channel. When complementary PWM mode, set a period in the GTPR register of the master channel.
Set initial value for counter	Set the initial value in the GTCNT counter of the corresponding channel.
Inter channel cooperation synchronous clear setting (Source channel)	Set the input capture factor using the GTIOCnA/B pin to the GTICASR register and set the same factor as the GTICASR register to the GTCSR register as the count clearing factor. In addition, Set GTINTAD.SCFA bit=1b and GTCSR.CSCMSC[2:0] bit=001b to enable synchronous clear source by the GTCCRA input capture. When complementary PWM mode, set the GTINTAD register of the master channel.
Inter channel cooperation synchronous clear setting (Cleared channels)	Set the same value to the GTCR.SSCGRP[1:0] bits in the source channel and cleared channels of inter channel cooperation synchronous clear and set them in the same synchronous set/clear group. When complementary PWM mode, set the GTCR register of the master channel.
Enable inter channel cooperation synchronous clear	Set the GTCR.SSCEN bits in the source channel and cleared channels of inter channel cooperation synchronous clear to enable synchronous clear.

22.3.9 PWM Output Operation Examples

(1) Synchronized PWM output

The GPT outputs 14 × 2 phases of linked PWM waveforms for a maximum of GPT × 14 channels.

Figure 22.101 shows an example in which four channels perform synchronized operation in saw-wave PWM mode 1 and eight phases of PWM waveforms are output. The GTIOCnA is set so that it outputs low as the initial value, high at a GTCCRA compare match, and low at the cycle end. The GTIOCnB is set so that it outputs low as the initial value, high at a GTCCRB compare match, and low at the cycle end.

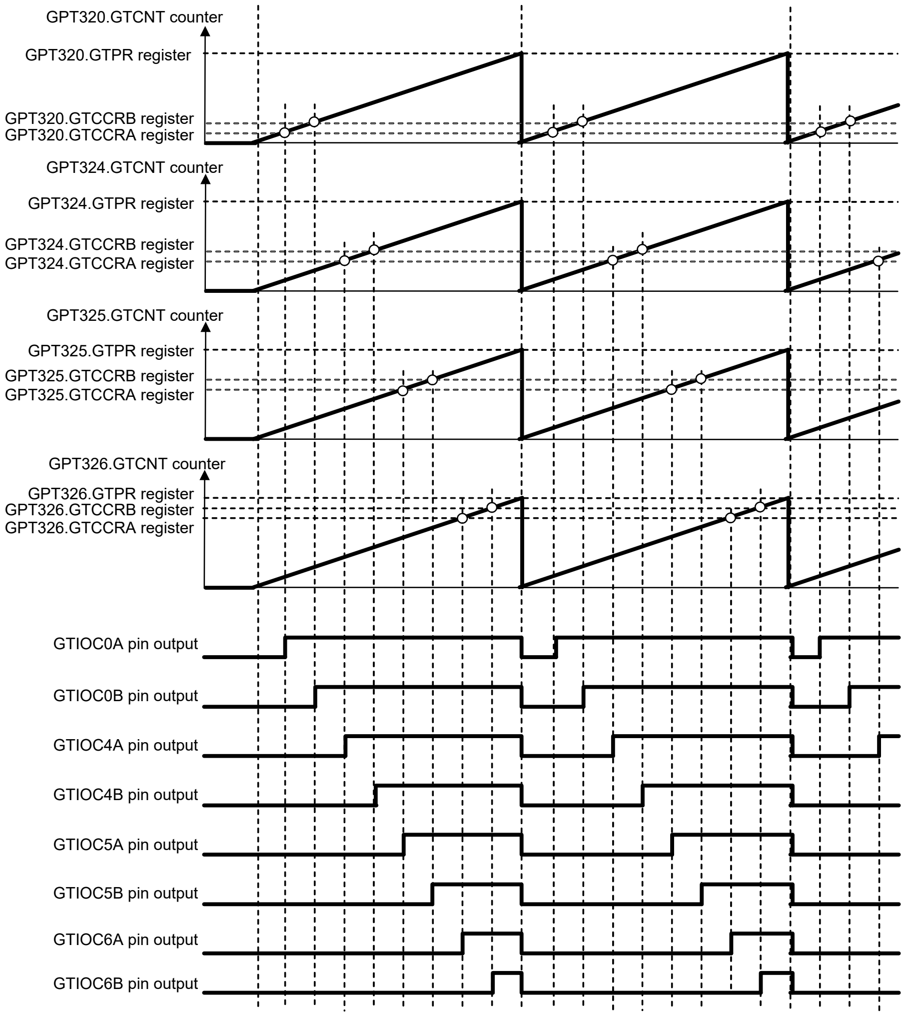

Figure 22.101 Example of synchronized PWM output

(2) 3-phase saw-wave complementary PWM output

Figure 22.102 shows an example in which three channels perform synchronized operation in saw-wave PWM mode 1 and 3-phase complementary PWM waveforms are output. The GTIOCnA pin is set so that it outputs low as the initial value, high at a GTCCRA compare match, and low at the cycle end. The GTIOCnB pin is set so that it outputs high as the initial value, low at a GTCCRB compare match, and high at the cycle end.

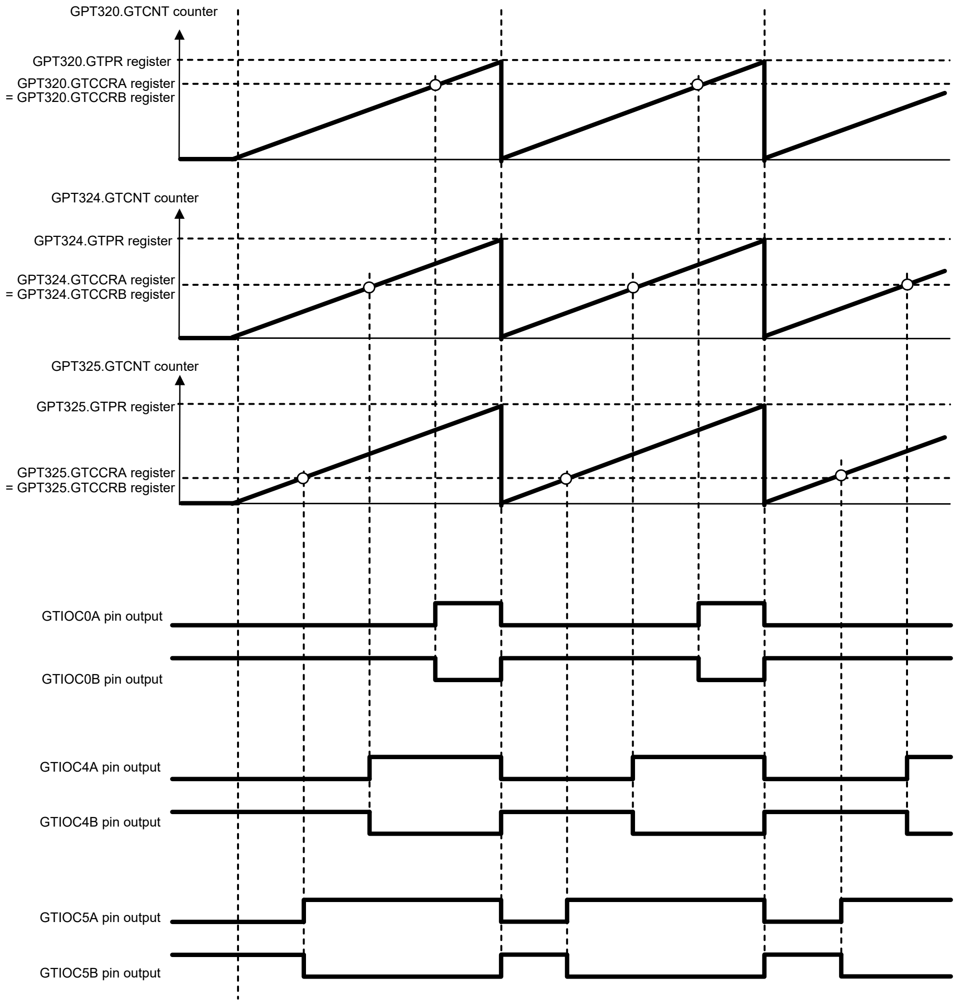

Figure 22.102 Example of 3-phase saw-wave complementary PWM output

(3) 3-phase saw-wave complementary PWM output with automatic dead time setting

Figure 22.103 shows an example in which three channels perform synchronized operation in saw-wave one-shot pulse mode with automatic dead time setting and 3-phase complementary PWM waveforms are output. The GTIOCnA pin is set so that it outputs low as the initial value, toggles the output at a GTCCRA compare match, and retains the output at the cycle end. The GTIOCnB pin is set so that it outputs high as the initial value, toggles the output at a GTIOCnB compare match, and retains the output at the cycle end.

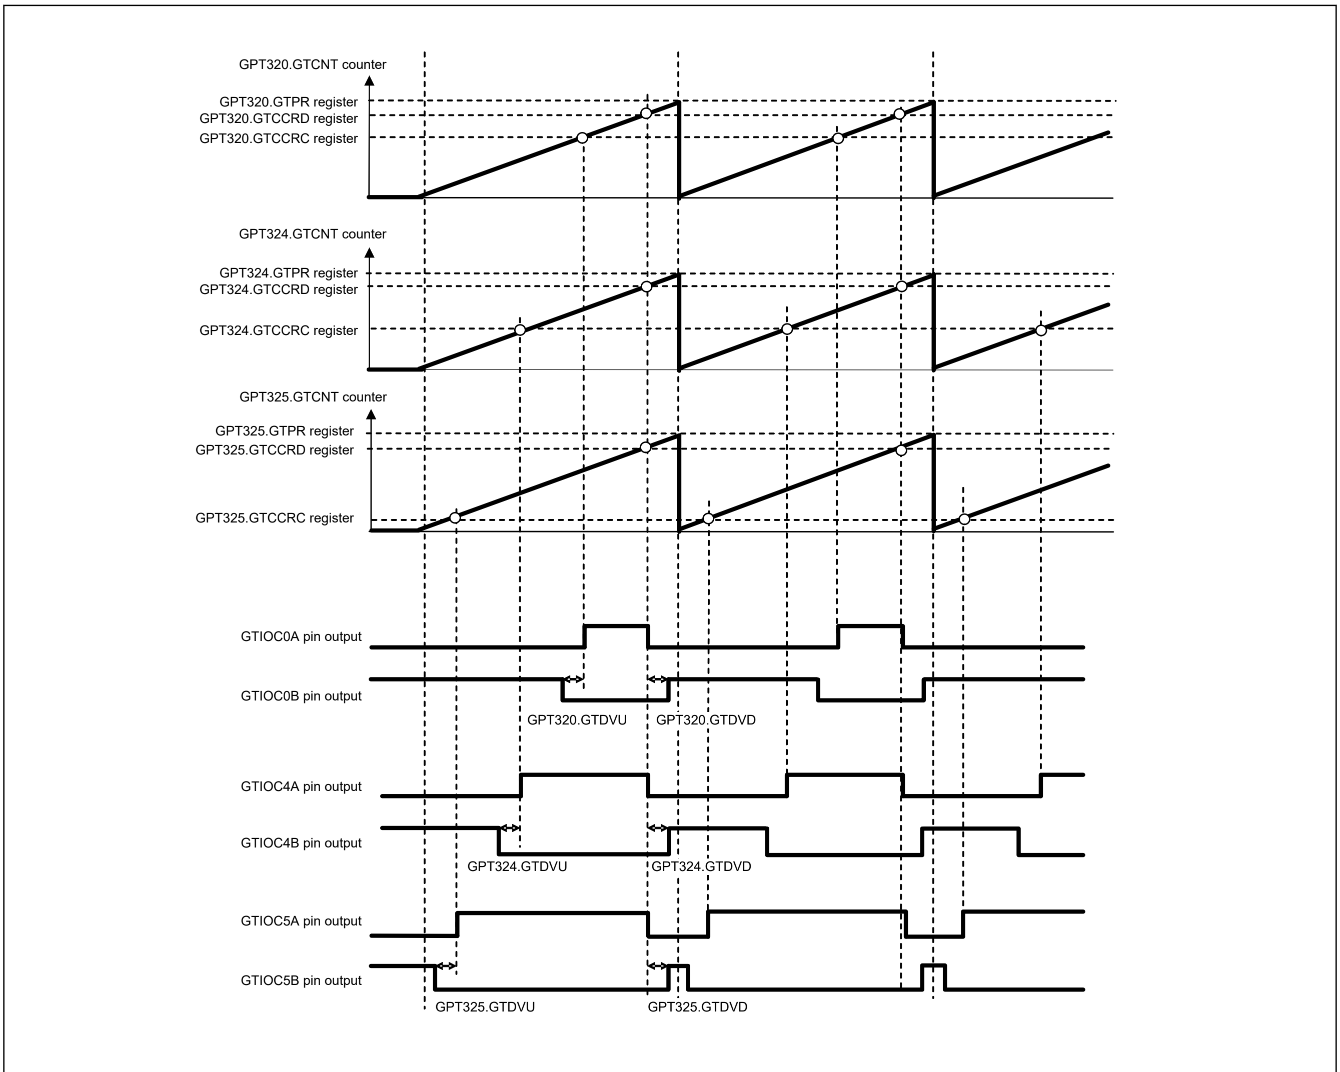

Figure 22.103 Example of 3-phase saw-wave complementary PWM output with automatic dead time setting

(4) 3-phase triangle-wave complementary PWM output

Figure 22.104 shows an example in which three channels perform synchronized operation in triangle-wave PWM mode 1 and 3-phase complementary PWM waveforms are output. The GTIOCnA pin is set so that it outputs low as the initial value, toggles the output at a GTCCRA compare match, and retains the output at the cycle end. The GTIOCnB pin is set so that it outputs high as the initial value, toggles the output at a GTCCRB compare match, and retains the output at the cycle end.

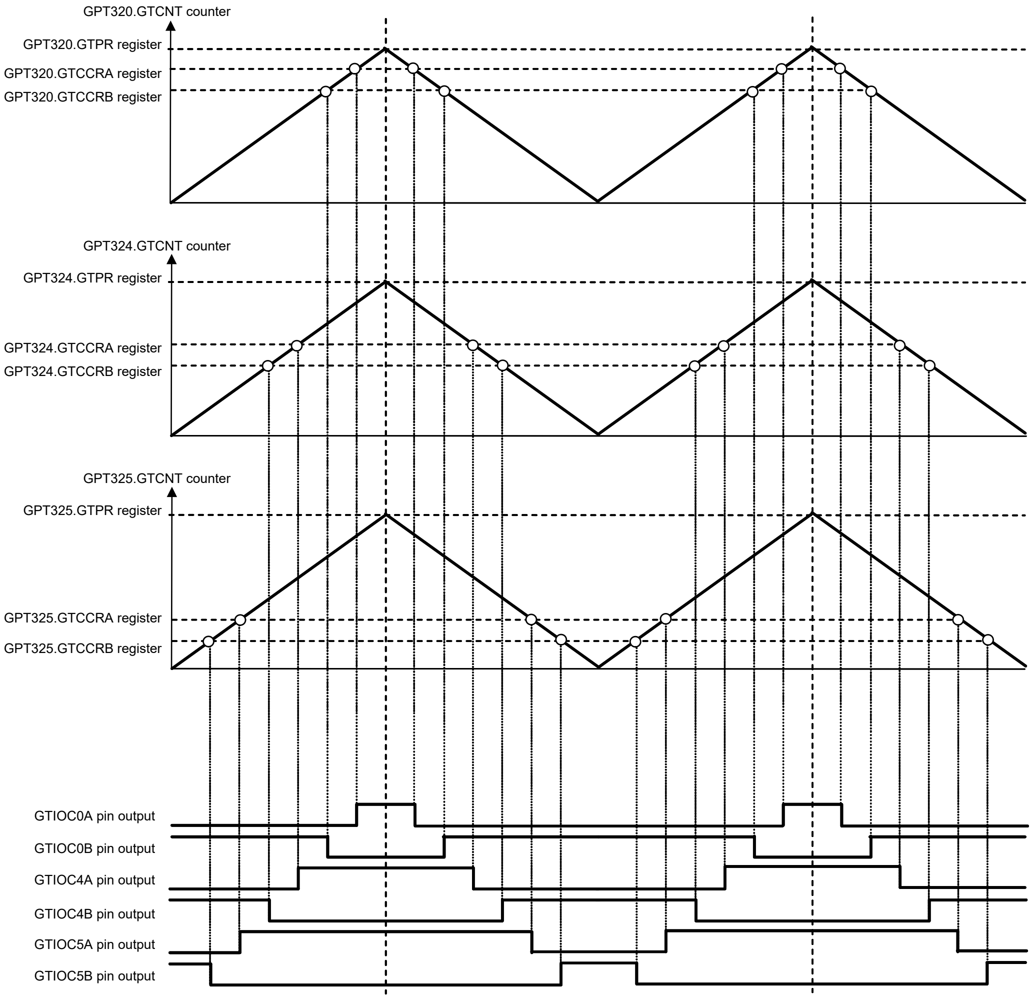

Figure 22.104 Example of 3-phase triangle-wave complementary PWM output

(5) 3-phase triangle-wave complementary PWM output with automatic dead time setting

Figure 22.105 shows an example in which three channels perform synchronized operation in triangle-wave PWM mode 1 with automatic dead time setting and 3-phase complementary PWM waveforms are output. The GTIOCnA pin is set so that it outputs low as the initial value, toggles the output at a GTCCRA compare match, and retains the output at the cycle end. The GTIOCnB pin is set so that it outputs high as the initial value, toggles the output at a GTCCRB compare match, and retains the output at the cycle end.

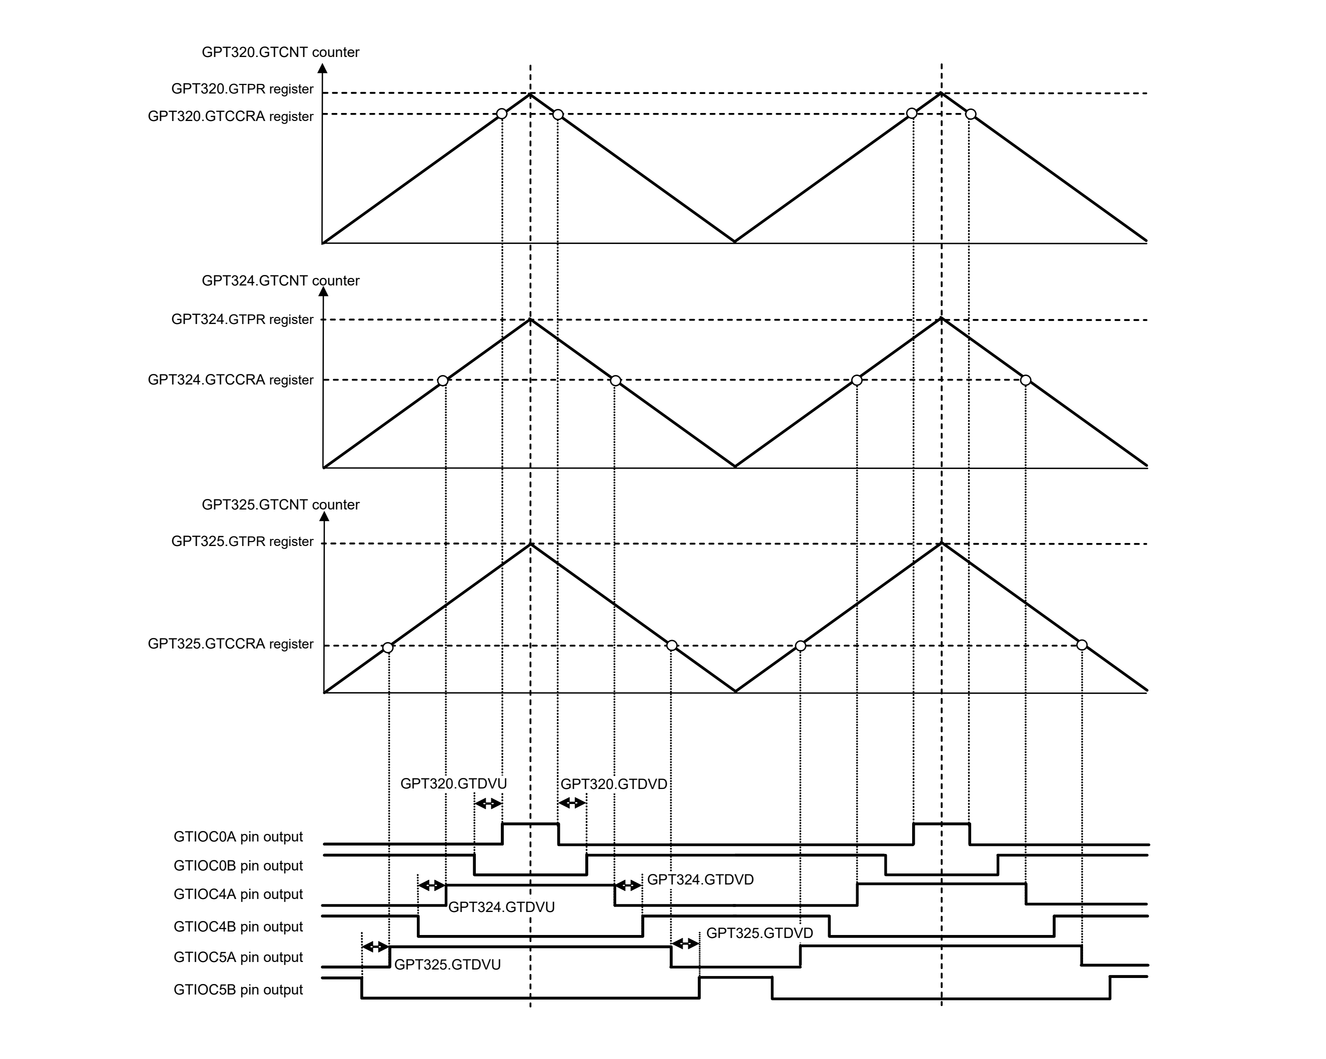

Figure 22.105 Example of 3-phase triangle-wave complementary PWM output with automatic dead time setting

(6) 3-phase asymmetric triangle-wave complementary PWM output with automatic dead time setting

Figure 22.106 shows an example in which three channels perform synchronized operation in triangle-wave PWM mode 3 with automatic dead time setting and 3-phase complementary PWM waveforms are output. The GTIOCnA is set so that it outputs low as the initial value, toggles the output at a GTCCRA compare match, and retains the output at the cycle end. The GTIOCnB is set so that it outputs high as the initial value, toggles the output at a GTCCRB compare match, and retains the output at the cycle end.

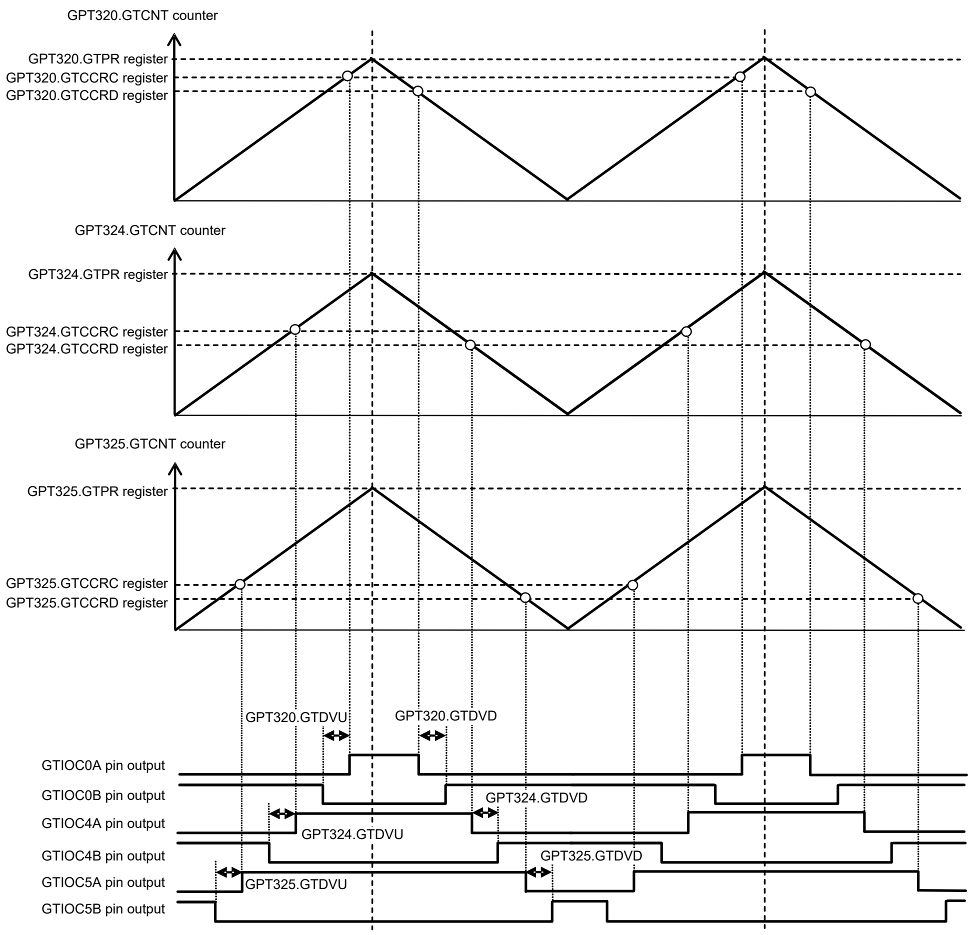

Figure 22.106 Example of 3-phase asymmetric triangle-wave complementary PWM output with automatic dead time setting

22.3.10 Period Count Function

By setting the GTPC register, the end of period can be counted.

The number of period to be counted should be set into the GTPC.PCNT counter when the GTPC.PCEN bit is 0. When the PCEN bit is 1, the PCNT counter can be read, but writing is disabled. When the PCEN bit is 1, down-counting is performed at the end of period. When the PCNT counter is 1 at the end of period, it becomes 0 and counting is stopped to finish the period count function. At that time, the GTST.PCF flag is set, and the period count function finish interrupt request GPTn_PC is generated. When the GTPC.ASTP bit is 1, the GTCNT counter is also stopped at the same time that the period count function is finished.

When the GTCNT counter is stopped while period count function is enabled, the PCNT counter keeps its value. When the GTCNT counter restarts counting and the PCEN bit is 1, the PCNT counter restarts down-counting from the hold value.

When the PCEN bit is changed from 0 to 1 while the PCNT counter is 0 and the ASTP bit is 1, the GTCNT counter is stopped at the count clock immediately after that.

When either GTSECR.SPCE bit or GTSECR.SPCD bit is set to 1, the PCEN bit in the channels set to 1 by the GTSECSR register is simultaneously set the value to enable or disable the period count function for multiple channels.

Figure 22.107 and Figure 22.108 show examples of PWM cycle count function.

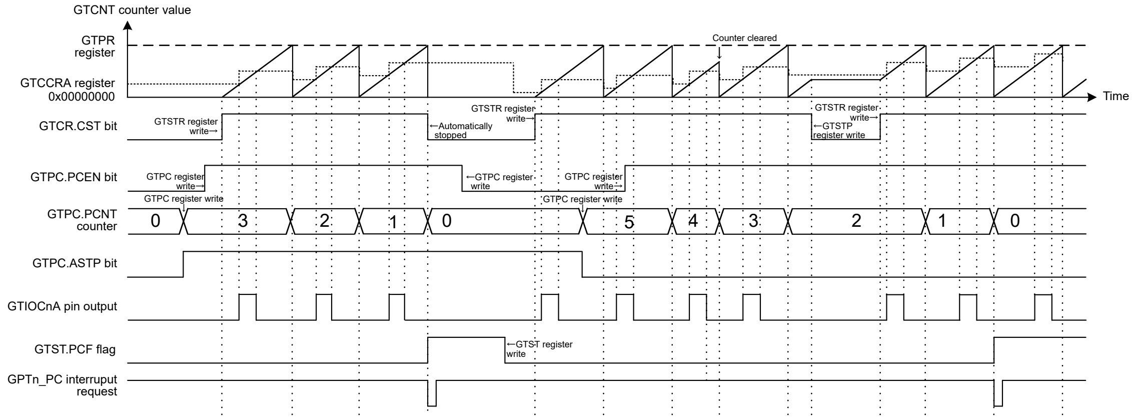

Figure 22.107 Example of PWM cycle count function (saw-wave one-shot pulse mode)

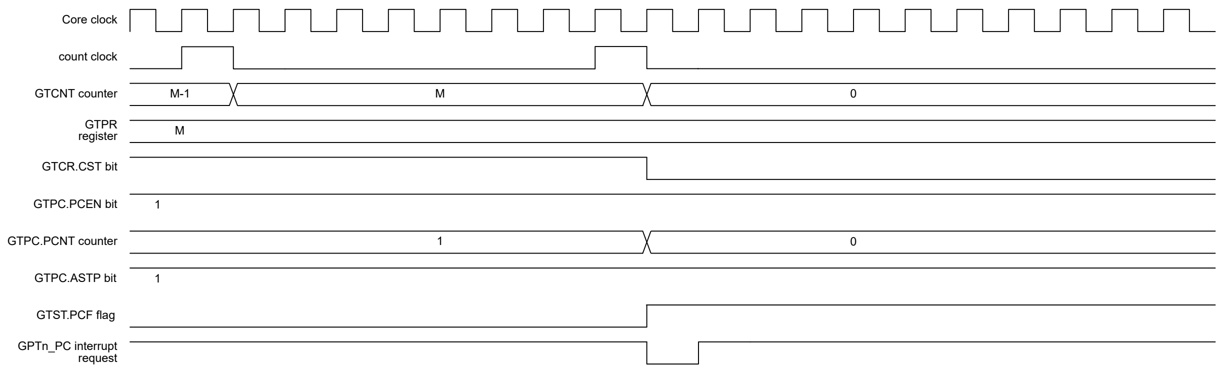

Note: Core clock: GTCLK

Figure 22.108 Example of the timing of operations for PWM cycle count function (saw-wave one-shot pulse mode, up-counting)

22.3.11 Phase Counting Function

The phase difference between the GTIOCnA and GTIOCnB pin (n = 0 to 13) inputs is detected and the associated GTCNT counts up or counts down. The detectable phase difference is available in any combination with the relationship between the edge and the level of GTIOCnA and GTIOCnB pin inputs being set in the GTUPSR and GTDNSR registers. For details on count operation, see section 22.3.1.1. Counter Operation.

Figure 22.109 to Figure 22.118 show an example of phase counting modes 1 to 5 operation when the GTIOCnA, GTIOCnB pins are used. Table 22.54 to Table 22.63 show conditions of up-counting or down-counting and list settings for the GTUPSR and GTDNSR registers which is corresponding to Figure 22.109 to Figure 22.118.

22.3.12 External Pulse Width Measuring Function

The pulse width of GTIOCnA pin input (n = 0 to 3), GTIOCnB pin input, and GTETRGA / GTETRGB / GTETRGC / GTETRGD pin inputs can be measured.

The setting to enable or disable count-up of the GTCNT counter and the input pin and level which measured pulse width are selected by the USILVL[3:0] bits of the GTUPSR register.

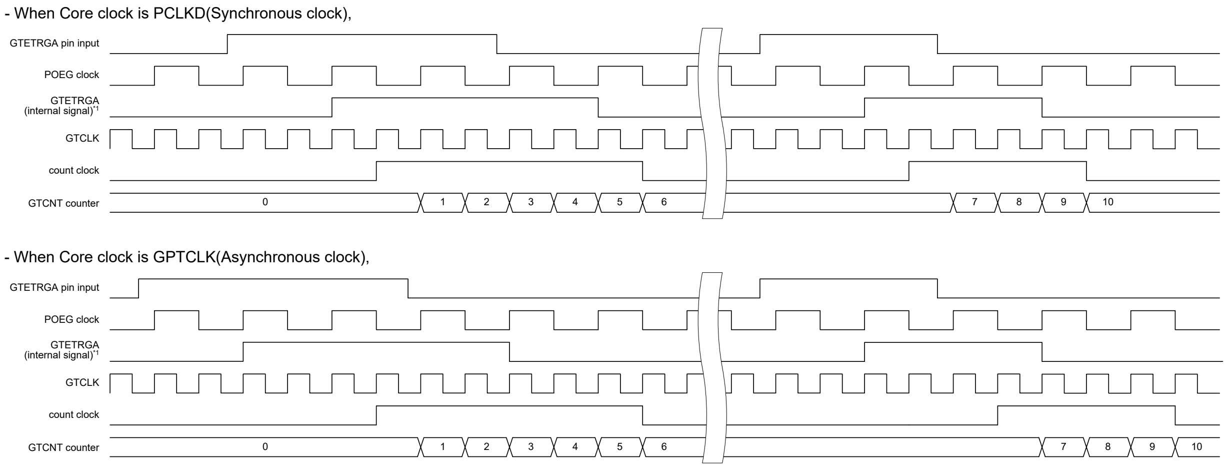
The setting to enable or disable count-down of the GTCNT counter and the input pin and level which measured pulse width are selected by the DSILVL[3:0] bits of the GTDNSR register.

The setting to enable both count-up and count-down of the GTCNT counter at the same time is prohibited.

The counting operation performs periodic counting with the period of the GTPR register.

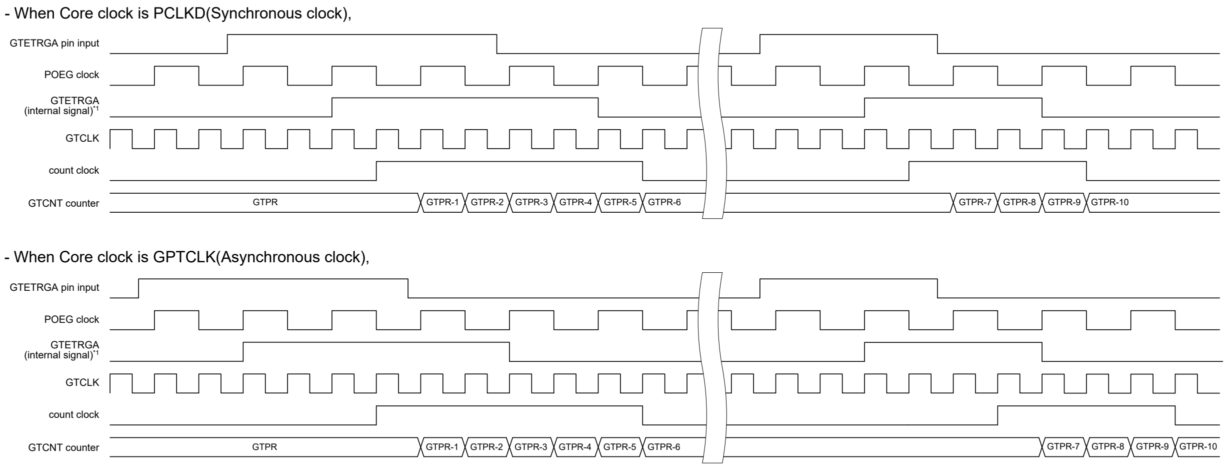
If the phase counting function and the pulse width measuring function are enabled at the same time, the pulse width measuring function does not work and the phase counting function works.

Figure 22.119, Figure 22.120 show examples of external pulse width measuring function and Table 22.64 shows example for setting external pulse width measuring function.



Note: POEG clock: PCLKB
Note 1. The input signal to GPT when the digital noise filter of GTETRGA pin is not used in POEG is shown.

Figure 22.119 Example of External pulse width measuring function(Up-counting)



Note: POEG clock: PCLKB
Note 1. The input signal to GPT when the digital noise filter of GTETRGA pin is not used in POEG is shown.

Figure 22.120 Example of External pulse width measuring function(Down-counting)

Table 22.64 Example for Setting External pulse width measuring function

No.	Step Name	Description
1	Set external pulse width measuring function	Enable external pulse width measuring function with the GTUPSR.USILVL[3:0] bits for up-counting operation and the GTDNSR.DSILVL[3:0] bits for down-counting operation and select the input pin and level to measure. In Figure 22.119, GTUPSR.USILVL[3:0] = 1001b (count up when GTETRGA pin is 1), In Figure 22.120, GTDNSR.DSILVL[3:0] = 1001b (count down when GTETRGA pin is 1)
2	Select count clock	Select the count clock with GTCR.TPCS[3:0] bits of the corresponding channel.
3	Set cycle	Set the cycle in GTPR of the corresponding channel.
4	Set initial value for counter	Set the initial value in the GTCNT counter of the corresponding channel. In Figure 22.119, 0000 0000h is set. In Figure 22.120, the GTPR register value is set.
5	Start count operation	Input a pulse to the input pin to be measured to start count operation.

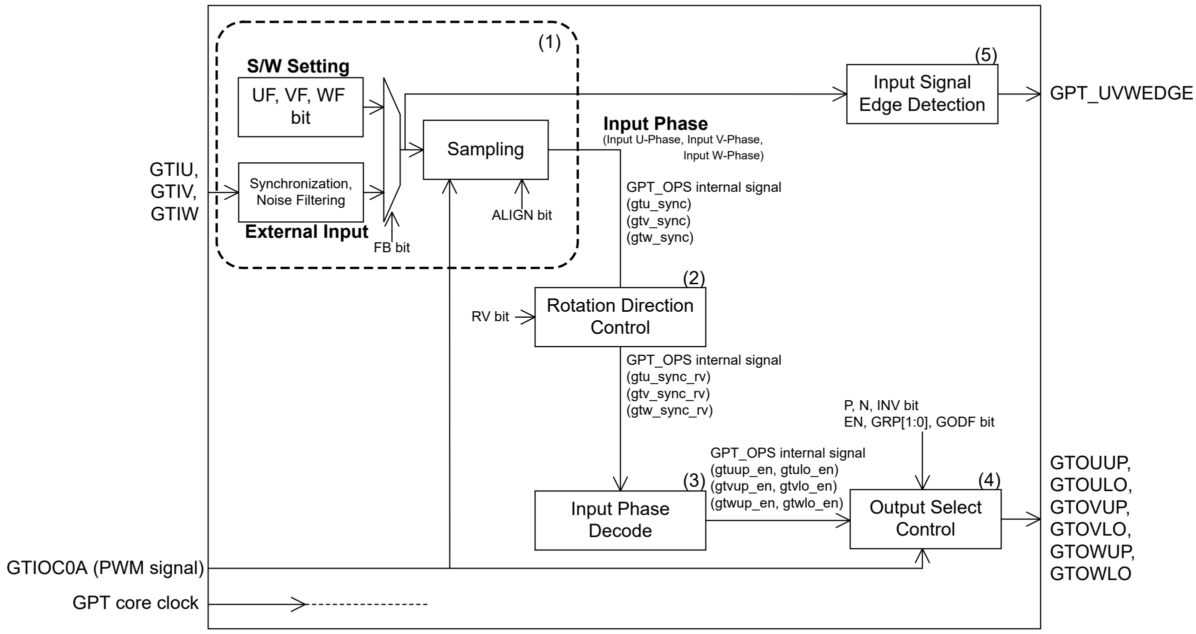
22.3.13 Output Phase Switching (GPT_OPS)

GPT_OPS can easily control Brushless DC motor using Output Phase Switching Control Register (OPSCR).

GPT_OPS uses S/W setting value (OPSCR.UF, VF, WF bits) or external signals detected by the Hall element as input signals. GPT_OPS outputs either level signals or chopped signals by GPT320's PWM as the 6-phase (U-positive phase / negative phase, V-positive phase / negative phase, W-positive phase / negative phase) signals to control motor.

Figure 22.121 shows the block diagram of GPT_OPS.

The GPT_UVWEDGE signal is output signal to ELC generated by detecting the edge of input signal.



Note: GPT core clock: GTCLK (PCLKD or GPTCLK)

Figure 22.121 GPT_OPS Block Diagram

Figure 22.122 and Figure 22.123 show examples of GPT_OPS level output operation.

Figure 22.126 Example of GPT_OPS Output Disable Control Operation

22.3.13.1 Input Selection and Sampling

The FB bit selects either the software setting value or external input for the input signal.

When the FB bit is 0, the GTIU, GTIV, GTIW external input are selected for the input signal to GPT_OPS after synchronization with the GPT core clock (GTCLK) and noise filtering.

When the FB bit is 1, the software setting value (UF, VF, WF bits) are selected for the input signal to GPT_OPS.

The selected input signals are sampled by the method selected by the ALIGN bit, and they are treated as input phase of GPT_OPS.

When the ALIGN bit is 0, the input signals are sampled by GTCLK.

When the ALIGN bit is 1, the input signals are sampled by the falling edge of GTIOC0A pin output.

The signals after sampling can be read by the U, V, W bits.

Table 22.65 shows the input selection by the FB bit and sampling method by the ALIGN bit.

Table 22.65 Input Selection and Sampling Method

OPSCR Register		Input Selection Sampling Method	Input Phase (GPT_OPS internal signal)
FB bit	ALIGN bit		
0	0	GTIU, GTIV, GTIW external input GTCLK sampling	Input U-phase (gtu_sync) Input V-phase (gtv_sync) Input W-phase (gtw_sync)
	1	GTIU, GTIV, GTIW external input GTIOC0A falling edge sampling	
1	0	Software setting value UF, VF, WF bits GTCLK sampling	
	1	Software setting value UF, VF, WF bits GTIOC0A falling edge sampling	

22.3.13.2 Rotation Direction Control

When the rotation direction is reverse (RV bit = 1), the input phase is inverted.

22.3.13.3 Input Phase Decode

The 6-phase signals by decoding input phase after rotation direction control are generated.

Table 22.66 and Table 22.67 show the decode tables of input phase to rotate motor in forward (RV = 0) and reverse (RV = 1).

Table 22.66 The Decode Table of Input Phase (Forward Rotation)

	Input Phase			Input Phase after Rotation Direction Control			6-Phase Signals					
	U Phase	V Phase	W Phase	U Phase	V Phase	W Phase	U Positive Phase	U Negative Phase	V Positive Phase	V Negative Phase	W Positive Phase	W Negative Phase

	1	1	0	0	0	1	0	0	0	1	1	0
	0	1	0	1	0	1	1	0	0	1	0	0
	0	1	1	1	0	0	1	0	0	0	0	1
	0	0	1	1	1	0	0	0	1	0	0	1
	0	0	0	0	0	0	0	0	0	0	0	0
	1	1	1	1	1	1	0	0	0	0	0	0

22.3.13.4 Output Selection Control

The EN, P, N, INV bits select the output wave.

The EN bit enables output of the 6-phase output. When the EN bit is 1, output of the 6-phase output is enabled. When the EN bit is 0, the external pin output is Hi-Z.

The P, N bits select whether chopping positive and negative phase are performed or not. When P, N bits are 1, chopping is performed by GTIOC0A pin output.

When the chopping is performed, there are cases where the PWM width of output is shorter than the width of the PWM used to chop just before or after switching of output phase, depending on the phase difference between the phase output switch timing and the phase of PWM.

The INV bit selects the polarity (either positive logic or negative logic) of phase output.

Table 22.68 and Table 22.69, show the output selection control method for positive and negative phase output.

Table 22.68 Output Selection Control Method (Positive Phase)

EN bit	P bit	INV bit	GTOUUP / GTOVUP / GTOWUP
0	x	x	0 (External pin output is Hi-Z)
1	0	0	Positive logic level output (gtuup_en) (gtvup_en) (gtwup_en)
1	0	1	Negative logic level output (~gtuup_en) (~gtvup_en) (~gtwup_en)
1	1	0	Positive logic chopped output (GTIOC0A & gtuup_en) (GTIOC0A & gtvup_en) (GTIOC0A & gtwup_en)
1	1	1	Negative logic chopped output (~(GTIOC0A & gtuup_en)) (~(GTIOC0A & gtvup_en)) (~(GTIOC0A & gtwup_en))

Table 22.69 Output Selection Control Method (Negative Phase)

EN bit	N bit	INV bit	GTOULO / GTOVLO / GTOWLO
0	x	x	0 (External pin output is Hi-Z)
1	0	0	Positive logic level output (gtulo_en) (gtvlo_en) (gtwlo_en)
1	0	1	Negative logic level output (~gtulo_en) (~gtvlo_en) (~gtwlo_en)
1	1	0	Positive logic chopped output (GTIOC0A & gtulo_en) (GTIOC0A & gtvlo_en) (GTIOC0A & gtwlo_en)
1	1	1	Negative logic chopped output (~(GTIOC0A & gtulo_en)) (~(GTIOC0A & gtvlo_en)) (~(GTIOC0A & gtwlo_en))

22.3.13.5 Output Selection Control (Group Output Disable Function)

When GODF = 1 and signal value selected by the GRP bit is Hi (Output Disable Request), GPT_OPS's output pins are changed to Hi-Z asynchronously and the OPSCR.EN bit is cleared to 0 by the output disable request signal synchronized with GTCLK.

For the return, after clearing the Output Disable Request by software, set the EN bit to 1.

The timing of EN bit cleared to 0 is 3 GTCLK cycles after generating the output disable request. In order to perform the output disable control surely, the output disable request flag in POEG should be cleared in the timing that terminating the output disable request is at least 4 GTCLK cycles after generating the output disable request.

The example of the operation of the group output disable control, see the above-mentioned Figure 22.126.

22.3.13.6 Event Link Controller (ELC) Output

The logical sum of the pulse detected by rising and falling edge of U, V, W phase input is output to the event link controller (ELC). When the high level period of input phase is short, there are cases that the detected edge is not transmitted to the ELC correctly because of the logical sum.

22.3.13.7 GPT_OPS Start Operation Setting Flow

Table 22.70 Example for Setting of GPT_OPS Start Operation

No.	Step Name	Description
1	Set Operation Mode of GPT320	Set the PWM output operation mode of GPT320. See section 22.3.3. PWM Output Operating Mode
2	Start Count Operation of GTP320	Start count operation of GPT320, and outputs PWM waveform.
3	Set GPT_OPS Input Condition	● When the soft setting is selected, set the soft setting values in the UF, VF, WF bits. ● When the external input is selected, if necessary, use noise filtering. Select the sampling clock for external input into NFCS[1:0] bits, and set NFEN bit to 1.
4	Select GPT_OPS Input phase and Alignment	Select input phase by FB bit. Select alignment of input phase by ALIGN bit.
5	Set GPT_OPS Output phase Condition	Set the rotation direction by RV bit. Select whether chopping is performed or not by P, N bits. Select the output polarity by INV bit.
6	Set GPT_OPS Output Disable Condition	Select the error group by GRP[1:0] bits Set ON/OFF of the group output disable function by GODF bit.
7	Set GPT_OPS Operation	Set EN bit to 1 to output the 6-phase output to drive the brushless DC motor.

22.3.14 Inter Channel Logical Operation Function

The logical operation function between compare match outputs can be performed.

Figure 22.127 shows the block diagram of inter channel logical operation.

To prevent hazard to the GPT output, the signal after logical operation is latched with GTCLK. After latching, the output disable control is performed.

When the logical operation function which causes the delay of 1 GTCLK is selected, the output enable signal is also delayed with 1 GTCLK and input to the output disable control.

When the same signal (C = A or D = B) to operate logical function AND, OR, EXOR and NOR is selected, C or D is treated as 1. In the case of GTIOCnA pin output, when A of same channel is selected for C, the result of AND is A, the result of OR is 1, the result of EXOR is NOT A, and the result of NOR is 0.

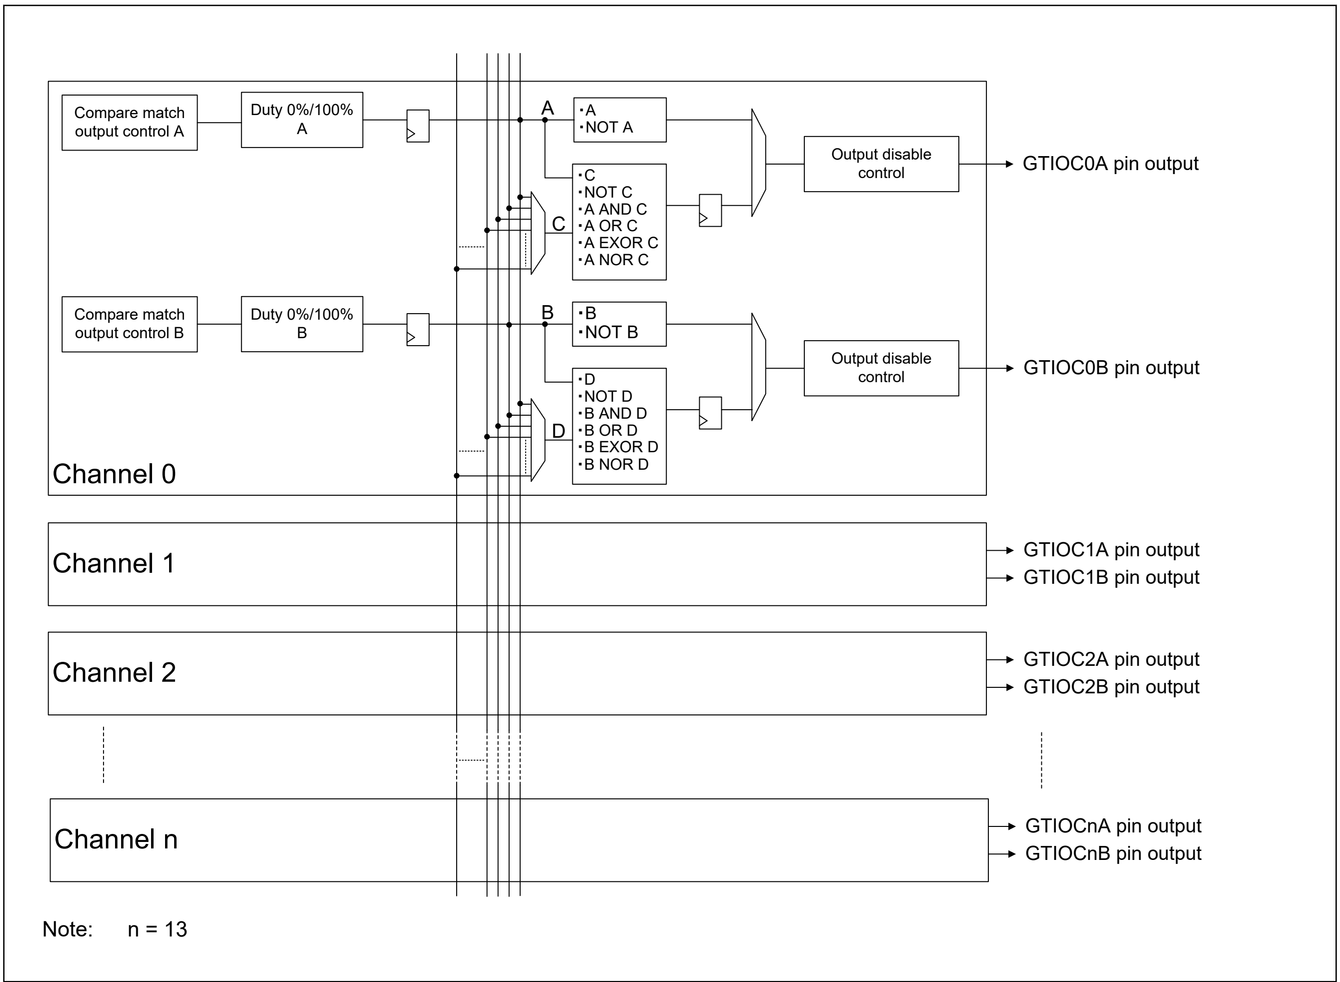

Figure 22.127 Block Diagram of Inter Channel Logical Operation

Figure 22.128 shows an example of inter channel logical operation.

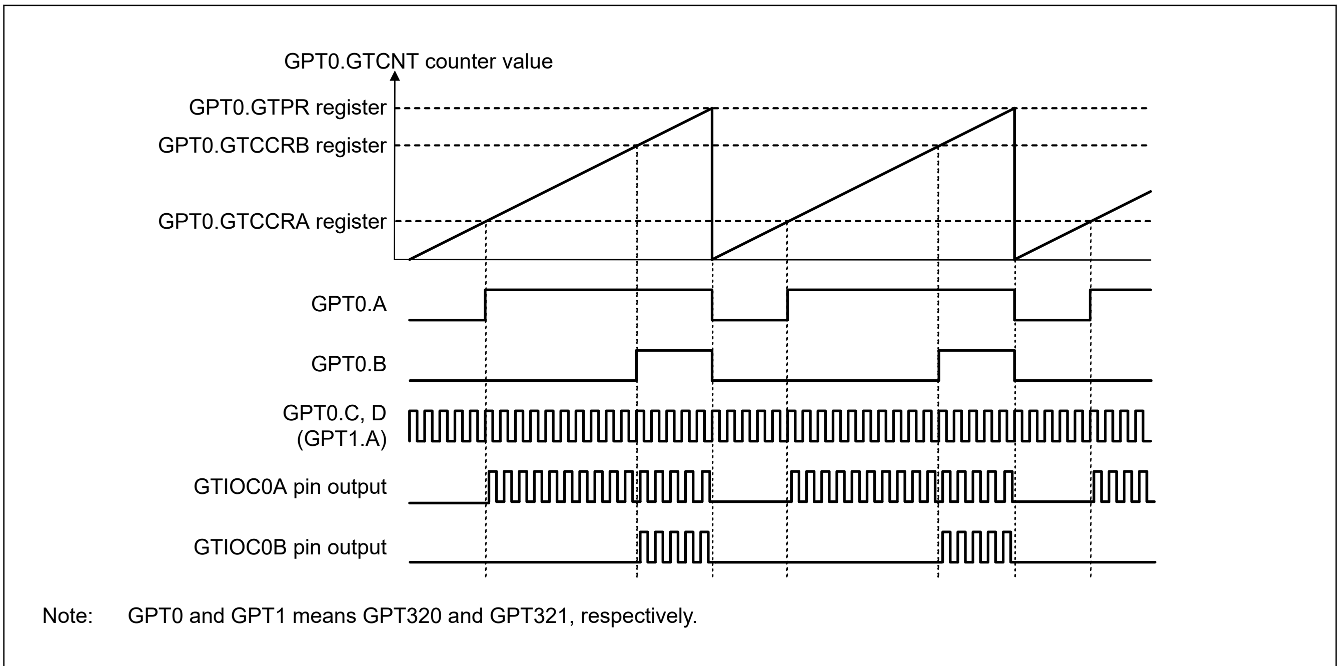

Figure 22.128 Example of Inter Channel Logical Operation

22.3.15 GTIOCnA/B Input/Output Pin Polarity Reversal Function

The polarity of the GTIOCnA, GTIOCnB input pins and the GTIOCnA, GTIOCnB output pins can be inverted according to the polarity of the external device.

When GTCR.AINV is "1", the input and output of GTIOCnA are inverted. When GTCR.BINV is "1", the input and output of GTIOCnB are inverted.

GTIOCnA and GTIOCnB are inverted at the final output stage immediately after input. When GTIOCnA and GTIOCnB are used as count start/stop/clear factors, countdown/up factors, and input capture factors, or when low/high/toggle output is used as PWM output, external input and external output are reversed. It is necessary to make settings that take this into consideration.

Set GTCR.AINV and BINV after setting the GTIOCnm pin functions during initial settings.

22.4 Interrupt Sources

22.4.1 Interrupt Sources

The GPT provides the following interrupt sources:

- GTCCR input capture/compare match
- GTADTR compare match
- GTCNT counter overflow (GTPR compare match)/underflow.
- period count function finish

Each interrupt source has its own status flag. When an interrupt source signal is generated, the associated status flag in GTST is set to 1, and an interrupt request is generated. The associated status flag in GTST can be cleared by writing 0. If flag set and flag clear occur at the same time, flag clear takes priority over flag set. These flags are automatically updated by the internal state. The Interrupt Controller Unit can change the relative channel priorities. However, the priority within a channel is fixed. For details, see section 14, Interrupt Controller Unit (ICU).

Table 22.71 lists the GPT interrupt sources.

Table 22.71 Interrupt sources

Channel	Name	Interrupt source	Interrupt flag	DTC activation
n = 0 to 13	GPTn_CCMPA	GPT32n.GTCCRA input capture/compare match	GTST[0] (TCFA)	Possible
	GPTn_CCMPB	GPT32n.GTCCRB input capture/compare match	GTST[1] (TCFB)	Possible
	GPTn_CMPC	GPT32n.GTCCRC compare match	GTST[2] (TCFC)	Possible
	GPTn_CMPD	GPT32n.GTCCRD compare match	GTST[3] (TCFD)	Possible
	GPTn_CMPE	GPT32n.GTCCRE compare match	GTST[4] (TCFE)	Possible
	GPTn_CMPF	GPT32n.GTCCRF compare match	GTST[5] (TCFF)	Possible
	GPTn_OVF	GPT32n.GTCNT overflow (GPT32n.GTPR compare match)	GTST[6] (TCFPO)	Possible
	GPTn_UDF	GPT32n.GTCNT underflow	GTST[7] (TCFPU)	Possible
	GPTn_PC	Period count function finish (n = 0 to 3, 10 to 13)	GTST[31] (PCF)	Possible

(1) GPTn_CCMPA interrupt (n = 0 to 13)

An interrupt request is generated under the following conditions:

- When the GTCCRA register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, the GTCNT counter value of master channel) matches with the GTCCRA register
- When the GTCCRA register functions as an input capture register, the input-capture signal causes transfer of the GTCNT counter value to the GTCCRA register. In complementary PWM mode, GTCCRA register does not function as an input capture register.

(2) GPTn_CCMPB interrupt (n = 0 to 13)

An interrupt request is generated under the following conditions:

- When the GTCCRB register functions as a compare match register, the GTCNT counter value matches with the GTCCRB register. In complementary PWM mode, GTCCRB register does not function as a compare match register.
- When the GTCCRB register functions as an input capture register, the input-capture signal causes transfer of the GTCNT counter value to the GTCCRB register. In complementary PWM mode, GTCCRB register does not function as an input capture register.

(3) GPTn_CMPC interrupt (n = 0 to 13)

An interrupt request is generated under the following condition:

- When the GTCCRC register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, GTCNT counter value of master channel) matches with the GTCCRC register.

A compare match is not performed and therefore, an interrupt is not requested in the following conditions:

- GTCR.MD[3:0] = 0001b (saw-wave one-shot pulse mode)
- GTCR.MD[3:0] = 0110b (triangle-wave PWM mode 3)
- GTBER.CCRA[1:0] = 01b, 10b, 11b (buffer operation with the GTCCRC register).

(4) GPTn_CMPD interrupt (n = 0 to 13)

An interrupt request is generated under the following condition:

- When the GTCCRD register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, the GTCNT counter value of master channel) matches with the GTCCRD register.

A compare match is not performed and therefore, an interrupt is not requested in the following conditions:

- GTCR.MD[3:0] = 0001b (saw-wave one-shot pulse mode)
- GTCR.MD[3:0] = 0110b (triangle-wave PWM mode 3)
- GTBER.CCRA[1:0] = 10b, 11b (buffer operation with the GTCCRD register).

(5) GPTn_CMPE interrupt (n = 0 to 13)

An interrupt request is generated under the following condition:

- When the GTCCRE register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, the GTCNT counter value of master channel) matches with the GTCCRE register.

A compare match is not performed and therefore, an interrupt is not requested in the following conditions:

- GTCR.MD[3:0] = 0001b (saw-wave one-shot pulse mode)
- GTCR.MD[3:0] = 0110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] = 01b, 10b, 11b (buffer operation with the GTCCRE register).

(6) GPTn_CMPF interrupt (n = 0 to 13)

An interrupt request is generated under the following condition:

- When the GTCCRF register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, the GTCNT counter value of master channel) matches with the GTCCRF register.

A compare match is not performed and therefore, an interrupt is not requested in the following conditions:

- GTCR.MD[3:0] = 0001b (saw-wave one-shot pulse mode)
- GTCR.MD[3:0] = 0110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] = 10b, 11b (buffer operation with the GTCCRF register).

(7) GPTn_OVF interrupt (n = 0 to 13)

An interrupt request is generated in the following conditions:

- In saw-wave PWM mode 1 and saw-wave one-shot pulse mode, interrupt requests are enabled at overflows (when the GTCNT counter value changes from GTPR to 0 during up-counting)
- In saw-wave PWM mode 2, interrupt requests are enabled at overflows (GTCNT counter value changes from GTCCRm (m = A to F) register value selected with GTCSR.CSCMSC[2:0] bits to 0) or the time when GTCNT counter value matches GTPR register value.
- In triangle-wave mode, interrupt requests are enabled at crests (the GTCNT changes from GTPR to GTPR-1)
- In complementary PWM mode, interrupt requests are enabled at crests (GTCNT counter value of master channel changes from GTPR register value to GTPR register value minus 1).
- In counting by hardware sources (include external pulse width measuring function), an overflow (GTCNT changes from GTPR to 0 in up count) has occurred.

(8) GPTn_UDF interrupt (n = 0 to 13)

An interrupt request is generated in the following conditions.

- In saw-wave PWM mode 1 and saw-wave one-shot pulse mode, interrupt requests are enabled at underflows (when the GTCNT counter value changes from 0 to GTPR during down-counting)
- In triangle-wave mode, interrupt requests are enabled at troughs (the GTCNT changes from 0 to 1)
- In complementary PWM mode, interrupt requests are enabled at troughs (GTCNT counter value of master channel changes from 0 to 1).
- In counting by hardware sources (include external pulse width measuring function), underflow (GTCNT changes from 0 to GTPR in down count) has occurred.

About Interrupt signals and interrupt status flags, see section 22.2.16. GTST : General PWM Timer Status Register.

(9) GPTn_PC Interrupt (n = 0 to 3, 10 to 13)

When the GTPC.PCEN bit is 1 and the GTPC.PCNT counter is 1, an interrupt request is generated at the end of cycle.

22.4.2 DMAC and DTC Activation

The DMAC and DTC can be activated by the interrupt in each channel. For details, see section 14, Interrupt Controller Unit (ICU), section 17, DMA Controller (DMAC), and section 18, Data Transfer Controller (DTC).

22.4.3 Interrupt and A/D Conversion Start Request Skipping Function

22.4.3.1 Interrupt Skipping Function by GTITC Register

By setting the GTITC register, the GTCNT counter overflow (GTPR register compare match) interrupt (GPTn_OVF) and underflow interrupt (GPTn_UDF) can be skipped. Other interrupts and A/D conversion start request signals can be skipped in coordination with the GPTn_OVF/GPTn_UDF skipping function. When the interrupt is skipped, the updating of relevant status flag is also skipped. The interrupt skipping is continued even if the status flag is set to 1.

The interrupt skipping function is related only to the GTITC register setting, and is not related to setting of the GTINTAD register interrupt enable bit. The interrupt skipping is continued even if the interrupt is disabled with GTINTAD register setting.

When both troughs and crests are counted and skipped in triangle-wave mode, if the number of times of skipping is odd, GPTn_OVF/GPTn_UDF interrupt requests cannot be generated at troughs only or at crests only depending on the skipping counter start timing. Therefore, in order to count both troughs and crests and generate the GPTn_OVF/GPTn_UDF interrupts at troughs only or crests only in triangle-wave mode, the number of times of skipping should be even.

Similarly, in saw-wave mode, when both overflows and underflows are counted and skipped with the count direction changed, GPTn_OVF/GPTn_UDF interrupt requests are sometimes not generated at overflows only or at underflows only. Therefore, in order to count both overflows and underflows with the count direction changed and generate the GPTn_OVF/GPTn_UDF interrupts at overflows only or underflows only in saw-wave mode, the skipping state should be carefully checked before using.

When changing the skipping count, be sure to release the skipping count setting (GTITC.IVTC[1:0] bits = 00b).

Figure 22.129 to Figure 22.134 show examples of skipping function operation.

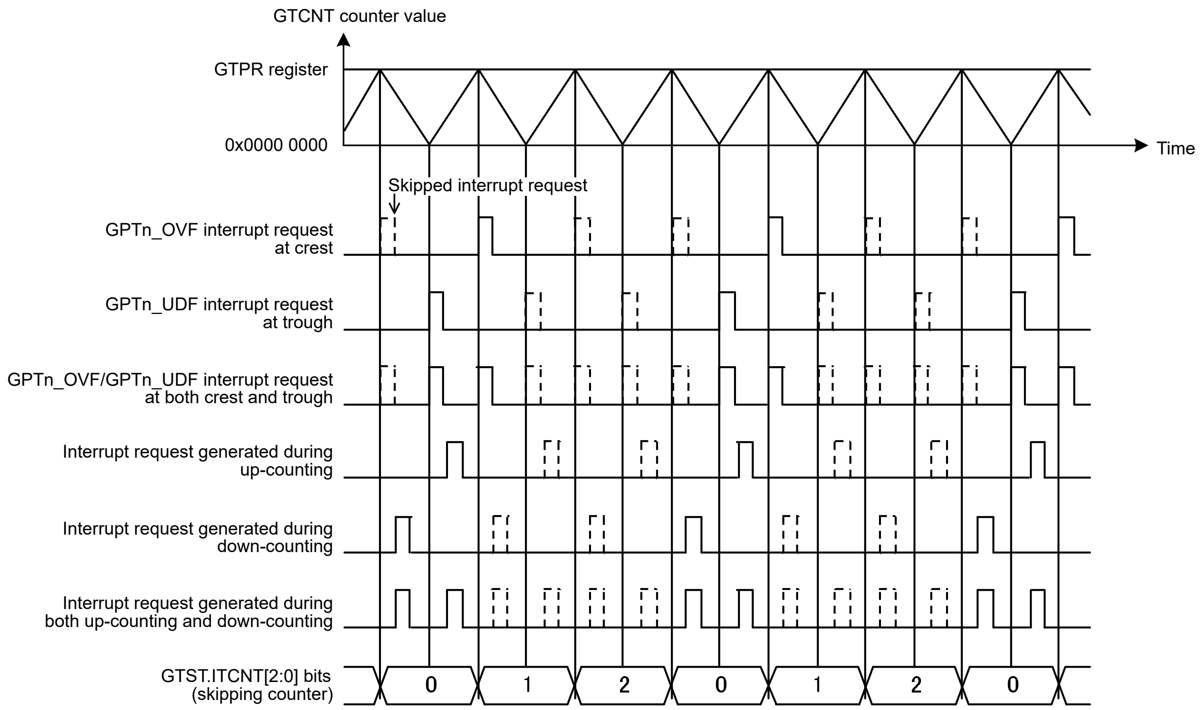

Figure 22.129 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Crests, Skipping Count: 2)

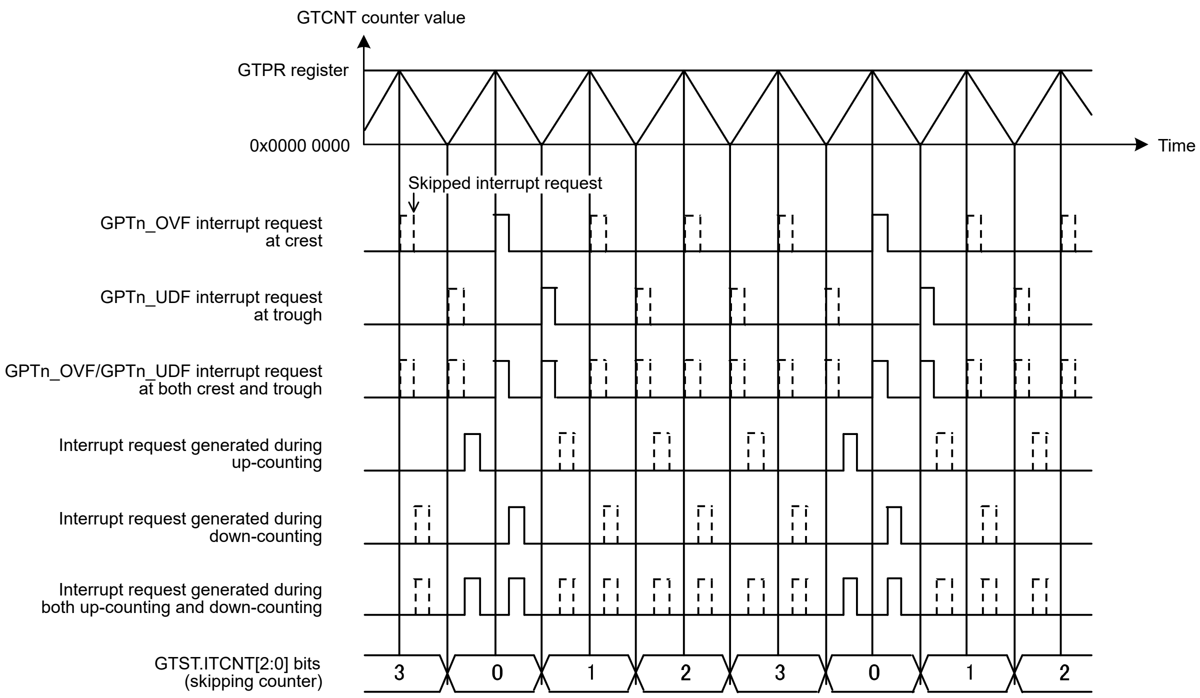

Figure 22.130 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Troughs, Skipping Count: 3)

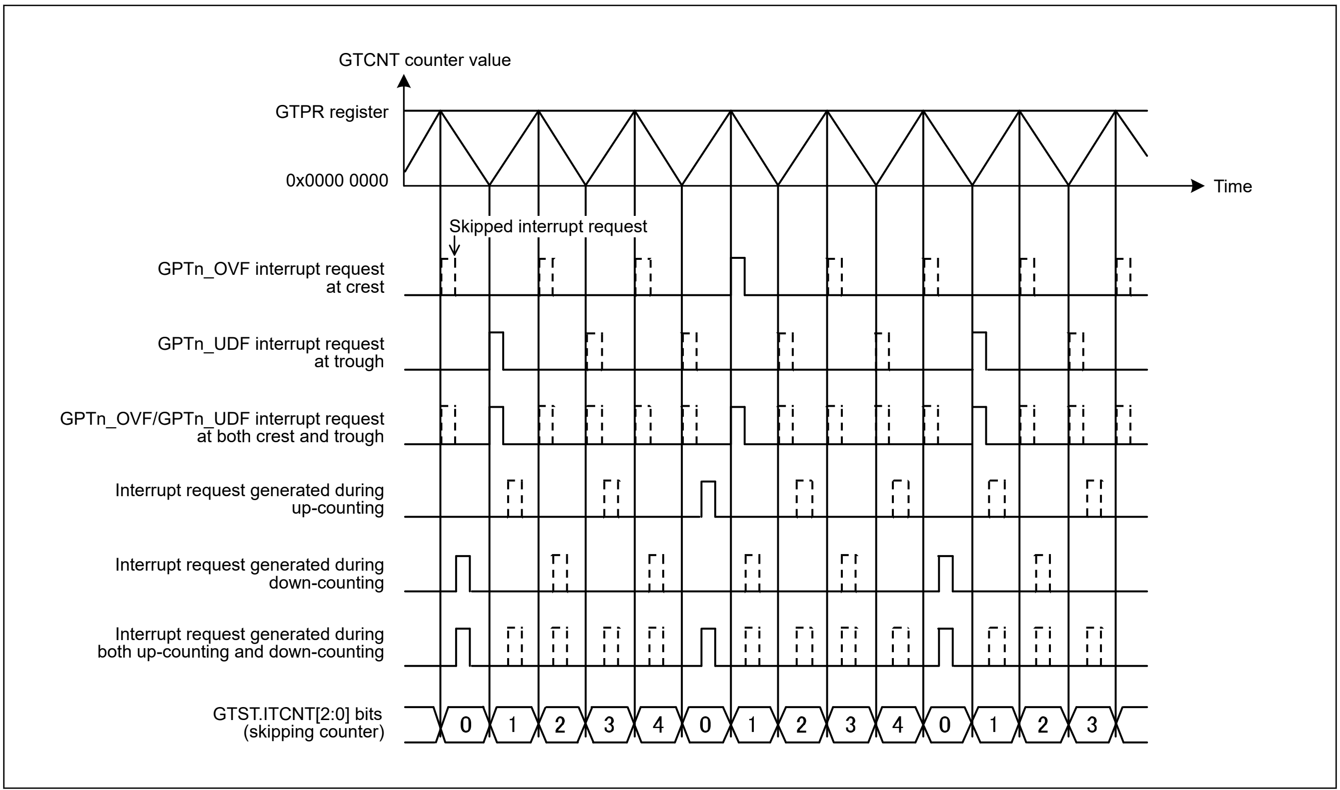

Figure 22.131 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Both Troughs and Crests, Skipping Count: 4)

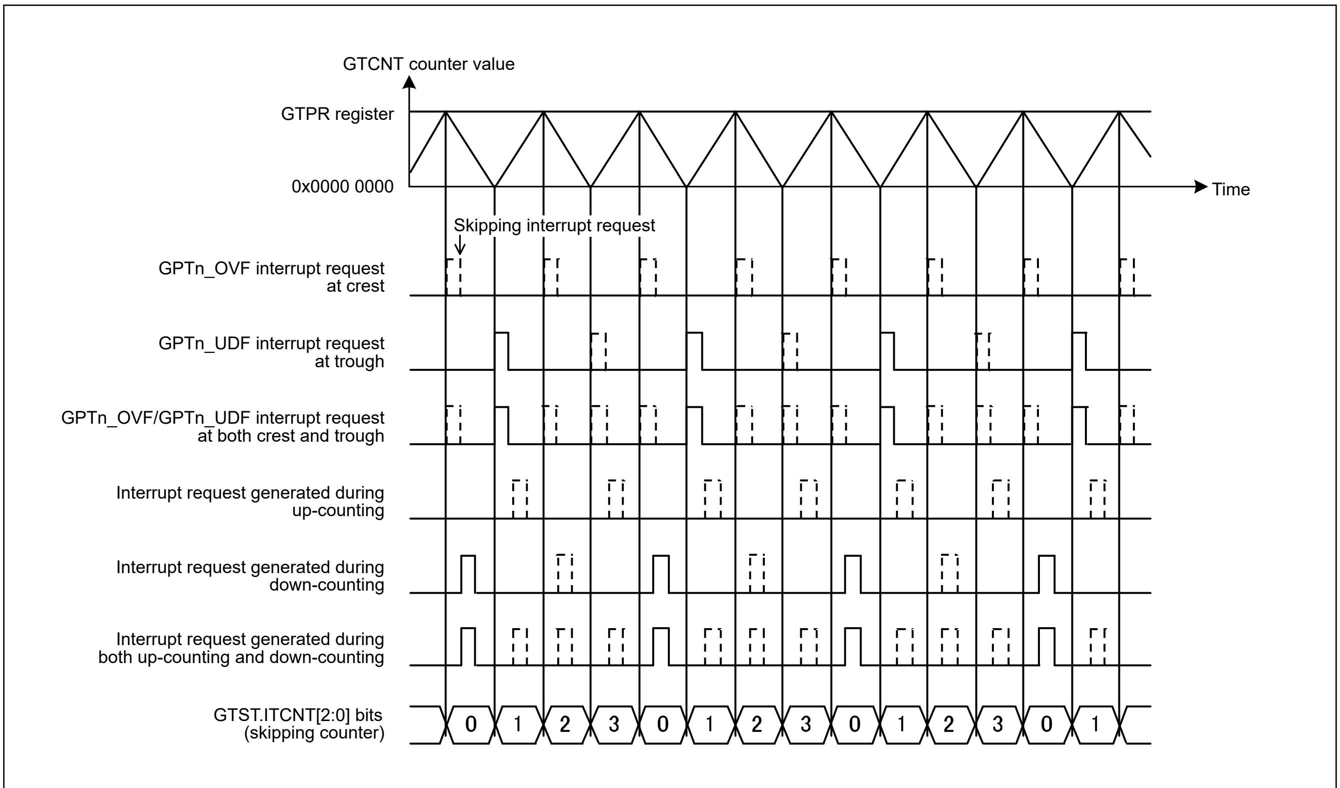

Figure 22.132 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Both Troughs and Crests, Skipping Count: 3, Skipping Started at Up-Counting)

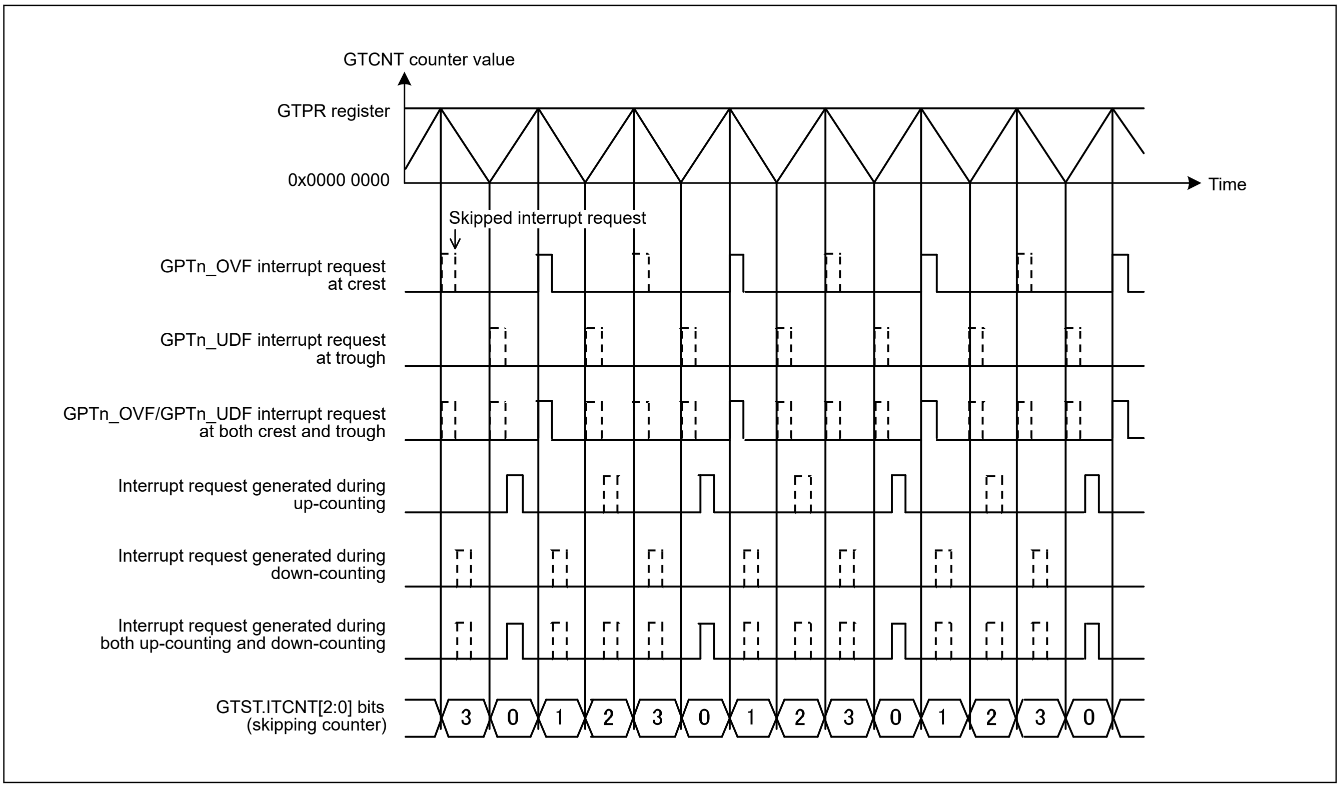

Figure 22.133 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Both Troughs and Crests, Skipping Count: 3, Skipping Started at Down-Counting)

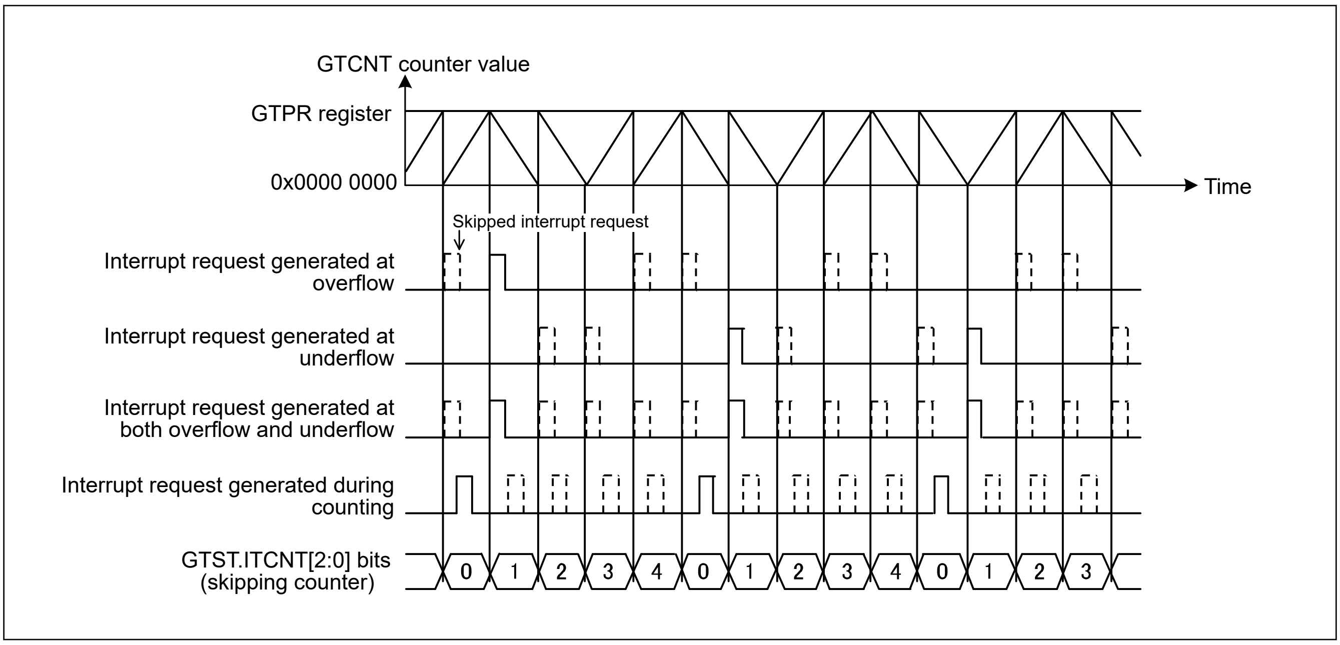

Figure 22.134 Example of Interrupt Skipping Function Operation (Saw Waves, Operation with Count Direction Changed, Counting and Skipping Both Overflows and Underflows, Skipping Count: 4)

22.4.3.2 Extended Interrupt Skipping Function

Overflow/underflow interrupt, compare match/input capture interrupt, A/D conversion start request, and buffer transfer can be skipped by counting the GTCNT counter overflow or underflow based on settings of the GTEITC, GTEITLI1, GTEITLI2 and GTEITLB registers.

Overflow/underflow interrupt, compare match/input capture interrupt, A/D conversion start request, and buffer transfer can individually be set for skipping and the skipping period using the GTEITLI1, GTEITLI2, and GTEITLB registers.

The skipping period is set, related to the operation of the two independent extended interrupt skipping counters (EITCNT1[3:0] and EITCNT2[3:0] bits in the GTEITC registers), as a period that either of the counter value for such skipping counters is other than 0 or other than the skipping count. The skipping period can also be set as a period that the both skipping counters are set as other than 0 or other than the skipping count for the counter value.

Figure 22.135 shows the counter operation for interrupt skipping by the GTITC register and extended interrupt skipping.

The counter operation for extended interrupt skipping is set by the GTEITC register.

The EITCNT1[3:0] bits are set for 0 as initial value and then they count the count source (in Figure 22.135, a crest is selected) selected by the extended interrupt counter 1 count source select bit (GTEITC.EIVTC1[1:0] bits), and repeat the count operation which returns to 0 when the skipping count (in Figure 22.135, count is 2) set by the extended interrupt skipping 1 skipping count setting bit (EIVTT1[3:0] bits) is achieved.

The EITCNT2[3:0] bits can be set for the initial value and they count the count source (in Figure 22.135, a trough is selected) selected by the extended interrupt counter 2 count source select bit (EIVTC2[1:0] bits), and repeat the count operation which return to 0 when the skipping count (in Figure 22.135 count is 2) set by the EIVTT2[3:0] bits is achieved. The initial value is set when the GTEITC register is written by the access of upper 16 bits or 32 bits while the setting for the extended interrupt skipping counter 2 is not counted (EIVTC2[1:0] bits are 00b) and when the write value to the EIVTC2[1:0] bits is other than 00b. When the initial value is set, the write value to the extended interrupt skipping counter 2 initial value bits (EITCNT2IV[3:0] bits) are set as the initial value for the EITCNT2[3:0] bits.

The extended interrupt skipping counter starts up-counting at the first count clock after the setting is modified from not counting to counting.

The interrupt skipping count counter (GTST.ITCNT[2:0] bits) for the interrupt skipping function set by the GTITC register is reset to 000b when the GTCNT counter operation is stopped: however, the EITCNT1[3:0] and EITCNT2[3:0] bits for the extended interrupt skipping function retain the value even after the GTCNT counter operation is stopped, and the counting can be resumed from the value before the counter is stopped. When values for the EITCNT1[3:0] and EITCNT2[3:0] bits are to be reset (0000b), set the EIVTC1[1:0] and EIVTC2[1:0] bits to the setting for not counting (not skipping) (00b).

When the skipping count is to be changed, change the count after stopping the skipping counter operation (set either of the EIVTC1[1:0] bit or the EIVTC2[1:0] bit to 00b).

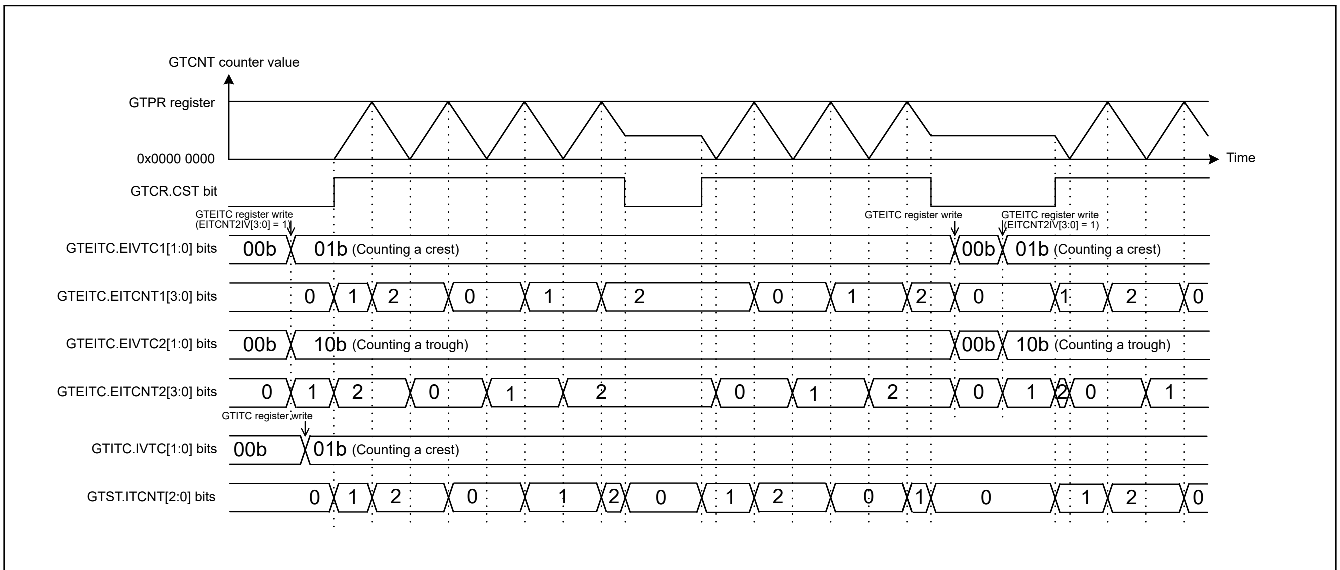

Figure 22.135 Example of Counter Operation for Interrupt Skipping

Interrupt skipping by the GTEITL1 register and A/D conversion start request skipping by the GTEITLI2 register can be performed simultaneously with skipping by the GTITC register or GTADCMSC register. A skipping period in this case is represented by OR-ed skipping periods of respective registers.

Figure 22.136 shows corresponding interrupt skipping operations by different registers are performed simultaneously.

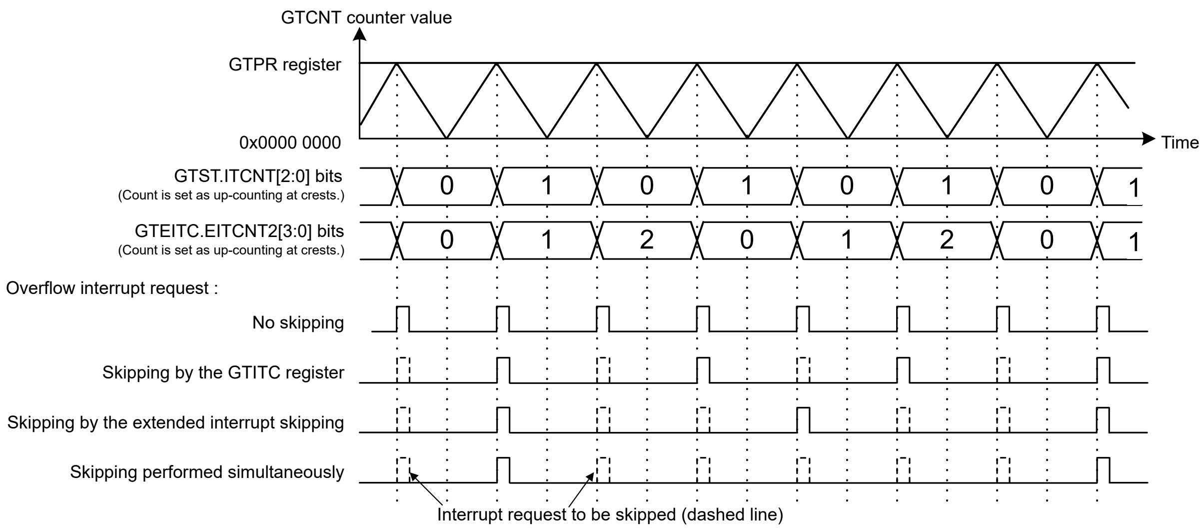

Figure 22.136 Example of Interrupt Skipping Operation (Skipping by the GTITC Register: Counting crests, Extended Interrupt Skipping: EIVTC1[1:0] bits = 00b, EIVTC2[1:0] bits = 01b, EITLV[2:0] bits = 010b)

When the extended interrupt skipping selected by GTEITLI1 is performed, the relevant status flag is also skipped. The skipping function is continued even if the status flag is set to 1.

When A/D conversion start request skipping selected by GTEITLI2 is performed, the relevant status flag is also skipped. The skipping function is continued even if the status flag is set to 1.

Skipping of updating of status flag and ELC event source outputs corresponding to A/D conversion start request for which skipping can be set up in the GTEITLI2 register is only based on the settings of the GTITC register and the extended interrupt skipping register, and has no connection with the setting of A/D conversion start request enable bit in the GTINTAD register. The A/D conversion start request enable bit is used only for A/D conversion start request output(ELC event source output) after skipping.

A buffer transfer skipping by the GTEITLB register is performed in all of the buffer operations which is enabled in the GTBER and GTDTCR registers and GTBER2 register, or all buffer operations performed by saw-wave one-shot pulse mode or triangle-wave PWM mode 3 or complementary PWM mode (excludes buffer transfer from GTCCRC, GTCCRE to GTCCRA).

An interrupt skipping and a buffer transfer skipping are operated individually. An interrupt output without performing a buffer transfer and performing a buffer transfer without an interrupt output can also be operated.

Figure 22.137 to Figure 22.144 show examples of extended skipping function operation.

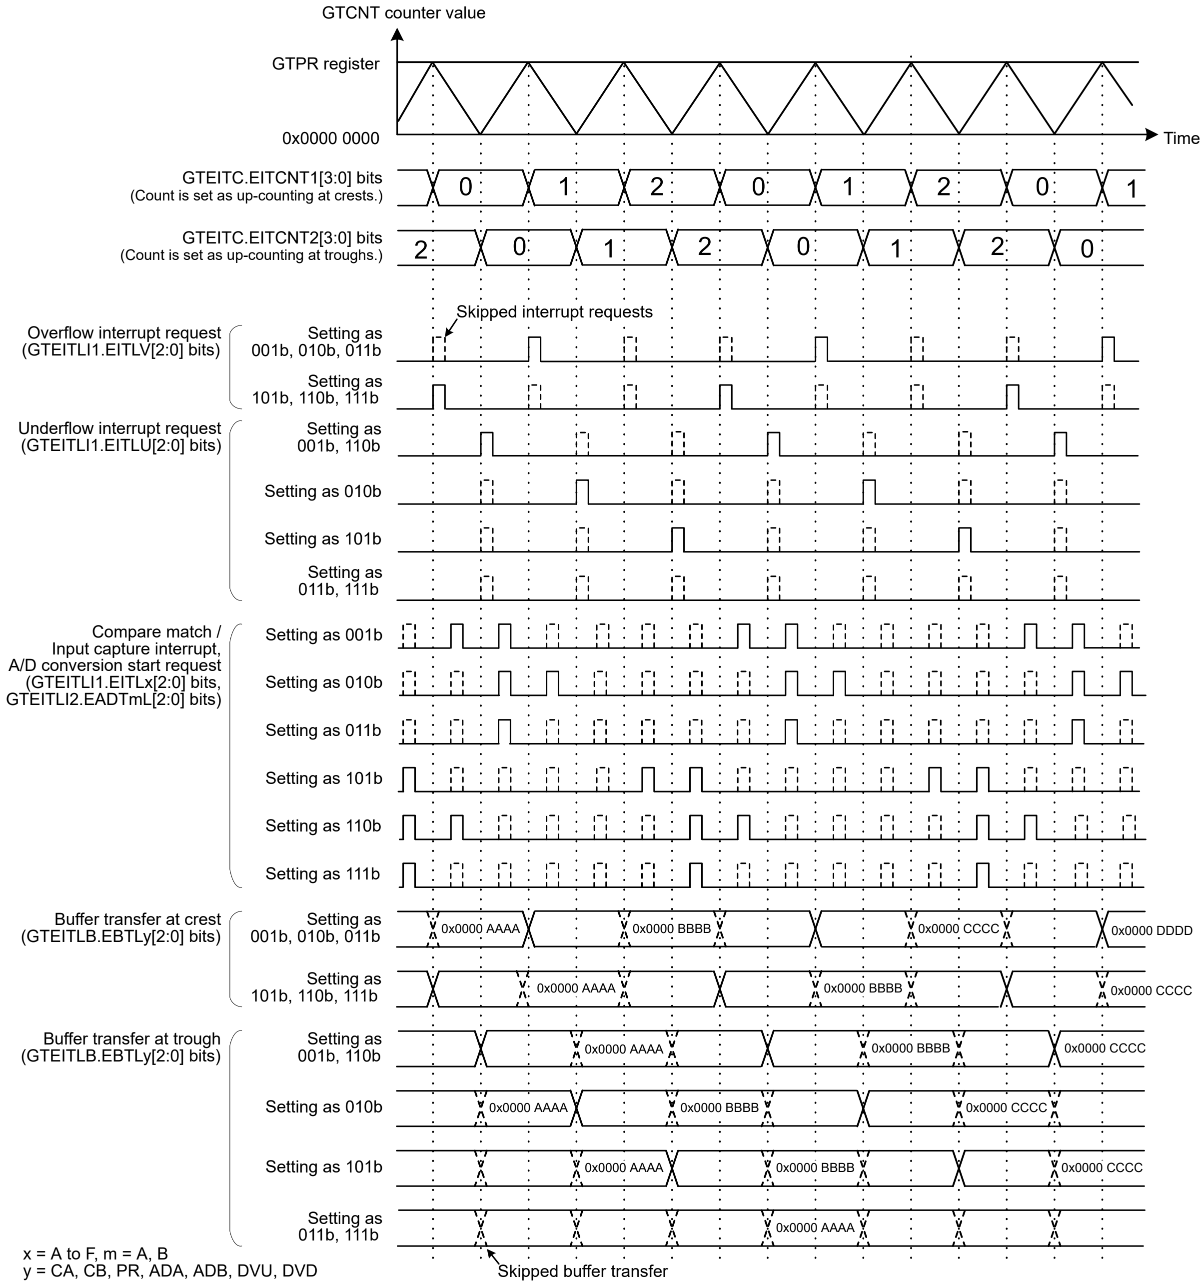

Figure 22.137 Example of Extended Interrupt Skipping Function (Triangle wave, Counting Crests, Extended Interrupt Skipping 1 Skipping Count: 2, Counting Troughs, Extended Interrupt Skipping 2 Skipping Count: 2, Extended Interrupt Skipping Counter 2 Initial Value: 0)

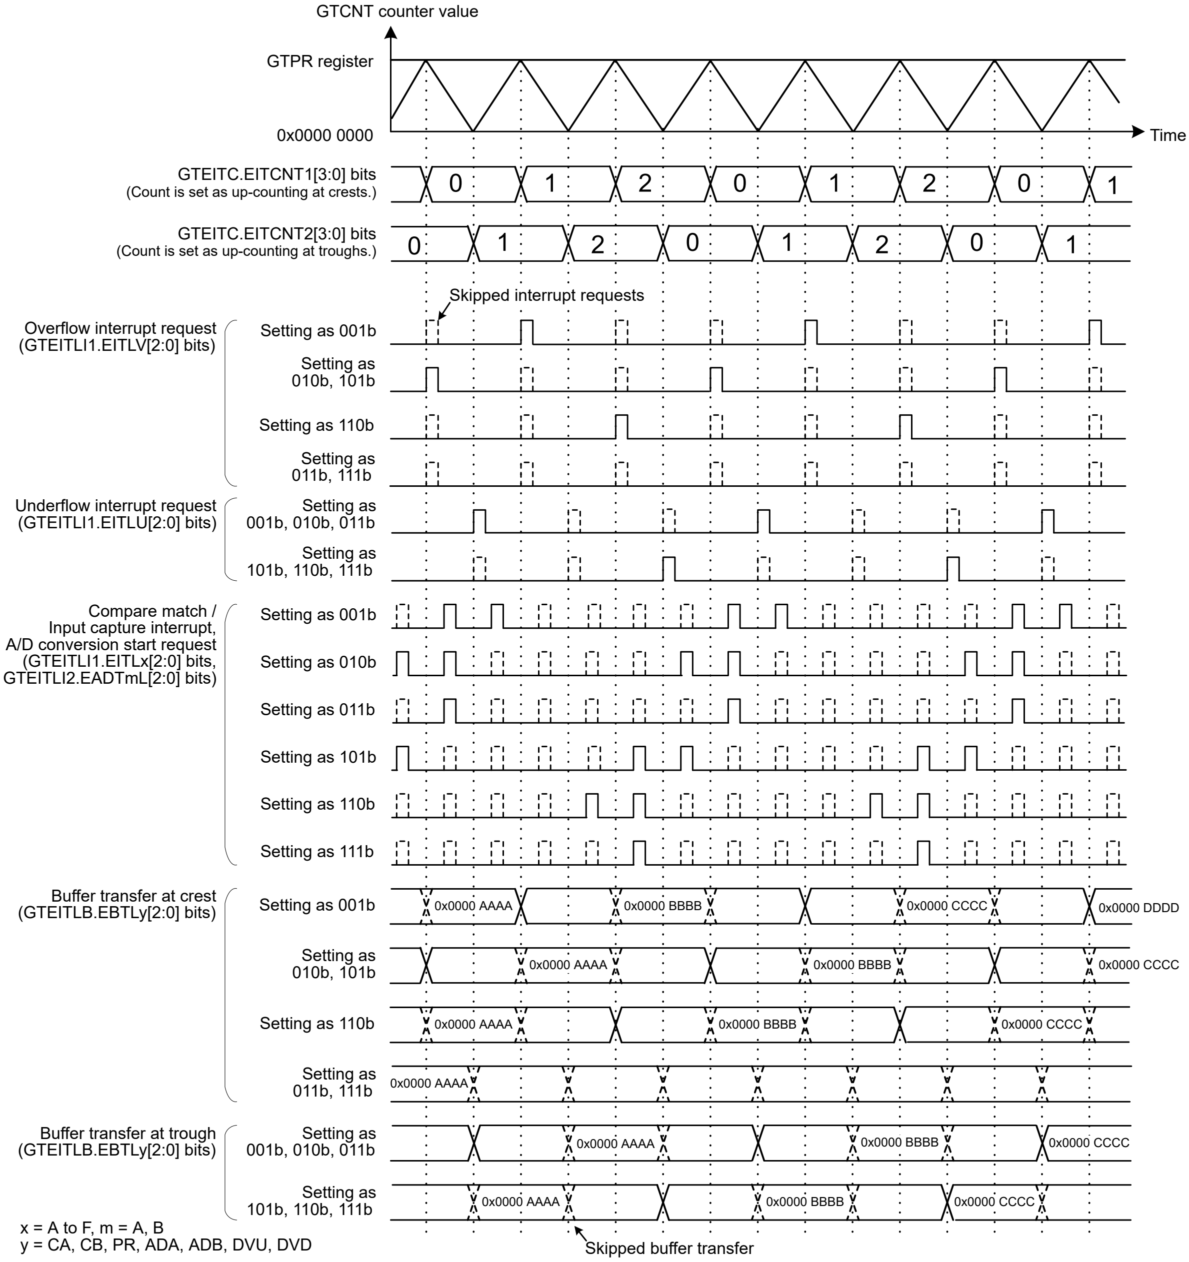

Figure 22.138 Example of Extended Interrupt Skipping Function (Triangle Waves, Count Crests by the Extended Interrupt Skipping 1 with Skipping Count: 2, Count Troughs by the Extended Interrupt Skipping 2 with Skipping Count: 2, Extended Interrupt Skipping Counter 2 Initial Value: 1)

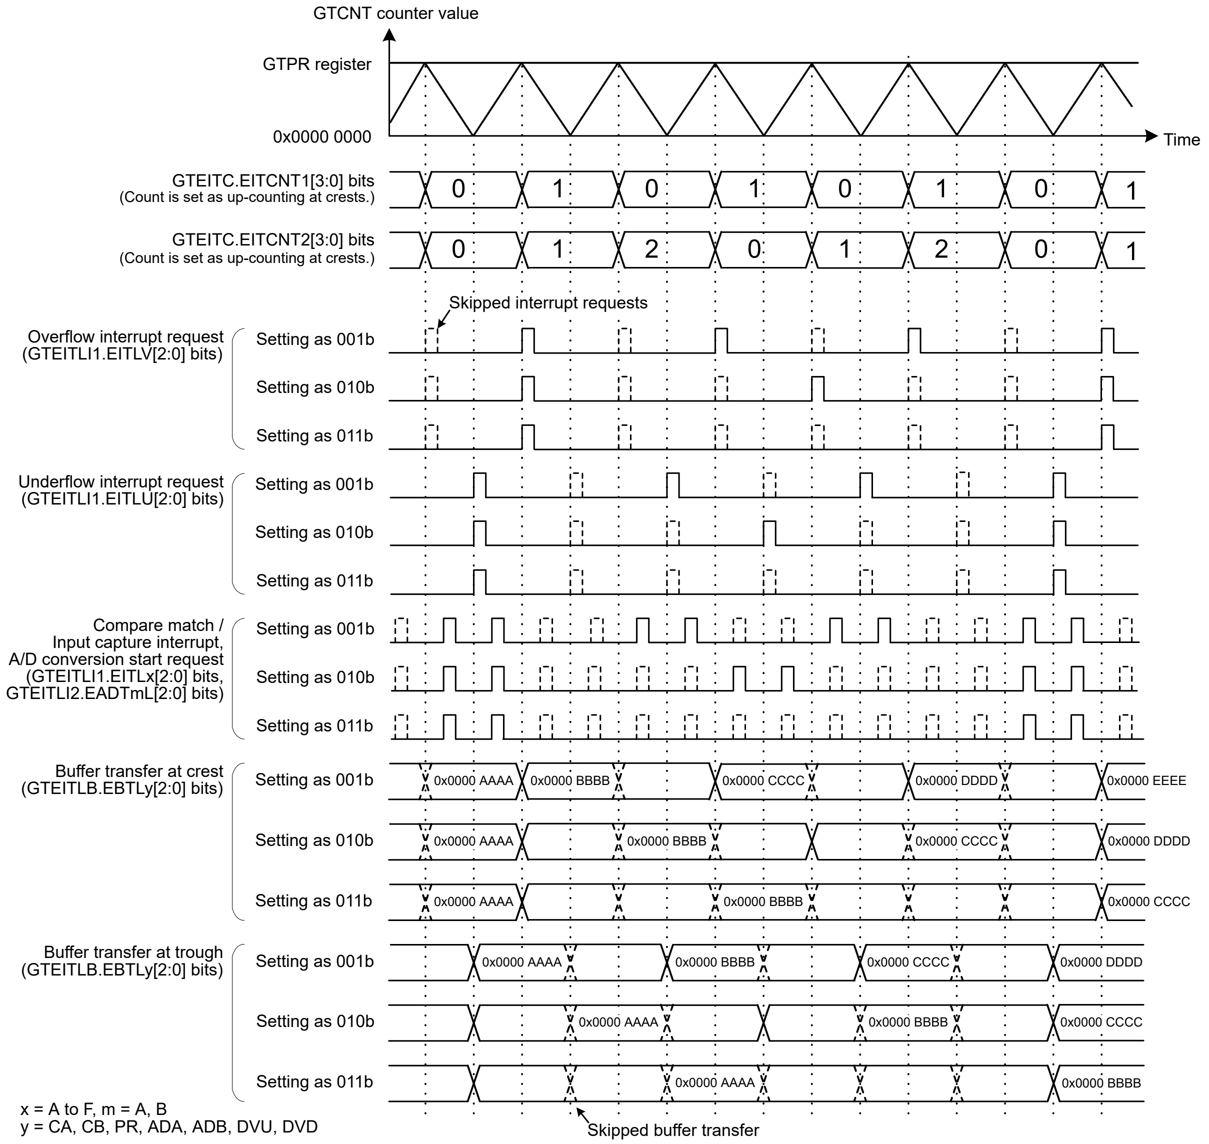

Figure 22.139 Example of Extended Interrupt Skipping Function Operation (Triangle Waves, Counting Crests, Extended Interrupt Skipping 1 Skipping Count: 1, Counting Crests, Extended Interrupt Skipping 2 Skipping Count: 2, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as 0)

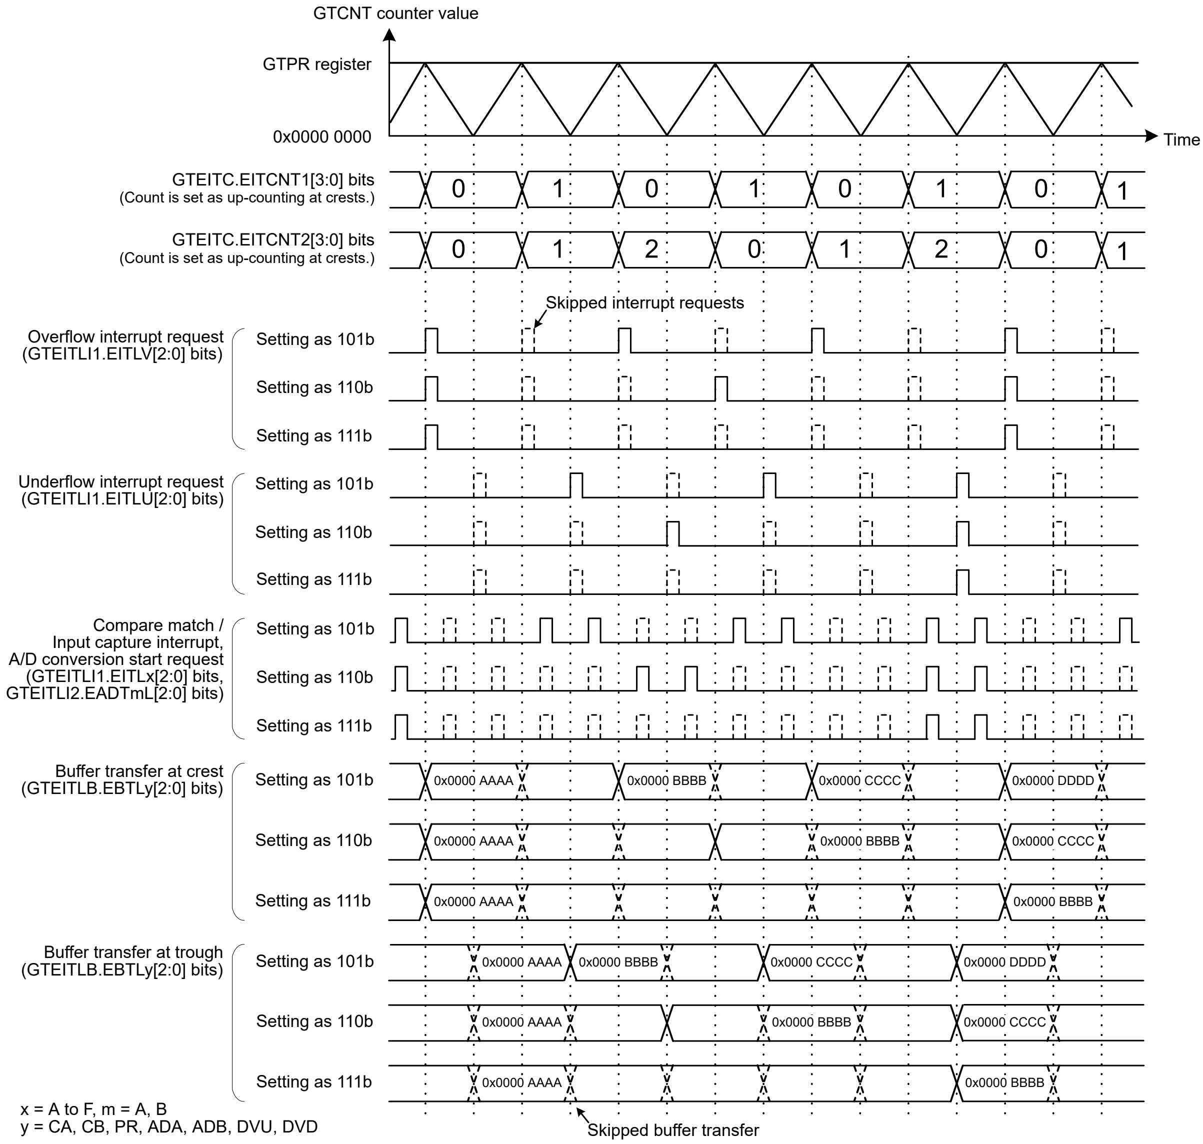

Figure 22.140 Example of Extended Interrupt Skipping Function Operation (Triangle Waves, Counting Crests, Extended Interrupt Skipping 1 Skipping Count: 1, Counting Crests, Extended Interrupt Skipping 2 Skipping Count: 2, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as GTEITC.EIVTTk bits.)

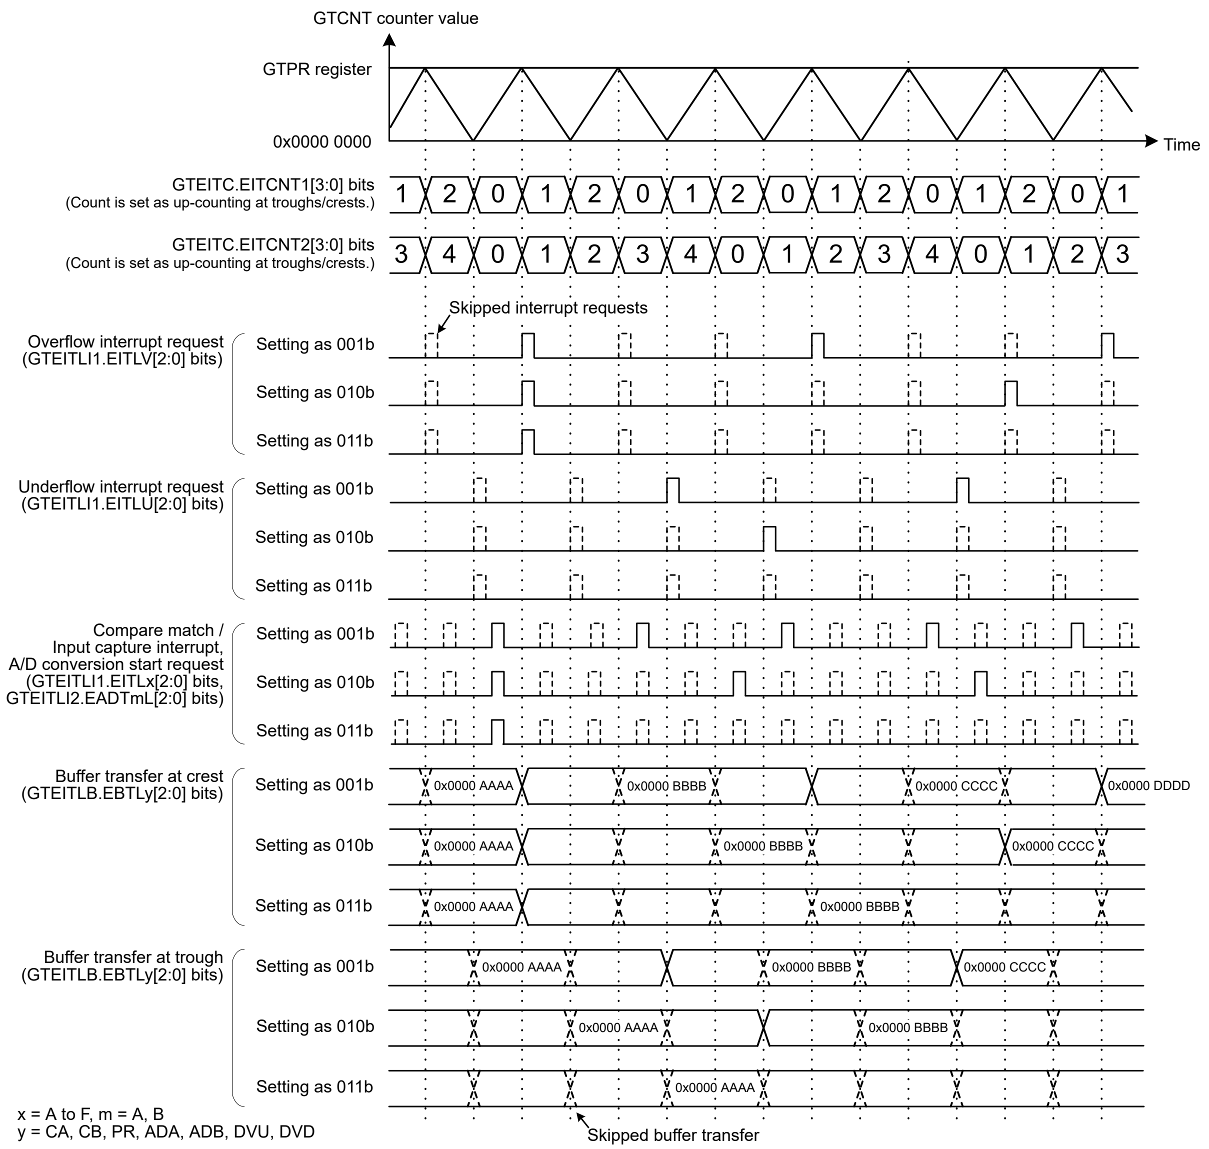

Figure 22.141 Example of Extended Interrupt Skipping Function Operation (Triangle Waves, Counting both Crests and Troughs, Extended Interrupt Skipping 1 Skipping Count: 2, Counting both Crests and Troughs, Extended Interrupt Skipping 2 Skipping Count: 4, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as 0)

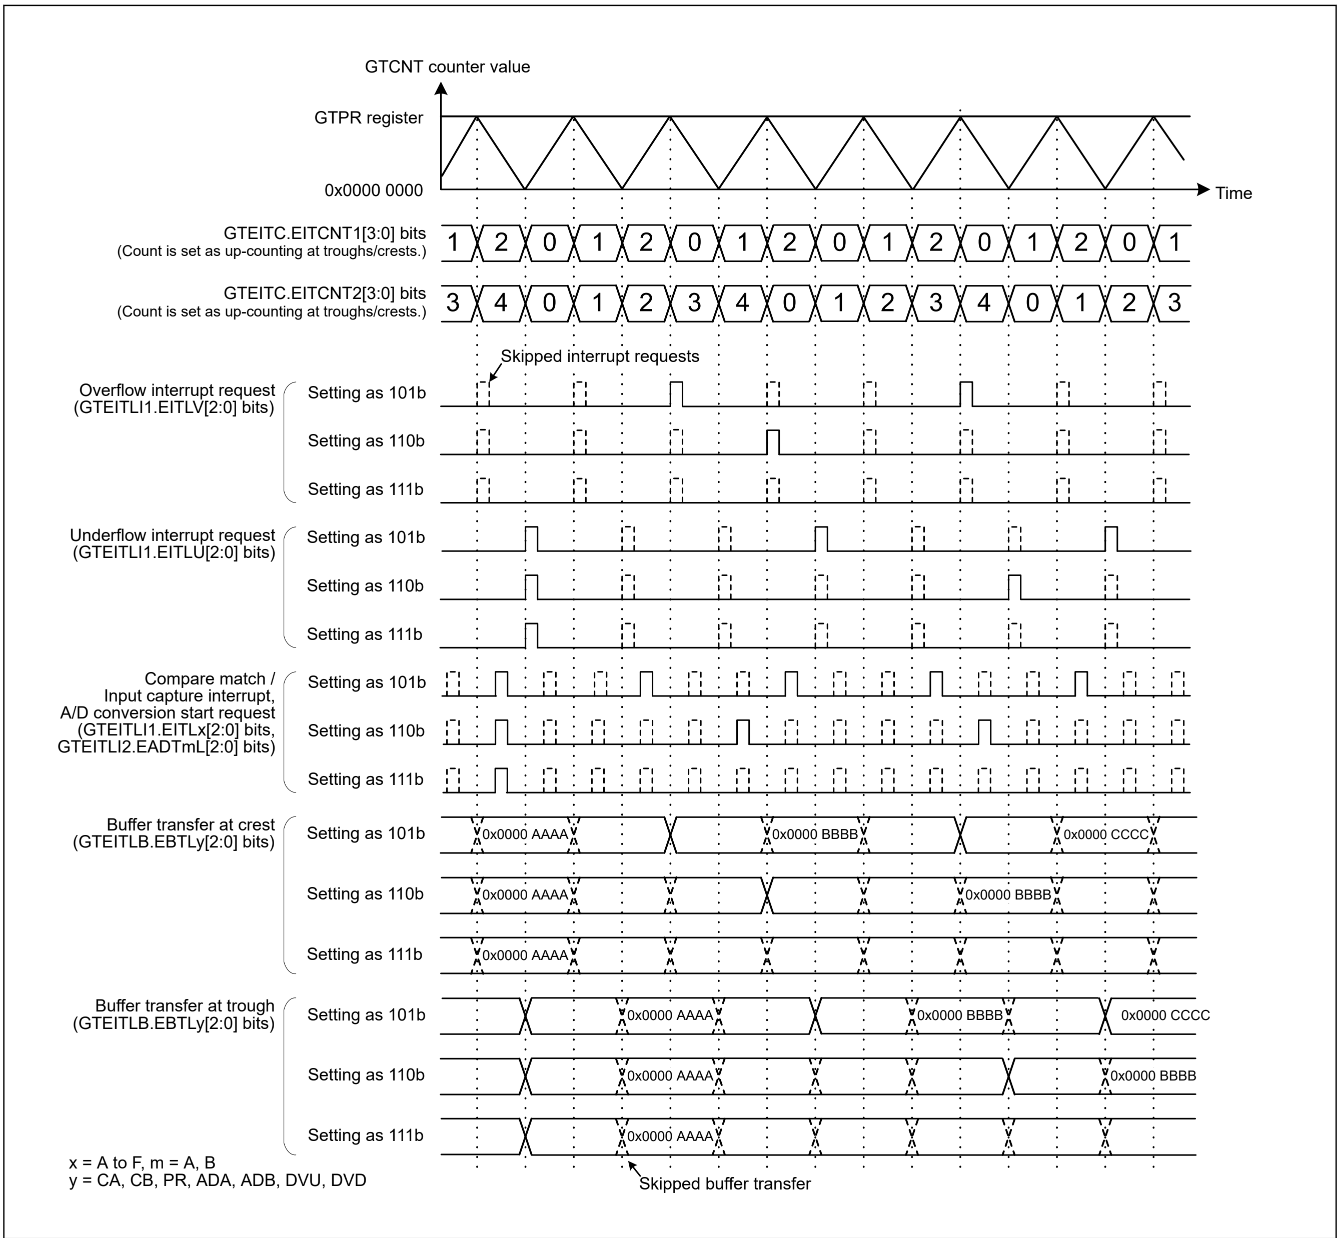

Figure 22.142 Example of Extended Interrupt Skipping Function Operation (Triangle Waves, Counting both Crests and Troughs, Extended Interrupt Skipping 1 Skipping Count: 2, Counting both Crests and Troughs, Extended Interrupt Skipping 2 Skipping Count: 4, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as GTEITC.EIVTTk bit.)

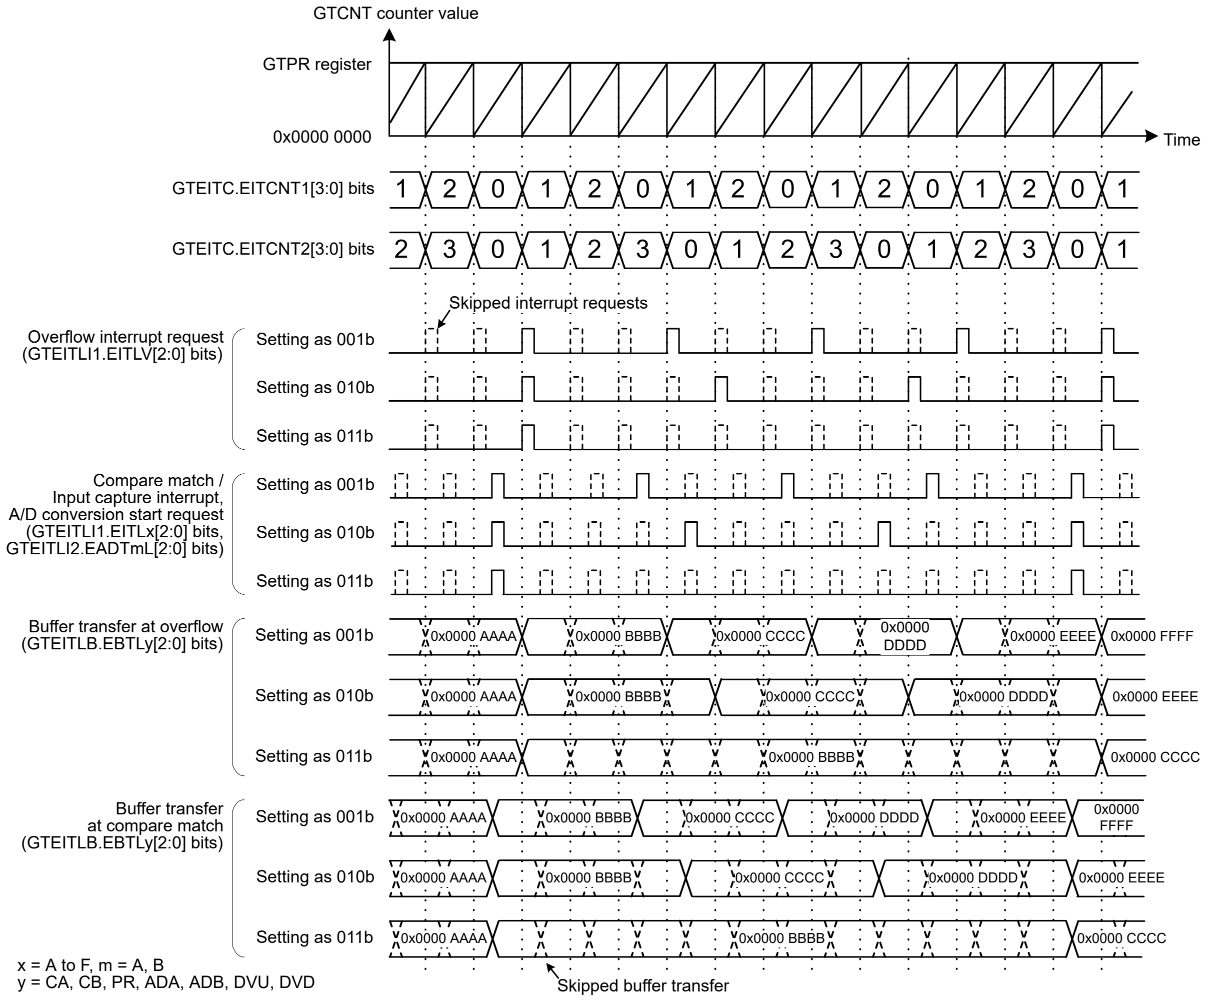

Figure 22.143 Example of Extended Interrupt Skipping Function Operation (Up-Counting in Saw Waves, Counting Overflow, Extended Interrupt Skipping 1 Skipping Count: 2, Counting Overflow, Extended Interrupt Skipping 2 Skipping Count: 3, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as 0)

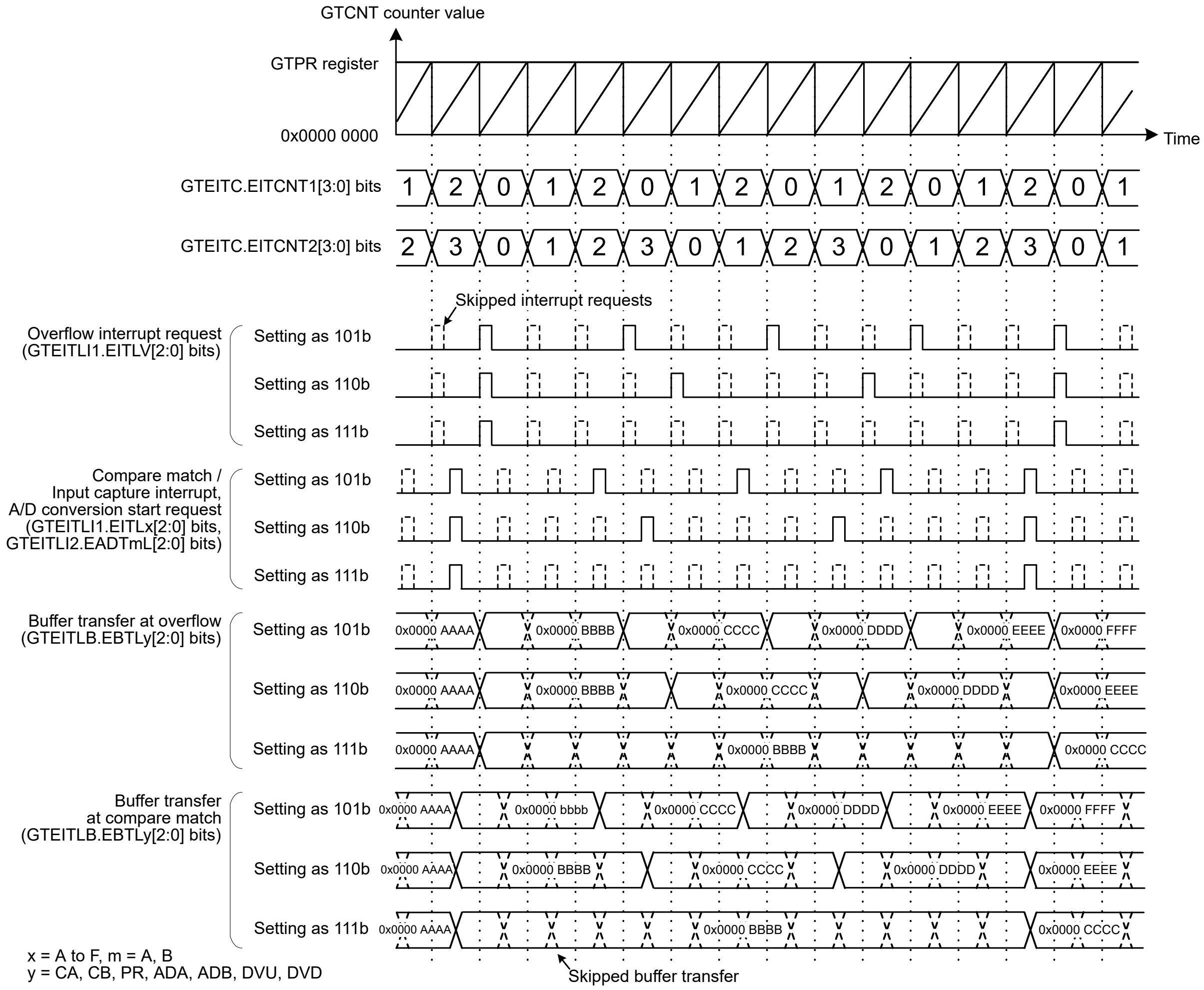

Figure 22.144 Example of Extended Interrupt Skipping Function Operation (Up-Counting Saw Waves, Counting Overflow, Extended Interrupt Skipping 1 Skipping Count: 2, Counting Overflow, Extended Interrupt Skipping 2 Skipping Count: 3, Extended Interrupt Skipping Counter 2 Initial Value: 0, Skipped in the Period other than GTEITC.EITCNTk bits (k = 1, 2) as GTEITC.EIVTTk bits.)

Figure 22.145 shows an example of the extended interrupt skipping operation on the input capture. When the setting is for the input capture operation setting (GTCR.ICDS bit = 0) at count stop of the GTCNT counter, the interrupt by the input capture and the extended skipping on buffer transfer is enabled even at count stop of the GTCNT counter.

When the input capture is generated at count stop of the GTCNT counter by setting the ICDS bit as 0, an interrupt and a buffer transfer are skipped if the skipping counter value is the same with the skipping period set in a corresponding interrupt skipping function select bit.

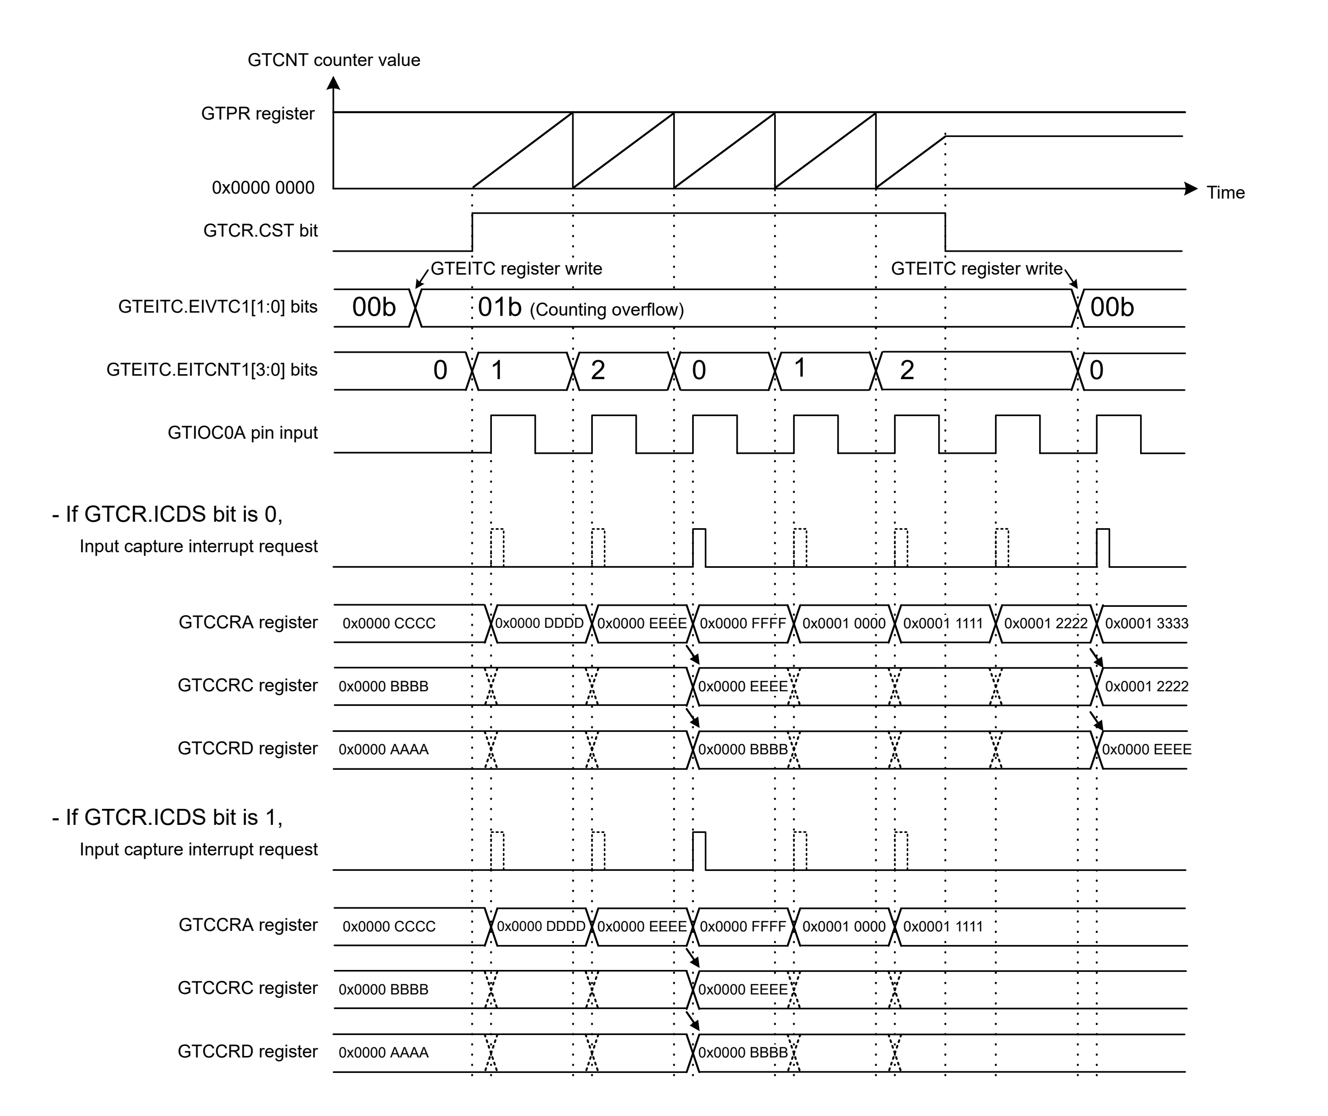

Figure 22.145 Example of Input Capture Operation in the Extended Interrupt Skipping Function Operation (Up-Counting Saw Waves, Counting Overflow, Extended Interrupt Skipping 1 Skipping Count: 2, Skipped in the Period other than the EITCNT1 as 0, Input Capture at the Input Rising)

Table 22.72 shows an example of setting the extended interrupt skipping.

The extended interrupt skipping counter 2 initial value is set by the written value to the ETICNT2IV[3:0] bits which is applied to change the setting from not counting the extended interrupt skipping counter 2 count source (GTEITC.EIVTC2[1:0] bits = 00b) to counting (EIVTC2[1:0] bits = other than 00b). Writing to the extended interrupt skipping counter 2 initial value bit (ETICNT2IV[3:0] bits) is performed only when the setting of the above-mentioned extended interrupt skipping counter 2 initial value is written.

Table 22.72 Example for Setting the Extended Interrupt Skipping (1 of 2)

No.	Step Name	Description
1	Set GTCNT counter operation, Set buffer operation, Set compare match value	See section 22.3.2. Buffer Operation, section 22.3.3. PWM Output Operating Mode, and so on.
2	Set the extended interrupt skipping function	Select the skipping counter used for skipping and the skipping period with the skipping function select bit for the interrupt, for the A/D conversion start request, and for a buffer transfer, all which are to be skipped, in the GTEITLI1, GTEITLI2, and GTEITLB registers respectively.

Table 22.72 Example for Setting the Extended Interrupt Skipping (2 of 2)

No.	Step Name	Description
3	Set the extended skipping counter	With the GTEITC register, set a count source of the skipping counter used for skipping, skipping count, and the skipping counter 2 initial value as the following order. Set EIVTCk[1:0] bits (k = 1,2) as value other than 00b, and set EIVTTk[3:0] bits as value other than 0000b. When the skipping counter 2 is used, change EIVTC2[1:0] bits from 00b to value other than 00b as well as set EITCNT2IV[3:0] bits to the skipping counter 2 initial value.
4	Start count operation	Set GTCR.CST to 1 to start count operation.
5	Set buffer value for each cycle	See section 22.3.2. Buffer Operation, section 22.3.3. PWM Output Operating Mode, and so on.

22.4.3.3 A/D conversion Start Request Compare Match Skipping Function

The A/D conversion start request and GTADTR register buffer transfer can be skipped by counting the compare matches of GTADTRA register and GTADTRB register based on settings of the GTADCMSC register and GTADCMSS register.

The skipping period is set, related to the operation of the two independent A/D conversion start request compare match skipping counters (ADCMSCNT1[3:0] and ADCMSCNT2[3:0] bits in the GTADCMSC register), as a period that either of the counter value for such skipping counters is other than 0 or other than the skipping count. The skipping period can also be set as a period that the both skipping counters are set as other than 0 or other than the skipping count for the counter value.

Figure 22.146 shows the counter operation for A/D conversion start request compare match skipping.

The counter operation for A/D conversion start request compare match skipping is set by the GTADCMSC register.

The ADCMSCNT1[3:0] bits count the count source (in Figure 22.146, a crest is selected) selected by the A/D conversion start request compare match skipping counter 1 count source select bit (GTADCMSC.ADCMSC1[1:0] bits), and repeat the count operation which returns to 0 when the skipping count (in Figure 22.146, count is 2) set by the A/D conversion start request compare match skipping 1 skipping count setting bit (ADCMST1[3:0] bits) is achieved.

The ADCMSCNT2[3:0] bits count the count source (in Figure 22.146, a trough is selected) selected by the A/D conversion start request compare match skipping counter 2 count source select bit (GTADCMSC.ADCMSC2[1:0] bits), and repeat the count operation which returns to 0 when the skipping count (in Figure 22.146, count is 2) set by the A/D conversion start request compare match skipping 2 skipping count setting bit (ADCMST2[3:0] bits) is achieved.

The ADCMSCNTk[3:0] bits (k = 1, 2) can be set for the initial value. The initial value is set when the GTADCMSC register is written by the access of 16 bits or 32 bits while the setting for the A/D conversion start request compare match skipping counter k is not counted (ADCMSCk [1:0] bits are 00b) and the write value to the ADCMSCk[1:0] bits is other than 00b. When the initial value is set, the write value to the A/D conversion start request compare match skipping counter k initial value bits (ADCMSCNTkIV[3:0] bits) are set as the initial value for the ADCMSCNT2[3:0] bits.

The A/D conversion start request compare match skipping counter starts up-counting at the first count clock after the setting is modified from not counting to counting.

The ADCMSCNT1[3:0] and ADCMSCNT2[3:0] bits for the A/D conversion start request compare match skipping function retain the value even after the GTCNT counter operation is stopped, and the counting can be resumed from the value before the counter is stopped. When values for the ADCMSCNT1[3:0] and ADCMSCNT2[3:0] bits are to be reset (0000b), set the ADCMSC1[1:0] and ADCMSC2[1:0] bits to the setting for not counting (not skipping) (00b).

When the skipping count is to be changed, change the count after stopping the skipping counter operation (set either of the ADCMSC1[1:0] bit or the ADCMSC 2[1:0] bit to 00b).

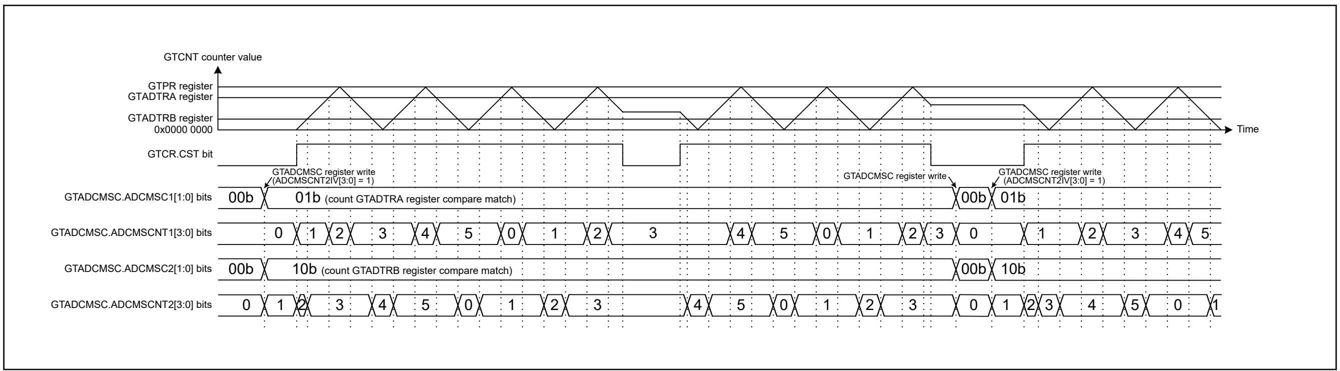

Figure 22.146 Example of A/D Conversion Start Request Compare Match Skipping Function Operation

A/D conversion start request skipping by the ADCMSC register can be performed simultaneously with skipping by the GTITC register or GTEITC register. A skipping period in this case is represented by OR-ed skipping periods of respective registers.

Figure 22.147 shows corresponding interrupt skipping operations and A/D conversion start request skipping operation are performed simultaneously.

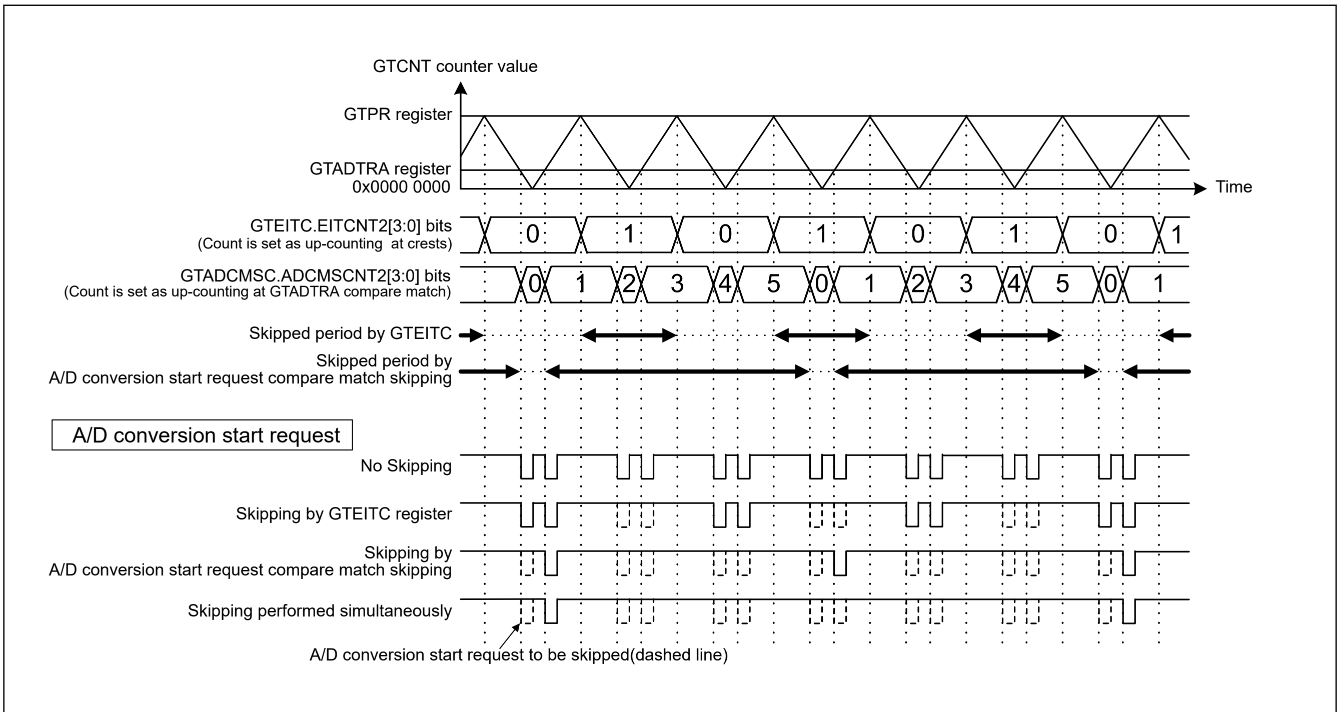

Figure 22.147 Example of A/D Conversion Start Request Compare Match Skipping Function Operation (Extended Interrupt Skipping: EIVTC2[1:0] = 01b, EADTAL[2:0] = 010b, A/D Conversion Start Request Compare Match Skipping: ADCMSC2[1:0] = 01b, ADCMSAL[2:0] = 010b)

When A/D conversion start request skipping which can be set by the GTADCMSS register is performed, updating of status flag and the ELC event output depend on the A/D conversion start request enable bit in the GTINTAD register. All the operations by A/D conversion start request which are set as disable by the GTINTAD register is not performed.

A buffer transfer skipping by the GTADCMSS register is performed in all of the buffer operations which is enabled in the GTBER and GTBER2 register, or all buffer operations performed by saw-wave one-shot pulse mode or triangle-wave PWM mode 3 or complementary PWM mode (excludes buffer transfer from GTCCRC, GTCCRE to GTCCRA).

An A/D conversion start request skipping and a buffer transfer skipping are operated individually.

Figure 22.148, Figure 22.149 show examples of extended skipping function operation.

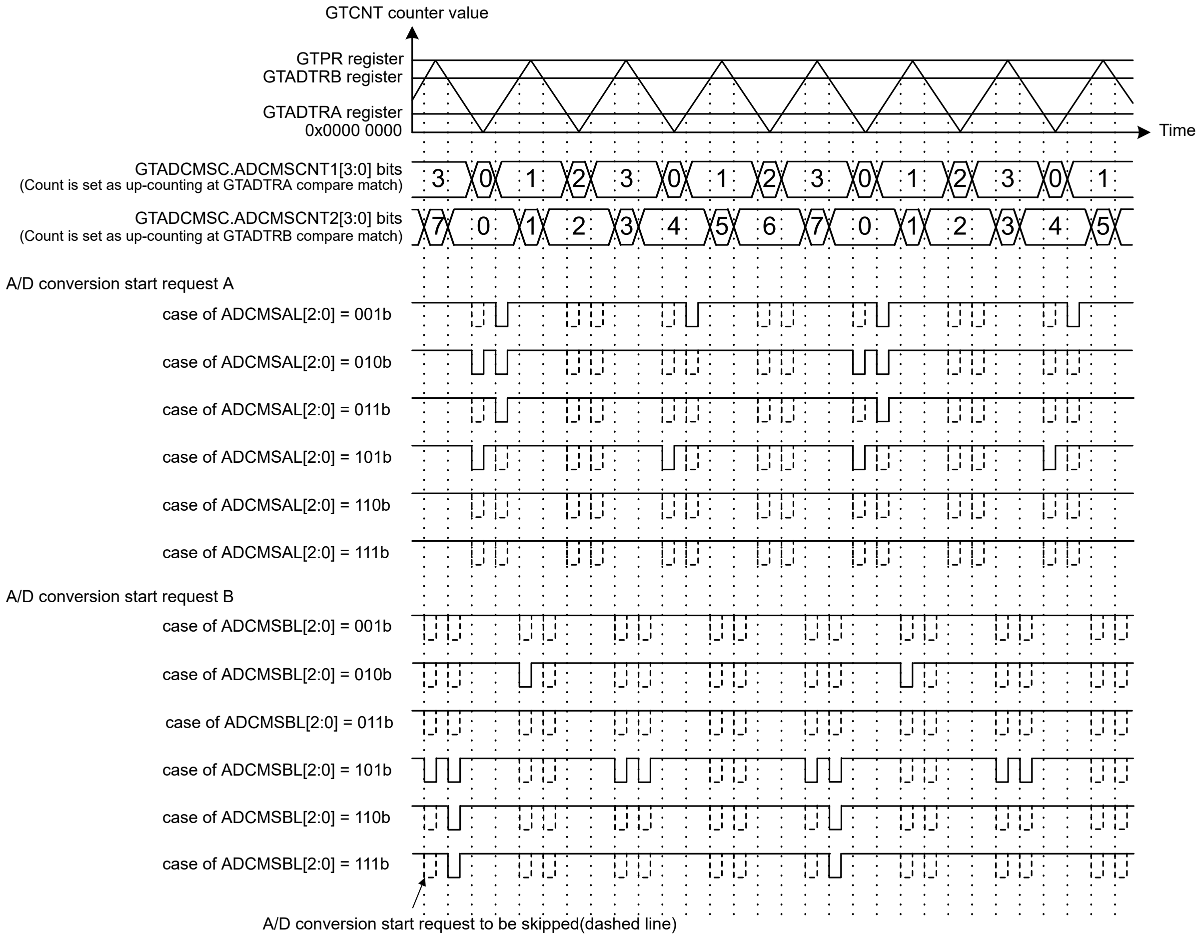

Figure 22.148 Example of A/D Conversion Start Request Compare Match Skipping Function Operation (Triangle wave, A/D Conversion Start Request Compare Match Skipping 1 Skipping Count: 3 Counting GTADTRA compare match, A/D Conversion Start Request Compare Match Skipping 2 Skipping Count: 7 Counting GTADTRB compare match)

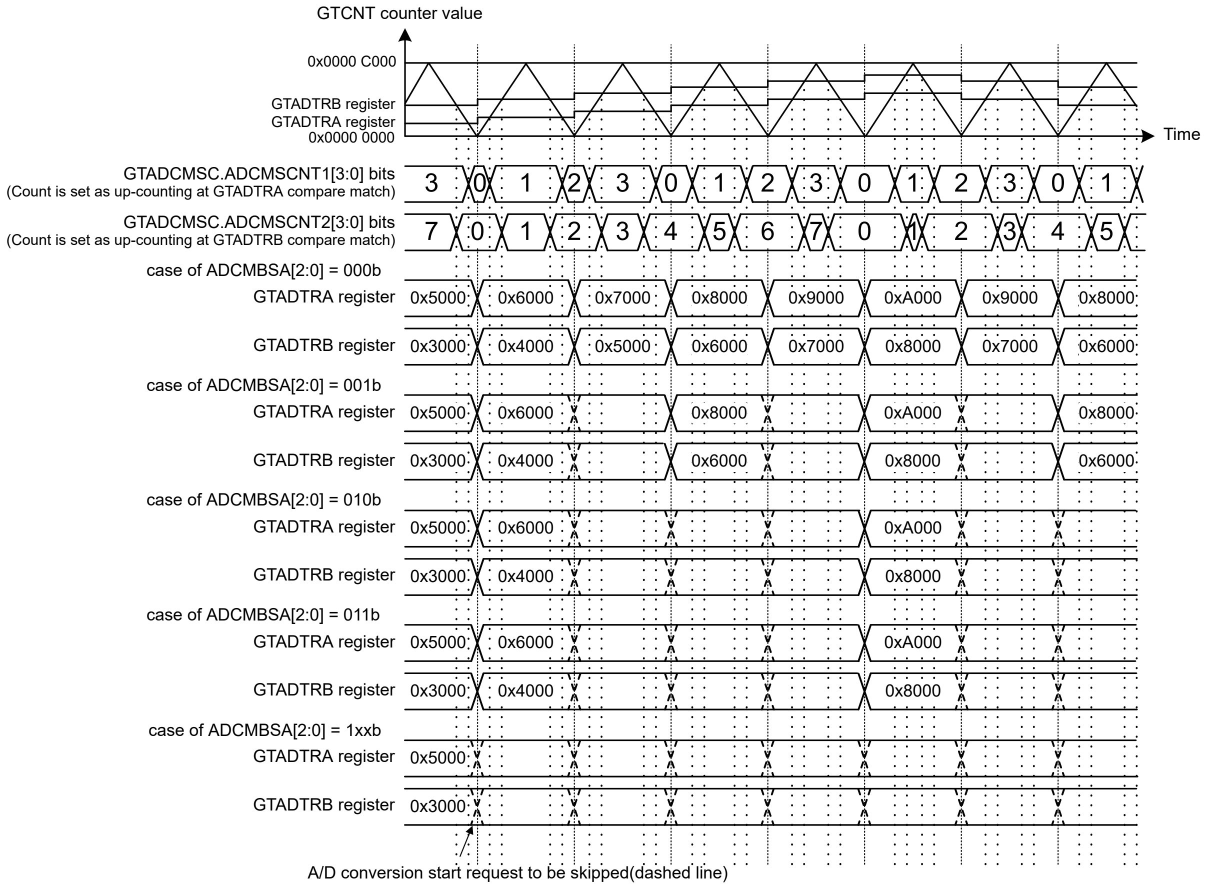

Figure 22.149 Example of A/D Conversion Start Request Compare Match Skipping Function Operation (Triangle wave, A/D Conversion Start Request Compare Match Skipping 1 Skipping Count: 3 Counting GTADTRA compare match, A/D Conversion Start Request Compare Match Skipping 2 Skipping Count: 7 Counting GTADTRB compare match, Buffer transfer of GTADTRA and GTADTRB at trough)

Table 22.73 shows an example of setting the A/D conversion start request compare match skipping.

The A/D conversion start request compare match skipping counter 2 initial value is set by the written value to the ADCMSCNT2IV[3:0] bits which is applied to change the setting from not counting the extended interrupt skipping counter 2 count source (GTADCMSC.ADCMSC2[1:0] bits = 00b) to counting (ADCMSC2[1:0] bits = other than 00b). Writing to the A/D conversion start request compare match skipping counter 2 initial value bit (ADCMSCNT2IV[3:0] bits) is performed only when the setting of the above-mentioned A/D conversion start request compare match skipping counter 2 initial value is written.

Table 22.73 Example for Setting the A/D Conversion Start Request Compare Match Skipping (1 of 2)

No.	Step Name	Description
1	Set GTCNT counter operation, Set buffer operation, Set compare match value	See section 22.3.2. Buffer Operation, section 22.3.3. PWM Output Operating Mode, section 22.5. A/D Conversion Start Request, and so on.
2	Set the A/D conversion start request compare match skipping function	Select the skipping counter and the skipping period with the skipping function select bit for the A/D conversion start request or the bit for the buffer transfer to be skipped in the GTADCMSS register.

Table 22.73 Example for Setting the A/D Conversion Start Request Compare Match Skipping (2 of 2)

No.	Step Name	Description
3	Set the A/D conversion start request compare match skipping counter k (k = 1, 2)	With the GTADCMSC register, set a count source of the skipping counter, skipping count, and the skipping counter k initial value as the following order. Set the GTADCMSC.ADCMSCk[1:0] bits as value other than 00b, and set the ADCMSTk[3:0] bits as value other than 0000b. Change the ADCMSCk[1:0] bits from 00b to value other than 00b as well as set the ADCMSCNTkIV[3:0] bits to the skipping counter k initial value.
4	Start count operation	Set GTCR.CST to 1 to start count operation.
5	Set buffer value for each cycle	See section 22.3.2. Buffer Operation, section 22.3.3. PWM Output Operating Mode, section 22.5. A/D Conversion Start Request, and so on.

22.5 A/D Conversion Start Request

The A/D conversion start request can be issued at a compare match between the GTCNT counter and the GTADTRA or GTADTRB register. Up-counting only, down-counting only, or both up-counting and down-counting can be specified by setting the GTINTAD register.

In complementary PWM mode, the A/D conversion start request can be issued at a compare match with the GTCNT counter of master channel.

During event count operation, the A/D conversion start request cannot be generated.

The A/D conversion start request is output directly to ADC16H.

The GTADTRA and GTADTRB registers each has two buffer registers. Buffer operation with the GTADTRA register used together with the GTADTBRA and GTADTDBRA registers, and buffer operation with the GTADTRB register used together with the GTADTBRB and GTADTDBRB registers can be performed.

The timing of the generation of requests to start A/D conversion can be monitored by an external pin. When the A/D conversion start request signal to be monitored is selected in the GTADSMR.ADSMSk bit (k = 0, 1) and when the output is enabled in the ADSMENk bit, a signal is output synchronized with a cycle frame of the timer used to generate the A/D conversion start request signal, of which the output is driven high at the generation of the A/D conversion start request signal by the GTADSMk pin, or at the end of the cycle of which the output is driven low. When a signal to request the start of A/D conversion is generated at the end of the cycle, the generation of this signal has priority in terms of monitoring output and the output remains at the high level till the end of the next cycle. The registers (GTADTRA and GTADTRB) that are sources of generating the A/D conversion start request signals and their counting directions can be checked by the A/D conversion start request flags (ADTRAUF, ADTRADF, ADTRBUF, and ADTRBDF) in the GTST register. When the output of the same A/D conversion start request signal monitoring output is enabled for multiple channels, ORed signals will be output from the GPT32.

Figure 22.150 shows an example of A/D conversion start request operation, Table 22.74 shows example for setting A/D conversion start request operation.

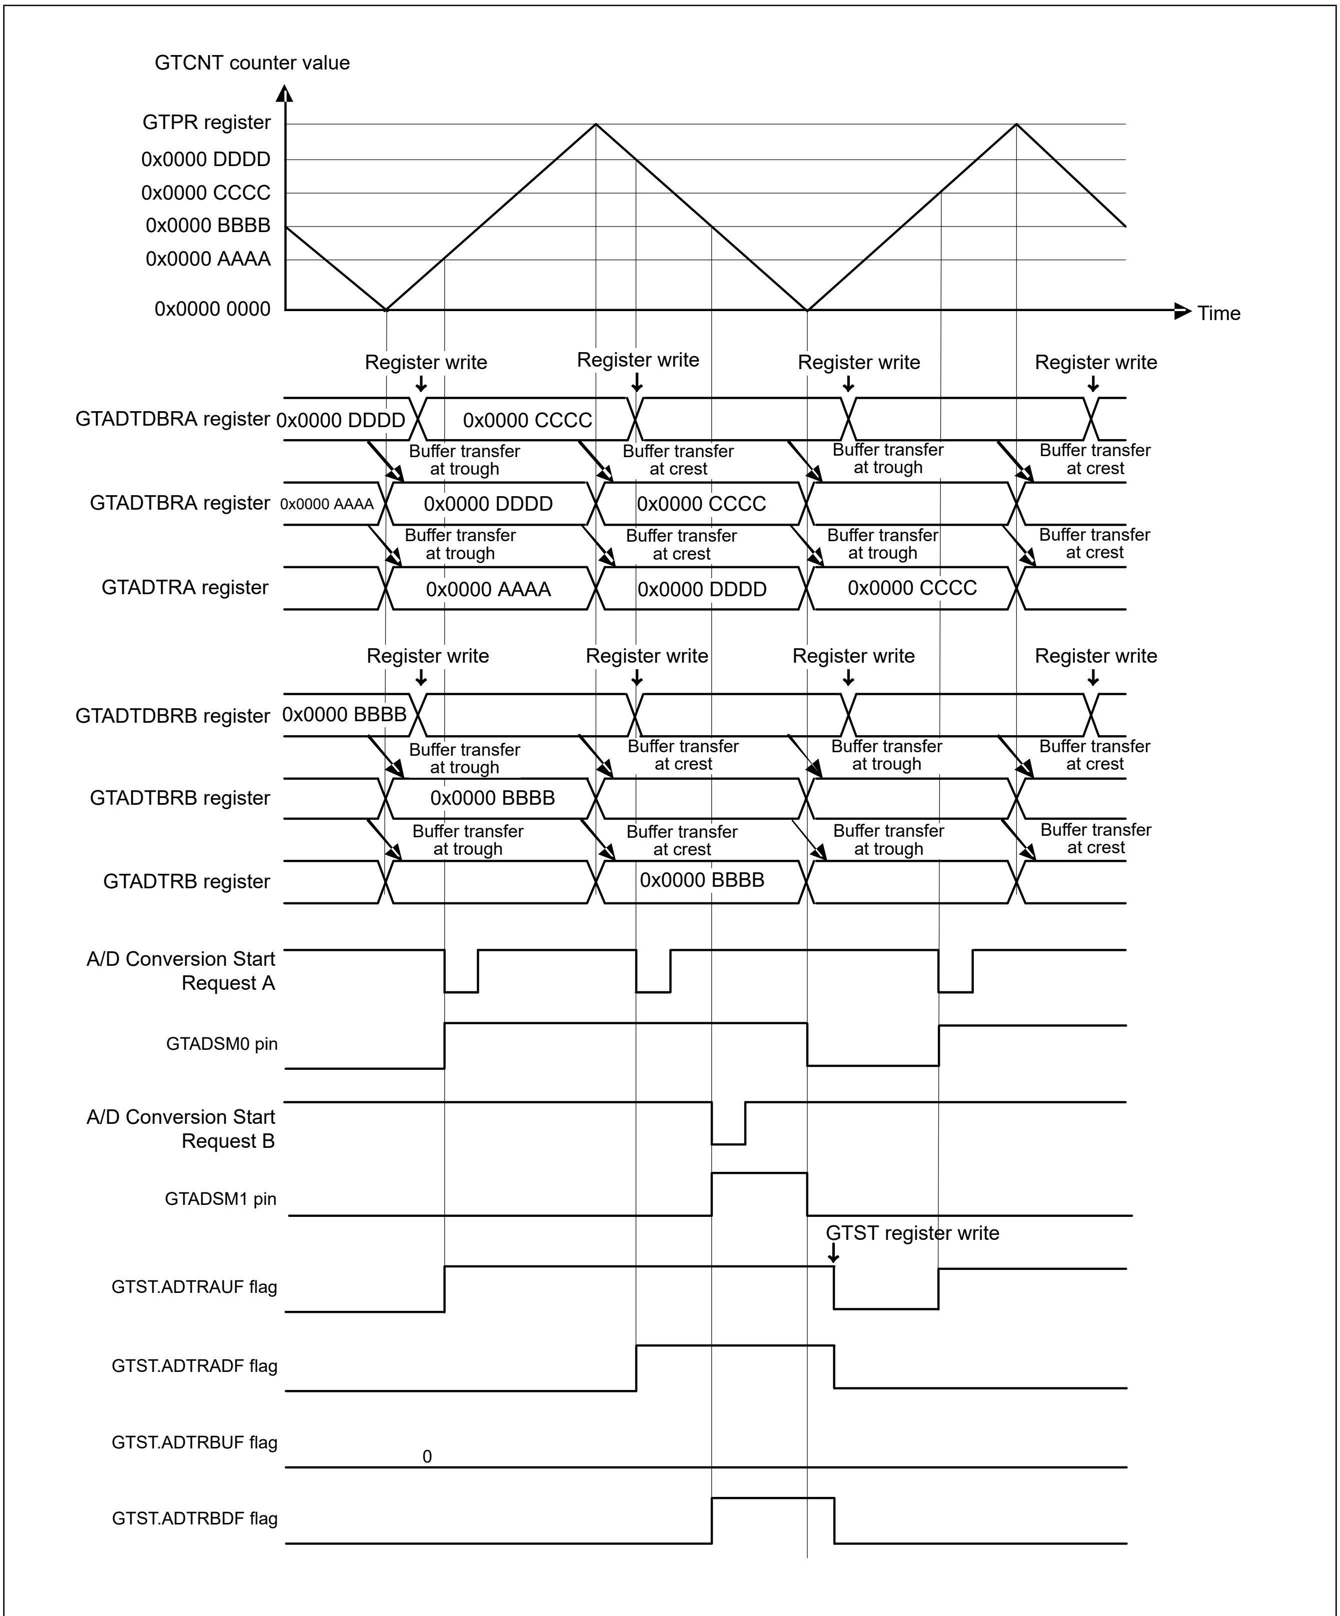

Figure 22.150 Example of A/D Conversion Start Request Timing Operation (Triangle Waves, Double Buffer Operation, Buffer Transfer at Both Troughs and Crests, A/D Conversion Start Request by GTADTRA Register at Both Up-Counting and Down-Counting, A/D Conversion Start Request by GTADTRB Register at Down-Counting, Monitoring of the GTADTRA Register Up-Counting by the GTADSM0 Pin, Monitoring of the GTADTRB Register Down-Counting by the GTADSM1 Pin)

Table 22.74 Example for Setting A/D Conversion Start Request Timing Operation

No.	Step Name	Description
1	Set operating mode	Set the operating mode with the GTCR.MD[2:0] bits or GTCR.MD[3:0] bits. In Figure 22.150, 100b, 101b, or 110b (0100b, 0101b, or 0110b) (triangle-wave PWM mode) is set.
2	Select count clock	Select the count clock with the GTCR.TPCS[3:0] bits.
3	Set cycle	Set the cycle in the GTPR register.
4	Set initial value for counter	Set the initial value in the GTCNT counter.
5	Set buffer operation	Set buffer operation with the ADTTA[1:0], ADTTB[1:0], ADTDA, and ADTDB bits in the GTBER register. In Figure 22.150, ADTTA[1:0] = 11b, ADTTB[1:0] = 11b, ADTDA = 1, and ADTDB = 1.
6	Set compare match value	Set the A/D conversion start request point in the GTADTRA and GTADTRB registers.
7	Set buffer value	For buffer operation, set the A/D conversion start request point in one cycle after the current cycle (in saw-wave mode or triangle-wave mode with buffer transfer at trough or crest) or half cycle after the current cycle (in triangle-wave mode with buffer transfer at both trough and crest) in the GTADTBRA and GTADTBRB registers. For double buffer operation, also set the A/D conversion start request point in two cycles after the current cycle (in saw-wave mode or triangle-wave mode with buffer transfer at trough or crest) or one cycle after the current cycle (in triangle-wave mode with buffer transfer at both trough and crest) in the GTADTDBRA and GTADTDBRB registers.
8	Set A/D conversion start request for monitoring	Select the A/D conversion start request signal to be monitored with ADSMS0[1:0] and ADSMS1[1:0] bits in GTADSMR from GTADSM0 and GTADSM1 pins and enable output of the A/D conversion start request signal being monitored to ADSMEN0 and ADSMEN1 bits in GTADSMR. In Figure 22.150, ADSMS0[1:0] = 00b, ADSMS1[1:0] = 11b, ADSMEN0 = 1, and ADSMEN1 = 1.
9	Enable A/D conversion start request	Set to enable A/D conversion start request with the ADTRAUEN, ADTRADEN, ADTRBUEN, and ADTRBDEN bits in the GTINTAD register. In Figure 22.150, ADTRAUEN = 1, ADTRADEN = 1, ADTRBUEN = 0, and ADTRBDEN = 1.
10	Start count operation	Set the GTCR.CST bit to 1 to start count operation.
11	Set buffer value for each cycle	For buffer operation, set the A/D conversion start request point in one cycle after the current cycle (in saw-wave mode or triangle-wave mode with buffer transfer at trough or crest) or half cycle after the current cycle (in triangle-wave mode with buffer transfer at both trough and crest) in the GTADTBRA and GTADTBRB registers. For double buffer operation, also set the A/D conversion start request point in two cycles after the current cycle (in saw-wave mode or triangle-wave mode with buffer transfer at trough or crest) or one cycle after the current cycle (in triangle-wave mode with buffer transfer at both trough and crest) in the GTADTDBRA and GTADTDBRB registers.

Figure 22.151 shows an example for A/D conversion start request timing operation.

This shows an example of the output of A/D conversion start request A as start source for the A/D converter. The A/D conversion start request A signal is output in response to a match in comparison with the GTADTRA register.

If GPT is operating with PCLKD and ADC is operating with PCLKA, A/D conversion start request A is passed to ADC on the next rising edge of PCLKA.

If GPT is operating with GPTCLK and ADC is also operating with GPTCLK, A/D conversion start request A is passed to ADC without delay.

For all other clock combinations, A/D conversion start request A is synchronized and passed to ADC.

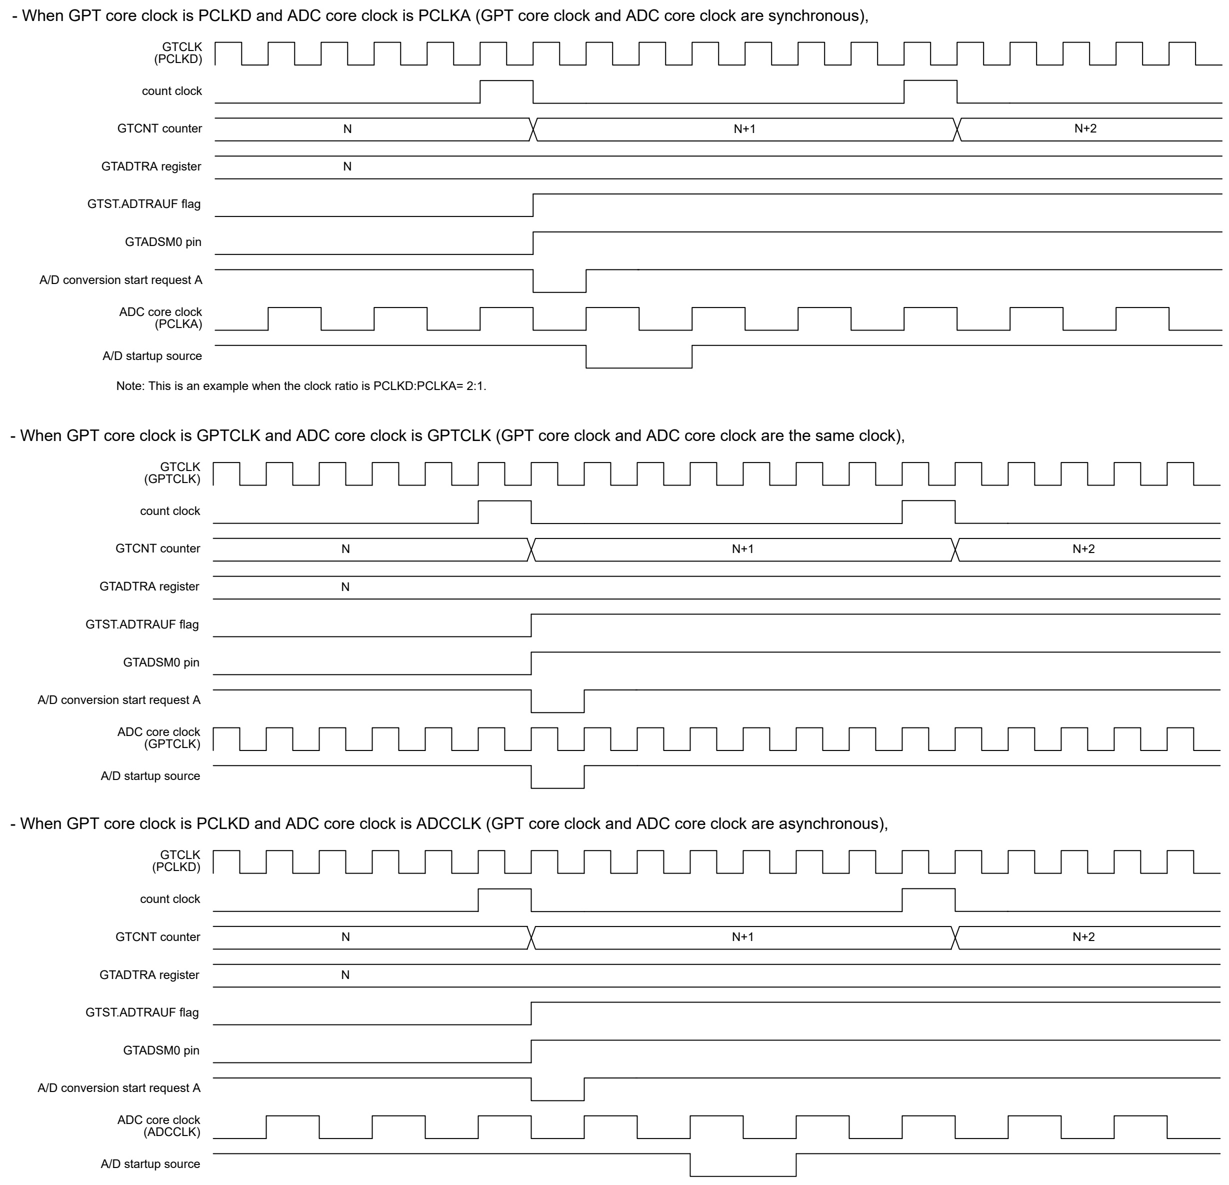

Figure 22.151 Example of A/D Conversion Start Request Timing Operation

For the restriction of A/D Conversion Start Request, see section 22.10.6. Interval of Interrupt Request.

22.6 Operations Linked by ELC

22.6.1 Event Signal Output to ELC

The GPT can perform operation linked with another module set in advance when its interrupt request signal is used as an event signal by the Event Link Controller (ELC).

The A/D conversion start request during up-counting/down-counting can be enabled/disabled individually with the A/D conversion start request enable bit to output events output to ELC.

The GPT has the following ELC event signals:

- Generation of compare match and input capture A interrupt (GPTn_CCMPA)
- Generation of compare match and input capture B interrupt (GPTn_CCMPB)
- Generation of compare match C interrupt (GPTn_CMPC)
- Generation of compare match D interrupt (GPTn_CMPD)

- Generation of compare match E interrupt (GPTn_CMPE)
- Generation of compare match F interrupt (GPTn_CMPF)
- Generation of overflow interrupt (GPTn_OVF)
- Generation of underflow interrupt (GPTn_UDF)
- Finish of period count function (GPTm_PC)

Note: n = 0 to 13

m = 0 to 3, 10 to 13

22.6.2 Event Signal Inputs from ELC

The GPT can perform the following operations in response to a maximum of 8 events from the ELC:

- Start counting, stop counting, clear counting
- Up-counting, down-counting
- Input capture.

See section 19, Event Link Controller (ELC) for the connection between the ELC and the event signal input.

22.7 Noise Filter Function

Each pin for use in input capture and Hall sensor input to the GPT is equipped with a noise filter. The noise filter samples input signals at the sampling clock and removes the pulses whose length is less than 3 sampling cycles.

The noise filter functionality includes enabling and disabling the noise filter for each pin and setting of the sampling clock for each channel.

Figure 22.152 shows the timing of noise filtering.

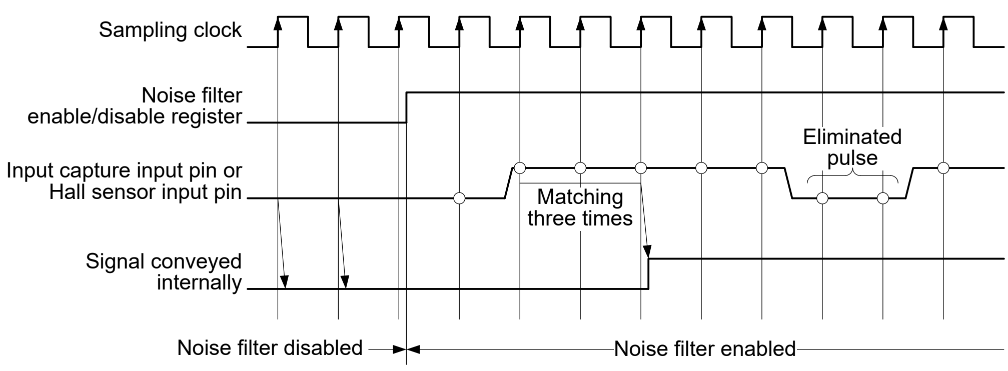

Figure 22.152 Timing of noise filtering

If noise filtering is enabled, the input capture operation or hall sensor input operation is performed on the edges of the noise filtered signal after a delay of (sampling interval × 2 + GTCLK) at the shortest. This is due to the noise filtering for the input capture input or hall sensor input.

22.8 Protection Function

22.8.1 Write-Protection for Registers

To prevent registers from being accidentally modified, registers can be write-protected in channel units by setting GTWP.WP. Write-protection can be set for the following registers:

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTITC, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTPDBR, GTADTRA, GTADTBRA, GTADTDBRA, GTADTRB, GTADTBRB, GTADTDBRB, GTDTCR, GTDVU,

GTDVD, GTDBU, GTDBD, GTSOS, GTSOTR, GTADSMR, GTEITC, GTEITLI1, GTEITLI2, GTEITLB, GTICLF, GTPC, GTADCMSC, GTADCMSS, GTBER2, GTOLBR, GTICCR.

Every bit in registers GTSTR, GTSTP and GTCLR which can update the corresponding registers in other channels and can be updated by any of the corresponding registers in other channels conversely, can be protected by setting the GTWP.STRWP, STPWP, and CLRWP bits, respectively, per channel.

Likewise, writing to the GTSECSR and GTSECR registers, which can control all channels by writing to the GTSECSR and GTSECR registers of a given channel, can by enabled or disabled by the setting of the GTWP.CMNWP bit.

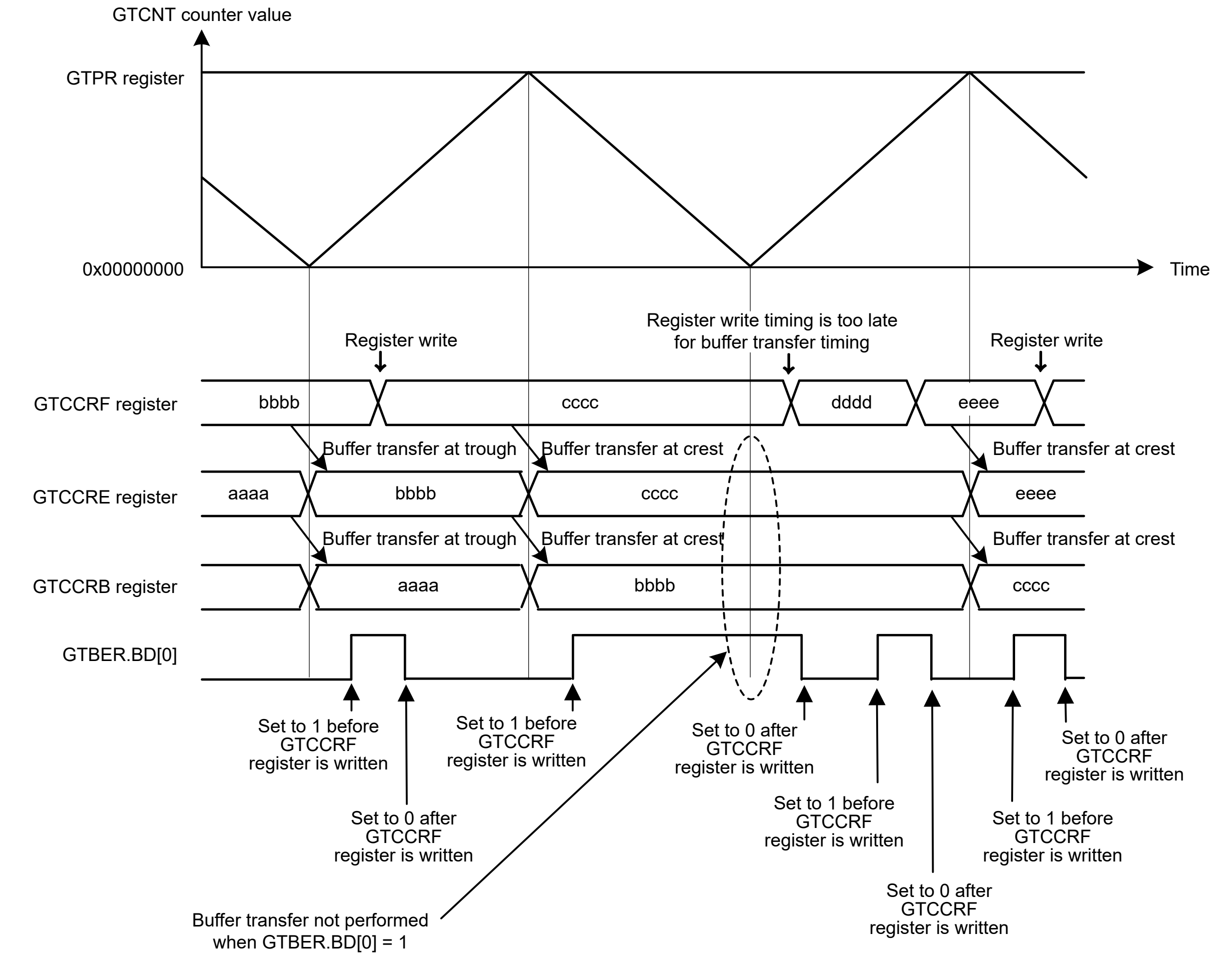
Protection using the GTWP register is only for write operations by the CPU. This protection does not cover updates to registers that occur in association with CPU writes.

22.8.2 Disabling of Buffer Operation

If the timing of the buffer register write is delayed relative to the timing for the buffer transfer, buffer operation can be suspended with the GTBER.BD[3], BD[2], BD[1] and BD[0] bits settings. Specifically, buffer transfer can be temporarily disabled even though a buffer transfer condition is generated during buffer register write, by setting the BD[3], BD[2], BD[1] and BD[0] bits to 1 (buffer operation disabled) before buffer register write, and setting the bits to 0 (buffer operation enabled) after completion of writing to all the buffer registers.

The BD[3], BD[2], BD[1] and BD[0] bits can be set on channel basis by writing directly to the GTBER register or it can be set to 0 simultaneously by setting the GTSECR register for multiple channels which were set by the GTSECSR register.

Figure 22.153 shows an example of operation for disabling buffer operation by writing to the GTBER register.



Note: The base address of registers are the same.

Figure 22.153 Example of operation for disabling buffer operation with triangle waves, double buffer operation, and buffer transfer at both troughs and crests

22.8.2.1 Simultaneous Control of Buffer Operations of Multiple Channels

The GTBER.BD bit can be set by writing directly to the GTBER register per channel or by making settings in the GTSECR register for multiple channels that have already set in the GTSECSR register.

Follow the procedure below to simultaneously set the GTBER.BD bits of multiple channels.

1. Select the channels for simultaneously setting by the GTSECSR register
   Set the GTSECSR register so that the values at the bit positions for the corresponding channels for simultaneously setting of the GTBER.BD bits become 1. All GTSECSR registers can be updated by writing to the GTSECSR register of any channel.
2. Simultaneously set the GTBER.BD bits by updating the GTSECR register
   In the GTSECR register, set the operation of the GTBER.BD bits (enabling or disabling of buffer operation) which are to be simultaneously set. Writing to a GTSECR register from any channel updates the GTBER.BD bits in all channels corresponding to the bits set as 1 in the GTSECSR register, in accordance with the value of the GTSECR register.

Figure 22.154 and Figure 22.155 show examples of simultaneously controlling the enabling or disabling of buffer operation for multiple channels.

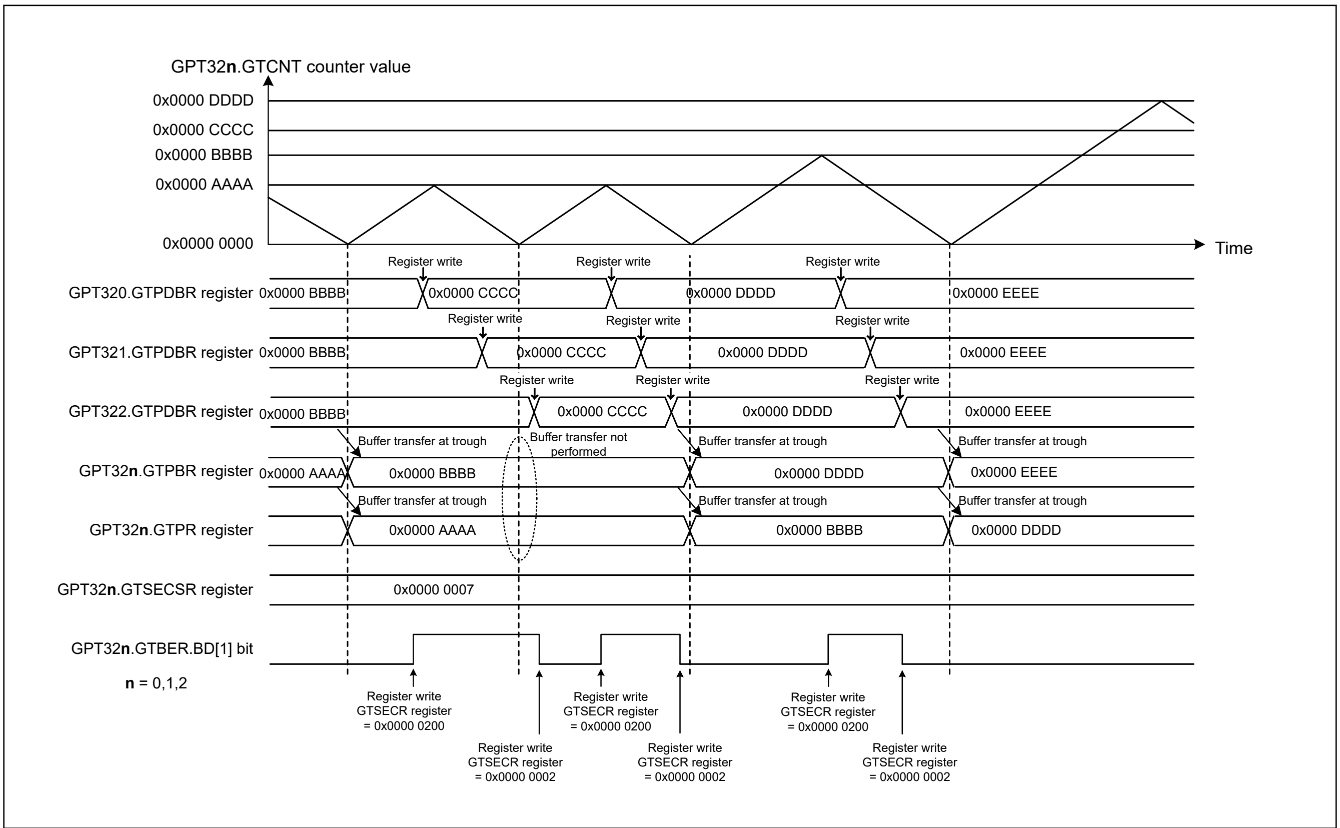


Figure 22.154 Example of Multiple Channel Operation for Disabling Buffer Operation (Triangle Waves, Double Buffer Operation)

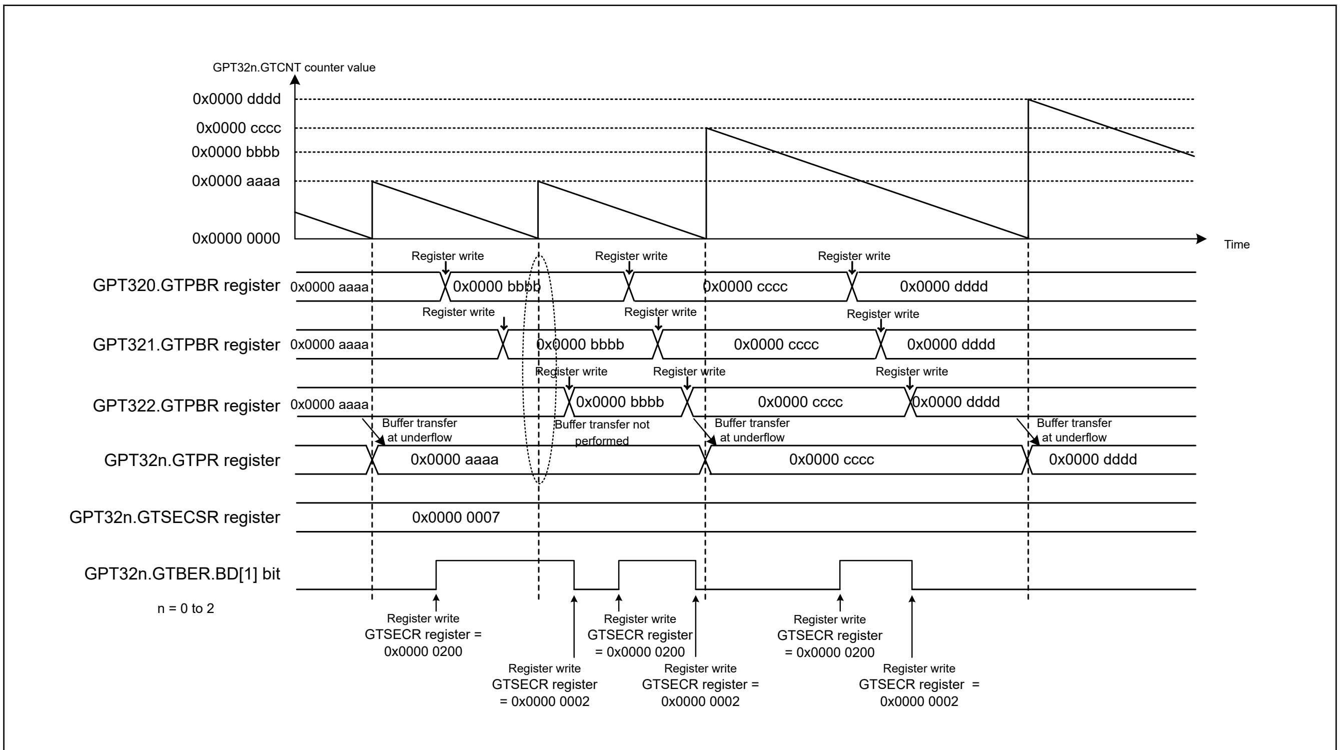

Figure 22.155 Example of Multiple Channel Operation for Disabling Buffer Operation (Saw Waves, Single Buffer Operation)

22.8.2.2 Repeated Double-Buffered Operation When Disabling GTCCR Buffer Transfer

When a GTBER.DBRTECm (m = A, B) bit is set to 1 in saw-wave one-shot pulse mode or triangle-wave PWM mode 3, transfer from the intermediate buffer to the GTCCRm (m = A, B) register is repeated on a cyclic basis even while buffer transfer is disabled by the setting of the GTBER.BD[0] bit or by the buffer transfer extended skipping function.

(1) In saw-wave one-shot pulse mode

In saw-wave one-shot pulse mode, the compare match value for the first half of a waveform is stored in temporary register x (x = C, E) as the intermediate buffer for the GTCCRx (x = C, E) register and the compare match value for the second half of a waveform is stored in temporary register m (m = A, B) as the intermediate buffer for the GTCCRy (y = D, F) register, respectively, for compare match values during repeated buffer operation, and the given values are alternately transferred to the GTCCRm (m = A, B) registers.

Table 22.75 lists the types of buffer transfer of the GTCCR register during counting in saw-wave one-shot pulse mode.

While counting is stopped, the setting of the value in the temporary register is transferred through forcible buffer transfer. In forcible buffer transfer, the values of the GTCCRy (y = D, F) registers are transferred to temporary registers m (m = A, B), and the values of the GTCCRx (x = C, E) are transferred to temporary registers x (x = C, E) when the setting of the corresponding GTBER.DBRTECm (m = A, B) bit is 1, respectively.

When the setting of the GTBER.DBRTECm (m = A, B) bit is 1, values written by the CPU to the GTCCRm (m = A, B) registers are reflected as the values of temporary registers x (x = C, E).

Table 22.75 GTCCR Buffer Transfer Operation in Saw-Wave One Shot Pulse Mode during GTCNT Counting

GTBER.DBRTECm	Buffer Transfer	Timing of transfer				
		GTCCRx ↓ GTCCRm	GTCCRx ↓ Temporary register x	Temporary register x ↓ GTCCRm	GTCCRy ↓ Temporary register m	Temporary register m ↓ GTCCRm
0	Transfer enabled period	Overflow or Underflow	No transfer	No transfer	Overflow or Underflow	GTCCRm compare match
	Transfer disabled period	No transfer	No transfer	No transfer	No transfer	No transfer
1	Transfer enabled period	Overflow or Underflow	Overflow or Underflow	No transfer	Overflow or Underflow	GTCCRm compare match
	Transfer disabled period	No transfer	No transfer	Overflow or Underflow	No transfer	GTCCRm compare match

Note: m = A, B
x = C, E
y = D, F

Figure 22.156 shows the operation of generating transfer-disabled period by extended buffer transfer skipping as an example of repeated double buffer operations when the GTCCR buffer transfer disabled in saw-wave one-shot pulse mode.

Figure 22.157 shows the operation of generating transfer-disabled period by updating the GTBER.BD[0] bit as an example of repeated double-buffer operations when the GTCCR buffer transfer is disabled in saw-wave one-shot pulse mode.

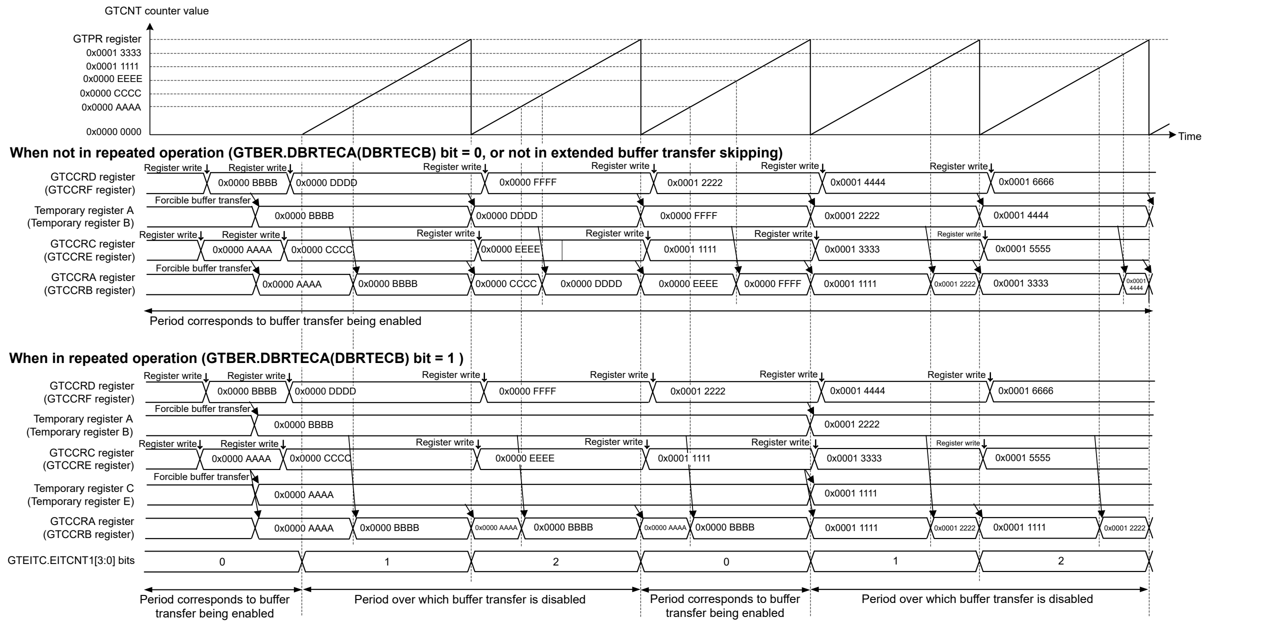

Figure 22.156 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Saw-Wave One-Shot Pulse Mode, Using Extended Buffer Transfer Skipping, GTBER.BD[0] is Constantly 0)

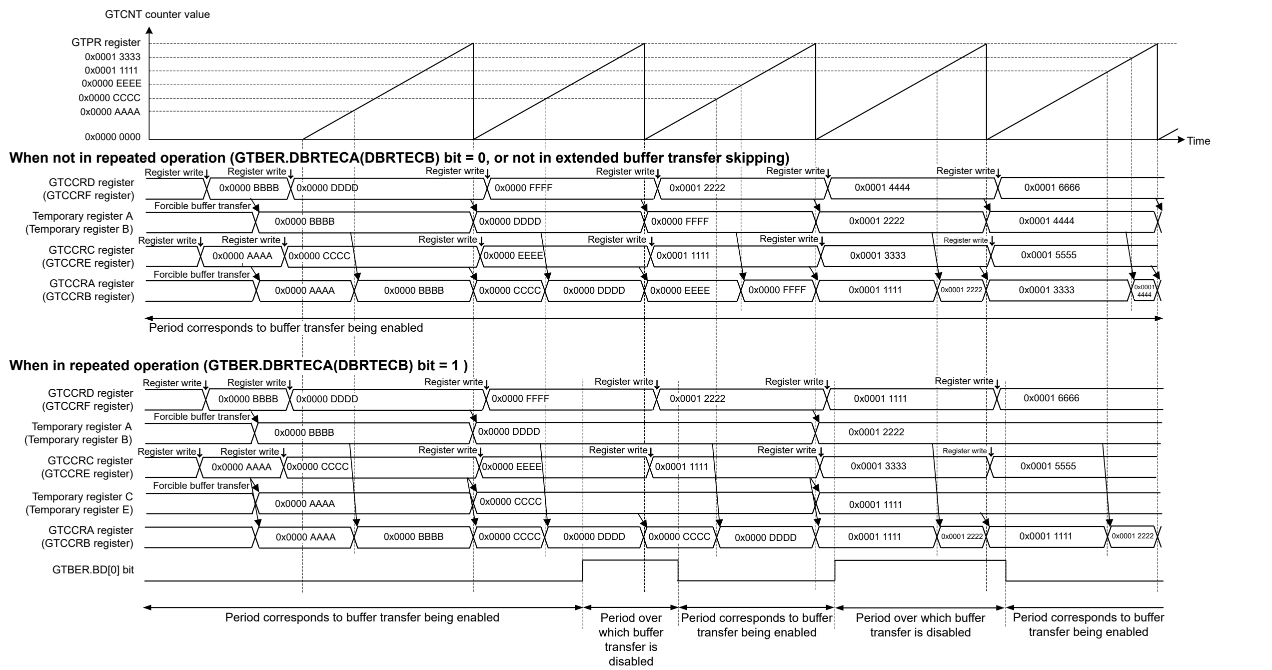

Figure 22.157 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Saw-Wave One-Shot Pulse Mode, Updating the GTBER.BD[0] Bit)

(2) In triangle-wave PWM mode 3

In triangle-wave PWM mode 3, the compare match value for the first half of a waveform is stored in the temporary register x (x = C, E) as the intermediate buffer for the GTCCRx (x = C, E) register and the compare match value for the second half of a waveform is stored in temporary register m (m = A, B) as the intermediate buffer for the GTCCRy (y = D, F) register, respectively, for compare match values during repeated buffer operation, and the given values are alternately transferred to the GTCCRm (m = A, B) register.

Table 22.76 lists the types of buffer transfer of the GTCCR register during counting operation in triangle-wave PWM mode 3.

While counting is stopped, the setting of the value in the temporary register is transferred through forcible buffer transfer. In forcible buffer transfer, the values of the GTCCRy (y = D, F) registers are transferred to temporary registers m (m = A, B), and the values of the GTCCRx (x = C, E) are transferred to temporary registers x (x = C, E), when the setting of the corresponding GTBER.DBRTECm (m = A, B) bit is 1, respectively.

When the setting of the GTBER.DBRTECm (m = A, B) bit is set to 1, values written by the CPU to the GTCCRm (m = A, B) registers are reflected as the values of temporary registers x (x = C, E).

Table 22.76 GTCCR Buffer Transfer Operation in Triangle-Wave PWM Mode 3 during GTCNT Counting

GTBER.DBRTECm	Buffer Transfer	Timing of transfer				
		GTCCRx ↓ GTCCRm	GTCCRx ↓ Temporary register x	Temporary register x ↓ GTCCRm	GTCCRy ↓ Temporary register m	Temporary register m ↓ GTCCRm
0	Transfer enabled period	Trough	No transfer	No transfer	Trough	Crest
	Transfer disabled period	No transfer	No transfer	No transfer	No transfer	No transfer
1	Transfer enabled period	Trough	Trough	No transfer	Trough	Crest
	Transfer disabled period	No transfer	No transfer	Trough	No transfer	Crest

Note: m = A, B
x = C, E
y = D, F

Figure 22.158 shows the operation of generating transfer-disabled period by extended buffer transfer skipping as an example of repeated double buffer operations when the GTCCR buffer transfer disabled in triangle-wave PWM mode 3.

Figure 22.159 shows the operation of generating transfer-disabled period by updating the GTBER.BD[0] bit as an example of repeated double-buffer operations when the GTCCR buffer transfer is disabled in triangle-wave PWM mode 3.

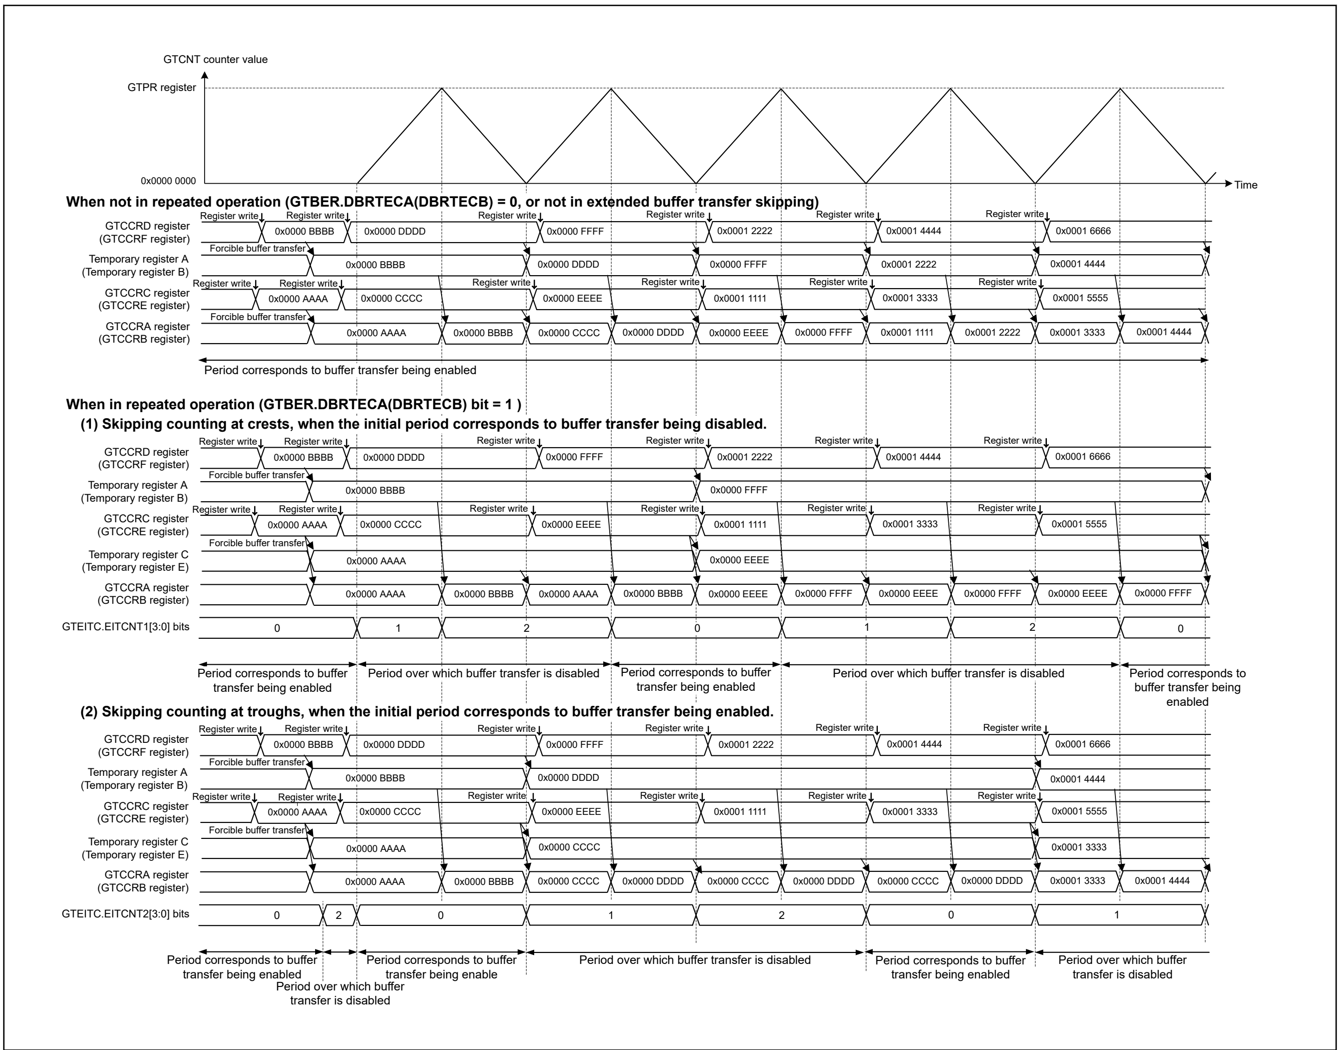

Figure 22.158 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Triangle-Wave PWM Mode 3, Using Extended Buffer Transfer Skipping, GTBER.BD[0] is Constantly 0)

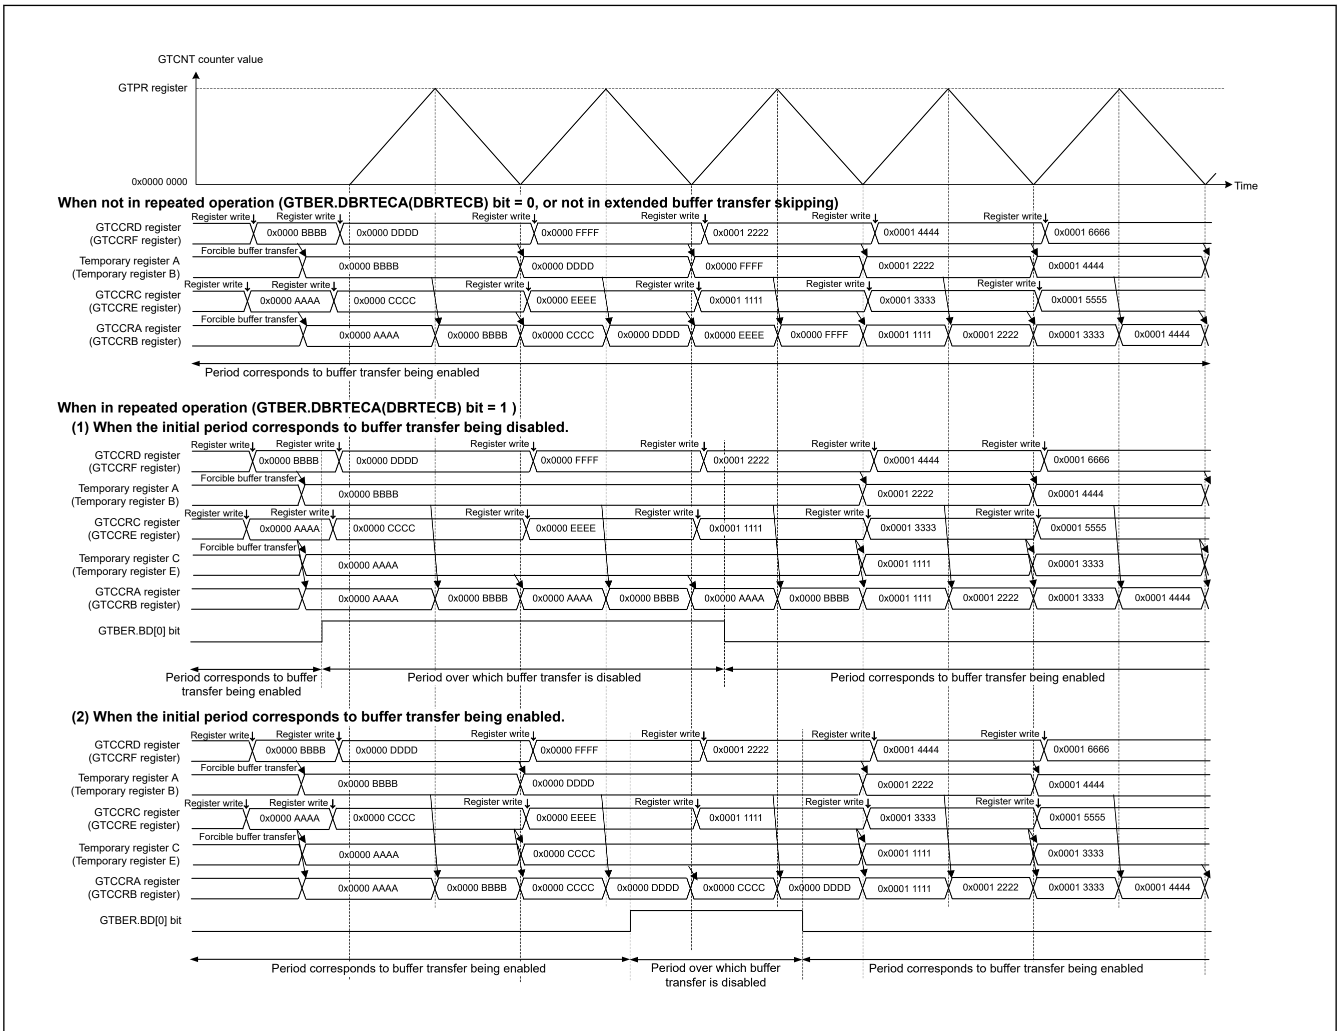

Figure 22.159 Example of Repeated Double-Buffer Operation When GTCCR Buffer Transfer is Disabled (Triangle-Wave PWM Mode 3, Updating the GTBER.BD[0] Bit)

22.8.3 GTIOCnm Pin Output Negate Control (n = 0 to 13, m = A, B)

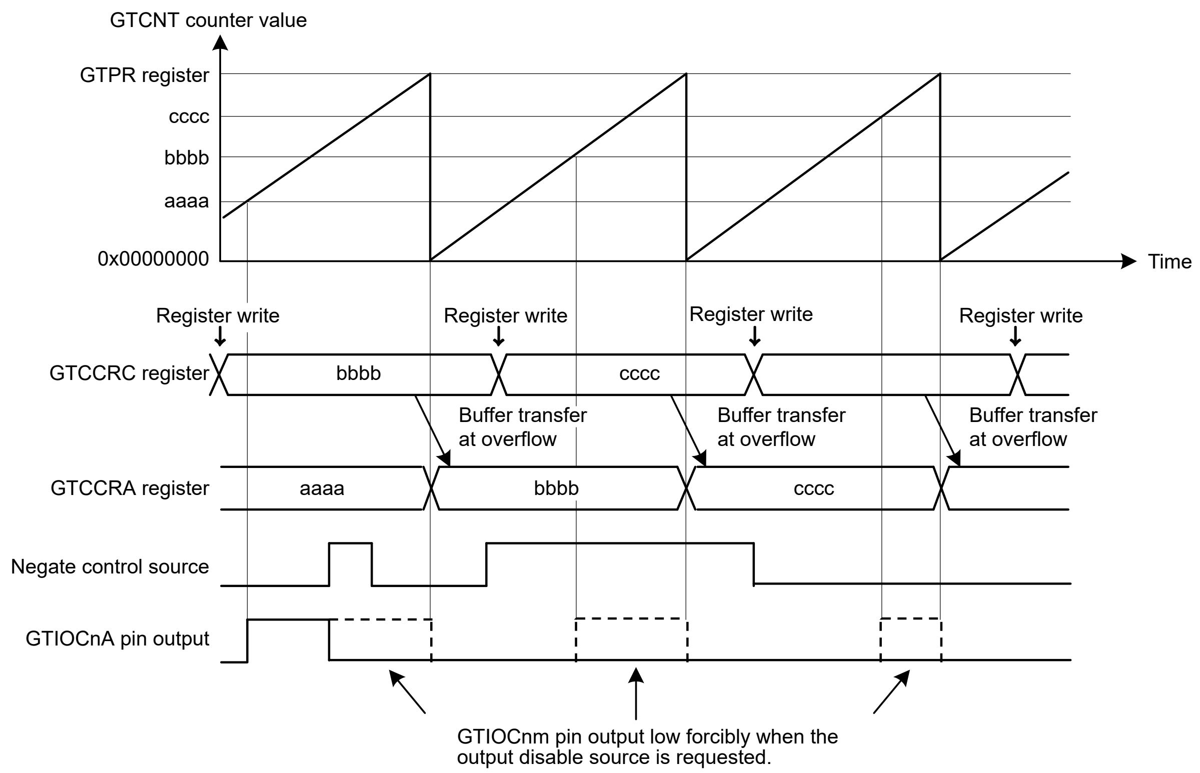
For protection from system failure, the output disable control that changes the GTIOCnm pin output value forcibly is provided for GTIOCnm pin output by the request of output disable from POEG. Output protection is required when a dead time error or the same output level being on the GTIOCnA and GTIOCnB pins is detected. GPT detects this condition and generates output disable requests to POEG according to the setting of the output disable request permission bits, such as GTINTAD.GRPDTE, GTINTAD.GRPABH, GTINTAD.GRPABL. After the POEG performs the logical OR of the output disable request from each channel and the output disable request from the external input, the POEG generates output disable requests to GPT.

One output disable signal (representing the shared output disable request signal of the GTIOCnA pin and the GTIOCnB pin) out of 4 output disable requests generated by the POEG is selected by setting GTINTAD.GRP[1:0]. The status of the selected disable output request is monitored by reading the GTST.ODF bit. The output level during output disable is set based on the GTIOR.OADF[1:0] bits for the GTIOCnA pin and the GTIOR.OBDF[1:0] setting for the GTIOCnB pin.

The change to the output disable state is performed asynchronously by generating the output disable request from the POEG. The release of the output disable state is performed at end of cycle by terminating the output disable request. It is after 3 GTCLK at shortest when the output disable condition is released after the output disable request becomes no longer satisfied. To reliably control output disabling, clear the flag of POEG for which the condition for the request to disable the output is no longer satisfied after 4 cycles of GTCLK.

When event count is performed or when the operating mode is saw-wave PWM mode 2 or when the output disable state should be released immediately without waiting for end of cycle, GTIOR.OADF[1:0] should be set to 00b (for GTIOCnA pin) or GTIOR.OBDF[1:0] should be set to 00b (for the GTIOCnB pin).

Figure 22.160 shows an example of the GTIOCnm pin output disable control operation. (n = 0 to 13, m = A, B)



Note: The base address of registers are the same.

Figure 22.160 Example of GTIOCnm pin output disable control operation in saw-wave up-counting, buffer operation, active level 1, high output at GTCCRA compare match, low output at cycle end, and low output at output disable (n = 0 to 13, m = A, B)

22.8.4 Output Protection Function for GTIOCnm Pin Output (n = 0 to 13; m = A, B)

To prepare for a case when an incorrect value (0x0000 0000 or a value greater than or equal to the GTPR register value) is set in the GTCCRA register, the output protection function for the GTIOCnm pin output (disabling function) is activated when the automatic dead time is set (GTDTCR.TDE bit = 1) in triangle-wave PWM mode.

The status of the output protection function can be read from the GTSOS.SOS[1:0] bits.

Figure 22.161 shows the output protection function state transition.

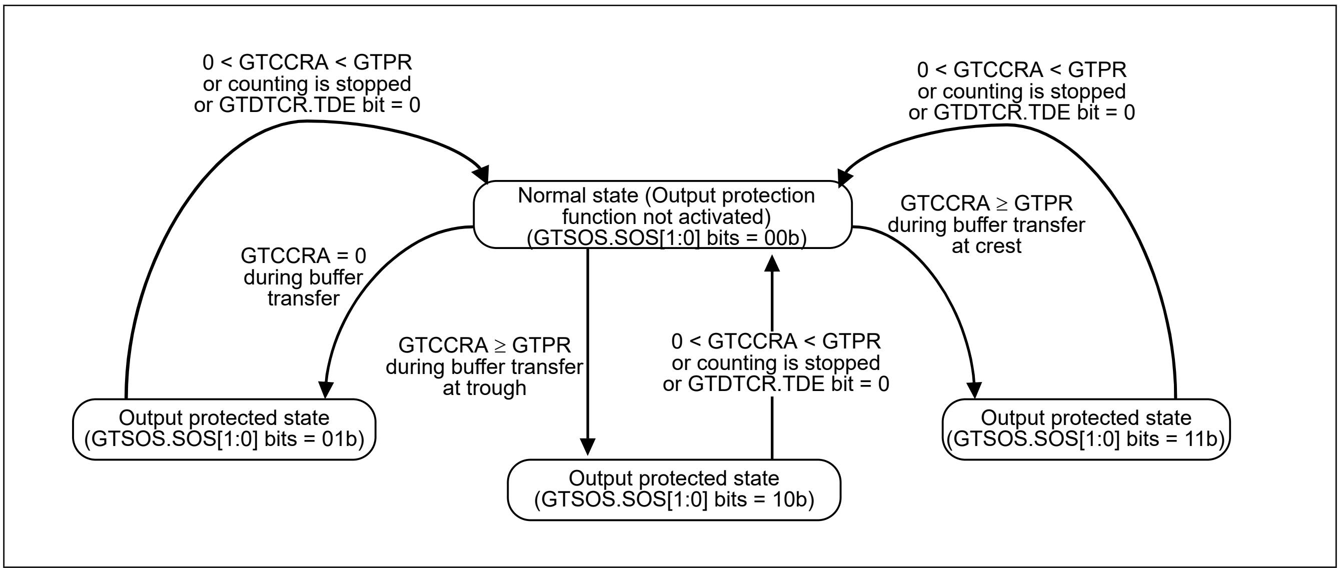


Figure 22.161 Output Protection Function

(1) Output Protection Function When the GTCCRA Register is Set to 0x0000 0000 during Buffer Transfer

Figure 22.162 and Figure 22.163 show examples of output protection function operation when the GTCCRA register is set to 0x0000 0000 during buffer transfer at troughs, and Figure 22.164 and Figure 22.165 show examples when the GTCCRA register is set to 0x0000 0000 during buffer transfer at crests.

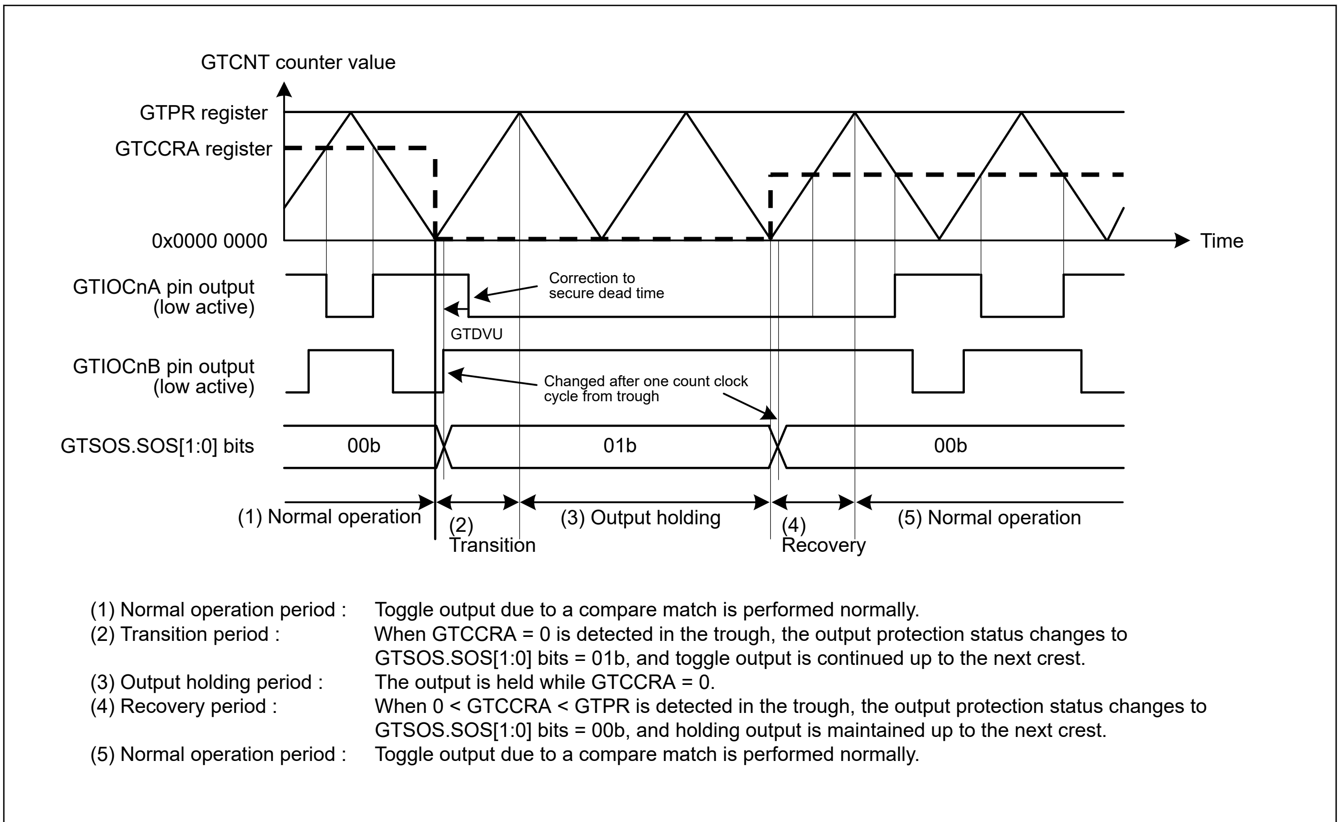

Figure 22.162 Example of Output Protection Function Operation When GTCCRA is Set to 0x0000 0000 during Buffer Transfer at Troughs (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 13)

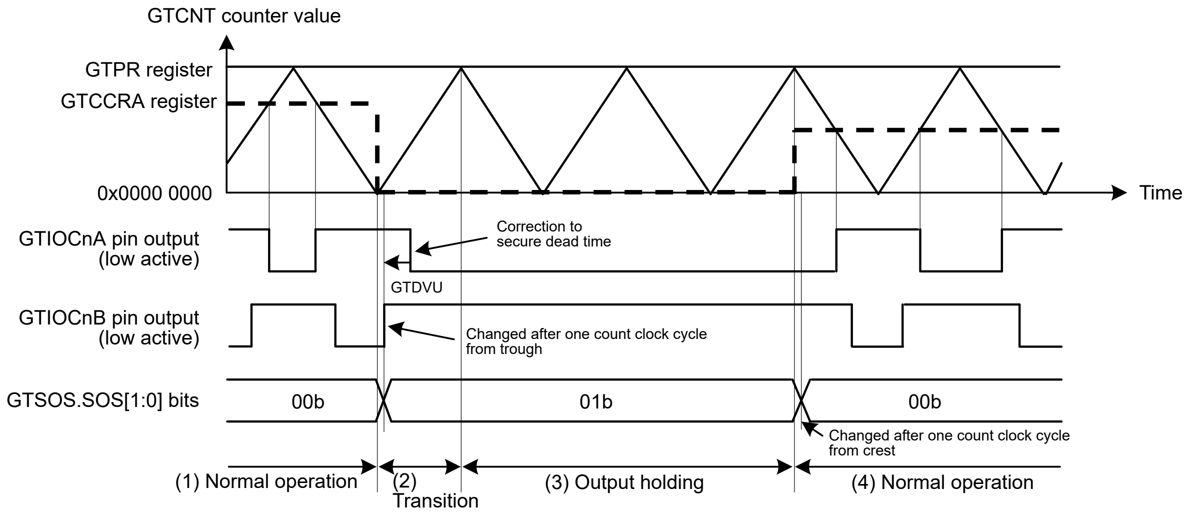
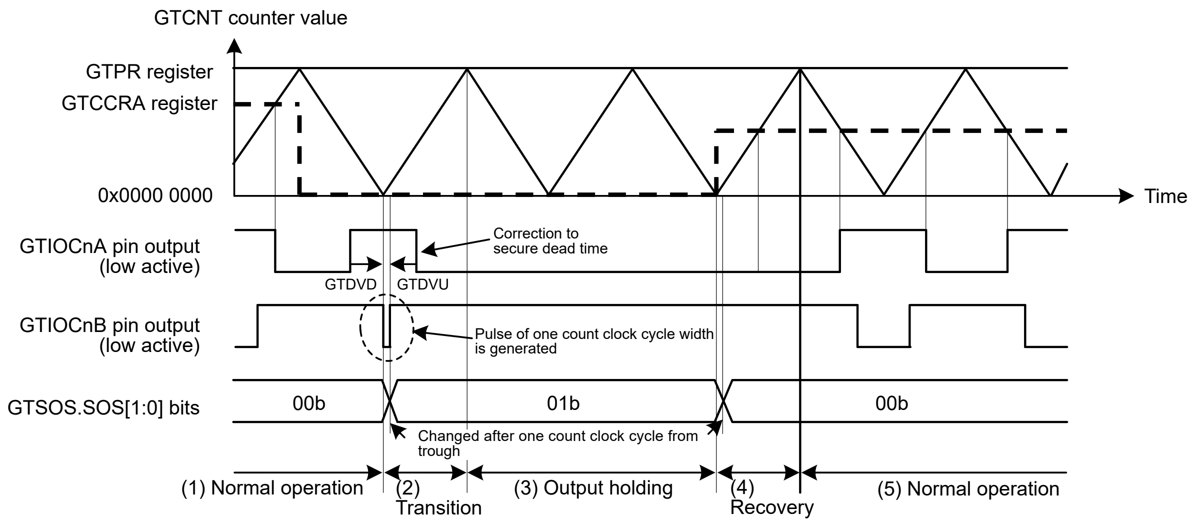


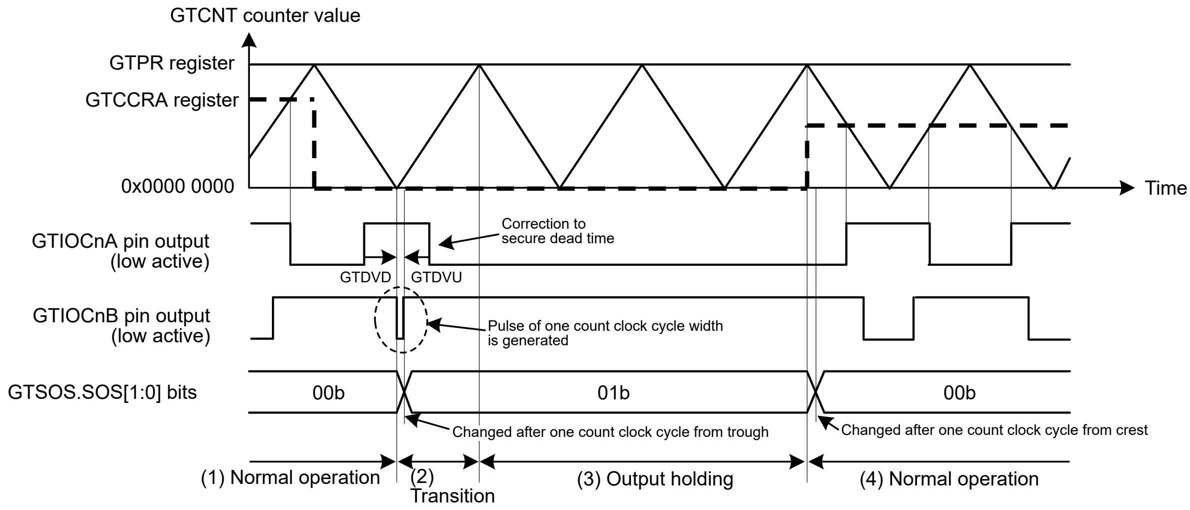
(1) Normal operation period : Toggle output due to a compare match is performed normally.
(2) Transition period : When GTCCRA = 0 is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 01b, and toggle output is continued up to the next crest.
(3) Output holding period : The output is held while GTCCRA = 0.
(4) Normal operation period : When 0 < GTCCRA < GTPR is detected in the crest, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

Figure 22.163 Example of Output Protection Function Operation When GTCCRA is Set to 0x0000 0000 during Buffer Transfer at Troughs (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Crests, Active Level: Low) (n = 0 to 13)



(1) Normal operation period : Toggle output due to a compare match is performed normally.
(2) Transition period : When GTCCRA = 0 is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 01b, and toggle output is continued up to the next crest.
(3) Output holding : The output is held while GTCCRA = 0.
(4) Recovery period : When 0 < GTCCRA < GTPR is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and holding output is maintained up to the next crest.
(5) Normal operation period : Toggle output due to a compare match is performed normally.

Figure 22.164 Example of Output Protection Function Operation When GTCCRA is Set to 0x0000 0000 during Buffer Transfer at Crests (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 13)

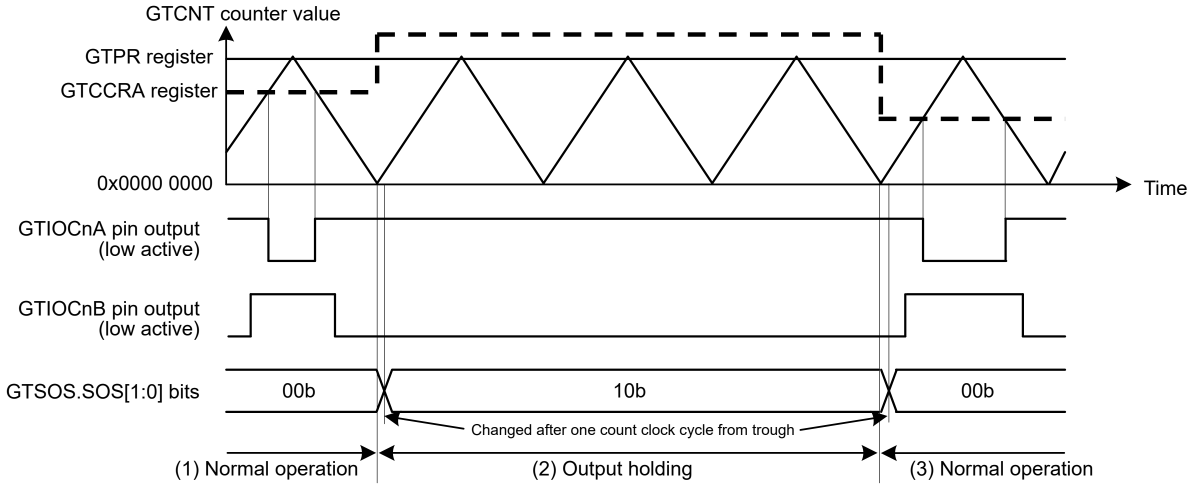


(1) Normal operation period :	Toggle output due to a compare match is performed normally.
(2) Transition period :	When GTCCRA = 0 is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 01b, and toggle output is continued up to the next crest.
(3) Output holding period :	The output is held while GTCCRA = 0.
(4) Normal operation period :	When 0 < GTCCRA < GTPR is detected in the crest, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

Figure 22.165 Example of Output Protection Function Operation When the GTCCRA is Set to 0x0000 0000 during Buffer Transfer at Crests (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Crests, Active Level: Low) (n = 0 to 13)

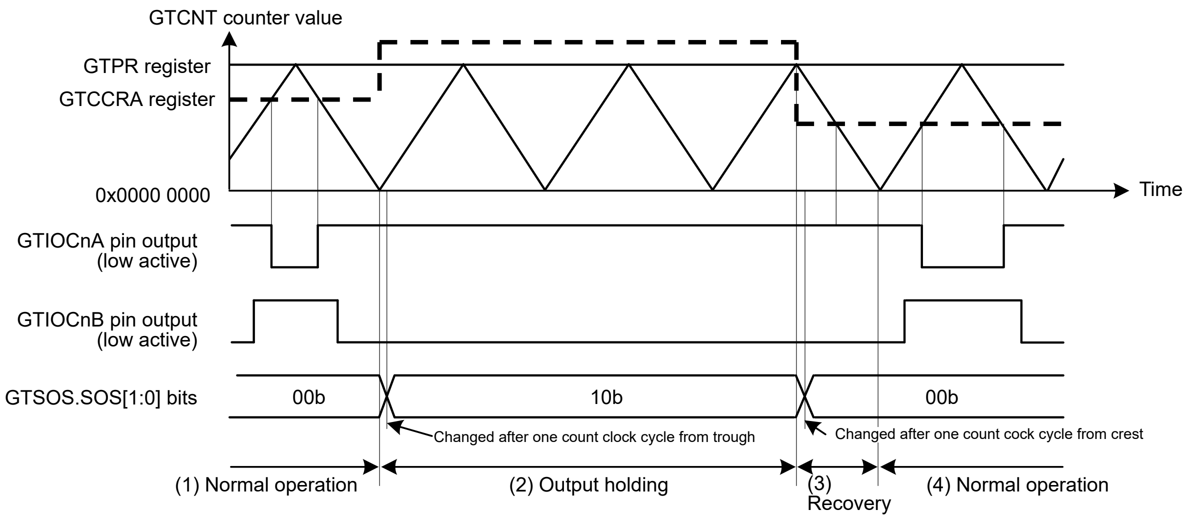
(2) Output Protection Function When GTCCRA Register ≥ GTPR Register is Set during Buffer Transfer at Troughs

Figure 22.166 and Figure 22.167 show examples of output protection function operation when GTCCRA register ≥ GTPR register is set during buffer transfer at troughs.



(1) Normal operation period :	Toggle output due to a compare match is performed normally.
(2) Output holding period :	When GTCCRA ≥ GTPR is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 10b, and the output is held while GTCCRA ≥ GTPR.
(3) Normal operation period :	When 0 < GTCCRA < GTPR is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

Figure 22.166 Example of Output Protection Function Operation When GTCCRA ≥ GTPR is set during Buffer Transfer at Troughs (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 13)

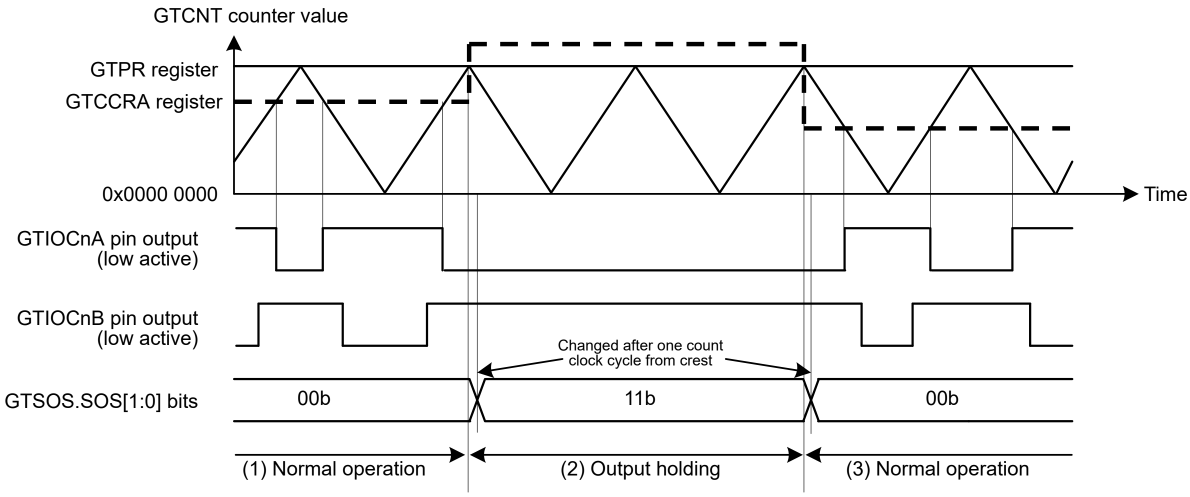


(1) Normal operation period :	Toggle output due to a compare match is performed normally.
(2) Output holding period :	When GTCCRA ≥ GTPR is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 10b, and the output is held while GTCCRA ≥ GTPR.
(3) Recovery period :	When 0 < GTCCRA < GTPR is detected in the crest, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and holding output is maintained up to the next trough.
(4) Normal operation period :	Toggle output due to a compare match is performed normally.

Figure 22.167 Example of Output Protection Function Operation When GTCCRA ≥ GTPR is Set during Buffer Transfer at Troughs (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Crests, Active Level: Low) (n = 0 to 13)

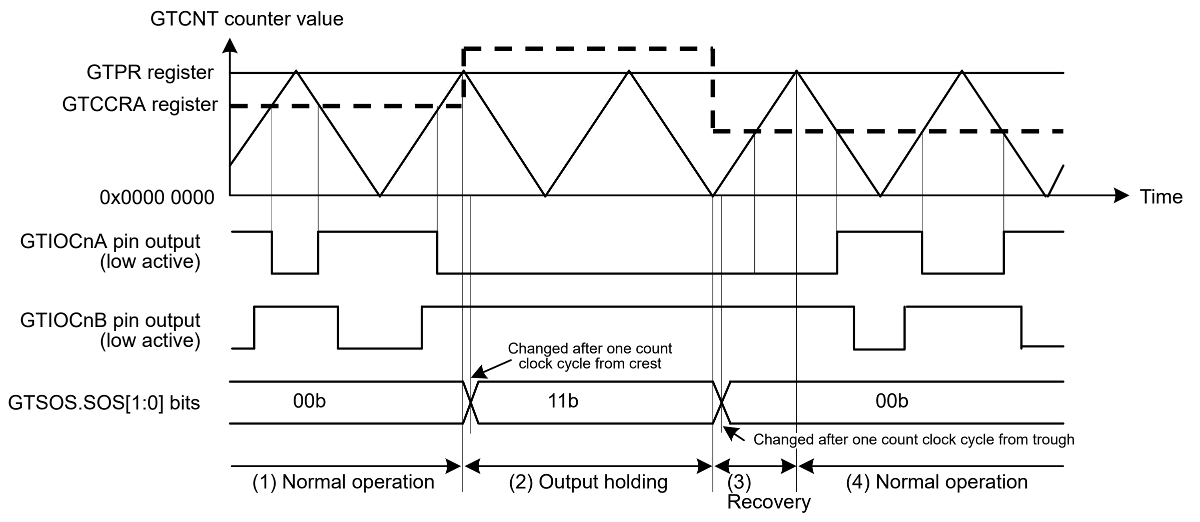
(3) Output Protection Function When GTCCRA ≥ GTPR is Set during Buffer Transfer at Crests

Figure 22.168 and Figure 22.169 show examples of output protection function operation when GTCCRA ≥ GTPR is set during buffer transfer at crests.



(1) Normal operation period : Toggle output due to a compare match is performed normally.
(2) Output holding period : When GTCCRA ≥ GTPR is detected in the crest, the output protection status changes to GTSOS.SOS[1:0] bits = 11b, and the output is held while GTCCRA ≥ GTPR.
(3) Normal operation period : When 0 < GTCCRA < GTPR is detected in the crest, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

Figure 22.168 Example of Output Protection Function Operation When GTCCRA ≥ GTPR is Set during Buffer Transfer at Crests (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Crests, Active Level: Low) (n = 0 to 13)



(1) Normal operation period :	Toggle output due to a compare match is performed normally.
(2) Output holding period :	When GTCCRA ≥ GTPR is detected in the crest, the output protection status changes to GTSOS.SOS[1:0] = 11b, and the output is held while GTCCRA ≥ GTPR.
(3) Recovery period :	When 0 < GTCCRA < GTPR is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] = 00b, and holding output is maintained up to the next crest.
(4) Normal operation period :	Toggle output due to a compare match is performed normally.

Figure 22.169 Example of Output Protection Function Operation When GTCCRA ≥ GTPR is Set during Buffer Transfer at Crests (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 13)

(4) Restricted Specification of Output Protection Function

Even if an incorrect value (0x0000 0000 or a value greater than or equal to the GTPR register value) is set in the GTCCRA register during count operation, the output protection functions in a specific way such that one of the positive- and negative-phase outputs becomes non-active. However, if the following condition is not satisfied, the output protection does not operate normally.

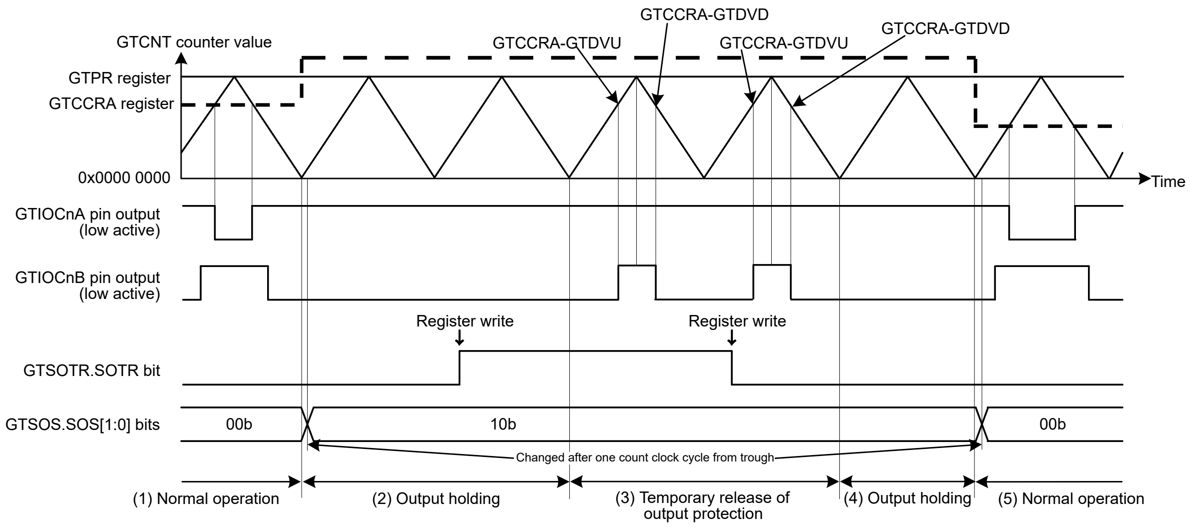
- When the GTCCRA register value at the start of count operation is greater than 0x0000 0000, and less than the setting value of the GTPR register

(5) Temporary Release of Output Protection Function

When the GTSOS.SOS[1:0] bits = 10b (protected state in which GTCCRA register ≥ GTPR register has occurred during transfer at trough), the protected state of the GTIOCnB pin output can be temporarily released by setting the GTSOTR.SOTR bit to 1. The SOS[1:0] bits retain 10b even if the output protection function is released.

When the SOTR bit is set to 0, the GTIOCnB pin output protection can be restarted.

Figure 22.170 shows examples of the operation of temporary release of output protection when the setting of the GTCCRA register ≥ GTPR register during buffer transfer at troughs.



(1) Normal operation period:	Toggle output due to a compare match is performed normally.
(2) Output holding period:	When GTCCRA ≥ GTPR is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 10b, and the output is held while GTCCRA ≥ GTPR. Even when the GTSOTR.SOTR bit is set to 1 during the output holding period, the GTIOCnB pin output is held until the first trough after the setting.
(3) Output protection temporary release period:	After GTSOTR.SOTR bit is set to 1, the GTIOCnB pin output is performed normally from the first trough after the setting. Even when the GTSOTR.SOTR bit is set to 0 during the output protection releasing period, the GTIOCnB pin output is held until the first trough after the setting.
(4) Output holding period:	The output is held until 0 < GTCCRA < GTPR is detected in the trough.
(5) Normal operation period:	When 0 < GTCCRA < GTPR is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

Figure 22.170 Example of Temporary Release of Output Protection When the Setting of the GTCCRA ≥ GTPR during Buffer Transfer at Trough s (Restored to 0 < GTCCRA < GTPR during Buffer Transfer at Troughs, Active Level: Low) (n = 0 to 13)

22.9 Initialization Method of Output Pins

22.9.1 Pin Settings After Reset

The GPT registers are initialized at a reset. Start counting after selecting the port pin function with the PmnPFS register, setting GTIOR.OAE and GTIOR.OBE bits, and outputting the GPT function to external pins.

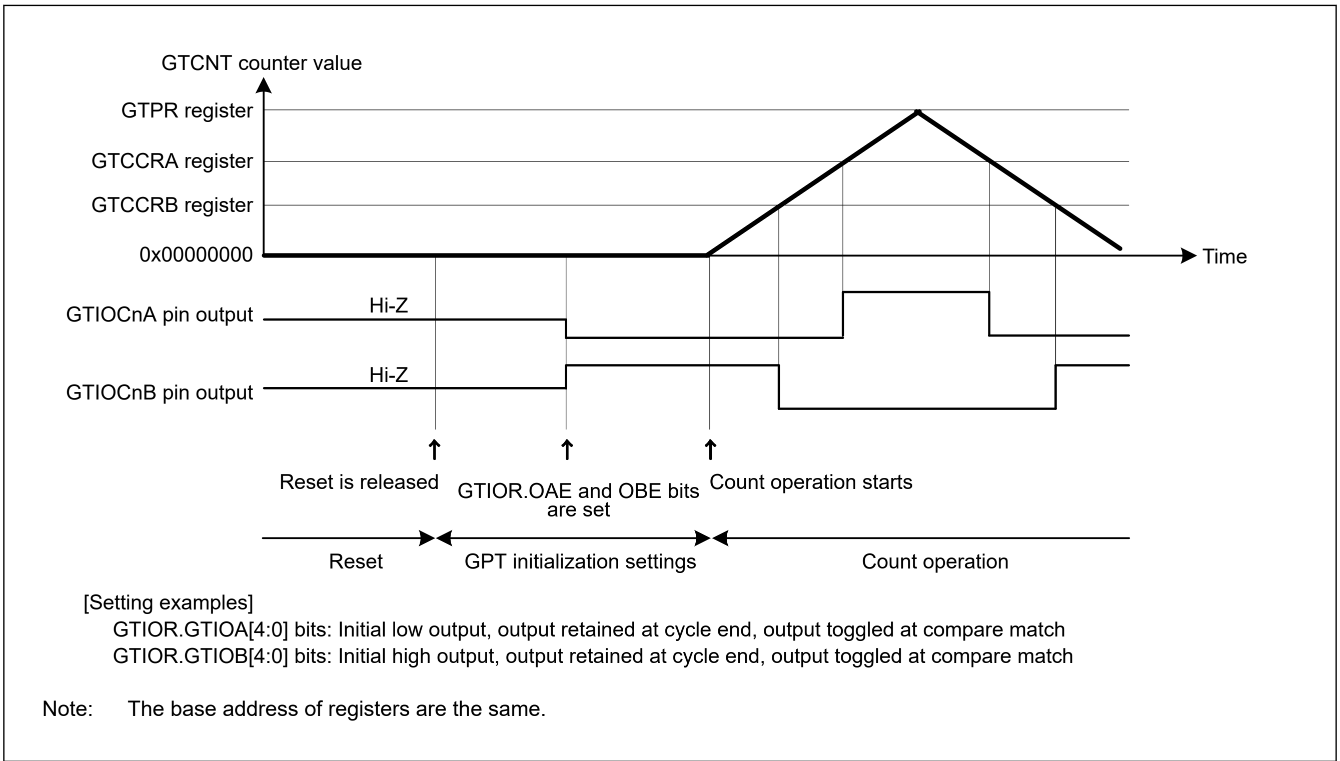


Figure 22.171 Example of pin settings after reset

22.9.2 Pin Initialization Due to Error During Operation

If an error occurs during GPT operation, the following four types of pin control can be performed before pin initialization:

- Set the OAHLD and OBHLD bits in GTIOR to 1 and retain the outputs at count stop
- Set the OAHLD and OBHLD bits in GTIOR to 0, specify arbitrary output values at OADFLT and OBDFLT in GTIOR, and output the arbitrary values at count stop
- Set the pin to output an arbitrary value as a general output port by setting the PDR, PODR registers and PmnPFS.PMR bit of the I/O port in advance. Set the OAE and OBE bits in GTIOR to 0, and the control bit associated with the pin in the PMR to 0 to allow arbitrary values to be output from the pin set as a general output port when an error occurs.
- Drive the output to a high impedance state using the POEG function.

If the automatic dead time setting is made, clear the GTDTCR.TDE bit to 0 after counting stops. When counting stops, only the values of registers that are changed by a GPT external source change. If counting is resumed, operation continues from where it stopped. If counting is stopped, the registers must be initialized before counting starts.

22.10 Usage Notes

22.10.1 Module-Stop Function Setting

The Module Stop Control Register can enable or disable GPT operation. The GPT is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Mode.

Set GTCLKCR register before releasing the module-stop state.

22.10.2 GTCCRn Settings During Compare Match Operation (n = A to F)

(1) When automatic dead time setting is made in triangle-wave PWM mode

The GTCCRA register must satisfy all of the following conditions:

- GTDVU < GTCCRA
- GTCCRA > GTDVD

- 0 < GTCCRA < GTPR

When the setting of GTCCRA = 0 or GTCCRA ≥ GTPR is made for the GTCCRA register during count operation, the output protection function is activated. However, if the following condition is not satisfied, the output protection function does not work normally:

- The value of the GTCCRA register at the start of counting is larger than 0 and less than GTPR.

For details, see section 22.8.4. Output Protection Function for GTIOCnm Pin Output (n = 0 to 13; m = A, B)

(2) When automatic dead time setting is not made in triangle-wave PWM mode

The GTCCRA register must be set within the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. When GTCCRA > GTPR, no compare match occurs.

Similarly, GTCCRB must be set within the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB is 0 or GTCCRB = GTPR is satisfied. When GTCCRB > GTPR, no compare match occurs.

(3) When automatic dead time setting is made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, the correct output waveforms with secured dead time may not be obtained.

- In up-counting: GTCCRC < GTCCRD, GTCCRC > GTDVU, GTCCRD < GTPR - GTDVD
- In down-counting: GTCCRC > GTCCRD, GTCCRC < GTPR - GTDVU, GTCCRD > GTDVD

(4) When automatic dead time setting is not made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRC < GTCCRD < GTPR
- In down-counting: GTPR > GTCCRC > GTCCRD > 0

Similarly, GTCCRE and GTCCRF must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRE < GTCCRF < GTPR
- In down-counting: GTPR > GTCCRE > GTCCRF > 0.

(5) In saw-wave PWM mode

The GTCCRA register must be set with the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. If GTCCRA > GTPR is set, no compare match occurs.

Similarly, GTCCRB must be set with the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB = 0 or GTCCRB = GTPR is satisfied. If GTCCRB > GTPR is set, no compare match occurs.

(6) In Complementary PWM mode 1, 2, 3

The GTCCRn register must be set with the range of 0 ≤ GTCCRn ≤ GTPR + GTDVU.

(7) In Complementary PWM mode 4

In single buffer operation, the GTCCRn register must be set with the range of 0 ≤ GTCCRn ≤ GTPR + GTDVU.

In double buffer operation, the GTCCRn register must be set with the range of GTDVU < GTCCRn < GTPR.

22.10.3 Setting Range for GTCNT Counter

Other than the Saw-wave PWM mode 2 and Complementary PWM mode, the GTCNT counter register must be set with the range of 0 ≤ GTCNT ≤ GTPR.

22.10.4 Starting and Stopping the GTCNT Counter

The control timing of starting and stopping the GTCNT counter by the GTCR.CST bit synchronizes the count clock that is selected in GTCR.TPCS[3:0]. When GTCR.CST is updated, the GTCNT counter starts/stops after a count clock that is selected in GTCR.TPCS[3:0]. Therefore, an event generated before the GTCNT counter actually starts is ignored, resulting in situations in which an event is accepted or an interrupt occurs after GTCR.CST is set to 0.

22.10.5 Priority Order of Each Event

(1) GTCNT register

Table 22.77 shows a priority order of events updating the GTCNT register.

Table 22.77 Priority order of sources updating GTCNT

Source updating GTCNT	Priority order
Writing by CPU (writing to GTCNT/GTCLR)	High
Clear by hardware sources set in GTCSR	↑
Count up or down by hardware sources set in GTUPSR/GTDNSR	↑
Count operation	Low

If up-counting and down-counting by hardware sources occur at the same time, the GTCNT counter value does not change. When there is a conflict between updating the GTCNT register and reading by the CPU, pre-update data is read.

(2) GTCR.CST bit

When there is a conflict between starting/stopping by hardware sources set in the GTSSR/GTPSR registers and writing by the CPU (writing to GTCR/GTSTR/GTSTP registers), the writing by CPU has priority over the starting/stopping by hardware sources.

In case that stop by the period count function conflicts with start by the CPU writing (GTCR register writing/GTSTR register writing), the period count function is finished with setting the GTST.PCF flag. The CST bit is not changed and the GTCNT continues to count.

When there is a conflict between starting by hardware sources set in the GTSSR register and stopping by hardware sources set in GTPSR register, the GTCR.CST bit value does not change. When there is a conflict between updating the GTCR.CST bit and reading by the CPU (reading from GTCR/GTSTR/GTSTP registers), pre-update data is read.

(3) GTCCRm registers (m = A to F)

When there is a conflict between input capture/buffer transfer operation and writing to the GTCCRm registers, the writing to GTCCRm registers has priority over input capture/buffer transfer operation. When there is a conflict between input capture and writing to the counter register by the CPU or updating the counter register by hardware sources, the pre-update counter value is captured. When there is a conflict between updating the GTCCRm registers and reading by the CPU, pre-update data is read.

(4) GTPR register

When there is a conflict between buffer transfer operation and writing to the GTPR register, writing to GTPR register has priority over buffer transfer operation. When there is a conflict between updating GTPR register and reading by the CPU, pre-update data is read.

(5) GTADTRm registers (m = A, B)

When there is a conflict between buffer transfer operation and writing to GTADTRm register, writing to GTADTRm register has priority over buffer transfer operation.

When there is a conflict between updating the GTADTRm register and reading by the CPU, pre-update data is read.

(6) GTDVm registers (m = U, D)

When there is a conflict between buffer transfer operation and writing to GTDVm register, writing to GTDVm register has priority over buffer transfer operation.

When there is a conflict between updating the GTDVm register and reading by the CPU, pre-update data is read.

(7) GTIOR.GTIOm registers (m = A, B)

When there is a conflict between buffer transfer operation and writing to GTIOR.GTIOm register, writing to GTIOR.GTIOm register has priority over buffer transfer operation.

When there is a conflict between updating the GTIOR.GTIOm and reading by the CPU, pre-update data is read.

22.10.6 Interval of Interrupt Request

When the core clock of GPT is GPTCLK, interrupt may be lost if the interval between the same interrupt signal is shorter than the following value. However, this restriction does not apply to different interrupt signals.

Interrupt_Interval [ns] = Period_of_GPTCLK [ns] * 6 + Period_of_PCLKA [ns] * 4

Also, ADC can receive the A/D conversion start request from GPT without going through ELC by setting ADTRGGPTx register (x = 0 to 8).

Again, when the clocks of GPT and ADC are combined as shown in Table 22.78, the A/D conversion start request may be lost if the interval between one A/D conversion start request and the next is less than the following value for the same A/D conversion start request.

However, this restriction does not apply to different A/D conversion start request.

Event_Interval [ns] = Period_of_GPT_core_clock [ns] * 6 + Period_of_ADC_core_clock [ns] * 4

Table 22.78 Combination of clocks with the restricted Event Interval

GPT core clock	ADC core clock
GPTCLK	PCLKA or ADCCLK
PCLKD	ADCCLK or GPTCLK

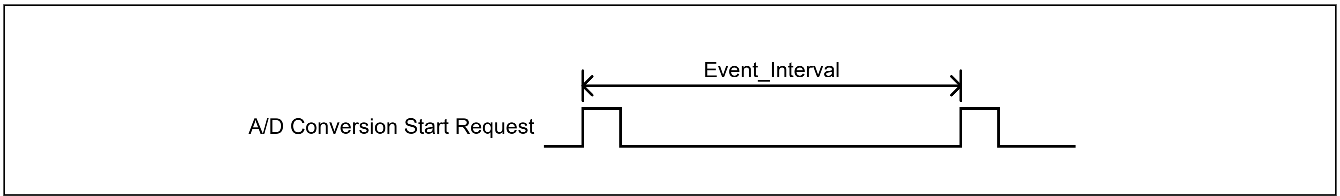

Figure 22.172 Example of A/D Conversion Start Request Event Interval

22.10.7 Notes on the GTIOCnm Signal Input to PWM Delay Generation Circuit (n = 0 to 3, m = A, B)

When controlling the delay of PWM waveform in PWM Delay Generation Circuit, the following limitations exist.

- In saw-wave mode, It is prohibited to change the GTIOCnm signal during the three clock cycles immediately before overflow or underflow.
- In saw-wave mode, it is prohibited to clear the GTCNT register by GTCSR during counting operation.
- In triangle-wave mode, It is prohibited to change the GTIOCnm signal during the three clock cycles immediately before trough.

If the above limitations are not followed, the edge of signal waveform output from PWM Delay Generation Circuit may disappear.

Figure 22.173 shows an example of the change timing of an unacceptable GTIOCnm signal.

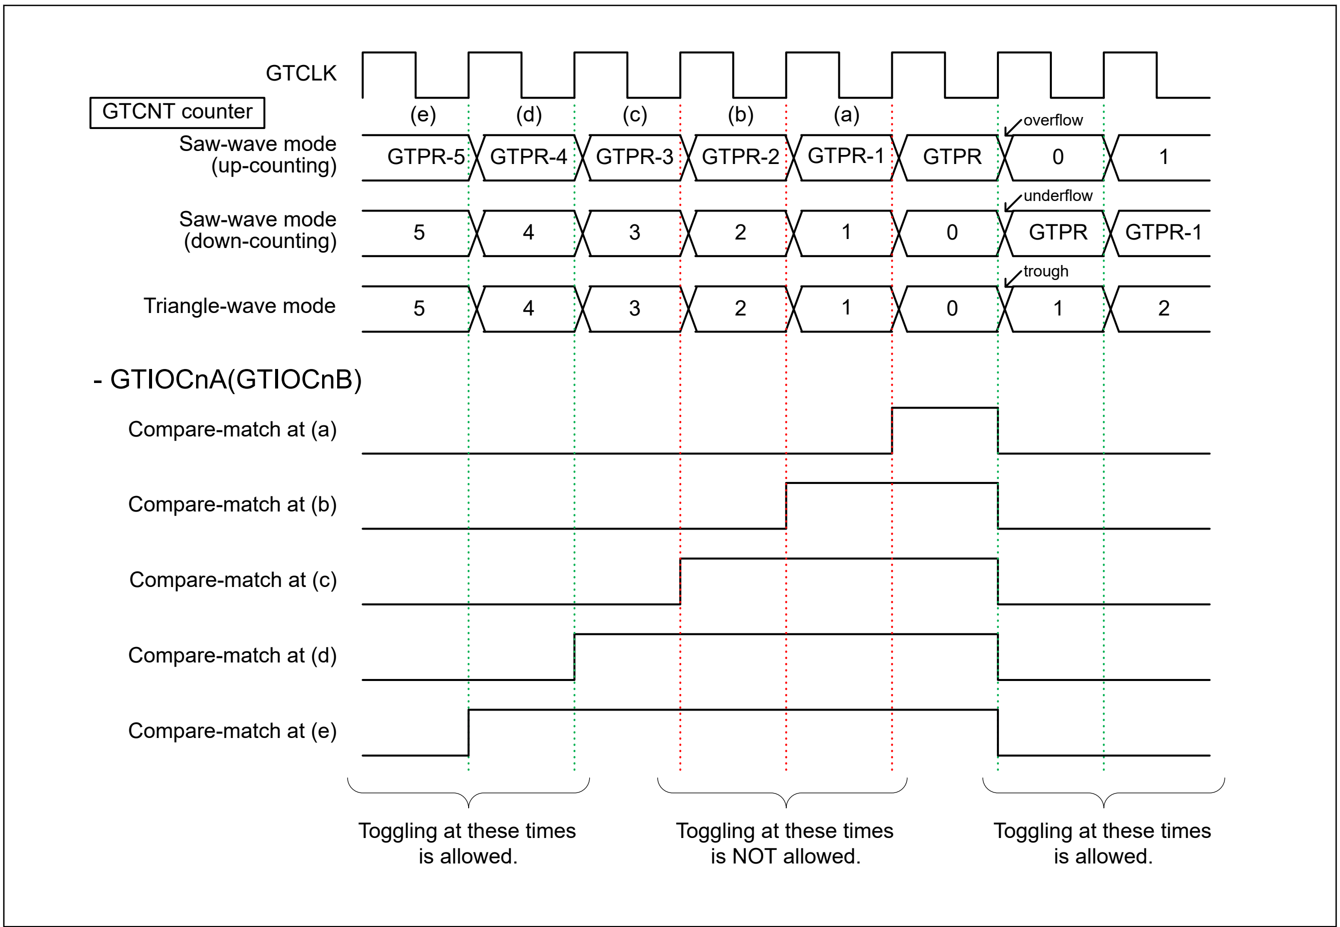

Figure 22.173 Example of unacceptable GTIOCnm signal timing (n = 0 to 3, m = A, B)

22.10.8 Setting Range of the Compare Match Registers when GTIOR.CPSCIR=1

In complementary PWM mode, when GTIOR.CPSCIR=1 and the initial output of the GTIOCnA/GTIOCnB pins after synchronization clearing is disabled, set the compare match registers (GTCCRA, GTCCRC, GTCCRD, GTCCRE, GTCCRF) to at least twice the GTDVU value.

22.10.9 Strobe Signal for Testing to PWM Delay Generation Circuit

Each channel output PWM output, PWM cycle synchronous signal (the cycle end), PWM output strobe signal for testing, register write protection signal (GTWP.WP bit) to the PWM Delay Generation circuit (PDG).

The strobe signals monitor each rising edge or falling edge of GTIOCxA output and GTIOCxB output. One GTCLK later from changing of PWM output, the strobe signal becomes 1. At the count clock of the cycle end, it becomes 0. The conditions that the strobe signal becomes 0 are reset and the cycle end.

When GTCNT counting is stopped, the status of strobe signal is retained. When GTCNT counting is restarted and PWM output is generated after GTCNT is stopped under the condition that strobe signal is 1, during first period after restarting to count, strobe signal does not change from 1. So the edge of PWM output is not monitored correctly. At the first cycle end after restarting, strobe signal returns to 0. The strobe signal is generated correctly from the second cycle.

In order to reset strobe signal keeping the status of 1 during GTCNT stopping, generate the cycle end by GTCNT counting as shown in Figure 22.174 or clear counter for sawtooth-wave operation as shown in Figure 22.175.

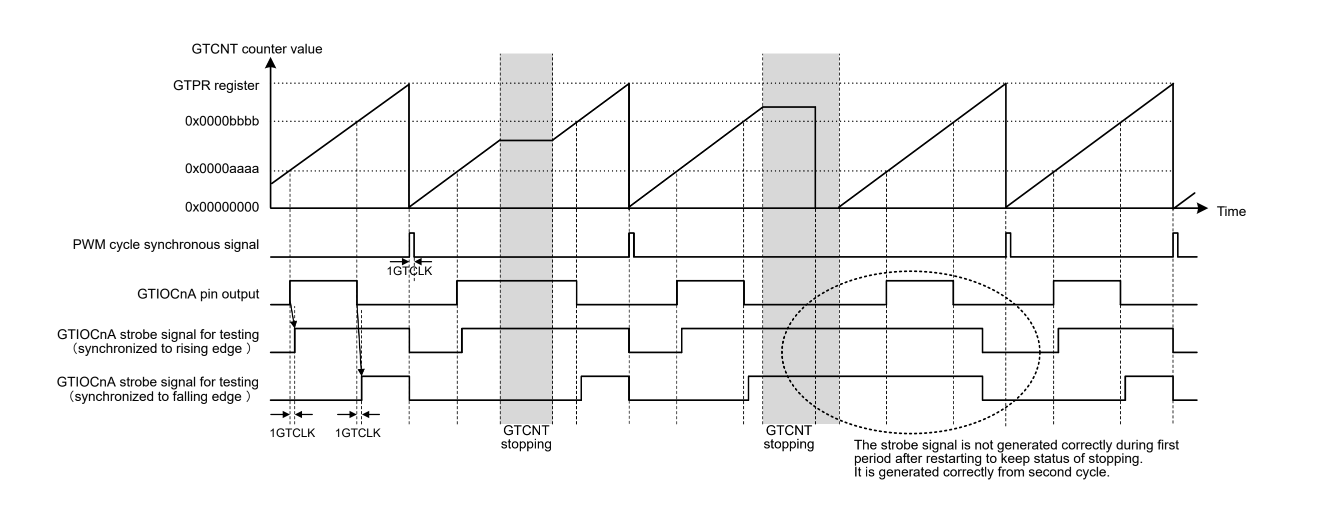

Figure 22.174 Example of output operation to PDG (1)

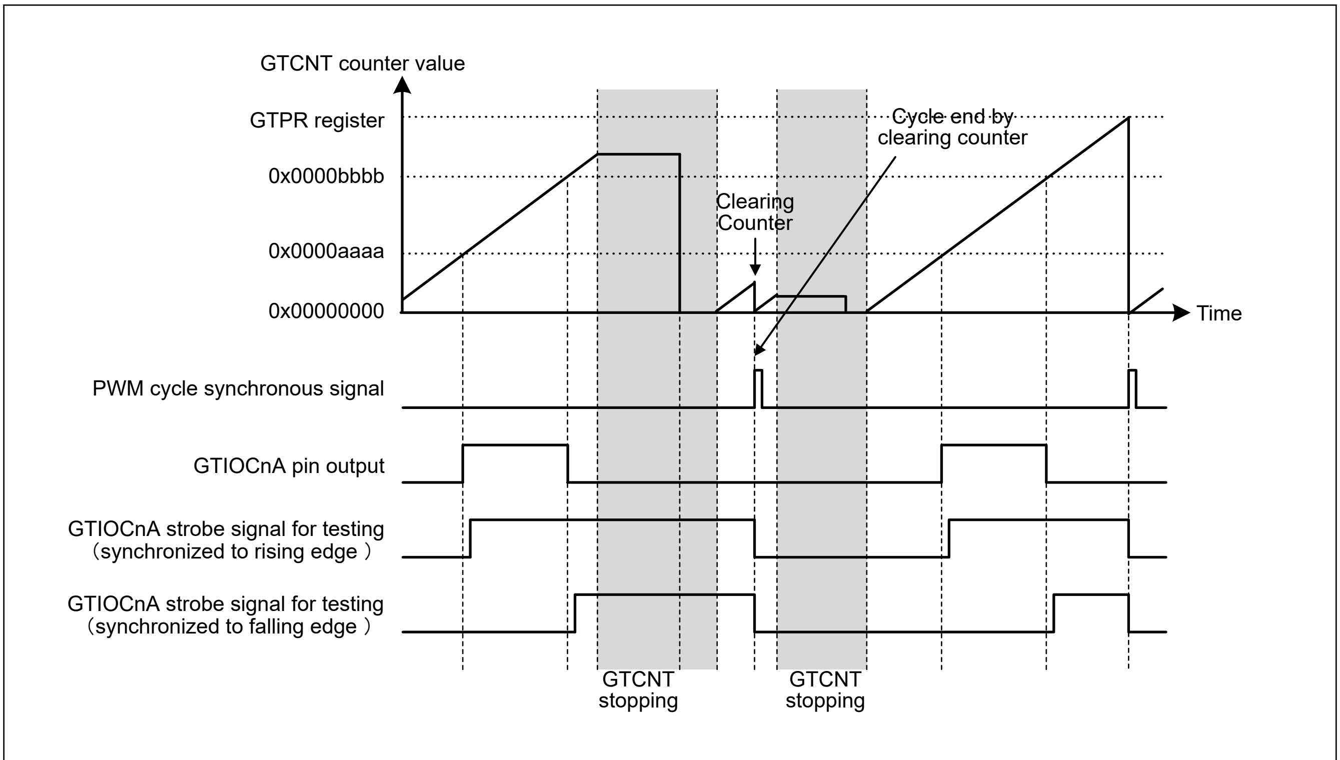

Figure 22.175 Example of output operation to PDG (2)

22.10.10 Notes on Transitioning to Standby Mode

Before transitioning to standby mode, it should be stopped counter operation (Set GTCR.CST = 0).

23. PWM Delay Generation Circuit (PDG)

23.1 Overview

The PWM Delay Generation circuit (PDG) has 4 channels delay circuits that can connect to the GPT. The PDG can control the rise and fall edge timing with which the PWM output for the GPT320 through the GPT323.

Table 23.1 lists the specifications for the PWM Delay Generation Circuit, Figure 23.1 shows a block diagram, and Table 23.2 lists the I/O pins.

Table 23.1 Specifications of the PWM Delay Generation Circuit

Parameter	Specifications
Function	The circuit can control the timing with which signals on the two PWM output pins for channel 0/1/2/3 rise and fall to an accuracy of up to 1/128 times the period of the GPT core clock (GTCLK). The GPT core clock (GTCLK) can be selected from PCLKD or GPTCLK.

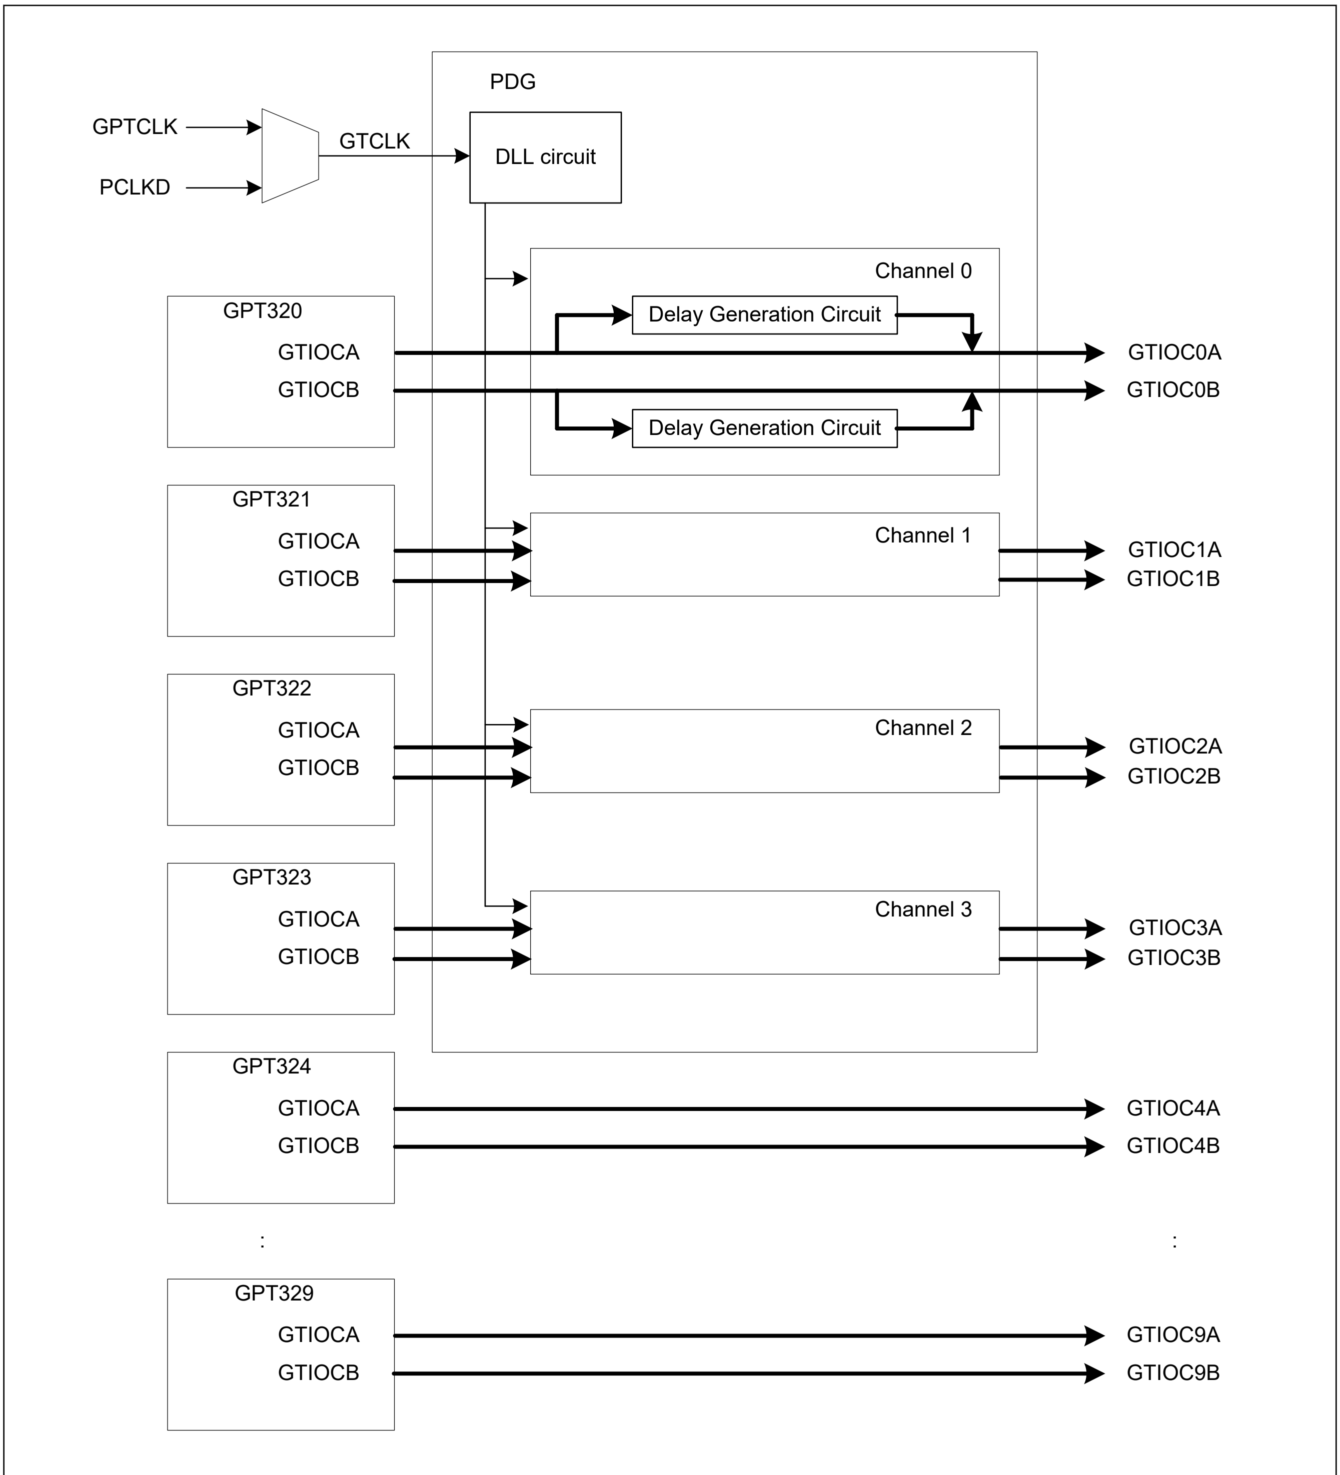

Figure 23.1 PWM delay generation circuit block diagram

Table 23.2 PWM delay generation circuit I/O pins (1 of 2)

I/O pin	I/O	Function
GTIOC0A	Output	Delayed output of GTIOCA pin of GPT channel 0
GTIOC0B	Output	Delayed output of GTIOCB pin of GPT channel 0

GTIOC3A	Output	Delayed output of GTIOCA pin of GPT channel 3
GTIOC3B	Output	Delayed output of GTIOCB pin of GPT channel 3

23.2 Register Descriptions

23.2.1 GTDLYCR : PWM Output Delay Control Register

Base address: PDG = 0x4032_4000
PDG_NS = 0x5032_4000

Offset address: 0x0000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	FRANGE[1:0]		—	—	—	—	—	—	DLYRST	DLLEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DLLEN	DLL Operation Enable 0: DLL operation disabled 1: DLL operation enabled	R/W
1	DLYRST	PWM Delay Generation Circuit Reset 0: Normal operation 1: Reset	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
9:8	FRANGE[1:0]	GPT core clock Frequency Range 0 0: GPT core clock frequency is 80 MHz to 160 MHz 0 1 GPT core clock frequency is 155 MHz to 300 MHz Others: Setting prohibited	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

The GTDLYCR register controls the PWM delay generation circuit, which applies delays to the PWM outputs. GTDLYCR register can be written when register write protection is disabled (GPT320.GTWP.WP = 0).

When changing GTDLYCR after changing the value of GPT320.GTWP.WP bit, be sure to read back the value of GTWP register before changing the value of GTDLYCR.

DLLEN bit (DLL Operation Enable)

The DLLEN bit selects whether the on-chip DLL in the PWM delay generation circuit is activated or not.

DLYRST bit (PWM Delay Generation Circuit Reset)

The DLYRST bit resets the internal state of the PWM delay generation circuit.

FRANGE[1:0] bit (GPT core clock Frequency Range)

The FRANGE[1:0] bits set the frequency range of the GPT core clock.

Set the FRANGE[1:0] bits only when the DLLEN bit is 0.

23.2.2 GTDLYCR2 : PWM Output Delay Control Register 2

Base address: PDG = 0x4032_4000
PDG_NS = 0x5032_4000

Offset address: 0x0002

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	DLYEN3	DLYEN2	DLYEN1	DLYEN0	—	—	—	—	DLYBS3	DLYBS2	DLYBS1	DLYBS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DLYBS0	PWM Delay Generation Circuit bypass for channel 0 0: Delay generation circuit of channel 0 bypassed 1: Delay generation circuit of channel 0 not bypassed	R/W
1	DLYBS1	PWM Delay Generation Circuit bypass for channel 1 0: Delay generation circuit of channel 1 bypassed 1: Delay generation circuit of channel 1 not bypassed	R/W
2	DLYBS2	PWM Delay Generation Circuit bypass for channel 2 0: Delay generation circuit of channel 2 bypassed 1: Delay generation circuit of channel 2 not bypassed	R/W
3	DLYBS3	PWM Delay Generation Circuit bypass for channel 3 0: Delay generation circuit of channel 3 bypassed 1: Delay generation circuit of channel 3 not bypassed	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	DLYEN0	PWM Delay Generation Circuit enable for channel 0 0: Delay generation circuit of channel 0 enabled 1: Delay generation circuit of channel 0 disabled	R/W
9	DLYEN1	PWM Delay Generation Circuit enable for channel 1 0: Delay generation circuit of channel 1 enabled 1: Delay generation circuit of channel 1 disabled	R/W
10	DLYEN2	PWM Delay Generation Circuit enable for channel 2 0: Delay generation circuit of channel 2 enabled 1: Delay generation circuit of channel 2 disabled	R/W
11	DLYEN3	PWM Delay Generation Circuit enable for channel 3 0: Delay generation circuit of channel 3 enabled 1: Delay generation circuit of channel 3 disabled	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W

The GTDLYCR2 register controls each channel of PWM delay generation circuit. GTDLYCR2 can be written when register write protection is disabled (GPT320.GTWP.WP = 0).

When changing GTDLYCR2 after changing the value of GPT320.GTWP.WP bit, be sure to read back the value of GTWP register before changing the value of GTDLYCR2.

DLYBSn (n = 0 to 3) bit (PWM Delay Generation Circuit Bypass for channel n)

The DLYBSn bit selects whether delays are applied to PWM output signals from the GTIOCnA and GTIOCnB pins (n = 0 to 3) by the PWM delay generation circuit or whether the circuit is bypassed.

A signal delayed in the PWM delay generation circuit is output 3 cycles of GPT core clock (GTCLK) later than if it bypasses the PWM delay generation circuit.

DLYENn (n = 0 to 3) bit (PWM Delay Generation Circuit Enable for channel n)

The DLYENn bit selects whether channel n (n = 0 to 3) of PWM delay generation circuit is power on or off. If channel n of the PWM delay generation circuit is not used, set to 1.

23.2.3 GTDLYRnA : GTIOCnA Rising Output Delay Register (n = 0 to 3)

Base address: PDG = 0x4032_4000
PDG_NS = 0x5032_4000

Offset address: 0x018 + 0x4 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	DLY[6:0]

The GTDLYRnA register sets a delay to be applied to rising edges of output signals on the GTIOCnA pin. On the timing for the transfer of settings, see section 23.3.2. Timing for Transfer of GTDLYRnA, GTDLYRnB, GTDLYFnA, and GTDLYFnB Register Settings.

GTDLYRnA can be written when register write protection is disabled (GPT32n.GTWP.WP = 0).

When changing GTDLYRnA after changing the value of GPT32n.GTWP.WP bit, be sure to read back the value of GTWP register before changing the value of GTDLYRnA.

23.2.4 GTDLYFnA : GTIOCnA Falling Output Delay Register (n = 0 to 3)

Base address: PDG = 0x4032_4000
PDG_NS = 0x5032_4000

Offset address: 0x028 + 0x4 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W
15:7	—	These bits are read as 0. The write value should be 0.	R/W

The GTDLYFnA register sets a delay to be applied to falling edges of output signals on the GTIOCnA pin. On the timing for the transfer of settings, see section 23.3.2. Timing for Transfer of GTDLYRnA, GTDLYRnB, GTDLYFnA, and GTDLYFnB Register Settings.

GTDLYFnA can be written when register write protection is disabled (GPT32n.GTWP.WP = 0).

When changing GTDLYFnA after changing the value of GPT32n.GTWP.WP bit, be sure to read back the value of GTWP register before changing the value of GTDLYFnA.

23.2.5 GTDLYRnB : GTIOCnB Rising Output Delay Register (n = 0 to 3)

Base address: PDG = 0x4032_4000
PDG_NS = 0x5032_4000

Offset address: 0x01A + 0x4 × n

R/W
15:7	—	These bits are read as 0. The write value should be 0.	R/W

The GTDLYRnB register sets a delay to be applied to rising edges of output signals on the GTIOCnB pin. On the timing for the transfer of settings, see section 23.3.2. Timing for Transfer of GTDLYRnA, GTDLYRnB, GTDLYFnA, and GTDLYFnB Register Settings.

GTDLYRnB can be written when register write protection is disabled (GPT32n.GTWP.WP = 0).

When changing GTDLYRnB after changing the value of GPT32n.GTWP.WP bit, be sure to read back the value of GTWP register before changing the value of GTDLYRnB.

23.2.6 GTDLYFnB : GTIOCnB Falling Output Delay Register (n = 0 to 3)

Base address: PDG = 0x4032_4000
PDG_NS = 0x5032_4000

Offset address: 0x02A + 0x4 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	DLY[6:0]	GTIOCnB Output Falling Edge Delay Setting (1) Case of GTDLYCR.FRANGE[1:0] = 00b 0x00: Delay on rising edges is not applied. 0x01: Delay of 1/128 times GTCLK period applied. 0x02: Delay of 2/128 times GTCLK period applied. 0x03: Delay of 3/128 times GTCLK period applied. 0x04: Delay of 4/128 times GTCLK period applied. 0x05: Delay of 5/128 times GTCLK period applied. 0x06: Delay of 6/128 times GTCLK period applied. ⋮ 0x7B: Delay of 123/128 times GTCLK period applied. 0x7C: Delay of 124/128 times GTCLK period applied. 0x7D: Delay of 125/128 times GTCLK period applied. 0x7E: Delay of 126/128 times GTCLK period applied. 0x7F: Delay of 127/128 times GTCLK period applied. (2) Case of GTDLYCR.FRANGE[1:0] = 01b 0x00: Delay on rising edges is not applied. 0x01: Delay on rising edges is not applied. 0x02: Delay of 1/64 times GTCLK period applied. 0x03: Delay of 1/64 times GTCLK period applied. 0x04: Delay of 2/64 times GTCLK period applied. 0x05: Delay of 2/64 times GTCLK period applied. 0x06: Delay of 3/64 times GTCLK period applied. ⋮ 0x7B: Delay of 61/64 times GTCLK period applied. 0x7C: Delay of 62/64 times GTCLK period applied. 0x7D: Delay of 62/64 times GTCLK period applied. 0x7E: Delay of 63/64 times GTCLK period applied. 0x7F: Delay of 63/64 times GTCLK period applied.	R/W
15:7	—	These bits are read as 0. The write value should be 0.	R/W

The GTDLYFnB register sets a delay to be applied to falling edges of output signals on the GTIOCnB pin. On the timing for the transfer of settings, see section 23.3.2. Timing for Transfer of GTDLYRnA, GTDLYRnB, GTDLYFnA, and GTDLYFnB Register Settings.

GTDLYFnB can be written when register write protection is disabled (GPT32n.GTWP.WP = 0).

When changing GTDLYFnB after changing the value of GPT32n.GTWP.WP bit, be sure to read back the value of GTWP register before changing the value of GTDLYFnB.

23.3 Operation

23.3.1 Adjustments to the Timing of Rising and Falling Edges in PWM Waveforms

The timing of rising and falling edges in PWM waveforms which are output from the GTIOCnA and GTIOCnB pins, where n = channel number, can be delayed to an accuracy of 1/64 or 1/128 of the GPT core clock (GTCLK) period.

If the timing of rising or falling edges in PWM waveforms output from the GTIOCnA and GTIOCnB pins must be adjusted, initialize the PWM generation circuit as shown in the procedure in Figure 23.2.

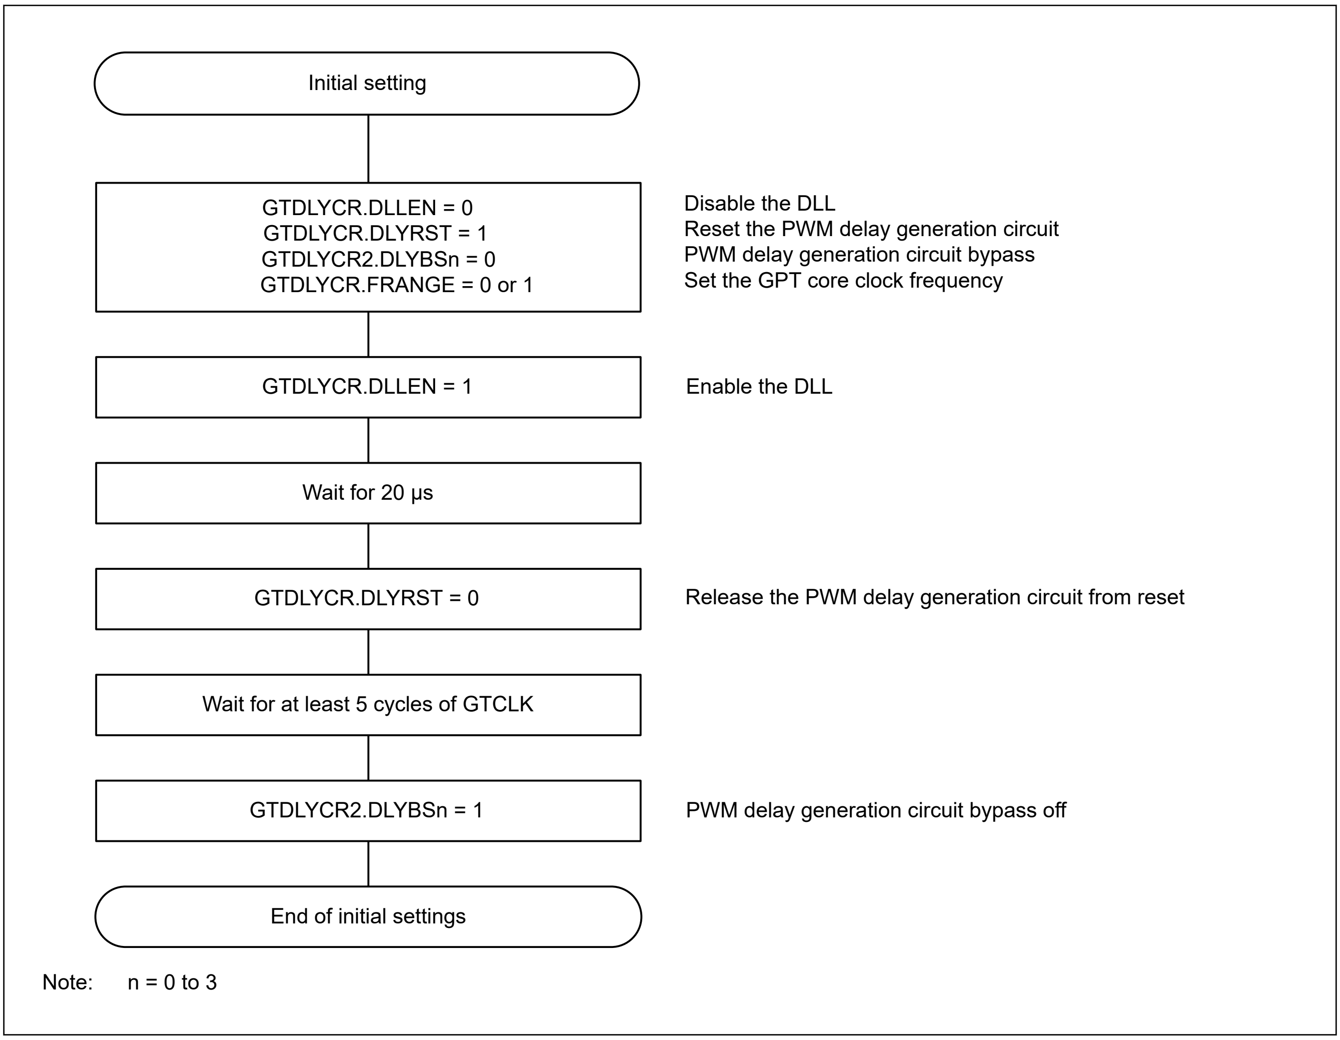

Figure 23.2 Example of initialization flow for the PWM delay generation circuit

In the PWM delay generation circuit, delay can be applied to rising and falling edges of the PWM output to an accuracy of 1/64 or 1/128 of the period of the GPT core clock (GTCLK). This is described in section 22.3.3. PWM Output Operating Mode. Delays associated with the settings are reflected in the PWM output with the timing described in section 23.3.2. Timing for Transfer of GTDLYRnA, GTDLYRnB, GTDLYFnA, and GTDLYFnB Register Settings. Table 23.3 shows the association between the GTDLYRnA, GTDLYRnB, GTDLYFnA, and GTDLYFnB registers and the PWM outputs.

Table 23.3 Association between PWM output pins and delay setting registers

PWM output pin	Rising-edge delay setting register	Falling-edge delay setting register
GTIOC0A	GTDLYR0A	GTDLYF0A
GTIOC0B	GTDLYR0B	GTDLYF0B
GTIOC1A	GTDLYR1A	GTDLYF1A
GTIOC1B	GTDLYR1B	GTDLYF1B
GTIOC2A	GTDLYR2A	GTDLYF2A
GTIOC2B	GTDLYR2B	GTDLYF2B
GTIOC3A	GTDLYR3A	GTDLYF3A
GTIOC3B	GTDLYR3B	GTDLYF3B

When the PWM delay generation circuit is in use, the timing with which a PWM output signal rises and falls can be controlled to an accuracy of 1/64 or 1/128 of the period of the GPT core clock (GTCLK). When this option is not in use, the period of the PWM output waveform is controlled to an accuracy of one period of the input clock for the timer counter, which is GTCLK. With the PWM delay generation circuit, the output can be controlled to an accuracy 32 times better.

Additionally, the delay settings also control the periods at high and low level for the PWM waveform to the given accuracy. PWM delay generation circuit channels can be individually enabled or disabled.

23.3.2 Timing for Transfer of GTDLYRnA, GTDLYRnB, GTDLYFnA, and GTDLYFnB Register Settings

Settings for the GTDLYRnA, GTDLYRnB, GTDLYFnA, and GTDLYFnB registers are initially transferred to temporary registers, and then reflected in the delay on the GTIOCnA and GTIOCnB (n = 0 to 3) outputs. Transfer of the settings takes place on overflows (in up-counting) or underflows (in down-counting) for saw waves, and in the troughs of triangle waves.

Figure 23.3 and Figure 23.4 show examples of the operation of the GTDLYR0A and GTDLYF0A registers.

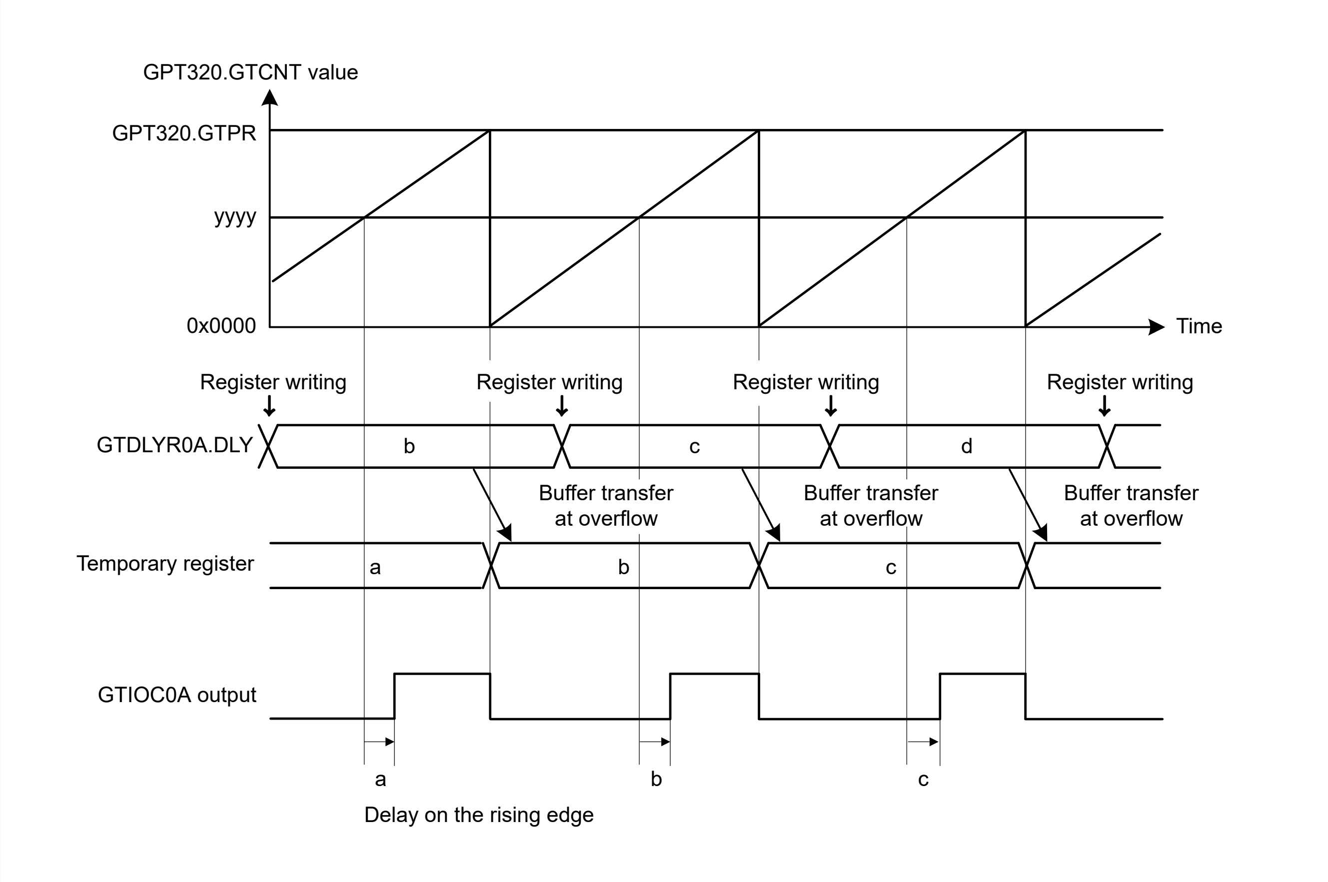

Figure 23.3 Example of GTDLYR0A register operation with PWM saw-wave generation

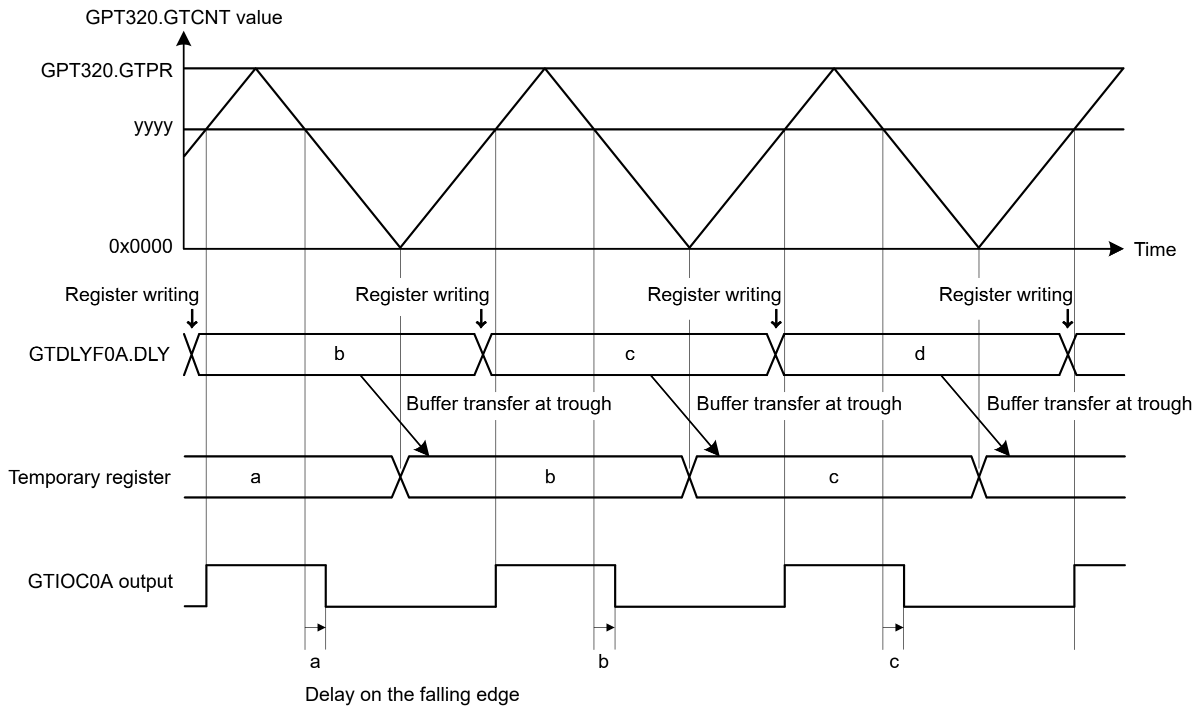

Figure 23.4 Example of GTDLYF0A register operation with PWM triangle-wave generation

23.4 Usage Notes

23.4.1 Settings for the Module-Stop Function

The Module Stop Control Register D (MSTPCRD) can enable or disable operation of the PWM delay generation circuit. The PWM delay generation circuit is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Mode.

23.4.2 Notes on Delay Settings for PWM Delay Generation Circuit

When the PWM delay generation circuit generates delays for a PWM output waveform and the waveform is toggled in response to compare-matches, do not change the settings for delay while the compare-match value is within the ranges listed in Table 23.4. This constraint applies to the GTDLYFnA, GTDLYRnA, GTDLYFnB, and GTDLYRnB registers.

Table 23.4 Constraints on delay settings

Mode	Direction of counting	Compare-match value
Saw-wave mode	Up	GTPR - 2 or above
	Down	2 or below
Triangle-wave mode	Down	2 or below

Figure 23.5 shows an example of how the constraints apply to the timing of setting GTDLYFnA in saw-wave waveform one-shot pulse mode (counting up). Do not change the value set in GTDLYFnA while GTCCRD ≥ GTPR - 2.

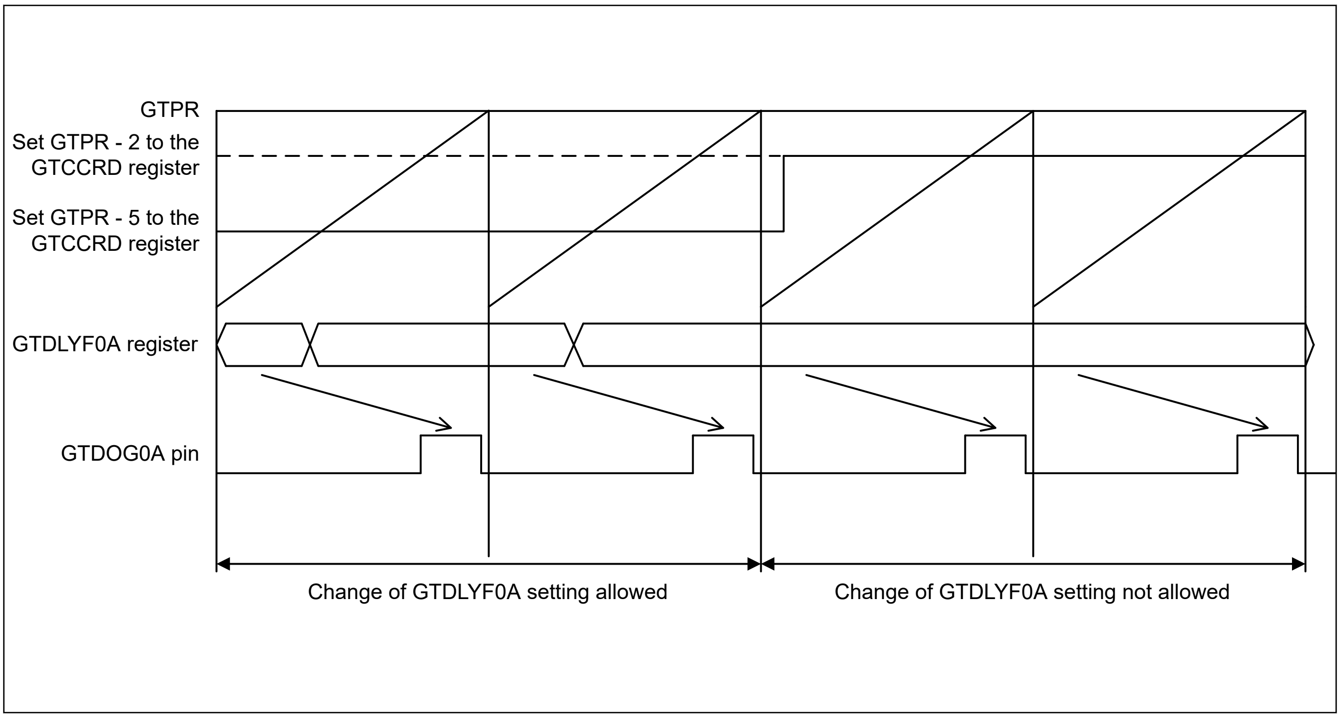

Figure 23.5 Constraints on the timing of GTDLYF0A register settings

Changing the values in the GTDLYFnA, GTDLYRnA, GTDLYFnB, and GTDLYRnB registers during periods where changes to settings are not allowed, might lead to faulty output waveforms such as shifts in the timing of output waveform transitions from the expected values.

23.4.3 Register Write Interval

When GPT core clock is GPTCLK, the writing value may not be reflected if the interval between writing to the GTDLYRnA/GTDLYFnA/GTDLYRnB/GTDLYFnA register is shorter than the following interval time. This restriction only applies to successive writes to the same register.

Write_Interval [ns] = Period_of_PCLKA [ns] × 6 + Period_of_GPTCLK [ns] × 4

24. Low Power Asynchronous General Purpose Timer (AGT)

24.1 Overview

The Low Power Asynchronous General Purpose Timer (AGT) is a 16-bit timer that can be used for pulse output, external pulse width or period measurement, and counting external events. This timer consists of a reload register and a down counter. The reload register and the down counter are allocated to the same address, and can be accessed with the AGT register.

Table 24.1 lists the AGT specifications, Figure 24.1 shows a block diagram, and Table 24.2 lists the I/O pins.

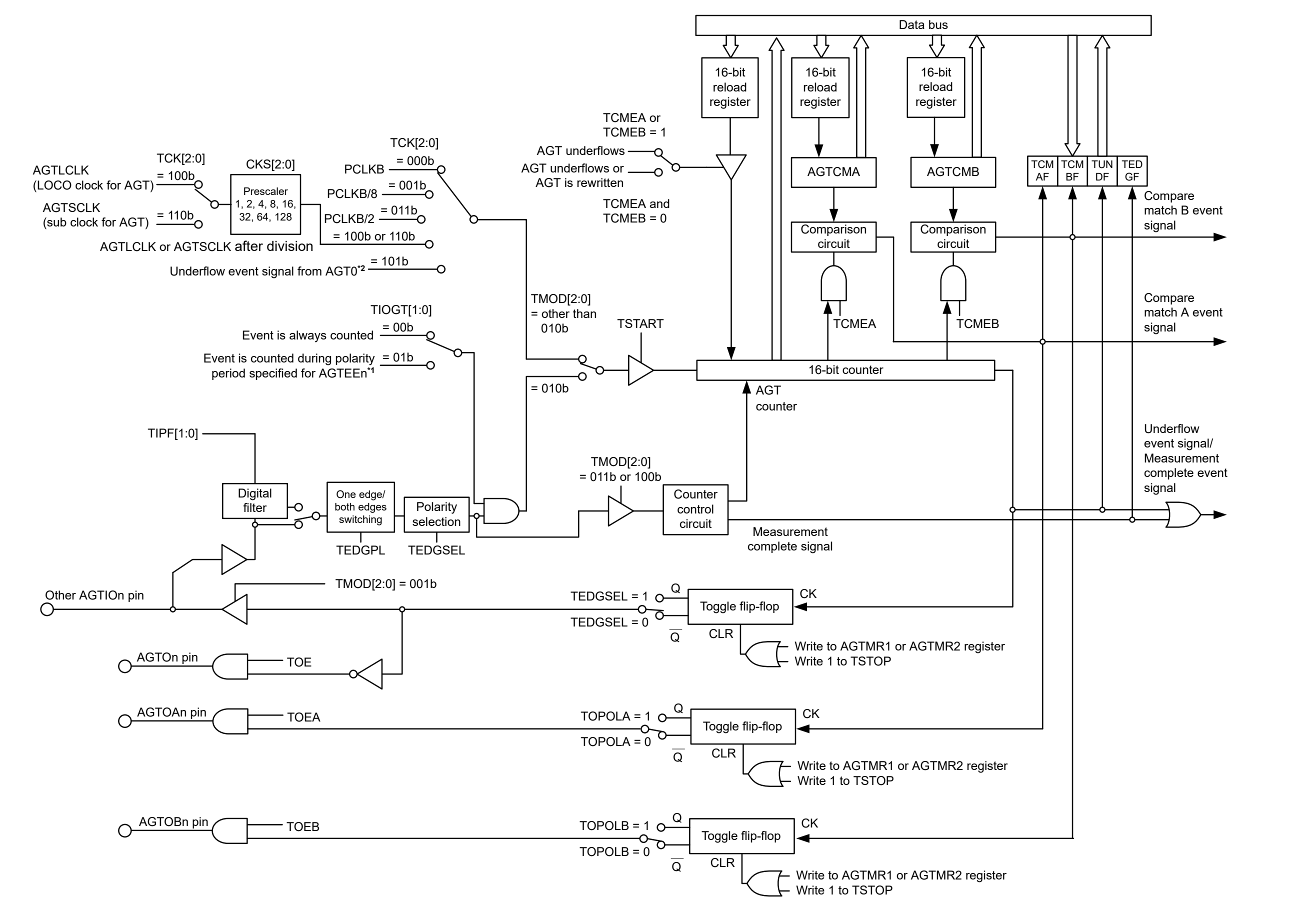
Table 24.1 AGT specifications

Parameter		Description
Operating modes	Timer mode	The count source is counted
	Pulse output mode	The count source is counted and the output is inverted at each timer underflow
	Event counter mode	An external event is counted
	Pulse width measurement mode	An external pulse width is measured
	Pulse period measurement mode	An external pulse period is measured
Number of Channels		16 bits × 2 channels (AGTn (n = 0, 1))
Count source (operating clock)[*2]	Timer mode	PCLKB, PCLKB/2, PCLKB/8, AGTLCLK/d, AGTSCLK/d (d = 1, 2, 4, 8, 16, 32, 64, or 128), or underflow signal of AGT0 selectable.[*1]
	Pulse output mode	
	Pulse width measurement mode	
	Pulse period measurement mode	
	Event counting mode	External event input
Interrupt and Event Link function		• Underflow event signal or measurement complete event signal – When the counter underflows – When the measurement of the active width of the external input pin (AGTIOn) completes in pulse width measurement mode – When the set edge of the external input pin (AGTIOn) is input in pulse period measurement mode. • Compare match A event signal – When the values of AGT register and AGTCMA register matched (compare match A function enabled). • Compare match B event signal – When the values of AGT and AGTCMB registers matched (compare match B function enabled). • Return from Software Standby mode can be performed with AGT1_AGTI, AGT1_AGTCMAI, or AGT1_AGTCMBI[*3]
Selectable functions		• Compare match function One or two of the AGT Compare Match A register and AGT Compare Match B register is selectable.
Module-stop function		Module-stop state can be set for each channel to reduce power consumption.
TrustZone Filter		Security and Privilege attribution can be set for each channel.

Note 1. AGT0 cannot use underflow signal. AGT1 connects directly with the underflow event signal from the AGT0 timer.

Note 2. Satisfy the frequency of the peripheral module clock (PCLKB) ≥ the frequency of the count source clock. When selecting AGTLCLK/d or AGTSCLK/d as the count source clock, the frequency of PCLKB should be at least twice that of the count source clock.

Note 3. For details, see section 11, Low Power Mode.



Note 1. The polarity can be selected by the EEPS bit in the AGTISR register.
Note 2. AGT0 cannot use AGT0 underflow event. AGT1 uses the underflow of AGT0.

Figure 24.1 AGT block diagram

Table 24.2 AGT I/O pins

Pin name	I/O	Function
AGTEEn	Input	External event input enable for AGT
AGTIOn	Input/output	External event input and pulse output for AGT
AGTOn	Output	Pulse output for AGT
AGTOAn	Output	Compare match A output for AGT
AGTOBn	Output	Compare match B output for AGT

Note: Channel number: n = 0, 1

24.2 Register Descriptions

24.2.1 AGT : AGT Counter Register

Base address: AGTn = 0x4022_1000 + 0x0100 × n (n = 0, 1)
AGTn_NS = 0x5022_1000 + 0x0100 × n (n = 0, 1)

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	n/a	16-bit counter and reload register Setting range : 0x0000 to 0xFFFF	R/W

Note: S-TYPE-3, P-TYPE-3

AGTn.AGT is a 16-bit register. The write value is written to the reload register and the read value is read from the counter.

The states of the reload register and the counter change according to the TSTART bit in the AGTCR register and TCMEA/TCMEB bit in the AGTCMSR register. For details, see section 24.3.1. Reload Register and Counter Rewrite Operation.

When 1 is written to the TSTOP bit in the AGTCR register, AGT counter is forcibly stopped and set to 0xFFFF.

When the TCK[2:0] bits setting in the AGTMR1 register are a value other than 001b (PCLKB/8) or 011b (PCLKB/2), if the AGT register is set to 0x0000, a request signal to the ICU, the DTC, the DMAC, and the ELC is generated once immediately after the count starts. The AGTOn, AGTIOn pin output are toggled.

When the AGT register is set to 0x0000 in event counter mode, regardless of the value of TCK[2:0] bits, a request signal to the ICU, the DTC, the DMAC, and the ELC is generated once immediately after the count starts.

In addition, the AGTOn pin output is toggled even during a period other than the specified count period. When the AGT register is set to 0x0001 or more, a request signal is generated each time AGT underflows.

24.2.2 AGTCMA : AGT Compare Match A Register

Base address: AGTn = 0x4022_1000 + 0x0100 × n (n = 0, 1)
AGTn_NS = 0x5022_1000 + 0x0100 × n (n = 0, 1)

Offset address: 0x02

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	n/a	16-bit compare match A data is stored.*1 Setting range : 0x0000 to 0xFFFF	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Set the AGTCMA register to 0xFFFF when compare match A is not used.

The AGTCMA register is a read/write register to set a value for compare match with the AGT counter. The states of the reload register and compare register A change according to the TSTART bit in the AGTCR register. For details, see section 24.3.2. Reload Register and AGT Compare Match A/B Register Rewrite Operation.

24.2.3 AGTCMB : AGT Compare Match B Register

Base address: AGTn = 0x4022_1000 + 0x0100 × n (n = 0, 1)
AGTn_NS = 0x5022_1000 + 0x0100 × n (n = 0, 1)

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	n/a	16-bit compare match B data is stored.*1 Setting range : 0x0000 to 0xFFFF	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Set the AGTCMB register to 0xFFFF when compare match B is not used.

The AGTCMB register is a read/write register to set a value for compare match with the AGT counter. The states of the reload register and compare register B change according to the TSTART bit in the AGTCR register. For details, see section 24.3.2. Reload Register and AGT Compare Match A/B Register Rewrite Operation.

24.2.4 AGTCR : AGT Control Register

Base address: AGTn = 0x4022_1000 + 0x0100 × n (n = 0, 1)
AGTn_NS = 0x5022_1000 + 0x0100 × n (n = 0, 1)

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TCMBF	TCMAF	TUNDF	TEDGF	—	TSTOP	TCSTF	TSTART
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TSTART	AGT Count Start*2 0: Count stops 1: Count starts	R/W
1	TCSTF	AGT Count Status Flag*2 0: Count stopped 1: Count in progress	R
2	TSTOP	AGT Count Forced Stop*1 0: Writing is invalid 1: The count is forcibly stopped	W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	TEDGF	Active Edge Judgment Flag 0: No active edge received 1: Active edge received	R/(W)*3
5	TUNDF	Underflow Flag 0: No underflow 1: Underflow	R/(W)*3
6	TCMAF	Compare Match A Flag 0: No match 1: Match	R/(W)*3
7	TCMBF	Compare Match B Flag 0: No match 1: Match	R/(W)*3

Note: S-TYPE-3, P-TYPE-3
Note 1. When 1 (count is forcibly stopped) is written to the TSTOP bit, the TSTART bit and TCSTF flag are initialized at the same time. The pulse output level is also initialized. The read value is 0.
Note 2. For information on using the TSTART bit and TCSTF flag, see section 24.4.1. Count Operation Start and Stop Control.
Note 3. Only 0 can be written to clear the flag.

TSTART bit (AGT Count Start)

The count operation is started by writing 1 to the TSTART bit and stopped by writing 0. When the TSTART bit is set to 1 (count starts), the TCSTF flag is set to 1 (count in progress) in synchronization with the count source. Also, after 0 is written to the TSTART bit, the TCSTF flag is set to 0 (count stops) in synchronization with the count source. For details, see section 24.4.1. Count Operation Start and Stop Control.

TCSTF flag (AGT Count Status Flag)

The TCSTF flag indicates the AGT count status.

[Setting condition]

- When 1 is written to the TSTART bit (the TCSTF flag is set to 1 in synchronization with the count source).

[Clearing conditions]

- When 0 is written to the TSTART bit (the TCSTF flag is set to 0 in synchronization with the count source)
- When 1 is written to the TSTOP bit.

TSTOP bit (AGT Count Forced Stop)

When 1 is written to the TSTOP bit, the count is forcibly stopped. The read value is 0.

TEDGF flag (Active Edge Judgment Flag)

The TEDGF flag indicates that an active edge was detected.

[Setting condition]

- When the measurement of the active width of the external input pin (AGTIOn) is complete in pulse width measurement mode
- When the set edge of the external input pin (AGTIOn) is input in pulse period measurement mode.

[Clearing condition]

- When 0 is written to this flag by software.

TUNDF flag (Underflow Flag)

The TUNDF flag indicates that the counter underflowed.

[Setting condition]

- When the counter underflows.

[Clearing condition]

- When 0 is written to this flag by software.

TCMAF flag (Compare Match A Flag)

The TCMAF flag indicates that compare match A was detected.

[Setting condition]

- When the value in the AGT register matches the value in the AGTCMA register.

[Clearing condition]

- When 0 is written to this flag by software.

TCMBF flag (Compare Match B Flag)

The TCMBF flag indicates that compare match B was detected.

[Setting condition]

- When the value in the AGT register matches the value in the AGTCMB register.

[Clearing condition]

- When 0 is written to this flag by software.

24.2.5 AGTMR1 : AGT Mode Register 1

Base address: AGTn = 0x4022_1000 + 0x0100 × n (n = 0, 1)
AGTn_NS = 0x5022_1000 + 0x0100 × n (n = 0, 1)

Offset address: 0x09

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	TCK[2:0]			TEDGPL	TMOD[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	TMOD[2:0]	Operating Mode*3 0 0 0: Timer mode 0 0 1: Pulse output mode 0 1 0: Event counter mode 0 1 1: Pulse width measurement mode 1 0 0: Pulse period measurement mode Others: Setting prohibited	R/W
3	TEDGPL	Edge Polarity*4 0: Single-edge 1: Both-edge	R/W
6:4	TCK[2:0]	Count Source*1 *2 *5 *7 0 0 0: PCLKB 0 0 1: PCLKB/8 0 1 1: PCLKB/2 1 0 0: Divided clock AGTLCLK specified by CKS[2:0] bits in the AGTMR2 register 1 0 1: Underflow event signal from AGT0*6 1 1 0: Divided clock AGTSCLK specified by CKS[2:0] bits in the AGTMR2 register Others: Setting prohibited	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Write access to the AGTMR1 register initializes the output from the AGTOn, AGTIOn, AGTOAn, and AGTOBn pins. For details on the output level at initialization, see section 24.2.7. AGTIOC : AGT I/O Control Register.
Note 1. When event counter mode is selected, the external input pin (AGTIOn) is selected as the count source regardless of the setting of TCK[2:0] bits.
Note 2. Do not switch count sources during count operation. Only switch count sources when both the TSTART bit and TCSTF flag in the AGTCR register are set to 0 (count stops).
Note 3. The operating mode can only be changed when the count is stopped while both the TSTART bit and TCSTF flag in the AGTCR register are set to 0 (count is stopped). Do not change the operating mode during count operation.
Note 4. The TEDGPL bit is enabled only in event counter mode.
Note 5. To run AGT in Software Standby mode, select AGTLCLK or AGTSCLK (TCK[2:0] = 100b, 110b).
Note 6. AGT0 cannot use AGT0 underflow (setting prohibited). AGT1 uses the AGT0 underflow.
Note 7. Do not change the TCK[2:0] bits when the CKS[2:0] bits in the AGTMR2 register is not 000b. First, change the CKS[2:0] bits in the AGTMR2 register to 000b. Then change the TCK[2:0] bits and wait for one cycle of the count source.

24.2.6 AGTMR2 : AGT Mode Register 2

Base address: AGTn = 0x4022_1000 + 0x0100 × n (n = 0, 1)
AGTn_NS = 0x5022_1000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	LPM	—	—	—	—	CKS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CKS[2:0]	AGTLCLK or AGTSCLK Count Source Clock Frequency Division Ratio*1 *2 *3 0 0 0: 1/1 0 0 1: 1/2 0 1 0: 1/4 0 1 1: 1/8 1 0 0: 1/16 1 0 1: 1/32 1 1 0: 1/64 1 1 1: 1/128	R/W
6:3	—	These bits are read as 0. The write value should be 0.	R/W
7	LPM	Low Power Mode 0: Normal mode 1: Low power mode	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Do not rewrite the CKS[2:0] bits during count operation. Only rewrite the CKS[2:0] bits when both the TSTART bit and TCSTF flag in the AGTCR register are set to 0 (count stops).
Note 2. When count source is AGTLCLK or AGTSCLK, the switch of CKS[2:0] bits is valid.
Note 3. Do not switch the TCK[2:0] bits in the AGTMR1 register when CKS[2:0] bits are not 000b. Switch the TCK[2:0] bits in the AGTMR1 register after CKS[2:0] bits are set to 000b, and wait for 1 cycle of the count source.

CKS[2:0] bit (AGTLCLK or AGTSCLK Count Source Clock Frequency Division Ratio)

CKS[2:0] bits select the Count Source Clock Frequency Division Ratio for AGTLCLK or AGTSCLK.

LPM bit (Low Power Mode)

The LPM bit sets the low power operation, which impacts access to certain AGT registers. Set this bit to 1 to operate in low power.

When this bit is 1, access to the following registers is prohibited:

- AGT/AGTCMA/AGTCMB/AGTCR.

After this bit is switched from 1 to 0, the first access to the register is constrained as follows:

- When reading from the AGT register, read AGT register twice. Only the second reading of data is valid.
- When writing to the AGT, AGTCMA, AGTCMB, and AGTCR register, allow at least 2 cycles of the count source clock when writing to the register.
- When confirm the value written to the AGT, AGTCMA, AGTCMB, and AGTCR registers.
  - When the count operation is stopped; after writing data, it can be read in the next cycle.
  - When the count operation is operating; after writing data, it can be read 4 cycles after the count source clock.

Figure 24.2 shows the flow of how to write LPM bit

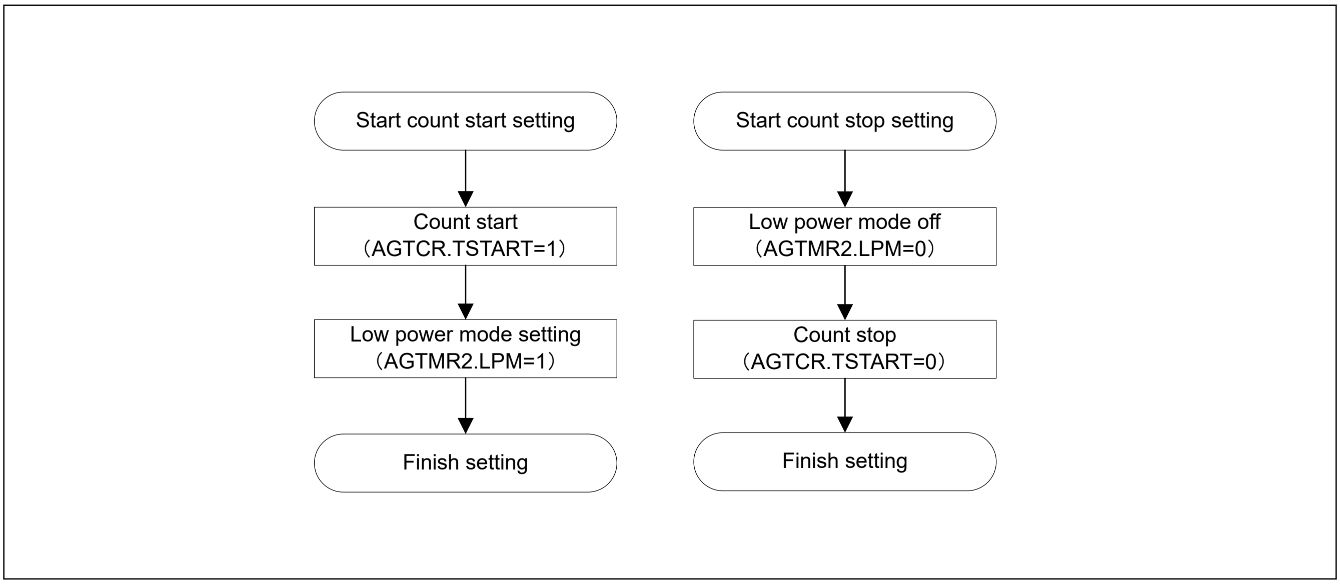


Figure 24.2 LPM how to write flow chart

24.2.7 AGTIOC : AGT I/O Control Register

Base address: AGTn = 0x4022_1000 + 0x0100 × n (n = 0, 1)
AGTn_NS = 0x5022_1000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TIOGT[1:0]		TIPF[1:0]		—	TOE	—	TEDGSEL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TEDGSEL	I/O Polarity Switch Function varies depending on the operating mode (see Table 24.3 and Table 24.4).	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	TOE	AGTOn pin Output Enable 0: AGTOn pin output disabled 1: AGTOn pin output enabled	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
5:4	TIPF[1:0]	Input Filter*3 These bits specify the sampling frequency of the filter for the AGTIOn input. If the input to the AGTIOn pin is sampled and the value matches three successive times, that value is taken as the input value. 0 0: No filter 0 1: Filter sampled at PCLKB 1 0: Filter sampled at PCLKB/8 1 1: Filter sampled at PCLKB/32	R/W
7:6	TIOGT[1:0]	Count Control*1 *2 0 0: Event is always counted 0 1: Event is counted during polarity period specified for AGTEEn pin Others: Setting prohibited	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. When AGTEEn pin is used, the polarity to count an event can be selected with the EEPS bit in the AGTISR register.
Note 2. TIOGT[1:0] bits are enabled only in event counter mode.
Note 3. When event counter mode operation is performed during Software Standby mode, the digital filter function cannot be used.

TEDGSEL bit (I/O Polarity Switch)

The TEDGSEL bit switches the AGTOn pin output polarity and the AGTIOn pin input/output edge and polarity.

In pulse output mode, it only controls polarity of the AGTOn pin output and AGTIOn pin output. AGTOn pin output and AGTIOn pin output are initialized when the AGTMR1 register is written or the TSTOP bit in the AGTCR register is written with 1.

TOE bit (AGTOn pin Output Enable)

The TOE bit selects whether the AGTOn pin output is disabled or enabled.

TIPF[1:0] bits (Input Filter)

The TIPF[1:0] bits specify the sampling frequency of the AGTIOn pin input filter. When the input to the AGTIOn pin is sampled and the values match three times in succession, the value is regarded as the input value.

TIOGT[1:0] bits (Count Control)

The TIOGT[1:0] bits control the event count.

Table 24.3 AGTIOn pin I/O edge and polarity switching

Operating mode	Function
Timer mode	Not used
Pulse output mode	0: Output is started at high (initialization level: high) i.e. inverted output 1: Output is started at low (initialization level: low). i.e. normal output
Event counter mode	0: Count on rising edge 1: Count on falling edge.
Pulse width measurement mode	0: Low-level width is measured 1: High-level width is measured.
Pulse period measurement mode	0: Measure from one rising edge to the next rising edge 1: Measure from one falling edge to the next falling edge.

Table 24.4 AGTOn pin output polarity switching

Operating mode	Function
All modes	0: Output is started at low (initial level: low): Normal output 1: Output is started at high (initial level: high): Inverted output

24.2.8 AGTISR : AGT Event Pin Select Register

Base address: AGTn = 0x4022_1000 + 0x0100 × n (n = 0, 1)
AGTn_NS = 0x5022_1000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	EEPS	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0. The write value should be 0.	R/W
2	EEPS	AGTEEn Polarity Selection 0: An event is counted during the low-level period 1: An event is counted during the high-level period	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

EEPS bit (AGTEEn Polarity Selection)

The EEPS bit selects the polarity of events to be counted.

24.2.9 AGTCMSR : AGT Compare Match Function Select Register

Base address: AGTn = 0x4022_1000 + 0x0100 × n (n = 0, 1)
AGTn_NS = 0x5022_1000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	TOPOLB	TOEB	TCMEB	—	TOPOLA	TOEA	TCMEA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TCMEA	AGT Compare Match A Register Enable*1 *2 0: AGT Compare match A register disabled 1: AGT Compare match A register enabled	R/W
1	TOEA	AGTOAn Pin Output Enable*1 *2 0: AGTOAn pin output disabled 1: AGTOAn pin output enabled	R/W
2	TOPOLA	AGTOAn Pin Polarity Select*1 *2 0: AGTOAn pin output is started on low. i.e. normal output 1: AGTOAn pin output is started on high. i.e. inverted output	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	TCMEB	AGT Compare Match B Register Enable*1 *2 0: Compare match B register disabled 1: Compare match B register enabled	R/W
5	TOEB	AGTOBn Pin Output Enable*1 *2 0: AGTOBn pin output disabled 1: AGTOBn pin output enabled	R/W

Bit	Symbol	Function	R/W
6	TOPOLB	AGTOBn Pin Polarity Select[*1][*2] 0: AGTOBn pin output is started on low. i.e. normal output 1: AGTOBn pin output is started on high. i.e. inverted output	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Do not rewrite the AGTCMSR register during a count operation. Only rewrite the AGTCMSR register when both the TSTART bit and TCSTF flag in the AGTCR register are set to 0 (count stops).

Note 2. Do not set 1 when in pulse width measurement mode or pulse period measurement mode.

24.2.10 AGTIOSEL : AGT Pin Select Register

Base address: AGTn = 0x4022_1000 + 0x0100 × n (n = 0, 1)
AGTn_NS = 0x5022_1000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TIES	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	TIES	AGTIOn Pin Input Enable 0: External event input is disabled during Software Standby mode 1: External event input is enabled during Software Standby mode	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The AGTIOSEL register sets the AGTIOn pin when using the AGTIOn pin in Software Standby mode.

TIES bit (AGTIOn Pin Input Enable)

The TIES bit enables or disables an external event input.

24.3 Operation

24.3.1 Reload Register and Counter Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to the reload register and the counter differs depending on the value of the TSTART bit in the AGTCR register and of the TCMEA or TCMEB bit in the AGTCMSR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and the counter. When the TSTART bit is 1 (count starts) and the TCMEA bit and TCMEB bit are 0 (AGT compare match A/B register are invalid), the value is written to the reload register in synchronization with the count source, and then to the counter in synchronization with the next count source. When the TSTART bit is 1 (count starts) and the TCMEA bit or the TCMEB bit is 1 (AGT compare match A register or compare match B register is valid), the value is written to the reload register in synchronization with the count source, and then to the counter in synchronization with the underflow of the counter.

Figure 24.3 and Figure 24.4 show the timing of rewrite operation with TSTART bit value and TCMEA/TCMEB bit value.

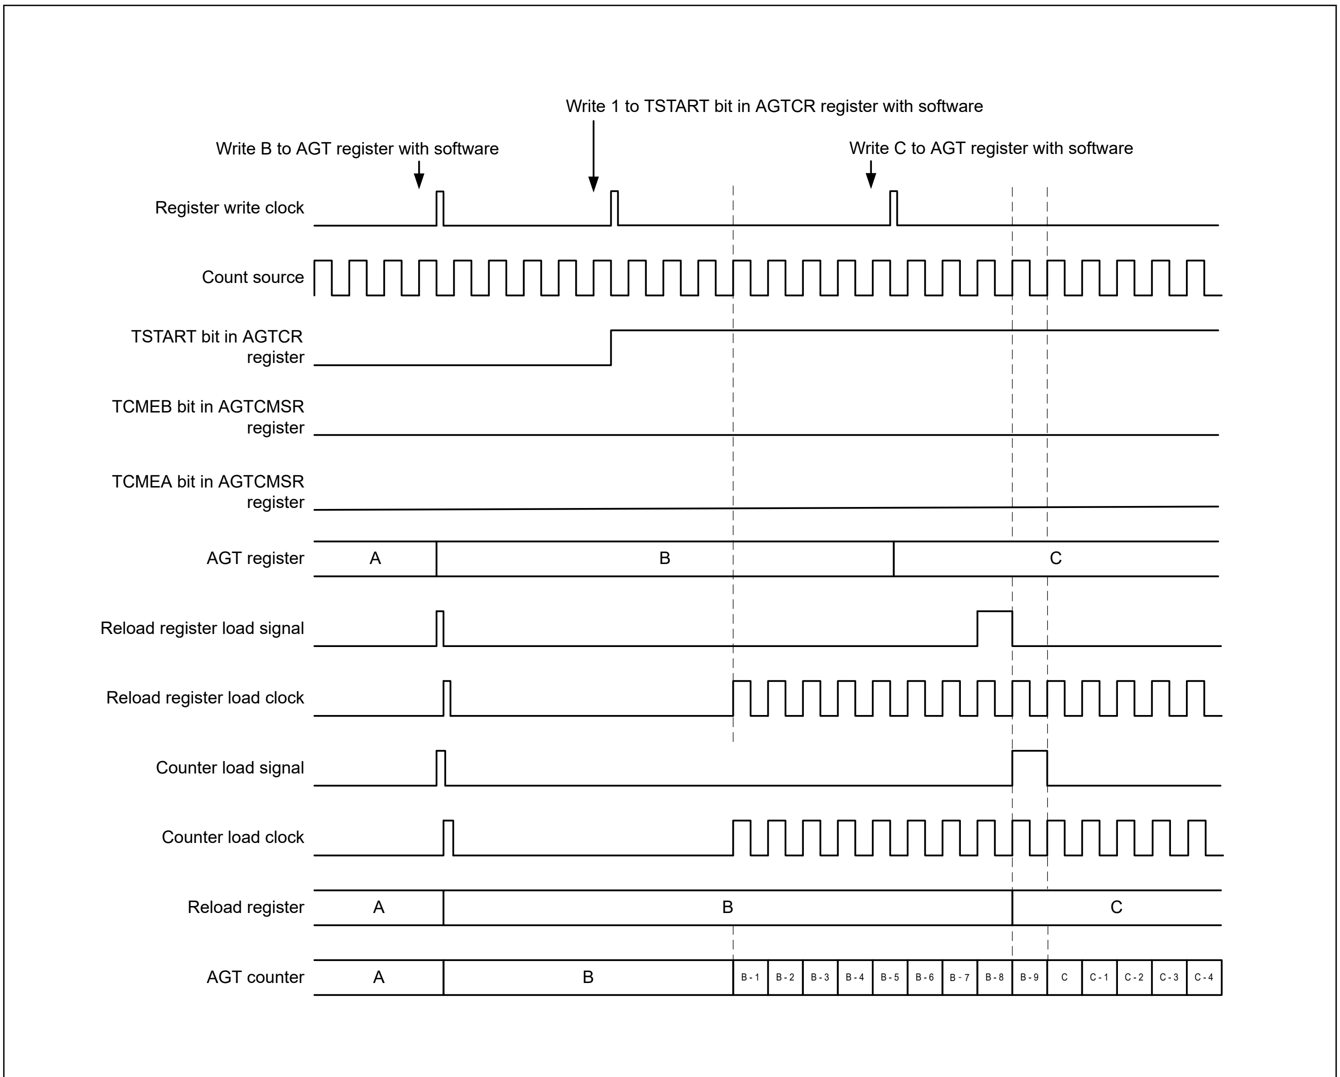

Figure 24.3 Timing of rewrite operation with TSTART, TCMEA, and TCMEB bit value when AGT compare match A register and AGT compare match B register is invalid

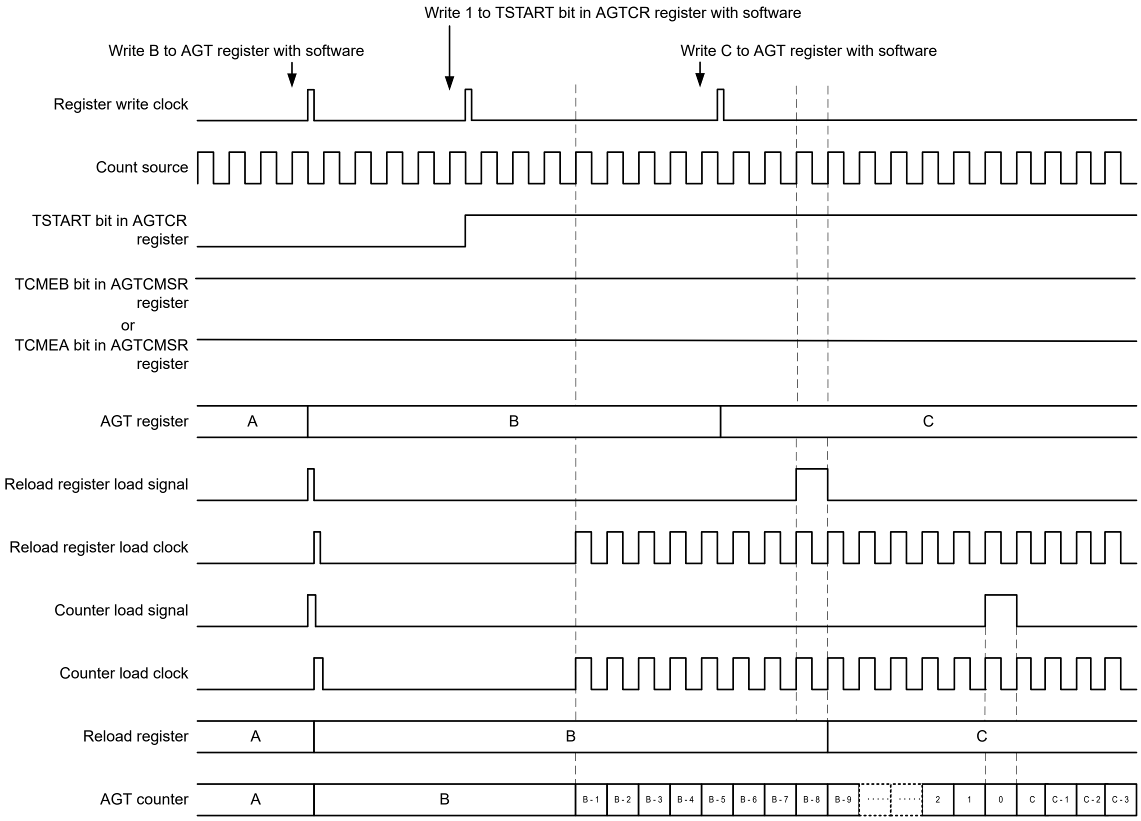

Figure 24.4 Timing of rewrite operation with TSTART bit value and TCMEA or TCMEB bit value when AGT compare match A register or AGT compare match B register is valid

24.3.2 Reload Register and AGT Compare Match A/B Register Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to the reload register and AGT compare register A/B depends on the value of the TSTART bit in the AGTCR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and AGT compare register A/B. When the TSTART bit is 1 (count starts), the value is written to the reload register in synchronization with the count source, and then to the compare register in synchronization with the underflow of the counter.

Figure 24.5 shows the timing of rewrite operation with TSTART bit value for compare register A. AGT Compare register B is of the same timing as AGT compare register A.

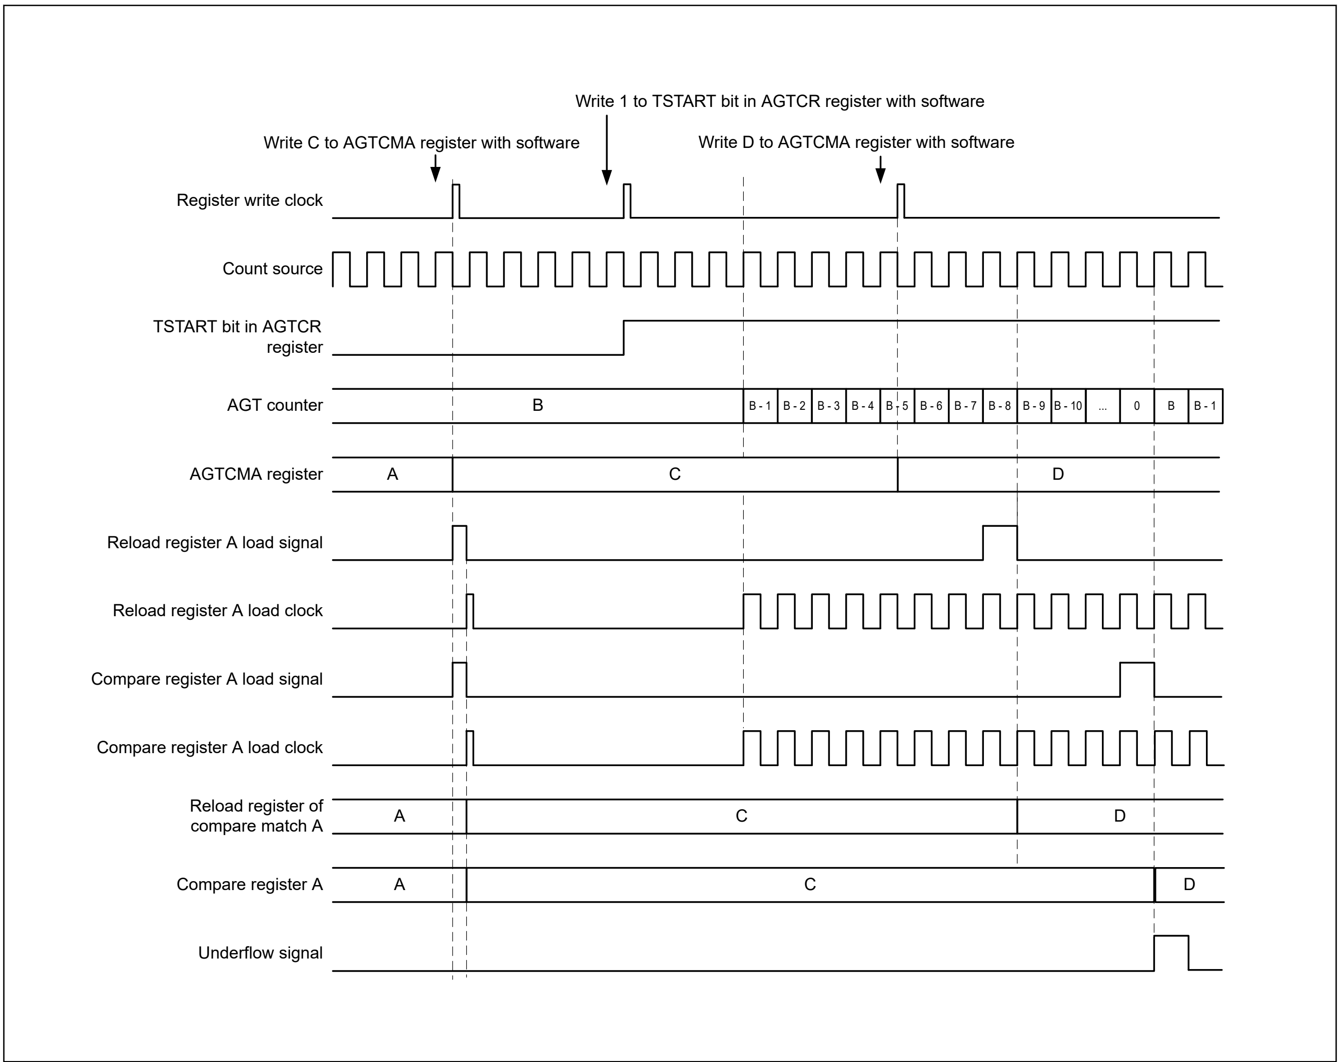

Figure 24.5 Timing of rewrite operation with the TSTART bit value for AGT compare register A

24.3.3 Timer Mode

In this mode, the AGT counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register. In timer mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0x0000 and the next count source is input, an underflow occurs, and an interrupt request is generated.

Figure 24.6 shows the operation example in timer mode.

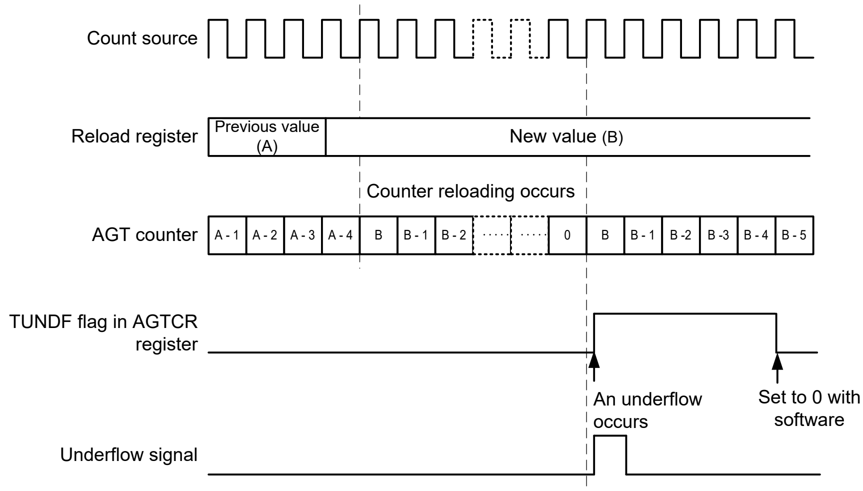

Figure 24.6 Operation example in timer mode

24.3.4 Pulse Output Mode

In pulse output mode, the counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and the output level of the AGTIOn and AGTOn pins inverted each time an underflow occurs.

In pulse output mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0x0000 and the next count source is input, an underflow occurs, and an interrupt request is generated. In addition, a pulse can be output from the AGTIOn and AGTOn pins. The output level is inverted each time an underflow occurs. The pulse output from the AGTOn pin can be stopped with the TOE bit in the AGTIOC register. The output level can be selected with the TEDGSEL bit in the AGTIOC register.

Figure 24.7 shows the operation example in pulse output mode.

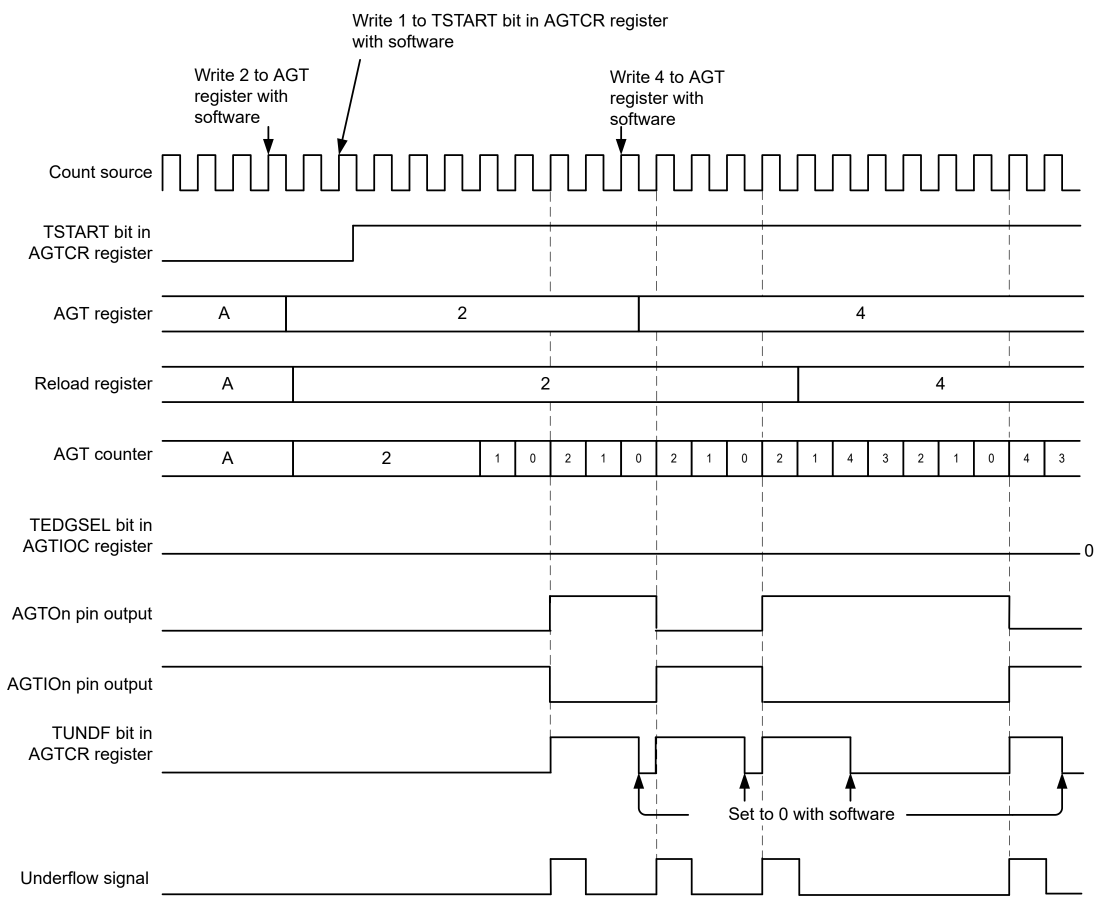

Figure 24.7 Operation example in pulse output mode

24.3.5 Event Counter Mode

In event counter mode, the counter is decremented by an external event signal (count source) input to the AGTIOn pin. Various periods for counting events can be set with the TIOGT[1:0] bits in the AGTIOC register and AGTISR registers. In addition, the filter function for the AGTIOn pin input can be specified with bits TIPF[1:0] in the AGTIOC register. The output from the AGTOn pin can be toggled even in event counter mode.

Figure 24.8 shows the operation example in event counter mode.

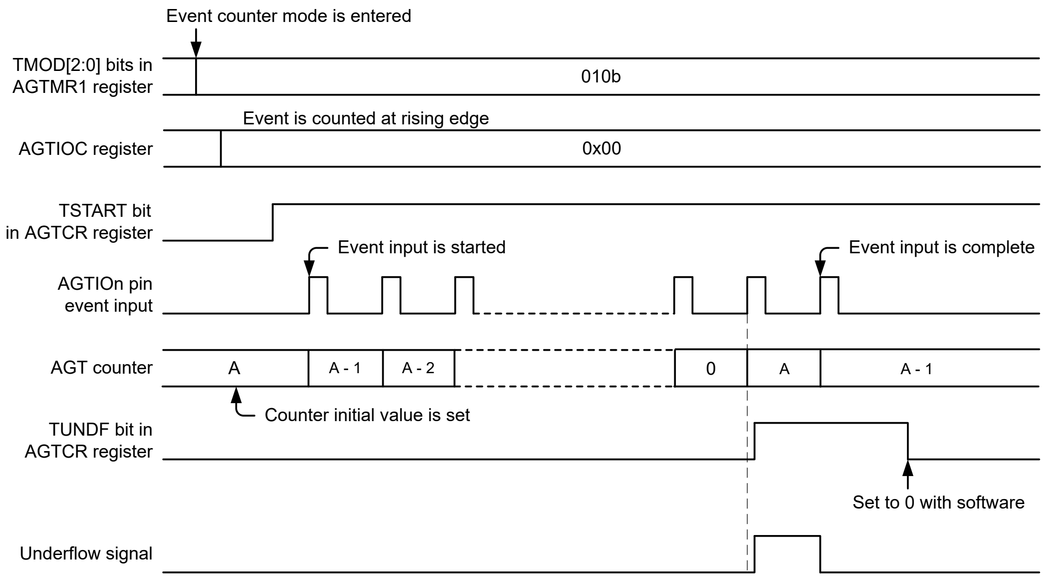

Figure 24.8 Operation example 1 in event counter mode

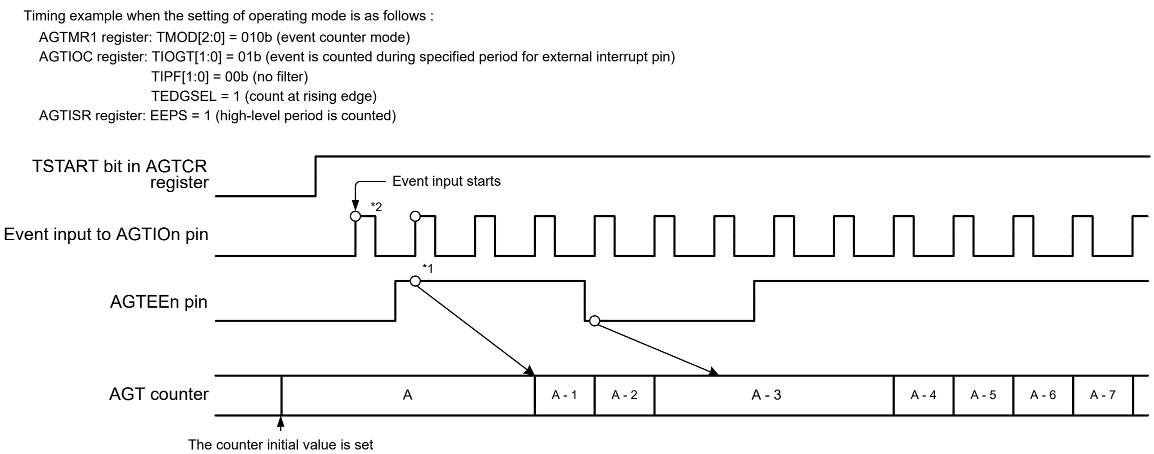
Figure 24.9 shows an operation example for counting during the specified period in event counter mode (TIOGT[1:0] bits in the AGTIOC register are set to 01b).



Note 1. To control synchronization, there is a delay of 2 cycles of the count source until the count operation is affected. It is also possible that the count start timing is shifted by 1 cycle because of the phase difference between the AGTEEn pin and the sampling clock.

Note 2. Count operation can be performed for 2 cycles of the count source immediately after the count starts, depending on the previous state before the count stops.
To disable the count for 2 cycles immediately after the count starts, write 1 to the TSTOP bit in the AGTCR register to initialize the internal circuit, and then complete the operation settings before starting the count operation.

Figure 24.9 Operation example 2 in event counter mode

24.3.6 Pulse Width Measurement Mode

In pulse width measurement mode, the pulse width of an external signal input to the AGTIOn pin is measured. When the level specified by the TEDGSEL bit in the AGTIOC register is input to the AGTIOn pin, the counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register. When the specified level on the AGTIOn pin ends, the counter is stopped, the TEDGF flag in the AGTCR register is set to 1 (active edge received), and an interrupt request is generated. The measurement of pulse width data is performed by reading the count value while the counter is stopped. Also, when the counter underflows during measurement, the TUNDF flag in the AGTCR register is set to 1 and an interrupt request is generated.

Figure 24.10 shows the operation example in pulse width measurement mode.

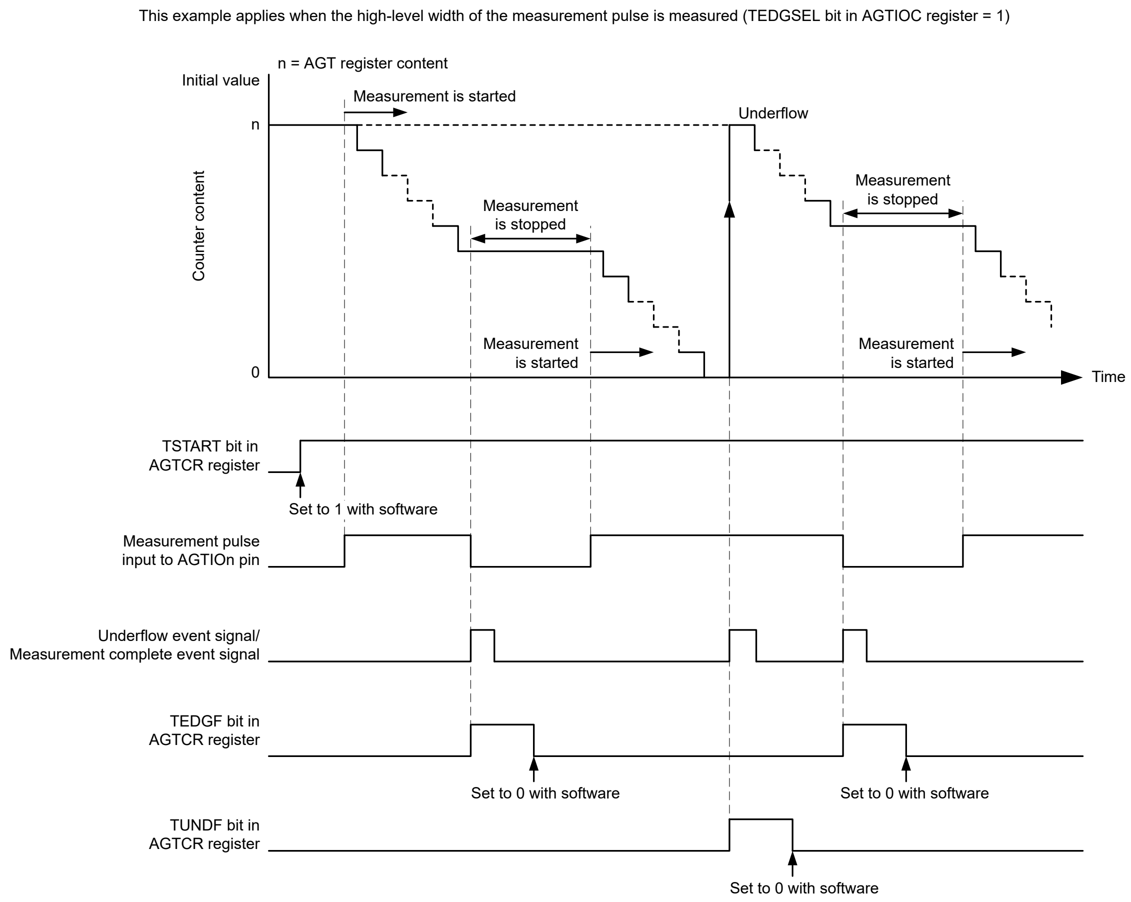


Figure 24.10 Operation example in pulse width measurement mode

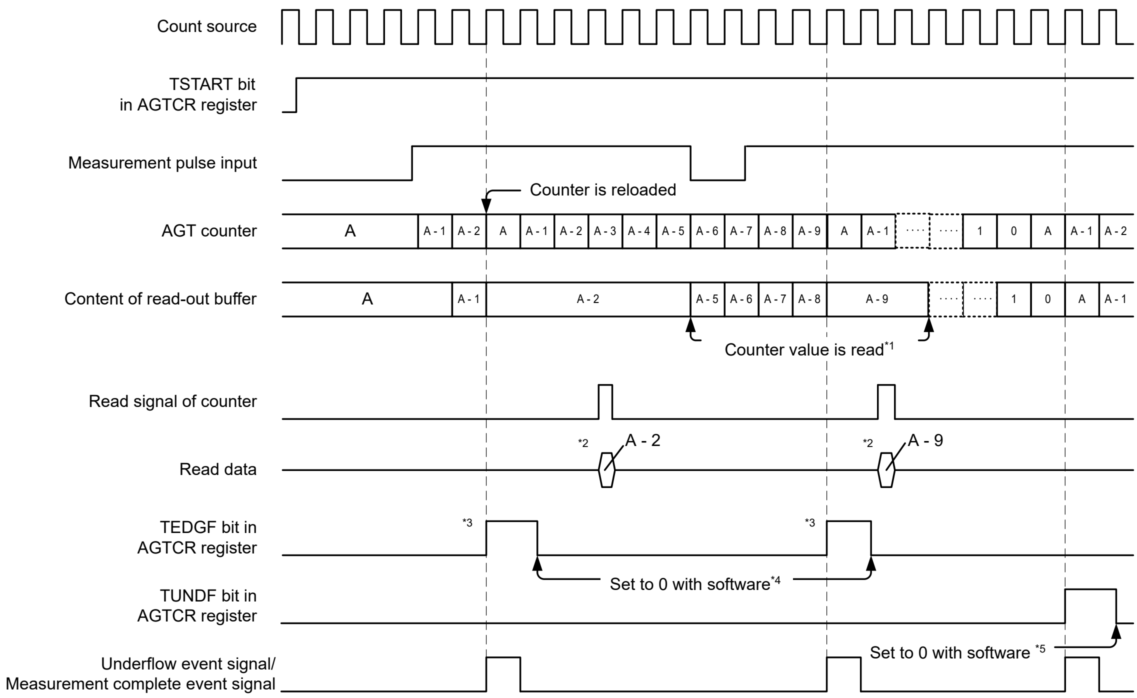
24.3.7 Pulse Period Measurement Mode

In pulse period measurement mode, the pulse period of an external signal input to the AGTIOn pin is measured. The counter is decremented by the count source selected with TCK[2:0] bits in the AGTMR1 register. When a pulse with the period specified by the TEDGSEL bit in the AGTIOC register is input to the AGTIOn pin, the count value is transferred to the read-out buffer on the rising edge of the count source. The value in the reload register is loaded to the counter at the next rising edge. Simultaneously, the TEDGF flag in the AGTCR register is set to 1 (active edge received) and an interrupt request is generated. The read-out buffer (AGT register) is read at this time and the difference from the reload value (see section 24.4.6. How to Calculate Event Number, Pulse Width, and Pulse Period) is the period data of the input pulse. The period data is retained until the read-out buffer is read. When the counter underflows, the TUNDF flag in the AGTCR register is set to 1 (underflow) and an interrupt request is generated.

Figure 24.11 shows the operation example in pulse period measurement mode.

Only input pulses with a period longer than twice the period of the count source are measured. Also, the low-level and high-level widths must both be longer than the period of the count source. If a pulse period shorter than these conditions is input, the input might be ignored.



This example applies when the initial value of the AGT register is set to A, the TEDGSEL bit in the AGTIOC register is set to 0, and the period from one rising edge to the next edge of the measurement pulse is measured.

Note 1. Reading from the AGT register must be performed during the period from when the TEDGF flag is set to 1 (active edge received) until the next active edge is input. The content of the read-out buffer is retained until the AGT register is read. If it is not read before the active edge is input, the measurement result of the previous period is retained.

Note 2. When the AGT register is read in pulse period measurement mode, the content of the read-out buffer is read.

Note 3. When the active edge of the measurement pulse is input and then the set edge of an external pulse is input, the TEDGF flag in the AGTCR register is set to 1 (active edge received).

Note 4. To set to 0 with software, write 0 to the TEDGF flag in the AGTCR register with an 8-bit memory manipulation instruction.

Note 5. To set to 0 with software, write 0 to the TUNDF flag in the AGTCR register with an 8-bit memory manipulation instruction.

Figure 24.11 Operation example in pulse period measurement mode

24.3.8 Compare Match Function

The compare match function detects matches (compare match) between the content of the AGTCMA or AGTCMB register and the content of the AGT register. This function is enabled when the TCMEA or TCMEB bit in the AGTCMSR register is 1 (compare match A register or compare match B register is valid). The counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and when the values of AGT and AGTCMA or AGTCMB match, the TCMAF/TCMBF flag in the AGTCR register is set to 1 (match), and an interrupt request is generated.

When the compare match function is enabled, the timing of the rewrite operation to the reload register and the counter differs. See section 24.3.1. Reload Register and Counter Rewrite Operation for details. In addition, the output level of the AGTOAn, AGTOBn pins is inverted by the match and by the underflow. The output level can be selected with the TOPOLA or TOPOLB bit in the AGTCMSR register.

Figure 24.12 shows the operation example in compare match function.

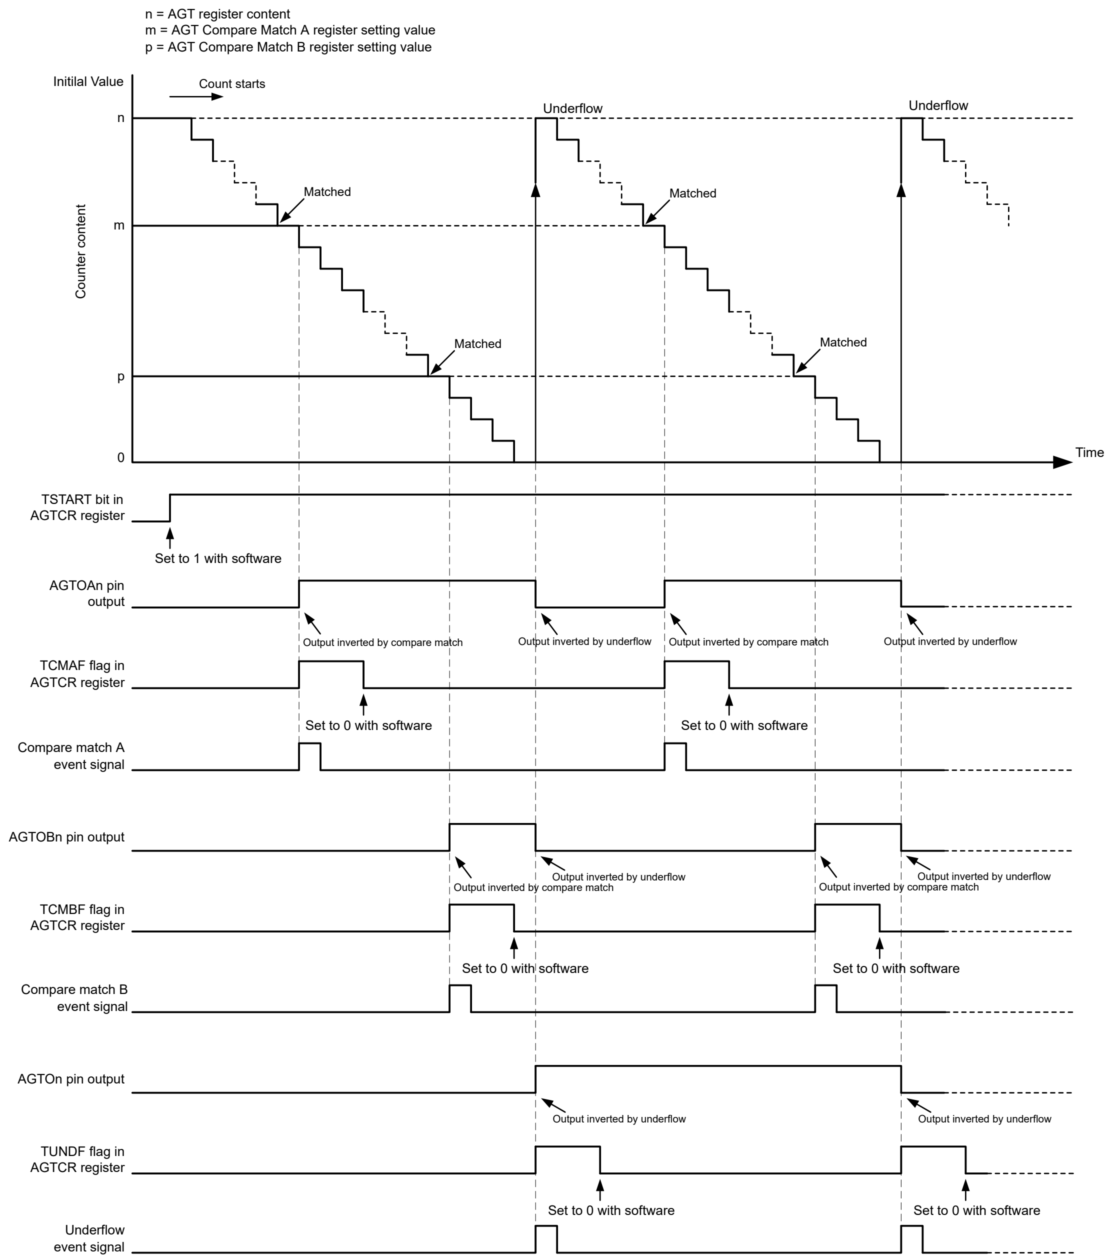


Figure 24.12 Operation example in compare match function (TOPOLA = 0, TOPOLB = 0)

24.3.9 Output Settings for Each Mode

Table 24.5 to Table 24.8 list the states of pins AGTOn, AGTIOn, AGTOAn, and AGTOBn pins in each mode.

Table 24.5 AGTOn pin setting

Operating mode	AGTIOC register		AGTOn pin output
	TOE bit	TEDGSEL bit	
All modes	1	1	Inverted output
		0	Normal output
	0	0 or 1	Output disabled

Table 24.6 AGTIOn pin setting

Operating mode	AGTIOC register	AGTIOn pin I/O
	TEDGSEL bit	
Timer mode	0 or 1	Input (not used)
Pulse output mode	1	Normal output
	0	Inverted output
Event counter mode	0 or 1	Input
Pulse width measurement mode		
Pulse period measurement mode		

Table 24.7 AGTOAn pin setting

Operating mode	AGTCMSR register		AGTOAn pin output
	TOEA bit	TOPOLA bit	
Timer mode	1	1	Inverted output
		0	Normal output
	0	0 or 1	Output disabled (not used)
Pulse output mode	1	1	Inverted output
		0	Normal output
	0	0 or 1	Output disabled (not used)
Event counter mode	1	1	Inverted output
		0	Normal output
	0	0 or 1	Output disabled (not used)
Pulse width measurement mode	0	0	Prohibited
Pulse period measurement mode			

Table 24.8 AGTOBn pin setting

	0	0 or 1	Output disabled (not used)
Event counter mode	1	1	Inverted output
		0	Normal output
	0	0 or 1	Output disabled (not used)
Pulse width measurement mode	0	0	Prohibited
Pulse period measurement mode			

24.3.10 Standby Mode

The AGT can operate in Software Standby mode. Set it to Software Standby mode with count operation start (TSTART = 1, TCSTF = 1).

Table 24.9 and Table 24.10 show the setting that can be used in Software Standby mode.

Table 24.9 Usable settings in Software Standby mode (AGT0)

Operating mode	AGTMR1.TCK[2:0]	Operating clock	Resurgence factor of CPU
Timer mode	100b or 110b	AGTLCLK or AGTSCLK	—
Pulse output mode	100b or 110b	AGTLCLK or AGTSCLK	—
Event counter mode*2 *3	—	AGTIO0*1	—
Pulse width measurement mode	100b or 110b	AGTLCLK or AGTSCLK	—
Pulse period measurement mode	100b or 110b	AGTLCLK or AGTSCLK	—

Note: —: invalid
Note 1. When using the AGTIO0 pin for external event input in Software Standby mode, set AGTIOSEL.TIES = 1.
Note 2. AGTEE pin is not available during Software Standby mode. External events are always enabled.
Note 3. When external event input is disabled during Software Standby mode (AGTIOSEL.TIES = 0), stop the count operation before the MCU enters Software Standby mode.
Restart the count operation after the MCU returns from Software Standby mode.

Table 24.10 Usable settings in Software Standby mode (AGT1)

Operating mode	AGTMR1.TCK[2:0]	Operating clock	Resurgence factor of CPU
Timer mode	100b or 110b or 101b*1	AGTLCLK or AGTSCLK or AGT0 underflow	• Underflow • Compare match A/B
Pulse output mode	100b or 110b or 101b*1	AGTLCLK or AGTSCLK or AGT0 underflow	• Underflow • Compare match A/B
Event counter mode*3 *4	—	AGTIO1*2	• Underflow • Compare match A/B
Pulse width measurement mode	100b or 110b or 101b*1	AGTLCLK or AGTSCLK or AGT0 underflow	• Underflow • Active edge
Pulse period measurement mode	100b or 110b or 101b*1	AGTLCLK or AGTSCLK or AGT0 underflow	• Underflow • Active edge

Note: —: invalid
Note: Release of Software Standby mode is only AGT1.
Note: Compare match A/B is resurgence factor of CPU from Software Standby mode.
Note 1. Only when AGT0 operates in Table 24.9
Note 2. When using the AGTIO1 pin for external event input in Software Standby mode, set AGTIOSEL.TIES = 1.
Note 3. AGTEE pin is not available during Software Standby mode. External events are always enabled
Note 4. When external event input is disabled during Software Standby mode (AGTIOSEL.TIES = 0), stop the count operation before the MCU enters Software Standby mode.
Restart the count operation after the MCU returns from Software Standby mode.

24.3.11 Interrupt Sources

The AGTn has three interrupt sources as listed in Table 24.11.

Table 24.11 AGT interrupt sources

Name	Interrupt source	DMAC/DTC activation
AGTn_AGTI	• When the counter underflows • When measurement of the active width of the external input pin (AGTIOn) is complete in pulse width measurement mode • When the set edge of the external input pin (AGTIOn) is input in pulse period measurement mode.	Possible
AGTn_AGTCMAI	• When the values of AGT register and AGTCMA register match	Possible
AGTn_AGTCMBI	• When the values of AGT register and AGTCMB register match	Possible

Note: Channel number (n = 0, 1)

24.3.12 Event Signal Output to ELC

The AGT uses the Event Link Controller (ELC) to perform a link operation to a specified module using the interrupt request signal as the event signal. The AGT outputs compare match A, compare match B, and underflow/measurement complete signals as event signals. For details, see section 19, Event Link Controller (ELC).

24.4 Usage Notes

24.4.1 Count Operation Start and Stop Control

- When the operating mode (see Table 24.1) is set to other than the event counter mode, or the count source is set to other than AGTn underflow event signal (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF flag in the AGTCR register remains 0 (count stops) for 3 cycles of the count source. Do not access the registers associated with AGT other than the TCSTF flag until this flag is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF flag remains 1 for 3 cycles of the count source. When the TCSTF flag is set to 0, the count is stopped. Do not access the registers associated with AGT other than the TCSTF flag until this flag is set to 0.
- When the operating mode (see Table 24.1) is set to event counter mode, or the count source is set to AGT1 underflow event signal (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF flag in the AGTCR register remains 0 (count stops) for 2 PCLKB cycles. Do not access the registers associated with AGT other than the TCSTF flag until this flag is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF flag remains 1 for 2 PCLKB cycles. When the TCSTF flag is set to 0, the count is stopped. Do not access the registers associated with AGT other than the TCSTF flag until this flag is set to 0.

24.4.2 Access to Counter Register

When the TSTART bit and TCSTF flag in the AGTCR register are both 1 (count starts), allow at least 3 cycles of the count source clock between writes when writing to the AGT register successively.

24.4.3 When Changing Mode

The registers associated with AGT operating mode (AGTMR1, AGTMR2, AGTIOC, AGTISR, and AGTCMSR) can be changed only when the count is stopped with both the TSTART bit and TCSTF flag set to 0 (count stops). Do not change these registers during count operation.

When the registers associated with AGT operating mode are changed, the values of TEDGF, TUNDF, TCMAF, and TCMBF flags are undefined. Before starting the count, write 0 to the following flags:

- TEDGF (no active edge received)
- TUNDF (no underflow)
- TCMAF (no match)
- TCMBF (no match).

24.4.4 Output Pin Setting

When using the AGTOn, AGTIOn, AGTOAn, or AGTOBn as an output pin, set up the Operation and determine the initial output values. Then set PmnPFS.PMR bit to 1.

When using the AGTIOn as an input pin in pulse width measurement mode or pulse period measurement mode, set up the Operation and start count operation. Then start to enter external events from the AGTIOn pin. Invalidate the first measurement and validate the second and later completed measurements.

24.4.5 Digital Filter

When using the digital filter, do not start the timer operation for 5 cycles of the digital filter clock after setting TIPF[1:0] bits and when the TEDGSEL bit in the AGTIOC register changes.

24.4.6 How to Calculate Event Number, Pulse Width, and Pulse Period

- In event counter mode, event number is expressed mathematically as follows:
  Event number = initial value of counter [AGT register] - counter value of active event end

- In pulse width measurement mode, pulse width is expressed mathematically as follows:
  Pulse width = counter value of stopping measurement - counter value of next stopping measurement
- In pulse period measurement mode, input pulse period is expressed mathematically as follows:
  Period of input pulse = (initial value of counter [AGT register] - reading value of the read-out buffer) + 1.

24.4.7 When Count is Forcibly Stopped by TSTOP Bit

After the counter is forcibly stopped by the TSTOP bit in the AGTCR register, do not access the following I/O registers for 1 cycle of the count source:

- AGT
- AGTCMA
- AGTCMB
- AGTCR
- AGTMR1
- AGTMR2.

24.4.8 When Selecting AGT0 Underflow as the Count Source

Operate according to the following procedures described in this section when selecting the underflow event signal as the count source.

(1) Procedure for starting operation

1. Set AGT.
2. Start the count operation of AGT1.
3. Start the count operation of AGT0.

(2) Procedure for stopping operation

1. Stop the count operation of AGT0.
2. Stop the count operation of AGT1.
3. Stop the count source clock of AGT1 (write 000b in the AGTMR1.TCK[2:0] bits).

24.4.9 Module-stop Function

AGT operation can be disabled or enabled using Module Stop Control Register D (MSTPCRD). The AGT module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Mode

24.4.10 When Switching Source Clock

When switching a clock source by changing SCKSCR.CKSEL[2:0], the clock output from the selector stops for 4 cycles of the switched clock. Therefore, when using the AGTIOn, AGTEEn, or both input as external event input, the clock source should not be switched. If switching the clock source while using the external event input, extend the input pulse width by 4 clock cycles of the switched source clock cycles.

25. Ultra-Low-Power Timer (ULPT)

25.1 Overview

This ultra-low power timer (ULPT) is a 32-bit timer that can output pulses or count external events.

This 32-bit timer consists of reload registers and a down-counter. The reload registers and the down-counter are allocated to the same address and can be accessed through the ULPTCNT register.

Table 25.1 lists the ULPT specifications.

Table 25.1 ULPT specifications

Item		Description
Operating mode	Timer mode	Count the internal clock
	Event counter mode	Count external events
Number of channels		32 bits × 2 channels (ULPTn (n = 0, 1))
Count source (operating clock)*1		The following signals can be selected: ● Internal clock: ULPTLCLK/d or ULPTSCLK/d (d = 1, 2, 4, 8, 16, 32, 64, 128) ● External event: ULPTEVIn pin.
Count operation		The following functions can be selected: ● Selection between continuous mode and one-shot mode ● Selection from count enable mode, count start mode, and count restart mode.
Interrupt/event link function (output)		● Underflow signal – When the counter underflows ● Compare match A signal – When the ULPTCNT value matches the ULPTCMA value The compare match A function is enabled. ● Compare match B signal – When the ULPTCNT value matches the ULPTCMB value The compare match B function is enabled.
Selectable functions		● Pulse output function – Inverts the output each time the counter underflows ● Compare match function – Either or both compare match A register and compare match B register are selectable ● Return from Software Standby mode can be performed with ULPTn_ULPTI, ULPTn_ULPTCMAI, or ULPTn_ULPTCMBI (n = 0, 1).*2 ● Return from Deep Software Standby mode 1 can be performed with ULPTn_ULPTI (n = 0, 1).*2
Module-stop function		Module-stop state can be set for each channel to reduce power consumption
TrustZone Filter		Security and privilege attribution can be set for each channel

Note 1. Make sure that the frequency of the peripheral module clock (PCLKB) is at least twice the frequency of the count source clock.
Note 2. For details, see section 11, Low Power Mode.

25.2 Configuration

Figure 25.1 shows the ULPT block diagram. Table 25.2 lists the I/O pins of the ULPT.

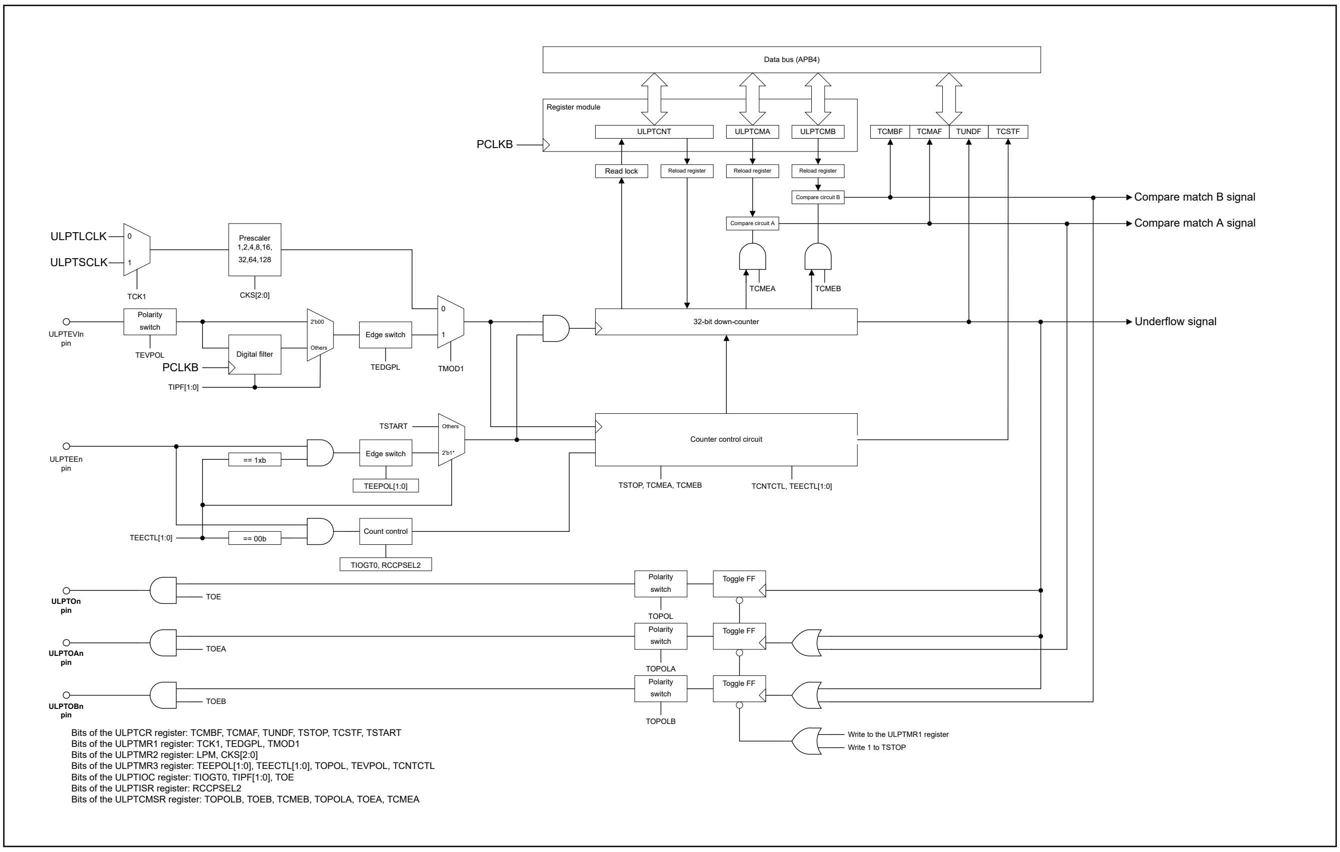

Figure 25.1 ULPT block diagram

Table 25.2 ULPT I/O pins

Pin name	I/O	Function
ULPTEEn*2	Input	External count control input*1
ULPTEVIn*2	Input	External event input
ULPTOn*2	Output	Pulse output
ULPTOAn*2	Output	Output compare match A output
ULPTOBn*2	Output	Output compare match B output

Note: Channel number: n = 0, 1

Note 1. The function of the ULPTEEn pin can be selected by the ULPTMR3.TEECTL[1:0] bits. For more details, see section 25.3.7. ULPTMR3 : ULPT Mode Register 3.

Note 2. Only pins marked "-DS" can be used in Deep Software Standby mode 1.

25.3 Register Descriptions

25.3.1 ULPTCNT : ULPT Counter Register

Base address: ULPTn = 0x4022_0000 + 0x0100 × n (n = 0, 1)
ULPTn_NS = 0x5022_0000 + 0x0100 × n (n = 0, 1)

Offset address: 0x00

Bit position:	31 … 0
Bit field:	ULPTCNT
Value after reset:	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1

Bit	Symbol	Function	R/W
31:0	ULPTCNT	32-bit counter and reload register*1*2 Setting range : 0x00000000 to 0xFFFFFFFF	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. When 1 is written to the ULPTCR.TSTOP bit, the counter is forcibly stopped and set to 0xFFFFFFFF. The reload register is set to 0xFFFFFFFF.
Note 2. When 0x00000000 is set in the ULPTCNT register, a request signal to the ICU, DTC, and ELC occurs only once immediately after the start of count operation (when the ULPTCR.TSTART bit is set to 1). However, the pulse output at the ULPTOn pin remains toggled.
The pulse output from the ULPTOn pin can be enabled or disabled by the ULPTIOC.TOE bit.
When the ULPTCNT register is set to a value equal to or greater than 0x00000001, a request signal is generated each time the counter underflows.

The ULPTCNT is a 32-bit register. The register value is written to the reload register and is read from the counter.

The states of the counter and reload register change according to the TSTART/TCSTF bit in the ULPTCR register and the TCMEA/TCMEB bit in the ULPTCMSR register. For details, see section 25.4.2. Rewriting the Counter and Reload Register.

The ULPTCNT register is only available for 32-bit read/write access.

25.3.2 ULPTCMA : ULPT Compare Match A Register

Base address: ULPTn = 0x4022_0000 + 0x0100 × n (n = 0, 1)
ULPTn_NS = 0x5022_0000 + 0x0100 × n (n = 0, 1)

Offset address: 0x04

Bit position:	31 ... 0
Bit field:	ULPTCMA
Value after reset:	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1

Bit	Symbol	Function	R/W
31:0	ULPTCMA	32-bit Compare Match A Data*1*2 Setting range : 0x00000000 to 0xFFFFFFFF	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. When 1 is written to the ULPTCR.TSTOP bit, 0xFFFFFFFF is set in the ULPTCMA register.
Note 2. Set the ULPTCMA register to 0xFFFFFFFF when compare match A is not used (ULPTCMSR.TCMEA bit = 0).

The ULPTCMA register is a readable/writable register to set a value for compare match with the counter.

The states of compare circuit A and the reload register change according to the TSTART and TCSTF bits in the ULPTCR register. For details, see section 25.4.3. Rewriting the Compare Circuits and Reload Registers for Compare Match A/B.

The ULPTCMA register is only available for 32-bit read/write access.

25.3.3 ULPTCMB : ULPT Compare Match B Register

Base address: ULPTn = 0x4022_0000 + 0x0100 × n (n = 0, 1)
ULPTn_NS = 0x5022_0000 + 0x0100 × n (n = 0, 1)

Offset address: 0x08

Bit position:	31 ... 0
Bit field:	ULPTCMB
Value after reset:	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1

Bit	Symbol	Function	R/W
31:0	ULPTCMB	32-bit Compare Match B Data*1*2 Setting range : 0x00000000 to 0xFFFFFFFF	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. When 1 is written to the ULPTCR.TSTOP bit, 0xFFFFFFFF is set in the ULPTCMB register.

Note 2. Set the ULPTCMB register to 0xFFFFFFFF when compare match B is not used (ULPTCMSR.TCMEB bit = 0).

The ULPTCMB register is a readable/writable register to set a value for compare match with the counter.

The states of compare circuit B and the reload register change according to the TSTART and TCSTF bits in the ULPTCR register. For details, see section 25.4.3. Rewriting the Compare Circuits and Reload Registers for Compare Match A/B.

The ULPTCMB register is only available for 32-bit read/write access.

25.3.4 ULPTCR : ULPT Control Register

Base address: ULPTn = 0x4022_0000 + 0x0100 × n (n = 0, 1)
ULPTn_NS = 0x5022_0000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TCMBF	TCMAF	TUNDF	—	—	TSTOP	TCSTF	TSTART
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TSTART	Counter Start 0: Stop the counter 1: Start the counter	R/W
1	TCSTF	Counter Status Flag*2 0: Counter stopped 1: Counter running	R
2	TSTOP	Counter Forcible Stop*1 0: Writing is invalid 1: Stop the counter forcibly	W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	TUNDF	Underflow Flag 0: No underflow occurred (counter ≠ 0x00000000) 1: Underflow occurred (counter = 0x00000000)	R/W*3
6	TCMAF	Compare Match A Flag 0: Not matched (counter ≠ ULPTCMA[31:0]) 1: Matched (counter = ULPTCMA[31:0])	R/W*3
7	TCMBF	Compare Match B Flag 0: Not matched (counter ≠ ULPTCMB[31:0]) 1: Matched (counter = ULPTCMB[31:0])	R/W*3

Note: S-TYPE-3, P-TYPE-3
Note 1. When 1 (stop the counter forcibly) is written to the TSTOP bit, the TSTOP, TSTART, and TCSTF bits are initialized. The pulse output, compare match A output and compare match B output are also initialized. This bit is read as 0.
Note 2. For precautions on using the TCSTF bit, see section 25.5.1. Start and Stop Control of the Counter.
Note 3. Only 0 can be written to clear the flag.

The ULPTCR register controls the start and stop of the counter and indicates the status of the ULPT.

The ULPTCR register is only available for 8-bit read/write access.

Set 1 to the TUNDF, TCMAF, and TCMBF bits when changing the TSTART or TSTOP bit to prevent clearing TUNDF, TCMAF, or TCMBF by mistake. At this time, setting 1 to TUNDF, TCMAF, and TCMBF bits is ignored.

TSTART bit (Counter Start)

When and how the counter is started depends on the setting of the ULPTMR3.TEECTL[1:0] bits.

The counter is stopped in the same way in any mode.

For details, see section 25.4.1. Count Operation.

[Starting the counter]

In count enable mode (ULPTMR3.TEECTL[1:0] bits = 00)

- When 1 is written to the TSTART bit.

In count start mode or count restart mode (ULPTMR3.TEECTL[1:0] bits = 10 or 11)

- When 1 is written to the TSTART bit, and then an edge at the ULPTEEn pin is input.

[Stopping the counter]

- When 0 is written to the TSTART bit
- When 1 is written to the TSTOP bit.

TCSTF bit (Counter Status Flag)

The operation of this bit depends on the settings of the TCNTCTL and TEECTL[1:0] bits of the ULPTMR3 register.

For details, see section 25.4.1. Count Operation.

[Setting conditions]

In timer mode (ULPTMR1.TMOD1 = 0) and count enable mode (ULPTMR3.TEECTL[1:0] bits = 00)

- When 1 is written to the TSTART bit (with the TCSTF bit set to 1 in synchronization with the count source).

In event counter mode (ULPTMR1.TMOD1 = 1) and count enable mode (ULPTMR3.TEECTL[1:0] bits = 00)

- When 1 is written to the TSTART bit (with the TCSTF bit set to 1 in synchronization with the count source).

In count start mode or count restart mode (ULPTMR3.TEECTL[1:0] bits = 10 or 11)

- When 1 is written to the TSTART bit, and then an edge at the ULPTEEn pin is input (with the TCSTF bit set to 1 in synchronization with the count source).

[Clearing conditions]

- When 0 is written to the TSTART bit (with the TCSTF bit set to 0 in synchronization with the count source)
- When 1 is written to the TSTOP bit
- When the counter underflows in one-shot mode (ULPTMR3.TCNTCTL = 1).
  Only under this condition, the TSTART bit does not change from 1.

TSTOP bit (Counter Forcible Stop)

When 1 is written to this bit, the counter is forcibly stopped. This bit is read as 0.

TUNDF bit (Underflow Flag)

[Setting condition]

- When the counter underflows (counter = 0x00000000).

[Clearing condition]

- When 0 is written to this bit.

TCMAF bit (Compare Match A Flag)

[Setting condition]

- When the ULPTCNT register value matches the ULPTCMA register value (counter = ULPTCMA[31:0]).

[Clearing condition]

- When 0 is written to this bit.

TCMBF bit (Compare Match B Flag)

[Setting condition]

- When the ULPTCNT register value matches the ULPTCMB register value (counter = ULPTCMB[31:0]).

[Clearing condition]

- When 0 is written to this bit.

25.3.5 ULPTMR1 : ULPT Mode Register 1

Base address: ULPTn = 0x4022_0000 + 0x0100 × n (n = 0, 1)
ULPTn_NS = 0x5022_0000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	TCK1	—	TEDGPL	—	TMOD1	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	TMOD1	Operating Mode*1 0: Timer mode 1: Event counter mode	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	TEDGPL	ULPTEVIn Edge Polarity 0: Either edge (rising) 1: Both edges This bit is valid only in event counter mode (TMOD1 = 1).	R/W
4	—	This bit is read as 0. The write value should be 0.	R/W
5	TCK1	Count Source*2 0: Divided clock specified by the ULPTMR2.CKS[2:0] bits (ULPTLCLK) 1: Divided clock specified by the ULPTMR2.CKS[2:0] bits (ULPTSCLK) This bit is valid only in timer mode (TMOD1 = 0).	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Do not rewrite this register while the counter is running. Rewrite this register only when the counter is stopped (both the TSTART and TCSTF bits of the ULPTCR register are set to 0).

Note: A write access to this register initializes the output from pins ULPTOn, ULPTOAn, and ULPTOBn, For details on the output level at initialization, see section 25.3.7. ULPTMR3 : ULPT Mode Register 3 and section 25.3.8. ULPTIOC : ULPT I/O Control Register.

Note 1. Timer mode: The internal clock (ULPTLCLK or ULPTSCLK) is used as the count source. The counter is decremented by 1 on each rising edge of the count source.
Event counter mode: The external event input (ULPTEVIn pin) is used as the count source. The counter is decremented on each edge of the count source. The edge polarity can be selected by the TEDGPL bit and the ULPTMR3.TEVPOL bit.
For details, see section 25.4.1. Count Operation.

Note 2. The TCK1 bit can be changed only when the ULPTMR2.CKS[2:0] bits are 000. Otherwise, do not change the bit. Set the ULPTMR2.CKS[2:0] bits to 000, and then change the TCK1 bit after one cycle of the count source.

The ULPTMR1 register sets the operating mode of the ULPT.

The ULPTMR1 register is only available for 8-bit read/write access.

25.3.6 ULPTMR2 : ULPT Mode Register 2

Base address: ULPTn = 0x4022_0000 + 0x0100 × n (n = 0, 1)
ULPTn_NS = 0x5022_0000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	LPM	—	—	—	—	CKS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CKS[2:0]	ULPTLCLK/ULPTSCLK Count Source Clock Division Ratio*1*2 0 0 0: 1/1 0 0 1: 1/2 0 1 0: 1/4 0 1 1: 1/8 1 0 0: 1/16 1 0 1: 1/32 1 1 0: 1/64 1 1 1: 1/128 This bit is valid only in timer mode (ULPTMR1.TMOD1 = 0).	R/W
6:3	—	These bits are read as 0. The write value should be 0.	R/W
7	LPM	Low Power Mode 0: Normal mode 1: Low power mode	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Do not rewrite this register while the counter is running. Rewrite this register only when the counter is stopped (both the TSTART and TCSTF bits of the ULPTCR register are set to 0).
Note 1. The CKS[2:0] bits can be changed only in timer mode (ULPTMR1.TMOD1 = 0). Set the CKS[2:0] bits to 000 in event counter mode (ULPTMR1.TMOD1 = 1).
Note 2. The ULPTMR1.TCK1 bit can be changed only when the CKS[2:0] bits are 000. Set the CKS[2:0] bits to 000, and then change the ULPTMR1.TCK1 bit after one cycle of the count source.

The ULPTMR2 register sets the operating mode of the ULPT.

The ULPTMR2 register is only available for 8-bit read/write access.

LPM bit (Low Power Mode)

This bit implements low power consumption by restricting register access. Set this bit to 1 for low-power mode operation.

When this bit is 1, access to the following registers is prohibited:

- ULPTCNT, ULPTCMA, ULPTCMB, and ULPTCR.

After this bit is switched from 1 to 0, the first access to an access-prohibited register is restricted as follows:

- ULPTCNT: The register must be read twice. Only the second reading of data is valid.
- ULPTCNT, ULPTCMA, ULPTCMB, ULPTCR: In write access, leave two cycles of the count source.

25.3.7 ULPTMR3 : ULPT Mode Register 3

Base address: ULPTn = 0x4022_0000 + 0x0100 × n (n = 0, 1)
ULPTn_NS = 0x5022_0000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TEEPOL[1:0]		TEECTL[1:0]		—	TOPOL	TEVPOL	TCNTCTL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TCNTCTL	Count Function Select*1*2 0: Continuous mode 1: One-shot mode	R/W
1	TEVPOL	ULPTEVIn Polarity Switch 0: External event input (ULPTEVIn pin) 1: External event input (ULPTEVIn pin) in reverse This bit is valid only in event counter mode (ULPTMR1.TMOD1 = 1).	R/W
2	TOPOL	ULPTOn Polarity Select*3 0: Start the ULPTOn output when in low level 1: Start the ULPTOn output when in high level	R/W

Bit	Symbol	Function	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
5:4	TEECTL[1:0]	ULPTEEn Function Select*1 0 0: Count enable mode 1 0: Count start mode 1 1: Count restart mode Other settings are prohibited. The count enable mode is valid only in event counter mode (ULPTMR1.TMOD1 = 1).	R/W
7:6	TEEPOL[1:0]	ULPTEEn Edge Polarity Select 0 0: Rising edge 0 1: Falling edge 1 0: Both edges Other settings are prohibited. This bit is valid only in count start mode or count restart mode. (TEECTL[1:0] = 10 or 11)	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Do not rewrite this register while the counter is running. Rewrite this register only when the counter is stopped (both the TSTART and TCSTF bits of the ULPTCR register are set to 0).

Note 1. For details, see section 25.4.1. Count Operation.

Note 2. Continuous mode: After starting counting, the counter continues to count down (reload value to underflow) repeatedly until the counter stops.
One-shot mode: After starting counting, the counter counts down once (reload value to underflow).

Note 3. When data is set to the ULPTMR1 register or 1 is set to the ULPTCR.TSTOP bit, the ULPTOn output is initialized.

The ULPTMR3 register sets the operating mode of the ULPT.

The ULPTMR3 register is only available for 8-bit read/write access.

TEECTL[1:0] bits (ULPTEEn Function Select)

The ULPTEEn pin functions differently depending on the mode. For details, see section 25.4.1. Count Operation.

In count enable mode, external events are counted while the ULPTEEn pin is valid. The duration can be selected by the ULPTIOC.TIOGT0 bit, and the polarity can be selected by the ULPTISR.RCCPSEL2 bit.

In count start mode, the counter starts counting at an edge trigger at the ULPTEEn pin. The operation of the ULPTEEn pin differs depending on the TSTART and TCSTF bits of the ULPTCR register.

In count restart mode, the counter starts counting at the first edge trigger at the ULPTEEn pin and resets the count at the second or following edge trigger. The operation of the ULPTEEn pin differs depending on the TSTART and TCSTF bits of the ULPTCR register.

Table 25.3 shows the operation of the ULPTEEn pin in count start or count restart mode.

Table 25.3 Operation of the ULPTEEn pin in count start mode or count restart mode

TEECTL[1:0]	ULPTCR.TSTART	ULPTCR.TCSTF	Function of the ULPTEEn pin and counter operation
10 (count start mode)	0 (stop the counter)	—	The edge input at the ULPTEEn pin is invalid. The counter remains stopped.
	1 (start the counter)	0 (counter stopped)	The counter starts counting from the reload value on the edge input at the ULPTEEn pin.
	1 (start the counter)	1 (counter running)	The edge input at the ULPTEEn pin is invalid. The counter continues to count.
11 (count restart mode)	0 (stop the counter)	—	The edge input at the ULPTEEn pin is invalid. The counter remains stopped.
	1 (start the counter)	0 (counter stopped)	The counter starts counting from the reload value on the edge input at the ULPTEEn pin.
	1 (start the counter)	1 (counter running)	The counter is reset on the edge input at the ULPTEEn pin, and it starts counting again from the reload value.

Note: The edge polarity of the ULPTEEn pin can be selected by the TEEPOL[1:0] bits.

25.3.8 ULPTIOC : ULPT I/O Control Register

Base address: ULPTn = 0x4022_0000 + 0x0100 × n (n = 0, 1)
ULPTn_NS = 0x5022_0000 + 0x0100 × n (n = 0, 1)

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	TIOGT0	TIPF[1:0]		—	TOE	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0. The write value should be 0.	R/W
2	TOE	ULPTOn Output Enable 0: Disable the ULPTOn output 1: Enable the ULPTOn output	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
5:4	TIPF[1:0]	ULPTEVIn Input Filter*2 0 0: No filter 0 1: Filter sampling at PCLKB 1 0: Filter sampling at PCLKB/8 1 1: Filter sampling at PCLKB/32 This bit is valid only in event counter mode (ULPTMR1.TMOD1 = 1).	R/W
6	TIOGT0	ULPTEVIn Count Control*1 0: Always count external events 1: Count external events while the ULPTEVIn pin is valid This bit is valid only in event counter mode (ULPTMR1.TMOD1 = 1) and count enable mode (ULPTMR3.TEECTL[1:0] = 00).	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Do not rewrite this register while the counter is running. Rewrite this register only when the counter is stopped (both the TSTART and TCSTF bits of the ULPTCR register are set to 0).

Note 1. The polarity for counting external events can be selected by the ULPTISR.RCCPSEL2 bit.

Note 2. Set the TIPF[1:0] bits to 00 before entering Software Standby mode or Deep Software Standby mode 1.

The ULPTIOC register controls the input/output of the ULPT.

The ULPTIOC register is only available for 8-bit read/write access.

TIPF[1:0] bits (ULPTEVIn Input Filter)

These bits are used to specify the sampling frequency of the ULPTEVIn input filter. Input to the ULPTEVIn pin is sampled. When a value matches three consecutive times, the value is regarded as the input value.

25.3.9 ULPTISR : ULPT Event Pin Select Register

Base address: ULPTn = 0x4022_0000 + 0x0100 × n (n = 0, 1)
ULPTn_NS = 0x5022_0000 + 0x0100 × n (n = 0, 1)

Offset address: 0x11

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	RCCPSEL2	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
2	RCCPSEL2	ULPTEEn Polarity Select 0: Count external events when low 1: Count external events when high This bit is valid only in event counter mode (ULPTMR1.TMOD1 = 1), count enable mode (ULPTMR3.TEECTL[1:0] = 00), and when ULPTIOC.TIOGT0 = 1.	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Do not rewrite this register while the counter is running. Rewrite this register only when the counter is stopped (both the TSTART and TCSTF bits of the ULPTCR register are set to 0).

The ULPTISR register sets the polarity of the ULPTEEn pin.

The ULPTISR register is only available for 8-bit read/write access.

25.3.10 ULPTCMSR : ULPT Compare Match Function Select Register

Base address: ULPTn = 0x4022_0000 + 0x0100 × n (n = 0, 1)
ULPTn_NS = 0x5022_0000 + 0x0100 × n (n = 0, 1)

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	TOPOLB	TOEB	TCMEB	—	TOPOLA	TOEA	TCMEA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TCMEA	Compare Match A Register Enable*1 0: Disable compare match A register 1: Enable compare match A register	R/W
1	TOEA	ULPTOAn Output Enable 0: Disable the ULPTOAn output 1: Enable the ULPTOAn output	R/W
2	TOPOLA	ULPTOAn Polarity Select*2 0: Start the ULPTOAn output when low 1: Start the ULPTOAn output when high	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	TCMEB	Compare Match B Register Enable*1 0: Disable compare match B register 1: Enable compare match B register	R/W
5	TOEB	ULPTOBn Output Enable 0: Disable the ULPTOBn output 1: Enable the ULPTOBn output	R/W
6	TOPOLB	ULPTOBn Polarity Select*2 0: Start the ULPTOBn output when low 1: Start the ULPTOBn output when high	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Do not rewrite this register while the counter is running. Rewrite this register only when the counter is stopped (both the TSTART and TCSTF bits of the ULPTCR register are set to 0).
Note 1. When 1 (stop the counter forcibly) is set to the ULPTCR.TSTOP bit, the TCMEA, and TCMEB bits are set to 0.
Note 2. When data is set to the ULPTMR1 register or 1 is set to the ULPTCR.TSTOP bit, the ULPTOAn and ULPTOBn output is initialized.

The ULPTCMSR register controls the interrupt request signal and input/output of compare match A and compare match B.

The ULPTCMSR register is only available for 8-bit read/write access.

25.4 Operation

25.4.1 Count Operation

The counter is decremented by one on each edge of the count source. When the count value reaches 0x00000000 and the next edge of the count source is input, an interrupt request of underflow is generated. The count operation is set by the ULPTMR1 and the ULPTMR3 registers. Table 25.4 lists the count operations.

Table 25.4 Count operation

Section No.	Count operation			Count source	ULPTMR1 register		ULPTMR3 register	
	Mode 1	Mode 2	Mode 3		TMOD1	TCK1	TCNTCTL	TEECTL[1:0]

section 25.4.1.7. Common, One-shot, and Count Start Modes			Count start					10
section 25.4.1.8. Common, One-shot, and Count Restart Modes			Count restart					11

Note: For details about register settings, see section 25.3.5. ULPTMR1 : ULPT Mode Register 1 and section 25.3.7. ULPTMR3 : ULPT Mode Register 3.

[Mode 1]

The clock used as the count source is selected by the TMOD1 and TCK1 bits of the ULPTMR1 register.

Timer mode: The internal clock (ULPTLCLK or ULPTSCLK) is used as the count source.

The counter is decremented on each rising edge of the count source.

Event counter mode: The external event input (ULPTEVIn pin) is used as the count source.

The counter is decremented on each edge of the count source.

The edge polarity can be selected by the ULPTMR1.TEDGPL bit and the ULPTMR3.TEVPOL bit.

[Mode 2]

The counter behavior is selected by the TCNTCTL bit of the ULPTMR3 register.

Continuous mode: After starting counting, the counter continues to count down (reload value to underflow) repeatedly until the counter stops.

One-shot mode: After starting counting, the counter counts down once (reload value to underflow).

[Mode 3]

The function of the ULPTEEn pin is selected by the TEECTL[1:0] bits of the ULPTMR3 register.

Count enable mode: External events are counted while the ULPTEEn pin is valid.

(This bit is valid only in event counter mode.)

Note: Because the ULPTEEn pin is synchronized with the count source, external events are counted after three cycles of the count source.

Count start mode: The counter starts counting at an edge trigger of the ULPTEEn pin.

The edge polarity of the ULPTEEn pin can be selected by the ULPTMR3.TEEPOL[1:0] bits.

Note: Because the ULPTEEn pin is synchronized and held with the count source, external events are counted after four cycles of the count source.

Count restart mode: The counter starts counting at the first edge trigger of the ULPTEEn pin.

The counter resets the count at the second or following edge trigger.

The edge polarity of the ULPTEEn pin can be selected by the ULPTMR3.TEEPOL[1:0] bits.

Note: Because the ULPTEEn pin is synchronized and held with the count source, external events are counted after four cycles of the count source.

25.4.1.1 Timer and Continuous Modes

This mode operates in timer mode only.

The counter continues to count down (reload value to underflow) repeatedly in synchronization with the count source.

When 1 is set to the ULPTCR.TSTART bit, the counter is started (with the ULPTCR.TCSTF bit set to 1).

When an underflow occurs, the counter counts down again from the reload value.

When 0 is set to the ULPTCR.TSTART bit, the counter is stopped (with the ULPTCR.TCSTF bit set to 0).

Figure 25.2 shows an operation example in timer and continuous modes.

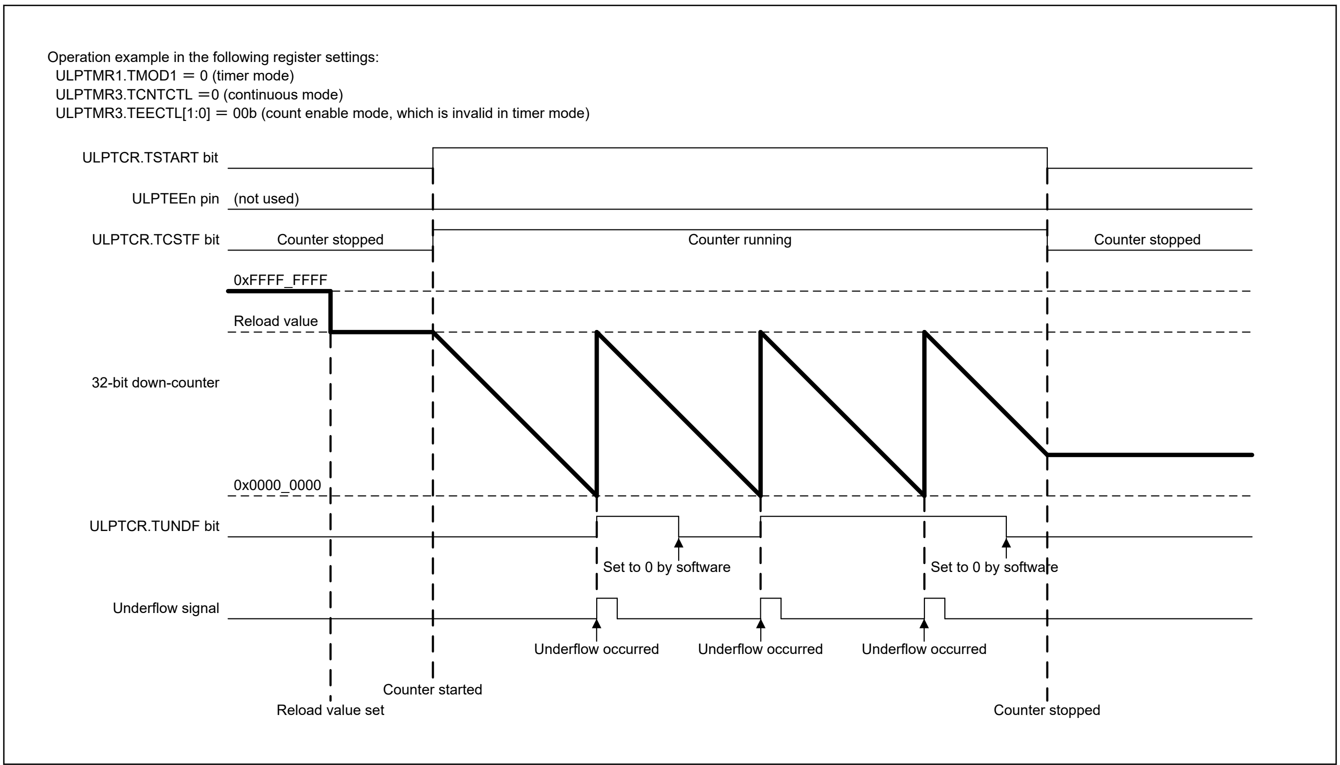

Figure 25.2 Operation example in timer and continuous modes

25.4.1.2 Timer and One-shot Modes

This mode operates in timer mode only.

The counter counts down (reload value to underflow) once in synchronization with the count source.

When 1 is set to the ULPTCR.TSTART bit, the counter is started (with the ULPTCR.TCSTF bit set to 1).

When an underflow occurs, the counter is stopped (with the ULPTCR.TSTART bit set to 1 and the ULPTCR.TCSTF bit set to 0).

To restart the counter after it is stopped, perform the following procedure:

1. Read the ULPTCR.TUNDF bit to confirm that it is set to 1 (underflow occurred).
   This is to make sure that counting down is finished.
2. Write 0 to the ULPTCR.TSTART bit to stop the counter.
3. Write 1 to the ULPTCR.TSTART bit to start the counter.

When 0 is set to the ULPTCR.TSTART bit, the counter is stopped (with the ULPTCR.TCSTF bit set to 0).

Figure 25.3 shows an operation example in timer and one-shot modes.

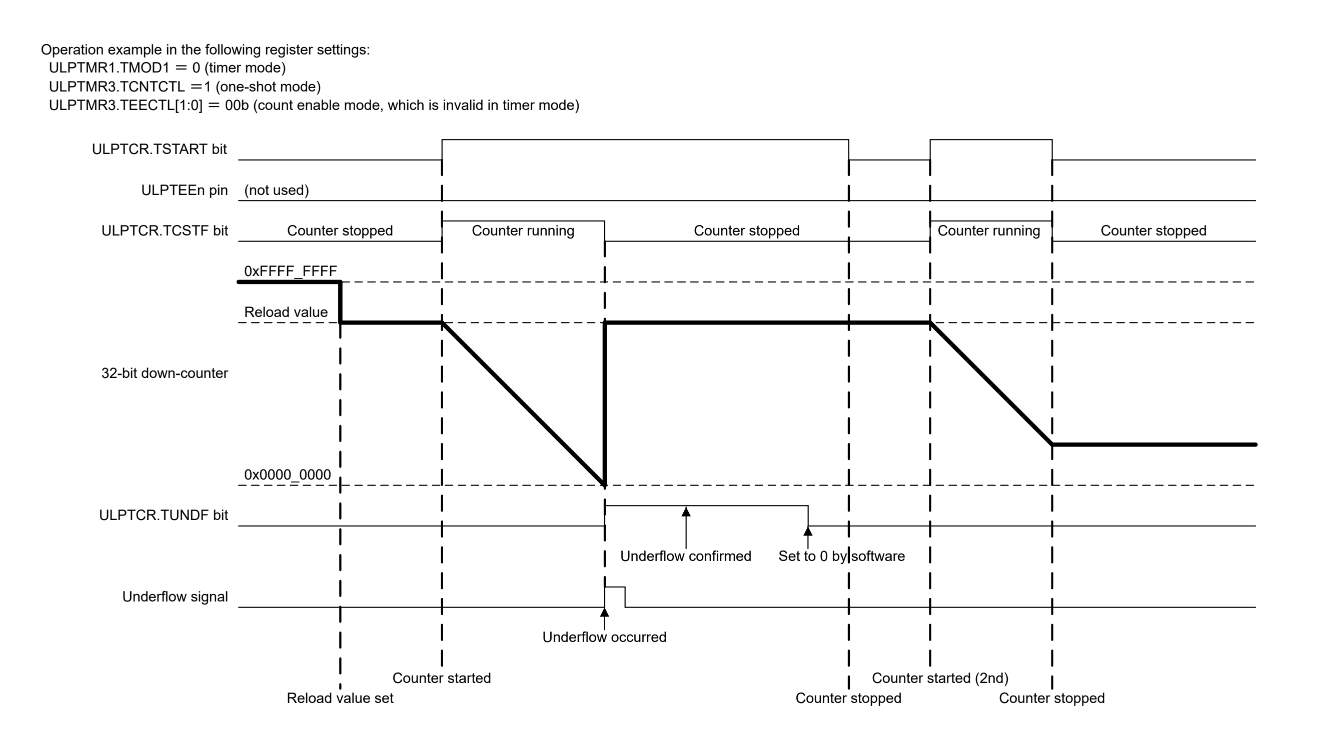

Figure 25.3 Operation example in timer and one-shot modes

25.4.1.3 Event Counter, Continuous, and Count Enable Modes

This mode operates in event counter mode only.

The counter continues to count down (reload value to underflow) repeatedly in synchronization with the count source. The duration in which the count source is counted can be specified by the ULPTIOC.TIOGT0 bit and ULPTISR.RCCPSEL2 bit.

When 1 is set to the ULPTCR.TSTART bit, the counter is started (with the ULPTCR.TCSTF bit set to 1).

When an underflow occurs, the counter counts down again from the reload value.

When 0 is set to the ULPTCR.TSTART bit, the counter is stopped (with the ULPTCR.TCSTF bit set to 0).

Figure 25.4 shows an operation example when the ULPTIOC.TIOGT0 bit is set to 0. Figure 25.5 and Figure 25.6 show operation examples when the ULPTIOC.TIOGT0 bit is set to 1.

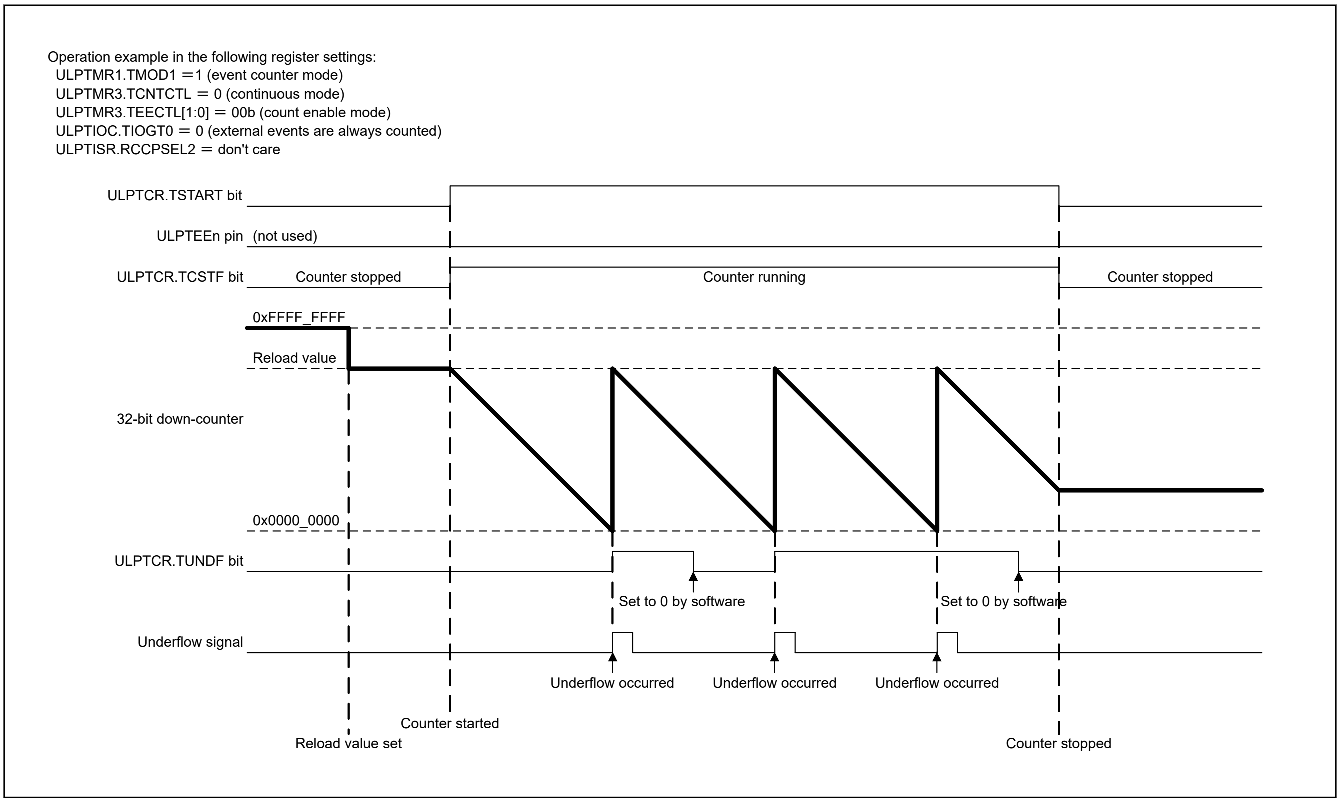

Figure 25.4 Operation example in event counter, continuous, and count enable modes (with the ULPTIOC.TIOGT0 bit set to 0)

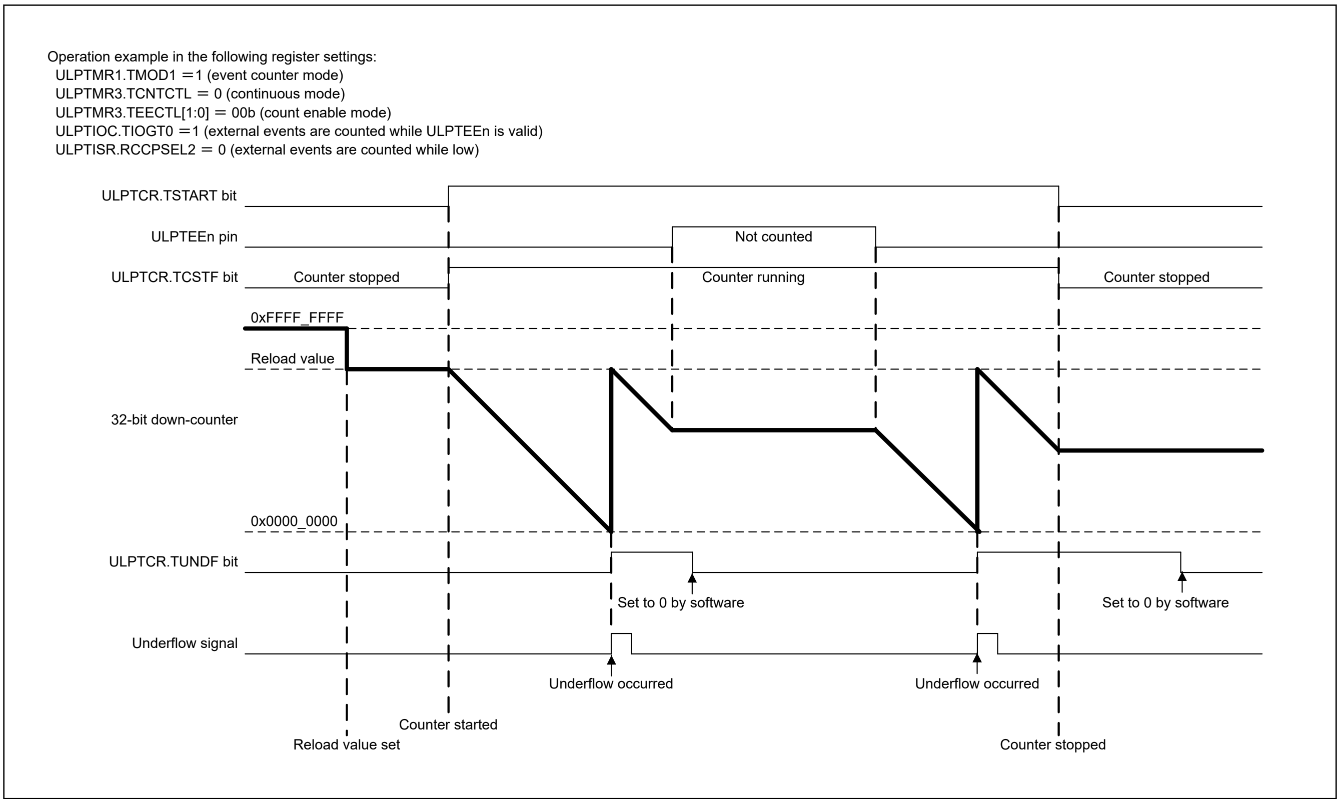

Figure 25.5 Operation example 1 in event counter, continuous, and count enable modes (with the ULPTIOC.TIOGT0 bit set to 1)

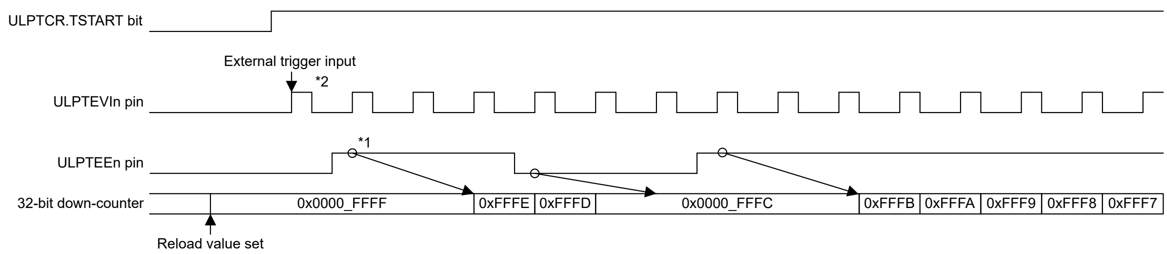
Operation example in the following register settings:
ULPTMR1.TMOD1 = 1 (event counter mode)
ULPTMR3.TCNTCTL = 0 (continuous mode)
ULPTMR3.TEECTL[1:0] = 00b (count enable mode)
ULPTIOC.TIOGT0 = 1 (external events are counted while ULPTEEn is valid)
ULPTISR.RCCPSEL2 = 1 (external events are counted while high)
ULPTMR3.TEVPOL = 0 (ULPTEVIn is inverted)



Note 1. When synchronization is controlled, there is a delay by two cycles of count source until external events are counted. In addition, the count start timing may be shifted by one cycle due to the phase difference between the ULPTEEn pin and the sampling clock.

Note 2. Depending on the state before the counter is stopped, counting may be performed during two cycles of the count source immediately after the counter is started.
To disable the counting operation during two cycles immediately after the counter is started, set 1 to the ULPTCR.TSTOP bit to initialize the internal circuits, and then finish the operation settings before starting the counter.

Figure 25.6 Operation example 2 in event counter, continuous, and count enable modes (with the ULPTIOC.TIOGT0 bit set to 1)

25.4.1.4 Event Counter, One-shot, and Count Enable Modes

This mode operates in event counter mode only.

The counter counts down (reload value to underflow) once in synchronization with the count source. The duration in which the count source is counted can be specified by the ULPTIOC.TIOGT0 bit and ULPTISR.RCCPSEL2 bit.

When 1 is set to the ULPTCR.TSTART bit, the counter is started (with the ULPTCR.TCSTF bit set to 1).

When an underflow occurs, the counter is stopped (with the ULPTCR.TSTART bit set to 1 and the ULPTCR.TCSTF bit set to 0).

To restart the counter after the counter is stopped, perform the following procedure:

1. Read the ULPTCR.TUNDF bit to confirm that it is set to 1 (underflow occurred).
   This is to make sure that counting down is finished.
2. Write 0 to the ULPTCR.TSTART bit to stop the counter.
3. Write 1 to the ULPTCR.TSTART bit to start the counter.

When 0 is set to the ULPTCR.TSTART bit, the counter is stopped (with the ULPTCR.TCSTF bit set to 0).

Figure 25.7 shows an operation example when the ULPTIOC.TIOGT0 bit is set to 00, and Figure 25.8 shows an operation example when the ULPTIOC.TIOGT0 bit is set to 01.

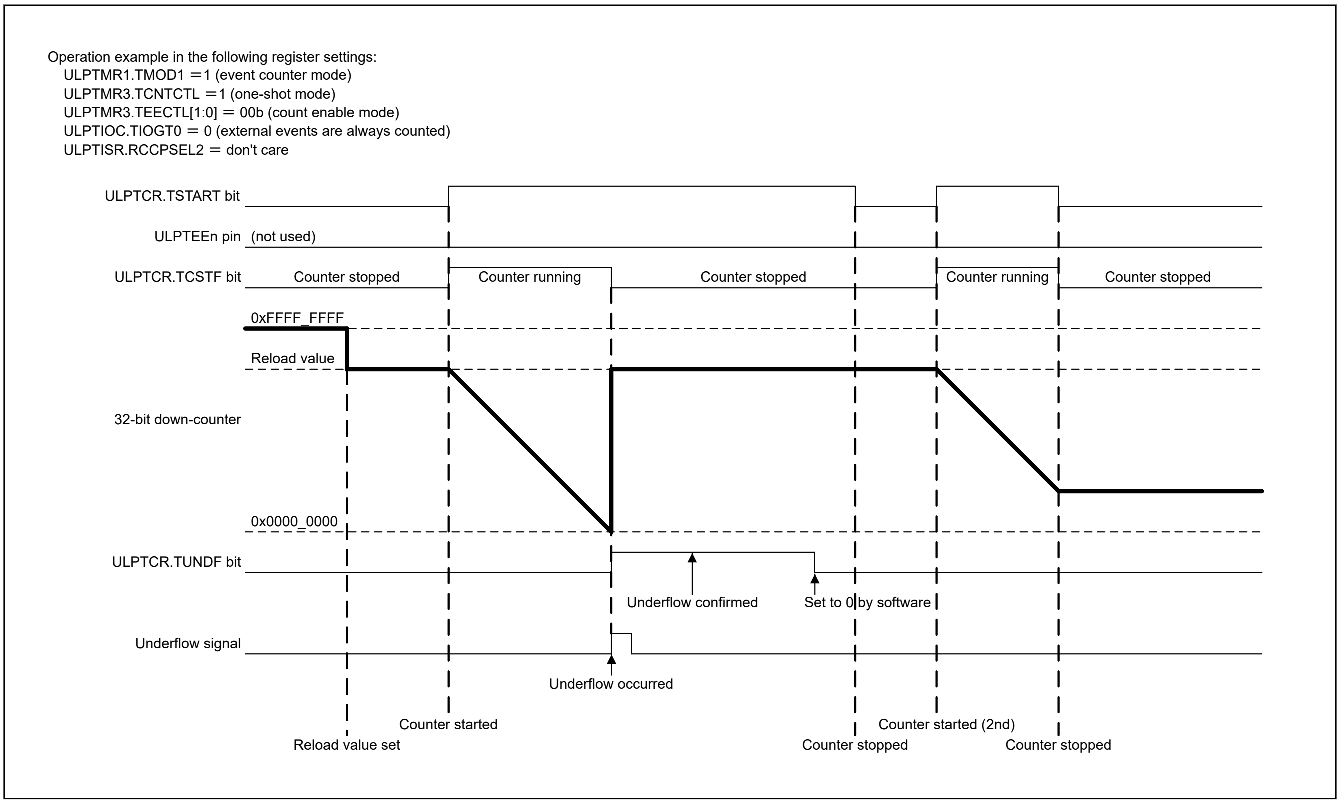


Figure 25.7 Operation example in event counter, one-shot, and count enable modes (with the ULPTIOC.TIOGT0 bit set to 0)

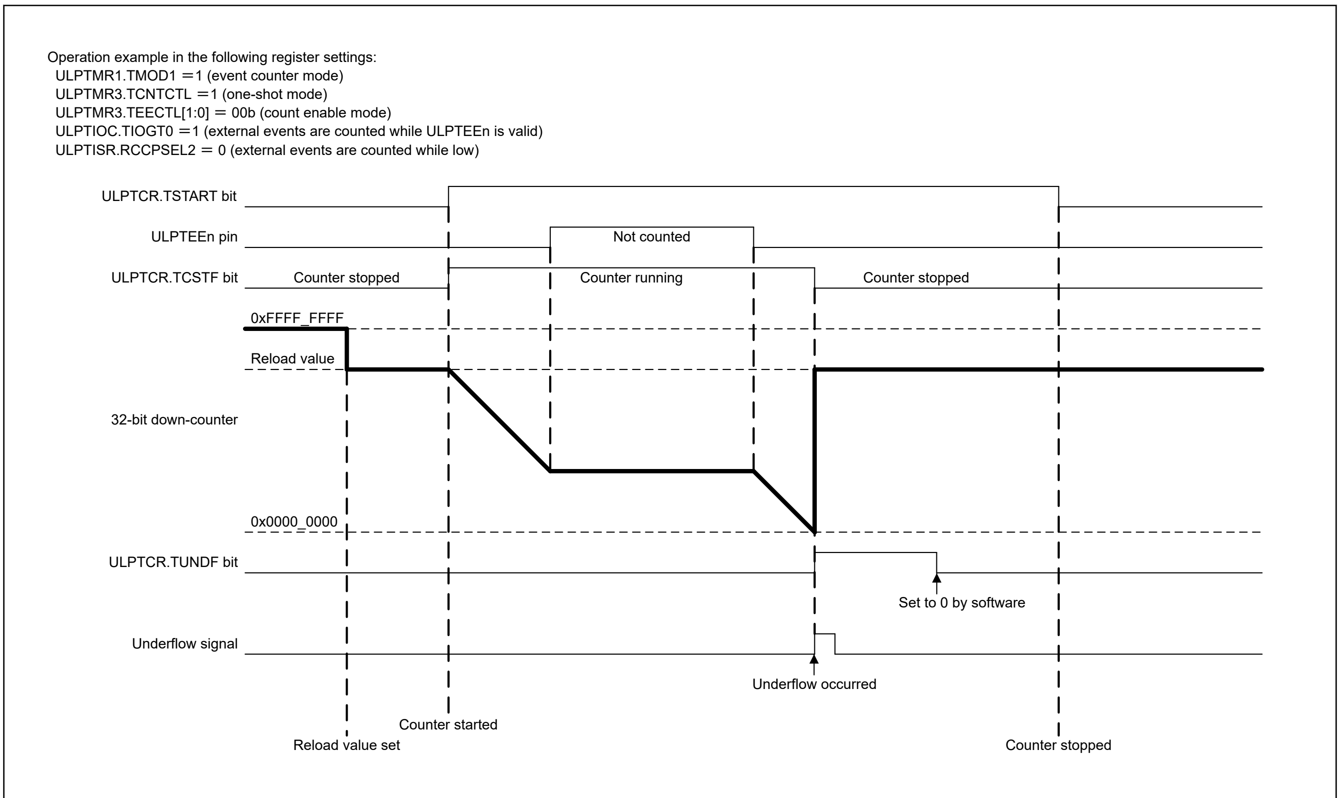

Figure 25.8 Operation example in event counter, one-shot, and count enable modes (with the ULPTIOC.TIOGT0 bit set to 1)

25.4.1.5 Common, Continuous, and Count Start Modes

This mode operates in both timer mode and event counter mode.

The counter continues to count down (reload value to underflow) repeatedly in synchronization with the count source.

After 1 is set to the ULPTCR.TSTART bit, the counter is started (with the ULPTCR.TCSTF bit set to 1) by an edge trigger at the ULPTEEn pin.

When an underflow occurs, the counter counts down again from the reload value.

When 0 is set to the ULPTCR.TSTART bit, the counter is stopped (with the ULPTCR.TCSTF bit set to 0).

Figure 25.9 shows an operation example in common, continuous, and count start modes.

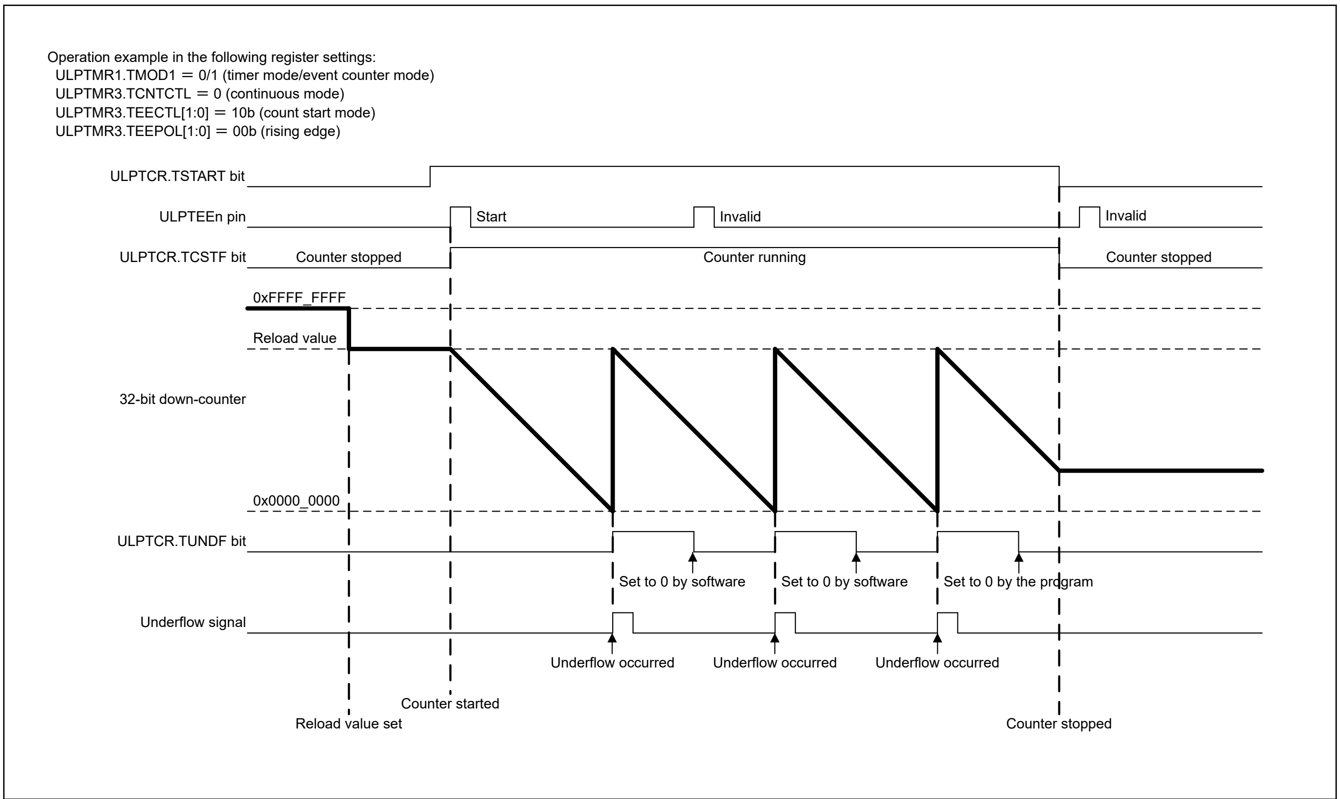

Figure 25.9 Operation example in common, continuous, and count start modes

25.4.1.6 Common, Continuous, and Count Restart Modes

This mode operates in both timer mode and event counter mode.

The counter continues to count down (reload value to underflow) repeatedly in synchronization with the count source.

After 1 is set to the ULPTCR.TSTART bit, the counter is started (with the ULPTCR.TCSTF bit set to 1) by an edge trigger at the ULPTEEn pin.

On an edge trigger input at the ULPTEEn pin when the counter is running (with the ULPTCR.TCSTF bit set to 1), the counter is reset and it starts counting again from the reload value.

If no edge trigger is input from the ULPTEEn pin and an overflow occurs, the counter starts counting again from the reload value.

When 0 is set to the ULPTCR.TSTART bit, the counter is stopped (with the ULPTCR.TCSTF bit set to 0).

Figure 25.10 shows an operation example in common, continuous, and count restart modes.

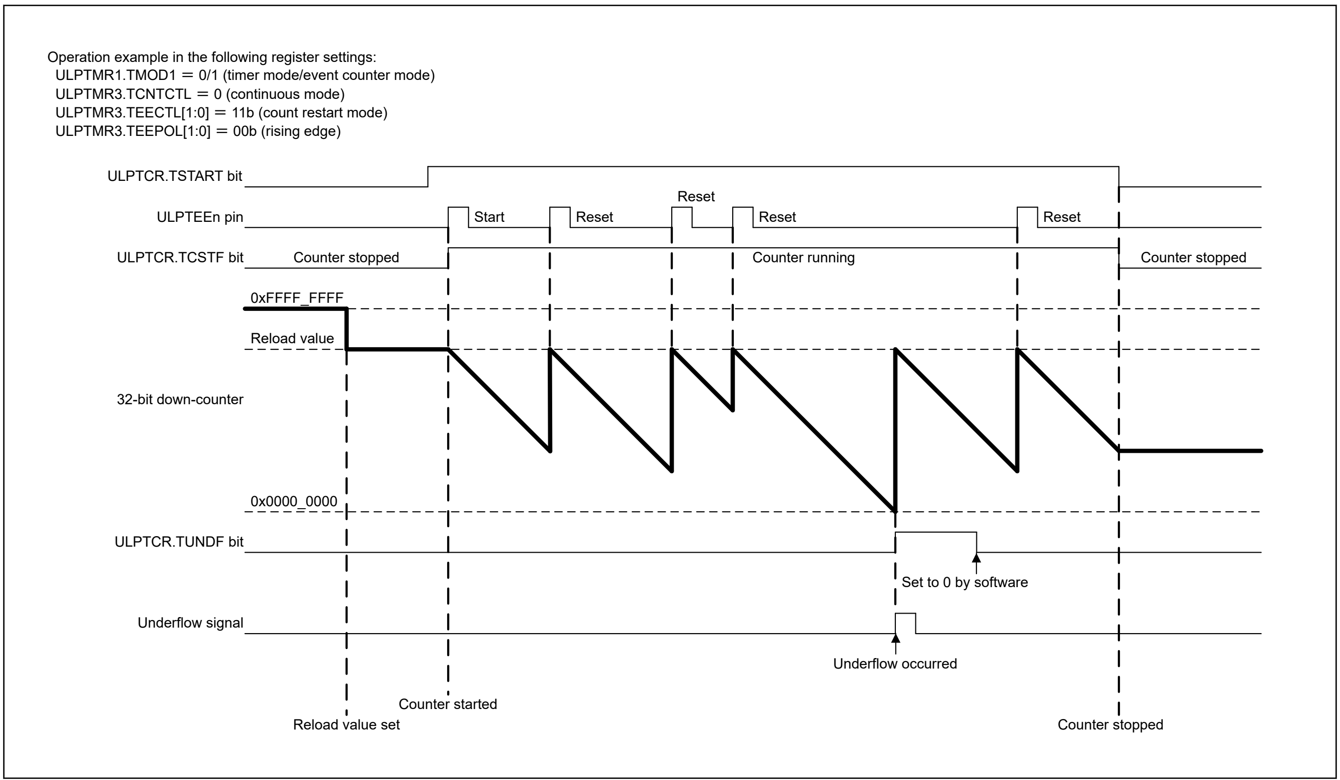

Figure 25.10 Operation example in common, continuous, and count restart modes

25.4.1.7 Common, One-shot, and Count Start Modes

This mode operates in both timer mode and event counter mode.

The counter counts down (reload value to underflow) once in synchronization with the count source.

After 1 is set to the ULPTCR.TSTART bit, the counter is started (with the ULPTCR.TCSTF bit set to 1) by an edge trigger at the ULPTEEn pin.

When an underflow occurs, the counter is stopped (with the ULPTCR.TSTART bit set to 1 and the ULPTCR.TCSTF bit set to 0).

On an edge trigger input at the ULPTEEn pin when the counter is running (with ULPTCR.TSTART bit set to 1 and the ULPTCR.TCSTF bit set to 0), the counter starts counting down again from the reload value.

When 0 is set to the ULPTCR.TSTART bit, the counter is stopped (with the ULPTCR.TCSTF bit set to 0).

Figure 25.11 shows an operation example in common, one-shot, and count start modes.

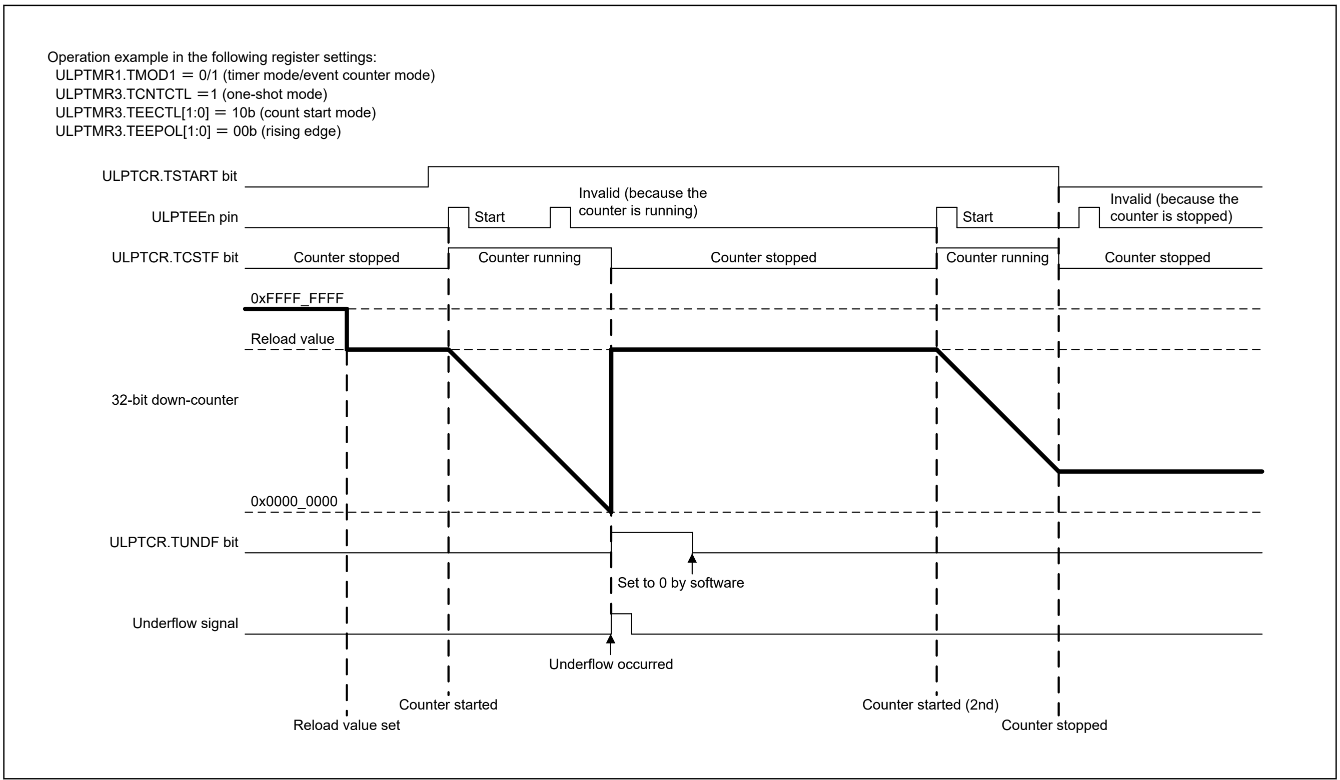

Figure 25.11 Operation example in common, one-shot, and count start modes

25.4.1.8 Common, One-shot, and Count Restart Modes

This mode operates in both timer mode and event counter mode.

The counter counts down (reload value to underflow) once in synchronization with the count source.

After 1 is set to the ULPTCR.TSTART bit, the counter is started (with the ULPTCR.TCSTF bit set to 1) by an edge trigger of the ULPTEEn pin.

On an edge trigger input at the ULPTEEn pin when the counter is running (with the ULPTCR.TCSTF bit set to 1), the counter is reset and it starts counting again from the reload value.

If no edge trigger is input at the ULPTEEn pin and an underflow occurs, the counter is stopped (with the ULPTCR.TSTART bit set to 1 and the ULPTCR.TCSTF bit set to 0).

On an edge trigger input at the ULPTEEn pin when the counter is running (with the ULPTCR.TSTART bit set to 1 and the ULPTCR.TCSTF bit set to 0), the counter starts counting down again from the reload value.

When 0 is set to the ULPTCR.TSTART bit, the counter is stopped (with the ULPTCR.TCSTF bit set to 0).

Figure 25.12 shows an operation example in common, one-shot, and count restart modes.

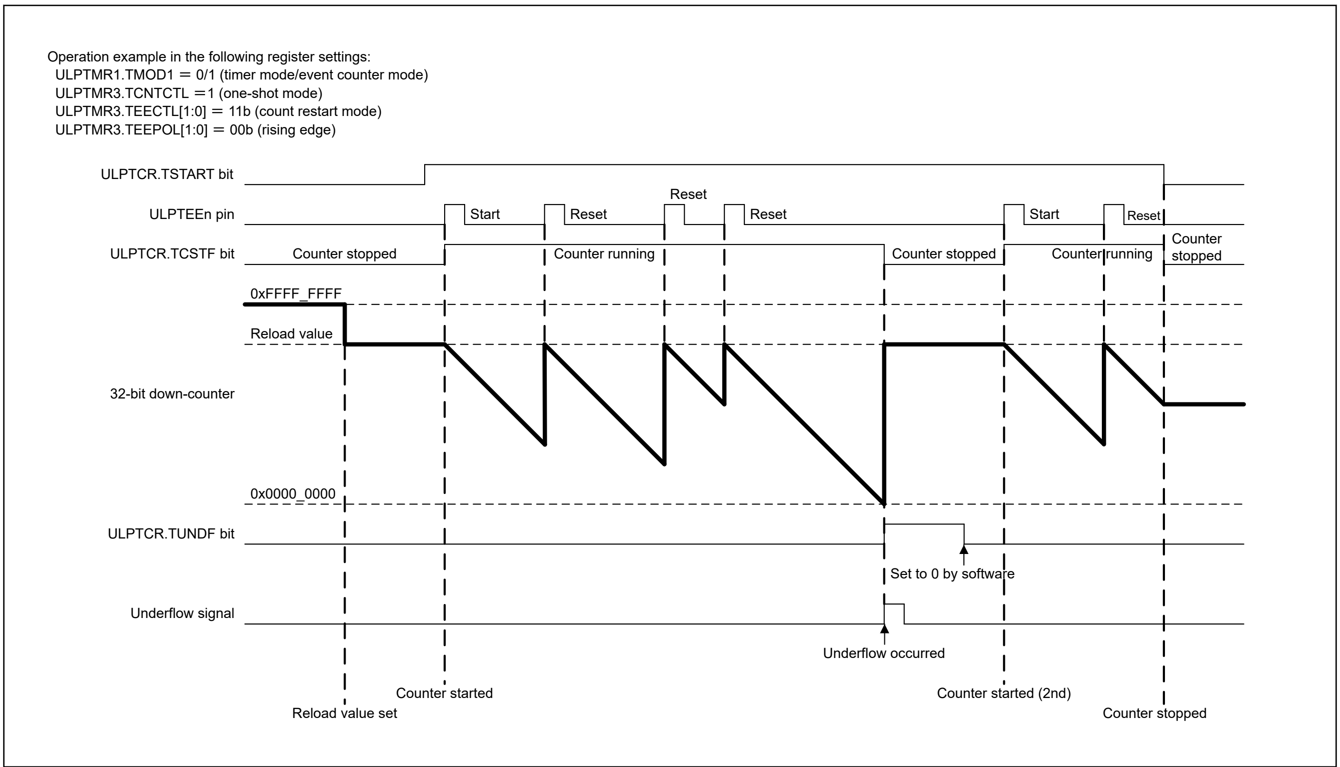

Figure 25.12 Operation example in common, one-shot, and count restart modes

25.4.2 Rewriting the Counter and Reload Register

Regardless of the operating mode, the counter and reload register rewrite timing changes depending on the following bits:

- TSTART and TCSTF bits of the ULPTCR register
- TCMEA and TCMEB bits of the ULPTCMSR register
- TEECTL[1:0] bits of the ULPTMR3 register.

Condition A: When the counter is stopped (both the TSTART and TCSTF bits of the ULPTCR register are set to 0)

A reload value is written directly to the counter and the reload register.

Condition B: When the counter is running (with the ULPTCR.TCSTF bit set to 1) and the compare match A/B registers are disabled (with both the TCMEA and TCMEB bits of the ULPTCR register set to 0)

After a reload value is written to the ULPTCNT register, the reload value is first set to the reload register, then to the counter in synchronization with the count source.

Condition C: When the counter is running (with the ULPTCR.TCSTF bit set to 1) and the compare match A/B registers are enabled (with either the TCMEA bit or the TCMEB bit of the ULPTCR register set to 1)

After a reload value is written to the ULPTCNT register, the reload value is written to the reload register in synchronization with the count source. Then, the reload value is set to the counter in synchronization with an underflow.

Condition D: When the counter is running (with ULPTCR.TCSTF bit set to 1) and when the count restart mode is enabled (with the ULPTMR3.TEECTL[1:0] bits set to 11)

After an edge trigger is input from the ULPTEEn pin, the reload value set in the reload register is set to the counter in synchronization with the count source. In this condition, the reload register is not rewritten.

Figure 25.13 to Figure 25.15 show the counter and reload register rewrite timing.

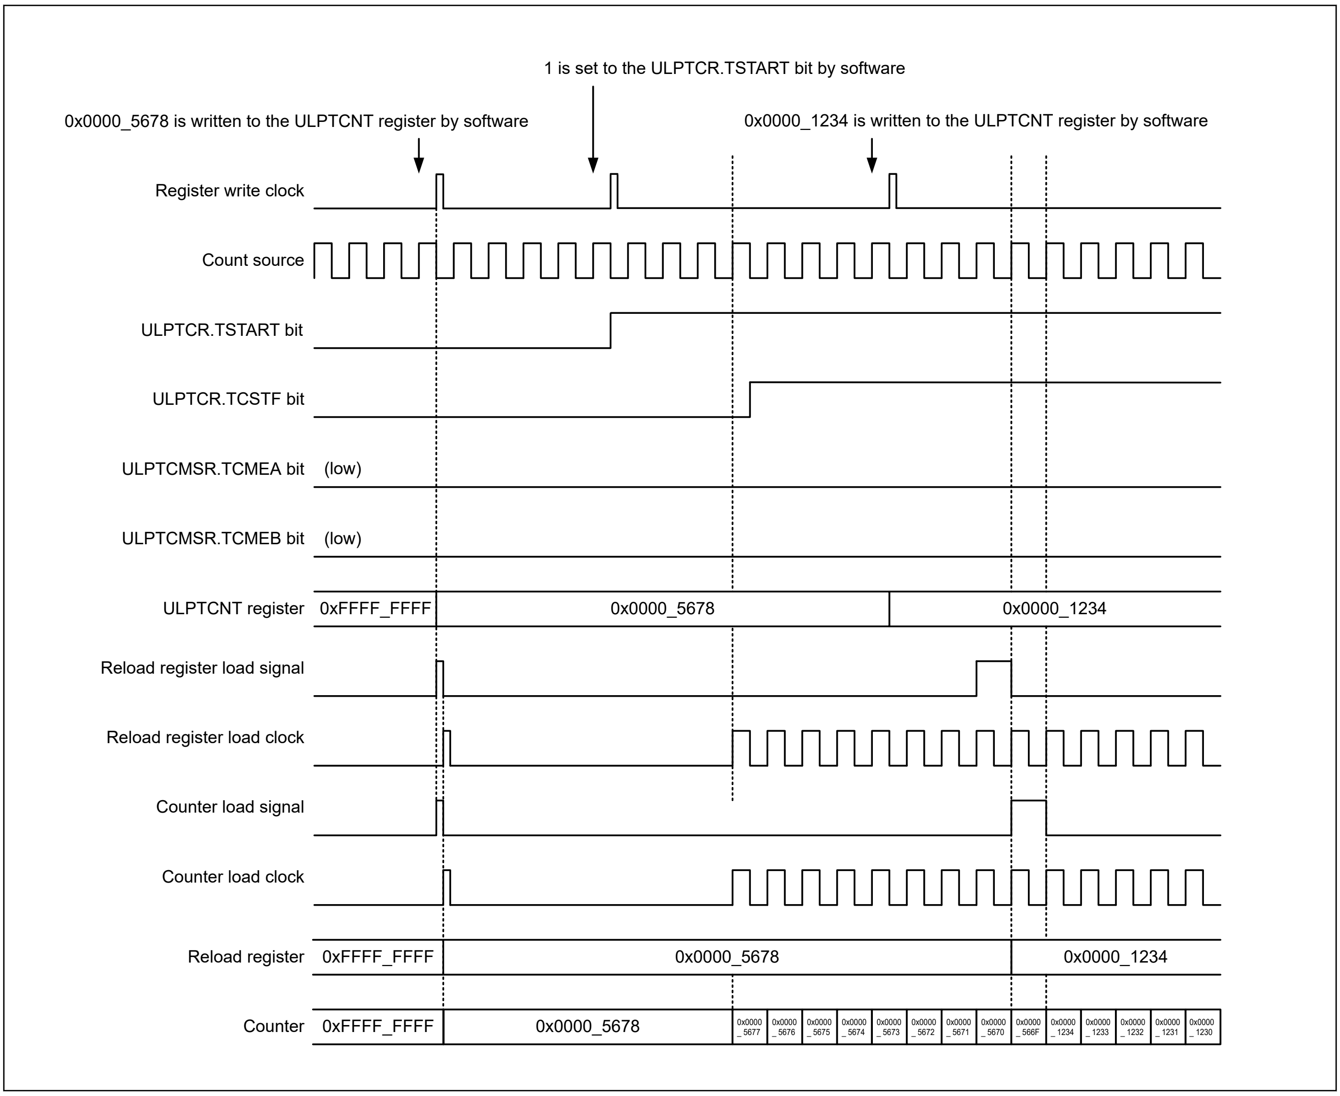

Figure 25.13 Counter and reload rewrite timing (under condition A or B)

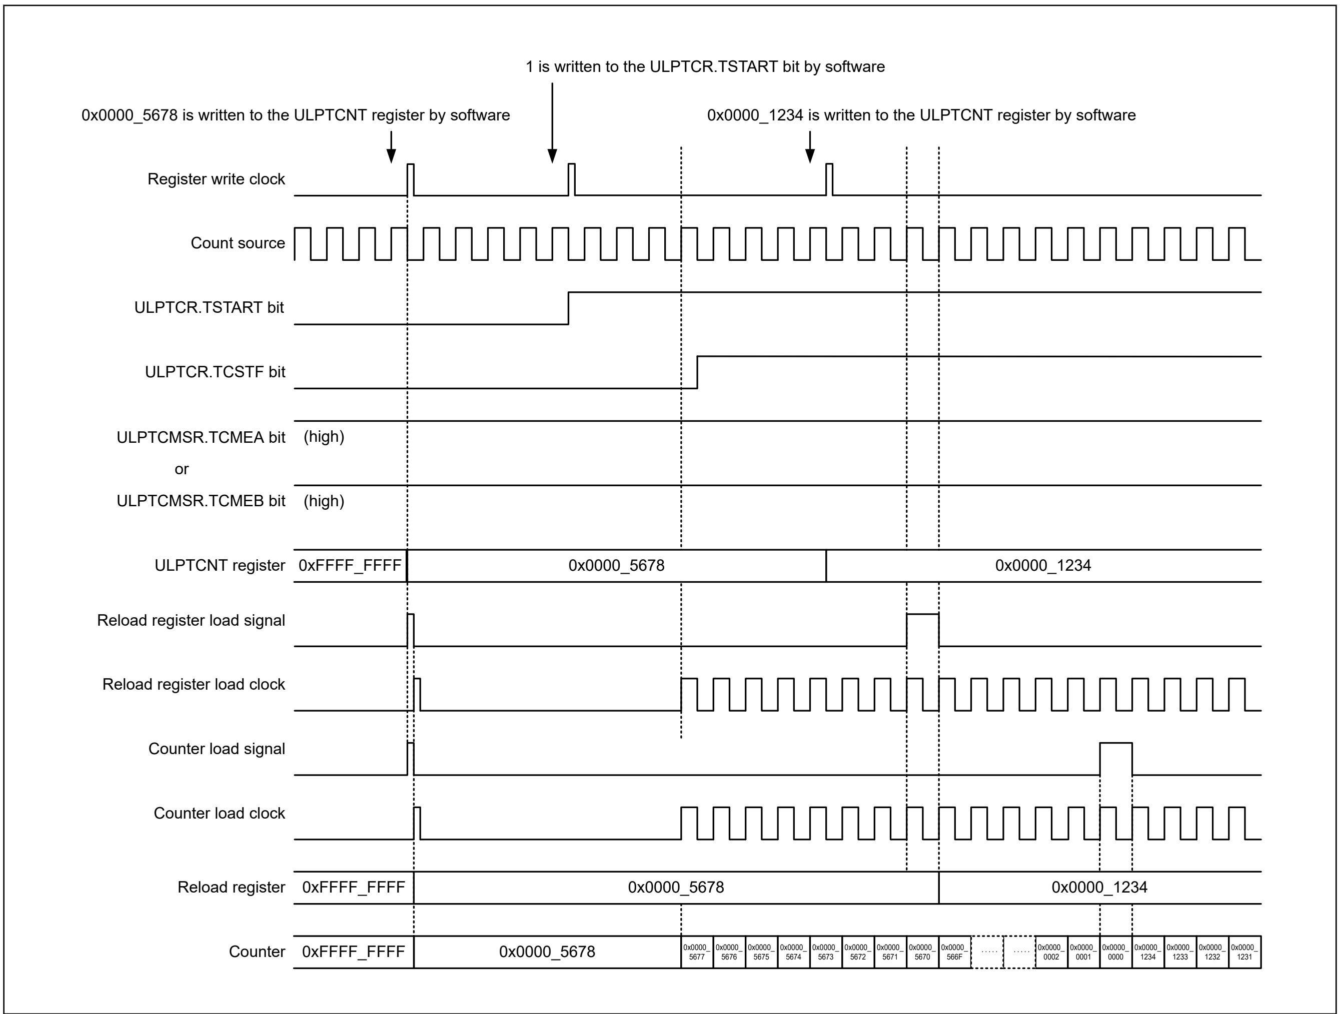

Figure 25.14 Counter and reload rewrite timing (under condition A or C)

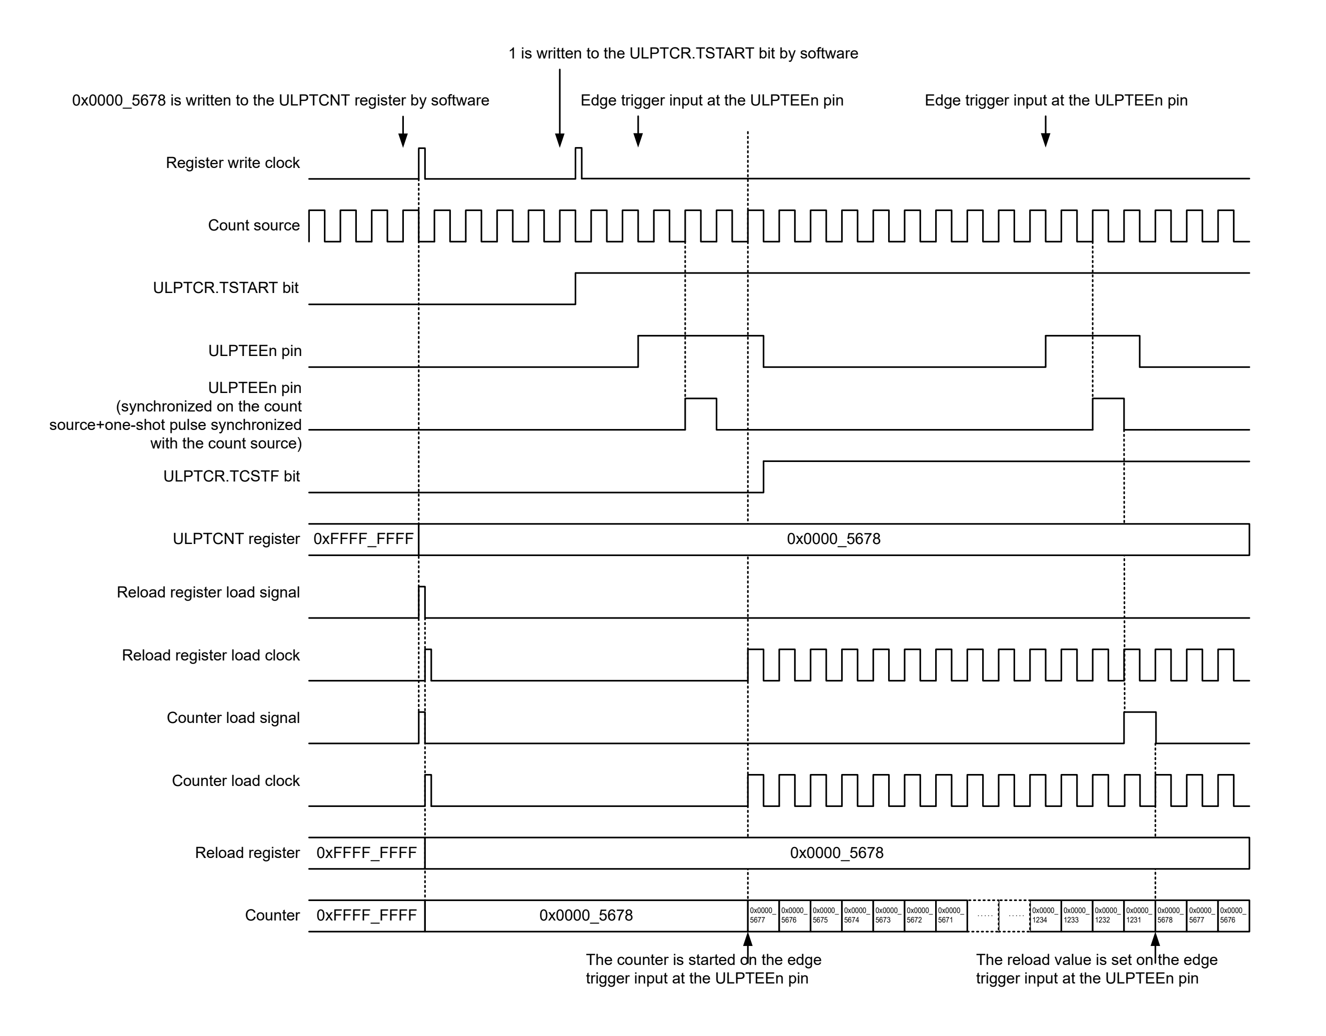

Figure 25.15 Counter and reload rewrite timing (under condition D)

25.4.3 Rewriting the Compare Circuits and Reload Registers for Compare Match A/B

Regardless of the operating mode, the rewrite timing for the compare circuits and reload registers for compare match A/B changes depending on the TSTART and TCSTF bits of the ULPTCR register.

Condition A: When the counter is stopped (both the TSTART and TCSTF bits of the ULPTCR register are set to 0)

Compare match A/B values are written directly to the compare circuits and reload registers.

Condition B: When the counter is running (with the ULPTCR.TCSTF bit set to 1)

After compare match A/B values are written to the ULPTCMA and ULPTCMB registers, the compare match A/B values are written to the reload registers in synchronization with the count source. Then, the compare match A/B values are written to the compare circuits in synchronization with an underflow.

Figure 25.16 shows the rewrite timing for the compare circuit and reload register for compare match A.

The timing for compare match B is similar to that for compare match A.

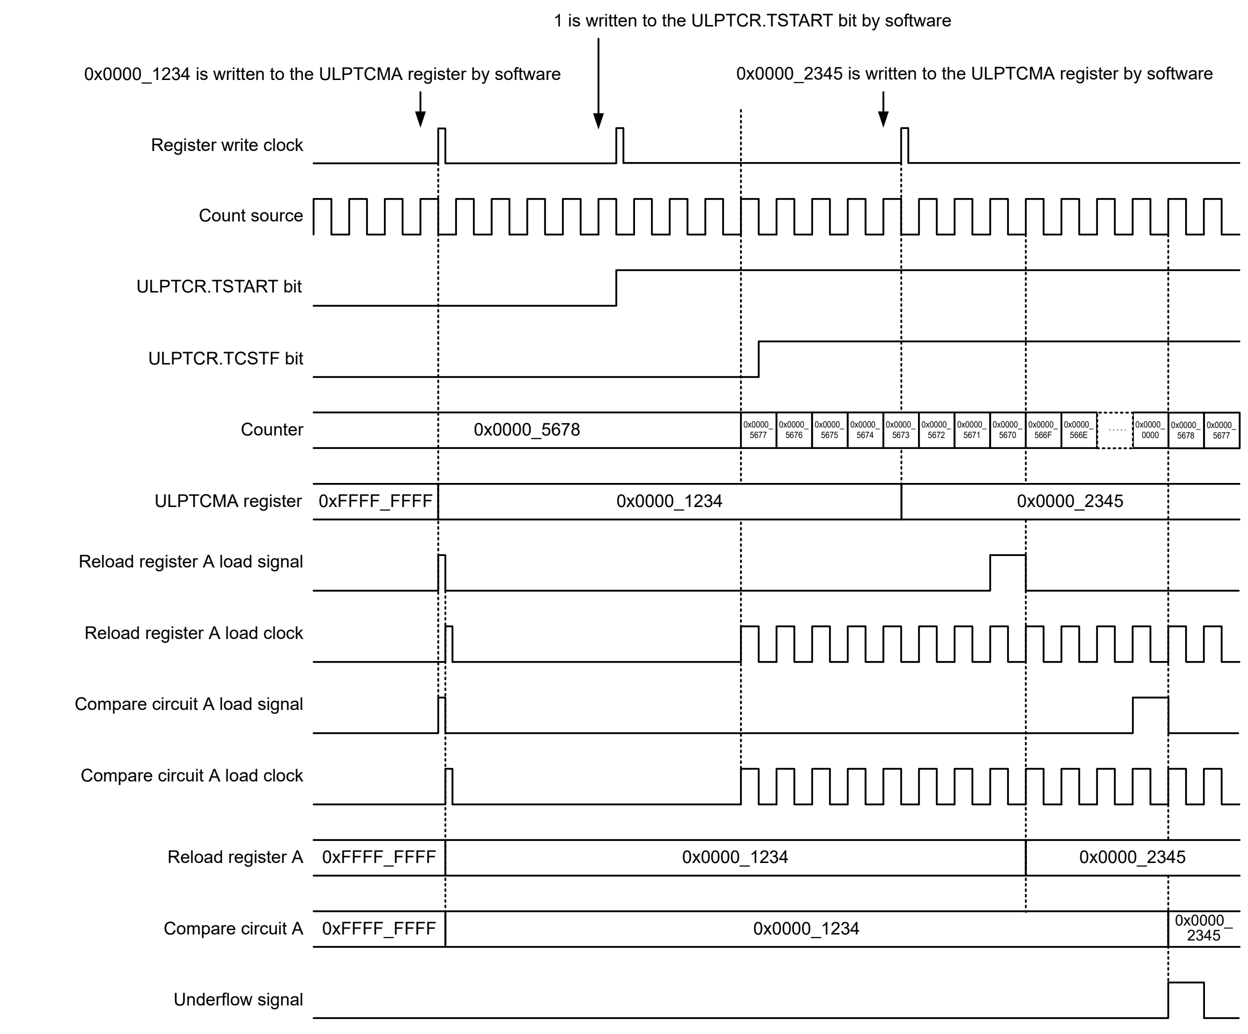

Figure 25.16 Rewrite timing for the compare circuit and reload register for compare match A

25.4.4 Pulse Output

Regardless of the operating mode, the ULPTOn pin can output pulses. The output level is inverted each time the counter underflows. The pulse output from the ULPTOn pin can be stopped by the ULPTIOC.TOE bit. The initial value of the output level can be selected by the ULPTMR3.TOPOL bit.

Figure 25.17 shows an operation example of a pulse output.

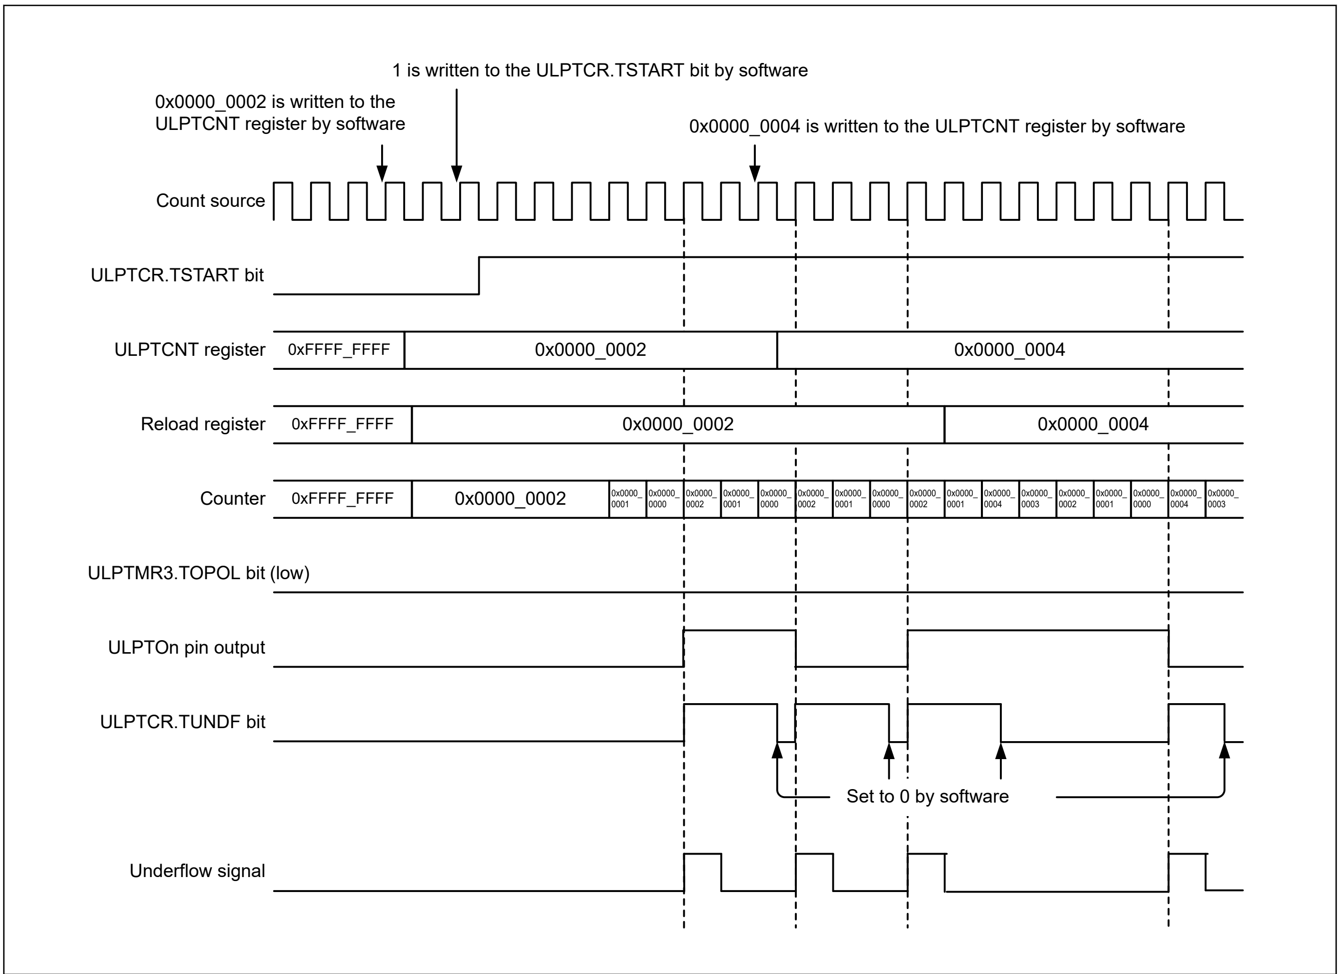

Figure 25.17 Operation example of pulse output

25.4.5 Compare Match Function

This function detects a match (compare match) between the ULPTCMA/ULPTCMB register contents and the ULPTCNT register contents. This function is enabled when the TCMEA or TCMEB bit of the ULPTCMSR register is set to 1 (the compare match A/B registers are enabled).

The counter is decremented in synchronization with the count source selected by the TMOD1/TCK1 bits of the ULPTMR1 register. When the ULPTCNT register value matches the ULPTCMA or ULPTCMB register value, the TCMAF or TCMBF bit of the ULPTCR register is set to 1 and an interrupt request is generated.

The counter and reload register rewrite timing differs depending on whether the compare match function is enabled. For details, see section 25.4.2. Rewriting the Counter and Reload Register.

The output level of the ULPTOAn/ULPTOBn pin is inverted on a match or underflow. The output level can be selected by the ULPTOAn/ULPTOBn bit of the ULPTCMSR register.

Figure 25.18 shows an operation example of the compare match function.

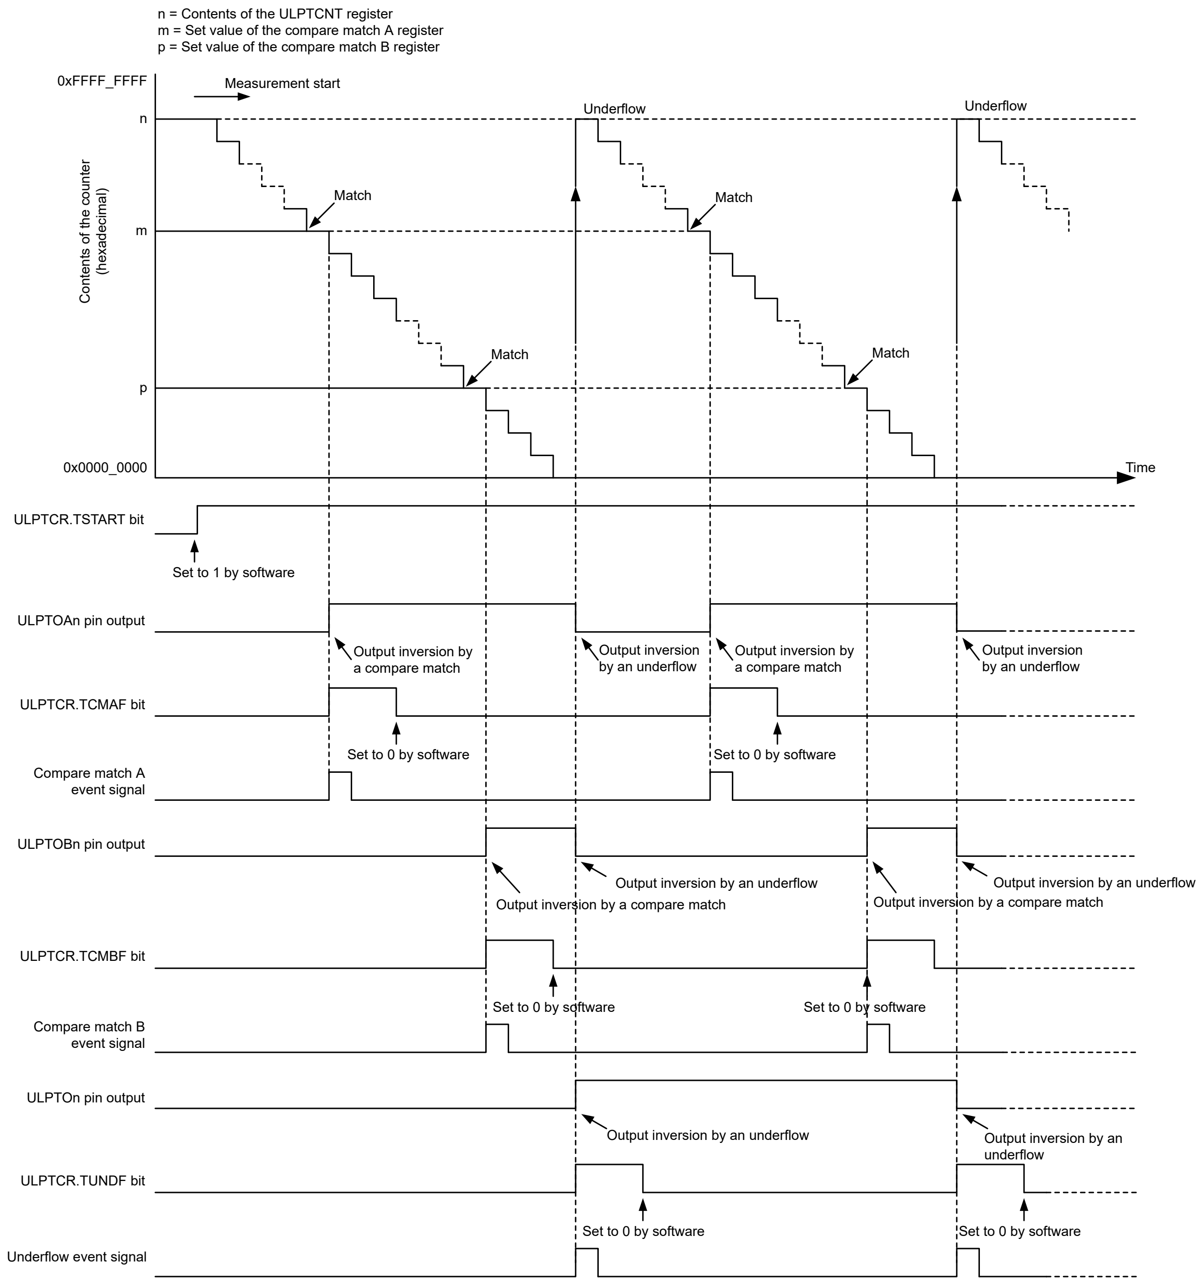

Figure 25.18 Operation example of the compare match function (both the TOPOLA and TOPOLB bits of the ULPTCMSR register are set to 0)

25.4.6 Input and Output Settings for each Mode

Table 25.5 to Table 25.9 show the states of the input pins (ULPTEEn and ULPTEVIn) and output pins (ULPTOn, ULPTOAn, and ULPTOBn) in each mode.

Table 25.5 ULPTEEn pin settings

Operating mode		ULPTMR1 register TMOD1 bit	ULPTMR3 register TEECTL[1:0] bit	ULPTEEn pin input
Timer mode	—	0	00	Input disabled
	Count start		10	Normal input
	Count restart		11	
Event counter mode	Count enable	1	00	
	Count start		10	
	Count restart		11	

Table 25.6 ULPTEVIn pin settings

Operating mode	ULPTMR1 register TMOD1 bit	ULPTMR3 register TEVPOL bit	ULPTEVIn pin input
Timer mode	0	0 or 1	Input disabled
Event counter mode	1	0	Normal input
		1	Inverted input

Table 25.7 ULPTOn pin settings

Operating mode	ULPTIOC register TOE bit	ULPTMR3 register TOPOL bit	ULPTOn pin output
All modes	1	1	Inverted output
		0	Normal output
	0	0 or 1	Output disabled

Table 25.8 ULPTOAn pin settings

Operating mode	ULPTCMSR register TOEA bit	 TOPOLA bit	ULPTOAn pin output
All modes	1	1	Inverted output
		0	Normal output
	0	0 or 1	Output disabled

section 25.4.1.2. Timer and One-shot Modes		One-shot	—		
section 25.4.1.7. Common, One-shot, and Count Start Modes			Count start		
section 25.4.1.8. Common, One-shot, and Count Restart Modes			Count restart		
section 25.4.1.3. Event Counter, Continuous, and Count Enable Modes	Event counter	Continuous	Count enable	ULPTEVIn pin*1	• Underflow • Compare match A/B
section 25.4.1.5. Common, Continuous, and Count Start Modes			Count start		
section 25.4.1.6. Common, Continuous, and Count Restart Modes			Count restart		
section 25.4.1.4. Event Counter, One-shot, and Count Enable Modes		One-shot	Count enable		
section 25.4.1.7. Common, One-shot, and Count Start Modes			Count start		
section 25.4.1.8. Common, One-shot, and Count Restart Modes			Count restart		

Note: The ULPT can operate in all modes even in Software Standby mode or Deep Software Standby mode 1. For details about the count operations and register settings, see section 25.4.1. Count Operation.

Note 1. Only ULPTEVIn pin can be used in Deep Software Standby mode 1.

Only in event counter mode (ULPTMR1.TMOD1 = 1), set the ULPTIOC.TIPF[1:0] bits to 00 (no filter) before entering standby mode.

In Software Standby mode or Deep Software Standby mode 1, the digital filter clock (PCLKB) stops (the digital filter does not function).

It is prohibited to rewrite the ULPTCNT, ULPTCMA, and ULPTCMB registers immediately before setting each standby mode.

If the ULPTCNT, ULPTCMA, and ULPTCMB registers are rewritten while the counter is running, set each standby mode after four or more cycles of the count source.

25.4.8 Interrupt Sources

The ULPT has three interrupt sources:

- ULPTI
- ULPTCMAI
- ULPTCMBI.

Table 25.11 lists the interrupt sources.

Table 25.11 ULPT interrupt sources (1 of 2)

Name	Interrupt source	DMAC/DTC activation
ULPTn_ULPTI	When the counter underflows	Possible
ULPTn_ULPTCMAI	When the ULPTCNT value matches the ULPTCMA value	Possible

Table 25.11 ULPT interrupt sources (2 of 2)

Name	Interrupt source	DMAC/DTC activation
ULPTn_ULPTCMBI	When the ULPTCNT value matches the ULPTCMB value	Possible

25.4.9 Event Output to the ELC

The ULPT is capable of link operation for a specified module through the event link controller (ELC) using the interrupt request signal as an event signal.

The ULPT outputs an event signal when compare match A/compare match B or an underflow occurs. For details, see section 19, Event Link Controller (ELC).

25.5 Usage Notes

25.5.1 Start and Stop Control of the Counter

Condition A: In timer mode (ULPTMR1.TMOD1 = 0), continuous mode (ULPTMR3.TCNTCTL = 0), and count enable mode (ULPTMR3.TEECTL[1:0] = 00)

When the counter is stopped (with the TCSTF bit of the ULPTCR register set to 0), even if 1 (start the counter) is set to the TSTART bit of the ULPTCR register, the TCSTF bit remains at 0 (counter stopped) for five cycles of the count source.

Do not access the registers*1 related to the ULPT other than the TCSTF bit until the TCSTF bit is set to 1 (counter running).

When the counter is running (with the TCSTF bit set to 1), even if 0 (stop the counter) is set to the TSTART bit, the TCSTF bit remains at 1 (counter running) for five cycles of the count source.

Do not access the registers*1 related to the ULPT other than the TCSTF bit until the TCSTF bit is set to 0 (counter stopped).

Before changing the TSTART bit from 0 to 1, clear the interrupt register. For details, see section 14, Interrupt Controller Unit (ICU).

Note 1. Registers related to the ULPT: ULPTCNT, ULPTCMA, ULPTCMB, ULPTCR, ULPTMR1, ULPTMR2, ULPTMR3, ULPTIOC, ULPTISR, and ULPTCMSR.

Condition B: In event counter mode (ULPTMR1.TMOD1 = 1), continuous mode (ULPTMR3.TCNTCTL = 0), and count enable mode (ULPTMR3.TEECTL[1:0] = 00)

When the counter is stopped (with the TCSTF bit of the ULPTCR register set to 0), even if 1 (start the counter) is set to the TSTART bit of the ULPTCR register, the TCSTF bit remains at 0 (counter stopped) for two cycles of the count source.

Do not access the registers*1 related to the ULPT other than the TCSTF bit until the TCSTF bit is set to 1 (counter running).

When the counter is running (with the TCSTF bit set to 1), even if 0 (stop the counter) is set to the TSTART bit, the TCSTF bit remains at 1 (counter running) for two cycles of the count source.

Do not access the registers*1 related to the ULPT other than the TCSTF bit until the TCSTF bit is set to 0 (counter stopped).

Before changing the TSTART bit from 0 to 1, clear the interrupt register. For details, see section 14, Interrupt Controller Unit (ICU).

Note 1. Registers related to the ULPT: ULPTCNT, ULPTCMA, ULPTCMB, ULPTCR, ULPTMR1, ULPTMR2, ULPTMR3, ULPTIOC, ULPTISR, and ULPTCMSR.

Condition C: In count start mode or count restart mode (ULPTMR3.TEECTL[1:0] bits = 10 or 11)

When the counter is stopped (with the TCSTF bit of the ULPTCR register set to 0), even if 1 is set to the TSTART bit of the ULPTCR register and then the counter is started on an edge trigger of the ULPTEEn pin, the TCSTF bit remains at 0 (counter stopped) for five cycles of the count source.

Do not access the registers*1 related to the ULPT other than the TCSTF bit until the TCSTF bit is set to 1 (counter running).

When the counter is running (with the TCSTF bit set to 1), even if 0 (stop the counter) is set to the TSTART bit, the TCSTF bit remains at 1 (counter running) for five cycles of the count source.

Do not access the registers*1 related to the ULPT other than the TCSTF bit until the TCSTF bit is set to 0 (counter stopped).

Before changing the TSTART bit from 0 to 1, clear the interrupt register. For details, see section 14, Interrupt Controller Unit (ICU).

Note 1. Registers related to the ULPT: ULPTCNT, ULPTCMA, ULPTCMB, ULPTCR, ULPTMR1, ULPTMR2, ULPTMR3, ULPTIOC, ULPTISR, and ULPTCMSR.

25.5.2 Access to Flags (TUNDF, TCMAF, and TCMBF bits in ULPTCR Register)

Set 1 to the TUNDF, TCMAF, and TCMBF bits when changing the TSTART or TSTOP bits to prevent clearing TUNDF, TCMAF, or TCMBF by mistake. At this time, setting 1 to TUNDF, TCMAF, and TCMBF bits are ignored.

25.5.3 Access to the ULPTCNT, ULPTCMA, and ULPTCMB Registers

When setting to the same register sequentially while the counter is running (ULPTCR.TCSTF bit = 1), leave three or more cycles of count source between writes. The following registers are applicable:

- ULPTCNT
- ULPTCMA
- ULPTCMB

25.5.4 Mode Changes

Registers related to the operating mode of the ULPT (ULPTMR1, ULPTMR2, ULPTMR3, ULPTIOC, ULPTISR, and ULPTCMSR) can be changed only while the counter is stopped (both the TSTART and TCSTF bits of the ULPTCR register are set to 0). Do not change these registers while the counter is running.

If a register related to the operating mode of the ULPT is changed, the values of the TUNDF, TCMAF, and TCMBF bits of the ULPTCR register are undefined. Before starting the counter, write 0 to the TUNDF, TCMAF, and TCMBF bits.

- TUNDF (no underflow)
- TCMAF (no match for compare match A)
- TCMBF (no match for compare match B)

25.5.5 Setting the ULPTOn, ULPTOAn, and ULPTOBn Pins

To use the ULPTOn, ULPTOAn, and ULPTOBn pins as output pins, set up the ULPT, and then set the output in the PORT register after determining the initial output values.

25.5.6 Calculating the Number of Events

In event counter mode, the number of events is calculated using the following formula:

Number of events = Initial counter value (ULPTCNT register write value) − Counter value at the end of a valid event

25.5.7 When the Counter is Stopped Forcibly by the TSTOP Bit

Do not access the ULPTCNT, ULPTCMA, ULPTCMB, ULPTCR, ULPTMR1, ULPTMR2, or ULPTMR3 register during one cycle of the count source after stopping the counter forcibly by the ULPTCR.TSTOP bit.

25.5.8 Digital Filter

When using a digital filter, do not start the timer within five cycles of the digital filter clock after setting the ULPTIOC.TIPF[1:0] bits.

Also, when ULPTMR3.TEVPOL bit is changed while a digital filter is in use, do not start the timer within five cycles of the digital filter clock after setting the bit.

In Software Standby mode or Deep Software Standby mode 1, the digital filter clock (PCLKB) stops and the digital filter does not function. Before entering Software standby mode or Deep Software Standby mode 1, set the ULPTIOC.TIPF[1:0] bits to 00 (no filter).

25.5.9 Module-Stop Function Setting

ULPT operation can be disabled or enabled using Module Stop Control Register E (MSTPCRE). The ULPT module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

25.5.10 Setting the ULPTEEn and ULPTEVIn Pins

To use the ULPTEEn and ULPTEVIn pins as input pins, set up the ULPT, and then set PmnPFS.PMR bit to 1.

26. Realtime Clock (RTC)

26.1 Overview

The realtime clock (RTC) has two counting modes, calendar count mode and binary count mode, that are used by switching register settings. For calendar count mode, the RTC has a 100-year calendar from 2000 to 2099 and automatically adjusts dates for leap years. For binary count mode, the RTC counts seconds and retains the information as a serial value. Binary count mode can be used for calendars other than the Gregorian (Western) calendar.

The sub-clock oscillator or LOCO can be selected as the count source of the time counters. The RTC uses a 128-Hz clock acquired by dividing the count source by a prescaler. Year, month, date, day-of-week, a.m. /p.m. (in 12-hour mode), hour, minute, second, or 32-bit binary is counted by 1/128 second.

Table 26.1 lists the RTC specifications, Figure 26.1 shows a block diagram, and Table 26.2 lists the I/O pins.

Table 26.1 RTC specifications

Parameter	Specifications
Count mode	Calendar count mode/binary count mode
Count source*1	Sub-clock (XCIN), External clock input (EXCIN) or LOCO
Clock and calendar functions	● Calendar count mode – Year, month, date, day of week, hour, minute, second are counted, BCD display – 12 hours/24 hours mode switching function – 30 seconds adjustment function (a number less than 30 is rounded down to 00 seconds, and 30 seconds or more are rounded up to 1 minute) – Automatic adjustment function for leap years ● Binary count mode – Count seconds in 32 bits, binary display ● Shared by both modes – Start/stop function – The sub-second digit is displayed in binary units (1 Hz, 2 Hz, 4 Hz, 8 Hz, 16 Hz, 32 Hz, or 64 Hz) – Clock error correction function – Clock (1-Hz/64-Hz) output
Interrupts	● Alarm interrupt (RTC_ALM) – As an alarm interrupt condition, selectable for comparison with the following: • Calendar count mode: Year, month, date, day-of-week, hour, minute, or second can be selected • Binary count mode: Each bit of the 32-bit binary counter ● Periodic interrupt (RTC_PRD) – 2 seconds, 1 second, 1/2 second, 1/4 second, 1/8 second, 1/16 second, 1/32 second, 1/64 second, 1/128 second, or 1/256 second can be selected as an interrupt period. ● Carry interrupt (RTC_CUP) – An interrupt is generated at either of the following conditions: • When a carry from the 64-Hz counter to the second counter is generated. • When the 64-Hz counter is changed and the R64CNT register is read at the same time. (32-KHz count mode is only for 64-Hz counter reading) ● Return from Software Standby or Deep Software Standby mode can be performed by the alarm interrupt or periodic interrupt
Time capture function	● Times can be captured when the edge of the time capture event input pin is detected. For every event input, month, date, hour, minute, and second are captured or the 32-bit binary counter value is captured. ● Interrupt can be generated when the edge of the time capture event input is detected. The time capture event input pin and IRQ are shared.
Event link function	Periodic event output (RTC_PRD)
TrustZone filter	Security and Privilege attribution can be set

Note 1. The frequency of the peripheral module clock (PCLKB) ≥ the frequency of the count source should be satisfied.

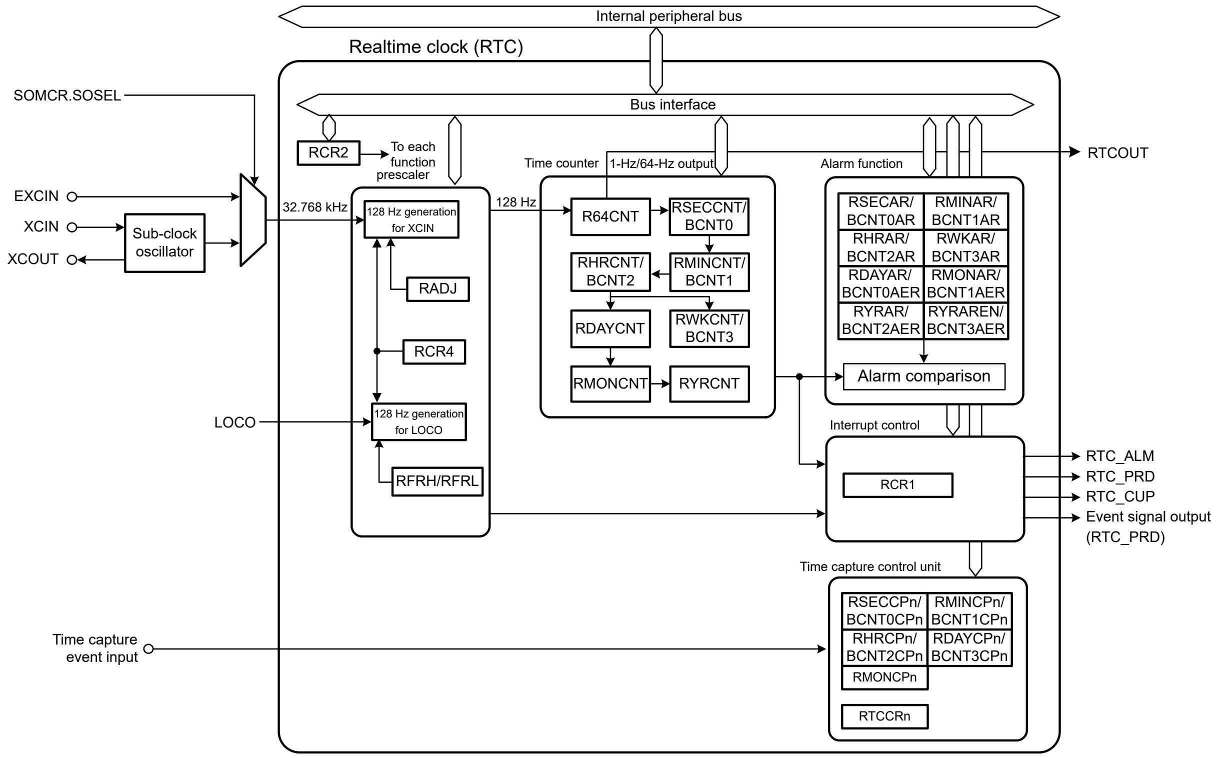

Figure 26.1 RTC block diagram

Table 26.2 RTC I/O pins

Pin name	I/O	Description
XCIN	Input	Connect a 32.768-kHz crystal to these pins
XCOUT	Output	
EXCIN	Input	External sub-clock input
RTCOUT	Output	This pin is used to output a 1-Hz/64-Hz waveform, but not in Deep Software Standby mode
RTCICn (n = 0 to 2)	Input	Time capture event input pins RTCICn can be controlled by the VBTICTLR register. For more information, see section 12, Battery Backup Function and section 20, I/O Ports.

26.2 Register Descriptions

Write or read from the RTC registers as described in section 26.6.5. Notes on Writing to and Reading from Registers.

If the value in an RTC register after a reset is given as x (undefined bits) in the list, it is not initialized by a reset. When RTC enters the reset state or a low power state during counting operations, for example, while the RCR2.START bit is 1, the year, month, day of the week, date, hours, minutes, seconds, and 64-Hz counters continue to operate.

Note: A reset generated while writing to a register might destroy the register value. In addition, do not allow the MCU to enter Software Standby mode, Deep Software Standby mode, or battery backup state immediately after setting any of these registers. For details, see section 26.6.4. Transitions to Low Power Modes After Setting Registers.

26.2.1 R64CNT : 64-Hz Counter

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	F1HZ	F2HZ	F4HZ	F8HZ	F16HZ	F32HZ	F64HZ
Value after reset:	0	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
0	F64HZ	64-Hz Flag This bit indicates the 64-Hz state of the sub-second digit.	R
1	F32HZ	32-Hz Flag This bit indicates the 32-Hz state of the sub-second digit.	R
2	F16HZ	16-Hz Flag This bit indicates the 16-Hz state of the sub-second digit.	R
3	F8HZ	8-Hz Flag This bit indicates the 8-Hz state of the sub-second digit.	R
4	F4HZ	4-Hz Flag This bit indicates the 4-Hz state of the sub-second digit.	R
5	F2HZ	2-Hz Flag This bit indicates the 2-Hz state of the sub-second digit.	R
6	F1HZ	1-Hz Flag This bit indicates the 1-Hz state of the sub-second digit.	R
7	—	This bit is read as 0.	R

Note: S-TYPE3, P-TYPE3

The R64CNT counter is used in both calendar count mode and binary count mode The 64-Hz counter (R64CNT) generates the period for a second by counting up periods of the 128-Hz clock. The state in the sub-second range can be confirmed by reading this counter.

This counter is set to 0x00 by an RTC software reset or an execution of a 30-second adjustment. To read this counter, follow the procedure in section 26.3.5. Reading 64-Hz Counter and Time.

26.2.2 RSECCNT : Second Counter (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	SEC10[2:0]			SEC1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	SEC1[3:0]	1-Second Count Counts from 0 to 9 every second. When a carry is generated, 1 is added to the tens place.	R/W
6:4	SEC10[2:0]	10-Second Count Counts from 0 to 5 for 60-second counting.	R/W
7	—	The read value is undefined. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

The RSECCNT counter sets and counts the BCD-coded second value. It counts the carries generated once per second in the 64-Hz counter.

The setting range is decimal 00 to 59. The RTC does not operate normally if any other value is set. Before writing to this register, you must stop the count operation using the START bit in RCR2.

To read this counter, follow the procedure in section 26.3.5. Reading 64-Hz Counter and Time.

26.2.3 RMINCNT : Minute Counter (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	MIN10[2:0]			MIN1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	MIN1[3:0]	1-Minute Count Counts from 0 to 9 every minute. When a carry is generated, 1 is added to the tens place.	R/W
6:4	MIN10[2:0]	10-Minute Count Counts from 0 to 5 for 60-minute counting.	R/W
7	—	The read value is undefined. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

The RMINCNT counter sets and counts the BCD-coded minute value. It counts the carries generated once every minute in the second counter.

A value from 00 through 59 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, you must stop the count operation using the START bit in RCR2. To read this counter, follow the procedure in section 26.3.5. Reading 64-Hz Counter and Time.

26.2.4 RHRCNT : Hour Counter (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	PM	HR10[1:0]		HR1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	HR1[3:0]	1-Hour Count Counts from 0 to 9 once per hour. When a carry is generated, 1 is added to the tens place.	R/W
5:4	HR10[1:0]	10-Hour Count Counts from 0 to 2 once per carry from the ones place.	R/W
6	PM	AM/PM select for time counter setting. 0: AM 1: PM	R/W
7	—	The read value is undefined. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

The RHRCNT counter sets and counts the BCD-coded hour value. It counts the carries generated once per hour in the minute counter. The specifiable time differs based on the setting in the hours mode bit (RCR2.HR24):

- When the RCR2.HR24 bit is 0 – from 00 to 11 (in BCD).
- When the RCR2.HR24 bit is 1 – from 00 to 23 (in BCD).

If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, you must stop the count operation using the START bit in RCR2. The PM bit is only enabled when the RCR2.HR24 bit is 0.

Otherwise, the setting in the PM bit has no effect. To read this counter, follow the procedure in section 26.3.5. Reading 64-Hz Counter and Time.

26.2.5 RWKCNT : Day-of-Week Counter (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	DAYW[2:0]		
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
2:0	DAYW[2:0]	Day-of-Week Counting 0 0 0: Sunday 0 0 1: Monday 0 1 0: Tuesday 0 1 1: Wednesday 1 0 0: Thursday 1 0 1: Friday 1 1 0: Saturday 1 1 1: Setting prohibited	R/W
7:3	—	The read values are undefined. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

The RWKCNT counter sets and counts in the coded day-of-week value. It counts the carries generated once per day in the hour counter. A value from 0 through 6 can be specified. If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, you must stop the count operation using the START bit in RCR2. To read this counter, follow the procedure in section 26.3.5. Reading 64-Hz Counter and Time.

26.2.6 BCNTn : Binary Counter n (n = 0 to 3) (in Binary Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x02 + 0x02 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	BCNT[7:0]							
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	BCNT[7:0]	Binary Counter	R/W

Note: S-TYPE3, P-TYPE3

BCNTn is a read/write 8-bit register to access BCNT[31:0] that is a 32-bit binary counter. BCNT3 is assigned to the BCNT[31:24] bits, BCNT2 is assigned to the BCNT[23:16] bits, BCNT1 is assigned to the BCNT[15:8] bits, and BCNT0 is assigned to the BCNT[7:0] bits. BCNTn performs count operation by a carry generated for each second of the 64-Hz counter. Before writing to this register, you must stop the count operation using the START bit in RCR2. To read this counter, follow the procedure in section 26.3.5. Reading 64-Hz Counter and Time.

26.2.7 RDAYCNT : Day Counter

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x0A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	DATE10[1:0]		DATE1[3:0]			
Value after reset:	0	0	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	DATE1[3:0]	1-Day Count Counts from 0 to 9 once per day. When a carry is generated, 1 is added to the tens place.	R/W
5:4	DATE10[1:0]	10-Day Count Counts from 0 to 3 once per carry from the ones place.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

The RDAYCNT counter is used in calendar count mode to set and count the BCD-coded date value. It counts the carries generated once per day in the hour counter. The count operation depends on the month and whether the year is a leap year. Leap years are determined according to whether the year counter (RYRCNT) value is divisible by 400, 100, and 4.

A value from 01 through 31 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. When specifying a value, the range of specifiable days depends on the month and whether the year is a leap year. Before writing to this register, you must stop the count operation using the START bit in RCR2. To read this counter, follow the procedure in section 26.3.5. Reading 64-Hz Counter and Time.

26.2.8 RMONCNT : Month Counter

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	MON10	MON1[3:0]			
Value after reset:	0	0	0	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	MON1[3:0]	1-Month Count Counts from 0 to 9 once per month. When a carry is generated, 1 is added to the tens place.	R/W
4	MON10	10-Month Count Counts from 0 to 1 once per carry from the ones place.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

The RMONCNT counter is used in calendar count mode to set and count the BCD-coded month value. It counts the carries generated once per month in the date counter.

A value from 01 through 12 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, you must stop the count operation using the START bit in RCR2. To read this counter, follow the procedure in section 26.3.5. Reading 64-Hz Counter and Time.

26.2.9 RYRCNT : Year Counter

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x0E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	YR10[3:0]				YR1[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	YR1[3:0]	1-Year Count Counts from 0 to 9 once per year. When a carry is generated, 1 is added to the tens place.	R/W
7:4	YR10[3:0]	10-Year Count Counts from 0 to 9 once per carry from ones place. When a carry is generated in the tens place, 1 is added to the hundreds place.	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

The RYRCNT counter is used in calendar count mode to set and count the BCD-coded year value. It counts the carries generated once per year in the month counter.

A value from 00 through 99 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, you must stop the count operation using the START bit in RCR2. To read this counter, follow the procedure in section 26.3.5. Reading 64-Hz Counter and Time.

26.2.10 RSECAR : Second Alarm Register (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENB	SEC10[2:0]			SEC1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	SEC1[3:0]	1 Second Value for the ones place of seconds.	R/W
6:4	SEC10[2:0]	10 Seconds Value for the tens place of seconds.	R/W
7	ENB	ENB 0: Do not compare register value with RSECCNT counter value 1: Compare register value with RSECCNT counter value	R/W

Note: S-TYPE3, P-TYPE3

RSECAR is an alarm register associated with the BCD-coded second counter RSECCNT. When the ENB bit is set to 1, the RSECAR value is compared with the RSECCNT value. From the following alarm registers, only those selected with the ENB bits set to 1 are compared with the associated counters:

- RSECAR
- RMINAR
- RHRAR
- RWKAR
- RDAYAR

- RMONAR
- RYRAREN

When all the respective values match, the IR flag associated with the RTC_ALM interrupt is set to 1. RSECAR values from 00 through 59 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. This register is set to 0x00 by an RTC software reset.

26.2.11 RMINAR : Minute Alarm Register (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENB	MIN10[2:0]			MIN1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	MIN1[3:0]	1 Minute Value for the ones place of minutes.	R/W
6:4	MIN10[2:0]	10 Minutes Value for the tens place of minutes.	R/W
7	ENB	ENB 0: Do not compare register value with RMINCNT counter value 1: Compare register value with RMINCNT counter value	R/W

Note: S-TYPE3, P-TYPE3

RMINAR is an alarm register associated with the BCD-coded minute counter RMINCNT. When the ENB bit is set to 1, the RMINAR value is compared with the RMINCNT value. From the following alarm registers, only those selected with the ENB bits set to 1 are compared with the associated counters:

- RSECAR
- RMINAR
- RHRAR
- RWKAR
- RDAYAR
- RMONAR
- RYRAREN

When all the respective values match, the IR flag associated with the RTC_ALM interrupt is set to 1. RMINAR values from 00 through 59 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. This register is set to 0x00 by an RTC software reset.

26.2.12 RHRAR : Hour Alarm Register (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x14

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENB	PM	HR10[1:0]		HR1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	HR1[3:0]	1 Hour Value for the ones place of hours.	R/W
5:4	HR10[1:0]	10 Hours Value for the tens place of hours.	R/W
6	PM	AM/PM select for alarm setting. 0: AM 1: PM	R/W
7	ENB	ENB 0: Do not compare register value with RHRCNT counter value 1: Compare register value with RHRCNT counter value	R/W

Note: S-TYPE3, P-TYPE3

RHRAR is an alarm register associated with the BCD-coded hour counter RHRCNT. When the ENB bit is set to 1, the RHRAR value is compared with the RHRCNT value. From the following alarm registers, only those selected with the ENB bits set to 1 are compared with the associated counters:

- RSECAR
- RMINAR
- RHRAR
- RWKAR
- RDAYAR
- RMONAR
- RYRAREN

When all the respective values match, the IR flag associated with the RTC_ALM interrupt is set to 1. The specifiable time differs according to the setting in the hours mode bit (RCR2.HR24):

- When the RCR2.HR24 bit is 0 – From 00 to 11 (in BCD).
- When the RCR2.HR24 bit is 1 – From 00 to 23 (in BCD).

If a value outside of this range is specified, the RTC does not operate correctly. When the RCR2.HR24 bit is 0, you must set the PM bit. When the RCR2.HR24 bit is 1, the setting in the PM bit has no effect. This register is set to 0x00 by an RTC software reset.

26.2.13 RWKAR : Day-of-Week Alarm Register (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x16

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENB	—	—	—	—	DAYW[2:0]		
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
2:0	DAYW[2:0]	Day-of-Week Setting 0 0 0: Sunday 0 0 1: Monday 0 1 0: Tuesday 0 1 1: Wednesday 1 0 0: Thursday 1 0 1: Friday 1 1 0: Saturday 1 1 1: Setting prohibited	R/W
6:3	—	The read values are undefined. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
7	ENB	ENB 0: Do not compare register value with RWKCNT counter value 1: Compare register value with RWKCNT counter value	R/W

Note: S-TYPE3, P-TYPE3

RWKAR is an alarm register associated with the coded day-of-week counter RWKCNT. When the ENB bit is set to 1, the RWKAR value is compared with the RWKCNT value. From the following alarm registers, only those selected with the ENB bits set to 1 are compared with the associated counters:

- RSECAR
- RMINAR
- RHRAR
- RWKAR
- RDAYAR
- RMONAR
- RYRAREN

When all the respective values match, the IR flag associated with the RTC_ALM interrupt is set to 1. RWKAR values from 0 through 6 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. This register is set to 0x00 by an RTC software reset.

26.2.14 BCNTnAR : Binary Counter n Alarm Register (n = 0 to 3) (in Binary Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x10 + 0x02 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	BCNTAR							
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	BCNTAR	Alarm register associated with the 32-bit binary counter	R/W

Note: S-TYPE3, P-TYPE3

BCNTnAR is a read/write alarm register associated with the 32-bit binary counter. BCNT3AR is assigned to the BCNTAR[31:24] bits, BCNT2AR is assigned to the BCNTAR[23:16] bits, BCNT1AR is assigned to the BCNTAR[15:8] bits, and BCNT0AR is assigned to the BCNTAR[7:0]. This register is set to 0x00 by an RTC software reset.

26.2.15 RDAYAR : Date Alarm Register (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x18

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENB	—	DATE10[1:0]		DATE1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	DATE1[3:0]	1 Day Value for the ones place of days.	R/W

Bit	Symbol	Function	R/W
5:4	DATE10[1:0]	10 Days Value for the tens place of days.	R/W
6	—	The read value is undefined. The write value should be 0.	R/W
7	ENB	ENB 0: Do not compare register value with RDAYCNT counter value 1: Compare register value with RDAYCNT counter value	R/W

Note: S-TYPE3, P-TYPE3

RDAYAR is an alarm register associated with the BCD-coded date counter RDAYCNT. When the ENB bit is set to 1, the RDAYAR value is compared with the RDAYCNT value. From the following alarm registers, only those selected with the ENB bits set to 1 are compared with the associated counters:

- RSECAR
- RMINAR
- RHRAR
- RWKAR
- RDAYAR
- RMONAR
- RYRAREN

When all the respective values match, the IR flag associated with the RTC_ALM interrupt is set to 1. The RDAYAR values from 01 through 31 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. This register is set to 0x00 by an RTC software reset.

26.2.16 RMONAR : Month Alarm Register (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x1A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENB	—	—	MON10	MON1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	MON1[3:0]	1 Month Value for the ones place of months.	R/W
4	MON10	10 Months Value for the tens place of months.	R/W
6:5	—	The read values are undefined. The write value should be 0.	R/W
7	ENB	ENB 0: Do not compare register value with RMONCNT counter value 1: Compare register value with RMONCNT counter value	R/W

Note: S-TYPE3, P-TYPE3

RMONAR is an alarm register associated with the BCD-coded month counter RMONCNT. When the ENB bit is set to 1, the RMONAR value is compared with the RMONCNT value. From the following alarm registers, only those selected with the ENB bits set to 1 are compared with the associated counters:

- RSECAR
- RMINAR
- RHRAR
- RWKAR

- RDAYAR
- RMONAR
- RYRAREN

When all the respective values match, the IR flag associated with the RTC_ALM interrupt is set to 1. The RMONAR values from 01 through 12 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. This register is set to 0x00 by an RTC software reset.

26.2.17 RYRAR : Year Alarm Register (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x1C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	YR10[3:0]				YR1[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	YR1[3:0]	1 Year Value for the ones place of years.	R/W
7:4	YR10[3:0]	10 Years Value for the tens place of years.	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

RYRAR is an alarm register associated with the BCD-coded year counter RYRCNT. The RYRAR values from 00 through 99 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. This register is set to 0x0000 by an RTC software reset.

26.2.18 RYRAREN : Year Alarm Enable Register (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x1E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENB	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
6:0	—	The read values are undefined. The write value should be 0.	R/W
7	ENB	ENB 0: Do not compare register value with the RYRCNT counter value 1: Compare register value with the RYRCNT counter value	R/W

Note: S-TYPE3, P-TYPE3

When the ENB bit in the RYRAREN register is set to 1, the RYRAR value is compared with the RYRCNT value. From the following alarm registers, only those selected with the ENB bits set to 1 are compared with the associated counters:

- RSECAR
- RMINAR
- RHRAR
- RWKAR

- RDAYAR
- RMONAR
- RYRAREN

When all the respective values match, the IR flag associated with the RTC_ALM interrupt is set to 1. This register is set to 0x00 by an RTC software reset.

26.2.19 BCNTnAER : Binary Counter n Alarm Enable Register (n = 0 to 3) (in Binary Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x18 + 0x02 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENB[7:0]							
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	ENB[7:0]	Setting the alarm enable associated with the 32-bit binary counter	R/W

Note: S-TYPE3, P-TYPE3

BCNTnAER is a read/write register for setting the alarm enable (BCNTAER) associated with the 32-bit binary counter. BCNT3AER is assigned to the BCNTAER.ENB[31:24] bits, BCNT2AER register is assigned to the BCNTAER.ENB[23:16] bits, BCNT1AER is assigned to the BCNTAER.ENB[15:8] bits, and BCNT0AER is assigned to the BCNTAER.ENB[7:0] bits. The binary counter (BCNT[31:0]) associated with the BCNTAER.ENB[31:0] bits that are set to 1 is compared with the binary alarm register (BCNTAR) and, when all match, the IR flag associated with the RTC_ALM interrupt is set to 1. This register is set to 0x00 by an RTC software reset.

26.2.20 RCR1 : RTC Control Register 1

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x22

Bit position:	7	6	5	4	3	2	1	0
Bit field:	PES[3:0]				RTCOS	PIE	CIE	AIE
Value after reset:	x	x	x	x	0	x	0	x

Bit	Symbol	Function	R/W
0	AIE	Alarm Interrupt Enable 0: Disable alarm interrupt requests 1: Enable alarm interrupt requests	R/W
1	CIE	Carry Interrupt Enable 0: Disable carry interrupt requests 1: Enable carry interrupt requests	R/W
2	PIE	Periodic Interrupt Enable 0: Disable periodic interrupt requests 1: Enable periodic interrupt requests	R/W
3	RTCOS	RTCOUT Output Select 0: Outputs 1 Hz on RTCOUT 1: Outputs 64 Hz RTCOUT	R/W

Bit	Symbol	Function	R/W
7:4	PES[3:0]	Periodic Interrupt Select 0x6: Generate periodic interrupt every 1/256 second*1 0x7: Generate periodic interrupt every 1/128 second 0x8: Generate periodic interrupt every 1/64 second 0x9: Generate periodic interrupt every 1/32 second 0xA: Generate periodic interrupt every 1/16 second 0xB: Generate periodic interrupt every 1/8 second 0xC: Generate periodic interrupt every 1/4 second 0xD: Generate periodic interrupt every 1/2 second 0xE: Generate periodic interrupt every 1 second 0xF: Generate periodic interrupt every 2 seconds Others: Do not generate periodic interrupts	R/W

Note: S-TYPE3, P-TYPE3

Note 1. When LOCO is selected (RCR4.RCKSEL = 1) while PES[3:0] = 0x6, a periodic interrupt is generated every 1/128 second.

The RCR1 register is used in both calendar count mode and binary count mode. Bits AIE, PIE, and PES[3:0] are updated synchronously with the count source. When the RCR1 register is modified, check that all the bits are updated before proceeding.

AIE bit (Alarm Interrupt Enable)

The AIE bit enables or disables alarm interrupt requests.

If the times indicated in the counters and alarm settings match in Deep Software Standby mode, the MCU returns from Deep Software Standby mode regardless of the AIE bit value.

CIE bit (Carry Interrupt Enable)

The CIE bit enables or disables interrupt requests when a carry to the RSECCNT/BCNT0 register occurs, or when a carry to the 64-Hz counter (R64CNT) occurs while reading the 64-Hz counter.

PIE bit (Periodic Interrupt Enable)

The PIE bit enables or disabled a periodic interrupt.

If the periods indicated in the counters and PES[3:0] settings match in Deep Software Standby mode, the MCU returns from Deep Software Standby mode regardless of the PIE bit value.

RTCOS bit (RTCOUT Output Select)

The RTCOS bit selects the RTCOUT output period. The RTCOS bit must be rewritten while the count operation is stopped (RCR2.START = 0) and the RTCOUT output is disabled (RCR2.RTCOE = 0). When RTCOUT is output to an external pin, the RCR2.RTCOE bit must be enabled.

PES[3:0] bits (Periodic Interrupt Select)

The PES[3:0] bits specify the period for the periodic interrupt. A periodic interrupt is generated with the period specified in these bits.

26.2.21 RCR2 : RTC Control Register 2 (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x24

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CNTMD	HR24	AADJP	AADJE	RTCOE	ADJ30	RESET	START
Value after reset:	x	x	x	x	0	0	0	x

Bit	Symbol	Function	R/W
0	START	Start 0: Stop prescaler and time counter 1: Operate prescaler and time counter normally	R/W

Bit	Symbol	Function	R/W
1	RESET	RTC Software Reset 0: In writing: Invalid (writing 0 has no effect). In reading: Normal time operation in progress, or an RTC software reset has completed. 1: In writing: Initialize the prescaler and target registers for RTC software reset*1. In reading: RTC software reset in progress.	R/W
2	ADJ30	30-Second Adjustment 0: In writing: Invalid (writing 0 has no effect). In reading: Normal time operation in progress, or 30-second adjustment has completed. 1: In writing: Execute 30-second adjustment. In reading: 30-second adjustment in progress.	R/W
3	RTCOE	RTCOUT Output Enable 0: Disable RTCOUT output 1: Enable RTCOUT output	R/W
4	AADJE	Automatic Adjustment Enable*2*3 0: Disable automatic adjustment 1: Enable automatic adjustment	R/W
5	AADJP	Automatic Adjustment Period Select*2*3 0: The RADJ.ADJ[5:0] setting from the count value of the prescaler every minute. 1: The RADJ.ADJ[5:0] setting value is adjusted from the count value of the prescaler every 10 seconds.	R/W
6	HR24	Hours Mode*3 0: Operate RTC in 12-hour mode 1: Operate RTC in 24-hour mode	R/W
7	CNTMD	Count Mode Select*4 0: Calendar count mode 1: Binary count mode	R/W

Note: S-TYPE3, P-TYPE3
Note 1. R64CNT, RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, RYRAR, RYRAREN, RADJ, RTCCRn, RSECCPn, RMINCPn, RHRCPn, RDAYCPn, RMONCPn, RCR2.ADJ30, RCR2.AADJE, RCR2.AADJP.
Note 2. When LOCO is selected, the setting of this bit is disabled.
Note 3. When rewriting this bit, confirm that the value has been rewritten before performing the following processing. See section 26.6.5. Notes on Writing to and Reading from Registers for notes on register writing/reading.
Note 4. When rewriting this bit, confirm that the value has been rewritten before performing the following processing.

The RCR2 register is related to hours mode, automatic adjustment function, enabling RTCOUT output, 30-second adjustment, RTC software reset, and controlling count operation.

START bit (Start)

The START bit stops or restarts the prescaler or time counter operation. This bit is updated in synchronization with the next cycle of the count source. When the START bit is modified, check that the bit is updated before proceeding.

RESET bit (RTC Software Reset)

The RESET bit initializes the prescaler and registers to be reset by RTC software. When 1 is written to this bit, initialization starts in synchronization with the count source. When the initialization is complete, the RESET bit is automatically set to 0. Check that this bit is 0 before proceeding.

ADJ30 bit (30-Second Adjustment)

The ADJ30 bit is for 30-second adjustment.

When 1 is written to the ADJ30 bit, the RSECCNT value of less than 30 seconds is rounded down to 00 second and the value of 30 seconds or more is rounded up to 1 minute.

The 30-second adjustment is performed in synchronization with the count source. When 1 is written to this bit, the ADJ30 bit is automatically set to 0 after the 30-second adjustment completes. If 1 is written to the ADJ30 bit, check that the bit is 0 before proceeding. When the 30-second adjustment is performed, the prescaler and R64CNT are also reset. The ADJ30 bit is set to 0 by an RTC software reset.

RTCOE bit (RTCOUT Output Enable)

The RTCOE bit enables output of a 1-Hz/64-Hz clock signal from the RTCOUT pin.

Use the START bit to stop counting before changing the value of the RTCOE bit. Do not stop counting (write 0 to the START bit) and change the value of the RTCOE bit at the same time.

When RTCOUT is to be output from an external pin, enable the RTCOE bit and set up the port control for the pin.

AADJE bit (Automatic Adjustment Enable)

The AADJE bit controls (enables or disables) automatic adjustment.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJE bit.

The AADJE bit is set to 0 by an RTC software reset.

AADJP bit (Automatic Adjustment Period Select)

The AADJP bit selects the automatic-adjustment period.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJP bit.

The AADJP bit is set to 0 by an RTC software reset.

HR24 bit (Hours Mode)

The HR24 bit specifies whether the RTC operates in 12- or 24-hour mode.

Use the START bit to stop counting before changing the value of the HR24 bit. Do not stop counting (write 0 to the START bit) and change the value of the HR24 bit at the same time.

CNTMD bit (Count Mode Select)

The CNTMD bit specifies whether the RTC count mode operates in calendar count mode or in binary count mode.

When setting the count mode, execute an RTC software reset and start again from the initial settings. This bit is updated in synchronization with the count source. However, the count mode switches only after the RTC software reset. (Bit switches before RTC reset, mode switches after RTC reset.)

For details on initial settings, see section 26.3.1. Outline of Initial Settings of Registers After Power On.

26.2.22 RCR2 : RTC Control Register 2 (in Binary Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x24

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CNTMD	—	AADJP	AADJE	RTCOE	—	RESET	START
Value after reset:	x	x	x	x	0	0	0	x

Bit	Symbol	Function	R/W
0	START	Start 0: Stop the 32-bit binary counter, 64-Hz counter, and prescaler 1: Operate the 32-bit binary counter, 64-Hz counter, and prescaler normally	R/W
1	RESET	RTC Software Reset 0: In writing: Invalid (writing 0 has no effect). In reading: Normal time operation in progress, or an RTC software reset has completed. 1: In writing: Initialize the prescaler and target registers for RTC software reset*1. In reading: RTC software reset in progress.	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
3	RTCOE	RTCOUT Output Enable 0: Disable RTCOUT output 1: Enable RTCOUT output	R/W
4	AADJE	Automatic Adjustment Enable*2*3 0: Disable automatic adjustment 1: Enable automatic adjustment	R/W
5	AADJP	Automatic Adjustment Period Select*2*3 0: Add or subtract RADJ.ADJ [5:0] bits from prescaler count value every 32 seconds 1: Add or subtract RADJ.ADJ [5:0] bits from prescaler count value every 8 seconds.	R/W
6	—	The read value is undefined. The write value should be 0.	R/W
7	CNTMD	Count Mode Select*4 0: Calendar count mode 1: Binary count mode	R/W

Note: S-TYPE3, P-TYPE3

Note 1. R64CNT, BCNTnAR, BCNTnAER, RADJ, RTCCRn, BCNTnCPm, RCR2.ADJ30, RCR2.AADJE, RCR2.AADJP.

Note 2. When LOCO is selected, the setting of this bit is disabled.

Note 3. When rewriting this bit, confirm that the value has been rewritten before performing the following processing. See section 26.6.5. Notes on Writing to and Reading from Registers for notes on register writing/reading.

Note 4. When rewriting this bit, confirm that the value has been rewritten before performing the following processing.

RCR2 in the binary count mode is a register related to the automatic correction function, RTCOUT output enable, RTC software reset, and count mode control.

START bit (Start)

The START bit stops or restarts the prescaler or counter (clock) operation. This bit is updated in synchronization with the count source. When the START bit is modified, check that the bit is updated before proceeding.

RESET bit (RTC Software Reset)

The RESET bit initializes the prescaler and registers to be reset by RTC software. When 1 is written to this bit, initialization starts in synchronization with the count source. When the initialization is complete, the RESET bit is automatically set to 0. When 1 is written to the RESET bit, check that the bit is 0 before proceeding.

RTCOE bit (RTCOUT Output Enable)

The RTCOE bit enables output of a 1-Hz/64-Hz clock signal from the RTCOUT pin.

Use the START bit to stop counting before changing the value of the RTCOE bit. Do not stop counting (write 0 to the START bit) and change the value of the RTCOE bit at the same time. When an RTCOUT signal is to be output from an external pin, enable the port control in addition to setting this bit.

AADJE bit (Automatic Adjustment Enable)

The AADJE bit controls (enables or disables) automatic adjustment.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJE bit. The AADJE bit is set to 0 by an RTC software reset.

AADJP bit (Automatic Adjustment Period Select)

The AADJP bit selects the automatic-adjustment period.

Correction period can be selected from 32 second units or 8 second units in binary count mode.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJP bit. The AADJP bit is set to 0 by an RTC software reset.

CNTMD bit (Count Mode Select)

The CNTMD bit specifies whether the RTC count mode operates in calendar count mode or in binary count mode.

When setting the count mode, execute an RTC software reset and start again from the initial settings. This bit is updated in synchronization with the count source. However, the count mode switches only after the RTC software reset. (Bit switches before RTC reset, mode switches after RTC reset.)

For details on initial settings, see section 26.3.1. Outline of Initial Settings of Registers After Power On .

26.2.23 RCR4 : RTC Control Register 4

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x28

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	RCKSEL
Value after reset:	0	0	0	0	0	0	0	x

Bit	Symbol	Function	R/W
0	RCKSEL	Count Source Select 0: Sub-clock oscillator is selected 1: LOCO is selected	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

The RCR4 register is used in both calendar count mode and binary count mode.

RCKSEL bit (Count Source Select)

The RCKSEL bit selects the count source from the sub-clock oscillator and LOCO.

The RCKSEL bit is only used in normal operation mode. When the RCKSEL bit is set to 0, the time is counted with the sub-clock oscillator. When the bit is set to 1, the time is counted with LOCO.

For details on count source setting, see section 26.3.1. Outline of Initial Settings of Registers After Power On and section 26.3.2. Clock and Count Mode Setting Procedure. The count source must be selected only once before specifying the initial settings of the RTC registers at power on.

26.2.24 RFRL : Frequency Register L

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x2C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RFC[15:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
15:0	RFC[15:0]	Frequency Comparison Value Write 0x00FF to this register when using the LOCO.	R/W

Note: S-TYPE3, P-TYPE3

RFRL is a register for controlling the prescaler when LOCO is selected.

The RTC time counter operates on a 128-Hz clock signal as the base clock. Therefore, when LOCO is selected, LOCO is divided by the prescaler to generate a 128-Hz clock signal. Set the frequency comparison value in the RFC[15:0] bits to generate a 128-Hz clock from the LOCO frequency. Before writing to RFC[15:0] after a cold start, write 0x0000 to the RFRH register.

A value from 0x0007 through 0x01FF can be specified as the frequency comparison value. If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2. The operating frequency of the peripheral module clock and the LOCO should be such that the peripheral module clock is ≥ LOCO.

Calculation method of frequency comparison value:

RFC[15:0] = (LOCO clock frequency) / 128 - 1

When the LOCO frequency is 32.768 kHz, the RFRL register should be set to 0x00FF.

26.2.25 RFRH : Frequency Register H

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x2A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFC16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x

Bit	Symbol	Function	R/W
0	RFC16	Write 0 before writing to the RFRL register after a cold start.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

Before writing to RFRHL.RFC[15:0] after a cold start, write 0x0000 to the RFRH register.

26.2.26 RADJ : Time Error Adjustment Register

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x2E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	PMADJ[1:0]		ADJ[5:0]					
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
5:0	ADJ[5:0]	Adjustment Value These bits specify the adjustment value from the prescaler.	R/W
7:6	PMADJ[1:0]	Plus-Minus 0 0: Do not perform adjustment. 0 1: Adjustment is performed by the addition to the prescaler 1 0: Adjustment is performed by the subtraction from the prescaler 1 1: Setting prohibited.	R/W

Note: S-TYPE3, P-TYPE3

The RADJ register is used in both calendar count mode and binary count mode. Adjustment is performed by the addition to or subtraction from the prescaler or 64-Hz counter. If the Automatic Adjustment Enable (RCR2.AADJE) bit is 0, adjustment is performed when writing to the RADJ. If the RCR2.AADJE bit is 1, adjustment is performed in the interval specified in the Automatic Adjustment Period Select (RCR2.AADJP) bit.

The current adjustment by software (disabling automatic adjustment) may be invalid if the following adjustment value is specified within 320 cycles of the count source after the register setting. To perform adjustment consecutively, wait for 320 cycles or more of the count source after the register setting, then specify the next adjustment value.

RADJ is updated in synchronization with the count source. When RADJ is modified, check that all the bits are updated before continuing with more processing. This register is set to 0x00 by an RTC software reset. The setting of this register is enabled only when the sub-clock oscillator is selected. When LOCO is selected, adjustment is not performed.

ADJ[5:0] bits (Adjustment Value)

The ADJ[5:0] bits specify the adjustment value (number of sub-clock cycles) from the prescaler.

PMADJ[1:0] bits (Plus-Minus)

The PMADJ[1:0] bits select whether the clock is set ahead or back depending on the error-adjustment value set in the ADJ[5:0] bits.

26.2.27 RTCCRn : Time Capture Control Register n (n = 0 to 2)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x40 + 0x02 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TCEN	—	TCNF[1:0]		—	TCST	TCCT[1:0]	
Value after reset:	x	0	x	x	0	x	x	x

Bit	Symbol	Function	R/W
1:0	TCCT[1:0]	Time Capture Control 0 0: Do not detect events 0 1: Detect rising edge 1 0: Detect falling edge 1 1: Detect both edges	R/W
2	TCST	Time Capture Status 0: No event detected 1: Event detected*1	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
5:4	TCNF[1:0]	Time Capture Noise Filter Control 0 0: Turn noise filter off 0 1: Setting prohibited 1 0: Turn noise filter on (count source) 1 1: Turn noise filter on (count source by divided by 32)	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	TCEN	Time Capture Event Input Pin Enable 0: Disable the RTCICn pin as the time capture event input pin 1: Enable the RTCICn pin as the time capture event input pin	R/W

Note: S-TYPE3, P-TYPE3

Note 1. Indicates that an event is detected. Writing 1 to this bit has no effect. Writing 0 sets this bit to 0.

The RTCCRn register is used both in calendar count mode and in binary count mode. RTCCR0, RTCCR1, and RTCCR2 control the RTCIC0, RTCIC1, and RTCIC2 pins, respectively.

RTCCRn is updated in synchronization with the count source. When RTCCRn is modified, check that all the bits except the TCST bit are updated before continuing with additional processing. This register is cleared to 0x00 by an RTC software reset. When RTCICm is used as the time capture pin, VBTICTLR.VCHnIEN (n = 0 to 2) must be set to 1.

TCCT[1:0] bits (Time Capture Control)

The TCCT[1:0] bits control the edge detection of the time capture event input pins, RTCIC0, RTCIC1, and RTCIC2. The detection edge is selectable. The TCCT[1:0] bits must be set while the VBTICTLR.VCHnIEN bit is 1.

TCST bit (Time Capture Status)

The TCST bit indicates that an event on the time capture event input pins, RTCIC0, RTCIC1, and RTCIC2,was detected. When the TCST bit is 0, no event is detected. When the TCST bit is 1, this bit indicates that an event was detected on the associated pin and the capture register is valid. When multiple events are detected, the capture time for the first event is retained.

The event is detected only during count operation (RCR2.START bit = 1). Before reading the capture register, make sure that this bit is set to 1.

Set the TCST bit while the TCCT[1:0] bits are 00b (no event is detected). The TCST bit is set to 0 in synchronization with the count source. When the TCST bit is 0, check that the bit is updated before continuing with additional processing.

TCNF[1:0] bits (Time Capture Noise Filter Control)

The TCNF[1:0] bits control the noise filter of the time capture event input pins (RTCIC0, RTCIC1, and RTCIC2).

When the noise filter is on, the count source divided by 1 or divided by 32 is selectable. In this case, when the input level on the time capture event input pin matches three consecutive times at the set sampling period, the input level is determined.

Set the TCNF[1:0] bits while the TCCT[1:0] bits are 00b (no event is detected). When the noise filter is used, set the TCNF[1:0] bits, wait for 3 cycles of the specified sampling period, then set the TCCT[1:0] bits. Set the TCNF[1:0] bits when the VBTICTLR.VCHnIEN bit is 1.

TCEN bit (Time Capture Event Input Pin Enable)

The TCEN bit enables or disables the time capture event input pins RTCIC0, RTCIC1, and RTCIC2.When the functions of the time capture event input pins are multiplexed, set VBTICTLR first. If the TCEN bit is set to 0, also set the TCCT[1:0] bits to 00b.

26.2.28 RSECCPn : Second Capture Register n (n = 0 to 2) (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x52 + 0x10 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	SEC10[2:0]			SEC1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	SEC1[3:0]	1-Second Capture Capture value for the ones place of seconds.	R
6:4	SEC10[2:0]	10-Second Capture Capture value for the tens place of seconds.	R
7	—	The read value is undefined.	R

Note: S-TYPE3, P-TYPE3

RSECCPn is a read-only register that captures the RSECCNT value when a time capture event is detected.

The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the RSECCP0, RSECCP1, and RSECCP2 registers, respectively. This register is cleared to 0x00 by an RTC software reset. Before reading from this register, the time capture event detection should be stopped using the RTCCRn.TCCT[1:0] bits.

26.2.29 RMINCPn : Minute Capture Register n (n = 0 to 2) (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x54 + 0x10 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	MIN10[2:0]			MIN1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	MIN1[3:0]	1-Minute Capture Capture value for the ones place of minutes.	R
6:4	MIN10[2:0]	10-Minute Capture Capture value for the tens place of minutes.	R
7	—	The read value is undefined.	R

Note: S-TYPE3, P-TYPE3

RMINCPn is a read-only register that captures the RMINCNT value when a time capture event is detected.

The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the RMINCP0, RMINCP1, and RMINCP2 registers, respectively.

This register is cleared to 0x00 by an RTC software reset. Before reading from this register, the time capture event detection should be stopped using the RTCCRn.TCCT[1:0] bits.

26.2.30 RHRCPn : Hour Capture Register n (n = 0 to 2) (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x56 + 0x10 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	PM	HR10[1:0]		HR1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	HR1[3:0]	1-Hour Capture Capture value for the ones place of hours	R
5:4	HR10[1:0]	10-Hour Capture Capture value for the tens place of hours	R
6	PM	PM 0: AM 1: PM	R
7	—	The read value is undefined.	R

Note: S-TYPE3, P-TYPE3

RHRCPn is a read-only register that captures the RHRCNT value when a time capture event is detected.

The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the RHRCP0, RHRCP1, and RHRCP2 registers, respectively.

The PM bit is only enabled when the RCR2.HR24 bit is 0 (in 12-hour mode).

This register is cleared to 0x00 by an RTC software reset. Before reading from this register, you must stop the time capture event detection using the RTCCRn.TCCT[1:0] bits.

26.2.31 RDAYCPn : Date Capture Register n (n = 0 to 2) (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x5A + 0x10 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	DATE10[1:0]		DATE1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	DATE1[3:0]	1-Day Capture Capture value for the ones place of days.	R
5:4	DATE10[1:0]	10-Day Capture Capture value for the tens place of days.	R
7:6	—	The read value is undefined.	R

Note: S-TYPE3, P-TYPE3

RDAYCPn is a read-only register that captures the RDAYCNT value when a time capture event is detected.

The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the RDAYCP0, RDAYCP1, and RDAYCP2 registers, respectively.

This register is cleared to 0x00 by an RTC software reset. Before reading from this register, the time capture event detection should be stopped using the RTCCRn.TCCT[1:0] bits.

26.2.32 RMONCPn : Month Capture Register n (n = 0 to 2) (in Calendar Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x5C + 0x10 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	MON10	MON1[3:0]			
Value after reset:	0	0	0	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	MON1[3:0]	1-Month Capture Capture value for the ones place of months.	R
4	MON10	10-Month Capture Capture value for the tens place of months.	R
7:5	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3

RMONCPn is a read-only register that captures the RMONCNT value when a time capture event is detected.

The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the RMONCP0, RMONCP1, and RMONCP2 registers, respectively.

This register is cleared to 0x00 by an RTC software reset. Before reading from this register, the time capture event detection should be stopped using the RTCCRn.TCCT[1:0] bits.

26.2.33 BCNTnCPm : BCNTn Capture Register m (n= 0 to 3, m = 0 to 2) (in Binary Count Mode)

Base address: RTC = 0x4020_2000
RTC_NS = 0x5020_2000

Offset address: 0x52 + 0x10 × m (BCNT0CPm)
0x54 + 0x10 × m (BCNT1CPm)
0x56 + 0x10 × m (BCNT2CPm)
0x5A + 0x10 × m (BCNT3CPm)

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	x	x	x	x	x	x	x	x

BCNTnCPm is a read-only register that captures the BCNTn value when a time capture event is detected. BCNT3CPm is assigned to the BCNTCPm[31:24] bits, BCNT2CPm is assigned to the BCNTCPm[23:16] bits, BCNT1CPm is assigned to the BCNTCPm[15:8] bits and BCNT0CPm is assigned to the BCNTCPm[7:0] bits. The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the BCNTnCP0, BCNTnCP1, and BCNTnCP2 registers, respectively.

This register is cleared to 0x00 by an RTC software reset. Before reading from this register, you must stop the time capture event detection using the RTCCRn.TCCT[1:0] bits.

26.3 Operation

26.3.1 Outline of Initial Settings of Registers After Power On

After the power is turned on, perform the initial settings for the clock, count mode, time error adjustment, time, alarm, interrupts, and time capture.

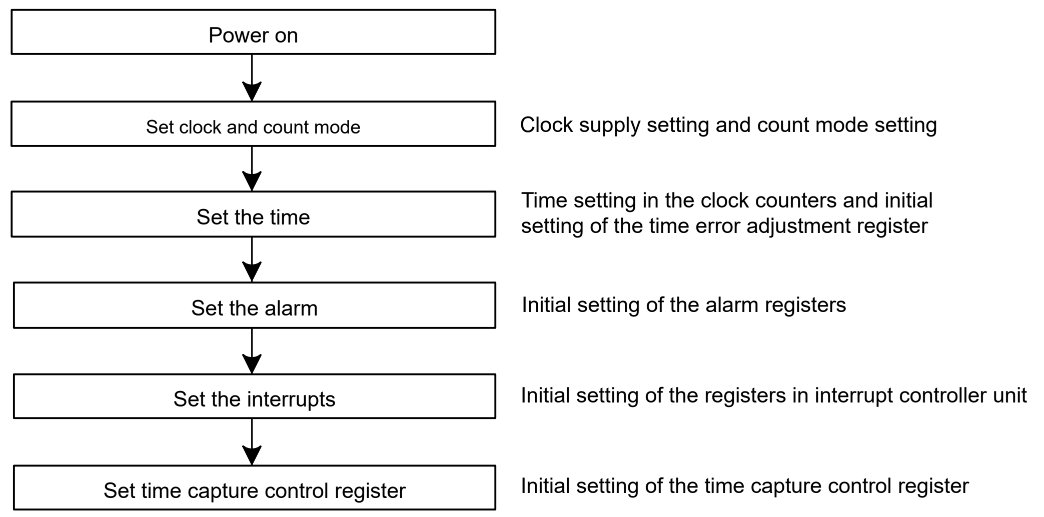

Figure 26.2 Outline of initial settings after a power on

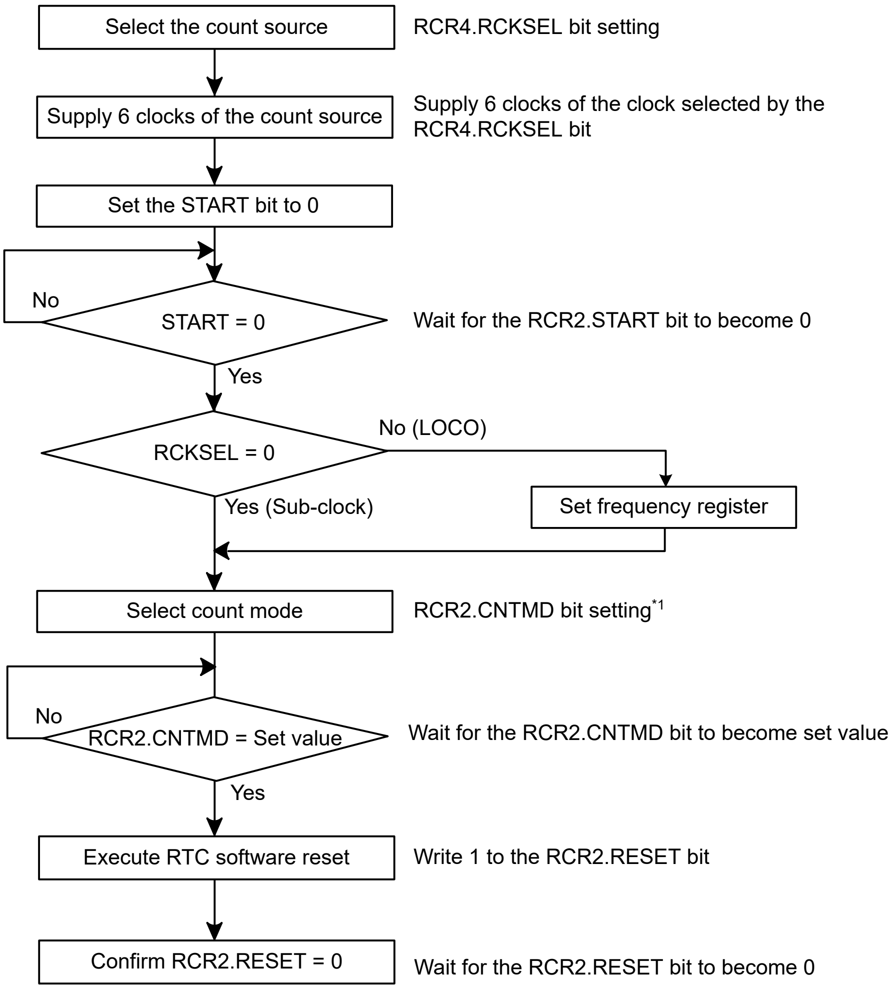
26.3.2 Clock and Count Mode Setting Procedure

Figure 26.3 shows how to set the clock and the count mode.

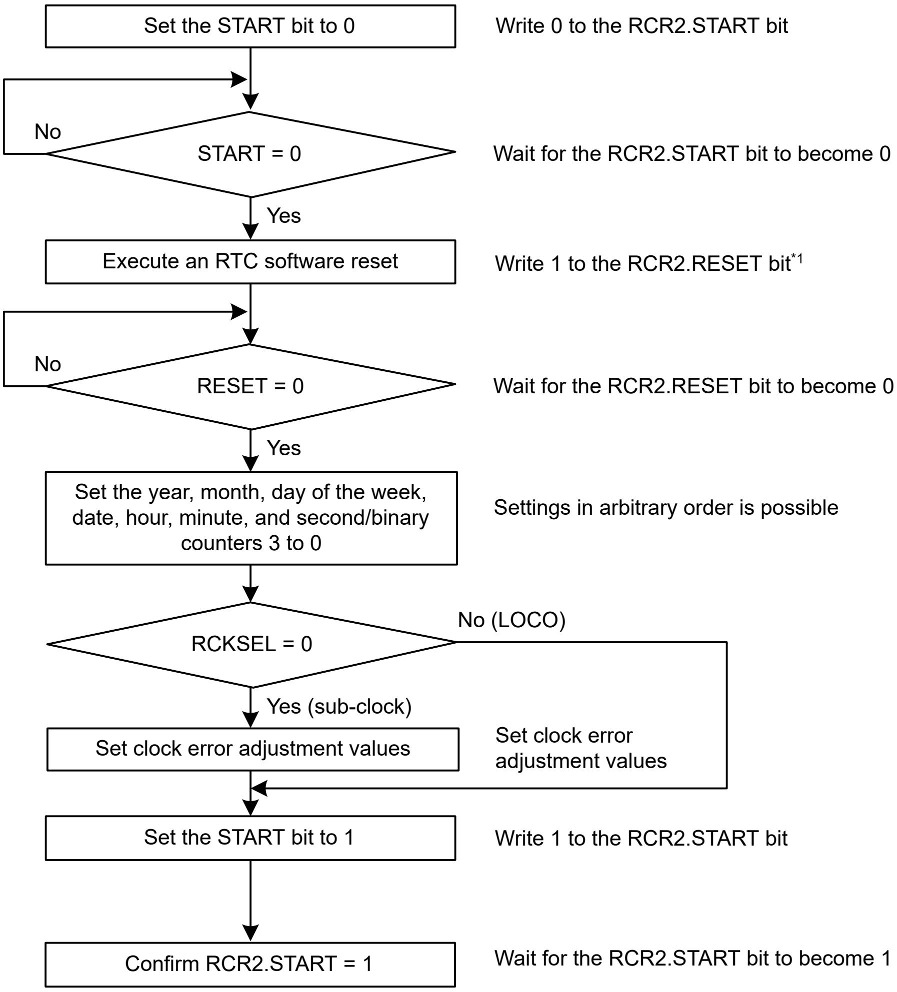


Note 1. This step is not required if the count mode is concurrently set by setting the START bit to 0. A value associated with the count mode setting must be written to the RCR2.CNTMD bit.

Figure 26.3 Clock and count mode setting procedure

26.3.3 Setting the Time

Figure 26.4 shows how to set the time.



Note 1. This step can be omitted in initial settings after power-on because an RTC software reset is executed in the clock setting procedure that is performed during initial settings at power-on.

Figure 26.4 Setting the time

26.3.4 30-Second Adjustment

Figure 26.5 shows how to execute a 30-second adjustment.

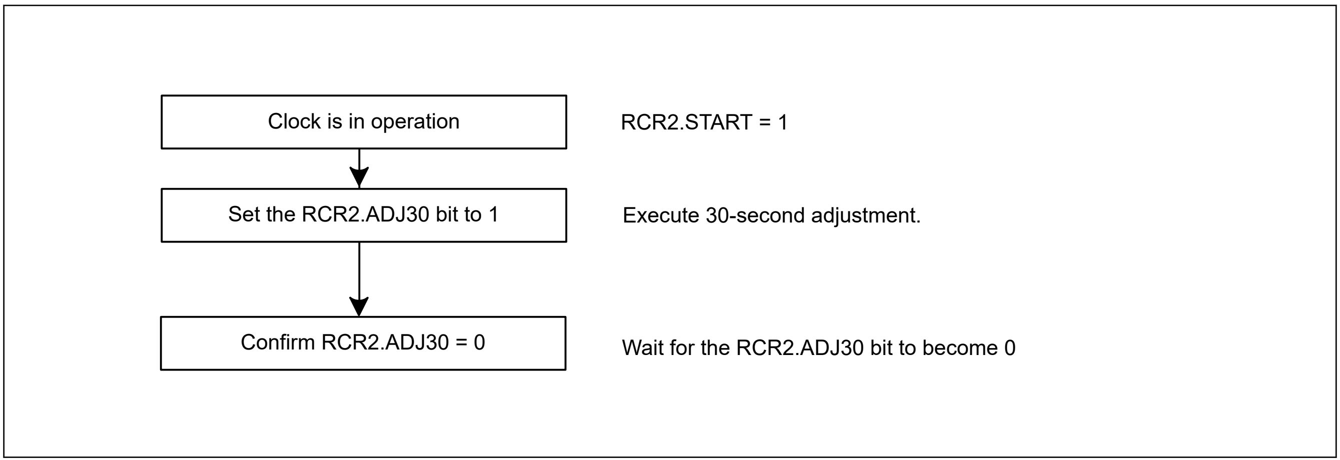


Figure 26.5 30-second adjustment

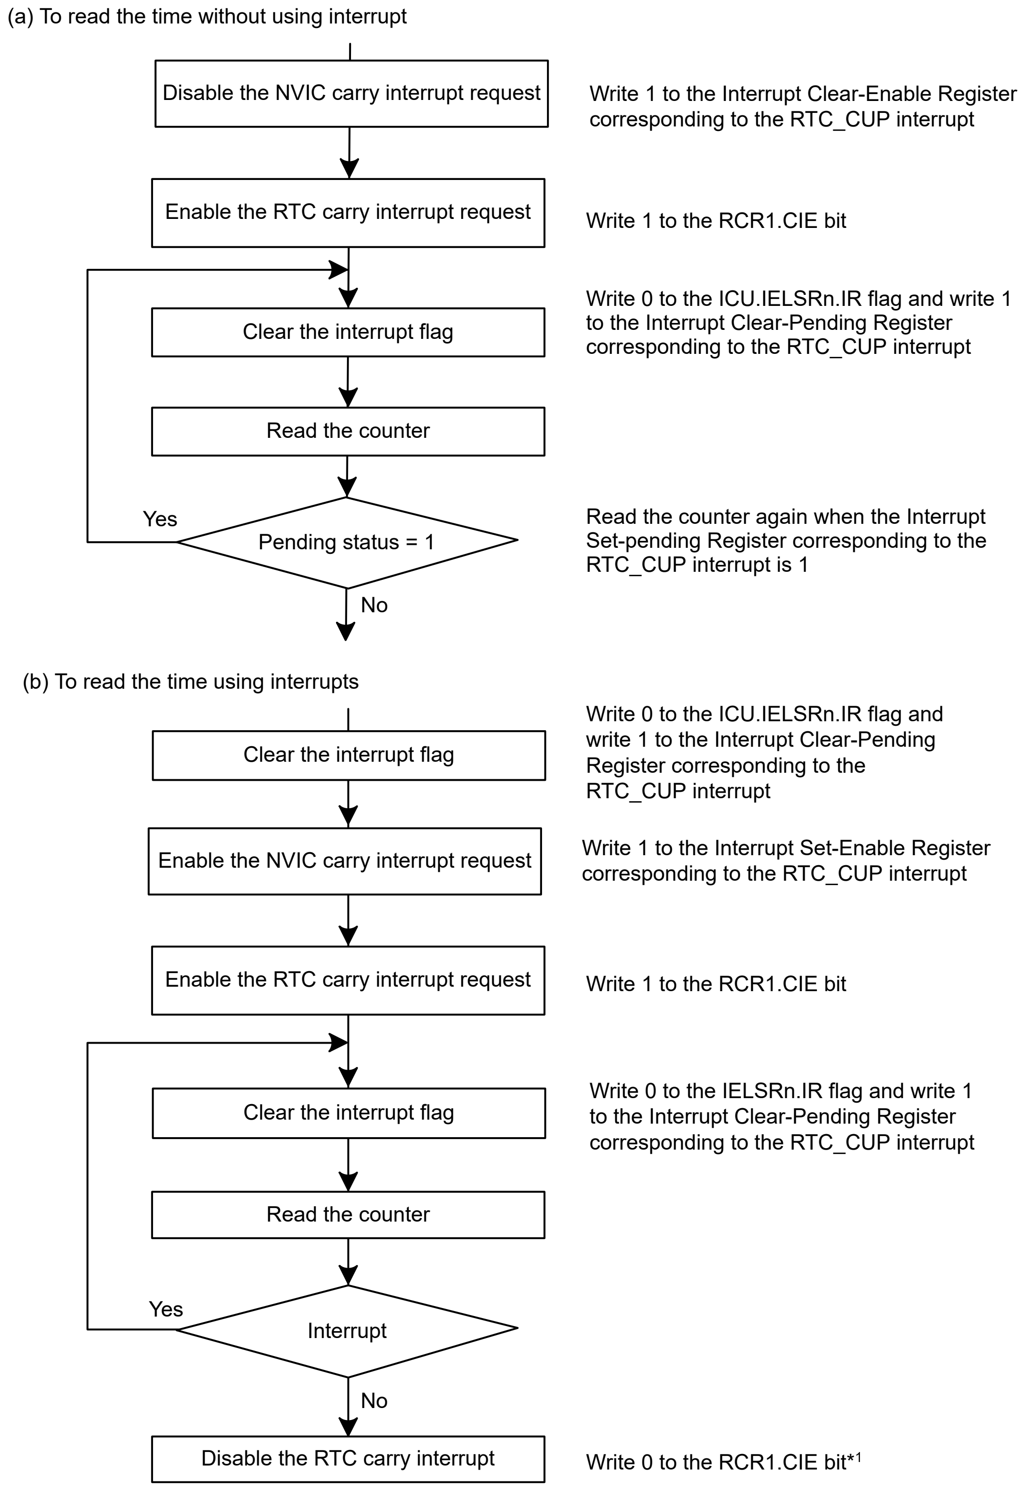
26.3.5 Reading 64-Hz Counter and Time

Figure 26.6 shows how to read a 64-Hz counter and time.



Note 1. Disable interrupts if required.

Figure 26.6 Reading time

If a carry occurs while the 64-Hz counter and time are read, the correct time is not obtained, therefore they must be read again. The procedure for reading the time without using interrupts is shown in (a) in Figure 26.6, and the procedure using carry interrupts is shown in (b). To keep the program simple, method (a) should be used in most cases.

26.3.6 Alarm Function

Figure 26.7 shows how to use the alarm function.

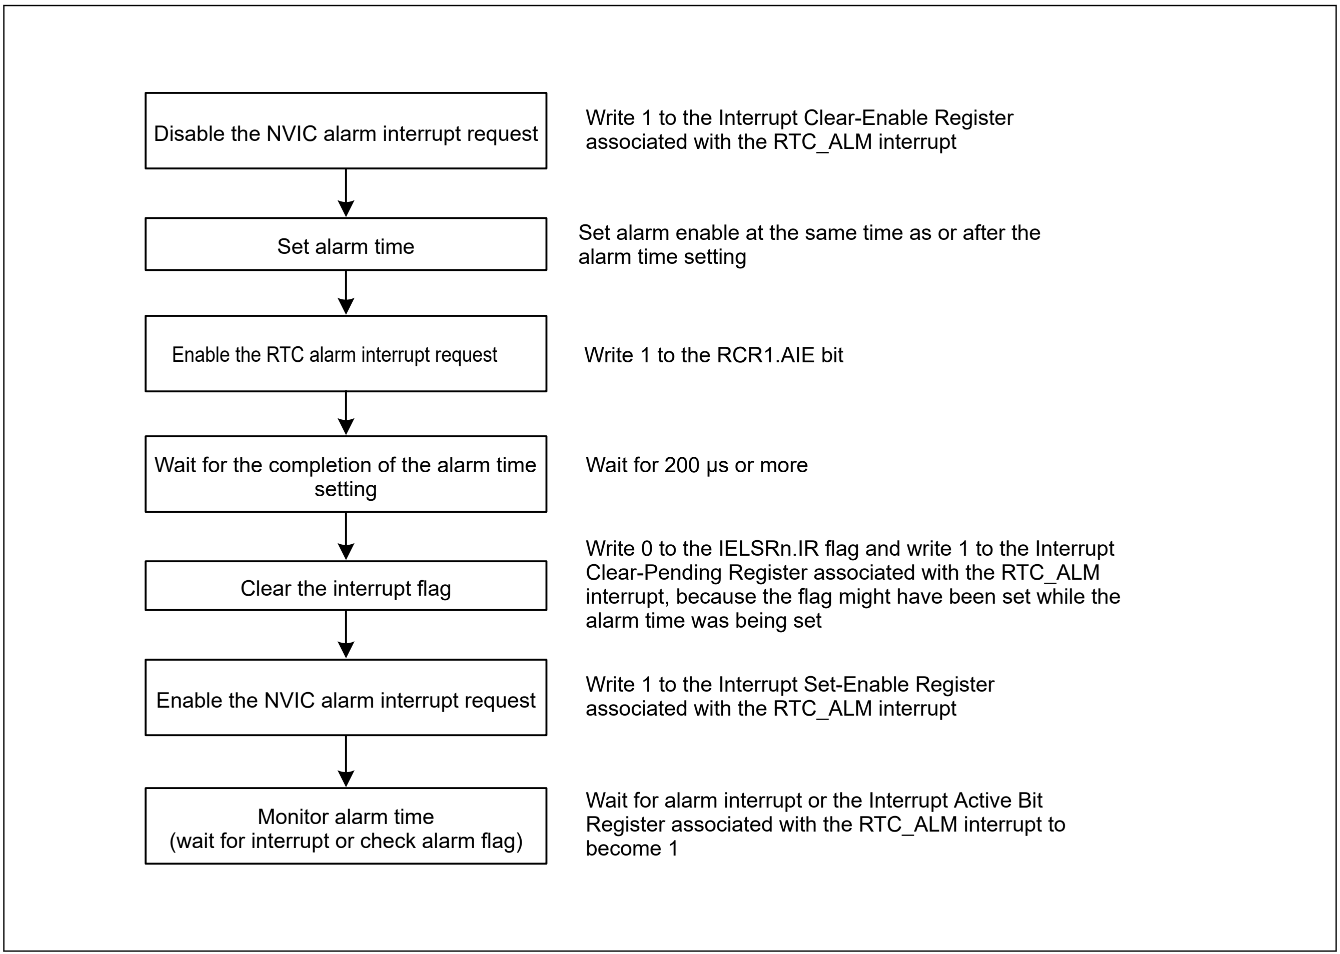


Figure 26.7 Using the alarm function

In calendar count mode, an alarm can be generated by any one of year, month, date, day-of-week, hour, minute or second, or any combination of those. Write 1 to the ENB bit in the alarm registers involved in the alarm setting, and set the alarm time in the lower bits. Write 0 to the ENB bit in registers not involved in the alarm setting.

In binary count mode, an alarm can be generated in any bit combination of 32 bits. Write 1 to the ENB bit of the Alarm Enable register associated with the target bit of the alarm, and set the alarm time in the alarm register. For bits that are not the target of the alarm, write 0 to the ENB bit of the Alarm Enable register.[*1]

For any of the ENB[31:0] bits that are set to 1, the bits in the corresponding positions in the binary counter (BCNT[31:0]) are compared with the values of the corresponding bits in the binary alarm registers[*1]. When all such bits match, the IR flag associated with the RTC_ALM interrupt is set to 1 and the corresponding bits in the Interrupt Set-Pending/Clear-Pending Registers are set to 1. Alarm detection can be confirmed by reading the Interrupt Set-Pending Register associated with the RTC_ALM interrupt, but an interrupt should be used in most cases. If 1 is set in the Interrupt Set-Enable Register associated with the RTC_ALM interrupt, an alarm interrupt is generated in the event of the alarm, enabling the alarm to be detected.

Writing 0 sets the IELSRn.IR flag associated with the RTC_ALM interrupt to 0. If interrupt is enabled, the Interrupt Set-Pending/Clear-Pending Register associated with the RTC_ALM interrupt is cleared automatically after exiting the interrupt handler. Otherwise, write 1 to the Interrupt Clear-Pending Register associated with the RTC_ALM interrupt to clear it.

When the counter and the alarm time match in a low power state, the MCU returns from the low power state.

Note 1. For any bits in the ENB bits that are set to 1, the values in the corresponding positions in the alarm registers from the following registers are compared with the corresponding bits of the counted values.

Counter registers: RSECCNT, RMINCNT, RHRCNT, RWKCNT, RDAYCNT, RMONCNT, RYRCNT

Alarm registers: RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, RYRAREN

26.3.7 Procedure for Disabling Alarm Interrupt

Figure 26.8 shows the procedure for disabling the enabled alarm interrupt request.

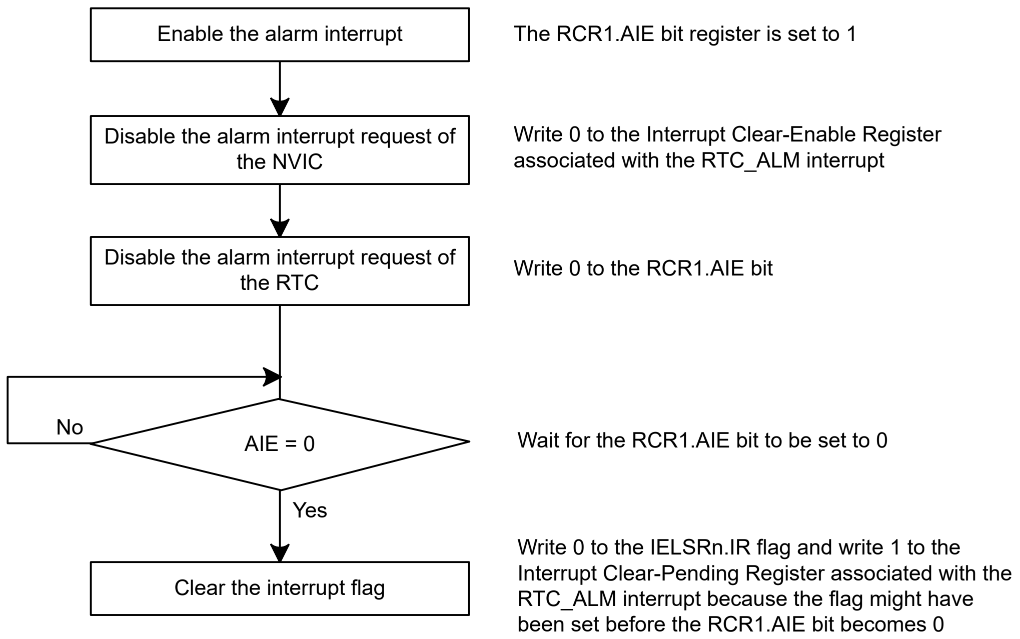

Figure 26.8 Procedure for disabling alarm interrupt request

26.3.8 Time Error Adjustment Function

The time error adjustment function is used to correct errors, running fast or slow, in the time caused by variation in the precision of oscillation by the sub-clock oscillator. Because 32768 cycles of the sub-clock oscillator constitute 1 second of operation when the sub-clock oscillator is selected, the clock runs fast if the sub-clock frequency is high and slow if the sub-clock frequency is low.

The time error adjustment functions include:

- Automatic adjustment
- Adjustment by software

Use the RCR2.AADJE bit to select automatic adjustment or adjustment by software.

26.3.8.1 Automatic Adjustment

Enable automatic adjustment by setting the RCR2.AADJE bit to 1.

Automatic adjustment is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register every time the adjustment period selected by the RCR2.AADJP bit elapses.

(1) Example 1: Sub-clock oscillator running at 32.769 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.769 kHz, 1 second elapses every 32769 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs fast by 1 clock cycle every second. The time on the clock is fast by 60 clock cycles per minute, so adjustment can take the form of setting the clock back by 60 cycles every minute.

Register settings when RCR2.CNTMD = 0:

- RCR2.AADJP = 0 (adjustment every minute)
- RADJ.PMADJ[1:0] = 10b (adjustment is performed by the subtraction from the prescaler)
- RADJ.ADJ[5:0] = 60 (0x3C)

(2) Example 2: Sub-clock oscillator running at 32.766 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.766 kHz, 1 second elapses every 32766 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs slow by 2 clock cycles every second. The time on the clock is slow by 20 clock cycles every 10 seconds, so adjustment can take the form of setting the clock forward by 20 cycles every 10 seconds.

Register settings when RCR2.CNTMD = 0:

- RCR2.AADJP = 1 (adjustment every 10 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler)
- RADJ.ADJ[5:0] = 20 (0x14)

(3) Example 3: Sub-clock oscillator running at 32.764 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.764 kHz, 1 second elapses on 32764 clock cycles. Because the RTC operates for 32768 clock cycles as 1 second, the clock is delayed for 4 clock cycles per second. In 8 seconds, the delay is 32 clock cycles, therefore correction can be made by advancing the clock 32 clock cycles every 8 seconds.

Register settings when RCR2.CNTMD = 1:

- RCR2.AADJP = 1 (adjustment every 8 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler)
- RADJ.ADJ[5:0] = 32 (0x20)

26.3.8.2 Adjustment by Software

Enable adjustment by software by setting the RCR2.AADJE bit to 0. Adjustment by software is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register on execution of a write instruction to the RADJ register.

(1) Example 1: Sub-clock oscillator running at 32.769 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.769 kHz, 1 second elapses every 32769 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs fast by 1 clock cycle every second. The time on the clock is fast by 1 clock cycle per second, so adjustment can take the form of setting the clock back by 1 cycle every second.

Register settings

- RADJ.PMADJ[1:0] = 10b (adjustment is performed by the subtraction from the prescaler)
- RADJ.ADJ[5:0] = 1 (0x01)
  This is written to the RADJ register once per 1-second interrupt.

26.3.8.3 Procedure to Change the Mode of Adjustment

When changing the mode of adjustment, change the value of the AADJE bit in RCR2 after setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

To change adjustment by software to automatic adjustment:

1. Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
2. Set the RCR2.AADJE bit to 1 (automatic adjustment is enabled).
3. Use the RCR2.AADJP bit to select the period of adjustment.
4. In RADJ, set the PMADJ[1:0] bits for addition or subtraction and the ADJ[5:0] bits to the value for use in time error adjustment.

To change automatic adjustment to adjustment by software:

1. Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
2. Set the RCR2.AADJE bit to 0 (adjustment by software is enabled).
3. Proceed with the adjustment by setting the RADJ.PMADJ[1:0] bits for addition or subtraction and the RADJ.ADJ[5:0] bits to the value for use in time error adjustment at the wanted time. After that, the time is adjusted every time a value is written to the RADJ register.

26.3.8.4 Procedure to Stop Adjustment

Stop the adjustment by setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

26.3.9 Capturing the Time

The RTC is capable of storing the month, date, hour, minute and second/binary counters 3 to 0 by detecting an edge of a signal on a time capture event input pin in calendar count mode or binary count mode.

A noise filter can also be used on a time capture event input pin. If the noise filter is enabled, the RTCCRn.TCST bit is set to 1 when the input level on the pin matches three times.

The noise filter can be switched on or off for each of the time capture event input pins.Set VBTICTLR.VCHnIEN (n = 0 to 2) to 1 to enable the RTCICn input. Operation when the noise filter is off is shown in Figure 26.9 and operation when the noise filter is on is shown in Figure 26.10.

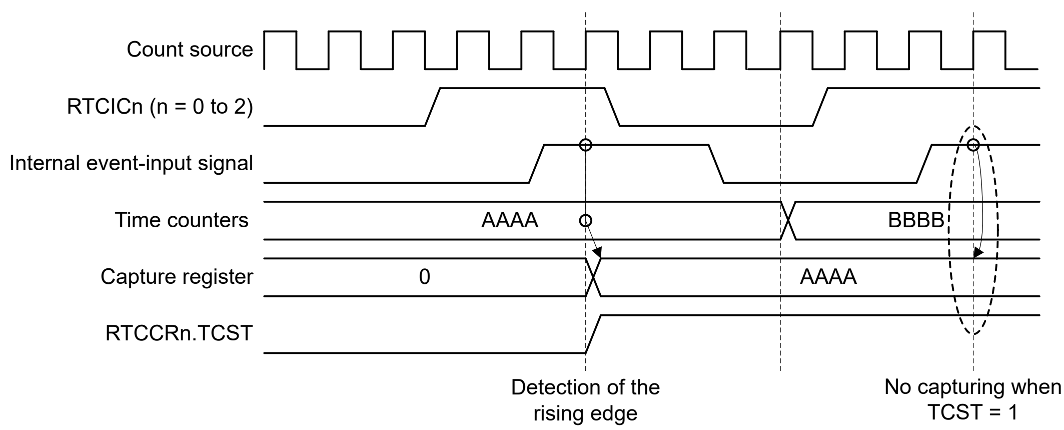

Figure 26.9 Timing of a time capture operation with the noise filter off

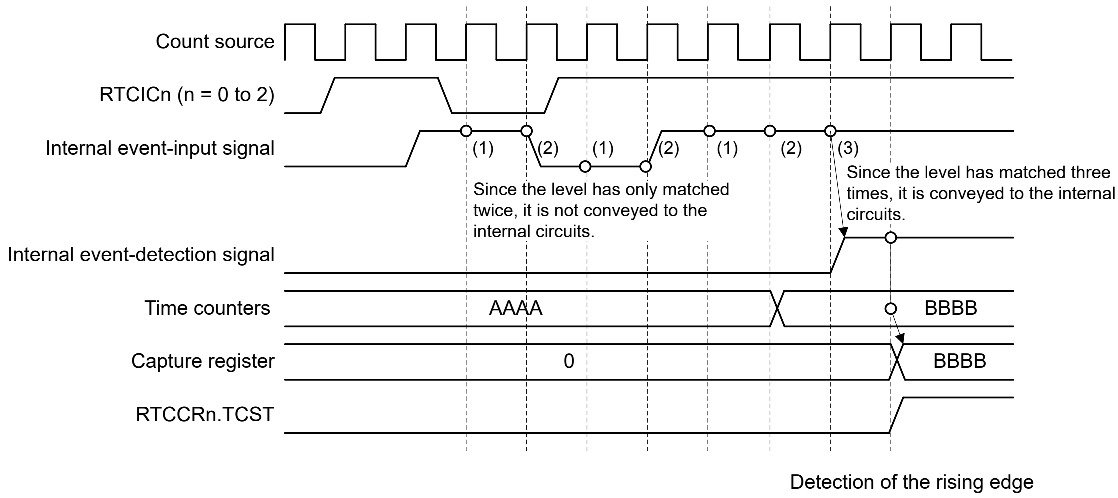

Figure 26.10 Timing of a time capture operation with the noise filter on

26.4 Interrupt Sources

The RTC has three interrupt sources, as listed in Table 26.3.

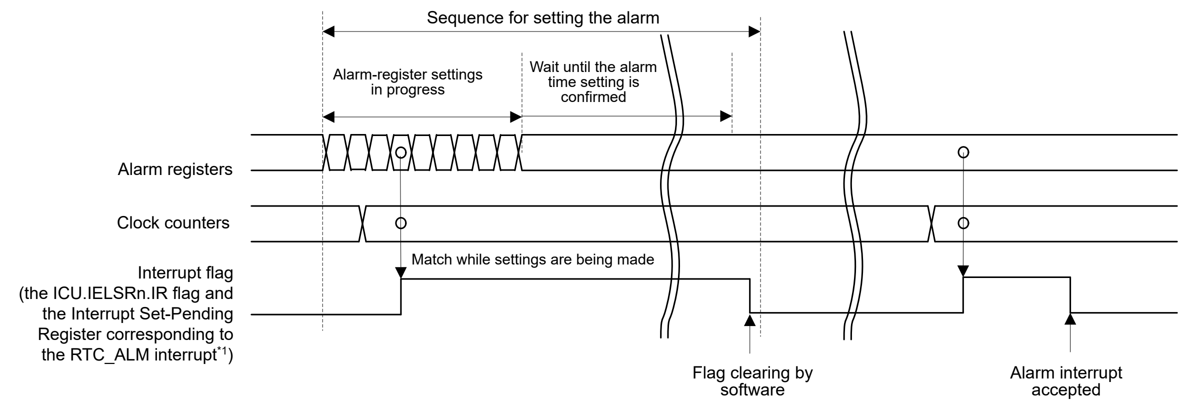
Table 26.3 RTC interrupt sources

Name	Interrupt source
RTC_ALM	Alarm interrupt
RTC_PRD	Periodic interrupt
RTC_CUP	Carry interrupt

(1) Alarm interrupt (RTC_ALM)

This interrupt is generated based on the comparison result between the alarm registers and RTC counters. For details, see section 26.3.6. Alarm Function.

Because there is a possibility that the interrupt flag might be set to 1 when the settings of the alarm registers match the clock counters, wait for the alarm time settings to be confirmed and clear the IELSRn.IR flag and the interrupt Set-Pending Register associated with the RTC_ALM interrupt to 0 again after modifying values of the alarm registers. After the interrupt flag for the alarm interrupt is set to 1 and the state is returned to mismatching of the alarm registers and clock counters, the flag is not 1 again until there is another match or the values of the alarm registers are modified again.



Note 1. See section 14, Interrupt Controller Unit (ICU) for details on the associated interrupt vector number.

Figure 26.11 Timing for the alarm interrupt (RTC_ALM)

(2) Periodic interrupt (RTC_PRD)

This interrupt is generated at intervals of 2 seconds, 1 second, 1/2 second, 1/4 second, 1/8 second, 1/16 second, 1/32 second, 1/64 second, 1/128 second, or 1/256 second. The interrupt interval can be selected in the RCR1.PES[3:0] bits.

(3) Carry interrupt (RTC_CUP)

This interrupt is generated when a carry to the second counter/binary counter 0 occurred or a carry to the R64CNT counter occurred during read access to the 64-Hz counter.

Figure 26.12 shows the timing of the carry interrupt (RTC_CUP).

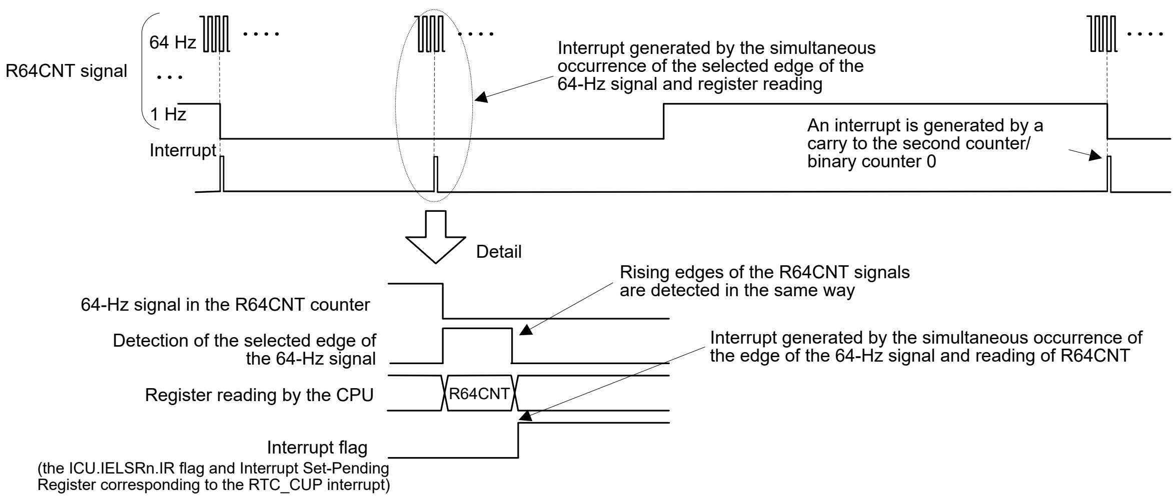


Figure 26.12 Timing for the carry interrupt (RTC_CUP)

26.5 Event Link Output

The RTC generates periodic event output (RTC_PRD) event signal for the ELC that can be used to initiate operations by other modules selected in advance.

The periodic event signal is output at the interval selected from 1/256, 1/128, 1/64, 1/32, 1/16, 1/8, 1/4, 1/2, 1, and 2 seconds by setting the RCR1.PES[3:0] bits.

The event generation period immediately after the event generation is selected is not guaranteed.

Note: If event linking from the RTC is used, only set the ELC after setting the RTC, for example initialization and time settings. Setting the RTC after the ELC can lead to output of unexpected event signals.

26.5.1 Interrupt Handling and Event Linking

The RTC has a bit to enable or disable periodic interrupts. An interrupt request signal is output to the CPU when an interrupt source is generated while the associated enable bit is enabled.

In contrast, an event link output signal is sent to other modules as an event signal through the ELC when an interrupt source is generated, regardless of the setting of the associated interrupt enable bit.

Note: Although alarm and periodic interrupts can still be output during Software Standby or Deep Software Standby mode, the periodic event signals for the ELC are not output.

26.6 Usage Notes

26.6.1 Register Writing During Counting

The following registers should not be written to during counting, that is, while the RCR2.START bit is 1:

- RSECCNT/BCNT0
- RMINCNT/BCNT1
- RHRCNT/BCNT2
- RDAYCNT
- RWKCNT/BCNT3
- RMONCNT
- RYRCNT
- RCR1.RTCOS
- RCR2.RTCOE
- RCR2.HR24
- RFRL

The counter should be stopped before writing to any of these registers.

26.6.2 Use of Periodic Interrupts

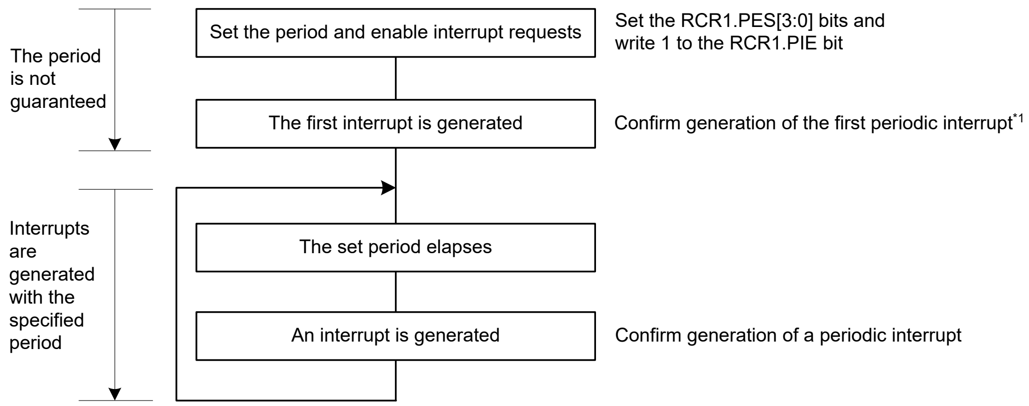
Figure 26.13 shows the procedure for using periodic interrupts.

The generation and period of the periodic interrupt can be changed by setting the RCR1.PES[3:0] bits. However, because the prescaler R64CNT and RSECCNT/BCNT0 are used to generate interrupts, the interrupt period is not guaranteed immediately after setting the RCR1.PES[3:0] bits.

In addition, any of the following operation can affect the interrupt period:

- Stopping/restarting or resetting counter operation
- Reset by RTC software
- 30-second adjustment by changing the RCR2 value

When the time error adjustment function is used, the interrupt generation period after adjustment is added or subtracted based on the adjustment value.



Note 1. When an interrupt generation period changes while the periodic interrupt is used, an interrupt might be generated at the completion of the setting. If the interrupt is generated immediately after the setting, the period is not guaranteed for two interrupts including the current interrupt.

Figure 26.13 Using the periodic interrupt function

26.6.3 RTCOUT (1-Hz/64-Hz) Clock Output

Stopping/restarting or resetting counter operation, reset by RTC software, and the 30-second adjustment by changing the RCR2 value affects the period of RTCOUT (1-Hz/64-Hz) output. When the time error adjustment function is used, the period of RTCOUT (1-Hz/64-Hz) output after adjustment is added or subtracted based on the adjustment value.

26.6.4 Transitions to Low Power Modes After Setting Registers

A transition to a low power state (Software Standby mode, Deep Software Standby mode, or battery backup state) during a write to an RTC register might corrupt the value of the register. After setting the register, confirm that the setting is in place before initiating a transition to a low power state.

26.6.5 Notes on Writing to and Reading from Registers

- When reading a counter register such as the second counter after writing to the counter register, follow the procedure in section 26.3.5. Reading 64-Hz Counter and Time.
- The value written to the count registers, alarm registers, year alarm enable register, bits RCR2.AADJE, AADJP, and HR24, RCR4 register, or frequency register is reflected when fourth read operations are performed after writing.
- The values written to the RCR1.CIE, RCR1.RTCOS, and RCR2.RTCOE bits can be read immediately after writing.
- To read the value from the timer counter after returning from a reset or a period in Software Standby mode, Deep Software Standby mode, or battery backup state, wait for 1/128 second while the clock is operating (RCR2.START bit = 1).
- After a reset is generated, write to the RTC register after 6 cycles of the count source clock have elapsed.

26.6.6 Changing the Count Mode

When changing the count mode (calendar count mode/binary count mode), set the RCR2.START bit to 0, stop the counting operation, then start it again from the initial setting. For details on the initial setting, see section 26.3.1. Outline of Initial Settings of Registers After Power On.

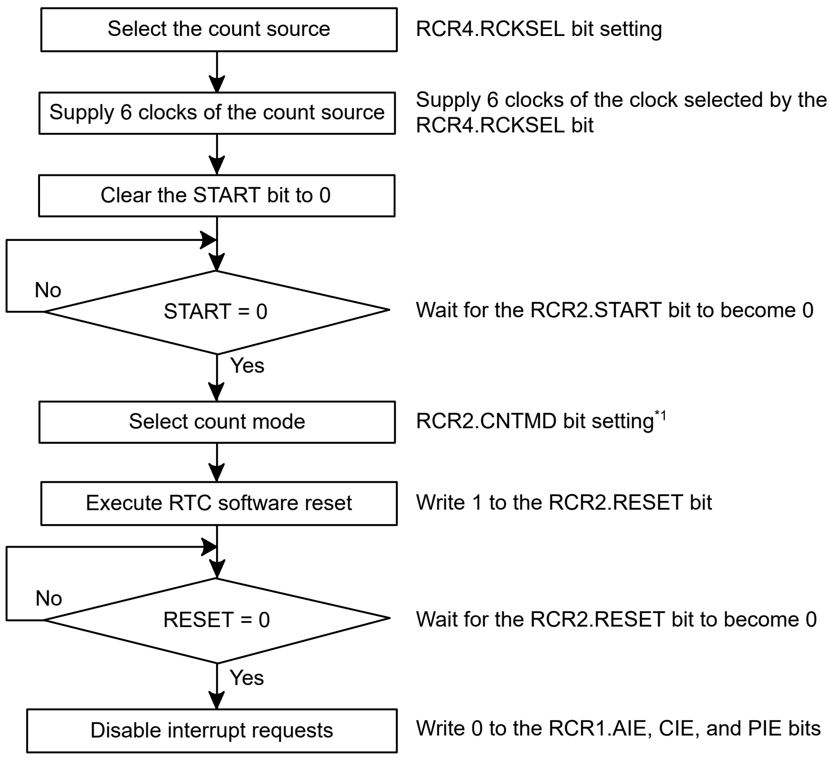
26.6.7 Initialization Procedure When the RTC Is Not to Be Used

Registers in the RTC are not initialized by a reset. Depending on the initial state, the generation of an unintentional interrupt request or operation of the counter might lead to increased power consumption.

For applications that do not require a realtime clock, initialize the registers by following the initialization procedure shown in Figure 26.14.

Alternatively, when the sub-clock oscillator is not used as the system clock source, realtime clock, operating clock of each peripheral modules or FLL function of HOCO, the counter can be stopped by writing 0 (sub-clock oscillator is selected) to the RCR4.RCKSEL bit and stopping the sub-clock oscillator. To stop the sub-clock oscillator, write 1 to the SOSCCR.SOSTP bit.

For details on the setting of the SOSCCR.SOSTP bit, see section 9, Clock Generation Circuit.



Note 1. This step is not necessary if the count mode is concurrently set by setting the START bit to 0.

Figure 26.14 Initialization procedure

26.6.8 When Switching Source Clock

When switching a clock source by changing SCKSCR.CKSEL[2:0], the clock output from the selector stops for 4 cycles of the switched clock. If the RTC periodical interrupt or RTC periodical event output was generated at this time, the interrupt or event is invalid.

26.6.9 When Writing to the RTC Registers

If VCC voltage of the MCU is lower than 1.8V and write access to the RTC registers is performed, read access should be performed at least once after one write access is performed, or for the consecutive write access, leave an interval of 167ns for each access.

27. Watchdog Timer (WDT)

27.1 Overview

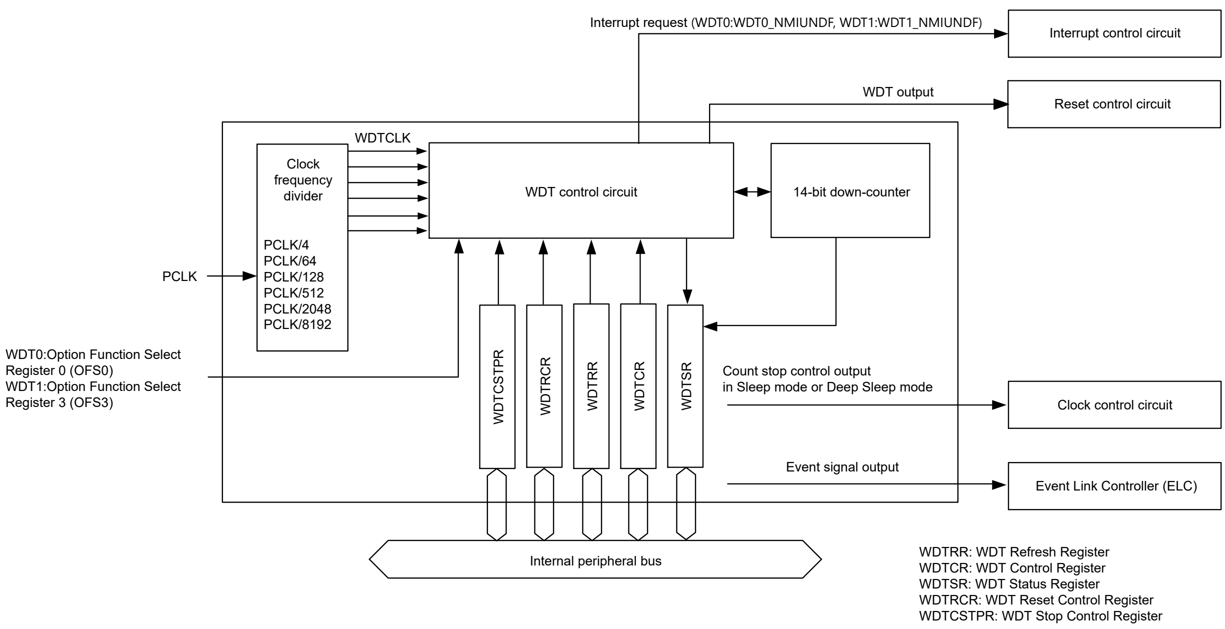
The Watchdog Timer (WDT) is a 14-bit down counter that can be used to reset the MCU when the counter underflows because the system has run out of control and is unable to refresh the WDT. In addition, the WDT can be used to generate a non-maskable interrupt or an underflow interrupt.

Table 27.1 lists the WDT specifications and Figure 27.1 shows a block diagram.

Table 27.1 WDT specifications

Parameter	Specifications
Number of units	2 (WDT0 for CPU0, WDT1 for CPU1)
Count source*1	Peripheral clock (PCLKB)
Clock division ratio	Division by 4, 64, 128, 512, 2048, or 8192
Counter operation	Counting down using a 14-bit down-counter
Condition for starting the counter	● Auto start mode: Counting automatically starts after a reset or after an underflow or refresh error occurs ● Register start mode: Counting is started with a refresh by writing to the WDTRR register ● Only secure developer can select Auto-start mode or Register-start mode
Conditions for stopping the counter	● Reset (the down-counter and other registers return to their initial values) ● A counter underflows or a refresh error is generated
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
Watchdog timer reset sources	● Down-counter underflows ● Refreshing outside the refresh-permitted period (refresh error)
Non-maskable interrupt/interrupt sources	● Down-counter underflows ● Refreshing outside the refresh-permitted period (refresh error)
Reading of the counter value	The down-counter value can be read by the WDTSR register
Event link function (output)	● Down-counter underflow event output ● Refresh error event output
Output signal (internal signal)	● Reset output ● Interrupt request output ● Sleep mode or Deep Sleep mode count stop control output
TrustZone Filter	Security and Privilege attribution can be set

Note 1. Satisfy the frequency of the peripheral module clock (PCLKB) ≥ 4 × (the frequency of the count clock source after division).



Note: PCLK = PCLKB

Figure 27.1 WDT block diagram

27.2 Register Descriptions

27.2.1 WDTRR : WDT Refresh Register

Base address: WDTn = 0x4020_2600 + 0x0100 × n (n = 0, 1)
WDTn_NS = 0x5020_2600 + 0x0100 × n (n = 0, 1)

Offset address: 0x00

Bit position:	7							0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	n/a	The down-counter is refreshed by writing 0x00 and then writing 0xFF to this register.	R/W

Note: S-TYPE-3, P-TYPE-3

The WDTRR register refreshes the down-counter of the WDT.

The down-counter of the WDT is refreshed by writing 0x00 and then writing 0xFF to WDTRR register (refresh operation) within the refresh-permitted period.

After the down-counter is refreshed, it starts counting down from the value selected by setting the WDT Timeout Period Select bits (OFS0.WDT0TOPS[1:0] or OFS3.WDT1TOPS[1:0]) in the Option Function Select Register m in auto start mode. In register start mode, counting down starts from the value selected by setting the Timeout Period Select bits (WDTCR.TOPS[1:0]) in the WDT Control Register.

When 0x00 is written, the read value is 0x00. When a value other than 0x00 is written, the read value is 0xFF. For details of the refresh operation, see section 27.3.3. Refresh Operation.

27.2.2 WDTCR : WDT Control Register

Base address: WDTn = 0x4020_2600 + 0x0100 × n (n = 0, 1)
WDTn_NS = 0x5020_2600 + 0x0100 × n (n = 0, 1)

Offset address: 0x02

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	RPSS[1:0]		—	—	RPES[1:0]		CKS[3:0]				—	—	TOPS[1:0]	
Value after reset:	0	0	1	1	0	0	1	1	1	1	1	1	0	0	1	1

Bit	Symbol	Function	R/W
1:0	TOPS[1:0]	Timeout Period Select 0 0: 1024 cycles (0x03FF) 0 1: 4096 cycles (0x0FFF) 1 0: 8192 cycles (0x1FFF) 1 1: 16384 cycles (0x3FFF)	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
7:4	CKS[3:0]	Clock Division Ratio Select 0 0 0 1: PCLKB/4 0 1 0 0: PCLKB/64 1 1 1 1: PCLKB/128 0 1 1 0: PCLKB/512 0 1 1 1: PCLKB/2048 1 0 0 0: PCLKB/8192 Others: Setting prohibited	R/W
9:8	RPES[1:0]	Window End Position Select 0 0: 75% 0 1: 50% 1 0: 25% 1 1: 0% (do not specify window end position).	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
13:12	RPSS[1:0]	Window Start Position Select 0 0: 25% 0 1: 50% 1 0: 75% 1 1: 100% (do not specify window start position).	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The WDTCR register is used to set the clock division ratio, and window start and end positions for refresh, and the timeout period until the down-counter underflows in register start mode.

Some constraints apply to writes to the WDTCR register. For details, see section 27.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the settings in the WDTCR register are disabled, and the settings in the Option Function Select Register m (OFSm) are enabled (m = 0, 3). The settings for the WDTCR register can also be made in the OFSm register (m = 0, 3). For details, see section 27.3.8. Association Between Option Function Select Register m (OFSm) and WDT Registers (m = 0, 3).

TOPS[1:0] bits (Timeout Period Select)

The TOPS[1:0] bits select the timeout period, the period until the down-counter underflows, from 1024, 4096, 8192, and 16384 cycles, taking the divided clock specified in the CKS[3:0] bits as 1 cycle. After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the number of PCLKB cycles until the counter underflows.

Table 27.2 lists the relationship between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of PCLKB cycles.

Table 27.2 Timeout period settings

CKS[3:0] bits	TOPS[1:0] bits	Clock division ratio	Timeout period (number of cycles)	PCLKB clock cycles
0x1	00b	PCLKB/4	1024	4096
	01b		4096	16384
	10b		8192	32768
	11b		16384	65536
0x4	00b	PCLKB/64	1024	65536
	01b		4096	262144
	10b		8192	524288
	11b		16384	1048576
0xF	00b	PCLKB/128	1024	131072
	01b		4096	524288
	10b		8192	1048576
	11b		16384	2097152
0x6	00b	PCLKB/512	1024	524288
	01b		4096	2097152
	10b		8192	4194304
	11b		16384	8388608
0x7	00b	PCLKB/2048	1024	2097152
	01b		4096	8388608
	10b		8192	16777216
	11b		16384	33554432
0x8	00b	PCLKB/8192	1024	8388608
	01b		4096	33554432
	10b		8192	67108864
	11b		16384	134217728

CKS[3:0] bits (Clock Division Ratio Select)

The CKS[3:0] bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from the PCLKB divided by 4, 64, 128, 512, 2048, and 8192. Combined with the TOPS[1:0] bit setting, this allows the WDT to be configured to a count period between 4096 and 134217728 PCLKB clock cycles.

RPES[1:0] bits (Window End Position Select)

The RPES[1:0] bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. Set the window end position to a value less than the value for the window start position (window start position > window end position). If the window start position is set to a value less than or equal to the window end position, the window start position setting is enabled, and the window end position is set to 0%.

RPSS[1:0] bits (Window Start Position Select)

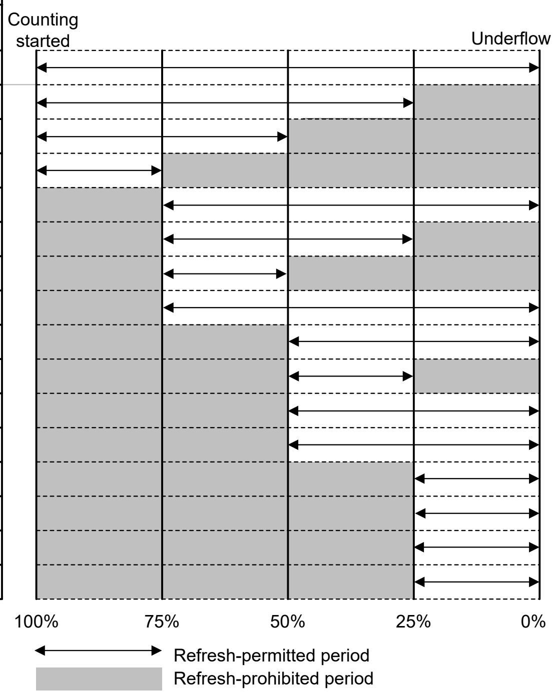
The RPSS[1:0] bits specify the window start position that indicates the refresh-permitted period. 100%, 75%, 50%, or 25% of the timeout period can be selected for the window start position. Set the window start position to a value greater than the value for the window end position. If the window start position is set to a value less than or equal to the window end position, the window start position setting is enabled, and the window end position is set to 0%.

Table 27.3 lists the counter values for the window start and end positions, and Figure 27.2 shows the refresh-permitted period set in the RPSS[1:0], RPES[1:0], and TOPS[1:0] bits.

Table 27.3 Relationship between the timeout period and window start and end counter values

TOPS[1:0]	Timeout period		Window start and end counter value			
	Cycles	Counter value	100%	75%	50%	25%
00b	1024	0x03FF	0x03FF	0x02FF	0x01FF	0x00FF
01b	4096	0x0FFF	0x0FFF	0x0BFF	0x07FF	0x03FF
10b	8192	0x1FFF	0x1FFF	0x17FF	0x0FFF	0x07FF
11b	16384	0x3FFF	0x3FFF	0x2FFF	0x1FFF	0x0FFF

RPSS[1:0] bits		RPES[1:0] bits		Window	
b13	b12	b9	b8	Start (%)	End (%)
1	1	1	1	100	0
		1	0		25
		0	1		50
		0	0		75
1	0	1	1	75	0
		1	0		25
		0	1		50
		0	0		75
0	1	1	1	50	0
		1	0		25
		0	1		50
		0	0		75
0	0	1	1	25	0
		1	0		25
		0	1		50
		0	0		75



Note: If window end position setting ≥ window start position setting, the window end position setting is set to 0%.

Figure 27.2 RPSS[1:0] and RPES[1:0] bits setting and refresh-permitted period

27.2.3 WDTSR : WDT Status Register

Base address: WDTn = 0x4020_2600 + 0x0100 × n (n = 0, 1)
WDTn_NS = 0x5020_2600 + 0x0100 × n (n = 0, 1)

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	REFEF	UNDFF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	CNTVAL[13:0]	Down-Counter Value Value counted by the down-counter	R
14	UNDFF	Underflow Flag 0: No underflow occurred 1: Underflow occurred	R/W*1

Bit	Symbol	Function	R/W
15	REFEF	Refresh Error Flag 0: No refresh error occurred 1: Refresh error occurred	R/W*1

Note: S-TYPE-3, P-TYPE-3
Note 1. Only 0 can be written to clear the flag.

The WDTSR register indicates the counter value of the down-counter and the status of whether an underflow or refresh error occurred in the down-counter.

CNTVAL[13:0] bits (Down-Counter Value)

Read the CNTVAL[13:0] bits to confirm the value of the down-counter. The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the counter. A value of 1 indicates that the down counter underflowed. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N + 1) PCLKB cycles. In addition, clearing of the flag is ignored for (N + 2) PCLKB cycles after an underflow. N is specified as follows:

Auto start mode:

- When OFSm.WDTnCKS[3:0] = 0x1, N = 4
- When OFSm.WDTnCKS[3:0] = 0x4, N = 64
- When OFSm.WDTnCKS[3:0] = 0xF, N = 128
- When OFSm.WDTnCKS[3:0] = 0x6, N = 512
- When OFSm.WDTnCKS[3:0] = 0x7, N = 2048
- When OFSm.WDTnCKS[3:0] = 0x8, N = 8192

Register start mode:

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error occurred, indicating that a refresh operation was performed during a prohibited period. A value of 1 indicates that a refresh error occurred. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N + 1) PCLKB cycles. In addition, clearing of the flag is ignored for (N + 2) PCLKB cycles after a refresh error. N is specified as follows:

Auto start mode:

- When OFSm.WDTnCKS[3:0] = 0x1, N = 4
- When OFSm.WDTnCKS[3:0] = 0x4, N = 64
- When OFSm.WDTnCKS[3:0] = 0xF, N = 128
- When OFSm.WDTnCKS[3:0] = 0x6, N = 512
- When OFSm.WDTnCKS[3:0] = 0x7, N = 2048
- When OFSm.WDTnCKS[3:0] = 0x8, N = 8192

Register start mode:

- When OFSm.WDTnCKS[3:0] = 0x1, N = 4
- When OFSm.WDTnCKS[3:0] = 0x4, N = 64
- When OFSm.WDTnCKS[3:0] = 0xF, N = 128
- When OFSm.WDTnCKS[3:0] = 0x6, N = 512
- When OFSm.WDTnCKS[3:0] = 0x7, N = 2048
- When OFSm.WDTnCKS[3:0] = 0x8, N = 8192

27.2.4 WDTRCR : WDT Reset Control Register

Base address: WDTn = 0x4020_2600 + 0x0100 × n (n = 0, 1)
WDTn_NS = 0x5020_2600 + 0x0100 × n (n = 0, 1)

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RSTIRQS	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	RSTIRQS	WDT Behavior Selection 0: Interrupt 1: Reset	R/W

Note: S-TYPE-3, P-TYPE-3

The WDTRCR register controls reset output by a WDT down-counter underflow or interrupt request output.

Some constraints apply to writes to the WDTRCR register. For details, see section 27.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the WDTRCR register settings are disabled, and the settings in the Option Function Select register m (OFSm) are enabled (m = 0, 3). The settings for the WDTRCR register can also be made for the OFSm register (m = 0, 3). For details, see section 27.3.8. Association Between Option Function Select Register m (OFSm) and WDT Registers (m = 0, 3).

27.2.5 WDTCSTPR : WDT Count Stop Control Register

Base address: WDTn = 0x4020_2600 + 0x0100 × n (n = 0, 1)
WDTn_NS = 0x5020_2600 + 0x0100 × n (n = 0, 1)

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SLCSTP	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	SLCSTP	Sleep-Mode Count Stop Control Register 0: Disable count stop 1: Stop count on transition to Sleep mode or Deep Sleep mode	R/W

Note: S-TYPE-3, P-TYPE-3

The WDTCSTPR register controls whether to stop the WDT counter in Sleep mode or Deep Sleep mode. Some constraints apply to writes to the WDTCSTPR register. For details, see section 27.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the WDTCSTPR register settings are disabled, and the settings in the Option Function Select register m (OFSm) are enabled (m = 0, 3). The settings for the WDTCSTPR register can also be made for the OFSm register (m = 0, 3). For details, see section 27.3.8. Association Between Option Function Select Register m (OFSm) and WDT Registers (m = 0, 3).

SLCSTP bit (Sleep-Mode Count Stop Control Register)

The SLCSTP bit of WDT0 selects whether to stop counting on CPU0 transition to Sleep mode or Deep Sleep mode.

The SLCSTP bit of WDT1 selects whether to stop counting on CPU1 transition to Sleep mode or Deep Sleep mode.

27.2.6 Option Function Select Register

For information on the OFS0 register and the OFS3 register, see section x, Option-Setting Memory.

27.3 Operation

27.3.1 Count Operation in each Start Mode

The WDT has two start modes:

- Auto start mode, in which counting automatically starts after a release from the reset state
- Register start mode, in which counting starts with a refresh by writing to the register.

In auto start mode, counting automatically starts after a release from the reset state according to the settings in the Option Function Select register OFS0 or OFS3/OFS3_SEC in the flash.

In register start mode, counting starts with a refresh by writing to the WDTRR register after the respective registers are set after a release from the reset state.

Select auto start mode or register start mode by setting the Select bit (OFS0.WDT0STRT or OFS3.WDT1STRT).

When the auto start mode is selected, the settings in the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled while the settings in the OFSm register are enabled (m = 0, 3).

When the register start mode is selected, the setting for the OFS0 or OFS3/OFS3_SEC register is disabled while the settings for the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

27.3.1.1 Register Start Mode

When the WDT Start Mode Select bit (OFS0.WDT0STRT or OFS3.WDT1STRT) is 1, register start mode is selected and the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

After the reset state is released, set the following:

- Clock division ratio in the WDTCR register
- Window start and end positions in the WDTCR register
- Timeout period in the WDTCR register
- Reset output or interrupt request output in the WDTRCR register
- Counter stop control during transitions to Sleep mode or Deep Sleep mode in the WDTCSTPR register

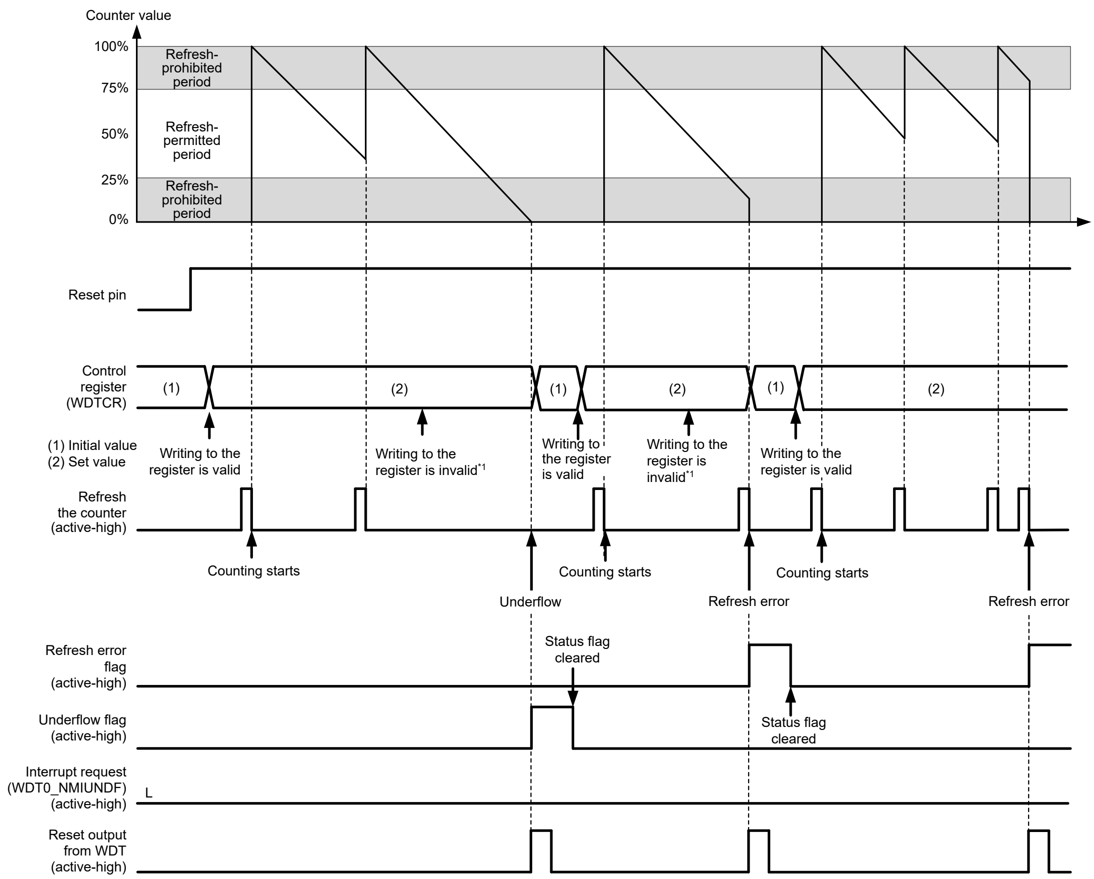
The WDT refresh register (WDTRR) refreshes the down counter. As a result, it starts counting down at the value set by the timeout period selection bit (WDTCR.TOPS[1:0]).

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The WDT does not output the reset signal or non-maskable interrupt request/interrupt request as long as counting continues. However, if the down-counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the WDT outputs the reset signal or a non-maskable interrupt request/interrupt request (WDTn_NMIUNDF) (n = 0, 1). Reset output or interrupt request output can be selected in the WDT Reset Interrupt Request

Select bit (WDTRCR.RSTIRQS). The interrupt enabled for operating the NMI can be selected in the WDT Underflow/ Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 27.3 shows an example of operation under the following conditions:

- Register start mode (OFS0.WDT0STRT or OFS3.WDT1STRT = 1)
- WDT reset interrupt request selection (WDTRCR.RSTIRQS = 1)
- The window start position is 75% (WDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (WDTCR.RPES[1:0] = 10b)



Note: Refreshing the counter requires up to 4 count signal cycles from refresh request to execution.

Note 1. See section 27.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.
Reset pin = RES

Figure 27.3 Operation example in register start mode

27.3.1.2 Auto Start Mode

When the WDT Start Mode Select bit (OFS0.WDT0STRT or OFS3.WDT1STRT = 1) in the Option Function Select Register m (OFSm) is 0, auto start mode is selected, the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled, and the settings in the OFS0 or OFS3 register are enabled.

Within the reset state, the setting values for the following in the Option Function Select Register m (OFS0 or OFS3) are set in the WDT registers:

- Clock division ratio

- Window start and end positions
- Timeout period
- Reset output or interrupt request
- Counter stop control during transition to Sleep mode or Deep Sleep mode

When the reset state is released, the down-counter automatically starts counting down from the value set in the WDT Timeout Period Select bits (OFS0.WDT0STRT[1:0] or OFS3.WDT1STRT[1:0]).

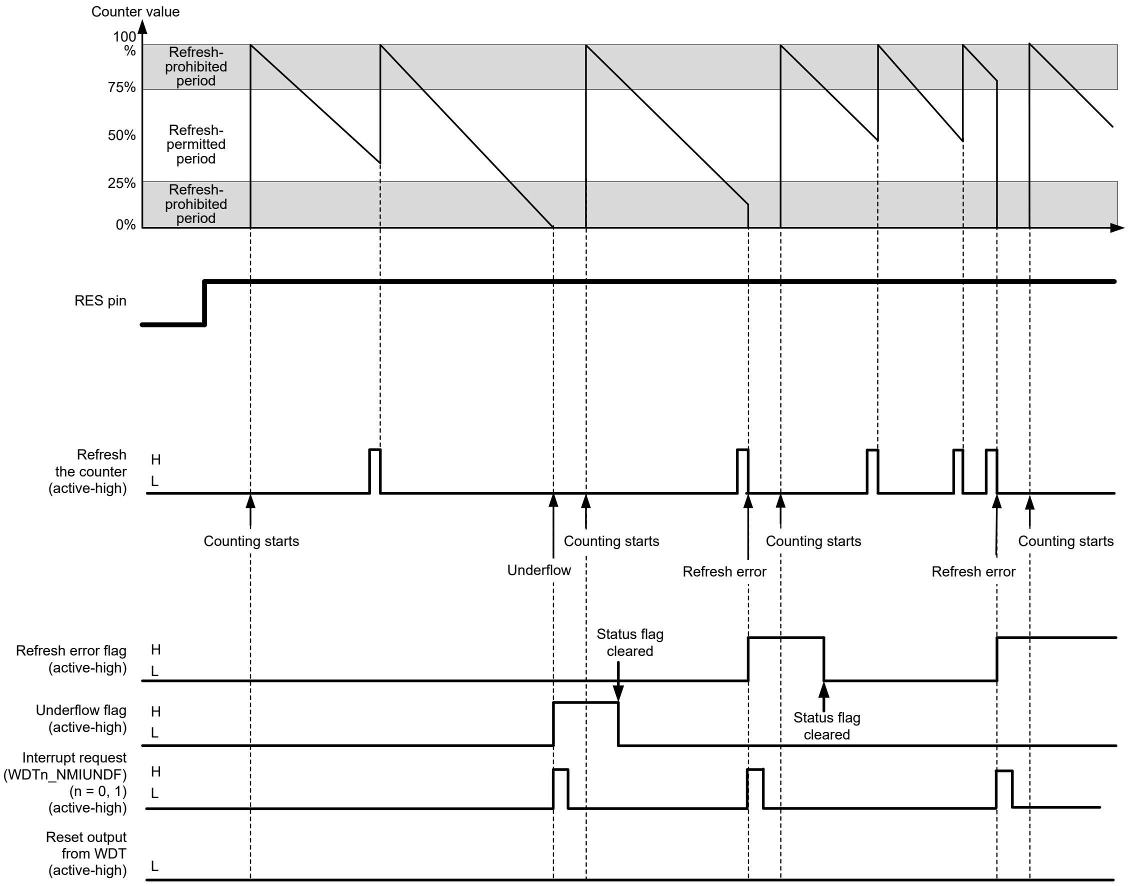
Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The WDT does not output the reset signal or non-maskable interrupt request/interrupt request (WDT_NMIUNDF) as long as the counting continues. However, if the down-counter underflows because refreshing of the down-counter is not possible due to a runaway program or if a refresh error occurs due to refreshing outside the refresh-permitted period, the WDT outputs the reset signal or non-maskable interrupt request/interrupt request (WDTn_NMIUNDF) (n = 0, 1).

After the reset signal or non-maskable interrupt request/interrupt request is generated, the counter reloads the timeout period after counting for 1 cycle. The value of the timeout period is set in the down-counter and counting restarts.

Reset output or interrupt request output can be selected by setting the WDT Reset Interrupt Request Select bit (OFS0.WDT0STRT or OFS3.WDT1STRT = 1). Non-maskable interrupt request or interrupt request can be selected in the WDT Underflow/ Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 27.4 shows an example of operation (non-maskable interrupt) under the following conditions:

- Auto start mode (OFSm.WDTnSTRT = 0) ((m,n) = (0,0), (3,1))
- Non-maskable interrupt request output is enabled (OFSm.WDTnRSTIRQS = 0) ((m,n) = (0,0), (3,1))
- The window start position is 75% (OFSm.WDTnRPSS[1:0] = 10b) ((m,n) = (0,0), (3,1))
- The window end position is 25% (OFSm.WDTnRPES[1:0] = 10b) ((m,n) = (0,0), (3,1))



Note: Refreshing the counter requires up to 4 count signal cycles from refresh request to execution.
Note: Reset pin = RES

Figure 27.4 Operation example in auto start mode

27.3.2 Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers

Writing to the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), or WDT Count Stop Control Register (WDTCSTPR) is possible once each between the release from the reset state and the first refresh operation.

After a refresh (counting starts) or a write to WDTCR, WDTRCR or WDTCSTPR register, the protection signal in the WDT becomes 1 to protect WDTCR, WDTRCR and WDTCSTPR register against subsequent write attempts. This protection is released by the reset source of the WDT. With other reset sources, the protection is not released.

Figure 27.5 shows control waveforms produced in response to writing to the WDTCR.

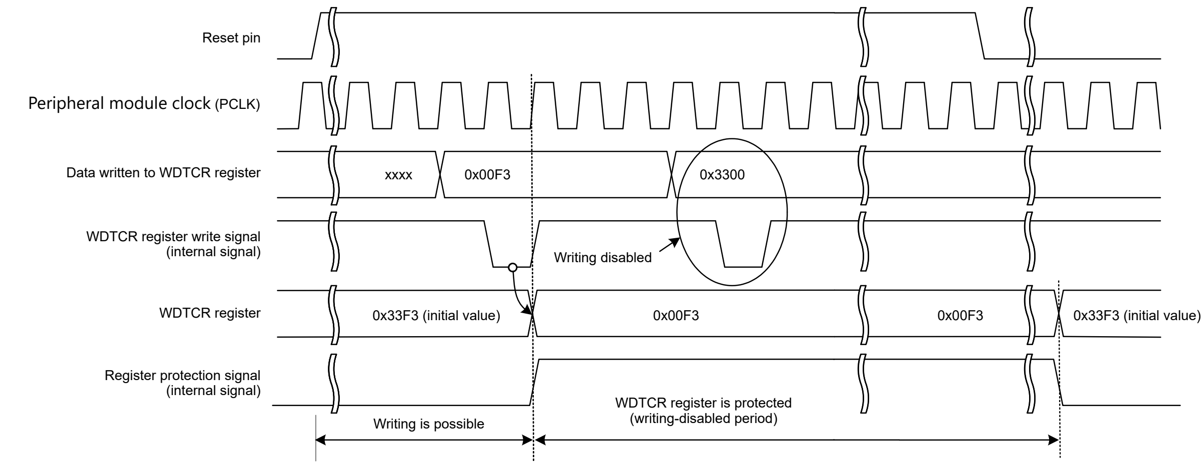


Figure 27.5 Control waveforms produced in response to writes to the WDTCR register

27.3.3 Refresh Operation

To refresh the down counter and start the counting operation, write to the WDT Refresh Register (WDTRR) in the order of values from 0x00 to 0xFF. If a value other than 0xFF is written after 0x00, the down-counter is not refreshed. If an invalid value is written, refreshing is performed normally by writing to the WDTRR register in the order of values from 0x00 to 0xFF.

Correct refreshing is also performed when a register other than WDTRR is accessed or WDTRR is read between writing 0x00 and writing 0xFF to WDTRR. Writes to refresh the counter must be made within the refresh-permitted period, and this is determined by the 0xFF write. For this reason, correct refreshing is performed even when 0x00 is written outside the refresh-permitted period.

[Example write sequences that are valid for refreshing the counter]

- 0x00 → 0xFF
- 0x00 ((n–1)th time) → 0x00 (nth time) → 0xFF
- 0x00 → access to another register or read from WDTRR → 0xFF

[Example write sequences that are invalid for refreshing the counter]

- 0x23 (a value other than 0x00) → 0xFF
- 0x00 → 0x54 (a value other than 0xFF)
- 0x00 → 0xAA (0x00 and a value other than 0xFF) → 0xFF

After 0xFF is written to the WDT Refresh Register (WDTRR), refreshing the down-counter requires up to 4 cycles of the signal for counting. To meet this requirement, complete writing 0xFF to WDTRR 4 count cycles before the down-counter underflows.

Figure 27.6 shows the WDT refresh-operation waveforms when the clock division ratio is PCLKB/64.

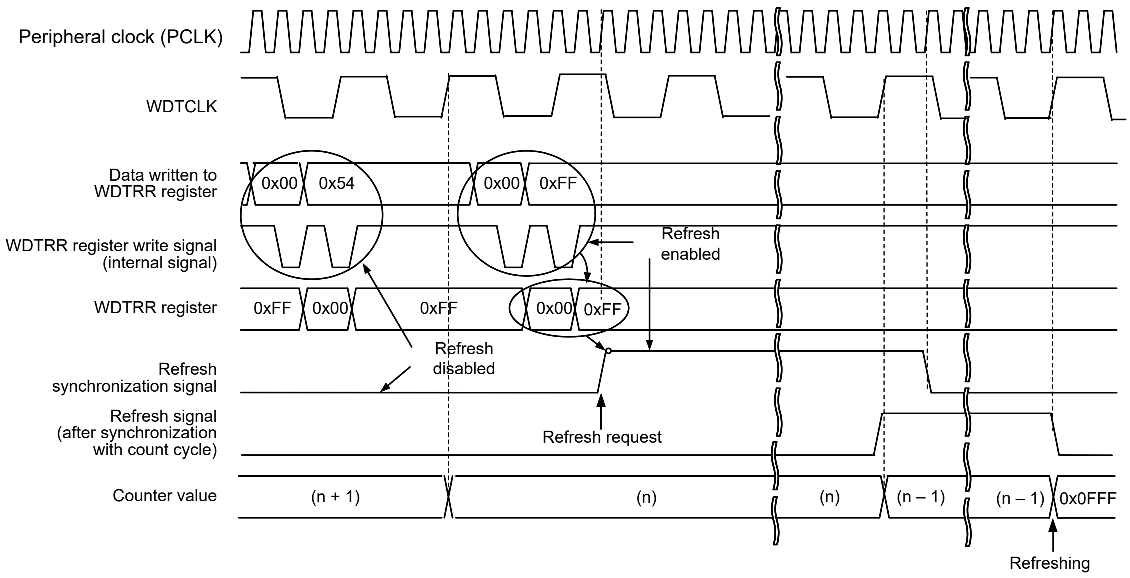

Figure 27.6 WDT refresh operation waveforms when WDTCR.CKS[3:0] = 0x4 and WDTCR.TOPS[1:0] = 01b

Note: When setting the refresh time, consider the oscillation accuracy of the clock sources of the PCLKB and WDTCLK. Set values which ensure that refreshing is possible even when the frequency varies in the range of error of the oscillation accuracy.

27.3.4 Status Flags

The refresh error (WDTSR.REFEF) and underflow (WDTSR.UNDFF) flags retain the source of the interrupt request from the WDT. After a release from the interrupt request generation, read the WDTSR.REFEF and WDTSR.UNDFF flags to check for the interrupt source. For each flag, writing 0 clears the bit. Writing 1 has no effect. Leaving the status flags unchanged does not affect operation. If the flags are not cleared at the next interrupt request from the WDT, the earlier interrupt source is cleared and the new interrupt source is written. For the time period between when 0 is written in each flag and when its value is reflected, see section 27.2.3. WDTSR : WDT Status Register.

27.3.5 Reset Output

When the Reset Interrupt Select bit (WDTRCR.RSTIRQS) is set to 1 in register start mode, or when the WDT Reset Interrupt Request Select bit (OFS0.WDT0RSTIRQS or OFS3.WDT1RSTIRQS) in the Option Function Select Register m (OFS0 or OFS3) is set to 1 in auto start mode, a reset signal is output for 1 cycle count when an underflow in the down-counter or a refresh error occurs.

In register start mode, the down-counter is initialized (all bits set to 0) and stopped in that state after output of a reset signal. After the reset state is released and the program is restarted, the counter is set up again and counting down starts again with a refresh. In auto start mode, counting down starts automatically after the reset state is released.

27.3.6 Interrupt Sources

When the Reset Interrupt Select bit (WDTRCR.RSTIRQS) is set to 0 in register start mode or when the WDT Reset Interrupt Request Select bit (OFS0.WDT0RSTIRQS or OFS3.WDT1RSTIRQS) in the Option Function Select Register m (OFS0 or OFS3) is set to 0 in auto start mode, an interrupt (WDTn_NMIUNDF) signal is generated when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or an interrupt. For details, see section 14, Interrupt Controller Unit (ICU).

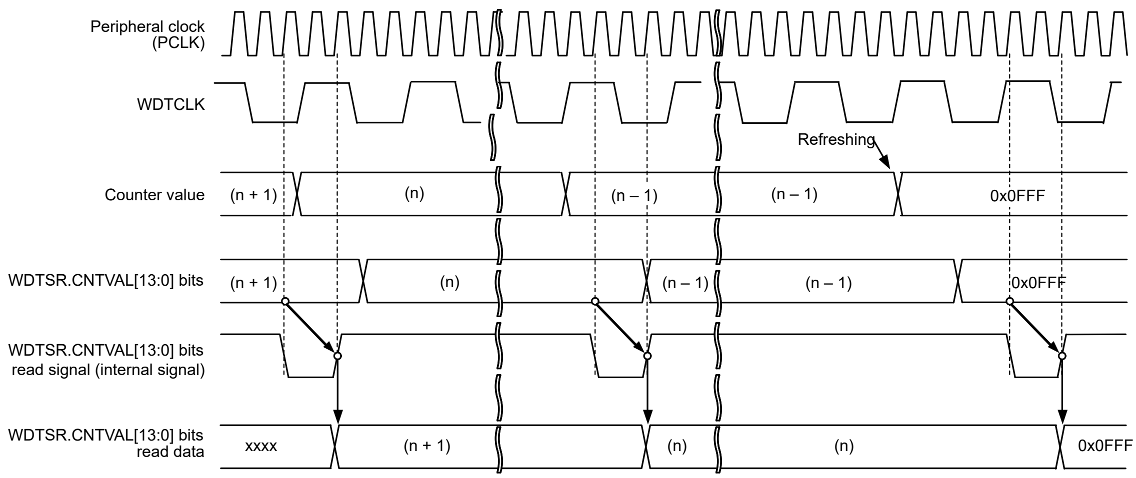
Table 27.4 WDT interrupt source

Name	Interrupt source	Interrupt to CPU	Start DMAC or DTC
WDTn_NMIUNDF (n = 0, 1)	• Down-counter underflow • Refresh error	Possible	Not possible

27.3.7 Reading the Down-Counter Value

The WDT stores the counter value in the down-counter value bits (WDTSR.CNTVAL[13:0]) of the WDT Status Register. Check these bits to obtain the counter value. The read value of the down-counter might differ from the actual count by one.

Figure 27.7 shows the processing for reading the WDT down-counter value when the clock division ratio is PCLKB/64.



Note: PCLK = PCLKB

Figure 27.7 Processing for reading WDT down-counter value when WDTCR.CKS[3:0] = 0x4 and WDTCR.TOPS[1:0] = 01b

27.3.8 Association Between Option Function Select Register m (OFSm) and WDT Registers (m = 0, 3)

Table 27.5 lists the association between the Option Function Select Register m (OFSm) used in auto start mode, and the registers used in register start mode. For details on the Option Function Select Register m (OFSm), see section 27.2.6. Option Function Select Register.

Table 27.5 Association between Option Function Select Register m (OFSm) and the WDT registers

Control target	Function	OFSm register (enabled in auto start mode) OFSm.WDTnSTRT = 0	WDT registers (enabled in register start mode) OFSm.WDTnSTRT = 1
Down-counter	Timeout period selection	OFSm.WDTnTOPS[1:0]	WDTCR.TOPS[1:0]
	Clock division ratio selection	OFSm.WDTnCKS[3:0]	WDTCR.CKS[3:0]
	Window start position selection	OFSm.WDTnRPSS[1:0]	WDTCR.RPSS[1:0]
	Window end position selection	OFSm.WDTnRPES[1:0]	WDTCR.RPES[1:0]
Reset output or interrupt request output	Select a reset interrupt request	OFSm.WDTnRSTIRQS	WDTRCR.RSTIRQS
Count stop	Sleep mode or Deep Sleep mode count stop control	OFSm.WDTnSTPCTL	WDTCSTPR.SLCSTP

27.4 Output to the Event Link Controller (ELC)

The WDT is capable of a link operation for the previously specified module when interrupt request signal is used as an event signal by the ELC. The event signal is output by the counter underflow and refresh error. An event signal is output regardless of the setting of the Reset Interrupt Request Select bit (WDTRCR.RSTIRQS) in register start mode or auto start mode. An event signal can also be output when the next interrupt source is generated while the Refresh Error flag (WDTSR.REFEF) or Underflow flag (WDTSR.UNDFF) is 1. For details, see section 19, Event Link Controller (ELC).

27.5 Usage Notes

27.5.1 ICU Event Link Setting Register n (IELSRn) Setting

Setting 0x53 to ICU Event Link Setting Register n (ICU.IELSRn) is prohibited when enabling the WDT reset assertion (OFS0.WDT0RSTIRQS or OFS3.WDT1RSTIRQS = 0 or WDTRCR.RSTIRQS = 0) or when enabling event link operation (ELSRn.ELS[8:0] = 0x93 or 0x94).

28. Independent Watchdog Timer (IWDT)

28.1 Overview

The Independent Watchdog Timer (IWDT) consists of a 14-bit down counter that must be serviced periodically to prevent counter underflow. The IWDT provides functionality to reset the MCU or to generate a non-maskable interrupt or an underflow interrupt. Because the timer operates with an independent clock from CPU clocks (CPUCLK0 and CPUCLK1) and System clock (ICLK), it is particularly useful in returning the MCU to a known state as a fail-safe mechanism when the system runs out of control. The IWDT can be triggered automatically by a reset, underflow, refresh error, or a refresh of the count value in the registers.

The IWDT functions differ from those of the WDT in the following respects:

The divided IWDT clock (IWDTCLK) is used as the count source (not affected by PCLKB)

Table 28.1 lists the IWDT specifications.

Table 28.1 IWDT specifications

Parameter	Specifications
Count source[*1]	IWDT clock (IWDTCLK)
Clock division ratio	Division by 1, 16, 32, 64, 128, or 256
Counter operation	Counting down using a 14-bit down-counter
Conditions for starting the counter	● Auto start mode: Counting automatically starts after a reset or after an underflow or refresh error occurs. ● Register start mode: Counting is started with a refresh by writing to the IWDTRR register. ● Only secure developer can select Auto-start mode or Register-start mode.
Conditions for stopping the counter	● Reset (the down-counter and other registers return to their initial values). ● A counter underflows or a refresh error is generated. ● The debug function of primary CPU is enabled.
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods).
Independent watchdog timer reset sources	● Down-counter underflows ● Refreshing outside the refresh-permitted period (refresh error)
Non-maskable interrupt/interrupt sources	● Down-counter underflows ● Refreshing outside the refresh-permitted period (refresh error)
Reading of the counter value	The down-counter value can be read by the IWDTSR register.
Event link function (output)	● Down-counter underflow event output ● Refresh error event output
Output signal (internal signal)	● Reset output ● Interrupt request output ● CPU Sleep mode, CPU Deep Sleep mode, Software Standby mode and Deep Software Standby mode count stop control output.
Trust Zone Filter	Security and Privilege attribution can be set.

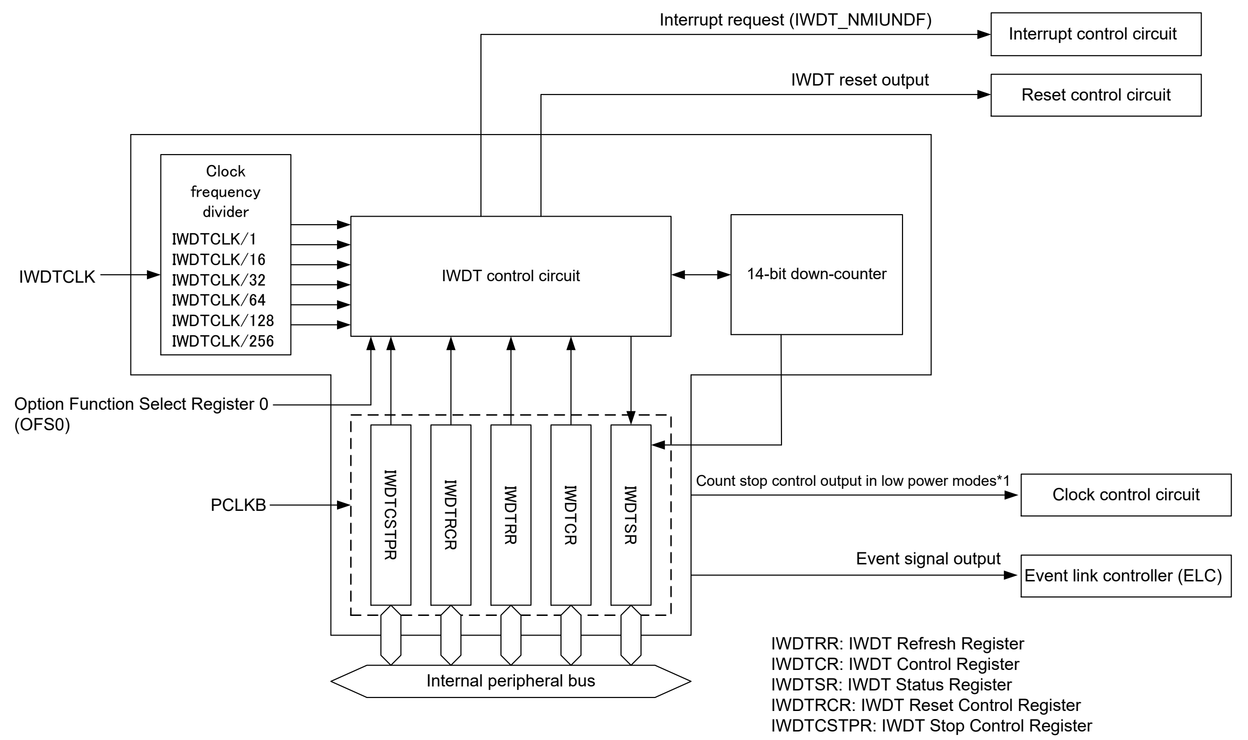
Note 1. Satisfy the frequency of the peripheral module clock (PCLKB) ≧ 32 × (the frequency of the count clock source after division). The bus interface and registers operate with PCLKB, and the 14-bit counter and control circuits operate with IWDTCLK.

28.1.1 Block Diagram

In addition to the peripheral clock (PCLKB), an MCU needs the IWDT clock (IWDTCLK) that does not stop even in low power modes so that the MCU runs even in low power modes in which the peripheral clock (PCLKB) stops. The bus interface and registers operate with the peripheral clock (PCLKB), and the 14-bit down-counter and control circuits operate with the IWDT clock (IWDTCLK).

Signals are connected between the block operating with the peripheral clock (PCLKB) and the block operating with the IWDT clock (IWDTCLK) via a synchronization circuit.

Figure 28.1 shows a block diagram.



Note 1. Low power modes indicate CPU Sleep mode, CPU Deep Sleep mode, Software Standby mode, Deep Software Standby mode 1

Figure 28.1 IWDT block diagram

28.2 Register Specifications

28.2.1 IWDTRR : IWDT Refresh Register

Base address: IWDT = 0x4020_2200
IWDT_NS = 0x5020_2200

Offset address: 0x0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	REFRESH[7:0]							
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	REFRESH[7:0]	Refresh Register The counter is refreshed by writing 0x00 and then writing 0xFF to this register.	R/W

Note: S-TYPE-3, P-TYPE-3

The IWDTRR register refreshes the down-counter of the IWDT.

REFRESH[7:0] bits (Refresh Register)

The down-counter of the IWDT is refreshed by writing 0x00 and then writing 0xFF to IWDTRR(refresh operation) within the refresh-permitted period. After the down-counter is refreshed, it starts counting down from the value selected by the IWDT time-out period selection bits (OFS0.IWDTTOPS[1:0]) in the auto start mode.

In the register start mode, counting down starts from the value set by the TOPS[1:0] bits in the IWDT Control Register (IWDTCR).

Also in the register start mode, counting down starts from the value set by the IWDTCR.TOPS[1:0] bits by the first refresh operation after the release from the reset state.

When 0x00 is written, the read value is always 0x00. When a value other than 0x00 is written, the read value is always 0xFF.

For details of the refresh operation, see section 28.3.3. Refresh Operation.

28.2.2 IWDTCR : IWDT Control Register

Base address: IWDT = 0x4020_2200
IWDT_NS = 0x5020_2200

Offset address: 0x2

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	RPSS[1:0]		—	—	RPES[1:0]		CKS[3:0]				—	—	TOPS[1:0]	
Value after reset:	0	0	1	1	0	0	1	1	1	1	1	1	0	0	1	1

Bit	Symbol	Function	R/W
1:0	TOPS[1:0]	Timeout Period Select 0 0: 128 cycles (0x007F) 0 1: 512 cycles (0x01FF) 1 0: 1024 cycles (0x03FF) 1 1: 2048 cycles (0x07FF) Each value in parentheses () denotes a start value of down-counting.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
7:4	CKS[3:0]	Clock Division Ratio Select 0 0 0 0: IWDTCLK 0 0 1 0: IWDTCLK/16 0 0 1 1: IWDTCLK/32 0 1 0 0: IWDTCLK/64 1 1 1 1: IWDTCLK/128 0 1 0 1: IWDTCLK/256 Other settings are prohibited.	R/W
9:8	RPES[1:0]	Window End Position Select 0 0: 75% 0 1: 50% 1 0: 25% 1 1: 0% (No window end position setting)	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
13:12	RPSS[1:0]	Window Start Position Select 0 0: 25% 0 1: 50% 1 0: 75% 1 1: 100% (No window start position setting)	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The IWDTCR register is used to specify the timeout period (time until the down-counter underflows in the register start mode), clock division ratio, and the window start and end positions of refresh-permitted period. Some restrictions apply to writes to this register. For details, see section 28.3.2. Controlling Writes to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers.

In auto start mode, the settings of this register are disabled and the settings for the option function select register 0 (OFS0) are enabled. The same settings as in the bits in this register can be performed at the option function select register 0 (OFS0). For details, see section 28.3.8. Correspondence Between Option Function Select Register 0 (OFS0) and IWDT Registers.

TOPS[1:0] bits (Timeout Period Select)

The TOPS[1:0] bits select the timeout period, the period until the down-counter underflows, from 128, 512, 1024, and 2048 cycles, taking the divided clock specified in the CKS[3:0] bits as one cycle.

After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the time (number of IWDT clock (IWDTCLK) cycles) until the counter underflows.

section 28.2.2. IWDTCR : IWDT Control Register shows the relationship among the CKS[3:0] and TOPS[1:0] bits settings, the timeout period, and the number of IWDT clock (IWDTCLK) cycles.

Table 28.2 IWDT timeout period settings

CKS[3:0]				TOPS[1:0]		Clock division ratio	Timeout period (Number of cycles)	Number of IWDT clock (IWDTCLK) cycles
0	0	0	0	0	0	IWDTCLK	128	128
				0	1		512	512
				1	0		1024	1024
				1	1		2048	2048
0	0	1	0	0	0	IWDTCLK/16	128	2048
				0	1		512	8192
				1	0		1024	16384
				1	1		2048	32768
0	0	1	1	0	0	IWDTCLK/32	128	4096
				0	1		512	16384
				1	0		1024	32768
				1	1		2048	65536
0	1	0	0	0	0	IWDTCLK/64	128	8192
				0	1		512	32768
				1	0		1024	65536
				1	1		2048	131072
1	1	1	1	0	0	IWDTCLK/128	128	16384
				0	1		512	65536
				1	0		1024	131072
				1	1		2048	262144
0	1	0	1	0	0	IWDTCLK/256	128	32768
				0	1		512	131072
				1	0		1024	262144
				1	1		2048	524288

CKS[3:0] bits (Clock Division Ratio Select)

These bits select IWDT clock (IWDTCLK) division ratio from among division by 1, 16, 32, 64, 128, and 256.

Combined with the TOPS[1:0] bits setting, a count period between 128 and 524288 cycles of the IWDT clock (IWDTCLK) can be selected for the IWDT.

Note: In order to read the down-counter value correctly, the relationship between the peripheral clock (PCLKB) frequency and the count clock (IWDTCLK) frequency must be set appropriately. For the setting, see Note1 in Table 28.1

RPES[1:0] bits (Window End Position Select)

These bits select 75%, 50%, 25% or 0% of the count period for the window end position of the down-counter. The selected window end position should be a value smaller than the value for the window start position (that is, window start position > window end position). If the value for the window end position is greater than the value for the window start position, only the value for the window start position is effective.

The counter values for the window start and end positions selected by setting the RPES[1:0] and RPSS[1:0] bits change depending on the TOPS[1:0] bits setting.

Table 28.3 lists the counter values for the window start and end positions corresponding to TOPS[1:0] bits values.

Table 28.3 Relationship between timeout periods and window start and end counter values

TOPS[1:0]		Timeout period		Window start and end counter value			
		Number of cycles	Counter value	100%	75%	50%	25%
0	0	128	0x007F	0x007F	0x005F	0x003F	0x001F
0	1	512	0x01FF	0x01FF	0x017F	0x00FF	0x007F
1	0	1024	0x03FF	0x03FF	0x02FF	0x01FF	0x00FF
1	1	2048	0x07FF	0x07FF	0x05FF	0x03FF	0x01FF

RPSS[1:0] bits (Window Start Position Select)

These bits select a counter window start position from 100%, 75%, 50%, or 25% of the count period (100% when the count starts and 0% when the counter underflows). The interval between the window start position and window end position is the refresh-permitted period and the other periods are refresh-prohibited periods.

Figure 28.2 shows the relationship between the RPSS[1:0] and RPES[1:0] bits settings and the refresh-permitted and refresh-prohibited periods.

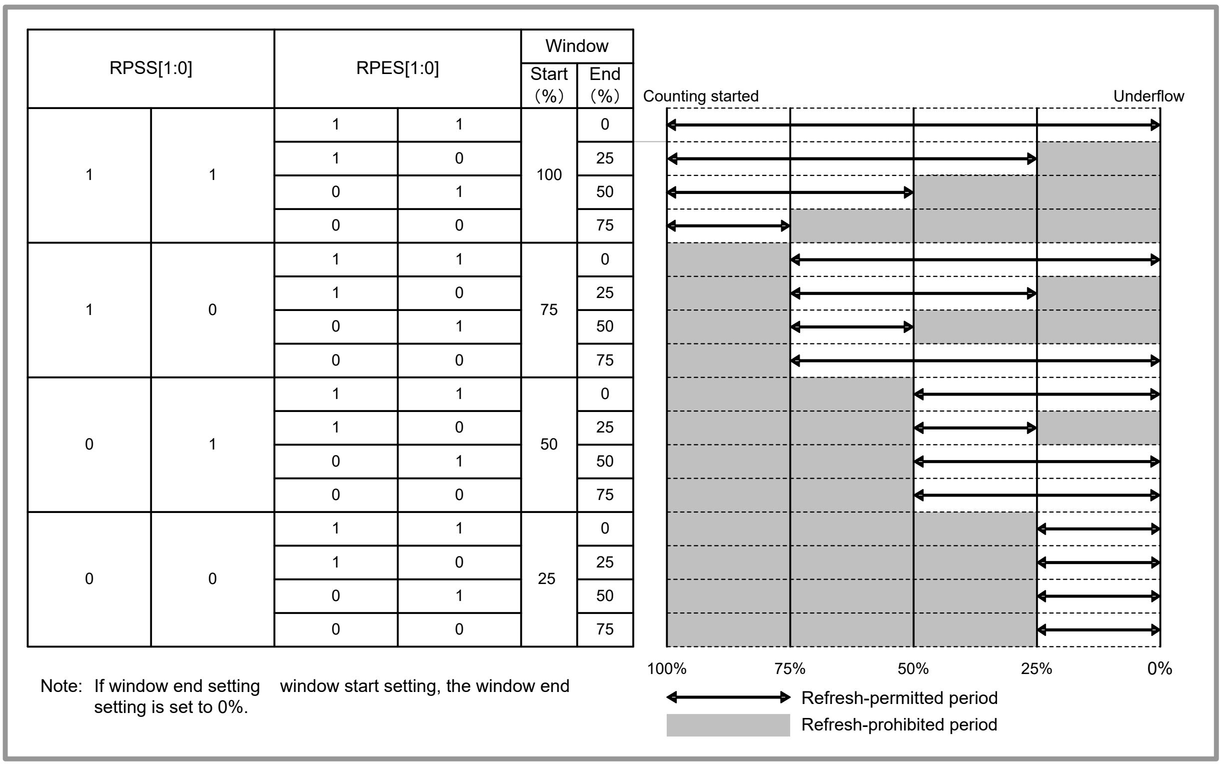


Figure 28.2 RPSS[1:0] and RPES[1:0] bits settings and refresh-permitted and refresh-prohibited periods

28.2.3 IWDTSR : IWDT Status Register

Base address: IWDT = 0x4020_2200
IWDT_NS = 0x5020_2200

Offset address: 0x4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	REFEF	UNDFF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	CNTVAL[13:0]	Down-Counter Value Counter value of the down-counter	R
14	UNDFF	Underflow Flag 0: No underflow occurred. 1: Underflow occurred.	R/W
15	REFEF	Refresh Error Flag 0: No refresh error occurred. 1: Refresh error occurred.	R/W

Note: S-TYPE-3, P-TYPE-3

The IWDTSR register indicates the counter value of the down-counter and whether an underflow or refresh error occurred in the down-counter.

It is initialized by the reset source of the IWDT. IWDTSR is not initialized by other reset sources.

CNTVAL[13:0] bits (Down-Counter Value)

Read these bits to confirm the counter value of the down-counter.

Note: The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the down-counter.

A value of 1 indicates that the down-counter underflowed. A value of 0 indicates that the down-counter has not underflowed.

Write 0 to the UNDFF flag to clear the value. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N + 2) IWDTCLK cycles and 32 PCLKB cycles. In addition, clearing of this flag is ignored for (N + 2) IWDTCLK cycles after an underflow. N is specified as follows:

Auto start mode:

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128
- When OFS0.IWDTCKS[3:0] = 0x5, N = 256

Register start mode:

- When IWDTCR.CKS[3:0] = 0x0, N = 1
- When IWDTCR.CKS[3:0] = 0x2, N = 16
- When IWDTCR.CKS[3:0] = 0x3, N = 32
- When IWDTCR.CKS[3:0] = 0x4, N = 64
- When IWDTCR.CKS[3:0] = 0xF, N = 128
- When IWDTCR.CKS[3:0] = 0x5, N = 256

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error (a refresh operation was performed during the prohibited period) occurred.

A value of 1 indicates that a refresh error occurred. A value of 0 indicates that no refresh error has occurred.

Write 0 to the REFEF flag to clear the value. Writing 1 has no effect.

Clearing of the REFEF flag takes (N + 2) IWDTCLK cycles and 32 PCLKB cycles. In addition, clearing of this flag is ignored for (N + 2) IWDTCLK cycles following a refresh error. N is specified as follows:

Auto start mode:

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128
- When OFS0.IWDTCKS[3:0] = 0x5, N = 256

Register start mode:

- When IWDTCR.CKS[3:0] = 0x0, N = 1
- When IWDTCR.CKS[3:0] = 0x2, N = 16
- When IWDTCR.CKS[3:0] = 0x3, N = 32
- When IWDTCR.CKS[3:0] = 0x4, N = 64
- When IWDTCR.CKS[3:0] = 0xF, N = 128
- When IWDTCR.CKS[3:0] = 0x5, N = 256

28.2.4 IWDTRCR : IWDT Reset Control Register

Base address: IWDT = 0x4020_2200
IWDT_NS = 0x5020_2200

Offset address: 0x6

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RSTIRQS	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	RSTIRQS	Reset Interrupt Request Select 0: Enable non-maskable interrupt requests or interrupt request output. 1: Enable reset output.	R/W

Note: S-TYPE-3, P-TYPE-3

IWDTRCR register controls the reset output or interrupt request output when the down-counter of the IWDT underflows. Some restrictions apply to writes to this register. For details, see section 28.3.2. Controlling Writes to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers.

In auto start mode, the settings of this register are disabled and the settings for the input ports (OFS0) are enabled. The same settings as in the bits in this register can be performed at the input ports (OFS0). For details, see section 28.3.8. Correspondence Between Option Function Select Register 0 (OFS0) and IWDT Registers.

RSTIRQS bit (Reset Interrupt Request Select)

The RSTIRQS bit selects the reset output or interrupt request output when the down-counter underflows or a refresh error occurs.

28.2.5 IWDTCSTPR : IWDT Count Stop Control Register

Base address: IWDT = 0x4020_2200
IWDT_NS = 0x5020_2200

Offset address: 0x8

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SLCSTP	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	—	This bit is read as 0.	R
7	SLCSTP	CPU Sleep-Mode Count Stop Select 0: Disable count stop. 1: Stop the counter when the primary CPU enters CPU Sleep mode or CPU Deep Sleep mode, and when the MCU enters Software Standby mode or Deep Software Standby mode 1.	R/W

Note: S-TYPE-3, P-TYPE-3

The IWDTCSTPR register is used to stop the down-counter of the IWDT in case the primary CPU enters low-power modes. Some restrictions apply to writes to this register. For details, see section 28.3.2. Controlling Writes to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers.

In auto start mode, the settings of this register are disabled and the settings for the option function select register 0 (OFS0) are enabled. The same settings as in the bits in this register can be performed at the option function select register 0 (OFS0). For details, see section 28.3.8. Correspondence Between Option Function Select Register 0 (OFS0) and IWDT Registers.

SLCSTP bit (CPU Sleep-Mode Count Stop Select)

The SLCSTP bit selects whether to stop the counter in case the primary CPU enters CPU Sleep mode or CPU Deep Sleep mode, and the MCU enters Software Standby mode or Deep Software Standby mode 1.

28.3 Operation

28.3.1 Count Operation in Each Start Mode

The start mode of the IWDT is selected by setting the IWDT start mode selection (OFS0.IWDTSTRT) bit during a reset.

When the IWDT start mode selection (OFS0.IWDTSTRT) bit is 1 (register start mode), the IWDT Control Register (IWDTCR), IWDT Reset Control Register (IWDTRCR), and IWDT Count Stop Control Register (IWDTCSTPR) are enabled, and counting is started by writing to the IWDT Refresh Register (IWDTRR) to refresh the counter. When the IWDT start mode selection (OFS0.IWDTSTRT) bit is 0 (auto start mode), the settings of the option function select register 0 (OFS0) are enabled, and counting automatically starts after a reset.

(1) Register start mode

When the register start mode is selected by setting the IWDT start mode selection (OFS0.IWDTSTRT) bit to 1 during a reset, the IWDT Control Register (IWDTCR), IWDT Reset Control Register (IWDTRCR), and IWDT Count Stop Control Register (IWDTCSTPR) are enabled.

After the reset state is released, set the clock division ratio, window start and end positions, and timeout period in the IWDTCR register, the reset output or interrupt request output in the IWDTRCR register, and the IWDT down-counter stop control at transitions to low power modes in the IWDTCSTPR register. Then, refresh the down-counter to set the value specified by the IWDTCR.TOPS[1:0] bits in the counter and start counting down.

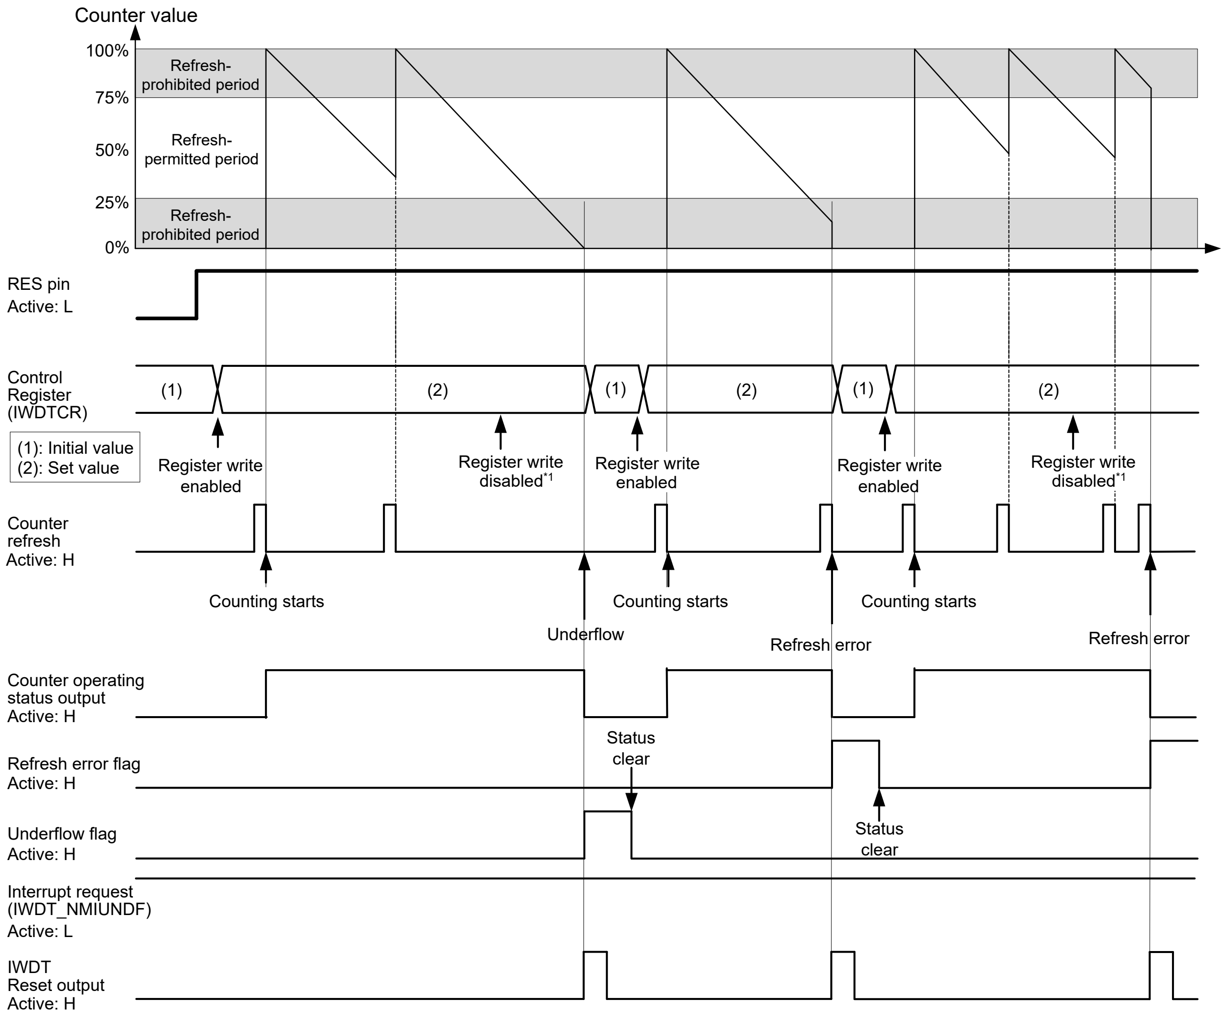
After that, as long as the program continues normal operation and the counter is refreshed in the refresh permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The IWDT does not output a reset signal as long as this continues.

However, if the down counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the IWDT outputs a reset signal or a non-maskable interrupt request (IWDT_NMIUNDF).

The reset output or interrupt request output is selected by setting the IWDTRCR.RSTIRQS bit.

Figure 28.3 shows an example of operation under the following conditions:

- Register start mode (OFS0.IWDTSTRT = 1)
- Reset output is enabled (IWDTRCR.RSTIRQS = 1)
- The window start position is 75% (IWDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (IWDTCR.RPES[1:0] = 10b)



Note 1. See section 28.3.2. Controlling Writes to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers

Figure 28.3 Operation example in register start mode

(2) Auto start mode

When the auto start mode is selected by setting the IWDT start mode selection (OFS0.IWDTSTRT) bit to 0 during a reset, the IWDT Control Register (IWDTCR), IWDT Reset Control Register (IWDTRCR), and IWDT Count Stop Control Register (IWDTCSTPR) are disabled.

During a reset, the clock division ratio, window start and end positions, timeout period, reset output or interrupt request output, and counter stop control at transitions to low power modes should be set through the option function select register 0

(OFS0). Then, when the reset state is released, the timeout period set through the option function select register 0 (OFS0) is set in the down-counter, and then the down-counter automatically starts counting down.

After that, as long as the program continues normal operation and the counter is refreshed in the refresh permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The IWDT does not output a reset signal as long as this continues.

However, if the down-counter underflows because the down counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the IWDT outputs a reset signal or a non-maskable interrupt request (IWDT_NMIUNDF).

The reset output or interrupt request output is selected by setting the IWDT reset interrupt request select bit (OFS0.IWDTRSTIRQS).

Figure 28.4 shows an example of operation under the following conditions:

- Auto start mode (OFS0.IWDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.IWDTRSTIRQS = 0)
- The window start position is 75% (OFS0.IWDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.IWDTRPES[1:0] = 10b)

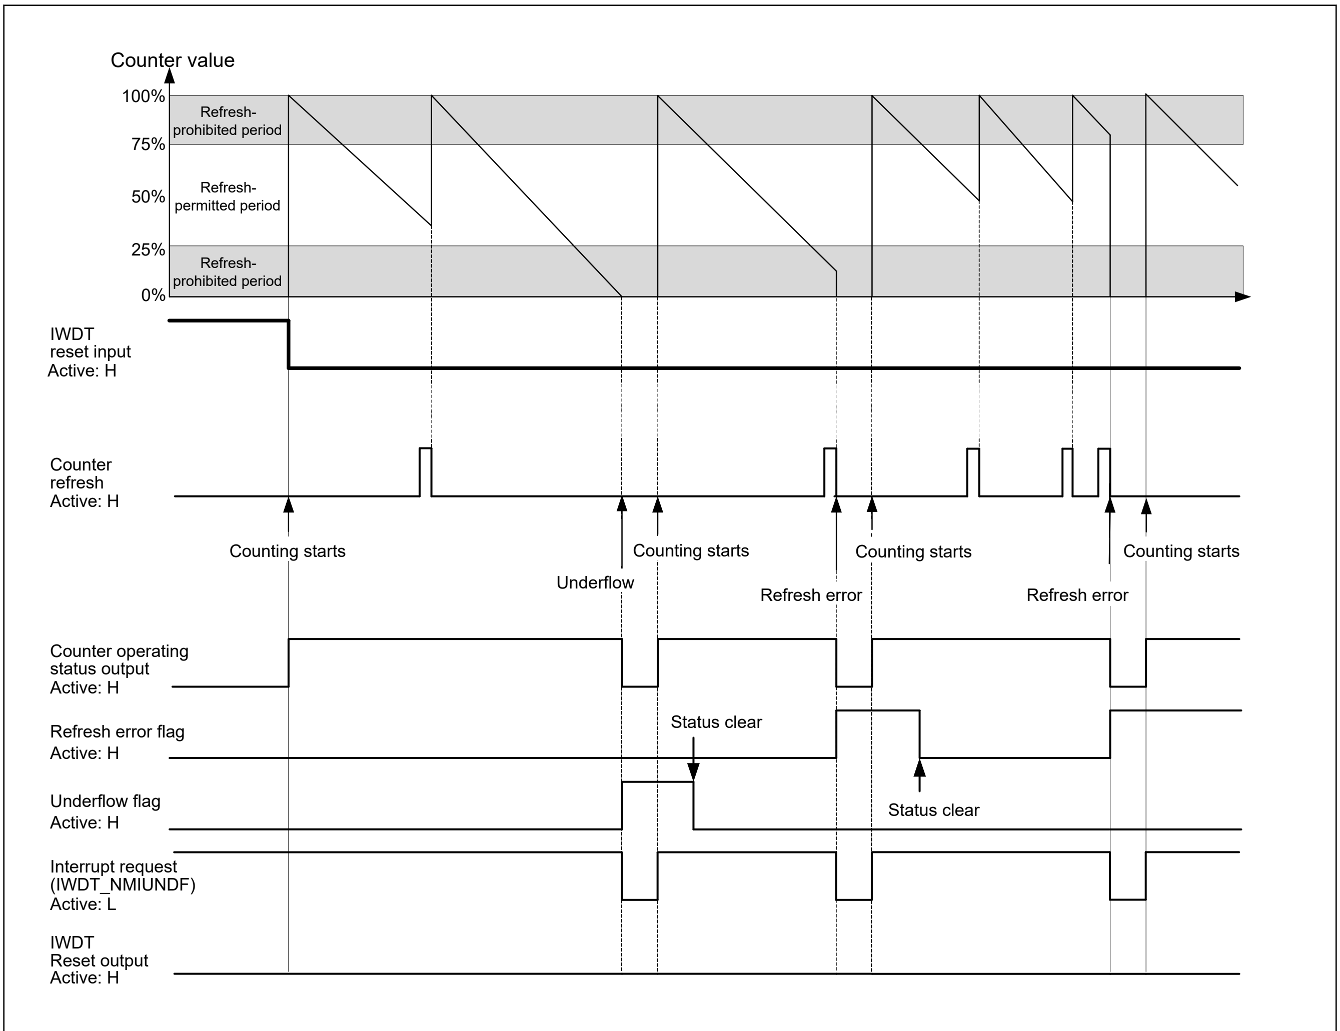


Figure 28.4 Operation example in auto start mode

28.3.2 Controlling Writes to the IWDTCR, IWDTRCR, and IWDTCSTPR Registers

Writing to the IWDT Control Register (IWDTCR) is possible only once between the release from the reset state and the first refresh operation.

After a refresh operation (counting starts) or by writing to the IWDTCR register, the protection signal in the IWDT becomes 1 to protect the IWDTCR register against subsequent attempts of writing.

The IWDT Reset Control Register (IWDTRCR) and the IWDT Count Stop Control Register (IWDTCSTPR) are also controlled in the same way.

This protection is released by a reset source to the IWDT. With other reset sources, the protection is not released.

Figure 28.5 shows control waveforms produced in response to writing to the IWDTCR register.

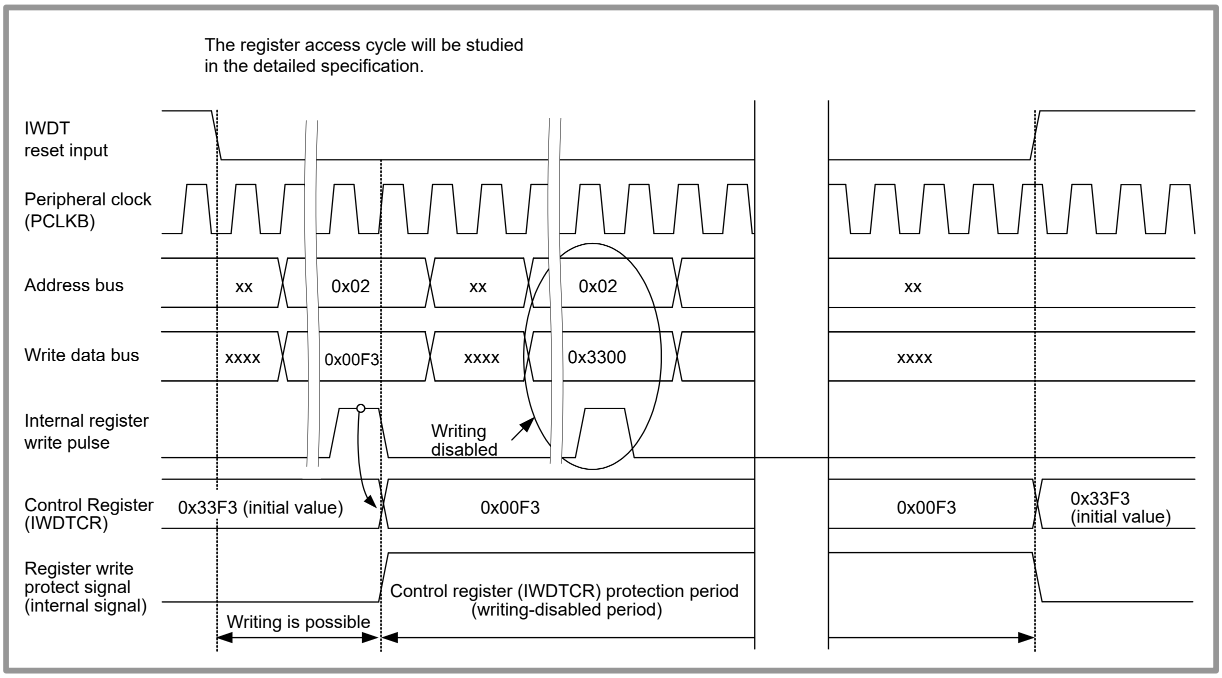

Figure 28.5 Control waveforms produced in response to writes to the IWDTCR register

28.3.3 Refresh Operation

The down-counter is refreshed and starts operation (counting is started by refreshing) by writing the values 0x00 and then 0xFF to the IWDT Refresh Register (IWDTRR). If a value other than 0xFF is written after 0x00, the counter is not refreshed. After such invalid writing, correct refreshing is performed by writing 0x00 and then 0xFF again to the IWDT Refresh Register (IWDTRR).

When writing is done in the order of 0x00 (first time) → 0x00 (second time), and if 0xFF is written after that, the writing order 0x00 → 0xFF is satisfied; writing 0x00 ((n–1) th time) → 0x00 (nth time) → 0xFF is valid and correct refreshing will be done. Even when the first value written before 0x00 is not 0x00, correct refreshing will be done if the operation contains the sequence of writing 0x00 → 0xFF. Correct refreshing is also performed when a register other than IWDTRR is accessed or IWDTRR is read between writing 0x00 and writing 0xFF to IWDTRR.

[Example write sequences that are valid for refreshing the counter]

- 0x00 → 0xFF
- 0x00 ((n-1) th time) → 0x00 (nth time) → 0xFF
- 0x00 → access to another register or read from IWDTRR → 0xFF

[Example write sequences that are invalid for refreshing the counter]

- 0x23 (a value other than 0x00) → 0xFF
- 0x00 → 0x54 (a value other than 0xFF)
- 0x00 → 0xAA (0x00 and a value other than 0xFF) → 0xFF

Even when 0x00 is written to IWDTRR outside the refresh-permitted period, if 0xFF is written to IWDTRR in the refresh-permitted period, the writing sequence is valid and refreshing will be done.

After 0xFF is written to the IWDTRR register, refreshing the counter requires up to four cycles of the signal for counting (the clock division ratio select bits (IWDTCR.CKS[3:0]) determine how many cycles of the IWDT clock (IWDTCLK) make up one cycle for counting).

Therefore, writing 0xFF to the IWDTRR register should be completed four count cycles before the end position of the refresh-permitted period or the down-counter underflow. The value of the down-counter can be checked using the down-counter value bits (IWDTSR.CNTVAL[13:0]).

[Example refreshing timings]

- When the window start position is set to 0x03FF, even if 0x00 is written to IWDTRR before 0x03FF is reached (at 0x0402, for example), refreshing occurs if 0xFF is written to the IWDTRR register after the value of the IWDTSR.CNTVAL[13:0] bits reaches 0x03FF.
- When the window end position is set to 0x03FF, refreshing is done if 0x0403 (four count cycles before 0x03FF) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 0x00 → 0xFF to the IWDTRR register.
- When the refresh-permitted period continues until count 0x0000, refreshing can be done immediately before an underflow. In this case, if 0x0003 (four count cycles before an underflow) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 0x00 → 0xFF to the IWDTRR register, no underflow occurs and refreshing is done.

Figure 28.6 shows the IWDT refresh operation waveforms when the peripheral clock (PCLKB) > IWDT clock (IWDTCLK) and the clock division ratio = IWDTCLK/1. Figure 28.7 shows the IWDT refresh operation waveforms when the peripheral clock (PCLKB) < IWDT clock (IWDTCLK) and the clock division ratio = IWDTCLK/16.

When transitioning to Software Standby mode or Deep Software Standby mode 1, the refresh procedure must be completed and the read value of the IWDTRR register must be 0xFF before the transitioning (Write 0xFF after writing 0x00 to the IWDTRR register, and confirm that the read value of the IWDTRR register is 0xFF).

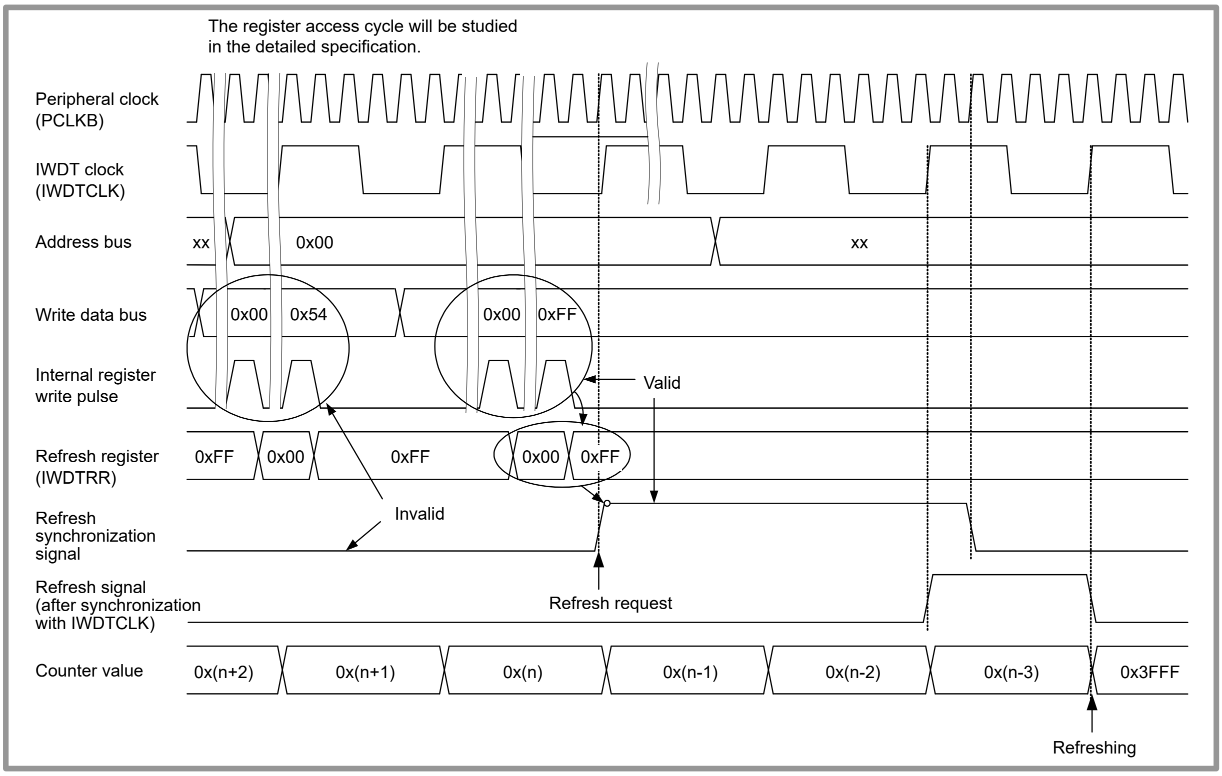

Figure 28.6 IWDT refresh operation waveforms (IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b)

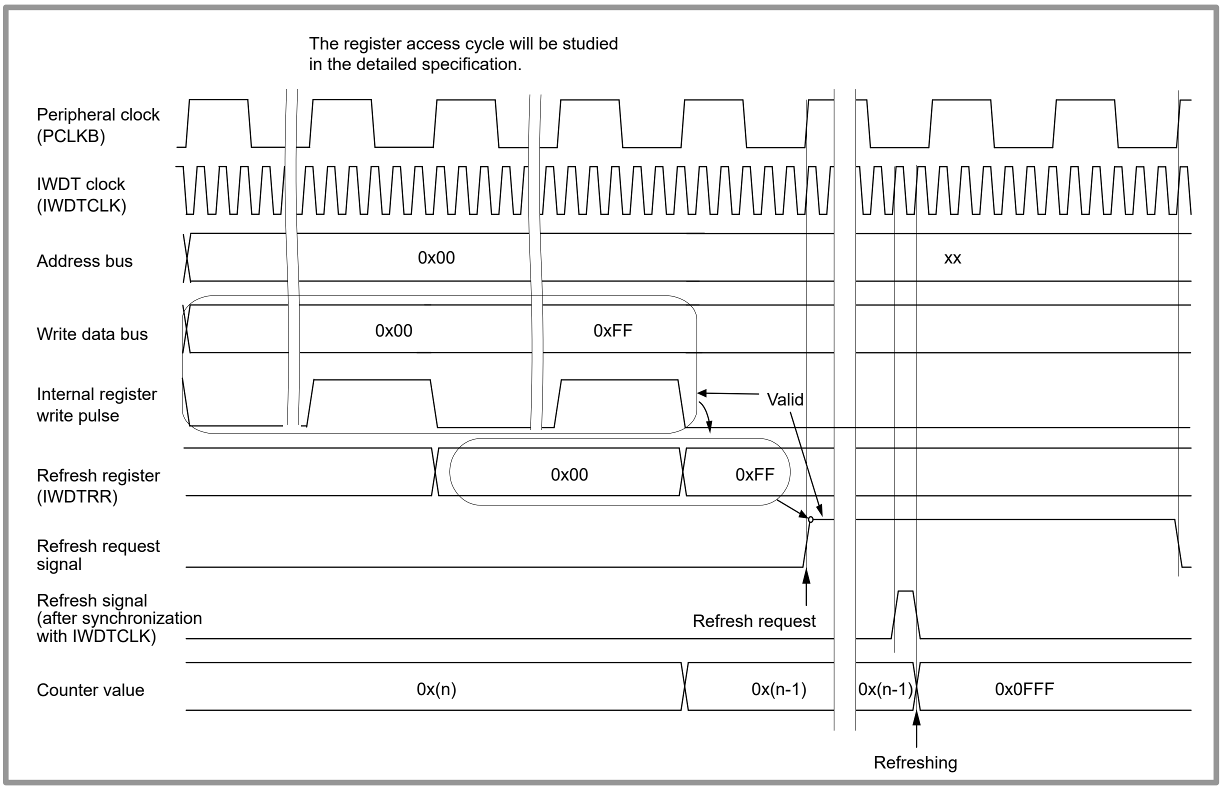

Figure 28.7 IWDT refresh operation waveforms (IWDTCR.CKS[3:0] = 0010b, IWDTCR.TOPS[1:0] = 01b)

28.3.4 Status Flags

The refresh error flag (IWDTSR.REFEF) and underflow flag (IWDTSR.UNDFF) retain the source of the reset output from the IWDT or the source of the interrupt request from the IWDT.

Thus, after release from the reset state or interrupt request generation, read the IWDTSR.REFEF and IWDTSR.UNDFF flags to check for the reset or interrupt source.

For each flag, writing 0 clears the bit and writing 1 has no effect.

Leaving each flag unchanged does not affect operation. If the flags are not cleared, the earlier reset or interrupt source is cleared and the new reset or interrupt source is written when the IWDT outputs a reset signal next.

28.3.5 Reset Output

When the reset interrupt select bit (IWDTRCR.RSTIRQS) is set to 1 in register start mode or when the IWDT reset interrupt request select bit (OFS0.IWDTRSTIRQS) is set to 1 in auto start mode, a reset signal is output for one count cycle when the down counter overflows or a refresh error occurs. In register start mode, the down counter is initialized (all bits set to 0) and kept in that state after assertion of the reset signal. After the reset is released and the program is restarted, the counter is set up again and counting down is started by refreshing. In auto start mode, counting down automatically starts after the reset output.

28.3.6 Interrupt Sources

When the reset interrupt select bit (IWDTRCR.RSTIRQS) is set to 0 in register start mode or when the IWDT reset interrupt request select bit (OFS0.IWDTRSTIRQS) is set to 0 in auto start mode, a non-maskable interrupt (IWDT_NMIUNDF) is generated for one-count cycle when the down-counter overflows or a refresh error occurs.

28.3.7 Reading the Down-counter Value

Because the down-counter in the IWDT operates on the IWDT clock (IWDTCLK), the counter value cannot be read directly.

Therefore, the IWDT synchronizes the counter value with the peripheral clock (PCLKB) and stores it in the down-counter value bits (CNTVAL[13:0]) of the IWDT Status Register (IWDTSR). The counter value can be checked indirectly by reading the value stored in the IWDTSR.CNTVAL[13:0] bits.

Reading the counter value requires multiple peripheral clock (PCLKB) cycles (up to four clock cycles), and the read counter value may differ from the actual counter value by a value of one count.

Figure 28.8 shows the processing for reading the IWDT counter value when the peripheral clock (PCLKB) > IWDT clock (IWDTCLK) and the clock division ratio = IWDTCLK/1. Figure 28.9 shows the processing for reading the IWDT counter value when the peripheral clock (PCLKB) < IWDT clock (IWDTCLK) and the clock division ratio = IWDTCLK/16.

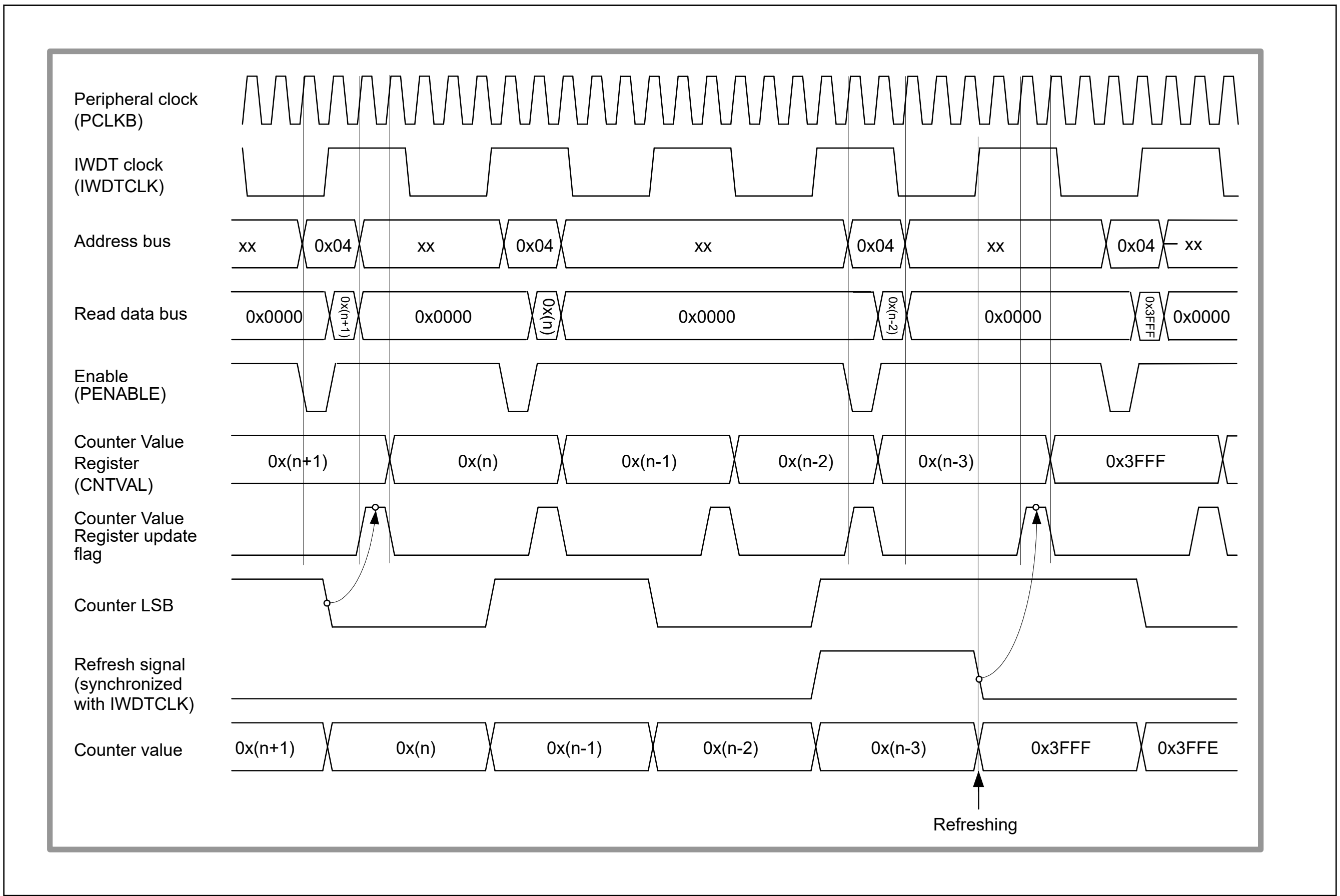

Figure 28.8 Processing for reading IWDT counter value when IWDTCR.CKS[3:0] = 0000b and IWDTCR.TOPS[1:0] = 11b

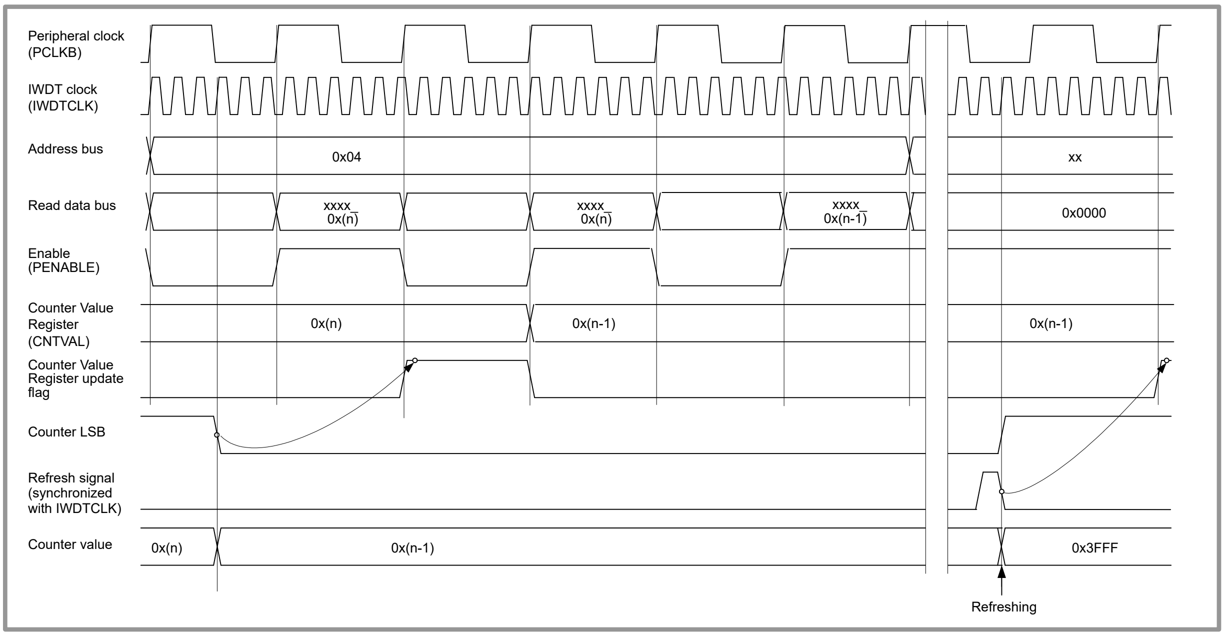

Figure 28.9 Processing for reading IWDT counter value when IWDTCR.CKS[3:0] = 0010b and IWDTCR.TOPS[1:0] = 11b

28.3.8 Correspondence Between Option Function Select Register 0 (OFS0) and IWDT Registers

Table 28.4 lists the correspondence between the option function select register 0 (OFS0) and the IWDT registers (IWDT control register (IWDTCR), IWDT reset control register (IWDTRCR), and IWDT count stop control register (IWDTCSTPR)) regarding control of the down-counter, reset or interrupt request output, and count stop function.

Control can be switched between the option function select register 0 (OFS0) and the IWDT registers (IWDTCR, IWDTRCR, and IWDTCSTPR) through the setting of the IWDT start mode selection (OFS0.IWDTSTRT) bit.

Note that the option function select register 0 (OFS0) setting should be kept unchanged during IWDT operation.

Table 28.4 Association between Option Function Select Register 0 (OFS0) and the IWDT register

Control	Function	OFS0 register (enabled in auto start mode) OFS0.IWDTSTRT = 0	IWDT register (enabled in register start mode) OFS0.IWDTSTRT = 1
Down-counter	Timeout period selection	OFS0.IWDTTOPS[1:0]	IWDTCR.TOPS[1:0]
	Clock division ratio selection	OFS0.IWDTCKS[3:0]	IWDTCR.CKS[3:0]
	Window start position selection	OFS0.IWDTRPSS[1:0]	IWDTCR.RPSS[1:0]
	Window end position selection	OFS0.IWDTRPES[1:0]	IWDTCR.RPES[1:0]
Reset output/ interrupt request output	Reset output/ interrupt request output select	OFS0.IWDTRSTIRQS	IWDTRCR.RSTIRQS
Stop the counter	CPU Sleep-mode count stop selection	OFS0.IWDTSTPCTL	IWDTCSTPR.SLCSTP

28.4 Link Operation by the Event Link Function

The IWDT is capable of link operation for a specified module when an interrupt request signal is used as an event signal. The IWDT outputs an event signal on an underflow of the down-counter or generation of a refresh error.

It outputs an event signal regardless of the setting of the reset interrupt request select bit (IWDTRCR.RSTIRQS) in register start mode or the IWDT reset interrupt request select bit (OFS0.IWDTRSTIRQS) in auto start mode. It can output an event signal at generation of the next interrupt source while retaining the refresh error flag (IWDTSR.REFEF) or underflow flag (IWDTSR.UNDFF).

28.5 Usage Notes

28.5.1 Transitioning to Low Power Mode

The refresh procedure must be completed before transitioning to low power mode. For details, see section 28.3.3. Refresh Operation.

28.5.2 Restriction on reading the counter value after returning from Deep Software Standby mode 1

After returning from Deep Software Standby mode 1, the counter value may not be read correctly and may read 0. To read the correct counter value after returning from Deep Software Standby mode 1, one of the following is required:

- Discard the read value until a value other than 0 is read.
- Wait one countdown period before reading the counter value.
- Refresh the counter when the refresh-permitted period is set to 100%.

29. Layer 3 Ethernet Switch Module (ESWM)

29.1 Overview

The Layer 3 Ethernet Switch Module (ESWM) consists of an Ethernet switch with higher-level routing capability and multi-protocol interface support. It allows autonomous frame routing within the same and between different network interface protocols (for now only Ethernet) for optimized gateway applications.

Table 29.1 lists the ESWM specifications and Figure 29.1 shows the ESWM block diagram.

Table 29.1 ESWM specifications

Item	Function		Specification
Basic function	PHY interface	Number or port	2 ports
		Type	MII, RMII, GMII, RGMII
		Speed	10 Mbps,100 Mbps, 1Gbps
		Mode	Full Duplex
		Management IF(MDIO)	Yes
		Energy Efficient Ethernet (low power idle)	Yes
		Magic Packet™	Yes
	Switch function	Layer 3 support	Yes
		Cut through	Yes
		VLAN	Yes
		Jumbo frame support	Max 64 KB
		MAC table	2048
		VLAN table	4096
		Stream (perfect filter, layer 3, layer 2) table	256
		Layer 2/Layer 3 update rule table	256
	gPTP	Number of channels	2
	PTP pulse generator	Number of channels	4
Ethernet AVB	IEEE802.1BA	The AVB profile	Yes
	IEEE1722-2011	Media transport protocol for audio and video	Yes
	IEEE 802.1AS-2011	gPTP (a profile of IEEE1588 for AVB systems)	Yes
	IEEE 802.1Qav-2009	Credit based shaper for bandwidth reservation	Yes
Ethernet TSN	IEEE802.1AS-Rev	Adds redundancy and enhancements to gPTP	Yes
	IEEE 802.1Qbv-2015	Time aware shaper	Yes
	IEEE 802.1Qbu-2016 (802.3br)	Frame preemption	Yes
	IEEE 802.1Qch-2017	Cyclic queuing and forwarding	Yes
	IEEE 802.1Qcr	Asynchronous traffic shaping	Yes
	IEEE 802.1Qci-2017	Stream based filtering and policing	Yes (without gate filter)
	IEEE 802.1CB-2017	Frame replication and elimination for reliability	Yes
TrustZone Filter	Security attribution and privilege attribution can be set		

Note: Please contact a Renesas Electronics sales office for network support.

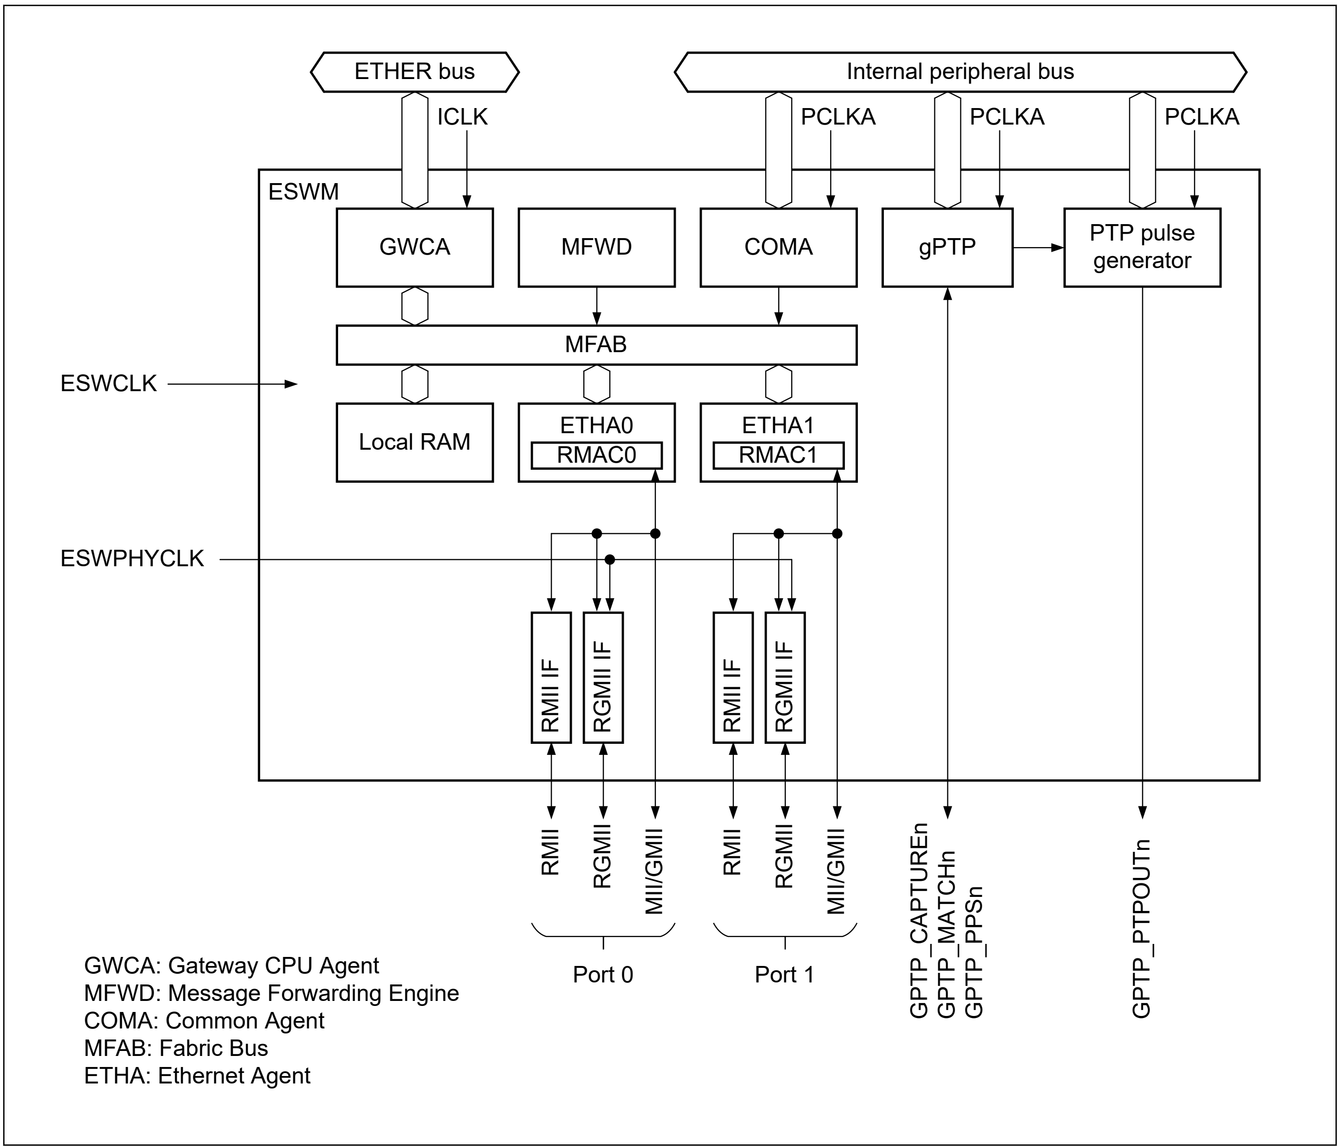

Figure 29.1 ESWM block diagram

Table 29.2 ESWM functional blocks (1 of 2)

Block name	Function
MFWD	Ethernet Message Forwarding Engine (MFWD) is part of ESWM and aims to filter, forward, and route the switch frames. MFWD snoops the frame information from fabric to redistribute them to the agent after filtering, forwarding, and routing mechanisms.
MFAB	Fabric Bus (MFAB) is an internal bus used to exchange data between Ethernet Agent [ETHA], Ethernet Common Agent [COMA], Ethernet CPU Agent [GWCA], local RAM, TAG RAM, pointer RAM, and Ethernet Message Forwarding Engine [MFWD].
ETHA	Ethernet Agent (ETHA) consists of an agent interface module to allow communication within ESWM. ETHA handles data exchange between ESWM and an Ethernet PHY.
RMAC	Ethernet MAC (RMAC) is an Ethernet controller that conforms to the definition of the MAC (Media Access Control) layer for Ethernet in the IEEE 802.3 standard. By connecting with a physical-layer LSI chip (PHY-LSI) that complies with the standard, RMAC can transmit and receive Ethernet (IEEE 802.3) frames. RMAC has a single MAC layer interface.
GWCA	Ethernet CPU Agent (GWCA) is a CPU interface that consists of an agent interface module allowing communication within ESWM. GWCA handles data exchange between ESWM and the GWCPU subsystem. Software is required for the configuration of Gateway AXI bus interface.
COMA	Ethernet Common Agent (COMA) is an agent of ESWM which aims at gathering common functionalities for other agents. COMA handles the APB to SFR bus conversion, the buffer pointer release for rejected frames and the pointer handling for local RAM. Software is required for the configuration of Ethernet Common Agent.

Table 29.2 ESWM functional blocks (2 of 2)

Block name	Function
gPTP	Ethernet Generic PTP timer (GPTP) enables accurate synchronization of the clock in the control system.
plsotim	The pulse output timer module (plsotim), a submodule of gPTP, produces a pulsed output according to the base period of a gPTP timer.

29.2 Register Descriptions

29.2.1 ESWM Interface Control Registers

29.2.1.1 MIIRR : Media-independent Interface Reset Register

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x19400

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RMRST1	RMRST0	—	—	—	—	—	—	RGRST1	RGRST0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RGRST0	RGMII0 Reset 0: Reset 1: Enable	R/W
1	RGRST1	RGMII1 Reset 0: Reset 1: Enable	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	RMRST0	RMII0 Reset 0: Reset 1: Enable	R/W

8	DIVSTP	Clock Divider Stop 0: Enable 1: Stop	R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W
12	TXCIDE	RGMII TXC Internal Delay Enable 0: TXC internal delay disable 1: TXC internal delay enable	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

29.2.1.3 MIICR1 : Media-independent Interface Control Register 1

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x19408

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TXCIDE	—	—	—	DIVSTP	—	—	—	—	—	—	MIISEL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	MIISEL[1:0]	Media-independent Interface Select 0 0: MII/GMII 0 1: RGMII 1 0: RMII 1 1: Setting prohibited	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
8	DIVSTP	Clock Divider Stop 0: Enable 1: Stop	R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W
12	TXCIDE	RGMII TXC Internal Delay Enable 0: TXC Internal delay disable 1: TXC Internal delay enable	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

29.2.1.4 MCCESR : Media Clock Capture Event Select Register

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x19410

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCES1	MCCES0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MCCES0	Media Clock 0 Capture Event Select 0: I/O Port 1: ELC	R/W
1	MCCES1	Media Clock 1 Capture Event Select 0: I/O Port 1: ELC	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

29.2.1.5 TASSTSR : TAS Status Monitor Signal Select Register

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x19420

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	MSS3[4:0]					—	—	—	MSS2[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	MSS1[4:0]					—	—	—	MSS0[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	MSS0[4:0]	ET_TAS_STA0 Monitor Signal Select Select signal to output ET_TAS_STA0 pin from race_etha0_tas_gate_state[8:0] and race_etha1_tas_gate_state[8:0]	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
12:8	MSS1[4:0]	ET_TAS_STA1 Monitor Signal Select Select signal to output ET_TAS_STA1 pin from race_etha0_tas_gate_state[8:0] and race_etha1_tas_gate_state[8:0]	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
20:16	MSS2[4:0]	ET_TAS_STA2 Monitor Signal Select Select signal to output ET_TAS_STA2 pin from race_etha0_tas_gate_state[8:0] and race_etha1_tas_gate_state[8:0]	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
28:24	MSS3[4:0]	ET_TAS_STA3 Monitor Signal Select Select signal to output ET_TAS_STA3 pin from race_etha0_tas_gate_state[8:0] and race_etha1_tas_gate_state[8:0]	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

29.2.2 Register Descriptions of Related ESWM Interrupts

29.2.2.1 TPEMIMC1 : Error and Monitoring Interrupt Mapping Configuration Register 1

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x0004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	CSICM[2:0]			—	—	CSIGM	CSIM	—	CEICM[2:0]			—	—	CEIGM	CEIM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	FSICM[2:0]			—	—	FSIGM	FSIM	—	FEICM[2:0]			—	—	FEIGM	FEIM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FEIM	MFWD Error Interrupt Mapping MFWD Error Interrupt contains the following interrupts: • FWEIS0 • FWEIS1 • FWEIS2 • FWEIS3 • FWEIS4 • FWEIS5 • FWEIS6 • FWEIS7 • FWEIS8 0: MFWD Error Interrupt is mapped to ETHER_FWEI 1: MFWD Error Interrupt is mapped to a specific core depending on TPEMIMC1.FEIGM register	R/W
1	FEIGM	MFWD Error Interrupt GWCA Mapping 0: When TPEMIMC1.FEIM is set to 1, MFWD Error Interrupt is mapped to ETHER_GWDI[TPEMIMC1.FEICM] 1: Setting prohibited	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
6:4	FEICM[2:0]	MFWD Error Interrupt Core Mapping Determine to which pin MFWD Error Interrupt is mapped when mapped to a GWCA	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
8	FSIM	MFWD Status Interrupt Mapping MFWD Status Interrupt contains the following interrupt: ● FWMIS0 [MFWD] 0: MFWD Status Interrupt is mapped to ETHER_FWSI 1: MFWD Status Interrupt is mapped to a specific core depending on TPEMIMC1.FSIGM register	R/W
9	FSIGM	MFWD Status Interrupt GWCA Mapping 0: When TPEMIMC1.FSIM is set to 1, MFWD Status Interrupt is mapped to ETHER_GWDI[TPEMIMC1.FSICM] 1: Setting prohibited	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
14:12	FSICM[2:0]	MFWD Status Interrupt Core Mapping Determine to which pin MFWD Status Interrupt is mapped when mapped to a GWCA	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
16	CEIM	COMA Error Interrupt Mapping COMA Error Interrupt contains the following interrupts: ● CAEIS0 [COMA] ● CAEIS1 [COMA] 0: COMA Error Interrupt is mapped to ETHER_CAEI 1: COMA Error Interrupt is mapped to a specific core depending on TPEMIMC1.CEIGM register	R/W
17	CEIGM	COMA Error Interrupt GWCA Mapping 0: When TPEMIMC1.CEIM is set to 1, COMA Error Interrupt is mapped to ETHER_GWDI[TPEMIMC1.CEICM] 1: Setting prohibited	R/W
19:18	—	These bits are read as 0. The write value should be 0.	R/W
22:20	CEICM[2:0]	COMA Error Interrupt Core Mapping Determine to which pin COMA Error Interrupt is mapped when mapped to a GWCA	R/W
23	—	This bit is read as 0. The write value should be 0.	R/W
24	CSIM	COMA Status Interrupt Mapping COMA Status Interrupt contains the following interrupts: ● CAMIS0 [COMA] ● CAMIS1 [COMA] 0: COMA Status Interrupt is mapped to ETHER_CAMI 1: COMA Status Interrupt is mapped to a specific core depending on TPEMIMC1.CSIGM register	R/W
25	CSIGM	COMA Status Interrupt GWCA Mapping 0: When TPEMIMC1.CSIM is set to 1, COMA Status Interrupt is mapped to ETHER_GWDI[TPEMIMC1.CSICM] 1: Setting prohibited	R/W
27:26	—	These bits are read as 0. The write value should be 0.	R/W
30:28	CSICM[2:0]	COMA Status Interrupt Core Mapping Used to decide to which pin COMA Status Interrupt are mapped when mapped to a GWCA.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

29.2.2.2 TPEMIMC2 : Error and Monitoring Interrupt Mapping Configuration Register 2

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x0008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	GEICM0[2:0]			—	—	GEIGM0	GEIM0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	GEIM0	GWCA0 Error Interrupt Mapping GWCA0 Error Interrupt contains the following interrupts: ● GWEIS0 except GWEIS0.TDFES for GWCA0 [GWCA] ● GWEIS1 for GWCA0 [GWCA] ● GWEIS4 for GWCA0 [GWCA] ● GWEIS5 for GWCA0 [GWCA] 0: GWCA0 Error Interrupt is mapped to ETHER_GWEI 1: GWCA0 Error Interrupt is mapped to a specific core depending on TPEMIMC2.GEIGM0 register	R/W
1	GEIGM0	GWCA0 Error Interrupt GWCA Mapping 0: When TPEMIMC2.GEIM0 is set to 1, GWCA0 Error Interrupt is mapped to ETHER_GWDI[TPEMIMC2.GEICM0] 1: Setting prohibited	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
6:4	GEICM0[2:0]	GWCA0 Error Interrupt Core Mapping Determine to which pin GWCA0 Error Interrupt is mapped when mapped to a GWCA.	R/W
31:7	—	These bits are read as 0. The write value should be 0.	R/W

29.2.2.3 TPEMIMC3 : Error and Monitoring Interrupt Mapping Configuration Register 3

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x000C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	ESICM0[2:0]			—	—	ESIGM0	ESIM0	—	EEICM0[2:0]			—	—	EEIGM0	EEIM0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EEIM0	ETHA0 Error Interrupt Mapping ETHA0 Error Interrupt contains the following interrupts: ● EAEIS0 for ETHA0 [ETHA] ● EAEIS1 for ETHA0 [ETHA] ● EAEIS2 for ETHA0 [ETHA] ● MEIS for RMAC0 [RMAC] 0: ETHA0 Error Interrupt is mapped to ETHER_EAEI0 1: ETHA0 Error Interrupt is mapped to a specific core depending on TPEMIMC3.EEIGM0 register	R/W
1	EEIGM0	ETHA0 Error Interrupt GWCA Mapping 0: When TPEMIMC3.EEIM0 is set to 1, ETHA0 Error Interrupt is mapped to ETHER_GWDI[TPEMIMC3.EEICM0] 1: Setting prohibited	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
6:4	EEICM0[2:0]	ETHA0 Error Interrupt Core Mapping Determine to which pin ETHA0 Error Interrupt is mapped when mapped to a GWCA.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	ESIM0	ETHA0 Status Interrupt Mapping ETHA0 Status Interrupt contains the following interrupt: ● MMIS0 for RMAC 0 [RMAC] 0: ETHA0 Status Interrupt is mapped to ETHER_EASI0 1: ETHA0 Status Interrupt is mapped to a specific core depending on TPEMIMC3.ESIGM0 register	R/W
9	ESIGM0	ETHA0 Status Interrupt GWCA Mapping 0: When TPEMIMC3.ESIM0 is set to 1, ETHA0 Status Interrupt is mapped to ETHER_GWDI[TPEMIMC3.ESICM0] 1: Setting prohibited	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
14:12	ESICM0[2:0]	ETHA0 Status Interrupt Core Mapping Determine to which pin ETHA0 Status Interrupt is mapped when mapped to a GWCA.	R/W
31:15	—	These bits are read as 0. The write value should be 0.	R/W

29.2.2.4 TPEMIMC4 : Error and Monitoring Interrupt Mapping Configuration Register 4

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x0010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	ESICM1[2:0]			—	—	ESIGM1	ESIM1	—	EEICM1[2:0]			—	—	EEIGM1	EEIM1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EEIM1	ETHA1 Error Interrupt Mapping ETHA1 Error Interrupt contains the following interrupt: ● EAEIS0 for ETHA1 [ETHA] ● EAEIS1 for ETHA1 [ETHA] ● EAEIS2 for ETHA1 [ETHA] ● MEIS for RMAC1 [RMAC] 0: ETHA1 Error Interrupt is mapped to ETHER_EAEI1 1: ETHA1 Error Interrupt is mapped to a specific core depending on TPEMIMC4.EEIGM1 register	R/W

Bit	Symbol	Function	R/W
1	EEIGM1	ETHA1 Error Interrupt GWCA Mapping 0: When TPEMIMC4.EEIM1 is set to 1, ETHA1 Error Interrupt is mapped to ETHER_GWDI[TPEMIMC4.EEICM1] 1: Setting prohibited	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
6:4	EEICM1[2:0]	ETHA1 Error Interrupt Core Mapping Determine to which pin ETHA1 Error Interrupt is mapped when mapped to a GWCA.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	ESIM1	ETHA1 Status Interrupt Mapping ETHA1 Status Interrupt contains the following interrupt: ● MMIS0 for RMAC 1 [RMAC] 0: ETHA1 Status Interrupt is mapped to ETHER_EASI1 1: ETHA1 Status Interrupt is mapped to a specific core depending on TPEMIMC4.ESIGM1 register	R/W
9	ESIGM1	ETHA1 Status Interrupt GWCA Mapping 0: When TPEMIMC4.ESIM1 is set to 1, ETHA1 Status Interrupt is mapped to ETHER_GWDI[TPEMIMC4.ESICM1] 1: Setting prohibited	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
14:12	ESICM1[2:0]	ETHA1 Status Interrupt Core Mapping Determine to which pin ETHA1 Status Interrupt is mapped when mapped to a GWCA.	R/W
31:15	—	These bits are read as 0. The write value should be 0.	R/W

29.2.2.5 TPEMIMC6t : Error and Monitoring Interrupt Mapping Configuration Register 6t (t = 0 to 1)

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x0080 + 0x04 × t

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	GTSICM0[2:0]			GTSIM0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	GTSIM0	GWCA0 Timestamp Interrupt Mapping GWCA0 Timestamp Interrupt contains the following interrupts: ● GWTDIS.TSDISt for GWCA0 [GWCA] ● GWEIS0.TDFESt for GWCA0 [GWCA] 0: GWCA0 Timestamp Interrupt t is mapped to ETHER_TSDI[t] 1: GWCA0 Timestamp Interrupt t is mapped to ETHER_GWDIn depending on TPEMIMC6t.GTSICM0 setting	R/W
3:1	GTSICM0[2:0]	GWCA0 Timestamp Interrupt Core Mapping Map GWCA0 Timestamp Interrupt t to ETHER_GWDI[TPEMIMC6t.GTSICM0] when TPEMIMC6t.GTSIM0 is set.	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

29.2.2.6 TPEMIMC7t : Error and Monitoring Interrupt Mapping Configuration Register 7t (t = 0 to 63)

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x0100 + 0x04 × t

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	GDICM0[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	GDICM0[2:0]	GWCA0 Data Interrupt Core Mapping Map GWCA0 Data Interrupts t to ETHER_GWDI[TPEMIMC7t.GDICM0]. RMAC2 Status Interrupt contains the following interrupts: ● GWDISi.DIS for GWCA0 [GWCA] ● GWEIS2i.DFES for GWCA0 [GWCA] ● GWEIS3.IAOESt for t = 0 to 4 for GWCA0 [GWCA]	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

29.2.2.7 TSIM : Summarized Interrupt Mirroring Register

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x0700

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	EIM1	EIM0	—	GIM0	CIM	FIM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FIM	MFWD Interrupt Mirroring 0: No interrupt is set in MFWD 1: An interrupt is set in MFWD	R
1	CIM	COMA Interrupt Mirroring 0: No interrupt is set in COMA agent 1: An interrupt is set in COMA agent	R
2	GIM0	GWCA0 Interrupt Monitoring 0: No interrupt is set in GWCA0 1: An interrupt is set in GWCA0	R
3	—	This bit is read as 0.	R
4	EIM0	ETHA0 Interrupt Monitoring 0: No interrupt is set in ETHA0 1: An interrupt is set in ETHA0	R

Bit	Symbol	Function	R/W
5	EIM1	ETHA1 Interrupt Monitoring 0: No interrupt is set in ETHA1 1: An interrupt is set in ETHA1	R
31:6	—	These bits are read as 0.	R

29.2.2.8 TFIM : MFWD Interrupt Mirroring Register

Base address: ESWM = 0x403C_8000
ESWM_NS = 0x503C_8000

Offset address: 0x0704

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	FWMISIM0	FWEISIM8	FWEISIM7	FWEISIM6	FWEISIM5	FWEISIM4	FWEISIM3	FWEISIM2	FWEISIM1	FWEISIM0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FWEISIM0	FWEIS0 Interrupt Mirroring 0: No interrupt is set in forwarding engine FWEIS0 register 1: An interrupt is set in forwarding engine FWEIS0 register	R
1	FWEISIM1	FWEIS1 Interrupt Mirroring 0: No interrupt is set in forwarding engine FWEIS1 register 1: An interrupt is set in forwarding engine FWEIS1 register	R
2	FWEISIM2	FWEIS2 Interrupt Mirroring 0: No interrupt is set in forwarding engine FWEIS2 register 1: An interrupt is set in forwarding engine FWEIS2 register	R
3	FWEISIM3	FWEIS3 Interrupt Mirroring 0: No interrupt is set in forwarding engine FWEIS3 register 1: An interrupt is set in forwarding engine FWEIS3 register	R
4	FWEISIM4	FWEIS4 Interrupt Mirroring 0: No interrupt is set in forwarding engine FWEIS4 register 1: An interrupt is set in forwarding engine FWEIS4 register	R
5	FWEISIM5	FWEIS5 Interrupt Mirroring 0: No interrupt is set in forwarding engine FWEIS5 register 1: An interrupt is set in forwarding engine FWEIS5 register	R
6	FWEISIM6	FWEIS6 Interrupt Mirroring 0: No interrupt is set in forwarding engine FWEIS6 register 1: An interrupt is set in forwarding engine FWEIS6 register	R
7	FWEISIM7	FWEIS7 Interrupt Mirroring 0: No interrupt is set in forwarding engine FWEIS7 register 1: An interrupt is set in forwarding engine FWEIS7 register	R

29.2.3 ESWM Core Registers

See the following sections:

- section 30.3. MFWD Register Descriptions
- section 31.3. COMA Register Descriptions
- section 32.3. ETHA Register Descriptions
- section 33.4. RMAC Register Descriptions
- section 34.3. GWCA Register Descriptions

29.2.4 gPTP and PTP Pulse Generator Registers

See the following sections:

- section 35.3. gPTP Register Descriptions
- section 35.6.3. Plsotim Register Descriptions

29.3 Register Utilization

29.3.1 Software Flows

Restrictions on software flows are as follows:

- SW: ESWM registers can only be written using the flows specified in this section

- SW: All the software flows described in this section can only be used sequentially.

29.3.1.1 Software Flow Legend

Figure 29.2 shows the software flow legend.

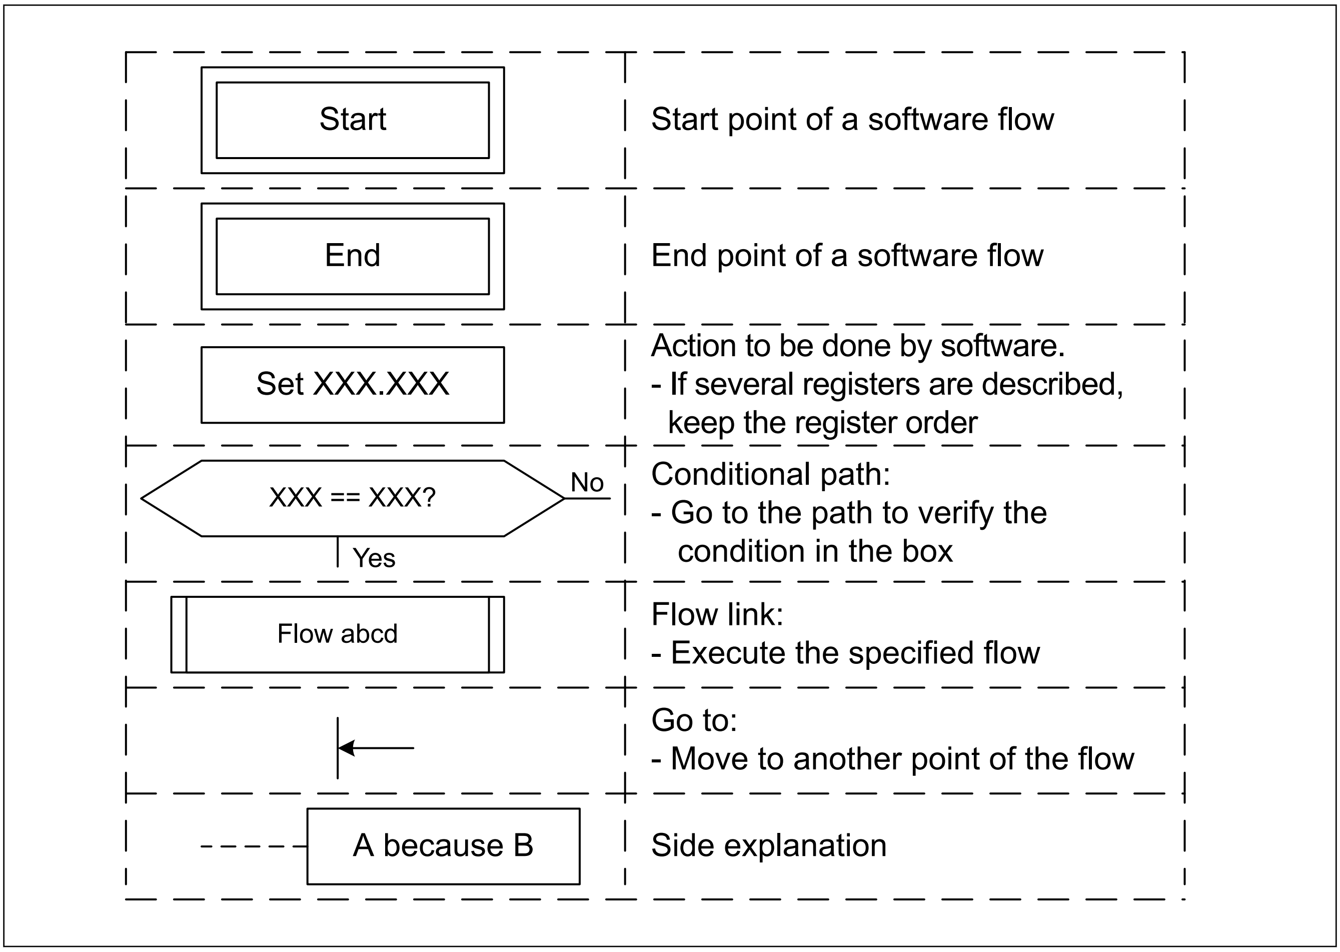

Figure 29.2 Software flow legend

29.3.1.2 Switch Initialization Flow

Figure 29.3 shows the switch initialization flow.

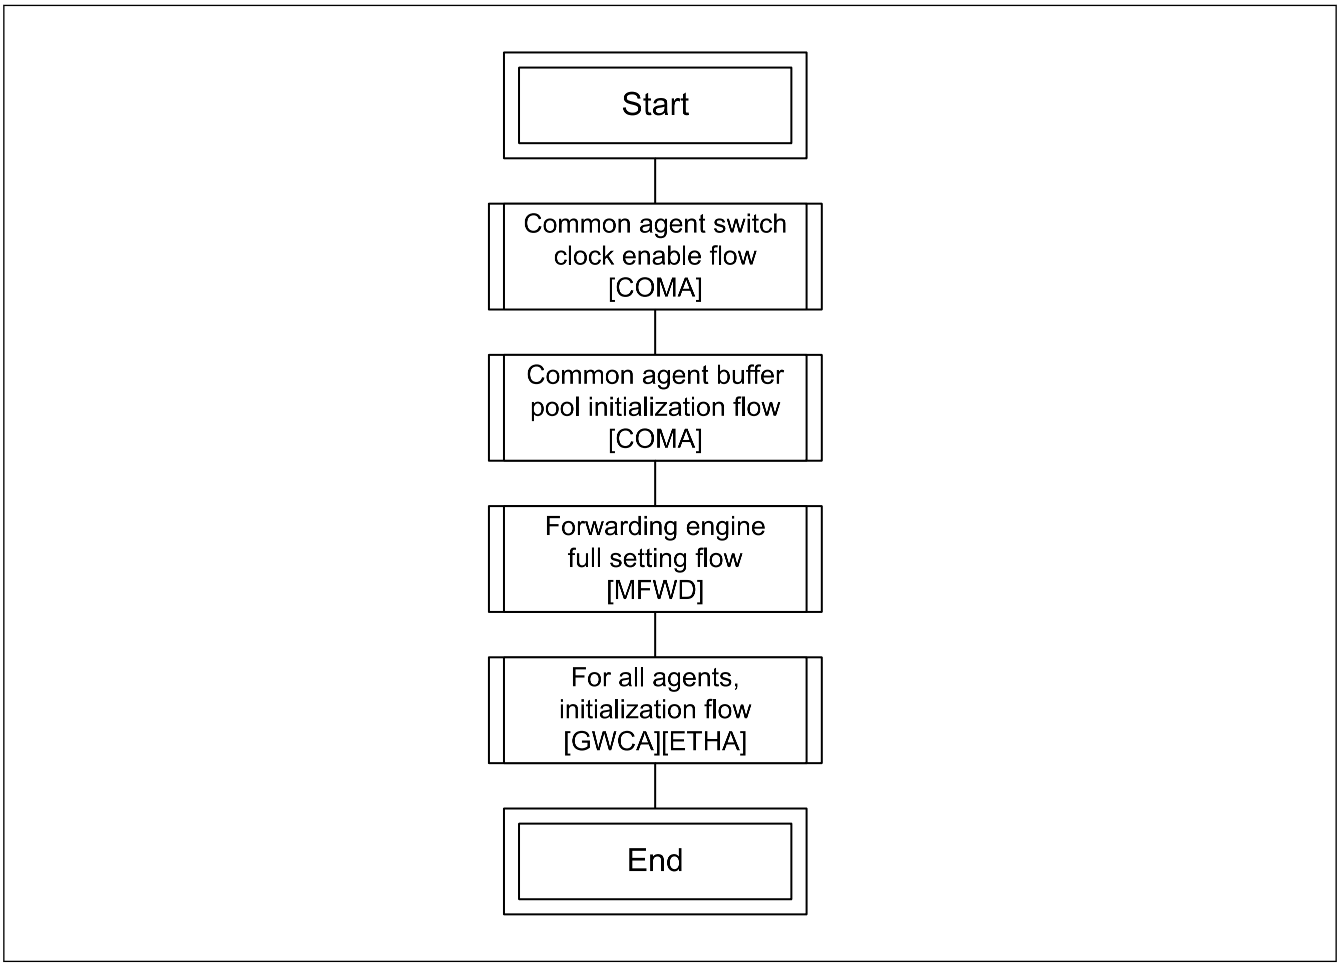

Figure 29.3 Switch initialization flow

29.3.1.3 Switch Disable Flow

Figure 29.4 shows the switch disable flow.

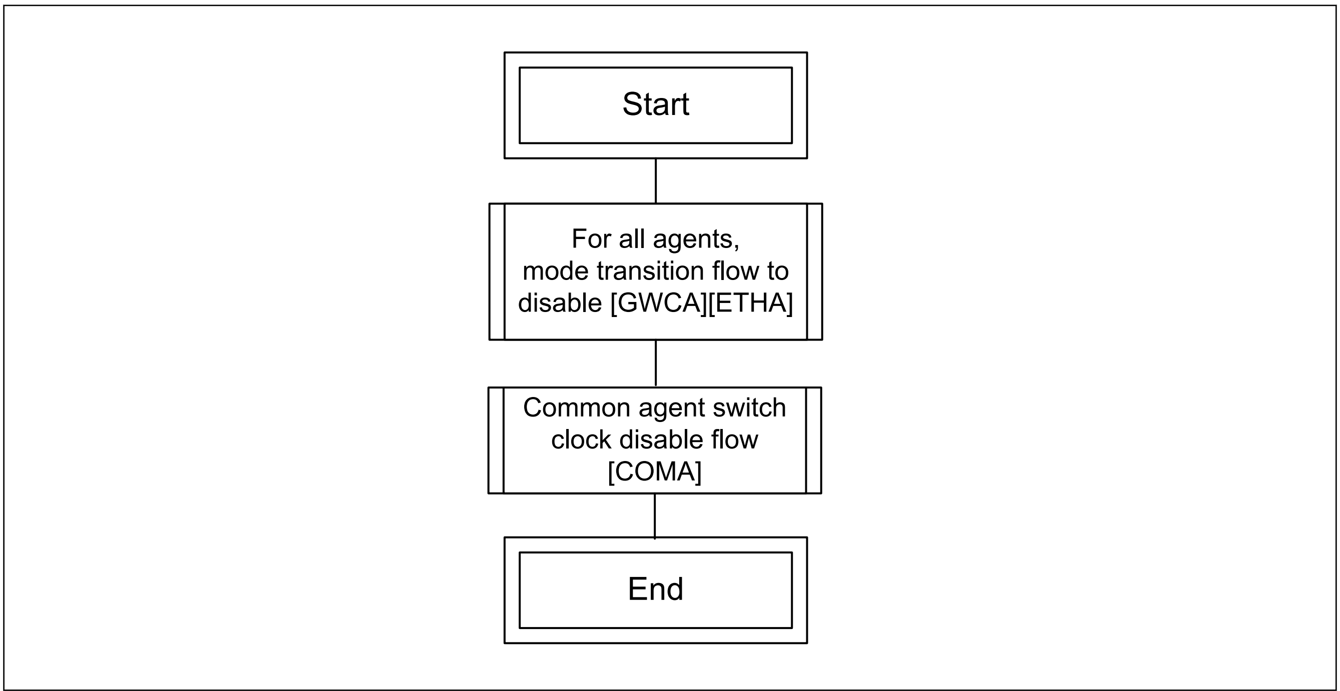

Figure 29.4 Switch disable flow

29.3.1.4 Switch Reset Flow

Figure 29.5 shows the switch reset flow.

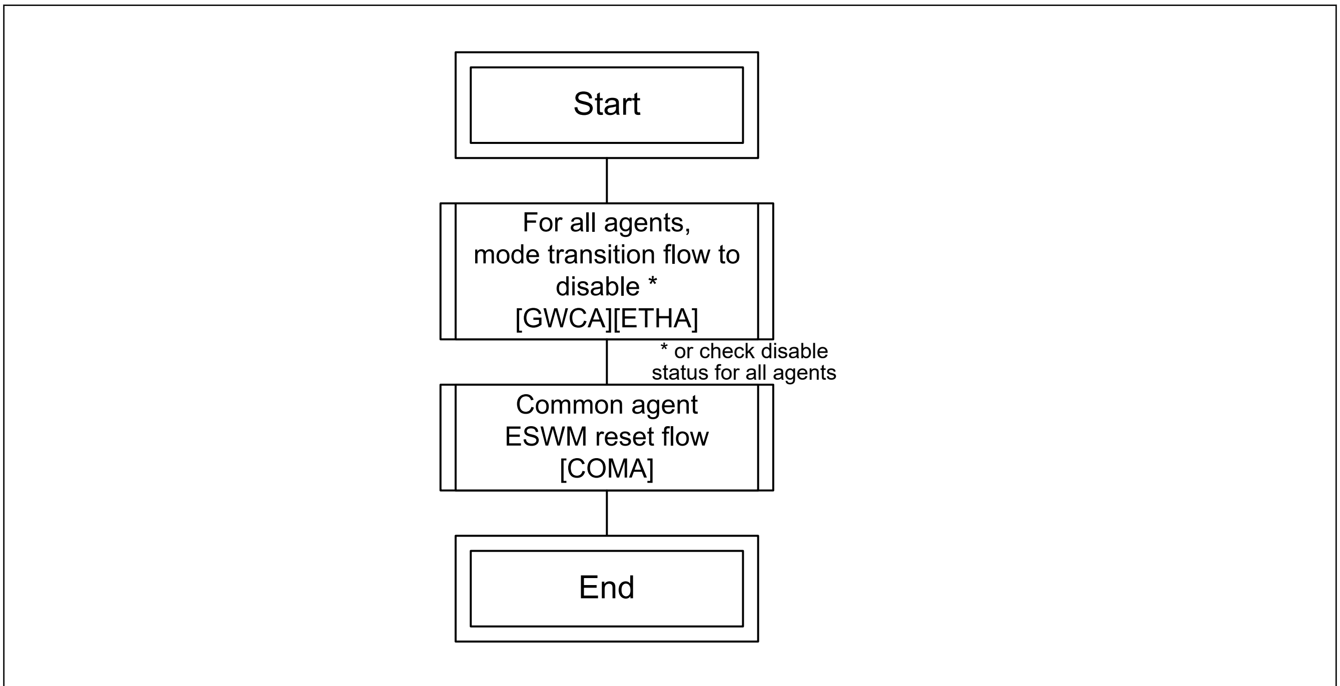

Figure 29.5 Switch reset flow

29.3.1.5 Switch Emergency Reset Flow

Figure 29.6 shows the switch emergency reset flow used when [ETHA] is locked.

For example, in the case of MII, if an error occurs in the PHY and the MII PHY TX clock stops, the switch cannot send data and cannot release the pointer (locked on [ETHA] Operation mode). The state clears when the MII PHY TX clock is restarted, but use emergency reset if required.

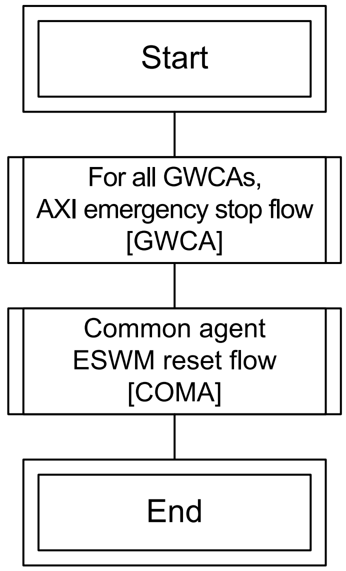

Figure 29.6 Switch emergency reset flow

29.3.1.6 Register Writable Without Software Flow

Table 29.3 describes the registers writable without software flow and in which mode they can be written.

Table 29.3 Writable without software flow registers (✓ = writable, × = not writable)

29.4 Functional Descriptions

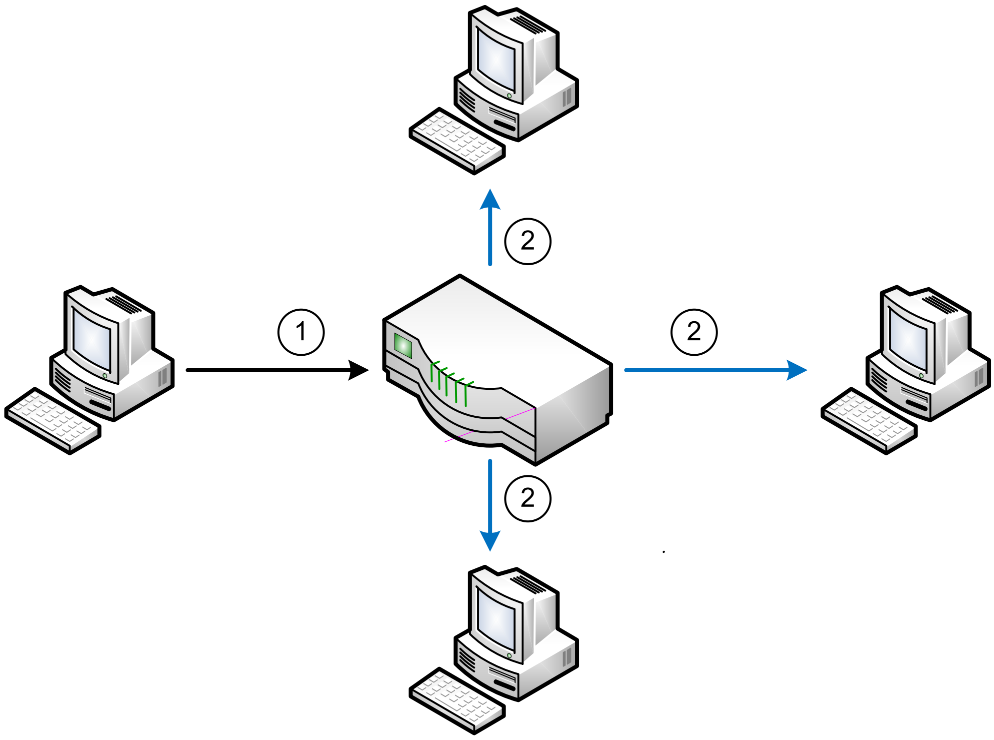
29.4.1 ESWM Forwarding Modes

29.4.1.1 Hub

29.4.1.1.1 Background

A hub is an ethernet network interconnection system (OSI) which only works on layer 1. It does not consider any kind of addressing and, consequently, is not aware of the kind of traffic that goes through it and can create security issues.

Figure 29.7 shows the hub operation.



1	The hub receives a packet from a port
2	The hub copies the packet to all ports except the ingress port

Figure 29.7 Hub operation

Note: In Hub mode, the internal port [GWCA] behaves like an ethernet port. In the following configuration, the internal port receives all frames by AXI descriptor queue number 0 and transmits all frames by AXI descriptor queue number 1.

29.4.1.1.2 Settings

Table 29.4 describes the setting required for ESWM in Hub mode. Specify this setting using the switch initialization flow described in section 29.3.1.2. Switch Initialization Flow. Any register not described in the table should be kept to its initial value, so it does not need to be set. After using the switch initialization flow, any used port should be moved to Operation mode when required.

Table 29.4 Hub settings (1 of 2)

Register name	Setting value	Description
Message Forwarding Engine [MFWD]		
FWPBFCi.PBDV	All 1s except for FWPBFCi.PBDV which is set to 0	All ports are set to send their incoming frames to all other ports
Ethernet Agent [ETHA]		
EAIRC	0	All frames are directed to descriptor queue 0
EATDQDCq.DQD	If q = 0, set to 512 Else set to 0	There is no QoS, so all frames are stored in priority 0 queue. As a result, all the output descriptor queue memory is reserved for queue 0.
EAVCC.VEM	011b	Allows SC-tagged frames and C-tagged frames to go through transparently
EATTFC.UT	0	Allows any TAG formats to go through even the unsupported ones

Table 29.4 Hub settings (2 of 2)

Register name	Setting value	Description
Ethernet MAC [RMAC]		
MPIC.PIS	User-defined	Set the PHY interface type
MPIC.LSC	User-defined	Set the PHY speed
MRAFC	03C703C7H	Set MAC reception in promiscuous mode
Gateway CPU Agent [GWCA]		
GWIRC	0	All frames are directed to descriptor queue 0
GWRDQDCq.DQD	If q = 0, set to 512 Else set to 0	There is no QoS, so all frames are stored in priority 0 queue. As a result, all the output descriptor queue memory is reserved for queue 0.
GWVCC.VEM	011	Allows SC-tagged frames and C-tagged frames to go through transparently
GWTTFC.UT	0	Allows any TAG formats to go through even the unsupported ones
GWDCBAC0/1	User-defined	Set the LINKFIX table base address
GWDCCi	For i = 1: ● Set DQT to 1 ● Set OSID to user-defined. Else: ● Set OSID to user-defined.	Queue 0 is used for data reception and queue 1 is used for data transmission. All other queues are not used.

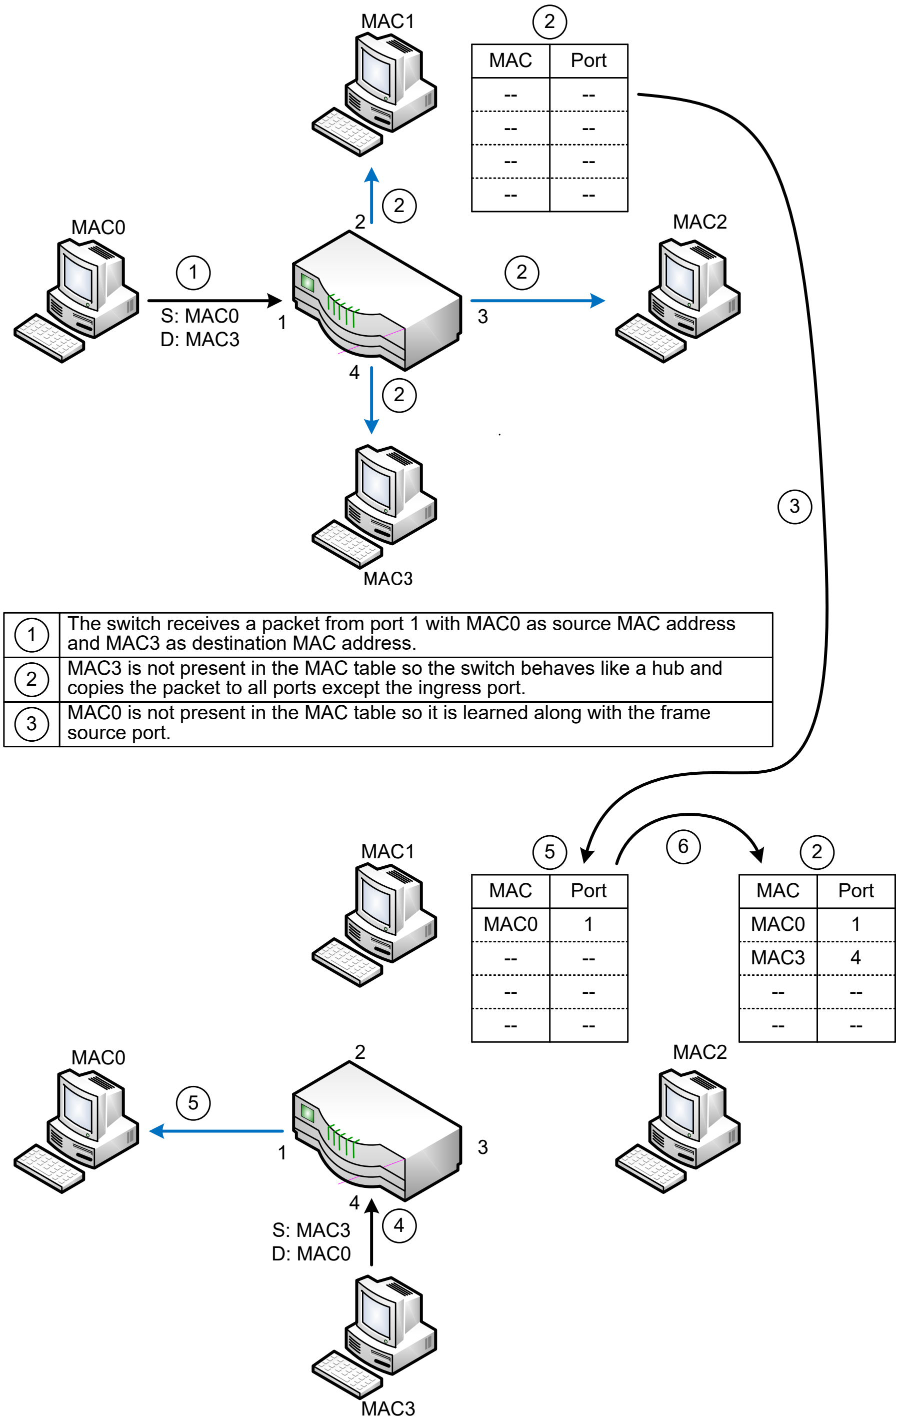
29.4.1.2 Layer 2 Switch

29.4.1.2.1 Background

A layer 2 switch is an ethernet network interconnection system (OSI) which only works on layer 2 using MAC addresses. MAC addresses are used to filter and forward messages. A layer 2 switch has three main functions:

- Address learning: A switch can learn MAC addresses by looking at received frame source MAC addresses
- Address aging: A switch can suppress a MAC address if a frame from the corresponding source has not been received since a given period (usually 5 minutes)
- Frame forward/filter: A switch can forward or filter a frame based on its destination MAC address.

Figure 29.8 shows the layer 2 switch operation.



1	The switch receives a packet from port 1 with MAC0 as source MAC address and MAC3 as destination MAC address.
2	MAC3 is not present in the MAC table so the switch behaves like a hub and copies the packet to all ports except the ingress port.
3	MAC0 is not present in the MAC table so it is learned along with the frame source port.

4	The switch receives a packet from port 4 with MAC3 as source MAC address and MAC0 as destination MAC address.
5	MAC0 is present in the MAC table along with port number 1 so the frame is only forwarded to port 1.
6	MAC3 is not present in the MAC table so it is learned along with the frame source port.

Figure 29.8 Layer 2 switch operation

29.4.1.2.2 Settings

Table 29.5 describes the setting required for ESWM in layer 2 switch mode. Specify this setting using the switch initialization flow described in section 29.3.1.2. Switch Initialization Flow. Any register not described in the table should be kept to its initial value, so it does not need to be set. After using the switch initialization flow, any used port should be moved to Operation mode when required.

Table 29.5 Layer 2 switch settings

Register name	Setting value	Explanation
Message Forwarding Engine [MFWD]		
FWPBFCi.PBDV	All 1s except for FWPBFCi.PBDV which is set to 0	All ports are set to send their incoming frames to all other ports
FWPCi0.MACDSA	1	MAC destination search occurs for all ports
FWPCi0.MACSSA	1	MAC source search occurs for all ports
FWPCi0.MACHLA	1	MAC source hardware learning is enabled for all ports
FWPCi0.MACHMA	1	MAC source hardware migration is enabled for all ports
FWCLPRC.USMACLF	User-defined	Unknown source MAC addresses can be sent to CPU for learning monitoring
FWCLPTC.LPCSD	2	Set the learning path queue number to 2
FWCLPTC.LPCS	User-defined	Select which CPU to be used for learning monitoring
Ethernet Agent [ETHA]		
EAIRC	0	All frames are directed to descriptor queue 0
EATDQDCq.DQD	If q = 0, set to 512 Else set to 0	There is no QoS, so all frames are stored in priority 0 queue. As a result, all the output descriptor queue memory is reserved for queue 0.
EAVCC.VEM	011b	Allows SC-tagged frames and C-tagged frames to go through transparently
EATTFC.UT	0	Allows any TAG formats to go through even the unsupported ones
Ethernet MAC [RMAC]		
MPIC.PIS	User-defined	Set the PHY interface type
MPIC.LSC	User-defined	Set the PHY speed
MRAFC	0x03C703C7	Set MAC reception in promiscuous mode
Gateway CPU Agent [GWCA]		
GWIRC	0	All frames are directed to descriptor queue 0
GWRDQDCq.DQD	If q = 0, set to 512 Else set to 0	There is no QoS, so all frames are stored in priority 0 queue. As a result, all the output descriptor queue memory is reserved for queue 0.
GWVCC.VEM	011b	Allows SC-tagged frames and C-tagged frames to go through transparently
GWTTFC.UT	0	Allows any TAG formats to go through even the unsupported ones
GWDCBAC0/1	User-defined	Set the LINKFIX table base address
GWDCCi	For i = 1: ● Set DQT to 1 ● Set OSID to user-defined. Else: ● Set OSID to user-defined.	Queue 0 is used for data reception, queue 1 is used for data transmission and queue 2 is used for learning monitoring. All other queues are not used. Note: For learning monitoring, use extended descriptors.

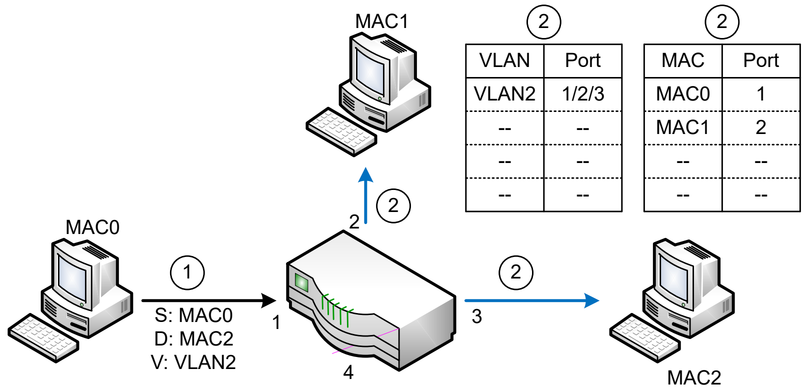
Note: Any MAC address learned by hardware coming from an internal port [GWCA] is always learned along with AXI descriptor queue 0. As a result, always reserve AXI descriptor queue 0 for hardware learned MAC addresses that correspond to frames reception queue.

29.4.1.3 VLAN Aware Layer 2 Switch

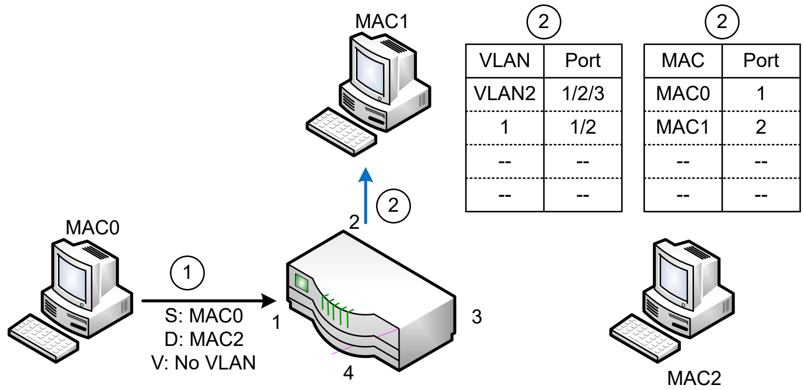
29.4.1.3.1 Background

A VLAN aware layer 2 switch is an ethernet network interconnection system (OSI) which works on layer 2 using MAC addresses and can reduce its broadcast domains in subdomains using VLAN IDs. A VLAN aware layer 2 switch has the same functions as a layer 2 switch but can also handle VLANs.

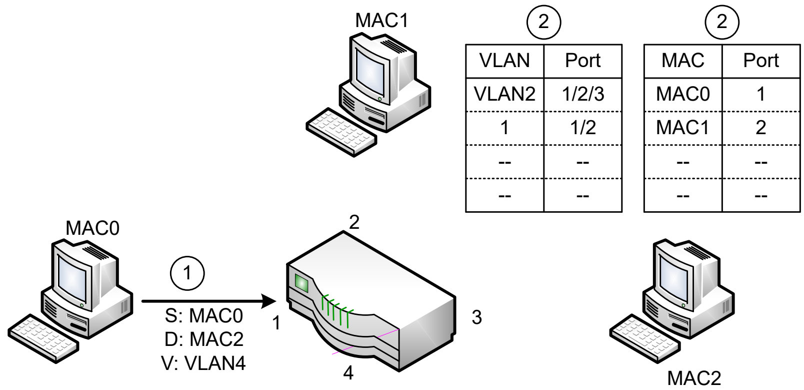
Figure 29.9 shows the VLAN aware layer 2 switch operation.



1	The switch receives a packet from port 1 with MAC0 as source MAC address, MAC2 as destination MAC address and VLAN2 as VLAN.
2	MAC2 is not present in the MAC table so the switch copies the packet to all ports present in VLAN2 domain (port 1/2/3) except the ingress port.



1	The switch receives a packet from port 1 with MAC0 as source MAC address, MAC2 as destination MAC address and no VLAN.
2	MAC2 is not present in the MAC table so the switch copies the packet to all ports present in default VLAN (1) domain (port 1/2) except the ingress port.



1	The switch receives a packet from port 1 with MAC0 as source MAC address, MAC2 as destination MAC address and VLAN4 as VLAN.
2	VLAN4 is unknown so the packet is rejected.

Figure 29.9 VLAN aware layer 2 switch operation

29.4.1.3.2 Settings

Table 29.6 describes the setting required for ESWM in VLAN aware layer 2 switch mode. Specify this setting using the switch initialization flow described in section 29.3.1.2. Switch Initialization Flow. Any register not described in the table should be kept to its initial value, so it does not need to be set. After using the switch initialization flow, any used port should be moved to Operation mode when required.

Table 29.6 VLAN aware layer 2 switch settings

Register name	Setting value	Explanation
Message forwarding engine [MFWD]		
FWGC.SVM	01	Set ESWM in C-TAG mode
FWPBFCi.PBDV	All 1s except for FWPBFCi.PBDV which is set to 0	All ports are set to send their incoming frames to all other ports
FWPCi0.MACDSA	1	MAC destination search occurs for all ports
FWPCi0.MACSSA	1	MAC source search occurs for all ports
FWPCi0.MACHLA	1	MAC source hardware learning is enabled for all ports
FWPCi0.MACHMA	1	MAC source hardware migration is enabled for all ports
FWPCi0.VLANSA	1	VLAN search occurs for all ports
FWPCi0.VLANRU	1	Unknown VLANs are rejected
FWCLPRC.USMACLF	User-defined	Unknown source MAC addresses can be sent to CPU for learning monitoring
FWCLPRC.UVLANLF	User-defined	Unknown VLANs can be sent to CPU for learning
FWCLPTC.LPCSD	2	Set the learning path queue number to 2
FWCLPTC.LPCS	User-defined	Select which CPU to be used for learning monitoring
FWVLANTL0/1/2/30/4	User-defined	New VLANs can be added to the VLAN table. For details, see Table 29.7.
Ethernet agent [ETHA]		
EATDQDCq.DQD	User-defined	The number of descriptors in descriptor queues can be set
EAVCC.VEM	011	Allows SC-tagged frames and C-tagged frames to go through transparently
EAVTC.CTV	1	Set the default VLAN value to 1
EATTFC.UT	0	Allows any TAG formats to go through even the unsupported ones
RMAC [RMAC]		
MPIC.PIS	User-defined	Set the PHY interface type
MPIC.LSC	User-defined	Set the PHY speed
MRAFC	03C703C7H	Set MAC reception in promiscuous mode
GWCA [GWCA]		
GWRDQDCq.DQD	User-defined	The number of descriptors in descriptor queues can be set
GWVCC.VEM	011	Allows SC-tagged frames and C-tagged frames to go through transparently
GWVTC.CTV	1	Set the default VLAN value to 1
GWTTFC.UT	0	Allows any TAG formats to go through even the unsupported ones
GWDCBAC0/1	User-defined	Set the LINKFIX table base address
GWDCCi	For i = 1: ● Set DQT to 1 ● Set OSID to user-defined. Else: ● Set OSID to user-defined.	Queue 0 is used for data reception, queue 1 is used for data transmission and queue 2 is used for learning monitoring. All other queues are not used. Note: For learning monitoring, use extended descriptors.

Table 29.7 VLAN learning in VLAN table

Field name VLAN	Setting value	Explanation
SL	0	No secure entry used
HLD	0	Hardware learning for MAC addresses not disabled for any VLAN
SLV	Set to 1 for ports included in VLAN	Only authorize to receive corresponding VLAN from ports included in this VLAN
DV	Set to 1 for ports included in VLAN	Only authorize to send corresponding VLAN to ports included in this VLAN
CSD	0	Frames received by CPUs on sub-destination 0
CME	0	No mirroring
EME	0	No mirroring
IPU	0	No frame priority update
IPV	0	No frame priority update

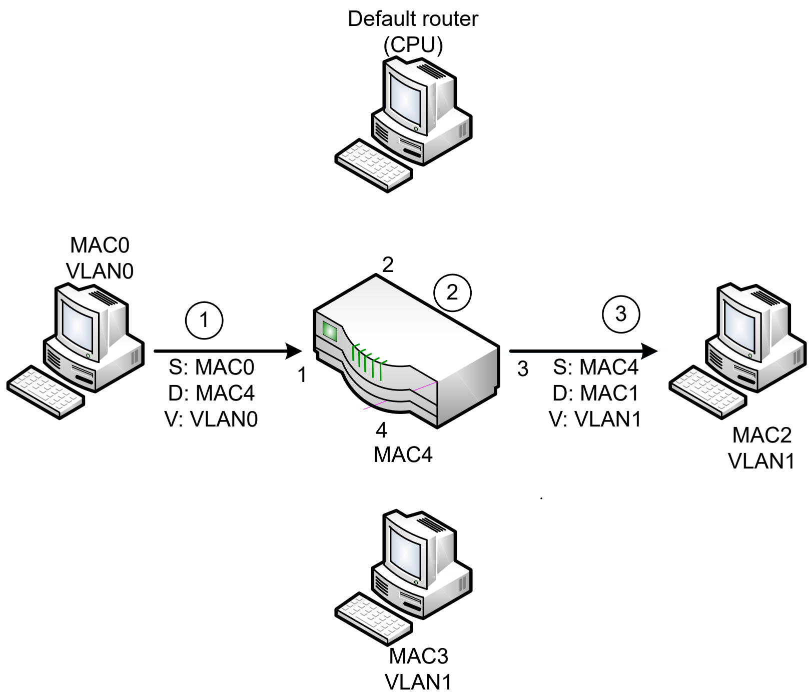
Note: When both VLAN and destination MAC addresses are found in forwarding tables and corresponding frame is forwarded to an internal port, the AXI descriptor queue (CPU sub-destination) chosen for forwarding is the one set in the MAC table. In this example, because both are set to 0, it raises no issue but, when AXI descriptor queues are used for virtualization, it should be taken in account during system design.

29.4.1.4 Layer 3 Switch

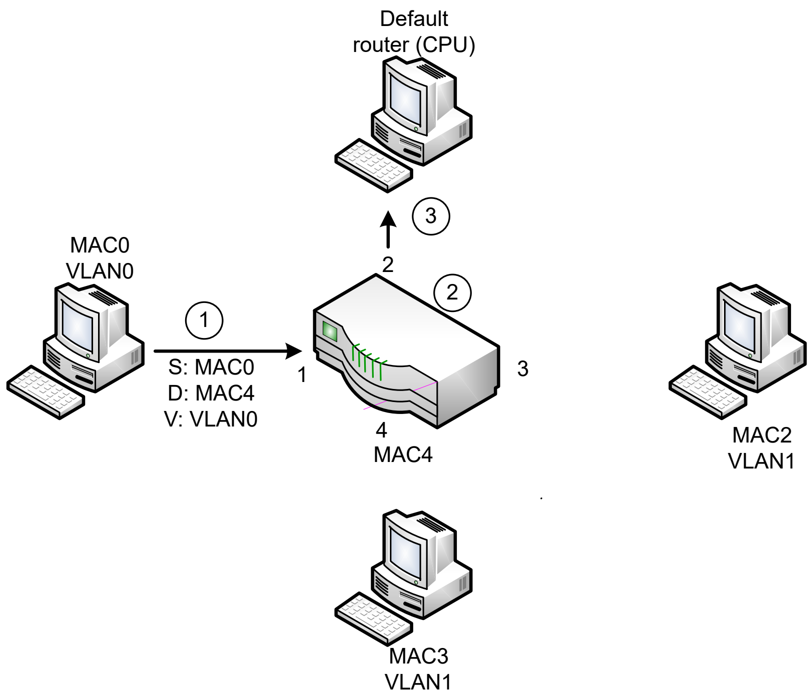
29.4.1.4.1 Background

A layer 3 switch is an ethernet network interconnection system (OSI) which works on layer 3 using IP addresses. Because ESWM can only perform perfect matches by stream forwarding, when developing a layer 3 switch, it is recommended to use perfect filters [FWD].

Figure 29.10 shows the layer 3 switch operation.



1	The switch receives a packet from port 1 with MAC0 as source MAC address, MAC4 as destination MAC address and VLAN0 as VLAN.
2	The packet IP address matches the cascade filter and should be routed to port 3.
3	The switch updates MAC destination to MAC1, MAC source to MAC4 and VLAN to VLAN1 and sends the frame to port 3.



1	The switch receives a packet from port 1 with MAC0 as source MAC address, MAC4 as destination MAC address and VLAN0 as VLAN.
2	The packet IP address is unknown so routing cannot happen.
3	The switch forwards the frame to the default router (CPU) without update for routing.

Figure 29.10 Layer 3 switch operation

29.4.1.4.2 Settings

Table 29.8 describes the setting required for ESWM in layer 3 switch mode. Specify this setting using the switch initialization flow described in section 29.3.1.2. Switch Initialization Flow. Any register not described in the table should be kept to its initial value, so it does not need to be set. After using the switch initialization flow, any used port should be moved to Operation mode when required.

Table 29.8 Layer 3 switch settings

Register name	Setting value	Explanation
Forwarding engine [MFWD]		
FWGC.SVM	01	Set ESWM in C-TAG mode
FWPBFCi.PBDV	All 1s except for FWPBFCi.PBDV which is set to 0	All ports are set to send their incoming frames to all other ports
FWPCi0.MACDSA	1	MAC destination search occurs for all ports
FWPCi0.MACSSA	1	MAC source search occurs for all ports
FWPCi0.MACHLA	1	MAC source hardware learning is enabled for all ports
FWPCi0.MACHMA	1	MAC source hardware migration is enabled for all ports
FWPCi0.VLANSA	1	VLAN search occurs for all ports
FWCLPRC.USMACLF	User-defined	Unknown source MAC addresses can be sent to CPU for learning monitoring
FWCLPRC.UVLANLF	1	Unknown VLANs are sent to CPU for learning
FWCLPTC.LPCSD	2	Set the learning path queue number to 2
FWCLPTC.LPCS	User-defined	Select which CPU to be used for learning monitoring
FWVLANTL0/1/2/30/4	User-defined	New VLANs can be added to the VLAN table. For details, see Table 29.7.
Ethernet agent [ETHA]		
EATDQDCq.DQD	User-defined	The number of descriptors in descriptor queues can be set
EAVCC.VEM	011	Allows SC-tagged frames and C-tagged frames to go through transparently
EAVTC.CTV	1	Set the default VLAN value to 1
EATTFC.UT	0	Allows any TAG formats to go through even the unsupported ones
RMAC [RMAC]		
MPIC.PIS	User-defined	Set the PHY interface type
MPIC.LSC	User-defined	Set the PHY speed
MRAFC	03C703C7H	Set MAC reception in promiscuous mode
GWCA [GWCA]		
GWRDQDCq.DQD	User-defined	The number of descriptors in descriptor queues can be set
GWVCC.VEM	011	Allows SC-tagged frames and C-tagged frames to go through transparently
GWVTC.CTV	1	Set the default VLAN value to 1
GWTTFC.UT	0	Allows any TAG formats to go through even the unsupported ones
GWDCBAC0/1	User-defined	Set the LINKFIX table base address
GWDCCi	For i = 1: ● Set DQT to 1 ● Set OSID to user-defined. Else: ● Set OSID to user-defined.	Queue 0 is used for data reception, queue 1 is used for data transmission and queue 2 is used for learning monitoring. All other queues are not used. Note: For learning monitoring, use extended descriptors.

Table 29.9 VLAN learning in VLAN table

Field name VLAN	Setting value	Explanation
SL	0	No secure entry used
HLD	0	Hardware learning for MAC addresses not disabled for any VLAN
SLV	Set to 1 for ports included in VLAN	Only authorize to receive corresponding VLAN from ports included in this VLAN
DV	Set to 1 for ports included in VLAN	Only authorize to send corresponding VLAN to ports included in this VLAN
CSD	0	Frames received by CPUs on sub-destination 0
CME	0	No mirroring
EME	0	No mirroring

IPV	0	No frame priority update

29.4.1.5 AVB scheduling

29.4.1.5.1 Forwarding and Queuing Enhancements for Time-Sensitive Streams [802.1Qav]

29.4.2 Precautions

- ESWM can support max (([Unused pointer number] × 128) / 4) bytes frame (supported maximum frame size). A buffer overflow occurs when the transmit frame size exceeds the supported maximum size. [Unused pointer number] = 512 − (Activated port number × 6).
  - Set to [RMAC] MRFSCE.EMXS smaller than maximum frame size for Ethernet ports
  - Do not transmit larger than maximum frame size for CPU ports.
- GWCA can only transmit/receive frames with maximum size of 63488 bytes for the first frame. For the upcoming frames, the maximum frame size can be 65535 bytes provided LINK/LINKFIX descriptors were not used in between the queue.
- When using Cut through, use it so as not to cause a buffer overflow. The following usage is recommended:
  - Only use from-one-to-one communication.
    (Example of prohibition : Multicast forwarding, to Ethernet mirroring, Loopback forwarding).
  - Prohibition of the function to stop transmission. Use flow control on reception port.
    (Example of prohibition : TX queue pause, CBS, TAS).
- The overall specifications of ESWM are determined on the frequency of the operating clock.
  See the following table for details to select the operating clock.

Selection			Definition	
Local RAM size*1	Clk*1	Internal bandwidth	Ethernet & CPU total bandwidth	Throughput (Ether2Ether)
64 KB	250 MHz	32 Gbps	MAX 1G bps (Exp 100M Ether 2 port + 100M CPU 1 port) × TX/RX	800 to 2000 ns
64 KB	50 MHz	6.4 Gbps	MAX 1G bps (Exp 100M Ether 2 port + 100M CPU 1 port) × TX/RX	2000 to 6000 ns
64 KB	250 MHz	32 Gbps	MAX 3G bps (Exp 1G Ether 2 port + 1G CPU 1 port) × TX/RX	400 to 600 ns
64 KB	150 MHz	19.2 Gbps	MAX 3G bps (Exp 1G Ether 2 port + 1G CPU 1 port) × TX/RX	500 to 800 ns

Note: At the frame end (forwarding source port) - frame start (forwarding destination port). When measuring, there is no dependency on the payload length of the frame.
Note: The frame start (forwarding destination port) is up to the point where the preamble starts to output.
Note 1. Specifications less than these are prohibited.
Throughput measurement conditions:

- From frame end (forwarding source port) to frame start (forwarding destination port)
- The forwarding (destination port) is not busy
- L2 forwarding unicast (1:1 forwarding).

29.5 Operation

29.5.1 Internal Clocks

Table 29.10 lists ESWM internal clocks. These clocks are supplied by the Clock Generation Circuit (CGC). Set the clock before starting the ESWM operation.

Table 29.10 Configurable range of clocks

VDD Voltage [V]	Speed [Mbps]	ICLK [MHz]	PCLKA [MHz]	ESWCLK [MHz]	ESWPHYCLK [MHz]
VSCR_1, voltage range 1	1000	150 to 250	up to 125	150 to 250	500
	100/10	50 to 250	up to 125	50 to 250*1	—
VSCR_2, voltage range 2	1000	100 to 150	up to 75	150 to 225	500
	100/10	50 to 150	up to 75	50 to 225*1	—

Note 1. When using products in the HLQFP176 package, set ESWCLK to 125 MHz or less.

Clock restrictions are as follows:

- ICLK × 1.5 ≥ ESWCLK
- ESWCLK > PCLKA
- ICLK > PCLKA.

29.5.2 PHY Interface

29.5.2.1 PHY Interface Select

Table 29.11 lists the configuration settings for the ESWM PHY interface. Set the MIICRn.MIISEL[1:0] bits first before setting the MPIC register in RMACn.

Table 29.11 Configuration settings for ESWM PHY interface

Type	Speed	RMACn.MPIC		MIICRn
		LSC[2:0]	PIS[2:0]	MIISEL[1:0]
MII	10 Mbps	000b	000b (MII)	00b
MII	100 Mbps	001b	000b (MII)	00b
GMII	1 Gbps	010b	010b (GMII)	00b
RGMII	10 Mbps	000b	000b (MII)	01b
RGMII	100 Mbps	001b	000b (MII)	01b
RGMII	1 Gbps	010b	010b (GMII)	01b
RMII	10 Mbps	000b	000b (MII)	10b
RMII	100 Mbps	001b	000b (MII)	10b

29.5.2.2 MII/GMII Interface

When MIICRn.MIISEL[1:0] = 00b, MII/GMII interface is selected. GTX_CLK is generated by dividing ESWPHYCLK by 4.

29.5.2.3 RGMII Interface

ESWM can be converted from an external RGMII to an internal GMII/MII. The RGMII interface is enabled when MIICRn.MIISEL[1:0] = 01b. Since the initial state of the ESWM PHY interface is MII/GMII, it becomes operational after the reset is released with the MIIRR.RGRST bit. At this time, TXC is generated by dividing ESWPHYCLK. MIICRn. Set MIISEL[1:0] to 01b before a release reset.

29.5.2.3.1 RGMII Internal Delay Mode

The RGMII interface supports internal delay mode for RGMIIn_TXC.

29.5.2.4 RMII Interface

ESWM can be converted from an external RMII to an internal MII. The RMII interface is enabled when MIICRn.MIISEL[1:0] = 10b. Since the initial state of the ESWM PHY interface is MII/GMII, it becomes operational after the reset is released with the MIIRR.RMRST bit. Set MIICRn.MIISEL[1:0] to 10b before a release reset.

29.5.3 ESWM Core Function

See the following chapters:

- section 30, Ethernet Message Forwarding Engine (MFWD)
- section 30.5.4. Fabric (MFAB)
- section 31, Ethernet Common Agent (COMA)
- section 32, Ethernet Agent (ETHA)
- section 33, Ethernet MAC (RMAC)
- section 34, Ethernet CPU Agent (GWCA).

29.5.4 gPTP and PTP Pulse Generator

See the following chapters:

- section 35, Ethernet Generic PTP Timer (GPTP)
- section 35.6. Pulse Output Timer Module (plsotim).

29.5.5 TAS Gate Status Monitor

The signal to be output to the ET_TAS_STAn pin can be selected using the TASSTMS register. Table 29.12 lists the TASSTMS register select table.

Table 29.12

MSSn[4:0]	Module	Signal
00000b to 01000b	ETHA0	eha_race_tas_gate_state[0] to eha_race_tas_gate_state[8]
10000b to 11000b	ETHA1	eha_race_tas_gate_state[0] to eha_race_tas_gate_state[8]

For details of eha_race_tas_gate_state[8:0], see section 32, Ethernet Agent (ETHA).

29.6 Interrupt and Event

Table 29.13 Interrupt and event output (1 of 2)

Symbol	Source flag	Description	Type
ETHER_FWEI	MFWD.FWEIS	Forwarding Error Interrupt	Level
ETHER_CAEI	COMA.CAEIS	Common Error Interrupt	Level
ETHER_GWEI	GWCA0.GWEIS0 (other than GWEIS0.TDFES), GWCA0.GWEIS1, GWCA0.GWEIS4, GWCA0.GWEIS5	GWCA0 Error Interrupt	Level
ETHER_EAEI0	ETHA0.EAEIS0, ETHA0.EAEIS1, ETHA0.EAEIS2, RMAC0.MEIS	ETHA0 Error Interrupt	Level
ETHER_EAEI1	ETHA1.EAEIS0, ETHA1.EAEIS1, ETHA1.EAEIS2, RMAC1.MEIS	ETHA1 Error Interrupt	Level

Table 29.13 Interrupt and event output (2 of 2)

Symbol	Source flag	Description	Type
ETHER_PTPSI0	GPTP.PTPIS0	gPTP Status Interrupt 0	Level
ETHER_PTPSI1	GPTP.PTPIS1	gPTP Status Interrupt 1	Level
ETHER_FWSI	MFWD.FWMIS	Forwarding Status Interrupt	Level
ETHER_CAMI	COMA.CAMIS	Common Status Interrupt	Level
ETHER_EASI0	RMAC0.MMIS	ETHA0 Status Interrupt	Level
ETHER_EASI1	RMAC1.MMIS	ETHA1 Status Interrupt	Level
ETHER_GWDI7	GWCA0.GWDIDS, GWCA0.GWEIS2, GWCA0.GWEIS3 with mapped by TOP.TPEMIMC7t	GWCA Data Interrupt	Level
ETHER_GWDI6			
ETHER_GWDI5			
ETHER_GWDI4			
ETHER_GWDI3			
ETHER_GWDI2

ETHER_MDIO1	RMAC1.MMIS1	MDIO Interrupt 1	Level
ETHER_RMPI0	RMAC0.MMIS.LPIAIS, RMAC0.MMIS.LPIDIS, RMAC0.MMIS.MPDIS	RMAC0 PHY Interrupt	Level
ETHER_RMPI1	RMAC1.MMIS.LPIAIS, RMAC1.MMIS.LPIDIS, RMAC1.MMIS.MPDIS	RMAC1 PHY Interrupt	Level
GPTP_MATCH0	—	Media Clock Recovery Match 0	Pulse
GPTP_MATCH1	—	Media Clock Recovery Match 1	Pulse
GPTP_PTPOUT0	—	PTP Pulse Out 0	Pulse
GPTP_PTPOUT1	—	PTP Pulse Out 1	Pulse
GPTP_PTPOUT2	—	PTP Pulse Out 2	Pulse
GPTP_PTPOUT3	—	PTP Pulse Out 3	Pulse

Table 29.14 Event input

Symbol	Event source	Description
ELC_GPTP0	ELSR31	gPTP Media clock capture event 0
ELC_GPTP1	ELSR32	gPTP Media clock capture event 1

The gPTP media clock capture can select event source using the PTP Capture Event Select register.

29.7 Usage Notes

29.7.1 Settings for the Module-Stop Function

The MSTPC30 bit in Module Stop Control Register C (MSTPCRC) can enable or disable the ESWM module operation. The modules are initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Mode.

29.7.2 Transition to Software Standby Mode

ESWM should run Switch disable flow to disable it before transitioning to software standby.

If RGMII interface or RMII interface is selected, these interfaces need to be reset after Switch disable flow by the MIIRR register.

29.7.3 Return from Software Standby Mode

After returning from Software Standby mode, ESWM should run the switch initialization flow to initialize it.

29.7.4 Transition to ESWM Power Domain off by Power Gating

ESWM should run Switch disable flow to disable it before transitioning to the ESWM power domain off.

If RGMII interface or RMII interface is selected, these interfaces need to be reset after switch disable flow by the MIIRR register.

29.7.5 Transition to ESWM Power Domain on by Power Gating

After the ESWM power domain is on, ESWM should run the switch initialization flow to initialize it.

30. Ethernet Message Forwarding Engine (MFWD)

30.1 Overview

Ethernet Message Forwarding Engine (MFWD) is part of ESWM and aims to filter, forward, and route the switch frames. MFWD snoops the frame information from fabric to redistribute them to the agent after filtering, forwarding, and routing mechanisms.

Table 30.1 lists the MFWD specifications and Figure 30.1 shows a block diagram.

Table 30.1 MFWD specifications

Function		Details
Overall function	Cut-through	Forwarding frames while receiving them depending on Layer 2
	Direct forwarding	Forwarding frames coming from GWCAs by bypassing the forwarding engine [GWCA]
	Layer 3 forwarding	Forwarding frames based on a stream ID
	Layer 2 forwarding	Forwarding frames based on destination MAC addresses and VLAN
	Port based forwarding	Forwarding frames depending on source port
	L23U	Update of Layer 2 and Layer 3 depending on Layer 3 forwarding
	PSFP	PSFP filtering [PSFP] depending on Layer 3 forwarding
	ATS	ATS traffic shaping [ATS]
	FRER	FRER [FRER] depending on Layer 3 forwarding
Data provision	Ethernet Frames	Corresponds to the IEEE 802.3, 802.1Q and 802.1CB standards [802.3] [802.1Q] [802.1CB].
	Descriptors	Local Ethernet Descriptor, Local Direct Descriptor (Agents to MFWD) Forwarding descriptor (MFWD to Agents)

Figure 30.1 shows MFWD block diagram.

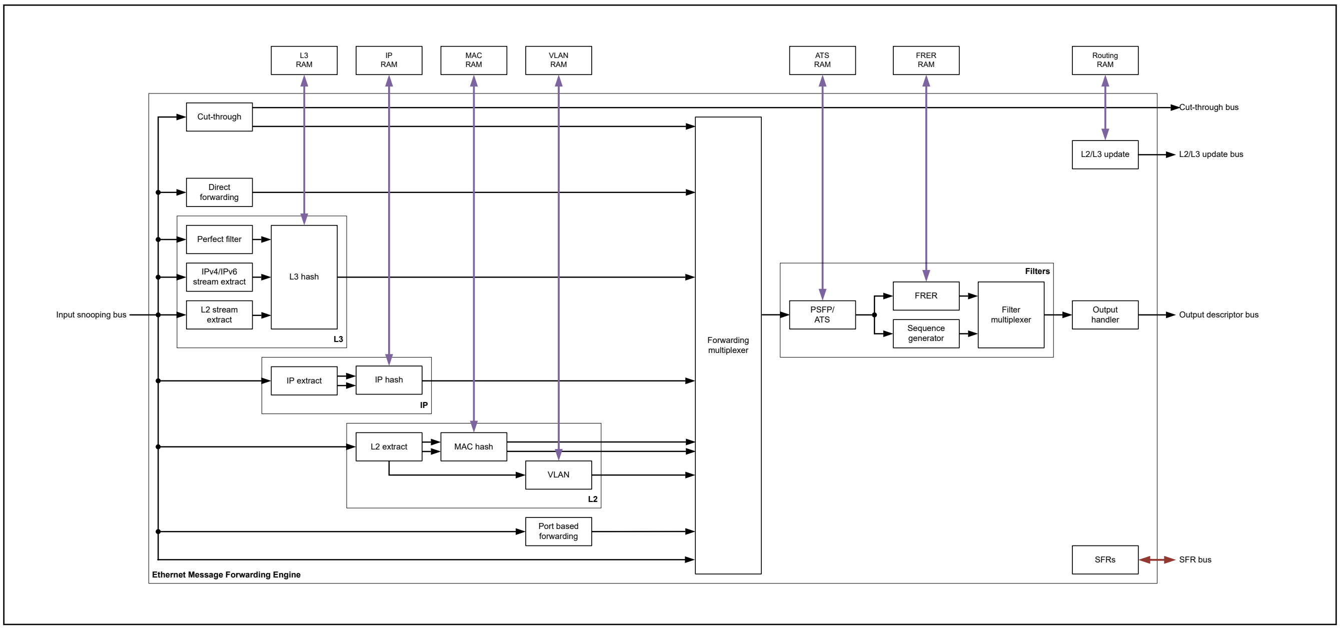

Figure 30.1 MFWD block diagram

Table 30.2 MFWD functional blocks (1 of 2)

Block name	Function
Cut-through	Filter frame L2 and send them to while receiving them.

Table 30.2 MFWD functional blocks (2 of 2)

Block name	Function
Direct forwarding	Forward frames coming from a CPU with the forwarding information already present.
L3	L2 to L4 Stream based forwarding/routing engine
L2	L2 switch
Port based forwarding	Source port-based forwarding
Forwarding multiplexer	Arbitrate between all the forwarding/routing mechanisms
PSFP/ATS	Per stream filtering and policing [802.1Qci] and asynchronous traffic shaping [802.1Qcr]
FRER	Frame Replication and Elimination for Reliability [802.1CB]
Sequence generator	Sequence number generation for FRER proxy functionality [802.1CB]
Filter multiplexer	Arbitrate between forwarding results and filtering results.
Output handler	Copy and send descriptors to targets. Manage overflow and security error recovery.

30.2 MFWD Register List

Table 30.3 MFWD registers (1 of 7)

Offset address	Register name	Register symbol
0x0000	General Configuration Register	FWGC
0x0010	TAG TPID Configuration Register 0	FWTTC0
0x0014	TAG TPID Configuration Register 1	FWTTC1
0x0020	CPU Exceptional Path Target Configuration Register	FWCEPTC

0x4E3C	Layer 2/Layer 3 Update Rule Read Result Register 2	FWL23URRR2
0x4E40	Layer 2/Layer 3 Update Rule Read Result Register 3	FWL23URRR3

Table 30.3 MFWD registers (5 of 7)

Offset address	Register name	Register symbol
0x4F00 + 0x04 × i	Layer 2/Layer 3 Update Remapping Configuration Register i (i = 0 to 31)	FWL23URMCi
0x5000 + 0x04 × i	PSFP MSDU Filter Global Configuration Register i (i = 0 to 15)	FWPMFGCi
0x5600 + 0x20 × i	PSFP Meter i Filter Configuration Register (i = 0 to 31)	FWPMTRFCi
0x5604 + 0x20 × i	PSFP Meter i CBS Configuration Register (i = 0 to 31)	FWPMTRCBSCi
0x5608 + 0x20 × i	PSFP Meter i CIR Configuration Register (i = 0 to 31)	FWPMTRCIRCi
0x560C + 0x20 × i	PSFP Meter i EBS Configuration Register (i = 0 to 7)	FWPMTREBSCi
0x5610 + 0x20 × i	PSFP Meter i EIR Configuration Register (i = 0 to 7)	FWPMTREIRCi
0x5614 + 0x20 × i	PSFP Meter i Filter Monitoring Register (i = 0 to 31)	FWPMTRFMi
0x6000	FRER Table Learn Register 0	FWFTL0
0x6004	FRER Table Learn Register 1	FWFTL1
0x6008	FRER Table Learn Result Register	FWFTLR
0x6010	FRER Timeout Configuration Register	FWFTOC
0x6014	FRER Timeout Prescaler Configuration Register 0	FWFTOPC
0x6020	FRER Table Initialization Monitoring Register	FWFTIM
0x6030	FRER Table Read Register	FWFTR
0x6034	FRER Table Read Result Register 0	FWFTRR0
0x6038	FRER Table Read Result Register 1	FWFTRR1
0x603C	FRER Table Read Result Register 2	FWFTRR2
0x6100 + 0x08 × i	Sequence Number Generation i Configuration Register (i = 0 to 31)	FWSEQNGCi
0x6104 + 0x08 × i	Sequence Number Generation i Monitoring Register (i = 0 to 31)	FWSEQNGMi
0x6200	Sequence Number Reset Configuration Register	FWSEQNRC
0x6300 + 0x20 × i E: 0x6E00 + 0x20 × i	Port i Cut-Through Forwarded Descriptor Counter Register (i = 0, 1)	FWCTFDCNi
0x6340 E: 0x6E40	Port 2 Direct Descriptor Forwarded Descriptor Counter Register	FWDDFDCN2
0x6304 + 0x20 × i E: 0x6E04 + 0x20 × i	Port i Layer 3 Forwarded Descriptor Counter Register (i = 0 to 2)	FWLTHFDCNi
0x630C + 0x20 × i E: 0x6E0C + 0x20 × i	Port i Layer 2 Forwarded Descriptor Counter Register (i = 0 to 2)	FWLTWFDCNi
0x6310 + 0x20 × i E: 0x6E10 + 0x20 × i	Port i Port Based Forwarded Descriptor Counter Register (i = 0 to 2)	FWPBFDCNi
0x6314 + 0x20 × i E: 0x6E14 + 0x20 × i	Port i MAC Hardware Learn Counter Register (i = 0 to 2)	FWMHLCNi
0x6504 + 0x20 × i E: 0x7004 + 0x20 × i	Port i Watermark Rejected Descriptor Counter Register (i = 0 to 2)	FWWMRDCNi
0x6508 + 0x20 × i E: 0x7008 + 0x20 × i	Port i Cut-Through Rejected Descriptor Counter Register (i = 0, 1)	FWCTRDCNi
0x6548 E: 0x7048	Port 2 Direct Descriptor Rejected Descriptor Counter Register	FWDDRDCN2
0x650C + 0x20 × i E: 0x700C + 0x20 × i	Port i Layer 3 Rejected Descriptor Counter Register (i = 0 to 2)	FWLTHRDCNi
0x6514 + 0x20 × i E: 0x7014 + 0x20 × i	Port i Layer 2 Rejected Descriptor Counter Register (i = 0 to 2)	FWLTWRDCNi
0x6518 + 0x20 × i E: 0x7018 + 0x20 × i	Port i Port Based Rejected Descriptor Counter Register (i = 0 to 2)	FWPBRDCNi
0x6700 + 0x04 × i E: 0x7200 + 0x04 × i	PSFP MSDU i Filtered Descriptor Counter Register (i = 0 to 15)	FWPMFDCNi

Table 30.3 MFWD registers (6 of 7)

Offset address	Register name	Register symbol
0x6800 + 0x10 × i E: 0x7300 + 0x10 × i	PSFP Meter i Green Descriptor Counter Register (i = 0 to 31)	FWPMGDCNi
0x6804 + 0x10 × i E: 0x7304 + 0x10 × i	PSFP Meter i Yellow Descriptor Counter Register (i = 0 to 7)	FWPMYDCNi
0x6808 + 0x10 × i E: 0x7308 + 0x10 × i	PSFP Meter i Red Descriptor Counter Register (i = 0 to 31)	FWPMRDCNi
0x6A00 + 0x08 × i E: 0x7500 + 0x08 × i	FRER i Passed Packet Counter Register (i = 0 to 127)	FWFRPPCNi
0x6A04 + 0x08 × i E: 0x7504 + 0x08 × i	FRER i Discarded Packet Counter Register (i = 0 to 127)	FWFRDPCNi
0x7900 + 0x10 × i	Port i Error Interrupt Status Register 0 (i = 0 to 2)	FWEIS0i
0x7904 + 0x10 × i	Port i Error Interrupt Enable Register 0 (i = 0 to 2)	FWEIE0i
0x7908 + 0x10 × i	Port i Error Interrupt Disable Register 0 (i = 0 to 2)	FWEID0i
0x7A00	Error Interrupt Status Register 1	FWEIS1
0x7A04	Error Interrupt Enable Register 1	FWEIE1
0x7A08	Error Interrupt Disable Register 1	FWEID1
0x7A10	Error Interrupt Status Register 2	FWEIS2
0x7A14	Error Interrupt Enable Register 2	FWEIE2
0x7A18	Error Interrupt Disable Register 2	FWEID2
0x7A40	Error Interrupt Status Register 5	FWEIS5
0x7A44	Error Interrupt Enable Register 5	FWEIE5
0x7A48	Error Interrupt Disable Register 5	FWEID5
0x7A50	Error Interrupt Status Register 60	FWEIS60
0x7A54	Error Interrupt Enable Register 60	FWEIE60
0x7A58	Error Interrupt Disable Register 60	FWEID60
0x7A60	Error Interrupt Status Register 61	FWEIS61
0x7A64	Error Interrupt Enable Register 61	FWEIE61
0x7A68	Error Interrupt Disable Register 61	FWEID61
0x7A70	Error Interrupt Status Register 62	FWEIS62
0x7A74	Error Interrupt Enable Register 62	FWEIE62
0x7A78	Error Interrupt Disable Register 62	FWEID62
0x7A80	Error Interrupt Status Register 63	FWEIS63
0x7A84	Error Interrupt Enable Register 63	FWEIE63
0x7A88	Error Interrupt Disable Register 63	FWEID63
0x7A90	Error Interrupt Status Register 70	FWEIS70
0x7A94	Error Interrupt Enable Register 70	FWEIE70
0x7A98	Error Interrupt Disable Register 70	FWEID70
0x7AA0	Error Interrupt Status Register 71	FWEIS71
0x7AA4	Error Interrupt Enable Register 71	FWEIE71
0x7AA8	Error Interrupt Disable Register 71	FWEID71
0x7AB0	Error Interrupt Status Register 72	FWEIS72
0x7AB4	Error Interrupt Enable Register 72	FWEIE72
0x7AB8	Error Interrupt Disable Register 72	FWEID72
0x7AC0	Error Interrupt Status Register 73	FWEIS73

Table 30.3 MFWD registers (7 of 7)

Offset address	Register name	Register symbol
0x7AC4	Error Interrupt Enable Register 73	FWEIE73
0x7AC8	Error Interrupt Disable Register 73	FWEID73
0x7AD0	Error Interrupt Status Register 80	FWEIS80
0x7AD4	Error Interrupt Enable Register 80	FWEIE80
0x7AD8	Error Interrupt Disable Register 80	FWEID80
0x7AE0	Error Interrupt Status Register 81	FWEIS81
0x7AE4	Error Interrupt Enable Register 81	FWEIE81
0x7AE8	Error Interrupt Disable Register 81	FWEID81
0x7AF0	Error Interrupt Status Register 82	FWEIS82
0x7AF4	Error Interrupt Enable Register 82	FWEIE82
0x7AF8	Error Interrupt Disable Register 82	FWEID82
0x7B00	Error Interrupt Status Register 83	FWEIS83
0x7B04	Error Interrupt Enable Register 83	FWEIE83
0x7B08	Error Interrupt Disable Register 83	FWEID83
0x7C00	Monitoring Interrupt Status Register 0	FWMIS0
0x7C04	Monitoring Interrupt Enable Register 0	FWMIE0
0x7C08	Monitoring Interrupt Disable Register 0	FWMID0

Note: Base address: MFWD = 0x403C_0000, MFWD_NS = 0x503C_0000
Note: The address preceded by “E:” correspond to an emulation address, which allows to read a register without modifying its content.

Note: If nothing specified, a register need an authorization from secured APB interface to be accessed by unsecured APB interface. This applies for Read and Write accesses. Any exception to this rule will be specified under “Security restrictions” or “Security no restrictions” labels.

30.3 MFWD Register Descriptions

30.3.1 MFWD Function Registers

This section describes MFWD function registers.

For MFWD function procedure details, see section 30.4.1. Software Flows.

30.3.1.1 General Function Registers

30.3.1.1.1 FWGC : General Configuration Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SVM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	SVM[1:0]	Switch VLAN Mode 0 0: No VLAN mode (VLAN not used for forwarding) 0 1: C-TAG mode (C-TAG used for forwarding) 1 0: SC-TAG mode (S-TAG used for forwarding) 1 1: Reserved	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

SVM[1:0] bits (Switch VLAN Mode)

HW: If FWGC.SVM is set to 00b, incoming packet PCP and DEI fields will be considered as 0 by MFWD.

For more details, see section 30.5.1.2. ESWM Modes.

30.3.1.1.2 FWTTC0 : TAG TPID Configuration Register 0

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	STT[15:0]															
Value after reset:	1	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CTT[15:0]															
Value after reset:	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CTT[15:0]	C-TAG TPID [801.2Q] Configure the C-TAG TPID.	R/W
31:16	STT[15:0]	S-TAG TPID [801.2Q] Configure the S-TAG TPID.	R/W

Note:
- SW: FWTTC0.CTT, FWTTC0.STT and FWTTC1.RTT registers should always be set to different values.
- SW: This register cannot be set to 0x0000 to 0x05FF, 0x0800 nor 0x86DD.

30.3.1.1.3 FWTTC1 : TAG TPID Configuration Register 1

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RTT[15:0]															
Value after reset:	1	1	1	1	0	0	0	1	1	1	0	0	0	0	0	1

Bit	Symbol	Function	R/W
15:0	RTT[15:0]	R-TAG TPID [801.2CB] Configure the R-TAG TPID.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note:
- SW: FWTTC0.CTT, FWTTC0.STT and FWTTC1.RTT registers should always be set to different values.
- SW: This register cannot be set to 0x0000 to 0x05FF, 0x0800 nor 0x86DD.

30.3.1.1.4 FWCEPTC : CPU Exceptional Path Target Configuration Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	EPSL	—	—	—	—	—	—	—	EPCS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	EPIPV[2:0]			—	—	—	—	—	—	EPCSD[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	EPCSD[5:0]	Exceptional Path CPU Sub Destination Configures the CPU sub destination to which exceptional frames will be sent.	R/W
11:6	—	These bits are read as 0. The write value should be 0.	R/W
14:12	EPIPV[2:0]	Exceptional Path Internal Priority Value Configures the priority to which exceptional frames will be sent.	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
16	EPCS	Exceptional Path CPU Select*1 Configures CPU to which exceptional frames will be sent. See Fabric specification for port mapping [MFAB].	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
24	EPSL	Exceptional Path Security Level Configures descriptor security level for exceptional path.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: These bits should not be set to a value greater than 1.

30.3.1.1.5 FWCEPRC0 : CPU Exceptional Path Reason Configuration Register 0

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0024

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	DDFSFEF	—	DDEEF	—	—	GDNEEF	GTFEF	—	GSEQEEF	GAXEEF	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	ETFEF	EOEEF	EUEEF	EBOEEF	ERPOOEF	ERFFEF	ECFFCEEF	ECFSEEF	EFFMEEF	EFCSEEF	ENIBEEF	EPCRCEEF	EPHYEEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EPHYEEF	Ethernet PHY Error Exceptional Forwarding 0: Frames received with PHY Error are discarded. 1: Frames received with PHY Error are forwarded to exceptional path.	R/W

Bit	Symbol	Function	R/W
1	EPCRCEEF	Ethernet PCH CRC Error Exceptional Forwarding 0: Frames received with PCH CRC Error are discarded. 1: Frames received with PCH CRC Error are forwarded to exceptional path.	R/W
2	ENIBEEF	Ethernet Nibble Error Exceptional Forwarding 0: Frames received with Nibble Error are discarded. 1: Frames received with Nibble Error are forwarded to exceptional path.	R/W
3	EFCSEEF	Ethernet FCS Error Exceptional Forwarding 0: Frames received with FCS Error are discarded. 1: Frames received with FCS Error are forwarded to exceptional path.	R/W
4	EFFMEEF	Ethernet Final Fragment Missing Error Exceptional Forwarding 0: Frames received with Final Fragment Missing Error are discarded. 1: Frames received with Final Fragment Missing Error are forwarded to exceptional path.	R/W
5	ECFSEEF	Ethernet C-Fragment SMD Error Exceptional Forwarding 0: Frames received with C-Fragment SMD Error are discarded. 1: Frames received with C-Fragment SMD Error are forwarded to exceptional path.	R/W
6	ECFFCEEF	Ethernet C-Fragment FRAG_COUNT Error Exceptional Forwarding 0: Frames received with C-Fragment FRAG_COUNT Error are discarded. 1: Frames received with C-Fragment FRAG_COUNT Error are forwarded to exceptional path.	R/W
7	ERFFEF	Ethernet RMAC Frame Filtered Exceptional Forwarding 0: Frames received with RMAC Frame Filtered flag are discarded. 1: Frames received with RMAC Frame Filtered flag are forwarded to exceptional path.	R/W
8	ERPOOEF	Ethernet Reception Partially Out of Operation Exceptional Forwarding 0: Frames received with Reception Partially Out of Operation flag are discarded. 1: Frames received with Reception Partially Out of Operation flag are forwarded to exceptional path.	R/W
9	EBOEEF	Ethernet Buffer Overflow Error Exceptional Forwarding 0: Frames received with Buffer Overflow Error are discarded. 1: Frames received with Buffer Overflow Error are forwarded to exceptional path.	R/W
10	EUEEF	Ethernet Undersize Error Exceptional Forwarding 0: Frames received with Undersize Error are discarded. 1: Frames received with Undersize Error are forwarded to exceptional path.	R/W
11	EOEEF	Ethernet Oversize Error Exceptional Forwarding 0: Frames received with Oversize Error are discarded. 1: Frames received with Oversize Error are forwarded to exceptional path.	R/W
12	ETFEF	Ethernet TAG Filtering Exceptional Forwarding 0: Frames received with TAG Filtering flag are discarded. 1: Frames received with TAG Filtering flag are forwarded to exceptional path.	R/W
16:13	—	These bits are read as 0. The write value should be 0.	R/W
17	GAXEEF	GWCA AXI Error Exceptional Forwarding 0: Frames received with AXI Error are discarded. 1: Frames received with AXI Error are forwarded to exceptional path.	R/W
18	GSEQEEF	GWCA Sequence Error Exceptional Forwarding 0: Frames received with Sequence Error are discarded. 1: Frames received with Sequence Error are forwarded to exceptional path.	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
20	GTFEF	GWCA TAG Filtering Exceptional Forwarding 0: Frames received with TAG Filtering flag are discarded. 1: Frames received with TAG Filtering flag are forwarded to exceptional path.	R/W
21	GDNEEF	GWCA Descriptor Number Error Exceptional Forwarding 0: Frames received with Descriptor Number Error are discarded. 1: Frames received with Descriptor Number Error are forwarded to exceptional path.	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
24	DDEEF	Direct Descriptor Error Exceptional Forwarding 0: Frames with Direct Descriptor Error are discarded. 1: Frames with Direct Descriptor Error are forwarded to exceptional path.	R/W
25	—	This bit is read as 0. The write value should be 0.	R/W
26	DDFSFEF	Direct Descriptor Format Security Filtering Exceptional Forwarding 0: Frames with Direct Descriptor Format Security Error are discarded. 1: Frames with Direct Descriptor Format Security Error are forwarded to exceptional path.	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note:
- For ethernet error/flag explanations, refer to Ethernet agent specification document [ETHA].
- For GWCA error/flag explanations, refer to GWCA specification document [GWCA].

30.3.1.1.6 FWCEPRC1 : CPU Exceptional Path Reason Configuration Register 1

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0028

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	FSFFEF	FIFFEF	—	—	—	—	—	FMTRFEF	—	FMSDUFEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FMSDUFEF	MSDU Filtering Exceptional Forwarding 0: Frames filtered by PSFP MSDU filter are discarded. 1: Frames filtered by PSFP MSDU filter are forwarded to exceptional path.	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	FMTRFEF	Meter Filtering Exceptional Forwarding 0: Frames filtered by PSFP Meter filter are discarded. 1: Frames filtered by PSFP Meter filter are forwarded to exceptional path.	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	FIFFEF	Individual FRER Filtering Exceptional Forwarding 0: Frames filtered by FRER individual recovery are discarded. 1: Frames filtered by FRER individual recovery are forwarded to exceptional path.	R/W
9	FSFFEF	Sequence FRER Filtering Exceptional Forwarding 0: Frames filtered by FRER Sequence recovery are discarded. 1: Frames filtered by FRER Sequence recovery are forwarded to exceptional path.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.1.7 FWCEPRC2 : CPU Exceptional Path Reason Configuration Register 2

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x002C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	FWMFEF	—	—	—	—	FVLANSLFEF	FSMACSLFEF	FDMACSLFEF	—	—	FLTHSLFEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	FPBNTFEF	FLTWNTFEF	—	FLTHNTFEF	FDDNTFEF	—	—	FVLANUFEF	FSMACUFEF	FDMACUFEF	—	—	FLTHUFEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FLTHUFEF	Layer 3 Unknown Filtering Exceptional Forwarding 0: Frames filtered because their stream ID is unknown are discarded. 1: Frames filtered because their stream ID is unknown are forwarded to exceptional path.	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	FDMACUFEF	Destination MAC Unknown Filtering Exceptional Forwarding 0: Frames filtered because their Destination MAC is unknown are discarded. 1: Frames filtered because their Destination MAC is unknown are forwarded to exceptional path.	R/W
4	FSMACUFEF	Source MAC Unknown Filtering Exceptional Forwarding 0: Frames filtered because their Source MAC is unknown are discarded. 1: Frames filtered because their Source MAC is unknown are forwarded to exceptional path.	R/W
5	FVLANUFEF	VLAN Unknown Filtering Exceptional Forwarding 0: Frames filtered because their VLAN is unknown are discarded. 1: Frames filtered because their VLAN is unknown are forwarded to exceptional path.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	FDDNTFEF	Direct Descriptor No Target Filtering Exceptional Forwarding 0: Frames filtered because no target during direct forwarding is detected are discarded. 1: Frames filtered because no target during direct forwarding is detected are forwarded to exceptional path.	R/W
9	FLTHNTFEF	Layer 3 No Target Filtering Exceptional Forwarding 0: Frames filtered because no target during Layer 3 forwarding is detected are discarded. 1: Frames filtered because no target during Layer 3 forwarding is detected are forwarded to exceptional path.	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	FLTWNTFEF	Layer 2 No Target Filtering Exceptional Forwarding 0: Frames filtered because the combination on VLAN destination vector and destination MAC destination vector is null are discarded. 1: Frames filtered because the combination on VLAN destination vector and destination MAC destination vector is null are forwarded to exceptional path.	R/W
12	FPBNTFEF	Port Based No Target Filtering Exceptional Forwarding 0: Frames filtered because no target during Port Based forwarding is detected are discarded. 1: Frames filtered because no target during Port Based forwarding is detected are forwarded to exceptional path.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	FLTHSLFEF	Layer 3 Source Lock Filtering Exceptional Forwarding 0: Frames filtered because of Layer 3 source lock are discarded. 1: Frames filtered because of Layer 3 source lock are forwarded to exceptional path.	R/W
18:17	—	These bits are read as 0. The write value should be 0.	R/W
19	FDMACSLFEF	Destination MAC Source Lock Filtering Exceptional Forwarding 0: Frames filtered because of Destination MAC source lock are discarded. 1: Frames filtered because of Destination MAC source lock are forwarded to exceptional path.	R/W
20	FSMACSLFEF	Source MAC Source Lock Filtering Exceptional Forwarding 0: Frames filtered because of Source MAC source lock are discarded. 1: Frames filtered because of Source MAC source lock are forwarded to exceptional path.	R/W
21	FVLANSLFEF	VLAN Source Lock Filtering Exceptional Forwarding 0: Frames filtered because of VLAN source lock are discarded. 1: Frames filtered because of VLAN source lock are forwarded to exceptional path.	R/W
25:22	—	These bits are read as 0. The write value should be 0.	R/W
26	FWMFEF	Watermark Filtering Exceptional Forwarding 0: Frames filtered because of watermark are discarded. 1: Frames filtered because of watermark are forwarded to exceptional path.	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.1.8 FWCLPTC : CPU Learning Path Target Configuration Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0030

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	LPSL	—	—	—	—	—	—	—	LPCS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	LPIPV[2:0]			—	—	—	—	—	—	LPCSD[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	LPCSD[5:0]	Learning Path CPU Sub Destination Configures the CPU sub destination to which Learning frames will be sent.	R/W
11:6	—	These bits are read as 0. The write value should be 0.	R/W
14:12	LPIPV[2:0]	Learning Path Internal Priority Value Configures the priority to which Learning frames will be sent.	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
16	LPCS	Learning Path CPU Select*1 Configures CPU to which Learning frames will be sent. See Fabric specification for port mapping [MFAB].	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
24	LPSL	Learning Path Security Level Configures descriptor security level for Learning path.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: These bits should not be set to a value greater than 1.

30.3.1.1.9 FWCLPRC : CPU Learning Path Reason Configuration Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	UVLANLF	UPSMACLF	USMACLF	UDMACLF	—	—	—	USIDLF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	USIDLF	Unknown Stream ID Learning Forwarding 0: Frames received with an unknown stream ID are not forwarded to Learning path. 1: Frames received with an unknown stream ID are forwarded to Learning path.	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	UDMACLF	Unknown Destination MAC Learning Forwarding 0: Frames received with an unknown destination MAC address are not forwarded to Learning path. 1: Frames received with an unknown destination MAC address are forwarded to Learning path.	R/W
5	USMACLF	Unknown Source MAC Learning Forwarding 0: Frames received with an unknown Source MAC are not forwarded to Learning path. 1: Frames received with an unknown Source MAC are forwarded to Learning path.	R/W
6	UPSMACLF	Unknown Port for Source MAC Learning Forwarding 0: Frames received with an unknown port for Source MAC are not forwarded to Learning path. 1: Frames received with an unknown port for Source MAC are forwarded to Learning path.	R/W
7	UVLANLF	Unknown VLAN Learning Forwarding 0: Frames received with an unknown VLAN are not forwarded to Learning path. 1: Frames received with an unknown VLAN are forwarded to Learning path.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.1.10 FWCMPTC : CPU Mirroring Path Target Configuration Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0040

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	CMPSL	—	—	—	—	—	—	—	CMPCS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPIPU	CMPIPV[2:0]			—	—	—	—	—	—	CMPCSD[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CMPCSD[5:0]	CPU Mirroring Path CPU Sub Destination Configures the CPU sub destination to which CPU mirroring frames will be sent.	R/W
11:6	—	These bits are read as 0. The write value should be 0.	R/W
14:12	CMPIPV[2:0]	CPU Mirroring Path Internal Priority Value	R/W
15	CMPIPU	CPU Mirroring Path Internal Priority Update 0: Frames mirrored to CPU path are sent with the same priority as for forwarding. 1: Frames mirrored to CPU path are sent with FWCMPTC.CMPIPV priority.	R/W
16	CMPCS	CPU Mirroring Path CPU Select*1 Configures CPU to which CPU mirroring frames will be sent. See Fabric specification for port mapping [MFAB].	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
24	CMPSL	CPU Mirroring Path Security Level Configures descriptor security level for CPU mirroring path.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: These bits should not be set to a value greater than 1.

30.3.1.1.11 FWEMPTC : Ethernet Mirroring Path Target Configuration Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0044

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	EMPSL	—	—	—	—	—	—	—	EMPPS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EMPIPU	EMPIPV[2:0]			—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	—	These bits are read as 0. The write value should be 0.	R/W
14:12	EMPIPV[2:0]	Ethernet Mirroring Path Internal Priority Value	R/W
15	EMPIPU	Ethernet Mirroring Path Internal Priority Update 0: Frames mirrored to Ethernet path are sent with the same priority as for forwarding. 1: Frames mirrored to Ethernet path are sent with FWEMPTC.EMPIPV priority.	R/W
16	EMPPS	Ethernet Mirroring Path Port Select*1 Configures port to which Ethernet mirroring frames will be sent. See Fabric specification for port mapping [MFAB].	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
24	EMPSL	Ethernet Mirroring Path Security Level Configures descriptor security level for Ethernet mirroring path.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: These bits should not be set to a value greater than 1.

30.3.1.1.12 FWSDMPTC : Source-Destination Mirroring Path Target Configuration Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0050

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	SDMPSL	—	—	—	—	—	—	SDMPPS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SDMPIPU	SDMPIPV[2:0]			—	—	—	—	—	—	SDMPCSD[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	SDMPCSD[5:0]	Source-Destination Mirroring Path CPU Sub Destination Configures the CPU sub destination to which Source-Destination mirroring frames will be sent.	R/W
11:6	—	These bits are read as 0. The write value should be 0.	R/W
14:12	SDMPIPV[2:0]	Source-Destination Mirroring Path Internal Priority Value	R/W
15	SDMPIPU	Source-Destination Mirroring Path Internal Priority Update 0: Frames mirrored to Source-Destination path are sent with the same priority as for forwarding. 1: Frames mirrored to Source-Destination path are sent with FWSDMPTC.SDMPIPV priority.	R/W
17:16	SDMPPS[1:0]	Source-Destination Mirroring Path Port Select*1 Configures Port to which Source-Destination mirroring frames will be sent. See Fabric specification for port mapping [MFAB].	R/W
23:18	—	These bits are read as 0. The write value should be 0.	R/W
24	SDMPSL	Source-Destination Mirroring Path Security Level Configures descriptor security level for Source-Destination mirroring path.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: These bits should not be set to a value greater than 3.

30.3.1.1.13 FWSDMPVC : Source-Destination Mirroring Path Vector Configuration Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0054

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	SDMSV[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	SDMDV[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SDMDV[2:0]	Source-Destination Mirroring Destination Vector	R/W
15:3	—	These bits are read as 0. The write value should be 0.	R/W
18:16	SDMSV[2:0]	Source-Destination Mirroring Source Vector	R/W
31:19	—	These bits are read as 0. The write value should be 0.	R/W

SDMDV[2:0] bits (Source-Destination Mirroring Destination Vector)

Frames coming from a port set in FWSDMPVC.SDMSV register and sent to a port set in FWSDMPVC.SDMDV register is also duplicated to Source-Destination mirroring path.

Setting this register to 0 disable Source-Destination mirroring path.

SDMSV[2:0] bits (Source-Destination Mirroring Source Vector)

Frames coming from a port set in FWSDMPVC.SDMSV register and sent to a port set in FWSDMPVC.SDMDV register is also duplicated to Source-Destination mirroring path.

Setting this register to 0 disable Source-Destination mirroring path.

30.3.1.1.14 FWLBWMCi : Port i Level Based Watermark Configuration Register (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0080 + 0x4 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	WMFLPR15 to WMFLPR0															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WMCLPR15 to WMCLPR0															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WMCLPR0 to WMCLPR15	Watermark Critical Level Priority n Reject (n = 0 to 15)*1 0: Frames coming for port i and that should be forwarded with {DEI,IPV} equal to j are forwarded. 1: Frames coming for port i and that should be forwarded with {DEI,IPV} equal to j are discarded when watermark critical level is set for port i (WM.CRITICAL[i] is set [COMA]).	R/W
31:16	WMFLPR0 to WMFLPR15	Watermark Flush Level Priority n Reject (n = 0 to 15)*1 0: Frames coming for port i and that should be forwarded with {DEI,IPV} equal to j are forwarded. 1: Frames coming for port i and that should be forwarded with {DEI,IPV} equal to j are discarded when watermark flush level is set for port i (WM.FLUSH[i] is set [COMA]).	R/W

Note 1. {DEI,IPV} refers to the bit association {DEI,IPV[2:0]}, so in decimal it can be written 8*DEI+IPV.

30.3.1.1.15 FWPCi0 : Port i Configuration Register 0 (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0100 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	VLAN RUS	VLAN RU	VLAN SA	MACH MA	MACH LA	MACR USSA	MACR USA	MACS SA	MACR UDSA	MACR UDA	MACD SA	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	L2SE	IP6OE	IP6TE	IP6UE	IP4OE	IP4TE	IP4UE	LTHR USS	LTHR US	LTHTA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LTHTA	L3 Table Active 0: L3 table is disabled for source port i. 1: L3 table is enabled for source port i.	R/W
1	LTHRUS	L3 Reject Unknown Streams 0: Unknown streams coming from source port i are not rejected. 1: Unknown streams coming from source port i are rejected.	R/W
2	LTHRUSS	L3 Reject Unknown Secure Streams 0: Unknown secure streams coming from source port i are not rejected. 1: Unknown secure streams coming from source port i are rejected.	R/W
3	IP4UE	IPv4 UDP Enable 0: IPv4/UDP detection disabled for source port i. 1: IPv4/UDP detection enabled for source port i.	R/W
4	IP4TE	IPv4 TCP Enable 0: IPv4/TCP detection disabled for source port i. 1: IPv4/TCP detection enabled for source port i.	R/W
5	IP4OE	IPv4 Other Enable 0: Non-TCP non-UDP IPv4 detection disabled for source port i. 1: Non-TCP non-UDP IPv4 detection enabled for source port i.	R/W
6	IP6UE	IPv6 UDP Enable 0: IPv6/UDP detection disabled for source port i. 1: IPv6/UDP detection enabled for source port i.	R/W
7	IP6TE	IPv6 TCP Enable 0: IPv6/TCP detection disabled for source port i. 1: IPv6/TCP detection enabled for source port i.	R/W
8	IP6OE	IPv6 Other Enable 0: Non-TCP non-UDP IPv6 detection disabled for source port i. 1: Non-TCP non-UDP IPv6 detection enabled for source port i.	R/W
9	L2SE	L2 Stream Enable 0: L2 stream disabled for source port i. 1: L2 stream enabled for source port i.	R/W
19:10	—	These bits are read as 0. The write value should be 0.	R/W
20	MACDSA	MAC Destination Search Active 0: MAC Destination search is disabled for source port i. 1: MAC Destination search is enabled for source port i.	R/W
21	MACRUDA	MAC Reject Unknown Destination Addresses 0: Unknown MAC Destination addresses coming from source port i are not rejected. 1: Unknown MAC Destination addresses coming from source port i are rejected.	R/W

Bit	Symbol	Function	R/W
22	MACRUDSA	MAC Reject Unknown Destination Secure Addresses 0: Unknown secure MAC Destination addresses coming from source port i are not rejected. 1: Unknown secure MAC Destination addresses coming from source port i are rejected.	R/W
23	MACSSA	MAC Source Search Active 0: MAC Source search is disabled for source port i. 1: MAC Source search is enabled for source port i.	R/W
24	MACRUSA	MAC Reject Unknown Source Addresses 0: Unknown MAC Source addresses coming from source port i are not rejected. 1: Unknown MAC Source addresses coming from source port i are rejected.	R/W
25	MACRUSSA	MAC Reject Unknown Source Secure Addresses 0: Unknown secure MAC Source addresses coming from source port i are not rejected. 1: Unknown secure MAC Source addresses coming from source port i are rejected.	R/W
26	MACHLA	MAC Hardware Learning Active 0: Unknown unicast MAC Source addresses coming from source port i are not added to the MAC table. 1: Unknown unicast MAC Source addresses coming from source port i are added to the MAC table.	R/W
27	MACHMA	MAC Hardware Migration Active 0: Known unicast MAC Source addresses coming from source port i with a wrong source port in MAC.DV are not overwritten. 1: Known unicast MAC Source addresses coming from source port i with a wrong source port in MAC.DV are overwritten.	R/W
28	VLANSA	VLAN Search Active*1 HW: If VLAN Destination search is disabled for port i, all frames coming from port i are considered as unknown for VLAN search. 0: VLAN search is disabled for source port i. 1: VLAN search is enabled for source port i.	R/W
29	VLANRU	VLAN Reject Unknown*1 0: Unknown VLAN coming from source port i are not rejected. 1: Unknown VLAN coming from source port i are rejected.	R/W
30	VLANRUS	VLAN Reject Unknown Secure*1 0: Unknown secure VLAN coming from source port i are not rejected. 1: Unknown secure VLAN coming from source port i are rejected.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note 1. SW: This bit should be set to 1 if FWGC.SVM is set to 00b.

30.3.1.1.16 FWPCi1 : Port i Configuration Register 1 (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0104 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	LTHFM2 to LTHFM0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CTMDE	Cut-Through MAC Destination Enable 0: MAC destination not included in Cut-Through separation for separation rule i. 1: MAC destination included in Cut-Through separation for separation rule i.	R/W
1	CTMSE	Cut-Through MAC Source Enable 0: MAC Source not included in Cut-Through separation for separation rule i. 1: MAC Source included in Cut-Through separation for separation rule i.	R/W
2	CTCVE	Cut-Through C-TAG VLAN Enable*1 0: C-TAG VLAN not included in Cut-Through separation for separation rule i. 1: C-TAG VLAN included in Cut-Through separation for separation rule i.	R/W
3	CTCPE	Cut-Through C-TAG PCP Enable*1 0: C-TAG PCP not included in Cut-Through separation for separation rule i. 1: C-TAG PCP included in Cut-Through separation for separation rule i.	R/W
4	CTCDE	Cut-Through C-TAG DEI Enable*1 0: C-TAG DEI not included in Cut-Through separation for separation rule i. 1: C-TAG DEI included in Cut-Through separation for separation rule i.	R/W
5	CTSVE	Cut-Through S-TAG VLAN Enable*2 0: S-TAG VLAN not included in Cut-Through separation for separation rule i. 1: S-TAG VLAN included in Cut-Through separation for separation rule i.	R/W
6	CTSPE	Cut-Through S-TAG PCP Enable*2 0: S-TAG PCP not included in Cut-Through separation for separation rule i. 1: S-TAG PCP included in Cut-Through separation for separation rule i.	R/W
7	CTSDE	Cut-Through S-TAG DEI Enable*2 0: S-TAG DEI not included in Cut-Through separation for separation rule i. 1: S-TAG DEI included in Cut-Through separation for separation rule i.	R/W
8	CTETE	Cut-Through Ethernet Type Enable 0: Ethernet Type not included in Cut-Through separation for separation rule i. 1: Ethernet Type included in Cut-Through separation for separation rule i.	R/W
10:9	—	These bits are read as 0. The write value should be 0.	R/W
11	CTFI	Cut-Through FCS In*3 This bit is used as FDESCR.FI for cut-through. 0: The frame matching separation rule i as no FCS included. 1: The frame matching separation rule i as an FCS included.	R/W
13:12	CTVCTRL[1:0]	Cut-Through VLAN Control [GWCA] [ETHA] These bits are used as FDESCR.VCTRL[1:0] for cut-through. 0 0: The ingress matching separation rule i frame is a No TAG frame. 0 1: The ingress matching separation rule i frame is a C-TAG frame. 1 0: The ingress matching separation rule i frame is an SC-TAG frame. 1 1: The ingress matching separation rule i frame is a CoS TAG frame.	R/W
14	CTRTGI	Cut-Through R-TAG In [GWCA] [ETHA] This bit is used as FDESCR.RTGI for cut-through. 0: R-TAG is not included in cut-through frame. 1: R-TAG is included in cut-through frame.	R/W
31:15	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: This bit can be set to 1 only if FWGC.SVM is set to 10b or 01b.
Note 2. SW: This bit can be set to 1 only if FWGC.SVM is set to 10b.
Note 3. SW: This bit should be set to the frame source port MRGC.RCPT (same) value [RMAC].

- Case 1: CTFI = 1, RCPT = 1 and correct FCS frame incoming
  → correct FCS frame forwarded
  (The FCS attached to the input frame is output as it is. If the tag is converted, the FCS value will be invalid.)
- Case 2: CTFI = 1, RCPT = 1 and incorrect FCS frame incoming
  → incorrect FCS frame forwarded
- Case 3: CTFI = 0, RCPT = 0 and correct FCS frame incoming
  → correct FCS frame forwarded
- Case 4: CTFI = 0, RCPT = 0 and incorrect FCS frame incoming
  → correct FCS frame forwarded (The correct FCS will be added after the incorrect FCS.)

30.3.1.2.2 FWCTGCi1 : Cut-Through General Configuration Register i1 (i = 0 to 7)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0404 + 0x40 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	CTMT[25:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CTMT[25:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
25:0	CTMT[25:0]	Cut-Through Maximum time	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

CTMT[25:0] bits (Cut-Through Maximum time)

Describes maximum time on the PHY in ns of frames matching separation rule I.

This time should take in account the whole frame (including preamble, SFD, TAGs and FCS) and IFG.

This size will be used for TAS calculations [ETHA].

Note:
- If this register does not have the correct value, some frames could cross a closed gate in TAS [ETHA].
- if TAS is enabled, sending frames smaller than this register value will decrease the PHY throughput because the frame time will be reserved at this register value [ETHA]. Therefore, TAS gate open time must be bigger than CTMT value.

30.3.1.2.3 FWCTTCi0 : Cut-Through Target Configuration Register i0 (i = 0 to 7)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x0408 + 0x40 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CTDFM1 to CTDFM0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CTDV[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CTDV[2:0]	Cut-through Destination Vector*1 Select the ports to which the frames matching separation rule i will be sent. Enables cut-through for separation rule i.	R/W
15:3	—	These bits are read as 0. The write value should be 0.	R/W
17:16	CTDFM1 to CTDFM0	Cut-Through Destination n Forwarding Mode (n = 0 to 1)*2 0: Frame is forwarded in Cut-through mode. 1: Frame is forwarded in Store and forward mode.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. When cut-through is enabled for rule i, at least one bit set to 1 in FWCTTCi0.CTDV[2:0] and should be set FWCTTCi0.CTDFM to 0 for a cut-through able destination agent (when cut-through is enabled, at least one Ethernet destination port should use with cut-through mode).

Note 2. HW: In Cut-through mode, a frame with an error cannot be rejected and is forwarded to its destination ports.

30.3.1.2.4 FWCTTCi1 : Cut-Through Target Configuration Register i1 (i = 0 to 7)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x040C + 0x40 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

16	CTSPN	Cut-Through Source Port Number*1	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. HW: In Cut-through mode (not Store and Forward modes), this bit should be set to a value smaller than 2.

30.3.1.3 Layer 3 Forwarding/Routing Perfect Filter Function Registers

30.3.1.3.1 FWTWBFCi : Two-Byte Filter Configuration Register i (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x1000 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	TWBFOV[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TWBFM	—	—	—	—	—	—	TWBFUM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	TWBFUM[1:0]	Two-Byte Filter Unit Mode*1 0 0: Mask mode 0 1: Expand mode 1 0: Precise mode 1 1: Reserved	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	TWBFM	Two-Byte Filtering Mode*2 0: Offset filtering 1: VLAN TAG filtering	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
23:16	TWBFOV[7:0]	Two-Byte Filter Offset Value*3	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: These bits should be set to 01b if FWTWBFCi.TWBFM is set to 1.
Note 2. SW: This bit should be set to 01b if FWGC.SVM is set to 00b.
Note 3. ● SW: If FWTWBFCi.TWBFM is set to 1, these bits should be set to 0 to filter S-TAG and set to 2 to filter C-TAG.
● SW: If FWTWBFCi.TWBFM is set to 1 and FWGC.SVM is set to 01b, these bits should not be set to 0.

TWBFOV[7:0] bits (Two-Byte Filter Offset Value)

- If FWTWBFCi.TWBFM is 0: Offset in byte where the filter i will start filtering the frame data.
- If FWTWBFCi.TWBFM is 1: Offset in byte where the filter i will start filtering the frame TAGs.

30.3.1.3.2 FWTWBFVCi : Two-Byte Filter Value Configuration Register i (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x1004 + 0x10 × i

Bit position:	31–16	15–0
Bit field:	TWBFV1[15:0]	TWBFV0[15:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
15:0	TWBFV0[15:0]	Two-Byte Filter Value 0	R/W
31:16	TWBFV1[15:0]	Two-Byte Filter Value 1	R/W

TWBFV0[15:0] bits (Two-Byte Filter Value 0)

- If FWTWBFCi.TWBFUM is 00b: Used as a 2-byte filter value masked by FWTWBFVCi.TWBFV1 with a filter ID of 2*i.
- If FWTWBFCi.TWBFUM is 01b: Used as the first 2-byte of a 4-byte filter extended by FWTWBFVCi.TWBFV1 with a filter ID of 2*i (Compare value is {FWTWBFVCi.TWBFV0, FWTWBFVCi.TWBFV1}).
- If FWTWBFCi.TWBFUM is 10b: Used as 2-byte filter value with a filter ID of 2*i.

TWBFV1[15:0] bits (Two-Byte Filter Value 1)

- If FWTWBFCi.TWBFUM is 00b: Used as a mask for FWTWBFVCi.TWBFV0.
- If FWTWBFCi.TWBFUM is 01b: Used as an extension for FWTWBFVCi.TWBFV0 (Compare value is { FWTWBFVCi.TWBFV0, FWTWBFVCi.TWBFV1}).
- If FWTWBFCi.TWBFUM is 10b: Used as 2-byte filter value with a filter ID of 2*i +1.

30.3.1.3.3 FWTHBFCi : Three-Byte Filter Configuration Register i (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x1400 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	THBFOV[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	THBFUM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	THBFUM[1:0]	Three-Byte Filter Unit Mode 0 0: Mask mode 0 1: Expand mode 1 0: Precise mode 1 1: Reserved	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W
23:16	THBFOV[7:0]	Three-Byte Filter Offset Value Offset in byte where the filter i will start filtering the frame. (The offset ignores all TAGs)	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.3.4 FWTHBFV0Ci : Three-Byte Filter Value 0 Configuration Register i (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x1404 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23																							0
Bit field:	—	—	—	—	—	—	—	—	THBFV0[23:0]																							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	THBFV0[23:0]	Three-Byte Filter Value 0	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

THBFV0[23:0] bits (Three-Byte Filter Value 0)

- If FWTHBFCi.THBFUM[1:0] is 00b: Used as a 3-byte filter value masked by FWTHBFV1Ci.THBFV1[23:0] with a filter ID of 2 × (i + 16).
- If FWTHBFCi.THBFUM[1:0] is 01b: Used as the first 3-byte of a 6-byte filter extended by FWTHBFV1Ci.THBFV1[23:0] with a filter ID of 2 × (i + 16) (Compare value is {FWTHBFV0Ci.THBFV0[23:0], FWTHBFV1Ci.THBFV1[23:0]}).
- If FWTHBFCi.THBFUM[1:0] is 10b: Used as 3-byte filter value with a filter ID of 2 × (i + 16).

30.3.1.3.5 FWTHBFV1Ci : Three-Byte Filter Value 1 Configuration Register i (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x1408 + 0x10 × i

Bit position:	31										23 ... 0
Bit field:	—	—	—	—	—	—	—	—	—	—	THBFV1[23:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
23:0	THBFV1[23:0]	Three-Byte Filter Value 1	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

THBFV1[23:0] bits (Three-Byte Filter Value 1)

- If FWTHBFCi.THBFUM[1:0] is 00b: Used as a mask for FWTHBFV0Ci.THBFV0[23:0].
- If FWTHBFCi.THBFUM[1:0] is 01b: Used as an extension for FWTHBFV0Ci.THBFV0[23:0] (Compare value is { FWTHBFV0Ci.THBFV0[23:0], FWTHBFV1Ci.THBFV1[23:0]}).
- If FWTHBFCi.THBFUM[1:0] is 10b: Used as 3-byte filter value with a filter ID of 2 × (i + 16) + 1.

30.3.1.3.6 FWFOBFCi : Four-Byte Filter Configuration Register i (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x1800 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	FOBFOV[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	FOBFUM[1:0]	Four-Byte Filter Unit Mode 0 0: Mask mode 0 1: Expand mode 1 0: Precise mode 1 1: Reserved	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W
23:16	FOBFOV[7:0]	Four-Byte Filter Offset Value Offset in byte where the filter i will start filtering the frame. (The offset ignores all TAGs)	R/W

Bit	Symbol	Function	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.3.7 FWFOBFV0Ci : Four-Byte Filter Value 0 Configuration Register i (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x1804 + 0x10 × i

Bit position:	31																															0
Bit field:	FOBFV0[31:0]																															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FOBFV0[31:0]	Four-Byte Filter Value 0	R/W

FOBFV0[31:0] bits (Four-Byte Filter Value 0)

- If FWFOBFCi. FOBFUM[1:0] is 00b: Used as a 4-byte filter value masked by FWFOBFV1Ci. FOBFV1[31:0] with a filter ID of 2 × (i + 36).
- If FWFOBFCi. FOBFUM[1:0] is 01b: Used as the first 4-byte of an 8-byte filter extended by FWFOBFV1Ci. FOBFV1[31:0] with a filter ID of 2 × (i + 36) (Compare value is {FWFOBFV0Ci.FOBFV0[31:0], FWFOBFV1Ci. FOBFV1[31:0]}).
- If FWFOBFCi. FOBFUM[1:0] is 10b: Used as 4-byte filter value with a filter ID of 2 × (i + 36).

30.3.1.3.8 FWFOBFV1Ci : Four-Byte Filter Value 1 Configuration Register i (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x1808 + 0x10 × i

Bit position:	31																															0
Bit field:	FOBFV1[31:0]																															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FOBFV1[31:0]	Four-Byte Filter Value 1	R/W

FOBFV1[31:0] bits (Four-Byte Filter Value 1)

- If FWFOBFCi. FOBFUM[1:0] is 00b: Used as a mask for FWFOBFV0Ci. FOBFV0[31:0].
- If FWFOBFCi. FOBFUM[1:0] is 01b: Used as an extension for FWFOBFV0Ci. FOBFV0[31:0] (Compare value is { FWFOBFV0Ci. FOBFV0[31:0], FWFOBFV1Ci. FOBFV1[31:0]}).
- If FWFOBFCi. FOBFUM[1:0] is 10b: Used as 4-byte filter value with a filter ID of 2 × (i + 36) + 1.

30.3.1.3.9 FWRFCi : Range Filter Configuration Register i (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x1C00 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	RFOV[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	RFM	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	RFM	Range Filtering Mode*1 0: Offset filtering 1: VLAN TAG filtering	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
23:16	RFOV[7:0]	Range Filter Offset Value*2	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: This bit should not be set to 1 if FWGC.SVM is set to 00b.
Note 2.
- SW: If FWRFCi.RFM is set to 1, these bits should be set to 0 or 1 to filter S-TAG and set to 2 or 3 to filter C-TAG.
- SW: If FWRFCi.RFM is set to 1 and FWGC.SVM is set to 01b, these bits should not be set to 0 or 1.

RFOV[7:0] bits (Range Filter Offset Value)

- If FWRFCi.RFM is 0: Offset in byte where the filter i will start filtering the frame data.
- If FWRFCi.RFM is 1: Offset in byte where the filter i will start filtering the frame TAGs.

30.3.1.3.10 FWRFVCi : Range Filter Value Configuration Register i (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x1C04 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	RFRV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RFSV1[7:0]								RFSV0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFSV0[7:0]	Range Filter Start Value 0	R/W
15:8	RFSV1[7:0]	Range Filter Start Value 1	R/W
19:16	RFRV[3:0]	Range Filter Range Value*1 Used as range value for filters values FWRFVCi.RFSV1 and FWRFVCi.RFSV0.	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: FWRFVCi.RFSV0+FWRFVCi.RFRV and FWRFVCi.RFSV1+FWRFVCi.RFRV should always be smaller or equal to 255.

RFSV0[7:0] bits (Range Filter Start Value 0)

Used has range filter start value with a filter ID of 2 × (i + 49) (matching values are contained in [FWRFVCi.RFSV0: FWRFVCi.RFSV0+FWRFVCi.RFRV]).

RFSV1[7:0] bits (Range Filter Start Value 1)

Used has range filter start value with a filter ID of 2 × (i + 48) + 1 (matching values are contained in [FWRFVCi.RFSV1: FWRFVCi.RFSV1+FWRFVCi.RFRV]).

30.3.1.3.11 FWCFCi : Cascade Filter Configuration Register i (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x2000 + 0x40 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFPFFV1 to CFPFFV0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CFEFFV2 to CFEFFV0		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CFEFFV2 to CFEFFV0	Cascade Filter E-Frame Filter Valid n (n = 0 to 2) Bit j is 0: Cascade filter i is disabled for port j e-frames (All slow ports frames are e-frames) [GWCA]. Bit j is 1: Cascade filter i is enabled for port j e-frames (All slow ports frames are e-frames) [GWCA].	R/W
15:3	—	These bits are read as 0. The write value should be 0.	R/W
17:16	CFPFFV1 to CFPFFV0	Cascade Filter E-Frame Filter Valid n (n = 0 to 1) Bit j is 0: Cascade filter i is disabled for port j p-frames. Bit j is 1: Cascade filter i is enabled for port j p-frames.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.3.12 FWCFMCij : Cascade Filter Mapping Configuration Register ij (i = 0 to 15) (j = 0 to 6)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x2004 + 0x40 × i + 0x4 ×j

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CFFV	—	—	—	—	—	—	—	—	CFFN[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	CFFN[6:0]	Cascade Filter Filter Number Map filter number FWCFMCij.CFFN to cascade filter number i.	R/W

Bit	Symbol	Function	R/W
14:7	—	These bits are read as 0. The write value should be 0.	R/W
15	CFFV	Cascade Filter Valid Enables FWCFMCij.CFFN for cascade filter i. If no one of the FWCFMCij.CFFV is equal to 1, cascade filter i is disabled.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.4 Layer 3 Forwarding/Routing L2 Stream/Hash Filter Function Registers

30.3.1.4.1 FWIP4SC : IPv4 Stream Configuration Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

15:0	SHCR[15:0]	Software Hash Calculation Result SW: These bits are used to accelerate hash calculation.	R
30:16	—	These bits are read as 0.	R
31	SHC	Software Hash Calculation	R

SHC bit (Software Hash Calculation)

SW: This bit is used to accelerate hash calculation.

[Setting condition]

HW: Writing FWSHCR13 register will set this bit.

[Clearing condition]

HW: This bit is deasserted when hash calculation is completed.

30.3.1.5 Layer 3/4 Forwarding/Routing Hash Function Registers

30.3.1.5.1 FWLTHHEC : L3 Hash Entry Configuration Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4090

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	LTHHMUE[8:0]

Bit field:	—	—	—	—	—	—	—	LTHSLL	—	—	—	—	—	LTHSLP0[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	LTHSLP0[2:0]	L3 Stream Learn Part 0	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	LTHSLL	L3 Security Level Learn Used for learning/overwriting an entry in L3 table.	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
16	LTHED	L3 Entry Delete 0: Learn/overwrite the set stream ID in L3 table. 1: Delete the set stream ID in L3 table.	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

LTHSLP0[2:0] bits (L3 Stream Learn Part 0)

Used for learning/overwriting an entry in L3 table.

Stream ID correspond to {FWLTHTL0. LTHSLP0, FWLTHTL1. LTHSLP1, FWLTHTL2. LTHSLP2, FWLTHTL3. LTHSLP3, FWLTHTL4. LTHSLP4}.

30.3.1.5.4 FWLTHTL1 : L3 Table Learn Register 1

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x40A4

Bit position:	31 … 0
Bit field:	LTHSLP1[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	LTHSLP1[31:0]	L3 Stream Learn Part 1	R/W

LTHSLP1[31:0] bits (L3 Stream Learn Part 1)

Used for learning/overwriting an entry in L3 table.

Stream ID correspond to {FWLTHTL0. LTHSLP0, FWLTHTL1. LTHSLP1, FWLTHTL2. LTHSLP2, FWLTHTL3. LTHSLP3, FWLTHTL4. LTHSLP4}.

30.3.1.5.5 FWLTHTL2 : L3 Table Learn Register 2

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x40A8

Bit position: 31 … 0

Bit field: LTHSLP2[31:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	LTHSLP2[31:0]	L3 Stream Learn Part 2	R/W

LTHSLP2[31:0] bits (L3 Stream Learn Part 2)

Used for learning/overwriting an entry in L3 table.

Stream ID correspond to {FWLTHTL0. LTHSLP0, FWLTHTL1. LTHSLP1, FWLTHTL2. LTHSLP2, FWLTHTL3. LTHSLP3, FWLTHTL4. LTHSLP4}.

30.3.1.5.6 FWLTHTL3 : L3 Table Learn Register 3

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x40AC

Bit position: 31 … 0

Bit field: LTHSLP3[31:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	LTHSLP3[31:0]	L3 Stream Learn Part 3	R/W

LTHSLP3[31:0] bits (L3 Stream Learn Part 3)

Used for learning/overwriting an entry in L3 table.

Stream ID correspond to {FWLTHTL0. LTHSLP0, FWLTHTL1. LTHSLP1, FWLTHTL2. LTHSLP2, FWLTHTL3. LTHSLP3, FWLTHTL4. LTHSLP4}.

30.3.1.5.7 FWLTHTL4 : L3 Table Learn Register 4

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x40B0

Bit position: 31 … 0

Bit field: LTHSLP4[31:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	LTHSLP4[31:0]	L3 Stream Learn Part 4	R/W

LTHSLP4[31:0] bits (L3 Stream Learn Part 4)

Used for learning/overwriting an entry in L3 table.

Stream ID correspond to {FWLTHTL0. LTHSLP0, FWLTHTL1. LTHSLP1, FWLTHTL2. LTHSLP2, FWLTHTL3. LTHSLP3, FWLTHTL4. LTHSLP4}.

30.3.1.5.8 FWLTHTL5 : L3 Table Learn Register 5

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x40B4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	LTHMSDUVL	—	—	—	—	—	—	—	—	—	—	—	LTHMSDUNL[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
19:16	LTHMSDUNL[3:0]	L3 MSDU Number Learn SW: Used for learning/overwriting an entry in L3 table.	R/W
30:20	—	These bits are read as 0. The write value should be 0.	R/W
31	LTHMSDUVL	L3 MSDU Valid Learn Used for learning/overwriting an entry in L3 table.	R/W

30.3.1.5.9 FWLTHTL6 : L3 Table Learn Register 6

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x40B8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	LTHMTRVL	—	—	—	—	—	—	—	—	—	—	LTHMTRNL[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

2	—	This bit is read as 0.	R

Bit	Symbol	Function	R/W
3	LTHLO	L3 Learn Overwrite Used for learning/overwriting an entry in L3 table. 0: The entry learning did not overwrite an existing entry. 1: The entry learning overwrote an existing entry.	R
15:4	—	These bits are read as 0.	R
23:16	LTHLCN[7:0]	L3 Learn Collision Number Used for learning/overwriting an entry in L3 table.	R
30:24	—	These bits are read as 0.	R
31	LTHTL	L3 Table Learn	R

LTHTL bit (L3 Table Learn)

Used for learning/overwriting an entry in L3 table.

[Setting condition]

HW: Writing FWLTHTL9 register will set this bit.

[Clearing condition]

HW: This bit will be de-asserted when learning is completed.

30.3.1.5.14 FWLTHTIM : L3 Table Initialization Monitoring Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x40E0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LTHTR	LTHTIOG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LTHTIOG	L3 Table Initialization Ongoing	R/W
1	LTHTR	L3 Table Ready	R
31:2	—	These bits are read as 0. The write value should be 0.	R/W

LTHTIOG bit (L3 Table Initialization Ongoing)

[Setting condition]

SW: By writing 1 to this bit. It starts L3 Table initialization.

[Clearing condition]

HW: This bit is cleared when L3 Table initialization is finished.

LTHTR bit (L3 Table Ready)

[Setting condition]

- HW: When FWLTHTIM.LTHTIOG is getting cleared.
- HW: This bit is set at clk_period [ns] × 256 time from L3 table initialization starting.

[Clearing condition]

SW: By writing 1 to FWLTHTIM.LTHTIOG.

30.3.1.5.15 FWLTHTEM : L3 Table Entry Monitoring Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x40E4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	LTHTUEN[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	LTHTEN[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	LTHTEN[8:0]	L3 Table Entry Number	R
15:9	—	These bits are read as 0.	R
24:16	LTHTUEN[8:0]	L3 Table Unsecure Entry Number	R
31:25	—	These bits are read as 0.	R

LTHTEN[8:0] bits (L3 Table Entry Number)

[Increment condition]

HW: An entry is learned successfully.

[Decrement condition]

HW: An entry is deleted successfully.

LTHTUEN[8:0] bits (L3 Table Unsecure Entry Number)

[Increment condition]

HW: An unsecure entry is learned successfully.

[Decrement condition]

HW: An unsecure entry is deleted successfully.

30.3.1.5.16 FWLTHTS0 : L3 Table Search Register 0

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4100

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LTHTR bit (L3 Table Read)

Used for reading an entry in L3 table.

[Setting condition]

HW: Writing FWLTHTR register will set this bit.

[Clearing condition]

HW: This bit will be de-asserted when reading is completed.

Bit	Symbol	Function	R/W
2:0	MACDVL[2:0]	MAC Destination Vector Learn Used for learning/overwriting an entry in MAC table.	R/W
15:3	—	These bits are read as 0. The write value should be 0.	R/W
18:16	MACIPVL[2:0]	MAC Internal Priority Value Learn Used for learning/overwriting an entry in MAC table.	R/W
19	MACIPUL	MAC Internal Priority Update Learn Used for learning/overwriting an entry in MAC table.	R/W
20	MACEMEL	MAC Ethernet Mirroring Enable Learn Used for learning/overwriting an entry in MAC table.	R/W
21	MACCMEL	MAC CPU Mirroring Enable Learn Used for learning/overwriting an entry in MAC table.	R/W
31:22	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.6.9 FWMACTLR : MAC Table Learn Result Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4654

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MACTL	—	—	—	—	MACLCN[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MACLO	—	MACLSF	MACLF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MACLF	MAC Learn Fail Used for learning/overwriting an entry in MAC table. 0: Entry learning did not fail. (See (2) SW Learning). 1: Entry learning failed. (See (2) SW Learning).	R
1	MACLSF	MAC Learn Security Fail 0: Entry learning did not fail because of a security error. (See (2) SW Learning). 1: Entry learning failed because of a security error. (See (2) SW Learning).	R
2	—	This bit is read as 0.	R
3	MACLO	MAC Learn Overwrite Used for learning/overwriting an entry in MAC table. 0: The entry learning did not overwrite an existing entry. 1: The entry learning overwrote an existing entry.	R
15:4	—	These bits are read as 0.	R
26:16	MACLCN[10:0]	MAC Learn Collision Number Used for learning/overwriting an entry in MAC table.	R
30:27	—	These bits are read as 0.	R
31	MACTL	MAC Table Learn	R

MACTL bit (MAC Table Learn)

Used for learning/overwriting an entry in MAC table.

[Setting condition]

HW: Writing FWMACTL5 register will set this bit.

[Clearing condition]

HW: This bit will be de-asserted when learning is completed.

30.3.1.6.10 FWMACTIM : MAC Table Initialization Monitoring Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4660

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MACTR	MACTIOG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MACTIOG	MAC Table Initialization Ongoing	R/W
1	MACTR	MAC Table Ready	R
31:2	—	These bits are read as 0. The write value should be 0.	R/W

MACTIOG bit (MAC Table Initialization Ongoing)

[Setting condition]

SW: By writing 1 to this bit. It starts MAC Table initialization.

[Clearing condition]

HW: This bit is cleared when MAC Table initialization is finished.

MACTR bit (MAC Table Ready)

[Setting condition]

- HW: When FWMACTIM.MACTIOG is getting cleared.
- HW: This bit is set at clk_period [ns] × 2048 time from MAC table initialization starting.

[Clearing condition]

SW: By writing 1 to FWMACTIM.MACTIOG.

30.3.1.6.11 FWMACTEM : MAC Table Entry Monitoring Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4664

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	MACTUEN[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	MACTEN[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	MACTEN[11:0]	MAC Table Entry Number	R

Bit	Symbol	Function	R/W
15:12	—	These bits are read as 0.	R
27:16	MACTUEN[11:0]	MAC Table Unsecure Entry Number	R
31:28	—	These bits are read as 0.	R

MACTEN[11:0] bits (MAC Table Entry Number)

[Increment condition]

HW: An entry is learned successfully.

[Decrement condition]

HW: An entry is deleted successfully.

MACTUEN[11:0] bits (MAC Table Unsecure Entry Number)

[Increment condition]

HW: An unsecure entry is learned successfully.

[Decrement condition]

HW: An unsecure entry is deleted successfully.

30.3.1.6.12 FWMACTS0 : MAC Table Search Register 0

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4670

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MACMASP0[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MACMASP0[15:0]	MAC MAC Address Search Part 0 Used for searching an entry in MAC table.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.6.13 FWMACTS1 : MAC Table Search Register 1

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4674

Bit position:	31 ... 0
Bit field:	MACMASP1[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	MACMASP1[31:0]	MAC MAC Address Search Part 1 Used for searching an entry in MAC table.	R/W

30.3.1.6.14 FWMACTSR0 : MAC Table Search Result Register 0

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4678

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MACTS	—	—	—	—	MACSCN[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	MACHLDS	MACDES	MACSLS	—	—	—	—	—	—	MACSNF	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	MACSNF	MAC Search Not found Used for searching an entry in MAC table. 0: MAC address found in MAC Table. 1: MAC address not found in MAC Table.	R
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	MACSLS	MAC Security Level Search Used for searching an entry in MAC table.	R
9	MACDES	MAC Dynamic Entry Search Used for searching an entry in MAC table.	R
10	MACHLDS	MAC Hardware Learning Disable Search Used for searching an entry in MAC table.	R
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	MACSCN[10:0]	MAC Search Collision Number Used for searching an entry in MAC table.	R
30:27	—	These bits are read as 0. The write value should be 0.	R/W
31	MACTS	MAC Table Search	R

MACTS bit (MAC Table Search)

Used for searching an entry in MAC table.

[Setting condition]

HW: Writing FWMACTS1 register will set this bit.

[Clearing condition]

HW: This bit will be de-asserted when searching is completed.

30.3.1.6.15 FWMACTSR1 : MAC Table Search Result Register 1

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x467C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	VLANLF	VLAN Learn Fail Used for learning/overwriting an entry in VLAN table. 0: Entry learning did not fail. (See (2) SW Learning.) 1: Entry learning failed. (See (2) SW Learning.)	R
1	VLANLSF	VLAN Learn Security Fail Used for learning/overwriting an entry in VLAN table. 0: Entry learning did not fail because of a security error. (See (2) SW Learning.) 1: Entry learning failed because of a security error. (See (2) SW Learning.)	R
2	—	This bit is read as 0.	R
3	VLANLO	VLAN Learn Overwrite Used for learning/overwriting an entry in VLAN table. 0: The entry learning did not overwrite an existing entry. 1: The entry learning overwrote an existing entry.	R
30:4	—	These bits are read as 0.	R
31	VLANTL	VLAN Table Learn	R

VLANTL bit (VLAN Table Learn)

Used for learning/overwriting an entry in VLAN table.

[Setting condition]

HW: Writing FWVLANTL4 register will set this bit.

[Clearing condition]

HW: This bit will be de-asserted when learning is completed.

30.3.1.6.37 FWVLANTIM : VLAN Table Initialization Monitoring Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4940

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VLANTR	VLANTIOG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VLANTIOG	VLAN Table Initialization Ongoing	R/W*1
1	VLANTR	VLAN Table Ready	R
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

VLANTIOG bit (VLAN Table Initialization Ongoing)

[Setting condition]

SW: By writing 1 to this bit. It starts VLAN Table initialization.

[Clearing condition]

HW: This bit is cleared when VLAN Table initialization is finished.

VLANTR bit (VLAN Table Ready)

[Setting condition]

HW: When FWVLANTIM.VLANTIOG is getting cleared.

HW: This bit is set at “clk_period[ns]*4096” time from VLAN table initialization starting.

[Clearing condition]

SW: By writing 1 to FWVLANTIM.VLANTIOG.

30.3.1.6.38 FWVLANTEM : VLAN Table Entry Monitoring Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4944

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	VLANTUEN[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	VLANTEN[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	VLANTEN[12:0]	VLAN Table Entry Number	R
15:13	—	These bits are read as 0.	R
28:16	VLANTUEN[12:0]	VLAN Table Unsecure Entry Number	R
31:29	—	These bits are read as 0.	R

VLANTEN[12:0] bits (VLAN Table Entry Number)

[Increment condition]

HW: An unsecure entry is learned successfully.

[Decrement condition]

HW: An unsecure entry is deleted successfully.

VLANTUEN[12:0] bits (VLAN Table Unsecure Entry Number)

[Increment condition]

HW: An entry is learned successfully.

[Decrement condition]

HW: An entry is deleted successfully.

30.3.1.6.39 FWVLANTS : VLAN Table Search Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4950

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit field:	—	—	—	—	—	VLAN HLDS	—	VLAN SLS	—	—	—	—	—	—	VLAN SNF	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0.	R
1	VLANSNF	VLAN Search Not found Used for searching an entry in VLAN table. 0: VLAN found in VLAN Table. 1: VLAN not found in VLAN Table.	R
7:2	—	These bits are read as 0.	R
8	VLANSLS	VLAN Security Level Search Used for searching an entry in VLAN table.	R
9	—	These bits are read as 0.	R
10	VLANHLDS	VLAN Hardware Learning Disable Search Used for searching an entry in VLAN table.	R
30:11	—	These bits are read as 0.	R
31	VLANTS	VLAN Table Search	R

VLANTS bit (VLAN Table Search)

Used for searching an entry in VLAN table.

[Setting condition]

HW: Writing FWVLANTS register will set this bit.

[Clearing condition]

HW: This bit will be de-asserted when searching is completed.

30.3.1.6.41 FWVLANTSR1 : VLAN Table Search Result Register 1

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4958

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	VLANSLVS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	VLANSLVS[2:0]	VLAN Source Lock Vector Search Used for searching an entry in VLAN table.	R
31:3	—	These bits are read as 0.	R

30.3.1.6.42 FWVLANTSR20 : VLAN Table Search Result Register 20

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4960 + 0x4 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	VLANCSDS[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	VLANCSDS[5:0]	VLAN CPU Sub-Destination Search Used for searching an entry in VLAN table.	R
31:6	—	These bits are read as 0.	R

30.3.1.6.43 FWVLANTSR3 : VLAN Table Search Result Register 3

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4970

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	VLANCMES	VLANEMES	VLANIPUS	VLANIPVS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	VLANDVS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	VLANDVS[2:0]	VLAN Destination Vector Search Used for searching an entry in VLAN table.	R
15:3	—	These bits are read as 0.	R
18:16	VLANIPVS[2:0]	VLAN Internal Priority Value Search Used for searching an entry in VLAN table.	R
19	VLANIPUS	VLAN Internal Priority Update Search Used for searching an entry in VLAN table.	R
20	VLANEMES	VLAN Ethernet Mirroring Enable Search Used for searching an entry in VLAN table.	R
21	VLANCMES	VLAN CPU Mirroring Enable Search Used for searching an entry in VLAN table.	R
31:22	—	These bits are read as 0.	R

30.3.1.7 Port Based Forwarding Function Registers

30.3.1.7.1 FWPBFCi : Port i Port Based Forwarding Configuration Register (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4A00 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	FAIFP	IP6PDE	IP4PDM	IP4PDE	PBSL	PBCME	PBEME	PBIPU	PBIPV[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	PBDV[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	PBDV[2:0]	Port Based Destination Vector Destination vector for port i port-based forwarding.	R/W
15:3	—	These bits are read as 0. The write value should be 0.	R/W
18:16	PBIPV[2:0]	Port Based Internal Priority Value Internal priority value for port i port-based forwarding.	R/W

Bit	Symbol	Function	R/W
19	PBIPU	Port Based Internal Priority Update Enables frame priority update to internal priority value (FWPBFCi.PBIPV) for port i.	R/W
20	PBEME	Port Based Ethernet Mirroring Enabled Enables ethernet mirroring for port i.	R/W
21	PBCME	Port Based CPU Mirroring Enabled Enables CPU mirroring for port i.	R/W
22	PBSL	Port Based Security Level Set descriptor security level for port i.	R/W
23	IP4PDE	IPv4 Priority Decode Enable 0: For port i, Input frame priority is taken from VLAN TAGs for port i. 1: For port i, If an IPv4 frame is detected, input frame priority is taken from precedence ToS. Else Input frame priority is taken from VLAN TAGs.	R/W
24	IP4PDM	IPv4 Priority Decode Mode 0: For port i, Input frame priority is taken from precedent field in ToS. 1: For port i, Input frame priority is decoded from DSCP field in ToS.	R/W
25	IP6PDE	IPv6 Priority Decode Enable 0: For port i, Input frame priority is taken from VLAN TAGs. 1: For port i, If an IPv6 frame is detected, input frame priority is decoded from DSCP field in ToS. Else Input frame priority is taken from VLAN TAGs.	R/W
26	FAIFP	Force All Input Frame Priority Enable 0: For port i, Input frame priority is given by frame decoding. 1: For port i, Input frame priority is forced to FWPBFCi.PBIPV.	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.7.2 FWPBFCSDCi0 : Port i Port Based Forwarding CSD Configuration Register 0 (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4A04 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	PBCSD[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	PBCSD[5:0]	Port Based CPU Sub Destination CPU Sub Destination from GWCAj [GWCA] for port i port-based forwarding.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.8 Layer 2/Layer 3 Update Function Registers

30.3.1.8.1 FWL23URL0 : Layer 2/Layer 3 Update Rule Learn Register 0

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4E00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	L23URPVL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	L23URNL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	L23URNL[7:0]	Layer 2/Layer 3 Update Routing Number Learn Used to learn a Layer 2/Layer 3 update rule	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
18:16	L23URPVL[2:0]	Layer 2/Layer 3 Update Routing Port Valid Learn Used to learn a Layer 2/Layer 3 update rule	R/W
31:19	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.8.2 FWL23URL1 : Layer 2/Layer 3 Update Rule Learn Register 1

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4E04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	L23ULF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	L23ULF	Layer 2/Layer 3 Update Learn Fail 0: Entry learning did not fail because the Layer 2/Layer 3 table is ready. 1: Entry learning failed because the Layer 2/Layer 3 table is not ready.	R
30:1	—	These bits are read as 0.	R
31	L23URL	Layer 2/Layer 3 Update Rule Learn	R

L23URL bit (Layer 2/Layer 3 Update Rule Learn)

[Setting condition]

HW: Writing FWL23URL3 register will set this bit.

[Clearing condition]

HW: This bit will be de-asserted when learning is completed.

30.3.1.8.6 FWL23UTIM : Layer 2/Layer 3 Update Table Initialization Monitoring Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4E20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	L23UTR	L23UTIOG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	L23UTIOG	Layer 2/Layer 3 Update Table Initialization Ongoing	R/W*1
1	L23UTR	Layer 2/Layer 3 Update Table Ready	R
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

L23UTIOG bit (Layer 2/Layer 3 Update Table Initialization Ongoing)

[Setting condition]

SW: By writing 1 to this bit. It starts Layer 2/Layer 3 Update Table initialization.

[Clearing condition]

HW: This bit is cleared when Layer 2/Layer 3 Update Table initialization is finished.

L23UTR bit (Layer 2/Layer 3 Update Table Ready)

[Setting condition]

- HW: When FWL23UTIM.L23UTIOG is getting cleared.
- HW: This bit is set at clk_period [ns] × 256 time from L23 update table initialization starting.

[Clearing condition]

SW: By writing 1 to FWL23UTIM.L23UTIOG.

30.3.1.8.7 FWL23URR : Layer 2/Layer 3 Update Rule Read Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4E30

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	L23RNR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	L23RNR[7:0]	Layer 2/Layer 3 Routing Number Read Used to read a Layer 2/Layer 3 update rule	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.8.8 FWL23URRR0 : Layer 2/Layer 3 Update Rule Read Result Register 0

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x4E34

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	L23URR	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	L23URPVR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	L23URPVR[2:0]	Layer 2/Layer 3 Update Routing Port Valid Read Used to read a Layer 2/Layer 3 update rule	R

Bit	Symbol	Function	R/W
30:3	—	These bits are read as 0.	R
31	L23URR	Layer 2/Layer 3 Update Rule Read	R

L23URR bit (Layer 2/Layer 3 Update Rule Read)

[Setting condition]

HW: Writing FWL23URR register will set this bit.

[Clearing condition]

HW: This bit will be de-asserted when reading is completed.

30.3.1.8.9 FWL23URRR1 : Layer 2/Layer 3 Update Rule Read Result Register 1

Base address: MFWD = 0x403C_0000

Bit field:	MSDUV[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MSDUV[15:0]	MSDU Value HW: Maximum frame size for stream linked to MSDU filter i thanks to L3 table.	R/W
30:16	—	These bits are read as 0. The write value should be 0.	R/W
31	MFM	MSDU Filter Mode 0: Normal mode: Any frame linked to MSDU filter i thanks to L3 table received with LDESCR.TPL [GWCA] bigger than FWPMPCi.MSDUV will be filtered. 1: Throttle mode: Any frame linked to MSDU filter i thanks to L3 table received with LDESCR.TPL [GWCA] bigger than FWPMPCi.MSDUV will be filtered. Any frame linked to MSDU filter i thanks to L3 table received when FWEIS2.PMFSi is set will be filtered.	R/W

30.3.1.9.2 FWPMTRFCi : PSFP Meter i Filter Configuration Register (i = 0 to 31)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x5600 + 0x20 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MTRCM15 to MTRCM0															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	MTRCF	MTRFRFD	MTRFM[1:0]		MTRFE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MTRFE	Meter Filter Enable 0: Meter i disabled (Pass through all frames.) 1: Meter i enabled (Reject target stream frames by meter filter.)	R/W
2:1	MTRFM[1:0]	Meter Filter Mode 0 0: Normal mode: Any frame linked to Meter filter i thanks to L3 table received when not enough token is available will be red. 0 1: Throttle mode: Any frame linked to Meter filter i thanks to L3 table received when not enough token is available or when FWEIS5.PMRFSi is set will be red. 1 0: ATS mode: Any frame linked to Meter filter i thanks to L3 table received when not enough token is available will be stored in ATS RAM until enough tokens are available. When enough tokens are available, frame will be forwarded as yellow or green. 1 1: ATS throttle mode: Any frame linked to Meter filter i thanks to L3 table received when not enough token is available will be stored in ATS RAM until enough tokens are available. When enough tokens are available, frame will be forwarded as yellow or green if FWEIS5.PMRFSi is not set and will be red if FWEIS5.PMRFSi is set.	R/W
3	MTRFRFD	Meter Filter Red Frame Drop 0: Red frames are not dropped by meter i. 1: Red frames are dropped by meter i.	R/W
4	MTRCF	Meter Coupling Flag*1 0: When green bucket is full, CIR tokens are lost. 1: When green bucket is full, CIR tokens are added to the yellow bucket.	R/W
15:5	—	These bits are read as 0. The write value should be 0.	R/W
31:16	MTRCM15 to MTRCM0	Meter Color Mode n (n = 0 to 15)*2	R/W

Note 1. HW: This bit is only valid if i = 0 to 7.
Note 2. HW: These bits are only valid if i = 0 to 7.
SW: in ATS mode (FWPMTRFCi.MTRFM set to 10b) or in ATS throttle mode (FWPMTRFCi.MTRFM set to 11b) Color mode is not available, so these bits should be set to All0.

MTRCMn bits (Meter Color Mode n (n = 0 to 15))

If bit j is set to 0: Incoming frame with {PCP,DEI} == j is coming as green (Green or yellow bucket can be used by the frame).

If bit j is set to 1: Incoming frame with {PCP,DEI} == j is coming as Yellow (Only yellow bucket can be used by the frame).

30.3.1.9.3 FWPMTRCBSCi : PSFP Meter i CBS Configuration Register (i = 0 to 31)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x5604 + 0x20 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CBS[17:16]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit field:	CBS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
17:0	CBS[17:0]	CBS Maximum number of tokens (in bytes) contained in meter i green bucket.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.9.4 FWPMTRCIRCi : PSFP Meter i CIR Configuration Register (i = 0 to 31)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x5608 + 0x20 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CIR[19:16]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CIR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
19:0	CIR[19:0]	CIR	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

CIR[19:0] bits (CIR)

Used to increment green token tokens when meter i green bucket is not full.

CIR[19:16] is the credit increment in byte per clock and CIR[15:0] is the credit increment in sub-byte per clock.

Note: SW: In ATS mode, setting these bits to 0 or a value close to 0 would set corresponding queue to a very low throughput or could stick the corresponding queue and lead to a queue overflow.

30.3.1.9.5 FWPMTREBSCi : PSFP Meter i EBS Configuration Register (i = 0 to 7)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x560C + 0x20 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EBS[17:16]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EBS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
17:0	EBS[17:0]	EBS Maximum number of tokens (in bytes) contained in meter i yellow bucket.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.9.6 FWPMTREIRCi : PSFP Meter i EIR Configuration Register (i = 0 to 7)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x5610 + 0x20 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	EIR[19:16]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EIR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
19:0	EIR[19:0]	EIR	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

EIR[19:0] bits (EIR)

Used to increment green token tokens when meter i yellow bucket is not full.

EIR[19:16] is the credit increment in byte per clock and EIR[15:0] is the credit increment in sub-byte per clock.

Note: SW: In ATS mode, setting these bits to 0 or a value close to 0 would set the corresponding queue to a very low throughput or could stick the corresponding queue and lead to a queue overflow.

30.3.1.9.7 FWPMTRFMi : PSFP Meter i Filter Monitoring Register (i = 0 to 31)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x5614 + 0x20 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	MTRARDNMN[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	MTRARDN[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	MTRARDN[4:0]	Meter ATS RAM Descriptor Number	R
15:5	—	These bits are read as 0.	R
20:16	MTRARDNMN[4:0]	Meter ATS RAM Descriptor Number Maximum Number	R
31:21	—	These bits are read as 0.	R

MTRARDN[4:0] bits (Meter ATS RAM Descriptor Number)

Shown the number of descriptors in the ATS RAM for meter number i.

[Increment condition]

A descriptor is received for meter i but there is already a descriptor in the ATS RAM for meter i or there is not even token available for the frame.

30.3.1.10 FRER (Frame Replication and Elimination for Reliability) [802.1CB]

30.3.1.10.1 FWFTL0 : FRER Table Learn Register 0

9:0	USP[9:0]	Microsecond Prescaler*1 Used to creates an internal clock for aging at 1 MHz to derive the Timeout 1 kHz clock.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: These bits should be set to the number of clk clocks contained in 1 μs.

30.3.1.10.6 FWFTIM : FRER Table Initialization Monitoring Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FTR	FTIOG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FTIOG	FRER Table Initialization Ongoing	R/W*1
1	FTR	FRER Table Ready	R
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

FTIOG bit (FRER Table Initialization Ongoing)

[Setting condition]

SW: By writing 1 to this bit. It starts FRER Table initialization.

[Clearing condition]

HW: This bit is cleared when FRER Table initialization is finished.

FTR bit (FRER Table Ready)

[Setting condition]

- HW: When FWFTIM.FTIOG is getting cleared.
- HW: This bit is set at clk_period [ns] × 128 time from buffer pool initialization starting.

[Clearing condition]

SW: By writing 1 to FWFTIM.FTIOG.

30.3.1.10.7 FWFTR : FRER Table Read Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6030

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	FEAR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	FEAR[6:0]	FRER Entry Address Read Used to read an FRER entry in FRER RAM.	R/W
31:7	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.10.8 FWFTRR0 : FRER Table Read Result Register 0

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	FTR	—	—	—	—	—	FSRRTR[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	FSRPVR	FTNSR	—	—	—	—	FSHLR[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	FSHLR[3:0]	FRER Sequence History Length Read	R
7:4	—	These bits are read as 0.	R
8	FTNSR	FRER Take No Sequence Read	R
9	FSRPVR	FRER Sequence Recovery Pointer Valid Read	R
15:10	—	These bits are read as 0.	R
25:16	FSRRTR[9:0]	FRER Set Recovery Remaining Ticks Read	R
30:26	—	These bits are read as 0.	R
31	FTR	FRER Table Read	R

FTR bit (FRER Table Read)

[Setting condition]

HW: Writing FWFTR register will set this bit.

[Clearing condition]

HW: This bit will be de-asserted when reading is completed.

30.3.1.10.9 FWFTRR1 : FRER Table Read Result Register 1

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6038

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	FSRPR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	FSHR[14:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
14:0	FSHR[14:0]	FRER Sequence History Read	R
15	—	This bit is read as 0.	R
22:16	FSRPR[6:0]	FRER Sequence Recovery Pointer Read	R
31:23	—	These bits are read as 0.	R

30.3.1.10.10 FWFTRR2 : FRER Table Read Result Register 2

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x603C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	FRRTR[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FRSNR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	FRSNR[15:0]	FRER Recovery Sequence Number Read	R
25:16	FRRTR[9:0]	FRER Recovery Remaining Ticks Read	R
31:26	—	These bits are read as 0.	R

30.3.1.10.11 FWSEQNGCi : Sequence Number Generation i Configuration Register (i = 0 to 31)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6100 + 0x8 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEQNGE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	SEQNGRN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SEQNGRN[7:0]	SEQuence Number Generation Routing Number Specifies the routing number for which sequence number will be generated.	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
16	SEQNGE	SEQuence Number Generation Enable 0: Sequence number generation disabled for routing number FWSEQNGCi.SEQNGRN 1: Sequence number generation enabled for routing number FWSEQNGCi.SEQNGRN	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

30.3.1.10.12 FWSEQNGMi : Sequence Number Generation i Monitoring Register (i = 0 to 31)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6104 + 0x8 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SEQN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SEQN[15:0]	SEQuence Number	R
31:16	—	These bits are read as 0.	R

SEQN[15:0] bits (SEQuence Number)

Displays the next sequence number to be appended to a descriptor for sequence number generation rule i.

[Increment condition]

HW: When FWSEQNGCi.SEQNGE is set and a descriptor is forwarded with FDESCR.RV set and FDESCR.RN set to FWSEQNGCi.SEQNGRN.

[Clearing condition]

SW: Writing 1 to FWSEQNRC.SEQNR will clear these bits.

30.3.1.10.13 FWSEQNRC : Sequence Number Reset Configuration Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6200

Bit position:	31 … 0
Bit field:	SEQNR31 to SEQNR0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	SEQNR31 to SEQNR0	Sequence Number Generation Reset n (n = 0 to 31) 0: No effect 1: Bit i of this register resets the sequence generator number i counter to 0	W

30.3.2 MFWD Counter Registers

This section describes MFWD counter registers.

30.3.2.1 FWCTFDCNi : Port i Cut-Through Forwarded Descriptor Counter Register (i = 0, 1)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6300 + 0x20 × i

Bit position:	31 … 0
Bit field:	CTFDN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	CTFDN[31:0]	Cut-Through Forwarded Descriptor Number	R

CTFDN[31:0] bits (Cut-Through Forwarded Descriptor Number)

These bits count the number of descriptors forwarded by Cut-Through forwarding for port i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame coming from port i is forwarded by Cut-Through Forwarding in store and forward mode and if these bits have a value other than 0xFFFFFFFF.

Note: HW: These bits do not take in account the cut-through path of cut-through forwarding but only the store and forward path so, any frame forwarded in store and forward with cut-through (for at least one value of j, if FWCTTCi0.CTDV[j] is set, FWCTTCi0.CTDFMj is also set) with be counted here.

30.3.2.2 FWDDFDCN2 : Port 2 Direct Descriptor Forwarded Descriptor Counter Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6340

Bit position:	31 … 0
Bit field:	DDFDN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	DDFDN[31:0]	Direct Descriptor Forwarded Descriptor Number	R

DDFDN[31:0] bits (Direct Descriptor Forwarded Descriptor Number)

These bits count the number of descriptors forwarded by Direct Descriptor forwarding for port 2.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame coming from port 2 is forwarded by Direct Descriptor Forwarding and if these bits have a value other than 0xFFFFFFFF.

30.3.2.3 FWLTHFDCNi : Port i Layer 3 Forwarded Descriptor Counter Register (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6304 + 0x20 × i

Bit position:	31–0
Bit field:	LTHFDN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	LTHFDN[31:0]	Layer 3 Forwarded Descriptor Number	R

LTHFDN[31:0] bits (Layer 3 Forwarded Descriptor Number)

These bits count the number of descriptors forwarded by Layer 3 forwarding for port i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame coming from port i is forwarded by Layer 3 Forwarding and if these bits have a value different from 0xFFFFFFFF.

Note: HW: These bits count the frame selected by Layer 3 forwarding mechanism before PSFP/ATS and FRER filtering functions. Frame rejected by these filtering functions are still taken in account here.

30.3.2.4 FWLTWFDCNi : Port i Layer 2 Forwarded Descriptor Counter Register (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x630C + 0x20 × i

Bit position:	31–0
Bit field:	LTWFDN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	LTWFDN[31:0]	Layer 2 Forwarded Descriptor Number	R

LTWFDN[31:0] bits (Layer 2 Forwarded Descriptor Number)

These bits count the number of descriptors forwarded by Layer 2 forwarding for port i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame coming from port i is forwarded by Layer 2 Forwarding and if these bits have a value different from 0xFFFFFFFF.

30.3.2.5 FWPBFDCNi : Port i Port Based Forwarded Descriptor Counter Register (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6310 + 0x20 × i

Bit position:	31 … 0
Bit field:	PBFDN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	PBFDN[31:0]	Port Based Forwarded Descriptor Number	R

PBFDN[31:0] bits (Port Based Forwarded Descriptor Number)

These bits count the number of descriptors forwarded by Port Based forwarding for port i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame coming from port i is forwarded by Port Based Forwarding and if these bits have a value different from 0xFFFFFFFF.

30.3.2.6 FWMHLCNi : Port i MAC Hardware Learn Counter Register (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6314 + 0x20 × i

Bit position:	31 … 0
Bit field:	MHLN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	MHLN[31:0]	MAC Hardware Learn Number	R

MHLN[31:0] bits (MAC Hardware Learn Number)

These bits count the number of MAC source addresses that has been learnt or migrated for port i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame is selected for source MAC address HW learning or HW migrated (section 30.5.1.5.2. CPU Learning Path) and learning rate is not too high and if these bits have a value different from {32 {1}}.

This counter is incremented regardless of the MAC learn result Table 30.45. (It counts even if it fails)

This counter is incremented only learning or migrated HW request. So, the counter increments twice even for consecutive requests with the same content. Since the processing is the same, it looks like one time.

30.3.2.7 FWWMRDCNi : Port i Watermark Rejected Descriptor Counter Register (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6504 + 0x20 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WMRDN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WMRDN[15:0]	Watermark rejected Descriptor Number	R
31:16	—	These bits are read as 0.	R

WMRDN[15:0] bits (Watermark rejected Descriptor Number)

These bits count the number of descriptors rejected by Watermark for port i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame coming from port i is rejected by Watermark and if these bits have a value different from 0xFFFFFFFF.

30.3.2.8 FWCTRDCNi : Port i Cut-Through Rejected Descriptor Counter Register (i = 0, 1)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6508 + 0x20 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CTRDN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CTRDN[15:0]	Cut-through rejected Descriptor Number	R
31:16	—	These bits are read as 0.	R

CTRDN[15:0] bits (Cut-through rejected Descriptor Number)

These bits count the number of descriptors rejected by Cut-through forwarding for port i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame coming from port i is forwarded by Cut-Through Forwarding but not in store and forward mode and if these bits have a value different from 0xFFFFFFFF.

Note: HW: These bits do not take in account the cut-through path of cut-through forwarding but only the store and forward path so, any frame not forwarded in store and forward with cut-through (for any j, if FWCTTCi0.CTDV[j] is set, FWCTTCi0.CTDFMj is not set) with be counted here.

30.3.2.9 FWDDRDCN2 : Port 2 Direct Descriptor Rejected Descriptor Counter Register

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6548

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DDRDN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DDRDN[15:0]	Direct Descriptor rejected Descriptor Number	R
31:16	—	These bits are read as 0.	R

DDRDN[15:0] bits (Direct Descriptor rejected Descriptor Number)

These bits count the number of descriptors rejected by Direct Descriptor forwarding for port 2.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame coming from port 2 is rejected by Direct Descriptor forwarding and if these bits have a value different from 0xFFFFFFFF.

30.3.2.10 FWLTHRDCNi : Port i Layer 3 Rejected Descriptor Counter Register (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x650C + 0x20 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	LTHRDN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	LTHRDN[15:0]	Layer 3 rejected Descriptor Number	R
31:16	—	These bits are read as 0.	R

LTHRDN[15:0] bits (Layer 3 rejected Descriptor Number)

These bits count the number of descriptors rejected by Layer 3 forwarding for port i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame coming from port i is rejected by Layer 3 forwarding and if these bits have a value other than 0xFFFF.

30.3.2.11 FWLTWRDCNi : Port i Layer 2 Rejected Descriptor Counter Register (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6514 + 0x20 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	LTWRDN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	LTWRDN[15:0]	Layer 2 rejected Descriptor Number	R
31:16	—	These bits are read as 0.	R

LTWRDN[15:0] bits (Layer 2 rejected Descriptor Number)

These bits count the number of descriptors rejected by Layer 2 forwarding for port i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame coming from port i is rejected by Layer 2 forwarding and if these bits have a value other than 0xFFFF.

30.3.2.12 FWPBRDCNi : Port i Port Based Rejected Descriptor Counter Register (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6518 + 0x20 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PBRDN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PBRDN[15:0]	Port Based rejected Descriptor Number	R
31:16	—	These bits are read as 0.	R

PBRDN[15:0] bits (Port Based rejected Descriptor Number)

These bits count the number of descriptors rejected by Port Based forwarding for port i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame coming from port i is rejected by Port Based forwarding and if these bits have a value other than 0xFFFF.

30.3.2.13 FWPMFDCNi : PSFP MSDU i Filtered Descriptor Counter Register (i = 0 to 15)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6700 + 0x4 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PMFDN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PMFDN[15:0]	PSFP MSDU Filtered Descriptor Number	R
31:16	—	These bits are read as 0.	R

PMFDN[15:0] bits (PSFP MSDU Filtered Descriptor Number)

These bits count the number of descriptors rejected by PSFP MSDU Filter i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame is rejected by PSFP MSDU Filter i and if these bits have a value different from 0xFFFF.

30.3.2.14 FWPMGDCNi : PSFP Meter i Green Descriptor Counter Register (i = 0 to 31)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6800 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PMGDN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PMGDN[15:0]	PSFP Meter Green Descriptor Number	R
31:16	—	These bits are read as 0.	R

PMGDN[15:0] bits (PSFP Meter Green Descriptor Number)

These bits count the number of descriptors with the color green given by PSFP meter Filter i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame has green color associated by PSFP meter Filter i and if these bits have a value different from 0xFFFF.

30.3.2.15 FWPMYDCNi : PSFP Meter i Yellow Descriptor Counter Register (i = 0 to 7)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6804 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PMYDN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PMYDN[15:0]	PSFP Meter Yellow Descriptor Number	R
31:16	—	These bits are read as 0.	R

PMYDN[15:0] bits (PSFP Meter Yellow Descriptor Number)

These bits count the number of descriptors with the color Yellow given by PSFP meter Filter i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame has yellow color associated by PSFP meter Filter i and if these bits have a value different from 0xFFFF.

30.3.2.16 FWPMRDCNi : PSFP Meter i Red Descriptor Counter Register (i = 0 to 31)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6808 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PMRDN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PMRDN[15:0]	PSFP Meter Red Descriptor Number	R
31:16	—	These bits are read as 0.	R

PMRDN[15:0] bits (PSFP Meter Red Descriptor Number)

These bits count the number of descriptors with the color Red given by PSFP meter Filter i. (All and only frames rejected by meter filter are accounted)

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

- HW: Incremented by 1 when a frame has Red color associated and is rejected by PSFP meter Filter i and if these bits have a value different from 0xFFFF.
- HW: Incremented by 1 when a frame is rejected by PSFP meter Filter i because ATS RAM corresponding queue is full and if these bits have a value different from 0xFFFF.
- HW: Incremented by 1 when a frame is rejected by PSFP meter Filter i because corresponding meter is disabled and if these bits have a value different from 0xFFFF.

30.3.2.17 FWFRPPCNi : FRER i Passed Packet Counter Register (i = 0 to 127)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6A00 + 0x8 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PPC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PPC[15:0]	Passed Packet Count	R

Bit	Symbol	Function	R/W
31:16	—	These bits are read as 0.	R

PPC[15:0] bits (Passed Packet Count)

These bits count the number of packets that passed FRER recovery rule number i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame passed FRER recovery rule number i and if these bits have a value different from 0xFFFF.

30.3.2.18 FWFRDPCNi : FRER i Discarded Packet Counter Register (i = 0 to 127)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x6A04 + 0x8 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DPC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DPC[15:0]	Discarded Packet Count	R
31:16	—	These bits are read as 0.	R

DPC[15:0] bits (Discarded Packet Count)

These bits count the number of packets that has been discarded by FRER recovery rule number i.

[Clearing condition]

SW: Reading these bits clears it.

[Increment condition]

HW: Incremented by 1 when a frame has been discarded by FRER recovery rule number i and if these bits have a value different from 0xFFFF.

30.3.3 MFWD Interrupt Registers

This section describes MFWD interrupt registers.

30.3.3.1 FWEIS0i : Port i Error Interrupt Status Register 0 (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7900 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	DDNTFS	DDSES	—	DDES	WMIUFS	WMISFS	WMFFS	WMCFS	—	—	SMHMFS	SMHLFS	PBNTFS	LTWVUFS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	LTWDUFS	LTWSUFS	LTWNTFS	LTWVSPFS	LTWSSPFS	LTWDSPFS	—	—	—	—	—	—	LTHUFS	LTHNTFS	—	LTHSPFS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LTHSPFS	Layer 3 Source Port Filtering Status Flag	R/W*1
1	—	These bits are read as 0. The write value should be 0.	R/W
2	LTHNTFS	Layer 3 No Target Filtering Status Flag	R/W*1
3	LTHUFS	Layer 3 Unknown Filtering Status Flag	R/W*1
9:4	—	These bits are read as 0. The write value should be 0.	R/W
10	LTWDSPFS	Layer 2 Destination Source Port Filtering Status Flag	R/W*1
11	LTWSSPFS	Layer 2 Source Source Port Filtering Status Flag	R/W*1
12	LTWVSPFS	Layer 2 VLAN Source Port Filtering Status Flag	R/W*1
13	LTWNTFS	Layer 2 No Target Filtering Status Flag	R/W*1
14	LTWSUFS	Layer 2 Source Unknown Filtering Status Flag	R/W*1
15	LTWDUFS	Layer 2 Destination Unknown Filtering Status Flag	R/W*1
16	LTWVUFS	Layer 2 VLAN Unknown Filtering Status Flag	R/W*1
17	PBNTFS	Port Based No Target Filtering Status Flag	R/W*1
18	SMHLFS	Source MAC Hardware Learning Fail Status Flag	R/W*1
19	SMHMFS	Source MAC Hardware Migration Fail Status Flag	R/W*1
21:20	—	These bits are read as 0. The write value should be 0.	R/W
22	WMCFS	Watermark Critical Filtering Status Flag	R/W*1
23	WMFFS	Watermark Flush Filtering Status Flag	R/W*1
24	WMISFS	Watermark IPV Secure Filtering Status Flag	R/W*1
25	WMIUFS	Watermark IPV Unsecure Filtering Status Flag	R/W*1
26	DDES	Direct Descriptor Error Status Flag*2	R/W*1
27	—	This bit is read as 0. The write value should be 0.	R/W
28	DDSES	Direct Descriptor Security Error Status Flag*2	R/W*1
29	DDNTFS	Direct Descriptor No Target Filtering Status Flag*2	R/W*1
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.
Note 2. HW: This bit is only valid for i = 2, 3.

LTHSPFS bit (Layer 3 Source Port Filtering Status Flag)

[Setting condition]

- HW: When forwarding flow for a frame coming from port i goes until “Layer 3 routing secure error” block in Figure 30.85 and L3.SLV[i] is not set.
- HW: When forwarding flow for a frame coming from port i goes until “Layer 3 routing error” block in Figure 30.86 and L3.SLV[i] is not set.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

LTHNTFS bit (Layer 3 No Target Filtering Status Flag)

[Setting condition]

- HW: When forwarding flow for a frame coming from port i goes until “Layer 3 routing secure error” block in Figure 30.85 and L3.DV & !FWPCi1.LTHFM is null.
- HW: When forwarding flow for a frame coming from port i goes until “Layer 3 routing error” block in Figure 30.86 and L3.DV & !FWPCi1.LTHFM is null.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

LTHUFS bit (Layer 3 Unknown Filtering Status Flag)

[Setting condition]

- HW: When forwarding flow for a frame coming from port i goes until “Layer 3 routing unknown secure stream error” block in Figure 30.85 and FWPCi0.LTHRUSS is set.
- HW: When forwarding flow for a frame coming from port i goes until “Layer 3 routing error” block in Figure 30.86 and FWPCi0.LTHRUS is set.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

LTWDSPFS bit (Layer 2 Destination Source Port Filtering Status Flag)

[Setting condition]

- HW: When forwarding flow for a frame coming from port i goes until “L2 forwarding secure error” block in Figure 30.95 and, FWPCi0.MACDSA is set, Destination MAC is set in the MAC table, MAC.SL is set and MAC.DSLV is not set for destination MAC.
- HW: When forwarding flow for a frame coming from port i goes until “L2 forwarding error” block in Figure 30.96 and, FWPCi0.MACDSA is set, Destination MAC is set in the MAC table and MAC.DSLV is not set for destination MAC.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

LTWSSPFS bit (Layer 2 Source Source Port Filtering Status Flag)

[Setting condition]

- HW: When forwarding flow for a frame coming from port i goes until "L2 forwarding secure error" block in Figure 30.95 and, FWPCi0.MACSSA is set, Source MAC is set in the MAC table, MAC.SL is set and MAC.SSLV is not set for source MAC.
- HW: When forwarding flow for a frame coming from port i goes until "L2 forwarding error" block in Figure 30.96 and, FWPCi0.MACSSA is set, Source MAC is set in the MAC table and MAC.SSLV is not set for source MAC.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

LTWVSPFS bit (Layer 2 VLAN Source Port Filtering Status Flag)

[Setting condition]

- HW: When forwarding flow for a frame coming from port i goes until "L2 forwarding secure error" block in Figure 30.95 and, FWPCi0.VLANSA is set, VLAN ID is valid, VLAN ID is set in the VLAN table, VLAN.SL is set and VLAN.SLV is not set for VLAN ID.
- HW: When forwarding flow for a frame coming from port i goes until "L2 forwarding error" block in Figure 30.96 and, FWPCi0.VLANSA is set, VLAN ID is valid, VLAN ID is set in the VLAN table and VLAN.SLV is not set for VLAN ID.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

LTWNTFS bit (Layer 2 No Target Filtering Status Flag)

[Setting condition]

- HW: When forwarding flow for a frame coming from port i goes until "L2 forwarding secure error" block inFigure 30.95 and, FWPCi0.MACDSA is set, Destination MAC is set in the MAC table, MAC.SL is set, FWPCi0.VLANSA is set, VLAN ID is valid, VLAN ID is set in the VLAN table, VLAN.SL is set and MAC.DV & VLAN.DV & ! FWPCi2.LTWFM is null.
- HW: When forwarding flow for a frame coming from port i goes until "L2 forwarding secure error" block in Figure 30.95 and, FWPCi0.MACDSA is set, Destination MAC is set in the MAC table, MAC.SL is set, { FWPCi0.VLANSA is not set or VLAN ID is not valid or VLAN ID is not set in the VLAN table or VLAN.SL is not set} and MAC.DV & !FWPCi2.LTWFM is null.
- HW: When forwarding flow for a frame coming from port i goes until "L2 forwarding secure error" block in Figure 30.95 and, {FWPCi0.MACDSA is not set or Destination MAC is not set in the MAC table or MAC.SL is not set}, VLAN ID is valid, VLAN ID is set in the VLAN table, VLAN.SL is set and VLAN.DV & !FWPCi2.LTWFM is null.
- HW: When forwarding flow for a frame coming from port i goes until "L2 forwarding error" block in Figure 30.96 and, FWPCi0.MACDSA is set, Destination MAC is set in the MAC table, FWPCi0.VLANSA is set, VLAN ID is valid, VLAN ID is set in the VLAN table and MAC.DV & VLAN.DV & !FWPCi2.LTWFM is null.
- HW: When forwarding flow for a frame coming from port i goes until "L2 forwarding error" block in Figure 30.96 and, FWPCi0.MACDSA is set, Destination MAC is set in the MAC table, { FWPCi0.VLANSA is not set or VLAN ID is not valid or VLAN ID is not set in the VLAN table } and MAC.DV & !FWPCi2.LTWFM is null.
- HW: When forwarding flow for a frame coming from port i goes until "L2 forwarding error" block in Figure 30.96 and, {FWPCi0.MACDSA is not set or Destination MAC is not set in the MAC table}, VLAN ID is valid, VLAN ID is set in the VLAN table and VLAN.DV & !FWPCi2.LTWFM is null.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

LTWSUFS bit (Layer 2 Source Unknown Filtering Status Flag)

[Setting condition]

- HW: When forwarding flow for a frame coming from port i goes until “L2 forwarding secure error” block in Figure 30.95 and, { FWPCi0.MACSSA is not set or Source MAC is not set in the MAC table or MAC.SL is not set for Source MAC} and FWPCi0.MACRUSSA is set.
- HW: When forwarding flow for a frame coming from port i goes until “L2 forwarding error” block in Figure 30.96 and, {FWPCi0.MACSSA is not set or Source MAC is not set in the MAC table} and FWPCi0.MACRUSA is set.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

LTWDUFS bit (Layer 2 Destination Unknown Filtering Status Flag)

[Setting condition]

- HW: When forwarding flow for a frame coming from port i goes until “L2 forwarding secure error” block in Figure 30.95 and, {FWPCi0.MACDSA is not set or Destination MAC is not set in the MAC table or MAC.SL is not set for destination MAC} and FWPCi0.MACRUDSA is set.
- HW: When forwarding flow for a frame coming from port i goes until “L2 forwarding error” block in Figure 30.96 and, {FWPCi0.MACDSA is not set or Destination MAC is not set in the MAC table} and FWPCi0.MACRUDA is set.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

LTWVUFS bit (Layer 2 VLAN Unknown Filtering Status Flag)

[Setting condition]

- HW: When forwarding flow for a frame coming from port i goes until “L2 forwarding secure error” block in Figure 30.95 and, {FWPCi0.VLANSA is not set or VLAN is not valid or VLAN ID is not set in the VLAN table or VLAN.SL is not set for VLAN ID} and FWPCi0.VLANRUS is set.
- HW: When forwarding flow for a frame coming from port i goes until “L2 forwarding error” block in Figure 30.96 and, {FWPCi0.VLANSA is not set or VLAN is not valid or VLAN ID is not set in the VLAN table} and FWPCi0.VLANRU is set.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

PBNTFS bit (Port Based No Target Filtering Status Flag)

[Setting condition]

- HW: When forwarding flow for a frame coming from port i goes until “Port based forwarding secure error” block in Figure 30.99 and FWPBFCi.PBDV is null.
- HW: When forwarding flow for a frame coming from port i goes until “Port based forwarding unsecure error” block in Figure 30.100 and FWPBFCi.PBDV is null.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

SMHLFS bit (Source MAC Hardware Learning Fail Status Flag)

[Setting condition]

HW: When a frame is selected for source MAC address HW learning (section 30.5.1.5.2. CPU Learning Path) and it could not be learnt because the learning rate is too high.

This error has nothing to do with fail of Table 30.45.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

SMHMFS bit (Source MAC Hardware Migration Fail Status Flag)

[Setting condition]

- HW: When a frame is selected for source MAC address HW migration (section 30.5.1.5.2. CPU Learning Path) and it could not be learnt because the learning rate is too high.
- HW: When a frame is selected for source MAC address HW migration and its source MAC address contained in the table in static (MAC.DE is not set).
- HW: When a frame is selected for source MAC address HW migration and its source MAC address contained in the table is secure (MAC.SL is set).
- HW: When a frame is selected for source MAC address HW migration and its source MAC address contained in the table has one of its destination port which does not allow migration (for at least one i, MAC.DV[i] is set and FWPCi0.MACHMA is not set).

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

WMCFS bit (Watermark Critical Filtering Status Flag)

[Setting condition]

HW: A frame coming from port i is forwarded with a Layer 3/IP/Layer 2/Port based normal descriptor and FWLBWMCi.WMCLPR bit {DEI,IPV} is set and coa_watermark_critical[i] pin is set (where DEI is set to input frame C-TAG DEI if FWGC.SVM is set to 01b, input frame S-TAG DEI if FWGC.SVM is set to 10b and set to 0 if FWGC.SVM is set to 00b and IPV is the Frame corresponding normal descriptor, selected by the forwarding flow, FDESCR.IPV value).

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

WMFFS bit (Watermark Flush Filtering Status Flag)

[Setting condition]

HW: A frame coming from port i is forwarded with a Layer 3/IP/Layer 2/Port based normal descriptor and FWLBWMCi.WMFLPR bit {DEI,IPV} is set and coa_watermark_flush[i] pin is set (where DEI is set to input frame C-TAG DEI if FWGC.SVM is set to 01b, input frame S-TAG DEI if FWGC.SVM is set to 10b and set to 0 if FWGC.SVM is set to 00b and IPV is the Frame corresponding normal descriptor, selected by the forwarding flow, FDESCR.IPV value).

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

WMISFS bit (Watermark IPV Secure Filtering Status Flag)

[Setting condition]

HW: A frame coming from port i is forwarded with a Layer 3/IP/Layer 2/Port based normal descriptor and corresponding IPV is rejected by IPV based unsecure watermark [COMA] (where IPV is Frame corresponding normal descriptor, selected by the forwarding flow, FDESCR.IPV value before filtering).

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

WMIUFS bit (Watermark IPV Unsecure Filtering Status Flag)

[Setting condition]

HW: A frame coming from port i is forwarded with a Layer 3/IP/Layer 2/Port based normal descriptor and SEC is not set and corresponding IPV is rejected by IPV based secure watermark [COMA] (where SEC and IPV are respectively Frame corresponding normal descriptor, selected by the forwarding flow, FDESCR.SEC and FDESCR.IPV values before filtering).

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

DDES bit (Direct Descriptor Error Status Flag)

[Setting condition]

HW: When a direct descriptor (LDESCR.FMT [GWCA] set to 1) is received from port 2 + i and FWPCi1.DDE is not set.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

DDSES bit (Direct Descriptor Security Error Status Flag)

[Setting condition]

HW: When a secure direct descriptor (LDESCR.FMT [GWCA] and LDESCR.SEC [GWCA] are both set to 1) is received from port 2 + i , FWPCi1.DDE is set and FWPCi1.DDSL is not set.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

DDNTFS bit (Direct Descriptor No Target Filtering Status Flag)

[Setting condition]

HW: When a directed descriptor (LDESCR.FMT [GWCA] set to 1) is received from port 2 + i and LDESCR.DV [GWCA] is set to All0.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.2 FWEIE0i : Port i Error Interrupt Enable Register 0 (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7904 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	DDNTFE	DDSEE	DDFEE	DDEE	WMIUFE	WMISFE	WMFFE	WMCFE	—	—	SMHMFE	SMHLFE	PBNTFE	LTWVUFE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

24	WMISFE	Watermark IPV Secure Filtering Enable 0: Interrupt i disabled. 1: Interrupt i Enabled.	R/W*1
25	WMIUFE	Watermark IPV Unsecure Filtering Enable 0: Interrupt i disabled. 1: Interrupt i Enabled.	R/W*1
26	DDEE	Direct Descriptor Error Enable 0: Interrupt i disabled. 1: Interrupt i Enabled.	R/W*1
27	DDFEE	Direct Descriptor Format Error Enable 0: Interrupt i disabled. 1: Interrupt i Enabled.	R/W*1
28	DDSEE	Direct Descriptor Security Error Enable 0: Interrupt i disabled. 1: Interrupt i Enabled.	R/W*1
29	DDNTFE	Direct Descriptor No Target Filtering Enable 0: Interrupt i disabled. 1: Interrupt i Enabled.	R/W*1
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

LTHSPFE bit (Layer 3 Source Port Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.LTHSPFD register will clear this bit.

LTHNTFE bit (Layer 3 No Target Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.LTHNTFD register will clear this bit.

LTHUFE bit (Layer 3 Unknown Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.LTHUFD register will clear this bit.

LTWDSPFE bit (Layer 2 Destination Source Port Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.LTWDSPFD register will clear this bit.

LTWSSPFE bit (Layer 2 Source Source Port Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.LTWSSPFD register will clear this bit.

LTWVSPFE bit (Layer 2 VLAN Source Port Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.LTWVSPFD register will clear this bit.

LTWNTFE bit (Layer 2 No Target Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.LTWNTFD register will clear this bit.

LTWSUFE bit (Layer 2 Source Unknown Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.LTWSUFD register will clear this bit.

LTWDUFE bit (Layer 2 Destination Unknown Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.LTWDUFD register will clear this bit.

LTWVUFE bit (Layer 2 VLAN Unknown Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.LTWVUFD register will clear this bit.

PBNTFE bit (Port Based No Target Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.PBNTFD register will clear this bit.

SMHLFE bit (Source MAC Hardware Learning Fail Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.SMHLFD register will clear this bit.

SMHMFE bit (Source MAC Hardware Migration Fail Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.SMHMFD register will clear this bit.

WMCFE bit (Watermark Critical Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.WMFFD register will clear this bit.

WMFFE bit (Watermark Flush Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.WMFFE register will clear this bit.

WMISFE bit (Watermark IPV Secure Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.WMISFD register will clear this bit.

WMIUFE bit (Watermark IPV Unsecure Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.WMIUFD register will clear this bit.

DDEE bit (Direct Descriptor Error Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.DDED register will clear this bit.

DDFEE bit (Direct Descriptor Format Error Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.DDFED register will clear this bit.

DDSEE bit (Direct Descriptor Security Error Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.DDSED register will clear this bit.

DDNTFE bit (Direct Descriptor No Target Filtering Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID0i.DDNTFD register will clear this bit.

30.3.3.3 FWEID0i : Port i Error Interrupt Disable Register 0 (i = 0 to 2)

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7908 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	DDNTFD	DDSED	DDFED	DDED	WMIUFD	WMISFD	WMFFD	WMCFD	—	—	SMHMFD	SMHLFD	PBNTFD	LTWVUFD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	LTWDUFD	LTWSUFD	LTWNTFD	LTWVSPFD	LTWSSPFD	LTWDSPFD	—	—	—	—	—	—	LTHUFD	LTHNTFD	—	LTHSPFD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LTHSPFD	Layer 3 Source Port Filtering Disable Writing 1 to this bit clears FWEIE0.LTHSPFE register.	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	LTHNTFD	Layer 3 No Target Filtering Disable Writing 1 to this bit clears FWEIE0.LTHNTFE register.	R/W
3	LTHUFD	Layer 3 Unknown Filtering Disable Writing 1 to this bit clears FWEIE0.LTHNTFE register.	R/W
9:4	—	These bits are read as 0. The write value should be 0.	R/W
10	LTWDSPFD	Layer 2 Destination Source Port Filtering Disable Writing 1 to this bit clears FWEIE0.LTWDSPFE register.	R/W
11	LTWSSPFD	Layer 2 Source Source Port Filtering Disable Writing 1 to this bit clears FWEIE0.LTWSSPFE register.	R/W
12	LTWVSPFD	Layer 2 VLAN Source Port Filtering Disable Writing 1 to this bit clears FWEIE0.LTWVSPFE register.	R/W
13	LTWNTFD	Layer 2 No Target Filtering Disable Writing 1 to this bit clears FWEIE0.LTWNTFE register.	R/W
14	LTWSUFD	Layer 2 Source Unknown Filtering Disable Writing 1 to this bit clears FWEIE0.LTWSUFE register.	R/W
15	LTWDUFD	Layer 2 Destination Unknown Filtering Disable Writing 1 to this bit clears FWEIE0.LTWDUFE register.	R/W
16	LTWVUFD	Layer 2 VLAN Unknown Filtering Disable Writing 1 to this bit clears FWEIE0.LTWVUFE register.	R/W
17	PBNTFD	Port Based No Target Filtering Disable Writing 1 to this bit clears FWEIE0.PBNTFE register.	R/W
18	SMHLFD	Source MAC Hardware Learning Fail Disable Writing 1 to this bit clears FWEIE0.SMHLFE register.	R/W

Bit	Symbol	Function	R/W
19	SMHMFD	Source MAC Hardware Migration Fail Disable Writing 1 to this bit clears FWEIE0.SMHMFE register.	R/W
21:20	—	These bits are read as 0. The write value should be 0.	R/W
22	WMCFD	Watermark Critical Filtering Disable Writing 1 to this bit clears FWEIE0.WMCFE register.	R/W
23	WMFFD	Watermark Flush Filtering Disable Writing 1 to this bit clears FWEIE0.WMFFE register.	R/W
24	WMISFD	Watermark IPV Secure Filtering Disable Writing 1 to this bit clears FWEIE0.WMISFE register.	R/W
25	WMIUFD	Watermark IPV Unsecure Filtering Disable Writing 1 to this bit clears FWEIE0.WMIUFE register.	R/W
26	DDED	Direct Descriptor Error Disable Writing 1 to this bit clears FWEIE0.DDEE register.	R/W
27	DDFED	Direct Descriptor Format Error Disable Writing 1 to this bit clears FWEIE0.DDFEE register.	R/W
28	DDSED	Direct Descriptor Security Error Disable Writing 1 to this bit clears FWEIE0.DDSEE register.	R/W
29	DDNTFD	Direct Descriptor No Target Filtering Disable Writing 1 to this bit clears FWEIE0.DDNTFE register.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

30.3.3.4 FWEIS1 : Error Interrupt Status Register 1

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	VLANTSES	—	MACTSES	—	—	—	LTHTSES	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	LTHTSES	L3 Table Security Error Status Flag	R/W*1
4:2	—	These bits are read as 0. The write value should be 0.	R/W
5	MACTSES	MAC Table Security Error Status Flag	R/W*1
6	—	This bit is read as 0. The write value should be 0.	R/W
7	VLANTSES	VLAN Table Security Error Status Flag	R/W*1
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

LTHTSES bit (L3 Table Security Error Status Flag)

[Setting condition]

HW: A CPU tried to learn an unsecure entry, but the unsecure entry maximum number is already reached.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

- HW: Unsecure entry won't be learned
- SW: System dependent, cannot be defined here.

MACTSES bit (MAC Table Security Error Status Flag)

[Setting condition]

HW: A CPU tried to learn an unsecure entry, but the unsecure entry maximum number is already reached.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

- HW: Unsecure entry won't be learned
- SW: System dependent, cannot be defined here.

VLANTSES bit (VLAN Table Security Error Status Flag)

[Setting condition]

HW: A CPU tried to learn an unsecure entry, but the unsecure entry maximum number is already reached.

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

- HW: Unsecure entry won't be learned
- SW: System dependent, cannot be defined here.

30.3.3.5 FWEIE1 : Error Interrupt Enable Register 1

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	VLANTSEE	—	MACTSEE	—	—	—	LTHTSEE	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	LTHTSEE	L3 Table Security Error Enable 0: Interrupt disabled. 1: Interrupt Enabled.	R/W*1
4:2	—	These bits are read as 0. The write value should be 0.	R/W
5	MACTSEE	MAC Table Security Error Enable 0: Interrupt disabled. 1: Interrupt Enabled.	R/W*1
6	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
7	VLANTSEE	VLAN Table Security Error Enable 0: Interrupt disabled. 1: Interrupt Enabled.	R/W*1
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

LTHTSEE bit (L3 Table Security Error Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID1.LTHTSED register will clear this bit.

MACTSEE bit (MAC Table Security Error Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID1.MACTSED register will clear this bit.

VLANTSEE bit (VLAN Table Security Error Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWEID1.VLANTSED register will clear this bit.

30.3.3.6 FWEID1 : Error Interrupt Disable Register 1

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	L23UEED	VLANTSED	—	MACTSED	—	—	—	LTHTSED	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	LTHTSED	L3 Table Security Error Disable Writing 1 to this bit will clear FWEIE1.LTHTSEE.	R/W
4:2	—	These bits are read as 0. The write value should be 0.	R/W
5	MACTSED	MAC Table Security Error Disable Writing 1 to this bit will clear FWEIE1.MACTSEE.	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	VLANTSED	VLAN Table Security Error Disable Writing 1 to this bit will clear FWEIE1.VLANTSEE.	R/W

Bit	Symbol	Function	R/W
8	L23UEED	Layer 2/Layer 3 Update Error Disable Writing 1 to this bit will clear FWEIE1.L23UEEE.	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

30.3.3.7 FWEIS2 : Error Interrupt Status Register 2

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PMFS15 to PMFS0															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PMFS15 to PMFS0	PSFP MSDU n Filtering Status Flag (n = 0 to 15)	R/W*1
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

PMFSn bits (PSFP MSDU n Filtering Status Flag (n = 0 to 15))

[Setting condition]

HW: Bit i is set when a descriptor is rejected by MSDU filter number i. (See section 30.5.3.1.1. MSDU Filter).

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.8 FWEIE2 : Error Interrupt Enable Register 2

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PMFE15 to PMFE0															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PMFE15 to PMFE0	PSFP MSDU n Filtering Enable (n = 0 to 15) 0: Interrupt disabled. 1: Interrupt Enabled.	R/W*1

Bit	Symbol	Function	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

PMFEn bits (PSFP MSDU n Filtering Enable (n = 0 to 15))

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID2.PMFD register bit i will clear this register bit i.

30.3.3.9 FWEID2 : Error Interrupt Disable Register 2

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A18

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PMFD15 to PMFD0															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PMFD15 to PMFD0	PSFP MSDU n Filtering Disable (n = 0 to 15) Writing 1 to this register bit i will clear FWEIE2.PMFE register bit i.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

30.3.3.10 FWEIS5 : Error Interrupt Status Register 5

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A40

Bit position: 31 to 0

Bit field: PMRFS31 to PMRFS0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	PMRFS31 to PMRFS0	PSFP Meter n Filtering Status Flag (n = 0 to 31)	R/W*1

Note 1. Read value differs from written value.

PMRFSn bits (PSFP Meter n Filtering Status Flag (n = 0 to 31))

[Setting condition]

HW: Bit i is set when a descriptor is filtered by PSFP Meter filter number i. (See section 30.5.3.1.2. Meter Filter/ATS).

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.11 FWEIE5 : Error Interrupt Enable Register 5

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A44

Bit position:	31 … 0
Bit field:	PMRFE31 to PMRFE0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	PMRFE31 to PMRFE0	PSFP Meter n Filtering Enable (n = 0 to 31)	R/W*1

Note 1. Read value differs from written value.

PMRFEn bits (PSFP Meter n Filtering Enable (n = 0 to 31))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID5.PMRFD register bit i will clear this register bit i.

30.3.3.12 FWEID5 : Error Interrupt Disable Register 5

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A48

Bit position:	31 … 0
Bit field:	PMRFD31 to PMRFD0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	PMRFD31 to PMRFD0	PSFP Meter n Filtering Disable (n = 0 to 31) Writing 1 to this register bit i will clear FWEIE5.PMRFD register bit i.	R/W

30.3.3.13 FWEIS60 : Error Interrupt Status Register 60

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A50

Bit position:	31 … 0
Bit field:	FFS31 to FFS0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FFS31 to FFS0	FRER n Filtering Status Flag (n = 96 to 127)	R/W*1

Note 1. Read value differs from written value.

FFSn bits (FRER n Filtering Status Flag (n = 96 to 127))

[Setting condition]

- HW: If FRER rule i+96 is used for individual recovery, bit i is set when a descriptor is filtered by FRER rule number i+96 because of no sequence error or struck error. (See (e) Individual recovery algorithms.)
- HW: If FRER rule i+96 is used for sequence recovery, bit i is set when a descriptor is filtered by FRER rule number i+96 because of no sequence error. (See (f) Sequence recovery algorithms.)

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.14 FWEIE60 : Error Interrupt Enable Register 60

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A54

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FFE31 to FFE0																															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FFE31 to FFE0	FRER n Filtering Enable (n = 96 to 127)	R/W*1

Note 1. Read value differs from written value.

FFEn bits (FRER n Filtering Enable (n = 96 to 127))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID60.FFDi register bit i will clear this register bit i.

30.3.3.15 FWEID60 : Error Interrupt Disable Register 60

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A58

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FFD31 to FFD0																															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FFD31 to FFD0	FRER n Filtering Disable (n = 96 to 127) Writing 1 to this register bit i will clear FWEIE60.FFEi register bit i.	R/W

30.3.3.16 FWEIS61 : Error Interrupt Status Register 61

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A60

Bit position:	31																														0
Bit field:	FFS31 to FFS0																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FFS31 to FFS0	FRER n Filtering Status Flag (n = 64 to 95)	R/W*1

Note 1. Read value differs from written value.

FFSn bits (FRER n Filtering Status Flag (n = 64 to 95))

[Setting condition]

- HW: If FRER rule i+64 is used for individual recovery, bit i is set when a descriptor is filtered by FRER rule number i+64 because of no sequence error or struck error. (See (e) Individual recovery algorithms.)
- HW: If FRER rule i+64 is used for sequence recovery, bit i is set when a descriptor is filtered by FRER rule number i+64 because of no sequence error. (See (f) Sequence recovery algorithms.)

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.17 FWEIE61 : Error Interrupt Enable Register 61

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A64

Bit position:	31																														0
Bit field:	FFE31 to FFE0																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FFE31 to FFE0	FRER n Filtering Enable (n = 64 to 95)	R/W*1

Note 1. Read value differs from written value.

FFEn bits (FRER n Filtering Enable (n = 64 to 95))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID61.FFDi register bit i will clear this register bit i.

30.3.3.18 FWEID61 : Error Interrupt Disable Register 61

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A68

Bit position: 31 ... 0

Bit field: FFD31 to FFD0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FFD31 to FFD0	FRER n Filtering Disable (n = 64 to 95) Writing 1 to this register bit i will clear FWEIE61.FFEi register bit i.	R/W

30.3.3.19 FWEIS62 : Error Interrupt Status Register 62

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A70

Bit position: 31 ... 0

Bit field: FFS31 to FFS0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FFS31 to FFS0	FRER n Filtering Status Flag (n = 32 to 63)	R/W*1

Note 1. Read value differs from written value.

FFSn bits (FRER n Filtering Status Flag (n = 32 to 63))

[Setting condition]

- HW: If FRER rule i+32 is used for individual recovery, bit i is set when a descriptor is filtered by FRER rule number i+32 because of no sequence error or struck error. (See (e) Individual recovery algorithms.)
- HW: If FRER rule i+32 is used for sequence recovery, bit i is set when a descriptor is filtered by FRER rule number i+32 because of no sequence error. (See (f) Sequence recovery algorithms.)

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.20 FWEIE62 : Error Interrupt Enable Register 62

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A74

Bit position: 31 ... 0

Bit field: FFE31 to FFE0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FFE31 to FFE0	FRER n Filtering Enable (n = 32 to 63)	R/W*1

Note 1. Read value differs from written value.

FFEn bits (FRER n Filtering Enable (n = 32 to 63))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID62.FFDi register bit i will clear this register bit i.

30.3.3.21 FWEID62 : Error Interrupt Disable Register 62

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A78

Bit position:	31 ... 0
Bit field:	FFD31 to FFD0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FFD31 to FFD0	FRER n Filtering Disable (n = 32 to 63) Writing 1 to this register bit i will clear FWEIE62.FFEi register bit i.	R/W

30.3.3.22 FWEIS63 : Error Interrupt Status Register 63

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A80

Bit position:	31 ... 0
Bit field:	FFS31 to FFS0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FFS31 to FFS0	FRER n Filtering Status Flag (n = 0 to 31)	R/W*1

Note 1. Read value differs from written value.

FFSn bits (FRER n Filtering Status Flag (n = 0 to 31))

[Setting condition]

- HW: If FRER rule i is used for individual recovery, bit i is set when a descriptor is filtered by FRER rule number i because of no sequence error or struck error. (See (e) Individual recovery algorithms.)
- HW: If FRER rule i is used for sequence recovery, bit i is set when a descriptor is filtered by FRER rule number i because of no sequence error. (See (f) Sequence recovery algorithms.)

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

Error recovery:

HW: Descriptor corresponding frame is rejected.

30.3.3.23 FWEIE63 : Error Interrupt Enable Register 63

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A84

Bit position:	31 to 0
Bit field:	FFE31 to FFE0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FFE31 to FFE0	FRER n Filtering Enable (n = 0 to 31)	R/W*1

Note 1. Read value differs from written value.

FFEn bits (FRER n Filtering Enable (n = 0 to 31))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID63.FFDi register bit i will clear this register bit i.

30.3.3.24 FWEID63 : Error Interrupt Disable Register 63

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A88

Bit position:	31 to 0
Bit field:	FFD31 to FFD0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FFD31 to FFD0	FRER n Filtering Disable (n = 0 to 31) Writing 1 to this register bit i will clear FWEIE63.FFEi register bit i.	R/W

30.3.3.25 FWEIS70 : Error Interrupt Status Register 70

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A90

Bit position:	31 to 0
Bit field:	FOORS31 to FOORS0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FOORS31 to FOORS0	FRER n Out Of Range Status Flag (n = 96 to 127)	R/W*1

Note 1. Read value differs from written value.

FOORSn bits (FRER n Out Of Range Status Flag (n = 96 to 127))

[Setting condition]

- HW: If FRER rule i+96 is used with match algorithm, bit i is set when a descriptor an out of order error occurs. (See (e) Individual recovery algorithms and (f) Sequence recovery algorithms).
- HW: : If FRER rule i+96 is used with vector algorithm, bit i is set when a descriptor is filtered by FRER rule number i+96 because of an out of range error. (See (e) Individual recovery algorithms and (f) Sequence recovery algorithms).

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.26 FWEIE70 : Error Interrupt Enable Register 70

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A94

Bit position:	31	0
Bit field:	FOORE31 to FOORE0	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	FOORE31 to FOORE0	FRER n Out Of Range Enable (n = 96 to 127)	R/W*1

Note 1. Read value differs from written value.

FOOREn bits (FRER n Out Of Range Enable (n = 96 to 127))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID70.FOORDi register bit i will clear this register bit i.

30.3.3.27 FWEID70 : Error Interrupt Disable Register 70

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7A98

Bit position:	31	0
Bit field:	FOORD31 to FOORD0	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	FOORD31 to FOORD0	FRER n Out Of Range Disable (n = 96 to 127) Writing 1 to this register bit i will clear FWEIE70.FOOREi register bit i.	R/W

30.3.3.28 FWEIS71 : Error Interrupt Status Register 71

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AA0

Bit position:	31 … 0
Bit field:	FOORS31 to FOORS0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FOORS31 to FOORS0	FRER n Out Of Range Status Flag (n = 64 to 95)	R/W*1

Note 1. Read value differs from written value.

FOORSn bits (FRER n Out Of Range Status Flag (n = 64 to 95))

[Setting condition]

- HW: If FRER rule i+64 is used with match algorithm, bit i is set when a descriptor an out of order error occurs. (See (e) Individual recovery algorithms and (f) Sequence recovery algorithms).
- HW: : If FRER rule i+64 is used with vector algorithm, bit i is set when a descriptor is filtered by FRER rule number i+64 because of an out of range error. (See (e) Individual recovery algorithms and (f) Sequence recovery algorithms).

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.29 FWEIE71 : Error Interrupt Enable Register 71

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AA4

Bit position:	31 … 0
Bit field:	FOORE31 to FOORE0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FOORE31 to FOORE0	FRER n Out Of Range Enable (n = 64 to 95)	R/W*1

Note 1. Read value differs from written value.

FOOREn bits (FRER n Out Of Range Enable (n = 64 to 95))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID71.FOORDi register bit i will clear this register bit i.

30.3.3.30 FWEID71 : Error Interrupt Disable Register 71

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AA8

Bit position:	31 … 0
Bit field:	FOORD31 to FOORD0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FOORD31 to FOORD0	FRER n Out Of Range Disable (n = 64 to 95) Writing 1 to this register bit i will clear FWEIE71.FOOREi register bit i.	R/W

30.3.3.31 FWEIS72 : Error Interrupt Status Register 72

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AB0

Bit position:	31 … 0
Bit field:	FOORS31 to FOORS0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FOORS31 to FOORS0	FRER n Out Of Range Status Flag (n = 32 to 63)	R/W*1

Note 1. Read value differs from written value.

FOORSn bits (FRER n Out Of Range Status Flag (n = 32 to 63))

[Setting condition]

- HW: If FRER rule i+32 is used with match algorithm, bit i is set when a descriptor an out of order error occurs. (See (e) Individual recovery algorithms and (f) Sequence recovery algorithms).
- HW: If FRER rule i+32 is used with vector algorithm, bit i is set when a descriptor is filtered by FRER rule number i+32 because of an out of range error. (See (e) Individual recovery algorithms and (f) Sequence recovery algorithms).

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.32 FWEIE72 : Error Interrupt Enable Register 72

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AB4

Bit position:	31 … 0
Bit field:	FOORE31 to FOORE0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FOORE31 to FOORE0	FRER n Out Of Range Enable (n = 32 to 63)	R/W*1

Note 1. Read value differs from written value.

FOOREn bits (FRER n Out Of Range Enable (n = 32 to 63))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID72.FOORDi register bit i will clear this register bit i.

30.3.3.33 FWEID72 : Error Interrupt Disable Register 72

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AB8

Bit position:	31 … 0
Bit field:	FOORD31 to FOORD0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FOORD31 to FOORD0	FRER n Out Of Range Disable (n = 32 to 63) Writing 1 to this register bit i will clear FWEIE72.FOOREi register bit i.	R/W

30.3.3.34 FWEIS73 : Error Interrupt Status Register 73

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AC0

Bit position:	31 … 0
Bit field:	FOORS31 to FOORS0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FOORS31 to FOORS0	FRER n Out Of Range Status Flag (n = 0 to 31)	R/W*1

Note 1. Read value differs from written value.

FOORSn bits (FRER n Out Of Range Status Flag (n = 0 to 31))

[Setting condition]

- HW: If FRER rule i is used with match algorithm, bit i is set when a descriptor an out of order error occurs. (See (e) Individual recovery algorithms and (f) Sequence recovery algorithms).
- HW: If FRER rule i is used with vector algorithm, bit i is set when a descriptor is filtered by FRER rule number i because of an out of range error. (See (e) Individual recovery algorithms and (f) Sequence recovery algorithms).

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.35 FWEIE73 : Error Interrupt Enable Register 73

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AC4

Bit position:	31 … 0
Bit field:	FOORE31 to FOORE0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FOORE31 to FOORE0	FRER n Out Of Range Enable (n = 0 to 31)	R/W*1

Note 1. Read value differs from written value.

FOOREn bits (FRER n Out Of Range Enable (n = 0 to 31))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID73.FOORDi register bit i will clear this register bit i.

30.3.3.36 FWEID73 : Forwarding Engine Error Interrupt Disable 73

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AC8

Bit position:	31 … 0
Bit field:	FOORD31 to FOORD0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FOORD31 to FOORD0	FRER n Out Of Range Disable (n = 0 to 31) Writing 1 to this register bit i will clear FWEIE73.FOOREi register bit i.	R/W

30.3.3.37 FWEIS80 : Error Interrupt Status Register 80

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AD0

Bit position:	31 … 0
Bit field:	TOS31 to TOS0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TOS31 to TOS0	Timeout Status Flag n (n = 96 to 127)	R/W*1

Note 1. Read value differs from written value.

TOSn bits (Timeout Status Flag n (n = 96 to 127))

[Setting condition]

HW: When timeout happens for FRER rule i+96. (See (3) Timeout.)

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.38 FWEIE80 : Error Interrupt Enable Register 80

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AD4

Bit position:	31																														0
Bit field:	TOE31 to TOE0																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TOE31 to TOE0	Timeout Enable n (n = 96 to 127)	R/W*1

Note 1. Read value differs from written value.

TOEn bits (Timeout Enable n (n = 96 to 127))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID80.TODi register bit i will clear this register bit i.

30.3.3.39 FWEID80 : Error Interrupt Disable Register 80

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AD8

Bit position:	31																														0
Bit field:	TOD31 to TOD0																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	TOD31 to TOD0	Timeout Disable n (n = 96 to 127) Writing 1 to this register bit i will clear FWEIE80.TOEi register bit i.	R/W

30.3.3.40 FWEIS81 : Error Interrupt Status Register 81

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AE0

Bit position:	31	0
Bit field:	TOS31 to TOS0	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	TOS31 to TOS0	Timeout Status Flag n (n = 64 to 95)	R/W*1

Note 1. Read value differs from written value.

TOSn bits (Timeout Status Flag n (n = 64 to 95))

[Setting condition]

HW: When timeout happens for FRER rule i+64. (See (3) Timeout.)

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.41 FWEIE81 : Error Interrupt Enable Register 81

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AE4

Bit position:	31	0
Bit field:	TOE31 to TOE0	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	TOE31 to TOE0	Timeout Enable n (n = 64 to 95)	R/W*1

Note 1. Read value differs from written value.

TOEn bits (Timeout Enable n (n = 64 to 95))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID81.TODi register bit i will clear this register bit i.

30.3.3.42 FWEID81 : Error Interrupt Disable Register 81

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AE8

Bit position:	31 … 0
Bit field:	TOD31 to TOD0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TOD31 to TOD0	Timeout Disable n (n = 64 to 95) Writing 1 to this register bit i will clear FWEIE81.TOEi register bit i.	R/W

30.3.3.43 FWEIS82 : Error Interrupt Status Register 82

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AF0

Bit position:	31 … 0
Bit field:	TOS31 to TOS0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TOS31 to TOS0	Timeout Status Flag n (n = 32 to 63)	R/W*1

Note 1. Read value differs from written value.

TOSn bits (Timeout Status Flag n (n = 32 to 63))

[Setting condition]

HW: When timeout happens for FRER rule i+32. (See (3) Timeout.)

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.44 FWEIE82 : Error Interrupt Enable Register 82

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AF4

Bit position:	31 … 0
Bit field:	TOE31 to TOE0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TOE31 to TOE0	Timeout Enable n (n = 32 to 63)	R/W*1

Note 1. Read value differs from written value.

TOEn bits (Timeout Enable n (n = 32 to 63))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID82.TODi register bit i will clear this register bit i.

30.3.3.45 FWEID82 : Error Interrupt Disable Register 82

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7AF8

Bit position:	31 to 0
Bit field:	TOD31 to TOD0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TOD31 to TOD0	Timeout Disable n (n = 32 to 63) Writing 1 to this register bit i will clear FWEIE82.TOEi register bit i.	R/W

30.3.3.46 FWEIS83 : Error Interrupt Status Register 83

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7B00

Bit position:	31 to 0
Bit field:	TOS31 to TOS0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TOS31 to TOS0	Timeout Status Flag n (n = 0 to 31)	R/W*1

Note 1. Read value differs from written value.

TOSn bits (Timeout Status Flag n (n = 0 to 31))

[Setting condition]

HW: When timeout happens for FRER rule i. (See (3) Timeout.)

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Descriptor corresponding frame is rejected.

30.3.3.47 FWEIE83 : Error Interrupt Enable Register 83

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7B04

Bit position:	31–0
Bit field:	TOE31 to TOE0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TOE31 to TOE0	Timeout Enable n (n = 0 to 31)	R/W*1

Note 1. Read value differs from written value.

TOEn bits (Timeout Enable n (n = 0 to 31))

- Bit i set to 0: Interrupt i disabled.
- Bit i set to 1: Interrupt i Enabled.

[Setting condition]

Writing 1 to one of these bits will set it.

[Clearing condition]

Writing 1 to FWEID83.TODi register bit i will clear this register bit i.

30.3.3.48 FWEID83 : Error Interrupt Disable Register 83

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7B08

Bit position:	31–0
Bit field:	TOD31 to TOD0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TOD31 to TOD0	Timeout Disable n (n = 0 to 31) Writing 1 to this register bit i will clear FWEIE83.TOEi register bit i.	R/W

30.3.3.49 FWMIS0 : Monitoring Interrupt Status Register 0

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7C00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MACADAS	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	VLANTFS	MACTFS	—	LTHTFS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LTHTFS	L3 Table Full Status Flag	R/W*1
1	—	This bit is read as 0. The write value should be 0.	R/W
2	MACTFS	MAC Table Full Status Flag	R/W*1
3	VLANTFS	VLAN Table Full Status Flag	R/W*1
16:4	—	These bits are read as 0. The write value should be 0.	R/W
17	MACADAS	MAC Address Deleted Aging Status Flag	R/W*1
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

LTHTFS bit (L3 Table Full Status Flag)

[Setting condition]

HW: L3 table becomes full

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

MACTFS bit (MAC Table Full Status Flag)

[Setting condition]

HW: MAC table becomes full

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

VLANTFS bit (VLAN Table Full Status Flag)

[Setting condition]

HW: VLAN table becomes full

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

MACADAS bit (MAC Address Deleted Aging Status Flag)

[Setting condition]

HW: A MAC address has been suppressed by aging or dynamic entry delete

[Clearing condition]

SW: Writing 1 to one of these bits will clear it.

30.3.3.50 FWMIE0 : Monitoring Interrupt Enable Register 0

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7C04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MACADAE	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	VLANTFE	MACTFE	—	LTHTFE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LTHTFE	L3 Table Full Enable 0: Interrupt disabled. 1: Interrupt Enabled.	R/W*1
1	—	This bit is read as 0. The write value should be 0.	R/W
2	MACTFE	MAC Table Full Enable 0: Interrupt disabled. 1: Interrupt Enabled.	R/W*1
3	VLANTFE	VLAN Table Full Enable 0: Interrupt disabled. 1: Interrupt Enabled.	R/W*1
16:4	—	These bits are read as 0. The write value should be 0.	R/W
17	MACADAE	MAC Address Deleted Aging Enable 0: Interrupt disabled. 1: Interrupt Enabled.	R/W*1
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

LTHTFE bit (L3 Table Full Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWMID0.LTHTFD register will clear this bit.

MACTFE bit (MAC Table Full Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWMID0.MACTFD register will clear this bit.

VLANTFE bit (VLAN Table Full Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWMID0.VLANTFD register will clear this bit.

MACADAE bit (MAC Address Deleted Aging Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to FWMID0.MACADAD register will clear this bit.

30.3.3.51 FWMID0 : Monitoring Interrupt Disable Register 0

Base address: MFWD = 0x403C_0000
MFWD_NS = 0x503C_0000

Offset address: 0x7C08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MACADAD	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	VLANTFD	MACTFD	—	LTHTFD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LTHTFD	L3 Table Full Disable Writing 1 to this bit will clear FWMIE0.LTHTFE.	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	MACTFD	MAC Table Full Disable Writing 1 to this bit will clear FWMIE0.MACTFE.	R/W
3	VLANTFD	VLAN Table Full Disable Writing 1 to this bit will clear FWMIE0.VLANTFE.	R/W
16:4	—	These bits are read as 0. The write value should be 0.	R/W
17	MACADAD	MAC Address Deleted Aging Disable Writing 1 to this bit will clear FWMIE0.MACADAD.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

30.4 Register Utilization

30.4.1 Software Flows

Note:
- SW: Forwarding engine registers can only be written using the flows specified in this section
- SW: All the software flows described in this section can only be used sequentially.

30.4.1.1 Software Flow Legend

Figure 30.2 shows the software flow legend.

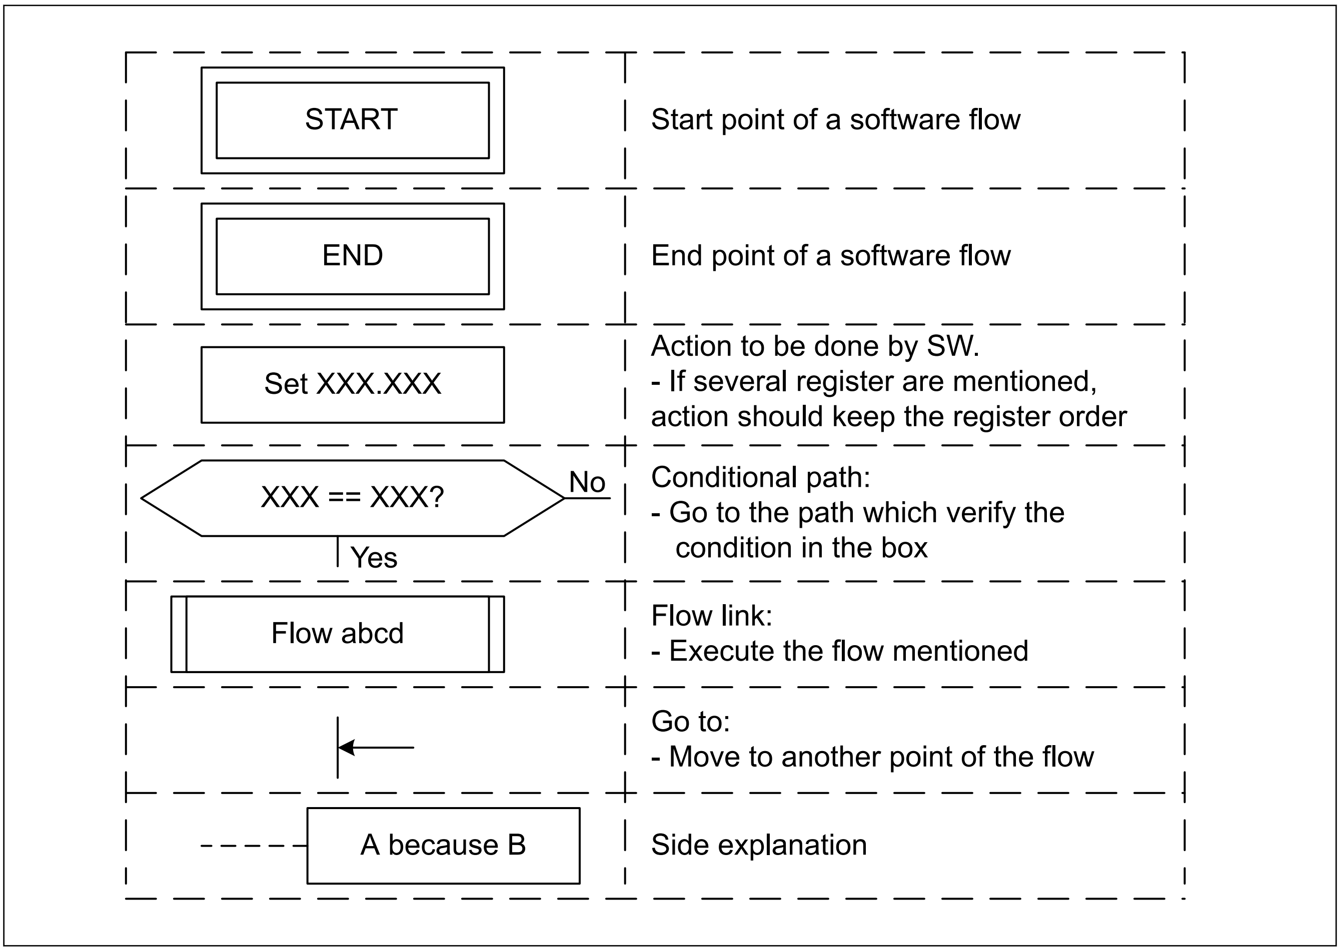

Figure 30.2 Software flow legend

30.4.1.2 Interrupt Handling Flow

Interrupt handling flow can be used in any mode except RESET mode.

Figure 30.3 describes the interrupt handling flow.

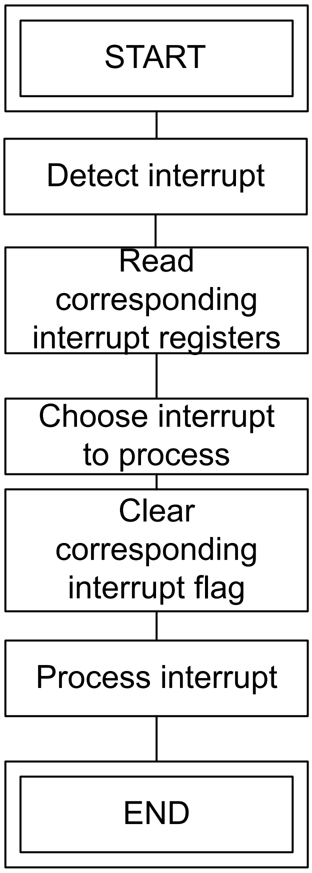

Figure 30.3 Interrupt handling flow

30.4.1.3 Port i Setting Flow

Port i setting flow is described in Figure 30.4.

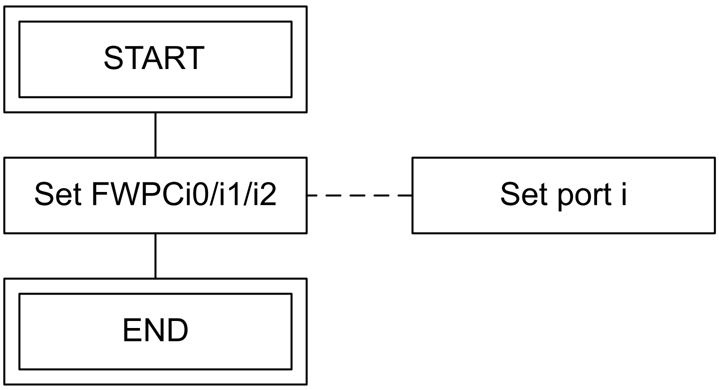

Figure 30.4 Port i setting flow

30.4.1.4 Cut-through Forwarding Flows

30.4.1.4.1 Cut-through Rule i Setting Flow

Cut-through rule i setting flow is described in Figure 30.5.

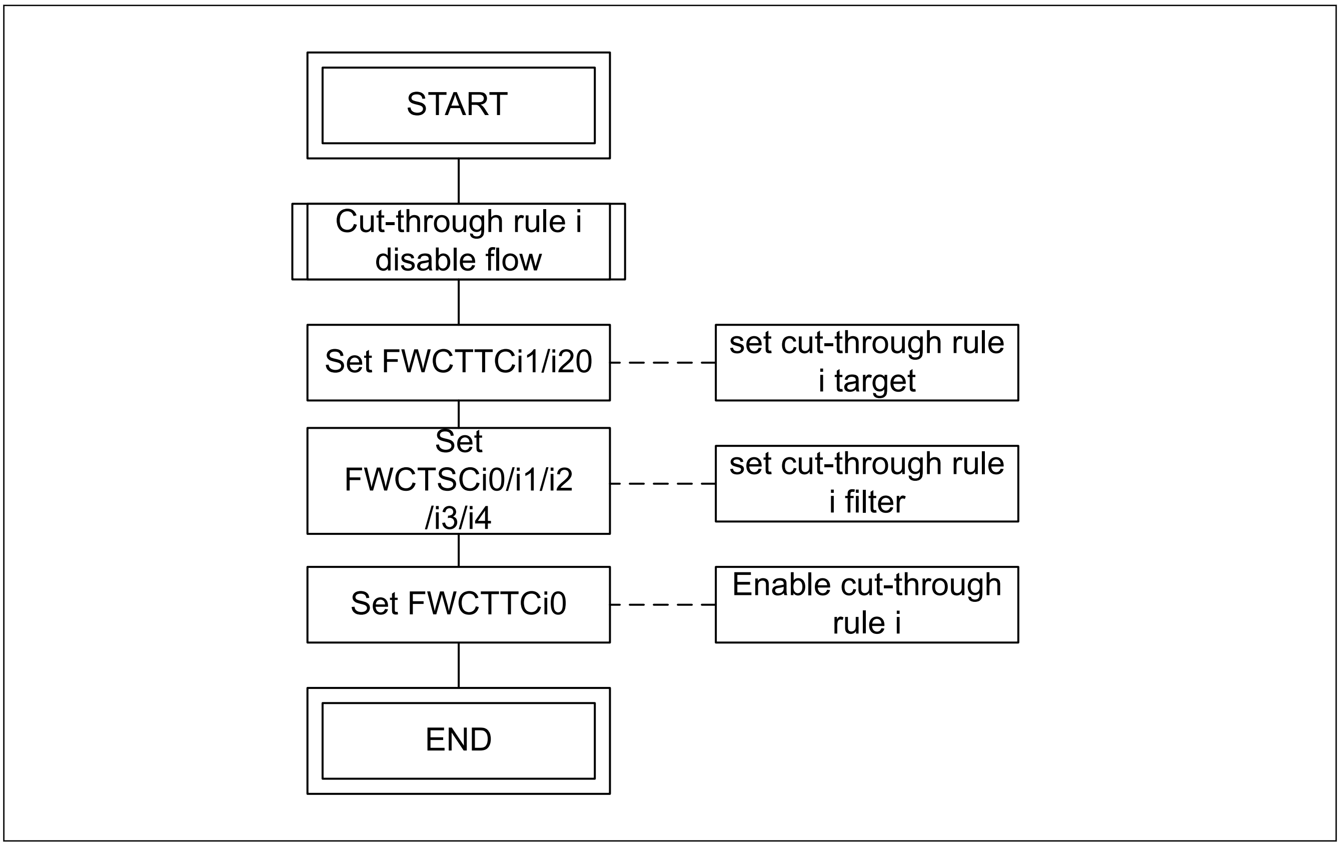

Figure 30.5 Cut-through rule i setting flow

30.4.1.4.2 Cut-through Rule i Disable Flow

Cut-through rule i disable flow is described in Figure 30.6.

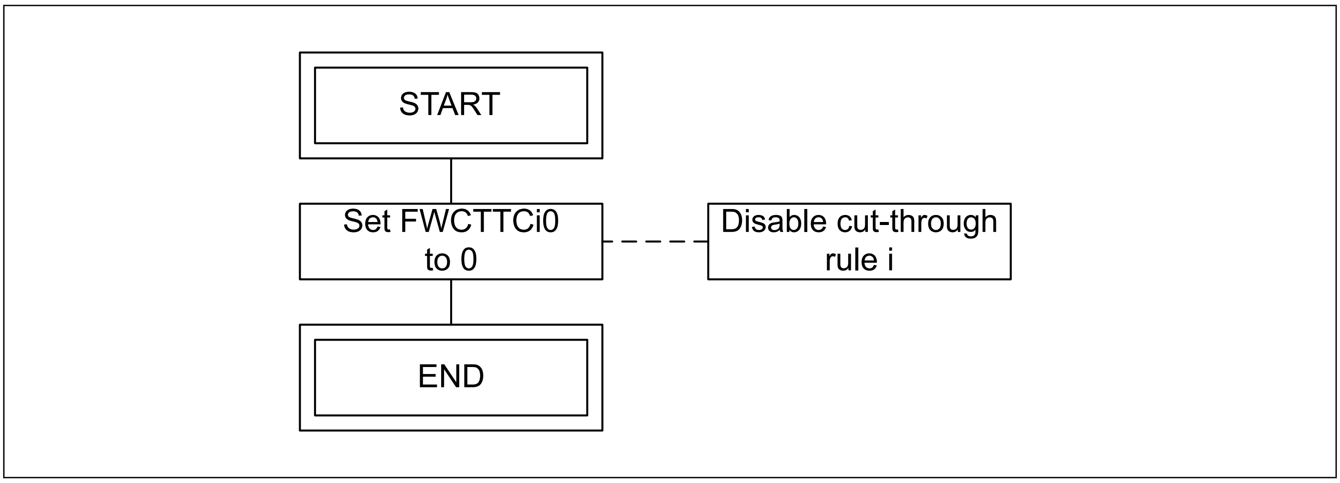

Figure 30.6 Cut-through rule i disable flow

30.4.1.5 Layer 3 Forwarding/Routing/Filtering Flows

30.4.1.5.1 Perfect Filter i Setting Flow

Figure 30.7 describes the setting flow of perfect filter i.

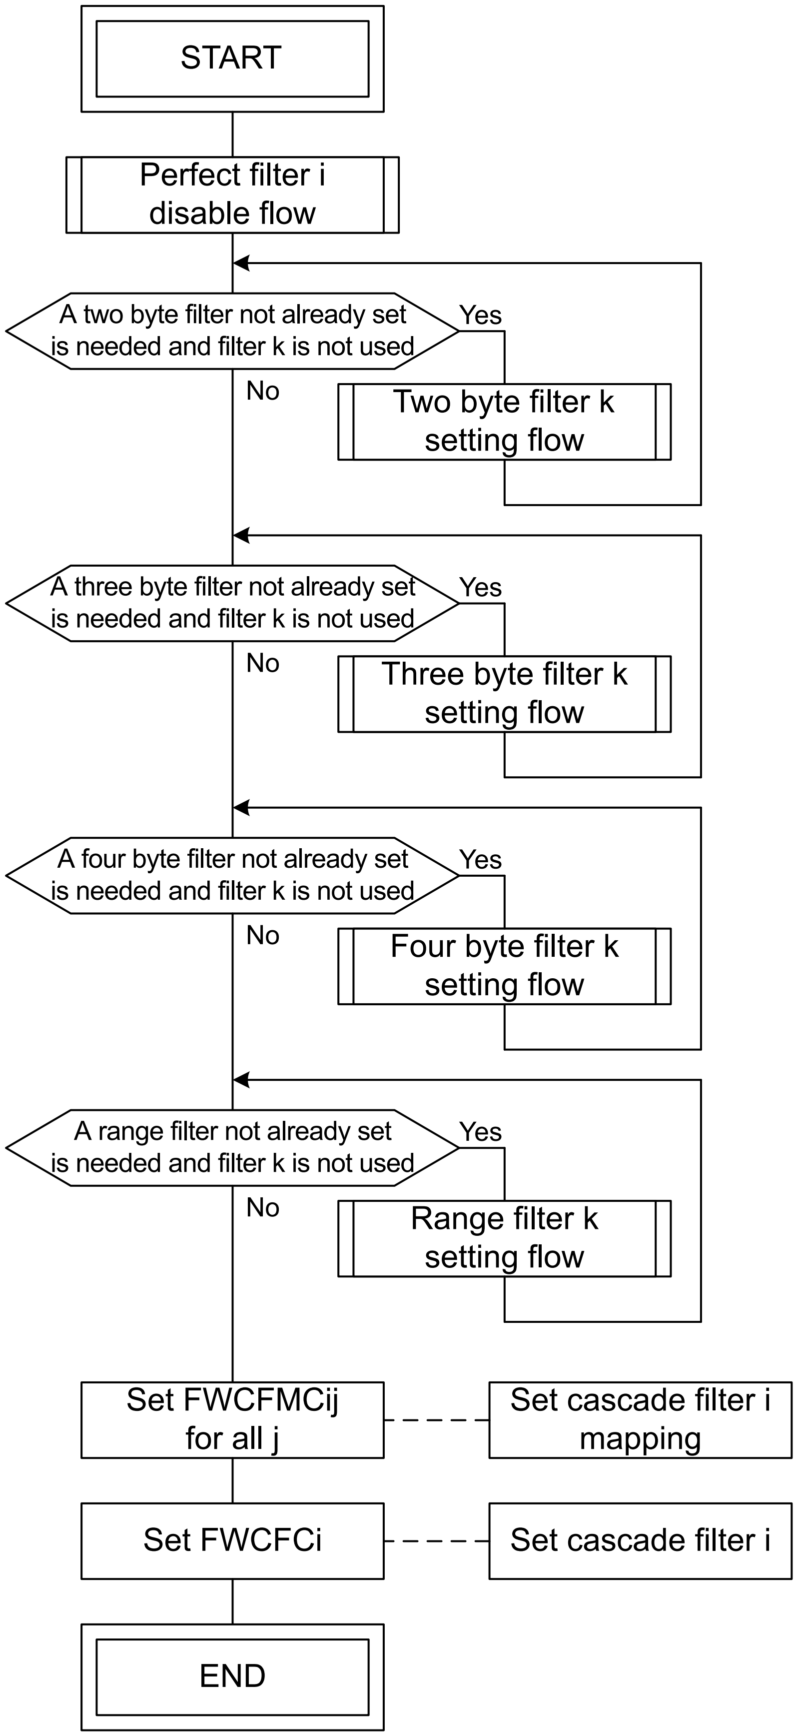

Figure 30.7 Setting flow of perfect filter i

30.4.1.5.2 Perfect Filter i Disable Flow

Figure 30.8 describes the disable flow of perfect filter i.

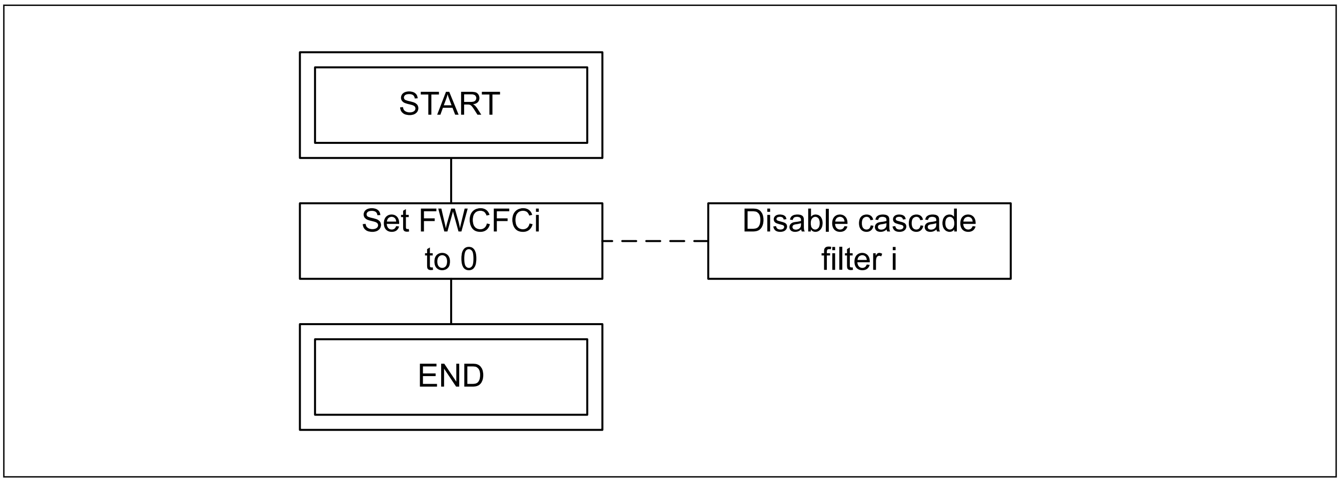

Figure 30.8 Disable flow of perfect filter i

30.4.1.5.3 Perfect Filter Priority Change Flow

Figure 30.9 describes the change flow of perfect filter priority.

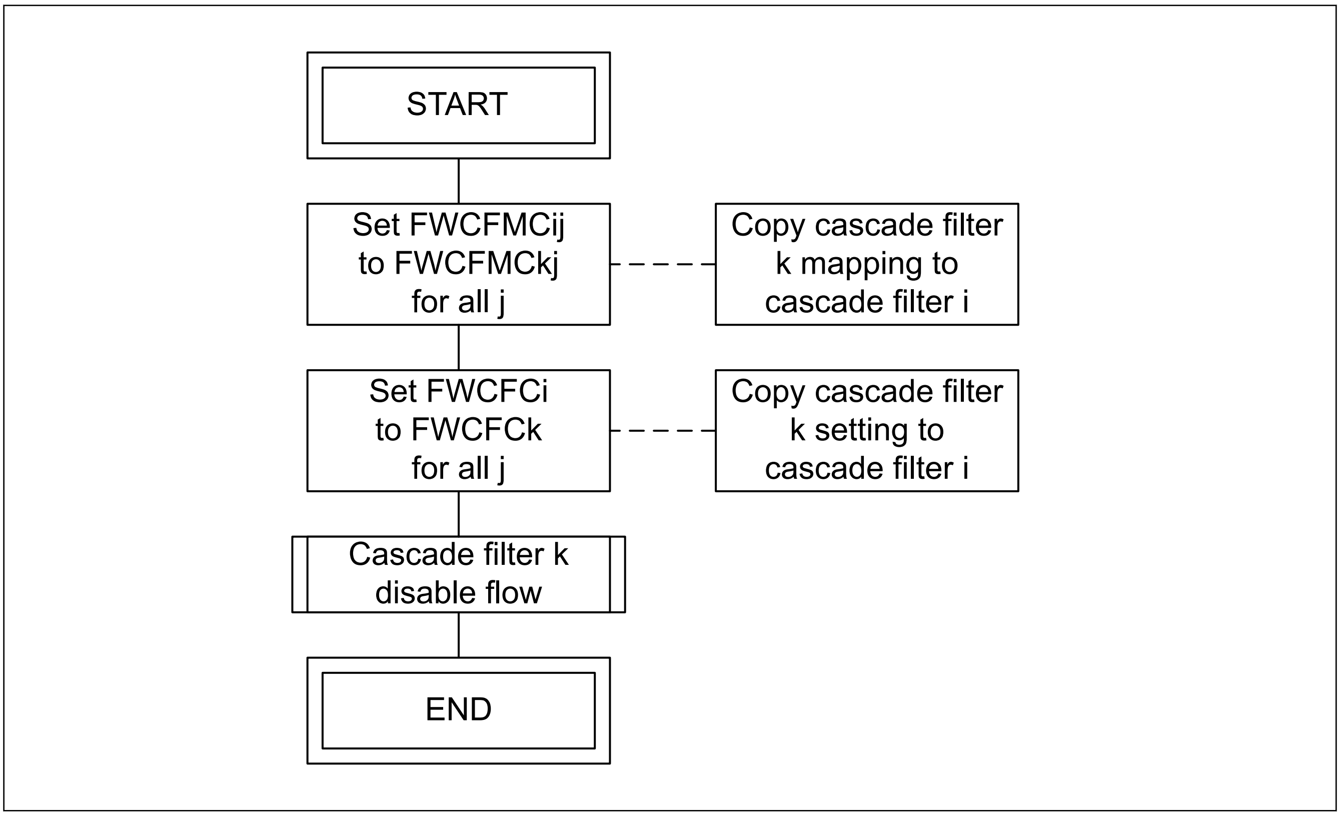

Figure 30.9 Change flow of perfect filter priority (from k to i)

30.4.1.5.4 Hash Hardware Calculation Flow (for IPv4/IPv6 Stream Creation)

Hash hardware calculation flow is described in Figure 30.10.

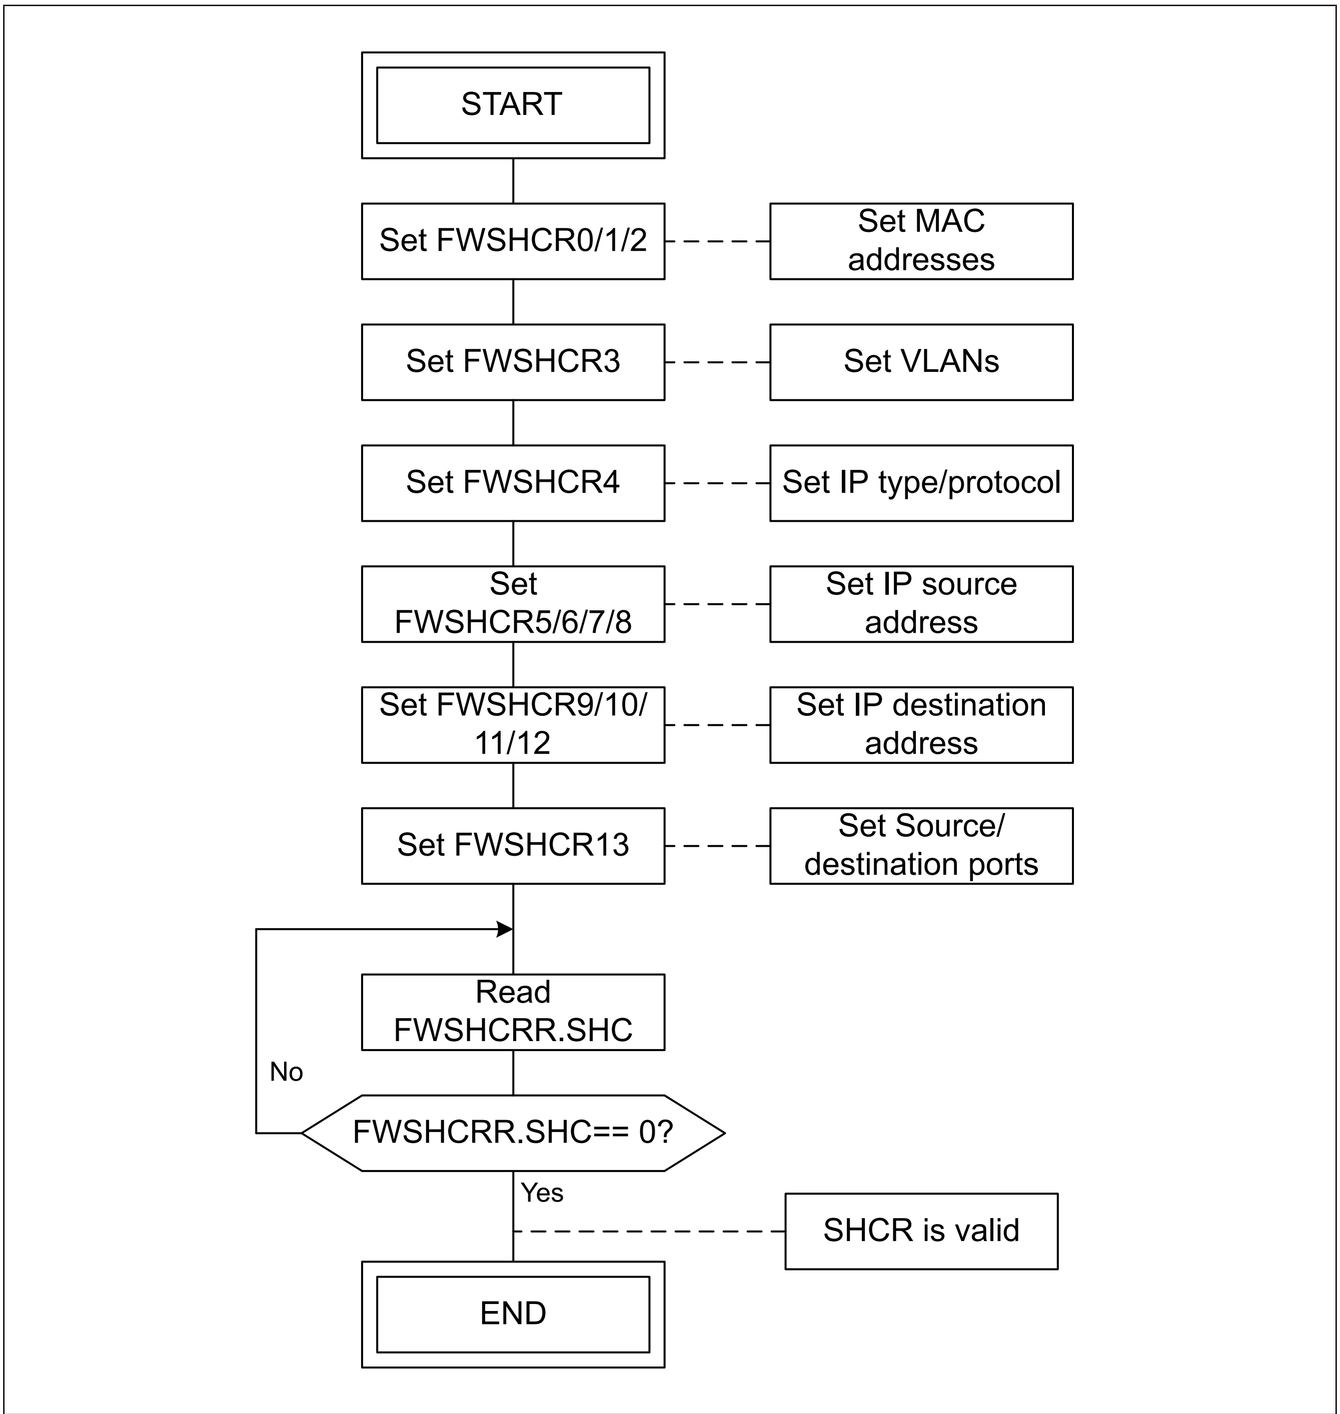

Figure 30.10 Hash hardware calculation flow

30.4.1.5.5 Layer 3 Table Reset Flow

Figure 30.11 describes the reset flow of Layer 3 table.

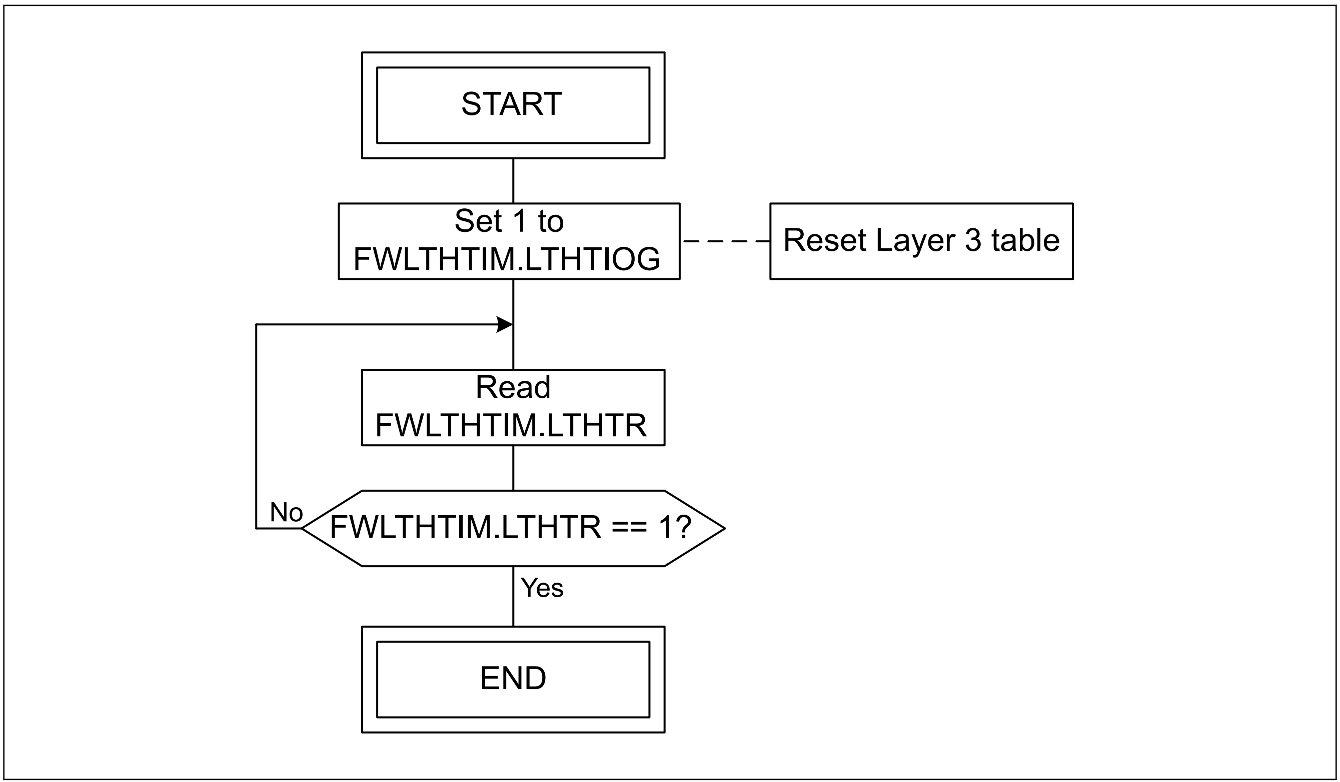

Figure 30.11 Reset flow of Layer 3 table

30.4.1.5.6 Layer 3 Entry Learn Flow

Layer 3 entry learn flow is described in Figure 30.12.

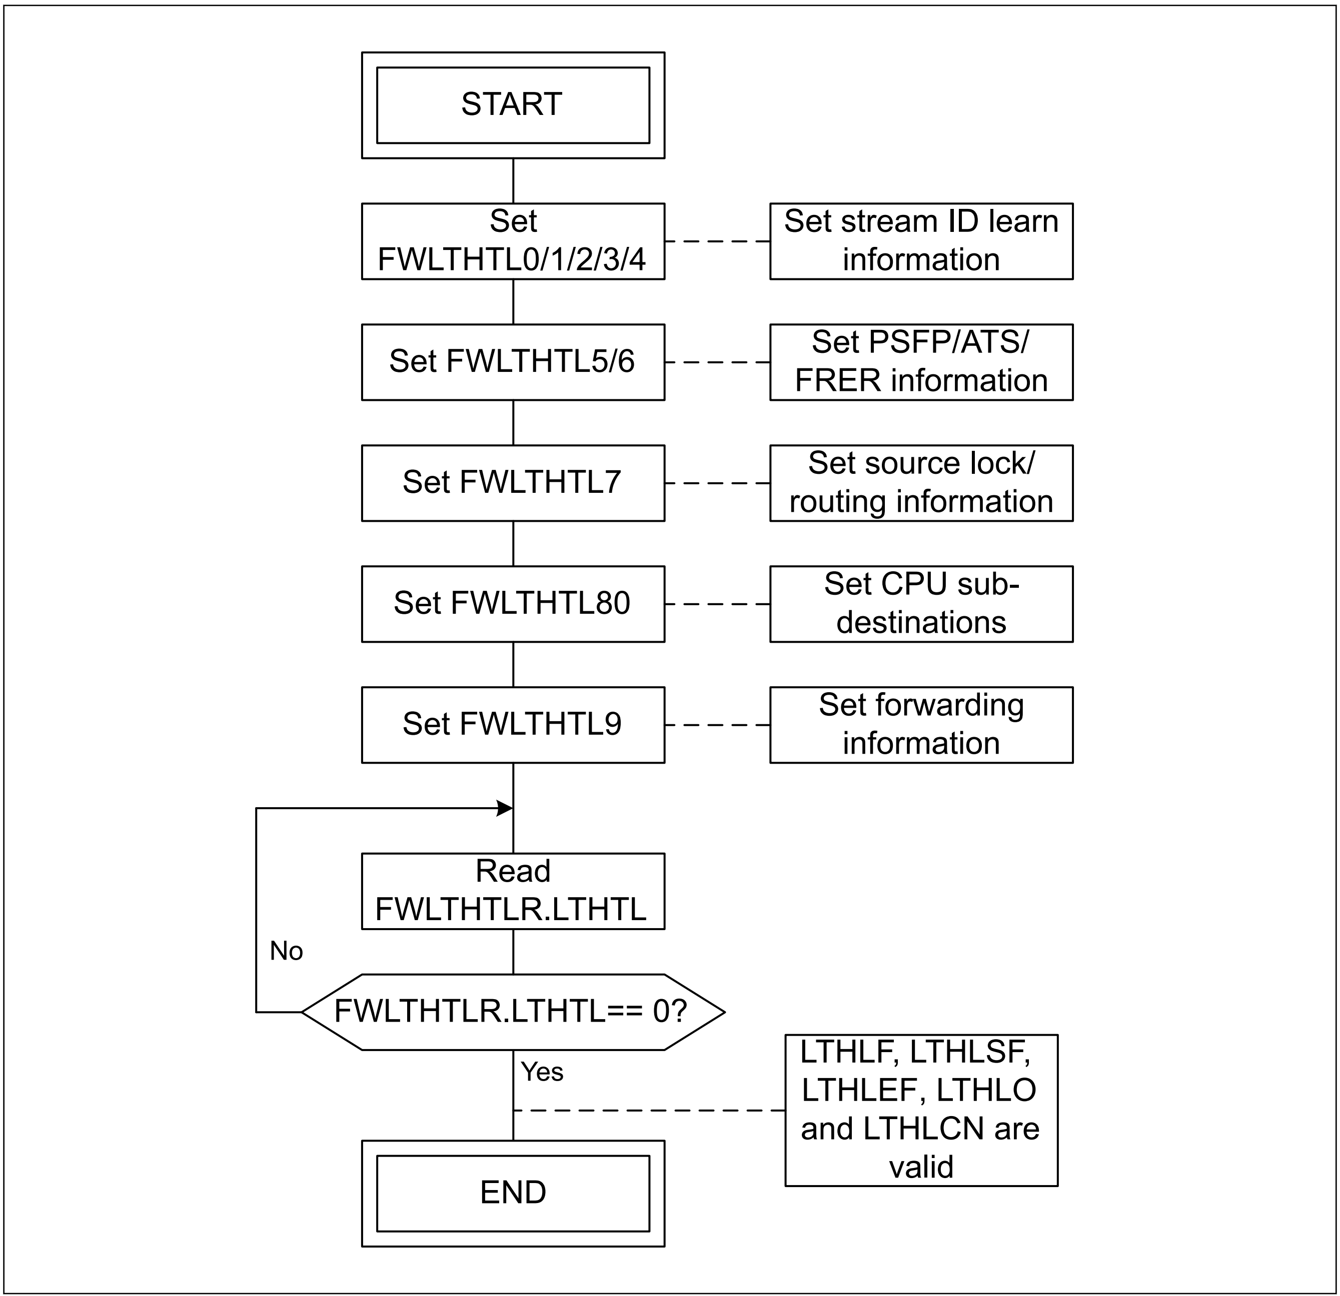

Figure 30.12 Layer 3 entry learn flow

30.4.1.5.7 Layer 3 Entry Search Flow

Layer 3 entry search flow is described in Figure 30.13.

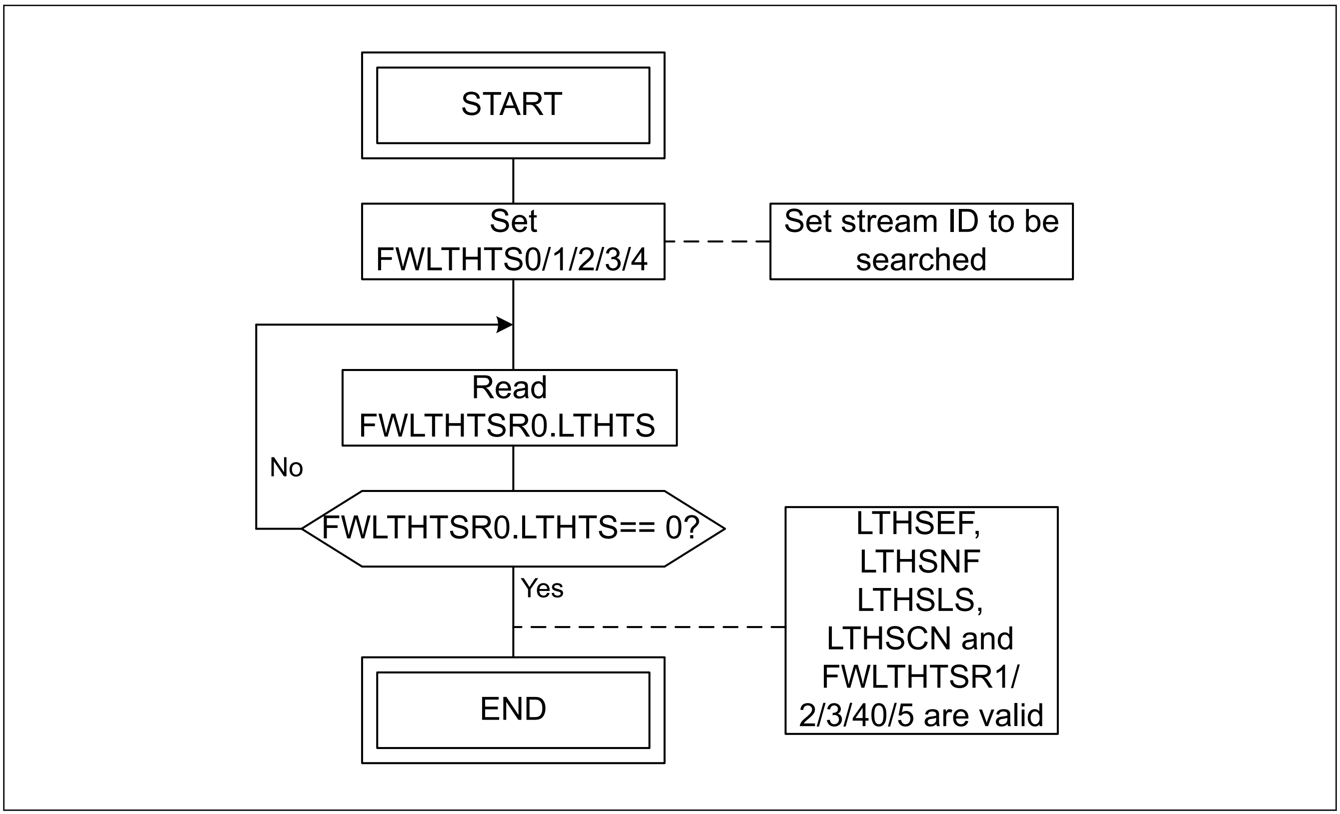

Figure 30.13 Layer 3 entry search flow

30.4.1.5.8 Layer 3 Entry Read Flow

Layer 3 entry read flow is described in Figure 30.14.

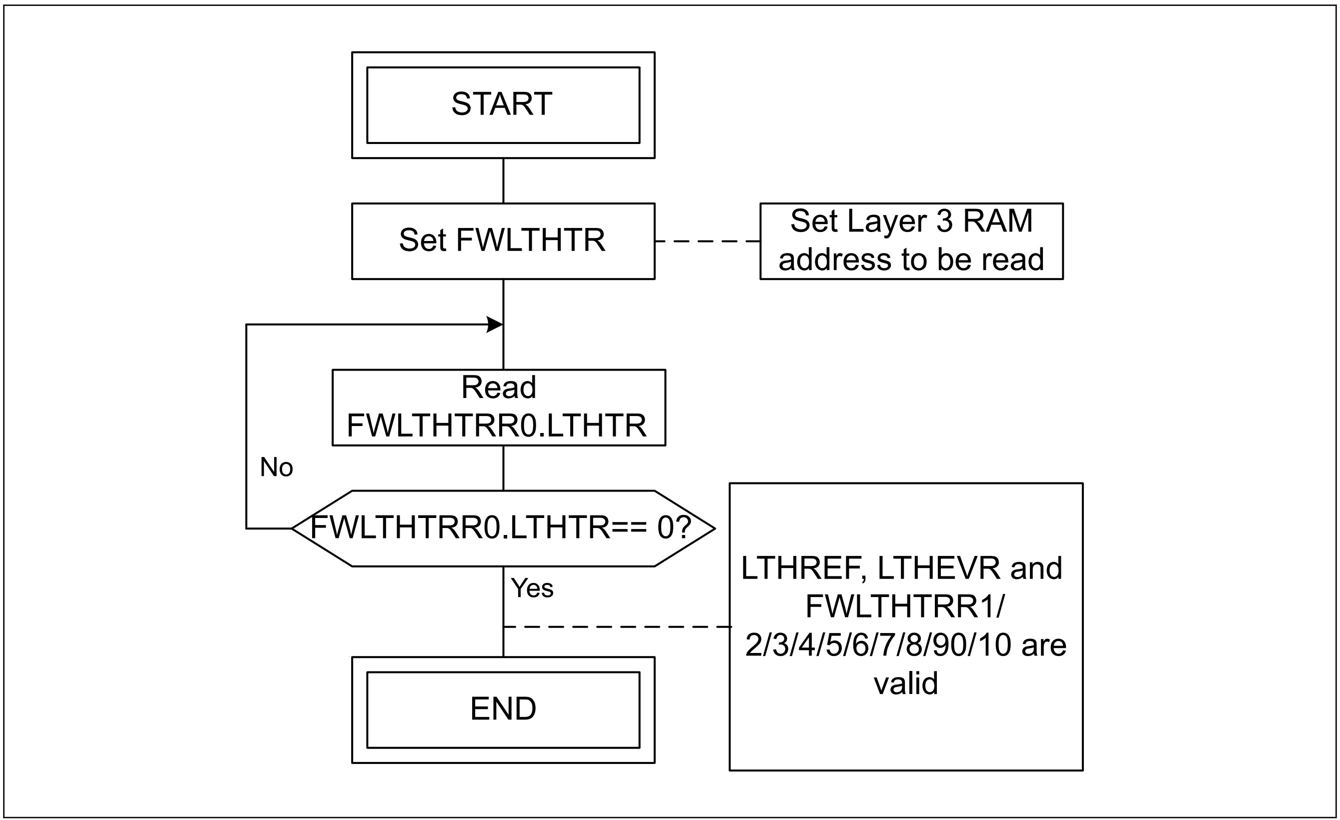

Figure 30.14 Layer 3 entry read flow

30.4.1.6 Layer 2 Forwarding Flows

30.4.1.6.1 MAC Table Reset Flow

Figure 30.15 describes the reset flow of MAC table.

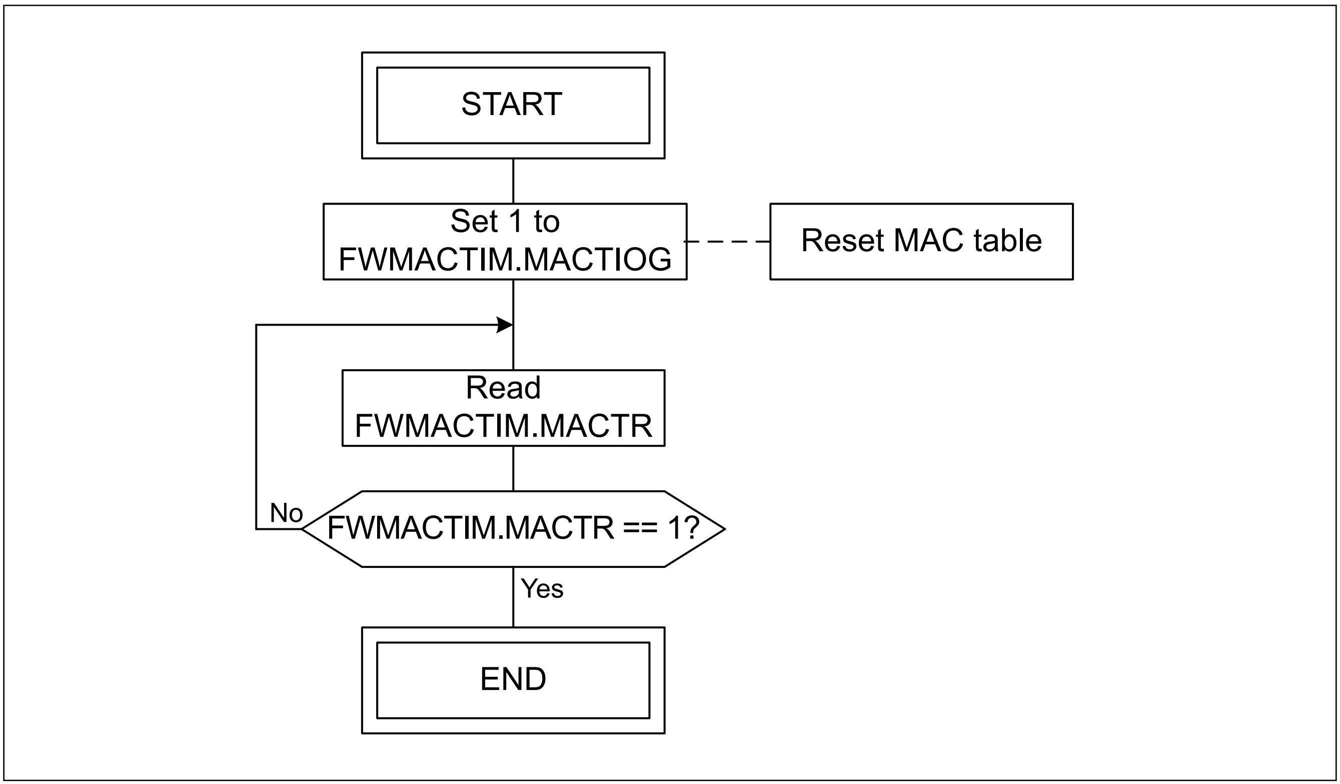

Figure 30.15 Reset flow of MAC table

30.4.1.6.2 VLAN Table Reset Flow

Figure 30.16 describes the reset flow of VLAN table.

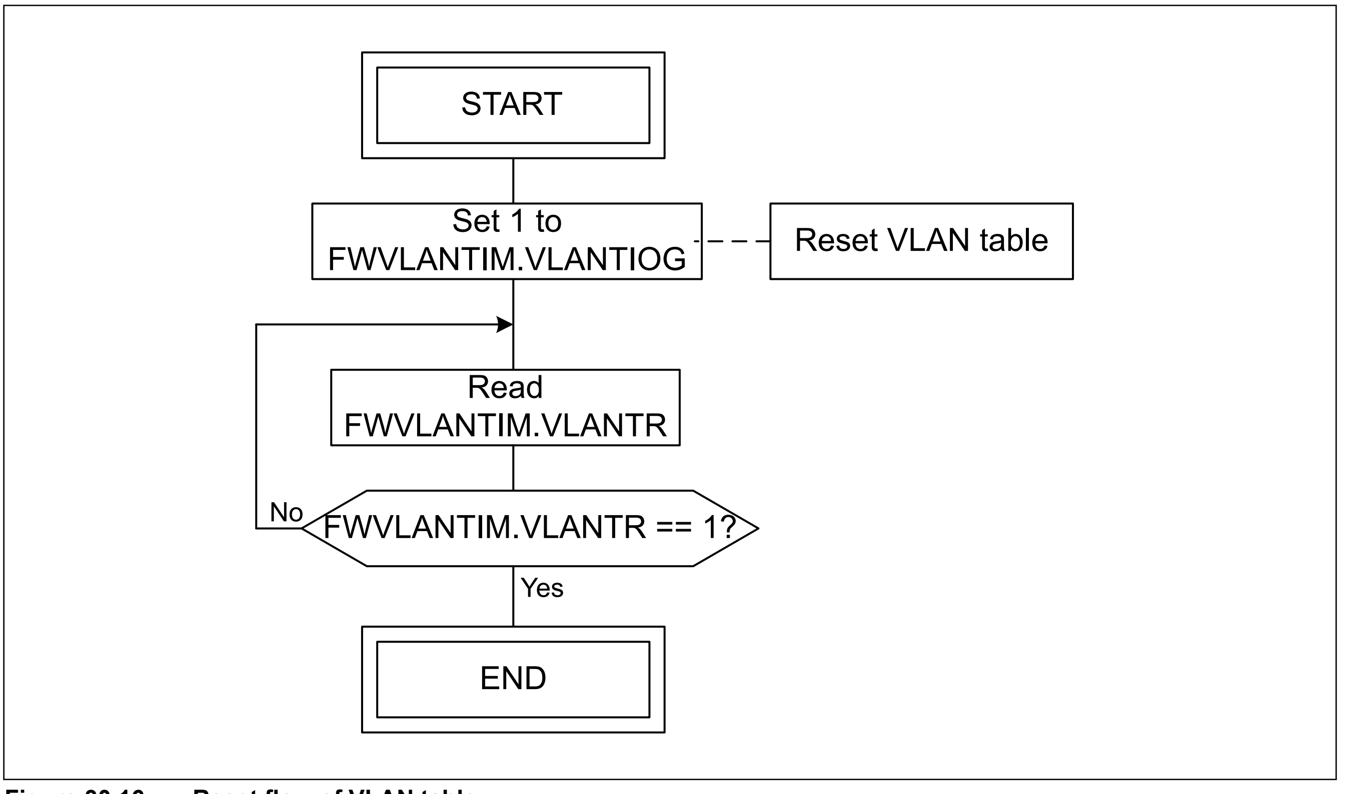

Figure 30.16 Reset flow of VLAN table

30.4.1.6.3 MAC Entry Learn Flow

MAC entry learn flow is described in Figure 30.17.

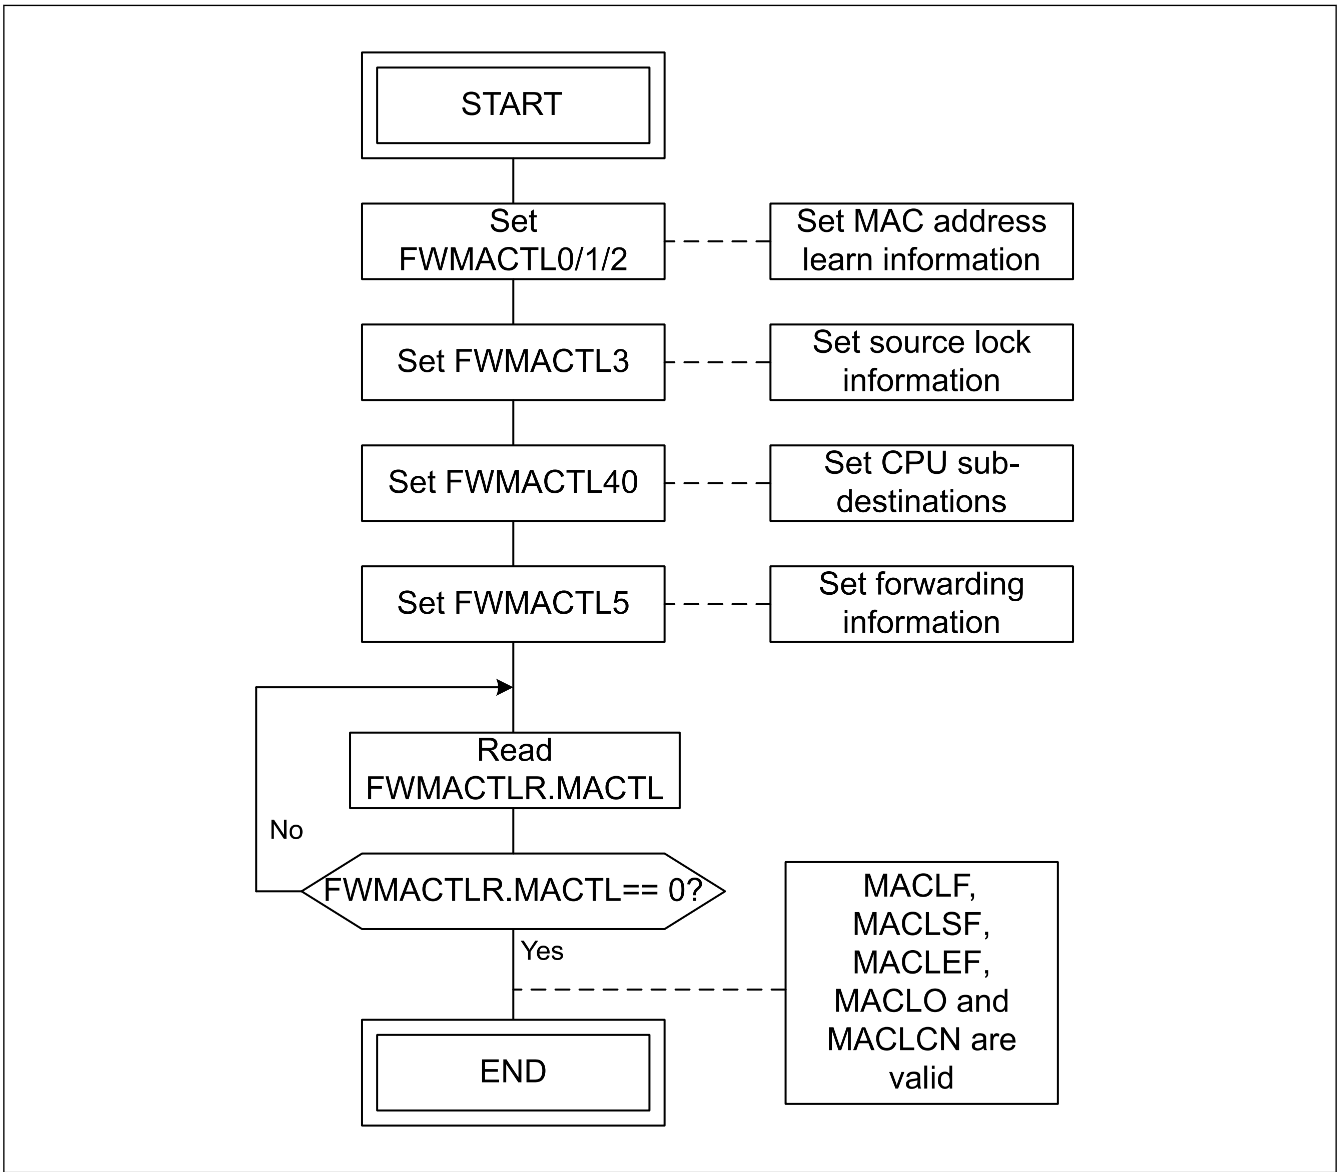

Figure 30.17 MAC entry learn flow

30.4.1.6.4 VLAN Entry Learn Flow

VLAN entry learn flow is described in Figure 30.18.

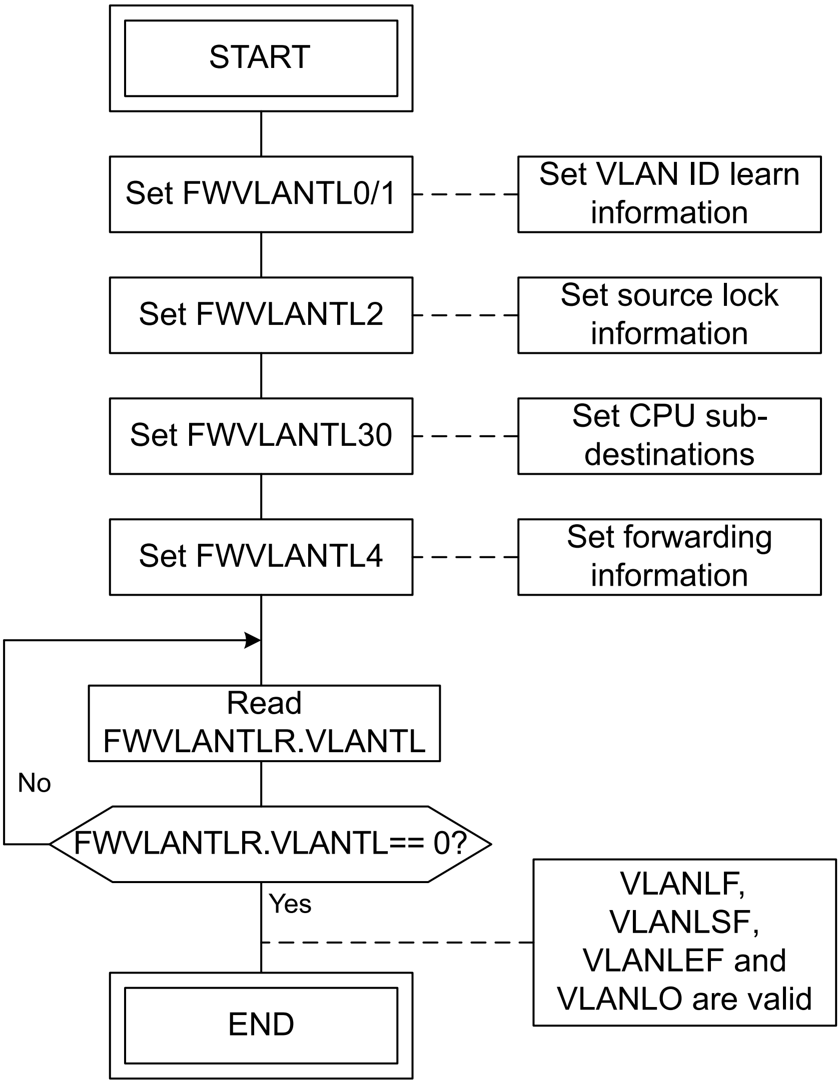

Figure 30.18 VLAN entry learn flow

30.4.1.6.5 MAC Entry Search Flow

MAC entry search flow is described in Figure 30.19.

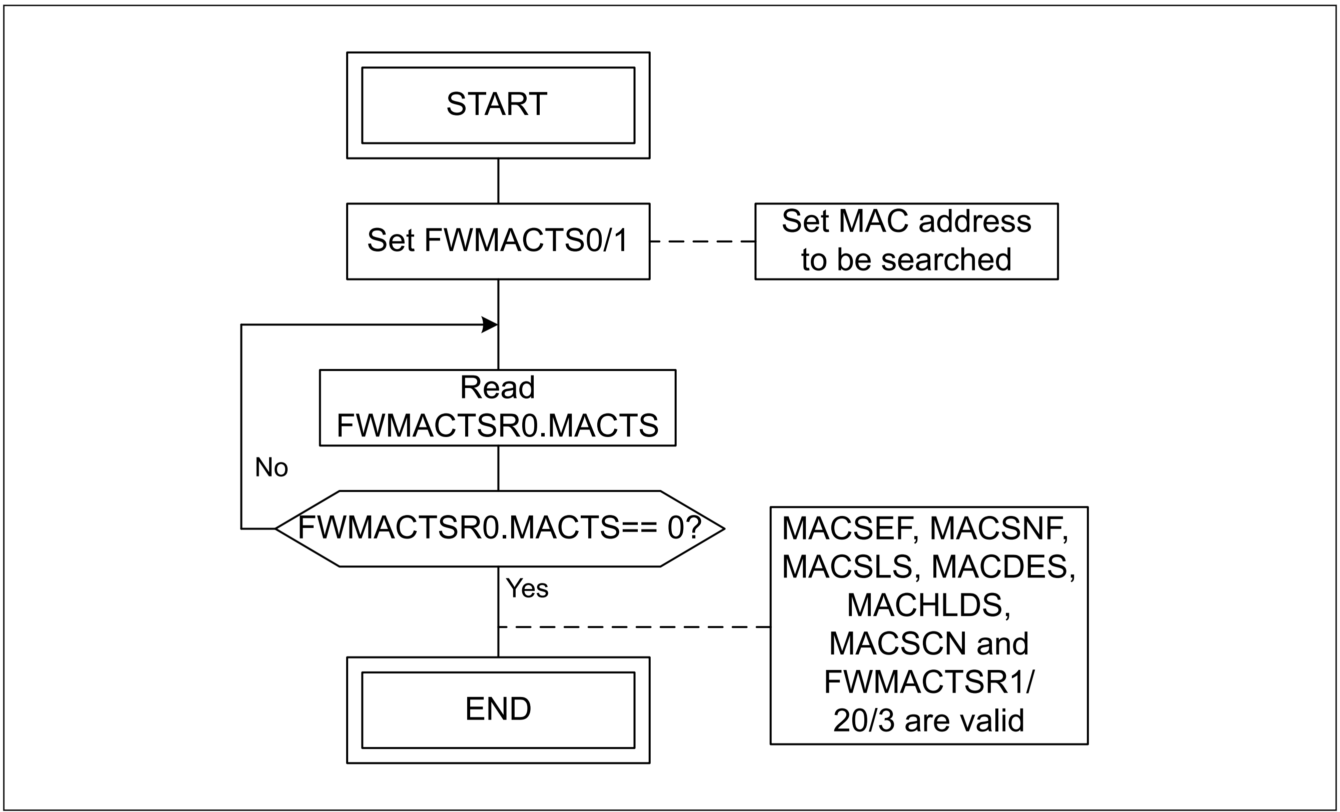

Figure 30.19 MAC entry search flow

30.4.1.6.6 VLAN Entry Search Flow

VLAN entry search flow is described in Figure 30.20.

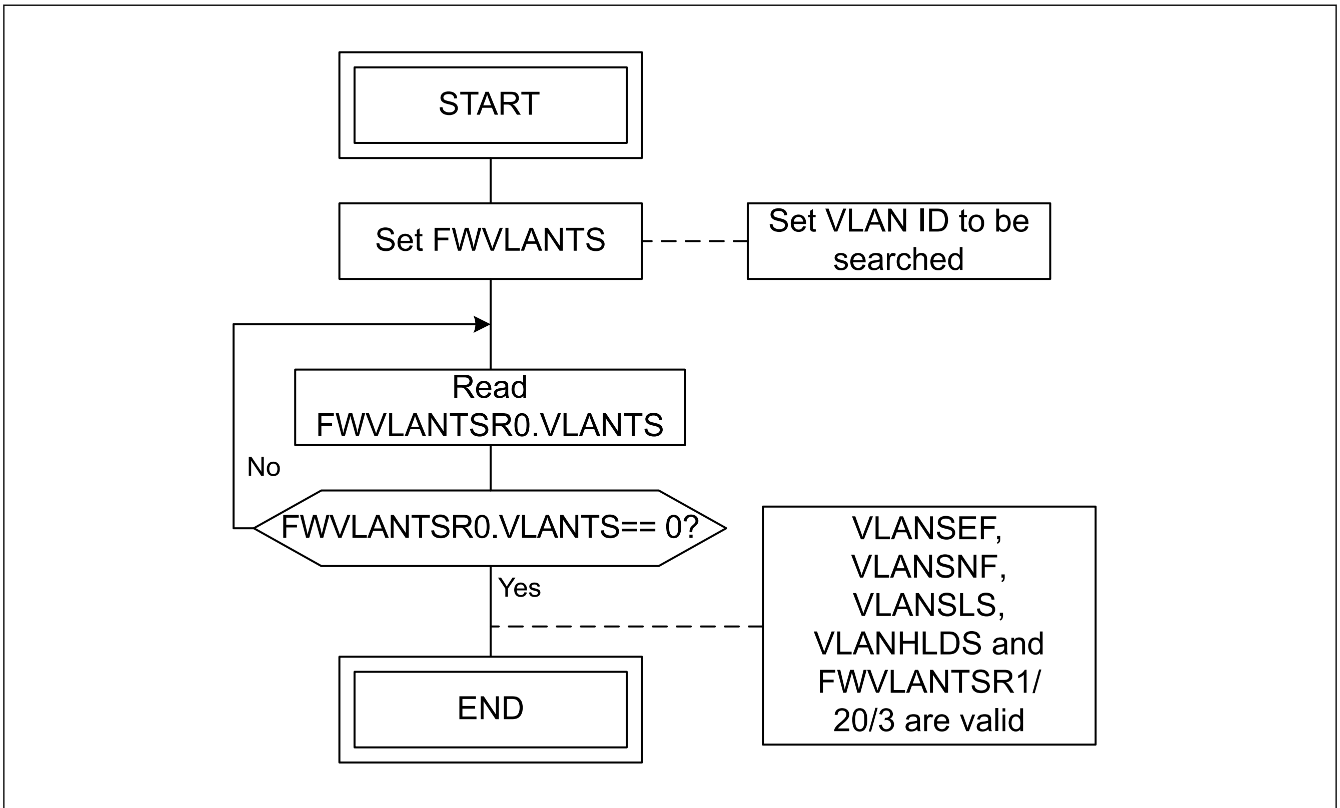

Figure 30.20 VLAN entry search flow

30.4.1.6.7 MAC Entry Read Flow

MAC entry read flow is described in Figure 30.21.

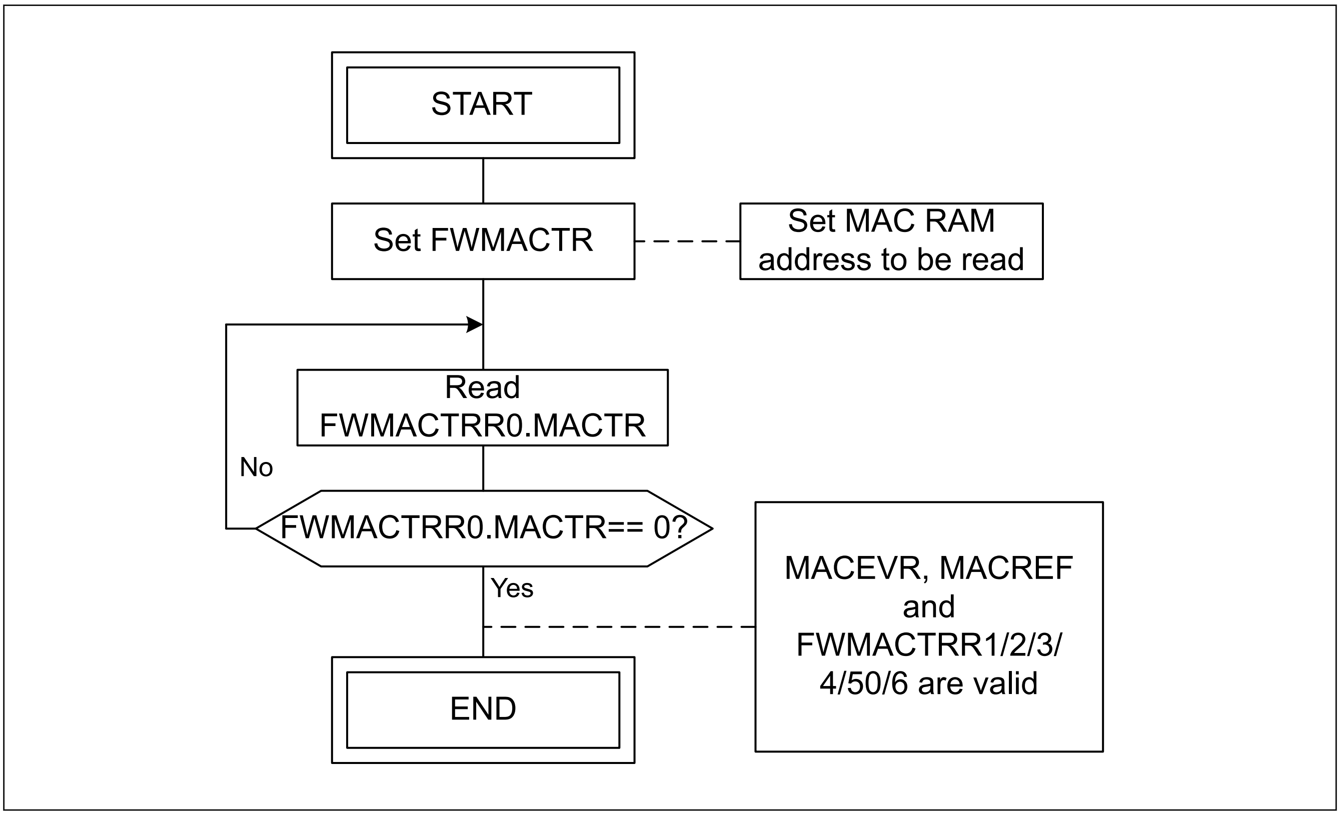

Figure 30.21 MAC entry read flow

30.4.1.7 Port based forwarding flows

30.4.1.7.1 Port i Port-based Setting Flow

Port i port-based setting flow is described in Figure 30.22.

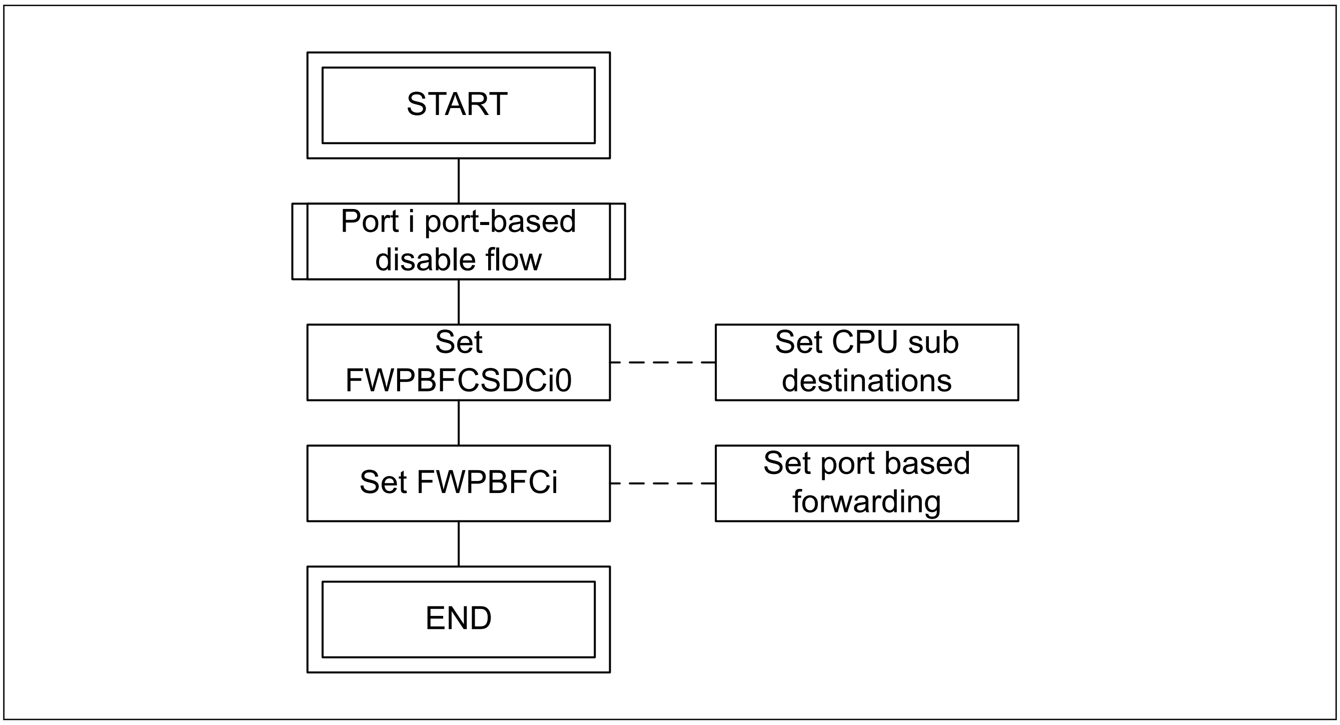

Figure 30.22 Port i port-based setting flow

30.4.1.7.2 Port i Port-based Disable Flow

Port i port-based disable flow is described in Figure 30.23.

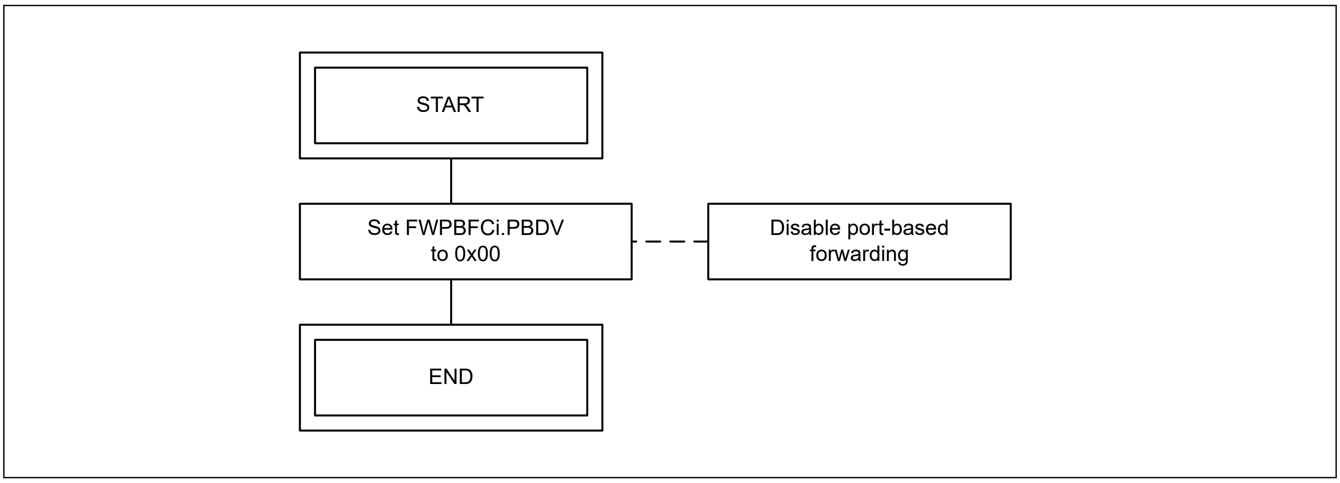

Figure 30.23 Port i port-based disable flow

30.4.1.8 Layer 2/Layer 3 Update Flows

30.4.1.8.1 Layer 2/Layer 3 Update Table Reset Flow

Figure 30.24 describes the reset flow of Layer 2/Layer 3 Update table.

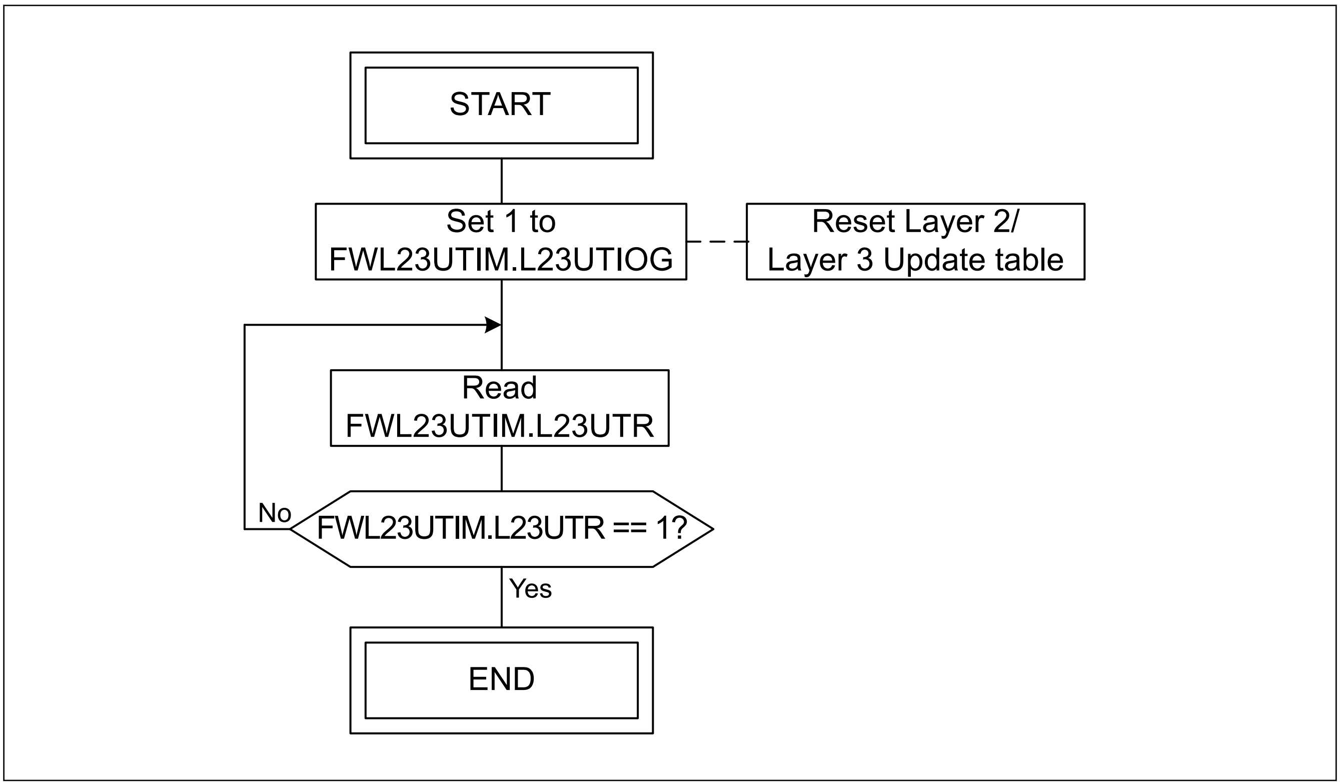

Figure 30.24 Reset flow of Layer 2/Layer 3 Update table

30.4.1.8.2 Layer 2/Layer 3 Update Rule Learn Flow

Figure 30.25 describes the learn flow of Layer 2/Layer 3 update rule.

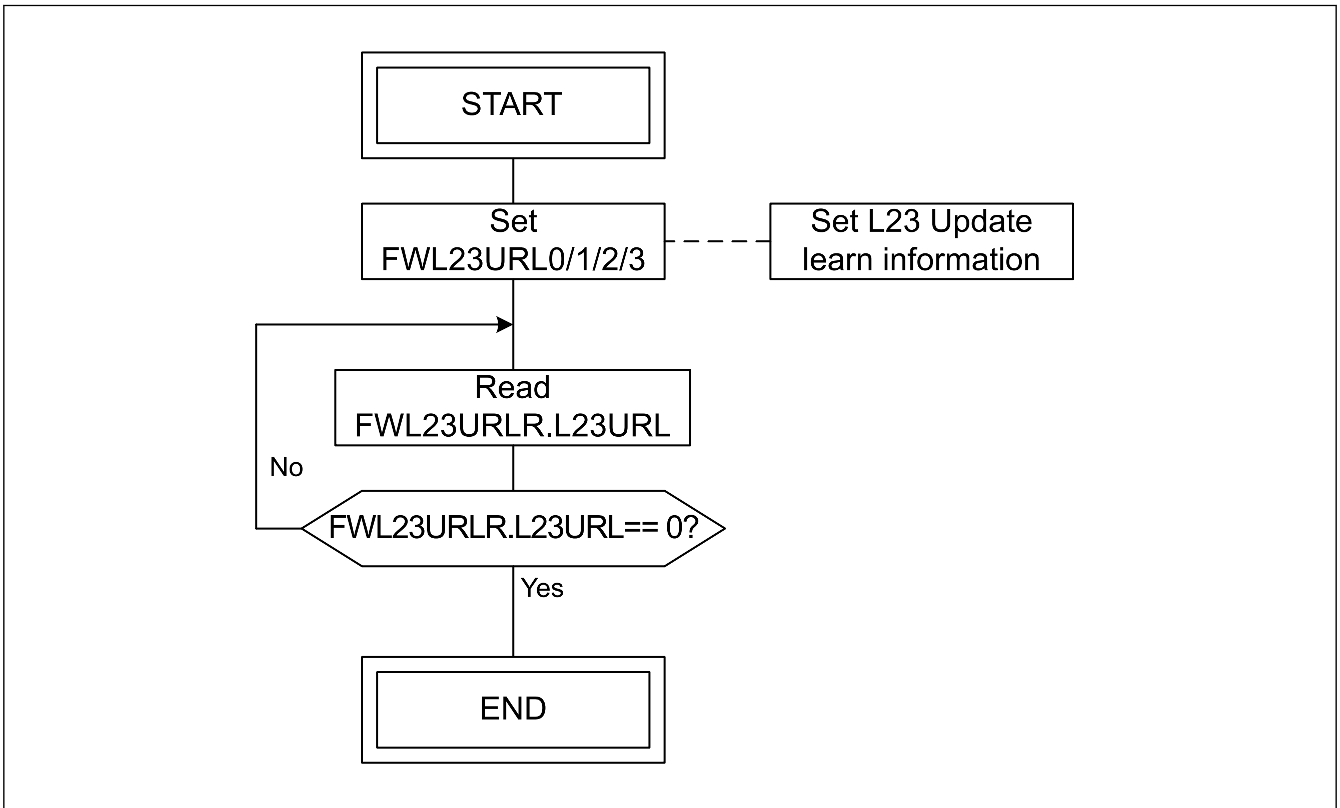

Figure 30.25 Learn flow of Layer 2/Layer 3 update rule

30.4.1.8.3 Layer 2/Layer 3 Update Rule Read Flow

Figure 30.26 describes the read flow of Layer 2/Layer 3 Update rule.

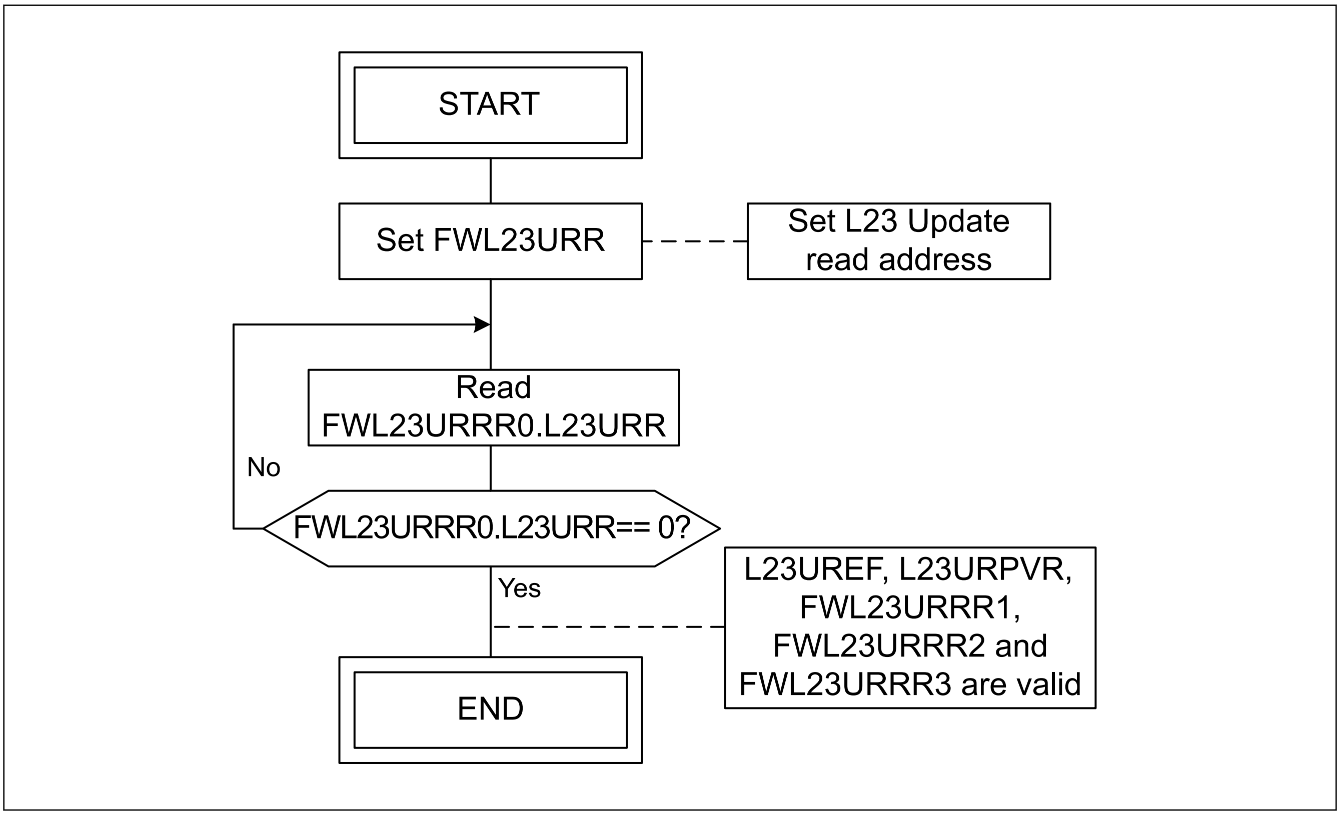

Figure 30.26 Read flow of Layer 2/Layer 3 Update rule

30.4.1.9 PSFP Flows

30.4.1.9.1 MSDU Filter i Setting Flow

Figure 30.27 describes the setting flow of MSDU filter i.

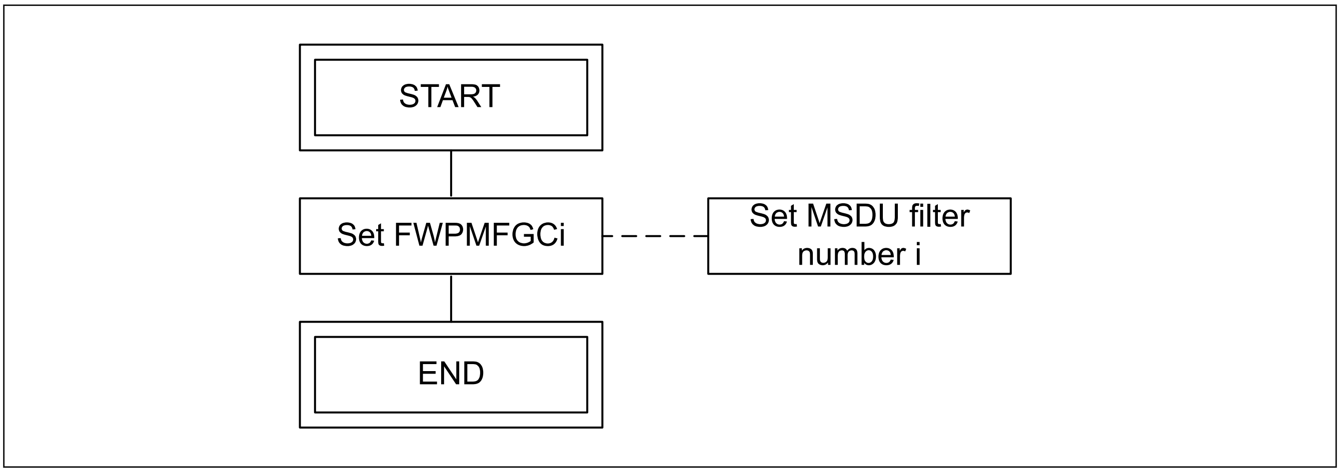

Figure 30.27 Setting flow of MSDU filter i

30.4.1.9.2 Meter i Setting Flow

Meter i setting flow is described in Figure 30.28.

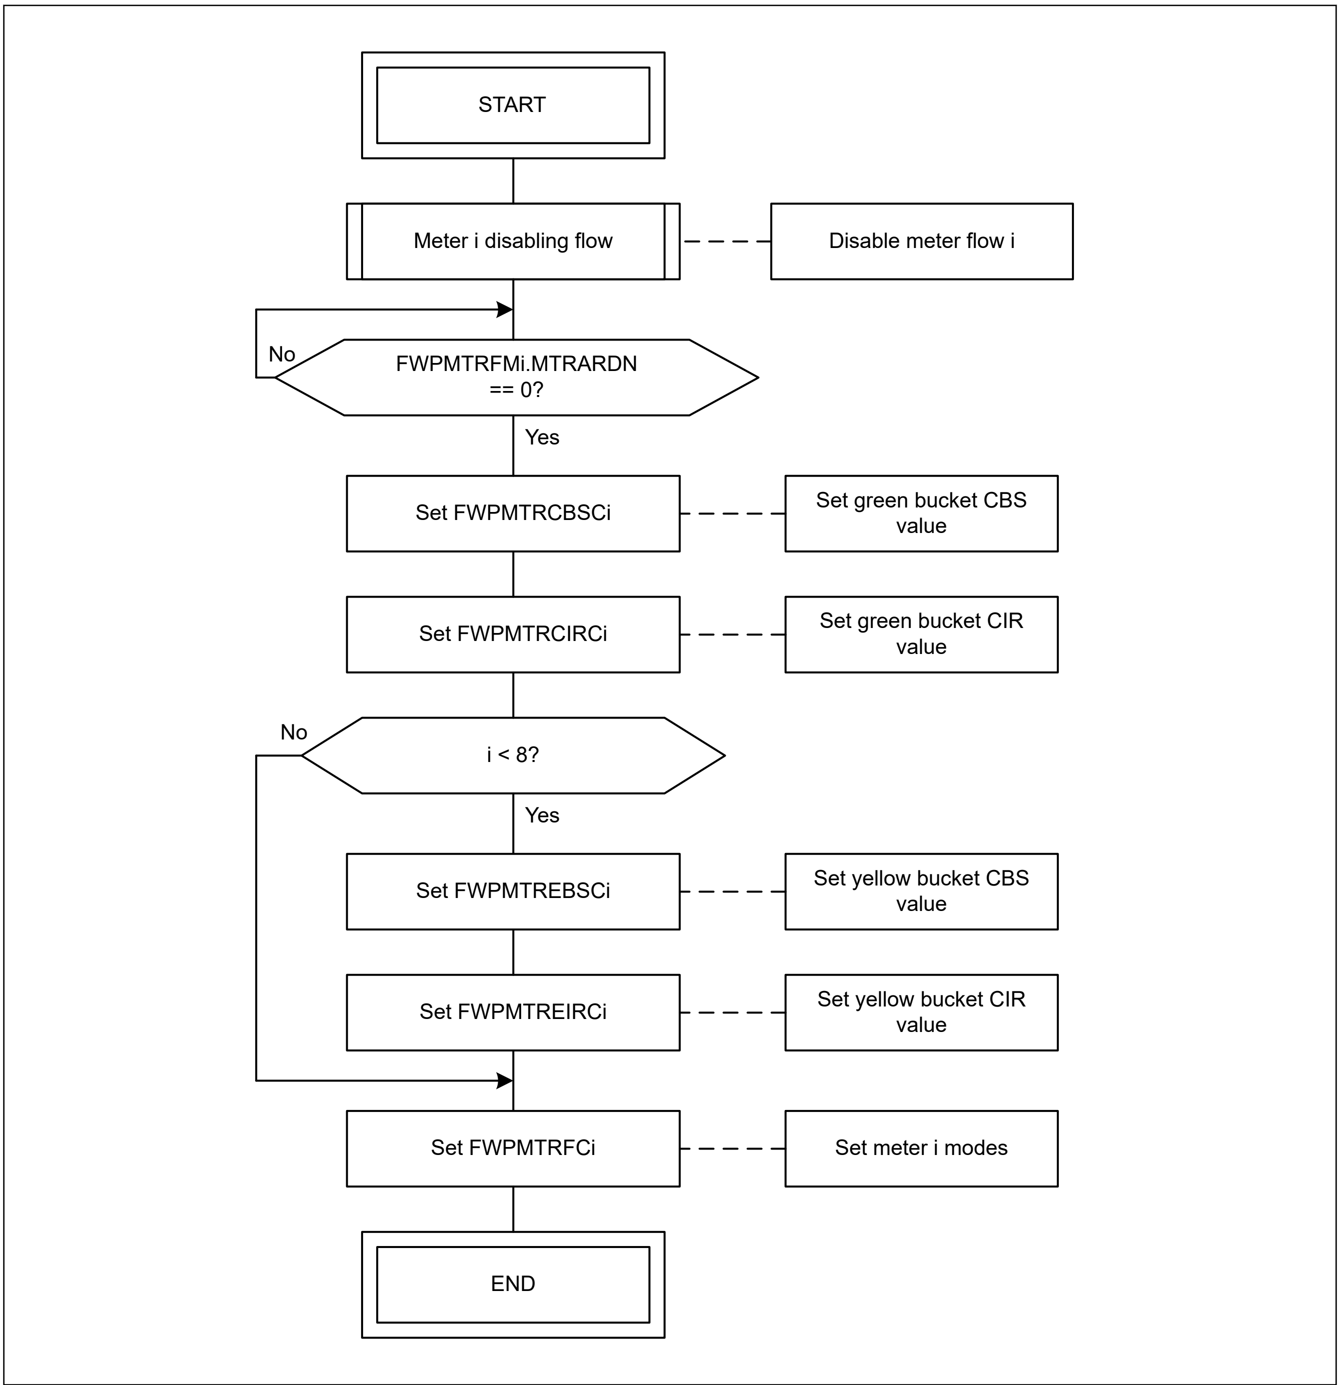

Figure 30.28 Meter i setting flow

30.4.1.9.3 Meter i Disabling Flow

Figure 30.29 describes the disabling flow of meter i.

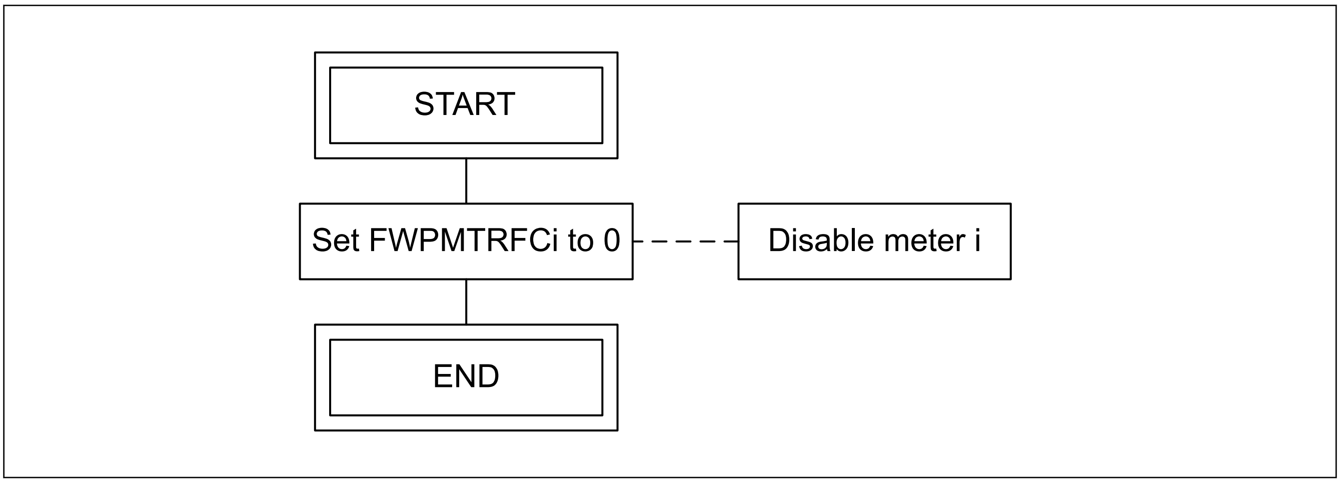

Figure 30.29 Disabling flow of meter i

30.4.1.10 FRER Flows

30.4.1.10.1 FRER Table Reset Flow

Figure 30.30 describes the reset flow of FRER table.

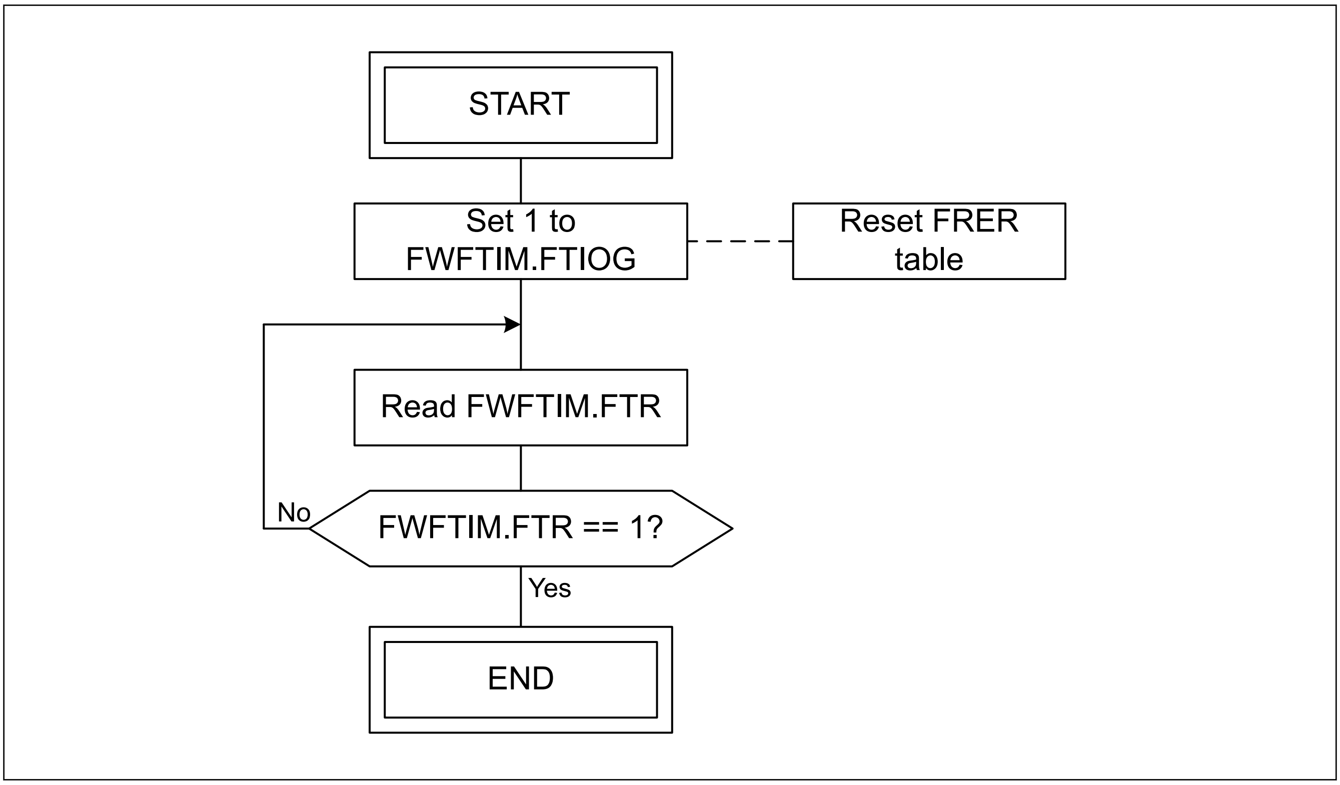

Figure 30.30 Reset flow of FRER table

30.4.1.10.2 FRER Entry i Learn Flow

Figure 30.31 describes the learn flow of FRER entry i.

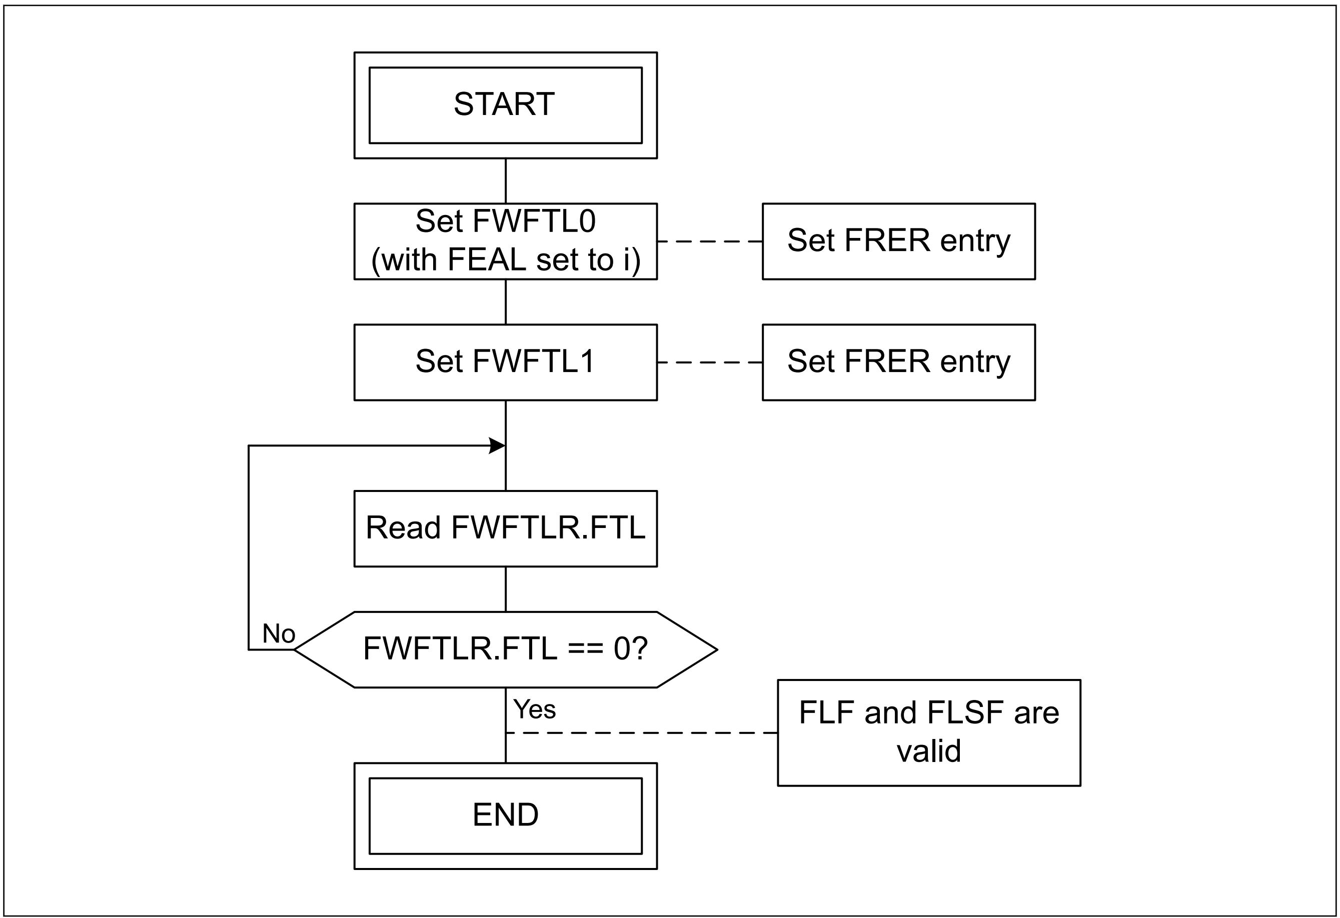

Figure 30.31 Learn flow of FRER entry i

30.4.1.10.3 FRER Entry i Read Flow

Figure 30.32 describes the read flow of FRER entry i.

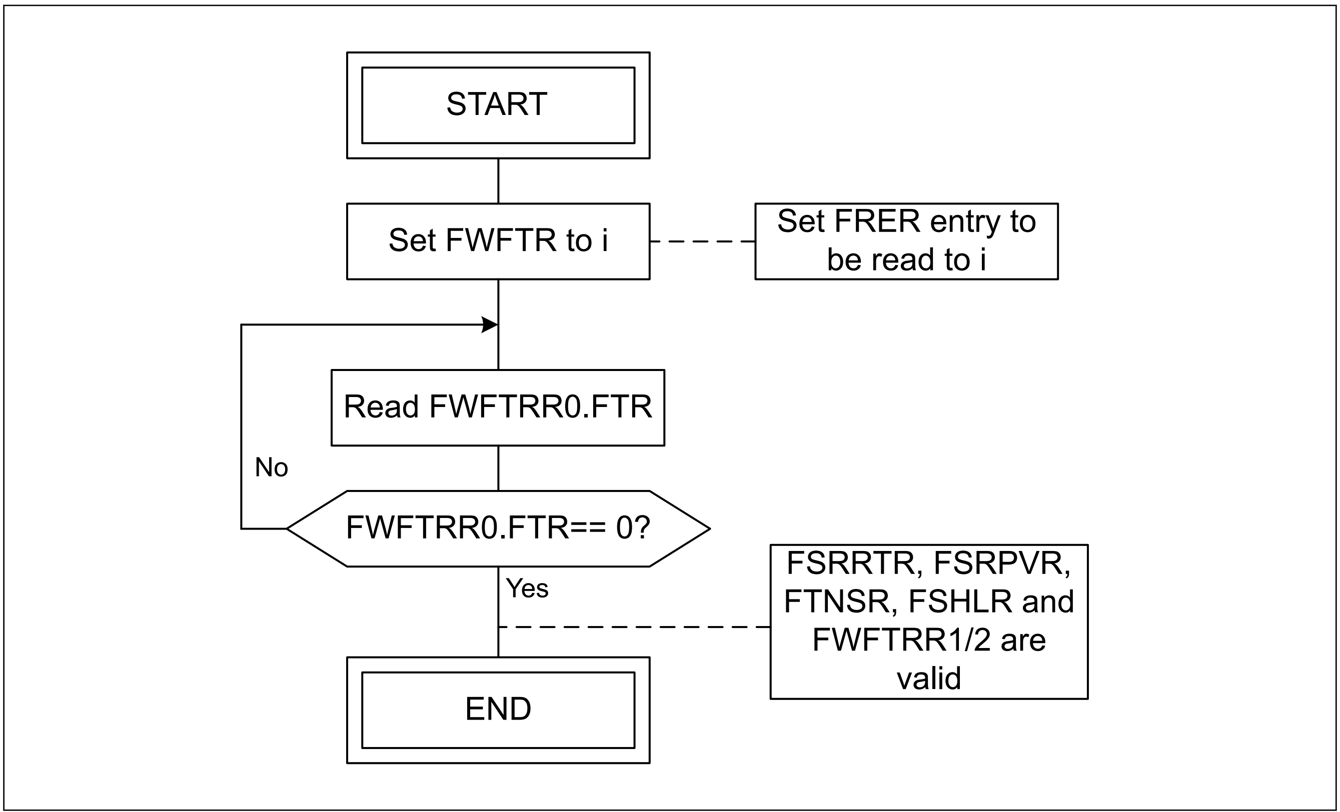

Figure 30.32 Read flow of FRER entry i

30.4.1.11 Called Software Flows

The flows described in this section can only be called from other flows (as shown in the "flow link" box in Figure 30.2) and cannot be used alone.

30.4.1.11.1 Full Setting Flow

Full setting flow is described in Figure 30.33.

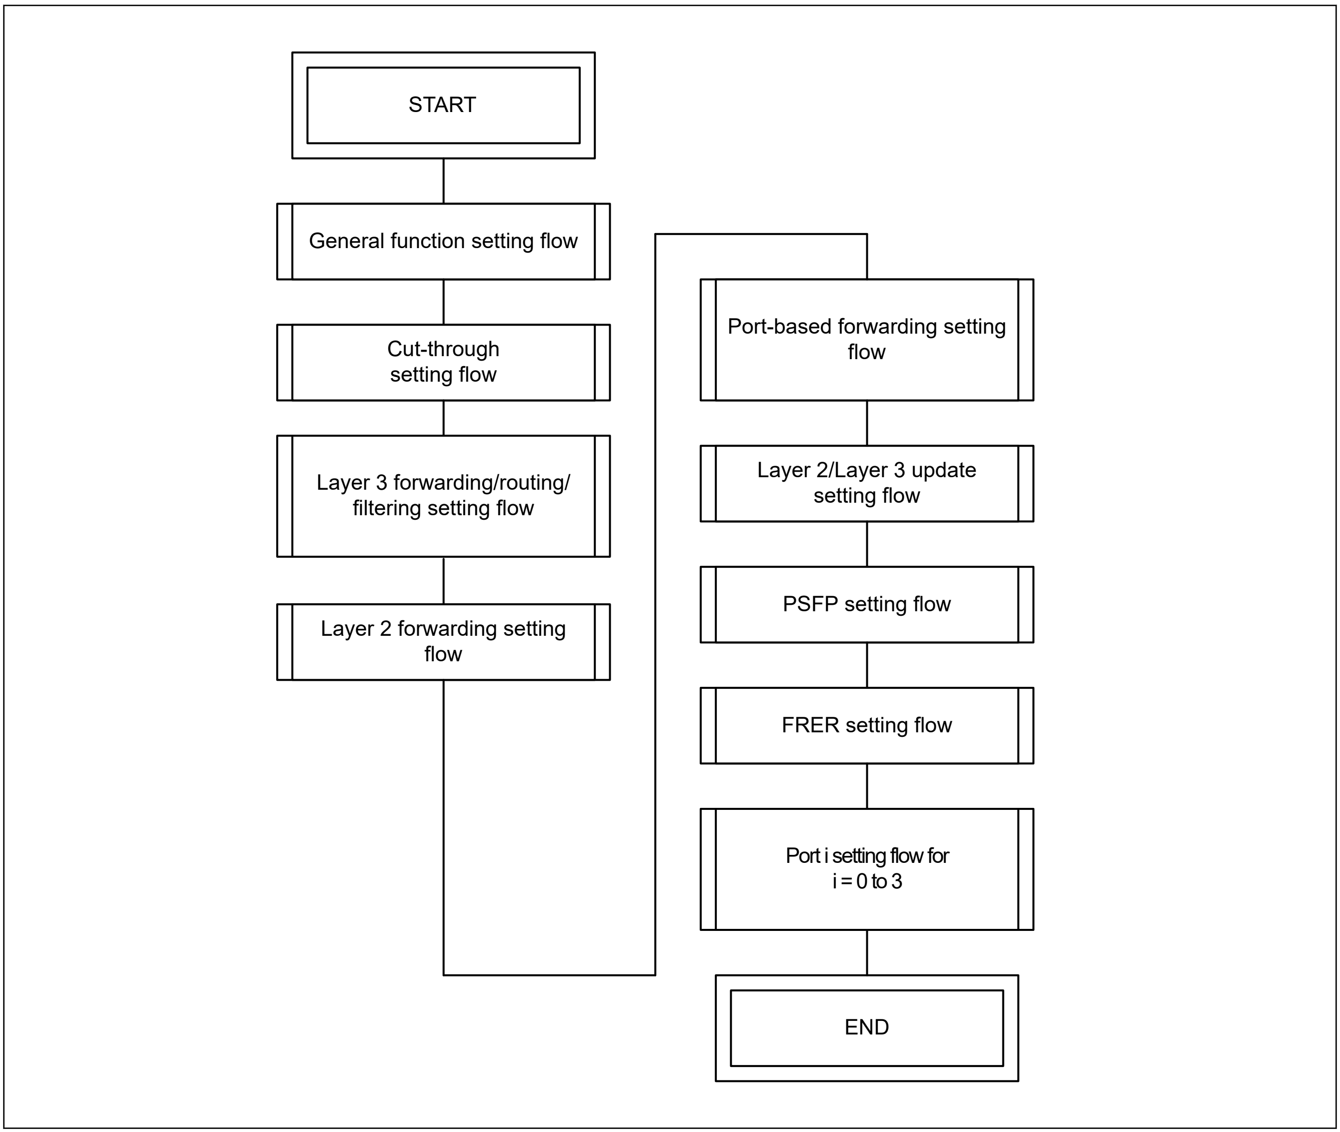

Figure 30.33 Full setting flow

30.4.1.11.2 General Function Setting Flow

Figure 30.34 decribes the setting flow of general function.

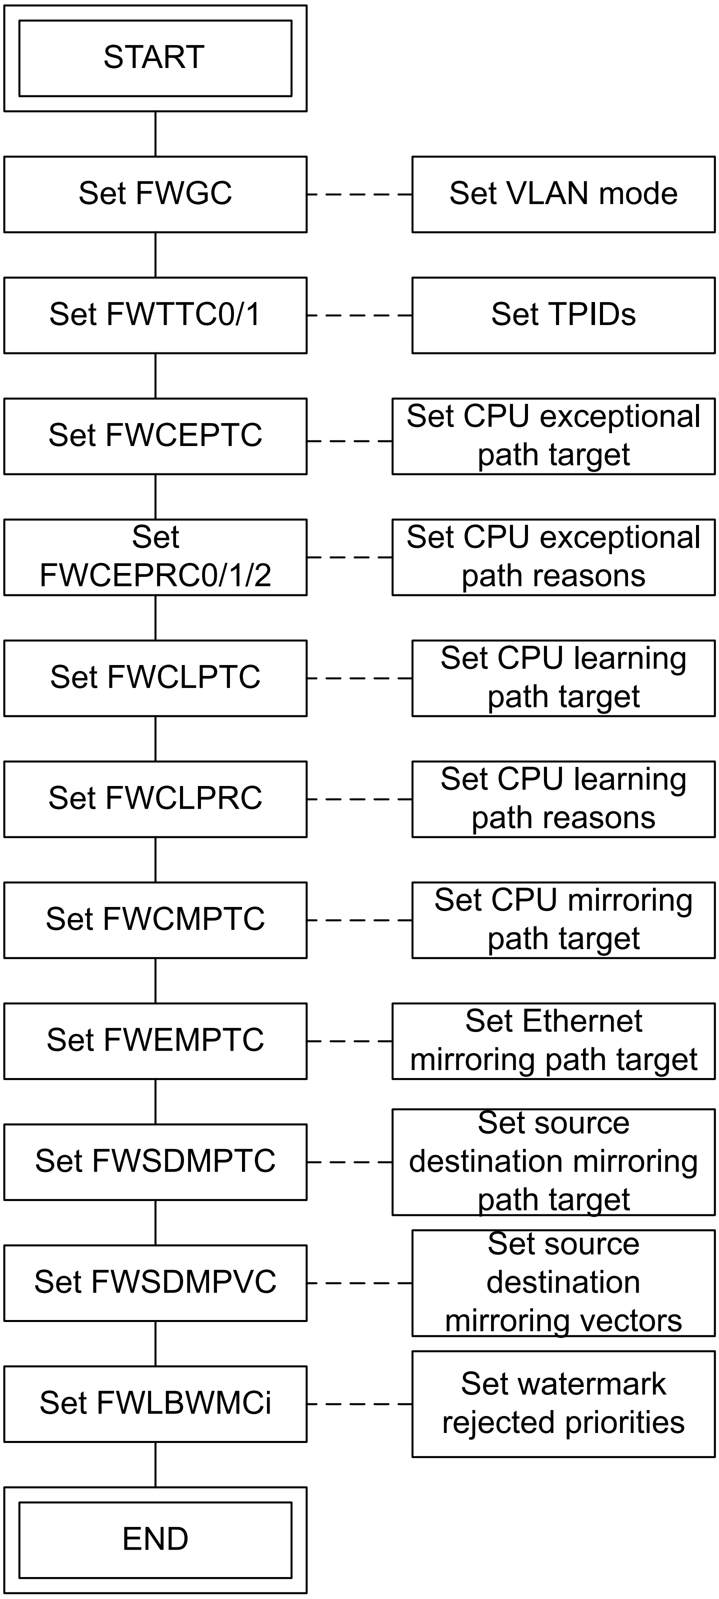

Figure 30.34 Setting flow of general function

30.4.1.11.3 Cut-through Setting Flow

Figure 30.35 describes the setting flow of cut-through.

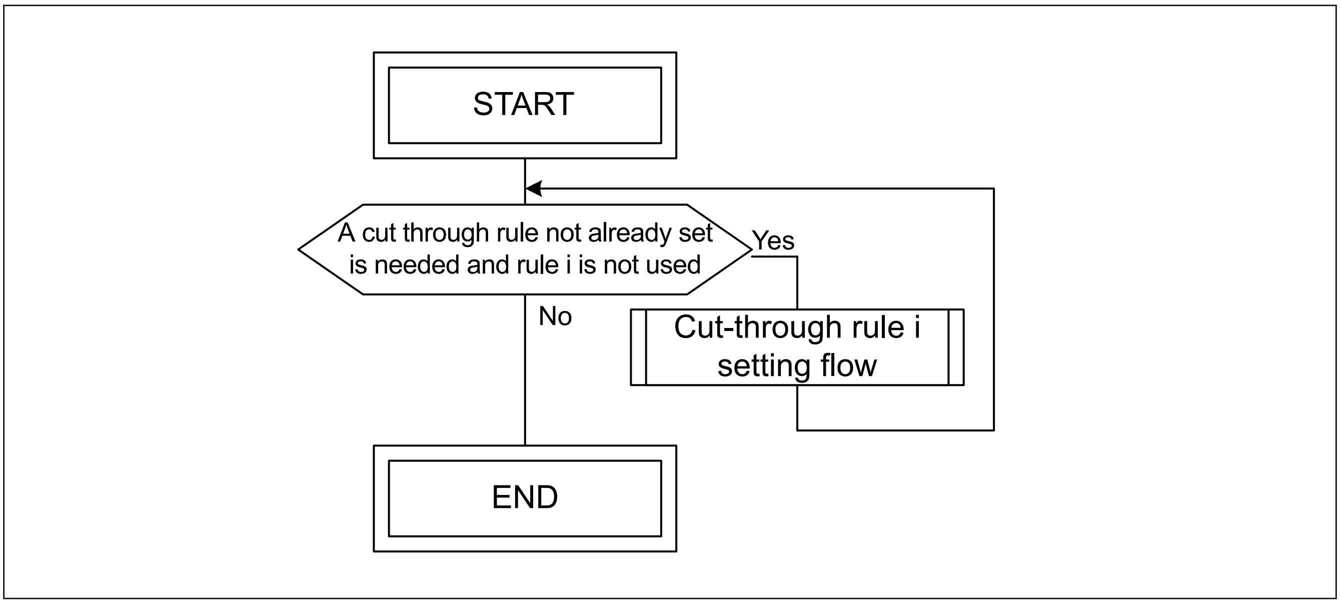

Figure 30.35 Setting flow of cut-through

30.4.1.11.4 Two-byte Filter i Setting Flow

Figure 30.36 describes the setting flow of two-byte filter i.

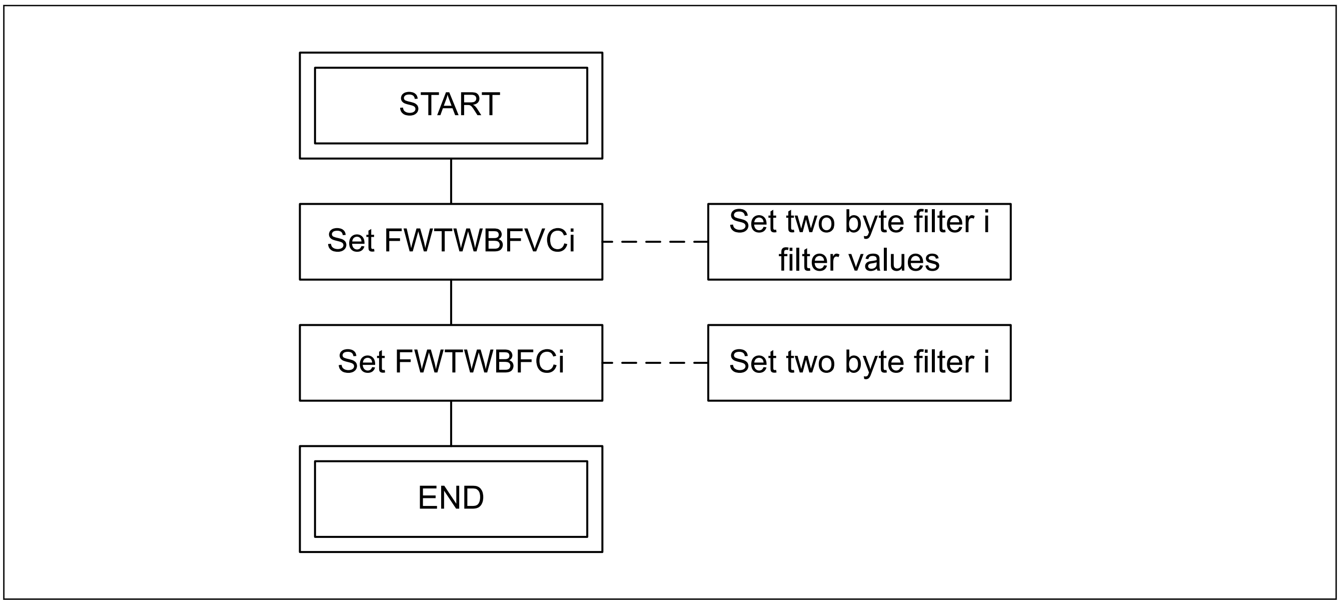

Figure 30.36 Setting flow of two-byte filter i

30.5 Functional Details

30.5.1 General Functionalities

General functionalities are separated in several types:

- Descriptors
- ESWM modes
- ESWM TPIDs
- ESWM debug functions
- ESWM watermark

30.5.1.1 Descriptors

To forward a frame to one or several port, the forwarding emits descriptors through the descriptor bus. All descriptor emitted by the forwarding engine shall follow the descriptor format described in Table 30.5. In following sections when a function emits a descriptor it will be explained using the field name. Only fields that are not determined by the input local descriptor or the input frame will be explained.

Table 30.5 Descriptor field (1 of 2)

Field name FDESCR	Bit width	Field description	Values
DV	3	Values: ● Bit i set to 0: Descriptor not valid for port i ● Bit i set to 1: Descriptor valid for port i	Depends on descriptor. Will be explained per descriptor in following sections.
SEC	1	Values: ● 0: Descriptor is unsecure ● 1: Descriptor is secure	Depends on descriptor. Will be explained per descriptor in following sections.
CSD	6	Bits [5:0] (written as FDESCR.CSDi) define the CPU sub-destination for GWCA number i (CPU sub-destination is equivalent to AXI descriptor queue number)	Depends on descriptor. Will be explained per descriptor in following sections.
IPV	3	Internal priority value before agent internal priority remapping	Depends on descriptor. Will be explained per descriptor in following sections.
SPN	2	Port number from which the frame came from	Set to the source agent port number given by mfw_spn_fwd pin
TPL	16	Input frame total payload length.	Set to the TPL value given by agent through local descriptors
MINFO	24	Meta-information associated to a frame for CPU forwarding	Depends on descriptor. Will be explained per descriptor in following sections.
RV	1	Routing valid. Informs agents that routing rules should be fetched to forwarding engine through L23 update bus to update frame information	Depends on descriptor. Will be explained per descriptor in following sections.
RN	8	Routing number. Informs agents that routing number should be used when FDESCR.RV is set.	Depends on descriptor. Will be explained per descriptor in following sections.
VCTRL	3	VLAN control information	Set to the VCTRL value given by agent through local descriptors

Table 30.5 Descriptor field (2 of 2)

Field name FDESCR	Bit width	Field description	Values
RTGI	1	R-TAG in	Set to the RTGI value given by agent through local descriptors
SEQN	16	Frame sequence number	Depends on descriptor. Will be explained per descriptor in following sections.
FI	1	Values: ● 0: Input frame does not contain its FCS ● 1: Input frame contains its FCS	Set to the FI value given by agent through local descriptors
FW	1	Values: ● 0: If input frame contains its FCS, it was correct when given to the switch ● 1: If input frame contains its FCS, it was incorrect when given to the switch	Set to the FW value given by agent through local descriptors

30.5.1.2 ESWM Modes

ESWM modes define the general behavior of the switch using FWGC registers. The functions of ESWM modes are as follows:

- FWGC register sets the VLAN format that is used by the forwarding engine. Depending on this setting, all the agents should convert ethernet frames in the required format (for format conversion, see GWCA specification document [GWCA]).

30.5.1.3 ESWM TPIDs

ESWM TPIDs for C-TAG, S-TAG and R-TAG [801.2Q] [801.2CB] can be set by the user using FWTTC0 and FWTTC1 registers.

Functions:

- FWTTC0 register sets the S-TAG and C-TAG TPIDs [801.2Q].
- FWTTC1 register sets the R-TAG TPID [801.2CB].
- FWTTC0 and FWTTC1 register reset values are as per defined in IEEE standards [801.2Q] [801.2CB].

30.5.1.4 ESWM Frame Input Priority

Any incoming frame has an input priority given by forwarding engine depending on the switch mode FWGC.SVM, and the incoming priority settings in FWPBFCi register including the frame format. Figure 30.47 describes the frame input priority assignment for a frame coming from port i (the ToS DSCP field decoding is fixed in hardware and described in Table 30.6).

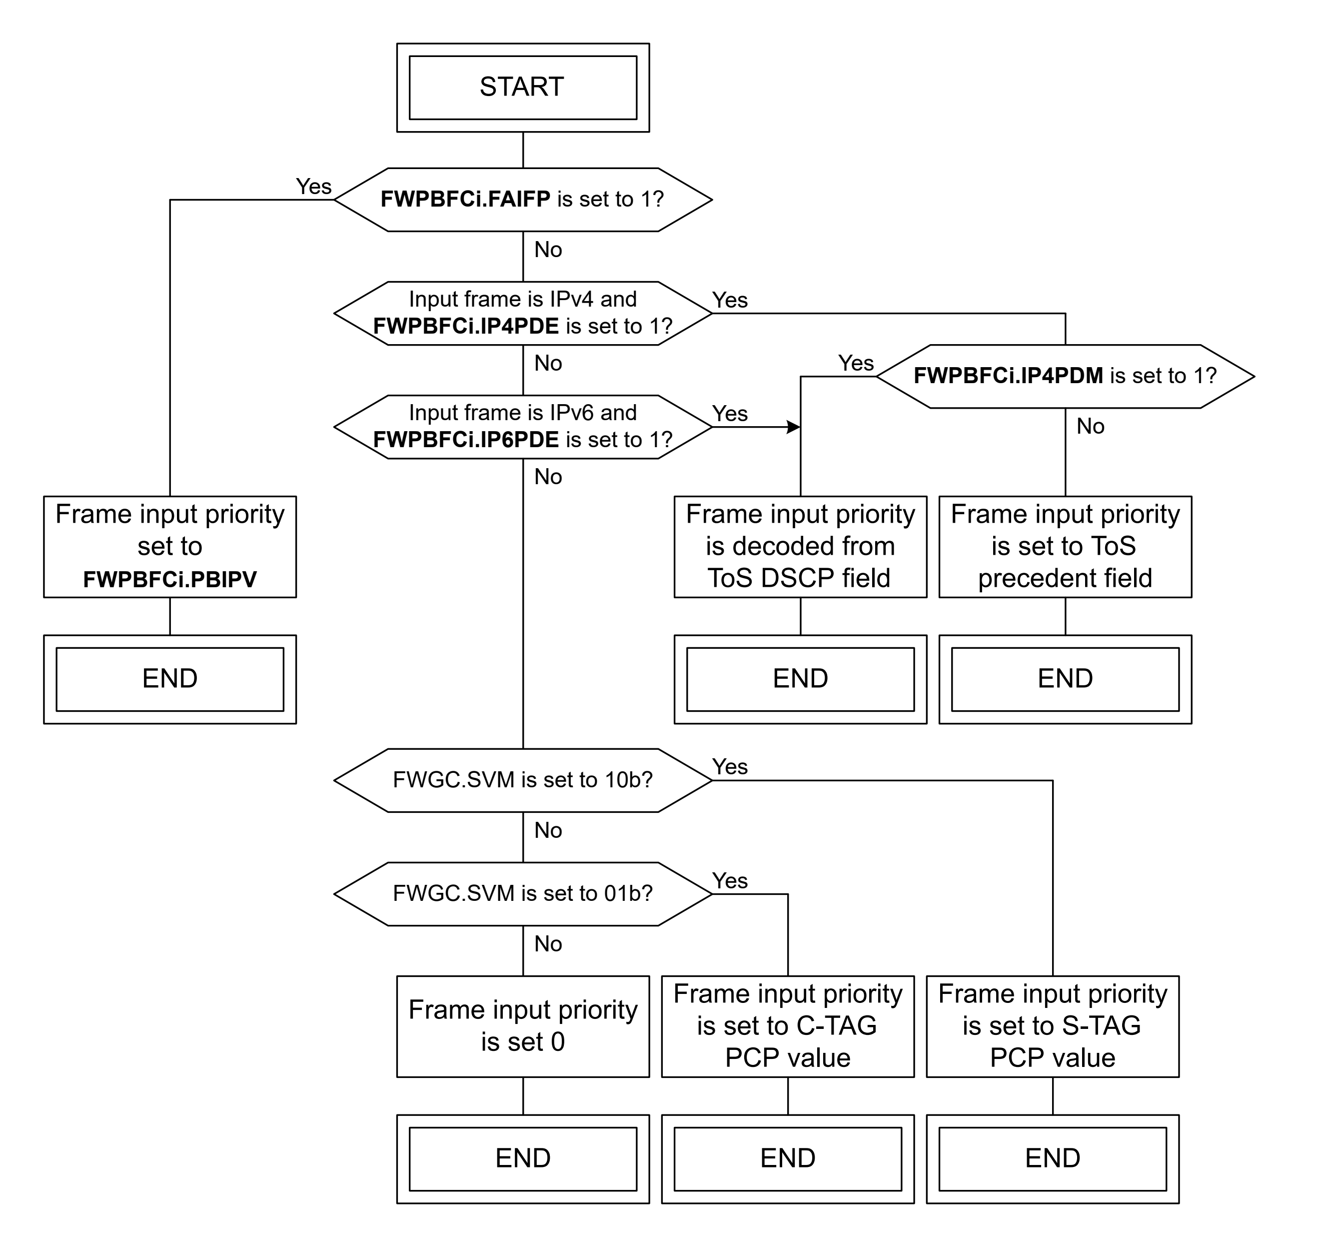

Figure 30.47 Priority assignment of frame input for port i

Note: HW: For cut-through forwarding, ToS and DSCP are not considered as frame input priority. Frame input priority is always extracted from S-TAG, S-TAG or set to 0.

Table 30.6 DSCP to priority mapping

DSCP values in decimal	Frame input priority
56	7
48	6
40, 46	5
32, 34, 36, 38	4
24, 26, 28, 30	3
16, 18, 20, 22	2
8, 10, 12, 14	1
Others	0

30.5.1.5 ESWM Debug Functions

30.5.1.5.1 CPU Exceptional Path

Exceptional path is used to forward faulty frames to CPU for diagnosis using FWCEPTC and FWCEPRC0/1/2 registers. When a frame is selected by exceptional path, an exceptional descriptor is emitted. The functions of exceptional path are as follows:

- FWCEPTC register sets the target to which type of faulty frames is forwarded
- FWCEPRC0/1/2 registers set which error frame is forwarded to the exceptional path.

Note: For exceptional path descriptor formats and associated error details, see section 30.5.2.3.3. Direct Exceptional Descriptor, (4) Layer 3 exceptional descriptor, (3) Layer 2 exceptional descriptor, section 30.5.2.6.3. Port Based Exceptional Descriptor and (5) Filter exceptional descriptor.

30.5.1.5.2 CPU Learning Path

Learning path is used to forward frames containing an unknown field to CPU for learning by using the FWCLPTC and FWCLPRC registers for the CPU to learn it. Learning can also be done by hardware using the FWPCi0 register and can be monitored using the FWEIS0i interrupt register. Table 30.7 sums-up the field that can be learned in software (corresponding frames will be forwarded to learning path) and Table 30.8. Any frame sent to learning path will be sent using learning descriptor described in (1) Learning descriptor.

Note: HW: Any frame rejected by Watermark is not analyzed for learning. As a result, learning path is deactivated and hardware learning does not happen.

Functions:

- FWCLPTC register sets the target to which unknown frames will be forwarded.
- FWCLPRC registers set which field should be unknown for a frame to be forwarded to the learning path.
- FWPCi0 registers sets for which fields hardware learning should happen.
- FWEIS0i interrupt register notifies that a field could not be learnt in hardware.

Table 30.7 Software learning summary table

Field to learn	Learning type	Learning detection conditions for a frame coming from port i	Learning enable bit in FWCLPRC register	Hardware learning possible
Stream ID	Learning	FWPCi0.LTHTA is set. At least a stream ID is valid. Stream ID is not set in the layer 3 table.	USIDLF	No
Destination MAC	Learning	FWPCi0.MACDSA is set. Destination MAC is not set in the MAC table.	UDMACLF	No
Source MAC	Learning	FWPCi0.MACSSA is set. Source MAC is a unicast address. Source MAC is not set in the MAC table.	USMACLF	Yes See Table 30.8.
Source MAC port	Migration	FWPCi0.MACSSA is set. Source MAC is a unicast address. Source MAC is set in the MAC table. MAC.DV[i] is not set.	UPSMACLF	Yes See Table 30.8.
VLAN	Learning	FWPCi0.VLANSA is set. VLAN is valid. VLAN ID is not set in the VLAN table.	UVLANLF	No

Table 30.8 Hardware learning summary table

Field to learn	Learning type	Hardware learning enable bit in FWPCi0 register for port i	Hardware learning fail interrupt in FWEIS0i register for port i	Hardware learning condition	Hardware learning disable condition (for certain frames HW learning can be disabled)
Source MAC	Learning	MACHLA	SMHLFS	Same as SW learning. See Table 30.7.	FWPCi0.MACDSA is set. Destination MAC is set in the MAC table. MAC.HLD is set. Or FWPCi0.VLANSA is set. VLAN is valid. VLAN ID is set in the VLAN table. VLAN.HLD is set.
Source MAC port	Migration	MACHMA	SMHMFS	Same as SW learning. See Table 30.7.	FWPCi0.MACDSA is set. Destination MAC is set in the MAC table. MAC.HLD is set. Or FWPCi0.VLANSA is set. VLAN is valid. VLAN ID is set in the VLAN table. VLAN.HLD is set.

Note: A multicast MAC address is an address with bit 40 set to 1.

(1) Learning descriptor

Learning descriptor fields are described in Table 30.9.

Table 30.9 Learning descriptor fields

Field name FDESCR.	Values
DV	Learning descriptors are forwarded to GWCA number FWCLPTC.LPCS (port number 2 + FWCLPTC.LPCS).
SEC	FWCLPTC.LPSL
CSDj	FWCLPTC.LPCSD
IPV	FWCLPTC.LPIPV

SMHMF	1	Source MAC Hardware Migration Fail*1	See section 30.5.1.5.2. CPU Learning Path.

Note 1. "Hardware Learn/Migration" will set regardless of "Hardware Learn/Migration Fail". (If "Hardware Learn Fail" is set, "Hardware Learn" is always set.)

30.5.1.5.3 Mirroring Paths

Forwarding engine contains 3 mirroring paths:

- CPU mirroring path
- Ethernet mirroring path
- Source-destination mirroring path

(1) CPU mirroring path

CPU Mirroring path is used to copy frames to a CPU for monitoring purpose using FWCMPTC register. Table 30.11 describes CPU mirroring selection conditions depending on the forwarding mechanism selected by forwarding flow. When a frame is selected for CPU mirroring, a mirroring descriptor is emitted ((4) Mirroring descriptor).

Functions:

- FWCMPTC register sets the target to which mirrored frames will be forwarded.

Table 30.11 CPU mirroring selection conditions

Descriptor selected by forwarding flow	Mirroring selection conditions
Cut-through normal descriptor (Figure 30.53)	Cut-through rule corresponding FWCTTCi1.CTCME is set.
Layer 3 normal descriptor (Figure 30.85, Figure 30.86)	L3.CME is set for stream ID
Layer 2 normal descriptor (Figure 30.95, Figure 30.96)	If {MAC.CME is set for destination MAC or VLAN.CME is set} when MAC destination address and VLAN ID are both found and MAC.SL = VLAN.SL. If MAC.CME is set for destination MAC when MAC destination only is found or if MAC destination address and VLAN ID are both found and MAC.SL & !VLAN.SL. If VLAN.CME is set when VLAN ID only is found or if MAC destination address and VLAN ID are both found and !MAC.SL & VLAN.SL.
Port based normal descriptor (Figure 30.99, Figure 30.100)	If FWPBFCi.PBCME is set for incoming frame source port.

(2) Ethernet mirroring path

Ethernet Mirroring path is used to copy frames to an ethernet agent for monitoring purpose using FWEMPTC register. Table 30.12 describes Ethernet mirroring selection conditions depending on the forwarding mechanism selected by forwarding flow. When a frame is selected for Ethernet mirroring, a mirroring descriptor is emitted ((4) Mirroring descriptor).

Functions:

- FWEMPTC register sets the target to which mirrored frames will be forwarded.

Table 30.12 Ethernet mirroring selection conditions

Descriptor selected by forwarding flow	Mirroring selection conditions
Cut-through normal descriptor (Figure 30.53)	Cut-through rule corresponding FWCTTCi1.CTEME is set.
Layer 3 normal descriptor (Figure 30.85, Figure 30.86)	L3.EME is set for stream ID
Layer 2 normal descriptor (Figure 30.95, Figure 30.96)	If {MAC.EME is set for destination MAC or VLAN.EME is set} when MAC destination address and VLAN ID are both found and MAC.SL = VLAN.SL. If MAC.EME is set for destination MAC when MAC destination only is found or if MAC destination address and VLAN ID are both found and MAC.SL & !VLAN.SL. If VLAN.EME is set when VLAN ID only is found or if MAC destination address and VLAN ID are both found and !MAC.SL & VLAN.SL.
Port based normal descriptor (Figure 30.99, Figure 30.100)	If FWPBFCi.PBEME is set for incoming frame source port.

(3) Source-destination Mirroring path

Mirroring path is used to copy frames to an Ethernet port or a CPU for monitoring purpose using FWSDMPTC and FWSDMPVC register. When a frame is selected for Source-destination mirroring, a mirroring descriptor is emitted ((4) Mirroring descriptor).

Functions:

- FWSDMPTC register sets the target to which mirrored frames will be forwarded.
- FWSDMPVC register sets the source from which should come and the destination where should go a frame to be mirrored.
- A frame is selected for source-destination mirroring if the descriptor selected by forwarding flow is {Layer 3 normal descriptor (Figure 30.85, Figure 30.86) or IP normal descriptor (Figure 30.95, Figure 30.96) or Layer 2 normal descriptor (Figure 30.95, Figure 30.96) or Port based normal descriptor (Figure 30.99, Figure 30.100)}, if the frame source port is set in FWSDMPVC.SDMSV register and if FDESCR.DV & FWSDMPVC.SDMDV is not null.

(4) Mirroring descriptor

Mirroring descriptor fields are described in Table 30.13.

Table 30.13 Mirroring descriptor fields (1 of 2)

Field name FDESCR.	Values for CPU mirroring	Values for Ethernet mirroring	Values for Source-destination mirroring
DV	Mirroring descriptors are forwarded to GWCA number FWCMPTC.CMPCS (port number 2 + FWCMPTC.CMPCS)	Mirroring descriptors are forwarded to ETHA number FWEMPTC.EMPPS (port number FWEMPTC.EMPPS)	Mirroring descriptors are forwarded to port number FWSDMPTC.SDMPPS
SEC	FWCMPTC.CMPSL	FWEMPTC.EMPSL	FWSDMPTC.SDMPSL
CSDj	FWCMPTC.CMPCSD	All0	All0
IPV	If FWCMPTC.CMPIPU is set, FWCMPTC.CMPIPV If FWCMPTC.CMPIPU is not set, same IPV as normal descriptor	If FWEMPTC.EMPIPU is set, FWEMPTC.EMPIPV If FWEMPTC.EMPIPU is not set, same IPV as normal descriptor	If FWSDMPTC.SDMPIPU is set, FWSDMPTC.SDMPIPV If FWSDMPTC.SDMPIPU is not set, same IPV as normal descriptor
MINFO	See Figure 30.49 and Table 30.14.	See Figure 30.49 and Table 30.14.	See Figure 30.49 and Table 30.14.
RV	0	0	0

NDFB	8	Normal Descriptor First Byte	Set to mirrored frame corresponding normal descriptor FDESCR.MINFO[7:0] value

30.5.1.6 Watermark

ESWM watermark defines the switch behavior in case of overflow using FWLBWMCi and FWCEPRC2 registers and can be monitored using FWEIS0i interrupt register.

Functions:

- FWLBWMCi is used to set which frame should be discarded by level-based watermark [COMA].
- FWCEPRC2 register enables exceptional path for error descriptors.
- FWEIS0i interrupt register notifies that a frame coming from port i has been rejected because of watermark.
- Watermark uses has frame priority the IPV value given by forwarding mechanism before filtering. This correspond to the FDESCR.IPV in the normal descriptor emitted by the selected forwarding.
- Watermark uses as DEI value the value extracted from the input frame which is the S-TAG DEI value when FWGC.SVM is set to 10b, the C-TAG DEI value when FWGC.SVM is set to 01b, and 0 when FWGC.SVM is set to 00b.

Note:
- SW: The watermark is an indispensable functionality for switch QoS behavior definition, it is not advised to disable it.
- Error frames are not going through watermark.

(1) Watermark errors

Table 30.15 describes the Watermark errors. Instead of being discarded by forwarding engine, an error frame can be forwarded to exceptional path using Watermark exceptional descriptor described in (2) Watermark exceptional descriptor by setting corresponding error exceptional bit. For error set conditions, refer to corresponding error interrupt register explanations.

Table 30.15 Watermark errors (1 of 2)

Error	Error name	Error interrupt	Error exceptional bit
WMCF	Watermark Critical Filtering	FWEIS0i.WMCFS	FWCEPRC2.FWMFEF

30.5.2 Forwarding/Routing

Forwarding engine contains different types of forwarding which are:

- Cut-through forwarding
- Direct descriptor forwarding
- L3 forwarding/routing
- L2 forwarding
- Port based forwarding

30.5.2.1 Cut-through Forwarding

Cut-through forwarding is used to forward high priority frames without storing them in the local memory to suppress the frame reception time impact on the latency. Under the condition of ESWM insure best latency (no busy traffic on MFWD and no TAG frame) of

0.7 µs* + "PHY clock 4 cycle"(ns), 4.6 µs* + "PHY clock 4 cycle"(ns) and 46 µs* + "PHY clock 4 cycle"(ns) at respectively 10/5/2.5/1 Gbps, 100 Mbps and 10 Mbps [ETHA].

Depending on the setting conditions, the value may be smaller than these.

Generally, "Cut-through" only checks 6 bytes (Destination MAC Address) of a frame head and starts frame forwarding after this check immediately. Since internal data bus width in this switch is wider than 6 bytes, it needs more data bytes to start frame forwarding. Because of this logic, "Cut-through" forwarding time of this switch needs above times.

The Cut-through forwarding block diagram is represented in Figure 30.51.

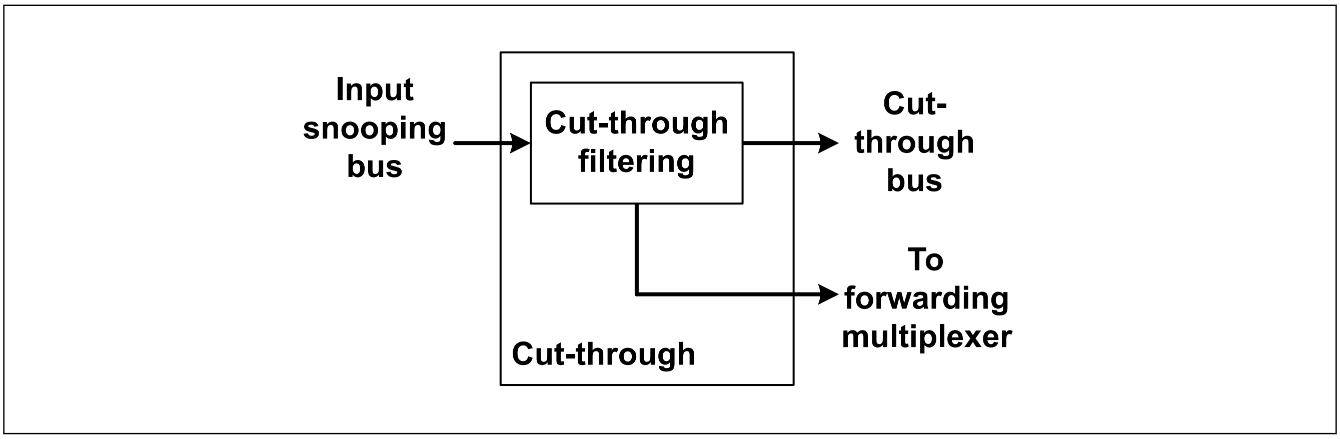

Figure 30.51 Cut-through forwarding block diagram

The Cut-through forwarding function has one functional block:

- Cut-through filtering: This function filters incoming frame first beat of data to select set frames for cut-through forwarding, creates the cut-through bus protocol destinated to time agents [ETHA] and send required information to forwarding multiplexer to apply store and forward to cut-through frames.

Note:
- Forwarding multiplexer contains the forwarding flow. The forwarding flow is explained per forwarding type. For Cut-though, related Forwarding flow is described in Figure 30.53
- HW: The usage "From-one-to-one between same PHY speed" is recommended. So in case of forwarding engine back pressure, it can happen that cut-through frames are cut in the middle and lost.
- HW: P-frames cannot be forwarded by cut-through.
- HW: Cut-through forwarding should not be set for ingress ports in Port-based VLAN mode because cut-through can only forward frame as they were received. ([ETHA] EAVCC.VIM set to 0)
- HW: Watermark is not applied on Cut-through frames.
- HW: Cut-through frames can be ingress tagging by FWCTGCi0.CTVCRL but not egress tagging.
- HW: L23 update is not applied on Cut-through frames.
- HW: Data padding applied on Cut-through frames.
- HW: Cut-through frames can be shaped using TAS but not CBS.
- HW: Cut-through frames will be forward in cut-through mode as there are received and will not be updated.
- HW: For cut-through, only mirroring set in FWCTTCi1/i2 register is available. All other debugging and mirroring are disabled.
- HW: Cut-through frames will not be filtered by [RMAC] MAC Address filtering on Reception. Because [ETHA] and [GWCA] reception filter information are ignored.
  For example, a frame which is having a nibble alignment error ([ETHA] reception filter information) is ignored by cut through forwarding. And a frame is transmitted out by padding bits of data to complete a byte.

30.5.2.1.1 Cut-through Filtering

Cut-through filtering is used to identify cut-through frames using FWCTGCi0/i1 and FWCTSCi0/i1/i2/i3/i4 registers. Cut-through filtering and register utilization are summarized in Figure 30.52.

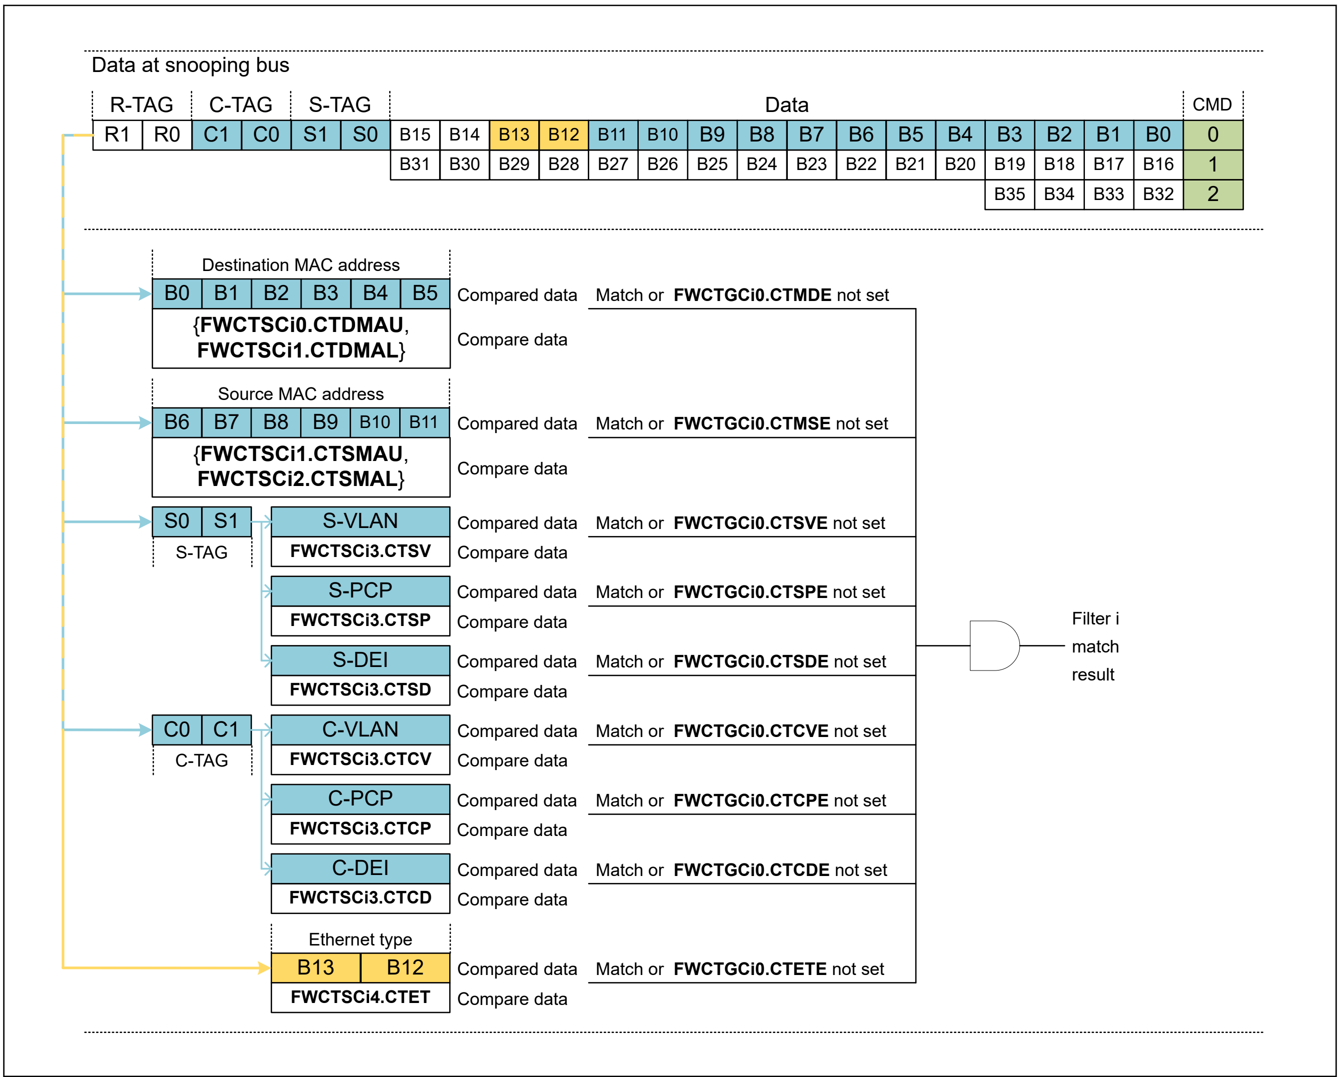

Figure 30.52 Cut-through filtering

Functions:

- A cut-through rule can only match frames from corresponding source port FWCTSCi4.CTSPN.
- If several Cut-through rules match the same frame, the Cut-through rules with the highest number will be selected.
- A cut-through rule is only valid when corresponding FWCTTCi0.CTDV is different from All0.
- A cut-through matching frames is forwarded by cut-through and store and forward independently of any error that could have happened in the ingress agent.
- For register FWCTGCi0 bit 0-8 set to 0 (all fields compare match is disabled), Cut through becomes “port based cut through” by FWCTTCi0.CTDV.

30.5.2.1.2 Cut-through Forwarding

Cut-through forwarding function creates the cut-through bus protocol destinated to time agents [ETHA] using FWCTTCi0, FWCTGCi0/i1 registers. It is used to send frames while receiving them to reduce latency though cut-through bus.

Functions:

- FWCTTCi0 register is to determine the target port for cut-through. All ports set in FWCTTCi0.CTDV[PORT_TIME_N-1:0] and not set in FWCTTCi0.CTDFM are targeted for rule i cut-through forwarding. Any frame received from an agent with an error will still be forwarded/mirrored by cut-through forwarding.
- FWCTGCi1.CTMT, FWCTGCi0.CTVCTRL, and FWCTGCi0.CTFI registers are respectively used as Maximum Time on the PHY, VLAN control and FCS in for the matching cut-through frame.

Note:
- HW: Ethernet timestamping functionalities are not available during cut-through forwarding [ETHA]. E.g. while forwarding frames to RMAC [RMAC], the ethernet agent will fix “Timestamp capture”, “Insert egress timestamp” and “Calculate residence time” TX interface bit to 0.
- HW: For cut-through forwarding, all (From & To) PHY speeds have to be the same[ETHA] [RMAC].
- SW: FWCTGCi0.CTRTGI and FWCTGCi0.CTVCTRL should always correspond to the ingress frame format. If then do no correspond, errors can happen.

30.5.2.1.3 Store and Forward Forwarding

Store and forward forwarding function apply store and forward to cut-through frames using FWCTTCi0/i1/i2. Cut-through forwarding flow for Store and forward forwarding is described in Figure 30.53.

Functions:

- FWCTTCi0 register is to determine the target port for store and forward. All ports set in FWCTTCi0.CTDV[2:0] and set in FWCTTCi0.CTDFM are targeted for rule i store and forward forwarding, so are ports set in FWCTTCi0.CTDV[3:2]. Any frame received from an agent with an error will still be forwarded/mirrored in store and forward mode.
- FWCTTCi1/i2 registers sets the forwarding information.

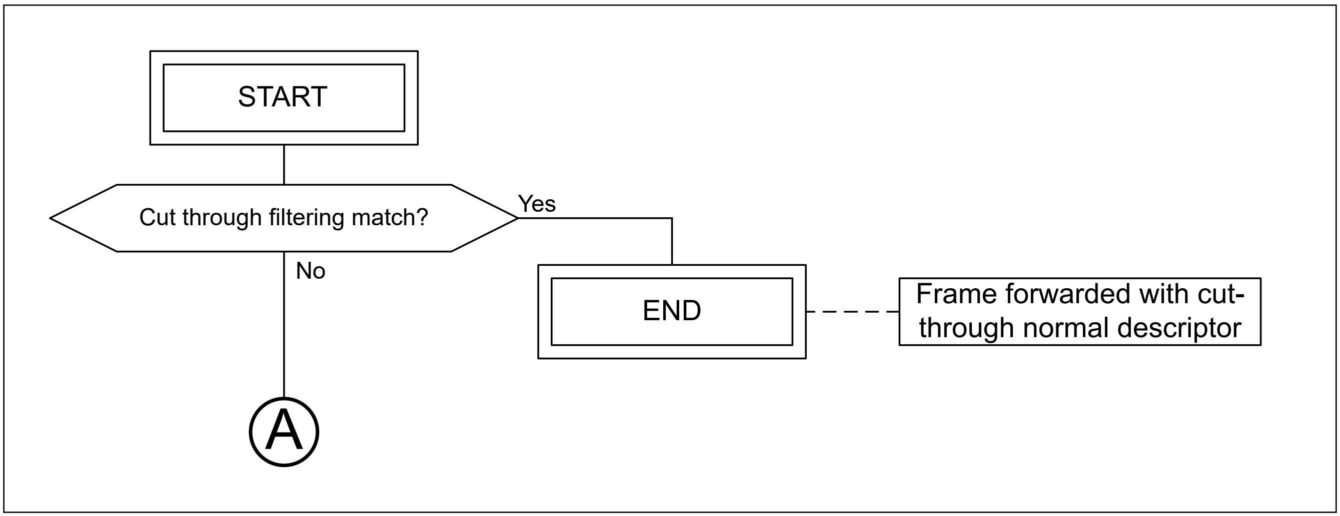

Figure 30.53 Cut-through forwarding flow

Note: Link A links to Figure 2.

(1) Cut-through normal descriptor

Cut-through normal descriptor fields for a frame matching cut-through rule number i are described in Table 30.18.

Table 30.18 Cut-through normal descriptor fields

Field name FDESCR.	Values
DV	{FWCTTCi0.CTDV[3:2], {FWCTTCi0.CTDV[1] & FWCTTCi0.CTDFM}}
SEC	1
CSDj	FWCTTC2ji.CTCSD
IPV	If FWCTTCi1.CTIPU is set, set to FWCTTCi1.CTIPV If FWCTTCi1.CTIPU not set and FWGC.SVM is set to 10b, set to frame input S-TAG PCP If FWCTTCi1.CTIPU not set and FWGC.SVM is set to 01b, set to frame input C-TAG PCP If FWCTTCi1.CTIPU not set and FWGC.SVM is set to 00b, set to frame input 0

—	- -	Reserved field	Set to 0

30.5.2.2 Integrity Check

Integrity check is used to check it a frame can be forwarded or if it contains an error. The Integrity check block diagram is represented in Figure 30.55. Integrity check flow is described in Figure 30.56.

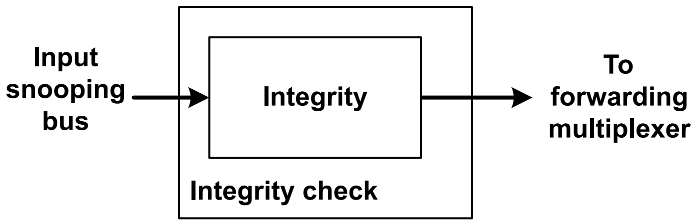

Figure 30.55 Integrity check block diagram

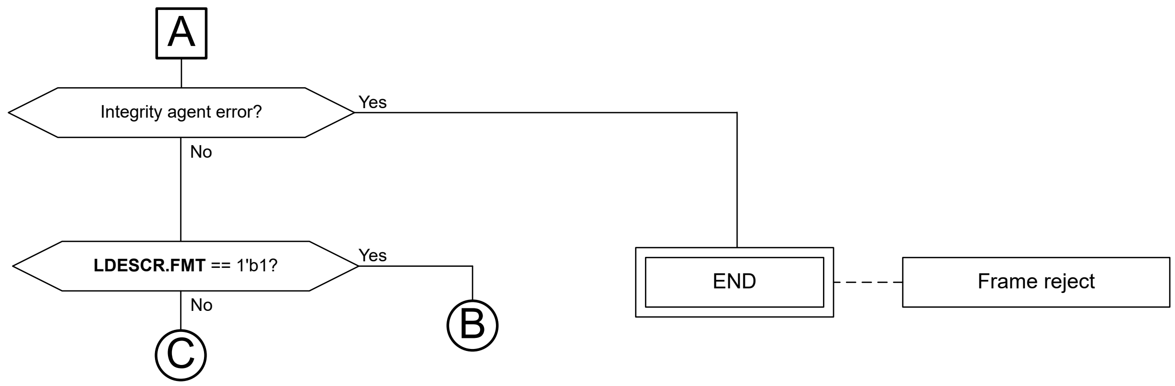
The Integrity check function has one functional block:

- Integrity: The ether type 0x8100, 0x88A8 and 0xF1C1 are ignored and the next ether type field are extracted. However, invalid frames (exp CC-TAG) are judged to have no header, and the first ether type field is the extract.
- Integrity: This functions check if an error has been received from the input agent or if incoming frames don't respect the required format.
- Integrity check for both IPv4 filtering and IPv6 filtering will happen based on ether type field. i.e. Ether type is only used for parsing frame type in MFWD integrity check and is irrespective of header length or TPL size of the required frame type.

Note: • Forwarding multiplexer contains the forwarding flow. The forwarding flow is explained per forwarding type. For integrity check, related Forwarding flow is described in Figure 30.56.



Note:
- Integrity check errors are described in section 30.5.2.2.1. Integrity Check Errors.
- Link A is linked from Figure 30.53.
- Link B links to Figure 30.58.
- Link C links to Figure 30.85.

Figure 30.56 Integrity check flow

30.5.2.2.1 Integrity Check Errors

Table 30.20 describes the Integrity check errors. Instead of being discarded by forwarding engine, an error frame can be forwarded to exceptional path using Integrity exceptional descriptor described in section 30.5.2.2.2. Integrity Exceptional Descriptor by setting its corresponding error exceptional bit.

Table 30.20 Integrity check errors (1 of 2)

Error	Error name	Error interrupt/Explanation	Error exceptional bit
Integrity agent errors			
GTFE	GWCA TAG filtering error	Happens when a frame is received from a GWCA and LDESCR.SAEF[0] is set [GWCA]	FWCEPRC0.GTFEF
GAXE	GWCA AXI Error	Happens when a frame is received from a GWCA and LDESCR.SAEF[3] is set [GWCA]	FWCEPRC0.GAXEEF
GSEGE	GWCA Sequence Error	Happens when a frame is received from a GWCA and LDESCR.SAEF[4] is set [GWCA]	FWCEPRC0.GSEQEEF
GDNE	GWCA Descriptor Number Error	Happens when a frame is received from a GWCA and LDESCR.SAEF[6] is set [GWCA]	FWCEPRC0.GDNEEF
ETFE	Ethernet TAG filtering Error	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF[0] is set [ETHA]	FWCEPRC0.ETFEF
EPHYE	Ethernet TAG PHY Error	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC0 is set to 4’d1 [ETHA]	FWCEPRC0.EPHYEEF
EPCRCE	Ethernet PCH CRC Error	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC0 is set to 4’d2 [ETHA]	FWCEPRC0.EPCRCEEF
ENIBE	Ethernet Nibble Error	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC0 is set to 4’d3 [ETHA]	FWCEPRC0.ENIBEEF
EFCSE	Ethernet FCS Error	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC0 is set to 4’d4 [ETHA]	FWCEPRC0.EFCSEEF
EFFME	Ethernet Final Fragment Missing Error	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC0 is set to 4’d5 [ETHA]	FWCEPRC0.EFFMEEF
ECFSE	Ethernet C-Fragment SMD Error	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC0 is set to 4’d6 [ETHA]	FWCEPRC0.ECFSEEF
ECFFCE	Ethernet C-Fragment FRAG_COUNT Error	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC0 is set to 4’d7 [ETHA]	FWCEPRC0.ECFFCEEF

Table 30.20 Integrity check errors (2 of 2)

Error	Error name	Error interrupt/Explanation	Error exceptional bit
ERFF	Ethernet RMAC Frame Filtered	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC0 is set to 4'd8 [ETHA]	FWCEPRC0.ERFFEF
ERPOO	Ethernet Reception Partially Out of Operation	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC0 is set to 4'd9 [ETHA]	FWCEPRC0.ERPOOEF
EBOE	Ethernet Buffer Overflow Error	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC1 is set to 2'd1 [ETHA]	FWCEPRC0.EBOEEF
EUE	Ethernet Undersize Error	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC1 is set to 2'd2 [ETHA]	FWCEPRC0.EUEEF
EOE	Ethernet Oversize Error	Happens when a frame is received from an Ethernet agent and LDESCR.SAEF.EC1 is set to 2'd3 [ETHA]	FWCEPRC0.EOEEF

30.5.2.2.2 Integrity Exceptional Descriptor

Integrity exceptional descriptor fields are described in Table 30.21.

30.5.2.3 Direct Descriptor Forwarding

Direct descriptor forwarding is used to forward local direct descriptors (LDESCR.FMT [GWCA] set to 1) received from a slow interface [GWCA] using FWPCi1 and FWCEPRC0 register and can be monitored using FWEIS0i interrupt register. Direct descriptor forwarding flow is described in Figure 30.58.

Functions:

- FWPCi1.DDE register is used to enable direct descriptor reception from port i.
- FWPCi1.DDSL register is used to enable secure direct descriptor reception from port i when direct descriptor reception from port I is enabled.
- FWCEPRC0 register enables exceptional path for error descriptors.
- FWEIS0i interrupt register notifies that a direct descriptor has been rejected.

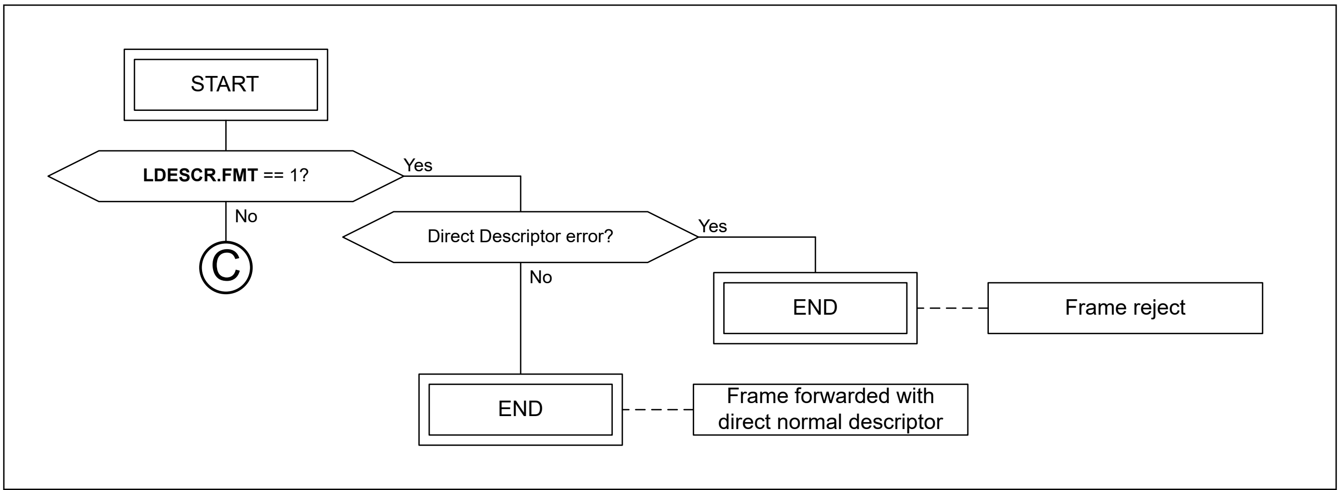

Figure 30.58 Direct descriptor forwarding flow

Note:
- Direct descriptor errors are described in section section 30.5.2.3.1. Direct Descriptor Forwarding Errors.
- Direct normal descriptor format is described in section section 30.5.2.3.2. Direct Normal Descriptor.
- Link C links to Figure 30.85.

30.5.2.3.1 Direct Descriptor Forwarding Errors

Table 30.23 describes the Direct descriptor forwarding errors. Instead of being discarded by forwarding engine, an error frame can be forwarded to exceptional path using Direct exceptional descriptor described in section section 30.5.2.3.3. Direct Exceptional Descriptor by setting corresponding error exceptional bit. For error set conditions, refer to corresponding error interrupt register explanations.

Table 30.23 Direct descriptor errors

Error	Error name	Error interrupt	Error exceptional bit

30.5.2.4 Layer 3 Forwarding/Routing/Filtering

Figure 30.61 shows the block diagram of Layer 3 forwarding/routing/filtering. This block is denoted by L3, but it contains all the stream-based functions of the forwarding engine, even the Layer 2 streams.

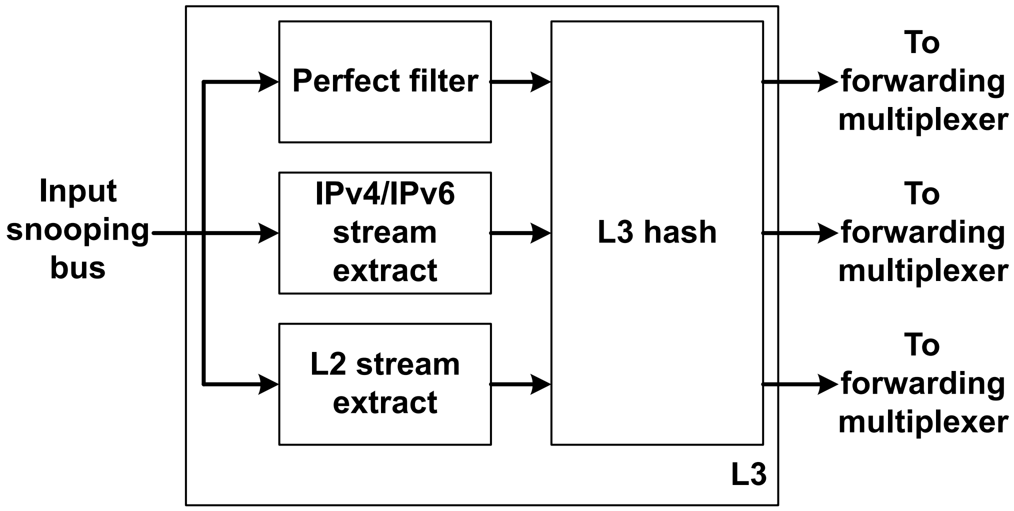

Figure 30.61 Block diagram of Layer 3 forwarding/routing/filtering

The Layer 3 forwarding/routing/filtering function is separated in four functional blocks:

- Perfect filter: This block snoops all the required information from the Forwarding engine snooping bus and create a user-defined stream.
- IPv4/IPv6 stream extract: This block snoops all the required information from the Forwarding engine snooping bus and create an IPv4/IPv6 stream.

- L2 stream extract: This block snoops all the required information from the Forwarding engine snooping bus and create a L2 stream.
- L3 hash: This block handles the stream meta information such as forwarding, routing and filtering information using a hash function.

Note: Forwarding multiplexer contains the forwarding flow. The forwarding flow is explained by forwarding type. For Layer 3 forwarding/routing/filtering, related forwarding flows are described in Figure 30.85, Figure 30.86 and Figure 30.87.

30.5.2.4.1 Perfect Filter

The perfect filter is used to identify streams. This filter has the advantage to be flexible and can identify a stream without any statistic error but, because of its high cost, is available in a limited number (16 streams available).

The Perfect filter block diagram is represented in Figure 30.62.

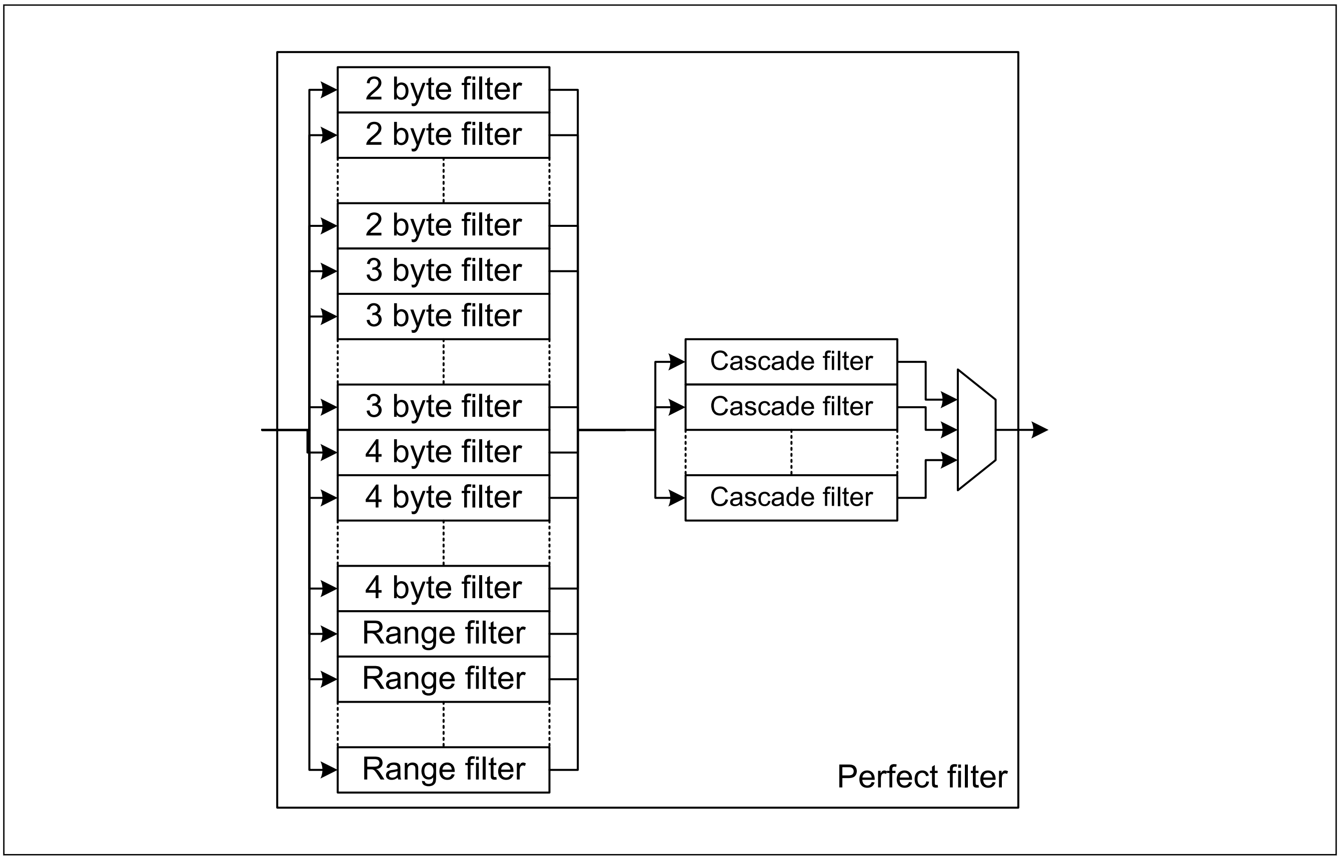

Figure 30.62 Perfect filter block diagram

The perfect filtering happens in two steps:

- The first step is done by 2-byte, 3-byte, 4-byte and range filters. Each one of these filters is independent of others but only able to filter a precise part of a frame.
- The second step is done by Cascade filters. Each one of the cascade filters can associate 7 filtering results from the first step to create a stream ID.

Note: HW: All frames smaller than 33 bytes (received with no command 1 from snooping bus, the 33 bytes are not including the TAG saved in the TAG RAM) will be considered has unknown frames by the perfect filter.

(1) 2-byte filters

A 2-byte filter aims at filtering a specific a portion of a frame and happens in two steps, the data extraction and the filtering.

(a) Data extraction for filtering

A 2-byte filter has two modes to extract the data from a frame. Figure 30.63 describes these modes using examples.

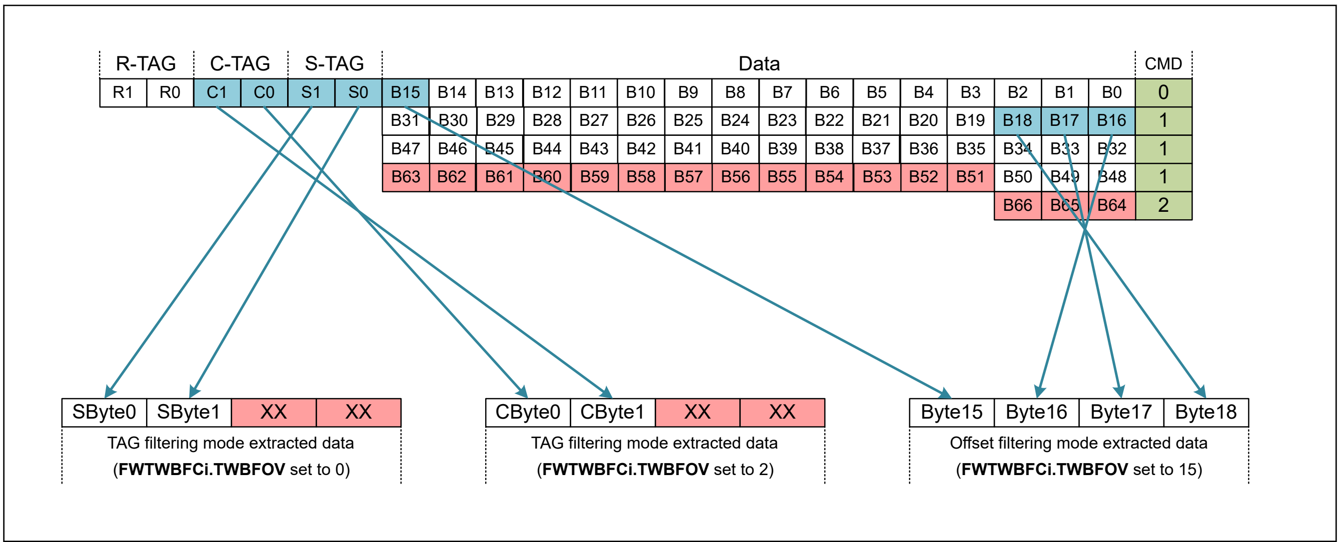

Figure 30.63 2-byte filter data extraction for filtering

In Offset filtering mode (FWTWBFCi.TWBFM == 0):

- Data bytes from byte FWTWBFCi.TWBFOV to byte FWTWBFCi.TWBFOV+3 are extracted for filtering.

In TAG filtering mode (FWTWBFCi.TWBFM == 1):

- If FWTWBFCi.TWBFOV is set to 0, VLAN S-TAG is extracted for filtering.
- If FWTWBFCi.TWBFOV is set to 2, VLAN C-TAG is extracted for filtering.

Note:
- HW: The data for filtering in 2-byte filters can only be extracted until the first three bytes in the penultimate beat of data (first three bytes of the last time CMD is equal to 1. In Figure 30.63, the bytes colored in red are the none-extractible bytes for filtering). I.e., the offset filtering will only be effective if the offset value is set until the last byte of the antepenultimate beat of data (the last before last time CMD is equal to 1. Byte 47 in Figure 30.63).
- HW: A filter with a setting that should use non-extractible data for filtering will always unmatched.
- HW: In TAG filtering mode, if S-TAG or C-TAG is not present in the frame for filtering, the value 0 will be extracted by the filter.

(b) Extracted data filtering

A 2-byte filter has three modes to filter extracted data. Figure 30.64 describes these modes.

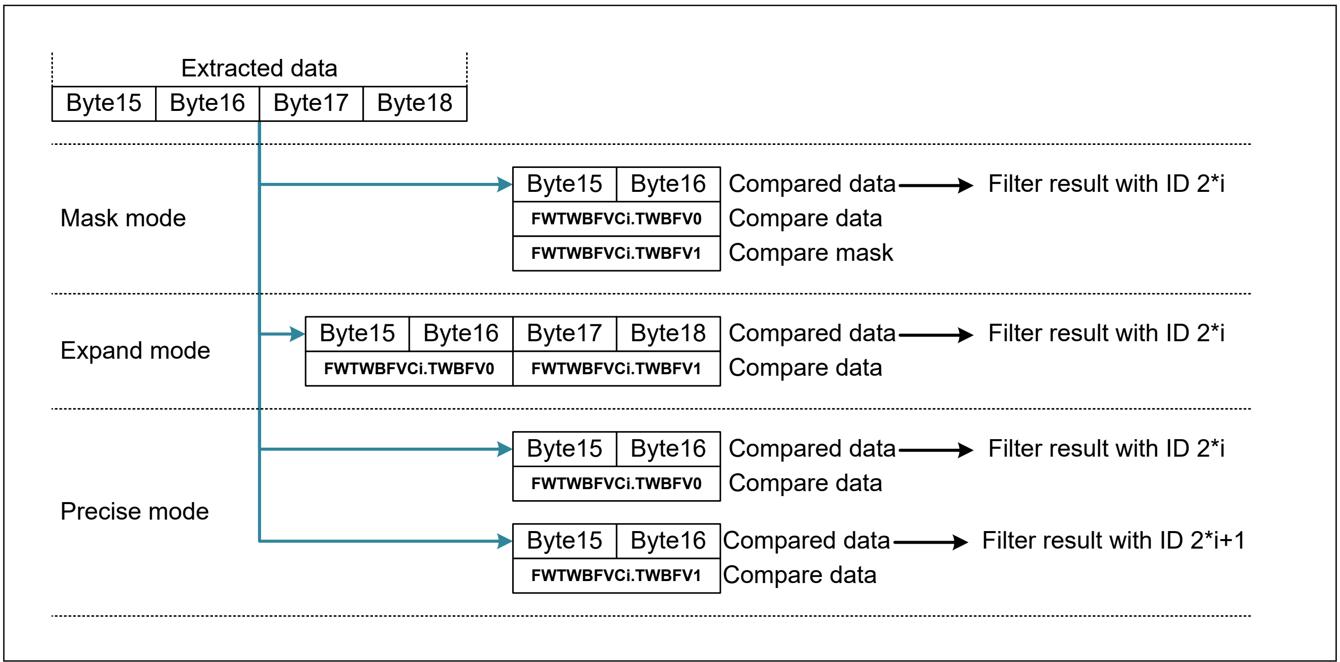

Figure 30.64 2-byte filter data extraction for filtering

In mask mode (FWTWBFCi.TWBFUM == 00b):

- The first two bytes of the extracted data are compared to FWTWBFVCi.TWBFV0 using FWTWBFVCi.TWBFV1 as a mask (when a bit is set to 1, the corresponding bit is not used for comparison). The result is associated to 2*i filter ID.

In Expand mode (FWTWBFCi.TWBFUM == 01b):

- The four-byte extracted data is compared to {FWTWBFVCi.TWBFV0,FWTWBFVCi.TWBFV1}. The result is associated to 2*i filter ID.

In Precise mode (FWTWBFCi.TWBFUM == 10b):

- The first two bytes of the extracted data are compared to FWTWBFVCi.TWBFV0. The result is associated to 2*i filter ID.
- The first two bytes of the extracted data are compared to FWTWBFVCi.TWBFV1. The result is associated to 2*i+1 filter ID.

(2) 3-byte filters

A 3-byte filter aims at filtering a specific a portion of a frame and happens in two steps, the data extraction and the filtering.

(a) Data extraction for filtering

A 3-byte filter has one mode to extract the data from a frame. Figure 30.65 describes this mode using an example.

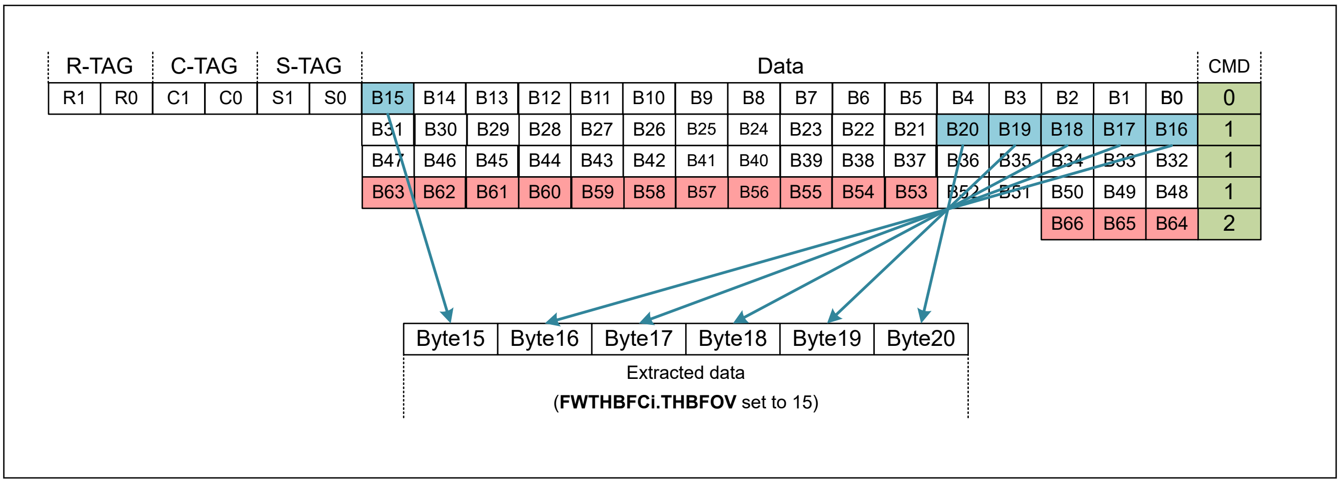

Figure 30.65 3-byte filter data extraction for filtering

For 3-byte filters:

- Data bytes from byte FWTHBFCi.THBFOV to byte FWTHBFCi.THBFOV+5 are extracted for filtering.

Note:
- HW: The data for filtering in 3-byte filters can only be extracted until the first five bytes in the penultimate beat of data (first five bytes of the last time CMD is equal to 1. In Figure 30.65, the bytes colored in red are the none-extractible bytes for filtering). I.e. the offset filtering will only be effective if the offset value is set until the last byte of the antepenultimate beat of data (the last before last time CMD is equal to 1. Byte 47 in Figure 30.65).
- HW: A filter with a setting that should use non-extractible data for filtering will always unmatched.

(b) Extracted data filtering

A 3-byte filter has three modes to filter extracted data. Figure 30.66 describes these modes.

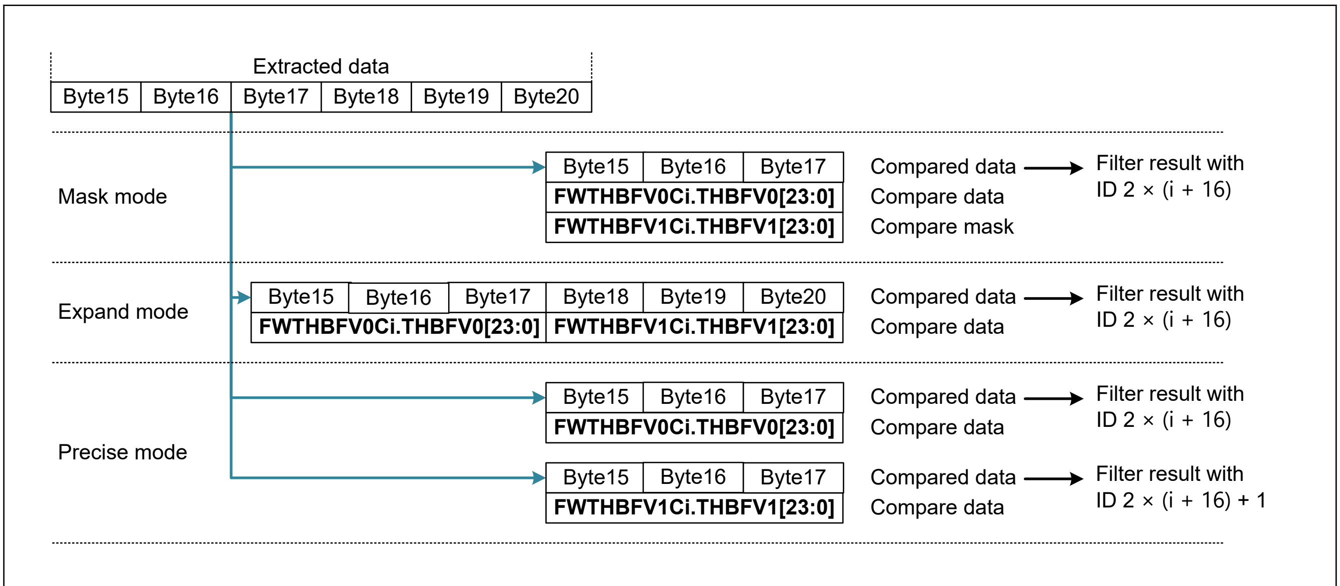

Figure 30.66 3-byte filter data extraction for filtering

In mask mode (FWTHBFCi.THBFUM[1:0] == 00b):

- The first three bytes of the extracted data are compared to FWTHBFV0Ci.THBFV0[23:0] using FWTHBFV1Ci.THBFV1[23:0] as a mask (when a bit is set to 1, the corresponding bit is not used for comparison). The result is associated to 2 × (i + 16) filter ID.

In Expand mode (FWTHBFCi.THBFUM[1:0] == 01b):

- The six-byte extracted data is compared to {FWTHBFV0Ci.THBFV0[23:0],FWTHBFV1Ci.THBFV1[23:0]}. The result is associated to 2 × (i + 16) filter ID.

In Precise mode (FWTHBFCi.THBFUM[1:0] == 10b):

- The first three bytes of the extracted data are compared to FWTHBFV0Ci.THBFV0[23:0]. The result is associated to 2 × (i + 16) filter ID.
- The first three bytes of the extracted data are compared to FWTHBFV1Ci.THBFV1[23:0]. The result is associated to 2 × (i + 16) + 1 filter ID.

(3) 4-byte filters

A 4-byte filter aims at filtering a specific a portion of a frame and happens in two steps, the data extraction and the filtering.

(a) Data extraction for filtering

A 4-byte filter has one mode to extract the data from a frame. Figure 30.67 describes this mode using an example.

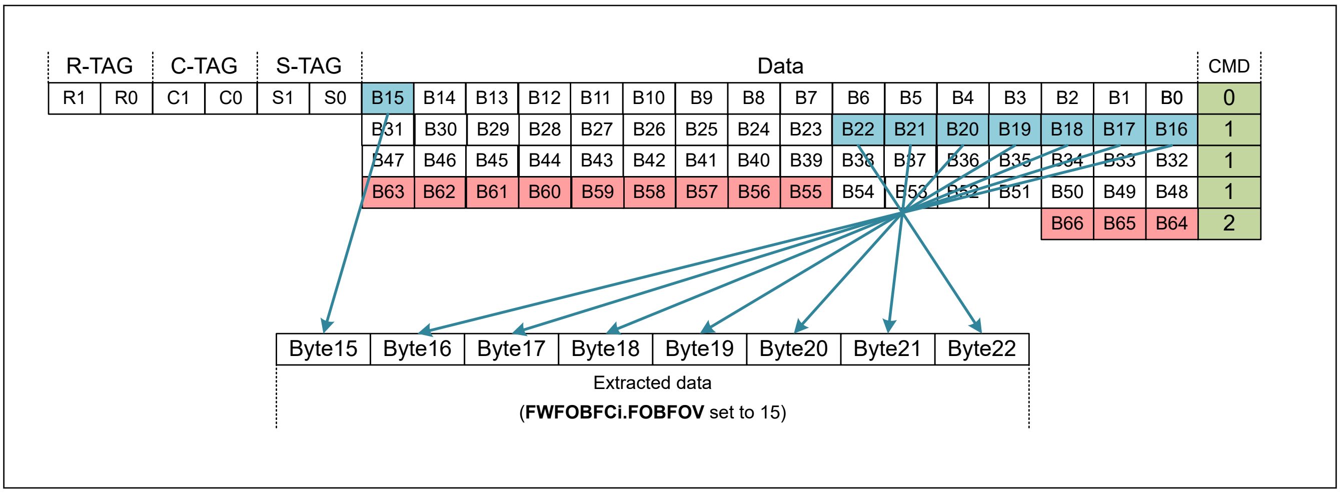

Figure 30.67 4-byte filter data extraction for filtering

For 4-byte filters:

- Data bytes from byte FWFOBFCi.FOBFOV to byte FWFOBFCi.FOBFOV+7 are extracted for filtering.

Note:
- HW: The data for filtering in 4-byte filters can only be extracted until the first seven bytes in the penultimate beat of data (first seven bytes of the last time CMD is equal to 1. In Figure 30.67, the bytes colored in red are the none-extractible bytes for filtering). I.e. the offset filtering will only be effective if the offset value is set until the last byte of the antepenultimate beat of data (the last before last time CMD is equal to 1. Byte 47 in Figure 30.67).
- HW: A filter with a setting that should use non-extractible data for filtering will always unmatched.

(b) Extracted data filtering

A 4-byte filter has three modes to filter extracted data. Figure 30.68 describes these modes.

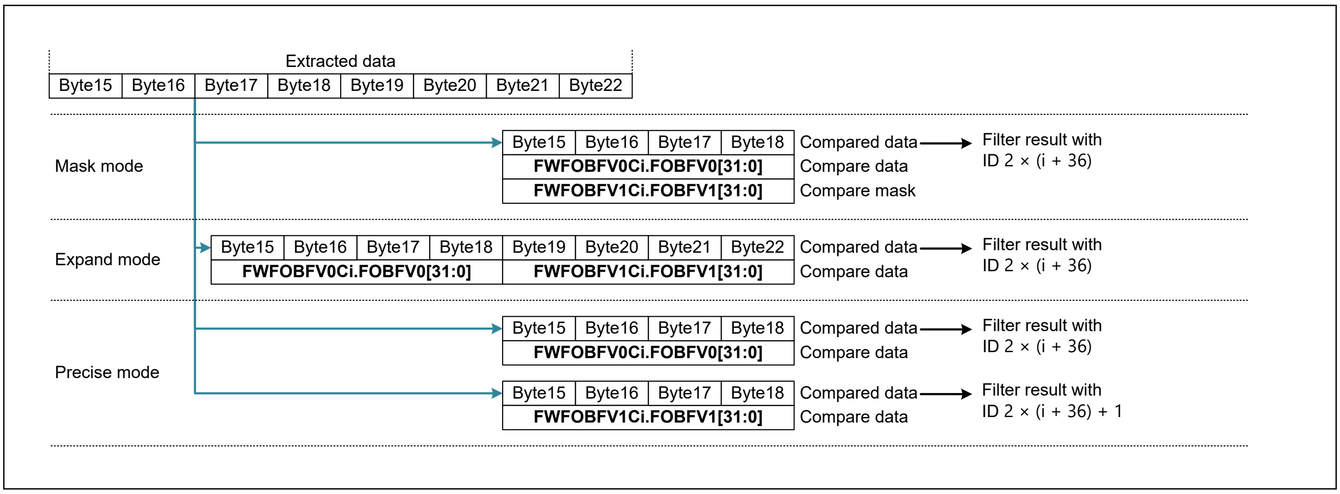

Figure 30.68 4-byte filter data extraction for filtering

In mask mode (FWFOBFCi.FOBFUM[1:0] == 00b):

- The first four bytes of the extracted data are compared to FWFOBFV0Ci.FOBFV0[31:0] using FWFOBFV1Ci.FOBFV1[31:0] as a mask (when a bit is set to 1, the corresponding bit is not used for comparison). The result is associated to 2 × (i + 36) filter ID.

In Expand mode (FWFOBFCi.FOBFUM[1:0] == 01b):

- The eight-byte extracted data is compared to {FWFOBFV0Ci.FOBFV0[31:0],FWFOBFV1Ci.FOBFV1[31:0]}. The result is associated to 2 × (i + 36) filter ID.

In Precise mode (FWFOBFCi.FOBFUM[1:0] == 10b):

- The first three bytes of the extracted data are compared to FWFOBFV0Ci.FOBFV0[31:0]. The result is associated to 2 × (i + 36) filter ID.
- The first three bytes of the extracted data are compared to FWFOBFV1Ci.FOBFV1[31:0]. The result is associated to 2 × (i + 36) + 1 filter ID.

(4) Range filters

A Range filter aims at filtering a specific a portion of a frame and happens in two steps, the data extraction and the filtering.

(a) Data extraction for filtering

A Range filter has two modes to extract the data from a frame. Figure 30.69 describes these modes using examples.

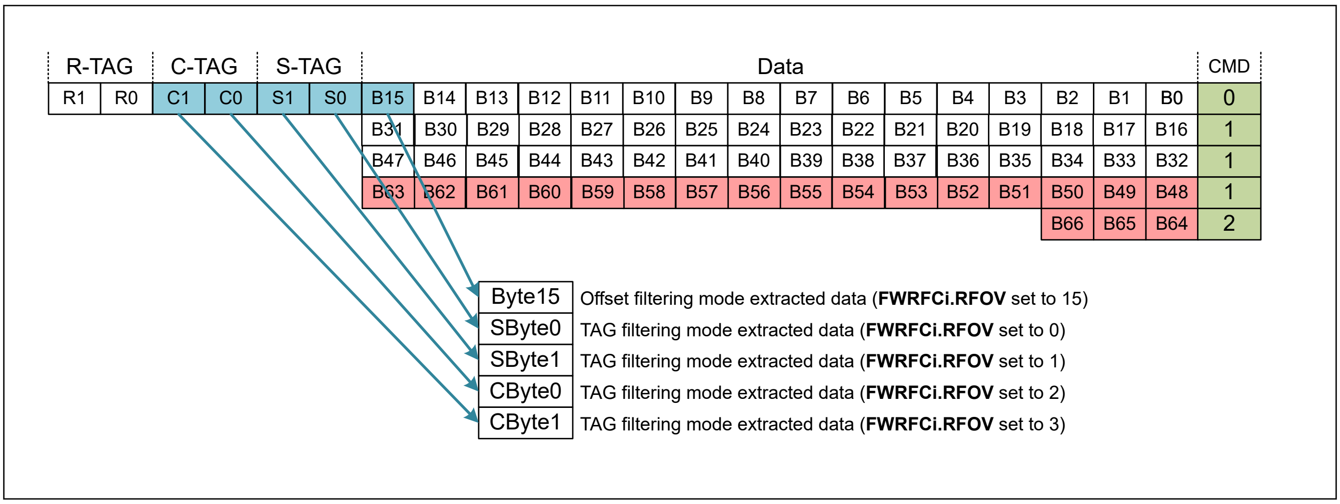

Figure 30.69 Range filter data extraction for filtering

In Offset filtering mode (FWRFCi.RFM == 0):

- Data byte FWRFCi.RFOV is extracted for filtering.

In TAG filtering mode (FWRFCi.RFM == 1):

- If FWRFCi.RFOV is set to 0, VLAN S-TAG VID upper 4 bits are extracted for filtering (PCP and DEI are fixed to 0).
- If FWRFCi.RFOV is set to 1, VLAN S-TAG VID lower 8 bits are extracted for filtering.
- If FWRFCi.RFOV is set to 2, VLAN C-TAG VID upper 4 bits are extracted for filtering (PCP and DEI are fixed to 0).
- If FWRFCi.RFOV is set to 3, VLAN C-TAG VID lower 8 bits are extracted for filtering.

Restrictions:

Note:
- HW: PCP and DEI values in C-TAGs and S-TAGs are ignored by the range filter (Set to 0).
- HW: The data for filtering in range filters can only be extracted until the antepenultimate beat of data (the last before last time CMD is equal to 1. In Figure 30.69, the bytes colored in red are the none-extractible bytes for filtering). I.e. the offset filtering will only be effective if the offset value is set until the last byte of the antepenultimate beat of data (the last before last time CMD is equal to 1. Byte 47 in Figure 30.69).
- HW: A filter with a setting that should use non-extractible data for filtering will always unmatched.

(b) Extracted data filtering

A Range filter has one mode to filter extracted data. Figure 30.70 describes this mode.

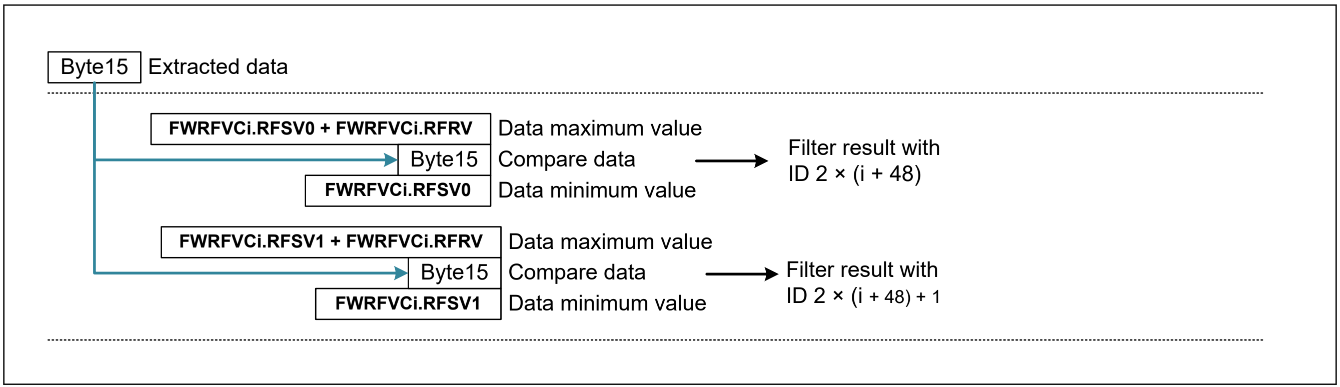

Figure 30.70 Range filter data extraction for filtering

For Range filters:

- The one-byte extracted data is checked to be included in [FWRFVCi.RFSV0: FWRFVCi.RFSV0 + FWRFVCi.RFRV]. The result is associated to 2 × (i + 48) filter ID.
- The one-byte extracted data is checked to be included in [FWRFVCi.RFSV1: FWRFVCi.RFSV1 + FWRFVCi.RFRV]. The result is associated to 2 × (i + 48) + 1 filter ID.

(5) Cascade filters

A Cascade filter aims at gathering several filter results (from 2-byte, 3-byte, 4byte and Range filters) to regroup them to create a stream ID. The number of cascade filters defines the number of possible stream IDs in the perfect filter 16.

Functions:

- FWCFMCij register is used to map until 7 filters results to cascade filter i.
- FWCFCi register is used to select from which port the stream is expected and with which type of frame (p or e)
- If several cascade filters match the same frame, the cascade filter with the highest number will be selected.
- If a cascade filter matches a frame, a frame format code of 3 bits equal to 0 is associated to the frame.

Cascade filter stream ID:

- When cascade filter i matches a frame, the stream ID associated to this frame will be a 131-bit stream ID equal to {frame format code,128’di}.

(6) Perfect filter utilization example

Figure 30.71 contains an example of perfect filter utilization. In this example, the user wants to filter a frame which:

- Has a stream ID based on MAC destination address, and VLAN C-TAG.
- Has a MAC destination address equal to ‘hAABBCCDDEEFF.
- Has a VLAN C-TAG equal to ABCD.
- Is known to be and IPv4 frame (IPv4 type is added in filtering for security).

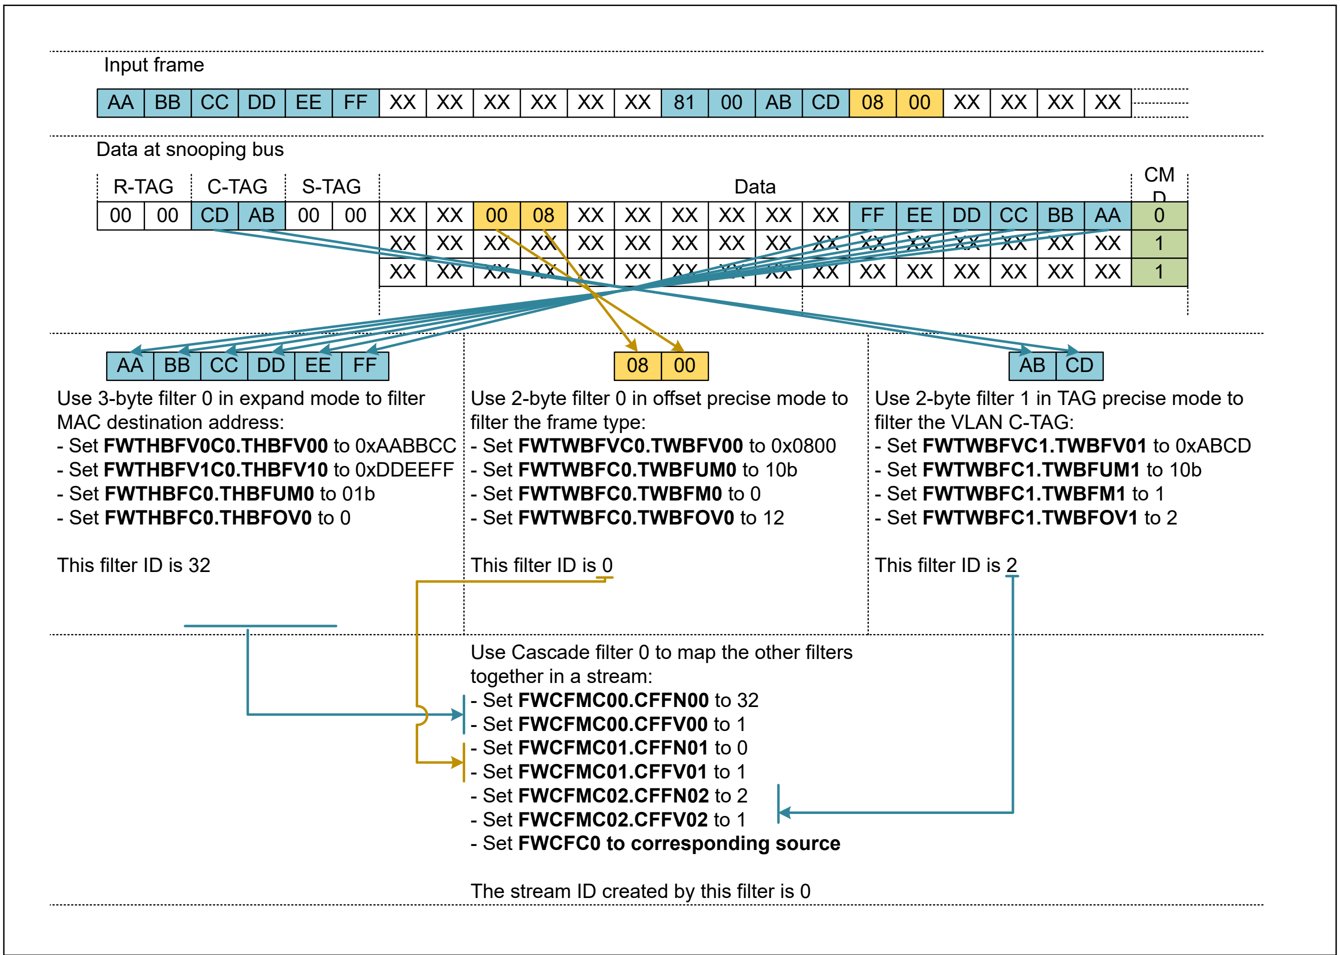

Figure 30.71 Perfect filter utilization example

30.5.2.4.2 IPv4/IPv6 Hash Stream Filter

The Hash filter is used to identify streams. This filter has the advantage to be able to generate a big number of streams but, because of the use of hash, can have some stream ID collision problem (that should be resolved using the perfect filter).

The Hash filter block diagram is represented in Figure 30.72.

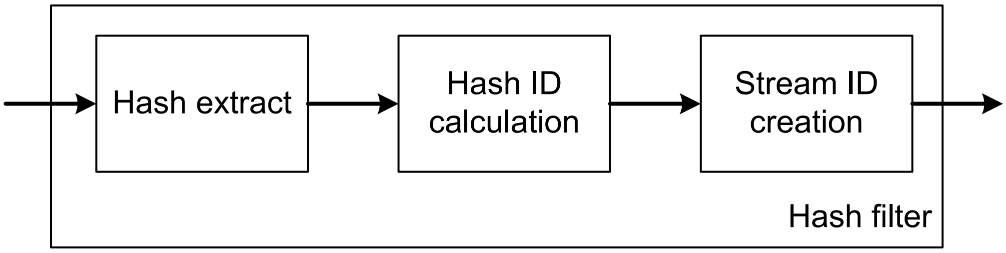

Figure 30.72 Hash filter block diagram

The Hash filtering happens in Three steps:

- The first step is done by Hash extract. It consists in extracting all the possible field for the IPv4/IPv6 stream ID creation.
- The second step is done by Hash ID calculation. It consists in calculating the hash ID associated to each frame depending on the extracted data and the fields chosen by user for Hash.
- The third step is done by Stream ID creation. It consists in the stream ID assembling depending on the fields chosen by user.

(1) Hash extract

The Hash extract is used to extract the Stream IDs from IPv4 and IPv6 frames to create their associated stream ID. The extraction happens on six formats which are IPv4, IPv4/TCP, IPv4/UDP, IPv6, IPv6/TCP and IPv6/UDP.

Note: • HW: Hash extract will ignore any data received from Fabric [MFAB] with command 2.

(a) IPv4 detection and data extraction

Figure 30.73 describes how IPv4 detection and data extraction happens. This data extraction happens only if the frame did not match a cascade filter, if the frame format decode condition are satisfied and if FWPCi0.IP4OE is set for the corresponding source port. In this case, a frame format code of 3 bits equal to 1 is associated to the frame.

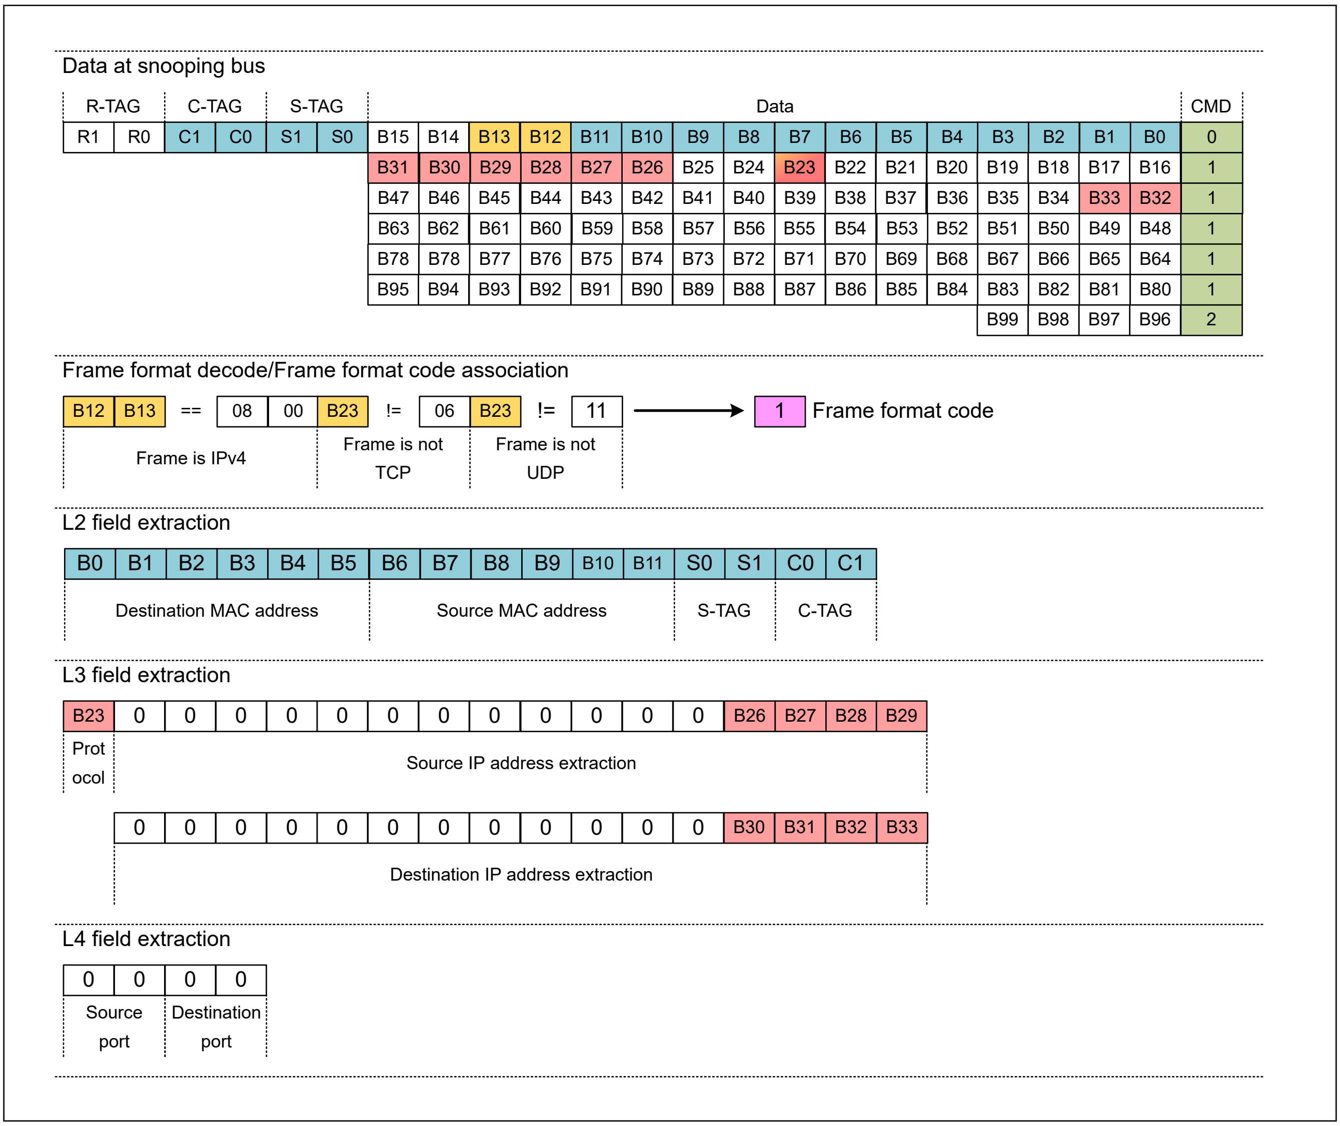

Figure 30.73 IPv4 detection and data extraction

(b) IPv4/UDP detection and data extraction

Figure 30.74 describes how IPv4/UDP detection and data extraction happens. This data extraction happens only if the frame did not match a cascade filter, if the frame format decode condition are satisfied and if FWPCi0.IP4UE is set for the corresponding source port. In this case, a frame format code of 3 bits equal to 2 is associated to the frame.

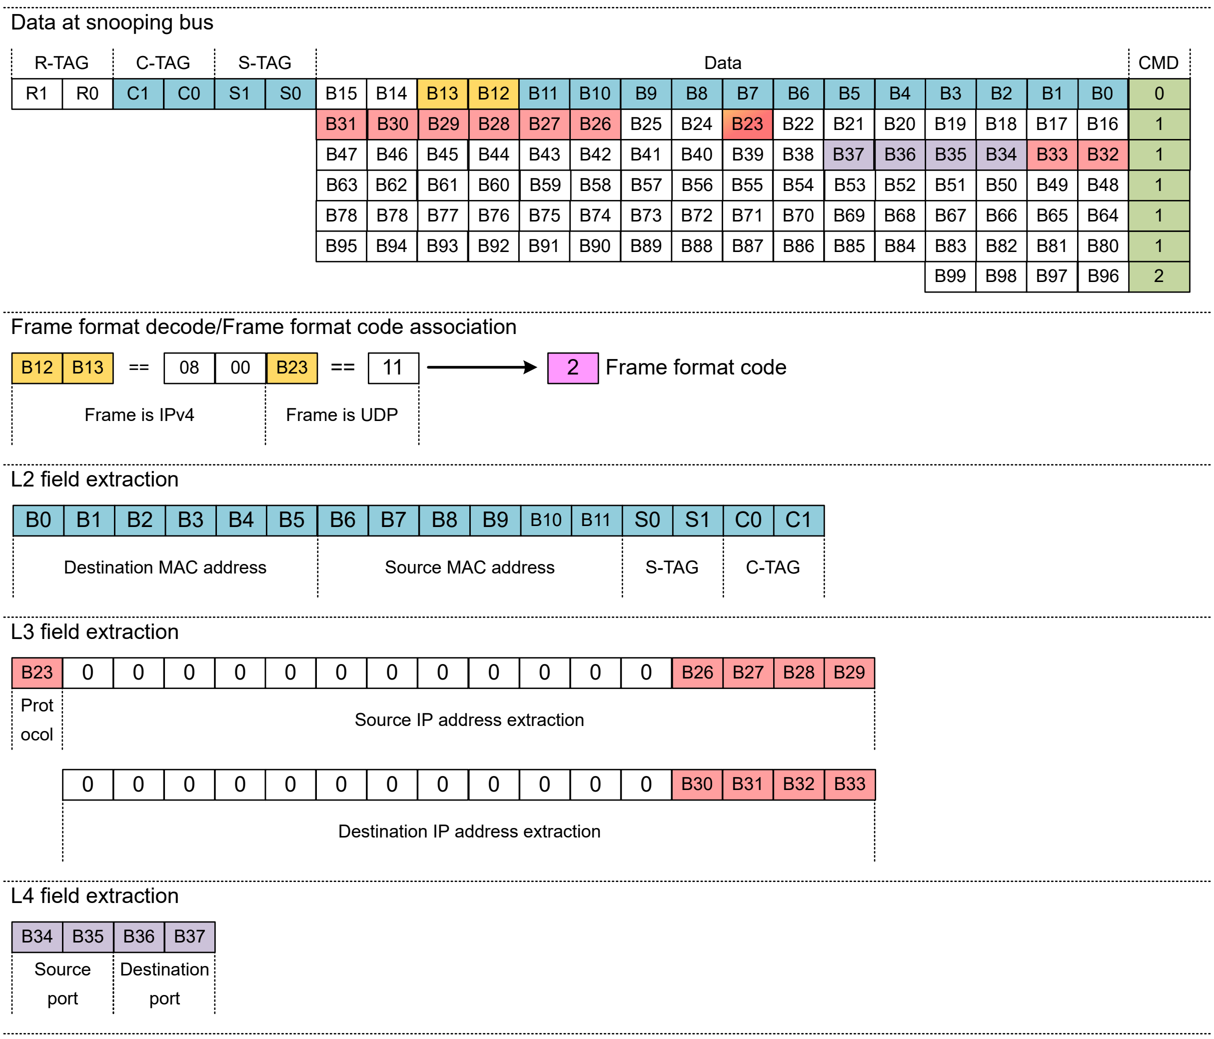

Figure 30.74 IPv4/UDP detection and data extraction

Function:

- The L4 extraction function takes in account the IPv4 HeaderLength field. Figure 30.74 only describes the case where HeaderLength is equal to 5 (default value).

(c) IPv4/TCP detection and data extraction

Figure 30.75 describes how IPv4/TCP detection and data extraction happens. This data extraction happens only if the frame did not match a cascade filter, if the frame format decode condition are satisfied and if FWPCi0.IP4TE is set for the corresponding source port. In this case, a frame format code of 3 bits equal to 3 is associated to the frame.

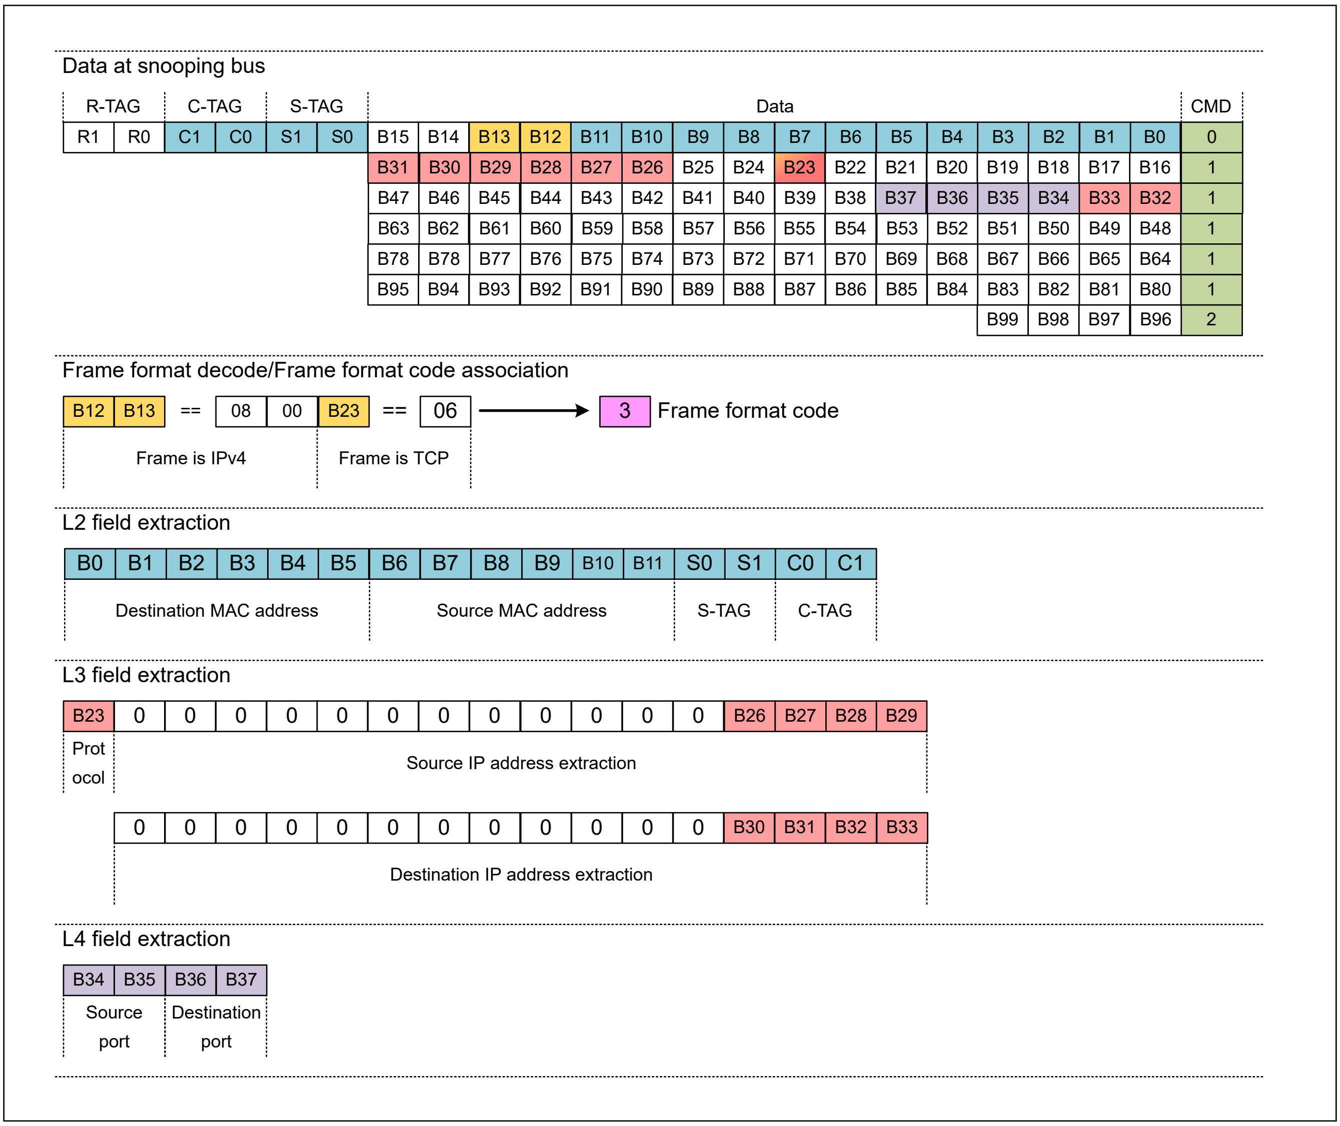

Figure 30.75 IPv4/TCP detection and data extraction

Function:

- The L4 extraction function takes in account the IPv4 HeaderLength field. Figure 30.75 only describes the case where HeaderLength is equal to 5 (default value).

(d) IPv6 detection and data extraction

Figure 30.76 describes how IPv6 detection and data extraction happens. This data extraction happens only if the frame did not match a cascade filter, if the frame format decode condition are satisfied and if FWPCi0.IP6OE is set for the corresponding source port. In this case, a frame format code of 3 bits equal to 4 is associated to the frame.

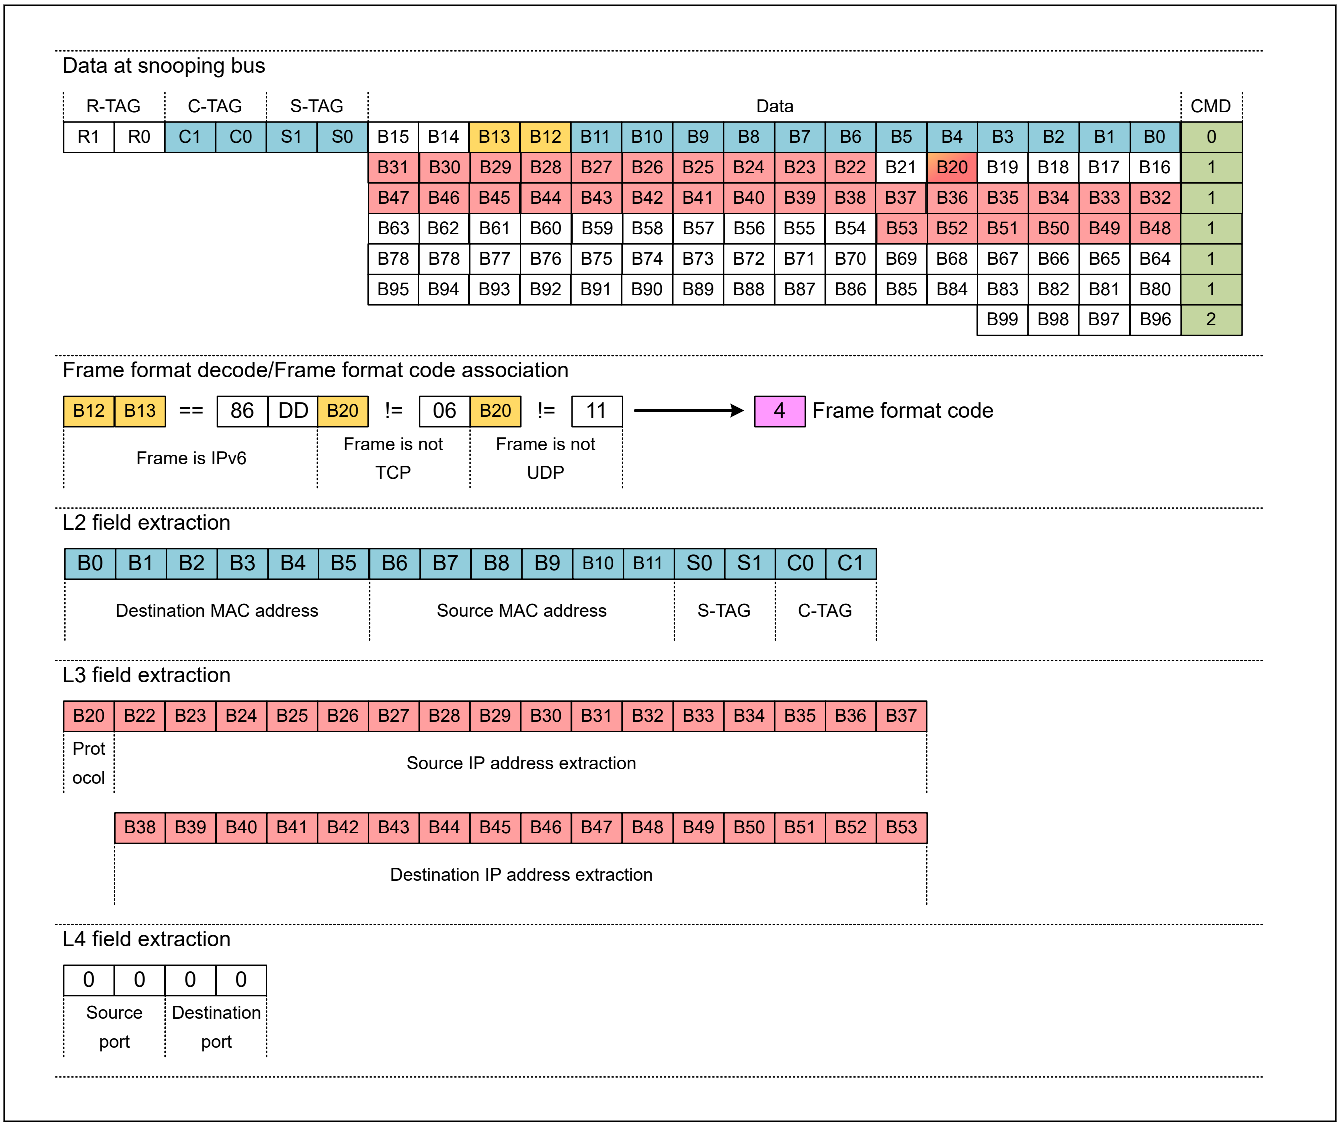

Figure 30.76 IPv6 detection and data extraction

(e) IPv6/UDP detection and data extraction

Figure 30.77 describes how IPv6/UDP detection and data extraction happens. This data extraction happens only if the frame did not match a cascade filter, if the frame format decode condition are satisfied and if FWPCi0.IP6UE is set for the corresponding source port. In this case, a frame format code of 3 bits equal to 5 is associated to the frame.

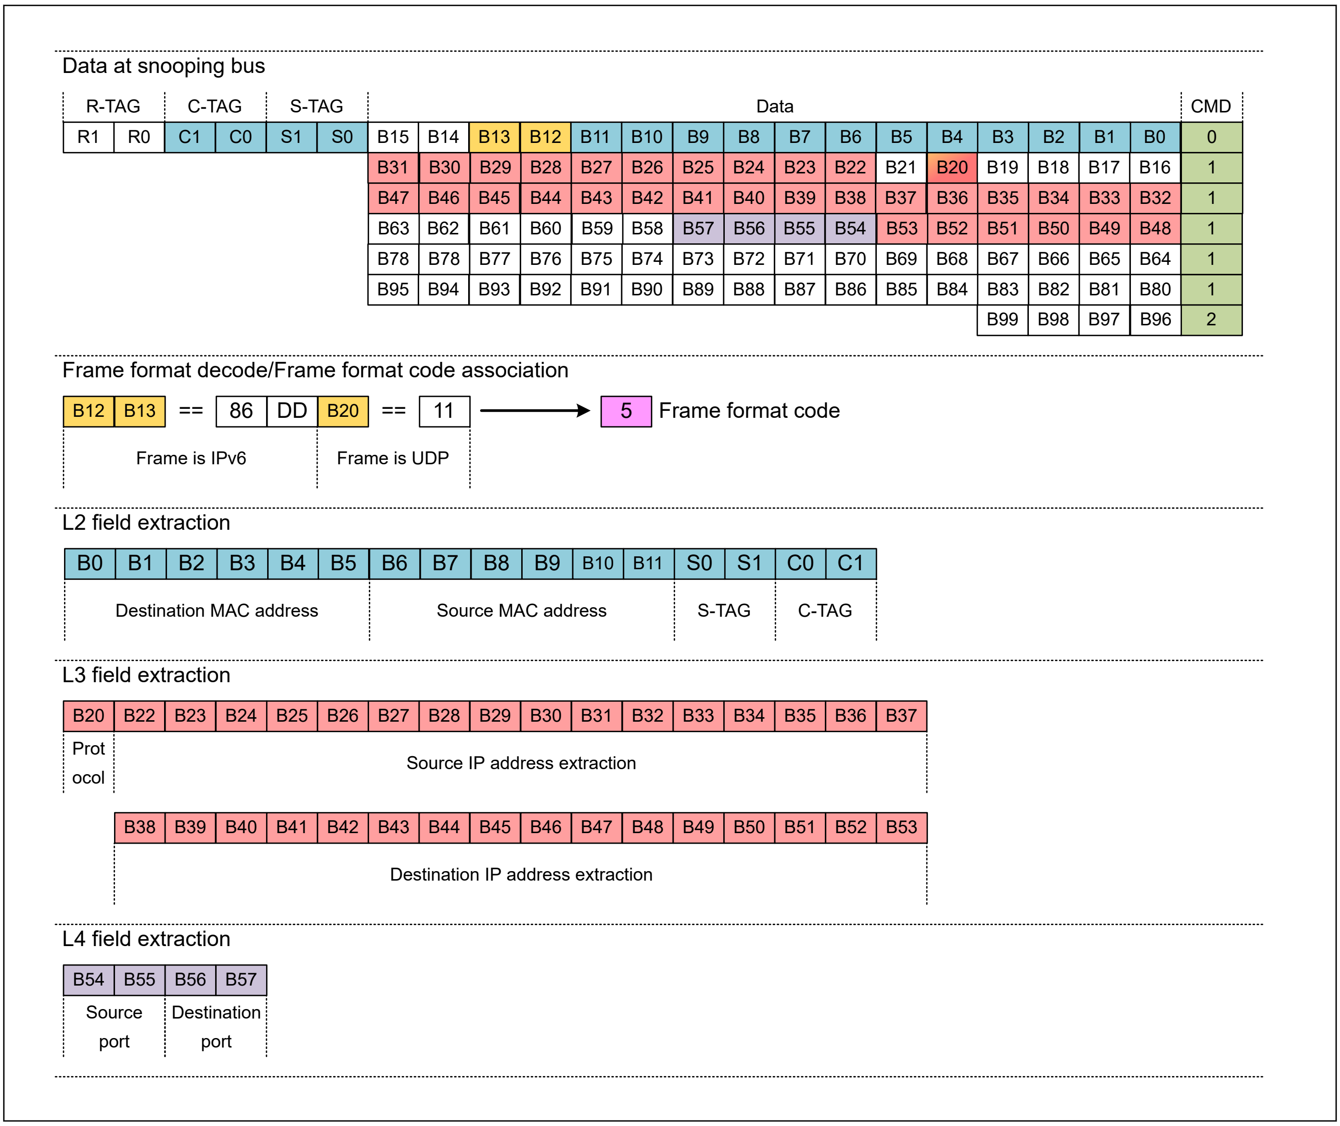

Figure 30.77 IPv6/UDP detection and data extraction

(f) IPv6/TCP detection and data extraction

Figure 30.78 describes how IPv6/TCP detection and data extraction happens. This data extraction happens only if the frame did not match a cascade filter, if the frame format decode condition are satisfied and if FWPCi0.IP6TE is set for the corresponding source port. In this case, a frame format code of 3 bits equal to 6 is associated to the frame.

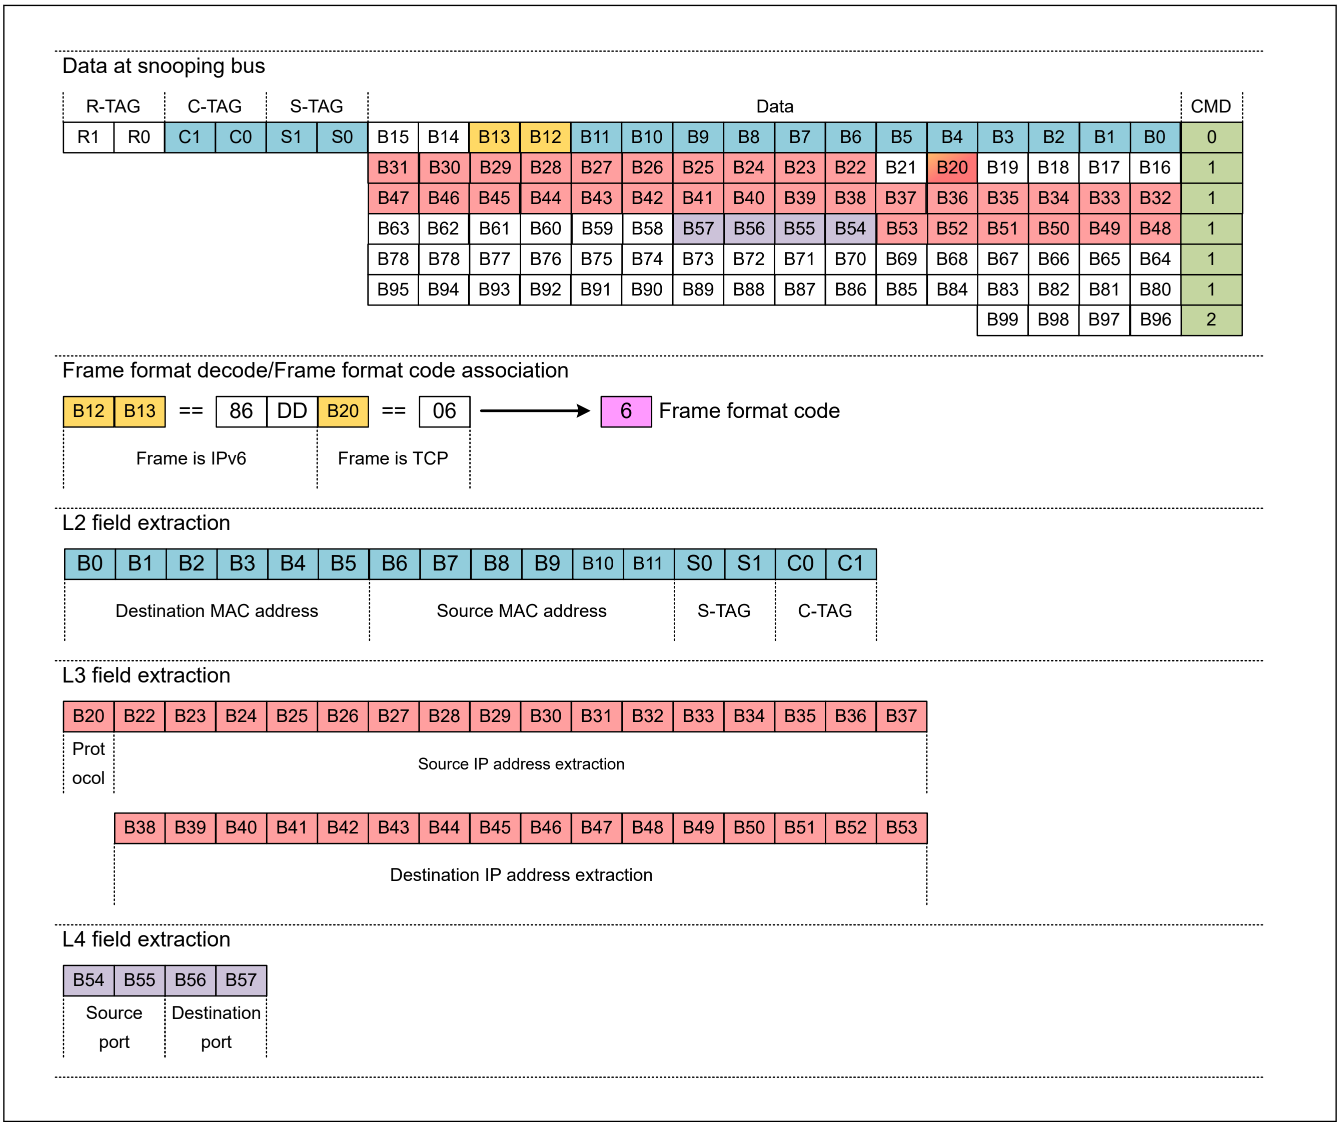

Figure 30.78 IPv6/TCP detection and data extraction

(2) Hash ID calculation

The Hash ID calculation is used to select the interesting fields for the Hash ID (security purpose) and to calculate the hash ID.

(a) Hash equation

Refer to FWSFHEC register explanation.

(b) IPv4 Hash ID calculation

The IPv4 Hash ID calculation is done depending on extracted fields in Hash extract. The calculation is described in Figure 30.79.

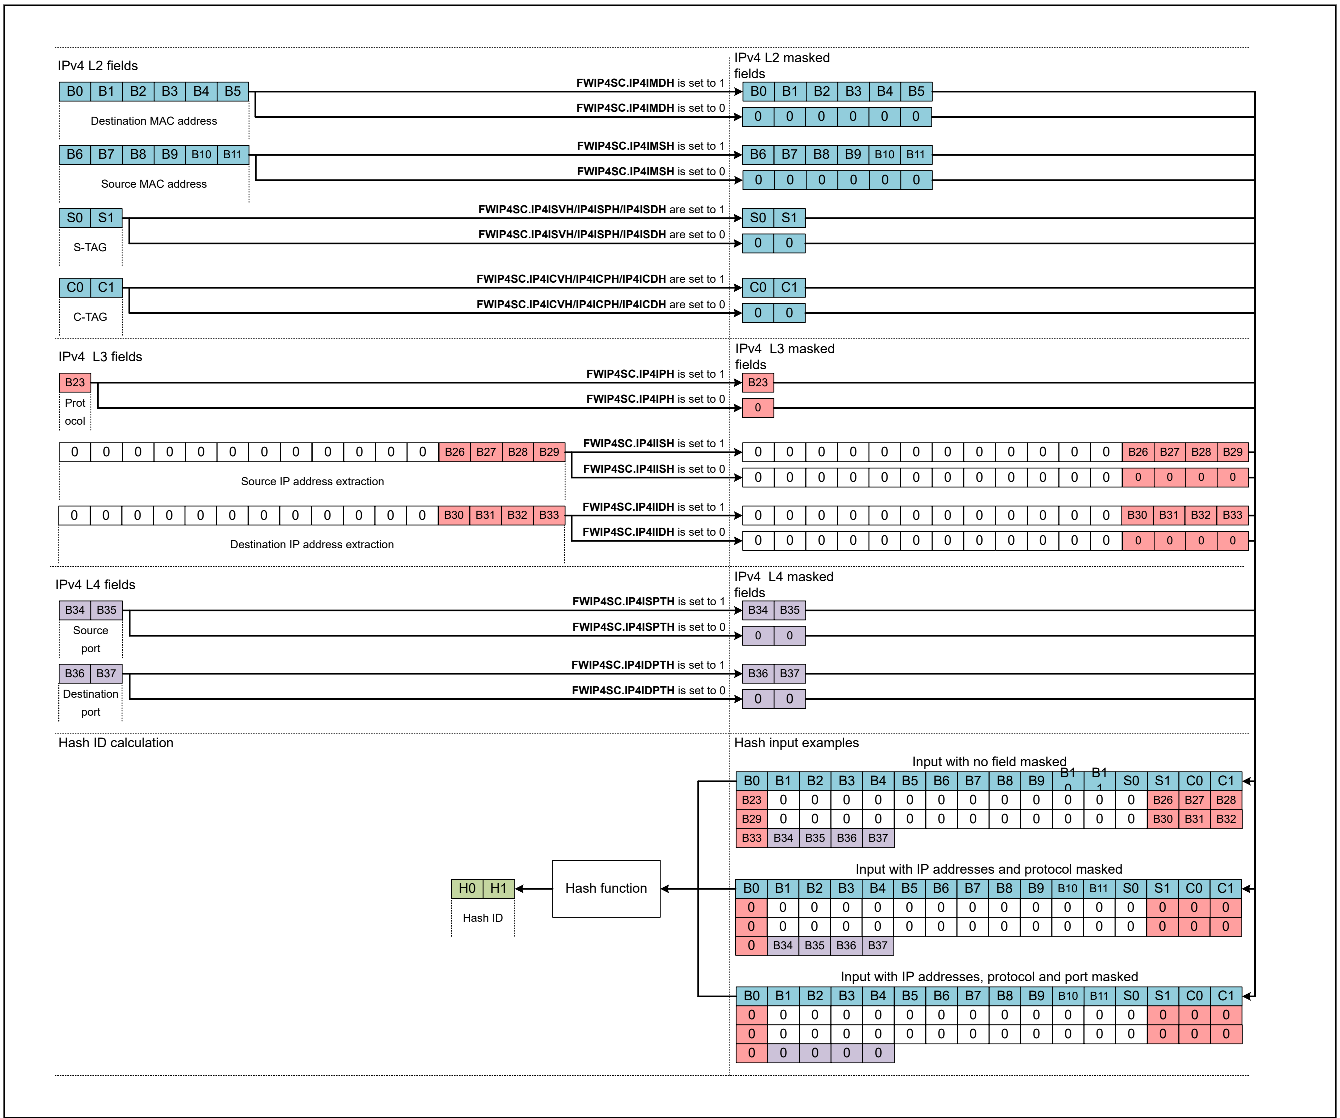

Figure 30.79 IPv4 Hash ID calculation

Functions:

- In Figure 30.79, The C-TAG and S-TAG masking is represented done at once, but masking is possible independently on PCP, DEI and VID.
- Setting all the field inclusion bits for Hash to 0 will fix the Hash ID to 0 in the stream (FWIP4SC.IP4IDPTH/IP4ISPTH/IP4IPH/IP4IIDH/IP4IISH/IP4ICDH/IP4ICPH/IP4ICVH/IP4ISDH/IP4ISPH/IP4ISVH/IP4IMSH/IP4IMDH).
- Setting the hash equation to 0 will fix the Hash ID to 0 in the stream (FWSFHEC.IP4HE).

(c) IPv6 Hash ID calculation

The IPv6 Hash ID calculation is done depending on extracted fields in Hash extract. The calculation is described in Figure 30.80.

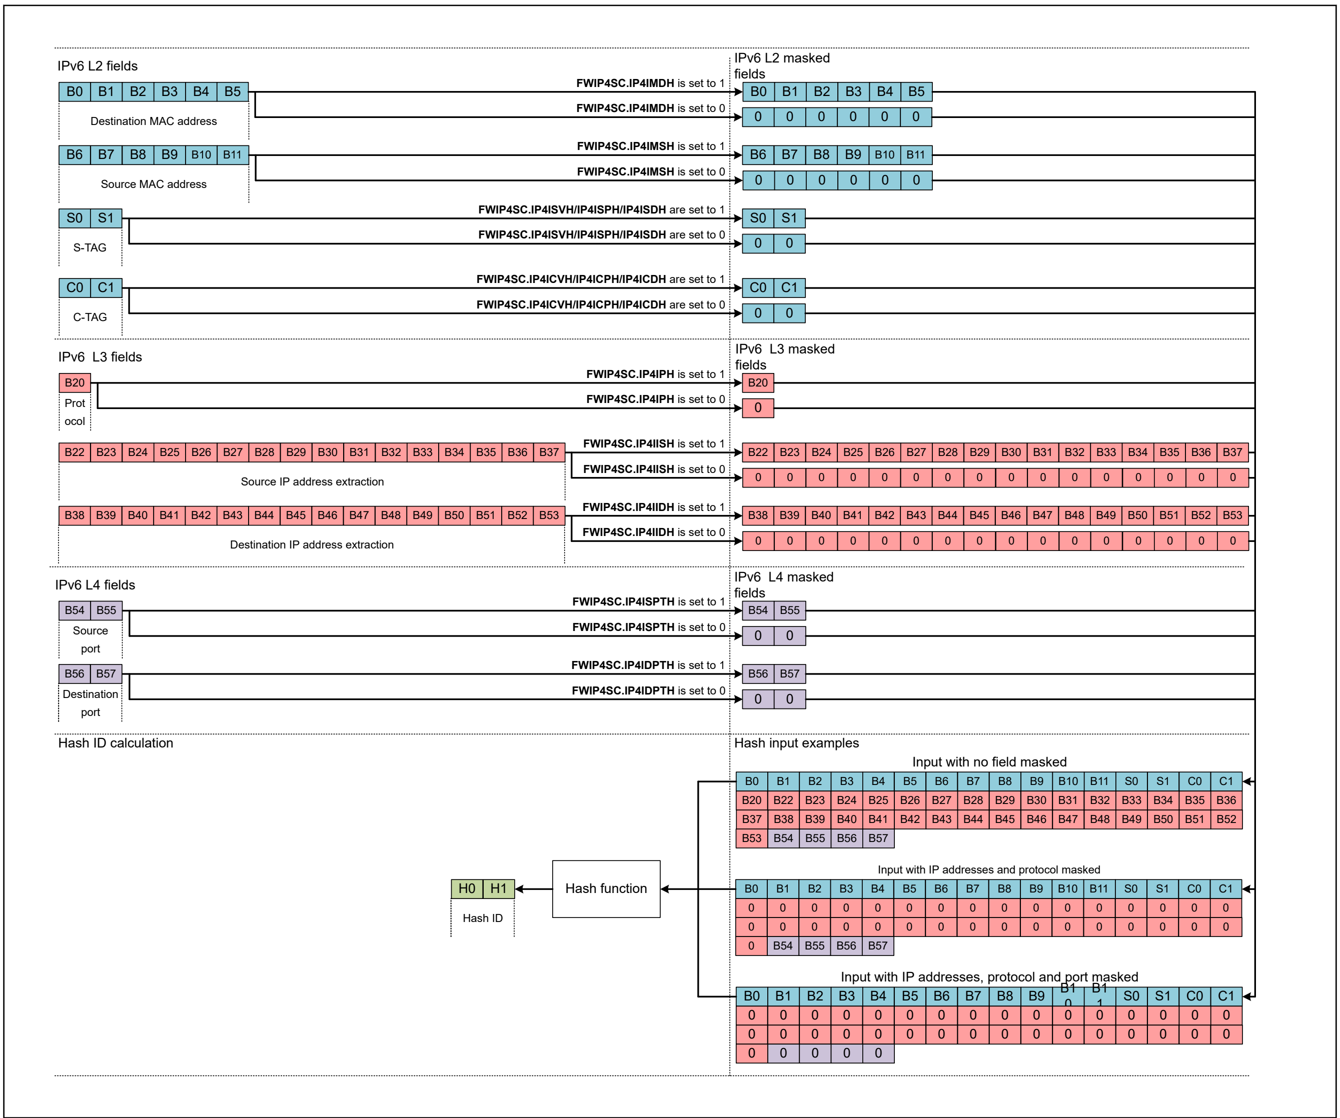

Figure 30.80 IPv6 Hash ID calculation

Functions:

- In Figure 30.80, The C-TAG and S-TAG masking is represented done at once, but masking is possible independently on PCP, DEI and VID.
- Setting all the field inclusion bits for Hash to 0 will fix the Hash ID to 0 in the stream (FWIP6SC.IP6IDPTH/IP6ISPTH/IP6IPH/IP6IIDH/IP6IISH/IP6ICDH/IP6ICPH/IP6ICVH/IP6ISDH/IP6ISPH/IP6ISVH/IP6IMSH/IP6IMDH)
- Setting the hash equation to 0 will fix the Hash ID to 0 in the stream (FWSFHEC.IP6HE)

(3) Stream ID creation

(a) IPv4 Stream ID creation

The IPv4 Stream ID is assembled from some of the extracted fields in Hash extract, the Hash ID calculated in Hash ID calculation and the frame format code. The stream ID creation is described in Figure 30.81.

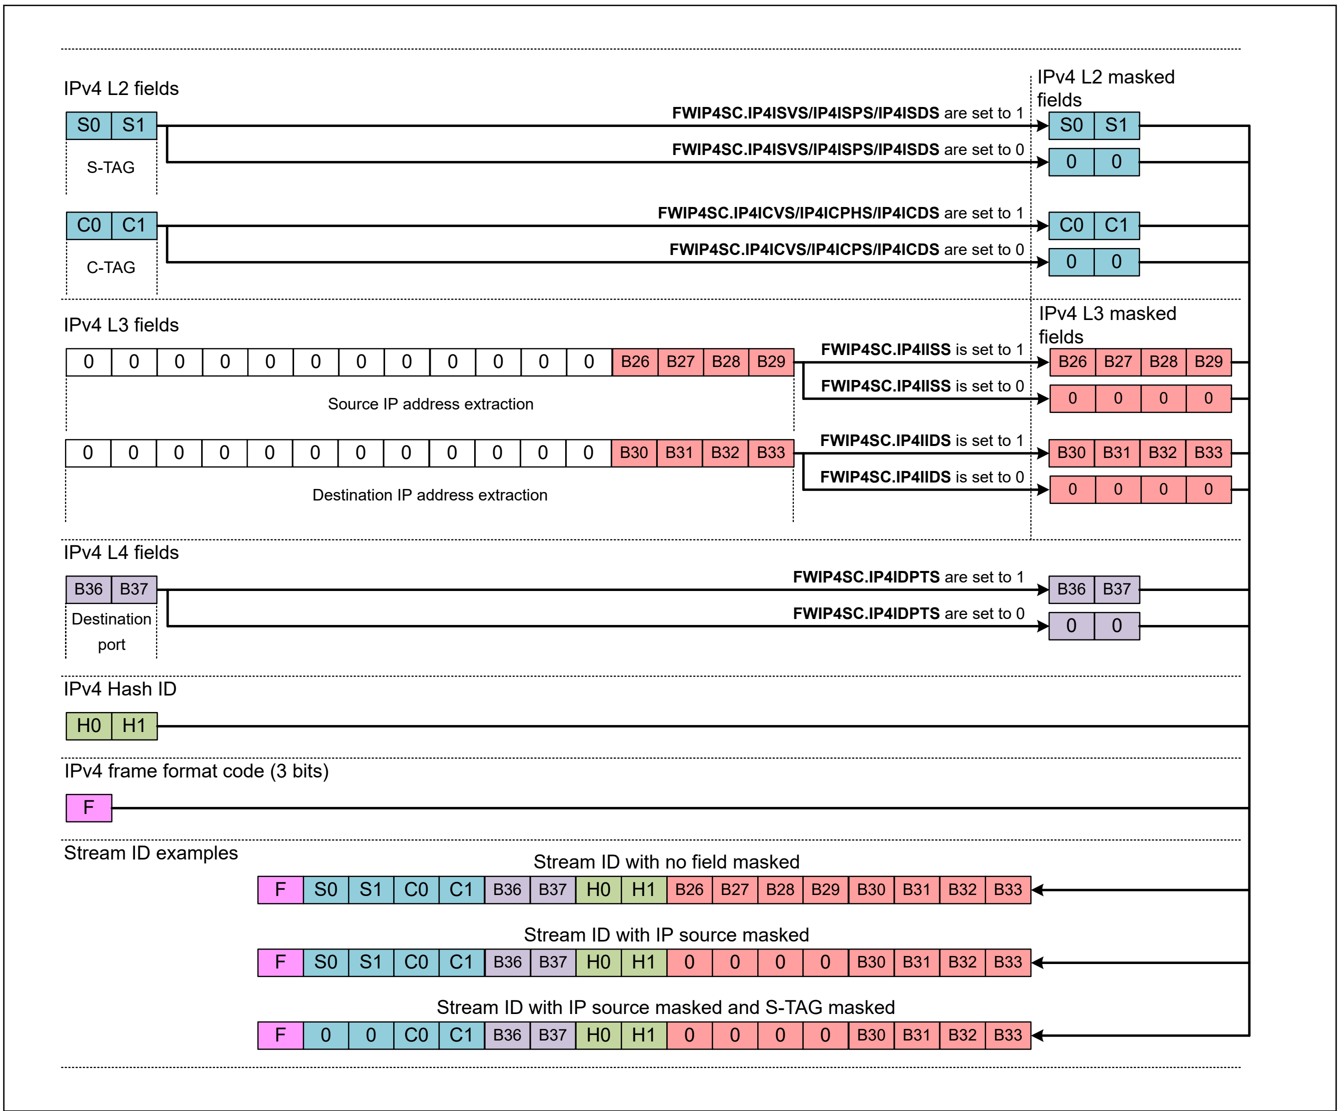

Figure 30.81 IPv4 Stream ID creation

Functions:

- In Figure 30.81, The C-TAG and S-TAG masking is represented done at once, but masking is possible independently on PCP, DEI and VID.
- The Stream ID field (FWLTHTL1-4) should be configured as 0 related to disabled part (bits) with “Stream in (FWIP4SC.IP4IDPTS/IP4IIDS/IP4IISS/IP4ICDS/IP4ICPS/IP4ICVTS/IP4ISDS/IP4ISPS/IP4ISVS) = 0x0”

(b) IPv6 Stream ID creation

The IPv6 Stream ID is assembled from some of the extracted fields in Hash extract, the Hash ID calculated in Hash ID calculation and the frame format code. The stream ID creation is described in Figure 30.82.

Figure 30.82 IPv6 Stream ID creation

Functions:

- In Figure 30.82, The C-TAG and S-TAG masking is represented done at once, but masking is possible independently on PCP, DEI and VID.
- In Figure 30.82, IP 0 is extracted from IPv6 source IP address and IP 1 is extracted from destination IP address, but it both can extract their 4 bytes from any of the IP addresses. This setting is done through FWIP6OC register.
- The Stream ID field (FWLTHTL1-4) should be configured as 0 related to disabled part (bits) with “Stream in (FWIP6SC.IP6IDPTS/IP6II1S/IP6II0S/IP6ICDS/IP6ICPS/IP6ICVS/IP6ISDS/IP6ISPS/IP6ISVS) = 0x0”

(4) Software Hash ID calculation

Because hash ID calculation is complex to implement in software, a hardware accelerator is available for hash ID calculation. Figure 30.83 gives software hash ID calculation examples.

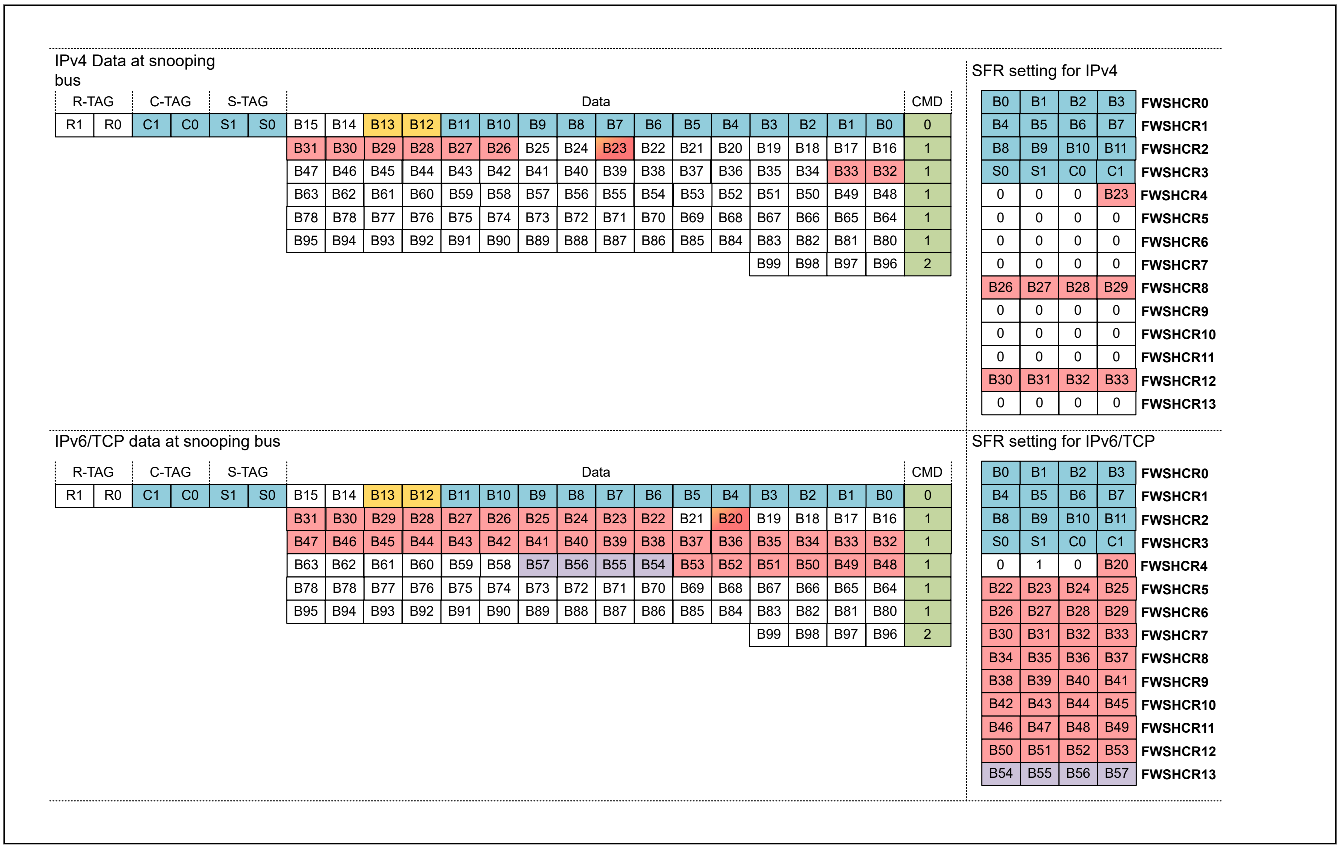

Figure 30.83 Software hash ID calculation example

Note: SW: For software hash ID calculation, the software should set to 0 the fields that are masked by the Hash ID calculation function.

30.5.2.4.3 L2 Stream Filter

The L2 stream filter is used to create a stream based on L2 fields. This stream creating happens only if the frame did not match a cascade filter or an IPv4/IPv6 hash stream filter and if FWPCi0.L2SE is set for the corresponding source port. In this case, a frame format code of 3 bits equal to 7 is associated to the frame. Figure 30.84 describes how the L2 stream ID is created.

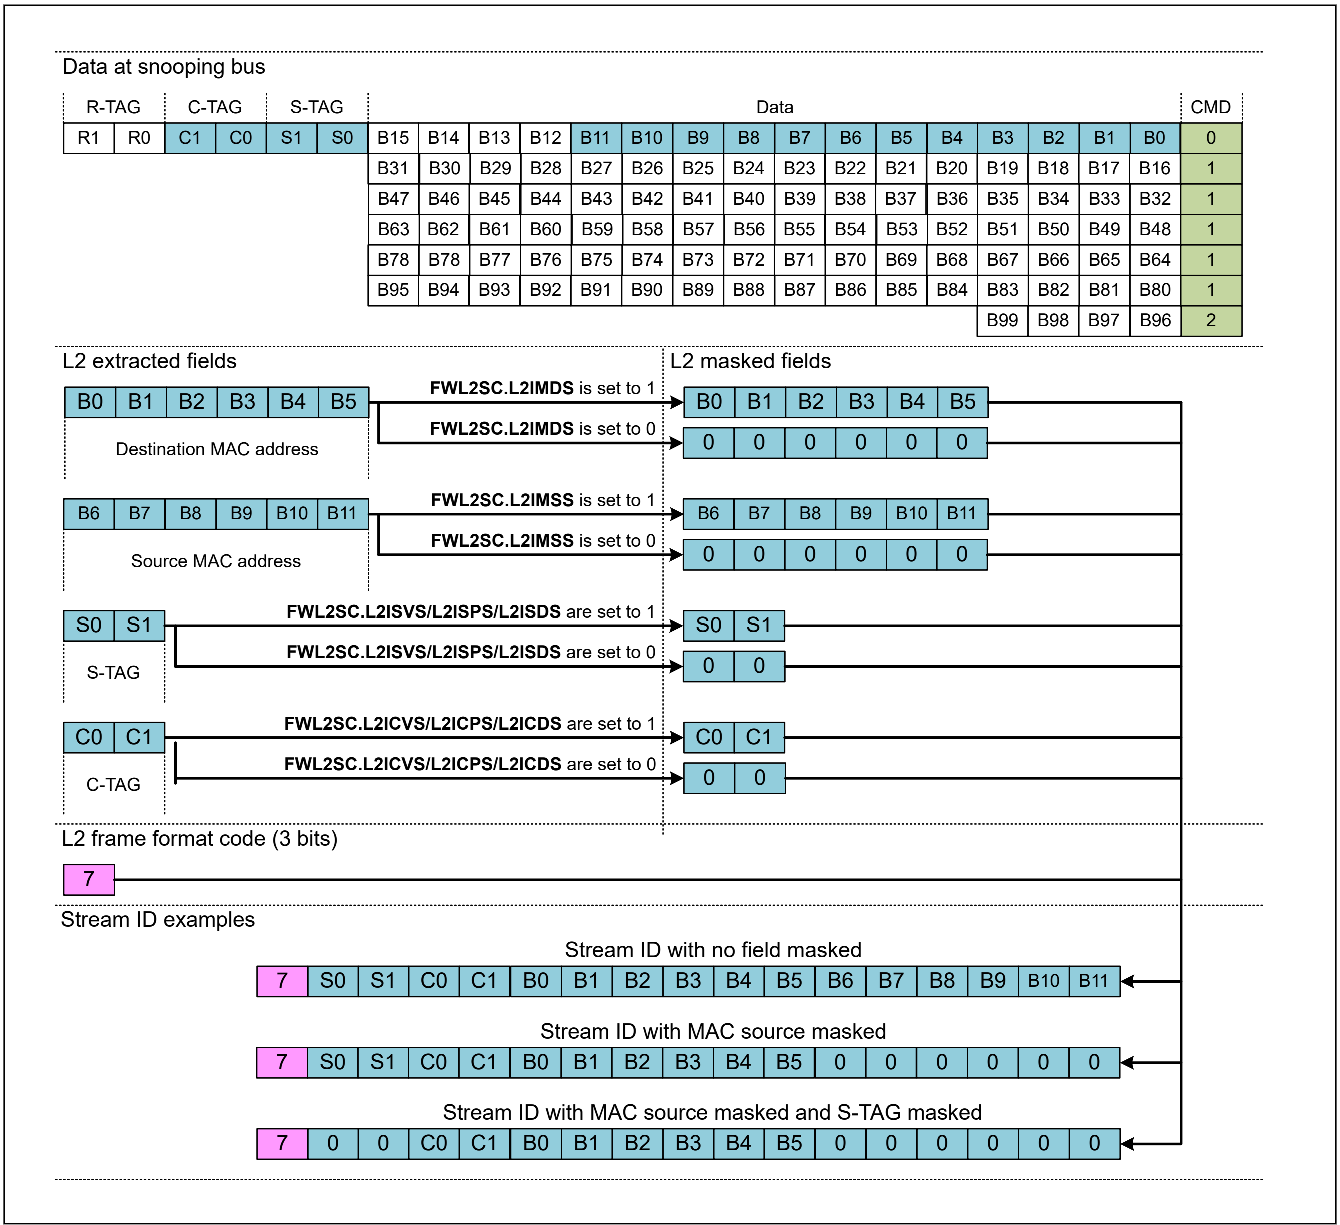

Figure 30.84 L2 stream ID creation

Functions:

- In Figure 30.84, The C-TAG and S-TAG masking is represented done at once, but masking is possible independently on PCP, DEI and VID.
- A frame which did not match a cascade filter, an IPv4/IPv6 hash stream filter or the L2 stream filter is considered an unknown frame.
- The Stream ID field (FWLTHTL1-4) should be configured as 0 related to disabled part (bits) with “Stream in (FWL2SC.L2ICDS/L2ICPS/L2ICVS/L2ISDS/L2ISPS/L2ISVS/L2IMSS/L2IMDS) = 0x0”.

30.5.2.4.4 L3 Hash

L3 hash aims at searching/learning/reading L3 rules thanks to a programmable hash. The hash algorithm is able to solve all the collisions in hardware, so it does not need any software intervention to operate.

L3 hash is divided in the following items:

- Rule format: Determines what information will be store along with the stream ID in the table.
- SW Learning: Function to add/suppress an entry from the L3 table by software.

- Hash maximum collision number: Avoids hash search to slow down the forwarding pipeline and apply back pressure on the ingress ports.
- Hash equation: Function to set hash calculation to minimize collisions.
- SW Searching: Function to find the forwarding/routing/filtering information related to a stream by software.
- SW Reading: Function to read the entries in the L3 table by software.
- HW searching: Function to find the forwarding/routing/filtering information related to a stream by forwarding mechanism.

(1) Rule format

The L3 table is used to store L3 rules. A L3 rule contains the information the frame forwarding, routing and filtering. All the fields in this table, if quoted, will be written L3.{Field name}. Table 30.28 describes fields contained in a L3 rule.

Table 30.28 L3 rule format (1 of 2)

Field name	Field size (bit)	Field Explanation
EV	1	Entry Valid Values: ● 0: Entry is not valid ● 1: Entry is valid
SID	131	Stream ID of the entry. The stream ID is created in perfect filter, IPv4/IPv6 hash stream filter or L2 stream filter (respectively refer to section (5) Cascade filters, section (3) Stream ID creation and section section 30.5.2.4.3. L2 Stream Filter)
SL	1	Security Level Values: ● 0: Entry is unsecure ● 1: Entry is secure
MSDUV	1	MSDU Valid Values: ● 0: Frames matching this entry will be ignored by PSFP MSDU filter. ● 1: Frames matching this entry will be processed by PSFP MSDU filter.
MSDUN	4	MSDU Number Functions: ● HW: If corresponding entry L3.MSDUV value is set to 1, frames matching this entry will be processed by PSFP MSDU filter number L3.MSDUN.
MTRV	1	Meter Valid Values: ● 0: Frames matching this entry will be ignored by PSFP Meter filter. ● 1: Frames matching this entry will be processed by PSFP Meter filter.
MTRN	5	Meter Number Functions: ● HW: If corresponding entry L3.MTRV value is set to 1, frames matching this entry will be processed by PSFP MSDU filter number L3.MTRN.
FRERV	1	FRER Valid Values: ● 0: Frames matching this entry will be ignored by FRER individual recovery. LINK ● 1: Frames matching this entry will be processed by FRER individual recovery. LINK
FRERN	7	FRER Number Functions: ● HW: If corresponding entry L3.FRERV value is set to 1, frames matching this entry will be processed by FRER entry number L3.FRERN for individual recovery.
RV	1	Routing Valid Values: ● 0: Frames matching this entry will be ignored by routing. ● 1: Frames matching this entry will be processed by routing.
RN	8	Routing Number Functions: ● HW: If corresponding entry L3.RV value is set to 1, frames matching this entry will be processed by routing rule number L3.RN.

Table 30.28 L3 rule format (2 of 2)

Field name	Field size (bit)	Field Explanation
SLV	4	Source Lock Vector Values: ● Bit i set to 0: Frames matching this entry coming from port i are rejected by source port lock error. ● Bit i set to 1: Frames matching this entry coming from port i are forwarded/routed.
DV	4	Destination vector Functions: ● HW: Ports to where the frame should be sent.
CSD	6	CPU Sub-Destinations Functions: ● HW: CPU Sub-Destinations the frame should be sent.
CME	1	CPU Mirroring Enable Values: ● 0: CPU mirroring is disabled. ● 1: CPU mirroring is enabled.
EME	1	Ethernet Mirroring Enable Values: ● 0: Ethernet mirroring is disabled. ● 1: Ethernet mirroring is enabled.
IPU	1	Internal Priority Update Values: ● 0: Frames matching this entry will not have their internal priority updated. ● 1: Frames matching this entry will have their internal priority updated.
IPV	3	Internal Priority Value Functions: ● HW: If corresponding entry L3.IPU value is set to 1, frames matching this entry will have their priority updated to L3.IPV.

(2) SW Learning

Learning is used to add/remove an entry in the L3 table. Table 30.29 describes register used to learn a stream ID in the Layer 3 table. Table 30.30 describes the learn results.

Table 30.29 L3 learn registers (1 of 2)

Register name	Field name/corresponding field in l3 table	Field explanation
FWLTHTL0.LTHED	Entry delete	Not present in L3 table, used to select between learning an entry and deleting an entry
FWLTHTL0.LTHSLL	L3.SL	See (1) Rule format.
FWLTHTL0.LTHSLP0/ FWLTHTL1.LTHSLP1/ FWLTHTL2.LTHSLP2/ FWLTHTL3.LTHSLP3/ FWLTHTL4.LTHSLP4	L3.SID	See (1) Rule format.
FWLTHTL5.LTHMSDUVL	L3.MSDUV	See (1) Rule format.
FWLTHTL5.LTHMSDUNL	L3.MSDUN	See (1) Rule format.
FWLTHTL6.LTHMTRVL	L3.MTRV	See (1) Rule format.
FWLTHTL6.LTHMTRNL	L3.MTRN	See (1) Rule format.
FWLTHTL6.LTHFRERVL	L3.FRERV	See (1) Rule format.
FWLTHTL6.LTHFRERNL	L3.FRERN	See (1) Rule format.
FWLTHTL7.LTHRVL	L3.RV	See (1) Rule format.
FWLTHTL7.LTHRNL	L3.RN	See (1) Rule format.
FWLTHTL7.LTHSLVL	L3.SLV	See (1) Rule format.
FWLTHTL80.LTHCSDL	L3.CSD[5:0]	See (1) Rule format.
FWLTHTL9.LTHDVL	L3.DV	See (1) Rule format.

Table 30.29 L3 learn registers (2 of 2)

Register name	Field name/corresponding field in l3 table	Field explanation
FWLTHTL9.LTHCMEL	L3.CME	See (1) Rule format.
FWLTHTL9.LTHEMEL	L3.EME	See (1) Rule format.
FWLTHTL9.LTHIPUL	L3.IPU	See (1) Rule format.
FWLTHTL9.LTHIPVL	L3.IPV	See (1) Rule format.

Table 30.30 L3 learn result

Register name	Field name/ corresponding field in l3 table	Field explanation
FWLTHTLR.LTHLF	Learning fail	Learning fail with happen in one of the following conditions: ● The learn entry is not yet in the table and the table is already full (FWLTHTEM.LTHTEN == 256). ● The Layer 3 table is not ready (FWLTHTIM.LTHTR is not set) ● The learning function is used to delete an entry (FWLTHTL0.LTHED set for learning) and the entry is not found in the Layer 3 table
FWLTHTLR.LTHLSF	Learning security fail	Security fail with happen in one of the following conditions: ● The learn entry is an unsecure entry (FWLTHTL0.LTHSLL not set for learning) and the unsecure entry number FWLTHTEM.LTHTUEN has reached the maximum unsecure entry number FWLTHHEC.LTHHMUE. ● The learn action is done by the APB which tries to learn an unsecure entry when the entry is already in the table, is secure (L3.SL is set) and when FWLTHTEM.LTHTUEN has reached the maximum unsecure entry number FWLTHHEC.LTHHMUE.
FWLTHTLR.LTHLO	Learning overwrite	Overwrite with happen in one of the following conditions: ● The learn stream ID is already present in the table, and no error happened during learning.
FWLTHTLR.LTHLCN	Learning collision number	Give the number of collisions that needs to be resolved to access the learnt entry if the lean succeeded. If FWLTHTLR.LTHLCN value comes out bigger than FWLTHHEC.LTHHMC register value, the newly learnt entry will be ignored by forwarding engine during forwarding. A switch reconfiguration with a different L3 Hash equation should be considered.

Note: HW: The fuller the table is, the slower Learning gets.

(3) Hash maximum collision number

Hash maximum number avoids the ESWM to have back pressure due to a slow forwarding mechanism.

Equation (1) shows how to calculate this number. This number should be set in FWLTHHEC.LTHHMC register.

(1) FWLTHHEC.LTHHMC = (*clk_freq*[Hz] * *Average_frame_size*[bit] / *Incoming_throughput*[bps] - 4) / 3

Where:

- *clk_freq* is the clock frequency of ESWCLK.
- *Average_frame_size* is the average frame size expected on switch inputs
- *Incoming_throughput* is the total throughput expected on switch inputs.

For example, if *clk_freq* is 150 MHz, *Average_frame_size* is 128 bytes and *Incoming_throughput* is 3 Gbps (1 Gbps of data on 2 GMII and 1 Gbps of data on 1 GWCA), the value 15 should be set to FWLTHHEC.LTHHMC register.

(4) Hash equation

The hash equation is controlled by register FWLTHHC.LTHHE.

The initial value of the equation is $1 + x^8$.

If there are too many collisions in the table (FWLTHTLR.LTHLCN > FWLTHHEC.LTHHMC during learning), this hash equation can be changed to minimize the number of collisions by:

- SW: Modelling the hash equations and find an equation which have a reasonable number of collisions.

- SW: Trying randomly some equations until finding an equation which have a reasonable number of collisions.

(5) SW Searching

Searching is used to find the information related to a stream ID. Table 30.31 describes register used to search a stream ID in the Layer 3 table. Table 30.32 describes the search results.

Table 30.31 L3 search registers

Register name	Field name/corresponding field in l3 table	Field explanation
FWLTHTS0.LTHSSP0/ FWLTHTS1.LTHSSP1/ FWLTHTS2.LTHSSP2/ FWLTHTS3.LTHSSP3/ FWLTHTS4.LTHSSP4	L3.SID	See (1) Rule format.

Table 30.32 L3 search result

Register name	Field name/corresponding field in l3 table	Field explanation
FWLTHTSR0.LTHSNF	Search not found.	Search failed because the searched stream ID is not in the table
FWLTHTSR0.LTHSCN	Search collision number	Give the number of collisions occurred to find the entry.
FWLTHTSR0.LTHSLS	L3.SL	See (1) Rule format.
FWLTHTSR1.LTHMSDUVS	L3.MSDUV	See (1) Rule format.
FWLTHTSR1.LTHMSDUNS	L3.MSDUN	See (1) Rule format.
FWLTHTSR2.LTHMTRVS	L3.MTRV	See (1) Rule format.
FWLTHTSR2.LTHMTRNS	L3.MTRN	See (1) Rule format.
FWLTHTSR3.LTHFRERVS	L3.FRERV	See (1) Rule format.
FWLTHTSR3.LTHFRERNS	L3.FRERN	See (1) Rule format.
FWLTHTSR3.LTHSLVS	L3.SLV	See (1) Rule format.
FWLTHTSR3.LTHRVS	L3.RV	See (1) Rule format.
FWLTHTSR3.LTHRNS	L3.RN	See (1) Rule format.
FWLTHTSR40.LTHCSDS	L3.CSD[5:0]	See (1) Rule format.
FWLTHTSR5.LTHDVS	L3.DV	See (1) Rule format.
FWLTHTSR5.LTHCMES	L3.CME	See (1) Rule format.
FWLTHTSR5.LTHEMES	L3.EME	See (1) Rule format.
FWLTHTSR5.LTHIPUS	L3.IPU	See (1) Rule format.
FWLTHTSR5.LTHIPVS	L3.IPV	See (1) Rule format.

(6) SW Reading

Reading is used to dump the Layer 3 table content. This function cannot be used to read a specific entry because it is not possible for the software to know at which address an entry can be found in the Layer 3 RAM. Table 30.33 describes register used to read an entry in the Layer 3 table. Table 30.34 describes the read results.

Table 30.33 L3 read registers

Register name	Field name/corresponding field in l3 table	Field explanation
FWLTHTR.LTHAR	Read address	Address that will be used to read an entry in the Layer 3 table

Table 30.34 L3 read result

Register name	Field name/corresponding field in l3 table	Field explanation
FWLTHTRR0.LTHEVR	L3.EV	The read address holds a valid entry Only if this bit is set when reading an address, the corresponding entry and the following registers in this table are valid. See (1) Rule format
FWLTHTRR1.LTHSRP0/ FWLTHTRR2.LTHSRP1/ FWLTHTRR3.LTHSRP2/ FWLTHTRR4.LTHSRP3/ FWLTHTRR5.LTHSRP4	L3.SID	See (1) Rule format.
FWLTHTRR1.LTHSLR	L3.SL	See (1) Rule format.
FWLTHTRR6.LTHMSDUVR	L3.MSDUV	See (1) Rule format.
FWLTHTRR6.LTHMSDUNR	L3.MSDUN	See (1) Rule format.
FWLTHTRR7.LTHMTRVR	L3.MTRV	See (1) Rule format.

FWLTHTRR10.LTHIPUR	L3.IPU	See (1) Rule format.
FWLTHTRR10.LTHIPVR	L3.IPV	See (1) Rule format.

30.5.2.4.5 Layer 3 Forwarding/Routing/Filtering

Layer 3 forwarding/routing/filtering is used to forward local ethernet descriptors (LDESCR.FMT [GWCA] set to 1’b0) received from agents using FWPCi0/FWPCi1 and FWCEPRC2 register and can be monitored using FWEIS0i interrupt register. Layer 3 forwarding/routing/filtering searches received valid stream IDs (section (5) Cascade filters, section (a) IPv4 Stream ID creation and section (b) IPv6 Stream ID creation) in the layer 3 table to extract corresponding entry fields (section (1) Rule format). Depending on the entry fields, Layer 3 forwarding/routing/filtering will forward/route/filter frames following Layer 3 forwarding/routing secure flow in Figure 30.85, Layer 3 forwarding/routing unsecure flow in Figure 30.86 and Layer 3 filtering flow in Figure 30.87.

Functions:

- FWPCi0.LTHTA register is used to activate layer 3 table for frames received from port i.
- FWPCi0.LTHRUS register is used to reject unknown streams received from port i.
- FWPCi0.LTHRUSS register is used to reject secure unknown streams received from port i.
- FWPCi1.LTHFM register is used to set to which ports frames received from port i can be forwarded.
- FWCEPRC2 register enables exceptional path for error descriptors.
- FWEIS0i interrupt register notifies that an ethernet descriptor has been rejected because of an error.

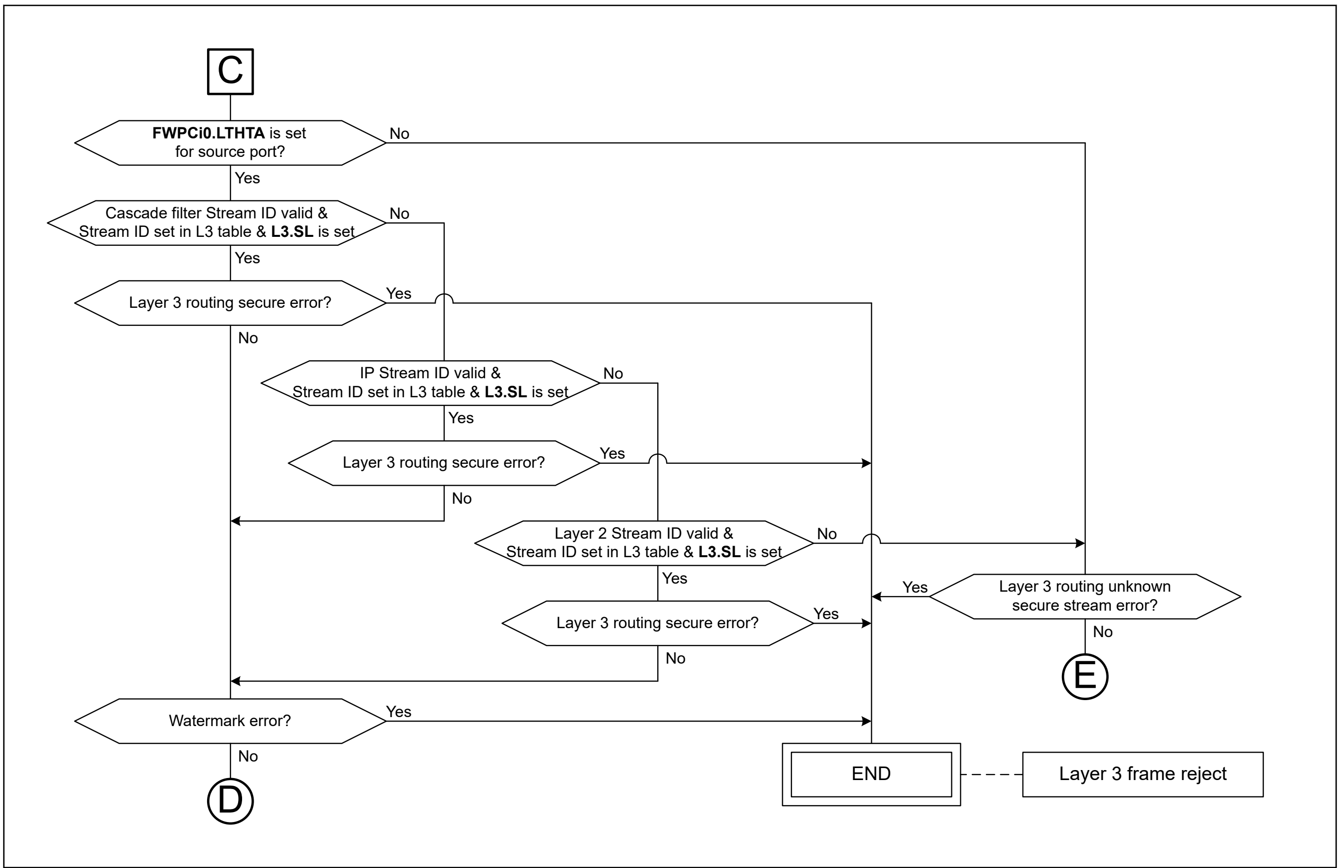

Figure 30.85 Layer 3 forwarding/routing secure flow

Note:
- Layer 3 routing secure errors and Layer 3 routing unknown secure stream errors are described in section (1) Layer 3 routing errors.
- Watermark errors are described in section (1) Watermark errors.
- Link C is linked from Figure 2.
- Link D links to Figure 30.87.
- Link E links to Figure 30.95

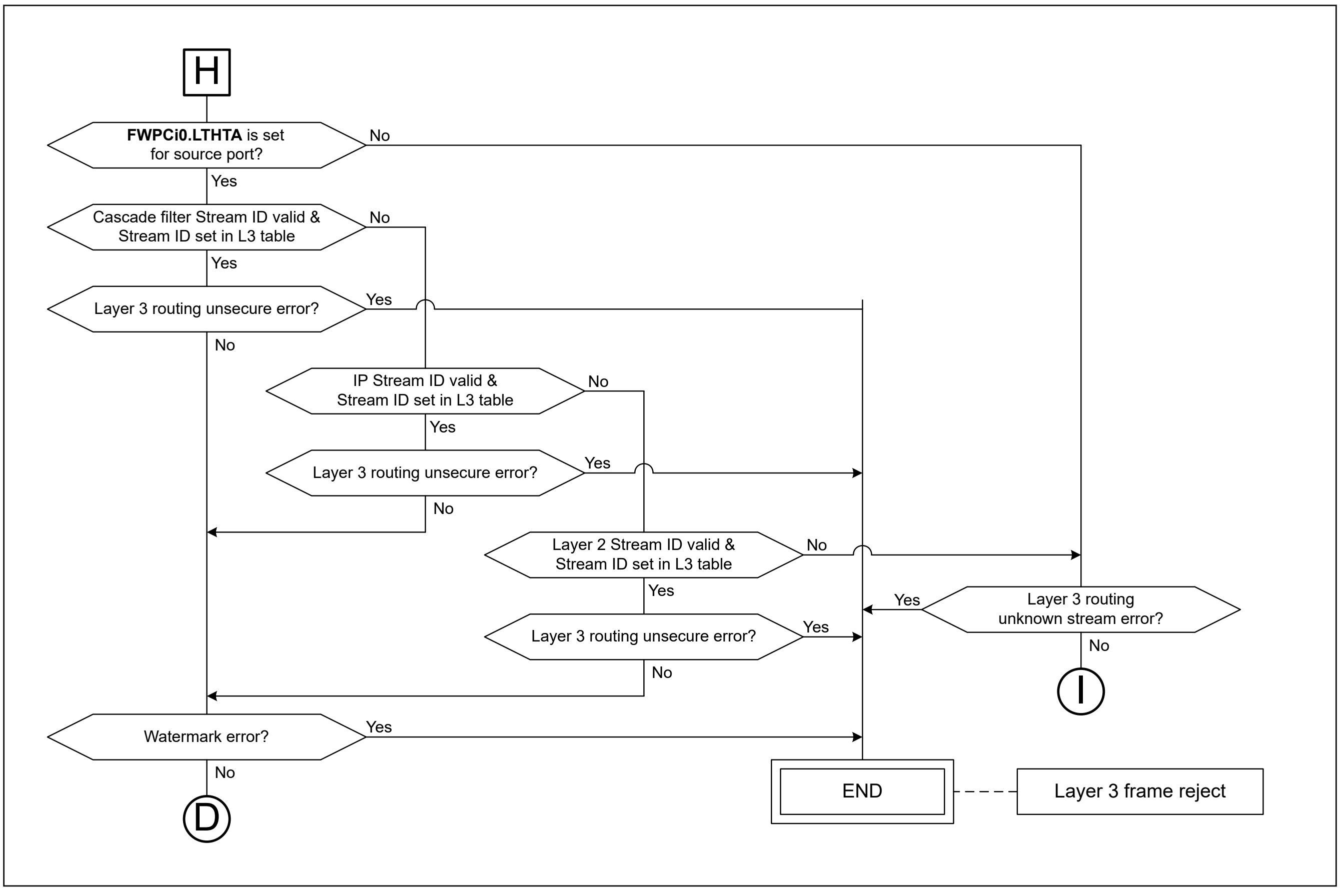

Figure 30.86 Layer 3 forwarding/routing unsecure flow

Note:
- Layer 3 routing errors and Layer 3 routing unknown stream errors are described in section (1) Layer 3 routing errors.
- Watermark errors are described in section (1) Watermark errors.
- Link H is linked from Figure 30.99.
- Link D links to Figure 30.87.
- Link I links to Figure 30.96.

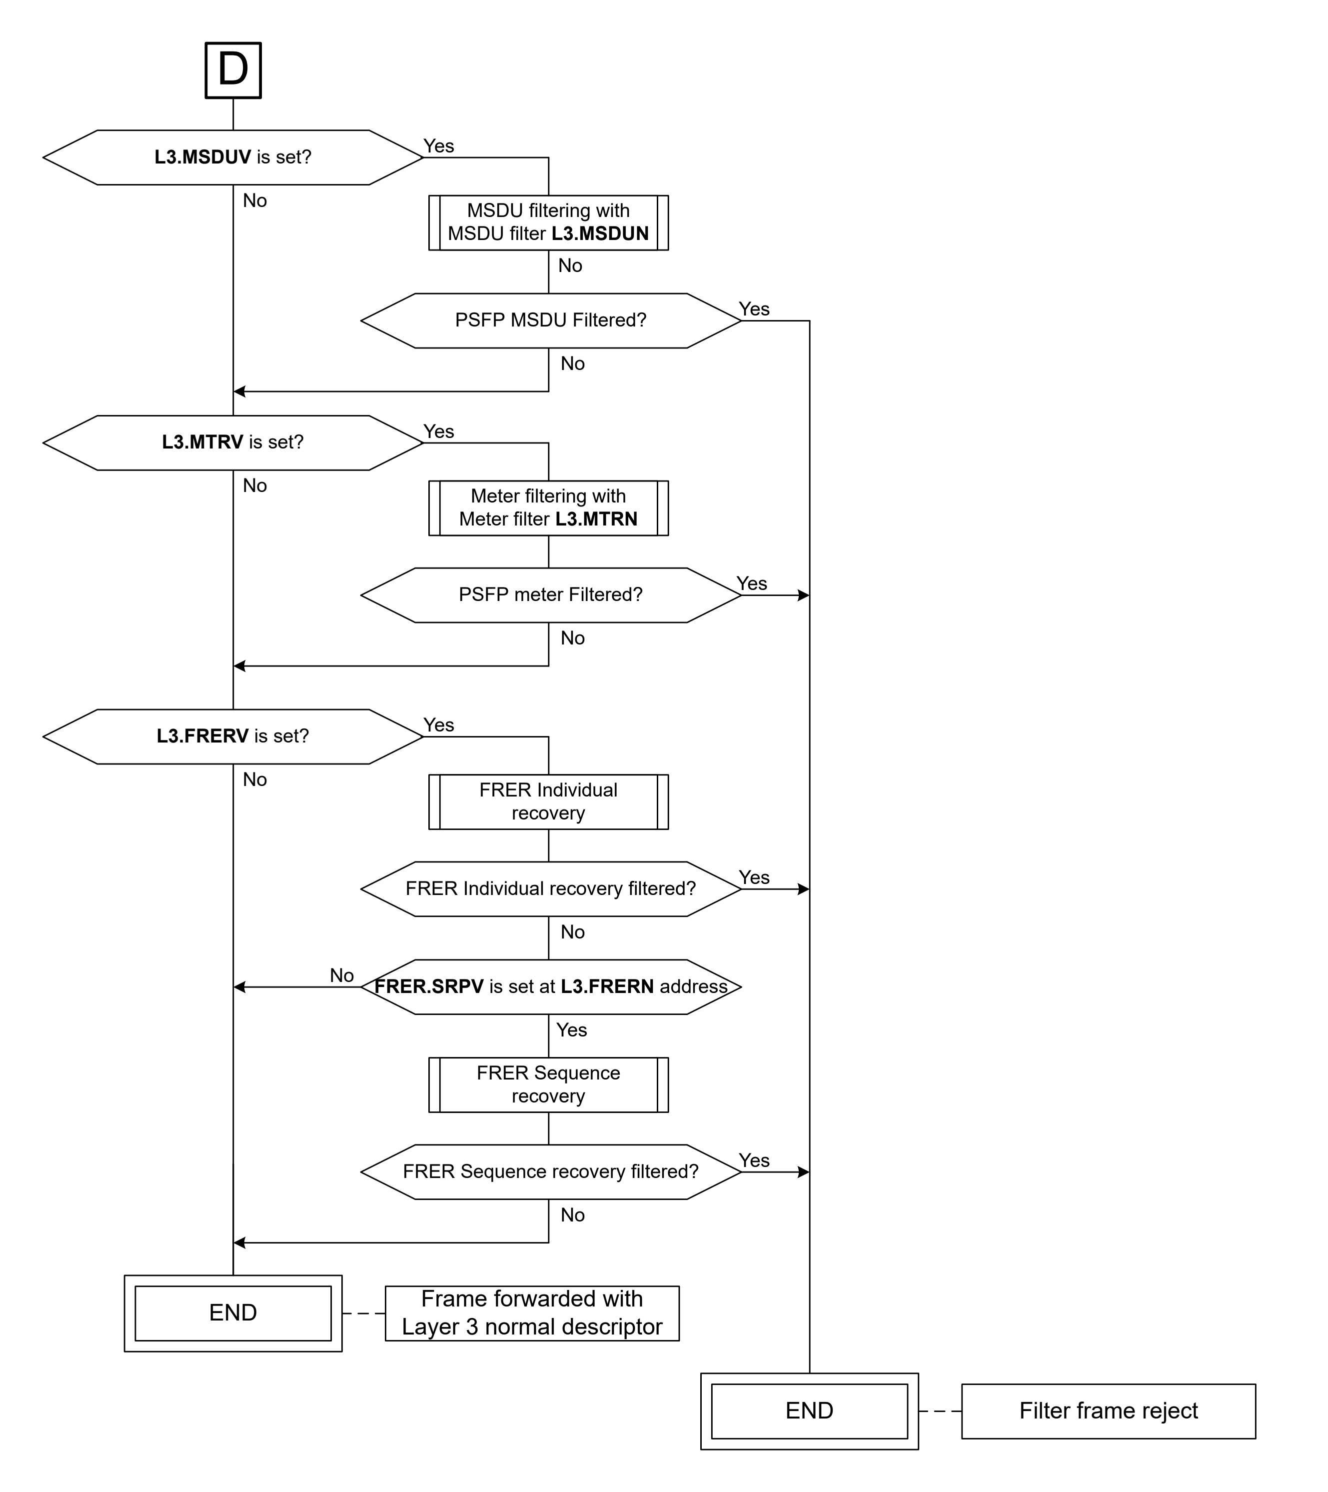

Figure 30.87 Layer 3 filtering flow

Note:
- Link D is linked from Figure 30.85 and Figure 30.86.
- Filter frame reject is described in section (2) Filtering errors.
- MSDU filtering is described in Figure 30.103.
- Meter filtering is described in Figure 30.104.
- Individual recovery is described in section (e) Individual recovery algorithms.
- Sequence recovery is described in section (f) Sequence recovery algorithms.

(1) Layer 3 routing errors

Table 30.35 describes the Layer 3 routing errors. Instead of being discarded by forwarding engine, an error frame can be forwarded to exceptional path using Layer 3 exceptional descriptor described in section (4) Layer 3 exceptional descriptor by setting corresponding error exceptional bit. For error set conditions, refer to corresponding error interrupt register explanations.

Table 30.35 Layer 3 routing errors

Error	Error name	Error interrupt	Error exceptional bit
Layer 3 routing secure errors			
SNTF	Secure No Target Filtering	FWEIS0i.LTHNTFS	FWCEPRC2.FLTHNTFEF
SSPF	Secure Source Port Filtering	FWEIS0i.LTHSPFS	FWCEPRC2.FLTHSLFEF
Layer 3 routing unknown secure stream errors			
SUF	Secure Unknown filtering	FWEIS0i.LTHUFS	FWCEPRC2.FLTHUFEF
Layer 3 routing errors			
NTF	No Target Filtering	FWEIS0i.LTHNTFS	FWCEPRC2.FLTHNTFEF
SPF	Source Port Filtering	FWEIS0i.LTHSPFS	FWCEPRC2.FLTHSLFEF
Layer 3 routing unknown stream errors			
UF	Unknown filtering	FWEIS0i.LTHUFS	FWCEPRC2.FLTHUFEF

(2) Filtering errors

Table 30.36 describes the Filter errors. Instead of being discarded by forwarding engine, an error frame can be forwarded to exceptional path using Filter exceptional descriptor described in section (5) Filter exceptional descriptor by setting corresponding error exceptional bit. For error set conditions, refer to corresponding error interrupt register explanations.

Table 30.36 Filtering errors

Error	Error name	Error interrupt	Error exceptional bit
MSDUF	MSDU filtered	FWEIS2.PMFS	FWCEPRC1.FMSDUFEF
MTRF	Meter filtered	FWEIS5.PMRFS	FWCEPRC1.FMTRFEF
IFRERF	Individual FRER Filtered	FWEIS60/61/62/63.FFS for no sequence error of stuck error FWEIS70/71/72/73.FOORS for out of range error	FWCEPRC1.FIFFEF
SFRERF	Sequence FRER Filtered	FWEIS60/61/62/63.FFS for no sequence error FWEIS70/71/72/73.FOORS for out of range error No interrupt if a frame is discarded because it was a duplicate	FWCEPRC1.FSFFEF

(3) Layer 3 normal descriptor

Layer 3 normal descriptor fields are described in Table 30.37.

Table 30.37 Layer 3 normal descriptor fields (1 of 2)

Field name FDESCR.	Values
DV	L3.DV & !FWPCi1.LTHFM
SEC	L3.SL
CSD	L3.CSD
IPV	If L3.IPU is set, set to L3.IPV. If L3.IPU is not set, set to the frame input priority. (See section 30.5.1.4. ESWM Frame Input Priority.)
MINFO	See Figure 30.88 and Table 30.38.

Table 30.37 Layer 3 normal descriptor fields (2 of 2)

Field name FDESCR.	Values
RV	L3.RV
RN	L3.RN
SEQN	Set to frame input sequence number if L3.RN is not mapped to a sequence number generation function (refer to section section 30.5.3.2.2. Sequence Number Generation)

Byte	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
0	FCLR[2:0]		FFC[2:0]		FWDC[3:0]			
1	FID[15:0]							
2								

Figure 30.88 Layer 3 normal descriptor MINFO format

Table 30.38 Layer 3 normal descriptor MINFO field explanation

Field name FDESCR.	Bit width	Field explanation	Values
FWDC	4	ForWarDing Code Present in all descriptors, allowing the type of forwarding to be identified	Fixed to 5 for Layer 3 normal descriptors
FFC	2	Frame Format Code	Set to 0 for perfect filter forwarding Set to 1 for IPv4 forwarding Set to 2 for IPv6 forwarding Set to 3 for Layer 2 stream forwarding
FCLR	2	Frame CoLoR	Set to 0 when frame has no color Set to 1 when frame is green Set to 2 when frame is yellow Set to 3 when frame is red Refer to section section 30.5.3.1.2. Meter Filter/ATS for color attribution
FID	16	Frame IDentifier	For Cascade filter stream ID, set to the cascade filter number that matched. For IPV stream ID, set to the hash ID inserted in the stream ID. For L2 stream, set to All0.

(4) Layer 3 exceptional descriptor

Layer 3 exceptional descriptor fields are described in Table 30.39.

Table 30.39 Layer 3 exceptional descriptor fields

Field name FDESCR.	Values
DV	Exceptional descriptors are forwarded to GWCA number FWCEPTC.EPCS (port number 2)
SEC	FWCEPTC.EPSL
CSDj	FWCEPTC.EPCSD
IPV	FWCEPTC.EPIPV
MINFO	See Figure 30.89 and Table 30.40.
RV	0
RN	ALL0
SEQN	Set to frame input sequence number

Byte	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
0	FCLR[1:0]		FFC[1:0]		FWDC[3:0]			
1	—					MTRF	GATEF	MSDUF
2	—							

Figure 30.89 Layer 3 exceptional descriptor MINFO format

Table 30.40 Layer 3 exceptional descriptor MINFO field explanation

Field name FDESCR.	Bit width	Field explanation	Values
FWDC	4	ForWarDing Code Present in all descriptors, allowing the type of forwarding to be identified	Fixed to 6 for Layer 3 exceptional descriptors
FFC	2	Frame Format Code	Set to 0 for perfect filter forwarding Set to 1 for IPv4 forwarding Set to 2 for IPv6 forwarding Set to 3 for Layer 2 stream forwarding Restrictions: • HW: This field is not valid when Secure Unknown filtering or Unknown filtering happened.
SNTF	1	Secure No Target Filtering	See (1) Layer 3 routing errors.
SSPF	1	Secure Source Port Filtering	See (1) Layer 3 routing errors.
SUF	1	Secure Unknown filtering	See (1) Layer 3 routing errors.
NTF	1	No Target Filtering	See (1) Layer 3 routing errors.
SPF	1	Source Port Filtering	See (1) Layer 3 routing errors.
UF	1	Unknown filtering	See (1) Layer 3 routing errors.

(5) Filter exceptional descriptor

Filter exceptional descriptor fields are described in Table 30.41.

Table 30.41 Filter exceptional descriptor fields

Field name FDESCR.	Values
DV	Exceptional descriptors are forwarded to GWCA number FWCEPTC.EPCS (port number 2)
SEC	FWCEPTC.EPSL

30.5.2.5 Layer 2 Forwarding

Figure 30.91 describes the block diagram of Layer 2 forwarding.

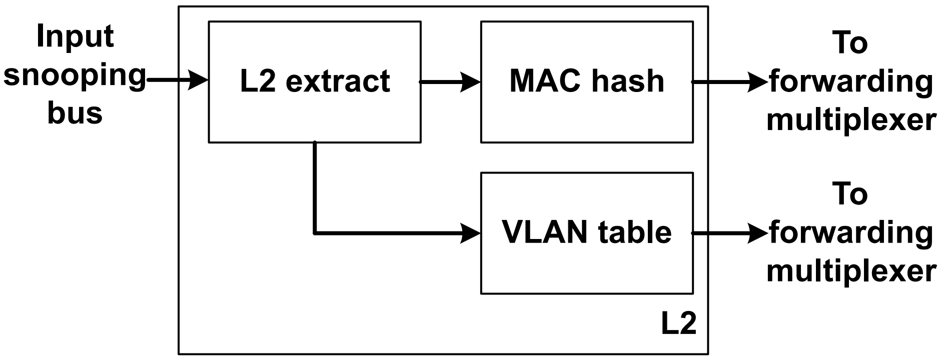

Figure 30.91 Block diagram of Layer 2 forwarding

The Layer 2 forwarding function is separated in three functional blocks:

- L2 extract: This block snoops all the required information from the forwarding engine snooping bus and extracts the MAC destination, MAC source addresses and the VLAN ID from frames.
- MAC hash: This block handles the MAC addresses meta information such as forwarding and routing information using a hash function.

- VLAN table: This block handles the VLAN ID meta information such as forwarding and routing information.

Note: Forwarding multiplexer contains the forwarding flow. The forwarding flow is explained by forwarding type. For Layer 3 forwarding/routing/filtering, related forwarding flows are described in Figure 30.95 and Figure 30.96.

30.5.2.5.1 L2 Extract

The L2 extract is used to extract the source and destination MAC addresses and the VLAN ID all frames.

Figure 30.92 describes MAC addresses and VLAN ID extraction. MAC addresses extraction always occurs. VLAN extraction only occurs when FWGC.SVM is different from 00b. If VLAN ID extraction does not occur, all VLANs are considered as unknown.

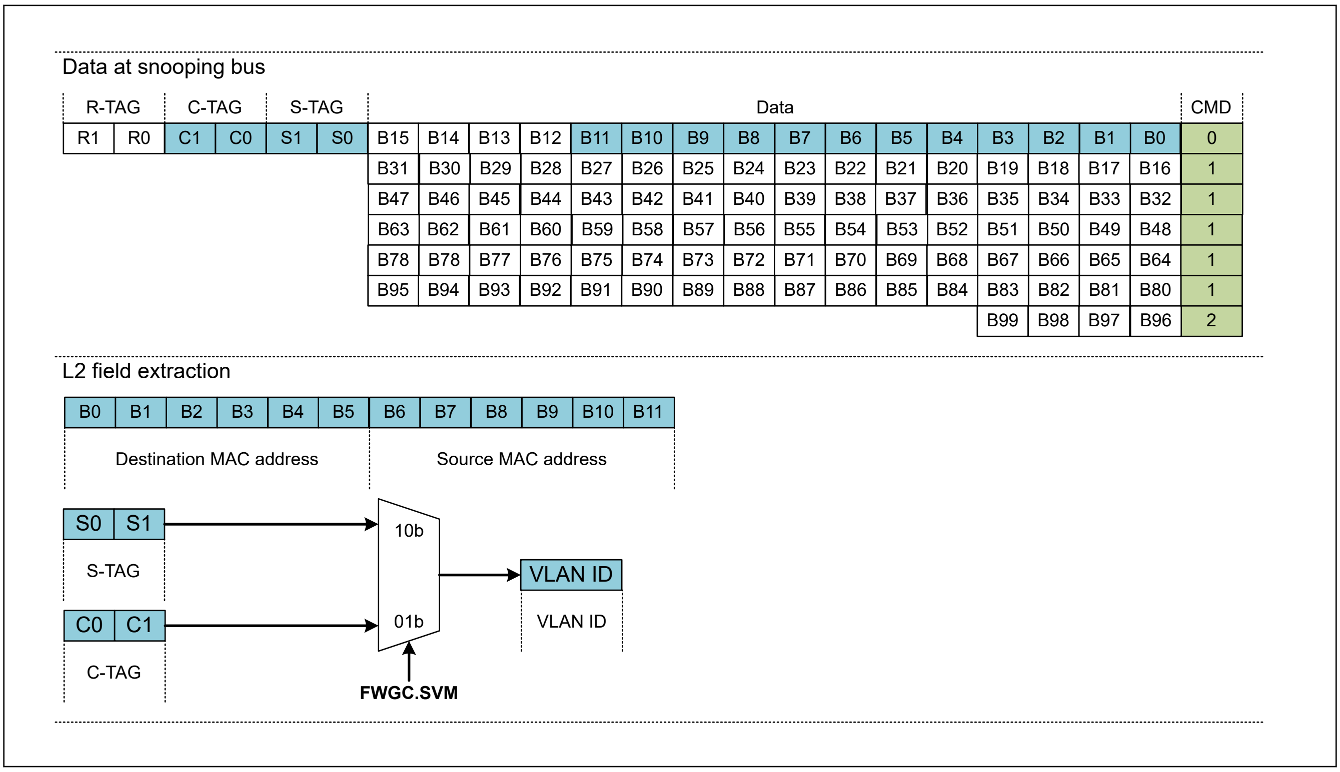

Figure 30.92 MAC address and VLAN ID extraction

30.5.2.5.2 MAC Hash

MAC hash aims at searching/learning/reading MAC rules thanks to a programmable hash. The hash algorithm is able to solve all the collisions in hardware, so it does not need any software intervention to operate.

MAC hash is divided in the following items:

- Rule format: Determines what information will be store along with the MAC address in the table.
- SW Learning: Function to add/suppress an entry from the MAC table by software.
- Hash maximum collision number: Avoids hash search to slow down the forwarding pipeline and apply back pressure on the ingress ports.
- Hash equation: Function to set hash calculation to minimize collisions.
- SW Searching: Function to find the forwarding information related to a MAC address by software.
- SW Reading: Function to read the entries in the MAC table by software.
- HW Searching: Function to find the forwarding information related to a MAC address by forwarding mechanism.
- HW Learning: Function to learn unicast MAC source addresses by forwarding mechanism.
- HW aging: Function used to suppress unused dynamic MAC addresses.

(1) Rule format

The MAC table is used to store MAC rules. A MAC rule contains the information for the frame forwarding. All the fields in this table, if quoted, will be written MAC.{Field name}. Table 30.43 describes fields contained in a MAC rule.

Table 30.43 MAC rule format (1 of 2)

Field name	Field size (bit)	Field Explanation
EV	1	Entry Valid Values: ● 0: Entry is not valid ● 1: Entry is valid
SL	1	Security Level Values: ● 0: Entry is unsecure ● 1: Entry is secure
MA	48	MAC Address of the entry. The MAC address is extracted by L2 extract. (See section 30.5.2.5.1. L2 Extract) This address is in big endian.
HLD	1	Hardware Learn Disable Values: ● 0: Source MAC hardware learning is enabled for frames containing MAC.MAC as destination MAC address. ● 1: Source MAC hardware learning is disabled for frames containing MAC.MAC as destination MAC address.
DSLV	4	Destination Source Lock Vector Values: ● Bit i set to 0: Frames with a destination MAC matching this entry coming from port i are rejected by source port lock error. ● Bit i set to 1: Frames with a destination MAC matching this entry coming from port i are forwarded/routed.
SSLV	4	Source Source Lock Vector Values: ● Bit i set to 0: Frames with a source MAC matching this entry coming from port i are rejected by source port lock error. ● Bit i set to 1: Frames with a source MAC matching this entry coming from port i are forwarded/routed.
DV	4	Destination vector Functions: ● HW: Ports to where the frame should be sent.
CSD	6	CPU Sub-Destinations Functions: ● HW: CPU Sub-Destinations the frame should be sent.
CME	1	CPU Mirroring Enable Values: ● 0: CPU mirroring is disabled. ● 1: CPU mirroring is enabled.
EME	1	Ethernet Mirroring Enable Values: ● 0: Ethernet mirroring is disabled. ● 1: Ethernet mirroring is enabled.
IPU	1	Internal Priority Update Values: ● 0: Frames matching this entry will not have their internal priority updated. ● 1: Frames matching this entry will have their internal priority updated.
IPV	3	Internal Priority Value Functions: ● HW: If corresponding entry MAC.IPU value is set to 1, frames matching this entry will have their priority updated to MAC.IPV.
DE	1	Dynamic Entry Values: ● 0: Entry is static. Migration and aging cannot be applied to the entry. ● 1: Entry is dynamic. Migration and aging can be applied to the entry.

Table 30.43 MAC rule format (2 of 2)

Field name	Field size (bit)	Field Explanation
AB	1	Aging Bit: Values: ● 0: Entry has been searched as a MAC source address by forwarding mechanism since previous aging. The entry should not be deleted during next aging. ● 1: Entry has not been searched as a MAC source address by forwarding mechanism since previous aging. The entry should be deleted during next aging if it is not searched as a MAC source address by forwarding mechanism before.

(2) SW Learning

Learning is used to add/remove an entry in the MAC table.Table 30.44 describes register used to learn an entry in the MAC table. Table 30.45 describes the learn results.

Table 30.44 MAC learn registers

Register name	Field name/corresponding field in MAC table	Field explanation
FWMACTL0.MACED	Entry delete	Not present in L3 table, used to select between learning an entry and deleting an entry
FWMACTL0.MACSLL	MAC.SL	See (1) Rule format.
{FWMACTL1.MACMALP0, FWMACTL2.MACMALP1}	MAC.MA	See (1) Rule format.
FWMACTL0.MACDEL	MAC.DE	See (1) Rule format.
FWMACTL0.MACHLDL	MAC.HLD	See (1) Rule format.
FWMACTL3.MACDSLVL	MAC.DSLV	See (1) Rule format.
FWMACTL3.MACSSLVL	MAC.SSLV	See (1) Rule format.
FWMACTL40.MACCSD	MAC.CSD[5:0]	See (1) Rule format.
FWMACTL5.MACDVL	MAC.DV	See (1) Rule format.
FWMACTL5.MACCMEL	MAC.CME	See (1) Rule format.
FWMACTL5.MACEMEL	MAC.EME	See (1) Rule format.
FWMACTL5.MACIPUL	MAC.IPU	See (1) Rule format.
FWMACTL5.MACIPVL	MAC.IPV	See (1) Rule format.

Table 30.45 MAC learn result (1 of 2)

Register name	Field name/ corresponding field in MAC table	Field explanation
FWMACTLR.MACLF	Learning fail	Learning fail with happen in one of the following conditions: ● The learn entry is not yet in the table and the table is already full (FWMACTEM.MACTEN == 2048). ● The MAC table is not ready (FWMACTIM.MACTR is not set) ● The learning function is used to delete an entry (FWMACTL0.MACED set for learning) and the entry is not found in the MAC table
FWMACTLR.MACLSF	Learning security fail	Security fail with happen in one of the following conditions: ● The learn entry is an unsecure entry (FWMACTL0.MACSLL not set for learning) and the unsecure entry number FMACTEM.MACTUEN has reached the maximum unsecure entry number FWMACHEC.MACHMUE. ● The learn action is done by the APB which tries to learn an unsecure entry when the entry is already in the table, is secure (MAC.SL is set) and when FWMACTEM.MACTUEN has reached the maximum unsecure entry number FWMACHEC.MACHMUE.
FWMACTLR.MACLO	Learning overwrite	Overwrite with happen in one of the following conditions: ● The learn MAC is already present in the table, and no error happened during learning.

Table 30.45 MAC learn result (2 of 2)

Register name	Field name/ corresponding field in MAC table	Field explanation
FWMACTLR.MACLCN	Learning collision number	Give the number of collisions that needs to be resolved to access the learnt entry if the lean succeeded. If FWMACTLR.MACLCN value comes out bigger than FWMACHEC.MACHMC register value, the newly learnt entry will be ignored by forwarding engine during forwarding. A switch reconfiguration with a different MAC Hash equation should be considered.

Note: HW: The fuller the table is, the slower Learning gets.

(3) Hash maximum collision number

Hash maximum number avoids the ESWM to have back pressure due to a slow forwarding mechanism.

Equation (2) shows how to calculate this number. This number should be set in FWMACHEC.MACHMC register.

(2) FWMACHEC.MACHMC = (*clk_freq*[Hz] * *Average_frame_size*[bit] / *Incoming_throughput*[bps] - 4) / 3

Where:

- *clk_freq* is the clock frequency of ESWCLK.
- *Average_frame_size* is the average frame size expected on switch inputs
- *Incoming_throughput* is the total throughput expected on switch inputs.

For example, if *clk_freq* is 150 MHz, *Average_frame_size* is 128 bytes and *Incoming_throughput* is 3 Gbps (1 Gbps of data on 2 GMII and 1 Gbps of data on 1 GWCA), the value 15 should be set to FWLTHHEC.LTHHMC register.

(4) Hash equation

The hash equation is controlled by register FWMACHC.MACHE.

The initial value of the equation is $1 + x^{11}$.

If there are too many collisions in the table (FWMACTLR.MACLCN > FWMACHEC.MACHMC during learning), this hash equation can be changed to minimize the number of collisions by:

- SW: Modelling the hash equations and find an equation which have a reasonable number of collisions.
- SW: Trying randomly some equations until finding an equation which have a reasonable number of collisions.

(5) SW Searching

Searching is used to find the information related to a MAC address. Table 30.46 describes register used to search an MAC address in the MAC table. Table 30.47 describes the search results.

Table 30.46 MAC search registers

Register name	Field name/corresponding field in MAC table	Field explanation
{FWMACTS0.MACMASP0, FWMACTS1.MACMASP1}	MAC.MA	See (1) Rule format.

Table 30.47 MAC search result (1 of 2)

Register name	Field name/corresponding field in MAC table	Field explanation
FWMACTSR0.MACSNF	Search not found.	Search failed because the searched MAC address is not in the table
FWMACTSR0.MACSCN	Search collision number	Give the number of collisions occurred to find the entry.
FWMACTSR0.MACSLS	MAC.SL	See (1) Rule format.
FWMACTSR0.MACDES	MAC.DE	See (1) Rule format.

Table 30.47 MAC search result (2 of 2)

Register name	Field name/corresponding field in MAC table	Field explanation
FWMACTSR0.MACHLDS	MAC.HLD	See (1) Rule format.
FWMACTSR1.MACDSLVS	MAC.DSLV	See (1) Rule format.
FWMACTSR1.MACSSLVS	MAC.SSLV	See (1) Rule format.
FWMACTSR20.MACCSDS	MAC.CSD[5:0]	See (1) Rule format.
FWMACTSR3.MACDVS	MAC.DV	See (1) Rule format.
FWMACTSR3.MACCMES	MAC.CME	See (1) Rule format.
FWMACTSR3.MACEMES	MAC.EME	See (1) Rule format.
FWMACTSR3.MACIPUS	MAC.IPU	See (1) Rule format.
FWMACTSR3.MACIPVS	MAC.IPV	See (1) Rule format.

(6) SW Reading

Reading is used to dump the MAC table content. This function cannot be used to read a specific entry because it is not possible for the software to know at which address an entry can be found in the MAC RAM.

Table 30.48 MAC read registers

Register name	Field name/corresponding field in MAC table	Field explanation
FWMACTR.MACAR	Read address	Address that will be used to read an entry in the Layer 3 table

Table 30.49 MAC read result

Register name	Field name/corresponding field in MAC table	Field explanation
FWMACTRR0.MACEVR	MAC.EV	The read address holds a valid entry Only if this bit is set when reading an address, the corresponding entry and the following registers in this table are valid. See (1) Rule format.
{FWMACTRR2.MACMARP0, FWMACTRR3.MACMARP1}	MAC.MA	See (1) Rule format.
FWMACTRR1.MACSLR	MAC.SL	See (1) Rule format.
FWMACTRR1.MACDER	MAC.DE	See (1) Rule format.
FWMACTRR1.MACHLDR	MAC.HLD	See (1) Rule format.
FWMACTRR1.MACAB	MAC.AB	See (1) Rule format.
FWMACTRR4.MACDSLVR	MAC.DSLV	See (1) Rule format.
FWMACTRR4.MACSSLVR	MAC.SSLV	See (1) Rule format.
FWMACTRR50.MACCSDR	MAC.CSD[5:0]	See (1) Rule format.
FWMACTRR6.MACDVR	MAC.DV	See (1) Rule format.
FWMACTRR6.MACCMER	MAC.CME	See (1) Rule format.
FWMACTRR6.MACEMER	MAC.EME	See (1) Rule format.
FWMACTRR6.MACIPUR	MAC.IPU	See (1) Rule format.
FWMACTRR6.MACIPVR	MAC.IPV	See (1) Rule format.

(7) HW learning/migration

MAC HW learning/migration conditions and settings are described in section section 30.5.1.5.2. CPU Learning Path. Table 30.50 describes to what value the MAC entry fields will be set while learning in hardware a frame coming from port i.

For Source MAC multicast address, HW learning/migration will invalid (ignored).

Table 30.50 MAC hardware learning values

Field name	Field Explanation
MAC.EV	1
MAC.SL	0
MAC.MA	Incoming frame MAC source
MAC.HLD	0
MAC.DSLV	0xF
MAC.SSLV	0xF
MAC.DV	001b << i
MAC.CSD	0x00
MAC.CME	0
MAC.EME	0
MAC.IPU	0
MAC.IPV	000b
MAC.DE	1
MAC.AB	0

(8) HW Aging

MAC HW aging function is used to remove the unused MAC addresses conditions using FWMACAGUSPC and FWMACAGC registers and can be monitored using FWMACAGM0/1 registers and FWMIS0.MACADAS interrupt register. MAC HW aging function thanks to two algorithms, the aging algorithm described in Figure 30.93 and the MAC source address search algorithm described in Figure 30.94.

Functions:

- FWMACAGUSPC register sets a prescaler to create a 1 Hz for aging.
- FWMACAGC register sets/enables the aging function
- FWMIS0.MACADAS and FWMACAGM0/1 can be used to keep track in SW of the aged MAC addresses. These registers should be used only in polling mode (FWMACAGC.MACAGPM set).

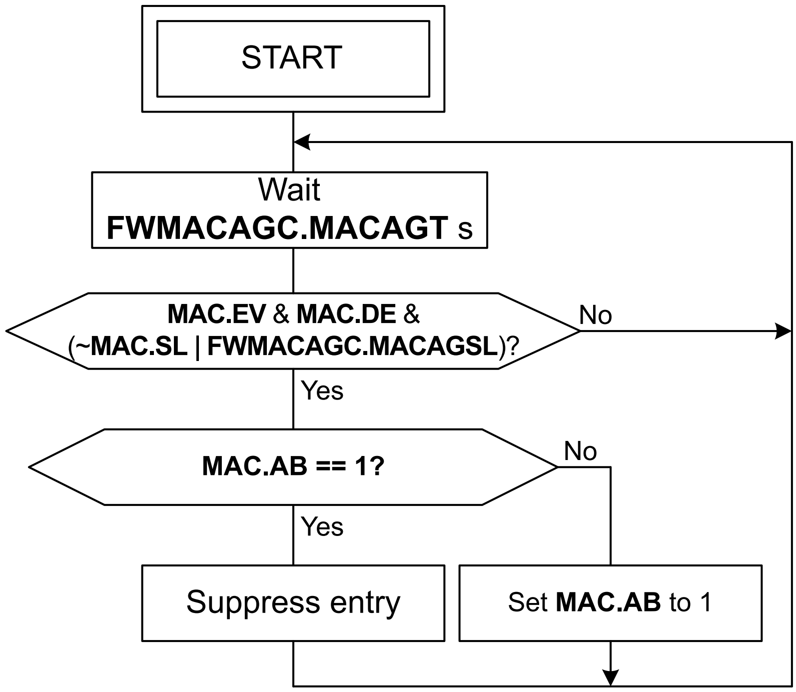

Figure 30.93 MAC aging algorithm

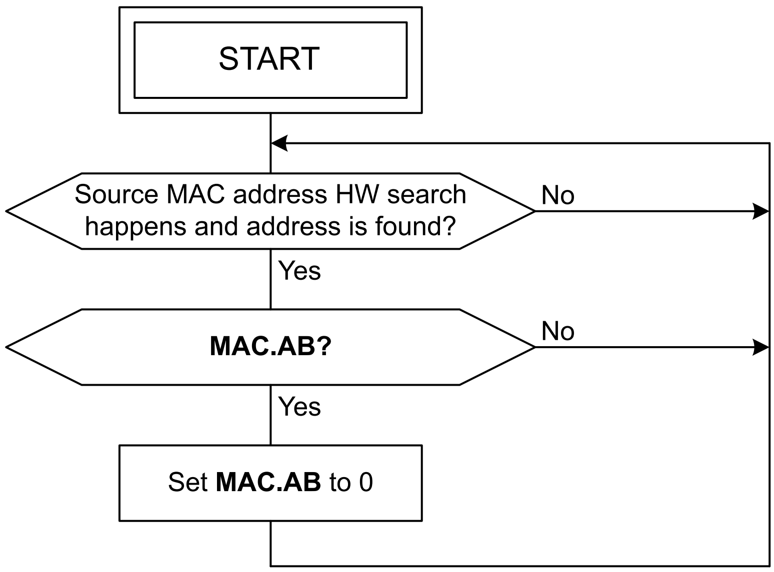

Figure 30.94 MAC source address search algorithm

30.5.2.5.3 VLAN Table

VLAN hash aims at searching/learning VLAN rules. The VLAN ID to VLAN RAM address mapping is a 1:1 mapping, so no hash is needed for VLAN handling.

VLAN table is divided in the following items:

- Rule format: Determines what information will be store in a VLAN rule. The VLAN ID is not stored a VLAN rule.
- SW Learning: Function to add/suppress an entry from the VLAN table by software.

- SW Searching: Function to find the forwarding information related information to a VLAN ID by software.
- HW Searching: Function to find the forwarding information related to a VLAN ID by forwarding mechanism.

(1) Rule format

The VLAN table is used to store VLAN rules. A VLAN rule contains the information for the frame forwarding. All the fields in this table, if quoted, will be written VLAN.{Field name}. Table 30.51 describes fields contained in a VLAN rule.

Table 30.51 VLAN rule format

Field name	Field size (bit)	Field description
EV	1	Entry Valid Values: ● 0: Entry is not valid ● 1: Entry is valid
SL	1	Security Level Values: ● 0: Entry is unsecure ● 1: Entry is secure
HLD	1	Hardware Learn Disable Values: ● 0: Source MAC hardware learning is enabled for frames containing corresponding VLAN ID. ● 1: Source MAC hardware learning is disabled for frames containing corresponding VLAN ID.
SLV	4	Source Lock Vector Values: ● Bit i set to 0: Frames with a VLAN ID matching this entry coming from port i are rejected by source port lock error. ● Bit i set to 1: Frames with a VLAN ID matching this entry coming from port i are forwarded/routed.
DV	4	Destination vector Functions: ● HW: Ports to where the frame should be sent.
CSD	6	CPU Sub-Destinations Functions: ● HW: CPU Sub-Destinations the frame should be sent
CME	1	CPU Mirroring Enable Values: ● 0: CPU mirroring is disabled. ● 1: CPU mirroring is enabled.
EME	1	Ethernet Mirroring Enable Values: ● 0: Ethernet mirroring is disabled. ● 1: Ethernet mirroring is enabled.
IPU	1	Internal Priority Update Values: ● 0: Frames matching this entry will not have their internal priority updated. ● 1: Frames matching this entry will have their internal priority updated.
IPV	3	Internal Priority Value Functions: ● HW: If corresponding entry VLAN.IPU value is set to 1, frames matching this entry will have their priority updated to VLAN.IPV.

(2) SW Learning

Learning is used to add/remove an entry in the VLAN table. Table 30.52 describes register used to learn an entry in the VLAN table. Table 30.53 describes the learn results.

Table 30.52 VLAN learn registers

Register name	Field name/corresponding field in VLAN table	Field explanation
FWVLANTL0.VLANED	Entry delete	Not present in L3 table, used to select between learning an entry and deleting an entry
FWVLANTL0.VLANSLL	VLAN.SL	See (1) Rule format.
FWVLANTL1.VLANVIDL	VLAN ID	Correspond to the address of the learnt entry.
FWVLANTL0.VLANHLDL	VLAN.HLD	See (1) Rule format.
FWVLANTL2.VLANSLVL	VLAN.SLV	See (1) Rule format.
FWVLANTL30.VLANCSDL	VLAN.CSD[5:0]	See (1) Rule format.
FWVLANTL4.VLANDVL	VLAN.DV	See (1) Rule format.
FWVLANTL4.VLANCMEL	VLAN.CME	See (1) Rule format.
FWVLANTL4.VLANEMEL	VLAN.EME	See (1) Rule format.
FWVLANTL4.VLANIPUL	VLAN.IPU	See (1) Rule format.
FWVLANTL4.VLANIPVL	VLAN.IPV	See (1) Rule format.

Table 30.53 VLAN learn result

Register name	Field name/ corresponding field in VLAN table	Field explanation
FWVLANTLR.VLANLF	Learning fail	Learning fail with happen in one of the following conditions: ● The VLAN table is not ready (FWVLANTIM.VLANTR is not set). ● The learning function is used to delete an entry (FWVLANTL0.VLANED set for learning) and the entry is not VLAN table.
FWVLANTLR.VLANLSF	Learning security fail	Security fail with happen in one of the following conditions: ● The learning entry is an unsecure entry (FWVLANTL0.VLANSLL not set for learning) and the unsecure entry number FWVLANTEM.VLANTUEN has reached the maximum unsecure entry number FWVLANTEC.VLANTMUE. ● The learning action is done by the APB which tries to learn an unsecure entry when the entry is already in the table, is secure (VLAN.SL is set) and when FWVLANTEM.VLANTUEN has reached the maximum unsecure entry number FWVLANTEC.VLANTMUE.
FWVLANTLR.VLANLO	Learning overwrite	Overwrite with happen in one of the following conditions: ● The learning VLAN is already present in the table, and no error happened during learning.

(3) SW Searching

Searching is used to find the information related to a VLAN address. Table 30.54 describes register used to search a VLAN address in the VLAN table. Table 30.55 describes the search results. This function is not actually searching the address but only reading the address corresponding to the VLAN ID in the VLAN table.

Table 30.54 VLAN search registers

FWVLANTSR3.VLANIPVS	VLAN.IPV	See (1) Rule format.

30.5.2.5.4 Layer 2 Forwarding

Layer 2 forwarding is used to forward local ethernet descriptors (LDESCR.FMT [GWCA] set to 0) received from agents using FWPCi0 and FWCEPRC2 register and can be monitored using FWEIS0i interrupt register. Layer 2 forwarding searches received MAC addresses (section 30.5.2.5.1. L2 Extract) in the MAC table to extract corresponding entry fields ((1) Rule format) and searches valid VLAN IDs (section 30.5.2.5.1. L2 Extract) in the VLAN table to extract corresponding entry fields ((1) Rule format). Depending on the entry fields, Layer 2 forwarding will forward frames following L2 forwarding secure flow in Figure 30.95 and L2 forwarding unsecure flow in Figure 30.96.

Functions:

- FWPCi0.MACDSA register is used to activate MAC table for frames received from port i for destination MAC.
- FWPCi0.MACRUDA register is used to reject unknown destination MAC received from port i.
- FWPCi0.MACRUDSA register is used to reject secure unknown destination MAC received from port i.
- FWPCi0.MACSSA register is used to activate MAC table for frames received from port i for source MAC.
- FWPCi0.MACRUSA register is used to reject unknown source MAC received from port i.
- FWPCi0.MACRUSSA register is used to reject secure unknown source MAC received from port i.
- FWPCi0.VLANSA register is used to activate VLAN table for frames received from port i for source MAC.
- FWPCi0.VLANRU register is used to reject unknown VLAN IDs received from port i.
- FWPCi0.VLANRUS register is used to reject secure unknown VLAN IDs received from port i.
- FWPCi2.LTWFM register is used to set to which ports frames received from port i can be forwarded.
- FWCEPRC2 register enables exceptional path for error descriptors.
- FWEIS0i interrupt register notifies that an ethernet descriptor has been rejected because of an error.

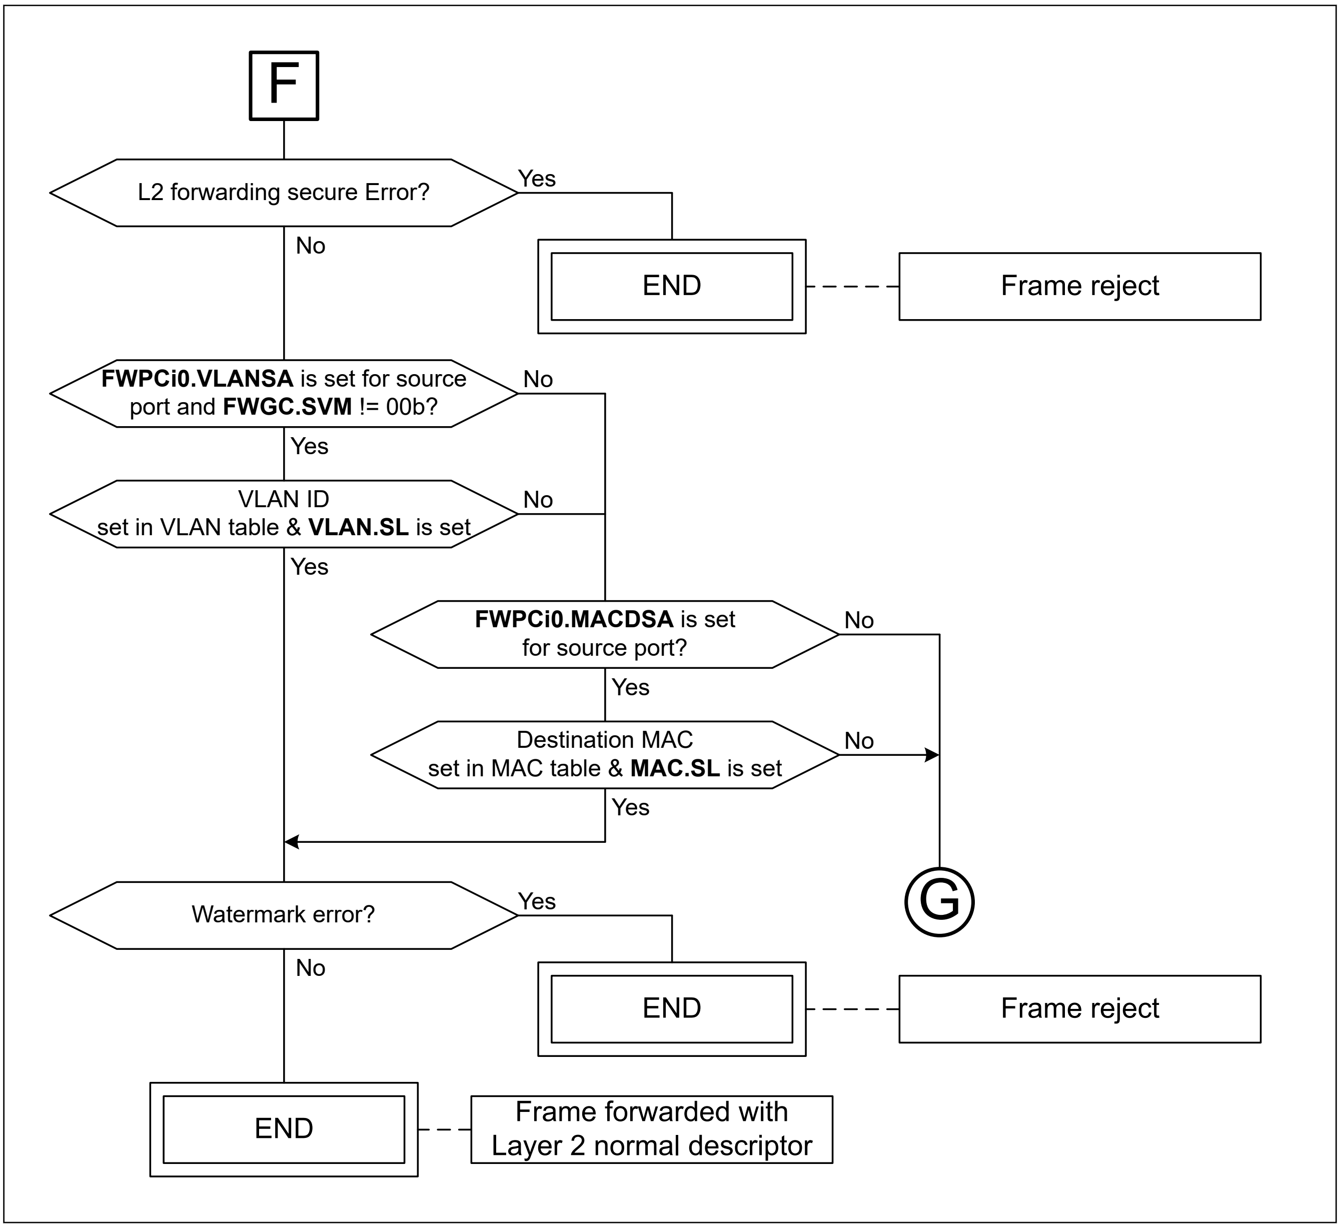

Figure 30.95 L2 forwarding secure flow

Note:
- L2 forwarding secure errors are described in section (1) L2 forwarding errors.
- Watermark errors are described in section (1) Watermark errors.
- Link F is linked from Figure 30.85 point E.
- Link G links to Figure 30.99.

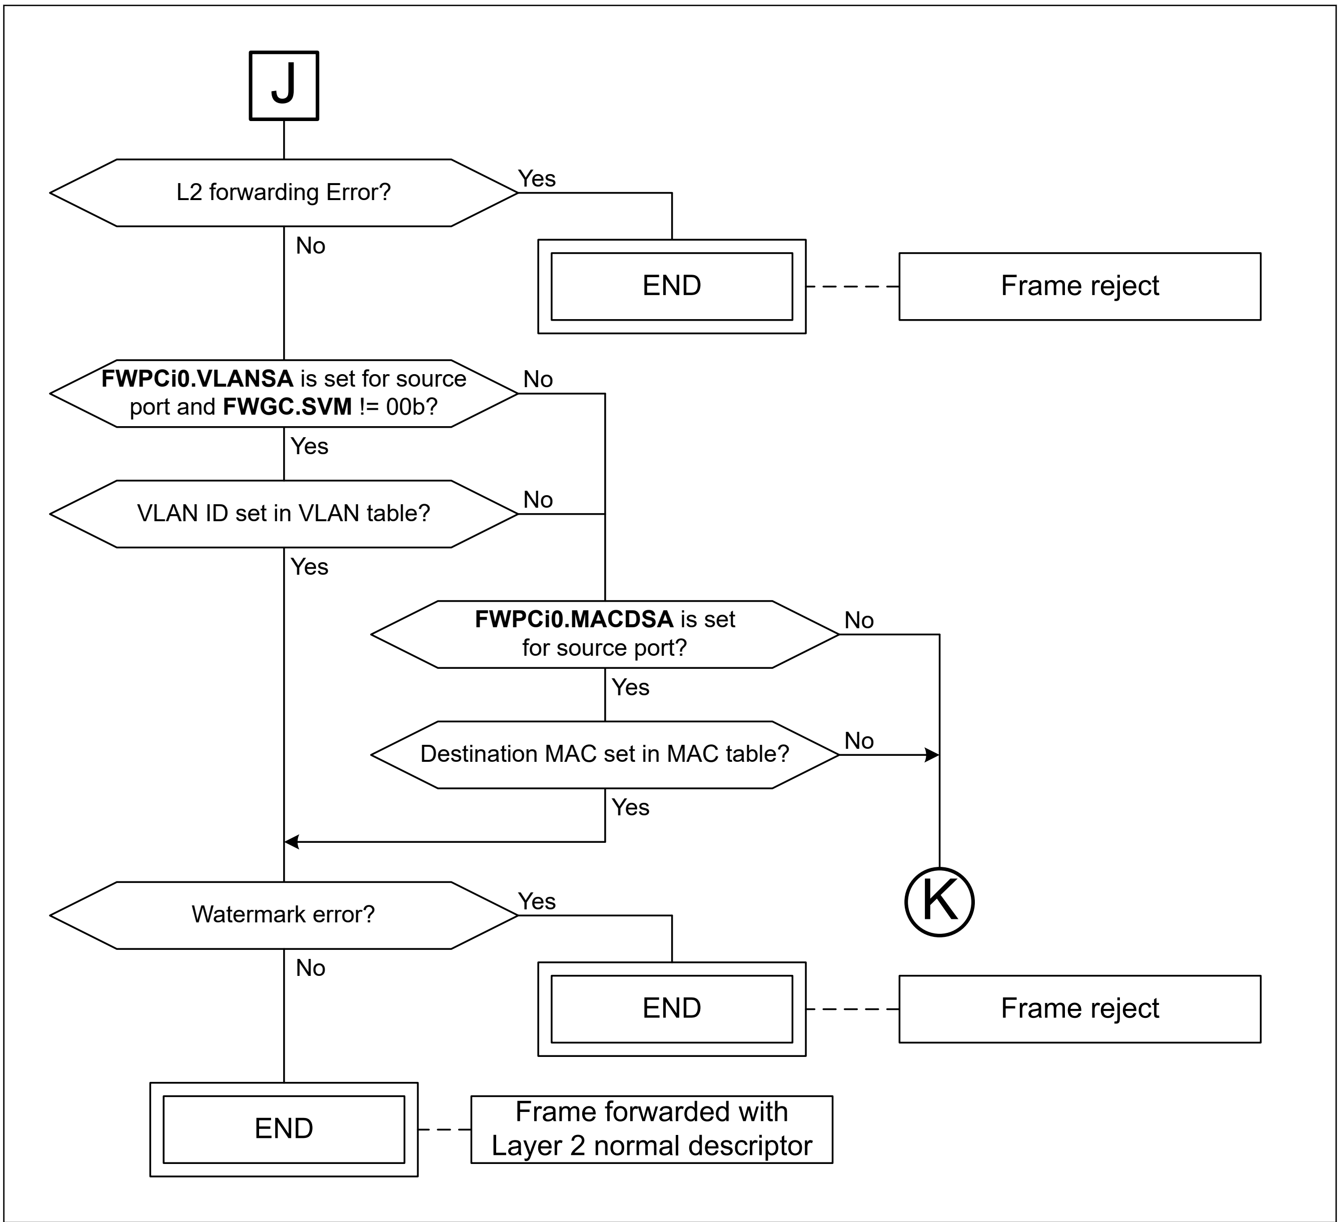

Figure 30.96 L2 forwarding unsecure flow

Note:
- L2 forwarding errors are described in section (1) L2 forwarding errors.
- Watermark errors are described in section (1) Watermark errors.
- Link J is linked from Figure 30.86 point I.
- Link K links to Figure 30.100.

(1) L2 forwarding errors

Table 30.56 describes the L2 forwarding errors. Instead of being discarded by forwarding engine, an error frame can be forwarded to exceptional path using Layer 2 exceptional descriptor described in section (3) Layer 2 exceptional descriptor by setting corresponding error exceptional bit. For error set conditions, refer to corresponding error interrupt register explanations.

Table 30.56 L2 forwarding Errors (1 of 2)

Error	Error name	Error interrupt	Error exceptional bit
L2 forwarding secure errors			
SNTF	Secure No Target Filtering	FWEIS0i.LTWNTFS	FWCEPRC2.FLTWNTFEF
SDSPF	Secure Destination Source Port Filtering	FWEIS0i.LTWDSPFS	FWCEPRC2.FDMACSLFEF

Table 30.56 L2 forwarding Errors (2 of 2)

Error	Error name	Error interrupt	Error exceptional bit
SSSPF	Secure Source Source Port Filtering	FWEIS0i.LTWSSPFS	FWCEPRC2.FSMACSLFEF
SVSPF	Secure VLAN Source Port Filtering	FWEIS0i.LTWVSPFS	FWCEPRC2.FVLANSLFEF
SDUF	Secure Destination Unknown filtering	FWEIS0i.LTWDUFS	FWCEPRC2.FDMACUFEF
SSUF	Secure Source Unknown filtering	FWEIS0i.LTWSUFS	FWCEPRC2.FSMACUFEF
SVUF	Secure VLAN Unknown filtering	FWEIS0i.LTWVUFS	FWCEPRC2.FVLANUFEF
L2 forwarding errors			
NTF	No Target Filtering	FWEIS0i.LTWNTFS	FWCEPRC2.FLTWNTFEF
DSPF	Destination Source Port Filtering	FWEIS0i.LTWDSPFS	FWCEPRC2.FDMACSLFEF
SSPF	Source Source Port Filtering	FWEIS0i.LTWSSPFS	FWCEPRC2.FSMACSLFEF
VSPF	VLAN Source Port Filtering	FWEIS0i.LTWVSPFS	FWCEPRC2.FVLANSLFEF

SUF	Source Unknown filtering	FWEIS0i.LTWSUFS	FWCEPRC2.FSMACUFEF
VUF	VLAN Unknown filtering	FWEIS0i.LTWVUFS	FWCEPRC2.FVLANUFEF

(2) Layer 2 normal descriptor

For Layer 2 normal descriptor creation, only MAC table fields read from MAC table thanks to the destination MAC and VLAN table fields read from VLAN table are used. Layer 2 normal descriptor fields are described in Table 30.57.

Table 30.57 Layer 2 normal descriptor fields

Field name FDESCR.	Values if MAC destination address and VLAN ID are both found and MAC.SL = VLAN.SL	Values if MAC destination only is found or if MAC destination address and VLAN ID are both found and MAC.SL & !VLAN.SL	Values if VLAN ID only is found or if MAC destination address and VLAN ID are both found and !MAC.SL & VLAN.SL

30.5.2.6 Port Based Forwarding

Port based forwarding aims at forwarding all frames from a port to other ones. It used FWPBFCi and FWPBFCSDCi0 registers. Port based forwarding will forward frames following Port based forwarding secure flow in and Port based forwarding unsecure flow in .

Functions:

- FWPBFCi and FWPBFCSDCi0 registers are used to set forwarding information for frames coming from port i.

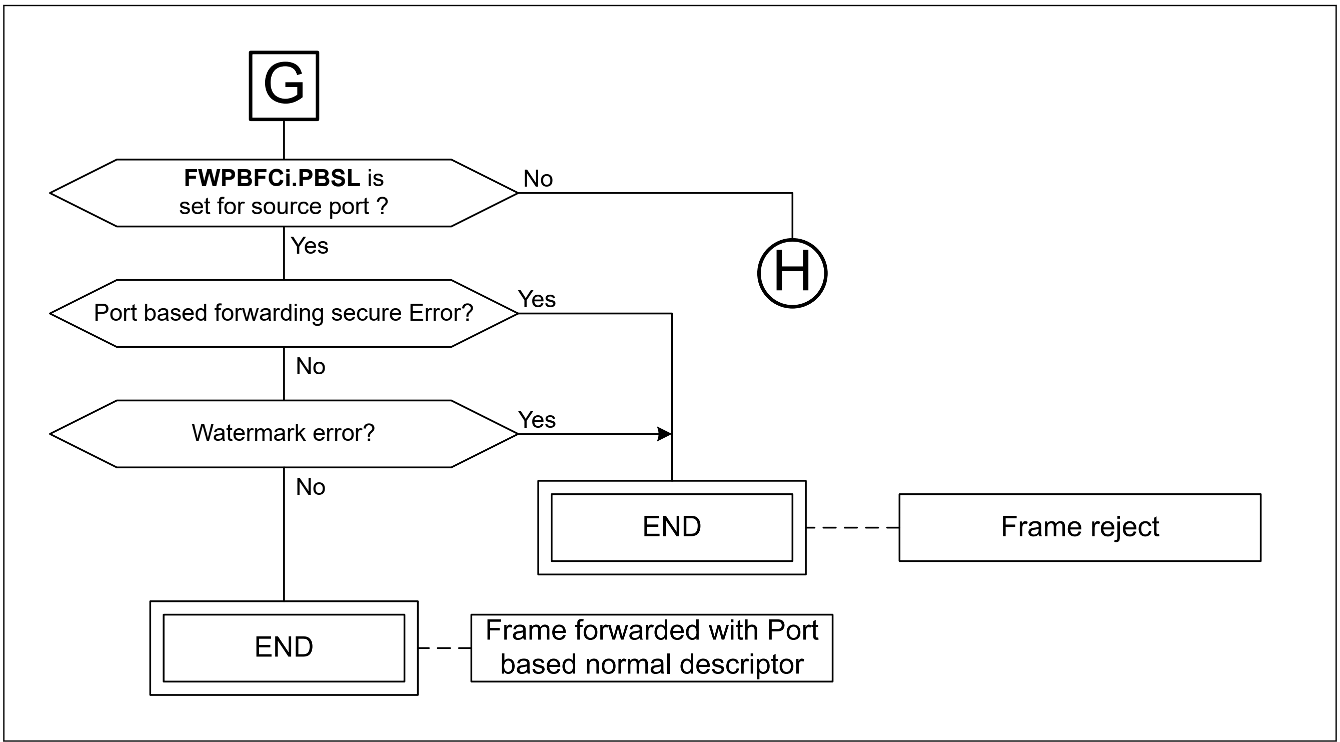

Figure 30.99 Port based forwarding secure flow

Note:
- Port based forwarding secure errors are described in section.
- Watermark errors are described in section (1) Watermark errors.
- Link G is linked from Figure 30.95.
- Link H links to Figure 30.86.

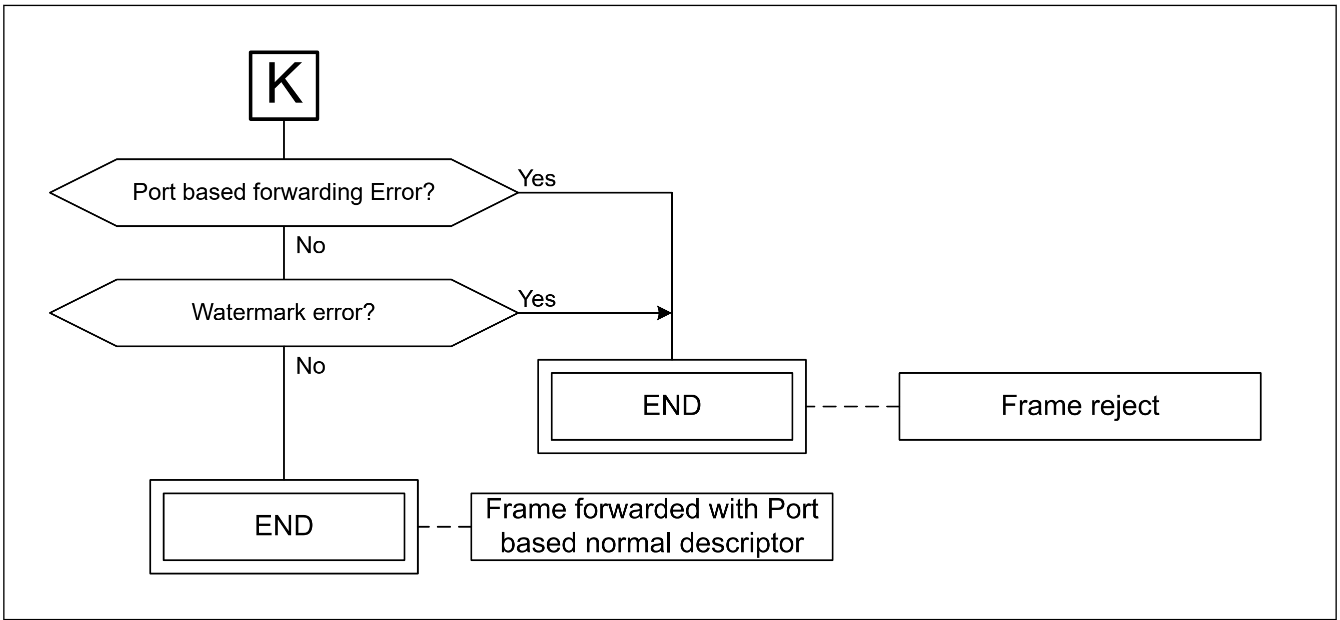

Figure 30.100 Port based forwarding unsecure flow

Note:
- Port based forwarding errors are described in (1) L2 forwarding errors.
- Watermark errors are described in (1) Watermark errors.
- Link K is linked from Figure 30.96.

30.5.2.6.1 Port based Forwarding Errors

Table 30.61describes the Port based forwarding errors. Instead of being discarded by forwarding engine, an error frame can be forwarded to exceptional path using Port based exceptional descriptor described in section 30.5.2.6.3. Port Based Exceptional Descriptor by setting corresponding error exceptional bit. For error set conditions, refer to corresponding error interrupt register explanations.

Table 30.61 Port based forwarding Errors

Error	Error name	Error interrupt	Error exceptional bit
Port based forwarding secure errors			
SNTF	Secure No Target Filtering	FWEIS0i.PBNTFS	FWCEPRC2.FPBNTFEF
Port based forwarding errors			
NTF	No Target Filtering	FWEIS0i.PBNTFS	FWCEPRC2.FPBNTFEF

30.5.2.6.2 Port based Normal Descriptor

Port based normal descriptor fields are described in Table 30.62.

Table 30.62 Port based normal descriptor fields (1 of 2)

Field name FDESCR.	Values
DV	FWPBFCi.PBDV
SEC	FWPBFCi.PBSL
CSDj	FWPBFCSDCi0.PBCSD
IPV	If FWPBFCi.PBIPU is set, set to FWPBFCi.PBIPV If FWPBFCi.PBIPU is not set, set to the frame input priority (section section 30.5.1.4. ESWM Frame Input Priority)

30.5.2.7 Layer 2/Layer 3 Update

Layer 2/Layer 3 Update aims at updating frames before sending them. Agents will use the L23 update interface to fetch the update information from the forwarding engine and will automatically update the frames following the Layer 2/Layer 3 Update rule. Frames Layer 2/Layer 3 Update information fetching will happen for Layer 3 forwarding/routing/filtering frames with respectively L3.RV set.

Layer 2/Layer 3 Update is divided in the following items:

- Rule format: Determines what information will be store along with the stream ID in the table.
- Learning: Function to add/suppress a Layer 2/Layer 3 Update rule by software.
- Reading: Function to read a Layer 2/Layer 3 Update rule by software.
- Rule fetching: Function used by agents to read a Layer 2/Layer 3 Update rule.

30.5.2.7.1 Rule Format

The Layer 2/Layer 3 Update RAM is used to store Layer 2/Layer 3 Update rules. A Layer 2/Layer 3 Update rule contains the information for the frame routing. All the fields in this table, if quoted, will be written L23U.{Field name}. Table 30.66 describes fields contained in a L3 rule.

Table 30.66 Layer 2/Layer 3 Update rule format (1 of 2)

Field name	Field size (bit)	Field Explanation
RPV	4	Routing Port Valid. Values: • Bit i set to 0: Routing rule won't apply for port i. • Bit i set to 1: Routing rule will apply for port i. Functions: • If set to all0, this field will disable the corresponding routing entry. In case RPV is 0 for an egress port, the frame is not updated and will be transmitted unmodified.
TTLU	1	TimeToLive update Functions: • If this bit is set and the corresponding frame is detected as an IPv4 frame, the TTL field will be decremented by 1 and the header checksum will be updated accordingly. • If this bit is set and the corresponding frame is detected as an IPv6 frame, the HopLimit field will be decremented by 1.
MDAU	1	MAC Destination Address Update Functions: • If this bit is set, the rule corresponding frame MAC address will be updated to L23U.MDA.
MSAU	1	MAC Source Address Update Functions: • If this bit is set, the rule corresponding frame MAC address will be updated to corresponding agent MAC address.
CVIDU	1	C-tag VLAN ID Update Functions: • If this bit is set, the rule corresponding frame C-tag VLAN ID will be updated to L23U.CVID.
CPCPU	1	C-tag PCP Update Functions: • If this bit is set, the rule corresponding frame C-tag PCP will be updated to L23U.CPCP.

Table 30.66 Layer 2/Layer 3 Update rule format (2 of 2)

Field name	Field size (bit)	Field Explanation
CDEIU	1	C-tag DEI Update Functions: ● If this bit is set, the rule corresponding frame C-tag DEI will be updated to L23U.CDEI.
SVIDU	1	S-tag VLAN ID Update Functions: ● If this bit is set, the rule corresponding frame S-tag VLAN ID will be updated to L23U.SVID.
SPCPU	1	S-tag PCP Update Functions: ● If this bit is set, the rule corresponding frame S-tag PCP will be updated to L23U.SPCP.
SDEIU	1	S-tag DEI Update Functions: ● If this bit is set, the rule corresponding frame S-tag DEI will be updated to L23U.SDEI.
RTU	2	R-TAG update Values: ● 00b: Frame received without R-TAG will be forwarded without R-TAG, Frame received with R-TAG will be forwarded with an R-TAG containing FDESCR.SEQN sequence number. ● 01b: All frames will be forwarded with an R-TAG containing FDESCR.SEQN sequence number (used for sequence number generation, refer to section section 30.5.3.2.2. Sequence Number Generation). ● 10b: All frames will be forward without R-TAG (used to strip R-TAG after elimination, refer to section (1) Stream identification, FRER recovery, initial stream recovery).
MDA	48	MAC Destination Address Functions: ● Used to update MAC destination address.
CVID	12	C-tag VLAN ID Functions: ● Used to update C-tag VLAN ID.
CPCP	3	C-tag PCP Functions: ● Used to update C-tag PCP.
CDEI	1	C-tag DEI Functions: ● Used to update C-tag DEI.
SVID	12	S-tag VLAN ID Functions: ● Used to update S-tag VLAN ID.
SPCP	3	S-tag PCP Functions: ● Used to update S-tag PCP.
SDEI	1	S-tag DEI Functions: ● Used to update S-tag DEI.

30.5.2.7.2 SW Learning

Learning is used to add/remove an entry in the Layer 2/Layer 3 Update rule table.Table 30.67 describes register used to learn an entry in the Layer 2/Layer 3 Update rule table. Table 30.68 describes the learn results.

Table 30.67 Layer 2/Layer 3 Update rule learn registers (1 of 2)

Register name	Field name/corresponding field in l23u table	Field explanation

30.5.2.7.4 HW Reading

Hardware reading is used by agents [GWCA][ETHA] to fetch the Layer 2/Layer 3 Update rule corresponding to a frame and update the frame. The read result is given to agents to perform Layer 2/Layer 3 update along with L23U.ERR which is used to notify to agents that the corresponding data should be rejected.

30.5.2.7.5 Routing Number Remapping Function

The routing number remapping function is used to change the routing number for a specific port using FWL23URMCi register. That way, different ports can use different Routing Rules for the same frame. It can be used for FRER during replication (section section 30.5.3.2.1. Replication) to send a duplicated frame through several ports with a different stream ID.

Functions:

- When FWL23URMCi.RME is set, a frame sent to port FWL23URMCi.RMDPN with FDESCR.RV set and FDESCR.RN equal to FWL23URMCi.RMRN will be routed with rule number FWL23URMCi.RMNRN.

30.5.3 Filtering

Forwarding engine allows frame filtering and shaping using the following functions:

- PSFP (Per Stream Filtering and Policing) [802.1Qci]
- ATS (Asynchronous Traffic Shaping) [802.1Qcr]
- FRER (Frame Replication and Elimination for Reliability) [802.1CB]

30.5.3.1 PSFP/ATS

PSFP functions is divided in three functions that happen sequential following forwarding flow in Figure 30.87:

- MSDU filter
- Meter filter/ATS

30.5.3.1.1 MSDU Filter

The MSDU filter aims at checking frame size using FWPMFGCi register and can be monitored using FWEIS2 interrupt register. MSDU filtering flow for MSDU filter i is described in Figure 30.103.

Functions:

- FWPMFGCi is used to set MSDU filter number i maximum frame size and mode.
- FWEIS2 interrupt register notifies that an ethernet descriptor has been rejected because of an error.

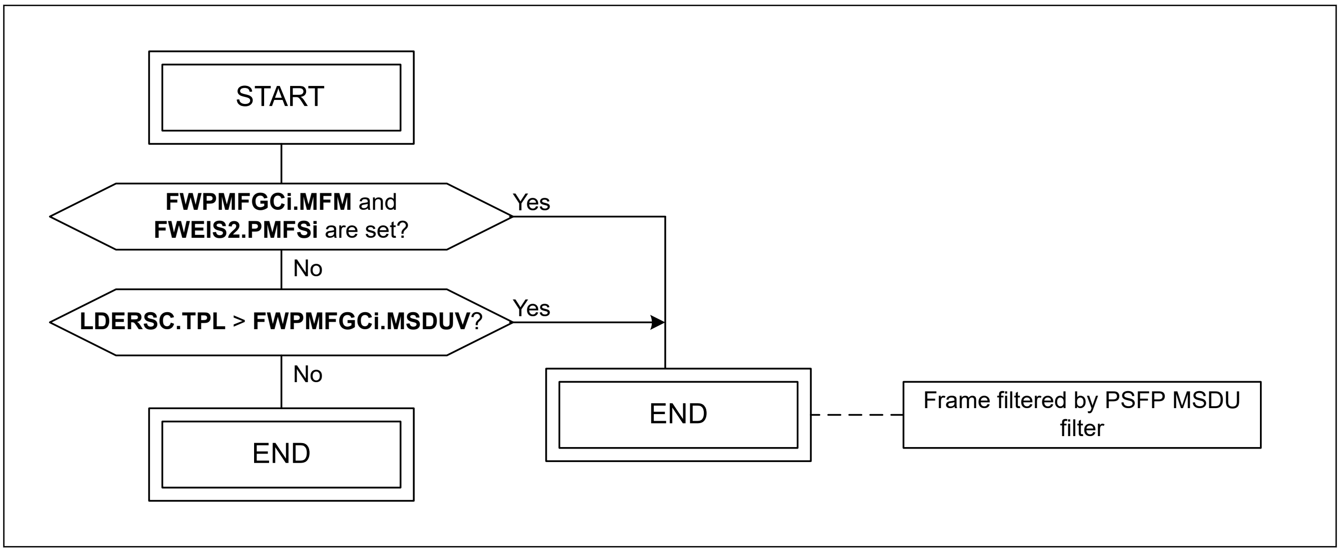

Figure 30.103 MSDU filtering flow for MSDU filter i

30.5.3.1.2 Meter Filter/ATS

The meter filter aims at checking a stream throughput or, in ATS, at controlling a stream throughput using FWPMTRFCi, FWPMTRCBSCi, FWPMTRCIRCi, FWPMTREBSCi, FWPMTREIRCi registers and can be monitored using FWPMTRFMi register and FWEIS5 interrupt registers. Meter filtering flow for meter i is described in Figure 30.104.

Functions:

- FWPMTRFCi register is used to set Meter filter i modes.
- FWPMTRCBSCi and FWPMTRCIRCi registers are used to set Meter filter i green bucket.
- FWPMTREBSCi and FWPMTREIRCi registers are used to set Meter filter i yellow bucket.
- FWPMTRFMi is used to monitor ATS shaper i.
- FWEIS5 interrupt register notifies that an ethernet descriptor has been rejected because of an error.

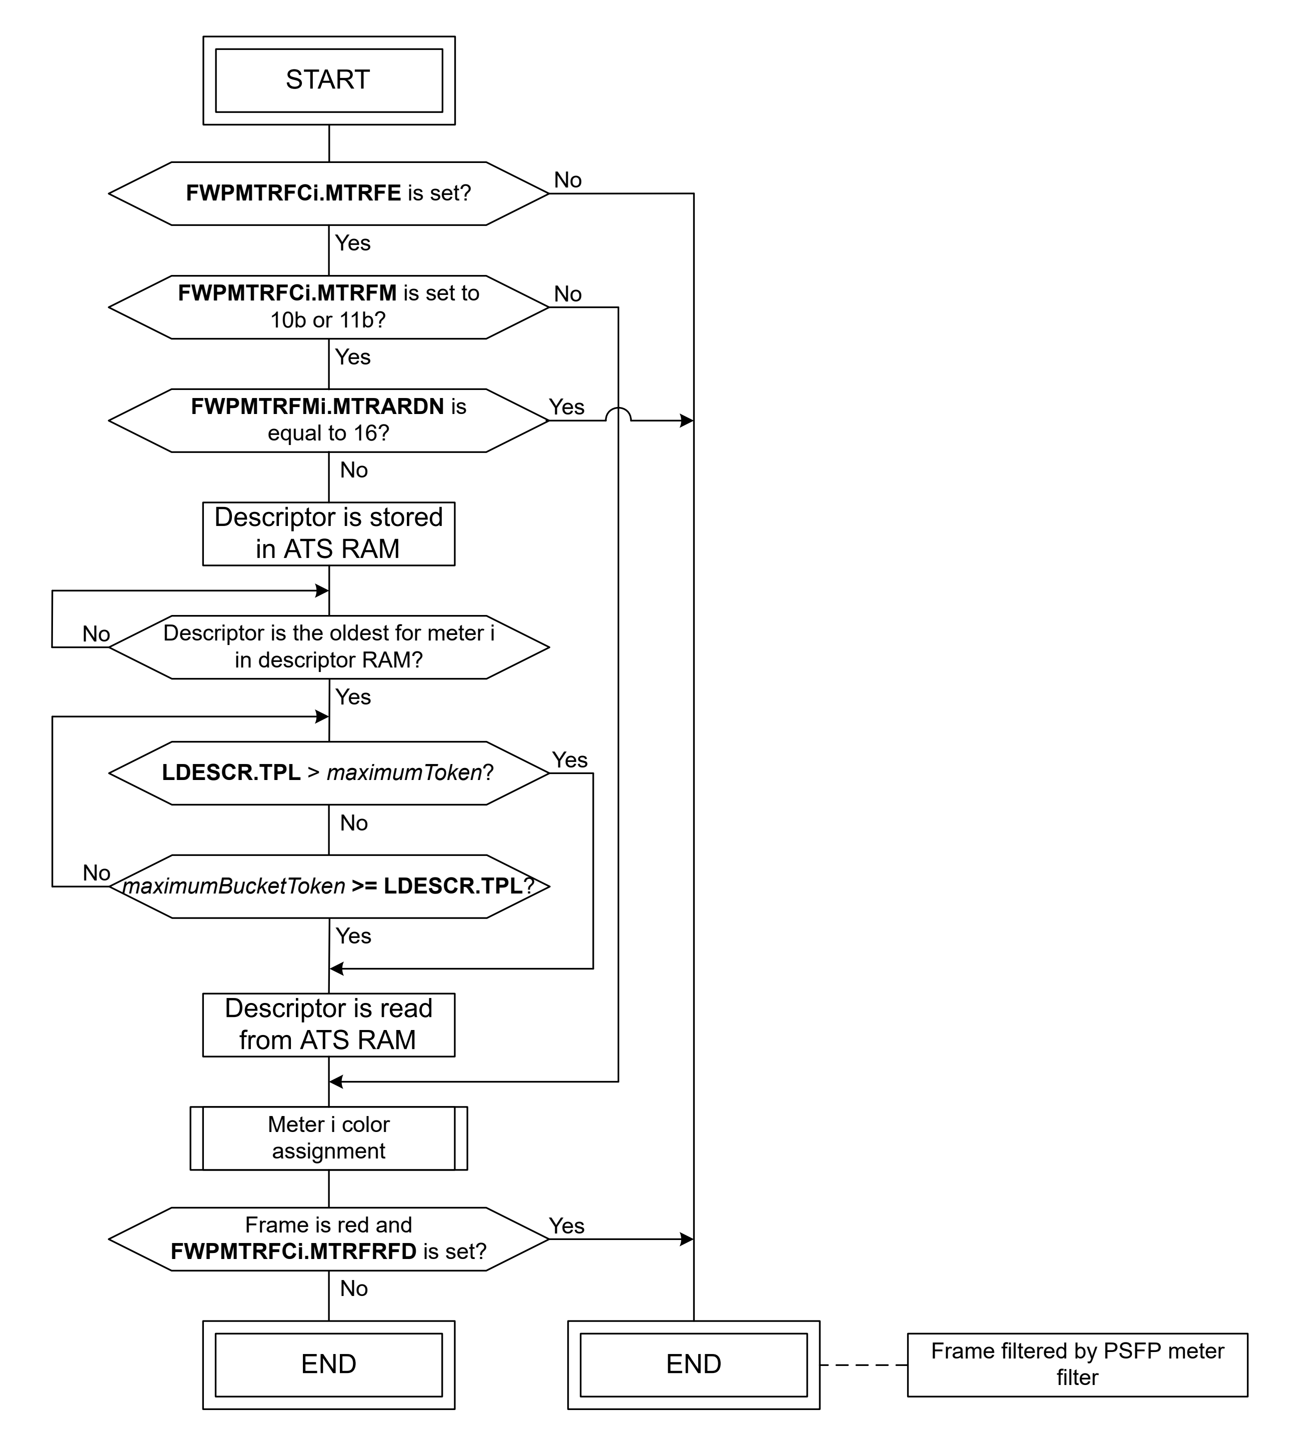

Figure 30.104 Meter filtering flow for meter i

Note:
- For Meter i color assignment refer to Figure 30.105 and Figure 30.106
- In Figure 30.104, *maximumToken* is the maximum number of tokens that can be contained in one meter biggest bucket. For Double bucket meters, it corresponds to the maximum value between FWPMTRCBSCi and FWPMTREBSCi and for Single bucket meters, it corresponds to FWPMTRCBSCi value. Any frame rejected by "LDESCR.TPL [GWCA] > *maximumToken*" condition will be marked as red.
- In Figure 30.104, *maximumBucketToken* is, for a double bucket the maximum number between the number of tokens actually contained in the yellow bucket and the number of tokens actually contained in the green bucket, for a single bucket the number of tokens actually contained in the green bucket.
- In Figure 30.104, any frame rejected by "FWPMTRFMi.MTRARDN is equal to 16" conditions (meter corresponding ATS descriptor queue full) will have no color.

Recommendations:

- For every L3 rule mapped to a meter, it is recommended to map also an MSDU filter with a value smaller or equal to the meter corresponding *maximumToken* value. It will be allowed to know that whenever FWEIS5.PMRFSi is set, it is due to an ATS RAM overflow in ATS mode and due to a maximum throughput reached error in other modes and, not due to a frame format error (frame being too big for the corresponding meter).

(1) Double bucket meters

Double bucket meters aim at giving a color to a frame. Meters from meter number 0 to meter number 7 are Double bucket meters.

(a) Double bucket color assignment

Double bucket meter i color assignment flow is described in Figure 30.105.

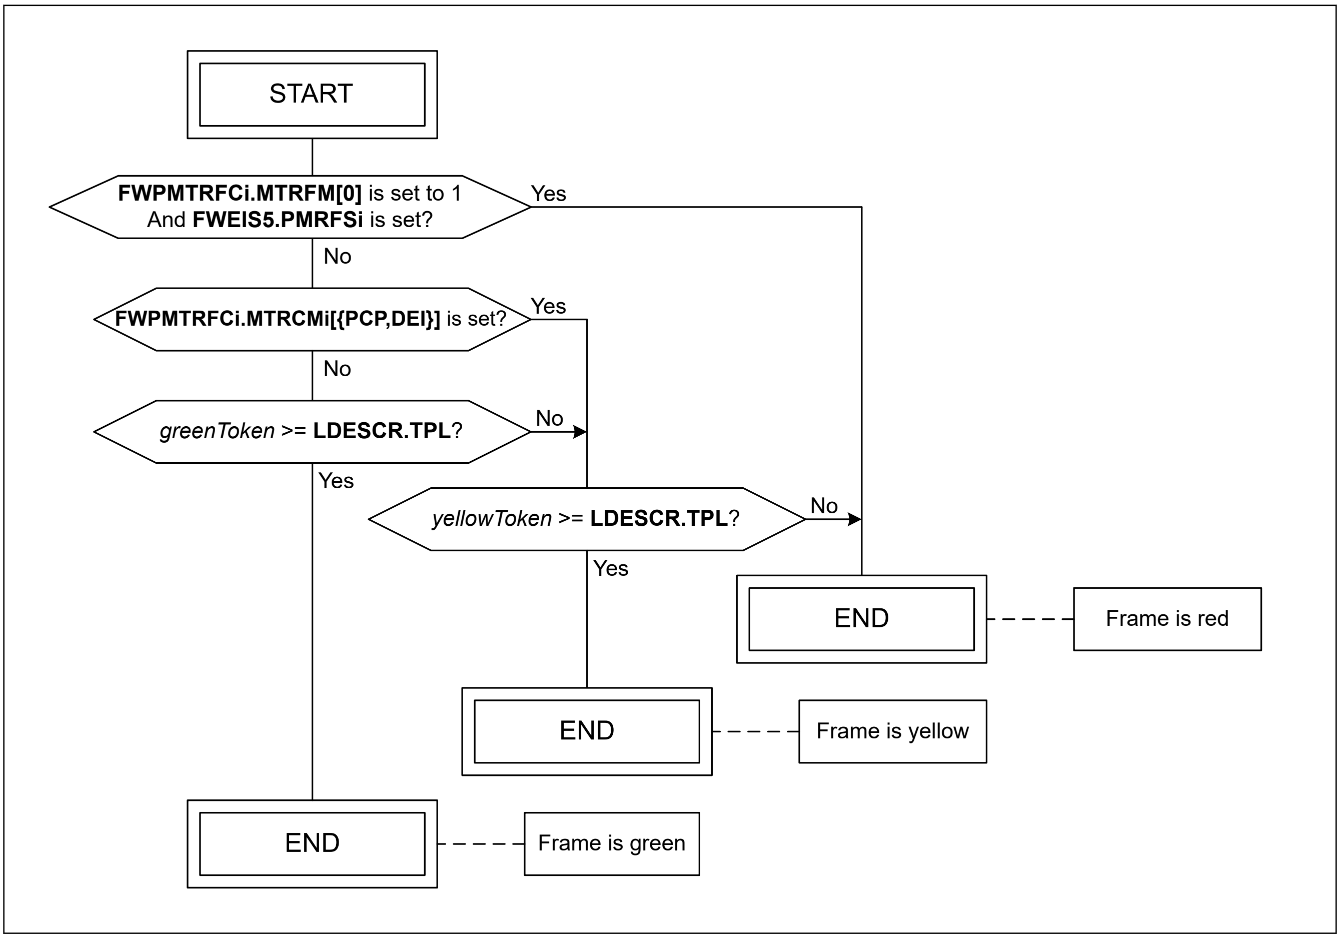

Figure 30.105 Double bucket meter i color assignment flow

In Figure 30.105:

- PCP and DEI are respectively the frame incoming S-TAG PCP and DEI values if **FWGC.SVM** is set to 10b, the frame incoming C-TAG PCP and DEI values if **FWGC.SVM** is set to 01b and, 000b and 0 if **FWGC.SVM** is set to 00b.
- *greenToken* is the number of tokens contained in the green bucket.
- *yellowToken* is the number of tokens contained in the yellow bucket.

(b) Double bucket setting

For double buckets, the green bucket (‘Committed' or ‘C' bucket) and the yellow bucket (‘Excess' or ‘E' bucket) needs to be set. For detail explanations concerning coupling flag, color mode and bucket utilization, refer to MEF standard [MEF10.3]. Equation (6) shows how to set information rates in FWPMTRCIRCi.CIR and FWPMTREIRCi.EIR. FWPMTRCBSCi.CBS and FWPMTREBSCi.EBS should be respectively set to the maximum excepted burst size for green and yellow frame in byte.

(6) *InformationRate[byte/cycle]* = *MaximumThroughput[bps]*/(8**clk_freq[Hz]*)

Where:

- *InformationRate* is the value to set to FWPMTRCIRCi.CIR or FWPMTREIRCi.EIR register.
- *MaximumThroughput[bps]* is the expected maximum throughput.
- *clk_freq* is the clock frequency of ESWCLK.

[Example]

If the meter is to be programmed for information rate of 200Mbps and system clock of 100 MHz :

InformationRate = $((200 * 1000000) / (8 * 100 * 1000000)) * 2^{16}$

CIR[15:0] or EIR[15:0] = $(\underline{0}.25) * 2^{16} = 16384$ (0x4000)

CIR[19:16] or EIR[19:16] = 0 (Underlined integer)

$(\text{CIR} \times 2^{-16})$ is added to the committed token bucket every system clock.

If the meter is to be programmed for information rate of 200 Mbps and system clock of 320 MHz :

InformationRate = $((1000 * 1000000) / (8 * 320 * 1000000)) \times 2^{16}$

CIR[15:0] or EIR[15:0] = $(\underline{0}.078125) \times 2^{16} = 5120$ (0x1400)

CIR[19:16] or EIR[19:16] = 0 (Underlined integer)

$(\text{CIR} \times 2^{-16})$ is added to the committed token bucket every system clock.

Note: • HW: DropOnYellow is not available in PSFP. To achieve drop on yellow function, the yellow bucket *InformationRate* FWPMTREIRCi.EIR and FWPMTREBSCi.EBS should be set to 0. As a result, all yellow frames will be marked as red and dropped.

(2) Single bucket meters

Single bucket meters aim at giving a color to a frame. Meters from meter number 8 to meter number 31 are Single bucket meters.

(a) Single bucket color assignment

Single bucket meter i color assignment flow is described in Figure 30.106.

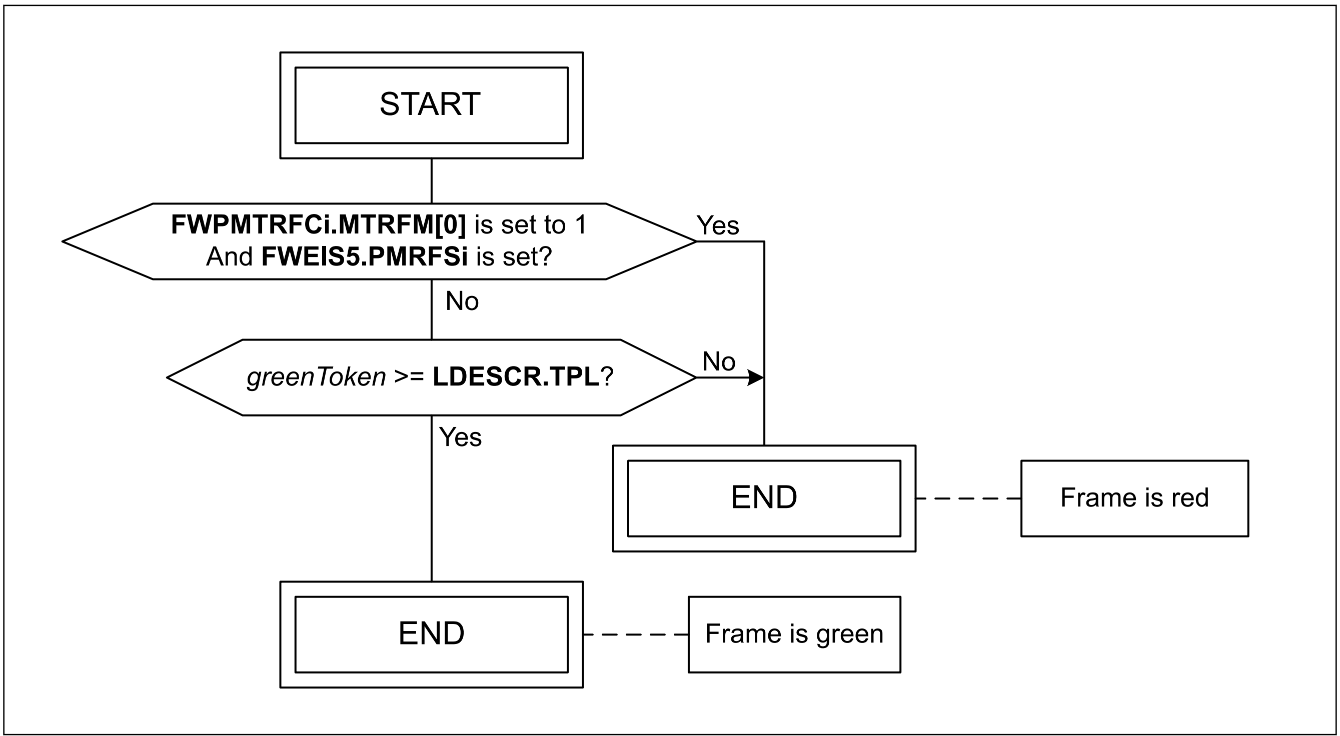

Figure 30.106 Single bucket meter i color assignment flow

In Figure 30.106:

- *greenToken* is the number of tokens contained in the green bucket.

(b) Single bucket setting

The single bucket should be set as the double bucket green bucket, refer to section (b) Double bucket setting.

30.5.3.2 FRER

FRER functions is divided in three functions that happen independently (they can be used simultaneously):

- Replication
- Sequence number generation
- Elimination

Note: • SW: Latent error detection is not implemented in HW and should be implemented in SW using FWFRPPCNi and FWFRDPCNi counters.

30.5.3.2.1 Replication

FRER replication function is used to send a same frame to different ports with different streams. To do so, Layer 3 forwarding/routing/filtering (section section 30.5.2.4. Layer 3 Forwarding/Routing/Filtering) should be used along with Layer 2/Layer 3 Update function (section section 30.5.2.7. Layer 2/Layer 3 Update).

Layer 3 forwarding/routing/filtering is used to multicast the incoming FRER stream to several ports and to map the FRER stream to a routing number. Table 30.71 shows an example where Layer 3 table is used to multicast a frame coming from port 2 to port 0 and port 1 and to map the corresponding stream to routing number 5.

Table 30.71 Layer 3 table setting for replication (1 of 2)

Field name L3.	Values	Explanation
SLV	100b	Not mandatory, ensure that the corresponding stream only comes from port 2.
DV	011b	Send the frame to port 0 and port 1
RV	1	Enable routing

Table 30.71 Layer 3 table setting for replication (2 of 2)

Field name L3.	Values	Explanation
RN	5	Map the stream to Layer 2/Layer 3 Update rule number 5

Layer 2/Layer 3 rule remapping is used to remap Routing number L3.RN for one of the ports to send the frame with different stream IDs and allow to learn the rules and the new fields for stream update. Table 30.72 shows an example where port 1 Layer 2/Layer 3 Update rule number is remapped to rule number 8 with 8.2.8.5 Routing number remapping rule number 4. Table 30.73 shown an example for Layer 2/Layer 3 Update rule setting for FRER.

Table 30.72 Layer 2/Layer 3 Update rule number remapping

Register name	Values	Explanation
FWL23URMC4.RME	1	Enable rule number remapping
FWL23URMC4.RMRN	5	Remap rule number 5
FWL23URMC4.RMDPN	1	Remap when routing access comes from port 1
FWL23URMC4.RMNRN	8	Remap rule to rule number 8

Table 30.73 Layer 2/Layer 3 Update rule settings

Field name L23U.	Values for rule 5	Values for rule 8	Explanation
RPV	001b	001b	Each rule is used for its corresponding port
TTLU	0	0	Do not update TimeToLive (user define)
MDAU	1	1	Update destination MAC address (user define)
MSAU	0	0	Do not update source MAC address (user define)
CVIDU	1	1	Update C-TAG (user define)
CPCPU	1	1	Update C-TAG (user define)
CDEIU	1	1	Update C-TAG (user define)
SVIDU	0	0	Do not update S-TAG (user define)
SPCPU	0	0	Do not update S-TAG (user define)
SDEIU	0	0	Do not update S-TAG (user define)
RTU	00b or 01b	00b or 01b	Set to 00b if the replicated stream contains an R-TAG at ingress Set to 01b if the replicated stream does not contain R-TAG at ingress (section section 30.5.3.2.2. Sequence Number Generation)
MDA	MAC0	MAC1	Set the new MAC address per each rule (user define)
CVID	VLAN0	VLAN1	Set the new VLAN ID per each rule (user define)
CPCP	PCP0	PCP1	Set the new PCP per each rule (user define)
CDEI	DEI0	DEI1	Set the new DEI per each rule (user define)
SVID	0x0	0x0	Do not update S-TAG (user define)
SPCP	000b	000b	Do not update S-TAG (user define)
SDEI	0	0	Do not update S-TAG (user define)

30.5.3.2.2 Sequence Number Generation

FRER sequence number generation is used during replication to generate a sequential sequence number to insert in stream corresponding frames (refer to section section 30.5.3.2.1. Replication for replication) using FWSEQNGCi and FWSEQNRC and can be monitored using FWSEQNGMi.

Functions:

- FWSEQNGCi register is used to enable sequence generation. While enabled, any frame forwarded with FWSEQNGCi.SEQNGRN as routing number will see its sequence number (FDESCR.SEQN) set to FWSEQNGMi.SEQN.
- FWSEQNGMi register is used to monitor the next sequence number to be used by sequence number generation rule i.

- FWSEQNRC.SEQNR is used to reset to 16’b0 the next sequence number to be used by sequence number generation rule i.

Note:
- SW: Sequence number generation should not be used along with elimination.
- A frame rejected by PSFP will not see its sequence number updated by sequence number generation.

30.5.3.2.3 Elimination

FRER elimination aims at identifying the FRER streams (Layer 3 forwarding/routing/filtering, section section 30.5.2.4. Layer 3 Forwarding/Routing/Filtering), verifying the integrity of a stream (FRER individual recovery, section (e) Individual recovery algorithms), at eliminating duplicated frames (FRER sequence recovery, (f) Sequence recovery algorithms), at recovering the stream ID (Layer 2/Layer 3 Update function (section section 30.5.2.7. Layer 2/Layer 3 Update)) and at checking that either the individual recovery or sequence recovery algorithm are stuck (Timeout function, section (3) Timeout). FRER elimination uses FWFTL0/1/R, FWFTOC and FWFTOPC registers and can be monitored using FWFTIM and FWFTR/RR0/RR1/RR2 registers and FWEIS60/61/62/63, FWEIS70/71/72/73 and FWEIS80/81/82/83 interrupt registers.

Functions:

- FWFTL0/1/R registers are used to set/reset an entry in FRER table.
- FWFTOC and FWFTOPC registers are used to set timeout function.
- FWFTIM register is used to reset the FRER table before utilization.
- FWFTR/RR0/RR1/RR2 registers are used to monitor FRER entries in FRER table.
- FWEIS60/61/62/63, FWEIS70/71/72/73 and FWEIS80/81/82/83 interrupt registers notify that an error happened during FRER elimination.

Note:
- SW: Sequence number generation should not be used along with elimination.

(1) Stream identification, FRER recovery, initial stream recovery

In this section, example will be given to explain the different function dependencies and settings. In this example two streams, 0 and 1, are respectively entering the switch from port 0 and 1 that separately should pass through individual recovery algorithm for integrity check and through the same sequence recovery algorithm for duplicate elimination. The eliminated stream should see its stream ID updated to new one and should be forwarded to port 2.

Stream identification is done by Layer 3 forwarding/routing/filtering function, refer to section section 30.5.2.4. Layer 3 Forwarding/Routing/Filtering. L3 table is used to map each stream to its corresponding FRER individual recovery individual recovery algorithm and also used to map stream to a Layer 2/Layer 3 update rule for stream ID recovery. In Table 30.74 example, stream 0 and stream 1 are respectively mapped to FRER entry number 15 and 23 for individual recovery and both streams are mapped to routing rule number 5 for stream ID recovery.

Table 30.74 Layer 3 table setting for elimination

Field name L3.	Values for stream 0	Values for stream 1	Explanation
SLV	001b	010b	Not mandatory, ensure that each stream comes from its corresponding source port.
DV	100b	100b	All streams for the same sequence recovery algorithm are targeting the port
FRERV	1	1	FRER individual recovery
FRERN	15	23	All streams are targeting a different individual recovery algorithm
RV	1	1	Enable routing
RN	5	5	All streams for the same sequence recovery algorithm are targeting the same Layer 2/Layer 3 update rule for stream ID recovery

FRER table is then used to map stream 0 and 1 individual recovery algorithms to a sequence recovery algorithm and used to set all the recovery algorithms. Table 30.75 shows an example were individual recovery algorithm are mapped to FRER entry number 67 for sequence recovery.

Table 30.75 FRER table setting for sequence recovery

Field name FRER.	Values for FRER entry number 15	Values for FRER entry number 23	Values for FRER entry number 67	Explanation
SRPV	1	1	0	Enable sequence recovery for an individual recovery algorithm
SRP	67	67	All0	Sequence recovery entry number

Layer 2/Layer 3 Update functions is used to recover the output stream ID in the frame. Table 30.76 shown an example for Layer 2/Layer 3 Update rule setting for FRER.

Table 30.76 Layer 2/Layer 3 Update rule settings

Field name L23U.	Values for rule 5	Explanation
RPV	100b	Set to the target port
TTLU	0	Do not update TimeToLive (user define)
MDAU	1	Update destination MAC address (user define)
MSAU	0	Do not update source MAC address (user define)
CVIDU	1	Update C-TAG (user define)
CPCPU	1	Update C-TAG (user define)
CDEIU	1	Update C-TAG (user define)
SVIDU	0	Do not update S-TAG (user define)
SPCPU	0	Do not update S-TAG (user define)
SDEIU	0	Do not update S-TAG (user define)
RTU	00b or 01b	Set to 00b if the output stream should contain the ingress R-TAG Set to 10b if the output stream should be sent without R-TAG
MDA	MAC0	Set the new MAC address per each rule (user define)
CVID	VLAN0	Set the new VLAN ID per each rule (user define)
CPCP	PCP0	Set the new PCP per each rule (user define)
CDEI	DEI0	Set the new DEI per each rule (user define)
SVID	0x0	Do not update S-TAG (user define)
SPCP	000b	Do not update S-TAG (user define)
SDEI	0	Do not update S-TAG (user define)

In this section only an example has been developed, by using the same kind of settings it is possible to:

- Have only one ingress stream and one output stream with the same stream ID and only apply individual recovery.
- Have more than 2 input streams for elimination.
- Have more than 1 output stream after elimination (by applying FRER replication, section section 30.5.3.2.1. Replication)

(2) FRER table

FRER table is used to store setting and information used for recovery algorithms.

FRER table is divided in the following items:

- Rule format: Determines what information will be store in the FRER table
- SW Learning: Function to set an FRER entry in the FRER table.
- SW Reading: Function to read an FRER entry in the FRER table.

(a) Rule format

The FRER table is used to store FRER entries. A FRER entry contains information recovery algorithms. All the fields in this table, if quoted, will be written FRER.{Field name}. Table 30.77 describes fields contained in a FRER entry.

Table 30.77 FRER entry format

Field name	Field size (bit)	Field explanation
SHL	4	Sequence History Length Values: ● 0: Recovery match algorithm ● i different from 0: Recovery vector algorithm with history length of i+1
SH	15	Sequence History: Functions: ● Used to save sequence history for recovery algorithms
RSN	16	Recovery Sequence Number Functions: ● Used to save last highest sequence number (modulo 2^{16}) for recovery algorithms
TNS	1	Take No Sequence Values: ● 0: Frames received without R-TAG (LDESCR.RTGI [GWCA] not set) are rejected ● 1: Frames received without R-TAG (LDESCR.RTGI [GWCA]not set) are forwarded
SRPV	1	Sequence Recovery Pointer Valid Values: ● 0: After using this entry for individual recovery, sequence recovery will not happen ● 1: After using this entry for individual recovery, sequence recovery will happen using FRER entry number FRER.SRP
SRP	7	Sequence Recovery Pointer Functions: ● Set the number of the FRER entry that should be used for sequence recovery Note: Any entry used for sequence recovery cannot be used for individual recovery. As a result, when a Recovery number is set in FRER.SRT when FRER.SRPV is set, the same number cannot be set in L3.FRERN when L3.FRERV is set.
SRRT	10	Set Recovery Remaining Tick Functions: ● Time in tick (one tick is FWFTOC.TOCE) before timeout. ● Setting this register to All0 disable timeout function for the corresponding entry
RRT	10	Recovery Remaining Tick Functions: ● Used by timeout function to detect timeout error.

(b) SW Learning

Learning is used to set/reset an entry in the FRER table. Table 30.78 describes register used to learn an entry in the FRER table. Table 30.79 describes the learn results. To reset an entry, software should re-learn the same entry again.

Table 30.78 FRER entry learn registers

Register name	Field name/corresponding field in l23u table	Field explanation
FWFTL0.FEAL	Entry Learn address	Corresponding the entry number that should be learnt in FRER table
FWFTL1.FSHLL	FRER.SHL	See (a) Rule format.
No register Set to All0 While learning (TakeAny)	FRER.SH	See (a) Rule format.
No register Set to All1 While learning	FRER.RSN	See (a) Rule format.
FWFTL1.FTNSL	FRER.TNS	See (a) Rule format.
FWFTL1.FSRPVL	FRER.SRPV	See (a) Rule format.
FWFTL0.FSRPL	FRER.SRP	See (a) Rule format.
FWFTL1.FSRRTL	FRER.SRRT	See (a) Rule format.
No register Set to All0 While learning	FRER.RRT	See (a) Rule format.

Table 30.79 FRER entry learn result

Register name	Field name/corresponding field in FRER table	Field explanation
FWFTLR.FLF	Learning fail	Learning fail with happen in one of the following conditions: ● The FRER table is not ready (FWFTIM.FTR is not set)

(c) SW Reading

Learning is used to read an entry in the FRER table. Table 30.80 describes register used to read an entry in the FRER table. Table 30.81 describes the read results.

Table 30.80 FRER entry read registers

Register name	Field name/corresponding field in l23u table	Field explanation
FWFTR.FEAR	Entry Read address	Corresponding the entry number that should be read from FRER table

Table 30.81 FRER entry learn result

Register name	Field name/corresponding field in l23u table	Field explanation
FWFTRR0.FSHLR	FRER.SHL	See (a) Rule format.
FWFTRR1.FSHR	FRER.SH	See (a) Rule format.
FWFTRR2.FRSNR	FRER.RSN	See (a) Rule format.
FWFTRR0.FTNSR	FRER.TNS	See (a) Rule format.
FWFTRR0.FSRPVR	FRER.SRPV	See (a) Rule format.
FWFTRR0.FSRPR	FRER.SRP	See (a) Rule format.
FWFTRR0.FSRRTR	FRER.SRRT	See (a) Rule format.
FWFTRR2.FRRTR	FRER.RRT	See (a) Rule format.

(d) Recovery algorithms

Individual recovery or sequence recovery algorithm can both be performed using either a match recovery algorithm or a vector recovery algorithm. For an entry, match recovery algorithm can be selected by setting All0 to its corresponding FRER.SHL field. If any other value is set vector recovery algorithm will be selected.

Match recovery algorithm is only used to detect if a stream is stuck (two frames are received consecutively with the same sequence number).

Vector recovery algorithm is used to check a stream sequence by accepting all packets within a given range (±FRER.SHL) from the last accepted highest sequence recovery number. This algorithm also ensures than within this range no sequence number is received more than on time.

(e) Individual recovery algorithms

Individual recovery match algorithm and vector algorithm are respectively described in Figure 30.107 and Figure 30.108. The variable *Delta* present in these figures is the distance from the ingress frame sequence number to FRER.RSN (This number should be considering overflow and should be contained in [-32767:32768] range).

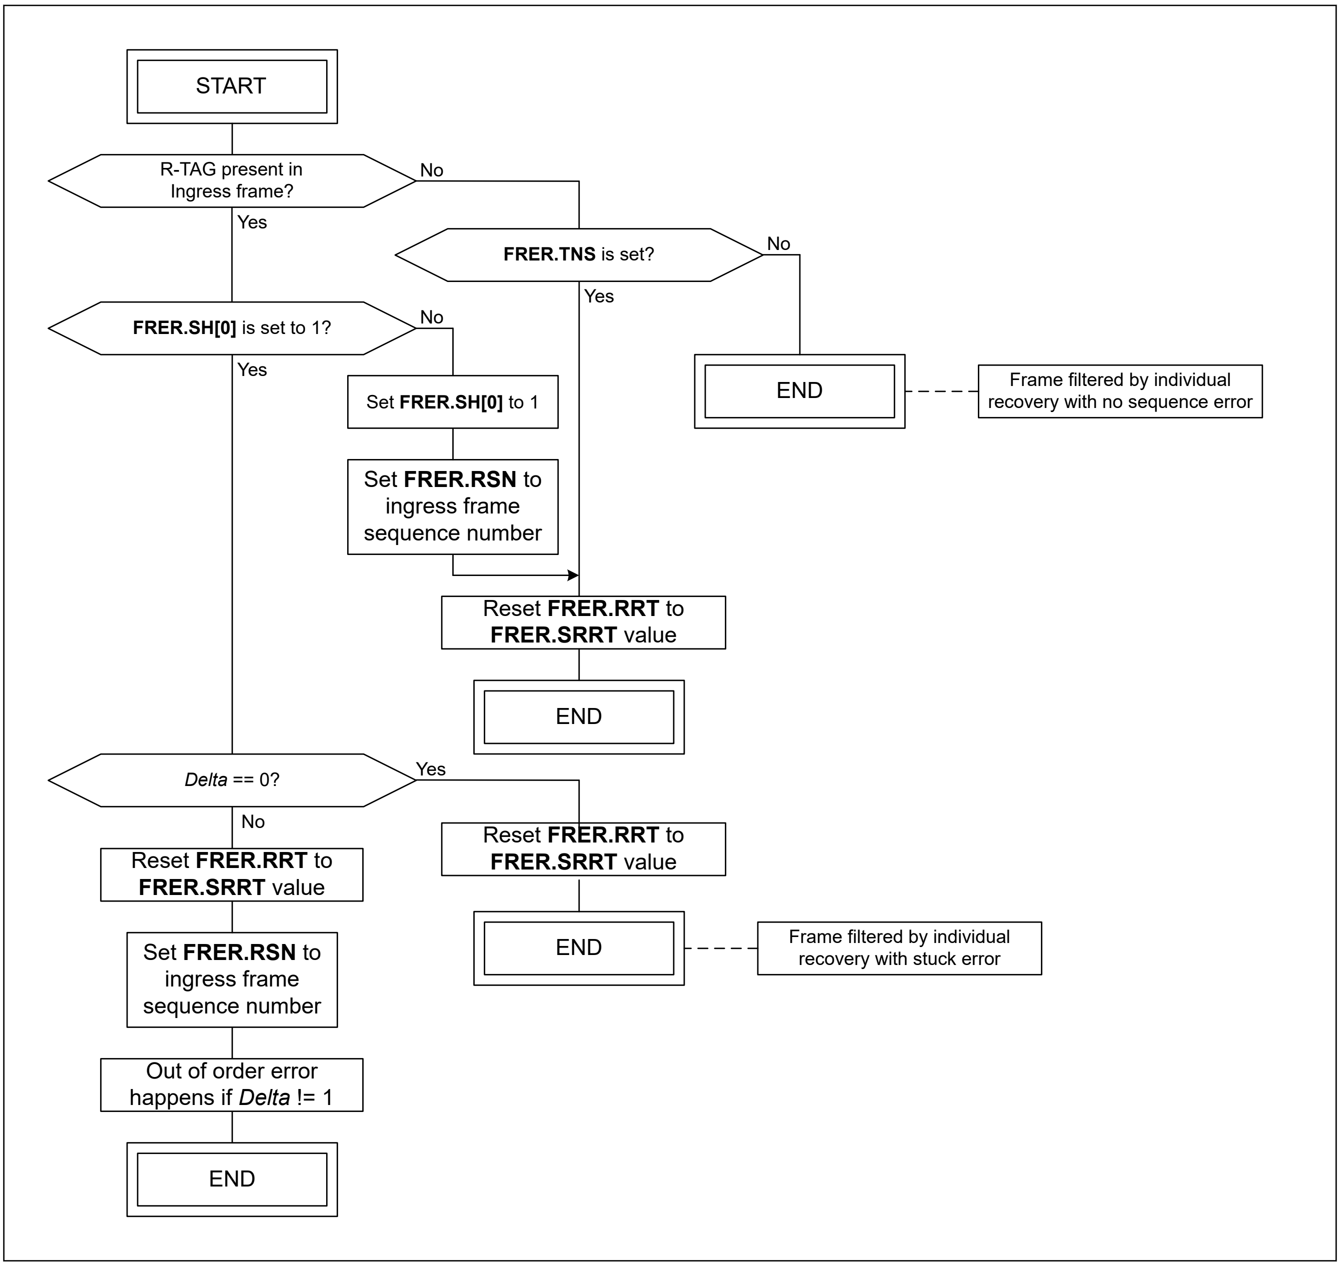

Figure 30.107 Individual recovery match algorithm

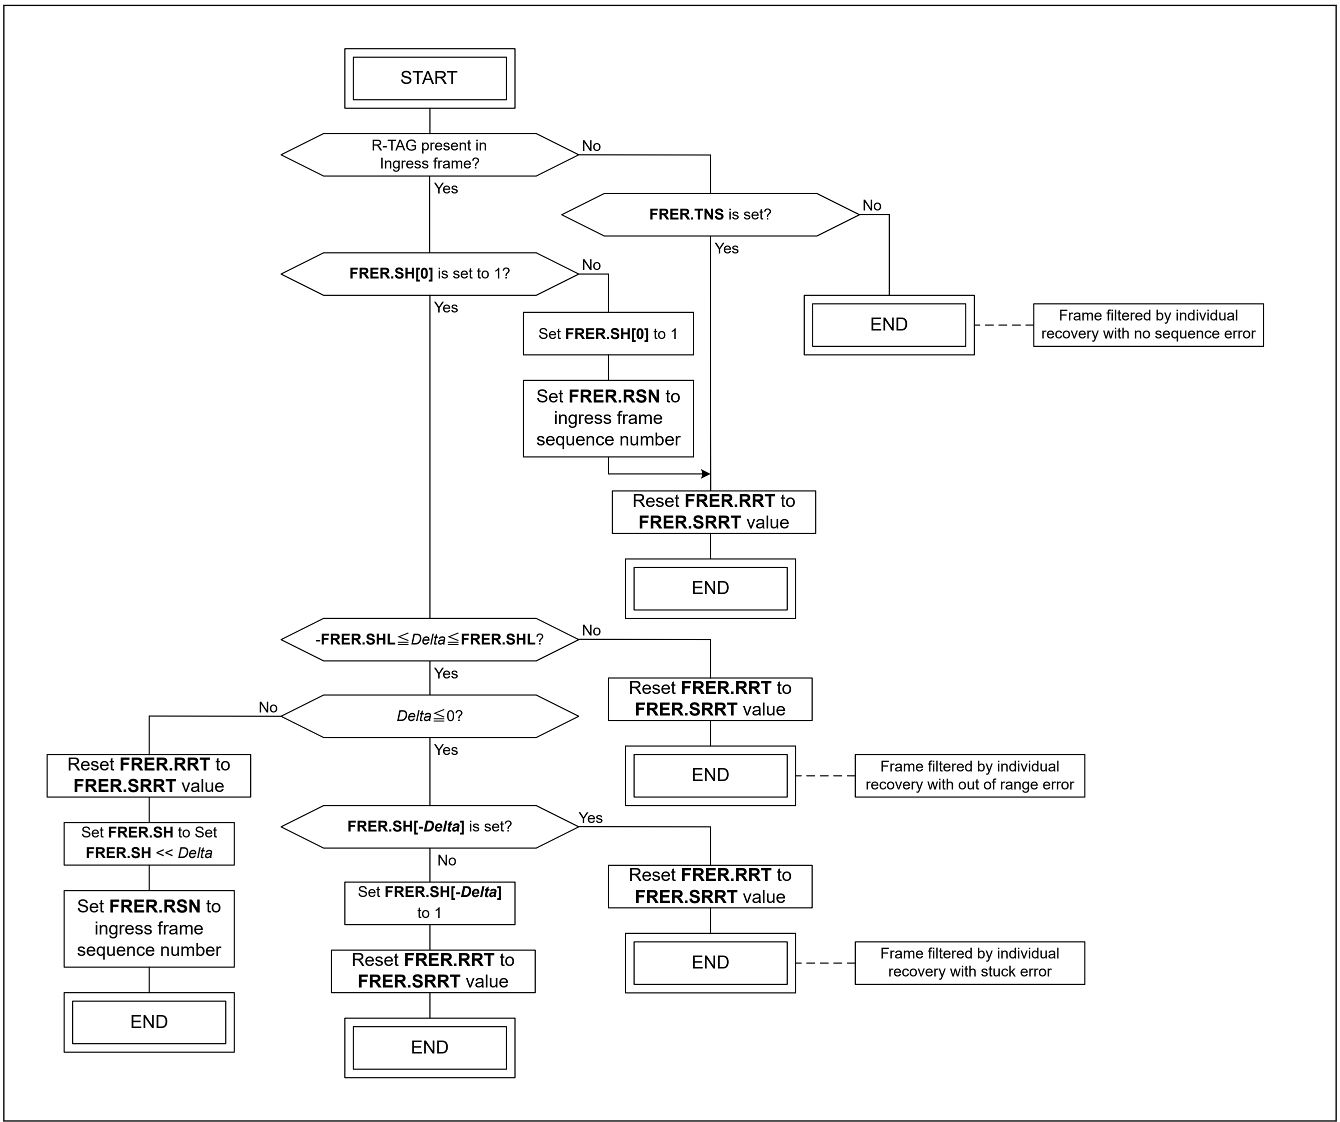

Figure 30.108 Individual recovery vector algorithm

Note: Even if the recovery length is smaller than 14, the sequence history saved in the FRER table will contain the history until 14. Vector recovery algorithm will ignore the useless bits.

(f) Sequence recovery algorithms

Sequence recovery match algorithm and vector algorithm are respectively described in Figure 30.109 and Figure 30.110. The variable *Delta* present in these figures is the distance from the ingress frame sequence number to FRER.RSN (This number should be considering overflow and should be contained in [-32767:32768] range).

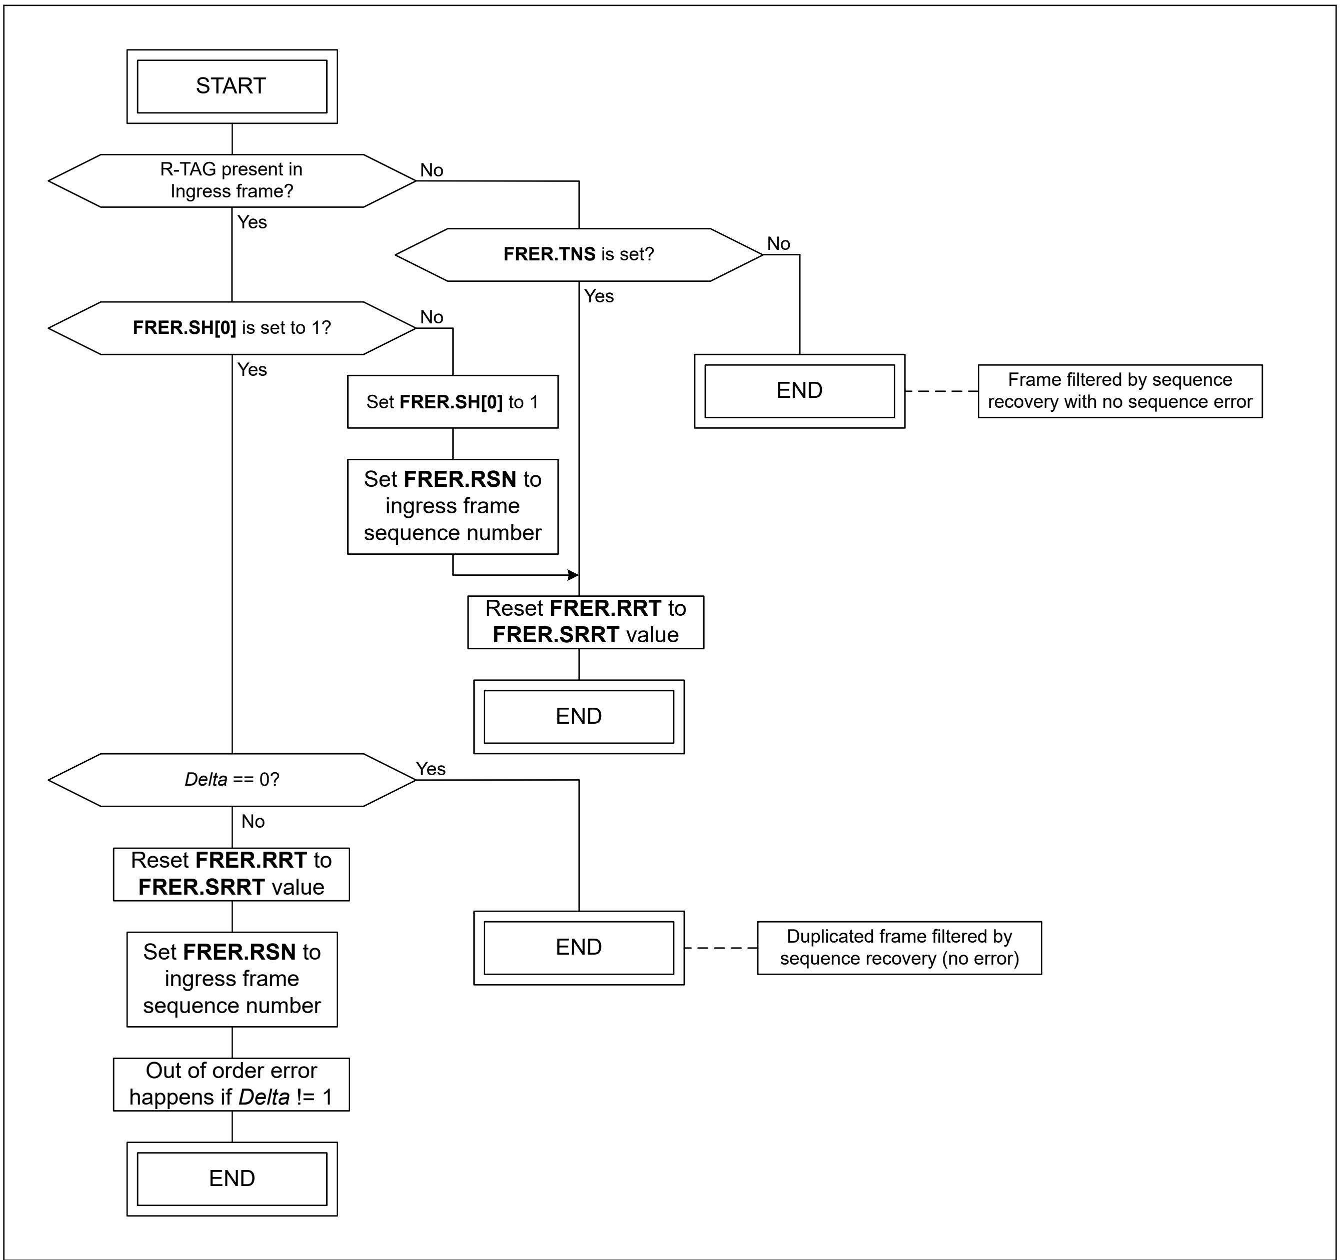

Figure 30.109 Sequence recovery match algorithm

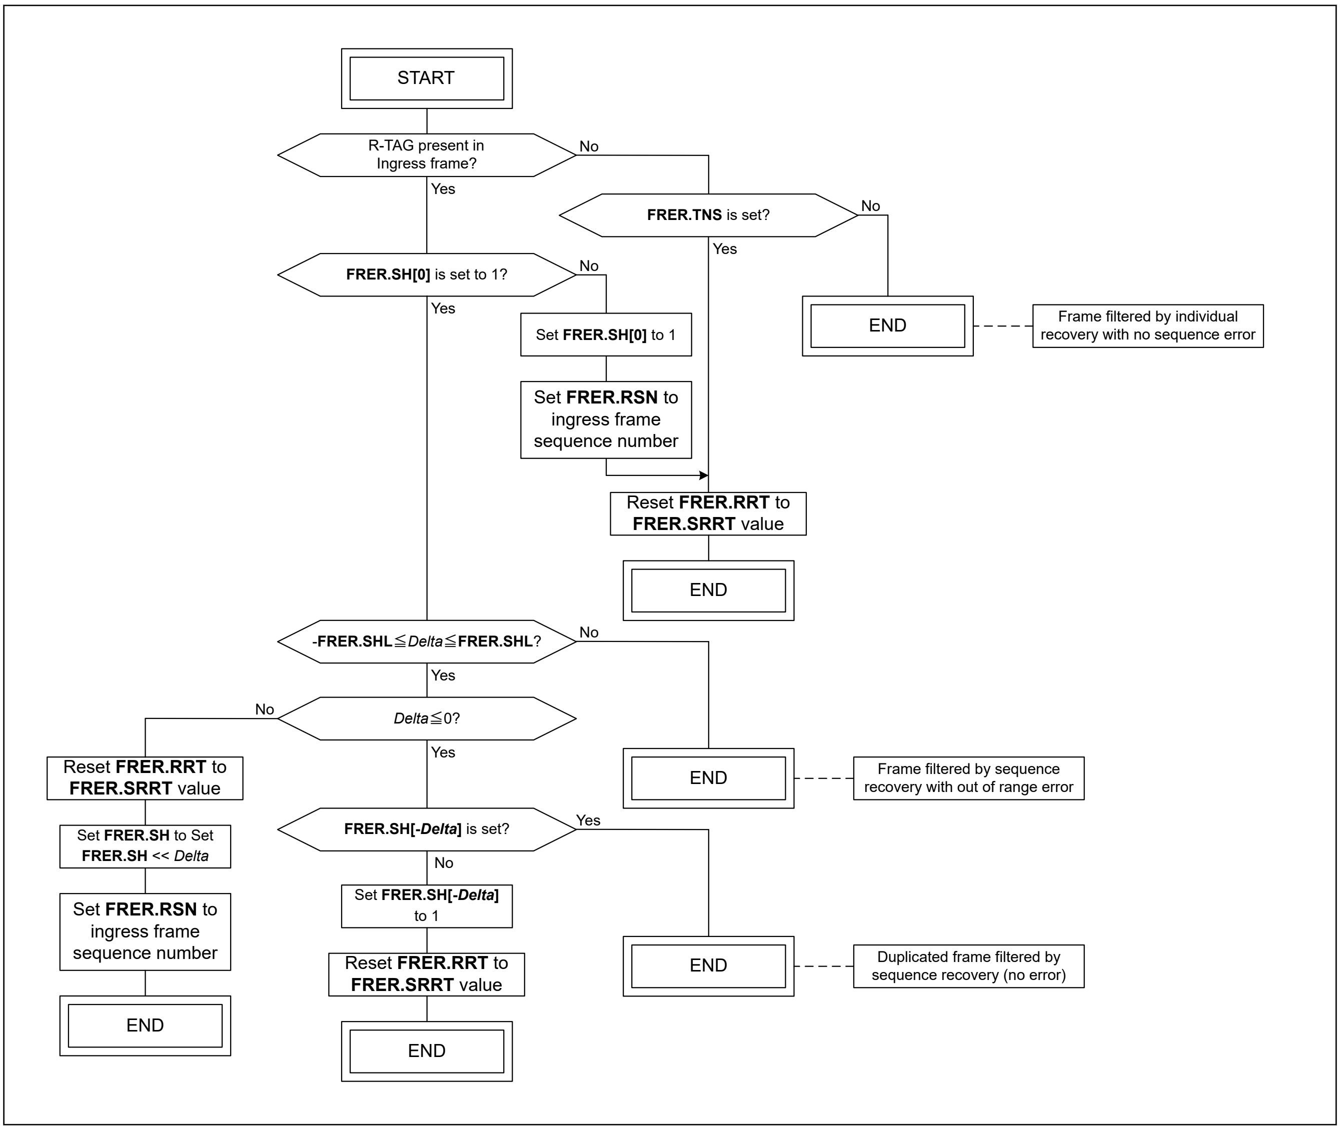

Figure 30.110 Sequence recovery vector algorithm

Note: Even if the recovery length is smaller than 14, the sequence history saved in the FRER table will contain the history until 14. Vector recovery algorithm will ignore the useless bits.

(3) Timeout

The timeout function aims at detecting when a recovery algorithm had no passing frame since a certain time and should be reset because it could be stuck. The timeout functional flow is described in for when timeout functions is enabled (FWFTOC.TOCE set to 1). This flow happens for all the FRER entries.

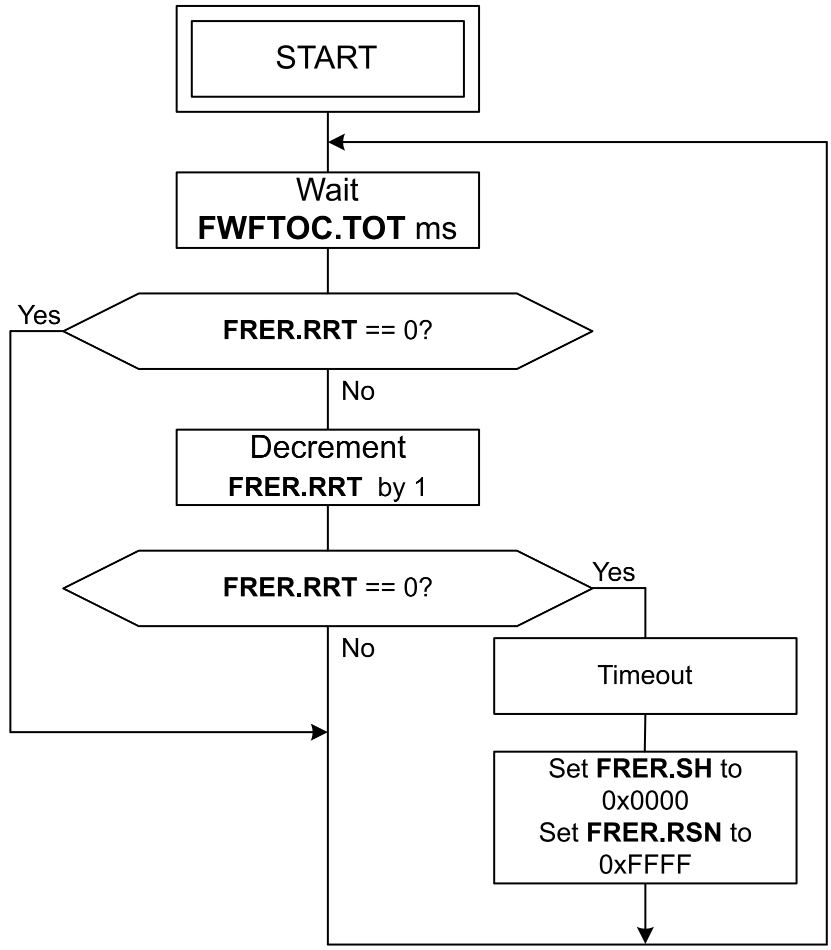

Figure 30.111 Timeout functional flow

30.5.4 Fabric (MFAB)

Fabric Bus (MFAB) is an internal bus used to exchange data between Ethernet Agent [ETHA], Ethernet Common Agent [COMA], Ethernet CPU Agent [GWCA], local RAM, TAG RAM, pointer RAM, and Ethernet Message Forwarding Engine [MFWD].

Table 30.82 lists Fabric features.

Table 30.82 Fabric feature list (1 of 2)

Function		Details
Overall function	Data transfer	• Function to transfer data and access to RAMs
Data provision		• Data for Fabric • Initial frame data + Intermediate data + Last frame data + Frame Descriptor • Data width: 128 + 48 + 9 bits

Table 30.82 Fabric feature list (2 of 2)

Function		Details
Control function	Time arbiter	● Arbitration between Time-critical agents [ETHA] for data bus. Arbitration scheme depends on each Time critical agents [ETHA] PHY link/Internal speed.
	Arbitration	● LRU for Time critical-agents [ETHA], Slow agents [GWCA] and Ethernet Common Agent [COMA] error read requests arbitration. ● LRU between Slow agents [GWCA] for read/write bus arbitration. ● Strict priority like arbitration between time arbiter, Error LRU, and slow LRU. ● Priority: time arbiter > slow LRU > Error LRU
	RAM access	● Function that writes and reads to RAM
	Transfer write request to Forwarding Engine	● Function to transfer write request sent from ETHA Agents [ETHA] or GWCAs [GWCA] to Forwarding Engine.

Figure 30.112 shows Fabric interface protocol.

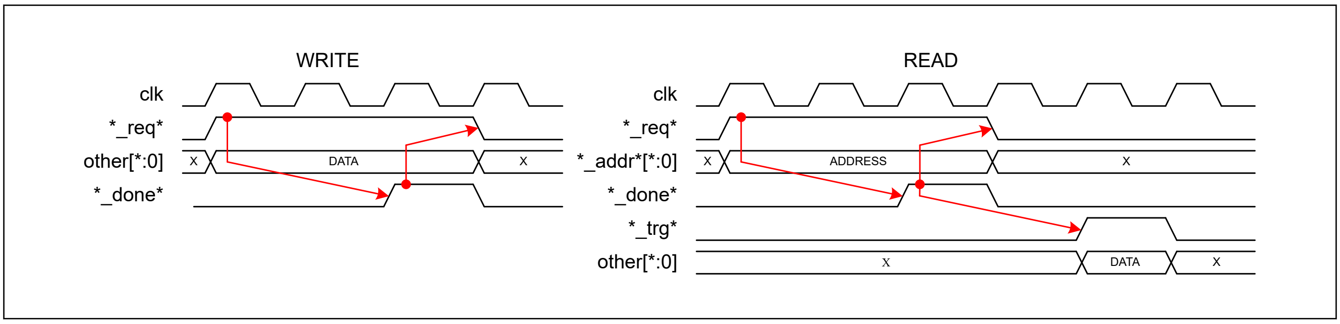

Figure 30.112 Fabric interface protocol

30.5.4.1 Fabric Time Arbiter

Time arbiter controls done signal of Ethernet Agent [ETHA] Write and Read buses depending on link speed.

The faster a link is the more the corresponding agent will be able access to the local RAM.

Agents Done Signal Distribution

Table 30.83 lists done signal distribution depending on PHY link speed possible combinations. Any disabled agent has a doneSignalDistributionValue equal to 0.

Table 30.83 Done signal output ratio by combination of PHY link speed

PHY link speeds of time-critical agents in OPERATION mode [ETHA]	doneSignalDistributionValue [cycle]
Only one Agent enabled	1
PHY link speed of all Agents is the same	1
100 Mbps : 1 Gbps	1 : 10

Done Signal Patterns

Figure 30.113 shows a done signal pattern example where time-critical port 0 has a 100 Mbps link and time-critical port 1 has a 1 Gbps link. When a request signals is not asserted at the timing when the corresponding done signal should have been asserted the done signals is not asserted and the handshake does not happen. In Figure 30.113 the request signals are always asserted to make the done pattern visible but, in a real system, request signals can be asserted anytime.

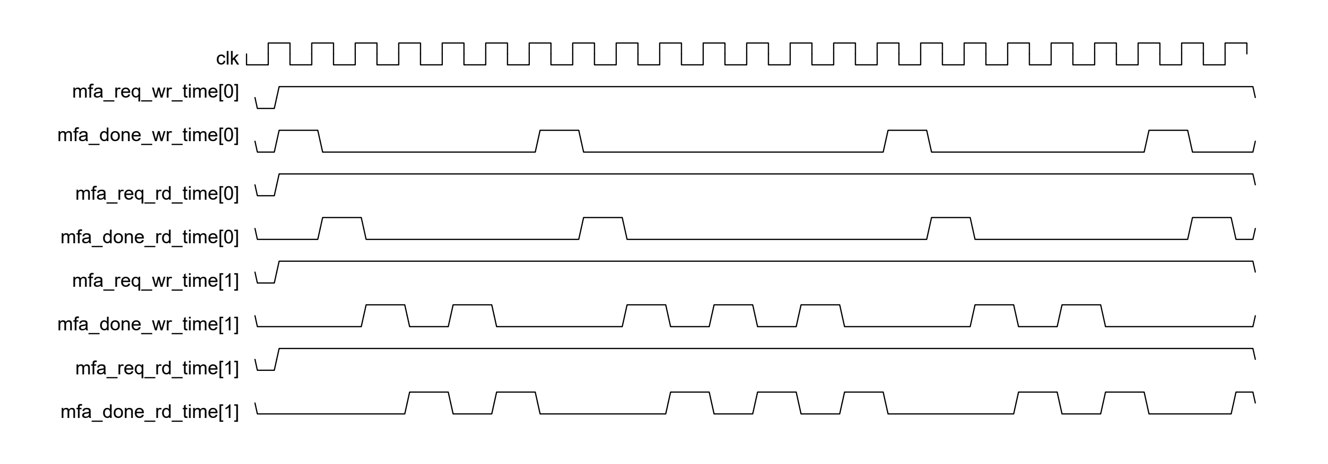

Figure 30.113 Done signal pattern example

The done signal pattern has inherent properties that are always respected:

- For a static configuration the done pattern is cyclic with a constant cycle time *doneCycleClk* described in equation (4).
- During a period of doneCycleClk clocks starting from anywhere, a time-critical agent receives for both read and write buses a number of done signals equal to its associated done signal distribution value (Table 30.83).

(4) doneCycleClk [cycle] = (Σ_2 doneSignalDistributionValue [cycle]) × 2

Where:

- Σ_2 doneSignalDistributionValue is the sum of all time-critical agents in OPERATION mode doneSignalDistributionValue (Table 30.83).

Restriction:

- HW: Done signals are only given to ethernet agents in OPERATION mode [ETHA].
- HW: If an unknown link speed is set for time-critical port i [ETHA] (mfa_xmii_speed[3 × (i + 1) - 1:3 × i] > 101b [RMAC]), Fabric will consider port i as disabled and port i will not be able to access the time arbiter.

Fabric Jitter

When an Ethernet Agent reads data using fabric time arbiter, some jitter is induced in the reading process by Fabric and it should be taken in account while using TAS [802.1Qbv] or PSFP [802.1Qci]. The fabric jitter can be calculated for an agent using equation (6).

(6) fabricJitter [ns] = (⌈ doneCycleClk[cycle] / doneSignalDistributionValue[cycle] ⌉ + (PortTimeOperation[number] - 1) × 2) × clk_period [ns]

Where:

- doneCycleClk is detailed in Done Signal Patterns.
- doneSignalDistributionValue is corresponding agent value detailed in Agents Done Signal Distribution.
- PortTimeOperation is the number of Ethernet Agents in OPERATION mode.
- clk_period is the clock clk period.

Restrictions:

- SW: The fabricJitter equation takes in account the number of Ethernet Agents [ETHA] in OPERATION mode and also doneCycleClk. In fact, enabling/disabling an agent or changing an agent PHY speed will indeed affect the fabric jitter value. However, reconfiguration TAS [802.1Qbv] or PSFP [802.1Qci] jitter in OPERATION is not a recommended option, so the maximum number of Ethernet Agents in OPERATION mode and their corresponding maximum PHY speed should be determined to calculate the worst fabricJitter per agent and it should be kept to the same value all the time.

Fabric Minimum Latency

When an Ethernet Agent reads data using fabric time arbiter, some latency is induced in the reading process by Fabric and it should be taken in account while using TAS [802.1Qbv] or PSFP [802.1Qci]. The fabric minimum latency can be calculated for an agent using equation (7).

(7) fabricLatency [ns] = (⌊ doneCycleClk [cycle] / doneSignalDistributionValue [cycle] ⌋ - 1) × clk_period [ns]

Where:

- doneCycleClk is detailed in Done Signal Patterns.
- doneSignalDistributionValue is corresponding agent value detailed in Agents Done Signal Distribution.
- clk_period is the clock clk period.

Restrictions:

- SW: The fabricLatency equation takes in account doneCycleClk. In fact, enabling/disabling an agent or changing an agent PHY speed will indeed affect the fabric latency value. However, reconfiguration TAS [802.1Qbv] or PSFP [802.1Qci] latency in OPERATION is not a recommended option, so if ethernet agent are disabled or PHY speed is changed during OPERATION, it is recommended to set the fabricLatency to 2 × clk_period [ns] and add the fabricLatency calculated value in the worst case to fabricJitter.
- SW: When preemption is enabled for a port, fabricLatency should be set to 0ns and fabricLatency calculated value when all agents are enabled should be added to fabricJitter.

30.5.4.2 Source Port Generation

Fabric gives automatically a source port number to each Agent depending on the bus they are accessing to. Table 30.84 shows the relation between the Bus accessed by an agent and its source port number.

Table 30.84 Source port number assignment

Bus from which agent accesses the fabric	Source port number
ETHA0	0
ETHA1	1
GWCA0	2

31. Ethernet Common Agent (COMA)

31.1 Overview

Ethernet Common Agent (COMA) is an agent of ESWM which aims at gathering common functionalities for other agents. COMA handles the APB to SFR bus conversion, the buffer pointer release for rejected frames and the pointer handling for local RAM. Software is required for the configuration of Ethernet Common Agent.

Table 31.1 lists the COMA specifications and Figure 31.1 shows the block diagram.

Table 31.1 COMA specifications

Item	Function	Description
Overall function	Pointer management	• Manage the local RAM pointers and their distribution
	APB to SFR	• Convert APB bus to SFR bus • Distribute SFR access among other switch IPs
	Descriptor reject	• Reject the unused descriptors by agents for transmission
Data provision	Fabric error bus	• Pointer received from fabric through error bus
	Descriptor bus	• Descriptor received from MFWD for rejection
Control function	RAM access	• Function that writes and reads to RAM

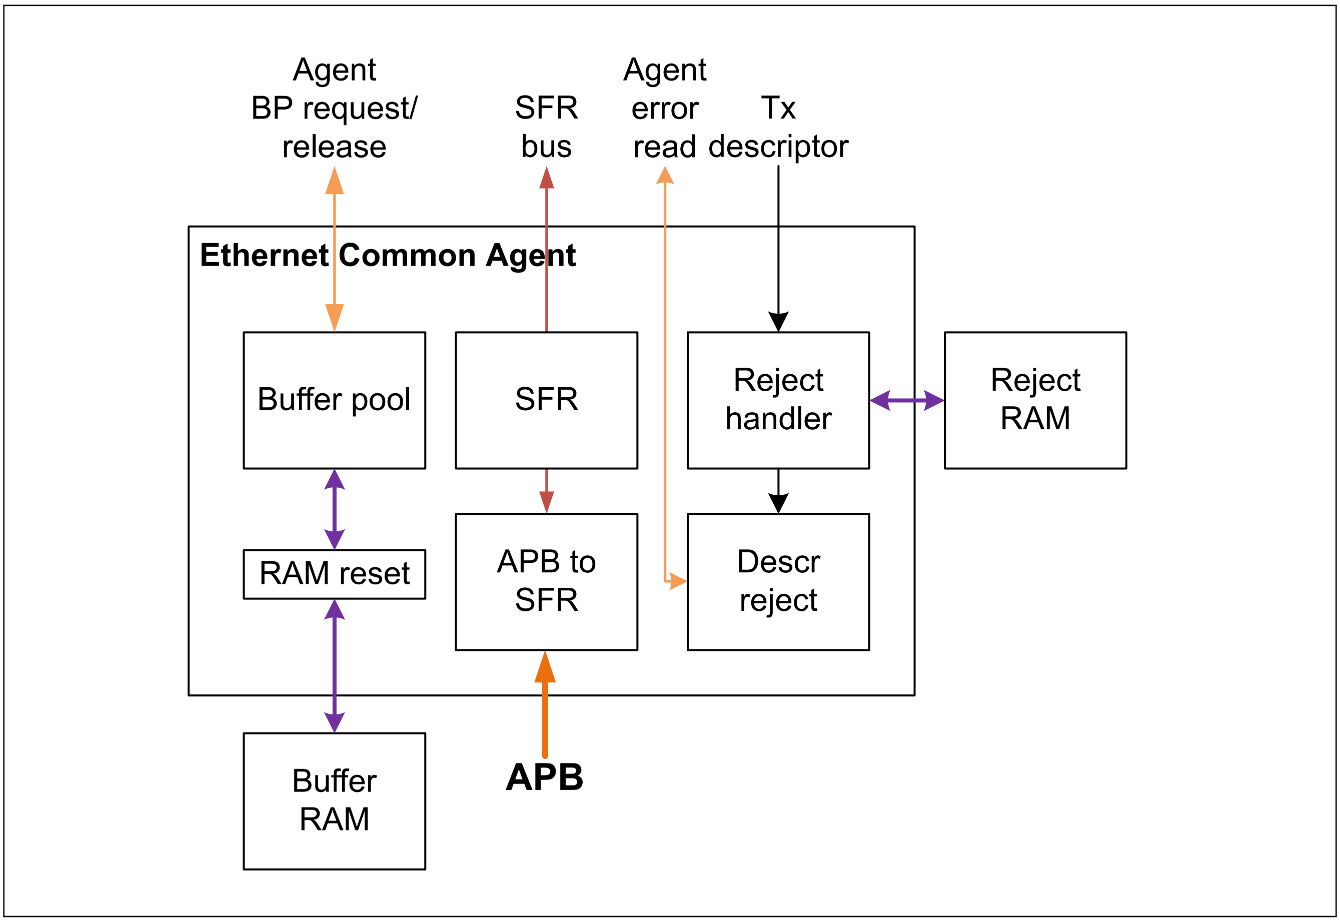

Figure 31.1 COMA block diagram

Table 31.2 COMA functional blocks (1 of 2)

Block name	Function
APB to SFR	Convert APB bus to SFR bus for every IP in ESWM
SFR	Ethernet Common Agent SFR

Table 31.2 COMA functional blocks (2 of 2)

Block name	Function
Reject handler	Receive descriptors to be rejected from forwarding engine and save them in reject RAM
Descriptor reject	Reject the descriptors
Free buffer pool	Handles the free buffer pointers
RAM reset	Handle RAM reset

31.2 COMA Register List

Table 31.3 COMA registers

Offset address	Register symbol	Register name
0x0000	RIPV	IP Version Register
0x0004	RRC	Reset Configuration Register
0x0008	RCEC	Clock Enable Configuration Register
0x000C	RCDC	Clock Disable Configuration Register
0x0020 + 0x04 × i	CABPIBWMCi	Buffer Pool IPV Based Watermark Configuration Register i (i = 0 to 7)
0x0040	CABPWMLC	Buffer Pool Watermark Level Configuration Register
0x0050 + 0x04 × i	CABPPFLCi	Buffer Pointer Pause Frame Level i Configuration Register (i = 0, 1)
0x0060 + 0x04 × i	CABPPWMLCi	Port i Buffer Pool Watermark Level Configuration Register i (i = 0 to 2)
0x00A0 + 0x04 × (i × 2 + j)	CABPPPFLCij	Port i Buffer Pointer Pause Frame Level j Configuration Register (i = 0 to 2) (j = 0, 1)
0x0100 + 0x04 × i	CABPULCi	Port i Buffer Pointer Utilization Level Configuration Register i (i = 0 to 2)
0x0140	CABPIRM	Buffer Pool Initialization Register Monitoring Register
0x0144	CABPPCM	Buffer Pool Pointer Count Monitoring Register

31:24	—	These bits are read as 0.	R

31.3.1.2 RRC : Reset Configuration Register

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RR	Software Reset 0: ESWM not reset 1: ESWM reset	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

RR bit (Software Reset)

- When set, this bit resets all the ESWM except the APB interface

- The synchronous reset RCC.RR is power-consuming, so it is only internally asserted for 7 clock cycles
- The synchronous reset is also internally asserted for 7 clock cycles after a hardware reset release.

[Caution]

- Because the synchronous reset RCC.RR is power-consuming, it should always be deasserted right after assertion to avoid power consumption.

31.3.1.3 RCEC : Clock Enable Configuration Register

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	ACE2 to ACE0		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ACE2 to ACE0	Agent i Clock Enable (i = 0 to 2) Bit i enables agent i clock. 0: Agent i clock disabled 1: Agent i clock enabled	R/W*1
15:3	—	These bits are read as 0. The write value should be 0.	R/W
16	RCE	Clock Enable 0: ESWM clock disabled 1: ESWM clock enabled	R/W*1
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: ESWM has three system clocks:

- Peripheral clock: Can be stopped only by the upper layer (MCU)
- MFWD clock: Controlled by RCE
- Agent clock: Controlled by ACEi.

Note 1. Read value differs from written value.

The COMA registers are controlled by peripheral clocks, which can only be stopped by the upper layer (MCU). Therefore, COMA registers always have read and write access.

When peripheral clock is running and agent clock is stopped (ACEi is 0):

- GWCA and ETHA have APB read access but do not have APB write access.

When peripheral clock is running and MFWD clock is stopped (RCE is 0):

- MFWD has APB read access but does not have APB write access
- Agent clocks are stopped.

ACEi bits (Agent i Clock Enable (i = 0 to 2))

- Bit i enables agent i clock. For agent mapping details, see the Fabric specifications [MFAB].
- When RRC.RR register is set, all agent i clock is internally enabled to allow software reset even if RCC.ACEi is not set.
- When RCC.RCE register is not set, agent i clock is internally disabled even if RCC.ACEi is set.

[Setting condition]

- SW: Writing 1 to this bit.

[Clearing condition]

- SW: Writing 1 to RCDC.ACDi register.

RCE bit (Clock Enable)

The RCE bit enables the switch clocks. When RRC.RR register is set, ESWM clock is internally enabled to allow software reset even if RCC.RCE is not set.

[Setting condition]

- SW: Writing 1 to this bit.

[Clearing condition]

- SW: Writing 1 to RCDC.RCD register.

31.3.1.4 RCDC : Clock Disable Configuration Register

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x000C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RCD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	ACD2 to ACD0		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ACD2 to ACD0	Agent i Clock Disable (i = 0 to 2) 0: No effect 1: Clears bit i in RCEC.ACEi register	W*2
15:3	—	These bits are read as 0.	R
16	RCD	Clock Disable*1 Writing 1 to this bit clears RCEC.RCE register.	W*2
31:17	—	These bits are read as 0.	R

Note 1. SW: Only write to this bit when all agents are disabled and when CABPPCM.RPC is equal to 512.
Note 2. Read value differs from written value.

31.3.2 Ethernet Common Agent Function Registers

31.3.2.1 CABPIBWMCi : Buffer Pool IPV Based Watermark Configuration Register i (i = 0 to 7)

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0020 + 0x04 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	IBSWMPN[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	IBUWMPN[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	IBUWMPN[9:0]	IPV Based Unsecure Watermark Pointer Number*1	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
25:16	IBSWMPN[9:0]	IPV Based Secure Watermark Pointer Number*2	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not set this register to a value greater than the following:

- SW: 512
- SW: CABPIBWMC{i + 1}.IBUWMPN{i + 1}.

Note 2. Do not set this register to a value greater than the following:

- SW: 512
- SW: CABPIBWMC{i + 1}.IBSWMPN{i + 1}.

IBUWMPN[9:0] bits (IPV Based Unsecure Watermark Pointer Number)

- For i equal to 7, setting this register to 512 disables the IPV based watermark function for IPV 7
- For i other than 7, setting this register to CABPIBWMC{i + 1}.IBUWMPN{i + 1} disables the IPV-based watermark function for IPV
- See section 31.5.1.1. IPV-based Watermark for details.

IBSWMPN[9:0] bits (IPV Based Secure Watermark Pointer Number)

- For i equal to 7, setting this register to 512 disables the IPV based watermark function for IPV 7
- For i other than 7, setting this register to CABPIBWMC{i + 1}.IBSWMPN{i + 1} disables the IPV-based watermark function for IPV i
- See section 31.5.1.1. IPV-based Watermark for details.

31.3.2.2 CABPWMLC : Buffer Pool Watermark Level Configuration Register

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0040

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	WMCL[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	WMFL[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	WMFL[9:0]	Watermark Flush Level*1 • Setting this register to 512 disables the watermark flush level function • See section 31.5.1.2. Global Level-based Watermark for details	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
25:16	WMCL[9:0]	Watermark Critical Level*2 • Setting this register to 512 disables the watermark critical level function • See section 31.5.1.2. Global Level-based Watermark for details	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: Do not set this register to a value greater than 512.
Note 2. SW: Always set this register to a value less than or equal to CABPWMLC.WMFL but not greater than 512.

31.3.2.3 CABPPFLCi : Buffer Pointer Pause Frame Level i Configuration Register

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0050 + 0x0004 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	PAL[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PDL[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PDL[9:0]	Pause De-Assertion Level*1 • See section 31.5.2.1. Global Pause Function for details.	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
25:16	PAL[9:0]	Pause Assertion Level*2 • Setting this register to 512 disables pause frames • See section 31.5.2.1. Global Pause Function for details.	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. • SW: Always set this register to a value less than or equal to CABPPFLCi.PAL.
• SW: Do not set this register to a value greater than 512 or less than 24.
Note 2. SW: Do not set this register to a value greater than 512 or less than 24.

PDL[9:0] bits (Pause De-Assertion Level)

[Precautions]

If CABPPFLCi.PAL value is too close to CABPPFLCi.PDL value, the corresponding PAUSE signals change state rapidly. Additionally, if no automatic pause frames are activated [RMAC], this can result in a succession of pause frames on RMAC transmission which can decrease the link performance.

31.3.2.4 CABPPWMLCi : Port i Buffer Pool Watermark Level Configuration Register (i = 0 to 2)

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0060 + 0x0004 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	PWMCL[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PWMFL[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PWMFL[9:0]	Watermark Flush Level*1 ● Setting this register to 512 disables the watermark flush level function ● See section 31.5.1.3. Per-port Level-based Watermark i (i = 0 to 3) for details	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
25:16	PWMCL[9:0]	Watermark Critical Level*2 ● Setting this register to 512 disables the watermark critical level function ● See section 31.5.1.3. Per-port Level-based Watermark i (i = 0 to 3) for details	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: Do not set this register to a value greater than 512.
Note 2. SW: Always set this register to a value less than or equal to CABPPWMLCi.PWMFL but not greater than 512.

31.3.2.5 CABPPPFLCij : Port i Buffer Pointer Pause Frame Level j Configuration Register (i = 0 to 2) (j = 0, 1)

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x00A0 + 0x04 × (i × 2 + j)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	PPAL[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PPDL[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PPDL[9:0]	Pause De-Assertion Level*1 See section 31.5.2.2. Per-port Pause Function i (i = 0 to 3) for details. If CABPPPFLCij.PPAL value is too close to CABPPPFLCij.PPDLij value, the corresponding PAUSE signals change state rapidly. Additionally, if no automatic pause frames are activated [RMAC], this can result in a succession of pause frames on RMAC transmission which can decrease the link performance.	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
25:16	PPAL[9:0]	Pause Assertion Level*2 Setting this register to 512 disables pause frames. See section 31.5.2.2. Per-port Pause Function i (i = 0 to 3) for details.	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Restrictions:

- SW: Always set this register to a value less than or equal to CABPPPFLCij.PPAL.
- SW: Do not set this register to a value greater than 512 or less than 6.

Note 2. SW: Do not set this register to a value greater than 512 or less than 6.

31.3.2.6 CABPULCi : Port i Buffer Pointer Utilization Level Configuration Register (i = 0 to 2)

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0100 + 0x0004 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	MNNPN[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	MXNPN[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	MXNPN[9:0]	Maximum Number of Pointer*1 Maximum number of pointers that can be used by port i.	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
25:16	MNNPN[9:0]	Minimum Number of Pointer*2 Minimum number of pointers that can be used by port i.	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note: If CABPULC[i].MNNPN[i] of port[i] is changed (reconfigured) from its default value, then it restricts the reception maximum frame size of ports other than port[i]. The restricted reception maximum frame size of ports other than port[i] in such case is given in the following expression.
Restricted reception maximum frame size = ((512 – CABPULC[i].MNNPN[i])/(3)) × 128 bytes. This is because ports other than port[i] must share the remaining pointers (512 – CABPULC[i].MNNPN[i]).
If this restriction is not followed, then the consumed buffer pointers are not released by other ports and the frame is stuck inside the switch. Because the total buffer pointers are insufficient for the port in the middle of reception, to resolve this, reconfigure CABPULC[i].MNNPN[i] value to a smaller value.

Note 1. SW: Set the maximum number of pointers to a value large enough to save two frames with a size equal to RMAC reception maximum frame size (set in RMAC).

Note 2.
- SW: The sum of all CABPULCi.MNNPN should be smaller or equal to 512.
- SW: This register should always be smaller or equal to CABPULCi.MXNPN.

MXNPN[9:0] bits (Maximum Number of Pointer)

- If register CABPCPMi.RPCP is equal to this register value, port i no longer receives pointer
- See section 31.5.3. Per-port Memory Allocation Function for details.

MNNPN[9:0] bits (Minimum Number of Pointer)

- If SUM (CABPULCi.MNNPN) >= CABPPCM.RPC + SUM (CABPCPMi.RPCP) only ports for which CABPCPMi.RPCP < CABPULCi.MNNPN can receive pointers
- See section 31.5.3. Per-port Memory Allocation Function for details.

31.3.2.7 CABPIRM : Buffer Pool Initialization Register Monitoring Register

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0140

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BPR	BPIOG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPIOG	Buffer Pool Initialization Ongoing*1	R/W*2
1	BPR	Buffer Pool Ready	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. HW: CPU cannot write 1 to this bit when CABPIRM.BPR is set.
Note 2. Read value differs from written value.

BPIOG bit (Buffer Pool Initialization Ongoing)

[Setting condition]

- SW: Writing 1 to this register.

[Clearing condition]

- HW: When buffer pool initialization is complete.

BPR bit (Buffer Pool Ready)

[Setting conditions]

- When CABPIRM.BPIOG is cleared
- HW: This bit is set at clk_period [ns] × 512 time from the start of buffer pool initialization.

31.3.2.8 CABPPCM : Buffer Pool Pointer Count Monitoring Register

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0144

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	TPC[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RPC[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	RPC[9:0]	Remaining Pointer Count	R
15:10	—	These bits are read as 0.	R
25:16	TPC[9:0]	Total Pointer Count	R
31:26	—	These bits are read as 0.	R

RPC[9:0] bits (Remaining Pointer Count)

[Increment condition]

- HW: Incremented by 1 when a pointer is released.

[Decrement condition]

- HW: Decremented by 1 when a pointer is given to an agent.

TPC[9:0] bits (Total Pointer Count)

- Read 512, fixed to 512
- Reading this register gives the number of pointers contained in the buffer pool. The switch local data RAM size is equal to 128 × CABPPCM.TPC bytes.

31.3.2.9 CABPLCM : Buffer Pool Pointer Least Count Monitoring Register

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0148

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	LRC[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	LRC[12:0]	Least Remaining Pointer Count This register remembers the smaller value that is taken by the remaining counter pointer. [Update condition] ● HW: This register is updated to CABPPCM.RPC when CABPPCM.RPC < CABPLCM.LRC. [Clear condition] ● Reading this register clears it to CABPPCM.RPC value.	R
31:13	—	These bits are read as 0.	R

31.3.2.10 CABPCPMi : Port i Buffer Pointer Count Monitoring Register (i = 0 to 2)

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0180 + 0x0004 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	RPCP[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	RPCP[12:0]	Received Pointer Count	R
31:13	—	These bits are read as 0.	R

RPCP[12:0] bits (Received Pointer Count)

This register shows the number of pointers that are used by agent i to store data.

[Increment condition]

- HW: Incremented by 1 when a pointer is given to port I.

[Decrement condition]

- HW: Decremented by 1 when a pointer given to port i is being released.

31.3.2.11 CABPMCPMi : Port i Buffer Pointer Maximum Count Monitoring Register (i = 0 to 2)

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0200 + 0x0004 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	RPMCP[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	RPMCP[12:0]	Received Pointer Maximum Count*1	R
31:13	—	These bits are read as 0.	R

Note 1. May exceed several upper and lower limit settings.

RPMCP[12:0] bits (Received Pointer Maximum Count)

This register remembers the biggest value that is taken by CABPMCPMi.RPCP since the last read access.

[Update condition]

- HW: This register is updated to CABPMCPMi.RPCP when CABPMCPMi.RPCP > CABPMCPMi.RPMCP.

[Clear condition]

- Reading this register clears it to CABPMCPMi.RPCP value.

31.3.2.12 CARDNM : Rejected Descriptor Number Monitoring Register

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0300

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	RDNRR[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	RDNRR[12:0]	Rejected Descriptor Number in Reject RAM	R
31:13	—	These bits are read as 0.	R

RDNRR[12:0] bits (Rejected Descriptor Number in Reject RAM)

This register shows the number of descriptors currently contained in the reject RAM.

[Increment condition]

- HW: Incremented by 1 when a descriptor is received from the forwarding engine.

[Decrement condition]

- HW: Decremented by 1 when a descriptor is read from the reject RAM.

31.3.2.13 CARDMNM : Rejected Descriptor Maximum Number Monitoring Register

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0304

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	RDMNRR[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	RDMNRR[12:0]	Rejected Descriptor Maximum Number in Reject RAM	R
31:13	—	These bits are read as 0.	R

RDMNRR[12:0] bits (Rejected Descriptor Maximum Number in Reject RAM)

This register remembers the biggest value that is taken by CARDNM.RDNRR since the last read access.

[Update condition]

- Set to CARDNM.RDNRR when CARDNM.RDNRR > CARDMNM.RDMNRR.

[Clearing condition]

- Reading this register clears it to CARDNM.RDNRR value.

31.3.3 Ethernet Common Agent Counter Registers

This section describes Ethernet Common Agent Counter registers.

31.3.3.1 CARDCN : Rejected Descriptor Counter Register

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0310

Bit position:	31–0
Bit field:	RDN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RDN[31:0]	Rejected Descriptor Number	R

RDN[31:0] bits (Rejected Descriptor Number)

This register counts the number of descriptors that is rejected since the last read.

[Clearing condition]

- SW: Reading this register clears it.

[Increment condition]

- HW: Incremented by 1 when a rejected descriptor is received from MFWD and if this register has a value other than 0xFFFF.

31.3.4 Ethernet Common Agent Interrupt Registers

This section describes Ethernet Common Agent Interrupt registers.

31.3.4.1 CAEIS0 : Error Interrupt Status Register 0

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0400

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	WMFLOS	WMCLOS	BPOPS	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	BPOPS	Buffer Pool Out of Pointer Status Flag	R/W*1
9	WMCLOS	Watermark Critical Level Overtook Status Flag	R/W*1
10	WMFLOS	Watermark Flush Level Overtook Status Flag	R/W*1
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

BPOPS bit (Buffer Pool Out of Pointer Status Flag)

[Setting condition]

- HW: When CABPPCM.RPC becomes null.

[Clearing condition]

- SW: Writing 1 to this bit.

[Error recovery]

- SW: When there is no error recovery, the switch can overflow [RMAC]. When using Cut through, use the watermark function so that this status does not occur. If this error occurs (it may get hung-up in the transmit state [ETHA and RMAC]), initialize the state with the emergency reset flow [TOP].

WMCLOS bit (Watermark Critical Level Overtook Status Flag)

[Setting condition]

- HW: When watermark critical level WM.CRITICAL is asserted to all 1s because of global level-based watermark (see Figure 31.12).

[Clearing condition]

- SW: Writing 1 to this bit.

[Error recovery]

- SW: When there is no recovery, data can be lost [FWD].

WMFLOS bit (Watermark Flush Level Overtook Status Flag)

[Setting condition]

- HW: When watermark flush level WM.FLUSH is asserted to all 1s because of global level-based watermark (see Figure 31.12).

[Clearing condition]

- SW: Writing 1 to this bit.

[Error recovery]

- SW: When there is no recovery, data can be lost [FWD].

31.3.4.2 CAEIE0 : Error Interrupt Enable Register 0

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0404

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	WMFLOE	WMCLOE	BPOPE	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	BPOPE	Buffer Pool Out of Pointer Enable	R/W*1
9	WMCLOE	Watermark Critical Level Overtook Enable	R/W*1
10	WMFLOE	Watermark Flush Level Overtook Enable	R/W*1
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

BPOPE bit (Buffer Pool Out of Pointer Enable)

[Setting condition]

- Writing 1 to this bit.

[Clearing condition]

- Writing 1 to CAEID0.BPOPD register.

WMCLOE bit (Watermark Critical Level Overtook Enable)

[Setting condition]

- Writing 1 to this bit.

[Clearing condition]

- Writing 1 to CAEID0.WMCLOD register.

WMFLOE bit (Watermark Flush Level Overtook Enable)

[Setting condition]

- Writing 1 to this bit.

[Clearing condition]

- Writing 1 to CAEID0.WMFLOD register.

31.3.4.3 CAEID0 : Error Interrupt Disable Register 0

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0408

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	WMFLOD	WMCLOD	BPOPD	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0.	R
8	BPOPD	Buffer Pool Out of Pointer Disable Writing 1 to this bit clears CAEIE0.BPOPE register.	R
9	WMCLOD	Watermark Critical Level Overtook Disable Writing 1 to this bit clears CAEIE0.WMCLOE register.	R
10	WMFLOD	Watermark Flush Level Overtook Disable Writing 1 to this bit clears CAEIE0.WMFLOE register.	R
31:11	—	These bits are read as 0.	R

31.3.4.4 CAEIS1 : Error Interrupt Status Register 1

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0410

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	PWMFLOS2 to PWMFLOS0		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	PWMCLOS2 to PWMCLOS0		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	PWMCLOS2 to PWMCLOS0	Port n Watermark Critical Level Overtook Status Flag (n = 0 to 2)	R/W*1
15:3	—	These bits are read as 0.	R/W
18:16	PWMFLOS2 to PWMFLOS0	Port n Watermark Flush Level Overtook Status Flag (n = 0 to 2)	R/W*1
31:19	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

PWMCLOSn bits (Port n Watermark Critical Level Overtook Status Flag (n = 0 to 2))

[Setting condition]

- HW: For bit i, when watermark critical level bit i WM.CRITICAL[i] is asserted to 1 because of per-port level-based watermark (see Figure 31.13).

[Clearing condition]

- SW: Writing 1 to one of these bits.

[Error recovery]

- When there is no error recovery, data can be lost [FWD].

PWMFLOSn bits (Port n Watermark Flush Level Overtook Status Flag (n = 0 to 2))

[Setting condition]

- HW: For bit i, when watermark flush level bit i WM.FLUSH[i] is asserted to 1 because of per-port level-based watermark (see Figure 31.13).

[Clearing condition]

- SW: Writing 1 to one of these bits.

[Error recovery]

- When there is no error recovery, data can be lost [FWD].

31.3.4.5 CAEIE1 : Error Interrupt Enable Register 1

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0414

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	PWMFLOE2 to PWMFLOE0		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	PWMCLOE2 to PWMCLOE0		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	PWMCLOE2 to PWMCLOE0	Port n Watermark Critical Level Overtook Enable (n = 0 to 2)	R/W*1
15:3	—	These bits are read as 0. The write value should be 0.	R/W
18:16	PWMFLOE2 to PWMFLOE0	Port n Watermark Flush Level Overtook Enable (n = 0 to 2)	R/W*1
31:19	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

PWMCLOEn bits (Port n Watermark Critical Level Overtook Enable (n = 0 to 2))

[Setting condition]

- Writing 1 to one of these bits.

[Clearing condition]

- SW: Writing 1 to one of CAEID1.PWMCLOD bits.

PWMFLOEn bits (Port n Watermark Flush Level Overtook Enable (n = 0 to 2))

[Setting condition]

- Writing 1 to one of these bits.

[Clearing condition]

- SW: Writing 1 to one of CAEID1.PWMFLOD bits.

31.3.4.6 CAEID1 : Error Interrupt Disable Register 1

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0418

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	PWMFLOD2 to PWMFLOD0		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	PWMCLOD2 to PWMCLOD0		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	PWMCLOD2 to PWMCLOD0	Port n Watermark Critical Level Overtook Disable (n = 0 to 2)	R
15:3	—	These bits are read as 0. The write value should be 0.	R
18:16	PWMFLOD2 to PWMFLOD0	Port n Watermark Flush Level Overtook Disable (n = 0 to 2)	R
31:19	—	These bits are read as 0. The write value should be 0.	R

PWMCLODn bits (Port n Watermark Critical Level Overtook Disable (n = 0 to 2))

[Clearing condition]

- SW: Writing 1 to one of these bits clears the corresponding CAEIE1.PWMCLOE bit.

PWMFLODn bits (Port n Watermark Flush Level Overtook Disable (n = 0 to 2))

[Clearing condition]

- SW: Writing 1 to one of these bits clears the corresponding CAEIE1.PWMFLOE bit.

31.3.4.7 CAMIS0 : Monitoring Interrupt Status Register 0

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0440

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PFS1 to PFS0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PFS1 to PFS0	Pause Frame Status Flag n (n= 0 to 1)	R/W*1
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

PFSn bits (Pause Frame Status Flag n (n= 0 to 1))

[Setting condition]

- HW: For bit i, when pause frame i begins (pause assertion timing), see section 31.5.2. Pause Function.

[Clearing condition]

- SW: Writing 1 to one of these bits.

31.3.4.8 CAMIE0 : Monitoring Interrupt Enable Register 0

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0444

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PFE1 to PFE0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PFE1 to PFE0	Pause Frame Enable n (n = 0 to 1)	R/W*1
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

PFEn bits (Pause Frame Enable n (n = 0 to 1))

[Setting condition]

- Writing 1 to one of these bits.

[Clearing condition]

- SW: Writing 1 to one of CAMID0.PFD bits.

31.3.4.9 CAMID0 : Monitoring Interrupt Disable Register 0

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0448

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PFD1 to PFD0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PFD1 to PFD0	Pause Frame Disable n (n = 0 to 1)	R
31:2	—	These bits are read as 0. The write value should be 0.	R

PFDn bits (Pause Frame Disable n (n = 0 to 1))

[Clearing condition]

- SW: Writing 1 to one of these bits clears the corresponding CAMIE0.PFE bit.

31.3.4.10 CAMIS1 : Monitoring Interrupt Status Register 1

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0450

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	PPFS21	PPFS20	PPFS11	PPFS10	PPFS01	PPFS00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PPFS00	Port 0 Pause Frame Status Flag 0	R/W*1
1	PPFS01	Port 0 Pause Frame Status Flag 1	R/W*1
2	PPFS10	Port 1 Pause Frame Status Flag 0	R/W*1
3	PPFS11	Port 1 Pause Frame Status Flag 1	R/W*1
4	PPFS20	Port 2 Pause Frame Status Flag 0	R/W*1
5	PPFS21	Port 2 Pause Frame Status Flag 1	R/W*1
31:6	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

PPFSmn bits (Port m Pause Frame Status n)

[Setting condition]

- HW: For bit i, when pause frame i begins (pause assertion timing), see section 31.5.2. Pause Function.

[Clearing condition]

- SW: Writing 1 to one of these bits.

31.3.4.11 CAMIE1 : Monitoring Interrupt Enable Register 1

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0454

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	PPFE21	PPFE20	PPFE11	PPFE10	PPFE01	PPFE00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PPFE00	Port 0 Pause Frame Enable 0	R/W*1
1	PPFE01	Port 0 Pause Frame Enable 1	R/W*1
2	PPFE10	Port 1 Pause Frame Enable 0	R/W*1
3	PPFE11	Port 1 Pause Frame Enable 1	R/W*1
4	PPFE20	Port 2 Pause Frame Enable 0	R/W*1
5	PPFE21	Port 2 Pause Frame Enable 1	R/W*1
31:6	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

PPFEmn bits (Port m Pause Frame Enable n)

[Setting condition]

- Writing 1 to one of these bits.

[Clearing condition]

- SW: Writing 1 to one of CAMID1.PPFD bits.

31.3.4.12 CAMID1 : Monitoring Interrupt Disable Register 1

Base address: COMA = 0x403C_9000
COMA_NS = 0x503C_9000

Offset address: 0x0458

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	PPFD21	PPFD20	PPFD11	PPFD10	PPFD01	PPFD00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PPFD00	Port 0 Pause Frame Disable 0	W*1
1	PPFD01	Port 0 Pause Frame Disable 1	W*1
2	PPFD10	Port 1 Pause Frame Disable 0	W*1
3	PPFD11	Port 1 Pause Frame Disable 1	W*1
4	PPFD20	Port 2 Pause Frame Disable 0	W*1
5	PPFD21	Port 2 Pause Frame Disable 1	W*1
31:6	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

PPFDmn bits (Port m Pause Frame Disable n)

[Clearing condition]

- SW: Writing 1 to one of these bits clears the corresponding CAMIE1.PPFE bit.

31.4 Register Utilization

31.4.1 Software Flows

SW: Follow the flows described in this section.

31.4.1.1 Software Flow Legend

Figure 31.2 shows the software flow legend.

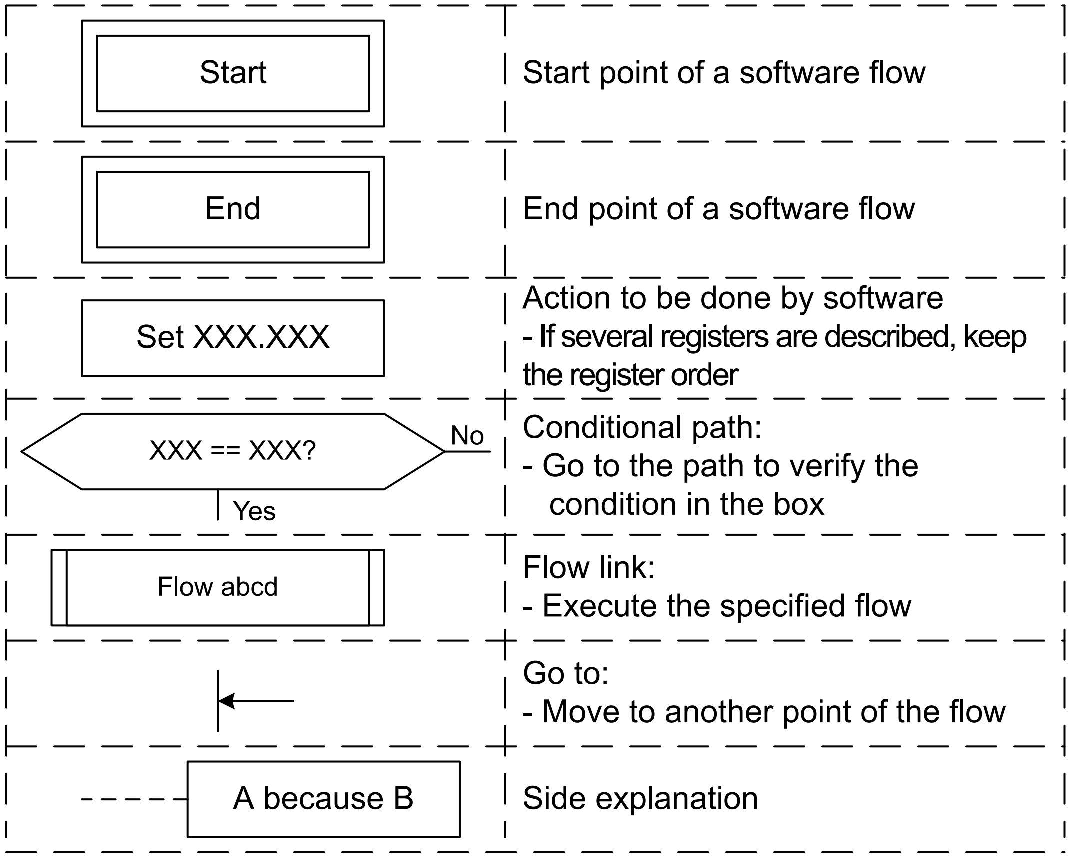

Figure 31.2 Software flow legend

31.4.1.2 Interrupt Handling Flow

Interrupt handling flow can be used in any mode except Reset mode.

Figure 31.3 shows the interrupt handling flow.

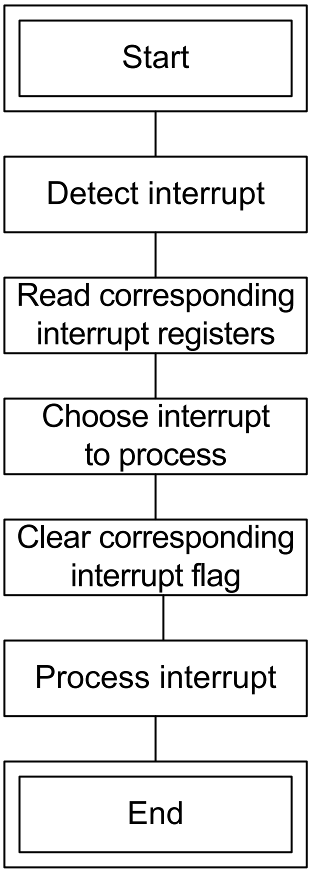

Figure 31.3 Interrupt handling flow

31.4.1.3 Called Software Flows

The flows described in this section can only be called from other flows as indicated in the flow link step in Figure 31.2 and cannot be used alone.

31.4.1.3.1 Buffer Pool Initialization Flow

Figure 31.4 shows the buffer pool initialization flow.

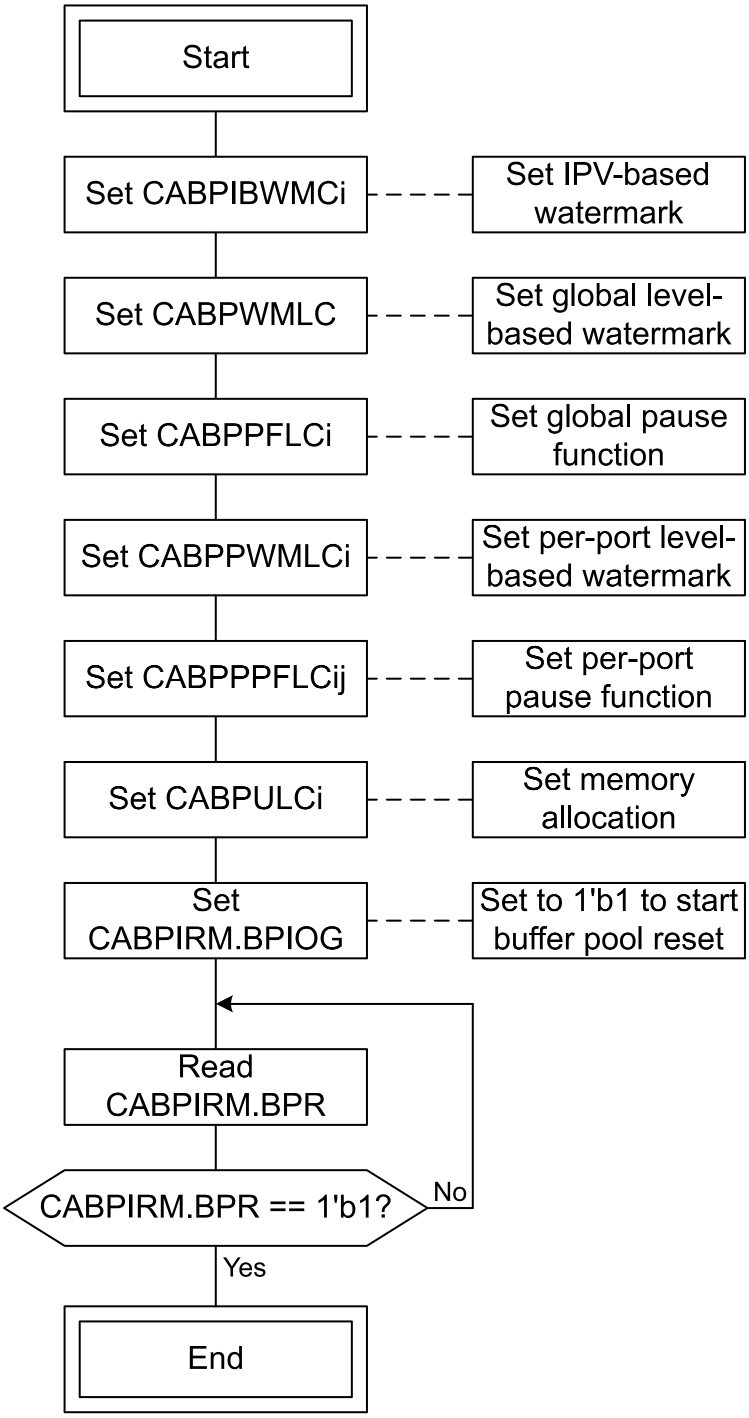

Figure 31.4 Buffer pool initialization flow

31.4.1.3.2 ESWM Reset Flow

Figure 31.5 shows the ESWM reset flow.

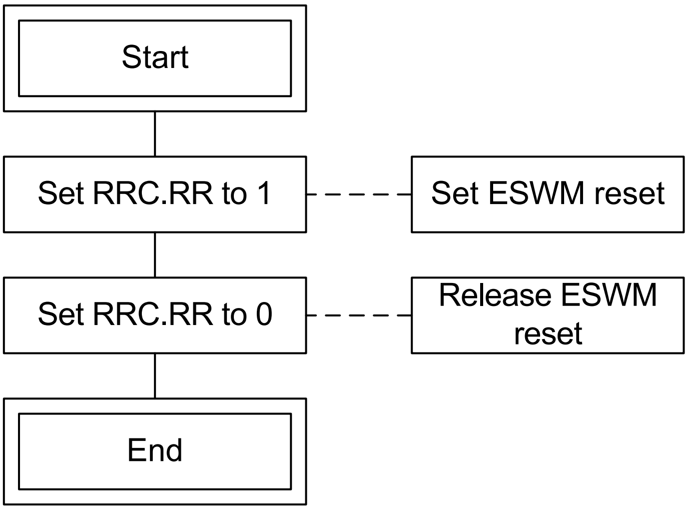

Figure 31.5 ESWM reset flow

31.4.1.3.3 Agent i Clock Control Flows (i = 0 to 3)

Figure 31.6, Figure 31.7 and Figure 31.8 show the agent i clock control flows.

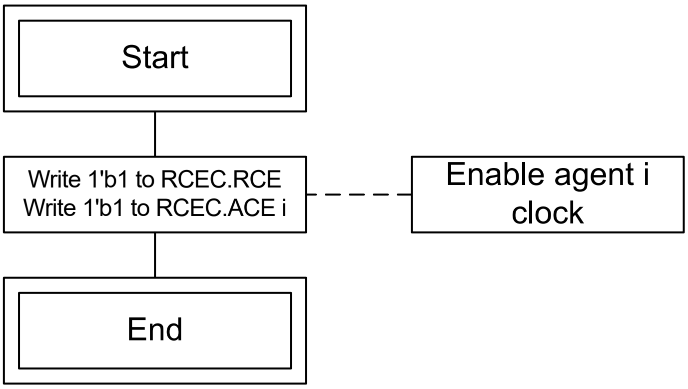

Figure 31.6 Agent i clock enable flow

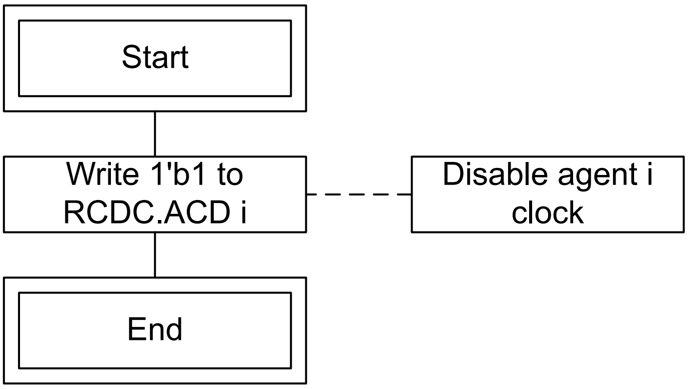

Figure 31.7 Agent i clock disable flow

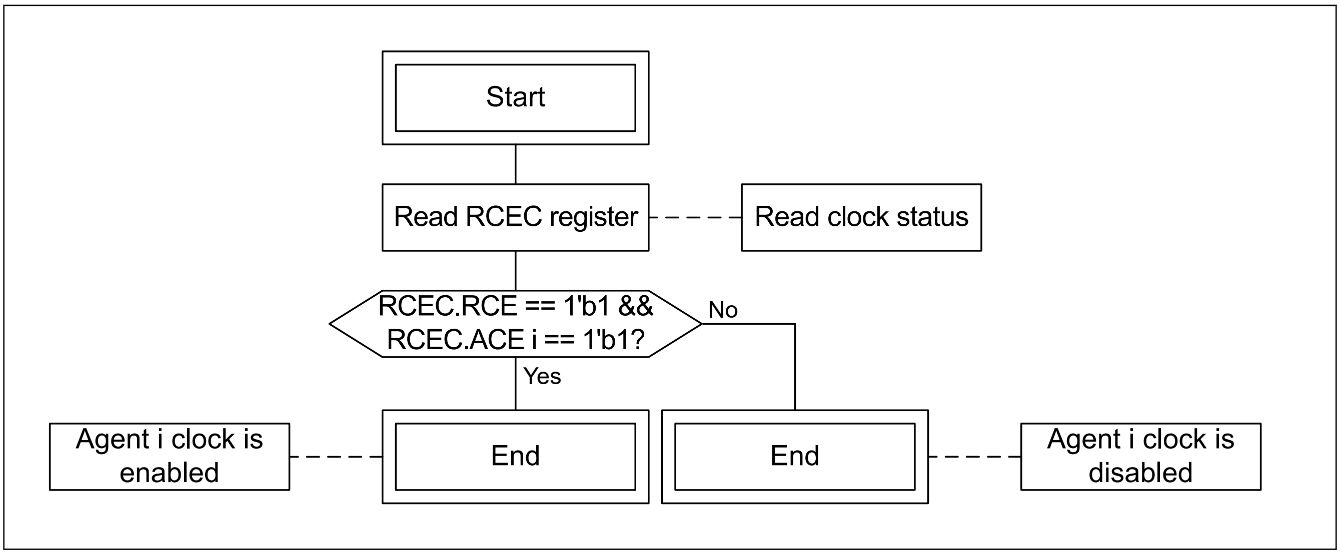

Figure 31.8 Agent i clock status check flow

31.4.1.3.4 Switch Clock Control Flows

Figure 31.9 and Figure 31.10 show the switch clock control flows.

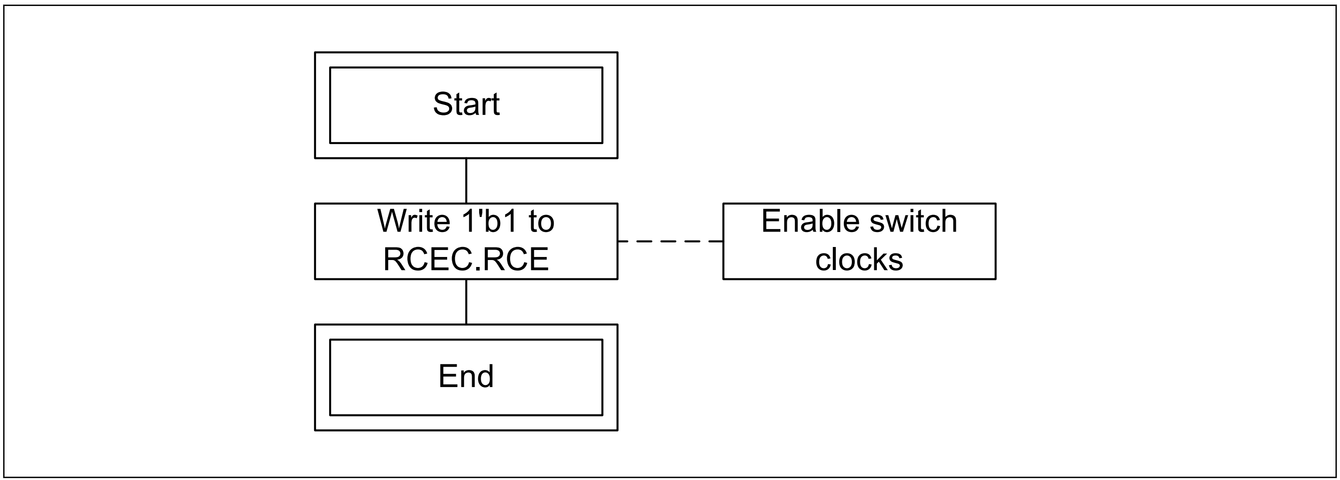

Figure 31.9 Switch clock enable flow

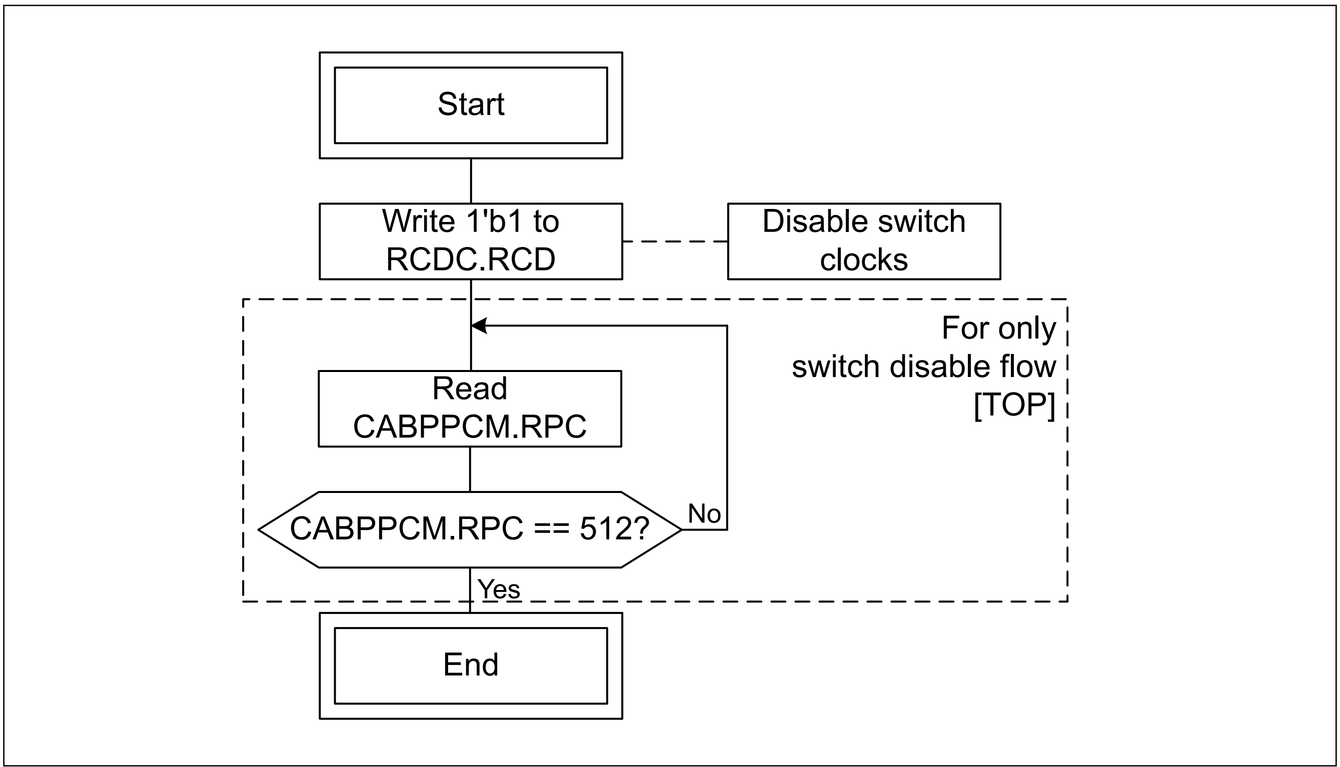

Figure 31.10 Switch clock disable flow

31.4.1.4 Register Writable Without Software Flow

This section describes registers that have not been described. These registers can be changed dynamically. However, it is necessary that the initial settings such as clock enabling have been completed.

31.5 Functional Description

31.5.1 Watermark Function

If a switch overflow occurs, frames in the switch are lost at the ingress part of agents [GWCA] [ETHA]. This result in a random loss of data is independent of the actual priority of frames. To avoid this, the watermark function allows to selectively reject frames in MFWD before a switch overflow occurs.

Ethernet Common Agent includes three watermark functions:

- IPV-based watermark
- Global level-based watermark
- Per-port level-based watermark

The watermark functions aim at controlling the switch behavior in case of overflow by generating data loss. All watermark functions are running in parallel and a frame can be rejected by one or more watermark functions.

31.5.1.1 IPV-based Watermark

The IPV-based watermark ensures the minimum QoS requirement for a switch. It is enabled by the default configurations for a switch maximum frame size of 256 bytes. This function is controlled by the Ethernet Common Agent, however, data loss is performed by the Forwarding Engine [FWD]. IPV-based watermark with a combination of other functions, is affected by the queue pause regardless of frame size (256).

Figure 31.11 shows an example of IPV-based unsecure watermark setting for Pointer number to address local RAM = = 4096. The IPV-based secure watermark works the same way but using CABPIBWMCi.IBSWMPN registers.

Note: The variations of 512 - CABPPCM.RPC in Figure 31.11 are arbitrary and do not correspond to anything relevant.

	Explanation
0	No descriptor is rejected because **CABPIBWMC.IBUWMPN2** is larger than 512 - **CABPPCM.RPC**
1	Descriptors with **FDESCR.IPV** 0, 1 or 2 are rejected because **CABPIBWMC.IBUWMPN2** is smaller than 512 - **CABPPCM.RPC**
2	Descriptors with **FDESCR.IPV** 0, 1, 2, 3, 4, 5 or 6 are rejected because **CABPIBWMC.IBUWMPN6** is smaller than 512 - **CABPPCM.RPC**
3	All descriptor are rejected because **CABPIBWMC.IBUWMPN7** is smaller than 512 - **CABPPCM.RPC**

Figure 31.11 Example for IPV-based watermark setting

Note: FDESCR.IPV refers to the internal priority value given to a frame by forwarding engine in the forwarding descriptor but before filtering. For more details, see the Forwarding Engine specification [FWD].

31.5.1.2 Global Level-based Watermark

The global level-based watermark aims at rejecting frames with targeted IPVs depending on the number of pointers currently used by the switch (CABPPCM.RPC register). This function is controlled by the Ethernet Common Agent (through WM.CRITICAL[3:0] and WM.FLUSH[3:0]), however, data loss is performed by the Forwarding Engine [FWD].

Note: WM.CRITICAL and WM.FLUSH interfaces can also be set by the per-port level-based watermark (one of these pins is set if the per-port level-based watermark or the global level-based watermark is in the required setting conditions).

Figure 31.12 shows an example for global level-based watermark setting for Pointer number to address local RAM = = 4096.

Note: The variations of 512 - CABPPCM.RPC in Figure 31.12 are arbitrary and do not correspond to anything relevant.

	Explanation	WM.CRITICAL/ WM.FLUSH values
0	No descriptor is rejected because **CABPWMLC.WMCL** is larger than 512 - **CABPPCM.RPC**	All0/All0
1	Descriptors associated with all port-critical level are rejected because 512 - **CABPPCM.RPC** is larger **CABPWMLC.WMCL**	All1/All0
2	Descriptors associated with all port-critical/flush level are rejected because 512 - **CABPPCM.RPC** is larger than **CABPWMLC.WMFL**	All1/All1

Figure 31.12 Example for global level-based watermark setting

31.5.1.3 Per-port Level-based Watermark i (i = 0 to 3)

The per-port level-based watermark aims at rejecting frames with targeted IPVs depending on CABPPWMLCi.PWMCL. This function is controlled by the Ethernet Common Agent (through WM.CRITICAL[i] and WM.FLUSH[i]), however, data loss is performed by the Forwarding Engine [FWD].

Note: WM.CRITICAL and WM.FLUSH interfaces can also be set by the global level-based watermark (one of these pins is set if the per-port level-based watermark or the global level-based watermark is in the required setting conditions).

Figure 31.13 shows an example of per-port level-based watermark setting for port i when Pointer number to address local RAM = = 4096.

Note: The variations of CABPCPMi.RPCP in Figure 31.13 are arbitrary and do not correspond to anything relevant.

	Explanation	WM.CRITICAL[i]/ WM.FLUSH[i] values
0	No descriptor is rejected because **CABPPWMLCi.PWMCL** is larger than **CABPCPMi.RPCP**	0/0
1	Descriptors associated with all port-critical level are rejected **CABPPWMLCi.PWMCL** is smaller than **CABPCPMi.RPCP**	1/0
2	Descriptors associated with all port-critical/flush level are rejected **CABPPWMLCi.PWMFL** is smaller than **CABPCPMi.RPCP**	1/1

Figure 31.13 Example for per-port level-based watermark setting for port i

31.5.2 Pause Function

If a switch overflow occurs, frames in the switch are lost at the ingress part of agents [GWCA] [ETHA]. This result in a random loss of data is independent of the actual priority of frames. To avoid this, the pause function allows to selectively pause frame injection by agents [GWCA] [ETHA].

Ethernet Common Agent includes two pause functions, the global pause function and the per-port pause function. The pause functions aim at controlling the switch behavior in case of overflow by generating backpressure. All pause functions are running in parallel and backpressure can be applied by one or more pause functions.

31.5.2.1 Global Pause Function

The global pause function aims at applying backpressure on agents for targeted IPVs depending on CABPPCM.RPC. The pause function can pause agents with two combinations of IPVs.

The global pause function is controlled by the Ethernet Common Agent PAUSE[3:0][1:0] interface, however, backpressure is performed by the agents [ETHA] [GWCA].

Note: The pause interface can also be set by the per-port pause function (one of these pins is set if the per-port pause function or the global pause function is in the required setting conditions).

Figure 31.14 shows an example of global pause function setting for Pause level number = = 2 and Pointer number to address local RAM = = 4096.

Note: The variations of 512 - CABPPCM.RPC in Figure 31.14 are arbitrary and do not correspond to anything relevant.

	Explanation	PAUSE[i][0]/ PAUSE[i][1] values (for all i = 0 to 2)
0	No agent paused because 512 - **CABPPCM.RPC** never exceeded **CABPPFLC0.PAL0** level nor **CABPPFLC1.PAL1** level	0/0
1	Agents are paused with level 0 because 512 - **CABPPCM.RPC** exceeded **CABPPFLC0.PAL0** level and not **CABPPFLC1.PAL1** level	1/0
2	Agents are paused with level 0 and 1 because 512 - **CABPPCM.RPC** exceeded **CABPPFLC0.PAL0** level and **CABPPFLC1.PAL1** level	1/1
3	Agents are paused with level 0 because 512 - **CABPPCM.RPC** exceeded **CABPPFLC0.PAL0** and dropped under **CABPPFLC1.PDL1**	1/0

Figure 31.14 Example for global pause function setting

31.5.2.2 Per-port Pause Function i (i = 0 to 3)

The per-port pause function aims at applying backpressure on agents for targeted IPVs depending on CABPPWMLCi.PWMCL. The pause function can pause agents with two combinations of IPVs.

This function is controlled by the Ethernet Common Agent PAUSE[i] interface, however, backpressure is performed by the agents [ETHA] [GWCA].

Note: The pause interface can also be set by the per-port pause function (one of these pins is set if the per-port pause function or the global pause function is in the required setting conditions).

Figure 31.15 shows an example of per-port pause function setting for port i when Pause level number = = 2 and Pointer number to address local RAM = = 4096.

Note: The variations of CABPPWMLCi.PWMCL in Figure 31.15 are arbitrary and do not correspond to anything relevant.

	Explanation	**PAUSE[i][0]**/ **PAUSE[i][0]** values
0	No agent paused because **CABPCPMi.RPCP** never exceeded **CABPPPFLCi0.PPAL** level nor **CABPPPFLCi1.PPAL** level	0/0
1	Agents are paused with level 0 because **CABPCPMi.RPCP** exceeded **CABPPPFLCi0.PPAL** level and not **CABPPPFLCi1.PPAL** level	1/0
2	Agents are paused with level 0 and level 1 because **CABPCPMi.RPCP** exceeded **CABPPPFLCi0.PPAL** level and **CABPPPFLCi1.PPAL** level	1/1
3	Agents are paused with level 0 because **CABPCPMi.RPCP** exceeded **CABPPPFLCi0.PPAL** and dropped under **CABPPPFLCi1.PPDL**	1/0

Figure 31.15 Example for per-port pause function setting for port i

31.5.3 Per-port Memory Allocation Function

It is possible to control the maximum and the minimum number of pointers that can be used per port due to CABPULCi.MNNPN and CABPULCi.MXNPN. Any agent can use at least its minimum number of pointers and at most its maximum number of pointers. This section provides some setting examples for the memory allocation function.

31.5.3.1 Shared Memory Setting (Default Setting)

In shared memory, the data RAM is shared by all the ports and is the reset state of the Ethernet Common Agent.

Figure 31.16 describes the shared memory setting for Pointer number to address local RAM = = 4096 and Port number on the switch = = 3.

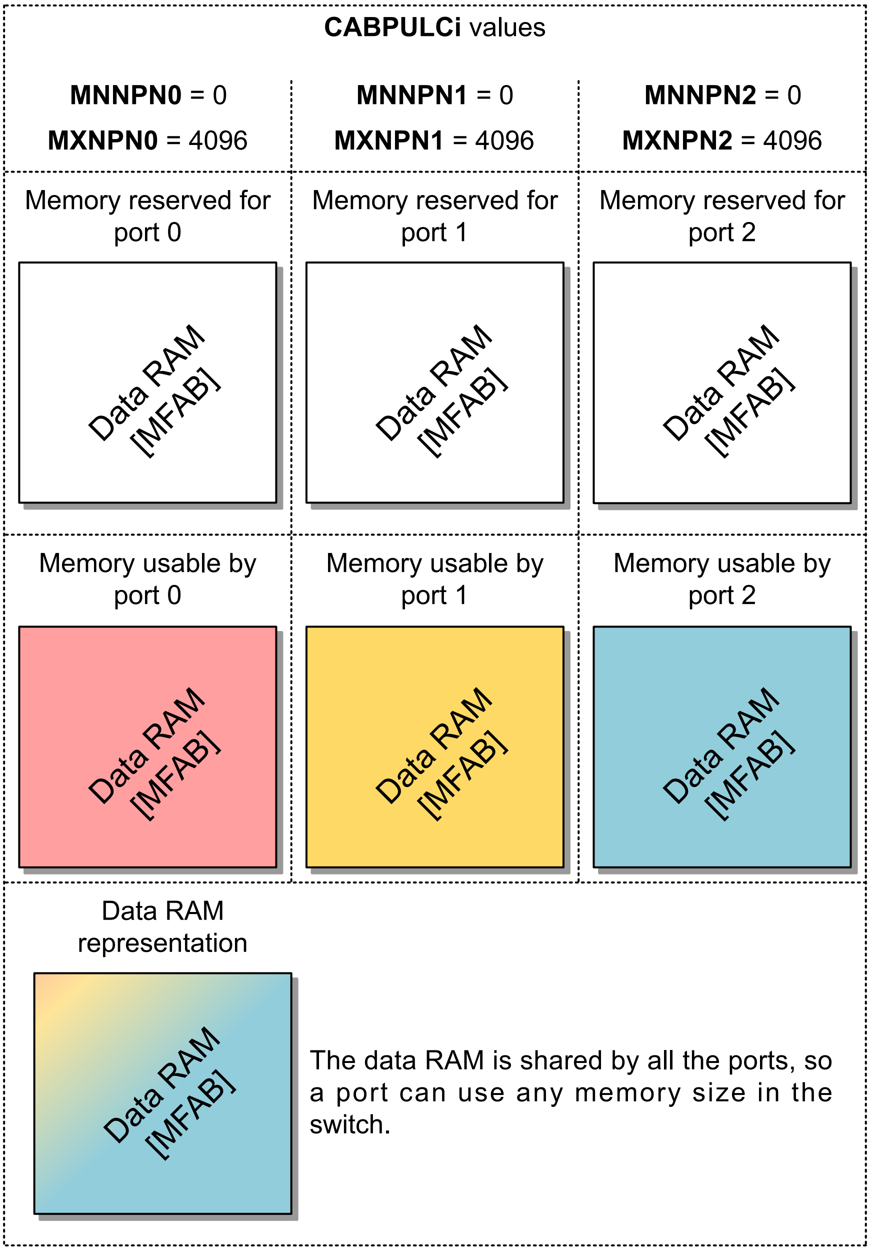

Figure 31.16 Shared memory setting

31.5.3.2 Reduced Memory Setting 1 (Recommended Setting)

In reduced memory, the data RAM is shared by all agents but some of them are not able to use all the memory because they can make the switch overflow (especially for CPU ports [GWCA]). To set this mode, use the CABPULCi.MXNPN register.

Figure 31.17 shows an example of reduced memory setting for Pointer number to address local RAM = = 4096 and Port number on the switch = = 3. For example, if port 2 is a fast CPU port, CABPULCi.MXNPN register can limit the number of reception frames.

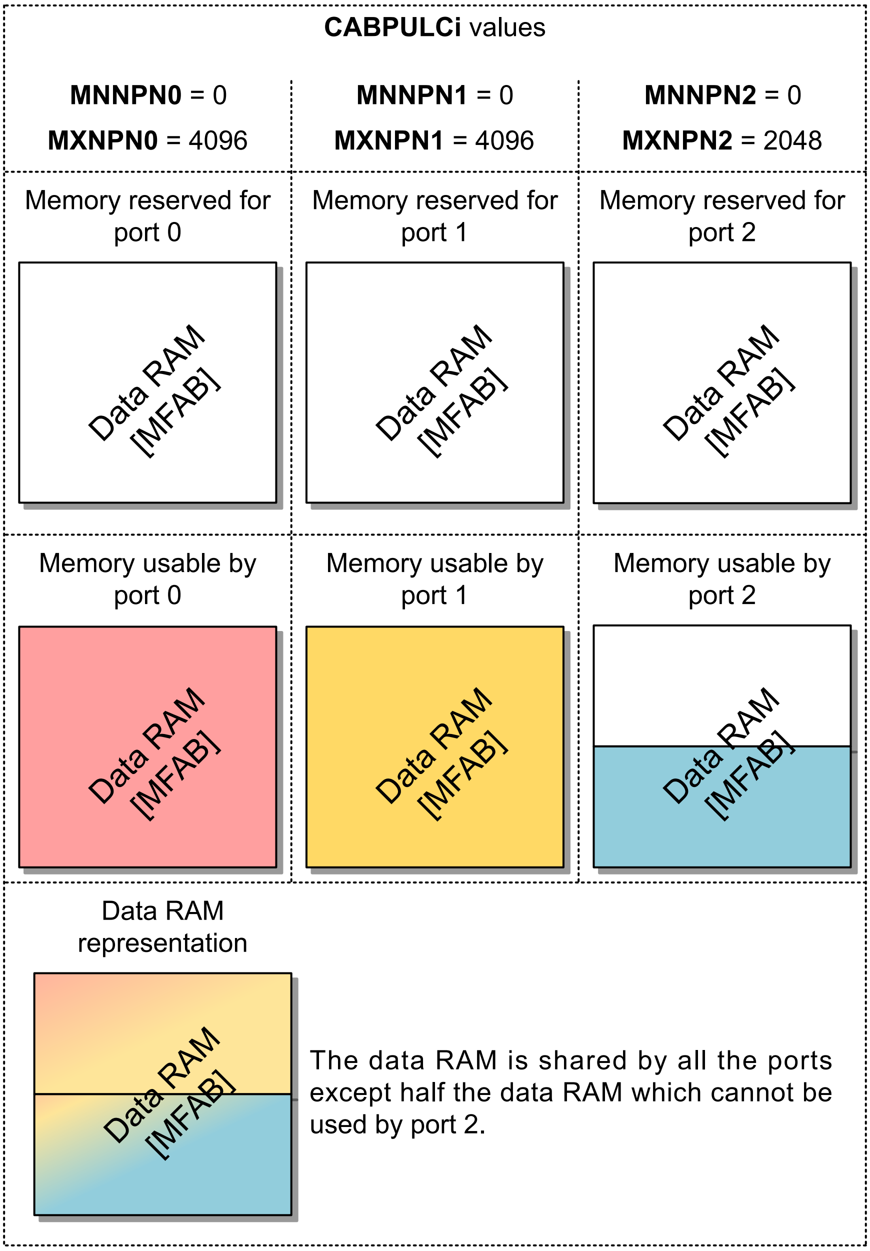

Figure 31.17 Reduced memory setting example

31.5.3.3 Reduced Memory Setting 2 (Recommended Setting)

In reduced memory, the data RAM is shared by all agents but some of them are not able to use all the memory because they can make the switch overflow (especially for CPU ports [GWCA]). To set this mode, use the CABPULCi.MNNPN register.

Figure 31.18 shows an example of reduced memory setting for Pointer number to address local RAM = = 4096 and Port number on the switch = = 3. For example, if port 0 or port 1 is a slow Ethernet port, CABPULCi.MNNPN register can protect the number of frame buffer.

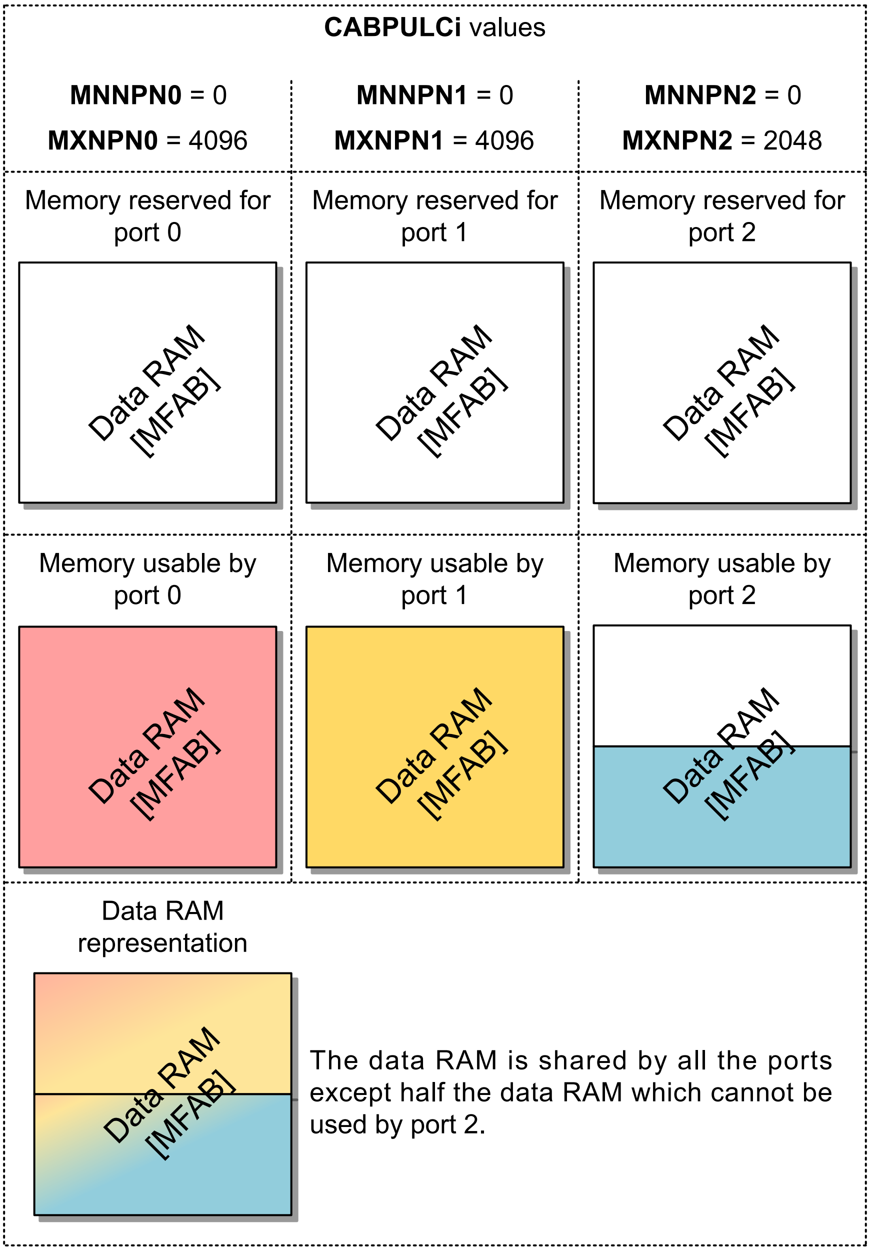

Figure 31.18 Reduced memory setting example

31.5.3.4 Hybrid Memory Setting

All the setting described in section 31.5.3.1. Shared Memory Setting (Default Setting), section 31.5.3.2. Reduced Memory Setting 1 (Recommended Setting) and section 31.5.3.3. Reduced Memory Setting 2 (Recommended Setting) can be used in combination to describe a complex memory such as the hybrid memory setting.

Figure 31.19 shows an example of hybrid memory setting for Pointer number to address local RAM = = 4096 and Port number on the switch = = 4.

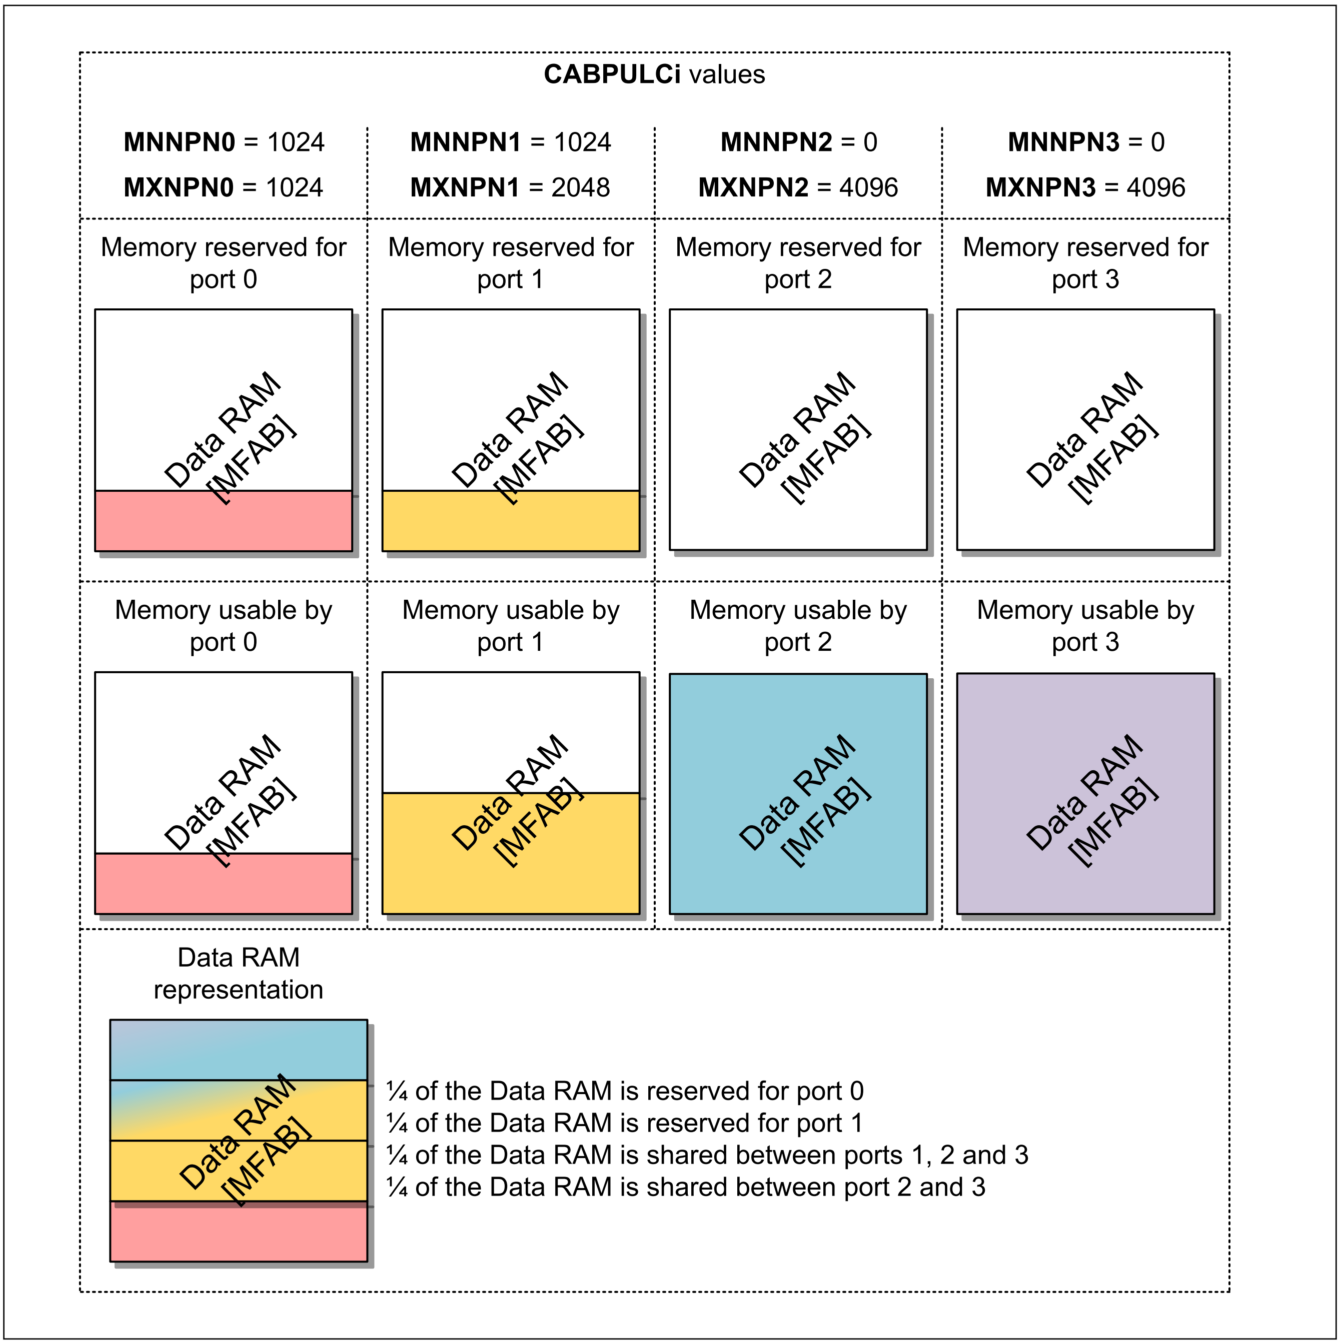

Figure 31.19 Hybrid memory setting example

32. Ethernet Agent (ETHA)

32.1 Overview

Ethernet Agent (ETHA) consists of an agent interface module to allow communication within ESWM. ETHA handles data exchange between ESWM and an Ethernet PHY.

Table 32.1 lists the ETHA specifications and Figure 32.1 shows a ETHA block diagram.

Table 32.1 ETHA specifications

Item	Function	Description
Interfaces	Clock/Reset interface	Clock/Reset interface [TOP]
	Scan interface	Scan interface [TOP]
	Switch mode	Interface to receive the switch mode [MFWD]
	Pause interface	Interface to pause TX queues [COMA]
	SFR interface	Interface to access GWCA SFRs [COMA]
	Interrupts	GWCA interrupt to CPU
	Fabric interface	Interface to communicate with the data, TAG and pointer RAM [MFAB]
	Descriptor bus	Interface to receive frame information to send to CPU [MFWD]
	L2/L3 update bus	Interface to fetch the frame routing information [MFWD]
	BP request	Interface to receive BPs to store frames in the data, TAG and pointer RAM [COMA]
	BP release	Interface to release the BPs that has been used [COMA]
	TX timestamp capture interface	Interface to send TX timestamps to CPU [RMAC]
	RAM interfaces	Interface to communicate with RAMs [TOP]
Data provision	Ethernet frames	Corresponds to the IEEE 802.3, 802.1Q and 802.1CB standards [802.3] [802.1Q] [802.1CB]
	Descriptors	Local ethernet descriptor (ETHA to MFWD). Forwarding descriptor (MFWD to ETHA).

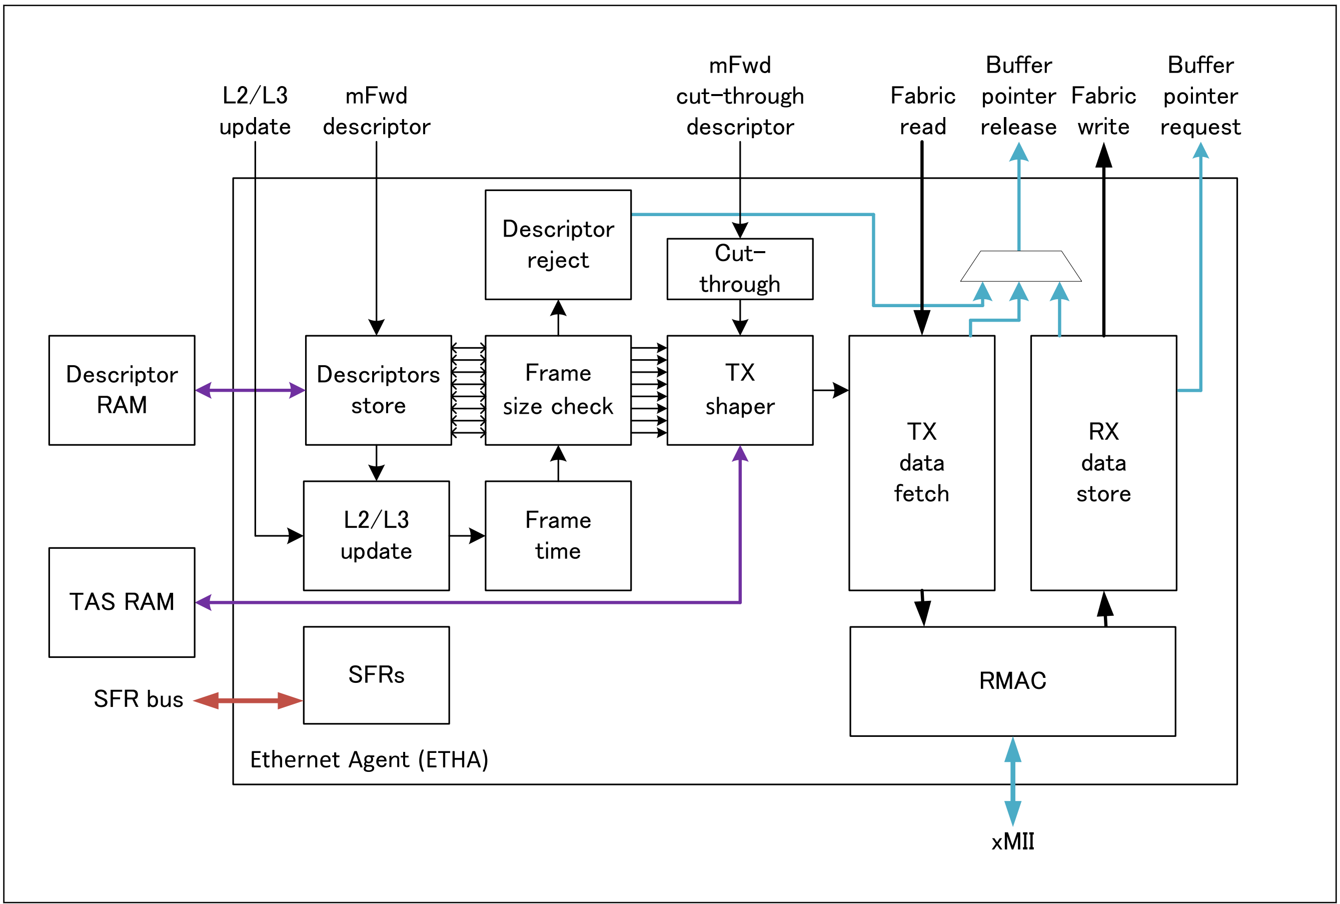

Figure 32.1 ETHA block diagram

Table 32.2 ETHA functional blocks

Block name	Function
RX data store	Transmits frames from RMAC to the local RAM
TX data fetch	Transmits frame from local RAM to RMAC
Cut-through	Receives cut-through descriptors from the forwarding engine
Descriptor store	Receives the descriptors from forwarding engine and controls the priority between descriptors
L2/L3 update	Fetches L2/L3 update information
Frame time	Calculates the frame time for TAS scheduling
Frame size check	Checks the frame size
Descriptor reject	Rejects descriptors
TX shaper	Shapes the traffic on TX side
RMAC	Mac interface [RMAC]
SFRs	ETHA SFRs

Note:
- Base address: ETHA0 = 0x403C_A000, ETHA1 = 0x403C_C000, ETHA0_NS = 0x503C_A000, ETHA1_NS = 0x503C_C000
- The address preceded by “E:” corresponds to an emulation address which allows a register to be read without modifying its content.
- All registers can be read in any mode
- Access modes:
  - Any: Register can be accessed in any mode
  - D: Register can be accessed in DISABLE mode
  - C: Register can be accessed in CONFIG mode
  - O: Register can be accessed in OPERATION mode.

32.3 ETHA Register Descriptions

32.3.1 ETHA Mode Function Registers

32.3.1.1 EAMC : Mode Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OPC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
1:0	OPC[1:0]	Operating Mode Command Used to set ETHA mode 0 0: Enter RESET mode 0 1: Enter DISABLE mode 1 0: Enter CONFIG mode 1 1: Enter OPERATION mode	R/W
31:2	—	These bits are read as 0.	R

Note: HW: This register is not writable if its value is different than EAMS.OPS.

32.3.1.2 EAMS : Mode Status Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OPS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
1:0	OPS[1:0]	Operating Mode Status Flag Indicates the current ETHA mode 0 0: RESET mode 0 1: DISABLE mode 1 0: CONFIG mode 1 1: OPERATION mode	R
31:2	—	These bits are read as 0.	R

32.3.2 Transmission Function Registers

32.3.2.1 EAIRC : IPV Remapping Configuration Register [802.1Q]

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	IPVR7[2:0]			—	IPVR6[2:0]			—	IPVR5[2:0]			—	IPVR4[2:0]		
Value after reset:	0	1	1	1	0	1	1	0	0	1	0	1	0	1	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	IPVR3[2:0]			—	IPVR2[2:0]			—	IPVR1[2:0]			—	IPVR0[2:0]		
Value after reset:	0	0	1	1	0	0	1	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
2:0	IPVR0[2:0]	IPV Remapping 0 Configure to which queue descriptor received with IPV 0 is stored (when a descriptor is received from forwarding engine with FDESCR.IPV [MFWD] equal to 0).	R/W

Bit	Symbol	Function	R/W
3	—	This bit is read as 0.	R
6:4	IPVR1[2:0]	IPV Remapping 1 Configure to which queue descriptor received with IPV 1 is stored (when a descriptor is received from forwarding engine with FDESCR.IPV [MFWD] equal to 1).	R/W
7	—	This bit is read as 0.	R
10:8	IPVR2[2:0]	IPV Remapping 2 Configure to which queue descriptor received with IPV 2 is stored (when a descriptor is received from forwarding engine with FDESCR.IPV [MFWD] equal to 2).	R/W
11	—	This bit is read as 0.	R
14:12	IPVR3[2:0]	IPV Remapping 3 Configure to which queue descriptor received with IPV 3 is stored (when a descriptor is received from forwarding engine with FDESCR.IPV [MFWD] equal to 3).	R/W
15	—	This bit is read as 0.	R
18:16	IPVR4[2:0]	IPV Remapping 4 Configure to which queue descriptor received with IPV 4 is stored (when a descriptor is received from forwarding engine with FDESCR.IPV [MFWD] equal to 4).	R/W
19	—	This bit is read as 0.	R
22:20	IPVR5[2:0]	IPV Remapping 5 Configure to which queue descriptor received with IPV 5 is stored (when a descriptor is received from forwarding engine with FDESCR.IPV [MFWD] equal to 5).	R/W
23	—	This bit is read as 0.	R
26:24	IPVR6[2:0]	IPV Remapping 6 Configure to which queue descriptor received with IPV 6 is stored (when a descriptor is received from forwarding engine with FDESCR.IPV [MFWD] equal to 6).	R/W
27	—	This bit is read as 0.	R
30:28	IPVR7[2:0]	IPV Remapping 7 Configure to which queue descriptor received with IPV 7 is stored (when a descriptor is received from forwarding engine with FDESCR.IPV [MFWD] equal to 7).	R/W
31	—	This bit is read as 0.	R

32.3.2.2 EATDQSC : TX Descriptor Queue Security Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	TDQSL7 to TDQSL0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TDQSL7 to TDQSL0	TX Descriptor Queue n Security Level (n = 0 to 7) When a queue is secured, an unsecure descriptor cannot enter it (when a descriptor is from the forwarding engine with FDESCR.SEC [FWD] equal to 0). 0: Queue i unsecure 1: Queue i secure	R/W
31:8	—	These bits are read as 0.	R

32.3.2.3 EATDQC : TX Descriptor Queue Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	TDQP7 to TDQP0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TCTDQD	TDQD7 to TDQD0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TDQD7 to TDQD0	TX Descriptor Queue n Disable (n = 0 to 7) 0: Queue i enabled 1: Queue i disabled	R/W
8	TCTDQD	TX Cut-Through Descriptor Queue Disable 0: Cut-through queue enabled 1: Cut-through queue disabled	R/W*1
15:9	—	These bits are read as 0.	R
23:16	TDQP7 to TDQP0*2	TX Descriptor Queue n Pause (n = 0 to 7) 0: Queue i active 1: Queue i paused	R/W*1
31:24	—	These bits are read as 0.	R

Note 1. Read value differs from written value.
Note 2. SW: Pausing a queue for a long time can result in switch overflow. In case of a switch overflow [COMA], set this register to 0.

TDQDn bits (TX Descriptor Queue n Disable (n = 0 to 7))

Avoid descriptor from MFWD to enter the corresponding queue. The forwarding engine rejects the corresponding descriptor.

If disabled queue data is no longer required, the corresponding EATMFSCq.MFS register can be set to 0 to avoid more frames going to the RMAC.

[Setting condition]

- SW: Writing 1 to this bit.

[Clearing conditions]

- SW: Writing 0 to this bit
- HW: Exiting OPERATION mode clears this register (EAMC.OPC ≠ 11).

TCTDQD bit (TX Cut-Through Descriptor Queue Disable)

Avoid descriptor from MFWD to enter the cut-through queue by deasserting eha_ct_ready pin. The forwarding engine rejects the corresponding descriptor using the Common Agent reject bus [COMA].
[Setting condition]

- SW: Writing 1 to this bit.

[Clearing conditions]

- SW: Writing 0 to this bit
- HW: Exiting OPERATION mode clears this register (EAMC.OPC ≠ 11).

TDQPn bits (TX Descriptor Queue n Pause (n = 0 to 7))

Avoid frames to be sent to the RMAC [RMAC] by stopping descriptor fetching from the descriptor RAM.
[Setting condition]

- SW: Writing 1 to this bit.

[Clearing conditions]

- SW: Writing 0 to this bit
- HW: Exiting OPERATION mode clears this register (EAMC.OPC ≠ 11).

Note:
- This register is used to stop a queue but MFWD does not stop sending descriptor to the corresponding queue. In this case the queue might overflow.
- When a queue is paused, the CBS module is still active, so the credit value continues to increase.

32.3.2.4 EATDQAC : TX Descriptor Queue Arbitration Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x001C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TDQA7[3:0]				TDQA6[3:0]				TDQA5[3:0]				TDQA4[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TDQA3[3:0]				TDQA2[3:0]				TDQA1[3:0]				TDQA0[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	TDQA0[3:0]	TX Descriptor Queue Arbitration 0 0: Queue 0 strict arbitration Others: Queue 0 WRR arbitration	R/W
7:4	TDQA1[3:0]	TX Descriptor Queue Arbitration 1 0: Queue 1 strict arbitration Others: Queue 1 WRR arbitration	R/W
11:8	TDQA2[3:0]	TX Descriptor Queue Arbitration 2 0: Queue 2 strict arbitration Others: Queue 2 WRR arbitration	R/W
15:12	TDQA3[3:0]	TX Descriptor Queue Arbitration 3 0: Queue 3 strict arbitration Others: Queue 3 WRR arbitration	R/W
19:16	TDQA4[3:0]	TX Descriptor Queue Arbitration 4 0: Queue 4 strict arbitration Others: Queue 4 WRR arbitration	R/W
23:20	TDQA5[3:0]	TX Descriptor Queue Arbitration 5 0: Queue 5 strict arbitration Others: Queue 5 WRR arbitration	R/W
27:24	TDQA6[3:0]	TX Descriptor Queue Arbitration 6 0: Queue 6 strict arbitration Others: Queue 6 WRR arbitration	R/W
31:28	TDQA7[3:0]	TX Descriptor Queue Arbitration 7 0: Queue 7 strict arbitration Others: Queue 7 WRR arbitration	R/W

Note:
- For more details, see GWRDQAC register description [GWCA] in the GWCA specification
- SW: In hybrid arbitration mode, all the queues with an EATDQAC.TDQAi value other than 0 should have a consecutive priority

- SW: In all arbitration mode except strict priority arbitration mode, at least two queues should have an EATDQAC.TDQAi value other than 0
- SW: WRR arbitration is only possible between queues with the same type (e or p), see EATPEC.TTQ register description (for example, all queues with an EATDQAC.TDQAi value other than 0 should have the same setting in EATPEC.TTQi register)
- SW: Only queues set to strict arbitration can use CBS functions
- SW: When using TAS, all queues not set to strict arbitration should be opened simultaneously.

32.3.2.5 EATPEC : TX Preemption Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	AFS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	TTQ7 to TTQ0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TTQ7 to TTQ0	Transmission Type Queue n (n = 0 to 7) See section 32.5.1.7.2. Preemption. 0: Queue i contains e-frames 1: Queue i contains p-frames	R/W
15:8	—	These bits are read as 0.	R
17:16	AFS[1:0]	Additional Fragment Size Used for preemption. It defines the minimum size of a fragment which is not the last fragment of a frame. 0 0: 0 byte is added to minimum fragment size (minimum fragment size = 64 bytes) 0 1: 64 bytes are added to minimum fragment size (minimum fragment size = 128 bytes) 1 0: 128 bytes are added to minimum fragment size (minimum fragment size = 192 bytes) 1 1: 192 bytes are added to minimum fragment size (minimum fragment size = 256 bytes)	R/W
31:18	—	These bits are read as 0.	R

32.3.2.6 EATMFSCq : Transmission Maximum Frame Size Configuration Register q (q = 0 to 7)

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0040 + 0x4 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MFS[15:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	MFS[15:0]	Maximum Frame Size Maximum frame size for descriptor queue q. All bigger frames are rejected.	R/W
31:16	—	These bits are read as 0.	R

Note: HW: The MFS size comparison takes the frame size on the PHY interface.

32.3.2.7 EATDQDCq : Transmission Descriptor Queue Depth Configuration Register q (q = 0 to 7)

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0060 + 0x4 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	DQD[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	DQD[9:0]	Descriptor Queue Depth Set the number of descriptors that can contain descriptor queue q. For details, see GWRDQDCq register description [GWCA] in the GWCA specification.	R/W
31:10	—	These bits are read as 0.	R

Note: SW: The sum of DQD fields should always be smaller or equal to 512.

32.3.2.8 EATDQMq : Transmission Descriptor Queue q Monitoring Register (q = 0 to 7)

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0080 + 0x4 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	DNQ[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	DNQ[9:0]	Descriptor Number in Queue These bits indicate the current number of descriptors stored in TX descriptor queue q. All descriptors stored in the TX descriptor queue q are rejected/dropped when exiting OPERATION mode.	R
31:10	—	These bits are read as 0.	R

DNQ[9:0] bits (Descriptor Number in Queue)

[Increment condition]

- HW: Incremented by 1 when a descriptor is received from the MFWD for the corresponding queue, the queue is not full and there is no descriptor security error.

[Decrement condition]

- HW: Decremented by 1 when a descriptor is read by Ethernet Agent to send data to RMAC [RMAC] or to reject data.

32.3.2.9 EATDQMLMq : Transmission Descriptor Queue q Max Level Monitoring Register (q = 0 to 7)

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x00A0 + 0x4 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	DMLQ[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	DMLQ[9:0]	Descriptor Max Level in Queue These bits indicate the maximum number of descriptors that is stored in TX descriptor queue q.	R
31:10	—	These bits are read as 0.	R

DMLQ[9:0] bits (Descriptor Max Level in Queue)

[Clearing conditions]

- HW: RESET mode clears this register (EAMC.OPS == 00)
- SW: Reading this register clears to EATDQMq.DNQ.

[Increment condition]

- HW: Increments to EATDQMq.DNQ value when smaller than EATDQMq.DNQ.

32.3.2.10 EACTQC : Cut-Through Queue Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0100

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CTQD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CTQD[15:0]*1	Cut-Through Queue Delay (clk Cycle Number) Set the number of clocks to wait for descriptor transmission.	R/W

Bit	Symbol	Function	R/W
31:16	—	These bits are read as 0.	R

Note 1. Set to 0 for this product.

32.3.2.11 EACTDQDC : Cut-Through Descriptor Queue Depth Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0104

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CTDQD[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CTDQD[3:0]	Cut-Through Descriptor Queue Depth Number of descriptors that can contain cut-through descriptor queue.	R/W
31:4	—	These bits are read as 0.	R

Note: SW: The maximum value of this register is 8.

32.3.2.12 EACTDQM : Cut-Through Descriptor Queue Monitoring Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0108

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CTQDN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CTQDN[3:0]	Cut-Though Queue Descriptor Number	R
31:4	—	These bits are read as 0.	R

CTQDN[3:0] bits (Cut-Though Queue Descriptor Number)

These bits indicate the current number of descriptors stored in the cut-through descriptor queue.

All cut-through descriptors stored in the queue are not rejected/dropped when exiting OPERATION mode. But the frame being received by ETHA is rejected/dropped, if ETHA transitioned to reset before the frame is completely received.

All cut-through descriptors stored in the queue are not rejected/dropped when exiting OPERATION mode but are rejected/dropped when transitioning to RESET mode.

[Increment condition]

- HW: Incremented by 1 when a descriptor is received from the forwarding engine for the cut-through queue and the queue is not full.

[Decrement condition]

- HW: Decremented by 1 when a descriptor is read by Ethernet Agent to send data to RMAC [RMAC].

32.3.2.13 EACTDQMLM : Cut-Through Descriptor Queue Max Level Monitoring Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x010C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CTDMLQ[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CTDMLQ[3:0]	Cut-Through Descriptor Max Level in Queue These bits indicate the maximum number of descriptors that is stored in cut-through descriptor queue.	R
31:4	—	These bits are read as 0.	R

CTDMLQ[3:0] bits (Cut-Through Descriptor Max Level in Queue)

[Clearing conditions]

- HW: RESET mode clears this register (EAMC.OPS == 00)
- SW: Reading this register clears to EACTDQM.CTQDN.

[Increment condition]

- HW: Increments to EACTDQM.CTQDN value when smaller than EACTDQM.CTQDN.

32.3.3 TAG Function Registers

32.3.3.1 EAVCC : VLAN Control Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0130

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:9	—	These bits are read as 0.	R

32.3.4 CBS Function Registers [802.1Qav]

32.3.4.1 EACAEC : CBS Admin Enable Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0200

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CE7 to CE0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CE7 to CE0	CBS Enable n (n = 0 to 7) This register is only used to configure CBS and is not directly used by CBS modules. 0: CBS for descriptor queue i disabled 1: CBS for descriptor queue i enabled	R/W
31:8	—	These bits are read as 0.	R

32.3.4.2 EACC : CBS Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0204

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CC7 to CC0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CC7 to CC0	Configuration Change n (n = 0 to 7) 0: No effect 1: The Admin settings of CBS i are copied to its Oper settings (EACAEC.CEi, EACAIVCq.CIV, and EACAULCq.CUL are respectively copied to EACOEM.CEi, EACOIVMq.CIV, and EACOULMq.CUL)	W*1
31:8	—	These bits are read as 0.	R

Note 1. Read value differs from written value.

32.3.4.3 EACAIVCq : CBS Admin Increment Value Configuration Register q (q = 0 to 7)

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0220 + 0x4 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CIV[19:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CIV[19:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
19:0	CIV[19:0]	Credit Increment Value	R/W
31:20	—	These bits are read as 0.	R

CIV bits (Credit Increment Value)

Configure CBS throughput.

CIV[3:0] is the credit increment in byte per clock and CIV[15:0] is the credit increment in sub-byte per clock.

This register is only used to configure CBS and is not directly used by CBS modules.

For more details, see section 32.5.1.5. CBS (Credit-based shaper) [802.1Qav].

Caution: SW: Setting this register to 0 or a value close to 0 sets the corresponding transmission queue to a very low throughput and can lead to a queue overflow.

32.3.4.4 EACAULCq : CBS Admin Upper Limit Configuration Register q (q = 0 to 7)

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0240 + 0x4 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	CUL[30:0]														
Value after reset:	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CUL[30:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
30:0	CUL[30:0]	Credit Upper Limit	R/W
31	—	This bit is read as 0.	R

CUL bits (Credit Upper Limit)

Configure queue q interference time.

This register is only used to configure CBS and is not directly used by CBS modules.

For more details, see section 32.5.1.5. CBS (Credit-based shaper) [802.1Qav].

32.3.4.5 EACOEM : CBS Oper Enable Monitoring Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0260

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CE7 to CE0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CE7 to CE0	CBS Enable n (n = 0 to 7) [Update conditions] HW: This register is updated to EACACC.CEi when 1 is written to EACC.CCi. 0: CBS for descriptor queue i disabled 1: CBS for descriptor queue i enabled	R
31:8	—	These bits are read as 0.	R

32.3.4.6 EACOIVMq : CBS Oper Increment Value Monitoring Register q (q = 0 to 7)

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0280 + 0x4 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CIV[19:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CIV[19:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
19:0	CIV[19:0]	Credit Increment Value	R
31:20	—	These bits are read as 0.	R

CIV bits (Credit Increment Value)

Configure CBS throughput.

CIV[3:0] is the credit increment in byte per clock and CIV[15:0] is the credit increment in sub-byte per clock.

This register is only used to configure CBS and is not directly used by CBS modules.

[Update condition]

- HW: This register is updated to EACAIVq.CIV when 1 is written to EACC.CCi.

32.3.4.7 EACOULMq : CBS Oper Upper Limit Monitoring Register q (q = 0 to 7)

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x02A0 + 0x4 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	CUL[30:0]														
Value after reset:	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CUL[30:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
30:0	CUL[30:0]	Credit Upper Limit	R
31	—	This bit is read as 0.	R

CUL bits (Credit Upper Limit)

Configure queue q interference time.

This register is only used to configure CBS and is not directly used by CBS modules.

[Update condition]

- HW: This register is updated to EACAULq.CUL when 1 is written to EACC.CCi.

32.3.4.8 EACGSM : CBS Gate State Monitoring Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x02C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CGS7 to CGS0							
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	CGS7 to CGS0	CBS Gate State n (n = 0 to 7) 0: CBS does not authorize queue i transmission (CBS credit negative) 1: CBS authorizes queue i transmission (CBS credit positive)	R
31:8	—	These bits are read as 0.	R

32.3.5 TAS Function Registers [802.1Qbv]

32.3.5.1 EATASC : TAS Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0300

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	TASCA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TASTS	—	—	—	—	—	TASCI	TASCC	TASE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TASE	TAS Enable Enables the TAS schedule See section 32.5.1.6.1. TAS General Behavior. 0: TAS disabled 1: TAS enabled	R/W*1
1	TASCC	TAS Configuration Change 0: TAS is not changing configuration 1: TAS is changing configuration	R/W*1
2	TASCI	TAS Configuration Impossible This bit aids the software in detecting when TAS configuration is possible, it is equal to (EATASC.TASE & ~ EATASSM.TASSO) | EATASC.TASCC. 0: TAS configuration is possible 1: TAS configuration is not possible	R
7:3	—	These bits are read as 0.	R
8	TASTS	TAS Timer Select Selects the gPTP to be used for TAS module.	R/W
15:9	—	These bits are read as 0.	R
23:16	TASCA[7:0]	TAS Configuration Address Shows the address from which entry learning occurs in TAS RAM for the next configuration.	R
31:24	—	These bits are read as 0.	R

Note 1. Read value differs from written value.

TASE bit (TAS Enable)

[Setting condition]

- SW: Writing 1 to this bit.

[Clearing conditions]

- SW: Writing 0 to this bit
- HW: When in RESET mode.

TASCC bit (TAS Configuration Change)

[Setting condition]

- SW: Writing 1 to this bit.

[Clearing conditions]

- HW: When TAS configuration change is complete

- HW: When in RESET mode.

See section 32.5.1.6.1. TAS General Behavior.

TASCI bit (TAS Configuration Impossible)

[Clearing condition]

- HW: When in RESET mode.

TASCA[7:0] bits (TAS Configuration Address)

[Clearing condition]

- HW: When in RESET mode.

32.3.5.2 EATASIGSC : TAS Initial Gate State Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0304

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TASCTIGS	TASIGS7 to TASIGS0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TASIGS7 to TASIGS0	TAS Initial Gate State n (n = 0 to 7) Bit q is the gate state used for initialization of descriptor queue q gate. 0: Initial gate state is closed 1: Initial gate state is opened	R/W
8	TASCTIGS	TAS Cut-Through Initial Gate State Gate state used for initialization of cut-through gate. 0: Initial gate state is closed 1: Initial gate state is opened	R/W
31:9	—	These bits are read as 0.	R

32.3.5.3 EATASENCi : TAS Entry Number Configuration Register i (i = 0 to 7)

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0320 + 0x4 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TASAEN[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	TASAEN[8:0]	TAS Admin Entry Number This register is only used to configure TAS and is not directly used by TAS module. Sets the number of TAS RAM entries used for gate i schedule.	R/W
31:9	—	These bits are read as 0.	R

Note:
- SW: If the TAS module is dynamically used (TAS setting flow in Figure 32.11 is used when EATASC.TASE is already set), the sum of EATASENCi.TASAEN should be smaller or equal to 119.
- SW: If the TAS module is statistically used (TAS setting flow in Figure 32.11 is not used when EATASC.TASE is already set), the sum of EATASENCi.TASAEN should be smaller or equal to 247.

32.3.5.4 EATASCTENC : TAS Cut-Through Entry Number Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0340

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TASCTAEN[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	TASCTAEN[8:0]	TAS Admin Cut-Through Entry Number This register is only used to configure TAS and is not directly used by TAS module. Sets the number of TAS RAM entries used for cut-through gate schedule.	R/W
31:9	—	These bits are read as 0.	R

Note:
- SW: If the TAS module is dynamically used (TAS setting flow in Figure 32.11 is used when EATASC.TASE is already set), the sum of EATASENCi.TASAEN and EATASCTENC.TASCTAEN should be smaller or equal to 119.
- SW: If the TAS module is statistically used (TAS setting flow in Figure 32.11 is not used when EATASC.TASE is already set), the sum of EATASENCi.TASAEN and EATASCTENC.TASCTAEN should be smaller or equal to 247.

32.3.5.5 EATASENMi : TAS Entry Number Monitoring Register i (i = 0 to 7)

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0360 + 0x4 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TASOEN[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	TASOEN[8:0]	TAS Oper Entry Number	R
31:9	—	These bits are read as 0.	R

TASOEN[8:0] bits (TAS Oper Entry Number)

[Update condition]

- HW: This register is updated to EATASENCi.TASAEN when configuration change occurs or when schedule start occurs. See section 32.5.1.6.1. TAS General Behavior.

[Clearing condition]

- HW: When in RESET mode.

32.3.5.6 EATASCTENM : TAS Cut-Through Entry Number Monitoring Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0380

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TASCTOEN[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	TASCTOEN[8:0]	TAS Cut-Through Oper Entry Number	R
31:9	—	These bits are read as 0.	R

TASCTOEN[8:0] bits (TAS Cut-Through Oper Entry Number)

[Update condition]

- HW: This register is updated to EATASCTENC.TASCTAEN when configuration change occurs or when schedule start occurs. See section 8.1.6.1.

[Clearing condition]

- HW: When in RESET mode.

32.3.5.7 EATASCSTC0 : TAS Cycle Start Time Configuration Register 0

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03A0

Bit position:	31 … 0
Bit field:	TASACSTP0[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TASACSTP0[31:0]	TAS Admin Cycle Start Time Part 0 Time at which TAS scheduler should start/change configuration. This register is in ns.	R/W

32.3.5.8 EATASCSTC1 : TAS Cycle Start Time Configuration Register 1

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03A4

Bit position: 31 … 0

Bit field: TASACSTP1[31:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TASACSTP1[31:0]	TAS Admin Cycle Start Time Part 1 Time at which TAS scheduler should start/change configuration. This register is in 2^{32} × ns.	R/W

32.3.5.9 EATASCSTM0 : TAS Cycle Start Time Monitoring Register 0

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03A8

Bit position: 31 … 0

Bit field: TASOCSTP0[31:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TASOCSTP0[31:0]	TAS Oper Cycle Start Time Part 0	R

TASOCSTP0[31:0] bits (TAS Oper Cycle Start Time Part 0)

[Update conditions]

- HW: {EATASCSTM1, EATASCSTM0} is updated to {EATASCSTC1, EATASCSTC0} + EATASCTC when configuration change occurs or when schedule start occurs. See section 32.5.1.6.1. TAS General Behavior.
- HW: This register is updated to the next cycle start time every time a new cycle starts.

[Clearing condition]

- HW: When in RESET mode.

32.3.5.10 EATASCSTM1 : TAS Cycle Start Time Monitoring Register 1

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03AC

Bit position: 31 … 0

Bit field: TASOCSTP1[31:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TASOCSTP1[31:0]	TAS Oper Cycle Start Time Part 1	R

TASOCSTP1[31:0] bits (TAS Oper Cycle Start Time Part 1)

[Update conditions]

- HW: {EATASCSTM1, EATASCSTM0} is updated to the value of {EATASCSTC1, EATASCSTC0} + EATASCTC when configuration change occurs or when schedule start occurs. See section 32.5.1.6.1. TAS General Behavior.
- HW: This register is updated to the next cycle start time every time a new cycle starts.

[Clearing condition]

- HW: When in RESET mode.

32.3.5.11 EATASCTC : TAS Cycle Time Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03B0

Bit position:	31–0
Bit field:	TASACT[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TASACT[31:0]	TAS Admin Cycle Time Configure the cycle time for TAS in ns.	R/W

Note: SW: Set this register to a value greater than 100 ns.

32.3.5.12 EATASCTM : TAS Cycle Time Monitoring Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03B4

Bit position:	31–0
Bit field:	TASOCT[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TASOCT[31:0]	TAS Oper Cycle Time	R

TASOCT[31:0] bits (TAS Oper Cycle Time)

[Update condition]

- HW: This register is updated to EATASCTC.TASACT when configuration change occurs or when schedule start occurs. See section 32.5.1.6.1. TAS General Behavior.

[Clearing condition]

- HW: When in RESET mode.

32.3.5.13 EATASGL0 : TAS Gate Learn Register 0

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	TASGAL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TASGAL[7:0]	TAS Gate Address Learn Configures the address in which the TAS entry is learned.	R/W
31:8	—	These bits are read as 0.	R

32.3.5.14 EATASGL1 : TAS Gate Learn Register 1

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03C4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	TASGSL	TASGTL[27:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TASGTL[27:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
27:0	TASGTL[27:0]	TAS Gate Time Learn Configures gate time	R/W
28	TASGSL	TAS Gate State Learn Configures gate state	R/W
31:29	—	These bits are read as 0.	R

32.3.5.15 EATASGLR : TAS Gate Learn Result Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03C8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	GL	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
30:0	—	These bits are read as 0.	R
31	GL	Gate Learn	R

GL bit (Gate Learn)

[Setting condition]

- HW: Writing to the EATASGL1 register.

[Clearing condition]

- HW: When learning is completed, this bit is deasserted.

32.3.5.16 EATASGR : TAS Gate Read Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03D0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	TASGAR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TASGAR[7:0]	TAS Gate Address Read Configures the address in which the TAS entry is read.	R/W
31:8	—	These bits are read as 0.	R

32.3.5.17 EATASGRR : TAS Gate Read Result Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03D4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	GR	—	—	TASGSR	TASGTR[27:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TASGTR[27:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
27:0	TASGTR[27:0]	TAS Gate Time Read Displays gate time read value.	R
28	TASGSR	TAS Gate State Read Displays gate state read value.	R
30:29	—	These bits are read as 0.	R
31	GR	Gate Read	R

TASGTR bits (TAS Gate Time Read)

[Update condition]

- EATASGRR.GR clear event

TASGSR bit (TAS Gate State Read)

[Update condition]

- EATASGRR.GR clear event

GR bit (Gate Read)

[Setting condition]

- HW: Writing to the EATASGR register.

[Clearing condition]

- HW: When reading is completed, this bit is deasserted.

32.3.5.18 EATASHCC : TAS Hardware Calibration Configuration Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03E0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TASJ[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TASJ[15:0]	TAS Jitter Configure the jitter between the TAS data transmission and RMAC PHY interface [RMAC]. See section 32.5.1.6.3. TAS Hardware Calibration.	R/W
31:16	—	These bits are read as 0.	R

32.3.5.19 EATASRIRM : TAS RAM Initialization Register Monitoring Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03E4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TASRR	TASRIOG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TASRIOG	TAS RAM Initialization Ongoing	R/W*1
1	TASRR	TAS RAM Ready	R
31:2	—	These bits are read as 0.	R

Note 1. Read value differs from written value.

TASRIOG bit (TAS RAM Initialization Ongoing)

[Setting condition]

- SW: Writing 1 to this register starts TAS RAM initialization.

[Clearing condition]

- HW: When TAS RAM initialization is completed.

TASRR bit (TAS RAM Ready)

[Setting condition]

- When EATASRIRM.TASRIOG is cleared.

[Clearing condition]

- Writing 1 to EATASRIRM.TASRIOG.

32.3.5.20 EATASSM : TAS Status Monitoring Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x03E8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TASSO
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TASCTGS	TASGS7 to TASGS0							
Value after reset:	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	TASGS7 to TASGS0	TAS Gate n State (n = 0 to 7) 0: Gate i is closed 1: Gate i is opened	R
8	TASCTGS*1	TAS Cut-Through Gate State 0: Cut-through gate is closed 1: Cut-through gate is opened	R
15:9	—	These bits are read as 0.	R
16	TASSO	TAS Scheduler Ongoing 0: TAS scheduler is not ongoing 1: TAS scheduler is ongoing	R
31:17	—	These bits are read as 0.	R

Note 1. HW: This register only exists if UCIAPRACE020_CT_ON is defined.

TASSO bit (TAS Scheduler Ongoing)

[Clearing condition]

- HW: When in RESET mode.

32.3.6 ETHA Counter Registers

32.3.6.1 EAUSMFSECN : Under Minimum Frame Size Error Counter Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0400

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	USMFSEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	USMFSEN[15:0]	Under Minimum Frame Size Error Number This register counts the number of received data lost because of under minimum size error.	R

Bit	Symbol	Function	R/W
31:16	—	These bits are read as 0.	R

USMFSEN[15:0] bits (Under Minimum Frame Size Error Number)

[Clearing conditions]

- HW: When in RESET mode
- SW: Reading this register.

[Increment condition]

- HW: Incremented by 1 when an Under Minimum Frame Size Error occurs and if this register has a value other than 0xFFFF.

32.3.6.2 EATFECN : TAG Filtering Error Counter Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0404

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TFEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TFEN[15:0]	TAG Filtering Error Number This register counts the number of received data lost because of TAG filtering.	R
31:16	—	These bits are read as 0.	R

TFEN[15:0] bits (TAG Filtering Error Number)

[Clearing conditions]

- HW: When in RESET mode
- SW: Reading this register.

[Increment condition]

- HW: Incremented by 1 when a TAG filter error occurs and if this register has a value other than 0xFFFF.

32.3.6.3 EAFSECN : Frame Size Error Counter Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0408

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FSEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	FSEN[15:0]	Frame Size Error Number This register counts the number of received data lost because of a Frame Size Error.	R
31:16	—	These bits are read as 0.	R

FSEN[15:0] bits (Frame Size Error Number)

[Clearing conditions]

- HW: When in RESET mode
- SW: Reading this register.

[Increment condition]

- HW: Incremented by 1 when a Frame Size Error occurs and if this register has a value other than 0xFFFF.

32.3.6.4 EADQOECN : Descriptor Queue Overflow Error Counter Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x040C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DQOEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DQOEN[15:0]	Descriptor Queue Overflow Error Number This register counts the number of transmit data lost because of a Descriptor Queue Overflow Error.	R
31:16	—	These bits are read as 0.	R

DQOEN[15:0] bits (Descriptor Queue Overflow Error Number)

[Clearing conditions]

- HW: When in RESET mode
- SW: Reading this register.

[Increment condition]

- HW: Incremented by 1 when a Descriptor Queue Overflow Error occurs and if this register has a value other than 0xFFFF.

32.3.6.5 EADQSECN : Descriptor Queue Security Error Counter Register

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0410

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DQSEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DQSEN[15:0]	Descriptor Queue Security Error Number This register counts the number of transmit data lost because of a Descriptor Queue Security Error.	R
31:16	—	These bits are read as 0.	R

DQSEN[15:0] bits (Descriptor Queue Security Error Number)

[Clearing conditions]

- HW: When in RESET mode
- SW: Reading this register.

[Increment condition]

- HW: Incremented by 1 when a Descriptor Queue Security Error occurs and if this register has a value other than 0xFFFF.

32.3.7 ETHA Interrupt Registers

32.3.7.1 Error Interrupt Registers

32.3.7.1.1 EAEIS0 : Error Interrupt Status Register 0

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0500

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FSES7 to FSES0								—	TFES	USMFSES	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	—	These bits are read as 0.	R
5	USMFSES	Under Switch Minimum Frame Size Error Status Flag	R/W*1
6	TFES	TAG Filtering Error Status Flag	R/W*1
7	—	This bit is read as 0.	R
15:8	FSES7 to FSES0	Frame Size Error Status Flag n (n = 0 to 7)	R/W*1
31:16	—	These bits are read as 0.	R

Note 1. Read value differs from written value.

USMFSES bit (Under Switch Minimum Frame Size Error Status Flag)

[Setting condition]

- HW: A frame smaller than 32 bytes has been received from RMAC.

This error occurs with [RMAC] MEIS.RPOES.

[Clearing conditions]

- HW: When in RESET mode
- SW: Writing 1 to one of these bits.

[Error recovery]

- HW: The frame is discarded
- SW: System-dependent, therefore cannot be defined.

TFES bit (TAG Filtering Error Status Flag)

[Setting condition]

- HW: An unauthorized TAG format has been detected. (See section 32.5.2.1. RX Data Store).

[Clearing conditions]

- HW: When in RESET mode
- SW: Writing 1 to one of these bits.

[Error recovery]

- HW: Frame is sent to MFWD with local descriptor DESCR.TFE bit set. (See section 32.5.2.1. RX Data Store).
- SW: System-dependent, therefore cannot be defined.

FSESn bits (Frame Size Error Status Flag n (n = 0 to 7))

[Setting condition]

- HW: Bit q of this register is set when a frame bigger than EATMFSC.MFS has been received for descriptor queue q.

[Clearing conditions]

- HW: When in RESET mode
- SW: Writing 1 to one of these bits.

[Error recovery]

- HW: The current frame is lost and the following data is processed normally
- SW: System-dependent, therefore it cannot be defined.

32.3.7.1.2 EAEIE0 : Error Interrupt Enable Register 0

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0504

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FSEE7 to FSEE0								—	TFEE	USMFSEE	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	—	These bits are read as 0.	R
5	USMFSEE	Under Switch Minimum Frame Size Error Enable 0: Interrupt disabled 1: Interrupt enabled	R/W*1
6	TFEE	TAG Filtering Error Enable 0: Interrupt disabled 1: Interrupt enabled	R/W*1
7	—	This bit is read as 0.	R
15:8	FSEE7 to FSEE0	Frame Size Error Enable n (n = 0 to 7) 0: Interrupt disabled for descriptor queue i 1: Interrupt enabled for descriptor queue i	R/W*1
31:16	—	These bits are read as 0.	R

Note 1. Read value differs from written value.

USMFSEE bit (Under Switch Minimum Frame Size Error Enable)

[Setting condition]

- Writing 1 to this bit.

[Clearing condition]

- Writing 1 to EAEID0.USMFSED register clears this bit.

TFEE bit (TAG Filtering Error Enable)

[Setting condition]

- Writing 1 to this bit.

[Clearing condition]

- Writing 1 to EAEID0.TFED register clears this bit.

FSEEn bits (Frame Size Error Enable n (n = 0 to 7))

[Setting condition]

- Writing 1 to one of these bits.

[Clearing condition]

- Writing 1 to one of EAEID0.FSED bits clears the corresponding bit in this register.

32.3.7.1.3 EAEID0 : Error Interrupt Disable Register 0

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0508

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FSED7 to FSED0								—	TFED	USMFSED	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	—	These bits are read as 0.	R
5	USMFSED	Under Switch Minimum Frame Size Error Disable Writing 1 to this bit clears EAEIE0.USMFSEE register.	R
6	TFED	TAG Filtering Error Disable Writing 1 to this bit clears EAEIE0.TFEE register.	R
7	—	This bit is read as 0.	R
15:8	FSED7 to FSED0	Frame Size Error Disable n (n = 0 to 7) Writing 1 to one of these bits clears the corresponding bit in EAEIE0.FSEE register.	R
31:16	—	These bits are read as 0.	R

32.3.7.1.4 EAEIS1 : Error Interrupt Status Register 1

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0510

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	TASCTGES	TASGES7 to TASGES0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CULES7 to CULES0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CULES7 to CULES0	CBS n Upper Limit Error Status Flag (n = 0 to 7)	R/W*1
15:8	—	These bits are read as 0.	R
23:16	TASGES7 to TASGES0	TAS Gate n Error Status Flag (n = 0 to 7)	R/W*1*2
24	TASCTGES	TAS Cut-Through Gate Error Status Flag	R/W*1*2
31:25	—	These bits are read as 0.	R

Note 1. Read value differs from written value.
Note 2. This error can occur for the following reasons:

- TAS start time EATASCSTC0/1 is set in the past
- gPTP timer had an offset correction [gPTP]
- The minimum gate time has not been satisfied.

CULESn bits (CBS n Upper Limit Error Status Flag (n = 0 to 7))

[Setting condition]

- HW: Bit q of this register is set when descriptor queue q corresponding CBS credits has reached its upper limit EACOULMq.CUL.

[Clearing conditions]

- HW: When in RESET mode
- SW: Writing 1 to one of these bits.

[Error recovery]

- HW: Credit calculation stops at EACOULMq.CUL and no further credit are added until frame transmission for the corresponding queue. As a result, the queue throughput is lower than expected.
- SW: This is a software error and should not occur. (Setting TAS with gates that are partially overlapping each other can trigger this error).

TASGESn bits (TAS Gate n Error Status Flag (n = 0 to 7))

[Setting condition]

- HW: Bit q of this register is set when descriptor queue q corresponding TAS gate had no time to fetch the next gate state value until it starts.

[Clearing conditions]

- HW: When in RESET mode
- SW: Writing 1 to one of these bits.

[Error recovery]

- HW: Gate with restart during next cycle
- SW: If this error occurs frequently, TAS should be reconfigured with a different schedule (this is a software issue because the minimum gate time has not been satisfied). During reconfiguration, this error continues to occur until the new start time is reached and so, it should be ignored.

Caution: This error can occur for the following reasons:

- **TAS start time EATASCSTC0/1 is set in the past**
- **gPTP timer had an offset correction [gPTP]**
- **The minimum gate time has not been satisfied (a gate time is smaller than 50 ns + EATASHCC.TASJ).**

TASCTGES bit (TAS Cut-Through Gate Error Status Flag)

[Setting condition]

- HW: This register is set when cut-through corresponding TAS gate has no time to fetch the next gate state value until it starts.

[Clearing conditions]

- HW: When in RESET mode
- SW: Writing 1 to one of these bits.

[Error recovery]

- HW: Gate with restart during next cycle
- SW: If this error occurs frequently, TAS should be reconfigured with a different schedule (this is a software issue because the minimum gate time has not been satisfied). During reconfiguration, this error continues to occur until the new start time is reached and so, it should be ignored.

Caution: This error can occur for the following reasons:

- **TAS start time EATASCSTC0/1 is set in the past**

- **gPTP timer had an offset correction [gPTP]**
- **The minimum gate time has not been satisfied.**

32.3.7.1.5 EAEIE1 : Error Interrupt Enable Register 1

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0514

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	TASCTGEE	TASGEE7 to TASGEE0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CULEE7 to CULEE0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CULEE7 to CULEE0	CBS n Upper Limit Error Enable (n = 0 to 7) 0: Interrupt disabled for descriptor queue i 1: Interrupt enabled for descriptor queue i	R/W*1
15:8	—	These bits are read as 0.	R
23:16	TASGEE7 to TASGEE0	TAS Gate n Error Enable (n = 0 to 7) 0: Interrupt disabled for descriptor queue i 1: Interrupt enabled for descriptor queue i	R/W*1
24	TASCTGEE	TAS Cut-through Gate Error Enable 0: Interrupt disabled 1: Interrupt enabled	R/W*1
31:25	—	These bits are read as 0.	R

Note 1. Read value differs from written value.

CULEEn bits (CBS n Upper Limit Error Enable (n = 0 to 7))

[Setting condition]

- Writing 1 to one of these bits.

[Clearing condition]

- Writing 1 to one of EAEID1.CULED bits clears the corresponding bit in this register.

TASEEn bits (TAS Gate n Error Enable (n = 0 to 7))

[Setting condition]

- Writing 1 to one of these bits.

[Clearing condition]

- Writing 1 to one of EAEID1.TASGED bits clears the corresponding bit in this register.

TASCTGEE bit (TAS Cut-through Gate Error Enable)

[Setting condition]

- Writing 1 to this bit.

[Clearing condition]

- Writing 1 to EAEID1.TASCTGED register.

32.3.7.1.6 EAEID1 : Error Interrupt Disable Register 1

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0518

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	TASCTGED	TASGED7 to TASGED0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CULED7 to CULED0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CULED7 to CULED0	CBS n Upper Limit Error Disable (n = 0 to 7) Writing 1 to one of these bits clears the corresponding bit in EAEIE1.CULEE register.	R
15:8	—	These bits are read as 0.	R
23:16	TASGED7 to TASGED0	TAS Gate n Error Disable (n = 0 to 7) Writing 1 to one of these bits clears the corresponding bit in EAEIE1.TASGEE register.	R
24	TASCTGED	TAS Cut-through Gate Error Disable Writing 1 to this bit clears EAEIE1.TASCTGEE register.	R
31:25	—	These bits are read as 0.	R

32.3.7.1.7 EAEIS2 : Error Interrupt Status Register 2

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0520

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	DQSES7 to DQSES0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CTDQOES	DQOES7 to DQOES0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DQOES7 to DQOES0	Descriptor Queue n Overflow Error Status Flag (n = 0 to 7)	R/W*1
8	CTDQOES	Cut-Through Descriptor Queue Overflow Error Status Flag	R/W*1
15:9	—	These bits are read as 0.	R
23:16	DQSES7 to DQSES0	Descriptor Queue n Security Error Status Flag (n = 0 to 7)	R/W*1
31:24	—	These bits are read as 0.	R

Note 1. Read value differs from written value.

DQOESn bits (Descriptor Queue n Overflow Error Status Flag (n = 0 to 7))

[Setting condition]

- HW: Bit q of this register is set.

[ETHA is operating] (EAMC.OPC == 11 and EAMC.OPS == 11)

Descriptor queue is "full (EATDQDCq.DQD == EATDQMq.DNQ)" or "not disabled (EATDQC.TDQDn is not set)" when a descriptor is received for queue q.

[ETHA is not operating] (EAMC.OPC != 11 and EAMC.OPS == 11)

When a descriptor is received for queue q.

[Clearing conditions]

- HW: When in RESET mode
- SW: Writing 1 to this bit.

[Error recovery]

- HW: Any descriptor received for a full descriptor queue is not accepted by ETHA and is not forwarded to RMAC [RMAC]
- SW: Too many descriptors are received for the corresponding queue. EATDQDCq.DQD setting should be reviewed.

CTDQOES bit (Cut-Through Descriptor Queue Overflow Error Status Flag)

[Setting conditions]

HW: This register has two exclusive set conditions:

- [ETHA is operating] (EAMC.OPC == 11 and EAMC.OPS == 11) Descriptor queue is "full (EACTDQDCq.CTDQD == EACTDQM.CTQDN)" and "not disabled (EATDQC.TCTDQD is not set)" when descriptor is received for cut-through descriptor
- [ETHA is not operating] (EAMC.OPC != 11 or EAMC.OPS != 11) When descriptor is received for cut-through descriptor.

[Clearing conditions]

- HW: When in RESET mode
- SW: Writing 1 to this bit.

[Error recovery]

- HW: Any descriptor received for a full descriptor queue is not accepted by ETHA and is not forwarded to RMAC [RMAC]
- SW: Too many descriptors are received for the corresponding queue. EACTDQDC.CTDQD setting should be reviewed.

DQSESn bits (Descriptor Queue n Security Error Status Flag (n = 0 to 7))

[Setting condition]

- HW: Bit q of this register is set when a non-secure descriptor is received (FDESCR.SEC is not set [FWD]) and queue q is a secure queue (EATDQSC.TDQSLn is set).

[Clearing conditions]

- HW: When in RESET mode
- SW: Writing 1 to this bit.

[Error recovery]

- HW: Any non-secure descriptor received for secure descriptor queue is not accepted by ETHA and is not forwarded to CPU
- SW: System-dependent, therefore cannot be defined.

32.3.7.1.8 EAEIE2 : Error Interrupt Enable Register 2

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0524

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	DQSEE7 to DQSEE0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CTDQOEE	DQOEE7 to DQOEE0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DQOEE7 to DQOEE0	Descriptor Queue n Overflow Error Enable (n = 0 to 7) 0: Interrupt disabled for descriptor queue i 1: Interrupt enabled for descriptor queue i	R/W*1
8	CTDQOEE	Cut-Through Descriptor Queue Overflow Error Enable 0: Interrupt disabled 1: Interrupt enabled	R/W*1
15:9	—	These bits are read as 0.	R
23:16	DQSEE7 to DQSEE0	Descriptor Queue n Security Error Enable (n = 0 to 7) 0: Interrupt disabled for descriptor queue i 1: Interrupt enabled for descriptor queue i	R/W*1
31:24	—	These bits are read as 0.	R

Note 1. Read value differs from written value.

DQOEEn bits (Descriptor Queue n Overflow Error Enable (n = 0 to 7))

[Setting condition]

- Writing 1 to one of these bits.

[Clearing condition]

- Writing 1 to one of EAEID2.DQOED bits clears the corresponding bit in this register.

CTDQOEE bit (Cut-Through Descriptor Queue Overflow Error Enable)

[Setting condition]

- Writing 1 to this bit.

[Clearing condition]

- Writing 1 to EAEID2.CTDQOED register clears this bit.

DQSEEn bits (Descriptor Queue n Security Error Enable (n = 0 to 7))

[Setting condition]

- Writing 1 to one of these bits.

[Clearing condition]

- Writing 1 to one of EAEID2.DQSED bits clears the corresponding bit in this register.

32.3.7.1.9 EAEID2 : Error Interrupt Disable Register 2

Base address: ETHAm = 0x403C_A000 + 0x2000 × m (m = 0, 1)
ETHAm_NS = 0x503C_A000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0528

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	DQSED7 to DQSED0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CTDQOED	DQOED7 to DQOED0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DQOED7 to DQOED0	Descriptor Queue n Overflow Error Disable (n = 0 to 7) Writing 1 to one of these bits clears the corresponding bit in EAEIE2.DQOEE register.	R
8	CTDQOED	Cut-Through Descriptor Queue Overflow Error Disable Writing 1 to this bit clears EAEIE2.CTDQOEE register.	R
15:9	—	These bits are read as 0.	R
23:16	DQSED7 to DQSED0	Descriptor Queue n Security Error Disable (n = 0 to 7) Writing 1 to one of these bits clears the corresponding bit in EAEIE2.DQSEE register.	R
31:24	—	These bits are read as 0.	R

32.4 Register Utilization

32.4.1 Operation Modes

Table 32.4 describes ETHA operation modes.

Table 32.4 ETHA operation modes

Operation mode	GWMS.OPS value	Description
DISABLE	1	• No ongoing transaction • Only status registers are accessible for writing when the agent clock is enabled.
RESET	0	• No ongoing transaction • An internal reset is asserted to reset ETHA logic with the status registers • No register is accessible for writing • RAM values are held.
CONFIG	2	• No ongoing transaction • Static and some dynamic registers are accessible for writing.
OPERATION	3	• Transactions are ongoing • Dynamic registers are accessible for writing.

32.4.1.1 Operation Mode Transitions

Figure 32.2 shows the operating mode transitions.

A mode transition can be triggered by:

- Hardware reset
- Software reset
- Configuration of EAMC.OPC. In this case, mode transition is confirmed by EAMS.OPS.

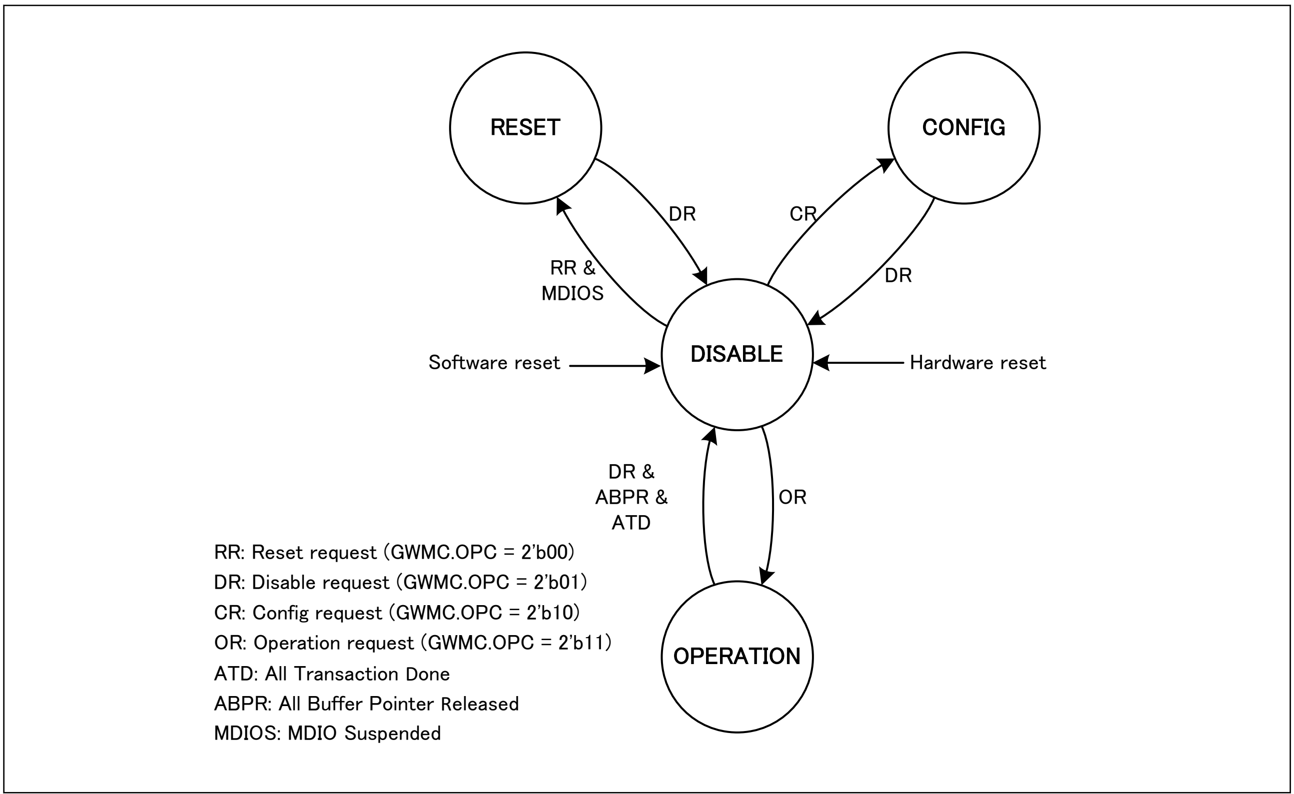

Figure 32.2 Operating mode transitions

Complementary information on transition conditions

ABPR:

- All the buffer pointers contained in the ETHA are released to the MFWD.

ATD:

- All the descriptors already received are processed and corresponding frames are transmitted to the Ethernet PHY
- All ongoing reception frames are fully sent to the MFWD.

MDIOS:

- MDIO has no ongoing access.

[Restrictions]

- Software shall only trigger transitions shown in Figure 32.2
  Do not directly transition from OPERATION to CONFIG.

32.4.2 Software Flows

SW: Follow the flows described in this section.

32.4.2.1 Software Flow Legend

Figure 32.3 describes the software flow legend.

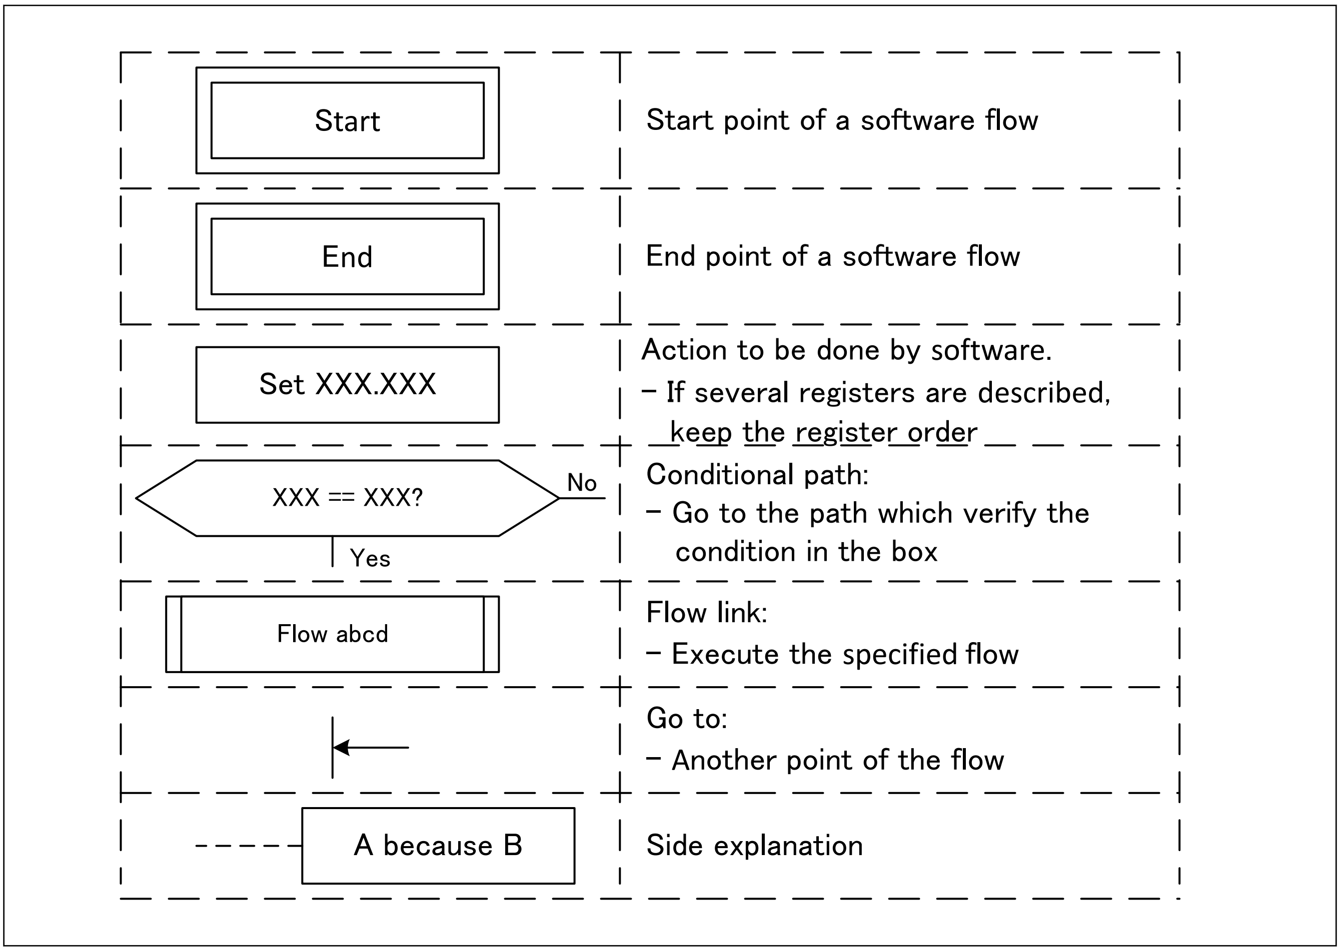

Figure 32.3 Software flow legend

32.4.2.2 Mode Transition Flow

Figure 32.4 describes the mode transition flow.

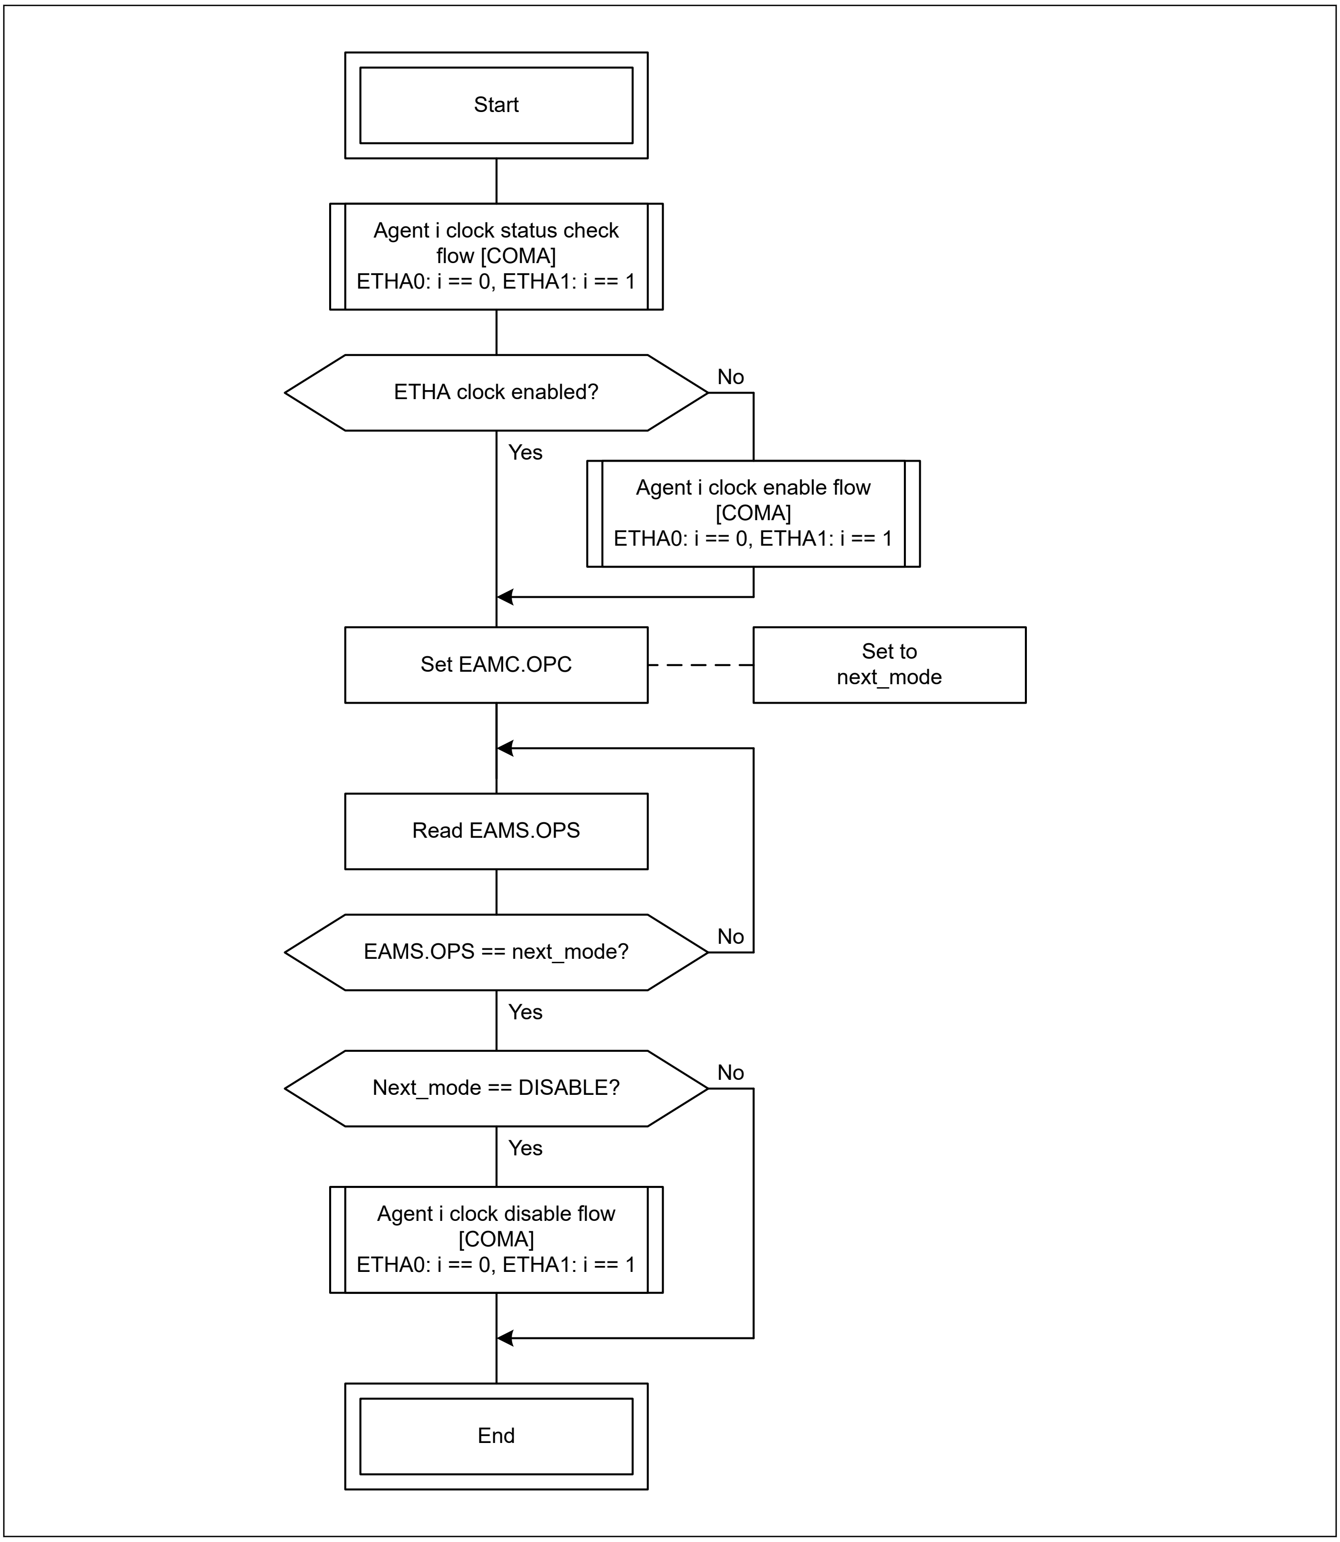

Figure 32.4 Mode transition flow

Note:
- If software already determines that the clock is enabled, the clock status check step can be skipped.
- If software does not need to disable the agent clock in DISABLE mode (because it goes directly to another mode or because the clock does not need to be disabled), the clock disable step can be skipped.

32.4.2.3 Reset Flow

Figure 32.5 describes the reset flow.

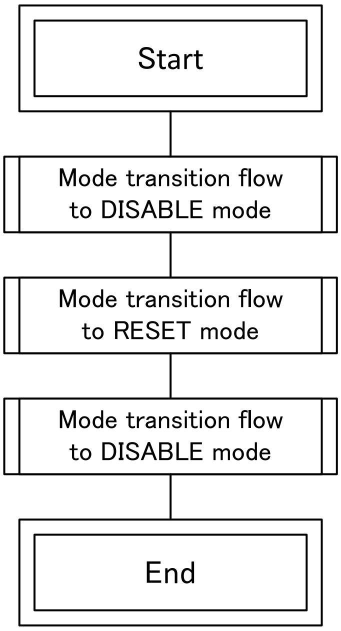

Figure 32.5 Reset flow

32.4.2.4 Initialization Flow

Figure 32.6 describes the initialization flow.

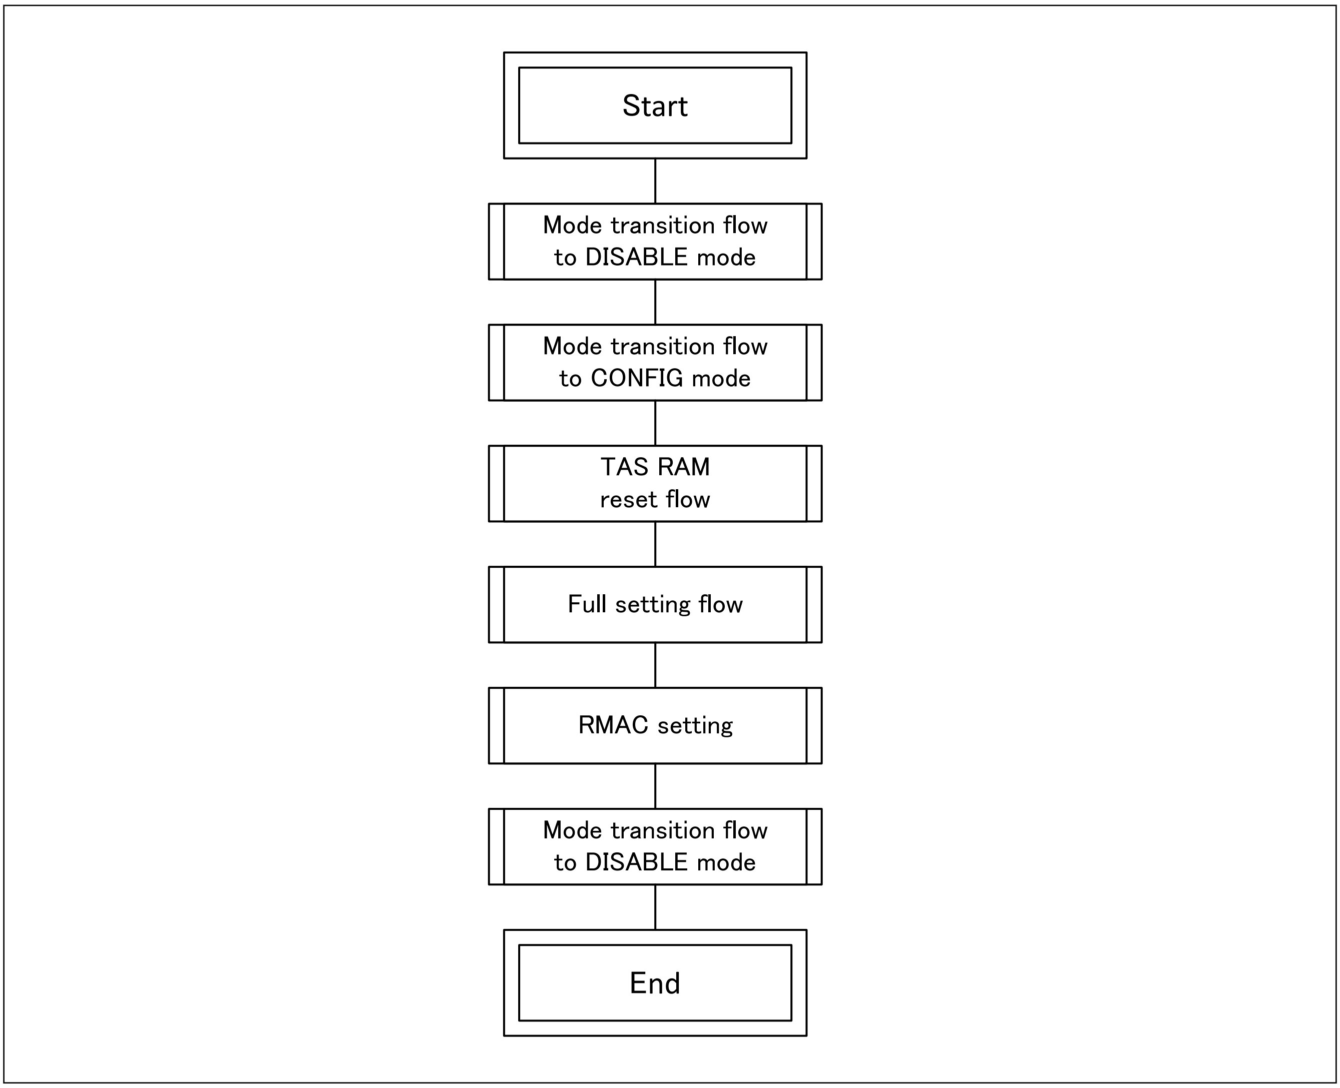

Figure 32.6 Initialization flow

Note: For RMAC setting, see RMAC specification [RMAC].

32.4.2.5 Reinitialization Flow

Figure 32.7 describes the reinitialization flow.

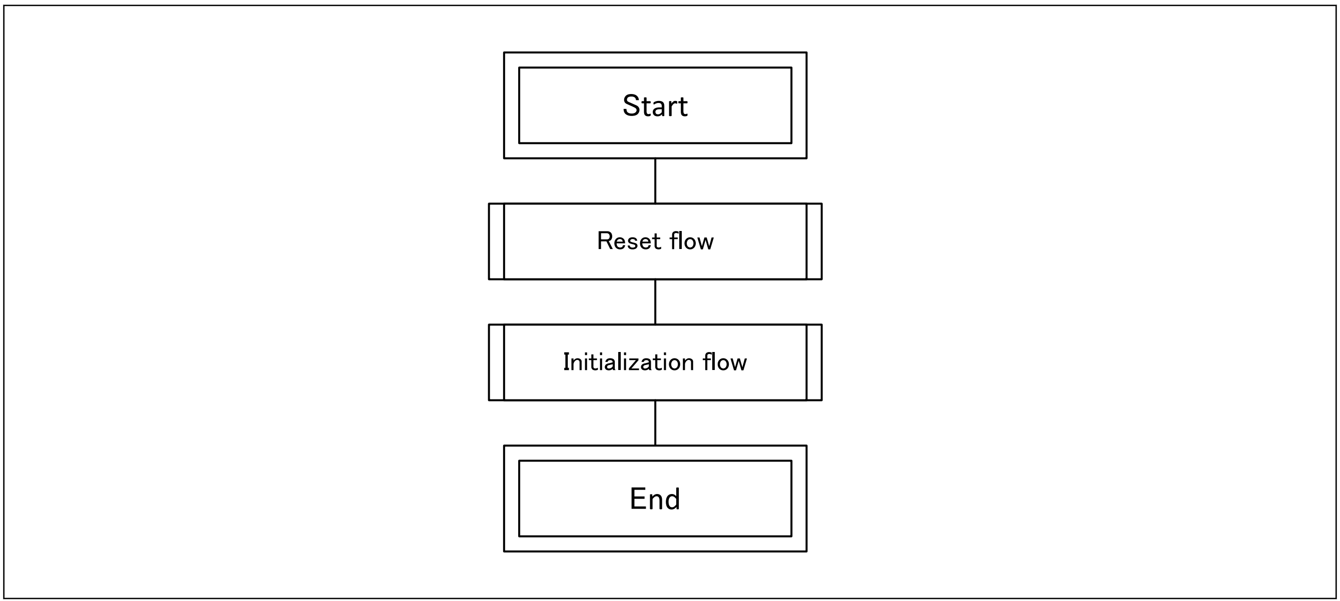

Figure 32.7 Reinitialization flow

32.4.2.6 TAS RAM Reset Flow

Figure 32.8 describes the TAS RAM reset flow.

Note: This flow is not usable in RESET and DISABLE modes.

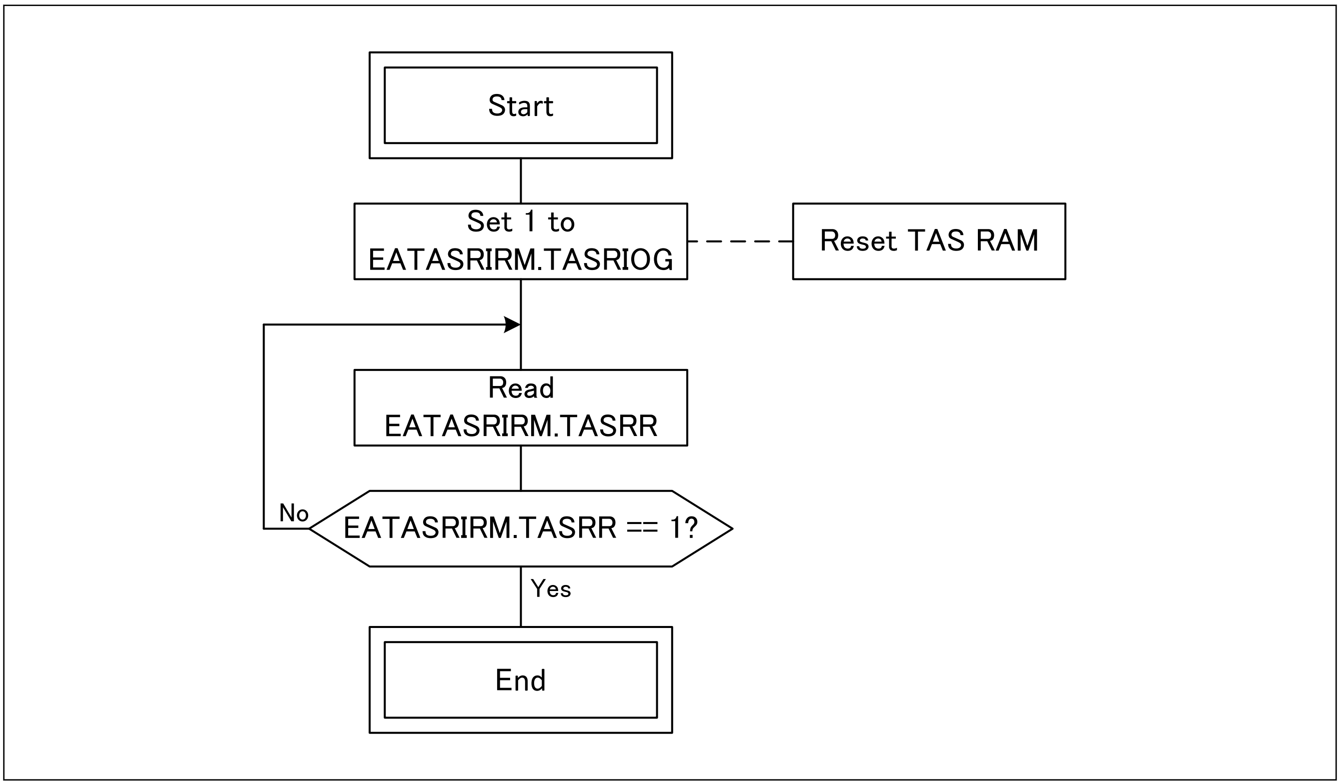

Figure 32.8 TAS RAM reset flow

32.4.2.7 CBS q Setting Flow (q = 0 to 7)

Figure 32.9 describes the CBS q setting flow.

Note: This flow is not usable in RESET and DISABLE modes.

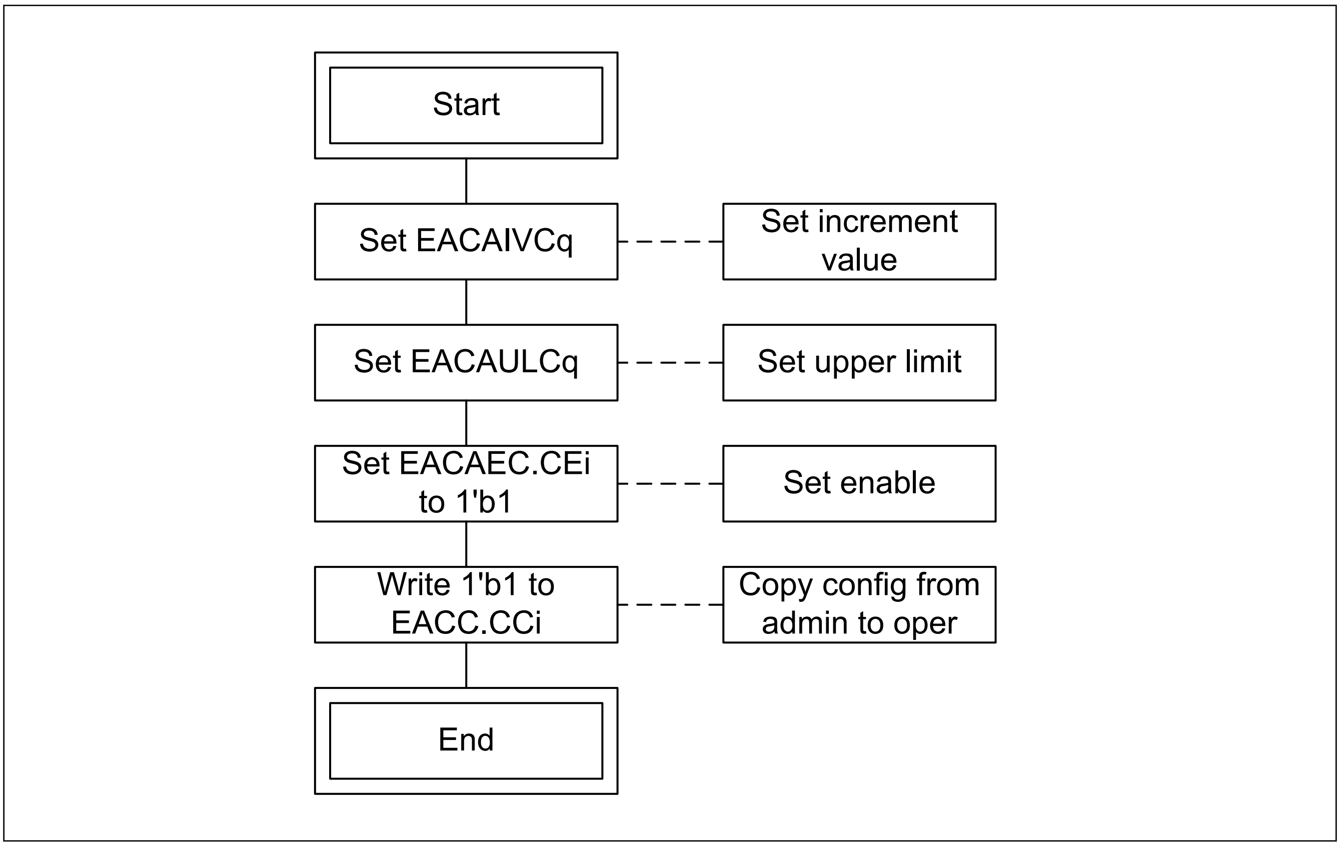

Figure 32.9 CBS q setting flow

32.4.2.8 CBS q Disabling Flow (q = 0 to 7)

Figure 32.10 describes the CBS q disabling flow.

Note: This flow is not usable in RESET and DISABLE modes.

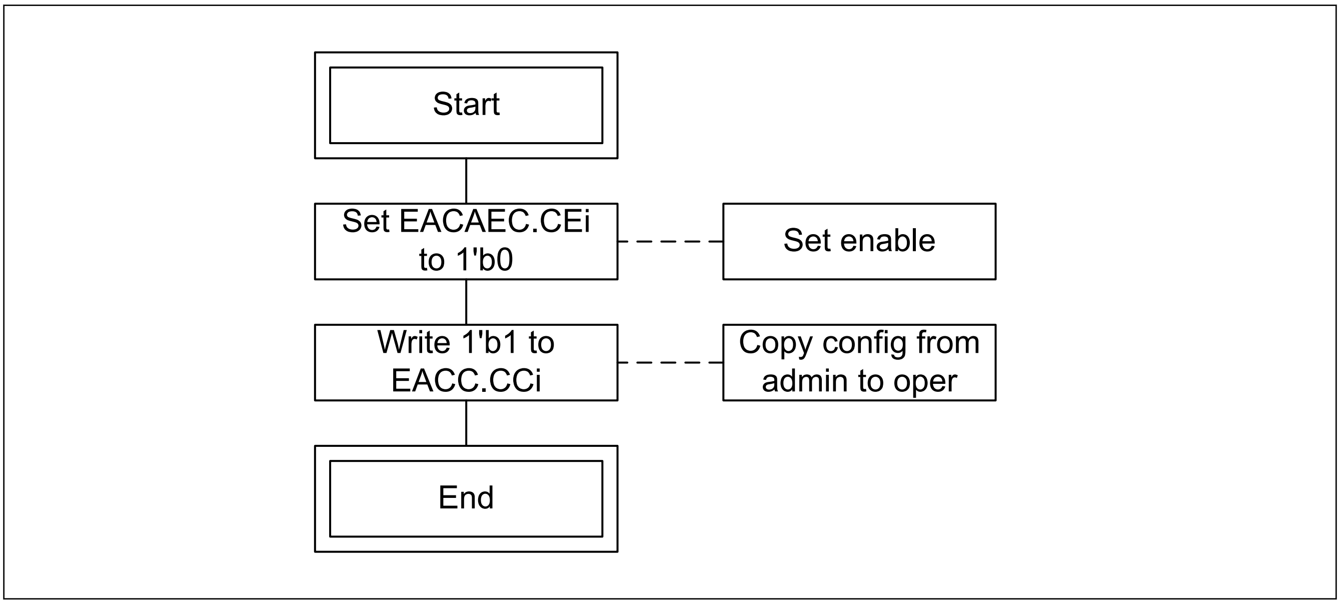

Figure 32.10 CBS q disabling flow

32.4.2.9 TAS Setting Flow

Figure 32.11 describes the TAS setting flow.

Note: This flow is not usable in RESET and DISABLE modes.

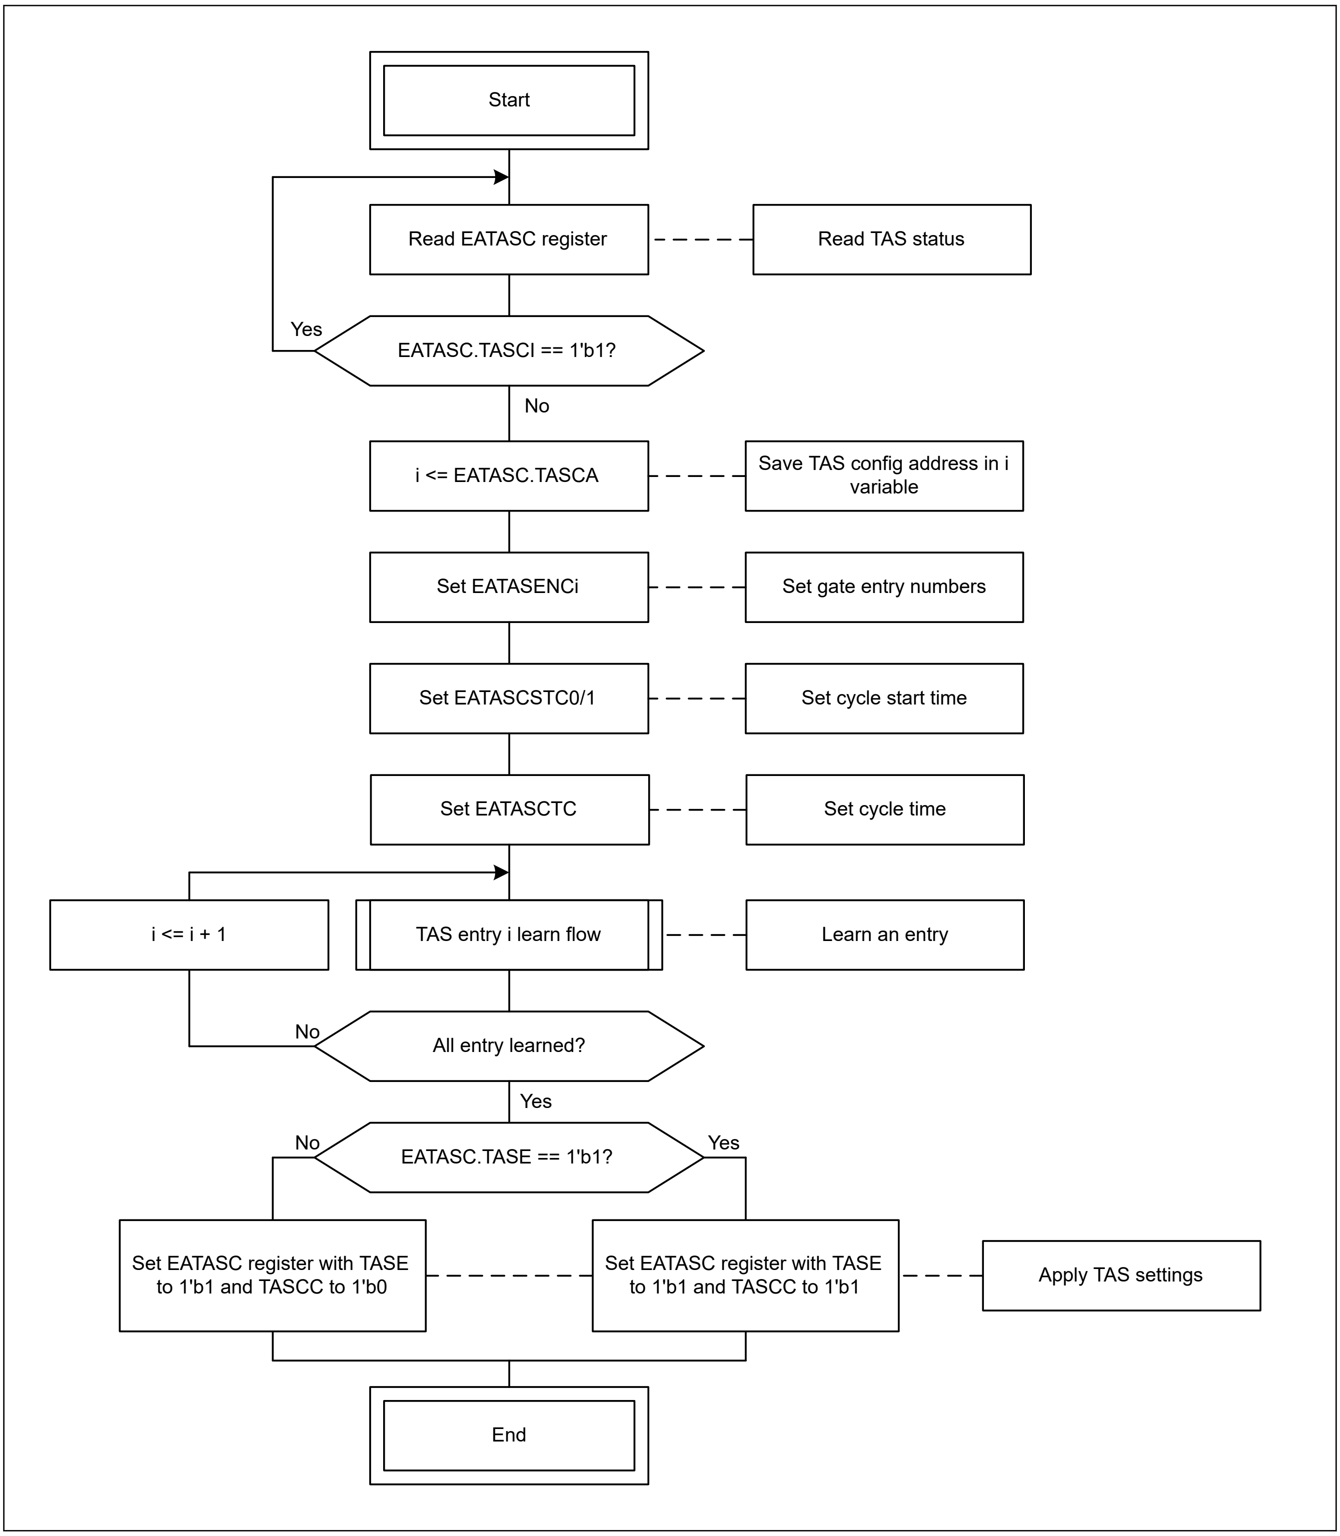

Figure 32.11 TAS setting flow

32.4.2.10 TAS Disabling Flow

Figure 32.12 describes the TAS disabling flow.

Note: This flow is not usable in RESET and DISABLE modes.

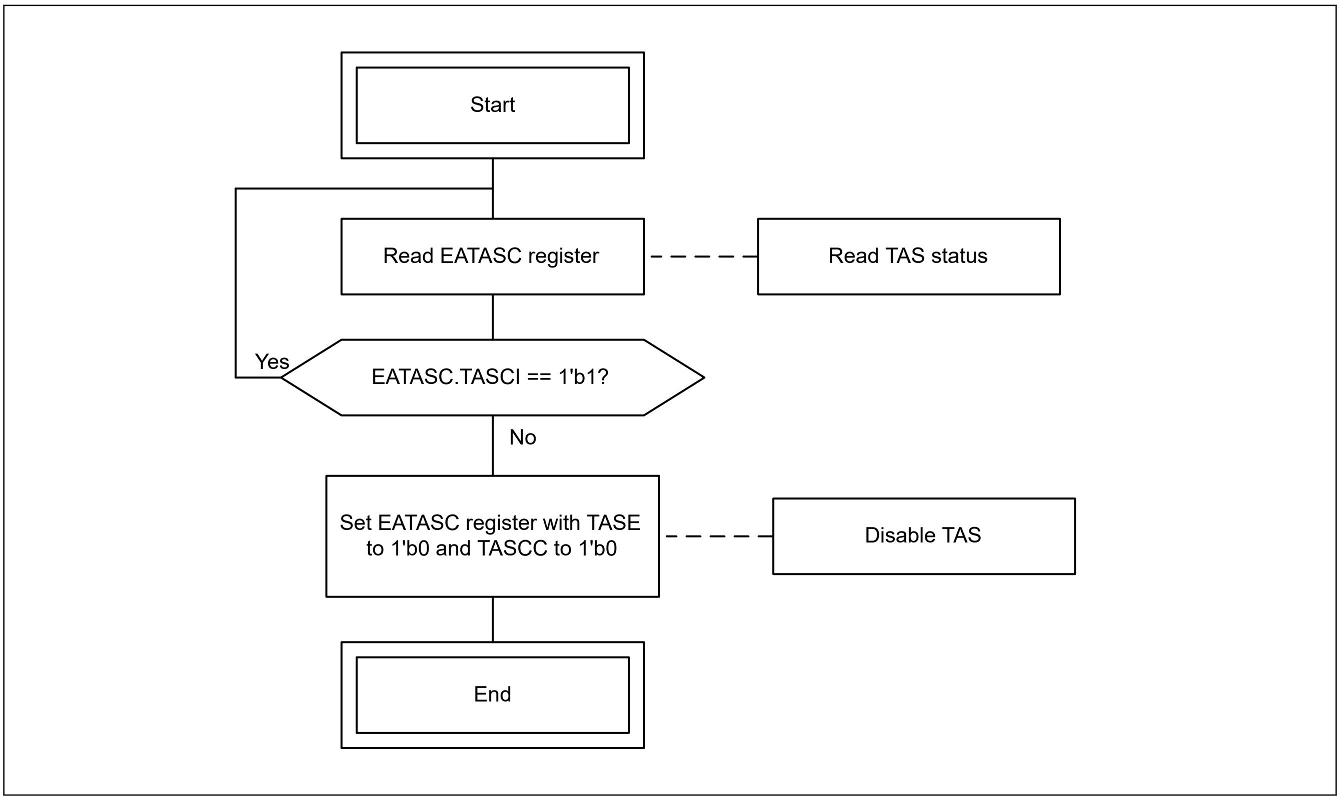

Figure 32.12 TAS disabling flow

32.4.2.11 TAS Enabling Flow

Figure 32.13 describes the TAS enabling flow.

Note: This flow is not usable in RESET and DISABLE modes.

The TAS enabling flow can only be applied after the TAS setting flow has been done at least once. By using the TAS enabling flow, TAS starts with the schedule previously set for the TAS setting flow.

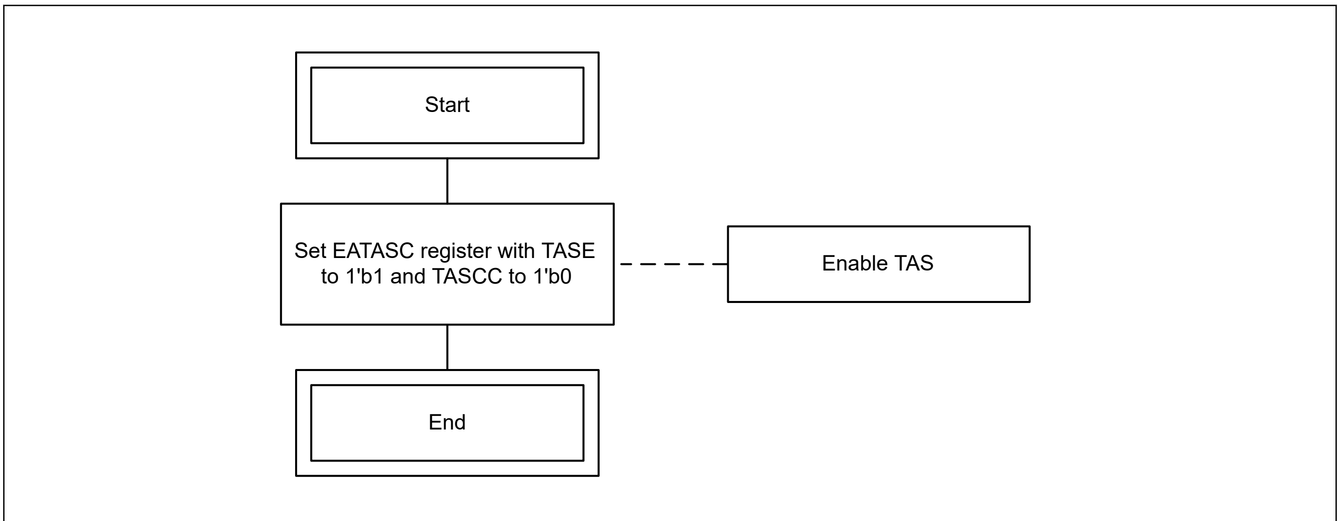

Figure 32.13 TAS enabling flow

32.4.2.14 Interrupt Handling Flow

Figure 32.16 describes the interrupt handling flow.

Note: This flow is not usable in RESET mode.

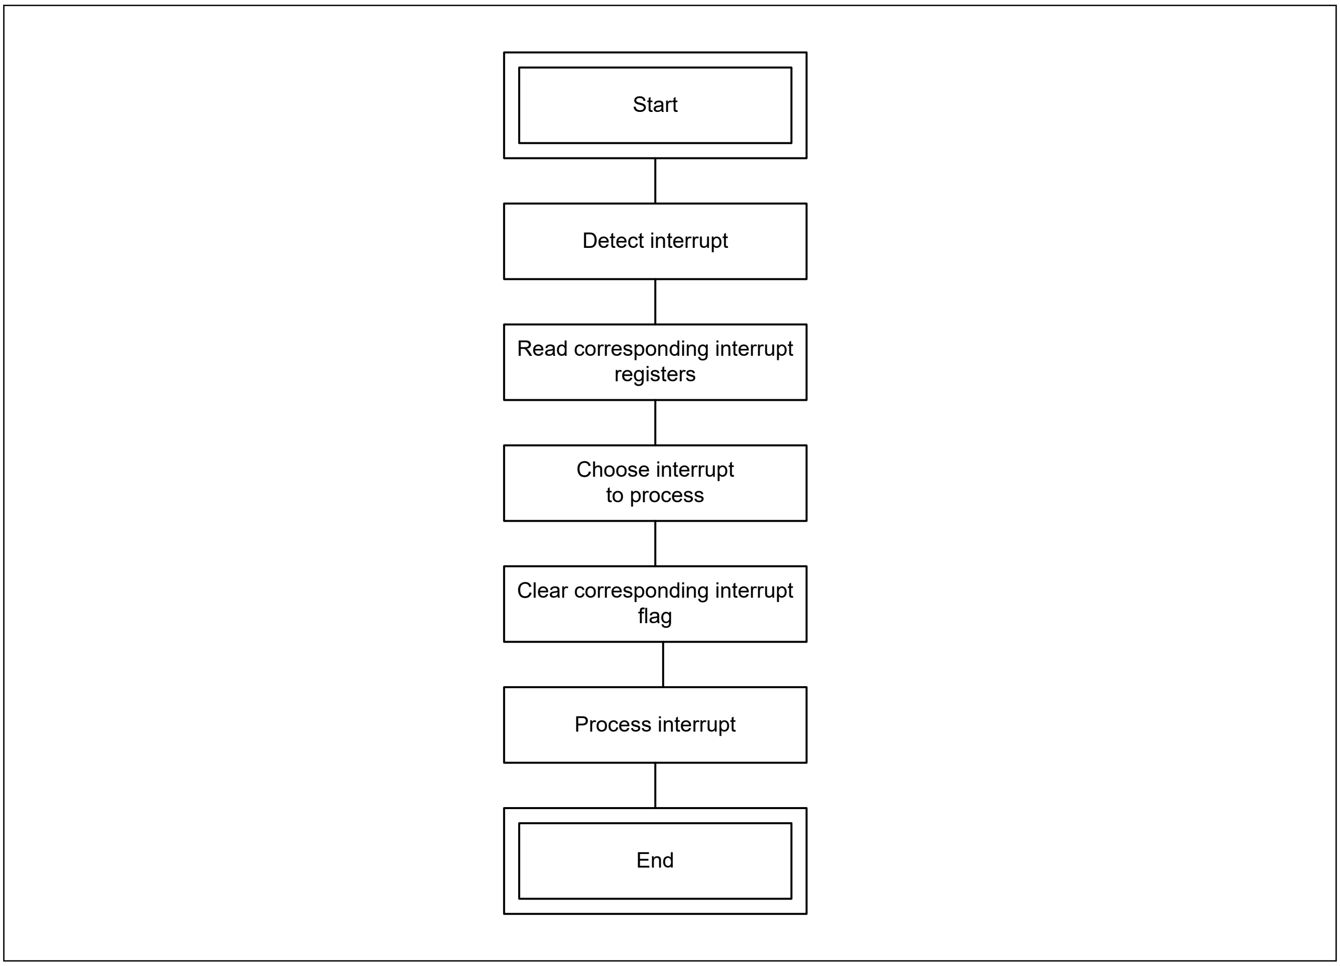

Figure 32.16 Interrupt handling flow

32.4.2.15 Called Software Flows

The flows described in this section can only be called from other flows as indicated in the flow link box in Figure 32.3 and cannot be used alone.

32.4.2.15.1 Full Setting Flow

Figure 32.17 shows the full setting flow.

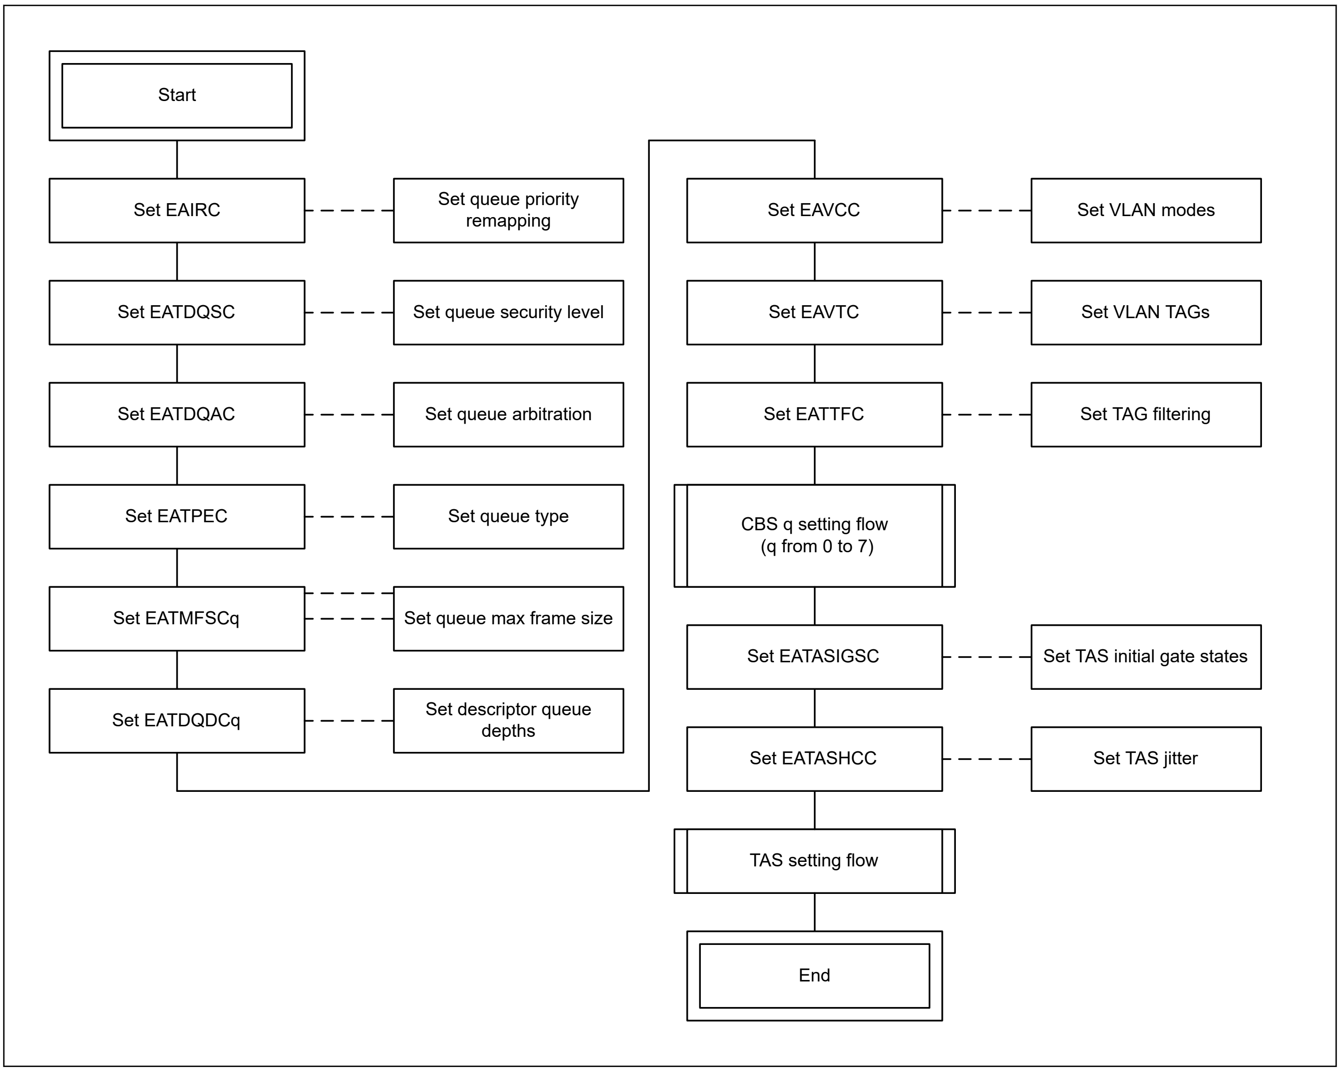

Figure 32.17 Full setting flow

32.4.2.16 Register Writable Without Software Flow

This section details registers that have not been described. These registers can be changed dynamically. However, it is necessary that the initial settings such as the clock enabling have been completed.

32.5 Functional Description

32.5.1 Data Transmission

Ethernet Agent allows data transmission through the ETHA TX data path. Figure 32.18 describes the TX data path.

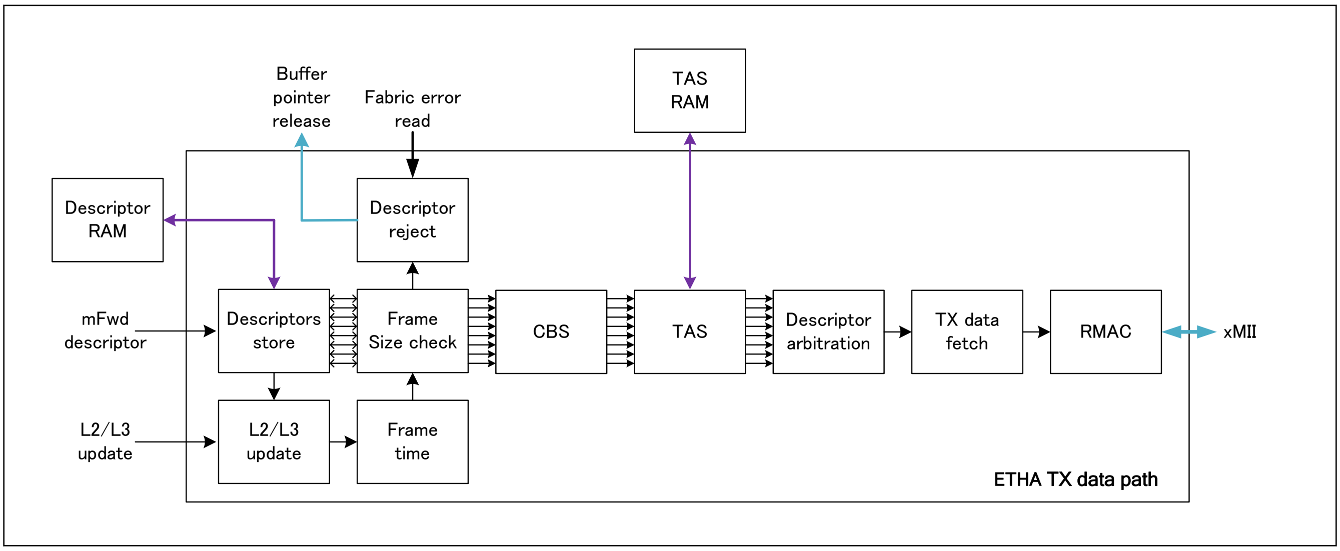

Figure 32.18 ETHA TX data path block diagram

The RX data path is separated in 11 blocks:

- Descriptor store: This block aims at storing the descriptor received from the MFWD in the descriptor RAM, reads it and sends it to the L2/L3 update.
- L2/L3 update: This block aims at fetching the L2/L3 update rules from the Forwarding Engine to update the frame while sending it.
- Frame time: This block aims at calculating how many nanosecond a frame is sent on the ethernet PHY for TAS arbitration. This block exists for TAS hardware purpose and its description is not required for switch utilization so it is not described.
- Frame size check: This block checks the frame size and can forward or discard frames.
- Descriptor reject: This block aims at releasing the pointer of the frames rejected by the frame size control block. This block exists for switch hardware purpose and its description is not required for switch utilization so it is not described.
- Cut-though: This block handles cut-through descriptor coming from MFWD.
- CBS: This block aims at shaping the data traffic per descriptor queue by controlling the data throughput per queue [802.1Qav].
- TAS: This block aims at shaping the data traffic per descriptor queue by controlling the data transmission with a schedule [802.1Qbv].
- Descriptor arbitration: Arbitrates between descriptors based on the descriptor queue using strict priority and/or WRR arbitration.
- TX data fetch: This block fetches the frame data from the local RAM, updates it depending on the information obtained by L2/L3 update module and on VLAN control information and releases the frame pointers. The pointer release exists for switch hardware purpose and its description is not required for switch utilization so it is not described.
- RMAC: This block handles the data exchange with the Ethernet PHY. The functionalities of this block are described in the RMAC specification [RMAC] so it is not described.

32.5.1.1 Descriptor Store

Descriptor store aims at storing the descriptors coming from the descriptor bus MFWD in the descriptor RAM. This function is the same as the descriptor storage function in the descriptor store block in GWCA. See GWCA specification for more details [GWCA]. Table 32.5 describes the association between ETHA and GWCA registers.

Table 32.5 Descriptor store ETHA/GWCA register association (1 of 2)

Register/signal name in GWCA [GWCA]	Register/signal name in ETHA
GWIRC.IPVRi (i = 0 to 7)	EAIRC.IPVRi (i = 0 to 7)
GWRDQSC.RDQSL	EATDQSC.TDQSL

Table 32.5 Descriptor store ETHA/GWCA register association (2 of 2)

Register/signal name in GWCA [GWCA]	Register/signal name in ETHA
GWRDQC.RDQD	EATDQC.TDQD
GWRDQC.RDQP	EATDQC.TDQP
GWRDQDCq.DQD (q = 0 to 7)	EATDQDCq.DQD (q = 0 to 7)
GWRDQMq.DNQ (q = 0 to 7)	EATDQMq.DNQ (q = 0 to 7)
GWRDQMLMq.DMLQ (q = 0 to 7)	EATDQMLMq.DMLQ (q = 0 to 7)
GWEIS1.DQOES	EAEIS2.DQOES
GWEIS1.DQSES	EAEIS2.DQSES

32.5.1.2 L2/L3 Update

This block is the same as the L2/L3 update block in GWCA. See GWCA specification for more details [GWCA].

32.5.1.3 Frame Size Check

Frame size check aims at checking if a frame has the right properties to be received by CPU using EATMFSCq (q = 0 to 7) registers.

EATMFSCq (q = 0 to 7) registers are used to set the maximum frame size accepted for each descriptor queue. Any frame received for queue q with a size larger than EATMFSCq.MFS is discarded and EAEIS0.FSESq flag is set. The frame size considered is the size of frame on the PHY.

32.5.1.4 Cut-through

Cut-through controls the cut-through descriptors queue to store cut-through descriptors received from MFWD using EATDQC.TCTDQD, EACTQC.CTQD and EACTDQDC.CTDQD registers and can be monitored using EACTDQM.CTQDN and EACTDQMLM.CTDMLQ registers.

- EATDQC.TCTDQD register is used to disable the cut-through queue. If the cut-through queue is disabled, eha_ct_ready bit is deasserted, and no descriptor is stored.
- EACTQC.CTQD is used to control the number of clocks that should be waited after receiving a cut-through descriptor to be able to send it for transmission.
- EACTDQDC.CTDQD register is used to set the maximum number of descriptors that can be stored in the cut-through descriptor queue. If the descriptor queue becomes full (EACTDQDC.CTDQD == EACTDQM.CTQDN) eha_ct_ready signal is deasserted. If a descriptor is received for cut-through descriptor queue while it is full, the descriptor is not stored and EAEIS2.CTDQOES flag is set.
- EACTDQM.CTQDN register is used to monitor the current number of descriptors in the cut-through descriptor queue.
- EACTDQMLM.CTDMLQ register is used to monitor the maximum number of descriptors that has been held in cut-through descriptor queue since the previous reset or since the previous time that this has been read.

32.5.1.5 CBS (Credit-based shaper) [802.1Qav]

CBS aims at shaping the data traffic per descriptor queue by controlling the data throughput per queue using EACAEC.CE, EACC.CC, EACAIVCq.CIV (q = 0 to 7) and EACAULCq.CUL (q = 0 to 7) registers and can be monitored using EACOEM.CE, EACOIVMq.CIV (q = 0 to 7), EACOULMq.CUL (q = 0 to 7) and EACGSM.CGS registers and, EAEIS1.CULES interrupt register.

- EACAEC.CE register is used to enable or disable CBS modules.
- EACAIVCq.CIV register is used to configure descriptor queue q CBS throughput.
- EACAULCq.CUL register is used to configure the maximum credit number that can be stored in descriptor queue q CBS module. It is used to monitor associated descriptor queue of CBS module with a long back pressure due to high priority non-CBS-shaped queues interference traffic, or due to queue open time partial overlapping in TAS. If too much back pressure has been applied to a CBS-related descriptor queue, the corresponding EAEIS1.CULES flag is set.
- EACC.CC register is used to apply configurations set in EACAEC.CE, EACC.CC, EACAIVCq.CIV and EACAULCq.CUL registers by copying them to EACOEM.CE, EACOIVMq.CIV and EACOULMq.CUL registers.

- EACOEM.CE register is used to monitor which descriptor queue is used as its CBS module enabled.
- EACOIVMq.CIV register is used to monitor the current throughput set for descriptor queue q.
- EACOULMq.CUL register is used to monitor the current maximum credit number for descriptor queue q.
- EACGSM.CGS register is used to monitor which queue is allowed by CBS to transmit.
- EAEIS1.CULES register is used to flag CBS Upper Limit Errors.

32.5.1.5.1 CBS Setting

CBS setting should follow equation (1) and equation (2). While setting descriptor queue q CBS, CIV should be set to EACAIVCq.CIV register and CUL should be set to EACAULCq.CUL register.

(1) CIV[byte/cycle] = ((portTransmitRate[bps] / 8) × (bandwidthFraction[%] / 100)) / clk_f[Hz] × (CycleTime / GateOpenTime).

For example, when *portTransmitRate* is 1 Gbps, *bandwidthFraction* is 25% and clk_f is 200 MHz, CIV is $\underline{0}$.15625.
CIV[19:16] = $\underline{0}$ CIV[15:0] = 0.15625 × 2^{16} = 10,240 = 2800 H.

(2) CUL[byte] = (maxInterferenceSize[bit] × clk_f[Hz] / portTransmitRate[bps] + requestDelay[cycle]) × CIV[byte/cycle].

Where:

- *portTransmitRate* is the ETHA link throughput [RMAC].
- *bandwidthFraction* is the percentage of bandwidth that the CBS corresponding should use.
- *clk_f* is the clock clk frequency.
- *(CycleTime / GateOpenTime)* is the ratio between the current TAS cycle time (EATASCTM.TASOCT) and the time the CBS corresponding descriptor queue TAS gate is opened during EATASCTM.TASOCT time. When TAS is disabled, *(CycleTime / GateOpenTime)* is equal to 1.
- *maxInterferenceSize* is the maximum size of any burst of traffic that can delay the transmission of a frame that is available for transmission for this traffic class (see section 32.5.1.5.2. Maximum Interference Size Calculation).
- *requestDelay* is the time required from descriptor reception to frame transmission ready and is fixed to 50 cycles.

Restrictions:

- SW: All CBS *bandwidthFraction* sum should be smaller than 70% for queues with simultaneously opened TAS gates.

32.5.1.5.2 Maximum Interference Size Calculation

The maximum interface *maxInterferenceSize* size can be calculated for a queue q using equation (3).

Each interference size includes preamble and inter frame gap (IFG).

(3) *maxInterferenceSize* = *queueInterferenceSizeLow* + *queueInterfereSize* + Σ_i(*queueInterferenceSizeHigh*[i])

Where:

- *queueInterferenceSizeLow* is the interference created by all the queues which have a priority smaller than q. This interface size is equal to (queueLowMaxSize + 20) × 8 where *queueLowMaxSize* is **EATMFSCi.MFSi** maximum values for all i smaller than q.
- *queueInterfereSize* is the interference created by queue q and is equal to (**EATMFSCq.MFS** + 20) × 8
- *queueInterferenceSizeHigh*[i] is the interference created by queue i with a higher priority than q. If CBS is enabled for queue i, *queueInterferenceSizeHigh*[i] is equal to (**EATMFSCi.MFSi** + *queueLowMaxSize* + 40) × 8 where *queueLowMaxSize* is **EATMFSCj.MFSj** maximum values for all j smaller than i. If CBS is disabled for queue i, *queueInterferenceSizeHigh*[i] is equal to (*MaxFrameBurst* × EATMFSCi.MFSi + *queueLowMaxSize* + 40) × 8 where *queueLowMaxSize* is EATMFSCj.MFSj maximum values for all j smaller than i and where *MaxFrameBurst* is the maximum number of frames that can be expected in a burst. *MaxFrameBurst* is a variable which is system-dependent and cannot be defined.

32.5.1.6 TAS (Time Aware Shaper) [802.1Qbv]

TAS aims at shaping the data traffic per descriptor queue by controlling a AVTP based schedule using EATASC, EATASIGSC, EATASENCi (i = 0 to 7), EATASCTENC, EATASCSTC0/1, EATASCTC, EATASGL0/1, EATASGLR, EATASHCC registers and can be monitored using ENTASENMi (q = 0 to 7), EATASCTENM, EATASCSTM0/1, EATASCTM, EATASGR, EATASGRR, EATASRIRM, EATASSM registers and, EAIEIS0.TASCTGEES, EAIEIS1.TASGES and EAIEIS1.TASCTGES interrupt registers.

- EATASC register is used for TAS configuration and enabling.
- EATASIGSC register is used to set the initial gate states.
- EATASENCi register is used to set the number of entries used in TAS RAM by gate i.
- EATASCTENC register is used to set the number of entries used in TAS RAM by cut-through gate.
- EATASCSTC0/1 registers are used to set the cycle start time.
- EATASCTC register is used to set the cycle time.
- EATASGL0/1 and EATASGLR registers are used to write entries in the TAS RAM.
- EATASHCC is used to set the TAS jitter caused by the switch architecture. ENTASENMi register is used to monitor the number of entries used in the TAS RAM by gate i for the ongoing schedule.
- EATASCTENM register is used to monitor the number of entries used in the TAS RAM by cut-through gate for the ongoing schedule.
- EATASCSTM0/1 registers are used to monitor the next cycle start time for the ongoing schedule.
- EATASCTM register is used to monitor the cycle time for the ongoing schedule.
- EATASGR and EATASGRR registers are used to read entries in the TAS RAM.
- EATASRIRM register is used to initialize TAS RAM entries to all 0s.
- EATASSM register is used to monitor TAS operation.
- EAIEIS1.TASGES and EAIEIS1.TASCTGES registers are used to monitor gates errors due to a lack of time to read the TAS RAM.

32.5.1.6.1 TAS General Behavior

TAS module is a scheduler which allows frames to be transmitted depending on their descriptor queue and time by allowing frame transmission when its corresponding gate is opened. TAS scheduler uses a time reference of 64-bit AVTP timer (derived from gPTP timer [gPTP]).

TAS general behavior can be summed up in the following four categories and is described in this section. The TAS schedule is described in section 8.1.6.2.

- TAS enabling
- TAS configuration change
- TAS disabling
- gPTP offset correction recovery [gPTP].

Note: HW: TAS module does not support 64-bit AVTP timer overflows.

1. TAS enabling
   TAS enabling happens when TAS is set while being disabled (EATASC.TASE not set).
   (a) TAS enabling in the future
   TAS module can be such that its schedule starts in the future. Figure 32.19 describes TAS behavior when its schedule starts in the future. The schedule used in this figure is just an example and does not correspond to anything relevant for TAS general behavior explanation.
   Restrictions:
      - SW: To enable TAS in the future, ensure that EATASC.TASE is set before the AVTP timer reaches the following time: {EATASCSTC1, EATASCSTC0} – 2 × EATASCTC.TASACT.

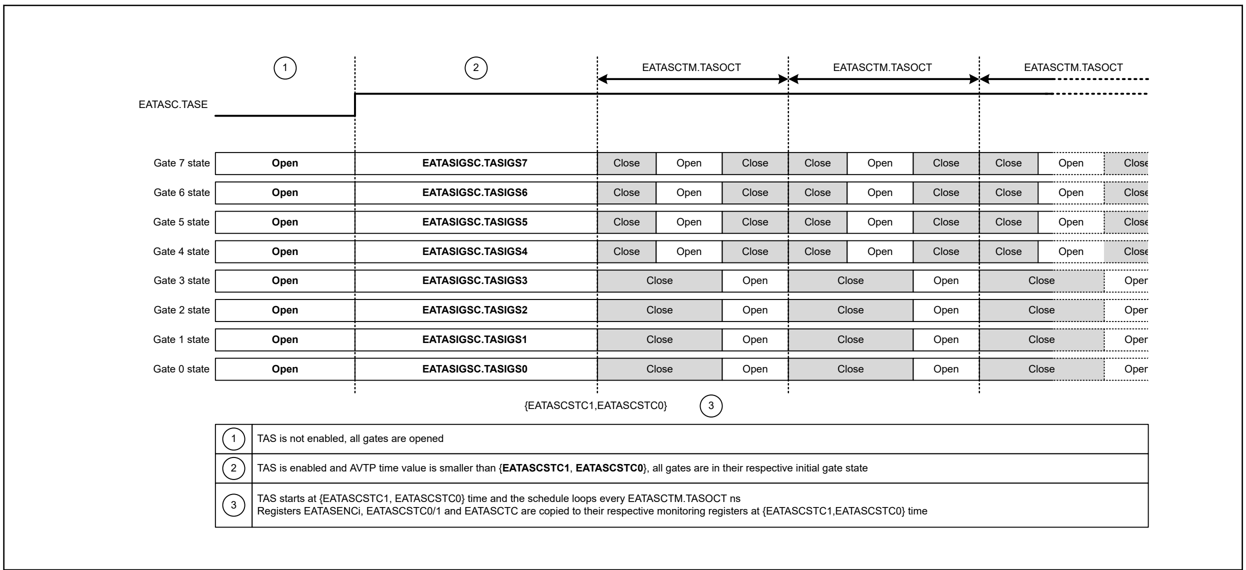

Figure 32.19 TAS behavior when its schedule starts in the future

Restrictions:

- HW: When EATASC.TASE is set, an ongoing frame crosses a gate close state if its initial gate state is closed
- HW: If EATASC.TASE is set such that an ongoing frame does not have the time to finish transmitting before {EATASCSTC1, EATASCSTC0} is reached, the ongoing frame can cross a gate close state in the schedule first cycle
- HW: If EATASC.TASE is set between {EATASCSTC1, EATASCSTC0} – 2 × EATASCTC.TASACT and {EATASCSTC1, EATASCSTC0}, there is a possibility that enabling cannot happen properly and TAS module recovers during 2 × cycle_time[ns] from the start of the new cycle where cycle_time is the schedule cycle time set in EATASCTC.

(b) TAS enabling in the past
TAS module can be such that its schedule should have started in the past. Figure 32.20 describes TAS behavior when its schedule should have started in the past. The schedule used in this figure is just an example and does not correspond to anything relevant for TAS general behavior explanation.

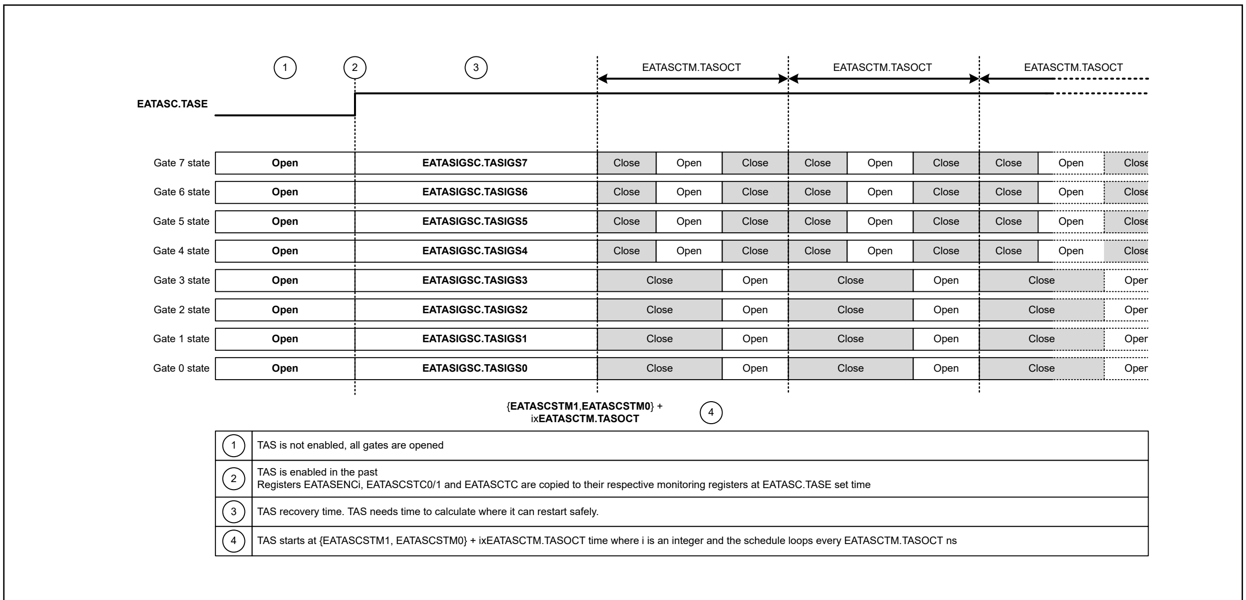

Figure 32.20 TAS behavior when its schedule should have started in the past

TAS recovery time (*tas_recovery_time*) maximum value can be calculated by equation (4).

(4) *tas_recovery_time[ns] = clk_period[ns]* × (*tase_set_time[ns]* – *start_time[ns]*) / *cycle_time[ns]* + 2 × *cycle_time[ns]*
Where:

- *clk_period* is the clock clk period
- *tase_set_time* is the AVTP timer time at which the EATASC.TASE has been set
- *start_time* is the AVTP timer time at which the schedule has been set to start ({EATASCSTC1, EATASCSTC0})
- *cycle_time* is the schedule cycle time set in EATASCTC.

Functions:

- Equation (4) comes from the fact that TAS switches its start time by *cycle_time* every clock during recovery. A problem resulting from that is that the recovery time increases proportionally with *tase_set_time[ns]* – *start_time[ns]*. To avoid this issue, TAS can switch its start time by 256^i × *cycle_time* (i = 0 to 6) every clock when start time is too far in the past.

Restrictions:

- HW: Because of the start setting in the past, the hardware guard band cannot guarantee from EATASC.TASE setting time to the end of the first cycle (frames can cross a gate close state)
- HW: Because of the start setting in the past, EAEIS1.TASGES gate errors can be set.

2. TAS configuration change
TAS configuration change happens when TAS is set while being enabled (EATASC.TASE already set).

(a) TAS configuration change in the future
TAS module can be such that its schedule is reconfigured in the future. Figure 32.21 describes TAS behavior when its schedule is reconfigured in the future.
The schedule used in this figure is just an example and does not correspond to anything relevant for TAS general behavior explanation.
Restrictions:

- SW: To enable TAS in the future, ensure that EATASC.TASCC is set before the AVTP timer reaches the following time: {EATASCSTC1, EATASCSTC0} – 2 × EATASCTC.TASACT.

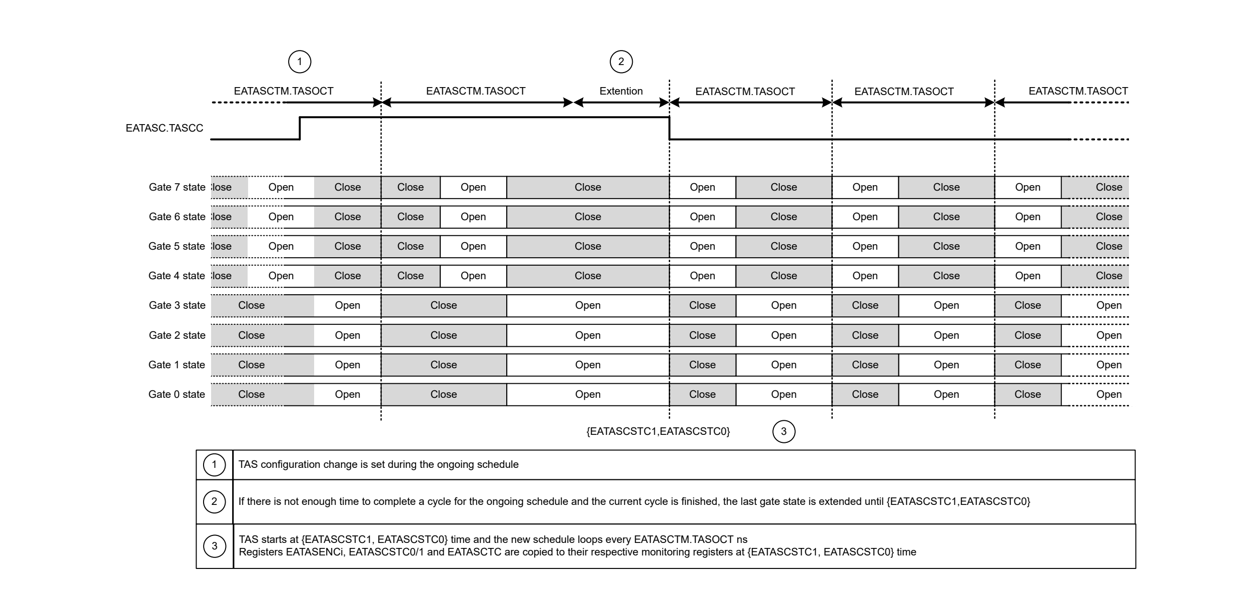

Figure 32.21 TAS behavior when its schedule is reconfigured in the future

Restrictions:

- HW: If EATASC.TASCC is set between {EATASCSTC1, EATASCSTC0} – 2 × EATASCTC.TASACT and {EATASCSTC1, EATASCSTC0} there is a possibility that configuration change cannot happen properly and

TAS module recovers during 2 × cycle_time[ns] from the start of the new cycle where cycle_time is the schedule cycle time set in EATASCTC.

(b) TAS configuration change in the past

TAS module can be such that its schedule reconfiguration should have happened in the past. Figure 32.22 describes TAS behavior when its schedule reconfiguration should have happened in the past. The schedule used in this figure is just an example and does not correspond to anything relevant for TAS general behavior explanation.

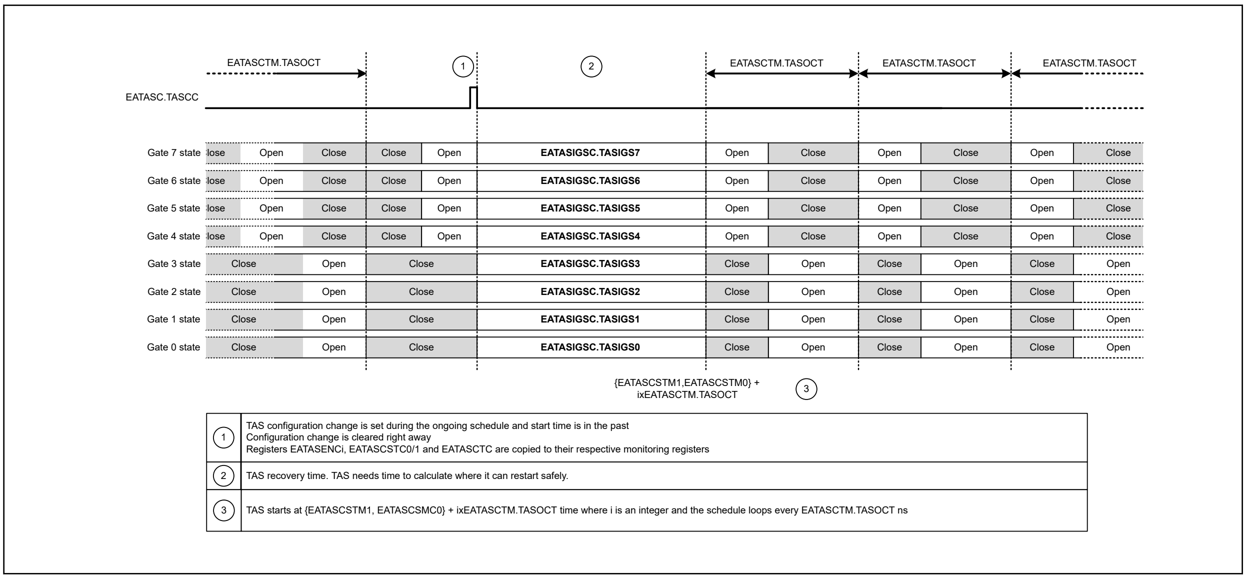

Figure 32.22 TAS behavior when its schedule reconfiguration should have happened in the past

TAS recovery time (*tas_recovery_time*) maximum value can be calculated by equation (5).

(5) $tas\_recovery\_time[ns] = clk\_period[ns] \times (tascc\_set\_time[ns] - restart\_time[ns]) / cycle\_time[ns] + 2 \times cycle\_time[ns]$

Where:

- *clk_period* is the clock clk period
- *tascc_set_time* is the AVTP timer time at which the EATASC.TASCC has been set
- *restart_time* is the AVTP timer time at which the schedule has been set to restart ({EATASCSTC1, EATASCSTC0})
- *cycle_time* is the schedule cycle time set in EATASCTC.

Functions:

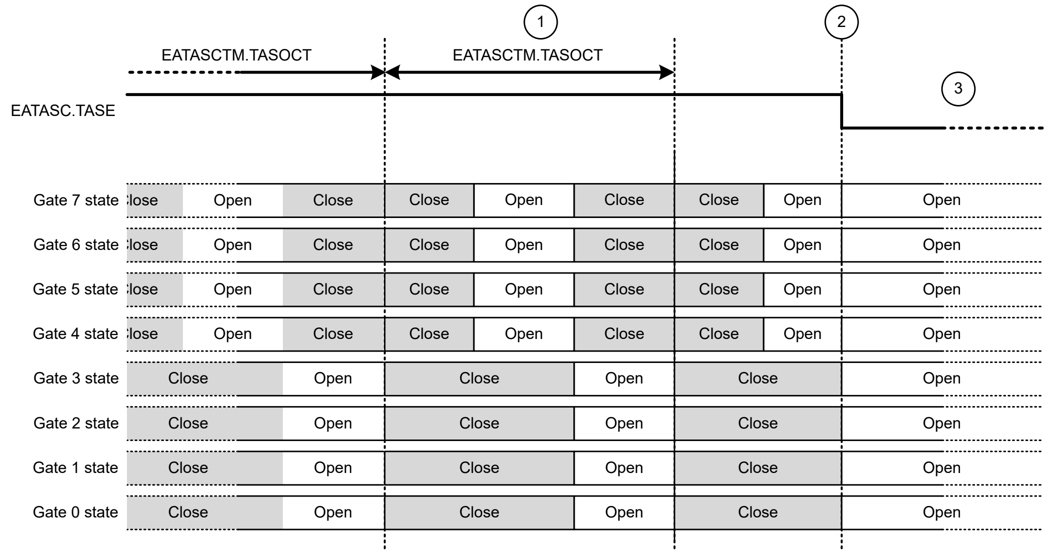
- Equation (5) comes from the fact that TAS switches its start time by *cycle_time* every clock during recovery. A problem resulting from that is that the recovery time increases proportionally with *tase_set_time[ns] – start_time[ns]*. To avoid this issue, TAS can switch its start time by 256^i × *cycle_time* (i = 0 to 6) every clock when start time is too far in the past.

Restrictions:

- HW: Because of the start setting in the past, the hardware guard band cannot guarantee from EATASC.TASCC setting time to the end of the first new cycle (frames can cross a gate close state)
- HW: Because of the start setting in the past, EAEIS1.TASGES gate errors can be set.

3. TAS disabling

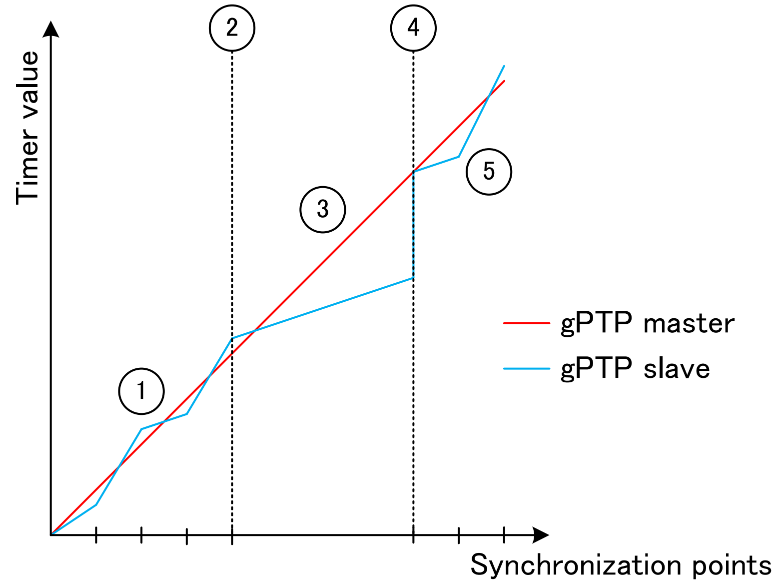
TAS module can be disabled during run-time. Figure 32.23 describes TAS behavior when its schedule is disabled. The schedule used in this figure is just an example and does not correspond to anything relevant for TAS general behavior explanation.



1	TAS is enabled and current schedule is ongoing
2	TAS is disabled
3	TAS is not enabled, all gates are opened

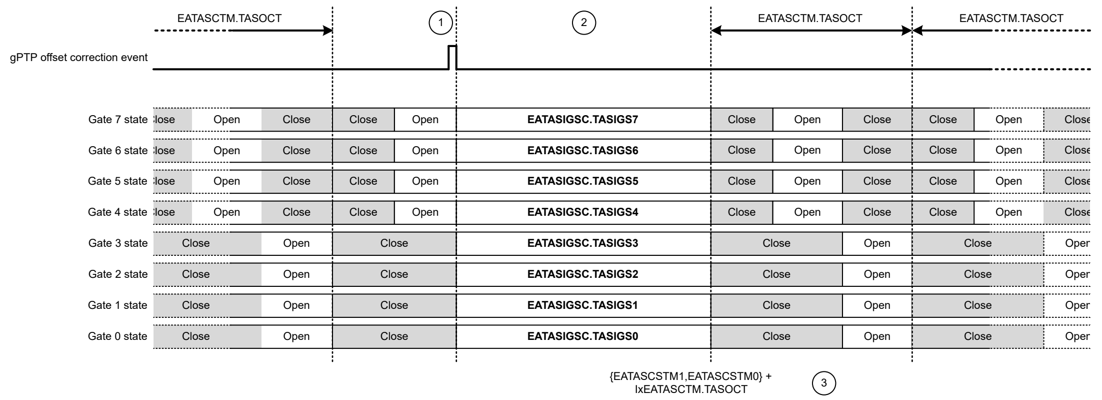
Figure 32.23 TAS behavior when its schedule is disabled

4. gPTP offset correction recovery [gPTP]
   gPTP timer control loop in normal condition corrects the gPTP timer using the gPTP incremental value. In this case the gPTP timer should be incremented for every clock by *clk_period* ns (clock clk period) for TAS to operate normally. However, when the gPTP timer is deviating from its corresponding master timer value, software might correct the gPTP offset value instead of the incremental value. Therefore, the gPTP timer and the AVTP timer can increase in time as described in Figure 32.24. In this case, TAS cannot operate normally and must recover as described in Figure 32.25.



1	The slave is synchronized to the master
2	Last successful synchronization point
3	Synchronization is lost. The gPTP slave is deriving
4	Synchronization is done successfully, the gPTP slave offset gets corrected.
5	The slave is synchronized to the master

Figure 32.24 gPTP offset correction



1	gPTP offset is corrected by the software so gPTP timer jumps in time
2	TAS recovery time. TAS needs time to calculate where it can restart safely.
3	TAS resynchronizes at {EATASCSTM1, EATASCSMC0} + IxEATASCTM.TASOCT time where I is an integer and the schedule loops every EATASCTM.TASOCT ns

Figure 32.25 TAS recovery during gPTP offset correction

TAS recovery time (*tas_recovery_time*) maximum value can be calculated by equation (6).

(6) $tas\_recovery\_time[ns] = clk\_period[ns] \times gptp\_jump\_time[ns] \,/\, cycle\_time[ns] + 2 \times cycle\_time[ns]$

Where:

- *clk_period* is the clock clk period

- *gptp_jump_time* is the time that has been jumped by the gPTP time
- *cycle_time* is the schedule cycle time contained in EATASCTM register.

Functions:

- For gPTP offset correction in the future, equation (6) comes from the fact that TAS switches its start time by *cycle_time* every clock during recovery. A problem resulting from that is that the recovery time increases proportionally with *tase_set_time[ns] – start_time[ns]*. To avoid this issue, TAS can switch its start time by $256^i \times$ *cycle_time* (i = 0 to 6) every clock when AVTP timer is too far in the future.

Restrictions:

- HW: Because of the gPTP offset correction, the hardware guard band cannot guarantee from the gPTP offset correction event time to the end of the first new cycle (frames can cross a gate close state)
- HW: Because of the gPTP offset correction, EAEIS1.TASGES gate errors can be set
- HW: If *gptp_jump_time* is too small (less than 2 × *cycle_time*), there is a possibility that the TAS cannot go back to its initial gate states but the recovery can still happen
- HW: For gPTP offset correction in the past, TAS cannot switch its start time by $256^i \times$ *cycle_time* (i = 0 to 6) every clock. Therefore, a gPTP offset correction too far in the past might result in a long recovery time.

32.5.1.6.2 TAS Schedule

TAS schedule defines the time of a cycle when a queue is allowed to transmit frames. A TAS schedule should be learned in the TAS RAM using TAS RAM learning functionality. This section describes the following information:

- TAS entry format
- TAS entry learning function
- TAS entry reading function
- Conversion between TAS schedule to a set of TAS entries.

1. TAS entry format
The TAS RAM is used to store TAS entries which compose the TAS schedule. A TAS entry contains the information of a gate state. All the fields in this table, if quoted, are written as TAS.{Field name}. Table 32.6 describes fields contained in a TAS entry.

Table 32.6 TAS entry format

Field name	Field size (bit)	Field description
GS	1	Gate state Values: ● 0: Gate state is closed ● 1: Gate state is opened
GT	28	Gate time Functions: ● Values of time in nanoseconds associated with the entry gate state TAS.GS

2. TAS entry learning
Learning is used to overwrite entries in the TAS RAM. Table 32.7 describes register used to learn an entry in the TAS RAM. There is no learning result because learning never fails.

Table 32.7 TAS entry learn registers (1 of 2)

Register name	Field name/corresponding field in TAS RAM	Field description
EATASGL0.TASGAL	Entry address	Not present in TAS RAM, new entry is written at this address
EATASGL1.TASGSL	TAS.GS	See section 32.5.1.6. TAS (Time Aware Shaper) [802.1Qbv].

Table 32.7 TAS entry learn registers (2 of 2)

Register name	Field name/corresponding field in TAS RAM	Field description
EATASGL1.TASGTL	TAS.GT	See section 32.5.1.6. TAS (Time Aware Shaper) [802.1Qbv].

3. TAS entry reading
Reading is used to read entries in the TAS RAM. Table 32.8 describes register used to read an entry in the TAS RAM and Table 32.9 describes the read results.

Table 32.8 TAS entry read registers

Register name	Field name/corresponding field in TAS RAM	Field description
EATASGR.TASGAR	Entry address	Not present in TAS RAM, entry is read from this address

Table 32.9 TAS entry read result

Register name	Field name/corresponding field in TAS RAM	Field description
EATASGRR.TASGSR	TAS.GS	See section 32.5.1.6. TAS (Time Aware Shaper) [802.1Qbv]
EATASGRR.TASGTR	TAS.GT	See section 32.5.1.6. TAS (Time Aware Shaper) [802.1Qbv]

4. Conversion between TAS schedule to a set of TAS entries

   (a) Schedule example
   Figure 32.26 describes a basic schedule example with basic gate behavior and recommendations while designing a schedule.

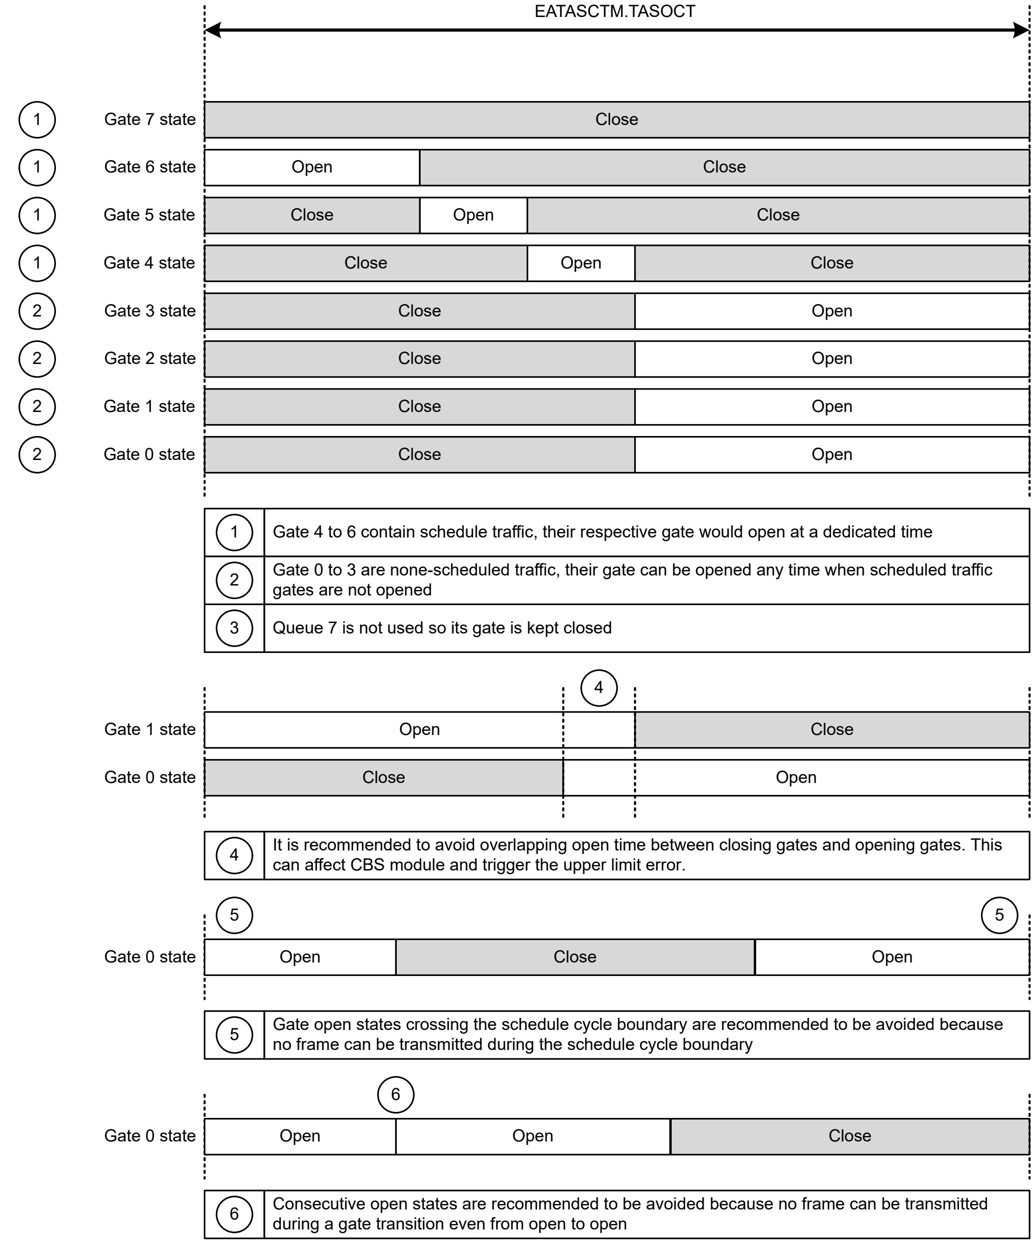


Figure 32.26 Schedule example and recommendations

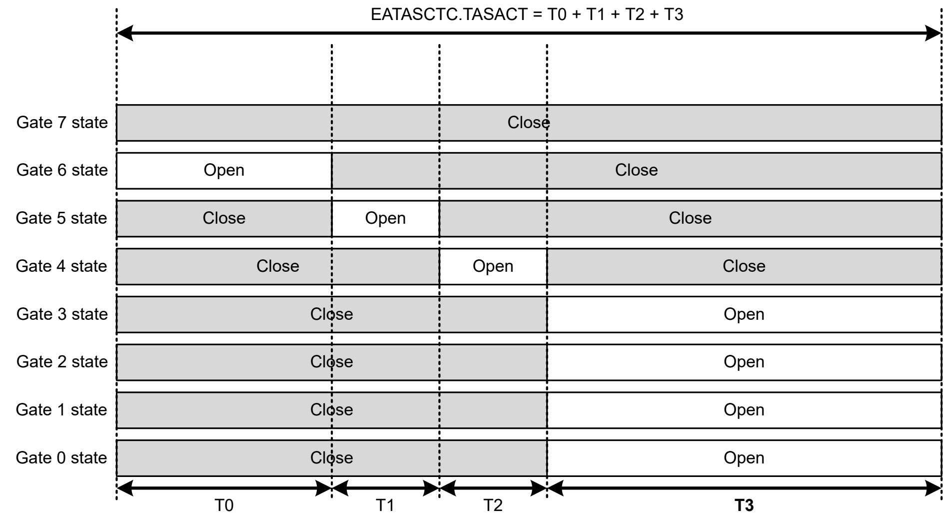
Restrictions:

- SW: All p-frames queues (EATPEC.TTQ corresponding bit set to 1) should be opened simultaneously. For preemption, see section 32.5.1.7.2. Preemption.

(b) Schedule setting

Figure 32.27 describes how to convert a schedule into a set of TAS entries and how to set the schedule corresponding register through an example.



Corresponding gate	Entry number	TAS.GS	TAS.GT	Entry number
1 Gate 0 states	2 0	0	T0 + T1 + T2	EATASENC0.TASAEN0 = 1
	1	1	3 0	
Gate 1 states	2	0	T0 + T1 + T2	EATASENC1.TASAEN1 = 1
	3	1	0	
Gate 2 states	4	0	T0 + T1 + T2	EATASENC2.TASAEN2 = 1
	5	1	0	
Gate 3 states	6	0	T0 + T1 + T2	EATASENC3.TASAEN3 = 1
	7	1	0	
Gate 4 states	8	0	T0 + T1	4 EATASENC4.TASAEN4 = 2
	9	1	T2	
	10	0	0	
Gate 5 states	11	0	T0	EATASENC5.TASAEN5 = 2
	12	1	T1	
	13	0	0	
Gate 6 states	14	1	T0	EATASENC6.TASAEN6 = 1
	15	0	0	
Gate 7 states	16	0	5 0	EATASENC7.TASAEN7 = 0

1	Entries should be written in the TAS RAM from gate 0 to cut-through gate
2	For each gate, entries should be written along with their time in order of appearance
3	A gate corresponding to the last entry time should always be set to 0, the last gate is extended to the cycle end
4	A gate corresponding to an entry number register should be set as the number of entries - 1 used by the gate
5	If a gate has a constant state, the corresponding entry number should be set to 0 and the corresponding constant state should be set in TAS RAM with a gate time of 0

Figure 32.27 Schedule example

Restrictions:

- SW: Each gate time (T_0, T_1, T_2, T_3 in Figure 32.27) should be greater or equal to 50 ns + EATASHCC.TASJ.

5. Gate open time calculation
   Restrictions:

- SW: To avoid TAS module from clogging, gate open time should respect a minimum time value *minimumOpenTime* per queue. This time can be calculated by equation (7) for e-queues and equation (8) for p-queues (for preemption explanation, see section section 32.5.1.7.2. Preemption).
  (7) *minimumOpenTime[ns]* = (*maximumFrameSize[byte]* × 8 + 160) / *portTransmitRate[Gbps]* + *jitter[ns]* + *clk_period[ns]*
  (8) *minimumOpenTime[ns]* = (*MinimumFragmentSize[byte]* × *8* + 704) / *portTransmitRate[Gbps]* + *jitter[ns]* + *clk_period[ns]*

Where:

- *minimumOpenTime* is the smallest open time for a gate in the schedule.
- *maximumFrameSize* is the maximum frame size a queue can receive. Its value for descriptor queue q is equal to **EATMFSCq.MFS**.
- *portTransmitRate* is the ETHA link throughput [RMAC].
- *Jitter* is the internal jitter set in **EATASHCC.TASJ** register.
- *clk_period* is the clock clk period.
- *MinimumFragmentSize* is the minimum fragment size set in **EATPEC.AFS** register.

32.5.1.6.3 TAS Hardware Calibration

TAS transmission authorization is given to a frame before the frame read by TX data fetch block appends and before frame is sent to RMAC for transmission. Because of that, there is an internal minimum latency and an internal maximum jitter (Figure 32.28) that should be taken in account while setting TAS module. Latency calibration should be handled by software and jitter calibration should be set by software and handled by hardware. This section describes how to calibrate the TAS module in latency and jitter until the PHY interface [RMAC]. By adding, for example, the minimum latency and the maximum jitter until the next IP PSFP gate filtering module, it is possible to calibrate the TAS to it.

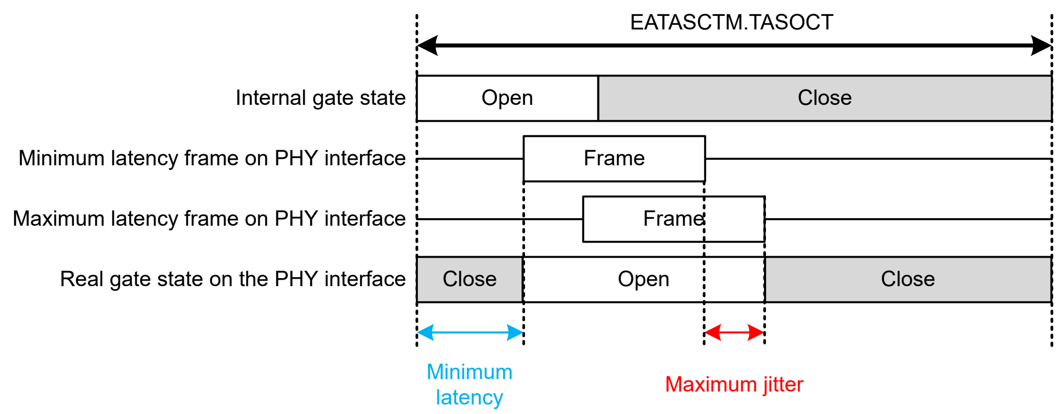


Figure 32.28 Minimum latency and maximum jitter

1. Latency calibration
   Because of the internal minimum latency, with a non-calibrated schedule, a frame always starts to transmit late on the PHY interface [RMAC]. To correct this, the TAS schedule should always be in advance compared to the expected schedule of the minimum latency between the TAS transmission decision and the actual transmission on the PHY interface (Figure 32.29). Table 32.10 describes this minimum latency. To calibrate the schedule, software should always subtract the minimum latency from the cycle start time before setting it in EATASCSTC0/1 registers.

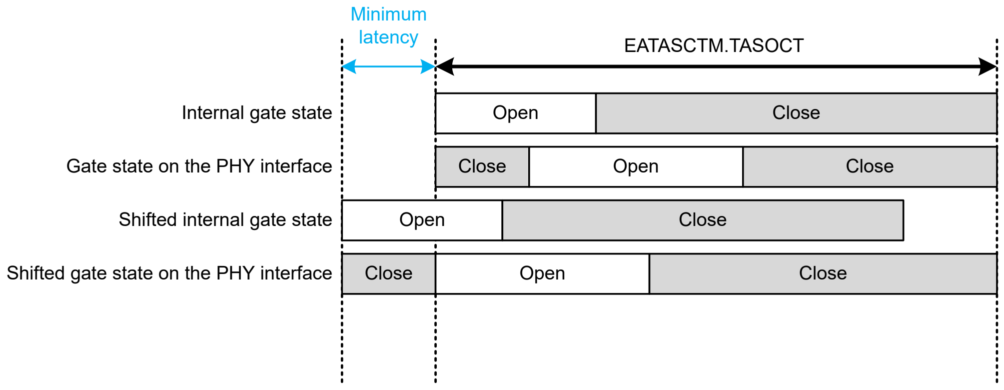

Figure 32.29 Minimum latency calibration

Table 32.10 Minimum latency values

PHY speed	Minimum latency when preemption disabled (EATPEC.TTQ set to All0)	Minimum latency when preemption enabled (at least one bit of EATPEC.TTQ set to 1)
10 Mbps	8 × *clk_period[ns]* + 10 × *clk_phy_tx_period[ns]* + *fabricLatency[ns]*	3 × *clk_period[ns]* + 10 × *clk_phy_tx_period[ns]* + *fabricLatency[ns]*
100 Mbps	8 × *clk_period[ns]* + 10 × *clk_phy_tx_period[ns]* + *fabricLatency[ns]*	3 × *clk_period[ns]* + 10 × *clk_phy_tx_period[ns]* + *fabricLatency[ns]*
1 Gbps	8 × *clk_period[ns]* + 10 × *clk_phy_tx_period[ns]* + *fabricLatency[ns]*	3 × *clk_period[ns]* + 10 × *clk_phy_tx_period[ns]* + *fabricLatency[ns]*

Where:

- *clk_period* is the clock clk period.
- *clk_phy_tx_period* is the clock clk_phy_tx period.
- *fabricLatency* is the latency induced by the fabric. See fabric specification document for calculation [MFAB].

2. Jitter calibration
   Because of the internal maximum jitter, with a non-calibrated schedule, a frame always finishes transmitting late on the PHY interface [RMAC]. To correct this, a TAS schedule opened gate should always be closed in advance compared to the expected close time of the maximum jitter (Figure 32.30). This maximum jitter should be calculated using equation (9). To calibrate the schedule, software should set the maximum jitter in EATASHCC.TASJ register.

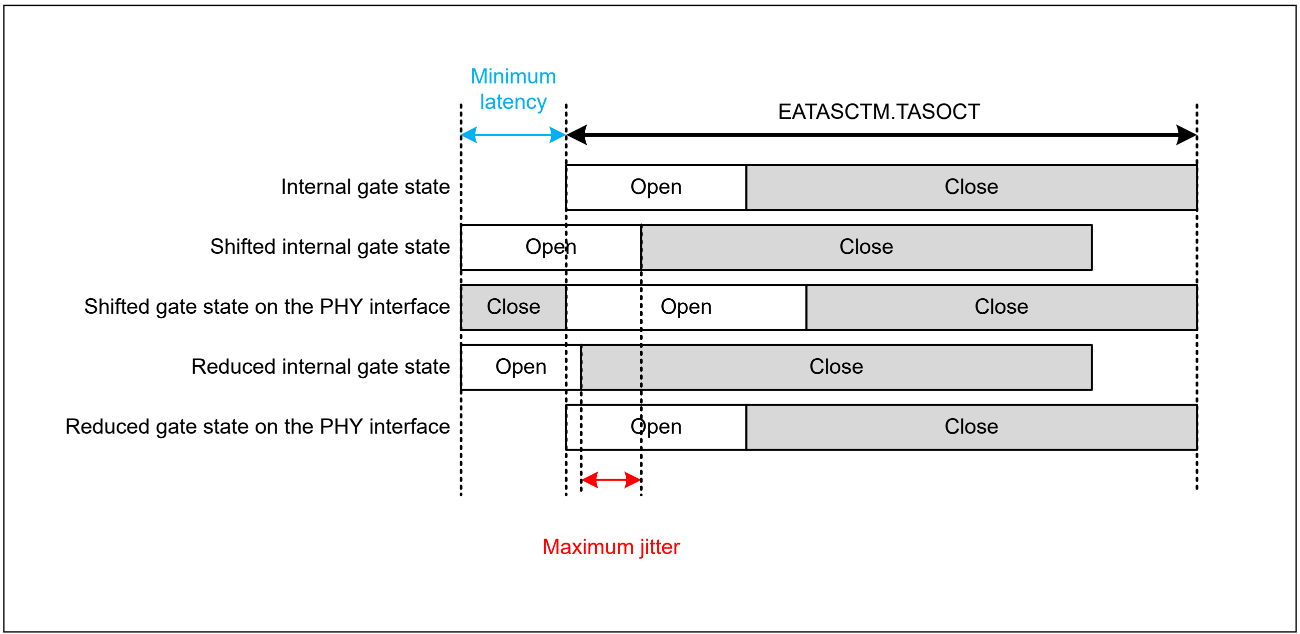

Figure 32.30 Maximum jitter calibration

(9) *jitter[ns] = tasInternalJitter[ns] + fabricJitter[ns] + preemptionJitter[ns] + asynchronousJitter[ns] + gptpSyncJitter[ns] + clkDerivationJitter[ns]*

Where:

- *tasInternalJitter* is the jitter induced by TAS module and is equal to 2 × *clk_period[ns]* where *clk_period* is the clock clk period.
- *fabricJitter* is the jitter induced by the fabric. See the Fabric specification for calculation [MFAB].
- *asynchronousJitter* is the jitter induced by the asynchronous conversion in RMAC [RMAC] and is equal to *clk_period[ns]* + *clk_phy_tx_period[ns]* where *clk_period* is the clock clk period and *clk_phy_tx_period*s the clock clk_phy_tx period.
- *gptpSyncJitter* is the jitter induced by gPTP synchronization between the gPTP master clock and the gPTP slave clock.
- *clkDerivationJitter* is the jitter induced by clock derivation between the gPTP clock clk and the PHY TX clock clk_phy_tx and is equal to *clkRelativeDerivation* × *maxGateTime[ns]* where *clkRelativeDerivation* is the clock derivation and *maxGateTime* is the longest opened gate in the TAS schedule. *clkRelativeDerivation* is equal to 0 when TAS corresponding gPTP timer is the master and the gPTP clock is phase synchronous to the TX PHY clock.
- *preemptionJitter* is the jitter induced by preemption and is equal to 5 × *clk_period[ns]* where *clk_period* is the clock clk period when preemption is enabled (at least one bit of EATPEC.TTQ register is set to 1) and 0 ns otherwise.

32.5.1.6.4 TAS Debug Interface

This interface aims at debugging the TAS gate states by giving it out of the IP.

Functions:

- eha_race_tas_gate_state[8] reflects the cut-through queue of the current TAS gate state.
- eha_race_tas_gate_state[7:0] reflects the current TAS gate states.

32.5.1.7 TX Data Fetch

TX data fetch is the same as RX data fetch in the GWCA except that it can handle preemption and also data fetching for cut-through queues. See GWCA specification for more details [GWCA] about data update for none cut-through frames. Table 32.11 describes the association between ETHA and GWCA registers/signals.

Table 32.11 TX data fetch ETHA/GWCA register correspondence

Register/signal name in GWCA [GWCA]	Register/signal name in ETHA
GWVCC.VEM	EAVCC.VEM
{GWMAC0.MAU, GWMAC1.MAL}	{MRMAC0.MAU, MRMAC1.MAL} [RMAC]
GWRGC.RCPT	Fixed to 1. RMAC adds an FCS to all frames sent without it.

32.5.1.7.1 Cut-through Frames

Cut-through frames handling by data fetched is transparent for TX data fetch. All cut-through frames has e-frames for transmission.

32.5.1.7.2 Preemption

Preemption functions allow express frames (e-frames) to interrupt a preemptable frame (p-frame) to start transmitting faster (a preemptable frame can also be interrupted by TAS gate close event) using the EATPEC register. Figure 32.31 describes a transmission between two e-queues, Figure 32.32 describes the same transmission but with the highest priority queue being a p-queue and Figure 32.33 describes how preemption occurs for a p-frame.

Functions:

- EATPEC.AFS is used to set the minimum fragment size
- EATPEC.TTQi is used to set descriptor queue q traffic to p-traffic or e-traffic.

Restrictions:

- HW: In Ethernet agent, preemption occurs on a 64-bit bus. As a result, preemption can only be performed every 16 bytes in a frame.
- HW: P-frames can only be preempted by e-frames with a higher priority. As a result, if p-frames are to be preempted by e-frames, always set low priority queues to p-frames and high priority queue to e-frames. The EAIRC register can be used to remap IPVs coming from MFWD to p-queues or e-queues.

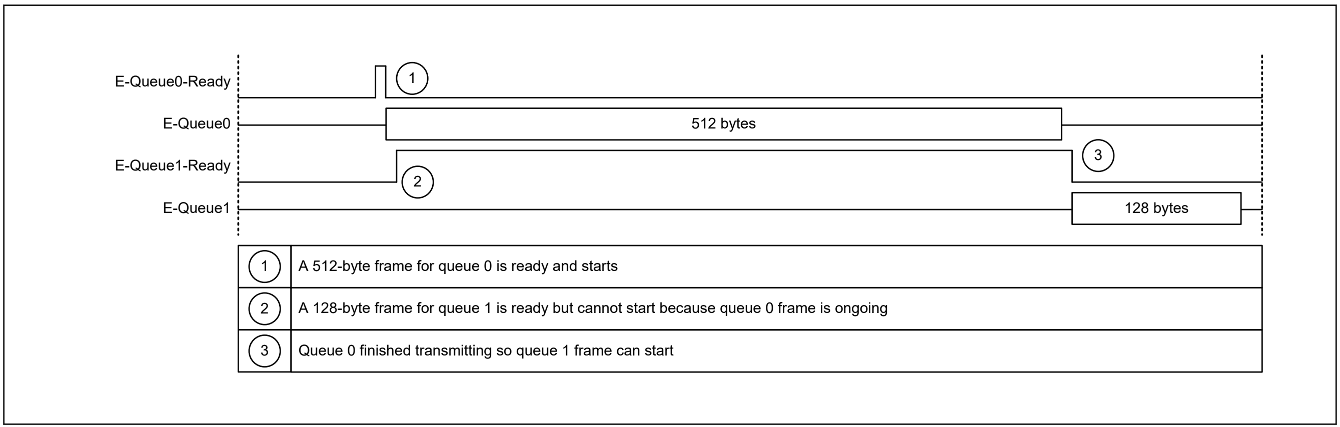

Figure 32.31 E-frame transmission

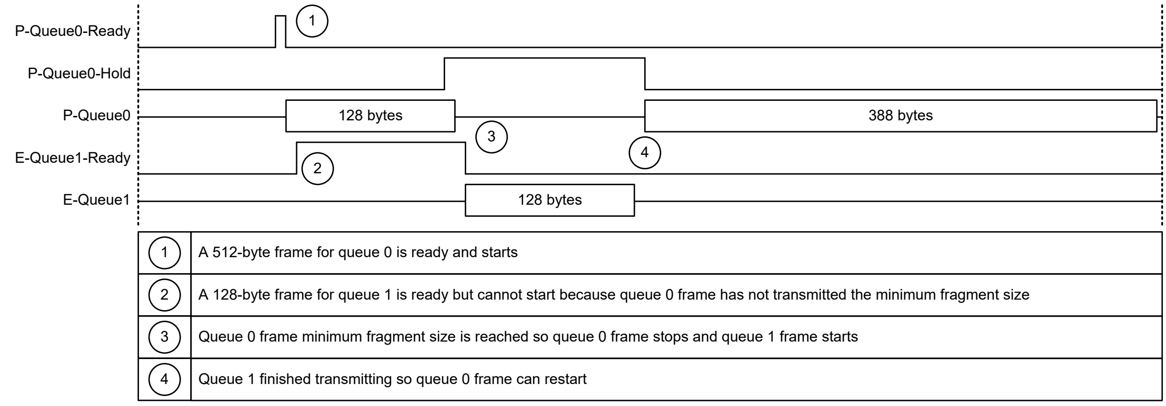

Figure 32.32 E-frame and p-frame transmission (EATPEC.AFS == 01)

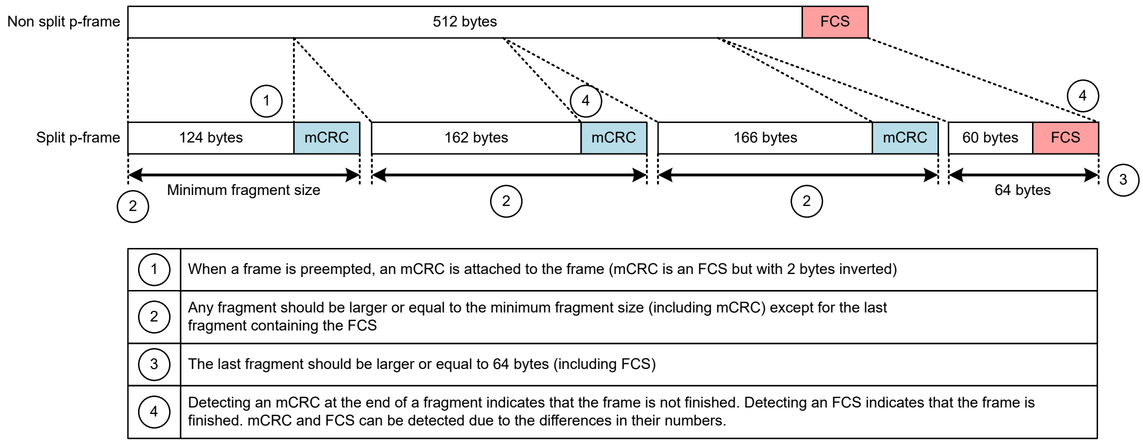

Figure 32.33 P-frame preemption (EATPEC.AFS == 01)

32.5.1.8 RMAC TX Interface Control

After TX data fetch, data is sent to the RMAC through MHD TX interface [RMAC]. Table 32.12 shows how MHD TX interface status information are provided to the RMAC.

Table 32.12 MHD TX interface status provided by ETHA to RMAC

Signal name in RMAC [RMAC]	Bus width	Value provided by ETHA
FCS in	1	Set to 1 if the corresponding transmit frame is an FCS (descriptor is received from forwarding engine with FDESCR.FI equal to 1) and if the frame has not been modified by the switch (no update due to VLAN tagging/ untagging and no update requested by L3 routing [FWD])
Timestamp capture	1	Set to LDESCR.TXC
Insert egress timestamp	1	Set to LDESCR.IET
Calculate residence time	1	Set to LDESCR.CRT
Timer number	1	Set to LDESCR.TN
Timestamp unique number	10	Set to {SPN, LDESCR.TSUN} where SPN is the source port number of the corresponding frame

32.5.2 Data Reception

Ethernet agent allows data reception through the ETHA RX data path. Figure 32.34 describes the RX data path.

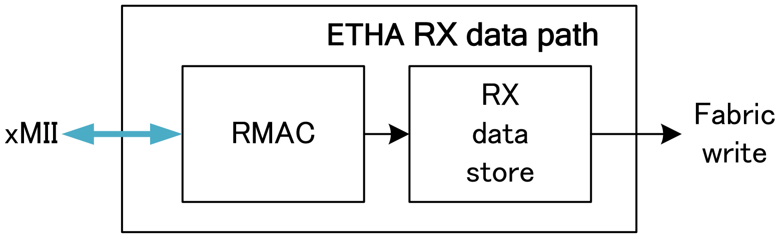

Figure 32.34 ETHA RX data path block diagram

The RX data path is separated in two blocks:

- RMAC: This block handles the data exchange with the Ethernet PHY. The functionalities of this block are described in the RMAC specification [RMAC].
- RX data store: This block extracts TAG information for frames, applies VLAN tagging and saves the frames in the local RAM. This block can also release pointers while exiting OPERATION mode. The pointer release exists for switch hardware purpose and its description is not required for switch utilization.

Restrictions:

- SW: The switch maximum input frame size is 60 KB. Set RMAC so it does not send frames larger than 60 KB (set MRFSCE.EMXS and MRFSCP.PMXS to a value smaller or equal to 61440 [RMAC]).

32.5.2.1 RX Data Store

The function of RX data store is the same as the function of TX data store in GWCA except for the local descriptor format. See GWCA specification for more details [GWCA]. Table 32.13 describes the association between ETHA and GWCA registers.

Table 32.13 Data store ETHA/GWCA register correspondence

Register/signal name in GWCA [GWCA]	Register/signal name in ETHA
GWTTFC	EARTFC
GWVCC.VIM	EAVCC.VIM
GWVTC	EAVTC
GWEIS0.USMFSES	EAEIS0.USMFSES

As local descriptor format, ETHA can only use ethernet local descriptors. Ethernet local descriptor is explained in GWCA specification and the field corresponding values for ethernet agent is described in Table 32.14.

Table 32.14 Ethernet local descriptor field description (1 of 2)

Field name	Bit width	Value for ETHA
FI	1	Set to RMAC MHD Rx Interface “FCS included” field [RMAC]
FMT	1	Set to 0 for ethernet descriptors
TXC	1	Set to RMAC MHD Rx Interface “Timestamp capture at TX side” field [RMAC]
IET	1	Set to 0
CRT	1	Set to 0
TN	1	Set to RMAC MHD Rx Interface “Time domain number” field [RMAC]
TSUN	8	Set to RMAC MHD Rx Interface “Timestamp unique number” field [RMAC]

Table 32.14 Ethernet local descriptor field description (2 of 2)

Field name	Bit width	Value for ETHA
SAEF	8	See Figure 32.35 and Table 32.15
VCTRL	3	VCTRL[2] values: ● Set to EAVCC.VIM VCTRL[1:0] values ● 00: For No TAG, R-TAG and Unknown TAG frames ● 01: For C-TAG and CR-TAG frames ● 10: For SC-TAG and SCR-TAG frames ● 11: For CoS-TAG and CoSR-TAG frames
RTGI	1	Values: ● 0: For No TAG, CoS-TAG, C-TAG, SC-TAG and Unknown TAG frames ● 1: For R-TAG, CoSR-TAG, CR-TAG and SCR-TAG frames
TPL	16	Payload length of frame. Only includes data saved in the data RAM [MFAB].
TSV	1	Values: ● 0: Timestamp has not been received along with the frame from RMAC [RMAC] ● 1: Timestamp has been received along with the frame from RMAC [RMAC]
TSD	1	Set to RMAC MHD Rx Interface “Timestamp is a default timestamp” field [RMAC]
TSNS	30	Set to 0 if timestamp has not been received. Set to timestamps nanosecond part if timestamp has not been received.
TSS	32	Set to 0 if timestamp has not been received. Set to timestamps second part if timestamp has not been received.
—	- -	Set to 0

Byte	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
0	EC1[1:0]		EC0[3:0]				—	TFE

Figure 32.35 Source agent error flag format

Table 32.15 Source agent error flag field description (1 of 2)

Field name	Bit width	Description
TFE	1	TAG Filtering Error Set conditions: ● HW: When a frame does not fit the required TAG ingress format. See section 32.3.3.3. EARTFC : Reception TAG Filtering Configuration Register.
—	- -	Reserved Set to 0

Table 32.15 Source agent error flag field description (2 of 2)

Field name	Bit width	Description
EC0	4	Error Code 0 [RMAC] Values: ● 0: No error ● 1: Frame received from RMAC with “PHY error” bit set ● 2: Frame received from RMAC with “PCH CRC error” bit set ● 3: Frame received from RMAC with “Nibble error” bit set ● 4: Frame received from RMAC with “FCS (mCRC) error” bit set ● 5: Frame received from RMAC with “Final fragment missing error” bit set ● 6: Frame received from RMAC with “C Fragment SMD Error” bit set ● 7: Frame received from RMAC with “C Fragment FRAG_COUNT Error” bit set ● 8: Frame received from RMAC with “RMAC Frame filtered” bit set ● 9: Frame received from RMAC with “Reception partially out of operation” bit set ● Others: Reserved Restrictions: ● HW: Because of the coding mechanism only one error can be flagged in this field ● HW: If several errors occur for the same frame, the error with the smallest EC0 value is flagged.
EC1	2	Error Code 1 [RMAC] Values: ● 0: No error ● 1: Frame received from RMAC with “Buffer overflow error” bit set ● 2: Frame received from RMAC with “Undersize error” bit set ● 3: Frame received from RMAC with “Oversize error” bit set Restrictions: ● HW: Because of the coding mechanism only one error can be flagged in this field ● HW: If several errors occur for the same frame, the error with the smallest EC0 value is flagged.
—	- -	Reserved Set to 0

33. Ethernet MAC (RMAC)

33.1 Overview

Ethernet MAC (RMAC) is an Ethernet controller that conforms to the definition of the MAC (Media Access Control) layer for Ethernet in the IEEE 802.3 standard. By connecting with a physical-layer LSI chip (PHY-LSI) that complies with the standard, RMAC can transmit and receive Ethernet (IEEE 802.3) frames. RMAC has a single MAC layer interface.

Table 33.1 lists the RMAC specifications and Figure 33.1 shows a block diagram.

Table 33.1 RMAC specifications

Item	Description
Protocol	Flow control conforming with the IEEE 802.3x standard
	Priority-based Flow Control with 802.1Qbb
	Interspersing Express Traffic (preemption) conforming with IEEE 802.3br
	Support for IEEE 1588 time synchronization, Support for IEEE AS and IEEE AS-Rev acceleration
Transfer speed	Supports transfer at 10,100,1000, 2500Mbps
Mode	Full-duplex mode
	Energy Efficient Ethernet (Low Power Idle)
Interface	Supports the IEEE 802.3 standard MII (Media Independent Interface), GMII (Gigabit Media Independent Interface)
	PHY MDIO programming Interface
	Supports internal register interface (32bit data width) Supports internal data interface (64bit data width)
Original function	Configurable frame data padding A variety of flexible RX address filtering modes Configurable CRC pass through for transmit and receive Network statistic counter (IEEE 802.3, ROMN RFC2819)
Magic Packet™	Detection of Magic Packet™*1 and output of a detected signal

Note 1. Magic Packet™ is a trademark of Advanced Micro Devices, Inc.

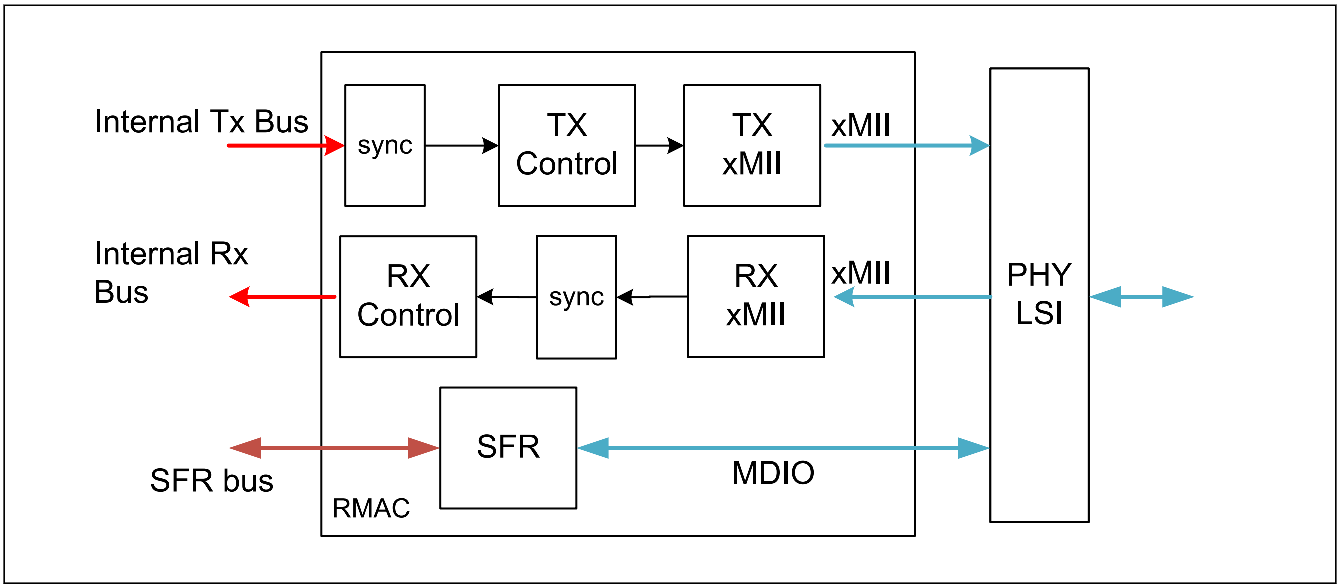

Figure 33.1 RMAC block diagram

Table 33.3 RAC functional blocks

Block name	Function
SFR	Contains all the RMAC SFRs and the bridging system to access PHY registers. RMAC registers are on clk.
Rx Control	Consists of the receive FSM and Data path logic, which disassembles the received Ethernet frame. It controls functions like checking and removing FCS, Destination Address filtering, Flow Control etc.
Tx Control	Consists of the transmission FSM and Data path logic, which facilitates the transmitted Ethernet frame. It controls functions like adding the Preamble and SFD, adding PAD bytes, calculating the FCS etc.
Rx xMII / Tx xMII	Provides the connectivity to the PHY. It supports several types of xMII (MII, GMII).
RMAC	IP described in this documentation.
Sync	Synchronized between bus clock domain and mii clock domain.

33.2 Pin Function

33.2.1 Pin Description

33.2.1.1 PHY Interfaces

PHY interface supports several Media Interfaces. Each media interface has its own interface signals.

PHY interface are described in “IEEE Std 802.3™-2008”

IPG (inter packet gap) of RMAC is defined as follows.

MII TYPE	Tx/Rx	IPG
GMII	Tx	Fixed 12 byte
	Rx	Minimum 12 byte
MII	Tx	Fixed 12 byte
	Rx	Minimum 12 byte

33.2.1.2 MDIO Interface

See MDIO standard “IEEE Std 802.3™-2018”.

33.2.1.3 MHD TX Timestamp Capture Interface

If a timestamp capture is request to RMAC on TX side (by SW or HW), this interface is used to transmit the timestamp.

This interface is based on a handshake, the interface time diagram is described in the figure bellow.

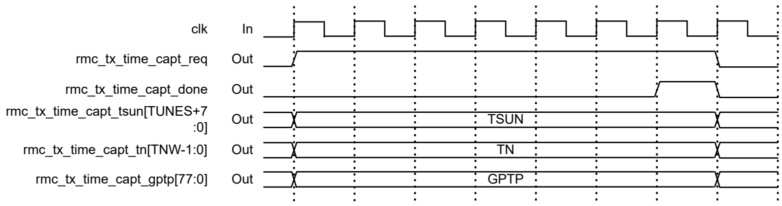

Figure 33.2 TX capture interface time chart

33.4 RMAC Register Descriptions

33.4.1 RMAC Function Registers

33.4.1.1 MPSM : PHY Station Management Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PRD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	POP[1:0]		PRA[4:0]					PDA[4:0]					MFF	—	PSME
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PSME*2*3*4	PHY Station Management Enable 0: PHY register access is not on progress. 1: PHY register access is requested and on progress.	R/W*1
1	—	This bit is read as 0.	R

Bit	Symbol	Function	R/W
2	MFF	Management Frame Format 0: Normal management frame format defined in Clause 22 of IEEE802.3 Describe "MDIO" in this document. 1: Extension management frame format defined in Clause 45 of IEEE802.3 Describe "eMDIO" in this document.	R/W
7:3	PDA[4:0]	PHY Device Address These bits specify following value according to MPSM.MFF. See 8.5 for more details. ● Case of MPSM.MFF = 0: The PHY Address field ● Case of MPSM.MFF = 1: The PHY Address field	R/W
12:8	PRA[4:0]	PHY Register Address These bits specify following value according to MPSM.MFF. See 8.5 for more details. ● Case of MPSM.MFF = 0: Register Address ● Case of MPSM.MFF = 1: Device address	R/W
14:13	POP[1:0]	PHY Operation Code These bits specify the operation code. See 8.5 for more details. These bits specify following value according to MPSM.MFF. ● Case of MPSM.MFF = 0 0 1: Write Frame 1 0: Read Frame Others: Reserved (0 0 or 1 1 should not be set when MPSM.MFF = 0) ● Case of MPSM.MFF = 1 0 0: Address Frame 0 1: Write Frame 1 0: Post-read-increment-address frame 1 1: Read Frame	R/W
15	—	This bit is read as 0.	R
31:16	PRD[15:0]	PHY Register Data These bits specify following value according to MPSM.MFF. See 8.5 for more details. ● Case of MPSM.MFF = 0: Data field of the PHY register ● Case of MPSM.MFF = 1: Data/Address filed of the PHY register	R/W*1

Note 1. Read value differs from written value.
Note 2. Accessing to MPSM register while this bit is asserted has no effect.
Note 3. This bit cannot be set when MPIC.PSMCS = 0.
Note 4. Before resetting RMAC, this register should always be checked. If this register is set, no reset should be performed.

Provides access to the PHY-LSI internal registers via the MDIO.

PSME bit (PHY Station Management Enable)

Set this bit to access PHY registers.

[Setting condition]

SW: By writing 1 to this register. It starts phy access.

[Clearing condition]

HW: When PHY register access is completed, this bit returns automatically to 0.

PRD[15:0] bits (PHY Register Data)

Write operation: HW send register value to PHY in write operation.

Read operation: HW write read data to this register from PHY in read operation.

33.4.1.2 MPIC : PHY Interfaces Configuration Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Symbol	Function	R/W
27	—	This bit is read as 0.	R
30:28	PSMCT[2:0][*2*3]	PHY Station Management Capture Time Adjustment The configured value will shift the data capture timing of MDI with respect to the rising edge of MDC clock. 0 0 0: No adjusted capture time (i.e. capture MDI at the rising edge of MDC) 0 0 1: Capture before 1 clk cycle ⋮ 1 1 1: Capture before 7 clk cycle	R/W[*1]
31	—	This bit is read as 0.	R

Note 1. Read value differs from written value.
Note 2. SW: This register cannot be set if MPSM.PSME is set.
Note 3. SW: The configured value must be less than MDC clock cycle (less than MPIC.PSMCS*2)

Configures MDIO and xMII interface.

PSMCS[6:0] bits (PHY Station Management Clock Selection)

These bits configure the cycle of MDC clock. MDC clock is divided from clk clock. The duty cycle of MDC clock is 50%.

See to section 8.4 for detail.

PSMDP bit (PHY Station Management Disable Preamble)

This bit could cut the preamble pattern (sequence of 32 contiguous bits). When it is asserted, the preamble pattern is skipped and the management frame starts with the ST (Start of Frame) pattern.

PSMHT[2:0] bits (PHY Station Management Hold Time Adjustment)

The configured value will shift the data change timing of MDO with respect to the rising edge of MDC clock.

33.4.1.3 MPIM : PHY Interfaces Monitoring Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LPIA	PLS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PLS	PHY Link Status Flag 0: PHY link signal is at the low level. 1: PHY link signal is at the high level.	R
1	LPIA	LPI Active This bit indicates that LPI is active on RX side. 0: No LPI 1: LPI active	R
31:2	—	These bits are read as 0.	R

PLS bit (PHY Link Status Flag)

This bit indicates PHY link state. It could be used only when the link status pin (rmc_phy_link) is connected to the link signal from PHY-LSI.

For the active level, refer to the specifications of PHY-LSI to be connected.

LPIA bit (LPI Active)

[Setting condition]

HW: When LPI code is appeared on detected on xMII Rx data signals (rmc_rx_data_valid_in, rmc_rx_data_data_in[31:0], rmc_rx_data_err_in). For more details, see xMII specification.

[Clearing condition]

HW: When LPI code is not appeared on detected on xMII Rx data signals.

33.4.1.4 MIOC : I/O Configuration Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MIOC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MIOC0	I/O Configuration 0 0: Normal mode. clk_phy_tx and clk_phy_rx are provided. 1: Emergency clock recovery mode. clk_phy_tx and clk_phy_rx are provided free-run clock (clk_common). (So transmission is not possible in this state.)	R/W
31:1	—	These bits are read as 0.	R

Note: SW can write 1 to bit[0] when clock derivation from PHY is unexpectedly stopped.
In this case, write 1 to bit[0] to flush all internal condition in RMAC. After waiting to flush and change DISABLE mode, write 0 to bit[0] and change RESET mode.

33.4.1.5 MTFFC : Transmission Frame Format Configuration Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCM	DPAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DPAD*1*2	Data Padding Disable Disables the automatic padding of too small transmit frames (less than 60 bytes) with no FCS If a too small transmit frame (less than 60 bytes) with no FCS is received when this bit is set, RMAC adds FCS and sends such a frame. 0: Padding is inserted. 1: Padding is not inserted.	R/W

Bit	Symbol	Function	R/W
1	FCM	Flow Control Mode This bit specifies the flow control mode 0: PAUSE 1: PFC	R/W
31:2	—	These bits are read as 0.	R

Note 1. HW: A Verify frame, a Pause frame and a PFC frame are not affected by this bit.
Note 2. HW: Padding is not executed when “fcs included(FI==1)” indication is applied by upper layer.

The register is used to configure the frame format to be transmitted.

33.4.1.6 MTPFC : Transmission Pause or PFC Frame Configuration Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0024

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PFRLV[4:0]					PFM	—	—	PFRT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PT[15:0]*1	Pause Time These bits are common bit for PAUSE and PFC. 0x0000 Pause frame disable : 0x0001 512 × 1 bit-time : : 0xFFFF 512 × 65,535 bit-time :	R/W
23:16	PFRT[7:0]*1*2	Pause Frame Retransmission Time These bits are common bit for PAUSE and PFC. 0x00: 512 × 0 bit-time 0x01: 512 × 1 bit-time : 0xFF: 512 × 255 bit-time	R/W
25:24	—	These bits are read as 0.	R
26	PFM*1	Pause Frame Mode This bit is common bit for PAUSE and PFC. 0: Automatic pause frame. Sending a pause frame will be triggered by a hardware pause request. 1: Manual pause frame. Sending a Pause frame will be triggered by MTPFC2.MPFR or MTPFC2.MPFCFR.	R/W
31:27	PFRLV[4:0]*1	Pause or PFC Frame Retry Limit Value 0x00: No interrupt 0x01: Interrupt at 1 pause frame : 0x1F: Interrupt at 31 pause frames	R/W

Note 1. SW: This register is only writable in CONFIG mode
Note 2. SW: This register should be set to a smaller value than one of MTPFC.PT.

The register is used to configure the TIME parameter value for pause frames.

PT[15:0] bits (Pause Time)

These bits set the TIME parameter value for pause frames.

- The value of these bits is set to Time field of a PAUSE or PFC frame.
- If the value of these bits is 0, PAUSE of PFC is not sent.
- The unit for the setting is 512 bit-time. 1 bit-time is equal to 1ns in 1000 Mbps, 10 ns in 100 Mbps, 100 ns in 10 Mbps.

PFRT[7:0] bits (Pause Frame Retransmission Time)

These bits set the TIME parameter value of pause frame retransmission.

- A pause frame will be retransmitted when the previous frame has been sent more than (PT-PFRT) ± 10 cycles bit-time ago.
- The unit for the setting is 512 bit-time. 1 bit-time is equal to 1ns in 1000 Mbps, 10 ns in 100 Mbps, 100 ns in 10 Mbps.

PFRLV[4:0] bits (Pause or PFC Frame Retry Limit Value)

Value of pause frame sent without pause frame request signal deassertion from which at which RMAC will emit an interrupt.

This bit is common bit for PAUSE and PFC.

The number of pause (pfc) frames in this field indicates the total number of transmission attempt.

33.4.1.7 MTPFC2 : Transmission Pause or PFC Frame Configuration Register 2

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0028

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MPFR	PFTTZ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	MPFCFR1 to MPFCFR0		—	—	—	—	—	—	PFCTTZ1 to PFCTTZ0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PFCTTZ1 to PFCTTZ0*1*2	PFC Frame n Transmission with TIME = 0 (n = 0, 1) 0: The transmission of PFC frames with TIME value zero is disabled. 1: The transmission of PFC frames with TIME value zero is enabled.	R/W
7:2	—	These bits are read as 0.	R
9:8	MPFCFR1 to MPFCFR0*3	Manual PFC Frame n Request (n = 0, 1)	R/W
15:10	—	These bits are read as 0.	R
16	PFTTZ*2	Pause Frame Transmission with TIME = 0 0: The transmission of Pause frames with TIME value zero is disabled. 1: The transmission of Pause frames with TIME value zero is enabled.	R/W
17	MPFR*3	Manual Pause Frame Request	R/W
31:18	—	These bits are read as 0.	R

Note 1. SW: This bit has no effect for Manual PFC frame transmission.
Note 2. SW: This register is only writable in CONFIG mode.
Note 3. SW: This register is only writable in OPERATION mode.

The register is used to set the TIME parameter value for PFC frames.

PFCTTZn bits (PFC Frame n Transmission with TIME = 0 (n = 0, 1))

This bit enables the transmission of automatic PFC frames with TIME value zero.

It is transmitted when the MHD negated the PFC request in automatic PFC frame mode or when the software negate MTPFC2.

MPFCFR register in manual PFC frame mode and the remaining PFC time is more than PFRT.

MPFCFRn bits (Manual PFC Frame n Request (n = 0, 1))

Writing 1 to this bit request manual pfc frame.

If a pfc frame is requested so fast that the hardware did not have time to send the previous one (because a long frame is ongoing or because the software requests too many pfc frames), the hardware will ignore the pfc frame requests.

After completion of non-pause frame transmission the next attempt for PFC frame will be only when timer expires if request for PFC frame is still high.

[Setting condition]

SW: Writing 1 to this bit will set.

[Clearing condition]

SW: Writing 0 to this bit will clear.

HW: Going out of OPERATION mode will clear this register.

PFTTZ bit (Pause Frame Transmission with TIME = 0)

This bit is used for PAUSE frame only.

This bit enables the transmission of automatic Pause frames with TIME value zero. It is transmitted when the MHD negates the pause request in automatic pause frame mode or when the software negates MTPFC2.MPFR register in manual pause frame mode and the remaining pause time is more than PFRT.

This bit has no effect for Manual Pause frame transmission.

MPFR bit (Manual Pause Frame Request)

This bit is used for a PAUSE frame only.

Writing 1 to this bit requests a manual pause frame.

If a pause frame is requested so fast that the hardware has time to send the previous one (because a long frame is ongoing or because the software requests too many pause frames), the hardware will ignore the pause frame requests.

[Setting condition]

SW: Writing 1 to this bit will set the bit

[Clearing condition]

SW: Writing 0 to this bit will clear the bit.

HW: Going out of OPERATION mode will clear this register.

33.4.1.8 MTPFC3t : Transmission Pause or PFC Frame Configuration Register 3 for Priority Group t

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0030 + 0x4 × t

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	PFCPG7 to PFCPG0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PFCPG7 to PFCPG0*1	PFC Priority Enable n (n = 0 to 7) 0: Priority x is not assigned to priority group t. 1: Priority x is assigned to group t.	R/W
31:8	—	These bits are read as 0.	R

Note 1. SW: This register is only writable in CONFIG mode.

The register is used to set the TIME parameter value for PFC frames.

PFCPGn bits (PFC Priority Enable n (n = 0 to 7))

Function when MTFFC.FCM=1(PFC)

- When PFC frame transmission request (hardware request for automatic request, MTPFC2.MPFCFR for manual request) is set, PFC frame is generated. Then, the Field of Class-Enable vector is set to this register value.
- When all bits of PFCPGn = 0, the transmission request is ignored.

Function when MTFFC.FCM = 0 (PAUSE)

- PAUSE frame transmission request is set by hardware pause request or MTPFC2.MPFR.
- When PFCPG0 = 0, the transmission request is ignored.

33.4.1.9 MRGC : Reception General Configuration Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0080

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	PFCRC7 to PFCRC0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RFCFE	MPDE	PFRTZ	PFRC	RCPT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RCPT	Receive CRC Pass Through This bit selects to pass FCS field of the received frame. The CRC is checked regardless of this configuration. 0: Correct FCS is not passed to the MHD. Incorrect FCS is passed to the MHD. 1: Both Correct and Incorrect FCS are passed to the MHD.	R/W
1	PFRC*1*2	Pause Frame Reception Control This bit enables the Flow Control (Pause frame detection) function. 0: Flow control for the receiving port is disabled. 1: Flow control for the receiving port is enabled.	R/W
2	PFRTZ	Pause or PFC Frame Reception with Time = 0 When this bit is set to 1, the reception of Pause or PFC frame with the Timer value 0 releases the transmission wait state. 0: Reception of Pause or PFC frames with the TIME value 0 is disabled. 1: Reception of Pause or PFC frames with the TIME value 0 is enabled.	R/W
3	MPDE	Magic Packet™ Detection Enable This bit enables Magic Packet™ detection by hardware to allow activation via the Ethernet connection. (Only for e-frames) 0: Magic Packet™ detection is disabled. 1: Magic Packet™ detection is enabled.	R/W
4	RFCFE	Reception Flow Control Forwarding Enable This bit enables the Flow Control Frame (PAUSE or PFC frame) forwarding function. 0: Flow Control Frame (PAUSE or PFC frame) is not forward to Rx MHD I/F. 1: Flow Control Frame (PAUSE or PFC frame) is forward to Rx MHD I/F.	R/W
15:5	—	These bits are read as 0.	R
23:16	PFCRC7 to PFCRC0*1*3	PFC Frame Reception Control n (n = 0 to 7) This bit enables the Flow Control (Pause frame detection) function. 0: Flow control for the receiving priority level x (8) is disabled. 1: Flow control for the receiving priority level x (8) is enabled.	R/W
31:24	—	These bits are read as 0.	R

Note 1. HW: Only for e-frames
Note 2. SW: When any bits of MRGC.PFCRC is set, SW should not set this bit.
Note 3. SW: When MRGC.PFRC is set, SW should not set this bit.

The resister is used to configure the frame reception.

33.4.1.10 MRMAC0 : Reception MAC Address Configuration Register 0

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0084

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MAU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MAU[15:0]	MAC Address Upper Part These bits are used to set the 16 higher-order bits of the MAC address. For example, if the MAC address is 01-23-45-67-89-AB (hexadecimal), set H'0123 in this register.	R/W
31:16	—	These bits are read as 0.	R

Specifies the 16 higher-order bits of the 48-bit unicast MAC address. This register is also used as source address filed when the IP transmits a Pause frame or a PFC frame.

33.4.1.11 MRMAC1 : Reception MAC Address Configuration Register 1

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0088

Bit position:	31–0
Bit field:	MAL[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	MAL[31:0]	MAC Address Lower Part These bits are used to set the 32 lower-order bits of the MAC address. For example, if the MAC address is 01-23-45-67-89-AB (hexadecimal), set H'456789AB in this register.	R/W

The register is to use to specify the 32 lower-order bits of the 48-bit unicast MAC address. This register is also used as source address filed when the IP transmits a Pause frame or a PFC frame.

33.4.1.12 MRAFC : Reception Address Filter Configuration Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x008C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	MSAREP	NSAREP	SDSFREP	NDAREP	BCACP	MCACP	BSTENP	MSTENP	BCENP	MCENP	UCENP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	MSAREE	NSAREE	SDSFREE	NDAREE	BCACE	MCACE	BSTENE	MSTENE	BCENE	MCENE	UCENE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
0	UCENE	Unicast Reception Enable E-Frames This bit enables the unicast filtering based on MAC address (MRMAC0/1). 0: Unicast reception disabled 1: Unicast reception enabled	R/W
1	MCENE	Multicast Reception Enable E-Frames This bit enables the multicast filtering. 0: Multicast reception disabled 1: Multicast reception enabled	R/W
2	BCENE	Broadcast Reception Enable E-Frames This bit enables the broadcast filtering. 0: Broadcast reception disabled 1: Broadcast reception enabled	R/W
3	MSTENE*1	Multicast Storm Filter Reception Enable E-Frames This bit enables the multicast storm filtering. When it is asserted, Multicast frames are rejected after the number of received multicast e-frames reaches the configured threshold (MRSCE.CMFE). 0: Multicast storm filter reception disabled 1: Multicast storm filter reception enabled	R/W

Bit	Symbol	Function	R/W
4	BSTENE*2	Broadcast Storm Filter Reception Enable E-Frames This bit enables the broadcast storm filtering. When it is asserted, Broadcast frames are rejected after the number of received broadcast e-frames reaches to the configured threshold (MRSCE.CBFE). 0: Broadcast storm filter reception disabled 1: Broadcast storm filter reception enabled	R/W
5	MCACE*3	Multicast Storm Autoclear E-Frames This bit enables auto-clear of multicast frame storm counter. When it is asserted, multicast frame storm counter is cleared by detecting a frame with non-multicast destination address. After the counter is cleared, the IP can receive multicast frame again. 0: Multicast Storm Autoclear disabled 1: Multicast Storm Autoclear enabled	R/W
6	BCACE	Broadcast Storm Autoclear E-Frames This bit enables auto-clear of broadcast frame storm counter. When it is asserted, broadcast frames storm counter is cleared by detecting a frame with non-broadcast destination address. After the counter is cleared, the IP can receive Broadcast frame again. 0: Broadcast Storm Autoclear disabled 1: Broadcast Storm Autoclear enabled	R/W
7	NDAREE	Null Destination Address Reception Enable E-Frames This bit enables the reception of e-frames with destination MAC address null. 0: disable 1: enable	R/W
8	SDSFREE	Same DA and SA Frames Reception Enable E-Frames This bit enables the reception of e-frame with equal destination address and source address. 0: disable 1: enable	R/W
9	NSAREE	Null Source Address Reception Enable E-Frames This bit enables the reception of e-frames with destination MAC address null. 0: disable 1: enable	R/W
10	MSAREE	Multicast Source Address Reception Enable E-Frames This bit enables the reception of e-frame with multicast and broadcast source address 0: disable 1: enable	R/W
15:11	—	These bits are read as 0.	R
16	UCENP	Unicast Reception Enable P-Frames This bit enables the unicast filtering based on MAC address (MRMAC0/1). 0: Unicast reception disabled 1: Unicast reception enabled	R/W
17	MCENP	Multicast Reception Enable P-Frames This bit enables the multicast filtering. 0: Multicast reception disabled 1: Multicast reception enabled	R/W
18	BCENP	Broadcast Reception Enable P-Frames This bit enables the broadcast filtering. 0: Broadcast reception disabled 1: Broadcast reception enabled	R/W
19	MSTENP*1	Multicast Storm Filter Reception Enable P-Frames This bit enables the multicast storm filtering. When it is asserted, Multicast frames are rejected after the number of received multicast p-frames reaches the configured threshold (MRSCP.CMFP). 0: Multicast storm filter reception disabled 1: Multicast storm filter reception enabled	R/W
20	BSTENP*2	Broadcast Storm Filter Reception Enable P-Frames This bit enables the broadcast storm filtering. When it is asserted, Broadcast frames are rejected after the number of received broadcast p-frames reaches the configured threshold (MRSCP.CBFP). 0: Broadcast storm filter reception disabled 1: Broadcast storm filter reception enabled	R/W

Bit	Symbol	Function	R/W
21	MCACP*3	Multicast Storm Autoclear P-Frames This bit enables auto-clear of multicast frame storm counter. When it is asserted, multicast frame storm counter is cleared by detecting a frame with non-multicast destination address. After the counter is cleared, the bit can receive multicast frame again. 0: Multicast Storm Autoclear disabled 1: Multicast Storm Autoclear enabled	R/W
22	BCACP	Broadcast Storm Autoclear P-Frames This bit enables auto-clear of broadcast frame storm counter. When it is asserted, broadcast frames storm counter is cleared by detecting a frame with non-broadcast destination address. After the counter is cleared, the IP can receive Broadcast frame again 0: Broadcast Storm Autoclear disabled 1: Broadcast Storm Autoclear enabled	R/W
23	NDAREP	Null Destination Address Reception Enable P-Frames This bit enables the reception of p-frames with destination MAC address null. 0: disable 1: enable	R/W
24	SDSFREP	Same DA and SA Frames Reception Enable P-Frames This bit enables the reception of p-frame with equal destination address and source address. 0: disable 1: enable	R/W
25	NSAREP	Null Source Address Reception Enable P-Frames This bit enables the reception of p-frames with a destination MAC address null. 0: disable 1: enable	R/W
26	MSAREP	Multicast Source Address Reception Enable P-Frames This bit enables the reception of p-frame with multicast and broadcast source address 0: disable 1: enable	R/W
31:27	—	These bits are read as 0.	R

Note 1. SW: It is valid only when Multicast reception is enabled (MRAFC.MCENE=1).
Note 2. SW: It is valid only when Broadcast reception is enabled (MRAFC.BCENE=1)
Note 3. HW: Broadcast frames are not taken in account by multicast storm counter.

33.4.1.13 MRSCE : Reception Storm Configuration for E-Frames Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0090

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CBFE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMFE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMFE[15:0]	Consecutive Multicast Frame Reception Count Setting for E-Frames These bits specify the upper-limitation of received consecutive multicast frames. After the number of received consecutive multicast frames reaches the set value, the subsequent multicast frames are discarded. 0x0000: 1 Multicast frame accepted until multicast frame counter reset 0x0001: 2 Multicast frame accepted until multicast frame counter reset ⋮ 0xFFFE: 65535 Multicast frames accepted until frame counter reset 0xFFFF: Reserved	R/W
31:16	CBFE[15:0]	Consecutive Broadcast Frame Reception Count Setting for E-Frames These bits specify the upper-limitation of received consecutive broadcast frames. After the number of received consecutive broadcast frames reaches the set value, the subsequent broadcast frames are discarded. 0x0000: 1 Broadcast frame accepted until broadcast frame counter reset 0x0001: 2 Broadcast frame accepted until broadcast frame counter reset ⋮ 0xFFFE: 65535 Broadcast frames accepted until broadcast frame counter reset 0xFFFF: Reserved	R/W

The register is to use to configure the number of times how many broadcast/multicast frames can be received consecutively.

33.4.1.14 MRSCP : Reception Storm Configuration for P-Frames Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0094

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CBFP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMFP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMFP[15:0]	Consecutive Multicast Frame Reception Count Setting for P-Frames These bits specify the upper-limitation of received consecutive multicast frames. After the number of received consecutive multicast frames reaches the set value, the subsequent multicast frames are discarded. 0x0000: 1 Multicast frame accepted until multicast frame counter reset 0x0001: 2 Multicast frame accepted until multicast frame counter reset ⋮ 0xFFFE: 65535 Multicast frames accepted until multicast frame counter reset 0xFFFF: Reserved	R/W
31:16	CBFP[15:0]	Consecutive Broadcast Frame Reception Count Setting for P-Frames These bits specify the upper-limitation of received consecutive Broadcast frames. After the number of received consecutive broadcast frames reaches the set value, the subsequent broadcast frames are discarded. 0x0000: 1 Broadcast frame accepted until broadcast frame counter reset 0x0001: 2 Broadcast frame accepted until broadcast frame counter reset ⋮ 0xFFFE: 65535 Broadcast frames accepted between two broadcast frame counter resets 0xFFFF: Reserved	R/W

Configures the number of times how many broadcast/multicast frames can be received consecutively.

33.4.1.15 MRSCC : Reception Storm Counter Configuration Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0098

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BSCCP	MSCCP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BSCCE	MSCCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MSCCE	Multicast Storm Counter Clear E-Frames This bit requests to clear the multicast frames storm counter. After the counter is cleared, the IP can receive multicast frames again until the upper-limitation of received consecutive multicast frames (MRSCE.CMFE). It should be used with multicast Storm Autoclear disabled (MRAFC.MCACE = 0). Writing 1 to this bit clear the multicast storm counter	R
1	BSCCE	Broadcast Storm Counter Clear E-Frames This bit requests to clear the broadcast frames storm counter. After the counter is cleared, the IP can receive Broadcast frames again until the upper-limitation of received consecutive Broadcast frames (MRSCE.CBFE). It should be used with Broadcast Storm Autoclear disabled (MRAFC.BCACE = 0). Writing 1 to this bit clear the broadcast storm counter	R
15:2	—	These bits are read as 0.	R
16	MSCCP	Multicast Storm Counter Clear P-Frames This bit requests to clear the multicast frames storm counter. After the counter is cleared, the IPt can receive multicast frames again until the upper-limitation of received consecutive multicast frames (MRSCP.CMFP). It should be used with multicast Storm Autoclear disabled (MRAFC.MCACP = 0). Writing 1 to this bit clears the multicast storm counter	R
17	BSCCP	Broadcast Storm Counter Clear P-Frames This bit requests to clear the broadcast frames storm counter. After the counter is cleared, the IP can receive broadcast frames again until the upper-limitation of received consecutive broadcast frames (MRSCP.CBFP). It should be used with Broadcast Storm Autoclear disabled (MRAFC.BCACP = 0). Writing 1 to this bit clears the broadcast storm counter	R
31:18	—	These bits are read as 0.	R

Register to clear Broadcast and Multicast Storm Counters.

33.4.1.16 MRFSCE : Reception Frame Size Configuration for E-Frames Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x009C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	EMNS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EMXS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	EMXS[15:0]	E-Frame Maximum Size A part of received frame which exceeds the set value are truncated. Don’t set a value under 16 bytes. MRFSCE.EMXS have to set 3FFFH or less.	R/W
31:16	EMNS[15:0]	E-Frame Minimum Size	R/W

Note: The size limitations concern the frame size RMAC outputs to an upper layer (e.g. MHD), and so the FCS removal impacts the register values.

33.4.1.17 MRFSCP : Reception Frame Size Configuration for P-Frames Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x00A0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PMNS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PMXS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PMXS[15:0]	P-Frame Maximum Size A part of received frame which exceeds the set value are truncated. Don’t set a value under 16 bytes.	R/W
31:16	PMNS[15:0]	P-Frame Minimum Size	R/W

Note: The size limitations concern the frame size RMAC outputs to an upper layer (e.g. MHD), and so the FCS removal impacts the register values.

33.4.1.18 MTRC : Timestamp Reception Configuration Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x00A4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	DTN[1:0]		TCTSP	TCTSE	TRDDP	TRDDE	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TRHFME1 to TRHFME0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	TRHFME1 to TRHFME0	Timestamp Reception Hardware Filter Match Enable n (n = 0 to 1) 0: disable 1: enable	R/W
23:2	—	These bits are read as 0.	R
24	TRDDE	Timestamp Reception Default Disable E-Frame A timestamp for every frame will be transmitted to the MHD. This timestamp will be taken on the default timer except when TRHFME is set and the hardware filter matches. 0: enable 1: disable	R/W
25	TRDDP	Timestamp Reception Default Disable P-Frame A timestamp for every frame will be transmitted to the MHD. This timestamp will be taken on the default timer. 0: enable 1: disable	R/W
26	TCTSE	Timestamp Capture on TX Side E-Frame The bit enables the timestamp capture on TX side for e-frames 0: disable 1: enable	R/W
27	TCTSP	Timestamp Capture on TX Side P-Frame The bit enables the timestamp capture on TX side for p-frames 0: disable 1: enable	R/W
29:28	DTN[1:0]	Default Timer Number The bit set Timer used for timestamp forwarding on rx mhd i/f when no timer is detected.	R/W
31:30	—	These bits are read as 0.	R

TRHFMEn bits (Timestamp Reception Hardware Filter Match Enable n (n = 0 to 1))

Setting bit i to 1 in this register will enable hardware filtering for timer i.

When bit i is set to 1, at least one of the bit i in MPFCn registers should be set to one.

When hardware filter matches, the timestamp from the matched timer will be sent along with the frame.

33.4.1.19 MRPFM : Reception Pause or PFC Frame Monitoring Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x00AC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	PFCTCA7 to PFCTCA0							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PTCA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PTCA	Pause Time Counting Active This bit indicates that the Pause time of a received Pause frame has not been completed. 0: No pause state 1: Pause state	R
15:1	—	These bits are read as 0.	R
23:16	PFCTCA7 to PFCTCA0	PFC Time Counting Active n (n = 0 to 7) This bit indicates that the Pause time of a received PFC frame has not been completed. 0: No pause state 1: Pause state	R
31:24	—	These bits are read as 0.	R

33.4.1.20 MPFCt : PTP Filtering Register Configuration Register t (t = 0 to 15)

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0100 + 0x4 × t

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TEF1 to TEF0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PFBV[7:0]								PFBN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PFBN[7:0]	PTP Filtering Byte Number 0x00: Byte number 0 will be filtered. ⋮ 0xFF: Byte number 255 will be filtered.	R/W
15:8	PFBV[7:0]	PTP Filtering Byte Value When the filtered byte has a value equal to this register, the byte will be eligible for the corresponding timers.	R/W
17:16	TEF1 to TEF0	Timer Enable for Filtering n (n = 0 to 1) Setting bit i to 1 in this register will apply the filter to timer i.	R/W
31:18	—	These bits are read as 0.	R

Note: This register is used for RX time domain selection.
When an overlapping configuration is done, HW will always choose the timer with the smaller number.

The register is used to configure the PTP frame filtering for time domain selection.

33.4.1.21 MLVC : Link Verification Configuration Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0180

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PLV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	PASE	—	LVT[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	LVT[6:0]	Link Verification Timer These bits define the nominal wait time between verification attempts in unit of milliseconds. It means the time of retransmitting SMD-V frame. 000 0000: 1ms wait time 000 0001: 2ms wait time ⋮ 000 1001: 10ms wait time (default specified by IEEE 802.3) ⋮ 111 1111: 128ms wait time	R/W
7	—	This bit is read as 0.	R
8	PASE	Preemption Auto Response Enable This bit enables the automatic response to verify frames.	R/W
15:9	—	These bits are read as 0.	R
16	PLV	Preemption Link Verification 0: Preemption Link Verification not requested 1: Preemption Link Verification requested	R/W*1
31:17	—	These bits are read as 0.	R

Note: When PLV is set to 1, do not make write access continuously. Please wait completion of Link Verification Procedure for re-write access.

Note 1. Read value differs from written value.

PLV bit (Preemption Link Verification)

By asserting this bit, link verification is requested.

This bit requests the Link Verification process. When link verification is completed, this bit is cleared.

When Link Verification succeeded, Preemption status bit (MMIS0.LVSS) are set. While it failed, the status bit (MMIS0.LVFS) is set.

Going out of OPERATION mode will clear this register.

As described in 7.2.2, this bit should only be used in initialization.

SW set this bit when another transmission is not requested.

33.4.1.22 MEEEC : Energy Efficient Ethernet Configuration Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0184

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LPITR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LPITR*1	LPI Transmit Request This bit requests to enter Low Power Idle (LPI) mode. RMAC enters to LPI state after all ongoing transmissions have been completed. When this bit is negated, this IP leaves LPI state. LPI signal should be transmitted only when TX is disabled. Going out of OPERATION mode will clear this register. 0: LPI mode is not requested 1: LPI mode is requested	R/W
31:1	—	These bits are read as 0.	R

Note 1. SW: LPITR bit can only be set when transmission request to RMAC is stopped, and transmission request can only be allowed after LPITR is cleared.
It is prohibited to request transmission from HMD when LPITR bit is set.

33.4.1.23 MLBC : Loopback Configuration Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0188

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LBME
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LBME	Loopback Mode Enable Transmit xMII signals are connected to reception xMII signals internally. 0: disable 1: enable	R/W
31:1	—	These bits are read as 0.	R

Note: When loopback mode is enabled, frame received by external PHY Interface are ignored.
If this bit is set, clk_phy_tx and clk_phy_rx must be synchronized with each other.

33.4.2 RMAC Counter Registers

Counter registers

Note: All counter registers in RMAC are read clear registers.

When counters reach their own maximum value, they stop.

33.4.2.1 MMPFTCT : Manual Pause Frame Transmit Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0300

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MPFTC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MPFTC[15:0]	Manual Pause frame Transmit Counter	R
31:16	—	These bits are read as 0.	R

MPFTC[15:0] bits (Manual Pause frame Transmit Counter)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

HW: Incremented by 1 when manual Pause frame is transmitted.

33.4.2.2 MAPFTCT : Automatic Pause Frame Transmit Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0304

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	APFTC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	APFTC[15:0]	Automatic pause Frame Counter	R
31:16	—	These bits are read as 0.	R

APFTC[15:0] bits (Automatic pause Frame Counter)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

HW: Incremented by 1 when automatic Pause frame is transmitted.

33.4.2.3 MPFRCT : Pause Frame Receive Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0308

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PFRC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PFRC[15:0]*1	Pause Frame Receive Counter	R
31:16	—	These bits are read as 0.	R

Note 1. SW: Set condition is only available when Flow Control is enabled in reception. (MRGC.PFRC = 1)

PFRC[15:0] bits (Pause Frame Receive Counter)

[Clearing condition]

HW: Being in RESET mode will clear this register

SW: Reading this register clears it.

[Increment condition]

HW: Incremented by 1 when automatic Pause frame is received.

33.4.2.4 MFCICT : False Carrier Indication Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x030C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FCIC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	FCIC[15:0]	False Carrier Indication Counter	R
31:16	—	These bits are read as 0.	R

Note: This register is counter of “False Carrier Indication” event. This event goes through the synchronizer between clk and clk_phy_rx. If the event occurs continuously, there is a possibility of miss counting.

FCIC[15:0] bits (False Carrier Indication Counter)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

HW: Incremented by 1 when False Carrier Indication pattern is detected.

33.4.2.5 MEEECT : Energy Efficient Ethernet Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0310

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EEERC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	EEERC[15:0]	Energy Efficient Ethernet Receive Counter	R
31:16	—	These bits are read as 0.	R

EEERC[15:0] bits (Energy Efficient Ethernet Receive Counter)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

HW: Incremented by 1 when LPI signal is detected on xMII reception bus.

33.4.2.6 MMPCFTCTt : Manual PFC Frame Transmit Counter Register (t = 0, 1)

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0320 + 0x4 × t

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MPCFCTC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MPCFCTC[15:0]	Manual PFC frame Transmit Counter	R
31:16	—	These bits are read as 0.	R

MPCFCTC[15:0] bits (Manual PFC frame Transmit Counter)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

HW: Incremented by 1 when manual PFC frames is transmitted.

33.4.2.7 MAPCFTCTt : Automatic PFC Frame Transmit Counter Register (t = 0, 1)

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0330 + 0x4 × t

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	APCFCTC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	APCFCTC[15:0]	Automatic PFC Frame Counter	R
31:16	—	These bits are read as 0.	R

APCFCTC[15:0] bits (Automatic PFC Frame Counter)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

HW: Incremented by 1 when manual PFC frames is transmitted.

33.4.2.8 MPCFRCTt : PFC Frame Receive Counter Register (t = 0, 1)

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0340 + 0x4 × t

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PCFCRC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PCFCRC[15:0]*1	PFC Frame Receive Counter	R
31:16	—	These bits are read as 0.	R

Note 1. SW: Set condition is only available when Flow Control is enabled in reception (MRGC.PFRC = 1).

PCFCRC[15:0] bits (PFC Frame Receive Counter)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

HW: Incremented by 1 when manual PFC frames is received.

33.4.2.9 MROVFC : Receive Overflow Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0360

Bit position:	31 ... 0
Bit field:	ROVFC[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	ROVFC[31:0]	Receive overflow counter	R

ROVFC[31:0] bits (Receive overflow counter)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

HW: Incremented by 1 when frame receive overflow occurred (when set condition for MEIS.REOES or MEIS.RPOES are met).

33.4.2.10 MRXBCEU : Received Byte Counter E-Frames Upper Side Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x044C

Bit position:	31 ... 0
Bit field:	RBNEU[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RBNEU[31:0]	Received byte number E-frames upper side When the RMAC does not pass the FCS to the upper layer, FCS is not taken in account in total byte calculation. Read before reading MRXBCEL.	R

RBNEU[31:0] bits (Received byte number E-frames upper side)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented each time the received data of e-Frame is sent to the rx mhd interface regardless error is detected.

33.4.2.11 MRXBCEL : Received Byte Counter E-Frames Lower Side Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0450

Bit position:	31	...	0
Bit field:	RBNEL[31:0]		
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0		

Bit	Symbol	Function	R/W
31:0	RBNEL[31:0]	Received byte number E-frames lower side When the RMAC does not pass the FCS to the upper layer, FCS is not taken in account in total byte calculation. Read after reading MRXBCEU.	R

RBNEL[31:0] bits (Received byte number E-frames lower side)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: None. (Reading MRXBCEL register holds it.) Increment condition

[Increment condition]

Incremented each time the received data of e-frame is sent to the rx mhd interface regardless the error detection.

33.4.2.12 MRXBCPU : Received Byte Counter P-Frames Upper Side Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0454

Bit position:	31	...	0
Bit field:	RBNPU[31:0]		
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0		

Bit	Symbol	Function	R/W
31:0	RBNPU[31:0]	Received byte number P-frames upper side If the RMAC does not pass the FCS to the upper layer, FCS is not taken in account in total byte calculation. Read before reading MRXBCPL.	R

RBNPU[31:0] bits (Received byte number P-frames upper side)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented each time the received data of p-frame is sent to the rx mhd interface regardless the error detection.

33.4.2.13 MRXBCPL : Received Byte Counter P-Frames Lower Side Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0458

Bit position:	31 … 0
Bit field:	RBNPL[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RBNPL[31:0]	Received byte number P-frames lower side When the RMAC does not pass the FCS to the upper layer, FCS is not taken in account in total byte calculation. Read after reading MRXBCPU.	R

RBNPL[31:0] bits (Received byte number P-frames lower side)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: None. (Reading MRXBCPL register holds it.)

[Increment condition]

Incremented each time the received data of p-frame is sent to the rx mhd interface regardless the error detection.

33.4.2.14 MRGFCE : Received Good Frame Counter E-Frames Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0408

Bit position:	31 … 0
Bit field:	RGFNE[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RGFNE[31:0]	Received good frame number E-frames	R

RGFNE[31:0] bits (Received good frame number E-frames)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when the reception of e-frame is completed without error.

33.4.2.15 MRGFCP : Received Good Frame Counter P-Frames Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x040C

Bit position:	31–0
Bit field:	GFNP[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	GFNP[31:0]	Received good frame number P-frames	R

GFNP[31:0] bits (Received good frame number P-frames)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when the reception of p-frame is completed without error.

33.4.2.16 MRBFC : Received Good Broadcast Frame Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0410

Bit position:	31–0
Bit field:	RBFN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RBFN[31:0]	Received good broadcast frame number	R

RBFN[31:0] bits (Received good broadcast frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when destination address filed of broadcast frame is sent to rx mhd interface without error.

33.4.2.17 MRMFC : Received Good Multicast Frame Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0414

Bit position:	31–0
Bit field:	RMFN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RMFN[31:0]	Received good multicast frame number	R

RMFN[31:0] bits (Received good multicast frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when destination address filed of multicast frame is sent to rx mhd interface without error.

33.4.2.18 MRUFC : Received Good Unicast Frame Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0418

Bit position:	31–0
Bit field:	RUFN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RUFN[31:0]	Received good unicast frame number	R

RUFN[31:0] bits (Received good unicast frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when destination address filed of unicast frame is sent to rx mhd interface without error.

33.4.2.19 MRPEFC : Received PHY Error Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x041C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RPEFN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RPEFN[15:0]	Received PHY error frame number	R
31:16	—	These bits are read as 0.	R

RPEFN[15:0] bits (Received PHY error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received data is sent to rx mhd interface with phy error.

33.4.2.20 MRNEFC : Received Nibble Error Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0420

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RNEFN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RNEFN[15:0]	Received nibble error frame number	R
31:16	—	These bits are read as 0.	R

RNEFN[15:0] bits (Received nibble error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received data is sent to rx mhd interface with nibble error.

33.4.2.21 MRFMEFC : Received FCS/mCRC Error Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0424

Bit position: 31 … 0

Bit field: RFMEFN[31:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RFMEFN[31:0]	Received FCS/mCRC error frame number	R

RFMEFN[31:0] bits (Received FCS/mCRC error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received data is sent to rx mhd interface with FCS/mCRC error.

33.4.2.22 MRFFMEFC : Received Final Fragment Missing Error Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0428

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RFFMEFN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RFFMEFN[15:0]	Received final fragment missing error frame number	R
31:16	—	These bits are read as 0.	R

RFFMEFN[15:0] bits (Received final fragment missing error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received data is sent to rx mhd interface with final fragment error.

33.4.2.23 MRCFCEFC : Received C-Fragment Count Error Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x042C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RCFCEFN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RCFCEFN[15:0]	Received C-fragment count error frame number	R
31:16	—	These bits are read as 0.	R

RCFCEFN[15:0] bits (Received C-fragment count error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received data is sent to rx mhd interface with C-fragment count error.

33.4.2.24 MRFCEFC : Received Fragment Count Error Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0430

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RFCEFN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RFCEFN[15:0]	Received fragment count error frame number	R
31:16	—	These bits are read as 0.	R

RFCEFN[15:0] bits (Received fragment count error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received data is sent to rx mhd interface with fragment count error.

33.4.2.25 MRRCFEFC : Received RMAC Filter Error Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0434

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RRCFEFN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RRCFEFN[15:0]	Received RMAC filter error frame number	R
31:16	—	These bits are read as 0.	R

RRCFEFN[15:0] bits (Received RMAC filter error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received data is sent to rx mhd interface with RMAC filtered.

33.4.2.26 MRFC : Received Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0438

Bit position:	31–0
Bit field:	RFN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RFN[31:0]	Received frame number	R

RFN[31:0] bits (Received frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received frame is sent to rx mhd interface.

33.4.2.27 MRGUEFC : Received Good Undersize Error Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x043C

Bit position:	31–0
Bit field:	RUEFN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RUEFN[31:0]	Received good undersize error frame number	R

RUEFN[31:0] bits (Received good undersize error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received data is sent to rx mhd interface with undersize error but without fcs/mcrc error.

33.4.2.28 MRBUEFC : Received Bad Undersize Error Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0440

Bit position:	31–0
Bit field:	RUEFN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RUEFN[31:0]	Received bad undersize error frame number	R

RUEFN[31:0] bits (Received bad undersize error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received data is sent to rx mhd interface with undersize error and fcs/mcrc error.

33.4.2.29 MRGOEFC : Received Good Oversize Error Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0444

Bit position:	31 — 0
Bit field:	RGOEFN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RGOEFN[31:0]	Received good oversize error frame number	R

RGOEFN[31:0] bits (Received good oversize error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received data is sent to rx mhd interface with oversize error, but without fcs/mcrc error.

33.4.2.30 MRBOEFC : Received Bad Oversize Error Frame Count Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0448

Bit position:	31 — 0
Bit field:	RBOEFN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RBOEFN[31:0]	Received bad oversize error frame number	R

RBOEFN[31:0] bits (Received bad oversize error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Incremented when received data is sent to rx mhd interface with oversize error and fcs/mcrc error.

33.4.2.31 MTXBCEU : Transmitted Byte Counter E-Frames Upper Side Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0520

Bit position:	31 ... 0
Bit field:	TBNEU[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TBNEU[31:0]	Transmitted byte number E-frames upper side	R

Note: If the FCS is not passed to the upper layer FCS is not taken in account in total byte calculation.

TBNEU[31:0] bits (Transmitted byte number E-frames upper side)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Increment every time transmit data for e-frame is received on tx mhd i/f.

Read before reading MTXBCEL.

33.4.2.32 MTXBCEL : Transmitted Byte Counter E-Frames Lower Side Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0524

Bit position:	31 ... 0
Bit field:	TBNEL[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TBNEL[31:0]	Transmitted byte number E-frames lower side	R

Note: If the FCS is not passed to the upper layer FCS is not taken in account in total byte calculation.

TBNEL[31:0] bits (Transmitted byte number E-frames lower side)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: None. (Reading MTXBCEL register holds it.)

[Increment condition]

Increment every time transmit data for e-frame is received on tx mhd i/f.

Read before reading MTXBCEU.

33.4.2.33 MTXBCPU : Transmitted Byte Counter P-Frames Upper Side Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0528

Bit position:	31 ... 0
Bit field:	TBNPU[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TBNPU[31:0]	Transmitted byte number P-frames upper side	R

Note: If the FCS is not passed to the upper layer, FCS is not taken in account in total byte calculation.

TBNPU[31:0] bits (Transmitted byte number P-frames upper side)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Increment every time transmit data for p-frame is received on tx mhd i/f.

Read before reading MTXBCPL.

33.4.2.34 MTXBCPL : Transmitted Byte Counter P-Frames Lower Side Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x052C

Bit position:	31 ... 0
Bit field:	TBNPL[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TBNPL[31:0]	Transmitted byte number P-frames lower side	R

Note: If the FCS is not passed to the upper layer, FCS is not taken in account in total byte calculation.

TBNPL[31:0] bits (Transmitted byte number P-frames lower side)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: None. (Reading MTXBCPL register holds it.)

[Increment condition]

Increment every time transmit data for p-frame is received on tx mhd i/f.

Read before reading MTXBCPU.

33.4.2.35 MTGFCE : Transmitted Good Frame Counter E-Frames Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0508

Bit position:	31 … 0
Bit field:	TGFNE[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TGFNE[31:0]	Transmitted good frame number E-frames	R

TGFNE[31:0] bits (Transmitted good frame number E-frames)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Increment when transmission of e-frame is completed on tx mhd i/f without error.

33.4.2.36 MTGFCP : Transmitted Good Frame Counter P-Frames Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x050C

Bit position:	31 … 0
Bit field:	TGFNP[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TGFNP[31:0]	Transmitted good frame number P-frames	R

TGFNP[31:0] bits (Transmitted good frame number P-frames)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Increment when transmission of p-frame is completed on tx mhd i/f without error.

33.4.2.37 MTBFC : Transmitted Broadcast Frame Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0510

Bit position:	31 … 0
Bit field:	TBFN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TBFN[31:0]	Transmitted broadcast frame number	R

TBFN[31:0] bits (Transmitted broadcast frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Increment when destination address field of broadcast frame is sent on tx mhd i/f.

33.4.2.38 MTMFC : Transmitted Multicast Frame Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0514

Bit position:	31–0
Bit field:	TMFN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TMFN[31:0]	Transmitted multicast frame number	R

TMFN[31:0] bits(Transmitted multicast frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Increment when destination address field of multicast frame is sent on tx mhd i/f.

33.4.2.39 MTUFC : Transmitted Unicast Frame Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0518

Bit position:	31–0
Bit field:	TUFN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TUFN[31:0]	Transmitted unicast frame number	R

TUFN[31:0] bits (Transmitted unicast frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Increment when destination address field of unicast frame is sent on tx mhd i/f.

33.4.2.40 MTEFC : Transmitted Error Frame Counter Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x051C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TEFN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TEFN[15:0]	Transmitted error frame number	R
31:16	—	These bits are read as 0.	R

TEFN[15:0] bits (Transmitted error frame number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment condition]

Increment when frame transmission is completed on tx mhd interface with error.

33.4.3 RMAC Interrupt Registers

33.4.3.1 MEIS : Error Interrupt Status Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0200

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	FOES	FUES	FFS	RPOOMS	FRCES	CFCES	FFMES	FCMCES	PNAES	PDES	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CTLES1 to CTLES0		—	RPOES	REOES	FCES	BFES	TBCIS	TCES	FCDS	PFRROS	PRES	—	TSLS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TSLS	Transmission Stream Lost Status Flag When using Cut through, this flag set condition may be due to the state ([COMA] CAEIS0.BPOPS) where all Buffer pointers are used. Please use the Watermark function so that Buffer Pool Out of Pointer Status does not occur. If it gets this error with Buffer Pool Out of Pointer Status using Cut through (it may get hung-up in the transmit state), initialize the state with Emergency reset flow [TOP].	R/W*1
1	—	This bit is read as 0.	R
2	PRES	Pause or PFC Frame Reception Error Status Flag	R/W*1
3	PFRROS	Pause or PFC Frame Retransmit Retry Over Status Flag	R/W*1

Bit	Symbol	Function	R/W
4	FCDS	False Carrier Detection Status Flag	R/W*1
5	TCES	TX CRC Error Status Flag	R/W*1
6	TBCIS	TX Bad CRC Insertion Status Flag	R/W*1
7	BFES	Bad Fragment Error Status Flag When C-fragment is received at very first time before any valid S-fragment is received or C-fragment is received after frame termination is occurred before any valid S-fragment is received, then RMAC will discard the fragment and this error status flag will not be set. For Error status flag to get set, RMAC should have received one valid S-fragment before error condition (bad fragment error) has occurred.	R/W*1
8	FCES	Frame Count Error Status Flag When C-fragment is received at very first time before any valid S-fragment is received or C-fragment is received after frame termination is occurred before any valid S-fragment is received, then RMAC will discard the fragment and this error status flag will not be set. For Error status flag to get set, RMAC should have received one valid S-fragment before error condition (frame count error) has occurred.	R/W*1
9	REOES*2	E-Frame Overflow Error Status Flag When frame reception is already ongoing and buffer overflow occurs i.e. CABPPCM.RPC = 0, RMAC adds one byte padding to the reception error Frames to terminate the protocol internally. When new frame is received, during buffer overflow i.e. CABPPCM.RPC = 0, the incoming frame will be rejected completely. 0: No overflow error 1: Overflow error occurred during e-frame reception.	R/W*1
10	RPOES*2	P-Frame Overflow Error Status Flag When frame reception is already ongoing and buffer overflow occurs i.e. CABPPCM.RPC = 0, RMAC adds one byte padding to the reception error Frames to terminate the protocol internally. When new frame is received, during buffer overflow i.e. CABPPCM.RPC = 0, the incoming frame will be rejected completely. 0: No overflow error 1: Overflow error occurred during p-frame reception.	R/W*1
11	—	This bit is read as 0.	R
13:12	CTLES1 to CTLES0	Captured Timestamp Lost Error Status Flag n (n = 0 to 1)	R/W*1
19:14	—	These bits are read as 0.	R
20	PDES	PHY Data Error Status Flag	R/W*1
21	PNAES	PHY Nibble Alignment Error Status Flag	R/W*1
22	FCMCES	FCS/mCRC Error Status Flag	R/W*1
23	FFMES	Final Fragment Missing Error Status Flag	R/W*1
24	CFCES	C Fragment Count Error Status Flag	R/W*1
25	FRCES	Fragment Count Error Status Flag	R/W*1
26	RPOOMS	Reception Partially out of Operation Mode Status Flag This error has nothing to do with partial rejection due to buffer overflow. E-Frames can only be fragmented/partialized by buffer overflows and it is not affected by partial out of operation.	R/W*1
27	FFS	Frame Filtered Status Flag	R/W*1
28	FUES	Undersize Error Status Flag	R/W*1
29	FOES	Oversize Error Status Flag	R/W*1
31:30	—	These bits are read as 0.	R

Note: This interrupt register is mapped to rmc_meis_int interrupt wire.
Note 1. Read value differs from written value.
Note 2. HW: Pulse is generated per 1 frame although multiple deassertion is generated.

TSLS bit (Transmission Stream Lost Status Flag)

[Setting condition]

HW: when MHD do not provide the transmitted data timely. In this case an invalid FCS is transmitted. (only for e-frames)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

PRES bit (Pause or PFC Frame Reception Error Status Flag)

[Setting condition]

HW: When Pause or PFC frame is received with lower than minimum pause/pfc frame length.

Minimum PAUSE Length: 18Byte (MRGC.RCPT==0) or 22 Byte ((MRGC.RCPT==1)

Minimum PFC Length: 34Byte (MRGC.RCPT==0) or 38 Byte ((MRGC.RCPT==1)

HW: When PAUSE/PFC frame is received with fcs error in MRGC.RFCFE==0.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

PFRROS bit (Pause or PFC Frame Retransmit Retry Over Status Flag)

[Setting condition]

HW: when the total number of Pause (pfc) transmit count reaches the configured upper limit and Pause time expires.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

FCDS bit (False Carrier Detection Status Flag)

[Setting condition]

HW: When PHY-LSI has detected a false carrier on the line in case of MII and GMII.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

TCES bit (TX CRC Error Status Flag)

[Setting condition]

HW: When CRC error occurred.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

TBCIS bit (TX Bad CRC Insertion Status Flag)

[Setting condition]

HW: A bad CRC is inserted from the upper layer (e.g. MHD).

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

BFES bit (Bad Fragment Error Status Flag)

[Setting condition]

HW: C fragment has been detected without receiving S fragment.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

FCES bit (Frame Count Error Status Flag)

[Setting condition]

When S fragment has been received in the wrong order.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

REOES bit (E-Frame Overflow Error Status Flag)

[Setting condition]

HW: The acknowledgment signal was not received successfully from an upper layer (e.g. MHD) during e-frame reception.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

RPOES bit (P-Frame Overflow Error Status Flag)

[Setting condition]

HW: The acknowledgment signal was not received successfully from an upper layer (e.g. MHD) during p-frame reception.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

CTLESn bits (Captured Timestamp Lost Error Status Flag n (n = 0 to 1))

[Setting condition]

HW: When captured timestamp is lost.

This bit is fixed to 0

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

[Error recovery]

No recovery. Timestamp is lost.

PDES bit (PHY Data Error Status Flag)

[Setting condition]

HW: When frame is received with error.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

PNAES bit (PHY Nibble Alignment Error Status Flag)

[Setting condition]

HW: When residual-bit is received.

[Clearing condition]

SW: Writing 1 to this register will clear it.

FCMCES bit (FCS/mCRC Error Status Flag)

[Setting condition]

HW: When unexpected FCS/mCRC are received.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

FFMES bit (Final Fragment Missing Error Status Flag)

[Setting condition]

HW: When an S-fragment is received even though the previous fragment has been terminated by a mCRC.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

CFCES bit (C Fragment Count Error Status Flag)

[Setting condition]

HW: When a C fragment not corresponding to the current frame is received For example: S0-C0-C0-C1.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

FRCES bit (Fragment Count Error Status Flag)

[Setting condition]

HW: When a C-fragment is received with a bad fragment count field.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

RPOOMS bit (Reception Partially out of Operation Mode Status Flag)

[Setting condition]

HW: When a frame is being received while RMAC is moving out of operation mode (suspending).

1. Initial or intermediate fragment of p-frame is receiving.
2. E-frame is receiving when initial p-frame is already received and last fragment of p-frame is not received.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

FFS bit (Frame Filtered Status Flag)

[Setting condition]

HW: When frame did not pass the RMAC filters

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

FUES bit (Undersize Error Status Flag)

[Setting condition]

HW: When too short frame is received. (When the received frame size is shorter than the setting in MRFSCE.EMNS and MRFSCP.PMNS)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

FOES bit (Oversize Error Status Flag)

[Setting condition]

HW: When too big frame is received. (When the received frame size is bigger than the setting in MRFSCE.EMXS and MRFSCP.PMXS)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this register will clear it.

Table 33.5 Transmission error list

Error type	Event	Status Bit
TX Bad CRC Insertion Status	A packet has been received for transmission by RMAC with an error and a wrong FCS has been inserted.	MEIS.TBCIS
TX CRC Error Status	A packet which included a presupposed valid FCS had a faulty FCS.	MEIS.TCES
Pause frame Retransmit Retry Over Status	A Pause or PFC retransmit count reaches the configured upper limit(MTPFC.APFRLV) and Pause time expires.	MEIS.PFRROS
Transmission Stream Lost Status	An e-frame data has not been provided on time to RMAC.	MEIS.TSLS

Table 33.6 Reception error list

No	Error type	Event	Frame status bit	Status register
1	PHY data error	Received a data with error.	Bit 0	MEIS.PDES
2	PHY nibble alignment error	Received residual-bit.	Bit 1	MEIS.PNAES
3	FCS/mCRC error	Received unexpected FCS field value.	Bit 2	MEIS.FCMCES
4	Final fragment missing error	Occurs when an S-fragment is received even though the previous fragment has been terminated by a mCRC.	Bit 3	MEIS.FFMES
5	C fragment count error	Occurs when a C fragment not corresponding to the current frame is received. For example: S0-C0-C0-C1	Bit 4	MEIS.CFCES
6	Fragment count error	Occurs when a C-fragment is received with a bad fragment count field.	Bit 5	MEIS.FRCES
7	Reception partially out of operation mode	Occurs when a frame is being received while RMAC is moving out of operation mode.	Bit 6	MEIS.RPOOMS
8	Frame filtered	The frame did not pass the RMAC filters.	Bit 7	MEIS.FFS
9	Undersize error	The frame is too small.	Bit 8	MEIS.FUES
10	Oversize error	The frame is too big.	Bit 9	MEIS.FOES
11	Buffer overflow error	Occurs when the rx done signal has been deasserted during frame reception.	Bit 12	MEIS.REOES MEIS.RPOES
12	Frame Count Error Status	Occurs when a wrong S-frame order is received. For example: S0-S1-S2-S1	—	MEIS.FCES
13	Bad Fragment Error Status	Occurs when a C fragment has been detected without receiving S fragment.	—	MEIS.BFES
14	False Carrier Detection Status	Occurs when PHY-LSI has detected a false carrier on the line.	—	MEIS.FCDS

33.4.3.2 MEIE : Error Interrupt Enable Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0204

26	RPOOME	Reception Partially out of Operation Mode Enable	R/W*1
27	FFE	Frame Filtered Enable	R/W*1
28	FUEE	Undersize Error Enable	R/W*1
29	FOEE	Oversize Error Enable	R/W*1
31:30	—	These bits are read as 0.	R

Note 1. Read value differs from written value.

TSLE bit (Transmission Stream Lost Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.TSLD will clear this bit.

PREE bit (Pause or PFC Frame Reception Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.PRED will clear this bit.

PFRROE bit (Pause or PFC Frame Retransmit Retry Over Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.PFRROD will clear this bit.

FCDE bit (False Carrier Detection Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.FCDD will clear this bit.

TCEE bit (Tx CRC Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.TCED will clear this bit.

TBCIE bit (TX Bad CRC Insertion Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.TBCID will clear this bit.

BFEE bit (Bad Fragment Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.BFED will clear this bit.

FCEE bit (Frame Count Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.FCED will clear this bit.

REOEE bit (E-Frame Overflow Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.REOED will clear this bit.

RPOEE bit (P-Frame Overflow Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.RPOED will clear this bit.

CTLEEn bits (Captured Timestamp Lost Error Enable n (n = 0 to 1))

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.CTLED will clear this bit.

PDEE bit (PHY Data Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.PDED will clear this bit.

PNAEE bit (PHY Nibble Alignment Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.PNAED will clear this bit.

FCMCEE bit (FCS/mCRC Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.FCMCED will clear this bit.

FFMEE bit (Final Fragment Missing Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.FFMED will clear this bit.

CFCEE bit (C Fragment Count Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.CFCED will clear this bit.

FRCEE bit (Fragment Count Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.FRCED will clear this bit.

RPOOME bit (Reception Partially out of Operation Mode Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.RPOOMD will clear this bit.

FFE bit (Frame Filtered Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.FFD will clear this bit.

FUEE bit (Undersize Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

Writing 1 to MEID.FUED will clear this bit.

FOEE bit (Oversize Error Enable)

[Setting condition]

Writing 1 to one of this bit will set it.

[Clearing condition]

SW: Writing 1 to MEID.FOED will clear this bit.

33.4.3.3 MEID : Error Interrupt Disable Register

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0208

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	FOED	FUED	FFD	RPOOMD	FRCED	CFCED	FFMED	FCMCED	PNAED	PDED	—	—	—	—

25	FRCED	Fragment Count Error Disable Writing 1 to this register will clear MEIE.FCEE register.	R/W*1
26	RPOOMD	Reception Partially out of Operation Mode Disable Writing 1 to this register will clear MEIE.RPOOME register.	R/W*1
27	FFD	Frame Filtered Disable Writing 1 to this register will clear MEIE.FFE register.	R/W*1
28	FUED	Undersize Error Disable Writing 1 to this register will clear MEIE.FUEE register.	R/W*1
29	FOED	Oversize Error Disable Writing 1 to this register will clear MEID.FOEE register.	R/W*1
31:30	—	These bits are read as 0.	R

Note 1. Read value differs from written value.

33.4.3.4 MMIS0 : Monitoring Interrupt Status Register 0

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0210

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	VFRS	LVFS	LVSS	PIDS	PLSCS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PLSCS*2*3	PHY Link Signal Change Status Flag	R/W*1
1	PIDS*2*4	PHY Interrupt Detection Status Flag	R/W*1
2	LVSS*2*5	Link Verification Succeed Status Flag	R/W*1
3	LVFS*2*5	Link Verification Failed Status Flag	R/W*1
4	VFRS*2*5	Verify Frame Reception Status Flag	R/W*1
31:5	—	These bits are read as 0.	R

Note: This interrupt register is mapped to rmc_mmis0_int interrupt wire.
Note 1. Read value differs from written value.
Note 2. SW: Writing 0 to this bit has no effect.
Note 3. SW: To check the current link state, refer to the link status pin state bit in the PHY link status register (MPIM.PLS).
Note 4. HW: This flag could be asserted unintentionally before configuring PHY interrupt polarity (MPIC.PIP) into the right value. In the phase, this flag should be ignored.
Note 5. It’s no effect when suspending, e.g. an upper layer (e.g. MHD) is not in OPERATION state.

PLSCS bit (PHY Link Signal Change Status Flag)

[Setting condition]

HW: When the value of link status pin (rmc_phy_link port) is changed.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

PIDS bit (PHY Interrupt Detection Status Flag)

[Setting condition]

HW: PHY interrupt pin (rmc_phy_int port) is active level.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

LVSS bit (Link Verification Succeed Status Flag)

[Setting condition]

HW: When Link Verification process succeed.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

LVFS bit (Link Verification Failed Status Flag)

[Setting condition]

HW: When Link Verification process failed. It means that the remote node is not able to handle Preemptable frames.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

VFRS bit (Verify Frame Reception Status Flag)

[Setting condition]

HW: When valid verify frame has been received.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

33.4.3.5 MMIE0 : Monitoring Interrupt Enable Register 0

Base address: RMACm = 0x403C_B000 + 0x2000 × m (m = 0, 1)
RMACm_NS = 0x503C_B000 + 0x2000 × m (m = 0, 1)

Offset address: 0x0214

The result of write access is reflected to each SFR bit after “5clk + 4clk_phy_rx” in Worst Case in RMAC.
Do not make write access continuously. Please wait following time for re-write access.

33.5 Register Utilizations

33.5.1 Operation Modes

Operational mode is controlled. Please refer to IPS. RMAC received a mode control signal for controlling operational mode of RMAC.

33.5.1.1 Frame Handling

In transmission, this IP transmits all frames from an upper module (e.g. MHD) when this IP is in operation state, e.g. when MHD is in OPERATION state. This IP receives an e-frame and a p-frame from the MHD.

In reception, this IP only receives frames from PHY when this IP is in operation state, e.g. when MHD is in OPERATION state., and outputs them to the upper module (e.g. MHD). In other modes, this IP discards all received frames from PHY internally, and does not output them to the upper module.

When the system supports preemption and the Mode change is executed, this IP of the Rx side behaves like the following figures.

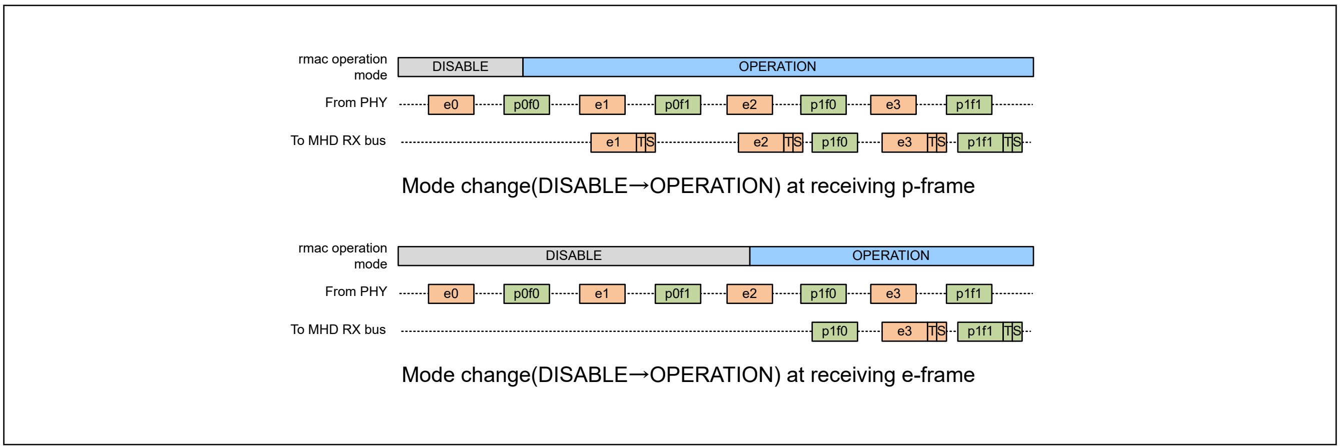

Figure 33.3 Mode change (DISABLE→OPERATION) on Rx

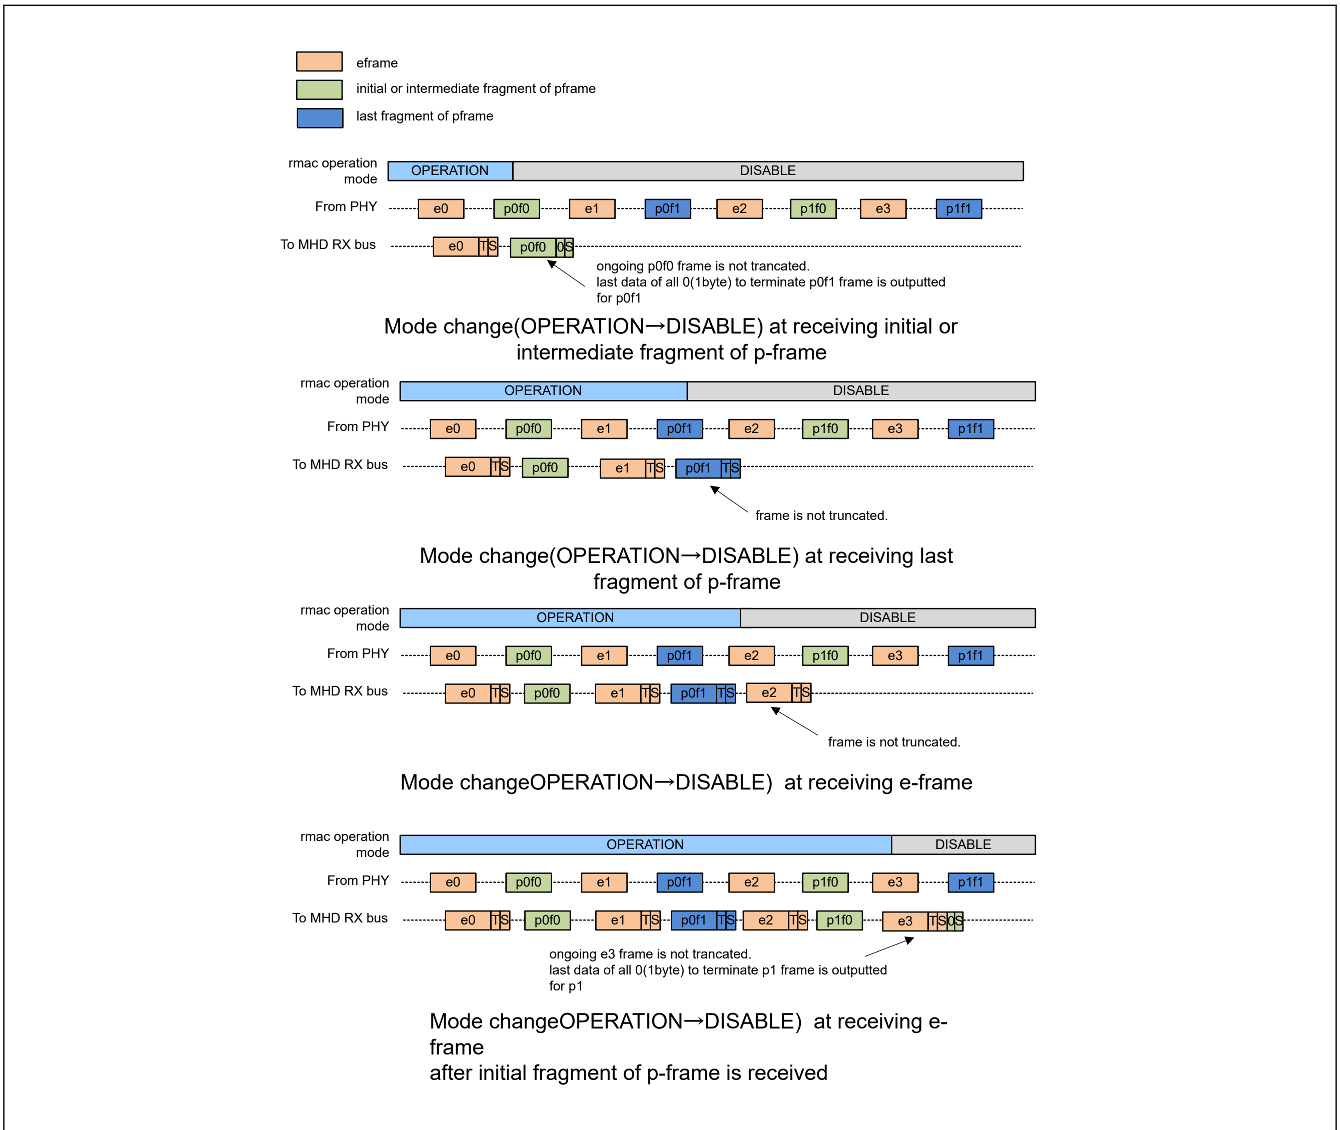

Figure 33.4 Mode change (OPERATION→DISABLE) on Rx

33.5.2 Software Flows

Restrictions:

SW: Please follow to the flow in this section.

33.5.2.1 Software Flow Legend

Software flow legend is described in Figure 33.5.

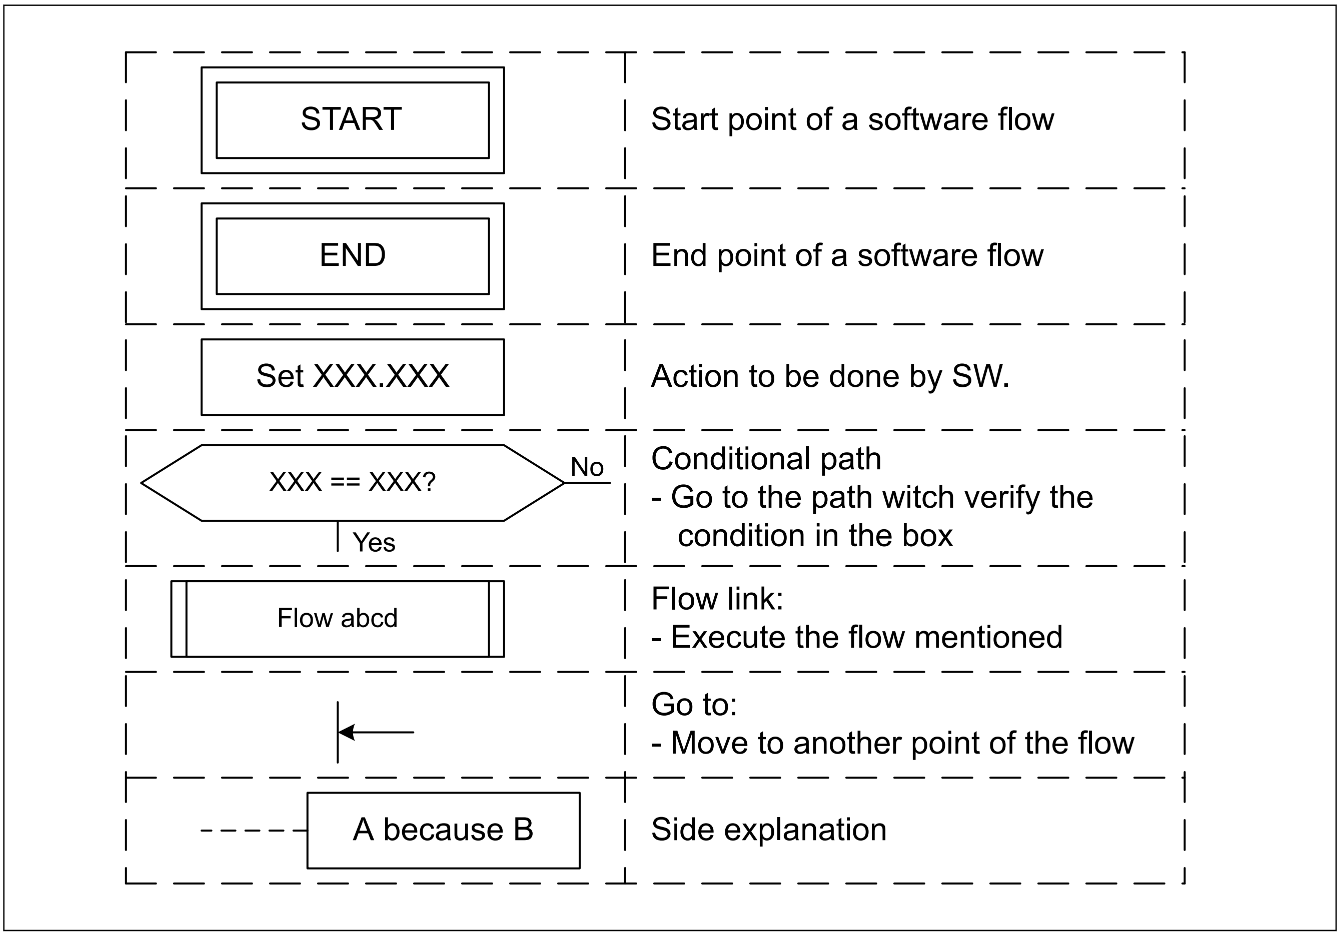

Figure 33.5 Software flow legend

33.5.2.2 Initialization Flow

The figure below shows the initialization flow.

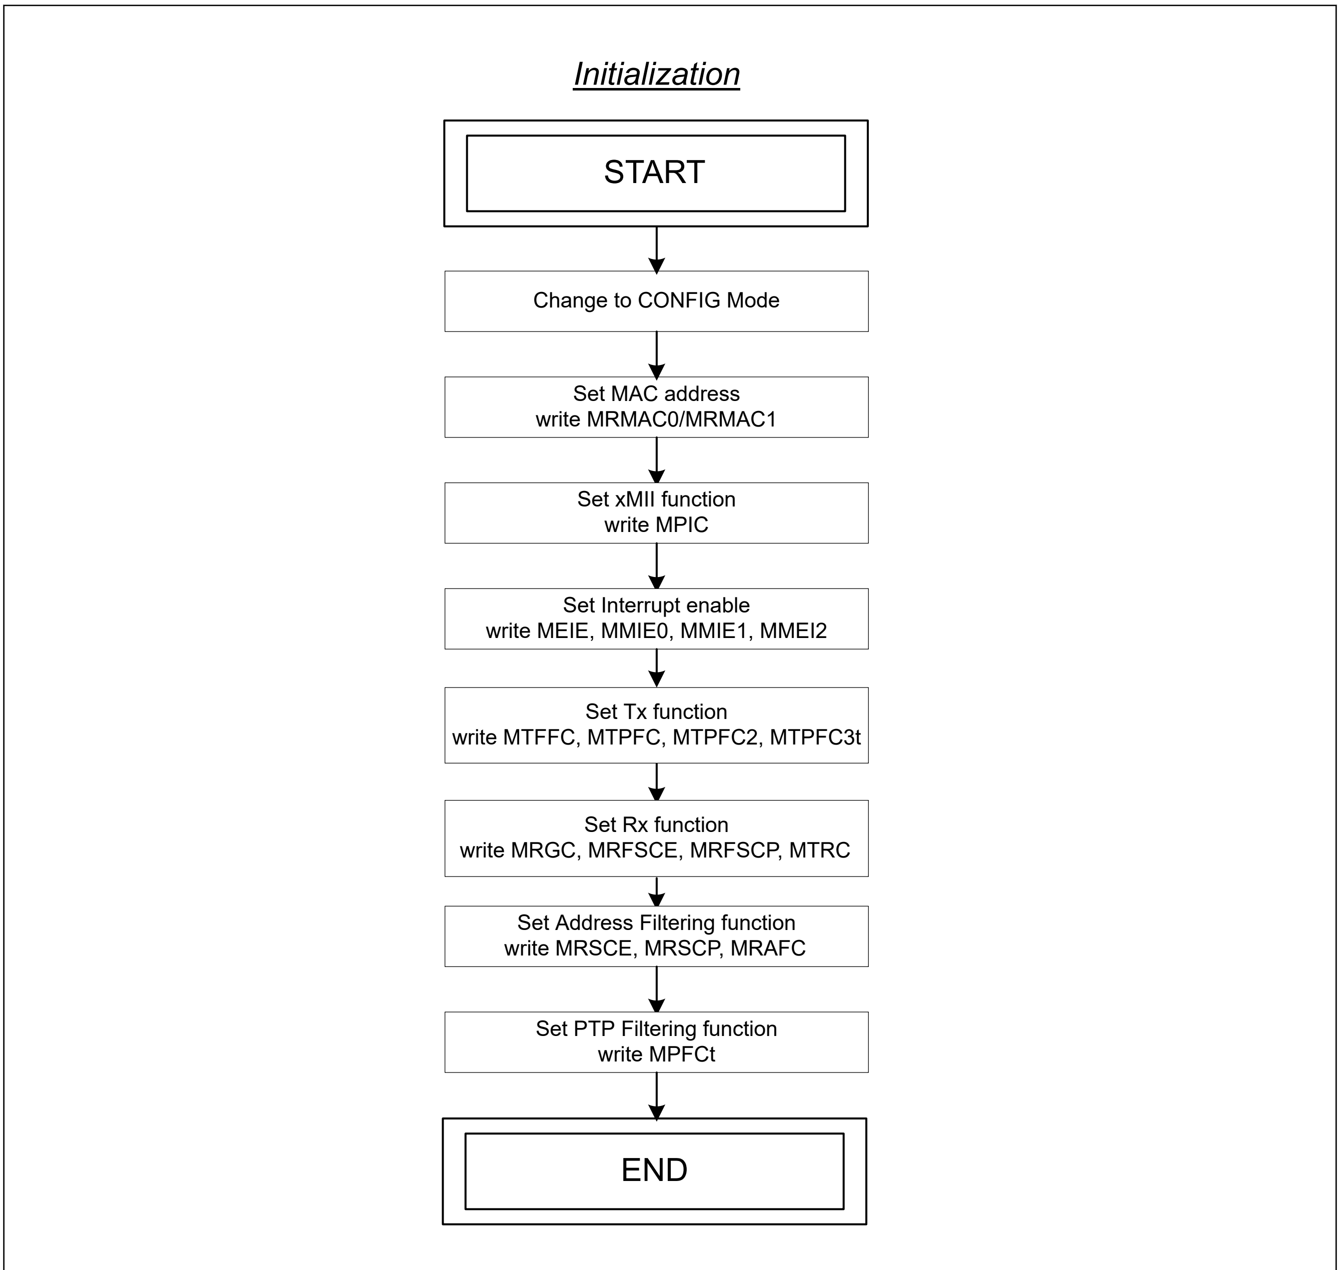

Figure 33.6 Initialization flow

33.5.2.3 Interrupt Handling Flow

Interrupt handling flow can be used in any mode except RESET mode.

The figure below shows the interrupt handling flow.

Restrictions:

This flow is not usable in RESET modes.

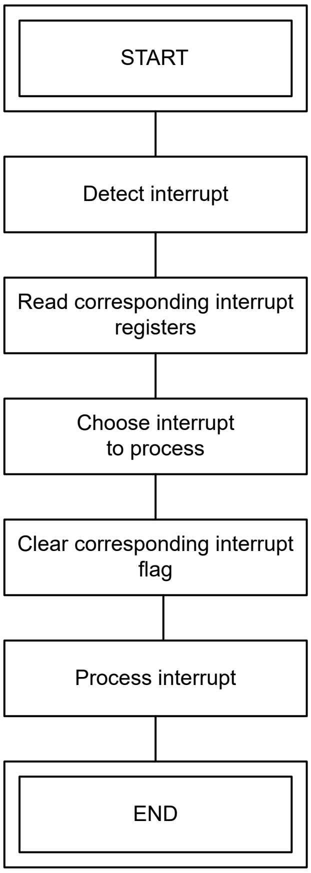

Figure 33.7 Interrupt handling flow

33.5.2.4 PHY MDIO and eMDIO Access Flows

The figure below shows the PHY MDIO and eMDIO access flow.

Restrictions:

This flow is not usable in RESET modes.

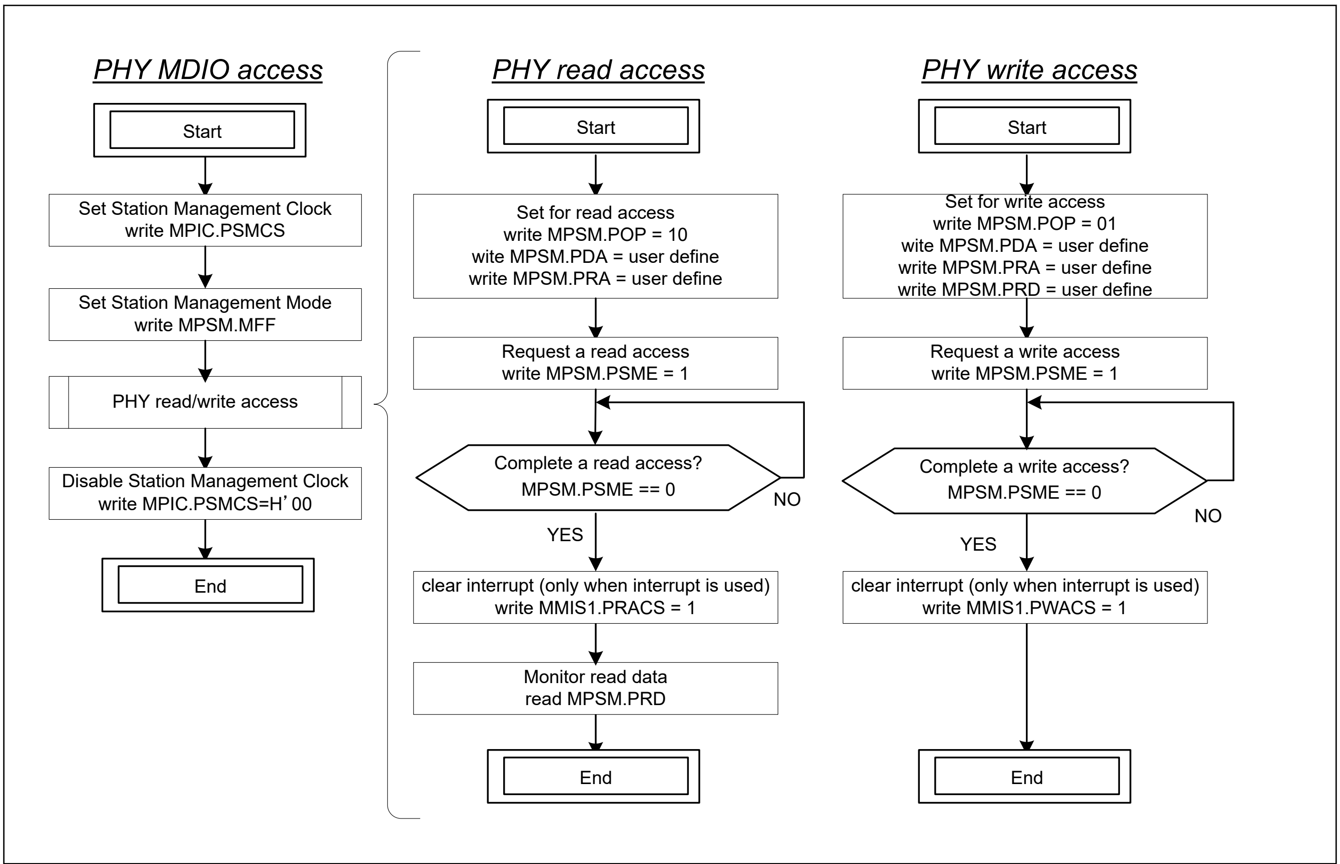

Figure 33.8 PHY MDIO access flow

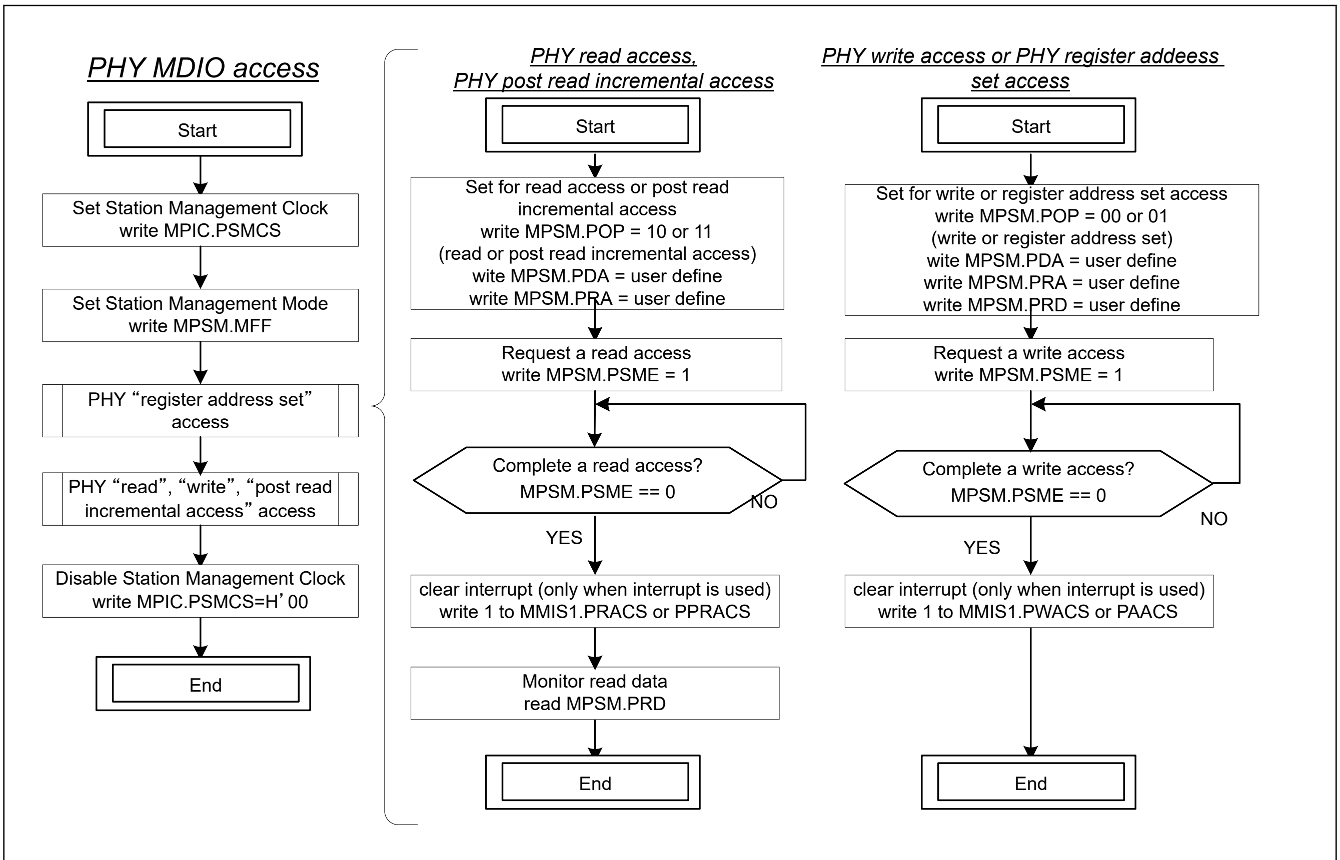

Figure 33.9 PHY eMDIO access flow

33.5.2.5 LPI Transition for Tx Port

Figure 33.10 shows the LPI transition flow. When resumed from LPI, the transmission should be requested until PHY wake-up completed.

Restrictions:

This flow is not usable in RESET modes.

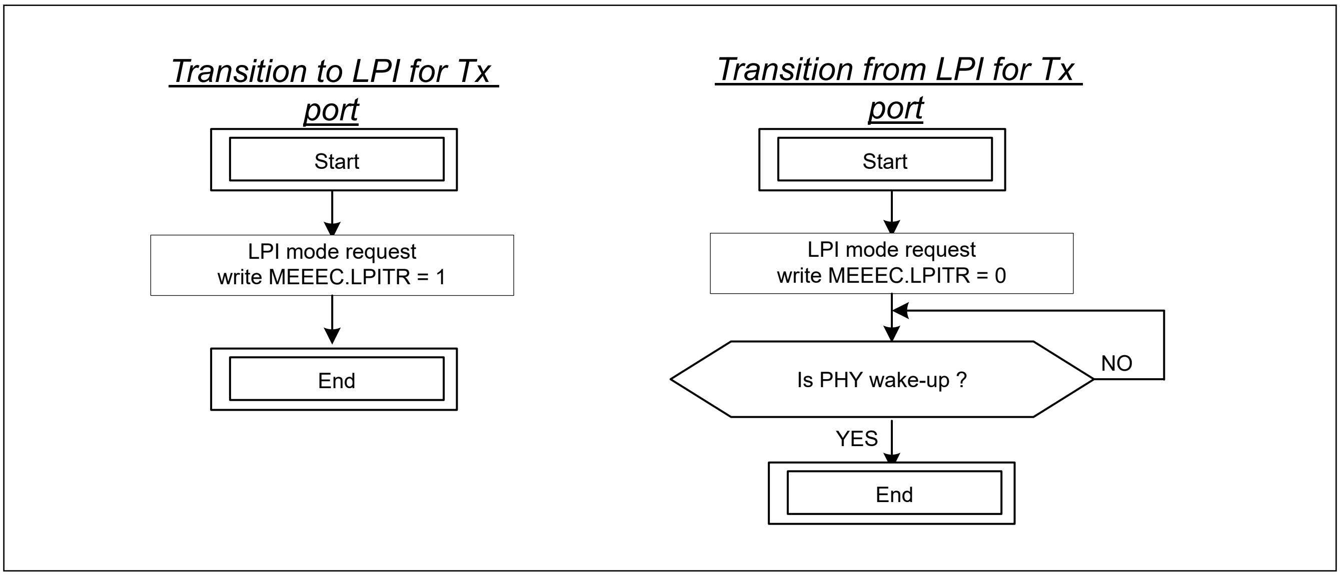

Figure 33.10 LPI transition for Tx port

33.5.2.6 LINK Verification

The figure below shows Link Verification flow.

Restrictions:

This flow is usable in OPERATIONAL mode.

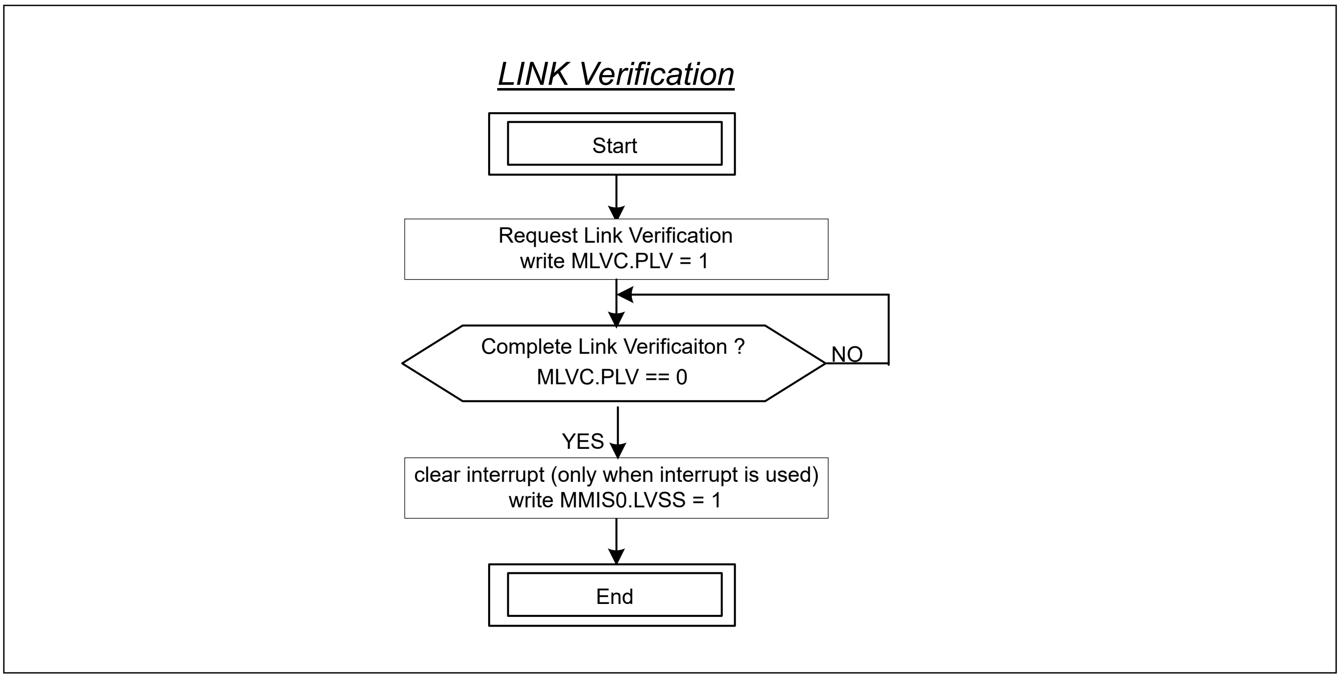

Figure 33.11 Link Verification flow

33.5.2.7 Called Software Flows

The flows described in this section can only be called from other flows thanks to a "flow link" box (Figure 33.5) and cannot be used alone.

33.5.3 Register Writable Without Software Flow

This section describes registers that have not been described so far. These registers can be changed dynamically. (However, it is necessary that the initial settings such as the clock enabling have been completed.)

33.6 Functional Details

33.6.1 Preemption

"Preemption" is the function specified in IEEE802.3.br. This function separates an ethernet frame to several fragments like Figure 33.12. This figure shows an example of preemption of 3 fragments. Preemption for only two fragments or over three fragments is possible.

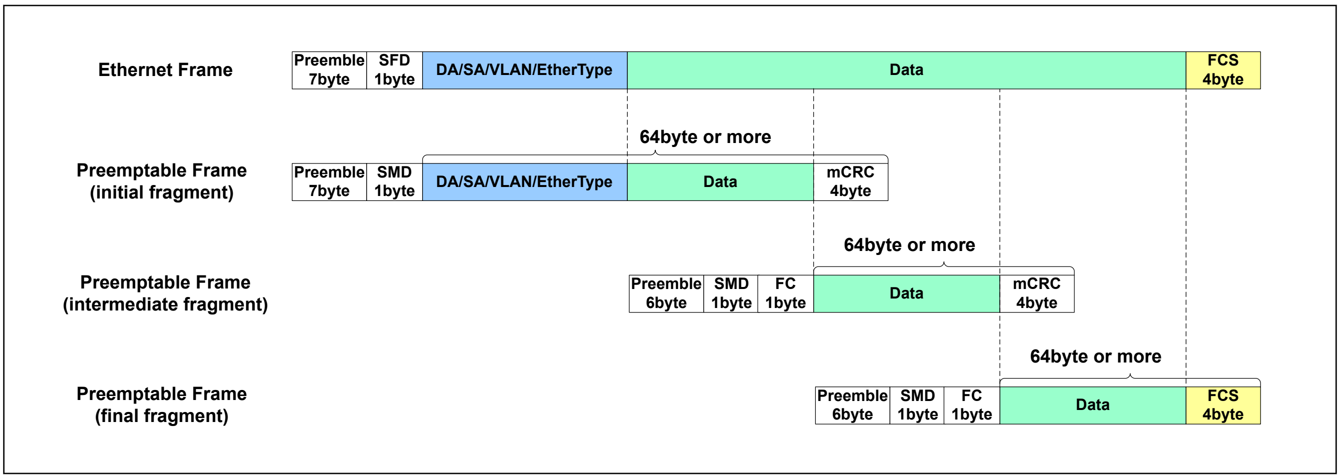

Figure 33.12 Outline of preemption

This function is handled by this IP and an upper module (e.g. MHD).

On the Tx Side, This IP only generates the fields of "Preamble", "SMD", "FC" and "mCRC" of the Preemptable frame complying with the rule of IEEE802.3.br. The upper module (e.g. MHD) has to separate a transmit frame appropriately.

On the Rx Side, this IP removes the fields of "Preamble", "SMD", "FC" and "mCRC" of the Preemptable frame and outputs the fields of "DA/SA/VLAN/EtherType", "Data" and "FCS" (To output FCS part whether or not it is selectable by MRGC.RCPT) to upper module. The upper module (e.g. MHD) has to re-assemble a received frame.

"Preemption" is effective to prevent decreasing of throughput for high priority frame by transferring of low priority frames. Figure 33.13 shows one of examples. The software does not care the length of Low priority frames.

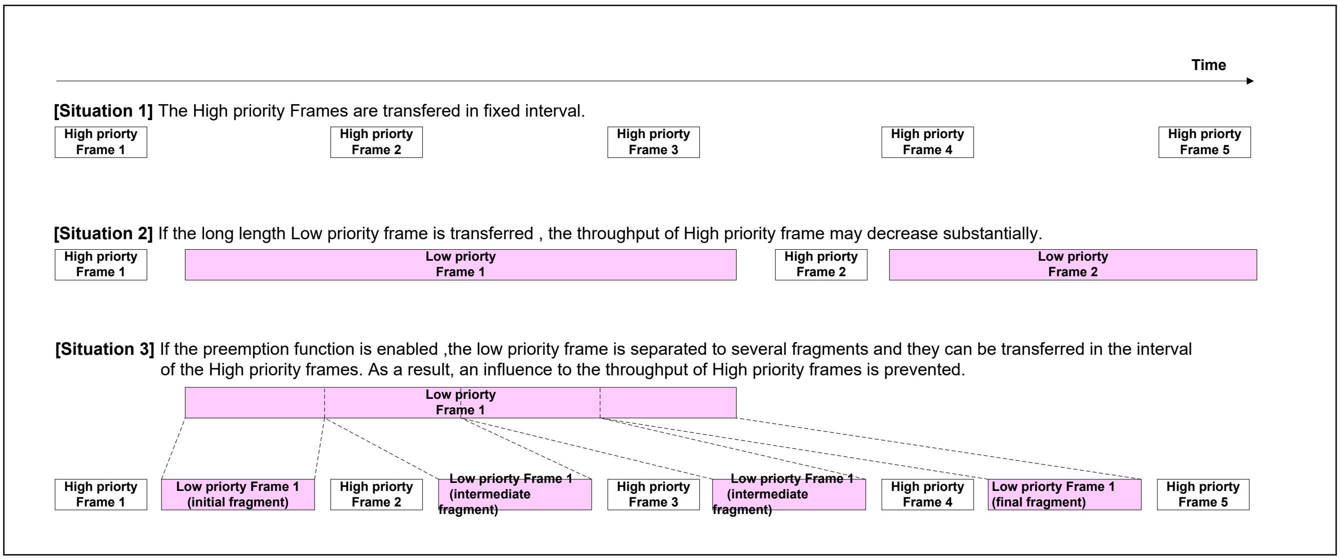

Figure 33.13 Effective of Preemption

To use “Preemption”, the Link Verification process should be executed on the system level.

Note: This IP does not hold an information whether the preemption function is valid or not in the system.

33.6.1.1 Link Verification

This IP supports Link Verification process of Figure 33.14.

By setting MLVC.PASE this IP answers to a Verify frame by a Response frame to authorize the linked IP that preemption is possible. When a valid Verify frame is received, MMIS.VFRS is asserted as an interrupt.

When MLVC.PLV is set to 1, this IP starts to transmit Verify frame. The transmission attempts 3 times with the configured interval (MLVC.LVT) until Response frame is received from remote node. If the received Response frame is valid, MMIS.LVSS is asserted as an interrupt.

If not receiving Response frame after attempted 3 times, MMIS.LVFS is asserted as an interrupt.

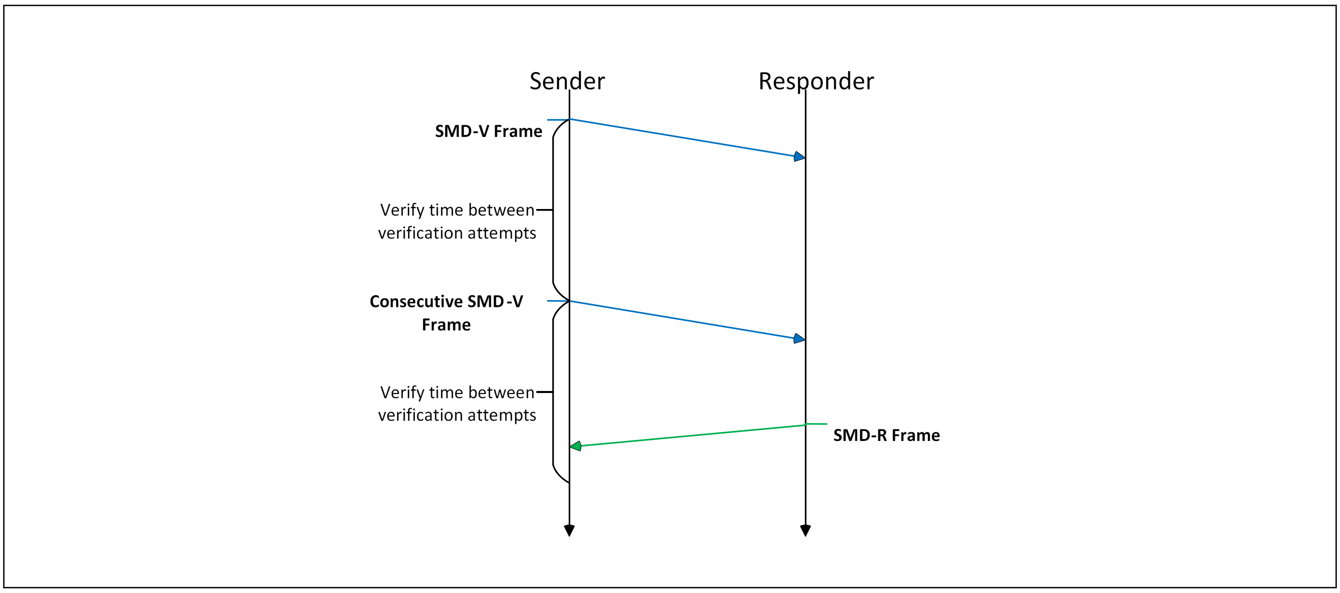

Figure 33.14 Example of link verification flow

33.6.2 Flow Control

This IP supports the following two types of Flow Control functions.

1. Flow Control specified in IEEE 802.3 for a full-duplex operation using a PAUSE frame.

2. Priority Based Flow Control specified in IEEE 802.1Qbb for a full-duplex operation using a PFC frame.

33.6.2.1 Flow Control by PAUSE Frame

This Flow Control is only for a full-duplex operation and this consists of Transmission and Reception of a PAUSE frame.

33.6.2.1.1 Transmission of PAUSE Frame

1. While MTFFC.FCM = 0 and MTPFC.PT[15:0] ≠ 0, the transmission function of a PAUSE frame is enabled. This IP transmits a PAUSE frame as described in Figure 33.15 by asserting a transmission request. The value of MTPFC.PT[15:0] is used for "PAUSE_TIME" field, and MRMAC0 and MRMAC1 are used for "SA" field.

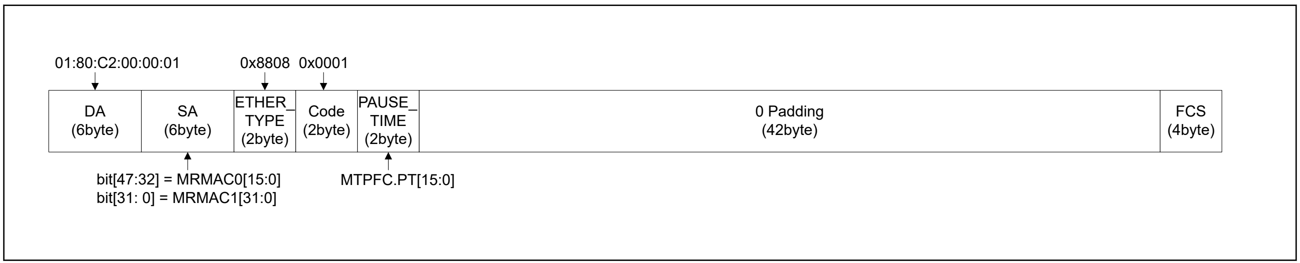

Figure 33.15 PAUSE frame format

- Auto PAUSE Frame
  When MTPFC.PFM = 0, this IP uses a hardware pause transmission request as a transmit request. After transmitting the PAUSE Frame, MAPFTCT is incremented.
- Manual PAUSE Frame
  When MTPFC.PFM = 1, this IP uses MTPFC2.MPFR as a transmit request. After transmitting the PAUSE Frame, MMPFTCT is incremented.

When the transmit request of the PAUSE frame is asserted while the IP is transmitting the other frame, the PAUSE frame is transmitted after the transmitting frame.

2. While the transmit request is asserted, a PAUSE frame is continuously re-transmitted at a fixed interval of time configured by MTPFC.PFRT. If the number of re-transmission reaches the value of MTPFC.PFRLV, this IP sets MEIS.PFRROS to 1 for an interrupt. Even if the interrupt is detected, this IP continues re-transmission of a PAUSE frame while the transmit request is asserted.
3. After deasserting the transmission request, this IP stops a transmission of PAUSE frame. At that time, when MTPFC2.PFTTZ = 1 and an internal counter to count a pausing-period exceeds the value of MTPFC.PFRT (*), this IP transmits one more a PAUSE frame with "PAUSE_TIME" field as 0.

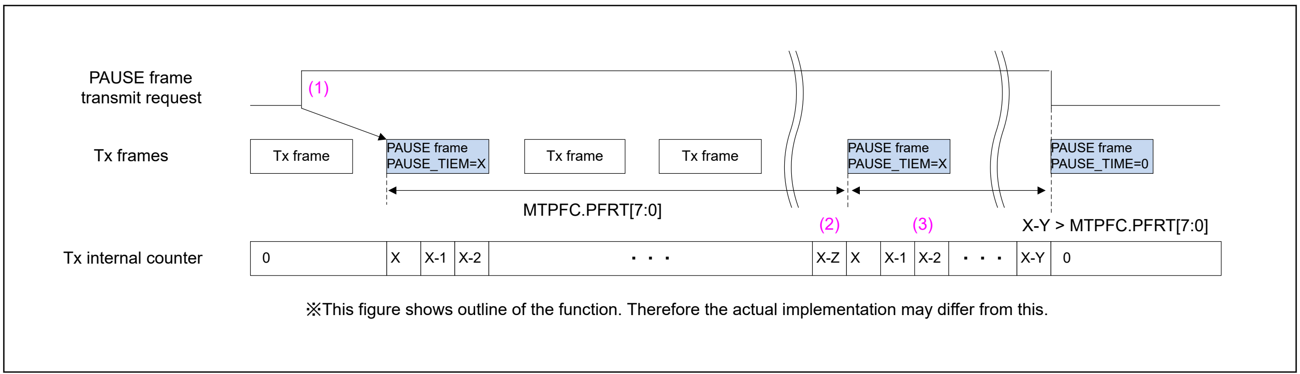

Figure 33.16 Transmission of PAUSE frame

33.6.2.1.2 Reception of PAUSE Frame

1. While MRGC.PFRC = 1, this IP receives a PAUSE frame and it starts internally counting a pausing-period specified by "PAUSE_TIME" field of a received PAUSE frame. While counting the pausing-period, notification of pause frame reception to an upper layer (e.g. MHD) and MRPFM.PTCA is asserted. And any transmissions except for a

Verify_packet, a Respond_packet, and a PAUSE frame are inhibited. When this IP receives a PAUSE frame while transmitting any frames, transmissions are inhibited after the transmission completion.

2. When a PAUSE frame with "PAUSE_TIME ≠ 0" is received again before expiring the internal pausing-period, the internal counter is updated to that value.
3. When the internal pausing-period is expired, notification of pause frame reception to an upper layer (e.g. MHD) and MRPFM.PTCA is deasserted.
4. When MRGC.PFRTZ = 1 and PAUSE frame with "PAUSE_TIME = 0" is received before expiring the internal pause-period, the internal counter is cleared. Then notification of pause frame reception to an upper layer (e.g. MHD) and MRPFM.PTCA is deasserted.
In any case, MPFRCT is incremented after receiving a PAUSE frame in MRGC.PFRC = 1. And the received PAUSE frames are discarded internally.

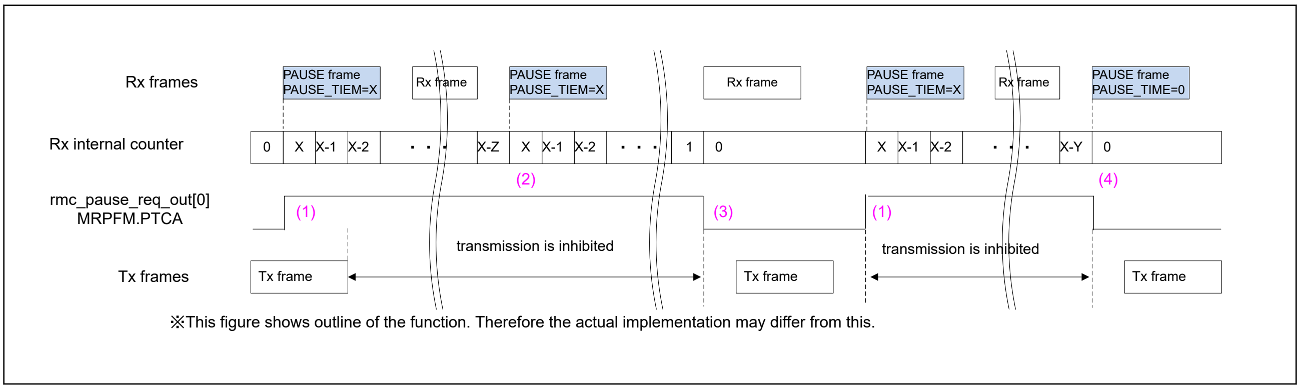

Figure 33.17 Reception of PAUSE frame

33.6.2.2 Flow Control by PFC Frame

This Flow Control is for a full-duplex operation and this consists of Transmission and Reception of a PFC frame.

33.6.2.2.1 Transmission of PFC Frame

When MTFFC.FCM = 1 and MTPFC.PT[15:0] ≠ 0, the transmission function of a PFC frame is enabled.

This IP treats several priorities as one priority-group to transmission of the PFC frame. The number of priority-group is 2. Each priority-group is configured by MTPFC30 and MTPFC31.

This IP transmits a PFC frame as described in Figure 33.18 for each priority-group by asserting a transmission request. The value of MTPFC.PT[15:0] is used for all "PAUSE_TIME" fields. "Priority_Enable" field value is different for each priority-group and the values of MTPFC30.PFCPG and MTPFC31.PFCPG are used for these. And MRMAC0 and MRMAC1 are used for "SA" field. When MTPFC30.PFCPG (or MTPFC31.PFCPG) is set to all 0, this IP does not transmit a PFC frame for the priority-group 0 (or priority-group 1) even when a transmission request is asserted.

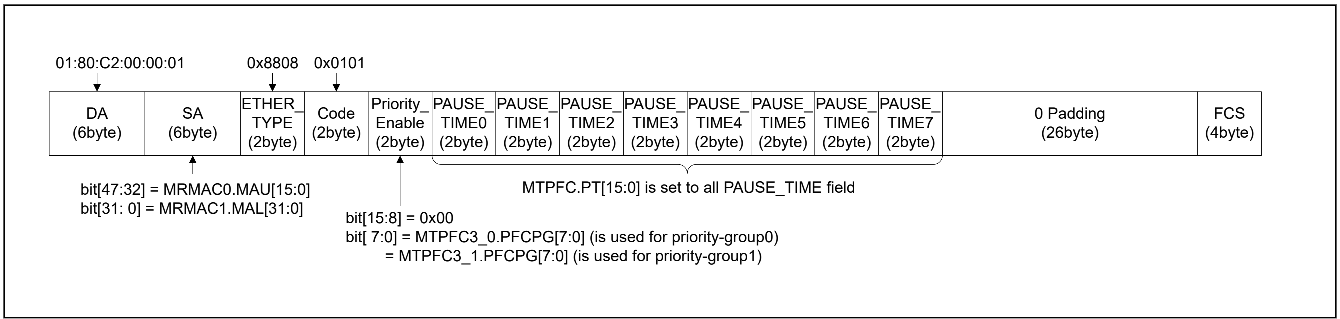

Figure 33.18 PFC frame Format

- Auto PFC Frame
  When MTPFC.PFM = 0, this IP uses a hardware pause transmission request as a transmit request. The bit[0] is for priority-group0 and the bit[1] is for priority-group1. MAPCFTCT0 and MAPCFTCT1 are incremented respectively after transmitting a PFC Frame of each priority-group.

- Manual PFC Frame
  When MTPFC.PFM = 1, this IP uses MTPFC2.MPFCFRn as a transmit request. The bit[0] is for priority-group 0 and the bit[1] is for priority-group 1. MMPCFTCT0 and MMPCFTCT1 are incremented respectively after transmitting a PFC Frame of each priority-group.

If several transmit requests are asserted at same time, one PFC frame which has merged priority_enable information is transmitted.

If several transmit requests are asserted while transmitting other frames, an internal counter is cleared and one PFC frame which has merged priority_enable information is transferred.

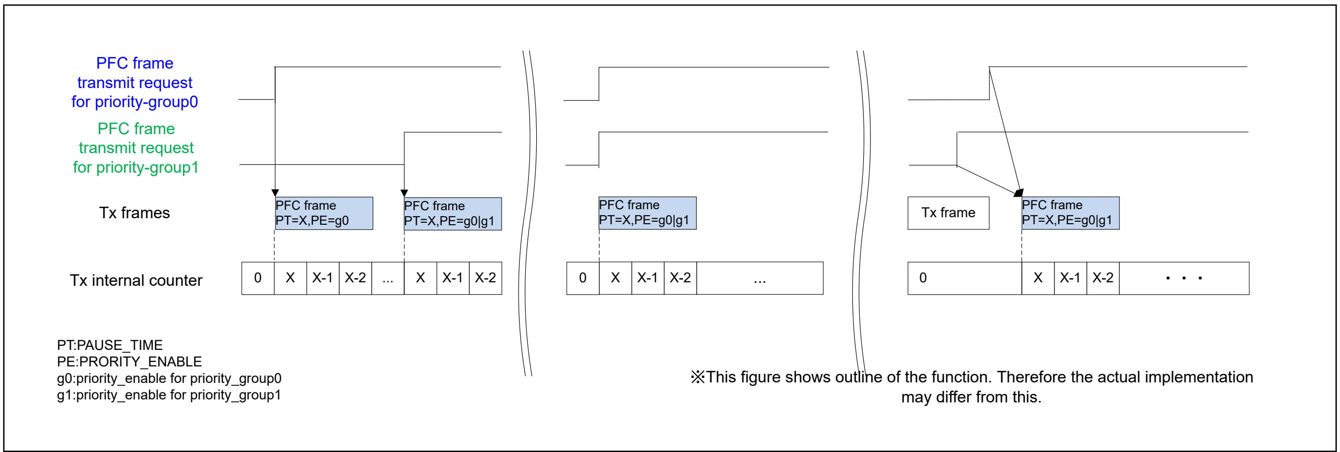

Figure 33.19 Transmitting PFC frame (part 1)

While the transmit request is asserted, a PFC frame corresponding to that request is continuously re-transmitted at a fixed interval configured by MTPFC.PFRT. When the number of re-transmissions for one of priority-groups reaches the value of MTPFC.PFRLV, this IP sets MEIS.PFRROS to 1 for an interrupt. Even when the interrupt is detected, this IP continues re-transmission of a PFC frame while the transmit request is asserted.

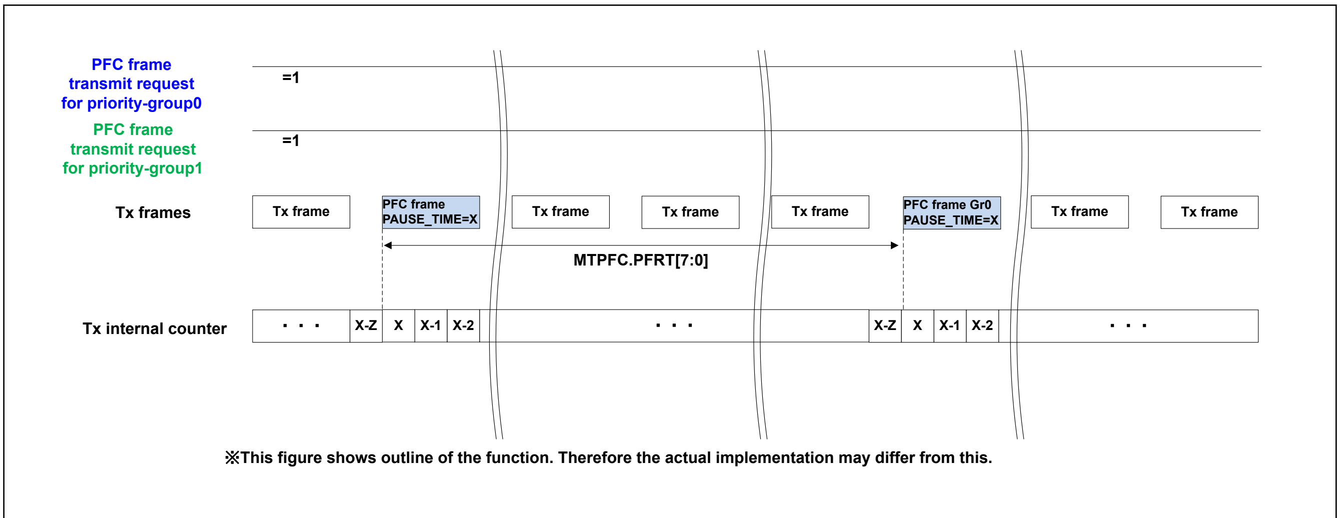

Figure 33.20 Transmitting PFC frame (part 2)

After deasserting the transmission request, this IP stops the transmission of the PFC frame corresponding to that request. At that time, if the corresponding bit of MTPFC2.PFCTTZn for deasserted priority-group request is 1 and an internal counter to count the pausing-period exceeds MTPFC.PFRT (*), this IP transmits one more PFC frame with all “PAUSE_TIME” fields as 0 for that priority-group.

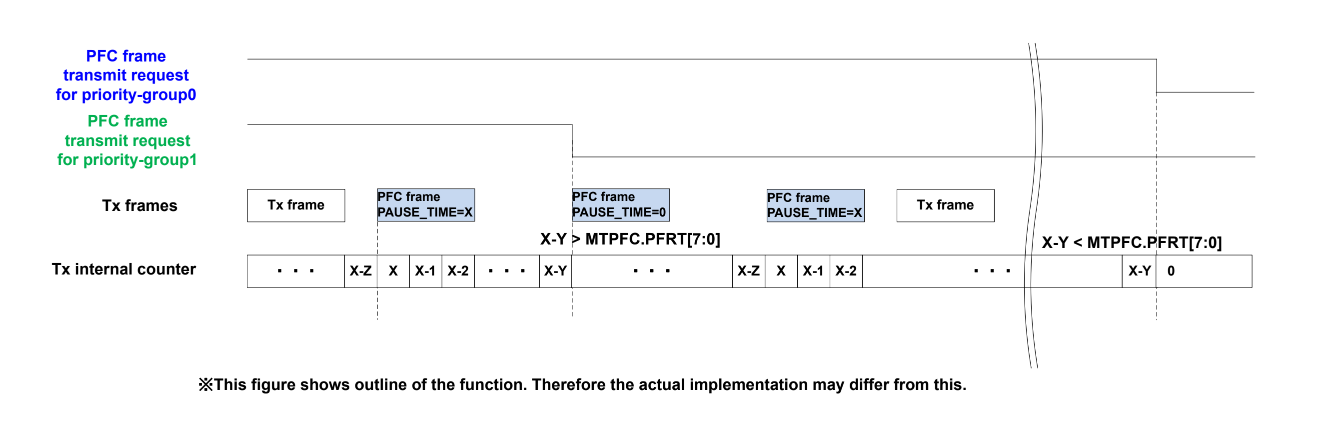

Figure 33.21 Transmitting PFC frame (part 3)

33.6.2.2.2 Reception of PFC Frame

This IP treats several priorities specified in received PFC frames. The number of supported priorities is 8.

1. When this IP receives a PFC frame with a priority-enable field which is corresponding to a priority configured by MRGC.PFCRCn, it starts internally counting a pausing-period for each priority respectively specified by each “PAUSE_TIME” fields of a received PFC frame. During counting the pausing-period, notification of PFC frame reception to an upper layer (e.g. MHD) and MRPFM.PFCTCAn corresponding to each priority are asserted. The bit number is corresponding to priority number.
2. When PFC frame with “PAUSE_TIME ≠ 0” with corresponding to valid “priority_enable” field is received again before expiring the internal pausing-period, the internal counter for that priority is updated to that value.
3. When MRGC.PFRTZ = 1 and PFC frame with “PAUSE_TIME = 0” with corresponding to valid “priority_enable” field is received before expiring the internal pause-period, the internal counter for that priority is cleared and notification of pause frame reception to an upper layer (e.g. MHD) and MRPFM.PFCTCAn for that priority is deasserted.
4. When the internal pausing-period is expired, notification of pause frame reception to an upper layer (e.g. MHD) and MRPFM.PFCTCAn for that priority are deasserted.
   In any case, MPCFRCT0 to MPCFRCT7 are incremented respectively after receiving a PFC frame for enabled priority by MRGC.PFCRCn. And all received PFC frames are discarded internally.

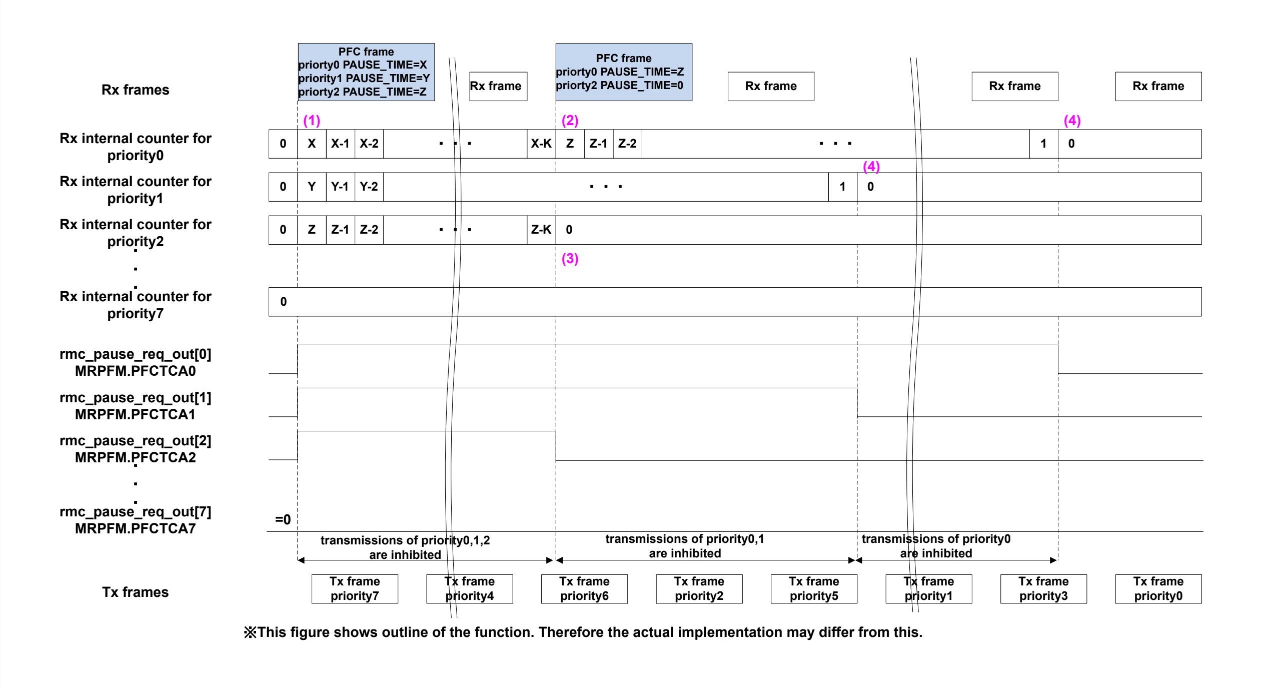

Figure 33.22 Reception of PAUSE frame

33.6.3 Timestamping

This IP supports time synchronization for IEEE 1588. It supports time synchronization accuracy in the sub-microsecond range.

33.6.3.1 Timestamp Capture

This IP can capture timestamps on both TX and RX side. gPTP timer value includes two 62bit timers, bit[61:0] is a Timer0, bit[123:62] is a Timer1.

[Timestamp capture on TX side]

“Timestamp capture” and “Timer number” fields in [GWCA] control this function for both e-frame and p-frame. These are configured by a Tx Descriptor. If “Timestamp capture” =1, the timer specified by “Timer number” field is captured.

The captured timestamp is sent to an upper module(e.g. MHD) with “Timestamp unique number” in [GWCA] via MHD Tx timestamp capture Interface.

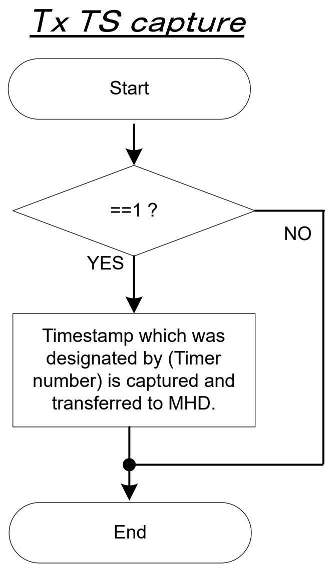

Figure 33.23 Tx Timestamp capture flow

Note: On the TX Side, the timestamp capture function by this IP and PHY can be enabled at same time.

[Timestamp capture on RX side]

MTRC.TRDDE, MTRC.TRDDP, and MTRC.TRHFMEn control this function.

The configuration of the timestamp capture is following.

- MTRC.TRDDE controls this function for e-frames.
  - MTRC.TRDDE = 0
    The default timer configured by MTRC.DTN is captured for a received e-frame.
- MTRC.TRDDP controls this function for p-frames.
  - MTRC.TRDDP = 0
    the default timer configured by MTRC.DTN is captured for a received p-frame.
- MTRC.TRHFMEn controls this function for e-frames using the HW PTP message filtering.
  The bit[0] is for Timer0 and bit[1] is for Timer1.
  See Figure 33.26 to use the HW PTP message filter.
  - TRHFMEn = x1 and the received e-frame matched the HW PTP messaged filter for Timer0
    The Timer0 is captured for that received e-frames.
  - TRHFMEn = 10 and the received e-frame matched the HW PTP messaged filter for Timer1
    The Timer1 is captured for that received e-frames.
  - TRHFMEn = 11 and the received e-frame matches the HW PTP messaged filter for Timer0 and 1
    The Timer0 is captured for that received e-frames.

A captured timestamp is outputted from this IP with the received frame.

Figure 33.25 shows Rx Timestamp capture flow.

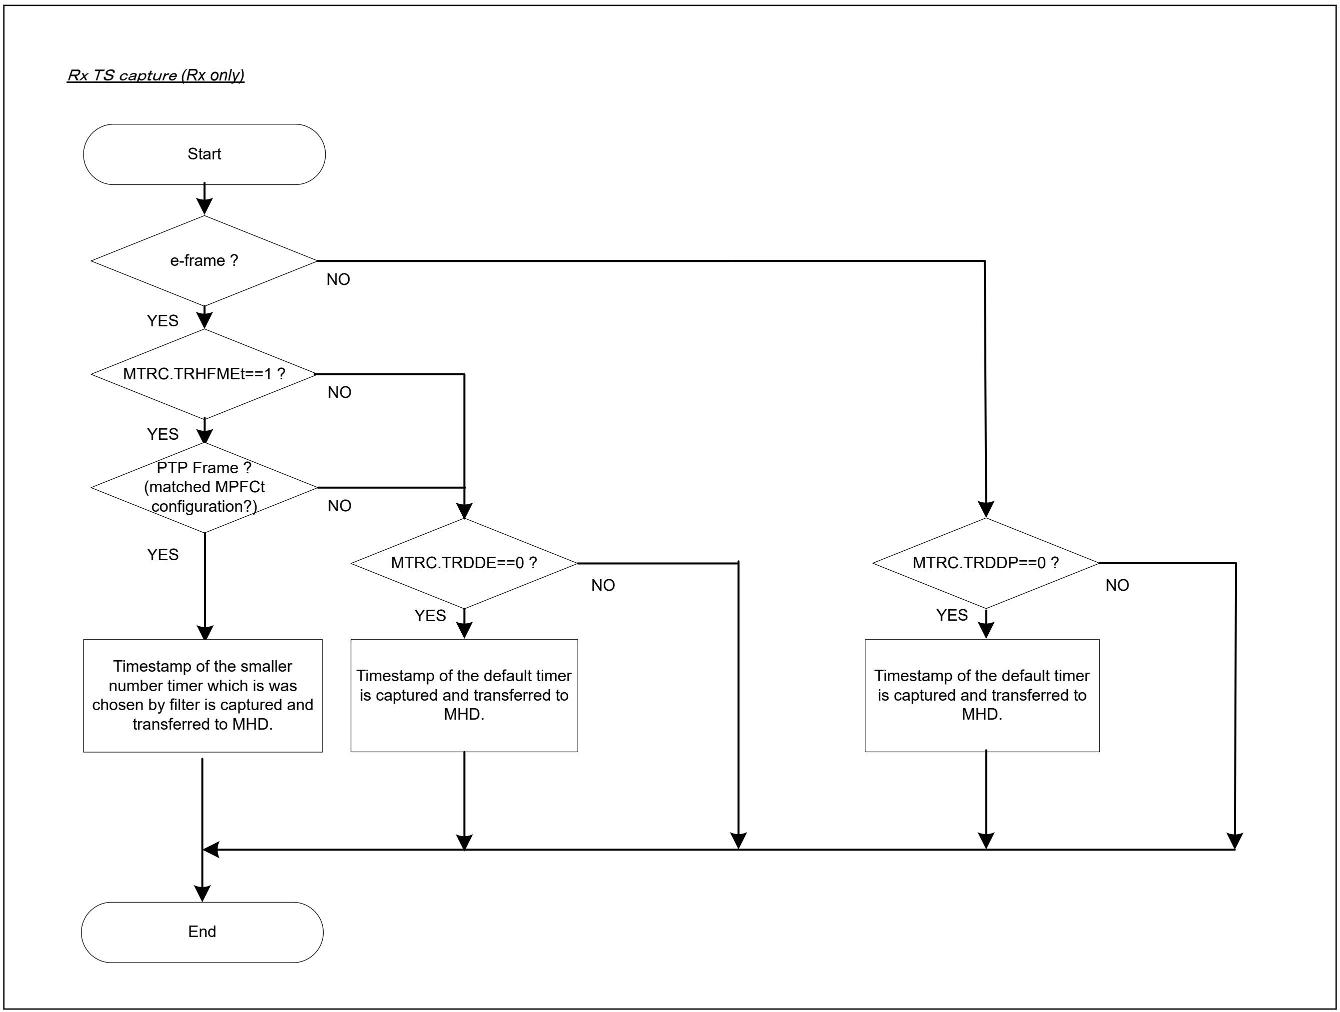

Figure 33.24 Rx TS capture (Rx only)

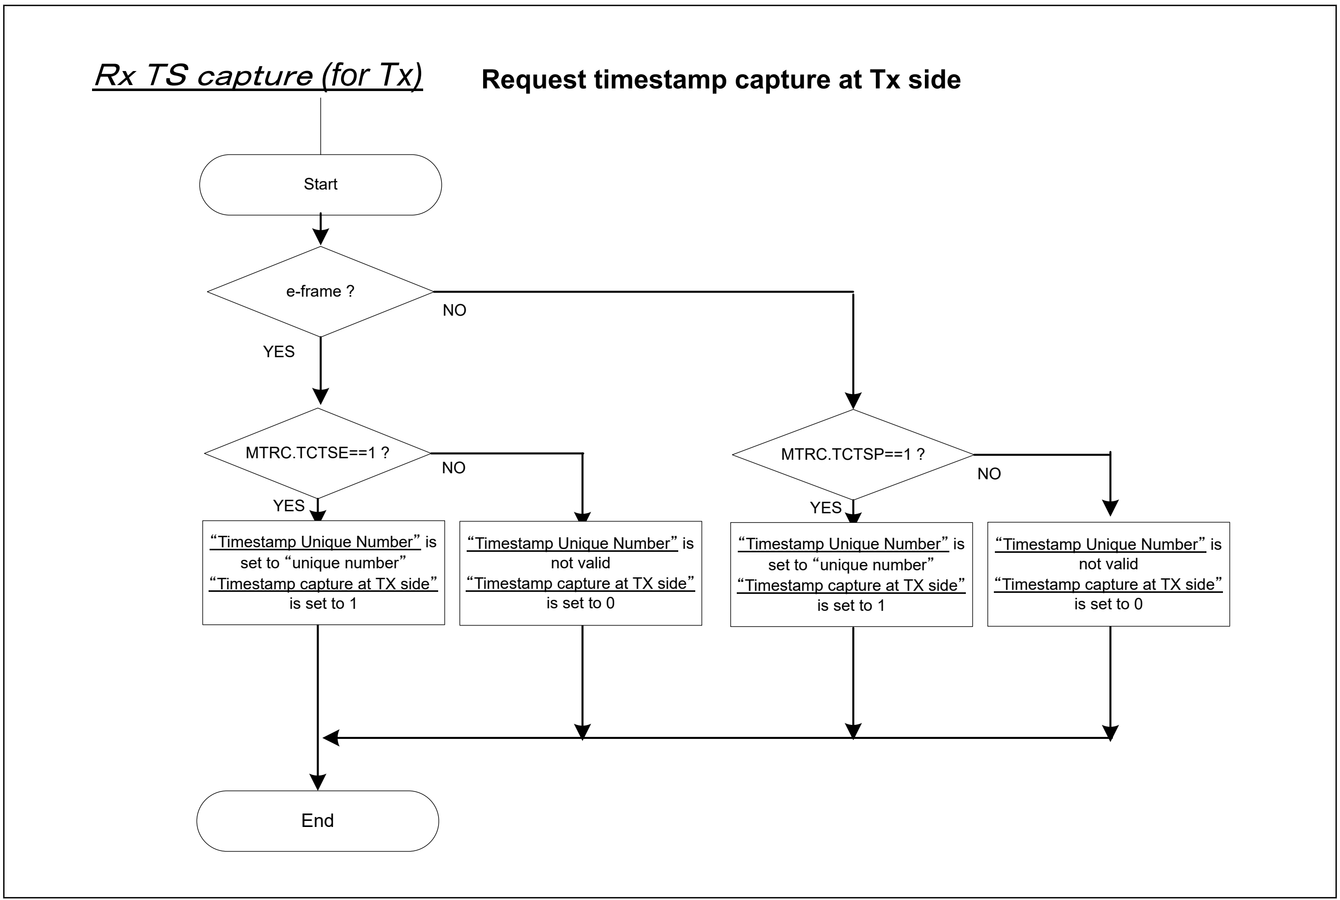

Figure 33.25 Rx timestamp capture flow

[Configuration of HW PTP Filter]

HW PTP message filter is configured by using MPFC0-15. The Figure 33.26 shows an example configuration of PTP Message Filter. This is a case of MTRC.TRHFMEn = 11.

In this case:

MPFC0-7 are used as the filters for both Timer0 and Timer1. Because TEF field is set to 0x03.

MPFC8 is used as the filter for Timer0. Because TEF field is set to 0x01.

MPFC9 is used as the filter for Timer1. Because TEF field is set to 0x02.

MPFC10-15 are not used. Because TEF field is set to 0x00.

If an e-frame matches all MPFC0-7 and MPFC8, it is judged as a frame of Timer0 domain.

If an e-frame matches all MPFC0-7 and MPFC9, it is judged as a frame of Timer1 domain.

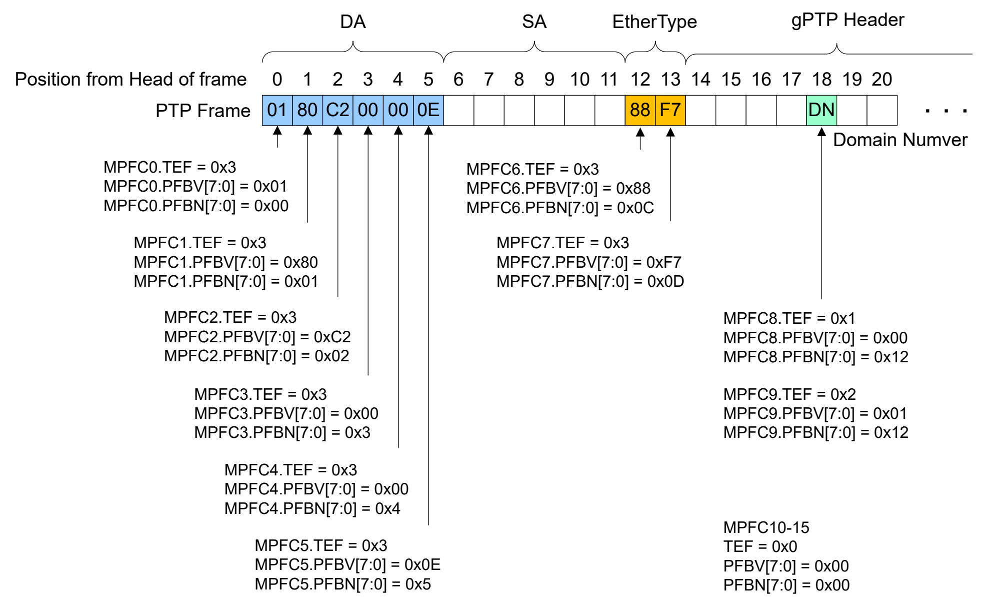

Figure 33.26 Example configuration of PTP message filter

Note:
- Depending on the configuration of the filter, a frame may match both filters. In this case, Timer0 is selected.
- PFBN should not select a position that exceeds the end of frame. Therefore, this value less than or equal to the minimum frame size is recommended.

33.6.4 Station Management

The Station Management controls the access to Management registers in PHY.

rmc_mdi, rmc_mdo, rmc_mde, rmc_mdc and rmc_mdio_int are used for this function.

33.6.4.1 Management Register Access

This IP has two types of access methods, one is specified by clause 22 the other is specified by clause 45 in IEEE802.3.

33.6.4.1.1 Access Method Specified in Clause 22

To write or read of Management register of PHY which supports this access method using management frame format, execute the following steps.

[write access]

Set MPSM as following.

PRD[15:0]="Write Data"

POP[1:0]=01

PRA[4:0]="Register Address"

PDA[4:0]="PHY Address"

MFF=0

PSME=1

After setting MPSM.PSME is kept to 1 during the access. Wait an interrupt is detected (MMIS1.PWACS=1) or MPSM.PSME turns to 0 as a sign of an access completion.

At this time, when MMIE1.PWACE is set to 1, the interrupt appears on rmc_mdio_int.

Set MMIS1.PWACS to 0 to clear the interrupt.

[Read access]

Set MPSM as following.

PRD[15:0]="0x00"

POP[1:0]=10

PRA[4:0]="Register Address"

PDA[4:0]="PHY Address"

MFF=0

PSME=1

After setting MPSM.PSME is kept to 1 during the access. Wait an interrupt is detected (MMIS1.PRACS=1) or MPSM.PSME turns to 0 as a sign of an access completion.

At this time, when MMIE1.PRACE is set to 1, the interrupt appears on rmc_mdio_int.

After the completion of read access, the read data is stored in MPSM.PRD[15:0]. So read it.

Set MMIS1.PRACS to 0 to clear the interrupt.

Note: When MPSM.PSME is set to 1, this IP outputs preamble code of fixed length specified in standard on rmc_mdo before write or read access. IEEE802.3 clause 22 allows skipping preamble code. When the preamble code is not needed and PHY also supports to skip the preamble code, this IP does not output the preamble code by setting MPIC.PSMDP to 1.

33.6.4.1.2 Access Method Specified in Clause 45

To write or read Management register of PHY which supports this access method using extended management frame format, execute the following steps.

[write access]

1. Set MPSM as following. ("Register Address" is set to a PHY)
   PRD[15:0] = "Register Address"
   POP[1:0] = 00
   PRA[4:0] = "Device Address"
   PDA[4:0] = "Port Address"
   MFF = 1
   PSME = 1
   After setting MPSM.PSME is kept to 1 during the access. Wait an interrupt is detected (MMIS1.PAACS = 1) or MPSM.PSME turns to 0 as a sign of an access completion.
   At this time, when MMIE1.PAACE is set to 1, the interrupt appears on rmc_mdio_int.
   Set MMIS1.PWACS to 0 to clear interrupt.
2. Set MPSM as following. ("Write Data" is set to the "Register Address" which was configured by step 1.)
   PRD[15:0] = "Write Data"
   POP[1:0] = 01
   PRA[4:0] = "Device Address"
   PDA[4:0] = "Port Address"
   MFF = 1
   PSME = 1
   After setting MPSM.PSME is kept to 1 during the access. Wait an interrupt is detected (MMIS1.PWACS = 1) or MPSM.PSME turns to 0 as a sign of an access completion.
   At this time, if MMIE1.PWACE is set to 1, the interrupt appears on rmc_mdio_int.
   Set MMIS1.PWACS to 0 to clear interrupt.

[Read access]

1. Set MPSM as following. ("Register Address" is set to a PHY)
   PRD[15:0] = "Register Address"
   POP[1:0] = 00
   PRA[4:0] = "Device Address "

PDA[4:0] = “Port Address”
MFF = 1
PSME = 1
After setting MPSM.PSME is kept to 1 during the access. Wait an interrupt is detected (MMIS1.PAACS = 1) or MPSM.PSME turns to 0 as a sign of an access completion.
At this time, when MMIE1.PAACE is set to 1, the interrupt appears on rmc_mdio_int.
Set MMIS1.PWACS to 0 to clear interrupt.

2. Set MPSM as following. (Read access of the Register Address which was pointed by previous step)
PRD[15:0] = 0x00
POP[1:0] = 11
PRA[4:0] = “Device Address”
PDA[4:0] = “Port Address”
MFF = 1
PSME = 1
After setting MPSM.PSME is kept to 1 during the access. Wait an interrupt is detected (MMIS1.PRACS = 1) or MPSM.PSME turns to 0 as a sign of an access completion.
At this time, when MMIE1.PRACE is set to 1, the interrupt appears on rmc_mdio_int.
After the completion of read access, the read data is stored in MPSM.PRD[15:0]. So read it.
Set MMIS1.PRACS to 0 to clear interrupt.

[Post read incremental access]

Read access needs setting “Register Address” every time. Only when continuous Register Address fields are read continuously, using this access (POP[1:0] = 10) is efficient.

1. Set MPSM as following. (“Register Address” is set to a PHY)
PRD[15:0] = “Register Address”
POP[1:0] = 00
PRA[4:0] = “Device Address ”
PDA[4:0] = “Port Address”
MFF = 1
PSME = 1
After setting MPSM.PSME is kept to 1 during the access. Wait an interrupt is detected (MMIS1.PAACS = 1) or MPSM.PSME turns to 0 as a sign of an access completion.
At this time, when MMIE1.PAACE is set to 1, the interrupt appears on rmc_mdio_int.
Set MMIS1.PWACS to 0 to clear the interrupt.

2. Set MPSM as following. (Read access of the Register Address which was pointed by previous step)
PRD[15:0] = 0x00
POP[1:0] = 10
PRA[4:0] = “Device Address ”
PDA[4:0] = “Port Address”
MFF = 1
PSME = 1
After setting MPSM.PSME is kept to 1 during the access. Wait an interrupt is detected (MMIS1.PPRACS = 1) or MPSM.PSME turns to 0 as a sign of an access completion.
At this time, when MMIE1.PPRACE is set to 1, the interrupt appears on rmc_mdio_int.
After the completion of read access, the read data is stored in MPSM.PRD[15:0]. So read it. And “Register Address” set by step 1 is automatically changed in the PHY to point a next register address field. So don’t need to re-configuration of “Register Address” for next read access.
Set MMIS1.PPRACS to 0 to clear the interrupt.

3. Repeat step 2 for the read access from the Next Register Address field.

Note: When MPSM.PSME set to 1, this IP outputs preamble code of fixed length specified in standard on rmc_mdo before write or read access. IEEE802.3 clause 45 does not allow skipping the preamble code. But skipping preamble code is also supported in this access method by setting MPIC.PSMDP to 1. To use this function, check a PHY specification.

33.6.4.2 Management Data Clock (MDC) Setting

To access Management registers in PHY, this IP outputs MDC. This is generated by dividing CHI clock (clk) in this IP and outputted from rmc_mdc. The division ratio can be set by the MPIC.PSMCS.

The following table shows the programmed MDC frequency depending on MPIC.PSMCS. MDC frequency is calculated by clk[MHz] / ((MPIC.PSMCS +1)*2).

Table 33.7 Programming example for MPIC.PSMCS

clk frequency	MPIC.PSMCS	MDC frequency
100MHz	0x13	2.5MHz
200MHz	0x27	2.5MHz

Note: IEEE 802.3 specifies as the clock should be slower than 2.5MHz. But some PHY could operate with a higher frequency. See the PHY specification for detail.

33.6.4.3 Management Data Timing Adjustment

This IP can adjust the drive timing of MDO (rmc_mdo and rmc_mde) and the capture timing of MDI (rmc_mdi). It may be used for the propagation delay on the PCB.

The drive timing could be adjusted by PHY Station Management Hold Time Adjustment (MPIC.PSMHT). The capture timing could be adjusted by PHY Station Management Capture Time Adjustment (MPIC.PSMCT). The figure below is an example shifted by 2clk cycles.

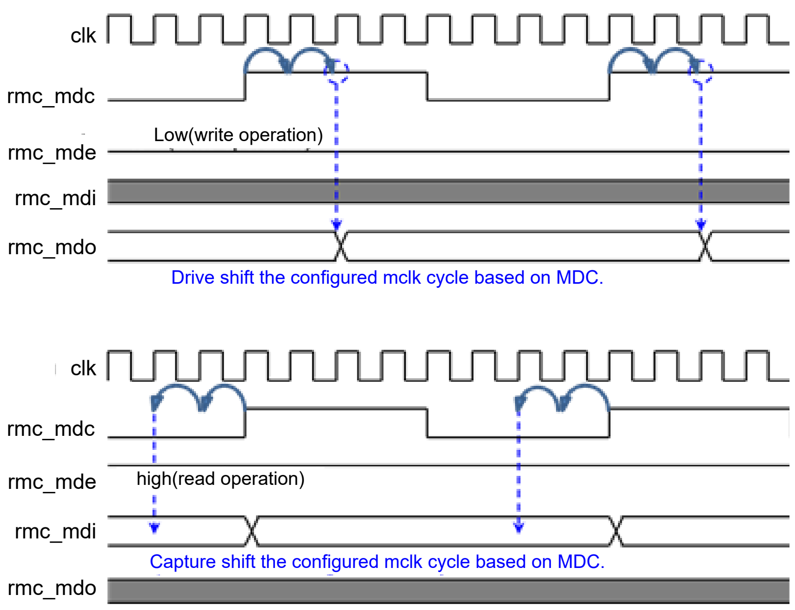

Figure 33.27 Management data timing adjustment

33.6.5 Energy Efficient Ethernet

This IP supports Energy Efficient Ethernet (EEE) which is standardized in IEEE 802.3. Tx-LPI mode and Rx-LPI mode can be activated independently.

33.6.5.1 LPI Control

This IP can request LPI mode for Tx port to the PHY when the LPI request bit (MEEEC.LPITR) is asserted. LPI mode is released when the bit is negated. The operation flow is shown in section 33.5.2.5. LPI Transition for Tx Port in detail.

The LPI mode for Rx port can be recognized by the reception LPI interrupt status bit (MMIS2.LPIAIS). When the bit (MMIS2.LPIDIS) is asserted, it means RMAC detected deassertion of LPI.

Table 33.8 and Table 33.9 show LPI specification on each xMII interface. The specification for MII or GMII is specified by IEEE802.3.

Table 33.8 Rx LPI specification on each xMII interface

PHY IF	RX_DV	RX_ER	RXD
MII	rmc_rx_valid_gmii = 0	rmc_rx_err_gmii = 1	rmc_rx_data_gmii[3:0] = 0001
GMII	rmc_rx_valid_gmii= 0	rmc_rx_err_gmii = 1	rmc_rx_data_gmii[7:0] = 00000001

Table 33.9 Tx LPI specification on each xMII interface

PHY IF	TX_EN	TX_ER	TXD
MII	rmc_tx_valid_gmii = 0	rmc_tx_err_gmii = 1	rmc_tx_data_gmii [3:0] = 0001
GMII	rmc_tx_valid_gmii = 0	rmc_tx_err_gmii = 1	rmc_tx_data_gmii [7:0] = 00000001

33.6.6 MAC Address Filtering on Reception

This IP supports the frame reception in a full-duplex operation mode.

This IP can pass all received Ethernet frames data to an upper layer via xMII Interface.

This IP strips off automatically SFDs/SMDs, preambles, FRAG_COUNTs and mCRCs from all the frames.

The FCS reception by the upper layer can be set though MRGC.RCPT register.

This IP identifies the frames with the special format and informs to the upper layer. It is indicated with the dedicated flag in status information followed payload data. The table below indicates the frames with the special format.

Table 33.10 Operation for special format frame

Frame	Format	Operation
Broadcast frame	DA: FF_FF_FF_FF_FF_FF	Filtering possible.
Multicast frame	DA: B'xxxx_xxx1_xxxx_xxxx_xxxx_xxxx_xxxx_xxxx_xxxx_xxxx_xxxx_xxxx	Filtering possible.
Pause frame	DA: 01_80_C2_00_00_01 TYPE: 88_08 OPCODE: 00_01	This IP handles Flow Control, refer to section 8.2. Pause information is not sent to upper layer.
PFC frame	DA: 01_80_C2_00_00_01 TYPE: 88_08 OPCODE: 01_01	This IP handles Flow Control, refer to section 8.2. Pause information is not sent to upper layer.
Magic packet	When the MAC address (MRMAC.MA) is 00-11-22-33-44-55h, this IP would scan for the data sequence: Destination-Address Source-Address ....MISC....... FF FF FF FF FF FF 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 ....MISC...... FCS This sequence can be located anywhere in the Magic Packet payload. The Magic Packet is formed with a standard Ethernet header and FCS.	Interrupt. Provide information to upper layer. Provide magic packet interrupt (MMIS2.MPDIS). Magic packets are only detected as E-frame.

This IP supports the MAC address filtering for Unicast, Multicast, Broadcast, Broadcast storm (continuous Broadcast frame reception) and Multicast storm (continuous Multicast frame reception). It uses the destination address (DA) and source Address(SA) of a received frame for the address filtering. When the filter condition is satisfied, the received frames are transferred to an upper layer. If not satisfied, the received frames are transferred to the upper layer with the error flag of “Frame filtered” in [ETHA].

The filter condition is configured in Reception filter configuration register (MRAFC). It can be individually configured for Unicast address, Multicast address, and Broadcast address.

And this IP also supports Promiscuous mode.

When MRAFC.UCEN*, MCEN*, BCEN*, NDARE*, SDSFRE*, NSARE* and MSARE* are set to 1, all frames are transferred to the upper layer without error flag of “Frame filtered”.

Note : Regardless of MRAFC configuration, Verify and Respond are not transferred to the upper layer.

The flow of Figure 33.28 shows the MAC Address filtering.

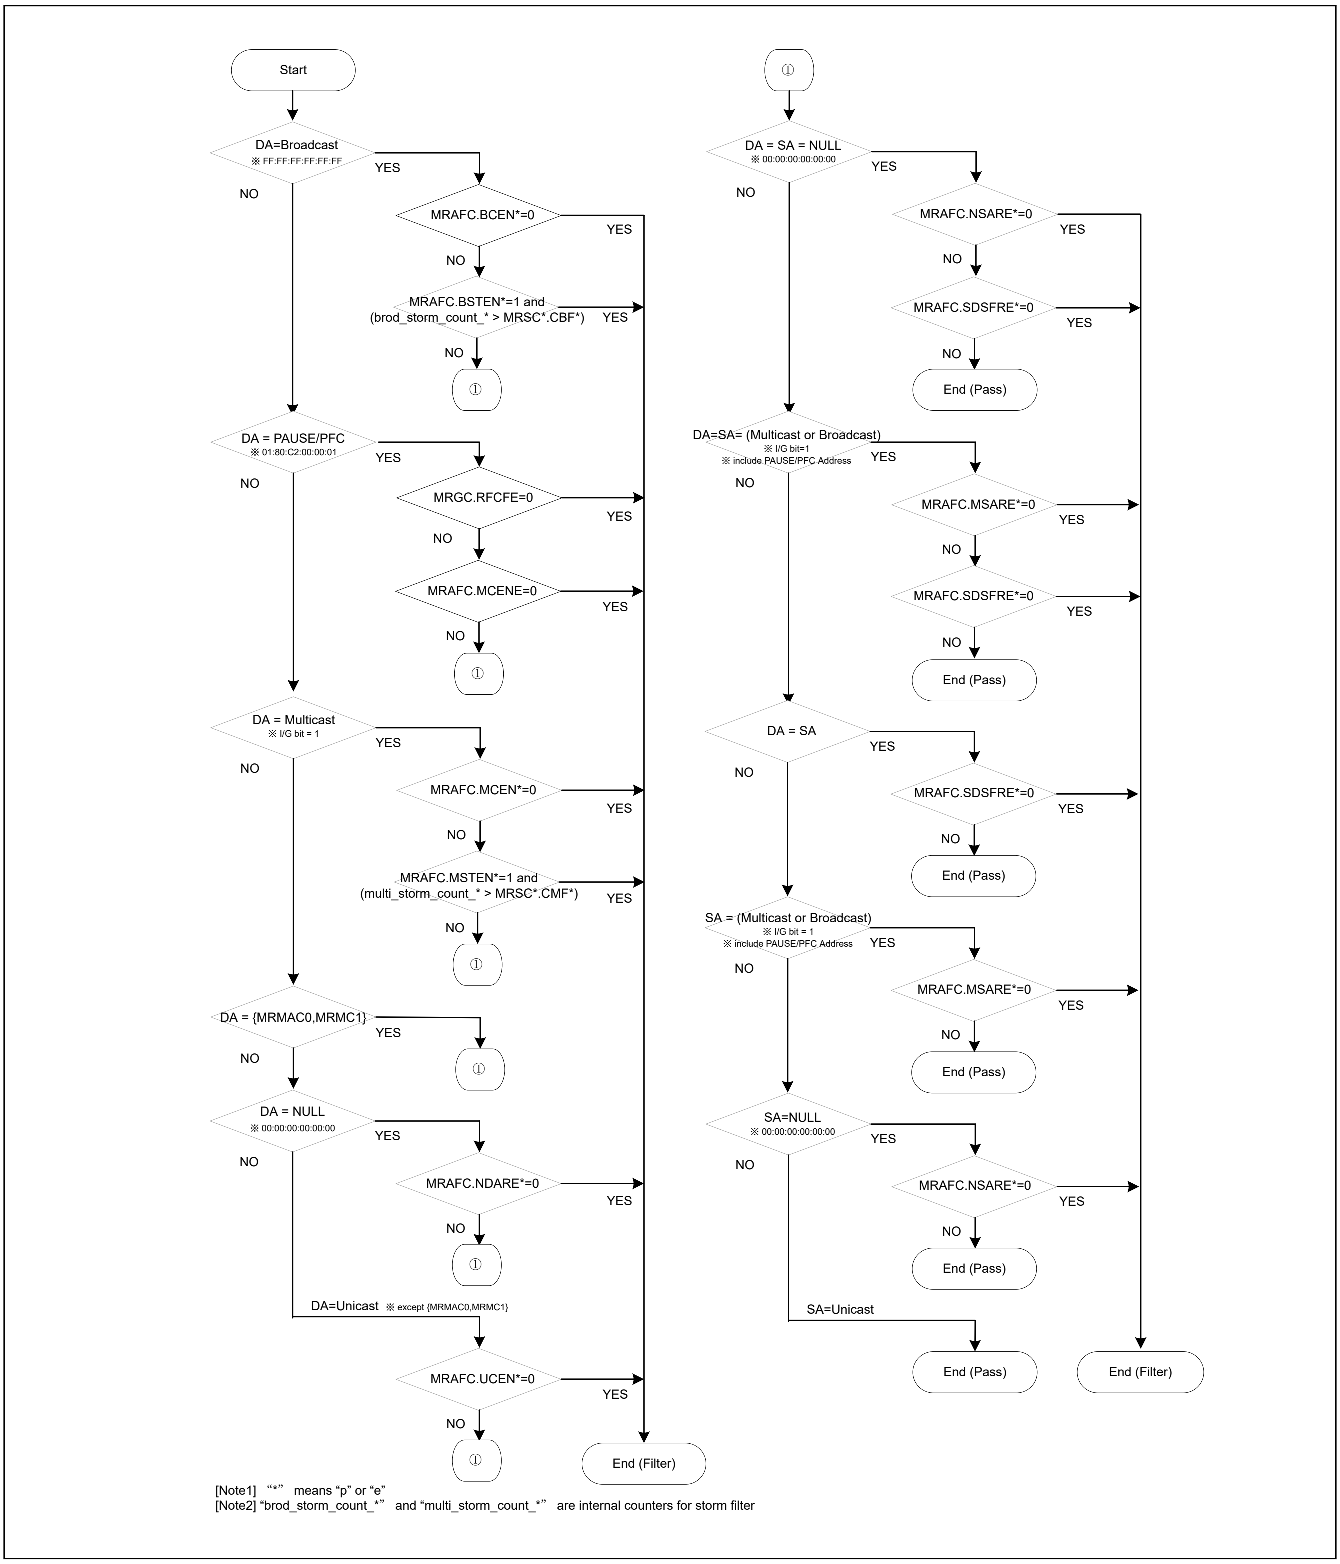

Figure 33.28 MAC address filtering

34. Ethernet CPU Agent (GWCA)

34.1 Overview

Ethernet CPU Agent (GWCA) is a CPU interface that consists of an agent interface module allowing communication within ESWM. GWCA handles data exchange between ESWM and the GWCPU subsystem. Software is required for the configuration of Gateway AXI bus interface.

Table 34.1 lists the GWCA specifications and Figure 34.1 shows a block diagram.

.

Table 34.1 GWCA Specifications

Function		Description
Interfaces	Switch mode	Interface to receive the switch mode [MFWD]
	Pause interface	Interface to pause TX queues [COMA]
	AXI Master interface	Master interface conforming to AXI 3 AMBA protocol. It is used for data transfer between GWCPU and GWCA. ● Data bit width: 128 bits ● Number of outstanding read: 8 ● Number of outstanding write: 8 ● Number of ID read: 8 (from 0 to 7) ● Number of ID write: 8 (from 0 to 8-1) ● Incremental Access only ● Supports unaligned transactions ● Supports out of order ● Supports interleave on read bus
	SFR interface	Interface to access GWCA SFRs [COMA]
	Interrupts	GWCA interrupt to CPU
	Fabric interface	Interface to communicate with the data, TAG and pointer RAM [MFAB]
	Descriptor bus	Interface to receive frame information to send them to CPU [MFWD]
	L2/L3 update bus	Interface to fetch the frame routing information [MFWD]
	BP Request	Interface to receive BPs to store frames in the data, TAG and pointer RAM [COMA]
	BP Release	Interface to release the BPs that has been used [COMA]
	TX Timestamp Capture interface	Interface to receive TX timestamps and send it to CPU [RMAC]
	RAM interfaces	Interface to communication with RAMs [TOP]
Data provision	Ethernet Frames	Corresponds to the IEEE 802.3, 802.1Q and 802.1CB standards [802.3] [802.1Q] [802.1CB]
	Descriptors	AXI TX Descriptor (CPU to GWCA) AXI RX Descriptor (GWCA to CPU) Local Ethernet Descriptor, Local Direct Descriptor (GWCA to Forwarding engine) Forwarding descriptor (Forwarding engine to GWCA)
	Timestamp	TX timestamp for transmission to CPU RAM [RMAC]

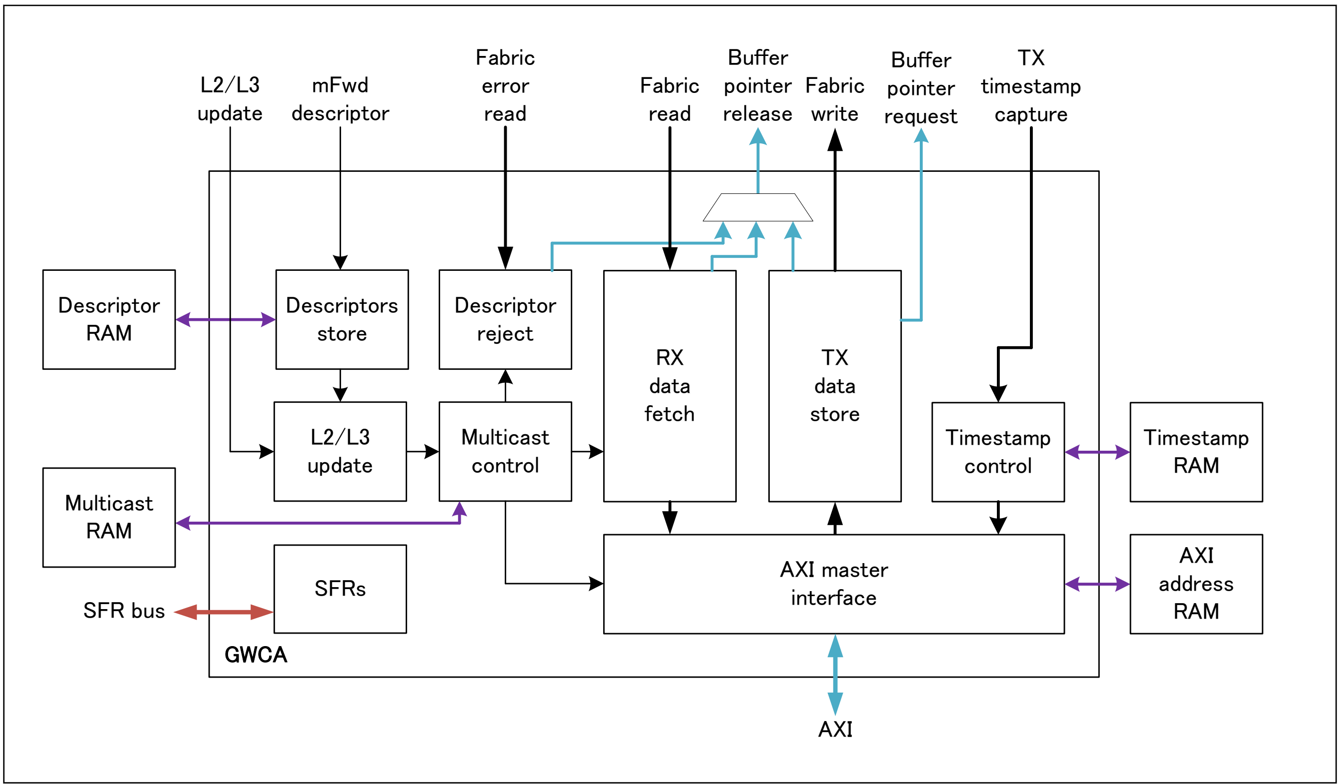

Figure 34.1 GWCA block diagram

Table 34.2 GWCA functional blocks

Block name	Function
TX data store	Transmits frames from AXI master to the local RAM.
RX data fetch	Transmits frame from local RAM to AXI master.
Descriptor store	Receives the descriptors from forwarding engine and controls the priority between descriptors.
L2/L3 update	Fetches L2/L3 update information.
Descriptor reject	Reject descriptors.
Multicast control	Controls multicast transactions.
Timestamp control	Receives timestamps for Ethernet Agents, saves them and transmits them to the AXI master.
AXI master interface	AXI master for data exchange with the CPU
SFRs	GWCA SFRs

34.2 GWCA Register List

Table 34.3 GWCA registers (1 of 4)

Offset address	Register symbol	Register name	Write access mode

Table 34.3 GWCA registers (4 of 4)

Offset address	Register symbol	Register name	Write access mode
0x1104 + 0x10 × i	GWDIEi	Data Interrupt Enable Register i (i = 0, 1)	C, O, D
0x1108 + 0x10 × i	GWDIDi	Data Interrupt Disable Register i (i = 0, 1)	C, O, D
0x110C + 0x10 × i	GWDIDSi	Data Interrupt Delayed Status Register i (i = 0, 1)	—
0x1180	GWTSDIS	Timestamp Data Interrupt Status Register	C, O, D
0x1184	GWTSDIE	Timestamp Data Interrupt Enable Register	C, O, D
0x1188	GWTSDID	Timestamp Data Interrupt Disable Register	C, O, D
0x1190	GWEIS0	Error Interrupt Status Register 0	C, O, D
0x1194	GWEIE0	Error Interrupt Enable Register 0	C, O, D
0x1198	GWEID0	Error Interrupt Disable Register 0	C, O, D
0x11A0	GWEIS1	Error Interrupt Status Register 1	C, O, D
0x11A4	GWEIE1	Error Interrupt Enable Register 1	C, O, D
0x11A8	GWEID1	Error Interrupt Disable Register 1	C, O, D
0x1200 + 0x10 × i	GWEIS2i	Error Interrupt Status Register 2i (i = 0, 1)	C, O, D
0x1204 + 0x10 × i	GWEIE2i	Error Interrupt Enable Register 2i (i = 0, 1)	C, O, D
0x1208 + 0x10 × i	GWEID2i	Error Interrupt Disable Register 2i (i = 0, 1)	C, O, D
0x1280	GWEIS3	Error Interrupt Status Register 3	C, O, D
0x1284	GWEIE3	Error Interrupt Enable Register 3	C, O, D
0x1288	GWEID3	Error Interrupt Disable Register 3	C, O, D
0x1290	GWEIS4	Error Interrupt Status Register 4	C, O, D
0x1294	GWEIE4	Error Interrupt Enable Register 4	C, O, D
0x1298	GWEID4	Error Interrupt Disable Register 4	C, O, D
0x12A0	GWEIS5	Error Interrupt Status Register 5	C, O, D
0x12A4	GWEIE5	Error Interrupt Enable Register 5	C, O, D
0x12A8	GWEID5	Error Interrupt Disable Register 5	C, O, D

Note:
- Base address: GWCA0 = 0x403C_E000, GWCA0_NS = 0x503C_E000
- All registers can be read in any mode.
- The address preceded by “E:” correspond to an emulation address which allows a register to be read without modifying its content.
- Write Access Mode:
  - Any: Register can be written in any mode.
  - R: Register can be written in RESET mode
  - D : Register can be written in DISABLE mode
  - C: Register can be written in CONFIG mode
  - O: Register can be written in OPERATION mode

34.3 GWCA Register Descriptions

34.3.1 GWCA Mode Function Registers

34.3.1.1 GWMC : Mode Configuration Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OPC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
1:0	OPC[1:0]	Operating Mode Command[*1] Used to set GWCA mode. For more details, see section 34.4.1. Operation Modes. 0 0: Enter RESET mode 0 1: Enter DISABLE mode 1 0: Enter CONFIG mode 1 1: Enter OPERATION mode	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. HW: This register is not writable if its value is different than GWMS.OPS.

34.3.1.2 GWMS : Mode Status Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OPS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
1:0	OPS[1:0]	Operating Mode Status Indicates the current GWCA mode. For more details, see section 34.4.1. Operation Modes. 0 0: RESET mode 0 1: DISABLE mode 1 0: CONFIG mode 1 1: OPERATION mode	R
31:2	—	These bits are read as 0.	R

OPS[1:0] bits (Operating Mode Status)

[Update conditions]

HW: Mode change completed.

This register is change at “Maximum frame communication time (exp: 64 KB / 100 Mbps = 5.12 ms)” from OPERATION to DISABLE.

34.3.2 Reception Function Registers

34.3.2.1 GWIRC : IPV Remapping Configuration Register [802.1Q]

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	IPVR7[2:0]			—	IPVR6[2:0]			—	IPVR5[2:0]			—	IPVR4[2:0]		
Value after reset:	0	1	1	1	0	1	1	0	0	1	0	1	0	1	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	IPVR3[2:0]			—	IPVR2[2:0]			—	IPVR1[2:0]			—	IPVR0[2:0]		
Value after reset:	0	0	1	1	0	0	1	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
2:0	IPVR0[2:0]	IPV remapping 0	R/W
3	—	These bits are read as 0. The write value should be 0.	R/W
6:4	IPVR1[2:0]	IPV remapping 1	R/W
7	—	These bits are read as 0. The write value should be 0.	R/W
10:8	IPVR2[2:0]	IPV remapping 2	R/W
11	—	These bits are read as 0. The write value should be 0.	R/W
14:12	IPVR3[2:0]	IPV remapping 3	R/W
15	—	These bits are read as 0. The write value should be 0.	R/W
18:16	IPVR4[2:0]	IPV remapping 4	R/W
19	—	These bits are read as 0. The write value should be 0.	R/W
22:20	IPVR5[2:0]	IPV remapping 5	R/W
23	—	These bits are read as 0. The write value should be 0.	R/W
26:24	IPVR6[2:0]	IPV remapping 6	R/W
27	—	These bits are read as 0. The write value should be 0.	R/W
30:28	IPVR7[2:0]	IPV remapping 7	R/W
31	—	These bits are read as 0. The write value should be 0.	R/W

IPVRi (i = 0 to 7) bits (IPV remapping i)

Configure to which descriptor queue descriptor received with IPV i will be stored (when a descriptor is received from forwarding engine with FDESCR.IPV [MFWD] equal to i).

34.3.2.2 GWRDQSC : RX Descriptor Queue Security Configuration Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	RDQSL7	RDQSL6	RDQSL5	RDQSL4	RDQSL3	RDQSL2	RDQSL1	RDQSL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RDQSL7 to RDQSL0	RX Descriptor Queue i Security Level (The variable i corresponds to the bit number.) When a queue is secured, an unsecure descriptor cannot enter it (when a descriptor is from MFWD with FDESCR.SEC equal to 0). 0: Queue i unsecure 1: Queue i secure	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

34.3.2.3 GWRDQC : RX Descriptor Queue Control Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	RDQP7	RDQP6	RDQP5	RDQP4	RDQP3	RDQP2	RDQP1	RDQP0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	RDQD7	RDQD6	RDQD5	RDQD4	RDQD3	RDQD2	RDQD1	RDQD0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RDQD7 to RDQD0	RX Descriptor Queue i Disable (The variable i corresponds to the bit position number.) Avoid descriptor from MFWD to enter the corresponding queue. The Forwarding Engine will reject the corresponding descriptor. If disabled queue data is not needed anymore, corresponding GWRMFSCq.MFS register can be set to 0 in order to avoid more frames to go to the CPU RAM. 0: Queue i enabled 1: Queue i disabled	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
23:16	RDQP7 to RDQP0	RX Descriptor Queue i Pause*1 (The variable i corresponds to the bit position number.) Avoid frames to be sent to the CPU by stopping descriptor fetching from the descriptor RAM. 0: Queue i active 1: Queue i paused	R/W*2
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: Pausing a queue during a long time could result in switch overflow. In case of switch overflow [COMA] this register should be set to 0.

Note 2. Read value differs from written value.

RDQDi bits (RX Descriptor Queue i Disable)

[Setting condition]

SW: Writing 1 to this bit will set it.

[Clearing condition]

SW: Writing 0 to this bit will clear it.

HW: Going out of OPERATION mode will clear this register (GWMC.OPC != 11b).

RDQPi bits (RX Descriptor Queue i Pause)

[Setting condition]

SW: Writing 1 to this bit will set it.

[Clearing condition]

SW: Writing 0 to this bit will clear it.

HW: Going out of OPERATION mode will clear this register (GWMC.OPC != 11b).

[Cautions]

This register is used to stop a queue but MFWD does not stop sending descriptor to the corresponding queue. In this case the queue might overflow.

34.3.2.4 GWRDQAC : RX Descriptor Queue Arbitration Control Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x001C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RDQA7[3:0]				RDQA6[3:0]				RDQA5[3:0]				RDQA4[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RDQA3[3:0]				RDQA2[3:0]				RDQA1[3:0]				RDQA0[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	RDQA0[3:0]	RX Descriptor Queue 0 Arbitration*1 For more details, see section 34.5.3.1.2. Descriptor Arbitration. 0: Queue i strict arbitration Others: Queue i WRR arbitration	R/W
7:4	RDQA1[3:0]	RX Descriptor Queue 1 Arbitration*1 For more details, see section 34.5.3.1.2. Descriptor Arbitration. 0: Queue i strict arbitration Others: Queue i WRR arbitration	R/W
11:8	RDQA2[3:0]	RX Descriptor Queue 2 Arbitration*1 For more details, see section 34.5.3.1.2. Descriptor Arbitration. 0: Queue i strict arbitration Others: Queue i WRR arbitration	R/W
15:12	RDQA3[3:0]	RX Descriptor Queue 3 Arbitration*1 For more details, see section 34.5.3.1.2. Descriptor Arbitration. 0: Queue i strict arbitration Others: Queue i WRR arbitration	R/W
19:16	RDQA4[3:0]	RX Descriptor Queue 4 Arbitration*1 For more details, see section 34.5.3.1.2. Descriptor Arbitration. 0: Queue i strict arbitration Others: Queue i WRR arbitration	R/W

Bit	Symbol	Function	R/W
23:20	RDQA5[3:0]	RX Descriptor Queue 5 Arbitration*1 For more details, see section 34.5.3.1.2. Descriptor Arbitration. 0: Queue i strict arbitration Others: Queue i WRR arbitration	R/W
27:24	RDQA6[3:0]	RX Descriptor Queue 6 Arbitration*1 For more details, see section 34.5.3.1.2. Descriptor Arbitration. 0: Queue i strict arbitration Others: Queue i WRR arbitration	R/W
31:28	RDQA7[3:0]	RX Descriptor Queue 7 Arbitration*1 For more details, see section 34.5.3.1.2. Descriptor Arbitration. 0: Queue i strict arbitration Others: Queue i WRR arbitration	R/W

Note 1.
- SW: In hybrid arbitration mode, all the queues with a GWRDQAC.RDQAi value other than 0 should have a consecutive priority (priority refers to the queue number i).
- SW: In all arbitration mode except strict priority arbitration mode, at least two queues should have a GWRDQAC.RDQAi other than 0.

34.3.2.5 GWRGC : RX General Configuration Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RCPT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RCPT	Receive CRC Pass Through [802.3]*1 This bit selects to pass FCS field on the reception frame. 0: FCS is not passed to GWCPU. If a descriptor is received from forwarding engine with FDESCR.FI equal to 1, GWCA remove the last 4 bytes of the Frame Data (FCS). 1: FCS is passed to GWCPU GWCA don't remove FCS from the Frame which has one (a descriptor is received from forwarding engine with FDESCR.FI equal to 1) if the frame has not been modified by the switch (No update due to VLAN tagging/untagging and no update requested by L3 routing [FWD]).	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. HW: GWCA does not check FCS integrity.

34.3.2.6 GWRMFSCq : Reception Maximum Frame Size Configuration Register q (q = 0 to 7)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0040 + 0x04 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MFS[15:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	MFS[15:0]	Maximum Frame Size*1 Maximum frame size for descriptor queue q. All bigger frames will be rejected.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. HW: The maximum frame size comparison takes in account the frame size which will actually be written by the AXI master (after VLAN untagging, R-TAG insertion and L2L3 update) but always counts in this size FCS even if not received by CPU.

34.3.2.7 GWRDQDCq : Reception Descriptor Queue q Depth Configuration Register (q = 0 to 7)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0060 + 0x04 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	DQD[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	DQD[9:0]	Descriptor Queue Depth*1 Number of descriptors that can contain descriptor queue q. For details see section 34.5.3.1.1. Descriptor Storage.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: The sum of DQD fields should always be smaller or equal to 512.

34.3.2.8 GWRDQMq : RX Descriptor Queue q Monitoring Register (q = 0 to 7)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0080 + 0x04 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	DNQ[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	DNQ[9:0]	Descriptor Number in Queue Indicate the current number of descriptors stored in RX Descriptor Queue q.	R
31:10	—	These bits are read as 0.	R

DNQ[9:0] bits (Descriptor Number in Queue)

[Increment conditions]

HW: Incremented by 1 when a descriptor is received from MFWD for the corresponding queue and, the queue is not full, there is no descriptor security error and the queue is not disabled.

[Decrement conditions]

HW: Decremented by 1 when a descriptor is read by GWCA to send data to AXI Master Interface or to reject data.

34.3.2.9 GWRDQMLMq : RX Descriptor Queue q Max Level Monitoring Register (q = 0 to 7)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x00A0 + 0x04 × q

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	DMLQ[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	DMLQ[9:0]	Descriptor Max Level in Queue Indicates the maximum number of descriptors that has been stored in RX Descriptor Queue q.	R
31:10	—	These bits are read as 0.	R

DMLQ[9:0] bits (Descriptor Max Level in Queue)

[Clearing condition]

HW: Being in RESET mode will clear this register (GWMC.OPS == 00).

SW: By reading this register, it is cleared to GWRDQMq.DNQ.

[Increment conditions]

HW: Increment to GWRDQMq.DNQ value when smaller than GWRDQMq.DNQ.

34.3.3 Reception Multicast Function Registers

34.3.3.1 GWMTIRM : Multicast Table Initialization Register Monitoring Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0100

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MTR	MTIOG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MTIOG	Multicast Table Initialization Ongoing [Setting condition] SW: By writing 1 to this register. It starts Multicast Table initialization. [Clearing condition] HW: This bit is cleared when Multicast Table initialization is finished. Min clk_period * 64 = [exp] (1000/320) * 128 = 400 ns	R/W*1
1	MTR	Multicast Table Ready [Setting condition] When GWMTIRM.MTIOG is getting cleared. [Clearing condition] By writing 1 to GWMTIRM.MTIOG.	R
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

34.3.3.2 GWMSTLS : Multicast Table Learning Setting Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0104

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	MSENL[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	MNL[2:0]			—	—	MNRCNL[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	MNRCNL[5:0]	Multicast Next Descriptor Chain Number Learn This register is used to set the next address in the multicast table to be learnt in GWMSTLS.MSENL multicast table entry, see section 34.5.3.3.3. Multicast Learning.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
10:8	MNL[2:0]	Multicast Number Learn This register is used to set the multicast number that should be learnt in GWMSTLS.MSENL multicast table entry. 0 0 0: Multicast 0 (1 target, no multicast) 0 0 1: Multicast 1 (2 targets) : 1 1 1: Multicast 7 (8 targets)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
21:16	MSENL[5:0]	Multicast Setting Entry Number Learn This register is used to set in which address the current learning should happen.	R/W
31:22	—	These bits are read as 0. The write value should be 0.	R/W

34.3.3.3 GWMSTLR : Multicast Table Learning Result Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0108

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MTL	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MTLF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MTLF	Multicast Table Learning Fail [Update Conditions] HW: GWMSTLR.MTL clear event. 0: Entry learning did not fail because the Multicast table is not ready. 1: Entry learning failed the Multicast table is not ready.	R
30:1	—	These bits are read as 0.	R
31	MTL	Multicast Table Learning [Setting condition] SW: Writing GWMSTLS register will set this bit. [Clearing condition] HW: This bit will be deasserted when the Multicast RAM write is completed.	R

34.3.3.4 GWMSTSS : Multicast Table Searching Setting Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x010C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	MSENS[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	MSENS[5:0]	Multicast Setting Entry Number Search This register is used to read multicast table.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

34.3.3.5 GWMSTSR : Multicast Table Searching Result Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0110

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MTS	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	MNR[2:0]			—	—	MNRCNR[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	MNRCNR[5:0]	Multicast Next RX Descriptor Chain Number Result This register is used to read multicast table. [Update conditions] HW: GWMSTSR.MTS clear event.	R
7:6	—	These bits are read as 0.	R
10:8	MNR[2:0]	Multicast Number Result This register is used to read multicast table. [Update conditions] HW: GWMSTSR.MTS clear event.	R
30:11	—	These bits are read as 0.	R
31	MTS	Multicast Table Searching This register is used to read multicast table. [Setting condition] SW: Writing GWMSTSS register will set this bit. [Clearing condition] HW: This bit will be deasserted when the Multicast RAM read is completed.	R

34.3.4 MAC Function Registers

34.3.4.1 GWMAC0 : MAC Address Configuration Register 0

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0120

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MAU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MAU[15:0]	MAC Address Upper Part These bits are used to set the 16 higher-order bits of the MAC address. For example, if the MAC address is 01-23-45-67-89-AB (hexadecimal), set 0x0123 in this register.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

34.3.4.2 GWMAC1 : MAC Address Configuration Register 1

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0124

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MAL[31:0]																															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MAL[31:0]	MAC Address Lower Part These bits are used to set the 32 lower-order bits of the MAC address. For example, if the MAC address is 01-23-45-67-89-AB (hexadecimal), set 0x456789AB in this register.	R/W

34.3.5 TAG Function Registers

34.3.5.1 GWVCC : VLAN Control Configuration Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0130

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	VEM[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VIM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VIM	VLAN Ingress Mode*1 0: Incoming VLAN mode 1: Port based VLAN mode	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
18:16	VEM[2:0]	VLAN Egress Mode 000: No VLAN mode, frames are transmitted with no VLAN. 001: C-TAG VLAN mode, frames are transmitted with ingress C-TAG if there is one stored in the Local RAM. 010: HW C-TAG VLAN mode, frames are transmitted with the C-TAG stored in local RAM. 011: SC-TAG VLAN mode, frames are transmitted with ingress C-TAG and S-TAG if they were stored in the Local RAM. 100: HW SC-TAG VLAN mode, frames are transmitted with the C-TAG and S-TAG stored in local RAM.	R/W
31:19	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: This register should not be set to 1 is the switch is in no VLAN mode (In forwarding engine, FWGC.SVM is set to 00 [FWD])

34.3.5.2 GWVTC : VLAN TAG Configuration Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0134

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	STD	STP[2:0]			STV[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CTD	CTP[2:0]			CTV[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	CTV[11:0]	C-TAG VLAN	R/W
14:12	CTP[2:0]	C-TAG PCP	R/W
15	CTD	C-TAG DEI	R/W
27:16	STV[11:0]	S-TAG VLAN	R/W
30:28	STP[2:0]	S-TAG PCP	R/W
31	STD	S-TAG DEI	R/W

34.3.5.3 GWTTFC : Transmission TAG Filtering Configuration Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0138

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	UT	SCRT	SCT	CRT	CT	CSRT	CST	RT	NT
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	NT	No Tag 0: No Tag frame passed 1: No Tag frame rejected	R/W
1	RT	R-TAG 0: R-TAG frame passed 1: R-TAG frame rejected	R/W
2	CST	CoS-TAG 0: CoS-TAG frame passed 1: CoS-TAG frame rejected	R/W
3	CSRT	CoSR-TAG 0: CoSR-TAG frame passed 1: CoSR-TAG frame rejected	R/W

Bit	Symbol	Function	R/W
4	CT	C-TAG 0: C-TAG frame passed 1: C-TAG frame rejected	R/W
5	CRT	CR-TAG 0: CR-TAG frame passed 1: CR-TAG frame rejected	R/W
6	SCT	SC-TAG 0: SC-TAG frame passed 1: SC-TAG frame rejected	R/W
7	SCRT	SCR-TAG 0: SCR-TAG frame passed 1: SCR-TAG frame rejected	R/W
8	UT	Unknown TAG 0: Unknown Tag frame passed 1: Unknown Tag frame rejected	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

34.3.6 Timestamp Function Registers

34.3.6.1 GWTDCACs0 : Timestamp Descriptor Chain s Address Configuration Register 0 (s = 0, 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0140 + 0x08 × s

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	TSCCAU[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TSCCAU[7:0]	TS Descriptor Chain s Current Address Upper Part*1	R/W *2
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: To overwrite the current address, GWTDCACs0 and GWTDCACs1 should always both be written stating by GWTDCACs1 and finishing by GWTDCACs0.
Note 2. Read value differs from written value.

TSCCAU[7:0] bits (TS Descriptor Chain s Current Address Upper Part)

[Update conditions]

SW: Writing to this field with update it to the write value.

HW: When an FEMPTY_ND descriptor is read for descriptor queue s, this field value is automatically updated to the next descriptor address upper part.

HW: When a LINK or LINKFIX descriptor is read, this register value is updated to DESCR.PTR[39:32].

34.3.6.2 GWTDCACs1 : Timestamp Descriptor Chain s Address Configuration Register 1 (s = 0, 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0144 + 0x08 × s

Bit position:	31–0
Bit field:	TSCCAL[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TSCCAL[31:0]	TS Descriptor Chain s Current Address Lower Part*1	R/W*2

Note 1. SW: To overwrite the current address, GWTDCACs0 and GWTDCACs1 should always both be written stating by GWTDCACs1 and finishing by GWTDCACs0.

Note 2. Read value differs from written value.

TSCCAL[31:0] bits (TS Descriptor Chain s Current Address Lower Part)

[Update conditions]

SW: Writing GWTDCACs0 register with update this field to the previous value written on it by the same APB.

HW: When an FEMPTY_ND descriptor is read for descriptor queue s, this field value is automatically updated to the next descriptor address downer part.

HW: When a LINK or LINKFIX descriptor is read, this register value is updated to DESCR.PTR[31:0].

34.3.6.3 GWTSDCCs : Timestamp Descriptor Chain s Configuration Register (s = 0, 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0160 + 0x04 × s

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	OSID[2:0]			—	—	—	—	—	—	DCS	TE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TE	Timer Enable*1 Enable timestamp reception for timestamps taken with timer s.	R/W
1	DCS	Descriptor Chain Select Select to which chain timestamps taken with timer s will be received.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
10:8	OSID[2:0]	OS ID When a memory access is done for timer number s, the OSID set in this register will be used.	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. HW: If a timestamp is received from RMAC for a timer which is disabled for timestamp reception, the timestamp will be ignored and lost. This is a valid setting (Another GWCA could have taken the timestamp) so there is no flag to monitor this event.

34.3.6.4 GWTSNM : Timestamp Number Monitoring Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0180

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	TNTR[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	TNTR[4:0]	Timestamp Number in Timestamp RAM [Increment conditions] HW: Incremented by 1 when a timestamp is received from Ethernet Agents. [Decrement conditions] HW: Decremented by 1 when a timestamp is read from timestamp RAM.	R
31:5	—	These bits are read as 0.	R

34.3.6.5 GWTSMNM : Timestamp Maximum Number Monitoring Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0184

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	TMNTR[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	TMNTR[4:0]	Timestamp Maximum Number in Timestamp RAM [Update conditions] HW: Set to GWTSNM.TNTR when GWTSNM.TNTR> GWTSNM.TMNTR. [Clearing condition] HW: Being in RESET mode will clear this register. SW: Reading this register clears it to GWTSNM.TNTR value.	R
31:5	—	These bits are read as 0.	R

34.3.7 AXI Master Registers

34.3.7.1 GWAC : AXI Control Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0190

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	AMP	AMPR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AMPR	AXI Master Pause Request This register blocks the AXI master from making new accesses (Because the AXI master has register slices for timing purpose few AXI accesses can be emitted before stopping). 0: AXI master pause not requested 1: AXI master pause requested	R/W
1	AMP	AXI Master Paused “AXI Master Pause” stop only the final processing of the AXI interface. (Internal processing cannot be stopped.) For example, the AXI address for chain [i] is loaded immediately before “AXI Master Paused”. This address will used after “AXI Master not paused” regardless of AXI address re-configuration (by GWDCCi) during “AXI Master Pause”. 0: AXI master not paused (transaction ongoing) 1: AXI master paused (no transaction ongoing)	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

AMP bit (AXI Master Paused)

[Setting condition]

HW: When GWAC.AMPR is set to 1’b1 and all ongoing AXI transactions are completed, this bit will be set.

[Clearing condition]

HW: When GWAC.AMPR is set to 0, this bit will be set to 0 (it can take time because of asynchronous modules).

34.3.7.2 GWDCBAC0 : Descriptor Chain Base Address Configuration Register 0

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0194

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	DCBAU[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DCBAU[7:0]	Descriptor Chain Base Address Upper Part For further setting information, see section 34.5.1.3.1. LINKFIX Table Initialization.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

34.3.7.3 GWDCBAC1 : Descriptor Chain Base Address Configuration Register 1

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0198

Bit position:	31–0
Bit field:	DCBAL[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	DCBAL[31:0]	Descriptor Chain Base Address Lower Part For further setting information, see section 34.5.1.3.1. LINKFIX Table Initialization.	R/W

34.3.7.4 GWMDNC : Maximum Descriptor Number Configuration Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x01A0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSDMN[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TXDMN[4:0]					—	—	—	RXDMN[4:0]				
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
4:0	RXDMN[4:0]	RX Descriptor Maximum Number Configures the maximum number of descriptors that can be processed at once for an RX queue (It limits to GWMDNC.RXDMN+1 the number of descriptors read that can be done for an RX frame). See GWEIS0.RXDNES register explanation.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
12:8	TXDMN[4:0]	TX Descriptor Maximum Number*1 Configures the maximum number of descriptors that can be processed at once for a TX queue (It limits to GWMDNC.TXDMN+1 the number of descriptors read that can be done for a TX frame). See GWEIS0.TXDNES.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
17:16	TSDMN[1:0]	Timestamp Descriptor Maximum Number Configures the maximum number of descriptors that can be processed at once for a TS queue (It limits to GWMDNC.TSDMN+1 the number of descriptors read that can be done for a timestamp). See GWEIS0.TSDNES.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: The switch maximum input frame size is 60 KB so this register should be set to a value smaller or equal to 30. To avoid any unexpected frame loss due to this register, any software sending frames bigger than 58 KB should avoid having more than one consecutive LINK/LINKFIX descriptor in a descriptor chain.

RXDMN[4:0] bits (RX Descriptor Maximum Number)

[Cautions]

SW: This maximum descriptor number takes in account all descriptors including LINK, LINKFIX descriptors and descriptors remaining from a previous error frame like FMID_EMPTY and FEND_EMPTY descriptors. It should be taken in account in account while setting this register.

TXDMN[4:0] bits (TX Descriptor Maximum Number)

[Cautions]

SW: This maximum descriptor number takes in account all descriptors including LINK, LINKFIX descriptors and descriptors remaining from a previous error frame like FMID and FEND descriptors. It should be taken in account while setting this register.

34.3.7.5 GWTRCi : Transmission Request Configuration Register i (i = 0, 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0200 + 0x04 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj	TSRj
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
b (b = 0 to 31)	TSRj (j = 32 × i + b)	Transmission Start Request j (j = 0 to 63)*1 This register is used to start transfer from CPU to switch for its corresponding TX queue. 0: TX Descriptor Chain is empty. 1: Transmission request is ongoing.	R/W*2

Note 1. HW: For RX queues, this bit cannot be set.
Note 2. Read value differs from written value.

TSRj bits (Transmission Start Request j (j = 0 to 63))

[Setting condition (only for TX queues)]

SW: Writing 1 to this bit will this bit set if queue t is a transmission queue (GWDCCi.DQT is set).

HW: a transmission request received through INTER_TX[t] interface will set this bit if queue t is a transmission queue (GWDCCi.DQT is set).

[Clearing condition]

HW: When HW read a descriptor other than FSINGLE, FSTART, FMID, FEND, LINK and LINKFIX. *

HW: When an AXI error occurs while reading a descriptor in the corresponding AXI descriptor queue. *

HW: When a descriptor number error occurs while reading the corresponding AXI descriptor queue. *

HW: Going out of OPERATION mode will clear this register.

34.3.7.6 GWTPCp : Transmission Pause Configuration Register p (p = 0 to 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0300 + 0x04 × p

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	PPPL7	PPPL6	PPPL5	PPPL4	PPPL3	PPPL2	PPPL1	PPPL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PPPL7 to PPPL0	Per Priority Pause Level i (The variable i corresponds to the bit position number.) 0: Transmission queues with their priority GWDCCi.DCP set to i are not paused when pause level p is set (PAUSE[2][p] is set [COMA]). 1: Transmission queues with the priority GWDCCi.DCP set to i are paused when pause level p is set (PAUSE[2][p] is set [COMA]).	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

34.3.7.7 GWARIRM : AXI RAM Initialization Register Monitoring Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0380

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ARR	ARIOG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ARIOG	AXI RAM Initialization Ongoing [Setting condition] SW: By writing 1 to this register. It starts AXI RAM initialization. [Clearing condition] HW: This bit is cleared when AXI RAM initialization is finished. Min clk_period * 64 = [exp] (1000/320) * 128 = 400 ns	R/W*1
1	ARR	AXI RAM Ready [Setting condition] When GWARIRM.ARIOG is getting cleared. [Clearing condition] By writing 1 to GWARIRM.ARIOG.	R
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

34.3.7.8 GWDCCi : Descriptor Chain i Configuration Register (i = 0 to 63)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0400 + 0x04 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	OSID[2:0]			—	—	—	BALR	—	—	—	—	—	DCP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	DQT	SL	ETS	EDE	—	—	—	—	—	—	SM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	SM[1:0]	Synchronization Mode 0 0: Normal mode (full descriptor write back) 0 1: No-write-back mode (no descriptor write back) 1 0: Keep-DT mode (no update of DT field at descriptor write back) 1 1: Reserved	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	EDE	Extended Descriptor Enable 0: Basic Descriptor 1: Extended Descriptor	R/W
9	ETS	Enable Timestamp Storage*1 0: Timestamp is not added in the Descriptor. 1: Timestamp is added in the Descriptor.	R/W
10	SL	Security Level*1 When a chain is secured, an unsecure descriptor cannot enter it (when a descriptor is received from MFWD with FDESCR.SEC equal to 0). 0: Chain i unsecure 1: Chain i secure	R/W
11	DQT	Descriptor Queue Type 0: Descriptor queue i is a reception queue. 1: Descriptor queue i is a transmission queue.	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
18:16	DCP[2:0]	Descriptor Chain Priority*2 0 0 0: Lowest priority 1 1 1: Highest priority	R/W*3
23:19	—	These bits are read as 0. The write value should be 0.	R/W
24	BALR	Base Address Load Request This bit is used to reset current_address field in the AXI address RAM to {{GWDCBAC.DCBAU, GWDCBAC.DCBAL} + I × 8} [Setting condition] SW: Writing 1 to this bit will set it. [Clearing condition] HW: This bit will be cleared when the current_address field in the AXI address RAM is reset.	R/W*3
27:25	—	These bits are read as 0. The write value should be 0.	R/W
30:28	OSID[2:0]	OS ID When a memory access is done for descriptor queue number i the OSID set in this register will be used.	R/W
31	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. HW: This register is only valid for RX queues.
Note 2. • HW: This register is only valid for TX queues.

- SW: This register value should not be changed for a TX queue when GWTRCj.TSRj is set. (When transmission is ongoing for the corresponding queue)

Note 3. Read value differs from written value.

34.3.7.9 GWAARSS : AXI Address RAM Searching Setting Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0800

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	AARA[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	AARA[5:0]	AXI Address RAM Address*1 This register is used to read the current address used in AXI master for GWAARSS.AARA descriptor queue.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. HW: Due to the pipeline architecture of the AXI master, the AXI read can just give an idea of which address is processing the AXI master and is not precise enough to be used for HW/SW synchronization. This register is only here for debug purpose.

34.3.7.10 GWAARSR0 : AXI Address RAM Searching Result Register 0

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0804

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	AARS	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	ACARU[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ACARU[7:0]	AXI Current Address Result Upper Part*1 Displays AXI address read value. [Update conditions] HW: GWAARSR0.AARS clear event.	R
30:8	—	These bits are read as 0.	R
31	AARS	AXI Address RAM Searching This register is used to read an in AXI address RAM. [Setting condition] SW: Writing GWAARSS will set this bit. [Clearing condition] HW: This bit will be deasserted when the AXI address RAM search is completed.	R

Note 1. AXI address read will not restart from the base address of chain after RESET mode (Because being in RESET mode will not clear this register).

34.3.7.11 GWAARSR1 : AXI Address RAM Searching Result Register 1

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0808

Bit position:	31–0
Bit field:	ACARL[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	ACARL[31:0]	AXI Current Address Result Lower Part*1 Displays AXI address read value. [Update conditions] HW: GWAARSR0.AARS clear event.	R

Note 1. AXI address read will not restart from the base address of chain after RESET mode (Because being in RESET mode will not clear this register).

34.3.7.12 GWIDAUASi : Incremental Data Area i Used Area Size Register (i = 0 to 3)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0840 + 0x04 × i

Bit position:	31								23–0
Bit field:	—	—	—	—	—	—	—	—	IDAUAS[23:0]
Value after reset:	0	0	0	0	0	0	0	0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
23:0	IDAUAS[23:0]	Incremental Data Area Used Size of RX Descriptor Chain i*1 Represents the byte numbers that have been used in the corresponding incremental area. [Clearing condition] HW: Being in RESET mode will clear this register. HW: When a FEMPTY_IS descriptor is read in the corresponding descriptor queue, this register gets cleared. [Increment conditions] HW: When a frame has been stored in the corresponding incremental area, this register is incremented by the frame size. [Decrement conditions] SW: By writing a value, SW will decrement this register by this value.	R/W*2
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: should always write a value smaller than the current register value.
Note 2. Read value differs from written value.

34.3.7.13 GWIDASMi : Incremental Data Area i Size Monitoring Register (i = 0 to 3)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0880 + 0x04 × i

Bit position:	31								23–0
Bit field:	—	—	—	—	—	—	—	—	IDAS[23:0]
Value after reset:	0	0	0	0	0	0	0	0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
23:0	IDAS[23:0]	Incremental Data Area Size of RX Descriptor Chain i This register indicates the size of RX descriptor chain i incremental area in bytes. [Clearing condition] HW: Being in RESET mode will clear this register. [Update conditions] HW: When a FEMPTY_IS descriptor is read in the corresponding descriptor queue, this register is updated to DESCR.DS × 4096.	R
31:24	—	These bits are read as 0.	R

34.3.7.14 GWIDASAMi0 : Incremental Data Area i Start Address Monitoring Register 0 (i = 0 to 3)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0900 + 0x08 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	IDASAU[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	IDASAU[7:0]	Incremental Data Area Start Address Upper Part of RX Descriptor Chain i [Clearing condition] HW: Being in RESET mode will clear this register. [Update conditions] HW: When a FEMPTY_IS descriptor is read in the corresponding descriptor queue, this register is updated to DESCR.PTR[39:32].	R
31:8	—	These bits are read as 0.	R

34.3.7.15 GWIDASAMi1 : Incremental Data Area i Start Address Monitoring Register 1 (i = 0 to 3)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0904 + 0x08 × i

Bit position:	31–0
Bit field:	IDASAL[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	IDASAL[31:0]	Incremental Data Area Start Address Lower Part of RX Descriptor Chain i [Clearing condition] HW: Being in RESET mode will clear this register. [Update conditions] HW: When a FEMPTY_IS descriptor is read in the corresponding descriptor queue, this register is updated to DESCR.PTR[31:0].	R

34.3.7.16 GWIDACAMi0 : Incremental Data Area i Current Address Monitoring Register 0 (i = 0 to 3)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0980 + 0x08 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	IDACAU[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	IDACAU[7:0]	Incremental Data Area Current Address Upper Part of RX Descriptor Chain i [Clear conditions] HW: Being in RESET mode will clear this register. [Update conditions] HW: When a FEMPTY_IS descriptor is read in the corresponding descriptor queue, this register is updated to DESCR.PTR[39:32]. HW: When a burst is decided to be sent in the incremental area, {GWIDACAMi0.IDACAU, GWIDACAMi1.IDACAL} is incremented by the burst size. HW: {GWIDACAMi0.IDACAU, GWIDACAMi1.IDACAL} overflows at {GWIDASAMi0.IDASAU, GWIDASAMi1.IDASAL} + GWIDASMi.IDAS-1.	R
31:8	—	These bits are read as 0.	R

34.3.7.17 GWIDACAMi1 : Incremental Data Area i Current Address Monitoring Register 1 (i = 0 to 3)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0984 + 0x08 × i

Bit position: 31 … 0

Bit field: IDACAL[31:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	IDACAL[31:0]	Incremental Data Area Current Address Lower Part of RX Descriptor Chain i [Clear conditions] HW: Being in RESET mode will clear this register. [Update conditions] HW: When a FEMPTY_IS descriptor is read in the corresponding descriptor queue, this register is updated to DESCR.PTR[31:0]. HW: When a burst is decided to be sent in the incremental area, {GWIDACAMi0.IDACAU, GWIDACAMi1.IDACAL} is incremented by the burst size. HW: {GWIDACAMi0.IDACAU, GWIDACAMi1.IDACAL} overflows at {GWIDASAMi0.IDASAU, GWIDASAMi1.IDASAL} + GWIDASMi.IDAS-1.	R

34.3.8 Rate Limiter Function Registers

34.3.8.1 GWGRLC : Global Rate Limiter Configuration Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0A00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	GRLULRS	GRLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GRLIV[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	GRLIV[15:0]	Global Rate Limiter Incremental Value For further setting information see section 34.5.2.1.2. Rate Limiters. [Cautions] SW: Setting this register to 0 or a value close to 0 would set GWCA to a very low throughput or could stuck GWCA in transmission.	R/W
16	GRLE	Global Rate Limiter Enable The global rate limiter limits the throughput through all TX queues to avoid the switch to take in too much data at once. 0: Global Rate limiter disabled 1: Global Rate limiter enabled	R/W
17	GRLULRS	Global Rate Limiter Upper Limit Reached Status Flag If this bit gets set when only the global rate limiter is enabled (per port rate limiters disabled), it means that the AXI master is too slow to provide the throughput set in the global rate limiter or that the AXI latency has been underestimated. This bit can get set while using per port rate limiters. In this case it should be ignored. [Setting condition] HW: When the global rate limit reaches its upper limit GWGRLULC.GRLUL, this bit gets set. [Clearing condition] HW: Being in RESET mode will clear this register. SW: Writing one to this bit will clear it.	R/W*1
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

34.3.8.2 GWGRLULC : Global Rate Limiter Upper Limit Configuration Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0A04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	GRLUL[23:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GRLUL[23:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	GRLUL[23:0]	Global Rate Limiter Upper Limit*1 Set the maximum number of credits in bit rate limiter that can accumulate before stopping. For further setting information see section 34.5.2.1.2. Rate Limiters.	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: This register should not be set to a value bigger than 0x800000.

34.3.8.3 GWRLCi : Rate Limiter i Configuration Register (i = 0 to 7)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0A80 + 0x8 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	RLIV[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	RLIV[11:0]	Rate Limiter Incremental Value For further setting information see section 34.5.2.1.2. Rate Limiters. [Cautions] SW: Setting this register to 0 or a value close to 0 would set corresponding queue to a very low throughput or could stuck the corresponding queue.	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
16	RLE	Rate Limiter Enable Rate limiter i limit the through put for AXI descriptor queue number 63-I. For details, see section 34.5.1.1. AXI Descriptor Queue Mapping. 0: Rate limiter i disabled 1: Rate limiter i enabled	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

34.3.8.4 GWRLULCi : Rate Limiter i Upper Limit Configuration Register (i = 0 to 7)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0A84 + 0x8 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	RLUL[23:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RLUL[23:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	RLUL[23:0]	Rate Limiter Upper Limit*1 Set the maximum number of credits in bit rate limiter i can accumulate before stopping. This register can be used if a lot of traffic happens on the AXI bus so burst on queues i make the switch overflow. If not required, set this register to 0x80_0000. For further setting information see section 34.5.2.1.2. Rate Limiters.	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: This register should not be set to a value bigger than 0x80_0000.

34.3.9 Interrupt Function Registers

34.3.9.1 GWIDPC : Interrupt Delay Prescaler Configuration Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0B80

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	IDPV[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	IDPV[9:0]	Interrupt Delay Prescaler Value This register is used to create an internal clock. This internal clock period will be clk_delay_period = clk_period*(GWIDPC.IDPV+1) where clk_period is the period of clk. For further information, see section 34.5.6. Interrupt Delay Function.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

34.3.9.2 GWIDCi : Interrupt Delay i Configuration Register (i = 0 to 63)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x0C000 + 0x4 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	IDV[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	IDV[11:0]	Interrupt Delay Value Configures the delay between the interrupt status flag GWDISi.DISt setting and the actual interrupt event in us. If this register is set to 0, data interrupt will occur without delay. If value X is set to this register, the interrupt will be delayed by a time between X-1*clk_delay_period us and X*clk_delay_period us where clk_delay_period is the internal clock created using GWIDPC register period. For further information, see section 34.5.6. Interrupt Delay Function.	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

34.3.10 GWCA Counter Registers

34.3.10.1 GWRDCN : Received Data Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1000

Bit position:	31 ... 0
Bit field:	RDN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	RDN[31:0]	Received Data Number This register counts data that has been received by GWCA (data aborted by AXI error are accounted here).	R

RDN[31:0] bits (Received Data Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a frame is passed from multicast control to AXI master interface and if this register has a value other than 32.

34.3.10.2 GWTDCN : Transmitted Data Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1004

Bit position:	31 ... 0
Bit field:	TDN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TDN[31:0]	Transmitted Data Number This register counts data that has been transmit by GWCA (this includes data transmitted with an error and frames smaller than 32 bytes).	R

TDN[31:0] bits (Transmitted Data Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a frame is passed from AXI master interface to TX data store and if this register has a value different than 32.

34.3.10.3 GWTSCN : Timestamp Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1008

Bit position:	31–0
Bit field:	TN[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TN[31:0]	Timestamp Number This register counts timestamp processed by GWCA (TS lost because of AXI errors are accounted here).	R

TN[31:0] bits (Timestamp Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a Timestamp is saved in timestamp RAM and if this register has a value other than 32.

34.3.10.4 GWTSOVFECN : Timestamp Overflow Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x100C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSOVFEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TSOVFEN[15:0]	Timestamp Overflow Error Number This register counts the number of timestamps lost because of timestamp RAM overflow.	R
31:16	—	These bits are read as 0.	R

TSOVFEN[15:0] bits (Timestamp Overflow Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a timestamp overflow error happens and if this register has a value other than 16.

34.3.10.5 GWUSMFSECN : Under Minimum Frame Size Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	USMFSEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	USMFSEN[15:0]	Under Switch Minimum Frame Size Error Number This register counts the number of transmit data lost because of under switch minimum size error.	R
31:16	—	These bits are read as 0.	R

USMFSEN[15:0] bits (Under Switch Minimum Frame Size Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when an Under Switch Minimum Frame Size Error happens and if this register has a value other than 16.

34.3.10.6 GWTFECN : TAG Filtering Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TFEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TFEN[15:0]	TAG Filtering Error Number This register counts the number of transmit data lost because of TAG filtering.	R
31:16	—	These bits are read as 0.	R

TFEN[15:0] bits (TAG Filtering Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a TAG filter error happens and if this register has a value different than 16.

34.3.10.7 GWSEQECN : Sequence Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SEQEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SEQEN[15:0]	Sequence Error Number This register counts the number of transmit data lost because of a sequence error.	R
31:16	—	These bits are read as 0.	R

SEQEN[15:0] bits (Sequence Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a sequence error happens and if this register has a value different than 16.

34.3.10.8 GWTXDNECN : TX Descriptor Number Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TXDNEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TXDNEN[15:0]	TX Descriptor Number Error Number This register counts the number of transmit data lost because of a TX Descriptor Number Error.	R
31:16	—	These bits are read as 0.	R

TXDNEN[15:0] bits (TX Descriptor Number Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a TX Descriptor Number Error happens and if this register has a value other than 16.

34.3.10.9 GWFSECN : Frame Size Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1024

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FSEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	FSEN[15:0]	Frame Size Error Number This register counts the number of receive data lost because of a Frame Size Error.	R
31:16	—	These bits are read as 0.	R

FSEN[15:0] bits (Frame Size Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a Frame Size Error happens and if this register has a value different than 16.

34.3.10.10 GWTDFECN : Timestamp Descriptor Full Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1028

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TDFEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TDFEN[15:0]	Timestamp Descriptor Full Error Number This register counts the number of timestamps lost because of a Timestamp Descriptor Full Error.	R
31:16	—	These bits are read as 0.	R

TDFEN[15:0] bits (Timestamp Descriptor Full Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a Timestamp Descriptor Full Error happens and if this register has a value other than 16.

34.3.10.11 GWTSDNECN : Timestamp Descriptor Number Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x102C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSDNEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TSDNEN[15:0]	Timestamp Descriptor Number Error Number This register counts the number of timestamps loss because of a Timestamp Descriptor Number Error.	R
31:16	—	These bits are read as 0.	R

TSDNEN[15:0] bits (Timestamp Descriptor Number Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a Timestamp Descriptor Number Error happens and if this register has a value other than 16.

34.3.10.12 GWDQOECN : Descriptor Queue Overflow Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1030

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DQOEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DQOEN[15:0]	Descriptor Queue Overflow Error Number This register counts the number of receive data lost because of a Descriptor Queue Overflow Error.	R
31:16	—	These bits are read as 0.	R

DQOEN[15:0] bits (Descriptor Queue Overflow Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a Descriptor Queue Overflow Error happens and if this register has a value other than 16.

34.3.10.13 GWDQSECN : Descriptor Queue Security Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DQSEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DQSEN[15:0]	Descriptor Queue Security Error Number This register counts the number of receive data lost because of a Descriptor Queue Security Error.	R
31:16	—	These bits are read as 0.	R

DQSEN[15:0] bits (Descriptor Queue Security Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a Descriptor Queue Security Error happens and if this register has a value other than 16.

34.3.10.14 GWDFECN : Descriptor Full Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1038

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DFEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DFEN[15:0]	Descriptor Full Error Number This register counts the number of receive data lost because of a Descriptor Full Error.	R
31:16	—	These bits are read as 0.	R

DFEN[15:0] bits (Descriptor Full Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a Descriptor Full Error happens and if this register has a value other than 16.

34.3.10.15 GWDSECN : Descriptor Security Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x103C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DSEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DSEN[15:0]	Descriptor Security Error Number This register counts the number of receive data lost because of a Descriptor Security Error.	R
31:16	—	These bits are read as 0.	R

DSEN[15:0] bits (Descriptor Security Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a Descriptor Security Error happens and if this register has a value other than 16.

34.3.10.16 GWDSZECN : Data Size Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1040

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DSZEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DSZEN[15:0]	Data Size Error Number This register counts the number of receive data lost because of a Data Size Error.	R
31:16	—	These bits are read as 0.	R

DSZEN[15:0] bits (Data Size Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a Data Size Error happens and if this register has a value other than 16.

34.3.10.17 GWDCTECN : Descriptor Chain Type Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1044

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DCTEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DCTEN[15:0]	Descriptor Chain Type Error Number This register counts the number of receive data lost because of a Descriptor Chain Type Error.	R
31:16	—	These bits are read as 0.	R

DCTEN[15:0] bits (Descriptor Chain Type Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a Descriptor Chain Type Error happens and if this register has a value different than 16.

34.3.10.18 GWRXDNECN : RX Descriptor Number Error Counter Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1048

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RXDNEN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RXDNEN[15:0]	RX Descriptor Number Error Number This register counts the number of receive data lost because of a RX Descriptor Number Error.	R
31:16	—	These bits are read as 0.	R

RXDNEN[15:0] bits (RX Descriptor Number Error Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Reading this register clears it.

[Increment conditions]

HW: Incremented by 1 when a RX Descriptor Number Error happens and if this register has a value different than 16.

34.3.11 GWCA Interrupt Registers

34.3.11.1 GWDISi : Data Interrupt Status Register i (i = 0, 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1100 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt	DISt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
b (b = 0 to 31)	DISt (t = 32 × i + b)	Data t Interrupt Status Flag (t = 0 to 63)	R/W*1

Note 1. Read value differs from written value.

DISt bits (Data t Interrupt Status Flag (t = 0 to 63))

[Setting condition TX]

HW: A descriptor has been processed in the corresponding queue and DESCR.DIE was set in the corresponding read descriptor. [About set timing information for normal TX] A descriptor is considered as processed when written back. All descriptor which are not written back are considered as processed at the timing it should have been written back so that SW can know that all the previous at the actual descriptor has been fully processed.

[Setting condition RX]

HW: A frame has been processed in the corresponding queue and DESCR.DIE was set in at least one of the corresponding read descriptors. [About set timing information for normal RX] A frame is considered as processed when frame FSTART or FSINGLE descriptor is processed. A descriptor is considered as processed when written back. All descriptor which are not written back are considered as processed at the timing it should have been written back so that SW can know that all the previous at the actual descriptor has been fully processed. All unknown descriptors are never considered as processed (See GWEIS2i.DFESt).

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

34.3.11.2 GWDIEi : Data Interrupt Enable Register i (i = 0, 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1104 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt	DIEt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
b (b = 0 to 31)	DIEt (t = 32 × i + b)	Data t Interrupt Enable (t = 0 to 63) [Setting condition] Writing 1 to this bit will set it. [Clearing condition] Writing 1 to GWDIDi.DIDt register will clear this bit. 0: Interrupt disabled 1: Interrupt Enabled	R/W*1

Note 1. Read value differs from written value.

34.3.11.3 GWDIDi : Data Interrupt Disable Register i (i = 0, 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1108 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt	DIDt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
b (b = 0 to 31)	DIDt (t = 32 × i + b)	Data t Interrupt Disable (t = 0 to 63) Writing 1 to this bit will clear GWDIEi.DIEt register.	R

34.3.11.4 GWDIDSi : Data Interrupt Delayed Status Register i (i = 0, 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x110C + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt	DIDSt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
b (b = 0 to 31)	DIDSt (t = 32 × i + b)	Data t Interrupt Delayed Status Flag (t = 0 to 63) Displays the interrupt GWDISi.DISt delayed by interrupt delay function.	R

34.3.11.5 GWTSDIS : Timestamp Data Interrupt Status Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1180

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSDIS1	TSDIS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	TSDIS1 to TSDIS0	Timestamp Data i Interrupt Status Flag (The variable i corresponds to the bit position number.)	R/W*1
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

TSDISi bits (Timestamp Data i Interrupt Status Flag)

[Setting condition]

HW: A descriptor is processed in the corresponding queue and DESCR.DIE was set in the corresponding read descriptor. A descriptor is considered as processed when written back. All descriptor which are not written back are considered as processed at the timing it should have been written back so that SW can know that all the previous at the actual descriptor has been fully processed. All unknown descriptors are never considered as processed (See GWEIS0.TDFES).

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

34.3.11.6 GWTSDIE : Timestamp Data Interrupt Enable Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1184

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSDIE 1	TSDIE 0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	TSDIE1 to TSDIE0	Timestamp Data i Interrupt Enable (The variable i corresponds to the bit position number.) [Setting condition] Writing 1 to this bit will set it. [Clearing condition] Writing 1 to GWTSDID.TSDIDs register will clear this bit. 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

34.3.11.7 GWTSDID : Timestamp Data Interrupt Disable Register

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1188

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSDID1	TSDID0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	TSDID1 to TSDID0	Timestamp Data i Interrupt Disable (The variable i corresponds to the bit position number.) Writing 1 to this bit will clear GWTSDIE.TSDIEs register.	R
31:2	—	These bits are read as 0. The write value should be 0.	R

34.3.11.8 GWEIS0 : Error Interrupt Status Register 0

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1190

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	TSDNES1	TSDNES0	—	—	TDFES1	TDFES0	FSES7	FSES6	FSES5	FSES4	FSES3	FSES2	FSES1	FSES0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSHES	TXDNES	—	SEQES	TFES	USMFSES	TSOVFES	—	—	—	—	—	—	—	—	AES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AES	AXI Error Status Flag	R/W*1
8:1	—	These bits are read as 0. The write value should be 0.	R/W
9	TSOVFES	Timestamp Overflow Error Status Flag	R/W*1
10	USMFSES	Under Switch Minimum Frame Size Error Status Flag	R/W*1
11	TFES	TAG Filtering Error Status Flag	R/W*1
12	SEQES	Sequence Error Status Flag*2	R/W*1
13	—	This bit is read as 0. The write value should be 0.	R/W
14	TXDNES	TX Descriptor Number Error Status Flag*2	R/W*1
15	TSHES	Timestamp Hardware Error Status Flag	R/W*1
23:16	FSES7 to FSES0	Frame Size Error Status Flag i (The variable i corresponds to the bit position number.)	R/W*1
25:24	TDFES1 to TDFES0	Timestamp Descriptor i Full Error Status Flag (The variable i corresponds to the bit position number.)	R/W*1
27:26	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
29:28	TSDNES1 to TSDNES0	Timestamp Descriptor i Number Error Status Flag (The variable i corresponds to the bit position number.)	R/W*1
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.
Note 2. HW: This flag is only available for TX descriptor queues.

AES bit (AXI Error Status Flag)

[Setting condition]

HW: When an error is detected on an AXI access (xRESP != 00)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Error recovery]

HW: For reception, if an AXI error happens during descriptor read before a frame/timestamp transfer started, the frame/timestamp is rejected.

HW: For reception, if an AXI error happens during descriptor read after a frame transfer started, the remaining part of the frame is rejected and DESCR.AXIE is set in the frame corresponding first written back data descriptor, which is FSTART in normal synchronization mode (for GWDCCi.SM == 00).

HW: For reception, if an AXI error happens during data write, DESCR.AXIE is set in the frame corresponding first written back data descriptor, which a FSTART or a FSINGLE descriptor in normal synchronization mode (for GWDCCi.SM == 00).

HW: For reception, if an AXI error happens during RX/TS descriptor write, nothing happens.

HW: For transmission, if an AXI error happens during descriptor read and no frame is ongoing, corresponding GWTRCi.TSRj bit is cleared and no frame is transmitted.

HW: For transmission, if an AXI error happens during descriptor read and a frame is ongoing, the ongoing frame is padded with 0, sent to MFWD with AXE error set ((3) SAEF format) and corresponding GWTRCi.TSRj bit is cleared.

HW: For transmission, if an AXI error happens during data read, the ongoing frame is sent to MFWD with AXE error set ((3) SAEF format).

HW: For transmission, if an AXI error happens during descriptor write, nothing happens.

SW: System reset.

TSOVFES bit (Timestamp Overflow Error Status Flag)

[Setting condition]

HW: When a timestamp is received when the timestamp RAM is full.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Error recovery]

HW: A timestamp is lost.

SW: Nothing if it is acceptable to lose a timestamp else switch reset.

USMFSES bit (Under Switch Minimum Frame Size Error Status Flag)

[Setting condition]

HW: A frame smaller than 32 bytes has been received from CPU for transmission.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: The frame is discarded.

SW: Software error, software should be reviewed.

TFES bit (TAG Filtering Error Status Flag)

[Setting condition]

HW: An unauthorized TAG format has been detected. (See section 34.5.2.3.2. VLAN Tagging).

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Frame is sent to MFWD with local descriptor DESCR.TFE bit set (See section 34.5.2.3.3. Frame Saving in Local RAM).

SW: Software error, software should be reviewed.

SEQES bit (Sequence Error Status Flag)

[Setting condition]

HW: A FMID, FEND has been received before a frame transfer started.

HW: A descriptor different than FMID, FEND, LINK and LINKFIX has been received after a frame transfer started.

HW: An FSTART, FMID, FEND or FSINGLE descriptor has been received with DESCR.DS set to 0.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: If a SEQuence Error happens before a frame transfer started, nothing happens.

HW: If a SEQuence Error happens after a frame transfer started, The ongoing frame is padded with 0 and sent to MFWD with SEQE error set ((3) SAEF format).

SW: Software error, software should be reviewed.

TXDNES bit (TX Descriptor Number Error Status Flag)

[Setting condition]

HW: GWMDNC.TXDMN+1 descriptor has already been used to process one frame and the frame processing is not finished.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: If a TX Descriptor Number Error happens before a frame transfer started, GWTRCi.TSRj bit is cleared.

HW: If an TX Descriptor Number Error happens after a frame transfer started, the ongoing frame is padded with 0, sent to MFWD with DNE error set ((3) SAEF format) and corresponding GWTRCi.TSRj bit is cleared.

SW: Software error, software should be reviewed.

TSHES bit (Timestamp Hardware Error Status Flag)

[Setting condition]

HW: This error happens when timestamps are coming too fast to GWCA to be stored in time, so timestamp are lost even if the timestamp RAM is not full. This error should never happen and tells that the number of captured timestamps is too high or the bus clock clk has a too low frequency.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: timestamp lost.

SW: No recovery, this error should not happen.

FSESi bits (Frame Size Error Status Flag i)

[Setting condition]

HW: Bit q of this register is set when a frame bigger than GWRMFSC.MFS has been received for descriptor queue q.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: The current frame will be lost. Following data will be processed normally.

SW: System dependent, cannot be defined here.

TDFESi bits (Timestamp Descriptor i Full Error Status Flag)

[Setting condition]

HW: Bit i sets when a timestamp has been received for descriptor chain i which is full (read any other descriptor than a FEMPTY_ND, LINKFIX or LINK descriptor).

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Timestamp lost.

SW: Nothing if it is acceptable to lose a timestamp else switch reset.

SW: AXI is too slow to save all timestamps in the CPU RAM. Less timestamps should be captured or more bandwidth on AXI should be reserved for ESWM.

TSDNESi bits (Timestamp Descriptor i Number Error Status Flag)

[Setting condition]

HW: Bit i sets when GWMDNC.TSDMN+1 descriptor has already been used to process one timestamp for descriptor chain i and the timestamp processing is not finished.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: Timestamp lost.

SW: Software error, software should be reviewed.

34.3.11.9 GWEIE0 : Error Interrupt Enable Register 0

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1194

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	TSDNEE1	TSDNEE0	—	—	TDFEE1	TDFEE0	FSEE7	FSEE6	FSEE5	FSEE4	FSEE3	FSEE2	FSEE1	FSEE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSHEE	TXDNEE	—	SEQEE	TFEE	USMFSEE	TSOVFEE	—	—	—	—	—	—	—	—	AEE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AEE	AXI Error Enable [Setting condition] Writing 1 to this bit will set it. [Clearing condition] Writing 1 to GWEID0.AED register will clear this bit. 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
8:1	—	These bits are read as 0. The write value should be 0.	R/W
9	TSOVFEE	Timestamp Overflow Error Enable [Setting condition] Writing 1 to this bit will set it. [Clearing condition] Writing 1 to GWEID0.TSOVFED register will clear this bit. 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
10	USMFSEE	Under Minimum Frame Size Error Enable [Setting condition] Writing 1 to this bit will set it. [Clearing condition] Writing 1 to GWEID0.USMFSED register will clear this bit. 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
11	TFEE	TAG Filtering Error Enable [Setting condition] Writing 1 to this bit will set it. [Clearing condition] Writing 1 to GWEID0.TFED register will clear this bit. 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
12	SEQEE	Sequence Error Enable [Setting condition] Writing 1 to this bit will set it. [Clearing condition] Writing 1 to GWEID0.SEQED register will clear this bit. 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
13	—	This bit is read as 0. The write value should be 0.	R/W
14	TXDNEE	TX Descriptor Number Error Enable [Setting condition] Writing 1 to one of these bits will set it. [Clearing condition] Writing 1 to GWEID0.TXDNED register will clear this bit. 0: Interrupt disabled 1: Interrupt Enabled	R/W*1

Bit	Symbol	Function	R/W
15	TSHEE	Timestamp Hardware Error Enable [Setting condition] Writing 1 to one of these bits will set it. [Clearing condition] Writing 1 to GWEID0.TSHED register will clear this bit. 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
23:16	FSEE7 to FSEE0	Frame Size Error Enable i (The variable i corresponds to the bit position number.) [Setting condition] Writing 1 to one of these bits will set it. [Clearing condition] Writing 1 to one of GWEID0.FSED bits will clear the corresponding bit in this register. 0: Interrupt disabled for error q 1: Interrupt enabled for error q	R/W*1
25:24	TDFEE1 to TDFEE0	Timestamp Descriptor i Full Error Enable (The variable i corresponds to the bit position number.) [Setting condition] Writing 1 to one of these bits will set it. [Clearing condition] Writing 1 to one of GWEID0.TDFEID bits will clear the corresponding bit in this register. 0: Interrupt disabled for descriptor queue i 1: Interrupt enabled for descriptor queue i	R/W*1
27:26	—	These bits are read as 0. The write value should be 0.	R/W
29:28	TSDNEE1 to TSDNEE0	Timestamp Descriptor i Number Error Enable (The variable i corresponds to the bit position number.) [Setting condition] Writing 1 to one of these bits will set it. [Clearing condition] Writing 1 to one of GWEID0.TSDNED bits will clear the corresponding bit in this register. 0: Interrupt disabled 1: Interrupt enabled	R/W*1
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

34.3.11.10 GWEID0 : Error Interrupt Disable Register 0

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1198

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	TSDNED1	TSDNED0	—	—	TDFED1	TDFED0	FSED7	FSED6	FSED5	FSED4	FSED3	FSED2	FSED1	FSED0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSHED	TXDNED	—	SEQED	TFED	USMFSED	TSOVFED	—	—	—	—	—	—	—	—	AED
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AED	AXI Error Disable Writing 1 to this bit will clear GWEIE0.AEE register.	R
8:1	—	These bits are read as 0.	R
9	TSOVFED	Timestamp Overflow Error Disable Writing 1 to this bit will clear GWEIE0.TSOVFEE register.	R
10	USMFSED	Under Minimum Frame Size Error Disable Writing 1 to this bit will clear GWEIE0.USMFSEE register.	R

Bit	Symbol	Function	R/W
11	TFED	TAG Filtering Error Disable Writing 1 to this bit will clear GWEIE0.TFEE register.	R
12	SEQED	Sequence Error Disable Writing 1 to this bit will clear GWEIE0.SEQEE register.	R
13	—	This bit is read as 0.	R
14	TXDNED	TX Descriptor Number Error Disable Writing 1 to this bit will clear GWEIE0.TXDNEE register.	R
15	TSHED	Timestamp Hardware Full Error Disable Writing 1 to this bit will clear GWEIE0.TSHEE register.	R
23:16	FSED7 to FSED0	Frame Size Error Disable i (The variable i corresponds to the bit position number.) Writing 1 to one of these bits will clear the corresponding bit in GWEIE0.FSEE register.	R
25:24	TDFED1 to TDFED0	Timestamp Descriptor i Full Error Disable (The variable i corresponds to the bit position number.) Writing 1 to one of these bits will clear the corresponding bit in GWEIE0.TDFEIE register.	R
27:26	—	These bits are read as 0.	R
29:28	TSDNED1 to TSDNED0	Timestamp Descriptor i Number Error Disable (The variable i corresponds to the bit position number.) Writing 1 to one of these bits will clear the corresponding bit in GWEIE0.TSDNED register.	R
31:30	—	These bits are read as 0.	R

34.3.11.11 GWEIS1 : Error Interrupt Status Register 1

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x11A0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	DQSES7	DQSES6	DQSES5	DQSES4	DQSES3	DQSES2	DQSES1	DQSES0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	DQOES7	DQOES6	DQOES5	DQOES4	DQOES3	DQOES2	DQOES1	DQOES0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DQOES7 to DQOES0	Descriptor Queue i Overflow Error Status Flag (The variable i corresponds to the bit position number.)	R/W*1
15:8	—	These bits are read as 0. The write value should be 0.	R/W
23:16	DQSES7 to DQSES0	Descriptor Queue i Security Error Status Flag (The variable i corresponds to the bit position number.)	R/W*1
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

DQOESi bits (Descriptor Queue i Overflow Error Status Flag)

[Setting condition]

HW: Bit q of this register is set when a descriptor is received for queue q when it is full (GWRDQDCq.DQD == GWRDQMq.DNQ), not disabled (GWRDQC.RDQDi is not set) and GWCA is not going out or out of OPERATION mode (GWMC.OPC == 11).

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Error recovery]

HW: Any descriptor received for a full Descriptor queue will not be accepted by GWCA and will not be forwarded to CPU.

SW: Too many descriptors are received for the corresponding queue. GWRDQDCq.DQD setting should be reviewed.

DQSESi bits (Descriptor Queue i Security Error Status Flag)

[Setting condition]

HW: Bit q of this register is set when a non-secure descriptor is received (FDESCR.SEC is not set [FWD]) and queue q is a secure queue (GWRDQSC.RDQSLn is set)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Error recovery]

HW: Any non-secure descriptor received for secure Descriptor queue will not be accepted by GWCA and will not be forwarded to CPU.

SW: System dependent, cannot be defined here.

34.3.11.12 GWEIE1 : Error Interrupt Enable Register 1

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x11A4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	DQSEE7	DQSEE6	DQSEE5	DQSEE4	DQSEE3	DQSEE2	DQSEE1	DQSEE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	DQOEE7	DQOEE6	DQOEE5	DQOEE4	DQOEE3	DQOEE2	DQOEE1	DQOEE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DQOEE7 to DQOEE0	Descriptor Queue i Overflow Error Enable (The variable i corresponds to the bit position number.) [Setting condition] Writing 1 to one of these bits will set it. [Clearing condition] Writing 1 to bit q in GWEID1.DQOED register will clear the bit q in this register. 0: Interrupt disabled for error q 1: Interrupt enabled for error q	R/W*1
15:8	—	These bits are read as 0. The write value should be 0.	R/W
23:16	DQSEE7 to DQSEE0	Descriptor Queue i Security Error Enable (The variable i corresponds to the bit position number.) [Setting condition] Writing 1 to one of these bits will set it. [Clearing condition] Writing 1 to bit q in GWEID1.DQSED register will clear the bit q in this register. 0: Interrupt disabled for error q 1: Interrupt enabled for error q	R/W*1
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

34.3.11.13 GWEID1 : Error Interrupt Disable Register 1

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x11A8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	DQSED7	DQSED6	DQSED5	DQSED4	DQSED3	DQSED2	DQSED1	DQSED0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	DQOED7	DQOED6	DQOED5	DQOED4	DQOED3	DQOED2	DQOED1	DQOED0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DQOED7 to DQOED0	Descriptor Queue i Overflow Error Disable (The variable i corresponds to the bit position number.) Writing 1 to bit q in this register will clear bit q in GWEIE1.DQOEE register.	R
15:8	—	These bits are read as 0.	R
23:16	DQSED7 to DQSED0	Descriptor Queue i Security Error Disable (The variable i corresponds to the bit position number.) Writing 1 to bit q in this register will clear bit q in GWEIE1.DQSEE register.	R
31:24	—	These bits are read as 0.	R

34.3.11.14 GWEIS2i : Error Interrupt Status Register 2i (i = 0, 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1200 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt	DFESt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
b (b = 0 to 31)	DFESt (t = 32 × i + b)	Descriptor t Full Error Status Flag (t = 0 to 63)*1	R/W*2

Note 1. HW: This register is only valid for RX queues.
Note 2. Read value differs from written value.

DFESt bits (Descriptor t Full Error Status Flag (t = 0 to 63))

[Setting condition]

HW: When a frame has been received for descriptor queue t which is full (read a descriptor other than FEMPTY, FEMPTY_IS, FEMPTY_IC, FEMPTY_ND, FEMPTY_START, FEMPTY_MID, FEMPTY_END, LINKFIX and LINK). This flag is set at the timing the frame last descriptor write-back should have been completed.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Error recovery]

HW: set of the DESCR.ERR bit in RX descriptor if a part of the frame has been already sent.

HW: Current frame or remaining part of the frame will be discarded, and next frames will be processed normally (as long as software does not insert new descriptors for reception the queue will continue overflowing).

SW: Discard data which have DESCR.ERR bit set.

34.3.11.15 GWEIE2i : Error Interrupt Enable Register 2i (i = 0, 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1204 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt	DFEEt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
b (b = 0 to 31)	DFEEt (t = 32 × i + b)	Descriptor t Full Error Enable (t = 0 to 63) 0: Interrupt disabled 1: Interrupt Enabled	R/W*1

Note 1. Read value differs from written value.

DFEEt bits (Descriptor t Full Error Enable (t = 0 to 63))

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to GWEID2i.DFEDt register will clear this bit.

34.3.11.16 GWEID2i : Error Interrupt Disable Register 2i (i = 0, 1)

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1208 + 0x10 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt	DFEDt
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
b (b = 0 to 31)	DFEDt (t = 32 × i + b)	Descriptor t Full Error Disable (t = 0 to 63) Writing 1 to this bit will clear GWEIE2i.DFEEt register.	R

34.3.11.17 GWEIS3 : Error Interrupt Status Register 3

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1280

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IAOES3	IAOES2	IAOES1	IAOES0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	IAOES3 to IAOES0	Incremental Area i Overflow Error Status Flag*1 (The variable i corresponds to the bit position number.)	R/W*2
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. HW: This register is only valid for RX incremental queues.
Note 2. Read value differs from written value.

IAOESi bits (Incremental Area i Overflow Error Status Flag)

[Setting condition]

HW: When incremental area i overflows, for further information, see section 34.5.3.5.3. Single Page Incremental Data Reception. This flag is only set when GWIDAUASi.IDAUAS crosses GWIDASMi.IDAS value (if incremental area is already overflowing, this flag will not be set again except if GWIDAUASi.IDAUAS overflows).

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Error recovery]

HW: The data coming for this incremental area will still be written.

SW: Set a new incremental area.

34.3.11.18 GWEIE3 : Error Interrupt Enable Register 3

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1284

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IAOEE3	IAOEE2	IAOEE1	IAOEE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	IAOEE3 to IAOEE0	Incremental Area i Overflow Error Enable (The variable i corresponds to the bit position number.) 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

IAOEEi bits (Incremental Area i Overflow Error Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to GWEID3.IAOEDi register will clear this bit.

34.3.11.19 GWEID3 : Error Interrupt Disable Register 3

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1288

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IAOED3	IAOED2	IAOED1	IAOED0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	IAOED3 to IAOED0	Incremental Area i Overflow Error Disable (The variable i corresponds to the bit position number.) Writing 1 to this bit will clear GWEIE3.IAOEDi register.	R
31:4	—	These bits are read as 0.	R

34.3.11.20 GWEIS4 : Error Interrupt Status Register 4

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1290

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	DSECN[5:0]						—	—	—	—	—	—	DSEIOS	DSES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	DSSECN[5:0]						—	—	—	—	—	—	DSSEIOS	DSSES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DSSES	Descriptor Security Error Status Flag	R/W*1
1	DSSEIOS	Descriptor Security Error Interrupt Overflow Status Flag*2	R/W*1
7:2	—	These bits are read as 0. The write value should be 0.	R/W
13:8	DSSECN[5:0]	Descriptor Security Error Chain Number*2	R
15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	DSES	Data Size Error Status Flag*2	R/W*1
17	DSEIOS	Data Size Error Interrupt Overflow Status Flag*2	R/W*1
23:18	—	These bits are read as 0. The write value should be 0.	R/W
29:24	DSECN[5:0]	Data Size Error Chain Number*2	R
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.
Note 2. HW: This register is only valid for RX queues.

DSSES bit (Descriptor Security Error Status Flag)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Setting condition]

HW: During reception, when an unsecure descriptor has been received for a secure queue (GWDCCi.SL is set).

[Error recovery]

HW: During reception, the current frame will be lost. Following data will be processed normally.

SW: Secure CPU should read the unsecure forwarding engine registers to find which entry is trying to use a secure queue for unsecure traffic and suppress it.

SW: Secure CPU could block access to switch from unsecure CPU.

DSSEIOS bit (Descriptor Security Error Interrupt Overflow Status Flag)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Setting condition]

When a Descriptor Security Error occurs and GWEIS4.DSSES is already set to one. In this case, the descriptor chain number in which the new error occurred is lost.

[Error recovery]

SW: Switch reset.

DSSECN[5:0] bits (Descriptor Security Error Chain Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

[Update conditions]

This field is update to the descriptor chain number in which a Descriptor Security Error occurred when GWEIS4.DSSES is being set.

DSES bit (Data Size Error Status Flag)

[Setting condition]

HW: When a frame has been received with an unexpected size, for more information see section 34.5.3.5.2. Size-controlled Data Reception. This flag is set after the frame last descriptor write back is completed.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Error recovery]

HW: set of DESCR.DSE bit in FSTART RX descriptor.

HW: If the frame was an undersized frame the frame is written with the normal descriptor sequence (FSINGLE or FSTART/FEND or FSTART/n*FMID/ FEND)

HW: If the frame was an undersized frame, when a new frame comes for the corresponding queue, the AXI master will skip all following descriptors until an empty descriptor which is not FEMPTY_MID or FEMPTY_END (at start of a frame, FEMPTY_MID and FEMPTY_END descriptors are always ignored).

If the frame is an oversized frame, the frame will be truncated.

SW: Discard data which have DESCR.DSE bit set.

SW: Because DESCR.DSE is set in RX descriptors with a size error, it is not mandatory to read this flag for error recovery.

DSEIOS bit (Data Size Error Interrupt Overflow Status Flag)

[Setting condition]

When a Data Size Error occurs and GWEIS4.DSES is already set to one. In this case, the descriptor chain number in which the new error occurred is lost.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Error recovery]

SW: Switch reset.

DSECN[5:0] bits (Data Size Error Chain Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

[Update conditions]

This field is update to the descriptor chain number in which a Data Size Error occurred when GWEIS4.DSEIS is being set.

34.3.11.21 GWEIE4 : Error Interrupt Enable Register 4

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1294

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DSEIOE	DSEE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DSSEIOE	DSSEE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DSSEE	Descriptor Security Error Enable 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
1	DSSEIOE	Descriptor Security Error Interrupt Overflow Enable 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
15:2	—	These bits are read as 0. The write value should be 0.	R/W
16	DSEE	Data Size Error Enable 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
17	DSEIOE	Data Size Error Interrupt Overflow Interrupt Enable 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

DSSEE bit (Descriptor Security Error Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to GWEID4.DSSED register will clear this bit.

DSSEIOE bit (Descriptor Security Error Interrupt Overflow Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to GWEID4.DSSEIOD register will clear this bit.

DSEE bit (Data Size Error Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to GWEID4.DSED register will clear this bit.

DSEIOE bit (Data Size Error Interrupt Overflow Interrupt Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to GWEID4.DSEIOD register will clear this bit.

34.3.11.22 GWEID4 : Error Interrupt Disable Register 4

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x1298

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DSEIOD	DSED
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DSSEIOD	DSSED
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DSSED	Descriptor Security Error Disable Writing 1 to this bit will clear GWEIE4.DSSEE register.	R
1	DSSEIOD	Descriptor Security Error Interrupt Overflow Disable Writing 1 to this bit will clear GWEIE4.DSSEIOE register.	R
15:2	—	These bits are read as 0.	R
16	DSED	Data Size Error Disable Writing 1 to this bit will clear GWEIE4.DSEE register.	R
17	DSEIOD	Data Size Error Interrupt Overflow Disable Writing 1 to this bit will clear GWEIE4.DSEIOE register.	R
31:18	—	These bits are read as 0.	R

34.3.11.23 GWEIS5 : Error Interrupt Status Register 5

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x12A0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	RXDNECN[5:0]						—	—	—	—	—	—	RXDNEIOS	RXDNES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	DCTECN[5:0]						—	—	—	—	—	—	DCTEIOS	DCTES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DCTES	Descriptor Chain Type Error Status Flag	R/W*1
1	DCTEIOS	Descriptor Chain Type Error Interrupt Overflow Status Flag	R/W*1
7:2	—	These bits are read as 0. The write value should be 0.	R/W
13:8	DCTECN[5:0]	Descriptor Chain Type Error Chain Number	R
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	RXDNES	RX Descriptor Number Error Status Flag	R/W*1
17	RXDNEIOS	RX Descriptor Number Error Interrupt Overflow Status Flag	R/W*1
23:18	—	These bits are read as 0. The write value should be 0.	R/W
29:24	RXDNECN[5:0]	RX Descriptor Number Error Chain Number	R
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

DCTES bit (Descriptor Chain Type Error Status Flag)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Setting condition]

HW: When a descriptor is received for a transmission descriptor queue (GWDCCi.DQT is set).

[Error recovery]

HW: When a descriptor is received for a transmission descriptor queue, the corresponding frame is discarded.

SW: It is a software error. Software should be reviewed.

DCTEIOS bit (Descriptor Chain Type Error Interrupt Overflow Status Flag)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Setting condition]

Descriptor Chain Type Error occurs and GWEIS5.DCTES is already set to one. In this case, the descriptor chain number in which the new error occurred is lost.

[Error recovery]

SW: Switch reset.

DCTECN[5:0] bits (Descriptor Chain Type Error Chain Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

[Update conditions]

This field is update to the descriptor chain number in which a Descriptor Chain Type Error occurred when GWEIS5.DCTES is being set.

RXDNES bit (RX Descriptor Number Error Status Flag)

[Setting condition]

HW: GWMDNC.RXDMN+1 descriptor has already been used to process one frame and the frame processing is not finished.

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to one of these bits will clear it.

[Error recovery]

HW: set of the DESCR.ERR bit in RX descriptor if a part of the frame has been already sent.

HW: Current frame or remaining part of the frame will be discarded, and next frames will be processed normally.

SW: Discard data which have DESCR.ERR bit set.

SW: Software error, software should be reviewed.

RXDNEIOS bit (RX Descriptor Number Error Interrupt Overflow Status Flag)

[Clearing condition]

HW: Being in RESET mode will clear this register.

SW: Writing 1 to this bit will clear it.

[Setting condition]

RX Descriptor Number Error occurs and GWEIS5.RXDNES is already set to one. In this case, the descriptor chain number in which the new error occurred is lost.

[Error recovery]

SW: Switch reset.

RXDNECN[5:0] bits (RX Descriptor Number Error Chain Number)

[Clearing condition]

HW: Being in RESET mode will clear this register.

[Update conditions]

This field is update to the descriptor chain number in which a RX Descriptor Number Error occurred when GWEIS5.RXDNES is being set.

34.3.11.24 GWEIE5 : Error Interrupt Enable Register 5

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x12A4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RXDNEIOE	RXDNEE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DCTEIOE	DCTEE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DCTEE	Descriptor Chain Type Error Enable 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
1	DCTEIOE	Descriptor Chain Type Error Interrupt Overflow Enable 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
15:2	—	These bits are read as 0. The write value should be 0.	R/W
16	RXDNEE	RX Descriptor Number Error Enable 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
17	RXDNEIOE	RX Descriptor Number Error Interrupt Overflow Enable 0: Interrupt disabled 1: Interrupt Enabled	R/W*1
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

DCTEE bit (Descriptor Chain Type Error Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to GWEID5.DCTED register will clear this bit.

DCTEIOE bit (Descriptor Chain Type Error Interrupt Overflow Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to GWEID5.DCTEIOD register will clear this bit.

RXDNEE bit (RX Descriptor Number Error Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to GWEID5.RXDNED register will clear this bit.

RXDNEIOE bit (RX Descriptor Number Error Interrupt Overflow Enable)

[Setting condition]

Writing 1 to this bit will set it.

[Clearing condition]

Writing 1 to GWEID5.RXDNEIOD register will clear this bit.

34.3.11.25 GWEID5 : Error Interrupt Disable Register 5

Base address: GWCA0 = 0x403C_E000
GWCA0_NS = 0x503C_E000

Offset address: 0x12A8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RXDNEIOD	RXDNED
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DCTEIOD	DCTED
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DCTED	Descriptor Chain Type Error Disable Writing 1 to this bit will clear GWEIE5.DCTEE register.	R
1	DCTEIOD	Descriptor Chain Type Error Interrupt Overflow Disable Writing 1 to this bit will clear GWEIE5.DCTEIOE register.	R
15:2	—	These bits are read as 0.	R
16	RXDNED	RX Descriptor Number Error Disable Writing 1 to this bit will clear GWEIE5.RXDNEE register.	R
17	RXDNEIOD	RX Descriptor Number Error Interrupt Overflow Disable Writing 1 to this bit will clear GWEIE5.RXDNEIOE register.	R
31:18	—	These bits are read as 0.	R

34.4 Register Utilization

34.4.1 Operation Modes

Table 34.4 describes GWCA operation modes.

Table 34.4 GWCA operation modes

Operation mode	GWMS.OPS value	Description
DISABLE	1	• No transaction is ongoing. But there can be tolerance (left behind) of transactions*1 from GWCA when the agent has moved from OPERATION to DISABLE. • Only status registers are accessible for writing when the agent clock is enabled.
RESET	0	• No transaction is ongoing. • An internal Reset is asserted to reset GWCA logic with status registers (When a register is reset in RESET mode, it is mentioned in its description). • No register is accessible for writing. • RAM values are held.
CONFIG	2	• No transaction is ongoing. • Static and some dynamic registers are accessible for writing.
OPERATION	3	• Transactions are ongoing. • Dynamic registers are accessible for writing.

Note 1. max 8 read transactions or max 8 write transactions.

34.4.1.1 Operation Mode Transitions

Figure 34.2 shows the operating mode transitions.

A mode transition can be trigger by:

- Hardware reset.
- Software reset.
- Configuration of **GWMC.OPC**. In that case, mode transition will be confirmed by GWMS.OPS.

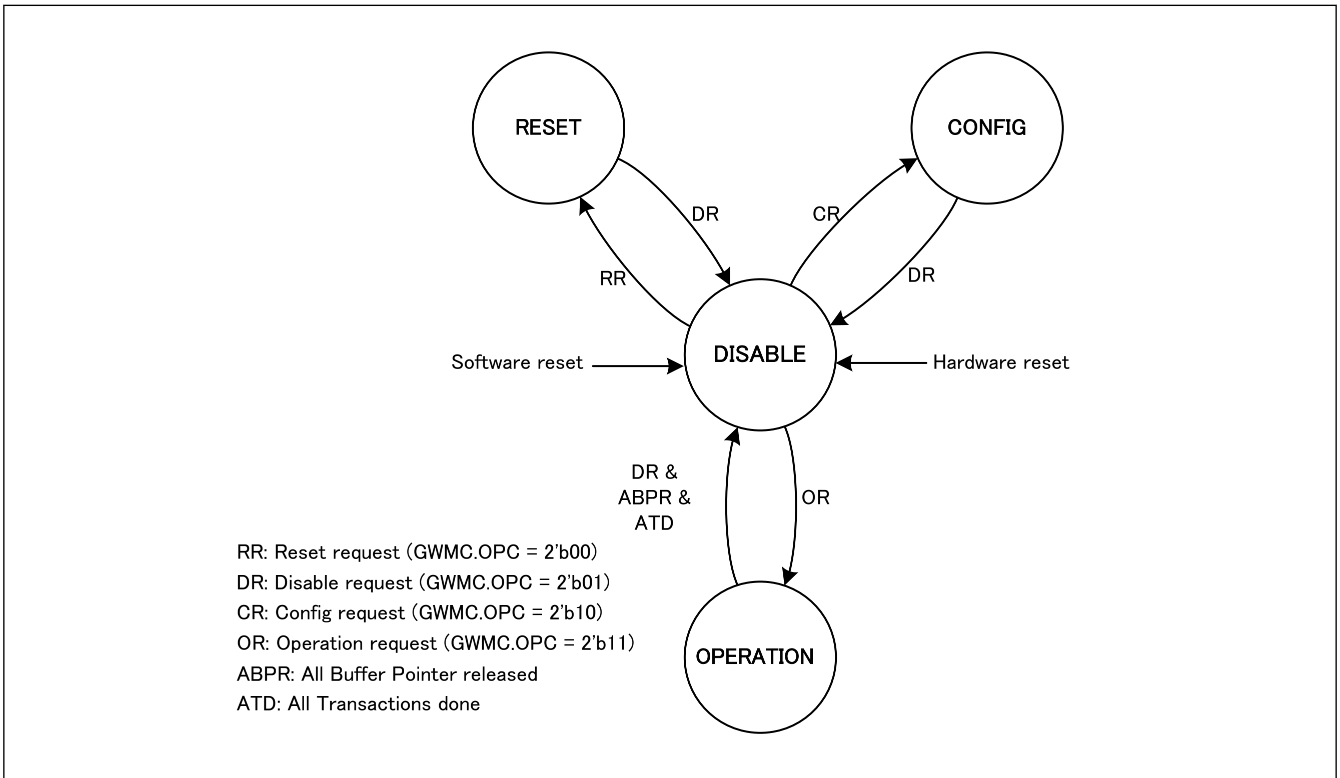

Figure 34.2 Operating mode transitions

Complementary information on transition conditions

ABPR:

- All the buffer pointers contained in the GWCA are release to the forwarding engine [FWD].

ATD:

- All the descriptors already received are processed and corresponding frames are sent to CPU and AXI descriptors are written back.

All ongoing transmit frames are fully sent to MFWD and AXI descriptors are written back.

[Restrictions]

- Software shall only trigger transitions shown to Figure 34.2.
  Exp : Do not directory transition from OPERATION to CONFIG.

34.4.2 Software Flows

Restrictions:

- SW: Please follow to the flow in this section.

34.4.2.1 Software Flows Legend

Software flow legend is described in Figure 34.3.

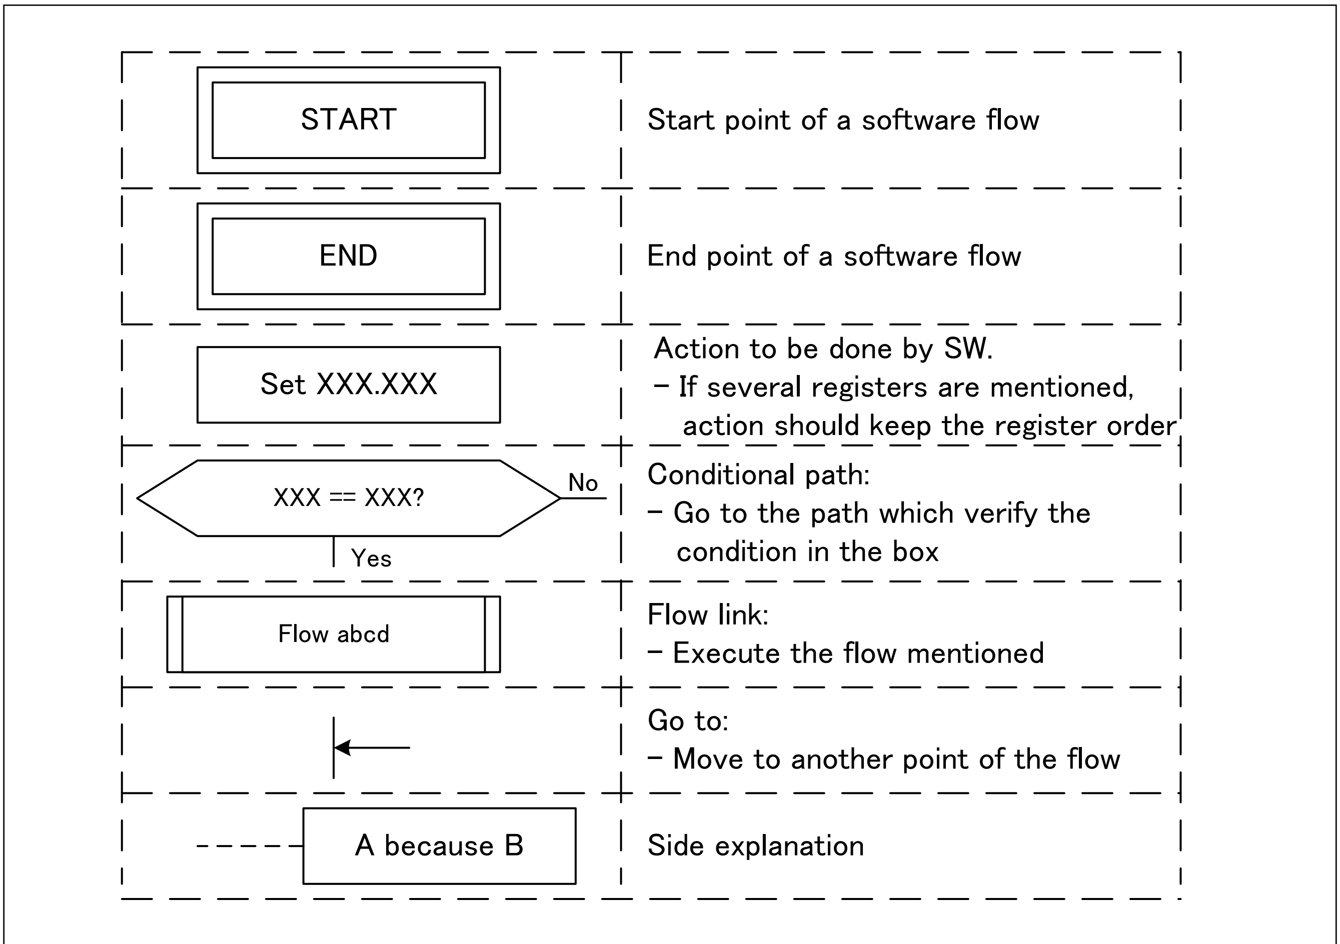

Figure 34.3 Software flow legend

34.4.2.2 Mode Transition Flow

The mode transition flow is described in Figure 34.4.

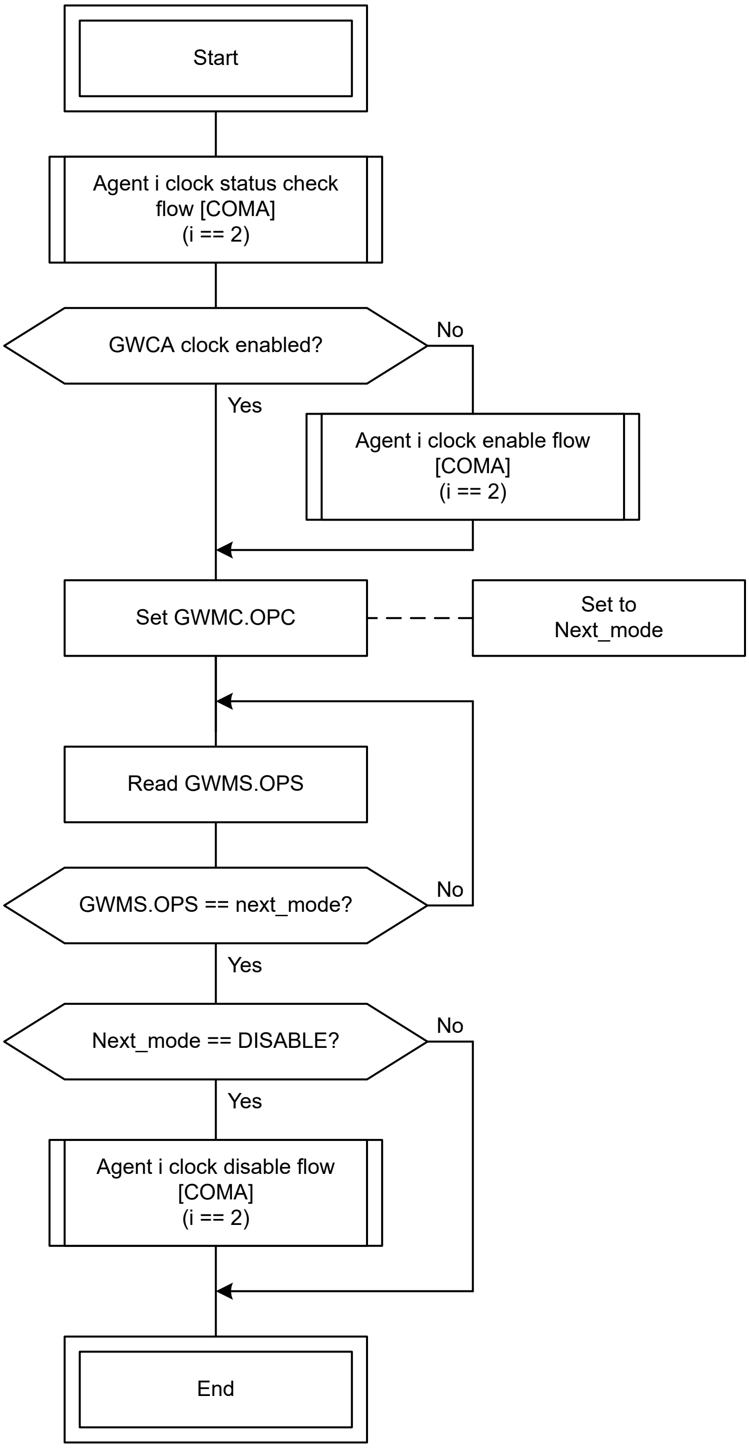

Figure 34.4 Mode transition flow

Note:
- If SW already knows that the clock is enabled, clock status check step can be skipped.
- If SW does not need to disable the agent clock in DISABLE mode (because it will go directly to another mode or because the clock never needs to be disabled), clock disable step can be skipped.

34.4.2.3 Reset Flow

The reset flow is described in Figure 34.5.

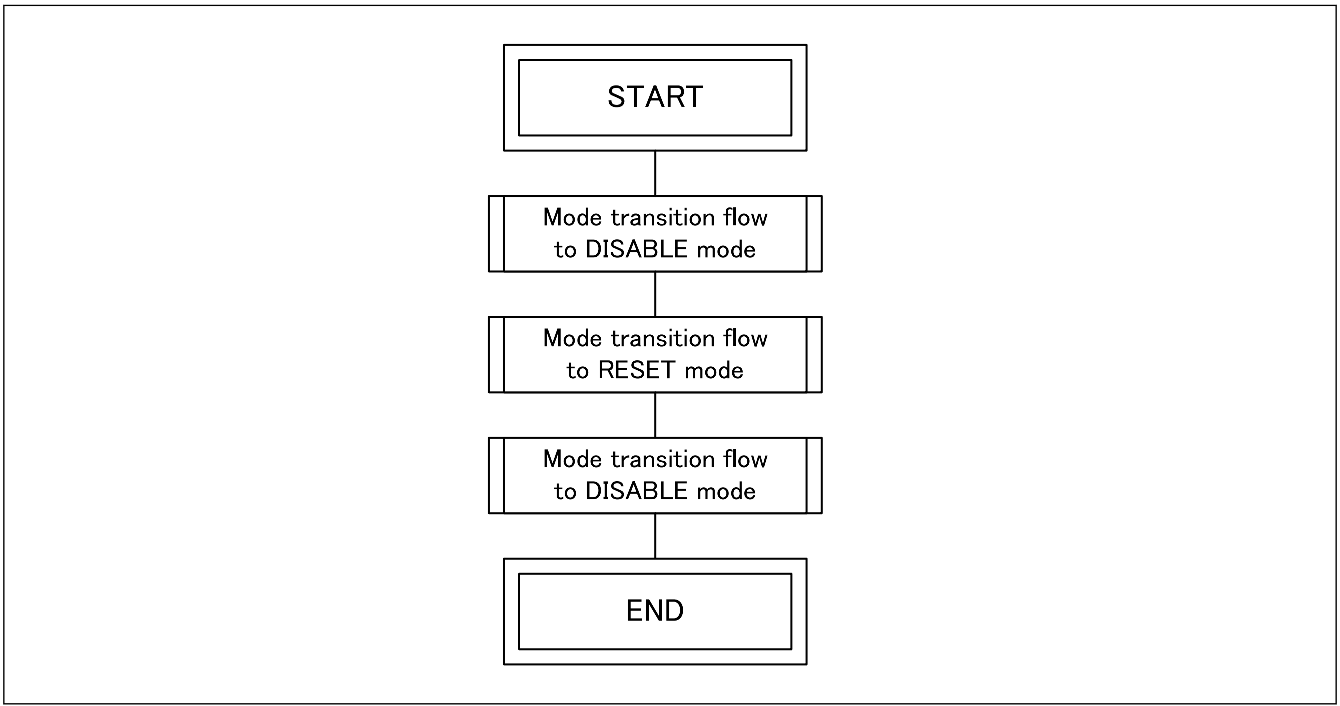

Figure 34.5 Reset flow

34.4.2.4 Initialization Flow

The initialization flow is described in Figure 34.6.

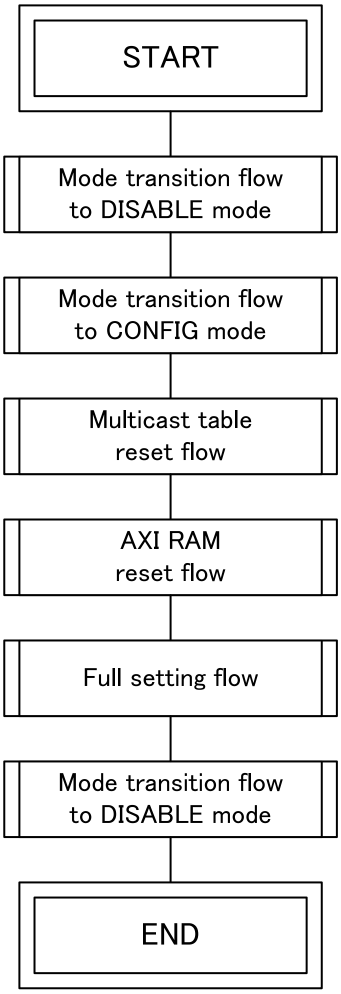

Figure 34.6 Initialization flow

34.4.2.5 Reinitialization Flow

The reinitialization flow is described in Figure 34.7.

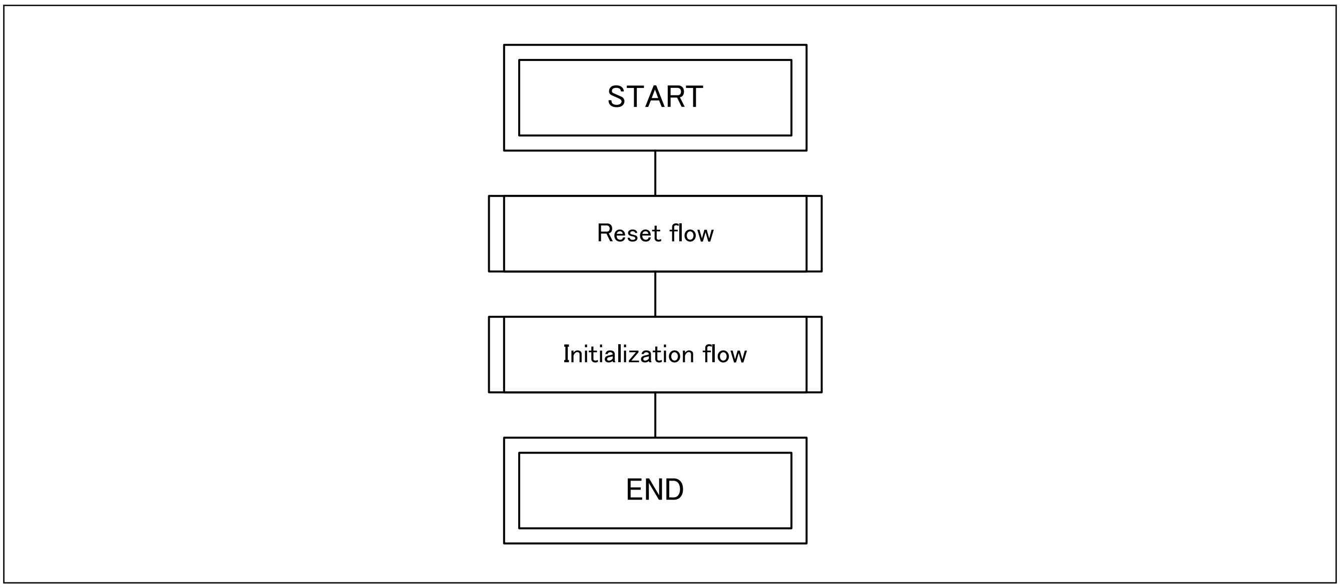

Figure 34.7 Reinitialization flow

34.4.2.6 Multicast Table Reset Flow

The multicast table reset flow is described in Figure 34.8.

Restrictions:

- This flow is not usable in RESET and DISABLE modes.

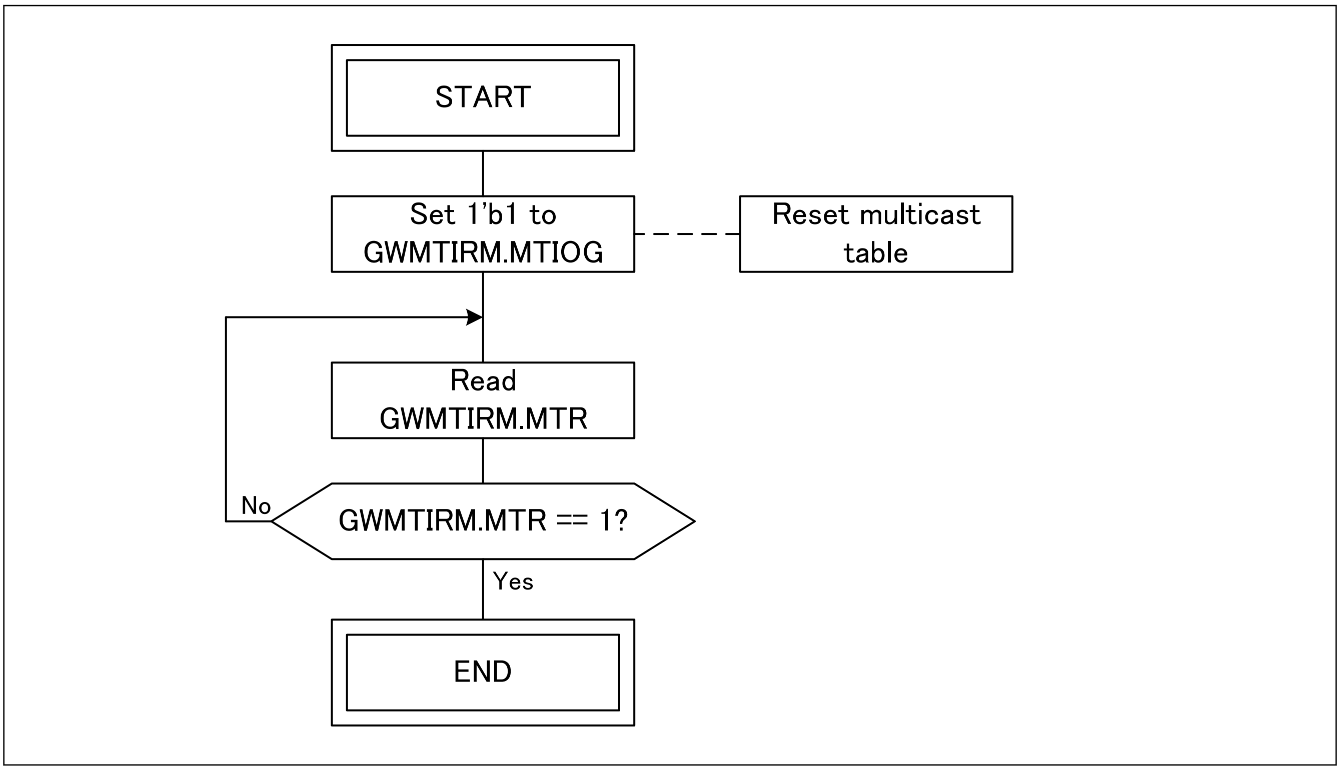

Figure 34.8 Multicast table reset flow

34.4.2.7 Multicast Table Setting Flow

The multicast table setting flow is described in Figure 34.9.

Restrictions:

- This flow is not usable in RESET and DISABLE modes.

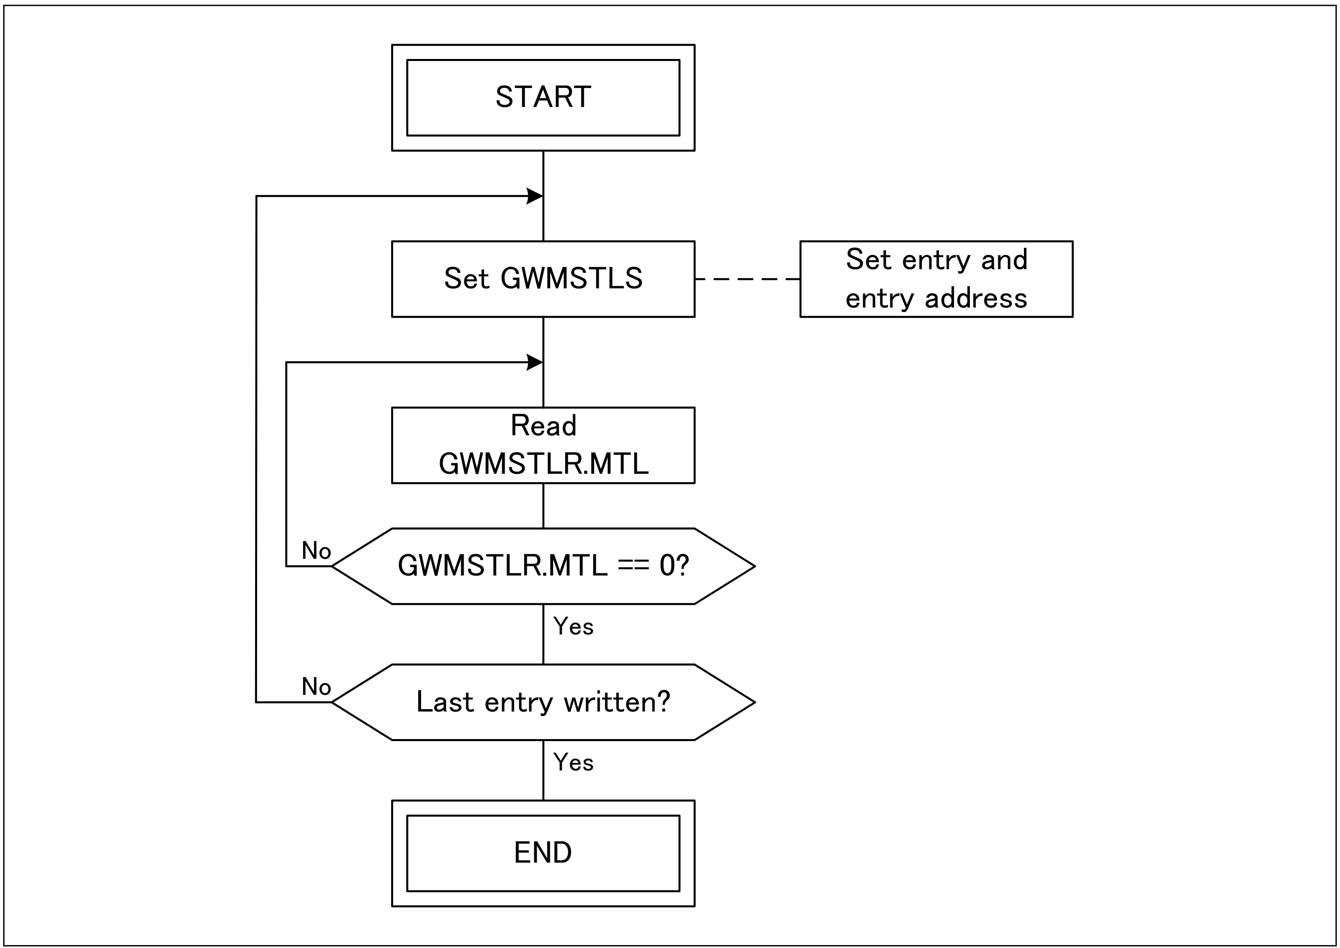

Figure 34.9 Multicast table setting flow

34.4.2.8 Multicast Table Read Flow

The multicast table read flow is described in Figure 34.10.

Restrictions:

- This flow is not usable in RESET and DISABLE modes.

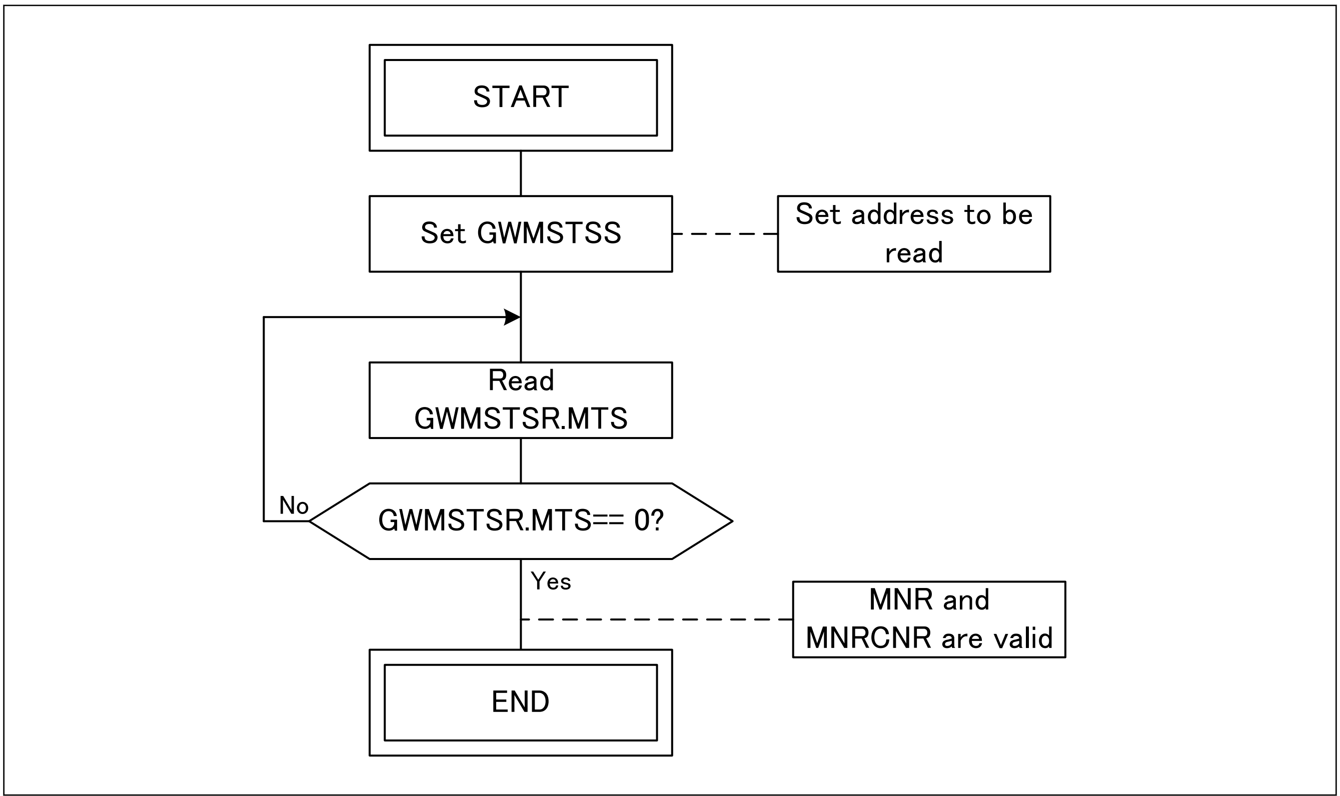

Figure 34.10 Multicast table read flow

34.4.2.9 AXI RAM Reset Flow

The AXI RAM reset flow is described in Figure 34.11.

Restrictions:

- This flow is not usable in RESET, DISABLE and OPERATION modes.

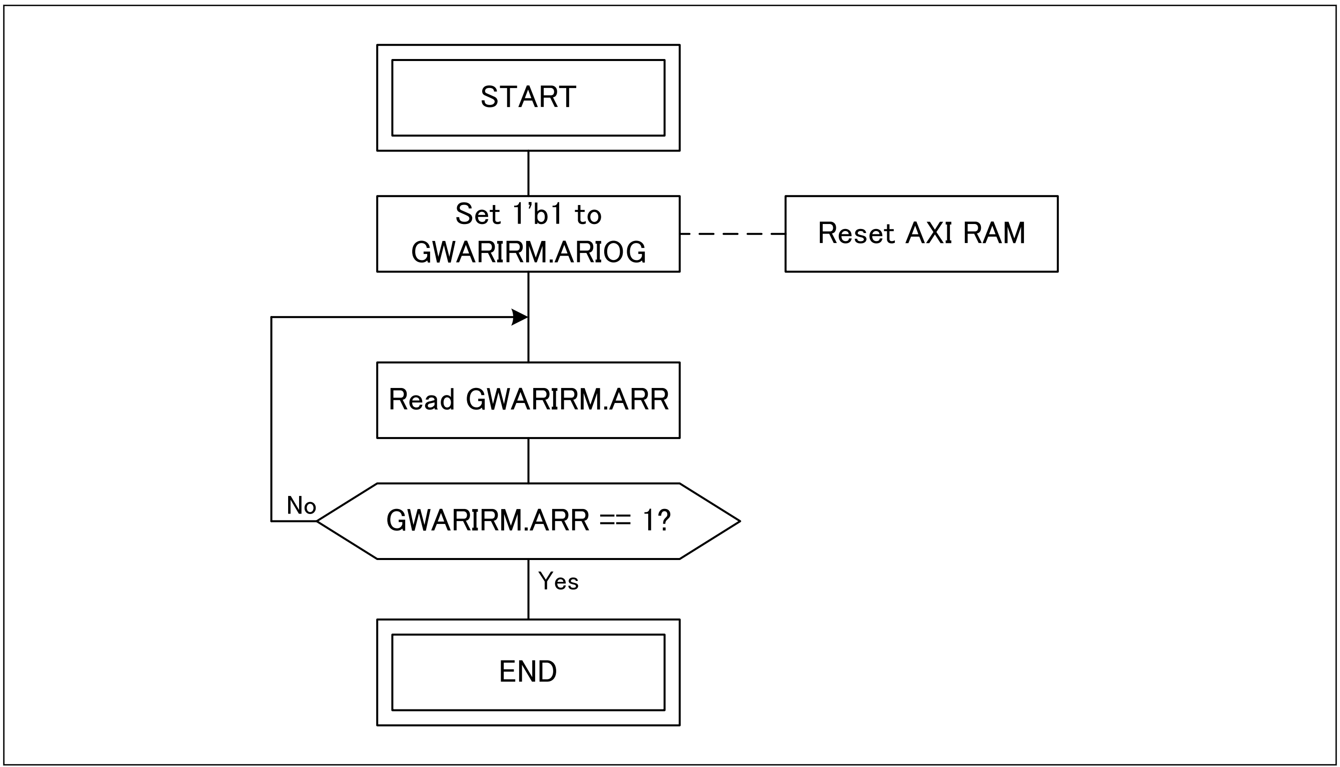

Figure 34.11 AXI RAM reset flow

34.4.2.10 AXI RAM Read Flow

The AXI RAM read flow is described in Figure 34.12.

Restrictions:

- This flow is not usable in RESET and DISABLE modes.

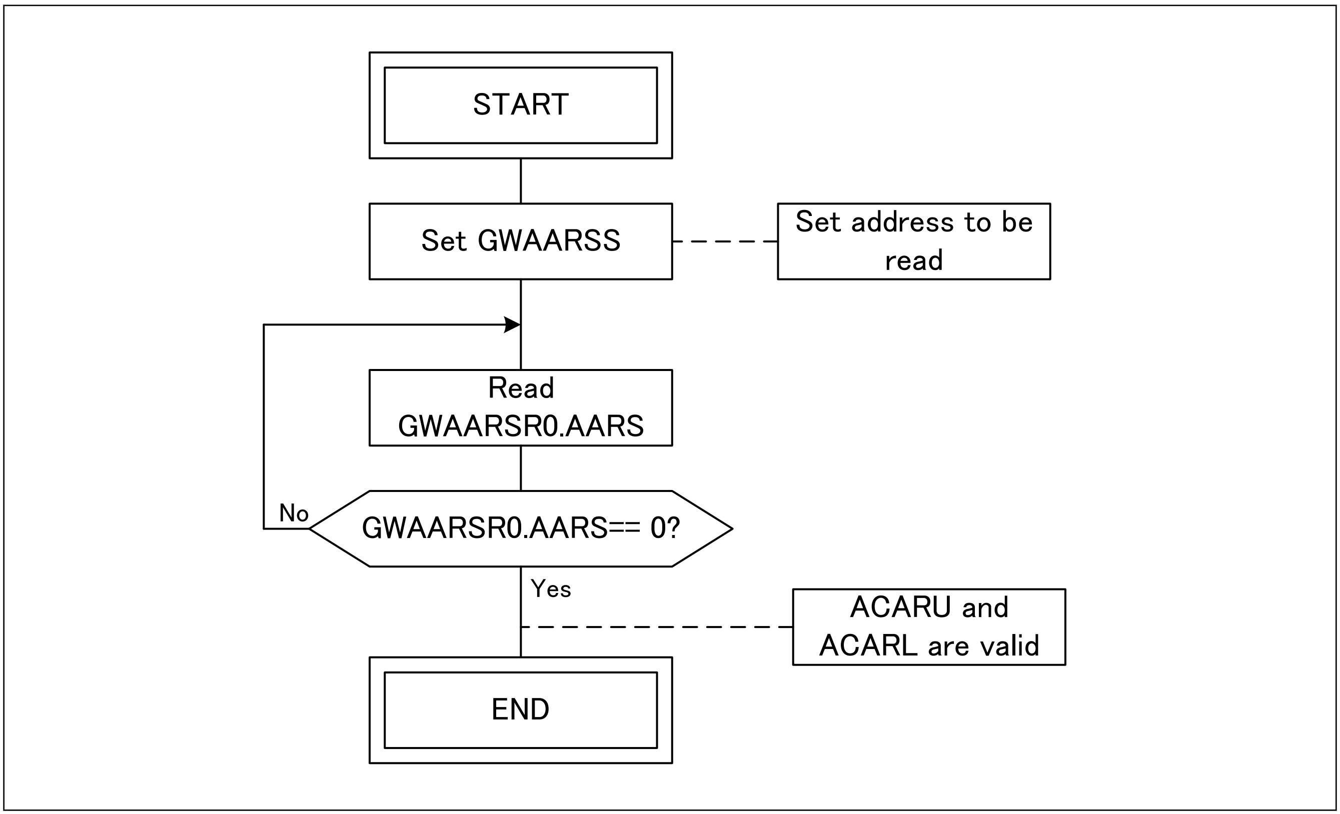

Figure 34.12 AXI RAM read flow

34.4.2.11 Global Rate Limiter Setting Flow

The global rate limiter setting flow is described in Figure 34.13.

Restrictions:

- This flow is not usable in RESET and DISABLE modes.

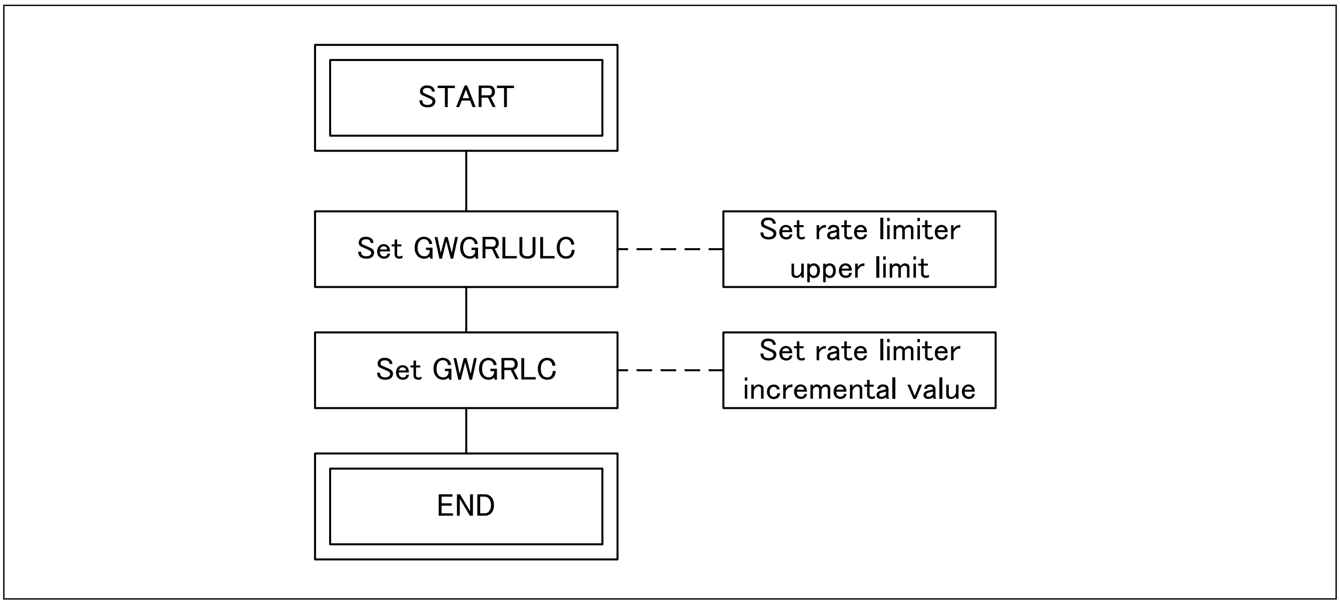

Figure 34.13 Global Rate limiter setting flow

34.4.2.12 Global Rate Limiter Disabling Flow

The global rate limiter disabling flow is described in Figure 34.14.

Restrictions:

- This flow is not usable in RESET and DISABLE modes.

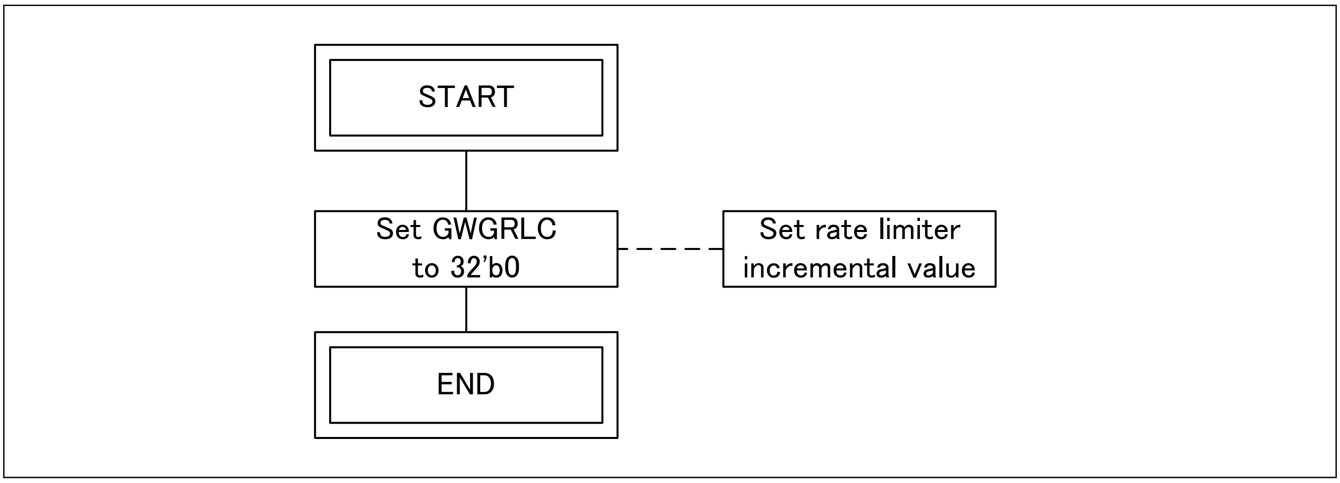

Figure 34.14 Global Rate limiter disabling flow

34.4.2.13 Rate Limiter i Setting Flow

The rate limiter i setting flow is described in Figure 34.15.

Restrictions:

- This flow is not usable in RESET and DISABLE modes.

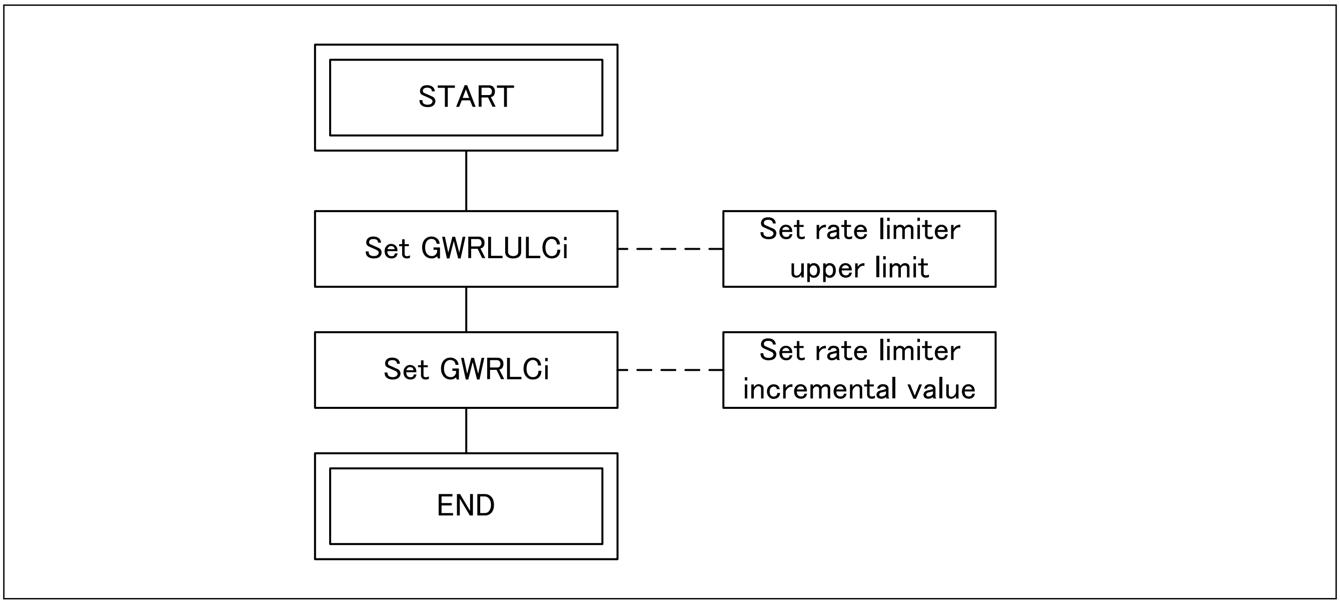

Figure 34.15 Rate limiter i setting flow

34.4.2.14 Rate Limiter i Disabling Flow

The rate limiter i disabling flow is described in Figure 34.16.

Restrictions:

- This flow is not usable in RESET and DISABLE modes.

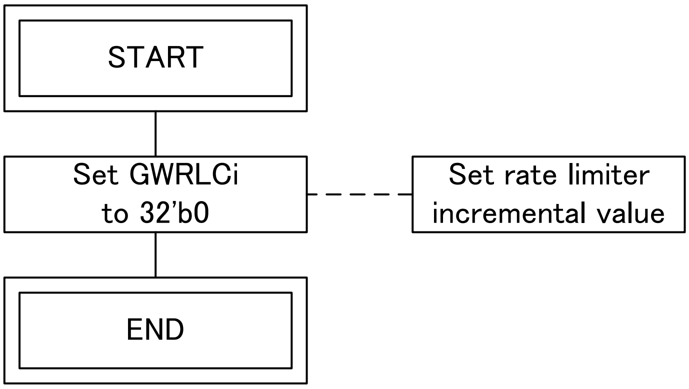

Figure 34.16 Rate limiter i disabling flow

34.4.2.15 AXI Table Read Flow

The AXI table read flow is described in Figure 34.17.

Restrictions:

- This flow is not usable in RESET and DISABLE modes.

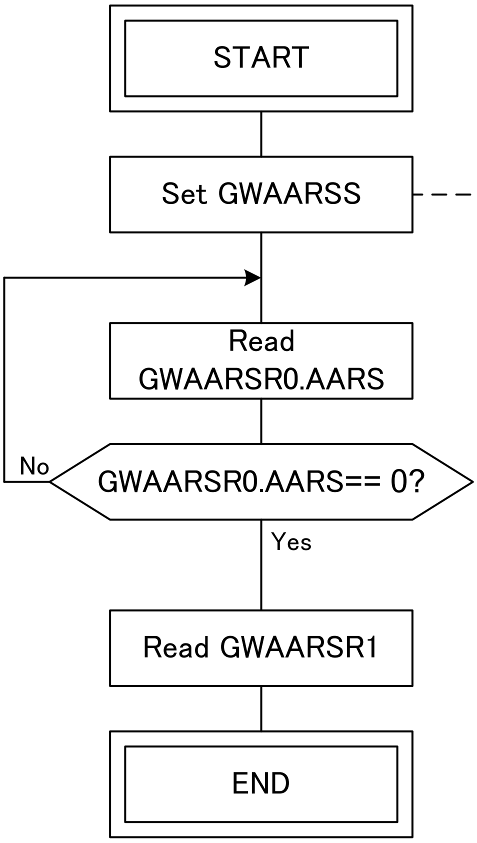

Figure 34.17 AXI table read flow

34.4.2.16 Interrupt Handling Flow

The interrupt handling flow is described in Figure 34.18.

Restrictions:

- This flow is not usable in RESET mode.

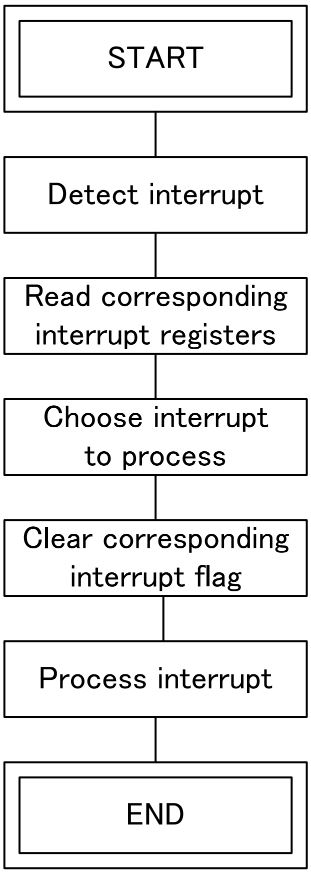

Figure 34.18 Interrupt handling flow

34.4.2.17 Called Software Flows

The flows described in this section can only be called from other flows thanks to a “flow link” box (Figure 34.3) and cannot be used alone.

34.4.2.17.1 Full Setting Flow

The full setting flow is described in Figure 34.19.

For LINKFIX table setting see section 34.5.1.3.1. LINKFIX Table Initialization.

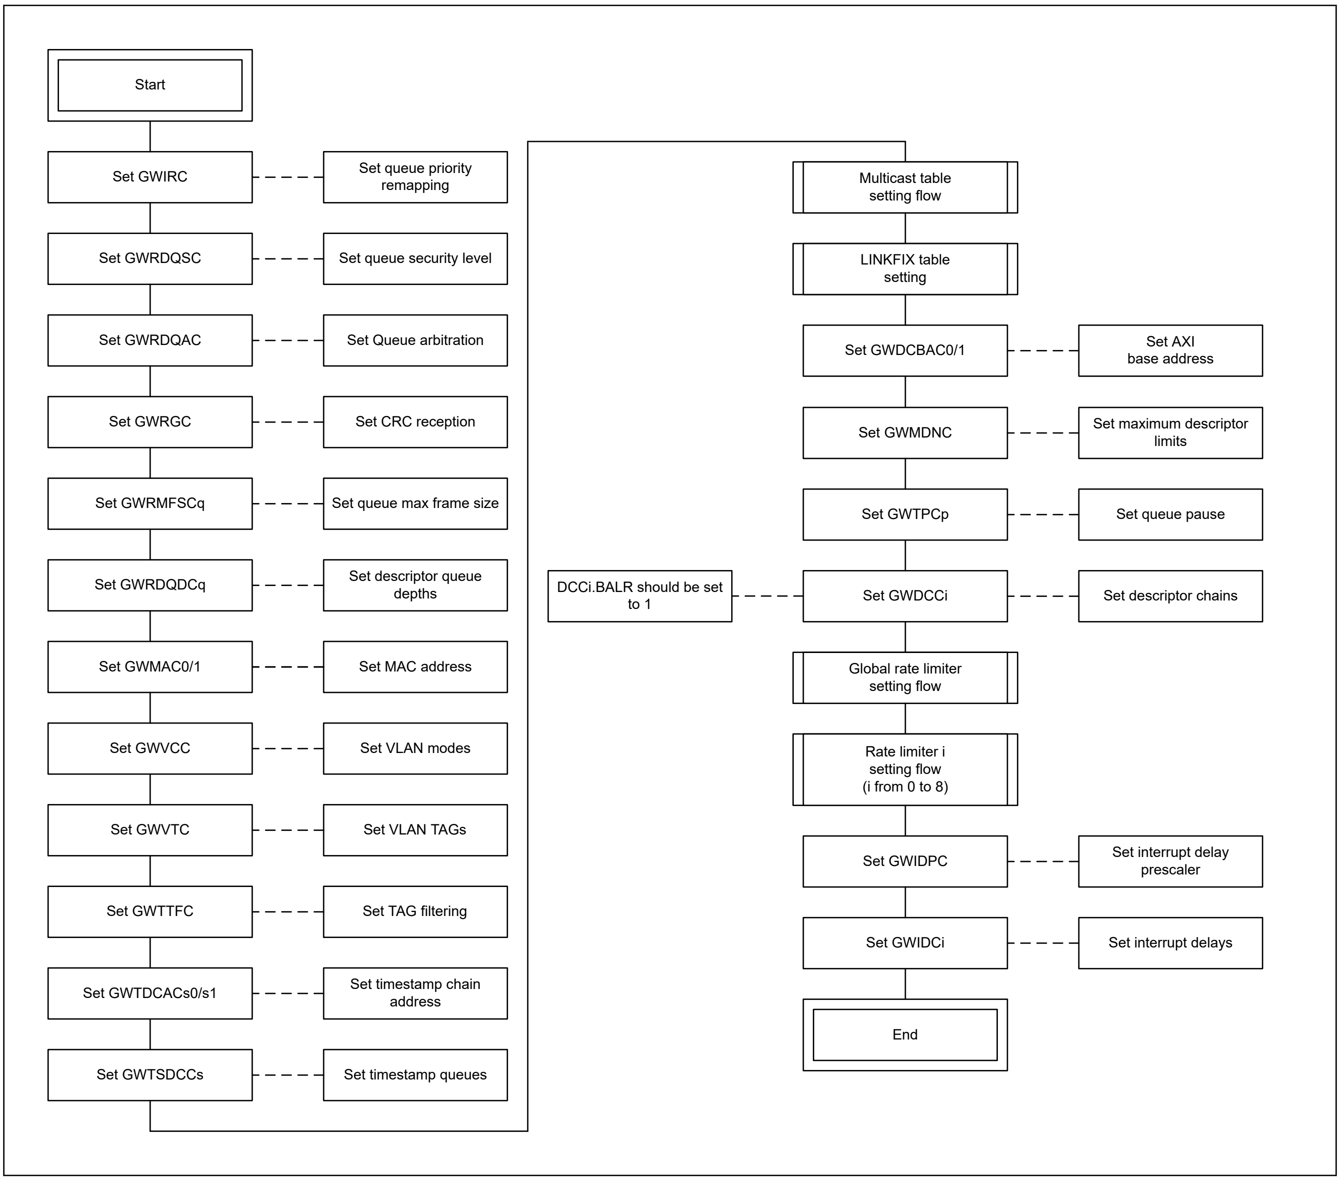

Figure 34.19 Full setting flow

34.4.2.17.2 AXI Emergency Stop Flow

The AXI emergency stop flow is described in Figure 34.20.

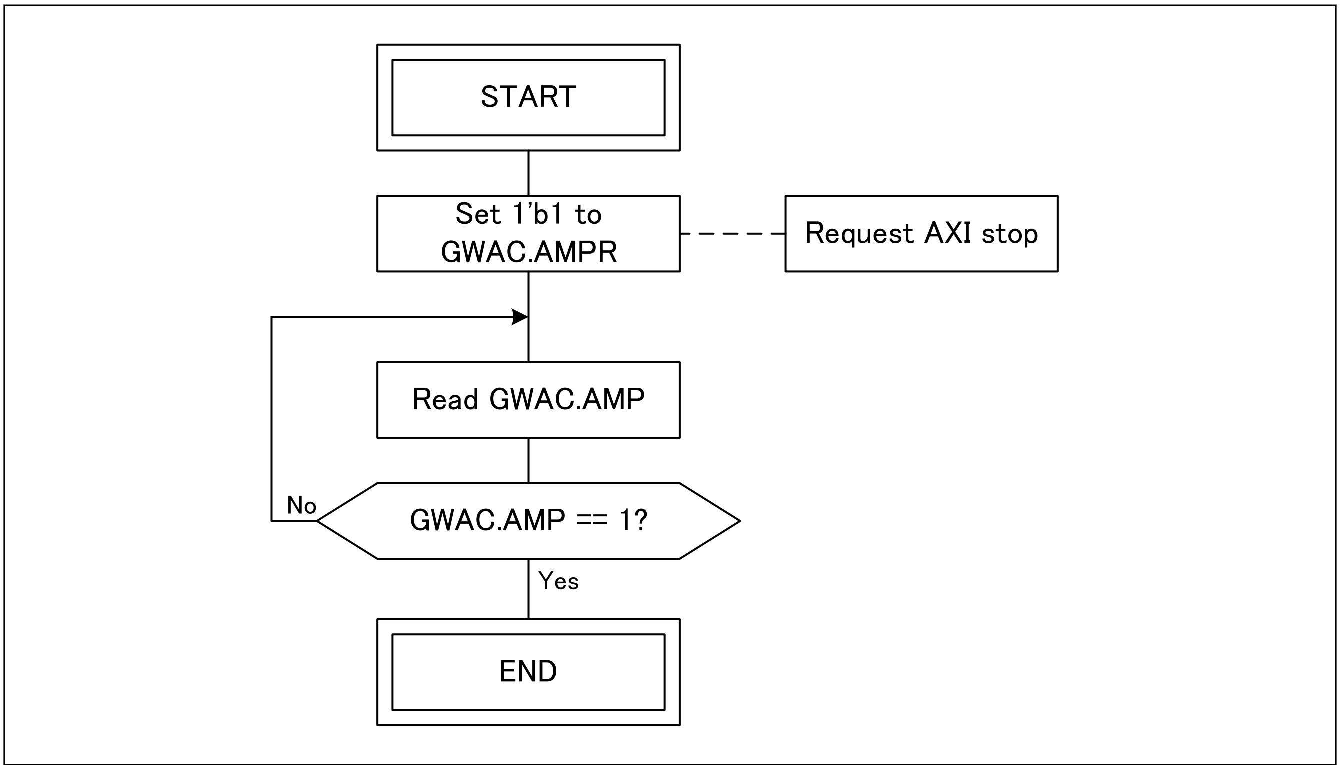

Figure 34.20 AXI emergency stop flow

34.4.2.18 Register Writable Without Software Flow

This section describes registers that have not been described so far. These registers can be changed dynamically. (However, it is necessary that the initial settings such as the clock enabling have been completed.)

Note: When a frame has reached GWCA and before the frame has been written into URAM by AXI BMI if GWDCC configurations of target chain is reconfigured by the user then the frame will be handled using the GWDCC register settings before reconfiguration and not using the reconfigured GWDCC settings.

34.5 Functional Details

34.5.1 AXI Master General Information

In this section is described the knowledge required to utilize the GWCA AXI master. It contains the AXI address table handling, the AXI descriptor general description, and the AXI IDs utilization description.

34.5.1.1 AXI Descriptor Queue Mapping

The AXI descriptor queue mapping is described along with its mapping to the **INTER_TX** interface, the incremental queues and the rate limiters in Figure 34.21. The global rate limiter is not represented because it limits throughput for all the TX queues.

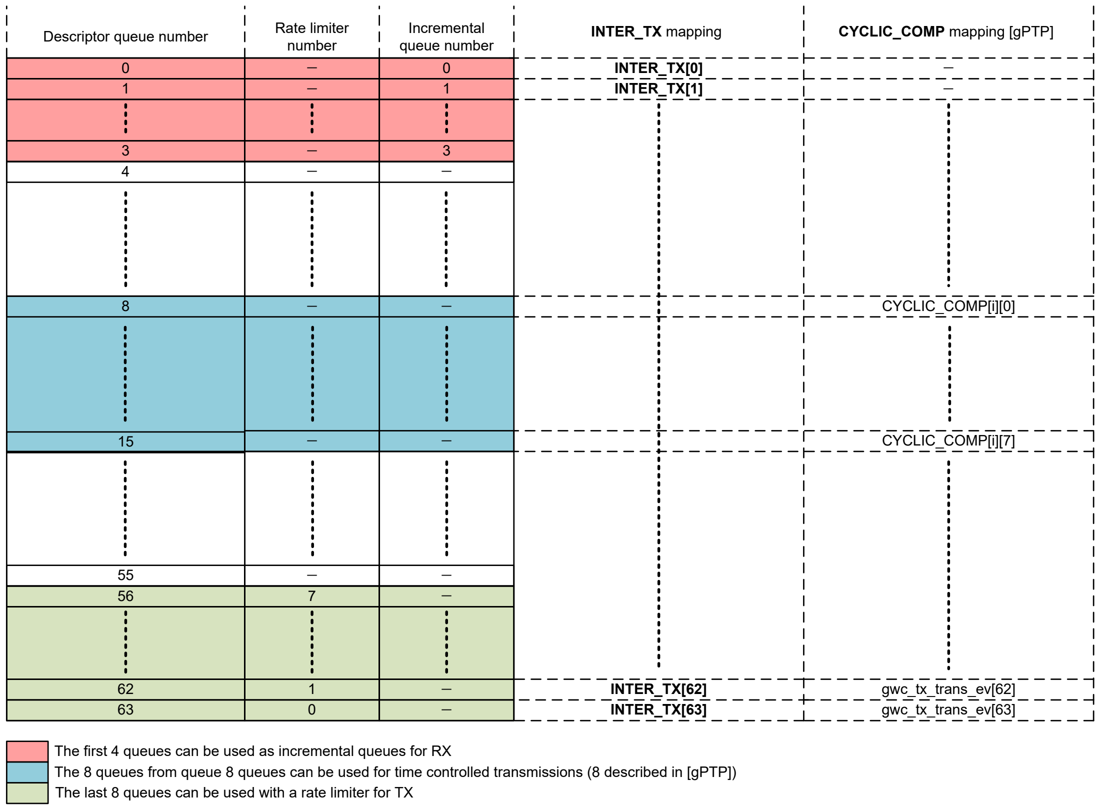

Figure 34.21 AXI descriptor queue mapping

34.5.1.2 AXI Descriptor General Description

34.5.1.2.1 General Formats

AXI descriptor general formats are described in Figure 34.22, Figure 34.23, Figure 34.24 and Figure 34.25. The fields are explained in Table 34.5. The fields utilization will be explained per transaction type (Data reception, Data transmission and Timestamp reception).

Table 34.5 General format descriptor field explanation

Field name	Bit width	Description
DS	12	Descriptor size Restrictions: ● SW: DS field maximum value is 2048. ● SW: For other descriptors that LINKFIX, LEMPTY, EEMPTY, LINK and EOS, DS should not be set to 0.
INFO0	4	Information 0
ERR	1	Error
DSE	1	Data Size Error
AXIE	1	AXI Bus Error
DIE	1	Descriptor Interrupt Enable This (DESCR.DIE) field should not be set for LINK/LINKFIX descriptors in Rx chain.
DT	4	Descriptor Type, see section 34.5.1.2.2. Descriptor Types.
PTR	40	Pointer
INFO1	64	Information 1
TS	64	Timestamp

Note: General format descriptor field utilization is described per use-case later in the following sections.

34.5.1.2.2 Descriptor Types

The table below gives an overview of all descriptor types used by GWCA. The first column shows the descriptor type name and the second column the 4-bit number to be written to DESCR.DT.

Table 34.6 Descriptor Type

Name	DT	Description
Empty data descriptors		
FEMPTY_IS	1	Frame Empty Incremental Start Frame data related descriptor without valid frame data. Used to set an incremental area.
FEMPTY_IC	2	Frame Empty Incremental Continue Frame data related descriptor without valid frame data. Used to continue using an incremental area.
FEMPTY_ND	3	Frame Empty No Data Storage Frame data related descriptor without valid frame data. Used to reject data.
FEMPTY	4	Frame Empty Frame complete data related descriptor without valid frame data. Used to save frame data.
FEMPTY_START	5	Frame Empty start Frame start data related descriptor without valid frame data. Used to save first part of a frame.
FEMPTY_MID	6	Frame Empty Middle Frame continues data related descriptor without valid frame data. Used to save middle part of a frame.
FEMPTY_END	7	Frame Empty End Frame end data related descriptor without valid frame data. Used to save end part of a frame.
Data descriptors		
FSINGLE	8	Frame Single Storage Element has valid frame data of a complete frame.
FSTART	9	Frame Start Storage Element has valid frame data. Frame starts with this descriptor and continues in next descriptor.
FMID	10	Frame Middle Storage Element has valid frame data. Frame has started with a previous descriptor and continues in next descriptor.
FEND	11	Frame End Storage Element has valid frame data. Frame has started with a previous descriptor and ends with this descriptor.
Chain control / HW/SW arbitration		
LINKFIX	0	Linkfix Control element pointing to next descriptor in chain.
LEMPTY	12	Link Empty Used control element pointing to next descriptor in chain.
EEMPTY	13	EOS Empty Used control element pausing a transmit chain.
LINK	14	Link Control element pointing to next descriptor in chain.
EOS	15	End Of Set Control element pausing a transmit chain.

34.5.1.3 LINKFIX Table

34.5.1.3.1 LINKFIX Table Initialization

The usage of AXI address table requires the setting of a LINKFIX table in the CPU USER RAM at {GWDCBAC.DCBAU, GWDCBAC.DCBAL} location. This table will be used to set the first address of descriptor chains. It can be used any time to change a chain base address or to return to the previous base address.

The LINKXFIX table setting is described in Figure 34.26 through an example. Note that SW and HW initialization are happening simultaneously.

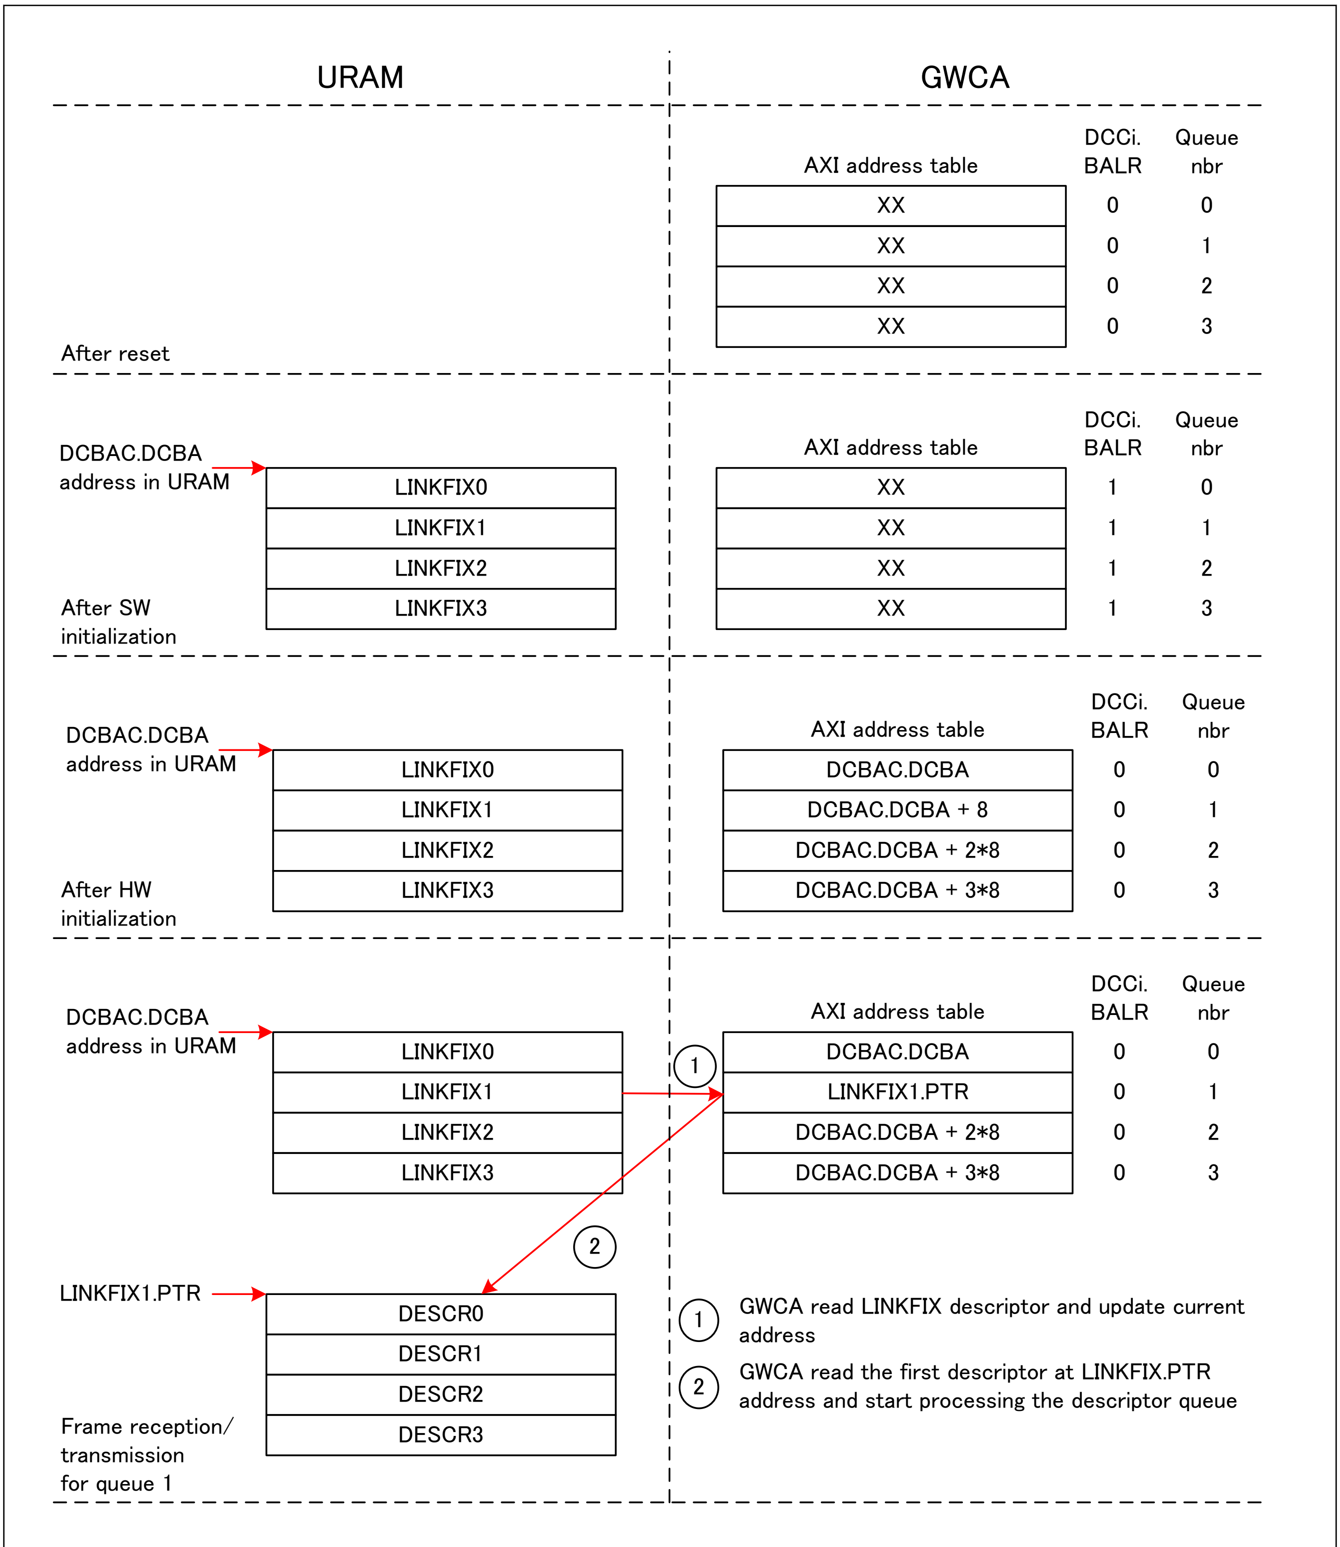

Figure 34.26 LINKXFIX table setting example

Restrictions:

- SW: A LEMPTY descriptor queues must be written for preventing them from starting.
- HW: Added descriptors in the LINKFIX table are 8 byte-descriptors which are independent of GWDCCi.EDE and GWDCCi.ETS register settings.

Note: LINKFIX and LINK descriptors are interchangeable. The only difference is that the LINK descriptor can be written back by HW.

34.5.1.3.2 LINKFIX Table Descriptors

For the LINKFIX table, a LINKFIX descriptor is used to start a descriptor queue, a LEMPTY descriptor is used to disable a TX queues (GWDCCi.DQT == 1) and a LEMPTY descriptor is used to disable a RX queues (GWDCCi.DQT == 0). In the LINKFIX table, only basic descriptors can be used (section 34.5.1.2.1. General Formats). The descriptor formats for LINKFIX table are describes in Figure 34.27 and Table 34.7. If a reception disabled queue is started despite being disabled in the LINKFIX table, the descriptor queue be considered as full (see register GWEIS2i explanation).

34.5.1.4 AXI Common Descriptor Utilization

AXI common descriptors are the descriptors which are not reserved to a special use-case and can be inserted in any descriptor chain at any time. It includes LINKFIX and LINK descriptors.

34.5.1.4.1 LINKFIX Descriptor Utilization

A LINKFIX descriptor is used to change a descriptor queue pointer in the GWCA to move it to another place and is described in Figure 34.28. The LINKFIX descriptor is never written back to decrease the AXI load.

The LINKFIX descriptor format is described in Figure 34.29 (for basic descriptor, section 34.5.1.2.1. General Formats) and Table 34.8.

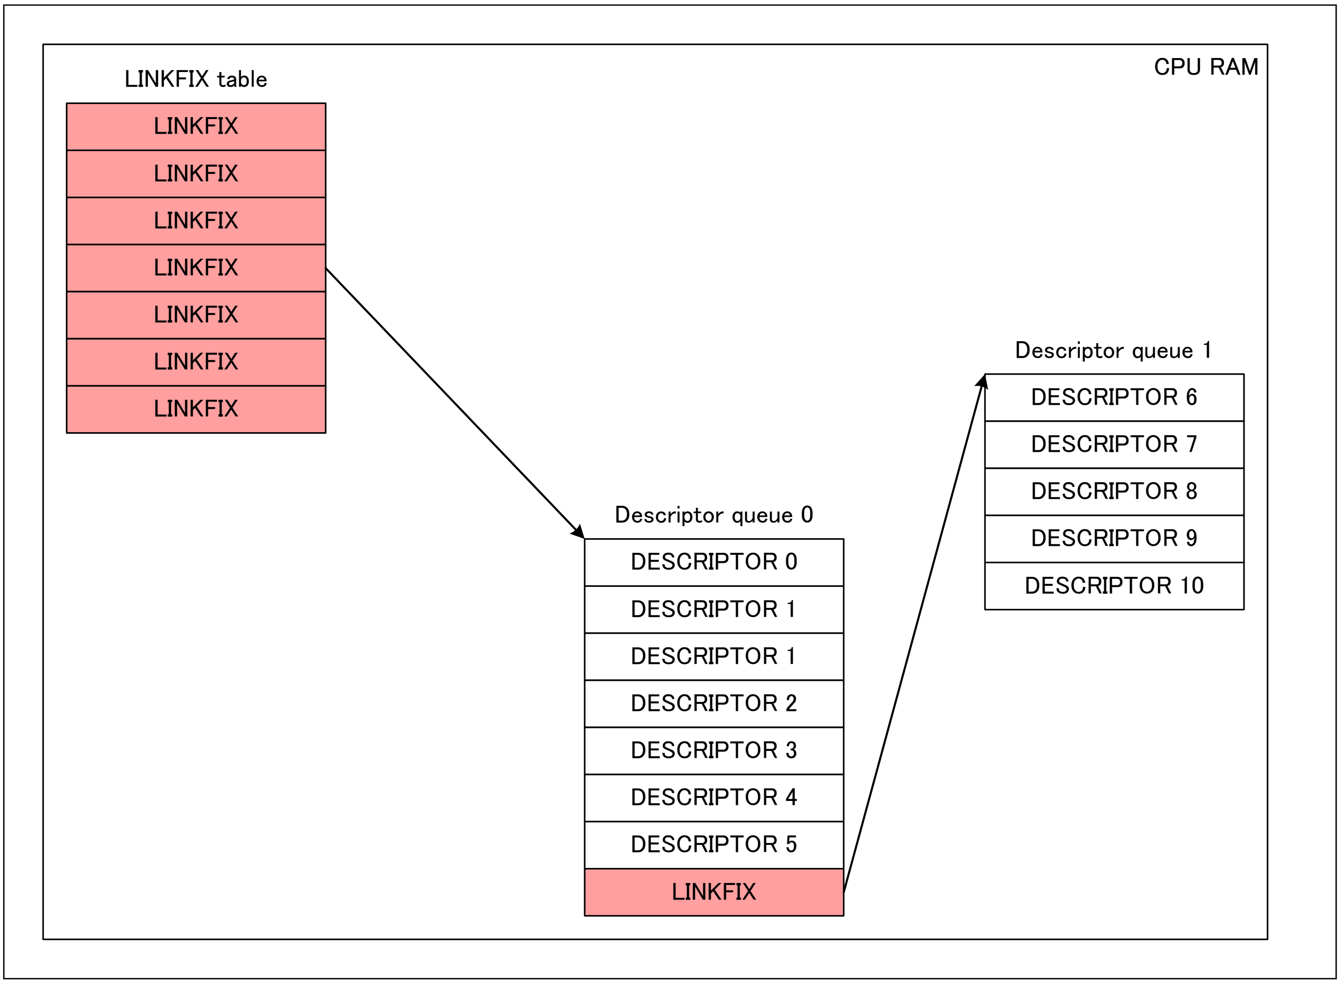

Figure 34.28 LINKFIX descriptor utilization

Note:
- The LINKFIX table is described in section 34.5.1.3. LINKFIX Table.
- A LINKFIX descriptor can be placed anywhere in a descriptor queue.
- LINKFIX and LINK descriptors are interchangeable. The only difference is that the LINK descriptor can be written back by HW.

Byte	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
0	8'b0

34.5.1.4.2 LINK Descriptor Utilization

A LINK descriptor has the same usage as a LINKFIX descriptor (see section 34.5.1.4.1. LINKFIX Descriptor Utilization). Contrary to the LINKFIX descriptor the LINK descriptor can be written back by HW. The LINK descriptor format is described in Figure 34.30 (for basic descriptor, section 34.5.1.2.1. General Formats) and Table 34.9.

Note: LINKFIX and LINK descriptors are interchangeable. The only difference is that the LINK descriptor can be written back by HW.

TS (GWDCCi.ETS == 1)	0	NA: TS not written back for LINK descriptors

34.5.1.5 AXI Descriptor Queue Format

The AXI master accepts two kinds of descriptor queues: linear descriptor queues and cyclic descriptor queues. A linear descriptor queue is a queue which is ended by a terminate descriptor. A linear descriptor queue example is described in figure Figure 34.31. A cyclic descriptor queue is a queue which is looping on itself. A cyclic descriptor queue example is described in figure Figure 34.32.

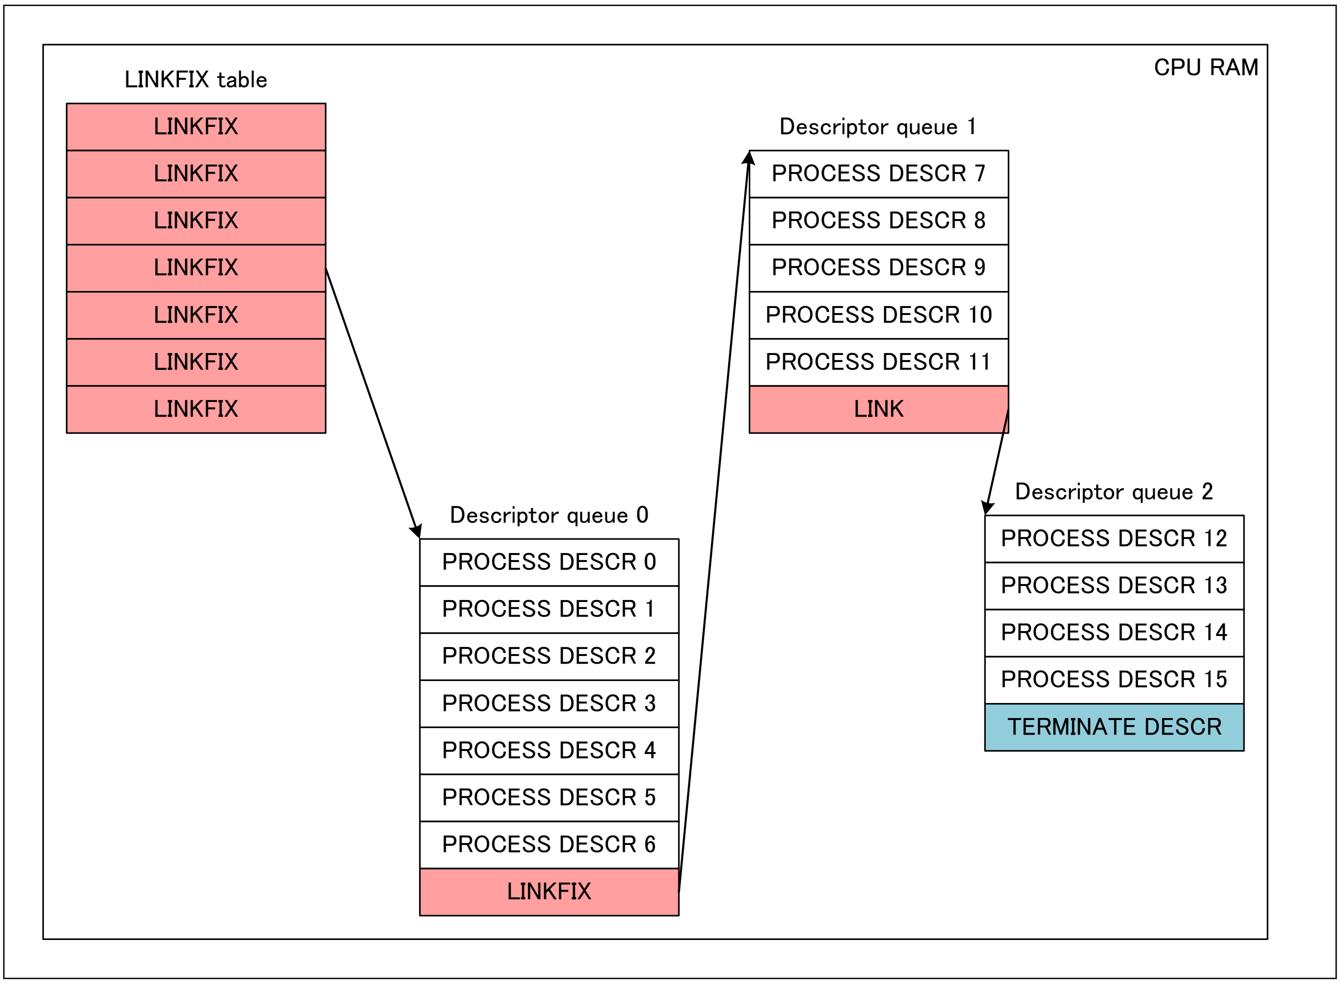

Figure 34.31 Linear descriptor queue example

Restrictions:

- SW: To add data to a linear queue, the SW should write the data and process/terminate descriptor and overwrite the previous terminate descriptor with a LINK/LINKFIX descriptor pointing to the new descriptor chain.

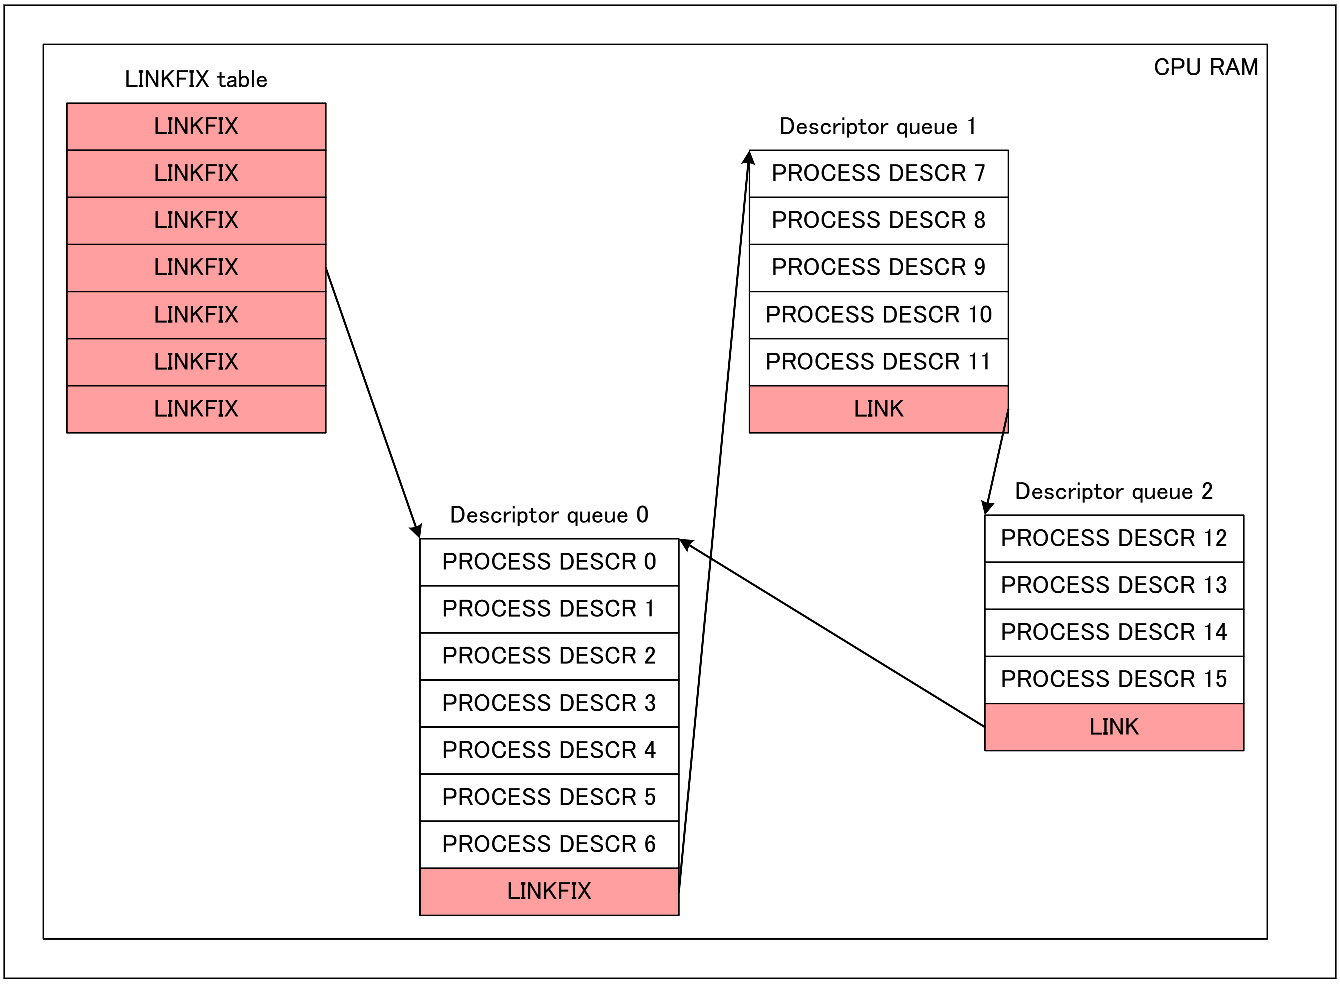

Figure 34.32 Cyclic descriptor queue example

Note:
- The LINKFIX table is described in section 34.5.1.3. LINKFIX Table.
- The LINK, LINKFIX utilization is described in section 34.5.1.4. AXI Common Descriptor Utilization.
- A terminate descriptor (TERMINATE DESCR in Figure 34.31) correspond to a FSINGLE or a LEMPTY descriptor for an RX queue, a FEMPTY or a LEMPTY descriptor for a TX queue and a FSINGLE or a LEMPTY descriptor for a TS queue.
- A process descriptor (PROCESS DESCR in Figure 34.31 and Figure 34.32) correspond to a FEMPTY_IS, FEMPTY_IC, FEMPTY_ND, FEMPTY, FEMPTY_START, FEMPTY_MID or FEMPTY_END descriptor for an RX queue (see section 34.5.3.5. AXI Master Interface), to a FSINGLE, FSTART, FMID, FEND or EOS descriptor for a TX queue (see section 34.5.2.2. AXI Master Interface) and to a FEMPTY_ND for a TS queue (see section 34.5.4.2. AXI Master Interface).

34.5.1.6 AXI Address RAM Searching

Searching functions is used to read entries in the AXI address RAM. Table 34.10 describes register used to read an entry in the TAS RAM. Table 34.11 describes the read results.

Table 34.10 AXI Address read registers

Register name	Field name/corresponding field in MAC table	Field explanation
GWAARSS.AARA	Entry address Set the descriptor queue number from which AXU address should be read.	Not present in AXI address RAM, entry will be read from this address.

Table 34.11 AXI Address read result

Register name	Field name/corresponding field in MAC table	Field explanation
{GWAARSR0.ACARU, GWAARSR1.ACARL}	AXI address value	Address of the next descriptor to be processed for AXI descriptor queue number GWAARSS.AARA.

Note: {GWAARSR0.ACARU, GWAARSR1.ACARL} indicates the address of the next descriptor to be processed for AXI descriptor queue number but it does not mean that the previous descriptor process is completed. That’s why this register only has debugging purpose and not HW/SW synchronization purposes.

34.5.2 Data Transmission

GWCA allows data transmission through the GWCA TX data path, The TX data path is described in Figure 34.33.

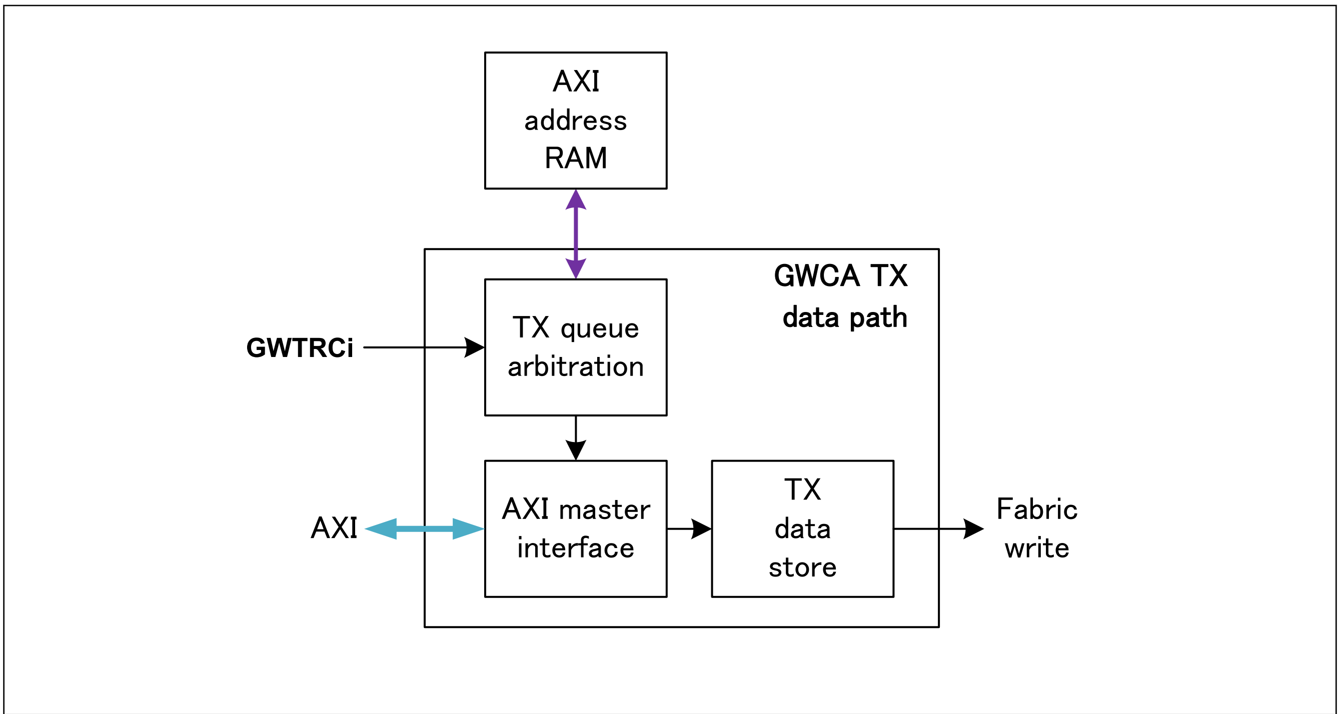

Figure 34.33 GWCA TX data path block diagram

The TX data path is separated in three blocks:

- TX queue arbitration: This block arbitrates between TX queues when several queues are requesting for transmission.
- AXI master interface: This block handles the data/AXI descriptor exchange with the CPU.
- TX data store: This block extracts TAG information for frames, applies VLAN tagging and save the frames in the local RAM. This block can also release pointers while going out of OPERATION mode. The pointer release is here for switch hardware purpose and its description is not required for switch utilization so it will not be described.

34.5.2.1 TX Queue Arbitration

TX queue arbitration has four functions. Pausing certain queues when switch is about to overflow, limiting TX queue data rates, arbitrating between TX descriptor queue with a strict priority algorithm and arbitrating between same priority queues with a round-robin algorithm.

34.5.2.1.1 Per Priority Pause

Per priority pause aims at pausing descriptor queue transmission depending on their priority using PAUSE[2] values [COMA] and GWTPCp register. It avoids the AXI master to inject uncritical data in the switch when it is about to overflow.

Functions:

- GWTPCp sets the priorities that should be paused when PAUSE[2][p] is set.

34.5.2.1.2 Rate Limiters

Rate limiters are controlling the input flow of the switch. Using these limiters could prevent the switch from overflowing. GWCA has two types of rate limiters, a global rate limiter and 8 per-queue rate limiters. By setting the rate limiter configurations correctly, expected bandwidth with a tolerance value of less than ± 2% can be achieved.

(1) Per-queue rate-limiter

A per-queue rate-limiter aims at limiter the data throughput per one descriptor queue using GWRLCi.RLE, GWRLCi.RLIV and GWRLULCi.RLUL registers. For per-port rate limiter/descriptor queue mapping information see section 34.5.1.1. AXI Descriptor Queue Mapping.

Functions:

- GWRLCi.RLE register enables rate-limiter number i.
- GWRLCi.RLIV register sets the maximum throughput accepted by rate limiter number i and should be set respecting equation (1).
- GWRLULCi.RLUL register sets the maximum collision time accepted by rate limiter number i and should be set respecting equation (2).

1. GWRLCi.RLIV = 256 x *ACLK_period[ns]* x *maxBandwidth[Gbps]*
2. GWRLULCi.RLUL = *maximumBurst[bit]*

Where:

- *ACLK_period* is ACLK clock period.
- *maxBandwidth* is the expected maximum throughput accepted by rate limiter number i.
- *maximumBurst* is the maximum burst in bit accepted for corresponding queue.

(2) Global rate limiter

The global rate limiter aims at limiting all AXI data transmission throughput using GWGRLC.GRLE, GWGRLC.GRLIV and GWGRLULC.GRLUL registers and can be monitored using GWGRLC.GRLULRS.

Functions:

- GWGRLC.GRLE register enables the global rate limiter.
- GWGRLC.GRLIV register sets the maximum throughput accepted by AXI data transmission and should be set respecting equation (1).
- GWGRLULC.GRLUL register sets the maximum number of credits that the global rate limiter can stack and should be set respecting equation (2).
- GWGRLC.GRLULRS register shows if some credit has been lost because of a too high AXI latency or because of a too slow AXI.

1. GWGRLC.GRLIV = 256 x *ACLK_period[ns]* x *max_bandwidth[Gbps]*
2. GWGRLULC.GRLUL = *ACLK_period[ns]* x *max_bandwidth[Gbps]* x 2**maximum_axi_latency[cycle]*

Where:

- ACLK_period is ACLK clock period in ns.
- max_bandwidth is the expected maximum throughput accepted by GWCA.
- maximum_axi_latency is the AXI maximum latency in ACLK clock number.

Restrictions:

- SW: The sum of all GWRLCi.RLIV registers should always be smaller or equal to GWGRLC.GRLIV.

34.5.2.1.3 Strict Priority

Strict priority arbitrates between TX queue which are authorized by rate limiters to transmit using GWDCCi.DCP. The strict priority algorithm operates as the one in the data reception descriptor store. See section (1) Strict priority (SP) for more information.

Functions:

- GWDCCi.DCP register sets descriptor queue i priority. The highest priority is the biggest value.

34.5.2.1.4 Round Robin

Round robin arbitrates between the highest priority queues selected by the strict arbiter. The round robin operates as the one in the data reception descriptor store. See (2) Round Robin (RR) for more information.

34.5.2.2 AXI Master Interface

The AXI master interface handles the data/AXI descriptor exchange with the CPU. It receives the queue number of the descriptor queue number authorized to transmit by the TX queue arbitration, reads the corresponding data from the CPU RAM, and sends the data to TS data store. To do so, it uses GWTRCi.TSRj, GWDCCi.EDE, GWDCCi.ETS, and GWDCCi.SM, and can be monitored using GWAARSS, GWAARSR0, and GWAARSR1 interrupt registers.

Functions:

- GWTRCi.TSRj register is used to start transmission when a descriptor queue is ready.
- GWDCCi.EDE and GWDCCi.ETS registers set the descriptor format that will be used for descriptor queue number i. See section 34.5.1.2.1. General Formats.
- GWDCCi.SM register sets how GWCA will write back descriptors. In this section all explanation will use GWDCCi.SM equal to 00. For GWDCCi.SM equal to 01 or 10 see the register explanation.
- For GWAARSS, GWAARSR0, and GWAARSR1 registers, see section 34.5.1.6. AXI Address RAM Searching.

Restrictions:

- SW: Only basic descriptors and extended descriptors are authorized for data transmission. See section 34.5.1.2.1. General Formats.

Data transmission can be done using linear or cyclic descriptor queues (see section 34.5.1.5. AXI Descriptor Queue Format). Data transmission process descriptors can be set two different ways, through the basic data transmission descriptor chain (section 34.5.2.2.1. Basic Data Transmission) and the time-controlled data transmission descriptor chain (section 34.5.2.2.2. Time-controlled Data Transmission).

34.5.2.2.1 Basic Data Transmission

Basic data transmission process descriptor utilization is described in Figure 34.34. Basic data transmission process descriptor format is described in Figure 34.35 (for basic descriptor, section 34.5.1.2.1. General Formats) and Table 34.12.

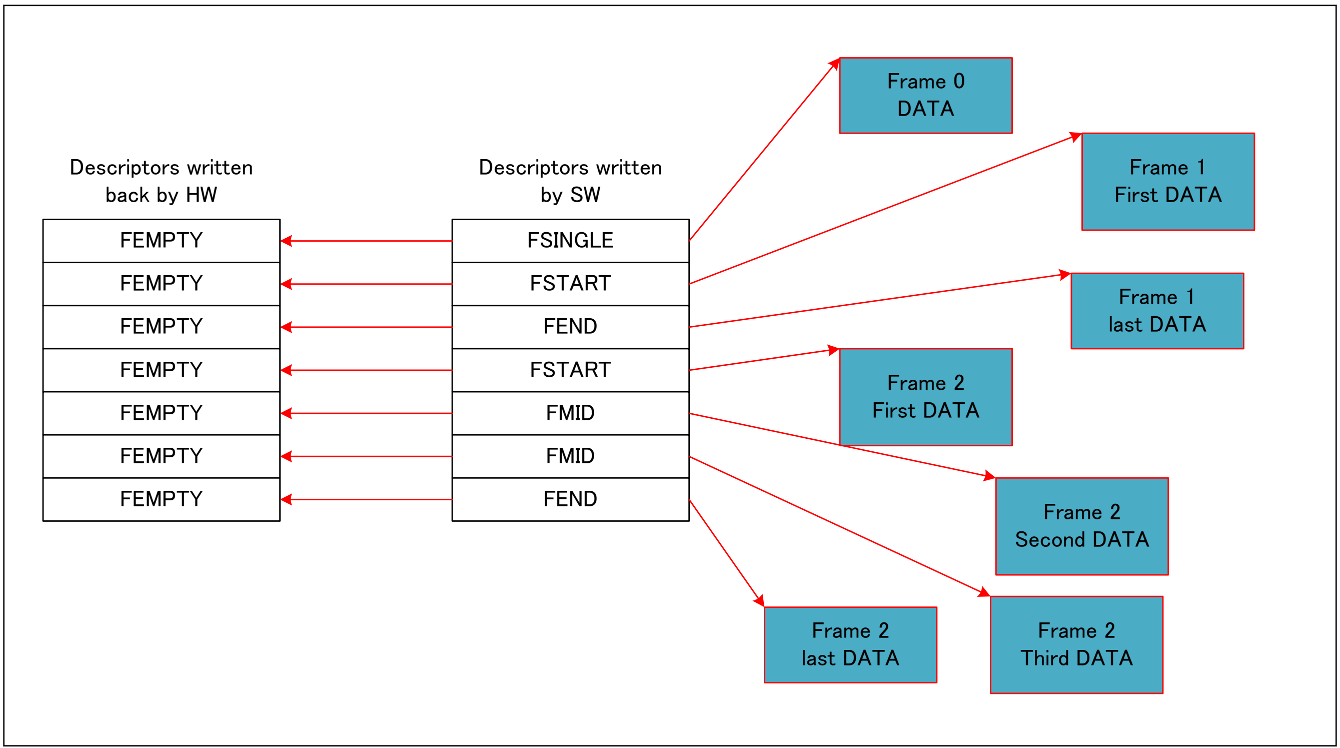

Figure 34.34 Data transmission process descriptor utilization

Note:
- If needed, the SW can split a frame between several descriptors. The first descriptor should be a FSTART descriptor, the last descriptor should be a FEND descriptor and all other descriptors should be FMID descriptors.
- When data is ready, CPU should set the corresponding GWTRCi.TSRj bit to start transfer. See GWTRCi.TSRj description.
- GWTRCi.TSRj can be set anytime even if data is not available. The GWCA will in this case read the terminate descriptor and clear GWTRCi.TSRj bit.

Restrictions:

- SW: When a frame is split, the FSTART descriptor should be written after FMIDs and FEND descriptor for a given frame.

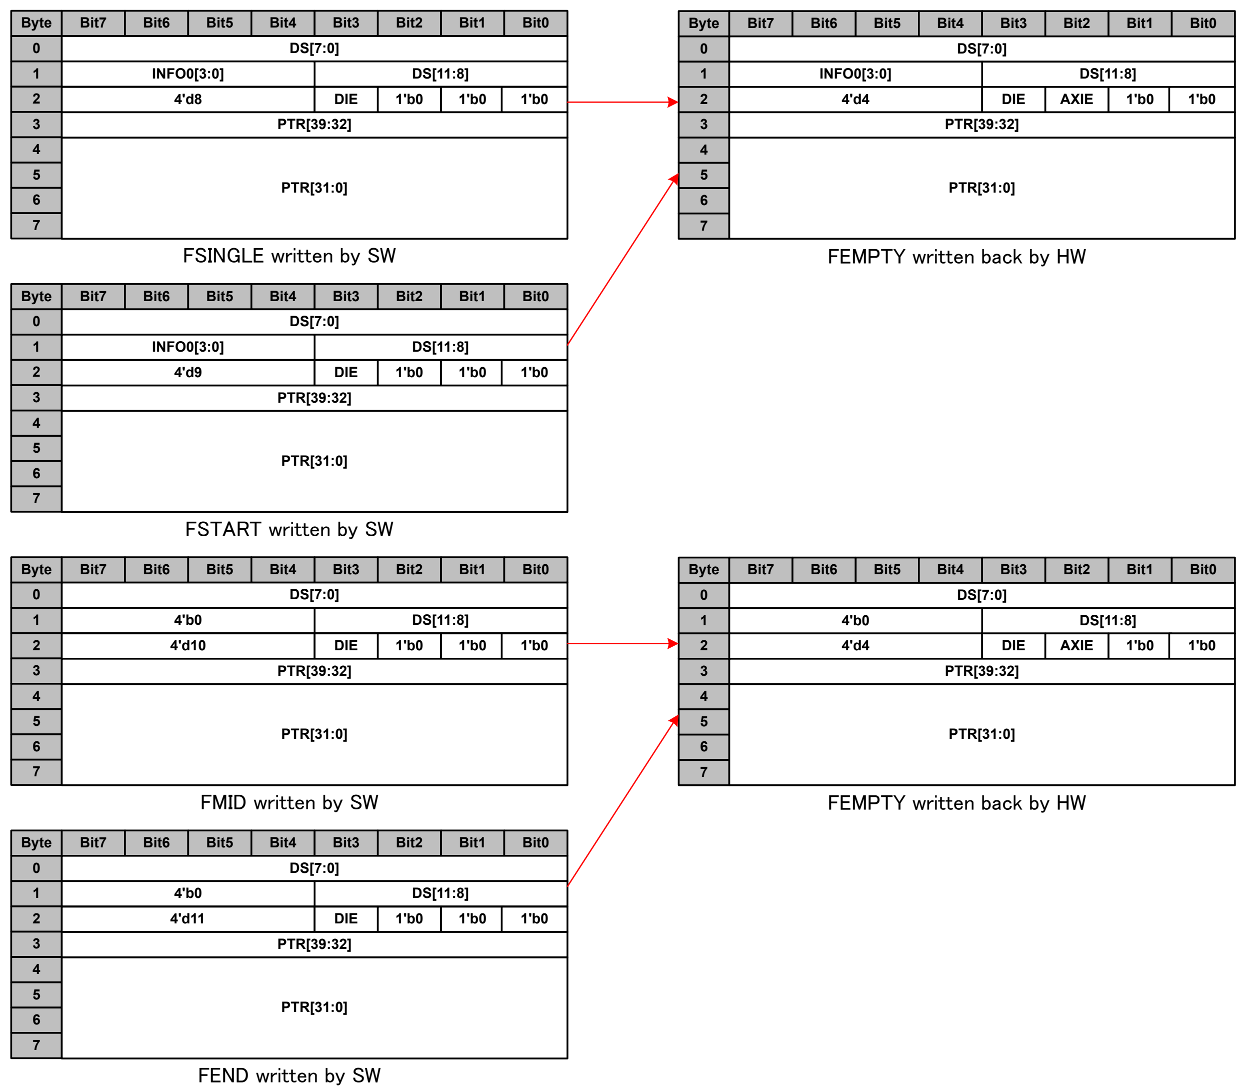

Figure 34.35 Data transmission process descriptor utilization format

Table 34.12 Data transmission process descriptor utilization field description (1 of 2)

Field name	Field description written by SW	Field description after HW write-back
DS	Data what has been written to the URAM by SW	DS (Value is copied from read descriptor)

DT	8 for FSINGLE 9 for FSTART 10 for FMID 11 for FEND	4 for FEMPTY
PTR	Address where data is written in the URAM	PTR (Value is copied from read descriptor)

Table 34.12 Data transmission process descriptor utilization field description (2 of 2)

Field name	Field description written by SW	Field description after HW write-back
INFO1 (GWDCCi.EDE == 1)	For FSINGLE and FSTART see section 34.5.2.2.3. Data Transmission Common Descriptor Format 0 for FMID and FEND.	NA: INFO1 not written back for transmission
TS (GWDCCi.ETS == 1)	NA: No timestamp descriptor for transmission	NA: No timestamp descriptor for transmission

34.5.2.2.2 Time-controlled Data Transmission

Time-controlled data transmission process descriptor utilization is described in Figure 34.36. Time-controlled data transmission process descriptor format is described in section 34.4.2.11. Global Rate Limiter Setting Flow (for basic descriptor, section 34.5.1.2.1. General Formats) and Table 34.13. FSINGLE, FSTART, FMID, FEND and FEMPTY formats are not described in this section, for their description see Figure 34.35 and Table 34.12.

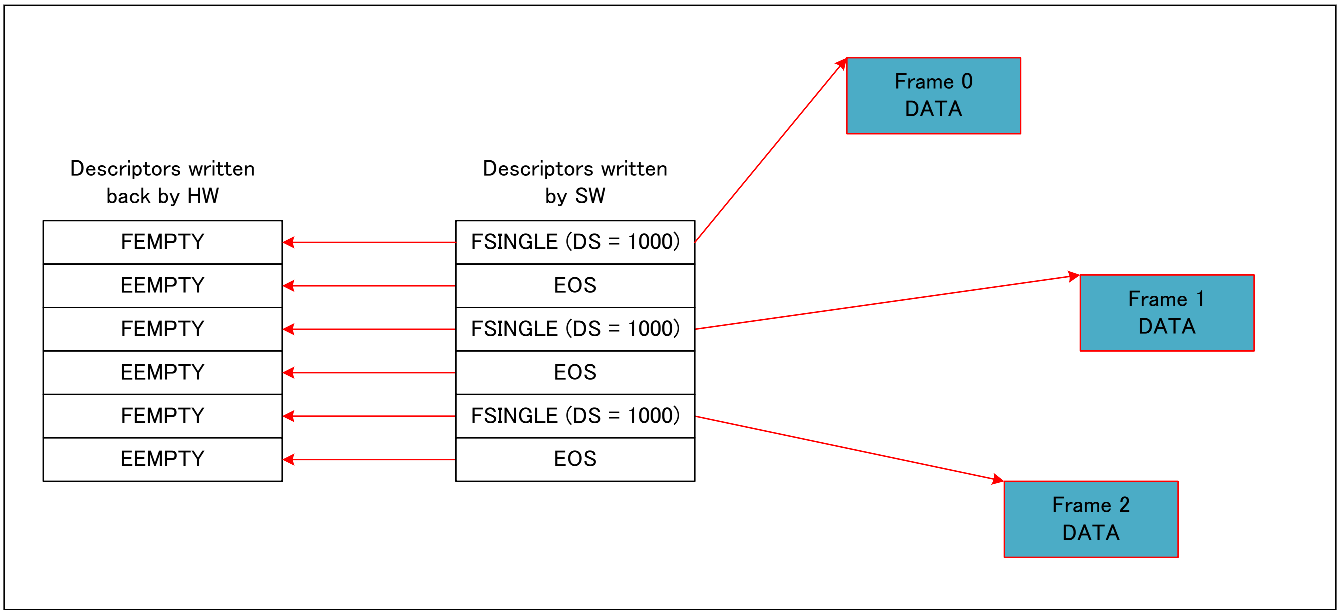

Figure 34.36 Data transmission process descriptor utilization

Note:
- If needed, the SW can split a frame between several descriptors. The first descriptor should be a FSTART descriptor, the last descriptor should be a FEND descriptor and all other descriptors should be FMID descriptors.
- When data is ready, CPU should set the corresponding GWTRCi.TSRj bit to start transfer. See GWTRCi.TSRj description.
- Reading an EOS descriptor will have per effect to clear GWTRCi.TSRj bit. So, if the CPU set GWTRCi.TSRj bit at a cyclic timing, CPU can control the data throughput (If TSR is already set when the CPU tries to set it the next time, only one frame will be sent, so a decrease in throughput can happen).
- GWTRCi.TSRj bit can be set automatically using gPTP timer [gPTP]. See section 34.5.5. gPTP Triggered Transmission.
- GWTRCi.TSRj can be set anytime even if data is not available. The GWCA will in this case read the terminate descriptor and clear GWTRCi.TSRj bit.

Restrictions:

- SW: When a frame is split, the FSTART descriptor should be written after FMIDs and FEND descriptor for a given frame.

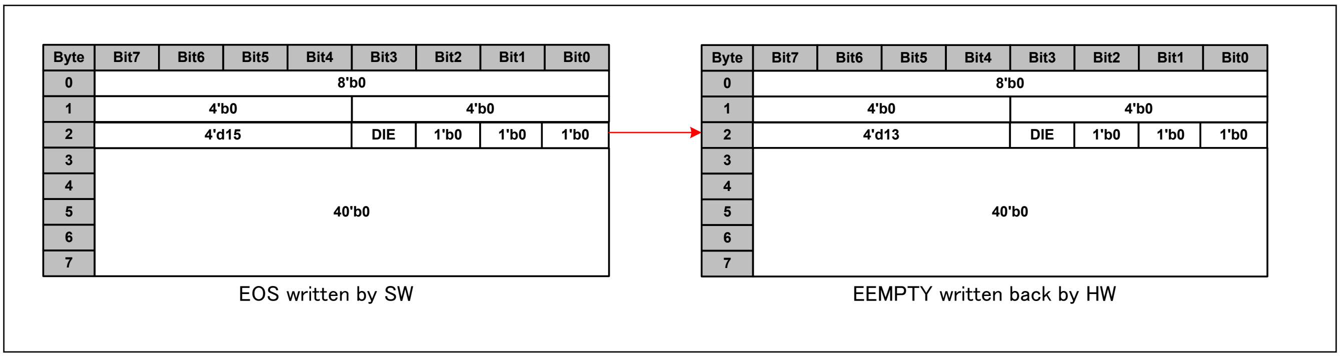

Figure 34.37 Time-controlled data transmission process descriptor utilization format

Table 34.13 Time-controlled data transmission process descriptor utilization field description

34.5.2.2.3 Data Transmission Common Descriptor Format

In this section are described the fields which are common for any data transmission (INFO0 and INFO1). There are two types of formats, the transmission direct descriptor and the transmission ethernet descriptor formats. The transmission direct descriptor could be used, for example, for non-routable protocol forwarding (network control) or for CPU-CPU communication and the transmission ethernet descriptor could be used for all normal ethernet transmissions. All the fields contained in AXI descriptors, if quoted, will be written ADESCR.{Field name}.

(1) Transmission direct descriptor

Transmission direct descriptor is used by a CPU to send frames by deciding their target directly (Forwarding engine processing will be by-passed [FWD]). Transmission direct descriptor INFO formats are described in Figure 34.38 and Table 34.14.

Restrictions:

- SW: The Transmission direct descriptor can only be and extended descriptor, see section 34.5.1.2.1. General Formats.

Figure 34.38 Transmission direct descriptor INFO formats

Table 34.14 Transmission direct descriptor INFO field descriptions

Field name	Bit width	Description
FI	1	FCS in.
SEC	1	Secure descriptor
FMT	1	Descriptor format Restrictions: ● SW: Fixed to 1 for Direct descriptor.
TXC	1	TX Timestamp capture [RMAC]. Used to set corresponding bit in RMAC TX interface.
TN	1	Timer utilized for capture [RMAC]. Used to set corresponding bit in RMAC TX interface.
TSUN	8	Timestamp unique number [RMAC]. Used to set corresponding bit in RMAC TX interface.
RV	1	Routing valid. See section 34.5.3.2. L2/L3 Update, to ethernet agent L2/3 update [ETHA] and to forwarding engine L3 routing table [FWD].
RN	5	Routing valid. See section 34.5.3.2. L2/L3 Update, to ethernet agent L2/3 update [ETHA] and to forwarding engine L3 routing table [FWD].
IPV	3	Internal priority value Target priority of the frame.
FW	1	The FCS contained in the frame is wrong (It will be corrected in the switch).
CSD0	6	CPU sub destination for GWCA0
DV	4	Destination vector [MFWD]
—	—	Reserved area Restrictions: ● SW: these fields should be set to 0.

(2) Transmission ethernet descriptor

Transmission ethernet descriptor is used by a CPU to send frames that will be forwarded by the Forwarding engine [FWD]. Transmission ethernet descriptor INFO formats are described in Figure 34.39 and Table 34.15.

Restrictions:

- SW: Because FW field (see (1) Transmission direct descriptor) is not present in an Ethernet descriptor. Any transmit frame should have either a correct FCS or no FCS.

Table 34.15 Transmission ethernet descriptor INFO field descriptions

Field name	Bit width	Description
FI	1	FCS in.
FMT	1	Descriptor format Restrictions: ● SW: Fixed to 0 for Ethernet descriptors.
TXC	1	TX Timestamp capture [RMAC]. Used to set corresponding bit in RMAC TX interface.
TN	1	Timer utilized for capture [RMAC]. Used to set corresponding bit in RMAC TX interface.
TSUN	8	Timestamp unique number [RMAC]. Used to set corresponding bit in RMAC TX interface.
—	—	Reserved Restrictions: ● SW: these fields should be set to 0.

34.5.2.3 TX Data Store

TX data store has follow functions, it extracts TAG information for frames, applies VLAN tagging, and save the frames in the local RAM. These functions are applied to all frames independently from their descriptor format.

34.5.2.3.1 TAG Information Extraction

TAG information extraction is done in HW without setting intervention. The extracted format can be filtered using GWTTFC register. TAG information extraction is described in Figure 34.40 along with GWTTFC register bit explanation for TAG filtering. The extracted fields are SN, CoS-TCI, C-TCI and S-TCI.

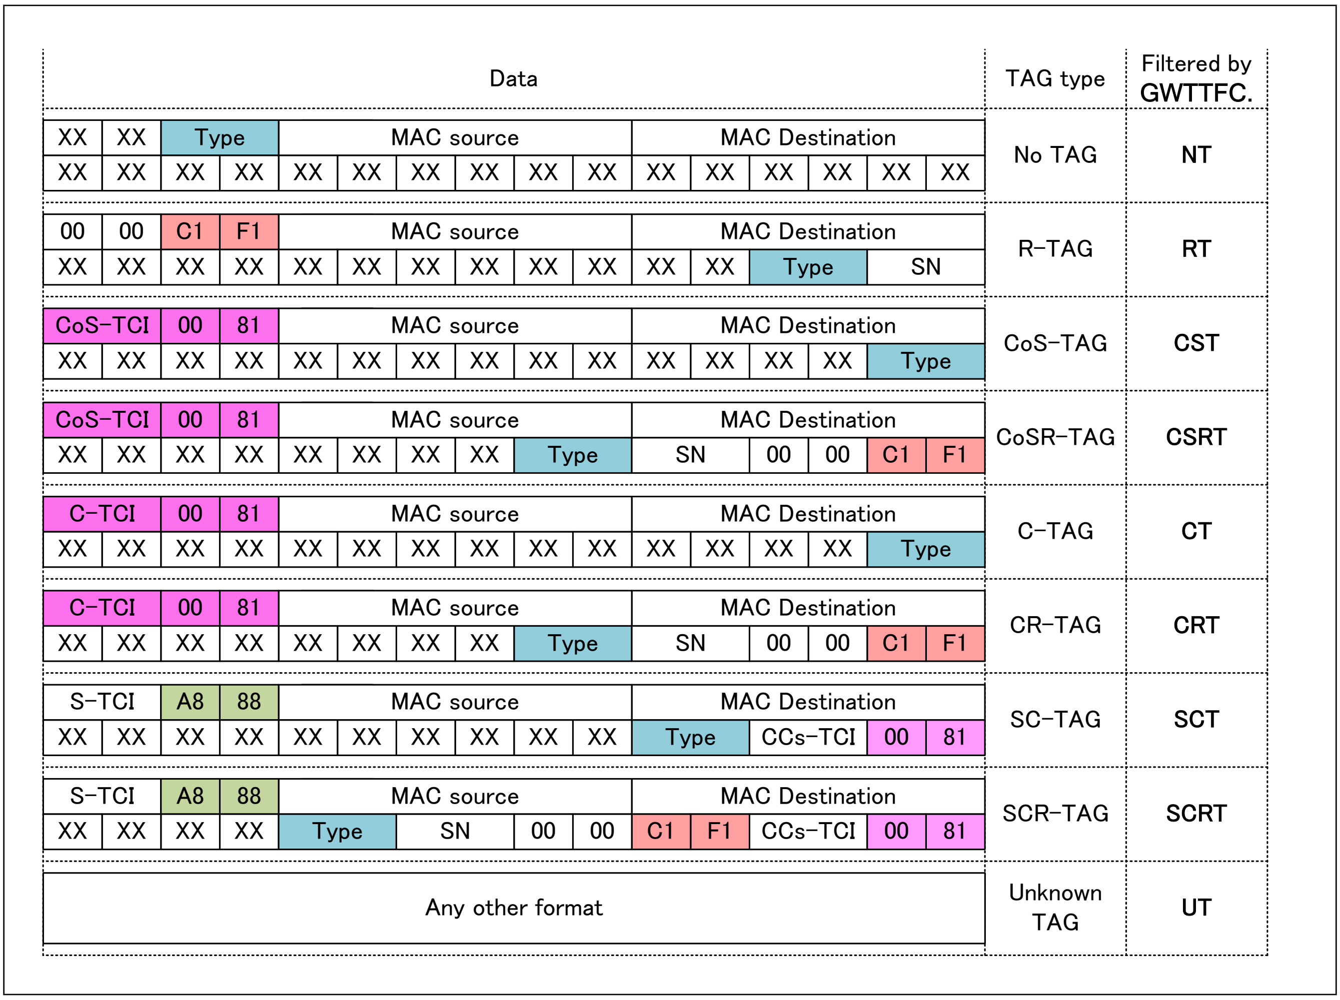

Figure 34.40 TAG information extraction

Note:
- Only colored part in are considered for TAG information extraction.
- HF1C1 corresponds to R-TAG TPID and SN correspond to R-TAG sequence number [802.1CB].
- H8100 corresponds to C-TAG TPID, C-TCI corresponds to a C-TAG TCI with a non-null VID, CoS-TCI corresponds to a C-TAG TCI with a null VID and CCs-TCI corresponds to C-TCI or CoS-TCI [802.1Q].
- H88A8 corresponds to S-TAG TPID and S-TCI corresponds to an S-TAG TCI [802.1Q].
- Type corresponds to any Ethernet type value which is not HF1C1, H88A8 or H8100.
- TPID values can be configured in Forwarding Engine [FWD]. Values for TPIDs can be set in forwarding engine (in FWTTC0 and FWTTC1 registers).

Restrictions:

- HW: Because 32 bytes are needed for TAG extraction, GWCA will reject transmit frames smaller than 32 bytes and set GWEIS0.USMFSES interrupt register.
- SW: In R-TAG, the reserved part should always be set to 0. If the reserved part is not set to 0 and corresponding frame contains an FCS, the frame could be forwarded with an error.

34.5.2.3.2 VLAN Tagging

VLAN tagging replaces or overwrites present TAGs in a frame using the format given by TAG information extraction (section 34.5.2.3.1. TAG Information Extraction), switch VLAN mode (FWGC.SVM register in MFWD) and, GWVCC and GWVTC registers. After VLAN tagging, any frame has three TAGs, one R-TAG, one C-TAG and one S-TAG which will be directly saved in the TAG RAM [MFAB].

Functions:

- GWVCC.VIM register sets the TX data path in Port based VLAN (all incoming frames are sent to the forwarding engine with the same VLAN ID). GWVCC.VIM setting is ignored when the switch in is No VLAN mode (FWGC.SVM register in forwarding engine set to 00) [MFWD].
- GWVTC register is used to set the HW TAGs. There are three possible HW TAGs. The HW C-TAG made from GWVTC.CTV as VID, GWVTC.CTP as PCP and GWVTC.CTD as DEI. The HW S-TAG made from GWVTC.STV as VID, GWVTC.STP as PCP and GWVTC.STD as DEI. The HW CoS-TAG made from GWVTC.CTV as VID, the incoming frame PCP as PCP and the incoming frame DEI as DEI.

TAGs after VLAN tagging are described in Figure 34.41, Figure 34.42 and Figure 34.43 depending on Switch VLAN mode (FWGC.SVM register in MFWD) and the type of frame given by TAG information extraction (section 34.5.2.3.1. TAG Information Extraction). In the figures, the data extracted from the incoming frames are in blue and the added HW TAGs are in red.

TAG type	R-TAG	C-TAG	S-TAG
No TAG	0	0	0

34.5.2.3.3 Frame Saving in Local RAM

For frame saving in the local RAM, see Fabric specification document [MFAB], section “Data representation in RAMs”. Only the frame descriptor mentioned in Fabric specification document [MFAB] will be described in this section.

There are two types of Local RAM descriptors, direct local descriptors and the ethernet local descriptors. They are respectively created from direct descriptors and ethernet descriptors, see section 34.5.2.2.3. Data Transmission Common Descriptor Format.

All the fields in these descriptors, if quoted, will be written LDESCR.{Field name}.

(1) Direct local descriptor

Direct local descriptor format is described in Figure 34.44 and Table 34.16.

Byte	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0

TPL	16	Total payload length	Payload length of frame. It only includes the data saved in the data RAM [MFAB].
TSV	1	Timestamp valid	Set to 0. Unused in GWCA.
TSD	1	Timestamp default	Set to 0. Unused in GWCA.
TSNS	30	Timestamp nanosecond [gPTP]	Set to 0. Unused in GWCA.
TSS	32	Timestamp second [gPTP] Restrictions: ● HW: The 16-upper bits of the gPTP second part are truncated.	Set to 0. Unused in GWCA.
—	—	Reserved area	Set to 0

(3) SAEF format

Source agent error flag format is described in Figure 34.46 and Table 34.18.

Byte	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
0	—	DNE	—	SEQE	AXE	—	—	TFE

Figure 34.46 Source agent error flag format

Table 34.18 Source agent error flag field description

Field name	Bit width	Description
TFE	1	TAG Filtering Error Set conditions: ● HW: When a frame does not fit the required TAG ingress format. See GWTTFC register explanation.
AXE	1	AXI Error Set conditions: ● HW: When an AXIE error happened during a split frame, the frame is sent incomplete.
SEQE	1	Sequence Error Set conditions: ● HW: When a FSINGLE, FSTART, EOS or unknown descriptor is received during a split frame, the frame is sent incomplete.
DNE	1	Descriptor Number Error ● HW: When a number GWMDNC.TXDMN+1 of descriptor has been already read to fetch a frame during a spit frame and the frame is not finished. The frame is sent incomplete.
—	—	Reserved Set to 0

34.5.3 Data Reception

GWCA allows data reception through the GWCA RX data path, The RX data path is described in section 34.4.2.11. Global Rate Limiter Setting Flow.

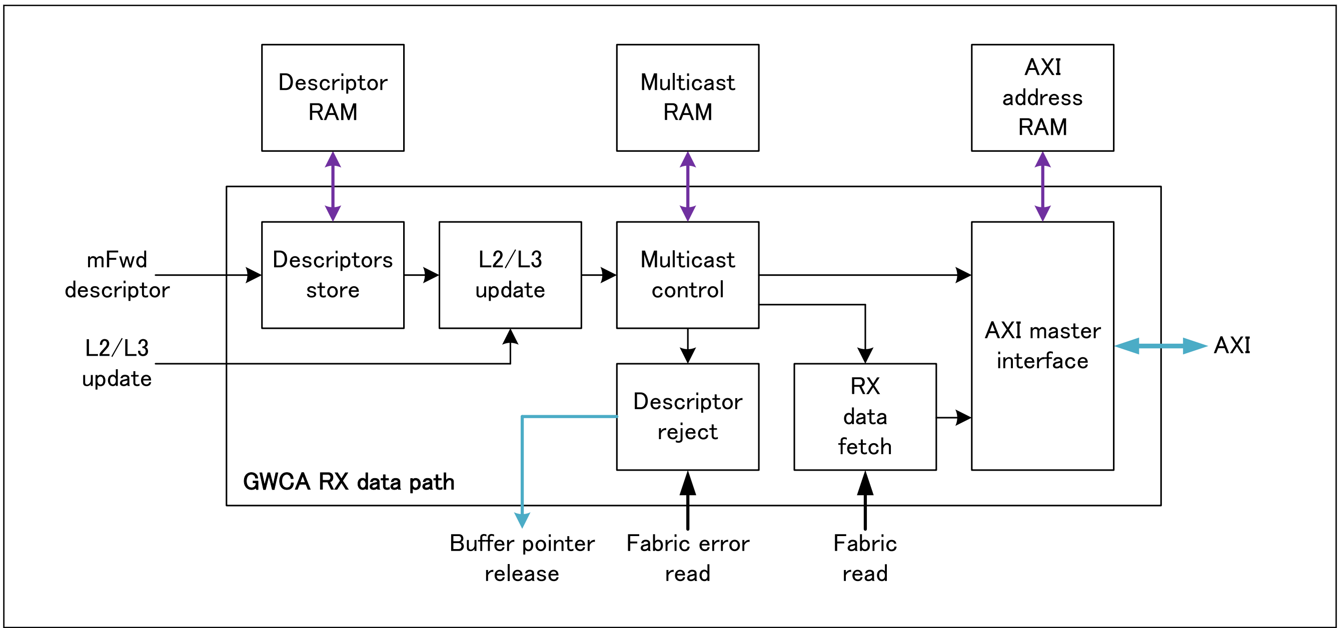

Figure 34.47 GWCA RX data path block diagram

The RX data path is separated in seven blocks:

- Descriptor store: This block aims at storing the descriptor received from the MFWD in the Descriptor RAM and controls the arbitration between descriptors.
- L2/L3 update: This block aims at fetching the L2/L3 update rules from the Forwarding Engine to update the frame while sending it.
- Frame size check: This block aims at checking the frame size and security level and decide to forward or discard frames.
- Multicast control: This block aims at checking the frame size and security level and decide to forward or discard frames and at copying the descriptors to be able to send the data at several CPU sub-destinations.
- Descriptor reject: This block aims at releasing the pointer of the frames rejected by Frame size control block. This block is here for switch hardware purpose and its description is not required for switch utilization so it will not be described.
- RX data fetch: This block fetches frames data from the local RAM, update frames depending on the information obtained by L2/L3 update module, on VLAN control information and the R-TAG information, can remove frame FCSs, and release frame pointers. The pointer release is here for switch hardware purpose and its description is not required for switch utilization so it will not be described.
- AXI master interface: This block handles the data/AXI descriptor exchange with the CPU.

34.5.3.1 Descriptor Store

Descriptor store has two functions. Storing the descriptors coming from the descriptor bus MFWD in the descriptor RAM and arbitrating descriptor read from the descriptor RAM to decide in which order the descriptors will be sent to the CPU.

34.5.3.1.1 Descriptor Storage

Descriptor storage controls the descriptor storage using GWIRC.IPVRi, GWRDQSC.RDQSL, GWRDQC.RDQD, GWRDQC.RDQP and GWRDQDCq.DQD registers and can be monitored using GWRDQMq.DNQ and GWRDQMLMq.DMLQ registers, GWEIS1.DQOES and GWEIS1.DQSES interrupt registers. Figure 34.48 describes an example for Descriptor storage setting.

Functions:

- GWIRC.IPVRi register is used to map descriptor received from forwarding engine with a given FDESCR.IPV [MFWD] value to a determined descriptor queue. For example, by setting GWIRC.IPVR6 to 1 all the descriptors received with FDESCR.IPV equal to 6 will be stored in descriptor queue number 1.

- GWRDQSC.RDQSLn is used to set a queue's security level. If a queue is secure (GWRDQSC.RDQSLn is set) and a non-secure descriptor is received (FDESCR.SEC [MFWD] is not set) for this queue, the descriptor will not be stored and GWEIS1.DQSESi flag will be set.
- GWRDQC.RDQP register is used to pause descriptor queues. For paused descriptor queues, the descriptor transmission to CPU will stop but the descriptor storage in the descriptor RAM will continue.
- GWRDQC.RDQD register is used to disable descriptor queues. For disabled descriptor queues and no descriptor will be stored in the Descriptor RAM.
- GWRDQDCq.DQD registers are used to set the maximum number of descriptors that can be stored in each descriptor queue. If a descriptor is received for descriptor q while queue q is full (GWRDQDCq.DQD == GWRDQMq.DNQ), the descriptor will not be stored and GWEIS1.DQOESi flag will be set.
- GWRDQMq.DNQ registers are used to monitor the current number of descriptors in each descriptor queue.
- GWRDQMLMq.DMLQ registers are used to monitor the maximum number of descriptors that has been held in each queue since the previous reset or the previous time corresponding register has been read.
- GWEIS1.DQOES register signals that descriptors have been discarded because of a descriptor queue overflow.
- GWEIS1.DQSES register signals that descriptors have been discarded because of a descriptor queue security error.

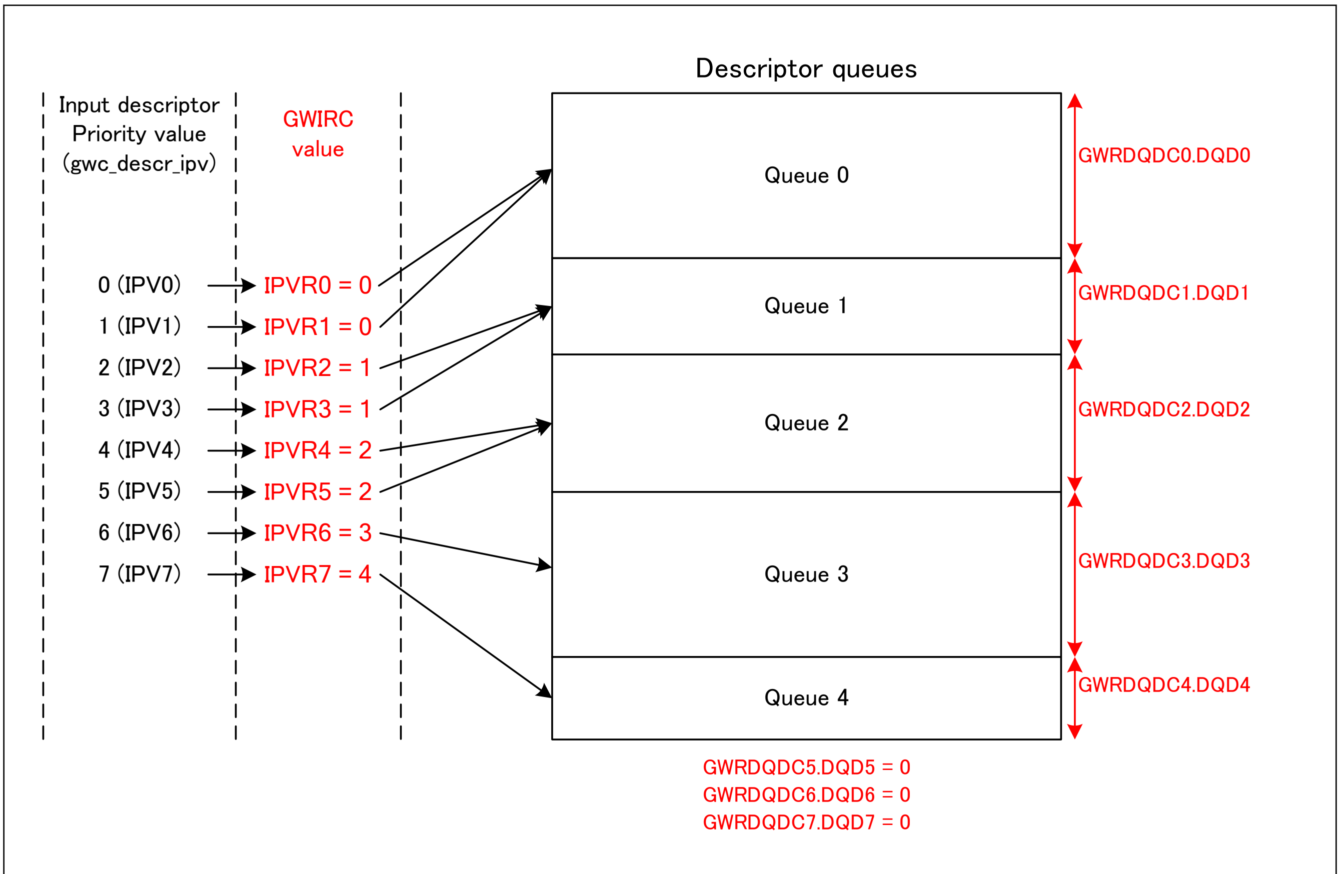

Figure 34.48 Descriptor storage setting example

34.5.3.1.2 Descriptor Arbitration

Descriptor arbitration controls the descriptor reading order for reception using GWRDQAC register. It has 4 modes. The Strict Priority, the Round Robin, the Weight Round Robin and the Hybrid mode. This function is used to ensure QoS when the AXI access allows a throughput which is too small to allow all the data to be stored in the user RAM.

(1) Strict priority (SP)

To set the descriptor arbitration in strict priority mode, all the GWRDQAC.RDQAq (q = 0 to 7) registers should be set to 0. In this case a strict priority algorithm will be applied for descriptor arbitration. The strict priority algorithm is described through an example in Figure 34.49.

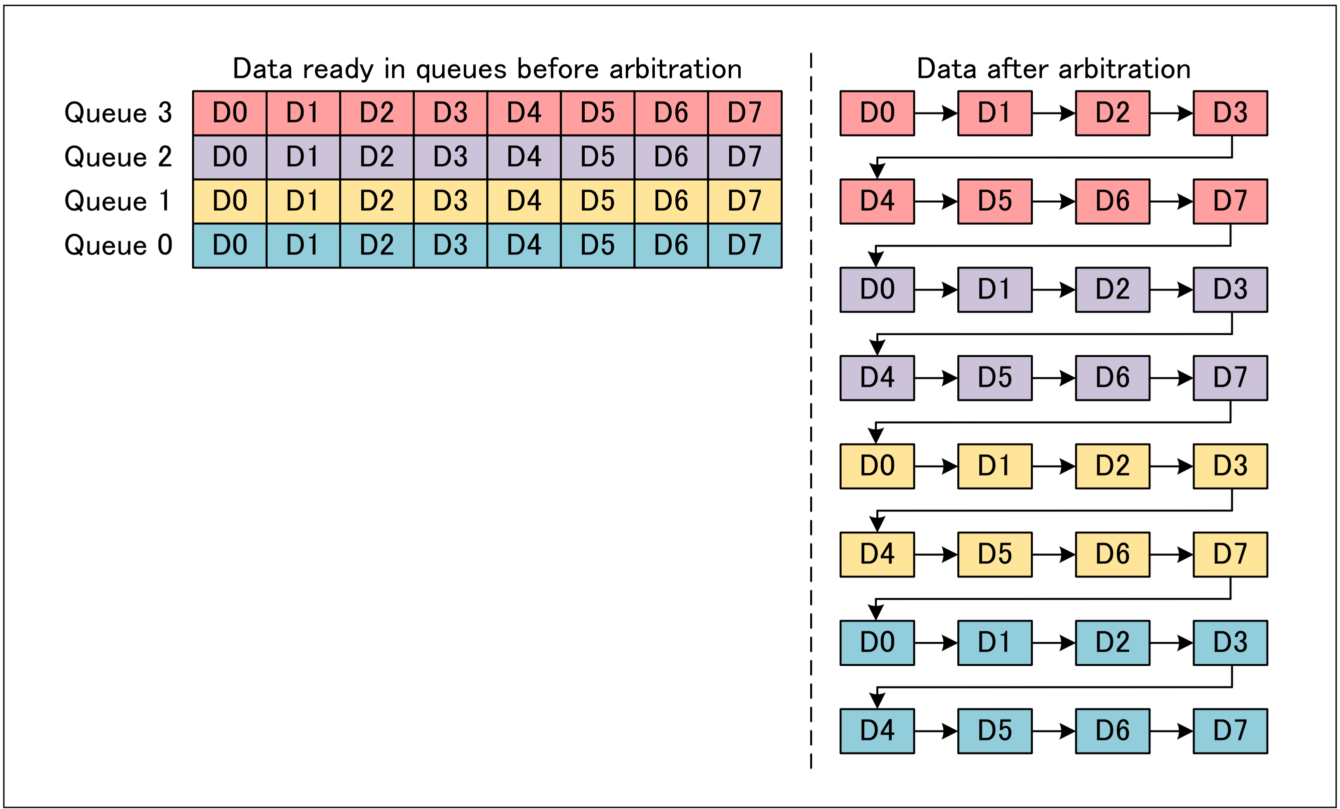

Figure 34.49 Strict priority arbitration example

(2) Round Robin (RR)

To set the descriptor arbitration in round robin mode, all the GWRDQAC.RDQAq (q = 0 to 7) registers should be set to 1. In this case a round robin algorithm will be applied for descriptor arbitration. The round robin algorithm is described through an example in Figure 34.50.

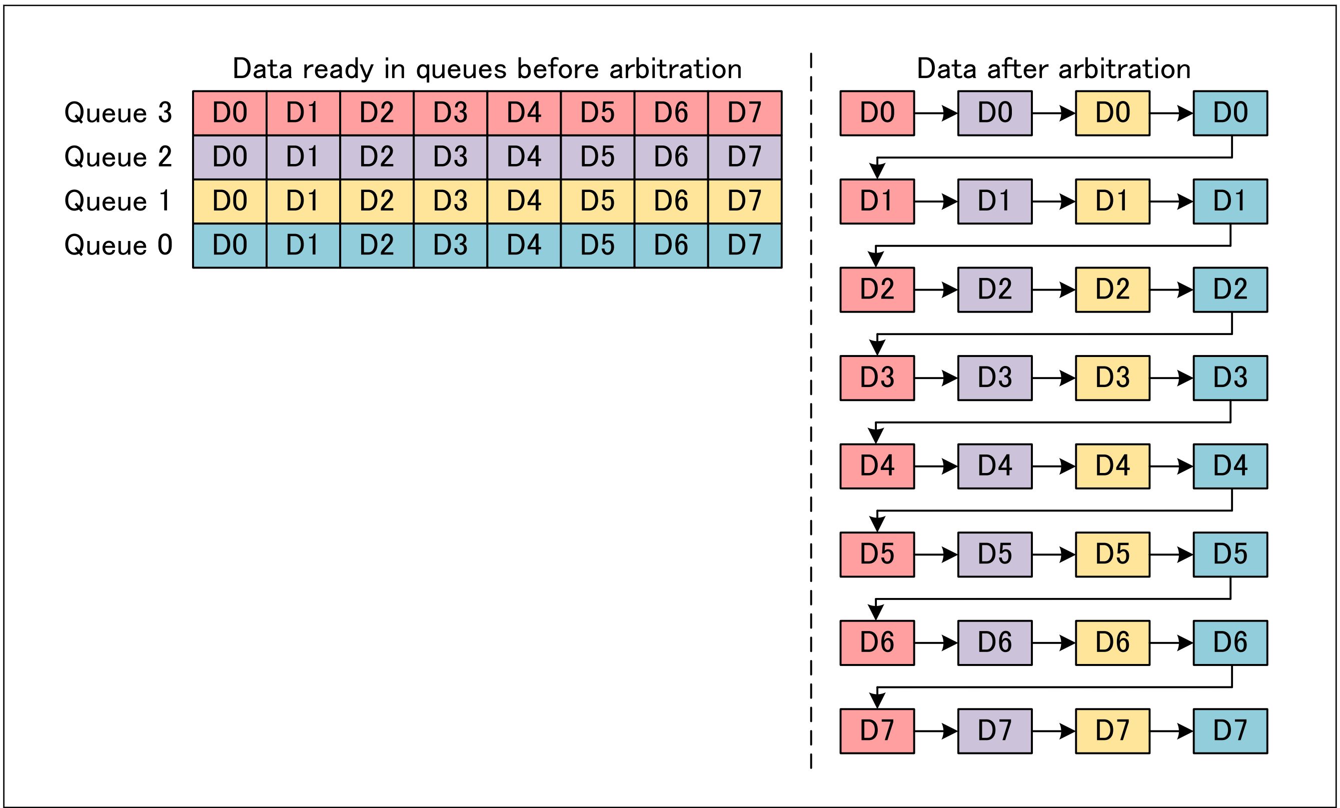

Figure 34.50 Round robin arbitration example

(3) Weight Round Robin (WRR)

To set the descriptor arbitration in weight round robin mode, all the GWRDQAC.RDQAq (q = 0 to 7) registers should be set to a value different than 0 with at least one queue set to a value different than 1. In this case a weight round robin algorithm will be applied for descriptor arbitration. The weight round robin algorithm is described through an example in Figure 34.51 (RDQA0 = 2, RDQA1 = 1, RDQA2 = 3 and RDQA3 = 4). In this arbitration GWRDQAC.RDQAq register represents the weight of queue q. the heavier a queue is the more chance it will have to transmit data.

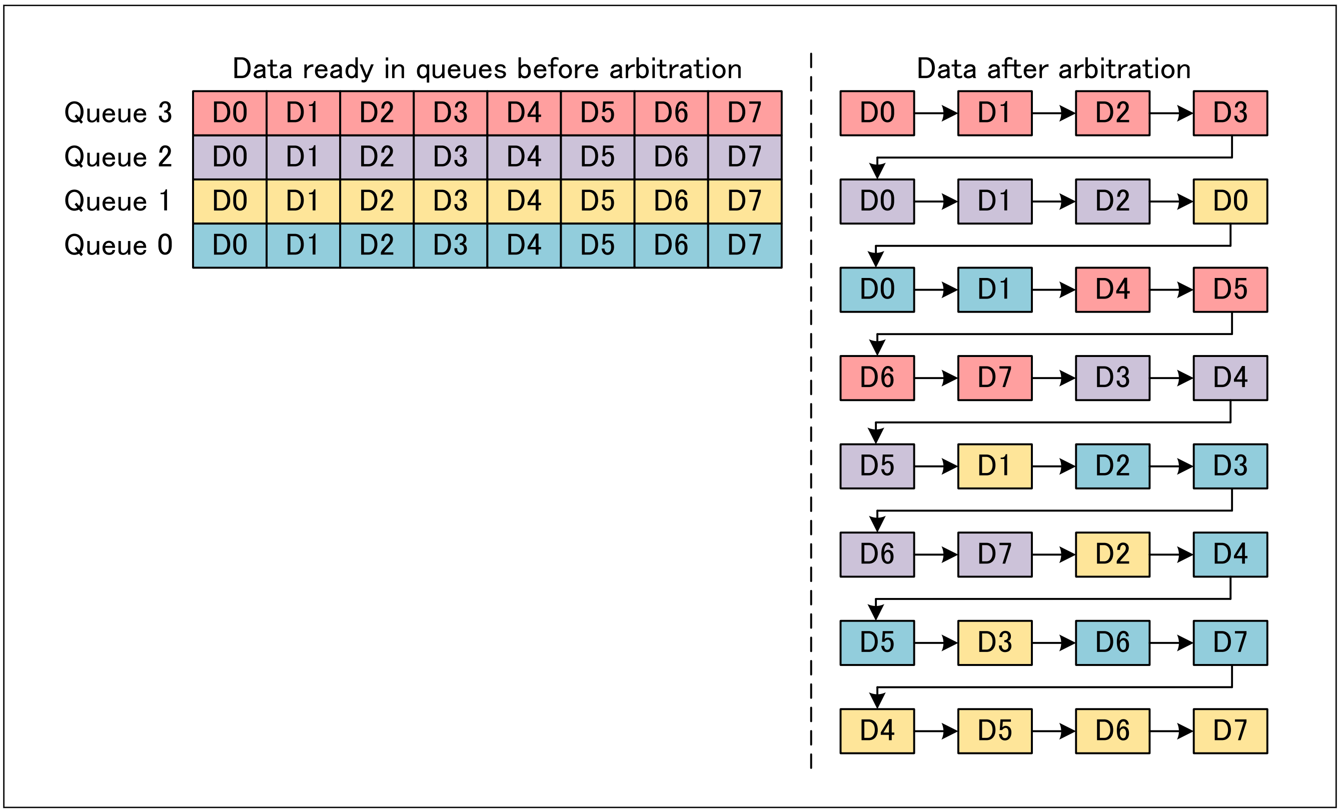

Figure 34.51 Weight round robin arbitration example

(4) Hybrid arbitration

It is allowed to use at the same time SP and RR or SP and WRR. This mode is called the hybrid arbitration mode. To set the descriptor arbitration in hybrid arbitration mode, some of the GWRDQAC.RDQAq (q = 0 to 7) registers should be set to 0 and some others to a value different than 0 (For restrictions see GWRDQAC.RDQAq register explanation). The hybrid arbitration algorithm is described through an example in Figure 34.52 (RDQA0 = 0, RDQA1 = 1, RDQA2 = 2 and RDQA3 = 0).

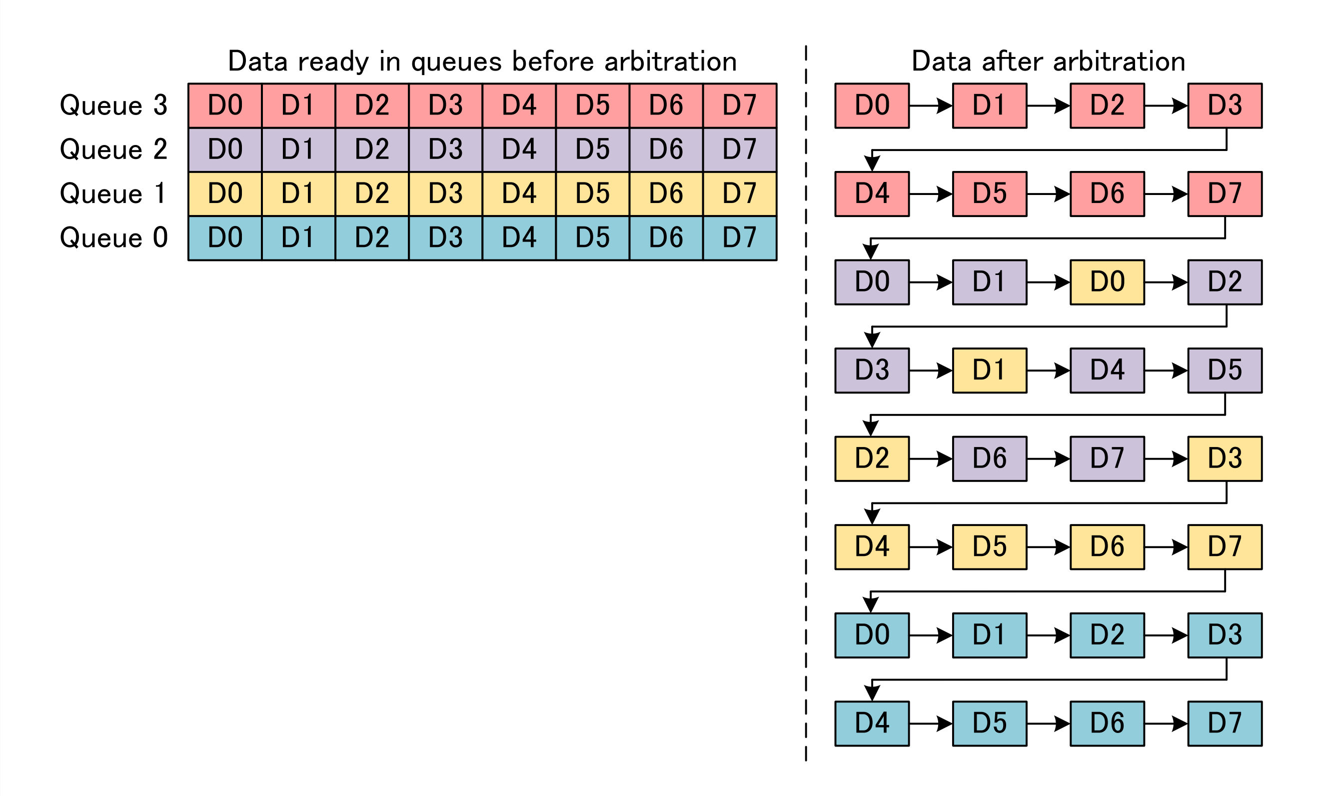

Figure 34.52 Hybrid arbitration example

34.5.3.2 L2/L3 Update

L2/L3 update aims at fetching the update rules thanks to L2/L3 update bus [MFWD].

The L2/L3 update rules will be fetched for any descriptor received with FDESCR.RV set [MFWD]. Rule number FDESCR.RN [MFWD] will be used for L2/L3 update.

Functions:

- For rule fetching setting details see Forwarding Engine specification document [MFWD].
- For frame update information see RX data fetch block explanation in section 34.5.3.4. RX Data Fetch.

34.5.3.3 Multicast Control

Multicast function aims at copying the same frame to several AXI descriptor queue. It allows different CPU to process same frames at the same time without interfering with each other. If nothing is set, all the descriptor queues are initialized as unicast queues.

Multicast control has four functions. Checking the frame size, security level and queue type (TX or RX), copying the descriptor coming from L2/L3 update using the multicast table, modifying the multicast table using multicast learning and reading the multicast table using multicast searching.

34.5.3.3.1 Frame Check

Frame check aims at checking if a frame has the right properties to be received by CPU using GWRMFSCq, GWDCCi.SL, GWDCCi.DQT registers and can be monitored using GWEIS0.FSES, GWEIS4.DSSES, GWEIS4.DSSEIOS, GWEIS4.DSSECN, GWEIS5.DCTES, GWEIS5.DCTEIOS, GWEIS5.DCTECN interrupt registers.

Functions:

- GWRMFSCq registers are used to set the maximum frame size accepted for each descriptor queue. Any frame received for queue q with a size bigger than GWRMFSCq.MFS will be discarded and GWEIS0.FSES flag will be set. The frame size considered is the size after VLAN update and with FCS. In this case, multicast will not happen and the frame will totally be discarded.

- GWDCCi.SL registers are used to set the security level of a CPU sub destination. Any frame received unsecure (FDESCR.SEC [MFWD] is not set) for a secure CPU sub destination (GWDCCi.SL is set) discarded and GWEIS4.DSSES flag will be set (during multicast, for all CPU sub destination for which GWDCCi.SL is set frame will be discarded and for all CPU sub destination for which GWDCCi.SL is not set, frame will be received).
- GWDCCi.DQT is used to control is the received frame is going to a reception descriptor queue. Any frame received for a transmission descriptor queue will be discarded and GWEIS5.DCTES flag will be set. In case of multicast, only the targeted transmission queue will see their data lost.
- GWEIS0.FSES interrupt register signals that a descriptor has been rejected because the corresponding frame where oversized.
- GWEIS4.DSSES, GWEIS4.DSSEIOS and GWEIS4.DSSECN interrupt registers signal that a descriptor has been rejected because of an AXI descriptor queue security error.
- GWEIS5.DCTES, GWEIS5.DCTEIOS, GWEIS5.DCTECN interrupt registers signal that a descriptor has been rejected because of a descriptor chain type error.

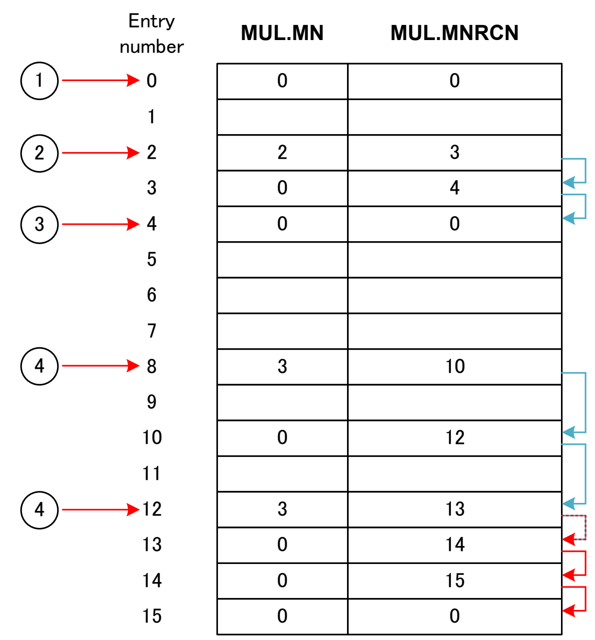
34.5.3.3.2 Descriptor Copy

Descriptor copy aims at multicasting descriptor to send them to the AXI master interface and the RX data fetch using the multicast table.

The multicast table is divided in two fields, MUL.MN[2:0] which is the multicast number and MUL.MNRCN[5:0] which is the next descriptor chain and is used to link AXI descriptor chains together. AXI descriptor chains linked together form a multicast chain to which a frame will be multicast.

Because the multicast table is based on links all the multicast patterns are not possible.

The multicast table utilization is described in Figure 34.53 through an example.



Case	Explanation
1	Unicast: − Input descriptor with CPUSD = 0 will be sent to AXI descriptor chain 0
2	Multicast: − Input descriptor with CPUSD = 2 will be sent to AXI descriptor chain 2,3 and 4.
3	Unicast in a multicast chain: − Input descriptor with CPUSD = 4 will be sent to AXI descriptor chain 4.
4	Multicast chain in a multicast chain: − Input descriptor with CPUSD = 8 will be sent to AXI descriptor chain 8,10,12,13. − Input descriptor with CPUSD = 12 will be sent to AXI descriptor chain 12,13,14,15.

Figure 34.53 Multicast table utilization example

34.5.3.3.3 Multicast Learning

Multicast learning aims at updating entries in the multicast table using GWMSTLS and GWMSTLR registers. Table 34.19 describes mapping between learning registers and fields in multicast table. Table 34.20 describes the learn results, their mapping with the multicast table and how to handle them. It is possible to multicast a frame to 8 AXI descriptor chains.

Functions:

- GWMSTLS register is used to set the information needed to overwrite an entry.

- GWMSTLR register is used to check if the previously set entry has been overwritten.
- To set entries in the multicast table, see software flow in section 34.4.2.7. Multicast Table Setting Flow.
- If GWAC.AMP = 1 (the AXI transaction is pending), learning will not complete. Release the AXI master pose.

Table 34.19 Learn registers/Multicast table mapping registers

Register name	Field name in L3 table
GWMSTLS.MSENL	Not present in multicast table, used to indicate which entry should be overwritten.
GWMSTLS.MNL	MUL.MN, see section 34.5.3.3.2. Descriptor Copy
GWMSTLS.MNRCNL	MUL.MNRCN, see section 34.5.3.3.2. Descriptor Copy

Table 34.20 Learn result

Register name	Field name	Field explanation
GWMSTLR.MTLF	Learning fail	Learning fail will happen in one of the following conditions: ● When an APB tries to learn a multicast entry and the multicast table is not ready (GWMTIRM.MTR is not set)

(1) Static learning

When a system aims at using the multicast table in a static way (set in CONFIG mode only) there is no restriction regarding the entry format, the entry link pointers and the learning order of entries.

(2) Dynamic learning

When a system aims at using the multicast table in a dynamic way (set in OPERATION mode), the restrictions described in Figure 34.54 should be respected.

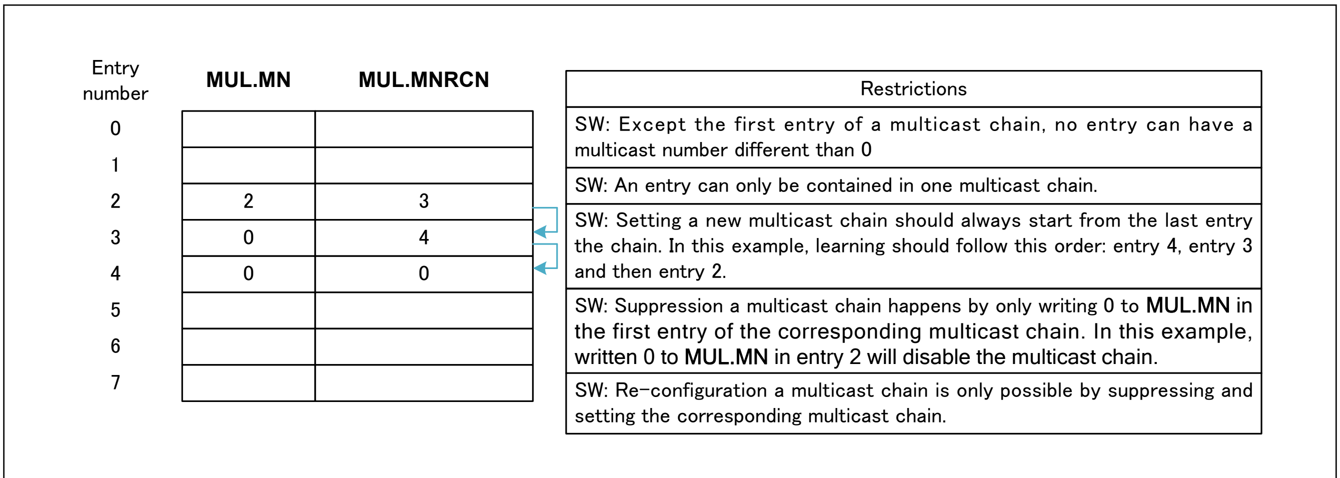


Figure 34.54 Multicast table dynamic utilization restrictions

34.5.3.3.4 Multicast Searching

Multicast searching aims at reading entries in the multicast table using GWMSTSS and GWMSTSR registers. Table 34.21 describes mapping between learning registers and fields in multicast table. Table 34.22

Functions:

- GWMSTSS register is used to set the entry that should be read.
- GWMSTSR register is used to read the read result.
- To read an entry in the multicast table, see software flow in section 34.4.2.9. AXI RAM Reset Flow.

Table 34.21 Search registers/Multicast table mapping registers

Register name	Field name in L3 table
GWMSTSS.MSENS	Not present in multicast table, used to indicate which entry should be read.

Table 34.22 Search result

Register name	Field name/ corresponding field in multicast table	Field explanation
GWMSTSR.MNR	MUL.MN	Multicast table read value
GWMSTSR.MNRCNR	MUL.MNRCN	Multicast table read value

34.5.3.4 RX Data Fetch

RX data fetch has the following functions. Fetching the data from the Local RAM, untagging/ VLANs depending on VLAN settings, inserting an R-TAG, updating the data depending on L2/L3 update information fetched in L2/L3 update, handling FCS, sending the data the AXI master interface and releasing the buffer pointer of the read frames.

The data fetching from Local RAM, the data sending to the AXI master interface and the pointer release are here for switch hardware purpose and its description is not required for switch utilization so it will not be described.

34.5.3.4.1 VLAN (SC-TAG)

Fetching the data from the Local RAM, updating the data depending on “L23 update” and “TAG function registers”. Updating VLANs data path is described in Figure 34.55.

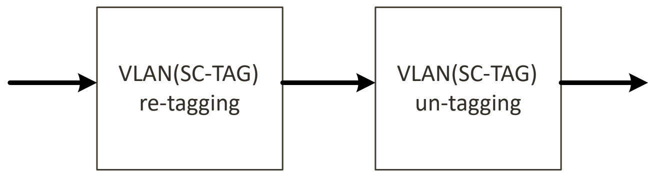

Figure 34.55 VLAN data path

(1) VLAN(SC-TAG) re-tagging

Layer 2 update can happen for the following fields:

- Destination MAC address updated to L23U.MDA when L23U.MDAU set.
- Source MAC address is updated to {GWMAC0.MAU, GWMAC1.MAL} when L23U.MSAU set.
- C-TAG VID is updated to L23U.CVID when L23U.CVIDU set.
- C-TAG PCP is updated to L23U.CPCP when L23U.CPCPU set.
- C-TAG VID is updated to L23U.CDEI when L23U.CDEIU set.
- S-TAG VID is updated to L23U.SVID when L23U.SVIDU set.
- S-TAG PCP is updated to L23U.SPCP when L23U.SPCPU set.
- S-TAG VID is updated to L23U.SDEI when L23U.SDEIU set.

Restrictions:

- HW: To update the C-TAG/S-TAG fields, the C-TAG/S-TAG should be present in the frame after VLAN untagging ((2) VLAN(SC-TAG) untagging). If not preset, the update will not happen (e.g. L2 update does not change the frame format and does not permit TAG insertion).

(2) VLAN(SC-TAG) untagging

VLAN update aims at modifying VLAN frame format depending on switch VLAN mode (FWGC.SVM register in MFWD), the VLAN control information given by the forwarding engine descriptor (FDESCR.VCTRL [FWD]) and GWVCC.VEM register.

Functions:

- GWVCC.VEM register sets the VLAN reception mode.

The frames format after VLAN untagging are described in Figure 34.56, Figure 34.57 and Figure 34.58 Switch VLAN mode (FWGC.SVM register in MFWD) and VLAN control information. The conversion between the frame stored in the Local RAM and the frame format after VLAN untagging is described in Figure 34.59.

Figure 34.58 Frame format after VLAN untagging: Switch in SC-VLAN mode [MFWD]

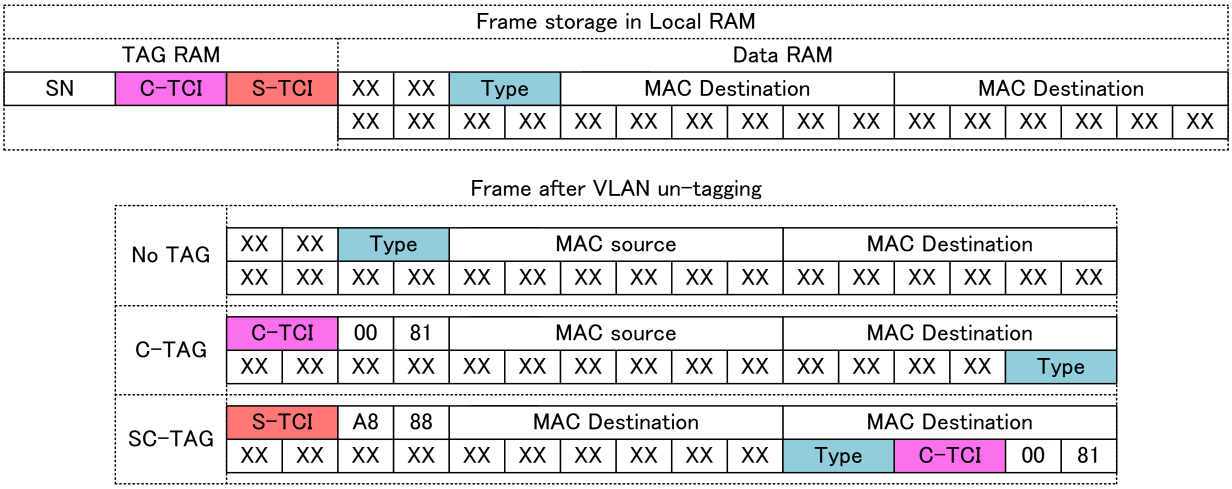

Figure 34.59 Local RAM frame to frame format after VLAN untagging conversion

Note:
- The Local RAM frame to frame format after VLAN untagging conversion for CoS-TAG is not described because it is the same as C-TAG except that the VID in the C-TCI will be fixed to 0.
- The R-TAG insertion is not described here because part of the L2/L3 update function, see section 34.5.3.4.2. R-TAG Insertion.
- H8100 corresponds to C-TAG TPID, C-TCI corresponds to a C-TAG TCI with a non-null VID, CoS-TCI corresponds to a C-TAG TCI with a null VID and CCs-TCI corresponds to C-TCI or CoS-TCI [802.1Q].
- H88A8 corresponds to S-TAG TPID and S-TCI corresponds to an S-TAG TCI [802.1Q].
- Type corresponds to any Ethernet type value which is not HF1C1, H88A8 or H8100.
- TPID values can be changed in Forwarding Engine [FWD]. Values for TPIDs can be set in forwarding engine (in FWTTC0 and FWTTC1 registers).

34.5.3.4.2 R-TAG Insertion

The R-TAG insertion happens for the two following cases:

- For frames received with an R-TAG (LDESCR.RTGI was set during reception, see section 34.5.2.3.3. Frame Saving in Local RAM, so, in descriptor received for forwarding, FDESCR.RTGI was also set) and for which routing is not requested (FDESCR.RV was not set in received descriptor [MFWD]) or for which routing is requested but the R-TAG stripping is not request by routing (L23U.RTU [MFWD] was not set to 10 in rule number FDESCR.RN [MFWD] during routing rule fetching by L2/L3 update block, see section 34.5.3.2. L2/L3 Update).

- For frames received without an R-TAG and for which routing and the R-TAG insertion is requested (L23U.RTU [MFWD] was not set to 01 in rule number FDESCR.RN [MFWD] during routing rule fetching by L2/L3 update block, see section 34.5.3.2. L2/L3 Update).

In both cases, the R-TAG sequence number (SN in Figure 34.60) will be set to the sequence number FDESCR.SEQN [MFWD] received in received descriptor.

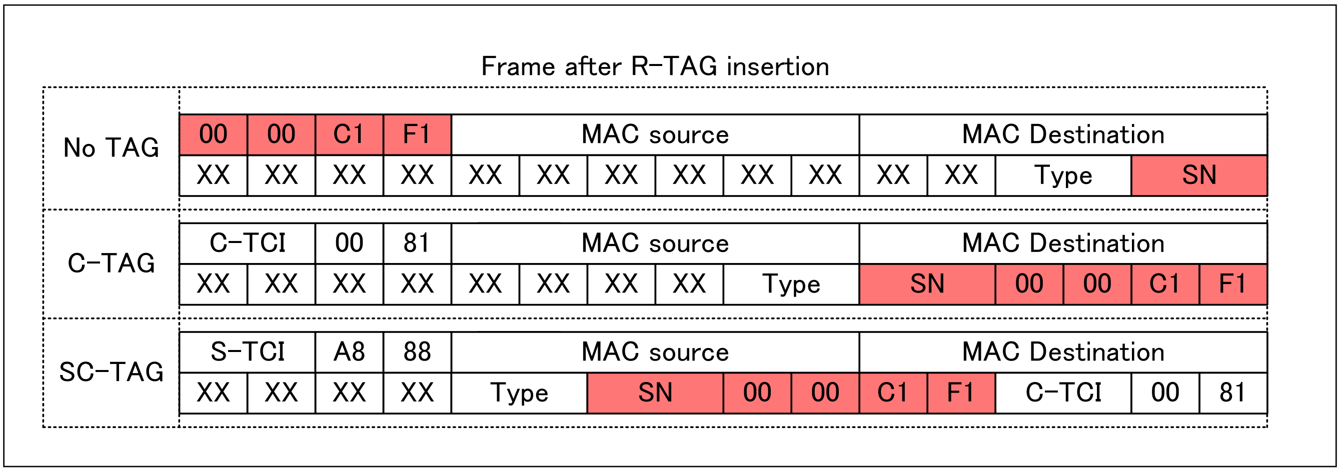

Figure 34.60 R-TAG inserted frame format

Note:
- HF1C1 corresponds to R-TAG TPID and SN correspond to R-TAG sequence number[802.1CB].
- H8100 corresponds to C-TAG TPID, C-TCI corresponds to a C-TAG TCI with a non-null VID, CoS-TCI corresponds to a C-TAG TCI with a null VID and CCs-TCI corresponds to C-TCI or CoS-TCI [802.1Q].
- H88A8 corresponds to S-TAG TPID and S-TCI corresponds to an S-TAG TCI [802.1Q].
- Type corresponds to any Ethernet type value which is not HF1C1, H88A8 or H8100.
- TPID values can be changed in Forwarding Engine [FWD]. Values for TPIDs can be set in forwarding engine (in FWTTC0 and FWTTC1 registers).

34.5.3.4.3 L2 /L3 Update

L2/L3 updates is used to the layer 2 and the layer 3 of frames. L2/L3 update happens for frames for which routing is requested (received descriptor with FDESCR.RV set [FWD]) and depending on the update information fetched by the L2/L3 update block (see section 34.5.3.2. L2/L3 Update).

(1) L2 update

See (1) VLAN(SC-TAG) re-tagging.

(2) L3 update

Layer 3 updates happens when L23U.TTLU was set. L3 update will happen in two steps, the frame decoding and the L3 update.

The decoder decodes the type field (see section 34.5.2.3.1. TAG Information Extraction) of the Layer 3 update frame and separate frames in the following formats:

- IPv4: When type field is equal to H0800.
- IPv6: When type field is equal to H86DD.
- Unknown: When type field is other than H0800 and H86DD.

Depending on the decoding result, the L3 update will happen has following:

- For IPv4: TimeToLive will be decremented by 1 if it is other than 0 and HeaderChecksum will be corrected using a relative equation (If the checksum were wrong in the input frame, the checksum will also be wrong for the output L3 updated frame).

- For IPv6: HopLimit will be decremented by 1 if it is other than 0.
- For Unknown: L3 update will be ignored.

34.5.3.4.4 FCS Handling

Ethernet frame FCS can be forwarded to the CPU using GWRGC.RCPT register.

Functions:

- GWRGC.RCPT is used to pass frame FCSs to the CPU.

However, following conditions should be met for GWCA to forward a frame FCS to the CPU:

- For Ethernet agent ETHA, RMAC should not have removed the FCS [RMAC] at the input port.
- For GWCA, the FCS should be present in the ingress frame and valid (FI set and FW not set in input descriptor, see section 34.5.2.2.3. Data Transmission Common Descriptor Format).
- The VLANs should be the same at the egress than at the ingress port.
- The frame should not be a routed frame (received descriptor FDESCR.RV field not set MFWD).

Note:
- If one of the above conditions is not met by a frame, the FCS will be removed from it even if GWRGC.RCPT register is set to 1.
- If a frame is received by CPU with an FCS, FI flag will be set in the reception descriptor. If not, it will not be set.

34.5.3.5 AXI Master Interface

The AXI master interface handles the data/AXI descriptor exchange with the CPU. It receives the updated data and the information related to the data for RX data fetch block and stores them in the CPU RAM. To do so, the AXI master interface uses GWDCCi.EDE, GWDCCi.ETS, GWDCCi.SM, and can be monitored using GWAARSS, GWAARSR0 and GWAARSR1, GWIDAUASi, GWIDASMi, GWIDASAMi0, GWIDASAMi1, GWIDACAMi0, GWIDACAMi1 registers and GWEIS2i.DFESt, GWEIS3.IAOESi, GWEIS4.DSES, GWEIS4.DSEIOS, GWEIS4.DSECN interrupt registers.

Functions:

- GWDCCi.EDE and GWDCCi.ETS registers set the descriptor format that are used for descriptor queue number i. See section 34.5.1.2.1. General Formats.
- GWDCCi.SM register sets how GWCA writes back descriptors. In this section, all explanation will use GWDCCi.SM equal to 00b. For GWDCCi.SM equal to 01b or 10b, see the register explanation.
- For GWAARSS, GWAARSR0 and GWAARSR1 registers, see section 34.5.1.6. AXI Address RAM Searching.
- GWIDAUASi, GWIDASMi, GWIDASAMi0, GWIDASAMi1, GWIDACAMi0, GWIDACAMi1 registers and GWEIS3.IAOESi interrupt register are used for incremental area monitoring, see section 34.5.3.5.3. Single Page Incremental Data Reception.
- GWEIS2i.DFESt interrupt register signals that frames have been lost because a full descriptor queue.
- GWEIS4.DSES, GWEIS4.DSEIOS, GWEIS4.DSECN interrupt registers signal that frames have been received with an unexpected size, see section 34.5.3.5.2. Size-controlled Data Reception.

Data reception can be done using linear or cyclic descriptor queues (see section 34.5.1.5. AXI Descriptor Queue Format). Data reception process descriptors can be set six different ways, through the basic data reception descriptor chain (section 34.5.3.5.1. Basic Data Reception), the Size-controlled data reception descriptor chain (section 34.5.3.5.2. Size-controlled Data Reception), the Single page incremental data reception descriptor chain (section 34.5.3.5.3. Single Page Incremental Data Reception), the Interrupt based multi-page incremental data reception descriptor chain (section 34.5.3.5.4. Interrupt Based on Multi-page Incremental Data Reception), the Header removal incremental data reception descriptor chain (section 34.5.3.5.5. Header Removal Incremental Data Reception).

34.5.3.5.1 Basic Data Reception

Basic data reception process descriptor utilization is described in Figure 34.61. Basic data reception process descriptor format is described in Figure 34.62 (for basic descriptor, section section 34.5.1.2.1. General Formats) and Table 34.23.

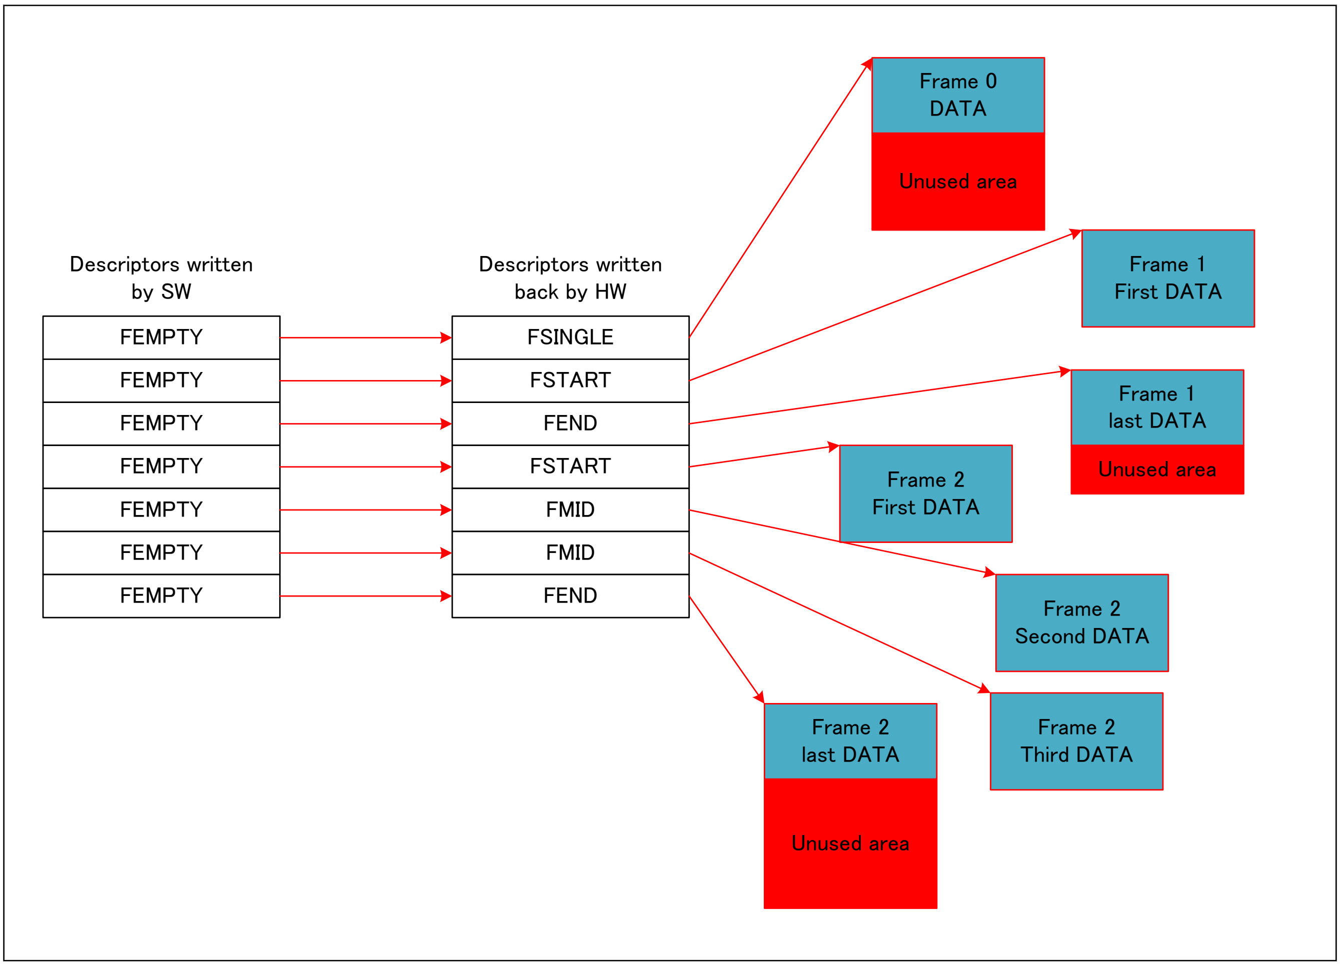

Figure 34.61 Basic data reception process descriptor utilization

Note:
- If a frame is too big to fit in an area reserved by one descriptor, it will be automatically split. The first descriptor will be FSTART, the last descriptor will be FEND and all other descriptors will be FMID.
- When a frame is split the hardware will write back the FSTART descriptor last. Even if the queue is set in keep DT mode, this order is kept.

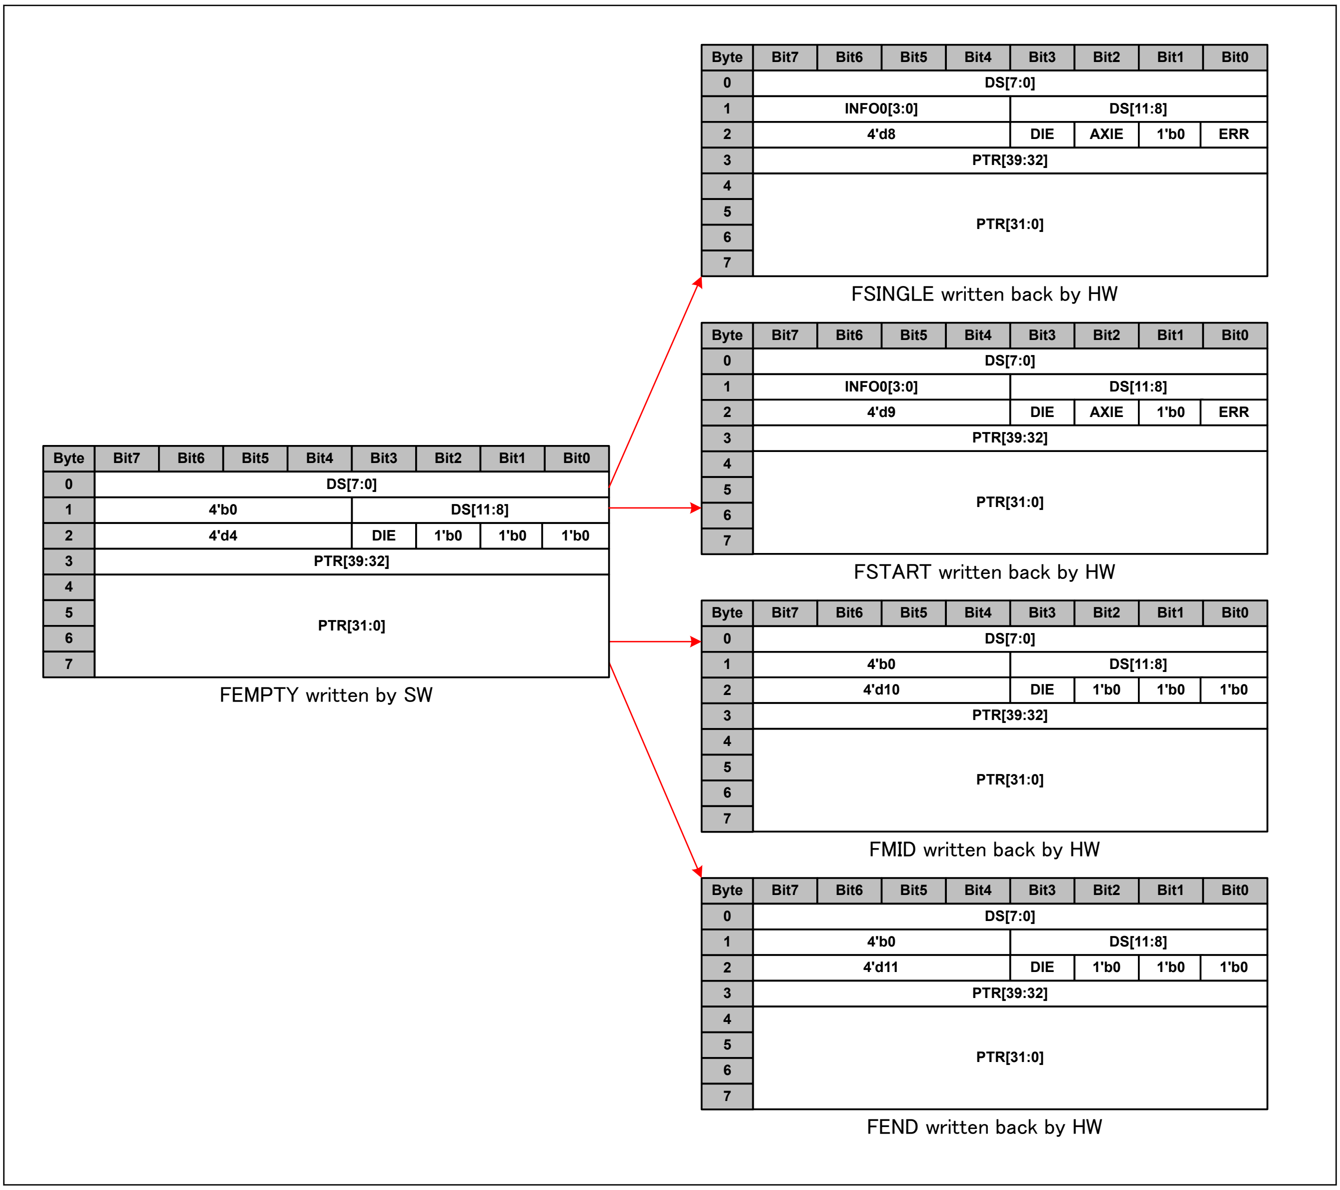

Figure 34.62 Basic data reception process descriptor utilization format

Table 34.23 Basic data reception process descriptor utilization field description (1 of 2)

Field name	Field description before write-back	Field description after write-back
DS	Size of available URAM memory associated to the pointer for data storage	Actual size that has been written by the AXIBMI in the URAM.

ERR	0	Set conditions: ● HW: A descriptor queue full error happened while reading an AXI address during a split frame (The first descriptor has been processed normally but the last part of the frame has no descriptor to be written) and a FSINGLE or a FSTART descriptor written back. ● HW: A descriptor number error happened while reading an AXI address during a split frame (The first descriptor has been processed normally but the last part of the frame will not be written) and a FSINGLE or a FSTART descriptor written back.
DSE	0	0

Table 34.23 Basic data reception process descriptor utilization field description (2 of 2)

Field name	Field description before write-back	Field description after write-back
AXIE	0	Set conditions: ● HW: An AXI error happened while writing a data (BRESP != 00) and a FSINGLE or a FSTART descriptor written back. ● HW: An AXI error happened while reading a descriptor during a split frame (The first descriptor has been processed normally but the last part of the frame has no descriptor to be written) and a FSINGLE or a FSTART descriptor written back.
DIE	DIE	DIE (Value is copied from read descriptor).
DT	4 for FEMPTY	8 for FSINGLE 9 for FSTART 10 for FMID 11 for FEND
PTR	Address where data should be written in the URAM	PTR (Value is copied from read descriptor).
INFO1 (GWDCCi.EDEi == 1)	0	0 for FEND and FMID, For FSTART and FSINGLE, see section 34.5.3.5.6. Data Reception Common Descriptor Format.
TS (GWDCCi.ETSi == 1)	0	0 for FEND and FMID, For FSTART and FSINGLE, see section 34.5.3.5.6. Data Reception Common Descriptor Format.

34.5.3.5.2 Size-controlled Data Reception

Size-controlled data reception aims at controlling the frame size at reception while purposely splitting the header and the payload of a frame. By size-controlled data reception the SW ensure that descriptor order is maintained even if a too short or too long frame is received. Size-controlled data reception process descriptor utilization is described in Figure 34.63. Size-controlled data reception process descriptor format is described Figure 34.64 (for basic descriptor, section 34.5.1.2.1. General Formats) in and Table 34.24. Size-controlled data reception can be monitored using GWEIS4.DSES, GWEIS4.DSEIOS, GWEIS4.DSECN interrupt registers.

Function:

- GWEIS4.DSES, GWEIS4.DSEIOS, and GWEIS4.DSECN interrupt registers signal a frame received with an unexpected size.

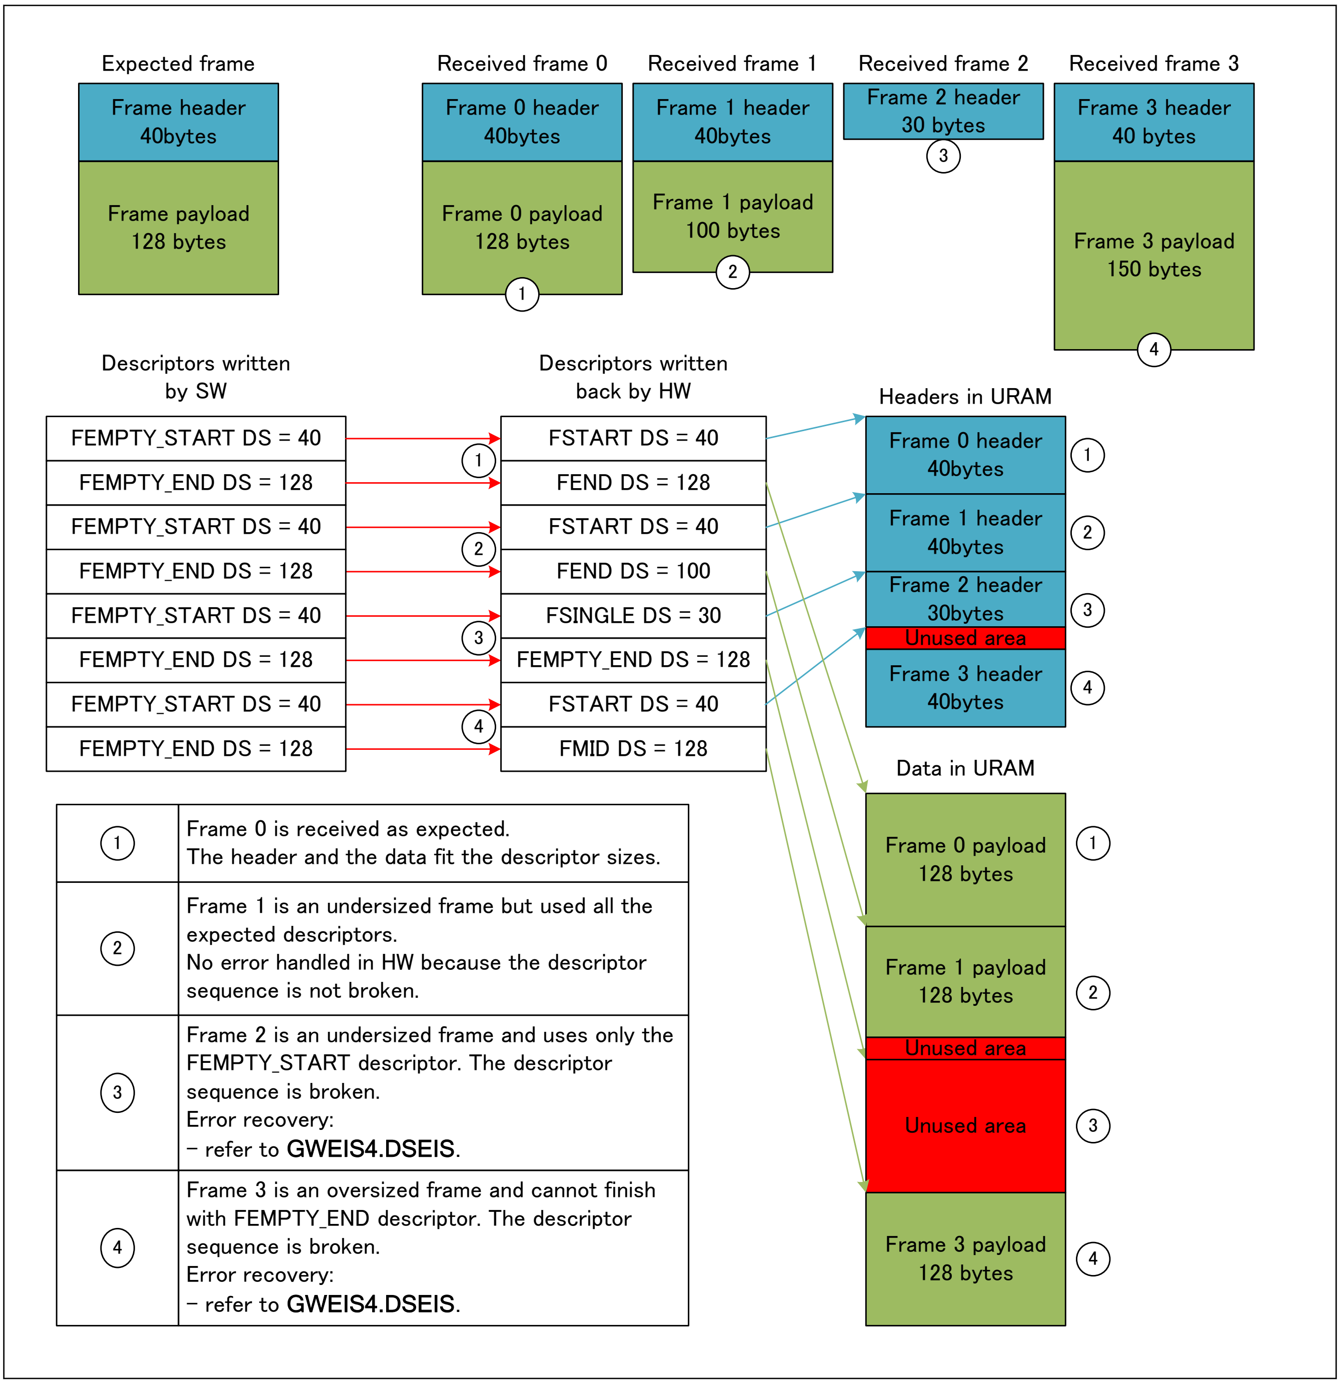

Figure 34.63 Size-controlled data reception process descriptor utilization

Note:
- When a frame is split the hardware will write back the FSTART descriptor last. Even if the queue is set in keep DT mode, this order is kept.
- A frame can be split in more than two descriptors by adding FEMPTY_MID descriptors between FEMPTY_START and FEMPTY_END descriptors.

Restrictions:

- SW: The process descriptor queue should always repeat the pattern of the same descriptors from the first descriptor to the descriptor before the termination descriptor. This pattern should start with an FEMPTY_START descriptor, finish by a FEMPTY_END descriptor and in between be only composed by FEMPTY_MID descriptors. If this is violated (for example, FEMPTY_START is detected in the middle), the frame will be discarded/rejected without notification.

34.5.3.5.3 Single Page Incremental Data Reception

Single page incremental data reception aims at saving the received frames back to back in a given memory area. By single page incremental data reception, the SW avoid wasting CPU power to stack data together. Single page incremental data reception process descriptor utilization is described in Figure 34.65 (for basic descriptor, section 34.5.1.2.1. General Formats). Single page incremental data reception process descriptor format is described Figure 34.66, Table 34.25, Figure 34.67 and Table 34.26. Single page incremental data reception HW/SW synchronization should be done by GWIDAUASi register and can be monitored by GWIDASMi, GWIDASAMi0, GWIDASAMi1, GWIDACAMi0, GWIDACAMi1 registers and GWEIS3.IAOESi interrupt register.

Functions:

- GWIDAUASi register shows the number of bytes that has been written in the incremental area. After reading the data from the CPU RAM, SW should write to this register the quantity of data that has been read. The CPU data handling can be done, either based on the written back descriptor in the corresponding descriptor queue, or on the byte value contained in the increment area than can be read in GWIDAUASi register.
- GWIDASMi register is used to monitor the total size of the incremental area.
- {GWIDASAMi0.IDASAU, GWIDASAMi1.IDASAL} register array is used to monitor the start address of the incremental area.
- {GWIDACAMi0.IDACAU, GWIDACAMi1.IDACAL} register array is used to monitor the next used address in the incremental area.
- GWEIS3.IAOESi interrupt register signals data loss due to incremental area overflow.

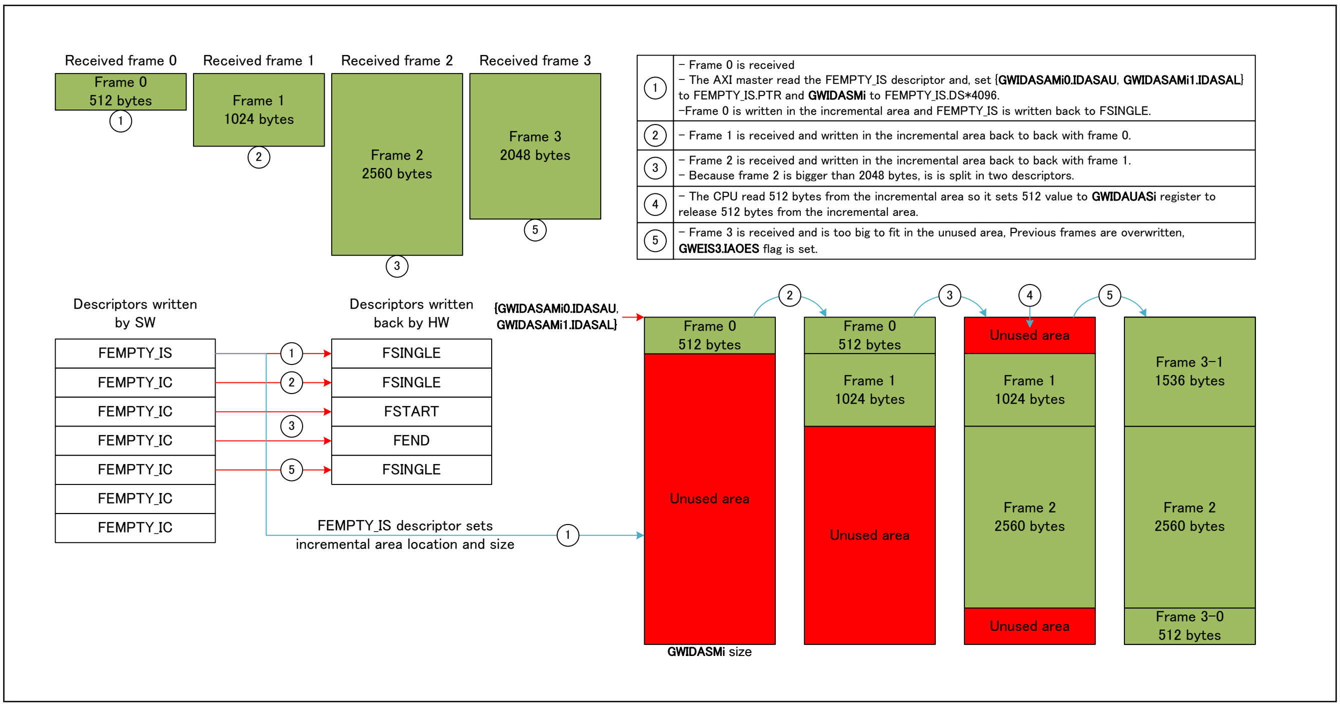

Figure 34.65 Single page incremental data reception process descriptor utilization

Restrictions:

- SW: This reception type can only be used for the first 4 RX chains, see section 34.5.1.1. AXI Descriptor Queue Mapping.

Note:
- If a frame is too big to fit in an area reserved by one descriptor, it will be automatically split. The first descriptor will be FSTART, the last descriptor will be FEND and all other descriptors will be FMID.
- When a frame is split the hardware will write back the FSTART descriptor last. Even if the queue is set in keep DT mode, this order is kept.
- When GWCA reset has been applied (GWMS.OPS set to 00), all the incremental registers (i.e. incremental page start address, current address, page size and used page size) were cleared. Therefore, when the GWCA has moved back again to OPERATION mode (GWMS.OPS set to 11) and a frame has been received by GWCA incremental chain, it is not able to write frame using FEMPTY_IC descriptor. Descriptor of AXI current address have to be (set up) a FEMPTY_IS.

TS (GWDCCi.ETS == 1)	0	0 for FEND and FMID. For FSTART and FSINGLE, see section 34.5.3.5.6. Data Reception Common Descriptor Format.

34.5.3.5.4 Interrupt Based on Multi-page Incremental Data Reception

An interrupt based on multi-page incremental data reception aims at saving the received frames back to back in a given memory area. By an interrupt based on multi-page incremental data reception, the SW avoids wasting CPU power to stack data together. An interrupt based on multi-page incremental data reception process descriptor utilization is described in Figure 34.68. An interrupt based on multi-page incremental data reception process descriptor format is the same as single page incremental data reception. For details, see section 34.5.3.5.3. Single Page Incremental Data Reception.

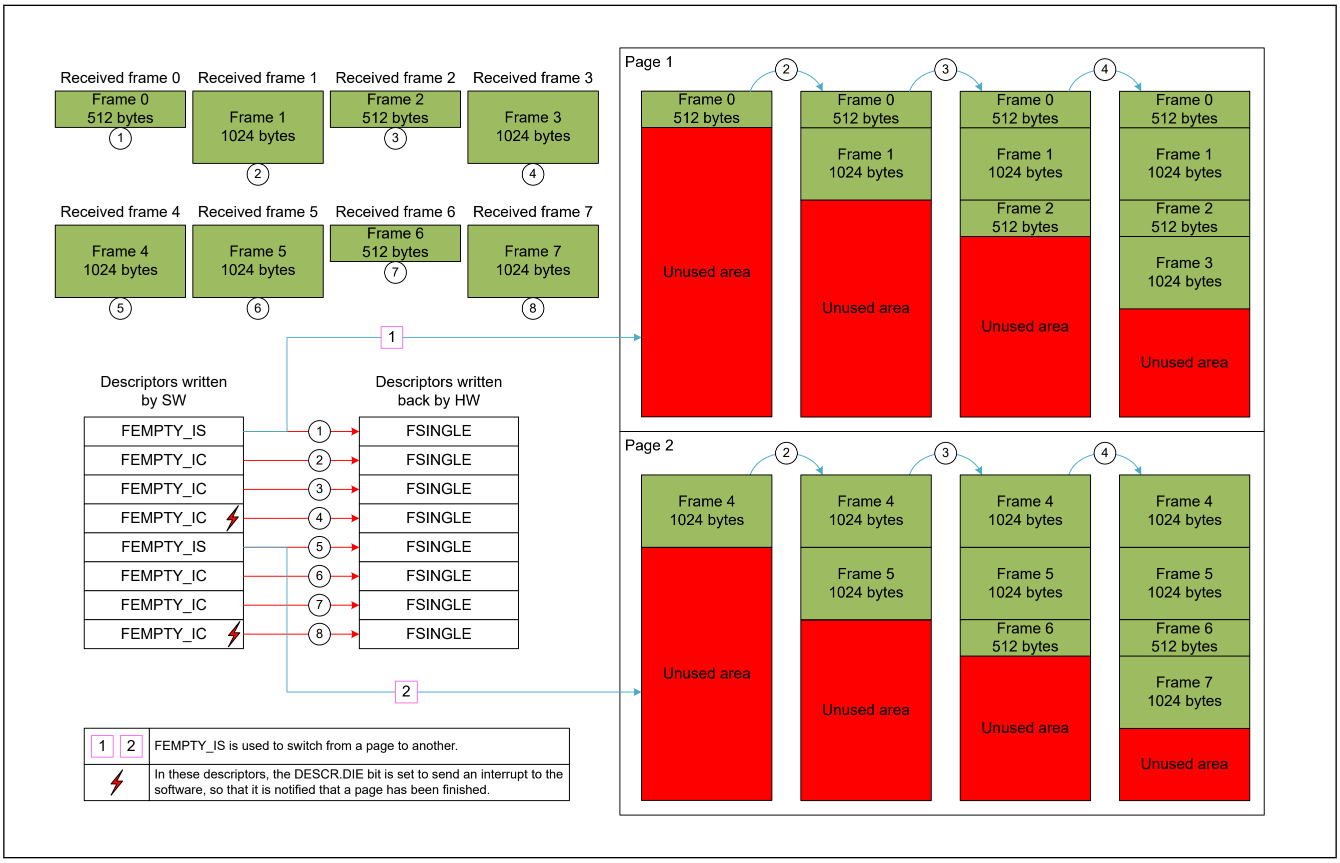

Figure 34.68 Interrupt based on multi-page incremental data reception process descriptor utilization

Restrictions:

- SW: It should be ensured that, recognizing the expected data and/or controlling page sizes and the number of descriptors for a page, a page cannot overflow.
- SW: This reception type can only be used for the first 4 RX chains.

Note:
- If a frame is too big to fit in an area reserved by one descriptor, it will be automatically split. The first descriptor will be FSTART, the last descriptor will be FEND, and all other descriptors will be FMID.
- When a frame is split, the hardware will write back the FSTART descriptor last. Even if the queue is set in keeping DT mode, this order is kept.
- An interrupt based on multi-page incremental data reception allows any number of pages to be used.
- When GWCA reset has been applied (GWMS.OPS is set to 00), all the incremental registers (i.e. incremental page start address, current address, page size, and used page size) were cleared. Therefore, when the GWCA has moved back again to OPERATION mode (GWMS.OPS is set to 11) and a frame has been received by GWCA incremental chain, it is not able to write a frame using FEMPTY_IC descriptor. A descriptor of AXI current address has to be (set up) a FEMPTY_IS.

34.5.3.5.5 Header Removal Incremental Data Reception

Header removal incremental data reception aims at suppressing header from incremental data. It is an update of single page incremental data reception (section 34.5.3.5.3. Single Page Incremental Data Reception) and interrupt based multi-page incremental data reception (section 34.5.3.5.4. Interrupt Based on Multi-page Incremental Data Reception) by adding a FEMPTY_ND between each incremental descriptor. Header removal incremental data reception process descriptor utilization is described in Figure 34.69. Header removal process descriptor format is described in Figure 34.70 (for basic descriptor, section 34.5.1.2.1. General Formats) and Table 34.27.

Restrictions:

- SW: A FEMPTY_IS/FEMPTY_IC descriptor can only contain 2048 bytes. It should be taken in account when setting the descriptor in the descriptor queue because the HW does not ensure that the descriptor sequence is correct.

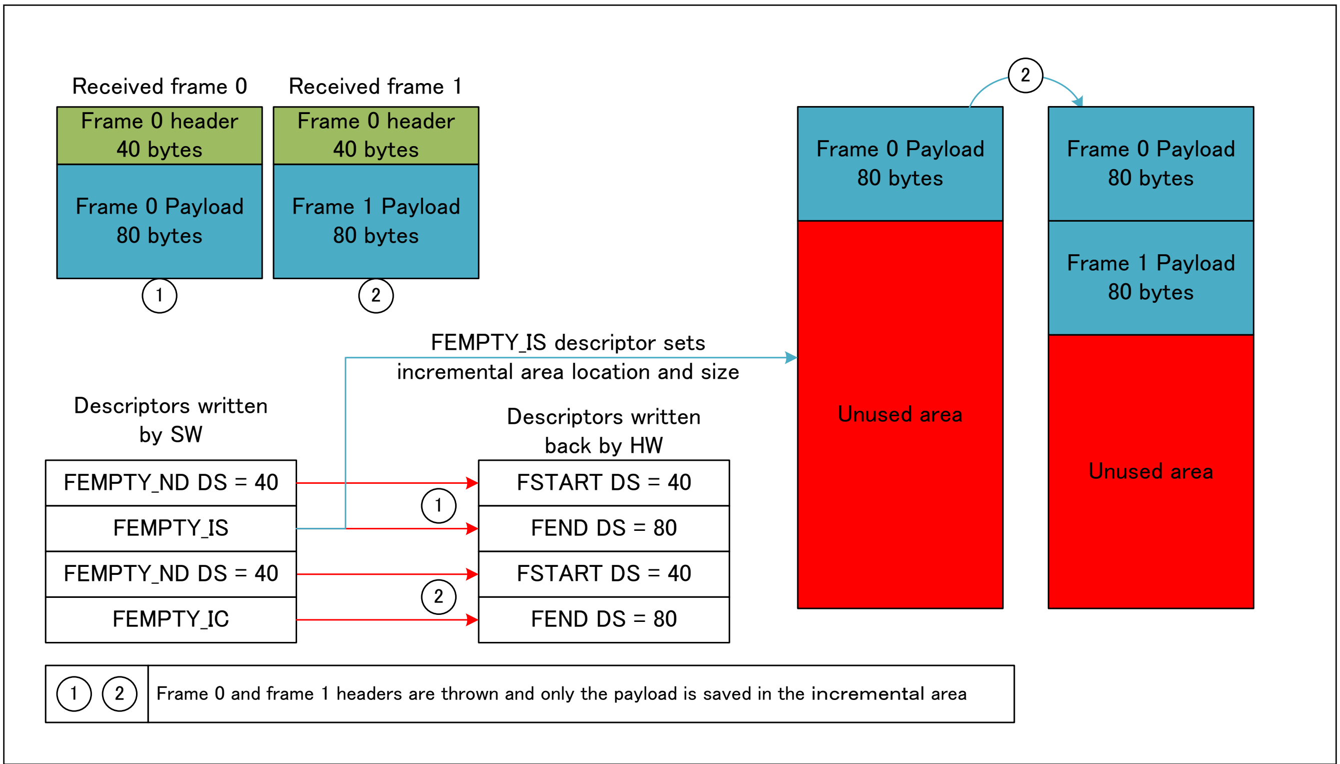

Figure 34.69 Header removal incremental data reception process descriptor utilization

Note:
- When using Size controlled data reception, to get rid of the header part of a frame and still keep the descriptor order, it is possible to start every frame with a FEMPTY_START descriptor always pointing toward the same memory address (by setting always the same pointer).
- When GWCA reset has been applied (GWMS.OPS set to 00), all the incremental registers (i.e incremental page start address, current address, page size and used page size) were cleared. Therefore, when the GWCA has moved back again to OPERATION mode (GWMS.OPS set to 11) and a frame has been received by GWCA incremental chain, it is not able to write frame using FEMPTY_IC descriptor. Descriptor of AXI current address have to be (set up) a FEMPTY_IS.

Table 34.27 Header removal process descriptor utilization field description

Field name	Field description before write-back	Field description after write-back
DS	Size to be rejected	Actual size that has been rejected (it should be the same as DS before write-back).
INFO0	0	0 for FEND and FMID. For FSTART and FSINGLE, see section 34.5.3.5.6. Data Reception Common Descriptor Format.
ERR	0	Set conditions: ● HW: A descriptor queue full error happened while reading an AXI address during a split frame (The first descriptor has been processed normally but the last part of the frame has no descriptor to be written) and a FSINGLE or a FSTART descriptor written back. ● HW: A descriptor number error happened while reading an AXI address during a split frame (The first descriptor has been processed normally but the last part of the frame will not be written) and a FSINGLE or a FSTART descriptor written back.
DSE	0	0
AXIE	0	Set conditions: ● HW: An AXI error happened while writing a data (BRESP != 00) and a FSINGLE or a FSTART descriptor written back. ● HW: An AXI error happened while reading a descriptor during a split frame (The first descriptor has been processed normally but the last part of the frame has no descriptor to be written) and a FSINGLE or a FSTART descriptor written back.
DIE	DIE	DIE (Value is copied from read descriptor).
DT	3 for FEMPTY_ND	8 for FSINGLE 9 for FSTART 10 for FMID 11 for FEND Restrictions: ● SW: Because the HW turns a FEMPTY_ND descriptor in a FSINGLE, FSTART, FMID or FEND descriptor, by reading the descriptor it is impossible to know that is contains no data. Consequently, SW should remember where the FEMPTY_ND descriptors have been written.
PTR	0	0
INFO1 (GWDCCi.EDE == 1)	0	0 for FEND and FMID, For FSTART and FSINGLE, see section 34.5.3.5.6. Data Reception Common Descriptor Format.
TS (GWDCCi.ETS == 1)	0	0 for FEND and FMID, For FSTART and FSINGLE, see section 34.5.3.5.6. Data Reception Common Descriptor Format.

34.5.3.5.6 Data Reception Common Descriptor Format

In this section are described the fields which are common for any data transmission (INFO0, INFO1 and TS). There are two types of formats, the reception direct descriptor and the reception ethernet descriptor formats. They are respectively created from direct local descriptors and ethernet local descriptors, see section 34.5.2.3.3. Frame Saving in Local RAM. All the fields contained in AXI descriptors, if quoted, will be written ADESCR.{Field name}.

(1) Reception direct descriptor

Reception direct descriptor corresponds to frames sent by a CPU and by deciding their target directly (Forwarding engine processing has been by-passed [FWD]). Reception direct descriptor INFO and TS formats are described in Figure 34.71 and Table 34.28.

TSNS	30	Timestamp nanosecond [gPTP] PCH header timestamp [29:0]	Copied from ethernet local descriptor from [GWCA Data transmission] or [ETHA Data reception]
TSS	32	Timestamp second [gPTP] PCH header timestamp [31:30] Restrictions: ● HW: The 16-upper bits of the gPTP second part are truncated.	Copied from ethernet local descriptor from [GWCA Data transmission] or [ETHA Data reception]
—	—	Reserved area	Set to 0

34.5.4 Timestamp Reception [gPTP]

GWCA allows Timestamp reception through the GWCA TS path, The TS path is described in Figure 34.73.

Timestamps received through this function are only Ethernet agent TX timestamps. Ethernet agent RX timestamps are stored in the local RAM along with their corresponding data and can only be received by CPU through RX data path with the corresponding data.

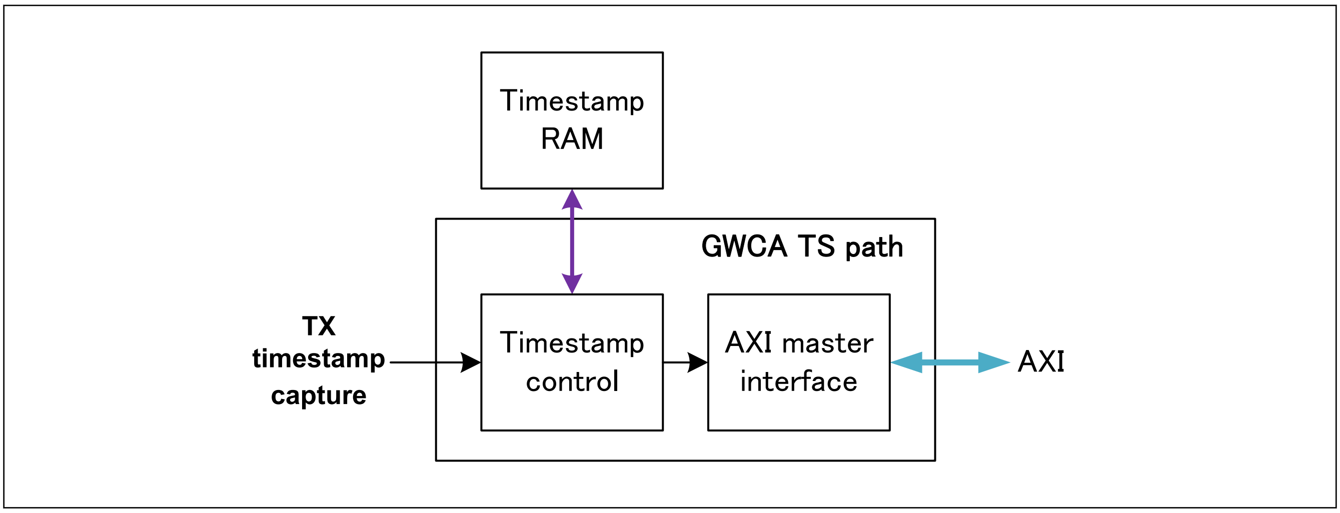

Figure 34.73 GWCA TS path block diagram

The TS path is separated in two blocks:

- Timestamp control: This block aims are receiving the timestamps from TX Timestamp Capture interface [RMAC], storing them in the Timestamp RAM and sending them to the AXI master interface.
- AXI master interface: This block handles the timestamp/AXI descriptor exchange with the CPU.

34.5.4.1 Timestamp Control

Timestamp control controls the descriptor storage/fetching to/from the Timestamp RAM using GWTSDCCs.TE register and can be monitored using GWTSNM and GWTSMNM registers and GWEIS0.TSOVFES interrupt registers.

Functions:

- GWTSDCCs.TE is used to enable timestamp reception for timer s. If enabled, all timestamps received from TX Timestamp Capture interfaces [RMAC] for timer s will be stored in the timestamp RAM and later given to the AXI master interface.
- GWTSNM register is used to monitor the current number of timestamps present in the timestamp RAM.
- GWTSMNM register is used to monitor the maximum number of timestamps that has been held in the timestamp RAM since the previous reset or the previous time corresponding register has been read.
- GWEIS0.TSOVFES interrupt register is used to flag a timestamp loss because of Timestamp RAM overflow.

34.5.4.2 AXI Master Interface

The AXI master interface handles the timestamp/AXI descriptor exchange with the CPU. It will receive the timestamps and the information related to the timestamps and store them in the CPU RAM. To do so, it uses GWTDCACs0, WTDCACs1, and GWTSDCCs.DCS registers and it can be monitored using GWTSDIS.TSDIS and GWEIS0.TDFES interrupt registers.

Functions:

- GWTDCACs0 and GWTDCACs1 registers form the AXI address {GWTDCACs0.TSCCAU, GWTDCACs1.TSCCAL} with correspond to the current address being processed by the GWCA for TS descriptor queue s. It can be used to set the first address of the descriptor queue during GWCA initialization, move an under-use TS descriptor queue to another location in the CPU RAM or monitor the currently processed descriptor address.
- GWTSDCCs.DCS register is used to map timer s timestamps to a TS descriptor queue number.
- GWTSDIS.TSDIS interrupt register is used to flag some timestamps are ready in the CPU RAM.
- GWEIS0.TDFES interrupt register is used to flag a timestamp loss because the timestamp descriptor queue is full.

Timestamp reception can be done using linear or cyclic descriptor queues (see section 34.5.1.5. AXI Descriptor Queue Format). Timestamp reception process descriptor utilization is described in Figure 34.74. Timestamp reception process descriptor format is described in Figure 34.75 and Table 34.30.

Field name	Bit width	Description
TSUN	8	Timestamp unique number [RMAC]
SPN	2	Port number from which the timestamp corresponding frame entered the switch [MFAB]
DPN	1	Port number by which the timestamp has been taken
TN	1	Timer Number

Table 34.32 TS reception process descriptor TS field explanation

Field name	Bit width	Description
TSNS	30	Timestamp nanosecond [gPTP]
TSS	32	Timestamp second [gPTP] Restrictions: ● HW: The 16-upper bits of the gPTP second part are truncated.

34.5.5 gPTP Triggered Transmission

It is possible to use gPTP timer to trig a periodic transmission start using time-controlled data transmission (see Table 34.13). To do so, CYCLIC_COMP[i][c] (Where i is 0 for GWCA0) functional interface is linked to INTER_TX[8+c] (see Figure 34.21).

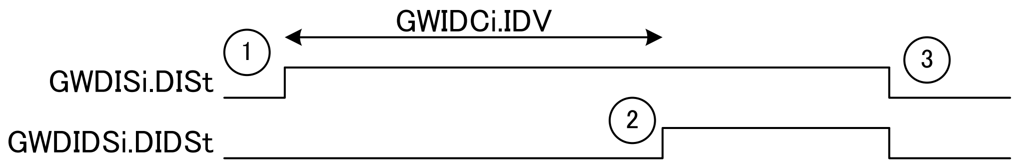
For 8 parameter explanation, see gPTP specification [gPTP].

34.5.6 Interrupt Delay Function

Interrupt delay function aims at delaying data interrupts (GWDISi.DISt) to accumulate data during a certain among of time before requesting software to process the data. As a result, software load is diminished, and data latency is still guaranteed. To operate, interrupt delay function uses GWIDPC and GWIDCi registers and can be monitored using GWDIDSi interrupt register. Interrupt delay function is described in Figure 34.76.

Functions:

- GWIDPC register sets an internal clock of period *clk_delay_period* used as base clock for interrupt delay function.
- GWIDCi register sets the delay time for descriptor queue i in *clk_delay_period*.
- GWDIDSi.DIDSt register is the delayed GWDISi.DISt interrupt register and triggers the interrupt gwc_gwdis_int[t].
- For interrupt handling, software can decide to read GWDIDSi register and to process only interrupts that have been set until their corresponding delay time is archived (allows a certain amount of data surely came before processing) or can decide to read GWDISi register and to process all the interrupts even the ones which did not reach their delay time (allows a certain amount of data surely came before processing at least for one queue can diminish the interrupt load).



1	GWDISi.DISt flag is set
2	After GWIDCi.IDV**clk_delay_period* GWDIDSi.DIDSt is asserted with the interrupt if GWDIEi.DIEt is set to 1
3	SW clears GWDISi.DISt flag, it de-asserts the interrupt

Figure 34.76 Interrupt delay function

Restrictions:

- HW: The maximum delay achievable by the interrupt delay function is clk_period*4194304. For example, it will be around 10 ms for a clock clk with a frequency of 400 MHz.

34.6 Precautions

- AXI address bus width
  The AXI address bus width degenerated from 40 bits to 32 bits by products connection. Please use AXI descriptor address with only 32 bits. Please fix to all 0 for upper 8 bits for AXI address. (For example, cannot use GWDCBAC0.)

35. Ethernet Generic PTP Timer (GPTP)

35.1 Overview

Ethernet Generic PTP timer (GPTP) enables accurate synchronization of the clock in the control system.

Table 35.1 lists the GPTP specifications and Figure 35.1 shows a block diagram.

Table 35.1 GPTP specifications

Item	Function	Description
Overall function	Timer	• GPTP and AVTP timer
Data provision	—	• GPTP timer Data width: 78 bits ([77:30] = second, [29:0] = nanosecond) • AVTP timer Data width: 64 bits/32 bits
Functions	Timer control	• GPTP timer incremental value control • GPTP timer offset control • Generation of GPTP and AVTP timer
	PPS	• PPS signal generation
	Media clock	• Media clock capture • Media clock recovery
	Cyclic compare	• Cyclic comparison to emit pulses

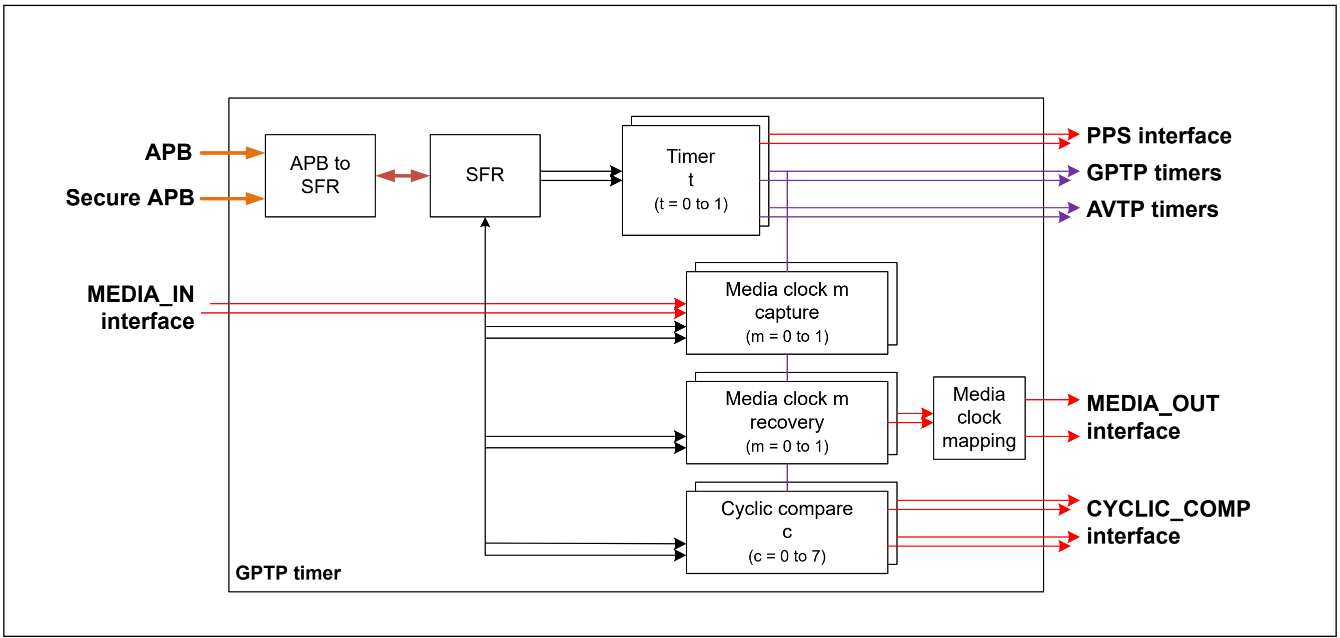


Figure 35.1 GPTP block diagram

Table 35.2 GPTP functional blocks

Block name	Function
APB to SFR	Handle SFR accesses
SFR	GPTP SFRs
Timer	Generate GPTP an AVTP timers
Media clock capture	Capture input media clocks
Media clock recovery	Recover output media clocks
Cyclic compare	Generate a cyclic pulse

Note: Base address: GPTP = 0x403E_0000, GPTP_NS = 0x503E_0000

35.3 gPTP Register Descriptions

35.3.1 Version Register

35.3.1.1 PTPIPV : IP Version Register

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0000

Bit position:	31 … 0
Bit field:	IPV[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1

Bit	Symbol	Function	R/W
31:0	IPV[31:0]	IP Version	R

35.3.2 Timer Configuration Registers

35.3.2.1 PTPTMEC : Timer Enable Configuration Register

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TE1 to TE0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	TE1 to TE0	Timer q Enable (q = 0, 1) Bit q enables timer q. 0: Timer q disabled 1: Timer q enabled	R/W*1
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

TEq bits (Timer q Enable (q = 0, 1))

When timer q is disabled, all counters are fixed to 0.

[Setting condition]

- SW: Writing 1 to one of these bits.

[Clearing condition]

- SW: Writing 1 to PTPTMDC.TDq clears this register bit q.

35.3.2.2 PTPTMDC : Timer Disable Configuration Register

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TD1 to TD0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	TD1 to TD0	Timer n Disable (n = 0, 1) 0: No effect 1: Bit q of this register clears PTPTMEC.TEq	W*1
31:2	—	These bits are read as 0.	R

Note 1. Read value differs from written value.

TDn bits (Timer n Disable (n = 0, 1))

[Clearing condition]

- SW: Writing 1 to bit q of this register clears PTPTMEC.TEq.

35.3.2.3 PTPTIVCt : Timer t Increment Value Configuration Register (t = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0020 + 0x40 × t

Bit position:	31 ... 0
Bit field:	TIV[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TIV[31:0]	Timer Increment Value	R/W

TIV[31:0] bits (Timer Increment Value)

Timer increment value in ns per clock clk. PTPTIVCt.TIV[31:27] is the nanosecond part and PTPTIVCt.TIV[26:0] is the nanosecond sub-part.

[Examples]

- If clk clock frequency is 50 MHz, 100 MHz, 200 MHz or 250 MHz, PTPTIVCt.TIV should be respectively set to a value around 0xA000_0000, 0x5000_0000, 0x2800_0000 or 0x2000_0000.

35.3.2.4 PTPTOVCtL : Timer t Offset Value Configuration Register L (t = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0030 + 0x40 × t

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	TOVL[29:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TOVL[29:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
29:0	TOVL[29:0]	Timer Offset Value Lower Part*1	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SW: Only value from 0x0000_0000 to 0x3b9a_c9ff can be set to this register.

TOVL[29:0] bits (Timer Offset Value Lower Part)

- Timer offset value in GPTP format. PTPTOVCtL.TOVL represents its nanosecond part.
- Writing to this register loads the new offset to timer t.
- {PTPTOVCtU.TOVU, PTPTOVCtM.TOVM, 0, PTPTOVCtL.TOVL} is timer t offset.

35.3.2.5 PTPTOVCMt : Timer t Offset Value Configuration Register M (t = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0034 + 0x40 × t

Bit position:	31 ... 0
Bit field:	TOVM[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	TOVM[31:0]	Timer Offset Value Middle Part	R/W*1

Note 1. Read value differs from written value.

TOVM[31:0] bits (Timer Offset Value Middle Part)

- Timer offset value in GPTP format. PTPTOVCtM.TOVM represents its second lower 32-bit part.
- {PTPTOVCtU.TOVU, PTPTOVCtM.TOVM, 0, PTPTOVCtL.TOVL} is timer t offset.

[Update condition]

- SW: Writing to the PTPTOVCtL register updates this register to the latest value

35.3.2.6 PTPTOVCtU : Timer t Offset Value Configuration Register U (t = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0038 + 0x40 × t

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TOVU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TOVU[15:0]	Timer Offset Value Upper Part	R/W*1
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

TOVU[15:0] bits (Timer Offset Value Upper Part)

- Timer offset value in GPTP format. PTPTOVCtU.TOVU represents its second higher 16-bit part.
- {PTPTOVCtU.TOVU, PTPTOVCtM.TOVM, 0, PTPTOVCtL.TOVL} is timer t offset.

[Update condition]

- SW: Writing to PTPTOVCtL register updates this register to its latest value.

35.3.3 Timer Monitoring Registers

35.3.3.1 PTPAVTPTMtL : AVTP Timer t Monitoring Register L (t = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0040 + 0x40 × t

Bit position:	31 … 0
Bit field:	AVTPL[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	AVTPL[31:0]	AVTP Timer Value Lower Part	R

AVTPL[31:0] bits (AVTP Timer Value Lower Part)

- AVTP time is in nanoseconds and derives from GPTP timer t. PTPAVTPTMtL.AVTPL represents either timer t 32-bit AVTP timer or timer t 64-bit AVTP timer lower bits.
- This register is always equal to timer t 32-bit AVTP timer or timer t 64-bit AVTP timer lower bits.

35.3.3.2 PTPAVTPTMtU : AVTP Timer t Monitoring Register U (t = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0044 + 0x40 × t

Bit position:	31	0
Bit field:	AVTPU[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	AVTPU[31:0]	AVTP Timer Value Upper Part	R

AVTPU[31:0] bits (AVTP Timer Value Upper Part)

AVTP time is in nanoseconds and derives from GPTP timer t. PTPAVTPTMtU.AVTPU represents timer t 64-bit AVTP timer higher bits.

[Update condition]

- HW: Reading PTPAVTPTMtL register updates this register to timer t 64-bit AVTP timer higher bits.

35.3.3.3 PTPGPTPTMtL : GPTP Timer t Monitoring Register L (t = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0050 + 0x40 × t

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	GPTPL[29:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GPTPL[29:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
29:0	GPTPL[29:0]	GPTP Timer Value Lower Part ● PTPGPTPTMtL.GPTPL represents timer t GPTP timer nanosecond part ● This register is always equal to timer t GPTP timer nanosecond part.	R
31:30	—	These bits are read as 0.	R

35.3.3.4 PTPGPTPTMtM : GPTP Timer t Monitoring Register M (t = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0054 + 0x40 × t

Bit position:	31	0
Bit field:	GPTPM[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	GPTPM[31:0]	GPTP Timer Value Middle Part	R

GPTPM[31:0] bits (GPTP Timer Value Middle Part)

PTPGPTPTMtM.GPTPM represents timer t GPTP timer second lower 32 bit part.

[Update condition]

- HW: Reading PTPGPTPTMtL register updates this register to timer t GPTP timer second lower 32-bit part.

35.3.3.5 PTPGPTPTMtU : GPTP Timer t Monitoring Register U (t = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0058 + 0x40 × t

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GPTPU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	GPTPU[15:0]	GPTP Timer Value Upper Part	R
31:16	—	These bits are read as 0.	R

GPTPU[15:0] bits (GPTP Timer Value Upper Part)

PTPGPTPTMtU.GPTPU represents timer t GPTP timer second higher 16-bit part.

[Update condition]

- HW: Reading PTPGPTPTMtL register updates this register to timer t GPTP timer second higher 16-bit part.

35.3.4 Media Clock Capture Registers

35.3.4.1 PTPMCCCm : Media Clock m Capture Configuration Register (m = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0200 + 0x10 × m

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MCTNS	MCTTS	MCNEE	MCPEE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MCPEE	Media Clock Capture Positive Edge Enable 0: Timer value is not captured on positive edge of MEDIA_IN[m] signal 1: Timer value is captured on positive edge of MEDIA_IN[m] signal	R/W

Bit	Symbol	Function	R/W
1	MCNEE	Media Clock Capture Negative Edge Enable 0: Timer value is not captured on negative edge of MEDIA_IN[m] signal 1: Timer value is captured on negative edge of MEDIA_IN[m] signal	R/W
2	MCTTS	Media Clock Capture Timer Type Select 0: Timer value is captured on GPTP timer 1: Timer value is captured on AVTP timer	R/W
3	MCTNS	Media Clock Capture Timer Number Select Selects from which timer the timer values are taken.	R/W
15:4	—	These bits are read as 0. The write value should be 0.	R/W
16	MCCR	Media Clock Capture Request Writing 1 to this register triggers timer capture.	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

35.3.4.2 PTPMCCMmL : Media Clock m Capture Monitoring Register L (m = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0204 + 0x10 × m

Bit position:	31 ... 0
Bit field:	MCCTVL[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	MCCTVL[31:0]	Media Clock Captured Timer Value Lower Part	R

MCCTVL[31:0] bits (Media Clock Captured Timer Value Lower Part)

- If a GPTP timer is captured, PTPMCCMmL.MCCTVL[29:0] represent the GPTP timer nanosecond part
- If an AVTP timer is captured, this register represents either the 32-bit AVTP timer or the 64-bit AVTP lower 32 bits.

[Update condition]

- Reading PTPMCCMmL register updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the next captures value
- Capturing a timer while the capture buffer is empty updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the captured value.

35.3.4.3 PTPMCCMmM : Media Clock m Capture Monitoring Register M (m = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0208 + 0x10 × m

Bit position:	31 ... 0
Bit field:	MCCTVM[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	MCCTVM[31:0]	Media Clock Captured Timer Value Middle Part	R

MCCTVM[31:0] bits (Media Clock Captured Timer Value Middle Part)

- If a GPTP timer is captured, this register represents the GPTP timer second part 32 lower bits

- If an AVTP timer is captured, this register represents the 64-bit AVTP higher 32 bits.

[Update condition]

- Reading PTPMCCMmL register updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the next captured value
- Capturing a timer while the capture buffer is empty updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the captured value.

35.3.4.4 PTPMCCMmU : Media Clock m Capture Monitoring Register U (m = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x020C + 0x10 × m

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	MCCN[1:0]		—	—	—	—	—	MCSWC	MCNEC	MCPEC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MCCTVU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MCCTVU[15:0]	Media Clock Captured Timer Value Upper Part	R
16	MCPEC	Media Clock Positive Edge Captured	R
17	MCNEC	Media Clock Negative Edge Captured	R
18	MCSWC	Media Clock Software Captured	R
23:19	—	These bits are read as 0.	R
25:24	MCCN[1:0]	Media Clock Capture Number	R
31:26	—	These bits are read as 0.	R

MCCTVU[15:0] bits (Media Clock Captured Timer Value Upper Part)

- If a GPTP timer is captured, this register represents the GPTP timer second part higher 16 bits
- If an AVTP timer is captured, this register is unused.

[Update condition]

- Reading PTPMCCMmL register updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the next captured value
- Capturing a timer while the capture buffer is empty updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the captured value.

MCPEC bit (Media Clock Positive Edge Captured)

[Update condition]

- Reading PTPMCCMmL register updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the next captured value
- Capturing a timer while the capture buffer is empty updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the captured value.

MCNEC bit (Media Clock Negative Edge Captured)

[Update condition]

- Reading PTPMCCMmL register updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the next captured value
- Capturing a timer while the capture buffer is empty updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the captured value.

MCSWC bit (Media Clock Software Captured)

[Update condition]

- Reading PTPMCCMmL register updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the next captured value
- Capturing a timer while the capture buffer is empty updates PTPMCCMmL, PTPMCCMmM and PTPMCCMmU to the captured value.

MCCN[1:0] bits (Media Clock Capture Number)

[Increment condition]

- HW: Incremented by one when Media Capture Unit m captures a timer other than 2.

[Decrement condition]

- SW: Decremented by one when reading by software is executed other than 0.

35.3.5 Media Clock Recovery Registers

35.3.5.1 PTPMCRCm : Media Clock m Recovery Configuration Register (m = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0300 + 0x10 × m

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MRPL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	MRTNS	MRAMS	MRTTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MRTTS	Media Clock Recovery Timer Type Select*1 0: Timer value is compared to GPTP timer 1: Timer value is compared to AVTP timer	R/W
1	MRAMS	Media Clock Recovery AVTP Mode Select*2 0: 64-bit AVTP is used for comparison 1: 32-bit AVTP is used for comparison	R/W
2	MRTNS	Media Clock Recovery Timer Number Select Selects from which timer the timer values are taken.	R/W
15:3	—	These bits are read as 0. The write value should be 0.	R/W
31:16	MRPL[15:0]	Media Clock Recovery Pulse Length Pulse length for clock recovery in clk clocks - 1.	R/W

Note 1. Restrictions:

- HW: For GPTP timer, overflow is not supported. If a time smaller than the current GPTP timer is set, the comparison instantaneously matches.

Note 2. Restrictions:

- HW: For 64-bit AVTP timer, overflow is not supported. If a time smaller than the current AVTP timer is set, the comparison instantaneously matches.

35.3.5.2 PTPMCRTCmL : Media Clock m Recovery Time Configuration Register L (m = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0304 + 0x10 × m

Bit position:	31 ... 0
Bit field:	MRTVL[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	MRTVL[31:0]	Media Clock Recovery Timer Value Lower Part	R/W

MRTVL[31:0] bits (Media Clock Recovery Timer Value Lower Part)

- If the compared timer is a GPTP timer, this register represents the GPTP timer nanosecond part
- If the compared timer is a 32-bit AVTP timer, this register represents the 32-bit AVTP timer
- If the compared timer is a 64-bit AVTP timer, this register represents the 64-bit AVTP lower 32 bits
- Writing to this register loads MCCTVU, MCCTVM and MCCTVL registers for comparison in the recovery buffer.

35.3.5.3 PTPMCRTCmM : Media Clock m Recovery Time Configuration Register M (m = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0308 + 0x10 × m

Bit position:	31 ... 0
Bit field:	MRTVM[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	MRTVM[31:0]	Media Clock Recovery Timer Value Middle Part	R/W

MRTVM[31:0] bits (Media Clock Recovery Timer Value Middle Part)

- If the compared timer is a GPTP timer, this register represents the GPTP timer second part 32 lower bits
- If the compared timer is a 32-bit AVTP timer, this register represents nothing relevant
- If the compared timer is a 64-bit AVTP timer, this register represents the 64-bit AVTP higher 32 bits.

35.3.5.4 PTPMCRTCmU : Media Clock m Recovery Time Configuration Register U (m = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x030C + 0x10 × m

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MRBCR	—	—	—	—	—	—	—	—	—	—	MCRN[2:0]			MRTT[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MRTVU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MRTVU[15:0]	Media Clock Recovery Timer Value Upper Part	R/W
17:16	MRTT[1:0]	Media Clock Recovery Trigger Type 0 0: When timer match, time recovery pin is set to 1 0 1: When timer match, time recovery pin is set to 0 1 0: When timer match, time recovery pin is inverted 1 1: When timer match, a positive pulse of length PTPMCRCm.MRPL is output on time recovery pin	R/W
20:18	MCRN[2:0]	Media Clock Recovery Number Displays the number on entry in the recovery buffer.	R
30:21	—	These bits are read as 0. The write value should be 0.	R/W
31	MRBCR	Media Clock Recovery Buffer Clear Request Writing one to this register clears the internal timer buffer along with PTPMCRTCmU.MCRN register.	R

MRTVU[15:0] bits (Media Clock Recovery Timer Value Upper Part)

- If the compared timer is a GPTP timer, this register represents the GPTP timer second part 16 higher bits
- If the compared timer is a 32-bit AVTP timer, this register represents nothing relevant
- If the compared timer is a 64-bit AVTP timer, this register represents nothing relevant.

35.3.5.5 PTPMCPCm : Media Clock m Pin Configuration Register (m = 0, 1)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0400 + 0x04 × m

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MRS	PE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PE	Pin Enable*1 0: MEDIA_OUT[p] fixed to 0 1: MEDIA_OUT[p] outputs the comparison result of PTPMCPCm.MRS Recovery logic	R/W
1	MRS	Media Clock Recovery Select*1 Select Recovery logic for MEDIA_OUT[p].	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Restrictions:

- Do not change this setting on any timer enabled (PTPTMEC.TEq = 1).

35.3.6 Cyclic Compare Registers

35.3.6.1 PTPCCCc0 : Cyclic Compare c Configuration Register 0 (c = 0 to 7)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0500 + 0x8 × c

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	CCOPS	—	—	—	CCTNS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CCTNS	Cyclic Compare Timer Number Select Selects from which timer the cyclic compare is based on.	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	CCOPS	Cyclic Compare Output Pin Select CYCLIC_COMP[PTPCCCc0.CCOPS][c] is selected as output for cyclic compare c.	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

35.3.6.2 PTPCCCc1 : Cyclic Compare c Configuration Register 1 (c = 0 to 7)

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0504 + 0x8 × c

Bit position:	31 … 0
Bit field:	CCV[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	CCV[31:0]	Cycle Compare Value ● Setting this bit to a value smaller than 32 disables the compare function ● Setting this bit to a value larger or equal to 32 enables the compare function.	R/W

35.3.7 Interrupt Registers

35.3.7.1 PTPIS0 : Interrupt Status Register 0

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0700

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCOES1 to MCCOES0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCS1 to MCCS0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	MCCS1 to MCCS0	Media Clock n Capture Status Flag (n = 0, 1)	R/W*1
15:2	—	These bits are read as 0. The write value should be 0.	R/W
17:16	MCCOES1 to MCCOES0	Media Clock n Capture Overflow Error Status Flag (n = 0, 1)	R/W*1
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

MCCSn bits (Media Clock n Capture Status Flag (n = 0, 1))

[Setting condition]

- HW: Media Capture Unit m captured a timer.

[Clearing condition]

- SW: Writing 1 to one of these bits.

MCCOESn bits (Media Clock n Capture Overflow Error Status Flag (n = 0, 1))

[Setting condition]

- HW: Bit m is set when Media Capture Unit m captured a timer, but it cannot be stored because the timer FIFO is full (PTPMCCMmU.MCCN equal to 2).

[Clearing condition]

- SW: Writing 1 to one of these bits.

[Error recovery]

- HW: The captured timer is lost, and the next capture continues normally
- SW: The timer reading is too slow, and software should be reviewed.

35.3.7.2 PTPIE0 : Interrupt Enable Register 0

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0704

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCOEE1 to MCCOEE0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

15:2	—	These bits are read as 0.	R
17:16	MCCOED1 to MCCOED0	Media Clock m Capture Overflow Error Disable (m = 0, 1)	R
31:18	—	These bits are read as 0.	R

MCCDm bits (Media Clock m Capture Disable (m = 0, 1))

[Clearing condition]

- SW: Writing 1 to one of these bits clears the corresponding bit of PTPIE0.MCCE register.

MCCOEDm bits (Media Clock m Capture Overflow Error Disable (m = 0, 1))

[Clearing condition]

- SW: Writing 1 to one of these bits clears the corresponding bit of PTPIE0.MCCOEE register.

35.3.7.4 PTPIS1 : Interrupt Status Register 1

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0710

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCRMS1 to MCRMS0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	MCRMS1 to MCRMS0	Media Clock m Recovery Match Status Flag (m = 0, 1)	R/W*1
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

MCRMSm bits (Media Clock m Recovery Match Status Flag (m = 0, 1))

[Setting condition]

- HW: The oldest timer in Media Capture Unit m is matched.

[Clearing condition]

- SW: Writing 1 to one of these bits.

35.3.7.5 PTPIE1 : Interrupt Enable Register 1

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0714

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCRME1 to MCRME0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	MCRME1 to MCRME0	Media Clock m Recovery Match Enable (m = 0, 1) Bit m enables media clock m recovery match. 0: Interrupt m disabled 1: Interrupt m enabled	R/W*1
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read value differs from written value.

MCRMEm bits (Media Clock m Recovery Match Enable (m = 0, 1))

[Setting condition]

- SW: Writing 1 to one of these bits.

[Clearing condition]

- SW: Writing 1 to bit m of PTPID1.MCRMD register clears the corresponding bit of this register.

35.3.7.6 PTPID1 : Interrupt Disable Register 1

Base address: GPTP = 0x403E_0000
GPTP_NS = 0x503E_0000

Offset address: 0x0718

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCRMD1 to MCRMD0	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	MCRMD1 to MCRMD0	Media Clock m Recovery Match Disable (m = 0, 1)	R
31:2	—	These bits are read as 0.	R

MCRMDm bits (Media Clock m Recovery Match Disable (m = 0, 1))

[Clearing condition]

- SW: Writing 1 to one of these bits clears the corresponding bit of PTPIE0.MCRME register.

35.4 Register Utilization

35.4.1 Software Flows

SW: Follow the flows described in this section.

35.4.1.1 Software Flow Legend

Figure 35.2 describes the software flow legend.

Register name	Writable anytime
PTPCCCc0	✓
PTPCCCc1	✓

35.4.1.7 Register Writable Without Software Flow

This section describes registers that have not been described. These registers can be changed dynamically. However, it is necessary that the initial settings such as the clock enabling have been completed.

35.5 Functional Description

35.5.1 Timer t (t = 0, 1) [gPTP]

Each timer instance includes three timers:

- A GPTP timer
- A 64-bit AVTP timer
- A 32-bit AVTP timer.

35.5.1.1 GPTP Timer t

The GPTP timer t GPTP[t] can be enabled by setting PTPTMEC.TE to 1. When enabled, GPTP timer t automatically calculates its value using equation (1).

(1) gptpTimer[t] = TimerOffset[t] + FreeRunningTimerValue[t]

Where:

- gptpTimer[t] is the calculated timer value GPTP[t] and is divided in two parts. The second part gptpSecond[t] is GPTP[t][77:30] and the nanosecond part gptpNano[t] is GPTP[t][29:0].
- TimerOffset[t] is {PTPTOVCtU.TOVU, PTPTOVCtM.TOVM, PTPTOVCtL.TOVL}
- FreeRunningTimerValue[t] is the value of a free running timer starting from 0 (when timer is disabled) and is incremented by PTPTIVCt.TIV every cycle (the free running timer has a 27-bit sub-nanosecond part not described here so it should be set to clk_period[ns] × 2^{27} where clk_period is clock clk period).

Functions:

- When GPTP timer t is a master, PTPTIVCt.TIV and {PTPTOVCtU.TOVU, PTPTOVCtM.TOVM, PTPTOVCtL.TOVL} registers can be kept to fixed values.
- When GPTP timer t is a slave, PTPTIVCt.TIV register can be used in priority for time resynchronization. If GPTP timer t exceeds the corresponding master value, {PTPTOVCtU.TOVU, PTPTOVCtM.TOVM, PTPTOVCtL.TOVL} registers can be used for time resynchronization.

35.5.1.2 64-bit AVTP Timer t

The 64-bit AVTP timer t AVTP64[t] is used as a reference to synchronize any necessary media clocks and to determine when the payload of a stream is to be presented to the time-sensitive application. Media clocks vary with audio/video types therefore the exact usage of the AVTP presentation time is media-format dependent [1722].

The 64-bit AVTP timer t is generated from the GPTP timer t and can be calculated using equation (2).

(2) $avtpTimer64[t] = (gptpSecond[t] \times 10^9 + gptpNano[t]) \bmod 2^{64}$

Where:

- avtpTimer64[t] is the calculated timer value AVTP64[t]
- gptpSecond[t] is gptpTimer[t] second part GPTP[t][77:30]
- gptpNano[t] is gptpTimer[t] nanosecond part GPTP[t][29:0].

35.5.1.3 32-bit AVTP Timer t

The 32-bit AVTP timer t AVTP32[t] is the 32-bit version of 64-bit AVTP timer t and can be calculated using equation (3).

(3) $avtpTimer32[t] = (gptpSecond[t] \times 10^9 + gptpNano[t]) \bmod 2^{32}$

Where:

- avtpTimer32[t] is the calculated timer value AVTP32[t] (AVTP64[t][31:0])
- gptpSecond[t] is gptpTimer[t] second part GPTP[t][77:30]
- gptpNano[t] is gptpTimer[t] nanosecond part GPTP[t][29:0].

35.5.1.4 PPS Signal t

The PPS[t] signal is used to check if GPTP synchronization is successful. As per GPTP standard [PTP], PPS[t] signal should be output as pins at the chip level to allow synchronization checking on oscilloscope. PPS[t] is the PPS signal corresponding to timer number t. For PPS signal details, see the GPTP standard [gPTP].

35.5.2 Media Clock m Capture (m = 0, 1)

Media clock m capture aims at capturing timer values on MEDIA_IN[m] positive edge and/or negative edge.

Functions:

- PTPMCCCm.MCPEE is used to enable timer value capture on MEDIA_IN[m] positive edge
- PTPMCCCm.MCNEE is used to enable timer value capture on MEDIA_IN[m] negative edge
- PTPMCCCm.MCTNS is used to select timer number for timer value capture
- PTPMCCCm.MCTTS is used to select between GPTP and AVTP timer for timer value capture
- PTPMCCMmL/mM/mU are used to read the captured timer values
- PTPIS0.MCCSn interrupt is used to signal to the CPU that a timer value has been captured
- PTPIS0.MCCOESn interrupt is used to signal to the CPU that a captured timer value has been lost because the timer capture value FIFO was full.

35.5.3 Media Clock m Recovery (m = 0, 1)

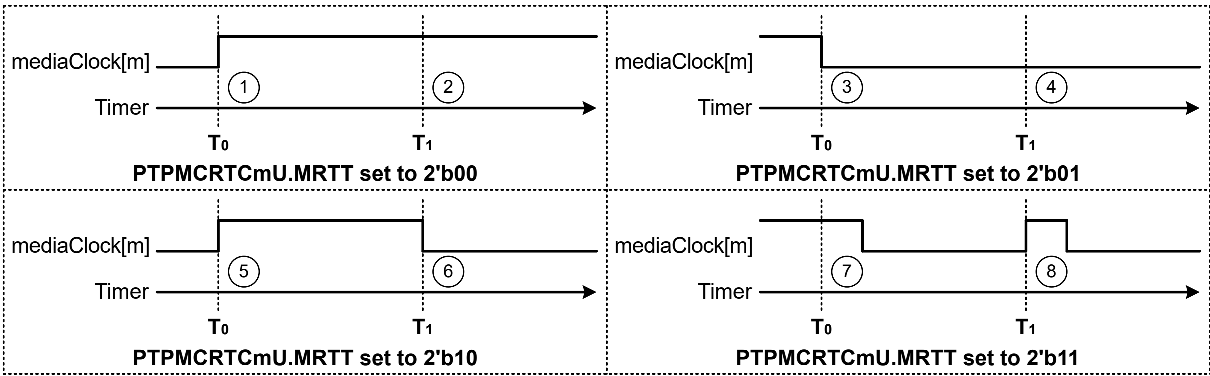
Media clock m recovery aims at creating an internal clock mediaClock[m] which can be mapped to an output pin, (see section 35.5.4. Media Clock m Mapping to Output Pins).

Functions:

- PTPMCRCm.MRTNS is used to select timer number for clock recovery
- PTPMCRCm.MRTTS is used to select between GPTP and AVTP timers for clock recovery
- PTPMCRCm.MRAMS is used to select between 32-bit AVTP timer and 64-bit AVTP timer for clock recovery when PTPMCRCm.MRTTS is set to AVTP timer
- PTPMCRCmL/mM/mU are used to add a timer value and command to execute to mediaClock[m]

- PTPIS0.MCRMS[m] interrupt is used to signal to the CPU that the oldest timer value (which has not matched yet) set in PTPMCRCmL/mM/mU matched the selected timer therefore mediaClock[m] value has been updated.

Figure 35.13 describes mediaClock[m] behavior when a timer value matches depending on the timer value type setting and the initial value of mediaClock[m].



1	Compare entry set with **PTPMCRTCmU.MRTT** set to 2'b00 matched at Timer T_0 when mediaClock[m] is not set. mediaClock[m] gets set.
2	Compare entry set with **PTPMCRTCmU.MRTT** set to 2'b00 matched at Timer T_1 when mediaClock[m] is set. mediaClock[m] stays set.
3	Compare entry set with **PTPMCRTCmU.MRTT** set to 2'b01 matched at Timer T_0 when mediaClock[m] is set. mediaClock[m] gets cleared.
4	Compare entry set with **PTPMCRTCmU.MRTT** set to 2'b01 matched at Timer T_1 when mediaClock[m] is not set. mediaClock[m] stays cleared.
5	Compare entry set with **PTPMCRTCmU.MRTT** set to 2'b10 matched at Timer T_0 when mediaClock[m] is not set. mediaClock[m] gets inverted.
6	Compare entry set with **PTPMCRTCmU.MRTT** set to 2'b10 matched at Timer T_0 when mediaClock[m] is set. mediaClock[m] gets inverted.
7	Compare entry set with **PTPMCRTCmU.MRTT** set to 2'b11 matched at Timer T0 when mediaClock[m] is set. mediaClock[m] stays set for **PTPMCRCm.MRPL**+1 clock cycles.
8	Compare entry set with **PTPMCRTCmU.MRTT** set to 2'b11 matched at Timer T0 when mediaClock[m] is not set. mediaClock[m] gets set for **PTPMCRCm.MRPL**+1 clock cycles.

Figure 35.13 mediaClock[m] behavior

Note: When timer matched an entry with PTPMCRTCmU.MRTT set to 2'b11 and the next match occurs before mediaClock[m] deassertion, mediaClock[m] deassertion command is overwritten and does not occur.

35.5.4 Media Clock m Mapping to Output Pins

The mediaClock[m] signal created by media clock m recovery (section 35.5.3. Media Clock m Recovery (m = 0, 1)) can be output to be used inside the chip or as a chip pin.

Functions:

- By setting PTPMCPCm.PE to 1 and PTPMCPCm.MRS to m, mediaClock[m] signal is assigned to MEDIA_OUT[p] output pin.

35.5.5 Cyclic Compare c (c = 0 to 7)

Cyclic compare c aims at creating a pulse cyclically on CYCLIC_COMP[i][c] for i = 0, 1 interface to trigger an event. It can be used, for example, to trigger a periodic data transmission for GPTP synchronization (network control frame transmission).

Functions:

- PTPCCCc0.CCTNS is used to select timer number for cyclic compare. During cyclic compare, timer offset is ignored, and only incremental value is taken in account.
- PTPCCCc1.CCV is used to enable cycle compare. When cycle compare c is enabled, a pulse is sent every PTPCCCc1.CCV to CYCLIC_COMP[PTPCCCc0.CCOPS][c].
- When this feature is enabled (when the PTPCCCc1.CCV configuration is updated to a value greater than 32), the first pulse from comparator c is output immediately (after one system clock), regardless of PTPCCCc1.CCV configuration.

35.6 Pulse Output Timer Module (plsotim)

35.6.1 Overview of plsotim

The pulse output timer module (plsotim), a submodule of gPTP, produces a pulsed output according to the base period of a gPTP timer.

Table 35.8 lists the plsotim specifications.

Table 35.8 plsotim specifications

Item	Function	Description
Overall function	Pulse generator	• Pulse generation timer, pulsed output, and interrupt output.
Data provision		• Pulsed output channel: 4 ch The pulse cycle: 80 bits ([79:32] = second and [31:0] = ns) Pulse width: 20 bits ([19:0] = counter) • Interruption output channel: 4 ch.
Functions	PTP timer select	• The PTP timer to be used as the reference time can be selected.
	PTP_PULSE_GEN	• Uses the reference time of the GPTP timer to generate pulse outputs of any period and any pulse width.
	Interrupt pulse output	• The rising edge of the pulse output is detected, and the interrupt pulse is output.

35.6.2 Plsotim Register List

Table 35.9 Plsotim registers

Offset address	Register name	Register symbol	Write access mode
0x1000	Pulse Output Timer Configuration Register	POTCFGR	—
0x1004 + 0x30 × n	Pulse Output Timer Control Register n (n = 0 to 3)	POTCRn	—

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
29:0	n/a	The nanosecond value for the pulse output start time.	R
31:30	—	These bits are read as 0.	R

35.6.4 Operation of plsotim

35.6.4.1 Pulse Output Timer Operation Settings

Figure 35.14 shows the operation setting flow of the pulse output timer n.

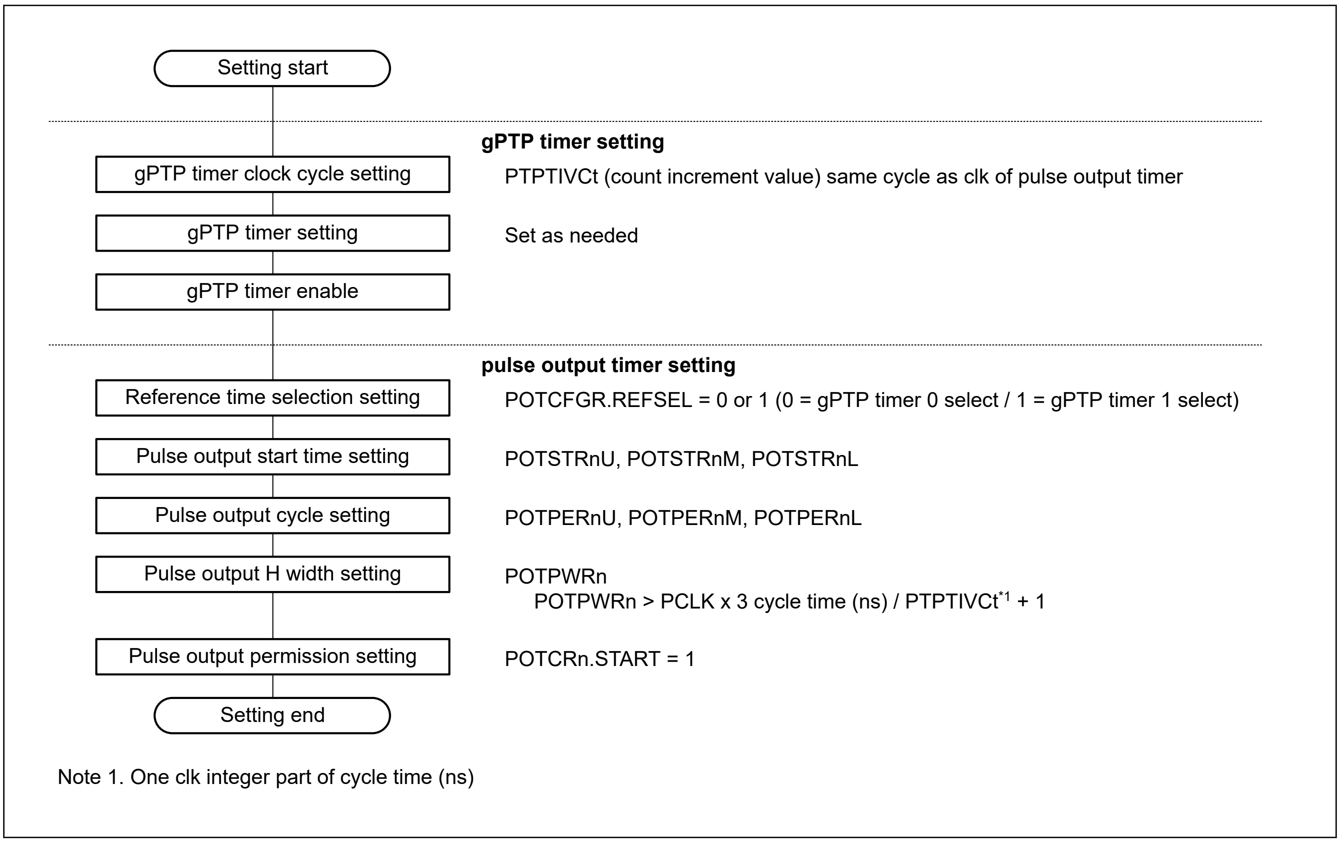

Figure 35.14 Operation setting flow of the pulse output timer

35.6.4.2 Pulse Output Timer n (n = 0 to 3)

This module uses the reference time of the GPTP timer to generate a pulse output of any period and any pulse width.

35.6.4.2.1 GPTP Timer Select

Select the GPTP timer of the reference time to be used by setting the POTCFGR register.

POTCFGR.REFSEL bit setting:

0 : Generates a pulse output using the reference time of GPTP timer 0.

1 : Generates a pulse output using the reference time of GPTP timer 1.

Functions:

- The reference time used for pulse generation can be selected by setting the POTCFGR register
- When POTCFGR.REFSEL = 0: Generates a pulse using the time input signal of GPTP timer 0
- When POTCFGR.RFGSEL = 1: Generate a pulse using the time input signal of GPTP timer 1
- When changing the POTCFGR register, stop the pulse output (POTCRn.START = 0) before modification.

35.6.4.2.2 Pulse Output Generation Register

By setting the following registers, it is possible to generate a pulse with an arbitrary start time, an arbitrary period, and an arbitrary H pulse width.

- Pulse output start time register: POTSTRnU, POTSTRnM, POTSTRnL
- Pulse output cycle register: POTPERnU, POTPERnM, POTPERnL
- Pulse output H width register: POTPWRn.

When the H width register of the pulse output is 0, the pulse is not generated, so the L output is fixed.

If the pulse output cycle is set to be less than or equal to the H width time of the pulse output, the H output is fixed.

35.6.4.2.3 Pulse Output Generation

By changing the POTCRn.START bit from 0 to 1, the value of the pulse output generation register is captured and held.

Pulse is generated according to the set value of the held pulse output generation.

The output pulse is as follows.

Rise of the first pulse:

Pulse output H width register ≠ 0: It becomes H at the set start time.

Pulse output H width register = 0: L output remains (no pulse output).

Pulse fall:

Pulse output cycle register value > Pulse output H width register value × clk cycle.

When the clk number is counted by the amount of the H width register value after the output becomes H, it becomes L.

Pulse output cycle register value ≤ H width register value of pulse output × clk cycle.

The output remains H (H output is fixed until the POTCRn.START bit is set to 0).

Rise from the second time onward:

When H width register = other than 0 and pulse output cycle > H width register value × clk cycle.

It becomes H at the time of the previous start time + pulse output cycle register value.

35.6.4.2.4 Pulse Output Stop

Pulse output can be stopped by setting the POTCRn.START bit to 0.

When stopped, the output is fixed at L.

When the POTCRn.START bit is set to 1 again, the register setting value is taken in and held, and a new pulse is generated and output.

Note: Even if the pulse output is stopped in the middle, it is not restarted. A new pulse is generated and output.

35.6.4.2.5 Timing of Pulse Output Permission

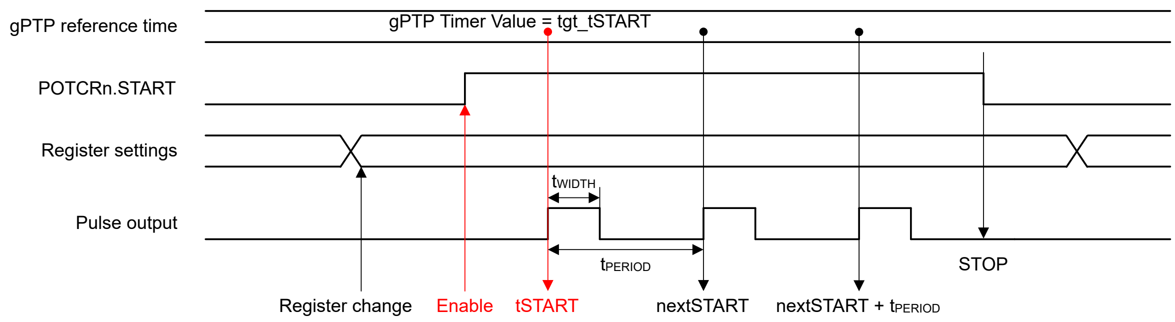
If the POTCRn.START bit is changed from 0 to 1 after the set pulse output start time, no pulse output is performed.

The pulse is output from the time when the reference time goes around once and the start time is reached again.

35.6.4.3 Pulse Output Timing Diagrams

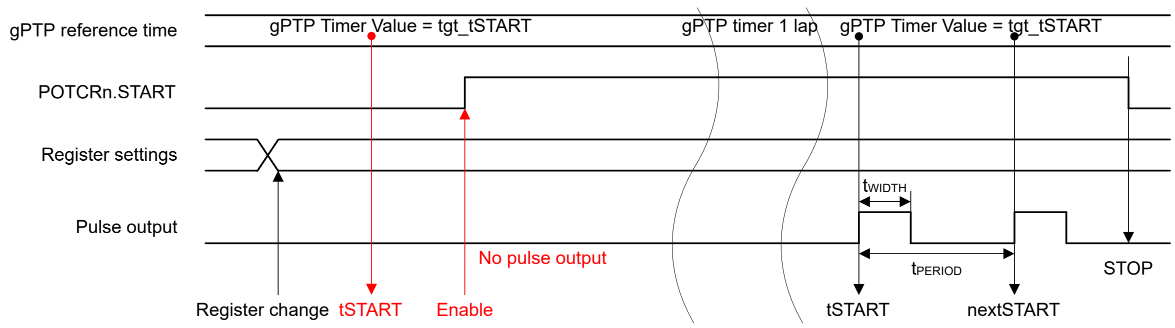
Six examples of pulse outputs are shown in the timing diagrams as following:

1. Figure 35.15 When changing the POTCRn.START bit from 0 to 1 after setting the register and before the start time
2. Figure 35.16 When changing the POTCRn.START bit from 0 to 1 after setting the register and after the start time
3. Figure 35.17 Pulse output H width register ≥ when the POTCRn.START bit is changed from 0 to 1 by setting the pulse output cycle
4. Figure 35.18 When changing the POTCRn.START bit from 0 to 1 with pulse output H width register = 0
5. Figure 35.19 When the pulse output is stopped with the POTCRn.START bit set to 0
6. Figure 35.20 When the register setting is changed with the POTCRn.START bit set to 1.



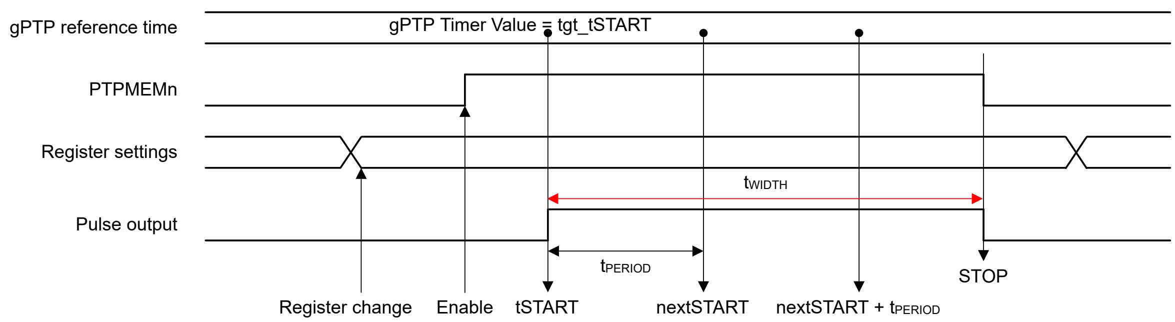
Note: tgt_tSTART = First time : {POTSTRnU, POTSTRnM, POTSTRnL}, From the time onwards (from nextSTART) : {tgt_tSTART + t_{PERIOD}}
t_{PERIOD} = {POTPERnU, POTPERnM, POTPERnL}
t_{WIDTH} = {POTPWRn}

Figure 35.15 When changing the POTCRn.START bit from 0 to 1 after setting the register and before the start time



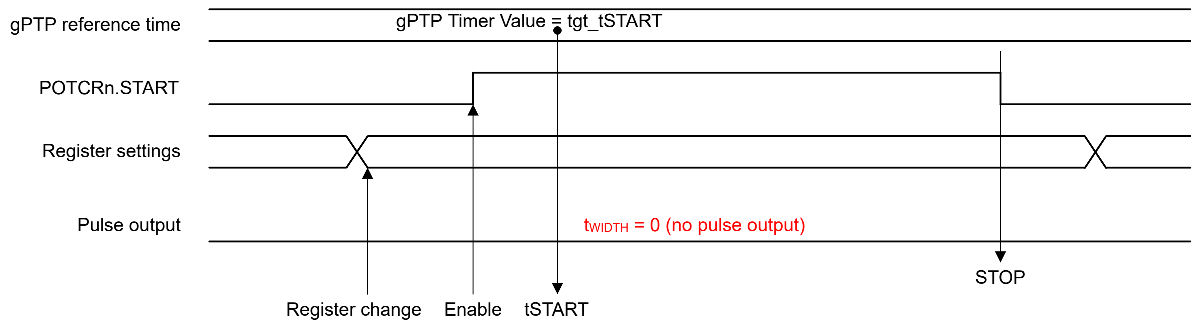
Note: tgt_tSTART = First time : {POTSTRnU, POTSTRnM, POTSTRnL}, From the time onwards (from nextSTART) : {tgt_tSTART + t_{PERIOD}}
t_{PERIOD} = {POTPERnU, POTPERnM, POTPERnL}
t_{WIDTH} = {POTPWRn}

Figure 35.16 When changing the POTCRn.START bit from 0 to 1 after setting the register and after the start time



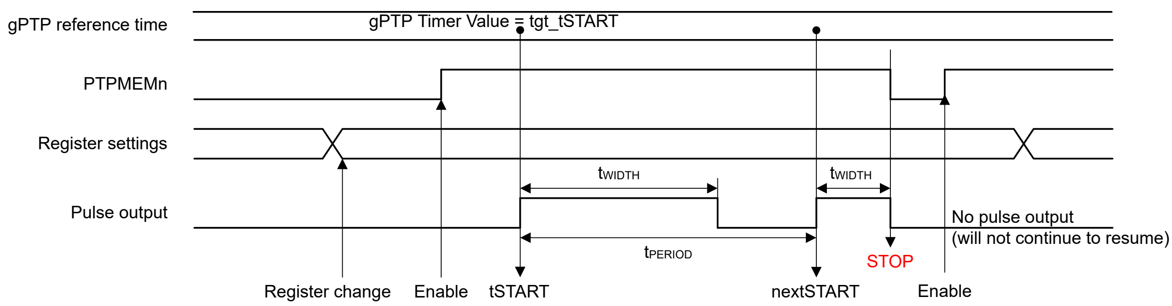
Note: tgt_tSTART = First time : {POTSTRnU, POTSTRnM, POTSTRnL}, From the time onwards (from nextSTART) : {tgt_tSTART + t_{PERIOD}}
t_{PERIOD} = {POTPERnU, POTPERnM, POTPERnL}
t_{WIDTH} = {POTPWRn}

Figure 35.17 Pulse output H width register ≥ when the POTCRn.START bit is changed from 0 to 1 by setting the pulse output cycle



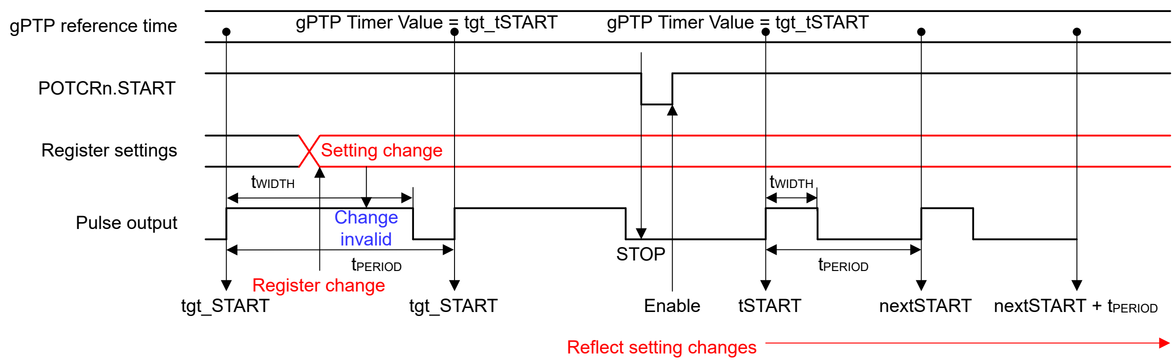
Note: tSTART = {POTSTRnU, POTSTRnM, POTSTRnL} = anything
t_{PERIOD} = {POTPERnU, POTPERnM, POTPERnL} = anything
t_{WIDTH} = {POTPWRn} = 0
nextSTART = Cannot calculate

Figure 35.18 When changing the POTCRn.START bit from 0 to 1 with pulse output H width register = 0



Note: tgt_tSTART = First time : {POTSTRnU, POTSTRnM, POTSTRnL}, From the time onwards (from nextSTART) : {tgt_tSTART + t_{PERIOD}}
t_{PERIOD} = {POTPERnU, POTPERnM, POTPERnL}
t_{WIDTH} = {POTPWRn}

Figure 35.19 When the pulse output is stopped with the POTCRn.START bit set to 0



Note: tgt_tSTART = First time : {POTSTRnU, POTSTRnM, POTSTRnL}, From the time onwards (from nextSTART) : {tgt_tSTART + t_{PERIOD}}
t_{PERIOD} = {POTPERnU, POTPERnM, POTPERnL}
t_{WIDTH} = {POTPWRn}

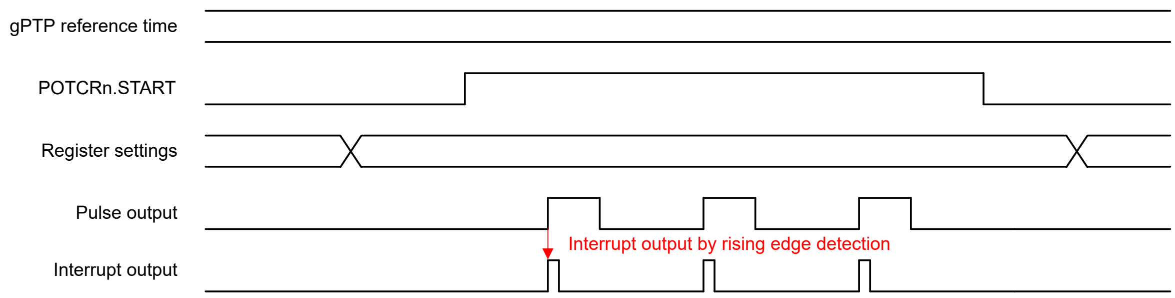
Figure 35.20 When the register setting is changed with the POTCRn.START bit set to 1

35.6.5 Interrupt Output

Interrupt output detects the rising edge of the pulse output and outputs an interrupt signal synchronized with PCLK.

There are four channels of interrupt output, and the interrupt signal corresponding to each pulse output channel is output. The interrupt signal outputs H with a width of 1 cycle of PCLK.

Figure 35.21 shows the timing diagram of interrupt output.



Note: There is no register to control the interrupt output, and one pulse is output in PCLK synchronization after the rising edge of the pulse output is detected.
The interrupt signal is output by generating one pulse after synchronizing the pulse output with PCLK.
It is necessary to set POTPWRn so that the H width of the pulse output is 3 cycles or more with the PCLK required for synchronization.

Figure 35.21 Detects the rising edge of the pulse output and outputs one pulse synchronized with PCLK

35.6.6 Precautions

35.6.6.1 Register Setting

The POTCFGR register switches the GPTP timer selection immediately when the setting is changed regardless of whether it is stopped or operating.

Be careful when changing setting during operation.

35.6.7 Restrictions (Including Known Problems)

35.6.7.1 Register Setting

The following registers should be set within the limit range of the set value:

- POTSTRnL, POTPERnL: Set the value in the range of 0 - 0x3B9AC9FF.
  0x3B9ACA00 is 1 second, so if it is 1 second or longer, reflect and set it in the register in seconds.
- POTPWRn: For settings other than 0, set for a time of 3 or more cycles of the PCLK cycle.
  The time required to generate the interrupt output signal.

36. USB 2.0 Full-Speed Module (USBFS)

36.1 Overview

The USB 2.0 Full-Speed module (USBFS) operates as a host or device controller compliant with the Universal Serial Bus (USB) specification revision 2.0. The host controller supports USB 2.0 full-speed and low-speed transfers, and the device controller supports USB 2.0 full-speed transfers. The USBFS has an internal USB transceiver and supports all of the transfer types defined in the USB 2.0 specification

The USBFS has FIFO buffer for data transfers, providing a maximum of 10 pipes. Any endpoint number can be assigned to pipes 1 to 9, based on the peripheral devices or the communication requirements for your system.

Table 36.1 lists the USBFS specifications, Figure 36.1 shows a block diagram, and Table 36.2 lists the I/O pins.

Table 36.1 USBFS specifications

Parameter	Specifications
Features	• USB Device Controller (UDC) and USB 2.0 transceiver supporting host controller, and device controller, and On-The-Go (OTG) functions • Host and device controller can be switched by software • Self-power or bus power mode selectable
	Host controller features: • Full-speed transfer (12 Mbps) and low-speed transfer (1.5 Mbps) • Automatic scheduling for SOF and packet transmissions • Programmable intervals for isochronous and interrupt transfers • Communications with multiple peripheral devices connected through a single hub
	Device controller features: • Full-speed transfer (12 Mbps)*1 • Control transfer stage control function • Device state control function • Auto response function for SET_ADDRESS request • SOF interpolation
Supported transfer types	• Control transfer • Bulk transfer • Interrupt transfer • Isochronous transfer
Pipe configuration	• FIFO buffer for USB communication • Up to 10 pipes selectable, including the Default Control Pipe (DCP) • Pipes 1 to 9 assignable to any endpoint number
	Transfer conditions specifiable for each pipe: • Pipe 0: Control transfer with 64-byte single buffer • Pipes 1 and 2: Selectable to bulk transfer with 64-byte double buffer or isochronous transfer with 256-byte double buffer • Pipes 3 to 5: Bulk transfer with 64-byte double buffer • Pipes 6 to 9: Interrupt transfer with 64-byte single buffer
Other features	• Reception end function using transaction count • Function that changes the BRDY interrupt event notification timing (BFRE) • Automatic clearing of the FIFO buffer after the data for the pipe specified in the DnFIFO port (n = 0, 1) is read (DCLRM) • NAK setting function for response PID generated on transfer end (SHTNAK) • On-chip pull-up and pull-down resistors for D+ and D–
Module-stop function	Module-stop state can be set to reduce power consumption
TrustZone Filter	Security and Privilege attribution can be set

Note 1. Low-speed transfer (1.5 Mbps) is not supported.

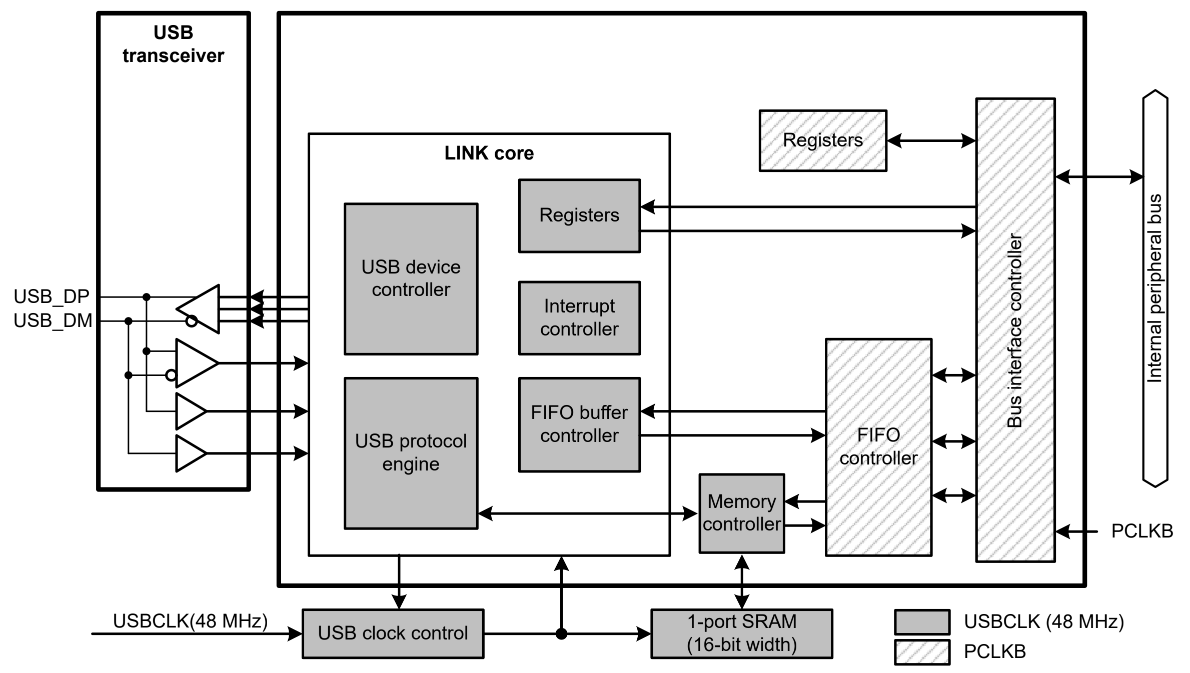


Figure 36.1 USBFS block diagram

Table 36.2 USBFS pin configuration

Function	Pin name	I/O	Description
USBFS	USB_DP	I/O	D+ I/O pin of the USB on-chip transceiver. This pin should be connected to the D+ pin of the USB bus.
	USB_DM	I/O	D– I/O pin of the USB on-chip transceiver. This pin should be connected to the D– pin of the USB bus.
	USB_VBUS	Input	USB cable connection monitor pin. This pin should be connected to VBUS of the USB bus. The VBUS pin status (connected or disconnected) can be detected when the USB module is operating as a function controller.
	USB_EXICEN	Output	Low-power control signal for external power supply (OTG) chip.
	USB_VBUSEN	Output	VBUS (5 V) supply enable signal for external power supply chip.
	USB_OVRCURA, USB_OVRCURB USB_OVRCURA-DS, USB_OVRCURB-DS	Input	External overcurrent detection signals should be connected to these pins. VBUS comparator signals should be connected to these pins when the OTG power supply chip is connected. USB_OVRCURA or USB_OVRCURB pins can be used in Software standby mode or in normal mode. USB_OVRCURA-DS, USB_OVRCURB-DS are dedicated pins that can generate interrupt in Software standby mode or in normal mode as well as for cancel Deep Software Standby mode 1.
	USB_ID	Input	MicroAB connector ID input signal should be connected to this pin during operation in OTG mode.
	VCC_USB	Input	Power supply pins.
	VSS_USB	Input	Ground pins.

36.2 Register Descriptions

36.2.1 SYSCFG : System Configuration Control Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SCKE	—	—	—	DCFM	DRPD	DPRPU	—	—	—	USBE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	USBE	USBFS Operation Enable 0: Disable 1: Enable	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	DPRPU	D+ Line Resistor Control 0: Disable line pull-up 1: Enable line pull-up	R/W
5	DRPD	D+/D– Line Resistor Control 0: Disable line pull-down 1: Enable line pull-down	R/W
6	DCFM	Controller Function Select 0: Select device controller 1: Select host controller	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
9:8	—	These bits are read as 0. The write value should be 0.	R/W
10	SCKE	USB Clock Enable 0: Stop clock supply to the USBFS 1: Enable clock supply to the USBFS	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: After writing 1 to the SCKE bit, read it to confirm that it is set to 1.

USBE bit (USBFS Operation Enable)

The USBE bit enables or disables operation of the USBFS.

Changing the USBE bit from 1 to 0 initializes the bits listed in Table 36.3. Only change this bit while the SCKE bit is 1. In host controller mode, this bit must be set to 1 after setting the DRPD bit to 1, eliminating SYSSTS0.LNST[1:0] flags chattering, and confirming that the USB bus state is stable.

Table 36.3 Registers initialized by writing 0 to the SYSCFG.USBE bit

Selected function	Register	Bit	Remarks
Device controller	SYSSTS0	LNST[1:0]	Value is saved in host controller mode
	DVSTCTR0	RHST[2:0]	—

Host controller	DVSTCTR0	RHST[2:0]	—
	FRMNUM	FRNM[10:0]	Value is saved in device controller mode

DPRPU bit (D+ Line Resistor Control)

The DPRPU bit enables or disables pulling up the D+ line in device controller mode.

When the DPRPU bit is set to 1 in device controller mode, the USBFS pulls up the D+ line to notify the USB host that it attached. Changing the DPRPU bit from 1 to 0 releases the pull-up, thereby notifying the USB host that it detached.

Set this bit to 1 in device controller mode and to 0 in host controller mode.

DRPD bit (D+/D– Line Resistor Control)

TheDRPD bit enables or disables pulling down D+ and D– lines in host controller mode.

Set this bit to 1 in host controller mode and to 0 in device controller mode.

DCFM bit (Controller Function Select)

The DCFM bit selects the host or device function of the USBFS.

Only change this bit when the DPRPU and DRPD bits are both 0.

SCKE bit (USB Clock Enable)

The SCKE bit stops or enables the 48-MHz clock supply to the USBFS.

When this bit is 0, only SYSCFG is permitted to be read from and written to; the other registers related to the USB should not be read from or written to.

36.2.2 SYSSTS0 : System Configuration Status Register 0

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x004

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	OVCMON[1:0]		—	—	—	—	—	—	—	HTACT	SOFEA	—	—	IDMON	LNST[1:0]	
Value after reset:	x	x	0	0	0	0	0	0	0	0	0	0	0	x	0	0

Bit	Symbol	Function	R/W
1:0	LNST[1:0]	USB Data Line Status Monitor Indicates the status of the USB data lines, see Table 36.4	R
2	IDMON	External ID0 Input Pin Monitor 0: USB_ID pin is low 1: USB_ID pin is high	R
4:3	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
5	SOFEA	Active Monitor When the Host Controller Is Selected 0: SOF output stopped 1: SOF output operating	R
6	HTACT	USB Host Sequencer Status Monitor 0: Host sequencer completely stopped 1: Host sequencer not completely stopped	R
13:7	—	These bits are read as 0.	R
15:14	OVCMON[1:0]	External USB_OVRCURA, USB_OVRCURA-DS, USB_OVRCURB or USB_OVRCURB-DS Input Pin Monitor OVCMON[1] indicates the USB_OVRCURA or USB_OVRCURA-DS pin status. OVCMON [0] indicates the USB_OVRCURB or USB_OVRCURB-DS pin status.	R

Note: S-TYPE-3, P-TYPE-3

Note: The values of the OVCMON[1:0] and IDMON bits depend on the status of the USB_OVRCURA, USB_OVRCURA-DS, USB_OVRCURB or USB_OVRCURB-DS and USB_ID pins.

LNST[1:0] bits (USB Data Line Status Monitor)

The LNST[1:0] bits indicate the state of the USB data lines, D+ and D–. For details, see Table 36.4.

In device controller mode, read the LNST[1:0] bits after connection processing (SYSCFG.DPRPU bit = 1). In host controller mode, read them after enabling pull-down of the lines (SYSCFG.DRPD bit = 1).

Table 36.4 Status of the USB data bus lines (D+ and D–)

LNST[1:0] bits	During full-speed operation	During low-speed operation
00b	SE0	SE0
01b	J-State	K-State
10b	K-State	J-State
11b	SE1	SE1

SOFEA bit (Active Monitor When the Host Controller Is Selected)

The SOFEA bit is used in host controller mode to check whether the output of the last SOF is complete when the USBFS is suspended because of a 0 setting to the DVSTCTR0.UACT bit.

In host controller mode, check that both the HTACT and SOFEA bits are 0 before setting the SYSCFG.USBE bit to 0 to stop the USBFS or setting the SYSCFG.SCKE bit to 0 to stop the clock signal supply during communication.

HTACT bit (USB Host Sequencer Status Monitor)

The HTACT bit is set to 0 when the host sequencer of the USBFS is completely stopped.

In host controller mode, check that the HTACT bit is 0 before setting the DVSTCTR0.UACT bit to 0 to place the USBFS in the suspended state or setting the SYSCFG.SCKE bit to 0 to stop the clock signal supply during communication.

OVCMON[1:0] bits (External USB_OVRCURA, USB_OVRCURA-DS, USB_OVRCURB or USB_OVRCURB-DS Input Pin Monitor)

The OVCMON[1:0] bits indicate the status of the overcurrent signals from an external power supply IC.

36.2.3 DVSTCTR0 : Device State Control Register 0

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x008

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	HNPBTOA	EXICEN	VBUSEN	WKUP	RWUPE	USBRST	RESUME	UACT	—	RHST[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	RHST[2:0]	USB Bus Reset Status 0 0 0: In host controller mode: Communication speed indeterminate (powered state or no connection) In device controller mode: Communication speed indeterminate 0 0 1: In host controller mode: Low-speed connection In device controller mode: USB bus reset in progress 0 1 0: In host controller mode: Full-speed connection In device controller mode: USB bus reset in progress or full-speed connection 0 1 1: Setting prohibited Others: In host controller mode: USB bus reset in progress In device controller mode: Setting prohibited	R
3	—	This bit is read as 0. The write value should be 0.	R/W
4	UACT	USB Bus Enable 0: Disable downstream port (disable SOF transmission) 1: Enable downstream port (enable SOF transmission)	R/W
5	RESUME	Resume Output 0: Do not output resume signal 1: Output resume signal	R/W
6	USBRST	USB Bus Reset Output 0: Do not output USB bus reset signal 1: Output USB bus reset signal	R/W
7	RWUPE	Wakeup Detection Enable 0: Disable downstream port remote wakeup 1: Enable downstream port remote wakeup	R/W
8	WKUP	Wakeup Output 0: Do not output remote wakeup signal 1: Output remote wakeup signal	R/W
9	VBUSEN	USB_VBUSEN Output Pin Control 0: Output low on external USB_VBUSEN pin 1: Output high on external USB_VBUSEN pin	R/W
10	EXICEN	USB_EXICEN Output Pin Control 0: Output low on external USB_EXICEN pin 1: Output high on external USB_EXICEN pin	R/W
11	HNPBTOA	Host Negotiation Protocol (HNP) Control Use this bit when switching from device B to device A in OTG mode. If the HNPBTOA bit is 1, the internal function control remains in the Suspend state until the HNP processing ends even if SYSCFG.DPRPU = 0 or SYSCFG.DCFM = 1.	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The USBFS controller does not support low-speed connections in device controller mode. When this value is read, abnormal connection processing must be executed in higher level application software.

RHST[2:0] bits (USB Bus Reset Status)

RHST[2:0] bits indicate the status of the USB bus reset.

In host controller mode, writing 1 to the USBRST bit causes the RHST[2:0] bits to set to 100b. When 0 is written to the USBRST bit and the USBFS ends the SE0 state, the RHST[2:0]bits update to a new value.

In device controller mode, if the USBFS detects a USB bus reset, the RHST[2:0] bits indicate 010b if the DPRPU bit is 1, and a DVST interrupt is generated.

UACT bit (USB Bus Enable)

When set to 1 in host controller mode, the UACT bit enables USB bus operation by controlling SOF packet transmission to the USB bus in addition to data and reception. The USBFS starts SOF packet output within one frame period after the UACT bit is set to 1. When UACT is set to 0, the USBFS enters the idle state after the SOF packet output.

The USBFS sets the UACT bit to 0 on any of the following conditions:

- A DTCH interrupt is detected during communication (when UACT = 1)

- An EOFERR interrupt is detected during communication (when UACT = 1)

Always write 1 to the UACT bit at the end of the USB bus reset processing (writing 0 to the USBRST bit) or at the end of resume processing from the suspended state (writing 0 to the RESUME bit).

In device controller mode, always set this bit to 0.

RESUME bit (Resume Output)

The RESUME bit controls the resume signal output in host controller mode.

When this bit is set to 1, the USBFS drives the USB port to the K-state and outputs the resume signal. The USBFS sets the bit to 1 on detection of a remote wakeup signal while the RWUPE bit is 1 and in the USB Suspend state.

The USBFS continues outputting the K-state while the RESUME bit is 1, until the bit is cleared to 0 by software. The RESUME bit must be 1 (resume period) for the time defined in the USB 2.0 specification. Only set this bit to 1 while the interface is in the Suspend state. Write 1 to the UACT bit simultaneously with the end of the resume processing (writing 0 to the RESUME bit).

Always set this bit to 0 in device controller mode.

USBRST bit (USB Bus Reset Output)

The USBRST bit controls the output of the USB bus signal in host controller mode. When this bit set to 1, the USBFS drives the USB port to the SE0 state to reset the USB bus. The USBFS continues outputting SE0 while the USBRST bit is 1, until the bit is cleared to 0 by software. The USBRST bit must be 1 (USB bus reset period) for the time defined in the USB 2.0 specification. Writing 1 to the USBRST bit during communication (UACT = 1) or during resume processing (RESUME = 1) prevents the USBFS from starting USB bus reset processing until both the UACT and RESUME bits become 0. Write 1 to the UACT bit simultaneously with the end of the USB bus reset processing (writing 0 to the USBRST bit).

Always set this bit to 0 in device controller mode.

RWUPE bit (Wakeup Detection Enable)

The RWUPE bit enables or disables remote wakeup signals (resume signals) from downstream peripheral devices in host controller mode. When this bit is set to 1, the USBFS detects a remote wakeup signal (K-state for 2.5 µs) from a downstream peripheral device, and performs resume processing, driving the K-state. When the RWUPE bit is set to 0, the USBFS ignores remote wakeup signals (K-states) from peripheral devices connected to the USB port.

Do not stop the internal clock when the RWUPE bit is 1, even in the Suspend state (SYSCFG.SCKE bit must be set to 1).

Always set this bit to 0 in device controller mode.

WKUP bit (Wakeup Output)

The WKUP bit enables or disables remote wakeup signals (resume signals) to the USB bus in device controller mode.

The USBFS controls the output timing of the remote wakeup signals. When this bit is set to 1, the USBFS clears it to 0 after outputting the K-state for 10 ms. The USB 2.0 specification specifies that the USB bus idle state must be kept for 5 ms or longer before a remote wakeup signal is sent. If the USBFS writes 1 to the WKUP bit immediately after detecting the Suspend state, the K-state is output after 2 ms.

Only write 1 to the WKUP bit when the device is in the Suspend state (INTSTS0.DVSQ[2:0] = 1xxb) and the USB host enables the remote wakeup signal. Do not stop the internal clock while this bit is 1, even in the Suspend state (SYSCFG.SCKE bit must be set to 1).

Always set this bit to 0 in host controller mode.

HNPBTOA bit (Host Negotiation Protocol (HNP) Control)

TheHNPBTOA bit is used when switching from device B to device A while in OTG mode.

If the HNPBTOA bit is 1, the internal function control maintains the Suspend state until HNP processing ends, even if the SYSCFG.DPRPU bit is set to 0 or the SYSCFG.DCFM bit is set to 1. Resume interrupts (RESM) are not generated even if a falling edge of D+ is detected.

After this bit is set to 1, the HNP processing ends when a host attach event is detected, because of a pull-up by the initiating party, or the HNPBTOA bit is cleared to 0 by software because the HNP processing times out.

36.2.4 CFIFO/CFIFOL : CFIFO Port Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x014

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FIFOPORT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	FIFOPORT[15:0]*1	FIFO Port Read receive data from the FIFO buffer or write transmit data to the FIFO buffer by accessing these bits	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The valid bits depend on the MBW settings (CFIFOSEL.MBW) and BIGEND settings (CFIFOSEL.BIGEND) in the associated port selection register. See Table 36.5 and Table 36.6.

Three FIFO ports are available:

- CFIFO
- D0FIFO
- D1FIFO

Each FIFO port is configured with:

- A port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer and writing of data to the FIFO buffer
- A port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that selects the pipe assigned to the FIFO port
- A port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR)

Each FIFO port has the following constraints:

- Access to the FIFO buffer for DCP control transfers is through the CFIFO port
- Access to the FIFO buffer for DMA or DTC transfers is through the D0FIO or D1FIFO port
- The D0FIFO and D1FIFO ports can also be accessed by the CPU
- When using functions specific to the FIFO port, such as the DMA or DTC transfer function, you cannot change the pipe number selected in the CURPIPE[3:0] bits of the port selection register
- Registers configuring a FIFO port do not affect other FIFO ports
- The same pipe must not be assigned to two or more FIFO ports
- There are two FIFO buffer states, one giving access rights to the CPU and the other to the serial interface engine (SIE). When the SIE has access rights, the FIFO buffer cannot be accessed by the CPU

FIFOPORT[15:0] bits (FIFO Port)

When the FIFOPORT[15:0] bit is accessed, the USBFS reads the received data from the FIFO buffer or writes the transmit data to the FIFO buffer. The FIFO port register can be accessed only when the FRDY bit in the associated port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is 1.

The valid bits in the FIFO port register depend on the MBW and BIGEND settings in the port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL). See Table 36.5 and Table 36.6.

Table 36.5 Endian operation in 16-bit access

CFIFOSEL.BIGEND bit	Bits [15:8]	Bits [7:0]
0	N + 1 data	N + 0 data
1	N + 0 data	N + 1 data

Table 36.6 Endian operation in 8-bit access

CFIFOSEL.BIGEND bit	Bits [15:8]	Bits [7:0]
0	Access prohibited[*1]	N + 0 data
1	Access prohibited[*1]	N + 0 data

Note 1. Writing to or reading from these areas is not allowed.

36.2.5 DnFIFO/DnFIFOL : DnFIFO Port Register (n = 0, 1)

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x018 + 0x4 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FIFOPORT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	FIFOPORT[15:0][*1]	FIFO Port Read receive data from the FIFO buffer or write transmit data to the FIFO buffer by accessing these bits	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The valid bits depend on the MBW settings (CFIFOSEL.MBW, D0FIFOSEL.MBW, and D1FIFOSEL.MBW) and BIGEND settings (CFIFOSEL.BIGEND, D0FIFOSEL.BIGEND, and D1FIFOSEL.BIGEND) in the associated port selection register. See Table 36.7 and Table 36.8.

Three FIFO ports are available:

- CFIFO
- D0FIFO
- D1FIFO

Each FIFO port is configured with:

- A port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer and writing of data to the FIFO buffer
- A port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that selects the pipe assigned to the FIFO port
- A port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR)

Each FIFO port has the following constraints:

- Access to the FIFO buffer for DCP control transfers is through the CFIFO port
- Access to the FIFO buffer for DMA or DTC transfers is through the D0FIO or D1FIFO port
- The D0FIFO and D1FIFO ports can also be accessed by the CPU
- When using functions specific to the FIFO port, such as the DMA or DTC transfer function, you cannot change the pipe number selected in the CURPIPE[3:0] bits of the port selection register
- Registers configuring a FIFO port do not affect other FIFO ports
- The same pipe must not be assigned to two or more FIFO ports
- There are two FIFO buffer states, one giving access rights to the CPU and the other to the serial interface engine (SIE). When the SIE has access rights, the FIFO buffer cannot be accessed by the CPU

FIFOPORT[15:0] bits (FIFO Port)

When the FIFOPORT bit is accessed, the USBFS reads the received data from the FIFO buffer or writes the transmit data to the FIFO buffer. The FIFO port register can be accessed only when the FRDY bit in the associated port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is 1.

The valid bits in the FIFO port register depend on the MBW and BIGEND settings in the port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL). See Table 36.7 and Table 36.8.

Table 36.7 Endian operation in 16-bit access

CFIFOSEL.BIGEND bit D0FIFOSEL.BIGEND bit D1FIFOSEL.BIGEND bit	Bits [15:8]	Bits [7:0]
0	N + 1 data	N + 0 data
1	N + 0 data	N + 1 data

Table 36.8 Endian operation in 8-bit access

CFIFOSEL.BIGEND bit D0FIFOSEL.BIGEND bit D1FIFOSEL.BIGEND bit	Bits [15:8]	Bits [7:0]
0	Access prohibited*1	N + 0 data
1	Access prohibited*1	N + 0 data

Note 1. Writing to or reading from these areas is not allowed.

36.2.6 CFIFOSEL : CFIFO Port Select Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x020

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RCNT	REW	—	—	—	MBW	—	BIGEND	—	—	ISEL	—	CURPIPE[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CURPIPE[3:0]	CFIFO Port Access Pipe Specification 0x0: Default Control Pipe 0x1: Pipe 1 0x2: Pipe 2 0x3: Pipe 3 0x4: Pipe 4 0x5: Pipe 5 0x6: Pipe 6 0x7: Pipe 7 0x8: Pipe 8 0x9: Pipe 9 Others: Setting prohibited	R/W
4	—	This bit is read as 0. The write value should be 0.	R/W
5	ISEL	CFIFO Port Access Direction When DCP Is Selected 0: Select reading from the FIFO buffer 1: Select writing to the FIFO buffer	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	BIGEND	CFIFO Port Endian Control 0: Little endian 1: Big endian	R/W
9	—	This bit is read as 0. The write value should be 0.	R/W
10	MBW	CFIFO Port Access Bit Width 0: 8-bit width 1: 16-bit width	R/W
13:11	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
14	REW	Buffer Pointer Rewind 0: Do not rewind buffer pointer 1: Rewind buffer pointer	W*1
15	RCNT	Read Count Mode 0: The DTLN[8:0] bits (CFIFOCTR.DTLN[8:0], D0FIFOCTR.DTLN[8:0], D1FIFOCTR.DTLN[8:0]) are cleared when all receive data is read from the CFIFO. In double buffer mode, the DTLN[8:0] value is cleared when all data is read from only a single plane. 1: The DTLN[8:0] bits are decremented each time the receive data is read from the CFIFO.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Only 0 can be read.

Do not specify the same pipe number in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

Do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (CFIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number to use for reading or writing data through the CFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, even when an attempt is made to change the CURPIPE[3:0] setting, the current access setting is retained until access is complete.

ISEL bit (CFIFO Port Access Direction When DCP Is Selected)

After writing a new value to the ISEL bit with the DCP as the selected pipe, read the ISEL bit to check that the written value agrees with the read value before proceeding to the next process. Set the ISEL and CURPIPE[3:0] bits simultaneously.

MBW bit (CFIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the CFIFO port.

When the selected pipe is receiving, set the CURPIPE[3:0] and MBW bits simultaneously. After a write to these bits starts a data read from the FIFO buffer, do not change the MBW bit until all of the data is read.

When the selected pipe is transmitting, the bit width cannot be changed from 8-bit to 16-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double buffering, this setting enables re-reading of the currently-read FIFO buffer plane from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY bit is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

36.2.7 DnFIFOSEL : DnFIFO Port Select Register (n = 0, 1)

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x028 + 0x4 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RCNT	REW	DCLRM	DREQE	—	MBW	—	BIGEND	—	—	—	—	CURPIPE[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CURPIPE[3:0]	FIFO Port Access Pipe Specification 0x0: Default Control Pipe 0x1: Pipe 1 0x2: Pipe 2 0x3: Pipe 3 0x4: Pipe 4 0x5: Pipe 5 0x6: Pipe 6 0x7: Pipe 7 0x8: Pipe 8 0x9: Pipe 9 Others: Setting prohibited	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	BIGEND	FIFO Port Endian Control 0: Little endian 1: Big endian	R/W
9	—	This bit is read as 0. The write value should be 0.	R/W
10	MBW	FIFO Port Access Bit Width 0: 8-bit width 1: 16-bit width	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
12	DREQE	DMA/DTC Transfer Request Enable 0: Disable DMA/DTC transfer request 1: Enable DMA/DTC transfer request	R/W
13	DCLRM	Auto Buffer Memory Clear Mode Accessed after Specified Pipe Data is Read 0: Disable auto buffer clear mode 1: Enable auto buffer clear mode	R/W
14	REW	Buffer Pointer Rewind 0: Do not rewind buffer pointer 1: Rewind buffer pointer	W
15	RCNT	Read Count Mode 0: Clear DTLN[8:0] bits in (CFIFOCTR.DTLN[8:0], D0FIFOCTR.DTLN[8:0], D1FIFOCTR.DTLN[8:0]) when all receive data is read from DnFIFO (after read of a single plane in double buffer mode) 1: Decrement DTLN[8:0] bits each time receive data is read from DnFIFO	R/W

Note: S-TYPE-3, P-TYPE-3

The same pipe must not be specified in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected. The pipe number must not be changed while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number to use for reading or writing data through the DnFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, even when an attempt is made to change the CURPIPE[3:0] setting, the current access setting is retained until access is complete.

MBW bit (FIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the DnFIFO port.

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the MBW bit until all of the data is read. Set the CURPIPE[3:0] and MBW bits simultaneously.

When the selected pipe is transmitting, the bit width cannot be changed from 8-bit to 16-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

DREQE bit (DMA/DTC Transfer Request Enable)

The DREQE bit enables or disables issuing of DMA or DTC transfer requests. To enable DMA or DTC transfer requests, set this bit to 1 after setting the CURPIPE[3:0] bits. To change the CURPIPE[3:0] setting, first set this bit to 0.

DCLRM bit (Auto Buffer Memory Clear Mode Accessed after Specified Pipe Data is Read)

The DCLRM bit enables or disables automatic FIFO buffer clearing after data in the selected pipe is read.

When this bit is set to 1, on receiving a zero-length packet while the FIFO buffer assigned to the selected pipe is empty, or when reading of a received short packet is complete while the PIPECFG.BFRE bit is 1, the USBFS sets the BCLR bit in the FIFO port control register to 1.

When using the USBFS with the SOFCFG.BRDYM bit set to 1, set this bit to 0.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double buffering, this setting enables re-reading of the currently-read FIFO buffer plane from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, be sure to check that the FRDY bit is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

The RCNT bit specifies the read mode for the value in the D0FIFOCTL.DTLN bit and D1FIFOCTL.DTLN bit. When accessing DnFIFO with the PIPECFG.BFRE bit set to 1, set the RCNT bit to 0.

36.2.8 CFIFOCTR : CFIFO Port Control Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x022

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BVAL	BCLR	FRDY	—	—	—	—	DTLN[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	DTLN[8:0]	Receive Data Length Indicates the receive data length. The meaning of the values differs depending on the RCNT bit setting in the port select register. For details, see the description of the DTLN[8:0] bits.	R
12:9	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
13	FRDY	FIFO Port Ready 0: FIFO port access disabled 1: FIFO port access enabled	R
14	BCLR	CPU Buffer Clear 0: No operation 1: Clear FIFO buffer on the CPU side	W
15	BVAL	Buffer Memory Valid Flag 0: Invalid (writing 0 has no effect) 1: Writing ended	R/W

Note: S-TYPE-3, P-TYPE-3

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[8:0] bits (Receive Data Length)

The DTLN[8:0] bits indicate the length of the receive data.

While the FIFO buffer is being read, the DTLN[8:0] bits indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1), as follows:

- RCNT = 0

  The USBFS sets the DTLN[8:0] bits to indicate the length of the receive data until the CPU or DMA/DTC has read all of the received data from a single FIFO buffer plane.

  While the PIPECFG.BFRE bit = 1, the USBFS retains the length of the receive data until the BCLR bit is set to 1, even after all the data is read.

- RCNT = 1

  The USBFS decrements the value indicated in the DTLN[8:0] bits each time data is read from the FIFO buffer. The value is decremented by 1 when MBW = 0, and by 2 when MBW = 1.

  The USBFS sets these bits to 0 when all the data is read from one FIFO buffer plane. In double buffer mode, if data is received in one FIFO buffer plane before all of the data is read from the other plane, the USBFS sets these bits to indicate the length of the receive data in the former plane when all of the data is read from the latter plane.

FRDY bit (FIFO Port Ready)

The FRDY bit indicates whether the FIFO port can be accessed by the CPU or DMA/DTC.

In the following cases, the USBFS sets the FRDY bit to 1 but data cannot be read through the FIFO port because there is no data to be read:

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit = 1

In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

BCLR bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU side for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USBFS clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the DCP is the selected pipe, setting the BCLR bit to 1 allows the USBFS to clear the FIFO buffer regardless of whether the CPU or SIE has access rights. To clear the buffer when the SIE has access rights, set the DCPCTR.PID[1:0] bits to 00b (NAK response) before setting the BCLR bit to 1.

When the selected pipe is transmitting, if 1 is written to the BVAL flag and the BCLR bit simultaneously, the USBFS clears the data that is already written, enabling transmission of a zero-length packet.

When the selected pipe is not the DCP, only write 1 to the BCLR bit while the FRDY bit in the FIFO port control register is 1 (set by the USBFS).

BVAL flag (Buffer Memory Valid Flag)

Set the BVAL flag to 1 when data is completely written to the FIFO buffer on the CPU side for the pipe selected in CURPIPE[3:0].

When the selected pipe is transmitting, set this flag to 1 in the following cases:

- To transmit a short packet, set this flag to 1 after data is written
- To transmit a zero-length packet, set this flag to 1 before data is written to the FIFO buffer

The USBFS then switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When data of the maximum packet size is written for the pipe in continuous transfer mode, the USBFS sets the BVAL flag to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

Only write 1 to the BVAL flag while the FRDY bit is 1 (set by the USBFS). When the selected pipe is receiving, do not set the BVAL flag to 1.

36.2.9 DnFIFOCTR : DnFIFO Port Control Register (n = 0, 1)

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x02A + 0x4 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BVAL	BCLR	FRDY	—	—	—	—	DTLN[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	DTLN[8:0]	Receive Data Length Indicates the receive data length. The meaning of the values differs depending on the RCNT bit setting in the port select register. For details, see the description of the DTLN[8:0] bits.	R
12:9	—	These bits are read as 0. The write value should be 0.	R/W
13	FRDY	FIFO Port Ready 0: FIFO port access disabled 1: FIFO port access enabled	R
14	BCLR	CPU Buffer Clear 0: No operation 1: Clear FIFO buffer on the CPU side	R/W*1
15	BVAL	Buffer Memory Valid Flag 0: Invalid (writing 0 has no effect) 1: Writing ended	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Only 0 can be read.

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[8:0] bits (Receive Data Length)

The DTLN[8:0] bits indicate the length of the receive data.

While the FIFO buffer is being read, the DTLN[8:0] bits indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1), as follows:

- RCNT = 0

  The USBFS sets the DTLN[8:0] bits to indicate the length of the receive data until the CPU or DMA/DTC has read all of the received data from a single FIFO buffer plane.

  While the PIPECFG.BFRE bit = 1, the USBFS retains the length of the receive data until the BCLR bit is set to 1, even after all the data is read.

- RCNT = 1

The USBFS decrements the value indicated in the DTLN[8:0] bits each time data is read from the FIFO buffer. The value is decremented by 1 when MBW = 0, and by 2 when MBW = 1.

The USBFS sets these bits to 0 when all the data is read from one FIFO buffer plane. In double buffer mode, if data is received in one FIFO buffer plane before all of the data is read from the other plane, the USBFS sets these bits to indicate the length of the receive data in the former plane when all of the data is read from the latter plane.

FRDY bit (FIFO Port Ready)

The FRDY bit indicates whether the FIFO port can be accessed by the CPU or DMA/DTC.

In the following cases, the USBFS sets the FRDY bit to 1 but data cannot be read through the FIFO port because there is no data to be read:

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit = 1

In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

BCLR bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU side for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USBFS clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the DCP is the selected pipe, setting the BCLR bit to 1 allows the USBFS to clear the FIFO buffer regardless of whether the CPU or SIE has access rights. To clear the buffer when the SIE has access rights, set the DCPCTR.PID[1:0] bits to 00b (NAK response) before setting the BCLR bit to 1.

When the selected pipe is transmitting, if 1 is written to the BVAL flag and the BCLR bit simultaneously, the USBFS clears the data that is already written, enabling transmission of a zero-length packet.

When the selected pipe is not the DCP, only write 1 to the BCLR bit while the FRDY bit in the FIFO port control register is 1 (set by the USBFS).

BVAL flag (Buffer Memory Valid Flag)

Set the BVAL flag to 1 when data is completely written to the FIFO buffer on the CPU side for the pipe selected in CURPIPE[3:0].

When the selected pipe is transmitting, set this flag to 1 in the following cases:

- To transmit a short packet, set this flag to 1 after data is written
- To transmit a zero-length packet, set this flag to 1 before data is written to the FIFO buffer

The USBFS then switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When data of the maximum packet size is written for the pipe in continuous transfer mode, the USBFS sets the BVAL flag to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

Only write 1 to the BVAL flag while the FRDY bit is 1 (set by the USBFS). When the selected pipe is receiving, do not set the BVAL flag to 1.

36.2.10 INTENB0 : Interrupt Enable Register 0

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x030

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	VBSE	RSME	SOFE	DVSE	CTRE	BEMPE	NRDYE	BRDYE	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	BRDYE	Buffer Ready Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
9	NRDYE	Buffer Not Ready Response Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
10	BEMPE	Buffer Empty Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
11	CTRE	Control Transfer Stage Transition Interrupt Enable *1 0: Disable interrupt request 1: Enable interrupt request	R/W
12	DVSE	Device State Transition Interrupt Enable *1 0: Disable interrupt request 1: Enable interrupt request	R/W
13	SOFE	Frame Number Update Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
14	RSME	Resume Interrupt Enable*1 0: Disable interrupt request 1: Enable interrupt request	R/W
15	VBSE	VBUS Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The RSME, DVSE, and CTRE bits can only be set to 1 in device controller mode. Do not set these bits to 1 in host controller mode.

When a status flag in the INTSTS0 register sets to 1 and the associated interrupt request enable bit setting in theINTENB0 register is 1, the USBFS issues a USBFS interrupt request.

Regardless of the INTENB0 register setting, the status flag in the INTSTS0 register sets to 1 in response to a state change that satisfies the associated condition.

When an interrupt request enable bit in the INTENB0 register is switched from 0 to 1 while the associated status flag in the INTSTS0 register is set to 1, a USBFS interrupt is requested.

36.2.11 INTENB1 : Interrupt Enable Register 1

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x032

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	OVRCRE	BCHGE	—	DTCHE	ATTCHE	—	—	—	—	EOFERRE	SIGNE	SACKE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	SACKE	Setup Transaction Normal Response Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
5	SIGNE	Setup Transaction Error Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W

Bit	Symbol	Function	R/W
6	EOFERRE	EOF Error Detection Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
10:7	—	These bits are read as 0. The write value should be 0.	R/W
11	ATTCHE	Connection Detection Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
12	DTCHE	Disconnection Detection Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
13	—	This bit is read as 0. The write value should be 0.	R/W
14	BCHGE	USB Bus Change Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
15	OVRCRE	Overcurrent Input Change Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W

Note: S-TYPE-3, P-TYPE-3
Note: The bits in INTENB1 can only be set to 1 in host controller mode. Do not set these bits to 1 in device controller mode.

INTENB1 specifies the interrupt masks in host controller mode and for the setup transaction.

When a status flag in the INTSTS1 register sets to 1 and the associated interrupt request enable bit setting in theINTENB1 register is 1, the USBFS issues a USBFS interrupt request.

Regardless of the INTENB1 register setting, the status flag in the INTSTS1 register sets to 1 in response to a state change that satisfies the associated condition.

When an interrupt request enable bit in the INTENB1 register is switched from 0 to 1 while the associated status flag in the INTSTS1 register is set to 1, a USBFS interrupt is requested.

Do not enable interrupts in device controller mode.

36.2.12 BRDYENB : BRDY Interrupt Enable Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x036

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPE9 BRDY E	PIPE8 BRDY E	PIPE7 BRDY E	PIPE6 BRDY E	PIPE5 BRDY E	PIPE4 BRDY E	PIPE3 BRDY E	PIPE2 BRDY E	PIPE1 BRDY E	PIPE0 BRDY E
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PIPE0BRDYE	BRDY Interrupt Enable for Pipe 0 0: Disable interrupt request 1: Enable interrupt request	R/W
1	PIPE1BRDYE	BRDY Interrupt Enable for Pipe 1 0: Disable interrupt request 1: Enable interrupt request	R/W
2	PIPE2BRDYE	BRDY Interrupt Enable for Pipe 2 0: Disable interrupt request 1: Enable interrupt request	R/W
3	PIPE3BRDYE	BRDY Interrupt Enable for Pipe 3 0: Disable interrupt request 1: Enable interrupt request	R/W

Bit	Symbol	Function	R/W
4	PIPE4BRDYE	BRDY Interrupt Enable for Pipe 4 0: Disable interrupt request 1: Enable interrupt request	R/W
5	PIPE5BRDYE	BRDY Interrupt Enable for Pipe 5 0: Disable interrupt request 1: Enable interrupt request	R/W
6	PIPE6BRDYE	BRDY Interrupt Enable for Pipe 6 0: Disable interrupt request 1: Enable interrupt request	R/W
7	PIPE7BRDYE	BRDY Interrupt Enable for Pipe 7 0: Disable interrupt request 1: Enable interrupt request	R/W
8	PIPE8BRDYE	BRDY Interrupt Enable for Pipe 8 0: Disable interrupt request 1: Enable interrupt request	R/W
9	PIPE9BRDYE	BRDY Interrupt Enable for Pipe 9 0: Disable interrupt request 1: Enable interrupt request	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The BRDYENB register enables or disables the INTSTS0.BRDY bit to be set to 1 when a BRDY interrupt is detected for each pipe.

When a status flag in the BRDYSTS register sets to 1 and the associated PIPEnBRDYE bit (n = 0 to 9) setting in theBRDYENB register is 1, the INTSTS0.BRDY flag sets to 1. In this case, if the BRDYE bit in INTENB0 is 1, the USBFS generates a BRDY interrupt request. While at least one PIPEnBRDY bit indicates 1, the USB generates the BRDY interrupt request when the associated interrupt request enable bit in the BRDYENB register is changed from 0 to 1 by software.

36.2.13 NRDYENB : NRDY Interrupt Enable Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x038

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPE9NRDYE	PIPE8NRDYE	PIPE7NRDYE	PIPE6NRDYE	PIPE5NRDYE	PIPE4NRDYE	PIPE3NRDYE	PIPE2NRDYE	PIPE1NRDYE	PIPE0NRDYE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PIPE0NRDYE	NRDY Interrupt Enable for Pipe 0 0: Disable interrupt request 1: Enable interrupt request	R/W
1	PIPE1NRDYE	NRDY Interrupt Enable for Pipe 1 0: Disable interrupt request 1: Enable interrupt request	R/W
2	PIPE2NRDYE	NRDY Interrupt Enable for Pipe 2 0: Disable interrupt request 1: Enable interrupt request	R/W
3	PIPE3NRDYE	NRDY Interrupt Enable for Pipe 3 0: Disable interrupt request 1: Enable interrupt request	R/W
4	PIPE4NRDYE	NRDY Interrupt Enable for Pipe 4 0: Disable interrupt request 1: Enable interrupt request	R/W

Bit	Symbol	Function	R/W
5	PIPE5NRDYE	NRDY Interrupt Enable for Pipe 5 0: Disable interrupt request 1: Enable interrupt request	R/W
6	PIPE6NRDYE	NRDY Interrupt Enable for Pipe 6 0: Disable interrupt request 1: Enable interrupt request	R/W
7	PIPE7NRDYE	NRDY Interrupt Enable for Pipe 7 0: Disable interrupt request 1: Enable interrupt request	R/W
8	PIPE8NRDYE	NRDY Interrupt Enable for Pipe 8 0: Disable interrupt request 1: Enable interrupt request	R/W
9	PIPE9NRDYE	NRDY Interrupt Enable for Pipe 9 0: Disable interrupt request 1: Enable interrupt request	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The NRDYENB register enables or disables the INTSTS0.NRDY bit to be set to 1 when a NRDY interrupt is detected for each pipe.

When a status flag in the NRDYSTS register sets to 1 and the associated PIPEnNRDYE (n = 0 to 9) bit setting in theNRDYENB register is 1, the INTSTS0.NRDY flag sets to 1. In this case, if the NRDYE bit in INTENB0 is 1, the USBFS generates a NRDY interrupt request. While at least one PIPEnNRDY bit indicates 1, the USBFS generates the NRDY interrupt request when the associated interrupt request enable bit in the NRDYENB register is changed from 0 to 1 by software.

36.2.14 BEMPENB : BEMP Interrupt Enable Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x03A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPE9BEMPE	PIPE8BEMPE	PIPE7BEMPE	PIPE6BEMPE	PIPE5BEMPE	PIPE4BEMPE	PIPE3BEMPE	PIPE2BEMPE	PIPE1BEMPE	PIPE0BEMPE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PIPE0BEMPE	BEMP Interrupt Enable for Pipe 0 0: Disable interrupt request 1: Enable interrupt request	R/W
1	PIPE1BEMPE	BEMP Interrupt Enable for Pipe 1 0: Disable interrupt request 1: Enable interrupt request	R/W
2	PIPE2BEMPE	BEMP Interrupt Enable for Pipe 2 0: Disable interrupt request 1: Enable interrupt request	R/W
3	PIPE3BEMPE	BEMP Interrupt Enable for Pipe 3 0: Disable interrupt request 1: Enable interrupt request	R/W
4	PIPE4BEMPE	BEMP Interrupt Enable for Pipe 4 0: Disable interrupt request 1: Enable interrupt request	R/W

Bit	Symbol	Function	R/W
5	PIPE5BEMPE	BEMP Interrupt Enable for Pipe 5 0: Disable interrupt request 1: Enable interrupt request	R/W
6	PIPE6BEMPE	BEMP Interrupt Enable for Pipe 6 0: Disable interrupt request 1: Enable interrupt request	R/W
7	PIPE7BEMPE	BEMP Interrupt Enable for Pipe 7 0: Disable interrupt request 1: Enable interrupt request	R/W
8	PIPE8BEMPE	BEMP Interrupt Enable for Pipe 8 0: Disable interrupt request 1: Enable interrupt request	R/W
9	PIPE9BEMPE	BEMP Interrupt Enable for Pipe 9 0: Disable interrupt request 1: Enable interrupt request	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The BEMPENB register enables or disables the INTSTS0.BEMP bit to be set to 1 when a BEMP interrupt is detected for each pipe.

When a status flag in the BEMPSTS register sets to 1 and the associated PIPEnBEMPE (n = 0 to 9) bit setting in the BEMPENB register is 1, the INTSTS0.BEMP flag sets to 1. In this case, if the BEMPE bit in INTENB0 is 1, the USBFS generates a BEMP interrupt request. While at least one PIPEnBEMP bit indicates 1, the USBFS generates the BEMP interrupt request when the associated interrupt request enable bit in the BEMPENB register is changed from 0 to 1 by software.

36.2.15 SOFCFG : SOF Output Configuration Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x03C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TRNENSEL	—	BRDYM	—	EDGESTS	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	EDGESTS	Edge Interrupt Output Status Monitor*1 Indicates 1 during the edge processing of an edge interrupt output signal.	R
5	—	This bit is read as 0. The write value should be 0.	R/W
6	BRDYM	BRDY Interrupt Status Clear Timing 0: Clear BRDY flag by software 1: Clear BRDY flag by the USBFS through a data read from the FIFO buffer or data write to the FIFO buffer	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	TRNENSEL	Transaction-Enabled Time Select*1 0: Not low-speed communication 1: Low-speed communication	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Confirm that the EDGESTS flag is 0 before stopping the clock supply to the USBFS.

EDGESTS bit (Edge Interrupt Output Status Monitor)

The EDGESTS bit indicates 1 during the edge processing of an edge interrupt output signal. Confirm that this bit is 0 before stopping the clock supply to the USBFS.

BRDYM bit (BRDY Interrupt Status Clear Timing)

The BRDYM bit specifies how the BRDY interrupt status flags for the pipes are cleared.

TRNENSEL bit (Transaction-Enabled Time Select)

When the USB port is in use for full- or low-speed communications, the TRNENSEL bit specifies the timing with which the USBFS issues tokens in a frame (transaction-enabled time).

Set this bit to 1 when a low-speed device is connected. The bit is only valid in host controller mode. Set this bit to 0 in device controller mode.

36.2.16 INTSTS0 : Interrupt Status Register 0

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x040

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	VBINT	RESM	SOFR	DVST	CTRT	BEMP	NRDY	BRDY	VBSTS	DVSQ[2:0]			VALID	CTSQ[2:0]		
Value after reset:	0	0	0	x	0	0	0	0	x	0	0	x	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CTSQ[2:0]	Control Transfer Stage 0 0 0: Idle or setup stage 0 0 1: Control read data stage 0 1 0: Control read status stage 0 1 1: Control write data stage 1 0 0: Control write status stage 1 0 1: Control write (no data) status stage 1 1 0: Control transfer sequence error	R
3	VALID	USB Request Reception 0: Setup packet not received 1: Setup packet received	R/W
6:4	DVSQ[2:0]	Device State Indicates the device state. 0 0 0: Powered state 0 0 1: Default state 0 1 0: Address state 0 1 1: Configured state Others: Suspend state	R
7	VBSTS	VBUS Input Status 0: USB_VBUS pin is low 1: USB_VBUS pin is high	R
8	BRDY	Buffer Ready Interrupt Status 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R
9	NRDY	Buffer Not Ready Interrupt Status 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R
10	BEMP	Buffer Empty Interrupt Status 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R
11	CTRT	Control Transfer Stage Transition Interrupt Status*2 0: No control transfer stage transition interrupt occurred 1: Control transfer stage transition interrupt occurred	R/W*1

Bit	Symbol	Function	R/W
12	DVST	Device State Transition Interrupt Status*2 0: No device state transition interrupt occurred 1: Device state transition interrupt occurred	R/W*1
13	SOFR	Frame Number Refresh Interrupt Status 0: No SOF interrupt occurred 1: SOF interrupt occurred	R/W*1
14	RESM	Resume Interrupt Status*2 *3 0: No resume interrupt occurred 1: Resume interrupt occurred	R/W*1
15	VBINT	VBUS Interrupt Status*3 0: No VBUS interrupt occurred 1: VBUS interrupt occurred	R/W*1

Note: S-TYPE-3, P-TYPE-3

Note: The value of the DVST bit is 0 when the MCU is reset and 1 after a USB bus reset.

Note: The value of the VBSTS bit is 1 when the USB_VBUS pin is high and 0 when the USB_VBUS pin is low.

Note: The value of the DVSQ[2:0] bits is 000b when the MCU is reset and 001b after a USB bus reset.

Note 1. To clear the VBINT, RESM, SOFR, DVST, CTRT, or VALID bits, write 0 only to the bits to be cleared. Write 1 to the other bits. Do not write 0 to the status bits indicating 0.

Note 2. The status of the RESM, DVST, and CTRT bits are changed only in device controller mode. Set the associated interrupt enable bits to 0 (disabled) in host controller mode.

Note 3. The USBFS detects a change in the status indicated in the VBINT andRESM bits even while the clock supply is stopped (SYSCFG.SCKE bit = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply before clearing the status by software.

CTSQ[2:0] bits (Control Transfer Stage)

In host controller mode, the read value of the CTSQ[2:0] bits is invalid.

VALID bit (USB Request Reception)

In host controller mode, the read value of the VALID bit is invalid.

DVSQ[2:0] bits (Device State)

The DVSQ[2:0] bits are initialized by a USB bus reset. In host controller mode, the read value is invalid.

BRDY flag (Buffer Ready Interrupt Status)

The BRDY flag indicates the BRDY interrupt status.

The USBFS sets the BRDY bit to 1 when it detects a BRDY interrupt status (PIPEnBRDY = 1, n = 0 to 9) on at least one pipe for which BRDY interrupts are enabled (BRDYENB.PIPEnBRDYE = 1).

For the conditions that cause the PIPEnBRDY status to be asserted, see section 36.3.3.1. BRDY Interrupt.

The USBFS sets the BRDY bit to 0 when the software writes 0 to all of the PIPEnBRDY bits associated with the PIPEnBRDYE bits that are set to 1. Writing 0 to the BRDY flag in the software does not clear the flag.

NRDY flag (Buffer Not Ready Interrupt Status)

The NRDY flag indicates the NRDY interrupt status.

The USBFS sets the NRDY bit to 1 when it detects a NRDY interrupt status (PIPEnNRDY = 1, n = 0 to 9) on at least one pipe for which NRDY interrupts are enabled (NRDYENB.PIPEnNRDYE = 1).

For the conditions that cause the PIPEnNRDY status to be asserted, see section 36.3.3.2. NRDY Interrupt.

The USBFS sets the NRDY bit to 0 when the software writes 0 to all of the PIPEnNRDY bits associated with the PIPEnNRDYE bits that are set to 1. Writing 0 to the NRDY flag in the software does not clear the flag.

BEMP flag (Buffer Empty Interrupt Status)

The BEMP flag indicates the BEMP interrupt status.

The USBFS sets the BEMP bit to 1 when it detects a BEMP interrupt status (PIPEnBEMP = 1, n = 0 to 9) on at least one pipe for which BEMP interrupts are enabled (BEMPENB.PIPEnBEMPE = 1).

For the conditions that cause the PIPEnBEMP status to be asserted, see section 36.3.3.3. BEMP Interrupt.

The USBFS sets the BEMP bit to 0 when the software writes 0 to all of the PIPEnBEMP bits associated with the PIPEnBEMPE bits that are set to 1. Writing 0 to the BEMP flag in the software does not clear the flag.

CTRT flag (Control Transfer Stage Transition Interrupt Status)

In device controller mode, the USBFS updates the value of the CTSQ[2:0] bits and sets the CTRT flag to 1 on detecting a transition in the control transfer stage. When a control transfer stage transition interrupt occurs, clear the CTRT flag before the USBFS detects the next control transfer stage transition.

Values read from the CTRT flag in host controller mode are invalid.

DVST flag (Device State Transition Interrupt Status)

In device controller mode, the USBFS updates the value of the DVSQ[2:0] bits and sets the DVST flag to 1 on detecting a change in the device state. When a device state transition interrupt occurs, clear theDVST flag before the USBFS detects the next device state transition.

Values read from the DVST flag in host controller mode are invalid.

SOFR flag (Frame Number Refresh Interrupt Status)

In host controller mode, the USBFS sets the SOFR flag to 1 on updating the frame number when the DVSTCTR0.UACT bit is set to 1 by software. A SOFR interrupt is detected every 1 ms.

In device controller mode, the USBFS sets the SOFR flag to 1 on updating the frame number. A frame number refresh interrupt is detected every 1 ms.

The USBFS can detect an SOFR interrupt through the internal interpolation function even when a corrupted SOF packet is received from the USB host.

RESM flag (Resume Interrupt Status)

In device controller mode, the USBFS sets the RESM flag to 1 on detecting the falling edge of the signal on the USB_DP pin in the Suspend state (DVSQ[2:0] = 1xxb). Values read from the RESM flag in host controller mode are invalid.

VBINT flag (VBUS Interrupt Status)

The USBFS sets the VBINT flag to 1 on detecting a level change (high to low or low to high) in the USB_VBUS pin input value. The USBFS sets the VBSTS flag to indicate the USB_VBUS pin input value. When a VBUS interrupt occurs, eliminate transient elements by reading the VBSTS flag at least three times through software processing and check that the values read are the same.

36.2.17 INTSTS1 : Interrupt Status Register 1

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x042

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	OVRCR	BCHG	—	DTCH	ATTCH	—	—	—	—	EOFERR	SIGN	SACK	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	SACK	Setup Transaction Normal Response Interrupt Status 0: No SACK interrupt occurred 1: SACK interrupt occurred	R/W*1
5	SIGN	Setup Transaction Error Interrupt Status 0: No SIGN interrupt occurred 1: SIGN interrupt occurred	R/W*1
6	EOFERR	EOF Error Detection Interrupt Status 0: No EOFERR interrupt occurred 1: EOFERR interrupt occurred	R/W*1

Bit	Symbol	Function	R/W
10:7	—	These bits are read as 0. The write value should be 0.	R/W
11	ATTCH	ATTCH Interrupt Status 0: No ATTCH interrupt occurred 1: ATTCH interrupt occurred	R/W*1
12	DTCH	USB Disconnection Detection Interrupt Status 0: No DTCH interrupt occurred 1: DTCH interrupt occurred	R/W*1
13	—	This bit is read as 0. The write value should be 0.	R/W
14	BCHG	USB Bus Change Interrupt Status*2 0: No BCHG interrupt occurred 1: BCHG interrupt occurred	R/W*1
15	OVRCR	Overcurrent Input Change Interrupt Status*2 0: No OVRCR interrupt occurred 1: OVRCR interrupt occurred	R/W*1

Note: S-TYPE-3, P-TYPE-3

Note 1. To clear the bits in INTSTS1, write 0 only to the bits to be cleared. Write 1 to the other bits.

Note 2. The USBFS detects a change in the status in the OVRCR or BCHG bit even when the clock supply is stopped (SYSCFG.SCKE = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply (SYSCFG.SCKE = 1) before clearing the status through the software. No other interrupts can be detected while the clock supply is stopped (SYSCFG.SCKE bit = 0).

INTSTS1 is used to confirm the status of each interrupt in host controller mode. Only enable the status change interrupts indicated in the bits in INTSTS1 in host controller mode.

SACK flag (Setup Transaction Normal Response Interrupt Status)

The SACK flag indicates the status of the setup transaction normal response interrupt in host controller mode.

The USBFS detects the SACK interrupt and sets this flag to 1 when an ACK response is returned from a peripheral device during the setup transactions issued by the USBFS. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

Values read from the SACK flag in device controller mode are invalid.

SIGN flag (Setup Transaction Error Interrupt Status)

The SIGN flag indicates the status of setup transaction error interrupts in host controller mode.

The USBFS detects the SIGN interrupt and sets this flag to 1 when an ACK response is not returned from a peripheral device three consecutive times during the setup transactions issued by the USBFS. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects the SIGN interrupt when any of the following response conditions occur for three consecutive setup transactions:

- Timeout is detected by the USBFS when the peripheral device has returned no response
- A corrupted ACK packet is received
- A handshake other than ACK (NAK, NYET, or STALL) is received

Values read from the SIGN flag in device controller mode are invalid.

EOFERR flag (EOF Error Detection Interrupt Status)

The EOFERR flag indicates the status of EOF error detection interrupts in host controller mode.

The USBFS detects the EOFERR interrupt and sets this flag to 1 on detecting that communication did not complete at the EOF2 timing defined in the USB 2.0 specification. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

After detecting the EOFERR interrupt, the USBFS controls the hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt was detected to 0
- Puts the port in which the EOFERR interrupt occurred into the idle state

The software must terminate all pipes in which communications are being carried out and re-enumerate the USB port.

Values read from the EOFERR flag in device controller mode are invalid.

ATTCH flag (ATTCH Interrupt Status)

The ATTCH flag indicates the status of USB attach detection interrupts in host controller mode.

The USBFS detects the ATTCH interrupt and sets this flag to 1 on detecting a J- or K-state on the full- or low-speed signal level for 2.5 µs. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects the ATTCH interrupt on any of the following conditions.

- K-state, SE0, or SE1 changes to J-state, and J-state continues for 2.5 µs
- J-state, SE0, or SE1 changes to K-state, and K-state continues for 2.5 µs

Values read from the ATTCH flag in device controller mode are invalid.

DTCH flag (USB Disconnection Detection Interrupt Status)

The DTCH flag indicates the status of USB disconnection detection interrupts in host controller mode.

The USBFS detects the DTCH interrupt and sets this flag to 1 on detecting a USB bus detach event. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects bus detach events based on the USB 2.0 specification.

After detecting the DTCH interrupt, the USBFS controls hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt was detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

The software must terminate all pipes in which communications are being carried out and transition to a wait state for connecting to the USB port (waiting for ATTCH interrupt generation).

Values read from the DTCH flag in device controller mode are invalid.

BCHG flag (USB Bus Change Interrupt Status)

The BCHG flag indicates the status of USB bus change interrupts in host controller mode.

The USBFS detects the BCHG interrupt and sets this flag to 1 when a change in the full- or low-speed signal level occurs on the USB port. This includes any change from J-state, K-state, or SE0 to J-state, K-state, or SE0. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS sets the LNST[1:0] flags to indicate the input state of the USB port. When a BCHG interrupt occurs, eliminate transient elements by repeat reading the LNST[1:0] flags by software until the same value is read at least three times.

Change in the USB bus state can be detected while the internal clock is stopped.

Values read from the BCHG flag in device controller mode are invalid.

OVRCR flag (Overcurrent Input Change Interrupt Status)

The OVRCR flag indicates the status of USB_OVRCURA, USB_OVRCURA-DS, USB_OVRCURB or USB_OVRCURB-DS input pin change interrupts.

The USBFS detects the OVRCR interrupt and sets this flag to 1 when a change (high to low or low to high) occurs in at least one of the input values to the USB_OVRCURA, USB_OVRCURA-DS, USB_OVRCURB or USB_OVRCURB-DS pins. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

36.2.18 BRDYSTS : BRDY Interrupt Status Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x046

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPE9 BRDY	PIPE8 BRDY	PIPE7 BRDY	PIPE6 BRDY	PIPE5 BRDY	PIPE4 BRDY	PIPE3 BRDY	PIPE2 BRDY	PIPE1 BRDY	PIPE0 BRDY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PIPE0BRDY	BRDY Interrupt Status for Pipe 0 *2 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R/W*1
1	PIPE1BRDY	BRDY Interrupt Status for Pipe 1 *2 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R/W*1
2	PIPE2BRDY	BRDY Interrupt Status for Pipe 2*2 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R/W*1
3	PIPE3BRDY	BRDY Interrupt Status for Pipe 3*2 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R/W*1
4	PIPE4BRDY	BRDY Interrupt Status for Pipe 4 *2 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R/W*1
5	PIPE5BRDY	BRDY Interrupt Status for Pipe 5 *2 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R/W*1
6	PIPE6BRDY	BRDY Interrupt Status for Pipe 6*2 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R/W*1
7	PIPE7BRDY	BRDY Interrupt Status for Pipe 7 *2 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R/W*1
8	PIPE8BRDY	BRDY Interrupt Status for Pipe 8 *2 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R/W*1
9	PIPE9BRDY	BRDY Interrupt Status for Pipe 9 *2 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R/W*1
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. When the SOFCFG.BRDYM bit is set to 0, to clear the status indicated in the bits in BRDYSTS, write 0 only to the bits to be cleared. Write 1 to the other bits.

Note 2. When the SOFCFG.BRDYM bit is set to 0, clear BRDY interrupts before accessing the FIFO.

36.2.19 NRDYSTS : NRDY Interrupt Status Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x048

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPE9 NRDY	PIPE8 NRDY	PIPE7 NRDY	PIPE6 NRDY	PIPE5 NRDY	PIPE4 NRDY	PIPE3 NRDY	PIPE2 NRDY	PIPE1 NRDY	PIPE0 NRDY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PIPE0NRDY	NRDY Interrupt Status for Pipe 0 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R/W*1
1	PIPE1NRDY	NRDY Interrupt Status for Pipe 1 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R/W*1
2	PIPE2NRDY	NRDY Interrupt Status for Pipe 2 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R/W*1
3	PIPE3NRDY	NRDY Interrupt Status for Pipe 3 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R/W*1
4	PIPE4NRDY	NRDY Interrupt Status for Pipe 4 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R/W*1
5	PIPE5NRDY	NRDY Interrupt Status for Pipe 5 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R/W*1
6	PIPE6NRDY	NRDY Interrupt Status for Pipe 6 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R/W*1
7	PIPE7NRDY	NRDY Interrupt Status for Pipe 7 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R/W*1
8	PIPE8NRDY	NRDY Interrupt Status for Pipe 8 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R/W*1
9	PIPE9NRDY	NRDY Interrupt Status for Pipe 9 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R/W*1
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. To clear the status indicated in the bits in NRDYSTS, write 0 only to the bits to be cleared. Write 1 to the other bits.

36.2.20 BEMPSTS : BEMP Interrupt Status Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x04A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPE9 BEMP	PIPE8 BEMP	PIPE7 BEMP	PIPE6 BEMP	PIPE5 BEMP	PIPE4 BEMP	PIPE3 BEMP	PIPE2 BEMP	PIPE1 BEMP	PIPE0 BEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PIPE0BEMP	BEMP Interrupt Status for Pipe 0 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R/W*1
1	PIPE1BEMP	BEMP Interrupt Status for Pipe 1 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R/W*1
2	PIPE2BEMP	BEMP Interrupt Status for Pipe 2 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R/W*1
3	PIPE3BEMP	BEMP Interrupt Status for Pipe 3 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R/W*1
4	PIPE4BEMP	BEMP Interrupt Status for Pipe 4 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R/W*1
5	PIPE5BEMP	BEMP Interrupt Status for Pipe 5 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R/W*1
6	PIPE6BEMP	BEMP Interrupt Status for Pipe 6 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R/W*1
7	PIPE7BEMP	BEMP Interrupt Status for Pipe 7 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R/W*1
8	PIPE8BEMP	BEMP Interrupt Status for Pipe 8 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R/W*1
9	PIPE9BEMP	BEMP Interrupt Status for Pipe 9 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R/W*1
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. To clear the status indicated in the bits in BEMPSTS, write 0 only to the bits to be cleared. Write 1 to the other bits.

36.2.21 FRMNUM : Frame Number Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x04C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	OVRN	CRCE	—	—	—	FRNM[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	FRNM[10:0]	Frame Number Latest frame number.	R
13:11	—	These bits are read as 0. The write value should be 0.	R/W
14	CRCE	Receive Data Error 0: No error occurred 1: Error occurred	R/W*1
15	OVRN	Overrun/Underrun Detection Status 0: No error occurred 1: Error occurred	R/W*1

Note: S-TYPE-3, P-TYPE-3
Note 1. To clear the status, write 0 only to the bits to be cleared. Write 1 to the other bits.

FRNM[10:0] flags (Frame Number)

The USBFS sets the FRNM[10:0] flags to indicate the latest frame number, which is updated every 1 ms, when an SOF packet is issued or received.

CRCE flag (Receive Data Error)

The CRCE flag sets to 1 when a CRC error or bit stuffing error occurs during isochronous transfer. On detecting a CRC error in host controller mode, the USBFS generates an internal NRDY interrupt.

To clear the CRCE flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

OVRN flag (Overrun/Underrun Detection Status)

The OVRN flag sets to 1 when an overrun or underrun error occurs during isochronous transfer. To clear the flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

In host controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the time to issue an OUT token comes before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the time to issue an IN token comes when no FIFO buffer planes are empty

In device controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the IN token is received before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the OUT token is received when no FIFO buffer planes are empty

36.2.22 DVCHGR : Device State Change Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x04E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DVCHG	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
14:0	—	These bits are read as 0. The write value should be 0.	R/W
15	DVCHG	Device State Change 0: Disable writes to the USBADDR.STSRECOV[3:0] and USBADDR.USBADDR[6:0] bits 1: Enable writes to the USBADDR.STSRECOV[3:0] and USBADDR.USBADDR[6:0] bits	R/W

Note: S-TYPE-3, P-TYPE-3

For details, see section 36.3.1.5. Release from Deep Software Standby Mode 1 Because of USB Suspend/Resume Interrupts.

36.2.23 USBADDR : USB Address Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x050

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	STSRECOV[3:0]				—	USBADDR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	USBADDR[6:0]	USB Address In device controller mode, these bits indicate the USB address assigned by the host when the USBFS processed the SET_ADDRESS request successfully.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
11:8	STSRECOV[3:0]	Status Recovery 0x4: Recovery in device controller mode: Setting prohibited Recovery in host controller mode: Return to the low-speed state (bits DVSTCTR0.RHST[2:0] = 001b) 0x8: Recovery in device controller mode: Setting prohibited Recovery in host controller mode: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b) 0x9: Recovery in device controller mode: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b), bits INTSTS0.DVSQ[2:0] = 001b (default state) Recovery in host controller mode: Setting prohibited 0xA: Recovery in device controller mode: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b), bits INTSTS0.DVSQ[2:0] = 010b (address state) Recovery in host controller mode: Setting prohibited 0xB: Recovery in device controller mode: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b), bits INTSTS0.DVSQ[2:0] = 011b (configured state) Recovery in host controller mode: Setting prohibited Others: Setting prohibited	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

USBADDR[6:0] bits (USB Address)

In device controller mode, the USBADDR[6:0] flags indicate the USB address received when the USBFS processed a SetAddress request successfully. The USBFS sets the USBADDR[6:0] bits to 0x00 on detecting a USB bus reset.

Writing to these bits is enabled while the DVCHGR.DVCHG bit is set to 1. On recovering from a USB power shut-off, the operation can resume from the USB address set before the software shut-off.

In host controller mode, the USBADDR[6:0] bits are invalid.

STSRECOV[3:0] bits (Status Recovery)

Use the STSRECOV[3:0] bits to resume the state of the internal sequencer on recovering from USB power shut-off. For details, see section 36.3.1.5. Release from Deep Software Standby Mode 1 Because of USB Suspend/Resume Interrupts.

Writing to these bits is enabled while the DVCHGR.DVCHG bit is set to 1.

36.2.24 USBREQ : USB Request Type Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x054

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BREQUEST[7:0]								BMREQUESTTYPE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	BMREQUESTTYPE [7:0]	Request Type USB request bmRequestType value	R/W*1
15:8	BREQUEST[7:0]	Request USB request bRequest value	R/W*1

Note: S-TYPE-3, P-TYPE-3

Note 1. In device controller mode, these bits can be read, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

USBREQ stores setup requests for control transfers.

In device controller mode, the USBREQ stores the received bRequest and bmRequestType values. In host controller mode, it sets to the bRequest and bmRequestType values to be transmitted.

USBREQ is initialized by a USB bus reset.

BMREQUESTTYPE[7:0] bits (Request Type)

The BMREQUESTTYPE[7:0] bits hold the bmRequestType value of USB requests.

- In host controller mode:

  Set these bits to the value of the USB request data in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.

- In device controller mode:

  These bits indicate the value of the USB request data in reception setup transactions. Writing to the bits has no effect.

BREQUEST[7:0] bits (Request)

The BREQUEST[7:0] bits store bRequest value of the USB request.

- In host controller mode:

  Set these bits to the value of the USB request data in setup transmission transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.

- In device controller mode:

  These bits indicate the value of the USB request data in reception setup transactions. Writing to the bits has no effect.

36.2.25 USBVAL : USB Request Value Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x056

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WVALUE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WVALUE[15:0]	Value USB request wValue value	R/W*1

Note: S-TYPE-3, P-TYPE-3

Note 1. In device controller mode, these bits can be read, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

In device controller mode, USBVAL stores the received wValue value. In host controller mode, it sets to the wValue value to be transmitted is set.

USBVAL is initialized by a USB bus reset.

WVALUE[15:0] bits (Value)

The WVALUE[15:0] bits store wValue value of the USB request.

- In host controller mode:

  Set these bits to the value of the wValue field in USB requests of transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.

- In device controller mode:

These bits indicate the wValue value of USB requests in reception setup transactions. Writing to the bits has no effect.

36.2.26 USBINDX : USB Request Index Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x058

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WINDEX[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WINDEX[15:0]	Index USB request wIndex value	R/W*1

Note: S-TYPE-3, P-TYPE-3

Note 1. In device controller mode, these bits can be read, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

USBINDX stores setup requests for control transfers.

In device controller mode, it stores the received wIndex value. In host controller mode, it sets to the wIndex value to be transmitted.

USBINDX is initialized by a USB bus reset.

WINDEX[15:0] bits (Index)

The WINDEX[15:0] bits hold the wIndex value of a USB request.

- In host controller mode:

  Set these bits to the wIndex value in USB requests in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.

- In device controller mode:

  These bits indicate the wIndex value in USB requests received in reception setup transactions. Writing to the bits has no effect.

36.2.27 USBLENG : USB Request Length Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x05A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WLENTUH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WLENTUH[15:0]	Length USB request wLength value	R/W*1

Note: S-TYPE-3, P-TYPE-3

Note 1. In device controller mode, these bits can be read, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

USBLENG stores setup requests for control transfers.

In device controller mode, the value of wLength that is received is stored. In host controller mode, the value of wLength to be transmitted is set.

USBLENG is initialized by a USB bus reset.

WLENTUH[15:0] bits (Length)

The WLENTUH[15:0]bits hold the wLength value of a USB request.

- In host controller mode:

  Set these bits to the wLength value in USB requests in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.

- In device controller mode:

  These bits indicate the wLength value in USB requests received in reception setup transactions. Writing to the bits has no effect.

36.2.28 DCPCFG : DCP Configuration Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x05C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	SHTNAK	—	—	DIR	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	DIR	Transfer Direction*1 0: Data receiving direction 1: Data transmitting direction	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	SHTNAK	Pipe Disabled at End of Transfer*1 0: Keep pipe open after transfer ends 1: Disable pipe after transfer ends	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Only set this bit while the PID is NAK. Before setting this bit, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

DIR bit (Transfer Direction)

In host controller mode, the DIR bit sets the transfer direction of the data stage and status stage for control transfers. In device controller mode, set the DIR bit to 0.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change PID to NAK on transfer end when the selected pipe is receiving. It is only valid when the selected pipe is receiving.

When the SHTNAK bit is 1, the USBFS changes the DCPCTR.PID[1:0] bits for the DCP to NAK on determining that a transfer has ended. The USBFS determines transfer end on the following condition:

- A short packet, including a zero-length packet, is successfully received.

36.2.29 DCPMAXP : DCP Maximum Packet Size Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x05E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DEVSEL[3:0]				—	—	—	—	—	MXPS[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	MXPS[6:0]	Maximum Packet Size*1 Maximum data payload specification (maximum packet size) for the DCP	R/W
11:7	—	These bits are read as 0. The write value should be 0.	R/W
15:12	DEVSEL[3:0]	Device Select*2 0x0: Address 0000b 0x1: Address 0001b 0x2: Address 0010b 0x3: Address 0011b 0x4: Address 0100b 0x5: Address 0101b Others: Setting prohibited	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Only set the MXPS[6:0] bits while PID is NAK. Before setting these bits, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary. After the MXPS[6:0] bits are set and the DCP is set to the CURPIPE[3:0] bits in a port select register, clear the buffer by setting the BCLR bit in the port control register to 1.

Note 2. Only set the DEVSEL[3:0] bits while PID is NAK and the DCPCTR.SUREQ bit is 0. Before setting these bits, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

MXPS[6:0] bits (Maximum Packet Size)

The MXPS[6:0] bits specify the maximum data payload (maximum packet size) for the DCP. The initial value is 0x40 (64 bytes). Set the bits to a USB 2.0-compliant value. Do not write to the FIFO buffer or set PID = BUF whileMXPS[6:0] is set to 0.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target peripheral device for a control transfer. Set up the associated DEVADDn (n = 0 to 5) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0010b, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0000b.

36.2.30 DCPCTR : DCP Control Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x060

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BSTS	SUREQ	—	—	SUREQCLR	—	—	SQCLR	SQSET	SQMON	PBUSY	—	—	CCPL	PID[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PID[1:0]	Response PID 0 0: NAK response 0 1: BUF response (depends on the buffer state) 1 0: STALL response 1 1: STALL response	R/W
2	CCPL	Control Transfer End Enable 0: Disable control transfer completion 1: Enable control transfer completion	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	PBUSY	Pipe Busy 0: DCP not used for the USB bus 1: DCP in use for the USB bus	R
6	SQMON	Sequence Toggle Bit Monitor 0: DATA0 1: DATA1	R
7	SQSET	Sequence Toggle Bit Set*2 Sets the sequence toggle bit in DCP transfers. 0: Invalid (writing 0 has no effect) 1: Set the expected value for the next transaction to DATA1	R/W*1
8	SQCLR	Sequence Toggle Bit Clear*2 Clears the sequence toggle bit in DCP transfers. 0: Invalid (writing 0 has no effect) 1: Clear the expected value for the next transaction to DATA0	R/W*1
10:9	—	These bits are read as 0. The write value should be 0.	R/W
11	SUREQCLR	SUREQ Bit Clear Clears the SUREQ bit in host controller mode. 0: Invalid (writing 0 has no effect) 1: Clear SUREQ to 0	R/W*1
13:12	—	These bits are read as 0. The write value should be 0.	R/W
14	SUREQ	Setup Token Transmission Sets up token transmission in host controller mode. 0: Invalid (writing 0 has no effect) 1: Transmit setup packet	R/W
15	BSTS	Buffer Status 0: Buffer access disabled 1: Buffer access enabled	R

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit is read as 0.
Note 2. Only set the SQSET and SQCLR bits while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

PID[1:0] bits (Response PID)

The PID[1:0] bits control the USB response type during control transfers.

In host controller mode, to change the PID[1:0] setting from NAK to BUF:

- When the transmitting direction is set:
  a. Write all of the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
     The USBFS then executes the OUT transaction.
- When the receiving direction is set:
  a. Check that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
     The USBFS then executes the IN transaction.

The USBFS changes the PID[1:0] setting as follows:

- When the PID[1:0] bits are set to BUF (01b) by software and the USBFS has received data exceeding MaxPacketSize, the USBFS sets the PID[1:0] to STALL (11b)
- When a reception error, such as a CRC error, is detected three times consecutively, the USBFS sets thePID[1:0] bits to NAK (00b)
- On receiving the STALL handshake, the USBFS sets PID[1:0] to STALL (11b)

In device controller mode, the USBFS changes the PID[1:0] setting as follows:

- On receiving a setup packet, the USBFS sets PID[1:0] to NAK (00b). The USBFS then sets the INTSTS0.VALID flag to 1, and the PID[1:0] setting cannot be changed until the software clears the VALID flag to 0.
- When the PID[1:0] bits are set to BUF (01b) by software and the USBFS has received data exceeding MaxPacketSize, the USBFS sets PID[1:0] to STALL (11b)
- On detecting a control transfer sequence error, the USBFS sets PID[1:0] to STALL (1xb)
- On detecting a USB bus reset, the USBFS sets PID[1:0] to NAK

The USBFS does not check the PID[1:0] setting while processing a SET_ADDRESS request.

The PID[1:0] bits are initialized by a USB bus reset.

CCPL bit (Control Transfer End Enable)

In device controller mode, setting the CCPL bit to 1 enables the status stage of the control transfer to be completed. When the bit is set to 1 by software while the associated PID[1:0] bits are set to BUF, the USBFS completes the control transfer status stage.

During control read transfers, the USBFS transmits the ACK handshake in response to the OUT transaction from the USB host. During control write or no-data control transfers, it transmits the zero-length packet in response to the IN transaction from the USB host. On detecting a SET_ADDRESS request, the USBFS operates in auto response mode from the setup stage up to status stage completion regardless of the CCPL bit setting.

The USBFS changes the CCPL bit from 1 to 0 on receiving a new setup packet. The software cannot write 1 to the bit while the INTSTS0.VALID bit is 1. The bit is initialized by a USB bus reset.

In host controller mode, always write 0 to the CCPL bit.

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether DCP is used for the transaction when USBFS changes the PID[1:0] bits from BUF to NAK. The USBFS changes the PBUSY bit from 0 to 1 on start of a USB transaction for the selected pipe. It changes the PBUSY bit from 1 to 0 on completion of one transaction.

After PID is set to NAK by software, the value in the PBUSY bit indicates whether changes to pipe settings can proceed.

For details, see section 36.3.4.1. Pipe Control Register Switching Procedures.

SQMON bit (Sequence Toggle Bit Monitor)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

The USBFS toggles the bit on normal completion of the transaction. It does not toggle the bit, however, when a DATAPID mismatch occurs during a transfer in the receiving direction.

In device controller mode, the USBFS sets the SQMON bit to 1 (specifies DATA1 as the expected value) on successful reception of the setup packet.

In device controller mode, the USBFS does not reference this bit during IN or OUT transactions at the status stage, and it does not toggle the bit on normal completion.

SQSET bit (Sequence Toggle Bit Set)

The SQSET bit specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SQCLR bit (Sequence Toggle Bit Clear)

The SQCLR bit specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer. It is read as 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SUREQCLR bit (SUREQ Bit Clear)

In host controller mode, setting the SUREQCLR bit to 1 clears the SUREQ bit to 0. The bit is read as 0.

If transfer stops while the SUREQ bit is set to 1 in a setup transaction, set the SUREQCLR bit to 1 by software. This is not necessary at the end of a normal setup transaction, because the USBFS automatically clears the SUREQ bit to 0.

Only control the SUREQ bit through the SUREQCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a bus disconnection was detected.

In device controller mode, always write 0 to this bit.

SUREQ bit (Setup Token Transmission)

In host controller mode, setting the SUREQ bit to 1 triggers the USBFS to transmit the setup packet. After completing the setup transaction process, the USBFS generates either the SACK or SIGN interrupt and clears the SUREQ bit to 0. The USBFS also clears the SUREQ bit to 0 when the software sets the SUREQCLR bit to 1.

Before setting the SUREQ bit to 1, set the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, and USBLENG appropriately to transmit the target USB request in the setup transaction. Also check that the PID[1:0] bits for the DCP are set to NAK. After setting the SUREQ bit to 1, do not change the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, or USBLENG until the setup transaction is complete (SUREQ bit = 1). Write 1 to the SUREQ bit only when transmitting the setup token. Otherwise, write 0.

In device controller mode, always write 0 to this bit.

BSTS flag (Buffer Status)

The BSTS flag indicates the status of access to the DCP FIFO buffer. The meaning of this flag varies as follows depending on the CFIFOSEL.ISEL setting:

- When ISEL = 0, the bit indicates whether receive data can be read from the buffer
- When ISEL = 1, the bit indicates whether transmit data can be written to the buffer

36.2.31 PIPESEL : Pipe Window Select Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x064

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	PIPESEL[3:0]	Pipe Window Select 0x0: No pipe selected 0x1: Pipe 1 0x2: Pipe 2 0x3: Pipe 3 0x4: Pipe 4 0x5: Pipe 5 0x6: Pipe 6 0x7: Pipe 7 0x8: Pipe 8 0x9: Pipe 9 Others: Setting prohibited	R/W
15:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Set pipes 1 to 9 using the PIPESEL, PIPECFG, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN registers (n = 1 to 9).

After selecting the pipe in the PIPESEL register, pipe functions must be set in the associated PIPECFG, PIPEMAXP, and PIPEPERI registers. PIPEnCTR, PIPEnTRE, and PIPEnTRN can be set independently of the pipe selection in this register.

PIPESEL[3:0] bits (Pipe Window Select)

The PIPESEL[3:0] bits select the pipe number associated with the PIPECFG, PIPEMAXP, and PIPEPERI registers used for data writing and reading. Selecting a pipe number in the PIPESEL[3:0] bits allows writing to and reading from PIPECFG, PIPEMAXP, and PIPEPERI associated with the selected pipe number.

When PIPESEL[3:0] = 0000b, 0 is read from all of the bits in PIPECFG, PIPEMAXP, and PIPEPERI. Writing to these bits has no effect.

36.2.32 PIPECFG : Pipe Configuration Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x068

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TYPE[1:0]		—	—	—	BFRE	DBLB	—	SHTNAK	—	—	DIR	EPNUM[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	EPNUM[3:0]	Endpoint Number*1 Specifies the endpoint number for the selected pipe. Setting 0000b indicates that the pipe is not used.	R/W
4	DIR	Transfer Direction*2 *3 0: Receiving direction 1: Transmitting direction	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	SHTNAK	Pipe Disabled at End of Transfer*1 0: Continue pipe operation after transfer ends 1: Disable pipe after transfer ends	R/W
8	—	This bit is read as 0. The write value should be 0.	R/W
9	DBLB	Double Buffer Mode*2 *3 0: Single buffer 1: Double buffer	R/W
10	BFRE	BRDY Interrupt Operation Specification*2 *3 0: Generate BRDY interrupt on transmitting or receiving data 1: Generate BRDY interrupt on completion of reading data	R/W
13:11	—	These bits are read as 0. The write value should be 0.	R/W
15:14	TYPE[1:0]	Transfer Type*1 0 0: Pipe not used 0 1: Pipes 1 and 2: Bulk transfer Pipes 3 to 5: Bulk transfer Pipes 6 to 9: Setting prohibited 1 0: Pipes 1 and 2: Setting prohibited Pipes 3 to 5: Setting prohibited Pipes 6 to 9: Interrupt transfer 1 1: Pipes 1 and 2: Isochronous transfer Pipes 3 to 5: Setting prohibited Pipes 6 to 9: Setting prohibited	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Only set the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 2. Only set the BFRE, DBLB, and DIR bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 3. To change the BFRE, DBLB, or DIR bits after completing USB communication on the selected pipe, in addition to the constraints described in Note 2, write 1 and 0 to the PIPEnCTR.ACLRM bit continuously through the software and clear the FIFO buffer assigned to the pipe.

PIPECFG specifies the transfer type, FIFO buffer access direction, and endpoint numbers for pipes 1 to 9. It also selects single or double buffer mode, and whether to continue or disable pipe operation at the end of transfer.

EPNUM[3:0] bits (Endpoint Number)

The EPNUM[3:0] bits specify the endpoint number for the selected pipe. Setting 0000b indicates the pipe not used.

Set these bits so that the combination of the DIR and EPNUM[3:0] settings is different from those for other pipes. The EPNUM[3:0] bits can be set to 0000b for all pipes.

DIR bit (Transfer Direction)

The DIR bit specifies the transfer direction for the selected pipe.

When the software sets this bit to 0, the USBFS uses the selected pipe for receiving. When the software sets this bit to 1, the USBFS uses the selected pipe for transmitting.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change the PIPEnCTR.PID[1:0] bits to 00b (NAK) at the end of transfer when the selected pipe is set in the receiving direction. The bit is valid for pipes 1 to 5 in the receiving direction.

When the software sets this bit to 1 for a receiving pipe, the USBFS changes the associated PIPEnCTR.PID[1:0] bits to 00b (NAK) on determining the transfer end. The USBFS determines that the transfer has ended on the following conditions:

- A short packet data (including a zero-length packet) was successfully received
- The transaction counter is used and the number of packets specified for the transaction counter are successfully received

DBLB bit (Double Buffer Mode)

The DBLB bit selects either single or double buffer mode for the FIFO buffer used by the selected pipe. The bit is valid for pipes 1 to 5.

BFRE bit (BRDY Interrupt Operation Specification)

The BFRE bit specifies the BRDY interrupt generation timing from the USBFS to the CPU for the selected pipe.

When the software sets the BFRE bit to 1 and the selected pipe is in the receiving direction, the USBFS detects the transfer completion and generates the BRDY interrupt on reading the packet.

When a BRDY interrupt is generated with this setting, the software must write 1 to the BCLR bit in the port control register. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to the BCLR bit.

When the BFRE bit is set to 1 by software and the selected pipe is in the transmitting direction, the USBFS does not generate the BRDY interrupt. For details, see section 36.3.3.1. BRDY Interrupt.

TYPE[1:0] bits (Transfer Type)

The TYPE[1:0] bits specify the transfer type for the pipe selected in the PIPESEL.PIPESEL[3:0] bits. Before setting PID to BUF and starting USB communication on the selected pipe, set the TYPE[1:0] bits to a value other than 00b.

36.2.33 PIPEMAXP : Pipe Maximum Packet Size Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x06C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DEVSEL[3:0]				—	—	—	MXPS[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	x	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	MXPS[8:0]	Maximum Packet Size*1 ● Pipes 1 and 2 1 byte (0x001) to 256 bytes (0x100) (Bit [9] not supported.) ● Pipes 3 to 5 8 bytes (0x008), 16 bytes (0x010), 32 bytes (0x020), 64 bytes (0x040) (Bits [9:7] and [2:0] not supported.) ● Pipes 6 to 9 1 byte (0x001) to 64 bytes (0x040) (Bits [9:7] not supported.)	R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W
15:12	DEVSEL[3:0]	Device Select*2 0x0: Address 0000b 0x1: Address 0001b 0x2: Address 0010b 0x3: Address 0011b 0x4: Address 0100b 0x5: Address 0101b Others: Setting prohibited	R/W

Note: S-TYPE-3, P-TYPE-3

Note: The value of the MXPS[8:0] bits is 0x000 when no pipe is selected in the PIPESEL.PIPESEL[3:0] bits and 0x040 when a pipe is selected.

Note 1. Only set the MXPS[8:0] bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 2. Only set the DEVSEL[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00b (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PIPEMAXP specifies the maximum packet size for pipes 1 to 9.

MXPS[8:0] bits (Maximum Packet Size)

The MXPS[8:0] bits specify the maximum data payload (maximum packet size) for the selected pipe.

Set these bits to the appropriate value for each transfer type based on the USB 2.0 specification. When MXPS[8:0] = 0, do not write to the FIFO buffer or set PID to BUF. These writes have no effect.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target device for USB communication. Set up the device address in the associated DEVADDn (n = 0 to 5) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0x2, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0x0.

36.2.34 PIPEPERI : Pipe Cycle Control Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x06E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	IITV[2:0]*1	Interval Error Detection Interval Specifies the interval error detection timing for the selected pipe as the n-th power of 2 of the frame timing	R/W
11:3	—	These bits are read as 0. The write value should be 0.	R/W
12	IFIS	Isochronous IN Buffer Flush 0: Do not flush buffer 1: Flush buffer	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Only set the IITV[2:0] bits while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PIPEPERI selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfers, and sets the interval error detection interval for pipes 1 to 9.

IITV[2:0] bits (Interval Error Detection Interval)

To change the IITV[2:0] bits to another value after they are set and USB communication is performed, set the PIPEnCTR.PID[1:0] bits to 00b (NAK) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer.

The IITV[2:0] bits are not provided for pipes 3 to 5. Write 000b to bit positions of the IITV[2:0] bits associated with pipes 3 to 5.

IFIS bit (Isochronous IN Buffer Flush)

The IFIS bit specifies whether to flush the buffer when the pipe selected in the PIPESEL.PIPESEL[3:0] bits is used for isochronous IN transfers.

In device controller mode when the selected pipe is for isochronous IN transfers, the USBFS automatically clears the FIFO buffer if the USBFS fails to receive the IN token from the USB host within the interval set in theIITV[2:0] bits in terms of frames.

When double buffering is specified (PIPECFG.DBLB = 1), the USBFS only clears the data in the previously used plane.

The USBFS clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USBFS expected to receive the IN token. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time the SOF packet is expected to be received by using the internal interpolation function.

When the host controller function is selected, set this bit to 0.

Set this bit to 0 when the selected pipe is not for isochronous transfer.

36.2.35 PIPEnCTR : PIPEn Control Registers (n = 1 to 5)

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x070 + 0x2 × (n - 1)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BSTS	INBUFM	—	—	—	ATREPM	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PID[1:0]	Response PID 0 0: NAK response 0 1: BUF response (depends buffer state) 1 0: STALL response 1 1: STALL response	R/W
4:2	—	These bits are read as 0. The write value should be 0.	R/W
5	PBUSY	Pipe Busy 0: Pipe n not in use for the transaction 1: Pipe n in use for the transaction	R
6	SQMON	Sequence Toggle Bit Confirmation 0: DATA0 1: DATA1	R
7	SQSET	Sequence Toggle Bit Set*2 Sets the sequence toggle bit for pipe n. 0: Invalid (writing 0 has no effect) 1: Set the expected value for the next transaction to DATA1	R/W*1
8	SQCLR	Sequence Toggle Bit Clear*2 Clears the sequence toggle bit for pipe n. 0: Invalid (writing 0 has no effect) 1: Clear the expected value for the next transaction to DATA0	R/W*1
9	ACLRM	Auto Buffer Clear Mode*3 0: Disable 1: Enable (initialize all buffers)	R/W
10	ATREPM	Auto Response Mode*2 0: Disable auto response mode 1: Enable auto response mode	R/W
13:11	—	These bits are read as 0. The write value should be 0.	R/W
14	INBUFM	Transmit Buffer Monitor 0: No data to be transmitted is in the FIFO buffer 1: Data to be transmitted is in the FIFO buffer	R
15	BSTS	Buffer Status 0: Buffer access by the CPU disabled 1: Buffer access by the CPU enabled	R

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit is read as 0.
Note 2. Only set the ATREPM bit or write 1 to the SQCLR or SQSETbit while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSYbit through the software is not necessary.
Note 3. Only set the ACLRM bit while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting this bit, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PIPEnCTR can be set for any pipe selection in the PIPESEL register.

PID[1:0] bits (Response PID)

The PID[1:0]bits specify the response type for the next transaction on the selected pipe.

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 36.9 and Table 36.10 show the basic operations of the USBFS (when there are no errors in the communication packets) based on the PID[1:0] bit setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the pipe has actually entered the NAK state. If the USBFS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBFS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBFS sets PID to NAK on recognizing completion of the transfer when the selected pipe is in the receiving direction and the PIPECFG.SHTNAK bit for the selected pipe is set to 1 by software
- The USBFS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBFS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBFS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBFS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode

To specify the response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, set 00b (NAK) and then 01b (BUF)

Table 36.9 Operation of the USBFS based on the PID[1:0] setting in host controller mode

PID[1:0] value	Transfer type	Transfer direction (DIR bit)	USBFS operation
00b (NAK)	Does not depend on the setting	Does not depend on the setting	Does not issue tokens
01b (BUF)	Bulk or interrupt	Does not depend on the setting	Issues tokens when the DVSTCTR0.UACT bit is 1 and the FIFO buffer associated with the selected pipe is ready for transmission and reception. Does not issue tokens when the DVSTCTR0.UACT bit is 0 or the FIFO buffer associated with the selected pipe is not ready for transmission or reception.
	Isochronous	Does not depend on the setting	Issues tokens regardless of the status of the FIFO buffer associated with the selected pipe.
10b (STALL) or 11b (STALL)	Does not depend on the setting	Does not depend on the setting	Does not issue tokens.

Table 36.10 Operation of the USBFS based on the PID[1:0] setting in device controller mode (1 of 2)

PID[1:0] value	Transfer type	Transfer direction (DIR bit)	USBFS operation
00b (NAK)	Bulk or interrupt	Does not depend on the setting	Returns NAK in response to the token from the USB host
	Isochronous	Does not depend on the setting	Returns nothing in response to the token from the USB host

Table 36.10 Operation of the USBFS based on the PID[1:0] setting in device controller mode (2 of 2)

PID[1:0] value	Transfer type	Transfer direction (DIR bit)	USBFS operation
01b (BUF)	Bulk	Receiving direction (DIR = 0)	Receives data and returns ACK in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception
	Interrupt	Receiving direction (DIR = 0)	Receives data and returns ACK in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception
	Bulk or interrupt	Transmitting direction (DIR = 1)	Transmits data in response to the token from the USB host if the FIFO buffer associated with the selected pipe is ready for transmission. Otherwise, returns NAK.
	Isochronous	Receiving direction (DIR = 0)	Receives data in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, discards the data.
	Isochronous	Transmitting direction (DIR = 1)	Transmits data in response to the token from the USB host if the associated FIFO buffer is ready for transmission. Otherwise, transmits a zero-length packet.
10b (STALL) or 11b (STALL)	Bulk or interrupt	Does not depend on the setting	Returns STALL in response to the token from the USB host
	Isochronous	Does not depend on the setting	Returns nothing in response to the token from the USB host

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether the selected pipe is being used for the current transaction.

The USBFS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible. For details, see section 36.3.4.1. Pipe Control Register Switching Procedures.

SQMON bit (Sequence Toggle Bit Confirmation)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

When the selected pipe is not the isochronous transfer type, the USBFS toggles the SQMON flag on successful completion of the transaction. However, the USBFS does not toggle the SQMON flag when a DATA-PID mismatch occurs during transfer in the receiving direction.

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBFS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe. The USBFS clears the SQSET bit to 0.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBFS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0. The USBFS clears the SQCLR bit to 0.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

Table 36.11 shows the data cleared by writing 1 and 0 to the ACLRM bit continuously and the cases in which this processing is required.

Table 36.11 Data cleared by the USBFS when ACLRM = 1 (1 of 2)

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
1	All data in the FIFO buffer allocated to the selected pipe (two FIFO buffers in double buffer mode)	When initializing the selected pipe

Table 36.11 Data cleared by the USBFS when ACLRM = 1 (2 of 2)

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
2	Interval count value when the selected pipe is the isochronous transfer type	When resetting the interval count value
3	Internal flags related to the PIPECFG.BFRE bit	When changing the PIPECFG.BFRE setting
4	FIFO buffer toggle control	When changing the PIPECFG.DBLB setting
5	Internal flags related to the transaction count	When forcing the transaction count function to terminate

ATREPM bit (Auto Response Mode)

The ATREPM bit enables or disables auto response mode for the selected pipe.

This bit can be set to 1 in device controller mode when the selected pipe is the bulk transfer type. When the bit is set to 1, the USBFS responds to the token from the USB host as follows:

- When the selected pipe is set for bulk IN transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 1):
  a. When the ATREPM bit = 1 and PID = BUF, the USBFS transmits a zero-length packet in response to the IN token.
  b. The USBFS updates the sequence toggle bit (DATA-PID) each time the USBFS receives ACK from the USB host. In a single transaction, the IN token is received, a zero-length packet is transmitted, and then ACK is received. The USBFS does not generate the BRDY or BEMP interrupt.

- When the selected pipe is set for bulk OUT transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 0):

  When the ATREPM bit = 1 and PID = BUF, the USBFS returns NAK in response to the OUT token and generates an NRDY interrupt.

For USB communication in auto response mode, set the ATREPM bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode. When the selected pipe uses isochronous transfer, always set this bit to 0.

In host controller mode, always set the ATREPM bit to 0.

INBUFM bit (Transmit Buffer Monitor)

The INBUFM bit indicates the FIFO buffer status for the selected pipe in the transmitting direction.

When the selected pipe is set in the transmitting direction (PIPECFG.DIR = 1), the USBFS sets this bit to 1 when the CPU or DMA/DTC completes writing data to at least one FIFO buffer plane.

The USBFS sets this bit to 0 when the USBFS completes transmission of the data from the FIFO buffer plane to which all the data is written. In double buffer mode (PIPECFG.DBLB = 1), the USBFS sets the INBUFM bit to 0 when the USBFS completes transmission of the data from the two FIFO buffer planes before the CPU or DMA/DTC completes writing data to one FIFO buffer plane.

The INBUFM bit indicates the same value as the BSTS bit when the selected pipe is in the receiving direction (PIPECFG.DIR = 0).

BSTS bit (Buffer Status)

The BSTS bit indicates the FIFO buffer status for the selected pipe.

The meaning of the BSTS bit depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 36.12.

Table 36.12 BSTS bit operation

DIR value	BFRE value	DCLRM value	BSTS bit function
0	0	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read
		1	Setting prohibited
	1	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 when the software sets the BCLR bit in the port control register to 1 after the data read is complete
		1	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read
1	0	0	Sets to 1 when transmit data can be written to the FIFO buffer, and clears to 0 on completion of data write
		1	Setting prohibited
	1	0	Setting prohibited
		1	Setting prohibited

36.2.36 PIPEnCTR : PIPEn Control Registers (n = 6 to 9)

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x07A + 0x2 × (n - 6)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BSTS	—	—	—	—	—	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PID[1:0]	Response PID 0 0: NAK response 0 1: BUF response (depends buffer state) 1 0: STALL response 1 1: STALL response	R/W
4:2	—	These bits are read as 0. The write value should be 0.	R/W
5	PBUSY	Pipe Busy 0: Pipe n not in use for the transaction 1: Pipe n in use for the transaction	R
6	SQMON	Sequence Toggle Bit Confirmation 0: DATA0 1: DATA1	R
7	SQSET	Sequence Toggle Bit Set*1 Sets the sequence toggle bit for pipe n. 0: Invalid (writing 0 has no effect) 1: Set the expected value for the next transaction to DATA0	W
8	SQCLR	Sequence Toggle Bit Clear*1 Clears the sequence toggle bit for pipe n. 0: Invalid (writing 0 has no effect) 1: Clear the expected value for the next transaction to DATA0	W
9	ACLRM	Auto Buffer Clear Mode*2 0: Disable 1: Enable (all buffers initialized)	R/W
14:10	—	These bits are read as 0. The write value should be 0.	R/W
15	BSTS	Buffer Status 0: Buffer access disabled 1: Buffer access enabled	R

Note: S-TYPE-3, P-TYPE-3

Note 1. Only write 1 to the SQCLR or SQSET bit while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00b (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 2. Only set the ACLRM bit while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting this bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00b (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PID[1:0] bits (Response PID)

The PID[1:0]bits specify the response type for the next transaction of the selected pipe.

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 36.9 and Table 36.10 show the basic operation (when there are no errors in the transmitted and received packets) of the USBFS depending on the PID[1:0] setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the selected pipe has actually entered the NAK state. If the USBFS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBFS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBFS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBFS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBFS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBFS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode

To specify each response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, set 00b (NAK) and then 01b (BUF)

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether the selected pipe is being used for the current transaction.

The USBFS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible.

SQMON bit (Sequence Toggle Bit Confirmation)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

The USBFS toggles the SQMON bit on successful completion of the transaction. However, the USBFS does not toggle the SQMON bit when a DATA-PID mismatch occurs during transfer in the receiving direction.

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBFS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe. The USBFS sets the SQSET bit to 0.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBFS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0. The USBFS sets the SQCLR bit to 0.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

Table 36.13 shows the data cleared by writing 1 and 0 continuously to the ACLRM bit and the cases in which this processing is required.

Table 36.13 Data cleared by the USBFS when ACLRM = 1

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
1	All data in the FIFO buffer allocated to the selected pipe	When initializing the selected pipe
2	Interval count value when the selected pipe is the isochronous transfer type	When resetting the interval count value
3	Internal flags related to the PIPECFG.BFRE bit	When changing the PIPECFG.BFRE setting
4	Internal flags related to the transaction count	When forcing the transaction count function to terminate

BSTS bit (Buffer Status)

The BSTS bit indicates the FIFO buffer status for the selected pipe.

The meaning of the BSTS bit depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 36.12.

36.2.37 PIPEnTRE : PIPEn Transaction Counter Enable Register (n = 1 to 5)

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x090 + 0x4 × (n - 1)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	TRCLR	Transaction Counter Clear 0: Invalid (writing 0 has no effect) 1: Clear counter value	R/W
9	TRENB	Transaction Counter Enable 0: Disable transaction counter 1: Enable transaction counter	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Set each bit in PIPEnTRE while PID is NAK. Before setting these bits after changing the PIPEnCTR.PID[1:0] bits for the selected pipe from BUF to NAK, check that the PIPEnCTR.PBUSY bit is 0. However, if the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

TRCLR bit (Transaction Counter Clear)

When the TRCLR bit sets to 1, the USBFS clears the value of the transaction counter associated with the selected pipe and then sets the TRCLR bit to 0.

TRENB bit (Transaction Counter Enable)

The TRENB bit enables or disables the transaction counter.

For receiving pipes, setting the TRENB bit to 1 after setting the total number of the packets to be received in the PIPEnTRN.TRNCNT[15:0] bits through the software allows the USBFS to control hardware on having received the number of packets equal to the TRNCNT[15:0] setting, as follows:

- When the PIPECFG.SHTNAK bit is 1, the USBFS changes the PID bits to NAK for the associated pipe on having received the number of packets equal to the TRNCNT[15:0] setting
- When the PIPECFG.BFRE bit is 1, the USBFS asserts the BRDY interrupt on having received the number of packets equal to the TRNCNT[15:0] setting and then reading the last received data

For transmitting pipes, set the TRENB bit to 0.

When the transaction counter is not used, set this bit to 0. When the transaction counter is used, set the TRNCNT[15:0] bits before setting this bit to 1. Set this bit to 1 before receiving the first packet to be counted by the transaction counter.

36.2.38 PIPEnTRN : PIPEn Transaction Counter Register (n = 1 to 5)

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x092 + 0x4 × (n - 1)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TRNCNT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TRNCNT[15:0]	Transaction Counter When written to, this bit specifies the total packets (number of transactions) to be received by the selected pipe. When read from, when PIPEnTRE.TRENB is 0, this bit indicates the specified number of transactions. When PIPEnTRE.TRENB is 1, this bit indicates the current transaction count.	R/W

Note: S-TYPE-3, P-TYPE-3

The PIPEnTRN registers retain their settings during a USB bus reset.

TRNCNT[15:0] bits (Transaction Counter)

The USBFS increments the value of the TRNCNT[15:0] bits by 1 when all of the following conditions are satisfied on receiving the packet:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value ≠ current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[9:0] setting

The USBFS clears the value of the TRNCNT[15:0] bits to 0 when any of the following conditions are satisfied:

All of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value = current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[9:0] setting

Both of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The USBFS received a short packet

Both of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The PIPEnTRE.TRCLR bit was set to 1 by software

For transmitting pipes, set the TRNCNT[15:0] bits to 0. When the transaction counter is not used, set the TRNCNT[15:0] bits to 0.

Setting the number of transactions to be transferred to the TRNCNT[15:0] bits is only enabled when the PIPEnTRE.TRENB bit is 0. To set the number of transactions to be transferred, set the TRCLR bit to 1 to clear the current counter value before setting the PIPEnTRE.TRENB bit to 1.

36.2.39 DEVADDn : Device Address n Configuration Register (n = 0 to 5)

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x0D0 + 0x2 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	USBSPD[1:0]		—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
7:6	USBSPD[1:0]	Transfer Speed of Communication Target Device 0 0: Do not use DEVADDn 0 1: Low-speed 1 0: Full-speed 1 1: Setting prohibited	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The DEVADDn register specifies the transfer speed of the peripheral device that is the communication target for pipes 0 to 9.

In host controller mode, set all DEVADDn bits before starting communication to any pipes. Only change the bits in DEVADDn when no valid pipes are using the bit settings. A valid pipe is defined as one that satisfies both of the following conditions:

- The target device of the DEVADDn register is selected in the DEVSEL[3:0] bits
- The PID[1:0] bits are set to BUF for the selected pipe, or the selected pipe is the DCP with the DCPCTR.SUREQ bit set to 1

In device controller mode, set all bits in this register to 0.

USBSPD[1:0] bits (Transfer Speed of Communication Target Device)

TheUSBSPD[1:0] bits specify the USB transfer speed of the target peripheral device. Set these bits to 10b when a full-speed device is connected through the hub. In host controller mode, the USBFS generates packets based on the USBSPD[1:0] setting. In device controller mode, set these bits to 00b.

36.2.40 DPUSR0R : Deep Software Standby USB Transceiver Control/Pin Monitor Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x400

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	DVBSTS0	—	DOVCB0	DOVCA0	—	—	DM0	DP0
Value after reset:	0	0	0	0	0	0	0	0	x	0	x	x	0	0	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	FIXPHY0	DRPD0	—	RPUE0	SRPC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRPC0*1	USB Single-ended Receiver Control 0: Disable input through DP and DM inputs 1: Enable input through DP and DM inputs	R/W
1	RPUE0*1	DP Pull-Up Resistor Control 0: Disable DP pull-up resistor 1: Enable DP pull-up resistor	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	DRPD0*1	D+/D- Pull-Down Resistor Control 0: Disable DP/DM pull-down resistor 1: Enable DP/DM pull-down resistor	R/W
4	FIXPHY0	USB Transceiver Output Fix 0: Fix outputs in Normal mode and on return from Deep Software Standby mode 1 1: Fix outputs on transition to Deep Software Standby mode 1	R/W
15:5	—	These bits are read as 0. The write value should be 0.	R/W
16	DP0	USB D+ Input Indicates D+ input signal on the USBFS side	R
17	DM0	USB D- Input Indicates D– input signal on the USBFS side	R
19:18	—	These bits are read as 0. The write value should be 0.	R/W
20	DOVCA0	USB OVRCURA-DS Input*2 Indicates OVRCURA-DS input signal on the USBFS side	R
21	DOVCB0	USB OVRCURB-DS Input*2 Indicates OVRCURB-DS input signal on the USBFS side	R
22	—	The read value is undefined. The write value should be 0.	R/W
23	DVBSTS0	USB VBUS Input Indicates VBUS input signal on the USBFS side	R
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This register is accessed by the clock of PCLKB/64 to reduce current consumption in Deep Software Standby mode1.

Note 1. Use this bit during operation in Deep Software Standby mode 1. For details, see section 36.3.1.5. Release from Deep Software Standby Mode 1 Because of USB Suspend/Resume Interrupts.

Note 2. OVRCURA or OVRCURB can not be used. Only OVRCURA-DS or OVRCURB-DS can be used in Deep software standby mode1.

SRPC0 bit (USB Single-ended Receiver Control)

The SRPC0 bit controls the D+ and D- inputs of the USB transceiver. In host controller mode, set this bit to 1. In device controller mode, set this bit to 0 when disconnected, set to 1 when suspended. This bit is only valid when the FIXPHY0 bit is 1.

FIXPHY0 bit (USB Transceiver Output Fix)

The FIXPHY0 bit keeps the outputs of the USB transceiver disabled.

36.2.41 DPUSR1R : Deep Software Standby USB Suspend/Resume Interrupt Register

Base address: USBFS = 0x4025_0000
USBFS_NS = 0x5025_0000

Offset address: 0x404

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	DVBINT0	—	DOVRCRB0	DOVRCRA0	—	—	DMINT0	DPINT0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	DVBSE0	—	DOVRCRBE0	DOVRCRAE0	—	—	DMINTE0	DPINTE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DPINTE0	USB DP Interrupt Enable/Clear 0: Disable recovery from Deep Software Standby mode 1 by DP input 1: Enable recovery from Deep Software Standby mode 1 by DP input	R/W
1	DMINTE0	USB DM Interrupt Enable/Clear 0: Disable recovery from Deep Software Standby mode 1 by DM input 1: Enable recovery from Deep Software Standby mode by DM input	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	DOVRCRAE0	USB OVRCURA-DS Interrupt Enable/Clear*1 0: Disable recovery from Deep Software Standby mode 1 by OVRCURA-DS input 1: Enable recovery from Deep Software Standby mode 1 by OVRCURA-DS input	R/W
5	DOVRCRBE0	USB OVRCURB-DS Interrupt Enable/Clear*1 0: Disable recovery from Deep Software Standby mode 1 by OVRCURB-DS input 1: Enable recovery from Deep Software Standby mode 1 by OVRCURB-DS input	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	DVBSE0	USB VBUS Interrupt Enable/Clear 0: Disable recovery from Deep Software Standby mode 1 by VBUS input 1: Enable recovery from Deep Software Standby mode 1 by VBUS input	R/W
15:8	—	These bits are read as 0. The write value should be 0..	R/W
16	DPINT0	USB DP Interrupt Source Recovery 0: System has not recovered from Deep Software Standby mode 1 1: System recovered from Deep Software Standby mode 1 because of DP	R
17	DMINT0	USB DM Interrupt Source Recovery 0: System has not recovered from Deep Software Standby mode 1 1: System recovered from Deep Software Standby mode 1 because of DM input	R
19:18	—	These bits are read as 0. The write value should be 0.	R/W
20	DOVRCRA0	USB OVRCURA-DS Interrupt Source Recovery*1 0: System has not recovered from Deep Software Standby mode 1 1: System recovered from Deep Software Standby mode 1 because of OVRCURA-DS input	R
21	DOVRCRB0	USB OVRCURB-DS Interrupt Source Recovery*1 0: System has not recovered from Deep Software Standby mode 1 1: System recovered from Deep Software Standby mode 1 because of OVRCURB-DS input	R
22	—	This bit is read as 0. The write value should be 0.	R/W
23	DVBINT0	USB VBUS Interrupt Source Recovery 0: System has not recovered from Deep Software Standby mode 1 1: System recovered from Deep Software Standby mode 1 because of VBUS input	R
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This register is accessed by the clock of PCLKB/64 to reduce current consumption in Deep Software Standby mode1.
Note 1. OVRCURA or OVRCURB can not be used. Only OVRCURA-DS or OVRCURB-DS can be used in Deep Software Standby mode1.

DPINTE0 bit (USB DP Interrupt Enable/Clear)

The DPINTE0 bit enables or disables triggering of recovery from Deep Software Standby mode 1 by the DP input of the USBFS. Writing 0 to this bit while the DPINT0 bit is 1 sets the DPINT0 bit to 0.

DMINTE0 bit (USB DM Interrupt Enable/Clear)

The DMINTE0 bit enables or disables triggering of recovery from Deep Software Standby mode 1 by the DM input of the USBFS. Writing 0 to this bit while the DMINT0 bit is 1 clears the DMINT0 bit to 0.

DOVRCRAE0 bit (USB OVRCURA-DS Interrupt Enable/Clear)

The DOVRCRAE0 bit enables or disables triggering of recovery from Deep Software Standby mode 1 by the OVRCURA-DS input of the USBFS. Writing 0 to this bit while the DOVRCRA0 bit is 1 clears the DOVRCRA0 bit to 0.

DOVRCRBE0 bit (USB OVRCURB-DS Interrupt Enable/Clear)

The DOVRCRBE0 bit enables or disables triggering of recovery from Deep Software Standby mode 1 by the OVRCURB-DS input of the USBFS. Writing 0 to this bit while the DOVRCRB0 bit is 1 clears the DOVRCRB0 bit to 0.

DVBSE0 bit (USB VBUS Interrupt Enable/Clear)

The DVBSE0 bit enables or disables triggering of recovery from Deep Software Standby mode 1 by the VBUS input of the USBFS. Writing 0 to this bit while the DVBINT0 bit is 1 clears the DVBINT0 bit to 0.

DPINT0 bit (USB DP Interrupt Source Recovery)

The DPINT0 bit indicates that the system has returned from Deep Software Standby mode 1 because of the DP input of the USBFS. This recovery is only enabled when the DPINTE0 bit is 1. Writing 0 to the DPINTE0 bit while this bit is 1 clears this bit to 0.

DMINT0 bit (USB DM Interrupt Source Recovery)

The DMINT0 bit indicates that the system has returned from Deep Software Standby mode 1 because of the DM input of the USBFS. This recovery is only enabled when the DMINTE0 bit is 1. Writing 0 to the DMINTE0 bit while this bit is 1 clears this bit to 0.

DOVRCRA0 bit (USB OVRCURA-DS Interrupt Source Recovery)

The DOVRCRA0 bit indicates that the system has returned from Deep Software Standby mode 1 because of the OVRCURA-DS input of the USBFS. This recovery is only enabled when the DOVRCRAE0 bit is 1. Writing 0 to the DOVRCRAE0 bit while this bit is 1 clears this bit to 0.

DOVRCRB0 bit (USB OVRCURB-DS Interrupt Source Recovery)

The DOVRCRB0 bit indicates that the system has returned from Deep Software Standby mode 1 because of the OVRCURB-DS input of the USBFS. This recovery is only enabled when the DOVRCRBE0 bit is 1. Writing 0 to the DOVRCRBE0 bit while this bit is 1 clears this bit to 0.

DVBINT0 bit (USB VBUS Interrupt Source Recovery)

The DVBINT0 bit indicates that the system has returned from Deep Software Standby mode 1 because of the VBUS input of the USBFS. This recovery is only enabled when the DVBSE0 bit is 1. Writing 0 to the DVBSE0 bit while this bit is 1 clears this bit to 0.

36.3 Operation

36.3.1 System Control

This section describes register settings required for initializing the USBFS and controlling power consumption.

36.3.1.1 Setting Data to the USBFS Registers

Setting the SYSCFG.USBE bit to 1 after starting the clock supply (SYSCFG.SCKE bit = 1) enables and starts USBFS operation.

36.3.1.2 Selecting the Controller Function

The USBFS can operate as either a host or device controller.

Use the SYSCFG.DCFM bit to select one of these USBFS functions. The DCFM bit must be changed in the initial settings immediately after a reset or in the D+ pull-up-disabled state (SYSCFG.DPRPU bit = 0) and D+ and D– pull-down-disabled state (SYSCFG.DRPD bit = 0).

36.3.1.3 Controlling the USB Data Bus Using Resistors

The USBFS provides pull-up and pull-down resistors for the D+ and D– lines. Pull these lines up or down by setting the SYSCFG.DPRPU and DRPD bits.

In device controller mode, confirm that connection to the USB host is made, and then set the SYSCFG.DPRPU bit to 1 and pull up the D+ line (in full-speed communication).

When the SYSCFG.DPRPU bit is set to 0 during communication with a PC, the USBFS disables the pull-up resistor of the USB data line, thereby notifying the USB host of disconnection.

In host controller mode, set the SYSCFG.DRPD bit to 1 to pull down the D+ and D– lines.

Table 36.14 USB data bus resistor control

SYSCFG register settings		USB data bus control		
DRPD bit	DPRPU bit	D–	D+	Function
0	0	Open	Open	When resistors not used
0	1	Open	Pull-up	When operating as a device controller at full-speed
1	0	Pull-down	Pull-down	When operating as a host controller
1	1	—	—	Setting prohibited

36.3.1.4 Example External Connection Circuits

Figure 36.2 shows an example OTG connection in the self-powered system. The USBFS controls the pull-up resistor of the D+ line and the pull-down resistor of D+ and D- lines. Select pull-up and pull-down for the lines in the SYSCFG.DPRPU and SYSCFG.DRPD bits. In device controller mode, the pull-up resistor of USB data line is disabled if SYSCFG.DPRPU bit is set to 0 while communicating with the USB host. The USBFS can use this to notify the USB host of a device disconnect.

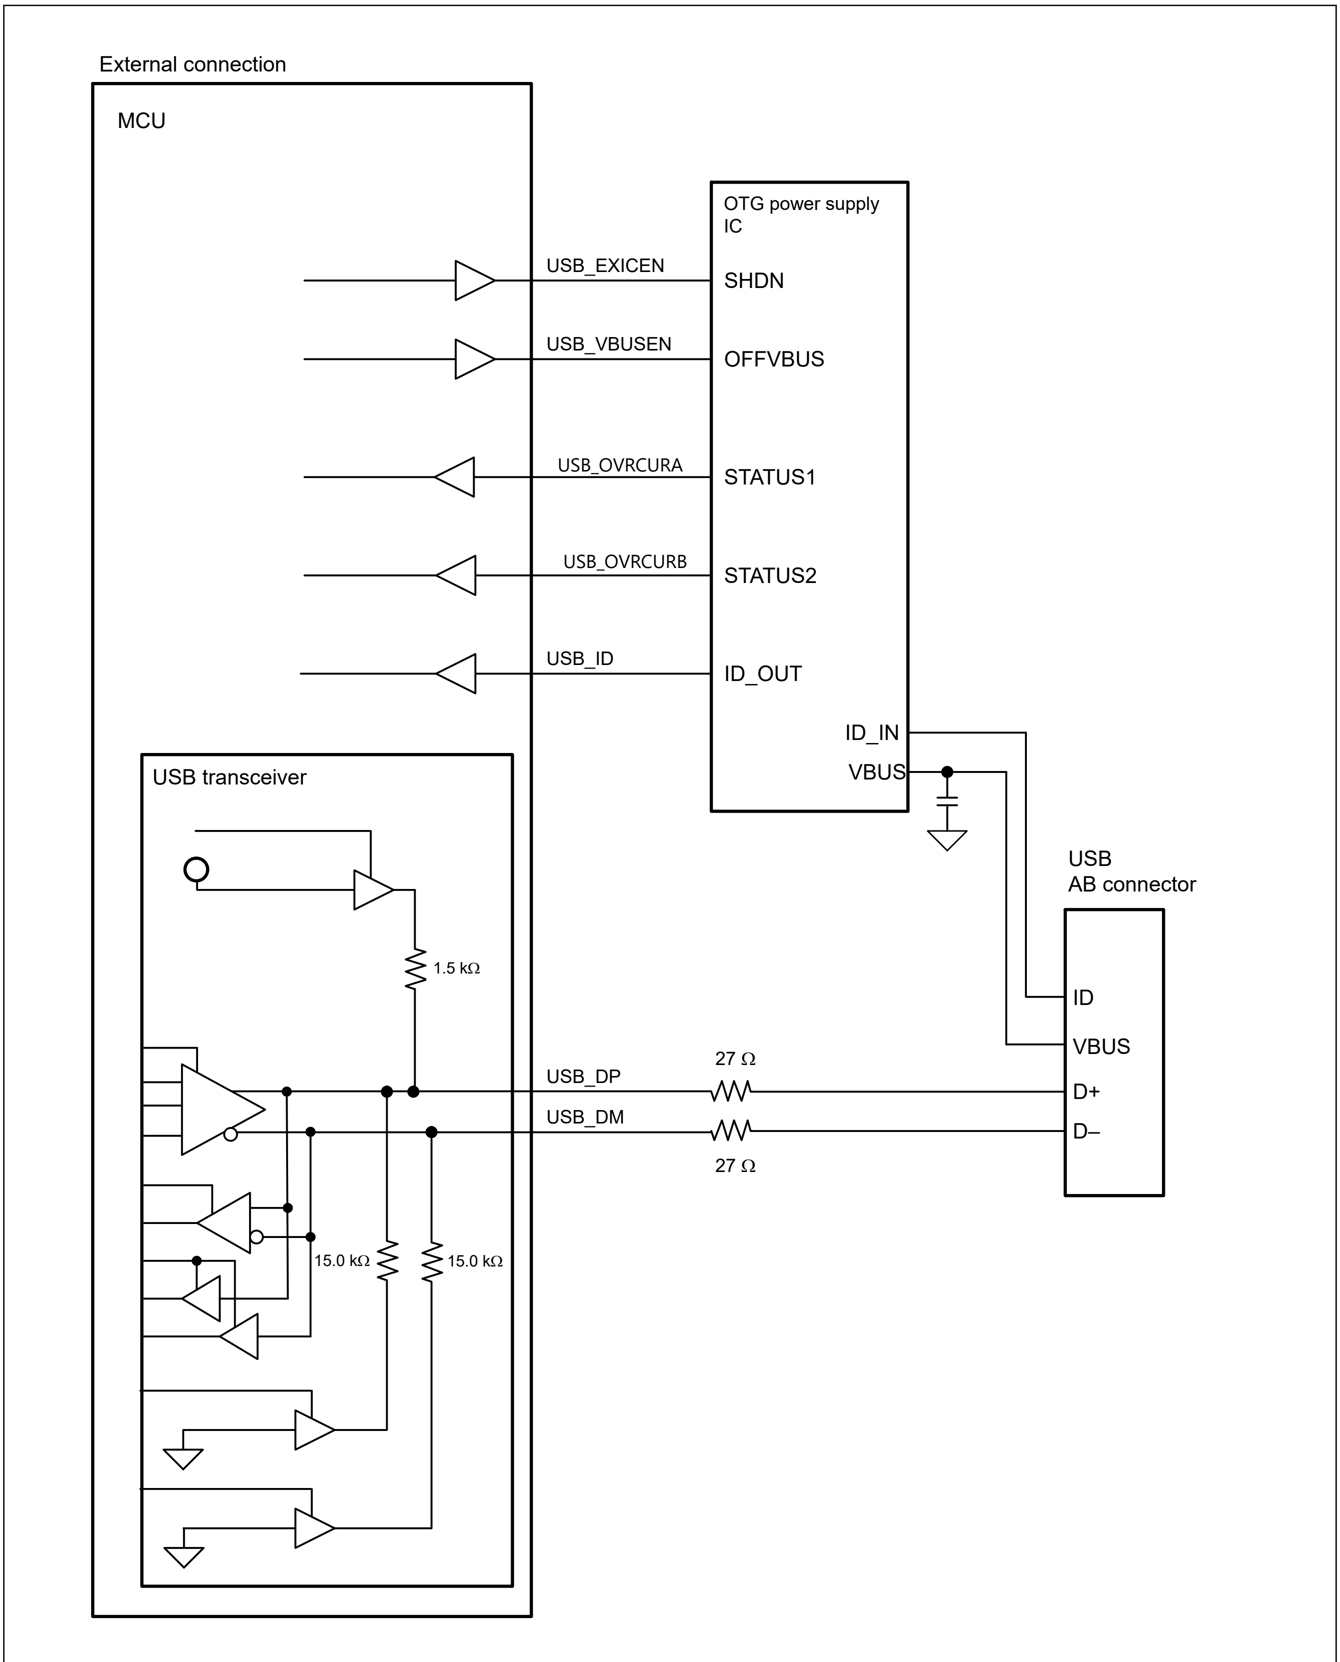

Figure 36.2 Example OTG connection in a self-powered system

Figure 36.3 shows an example device connection in a self-powered system.

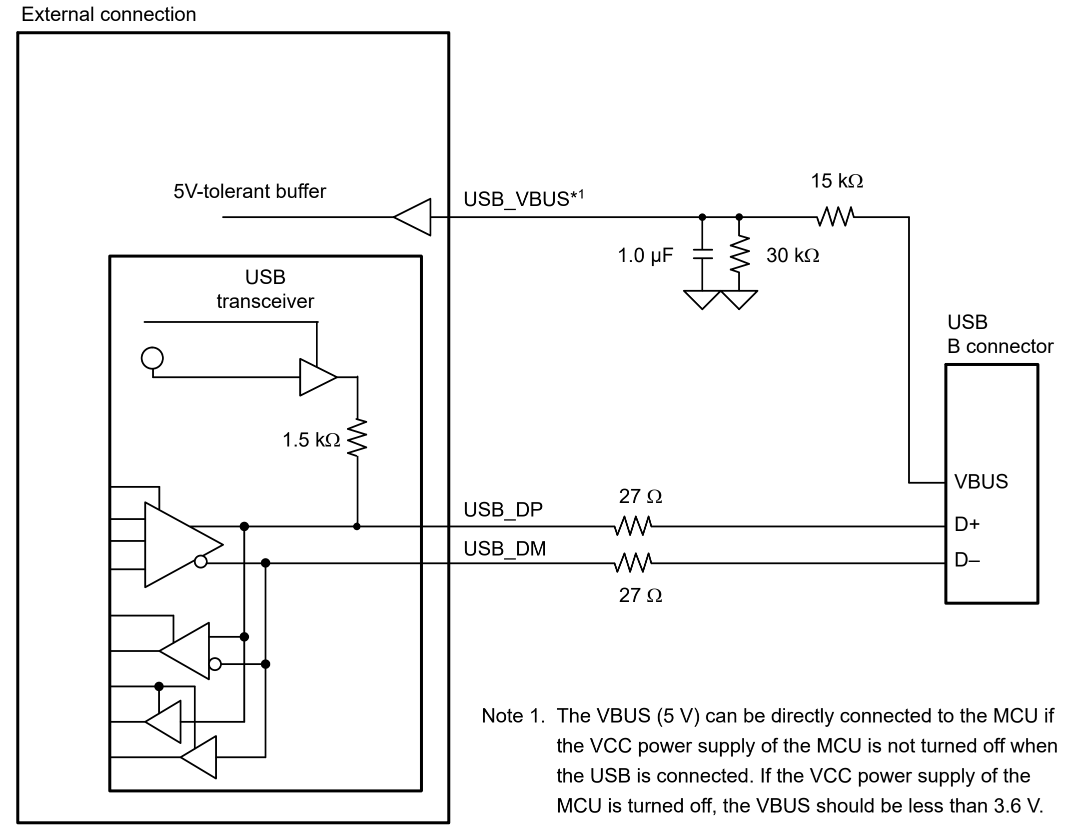

Figure 36.3 Example device connection in a self-powered system

Figure 36.4 shows an example host connection.

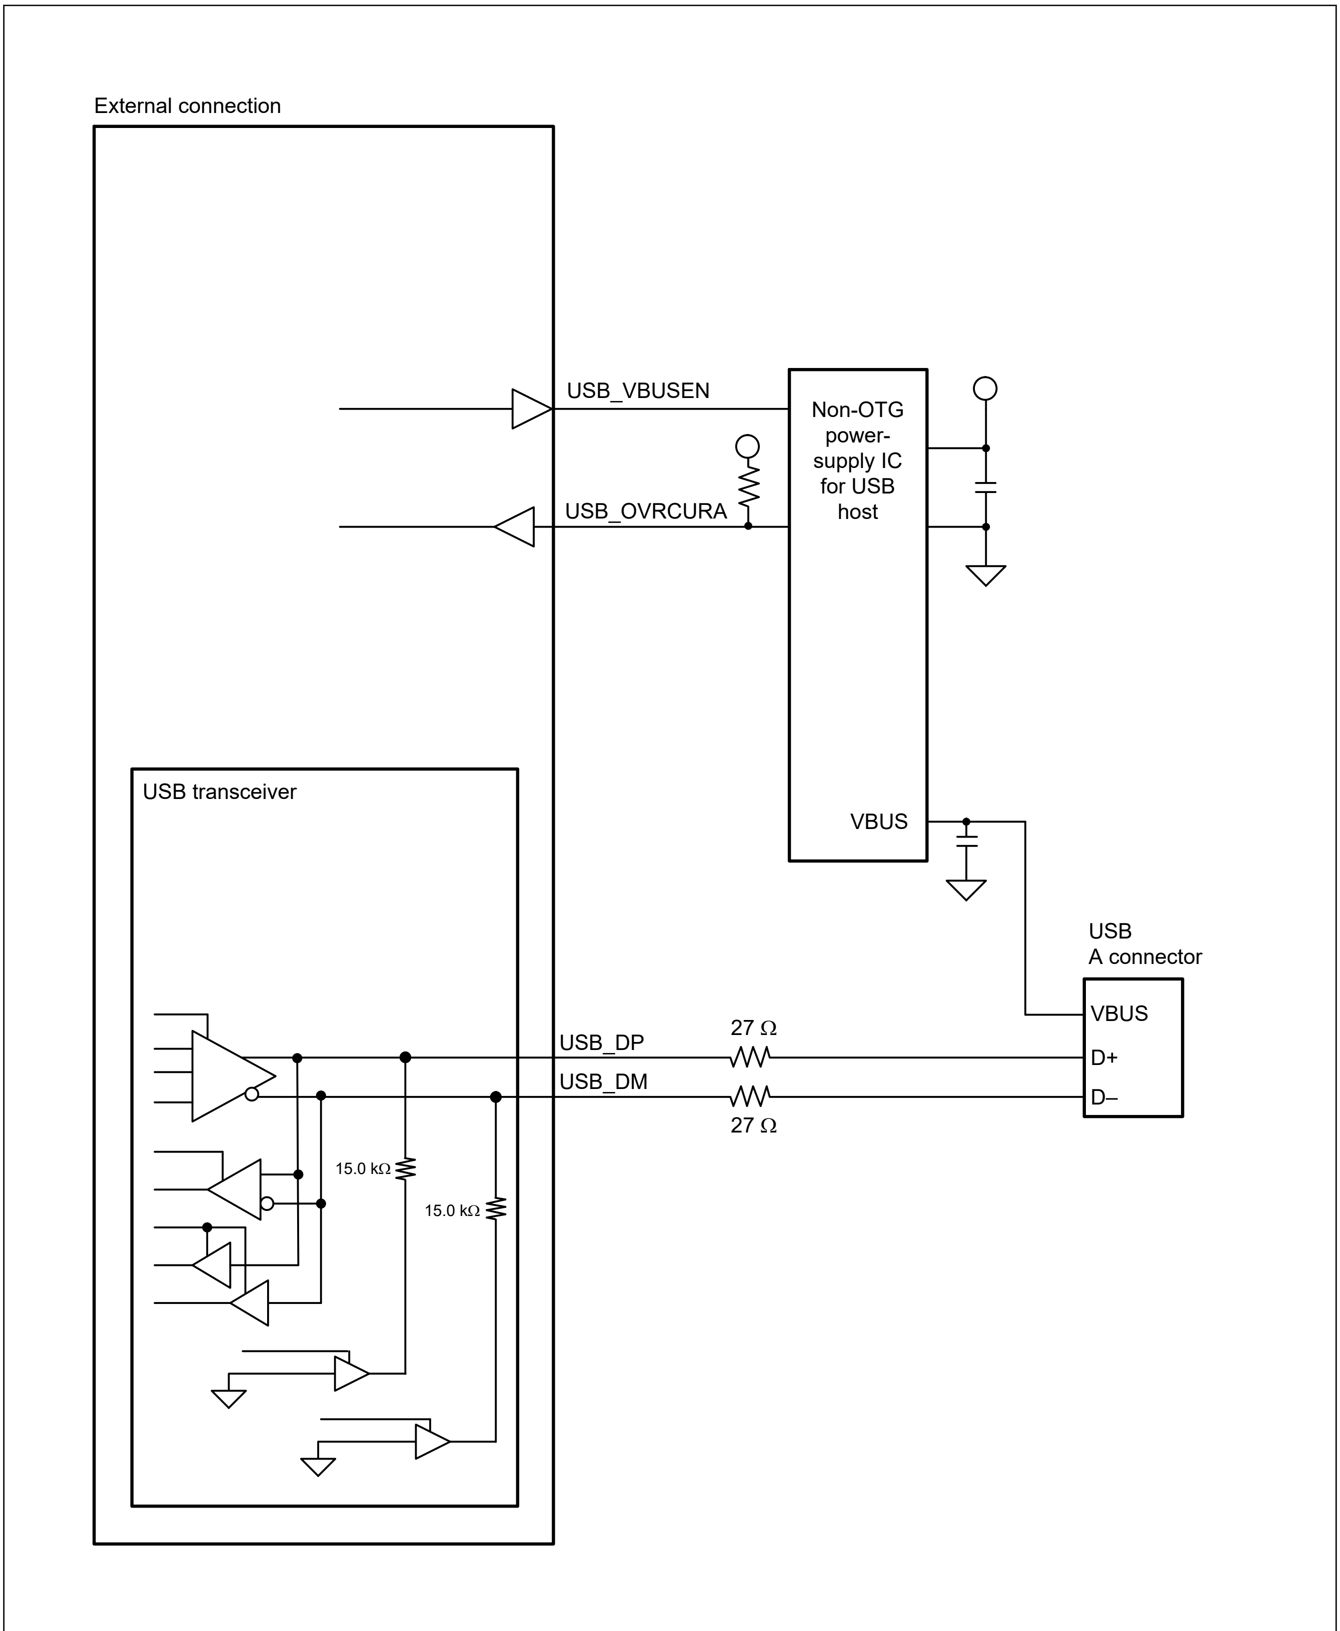

Figure 36.4 Example host connection

Figure 36.5 shows an example device connection in a bus-powered system.

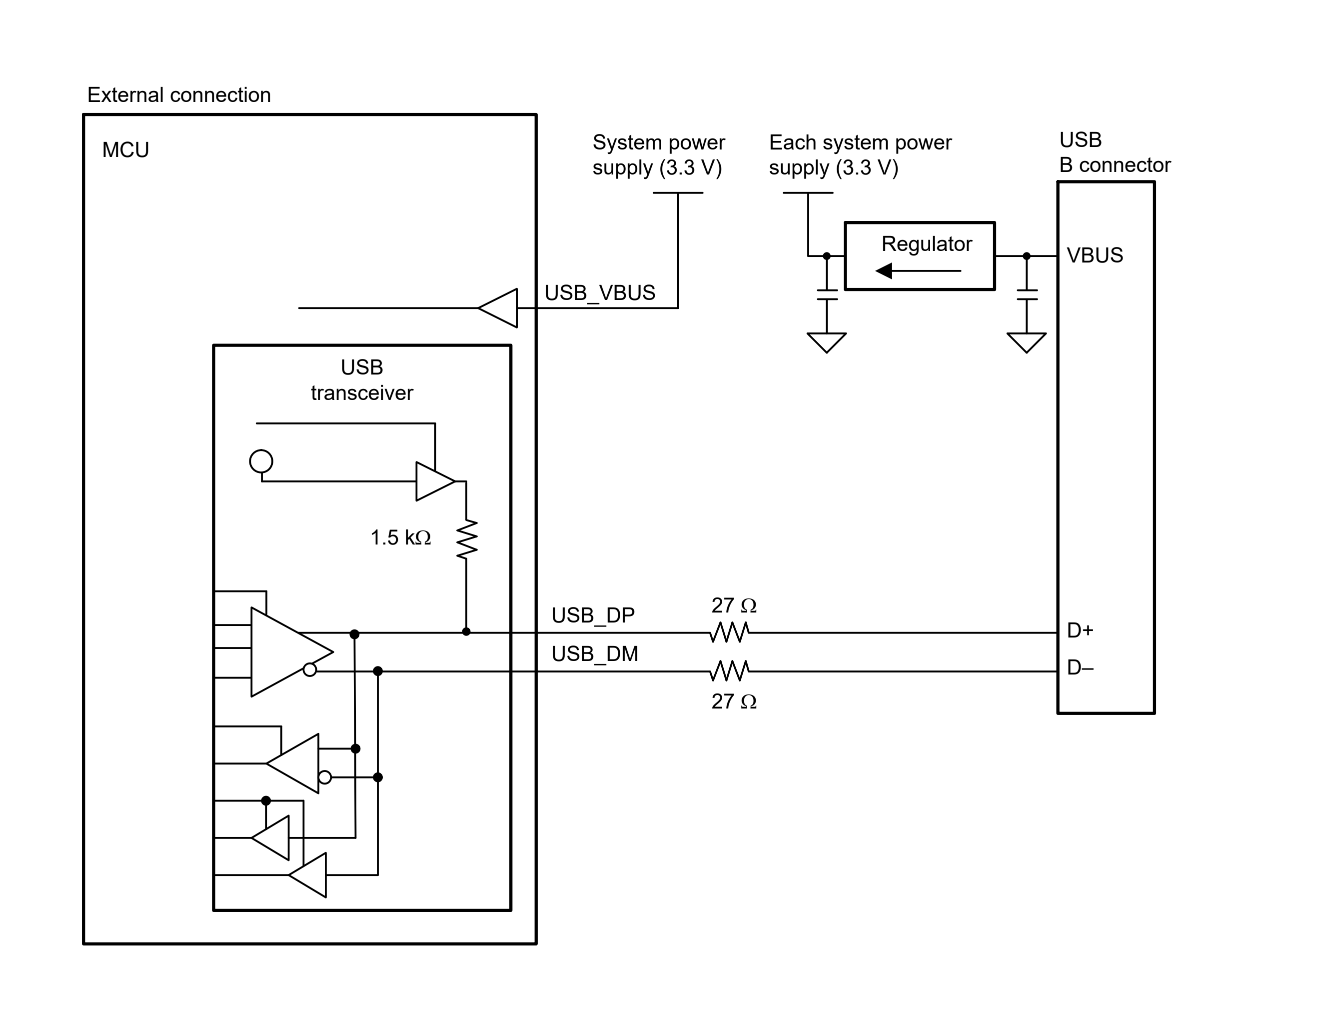

Figure 36.5 Example device connection in a bus-powered state

The examples of external circuits given in this section are simplified circuits, and their operation in every system is not guaranteed.

36.3.1.5 Release from Deep Software Standby Mode 1 Because of USB Suspend/ Resume Interrupts

Deep Software Standby mode1 can be canceled by a USB suspend/resume interrupt. USB suspend/resume interrupts are detected by the USB resume detecting unit, which controls and monitors the USB I/O pins to detect the interrupts.

Figure 36.6 shows a schematic diagram of the connection between the USB resume detecting unit and the USB I/O pins.

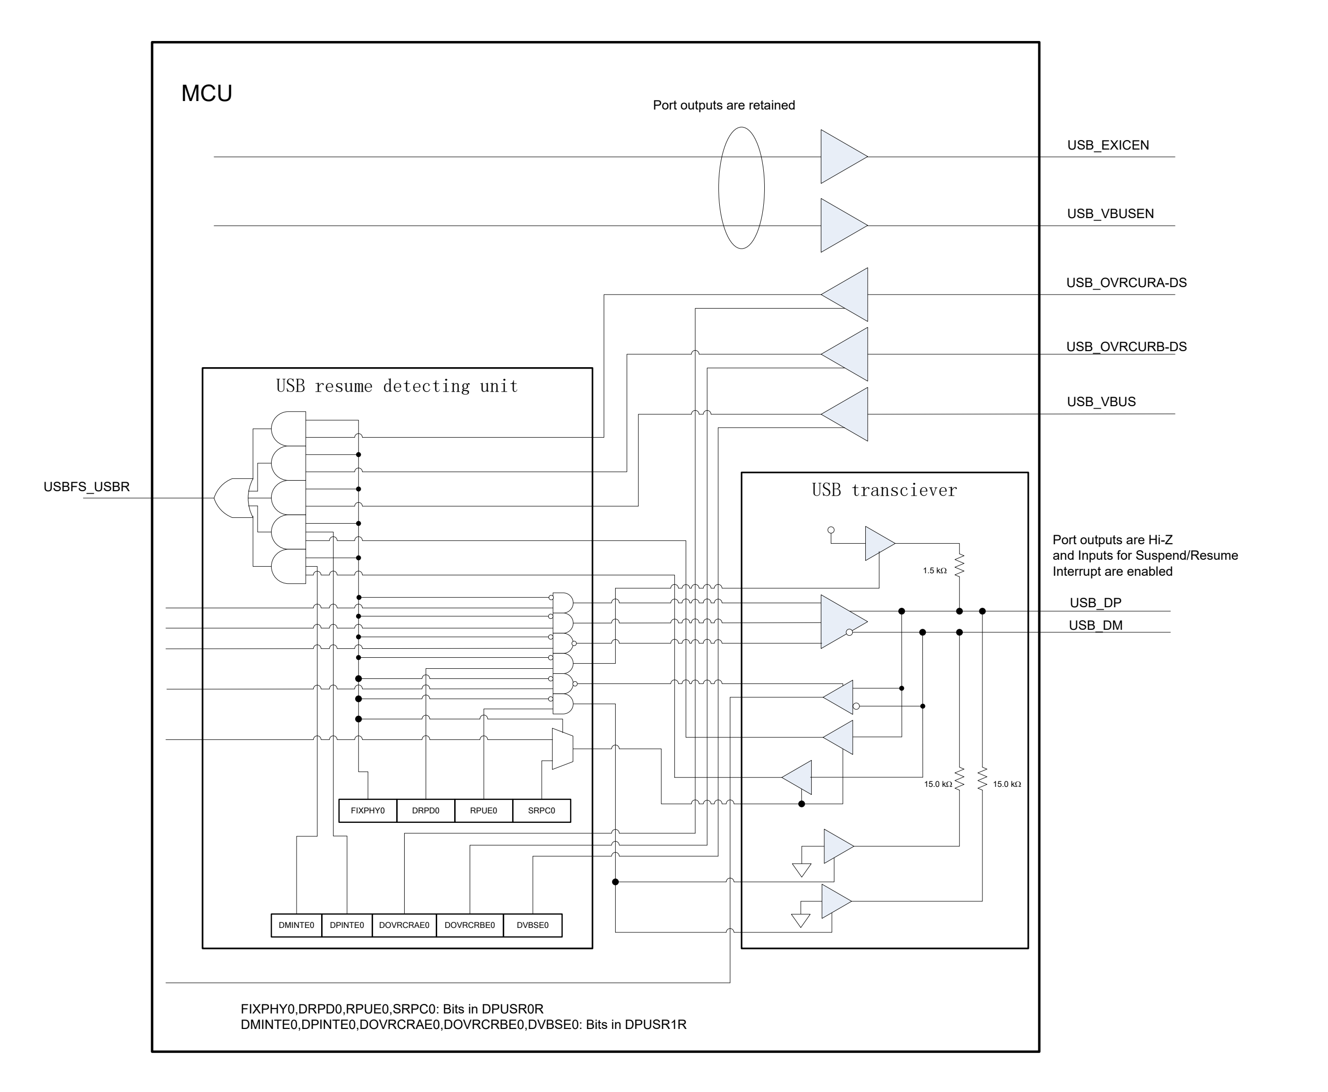

Figure 36.6 Connection between the USB resume detecting unit and the USB I/O pins

Table 36.15 shows the USB suspend and resume interrupt sources and their associated I/O pins.

Table 36.15 USB suspend and resume interrupt sources and their associated I/O pins

USB operating mode	Source	Pin name
Device, OTG	Resume	USB_DP
Host, OTG	Attach or detach	USB_DP, USB_DM
Device	Attach or detach	USB_VBUS
Host	Overcurrent detection	USB_OVRCURA-DS
OTG	Overcurrent detection	USB_OVRCURA-DS, USB_OVRCURB-DS

Figure 36.7 shows the flow for setting the USBFS when entering Deep Software Standby mode 1 from either host or device controller mode. Figure 36.8 shows the flow for setting the USBFS when canceling Deep Software Standby mode 1 from host controller mode. Figure 36.9 shows the flow for setting the USBFS when canceling Deep Software Standby mode 1 from device controller mode.

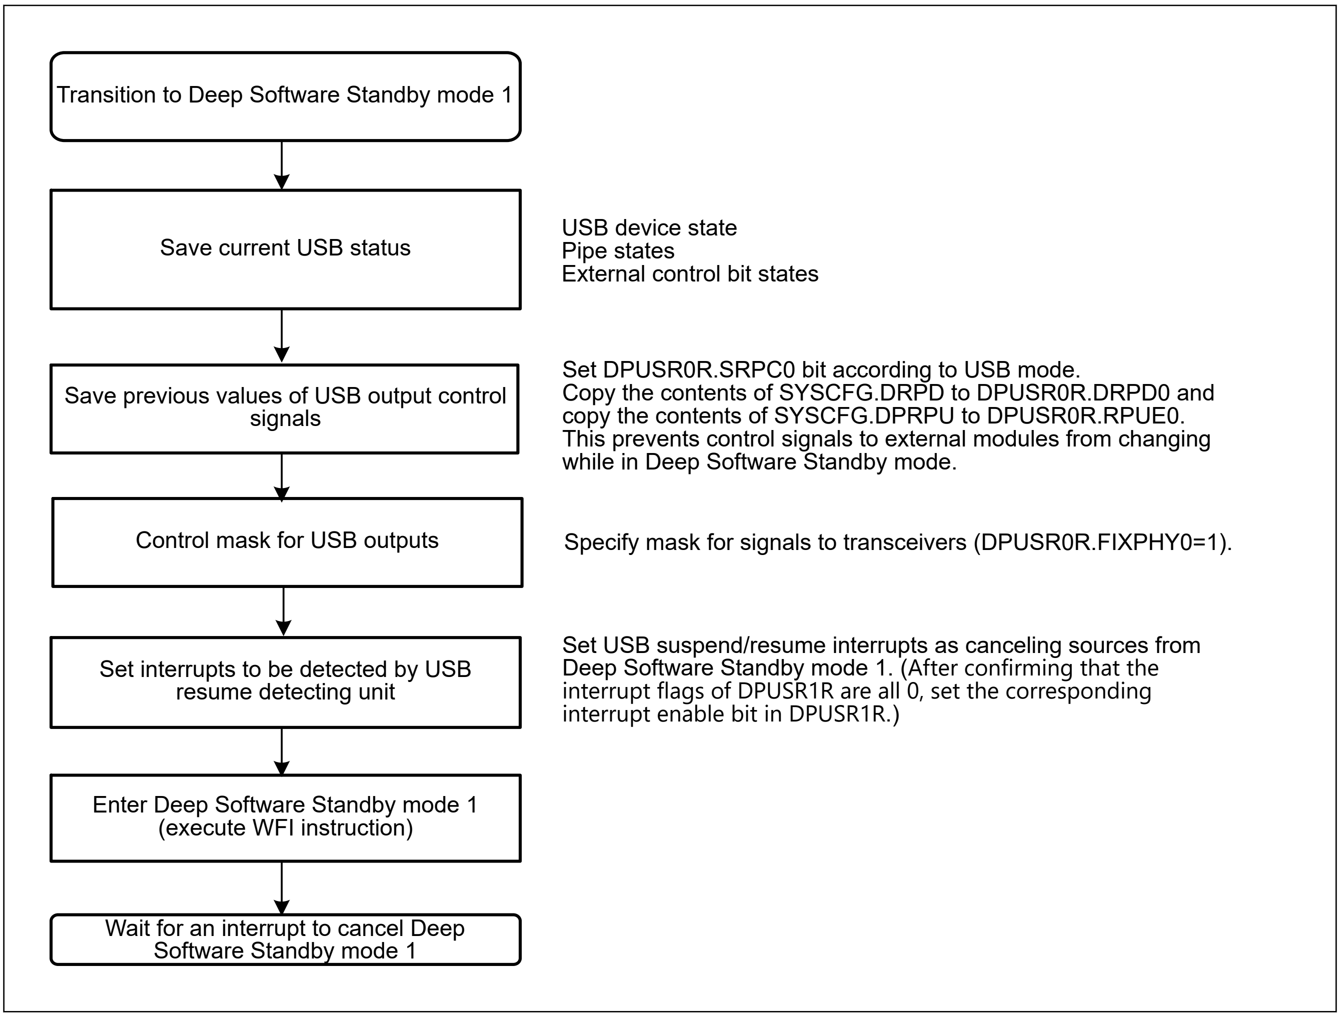

Figure 36.7 USBFS setup flow for transition to Deep Software Standby mode 1 as host or device controller

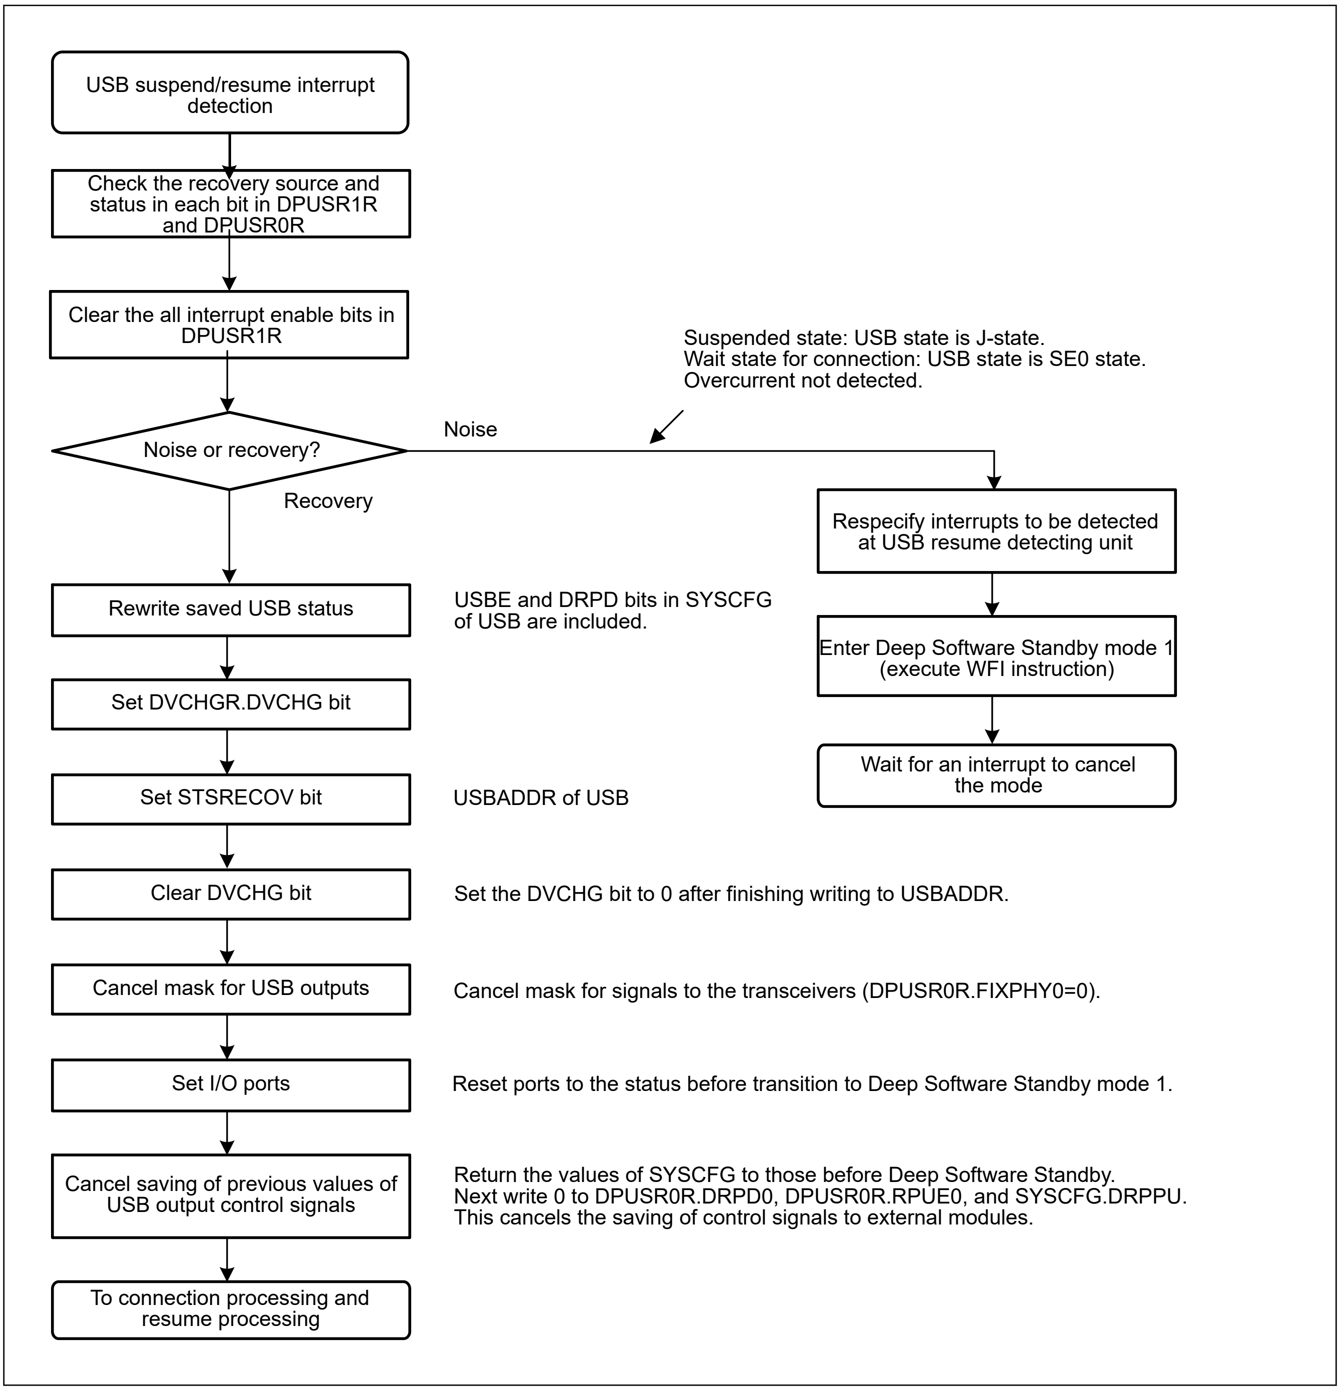

Figure 36.8 USBFS setup flow for canceling Deep Software Standby mode 1 as host controller

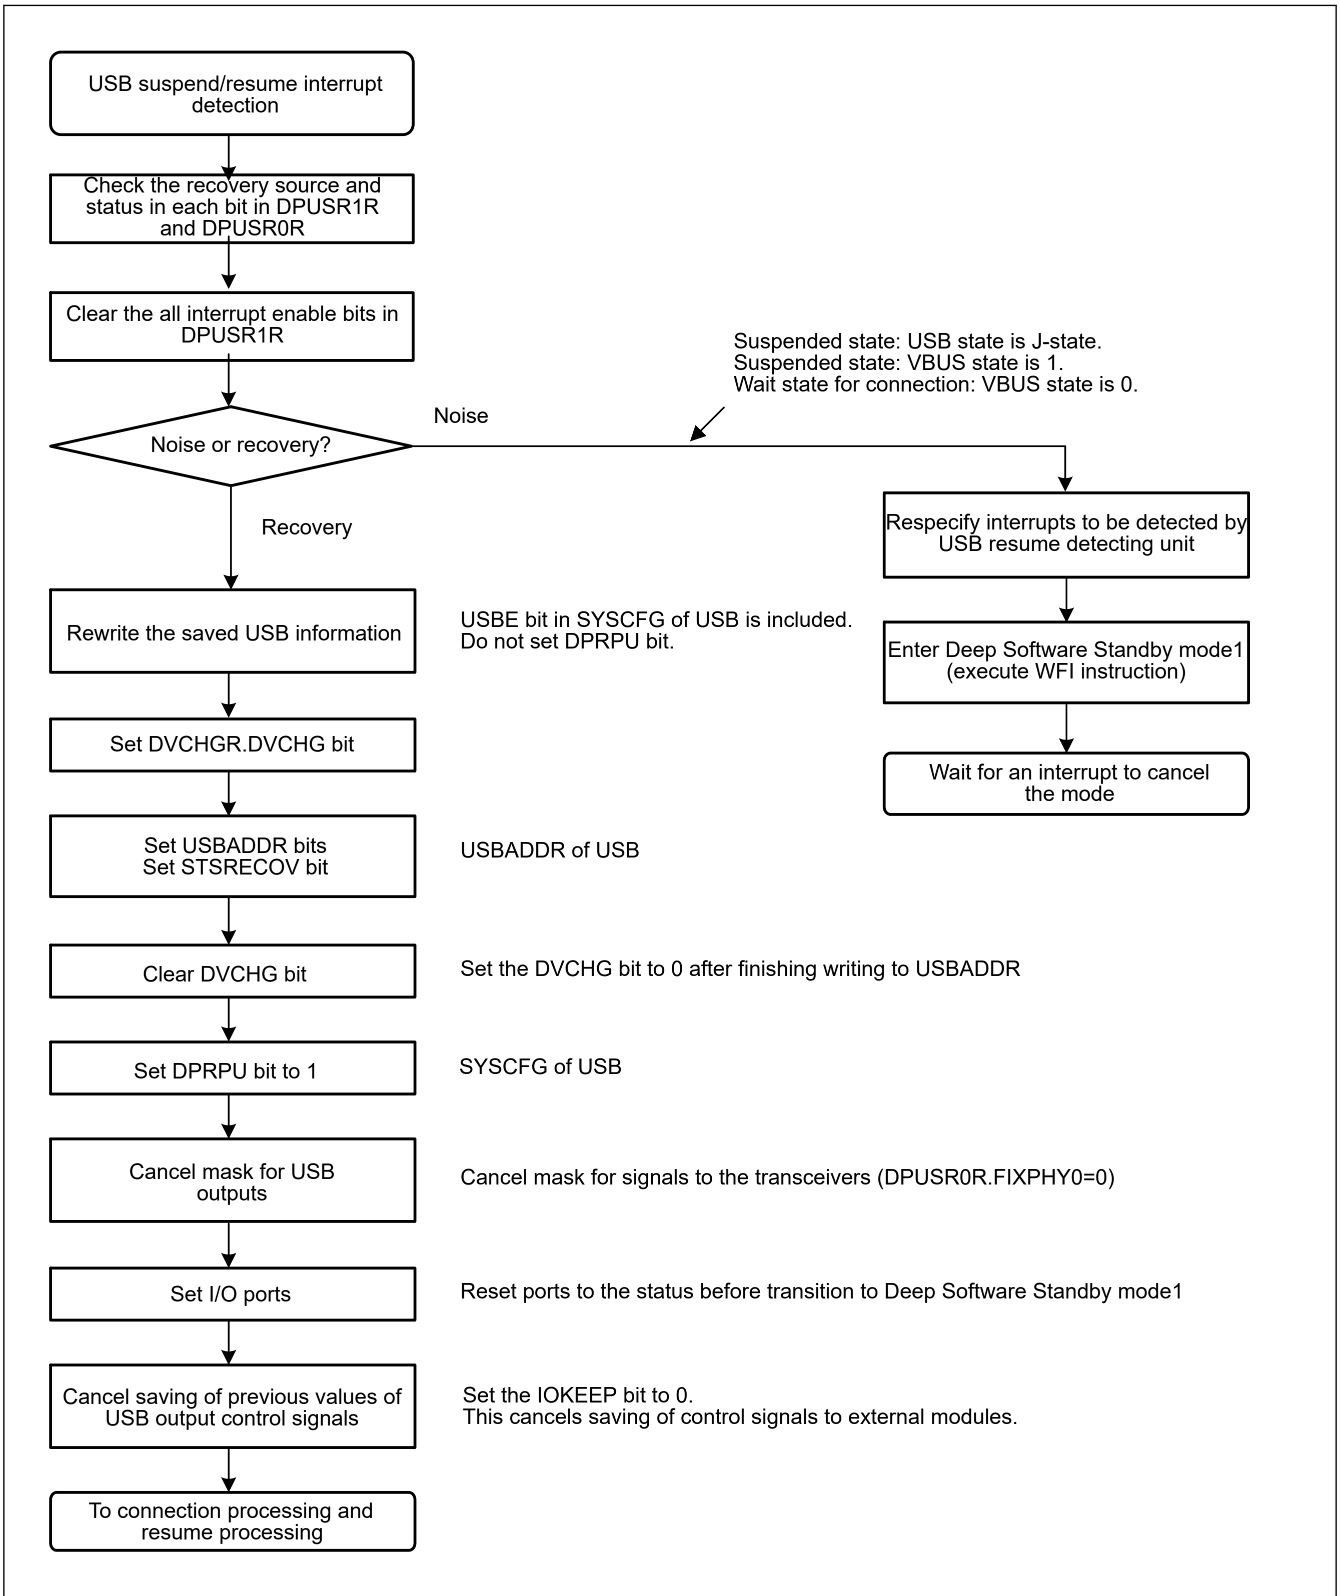

Figure 36.9 USBFS setup flow for canceling Deep Software Standby mode 1 as device controller

36.3.2 Interrupts

Table 36.16 lists the interrupt sources in the USBFS. When an interrupt generation condition is satisfied and the interrupt output is enabled using the associated interrupt enable register, a USBFS interrupt request is issued to the Interrupt Controller Unit (ICU) and an USBFS interrupt is generated.

Table 36.16 Interrupt sources (1 of 2)

Bit to be set to 1	Name	Interrupt source	Applicable controller function	Status flag
VBINT	VBUS interrupt	• A change in the state of the USB_VBUS input pin was detected (low to high or high to low)	Host or device*1	INTSTS0.VBSTS
RESM	Resume interrupt	• A change in the state of the USB bus was detected in the Suspend state (J-state to K-state or J-state to SE0)	Device	—
SOFR	Frame number update interrupt	In host controller mode: • An SOF packet with a different frame number was transmitted In device controller mode: • An SOF packet with a different frame number was received	Host or device	—
DVST	Device state transition interrupt	• One of the following device state transitions was detected: – USB bus reset was detected – Suspend state was detected – SET_ADDRESS request was received – SET_CONFIGURATION request was received	Device	INTSTS0.DVSQ[2:0]
CTRT	Control transfer stage transition interrupt	• A control transfer stage transition was detected because of one of the following: – Setup stage completed – Control write transfer status stage transition occurred – Control read transfer status stage transition occurred – Control transfer completed – Control transfer sequence error occurred	Device	INTSTS0.CTSQ[2:0]
BEMP	Buffer empty interrupt	• The buffer is empty after all FIFO buffer data was transmitted • A packet larger than the maximum packet size was received	Host or device	BEMPSTS.PIPEnBEMP
NRDY	Buffer not ready interrupt	In host controller mode • A STALL response was received from the peripheral device in response to the issued token • The response from the peripheral device in response to the issued token was not received successfully (no response three times consecutively or packet reception error three times consecutively) • An overrun or underrun error occurred during isochronous transfer In device controller mode • NAK was returned for an IN or OUT token while the PID [1:0] bits were set to 01b (BUF) • A CRC error or bit stuffing error occurred during data reception in isochronous transfer • An overrun or underrun occurred during data reception in isochronous transfer	Host or device	NRDYSTS.PIPEnNRDY
BRDY	Buffer ready interrupt	• The buffer is ready (readable or writable state)	Host or device	BRDYSTS.PIPEnBRDY
OVRCR	Overcurrent input change interrupt	• USB_OVRCURA, USB_OVRCURA-DS, USB_OVRCURB or USB_OVRCURB-DS input pin state change was detected (low to high or high to low)	Host	INTSTS1.OVRCR
BCHG	Bus change interrupt	• USB bus state change was detected	Host or device	SYSSTS0.LNST[1:0]
DTCH	Disconnect detection during full-speed operation	Peripheral device disconnect was detected in full-speed operation	Host	DVSTCTR0.RHST[2:0]
ATTCH	Device connect detection interrupt	• J-state or K-state was detected on the USB bus for 2.5 μs continuously This interrupt can be used to check whether peripheral devices are connected	Host	—

Table 36.16 Interrupt sources (2 of 2)

Bit to be set to 1	Name	Interrupt source	Applicable controller function	Status flag
EOFERR	EOF error detection interrupt	● An EOF error was detected for a peripheral device	Host	—
SACK	Setup normal interrupt	● A setup transaction normal response (ACK) was received	Host	—
SIGN	Setup error interrupt	● A setup transaction error (no response or ACK packet corruption) was detected three consecutive times	Host	—

Note 1. Although this interrupt can be generated in host controller mode, it is not usually used in this mode.

Figure 36.10 shows the circuits related to the USBFS interrupts.

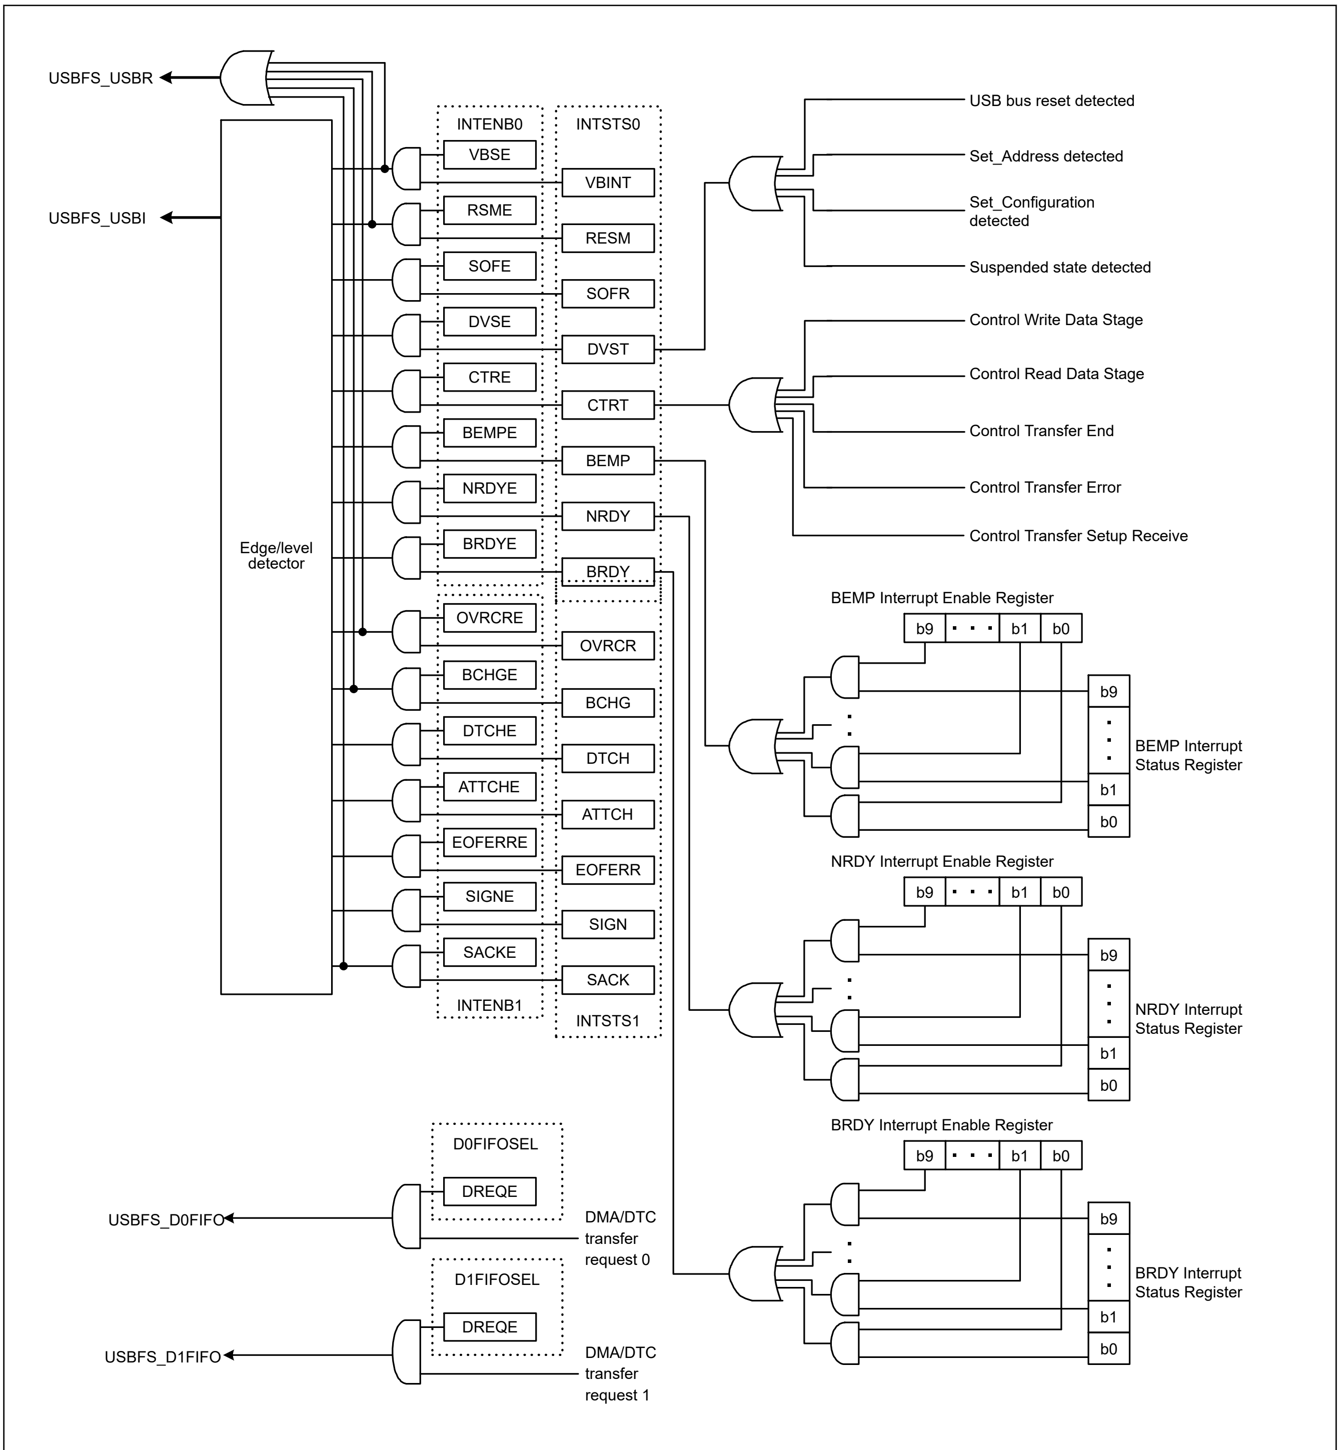

Figure 36.10 USBFS interrupt-related circuits

Table 36.17 shows the interrupts generated by the USBFS.

Table 36.17 USBFS interrupts

Interrupt name	Interrupt status flag	DTC activation	DMAC activation	Priority
USBFS_D0FIFO	DMA transfer request 0	Possible	Possible	High ↑ Low
USBFS_D1FIFO	DMA transfer request 1	Possible	Possible	
USBFS_USBI	VBUS interrupt, resume interrupt, frame number update interrupt, device state transition interrupt, control transfer stage transition interrupt, buffer empty interrupt, buffer not ready interrupt, buffer ready interrupt, overcurrent input change interrupt, bus change interrupt, disconnect detection interrupt during full-speed operation, device connect detection interrupt, EOF error detection interrupt, normal setup operation interrupt, and setup error interrupt	Not possible	Not possible	
USBFS_USBR*1	VBUS interrupt, resume interrupt, overcurrent input change interrupt and setup error interrupt	Not possible	Not possible	—

Note 1. Software Standby mode can be canceled. And Deep Software Standby mode 1 also can be canceled, but only dedicated pin (OVRCURA-DS, OVRCURB-DS) can be used for overcurrent pins.

36.3.3 Interrupt Descriptions

36.3.3.1 BRDY Interrupt

The BRDY interrupt is generated in both host and device controller modes. This section describes the conditions in which the USBFS sets the associated bit in BRDYSTS to 1. Under these conditions, the USBFS generates a BRDY interrupt if the software has set the bit in BRDYENB associated with the given pipe to 1 and the INTENB0.BRDYE bit to 1.

The conditions for generating and clearing the BRDY interrupt depend on the SOFCFG.BRDYM and PIPECFG.BFRE settings for each pipe as follows:

(1) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.

On any of the following conditions, the USBFS generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEnBRDY bit associated with the selected pipe to 1.

For transmitting pipes

- When the DIR bit is changed from 0 to 1 by software
- When packet transmission is complete for a pipe while write-access from the CPU to the FIFO buffer for the pipe is disabled (when the BSTS bit is read as 0)
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is complete
- When the hardware flushes the buffer of the pipe for isochronous transfers
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to transition from the write-disabled to write-enabled state

No request trigger is generated for the DCP, that is, during data transmission for control transfers.

For receiving pipes

- When packet reception is successfully complete, enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the given pipe is disabled (when the BSTS bit is read as 0). No request trigger is generated for transactions in which a DATA-PID mismatch has occurred.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer, even if reception by the other FIFO buffer is complete.

In device controller mode, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEBRDY interrupt status of the selected pipe can be set to 0 by writing 0 to the associated PIPEnBRDY bit through software. In this case, the other PIPEBRDY bit should be set to 1.

Clear the BRDY status before accessing the FIFO buffer.

(2) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 1

With these settings, the USBFS generates a BRDY interrupt on completion of reading all data for a single transfer using the receiving pipe, and sets the bit in BRDYSTS associated with the pipe to 1.

On any of the following conditions, the USBFS determines that the last data for a single transfer was received.

- When a short packet including a zero-length packet is received
- When the PIPEn transaction counter register (PIPEnTRN) is used and the number of packets specified in the PIPEnTRN.TRNCNT[15:0] bits are completely received

When the data is completely read after any of these conditions is satisfied, the USBFS determines that all data for a single transfer is completely read.

When a zero-length packet is received while the FIFO buffer is empty, the USBFS determines that all data for a single transfer is completely read when the FRDY bit in the FIFO port control register is 1 and the DTLN[8:0] bits are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the associated port control register through the software. With these settings, the USBFS does not detect a BRDY interrupt for the transmitting pipe.

The PIPEBRDY interrupt status of a pipe can be set to 0 by writing 0 to the associated BRDYSTS.PIPEnBRDY bit through the software. In this case, 1 must be written to the PIPEBRDY bits for the other pipes.

In this mode, do not change the PIPECFG.BFRE bit setting until all data for a single transfer is processed. When it is necessary to change the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pipe must be cleared using the PIPEnCTR.ACLRM bit.

(3) When SOFCFG.BRDYM = 1 and PIPECFG.BFRE = 0

With these settings, the BRDYSTS.PIPEnBRDY values are linked to the BSTS bit setting for each pipe. In other words, the BRDY interrupt status bits (PIPEBRDY) are set to 1 or 0 by the USB depending on the FIFO buffer status.

For transmitting pipes

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for write access, and are set to 0 when it is not ready. The BRDY interrupt is not generated for the DCP in the transmitting direction even when it is ready for write access.

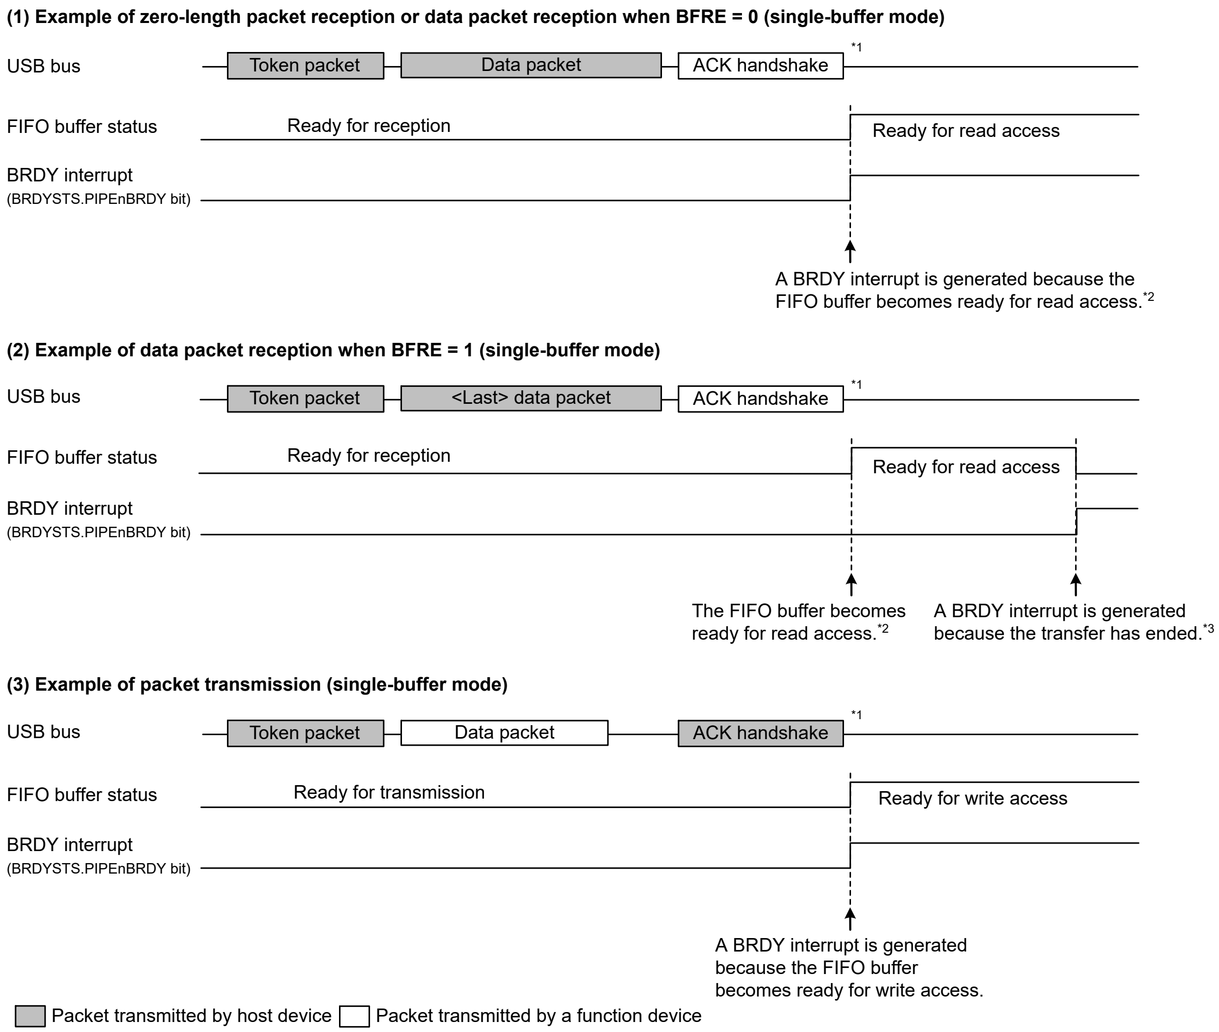
For receiving pipes

The BRDY interrupt status bits set to 1 when the FIFO buffer is ready for read access, and set to 0 when all data is read (not ready for read access).

When a zero-length packet is received while the FIFO buffer is empty, the associated bit is set to 1 and the BRDY interrupt is continuously generated until the software writes 1 to BCLR. With this setting, the PIPEnBRDY bit cannot be set to 0 by software.

When the SOFCFG.BRDYM bit is set to 1, set the PIPECFG.BFRE bit for all pipes to 0.

Figure 36.11 shows the timing of BRDY interrupt generation.



Note 1. The ACK handshake is not used in isochronous transfers.
Note 2. The FIFO buffer becomes ready for read access under the following condition:
When a packet is received while no data remains unread in the FIFO buffer in the CPU.
Note 3. A transfer ends under either of the following conditions:
1. When a short packet including a zero-length packet is received.
2. When the number of packets specified in the transaction counter are received.

Figure 36.11 Timing of BRDY interrupt generation

The condition for clearing the INTSTS0.BRDY bit depends on the SOFCFG.BRDYM bit setting, as shown in Table 36.18.

Table 36.18 Conditions for clearing the BRDY bit

BRDYM bit	Condition for clearing BRDY bit
0	The USBFS clears the BRDY bit to 0 when all bits in BRDYSTS are set to 0 by software.
1	The USBFS clears the BRDY bit to 0 when the BSTS bits for all pipes have cleared to 0.

36.3.3.2 NRDY Interrupt

On generating an internal NRDY interrupt request for the pipe whose PID bits are set to BUF by software, the USBFS sets the associated PIPEnNRDY bit in NRDYSTS to 1. If the associated bit in NRDYENB is set to 1 by software, the USBFS sets the INTSTS0.NRDY bit to 1 and generates a USBFS interrupt.

This section describes the conditions in which the USBFS generates the internal NRDY interrupt request for a given pipe.

The internal NRDY interrupt request is not generated during setup transaction execution in host controller mode. During setup transactions in host controller mode, the SACK or SIGN interrupt is detected.

The internal NRDY interrupt request is not generated during status stage execution of the control transfer in device controller mode.

(1) In host controller mode

For transmitting pipes

On any of the following conditions, the USBFS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBFS transmits a zero-length packet following the OUT token and sets the associated NRDYSTS.PIPEnNRDY bit and the FRMNUM.OVRN bit to 1.
- During communications other than setup transactions on pipes not used for isochronous transfers, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device
  - An error is detected in the packet from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the associated PID[1:0] setting for the pipe to NAK
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the PID[1:0] setting for the associated pipe to STALL (11b).

For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBFS discards the received data for the IN token and sets the PIPEnNRDY bit associated with the pipe and the OVRN bit to 1. When a packet error is detected in the received data for the IN token, the USBFS also sets the FRMNUM.CRCE bit to 1.
- For non-isochronous transfer pipes, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device for the IN token issued by the USBFS (when timeout is detected before detection of the DATA packet from the peripheral device)
  - An error is detected in the packet from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the associated PID[1:0] setting for the pipe to NAK
- For isochronous transfer pipes, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe to 1. The PID[1:0] setting for the pipe is not changed.
- For isochronous transfer pipes, when a CRC error or a bit stuffing error is detected in the received data packet. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe and the CRCE bit to 1.
- When the STALL handshake is received. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe to 1 and changes the PID[1:0] setting for the associated pipe to STALL.

(2) In device controller mode

For transmitting pipes

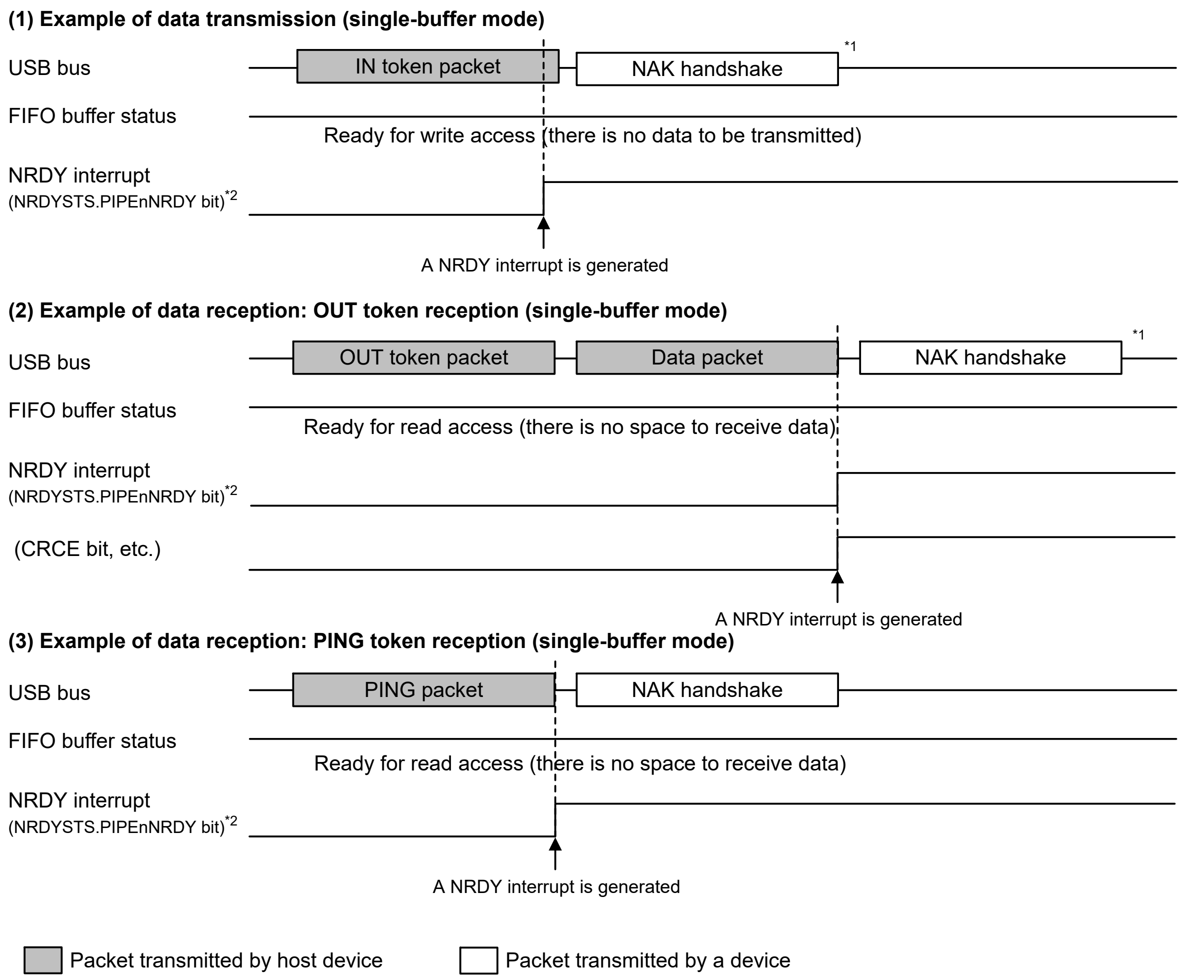
- When an IN token is received while there is no data to be transmitted in the FIFO buffer. In this case, the USBFS generates a NRDY interrupt request on reception of the IN token and sets the NRDYSTS.PIPEnNRDY bit to 1. For an isochronous transfer pipe in which an interrupt is generated, the USBFS transmits a zero-length packet and sets the FRMNUM.OVRN bit to 1.

For receiving pipes

- When an OUT token is received but there is no space available in the FIFO buffer. For an isochronous transfer pipe in which an interrupt is generated, the USBFS generates a NRDY interrupt request on reception of the OUT token and sets the PIPEnNRDY bit to 1 and OVRN bit to 1. For a non-isochronous transfer pipe in which an interrupt is generated, the USBFS generates a NRDY interrupt request when a NAK handshake is transferred after the data following the OUT token is received, and sets the PIPEnNRDY bit to 1. The NRDY interrupt request is not generated during retransmission because of a DATA-PID mismatch. In addition, the NRDY interrupt request is not generated if an error occurs in the DATA packet.

- For isochronous transfer pipes, when a token is not received successfully within an interval frame. In this case, the USBFS generates an NRDY interrupt request when the SOF is received, and sets the PIPEnNRDY bit to 1.

Figure 36.12 shows the timing of NRDY interrupt generation in device controller mode.



Note 1. The handshake is not used in isochronous transfers.
Note 2. The CRCE and OVRN bits change only while the target pipe is set to isochronous transfers.

Figure 36.12 Timing of NRDY interrupt generation in device controller mode

36.3.3.3 BEMP Interrupt

On detecting a BEMP interrupt for the pipe whose PID bits are set to BUF by software, the USBFS sets the associated BEMPSTS.PIPEnBEMP bit to 1. If the associated bit in BEMPENB is set to 1 by software, the USBFS sets the INTSTS0.BEMP bit to 1 and generates a USBFS interrupt. This section describes the conditions in which the USBFS generates an internal BEMP interrupt request.

(1) For transmitting pipes

When the FIFO buffer of the associated pipe is empty on completion of transmission, including zero-length packet transmission, and in single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for a non-DCP pipe. The internal BEMP interrupt request is not generated in any of the following conditions:

- When the CPU or DMA/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode

- When the buffer is cleared (emptied) by setting the PIPEnCTR.ACLRM or the BCLR bit to 1 in the port control register
- When an IN transfer (zero-length packet transmission) is performed during the control transfer status stage in device controller mode

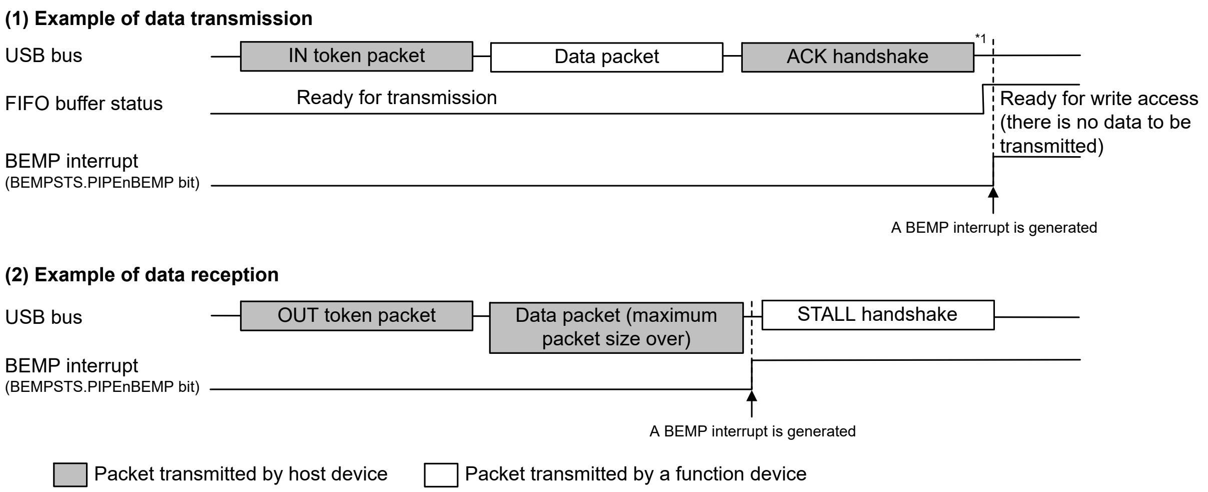
(2) For receiving pipes

When a successfully-received data packet size exceeds the specified maximum packet size. In this case, the USBFS generates a BEMP interrupt request, sets the associated BEMPSTS.PIPEnBEMP bit to 1, discards the received data, and changes the associated PID[1:0] setting for the pipe to STALL (11b). The USBFS returns no response in host controller mode, and returns STALL response in device controller mode.

The internal BEMP interrupt request is not generated in any of the following conditions:

- When a CRC error or a bit stuffing error is detected in the received data
- When a setup transaction is being performed:
  - Writing 0 to the BEMPSTS.PIPEnBEMP bit clears the status
  - Writing 1 to the BEMPSTS.PIPEnBEMP bit has no effect

Figure 36.13 shows the timing of BEMP interrupt generation in device controller mode.



Note 1. The handshake is not used in isochronous transfers.

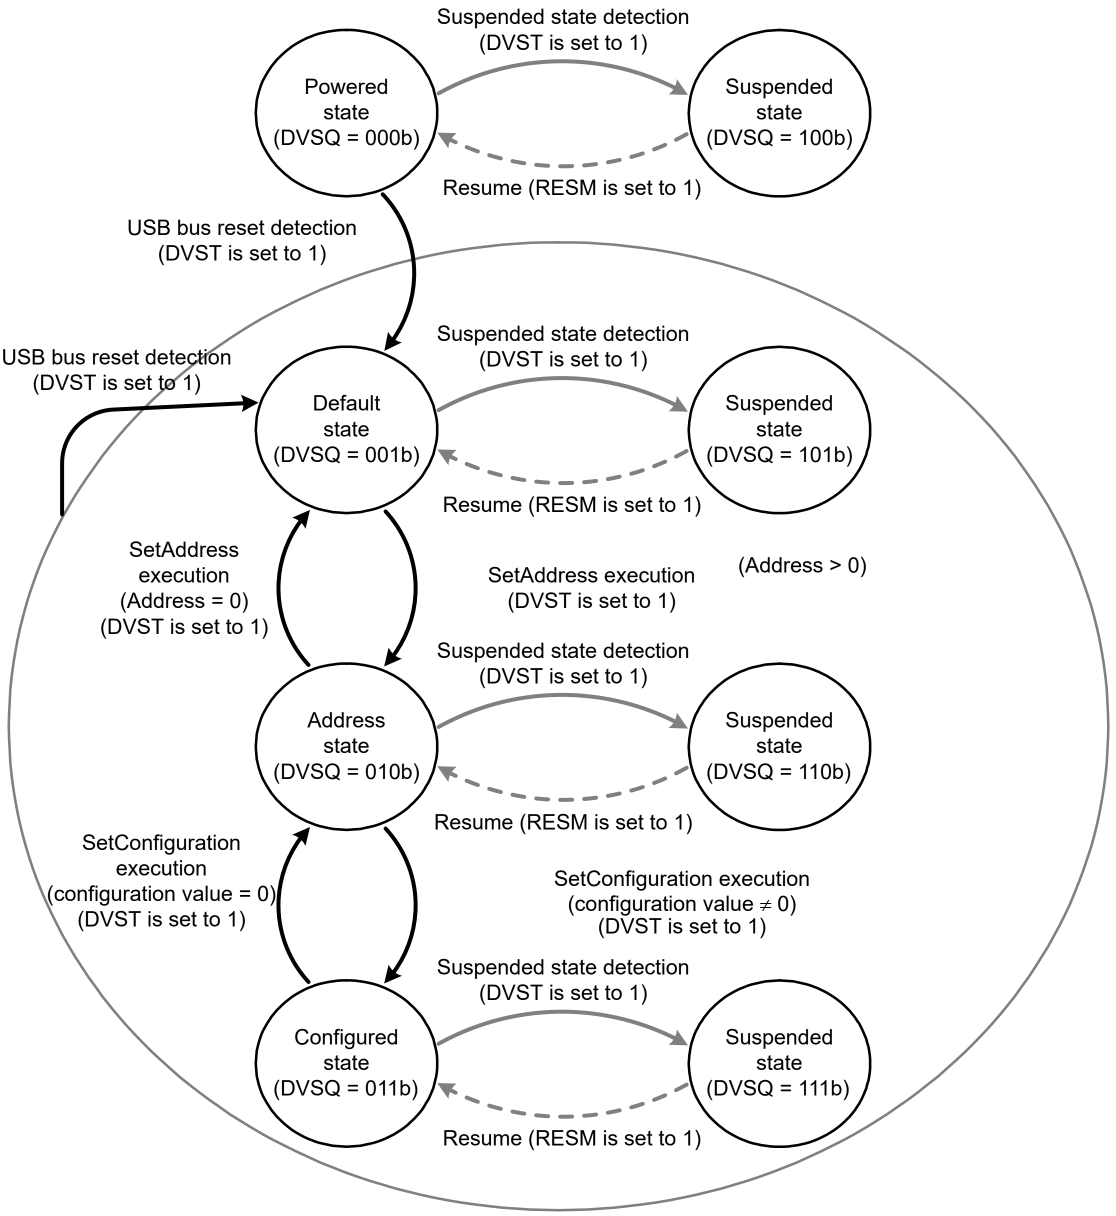
Figure 36.13 Timing of BEMP interrupt generation in device controller mode

36.3.3.4 Device State Transition Interrupt (Device Controller Mode)

Figure 36.14 shows a diagram of the USBFS device state transitions. The USBFS controls device states and generates device state transition interrupts. However, recovery from the Suspend state (resume signal detection) is detected by means of the resume interrupt. Device state transition interrupts can be enabled or disabled independently in INTENB0. Devices whose states have changed can be checked in the INTSTS0.DVSQ[2:0] bits.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is detected.

The USBFS controls device states, and device state transition interrupts can be generated, only in device controller mode.



Note: For a transition indicated by a solid line, the DVST bit is set to 1.
For a resume indicated by a dashed line, the RESM bit is set to 1.

Figure 36.14 Device state transitions

36.3.3.5 Control Transfer Stage Transition Interrupt (Device Controller Mode)

Figure 36.15 shows a diagram of the control transfer stage transitions of the USBFS. The USBFS controls the control transfer sequence and generates control transfer stage transition interrupts. Control transfer stage transition interrupts can be enabled or disabled independently in INTENB0. Transfer stages that have transitioned can be checked in the INTSTS0.CTSQ[2:0] bits.

Control transfer stage transition interrupts are generated only in device controller mode. This section describes control transfer sequence errors. If an error occurs, the DCPCTR.PID[1:0] bits are set to 1xb (STALL response).

(1) Control read transfer errors

- An OUT token is received but no data is transferred in response to the IN token at the data stage
- An IN token is received at the status stage

- A data packet with DATAPID = DATA0 is received at the status stage

(2) Control write transfer errors

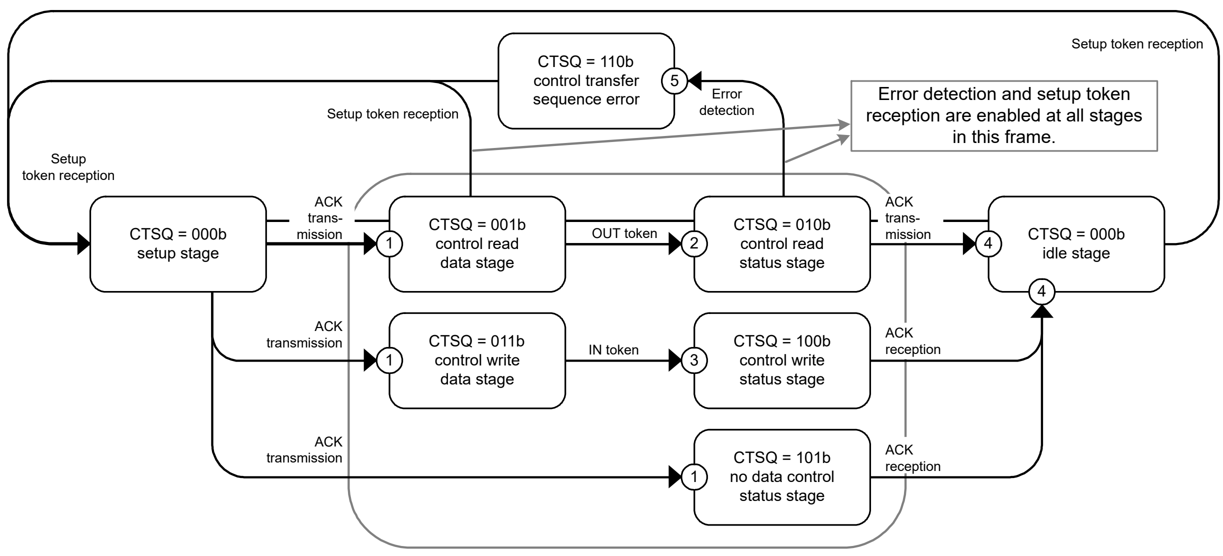
- An IN token is received but no ACK is returned in response to the OUT token at the data stage
- A data packet with DATAPID = DATA0 is received as the first data packet at the data stage
- An OUT token is received at the status stage

(3) Control write no data transfer errors

- An OUT token is received at the status stage

At the control write transfer data stage, if the receive data length exceeds the wLength value of the USB request, it is not recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT = 1), the CTSQ[2:0] = 110b value is saved until the CTRT bit is set to 0, clearing the interrupt status. While CTSQ[2:0] = 110b is being saved, no CTRT interrupt for ending the setup stage is generated, even if a new USB request is received. The USBFS saves the setup stage completion status, and it generates a CTRT interrupt after the interrupt status is cleared by software.



Note: CTRT interrupts
1. Setup stage end
2. Control read transfer status stage transition
3. Control write transfer status stage transition
4. Control transfer end
5. Control transfer sequence error

Figure 36.15 Control transfer stage transitions

36.3.3.6 Frame Update Interrupt

In host controller mode, an interrupt is generated when the frame number is updated.

In device controller mode, an SOFR interrupt is generated when the frame number is updated. The USBFS updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

36.3.3.7 VBUS Interrupt

When the USB_VBUS pin level changes, a VBUS interrupt is generated. The level of the USB_VBUS pin can be checked with the INTSTS0.VBSTS bit. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. If the system is activated with the host controller connected, the first VBUS interrupt is not generated, because there is no change in the USB_VBUS pin level.

36.3.3.8 Resume Interrupt

In device controller mode, a resume interrupt is generated when the device state is the Suspend state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the Suspend state is detected by means of the resume interrupt.

In host controller mode, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

36.3.3.9 OVRCR Interrupt

An OVRCR interrupt is generated when the USB_OVRCURA, USB_OVRCURA-DS, USB_OVRCURB or USB_OVRCURB-DS pin level has changed. The levels of the USB_OVRCURA, USB_OVRCURA-DS, USB_OVRCURB and USB_OVRCURB-DS pins can be checked in the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent is detected using the OVRCR interrupt.

For OTG connections, the OVRCR interrupt allows you to check whether a change is detected in the VBUS comparator.

36.3.3.10 BCHG Interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether a peripheral device is connected and can also be used to detect a remote wakeup in host controller mode. The BCHG interrupt is generated in both host and device controller modes.

36.3.3.11 DTCH Interrupt

A DTCH interrupt occurs when a USB bus disconnect is detected in host controller mode. The USBFS detects bus disconnects in compliance with the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software. The pipes enter the wait state for a bus connection to the port, waiting for an ATTCH interrupt to occur. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt is detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

36.3.3.12 SACK Interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet is received from the peripheral device in host controller mode. The SACK interrupt can be used to confirm that the setup transaction is successfully complete.

36.3.3.13 SIGN Interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet is not correctly received from the peripheral device three consecutive times in host controller mode. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

36.3.3.14 ATTCH Interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5 µs in host controller mode. To be more specific, an ATTCH interrupt is detected on any of the following conditions:

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5 µs
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5 µs

36.3.3.15 EOFERR Interrupt

An EOFERR interrupt occurs when the USBFS detects that communication is not complete at the EOF2 timing defined in the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software, and the port must be re-enumerated. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt is detected to 0
- Puts the port in which the EOFERR interrupt is generated into the idle state

36.3.4 Pipe Control

Table 36.19 lists the pipe settings for the USBFS. USB data transfer is performed through logical pipes that the software associates with endpoints. The USBFS provides 10 pipes that are used for data transfer. Set up the pipes based on your system specifications.

Table 36.19 Pipe settings

Register name	Bit name	Setting	Notes
DCPCFG PIPECFG	TYPE	Transfer type	Pipes 1 to 9: Settable
	BFRE	BRDY interrupt mode	Pipes 1 to 5: Settable
	DBLB	Double buffer select	Pipes 1 to 5: Settable
	DIR	Transfer direction select	IN or OUT settable
	EPNUM	Endpoint number	Pipes 1 to 9: Settable A value other than 0000b must be set when the pipe is used.
	SHTNAK	Selects disabled state for pipe when transfer ends	Pipes 1 and 2: Settable only for bulk transfers Pipes 3 to 5: Settable
DCPMAXP PIPEMAXP	DEVSEL	Device select	Referenced only in host controller mode.
	MXPS	Maximum packet size	Compliant with the USB 2.0 specification.
PIPEPERI	IFIS	Buffer flush	Pipes 1 and 2: Settable only for isochronous transfers Pipes 3 to 9: Setting disabled
	IITV	Interval counter	Pipes 1 and 2: Settable only for isochronous transfers Pipes 3 to 5: Setting disabled Pipes 6 to 9: Settable only in host controller mode
DCPCTR PIPEnCTR	BSTS	Buffer status	For the DCP, receive buffer status and transmit buffer status are switched with the ISEL bit.
	INBUFM	IN buffer monitor	Available only for pipes 1 to 5.
	SUREQ	Setup request	Settable only for the DCP and controlled in host controller mode
	SUREQCLR	SUREQ clear	Settable only for the DCP and controlled in host controller mode
	ATREPM	Auto response mode	Pipes 1 to 5: Settable only in device controller mode
	ACLRM	Auto buffer clear	Pipes 1 to 9: Settable
	SQCLR	Sequence clear	Clears the data toggle bit
	SQSET	Sequence set	Sets the data toggle bit
	SQMON	Sequence monitor	Monitors the data toggle bit
	PBUSY	Pipe busy status	—
	PID	Response PID	See section 36.3.4.6. Response PID.
PIPEnTRE	TRENB	Transaction counter enable	Pipes 1 to 5: Settable
	TRCLR	Current transaction counter clear	Pipes 1 to 5: Settable
PIPEnTRN	TRNCNT	Transaction counter	Pipes 1 to 5: Settable

36.3.4.1 Pipe Control Register Switching Procedures

The following bits in the pipe control registers can be changed only when USB communication is prohibited (PID = NAK).

Do not change the following registers and bits when USB communication is enabled (PID = BUF):

- Bits in DCPCFG and DCPMAXP

- SQCLR and SQSET bits in DCPCTR
- Bits in PIPECFG, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPEnCTR
- Bits in PIPEnTRE and PIPEnTRN

To set these bits when USB communication is enabled (PID = BUF):

1. A request to change the bits in the pipe control register occurs.
2. Set the PID[1:0] bits associated with the pipe to NAK.
3. Wait until the associated PBUSY bit clears to 0.
4. Set the bits in the pipe control register.

The following bits in the pipe control registers can be changed only when the selected pipe information is not set in the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Do not set the following registers when the CURPIPE[3:0] bits are set:

- Bits in DCPCFG and DCPMAXP
- Bits in PIPECFG, PIPEMAXP and PIPEPERI

To change pipe information, you must set the CURPIPE[3:0] bits in the port select registers to a pipe other than the one to be changed. For the DCP, the buffer must be cleared using the BCLR bit in the Port Control Register after the pipe information is changed.

36.3.4.2 Transfer Types

The PIPECFG.TYPE[1:0] bits specify the following transfer types for each pipe:

- DCP: No setting is necessary (fixed at control transfer)
- Pipes 1 and 2: Set to bulk or isochronous transfer
- Pipes 3 to 5: Set to bulk transfer
- Pipes 6 to 9: Set to interrupt transfer

36.3.4.3 Endpoint Number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to 15.

- DCP: No setting is necessary (fixed at endpoint 0)
- Pipes 1 to 9: Select and set the endpoint numbers from 1 to 15 so that the combination of the PIPECFG.DIR and EPNUM[3:0] bits is unique

36.3.4.4 Maximum Packet Size Setting

Specify the maximum packet size for each pipe in the DCPMAXP.MXPS[6:0] and PIPEMAXP.MXPS[9:0] bits. The DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined in the USB 2.0 specification. For pipes 6 to 9, the maximum packet size is 64 bytes. Set the maximum packet size as follows before starting a transfer (PID = BUF):

- DCP: Set to 8, 16, 32, or 64
- Pipes 1 to 5: Set to 8, 16, 32, or 64 for bulk transfers
- Pipes 1 and 2: Set between 1 and 256 for isochronous transfers
- Pipes 6 to 9: Set between 1 and 64

36.3.4.5 Transaction Counter for Pipes 1 to 5 in the Receiving Direction

When the specified number of transactions is complete in the data packet receiving direction, the USBFS recognizes that the transfer ended. Two transaction counters are provided: one is the PIPEnTRN register, which specifies the number of transactions to be executed, and the other is the current counter, which internally counts the number of executed transactions. If the PIPECFG.SHTNAK bit is set to 1, when the current counter value matches the specified number of transactions, the associated PIPEnCTR.PID[1:0] bits are set to NAK and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The data read from PIPEnTRN differs depending on the PIPEnTRE.TRENB setting as follows:

- The TRENB bit = 0: Specified transaction counter value can be read
- The TRENB bit = 1: Current counter value indicating the internally counted number of executed transactions can be read

The following constraints apply when working with the TRCLR bit:

- If the transactions are being counted and PID = BUF, the current counter cannot be cleared
- If there is any data left in the buffer, the current counter cannot be cleared

36.3.4.6 Response PID

Specify the response PID for each pipe in the PID[1:0] bits in DCPCTR and PIPEnCTR. This section describes the USBFS operation with different response PID settings.

(1) Software response PID settings in host controller mode

Select the response PID to specify the execution of transactions as follows:

- NAK setting: Using pipes is disabled and no transactions are executed
- BUF setting: Transactions are executed based on the FIFO buffer state:
  - OUT direction: An OUT token is issued if the FIFO buffer contains transmit data.
  - IN direction: An IN token is issued if the FIFO buffer is not full and can receive data.
- STALL setting: Using pipes is disabled and no transactions are executed

Note: Use the DCPCTR.SUREQ bit to execute setup transactions for the DCP.

(2) Software response PID settings in device controller mode

Select the response PID to respond as follows to transactions from the host:

- NAK setting: A NAK response is returned to all generated transactions
- BUF setting: A response is returned to transactions based on the FIFO buffer
- STALL setting: A STALL response is returned to all generated transactions

Note: For setup transactions, an ACK response is always returned, regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

Sections (3) and (4) describe situations in which the USBFS writes to the PID[1:0] bits because of specific transaction results.

(3) Hardware response PID settings in host controller mode

- NAK setting: PID = NAK is set in the following cases, and issuing of tokens is automatically stopped:
  - When a non-isochronous transfer is performed and an NRDY interrupt is generated

    (For details, see section 36.3.3.2. NRDY Interrupt.)
  - If a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
  - If transaction counting ends when the SHTNAK bit is set to 1 for bulk transfers
- BUF setting: The USBFS does not write this setting.
- STALL setting: PID = STALL is set in the following cases, and issuing of tokens is automatically stopped:
  - When STALL is received in response to a transmitted token
  - When a received data packet exceeds the maximum packet size

(4) Hardware response PID settings in device controller mode

- NAK setting: PID = NAK is set in the following cases, and a NAK response is returned to transactions:
  - When the setup token is received normally (DCP only)
  - If transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
- BUF setting: There is no BUF writing by the USBFS.
- STALL setting: PID = STALL is set in the following cases, and a STALL response is returned to transactions:
  - When a received data packet exceeds the maximum packet size
  - When a control transfer sequence error is detected (DCP only)

36.3.4.7 Data PID Sequence Bit

The USBFS automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON bit in DCPCTR and PIPEnCTR. When data is transmitted, the sequence bit toggles on ACK handshake reception. When data is received, the sequence bit toggles on ACK handshake transmission. The SQCLR bit in DCPCTR and the SQSET bit in PIPEnCTR can be used to change the data PID sequence bit.

In device controller mode when control transfers are used, the USBFS automatically sets the sequence bit for stage transitions. DATA1 is returned when the setup stage ends. The sequence bit is not referenced and PID = DATA1 is returned in the status stage. Therefore, no software settings are required. However, in host controller mode when control transfers are used, the sequence bit must be set by software for the stage transitions.

For ClearFeature requests for transmission or reception, the data PID sequence bit must be set by software in both host and device controller modes.

36.3.4.8 Response PID = NAK Function

The USBFS provides a function for disabling pipe operation (PID response = NAK) when the final data packet of a transaction is received. The USBFS automatically distinguishes this based on reception of a short packet or the transaction counter. Enable this function by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation is disabled, the software must enable the pipe again (PID response = BUF).

The response PID = NAK function can be used only for bulk transfers.

36.3.4.9 Auto Response Mode

For bulk transfer pipes (1 to 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (PIPECFG.DIR = 0), OUT-NAK mode is invoked, and during an IN transfer (DIR = 1), null auto response mode is invoked.

36.3.4.10 OUT-NAK Mode

For bulk OUT transfer pipes, NAK is returned in response to an OUT token, and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To transition from normal mode to OUT-NAK mode, specify OUT-NAK mode while pipe operation is disabled (PID[1:0] = 00b for NAK response). Next enable pipe operation (PID[1:0] = 01b for BUF response), on which OUT-NAK mode becomes valid. If an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To transition from OUT-NAK mode to normal mode, cancel OUT-NAK mode while pipe operation is disabled (NAK). Next enable pipe operation (BUF). In normal mode, reception of OUT data is enabled.

36.3.4.11 Null Auto Response Mode

For bulk IN transfer pipes, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To transition from normal mode to null auto response mode, specify null auto response mode while pipe operation is disabled (response PID = NAK). Next enable pipe operation (response PID = BUF) on which null auto response mode becomes valid. Before setting null auto response mode, check that PIPEnCTR.INBUFM = 0, because the mode can be set only when the buffer is empty. If the INBUFM bit is 1, empty the buffer using the PIPEnCTR.ACLRM bit. Do not write data from the FIFO port while a transition to null auto response mode is being made.

To transition from null auto response mode to normal mode, keep pipe operation disabled (response PID = NAK) for the period of the zero-length packet transmission (about 10 µs) before canceling the null auto response mode. In normal mode, data can be written from the FIFO port, so packet transmission to the host is enabled by enabling pipe operation (response PID = BUF).

36.3.5 FIFO Buffer

The USBFS provides a FIFO buffer for data transfers, and it manages the memory area used for each pipe. The FIFO buffer has two states depending on whether the access right is assigned to the system (CPU side) or the USBFS (SIE side).

(1) Buffer status

Table 36.20 and Table 36.21 show the buffer status in the USBFS. The FIFO buffer status can be confirmed using the DCPCTR.BSTS and PIPEnCTR.INBUFM bits. The transfer direction for the FIFO buffer can be specified in either the PIPECFG.DIR or CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM bit is valid for pipes 1 to 5 in the transmitting direction.

When a transmitting pipe uses double buffering, the software can read the BSTS bit to monitor the FIFO buffer status on the CPU side and the INBUFM bit to monitor the FIFO buffer status on the SIE side. When write access to the FIFO port by the CPU or DMA/DTC is slow and the buffer empty status cannot be determined using the BEMP interrupt, the software can use the INBUFM bit to confirm the end of transmission.

Table 36.20 Buffer status indicated in the BSTS bit

ISEL or DIR	BSTS	FIFO buffer status
0 (receiving direction)	0	There is no received data, or data is being received. Reading from the FIFO port is disabled.
0 (receiving direction)	1	There is received data, or a zero-length packet is received. Reading from the FIFO port is allowed. When a zero-length packet is received, reading is not possible and the buffer must be cleared.
1 (transmitting direction)	0	Transmission has not completed. Writing to the FIFO port is disabled.
1 (transmitting direction)	1	Transmission is complete. CPU write is allowed.

Table 36.21 Buffer status indicated in the INBUFM bit

DIR	INBUFM	FIFO buffer status
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	Transmission is complete. There is no data waiting to be transmitted.
1 (transmitting direction)	1	The FIFO port has written data to the buffer. There is data to be transmitted.

36.3.6 FIFO Buffer Clearing

Table 36.22 shows the methods for clearing the FIFO buffer. The FIFO buffer can be cleared using BCLR bit in the port control register, DnFIFOSEL.DCLRM, or the PIPEnCTR.ACLRM bit.

Single or double buffering can be selected for pipes 1 to 5 in the PIPECFG.DBLB bit.

Table 36.22 Buffer clearing methods (1 of 2)

FIFO buffer clearing mode	Clearing FIFO buffer on the CPU side	Mode for automatically clearing the FIFO buffer after reading the specified pipe data	Auto buffer clear mode for discarding all received packets
Register used	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR

Table 36.22 Buffer clearing methods (2 of 2)

FIFO buffer clearing mode	Clearing FIFO buffer on the CPU side	Mode for automatically clearing the FIFO buffer after reading the specified pipe data	Auto buffer clear mode for discarding all received packets
Bit used	BCLR	DCLRM	ACLRM
Clearing condition	Cleared by writing 1	1: Mode valid 0: Mode invalid	1: Mode valid 0: Mode invalid

(1) Auto buffer clear mode function

The USBFS discards all received data packets if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet is received, the ACK response is returned to the host controller. The auto buffer clear mode function can only be set in the FIFO buffer reading direction.

Setting the ACLRM bit to 1 and then to 0 clears the FIFO buffer of the selected pipe regardless of the access direction. An access cycle of at least 100 ns is required for the internal hardware sequence processing between ACLRM = 1 and ACLRM = 0.

36.3.7 FIFO Port Functions

Table 36.23 shows the settings for the FIFO port functions. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, set the BVAL flag in the port control register to end writing. To send a zero-length packet, use the BCLR bit to clear the buffer, and then set the BVAL flag to end writing.

In reading, reception of new packets is automatically enabled when all data is read. Data cannot be read when a zero-length packet is received (DTLN[8:0] = 0), so the buffer must be cleared with the BCLR bit. The length of the receive data can be confirmed in the DTLN[8:0] bits in the port control register.

Table 36.23 FIFO port function settings

Register name	Bit name	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	Selects DTLN[11:0] read mode
	REW	FIFO buffer rewind (re-read, rewrite)
	DCLRM	Automatically clears receive data for a specified pipe after the data is read (only for DnFIFO)
	DREQE	Enables DMA/DTC transfers (only for DnFIFO)
	MBW	FIFO port access bit width
	BIGEND	Selects FIFO port endian
	ISEL	FIFO port access direction (only for DCP)
	CURPIPE	Selects the current pipe
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	Ends writing to the FIFO buffer
	BCLR	Clears the FIFO buffer on the CPU side
	DTLN	Checks the length of receive data

(1) FIFO port selection

Table 36.24 shows the pipes that can be selected with the different FIFO ports. The pipe to be accessed must be selected in the CURPIPE[3:0] bits in the port select register. After the pipe is selected, the software must check whether the written value can be read correctly from the CURPIPE[3:0] bits. (If the previous pipe number is read, it indicates that the USBFS is modifying the pipe.) Next, the software checks that the FRDY bit in the port control register is 1.

In addition, the software must specify the bus width to be accessed in the MBW bit in the port select register. The FIFO buffer access direction conforms to the PIPECFG.DIR setting. For the DCP only, the ISEL bit in the port select register determines the direction.

Table 36.24 FIFO port access by pipe

Pipe	Access method	Ports that can be used
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	• CFIFO port register • D0FIFO/D1FIFO port register
	DMA/DTC access	D0FIFO/D1FIFO port register

(2) REW bit

It is possible to temporarily stop access to a pipe currently being accessed, access a different pipe, and then continue processing for the first pipe again. The REW bit in the port select register is used for this processing.

If a pipe is selected in the CURPIPE[3:0] bits in the port select register with the REW bit set to 1, the pointer used for reading from and writing to the FIFO buffer is reset, and reading or writing can be carried out from the first byte. If a pipe is selected with 0 set for the REW bit, data can be read and written in continuation from the previous selection, without the pointer being reset.

To access the FIFO port, the software must check that the FRDY bit in the port control register is 1 after selecting a pipe.

36.3.8 DMA Transfers (D0FIFO and D1FIFO Ports)

(1) Overview of DMA transfers

For pipes 1 to 9, the FIFO port can be accessed using the DMAC. When buffer access for a pipe targeted for DMA transfer is enabled, a DMA transfer request is issued.

Select the unit of transfer to the FIFO port in the DnFIFOSEL.MBW bit, and select the pipe targeted for the DMA transfer in the DnFIFOSEL.CURPIPE[3:0] bits. Do not change the selected pipe during the DMA transfer.

(2) DnFIFO auto clear mode (D0FIFO and D1FIFO port reading direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USBFS automatically clears the FIFO buffer of the selected pipe when reading of data from the FIFO buffer is complete.

Table 36.25 shows the packet reception and FIFO buffer clearing processing by software for each of the settings.
As shown in the table, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA transfers without involving software.

The DnFIFO auto clear mode can only be set in the FIFO buffer reading direction.

Table 36.25 Packet reception and FIFO buffer clearing processing by software

Buffer status when packet is received	Register setting			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	No clearing required	No clearing required	No clearing required	No clearing required
Zero-length packet reception	Clearing required	Clearing required	No clearing required	No clearing required
Normal short packet reception	No clearing required	Clearing required	No clearing required	No clearing required
Transaction count end	No clearing required	Clearing required	No clearing required	No clearing required

36.3.9 Control Transfers Using the DCP

The DCP is used for data transfers in the control transfer data stage. The FIFO buffer of the DCP is a 64-byte single buffer with a fixed area for both control reads and control writes. The FIFO buffer can be accessed only through the CFIFO port.

36.3.9.1 Control Transfers in Host Controller Mode

(1) Setup stage

The USQREQ, USBVAL, USBINDX, and USBLENG registers are used to transmit USB requests for setup transactions. Writing the setup packet data to the registers and then writing 1 to the DCPCTR.SUREQ bit transmits the specified data for the setup transaction. On completion of the transaction, the SUREQ bit clears to 0. Do not change these USB request registers while SUREQ = 1.

When an attached function device is detected, the software must issue the first setup transaction for the device using this sequence with the DCPMAXP.DEVSEL[3:0] bits cleared to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.

When an attached function device is shifted to the Address state, the software must issue setup transactions using this sequence with the assigned USB address set in the DEVSEL[3:0] bits and the bits in DEVADDn corresponding to the specified USB address set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in DEVADD2. When PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in DEVADD5.

When the setup transaction data is sent, an interrupt request is generated based on the response from the peripheral device (SIGN or SACK bit in INTSTS1). This interrupt request allows the software to check the setup transaction result.

A DATA0 data packet (USB request) for the setup transaction is always transmitted regardless of the status of the DCPCTR.SQMON bit.

(2) Data stage

The data stage is used to transfer data using the DCP FIFO buffer.

Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit. Specify the transfer direction in the DCPCFG.DIR bit.

For the first data packet of the data stage, the data PID must be transferred as DATA1. Set data PID = DATA1 in the DCPCTR.SQSET bit and set the PID bits = BUF. Completion of data transfer is detected using the BRDY or BEMP interrupt.

For control write transfers, when the number of data bytes to be sent is an integer multiple of the maximum packet size, the software must send a zero-length packet at the end.

(3) Status stage

The status stage is used for zero-length packet data transfers in the reverse direction of the data stage. As in the data stage, data is transfered using the DCP FIFO buffer. Transactions are executed using the same procedure as the data stage.

Data packets in the status stage must be transmitted and received with the data PID set to DATA1 using the DCPCTR.SQSET bit.

When a zero-length packet is received, check the receive-data length in the CFIFOCTR.DTLN[8:0] bits after a BRDY interrupt is generated, and then clear the FIFO buffer using the BCLR bit.

36.3.9.2 Control Transfers in Device Controller Mode

(1) Setup stage

The USBFS sends an ACK response to a normal setup packet for the USBFS. The USBFS operates in the setup stage as follows:

On receiving a new setup packet, the USBFS sets the following bits:

- Sets the INTSTS0.VALID bit to 1
- Sets the DCPCTR.PID[1:0] bits to NAK
- Sets the DCPCTR.CCPL bit to 0

When the USBFS receives a data packet following a setup packet, it stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Before performing the response processing for a control transfer, set the VALID flag to 0. When the VALID bit = 1, PID = BUF cannot be set, and the data stage cannot be terminated.

Using the VALID bit function, the USBFS can suspend a request being processed when it receives a new USB request during a control transfer and return a response to the latest request.

In addition, the USBFS automatically detects the direction bit (bmRequestType bit [8]) and the request data length (wLength) in the received USB request. It distinguishes between control read transfers, control write transfers, and no-data control transfers, and it controls stage transitions. For an incorrect sequence, a sequence error occurs in the control transfer stage transition interrupt, and the interrupt is reported to the software. For a diagram of the stage control by the USBFS, see Figure 36.15.

(2) Data stage

The DCP must be used to execute data transfers for received USB requests. Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit.

If the transfer data is larger than the size of the DCP FIFO buffer, execute the data transfer using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

(3) Status stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to BUF.

After this setting is made, the USBFS automatically executes the status stage based on the data transfer direction determined at the setup stage. The procedure is as follows:

- For control read transfers

  The USBFS receives a zero-length packet from the USB host and transmits an ACK response.
- For control write transfers and no-data control transfers

  The USBFS transmits a zero-length packet and receives an ACK response from the USB host.

(4) Control transfer auto response function

The USBFS automatically responds to a correct SET_ADDRESS request. If any of the following errors occurs in the SET_ADDRESS request, a response from the software is necessary.

- bmRequestType is not 0x00: Any transfer other than a control write transfer
- wIndex is not 0x00: Request error
- wLength is not 0x00: Any transfer other than a no-data control transfer
- wValue is larger than 0x7F: Request error
- INTSTS0.DVSQ[2:0] are 011b (Configured state): Control transfer of a device state error

For all requests other than the SET_ADDRESS request, a response is required from the corresponding software.

36.3.10 Bulk Transfers (Pipes 1 to 5)

The FIFO buffer usage (single/double buffer setting) is configurable for bulk transfers. The USBFS provides the following functions for bulk transfers:

- BRDY interrupt function (PIPECFG.BFRE bit), see section 36.3.3.1. BRDY Interrupt
- Transaction count function (PIPEnTRE.TRENB, TRCLR, and PIPEnTRN.TRNCNT[15:0] bits), see section 36.3.4.5. Transaction Counter for Pipes 1 to 5 in the Receiving Direction
- Response PID = NAK function (PIPECFG.SHTNAK bit), see section 36.3.4.8. Response PID = NAK Function
- Auto response mode (PIPEnCTR.ATREPM bit), see section 36.3.4.9. Auto Response Mode

36.3.11 Interrupt Transfers (Pipes 6 to 9)

In device controller mode, the USBFS performs interrupt transfers based on the timing dictated by the host controller.

In host controller mode, the software can set the timing for issuing tokens using the interval counter.

36.3.11.1 Interval Counter for Interrupt Transfers in Host Controller Mode

Specify the transaction interval for interrupt transfers in the PIPEPERI.IITV[2:0] bits. The USBFS issues interrupt transfer tokens based on this interval.

(1) Counter initialization

The USBFS initializes the interval counter under the following conditions:

- Power-on reset

  This initializes the IITV[2:0] bits.

- FIFO buffer initialization using the PIPEnCTR.ACLRM bit:

  This does not initialize the IITV[2:0] bits, but does initialize the count value. Setting the PIPEnCTR.ACLRM bit to 0 starts counting from the value set in IITV[2:0].

The interval counter is not initialized in the following case:

- USB bus reset or USB suspended

  The IITV[2:0] bits are not initialized. Setting 1 to the DVSTCTR0.UACT bit starts counting from the value saved before entering the USB bus reset state or USB suspend state.

(2) Operation when tokens cannot be transmitted or received even on token generation

No token is generated in the following cases even at token generation time. In these cases, the USBFS tries to execute the transaction in the next interval.

- When the PID is set to NAK or STALL
- When the FIFO buffer is full at token transmit time in the receiving (IN) direction
- When there is no data to be transmitted in the FIFO buffer at token transmit time in the transmitting (OUT) direction

36.3.12 Isochronous Transfers (Pipes 1 and 2)

The USBFS provides the following functions for isochronous transfers:

- Notification of isochronous transfer error
- Interval counter specified in the PIPEPERI.IITV[2:0] bits
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function specified in the PIPEPERI.IFIS bit

36.3.12.1 Error Detection in Isochronous Transfers

The USBFS provides a function for detecting the errors described in this section, so that when errors occur in isochronous transfers, they can be controlled by software. Table 36.26 and Table 36.27 show the priority order for errors detected by the USBFS and the associated interrupts.

PID errors

- The PID value of the received packet is invalid.

CRC errors and bit stuffing errors

- A CRC error is found in a received packet or the bit stuffing is illegal.

Maximum packet size exceeded

- The data size of the received packet exceeds the specified maximum packet size.

Overrun and underrun errors

In host controller mode:

- The FIFO buffer is full at token transmit time in the IN (receiving) direction
- There is no data to be sent in the FIFO buffer at token transmit time in the OUT (transmitting) direction

In device controller mode:

- There is no data to be sent in the FIFO buffer at token receive time in the IN (transmitting) direction
- The FIFO buffer is full at token receive time in the OUT (receiving) direction

Interval errors

In device controller mode, the following cases are treated as an interval error:

- Failure to receive an IN token in the interval frame during an isochronous IN transfer
- Failure to receive an OUT token in the interval frame during an isochronous OUT transfer

Table 36.26 Error detection for token transmission and reception

Detection priority	Error	Generated interrupt and status
1	PID error	No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)
2	CRC or bit stuffing error	No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)
3	Overrun or underrun error	An NRDY interrupt is generated to set the FRMNUM.OVRN bit to 1 in both host and device controller modes. In device controller mode, a zero-length packet is transmitted in response to an IN token. No data packets are received in response to OUT token.
4	Interval error	An NRDY interrupt is generated in device controller mode. No interrupt is generated in host controller mode.

Table 36.27 Error detection for data packet reception

Detection priority	Error	Generated interrupt and status
1	PID error	No interrupts are generated (ignored as a corrupted packet)
2	CRC or bit stuffing error	An NRDY interrupt is generated and the FRMNUM.CRCE bit sets to 1 in both host and device controller modes
3	Maximum packet size exceeded error	A BEMP interrupt is generated and the PID[1:0] bits set to STALL in both host and device controller modes

36.3.12.2 DATA-PID

In device controller mode, the USBFS responds to a received PID as follows:

(1) IN direction

- DATA0: Transmitted as data packet PID
- DATA1: Not transmitted
- DATA2: Not transmitted
- mDATA: Not transmitted

(2) OUT direction

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets ignored
- mDATA: Packets ignored

36.3.12.3 Interval Counter

The isochronous transfer interval can be set in the PIPEPERI.IITV[2:0] bits. In device controller mode, the interval counter enables the functions as shown in Table 36.28. In host controller mode, the USBFS generates the token issuance timing, and the interval counter operation is the same as that for interrupt transfers.

Table 36.28 Interval counter functions in device controller mode

Transfer direction	Function	Conditions for detection
IN	Transmit buffer flush	Failure to receive an IN token successfully in the interval frame during an isochronous IN transfer.
OUT	Notification of no reception of token	Failure to receive an OUT token successfully in the interval frame during an isochronous OUT transfer.

The interval count is performed when an SOF is received or for interpolated SOFs, so the isochronism can be maintained even if an SOF is corrupt. The frame interval can be set to 2^{IITV} frames.

(1) Counter initialization in device controller mode

The USBFS initializes the interval counter under the following conditions:

- Power-on reset

  This initializes the PIPEPERI.IITV[2:0] bits.
- FIFO buffer initialization using the ACLRM bit

  This does not initialize the IITV[2:0] bits, but does initialize the count value.

After the interval counter is initialized, the interval count starts under one of the following conditions when a packet is transferred successfully:

- An SOF is received after data is transmitted in response to an IN token when PID = BUF
- An SOF is received after data is received in response to an OUT token when PID = BUF

The interval counter is not initialized in the following conditions:

- When the PID[1:0] bits are set to NAK or STALL

  This does not stop the interval timer. The USBFS attempts the transaction in the next interval.
- When the USB bus is reset or USBFS is suspended

  This does not initialize the IITV[2:0] bits. When an SOF is received, the interval counter starts counting from the value set before SOF was received.

(2) Interval counting and transfer control in host controller mode

The USBFS controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bits settings. Specifically, the USBFS issues a token for a selected pipe once every 2^{IITV} frames.

The USBFS starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits are set to BUF by software.

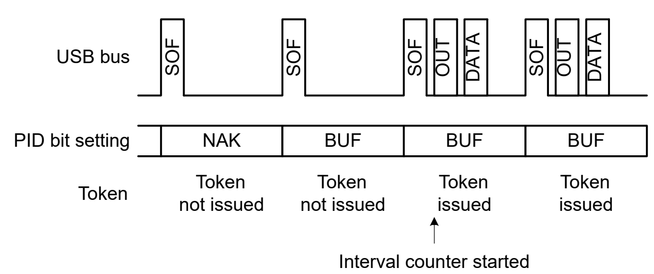


Figure 36.16 Token issuance when IITV = 0

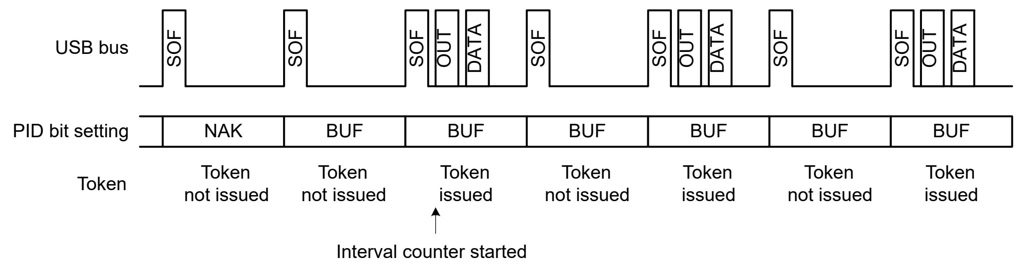

Figure 36.17 Token issuance when IITV = 1

When the selected pipe is set for isochronous transfers, the USBFS performs the following operation in addition to controlling the token issuance interval. The USBFS issues a token even when the NRDY interrupt generation condition is satisfied.

When the selected pipe is for isochronous IN transfers

The USBFS generates an NRDY interrupt when the USBFS issues an IN token but does not successfully receive a packet from a peripheral device (no response or packet error).

The USBFS sets the FRMNUM.OVRN bit to 1, generating an NRDY interrupt, when the time to issue an IN token occurs while the USBFS cannot receive data because the FIFO buffer is full, because the CPU or DMAC/DTC is too slow in reading data from the FIFO buffer.

When the selected pipe is for isochronous OUT transfers

The USBFS sets the OVRN bit to 1, generating an NRDY interrupt and transmitting a zero-length packet, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer, or because the CPU or DMAC/DTC is too slow in writing data to the FIFO buffer.

The token issuance interval is reset on any of the following conditions:

- When the USBFS is reset through a reset pin

  This initializes the IITV[2:0] bits.
- When the PIPEnCTR.ACLRM bit is set to 1 by software

(3) Interval counting and transfer control in device controller mode

When the selected pipe is for isochronous OUT transfers

The USBFS generates an NRDY interrupt when it fails to receive a data packet within the interval set in the PIPEPERI.IITV[2:0] bits.

The USBFS also generates an NRDY interrupt when it fails to receive data because of a CRC error or other errors contained in the data packet or because the FIFO buffer is full.

The NRDY interrupt is generated on SOF packet reception. Even if the SOF packet is corrupted, internal interpolation allows the interrupt to be generated when the SOF packet is received. However, when the IITV bits are set to a value other than 0, the USBFS generates an NRDY interrupt on receiving an SOF packet for every interval after interval counting starts.

When the PID[1:0] bits are set to NAK by software after starting the interval timer, the USBFS does not generate an NRDY interrupt on receiving an SOF packet.

The timing for starting interval counting depend on the IITV[2:0] setting as follows:

- When the IITV[2:0] bits = 0:

  Interval counting starts at the next frame after the software changes the PID[1:0] bits of the selected pipe to BUF.
- When the IITV[2:0] bits ≠ 0:

  Interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe are changed to BUF.

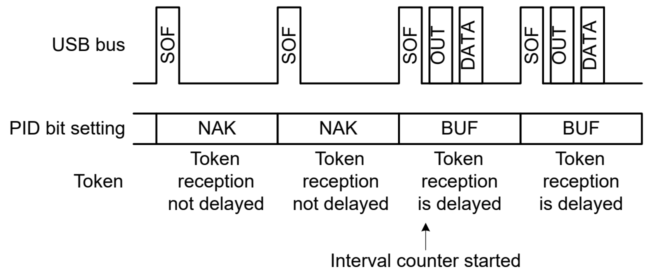

Figure 36.18 Relationship between frames and expected token reception when IITV[2:0] = 0

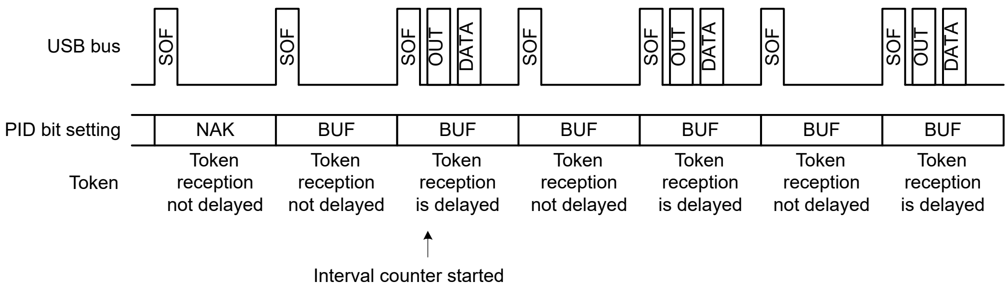

Figure 36.19 Relationship between frames and expected token reception when IITV[2:0] ≠ 0

When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit must be 1 for this use case. When IFIS = 0, the USBFS transmits a data packet in response to a received IN token regardless of the PIPEPERI.IITV[2:0] setting.

When IFIS is 1 and there is data to be transmitted in the FIFO buffer, the USBFS clears the FIFO buffer when it fails to receive an IN token in the frame at the interval set in the IITV[2:0] bits.

The USBFS also clears the FIFO buffer when it fails to receive an IN token successfully because of a bus error, such as a CRC error, contained in the IN token.

The FIFO buffer is cleared on SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the FIFO buffer to be cleared when the SOF packet is received.

The timing to start interval counting depends on the IITV[2:0] setting, as with OUT transfers.

The interval is counted on any of the following conditions in device controller mode:

- When a hardware reset is applied to the USBFS (which also sets the IITV[2:0] bits to 000b)
- When the PIPEnCTR.ACLRM bit is set to 1 by software
- When the USBFS detects a USB bus reset

(4) Transmit data setup for isochronous transfers in device controller mode

With isochronous data transmission using the USBFS in device controller mode, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This isochronous transfer transmit data setup function can identify the frame that started transmission.

When the double buffering is used, transmission is only enabled for the buffer where data writing was completed first, even after the data write to both buffers is complete. Accordingly, even if multiple IN tokens are received, only the one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transferred and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 36.20 shows an example transmission using the isochronous transfer transmission data setup function when IITV = 0 (every frame) is set.

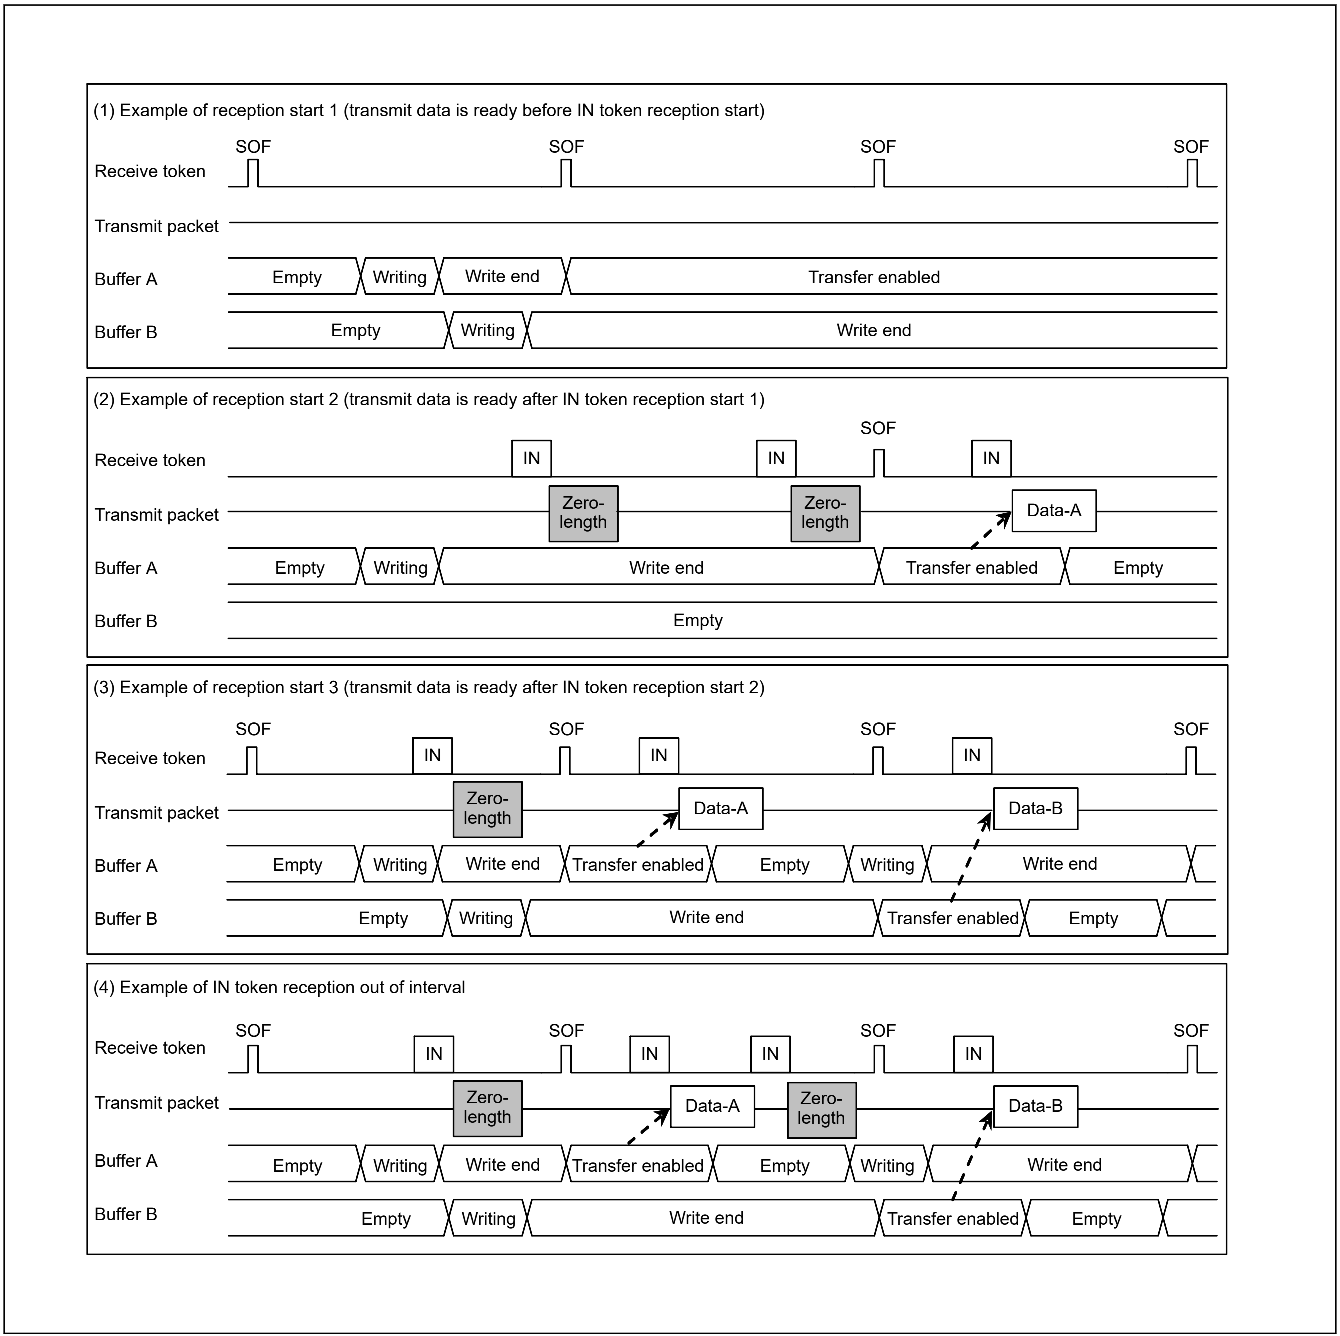

Figure 36.20 Example data setup operation

(5) Transmit buffer flush for isochronous transfers in device controller mode

In device controller mode during isochronous data transmission, if the USBFS receives an SOF packet for the next frame without receiving an IN token in the interval frame, it operates as if the IN token is corrupt and clears the buffer that is enabled for transmission, putting that buffer in the writing enabled state.

When double buffering is used and writing to both buffers is complete, the cleared FIFO buffer is assumed to be the one where the data was transmitted in the interval frame, and transmission is enabled for the FIFO buffer that was not cleared on SOF packet reception.

The timing of the buffer flush function depends on the PIPEPERI.IITV[2:0] setting as follows:

- When IITV = 0:

  The buffer flush operation starts from the first frame after the pipe is enabled.

- When IITV ≠ 0:

  The buffer flush operation starts after the first normal transaction.

Figure 36.21 shows an example buffer flush. When an unanticipated token is received before the interval frame, the USBFS sends the write data or a zero-length packet as an underrun error, depending on the data setup status.

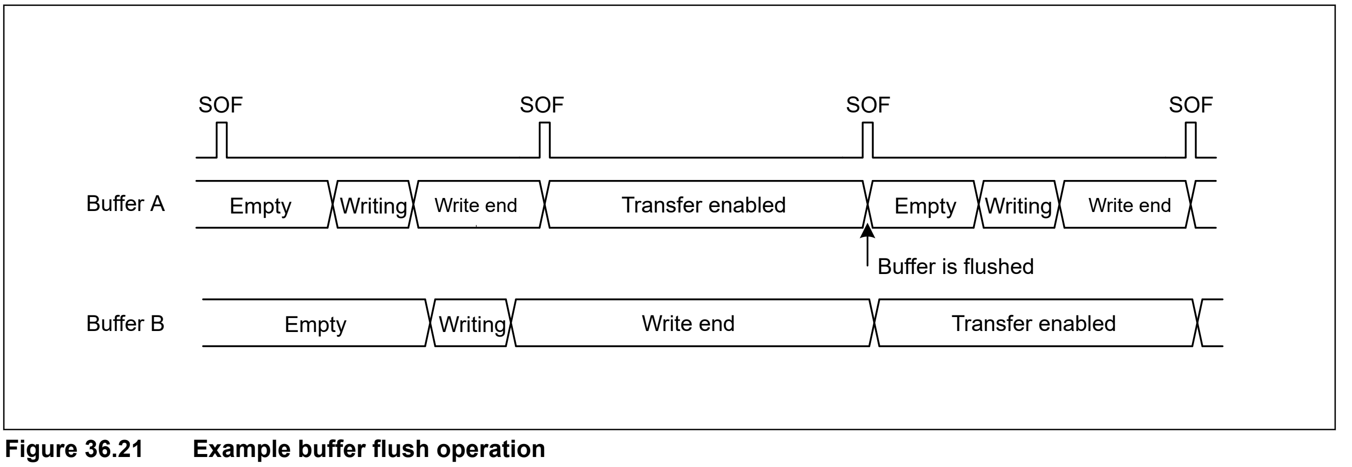

Figure 36.21 Example buffer flush operation

Figure 36.22 shows an example interval error occurrence. There are five types of interval errors, as shown in the figure. An interval error occurs at timing (A), and the buffer flush function is activated.

If an interval error occurs during an IN transfer, the buffer flush function is activated. If it occurs during an OUT transfer, an NRDY interrupt is generated. Use the FRMNUM.OVRN bit to distinguish between this and NRDY interrupts triggered by received packet errors and overrun errors.

For tokens that are shaded in the figure, responses are returned based on the FIFO buffer status.

- IN direction:
  - If the buffer is ready to transfer data, the data is transferred and a normal response is returned
  - If the buffer is not ready to transfer data, a zero-length packet is transmitted and an underrun error occurs
- OUT direction:
  - If the buffer is ready to receive data, the data is received and a normal response is returned
  - If the buffer is not ready to receive data, the received data is discarded and an overrun error occurs

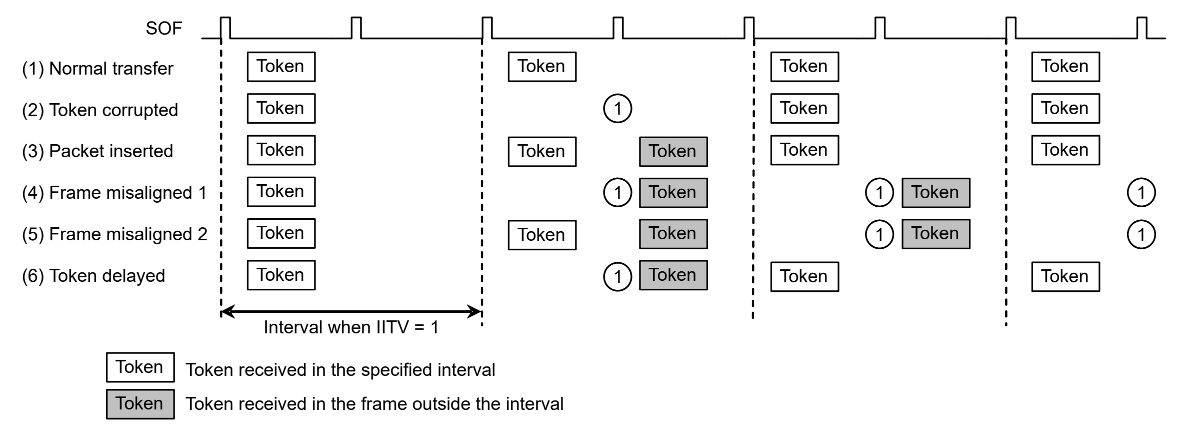

Figure 36.22 Example interval error occurrence when IITV = 1

36.3.13 SOF Interpolation Function

In device controller mode, if packet reception is disabled at intervals of 1 ms because the SOF packet is corrupted or missing, the USBFS interpolates the SOF. SOF interpolation begins when the USBE and SCKE bits in SYSCFG are set to 1 and an SOF packet is received.

The interpolation function is initialized under the following conditions:

- MCU reset
- USB bus reset
- Suspend state detection

The SOF interpolation operates as follows:

- The interpolation function is not activated until an SOF packet is received
- When the first SOF packet is received, interpolation is performed by counting 1 ms on the 48-MHz internal clock
- When the second and subsequent SOF packets are received, interpolation is performed at the previous reception interval
- Interpolation is not performed in the Suspend state or on reception of a USB bus reset

The USBFS supports the following functions controlled by SOF packet reception. These functions operate normally with SOF interpolation if the SOF packet is missing:

- Updating of the frame number
- SOFR interrupt timing
- Isochronous transfer interval count

If an SOF packet is missing during full-speed operation, the FRMNUM.FRNM[10:0] bits are not updated.

36.3.14 Pipe Schedule

36.3.14.1 Conditions for Generating Transactions

In host controller mode and when the DVSTCTR0.UACT bit is set to 1, the USBFS generates transactions under the conditions shown in Table 36.29.

Table 36.29 Conditions for generating transactions

Transaction	Conditions for generation				
	DIR	PID	IITV0	Buffer state	SUREQ
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	Invalid	Receive area exists	—*1
	OUT	BUF	Invalid	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid	Receive area exists	—*1
	OUT	BUF	Valid	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. An em dash (—) in the table indicates that the condition is unrelated to the generating of tokens. "Valid" indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. "Invalid" indicates that a transaction is generated regardless of the interval counter.
Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.
Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

36.3.14.2 Transfer Schedule

This section describes the transfer scheduling within a frame of the USBFS. After the USBFS sends an SOF, the transfer is carried out in the following sequence:

1. Execution of periodic transfers:

   A pipe is searched for in the order of pipe 1 → pipe 2 → pipe 6 → pipe 7 → pipe 8 → pipe 9, and then if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.

2. Setup transactions for control transfers:

   The DCP is checked, and if a setup transaction is possible, it is sent.

3. Execution of bulk transfers, control transfer data stages, and control transfer status stages:

   A pipe is searched for in the order of DCP → pipe 1 → pipe 2 → pipe 3 → pipe 4 → pipe 5, and then if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.

   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

36.3.14.3 Enabling USB Communication

Setting the DVSTCTR0.UACT bit to 1 initiates an SOF transmission, and transaction generation is enabled. Setting the UACT bit to 0 stops SOF transmission and the Suspend state is invoked. If the UACT setting is changed from 1 to 0, processing stops after the next SOF is sent.

36.4 Usage Notes

36.4.1 Settings for the Module-Stop State

USBFS operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The USBFS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Mode.

36.4.2 Clearing the Interrupt Status Register on Canceling Software Standby Mode

Because the input buffer is always enabled in Software Standby mode, an unexpected interrupt might occur under the following conditions:

- When the interrupt is enabled in Normal mode
- When the interrupt is disabled in Software Standby mode
- When the input level of the pin that cancels software standby mode is changed in Software Standby mode

These conditions might cause the associated interrupt flag in the Interrupt Status Register to set unexpectedly. After the MCU cancels the Software Standby mode, the unexpected interrupt might be sent to the interrupt controller. To avoid this, always clear the INTSTS0 and INTSTS1 registers in the canceling sequence.

36.4.3 Clearing the Interrupt Status Register after Setting Up the Port Function

The input buffer is disabled before the PmnPFS.PSEL and PmnPFS.PMR port is set up, so the internal signal is fixed high or low. The input buffer is enabled after the port is set so that the external pin state is propagated to the MCU. An unexpected interrupt might occur at this time, causing the VBINT and OVRCR bits in INTSTS0 and INTSTS1, or other interrupt status flags to set to 1. To avoid a malfunction, always clear the INTSTS0 and INTSTS1 registers after setting up the port.

36.4.4 Setting Up the Port Function Before Setting USB Function

USB_DP, USB_DM pins are compatible with P814, P815 I/O ports. So before setting USBFS registers to enable USBFS function, set register bit P814PFS.PMR and P815PFS.PMR to 1.

37. USB 2.0 High-Speed Module (USBHS)

37.1 Overview

The MCU provides a USB 2.0 High-Speed Module (USBHS) that operates as a host or a device controller compliant with the Universal Serial Bus (USB) Specification revision 2.0. The host controller supports USB 2.0 high-speed, full-speed, and low-speed transfers, and the device controller supports USB 2.0 high-speed and full-speed transfers. The USBHS has an internal USB transceiver and supports all of transfer types defined in the USB 2.0 specification.

The USBHS has FIFO buffer for data transfers, providing a maximum of 10 pipes. Any endpoint number can be assigned to pipes 1 to 9, based on the peripheral devices or the communication requirements for your system.

Table 37.1 lists the USBHS specifications, Figure 37.1 shows a block diagram, and Table 37.2 lists the I/O pins.

Table 37.1 USBHS specifications

Parameter	Specifications
Features	● USB Device Controller (UDC) and USB 2.0 transceiver supporting host controller, device controller, and On-The-Go (OTG) functions ● Software can switch between host and device controller modes
	Host controller features: ● High-speed transfer (480 Mbps), full-speed transfer (12 Mbps), and low-speed transfer (1.5 Mbps) ● Automatic scheduling for SOF and packet transmissions ● Programmable intervals for isochronous and interrupt transfers ● Communications with multiple peripheral devices connected through a single hub
	Device controller features: ● High-speed transfer (480 Mbps) and full-speed transfer (12 Mbps) ● Control transfer stage control function ● Device state control function ● Auto response function for SET_ADDRESS request ● SOF complementation
Supported transfer types	● Control transfer ● Bulk transfer ● Interrupt transfer ● Isochronous transfer
Pipe configuration	● FIFO buffer of up to 8.5 KB for USB communications ● Up to 10 pipes selectable, including the default control pipe ● Programmable pipe configurations ● Pipes 1 to 9 assignable to any endpoint number
	Transfer conditions specifiable for each pipe: ● Pipe 0: Control transfer with 64-byte single buffer ● Pipes 1 and 2: Bulk isochronous transfer continuous transfer mode with programmable buffer size up to 2 KB and optional double buffer ● Pipes 3 to 5: Bulk transfer continuous transfer mode with programmable buffer size up to 2 KB and optional double buffer ● Pipes 6 to 9: Interrupt transfer with 64-byte single buffer
Other features	● Force-end transfer function using transaction count ● Function that changes the BRDY interrupt event notification timing ● Automatic clearing of the FIFO buffer after data for the pipe specified in the DnFIFO port (n = 0, 1) is read ● NAK setting function for response PID generated on transfer end ● On-chip pull-up and pull-down resistors for D+ and D- ● Support for Link Power Management (LPM) ECN, including a new Sleep state (the L1 state) ● Compliance with Battery Charging Class Specification Revision 1.2 ● For power reduction, selectable classic-only mode (CL-only mode) in which operation is only USB 1.1-compliant
Module-stop function	Module-stop state can be set to reduce power consumption
TrustZone Filter	Security and Privilege attribution can be set

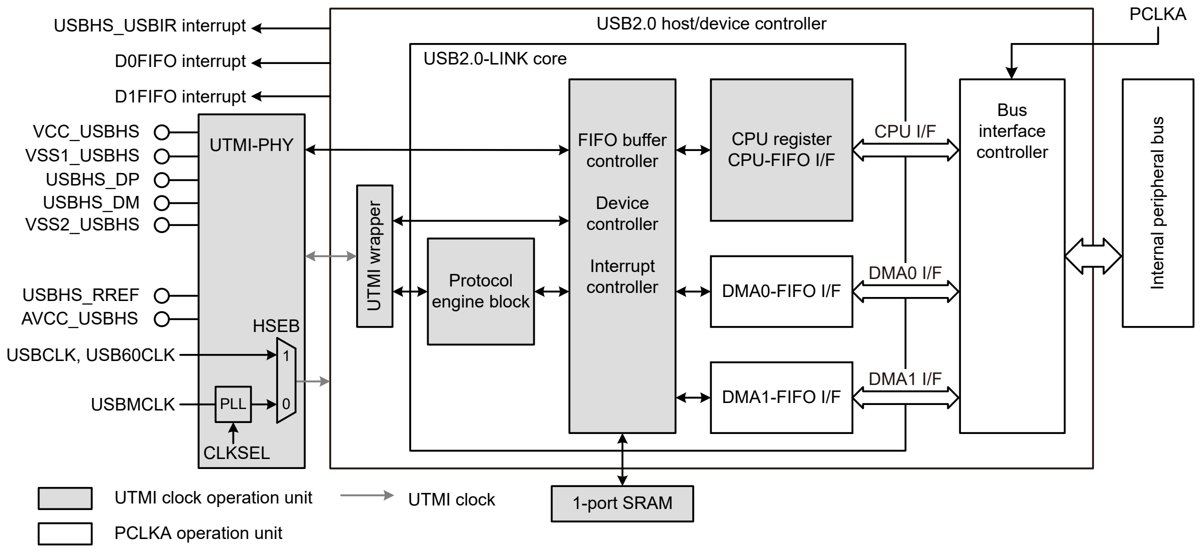

Figure 37.1 USBHS block diagram

Table 37.2 USBHS I/O pins

Pin name	I/O	Function
VCC_USBHS	Input	Power supply pin for the USBHS
VSS1_USBHS VSS2_USBHS	Input	Ground pin for the USBHS
AVCC_USBHS	Input	Analog power supply pin for the USBHS
USBHS_RREF	I/O	Reference current source pin for the USBHS Must be connected to the VSS2_USBHS pin through a 2.2-kΩ (±1%) resistor.
USBHS_DP	I/O	Input/output pin for the D+ data line of the USB bus
USBHS_DM	I/O	Input/output pin for the D- data line of the USB bus
USBHS_EXICEN	Output	Must be connected to the OTG power supply IC
USBHS_ID	Input	Must be connected to the OTG power supply IC
USBHS_VBUSEN	Output	VBUS power supply enable pin for the USBHS
USBHS_OVRCURA, USBHS_OVRCURB, USBHS_OVRCURA-DS, USBHS_OVRCURB-DS	Input	Overcurrent pin for the USBHS USBHS_OVRCURA or USBHS_OVRCURB pins can be used in Software standby mode or in normal mode. USBHS_OVRCURA-DS, USBHS_OVRCURB-DS are dedicated pins that can generate interrupt in Software standby mode or in normal mode as well as for cancel Deep Software Standby mode 1.
USBHS_VBUS	Input	USB cable connection monitor input pin

37.2 Register Descriptions

37.2.1 SYSCFG : System Configuration Control Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CNEN	HSE	DCFM	DRPD	DPRPU	—	—	—	USBE
Value after reset:	x	x	x	x	x	x	x	0	0	0	1	0	x	x	x	0

Bit	Symbol	Function	R/W
0	USBE	USBHS Operation Enable 0: Disable 1: Enable	R/W
3:1	—	The read values are undefined. The write value should be 0.	R/W
4	DPRPU	D+ Line Resistor Control 0: Disable line pull-up 1: Enable line pull-up	R/W
5	DRPD	D+/D- Line Resistor Control 0: Disable line pull-down 1: Enable line pull-down	R/W
6	DCFM	Controller Operation Select 0: Select device controller mode 1: Select host controller mode	R/W
7	HSE	High-Speed Operation Enable 0: Disable Device controller mode: full-speed Host controller mode: full-speed or low-speed 1: Enable The controller detects the communication speed	R/W
8	CNEN	Single-ended Receiver Enable 0: Disable 1: Enable	R/W
15:9	—	The read values are undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Writing to the SYSCFG register can proceed while the PHY clock is stopped. However, written values are only reflected in the SYSCFG register after the PHY clock is oscillating again.

USBE bit (USBHS Operation Enable)

The USBE bit enables or disables operation of USBHS.

Changing the USBE bit from 1 to 0 initializes the bits listed in Table 37.3. Only change this bit after specifying the input clock in the PHYSET.CLKSEL[1:0] bits and confirming that the PLLSTA.PLLLOCK flag is 1. In CL-only mode, change the USBE bit after setting the PHYSET.HSEB bit to 1. At that time, the USBCLK must be set to 48 MHz and USB60CLK must be set to 60 MHz. For the clock settings, see section 37.3.3. Supplying the Clock.

In host controller mode, always set this bit to 1 after setting the DRPD bit to 1, eliminating SYSSTS0.LNST[1:0] bit chattering, and confirming that the USB bus state is stable.

Table 37.3 Bits initialized by writing SYSCFG.USBE = 0

Selected function	Register	Bit	Remarks
Device controller (DCFM = 0)	SYSSTS0	LNST[1:0]	Value is saved in host controller mode
	DVSTCTR0	RHST[2:0]	—
	PL1CTRL1	DVSQ[3:0]	Value is saved in host controller mode
	USBADDR	USBADDR[6:0]	Value is saved in host controller mode
	USBREQ	• BREQUEST[7:0] • BMREQUESTTYPE [7:0]	Value is saved in host controller mode
	USBVAL	WVALUE[15:0]	Value is saved in host controller mode
	USBINDX	WINDEX[15:0]	Value is saved in host controller mode
	USBLENG	WLENTUH[15:0]	Value is saved in host controller mode
Host controller (DCFM = 1)	DVSTCTR0	RHST[2:0]	—
	FRMNUM	FRNM[10:0]	Value is saved in device controller mode
	UFRMNUM	UFRNM[2:0]	Value is saved in device controller mode

DPRPU bit (D+ Line Resistor Control)

The DPRPU bit enables or disables pulling up the D+ line in device controller mode.

When the DPRPU bit is set to 1 in device controller mode, the USBHS pulls up the D+ line to notify the USB host that it attached. Changing the DPRPU bit from 1 to 0 releases the pull-up, thereby notifying the USB host that it detached.

Set this bit to 1 in device controller mode and to 0 in host controller mode.

DRPD bit (D+/D- Line Resistor Control)

The DRPD bit enables or disables pulling down D+ and D- lines in host controller mode.

Set this bit to 1 in host controller mode. Set it to 0 when OTG is not used in device controller mode.

DCFM bit (Controller Operation Select)

The DCFM bit selects the host or device function of the USBHS.

Only change this bit when the DPRPU and DRPD bits are both 0.

HSE bit (High-Speed Operation Enable)

The HSE bit enables or disables high-speed operation.

When this bit is 1, the USBHS operates in high-speed or full-speed based on the results of the reset handshake.

In host controller mode, setting this bit to 0 allows the USBHS to operate in full-speed or low-speed. If the DVSTCTR0.RHST[2:0] flags indicate that a low-speed device has attached, set the HSE bit to 0.

In host controller mode, setting this bit to 1 allows the USBHS to operate in high-speed or full-speed based on the results of the reset handshake. Change the HSE bit after detection of an attach event (ATTCH interrupt) and before the USB bus reset (when DVSTCTR0.USBRST = 1), or after detection of a detach event.

In device controller mode, setting this bit to 0 allows the USBHS to operate in full-speed. Setting the bit to 1 allows the USBHS to perform the reset handshake and then operate in high-speed or full-speed, based on the results.

In device controller mode, only change this bit when the DPRPU bit is 0.

CNEN bit (Single-ended Receiver Enable)

Setting the CNEN bit to 1 enables single-ended receiver operation and selects monitoring of the D+ and D- line states in the SYSSTS0.LNST[1:0] flags. Use this bit to prevent through-current damage that might otherwise be caused during single-ended receiver operation, where the terminals are floating while the USBHS is detached.

In host controller mode, set this bit to 1 after confirming that the PHY clock is being supplied. In device controller mode, set this bit to 1 when the VBUS is detected because of a VBUS interrupt, and set it to 0 when the VBUS line is removed.

37.2.2 BUSWAIT : CPU Bus Wait Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x002

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3			0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	BWAIT[3:0]			
Value after reset:	x	x	0	0	0	0	0	0	x	x	0	0	1	1	1	1

Bit	Symbol	Function	R/W
3:0	BWAIT[3:0]	CPU Bus Access Wait Specification 0x0: 0 waits (2 access cycles) : 0x2: 2 waits (4 access cycles) : 0x4: 4 waits (6 access cycles) : 0xF: 15 waits (17 access cycles) (initial value)	R/W
5:4	—	These bits are read as 0. The write value should be 0.	R/W
7:6	—	The read values are undefined. The write value should be 0.	R/W
13:8	—	These bits are read as 0. The write value should be 0.	R/W
15:14	—	The read values are undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

BWAIT[3:0] bits (CPU Bus Access Wait Specification)

The BWAIT[3:0] bits specify the wait time for access to the USBHS registers.

When accessing the registers at offset addresses in range 0x004 to 0x15F for writing and range 0x004 to 0x167 for reading, set the cycle time for consecutive access to at least 41 ns. The initial value is 0xF (17 cycles), but Renesas recommends that you satisfy this condition by setting the best wait time for the frequency of PCLKA in your application.

This setting is the same as the wait time for accesses to the FIFO port register. The maximum speed of access to the FIFO port is as follows:

- MBW[1:0] = 10b (32-bit width): Maximum 60 MB/s
- MBW[1:0] = 01b (16-bit width): Maximum 30 MB/s
- MBW[1:0] = 00b (8-bit width): Maximum 15 MB/s

37.2.3 SYSSTS0 : System Configuration Status Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x004

Bit position:	15		13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	OVCMON[1:0]		—	—	—	—	—	—	—	HTACT	SOFEA	—	—	IDMON	LNST[1:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	0	0	x	x	x	x	x

Bit	Symbol	Function	R/W
1:0	LNST[1:0]	USB Data Line Status Monitor Flag Indicates the status of the USB data lines. See Table 37.4.	R
2	IDMON	USBHS_ID Pin Monitor Flag 0: USBHS_ID pin is low 1: USBHS_ID pin is high	R

Bit	Symbol	Function	R/W
4:3	—	The read values are undefined.	R
5	SOFEA	SOF Active Monitor Flag While Host Controller Operation Is Selected 0: SOF output stopped 1: SOF output operating	R
6	HTACT	Host Sequencer Status Monitor Flag 0: Host sequencer stopped 1: Host sequencer operating	R
13:7	—	The read values are undefined.	R
15:14	OVCMON[1:0]	External USBHS_OVRCURA or USBHS_OVRCURA-DS, and USBHS_OVRCURB or USBHS_OVRCURBB-DS Input Pin Monitor Flag OVCMON[1] indicates the USBHS_OVRCURA or USBHS_OVRCURA-DS pin status. OVCMON[0] indicates the USBHS_OVRCURB or USBHS_OVRCURB-DS pin status.	R

Note: S-TYPE-3, P-TYPE-3

LNST[1:0] flags (USB Data Line Status Monitor Flag)

The LNST[1:0] flags indicate the state of the USB data lines, D+ and D-. For details, see Table 37.4.

In device controller mode, read the LNST[1:0] flags after setting the SYSCFG.CNEN and SYSCFG.USBE bits to 1. In host controller mode, read them after setting the SYSCFG.DRPD bit to 1.

When you are checking hardware contacts for the battery charging function in device controller mode, read the LNST[1:0] flags after setting the SYSCFG.DRPD, SYSCFG.CNEN, and BCCTRL.IDPSRCE bits to 1. For details, see section 37.3.15. Battery Charging Detection Processing.

Table 37.4 Status of USB data bus lines (D+ and D-)

LNST[1]	LNST[0]	Low-speed operation (host controller mode only)	Full-speed operation	High-speed operation	Chirp operation
0	0	SE0	SE0	Squelch	Squelch
0	1	K-State	J-State	Unsquelch	Chirp J
1	0	J-State	K-State	Invalid	Chirp K
1	1	SE1	SE1	Invalid	Invalid

Chirp: The reset handshake protocol is being executed when high-speed operation is enabled (HSE bit is 1).

Squelch: SE0 or idle state

Unsquelch: High-speed J-state or high-speed K-state

Chirp J: Chirp J-State

Chirp K: Chirp K-State

SOFEA flag (SOF Active Monitor Flag While Host Controller Operation Is Selected)

The SOFEA flag is used in host controller mode to check whether the output of the last SOF is complete when the USBHS is suspended because of a 0 setting to the DVSTCTR0.UACT bit.

In host controller mode, check that both the HTACT and SOFEA flags are 0 before setting the SYSCFG.USBE bit to 0 to stop the USBHS or setting the LPSTS.SUSPENDM bit to 0 to stop the clock signal supply during communication.

HTACT flag (Host Sequencer Status Monitor Flag)

The HTACT flag clears to 0 when the host sequencer of the USBHS is completely stopped.

In host controller mode, check that the HTACT flag is 0 before setting the DVSTCTR0.UACT bit to 0 to place the USBHS in the Suspend state or setting the LPSTS.SUSPENDM bit to 0 to stop the clock signal supply during communication.

OVCMON[1:0] flags (External USBHS_OVRCURA or USBHS_OVRCURA-DS, and USBHS_OVRCURB or USBHS_OVRCURBB-DS Input Pin Monitor Flag)

The OVCMON[1:0] flags indicate the status of the overcurrent signals from an external power supply IC.

37.2.4 PLLSTA : PLL Status Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x006

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PLLLO CK
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
0	PLLLOCK	PLL Lock Flag 0: PLL not locked 1: PLL locked	R
15:1	—	The read values are undefined.	R

Note: S-TYPE-3, P-TYPE-3

PLLLOCK flag (PLL Lock Flag)

The PLLLOCK flag indicates whether the USB-PHY internal PLL is locked. When not using CL-only mode, make sure that the PLL is locked before starting USB communication.

37.2.5 DVSTCTR0 : Device State Control Register 0

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x008

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2		0
Bit field:	—	—	—	—	HNPB TOA	EXICE N	VBUS EN	WKUP	RWUP E	USBR ST	RESU ME	UACT	—	RHST[2:0]		
Value after reset:	x	x	x	x	0	0	0	0	0	0	0	0	x	0	0	0

Bit	Symbol	Function	R/W
2:0	RHST[2:0]	USB Bus Reset Status Flag 0 0 0: Communication speed indeterminate (powered state or no connection) 0 0 1: Host controller mode Low-speed connection 0 1 0: Host controller mode Full-speed connection Device controller mode USB bus reset in progress or full-speed connection 0 1 1: Host controller mode High-speed connection Device controller mode USB bus reset in progress or high-speed connection Others: Host controller mode USB bus reset in progress Device controller mode Setting prohibited	R
3	—	The read value is undefined. The write value should be 0.	R/W
4	UACT	USB Bus Operation Enable for the Host Controller Operation 0: Disable downstream port (disable SOF or micro-SOF transmission) 1: Enable downstream port (enable SOF or micro-SOF transmission)	R/W
5	RESUME	Resume Signal Output for the Host Controller Operation 0: Do not output resume signal 1: Output resume signal	R/W

Bit	Symbol	Function	R/W
6	USBRST	USB Bus Reset Output for the Host Controller Operation 0: Do not output USB bus reset signal 1: Output USB bus reset signal	R/W
7	RWUPE	Remote Wakeup Detection Enable for the Host Controller Operation 0: Disable downstream port remote wakeup 1: Enable downstream port remote wakeup	R/W
8	WKUP	Remote Wakeup Output for the Device Controller Operation 0: Do not output remote wakeup signal 1: Output remote wakeup signal	R/W
9	VBUSEN	USBHS_VBUSEN Output Pin Control 0: Output low on external USBHS_VBUSEN pin 1: Output high on external USBHS_VBUSEN pin	R/W
10	EXICEN	USBHS_EXICEN Output Pin Control 0: Output low on external USBHS_EXICEN pin 1: Output high on external USBHS_EXICEN pin	R/W
11	HNPBTOA	Host Negotiation Protocol (HNP) Control Use this bit when switching from device B to device A in OTG mode. If the HNPBTOA bit is 1, the internal function control remains in the Suspend state until the HNP processing ends even if SYSCFG.DPRPU = 0 or SYSCFG.DCFM = 1 is set.	R/W
15:12	—	The read values are undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

RHST[2:0] flags (USB Bus Reset Status Flag)

The RHST[2:0] flags indicate the USB bus reset status.

In host controller mode, writing 1 to the USBRST bit causes the RHST[2:0] flags to set to 100b. When 0 is written to the USBRST bit and the USBHS ends the SE0 state, the RHST[2:0] flags update to a new value.

In device controller mode, if the USBHS detects a USB bus reset, the RHST[2:0] flags set to 010b if an attach event occurs while the DPRPU bit is 1, and a DVST interrupt is generated.

UACT bit (USB Bus Operation Enable for the Host Controller Operation)

When set to 1 in host controller mode, the UACT bit enables USB bus operation by controlling SOF packet transmission to the USB bus in addition to data and reception. The USBHS starts SOF packet output within one frame period after this bit is set to 1. If UACT is set to 0, the USBHS enters the idle state after the SOF packet output.

The USBHS sets the bit to 0 on any of the following conditions:

- A DTCH interrupt is detected during communication (while UACT = 1)
- An EOFERR interrupt is detected during communication (while UACT = 1)

Always write 1 to the UACT bit at the end of the USB bus reset processing (on a 0 write to the USBRST bit) or at the end of resume processing from the Suspend state (on a 0 write to the RESUME bit).

The USBHS clears the UACT bit to 0 if it receives an ACK response to an LPM token while the HL1CTRL1.L1REQ bit is set to 1. The USBHS sets the UACT bit to 1 when it finishes resume processing from the L1 state.

In device controller mode, always set this bit to 0.

RESUME bit (Resume Signal Output for the Host Controller Operation)

The RESUME bit controls the resume signal output in host controller mode. When this bit is set to 1, the USBHS drives the USB port to the K-state and outputs the resume signal. The USBHS sets the bit to 1 on detection of a remote wakeup signal while the RWUPE bit is 1 and in the USB suspend state. The USBHS continues outputting the K-state while the RESUME bit is 1, until the bit is cleared to 0 by software. The RESUME bit must be 1 (= resume period) for the time defined in the USB 2.0 specification. Only set this bit to 1 while the interface is in the Suspend state. Write 1 to the UACT bit simultaneously with the end of the resume processing (0 write to the RESUME bit).

Setting the RESUME bit to 1 during transition to the L1 state allows the USBHS to drive the USB port to the K-state and output the resume signal. The USBHS clears the RESUME bit to 0 at the end of the resume period, the value set in the HL1CTRL2.HIRD[3:0] bits.

Always set this bit to 0 in device controller mode.

USBRST bit (USB Bus Reset Output for the Host Controller Operation)

The USBRST bit controls the output of the USB bus signal in host controller mode. When this bit set to 1, the USBHS drives the USB port to the SE0 state to reset the USB bus. The USBHS continues outputting SE0 while the USBRST bit is 1, until the bit is cleared to 0 by software. The USBRST bit must be 1 (= USB bus reset period) for the time defined in the USB 2.0 specification. Writing 1 to the USBRST bit during communication (UACT bit = 1) or during resume processing (RESUME bit = 1) prevents the USBHS from starting USB bus reset processing until both the UACT and RESUME bits clear to 0. Write 1 to the UACT bit simultaneously with the end of the USB bus reset processing (0 write to the USBRST bit).

Always set this bit to 0 in device controller mode.

RWUPE bit (Remote Wakeup Detection Enable for the Host Controller Operation)

The RWUPE bit enables or disables remote wakeup signals (resume signals) from downstream peripheral devices in host controller mode. When this bit is set to 1, the USBHS detects a remote wakeup signal (K-state for 2.5 µs) from a downstream peripheral device, and it performs resume processing, driving the K-state. When the RWUPE bit is set to 0, the USBHS ignores remote wakeup signals (K-states) from peripheral devices connected to the USB port.

Do not stop the PHY clock while the RWUPE bit is 1, even in the Suspend state (the LPSTS.SUSPENDM bit must be set to 1). Also, do not reset the USB bus (setting USBRST to 1) from the Suspend state. This is prohibited in the USB 2.0 specification.

The RWUPE bit is also used to enable or disable detection of a remote wakeup signal during transition to the L1 state.

Always set this bit to 0 in device controller mode.

WKUP bit (Remote Wakeup Output for the Device Controller Operation)

The WKUP bit enables or disables remote wakeup signals (resume signals) to the USB bus in device controller mode.

The USBHS controls the output timing of the remote wakeup signals. When this bit is set to 1, the USBHS clears it to 0 after outputting the K-state for 10 ms. The USB 2.0 specification dictates that the USB bus idle state must be maintained for 5 ms or longer before a remote wakeup signal is sent. If the USBHS writes 1 to the WKUP bit immediately after detecting the Suspend state, the K-state is output after 2 ms.

Only write 1 to the WKUP bit when the device is in the Suspend state (the PL1CTRL1.DVSQ[3:0] flags are 01xxb) and the USB host enables the remote wakeup signal (RWUPE = 1). Do not stop the PHY clock while this bit is 1, even in the Suspend state (the LPSTS.SUSPENDM bit must be set to 1).

If the WKUP bit is set to 1 during transition to the L1 state, the USBHS outputs the K-state for 50 µs and then clears the bit to 0. Before writing 1 to the bit during the L1 state, check that the PL1CTRL1.DVSQ[3:0] flags are 10xxb.

Always set this bit to 0 in host controller mode.

HNPBTOA bit (Host Negotiation Protocol (HNP) Control)

The HNPBTOA bit is used when switching from device B to device A while in OTG mode.

If the HNPBTOA bit is 1, the internal function control maintains the Suspend state until HNP processing ends, even if the SYSCFG.DPRPU bit is set to 0 or the SYSCFG.DCFM bit is set to 1. Resume interrupts (RESM) are not generated even if a falling edge of D+ is detected.

The HNP processing ends when a host attach event is detected, because of a pull-up by the initiating party, or the HNPBTOA bit is cleared to 0 by software because the HNP processing times out.

37.2.6 TESTMODE : USB Test Mode Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x00C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3			0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	UTST[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	UTST[3:0]	Test Mode These bits output the USB test signals. See Table 37.5	R/W
15:4	—	The read values are undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

UTST[3:0] bits (Test Mode)

Writing values to the UTST[3:0] bits allows the USBHS to output USB test signals in high-speed operation mode. Table 37.5 shows the test mode operation settings.

Table 37.5 Test mode operation settings

Test mode	UTST[3:0] bit setting	
	In device controller mode	In host controller mode
Normal operation	0x0	0x0
Test_J	0x1	0x9
Test_K	0x2	0xA
Test_SE0_NAK	0x3	0xB
Test_Packet	0x4	0xC
Test_Force_Enable	—	0xD
Reserved	0x5 to 0x7	0xE to 0xF

Host controller mode

In host controller mode, these bits can be set after setting the SYSCFG.DRPD bit to 1. After the UTST[3:0] bits are set, the USBHS outputs waveforms to the USB port by setting the DVSTCTR0.UACT bit to 1. The USBHS also performs high-speed termination for the USB port by setting these bits in host controller mode.

To set the UTST[3:0] bits in host controller mode:

1. Reset the hardware.
2. Start supplying the PHY clock, and then set the LPSTS.SUSPENDM bit to 1.
3. Set the SYSCFG.DCFM and SYSCFG.DRPD bits to 1. (Setting the SYSCFG.HSE bit to 1 is not required.)
4. Set the SYSCFG.USBE bit to 1.
5. Set the UTST[3:0] bits based on the test requirements.
6. Set the DVSTCTR0.UACT bit to 1.

Assuming the initial steps (1) to (6) are already complete, to change the UTST[3:0] bits in host controller mode:

1. Set the DVSTCTR0.UACT and SYSCFG.USBE bits to 0.
2. Set the SYSCFG.USBE bit to 1.
3. Set the UTST[3:0] bits based on the test requirements.
4. Set the DVSTCTR0.UACT bit to 1.

When the UTST[3:0] bits are set to 1011b (Test_SE0_NAK), the USBHS does not output SOF packets to ports for which the DVSTCTR0.UACT bit is set to 1.

When the UTST[3:0] bits are set to 1101b (Test_Force_Enable), the USBHS outputs SOF packets to ports for which the DVSTCTR0.UACT bit is set to 1. In this test mode, the USBHS does not control the hardware related to attach detection, even if it detects a high-speed detach event (DTCH interrupt).

Before setting the UTST[3:0] bits, set the PID[1:0] bits of all pipe control registers to 00b (NAK response). To return to normal USB communication after setting a test mode, issue a hardware reset.

Device controller mode

In device controller mode, set these bits using a SetFeature request from the USB host during high-speed communication. The USBHS does not enter the Suspend state while these bits are 0001b to 0100b. To return to normal USB communication after setting a test mode, issue a hardware reset.

37.2.7 CFIFO, DnFIFO : FIFO Port Register (n = 0, 1)

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x014 (CFIFO/CFIFOL/CFIFOLL)
0x016 (CFIFOH)
0x017 (CFIFOHH)
0x018 + 0x04 × n (DnFIFO/DnFIFOL/DnFIFOLL)
0x01A + 0x04 × n (DnFIFOH)
0x01B + 0x04 × n (DnFIFOHH)

Bit position:	31 … 0
Bit field:	FIFOPORT[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FIFOPORT[31:0]*1	Read receive data from the FIFO buffer or write transmit data to the FIFO buffer by accessing these bits.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The valid bits depend on the MBW[1:0] and BIGEND settings in the associated port selection register.

Three FIFO ports are provided:

- CFIFO
- D0FIFO
- D1FIFO

Each FIFO port is configured with:

- A port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer and writing of data to the FIFO buffer
- A port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that selects the pipe assigned to the FIFO port
- A port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR)

Each FIFO port has the following constraints:

- Access to the FIFO buffer for DCP control transfers is through the CFIFO port
- Access to the FIFO buffer for DMAC or DTC transfers is through the D0FIFO or D1FIFO port
- The D0FIFO and D1FIFO ports can also be accessed by the CPU
- When using functions specific to the FIFO port, such as the DMAC or DTC transfer function, you cannot change the pipe number selected in the CURPIPE[3:0] bits of the Port Selection Register
- Registers configuring one FIFO port do not affect other FIFO ports
- The same pipe must not be assigned to two or more FIFO ports

- There are two FIFO buffer states, one giving access rights to the CPU and the other to the serial interface engine (SIE). When the SIE has access rights, the FIFO buffer cannot be accessed by the CPU

FIFOPORT bits (FIFOPORT[31:0])

When the FIFOPORT bits are accessed, the USBHS reads the received data from the FIFO buffer or writes the transmission data to the FIFO buffer. The FIFO port register can be accessed only when the FRDY flag in the associated port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is 1.

The valid bits in the FIFO port register depend on the MBW[1:0] and BIGEND settings in the port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL). See Table 37.6 to Table 37.8.

Table 37.6 Endian operation in 32-bit access (MBW[1:0] = 10b)

BIGEND	CFIFO, D0FIFO, D1FIFO b31 to b24	CFIFO, D0FIFO, D1FIFO b23 to b16	CFIFO, D0FIFO, D1FIFO b15 to b8	CFIFO, D0FIFO, D1FIFO b7 to b0	Remarks
0	Located at N+3	Located at N+2	Located at N+1	Located at N+0	Transmit data is sent from the address N+0. Receive data is stored from the address N+0.
1	Located at N+0	Located at N+1	Located at N+2	Located at N+3	Transmission data is sent from the address N+3. Receive data is stored from the address N+3.

Table 37.7 Endian operation in 16-bit access (MBW[1:0] = 01b)

BIGEND	CFIFOL, D0FIFOL, D1FIFOL b15 to b8	CFIFOL, D0FIFOL, D1FIFOL b7 to b0	CFIFOH, D0FIFOH, D1FIFOH b15 to b8	CFIFOH, D0FIFOH, D1FIFOH b7 to b0	Remarks
0	Access prohibited*1		Located at N+1	Located at N+0	Transmit data is sent from the address N+0. Receive data is stored from the address N+0.
1	Located at N+0	Located at N+1	Access prohibited*1		Transmit data is sent from the address N+1. Receive data is stored from the address N+1.

Note 1. Writing to or reading from these areas is prohibited.

Table 37.8 Endian operation in 8-bit access (MBW[1:0] = 00b)

BIGEND	CFIFOLL, D1FIFOLL, D0FIFOLL	CFIFOHH, D1FIFOHH, D0FIFOHH
0	Access prohibited*1	Located at N+0
1	Located at N+0	Access prohibited*1

Note 1. Writing to or reading from these locations is prohibited.

37.2.8 CFIFOSEL : CFIFO Port Selection Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x020

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

9	—	The read value is undefined. The write value should be 0.	R/W
11:10	MBW[1:0]	CFIFO Port Access Bit Width 0 0: 8-bit width 0 1: 16-bit width 1 0: 32-bit width 1 1: Setting prohibited	R/W
13:12	—	The read values are undefined. The write value should be 0.	R/W
14	REW	Buffer Pointer Rewind 0: Do not rewind buffer pointer (Writing 0 has no effect.) 1: Rewind buffer pointer	W
15	RCNT	Read Count Mode 0: Clear DTLN[11:0] flags in the FIFO port control register to 0x000 when all receive data is read from CFIFO 1: Decrement DTLN[11:0] flags each time receive data is read from CFIFO	R/W

Note: S-TYPE-3, P-TYPE-3

Do not specify the same pipe number in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.

Do not change the pipe number while DMAC or DTC transfer is enabled.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number used to read or write data through the CFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, the pipe specification is maintained until the access is complete, even if the software attempts to change the CURPIPE[3:0] setting. Access continues after the current value is written back to the CURPIPE[3:0] bits.

ISEL bit (FIFO Port Access Direction when DCP Is Selected)

After writing a new value to the ISEL bit while the DCP is the selected pipe, read this bit to check that the written value agrees with the read value before proceeding to the next process. Set the ISEL and CURPIPE[3:0] bits simultaneously.

BIGEND bit (FIFO Port Endian Control)

Use the BIGEND bit to set the byte endian order of the CFIFO port.

MBW[1:0] bits (CFIFO Port Access Bit Width)

The MBW[1:0] bits specify the bit width for accessing the CFIFO port.

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. When reading the FIFO buffer, read with the access size set in MBW.

When the selected pipe is transmitting, set the CURPIPE[3:0] and MBW[1:0] bits simultaneously. The bit width cannot be changed from 8-bit to 16- or 32-bit, or from 16-bit to 32-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16- or 32-bit width is selected.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double-buffering when reading is already in progress, this setting enables reading either FIFO buffer from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, always check that the FRDY flag is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

When the RCNT bit set to 0, the USBHS clears the CFIFOCTR.DTLN[11:0] flags to 0 on finishing reading all of the received data in the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits, or after reading a single plane in double buffer mode.

With this bit set to 1, the USBHS decrements the value in the CFIFOCTR.DTLN[11:0] flags each time it reads data received from the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits.

37.2.9 DnFIFOSEL : DnFIFO Port Selection Register (n = 0, 1)

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x028 + 0x4 × n

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RCNT	REW	DCLRM	DREQE	MBW[1:0]		—	BIGEND	—	—	—	—	CURPIPE[3:0]			
Value after reset:	0	0	0	0	0	0	x	0	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CURPIPE[3:0]	FIFO Port Access Pipe Specification 0x0: No pipe specification 0x1: Pipe 1 0x2: Pipe 2 0x3: Pipe 3 0x4: Pipe 4 0x5: Pipe 5 0x6: Pipe 6 0x7: Pipe 7 0x8: Pipe 8 0x9: Pipe 9 Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
7:4	—	The read values are undefined. The write value should be 0.	R/W
8	BIGEND	FIFO Port Endian Control 0: Little endian 1: Big endian	R/W
9	—	The read value is undefined. The write value should be 0.	R/W
11:10	MBW[1:0]	FIFO Port Access Bit Width 0 0: 8-bit width 0 1: 16-bit width 1 0: 32-bit width 1 1: Setting prohibited	R/W
12	DREQE	DMAC/DTC Transfer Request Enable 0: Disable DMAC/DTC transfer request 1: Enable DMAC/DTC transfer request	R/W
13	DCLRM	Auto FIFO Buffer Clear Mode after Specified Pipe is Read 0: Disable auto buffer clear mode 1: Enable auto buffer clear mode	R/W
14	REW	Buffer Pointer Rewind 0: Do not rewind buffer pointer (writing 0 has no effect) 1: Rewind buffer pointer	W
15	RCNT	Read Count Mode 0: Clear DTLN[11:0] flags in the FIFO port control register to 0x000 when all receive data is read from DnFIFO (after read of a single plane in double buffer mode) 1: Decrement DTLN[11:0] flags each time receive data is read from DnFIFO	R/W

Note: S-TYPE-3, P-TYPE-3

Do not specify the same pipe number in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

Do not change the pipe number while DMAC or DTC transfer is enabled.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number used to read or write data through the DnFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, the pipe specification is maintained until the access is complete, even if the software attempts to change the CURPIPE[3:0] setting. Access continues after the current value is written back to the CURPIPE[3:0] bits.

BIGEND bit (FIFO Port Endian Control)

Use the BIGEND bit to set the byte endian order of the D0FIFO or D1FIFO port.

MBW[1:0] bits (FIFO Port Access Bit Width)

The MBW[1:0] bits specify the bit width for accessing the DnFIFO port.

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. When reading the FIFO buffer, read with the access size set in MBW.

When the selected pipe is transmitting, set the CURPIPE[3:0] and MBW[1:0] bits simultaneously. The bit width cannot be changed from 8-bit to 16- or 32-bit, or from 16-bit to 32-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16- or 32-bit width is selected.

DREQE bit (DMAC/DTC Transfer Request Enable)

The DREQE bit enables or disables issuing of DMAC or DTC transfer requests. Only change the settings of DREQE bit when the CURPIPE[3:0] bits are 0x0.

To enable DMAC or DTC transfer requests, set this bit to 1 after setting the CURPIPE[3:0] bits to 0x0, and then set the CURPIPE[3:0] bits to the PIPE number for the transfer.

DCLRM bit (Auto FIFO Buffer Clear Mode after Specified Pipe is Read)

The DCLRM bit enables or disables automatic FIFO buffer clearing after data in the selected pipe is read.

When this bit is set to 1, on receiving a zero-length packet while the FIFO buffer assigned to the selected pipe is empty, or when reading of a received short packet is complete while the PIPECFG.BFRE bit is 1, the USBHS sets the BCLR bit in the FIFO port control register to 1.

When using the USBHS with the SOFCFG.BRDYM bit set to 1, set this bit to 0.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double-buffering when reading is already in progress, this setting enables reading either FIFO buffer from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, always check that the FRDY flag is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

When the RCNT bit set to 0, the USBHS clears the DnFIFOCTR.DTLN[11:0] flags (n = 0, 1) to 0 on finishing reading all of the received data in the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits, or after reading a single plane in double buffer mode.

With this bit set to 1, the USBHS decrements the value in the CFIFOCTR.DTLN[11:0] flags each time it reads data received from the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits. When accessing DnFIFO with the PIPECFG.BFRE bit set to 1, set the RCNT bit to 0.

37.2.10 CFIFOCTR, DnFIFOCTR : FIFO Port Control Register (n = 0, 1)

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x022 (CFIFOCTR)
0x02A + 0x4 × n (DnFIFOCTR)

Bit position:	15	14	13	12	11											0
Bit field:	BVAL	BCLR	FRDY	—	DTLN[11:0]											
Value after reset:	0	0	0	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	DTLN[11:0]	Receive Data Length Flag The meaning of the values differs depending on the RCNT bit setting in the port selection register. For details, see the description of the DTLN[11:0] bits.	R
12	—	The read value is undefined. The write value should be 0.	R/W
13	FRDY	FIFO Port Ready Flag 0: FIFO port access disabled 1: FIFO port access enabled	R
14	BCLR	CPU Buffer Clear 0: No operation (writing 0 has no effect) 1: Clear FIFO buffer on the CPU side	W
15	BVAL	FIFO Buffer Valid Flag Set this bit to 1 when data is completely written to the FIFO buffer on the CPU side for the selected pipe (CURPIPE[3:0] setting). 0: Invalid (writing 0 has no effect) 1: Writing ended	R/W

Note: S-TYPE-3, P-TYPE-3

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[11:0] flags (Receive Data Length Flag)

The DTLN[11:0] flags indicate the length of the receive data.

While the FIFO buffer is being read, the DTLN[11:0] bits indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1), as follows:

- RCNT = 0:
  The USBHS sets the DTLN[11:0] flags to indicate the length of the receive data until the CPU or DMAC/DTC has read all of the received data in the FIFO buffer (or until it has read a single plane in double buffer mode).
  While the PIPECFG.BFRE bit is 1, the USBHS retains the length of the receive data until the BCLR bit is set to 1, even after all the data is read.
- RCNT = 1:
  The USBHS decrements the value indicated in the DTLN[11:0] flags each time the CPU or DMAC/DTC reads the receive data from the FIFO buffer. (The value is decremented by 1 when MBW[1:0] = 00b, by 2 when MBW[1:0] = 01b, and by 4 when MBW[1:0] = 10b.)
  The USBHS sets these flags to 0 when all the data is read from the FIFO buffer. In double buffer mode, if data is received in one FIFO buffer plane before all of the data is read from the other plane, the USBHS sets these bits to indicate the length of the receive data in the latter plane when all of the data is read from the former plane.
  When the RCNT bit is 1, reading the DTLN[11:0] flags while the FIFO buffer is being read returns the latest value within 150 ns after the FIFO port read cycle.

FRDY flag (FIFO Port Ready Flag)

The FRDY flag indicates whether the FIFO port can be accessed by the CPU or DMAC/DTC.

In the following cases, the USBHS sets the FRDY flag to 1 but data cannot be read through the FIFO port because there is no data to be read:

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit is 1

In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

BCLR bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USBHS clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the DCP is the selected pipe, setting the BCLR bit to 1 allows the USBHS to clear both sets of FIFO buffers regardless of whether the CPU or SIE has access rights. To clear the buffer when the SIE has access rights, set the DCPCTR.PID[1:0] bits to 00b (NAK response) before setting the BCLR bit to 1.

When the selected pipe is not the DCP, only write 1 to the BCLR bit while the FRDY flag in the FIFO port control register is 1 (set by the USBHS).

BVAL bit (FIFO Buffer Valid Flag)

Set the BVAL bit to 1 when data is completely written to the FIFO buffer on the CPU for the pipe selected in CURPIPE[3:0].

When the selected pipe is transmitting, set this bit to 1 in the following cases:

- To transmit a short packet, set this bit to 1 after data is written
- To transmit a zero-length packet, set this bit to 1 before data is written to the FIFO buffer
- Set this bit to 1 after the specified number of data bytes is written for the pipe in continuous transfer mode, where the number is a natural integer multiple of the maximum packet size and less than the buffer size

The USBHS then switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When the selected pipe is in use for transmission, simultaneously setting the BVAL flag and the BCLR bit to 1 causes the USBHS to clear the data that is already written and enables transmission of a zero-length packet. When data of the maximum packet size is written for the pipe in non-continuous transfer mode, the USBHS sets this bit to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

Only write 1 to the BVAL flag while the FRDY bit is 1 (set by the USBHS). When the selected pipe is receiving, do not set the BVAL flag to 1.

37.2.11 INTENB0 : Interrupt Enable Register 0

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x030

11	CTRE	Control Transfer Stage Transition Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
12	DVSE	Device State Transition Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
13	SOFE	Frame Number Update Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
14	RSME	Resume Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
15	VBSE	VBUS Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W

Note: S-TYPE-3, P-TYPE-3
Note: The RSME, DVSE, and CTRE bits can only be set to 1 in device controller mode. Do not set these bits to 1 in host controller mode.

When a status flag in the INTSTS0 register sets to 1 and the associated interrupt request enable bit setting in the INTENB0 register is 1, the USBHS issues a USBHS interrupt request.

Regardless of the INTENB0 register setting, the status flag in the INTSTS0 register sets to 1 in response to a state change that satisfies the associated condition.

When an interrupt request enable bit in the INTENB0 register is switched from 0 to 1 while the associated status flag in the INTSTS0 register is set to 1, a USBHS interrupt is requested.

37.2.12 INTENB1 : Interrupt Enable Register 1

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x032

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	OVRCRE	BCHGE	—	DTCHE	ATTCHE	—	L1RSMENDE	LPMENDE	—	EOFERRE	SIGNE	SACKE	—	—	—	PDDETINTE
Value after reset:	0	0	x	0	0	x	0	0	x	0	0	0	x	x	x	0

Bit	Symbol	Function	R/W
0	PDDETINTE	PDDETINT Detection Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
3:1	—	The read values are undefined. The write value should be 0.	R/W
4	SACKE	Setup Transaction Normal Response Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
5	SIGNE	Setup Transaction Error Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
6	EOFERRE	EOF Error Detection Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
7	—	The read values are undefined. The write value should be 0.	R/W
8	LPMENDE	LPM Transaction End Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
9	L1RSMENDE	L1 Resume End Interrupt Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
10	—	The read values are undefined. The write value should be 0.	R/W
11	ATTCHE	Connection Detection Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
12	DTCHE	Disconnection Detection Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
13	—	The read values are undefined. The write value should be 0.	R/W
14	BCHGE	USB Bus Change Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W
15	OVRCRE	OVRCRE Interrupt Request Enable 0: Disable interrupt request 1: Enable interrupt request	R/W

Note: S-TYPE-3, P-TYPE-3

When a status flag in the INTSTS1 register sets to 1 and the associated interrupt request enable bit setting in the INTENB1 register is 1, the USBHS issues a USBHS interrupt request.

Regardless of the INTENB1 register setting, the status flag in the INTSTS1 register sets to 1 in response to a state change that satisfies the associated condition.

When an interrupt request enable bit in the INTENB1 register is switched from 0 to 1 while the associated status flag in the INTSTS1 register is set to 1, a USBHS interrupt is requested.

37.2.13 BRDYENB : BRDY Interrupt Enable Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x036

Bit position:	15	14	13	12	11	10	9									0
Bit field:	—	—	—	—	—	—	PIPEBRDYE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPEBRDYE[9:0]	BRDY Interrupt Request Enable for Pipes [9:0]*1 0: Disable interrupt request 1: Enable interrupt request	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Each bit number corresponds to the same pipe number.

The BRDYENB register enables or disables the INTSTS0.BRDY bit to be set to 1 when a BRDY interrupt is detected for each pipe.

When a status flag in the BRDYSTS register sets to 1 and the associated PIPEBRDYEn (n = 9 to 0) bit setting in the BRDYENB register is 1, the INTSTS0.BRDY flag sets to 1. In this case, if the BRDYE bit in INTENB0 is 1, the USBHS generates a BRDY interrupt request. While at least one PIPEBRDYEn flag indicates 1, the INTSTS0.BRDY flag sets to 1 when the associated interrupt request enable bit in the BRDYENB register is changed from 0 to 1 by software.

37.2.14 NRDYENB : NRDY Interrupt Enable Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x038

Bit position:	15	14	13	12	11	10	9									0
Bit field:	—	—	—	—	—	—	PIPENRDYE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPENRDYE[9:0]	NRDY Interrupt Enable for Pipes [9:0]*1 0: Disable interrupt request 1: Enable interrupt request	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Each bit number corresponds to the same pipe number.

The NRDYENB register enables or disables the INTSTS0.NRDY bit to be set to 1 when a NRDY interrupt is detected for each pipe.

When a status flag in the NRDYSTS register sets to 1 and the associated PIPENRDYEn (n = 0 to 9) bit setting in the NRDYENB register is 1, the INTSTS0.NRDY flag sets to 1. In this case, if the NRDYE bit in INTENB0 is 1, the USBHS generates a NRDY interrupt request. While at least one PIPEBRDYEn flag indicates 1, the INTSTS0.NRDY flag sets to 1 when the associated interrupt request enable bit in the NRDYENB register is changed from 0 to 1 by software.

37.2.15 BEMPENB : BEMP Interrupt Enable Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x03A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PIPEBEMPE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPEBEMPE[9:0]	BEMP Interrupt Enable for Pipes [9:0]*1 0: Disable interrupt request 1: Enable interrupt request	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Each bit number corresponds to the same pipe number.

The BEMPENB register enables or disables the INTSTS0.BEMP bit to be set to 1 when a BEMP interrupt is detected for each pipe.

When a status flag in the BEMPSTS register sets to 1 and the associated PIPEBEMPEn (n = 0 to 9) bit setting in the BEMPENB register is 1, the INTSTS0.BEMP flag sets to 1. In this case, if the BEMPE bit in INTENB0 is 1, the USBHS generates a BEMP interrupt request. While at least one PIPEBEMPEn flag indicates 1, the INTSTS0.BEMP flag sets to 1 when the associated interrupt request enable bit in the BEMPENB register is changed from 0 to 1 by software.

37.2.16 SOFCFG : SOF Output Configuration Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x03C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TRNENSEL	—	BRDYM	INTL	EDGESTS	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	0	x	0	0	0	x	x	x	x

Bit	Symbol	Function	R/W
3:0	—	The read values are undefined. The write value should be 0.	R/W
4	EDGESTS	Interrupt Edge Processing Status Flag*1 Indicates 1 during the edge processing of an edge interrupt output signal.	R
5	INTL	Interrupt Output Sense Select*2 0: Edge detection 1: Level detection	R/W
6	BRDYM	PIPEBRDY Interrupt Status Clear Timing*3 0: Clear BRDY flag through software 1: Clear BRDY flag by the USBHS through a data read from the FIFO buffer or data write to the FIFO buffer	R/W
7	—	The read values are undefined. The write value should be 0.	R/W
8	TRNENSEL	Transaction-Enabled Time Select*4 0: Not low-speed communication 1: Low-speed communication	R/W
15:9	—	The read values are undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Confirm that the EDGESTS flag is 0 before stopping the clock supply to the USBHS.

Note 2. When the INTL bit is set to 0, to stop the PHY clock (LPSTS.SUSPENDM = 0) after clearing the interrupt status, write 0 to the LPSTS.SUSPENDM bit after confirming that the EDGESTS flag is cleared to 0.

Note 3. When setting the BRDYM bit to 1, set the INTL bit to 1.

Note 4. The setting in the TRNENSEL bit is only valid in host controller mode. Even in host controller mode, the setting of this bit has no effect on the transaction-enabled time during high-speed communication.

EDGESTS flag (Interrupt Edge Processing Status Flag)

The EDGESTS flag indicates 1 during the edge processing of an edge interrupt output signal. Confirm that this flag is 0 before stopping the PHY clock.

BRDYM bit (PIPEBRDY Interrupt Status Clear Timing)

The BRDYM bit specifies how the BRDY interrupt status flags for the pipes are cleared.

TRNENSEL bit (Transaction-Enabled Time Select)

When the USB port is in use for full-speed or low-speed communications, the TRNENSEL bit specifies the timing with which the USBHS issues tokens in a frame (transaction-enabled time).

Set this bit to 1 when a low-speed device is connected through a hub. The bit is only valid in host controller mode. Set this bit to 0 when the interface is in use as a device controller.

37.2.17 PHYSET : PHY Setting Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x03E

Bit position:	15	14	13	12	11	10	9		7	6	5		3	2	1	0
Bit field:	HSEB	—	—	—	REPSTART	—	REPSEL[1:0]		—	—	CLKSEL[1:0]		CDPEN	—	PLLRESET	DIRPD
Value after reset:	x	x	x	x	0	x	0	0	x	x	1	1	0	x	1	1

Bit	Symbol	Function	R/W
0	DIRPD	Power-Down Control 0: Do not enter low power mode 1: Enter low power mode	R/W
1	PLLRESET	PLL Reset Control*1 0: Disable PLL reset control for UTMI_PHY 1: Enable PLL reset control for UTMI_PHY	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CDPEN	Charging Downstream Port Enable 0: Disable downstream port charging 1: Enable downstream port charging	R/W
5:4	CLKSEL[1:0]	Input Clock Frequency Select 0 0: 12 MHz 0 1: 48 MHz 1 0: 20 MHz 1 1: 24 MHz	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
9:8	REPSEL[1:0]	Terminating Resistance Adjustment Cycle 0 0: No cycle is set 0 1: Adjust terminating resistance at 16-second intervals 1 0: Adjust terminating resistance at 64-second intervals 1 1: Adjust terminating resistance at 128-second intervals	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	REPSTART	Forcibly Start Terminating Resistance Adjustment 0: Force terminating resistance adjustment to start 1: Do not force terminating resistance adjustment to start	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15	HSEB	CL-only mode 0: Disable CL-only mode 1: Enable CL-only mode	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Because the value of the PLLRESET bit is 1 after a reset, changing the setting after release from the reset state is not required. Do not set the PLLRESET bit to 1 after setting the PLLRESET bit to 0. Operation is not guaranteed.

CLKSEL[1:0] bits (Input Clock Frequency Select)

The CLKSEL[1:0] bits select the transfer clock source for the USBHS.

For the transfer clock generated in the USB-PHY internal PLL, these bits set the input clock frequency. To input the clock source from the EXTAL pin, the USB 2.0 clock specification must be strictly followed.

Writing to the CKSEL[1:0] bits is invalid in CL-only mode because the internal PLL is stopped (see the description for HSEB bit (CL-only mode)). For the clock settings, see section 37.3.3. Supplying the Clock.

HSEB bit (CL-only mode)

The HSEB bit selects whether the USBHS operates in CL-only mode. High-speed transfer by the USBHS requires the use of internal high-speed analog circuits including the PLL, clock, and data recovery (CDR) circuit in the USB-PHY block.

CL-only mode limits the transfer to the USB 1.1 specification (full-speed and low-speed transfer only). Power consumption can be reduced by stopping the internal PLL of the PHY module and other high-speed analog circuits.

In CL-only mode, the USBHS requires supply clocks of 48 MHz and 60 MHz, generated in the Clock Generation Circuit. For the clock supply method, see section 9, Clock Generation Circuit.

37.2.18 INTSTS0 : Interrupt Status Register 0

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x040

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	VBINT	RESM	SOFR	DVST	CTRT	BEMP	NRDY	BRDY	VBSTS	DVSQ[2:0]			VALID	CTSQ[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	x	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CTSQ[2:0]	Control Transfer Stage Flag[*1] 0 0 0: Idle or setup stage 0 0 1: Control read data stage 0 1 0: Control read status stage 0 1 1: Control write data stage 1 0 0: Control write status stage 1 0 1: Control write (no data) status stage 1 1 0: Control transfer sequence error	R
3	VALID	USB Request Reception Flag[*1] 0: Setup packet not received 1: Setup packet received	R/W[*3]
6:4	DVSQ[2:0]	Device State[*1] Indicates the device state. 0 0 0: Powered state 0 0 1: Default state 0 1 0: Address state 0 1 1: Configured state Others: Suspend state	R
7	VBSTS	VBUS Input Status Flag 0: USBHS_VBUS pin is low 1: USBHS_VBUS pin is high	R

Bit	Symbol	Function	R/W
8	BRDY	BRDY Interrupt Status Flag 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R
9	NRDY	NRDY Interrupt Status Flag 0: No NRDY interrupt occurred 1: NRDY interrupt occurred	R
10	BEMP	BEMP Interrupt Status Flag 0: No BEMP interrupt occurred 1: BEMP interrupt occurred	R
11	CTRT	Control Transfer Stage Transition Interrupt Status Flag*2 0: No control transfer stage transition interrupt occurred 1: Control transfer stage transition interrupt occurred	R/W*3
12	DVST	Device State Transition Interrupt Status Flag*2 0: No device state transition interrupt occurred 1: Device state transition interrupt occurred	R/W*3
13	SOFR	Frame Number Refresh Interrupt Status Flag 0: No SOF interrupt occurred 1: SOF interrupt occurred	R/W*3
14	RESM	Resume Interrupt Status Flag*2 *4 0: No resume interrupt occurred 1: Resume interrupt occurred	R/W*3
15	VBINT	VBUS Interrupt Status Flag*4 0: No VBUS interrupt occurred on detecting a change in the USBHS_VBUS pin 1: VBUS interrupt occurred on detecting a change in the USBHS_VBUS pin	R/W*3

Note: S-TYPE-3, P-TYPE-3

Note 1. The CTSQ[2:0], VALID, and DVSQ[2:0] flags are only valid in device controller mode.

Note 2. The status of the CTRT, DVST, and RESM flags are changed only in device controller mode. Set the associated interrupt enable bits to 0 (disabled) in host controller mode.

Note 3. To clear the CTRT, DVST, SOFR, RESM, or VBINT flags, write 0 only to the flags to be cleared. Write 1 to the other flags. Do not write 0 to the status flags indicating 0.

Note 4. The USBHS detects a change in the status in the RESM or VBINT flag even while the clock supply is stopped (LPSTS.SUSPENDM = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply before clearing the status by software.

BRDY flag (BRDY Interrupt Status Flag)

The BRDY flag indicates the BRDY interrupt state. For the conditions that cause the flag to be set, see section 37.2.13. BRDYENB : BRDY Interrupt Enable Register.

The USBHS clears the BRDY flag to 0 when 0 is written to the BRDYSTS.PIPEBRDYn (n = 0 to 9) flags for all pipes for which the BRDY interrupt is enabled (BRDYENB.PIPEBRDYEn bits). Writing 0 to the BRDY flag in the software does not clear the flag.

NRDY flag (NRDY Interrupt Status Flag)

The NRDY flag indicates the NRDY interrupt state. For the conditions that cause the flag to be set, see section 37.2.14. NRDYENB : NRDY Interrupt Enable Register.

The USBHS clears the NRDY flag to 0 when 0 is written to the NRDYSTS.PIPENRDYn (n = 0 to 9) flags for all pipes for which the NRDY interrupt is enabled (NRDYENB.PIPENRDYEn bits). Writing 0 to the NRDY flag in the software does not clear the flag.

BEMP flag (BEMP Interrupt Status Flag)

The BEMP indicates the BEMP interrupt state. For the conditions that cause the flag to be set, see section 37.2.15. BEMPENB : BEMP Interrupt Enable Register.

The USBHS clears the BEMP flag to 0 when 0 is written to the BEMPSTS.PIPEBEMPn (n = 0 to 9) flags for all pipes for which the BEMP interrupt is enabled (BEMPENB.PIPEBEMPEn bits). Writing 0 to the BEMP flag in the software does not clear the flag.

CTRT flag (Control Transfer Stage Transition Interrupt Status Flag)

In device controller mode, the USBHS updates the value of the CTSQ[2:0] bits and sets the CTRT flag to 1 on detecting a transition in the control transfer stage. When a control transfer stage transition interrupt occurs, clear the CTRT flag before the USBHS detects the next control transfer stage transition.

Values read from the CTRT flag in host controller mode are invalid.

DVST flag (Device State Transition Interrupt Status Flag)

In device controller mode, the USBHS updates the value of the PL1CTRL1.DVSQ[3:0] bits and sets the DVST flag to 1 on detecting a change in the device state. When a device state transition interrupt occurs, clear the DVST flag before the USBHS detects the next device state transition.

Values read from the DVST flag in host controller mode are invalid.

SOFR flag (Frame Number Refresh Interrupt Status Flag)

In host controller mode, the USBHS sets the SOFR flag to 1 on updating the frame number when the DVSTCTR0.UACT bit is set to 1 by software. An SOFR interrupt is detected every 1 ms.

In device controller mode, the USBHS sets the SOFR flag to 1 on updating the frame number. An SOFR interrupt is detected every 1 ms. The USBHS can detect an SOFR interrupt through the SOF complementation function even when a corrupted SOF packet is received from the USB host. See section 37.3.13. SOF Complementation Function.

RESM flag (Resume Interrupt Status Flag)

In device controller mode, the USBHS sets the RESM flag to 1 on detecting the falling edge of the signal on the USBHS_DP pin in the Suspend state (PL1CTRL1.DVSQ[3:0] = 01xxb).

Values read from the RESM flag in host controller mode are invalid.

VBINT flag (VBUS Interrupt Status Flag)

The USBHS sets the VBINT flag to 1 on detecting a level change (high to low or low to high) in the USBHS_VBUS pin input value. The USBHS sets the VBSTS flag to indicate the USBHS_VBUS pin input value. When a VBINT interrupt occurs, eliminate transient elements by reading the VBSTS flag at least three times through software processing and check that the values read are the same.

37.2.19 INTSTS1 : Interrupt Status Register 1

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x042

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	OVRCR	BCHG	—	DTCH	ATTCH	—	L1RSMEND	LPMEND	—	EOFERR	SIGN	SACK	—	—	—	PDDETINT
Value after reset:	0	0	x	0	0	x	0	0	x	0	0	0	x	x	x	0

Bit	Symbol	Function	R/W
0	PDDETINT	PDDET Detection Interrupt Status Flag*1 0: No PDDET interrupt occurred 1: PDDET interrupt occurred	R/W*2
3:1	—	The read values are undefined. The write value should be 0.	R/W
4	SACK	Setup Transaction Normal Response Interrupt Status Flag 0: No SACK interrupt occurred 1: SACK interrupt occurred	R/W*2
5	SIGN	Setup Transaction Error Interrupt Status Flag 0: No SIGN interrupt occurred 1: SIGN interrupt occurred	R/W*2
6	EOFERR	EOF Error Detection Interrupt Status Flag 0: No EOFERR interrupt occurred 1: EOFERR interrupt occurred	R/W*2

Bit	Symbol	Function	R/W
7	—	The read value is undefined. The write value should be 0.	R/W
8	LPMEND	LPM Transaction End Interrupt Status Flag 0: No LPMEND interrupt occurred 1: LPMEND interrupt occurred	R/W*2
9	L1RSMEND	L1 Resume End Interrupt Status Flag 0: No L1RSMEND interrupt occurred 1: L1RSMEND interrupt occurred	R/W*2
10	—	The read value is undefined. The write value should be 0.	R/W
11	ATTCH	USB Connection Detection Interrupt Status Flag 0: No ATTCH interrupt occurred 1: ATTCH interrupt occurred	R/W*2
12	DTCH	USB Disconnection Detection Interrupt Status Flag 0: No DTCH interrupt occurred 1: DTCH interrupt occurred	R/W*2
13	—	The read value is undefined. The write value should be 0.	R/W
14	BCHG	USB Bus Change Interrupt Status Flag*1 0: No BCHG interrupt occurred 1: BCHG interrupt occurred	R/W*2
15	OVRCR	OVRCR Interrupt Status Flag*1 0: No OVRCR interrupt occurred 1: OVRCR interrupt occurred	R/W*2

Note: S-TYPE-3, P-TYPE-3

Note: Only enable the status change interrupts indicated in the flags in INTSTS1 in host controller mode, except for the PDDET detection interrupt.

Note 1. The USBHS detects a change in the status in the PDDETINT, BCHG, or OVRCR flag even while the clock supply is stopped (LPSTS.SUSPENDM = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply before clearing the status by software. No other interrupts can be detected while the clock supply is stopped (LPSTS.SUSPENDM = 0).

Note 2. To clear the flags in INTSTS1, write 0 only to the flags to be cleared. Write 1 to the other bits.

PDDETINT flag (PDDET Detection Interrupt Status Flag)

The USBHS sets the PDDETINT flag to 1 on detecting a level change (high to low or low to high) in the PDDET pin input value. When the PDDETINT interrupt is generated, perform debouncing by reading the PDDETSTS flag at least three times through software processing and checking that the values read are the same.

SACK flag (Setup Transaction Normal Response Interrupt Status Flag)

The SACK flag indicates the status of the setup transaction normal response interrupt in host controller mode.

The USBHS detects the SACK interrupt and sets this bit to 1 when an ACK response is returned from a peripheral device during the setup transactions issued by the USBHS. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

Values read from the SACK flag in device controller mode are invalid.

SIGN flag (Setup Transaction Error Interrupt Status Flag)

The SIGN flag indicates the status of setup transaction error interrupts in host controller mode.

The USBHS detects the SIGN interrupt and sets this bit to 1 when an ACK response is not returned from a peripheral device three consecutive times during the setup transactions issued by the USBHS. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects the SIGN interrupt when any of the following response conditions occur for three consecutive setup transactions:

- Timeout is detected by the USBHS when the peripheral device has returned no response
- A corrupted ACK packet is received
- A handshake other than ACK (NAK, NYET, or STALL) is received

Values read from the SIGN flag in device controller mode are invalid.

EOFERR flag (EOF Error Detection Interrupt Status Flag)

The EOFERR flag indicates the status of EOF error detection interrupts in host controller mode.

The USBHS detects the EOFERR interrupt and sets this bit to 1 on detecting that communication did not complete at the EOF2 timing defined in the USB 2.0 specification. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

After detecting the EOFERR interrupt, the USBHS controls the hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt was detected to 0
- Puts the port in which the EOFERR interrupt occurred into the idle state

The software must terminate all pipes in which communications are being carried out and re-enumerate the USB port.

Values read from the EOFERR flag in device controller mode are invalid.

LPMEND flag (LPM Transaction End Interrupt Status Flag)

The PLPMEND flag indicates the status of LPM transaction end interrupts in host controller mode.

When the HL1CTRL1.L1REQ bit sets to 1, the USBHS sends an LPM token. When the LPM transaction is ended because a response from the function device or a timeout is detected, the USBHS sets this flag to 1.

Values read from the LPMEND flag in device controller mode are invalid.

L1RSMEND flag (L1 Resume End Interrupt Status Flag)

The L1RSMEND flag indicates the status of L1 resume end interrupts in host controller mode.

When performing resume processing after transitioning to the L1 state because an ACK was received in response to an LPM token, the USBHS sets this flag to 1.

Values read from the L1RSMEND flag in device controller mode are invalid.

ATTCH flag (USB Connection Detection Interrupt Status Flag)

The ATTCH flag indicates the status of USB attach detection interrupts in host controller mode.

The USBHS detects the ATTCH interrupt and sets this bit to 1 on detecting a J-state or K-state on the full-speed or low-speed signal level for 2.5 µs. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects the ATTCH interrupt on any of the following conditions:

- K-state, SE0, or SE1 changes to J-state, and J-state continues for 2.5 µs
- J-state, SE0, or SE1 changes to K-state, and K-state continues for 2.5 µs

Values read from the ATTCH flag in device controller mode are invalid.

DTCH flag (USB Disconnection Detection Interrupt Status Flag)

The DTCH flag indicates the status of USB detach detection interrupts in host controller mode.

The USBHS detects the DTCH interrupt and sets this bit to 1 on detecting a USB bus detach event. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects bus detach events based on the USB 2.0 specification.

After detecting the DTCH interrupt, the USBHS controls hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt was detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

The software must terminate all pipes in which communications are being carried out and invoke the wait state for attaching to the USB port (waiting for ATTCH interrupt generation).

Values read from the DTCH flag in device controller mode are invalid.

BCHG flag (USB Bus Change Interrupt Status Flag)

The BCHG flag indicates the status of USB bus change interrupts in host controller mode.

The USBHS detects the BCHG interrupt and sets this bit to 1 when a change in the full-speed signal level occurs on the USB port. This includes any change from J-state, K-state, or SE0 to J-state, K-state, or SE0. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS sets the SYSSTS0.LNST[1:0] flags to indicate the input state of the USB port. When a BCHG interrupt occurs, eliminate transient elements by repeat reading the LNST[1:0] bits by software until the same value is read at least three times.

Changes in the USB bus state can be detected while the PHY clock is stopped.

Values read from the BCHG flag in device controller mode are invalid.

OVRCR flag (OVRCR Interrupt Status Flag)

The OVRCR flag indicates the input status on the USBHS_OVCUR0A pin or changes on the USBHS_OVCUR0B pin. If the INTENB1.OVRCRE bit sets to 1, the USBHS requests the interrupt.

The USBHS sets the SYSSTS0.OVCMON[1:0] flags to indicate the input state of the USBHS_OVCUR0A and USBHS_OVCUR0B pins.

These pins allow overcurrent detection by software in host controller mode. To implement this function, connect the overcurrent signal from the external power supply IC that supplies VBUS to connected USB devices to the OVCUR0A or OVCUR0B pin. On detection of an OVRCR interrupt, eliminate transients by repeatedly reading the OVCMON[1:0] flags through the software until the same value is read at least three times.

37.2.20 BRDYSTS : BRDY Interrupt Status Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x046

Bit position:	15	14	13	12	11	10	9									0
Bit field:	—	—	—	—	—	—	PIPEBRDY[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPEBRDY[9:0]	BRDY Interrupt Status Flag for Pipe[9:0]*1 0: No BRDY interrupt occurred 1: BRDY interrupt occurred	R/W*2
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Each bit number corresponds to the same pipe number.
Note 2. When the SOFCFG.BRDYM bit is set to 0, to clear the status indicated in the PIPEBRDY[9:0] flags, write 0 only to the bits to be cleared. Write 1 to the other bits.
When the SOFCFG.BRDYM bit is set to 0, clear BRDY interrupts before accessing the FIFO.

PIPEBRDY[9:0] flags (BRDY Interrupt Status Flag for Pipe[9:0])

When the BRDY interrupt is detected, the USBHS sets the associated bit in the PIPEBRDY[9:0] flags to 1. For details on BRDY interrupts, see section 37.3.6.1. BRDY Interrupt.

37.2.21 NRDYSTS : NRDY Interrupt Status Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x048

Bit position:	15	14	13	12	11	10	9									0
Bit field:	—	—	—	—	—	—	PIPENRDY[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPENRDY[9:0]	NRDY Interrupt Status Flag for Pipe[9:0]*1 0: No NRDY interrupt occurred 1: NRDY interrupt occurred.	R/W*2
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Each bit number corresponds to the same pipe number.
Note 2. To clear the status indicated in the PIPENRDY[9:0] flags, write 0 only to the bits to be cleared. Write 1 to the other bits.

PIPENRDY[9:0] flags (NRDY Interrupt Status Flag for Pipe[9:0])

If an internal NRDY interrupt is detected while the PID[1:0] bits in a pipe control register are 01b (BUF response), the USBHS sets the associated bit in the PIPENRDY[9:0] flags to 1. For details on NRDY interrupts, see section 37.3.6.2. NRDY Interrupt.

37.2.22 BEMPSTS : BEMP Interrupt Status Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x04A

Bit position:	15	14	13	12	11	10	9									0
Bit field:	—	—	—	—	—	—	PIPEBEMP[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	PIPEBEMP[9:0]	BEMP Interrupt Status Flag for Pipe[9:0]*1 0: No BEMP interrupt occurred 1: BEMP interrupt occurred.	R/W*2
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Each bit number corresponds to the same pipe number.
Note 2. To clear the status indicated in the PIPEBEMP[9:0] flags, write 0 only to the bits to be cleared. Write 1 to the other bits.

PIPEBEMP[9:0] flags (BEMP Interrupt Status Flag for Pipe[9:0])

If an BEMP interrupt is detected while the PID[1:0] bits in a pipe control register are 01b (BUF response), the USBHS sets the associated bit in the PIPEBEMP[9:0] flags to 1. For details on BEMP interrupts, see section 37.3.6.3. BEMP Interrupt.

37.2.23 FRMNUM : Frame Number Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x04C

Bit position:	15	14	13	12	11	10										0
Bit field:	OVRN	CRCE	—	—	—	FRNM[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	FRNM[10:0]*1	Frame Number Flag	R
13:11	—	These bits are read as 0. The write value should be 0.	R/W
14	CRCE	CRC Error Detection Status Flag 0: No error occurred 1: Error occurred	R/W
15	OVRN	Overrun/Underrun Detection Status Flag 0: No error occurred 1: Error occurred.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The OVRN flag is for debugging. Design the timing so that no overrun or underrun occurs in the system.

FRNM[10:0] flags (Frame Number Flag)

The USBHS sets the FRNM[10:0] flags to indicate the latest frame number, which is updated every 1 ms, when an SOF packet is issued or received.

CRCE flag (CRC Error Detection Status Flag)

The CRCE flag sets to 1 when a CRC error or bit stuffing error occurs during isochronous transfer. On detecting a CRC error, the USBHS generates an internal NRDY interrupt.

To clear the CRCE flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

OVRN flag (Overrun/Underrun Detection Status Flag)

The OVRN flag sets to 1 when an overrun or underrun error occurs during isochronous transfer. To clear the flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

In host controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the time to issue an OUT token comes before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the time to issue an IN token comes when no FIFO buffer planes are empty

In device controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the IN token is received before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the OUT token is received when no FIFO buffer planes are empty

37.2.24 UFRMNUM : μFrame Number Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x04E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2		0
Bit field:	DVCHG	—	—	—	—	—	—	—	—	—	—	—	—	UFRNM[2:0]		
Value after reset:	0	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	UFRNM[2:0]	Microframe number	R
14:3	—	These bits are read as 0. The write value should be 0.	R/W
15	DVCHG	Device State Change 0: Disable writes to the USBADDR.STSRECOV0[2:0] and USBADDR.USBADDR [6:0] bits 1: Enable writes to the USBADDR.STSRECOV0[2:0] and USBADDR.USBADDR[6:0] bits	R/W

Note: S-TYPE-3, P-TYPE-3

UFRNM[2:0] flags (Microframe number)

The USBHS sets the UFRNM[2:0] flags to indicate the microframe number during high-speed operation. When not in high-speed operation, the USBHS sets these bits to 00b.

Read these bits repeatedly until the same value is read twice.

37.2.25 USBADDR : USB Address Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x050

Bit position:	15	14	13	12	11	10			7	6						0
Bit field:	—	—	—	—	—	STSRECOV0[2:0]			—	USBADDR[6:0]						
Value after reset:	x	x	x	x	x	0	0	0	x	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	USBADDR[6:0]	USB Address Flag In device controller mode, these flags indicate the USB address assigned by the host when the USBHS processed the SET_ADDRESS request successfully.	R
7	—	The read value is undefined. The write value should be 0.	R/W
10:8	STSRECOV0[2:0]	Status Recovery [D]: In deice controller mode [H]: In host controller mode (settings other than 010b, 100b, or 110b are prohibited) 0 0 0: Reserved 0 0 1: [D] Return to the full-speed connection and Default state 0 1 0: [D] Return to the full-speed connection and Address state [H] Return to the low-speed state (bits DVSTCTR0.RHST[2:0] = 001b) 0 1 1: [D] Return to the full-speed connection and Configured state 1 0 0: [D] Return to the suspend connection and Suspend state [H] Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b) 1 0 1: [D] Return to the high-speed connection and Default state 1 1 0: [D] Return to the high-speed connection and Address state [H] Return to the high-speed state (bits DVSTCTR0.RHST[2:0] = 011b) 1 1 1: [D] Return to the high-speed connection and Configured state	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

USBADDR[6:0] flags (USB Address Flag)

In device controller mode, the USBADDR[6:0] flags indicate the USB address received when the USBHS processed a SetAddress request successfully. The USBHS sets the USBADDR[6:0] bits to 00b on detecting a USB bus reset.

In host controller mode, the USBADDR[6:0] bits are invalid.

STSRECOV0[2:0] bits (Status Recovery)

Use the STSRECOV[3:0] bits to resume the state of the internal sequencer on recovering from USB power shut-off. For details, see section 37.3.17. Deep Software Standby Mode 1 Because of USB Suspend/Resume Interrupts.

Writing to these bits is enabled while the UFRMNUM.DVCHG bit is set to 1.

37.2.26 USBREQ : USB Request Type Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x054

Bit position:	15								7							0
Bit field:	BREQUEST[7:0]								BMREQUESTTYPE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	BMREQUESTTYPE [7:0]	USB request bmRequestType value	R/W*1
15:8	BREQUEST[7:0]	USB request bRequest value	R/W*1

Note: S-TYPE-3, P-TYPE-3
Note 1. In device controller mode, these bits can be read, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

BMREQUESTTYPE[7:0] bits (USB request bmRequestType value)

The BMREQUESTTYPE[7:0] bits hold the bmRequestType value of USB requests.

- In host controller mode:
  Set these bits to the value of the USB request data in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the value of the USB request data in reception setup transactions. Writing to the bits has no effect.

BREQUEST[7:0] bits (USB request bRequest value)

The BREQUEST[7:0] bits hold the bRequest value of USB requests.

- In host controller mode:
  Set these bits to the value of the USB request data in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the value of the USB request data in reception setup transactions. Writing to the bits has no effect.

37.2.27 USBVAL : USB Request Value Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x056

Bit position:	15															0
Bit field:	WVALUE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WVALUE[15:0]	USB request wValue value	R/W*1

Note: S-TYPE-3, P-TYPE-3
Note 1. In device controller mode, these bits are readable, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

WVALUE[15:0] bits (USB request wValue value)

The WVALUE[15:0] bits hold the wValue value of USB requests.

- In host controller mode:

Set these bits to the wValue value for USB requests in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.

- In device controller mode:
  These bits indicate the wValue value of USB requests in reception setup transactions. Writing to the bits has no effect.

37.2.28 USBINDX : USB Request Index Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x058

Bit position:	15															0
Bit field:	WINDEX[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WINDEX[15:0]	USB request wIndex value	R/W*1

Note: S-TYPE-3, P-TYPE-3
Note 1. In device controller mode, these bits are readable, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

WINDEX[15:0] bits (USB request wIndex value)

- In host controller mode:
  Set these bits to the wIndex value of USB requests in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the wIndex value of USB requests received in reception setup transactions. Writing to the bits has no effect.

37.2.29 USBLENG : USB Request Length Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x05A

Bit position:	15															0
Bit field:	WLENTUH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	WLENTUH[15:0]	USB request wLength value	R/W*1

Note: S-TYPE-3, P-TYPE-3
Note 1. In device controller mode, these bits are readable, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

WLENTUH[15:0] bits (USB request wLength value)

The WLENTUH[15:0] bits hold the wLength value of USB requests.

- In host controller mode:
  Set the wLength value of USB requests in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the wLength value of USB requests in reception setup transactions. Writing to the bits has no effect.

37.2.30 DCPCFG : DCP Configuration Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x05C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CNTMD	SHTNAK	—	—	DIR	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	DIR	Transfer Direction 0: Data receiving direction 1: Data transmitting direction	R/W
6:5	—	The read values are undefined. The write value should be 0.	R/W
7	SHTNAK	Pipe Blocking on End of Transfer 0: Keep pipe open after transfer ends 1: Disable pipe after transfer ends	R/W
8	CNTMD	Continuous Transfer Mode 0: Non-continuous transfer mode 1: Continuous transfer mode	R/W
15:9	—	The read values are undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Only set the bits in the DCPCFG register while the PID is NAK. Before setting the bits, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBHS, checking the PBUSY bit through software is not necessary.

DIR bit (Transfer Direction)

In host controller mode, the DIR bit sets the transfer direction of the data stage and status stage for control transfers. In device controller mode, set the DIR bit to 0.

SHTNAK bit (Pipe Blocking on End of Transfer)

The SHTNAK bit specifies whether to change PID to NAK on transfer end when the selected pipe is receiving. It is only valid when the selected pipe is receiving.

When the SHTNAK bit is 1, the USBHS changes the DCPCTR.PID[1:0] bits for the DCP to NAK on determining that a transfer has ended. The USBHS determines transfer end on the following condition:

- A short packet, including a zero-length packet, is successfully received

CNTMD bit (Continuous Transfer Mode)

The CNTMD bit indicates whether transfer through the default control pipe is in continuous transfer mode.

37.2.31 DCPMAXP : DCP Maximum Packet Size Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x05E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DEVSEL[3:0]				—	—	—	—	—	MXPS[6:0]						
Value after reset:	0	0	0	0	x	x	x	x	x	1	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	MXPS[6:0]	Maximum Packet Size*1 Maximum data payload specification (maximum packet size) for the DCP	R/W
11:7	—	The read values are undefined. The write value should be 0.	R/W
15:12	DEVSEL[3:0]	Device Select*2 0x0: Address 0x0 0x1: Address 0x1 0x2: Address 0x2 0x3: Address 0x3 0x4: Address 0x4 0x5: Address 0x5	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Only set the MXPS[6:0] bits while PID is NAK. Before setting this bit, check that the CSSTS and PBUSY bits are 0, and then change the DCPCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK), and the CFIFOSEL.CURPIPE[3:0] bits to 0000b. If the DCPCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY bits through software is not necessary. After the MXPS[6:0] bits are set and the DCP is set to the CURPIPE[3:0] bits in a port select register, clear the buffer by setting the BCLR bit the port control register to 1.

Note 2. Only set the DEVSEL[3:0] bits while PID is NAK and the DCPCTR.SUREQ bits are 0. Before setting these bits, check that the CSSTS and PBUSY flags are 0, and then change the DCPCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK), and the DCPCTR.SUREQ[3:0] bits to 0. If the DCPCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY bits through software is not necessary.

MXPS[6:0] bits (Maximum Packet Size)

The MXPS[6:0] bits specify the maximum data payload (maximum packet size) for the DCP. The initial value is 0x40 (64 bytes). Set the bits to a USB 2.0-compliant value. Do not write to the FIFO buffer or set PID = BUF while MXPS[6:0] is set to 0.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target peripheral device for a control transfer. Set up the device address in the associated DEVADDn (n = 0 to A) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0010b, for example, first set the address in the DEVADD2 register. In device controller mode, set these bits to 0000b.

37.2.32 DCPCTR : DCP Control Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x060

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BSTS	SUREQ	CSCLR	CSSTS	SUREQCLR	—	—	SQCLR	SQSET	SQMON	PBUSY	PINGE	—	CCPL	PID[1:0]	
Value after reset:	0	0	0	0	x	x	x	0	0	1	0	0	x	0	0	0

Bit	Symbol	Function	R/W
1:0	PID[1:0]	Response PID 0 0: NAK response 0 1: BUF response (depends on buffer state) 1 x: STALL response	R/W
2	CCPL	Control Transfer End Enable 0: Disable control transfer completion 1: Enable control transfer completion	R/W
3	—	The read value is undefined. The write value should be 0.	R/W
4	PINGE	PING Token Issue Enable*1 0: Disable PING token 1: Enable normal PING operation	R/W

Bit	Symbol	Function	R/W
5	PBUSY	Pipe Busy Flag 0: DCP not used for the USB bus 1: DCP in use for the USB bus	R
6	SQMON	Sequence Toggle Bit Monitor Flag 0: DATA0 1: DATA1	R
7	SQSET	Sequence Toggle Bit Set*1 0: Invalid (writing 0 has no effect) 1: Set the expected value for the next transaction to DATA1	W
8	SQCLR	Sequence Toggle Bit Clear*1 0: Invalid (writing 0 has no effect) 1: Clear the expected value for the next transaction to DATA0	W
10:9	—	The read values are undefined. The write value should be 0.	R/W
11	SUREQCLR	SUREQ Bit Clear 0: Invalid (writing 0 has no effect) 1: Clear SUREQ to 0	W
12	CSSTS	CSSTS Status Flag 0: Start-split (SSPLIT) transaction, or processing for devices that are not using split transactions, in progress 1: Complete-split (CSPLIT) transaction in progress	R
13	CSCLR	CSSTS Status Flag Clear 0: (writing 0 has no effect) 1: Clear CSSTS to 0	W
14	SUREQ	SETUP Token Transmission 0: Invalid (writing 0 has no effect) 1: Transmit setup packet	R/W
15	BSTS	Buffer Status Flag 0: Buffer access disabled 1: Buffer access enabled	R

Note: S-TYPE-3, P-TYPE-3

Note 1. Only set the SQSET, SQCLR, and PINGE bits while PID is NAK. Before setting these bits, check that the CSSTS and PBUSY bits are 0, and then change the DCPCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the DCPCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY bits through the software is not necessary.

PID[1:0] bits (Response PID)

The PID[1:0] bits control the USB response type during control transfers.

In host controller mode, to change the PID[1:0] setting from NAK to BUF:

- When the transmitting direction is set:
  a. Write all of the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
  The USBHS then executes the OUT transaction (or PING transaction)
- When the receiving direction is set:
  a. Check that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
  The USBHS then executes the IN transaction.

The USBHS changes the PID[1:0] setting as follows:

- When the PID[1:0] bits are set to BUF (01b) by software and the USBHS has received data exceeding MaxPacketSize, the USBHS sets PID[1:0] to STALL (11b)
- When a reception error, such as a CRC error, is detected three times consecutively, the USBHS sets PID[1:0] to NAK (00b)
- On receiving the STALL handshake, the USBHS sets PID[1:0] to STALL (11b)

In device controller mode, the USBHS changes the PID[1:0] setting as follows:

- On receiving a setup packet, the USBHS sets PID[1:0] to NAK (00b). The USBHS then sets the INTSTS0.VALID flag to 1, and the PID[1:0] setting cannot be changed until the software clears the VALID flag to 0.
- When the PID[1:0] bits are set to BUF (01b) by software and the USBHS has received data exceeding MaxPacketSize, the USBHS sets PID[1:0] to STALL (11b)
- On detecting a control transfer sequence error, the USBHS sets PID[1:0] to STALL (1xb)
- On detecting a USB bus reset, the USBHS sets PID[1:0] to NAK

The USBHS does not check the PID[1:0] setting while processing a SET_ADDRESS request.

CCPL bit (Control Transfer End Enable)

In device controller mode, setting the CCPL bit to 1 enables the status stage of the control transfer to be completed. When the bit is set to 1 by software while the associated PID[1:0] bits are set to BUF, the USBHS completes the control transfer status stage.

During control read transfers, the USBHS transmits the ACK handshake in response to the OUT transaction from the USB host. During control write or no-data control transfers, it transmits the zero-length packet in response to the IN transaction from the USB host. On detecting a SET_ADDRESS request, the USBHS operates in auto response mode from the setup stage up to status stage completion regardless of the CCPL bit setting.

The USBHS changes the CCPL bit from 1 to 0 on receiving a new setup packet. The software cannot write 1 to the bit while the INTSTS0.VALID bit is 1. The bit is initialized by a USB bus reset.

In host controller mode, always write 0 to the CCPL bit.

PINGE bit (PING Token Issue Enable)

In host controller mode, when the software sets the PINGE bit to 1, the USBHS issues a PING token for transfer in the transmitting direction, which triggers the transfer to start. If an ACK handshake is detected in the PING transaction, the OUT transaction is executed in the next transaction. If a NAK or NYET handshake is detected in the OUT transaction, the PING transaction is executed in the next transaction.

If the software sets this bit to 0, the USBHS issues no PING token for transfer in the transmitting direction. All transfers in the transmitting direction are executed in the OUT transaction.

PBUSY flag (Pipe Busy Flag)

The PBUSY bit indicates whether DCP is used for the transaction when USBHS changes the PID[1:0] bits from BUF to NAK. The USBHS changes the PBUSY flag from 0 to 1 on start of a USB transaction for the selected pipe. It changes the PBUSY flag from 1 to 0 on completion of one transaction.

After PID is set to NAK by software, the value in the PBUSY flag indicates whether changes to pipe settings can proceed.

For details, see section 37.3.7.1. Pipe Control Register Switching Procedures.

SQMON flag (Sequence Toggle Bit Monitor Flag)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

The USBHS toggles the bit on normal completion of the transaction. It does not toggle the bit, however, when a DATAPID mismatch occurs during a transfer in the receiving direction.

In device controller mode, the USBHS sets the SQMON bit to 1 (specifies DATA1 as the expected value) on successful reception of the setup packet.

In device controller mode, the USBHS does not reference this bit during IN or OUT transactions at the status stage, and it does not toggle the bit on normal completion.

SQSET bit (Sequence Toggle Bit Set)

The SQSET bit specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SQCLR bit (Sequence Toggle Bit Clear)

The SQCLR bit specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer. It is read as 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SUREQCLR bit (SUREQ Bit Clear)

In host controller mode, setting the SUREQCLR bit to 1 clears the SUREQ bit to 0. The bit is read as 0.

If transfer stops while the SUREQ bit is set to 1 in a setup transaction, set the SUREQCLR bit to 1 through software. This is not necessary at the end of a normal setup transaction, because the USBHS automatically clears the SUREQ bit to 0.

Only control the SUREQ bit through the SUREQCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a bus disconnection was detected.

In device controller mode, always write 0 to the SUREQCLR bit.

CSSTS flag (CSSTS Status Flag)

In host controller mode, the CSSTS flag indicates the complete-split state in split transactions for pipes that are not isochronous. The USBHS sets the CSSTS flag to 1 at the beginning of a complete-split transaction and sets the flag back to 0 when it detects transaction completion.

Values read from the CSSTS flag in device controller mode are invalid.

CSCLR bit (CSSTS Status Flag Clear)

In host controller mode, setting the CSCLR bit to 1 clears the CSSTS bit to 0.

Set this bit to 1 through software when forcing the next transfer to restart from start-split in transfers using split transactions. This is not necessary at the end of a successful complete-split transaction in a normal split transaction, because the USBHS automatically clears the CSSTS flag to 0.

Only control the CSSTS flag through the CSCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a port disconnection was detected. Writing 1 to this bit while the CSSTS flag is 0 has no effect; the flag remains 0.

In device controller mode, always write 0 to this bit.

SUREQ bit (SETUP Token Transmission)

In host controller mode, setting the SUREQ bit to 1 triggers the USBHS to transmit the setup packet. After completing the setup transaction process, the USBHS generates either the SACK or SIGN interrupt and clears the SUREQ bit to 0. The USBHS also clears the SUREQ bit to 0 when the software sets the SUREQCLR bit to 1.

Before setting the SUREQ bit to 1, set the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, and USBLENG appropriately to transmit the wanted USB request in the setup transaction. Also check that the PID[1:0] bits for the DCP are set to NAK. After setting the SUREQ bit to 1, do not change the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, or USBLENG until the setup transaction is complete (SUREQ bit = 1). Write 1 to the SUREQ bit only when transmitting the setup token. Otherwise, write 0.

In device controller mode, always write 0 to this bit.

BSTS flag (Buffer Status Flag)

The BSTS flag indicates the status of access to the DCP FIFO buffer. The meaning of this flag varies as follows depending on the CFIFOSEL.ISEL setting:

- When ISEL = 0, the bit indicates whether receive data can be read from the buffer
- When ISEL = 1, the bit indicates whether transmit data can be written to the buffer

37.2.33 PIPESEL : Pipe Window Select Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x064

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3			0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	PIPESEL[3:0]	Pipe Window Select 0x0: No pipe selected 0x1: Pipe 1 0x2: Pipe 2 0x3: Pipe 3 0x4: Pipe 4 0x5: Pipe 5 0x6 Pipe 6 0x7: Pipe 7 0x8: Pipe 8 0x9: Pipe 9 Others: Setting prohibited	R/W
15:4	—	The read values are undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Set pipes 1 to 9 using the PIPESEL, PIPECFG, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN registers (n = 0 to 9).

After selecting the pipe in the PIPESEL register, pipe functions must be set in the associated PIPECFG, PIPEMAXP, and PIPEPERI registers. PIPEnCTR, PIPEnTRE, and PIPEnTRN can be set independently of the pipe selection in this register.

PIPESEL[3:0] bits (Pipe Window Select)

The PIPESEL[3:0] bits select the pipe number associated with the PIPECFG, PIPEMAXP, and PIPEPERI registers used for data writing and reading. Selecting a pipe number in the PIPESEL[3:0] bits allows writing to and reading from PIPECFG, PIPEMAXP, and PIPEPERI associated with the selected pipe number.

When PIPESEL[3:0] = 0x0, 0 is read from all of the bits in PIPECFG, PIPEMAXP, and PIPEPERI. Writing to these bits has no effect.

37.2.34 PIPECFG : Pipe Configuration Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x068

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3			0
Bit field:	TYPE[1:0]		—	—	—	BFRE	DBLB	CNTMD	SHTNAK	—	—	DIR	EPNUM[3:0]			
Value after reset:	0	0	x	x	x	0	0	0	0	x	x	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	EPNUM[3:0]	Endpoint Number*1 Specifies the endpoint number for the selected pipe. Setting 0x0 indicates the pipe is not used.	R/W
4	DIR	Transfer Direction*2 *3 0: Receiving direction 1: Transmitting direction	R/W

13:11	—	These bits are read as 0. The write value should be 0.	R/W
15:14	TYPE[1:0]	Transfer Type*1 0 0: Pipe not used 0 1: (Pipe 1 to 5) Bulk transfer (Pipe 6 to 9) Setting prohibited 1 0: (Pipe 1 to 5) Setting prohibited (Pipe 6 to 9) Interrupt transfer 1 1: (Pipe 1 to 2) Isochronous transfer (Pipe 3 to 9) Setting prohibited	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Only set the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

Note 2. Only set the BFRE, DBLB, CNTMD, and DIR bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

Note 3. To change the BFRE, DBLB, CNTMD, or DIR bit after completing USB communication on the selected pipe, in addition to the constraints described in note 2, write 1 and 0 to the PIPEnCTR.ACLRM bit continuously through software and clear the FIFO buffer assigned to the pipe.

EPNUM[3:0] bits (Endpoint Number)

The EPNUM[3:0] bits specify the endpoint number for the selected pipe. Setting 0000b indicates the pipe not used.

Set these bits so that the combination of the DIR and EPNUM[3:0] settings is different from those for other pipes. (The EPNUM[3:0] bits can be set to 0000b for all pipes.)

DIR bit (Transfer Direction)

The DIR bit specifies the transfer direction for the selected pipe.

When the software sets this bit to 0, the USBHS uses the selected pipe for receiving. When the software sets this bit to 1, the USBHS uses the selected pipe for transmitting.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change the PIPEnCTR.PID[1:0] bits to 00b (NAK) at the end of transfer when the selected pipe is set in the receiving direction. The bit is valid for pipes 1 to 5 in the receiving direction.

When the software sets this bit to 1 for a receiving pipe, the USBHS changes the associated PIPEnCTR.PID[1:0] bits to 00b (NAK) on determining the transfer end. The USBHS determines that the transfer has ended on the following conditions:

- Short packet data (including a zero-length packet) was successfully received
- The transaction counter is used and the number of packets specified for the transaction counter were successfully received

CNTMD bit (Continuous Transfer Mode)

The CNTMD bit specifies whether to operate the selected pipe in continuous transfer mode. The bit is valid for pipes 1 to 5 of the bulk transfer type.

Based on this bit setting, the USBHS determines the completion of transmission or reception for the FIFO buffer allocated to the selected pipe as shown in Table 37.9.

Table 37.9 Relationship between the CNTMD setting and methods for determining completion of FIFO buffer transmission or reception

CNTMD bit setting	Methods for determining readable state and transmittable state
0	Condition for FIFO buffer readable state in receiving direction (DIR = 0): ● The USBHS received one packet
	Conditions for FIFO buffer transmittable state in transmitting direction (DIR = 1): When one of the following is satisfied: 1. CPU or DMAC/DTC wrote data of the maximum packet size to the FIFO buffer 2. CPU or DMAC/DTC wrote data of the short packet size (including 0 bytes) to the FIFO buffer and set the BVAL flag in the port control register to 1
1	Condition for FIFO buffer readable state in receiving direction (DIR = 0): 1. The byte count of data received in the FIFO buffer allocated to the selected pipe is equal to the allocated byte count ((BUFSIZE + 1) × 64). 2. The USBHS received a short packet, other than a zero-length packet. 3. The USBHS received a zero-length packet when data was already contained in the FIFO buffer allocated to the selected pipe. 4. Software received the number of packets specified for the transaction counter set for the selected pipe.
	Conditions for FIFO buffer transmittable state in transmitting direction (DIR = 1): When one of the following is satisfied. 1. The amount of data written by CPU or DMAC/DTC is equal to the size of the FIFO buffer allocated to the selected pipe. 2. CPU or DMAC/DTC wrote data of smaller size than that of the FIFO buffer allocated to the selected pipe (including 0 bytes) and set the BVAL flag in the port control register to 1. 3. CPU or DMAC/DTC wrote data of smaller size than that of one FIFO buffer allocated to the selected pipe (including 0 bytes) and asserted the DENDx_N signal on the last write.

DBLB bit (Double Buffer Mode)

The DBLB bit selects either single or double buffer mode for the FIFO buffer used by the selected pipe. The bit is valid for pipes 1 to 5.

When the software sets this bit to 1, the USBHS allocates twice the FIFO buffer size specified in the PIPEBUF.BUFSIZE[5:0] bits for the selected pipe. The FIFO buffer size that the USBHS allocates to the selected pipe is as follows:

$$(\text{BUFSIZE} + 1) \times 64 \times (\text{DBLB} + 1) \text{ [bytes]}$$

BFRE bit (BRDY Interrupt Operation Specification)

The BFRE bit specifies the BRDY interrupt generation timing from the USBHS to the CPU for the selected pipe.

When the software sets the BFRE bit to 1 and the selected pipe is in the receiving direction, the USBHS detects the transfer completion and generates the BRDY interrupt on reading the packet.

When a BRDY interrupt is generated with this setting, the software must write 1 to the BCLR bit in the port control register. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to the BCLR bit.

When the BFRE bit is set to 1 by software and the selected pipe is in the transmitting direction, the USBHS does not generate the BRDY interrupt. For details, see section 37.3.6.1. BRDY Interrupt.

TYPE[1:0] bits (Transfer Type)

The TYPE[1:0] bits specify the transfer type for the pipe selected in the PIPESEL.PIPESEL[3:0] bits. Before setting PID to BUF and starting USB communication on the selected pipe, set the TYPE[1:0] bits to a value other than 00b.

37.2.35 PIPEBUF : Pipe Buffer Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x06A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	BUFSIZE[4:0]					—	—	BUFNMB[7:0]							
Value after reset:	x	0	0	0	0	0	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	BUFNMB[7:0]	Buffer Number Specifies the FIFO buffer number of the selected pipe (0x04 to 0x87).	R/W
9:8	—	The read values are undefined. The write value should be 0.	R/W
14:10	BUFSIZE[4:0]	Buffer Size 0x00: 64 bytes 0x01: 128 bytes : 0x1F: 2 KB	R/W
15	—	The read value is undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Only set the bits in the PIPEBUF register while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

BUFNMB[7:0] bits (Buffer Number)

The BUFNMB[7:0] bits specify the first block number of the FIFO buffer to be allocated to the selected pipe.

The USBHS allocates the FIFO buffer blocks to the selected pipe as follows:

Block number: BUFNMB to block number: BUFNMB + (BUFSIZE + 1) × (DBLB + 1) - 1

Set a value within the memory size range for these bits (0 [0x00] to 8640 [0x87] for 8.5 KB), while observing the following conditions:

- 0x00 is for DCP only
- 0x04 is for pipe 6 only, but is available for other pipes when pipe 6 is not used. When pipe 6 is selected, writes to these bits are disabled. The USBHS automatically allocates 0x04 to the BUFNMB bits for pipe 6.
- 0x05 is for pipe 7 only, but is available for other pipes when pipe 7 is not used. When pipe 7 is selected, writes to these bits are disabled. The USBHS automatically allocates 0x05 to the BUFNMB bits for pipe 7.
- 0x06 is for pipe 8 only, but is available for other pipes when pipe 8 is not used. When pipe 8 is selected, writes to these bits are disabled. The USBHS automatically allocates 0x06 to the BUFNMB bits for pipe 8.
- 0x07 is for pipe 9 only, but is available for other pipes when pipe 9 is not used. When pipe 9 is selected, writes to these bits are disabled. The USBHS automatically allocates 0x07 to the BUFNMB bits for pipe 9.

BUFSIZE[4:0] bits (Buffer Size)

The BUFSIZE[4:0] bits specify the FIFO buffer size (number of blocks) to be allocated to the selected pipe. One block is 64 bytes.

When the software sets the DBLB bit to 1, the USBHS allocates twice the FIFO buffer size specified in these bits to the selected pipe. The DBLB = 1 setting is valid for pipes 1 to 5.

The USBHS allocates the FIFO buffer blocks to the selected pipe as follows:

(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

Set the value within the following range:

- For pipes 1 to 5, set a value from 0x00 to 0x1F (up to 2 KB)

- For pipes 6 to 9, only set a value of 0x00 (64 bytes)

37.2.36 PIPEMAXP : Pipe Maximum Packet Size Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x06C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DEVSEL[3:0]				—	MXPS[10:0]										
Value after reset:	0	0	0	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	MXPS[10:0]*1 *2	Maximum Packet Size ● Pipes 1 and 2 1 byte (0x001) to 1024 bytes (0x400) ● Pipes 3 to 5 8 bytes (0x008), 16 bytes (0x010), 32 bytes (0x020), 64 bytes (0x040), 512 bytes (0x200) (Bits 2 to 0 not supported.) ● Pipes 6 to 9 1 byte (0x001) to 64 bytes (0x040) (Bits 10 to 7 not supported.)	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
15:12	DEVSEL[3:0]*3	Device Select 0x0: Address 0x0 0x1: Address 0x1 ⋮ 0x9: Address 0x9 0xA: Address 0xA Others: Reserved	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The initial value of the MXPS[10:0] bits is 0x00 when no pipe is selected in the PIPESEL.PIPESEL[3:0] bits and 0x40 when a pipe is selected.

Note 2. Only set the MXPS[10:0] bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

Note 3. Only set the DEVSEL[3:0] bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

MXPS[10:0] bits (Maximum Packet Size)

The MXPS[10:0] bits specify the maximum data payload (maximum packet size) for the selected pipe.

Set these bits to the appropriate value for each transfer type based on the USB 2.0 specification. When MXPS[10:0] = 0, do not write to the FIFO buffer or set PID to BUF. These writes have no effect.

To communicate on an isochronous pipe using a split transaction, set the value in the MXPS[10:0] bits to 188 bytes or less.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target device for USB communication. Set up the device address in the associated DEVADDn (n = 0 to A) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0x2, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0x0.

37.2.37 PIPEPERI : Pipe Cycle Control Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x06E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Value after reset:	x	x	x	0	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
2:0	IITV[2:0]*1	Interval Error Detection Interval Specifies the interval error detection timing for the selected pipe as the n-th power of 2 of the frame timing.	R/W
11:3	—	These bits are read as 0. The write value should be 0.	R/W
12	IFIS	Isochronous IN Buffer Flush 0: Do not flush buffer 1: Flush buffer	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Only set the IITV[2:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

PIPEPERI selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfers, and sets the interval error detection interval for pipes 1 to 9.

IITV[2:0] bits (Interval Error Detection Interval)

To change the IITV[2:0] bits to another value after they are set and USB communication is performed, set the PIPEnCTR.PID[1:0] bits to 00b (NAK) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer.

The IITV[2:0] bits are not provided for pipes 3 to 5. Write 000b to bit positions of the IITV[2:0] bits associated with pipes 3 to 5.

IFIS bit (Isochronous IN Buffer Flush)

The IFIS bit specifies whether to flush the buffer when the pipe specified in the PIPESEL.PIPESEL[3:0] bits is used for isochronous IN transfers.

In device controller mode when the selected pipe is for isochronous IN transfers, the USBHS automatically clears the FIFO buffer if the USBHS fails to receive the IN token from the USB host within the interval set in the IITV[2:0] bits in terms of frames.

When double buffering is specified (PIPECFG.DBLB = 1), the USBHS only clears the data in the previously used plane.

The USBHS clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USBHS expected to receive the IN token. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time the SOF packet is expected to be received by using the internal complementation function.

In host controller mode, set the IITV[2:0] bits to 000b.

Set the IITV[2:0] bits to 000b when the selected pipe is not used for isochronous transfers.

37.2.38 PIPEnCTR : Pipe n Control Register (n = 1 to 9)

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x070 + 0x2 × (n - 1)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BSTS	INBUFM	CSCLR	CSSTS	—	ATREPM	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Value after reset:	0	0	0	0	x	0	0	0	0	0	0	x	x	x	0	0

Bit	Symbol	Function	R/W
1:0	PID[1:0]	Response PID 0 0: NAK response 0 1: BUF response (depends on buffer state) 1 0: STALL response 1 1: STALL response	R/W
4:2	—	The read values are undefined. The write value should be 0.	R/W
5	PBUSY	Pipe Busy Flag 0: Pipe n not in use for the transaction 1: Pipe n in use for the transaction	R
6	SQMON	Sequence Toggle Bit Monitor Flag 0: DATA0 1: DATA1	R
7	SQSET	Sequence Toggle Bit Set*1 0: Invalid (writing 0 has no effect) 1: Set the expected value for the next transaction to DATA1. This bit is read as 0.	R/W
8	SQCLR	Sequence Toggle Bit Clear*1 0: Invalid (writing 0 has no effect) 1: Clear the expected value for the next transaction to DATA0	W
9	ACLRM	Auto Buffer Clear Mode*2 0: Disable 1: Enable (initialize all buffers)	R/W
10	ATREPM	Auto Response Mode*1 *3 0: Disable auto response mode 1: Enable auto response mode	R/W
11	—	The read value is undefined. The write value should be 0.	R/W
12	CSSTS	CSSTS Status Flag 0: Start-split (SSPLIT) transaction, or processing for devices that are not using split transactions, in progress. 1: Complete-split (CSPLIT) transaction in progress.	R
13	CSCLR	CSPLIT Status Clear 0: Invalid (writing 0 has no effect) 1: Clear CSSTS to 0	W
14	INBUFM	Transmit Buffer Monitor Flag*3 0: No data to be transmitted is in the FIFO buffer 1: Data to be transmitted is in the FIFO buffer	R
15	BSTS	Buffer Status Flag 0: Buffer access disabled 1: Buffer access enabled	R

Note: S-TYPE-3, P-TYPE-3

Note 1. Only set the ATREPM, SQCLR, and SQSET bits while PID is NAK. Before setting this bit, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

Note 2. Only set the ACLRM bit while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting this bit, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

Note 3. The ATREPM bit and the INBUFM flag in the PIPE6CTR to PIPE9CTR registers are reserved. The read value is undefined. The write value must be 0.

PID[1:0] bits (Response PID)

The PID[1:0] bits specify the response type for the next transaction on the selected pipe.

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 37.10 and Table 37.11 show the basic operations of the USBHS (when there are no errors in the communication packets) based on the PID[1:0] bit setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the selected pipe has actually entered the NAK state. If the USBHS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBHS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBHS sets PID to NAK on recognizing completion of the transfer when the selected pipe is in the receiving direction and the PIPECFG.SHTNAK bit for the selected pipe is set to 1 by software
- The USBHS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBHS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBHS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBHS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode

To specify the response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, set 00b (NAK) and then 01b (BUF)

Table 37.10 Operation of the USBHS based on the PIPEnCTR.PID[1:0] setting in host controller mode

PID[1:0] value	Transfer type (TYPE[1:0] value)	Transfer direction (DIR value)	USBHS operation
00b (NAK)	Does not depend on the setting	Does not depend on the setting	Does not issue tokens
01b (BUF)	Bulk or Interrupt	Does not depend on the setting	Issues tokens when the DVSTCTR0.UACT bit is 1 and the FIFO buffer associated with the selected pipe is ready for transmission and reception. Does not issue tokens when the DVSTCTR0.UACT bit is 0 or the FIFO buffer associated with the selected pipe is not ready for transmission or reception.
	Isochronous	Does not depend on the setting	Issues tokens when the DVSTCTR0.UACT bit is 1, regardless of the state of the FIFO buffer associated with the selected pipe. Does not issue tokens when UACT = 0.
10b (STALL) or 11b (STALL)	Does not depend on the setting	Does not depend on the setting	Does not issue tokens.

Table 37.11 Operation of the USBHS based on the PIPEnCTR.PID[1:0] setting in device controller mode

PID[1:0] value	Transfer type (TYPE[1:0] value)	Transfer direction (DIR value)	USBHS operation
00b (NAK)	Bulk or Interrupt	Does not depend on the setting	Returns NAK in response to the token from the USB host
	Isochronous	Receiving direction (DIR = 0)	Returns nothing in response to the token from the USB host
		Transmitting direction (DIR = 1)	Transmits a zero-length packet in response to the token from the USB host
01b (BUF)	Bulk	Receiving direction (DIR = 0)	Receives data and returns ACK or NYET in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, returns NAK. Returns ACK in response to the PING token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, returns NAK.
	Interrupt	Receiving direction (DIR = 0)	Receives data and returns ACK response in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, returns NAK.
	Bulk or Interrupt	Transmitting direction (DIR = 1)	Transmits data in response to the token from the USB host if the FIFO buffer associated with the selected pipe is ready for transmission. Otherwise, returns NAK.
	Isochronous	Receiving direction (DIR = 0)	Receives data in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, discards the data.
		Transmitting direction (DIR = 1)	Transmits data in response to the token from the USB host if the associated FIFO buffer is ready for transmission. Otherwise, transmits a zero-length packet.
10b (STALL) or 11b (STALL)	Bulk or Interrupt	Does not depend on the setting.	Returns STALL in response to the token from the USB host
	Isochronous	Does not depend on the setting.	Returns nothing in response to the token from the USB host

PBUSY flag (Pipe Busy Flag)

The PBUSY flag indicates whether the selected pipe is being used for the current transaction.

The USBHS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible. For details, see section 37.3.7.1. Pipe Control Register Switching Procedures.

SQMON flag (Sequence Toggle Bit Monitor Flag)

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

When the selected pipe is not the isochronous transfer type, the USBHS toggles the SQMON flag on successful completion of the transaction. However, the USBHS does not toggle the SQMON flag when a DATA-PID mismatch occurs during transfer in the receiving direction.

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBHS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBHS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0.

In host controller mode, when this bit is set to 1 for a bulk OUT transfer pipe, the USBHS starts the next transfer for the selected pipe from a PING token.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

Table 37.12 shows the data cleared by writing 1 and 0 continuously to the ACLRM bit and the cases in which this processing is required.

Table 37.12 Data cleared by the USBHS when ACLRM = 1

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
1	All data in the FIFO buffer allocated to the selected pipe (two FIFO buffers in double buffer mode)	When clearing all data in the FIFO buffer allocated to the selected pipe
2	Interval count value when the selected pipe is the isochronous transfer type	When resetting the interval count value

ATREPM bit (Auto Response Mode)

The ATREPM bit enables or disables auto response mode for the selected pipe.

This bit can be set to 1 in device controller mode when the selected pipe is the bulk transfer type. When the bit is set to 1, the USBHS responds to the token from the USB host as follows:

- When the selected pipe is set for bulk IN transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 1):
  - When the ATREPM bit = 1 and PID = BUF, the USBHS transmits a zero-length packet in response to the IN token.
  - The USBHS updates (allows toggling of) the sequence toggle bit (DATA-PID) each time the USBHS receives ACK from the USB host. In a single transaction, the IN token is received, a zero-length packet is transmitted, and then ACK is received. The USBHS does not generate the BRDY or BEMP interrupt.
- When the selected pipe is set for bulk OUT transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 0):
  When the ATREPM bit = 1 and PID = BUF, the USBHS returns NAK in response to the OUT token or PING token and generates an NRDY interrupt.

For USB communication in auto response mode, set the ATREPM bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode. When the selected pipe uses isochronous transfer, always set this bit to 0.

In host controller mode, always set the ATREPM bit to 0.

CSSTS flag (CSSTS Status Flag)

In host controller mode, the CSSTS flag indicates the complete-split status of a split transaction. It is valid for pipes that are not the isochronous transfer type.

The USBHS sets the CSSTS flag to 1 at the beginning of the complete-split transaction, and sets the CSSTS flag to 0 on detecting completion of the complete-split transaction. If a detach event is detected during the transaction, the CSSTS flag might stay set to 1. In this case, clear the CSSTS flag by setting the CSCLR bit to 1.

Values read from the CSSTS flag in device controller mode are invalid.

CSCLR bit (CSPLIT Status Clear)

In host controller mode, if the software sets the CSCLR bit to 1, the USBHS clears the CSSTS flag to 0. In split transactions, set the CSCLR bit to 1 by software to force the next transfer to restart from start-split. Because the USBHS automatically clears the CSSTS flag to 0 at the end of a successful complete-split transaction in a normal split transaction, clearing the flag through software is not required. Only clear the CSSTS flag using the CSCLR bit when the DVSTCTR0.UACT bit is set to 0 or when no transfer was made after a detach detect. If the CSCLR bit is set to 1 while the CSSTS flag is 0, the CSSTS flag remains 0.

In device controller mode, always write 0 to the CSCLR bit.

INBUFM flag (Transmit Buffer Monitor Flag)

The INBUMFM flag indicates the FIFO buffer status for the selected pipe in the transmitting direction.

When the selected pipe is set in the transmitting direction (PIPECFG.DIR = 1), the USBHS sets this bit to 1 when the CPU or DMAC/DTC completes writing data to at least one FIFO buffer plane.

The USBHS sets this bit to 0 when the USBHS completes transmission of data from the FIFO buffer plane to which all the data is written. In double buffer mode (PIPECFG.DBLB = 1), the USBHS sets the INBUFM flag to 0 when the USBHS completes transmission of data from the two FIFO buffer planes before the CPU or DMAC/DTC completes writing data to one FIFO buffer plane.

The INBUFM flag indicates the same value as the BSTS flag when the selected pipe is in the receiving direction (PIPECFG.DIR = 0).

BSTS flag (Buffer Status Flag)

The BSTS flag indicates the FIFO buffer status for the selected pipe. The meaning of the BSTS flag depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 37.13.

Table 37.13 BSTS flag operation

DIR value	BFRE value	DCLRM value	Meaning of BSTS flag
0	0	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read
		1	Setting prohibited
	1	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 when the software sets the BCLR bit in the port control register to 1 after the data read is complete
		1	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read
1	0	0	Sets to 1 when transmit data can be written to the FIFO buffer, and clears to 0 on completion of data write
		1	Setting prohibited
	1	0	Setting prohibited
		1	Setting prohibited

37.2.39 PIPEnTRE : Pipe n Transaction Counter Enable Register (n = 1 to 5)

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x090 + 0x4 × (n - 1)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	0	0	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	—	The read values are undefined. The write value should be 0.	R/W
8	TRCLR	Transaction Counter Clear 0: Invalid (writing 0 has no effect) 1: Clear current counter value	R/W
9	TRENB	Transaction Counter Enable 0: Disable transaction counter 1: Enable transaction counter	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Only change the PIPEnTRE register settings while the PIPEnCTR.CSSTS flag is 0 and the PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY and PIPEnCTR.CSSTS flags is 0. However, software processing to check the PIPEnCTR.PBUSY flag is not required if the USBHS has changed the PID[1:0] bits to 00b (NAK response).

TRCLR bit (Transaction Counter Clear)

When the TRCLR bit sets to 1, the USBHS clears the count value of the transaction counter associated with the selected pipe and then clears the TRCLR bit to 0.

TRENB bit (Transaction Counter Enable)

The TRENB bit enables or disables the transaction counter.

For receiving pipes, setting the TRENB bit to 1 after setting the total number of the packets to be received in the PIPEnTRN.TRNCNT[15:0] bits through the software allows the USBHS to control hardware on having received the number of packets equal to the TRNCNT[15:0] setting as follows:

- When the PIPECFG.SHTNAK bit is 1, the USBHS changes the PID bits to NAK for the associated pipe on having received the number of packets equal to the TRNCNT[15:0] setting
- When the PIPECFG.BFRE bit is 1, the USBHS asserts the BRDY interrupt on having received the number of packets equal to the TRNCNT[15:0] setting and then reading the last received data.

For transmitting pipes, set the TRENB bit to 0.

When the transaction counter is not used, set this bit to 0. When the transaction counter is used, set the TRNCNT[15:0] bits before setting this bit to 1. Set this bit to 1 before receiving the first packet to be counted by the transaction counter.

37.2.40 PIPEnTRN : Pipe n Transaction Counter Register (n = 1 to 5)

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x092 + 0x4 × (n - 1)

Bit position:	15															0
Bit field:	TRNCNT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TRNCNT[15:0]	Transaction Counter*1 • When written to: Specifies the total packets (number of transactions) to be received by pipe n. • When read from: When PIPEnTRE.TRENB is 0, indicates the specified number of transactions. When PIPEnTRE.TRENB is 1, indicates the current transaction count.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Only set the TRNCNT[15:0] bits while PID is NAK and PIPEnTRE.TRENB is 0. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

The PIPEnTRN registers retain their settings during a USB bus reset.

TRNCNT[15:0] bits (Transaction Counter)

The USBHS increments the value of the TRNCNT[15:0] bits by one when all of the following conditions are satisfied on receiving the packet:

- The PIPEnTRE.TRENB bit is 1
- (TRNCNT[15:0] set value ≠ current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[8:0] setting

The USBHS clears the value of the TRNCNT[15:0] bits to 0 when any of the following conditions is satisfied.

All of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value = current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[8:0] setting

Both the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The USBHS received a short packet

Both the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The PIPEnTRE.TRCLR bit was set to 1 by software

For transmitting pipes, set the TRNCNT[15:0] bits to 0. When the transaction counter is not used, set the TRNCNT[15:0] bits to 0.

Setting the number of transactions to be transferred to the TRNCNT[15:0] bits is enabled only when the PIPEnTRE.TRENB bit is 0. To set the number of transactions to be transferred, set the TRCLR bit to 1 to clear the current counter value before setting the PIPEnTRE.TRENB bit to 1.

37.2.41 DEVADDn : Device Address n Configuration Register (n = 0 to 9, A)

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x0D0 + 0x2 × n (n = 0 to 9)
0x0E4 (n = A)

Bit position:	15	14				10			7		5	4	3	2	1	0
Bit field:	—	UPPHUB[3:0]				HUBPORT[2:0]			USBSPD[1:0]		—	—	—	—	—	—
Value after reset:	x	0	0	0	0	0	0	0	0	0	x	x	x	x	x	x

Bit	Symbol	Function	R/W
5:0	—	The read values are undefined. The write value should be 0.	R/W
7:6	USBSPD[1:0]	Transfer Speed of Communication Target Device 0 0: Do not use DEVADDn 0 1: Low speed 1 0: Full speed 1 1: High speed	R/W
10:8	HUBPORT[2:0]	Communication Target Connecting Hub Port 0 0 0: Connect directly to the USBHS port Others: Port number of the hub	R/W
14:11	UPPHUB[3:0]	Communication Target Connecting Hub Register 0x0: Connect directly to the USBHS port Others: USB address of the hub. The value as 0xB or more is reserved.	R/W
15	—	The read value is undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The DEVADDn register specifies the transfer speed of the peripheral device that is the communication target for pipes 0 to 9.

In host controller mode, set all DEVADDn bits before starting communication to any pipes. Only change the bits in DEVADDn when no valid pipes are using the bit settings. A valid pipe is defined as one that satisfies both of the following conditions:

- DEVADDn is selected in the DEVSEL[3:0] bits
- The PID[1:0] bits are set to BUF for the selected pipe, or the selected pipe is the DCP with the DCPCTR.SUREQ bit set to 1

In device controller mode, set all bits in this register to 0.

USBSPD[1:0] bits (Transfer Speed of Communication Target Device)

The USBSPD[1:0] bits specify the USB transfer speed of the target peripheral device. In host controller mode, the USBHS generates packets based on the USBSPD[1:0] setting. In device controller mode, set these bits to 00b.

HUBPORT[2:0] bits (Communication Target Connecting Hub Port)

In host controller mode, the USBHS generates packets based on the HUBPORT[2:0] setting when performing a split transaction.

UPPHUB[3:0] bits (Communication Target Connecting Hub Register)

In host controller mode, the USBHS generates packets based on the UPPHUB[3:0] setting when performing a split transaction.

37.2.42 LPCTRL : Low Power Control Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x100

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	HWUPM	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	0	0	x	x	x	x	x	x	0

Bit	Symbol	Function	R/W
6:0	—	The read values are undefined. The write value should be 0.	R/W
7	HWUPM	Resume Return Mode Setting 0: Hardware does not recover while CPU clock inactive 1: Hardware recovers while CPU clock inactive	R/W
8	—	This bit is read as 0. The write value should be 0.	R/W
15:9	—	The read values are undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

HWUPM bit (Resume Return Mode Setting)

The HWUPM bit specifies whether to enable hardware processing for return from low power mode even while the CPU clock is inactive.

In device controller mode, processing for return from low power mode on detecting Resume is enabled even while the CPU clock is inactive.

This bit specifies whether to detect Resume while the CPU clock is inactive. The PL1CTRL1.L1EXTMD bit controls whether to make a hardware return. To make a hardware return from the LPM L1 low power state while the CPU clock is inactive, set this bit and the PL1CTRL1.L1EXTMD bit to 1.

37.2.43 LPSTS : Low Power Status Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x102

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	SUSPENDM	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	0	x	0	x	x	x	0	x	x	x	x	0	x	0	0

Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0. The write value should be 0.	R/W
2	—	The read value is undefined. The write value should be 0.	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
7:4	—	The read values are undefined. The write value should be 0.	R/W
8	—	This bit is read as 0. The write value should be 0.	R/W
11:9	—	The read values are undefined. The write value should be 0.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	—	The read value is undefined. The write value should be 0.	R/W
14	SUSPENDM	UTMI SuspendM Control 0: UTMI suspension mode 1: UTMI normal mode	R/W
15	—	The read value is undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SUSPENDM bit (UTMI SuspendM Control)

The SUSPENDM bit controls the SuspendM signal to be sent to the PHY designed under the UTMI specification. The initial value is 0 with the UTMI is in suspension mode.

Set this bit to 1 to supply the PHY clock to operate the USB2.0 host or device controller.

In compliance with the UTMI specification, clock output is normally controlled by the SuspendM signal. When the SUSPENDM bit is 0, the clock to LINK is stopped. Because the PHY in this MCU follows the UTMI specification, setting the SUSPENDM bit to 1 is required to supply the PHY clock. For the clock settings, see section 37.3.3. Supplying the Clock.

When the SUSPENDM bit is 0, the USBHS cannot be written to but can be read from. The registers listed in Table 37.14 are writable even when the SUSPENDM bit is 0.

Table 37.14 Registers that can be written to by software when SUSPENDM = 0

Address	Register or bit name
0x4006_0000	SYSCFG register
0x4006_0002	BUSWAIT register
0x4006_0032	INTENB1.PDDETINTE bit
0x4006_0100	LPCTRL register
0x4006_0102	LPSTS register
0x4006_0140	BCCTRL register

The value written to the SYSCFG register while the PHY clock is inactive is updated only after the PHY clock begins oscillating. The PHY clock oscillates in the following cases described in this section.

When SUSPENDM bit is set to 1, the PLLSTA.PLLLOCK flag is set to 1 after the predetermined time has passed. The USB-PHY internal PLL is stopped when the SUSPENDM bit is set to 0.

For details on CL-only mode, see section 37.2.17. PHYSET : PHY Setting Register.

If the PL1CTRL1.L1EXTMD bit is 0, setting or clearing of this bit is controlled by software. If the PL1CTRL1.L1EXTMD bit is 1, transitions to the L1 or L2 state of this bit are controlled by software and recovery from the L1 or L2 state is controlled by hardware.

37.2.44 BCCTRL : Battery Charging Control Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x140

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PDDETSTS	CHGDETSTS	—	—	DCPMODE	VDMSRCE	IDPSINKE	VDPSRCE	IDMSINKE	IDPSRCE
Value after reset:	x	x	x	x	x	x	0	0	x	x	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IDPSRCE	IDPSRC Control*2 0: Disable IDP_SRC circuit 1: Enable IDP_SRC circuit	R/W
1	IDMSINKE	IDMSINK Control*2 0: Disable IDM_SINK circuit 1: Enable IDM_SINK circuit	R/W*1
2	VDPSRCE	VDPSRC Control*2 0: Disable VDP_SRC circuit 1: Enable VDP_SRC circuit	R/W
3	IDPSINKE	IDPSINK Control*2 0: Disable IDP_SINK circuit 1: Enable IDP_SINK circuit	R/W
4	VDMSRCE	VDMSRC Control*2 0: Disable VDM_SRC circuit 1: Enable VDM_SRC circuit	R/W
5	DCPMODE	DCP Mode Control 0: Disable RDCP_DAT resistor 1: Enable RDCP_DAT resistor	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	CHGDETSTS	CHGDET Status Flag 0: The CHGDET pin is at low level 1: The CHGDET pin is at high level	R
9	PDDETSTS	PDDET Status Flag 0: The PDDET pin is at low level 1: The PDDET pin is at high level	R
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. All bits in the BCCTRL register can be changed while the UTMI clock is inactive.
Note 2. In device controller mode, set the IDPSRCE, IDMSINKE, VDPSRCE, IDPSINKE, and VDMSRCE bits to 1 after setting the SYSCFG.DRPD bit to 0.

IDPSRCE bit (IDPSRC Control)

In device controller mode, set the IDPSRCE bit to 1 to perform data contact detection.

The Battery Charging Standard provides two ways to handle data contact detection, one through the software and one using hardware to contact the data line. The IDPSRE bit uses the hardware method.

When the IDPSRE bit is set to 1, the USBHS enables the IDP_SRC circuit and, at the same time, controls D- pull-down.

(D- pull-down is controlled with the VUH_DMPULLDOWN signal.)

IDMSINKE bit (IDMSINK Control)

In device controller mode, set the IDMSINKE bit to 1 to perform primary detection.

VDPSRCE bit (VDPSRC Control)

In device controller mode, set the VDPSRCE bit to 1 to perform primary detection.

IDPSINKE bit (IDPSINK Control)

In device controller mode, set the IDPSINKE bit to 1 to perform secondary detection. In host controller mode, set this bit to 1 to enable the portable device detection circuit.

VDMSRCE bit (VDMSRC Control)

In device controller mode, set the VDMSRCE bit to 1 to perform secondary detection. Setting this bit to 1 enables the DCP detection circuit. In host controller mode, set this bit to 1 when a portable device is detected. Setting this bit to 1 allows the device that is performing primary detection to determine the charger detection method.

DCPMODE bit (DCP Mode Control)

Set the DCPMODE bit to 1 to operate as a dedicated charging port (DCP). Setting this bit to 1 disables USB communication.

CHGDETSTS flag (CHGDET Status Flag)

The CHGDETSTS flag indicates the charger port detection state.

PDDETSTS flag (PDDET Status Flag)

The PDDETSTS flag indicates the following states based on the controller mode:

- In host controller mode: PD detection state
- In device controller mode: DCP detection state

37.2.45 PL1CTRL1 : Function L1 Control Register 1

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x144

Bit position:	15	14	13		11				7				3	2		0
Bit field:	—	L1EXTMD	—		HIRDTHR[3:0]				DVSQ[3:0]				L1NEGOMD	L1RESPMD[1:0]		L1RESPEN
Value after reset:	x	0	x	x	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	L1RESPEN	L1 Response Enable 0: Do not support LPM 1: Support LPM	R/W
2:1	L1RESPMD[1:0]	L1 Response Mode 0 0: NYET response 0 1: ACK response 1 0: STALL response 1 1: Response based on L1NEGOMD setting	R/W
3	L1NEGOMD	L1 Response Negotiation Control This bit is only valid when the L1RESPMD[1:0] value is 11b. 0: Return ACK when received HIRD is larger than HIRDTHR[3:0]. Otherwise (including when HIRD = HIRDTHR[3:0]), return NYET 1: Return ACK when received HIRD is smaller than HIRDTHR[3:0]. Otherwise (including when HIRD = HIRDTHR[3:0]), return NYET	R/W

Bit	Symbol	Function	R/W
7:4	DVSQ[3:0]	DVSQ Extension Flag 0 0 0 0: Powered state 0 0 0 1: Default state 0 0 1 0: Address state 0 0 1 1: Configured state 0 1 x x: Suspend state 1 0 x x: L1 state	R
11:8	HIRDTHR[3:0]	L1 Response Negotiation Threshold Value HIRD threshold value used when the L1RESPMD[1:0] bits are 11b. The format is the same as the HIRD field in HL1CTRL.	R/W
13:12	—	The read values are undefined. The write value should be 0.	R/W
14	L1EXTMD	PHY Control Mode at L1 Return 0: Do not set LPSTS.SUSPENDM bit through hardware when Host K is received 1: Set LPSTS.SUSPENDM bit through hardware when Host K is received	R/W
15	—	The read value is undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

L1RESPEN bit (L1 Response Enable)

If the USBHS receives an LPM token while the L1RESPEN bit is 0, it returns no response. If the USBHS receives an LPM token while this bit is 1, it returns a response based on the L1RESPMD[1:0] setting.

L1RESPMD[1:0] bits (L1 Response Mode)

When the L1RESPEN bit is set to 1, the USBHS returns a response to the LPM token based on the setting in the L1RESPMD[1:0] bits.

L1NEGOMD bit (L1 Response Negotiation Control)

The L1NEGOMD bit specifies the negotiation function for the HIRD value.

HIRDTHR[3:0] bits (L1 Response Negotiation Threshold Value)

The HIRDTHR[3:0] bits specify the HIRD threshold value used for L1NEGOMD. The format of the set value is the same as the HIRD field in HL1CTRL.

L1EXTMD bit (PHY Control Mode at L1 Return)

The L1EXTMD bit specifies the LPSTS.SUSPENDM bit control method when a host K signal is received in the L1 state while the LPSTS.SUSPENDM bit is 0 and the PHY is inactive.

Similar to the Suspend constraints, because the minimum host K period is 50 µs, the PHY might not recover within the host K period specified for software settings on return. The initial value is within software control, so set this bit to 1 during the initialization process when the L1 state is supported.

The LPSTS.SUSPENDM bit is controlled by software on transition to the L1 state regardless of the setting in this bit. It is not cleared by hardware.

When this bit is set to 1, the LPSTS.SUSPENDM bit is also set to 1 on return from L2.

37.2.46 PL1CTRL2 : Function L1 Control Register 2

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x146

Bit position:	15	14	13	12	11				7	6	5	4	3	2	1	0
Bit field:	—	—	—	RWEMON	HIRDMON[3:0]				—	—	—	—	—	—	—	—
Value after reset:	x	x	x	0	0	0	0	0	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	—	The read values are undefined. The write value should be 0.	R/W
11:8	HIRDMON[3:0]	HIRD Value Monitor When set, indicates that the HIRD field value reflects the last received LPM token.	R
12	RWEMON	RWE Value Monitor When set, indicates that the RWE bit value reflects the last received LPM token.	R
15:13	—	The read values are undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

HIRDMON[3:0] bits (HIRD Value Monitor)

Access the HIRDMON[3:0] bits when monitoring the HIRD field value of the received LPM token. The bits reflect the HIRD field value of the last received LPM token.

RWEMON bit (RWE Value Monitor)

Access the RWEMON bit when monitoring the RWE field value of the received LPM token. The bits reflect the RWE field value of the last received LPM token.

37.2.47 HL1CTRL1 : Host L1 Control Register 1

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x148

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	L1STATUS[1:0]		L1REQ
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

Bit	Symbol	Function	R/W
0	L1REQ	L1 Transition Request Set this bit to 1 when requesting a transition to the L1 state. This bit is cleared to 0 by the hardware when the LPM transaction is complete.	R/W
2:1	L1STATUS[1:0]	L1 Request Completion Status Indicates the result of the LPM transaction made by the L1REQ bit: 0 0: ACK received 0 1: NYET received 1 0: STALL received 1 1: Transaction error	R
15:3	—	The read value is undefined. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

L1REQ bit (L1 Transition Request)

Set the L1REQ bit to 1 to transition to the L1 state. When the USBHS detects that this bit is 1, it starts the LPM transaction. The USBHS clears this bit to 0 through hardware on completion of the transaction.

L1STATUS[1:0] bits (L1 Request Completion Status)

The L1STATUS[1:0] bits indicate the result of the LPM transaction initiated by the L1REQ bit.

37.2.48 HL1CTRL2 : Host L1 Control Register 2

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x14A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BESL	—	—	L1RWE	HIRD[3:0]				—	—	—	—	L1ADDR[3:0]			
Value after reset:	0	x	x	0	0	0	0	0	x	x	x	x	0	0	0	0

Bit	Symbol	Function	R/W
3:0	L1ADDR[3:0]	LPM Token Device Address Specify the value to be set in the ADDR field of the LPM token	R/W
7:4	—	The read values are undefined. The write value should be 0.	R/W
11:8	HIRD[3:0]	LPM Token HIRD Specify the value to be set in the HIRD field of the LPM token	R/W
12	L1RWE	LPM Token L1 Remote Wake Enable Specify the value to be set in the RWE field of the LPM token	R/W
14:13	—	The read values are undefined. The write value should be 0.	R/W
15	BESL	BESL & Alternate HIRD Selects the K-State drive period on L1 Resume	R/W

Note: S-TYPE-3, P-TYPE-3

L1ADDR[3:0] bits (LPM Token Device Address)

The L1ADDR[3:0] bits specify the value to be set in the ADDR field of the LPM token that the USBHS transmits when the HL1CTRL1.L1REQ bit is set to 1.

HIRD[3:0] bits (LPM Token HIRD)

The HIRD[3:0] bits specify the value to be set in the HIRD field of the LPM token that the USBHS transmits when the HL1CTRL1.L1REQ bit is set to 1. Table 37.15 shows the relationship between the HIRD settings and the HIRD field values.

Table 37.15 Relationship between the HIRD bit settings and the HIRD field values (1 of 2)

HIRD[3:0] setting	When BESL = 0	When BESL = 1
0x0	50 μs (setting prohibited)	75 μs
0x1	125 μs	100 μs
0x2	200 μs	150 μs
0x3	275 μs	250 μs
0x4	350 μs	350 μs
0x5	425 μs	450 μs
0x6	500 μs	950 μs
0x7	575 μs	1950 μs
0x8	650 μs	2950 μs
0x9	725 μs	3950 μs
0xA	800 μs	4950 μs
0xB	875 μs	5950 μs
0xC	950 μs	6950 μs
0xD	1025 μs (setting prohibited)	7950 μs
0xE	1100 μs (setting prohibited)	8950 μs

Table 37.15 Relationship between the HIRD bit settings and the HIRD field values (2 of 2)

HIRD[3:0] setting	When BESL = 0	When BESL = 1
0xF	1175 µs (setting prohibited)	9950 µs

Note: The set value of the HIRD bit is used for the host K drive period on host resume and for the host K period on remote wakeup.

L1RWE bit (LPM Token L1 Remote Wake Enable)

The L1RWE bit specifies the value to be set in the RWE field of the LPM token that the USBHS transmits when the HL1CTRL1.L1REQ bit is set to 1.

The USBHS does not control detection of the remote wakeup signal in the L1 state with this bit. The remote wakeup signal is controlled by the DVSTCTR0.RWUPE bit, as with Suspend.

BESL bit (BESL & Alternate HIRD)

The BESL bit selects the K-state drive period on L1 Resume. For details, see the description of the HIRD bits.

37.2.49 DPUSR0R : Deep Software Standby USB Transceiver Control/Pin Monitor Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x160

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	DVBSTSHM	—	DOVCBHM	DOVCAHM	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	x	0	x	x	0	0	0	0

22	—	This bit is read as 0. The write value should be 0.	R/W
23	DVBSTSH	VBUS Interrupt Source Return Status Flag 0: System has not recovered from Deep Software Standby mode 1 1: System recovered from Deep Software Standby mode 1	R
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This register is accessed by the clock of PCLKA/64 to reduce current consumption in Deep Software Standby mode 1.

37.2.51 DPUSR2R : Deep Software Standby USB Suspend/Resume Interrupt Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x168

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	DPINTE	DMINTE	—	—	DMVAL	DPVAL	—	—	DPINT	DMINT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DMINT	Indication of Return from DM Interrupt Source 0: System has not recovered from Deep Software Standby mode 1 1: System recovered from Deep Software Standby mode 1	R
1	DPINT	Indication of Return from DP Interrupt Source 0: System has not recovered from Deep Software Standby mode 1 1: System recovered from Deep Software Standby mode 1	R
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	DPVAL	DP Input Indicates DP input signal on the USBHS side	R
5	DMVAL	DM Input Indicates DM input signal on the USBHS side	R
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	DMINTE	DM Interrupt Enable Clear 0: Disable recovery from Deep Software Standby mode 1 1: Enable recovery from Deep Software Standby mode 1	R/W
9	DPINTE	DP Interrupt Enable Clear 0: Disable recovery from Deep Software Standby mode 1 1: Enable recovery from Deep Software Standby mode 1	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This register is accessed by the clock of PCLKA/64 to reduce current consumption in Deep Software Standby mode 1.

37.2.52 DPUSRCR : Deep Software Standby USB Suspend/Resume Command Register

Base address: USBHS = 0x4035_1000
USBHS_NS = 0x5035_1000

Offset address: 0x16A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FIXPHYPD	FIXPHY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FIXPHY	USB Transceiver Control Fix 0: Normal mode 1: Invoke/recover from Deep Software Standby mode 1	R/W
1	FIXPHYPD	USB Transceiver Control Fix for PLL 0: Normal mode 1: Invoke/recover from Deep Software Standby mode 1	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: This register is accessed by the clock of PCLKA/64 to reduce current consumption in Deep Software Standby mode 1.

37.3 Operation

37.3.1 System Control

This section describes register settings required for initializing the USBHS and controlling power consumption.

37.3.1.1 Setting Data to the USBHS Registers

Setting the SYSCFG.USBE bit to 1 after starting the PHY clock supply enables and starts USBHS operation. For information on how to supply the PHY clock, see section 37.3.3. Supplying the Clock.

37.3.1.2 Selecting the Controller Function

The USBHS can operate as a host or device controller.

Use the SYSCFG.DCFM bit to select one of these USBHS functions. The DCFM bit must be changed in the initial settings immediately after a reset or in the D+ pull-up-disabled state (SYSCFG.DPRPU bit = 0) and D+ and D- pull-down- disabled state (SYSCFG.DRPD bit = 0).

37.3.2 Controlling the USB Data Bus Using Resisters

The USBHS provides pull-up and pull-down resistors for the D+ and D- lines. Pull these lines up or down by setting the SYSCFG.DPRPU and DRPD bits.

In device controller mode, confirm that connection to the USB host is made, and then set the SYSCFG.DPRPU bit to 1 and pull up the D+ line (in full-speed communication).

When the SYSCFG.DPRPU bit is set to 0 during communication with a PC, the USBHS disables the pull-up resistor for the USB data line, thereby notifying the USB host of disconnection.

Table 37.16 shows the settings for controlling the resistors for the USB data bus. Control the USB data bus appropriately for your system using the DRPD and DPRPU bit settings.

Table 37.16 Control settings for the USB data bus resistors (excluding OTG operation)

SYSCFG register settings		USB data bus control		
DRPD bit	**DPRPU bit**	**D-Line**	**D+Line**	**Function**
0	0	Open	Open	When resistors not used
0	1	Open	Pull-Up	When operating as a device controller at full-speed
1	0	Pull-Down	Pull-Down	When operating as a host controller
1	1	—	—	Setting prohibited except during OTG operation

37.3.3 Supplying the Clock

Table 37.17 shows the two input clocks required for the USBHS.

Table 37.17 Input clocks

Input clock name	Description
PCLKA	Peripheral module clock A input. There is no constraint on the frequency of the PCLKA input.
PHY clock	PHY clock generated from external input or internal supply ● External input: The clock is generated by the USB-PHY internal PLL based on a 12-MHz, 20-MHz, 24-MHz, or 48-MHz clock supplied to the EXTAL pin from outside the MCU. For the external clock specifications, especially the jitter characteristics, strictly follow the specifications of ±50 ppm. ● Internal supply: The clock is generated by supplying 48 MHz and 60 MHz to the USB-PHY module and selecting CL-only mode (PHYSET.HSEB). High-speed operation is not supported with this mode.

Figure 37.2 illustrates the PHY clock settings.

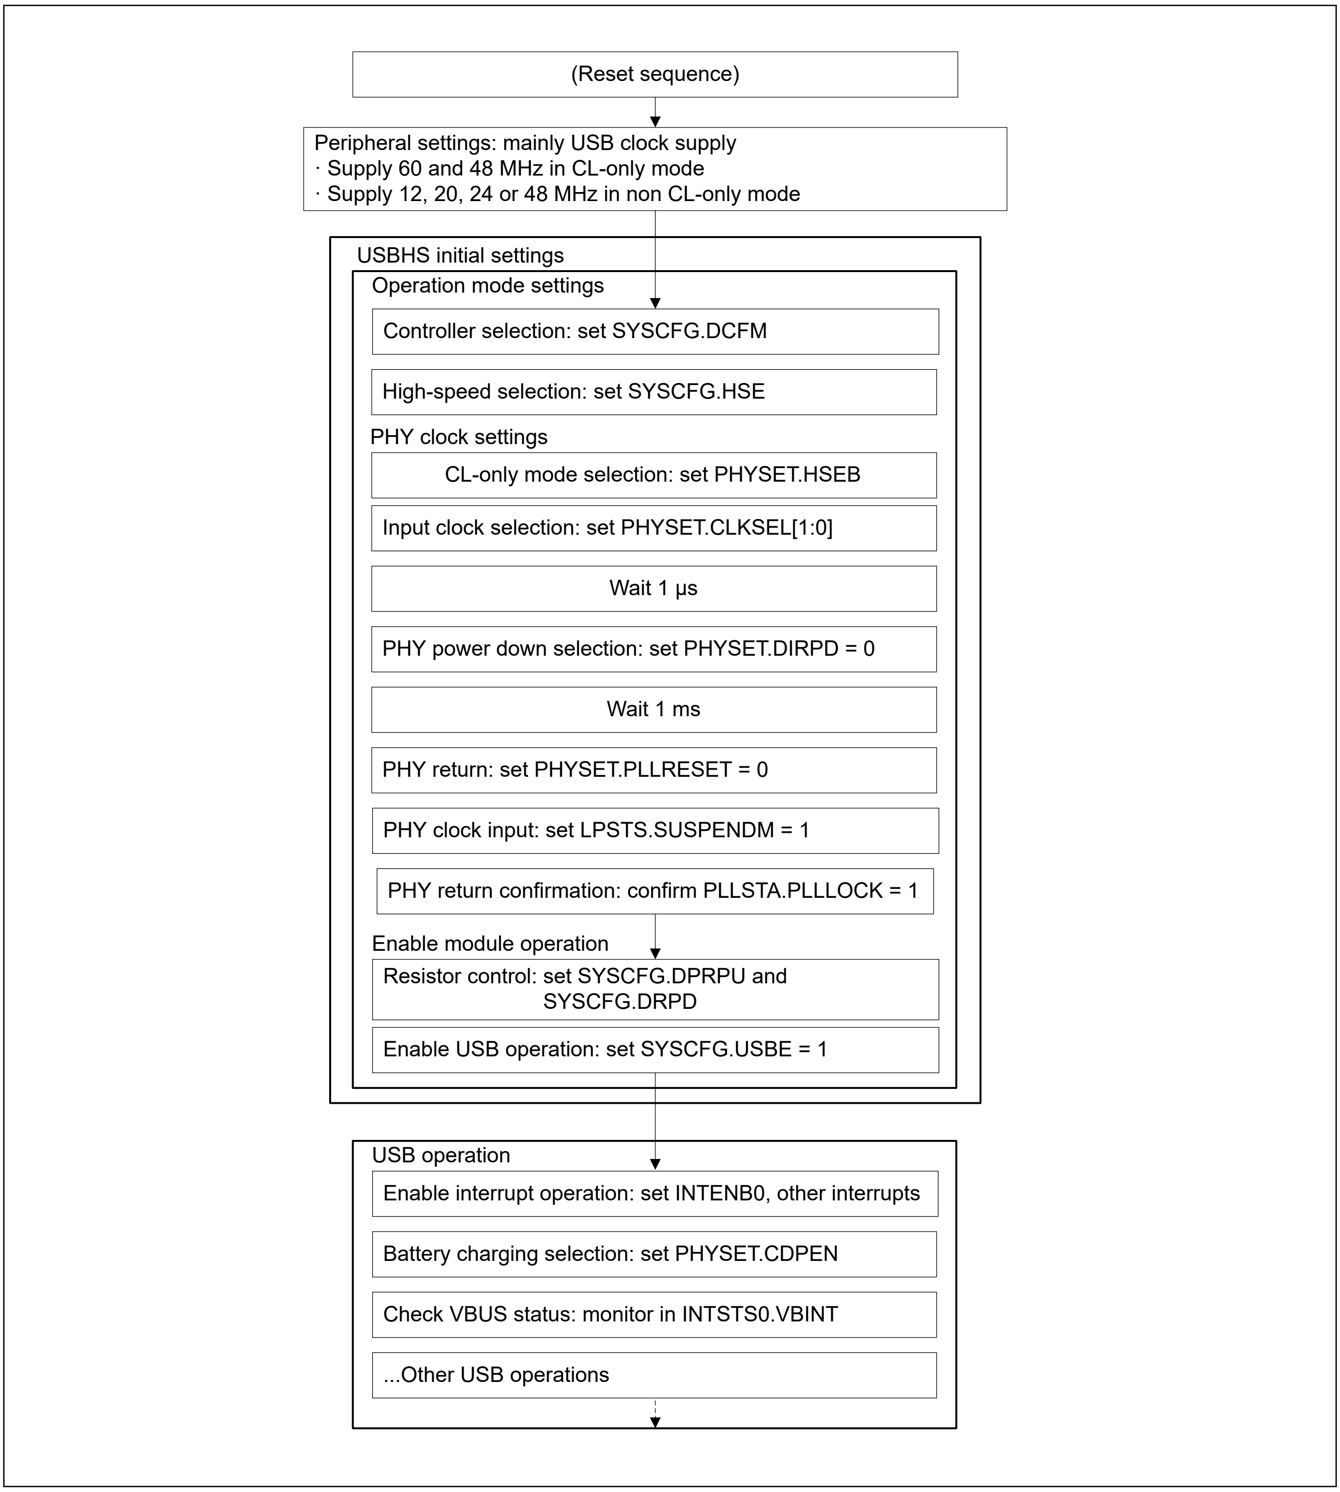

Figure 37.2 PHY clock settings

37.3.4 Constraints on Stopping the Clock

PCLKA and PHY clock can be stopped during disconnection or suspension. However, to stop any of these clocks while the USB is suspended in device controller mode, the stopped clock must be resupplied using the resume interrupt. The PHY clock must be resupplied within 5.5 ms after the resume interrupt is generated.

37.3.5 Interrupts

Table 37.18 lists the interrupt sources in the USBHS. When an interrupt generation condition is satisfied and the interrupt output is enabled using the associated interrupt enable register, the USBHS issues a USBHS interrupt request to the Interrupt Controller Unit (ICU) and a USBHS interrupt is generated.

Table 37.18 Interrupt sources (1 of 2)

Flag to be set to 1	Interrupt name	Interrupt source	Applicable controller function	Status flag
VBINT	VBUS interrupt	• A change in the state of the USB_VBUS input pin is detected (low to high or high to low)	Host or function*1	INTSTS0.VBSTS
RESM	Resume interrupt	• A change in the state of the USB bus is detected in the Suspend state (J-state to K-state or J-state to SE0)	Function	—
SOFR	Frame number update interrupt	In host controller mode: • An SOF packet with a different frame number is transmitted In device controller mode: • When SOFRM is 0: An SOF packet with a different frame number is received • When SOFRM is 1: Failed to receive an SOF packet with the μ frame number 0 because the packet is corrupted.	Host or function	—
DVST	Device state transition interrupt	• A device state transition is detected because of one of the following: – USB bus reset is detected – Suspend state is detected – SET_ADDRESS request is received – SET_CONFIGURATION request is received	Function	PL1CTRL.DVSQ[3:0]
CTRT	Control transfer stage transition interrupt	• A control transfer stage transition is detected because of one of the following: – Setup stage completed – Control write transfer status stage transition occurred – Control read transfer status stage transition occurred – Control transfer completed – Control transfer sequence error occurred	Function	INTSTS0.CTSQ[2:0]
BEMP	Buffer empty interrupt	• The buffer is empty after all FIFO buffer data is transmitted • A packet larger than the maximum packet size is received	Host or function	BEMPSTS.PIPEBEMP
NRDY	Buffer not ready interrupt	In host controller mode: • A STALL response is received from the peripheral device in response to the issued token • The response from the peripheral device in response to the issued token is not received successfully (no response three times consecutively or packet reception error three times consecutively) • An overrun or underrun error occurred during isochronous transfer In device controller mode: • NAK is returned for an IN or OUT token while the PID [1:0] bits were set to 01b (BUF) • A CRC error or bit stuffing error occurred during data reception in isochronous transfer • An interval error occurred during data reception in isochronous transfer	Host or function	NRDYSTS.PIPENRDY
BRDY	Buffer ready interrupt	• The buffer is ready (read or write state)	Host or function	BRDYSTS.PIPEBRDY
OVRCR	Overcurrent input change interrupt	• USBHS_OVRCURA, USBHS_OVRCURA-DS, USBHS_OVRCURB or USBHS_OVRCURAB-DS pin state change is detected (low to high or high to low)	Host or function	SYSSTS0.OVCMON [1:0]

Table 37.18 Interrupt sources (2 of 2)

Flag to be set to 1	Interrupt name	Interrupt source	Applicable controller function	Status flag
BCHG	Bus change interrupt	• USB bus state change is detected	Host	—
DTCH	Device disconnect detection interrupt	• Peripheral device disconnect is detected	Host	—
ATTCH	Device connect detection interrupt	• J-state or K-state is detected on the USB bus for 2.5 µs continuously This interrupt can be used to check whether peripheral devices are connected.	Host	—
EOFERR	EOF error detection interrupt	• An EOF error is detected for a peripheral device	Host	—
SACK	Setup normal interrupt	• A setup transaction normal response (ACK) is received	Host	—
SIGN	Setup error interrupt	• A setup transaction error (no response or ACK packet corruption) is detected three consecutive times	Host	—
PDDETINT	PDDETSTS change detect interrupt	• PDDET pin change is detected	Host or function	BCCTRL.PDDETSTS
LPMEND	LPM transaction end interrupt	• LPM transaction is complete	Host	PL1CTRL.DVSQ[3:0]
L1RSMEND	L1 resume end interrupt	• Resume (from L1 state) processing is complete	Host	PL1CTRL.DVSQ[3:0]

Note 1. Although this interrupt can be generated in host controller mode, it is not usually used in this mode.

37.3.5.1 Selecting the USBHS Interrupt Detection Method

Table 37.19 shows operations for an USBHS interrupt output from the USBHS. In case two or more interrupt sources are generated, the USBHS interrupt output method can be set in the SOFCFG.INTL bit. Set the USBHS interrupt output operation based on your system.

Table 37.19 USBHS interrupt operation

USBHS interrupt output (INTL setting)	When one interrupt source is generated	When two or more interrupt sources are generated
Edge detection (SOFCFG.INTL bit = 0)	Low level output until the source is cleared	When one source is cleared, the USBHS interrupt is negated for 32 clocks at 48 MHz (high pulse output)
Level detection (SOFCFG.INTL bit = 1)	Low level output until the source is cleared	Low level output until all sources are cleared

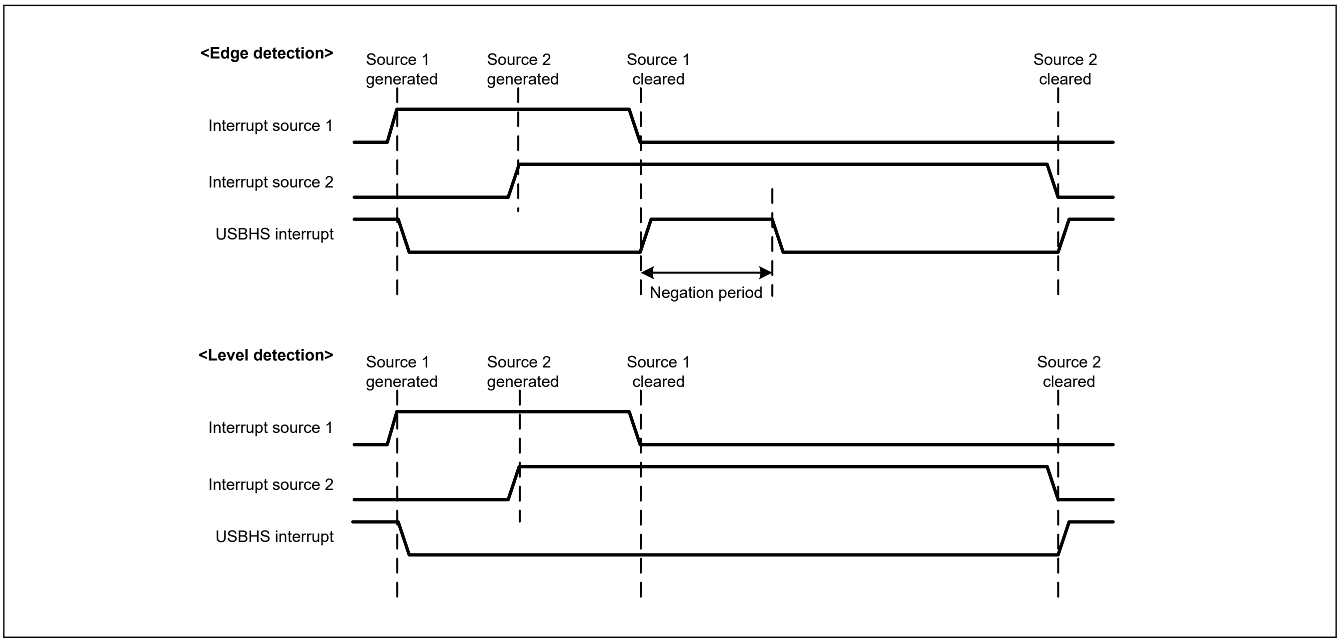

Figure 37.3 USBHS interrupt operation

Figure 37.4 shows an interrupt association chart of the USBHS.

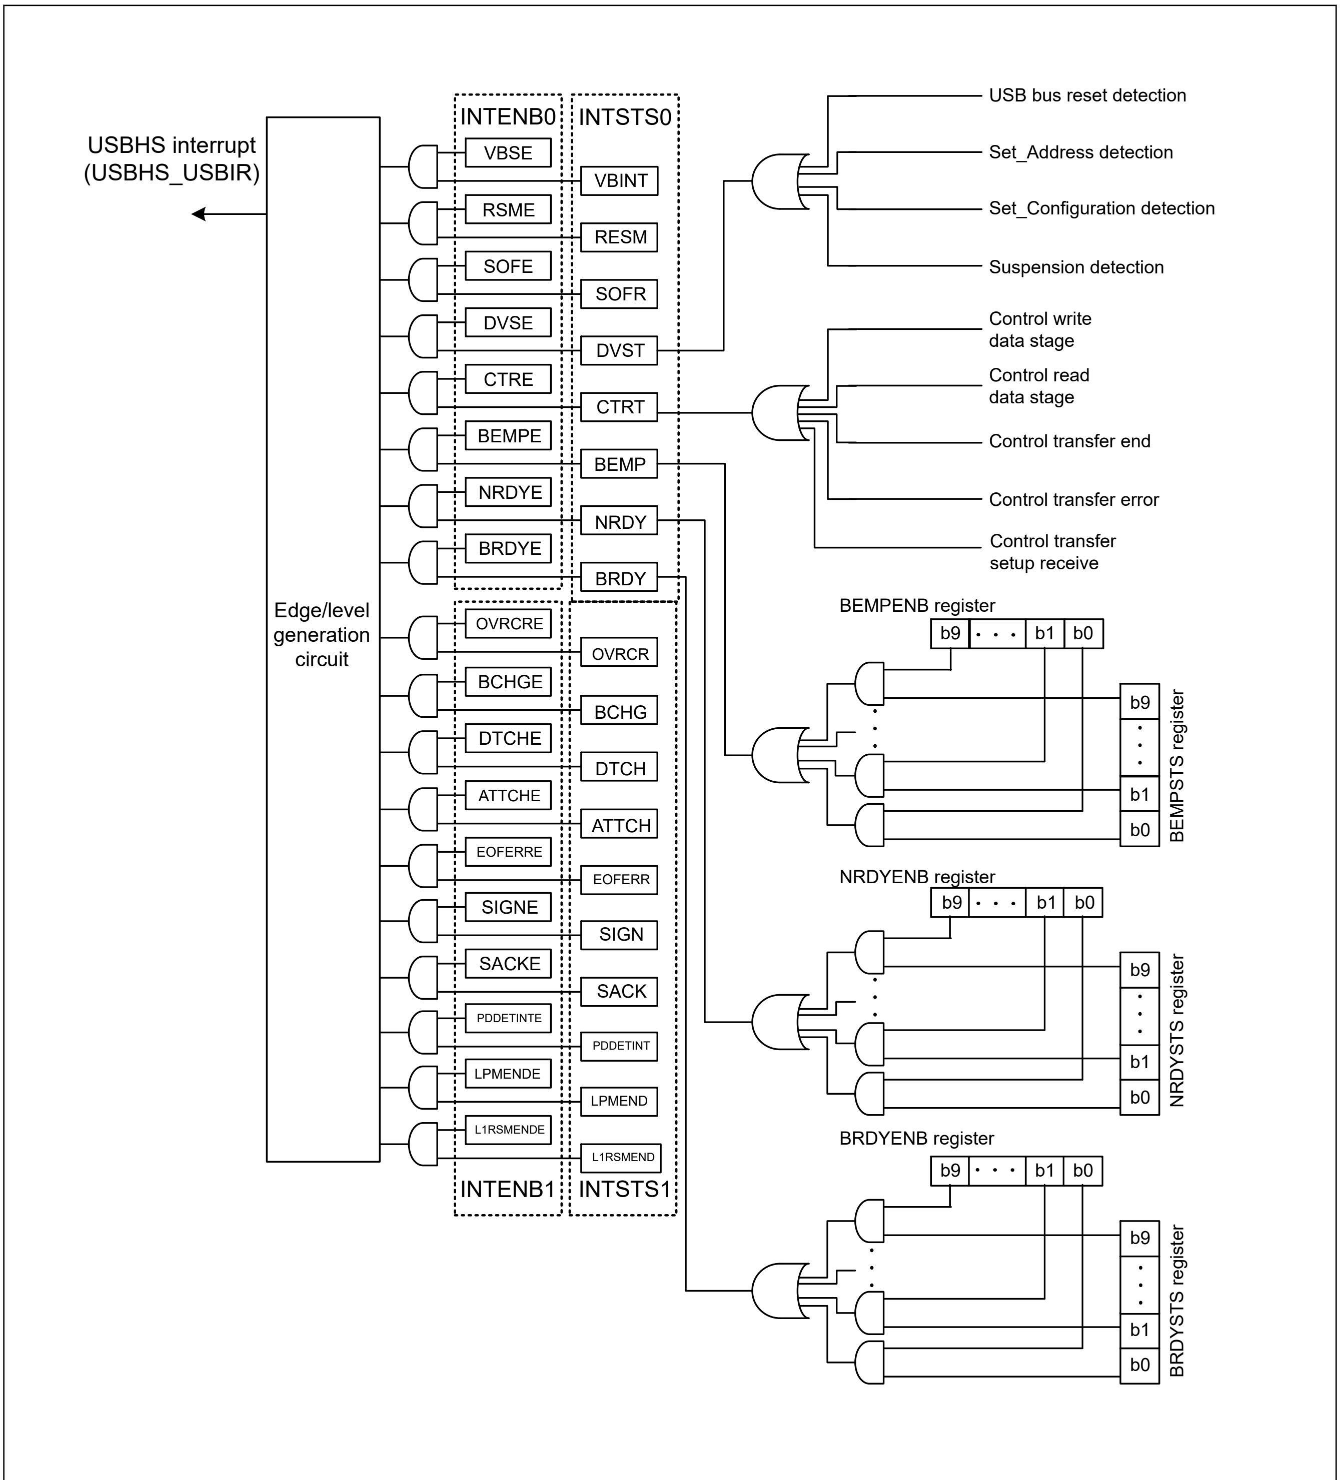

Figure 37.4 USBHS interrupt-related circuits

Table 37.20 shows the interrupts generated by the USBHS.

Table 37.20 USBHS interrupts (1 of 2)

Interrupt name	Interrupt status flag	DTC activation	DMAC activation
USBHS_D0FIFO	DMA transfer request 0	Possible	Possible
USBHS_D1FIFO	DMA transfer request 1	Possible	Possible

Table 37.20 USBHS interrupts (2 of 2)

Interrupt name	Interrupt status flag	DTC activation	DMAC activation
USBHS_USBIR	VBUS interrupt, resume interrupt, frame number update interrupt, device state transition interrupt, control transfer stage transition interrupt, buffer empty interrupt, buffer not ready interrupt, buffer ready interrupt, overcurrent interrupt, bus change interrupt, device disconnect detection interrupt, device connect detection interrupt, EOF error detection interrupt, normal setup operation interrupt, setup error interrupt, PDDETSTS change detection interrupt, LPM transaction end interrupt, and L1 resume end interrupt	Not possible	Not possible

37.3.6 Interrupt Descriptions

37.3.6.1 BRDY Interrupt

The BRDY interrupt is generated in both host and device controller modes. This section describes the conditions in which the USBHS sets the associated bit in BRDYSTS to 1. Under these conditions, the USBHS generates a BRDY interrupt if the software sets the bit in BRDYENB associated with the given pipe to 1 and INTENB0.BRDYE bit to 1.

The conditions for generating and clearing the BRDY interrupt depend on the SOFCFG.BRDYM and PIPECFG.BFRE settings for each pipe as follows:

(1) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.

On any of the following conditions, the USBHS generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEBRDY flag associated with the pipe to 1.

For transmitting pipes

- When the DIR bit is changed from 0 to 1 by software
- When writing by the CPU to the FIFO buffer is disabled for a pipe (when the BSTS flag is read as 0) and the USBHS has completed packet transmission. In continuous transfer, a BRDY interrupt is generated on completion of the transmission of data from one FIFO buffer.
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is complete
- When the hardware flushes the buffer of the pipe for isochronous transfers
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to transition from the write-disabled to write-enabled state.

No request trigger is generated for the DCP, that is, during data transmission for control transfers.

For receiving pipes

- When packet reception is successfully complete, enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the given pipe is disabled (when the BSTS flag is read as 0). No request trigger is generated for transactions in which DATA-PID mismatch has occurred. In continuous transmission or reception mode, the request trigger is not generated when the data is of the specified maximum packet size and the buffer has available space. When a short packet is received, the request trigger is generated even if the FIFO buffer has available space. When the transaction counter is used, the request trigger is generated on receiving the specified number of packets. In this case, the request trigger is generated even if the FIFO buffer has available space.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer, even if reception by the other FIFO buffer is complete.
  In device controller mode, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEBRDY interrupt status of the selected pipe can be set to 0 by writing 0 to the associated PIPEBRDY flag through the software. In this case, 1s must be written to the associated bits for the other pipes. Clear the BRDY status before accessing the FIFO buffer.

(2) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 1

With these settings, the USBHS generates a BRDY interrupt on completion of reading all data for a single transfer using the receiving pipe, and sets the bit in BRDYSTS associated with the pipe to 1.

On any of the following conditions, the USBHS determines that the last data for a single transfer was received:

- When a short packet including a zero-length packet is received
- When the PIPEnTRN register is used and the number of packets specified in the PIPEnTRN.TRNCNT[15:0] bits are completely received

When the data is completely read after any of these conditions is satisfied, the USBHS determines that all data for a single transfer is completely read.

When a zero-length packet is received while the FIFO buffer is empty, the USBHS determines that all data for a single transfer is completely read when the FRDY flag in the FIFO port control register is 1 and the DTLN[11:0] flags are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the associated port control register through software. With these settings, the USBHS does not detect a BRDY interrupt for the transmitting pipe.

The PIPEBRDY interrupt status of a pipe can be set to 0 by writing 0 to the associated BRDYSTS.PIPEBRDY flag through the software. In this case, 1s must be written to the PIPEBRDY bits for the other pipes.

In this mode, do not change the PIPECFG.BFRE bit setting until all data for a single transfer is processed. When it is necessary to change the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pipe must be cleared using the PIPEnCTR.ACLRM bit.

(3) When SOFCFG.BRDYM = 1 and PIPECFG.BFRE = 0

With these settings, the BRDYSTS.PIPEBRDY flag values are linked to the BSTS flag setting for each pipe. In other words, the BRDY interrupt status bits are set to 1 or 0 by the USBHS depending on the FIFO buffer status.

For transmitting pipes

The BRDY interrupt status bits are set to 1 when the FIFO port is ready for write access, and are set to 0 when it is not ready. The BRDY interrupt is not generated for the DCP in the transmitting direction even when it is ready for write access.

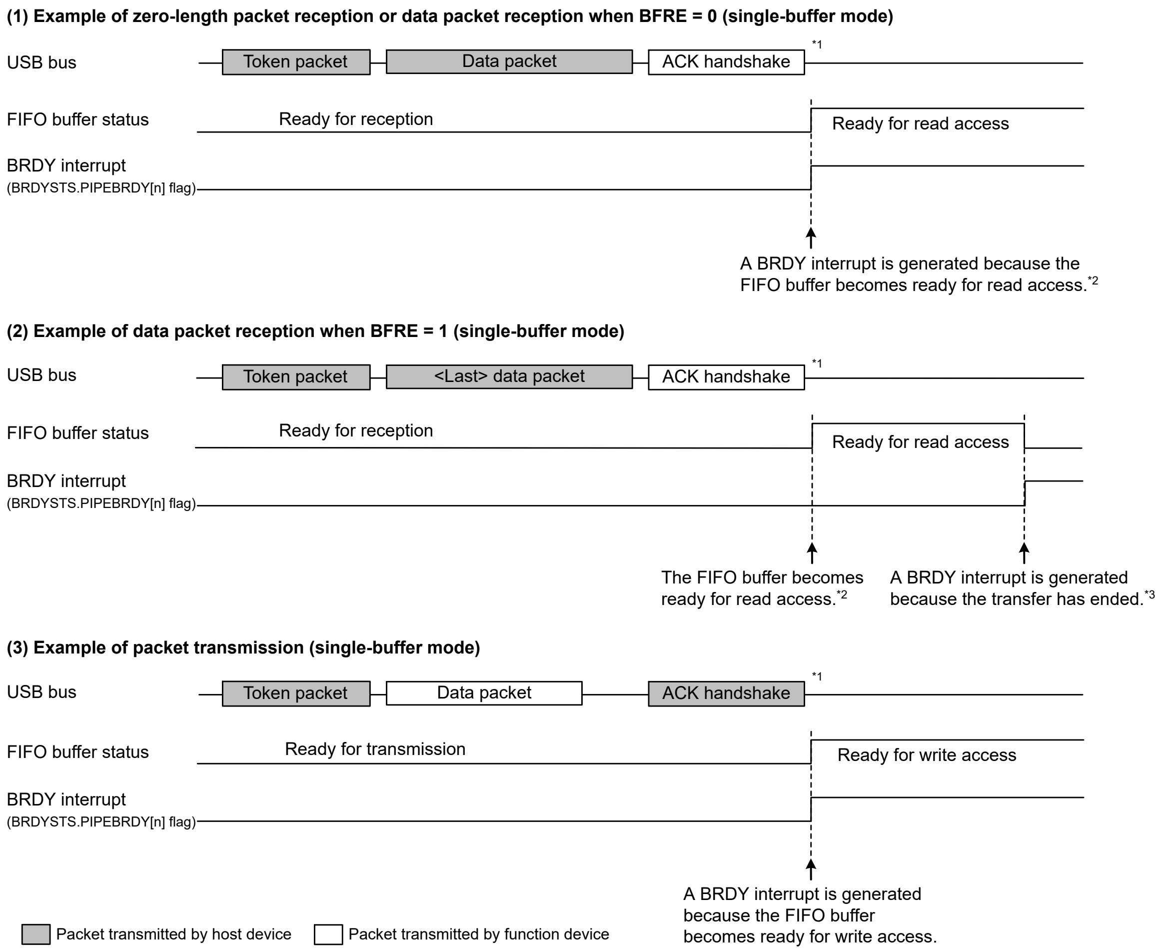
For receiving pipes

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for read access, and are set to 0 when all data is read (not ready for read access).

When a zero-length packet is received while the FIFO buffer is empty, the associated bit is set to 1 and the BRDY interrupt is continuously generated until the software writes 1 to BCLR. With this setting, the PIPEBRDY flag cannot be set to 0 by software.

When the SOFCFG.BRDYM bit is set to 1, set the PIPECFG.BFRE bit for all pipes to 0, and the SOFCFG.INTL bit to 1 for level detection.

Figure 37.5 shows the timing of BRDY interrupt generation.



Note 1. The ACK handshake is not used in isochronous transfers.
Note 2. The FIFO buffer becomes ready for read access under the following condition:
When a packet is received while no unread data remains in the FIFO buffer in the CPU.
Note 3. A transfer ends under either of the following conditions:
1. When a short packet including a zero-length packet is received
2. When the number of packets specified in the transaction counter are received

Figure 37.5 Timing of BRDY interrupt generation

The condition for clearing the INTSTS0.BRDY flag depends on the SOFCFG.BRDYM bit setting value, as shown in Table 37.21

Table 37.21 Conditions for clearing the BRDY flag

BRDYM bit	Condition for clearing BRDY flag
0	The USBHS clears the BRDY flag to 0 when all bits in BRDYSTS are set to 0 by software
1	The USBHS clears the BRDY flag to 0 when the BSTS flags for all pipes have cleared to 0

37.3.6.2 NRDY Interrupt

On generating an internal NRDY interrupt request for the pipe whose PID[1:0] bits are set to 01b (BUF response) by software, the USBHS sets the associated NRDYSTS.PIPENRDY flag to 1. If the associated bit in NRDYENB is set to 1 by software, the USBHS sets the INTSTS0.NRDY flag to 1 and generates a USBHS interrupt.

This section describes the conditions in which the USBHS generates the internal NRDY interrupt request for a given pipe.

The internal NRDY interrupt request is not generated during setup transaction execution in host controller mode. During setup transactions in host controller mode, the SACK or SIGN interrupt is detected.

The internal NRDY interrupt request is not generated during status stage execution of the control transfer in device controller mode

(1) In host controller mode when no split transactions occur in the connection

For transmitting pipes

On any of the following conditions, the USBHS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS transmits a zero-length packet following the OUT token and sets the associated NRDYSTS.PIPENRDY flag and the FRMNUM.OVRN flag to 1.
- During communications other than setup transactions on pipes not used for isochronous transfers, when any combination of the following two conditions occurs three consecutive times:
  - No response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device
  - An error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the PID[1:0] setting for the associated pipe to 00b (NAK response)
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device (includes STALL for both OUT and PING). In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the PID[1:0] setting for the associated pipe to 11b (STALL response).

For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBHS discards the received data for the IN token and sets the associated PIPENRDY flag and the OVRN flag to 1. When a packet error is detected in the received data for the IN token, the USBHS also sets the FRMNUM.CRCE flag to 1.
- For non-isochronous transfer pipes, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device for the IN token issued by the USBHS (when timeout is detected before detection of the DATA packet from the peripheral device)
  - An error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response).
- For isochronous transfer pipes, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1. The PID[1:0] setting for the pipe is not changed.
- For isochronous transfer pipes, when a CRC error or a bit stuffing error is detected in the received data packet. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe and the CRCE flag to 1.
- When the STALL handshake is received. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1 and changes the PID[1:0] setting for the associated pipe to STALL.

(2) In host controller mode when split transactions occur in the connection

For transmitting pipes

On any of the following conditions, the USBHS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS sets the associated RDYSTS.PIPENRDY flag for the given pipes to 1 on issuing a start-split transaction and sets the FRMNUM.OVRN flag to 1. The USBHS also transmits a zero-length packet following the OUT token.
- For non-isochronous transfer pipes, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for start-split and complete-split transactions (when timeout is detected before detection of the handshake packet from the hub)

  - An error is detected in the packet from the hub. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response). When an NRDY interrupt is detected on complete-split issuance, the USBHS clears the CSSTS flag to 0.
- When a STALL handshake is received for the complete-split transaction. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, changes the associated PID[1:0] setting for the pipe to 11b (STALL response), and clears the CSSTS flag to 0. An interrupt is not detected during setup transaction.

For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the given pipe and the FRMNUM.OVRN flag to 1 on start-split issuance. The USBHS discards the received data for the IN token.
- During bulk-pipe transfers or transfers other than setup transactions with the DCP, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for the IN token the USBHS issued on issuance of the start-split or complete-split transactions (when timeout is detected before detection of the data packet from the hub)
  - An error is detected in the packet from the hub. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response). When this condition occurs during complete-split, the USBHS clears the CSSTS flag to 0.
- During a complete-split transaction for isochronous transfer or interrupt transfer pipes, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for the IN token issued by the USBHS (when a timeout is detected before detection of the DATA packet from the hub)
  - An error is detected in the packet from the hub. On generating this condition for an interrupt transfer pipe, the USBHS sets the associated NRDYSTS.PIPENRDY flag to 1, changes the associated PID[1:0] setting for the pipe to 00b (NAK response), and clears the CSSTS flag to 0. On generating this condition for the pipe for isochronous transfers, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, CRCE flag to 1, and clears the CSSTS bit to 0. It does not change the PID[1:0] setting.
- During a complete-split transaction, when the STALL handshake is received for a non-isochronous transfer pipe. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, changes the associated PID[1:0] setting for the pipe to 11b (STALL response), and clears the CSSTS flag to 0.
- During a complete-split transaction, when the NYET handshake is received for an isochronous transfer or interrupt transfer pipe for the microframe number = 4. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1 and the CRCE flag to 1, and clears the CSSTS flag to 0. It does not change the PID[1:0] setting.

(3) In device controller mode

For transmitting pipes

- When an IN token is received while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS generates an NRDY interrupt request on reception of the IN token and sets the NRDYSTS.PIPENRDY flag to 1. For an isochronous transfer pipe in which an interrupt is generated, the USBHS transmits a zero-length packet and sets the FRMNUM.OVRN flag to 1.

For receiving pipes
