Rev.1.20 May, 2017

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other disputes involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawing, chart, program, algorithm, application examples.
3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You shall not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copy or otherwise misappropriation of Renesas Electronics products.
5. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.
   "Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots etc.
   "High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.
   Renesas Electronics products are neither intended nor authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems, surgical implantations etc.), or may cause serious property damages (space and undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for which the product is not intended by Renesas Electronics.
6. When using the Renesas Electronics products, refer to the latest product information (data sheets, user's manuals, application notes, "General Notes for Handling and Using Semiconductor Devices" in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat radiation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions or failure or accident arising out of the use of Renesas Electronics products beyond such specified ranges.
7. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please ensure to implement safety measures to guard them against the possibility of bodily injury, injury or damage caused by fire, and social damage in the event of failure or malfunction of Renesas Electronics products, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures by your own responsibility as warranty for your products/system. Because the evaluation of microcomputer software alone is very difficult and not practical, please evaluate the safety of the final products or systems manufactured by you.
8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please investigate applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive carefully and sufficiently and use Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
9. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall not use Renesas Electronics products or technologies for (1) any purpose relating to the development, design, manufacture, use, stockpiling, etc., of weapons of mass destruction, such as nuclear weapons, chemical weapons, or biological weapons, or missiles (including unmanned aerial vehicles (UAVs)) for delivering such weapons, (2) any purpose relating to the development, design, manufacture, or use of conventional weapons, or (3) any other purpose of disturbing international peace and security, and you shall not sell, export, lease, transfer, or release Renesas Electronics products or technologies to any third party whether directly or indirectly with knowledge or reason to know that the third party or any other party will engage in the activities described above. When exporting, selling, transferring, etc., Renesas Electronics products or technologies, you shall comply with any applicable export control laws and regulations promulgated and administered by the governments of the countries asserting jurisdiction over the parties or transactions.
10. Please acknowledge and agree that you shall bear all the losses and damages which are incurred from the misuse or violation of the terms and conditions described in this document, including this notice, and hold Renesas Electronics harmless, if such misuse or violation results from your resale or making Renesas Electronics products available any third party.
11. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.

(Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

(Rev.3.0-1 November 2016)

Notes for CMOS devices

(1) Voltage application waveform at input pin:

Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between VIL (MAX) and VIH (MIN) due to noise, etc., the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between VIL (MAX) and VIH (MIN).

(2) Handling of unused input pins:

Unconnected CMOS device inputs can be cause of malfunction. If an input pin is unconnected, it is possible that an internal input level may be generated due to noise, etc., causing malfunction. CMOS devices behave differently than Bipolar or NMOS devices. Input levels of CMOS devices must be fixed high or low by using pull-up or pull-down circuitry. Each unused pin should be connected to power supply or GND via a resistor if there is a possibility that it will be an output pin. All handling related to unused pins must be judged separately for each device and according to related specifications governing the device.

(3) Precaution against ESD:

A strong electric field, when exposed to a MOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop generation of static electricity as much as possible, and quickly dissipate it when it has occurred. Environmental control must be adequate. When it is dry, a humidifier should be used. It is recommended to avoid using insulators that easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors should be grounded. The operator should be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions need to be taken for PW boards with mounted semiconductor devices.

(4) Status before initialization:

Power-on does not necessarily define the initial status of a MOS device. Immediately after the power source is turned ON, devices with reset functions have not yet been initialized. Hence, power-on does not guarantee output pin levels, I/O settings or contents of registers. A device is not initialized until the reset signal is received. A reset operation must be executed immediately after power-on for devices with reset functions.

(5) Power ON/OFF sequence:

In the case of a device that uses different power supplies for the internal operation and external interface, as a rule, switch on the external power supply after switching on the internal power supply. When switching the power supply off, as a rule, switch off the external power supply and then the internal power supply. Use of the reverse power on/off sequences may result in the application of an overvoltage to the internal elements of the device, causing malfunction and degradation of internal elements due to the passage of an abnormal current. The correct power on/off sequence must be judged separately for each device and according to related specifications governing the device.

(6) Input of signal during power off state:

Do not input signals or an I/O pull-up power supply while the device is not powered. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Input of signals during the power off state must be judged separately for each device and according to related specifications governing the device.

How to Use This Manual

1. Purpose and Target Readers

This manual is designed to provide the user with an understanding of the hardware functions and electrical characteristics of the MCU. It is intended for users designing application systems incorporating the MCU. A basic knowledge of electric circuits, logical circuits, and MCUs is necessary in order to use this manual.
The manual comprises an overview of the product; descriptions of the CPU, system control functions, peripheral functions, and electrical characteristics; and usage notes.

Particular attention should be paid to the precautionary notes when using the manual. These notes occur within the body of the text, at the end of each section, and in the Usage Notes section.

The revision history summarizes the locations of revisions and additions. It does not list all revisions. Refer to the text of the manual for details.

The following documents apply to the RH850/E1x Group. Make sure to refer to the latest versions of these documents. The newest versions of the documents listed may be obtained from the Renesas Electronics Web site.

Document Type	Description	Document Title	Document No.
Data sheet	Overview of hardware and electrical characteristics		
User's manual: Hardware	Hardware specifications (pin assignments, memory maps, peripheral function specifications, electrical characteristics, timing charts) and operation description Note: Refer to the application notes for details on using peripheral functions.	RH850/E1M-S User's manual: Hardware	This User's Manual
User's manual: Software	Description of CPU instruction set	RH850G3M User's Manual: Software	R01US0123EJ0100
		RH850G3K User's Manual: Software	R01US0125EJ0100
Application note	Information on using peripheral functions and application examples Sample programs Information on writing programs in assembly language and C		
Renesas technical update	Product specifications, updates on documents, etc.		

2. Notation of Numbers and Symbols

The notation conventions for register names, bit names, numbers, and symbols used in this manual are described below.

(1) Register Names, Bit Names, and Pin Names

Registers, bits, and pins are referred to in the text by symbols. The symbol is accompanied by the word “register,” “bit,” or “pin” to distinguish the three categories.

Examples: the DEF bit in the ABC register
PA01 pin, VCC pin

(2) Notation of Numbers

Binary numbers are notated as nnnnB (However, the “B” may be omitted when it is clear that the number is binary), hexadecimal numbers are notated as nnnnH, and decimal numbers are notated as nnnn.

Examples Binary: 11B or 11
Hexadecimal: EFA0H
Decimal: 1234

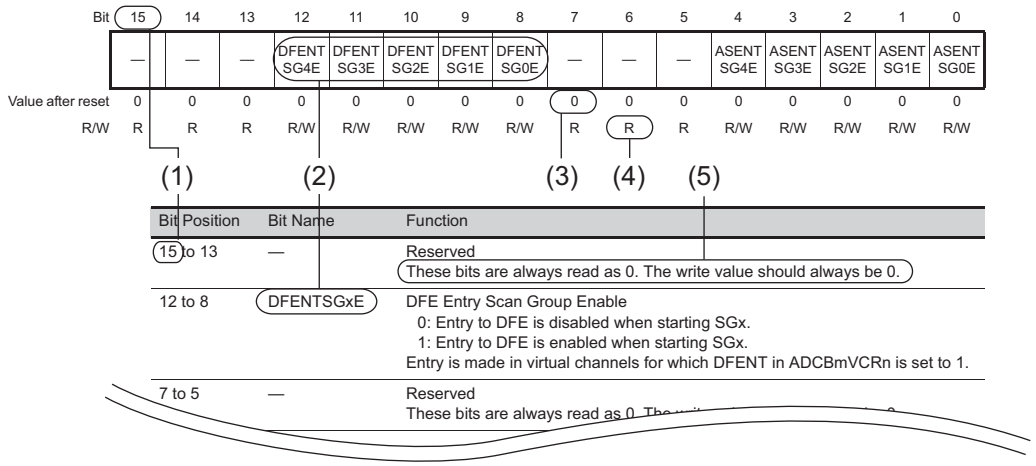
(3) Notation for Active-Low Signals

An overbar is added to the names of active-low signals.

Example $\overline{\text{ABCDEF}}$

3. Register Notation

Each section in this manual provides a table listing all the registers used by the corresponding module before the register descriptions in the section. The symbols and terms used in these tables are described below.



(1) Bit Position

Indicates the bit number.

The bits are shown in the order 31 to 0 for 32-bit registers, in the order 15 to 0 for 16-bit registers, and in the order 7 to 0 for 8-bit registers.

(2) Bit Name

The short form of the name of the bit or bit field within the register.

When the individual bits of bit fields have to be clearly indicated, notation allowing this is included (e.g. ABCD[3:0]).

A reserved bit is indicated by "—".

Instead of a bit name, a blank is used for some bits, such as those of timer counters.

(3) Value after reset

Indicates the value of each bit after a reset, i.e., the value after reset.

0: Value after reset is 0

1: Value after reset is 1

—: Value after reset is undefined

(4) R/W

Indicates whether each bit is readable or writable, or either writing to or reading from the bit is prohibited.

R/W: Bit or field is readable and writable.

R/(W): Bit or field is readable or writable.
However, writing is only performed to clear the flag.

R: Bit or field is readable.
However, "R" is indicated for all reserved bits. When writing to the bit is required, write the value stated in the bit table or the initial value.
In case of writing to writable registers that also include non-reserved bits with the R-attribute, writing to the R-attribute bits will be ignored unless otherwise specified.

W: Bit or field is writable.
However, only the value in the bit table is guaranteed when reading from the bit.

(5) Function

Describes the function enabled by setting the bit.

Table of Contents

Section 1 Overview

The RH850/E1M-S is a product of the single-chip microcomputer RH850 series of Renesas Electronics.

This section describes an overview of the RH850/E1M-S.

1.1 Outline

This product is a 32-bit single-chip microcomputer that incorporates multiple CPUs of the RH850 Series, code flash, RAM, DMA controller, CAN, high-speed communication interfaces including RHSB (microsecond bus), two types (sequential conversion type and delta-sigma type) of A/D converters, peripheral functions including digital filter processing, and an advance timer unit (ATU-IV) that is best suited for high-speed accurate power train control. This product also conforms to the Automotive Safety Integrity Level (ASIL) that is highly demanded in the recent automotive field.

(1) Installing multiple RH850 cores

This product contains a single RH850G3M as the main CPU (referred to as CPU1 hereafter) and a single RH850G3K as the peripheral control CPU (referred to as PCU: Peripheral Control Unit hereafter). The CPU1 and the PCU supports RISC-type instruction sets and have significantly improved the instruction execution speed with basic instructions (one clock cycle per instruction) and the optimized 7- and 5-stage pipeline configurations. Furthermore, this product also supports multiplication instructions using a 32-bit hardware multiplier, saturated product-sum operation instructions, and bit manipulation instructions as instructions best suited for various fields such as applications of the automobile power train control.

Two-byte basic instructions and high-level language instructions improve object code efficiency for the C compiler and reduce the program size. Furthermore, this product is suited for advanced real-time control fields thanks to high-speed interrupt response time including the processing time of the on-chip interrupt controller.

(2) On-chip code flash and data flash

This product incorporates 4-Mbyte code flash allowing high-speed accesses, which enables each CPU to access this flash memory. This memory can be reprogrammed while it is placed on an application system. This can shorten the system development period and significantly improve the serviceability after the system is delivered.

This product also has 64-Kbyte data flash that is available for storing EEPROM data.

(3) A variety of peripheral functions

The RH850/E1M-S incorporates timers (ATU-IV and APA) best suited for reducing hardware and software control loads in the automobile power train control (e.g. engine, transmission), digital filter engine (DFE), two types of A/D converters (ADCB and DS-ADC), and other devices. In addition, the RH850/E1M-S incorporates standard peripheral functions (UART, CAN, and RHSB) for the automotive field. It also has the global standard on-chip debug interface (NEXUS JTAG) as a debug interface. This allows construction of systems without providing these functions externally, reducing costs, quantity of components, and footprint.

(4) Conforming to functional safety

The memory protection function, peripheral device protection function, system/register protection function, and timing monitoring function are provided to ensure highly reliable operations of the CPU. With these function, the RH850/E1M-S conforms to the functional safety requirements (ASIL) in the automotive field.

1.2 Features

CPU1 core	RH850G3M: 1 unit (for high-speed operation and control)
CPU1 cache memory	8 Kbytes
Minimum CPU1 instruction execution time	3.125 ns (during internal 320 MHz operation)
General CPU1 registers	Thirty-two 32-bit registers
CPU1 instruction sets	Signed multiplication (32 bits × 32 bits → 64 bits): 1 to 2 CPU clocks Saturated operation instructions (with overflow/underflow detection function) 32-bit arithmetic/logical shift instructions: 1 CPU clock Bit manipulation instructions Load/store instructions with long/short formats Signed load instructions
PCU core	RH850G3K: 1 unit (for medium-speed operation and peripheral control)
Minimum PCU instruction execution time	12.5 ns (during internal 80 MHz operation)
General PCU registers	Thirty-two 32-bit registers
PCU instruction sets	Signed multiplication (32 bits × 32 bits → 64 bits): 1 and 2 CPU clocks Saturated operation instructions (with overflow/underflow detection function) 32-bit arithmetic/logical shift instructions: 1 CPU clock Bit manipulation instructions Load/store instructions with long/short formats Signed load instructions
Memory space	4-Gbyte address space (common to program and data) (128 Mbytes accessible by the PCU)
Code flash	Two types of memory area • User area: 4 Mbytes (common to CPU1 and PCU) • User boot area: 32 Kbytes High-speed reading through cache enabled (only for CPU1)
Data flash	64 Kbytes (common to CPU1 and PCU)
RAM	RAM local RAM: 64 Kbytes (CPU1), 32 Kbytes (PCU) Global RAM: 256 Kbytes (common to CPU1 and PCU) (32 Kbytes: Standby RAM) Emulation RAM 8 Kbytes (common to CPU1 and PCU)
Interrupts/exceptions	1 nonmaskable interrupt (NMI pin) 1 FE level interrupt (ECM) 483maskable interrupts (high-speed: 21, low-speed: 462) Simultaneous distribution of interrupt sources to multiple cores (CPU1, PCU) • Applicable sources: non-maskable interrupt (NMI pin), FE level interrupt, 21 high-speed maskable interrupts External interrupt input function (IRQ pins) Software interrupt function (SINT) Inter-processor interrupt function (IPIR) 16-level priority specifiable for maskable interrupts For RH850 G3M and G3K exceptions, see “RH850G3M User's Manual: Software”, and “RH850G3K User's Manual: Software”.
DMA controller	16 channels incorporated (8 channels × 2 modules) Transfer unit: 8 bits/16 bits/32 bits/64 bits/128 bits Dual-address transfer mode Address reloading function Chain transfer function Three transfer modes settable: Single transfer, block transfer 1 (specified by number of transfer times), and block transfer 2 (specified by address count) Transfer target: On-chip memory, on-chip peripheral modules (excluding DMAC and DTS) Transfer requests can be set by interrupt sources and the software.

DTS controller	128 channels incorporated Transfer unit: 8 bits/16 bits/32 bits/64 bits/128 bits Dual-address transfer mode Address reloading function Chain transfer function Three transfer modes settable: Single transfer, block transfer 1 (specified by number of transfer times), and block transfer 2 (specified by address count) Transfer target: On-chip memory, on-chip peripheral modules (excluding DMAC and DTS) Transfer requests can be set by interrupt sources and the software.
I/O	Output driving ability of specific input/output pins selectable Inversion or non-inversion of output values of specific input/output pins selectable Pull-down or pull-down off of specific input/output pins selectable
Safety functions	Flash memory ECC error detection function RAM ECC error detection function Peripheral module RAM ECC error detection function (DTS, APA, RS-CAN, FlexRay, DFE) Oscillation stop detection function and oscillation function by the backup clock Error control module (ECM) Duplexing of modules (e.g. CPU1, ECM, error output pins)
Error control module (ECM)	Collects information of each error check system and safety function and indicates error status. When an error is detected, an error signal can be output from the error pin to the external. Interrupts and internal reset signals can be generated upon detection of an error. Provided with a function to generate a pseudo-error for debugging and self-diagnosis.
Data CRC function	The data CRC (cyclic redundancy check) function can verify or generate data streams protected by CRC with various lengths and different bit widths.
Multi-Input signature generator (MISG)	Monitors write access to specific addresses by the CPU, and generates a 64-bit signature using the write data.
Window watchdog timer (WDTA)	Two channels incorporated Can generate a signal to the ECM when an error occurs. Can generate an interrupt at 75% of the error source (register write during counter overflow or window closing period) window.
Advanced timer unit IV (ATU-IV)	Timer A: 32-bit input capture × 7 channels Timer B: Angle clock generating timer × 1 channel Timer C: 32-bit input capture/output compare × 32 channels Timer D: 32-bit one-shot pulse × 40 channels 32-bit input capture × 40 channels 32-bit output compare × 40 channels Timer E: 24-bit PWM x 28 channels Timer F: 32-bit event counter × 16 channels Timer G: 32- bit interval timer × 10 channels Timer H: 32-bit interval timer × 1 channel Timer J: 32-bit input capture (with 9-stage FIFO) × 6 channels
Autonomous pulse adapter (APA)	16 channels incorporated Changes output at an event (compare match) with no CPU load using values of peripheral modules (ATU-IV, ADCB, DS-ADC) as reference. Can generate output patterns automatically by combining multiple events.
Motor control timer (TSG2) Timer option (TAPA)	TSG2, TAPA: Two units are incorporated individually. • Incorporates a timer unit that can control up to two 3-phase motor controls (U, V, and W). • Can forcibly set the TSG2 timer output to Hi-Z when an error is detected.
OS timer (OSTM)	Three units incorporated • A 32-bit timer assuming the use of OS • Interval timer mode or free-running timer mode settable • Synchronous start between units settable
Peripheral interconnection function (PIC)	One unit incorporated • Synchronous operation using TSG2 timer and timer input/output can be connected between timers.

Serial communication interface 3 (SCI3)	Four channels incorporated • Clock synchronization or start-stop system settable • Full-duplex communication enabled • Arbitrary bit rate settable by the on-chip baud rate generator • LSB first or MSB first selectable
Serial interface H (CSIH)	Four channels incorporated • Three-wire serial synchronous data transfer • Master mode or slave mode selectable • Settable six or four chip select output signals • Arbitrary bit rate settable by the on-chip baud rate generator
CAN interface (RS-CAN)	Four channels incorporated • Conforming to ISO-11898 • Maximum transfer speed: 1 Mbps • A total of 320 message buffers provided for 4 channels • On-chip reception filtering function
FlexRay	Two channels incorporated (Ach, Bch) • Conforming to Protocol Specification 2.1 • Buffer size: A 8-Kbyte space is divided into up to 128 (for transmission, reception, and receive FIFO) • Message filtering: ID filter, channel filter, cycle counter filter • Bit rate: 10 Mbps
LIN master interface (RLIN2)	One channel incorporated • Settable to support various frame sizes • Checksum type settable • Wake-up transmission/reception enabled • Arbitrary bit rate (2400, 9600, 10417, 19200 bps) settable by the on-chip baud rate generator
Renesas high-speed bus (RHSB)	Two channels incorporated Communication module supporting microsecond bus channels • Down-stream communication • Up to two slaves settable individually • Functions for emergencies
AD converter (ADCB)	48 channels incorporated • 12-bit resolution, sequential conversion • Conversion speed: 1.0 µs • Independent operation of 12-bit resolution for 24 channels (ADC0) and 12-bit resolution for 24 channels (ADC1) • Track and hold circuit (ADC0: 2 channels, ADC1: 2 channels) • Scan groups for five systems settable • Two scan modes (multi-scan mode and continuous scan mode) • Up to 40 virtual channels settable • Two types of A/D conversion and addition functions incorporated • Converts the converted results to floating-point format. • Can enter data directly to the digital filter engine. • Safety functions (including self-diagnosis, data register upper limit/lower limit check, and data register parity)
Delta-sigma AD converter (DS-ADC)	16 channels incorporated (8 channels × 2 inputs) • Advanced A/D conversion • A/D conversion system: Delta-sigma modulation system • Supports single-end input and differential input. • On-chip programmable gain amplifier (x1, x2, x4, and x8) • Can enter data directly to the digital filter engine. • Safety functions (including self-diagnosis, data register upper limit/lower limit check, and data register parity)

Power supply voltage monitor	Monitors VDD voltage internally. If VDD rises above or falls below the specified voltage, an error is reported outside the LSI. Can set a time filter for error detection.
Digital filter	16-channel digital filtering (FIR/IIR) functions • FIR with up to 32 taps selectable • Up to 6-order IIR selectable • Filter coefficients and data are stored in the RAM to be connected. • For filtered data: Accumulation processing or decimation processing enabled Peak-hold processing or comparison processing enabled • Directly inputs converted data from the on-chip A/D converter or delta-sigma AD converter to perform automatic filtering.
On-chip debugging unit (OCD)	NEXUS JTAG: One channel incorporated LDU: One channel incorporated
Boundary scan	Boundary scan compliant with the IEEE 1149.1 standard
Clock controller	An oscillation circuit incorporated 20 MHz oscillation enabled without using external capacitors 20 MHz (maximum) clock can be input from the EXTAL pin. Multiplication of clock enabled by the on-chip PLL A ring oscillator circuit incorporated SSCG for reducing radiation noise incorporated. However, clock without SSCG is supplied to the timer and the communication module.
Operating modes	Operating modes • User boot mode • Serial programming mode Power-down mode • Power shutoff standby
Package	304-pin plastic FBGA (0.8 mm ball pitch) (19 × 19) 252-pin plastic FBGA (0.8 mm ball pitch) (17 × 17)

1.3 Application Fields

- Automotive field (including engine control system and transmission control system)

1.4 Order Information

Product Name	Package	On-Chip ROM	Operating Temperature (T_j)	External Oscillator	Maximum Operating Frequency
R7F701202EABA	Plastic FBGA-304 0.8-mm ball pitch 19 mm × 19 mm	4 MB	max. 150°C	20 MHz	320 MHz
R7F701202EABG	Plastic FBGA-252 0.8-mm ball pitch 17 mm × 17 mm	4 MB	max. 150°C	20 MHz	320 MHz
R7F701204EABA	Plastic FBGA-304 0.8-mm ball pitch 19 mm × 19 mm	4 MB	max. 150°C	20 MHz	240 MHz
R7F701204EABG	Plastic FBGA-252 0.8-mm ball pitch 17 mm × 17 mm	4 MB	max. 150°C	20 MHz	240 MHz

We hereafter refer to FBGA as BGA unless the complete abbreviation is especially required.

1.6 Functional Block Configuration

1.6.1 Internal Block Diagram

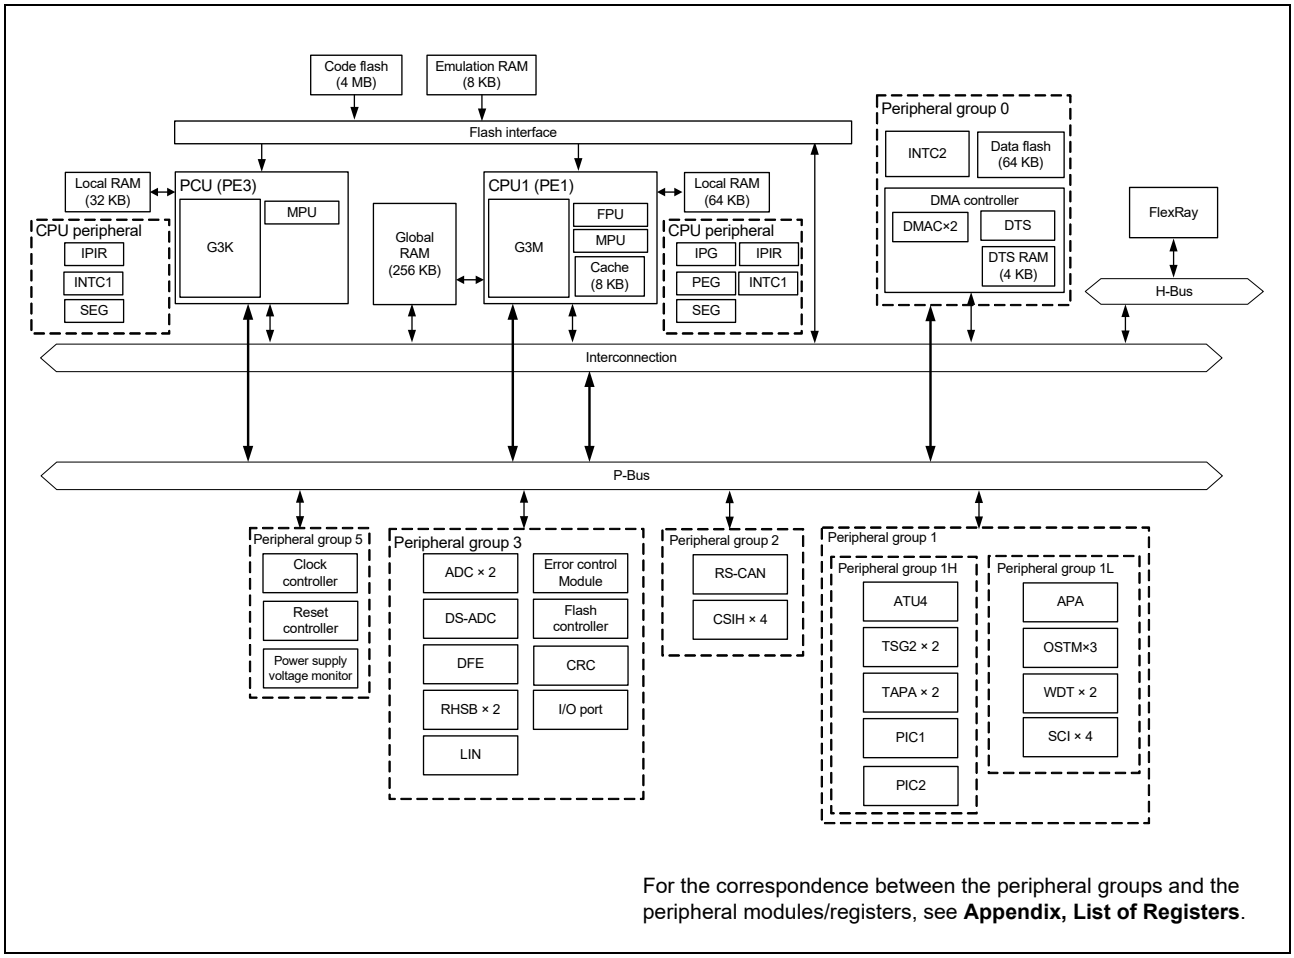

Figure 1.3 Internal Block Diagram

The CPU1 and the PCU incorporate the CPU peripherals. Only the CPU and the PCU can access the CPU peripherals. Same addresses are allocated to peripherals specific to the CPU1 and the PCU. When an access is made from the CPU1, a CPU1-specific peripheral is accessed. When an access is made from the PCU, a PCU-specific peripheral is accessed.

Section 2 Pins

2.1 Port Functions

2.1.1 Features

Port Group

This product has the following numbers of port groups:

Table 2.1 Port Groups of This Product

Product		Number of Group	Name of Group
E1M-S	BGA304	16	P0 - P8, P10, P11, P13 - P17
	BGA252	13	P0 - P6, P11, P13 - P17

Port Group Index n

Each port group is identified by its own index “n” (n = 0 to 17) throughout this section; e.g. PMCn for the port mode control register of the Pn pin.

Register Address

All port addresses are given as an offset from the individual base addresses, <PORT_Base2> and <PORT_Base1>.

Table 2.2 shows the base addresses, <PORT_Base2> and <PORT_Base1>.

Table 2.2 Port Base Address

Base Address	Address
<PORT_Base1>	FF61 0000_H
<PORT_Base2>	FFC1 0000_H

2.1.2 Overview

This product has various pins for input/output (I/O) functions, known as ports. The ports are organized in port groups.

This product also has several control registers to allocate the functions other than general I/O purpose to the corresponding pins.

For definitions of pin, port, and port group, see **Section 2.1.2.1, Terms**.

2.1.2.1 Terms

The terms described in this section are defined as follows.

- Port group:
  One port has up to 16 pins, and the number of pins differs according to the port. The multiple pins of a port share the same control registers.
- Port mode / Port:
  In port mode, a pin functions as a general-purpose I/O pin. The general-purpose I/O function is called a “port pin” and is indicated by the name Pn_m. For example, P0_7 indicates pin 7 of port 0.
- Alternative mode:
  In alternative mode, a pin functions as an I/O pin of a peripheral function. Multiple peripheral functions may be multiplexed on a pin, and control registers select the peripheral function to be used.

2.1.2.2 Overview of Pin Functions

The pin can operate in the following three different modes:

- Port mode (PMCn.PMCn_m = 0)
  The pin operates as a general purpose I/O port in port mode.
  PMn.PMn_m selects input or output.
- S/W I/O control alternative mode (PMCn.PMCn_m = 1, PIPCn.PIPCn_m = 0)
  The pin is operated by an alternative function in S/W I/O control alternative mode.
  The selection between input and output is made by S/W via the PMn.PMn_m control bits.
- Direct I/O control alternative mode (PMCn.PMCn_m = 1, PIPCn.PIPCn_m = 1)
  The pin is operated by an alternative function in direct I/O control alternative mode.
  In contrast to S/W I/O control alternative mode, input/out is directly controlled by the alternative function in this mode.

Table 2.3 shows the outline of the register settings.

Table 2.3 Pin Function Configuration (Outline)

Mode	Bit			I/O
	PMCn_m	PMn_m	PIPCn_m	
Port mode	0	0	0/1	Output mode
		1	0/1	Input mode*1
S/W I/O control alternative mode	1	0	0	Output mode
		1	0	Input mode*2
Direct I/O control alternative mode		0/1	1	Controlled by the alternative function*2

Note 1. The input buffer should be enabled (PIBCn_m = 1).
Note 2. When used as an input pin in alternative mode, be sure to set PIBCn_m = 0.

When a pin is operated in alternative mode (PMCn.PMCn_m = 1), one of different alternative functions (up to 7) can be selected by the PFCn, PFCEn, and PFCAEn registers.

- S/W I/O control alternative mode (PIPCn.PIPCn_m = 0):
  - Outputs (PMn_m = 0): ALT-OUT1 to ALT-OUT7
  - Inputs (PMn_m = 1): ALT-IN1 to ALT-IN7
- Direct I/O control alternative mode (PIPCn.PIPCn_m = 1):
  - Input/Output of ALT-OUT1 to ALT-OUT7 and ALT-IN1 to ALT-IN7 is directly controlled by the alternative function.

Table 2.4 Outline of Alternative Mode Selection (PMCn.PMCn_m = 1)

Function	Register				I/O
	PFCAE	PFCE	PFC	PM*1	
Alternative output mode 1 (ALT-OUT1)	0	0	0	0	O
Alternative input mode 1 (ALT-IN1)	0	0	0	1	I
Alternative output mode 2 (ALT-OUT2)	0	0	1	0	O
Alternative input mode 2 (ALT-IN2)	0	0	1	1	I
Alternative output mode 3 (ALT-OUT3)	0	1	0	0	O
Alternative input mode 3 (ALT-IN3)	0	1	0	1	I
Alternative output mode 4 (ALT-OUT4)	0	1	1	0	O
Alternative input mode 4 (ALT-IN4)	0	1	1	1	I
Alternative output mode 5 (ALT-OUT5)	1	0	0	0	O
Alternative input mode 5 (ALT-IN5)	1	0	0	1	I
Alternative output mode 6 (ALT-OUT6)	1	0	1	0	O
Alternative input mode 6 (ALT-IN6)	1	0	1	1	I
Alternative output mode 7 (ALT-OUT7)	1	1	0	0	O
Alternative input mode 7 (ALT-IN7)	1	1	0	1	I

Note 1. When PIPCn.PIPCn_m = 1, the I/O direction is directly controlled by the peripheral (alternative) function and PM is ignored.

When a pin is operated in alternative mode (PMCn.PMCn_m = 1), one of several alternative functions can be selected by the PFCn, PFCEn, and PFCAEn registers.

2.1.2.3 Pin Data Input/Output

The registers used for data input and output are described below.

The source of the data to be read via the PPRn register depends on pin mode.

Output data

In port mode (PMCn.PMCn_m = 0), the value of Pn.Pn_m is output from the Pn_m pin.

Input data

A read operation of the PPRn register returns either the value of the Pn_m pin, the associated bit of the port register Pn.Pn_m, or the data output by an alternative function.

The source of the data read via PPRn depends on pin mode and setting of several control bits.

Table 2.5 summarizes the differences of PPRn read modes.

Table 2.5 PPRn_m Read Values

PMC n_m	PM n_m	PIBC n_m	PIPC n_m	Mode	PPRn_m Read Value
0	1	0	X	Port input, input buffer disabled	Pn.Pn_m bit
		1		Port input, input buffer enabled	Pn_m pin
	0	X		Port push-pull output	Pn.Pn_m bit*1
1	1	X	0	S/W I/O control alternative input	Pn_m pin
	0			S/W I/O control alternative output	Alternative function internal output signal*1
	X		1	Direct I/O control alternative mode	I/O port in alternative mode: • Input: Pn_m pin • Output: alternative function internal output signal*1

Note 1. When PBDCn_m = 1, Pn_m pin level is read via PPRn_m bit.

The control registers in **Table 2.5** have the following effects:

- PMCn.PMCn_m
  This bit selects either port mode (PMCn_m = 0) or alternative mode (PMCn_m = 1).
- PMn.PMn_m
  This bit selects input (PMn_m = 1) or output (PMn_m = 0) in port mode (PMCn_m = 0) and S/W I/O control alternative mode (PMCn_m = 1, PIPCn_m = 0).
- PIBCn.PIBCn_m
  This bit disables (PIBCn_m = 0) or enables (PIBCn_m = 1) the input buffer in input port mode (PMCn_m = 0 and PMn_m = 1). When the input buffer is disabled, PPRn_m reads the Pn.Pn_m bit, otherwise the Pn_m pin level is returned.
- PIPCn.PIPCn_m
  This bit selects either the S/W or direct I/O control alternative mode.
- PBDCn.PBDCn_m
  Setting this bit to 1 in output mode enables bidirectional mode for the pin. In bidirectional mode, the level on pin Pn_m can be read from PPPn.PPRn_m.

Write to the Pn Register

The data to be output via port Pn_m in port mode (PMCn.PMCn_m = 0) is held in the port register Pn.

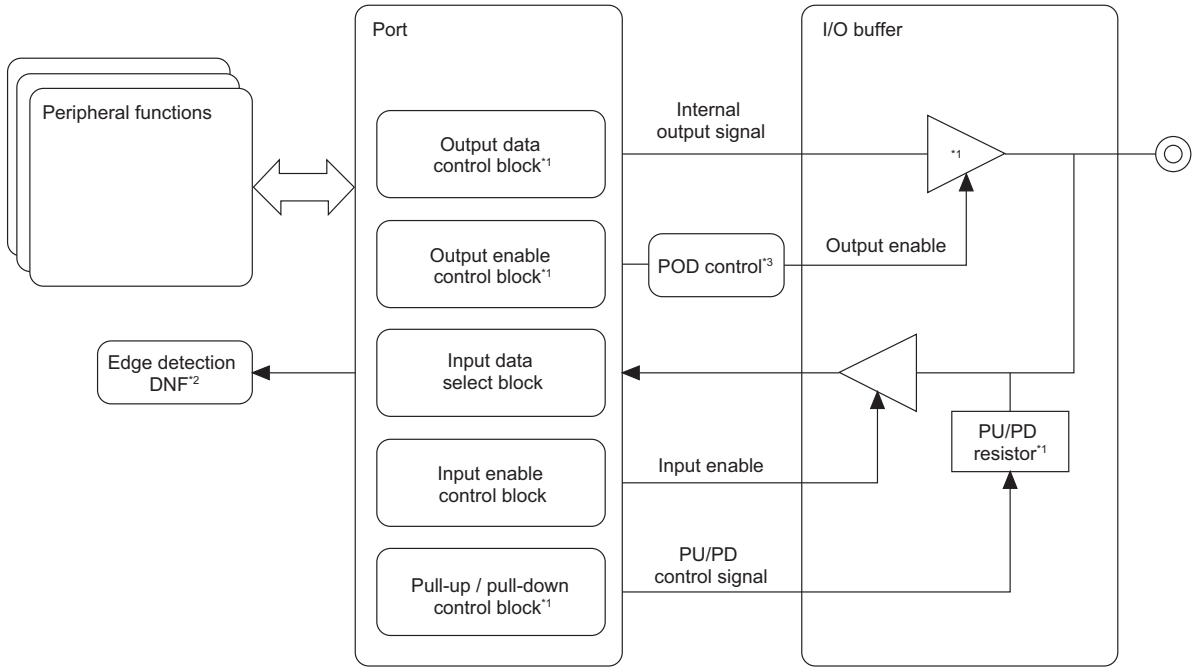
The Pn data can be rewritten in the following two different ways:

- Direct write to the Pn register
  New data can be directly written to the Pn register.
- Indirect operation to the Pn bit (set/reset/not)
  The indirect Pn operation is possible using the following two registers:
  - Port set/reset register: PSRn
    When the bit PSRn.PSRn_(m + 16) = 1, the value of bit PSRn.PSRn_m determines the value of Pn.Pn_m.
    Thus Pn_m can be set/reset without a direct write to Pn.
  - Port NOT register: PNOTn
    Setting PNOTn.PNOTn_m = 1 inverts the bit Pn.Pn_m without a direct write to Pn.

The indirect Pn set/reset/not operation provides access to single bits (not limited to one bit) of the Pn register while leaving all other Pn bits untouched.

2.1.3 Port Type

Figure 2.1 shows the overall configuration of the pins. For the details of port blocks, see **Figure 2.2**.



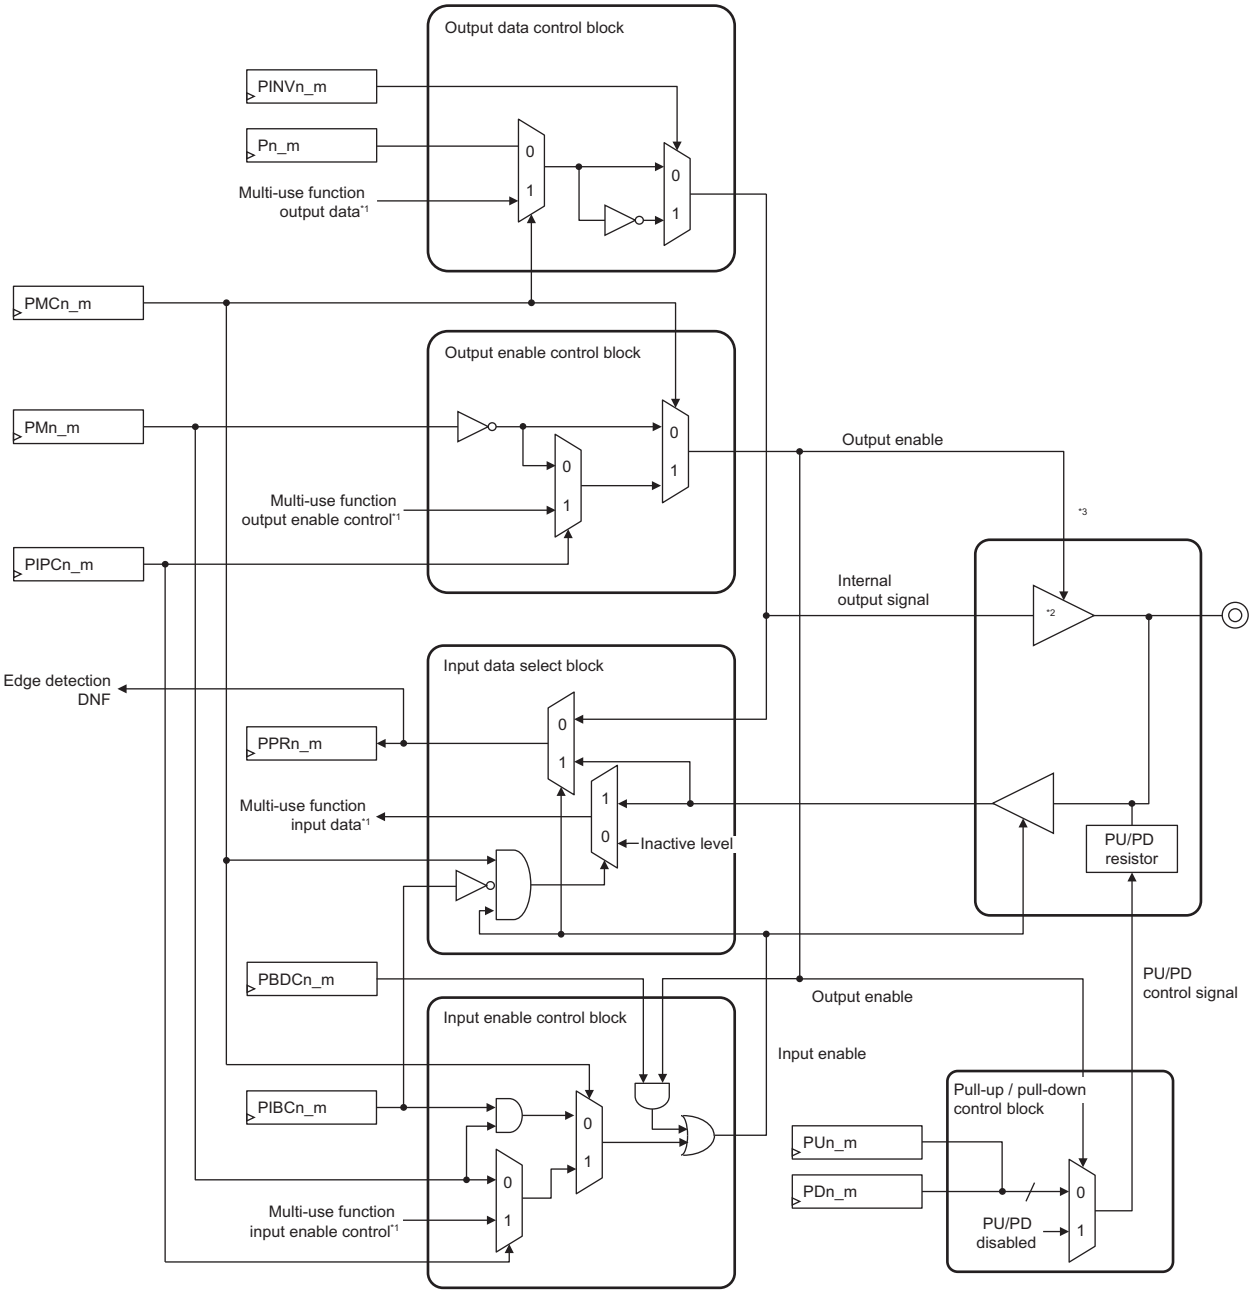
Note 1. Pins of ports P14, P15, and P16 have multiplexed analog input functions and, because these pins are only for input, they do not incorporate output-related functions. And these port groups do not incorporate pull-up and pull-down resistor.

Note 2. For details of the edge-detection DNF function and the relevant pins, see **Section 2.3.3, Edge Detection DNF**.

Note 3. For details of the POD control function and the relevant pins, see **Section 2.4, POD Control**.

Figure 2.1 Block Diagram of Pin Configuration

Figure 2.2 shows the logical circuitry of the port control functions. The diagram is only a logical reference and does not show the real circuitry.



Note 1. Multi-use function signal selected by PFCn_m, PFCEn_m, and PFCAEn_m
Note 2. Output drive strength can be set by PDSCn_m and PUCCn_m.
Note 3. The target pin of POD control forcibly disables the enabling of output when POD control is enabled.

Figure 2.2 Port Control Logic Diagram

2.1.4 Port Group Configuration Register

This section starts with an overview of all configuration registers and then presents all registers in detail. The configuration registers are classified as follows:

- **2.1.4.2, Configuration of Pin Function**
- **2.1.4.3, Pin Data Input/Output**
- **2.1.4.4, Configuration of Electrical Characteristics**
- **2.1.4.5, Port Register Protection**
- **2.1.4.6, Pin-Unit Register**

2.1.4.1 Outline

The following registers are used for the configuration of the individual pins of the port groups:

Table 2.6 Registers for Port Group Configuration

Register Name	Symbol	Register Configuration Unit	Address
Port register	Pn	Port group	<PORT_Base1> + 0000_H + n × 40_H
Port set/reset register	PSRn	Port group	<PORT_Base1> + 0004_H + n × 40_H
Port NOT register	PNOTn	Port group	<PORT_Base1> + 0008_H + n × 40_H
Port pin read register	PPRn	Port group	<PORT_Base1> + $000C_H$ + n × 40_H
Port mode register	PMn	Port group	<PORT_Base1> + 0010_H + n × 40_H
Port mode control register	PMCn	Port group	<PORT_Base1> + 0014_H + n × 40_H
Port function control register	PFCn	Port group	<PORT_Base1> + 0018_H + n × 40_H
Port function control expansion register	PFCEn	Port group	<PORT_Base1> + $001C_H$ + n × 40_H
Port mode set/reset register	PMSRn	Port group	<PORT_Base1> + 0020_H + n × 40_H
Port mode control set/reset register	PMCSRn	Port group	<PORT_Base1> + 0024_H + n × 40_H
Port function control additional expansion register	PFCAEn	Port group	<PORT_Base1> + 0028_H + n × 40_H
Port output level inversion register	PINVn	Port group	<PORT_Base1> + 0030_H + n x 40_H
Port input buffer control register	PIBCn	Port group	<PORT_Base2> + 4000_H + n × 40_H
Port bidirectional control register	PBDCn	Port group	<PORT_Base2> + 4004_H + n × 40_H
Port IP control register	PIPCn	Port group	<PORT_Base2> + 4008_H + n × 40_H
Pull-up option register	PUn	Port group	<PORT_Base2> + $400C_H$ + n × 40_H
Pull-down option register	PDn	Port group	<PORT_Base2> + 4010_H + n × 40_H
Port drive strength control register	PDSCn	Port group	<PORT_Base2> + 4018_H + n × 40_H
Port universal control register	PUCCn	Port group	<PORT_Base2> + 4028_H+ n × 40_H
Port register protection command register	PPCMDn	Port group	<PORT_Base2> + $402C_H$ + n × 40_H
Port protection status register	PPROTSn	Port group	<PORT_Base2> + 4034_H + n × 40_H
Port control register	PCRn_m	Pin	<PORT_Base1> + 2000_H + n × 40_H + m × 4_H

Note: n: Port group number
m: Bit number in a port group

Base address

The PORTn base addresses, <PORT_Base2> and <PORT_Base1> are defined in Register Addresses, **Section 2.1.1, Features**.

Register value after reset

The values after reset release depend on the port, and are not described in the following register descriptions, but are given in **Section 2.2.1.1, List of the E1M-S Port Registers**.

2.1.4.2 Configuration of Pin Function

(1) PMCn — Port Mode Control Register

This register specifies whether the individual pins of port group n are in port mode or in alternative mode.

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMCn_15	PMCn_14	PMCn_13	PMCn_12	PMCn_11	PMCn_10	PMCn_9	PMCn_8	PMCn_7	PMCn_6	PMCn_5	PMCn_4	PMCn_3	PMCn_2	PMCn_1	PMCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.7 PMCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PMCn_[15:0]	Specify the operation mode of the corresponding pin: 0: Port mode 1: Alternative mode

(2) PMCSRn — Port Mode Control Set/Reset Register

This register provides an alternative method to write data to a bit in the PMCn register.

The 16 higher-order bits of PMCSRn specify whether the data in the 16 lower-order bits of PMCSRn are written to PMCn.PMCn_m.

Even when pins being used by multiple programs belong to the same port group, the PMCSRn register allows masking of the unused bits when overwriting so that independent setting of the corresponding bits by each program is possible.

Access: This register is readable/writable in 32-bit units.
Bits 31 to 16 are always read as 0000_H. Reading bits 15 to 0 returns the value of the PMCn register.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PMCSRn_31	PMCSRn_30	PMCSRn_29	PMCSRn_28	PMCSRn_27	PMCSRn_26	PMCSRn_25	PMCSRn_24	PMCSRn_23	PMCSRn_22	PMCSRn_21	PMCSRn_20	PMCSRn_19	PMCSRn_18	PMCSRn_17	PMCSRn_16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMCSRn_15	PMCSRn_14	PMCSRn_13	PMCSRn_12	PMCSRn_11	PMCSRn_10	PMCSRn_9	PMCSRn_8	PMCSRn_7	PMCSRn_6	PMCSRn_5	PMCSRn_4	PMCSRn_3	PMCSRn_2	PMCSRn_1	PMCSRn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.8 PMCSRn Register Contents

Bit Position	Bit Name	Function
31 to 16	PMCSRn_ [31:16]	Specify whether the value of the corresponding lower bit of PMCSRn_m is written to PMCn_m: 0: PMCn_m does not depend on PMCSRn_m. 1: The value of PMCn_m is the same as that of PMCSRn_m. Example: When PMCSRn.PMCSRn_31 = 1, the value of bit PMCSRn.PMCSRn_15 is written to bit PMCn.PMCn_15 and output.
15 to 0	PMCSRn_ [15:0]	Specify the PMCn_m value when the corresponding upper bit PMCSRn_(m+16) is 1: 0: PMCn_m = 0 1: PMCn_m = 1

(3) PIPCn — Port IP Control Register

This register specifies whether the I/O direction of pin Pn_m is controlled by the port mode register PMn.PMn_m or by an alternative function.

When the Pn_m pin is operated in alternative mode (PMCn.PMCn_m = 1) and the alternative function directly controls the I/O direction of Pn_m, PIPCn.PIPCn_m must be set to 1 as well. This hands over I/O control to the alternative function and overrules the PMn.PMn_m setting.

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPCn_15	PIPCn_14	PIPCn_13	PIPCn_12	PIPCn_11	PIPCn_10	PIPCn_9	PIPCn_8	PIPCn_7	PIPCn_6	PIPCn_5	PIPCn_4	PIPCn_3	PIPCn_2	PIPCn_1	PIPCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.9 PIPCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PIPCn_[15:0]	Specify the I/O control mode: 0: I/O mode is selected by PMn.PMn_m (S/W I/O control). 1: I/O mode is selected by peripheral function (direct I/O control).

(4) PMn — Port Mode Register

The PMn register specifies whether the individual pins of port group n are in input mode or in output mode.

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMn_15	PMn_14	PMn_13	PMn_12	PMn_11	PMn_10	PMn_9	PMn_8	PMn_7	PMn_6	PMn_5	PMn_4	PMn_3	PMn_2	PMn_1	PMn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.10 PMn Register Contents

Bit Position	Bit Name	Function
15 to 0	PMn_[15:0]	Specify input/output mode of the corresponding pin: 0: Output mode (output enabled) 1: Input mode (output disabled)

NOTES

1. To use a pin in input port mode (PMCn.PMCn_m = 0 and PMn.PMn_m = 1), the input buffer must be enabled (PIBCn.PIBCn_m = 1).
2. PMn_m specifies the I/O direction in port mode (PMCn.PMCn_m = 0) and alternative mode (PMCn.PMCn_m=1) because PIPCn.PIPCn_m = 0 after reset.

(5) PMSRn — Port Mode Set/Reset Register

This register provides an alternative method to set a bit in the PMn register.

The 16 higher-order bits of PMSRn specify whether the data in the 16 lower-order bits of PMSRn are written to PMn.PMn_m.

Even when pins being used by multiple programs belong to the same port group, the PMSRn register allows masking of the unused bits when overwriting so that independent setting of the corresponding bits by each program is possible.

Access: This register is readable/writable in 32-bit units.
Bits 31 to 16 are always read as 0000_H. Reading bits 15 to 0 returns the value of the PMn register.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PMSRn_31	PMSRn_30	PMSRn_29	PMSRn_28	PMSRn_27	PMSRn_26	PMSRn_25	PMSRn_24	PMSRn_23	PMSRn_22	PMSRn_21	PMSRn_20	PMSRn_19	PMSRn_18	PMSRn_17	PMSRn_16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMSRn_15	PMSRn_14	PMSRn_13	PMSRn_12	PMSRn_11	PMSRn_10	PMSRn_9	PMSRn_8	PMSRn_7	PMSRn_6	PMSRn_5	PMSRn_4	PMSRn_3	PMSRn_2	PMSRn_1	PMSRn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.11 PMSRn Register Contents

Bit Position	Bit Name	Function
31 to 16	PMSRn_[31:16]	Specify whether the value of the corresponding lower bit of PMSRn_m is written to PMn_m: 0: PMn_m does not depend on PMSRn_m. 1: The value of PMn_m is the same as that of PMSRn_m. Example: When PMSRn.PMSRn_31 = 1, the value of bit PMSRn.PMSRn_15 is written to bit PMn.PMn_15 and output.
15 to 0	PMSRn_[15:0]	Specify the PMn_m value when the corresponding upper bit PMSRn_(m+16) is 1: 0: PMn_m = 0 1: PMn_m = 1

(6) PIBCn — Port Input Buffer Control Register

When a pin is being used in input port mode (PMCn.PMCn_m = 0 and PMn.PMn_m = 1), this register enables or disables the input buffer. However, when the pin is used as an input pin in S/W I/O control alternative mode (PMCn.PMCn_m = 1 and PIPCn.PIPCn_m = 0) or direct I/O control alternative mode (PMCn.PMCn_m = 1 and PIPCn.PIPCn_m = 1), set PIBCn.PIBCn_m = 0.

And when pins are in the both-direction mode(PBDCn.PBDCn_m-1), it is capable of selecting shared output level loop-back function and pin output level-read function with the setting of PIBCn.PIBCn_m.

Refer to **(1) PBDCn — Port Bidirectional Control Register** in **Section 2.1.4.3, Pin Data Input/Output**.

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIBCn_15	PIBCn_14	PIBCn_13	PIBCn_12	PIBCn_11	PIBCn_10	PIBCn_9	PIBCn_8	PIBCn_7	PIBCn_6	PIBCn_5	PIBCn_4	PIBCn_3	PIBCn_2	PIBCn_1	PIBCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.12 PIBCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PIBCn_[15:0]	These bits are used to enable and disable the input buffer in input port mode. 0: Input buffer is disabled. 1: Input buffer is enabled.

NOTE

When the input buffer is disabled, a shoot-through current does not flow even if the pin level is in Hi-Z state. Thus the pin does not need to be fixed to a high or low level externally.

(7) PFCn — Port Function Control Register

This register, together with the PFCEn and PFCAEn registers, specifies an alternative function of the pins.

Some alternative functions directly controls input/output of pin Pn_m. For such an alternative functions PIPCn.PIPCn_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCn_15	PFCn_14	PFCn_13	PFCn_12	PFCn_11	PFCn_10	PFCn_9	PFCn_8	PFCn_7	PFCn_6	PFCn_5	PFCn_4	PFCn_3	PFCn_2	PFCn_1	PFCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.13 PFCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PFCn_[15:0]	Specify an alternative function of a pin. See **Table 2.4, Outline of Alternative Mode Selection (PMCn.PMCn_m = 1)** for details.

(8) PFCEn — Port Function Control Expansion Register

This register, together with the PFCn and PFCAEn registers, specifies an alternative function of the pins.

Some alternative functions directly controls input/output of pin Pn_m. For such an alternative functions PIPCn.PIPCn_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCEn_15	PFCEn_14	PFCEn_13	PFCEn_12	PFCEn_11	PFCEn_10	PFCEn_9	PFCEn_8	PFCEn_7	PFCEn_6	PFCEn_5	PFCEn_4	PFCEn_3	PFCEn_2	PFCEn_1	PFCEn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.14 PFCEn Register Contents

Bit Position	Bit Name	Function
15 to 0	PFCEn_[15:0]	Specify an alternative function of a pin. See **Table 2.4, Outline of Alternative Mode Selection (PMCn.PMCn_m = 1)** for details.

(9) PFCAEn — Port Function Control Additional Expansion Register

This register, together with the PFCn and PFCEn registers, specifies an alternative function of the pins.

Some alternative functions directly controls input/output of pin Pn_m. For such an alternative functions PIPCn.PIPCn_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCAEn_15	PFCAEn_14	PFCAEn_13	PFCAEn_12	PFCAEn_11	PFCAEn_10	PFCAEn_9	PFCAEn_8	PFCAEn_7	PFCAEn_6	PFCAEn_5	PFCAEn_4	PFCAEn_3	PFCAEn_2	PFCAEn_1	PFCAEn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.15 PFCAEn Register Contents

Bit Position	Bit Name	Function
15 to 0	PFCAEn_[15:0]	Specify an alternative function of a pin. See **Table 2.4, Outline of Alternative Mode Selection (PMCn.PMCn_m = 1)** for details.

2.1.4.3 Pin Data Input/Output

(1) PBDCn — Port Bidirectional Control Register

This register enables the input buffer when a pin is used in output mode, and permits or prohibits bidirectional mode. The Pn_m pin level is read via PPRn.PPRn_m in bidirectional mode.

- Alternative output level loopback function
  When the Pn_m pin is used as the alternative output function, the actual pin output level based on the alternative output function can be looped back to the alternative input side by setting PBDCn.PBDCn_m = 1 and PIBCn.PIBCn_m= 0. For example, the pin output level based on the first alternative function can be looped back to the same alternative input side. Also the pin output level can be read via PPRn.PPRn_m.
- Pin output level read function
  When the Pn_m pin is used as the general output port function or the alternative output function, the actual pin output level can be read via PPRn.PPRn_m by setting PBDCn.PBDCn_m = 1 and PIBCn.PIBCn_m = 1. Under this setting, the pin output level will never be looped back to the alternative input side even in alternative output mode.

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PBDCn_15	PBDCn_14	PBDCn_13	PBDCn_12	PBDCn_11	PBDCn_10	PBDCn_9	PBDCn_8	PBDCn_7	PBDCn_6	PBDCn_5	PBDCn_4	PBDCn_3	PBDCn_2	PBDCn_1	PBDCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.16 PBDCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PBDCn_[15:0]	Enable/disable bidirectional mode of the corresponding pin: 0: Bidirectional mode is disabled. 1: Bidirectional mode is enabled.

(2) PPRn — Port Pin Read Register

This register reflects an actual Pn_m pin level, a Pn.Pn_m bit value, or an output level of the alternative function. The value to be read depends on various control settings as described in **Table 2.5, PPRn_m Read Values**.

Access: This register is only readable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PPRn_15	PPRn_14	PPRn_13	PPRn_12	PPRn_11	PPRn_10	PPRn_9	PPRn_8	PPRn_7	PPRn_6	PPRn_5	PPRn_4	PPRn_3	PPRn_2	PPRn_1	PPRn_0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 2.17 PPRn Register Contents

Bit Position	Bit Name	Function
15 to 0	PPRn_[15:0]	Indicate a Pn_m pin level, a Pn.Pn_m value, or alternative function output level.

(3) Pn — Port Register

This register sets and holds the Pn.Pn_m data to be output via the related Pn_m port in output port mode (PMCn.PMCn_m = 0 and PMn.PMn_m = 0).

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Pn_15	Pn_14	Pn_13	Pn_12	Pn_11	Pn_10	Pn_9	Pn_8	Pn_7	Pn_6	Pn_5	Pn_4	Pn_3	Pn_2	Pn_1	Pn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.18 Pn Register Contents

Bit Position	Bit Name	Function
15 to 0	Pn_[15:0]	Set the output level of pin m (m = 0 to 15): 0: Low level output 1: High level output

NOTE

The bits of this register can be manipulated by various means; refer to the subsection, Write to the Pn Register in **Section 2.1.2.3, Pin Data Input/Output**.

(4) PNOTn — Port NOT Register

This register enables inverting the Pn_m bit of the port register without directly writing to Pn.

Access: This register is writable in 16-bit units. The read value is always 0000_H.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PNOTn_15	PNOTn_14	PNOTn_13	PNOTn_12	PNOTn_11	PNOTn_10	PNOTn_9	PNOTn_8	PNOTn_7	PNOTn_6	PNOTn_5	PNOTn_4	PNOTn_3	PNOTn_2	PNOTn_1	PNOTn_0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 2.19 PNOTn Register Contents

Bit Position	Bit Name	Function
15 to 0	PNOTn_[15:0]	Specify if Pn.Pn_m is inverted or not: 0: Pn.Pn_m is not inverted (Pn_m → Pn_m). 1: Pn.Pn_m is inverted ($\overline{Pn\_m}$ → Pn_m)

(5) PSRn — Port Set/Reset Register

This register provides an alternative method to set a bit in the Pn register.

The 16 higher-order bits of PSRn specify whether the data in the 16 lower-order bits of PSRn are written to Pn.Pn_m.

Even when pins being used by multiple programs belong to the same port group, the PSRn register allows masking of the unused bits when overwriting so that independent setting of the corresponding bits by each program is possible.

Access: This register is readable/writable in 32-bit units.
Bits 31 to 16 are always read as 0000_H. Reading bits 15 to 0 returns the value of the PMCn register.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PSRn_31	PSRn_30	PSRn_29	PSRn_28	PSRn_27	PSRn_26	PSRn_25	PSRn_24	PSRn_23	PSRn_22	PSRn_21	PSRn_20	PSRn_19	PSRn_18	PSRn_17	PSRn_16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PSRn_15	PSRn_14	PSRn_13	PSRn_12	PSRn_11	PSRn_10	PSRn_9	PSRn_8	PSRn_7	PSRn_6	PSRn_5	PSRn_4	PSRn_3	PSRn_2	PSRn_1	PSRn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.20 PSRn Register Contents

Bit Position	Bit Name	Function
31 to 16	PSRn_[31:16]	Specify whether the value of the corresponding lower bit of PSRn_m is written to Pn_m: 0: Pn_m does not depend on PSRn_m. 1: The value of Pn_m is the same as that of PSRn_m. Example: When PSRn.PSRn_31 = 1, the value of bit PSRn.PSRn_15 is written to bit Pn.Pn_15 and output.
15 to 0	PSRn_[15:0]	Specify the Pn_m value when the corresponding upper bit PSRn_(m+16) is 1: 0: Pn_m = 0 1: Pn_m = 1

(6) PINVn — Port Output Level Inversion Register

This register enables inverting the output level from a pin. It is effective when the pin is in output mode regardless of port output mode or alternative output mode.

Access: This register is readable/writable in 32-bit units.
Updating of this register needs a correct write sequence using the PPCMDn register.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

CAUTION

The upper 16 bits are also intended for the inverted value of a port register write sequence that is to be protected. See Section 2.1.4.5, Port Register Protection for details.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 2.21 PINVn Register Contents

Bit Position	Bit Name	Function
15 to 0	PINVn_[15:0]	Specify whether the output level from a pin is inverted or not. 0: Pin output level is not inverted. 1: Pin output level is inverted.

2.1.4.4 Configuration of Electrical Characteristics

(1) PUn — Pull-Up Option Register

This register specifies whether an on-chip pull-up resistor is connected to an input pin.

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PUn_15	PUn_14	PUn_13	PUn_12	PUn_11	PUn_10	PUn_9	PUn_8	PUn_7	PUn_6	PUn_5	PUn_4	PUn_3	PUn_2	PUn_1	PUn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.22 PUn Register Contents

Bit Position	Bit Name	Function
15 to 0	PUn_[15:0]	Specify whether an on-chip pull-up resistor is connected to the corresponding pin: 0: No on-chip pull-up resistor is connected. 1: On-chip pull-up resistor is connected.

NOTES

1. Do not set PUn.PUn_m =1 and PDn.PDn_m =1 to a single pin.
2. The on-chip pull-up resistor has no effect when the pin is operated in output mode.

(2) PDn — Pull-Down Option Register

This register specifies whether an on-chip pull-down resistor is connected to an input pin.

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PDn_15	PDn_14	PDn_13	PDn_12	PDn_11	PDn_10	PDn_9	PDn_8	PDn_7	PDn_6	PDn_5	PDn_4	PDn_3	PDn_2	PDn_1	PDn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.23 PDn Register Contents

Bit Position	Bit Name	Function
15 to 0	PDn_[15:0]	Specify whether an on-chip pull-down resistor is connected to the corresponding pin: 0: No on-chip pull-down resistor is connected. 1: On-chip pull-down resistor is connected.

NOTES

1. Do not set PUn.PUn_m =1 and PDn.PDn_m =1 to a single pin.
2. The on-chip pull-down resistor has no effect when the pin is operated in output mode.

(3) PDSCn — Port Drive Strength Control Register

This register is used to configure driving ability (driving strength) of output port pins and multiplex output pin functions in combination with the PUCCn register. Specific driving ability settings may be required, depending on the pin function to be used. For details, see **Section 37 Electrical Characteristics**.

Access: This register is readable/writable in 32-bit units.
Updating of this register needs a correct write sequence using the PPCMDn register.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

CAUTION

For protected port registers, the inverse of the value of the 16 lower-order bits is written to the 16 higher-order bits as part of the sequence for writing to a protected register. See Section 2.1.4.5, Port Register Protection for details.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 2.24 PDSCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PDSCn_[15:0]	Set driving ability of output port pins and multiplex output pin functions in combination with the PUCCn register. See **Table 2.25 PUCCn Register Contents** for register setting and output driving ability.

(4) PUCCn — Port Universal Control Register

This register is used to configure driving ability (driving strength) of output port pins and multiplex output pin functions in combination with the PDSCn register. Specific driving ability settings may be required, depending on the pin function to be used. For details, see **Section 37, Electrical Characteristics**.

Access: This register is readable/writable in 32-bit units.
Updating of this register needs a correct write sequence using the PPCMDn register.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

CAUTION

For protected port registers, the inverse of the value of the 16 lower-order bits is written to the 16 higher-order bits as part of the sequence for writing to a protected register. See Section 2.1.4.5, Port Register Protection for details.

Table 2.25 PUCCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PUCCn_[15:0]	Set driving ability of output port pins and multiplex output pin functions in combination with the PDSCn register. For electrical characteristics for each setting, see **Section 37.3.4, Output Slew Rate**.

PUCCn_m	PDSCn_m	Output Driving Ability
0	0	Low
0	1	High
1	0	Mid
1	1	Setting is prohibited.

2.1.4.5 Port Register Protection

(1) PPCMDn — Port Register Protection Command Register

This register is a command register for the port register to be protected.

Access: This register is writable in 8-bit units.
The read value of bit 7 to 0 is always 0.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—
R/W	W	W	W	W	W	W	W	W

Table 2.26 PPCMDn Register Contents

Bit Position	Bit Name	Function
7 to 0	—	The protection unlock sequence is entered by writing the fixed value ($A5_H$).

(2) PPROTSn — Port Protection Status Register

This register indicates the status of a port register write sequence to be protected.

Access: This register is readable in 8-bit units.
Writing to this register is ignored.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	PPROTSn_0
R/W	R	R	R	R	R	R	R	R

Table 2.27 PPROTSn Register Contents

Bit Position	Bit Name	Function
0	PPROTSn_0	Checks a write sequence error of the port register to be protected. 0: Protection error does not occur. 1: Protection error occurs.

(3) Port Register to be Protected

- Port Drive Strength Control Register (PDSCn)
- Port Universal Control Register (PUCCn)
- Port Output Level Inversion Register (PINVn)

(4) Sequence of Writing to Port Registers for Protection

Writing to the write-protected registers is only possible with the protection unlock sequence described below.

Procedure

1) Write the fixed value ($A5_H$) to the port register protection command register PPCMDn.
2) Write the new setting to the write-protected register. Write the value after a reset to the reserved bits.
3) Write the bitwise inverse of the setting value to the same register as in step 2). Write the inverse of the value after a reset to the reserved bits.
4) Write the new setting to the same register as in step 2). Write the value after a reset to the reserved bits.

A value can only be written to a write-protected register by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting is not written to the write-protected register, and the PPROTSn_0 bit of the port protection status register PPROTSn is set to 1. (Although this is not a requirement, you can confirm if the values set in the targeted register was correctly written by checking that the setting of the PPROTSn_0 bit is 0 after step 4).)

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1) to 4) of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*1, writing to the protected register fails and the PPROTSn_0 bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. The port group configuration registers are divided into two modules. Each module includes the full set of port configuration registers, including protection-related registers.

- Port group 0
- Port groups other than port group 0

2.1.4.6 Pin-Unit Register

(1) PCRn_m — Port Control Register

Each register of a port group can be accessed via this register and a PCRn_m register can set all functions of a single pin. For example, setting bit 6 of the PCRn_m register to 1 sets bit m of the PMCn register to 1 also. Although writing to the PDSCn, PUCCn, and PINVn registers are protected, an access to them via the PCRn_m register does not require a protection unlock sequence.

CAUTIONS

- **Multiple bits in the PCRn_m register can be batch-set within the ranges described in Section 2.1.4.7, Example of Port Configuration Flow (2), Individual Setting.**
- **If the bits are batch-set out of the range for setting of PCRn_m, the pin may output an unexpected signal level.**

Access: This register is readable/writable in 32-bit units.

Value after reset: See **Section 2.2.1.1, List of the E1M-S Port Registers**.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 2.28 PCRn_m Register Contents

Bit Position	Bit Name	Function
31	—	Reserved. The read value is always 0. The write value should always be 0.
30	PINV	Same function as bit m of the PINVn register
29 to 26	—	Reserved. The read values are always 0. The write values should always be 0.
25	PUCC	Same function as bit m of the PUCCn register
24	PDSC	Same function as bit m of the PDSCn register
23 to 20	—	Reserved. The read values are always 0. The write values should always be 0.
19	PU	Same function as bit m of the PUn register
18	PD	Same function as bit m of the PDn register
17	PBDC	Same function as bit m of the PBDCn register
16	PIBC	Same function as bit m of the PIBCn register
15 to 13	—	Reserved. The read values are always 0. The write values should always be 0.
12	P	Same function as bit m of the Pn register
11 to 9	—	Reserved. The read values are always 0. The write values should always be 0.
8	PPR	Same function as bit m of the PPRn register
7	—	Reserved. The read value is always 0. The write value should always be 0.
6	PMC	Same function as bit m of the PMCn register
5	PIPC	Same function as bit m of the PIPCn register
4	PM	Same function as bit m of the PMn register
3	—	Reserved. The read value is always 0. The write value should always be 0.

Table 2.28 PCRn_m Register Contents

Bit Position	Bit Name	Function
2	PFCAE	Same function as bit m of the PFCAEn register
1	PFCE	Same function as bit m of the PFCEn register
0	PFC	Same function as bit m of the PFCn register

2.1.4.7 Example of Port Configuration Flow

The followings are examples of the port configuration flow. For port filter setting of each flow chart, see **Section 2.3.2.4, Setting Procedures of Peripheral Function DNF** or **Section 2.3.3.6, Setting Procedures of Edge Detection DNF**.

CAUTION

Even if a port is used in S/W I/O control alternative mode, it may be temporarily switched to alternative input mode in the following port configuration flows. This may occur during the period from setting of PMCn_m = 1 to that of PMn_m = 0.

(1) Batch Setting

The following shows an example to collectively set a port group.

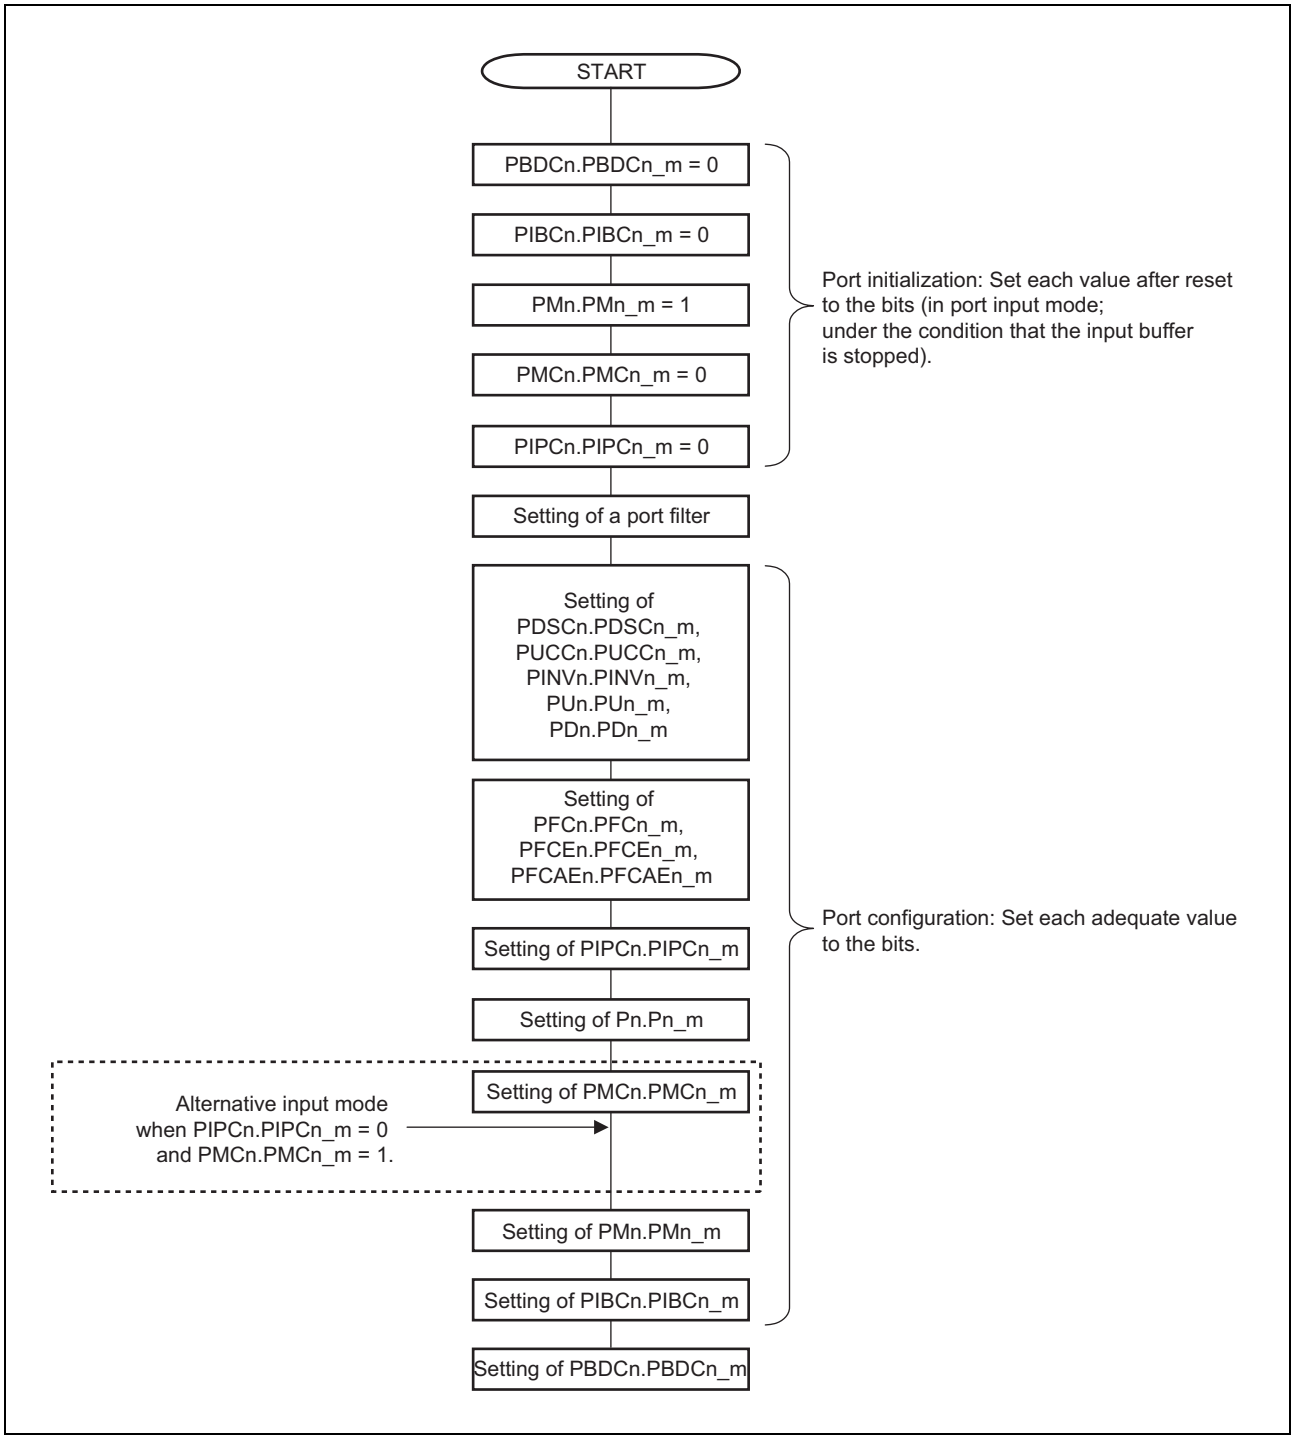

Figure 2.3 Example of Port Configuration Flow (Batch Setting)

(2) Individual Setting

The following shows an example to individually set a port group.

And it is capable of setting simultaneous bits at once within the Settable range described below by using PCRn_m register.

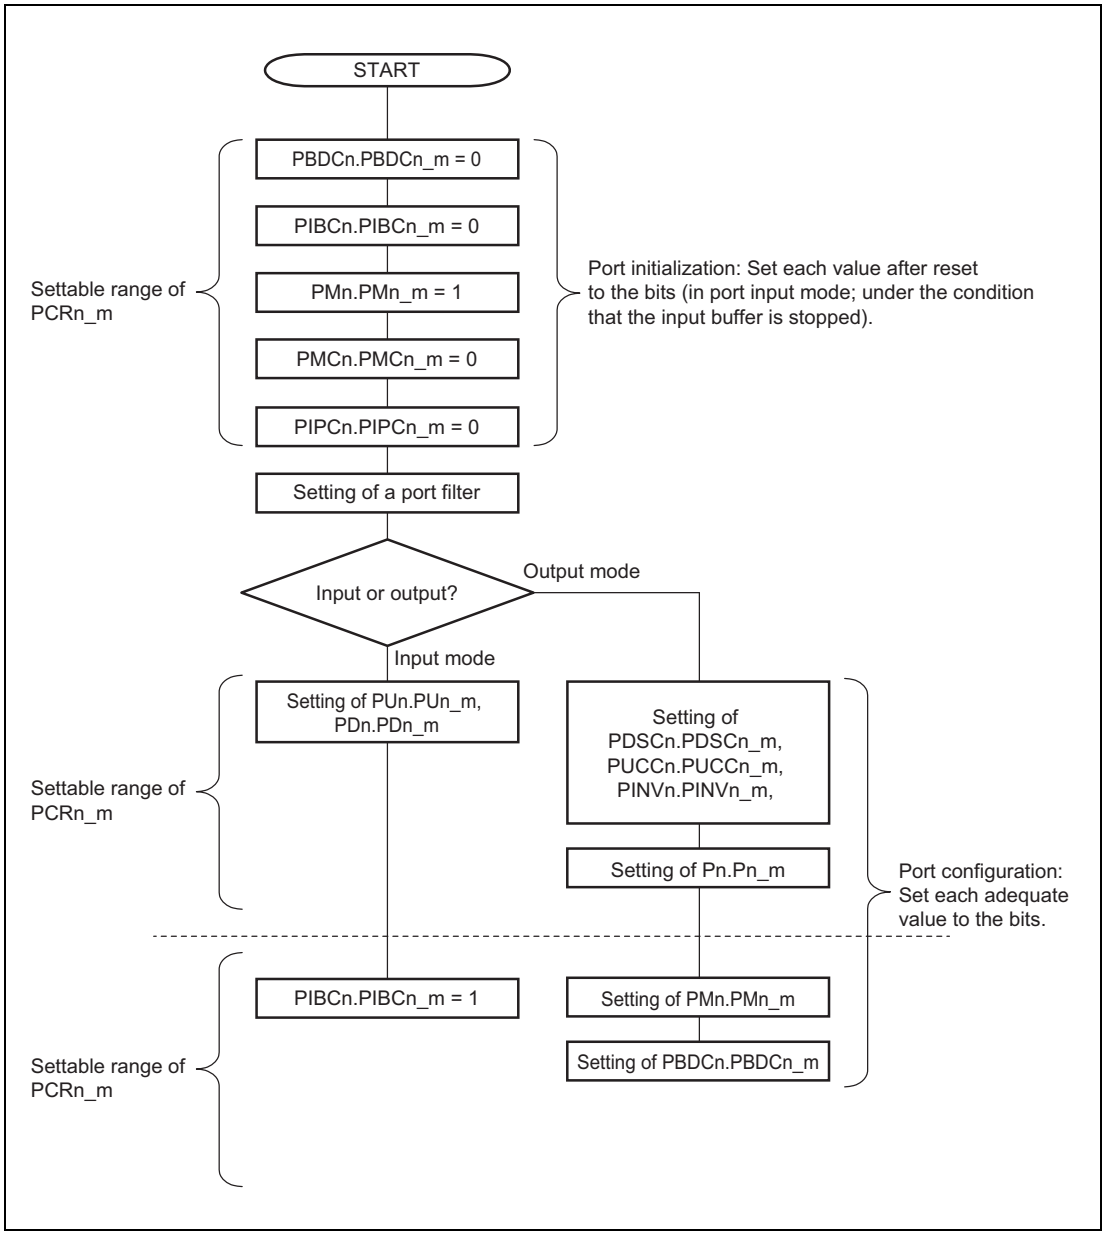

Figure 2.4 Example of Port Configuration Flow (in Port Mode)

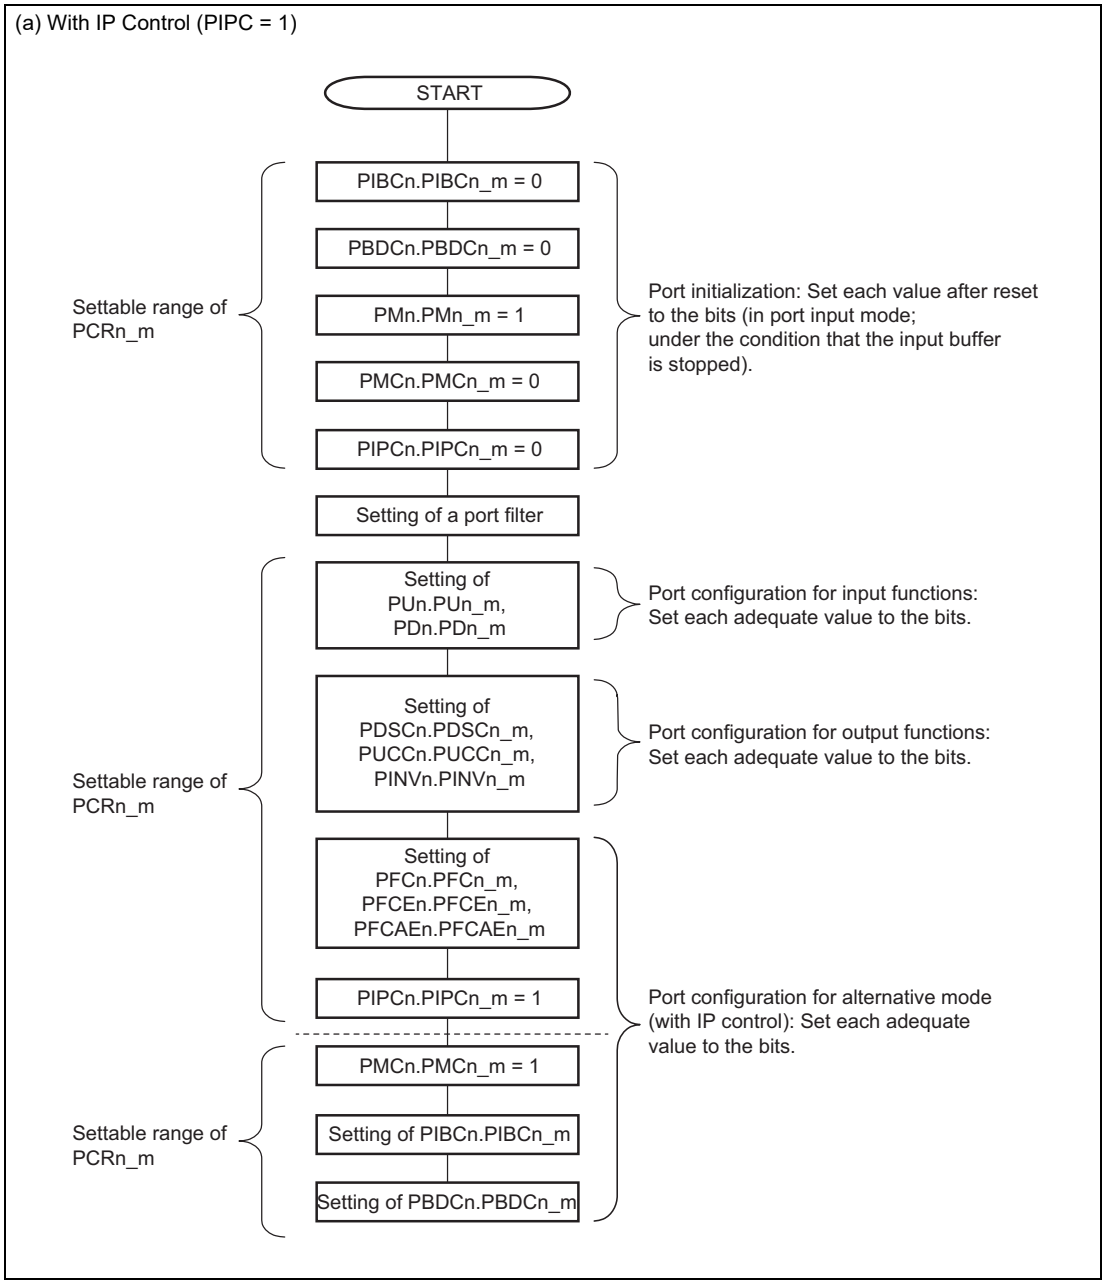

Figure 2.5 Example of Port Configuration Flow (in Alternative Mode)(1/2)

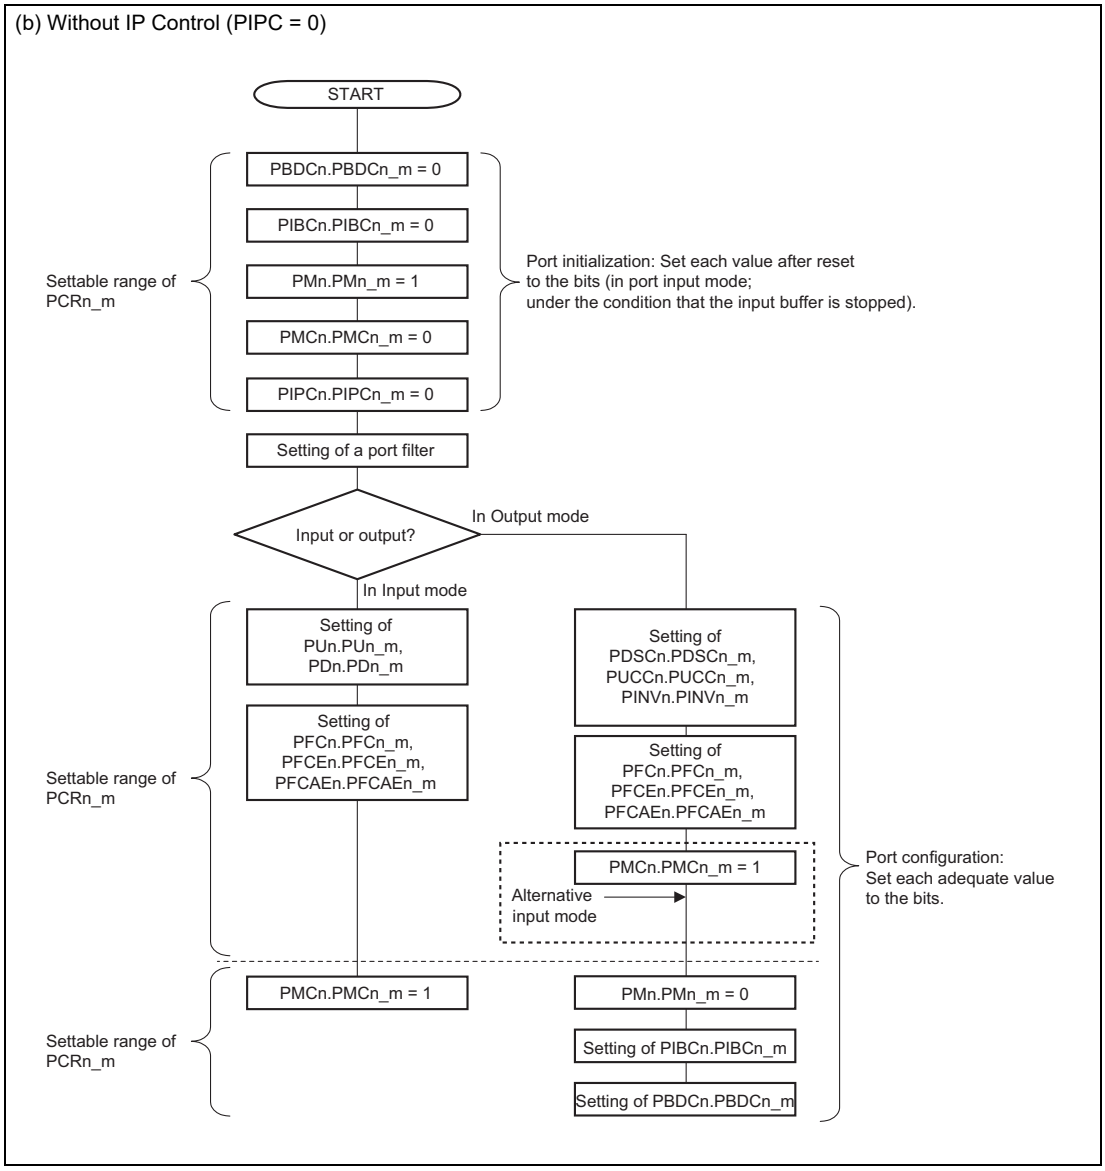

Figure 2.6 Example of Port Configuration Flow (in Alternative Mode) (2/2)

2.1.5 Functional Selection

2.1.5.1 Register Configuration in Use of the Alternative Function

When the pin alternative function is used, set PMCn_m = 1 and select the alternative numbers of PFCn_m, PFCEn_m, and PFCAEn_m. In several peripheral functions, a single alternative I/O function is allocated to multiple pins. However, such an alternative function should not be enabled in multiple pins at the same time. For example, an external interrupt input, IRQ0 is allocated to P0_3 and P2_0, but this alternative function can only be selected in either of them.

2.1.5.2 Alternative Function to be used in Direct I/O Control Alternative Mode

When the alternative functions described in **Table 2.29** are used, switch to direct I/O control alternative mode. When setting PIPCn_m = 1, the PMn_m value which has been set is ignored because the peripheral function enables or disables inputs and outputs of the buffer.

In addition, set PIPCn_m = 0 if you are using an alternative function not listed in **Table 2.29**.

Table 2.29 List of the Pins which Require PIPC Register Setting

Category	Pin Name	I/O	Pin Function	Input/Output Control by Peripheral Functions
SCIn	SCInRxD	I	Receive data input	Input through the pin is enabled when the SCI3nSCR.RE bit is enabling reception by SCI3.
	SCInTxD	O	Transmit data output	Output through the pin is enabled when the SCI3nSCR.TE bit is enabling transmission by SCI3.
	SCInSCK	I/O	Serial clock input/output	The SCI3nSCR.CKE[1:0] bits determine whether the pin is an input or output. • Asynchronous transfer CKE[1:0] = 00 : Both input and output through the pin are disabled. CKE[1:0] = 01 : The pin is an output. CKE[1:0] = 1x : Prohibited settings • Synchronous transfer CKE[1:0] = 0x : The pin is an output. CKE[1:0] = 1x : The pin is an input.
CSIHn	CSIHnTSO	O	Transmit data output (data integrity verification)	• Output control See **(3), Operation of CSIHTSSO** in **Section 13.5.9, Communication in Slave Mode**. • Input control When the CSIHnCTL1.DCS bit is enabling checking the consistency of data through CSIH, enabling the input buffer for the pin leads to the actual output level of the pin being looped back within the device.
	CSIHnTSCK	I/O	Serial clock input/output	When then setting of SCIHnCTL2 is for CSIH operation in slave mode, this pin is an input. When the setting is for master mode. it is an output.
	CSIHnTRY	I/O	Handshake signal input/output	When the setting of CSIHnCTL2 is for CSIH operation in slave mode, this pin is an output. When the setting is for master mode, it is an input.
TSG2n	TSOn1 to TSOn6	O	Timer PWM output (Hi-Z control)	This output pin is forcibly placed in the high-impedance state under TAPA control in the event of an abnormality. Output though the pin is enabled in normal operation.
ATU-IV Timer C	TIOCn0 to TIOCn3	I/O	Input capture trigger input, output compare output	This pin is an output when ATU-IV timer C is set for compare-match operation by the TIORCx register. This pin is an input when the setting is for input-capture operation.

Note: n indicates the number of a given peripheral module.

2.1.5.3 Setting of the $\overline{\text{ERROROUT\_C}}$ Pin

When an error output function of the $\overline{\text{ERROROUT\_C}}$ pin is used, enable the alternative output level loopback function for fault diagnosis.

2.1.5.4 Register Setting in Use of an Analog Input Pin

Since ANxxx(SAR-A/D) DSANxP and DSANxN(DS-A/D) for an analog input are always connected to the A/D converter, setting of a port register to select a pin function is not required. However, when an analog input pin, which is also used for a general input port, is used, set PMCn_m = 0*1 and PIBCn_m = 0 (the value after reset of the port register). This prevents shoot-through current of the input buffer on the digital side during an analog voltage input. The relevant pins of this product are port groups P14, P15, and P16.

Note 1. Some pins may not be equipped with a PMCn_m bit. For which pins are and are not thus equipped, see the list of registers in **Section 2.2, Organization of Port Groups**.

2.1.5.5 Register Setting in Use of the LVDS buffer

When the LVDS buffer of RHSB is to be used, set PM17_m = 0 to enable output. The output from the LVDS buffer actually being enabled takes at least 10 µs after setting PM17_m = 0.
The LVDS buffer and PM17_m mutually correspond as shown in the table below. " √ " indicates with a support function and " — " without. For the registers without support functions, the settings should not be modified (the settings should be fixed to their values after reset).

		E1M-S	
Port Register	**LVDS Buffer**	**BGA304**	**BGA252**
PM17_0	RHSB0SOP	√	√
	RHSB0SON		
PM17_1	RHSB0FCLP	√	√
	RHSB0FCLN		
PM17_2	RHSB1SOP	√	√
	RHSB1SON		
PM17_3	RHSB1FCLP	√	√
	RHSB1FCLN		

2.1.5.6 Selecting of Function for JTAG Port

For the connection of multiple tools to the JTAG port, the interface is multiplexed on multiple sets of pins. The interface is selected by the combination of the settings of mode pins and, if the mode pins are selecting user boot mode as the operating mode, option byte OPBT2.

When any other operating mode is selected, the setting of OPBT2 has no effect and the I/F that corresponds to the operating mode is selected. For details, refer to **Section 5.2, Operating Mode**.

2.2 Organization of Port Groups

2.2.1 E1M-S Port Function

2.2.1.1 List of the E1M-S Port Registers

Table 2.30 to **Table 2.45** show detailed bitmaps of control registers in each port group. In the bitmap field, " √ " means an effective bit and " — " means a reserved one. Reserved areas are always read as values after reset. The write value also should be a value after reset.

The pins of port groups 7, 8, and 10 are included in the BGA304 package, but not in BGA252. For the port registers of the pins not included, the setting should not be modified (the settings should be fixed to their values after reset).

Table 2.30 List of Registers in E1M-S Port Group 0

Port Group Name	Register Name	R/W	Value after Reset	Access Size	Bitmap 15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Remarks

2.2.1.2 Alternative Function List of the E1M-S Pins

Table 2.46 to **Table 2.61** show the list of alternative functions of each port pin. In the tables, " — " means a reserved bit which cannot be selected.

The pins of port groups 7, 8, and 10 is included in the BGA304 package, but not in BGA252. The setting of port registers should not be modified (the settings should be fixed to their values after reset) because the functions of the port groups, which are not included, cannot be used.

Table 2.46 List of Pin Alternative Functions in E1M-S Port Group 0

2.3 DNF

Digital Noise Filter (DNF) eliminates digital noise from external input signals. This product includes two sorts of DNF: peripheral function DNF and edge detection DNF.

2.3.1 Example of Noise Elimination

Figure 2.7 shows an example of noise elimination in peripheral function DNF and edge detection DNF. In this example, the sampling clock, the sampling count, and the current output level are set to 1/2 of the DNF input clock, two (twice), and low, respectively. "○" in the figure means that high level is detected.

In input examples 1, 2, and 3, the output level changes from low to high because the same level is detected twice in a row through sampling. In input examples 4, 5, and 6, on the other hand, the same level is not detected twice consecutively. Therefore, these inputs are regarded as noise and the input signal state is eliminated.

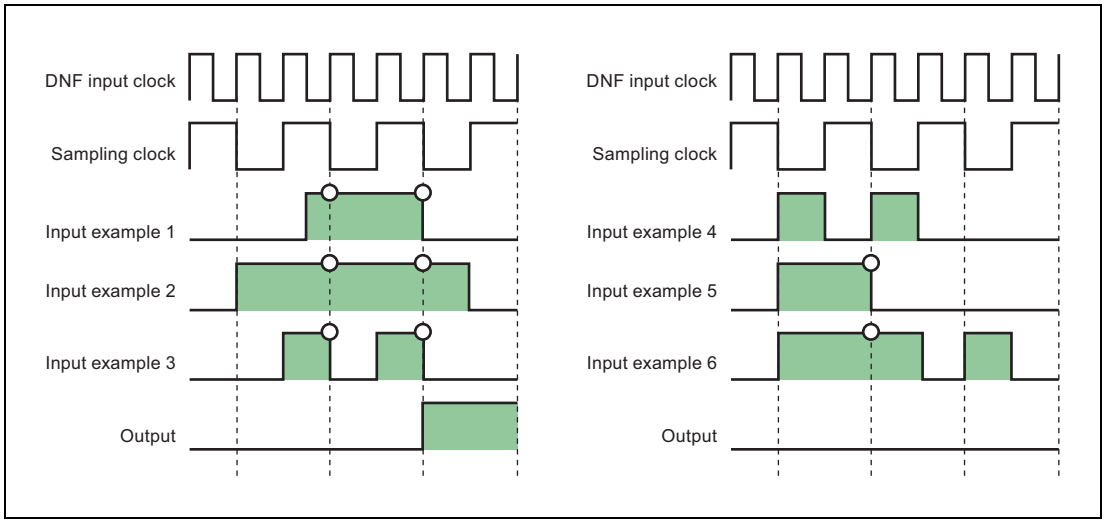

Figure 2.7 Timing Chart of Digital Noise Elimination

2.3.2 Peripheral Function DNF

2.3.2.1 Overview of Peripheral Function DNF

This DNF eliminates noise from the input function pins for the peripheral function.

Peripheral Function DNF has the following functions:

- Eliminates digital noise from input signals and outputs noiseless signals.
- Selects whether to output signals from which digital noise is eliminated or signals containing digital noise.
- Selects the digital noise elimination width from 2, 3, 4, and 5 counts of the sampling clock.
- Selects five types of sampling frequency shown below:
  1/1, 1/2, 1/4, 1/8, and 1/16 of the DNF input clock.
- The conditions for noise elimination can be set by each channel via the registers.
- The DNF input clock of DNF group number 0 is a low-speed peripheral clock.
- The DNF input clock of DNF group number 1 is an unmodulated high-speed peripheral clock.

2.3.2.2 Details of the Control Registers

Table 2.62 shows base addresses of peripheral function DNF. “n” indicates a number of the DNF group.

Table 2.62 Base Addresses of Peripheral Function DNF

DNFn	<DNFn_base> address
DNF0	FFC3 0000
DNF1	FFC3 0100

2.3.2.3 DNFP01nCTLm — Digital Noise Elimination Control Register

This register sets conditions for noise elimination of channel number m in DNF group number n.

Access: This register is readable/writable in 8-bit units.

Address: <DNFn_base> + 4_H × m (m: channel number)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NFEN	SLST[1:0]		—	—	PRS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W

Table 2.63 DNFP01nCTLm Register Contents

Bit Position	Bit Name	Function
7	NFEN	Enables/disables digital noise elimination. 0: Digital noise is not eliminated. 1: Digital noise is eliminated.
6, 5	SLST[1:0]	Specifies the sampling count for digital noise elimination. 00: Sampling count = 2 01: Sampling count = 3 10: Sampling count = 4 11: Sampling count = 5
4, 3	—	Reserved. The read values are always 0. The write values should always be 0.
2 to 0	PRS[2:0]	Specifies the sampling clock division ratio for digital noise elimination. 000: DNF input clock / 1 001: DNF input clock / 2 010: DNF input clock / 4 011: DNF input clock / 8 100: DNF input clock / 16 Other than the above: Setting is prohibited.

2.3.2.4 Setting Procedures of Peripheral Function DNF

The following shows the procedures to set peripheral function DNF. If the input level to a pin varies during (4) and (5), an unexpected signal may be input to the peripheral function. Therefore, the corresponding flag at the peripheral function side or the like should be cleared in (6).

(1) Set [2:0]PRS2-0 and [6:5]SLST1-0 in the DNFP01nCTLm register.

(2) Set [7]NFEN in the DNFP01nCTLm register. This setting can be made at the same time as (1).

(3) Set a port register to select an alternative function.

(4) Wait for the following time: sampling clock period × number of samples + DNF input clock period × 2.

(5) Enable an operation of a peripheral function in the destination to which DNF is connected.

(6) Clear the flag of peripheral function, and the like.

To change the setting while the DNF is in operation, clear the NFEN bit (bit 7) in the DNFP01nCTLm register first, and then execute the procedure in steps (1) to (6) above to remake the settings.

2.3.2.5 Peripheral Function Pin intended for DNF insertion

The signals shown in **Table 2.64** are the targets of DNF insertion. In the table below, " √ " indicates with a support function and " — " without. For the registers without support functions, the settings should not be modified (the settings should be fixed to their values after reset).

Table 2.64 DNF Insertion Targets

DNF Group Number n	DNF Channel Number m	DNF Insertion Target Pin			E1M-S	
		Pin Name	Pin Function	Peripheral Function	BGA304	BGA252
0	0	IRQ0	External interrupt input	INTC	√	√
	1	IRQ1	External interrupt input	INTC	√	√
	2	IRQ2	External interrupt input	INTC	√	√
	3	IRQ3	External interrupt input	INTC	√	√
	4	IRQ4	External interrupt input	INTC	√	√
	5	IRQ5	External interrupt input	INTC	√	√
	6	IRQ6	External interrupt input	INTC	√	√
	7	IRQ7	External interrupt input	INTC	√	√
	10	ESO2	Emergency Hiz request input (for TSG20 PWM)	TAPA2 (via PIC)	√	√
	11	ESO3	Emergency Hiz request input (for TSG21 PWM)	TAPA3 (via PIC)	√	√
1	0	ADTRG0	SAR-AD conversion startup trigger input	SAR-AD0	√	√
	1	ADTRG1	SAR-AD conversion startup trigger input	SAR-AD1	√	√
	2	TAPTS00	Hall sensor input	TSG20	√	√
	3	TAPTS01	Hall sensor input	TSG20	√	√
	4	TAPTS02	Hall sensor input	TSG20	√	√
	5	TAPTS10	Hall sensor input	TSG21	√	√
	6	TAPTS11	Hall sensor input	TSG21	√	√
	7	TAPTS12	Hall sensor input	TSG21	√	√
	8	RHSB0EMRG	Emergency signal input	RHSB0	√	√
	9	RHSB1EMRG	Emergency signal input	RHSB1	√	√

2.3.3 Edge Detection DNF

2.3.3.1 Overview of the Function

This DNF detects an effective edge of a pin input signal. The signals to be used for edge detection can be selected either before or after noise elimination.

Edge detection DNF has the following functions:

- Eliminates digital noise from input signals and outputs noiseless signals.
- Selects whether to output signals from which digital noise is eliminated or signals containing digital noise.
- Selects the digital noise elimination width from 2, 3, 4, and 5 counts of the sampling clock.
- Selects five types of sampling frequency shown below:
  1/1, 1/2, 1/4, 1/8, and 1/16 of the DNF input clock.
- The conditions for noise elimination can be set collectively by each DNF group.
- The DNF input clock is a low-speed peripheral clock.

2.3.3.2 Details of the Control Registers

Table 2.65 shows base addresses of edge detection DNF. “n” indicates a number of the DNF group.

Table 2.65 Base Addresses of Edge Detection DNF

		E1M-S	
DNFn	**<DNFn_base> address**	**BGA304**	**BGA252**
DNF2	FFC3 0200	√	√
DNF3	FFC3 0300	√	√
DNF4	FFC3 0400	√	√
DNF5	FFC3 0500	√	—
DNF6	FFC3 0600	√	√
DNF7	FFC3 0700	√	√

2.3.3.3 DNFP02nCTL — Digital Noise Elimination Control Register

This register sets noise elimination conditions which are commonly used for all channels in DNF group number n.

Access: This register is readable/writable in 8-bit units.

Address: <DNFn_base> + 00_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	SLST[1:0]		—	—	PRS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R	R	R/W	R/W	R/W

Table 2.66 DNFP02nCTL Register Contents

Bit Position	Bit Name	Function
7	—	Reserved. The read value is always 0. The write value should always be 0.
6, 5	SLST[1:0]	Specifies the sampling count for digital noise elimination. 00: Sampling count = 2 01: Sampling count = 3 10: Sampling count = 4 11: Sampling count = 5
4, 3	—	Reserved. The read values are always 0. The write values should always be 0.
2 to 0	PRS[2:0]	Specifies the sampling clock division ratio for digital noise elimination. 000: DNF input clock / 1 001: DNF input clock / 2 010: DNF input clock / 4 011: DNF input clock / 8 100: DNF input clock / 16 Other than the above: Setting is prohibited.

2.3.3.4 DNFP02nEDCm — Edge Detection Control Register

This register controls edge detection of channel number m in DNF group number n.

Access: This register is readable/writable in 8-bit units.

Address: <DNFn_base> + 4_H + 8_H × m (m: channel number)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NFEN	—	—	DMD[1:0]		—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R/W	R/W	R	R	R

Table 2.67 DNFP02nEDCm Register Contents

Bit Position	Bit Name	Function
7	NFEN	Enables/disables digital noise elimination. 0: Edge is detected for signals containing digital noise. 1: Edge is detected for signals from which digital noise is eliminated.
6, 5	—	Reserved. The read values are always 0. The write values should always be 0.
4, 3	DMD[1:0]	Enables/disables edge detection and sets edge to be detected 00: Edge detection is disabled. 01: Rising edge is detected. 10: Falling edge is detected. 11: Both edges are detected.
2 to 0	—	Reserved. The read values are always 0. The write values should always be 0.

2.3.3.5 DNFP02nEDFm — Edge Detection Flag Register

This register has an edge detection flag and a flag clear bit of channel number m in DNF group number n.

Access: This register is readable/writable in 8-bit units.

Address: <DNFn_base> + 8_H + 8_H × m (m: channel number)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	EDF	—	—	—	—	—	—	CLED
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 2.68 DNFP02nEDFm Register Contents

Bit Position	Bit Name	Function
7	EDF	This bit holds a result of edge detection based on the edge detection setting for channel number m. This bit is cleared by writing 1 to the CLED bit and continues to hold 1 unless it is cleared. Its state does not change while 1 is held, even if an edge is detected. 0: Effective edge has not been detected. 1: Effective edge has been detected.
6 to 1	—	Reserved. The read values are always 0. The write values should always be 0.
0	CLED	Writing 1 to this bit clears the status flag of EDF, bit 7. In case of contention between the writing of 1 and a setting source of bit 7, EDF clearing takes priority. Even writing 0 cannot change the state. The read value is always 0.

2.3.3.6 Setting Procedures of Edge Detection DNF

The following shows the procedures to set edge detection DNF. When edge detection is performed for signals containing digital noise, the steps with (*) can be skipped. If the input level to a pin varies during (4) and (5), an unexpected signal may be input to the peripheral function. Therefore, the corresponding flag at the peripheral function side and the like should be cleared in (6).

(1) Set [2:0]PRS2-0 and [6:5]SLST1-0 in the DNFP02nCTL register.(*)

(2) Set [7]NFEN in the DNFP02nEDCm register.

(3) Set a port register to general input port mode.

(4) Wait for the following time: sampling clock period × number of samples + DNF input clock period × 2. (*)

(5) Enable edge detection in [4:3]DMD1-0 of the DNFP02nEDCm register.

(6) Clear an edge detection flag in [0]CLED of the DNFP02nEDFm register.

Set [4:3]DMD1-0 in the DNFP02nEDCm register to 00B, and then proceed the setting again in the order from steps (1) to (6), if the setting is to be changed while edge detection DNF is under the operation.

2.3.3.7 Pn_m Pins Intended for DNF Insertion

The pins shown in **Table 2.69** are the targets of DNF insertion. In the table below, " √ " indicates with a support function and " — " without. For the registers without support functions, the settings should not be modified (the settings should be fixed to their values after reset).

Table 2.69 DNF Insertion Targets (1/2)

2.4 POD Control

2.4.1 Overview of the Function

The output buffer of the related pins shown in **Table 2.71** can be controlled according to the $\overline{\text{POD}}$ (port output disable) pin input level. This function is always available when target pins are set to output regardless of the selected function. The output buffer is controlled by the POD function independently of the bus cycle. POD control takes precedence over output settings of a port register and output designation of each IP, but its priority is lower than reset.

Table 2.70 State of the $\overline{\text{POD}}$ Pin

$\overline{\text{POD}}$ Pin State	Description
0	Pin output is not effective (high impedance).
1	Pin output is effective (each setting function).

2.5.3 Pin State

Definition of Reset State

In description of pin state, each reset state is defined as shown in **Table 2.73**.

Table 2.73 Definition of Reset State

Reset State	Definition
External reset	Reset state from an external pin ($\overline{RES}$ = L)
Internal reset	Between external reset release to internal reset release
After internal reset release	State where internal reset is released

Table 2.74 shows detailed pin states. Some pins may be excluded depending on grades and packages of this product. For the pins included in each product, see **Table 1.1, Pin Numbers and Pin Names (E1MS-BGA304)** and **Table 1.2, Pin Numbers and Pin Names (E1MS-BGA252)** in **Section 1.5, Pin Connection Diagram (Top View)**.

Table 2.74 Pin State (1/2)

Pin Function		Pin State			
		$\overline{RES}$ = L	$\overline{RES}$ = H		
Category	Pin Name (Value after Reset)	External Reset State	Before Internal Reset Release	After Internal Reset Release	Power-off Standby Mode
Clock	CK	O	O	O	Z
	XTAL	O	O	O	Z
	EXTAL	I	I	I	Z
System control	$\overline{RES}$	I (Pull-down)	I (Pull-down)	I (Pull-down)	I (Pull-down)
	MD0	I (Pull-down)	I (Pull-down)	I (Pull-down)	I (Pull-down)

Pull-down: On-chip pull-down resistor

2.5.4 Handling of Unused Pins

Examples of the handling of unused pins are listed in **Table 2.75**.

Table 2.75 Examples of the Handling of Unused Pins (1/4)

Classification	Pin	IO	Examples of handling of unused pins	On-chip pull-down/pull-up resistor
Clock	CK	O	• The pin is left open-circuit.	None
	XTAL	O	• The pin is left open-circuit.	None
	EXTAL	I	(This pin will always be used.)	None
System control	$\overline{\text{RES}}$	I	(This pin will always be used.)	This pin is equipped with an internal pull-down resistor.
	MD0, FLMODE	I	(These pins will always be used. When used in user boot mode, it is individually connected to VSS via a resistor.)	This pin is equipped with an internal pull-down resistor.
	MD1	I	• This pin is individually connected to VSS via a resistor.	This pin is equipped with an internal pull-down resistor.
Interrupt	NMI	I	• This pin is individually connected to VSS via a resistor.	This pin is equipped with an internal pull-down resistor.
ECM	$\overline{\text{ERROROUT\_M}}$	O	• The pin is left open-circuit.	None
General input/ output port	P0_m, P1_m, P2_m, P3_m, P4_m, P5_m, P6_m, P7_m, P8_m, P10_m, P11_m, P13_m	IO	[Input mode] • These pins are left open-circuit and the settings are to disable input (values after reset are PMCn_m = 0, PMn_m = 1, PIBCn_m = 0) • These pins are left open-circuit and the settings are to enable on-chip pull-up/pull-down resistors (use PUn_m,PDn_m) • These pins are individually connected to power supply or ground of each pin via a resistor. [Output mode] • These pins are left open-circuit.	The pins are equipped with internal pull-up or pull-down resistors which can be enabled by register settings.
ADCB, DS-ADC	AN000/DSAN0P, AN001/DSAN0N, AN002/DSAN1P, AN003/DSAN1N, AN10x, AN11x, AN12x, AN13x, AN14x (Analog input-only)	I	• These pins are left open-circuit.	None
	AN010/DSAN2P, AN011/DSAN2N, AN012/DSAN3P, AN013/DSAN3N, AN020/DSAN4P, AN021/DSAN4N, AN022/DSAN5P, AN023/DSAN5N, AN030/DSAN6P, AN031/DSAN6N, AN032/DSAN7P, AN033/DSAN7N, AN04x, AN05x, AN15x, AN16x, AN17x (Alternative analog input and digital input)	I	• These pins are left open-circuit and the settings are to disable input (values after reset are PMCn_m = 0, and PIBCn_m = 0)	None

Table 2.75 Examples of the Handling of Unused Pins (2/4)

Classification	Pin		IO	Examples of handling of unused pins	On-chip pull-down/pull-up resistor
RHSB LVDS buffer	RHSBxSOP, RHSBxSON, RHSBxFCLP, RHSBxFCLN		O	• These pins are left open-circuit and the settings are to disable output (value after reset is PM17_m = 1).	None
AUD RAM monitor	$\overline{\text{AUDRST}}$		I	• The pin is left open-circuit. • This pin is individually connected to VSS via a resistor.	This pin is equipped with an internal pull-down resistor.
	AUDCK, $\overline{\text{AUDSYNC}}$		I	• These pins are left open-circuit. • These pins are individually connected to VCC via a resistor.	This pin is equipped with an internal pull-up resistor.
	AUDATAn		IO	• The pin is left open-circuit.	This pin is equipped with an internal pull-up resistor.
Debug	$\overline{\text{EVTO}}$		O	• The pin is left open-circuit.	None
	$\overline{\text{EVTI}}$		I	• The pin is left open-circuit. • This pin is individually connected to VCC via a resistor.	This pin is equipped with an internal pull-up resistor.
	TDI/LPDI/ FLSCI3RX	TDI	I	• The pin is left open-circuit. • This pin is individually connected to VCC via a resistor.	This pin is equipped with an internal pull-up resistor.
		LPDI	I	• The pin is left open-circuit. • This pin is individually connected to VCC via a resistor.	This pin is equipped with an internal pull-up resistor.
		FLSCI3RX	I	• Do not select the FLSCI3RX pin function if the pin is not use in use.	The internal pull-up resistor is enabled in booting up by the boot firmware.
	TDO/LPDO/ FLSCI3TX	TDO	O	• The pin is left open-circuit.	None
		LPDO	O	• The pin is left open-circuit.	None
		FLSCI3TX	O	• Do not select the FLSCI3TX pin function if the pin is not use in use.	None
	TCK/ LPDCLKI/ FLSCI3SCK	TCK	I	• The pin is left open-circuit. • This pin is individually connected to VCC via a resistor.	This pin is equipped with an internal pull-up resistor.
		LPDCLKI	I	• The pin is left open-circuit. • This pin is individually connected to VCC via a resistor.	This pin is equipped with an internal pull-up resistor.
		FLSCI3SCK	I	• Do not select the FLSCI3SCK pin function if the pin is not use in use.	None
	TMS/$\overline{\text{EVTO}}$	TMS	I	• The pin is left open-circuit. • This pin is individually connected to VCC via a resistor.	This pin is equipped with an internal pull-up resistor.
		$\overline{\text{EVTO}}$	O	• The pin is left open-circuit.	None
	$\overline{\text{TRST}}$/$\overline{\text{LPDRST}}$		I	• This pin is individually connected to VSS via a resistor.	This pin is equipped with an internal pull-down resistor.
	$\overline{\text{DRDY}}$/ LPDCLKO	$\overline{\text{DRDY}}$	O	• The pin is left open-circuit.	None
		LPDCLKO	O	• The pin is left open-circuit.	None
NC	NC		—	• The pin is left open-circuit.	None

Table 2.75 Examples of the Handling of Unused Pins (3/4)

Classification	Pin	IO	Examples of handling of unused pins	On-chip pull-down/pull-up resistor
Power supply	EVCC		(This pin will always be used.)	—
	SYSVCC		(This pin will always be used.)	—
	VCC		(This pin will always be used.)	—
	PLLVCC		(This pin will always be used.)	—
	PLLVSS		(This pin will always be used.)	—
	VDD		(This pin will always be used.)	—
	RAMVCL		(This pin will always be used.)	—
	VSS		(This pin will always be used.)	—
	LVDVCC		• This pin is connected to VCC.	—
	LVDVSS		• This pin is connected to VSS.	—
	TTLVCC		• This pin is connected to VCC.	—
	EPTVOUT		• The pin is left open-circuit.	—
	ADSVCC, ADSVSS, ADSVREFH, ADSVREFL, ADSVCL		• Connections when the DS-ADC is not in use but the ADCB module is are listed below. ADSVCC : This pin is connected to A0VCC. ADSVSS : This pin is connected to A0VSS. ADSVREFH: This pin is connected to A0VCC. ADSVREFL: This pin is connected to A0VSS. ADSVCL : The pin is left open-circuit. • Connections when neither the DS-ADC nor the ADCB module is in use are listed below. ADSVCC : This pin is connected to EVCC. ADSVSS : This pin is connected to VSS. ADSVREFH: This pin is connected to EVCC. ADSVREFL: This pin is connected to VSS. ADSVCL : The pin is left open-circuit.	—

Table 2.75 Examples of the Handling of Unused Pins (4/4)

Classification	Pin	IO	Examples of handling of unused pins	On-chip pull-down/pull-up resistor
Power supply	A0VCC, A0VSS, A0VREFH, A1VCC, A1VSS, A1VREFH		• Connections when the ADCB module is not in use but the ADC is are listed below. A0VCC : This pin is connected to ADSVCC. A0VSS : This pin is connected to ADSVSS. A0VREFH : This pin is connected to ADSVCC. A1VCC : This pin is connected to ADSVCC. A1VSS : This pin is connected to ADSVSS. A1VREFH : This pin is connected to ADSVCC. • Connections when neither the DS-ADC nor the ADCB module is in use are listed below. A0VCC : This pin is connected to EVCC. A0VSS : This pin is connected to VSS. A0VREFH : This pin is connected to EVCC. A1VCC : This pin is connected to EVCC. A1VSS : This pin is connected to VSS. A1VREFH : This pin is connected to EVCC.	—

Note 1. For the correspondences between the various pins and the power supply or ground, see **Section 37 Electrical Characteristics**.

Note 2. Use a resistor with a value of at least 1 kΩ for externally pulling pins up or down.

Note 3. Take care regarding the resistive division effect when using an external resistor to pull up or pull down a pin that is equipped with an internal pull-up or pull-down resistor.

Section 3 CPU System

3.1 Overview

3.1.1 Block Configuration

Figure 3.1 shows the block configuration diagram.

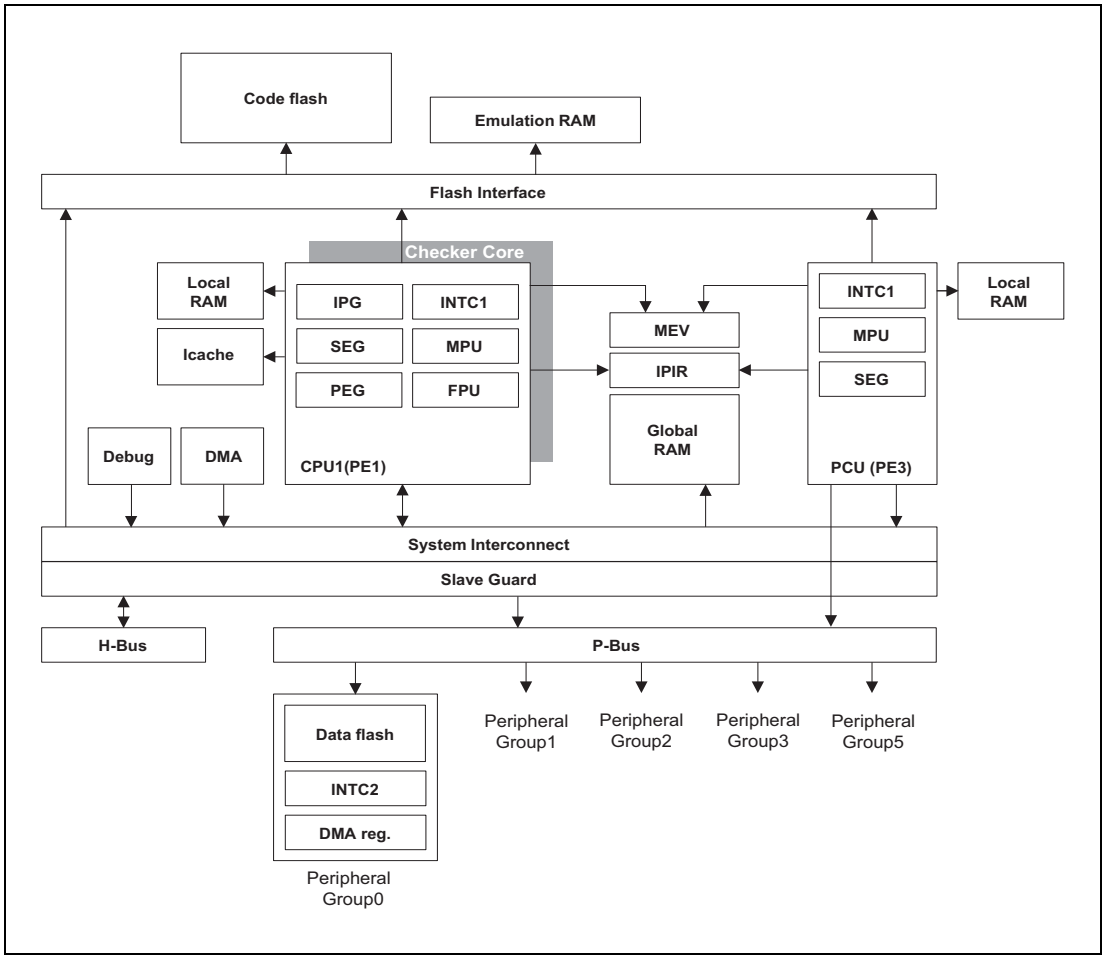

Figure 3.1 Block Configuration Diagram

CPU1 (PE1)

The RH850 G3M core is included as a main CPU. CPU1 also includes the checker core for safety assurance.

PCU (PE3)

The RH850 G3K core is included as a PCU to control peripheral IPs (peripheral control unit).

Local RAM

Each PE has a high-speed accessible local RAM.

Global RAM

The global RAM is a mass on-chip RAM that all PEs share. Some areas of this RAM function as the retention RAM.

Code Flash

A mass code flash is included for program storage. CPU1 and PCU share the code flash and they are connected with each other via the code flash interface.

Emulation RAM

It is a RAM to emulate the code flash. The programs can be replaced by controlling from an external tool without rewriting the code flash.

Data Flash

It is a flash memory being rewritable by the CPU.

P-Bus and H-Bus

The P-Bus and H-Bus connect the peripheral IPs. The P-Bus is divided into five, Peripheral Group 0 to 3, and 5.

For the correspondence between the peripheral groups and the peripheral modules/registers, see **Appendix, List of Registers**.

INTC1, INTC2

INTC1 is an interrupt controller exclusive to each PE. INTC2 is a common interrupt controller that all PEs share, being able to set the binding destination PE of an interrupt request by the registers.

DMA

Two DMA transfer modules, DMAC and DTS, are included.

Slave Guard

The slave guard is a system to prevent unauthorized access from the specific bus master, consisting of the following guard structures:

(1) PE Guard (PEG)

The PE guard is a system to prevent unauthorized access to the resources in the PE from the external master. Access from the PE itself is only enabled but all other accesses are disabled after release from the reset state.

(2) Global RAM Guard (GRG)

The global RAM guard is a system to prevent unauthorized access to the global RAM from the external master. The global RAM is in the unprotected state (accessible from all bus masters) after release from the reset state.

(3) Peripheral Guard (PBG)

The peripheral guard is a system to prevent unauthorized access to peripheral devices from the external master. Peripheral devices are in the unprotected state (accessible from all bus masters) after release from the reset state.

3.2 CPU

3.2.1 Core Functions

3.2.1.1 Features

Table 3.1 lists features of the RH850G3M core.

Table 3.1 Features of the RH850G3M Core

Item	Feature
CPU	• Advanced 32-bit architecture for embedded control • 32-bit internal data bus • Thirty-two 32-bit general-purpose registers • RISC-type instruction sets – Long-/short-format load/store instructions – Three-operand instructions – Instruction sets based on C language • CPU operating modes – User mode, supervisor mode • Address space: 4-Gbyte linear address space for both data and instructions • Instructions: A snooze instruction (SNOOZE) is included for temporary suspension by switching the CPU clock signal (CLK_CPU) off for 32 clock cycles.
Coprocessor	• A floating-point operation coprocessor (FPU) mounted – Supports single precision (32 bits) and double precision (64 bits). – Supports data types and exceptions conforming to IEEE754. – Rounding mode: Neighborhood, 0 direction, +∞ direction, and -∞ direction – Handling denormalized numbers: Rounding down to 0 or exception notification to conform to IEEE754
Exception/ Interrupt	• 16 interrupt priority levels settable for each channel • Vector selection method selectable according to performance request or memory usage – Direct branching exception vectors – Indirect branching exception vectors referring to the address table • Supports the high-speed save/restore processing of the context by the dedicated instructions (PUSHSP and POPSP) at the generation of an interrupt
Memory Management	• Memory protection function (MPU): 12 areas settable
Cache	• Instruction cache

3.2.1.2 Register Set

This subsection explains the program registers and system registers incorporated in this CPU.

(1) Program Registers

Program registers include the general-purpose registers (r0 to r31) and program counter (PC).

The general-purpose register r0 always retains 0, but the values of the registers r1 to r31 after reset are undefined.

Table 3.2 List of Program Registers

Program Register	Name	Function	Description
General-purpose registers	r0	Zero register	Always retains “0”
	r1	Assembler reserved register	Used as working register for generating addresses
	r2	Register for address and data variables (used when the real-time OS used does not use this register)	
	r3	Stack pointer (SP)	Used for generating a stack frame when a function is called
	r4	Global pointer (GP)	Used for accessing a global variable in the data area
	r5	Text pointer (TP)	Used as a register that indicates the start of the text area (area where program code is placed)
	r6 to r29	Register for addresses and data variables	
	r30	Element pointer (EP)	Used as a base pointer for generating addresses when accessing memory
	r31	Link pointer (LP)	Used when the compiler calls a function
Program counter	PC	Retains instruction addresses during execution of programs	

Note: For further descriptions of r1, r3 to r5, and r31 used for an assembler and/or C compiler, see the specification of each software development environment.

(a) General-Purpose Registers

A total of 32 general-purpose registers (r0 to r31) are provided. All of these registers can be used for either data variables or address variables.

Of the general-purpose registers, r0 to r5, r30, and r31 are assumed to be used for special purposes in software development environments, so it is necessary to note the following when using them.

1. r0, r3, and r30

   These registers are implicitly used by instructions.

   r0 is a register that always retains "0". It is used for operations that use 0 and addressing with base address being 0.

   r3 is implicitly used by the PREPARE, DISPOSE, PUSHSP, and POPSP instructions.

   r30 is used as a base pointer when the SLD instruction or SST instruction accesses memory.

2. r1, r4, r5, and r31

   These registers are implicitly used by the assembler and C compiler.

   When using these registers, register contents must first be saved so they are not lost and can be restored after the registers are used.

3. r2

   This register might be used by a real-time OS in some cases. If the real-time OS that is being used is not using r2, r2 can be used as a register for address variables or data variables.

(b) PC — Program Counter

The PC retains the address of the instruction being executed.

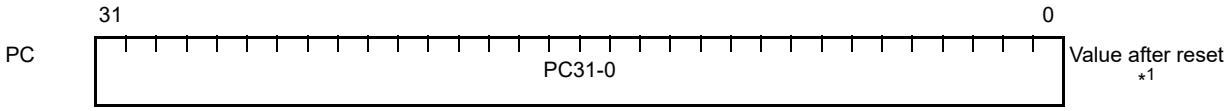

Table 3.3 PC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	PC31-1	These bits indicate the address of the instruction being executed.	R/W	*1
0	PC0	This bit is fixed to 0, and branching to an odd number address is disabled.	R/W	0

Note 1. The value after reset depends on the startup area in this product. For details, see **Section 4, Address Space**

(2) Basic System Registers

The basic system registers are used to control CPU status and to retain exception information.

System registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.4 Basic System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR0, 0	EIPC	Status save registers when acknowledging EI level exception	SV
SR1, 0	EIPSW	Status save registers when acknowledging EI level exception	SV
SR2, 0	FEPC	Status save registers when acknowledging FE level exception	SV
SR3, 0	FEPSW	Status save registers when acknowledging FE level exception	SV
SR 5, 0	PSW	Program status word	*1
SR 6, 0	FPSR	Refer to **(4) FPU Function Registers**	CU0 and SV
SR 7, 0	FPEPC	Refer to **(4) FPU Function Registers**	CU0 and SV
SR8, 0	FPST	Refer to **(4) FPU Function Registers**	CU0
SR9, 0	FPCC	Refer to **(4) FPU Function Registers**	CU0
SR10, 0	FPCFG	Refer to **(4) FPU Function Registers**	CU0
SR 11, 0	FPEC	Refer to **(4) FPU Function Registers**	CU0 and SV
SR 13, 0	EIIC	EI level exception cause	SV
SR 14, 0	FEIC	FE level exception cause	SV
SR 16, 0	CTPC	CALLT execution status save register	UM
SR 17, 0	CTPSW	CALLT execution status save register	UM
SR 20, 0	CTBP	CALLT base pointer	UM
SR 28, 0	EIWR	EI level exception working register	SV
SR 29, 0	FEWR	FE level exception working register	SV
SR 31, 0	(BSEL)	(Reserved for backwards compatibility with the V850E2 series)*2	SV
SR0, 1	MCFG0	Machine configuration	SV
SR2, 1	RBASE	Reset vector base address	SV
SR3, 1	EBASE	Exception handler vector address	SV
SR4, 1	INTBP	Base address of the interrupt handler table	SV
SR 5, 1	MCTL	CPU control	SV
SR 6, 1	PID	Processor ID	SV
SR 11, 1	SCCFG	SYSCALL operation setting	SV
SR 12, 1	SCBP	SYSCALL base pointer	SV
SR0, 2	HTCFG0	Thread configuration	SV
SR6, 2	MEA	Memory error address	SV
SR7, 2	ASID	Address space ID	SV
SR8, 2	MEI	Memory error information	SV

Note 1. The access permission differs depending on the bit. For details, see **(e) PSW — Program status word** in **(2) Basic System Registers**.

Note 2. Reserved for backwards compatibility with the V850E2 series. These registers are always read as 0. Writing to these registers is ignored.

(a) EIPC — Status save register when acknowledging EI level exception

When an EI level exception is acknowledged, the address of the instruction that was being executed when the EI level exception occurred, or of the next instruction, is saved to the EIPC register (see *section 4.1.3 Types of exceptions* in *RH850G3M User's Manual: Software*).

Because there is only one pair of EI level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

Be sure to set an even-numbered address to the EIPC register. An odd-numbered address must not be specified.

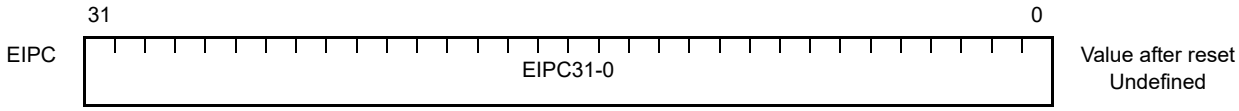

Table 3.5 EIPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	EIPC31-1	These bits indicate the PC saved when an EI level exception is acknowledged.	R/W	Undefined
0	EIPC0	This bit indicates the PC saved when an EI level exception is acknowledged. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the EIRET instruction is executed is 0.	R/W	Undefined

(b) EIPSW — Status save register when acknowledging EI level exception

When an EI level exception is acknowledged, the current PSW setting is saved to the EIPSW register.

Because there is only one pair of EI level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

CAUTION

Bits 11 to 9 cannot usually be changed since these bits are associated with debugging.

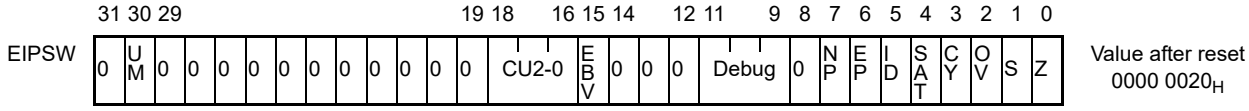

Table 3.6 EIPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
30	UM	This bit stores the PSW.UM bit setting when an EI level exception is acknowledged.	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-0	These bits store the PSW.CU2 to 0 field setting when an EI level exception is acknowledged. (CU2 and CU1 are reserved for future expansion. Be sure to clear to 0.)	R/W	0
15	EBV	This bit stores the PSW.EBV bit setting when an EI level exception is acknowledged.	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits store the PSW.Debug field when an EI level exception is acknowledged.	R/W	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	NP	This bit stores the PSW.NP bit setting when an EI level exception is acknowledged.	R/W	0
6	EP	This bit stores the PSW.EP bit setting when an EI level exception is acknowledged.	R/W	0
5	ID	This bit stores the PSW.ID bit setting when an EI level exception is acknowledged.	R/W	1
4	SAT	This bit stores the PSW.SAT bit setting when an EI level exception is acknowledged.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when an EI level exception is acknowledged.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when an EI level exception is acknowledged.	R/W	0
1	S	This bit stores the PSW.S bit setting when an EI level exception is acknowledged.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when an EI level exception is acknowledged.	R/W	0

(c) FEPC — Status save register when acknowledging FE level exception

When an FE level exception is acknowledged, the address of the instruction that was being executed when the FE level exception occurred, or of the next instruction, is saved to the FEPC register (see *section 4.1.3 Types of exceptions* in *RH850G3M User's Manual: Software*).

Because there is only one pair of FE level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

Be sure to set an even-numbered address to the FEPC register. An odd-numbered address must not be specified.

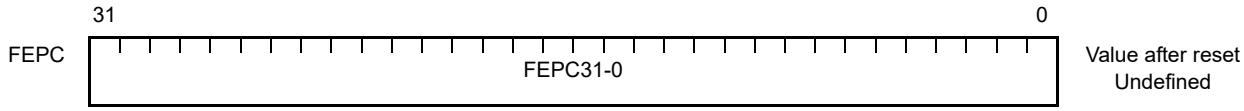

Table 3.7 FEPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	FEPC31-1	These bits indicate the PC saved when an FE level exception is acknowledged.	R/W	Undefined
0	FEPC0	This bit indicates the PC saved when an FE level exception is acknowledged. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the FERET instruction is executed is 0.	R/W	Undefined

(d) FEPSW — Status save register when acknowledging FE level exception

When an FE level exception is acknowledged, the current PSW setting is saved to the FEPSW register.

Because there is only one pair of FE level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

CAUTION

Bits 11 to 9 cannot usually be changed since these bits are associated with debugging.

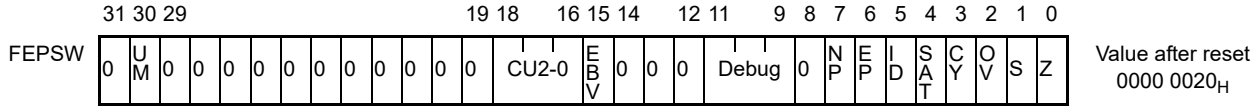

Table 3.8 FEPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R/W	0
30	UM	This bit stores the PSW.UM bit setting when an FE level exception is acknowledged.	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-0	These bits store the PSW.CU2 to 0 field setting when an FE level exception is acknowledged. (CU2 and CU1 are reserved for future expansion. Be sure to clear to 0.)	R/W	0
15	EBV	This bit stores the PSW.EBV bit setting when an FE level exception is acknowledged.	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits store the PSW.Debug field when an EI level exception is acknowledged.	R/W	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	NP	This bit stores the PSW.NP bit setting when an FE level exception is acknowledged.	R/W	0
6	EP	This bit stores the PSW.EP bit setting when an FE level exception is acknowledged.	R/W	0
5	ID	This bit stores the PSW.ID bit setting when an FE level exception is acknowledged.	R/W	1
4	SAT	This bit stores the PSW.SAT bit setting when an FE level exception is acknowledged.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when an FE level exception is acknowledged.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when an FE level exception is acknowledged.	R/W	0
1	S	This bit stores the PSW.S bit setting when an FE level exception is acknowledged.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when an FE level exception is acknowledged.	R/W	0

(e) PSW — Program status word

PSW (program status word) is a set of flags that indicate the program status (instruction execution result) and bits that indicate the operation status of the CPU (flags are bits in the PSW that are referenced by a condition instruction (Bcond, CMOV, etc.)).

CAUTIONS

1. **When the LDSR instruction is used to change the contents of bits 7 to 0 in this register, the changed contents become valid immediately after the completion of execution of the LDSR instruction.**
2. **The access permission for the PSW register differs with each bit. All bits can be read, but some bits can only be written under certain conditions. See Table 3.9, Access Permission for PSW Register for the access permission for each bit.**

Table 3.9 Access Permission for PSW Register

Bit		Access Permission When Reading	Access Permission When Writing
30	UM	UM	SV*1
18 to 16	CU2-0		SV*1
15	EBV		SV*1
11 to 9	Debug		Special*1
7	NP		SV*1
6	EP		SV*1
5	ID		SV*1
4	SAT		UM
3	CY		UM
2	OV		UM
1	S		UM
0	Z		UM

Note 1. The access permission for the whole PSW register is UM, so the PIE exception does not occur even if the register is written by using an LDSR instruction when PSW.UM is 1. In this case, writing is ignored.

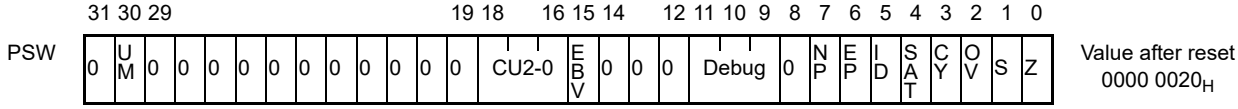

Table 3.10 PSW Register Contents (1/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
30	UM	This bit indicates that the CPU is in user mode (UM mode) 0: Supervisor mode 1: User mode	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-CU0	This bit indicates the coprocessor use permissions. When the bit corresponding to the coprocessor is 0, a coprocessor use prohibition exception is generated in response to execution of a coprocessor instruction or access to coprocessor resources (system registers). CU2 bit 18: (Reserved for future expansion. Be sure to clear to 0.) CU1 bit 17: (Reserved for future expansion. Be sure to clear to 0.) CU0 bit 16: FPU	R/W	000

Table 3.10 PSW Register Contents (2/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
15	EBV	This bit indicates the reset vector and exception vector operation. See the descriptions of the RBASE register in **(q) RBASE — Reset vector base address register** and the EBASE register in **(r) EBASE — Exception handler vector address register**.	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits are used in debugging for development tools. In normal operation, clear these bits to 0.	—	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	NP	Disables acceptance of FE level exceptions. Once an FE level exception is accepted, this bit is set to 1 and disables acceptance of EI level exceptions or FE level exceptions. For the exceptions disabled by the NP bit, see *table 4-1 Exception Cause List* in *RH850G3M User's Manual: Software*. 0 : An acceptance of FE level exceptions is enabled 1 : An acceptance of FE level exceptions is disabled	R/W	0
6	EP	This bit indicates that an exception other than an interrupt is being serviced. It is set to 1 when the corresponding exception occurs. This bit does not affect acknowledging an exception request even when it is set to 1. 0: An exception other than an interrupt is not being serviced. 1: An exception other than an interrupt is being serviced.	R/W	0
5	ID	Disables acceptance of EI level exceptions. Once an IE level exception or FE level exception is accepted, this bit is set to 1 and disables acceptance of EI level exceptions. For the exceptions disabled by the ID bit, see *table 4-1 Exception Cause List* in *RH850G3M User's Manual: Software*. This bit is also used to disable EI level exceptions from being acknowledged as a critical section while an ordinary program or interrupt is being serviced. It is set to 1 when the DI instruction is executed, and cleared to 0 when the EI instruction is executed. A change in the ID bit by the IE or DI instruction is effective from the next instruction. 0 : An acceptance of IE level exceptions is enabled 1 : An acceptance of IE level exceptions is disabled	R/W	1
4	SAT*[1]	This bit indicates that the operation result is saturated because the result of a saturated operation instruction operation has overflowed. This is a cumulative flag, so when the operation result of the saturated operation instruction becomes saturated, this bit is set to 1, but it is not cleared to 0 when the operation result for a subsequent instruction is not saturated. This bit is cleared to 0 by the LDSR instruction. This bit is neither set to 1 nor cleared to 0 when an arithmetic operation instruction is executed. 0: Not saturated 1: Saturated	R/W	0
3	CY	This bit indicates whether a carry or borrow has occurred in the operation result. 0: Carry and borrow have not occurred. 1: Carry or borrow has occurred.	R/W	0
2	OV*[1]	This bit indicates whether or not an overflow has occurred during an operation. 0: Overflow has not occurred. 1: Overflow has occurred.	R/W	0
1	S*[1]	This bit indicates whether or not the result of an operation is negative. 0: Result of operation is positive or 0. 1: Result of operation is negative	R/W	0
0	Z	This bit indicates whether or not the result of an operation is 0. 0: Result of operation is not 0. 1: Result of operation is 0.	R/W	0

Note 1. The operation result of the saturation processing is determined in accordance with the contents of the OV flag and S flag during a saturated operation. When only the OV flag is set to 1 during a saturated operation, the SAT flag is set to 1.

Operation result status	Flag status			Operation result after saturation processing
	SAT	OV	S	
Exceeded positive maximum value	1	1	0	7FFF FFFF$_H$
Exceeded negative maximum value	1	1	1	8000 0000$_H$
Positive (maximum value not exceeded)	Value prior to operation is retained.	0	0	Operation result itself
Negative (maximum value not exceeded)			1	

(f) EIIC — EI level exception source register

The EIIC register retains the source of any EI level exception that occurs. The value retained in this register is an exception code corresponding to a specific exception source.

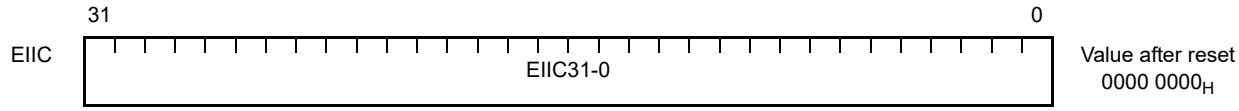

Table 3.11 EIIC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	EIIC31-0	These bits store the exception source code when an EI level exception occurs. Regarding the stored exception source code, see *Table 6.14, Interrupt Exception Handler and Priority* and *table 4-1 Exception Cause List* in *RH850G3M User's Manual: Software*. The EIIC31-16 field stores detailed exception source codes defined individually for each exception. If there is no particular definition, these bits are set to 0.	R/W	0

(g) FEIC — FE level exception source register

The FEIC register retains the source of any FE level exception that occurs. The value retained in this register is an exception code corresponding to a specific exception source.

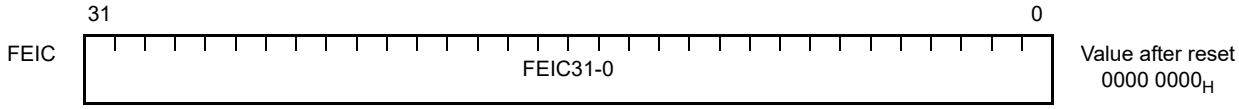

Table 3.12 FEIC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	FEIC31-0	These bits store the exception source code when an FE level exception occurs. Regarding the stored exception source code, see *Table 6.14, Interrupt Exception Handler and Priority* and *table 4-1 Exception Cause List* in *RH850G3M User's Manual: Software*. The FEIC31-16 field stores detailed exception source codes defined individually for each exception. If there is no particular definition, these bits are set to 0.	R/W	0

(h) CTPC — Status save register when executing CALLT register

When a CALLT instruction is executed, the address of the next instruction after the CALLT instruction is saved to CTPC. Be sure to set an even-numbered address to the CTPC register. An odd-numbered address must not be specified.

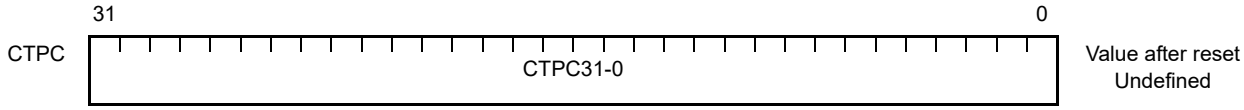

Table 3.13 CTPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	CTPC31-1	These bits indicate the PC of the instruction after the CALLT instruction.	R/W	Undefined
0	CTPC0	This bit indicates the PC of the instruction after the CALLT instruction. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the CTRET instruction is executed is 0.	R/W	Undefined

(i) CTPSW — Status save register when executing CALLT register

When a CALLT instruction is executed, some of the PSW (program status word) settings are saved to CTPSW.

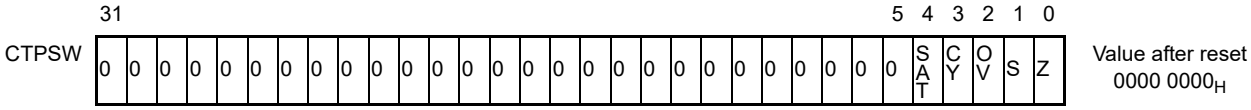

Table 3.14 CTPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
4	SAT	This bit stores the PSW.SAT bit setting when the CALLT instruction is executed.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when the CALLT instruction is executed.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when the CALLT instruction is executed.	R/W	0
1	S	This bit stores the PSW.S bit setting when the CALLT instruction is executed.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when the CALLT instruction is executed.	R/W	0

(j) CTBP — CALLT base pointer register

The CTBP register is used to specify table addresses of the CALLT instruction and generate target addresses. Be sure to set the CTBP register to a half word address.

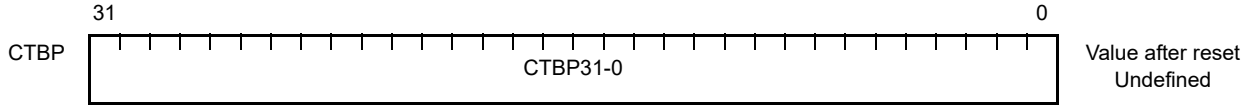

Table 3.15 CTBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	CTBP31-1	These bits indicate the base pointer address of the CALLT instruction. These bits indicate the first address in the table used by the CALLT instruction.	R/W	Undefined
0	CTBP0	These bits indicate the base pointer address of the CALLT instruction. These bits indicate the first address in the table used by the CALLT instruction. Always set this bit to 0.	R	0

(k) ASID — Address space ID register

This is the address space ID. This is used to identify the address space provided by the memory management function.

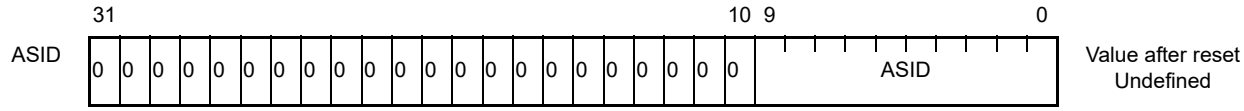

Table 3.16 ASID Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 10	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
9 to 0	ASID	This is the address space ID.	R/W	Undefined

(l) EIWR — EI level exception working register

The EIWR register is used as a working register when an EI level exception has occurred.

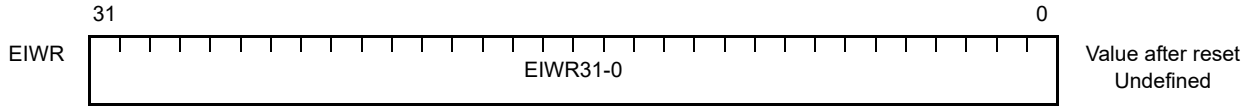

Table 3.17 EIWR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	EIWR31-0	These bits constitute a working register that can be used for any purpose during the processing of an EI level exception. Use this register for purposes such as storing the values of general-purpose registers.	R/W	Undefined

(m) FEWR — FE level exception working register

The FEWR register is used as a working register when an FE level exception has occurred.

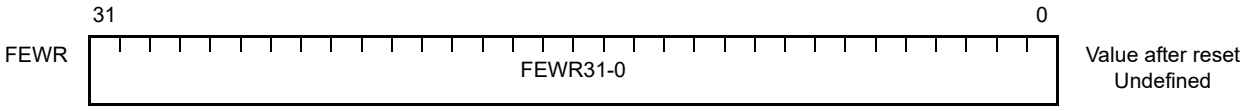

Table 3.18 FEWR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	FEWR31-0	These bits constitute a working register that can be used for any purpose during the processing of an FE level exception. Use this register for purposes such as storing the values of general-purpose registers.	R/W	Undefined

(n) HTCFG0 — Thread configuration register

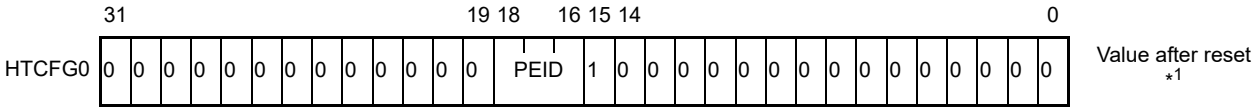

Table 3.19 HTCFG0 Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	PEID	These bits indicate the processor element number.	R	*2
15	—	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
14 to 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

Note 1. The value is 0001 8000_H in CPU1 (PE1) of this product.
Note 2. The value is 001_B in CPU1 (PE1) of this product.

(o) MEA — Memory error address register

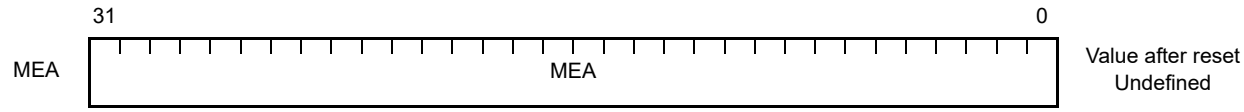

Table 3.20 MEA Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	MEA	These bits store an address when a MAE (misaligning) or MPU violation occurs.	R/W	Undefined

(p) MEI — Memory error information register

This register is used to store information about the instruction that caused the exception when a misaligned (MAE) or memory protection (MDP) exception occurs.

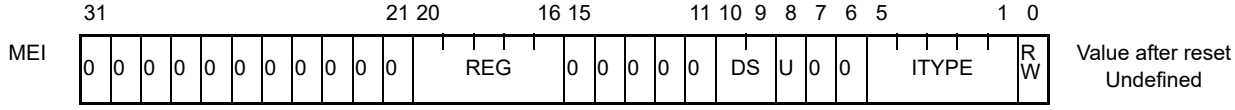

Table 3.21 MEI Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 21	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
20 to 16	REG4-0	These bits indicate the number of the source or destination register accessed by the instruction that caused the exception. For details, see **Table 3.22, Instructions Causing Exceptions and Values of MEI Register**.	R/W	Undefined
15 to 11	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
10, 9	DS	These bits indicate the type of data handled by the instruction that caused the exception.*1 0: Byte (8 bits) 1: Half word (16 bits) 2: Word (32 bits) 3: Double-word (64 bits) For details, see **Table 3.22, Instructions Causing Exceptions and Values of MEI Register**.	R/W	Undefined
8	U	These bits indicate the sign extension method of the instruction that caused the exception. 0: Signed 1: Unsigned For details, see **Table 3.22, Instructions Causing Exceptions and Values of MEI Register**.	R/W	Undefined
7, 6	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
5 to 1	ITYPE4-0	These bits indicate the instruction that caused the exception. For details, see **Table 3.22, Instructions Causing Exceptions and Values of MEI Register**.	R/W	Undefined
0	RW	This bit indicates whether the operation of the instruction that caused the exception was read (Load-memory) or write (Store-memory) 0: Read (Load-memory) 1: Write (Store-memory) For details, see **Table 3.22, Instructions Causing Exceptions and Values of MEI Register**.	R/W	Undefined

Note 1. Even if the data is divided and access is made several times due to the specifications of the hardware, the original data type indicated by the instruction is stored.

Table 3.22 Instructions Causing Exceptions and Values of MEI Register (1/2)

Instruction	REG	DS	U	RW	ITYPE
SLD.B	dst	0 (Byte)	0 (Signed)	0 (Read)	00000_B
SLD.BU	dst	0 (Byte)	1 (Unsigned)	0 (Read)	00000_B
SLD.H	dst	1 (Half-word)	0 (Signed)	0 (Read)	00000_B
SLD.HU	dst	1 (Half-word)	1 (Unsigned)	0 (Read)	00000_B

LD.B (disp16)	dst	0 (Byte)	0 (Signed)	0 (Read)	00001_B

Table 3.22 Instructions Causing Exceptions and Values of MEI Register (2/2)

Instruction	REG	DS	U	RW	ITYPE
LD.BU (disp16)	dst	0 (Byte)	1 (Unsigned)	0 (Read)	00001_B
LD.H (disp16)	dst	1 (Half-word)	0 (Signed)	0 (Read)	00001_B
LD.HU (disp16)	dst	1 (Half-word)	1 (Unsigned)	0 (Read)	00001_B
LD.W (disp16)	dst	2 (Word)	0 (Signed)	0 (Read)	00001_B
ST.B (disp16)	src	0 (Byte)	0 (Signed)	1 (Write)	00001_B
ST.H (disp16)	src	1 (Half-word)	0 (Signed)	1 (Write)	00001_B
ST.W (disp16)	src	2 (Word)	0 (Signed)	1 (Write)	00001_B
LD.B (disp23)	dst	0 (Byte)	0 (Signed)	0 (Read)	00010_B
LD.BU (disp23)	dst	0 (Byte)	1 (Unsigned)	0 (Read)	00010_B
LD.H (disp23)	dst	1 (Half-word)	0 (Signed)	0 (Read)	00010_B
LD.HU (disp23)	dst	1 (Half-word)	1 (Unsigned)	0 (Read)	00010_B
LD.W (disp23)	dst	2 (Word)	0 (Signed)	0 (Read)	00010_B
ST.B (disp23)	src	0 (Byte)	0 (Signed)	1 (Write)	00010_B
ST.H (disp23)	src	1 (Half-word)	0 (Signed)	1 (Write)	00010_B
ST.W (disp23)	src	2 (Word)	0 (Signed)	1 (Write)	00010_B
LD.DW (disp23)	dst	3 (Double-word)	0 (Signed)	0 (Read)	00010_B
ST.DW (disp23)	src	3 (Double-word)	0 (Signed)	1 (Write)	00010_B
LDL.W	dst	2 (Word)	0 (Signed)	0 (Read)	00111_B
STC.W	src	2 (Word)	0 (Signed)	1 (Write)	00111_B
CAXI	dst	2 (Word)	1 (Unsigned)	0 (Read)*1	01000_B
SET1	—	0 (Byte)	1 (Unsigned)	0 (Read)*1	01001_B
CLR1	—	0 (Byte)	1 (Unsigned)	0 (Read)*1	01001_B
NOT1	—	0 (Byte)	1 (Unsigned)	0 (Read)*1	01001_B
TST1	—	0 (Byte)	1 (Unsigned)	0 (Read)	01001_B
PREPARE	—	2 (Word)	1 (Unsigned)	1 (Write)	01100_B
DISPOSE	—	2 (Word)	1 (Unsigned)	0 (Read)	01100_B
PUSHSP	—	2 (Word)	1 (Unsigned)	1 (Write)	01101_B
POPSP	—	2 (Word)	1 (Unsigned)	0 (Read)	01101_B
SWITCH	—	1 (Half-word)	0 (Signed)	0 (Read)	10000_B
CALLT	—	1 (Half-word)	1 (Unsigned)	0 (Read)	10001_B
SYSCALL	—	2 (Word)	1 (Unsigned)	0 (Read)	10010_B
CACHE	—	—	—	0/1*2	10100_B
Interrupt (table reference)*3	—	2 (Word)	1 (Unsigned)	0 (Read)	10101_B

Note 1. This exception occurs when the instruction executes a read access.

Note 2. It depends on actual operation.

Note 3. An exception occurs when the table reference interrupt vector is read.

Note: dst: destination register number, src: source register number

(q) RBASE — Reset vector base address register

This register indicates the reset vector address when there is a reset. If the PSW.EBV bit is 0, this vector address is also used as the exception vector address.

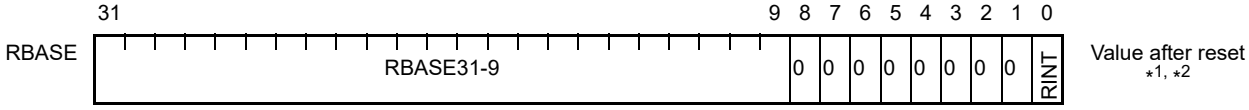

Table 3.23 RBASE Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	RBASE31-9	These bits indicate the reset vector when there is a reset. When PSW.EBV = 0, this address is also used as the exception vector. The RBASE8 to 0 bits are implicitly set to 0.	R	*1
8 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	RINT	When the RINT bit is set, the offset address of the exception handler used during interrupt servicing is decremented. See *(1) Direct vector method* in *section 4.5.1 Resets, Exceptions,* and Interrupts in *RH850G3M User's Manual: Software* for the details. This bit is valid when PSW.EBV = 0.	R	*2

Note 1. The reset vector differs depending on the startup area in this product. For details, see **Section 4, Address Space**.

Note 2. The value is 0_B in this product.

(r) EBASE — Exception handler vector address register

This register indicates the exception handler vector address. This register is valid when the PSW.EBV bit is 1.

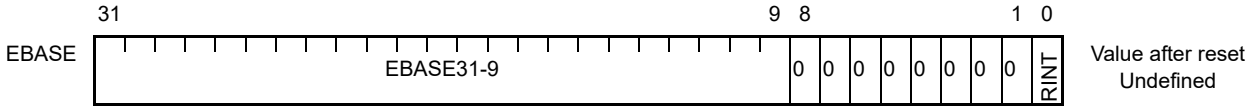

Table 3.24 EBASE Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	EBASE31-9	The exception handler routine address is changed to the address resulting from adding the offset address of each exception to the base address specified for this register. The EBASE8 to 0 bits are implicitly set to 0.	R/W	Undefined
8 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	RINT	When the RINT bit is set, the offset address of the exception handler used during interrupt servicing is decremented. See *(1) Direct vector method* in *section 4.5.1 Resets, Exceptions, and Interrupts* in *RH850G3M User's Manual: Software* for the details.	R/W	Undefined

(s) INTBP — Base address of the interrupt handler table register

This register indicates the base address of the address table when the table reference method is selected as the interrupt handler address selection method.

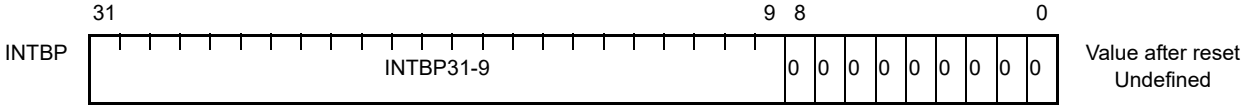

Table 3.25 INTBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	INTBP31-9	These bits indicate the base pointer address for an interrupt prescribed in the expanded specifications. The value indicated by these bits is the first address in the table used to determine the exception handler when the interrupt prescribed by the expanded specifications (EIINT0 to EIINT511) is acknowledged. The INTBP8 to 0 bits are implicitly set to 0.	R/W	Undefined
8 to 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

(t) PID — Processor ID register

The PID register retains a processor identifier that is unique to the CPU. The PID register is a read-only register.

CAUTION

The PID register indicates information used to identify the incorporated CPU core and CPU core configuration. Usage such that the software behavior varies dynamically according to the PID register information is not assumed.

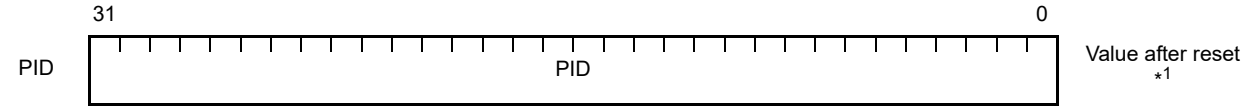

Table 3.26 PID Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 24	PID	Architecture identifier This identifier indicates the architecture of the processor.	R	05_H
23 to 8		Function identifier This identifier indicates the functions of the processor. These bits indicate whether or not functions defined per bit are implemented (1: implemented, 0: not implemented). Bit 23-11 Reserved Bit 10 Double-precision floating-point operation function Bit 9 Single-precision floating-point operation function Bit 8 Memory protection function (MPU)	R	8007_H
7 to 0		Version identifier This identifier indicates the version of the processor.	R	01_H

Note 1. The value is 0580 0701_H in this product.

(u) SCCFG — SYSCALL operation setting register

This register is used to specify operations related to the SYSCALL instruction. Be sure to set an appropriate value to this register before using the SYSCALL instruction.

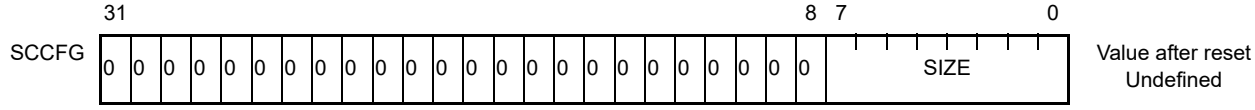

Table 3.27 SCCFG Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7 to 0	SIZE	These bits specify the maximum number of entries of a table that the SYSCALL instruction references. The maximum number of entries the SYSCALL instruction references is 1 if SIZE is 0, and 256 if SIZE is 255. By setting the maximum number of entries appropriately in accordance with the number of functions branched by the SYSCALL instruction, the memory area can be effectively used. If a vector exceeding the maximum number of entries is specified for the SYSCALL instruction, the first entry is selected. Place an error processing routine at the first entry.	R/W	Undefined

(v) SCBP — SYSCALL base pointer register

The SCBP register is used to specify a table address of the SYSCALL instruction and generate a target address. Be sure to set an appropriate value to this register before using the SYSCALL instruction.

Be sure to set a word address to the SCBP register.

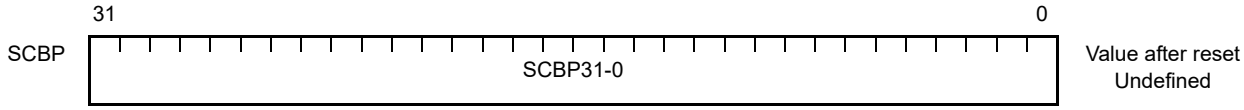

Table 3.28 SCBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	SCBP31-2	These bits indicate the base pointer address of the SYSCALL instruction. These bits indicate the first address in the table used by the SYSCALL instruction.	R/W	Undefined
1, 0	SCBP1-0	These bits indicate the base pointer address of the SYSCALL instruction. These bits indicate the first address in the table used by the SYSCALL instruction. Always set this bit to 0.	R	0

(w) MCFG0 — Machine configuration register

This register indicates the CPU configuration.

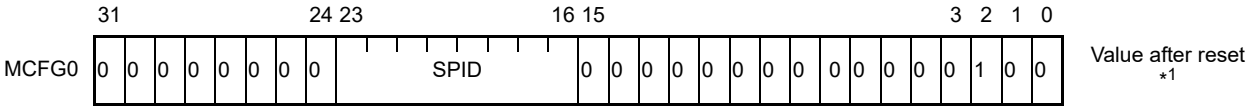

Table 3.29 MCFG0 Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 24	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
23 to 16	SPID	Bit 23 to 18: These are not supported in this product (Reserved for future expansion. Be sure to clear to 0.) Bit 17, 16: These bits indicate the system protection number.	R/W	*2
15 to 3	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
2	—	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
1, 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

Note 1. The value is 0001 0004_H in CPU1 (PE1) of this product.
Note 2. The value is 01_H in CPU1 (PE1) of this product.

(x) MCTL — Machine control register

This register is used to control the CPU.

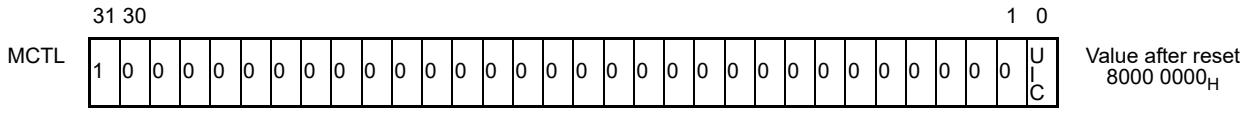

Table 3.30 MCTL Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
30 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	UIC	This bit is used to control the interrupt enable/disable operation in user mode. When this bit is set to 1, executing the EI/DI instruction become possible in user mode.	R/W	0

(3) Interrupt Function Registers

(a) Interrupt function system registers

The interrupt function system registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.31 Interrupt Function System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR7, 1	FPIPR	FPI exception interrupt priority setting	SV
SR10, 2	ISPR	Priority of interrupt being serviced	SV
SR11, 2	PMR	Interrupt priority masking	SV
SR12, 2	ICSR	Interrupt control status	SV
SR13, 2	INTCFG	Interrupt function setting	SV

(1) FPIPR — FPI exception interrupt priority setting register

This register is used to set the interrupt priority of the FPI exception.

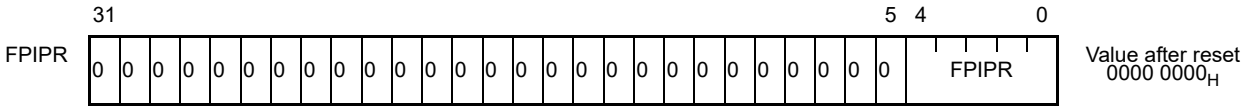

Table 3.32 FPIPR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
4 to 0	FPIPR	These bits specify the priority of the floating-point operation exception interrupt (FPI, indicating imprecision). Values from 0 to 15 should be used; the settings 16 and higher are prohibited. FPI exceptions are handled according to this interrupt priority, which is specified in advance. When generated at the same time as another interrupt with the same priority level, the FPI takes priority. **CAUTION** If these bits are set to 16 or a higher value, interrupt masking by the PMR register cannot be applied.	R/W	0

(2) ISPR — Priority of interrupt being serviced register

This register holds the priority of the EIINTn interrupt being serviced. This priority value is then used to perform priority ceiling processing when multiple interrupts are generated.

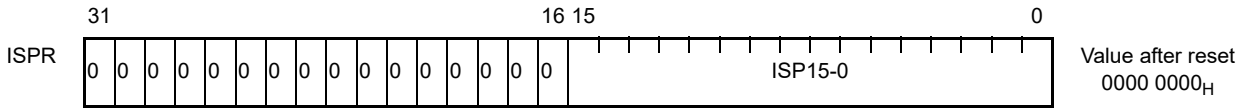

Table 3.33 ISPR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 16	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
15 to 0	ISP15-0	These bits indicate the acknowledgment status of an EIINTn interrupt with a priority*1 that corresponds to the relevant bit position. 0: An interrupt request for an interrupt whose priority corresponds to the relevant bit position has not been acknowledged. 1: An interrupt request for an interrupt whose priority corresponds to the relevant position is being serviced by the CPU core. The bit positions correspond to the following priority levels: **Bit / Priority** 0 — Priority 0 (highest) 1 — Priority 1 : 14 — Priority 14 15 — Priority 15 When an interrupt request (EIINTn) is acknowledged, the bit corresponding to the acknowledged interrupt request is automatically set to 1. If PSW.EP is 0 when the EIRET instruction is executed, the bit with the highest priority among the ISP15-0 bits that are set (0 is the highest priority) is cleared to 0.*2 While a bit in this register is set to 1, lower priority interrupts (EIINTn) and FPI exception*3 are masked. Priority level judgment is therefore not performed when the system is determining whether to acknowledge an exception, meaning that exceptions will not be acknowledged. See *section 4.1.5 Interrupt Exception Priority and Priority Masking* in *RH850G3M User's Manual: Software* for the details. When performing software-based priority control using the PMR register, be sure to clear this register by using the INTCFG.ISPC bit.	R*4	0

Note 1. See *section 4.1.5 Interrupt Exception Priority and Priority Masking* in *RH850G3M User's Manual: Software* for the details.

Note 2. Interrupt acknowledgment and auto-updating of values when the EIRET instruction is executed are disabled by setting the INTCFG.ISPC bit to 1. We recommend auto-updating, so in normal cases, clear the INTCFG.ISPC bit to 0.

Note 3. Since FPI exceptions have the same level of priority as this interrupt (EIINTn), they are affected by interrupts in the same way as the ISPR. The priority of the FPI exception is set by the FPIPR register.

Note 4. This is R or R/W, depending on the setting of the INTCFG.ISPC bit. It is recommended to use this register as a read-only (R) register.

(3) PMR — Interrupt priority masking register

This register is used to mask the specified interrupt priority.

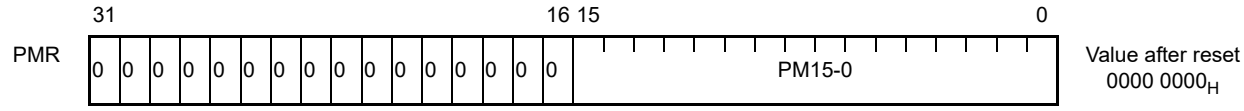

Table 3.34 PMR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 16	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
15 to 0	PM15-0	These bits mask an interrupt request with a priority level that corresponds to the relevant bit position. 0: Servicing of an interrupt request with a priority that corresponds to the relevant bit position is enabled. 1: Servicing of an interrupt request with a priority that corresponds to the relevant bit position is disabled. The bit positions correspond to the following priority levels: **Bit** / **Priority** 0 / Priority 0 (highest) 1 / Priority 1 : / : 14 / Priority 14 15 / Priority 15 (lowest) While a bit in this register is set to 1, interrupts (EIINTn) with the priority corresponding to that bit and FPI exception*1 are masked. Priority level judgment is therefore not performed when the system is determining whether to acknowledge an exception, meaning that exceptions will not be acknowledged*2.	R/W	0

Note 1. Since a FPI exception is specified as the same level of priority as that of an interrupt (EIINTn), it is affected by the PMR like interrupts. The priority of FPI exception is set by the FPIPR register.

Note 2. Specify the masks by setting the bits to 1 in order from the lowest-priority bit. For example, $FF00_H$ can be set, but $F0F0_H$ or $00FF_H$ cannot.

(4) ICSR — Interrupt control status register

This register indicates the interrupt control status in the CPU.

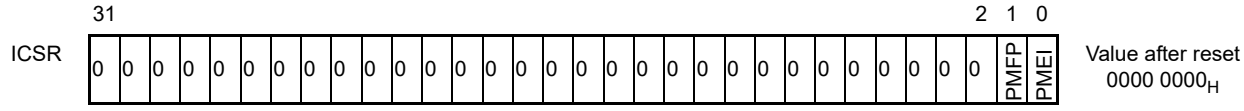

Table 3.35 ICSR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
1	PMFP	This bit indicates that an FPI exception with the priority level masked by the PMR register exists.	R	0
0	PMEI	This bit indicates that an interrupt (EIINTn) with the priority level masked by the PMR register exists	R	0

(5) INTCFG — Interrupt function setting register

This register is used to specify settings related to the CPU's internal interrupt function.

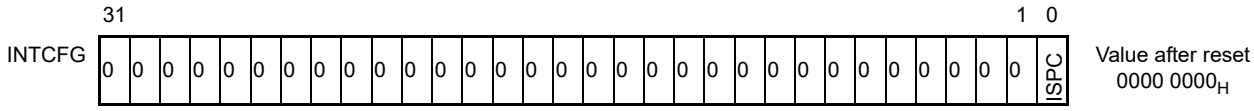

Table 3.36 INTCFG Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	ISPC	This bit changes how the ISPR register is written. 0: The ISPR register is automatically updated. Updates triggered by the program (via execution of LDSR instruction) are ignored. 1: The ISPR register is not automatically updated. Updates triggered by the program (via execution of LDSR instruction) are performed. If this bit is cleared to 0, the bits of the ISPR register are automatically set to 1 when an interrupt (EIINTn) is acknowledged, and cleared to 0 when the EIRET instruction is executed. In this case, the bits are not updated by an LDSR instruction executed by the program. If this bit is set to 1, the bits of the ISPR register are not updated by the acknowledgement of an interrupt (EIINTn) or by execution of the EIRET instruction. In this case, the bits can be updated by an LDSR instruction executed by the program. In normal cases, the ISPC bit should be cleared. When performing software-based priority control, however, set this bit to 1 and perform priority control by using the PMR register.	R/W	0

(4) FPU Function Registers

(a) Floating-point operation registers

The FPU uses the CPU general-purpose registers (r0 to r31). There are no register files used only for floating-point operations.

- Single-precision floating-point instruction
  Thirty-two 32-bit registers can be specified. These general-purpose registers correspond to r0 to r31.
- Double-precision floating-point instruction
  Sixteen 64-bit registers can be specified. Paired general-purpose registers are used as register pairs ({r1, r0}, {r3, r2} … {r31, r30}). Each register pair is specified in the instruction format with an even numbered register. Because r0 is a zero register (always holds “0”), in principle {r1, r0} should not be used by a double-precision floating-point instruction.

(b) Floating-point system registers

The FPU can use the following system registers to control floating-point operation. Reading from/ writing to a floating-point system register is performed by specifying the system register number, which consists of the register number and selection identifier, with the LDSR or STSR instructions. For details of the registers, see *section 3.4.2 Floating-Point Function System Registers* in *RH850G3M User’s Manual: Software*.

Table 3.37 FPU Function System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR6, 0	FPSR	Floating-point operation setting/status	CU0 and SV
SR7, 0	FPEPC	Floating-point operation exception program counter	CU0 and SV
SR8, 0	FPST	Floating-point status	CU0
SR9, 0	FPCC	Floating-point operation comparison result	CU0
SR10, 0	FPCFG	Floating-point function setting	CU0
SR11, 0	FPEC	Floating-point operation exception control	CU0 and SV

(5) MPU function registers

(a) MPU function system registers

The MPU function system registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.38 MPU Function System Registers (1/2)

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR0, 5	MPM	Memory protection operation mode setting	SV
SR1, 5	MPRC	MPU region control	SV
SR4, 5	MPBRGN	MPU base region number	SV
SR5, 5	MPTRGN	MPU end region number	SV
SR8, 5	MCA	Memory protection setting check address	SV
SR9, 5	MCS	Memory protection setting check size	SV
SR10, 5	MCC	Memory protection setting check command	SV
SR11, 5	MCR	Memory protection setting check result	SV
SR0, 6	MPLA0	Protection area minimum address	SV
SR1, 6	MPUA0	Protection area maximum address	SV
SR2, 6	MPAT0	Protection area attribute	SV
SR4, 6	MPLA1	Protection area minimum address	SV
SR5, 6	MPUA1	Protection area maximum address	SV
SR6, 6	MPAT1	Protection area attribute	SV
SR8, 6	MPLA2	Lower address of the protection area	SV
SR9, 6	MPUA2	Protection area maximum address	SV
SR10, 6	MPAT2	Protection area attribute	SV
SR12, 6	MPLA3	Protection area minimum address	SV
SR13, 6	MPUA3	Protection area maximum address	SV
SR14, 6	MPAT3	Protection area attribute	SV
SR16, 6	MPLA4	Protection area minimum address	SV
SR17, 6	MPUA4	Protection area maximum address	SV
SR18, 6	MPAT4	Protection area attribute	SV
SR20, 6	MPLA5	Protection area minimum address	SV
SR21, 6	MPUA5	Protection area maximum address	SV
SR22, 6	MPAT5	Protection area attribute	SV
SR24, 6	MPLA6	Protection area minimum address	SV
SR25, 6	MPUA6	Protection area maximum address	SV
SR26, 6	MPAT6	Protection area attribute	SV
SR28, 6	MPLA7	Protection area minimum address	SV
SR29, 6	MPUA7	Protection area maximum address	SV
SR30, 6	MPAT7	Protection area attribute	SV
SR0, 7	MPLA8	Protection area minimum address	SV
SR1, 7	MPUA8	Protection area maximum address	SV
SR2, 7	MPAT8	Protection area attribute	SV
SR4, 7	MPLA9	Protection area minimum address	SV
SR5, 7	MPUA9	Protection area maximum address	SV

Table 3.38 MPU Function System Registers (2/2)

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR6, 7	MPAT9	Protection area attribute	SV
SR8, 7	MPLA10	Protection area minimum address	SV
SR9, 7	MPUA10	Protection area maximum address	SV
SR10, 7	MPAT10	Protection area attribute	SV
SR12, 7	MPLA11	Protection area minimum address	SV
SR13, 7	MPUA11	Protection area maximum address	SV
SR14, 7	MPAT11	Protection area attribute	SV
SR16, 7	MPLA12	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV
SR17, 7	MPUA12	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV
SR18, 7	MPAT12	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV
SR20, 7	MPLA13	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV
SR21, 7	MPUA13	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV
SR22, 7	MPAT13	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV
SR24, 7	MPLA14	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV
SR25, 7	MPUA14	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV
SR26, 7	MPAT14	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV
SR28, 7	MPLA15	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV
SR29, 7	MPUA15	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV
SR30, 7	MPAT15	(Not implemented. A value of 0 is returned when read and writing is ignored.)	SV

Note 1. The number of the MPLAn, MPUAn, and MPATn registers incorporated is dependent on the product. The number of the protection area in this product is 12 (n = 0 to 11).

(1) MPM — Memory protection operation mode register

The memory protection mode register is used to define the basic operating state of the memory protection function.

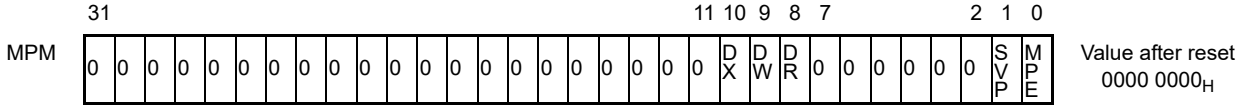

Table 3.39 MPM Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 11	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
10	DX	This bit is not supported in this product. (DX is reserved for future expansion. Be sure to clear to 0.)	R	0
9	DW	This bit is not supported in this product. (DW is reserved for future expansion. Be sure to clear to 0.)	R	0
8	DR	This bit is not supported in this product. (DR is reserved for future expansion. Be sure to clear to 0.)	R	0
7 to 2	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
1	SVP	In SV mode. (when PSW.UM = 0), this bit is used to specify whether to restrict access according to the SX, SW, and SR bits of the MPAT register for each protection area.*1 0: As usual, implicitly enable all access in SV mode. 1: Restrict access according to the SX, SW, and SR bits even in SV mode.*2	R/W	0
0	MPE	This bit is used to specify whether to enable or disable MPU function. 0: Disable 1: Enable	R/W	0

Note 1. If the SVP bit is set to 1, access will be restricted in accord with the setting for each protection area, even in SV mode. Therefore, specify the protection area before setting the SVP bit to prevent restriction of access by the program itself.

Note 2. If access is restricted in SV mode, execution of MDP exceptions or the MIP exception handling itself might not be possible depending on the settings. Be careful to specify settings so that access to the memory area necessary for the exception handler and exception handling is permitted.

(2) MPRC — MPU region control register

Bits used to perform special memory protection function operations are located in this register.

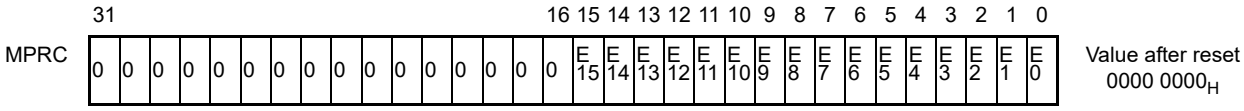

Table 3.40 MPRC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 16	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
15 to 12	E15-E12	These are not supported in this product. (Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 0	E11-E0	These are the enable bits for each protection area. Bit En is a copy of bit MPATn.E (where n = 11 to 0). The number of the protection areas in this product is 12.	R/W	0

(3) MPBRGN — MPU base region register

This register indicates the minimum usable MPU area number.

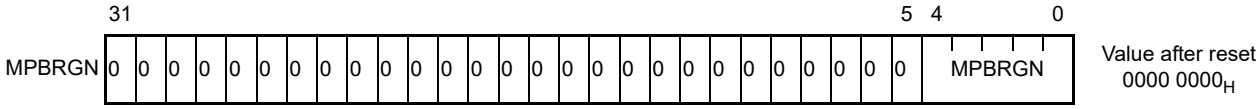

Table 3.41 MPBRGN Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
4 to 0	MPBRGN	These bits indicate the smallest number of an MPU area. These bits are always read as 0.	R	0

(4) MPTRGN — MPU end region register

This register indicates the maximum usable MPU area number + 1.

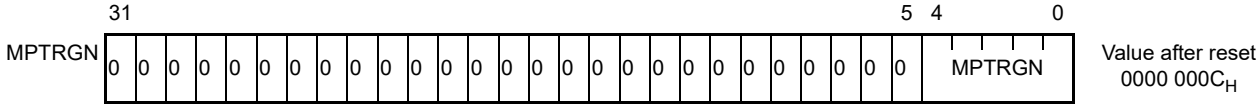

Table 3.42 MPTRGN Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
4 to 0	MPTRGN	These bits indicate the largest number of an MPU area plus one. These bits always indicate the maximum number of MPU areas that the hardware can support. The number of the protection areas in this product is 12.	R	12

(5) MCA — Memory protection setting check address register

This register is used to specify the base address of the area for which a memory protection setting check is to be performed.

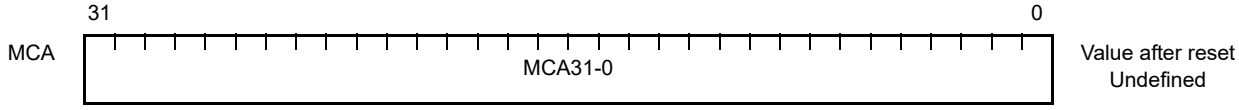

Table 3.43 MCA Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	MCA31-0	These bits are used to specify the start address of the memory area subject to a memory protection setting check in bytes.	R/W	Undefined

(6) MCS — Memory protection setting check size register

This register is used to specify the size of the area for which a memory protection setting check is to be performed.

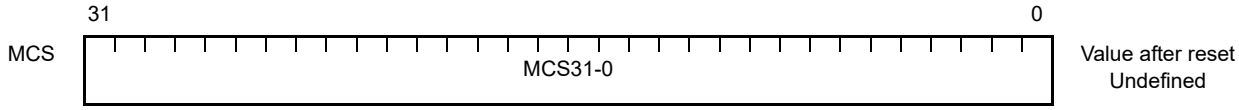

Table 3.44 MCS Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	MCS31-0	These bits specify the size of the target area to specify the size of memory area subject to a memory protection setting check in bytes. These bits specify the size in bytes of a memory area that is subject to a memory protection setting. Checking in areas below the address value in the MCS register is not possible because the specified size is handled as an unsigned integer. Do not set 0000 0000_H in the MCS register.	R/W	Undefined

(7) MCC — Memory protection setting check command register

This command register is used to start a memory protection setting check.

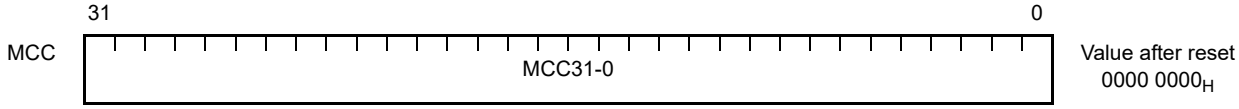

Table 3.45 MCC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	MCC31-MCC0	When any value is written to the MCC register, a memory protection setting check starts. Setting the MCA and MCS registers and then writing to this register leads to storage of the result of checking in the MCR register. Since writing any value to this register starts the check, doing so does not require any extra registers when r0 is used as a source register. The result of checking is reflected in MCR according to any area setting regardless of the setting of the PSW.UM bit. The value read from the MCC register is always 0000 0000_H.	R/W	0

(8) MCR — Memory protection setting check result register

This register is used to store the results of a memory protection setting check.

Be sure to clear bit 31 to 9, 7, and 6.

CAUTIONS

1. **If the area for which checking is specified crosses 0000 0000$_H$, the area is judged to have been specified incorrectly, and the MCR.OV bit is set to 1. For this reason, in access to the results of checking, check the MCR.OV bit and confirm that the result is valid (OV = 0) before using any results of checking.**
2. **With the default settings (for MPM.DX, MPM.DW, MPM.DR) of 1, the correct result may not be obtained. If the specified default is to be enabled, do not use the memory protection setting check function.**

	31																					9	8	7	6	5	4	3	2	1	0	
MCR	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	OV	0	0	SXE	SWE	SRE	UXE	UWE	URE	Value after reset Undefined

Table 3.46 MCR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
8	OV	If the specified area includes 0000 0000$_H$ or 7FFF FFFF$_H$, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
7, 6	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
5	SXE	If the specified area is contained within one protection area and execution is permitted for that area in supervisor mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
4	SWE	If the specified area is contained within one protection area and writing to that area is permitted in supervisor mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
3	SRE	If the specified area is contained within one protection area and reading from that area is permitted in supervisor mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
2	UXE	If the specified area is contained within one protection area and execution is permitted for that area in user mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
1	UWE	If the specified area is contained within one protection area and writing to that area is permitted in user mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
0	URE	If the specified area is contained within one protection area and reading from that area is permitted in user mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined

(9) MPLAn — Protection area minimum address register

These registers indicate the minimum address of area n (where n = 0 to 11). The number of the protection areas in this product is 12.

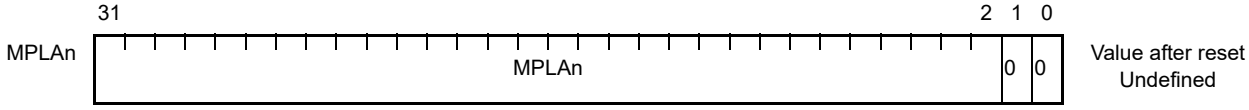

Table 3.47 MPLAn Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	MPLA31-2	These bits indicate the minimum address of area n. The MPLA1-0 bits are implicitly set to 0.	R/W	Undefined
1, 0	—	Reserved for future expansion. Be sure to clear these bits to 0.	R	0

(10) MPUAn — Protection area maximum address register

These registers indicate the maximum address of area n (where n = 0 to 11). The number of the protection areas in this product is 12.

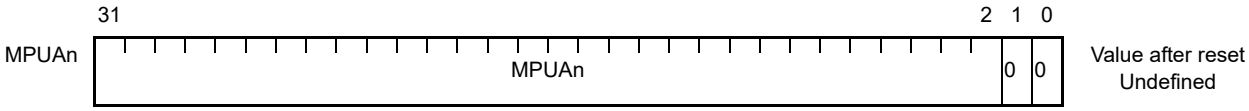

Table 3.48 MPUAn Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	MPUA31-2	These bits indicate the maximum address of area n. The MPUA1-0 bits are implicitly set to 1.	R/W	Undefined
1, 0	—	Reserved for future expansion. Be sure to clear these bits to 0.	R	0

(11) MPATn — Protection area attribute register

These registers indicate the attributes of area n (where n = 0 to 11). The number of the protection areas in this product is 12.

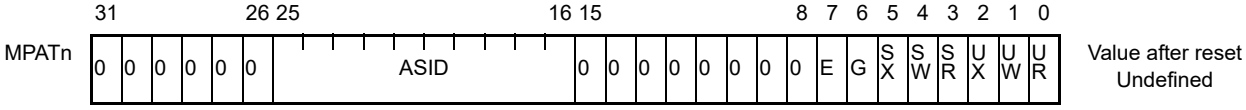

Table 3.49 MPATn Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 26	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
25 to 16	ASID	These bits indicate the ASID value to be used as the area match condition.	R/W	Undefined
15 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	E	This bit indicates whether area n is enabled or disabled. 0 : Area n is disabled. 1 : Area n is enabled.	R/W	0
6	G	0: ASID match is the condition. 1: ASID match is not the condition. When this bit is 0, the condition of the area match is MPATn.ASID = ASID.ASID. When this bit is 1, the area match of the values of MPATn.ASID and ASID.ASID is not the condition.	R/W	Undefined
5	SX	This bit indicates the execution privilege in supervisor mode.*1 0 : Execution is disabled. 1 : Execution is enabled.	R/W	Undefined
4	SW	This bit indicates the write permission in supervisor mode.*1 0 : Writing is disabled. 1 : Writing is enabled.	R/W	Undefined
3	SR	This bit indicates the read permission in supervisor mode*1 0 : Reading is disabled. 1 : Reading is enabled.	R/W	Undefined
2	UX	This bit indicates the execution privilege in user mode. 0 : Execution is disabled. 1 : Execution is enabled.	R/W	Undefined
1	UW	This bit indicates the write permission in user mode. 0 : Writing is disabled. 1 : Writing is enabled.	R/W	Undefined
0	UR	This bit indicates the read permission in user mode. 0 : Reading is disabled. 1 : Reading is enabled.	R/W	Undefined

Note 1. If access is restricted in SV mode, execution of MDP exceptions or the MIP exception handling itself might not be possible depending on the settings. Be careful to specify settings so that access to the memory area necessary for the exception handler and exception handling is permitted.

(6) Cache Operation Function registers

(a) Cache control function system registers

The cache control function system registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.50 Cache Control System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR16, 4	ICTAGL	Instruction cache tag Lo access	SV
SR17, 4	ICTAGH	Instruction cache tag Hi access	SV
SR18, 4	ICDATL	Instruction cache data Lo access	SV
SR19, 4	ICDATH	Instruction cache data Hi access	SV
SR24, 4	ICCTRL	Instruction cache control	SV
SR26, 4	ICCFG	Instruction cache configuration	SV
SR28, 4	ICERR	Instruction cache error	SV

(1) ICTAGL — Instruction cache tag Lo access register

This register is used for CIST and CILD instructions for the instruction cache. This register holds values to be stored in the tag RAM of the instruction cache by the execution of CIST instructions and values read from the tag RAM of the instruction cache by the execution of CILD instructions.

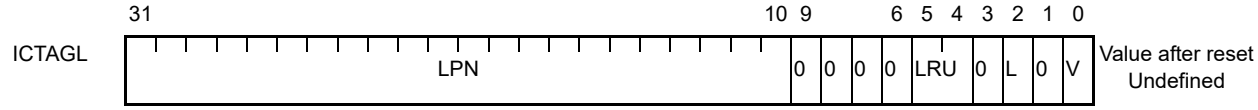

Table 3.51 ICTAGL Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 10	LPN	These bits hold the values of bits 24 to 11, i.e. the physical page numbers. When writing, always write 0 to bits 31 to 25 and to bit 10.	R/W	Undefined
9 to 6	—	Reserved for future expansion. When writing, always write 0 to these bits.	R	0
5, 4	LRU	These bits indicate the LRU information of the specified cache line. The CIST instruction cannot be used to change the LRU information to desired values.	R/W	Undefined
3	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
2	L	This bit holds the lock information.	R/W	Undefined
1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	V	This bit retains whether the specified cache line is enabled or disabled.	R/W	Undefined

(2) ICTAGH — Instruction cache tag Hi access register

This register is used for a CIST or CILD instruction for the instruction cache. This register stores the value to be stored in the instruction cache tag RAM on CIST execution and the value read from the instruction cache tag RAM on CILD execution.

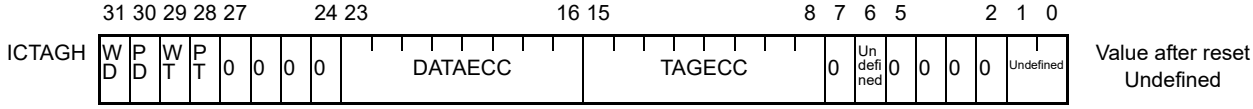

Table 3.52 ICTAGH Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	WD	When this bit is set to 1, executing a CIST instruction updates the cache data RAM.	R/W	Undefined
30	PD	When this bit is set to 1, executing a CIST instruction writes the value in the DATAECC field of this register to the ECC field of the data RAM.	R/W	Undefined
29	WT	This bit updates the cache tag RAM when this bit is set to 1 before CIST execution.	R/W	Undefined
28	PT	This bit writes the value in TAGECC field to ECC for tag RAM when this bit is set to 1 before CIST execution.	R/W	Undefined
27 to 24	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
23 to 16	DATAECC	These bits retain ECC of the data RAM.	R/W	Undefined
15 to 8	TAGECC	These bits retain ECC of the tag RAM. Be sure to clear bit 15 to 0.	R/W	Undefined
7	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
6	—	(Reserved for future expansion. Be sure to clear to 0.)	R	Undefined
5 to 2	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
1, 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	Undefined

(3) ICDATL — Instruction cache data Lo access register

This register is used for a CIST or CILD instruction for the instruction cache. This register stores the value to be stored in the instruction cache data RAM on CIST execution and the value read from the instruction cache data RAM on CILD execution.

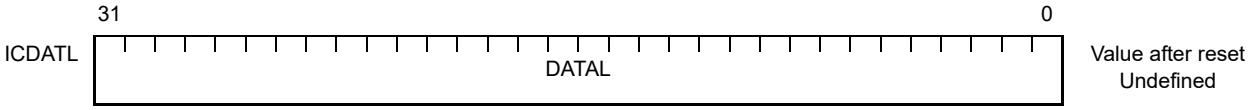

Table 3.53 ICDATL Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	DATAL	These bits retain the values of bits 31 to 0 or of bit 95 to 64 from the instruction data of the block within the specified cache line. The offset of the index specifies the target range of bit numbers. Index offset = 0000: bits 31 to 0 Index offset = 1000: bits 95 to 64	R/W	Undefined

(4) ICDATH — Instruction cache data Hi access register

This register is used for a CIST or CILD instruction for the instruction cache. This register stores the value to be stored in the instruction cache data RAM on CIST execution and the value read from the instruction cache data RAM on CILD execution.

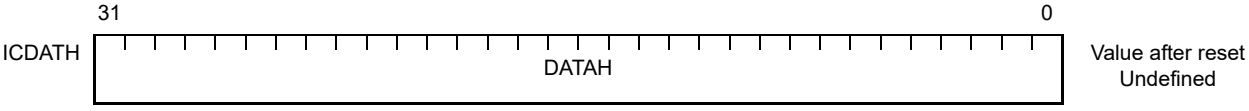

Table 3.54 ICDATH Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	DATAH	These bits retain the values of bit 63 to 32 or those of bit 127 to 96 from the instruction data of the block within the specified cache line. The index offset specifies the bit number to be retained. Index offset = 0000: bit 63 to 32 Index offset = 1000: bit 127 to 96	R/W	Undefined

(5) ICCTRL — Instruction cache control register

This register controls the instruction cache.

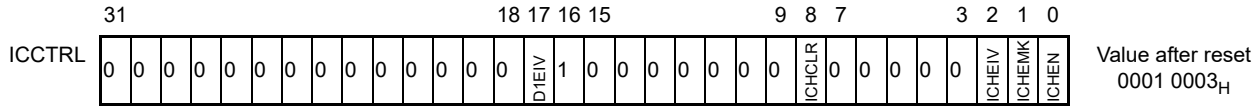

Table 3.55 ICCTRL Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 18	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
17	D1EIV	This bit selects the operation in response to 1-bit errors in the data RAM. 0: The error is corrected and then processing continues, but the address of the entry that had an error is retained. 1: The error is not corrected, the entry is cleared, and fetching is repeated. This bit is read as the previous value until the setting is actually reflected in the instruction cache.	R/W	0
16	—	(Reserved for future expansion. Be sure to set to 1.)	R	1
15 to 9	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
8	ICHCLR	Setting this bit to 1 selects clearing of the whole instruction cache in a single operation. After this bit has been set to 1, it will be read as 1 until clearing is completed. The bit is cleared to 0 once clearing of the cache is completed.	R/W	0
7 to 3	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
2	ICHEIV	Setting this bit to 1 allows the instruction cache to be automatically disabled (ICHEN bit to be cleared to 0) when a cache error occurs.	R/W	0
1	ICHEMK	Setting this bit to 1 selects masking of cache error exception notifications for the CPU when cache errors are encountered.	R/W	1
0	ICHEN	This bit disables or enables the instruction cache. 0: Instruction cache is disabled. 1: Instruction cache is enabled. This bit is read as the previous value until the setting is actually reflected in the instruction cache.	R/W	1

(6) ICCFG — Instruction cache configuration register

This register shows the configuration of the instruction cache.

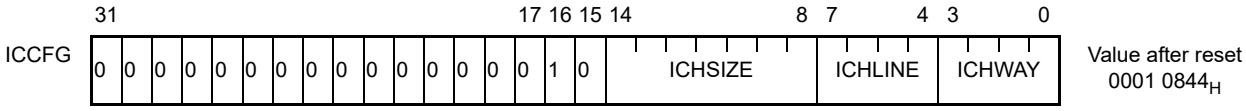

Table 3.56 ICCFG Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 17	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
16	—	(Reserved for future expansion. Be sure to set to 1.)	R	1
15	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
14 to 8	ICHSIZE	These bits indicate the capacity (in Kbytes) of the instruction cache. The setting is 8 Kbytes in this product. 000 1000: 8 Kbytes	R	08_H
7 to 4	ICHLINE	These bits indicate the number of lines per 1 way in the instruction cache. The setting is 128 lines in this product. 0100: 128 lines	R	4_H
3 to 0	ICHWAY	These bits indicate the number of ways of the instruction cache. The setting is 4 ways in this product. 0100: 4 ways	R	4_H

(7) ICERR — Instruction cache error register

This register stores cache error data of the instruction cache.

Once the ICHERR bit is set to 1, subsequent cache error data is not stored in this register until the ICHERR bit is cleared to 0.

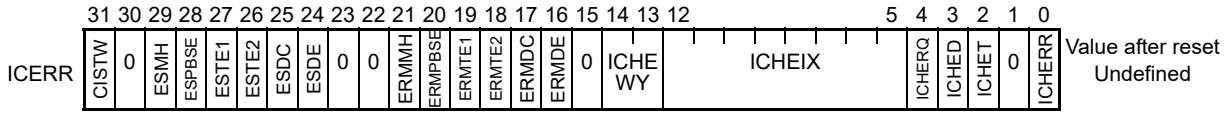

Table 3.57 ICERR Register Contents (1/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
31	CISTW	This bit is set to indicate that the destination way specified for a CISTI instruction was in error. Although the entry information is overwritten so that writing is completed, the V bit will be cleared the next time the cache line is read (i.e. reading will be judged to have missed the cache). However, setting of this bit is not accompanied by an exception for the CPU.	R/W	0
30	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
29	ESMH	Error status: multi-hit	R/W	Undefined
28	ESPBSE	Error status: way error	R/W	Undefined
27	ESTE1	Error status: 1-bit error in the tag RAM	R/W	Undefined
26	ESTE2	Error status: 2-bit error in the tag RAM	R/W	Undefined
25	ESDC	Error status: 1-bit correction in the data RAM	R/W	Undefined
24	ESDE	Error status: 2-bit error in the data RAM	R/W	Undefined
23, 22	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
21	ERMMH	Error exception notification mask: multi-hit	R/W	0
20	ERMPBSE	Error exception notification mask: way error	R/W	0

Table 3.57 ICERR Register Contents (2/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
19	ERMTE1	Error exception notification mask: 1-bit error in the tag RAM	R/W	0
18	ERMTE2	Error exception notification mask: 2-bit error in the tag RAM	R/W	0
17	ERMDC	Error exception notification mask: 1-bit correction in the data RAM	R/W	0
16	ERMDE	Error exception notification mask: 2-bit error in the data RAM	R/W	0
15	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
14, 13	ICHEWY	These bits retain a way number where a cache error occurs.	R/W	Undefined
12 to 5	ICHEIX	These bits retain a cache index where a cache error occurs.	R/W	Undefined
4	ICHERQ	Setting of this bit to 1 indicates that the CPU is being notified of a cache error exception. If cache error exceptions are masked, however, the CPU is not notified of an exception even when this bit is set to 1.	R/W	0
3	ICHED	This bit indicates that an error occurs in the data RAM.	R/W	0
2	ICHET	This bit indicates that an error occurs in the tag RAM.	R/W	0
1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	ICHERR	This bit is set to 1 when a cache error occurs.	R/W	0

(7) Data Buffer Operation Function Registers

(a) Data buffer control function system registers

The data buffer control function system registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.58 Data Buffer Operation Function Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR24,13	CDBCR	Data buffer control register	SV

(1) CDBCR — Data Buffer Control Register

This register controls the data buffer.

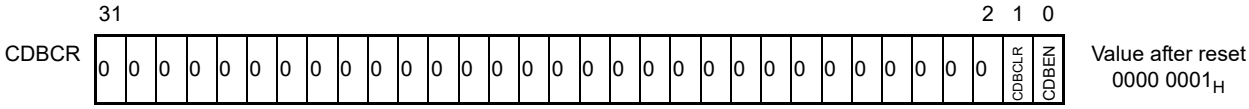

Table 3.59 CDBCR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
1	CDBCLR	When this bit is set to 1, the data buffer is cleared at a time. This bit is always read as 0.	W	0
0	CDBEN	This bit disables or enables the data buffer. 0: Data buffer is disabled. 1: Data buffer is enabled.	R/W	1

3.2.2 Instruction Cache and Data Buffer

3.2.2.1 Features

An 8-Kbyte and 4-way set-associative instruction cache is mounted between the CPU1 and the code flash. The instruction cache and the code flash are connected to each other via a 128-bit dedicated bus to minimize penalties caused by a cache miss-hit. Also a data buffer is mounted between the CPU1 and the code flash to achieve high-speed data access. The 32-MB area from 0000 0000_H to 01FF $FFFF_H$ in the address space is intended for the instruction cache and data buffer.

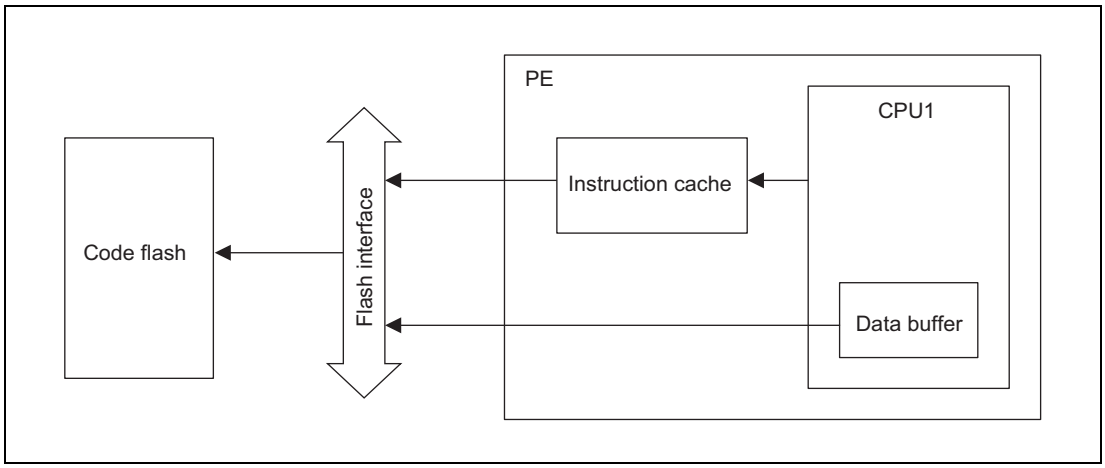

Figure 3.2 Instruction Cache and Data Buffer

3.2.2.2 Instruction Cache Function

The 8-Kbyte and 4-way set-associative cache includes four ways consisting of 128-entry blocks of four words per line, amounting to 8-Kbyte capacity in total. The ways are divided into two groups, way group 0 consisting of way 0 and way 1 and way group 1 consisting of way 2 and way 3. The way group can be selected and used by decoding of the address information of the access destination. If a cache error occurs, each line is refilled by a replace algorithm using LRU. CPU instruction fetches from the code flash are performed via the instruction cache.

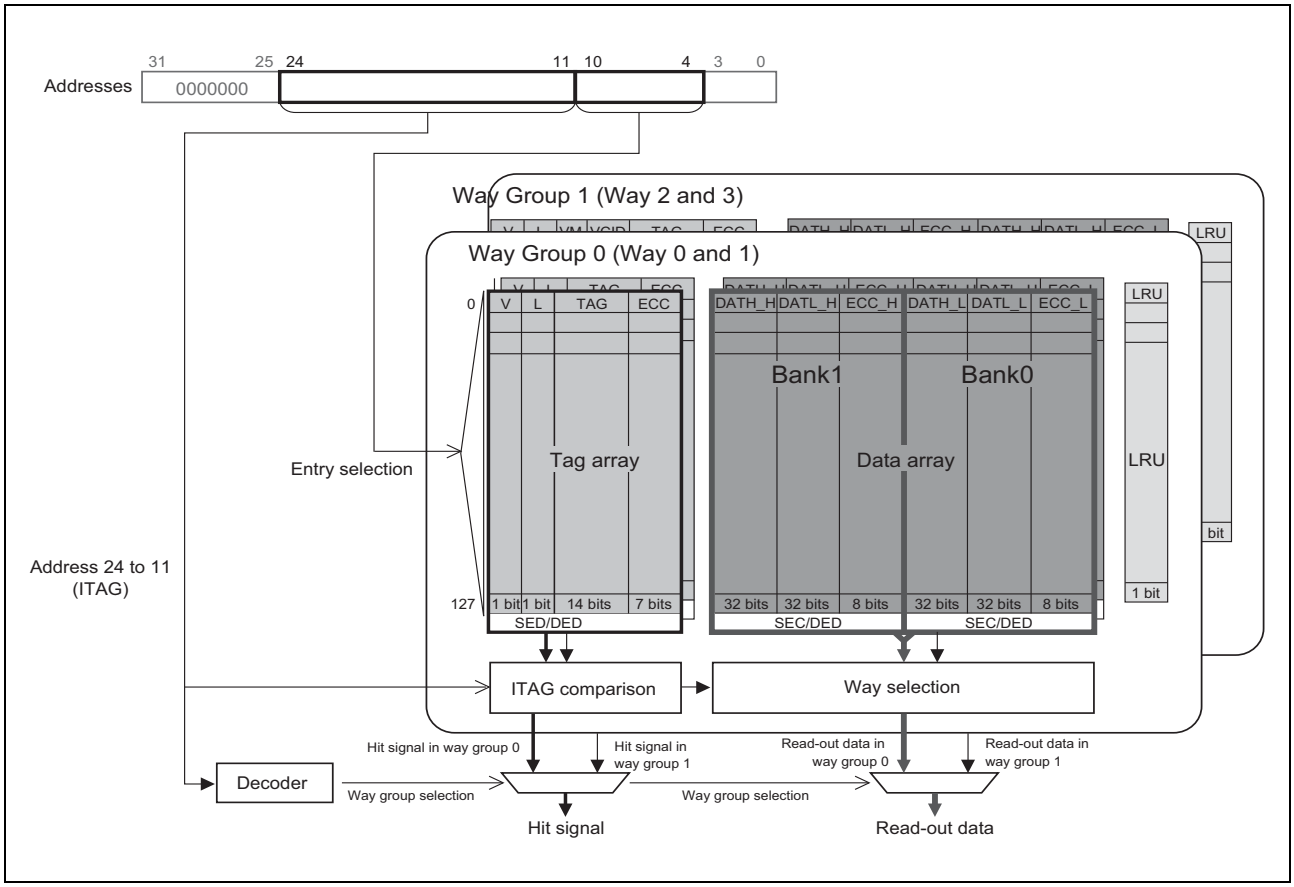

Figure 3.3 Instruction Cache Configuration

Tag Array

V bit	This bit indicates whether valid data is stored in the cache line. Setting of this bit to 1 makes the cache line data valid. The V bit is initialized to 0 by reset.
L bit	This bit indicates whether a cache line is locked or not. Setting of this bit to 1 locks the cache line and it cannot be replaced with new data. The L bit is valid only when the V bit is 1, and it is not initialized by reset.
TAG	Among 32 bits in the operable addresses of the data line to be cached, bits 24 to 11 are stored in this bit. The TAG bit is not initialized by reset.
ECC	The ECC of the tag array is stored in this bit. The ECC bit is not initialized by reset.

Data Array

DATH_H, DATL_H, DATH_L, DATL_L	The 128-bit cache line data is stored per 32 bits as follows: the bits [127:96], [95:64], [63:32], [31:0] in the DATH_H, DATL_H, DATH_L, and DATL_L, respectively. In the CIST or CILD operation in response to a cache instruction, the ICDATH register is used for DATH_H and DATH_L and ICDATL is used for DATL_H and DATL_L.
ECC_H, ECC_L	The ECC of the data in bits [127:64] and [63:0] are stored in ECC_H and ECC_L, respectively.

LRU

LRU	The LRU information in the same way group is stored in this data array. The LRU is initialized by reset.

CAUTION

When an instruction is fetched from an applicable line after issuing a CIST instruction for writing test data to the tag array of the instruction cache, the tag information must be written in a group unit. For example, when writing tag information to a line on the way 0 side of way group 0, also write tag information for the same line to way 1, and then execute the instruction fetch

- When writing to way group 0 (way 0 and way 1), write a value such that the exclusive OR of the ICTAGL.LPN bit is 0.
- When writing to way group 1 (way 2 and way 3), write a value such that the exclusive OR of the ICTAGL.LPN bit is 1.

Fetching an instruction after a value that does not follow the above rule has been written to the tag array causes a way error and setting of the ICERR.ESPBSE bit to 1. Fetching an instruction after the same tag information has been written to the same lines of both ways in a way group causes a multi-hit error and setting of the ICERR.ESMH bit to 1.

3.2.2.3 Data Buffer Function

The four-line buffer with 128 bits per line is mounted as a data buffer. The data of 128 bits per line read from the code flash is stored in the data buffer. The data is read out from the data buffer after the next access to the same address, so the code flash is not accessed again.

3.2.3 Inter-Processor Interrupts

Registers (IPIR_CHn) for interrupt communication between PEs are provided for four channels.

IPIR_CH0 to IPIR_CH3 are assigned to CH0 to CH3 of user interrupt (EIINT). An interrupt for specific PEs (including own PE) can be requested by manipulating bits corresponding to respective PEs.

3.2.3.1 Inter-Processor Interrupt Control Registers

This register is located in the CPU peripheral of each PE. IPIR_CH0 to IPIR_CH3 registers are assigned to each PE which are accessible only from their own PE.

Table 3.60 List of Registers

Register Symbol	Register Name	R/W	Value after Reset	Access Size				Address
				1	8	16	32	
IPIR_CH0	Inter-PE interrupt register 0	R/W	0000 0000$_H$	√	√	√	√	FFFE EC80$_H$
IPIR_CH1	Inter-PE interrupt register 1	R/W	0000 0000$_H$	√	√	√	√	FFFE EC84$_H$
IPIR_CH2	Inter-PE interrupt register 2	R/W	0000 0000$_H$	√	√	√	√	FFFE EC88$_H$
IPIR_CH3	Inter-PE interrupt register 3	R/W	0000 0000$_H$	√	√	√	√	FFFE EC8C$_H$

(1) IPIR_CHn — Inter-PE Interrupt Register n (n = 0 to 3)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 3.61 IPIR_CHn Interrupt Register Contents

Bit Position	Bit Name	Function
2	PE3	Inter-PE Interrupt Request to PE3 Writing 1 to this bit makes an interrupt request to PE3. This bit is automatically cleared to 0 when the interrupt request has been notified. 0: Inter-PE interrupt request output is not specified or an interrupt request is not being output. 1: Interrupt request output is specified or an interrupt request is being output.
0	PE1	Inter-PE Interrupt Request to PE1 Writing 1 to this bit makes an interrupt request to PE1. This bit is automatically cleared to 0 when the interrupt request has been notified. 0: Inter-PE interrupt request output is not specified or an interrupt request is not being output. 1: Interrupt request output is specified or an interrupt request is being output.

3.2.4 Reliability Functions

3.2.4.1 PE Guard Function (PEG)

(1) Overview of the PEG Function

The PEG is a constituent of the slave guard system to prevent unauthorized access to the resources in the PE from the external master. This function protects access to the local RAM in the PE. In the initial state after a reset, all access by masters other than the PE itself is disabled. Setting the registers listed in **(3) List of PEG Protection Setting Registers**, enables access by masters other than the PE itself.

(1) Detecting PE guard violation

If the external master outside the PE makes an unauthorized access to the resource area in the PE for which PE guard is set, the access is detected as a PE guard violation.

(2) Blocking unauthorized accesses

When a PE guard violation is detected, unauthorized accesses to the internal resources of the PE are blocked to prevent the contents of PE resources from being modified illegally.

(3) Notifying occurrence of violation

When a PE guard violation is detected, it is notified to ECM. When the DMAC or DTS makes an unauthorized access, a DMA transfer error is detected.

(2) Protection Made by SPID

- Setting PEG Protection
  - Up to four areas can be set depending on the local RAM address of the own PE.
  - The area range is specified by the base address and the mask bit (4 Kbytes to 4 Gbytes).
  - “Read enable” and “write enable” can be set for each area.
  - “Enable” or “disable” can be selected on each system protection identifier (SPID) basis for each area.
- Access permission by the system protection identifier (SPID) (see **Figure 3.4**)

1. When the local RAM area is to be accessed, go to step 2.
   Otherwise, return an error response.
2. When any of enabled area 0 to area 3 is to be accessed, go to step 3.
   Otherwise, return an error response.
3. Whether or not all the conditions below for the relevant area are met.
   - The system protection identifier (SPID) is enabled.
   - Required operations (read/write) are enabled.
     Otherwise, return an error response.

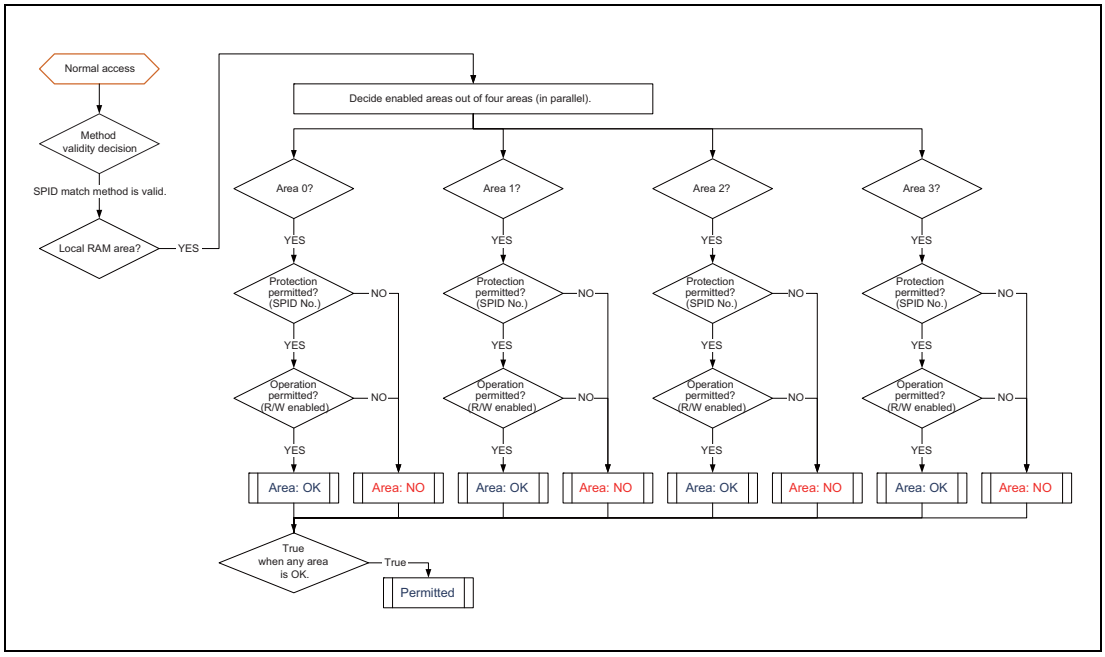

Figure 3.4 Access Permission by the System Protection Identifier (SPID)

(3) List of PEG Protection Setting Registers

Make necessary settings for the following registers to protect PE resources from unauthorized accesses by the external master.

- Accesses to the local RAM in the PE are permitted as detection targets.
- For accesses to the register set, no access restriction is provided independently for the PEG function. Set access protections such as IPG at the user side as necessary.
- PEG protection can be set by following the procedure below.

  1. Set the PE guard area n mask setting register as PEGGnMK.
  2. Set the PE guard area n base setting register (n = 0 to 3) as PEGGnBA.

Table 3.62 Base Address of PEG Register: FFFE_E600$_H$

Address Offset	Size (Byte)	Register Name	Abbreviation	Right	R/W	Operable Bit				Value after Reset
						1	8	16	32	
+00C$_H$	2	PE guard SPID master decision control register	PEGSP	—	R/W	—	√	√	—	0000$_H$
+080$_H$	4	PE guard area 0 mask setting register	PEGG0MK	—	R/W	—	√	√	√	0000 0000$_H$
+084$_H$	4	PE guard area 0 base setting register	PEGG0BA	—	R/W	—	√	√	√	0000 0000$_H$
+090$_H$	4	PE guard area 1 mask setting register	PEGG1MK	—	R/W	—	√	√	√	0000 0000$_H$
+094$_H$	4	PE guard area 1 base setting register	PEGG1BA	—	R/W	—	√	√	√	0000 0000$_H$
+0A0$_H$	4	PE guard area 2 mask setting register	PEGG2MK	—	R/W	—	√	√	√	0000 0000$_H$
+0A4$_H$	4	PE guard area 2 base setting register	PEGG2BA	—	R/W	—	√	√	√	0000 0000$_H$
+0B0$_H$	4	PE guard area 3 mask setting register	PEGG3MK	—	R/W	—	√	√	√	0000 0000$_H$
+0B4$_H$	4	PE guard area 3 base setting register	PEGG3BA	—	R/W	—	√	√	√	0000 0000$_H$

(4) Register Set

(a) PEGSP — PE Guard SPID Master Decision Control Register

This register is used to enable or disable access by an external master to the resources in the PE. The initial value of the SPEN bit is 0, which disables access to PE resources by an external master. Setting the SPEN bit to 1 enables access by an external master under the conditions set by PEGGnBA and PEGGnMK.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 3.63 PEGSP Register Contents

Bit Position	Bit Name	Function
15 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	SPEN	This bit enables or disables detection of accesses by the external master having SPID. 0: Detection of accesses by the external master having SPID is disabled. 1: Detection of accesses by the external master having SPID is enabled.

(b) PEGGnMK — PE Guard Area n Mask Setting Register

In combination with the PEGGnBA register, this register specifies a range or ranges within PE guard protection area n. Setting a GnMASK bit to 1 masks the corresponding address bit in the PEGGnBA register and places the corresponding area or areas inside the range of PE guard area n. The minimum size of the PE guard protection area is 4 KB.

Ex.) With the settings of PEGGnBA[31:12] = FEBF6$_H$ and PEGGnMK[31:12] = 00008$_H$, the PE guard protection area n is specified within the ranges from FEBF 6000$_H$ to FEBF 6FFF$_H$ and FEBF E000$_H$ to FEBF EFFF$_H$.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GnMASK															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 3.64 PEGGnMK Register Contents

Bit Position	Bit Name	Function
31 to 12	GnMASK	These bits determine whether to mask the base address PEGGnBA[31:12] that specifies the range of PE guard protection area n. 0: Target address bits are not compared when determining the PE guard area. 1: Target address bits are compared when determining the PE guard area.
11 to 0	—	Reserved These bits are always read as 0. The write value should always be 0.

(c) PEGGnBA — PE Guard Area n Base Setting Register

In combination with the PEGGnMK register, this register specifies a range or ranges within PE guard protection area n and sets the access enable conditions for the specified area. Setting the GnEN bit to 1 brings the address enable conditions specified by this register and the PEGGnMK register into effect.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 3.65 PEGGnBA Register Contents

Bit Position	Bit Name	Function
31 to 12	GnBASE	Base address that specifies PE guard protection area n
11 to 8	—	Reserved
7	GnSP3	Enables accesses to PE guard protection area n by the external master. 0: Access by an external master having SPID = 3 is disabled. 1: Access by an external master having SPID = 3 is enabled.
6	GnSP2	Enables accesses to PE guard protection area n by the external master. 0: Access by an external master having SPID = 2 is disabled. 1: Access by an external master having SPID = 2 is enabled.
5	GnSP1	Enables accesses to PE guard protection area n by the external master. 0: Access by an external master having SPID = 1 is disabled. 1: Access by an external master having SPID = 1 is enabled.
4	GnSP0	Enables accesses to PE guard protection area n by the external master. 0: Access by an external master having SPID = 0 is disabled. 1: Access by an external master having SPID = 0 is enabled.
3	—	Reserved This bit is always read as 0. The write value should always be 0.
2	GnWR	Enables write access to PE guard protection area n. 0: Write access is disabled. 1: Write access is enabled.
1	GnRD	Enables read access to PE guard protection area n. 0: Read access is disabled. 1: Read access is enabled.
0	GnEN	PE guard protection area n enable 0: Settings for access enable conditions are disabled 1: Settings for access enable conditions are enabled

CAUTION

PEGGnBA.GnEN is cleared by writing to the PEGGnMK register.

3.2.4.2 PE's Internal Peripheral Device Protection Function (IPG)

(1) Overview of the IPG Function

The IPG is a system to prevent unauthorized accesses to peripheral devices from the CPU core equipped with the IPG. The IPG achieves the following functions. The IPG covers accesses to resources except the ROM and the local RAM.

(1) Detecting violation of peripheral device protection

If the CPU makes an unauthorized access to an area (peripheral device) for which peripheral device protection is set, the access is detected as "violation of peripheral device protection."

(2) Storing unauthorized-access information

When a violation of peripheral device protection is detected, the unauthorized-access information is stored in the IPG's internal register.

(3) Blocking unauthorized accesses

When a violation of peripheral device protection is detected, unauthorized accesses to peripheral devices are blocked to prevent contents of peripheral devices from being modified illegally.

(4) Notifying violation

When a violation of peripheral device protection is detected, a system error exception (SYSERR exception) request for generating an exception is made to ask the CPU to stop the processing.

For system error exceptions (SYSERR exceptions), see **Section 3.2.4.3, System Error Notification Control Function (SEG)**.

(5) Invalidating subsequent accesses

When a violation of peripheral device protection is detected, subsequent accesses (regardless of authorized or unauthorized accesses) are blocked until instructions from the CPU are received.

NOTE

Even if a request for generating an exception is immediately sent to the CPU in step (4) above, a subsequent access issued (before receiving a request from the IPG) by the CPU that does not know an occurrence of violation may illegally modify contents of peripheral devices. (Accesses after a violation has occurred result in unauthorized accesses.)

(2) IPG Function

(1) This function invalidates accesses according to their attributes (including address, transfer type, and access right).

(2) After an access right violation is detected until the error flag (described later) is cleared by writing by the software, subsequent accesses are invalidated. However, invalidation is applied only to accesses from the CPU and is not applied to accesses from outside the CPU core. Invalidation is performed independently of addresses.

(3) When a request for accessing different peripheral devices simultaneously is made due to misalignment or double-word access, the access is executed when all such accesses are enabled.

(3) IPG Protection Setting Registers for Illegal Users

To protect peripheral devices from unauthorized accesses by programs in user mode, the registers below require the settings listed in the table.

- Accesses in user mode are to be detected.
- This register set is intended for IPG settings related to user mode and reading of the IPG settings within its own machine.

Table 3.66 Base Address of IPG Register: FFFE E000$_H$

Address Offset	Size (Byte)	Register Name	Abbreviation	Right *1	R/W	Operable Bit				Value after Reset
						1	8	16	32	
+002$_H$	2	Peripheral device protection violation access information register	IPGECRUM	SV	R/W	—	—	√	—	Undefined (retained)
+008$_H$	4	Peripheral device protection violation access address register	IPGADRUM	SV	R/W	—	—	—	√	Undefined (retained)
+00D$_H$	1	Peripheral device protection enable register	IPGENUM	SV	R/W	√	√	—	—	00$_H$

15, 14	—	Reserved These bits are always read as 0. The write value should always be 0.
13 to 8	—	Reserved These bits are read as an undefined value. The write value should always be 0.
7 to 4	DS	These bits store the data size of access that made a violation. 1000: Double-word (8 bytes) 0100: Word (4 bytes) 0010: Half-word (2 bytes) 0001: Byte Other than above: RFU
3	EX	This bit is set to 1 when a violation occurred in an instruction fetch read access. In other cases, this bit is cleared to 0.
2	WR	This bit is set to 1 when a violation occurred in a write access or bit operation or CAXI. In other cases, this bit is cleared to 0.
1	RD	This bit is set to 1 when a violation occurred in a read access or bit operation or CAXI. In other cases, this bit is cleared to 0.
0	VD	This bit is set to 1 when a violation of peripheral device protection is detected by a program with the relevant right. Even if another violation of peripheral device protection is detected while this bit is 1, data of this IPGECR register and the IPGADR register is not updated and is retained.

NOTE

When the IRE bit value of the IPGENUM register (described later) is 0 and violation of peripheral device protection by a program operating in user mode is an instruction fetch read access, no bit of this register is updated.

(b) IPGADRUM — Peripheral Device Protection Violation Access Address Register

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EADR															
Value after reset	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	EADR															
Value after reset	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

×: Undefined (retained)

Table 3.68 Register Contents of IPGADRUM

Bit Position	Bit Name	Function
31 to 0	EADR	These bits store the address of the access in which a violation occurred.

NOTE

When the IRE bit value of the IPGENUM register (described later) is 0 and violation of peripheral device protection by a program operating in user mode is an instruction fetch read access, no bit of this register is updated.

(c) IPGENUM — Peripheral Device Protection Enable Register

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	IRE	E
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 3.69 Register Contents of IPGENUM

Bit Position	Bit Name	Function
7 to 2	—	Reserved These bits are always read as 0. The write value should always be 0.
1	IRE	This bit sets whether to store the access information in the peripheral device protection violation access address register and the peripheral device protection violation access information register when a violation of peripheral device protection occurred in an instruction fetch access. 0: Instruction fetch access information is not stored. 1: Instruction fetch access information is stored. **CAUTION** If you do not want to detect speculative instruction fetches (no instruction is executed in some cases), clear this bit to 0.
0	E	This bit enables or disables the peripheral devices protection function against accesses by the relevant access right. 0: The peripheral device protection function is disabled. 1: The peripheral device protection function is enabled.

(d) IPGPMTUM0 — Peripheral Device Protection Setting Register 0

Bit	7	6	5	4	3	2	1	0
	—	X1	W1	R1	—	X0	W0	R0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Table 3.70 Register Contents of IPGPMTUM0

Bit Position	Bit Name	Function
7	—	Reserved This bit is always read as 0. The write value should always be 0.
6	X1	This bit sets whether to enable instruction fetch read access to Peripheral Groups 0 to 3 and 5. 0: Instruction fetch read access to Peripheral Groups 0 to 3 and 5 is treated as violation. 1: Instruction fetch read access to Peripheral Groups 0 to 3 and 5 is not restricted.
5	W1	This bit sets whether to enable write access to Peripheral Groups 0 to 3 and 5. 0: Write access to Peripheral Groups 0 to 3 and 5 is treated as violation. 1: Write access to Peripheral Groups 0 to 3 and 5 is not restricted.
4	R1	This bit sets whether to enable read access to Peripheral Groups 0 to 3 and 5. 0: Read access to Peripheral Groups 0 to 3 and 5 is treated as violation. 1: Read access to Peripheral Groups 0 to 3 and 5 is not restricted.
3	—	Reserved This bit is always read as 0. The write value should always be 0.
2	X0	This bit sets whether to enable instruction fetch read access to peripheral devices to be connected to the H-Bus. 0: Instruction fetch read access to peripheral devices to be connected to the H-Bus is treated as violation. 1: Instruction fetch read access to peripheral devices to be connected to the H-Bus is not restricted.
1	W0	This bit sets whether to enable write access to peripheral devices to be connected to the H-Bus. 0: Write access to peripheral devices to be connected to the H-Bus is treated as violation. 1: Write access to peripheral devices to be connected to the H-Bus is not restricted.
0	R0	This bit sets whether to enable read access to peripheral devices to be connected to the H-Bus. 0: Read access to peripheral devices to be connected to the H-Bus is treated as violation. 1: Read access to peripheral devices to be connected to the H-Bus is not restricted.

(e) IPGPMTUM1 — Peripheral Device Protection Setting Register 1

Bit	7	6	5	4	3	2	1	0
	—	X1	—	—	—	X0	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R	R	R	R/W	R	R

Table 3.71 Register Contents of IPGPMTUM1

Bit Position	Bit Name	Function
7	—	Reserved This bit is always read as 0. The write value should always be 0.
6	X1	This bit sets whether to enable instruction fetch read access to GRAM Bank#1. 0: Instruction fetch read access to GRAM Bank#1 is treated as violation. 1: Instruction fetch read access to GRAM Bank#1 is not restricted.
5 to 3	—	Reserved These bits are always read as 0. The write value should always be 0.
2	X0	This bit sets whether to enable instruction fetch read access to GRAM Bank#0. 0: Instruction fetch read access to GRAM Bank#0 is treated as violation. 1: Instruction fetch read access to GRAM Bank#0 is not restricted.
1, 0	—	Reserved These bits are always read as 0. The write value should always be 0.

(f) IPGPMTUM2 — Peripheral Device Protection Setting Register 2

Bit	7	6	5	4	3	2	1	0
	—	—	W1	R1	—	—	W0	R0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R/W	R/W

Table 3.72 Register Contents of IPGPMTUM2

Bit Position	Bit Name	Function
7, 6	—	Reserved These bits are always read as 0. The write value should always be 0.
5	W1	This bit sets whether to enable write access to IPIR, MEV, and COMPTEST. 0: Write access to IPIR, MEV, and COMPTEST is treated as violation. 1: Write access to IPIR, MEV, and COMPTEST is not restricted.
4	R1	This bit sets whether to enable read access to IPIR, MEV, and COMPTEST. 0: Read access to IPIR, MEV, and COMPTEST is treated as violation. 1: Read access to IPIR, MEV, and COMPTEST is not restricted.
3, 2	—	Reserved These bits are always read as 0. The write value should always be 0.
1	W0	This bit sets whether to enable write access to INTC1. 0: Write access to INTC1 is treated as violation. 1: Write access to INTC1 is not restricted.
0	R0	This bit sets whether to enable read access to INTC1. 0: Read access to INTC1 is treated as violation. 1: Read access to INTC1 is not restricted.

(g) IPGPMTUM3 — Peripheral Device Protection Setting Register 3

Bit	7	6	5	4	3	2	1	0
	—	—	W1	R1	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0

Bit Position	Bit Name	Function
7, 6	—	Reserved These bits are always read as 0. The write value should always be 0.
5	W1	This bit sets whether to enable write access to SysErrGen. 0: Write access to SysErrGen is treated as violation. 1: Write access to SysErrGen is not restricted.
4	R1	This bit sets whether to enable read access to SysErrGen. 0: Read access to SysErrGen is treated as violation. 1: Read access to SysErrGen is not restricted
3 to 0	—	Reserved These bits are always read as 0. The write value should always be 0.

(h) IPGPMTUM4 — Peripheral Device Protection Setting Register 4

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	W0	R0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 3.74 Register Contents of IPGPMTUM4

Bit Position	Bit Name	Function
7 to 2	—	Reserved These bits are always read as 0. The write value should always be 0.
1	W0	This bit sets whether to enable write access to the PEG. 0: Write access to the PEG is treated as violation. 1: Write access to the PEG is not restricted.
0	R0	This bit sets whether to enable read access the PEG. 0: Read access to the PEG is treated as violation. 1: Read access to the PEG is not restricted

3.2.4.3 System Error Notification Control Function (SEG)

Errors due to an instruction fetch or data access can be the sources of system error exceptions. A system error exception is an FE level exception from which return or recovery is not possible.

For source codes (FEIC) of the system error exceptions and error handling, see **Table 3.77, Error Factor Codes and Handling of G3M Core System Error Exceptions**.

SEG (SysErrGen) controls the notification and recording of the error by data access.

Errors due to instruction-fetch access are not conveyed via the SEG block, but the SEG block is notified of errors in RAM that has been cached in the instruction cache. For details, see **(2) Register Set**, **(a) SEGCONT — Error Notification Control Register**, and **(3) SEG Function**, **(c) Supplementary information on SYSERR exception**.

Multiple error occurrence inputs are categorized according to error factors, and are processed sequentially from the highest-priority error factor, generating an FE-level asynchronous exception (SYSERR).

The bit position of the SEGFLAG register becomes the priority of error factors. Error factors of lower bits take precedence over error factors of upper bits.

Error information is recorded once regardless of error frequency.

The error with the highest priority of error factor (in case errors occurred simultaneously) is valid. Recorded error information is not overwritten by subsequent errors.

(1) List of SEG Function Control Registers

Table 3.75 Base Address of SEG Register: FFFE E980$_H$

Address Offset	Size (Byte)	Register Name	Abbreviation	Right	R/W	Operable Bit				Value after Reset
						1	8	16	32	
+00$_H$	2	Error notification control register	SEGCONT	—	R/W *1	—	—	√	—	C774$_H$
+02$_H$	2	Error occurrence retention register	SEGFLAG	—	R/W *1	—	—	√	—	0000$_H$
+08$_H$	4	Error factor retention register (address)	SEGADDR	—	R/W *1	—	—	√	√	Undefined (retained)

Note 1. Write accesses from user mode are ignored.

NOTES

- If an access is made with an address offset or operable bits other than those specified above, an error response is returned.
- Write access is only possible with the supervisor mode (UM = 0). Attempting to write, if these conditions do not hold, leads to an error response being returned.
- No restriction is provided for read accesses.
  – Read accesses to ranges permitted by other protection systems are enabled at any time.

(2) Register Set

(a) SEGCONT — Error Notification Control Register

- This register is used to enable (= 1) or disable (= 0) notification of SYSERR request in response to error flags that store error occurrence status according to factors.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SS1E	—	—	—	—	—	VPGE	VCRE	—	TCME	ROME	VCIE	—	ICCE	—	—
Value after reset	1	1	0	0	0	1	1	1	0	1	1	1	0	1	0	0
R/W	R/W	R	R	R	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R	R

Table 3.76 SEGCONT Register Contents (1/2)

Bit Position	Bit Name	Function
15	SS1E	Notification of an address parity error in access to data in the local RAM for the given processor.
14	—	Reserved This bit is always read as 1. The write value should always be 1
13 to 11	—	Reserved These bits are always read as 0. The write value should always be 0.
10	—	Reserved This bit is always read as 1. The write value should always be 1.
9	VPGE	Notification of a response to an error in the P-Bus. The error includes the followings: • P-Bus guard error in writing access (P-bus guarding also applies to the guarding of all registers in the INTC2 module, and to all registers for peripheral DMA and the GRAM)
8	VCRE	Notification of the detection of illegal access by the IPG and subsequent access blocking.*2
7	—	Reserved This bit is always read as 0. The write value should always be 0.
6	TCME	Notification of an error in access to data in the local ROM for the given processor. The error includes the following cases: • When an ECC error which cannot be corrected occurs • When an access to the RAM-unimplemented area in the local RAM is detected
5	ROME	Notification of an error in access to the code flash when a table reference is read in response to a table reference interrupt. The error includes the following cases: • When an ECC error which cannot be corrected occurs • When an address parity error occurs

Table 3.76 SEGCONT Register Contents (2/2)

Bit Position	Bit Name	Function
4	VCIE	• Notification of a response to an error in the P-Bus (excluding errors in writing to the P-Bus). The error includes the following cases: – When an unimplemented area (FFFF 7900_H to FFFF $7EFF_H$) is accessed – P-Bus guard error in writing access ((P-bus guarding also applies to the guarding of all registers in the INTC2 module, and to all registers for peripheral DMA and the GRAM) – P-Bus data parity error (for a peripheral function which the data parity is applied to) – An error when DTSRAM is read • Notification of a response to an error in the code flash The error includes the following cases: – When an ECC error which cannot be corrected occurs – When an address parity error occurs • Notification of a response to an error in GRAM The error includes the following cases: – When an address parity error occurs – When an access protection violation occurs – When an ECC error which cannot be corrected occurs • Notification of a response to an error in data flash The error includes the following cases: – The occurrence of ECC error that cannot be corrected*1 • Notification of the detection of access to an interconnect reserved area – FFFF 0000_H to FFFF $4FFF_H$ – FFFE 0000_H to FFFE $BFFF_H$ – FB00 0000_H to FE9F $FFFF_H$ – F300 0000_H to F8FF $FFFF_H$ • Notification of the detection of illegal access by the IPG and subsequent access blocking*2 • Notification of violation of access permission – Read or write access to an IPG protection setting register in user mode (PSW.UM = 1) – Write access to an SEG function control register in user mode (PSW.UM = 1)
3	—	Reserved This bit is always read as 0. The write value should always be 0.
2	ICCE	Instruction cache error notification enable The error occurred in the instruction cache is handled when the instruction cache system register, ICCTRL.ICHEMK, is set to 0 (the value after reset is 1): Regarding the error occurred in the instruction cache, see **Section 3.2.1.2, Register Set**, **(7) ICERR — Instruction cache error register**.
1, 0	—	Reserved These bits are always read as 0. The write value should always be 0.

Note 1. This is a case where an uncorrectable ECC error has occurred while ECC error notification is enabled.

Note 2. For the address where an error occurred, see the description of the IPGADRUM register in **Section 3.2.4.2, PE's Internal Peripheral Device Protection Function (IPG)**.

Table 3.77 Error Factor Codes and Handling of G3M Core System Error Exceptions

Factor Codes	Error Contents
10	Reserved
11	Instruction fetch errors (from code flash memory)
12	Errors in which their notification is enabled by the SEGCONT second bit
13	Instruction fetch errors (from other than code flash memory)
14	Errors in which their notification is enabled by the SEGCONT fourth bit
15	Errors in which their notification is enabled by the SEGCONT fifth bit
16	Errors in which their notification is enabled by the SEGCONT sixth bit
17	Reserved
18	Errors in which their notification is enabled by the SEGCONT eighth bit
19	Errors in which their notification is enabled by the SEGCONT ninth bit
1A	Reserved
1B	Reserved
1C	Reserved
1D	Reserved
1E	Reserved
1F	Errors in which their notification is enabled by the SEGCONT fifteenth bit

(b) SEGFLAG — Error Occurrence Retention Register

- This register sets the flags of error occurrence, that store each error occurrence status by factors. Those are not automatically cleared (return to 0).
- Writing to the register enables both setting and clearing.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SS1F	—	—	—	—	—	VPGF	VCRF	—	TCMF	ROMF	VCIF	—	ICCF	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R	R

Table 3.78 SEGFLAG Register Contents

Bit Position	Bit Name	Function
15	SS1F	Flag corresponding to bit 15 of the SEGCONT register
14 to 10	—	Reserved These bits are always read as 0. The write value should always be 0.
9	VPGF	Flag corresponding to bit 9 of the SEGCONT register
8	VCRF	Flag corresponding to bit 8 of the SEGCONT register
7	—	Reserved This bit is always read as 0. The write value should always be 0.
6	TCMF	Flag corresponding to bit 6 of the SEGCONT register
5	ROMF	Flag corresponding to bit 5 of the SEGCONT register
4	VCIF	Flag corresponding to bit 4 of the SEGCONT register
3	—	Reserved This bit is always read as 0. The write value should always be 0.
2	ICCF	Flag corresponding to bit 2 of the SEGCONT register
1, 0	—	Reserved These bits are always read as 0. The write value should always be 0.

(c) SEGADDR — Error Factor Retention Register (Address)

This register records information of an error factor that notifies a SYSERR request (only one history is recorded). It records the addresses where the error factors for the VCIF, ROMF, and TCMF bits of the SEGFLAG register were found. For the error factors which are not recorded, 0000 0000_H is stored. The value cannot be modified while the error occurrence flag to enable notification is set.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Address[31:16]															
Value after reset	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Address[15:0]															
Value after reset	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

×: Undefined (retained)

Note 1. This cannot be modified when the error occurrence flag to enable notification is set.

Table 3.79 SEGADDR Register Contents

Bit Position	Bit Name	Function
31 to 0	Address[31:0]	These bits retain the address at which SYSERR source occurred. (If an error occurred by accessing to the local RAM area, the addresses of the 17 lower-order bits are retained and the addresses of the 15 higher-order bits are cleared to 0.)

(3) SEG Function

(a) SEG function: Notifying a SYSERR request due to an error flag

- Setting an error flag takes precedence over clearing the same flag.
  - Simultaneous clearing operation is ignored.
- Priority of error factors
  - The bit position of the notification-enabled SEGFLAG register becomes the priority of error factors. Error factors of lower bits take precedence over error factors of upper bits. Notification is made from the highest-priority error factor.
  - The bit position of error factors is notified as a “SYSERR factor code.”
- Conditions for starting SYSERR request notification
  - Even if a notification-disabled flag is set to 1, notification is not made.
  - Notification is made immediately after a notification-enabled flag is set to 1.
  - After clearing, notification is made depending on the flag state (re-arbitration).
- Finishing notification at a SYSERR request response
  - Even after notification is finished, the flag is not cleared automatically.
  - Notification is not made until re-arbitration is performed by setting or clearing the flag.
  - If an error flag that is prioritized higher than the error factor is set prior to a request response, the notification information may be replaced with an upper SYSERR factor code.

(b) SEG function: Recording error factor information

- When notification-enabled error occurrence is input, the error address is retained in the above register.
  - No information is retained by setting or clearing an error flag described in **(a) SEG function: Notifying a SYSERR request due to an error flag** above.
  - When multiple error occurrence inputs are present simultaneously, information other than the prioritized error factor is not retained.
- While the notification-enabled error flag described in **(a) SEG function: Notifying a SYSERR request due to an error flag** above is set to 1, overwrite to the above register is inhibited
  - If error occurrence input continues, information of subsequent error factors is not retained.
  - To reset the inhibition of overwrite to the register, clear either SEGCONT or SEGFLAG register (or both of them).

(c) Supplementary information on SYSERR exception

- The PSW.EBV bit retains its value and the base address for the exception handler is not changed even when a SYSERR exception is generated.
- Detection of errors in the instruction cache
  Even when an error is detected in the instruction cache, a rerun-typed SYSERR exception caused by instruction fetch does not occur. Execution of the instruction by the CPU still proceeds; the instruction cache automatically invalidates the entry which lead to the error and fetching is repeated, this time from the code flash memory. The SEG block will be informed that a cache error has occurred if the setting of the ICHEMK bit of the ICCTRL cache-control system register is 0. See **(7) ICERR — Instruction cache error register** in **Section 3.2.1.2, Register Set** for the details on instruction cache error.

3.2.4.4 Checker Core

The CPU1 has the checker core for safety assurance, resulting in a highly reliable system. Monitoring the outputs from the CPU1 and the checker core with the comparator all the time enables immediate detection of the CPU1 abnormal operations. Duplication by the checker core covers the CPU core, FPU, MPU, PEG, IPG, SEG, and INTC1. The CPU1 can also conduct a fault diagnosis test of its own comparator through a pseudo-error generated by the COMPTEST module. For details of the COMPTEST module, see **Section 29, Safety**.

CAUTION

Reading of any register with an undefined value after a reset in a PE or writing to memory or a register outside the PE may cause a lock step comparison error. The values of some program registers and system registers are undefined after a reset, so pay attention to this when saving register values on the stack in RAM.

3.3 PCU

3.3.1 Core Functions

3.3.1.1 Features

Table 3.80 lists features of the RH850G3K core.

Table 3.80 Features of the RH850G3K Core

Item	Feature
CPU	• Advanced 32-bit architecture for embedded control • 32-bit internal data bus • Thirty-two 32-bit general-purpose registers • RISC-type instruction sets – Long-/short-format load/store instructions – Three-operand instructions – Instruction sets based on C language • CPU operating modes – User mode and supervisor mode • Address space: 128-Mbyte linear address space for both data and instructions • Instructions: A snooze instruction (SNOOZE) is included for temporary suspension by switching the high-speed peripheral clock signal (CLK_HSB) off for 32 clock cycles.
Coprocessor	• Coprocessor is not incorporated
Exception/ Interrupt	• 8 interrupt priority levels settable for each channel • Vector selection method selectable according to performance request or memory usage – Direct branching exception vectors – Indirect branching exception vectors referring to the address table • Supports the high-speed save/restore processing of the context by the dedicated instructions (PUSHSP and POPSP) at the generation of an interrupt
Memory Management	• Memory protection function (MPU): four areas settable
Cache	• Cache is not incorporated

3.3.1.2 Register Set

(1) Program Registers

Program registers include the general-purpose registers (r0 to r31) and the program counter (PC).

The general-purpose register r0 always retains 0, but the values of the registers r1 to r31 after reset are undefined.

Table 3.81 Program Registers

Program Register	Name	Function	Description
General-purpose registers	r0	Zero register	Always retains “0”
	r1	Assembler reserved register	Used as a working register for generating addresses
	r2	Register for address and data variables (used when the real-time OS used does not use this register)	
	r3	Stack pointer (SP)	Used for generating a stack frame when a function is called
	r4	Global pointer (GP)	Used for accessing a global variable in the data area
	r5	Text pointer (TP)	Used as a register that indicates the start of the text area (area where program code is placed)
	r6 to r29	Register for addresses and data variables	
	r30	Element pointer (EP)	Used as a base pointer for generating addresses when accessing memory
	r31	Link pointer (LP)	Used when the compiler calls a function
Program counter	PC	Retains instruction addresses during execution of programs	

NOTE

For further descriptions of r1, r3 to r5, and r31 used for an assembler and/or C compiler, see the specification of each software development environment.

(a) General-Purpose Registers

A total of 32 general-purpose registers (r0 to r31) are provided. All of these registers can be used for either data variables or address variables. Of the general-purpose registers, r0 to r5, r30, and r31 are assumed to be used for special purposes in software development environments, so it is necessary to note the following when using them.

1. r0, r3, and r30

   These registers are implicitly used by instructions.

   r0 is a register that always retains "0". It is used for operations that use 0, addressing with base address being 0, etc.

   r3 is implicitly used by the PREPARE, DISPOSE, PUSHSP, and POPSP instructions.

   r30 is used as a base pointer when the SLD instruction or SST instruction accesses memory.

2. r1, r4, r5, and r31

   These registers are implicitly used by the assembler and C compiler.

   When using these registers, register contents must first be saved so they are not lost and can be restored after the registers are used.

3. r2

   This register might be used by a real-time OS in some cases. If the real-time OS that is being used is not using r2, r2 can be used as a register for address variables or data variables.

(b) PC — Program Counter

The PC retains the address of the instruction being executed.

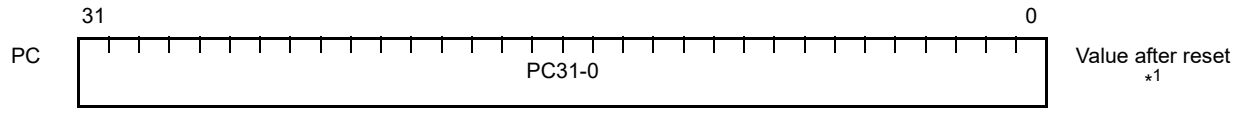

Table 3.82 PC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	PC31-1	These bits indicate the address of the instruction being executed.	R/W	*1
0	PC0	This bit is fixed to 0, and branching to an odd number address is disabled.	R/W	0

Note 1. In this product, the value after reset differs depending on the startup area. For details, see **Section 4, Address Space**.

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27.

(2) Basic System Registers

The basic system registers are used to control CPU status and to retain exception information.

System registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.83 Basic System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR0, 0	EIPC*1	Status save registers when acknowledging EI level exception	SV
SR1, 0	EIPSW	Status save registers when acknowledging EI level exception	SV
SR2, 0	FEPC*1	Status save registers when acknowledging FE level exception	SV
SR3, 0	FEPSW	Status save registers when acknowledging FE level exception	SV
SR 5, 0	PSW	Program status word	*2
SR 13, 0	EIIC	EI level exception cause	SV
SR 14, 0	FEIC	FE level exception cause	SV
SR 16, 0	CTPC *1	CALLT execution status save register	UM
SR 17, 0	CTPSW	CALLT execution status save register	UM
SR 20, 0	CTBP *1	CALLT base pointer	UM
SR 28, 0	EIWR	EI level exception working register	SV
SR 29, 0	FEWR	FE level exception working register	SV
SR 31, 0	(BSEL)	(Reserved for backwards compatibility with the V850E2 series)*3	SV
SR0, 1	MCFG0	Machine configuration	SV
SR2, 1	RBASE	Reset vector base address	SV
SR3, 1	EBASE*1	Exception handler vector address	SV
SR4, 1	INTBP*1	Base address of the interrupt handler table	SV
SR 5, 1	MCTL	CPU control	SV
SR 6, 1	PID	Processor ID	SV
SR 11, 1	SCCFG	SYSCALL operation setting	SV
SR 12, 1	SCBP*1	SYSCALL base pointer	SV
SR0, 2	HTCFG0	Process number	SV
SR6, 2	MEA*1	Memory error address	SV
SR7, 2	ASID	Address space ID	SV
SR8, 2	MEI	Memory error information	SV

Note 1. For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27.

Note 2. The access permission differs depending on the bit. For details, see **Table 3.88, Access Permission for PSW Register**.

Note 3. Reserved for backwards compatibility with the V850E2 series. These registers are always read as 0. Writing to these registers is ignored.

(a) EIPC — Status save register when acknowledging EI level exception register

When an EI level exception is acknowledged, the address of the instruction that was being executed when the EI level exception occurred, or of the next instruction, is saved to the EIPC register (see *section 4.1.3 Types of Exceptions* in *RH850G3K User's Manual: Software*) .

Because there is only one pair of EI level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

Be sure to set an even-numbered address to the EIPC register. An odd-numbered address must not be specified.

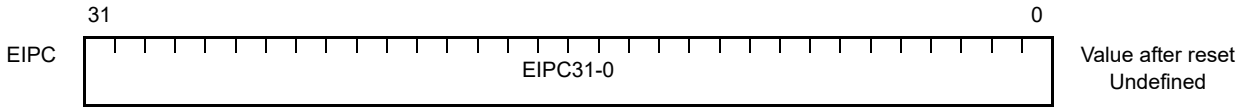

Table 3.84 EIPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	EIPC31-1	These bits indicate the PC saved when an EI level exception is acknowledged.	R/W	Undefined
0	EIPC0	This bit indicates the PC saved when an EI level exception is acknowledged. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the EIRET instruction is executed is 0.	R/W	Undefined

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of EIPC.

(b) EIPSW — Status save register when acknowledging EI level exception register

When an EI level exception is acknowledged, the current PSW setting is saved to the EIPSW register.

Because there is only one pair of EI level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

CAUTION

Bits 11 to 9 cannot usually be changed since these bits are associated with debugging.

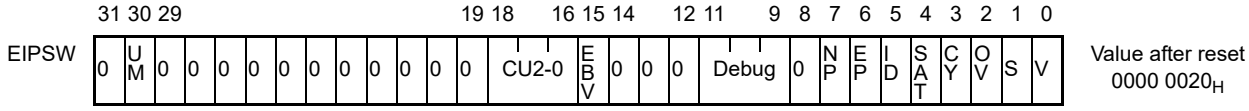

Table 3.85 EIPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
30	UM	This bit stores the PSW.UM bit setting when an EI level exception is acknowledged.	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-0	These bits store the PSW.CU2 to 0 field setting when an EI level exception is acknowledged. (Reserved for future expansion. Be sure to clear to 0.)	R	0
15	EBV	This bit stores the PSW.EBV bit setting when an EI level exception is acknowledged.	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits store the PSW.Debug field when an EI level exception is acknowledged.	R/W	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	NP	This bit stores the PSW.NP bit setting when an EI level exception is acknowledged.	R/W	0
6	EP	This bit stores the PSW.EP bit setting when an EI level exception is acknowledged.	R/W	0
5	ID	This bit stores the PSW.ID bit setting when an EI level exception is acknowledged.	R/W	1
4	SAT	This bit stores the PSW.SAT bit setting when an EI level exception is acknowledged.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when an EI level exception is acknowledged.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when an EI level exception is acknowledged.	R/W	0
1	S	This bit stores the PSW.S bit setting when an EI level exception is acknowledged.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when an EI level exception is acknowledged.	R/W	0

(c) FEPC — Status save register when acknowledging FE level exception register

When an FE level exception is acknowledged, the address of the instruction that was being executed when the FE level exception occurred, or of the next instruction, is saved to the FEPC register (see *section 4.1.3 Types of Exceptions* in *RH850G3K User's Manual: Software*) in the Software Manual.

Because there is only one pair of FE level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

Be sure to set an even-numbered address to the FEPC register. An odd-numbered address must not be specified.

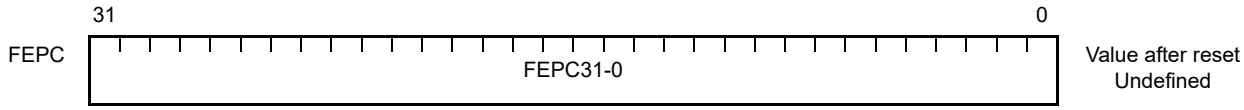

Table 3.86 FEPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	FEPC31-1	These bits indicate the PC saved when an FE level exception is acknowledged.	R/W	Undefined
0	FEPC0	This bit indicates the PC saved when an FE level exception is acknowledged. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the FERET instruction is executed is 0.	R/W	Undefined

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of FEPC.

(d) FEPSW — Status save register when acknowledging FE level exception register

When an FE level exception is acknowledged, the current PSW setting is saved to the FEPSW register.

Because there is only one pair of FE level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

CAUTION

Bits 11 to 9 cannot usually be changed since these bits are associated with debugging.

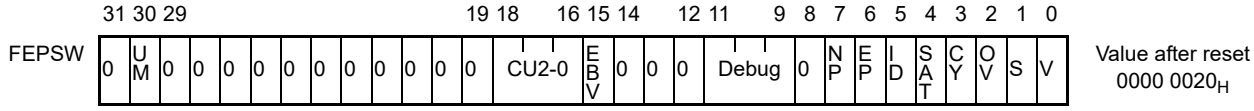

Table 3.87 FEPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
30	UM	This bit stores the PSW.UM bit setting when an FE level exception is acknowledged.	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-0	These bits store the PSW.CU2 to 0 field setting when an FE level exception is acknowledged. (Reserved for future expansion. Be sure to clear to 0.)	R	0
15	EBV	This bit stores the PSW.EBV bit setting when an FE level exception is acknowledged.	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits store the PSW.Debug field when an FE level exception is acknowledged.	R/W	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	NP	This bit stores the PSW.NP bit setting when an FE level exception is acknowledged.	R/W	0
6	EP	This bit stores the PSW.EP bit setting when an FE level exception is acknowledged.	R/W	0
5	ID	This bit stores the PSW.ID bit setting when an FE level exception is acknowledged.	R/W	1
4	SAT	This bit stores the PSW.SAT bit setting when an FE level exception is acknowledged.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when an FE level exception is acknowledged.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when an FE level exception is acknowledged.	R/W	0
1	S	This bit stores the PSW.S bit setting when an FE level exception is acknowledged.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when an FE level exception is acknowledged.	R/W	0

(e) PSW — Program status word register

PSW (program status word) is a set of flags that indicate the program status (instruction execution result) and bits that indicate the operation status of the CPU (flags are bits in the PSW that are referenced by a condition instruction (Bcond, CMOV, etc.)).

When the LDSR instruction is used to change the contents of each bit in this register, the changed contents become valid from the instruction following the LDSR instruction.

The access permission for the PSW register differs depending on the bit. All bits can be read, but some bits can only be written under certain conditions. See **Table 3.88, Access Permission for PSW Register** for the access permission for each bit.

Table 3.88 Access Permission for PSW Register

Bit		Access Permission When Reading	Access Permission When Writing
30	UM	UM	SV*1
18 to 16	CU2-0	UM	SV*1
15	EBV	UM	SV*1
11 to 9	Debug	UM	Special*1
7	NP	UM	SV*1
6	EP	UM	SV*1
5	ID	UM	SV*1
4	SAT	UM	UM
3	CY	UM	UM
2	OV	UM	UM
1	S	UM	UM
0	Z	UM	UM

Note 1. The access permission for the whole PSW register is UM, so the PIE exception does not occur even if the register is written by using an LDSR instruction when PSW.UM is 1. In this case, writing is ignored.

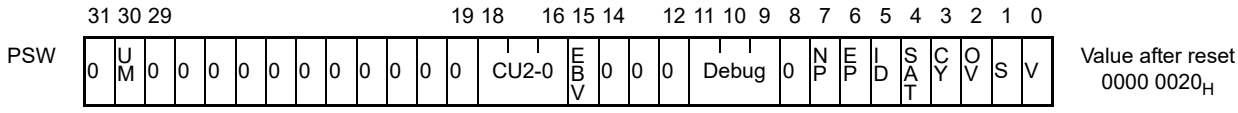

Table 3.89 PSW Register Contents (1/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
30	UM	This bit indicates that the CPU is in user mode (UM mode) 0: Supervisor mode 1: User mode	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-0	(Reserved for future expansion. Be sure to clear to 0.)	R	000
15	EBV	This bit indicates the reset vector and exception vector operation. See the descriptions of the RBASE register in **(q) RBASE — Reset vector base address register** and the EBASE register in **(r) EBASE — Exception handler vector address register**.	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits are used in the debugging functions of development tools. In normal operation, clear these bits to 0.	—	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

Table 3.89 PSW Register Contents (2/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
7	NP	Disables acceptance of FE level exceptions. Once an FE level exception is accepted, this bit is set to 1 and disables acceptance of EI level exceptions or FE level exceptions. For the exceptions disabled by the NP bit, see *table 4-1 Exception Cause List* in *RH850G3K User's Manual: Software*. 0 : An acceptance of FE level exceptions is enabled 1 : An acceptance of FE level exceptions is disabled	R/W	0
6	EP	Disables acceptance of EI level exceptions. Once an IE level exception or FE level exception is accepted, this bit is set to 1 and disables acceptance of EI level exceptions. For the exceptions disabled by the ID bit, see *table 4-1 Exception Cause List* in *RH850G3K User's Manual: Software*. This bit does not affect acknowledging an exception request even when it is set to 1. A change in the ID bit by the IE or DI instruction is enabled from the next instruction. 0: An interrupt is not being serviced. 1: An exception other than an interrupt is being serviced.	R/W	0
5	ID	Disables acceptance of EI level exceptions. Once an IE level exception or FE level exception is accepted, this bit is set to 1 and disables acceptance of EI level exceptions. For the exceptions disabled by the ID bit, see *table 4-1 Exception Cause List* in *RH850G3K User's Manual: Software*. This bit is also used to disable EI level exceptions from being acknowledged as a critical section while an ordinary program or interrupt is being serviced. It is set to 1 when the DI instruction is executed, and cleared to 0 when the EI instruction is executed. A change in the ID bit by the IE or DI instruction is enabled from the next instruction. 0 : An acceptance of IE level exceptions is enabled 1 : An acceptance of IE level exceptions is disabled	R/W	1
4	SAT*1	This bit indicates that the operation result is saturated because the result of a saturated operation instruction operation has overflowed. This is a cumulative flag, so when the operation result of the saturated operation instruction becomes saturated, this bit is set to 1, but it is not cleared to 0 when the operation result for a subsequent instruction is not saturated. This bit is cleared to 0 by the LDSR instruction. This bit is neither set to 1 nor cleared to 0 when an arithmetic operation instruction is executed. 0: Not saturated 1: Saturated	R/W	0
3	CY	This bit indicates whether a carry or borrow has occurred in the operation result. 0: Carry and borrow have not occurred. 1: Carry or borrow has occurred.	R/W	0
2	OV*1	This bit indicates whether or not an overflow has occurred during an operation. 0: Overflow has not occurred. 1: Overflow has occurred.	R/W	0
1	S*1	This bit indicates whether or not the result of an operation is negative. 0: Result of operation is positive or 0. 1: Result of operation is negative	R/W	0
0	Z	This bit indicates whether or not the result of an operation is 0. 0: Result of operation is not 0. 1: Result of operation is 0.	R/W	0

Note 1. The operation result of the saturation processing is determined in accordance with the contents of the OV flag and S flag during a saturated operation. When only the OV flag is set to 1 during a saturated operation, the SAT flag is set to 1.

Operation result status	Flag status			Operation result after saturation processing
	SAT	OV	S	
Exceeded positive maximum value	1	1	0	7FFF FFFF$_H$
Exceeded negative maximum value	1	1	1	8000 0000$_H$

Operation result status	Flag status			Operation result after saturation processing
	SAT	OV	S	
Positive (maximum value not exceeded)	Value prior to operation is retained.	0	0	Operation result itself
Negative (maximum value not exceeded)			1	

(f) EIIC — EI level exception cause register

The EIIC register retains the cause of any EI level exception that occurs. The value retained in this register is an exception code corresponding to a specific exception cause.

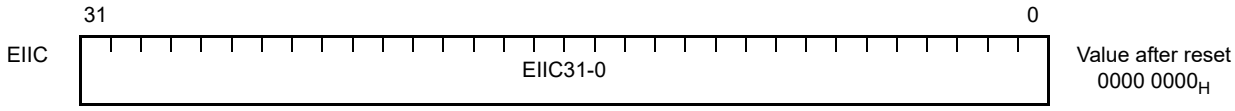

Table 3.90 EIIC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	EIIC31-0	These bits store the exception cause code when an EI level exception occurs. Regarding the stored exception source code, see *Table 6.14, Interrupt Exception Handler and Priority* and *table 4-1 Exception Cause List* in *RH850G3K User's Manual: Software*. The EIIC31-16 field stores detailed exception cause codes defined individually for each exception. If there is no particular definition, these bits are set to 0.	R/W	0

(g) FEIC — FE level exception cause register

The FEIC register retains the cause of any FE level exception that occurs. The value retained in this register is an exception code corresponding to a specific exception cause.

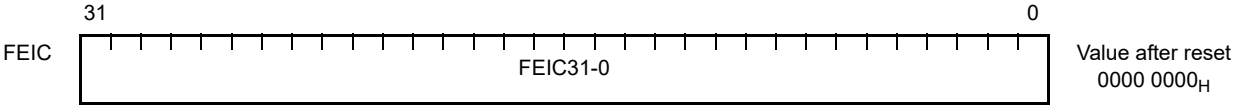

Table 3.91 FEIC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	FEIC31-0	These bits store the exception cause code when an FE level exception occurs. Regarding the stored exception source code, see *Table 6.14, Interrupt Exception Handler and Priority* and *table 4-1 Exception Cause List* in *RH850G3K User's Manual: Software*. The FEIC31-16 field stores detailed exception cause codes defined individually for each exception. If there is no particular definition, these bits are set to 0.	R/W	0

(h) CTPC — Status save register when executing CALLT register

When a CALLT instruction is executed, the address of the next instruction after the CALLT instruction is saved to CTPC. Be sure to set an even-numbered address to the CTPC register. An odd-numbered address must not be specified.

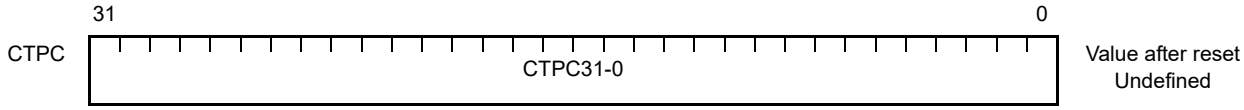

Table 3.92 CTPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	CTPC31-1	These bits indicate the PC of the instruction after the CALLT instruction.	R/W	Undefined
0	CTPC0	This bit indicates the PC of the instruction after the CALLT instruction. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the CTRET instruction is executed is 0.	R/W	Undefined

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of CTPC.

(i) CTPSW — Status save register when executing CALLT register

When a CALLT instruction is executed, some of the PSW (program status word) settings are saved to CTPSW.

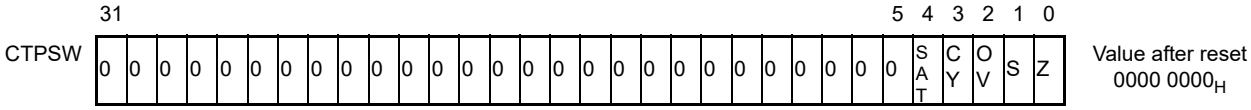

Table 3.93 CTPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
4	SAT	This bit stores the PSW.SAT bit setting when the CALLT instruction is executed.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when the CALLT instruction is executed.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when the CALLT instruction is executed.	R/W	0
1	S	This bit stores the PSW.S bit setting when the CALLT instruction is executed.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when the CALLT instruction is executed.	R/W	0

(j) CTBP — CALLT base pointer register

The CTBP register is used to specify table addresses of the CALLT instruction and generate target addresses. Be sure to set the CTBP register to a half word address.

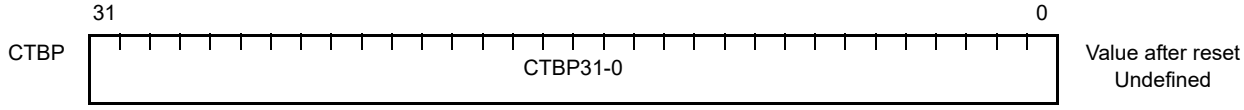

Table 3.94 CTBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	CTBP31-1	These bits indicate the base pointer address of the CALLT instruction. These bits indicate the first address in the table used by the CALLT instruction.	R/W	Undefined
0	CTBP0	These bits indicate the base pointer address of the CALLT instruction. These bits indicate the first address in the table used by the CALLT instruction. Always set this bit to 0.	R	0

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of CTBP.

(k) ASID — Address space ID register

This is the address space ID. This is used to identify the address space provided by the memory management function.

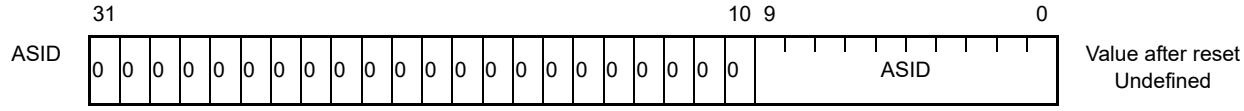

Table 3.95 ACID Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 10	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
9 to 0	ASID	This is the address space ID.	R/W	Undefined

(l) EIWR — EI level exception working register

The EIWR register is used as a working register when an EI level exception has occurred.

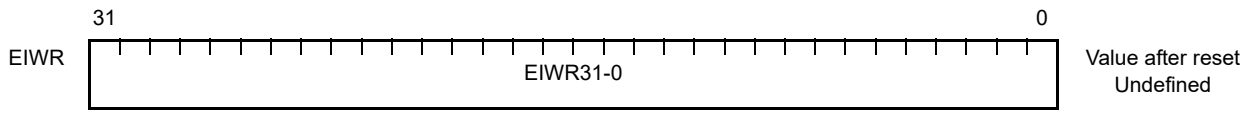

Table 3.96 EIWR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	EIWR31-0	These bits constitute a working register that can be used for any purpose during the processing of an EI level exception. Use this register for purposes such as storing the values of general-purpose registers.	R/W	Undefined

(m) FEWR — FE level exception working register

The FEWR register is used as a working register when an FE level exception has occurred.

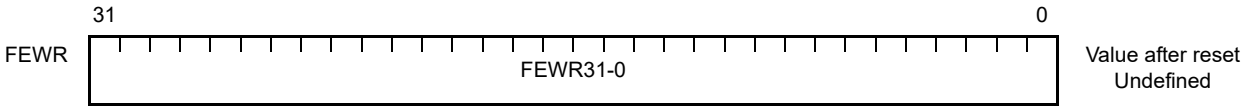

Table 3.97 FEWR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	FEWR31-0	These bits constitute a working register that can be used for any purpose during the processing of an FE level exception. Use this register for purposes such as storing the values of general-purpose registers.	R/W	Undefined

(n) HTCFG0 — Thread configuration register

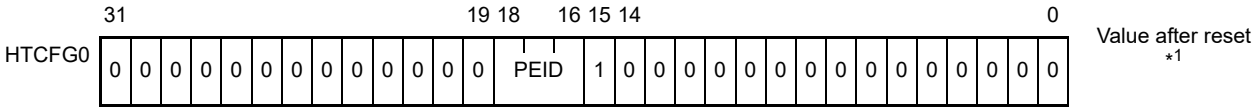

Table 3.98 HTCFG0 Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	PEID	These bits indicate the processor element number.	R	*2
15	—	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
14 to 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

Note 1. The value is 0003 8000_H in PCU (PE3) of this product.
Note 2. The value is 011_B in PCU (PE3) of this product.

(o) MEA — Memory error address register

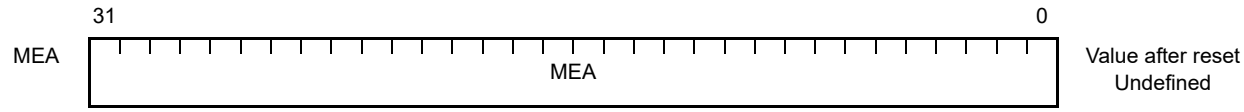

Table 3.99 MEA Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	MEA	These bits store the address when an MAE (misaligned) or MPU exception occurs.	R/W	Undefined

(p) MEI — Memory error information register

This register is used to store information about the instruction that caused the exception when a misaligned (MAE) or memory protection (MDP) exception occurs. This information is used during emulation.

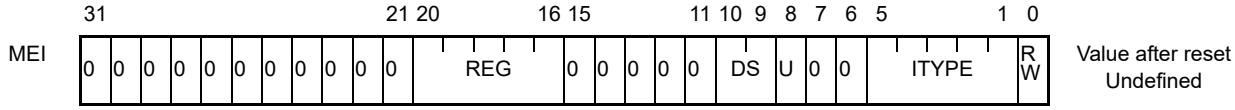

Table 3.100 MEI Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 21	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
20 to 16	REG4-0	These bits indicate the number of the source or destination register accessed by the instruction that caused the exception. For details, see **Table 3.101, Instructions Causing Exceptions and Values of MEI Register**.	R/W	Undefined
15 to 11	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
10, 9	DS	These bits indicate the type of data handled by the instruction that caused the exception.*1 0: Byte (8 bits) 1: Half word (16 bits) 2: Word (32 bits) 3: Double-word (64 bits) For details, see **Table 3.101, Instructions Causing Exceptions and Values of MEI Register**.	R/W	Undefined
8	U	These bits indicate the sign extension method of the instruction that caused the exception. 0: Signed 1: Unsigned For details, see **Table 3.101, Instructions Causing Exceptions and Values of MEI Register**.	R/W	Undefined
7, 6	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
5 to 1	ITYPE4-0	These bits indicate the instruction that caused the exception. For details, see **Table 3.101, Instructions Causing Exceptions and Values of MEI Register**.	R/W	Undefined
0	RW	This bit indicates whether the operation of the instruction that caused the exception was read (Load-memory) or write (Store-memory) 0: Read (Load-memory) 1: Write (Store-memory) For details, see **Table 3.101, Instructions Causing Exceptions and Values of MEI Register**.	R/W	Undefined

Note 1. Even if the data is divided and access is made several times due to the specifications of the hardware, the original data type indicated by the instruction is stored.

Table 3.101 Instructions Causing Exceptions and Values of MEI Register (1/2)

Instruction	REG	DS	U	RW	ITYPE
SLD.B	dst	0 (Byte)	0 (Signed)	0 (Read)	00000_B
SLD.BU	dst	0 (Byte)	1 (Unsigned)	0 (Read)	00000_B

PUSHSP	—	2 (Word)	1 (Unsigned)	1 (Write)	01101_B
POPSP	—	2 (Word)	1 (Unsigned)	0 (Read)	01101_B
SWITCH	—	1 (Half word)	0 (Signed)	0 (Read)	10000_B
CALLT	—	1 (Half word)	1 (Unsigned)	0 (Read)	10001_B
SYSCALL	—	2 (Word)	1 (Unsigned)	0 (Read)	10010_B
Interrupt (table reference)*2	—	2 (Word)	1 (Unsigned)	0 (Read)	10101_B

Note 1. This exception occurs when the instruction executes a read access.

Note 2. An exception occurs when the table reference interrupt vector is read.

NOTE

dst: destination register number, src: source register number

(q) RBASE — Reset vector base address register

This register indicates the reset vector address when there is a reset. If the PSW.EBV bit is 0, this vector address is also used as the exception vector address.

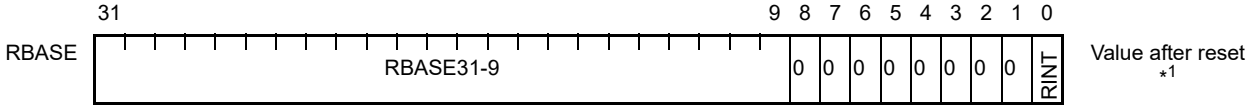

Table 3.102 RBASE Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	RBASE31-9	These bits indicate the reset vector when there is a reset. When PSW.EBV = 0, this address is also used as the exception vector. The EBASE8 to 0 bits are implicitly set to 0.	R	*1
8 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	RINT	When the RINT bit is set, the offset address of the exception handler used during interrupt servicing is decremented. This bit is valid when PSW.EBV = 0.	R	0

Note 1. The reset vector differs depending on the startup area. For details, see **Section 4, Address Space**.

(r) EBASE — Exception handler vector address register

This register indicates the exception handler vector address. This register is valid when the PSW.EBV bit is 1.

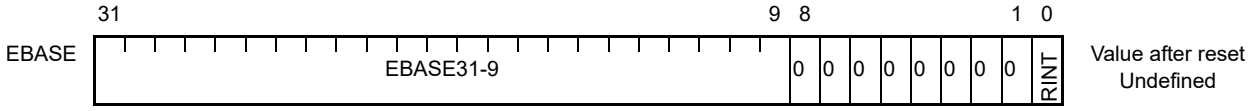

Table 3.103 EBASE Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	EBASE31-9	The exception handler routine address is changed to the address resulting from adding the offset address of each exception to the base address specified for this register. The EBASE8 to 0 bits are implicitly set to 0.	R/W	Undefined
8 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	RINT	When the RINT bit is set, the offset address of the exception handler used during interrupt servicing is decremented.	R/W	Undefined

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of EBASE.

(s) INTBP — Base address of the interrupt handler table register

This register indicates the base address of the address table when the table reference method is selected as the interrupt handler address selection method.

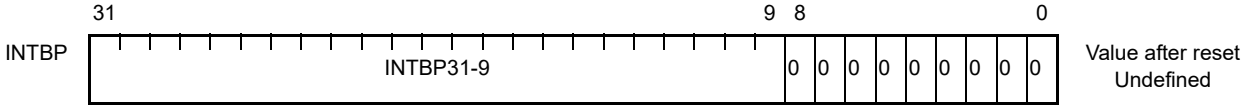

Table 3.104 INTBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	INTBP31-9	These bits indicate the base pointer address for an interrupt prescribed in the expanded specifications. The value indicated by these bits is the first address in the table used to determine the exception handler when the interrupt prescribed by the expanded specifications (EIINT0 to EIINT511) is acknowledged. The EBASE8 to 0 bits are implicitly set to 0.	R/W	Undefined
8 to 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of INTBP.

(t) PID — Processor ID register

The PID register retains a processor identifier that is unique to the CPU. The PID register is a read-only register.

CAUTION

The PID register indicates information used to identify the incorporated CPU core and CPU core configuration. Usage such that the software behavior varies dynamically according to the PID register information is not assumed.

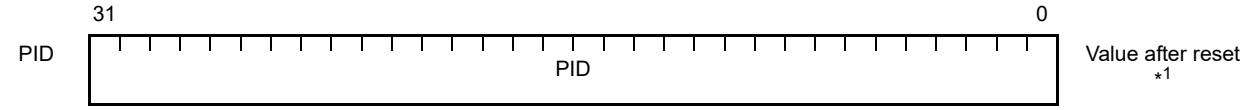

Table 3.105 PID Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 24	PID	Architecture identifier This identifier indicates the architecture of the processor.	R	$F5_H$
23 to 8		Function identifier This identifier indicates the functions of the processor. These bits indicate whether or not functions defined per bit are implemented (1: implemented, 0: not implemented). Bit 23 to 11 : Reserved Bit 10 : Double-precision floating-point operation function Bit 9 : Single-precision floating-point operation function Bit 8: Memory protection unit (MPU) function	R	0001_H
7 to 0		Version identifier This identifier indicates the version of the processor.	R	30_H

Note 1. The value is F500 0130_H in this product.

(u) SCCFG — SYSCALL operation setting register

This register is used to specify operations related to the SYSCALL instruction. Be sure to set an appropriate value to this register before using the SYSCALL instruction.

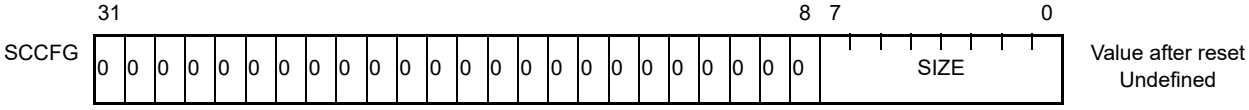

Table 3.106 SCCFG Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7 to 0	SIZE	These bits specify the maximum number of entries of a table that the SYSCALL instruction references. The maximum number of entries the SYSCALL instruction references is 1 if SIZE is 0, and 256 if SIZE is 255. By setting the maximum number of entries appropriately in accordance with the number of functions branched by the SYSCALL instruction, the memory area can be effectively used. If a vector exceeding the maximum number of entries is specified for the SYSCALL instruction, the first entry is selected. Place an error processing routine at the first entry.	R/W	Undefined

(v) SCBP — SYSCALL base pointer register

The SCBP register is used to specify a table address of the SYSCALL instruction and generate a target address. Be sure to set an appropriate value to this register before using the SYSCALL instruction.

Be sure to set a word address to the SCBP register.

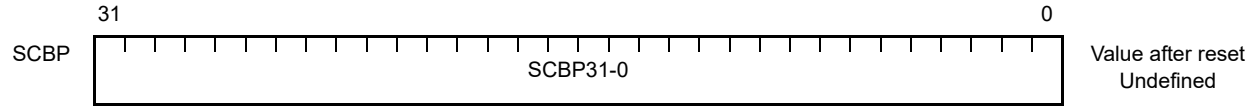

Table 3.107 SCBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	SCBP31-2	These bits indicate the base pointer address of the SYSCALL instruction. These bits indicate the first address in the table used by the SYSCALL instruction.	R/W	Undefined
1, 0	SCBP1-0	These bits indicate the base pointer address of the SYSCALL instruction. These bits indicate the first address in the table used by the SYSCALL instruction. Always set this bit to 0.	R	0

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of SCBP.

(w) MCFG0 — Machine configuration register

This register indicates the CPU configuration.

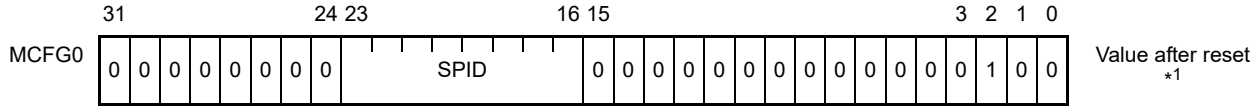

Table 3.108 MCFG0 Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 24	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
23 to 16	SPID	Bit 23 to 18: These are not supported in this product. (Reserved for the future expansion. Be sure to clear to 0) Bit 17, 16: These bits indicate the system protection number.	R/W	*2
15 to 3	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
2	—	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
1, 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

Note 1. The value is 0003 0004_H in PCU (PE3) of this product.
Note 2. The value is 03_H in PCU (PE3) of this product.

(x) MCTL — Machine control register

This register is used to control the CPU.

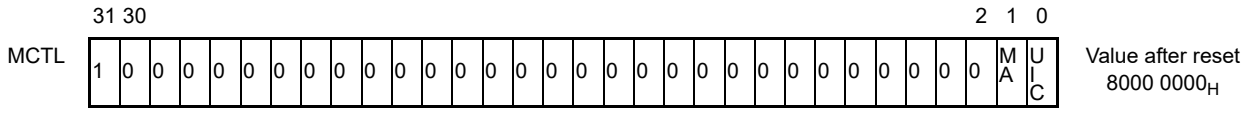

Table 3.109 MCTL Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	EN	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
30 to 2	MT	(Reserved for future expansion. Be sure to clear to 0.)	R	0
1	MA	This bit specifies the operation when a misaligned access occurs. 0: An exception is generated in response to a misaligned access.*1 1: A misalignment exception is not generated and access still proceeds.*1	R/W	0
0	UIC	This bit is used to control the interrupt enable/disable operation in user mode. When this bit is set to 1, executing the EI/DI instruction in user mode becomes possible.	R/W	0

Note 1. This bit does not control the generation of misalignment exceptions in response to access by double-word instructions.

(3) Interrupt function registers

Table 3.110 Interrupt Function System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR10, 2	ISPR	Priority of interrupt being serviced	SV
SR11, 2	PMR	Interrupt priority masking	SV
SR12, 2	ICSR	Interrupt control status	SV
SR13, 2	INTCFG	Interrupt function setting	SV

(a) ISPR — Priority of interrupt being serviced register

This register holds the priority of the EIINTn interrupt being serviced. This priority value is then used to perform priority ceiling processing when multiple interrupts are generated.

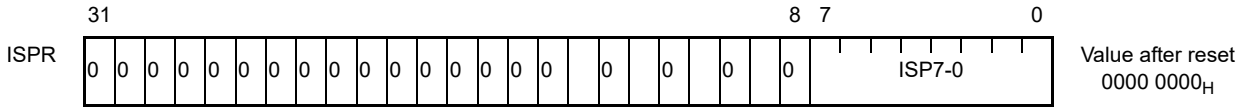

Table 3.111 ISPR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7 to 0	ISP7-0	These bits indicate the acknowledgment status of an EIINT*n* interrupt with a priority*1 that corresponds to the relevant bit position. 0: An interrupt request for an interrupt whose priority corresponds to the relevant bit position has not been acknowledged. 1: An interrupt request for an interrupt whose priority corresponds to the relevant position is being serviced by the CPU core. The bit positions correspond to the following priority levels: **Bit / Priority** 0 — Priority 0 (highest) 1 — Priority 1 : 6 — Priority 6 7 — Priority 7 When an interrupt request (EIINT*n*) is acknowledged, the bit corresponding to the acknowledged interrupt request is automatically set to 1. If PSW.EP is 0 when the EIRET instruction is executed, the bit with the highest priority among the ISP7 to 0 bits that are set (0 is the highest priority) is cleared to 0*2. While a bit in this register is set to 1, lower priority interrupts (EIINT*n*) are masked. Priority level judgment is therefore not performed when the system is determining whether to acknowledge an exception, meaning that exceptions will not be acknowledged. See *section 4.1.5 Interrupt Exception Priority and Priority Masking* in *RH850G3K User's Manual: Software*. When performing software-based priority control using the PMR register, be sure to clear this register by using the INTCFG.ISPC bit.	R*3	0

Note 1. See *section 4.1.5 Interrupt Exception Priority and Priority Masking* in *RH850G3K User's Manual: Software* for the details.

Note 2. Interrupt acknowledgment and auto-updating of values when the EIRET instruction is executed are disabled by setting the INTCFG.ISPC bit to 1. We recommend auto-updating, so in normal cases, clear the INTCFG.ISPC bit to 0.

Note 3. This is R or R/W, depending on the setting of the INTCFG.ISPC bit. It is recommended to use this register as a read-only (R) register.

(b) PMR — Interrupt priority masking register

This register is used to mask the specified interrupt priority.

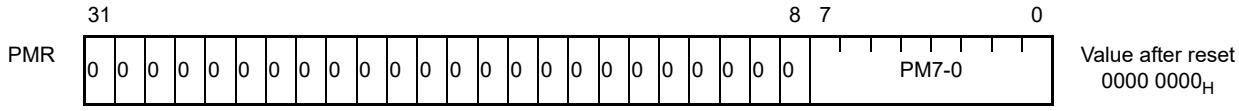

Table 3.112 PMR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7 to 0	PM7-0	These bits mask an interrupt request with a priority level that corresponds to the relevant bit position. 0: Servicing of an interrupt request with a priority that corresponds to the relevant bit position is enabled. 1: Servicing of an interrupt request with a priority that corresponds to the relevant bit position is disabled. The bit positions correspond to the following priority levels: **Bit** / **Priority** 0 / Priority 0 (highest) 1 / Priority 1 : / : 6 / Priority 6 7 / Priority 7 (lowest) While a bit in this register is set to 1, interrupts (EIINTn) with the priority corresponding to that bit are masked. Priority level judgment is therefore not performed when the system is determining whether to acknowledge an exception, meaning that exceptions will not be acknowledged*1.	R/W	0

Note 1. Specify the masks by setting the bits to 1 in order from the lowest-priority bit. For example, $F0_H$ can be set, but CC_H or $0F_H$ cannot.

(c) ICSR — Interrupt control status register

This register indicates the interrupt control status in the CPU.

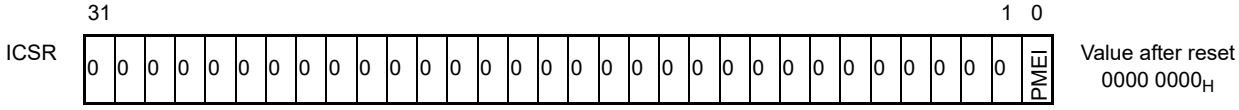

Table 3.113 ICSR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	PMEI	This bit indicates that an interrupt (EIINTn) with the priority level masked by the PMR register exists	R	0

(d) INTCFG — Interrupt function setting register

This register is used to specify settings related to the CPU's internal interrupt function.

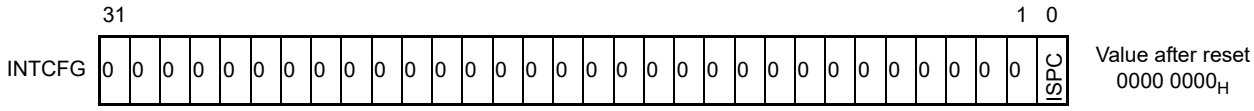

Table 3.114 INTCFG Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	ISPC	This bit changes how the ISPR register is written. 0: The ISPR register is automatically updated. Updates triggered by the program (via execution of LDSR instruction) are ignored. 1: The ISPR register is not automatically updated. Updates triggered by the program (via execution of LDSR instruction) are performed. If this bit is cleared to 0, the bits of the ISPR register are automatically set to 1 when an interrupt (EIINT*n*) is acknowledged, and cleared to 0 when the EIRET instruction is executed. In this case, the bits are not updated by an LDSR instruction executed by the program. If this bit is set to 1, the bits of the ISPR register are not updated by the acknowledgement of an interrupt (EIINT*n*) or by execution of the EIRET instruction. In this case, the bits can be updated by an LDSR instruction executed by the program. In normal cases, the ISPC bit should be cleared. When performing software-based priority control, however, set this bit to 1 and perform priority control by using the PMR register.	R/W	0

(4) FPU Function Registers

This product does not include an FPU.

(5) MPU Function Registers

(a) MPU function system registers

The MPU function system registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.115 MPU Function System Registers (1/2)

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR0, 5	MPM	Memory protection operation mode setting	SV
SR1, 5	MPRC	MPU region control	SV
SR4, 5	MPBRGN	MPU base region number	SV
SR5, 5	MPTRGN	MPU end region number	SV
SR11, 5	MCR	Memory protection setting check result	SV
SR0, 6	MPLA0	Protection area minimum address	SV
SR1, 6	MPUA0	Protection area maximum address	SV
SR2, 6	MPAT0	Protection area attribute	SV
SR4, 6	MPLA1	Protection area minimum address	SV
SR5, 6	MPUA1	Protection area maximum address	SV
SR6, 6	MPAT1	Protection area attribute	SV
SR8, 6	MPLA2	Lower address of the protection area	SV
SR9, 6	MPUA2	Protection area maximum address	SV
SR10, 6	MPAT2	Protection area attribute	SV
SR12, 6	MPLA3	Protection area minimum address	SV
SR13, 6	MPUA3	Protection area maximum address	SV
SR14, 6	MPAT3	Protection area attribute	SV

Table 3.115 MPU Function System Registers (2/2)

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR16, 6	MPLA4	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR17, 6	MPUA4		SV
SR18, 6	MPAT4		SV
SR20, 6	MPLA5		SV
SR21, 6	MPUA5		SV
SR22, 6	MPAT5		SV
SR24, 6	MPLA6		SV
SR25, 6	MPUA6		SV
SR26, 6	MPAT6		SV
SR28, 6	MPLA7		SV
SR29, 6	MPUA7		SV
SR30, 6	MPAT7		SV
SR0, 7	MPLA8		SV
SR1, 7	MPUA8		SV
SR2, 7	MPAT8		SV
SR4, 7	MPLA9		SV
SR5, 7	MPUA9		SV
SR6, 7	MPAT9		SV
SR8, 7	MPLA10		SV
SR9, 7	MPUA10		SV
SR10, 7	MPAT10		SV

SR26, 7	MPAT14		SV
SR28, 7	MPLA15		SV
SR29, 7	MPUA15		SV
SR30, 7	MPAT15		SV

(1) MPM — Memory protection operation mode register

The memory protection mode register is used to define the basic operating state of the memory protection function.

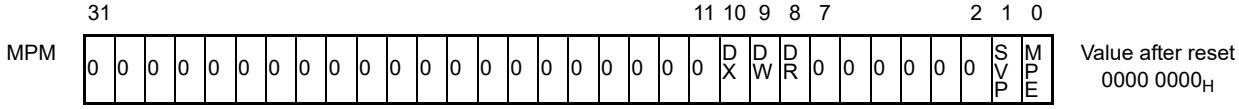

Table 3.116 MPM Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 11	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
10	DX	This bit specifies the default operation when an instruction is executed at an address that does not exist in a protection area. 0: Disable executing an instruction at an address that does not exist in a protection area. 1: Enable executing an instruction at an address that does not exist in a protection area.	R/W	0
9	DW	This bit specifies the default operation when writing to an address that does not exist in a protection area. 0: Disable writing to an address that does not exist in a protection area. 1: Enable writing to an address that does not exist in a protection area.	R/W	0
8	DR	This bit specifies the default operation when reading from an address that does not exist in a protection area. 0: Disable reading from an address that does not exist in a protection area. 1: Enable reading from an address that does not exist in a protection area.	R/W	0
7 to 2	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
1	SVP*3, *4	In SV mode (when PSW.UM = 0), this bit is used to specify whether to restrict access according to the SX, SW, and SR bits of the MPAT register for each protection area.*1 0: As usual, implicitly enable all access in SV mode. 1: Restrict access according to the SX, SW, and SR bits even in SV mode.*2	R/W*4	0
0	MPE	This bit is used to specify whether to enable or disable MPU function. 0: Disable 1: Enable	R/W	0

Note 1. When the SVP bit is set to 1, access will become restricted after a certain number of clock cycles, even in SV mode. Therefore, specify the protection area before setting the SVP bit to prevent restriction of access by the program itself.

Note 2. If access is restricted in SV mode., execution of MDP exceptions or the MIP exception handling itself might not be possible depending on the settings. Be careful to specify settings so that access to the memory area necessary for the exception handler and exception handling is permitted.

Note 3. Access by the CPU in supervisor mode is not restricted during the processing of SYSCALL instructions while SVP = 1 and in table references in response to EIINT interrupts involving table reference.

Note 4. When the SVP bit is set to 1 to use the debugger, enable execution of instruction by SV mode in the FE60 0000_H to FE7F $FFFF_H$ area. When a debugger manufactured by a third party executes instructions by downloading code to the global RAM area or local RAM area of PE1, enable instructions for SV mode in said areas.

(2) MPRC — MPU region control register

Bits used to perform special memory protection function operations are located in this register.

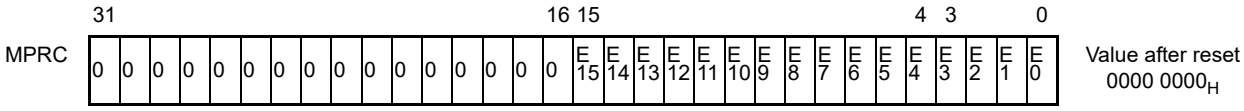

Table 3.117 MPRC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 16	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
15 to 4	E15-E4	These bits are not supported in this product. (Reserved for future expansion. Be sure to clear to 0.)	R	0
3 to 0	E15-E0	These are the enable bits for each protection area. Bit En is a copy of bit MPATn.E (where n = 3 to 0). The number of the protection areas in this product is 4.	R/W	0

(3) MPBRGN — MPU base region register

This register indicates the minimum usable MPU area number.

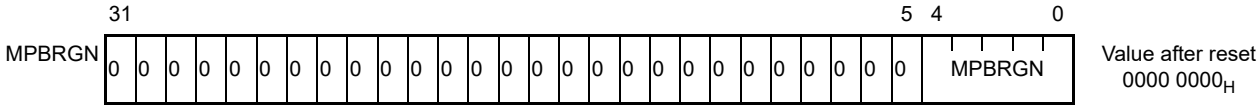

Table 3.118 MPBRGN Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
4 to 0	MPBRGN	These bits indicate the smallest number of an MPU area.	R	0000

(4) MPTRGN — MPU end region register

This register indicates the maximum usable MPU area number.

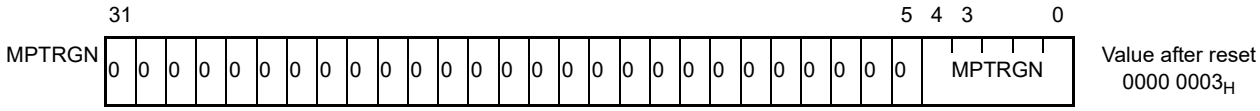

Table 3.119 MPTRGN Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
4 to 0	MPTRGN	These bits indicate the largest number of an MPU area.	R	0011

(5) MCR — Memory protection setting check result

This product does not incorporate the memory protection setting function.

This register is reserved for the future expansion.

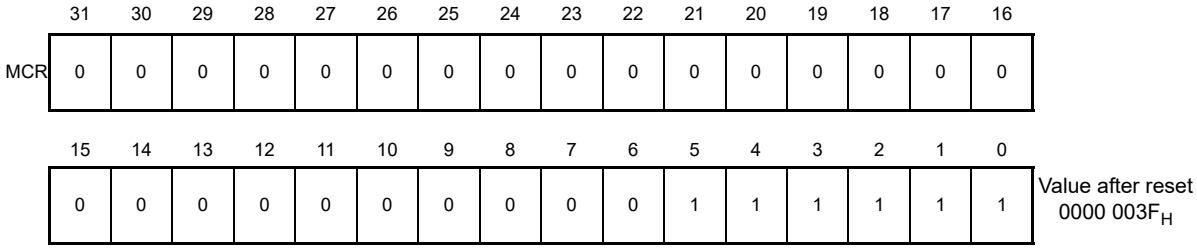

Table 3.120 MCR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	—	(Reserved for future expansion)	R	0000 003F$_H$

(6) MPLAn — Protection area minimum address register

These registers indicate the minimum address of area n (n = 0 to 3).

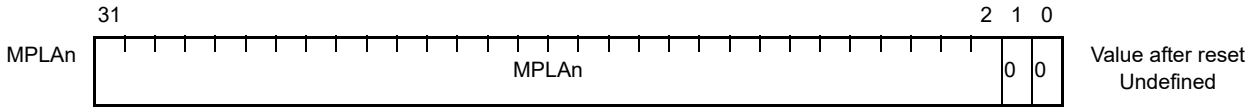

Table 3.121 MPLAn Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	MPLA31-2	These bits indicate the minimum address of area n. The MPLA1-0 bits are implicitly set to 0.	R/W	Undefined
1, 0	—	Reserved for future expansion. Be sure to clear these bits to 0.	R	0

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of MPLAn.

(7) MPUAn — Protection area maximum address register

These registers indicate the maximum address of area n (n = 0 to 3).

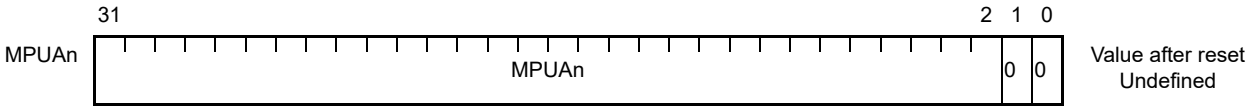

Table 3.122 MPUAn Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	MPUA31-2	These bits indicate the maximum address of area n. The MPUA1-0 bits are implicitly set to 1.	R/W	Undefined
1, 0	—	Reserved for future expansion. Be sure to clear these bits to 0.	R	0

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of MPUAn.

(8) MPATn — Protection area attribute register

These registers indicate the attributes of area n (where n = 0 to 3).

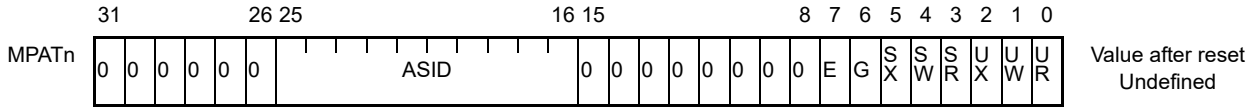

Table 3.123 MPATn Register Contents (1/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 26	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
25 to 16	ASID	These bits indicate the ASID value to be used as the area match condition.	R/W	Undefined
15 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	E	This bit indicates whether area n is enabled or disabled. 0: Area n is disabled. 1: Area n is enabled.	R/W	0
6	G	0: ASID match is the condition. 1: ASID match is not the condition. When this bit is 0, the condition of the area match is MPATn.ASID = ASID.ASID. When this bit is 1, the area match of the values of MPATn.ASID and ASID.ASID is the condition.	R/W	Undefined
5	SX	This bit indicates the execution privilege for supervisor mode.*1 0: The execution is disabled. 1: The execution is enabled.	R/W	Undefined
4	SW	This bit indicates the write permission for supervisor mode.*1 0: Writing is disabled. 1: Writing is enabled.	R/W	Undefined
3	SR	This bit indicates the read permission for supervisor mode*1 0: Reading is disabled. 1: Reading is enabled.	R/W	Undefined

Table 3.123 MPATn Register Contents (2/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
2	UX	This bit indicates the execution privilege for user mode. 0: The execution is disabled. 1: The execution is enabled.	R/W	Undefined
1	UW	This bit indicates the write permission for user mode. 0: Writing is disabled. 1: Writing is enabled.	R/W	Undefined
0	UR	This bit indicates the read permission for user mode. 0: Reading is disabled. 1: Reading is enabled.	R/W	Undefined

Note 1. If access is restricted in SV mode, execution of MDP exceptions or the MIP exception handling itself might not be possible depending on the settings. Be careful to specify settings so that access to the memory area necessary for the exception handler and exception handling is permitted.

(6) Cache operation function registers

The RH850/E1x does not have cache processing function registers.

(7) Data buffer operation function registers

The RH850/E1x does not have data buffer operation function registers.

3.3.2 Inter-Processor Interrupts

The PCU includes an inter-processor interrupt control register (IPIR_CH0-3). It is a CPU peripheral and its functions and addresses are the same as those of the CPU1. IPIR_CH0 to IPIR_CH3 registers are assigned to each PE which are accessible only from their own PE. For details, see **Section 3.2.3, Inter-Processor Interrupts**.

3.3.3 Reliability Functions

3.3.3.1 System Error Notification Control Function (SEG)

Errors due to an instruction fetch or data access can be the sources of system error exceptions. A SYSERR exception is an FE level exception from which return or recovery is not possible.

For source codes (FEIC) of the SYSTEM exceptions and error handling, see **Table 3.125, Error Factor Codes and Handling of G3K Core SYSERR Exceptions**. When a system error exception is accepted, the PSW.EBV bit is cleared to 0 and the exception handler always refers to RBASE.

SEG (SysErrGen) controls interrupt notification and recording after a system error occurred by a data access.

(1) Register Set

(a) SEG_CONT — System Error Control Register

This register enables and disables the error notification of each SYSERR source. When the bit is set to 1, SYSERR notification of error occurrence is enabled. When it is cleared to 0, SYSERR notification is disabled although the error flag in response to the error factor occurrence is set.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—									RMWE	—	RAME	—	EXTE	FCHE	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R/W	R

Table 3.124 SEG_CONT Register Contents

Bit Position	Bit Name	Function
15 to 7	—	Reserved These bits are always read as 0. The write value should always be 0.
6	RMWE	Local RAM Read/Modify/Write Error Notification Enable: This bit enables SYSERR notification of an ECC error that occurs when a read access is made to the local RAM during read/modify/write operation after a byte or half word write is made to the local RAM.
5	—	Reserved This bit is always read as 0. The write value should always be 0.
4	RAME	Local RAM ECC Error Notification Enable: This bit enables the SYSERR notification of an ECC error occurred when the CPU accesses the data in the local RAM area.
3	—	Reserved This bit is always read as 0. The write value should always be 0.
2	EXTE	P-Bus/H-Bus/GRAM Area Error Notification Enable: This bit enables SYSERR notification of an error occurring when the P-Bus/H-Bus/GRAM area is accessed. Such errors include: • P-Bus: Data Parity Error, Guard Error • H-Bus: Error response in the slave modules • GRAM: Data ECC Error, Address Parity Error, Guard Error
1	FCHE	Code Flash Error Notification Enable: This bit enables the SYSERR notification of an error occurred when the CPU accesses the data in the code flash. Such errors include: • Data ECC Error • Address Parity Error
0	—	Reserved This bit is always read as 0. The write value should always be 0.

Table 3.125 Error Factor Codes and Handling of G3K Core SYSERR Exceptions

Factor Code	Error Contents
10	Reserved
11	Instruction fetch errors
12	Reserved
13	Reserved
14	Errors in which their notification is enabled by the SEG_CONT register. Errors that have occurred can be identified by reading the SEG_FLAG register

1A	Reserved
1B	Reserved
1C	Reserved
1D	Reserved
1E	Reserved
1F	Reserved

(b) SEG_FLAG — System Error Flag Register

This register indicates the flags to store the status under which each SYSERR factor occurs. When a SYSERR factor occurs, the corresponding error factor flag is set to 1. The SYSERR can also be generated by direct writing to the register and setting the flag to 1. Each flag can be cleared by writing 0 after reading the state of 1.

Even if 0 is written in a subsequent write operation to a flag already set to 0 during reading, the flag is set in response to an error occurring between the read and the write.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	RMWF	—	RAMF	—	EXTF	FCHF	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R/W	R

Table 3.126 SEG_FLAG Register Contents

Bit Position	Bit Name	Function
15 to 7	—	Reserved These bits are always read as 0. The write value should always be 0.
6	RMWF	Flag corresponding to bit 6 of the SEG_CONT register
5	—	Reserved This bit is always read as 0. The write value should always be 0.
4	RAMF	Flag corresponding to bit 4 of the SEG_CONT register
3	—	Reserved This bit is always read as 0. The write value should always be 0.
2	EXTF	Flag corresponding to bit 2 of the SEG_CONT register
1	FCHF	Flag corresponding to bit 1 of the SEG_CONT register
0	—	Reserved This bit is always read as 0. The write value should always be 0.

3.4 Inter-CPU Functions

3.4.1 Processor Element Identifier

The PEID, each processor element ID number, can be read from the PEID field in the HTCFG0 register. Which CPU core performs a specific program can be understood by referring to the PEID. The following shows the PEID of this product.

CPU core	PEID
CPU1 (PE1)	001_B
PCU (PE3)	011_B

3.4.2 Inter-Processor Interrupt Function

Both CPU1 and the PCU individually have IPIR registers as their own peripheral functions. Setting of the IPIR register enables an EI-level interrupt request from a PE to another PE. For details, see **Section 3.2.3, Inter-Processor Interrupts**.

3.4.3 Exclusive Function

The local RAM, global RAM, and exclusive control register (MEV) are available as a resource for exclusive control. As atomic operation instruction, the instructions of LDL/STC, CAXI, SET1, CLR1, and NOT1 can be performed for the local RAM and global RAM, and the instructions of CAXI, SET1, CLR1, and NOT1 can be performed for the exclusive control register (MEV). These registers are also accessible by the LD and ST instructions but not regarded as atomic operation.

CAUTION

Access to the local RAM of the PCU or an MEV register by using the CAXI, SET1, CLR1, or NOT1 instructions are atomic operations, but access to the local RAM of CPU1 or global RAM by the same instructions is not. Use the MEV for exclusive control of PCU and CPU1.

3.4.3.1 Exclusive Control Register (MEV)

This register supports exclusive control for variables shared between PEs (common resources).

(MEV = Mutual Exclusion Variable Register)

- 32 32-bit MEV registers are included.
- 1-, 8-, 16-, and 32-bit accesses are available for each MEV.
- Accesses from CPU1 (PE1) and the PCU (PE3) can be made.
- Atomic operation instructions of CAXI, SET1, CLR1, and NOT1 can be performed.

CPU1 and the PCU each have an independent access path for the MEV registers. Therefore, when CPU1 and the PCU each access different MEV registers, they do not need to wait for access. When they access the same MEV register, however, waiting for access is required.

Table 3.127 Base Address of SEG Register: FFFE EC00$_H$

Register Symbol	Register Name	R/W	Value after Reset	Operable Bit				Access Size
				1	8	16	32	
G0MEV0	Exclusive Control Register 0	R/W	0000 0000$_H$	√	√	√	√	+00$_H$
G0MEV1	Exclusive Control Register 1	R/W	0000 0000$_H$	√	√	√	√	+04$_H$
G0MEV2	Exclusive Control Register 2	R/W	0000 0000$_H$	√	√	√	√	+08$_H$
G0MEV3	Exclusive Control Register 3	R/W	0000 0000$_H$	√	√	√	√	+0C$_H$
:	:	:	:	:	:	:	:	:
G0MEV31	Exclusive Control Register 31	R/W	0000 0000$_H$	√	√	√	√	+7C$_H$

3.4.3.2 Operation of the LDL.W and STC.W Instructions

The LDL.W and STC.W instructions can be used to obtain atomic read-modify-write operations for accurate processing in the updating of memory by multicore systems. The LDL.W and STC.W instructions operate as follows. The LDL.W and STC.W instructions are only in the instruction set for the CPU (G3M) and not in that for the PCU (G3K). For the operation of the LDL.W and STC.W instructions, refer to the *RH850G3M User's Manual: Software*.

- Link generation: The CPU is capable of generating links to both the local RAM and global RAM. Executing the LDL.W instruction on the target RAM for the operation leads to link address being registered, the link flag being set, and a link being generated in response to reading by the instruction. Two link flag systems are provided, one each for the following two areas of RAM.

  (1) The local RAM for the given processor: 1

  (2) The global RAM: 1

  Since these link flags are generated independently of each other, a link that was previously generated (e.g. by the CPU to the local RAM) is not lost when the CPU executes the LDL.W instruction for the other RAM (e.g. the global RAM).

- Success in storing: After a link has been generated, storing will only proceed in response to executing an STC.W instruction corresponding to the generated link.
- Failure in storing: If a link is lost, storing does not proceed even when an STC.W instruction for the corresponding address is processed. Storing also does not proceed when an STC.W instruction that does not correspond to the link is processed.
- Condition for successful storing: If the following condition is met, the STC.W instruction is judged to be for the address corresponding to the link.
  - The address for the LDL.W instruction which generated the link matches that for the STC.W instruction.
- Loss of the link: If any of the following occurs, the link flag is cleared and the link is lost.
  - Any of the following processing by the CPU for which the link was generated:
    - An STC.W instruction being executed. The corresponding link (for (1) or (2) above) will be lost irrespective of the success or failure of storing.
    - Occurrence of an exception or the CPU executing an instruction to return from an exception processing routine (FERET or EIRET). The link for the linked RAM area and the link flag are cleared.
    - A successive LDL.W instruction being executed for a location corresponding to the link flag for the linked RAM.
      The link generated in response to the preceding LDL.W instruction will be lost. Do not execute such processing.
    - Storing operations other than execution of a STC.W instruction for the address* indicated by the link. Do not execute such processing.

– Access as described below by another bus master:
  – Any storing operation, including execution of an STC.W instruction for the address* indicated by the link. The corresponding link will be lost.

Note. Refers to the addresses of locations that match the 27 higher-order address bits of the address for which the link was created.

Success of the STC.W instruction means that the LDL.W and STC.W instructions have realized an atomic Read-Modify-Write operation.

3.5 Usage Notes

3.5.1 Synchronization of Store Instruction Completion and Subsequent Instruction Generation

When a control register is updated by a store instruction, there is a time lag from execution of the store instruction by the CPU to actual updating of the control register. Therefore, appropriate synchronization processing is required to ensure the control register reflects updated contents before execution of a subsequent instruction. How to perform synchronization processing is shown below.

For details of the procedure regarding updating of the system registers by the LDSR instruction and synchronization with subsequent instructions, refer to APPENDIX A, HAZARD RESOLUTION PROCEDURE FOR SYSTEM REGISTERS in the *RH850G3M User's Manual: Software or the RH850G3K User's Manual: Software*.

3.5.1.1 When updated results in the control registers are reflected in the implementation of a subsequent instruction:

Example 1: An interrupt may be enabled by implementation of an EI instruction after an interrupt request is cleared by access from the control register in the INTC2 and the peripheral circuits. Proceed as follows in this case.

(1) Store instruction to update a control register (ST.W, etc.)

(2) Dummy reading of the above-mentioned control register (LD.W, etc.)*1

(3) SYNCP

(4) Subsequent instruction (EI, etc.)

Example 2: Implement the same processing even when the access required after waiting to secure the updating of a given control register (register A) is to another control register (register B). This includes the following cases: the interlinked operation of different peripheral modules and when releasing the interrupt mask in INTC after making peripheral module settings.
However, this processing is unnecessary if control registers A and B are in the same peripheral group.

For the correspondence between the peripheral groups and the peripheral modules/registers, see **Appendix, List of Registers**.

(1) Issue the instruction for storage to update control register A (TS.W, etc.)

(2) Dummy-read the above control register (LD.W, etc.)*1

(3) Issue SYNCP.

(4) Issue the instruction to access control register B (ST.W, LD.W, etc.)

The same processing is also required when access to control registers and memory within the scope of protection starts after waiting for the completion of settings for safety functions such as memory protection, ECC checking, and so on.

Note 1. Dummy reading of any register of the same peripheral group can be used instead.

3.5.1.2 When the updated results in the control registers and memories are reflected in the instruction fetch of a subsequent instruction:

(a) If you wish to write an instruction to the RAM and then branch to the RAM to execute the written instruction, handle this as follows.

(1) Store instruction to update a memory (ST.W, etc.)

(2) Dummy read of the above-mentioned memory (LD.W, etc.)

(3) SYNCP

(4) SYNCI

(5) Subsequent instruction (branch instruction, etc.)

(b) When branching to a target memory after waiting for the completion of updating the control registers for memory protection and ECC, handle this as follows.

(1) Store instruction to update a control register (ST.W, etc.)

(2) Dummy reading of the control register (LD.W, etc.)

(3) SYNCP

(4) SYNCI

(5) Subsequent instruction (branch instruction, etc.)

3.5.1.3 When switching the code flash area

In this case, refer to (7) Updating the FCUFAREA Register, in section 9, Usage Notes, in the *RH850/E1x Flash Memory User's Manual: Hardware Interface*.

3.5.1.4 When executing the SYNCM instruction to wait for the completion of update by the store instruction

When executing the SYNCM instruction to wait for the completion of updating the destination for access by the preceding store instruction, the CPU that executes the store instruction and the destination for access must be as follows.

CPU that Executes the Store Instruction	Destination for Access by the Store Instruction
CPU1	Local RAM (self), Local RAM (PE1), Global RAM

3.5.2 Accesses to Registers by Bit-Manipulation Instructions

Processing of a bit-manipulation instruction takes the form of atomic reading, modification, and writing of an eight-bit unit. Thus, access by a bit-manipulation instruction is only possible for registers for which reading and writing in 8-bit units is possible. However, take care in the cases of registers that contain multiple flag bits, since the read-modify-write cycle may also clear flags other than that which was the target for clearing.

Write access to the FlexRay registers by using bit-manipulation instructions is not atomic. Access by other masters may interrupt the read-modify-write processing of these instructions.

3.5.3 Ensuring Coherency after Code Flash Programming

The CPU has an efficient instruction cache and data buffer for the code flash area.

Therefore, after using self-programming to program the code flash memory, clear the instruction cache and data buffer to ensure coherency. The instruction cache and data buffer can be cleared by using the ICCTRL register and the CDBCR register, respectively. The instruction cache and data buffer can also be cleared at the same time by using the TM_CC register. For details of the TM_CC register, see **Section 35.4.5, TM_CC — Cache Clear Operation Register**.

When the PCU is in use, the TM_CC register can also be used in the same way to clear the cache and buffer after programming the code flash memory.

3.5.4 Overwriting Context when Acknowledging Multiple Exceptions

Exceptions may be acknowledged regardless of the states of the ID or NP bits of the PSW register. This depends on the type of exception. When multiple exceptions occur, the contents of the system registers which hold the context information are overwritten. Regarding the conditions for acknowledging exceptions from each source and the possibility of return and recovery, see the list of exception sources in *RH850G3M User's Manual: Software* and *RH850G3K User's Manual: Software*.

3.5.5 Usage Notes on Prefetching

CPU executes speculative instruction fetching from locations later than the current value of the program counter to maintain the throughput of instruction fetches. Reading from memory due to such prefetching may proceed even from locations to which instruction codes have not been assigned (note 1 in **Figure 3.5**). Please note the following. The CPU does not execute values read in such cases.

These notes apply to instruction fetching from memory in general.

- Occurrence of ECC errors due to values in memory being undefined

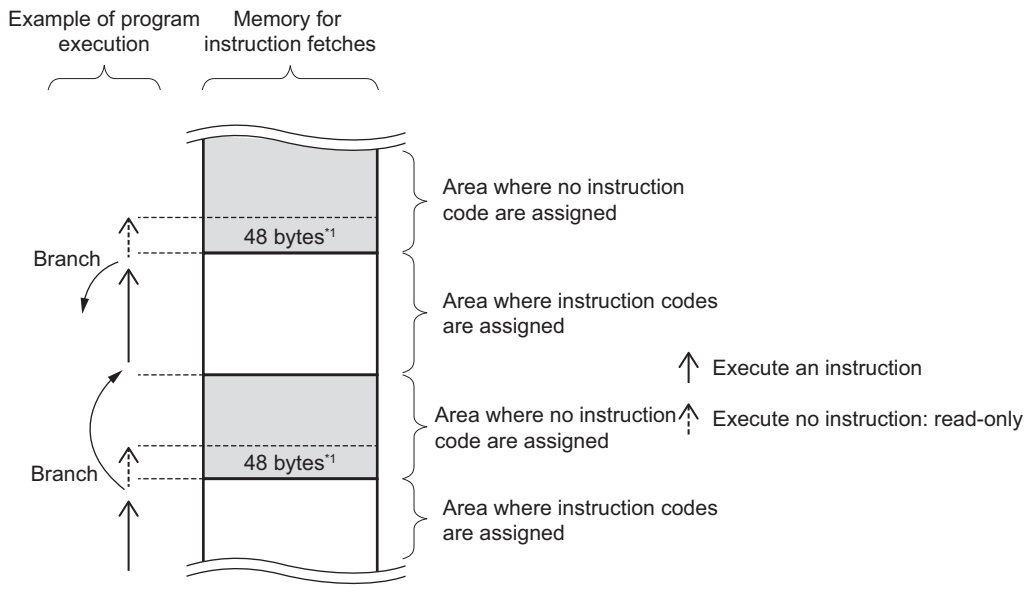
  This prefetching may lead to an ECC error in case of reading from the code flash memory after it has been erased or from the local RAM or global RAM before initialization. When instruction codes are assigned to memory, initialize said area with values as desired (note 1 in **Figure 3.5**).

- Detection of illegal access by the GRG or IPG

  The GRG or IPG may detect such prefetching as illegal access. To prevent prefetching being detected as an illegal access, do not allow any region of overlap area with said areas (note 1 in **Figure 3.5**) and areas to which access is prohibited by the GRG or IPG. Reading from an area protected by the MPU does not cause a memory protection exception.

- Access to Access Prohibited Area

  Assign instruction codes to memory without allowing any overlap between said area (note 1 in **Figure 3.5**) and an access-prohibited area.



Note 1. Area from final address of instruction code to final address + 48 bytes. Even if instruction codes are not placed in this area, requests for prefetching may lead to reading from memory at the time of branching.

Figure 3.5 Area that Requires Attention Regarding Prefetching

Section 4 Address Space

Table 4.1 shows the address space of the RH850/E1M-S.

When making an access to the on-chip I/O register space, access the addresses shown in Appendix, List of Registers. Do not access an address that is not specified in **Table 4.1** and an area where any access is prohibited. If an unspecified address or reserved area is accessed, operation is not guaranteed.

4.1 Address Space

Table 4.1 Address Space

Address	Address Space Type	Size
0000 0000_H to 003F $FFFF_H$ (0001 7000_H to 0001 $7FFF_H$)	Code flash (user area read) (FCU firmware area (Map is switched by FCUFAREA register))*3	4 MB (4 KB)
0040 0000_H to 00FF $FFFF_H$	Access prohibited	
0100 0000_H to 0100 $7FFF_H$	Code flash (user boot area read)	32 KB
0100 8000_H to 0FFF $FFFF_H$	Access prohibited	
1000 0000_H to 1FFF $FFFF_H$	On-chip I/O register	256 MB
2000 0000_H to FEBE $FFFF_H$	Access prohibited	
FEBF 0000_H to FEBF $FFFF_H$	Local RAM (PE1)	64 KB
FEC0 0000_H to FEDE $FFFF_H$	Access prohibited	
FEDF 0000_H to FEDF $FFFF_H$	Local RAM (self) *1	64 KB
FEE0 0000_H to FEED $FFFF_H$	Access prohibited	
FEEE 0000_H to FEF1 $FFFF_H$	Global RAM area	256 KB
FEF2 0000_H to FEFF $FFFF_H$	Access prohibited	
FF00 0000_H to FFFD $FFFF_H$ (FF20 0000_H to FF20 $FFFF_H$) (FFA1 2000_H to FFA1 $2FFF_H$)	On-chip I/O register (Data flash (read/write)) (FCU RAM)	16 MB to 128 KB (64 KB) (4 KB)
FFFE 0000_H to FFFE $DFFF_H$	Access prohibited	
FFFE $E000_H$ to FFFE $FFFF_H$	On-chip I/O register (self*2)	8 KB
FFFF 0000_H to FFFF $4FFF_H$	Access prohibited	
FFFF 5000_H to FFFF $FFFF_H$	On-chip I/O register	44 KB

Note 1. When accessing a local RAM from PE1 or other unit, accessing the local RAM (PE1) allows access to the local RAM in PE1 and accessing the local RAM (self) allows access to the local RAM in each PE (PE1/PCU). The local RAM (self) areas have the following differences because the local RAM (self) capacity differs between PE1 and the PCU.
- PE1 local RAM (self): FEDF 0000_H to FEDF $FFFF_H$ (64 KB)
- PCU local RAM (self): FEDF 8000_H to FEDF $FFFF_H$ (32 KB)

Also note that some tools do not support access to the local RAM of PE1 via the local RAM (self) area. If this is the case, access to the local RAM area for PE1 is via the local RAM (PE1) area and access to the local RAM of the PCU is via the local RAM (self) area.

Note 2. The on-chip I/O register (self) has CPU peripheral function. CPU peripheral function is typically unique to each PE and no access is allowed to the CPU peripheral of other PE. However, the exclusive control register (MEV) is an exception and shares the function between PEs.

Note 3. For details, see the *RH850/E1x Flash Memory User's Manual: Hardware Interface*.

4.2 Address Space Viewed from Each Bus Master

Figure 4.1 shows address spaces viewed from each bus master.

4.2.1 Space in which instructions can be fetched

1. Instructions of PE1 and the PCU can be fetched from the code flash, local RAM and global RAM.
2. The reset vector (RBASE initial value) of PE1 and the PCU:

- When starting up from the user boot area, its head address is 0100 0000_H.
- When starting up from the user area, its head address is 0000 0000_H.

4.2.2 Data space accessible by PE1

All spaces are accessible.

4.2.3 Data space accessible by PCU

All spaces are accessible. However, an access from PE1 to the on-chip I/O register, 1000 0000_H to 1FFF $FFFF_H$ is not available. Use FC00 0000_H to FE5F $FFFF_H$ for such access.

4.2.4 Data space accessible by DMA (DMAC, DTS)

See **Figure 4.1** for the accessible spaces from the DMA.

4.2.5 Data space accessible by H-Bus

See **Figure 4.1** for the accessible spaces from the H-Bus.

Figure 4.1 Address Space Viewed from Each Bus Master

4.3 Global RAM and Retention RAM

The global RAM is divided into two, bank A and bank B. Different banks can be accessed concurrently. The upper 32 Kbytes of bank A is the retention RAM that retains data even during power-off standby state.

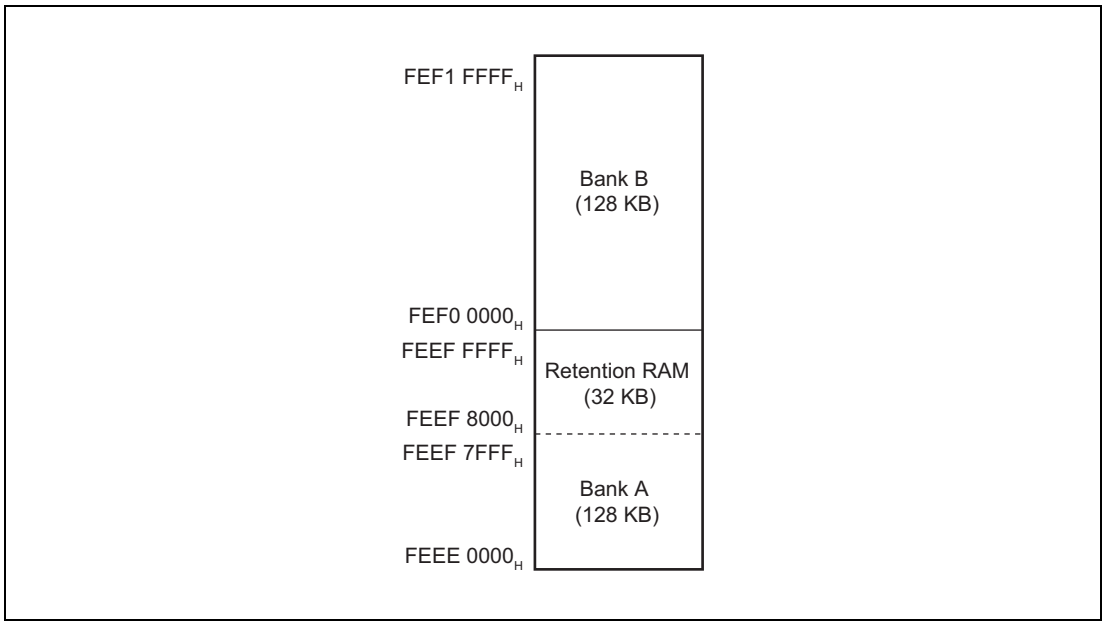


Figure 4.2 Global RAM

Section 5 Operating Mode

5.1 Features

- This LSI has three mode pins to determine the operating mode (MD0, MD1, and FLMODE).

5.2 Operating Mode

This LSI has multiple operating modes, which can be selected with the three pins (MD1, MD0, and FLMODE) and the setting of STMSEL1/STMSEL0 in option byte 0. For the procedures to set STMSEL1/STMSEL0, see **Section 33, Flash Memory**. **Table 5.1** shows the list of the operating modes.

Table 5.1 Selection of Operating Mode

Value Set in the Pin			Value Set in Option Byte 0 OPBT0		Operating Mode	Startup Area	Types of I/F*1	Remarks
MD1	MD0	FLMODE	STM SEL1	STM SEL0				
0	0	0	0	0	User boot mode	User area	It is possible to select I/F by OPBT2 in option byte. See **Section 33.10.2, OPBT2 — Option Byte 12 to 9 Bits Arrangement** for the details.	On-chip debug is available.
			0	1	User boot mode	User boot area		
			1	×	Serial programming mode	Boot area	Writer I/F (2-line UART)	Serial programming is available
0	0	1	×	×	Boundary scan mode	—	JTAG	Boundary scan is available.
0	1	0	×	×	Serial programming mode	Boot area	Writer I/F (2-line UART)	Serial programming is available
0	1	1	×	×	Serial programming mode	Boot area	Writer I/F (3-line clock synchronization)	Serial programming is available

Note: X = don't care.

Note 1. For the correspondence between the pin function and pin state in each interface, see Section 2.5.3, Pin State.

5.2.1 User Boot Mode

After release from the reset state, instruction fetch is carried out from the user boot area or the user area.

5.2.2 Serial Programming Mode

After release from the reset state, the LSI boots up from the on-chip boot program and starts connection in the specified transmission method. For details, see **Section 33, Flash Memory**.

5.2.3 Boundary Scan Mode

This is a mode to use the boundary scan function in accordance with the standard of IEEE1149.1. For details, see **Section 36, Boundary Scan**.

Section 6 Interrupt

The interrupt controller (INTC) determines priority of interrupt sources and controls interrupt requests to the CPU. The INTC has a register to set priority of each interrupt. Interrupt requests are processed according to the priority set in this register by the user.

6.1 Overview

- Simultaneous distribution of interrupt sources to multiple cores
  - A single interrupt source can be distributed to multiple CPU cores.
    (Distribution target cores: CPU1/PCU)
  - Target interrupt sources: Nonmaskable interrupt 1 source, FE level interrupt 1 source, EI level interrupts 21 sources
- Interrupt sources
  - Nonmaskable interrupt:
    External pin NMI interrupt (FENMI) 1 source
  - FE level interrupt:
    ECM interrupt (FEINT) 1 source
  - EI level interrupt (maskable) (EIINT)
    high-speed interrupts (EIINT0 to 31) 21 sources
    • Inter-processor interrupts
    • ECM interrupts
    • External pin IRQ interrupts
    • Software interrupts
    • Constant-cycle timer (OSTM)
    • DMA error interrupts
    Low-speed interrupts (EIINT32 to 511) 462 sources
    • Timer
    • Communication
    • A/D converter
    • DMAC/DTS, etc.
- Priority levels for Interrupt
  Priority levels of IRQ (external interrupts) and maskable interrupts can be set in 512 interrupt control registers according to interrupt requests, up to 16 levels for CPU1 and 8 levels for PCU.
- Detecting methods of external interrupt (NMI/IRQ)
  A method of detecting NMI sources can be selected from two types: rising edge and falling edge.
  A method of detecting IRQ sources can be selected from four types: high level, low level, rising edge, and falling edge.
- Direct branching method or table referencing method is selectable by setting two types of interrupt handler address setting registers.
- Inter-processor interrupts
  High-speed inter-processor interrupts are enabled.
- Software interrupts (SINT)
  Interrupts of desired priority can be generated from the program by setting software interrupt registers.

- Sharing interrupt sources
  The number of exception handler addresses can be decreased by merging multiple interrupt sources.

Interrupts are controlled by the following interrupt controllers:

- INTC1
  CPU1 and PCU have their own interrupt controllers.
  Each PE accesses to the INTC1 register that corresponds to respective PEs.
  INTC1 controls High-speed interrupt and has the following functions:
  - Priority setting
  - Interrupt mask setting
- INTC2
  INTC2 is a common interrupt controller that CPU1 and PCU share.
  INTC2 controls low-speed interrupts and has the following functions.
  - Priority setting
  - Interrupt mask setting
  - Binding setting

6.2 Register Specifications

The INTC has registers listed in tables below. These registers are mainly used to set interrupt priority and to control detection of external interrupt input signals.

6.2.1 Register Configuration

Table 6.1 Interrupt Control

Address	Register Symbol	Register Name	R/W	Value after Reset
FFFE EA00$_H$-FFFE EA3E$_H$ (EIC0 to 31) FFFF B040$_H$-FFFF B3FE$_H$ (EIC32 to 511)	EICn*1	EI level interrupt control register	R/W	008F$_H$*5 808F$_H$*6
FFFE EAF0$_H$ (IMR0) FFFF B404$_H$-FFFF B43C$_H$ (IMR1 to IMR15)	IMRn*2	EI level interrupt mask register	R/W	FFFF FFFF$_H$
FFFE EB00$_H$-FFFE EB7C$_H$ (EIBD0 to 31) FFFF B880$_H$-FFFF BFFC$_H$ (EIBD32 to 511)	EIBDn*3	EI level interrupt bind register	R/W	*4

Note 1. n = 0 to 511
Note 2. n = 0 to 15
Note 3. n = 0 to 511
Note 4. n = 0 to 31: the same value as that of the PEID bit
n = 32 to 511: 0000 0001$_H$
Note 5. When an edge is detected (The PCU register of EICn (n = 0 to 31) is located at 0087$_H$.)
Note 6. When a level signal is detected (The PCU register of EICn (n = 0 to 31) is located at 8087$_H$.)

Among the registers shown in **Table 6.1**, the EIC0 to 31, IMR0, and EIBD0 to 31 are located in INTC1 of the CPU peripheral field included in each CPU. Each register of these only can be accessed from CPU1 or PCU which includes it. Writing is only possible in supervisor mode (PSW.UM = 0).

Of the registers listed in **Table 6.1**, EIC32 to EIC511, IMR1 to IMR15, and EIBD32 to EIBD511 are located in INTC2, the controller for interrupts from peripheral group 0. Writing to these registers is only possible for a PE bound to EIBDn (n = 32 to 511) or in supervisor mode (UM = 0) by CPU1. When writing to IMR1 to IMR15, only the bits corresponding to the conditions described above are overwritten; other bits are not updated.

In the register areas listed in **Table 6.1**, the values of those listed as reserved for the given channel numbers in **Table 6.14, Interrupt Exception Handler and Priority**, must retain their values after a reset.

Table 6.2 External Interrupts, Software Interrupts, and NMI

Address	Register Symbol	Register Name	R/W	Value after Reset
FFC0 0000$_H$	NMICTL	NMI interrupt control register	R/W	00$_H$
FFC0 0010$_H$	EXINTCTL	External interrupt control register	R/W	0000$_H$
FFC0 0014$_H$	EXINTSTR	External interrupt status register	R	00$_H$
FFC0 0018$_H$	EXINTSTC	External interrupt status clear register	W	00$_H$
FFC0 0020$_H$	SINTR0	Software interrupt register 0	R/W	00$_H$
FFC0 0024$_H$	SINTR1	Software interrupt register 1	R/W	00$_H$
FFC0 0028$_H$	SINTR2	Software interrupt register 2	R/W	00$_H$
FFC0 002C$_H$	SINTR3	Software interrupt register 3	R/W	00$_H$

Table 6.3 Interrupt Merge Function

Address	Register Symbol	Register Name	R/W	Value after Reset
FFF9 8000$_H$	PINT0	Peripheral interrupt status register 0	R	0000 0000$_H$
FFF9 8004$_H$	PINT1	Peripheral interrupt status register 1	R	0000 0000$_H$
FFF9 8008$_H$	PINT2	Peripheral interrupt status register 2	R	0000 0000$_H$
FFF9 800C$_H$	PINT3	Peripheral interrupt status register 3	R	0000 0000$_H$
FFF9 8010$_H$	PINT4	Peripheral interrupt status register 4	R	0000 0000$_H$
FFF9 8014$_H$	PINT5	Peripheral interrupt status register 5	R	0000 0000$_H$
FFF9 8018$_H$	PINT6	Peripheral interrupt status register 6	R	0000 0000$_H$

FFF9 8040$_H$	TIMER	Timer interrupt mask enable register	R/W	00$_H$

6.2.2 EIC0 to EIC511 — EI Level Interrupt Control Registers 0 to 511

These registers are used to set interrupt control conditions for each EI level interrupt source, and one register is provided for each source of this type. For each source, see **Table 6.14, Interrupt Exception Handler and Priority**.

CAUTION

If 0 is written to the EIRFn bit immediately after a peripheral module generates the corresponding interrupt request upon detection of an edge (before an interrupt is accepted by the CPU), the request may be lost.

Writing 1 to the EIRFn bit immediately after an interrupt is accepted by the CPU may lead to re-issuing of the request.

This includes the use of bit-manipulation instructions (set1, clr1, and not1) for writing to any of these registers. For bit-manipulation instructions, see also Section 3.5.2, Accesses to Registers by Bit-Manipulation Instructions.

Executing a bit-manipulation instruction to the lower bytes including the EIMKn bit has no effect on the EIRFn bit.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EICTn	—	—	EIRFn	—	—	—	—	EIMKn	EITBn	—	—	EIPn			
Value after reset	*1	0	0	0	0	0	0	0	1	0	0	0	1	1	1	1

Note 1. 0: Edge detection, 1: Level detection

Table 6.5 EIC Register Contents (1/2)

Bit Position	Bit Name	Function
15	EICTn	Interrupt Channel Type The following values are read according to the interrupt input interface. This is a read-only bit. 0: Edge detection 1: Level detection The write value should be the value after reset.
14, 13	—	Reserved These bits are always read as 0. The write value should always be 0.
12	EIRFn	Interrupt Request Flag Operation varies with the interrupt input interface. 0: No interrupt request (Initial value) 1: Interrupt request present • Edge detection This flag is automatically cleared to 0 when an interrupt request of the self-channel is accepted by the CPU core. When the EIRFn bit is set to 1, an EI level maskable interrupt n (EIINTn) is generated in the same way as acceptance of an interrupt request. • Level detection This bit cannot be set or cleared by the software. This is a read-only bit.
11 to 8	—	Reserved These bits are always read as 0. The write value should always be 0.

Table 6.5 EIC Register Contents (2/2)

Bit Position	Bit Name	Function
7	EIMKn	Interrupt Mask While this bit is set to 1, interrupt requests set in the interrupt request flag (EIRFn) are masked to inhibit interrupt requests from the channel to the CPU core. Notification of presence of unprocessed interrupts is not made and the PMEI bit in ICSR is not set from channels for which this bit is set to 1. Even when interrupt processing is disabled by the setting of this bit, an input of interrupt signal is not masked and the interrupt request flag is set. Setting this bit is also reflected in the setting of corresponding bit of the interrupt mask register (IMR). 0: Interrupt processing is enabled. 1: Interrupt processing is disabled. (Initial value)
6	EITBn	Interrupt Vector Method Select 0: Direct branching method based on priority 1: Table referencing method
5, 4	—	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	EIPn[*1]	These bits specify 16 interrupt priority levels (0: highest priority, 15: lowest priority). If two or more EI level interrupt requests are generated simultaneously, a source with higher priority specified by these bits is selected and is sent to the CPU core. If the priority specified by these bits is equal, a source of smaller channel number is selected as fixed priority.

Note: n = 0 to 511
The values of those listed as reserved for the given channel numbers in **Table 6.14, Interrupt Exception Handler and Priority**, must retain their values after a reset.

Note 1. In the case of the EIC0 to EIC31 registers of the PCU, bits EIPn 2 to EIPn 0 are used to specify eight interrupt priority levels. (Set EIPn 3 to 0).
When interrupts corresponding to EIC32 to EIC511 are bound to the PCU, however, the interrupt priority is judged from the three bits of EIPn 3 to EIPn 1, which the PCU handles as if they were bits EIPn 2 to EIPn 0. (When an interrupt is bound to the PCU, the setting of EIPn 0 in the corresponding EICn is ignored.).

6.2.3 IMR0 to IMR15 — EI Level Interrupt Mask Registers 0 to 15

These registers are aggregation of the EIMK bit in the EIC register. Setting of the corresponding EIMK bit is reflected in each bit in the IMRn register. Furthermore, setting of the IMRn register is reflected in the corresponding EIMK bit.

6.2.4 EIBD0 to EIBD511 — EI Level Interrupt Bind Registers 0 to 511

These registers are provided for each EI level interrupt source to make correspondence between each source and PE. For each source, see **Table 6.14, Interrupt Exception Handler and Priority**.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 6.6 EIBD0 to EIBD511 Registers Contents

Bit Position	Bit Name	Function
31 to 18	—	Reserved The write value should always be 0.
17, 16	GPID	These bits are provided only in EIBD32 to EIBD511. Set either of the following values for these bits according to the PEID setting. 00: When CPU1 is selected by PEID as a bind destination 01: When PCU is selected by PEID as a bind destination These bits are reserved for EIBD0 to EIBD31. The write value should always be 0. These bits are always read as 0.
15 to 3	—	Reserved The write value should always be 0.
2 to 0	PEID	These bits specify an interrupt bind (request) destination. However, these bits are fixed in EIBD0 to EIBD31 and cannot be modified. 001: Interrupts are bound to CPU1. 011: Interrupts are bound to the PCU. To execute interrupt of the corresponding source, be sure to set either value above.

Note: The values of those listed as reserved for the given channel numbers in **Table 6.14, Interrupt Exception Handler and Priority**, must retain their values after a reset.

Note 1. EIBD32 to EIBD511: 001

NOTE

Changing the corresponding EIBDn register during the processing of an EIINT request is prohibited.

6.2.5 NMICTL — NMI Interrupt Control Register

NMICTL is an 8-bit register to set the detection mode of falling edge, or rising edge for the NMI interrupt input.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	NMIS	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 6.7 NMICTL Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved
1, 0	NMIS	NMI Interrupt Detecting Method Select These bits select an NMI interrupt signal detecting method from low level, high level, falling edge, and rising edge. 0 0: An interrupt request is detected by the NMI input falling edge. 0 1: An interrupt request is detected by the NMI input rising edge. 1 0: Setting prohibited 1 1: Setting prohibited

6.2.6 EXINTCTL — External Interrupt Control Register

EXINTCTL is a 16-bit register to specify a low level, high level, falling edge, or rising edge detection mode individually for external interrupt input pins IRQ7 to IRQ0.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ7S		IRQ6S		IRQ5S		IRQ4S		IRQ3S		IRQ2S		IRQ1S		IRQ1S	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 6.8 EXINTCTL Register Contents

Bit Position	Bit Name	Function
15, 14	IRQ7S	External Interrupt Detecting Method Select These bits select an IRQ7 to IRQ0 interrupt signal detecting method from low level, high level, falling edge, and rising edge. 0 0: An interrupt request is detected by the IRQn input low level.*1 0 1: An interrupt request is detected by the IRQn input high level.*1 1 0: An interrupt request is detected by the IRQn input falling edge. 1 1: An interrupt request is detected by the IRQn input rising edge.
13, 12	IRQ6S	
11, 10	IRQ5S	
9, 8	IRQ4S	
7, 6	IRQ3S	
5, 4	IRQ2S	
3, 2	IRQ1S	
1, 0	IRQ0S	

Note 1. When level detection is selected, the active level should be retained until an interrupt request is accepted.

6.2.7 EXINTSTR — External Interrupt Status Register

EXINTSTR is an 8-bit register that indicates interrupt requests of external interrupt input pins IRQ7 to IRQ0. When edge detection is specified for IRQ7 to IRQ0 interrupts, interrupt requests retained in the EXINTSTC register can be cleared.

Bit	7	6	5	4	3	2	1	0
	IRQ7F	IRQ6F	IRQ5F	IRQ4F	IRQ3F	IRQ2F	IRQ1F	IRQ0F
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 6.9 EXINTSTR Register Contents

Bit Position	Bit Name	Function
7	IRQ7F	External Interrupt Request These bits indicate IRQ7 to IRQ0 interrupt request status. • When level detection is selected 0: No IRQn interrupt request is present. 1: IRQn interrupt requests are present. [Clearing condition] The IRQn input is not the level corresponding to IRQn1S and IRQn0S in EXINTCTL. [Setting condition] The IRQn input is the level corresponding to IRQn1S and IRQn0S in EXINTCTL • When edge detection is selected 0: No IRQn interrupt request has been detected. 1: IRQn interrupt requests have been detected. [Clearing condition] Writing 1 to the IRQnC bit in EXINTSTC [Setting condition] An edge corresponding to IRQn1S and IRQn0S in EXINTCTL is generated.
6	IRQ6F	
5	IRQ5F	
4	IRQ4F	
3	IRQ3F	
2	IRQ2F	
1	IRQ1F	
0	IRQ0F	

Note 1. n = 0 to 7

6.2.8 EXINTSTC — External Interrupt Status Clear Register

EXINTSTC is an 8-bit register to clear IRQnF in EXINTSTR in case edge detection is selected as an IRQn detecting method. Writing 1 to IRQnC clears the corresponding IRQnF bit in EXINTSTR.

Bit	7	6	5	4	3	2	1	0
	IRQ7C	IRQ6C	IRQ5C	IRQ4C	IRQ3C	IRQ2C	IRQ1C	IRQ0C
Value after reset	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

Table 6.10 EXINTSTC Register Contents

Bit Position	Bit Name	Function
7	IRQ7C	External Interrupt Request Clear These bits clear the interrupt request status in case edge detection method is selected for detecting IRQ7 to IRQ0 interrupts. • When level detection is selected These bits have no function. • When edge detection is selected Writing 1 clears the corresponding IRQnF bit in the EXINTSTR register.
6	IRQ6C	
5	IRQ5C	
4	IRQ4C	
3	IRQ3C	
2	IRQ2C	
1	IRQ1C	
0	IRQ0C	

Note 1. n = 0 to 7

6.2.9 SINTR0 to SINTR3 — Software Interrupt Registers

SINTR0 to SINTR3 are 8-bit registers to control software interrupts 0 to 3 (SINT0 to SINT3).

Writing 01_H to these registers increments the value of a counter; writing 00_H decrements it. When the value of the counter for any of these registers is one or more, the corresponding interrupt from among software interrupts 0 to 3 (SINT0 to SINT3) is generated. When reading the value from any of these registers, it is the current value of the counter.

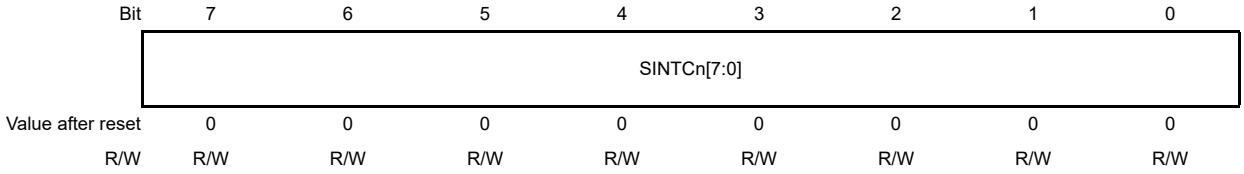

Table 6.11 SINTR0 to SINTR3 Register Contents

Bit Position	Bit Name	Function
7 to 0	SINTCn[7:0]	Software Interrupt Request This bit generates a software interrupt. [Reading operation] The number of SINTn interrupt request counts is read out. [Writing operation] Writing 01_H: increments the counter.*1 Writing 00_H: decrements the counter.*2

Note 1. When 01_H is written to the register while the value of the counter is FF_H, the counter is not incremented and its value remains FF_H

Note 2. When 00_H is written to the register while the value of the counter is 00_H, the counter is not decremented and its value remains 00_H.

6.2.10 PINT0 to PINT7, PINTCLR0 to PINTCLR7 — Peripheral Interrupt Status Registers and Peripheral Interrupt Status Clear Registers

The DTS transfer completion interrupt and transfer count match interrupt are merged in 32-channel units. PINT0 to PINT7 contain the interrupt status flags to indicate the originating channels for these interrupts. When multiple interrupt sources are generated within the same register among PINT0 to PINT7, only bit 1 on the lower-order side of the bits is set.

Writing the value read from the peripheral interrupt status register (PINT0 to PINT7) to the interrupt clear register (PINTCLR0 to PINTCLR7) of the same channel in the interrupt handler clears interrupts.

PINTCLR0

Bit Position	Bit Name	Function
31 to 0	INTCLR[31:0]	These bits clear the DTS transfer completion interrupt status on ch31 to ch0. These bits write the read value of the PINT0 in the interrupt handler.

PINTCLR1

Bit Position	Bit Name	Function
31 to 0	INTCLR[63:32]	These bits clear the DTS transfer completion interrupt status on ch63 to ch32. These bits write the read value of the PINT1 in the interrupt handler.

PINTCLR2

Bit Position	Bit Name	Function
31 to 0	INTCLR[95:64]	These bits clear the DTS transfer completion interrupt status on ch95 to ch64. These bits write the read value of the PINT2 in the interrupt handler.

PINTCLR3

Bit Position	Bit Name	Function
31 to 0	INTCLR[127:96]	These bits clear the DTS transfer completion interrupt status on ch127 to ch96. These bits write the read value of the PINT3 in the interrupt handler.

PINTCLR4

Bit Position	Bit Name	Function
31 to 0	INTCTCLR[31:0]	These bits clear the DTS transfer count match interrupt status on ch31 to ch0. These bits write the read value of the PINT4 in the interrupt handler.

PINTCLR5

Bit Position	Bit Name	Function
31 to 0	INTCTCLR [63:32]	These bits clear the DTS transfer count match interrupt status on ch63 to ch32. These bits write the read value of the PINT5 in the interrupt handler.

PINTCLR6

Bit Position	Bit Name	Function
31 to 0	INTCTCLR [95:64]	These bits clear the DTS transfer count match interrupt status on ch95 to ch64. These bits write the read value of the PINT6 in the interrupt handler.

PINTCLR7

Bit Position	Bit Name	Function
31 to 0	INTCTCLR [127:96]	These bits clear the DTS transfer count match interrupt status on ch127 to ch96. These bits write the read value of the PINT7 in the interrupt handler.

6.2.11 TIMER — Timer Interrupt Mask Enable Register

TIMER is an 8-bit readable/writable register to enable or disable interrupt requests of subblocks 4 to 6 of the ATU-IV timer D. **Table 6.13, TIMER Register Target Interrupts** lists applicable interrupts.

Since these interrupts are merged with the TSG2 interrupts and input to the INTC, set the corresponding IMEn bits to 1 when using the TSG2. When subblock 6 of the timer D is used only as an A/D converter or a trigger output to the DFE, set the IME0 bit to 1. Do not modify these bits while subblock 4, 5, or 6 of the ATU-IV timer D is operating.

TIMER can be read and written on a byte basis.

TIMER is initialized to 00_H by a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	IME2	IME1	IME0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 6.12 TIMER Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Nothing is allocated to these bits. These bits should always be 0.
2	IME2	This bit enables or disables interrupt requests of subblock 4 of ATU-IV timer D. 0: Interrupt requests are enabled. 1: Interrupt requests are disabled.
1	IME1	This bit enables or disables interrupt requests of subblock 5 of ATU-IV timer D. 0: Interrupt requests are enabled. 1: Interrupt requests are disabled.
0	IME0	This bit enables or disables interrupt requests of subblock 6 of ATU-IV timer D. 0: Interrupt requests are enabled. 1: Interrupt requests are disabled.

The following lists the target interrupts.

Table 6.13 TIMER Register Target Interrupts

TIMER Register Target Bit	ATU-IV Timer D Subblock	Interrupt Channel	Interrupt Name
IME2	4	180	DCNTD40 down-counter underflow interrupt
		181	DCNTD41 down-counter underflow interrupt

		203	OCR2D62 compare match interrupt
		204	OCR1D63 compare match interrupt
		205	OCR2D63 compare match interrupt
		206	TCNT1D6 overflow interrupt
		207	TCNT2D6 overflow interrupt

6.3 Interrupt Sources

Interrupt sources are grouped into five: external interrupt (NMI/IRQ), ECM interrupt, inter-processor interrupt, software interrupt, and peripheral module interrupt.

6.3.1 NMI Interrupts

NMI interrupts are external interrupts input from the NMI pin. Falling edge or rising edge is selectable by the setting of the NMI Interrupt Detecting Method Select bits (NMIS) in the NMI interrupt control register (NMICTL).

NMI interrupts are accepted at the high priority even when other FE level interrupt has been generated. NMI interrupts cannot be masked regardless of the state of PSW.NP in the CPU system register. NMI interrupts are non-maskable interrupts from which return or recovery is not possible.

6.3.2 IRQ Interrupts

IRQ interrupts are input from IRQ7 to IRQ0 pins. For IRQ interrupts, low level, high level, falling edge, or rising edge is selectable for each pin by the setting of the External Interrupt Detecting Method Select bits (IRQ7S to IRQ0S) in the external interrupt control register (EXINTCTL). Furthermore, interrupt priority levels can be set for each source in interrupt control registers, 16 levels for CPU1 and 8 levels for PCU.

When low level is selected as an IRQ interrupt detecting method, an interrupt request signal is sent to the INTC while IRQ7 to IRQ0 pins are low level. When IRQ7 to IRQ0 pins become high level, no interrupt request signal is sent to the INTC. The active level should be retained until an interrupt request is accepted. Interrupt requests can be checked by reading IRQ Interrupt Request bits (IRQ7F to IRQ0F) in the external interrupt status register (EXINTSTR).

When edge detection is selected as an IRQ interrupt detecting method, an interrupt request is detected by a change in IRQ7 to IRQ0 pins, and an interrupt request signal is sent to the INTC. Reading bits EXINTSTR.IRQ7F to EXINTSTR.IRQ0F checks whether the corresponding IRQ interrupt request is detected. In addition, the IRQ interrupt request can be cleared by writing 1 to the bit corresponding to EXINTSTC when an edge is detected.

When returning from the IRQ interrupt exception handler, clear the external interrupt status register (EXINTSTR) to prevent re-acceptance by mistake, and then issue an instruction to return from interrupt.

6.3.3 ECM Interrupts

The Error Control Module (ECM) generates ECM interrupt requests by merging error interrupts from multiple sources. For details, see **Section 30, Error Control Module (ECM)**.

6.3.4 Inter-Processor Interrupts

Four registers (IPIR_CHn) for conveying interrupts between PEs are provided.

IPIR_CH0 to IPIR_CH3 are assigned to CH0 to CH3 of user interrupt (EIINT). An interrupt for

specific PEs (including own PE) can be requested by manipulating bits corresponding to respective PEs. Interrupt priority levels can be set for each source in interrupt control registers, 16 levels for CPU1 and 8 levels for PCU.

6.3.5 Software Interrupts

The software interrupts (SINT) are generated by the setting of the SINTR0 to SINTR3 registers. Multiple interrupt requests can be queued.

Interrupt priority levels can be set for each source in interrupt control registers, 16 levels for CPU1 and 8 levels for PCU.

6.3.6 On-Chip Peripheral Module Interrupts

On-chip peripheral module interrupts occur in on-chip peripheral modules listed below.

- Code flash/Data flash
- Serial communication interface 3 (SCI3)
- OS timer (OSTM)
- Window watchdog timer (WDTA)
- Advanced timer unit IV (ATU-IV)
- Motor control timer (TSG2)
- Autonomous pulse control adapter (APA)
- AD converter (ADCB)
- AD addition function (ASF)
- Delta-sigma AD converter (DS-ADC)
- Serial communication interface H (CSIH)
- CAN interface (RS-CAN)
- FlexRay
- LIN master interface (RLIN2)
- Renesas high-speed bus (RHSB)
- Direct memory access controller (DMAC, DTS)
- Digital filter engine (DFE)

Since different interrupt vectors are assigned to each source, the interrupt exception handler need not decide sources. Interrupt priority levels can be set for each source in interrupt control registers, 16 levels for CPU1 and 8 levels for PCU.

6.4 Interrupt Exception Handler and Priority Operations

Table 6.14 lists interrupt sources, source codes, exception handler offset addresses, and interrupt priority.

There are two specifications for exception handler addresses: (1) standard specifications where exception handler addresses are determined by the PSW.EBV bit in the CPU core, RBASE register, and EBASE register and (2) extended specifications where exception handler addresses for interrupts are specified individually for each channel.

In the standard specifications, an offset address is added to the base address (RBASE register /EBASE register) in the CPU core to generate an exception handler address. The following two methods are provided for giving an interrupt offset address. For channels other than the interrupt channel, the specified offset address is given.

- An offset address is determined within a range of $+100_H$ to $+1F0_H$ according to the priority level (0 to 15) specified for each channel, regardless of interrupt channels (Note 1 in **Table 6.14**).
- Every offset address is $+ 100_H$ regardless of the priority level. This is a function to reduce the memory occupation size of the exception handler (Note 2 in **Table 6.14**).

In the extended specifications, a table for reading exception handler addresses for each interrupt channel is provided. The handler address is extracted by referencing the table. The table reference position is obtained by the following calculation formula (Note 3 in **Table 6.14**). The INTBP register exists in the CPU core.

Exception handler address read position = INTBP + channel number * 4-byte

For RH850 G3M and G3K exceptions, refer to “RH850G3M User's Manual: Software and RH850G3K User's Manual: Software”.

For system error exceptions, see **Section 3, CPU System**.

Priority can be set for each channel. If specified priority levels are equal, an interrupt source of smaller channel number is selected as fixed priority.

CAUTION

Be sure to place a SYNCP instruction at the start of handlers for the FENMI, FEINT, EIINT (direct vector method) and SYSERR and FPI exceptions.

For details, refer to the *RH850G3M User’s Manual: Software*.

Table 6.14 Interrupt Exception Handler and Priority (1/13)

Note: To clear an interrupt request of level interrupt, the status register in each module should be cleared during interrupt processing by software . To clear the status register, see **Section 3.5.1, Synchronization of Store Instruction Completion and Subsequent Instruction Generation**. The EICTn bit in EICn is set to 1. The EIRFn bit in EICn cannot be cleared by software.

Notes 1, 2, and 3: See **Section 6.4, Interrupt Exception Handler and Priority Operations**.

Note 1. See ***RH850/E1x Flash Memory User's Manual Hardware Interface***.

6.5 Operation

6.5.1 External Interrupts (NMI/IRQ)

NMI and IRQ interrupts are input from external devices. Four detection methods for these interrupts are selectable (2 types for NMI and 4 types for IRQ). For the interrupt detection flow, see **Section 6.5.6, Interrupt Processing Flow**.

6.5.2 Inter-Processor Interrupt

For the operation of software interrupts, see **Section 3.2.3.1, Inter-Processor Interrupt Control Registers** and **Section 6.5.6, Interrupt Processing Flow**.

6.5.3 Software Interrupt

For the operation of software interrupts, see **Section 6.2.9, SINTR0 to SINTR3 — Software Interrupt Registers** and **Section 6.5.6, Interrupt Processing Flow**.

6.5.4 DTS Interrupt Merge Function

Up to 128 transfer end interrupts and up to 128 transfer count match interrupts are aggregated into one interrupt in units of 32 interrupts.

When multiple interrupt source conditions are satisfied, only the single bit on the lower-order side of the corresponding bits in the status registers (PINT0 to PINT7) is set to judge which interrupt is accepted. For the flow of interrupts in the merging of DTS interrupts, see **Section 6.5.6, Interrupt Processing Flow**.

Table 6.15 DTS Interrupt-Related Registers

Interrupt Source	CH	Status Register	Clear Register
DTS transfer end interrupt	0 to 31	PINT0	PINTCLR0
	32 to 63	PINT1	PINTCLR1
	64 to 95	PINT2	PINTCLR2
	96 to 127	PINT3	PINTCLR3
DTS transfer count match interrupt	0 to 31	PINT4	PINTCLR4
	32 to 63	PINT5	PINTCLR5
	64 to 95	PINT6	PINTCLR6
	96 to 127	PINT7	PINTCLR7

6.5.5 ATU-IV/TSG2 Merge Function

ATU-IV timer interrupts and TSG2 interrupts are shared, and functional restrictions shown in **Table 6.16** are provided for these interrupts.

Table 6.17 shows combinations of share.

Table 6.16 Functional Restrictions for Interrupts when Using ATU-IV Timer D and TSG2

ATU-IV timerD (4, 5, 6)				TSG2*1		
(1)	(2)	(3)	(4)	(5)	(6)	
ch4	ch5	ch6	For the peripheral trigger	TSG2_0	TSG2_1	Functional Restriction
√	√	√	√	×	×	TSG2 is not available when ATU-IV is used.
×	×	×	×	√	√	ATU-IV timer D is not available when TSG2 is used.
×	×	×	√	√	√	ATU-IV (timer D4 to 6) is not available when TSG2 is used, but the peripheral trigger function of ATU-IV is available.
×	×	√	√	√	×	Combination of channels for ATU-IV and TSG2 is possible except for some channels.
√	×	×	√	×	√	

Note 1. Cycle interrupt, peak interrupt, and trough interrupt of TSG2 are not merged and can be independently used.

Table 6.17 Sharing of ATU-IV and TSG2

ATU-IV	TSG2*1	Sharing
(1) and (2)*2	(5)	OR
(2)*3 and (3)	(6)	OR

Note 1. Cycle interrupt, peak interrupt, and trough interrupt of TSG2 are not merged and can be independently used.

Note 2. Compare match interrupt (eight) and Overflow interrupt (two) of Timer D ch5

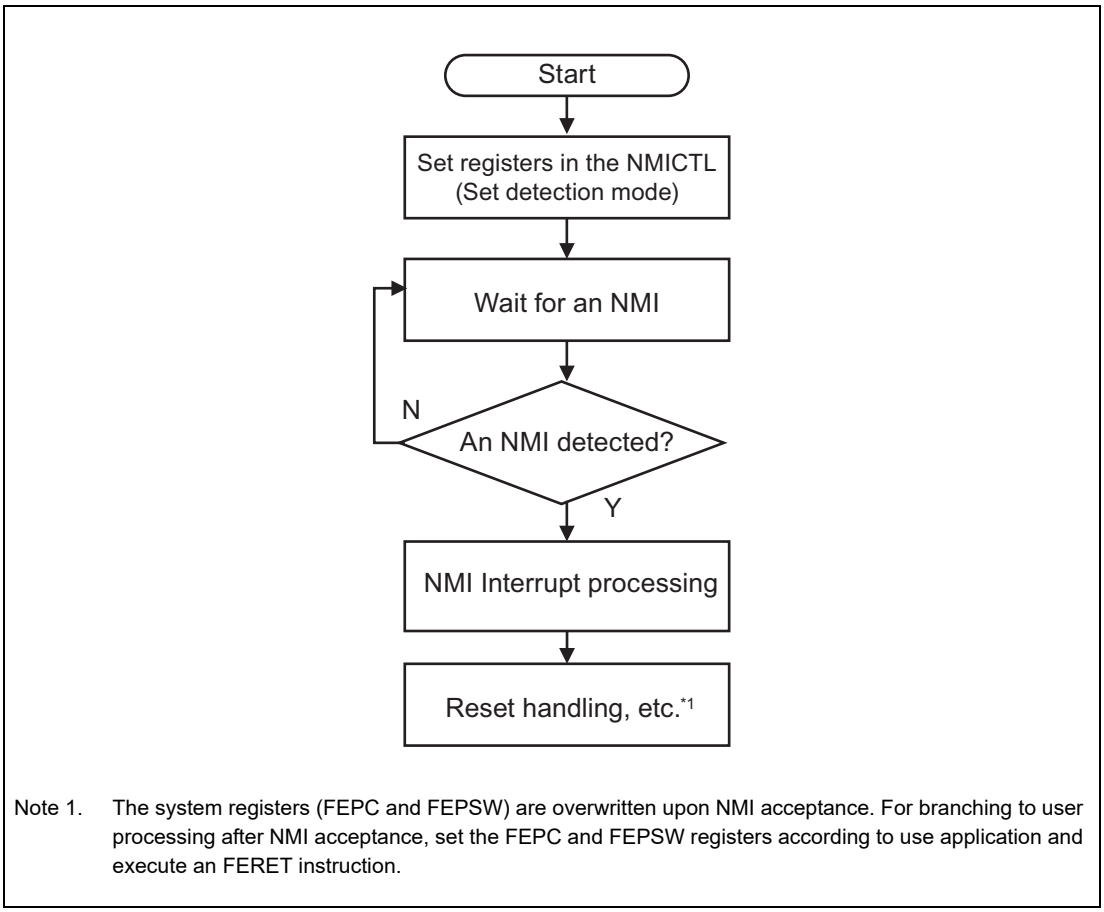
Note 3. Down-counter underflow interrupt of Timer D ch5 (four)

6.5.6 Interrupt Processing Flow

6.5.6.1 NMI Processing Flow

Figure 6.1 shows an example of NMI processing flow.

- Select an NMI detecting method (falling edge or rising edge) by setting the NMICTL register.
- After an NMI has been detected, an interrupt request is sent to the INTC.
- NMI interrupts are accepted at the high priority even when other FE level interrupt has been generated. NMI interrupts cannot be masked regardless of the state of PSW.NP in the CPU system register. NMI interrupts are non-maskable interrupts from which return or recovery is not possible.



Note 1. The system registers (FEPC and FEPSW) are overwritten upon NMI acceptance. For branching to user processing after NMI acceptance, set the FEPC and FEPSW registers according to use application and execute an FERET instruction.

Figure 6.1 Example of NMI Processing Flow

6.5.6.2 External Interrupt Processing Flow

Figure 6.2 shows an example of IRQ (external interrupt) processing flow.

- Select an IRQ detecting method (edge detection or level detection) by setting the EXINTCTL register.
- After detection of an IRQ, an interrupt request is issued to the INTC.
- After recovery on completion of interrupt processing within the INTC in the case of level detection, confirm that the IRQn pin is negated before issuing the instruction to return from the interrupt.
- After recovery on completion of interrupt processing within the INTC in the case of edge detection, clear the interrupt request bit in the EXINTSTR register, and then issue the instruction to return from the interrupt.

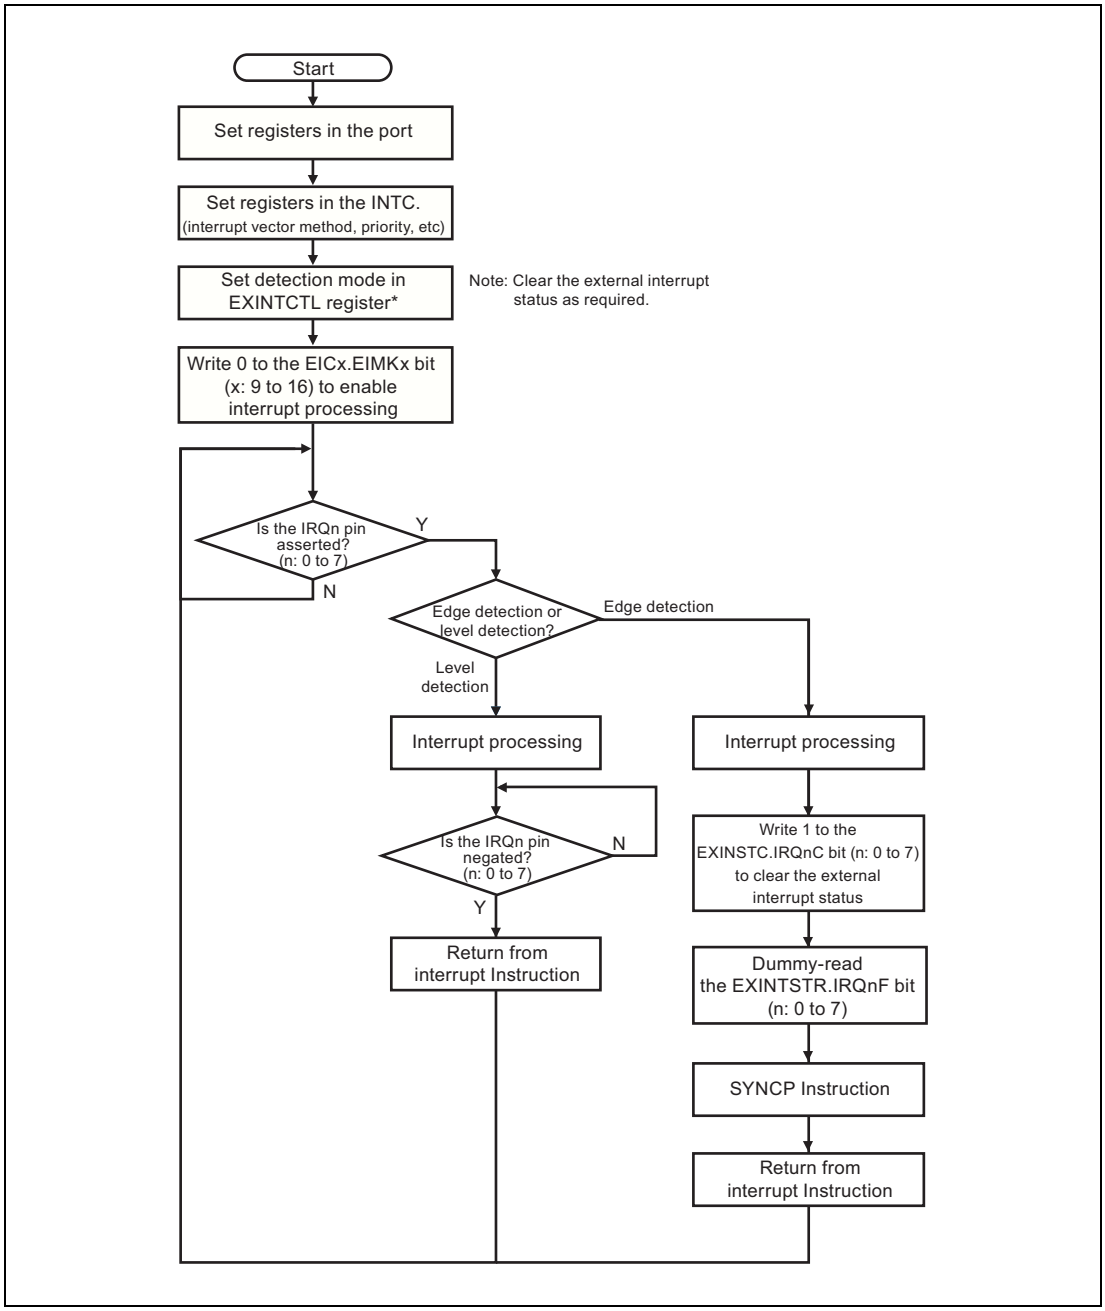


Figure 6.2 Example of External Interrupt Processing Flow

6.5.6.3 Inter-Processor Interrupt Flow

Figure 6.3 shows a flow example of inter-processor interrupt processing.

- Inter-processor interrupting generates an interrupt request by writing 1 to applicable bits of PE to which interrupts of the inter-PE interrupt registers (IPIR0 to IPIR3) are requested.
- The settings of interrupt request of the inter-PE interrupt registers (IPIR0 to IPIR3) are automatically cleared to 0 after notification of an interrupt request is complete.

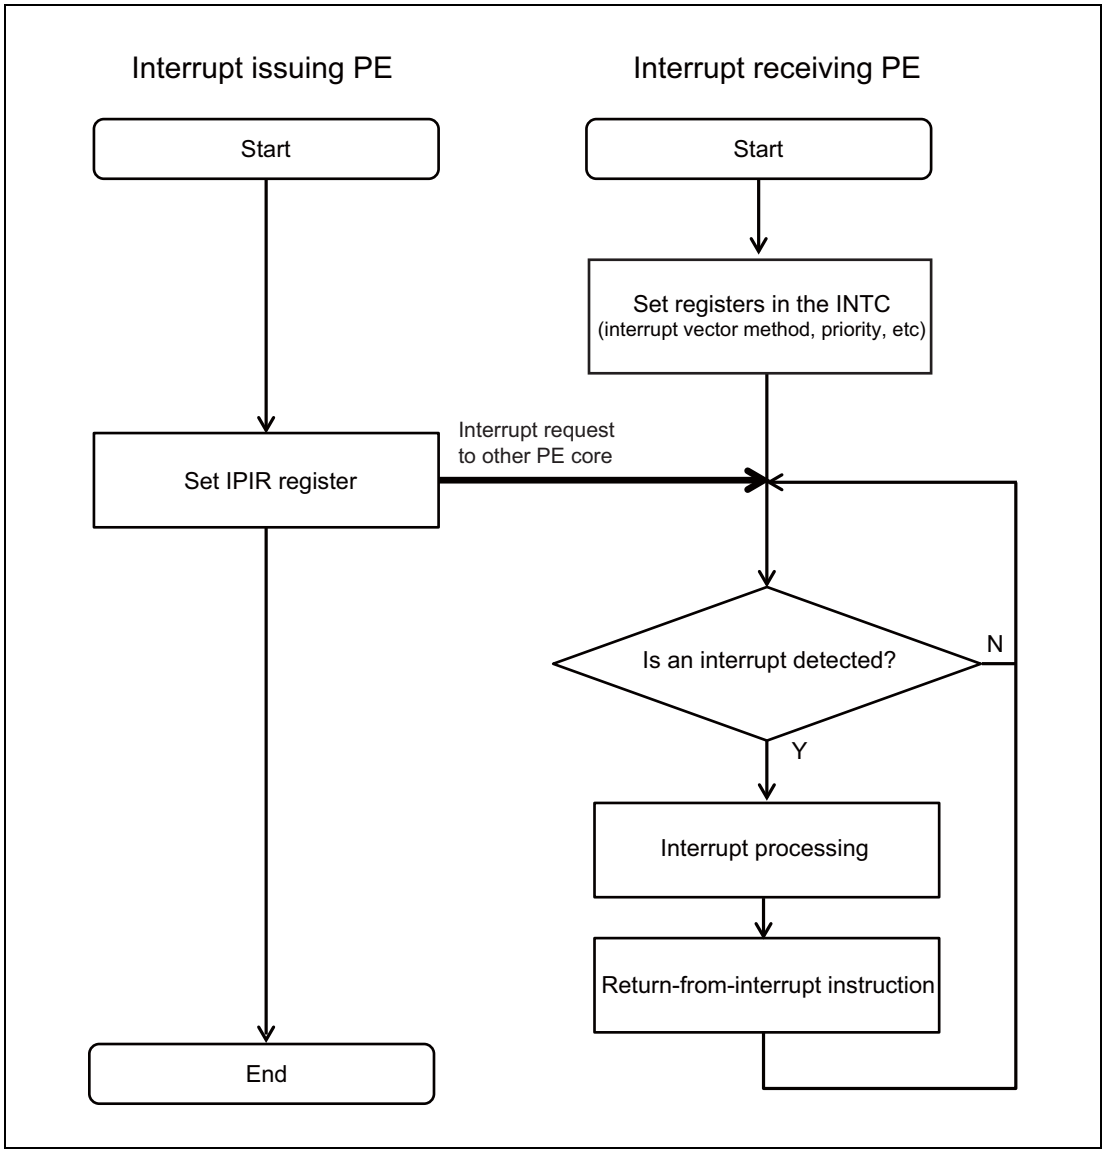

Figure 6.3 Example of Inter-Processor Interrupt Processing Flow

6.5.6.4 Software Interrupt Processing Flow

Figure 6.4 shows the flow example of software interrupt processing.

- Software interrupt requests are controlled by writing 00_H or 01_H to the counter registers (SINTR0 to SINTR3).
- Writing 00_H leads to the counter's value being decremented by 1.
- Writing 01_H leads to the counter's value being incremented by 1.
- If the incremented counter value is 1 or above, an interrupt request for the INTC is generated.
- Decrement the counter by 1 during interrupt processing in the INTC, and if SINTRn is 00_H after issuing the instruction to return from the interrupt, wait for the writing of 01_H to SINTRn.

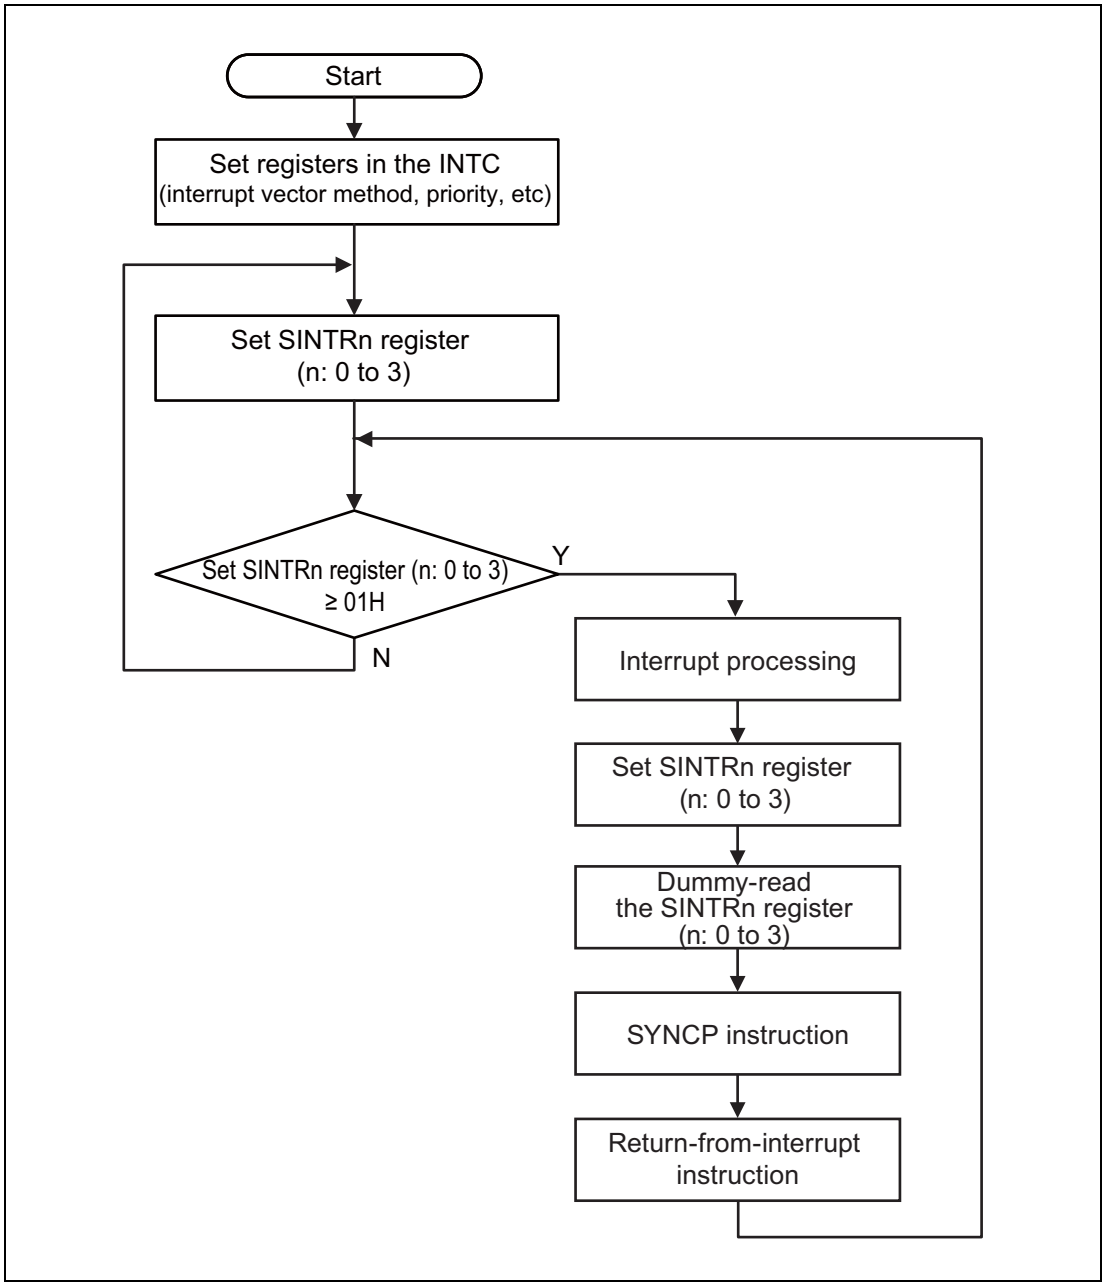

Figure 6.4 Example of Software Interrupt Processing Flow

6.5.6.5 DTS Interrupt Processing Flow

Figure 6.5 shows an example of DTS interrupt processing flow.

- When only one interrupt request is generated out of bundled 32 interrupt sources
  - The bit corresponding to the interrupt request in the PINTn register is set to 1 and an interrupt request is output.
  - On completion of other interrupt processing, write 1 to the interrupt clear register (PINTCLRn) to clear the interrupt request before issuing the return from interrupt instruction, then wait for the next one.
- When multiple interrupt sources are generated out of bundled 32 interrupt sources
  - The bit on the lower-order side is extracted out of bits with interrupt request and only the extracted bit in the PINTn register is set to 1, and an interrupt request is output.
  - On completion of other interrupt processing, write 1 to the target bit in the interrupt clear register (PINTCLRn) to clear the interrupt request, then issue the return from interrupt instruction.
  - After clearing the interrupt request bits for which interrupt processing has proceeded, in the same way as the previous time, the bit on the lower-order side of the PINTn register that corresponds to an interrupt request is extracted and an interrupt request is issued.
  - These steps are repeated until all interrupt sources bundled into 32 bits are cleared.

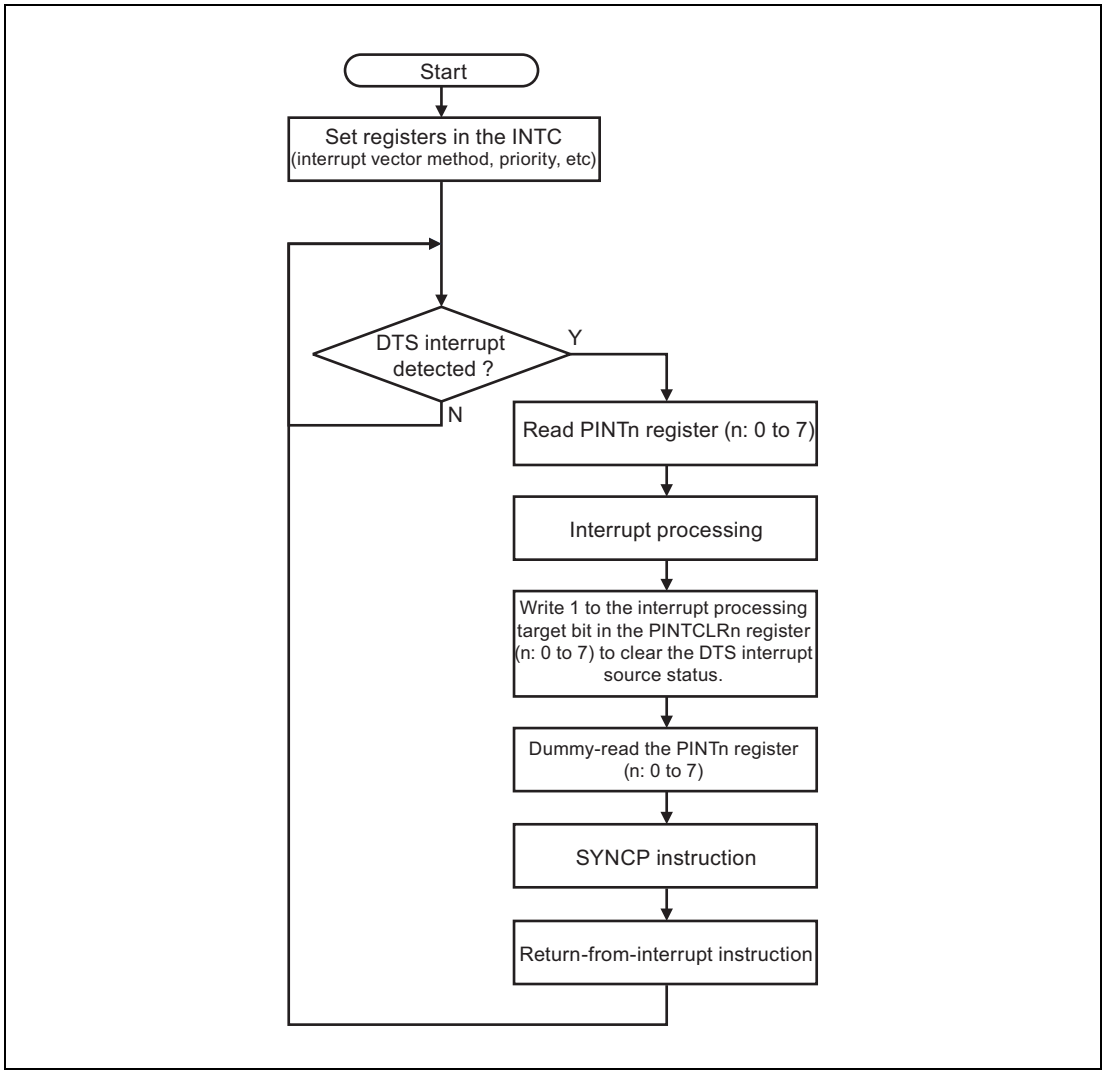

Figure 6.5 Example of DTS Interrupt Processing Flow

6.6 Interrupt Response Times

Table 6.18 Interrupt Response Times (min.)

Interrupt Request Source			Number of Cycles for Processing				
Target	INTC Connection	Operating Clock	Synchro-nization	INTC2	INTC1	In CPU1/ PCU	Total*1
CPU1	Directly input to INTC1	High-speed/low-speed peripheral clock	0	—	2 × Iϕ <1 × Iϕ>	Refer to the descriptions under CPU1 below	7 × Iϕ
		Unmodulated high-speed peripheral clock	—				—
		Unmodulated low-speed peripheral clock	5 × Pϕ <2 × Pϕ>				5 × Pϕ + 7 × Iϕ
	Input via INTC2	High-speed/low-speed peripheral clock	0	3 × Pϕ + 1 × Iϕ <2 × Pϕ + 1 × Iϕ>	—		3 × Pϕ + 6 × Iϕ
		Unmodulated high-speed peripheral clock	4 × Pϕ <2 × Pϕ>				7 × Pϕ + 6 × Iϕ
		Unmodulated low-speed peripheral clock	5 × Pϕ <2 × Pϕ>				8 × Pϕ + 6 × Iϕ
PCU	Directly input to INTC1	High-speed/low-speed peripheral clock	0	—	2 × Pϕ <1 × Pϕ>	Refer to the descriptions under PCU below	9 × Pϕ
		Unmodulated high-speed peripheral clock	—				—
		Unmodulated low-speed peripheral clock	5 × Pϕ <2 × Pϕ>				14 × Pϕ
	Input via INTC2	High-speed/low-speed peripheral clock	0	4 × Pϕ <3 × Pϕ>	—		11 × Pϕ
		Unmodulated high-speed peripheral clock	4 × Pϕ <2 × Pϕ>				15 × Pϕ
		Unmodulated low-speed peripheral clock	5 × Pϕ <2 × Pϕ>				16 × Pϕ

Notes 1. The numbers in < > indicate the numbers of cycles in the case of level detection.

Notes 2. Iϕ = CLK_CPU
Pϕ = 4 Iϕ at 320 MHz,
= 3 Iϕ at 240 MHz

Note 1. In the case of edge detection by fixed vector method a)

Vector method	Cache HIT/MISS	In CPU1 (320 MHz)	In CPU1 (240 MHz)	Vector method	In PCU (320 MHz)	In PCU (240 MHz)
Fixed vector method	a) ISR entry I$ hit	5 × Iϕ	5 × Iϕ	a) Fixed vector method	7 × Pϕ	8 × Pϕ
	b) ISR entry I$ missed	11 × Iϕ	10 × Iϕ			
Vector table reference method	c) Vector code Flash assigned, ISR entry I$ hit	15 × Iϕ	14 × Iϕ	b) Vector table reference method Code flash assigned	14 × Pϕ	15 × Pϕ
	d) Vector code Flash assigned, ISR entry I$ missed	21 × Iϕ	19 × Iϕ			

Note: Iϕ = CLK_CPU
Pϕ = 4 Iϕ at 320 MHz,
= 3 Iϕ at 240 MHz

6.7 Using Interrupt Request Signals to Initiate Data Transfer

An interrupt request signal activates the DMAC/DTS to perform data transfer.

For details, see Section 7, DMA.

Section 7 DMA

7.1 Overview

7.1.1 Overview

Direct memory access (DMA) is used to access data without going through the CPU.

DMA consists of two types of DMA transfer modules: DMAC and DTS. A DMAC includes registers for storing transfer information, and a DTS stores transfer information in the dedicated RAM (DTSRAM). DMA has two 8-channel DMAC modules and one 128-channel DTS module.

In this manual, DTFR denotes the function to select among hardware DMA transfer sources for a DMAC and retain the DMA transfer request, and DTSFSL denotes the function to retain a DMA transfer request for each DTS channel. The DTFR can handle 128 types of hardware DMA transfer sources, and the DTSFSL can handle 128 types of them.

The address space that can be used for DMA transfer is a 4 GB address space represented by a 32-bit address. For information about which resource is assigned to a particular area in the 4 GB address space and which area is accessible from DMA, see **Section 4, Address Space**.

7.1.2 Term Definition

Table 7.1 shows the terms used in this section.

Table 7.1 List of Term Definitions

Term	Meaning
DMA transfer	A general term for data transfer carried out by DMA.
DMA cycle	A series of actions that consist of reading an amount of data specified by the transfer size (8/16/32/64/128 bits) from the address specified by the source address and writing it to the address specified by the destination address. The first half of the DMA cycle (reading part) is called a read cycle, and the second half (writing part) is called a write cycle.
Hardware DMA transfer source	A trigger for a DMA transfer request given by an internal peripheral device.
Hardware DMA transfer request	A DMA transfer request generated by a hardware DMA transfer source.
Software DMA transfer request	A DMA transfer request generated by software writing to a register.
DMA transfer request	A trigger to start DMA transfer with a DMAC and DTS.
Transfer information (TI)	The information required for DMA transfer, including the source address, destination address, transfer data size, and transfer count. The transfer information for a DTS is specifically termed as TI.
DTSRAM	RAM used by a DTS to store the transfer information.
Single transfer	DMA transfer consisting of one DMA cycle started by one DMA transfer request.
Block transfer 1	DMA transfer consisting of a number of DMA cycles specified by the transfer count in the transfer information, started by one DMA transfer request.
Block transfer 2	DMA transfer consisting of a number of DMA cycles specified by the address reload count in the transfer information, started by one DMA transfer request.
Block transfer	A general term for both block transfer 1 and block transfer 2.
Last transfer	The DMA cycle carried out when the transfer count in the transfer information is 1.
Address reload transfer	The DMA cycle carried out when the address reload count in the transfer information is 1 if the reload function 2 is used.
Suspension	An action of pausing DMA transfer during block transfer. You can resume DMA transfer after suspension.
Resume	An action of resuming suspended DMA transfer.
Aborting transfer	An action of aborting DMA transfer in the middle. You cannot resume DMA transfer after that.

7.2 DMA Function

7.2.1 Basic Operation of DMA Transfer

7.2.1.1 Transfer Mode

DMA has three transfer modes.

Single Transfer

One DMA cycle is executed when a DMA transfer request is accepted.

Block Transfer 1

A number of DMA cycles specified in the transfer count register are executed when a DMA transfer request is accepted.

Block Transfer 2

A number of DMA cycles specified by the address reload count are executed when a DMA transfer request is accepted. If the address reload count is larger than the value in the transfer count register, a number of DMA cycles specified in the transfer count register are executed.

7.2.1.2 Executing a DMA Cycle

In a DMA cycle, dual-address transfer (two-cycle transfer) proceeds.

The DMA controller always executes a write cycle after a read cycle is complete. For example, if the transfer data size is 128 bits, a write cycle is executed after a read cycle for the 128-bit data is finished. A write cycle never starts in the middle of a read cycle.

7.2.1.3 Updating Transfer Information

When a DMA cycle is executed, DMA updates transfer information as follows.

Source Address and Destination Address

Transfer information will be updated as described in **Table 7.2** according to the settings for the source address and destination address and the settings in the transfer control register such as the count directions of source address and destination address and transfer data size.

Table 7.2 Updating the Source Address and the Destination Address

Direction of Counting	Transfer Data Size	Address after Update
Increment	8 bit	(address before update) + 0000 0001_H
	16 bit	(address before update) + 0000 0002_H
	32 bit	(address before update) + 0000 0004_H
	64 bit	(address before update) + 0000 0008_H
	128 bit	(address before update) + 0000 0010_H

Table 7.2 Updating the Source Address and the Destination Address

Direction of Counting	Transfer Data Size	Address after Update
Decrement	8 bit	(address before update) – 0000 0001_H
	16 bit	(address before update) – 0000 0002_H
	32 bit	(address before update) – 0000 0004_H
	64 bit	(address before update) – 0000 0008_H
	128 bit	(address before update) – 0000 0010_H
Fixed	—	Same as the address before update.

When you use the reload function, a special update rule is applied other than the one described in **Table 7.2** for the last transfer and the address reload transfer. For details, see **Section 7.2.3, Reload Function**.

Transfer Count/Address Reload Count

The transfer count is decremented by one for every DMA cycle.

The address reload count is decremented by one for every DMA cycle when the reload function 2 or block transfer 2 is used. When the reload function 2 or block transfer 2 is not used, it is not updated.

When you use the reload function, a special update rule is applied for the last transfer and the address reload transfer. For details, see **Section 7.2.3, Reload Function**.

Other transfer information

Other transfer information is not updated during execution of a DMA cycle.

7.2.1.4 Last Transfer and Address Reload Transfer

The last transfer means a DMA cycle executed when the value in the transfer count register, which shows the remaining number of transfers, is one. The last transfer differs in operation compared to other DMA cycles as follows.

- The transfer completion flag (DCSTn.TC) is set when the last transfer is complete. (Only applicable for a DMAC)
- The channel operation enable (DCENn.DTE) bit is cleared when the last transfer is complete. (Only applicable for a DMAC. When the continuous transfer is disabled.)
- When the transfer completion interrupt output enable is set, a transfer completion interrupt is output when the last transfer is complete.
- When the reload function 1 is enabled, the reload function 1 is executed at the timing of the last transfer. For details, see **Section 7.2.3, Reload Function**.

The address reload transfer means a DMA cycle executed when the reload function 2 is enabled and the address reload count is one. The reload function 2 is executed during the address reload transfer. For details, see **Section 7.2.3, Reload Function**.

7.2.1.5 Transfer Completion Interrupt and Transfer Count Match Interrupt Outputs

DMA can output a transfer completion interrupt and a transfer count match interrupt.

Transfer Completion Interrupt Output

When the transfer completion interrupt output enable (DTCTn.TCE) is set in the transfer control register, a DMAC requests a transfer completion interrupt when the last transfer is complete.

When the transfer completion interrupt output enable (DTTCTn.TCE) is set in the transfer control register, a DTS requests a DTS transfer completion interrupt when the last transfer is complete.

Transfer Count Match Interrupt Output

When the transfer count match interrupt enable (DTCTn.CCE) is set in the transfer control register, a DMAC requests a DMAC transfer count match interrupt when the DMA cycle in which the transfer count compare register and the transfer count have the same value is complete.

When the transfer count match interrupt enable (DTTCTn.CCE) is set in the transfer control register, a DTS requests a DTS transfer count match interrupt at the completion of the DMA cycle in which the transfer count compare register and the transfer count have the same value.

Figure 7.1 shows the operation of the transfer completion interrupt and the transfer count match interrupt.

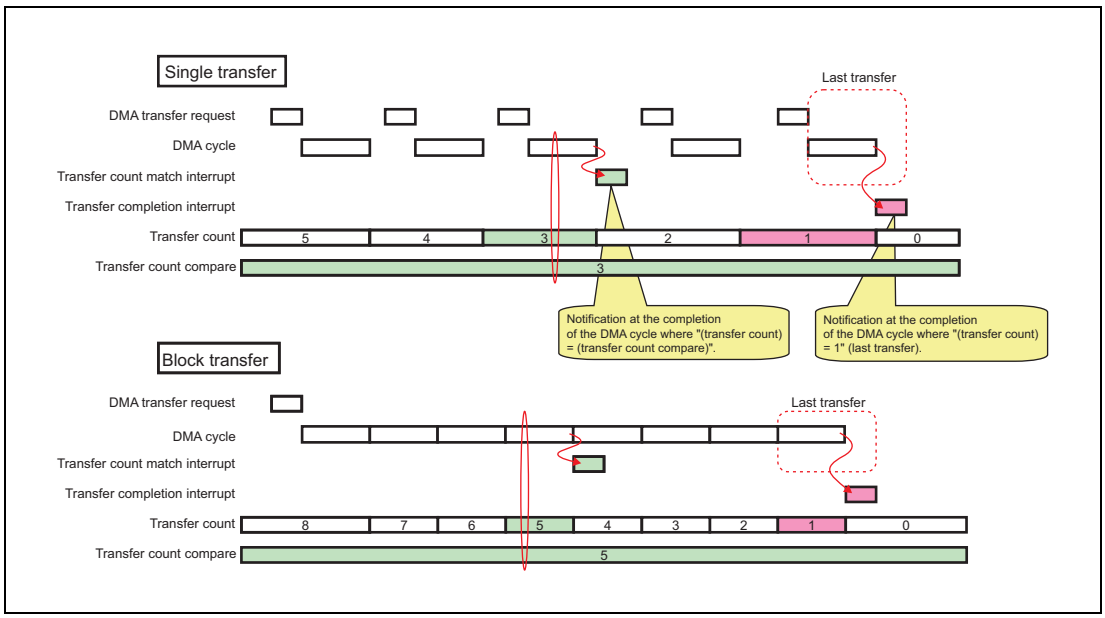

Figure 7.1 Transfer Completion Interrupt and Transfer Count Match Interrupt

7.2.1.6 Continuous Transfer

If the continuous transfer is not used, a DMAC sets the transfer completion flag (DCSTn.TC) and clears the channel operation enable (DCENn.DTE) bit when the last transfer is complete. In this case, a DMA transfer request is not accepted when the request is generated after the completion of the last transfer.

If the continuous transfer is used, the channel operation enable (DCENn.DTE) bit is not cleared when the last transfer is complete, and a DMA transfer request can be accepted even when the transfer completion flag is set. If DMA is used for a case where a specified number of DMA transfers are executed repetitively, software overhead associated with clearing the transfer completion flag and

setting the channel operation enable bit after the completion of the last transfer can be reduced by using the continuous transfer.

The continuous transfer is enabled by setting the continuous transfer enable (DTCTn.MLE) in the DMAC transfer control register.

The continuous transfer is designed to work with the reload function 1. The continuous transfer function itself does not update the source address register, destination address register, and transfer count register. If, after the last transfer is complete, you want to restore the source address register, destination address register, and transfer count register to the state before the DMA transfer starts, use the reload function 1 and set the values of the source address register, destination address register, and the transfer count register before the DMA transfer starts to the reload source address register, reload destination address register, and reload transfer count register respectively.

A DTS does not have a setting corresponding to the continuous transfer enable (DTCTn.MLE) for a DMAC. This is because a DTS does not have bits like the transfer completion flag (DCSTn.TC) and the channel operation enable (DCENn.DTE) a DMAC has.

A DTS does not start DMA transfer when a DMA transfer request is generated while the transfer count is 0. (This corresponds to the case for a DMAC where the continuous transfer is not used.)

If the reload function 1 is used for a DTS and the value other than 0 is reloaded to the transfer count when the last transfer is complete, DMA transfer can start when the next DMA transfer request is accepted. (This corresponds to the case for a DMAC where the continuous transfer is used.)

Figure 7.2 shows an operation of continuous transfer by a DMAC.

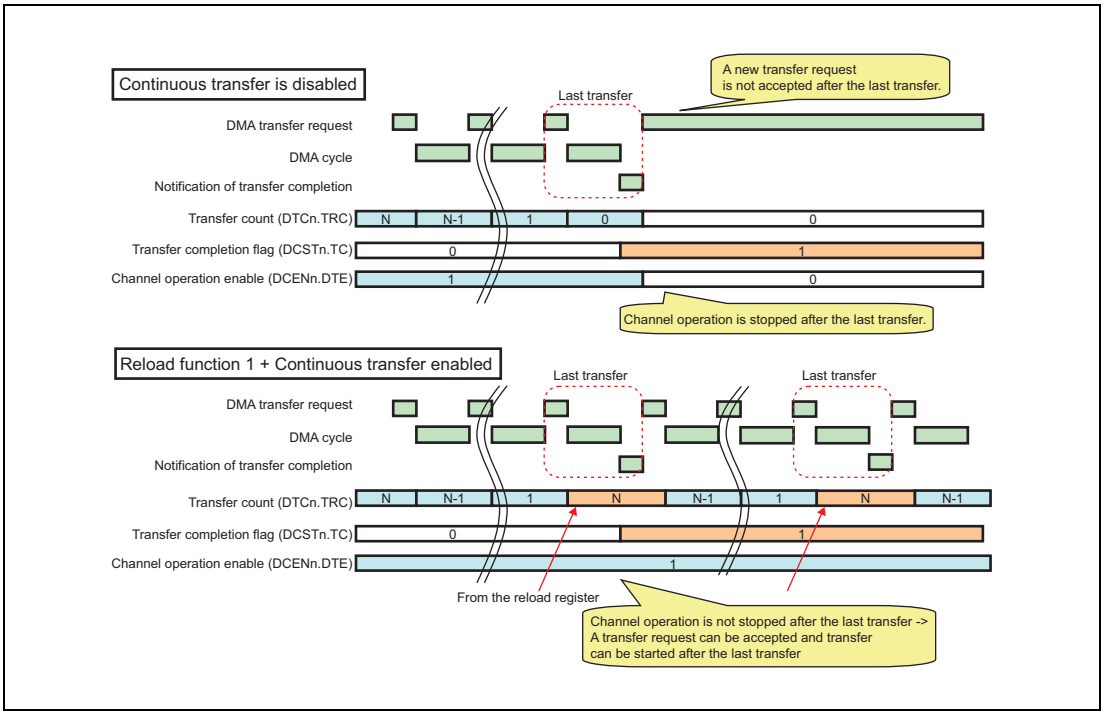

Figure 7.2 Operation of Continuous Transfer by a DMAC

7.2.2 Channel Priority Order

This subsection explains arbitration between multiple DMA channels.

7.2.2.1 DMAC Channel Arbitration

A DMAC selects one channel out of eight channels with arbitration. Arbitration is done according to the fixed priority order. The priority order is “channel 0 > channel 1 > channel 2 > channel 3 > channel 4 > channel 5 > channel 6 > channel 7” for DMAC0, and “channel 8 > channel 9 > channel 10 > channel 11 > channel 12 > channel 13 > channel 14 > channel 15” for DMAC1.

Arbitration is done for every DMA cycle. No arbitration occurs between the read and write of a DMA cycle.

If, at the timing when one DMA cycle in the middle of a block transfer by a channel is complete, there is a DMA transfer request from a channel with a higher priority than the channel, a DMA cycle of the channel with the higher priority will be executed next as the result of arbitration.

If a DMAC executes the block transfer 1 or block transfer 2, DMAC channel arbitration is done for every DMA cycle, and possibly a DMA cycle of another DMAC channel with a higher priority can cut in.

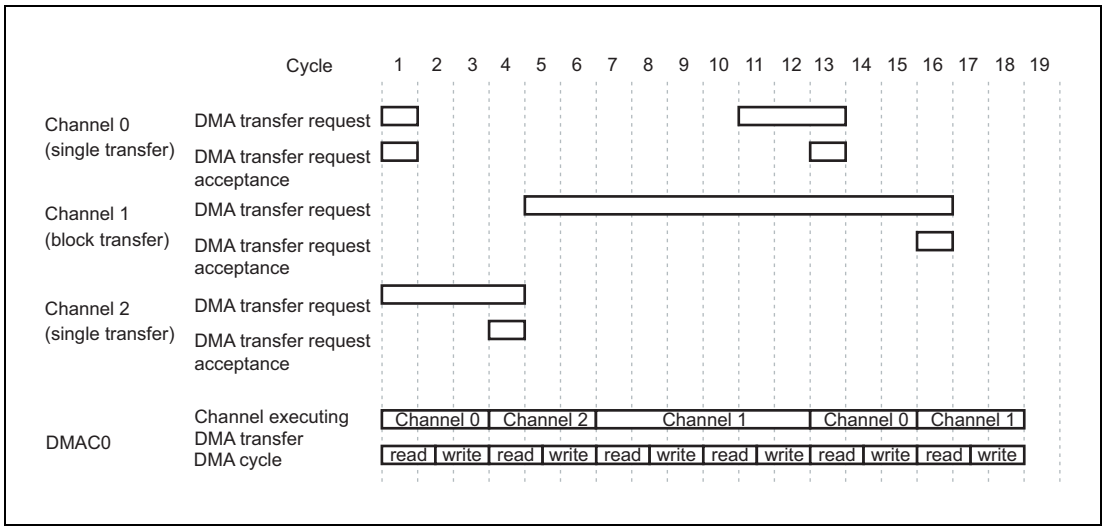

Figure 7.3 DMAC Channel Arbitration

Cycle numbers shown in **Figure 7.3** are for explanation purpose only. They do not indicate an actual number of cycles necessary for executing DMA transfer.

In **Figure 7.3**, DMA transfer requests for channels 0 and 2 are generated at Cycle 1. As a result of arbitration, a DMA cycle for channel 0 starts because its priority is higher. At Cycle 4, a DMA cycle for channel 2 starts. At Cycle 5, a DMA transfer request for channel 1 is generated. The DMA cycle for channel 2 is still ongoing and no arbitration is done at this point. At Cycle 7, a DMA cycle for channel 1 starts. Channel 1 uses block transfer. Another DMA cycle continues at Cycle 10 because there are no DMA transfer requests from other channels. At Cycle 11, a DMA transfer request for channel 0 is generated. The DMA cycle for channel 1 is still ongoing and no arbitration is done at this point. At Cycle 12, the DMA cycle for channel 1 is complete. At Cycle 13, a DMA cycle for channel 0 starts as a result of arbitration between DMA channels 0 and 1.

It should be noted that, even though a block transfer by channel 1 has been already started, a DMA cycle of not channel 1 but channel 0 is executed at Cycle 13 because the priority of the latter is higher.

At Cycle 15, the DMA cycle for channel 0 is complete. At Cycle 16, a DMA cycle for channel 1 starts again. At Cycle 18, the last DMA cycle of the block transfer by channel 1 is complete.

7.2.2.2 DTS Channel Arbitration

If there are DMA transfer requests from multiple DTS channels, the DTSFSL arbitrates those DTS channels. For each DTS channel, a priority can be selected from four levels using DTS channel priority setting registers.

If there are DMA transfer request from multiple DTS channels, the arbitration is done as follows.

1. A channel with a higher priority level in the setting of DTS channel priority setting registers has a priority.
2. If two channels have the same priority level in the setting of DTS channel priority setting registers, a channel with a lower channel number has a priority.

The DTSFSL sends the DTS a DMA transfer request for the channel selected by arbitration. The DTS executes DMA transfer when it accepts the DMA transfer request.

Unlike DMA transfer with a DMAC, DMA transfer with a DTS does not allow arbitration between DTS channels in the middle of a block transfer. That means, even if a DMA transfer request with a higher priority comes during a block transfer for a channel with a lower priority, the DMA transfer with a higher priority does not start until the current block transfer for the channel with a lower priority is complete*1.

Note 1. The timing of completion of the block transfer is when the last transfer for the block transfer 1 or the last transfer or address reload transfer for the block transfer 2 occurs.

When a DTS executes the block transfer 1 or block transfer 2, a DMA cycle of a DTS channel with a higher priority does not take over the ongoing block transfer until the last transfer.

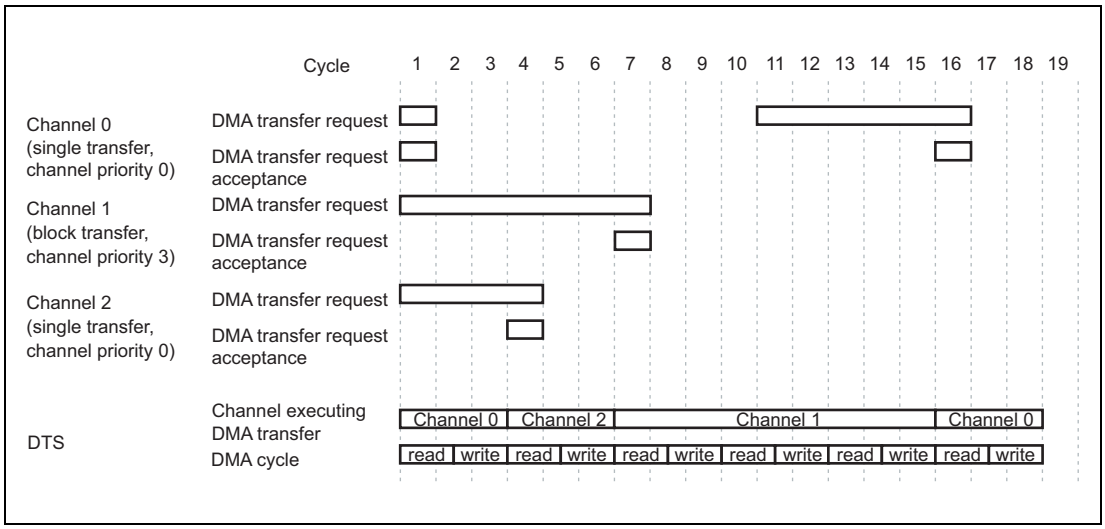

Figure 7.4 DTS Channel Arbitration

Cycle numbers shown in **Figure 7.4** are for explanation purpose only. They do not indicate an actual number of cycles necessary for executing DMA transfer.

In **Figure 7.4**, DMA transfer requests for channels 0, 1, and 2 are generated at Cycle 1. The channel priority for channels 0 and 2 is 0 and is higher than the channel priority for channel 1, which is 3. In addition, if two channels have the same priority, the channel with the smaller channel number has a higher priority. Consequently, the priority order for arbitration is “channel 0 > channel 2 > channel 1”, and a DMA cycle for channel 0 starts because its priority is the highest At Cycle 4, as a result of arbitration between channels 1 and 2, a DMA cycle for channel 2 starts. At Cycle 7, a DMA cycle for channel 1 starts. Channel 1 uses block transfer. Another DMA cycle continues at Cycle 10 because there are no DMA transfer requests from other channels. At Cycle 11, a DMA transfer request for channel 0 is generated. The DMA cycle for channel 1 is still ongoing and no arbitration is done until the block transfer by channel 1 is complete.

At Cycle 15, the block transfer by channel 1 is complete. At Cycle 16, a DMA cycle for channel 0 starts.

7.2.2.3 Interface Arbitration

DMAC0, DMAC1, and DTS work independently and execute DMA transfer.

When DMAC0, DMAC1, and DTS requests are in contention, the interface arbitrates this in round-robin fashion.

7.2.3 Reload Function

7.2.3.1 Overview of the Reload Function

The reload function updates a portion of transfer information, more specifically, the source address, destination address, transfer count, and address reload count, to the predefined values during DMA transfer.

The reload function has two types of functions: reload function 1 and reload function 2.

7.2.3.2 Operation of Reload Function 1

When the reload function 1 is enabled, actions described in **Table 7.3** are executed at the timing of the last transfer according to the reload function 1 setting.

Table 7.3 Operation of Reload Function 1

Reload Function 1 Setting (DTCTn.RLD1M[1:0])	Register	Action at the Last Transfer
00 (Reload function 1 disabled.)	Source address	Not reloaded.
	Destination address	Not reloaded.
	Transfer count	Not reloaded.
	Address reload count	Not reloaded.
01 (Reload function 1 enabled. Reloading source address and transfer count.)	Source address	The reload source address is copied to this.
	Destination address	Not reloaded.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	• If the reload function 2 is disable: Not reloaded. • If the reload function 2 is enabled: The reload address reload count is copied to this.
10 (Reload function 1 enabled. Reloading destination address and transfer count.)	Source address	Not reloaded.
	Destination address	The reload destination address is copied to this.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	• If the reload function 2 is disable: Not reloaded. • If the reload function 2 is enabled: The reload address reload count is copied to this.
11 (Reload function 1 enabled. Reloading source address, destination address, and transfer count.)	Source address	The reload source address is copied to this.
	Destination address	The reload destination address is copied to this.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	• If the reload function 2 is disable: Not reloaded • If the reload function 2 is enabled: The reload address reload count is copied to this.

Figure 7.5 shows an operation of the reload function 1.

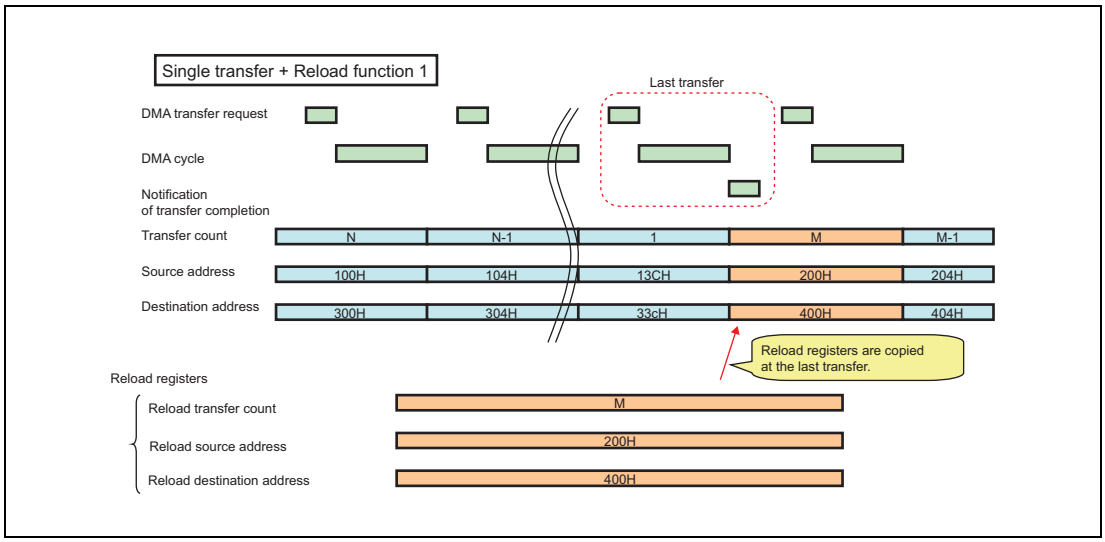

Figure 7.5 Operation of Reload Function 1

7.2.3.3 Reload Function 2

When the reload function 2 is enabled, actions described in **Table 7.4** are executed at the timing of the address reload transfer according to the reload function 2 setting.

Table 7.4 Operation of Reload Function 2

Reload Function 2 Setting (DTCTn.RLD2M[1:0])	Register	Action at the Address Reload Transfer
00 (Reload function 2 disabled.)	Source address	Not reloaded.
	Destination address	Not reloaded.
	Address reload count	Not reloaded.
01 (Reload function 2 enabled. Reloading source address.)	Source address	The reload source address is copied to this.
	Destination address	Not reloaded.
	Address reload count	The reload address reload count is copied to this.
10 (Reload function 2 enabled. Reloading destination address.)	Source address	Not reloaded.
	Destination address	The reload destination address is copied to this.
	Address reload count	The reload address reload count is copied to this.
11 (Reload function 2 enabled. Reloading source address and destination address.)	Source address	The reload source address is copied to this.
	Destination address	The reload destination address is copied to this.
	Address reload count	The reload address reload count is copied to this.

Figure 7.6 shows an operation of the reload function 2.

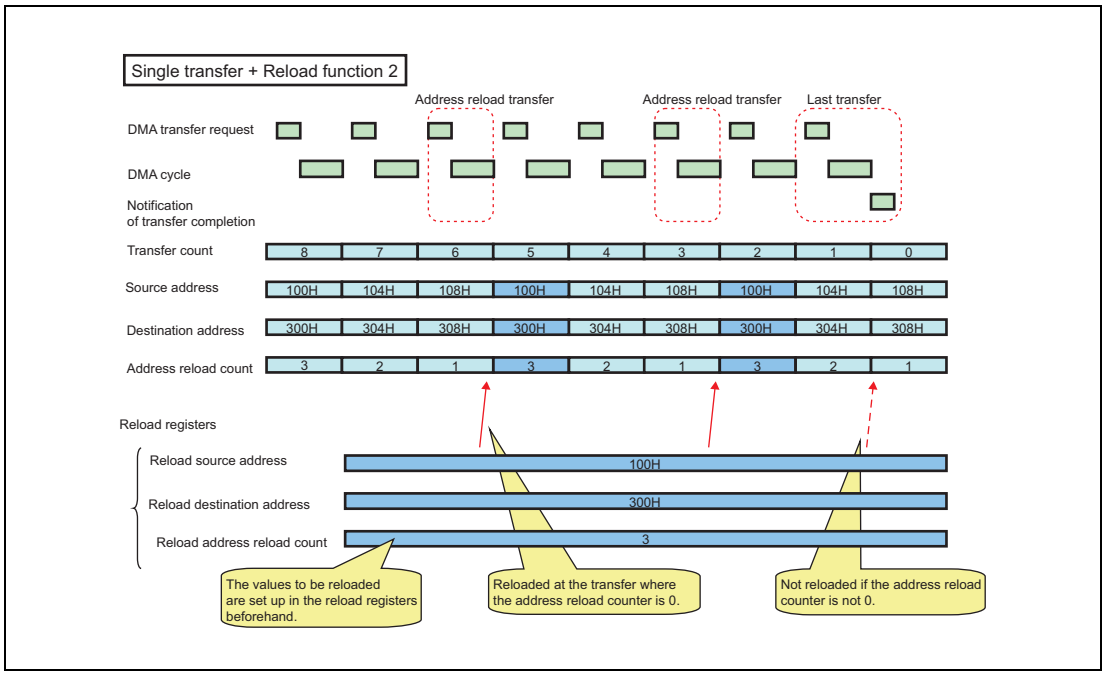

Figure 7.6 Operation of Reload Function 2

Figure 7.7 shows an operation when both the reload function 1 and the reload function 2 are used simultaneously.

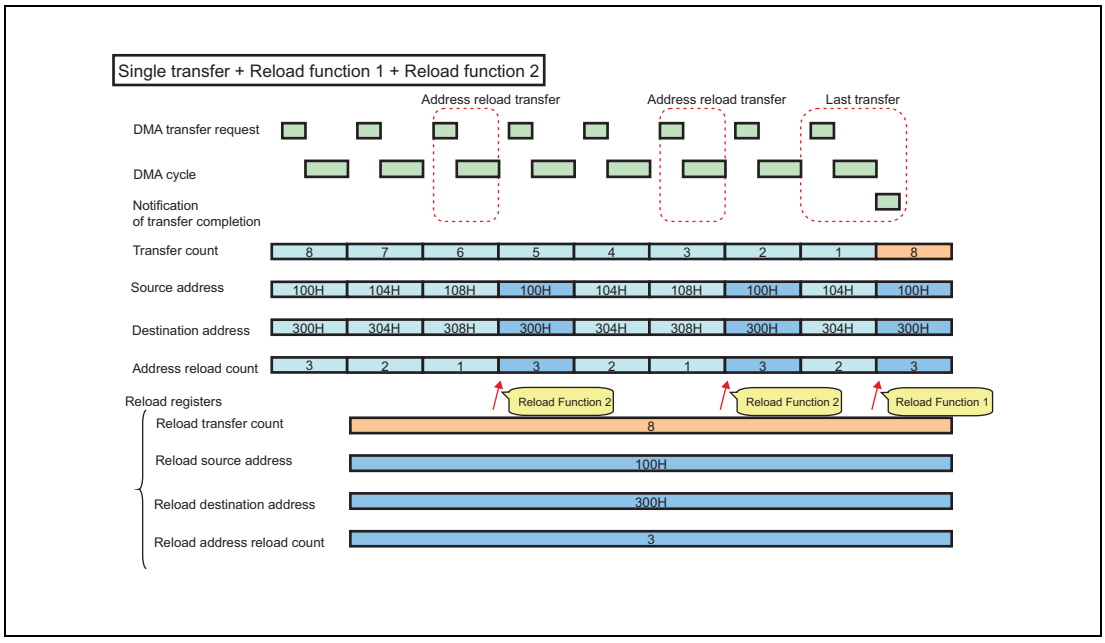

Figure 7.7 Operation when combining the reload function 1 and the reload function 2

7.2.3.4 Timing of Setting DMAC Reload Registers

You can set up the reload source address register, reload destination address register, and reload transfer count register any time (even during DMA transfer). As an exception, if you update the reload source address register, reload destination address register, and reload transfer count register during DMA transfer, there may be a conflict between reloading at the last transfer or address reload transfer and updating the reload register. In order to avoid this conflict, setting up reload registers must be completed before the last transfer or address reload transfer starts.

If you need to update the reload source address register, reload destination address register, and reload transfer count register during DMA transfer, one way to know the right timing of update is to use a DMA transfer count match interrupt. In this case, you must set up the DMA transfer count compare register (DTCCn) so that you can have enough margin for the time necessary to update the reload registers.

7.2.3.5 Timing of Setting DTS Reload Registers

It should be noted that the right timing of setting up the reload source address information, reload destination address information, and reload transfer count information differs depending on the transfer mode.

In the single transfer mode, the TI fetched at the beginning of the last transfer or address reload transfer is used for reload at the completion of the DMA cycle. Therefore, if you use the reload function for single transfer, the reload source address information, reload destination address information, and reload transfer count information in the TI must be set up before the beginning of the last transfer or address reload transfer.

During block transfer, TI is fetched only at the beginning of DMA transfer. The TI fetched at the beginning of the DMA transfer is used for reload at the last transfer or address reload transfer. Therefore, if you use the reload function for block transfer, the reload source address information, reload destination address information, and reload transfer count information in the TI must be set up before the beginning of the DMA transfer. If you update the reload source address information, reload destination address information, and reload transfer count information in the TI in the middle of a block transfer, those new settings will not be used for reload at the completion of the block transfer.

7.2.4 Chain Function

7.2.4.1 Overview

DMA offers a function called chain function. If you use the chain function, the completion of the DMA cycle or last transfer for one channel can trigger a DMA transfer request for another channel. A DMA transfer request for another channel initiated by the chain function is called a chain request.

You can select the condition for generating a chain request from the following two options.

- Always chain: A chain request is generated at the completion of every DMA cycle.
- Chain at the last transfer: A chain request is generated at the completion of the last transfer.

Figure 7.8 shows an operation of the case “always chain”.

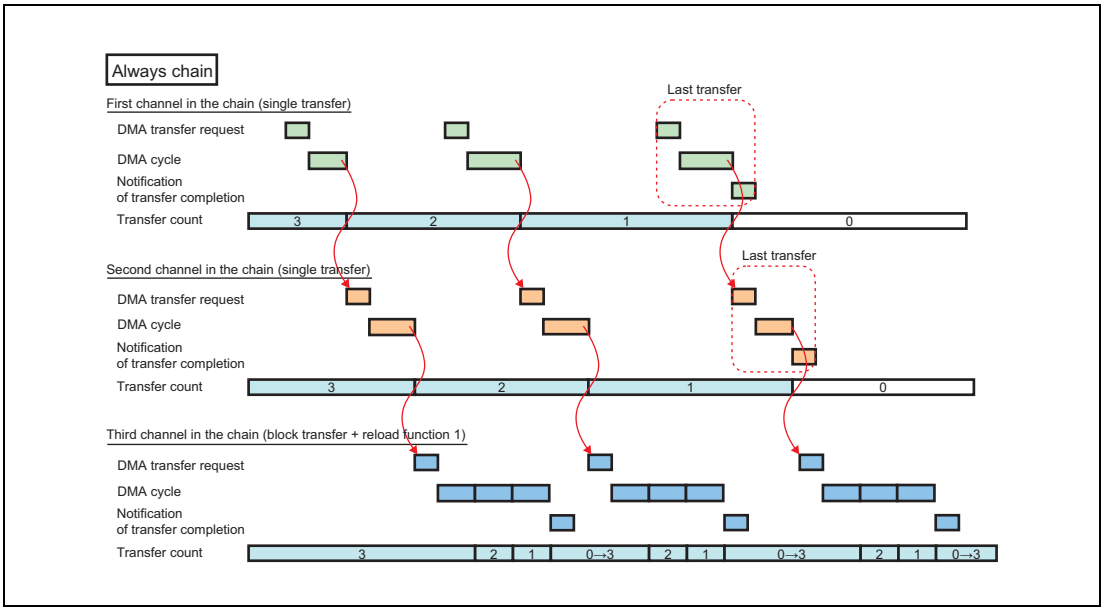

Figure 7.8 Operation of the Case “Always Chain”

Figure 7.9 shows an operation of the case “chain at the last transfer”.

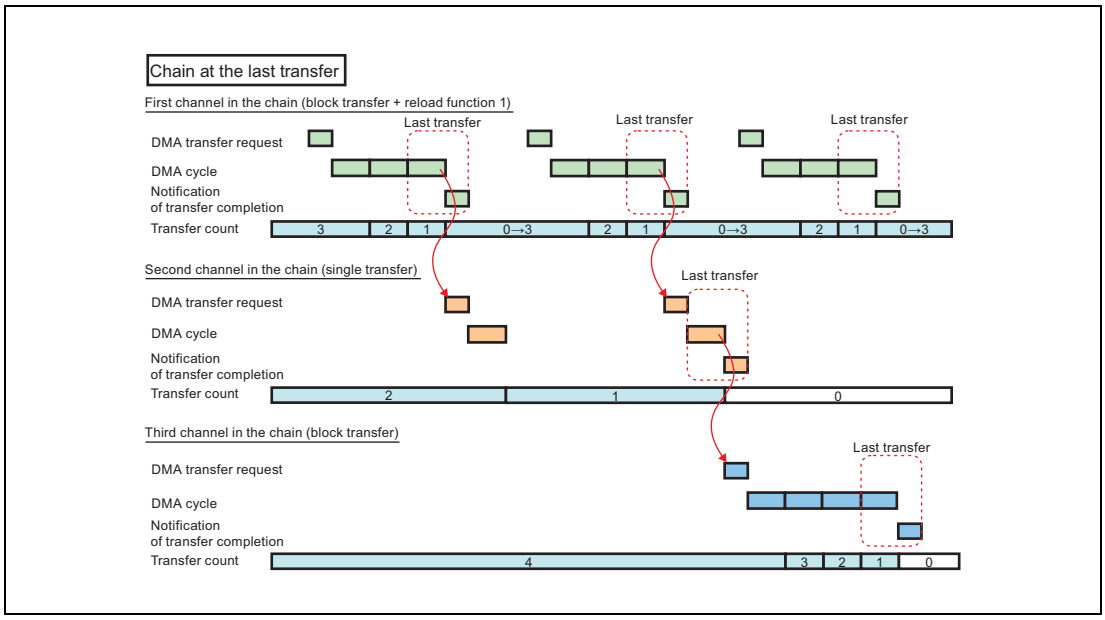

Figure 7.9 Operation of the Case “Chain at the Last Transfer”.

7.2.4.2 Setting Up the Chain Function

For a DMAC, you need to write to the chain enable (DTCTn.CHNE) and the next channel in the chain selection (DTCTn.CHNSEL) in the DMAC transfer control register in order to set up the type of chain function and the next channel number in the chain.

For a DTS, you need to write to the chain enable (DTTCTnnn.CHNE) and the next channel in the chain selection (DTTCTnnn.CHNSEL) in the DTS transfer control register in order to set up the type of chain function and the next channel number in the chain.

7.2.4.3 Caution for Using the Chain Function

The chain function sets the software DMA transfer request flag of the next channel in the chain as a part of its function. Therefore, you need to set up the channel settings of the next channel in the chain in the same way as when the software DMA transfer request is used. If you specify a channel using the hardware DMA transfer request for the next channel in the chain, the chain function does not work.

A channel and its next channel in the chain must belong to the same module (DMAC0, DMAC1, and DTS). You cannot specify a channel in another module for its next channel in the chain.

7.2.5 DMAC Operation

7.2.5.1 Types of DMA Transfer Requests and Assigning DMA Transfer Requests

A DMAC starts DMA transfer by accepting a hardware DMA transfer request or software DMA transfer request. The DMA transfer request selection assignment (DRS) bit in the DMAC transfer control register (DTCTn) determines whether a hardware DMA transfer request or a software DMA transfer request is used.

In the case of a hardware DMA transfer request for a DMAC, one out of 128 hardware DMA transfer sources is selected and assigned for each channel of the DMAC in the DTFR. This assignment is configured in the DTFR setting registers.

7.2.5.2 Generating and Accepting a Software DMA Transfer Request

By setting the software DMA transfer request flag (SR) in the DMAC transfer status register (DCSTn) using the DMAC transfer status set register (DCSTSn), a software DMA transfer request can be generated.

The software DMA transfer request flag is automatically cleared when the DMAC processes the DMA transfer request. The timing when the software DMA transfer request flag is automatically cleared differs depending on the transfer mode of the DMA transfer to be executed.

- In the single transfer mode, the software DMA transfer request flag is cleared whenever the software DMA transfer request is accepted.
- In the block transfer 1 mode, the software DMA transfer request flag is cleared when the last transfer starts.
- In the block transfer 2 mode, the software DMA transfer request flag is cleared when the last transfer or address reload transfer starts.

The software DMA transfer request flag can also be cleared by software using the DMAC transfer status clear register (DTSTCn). When you abort a DMA transfer by a DMAC channel, you must clear the software DMA transfer request flag.

7.2.6 DTS Operation

7.2.6.1 Types of DMA Transfer Requests and Assigning DMA Transfer Requests

A DTS starts DMA transfer by accepting a hardware DMA transfer request or software DMA transfer request. A transfer request for a DTS is retained in the transfer request pending bit of the DTSFSL for each channel.

As for the DTSFSL, both a hardware DMA transfer request and a software DMA transfer request are retained in the same transfer request pending bit. When executing DMA transfer, a DTS does not care whether a DMA transfer request is a hardware DMA transfer request or software DMA transfer request.

In the case of a hardware DMA transfer request for a DTS, each of 128 hardware DMA transfer sources is assigned to one of 128 channels in the DTSFSL in the fixed manner. You cannot change this assignment by, for example, register settings.

7.2.6.2 Generating and Accepting a DMA Transfer Request

When the DTSFSL detects a hardware DMA transfer source input, the DTSFSL sets the transfer request pending bit and retains the hardware DMA transfer source as a DMA transfer request. If the transfer request pending bit is set and the transfer request enable bit (DTFSLnnn.REQEN) in the DTSFSL operation setting register is set, the DTSFSL notifies the DTS of the DMA transfer request.

Software can also generate a DMA transfer request by setting the transfer request pending bit (DTFSTnnn.DRQ) using the DTSFSL transfer request set register (DTFSSnnn).

The DTSFSL can retain only one DMA transfer request per channel. If, while the transfer request pending bit for a channel is set, a new hardware DMA transfer source input for the same channel comes, the new hardware DMA transfer source input is ignored.

When the DTS accepts a DMA transfer request, it notifies of the acceptance of the DMA transfer request.

The transfer request pending bit is automatically cleared when the DTS accepts the DMA transfer request. The DTSFSL clears the transfer request pending bit automatically when the DTS accepts the DMA transfer request regardless of the type of the DMA transfer to be executed by the DTS.

The transfer request pending bit can also be cleared using the DTSFSL transfer request clear register (DTFSCnnn). If the transfer request pending bit of a channel is cleared before the DTS accepts the DMA transfer request, DMA transfer by the channel is not executed.

7.2.6.3 Executing DMA Transfer

When the DTS accepts a DMA transfer request for a channel, the DTS executes DMA transfer on the channel. If there are DMA transfer requests from multiple channels, the DTSFSL arbitrates the DTS channels and picks up one channel for a DMA transfer request.

While the DTS is executing DMA transfer, the DTS transfer status (DTSSTS.DTSACT) bit in the DTS status register is set. In addition, the channel number of the currently ongoing DMA transfer is set in the DTS transfer channel (DTSSTS.DTSACH).

When the DMA transfer is complete or aborted because of DMA transfer error or writing to registers and no channel is currently executing DMA transfer, the DTS transfer status (DTSSTS.DTSACT) bit is cleared.

7.2.6.4 DTSRAM Access

A DTS accesses the DTSRAM when DMA transfer starts and finishes.

A DTS's action of reading transfer information from the DTSRAM when DMA transfer starts is called TI fetch.

A DTS's action of updating the transfer information on the DTSRAM when DMA transfer finishes is called TI write back.

A single transfer performs a TI fetch at the beginning of a DMA cycle and a TI write back at the end of a DMA cycle.

A block transfer performs a TI fetch at the beginning of the first DMA cycle and a TI write back at the end of the DMA cycle that satisfies the block transfer completion condition (the last transfer or address reload transfer).

Therefore, in the case of single transfer, the transfer information on the DTSRAM is updated for each DMA cycle. In the case of block transfer, the transfer information on the DTSRAM is updated after the completion of the block transfer. If software reads the transfer information on the DTSRAM during execution of a block transfer, the transfer information at the beginning of the block transfer is read.

7.3 Suspending, Resuming, and Aborting DMA Transfer and Clearing the DMA Transfer Request

7.3.1 Suspending and Resuming DMA Transfer by Software Control

The DMA control register (DMACTL) is used to suspend DMA transfer for all channels.

When the DMA suspension bit (DMACTL.DMASPD) in the DMA control register is set, DMA puts all channels into the suspended state If all channels are in the suspended state and the DMA suspension bit (DMACTL.DMASPD) in the DMA control register is cleared, DMA restores all channels from the suspended state to the normal state and resumes the DMA transfer on the suspended channel.

When all channels are put into the suspended state, DMA transfer is suspended for all channels without changing the value of the DCENn.DTE bit of each DMAC channel and the DTSCTL1.DTSUST bit of the DTS.

CAUTION

To suspend or resume currently ongoing DMA transfer by the DTS, the DMA transfer request enable bit (DTFSLnnn.REQEN) must be switched to disable and enable arbitration for the given channel. For details, refer to the notes in Section 7.3.3, Suspending, Resuming, and Aborting Transfer by the DTS.

7.3.2 Suspending, Resuming, and Aborting Transfer by a DMAC Channel

You can suspend DMA transfer by a DMAC channel by clearing the channel operation enable bit in the DMAC channel operation enable setting register (DCENn.DTE) or setting the DMA suspension bit in the DMA control register (DMACTL.DMASPD). If a DMA cycle is ongoing, DMA transfer is suspended after the currently ongoing DMA cycle is finished. If you set the DCENn.DTE bit again or clear the DMACTL.DMASPD bit while DMA transfer is suspended, the suspended DMA transfer by the DMAC channel is resumed.

If you want to abort currently ongoing DMA transfer by a DMAC channel, clear the channel operation enable bit in the DMAC channel operation enable setting register (DCENn.DTE), and then clear the hardware DMA transfer request in the DTFR in the case of a hardware DMA transfer request, and clear the software DMA transfer request flag (DCSTn.SR) by using the DMAC transfer request flag clear bit in the DMAC transfer status clear register (DCSTCn.SRC) in the case of a software DMA transfer request.

While the continuous transfer enable bit (DTCTn.MLE) is set, the channel operation enable bit (DCENn.DTE) remains set. Even if the channel operation enable bit (DCENn.DTE) is cleared by software during the DMA cycle of the last transfer, the function of the continuous transfer enable bit (DTCTn.MLE) is given priority and the channel operation enable bit (DCENn.DTE) is set again after the completion of the last transfer.

If you want to suspend the DMAC channel while continuous transfer is in use, clear the continuous transfer enable bit (DTCTn.MLE) of the DMAC transfer control register, and then clear the channel operation enable bit (DCENn.DTE) of the DMAC channel operation enable setting register to suspend the DMA transfer. When and only when this operation is performed, writing to the DMAC transfer control register (DTCTn) is allowed while channel operation is enabled (DCENn.DTE = 1).

Figure 7.10 shows an example of suspending, resuming, and aborting transfer by a DMAC channel.

In **Figure 7.10**, both channels 0 and 1 are executing block transfer. At time tick 1, DMA transfer by channel 1 starts. At time tick 2, a DMA transfer request for channel 0 is accepted. As a result of DMAC channel arbitration, DMA transfer by channel 0 starts because channel 0 has a higher priority than channel 1. At time tick 3, the last transfer by channel 0 is complete, and the remaining DMA transfer in the block transfer by channel 1 starts. At time tick 4, the last transfer by channel 1 is complete. After time tick 5, DMA transfer by channel 0 and DMA transfer by channel 1 are executed similarly. At time tick 7, the DMA transfer by channel 0 is suspended and, as a result of DMAC channel arbitration, the DMA transfer by channel 1 starts. At time tick 8, the last transfer by channel 1 is complete, and then, at time tick 9, the DMA transfer by channel 0 resumes. At time tick 10, the last transfer by channel 0 is suspended again, and then, at time tick 11, the DMA transfer by channel 0 is aborted. At time tick 12, the suspended state for channel 0 is cleared, but DMA transfer is not executed because the DMA transfer is aborted at time tick 11.

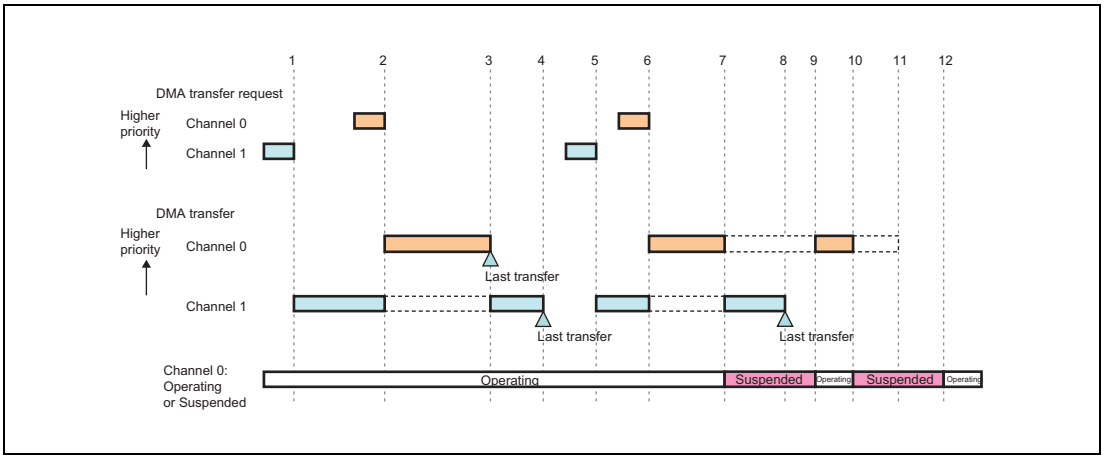

Figure 7.10 Example of Suspending, Resuming, and Aborting Transfer by a DMAC Channel

7.3.3 Suspending, Resuming, and Aborting Transfer by the DTS

You can suspend currently ongoing DMA transfer by the DTS by setting the DTS suspend bit in the DTS control register 1 (DTSCTL1.DTSUST) or the DMA suspend bit in the DMA control register (DMACTL.DMASPD). If a DMA cycle is ongoing, DMA transfer is suspended at the time when the DMA cycle is finished. If the ongoing DMA cycle is a single transfer or a transfer that completes a block transfer (the last transfer or address reload transfer), DMA transfer is suspended after a TI write back after the completion of the DMA cycle. If the ongoing DMA cycle is a type other than the above, the DMA transfer is suspended after the completion of the DMA cycle without a TI write back. To resume DMA transfer while it is suspended, clear the DTS suspend bit in the DTS control register 1 or the DMA suspend bit in the DMA control register.*1

Note 1. Before suspending or resuming currently ongoing DMA transfer by the DTS, the DMA transfer request enable bit (DTFSLnnn.REQEN) must be switched to disable and enable arbitration for the given channel. To suspend or resume DMA transfer, follow the procedure below.

(a) Procedure for suspending the DTS

1. Clear the DMA transfer request enable bit (DTFSLnnn.REQEN) for all DTS channels for which the DMA transfer request enable bit (DTFSLnnn.REQEN) has been set.
2. Set the DTSCTL1.DTSUST or DMACTL.DMASPD bit.

(b) Procedure for resuming the DTS

1. Set the DMA transfer request enable bit (DTFSLnnn.REQEN) for DTS channels, which was cleared in step 1 of (a).
2. Clear the DTSCTL1.DTSUST or DMACTL.DMASPD bit that was set in step 2 of (a).

If you want to abort currently ongoing DMA transfer by the DTS, suspend the DTS by using the DTS suspend bit in the DTS control register 1 (DTSCTL1.DTSUST), and then set the DTS transfer abort request bit in the DTS control register 2 (DTSCTL2.DTSTIT) to abort currently suspended DMA transfer. If transfer is aborted, no TI write back is executed. In addition, aborting DMA transfer does not change the value of the DTS suspend bit (DTSCTL1.DTSUST). If you want the DTS to accept another DMA transfer request after the transfer has been aborted, set the DMA transfer request enable bit (DTFSLnnn.REQEN) for DTS channels, and then clear the DTS suspend bit.

Figure 7.11 shows an example of suspending, resuming, and aborting transfer by the DTS.

In **Figure 7.11**, channels 0, 1, and 2 are executing block transfer. At time tick 1, a DMA transfer request for channel 1 is accepted and DMA transfer starts. At time tick 2, DMA transfer requests for channels 0 and 2 are generated. At time tick 3, the last transfer by channel 1 is complete, and as a result of DTS channel arbitration, a DMA transfer request for channel 0 is accepted, and DMA transfer by channel 0 starts because channel 0 has a higher priority than channel 2. At time tick 4, the last transfer by channel 0 is complete, and DMA transfer by channel 2 starts. At time tick 5, the DTS is put into the suspended state, and the DMA transfer by channel 2 is suspended. At time tick 6, DMA transfer requests for channels 0 and 1 are generated. At time tick 7, the suspended state for the DTS is cleared, and the DMA transfer by channel 2, which has been suspended in the middle of a block transfer, is resumed. If DMA transfer is suspended in the middle of a block transfer, no DTS channel arbitration is done when it is resumed. At time tick 8, the last transfer by channel 2 is complete, and as a result of DTS channel arbitration, a DMA transfer request for channel 0 is accepted and the DMA transfer starts because channel 0 has a higher priority than channel 1. At time tick 9, the DTS is put into the suspended state, and at time tick 10, the suspended DMA transfer by channel 0 is aborted. When the suspended state of the DTS 0 is cleared at time tick 11, DMA transfer by channel 1 starts because there is no currently ongoing DMA transfer and channel 1 is the only channel with a DMA transfer request.

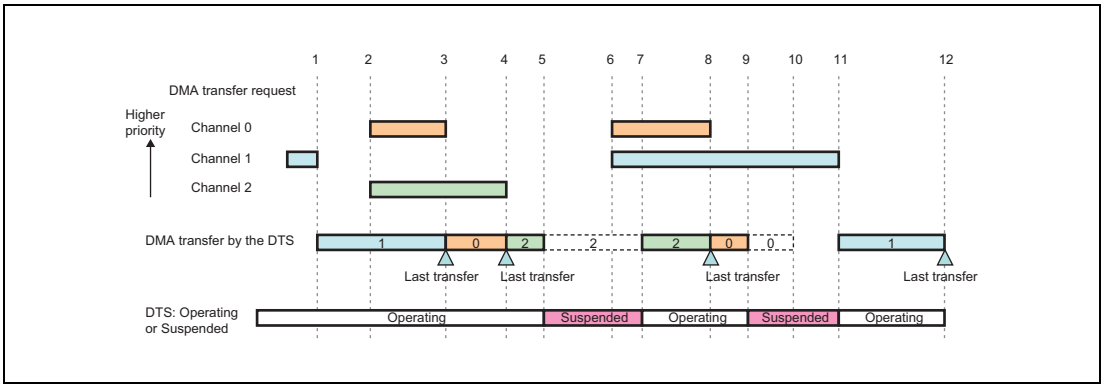

Figure 7.11 Example of Suspending, Resuming, and Aborting Transfer by the DTS

7.3.4 Masking and Clearing a Hardware DMA Transfer Request by the DTFR

If a DMAC uses a hardware DMA transfer request, you can temporarily disable (mask) the hardware DMA transfer request output from the DTFR to the DMAC by clearing the hardware DMA transfer source selection enable bit (DTFRn.REQEN) in the DTFR setting register.

Also, if a hardware DMA transfer source is used, you can clear a hardware DMA transfer request retained in the DTFR by using the hardware DMA transfer request clear (DTFRRQCn.DRQC) bit in the DTFR transfer request clear register.

Even if you suspend or abort DMA transfer by a DMAC channel, the hardware DMA transfer request selection/hold circuit of the DTFR is still running, and consequently, the DTFR may retain a hardware DMA transfer request that came to the DTFR during the suspension or transfer abort period of the DMAC channel. When you resume or start DMA transfer by a DMAC channel, clear the hardware DMA transfer request retained in the DTFR as required.

When a DMAC is used with hardware transfer request and block transfer 1 or 2, if the hardware transfer source selection enable bit is disabled (DTFRn.REQEN = 0), the ongoing block transfer is aborted.

7.3.5 Masking and Clearing a Hardware DMA Transfer Request by the DTSFSL

As for a DTS, you can temporarily disable (mask) a DMA transfer request from a channel to the DTS by clearing the transfer request enable bit (DTFSLnnn.REQEN) in the DTSFSL operation setting register. (The masking is actually done by excluding the channel from the candidates in DTS channel arbitration in the DTSFSL.)

Also, you can clear a DMA transfer request retained in the DTSFSL by using the transfer request clear (DTFSCnnn.DRQC) bit in the DTSFSL transfer request clear register.

Regardless of the state of the DTS and the transfer request enable bit (DTFSLnnn.REQEN) of the DTSFSL, the DTSFSL always monitors the hardware transfer source input, and a DMA transfer request for a channel is set when a hardware transfer source for the channel is input to the DTSFSL. When you resume or start DTS transfer, clear the hardware DMA transfer request retained in the DTSFSL as required.

7.3.6 List of Functions for Suspending, Resuming, and Aborting Transfer

Table 7.5 List of Functions for Suspending, Resuming, and Aborting Transfer

Function	How to execute the function	Operation	Possibility of aborting DMA transfer	Master that can execute the function (See Section 7.5, Reliability Function.)
Suspending and resuming DMA	Setting and clearing the DMACTL.DMASPD*2.	All channels are suspended.	Not possible*1	Special master
Suspending and resuming a DMAC channel	Clearing and setting the DCENn.DTE in each channel register.*3	DMA transfer by the channel is suspended.	Possible (by clearing the DMA transfer request flag during suspension)	Special master, and general master assigned to the channel.
Suspending and resuming the DTS	Setting and clearing the DTSCTL1.DTSUST*2.	DMA transfer by the DTS is suspended.	Possible (by setting the DTSCTL2.DTSTIT during suspension)	Special master

Note 1. In order to abort DMA transfer, you need to either abort transfer by the DMAC channel or abort transfer by the DTS.

Note 2. To suspend or resume currently ongoing DMA transfer by the DTS, the DMA transfer request enable bit (DTFSLnnn.REQEN) must be switched to disable and enable arbitration for the given channel. For details, refer to the notes in **Section 7.3.3, Suspending, Resuming, and Aborting Transfer by the DTS**.

Note 3. While continuous transfer is in use, set and clear the continuous transfer enable bit (DTCTn.MLE) first.

7.4 Error Control

7.4.1 Type of Error

DMA can generate the following two types of errors.

- DMA Transfer Error
  This error is generated when error is detected in the read cycle or write cycle in a DMA cycle.
  This error can be generated in all DMAC and DTS channels during execution of DMA transfer.
- DTSRAM Error
  This error is generated when ECC error is detected in the DTSRAM read access by a DTS.
  This error can be generated in the TI fetch during execution of DMA transfer by the DTS or while software is accessing the DTS channel registers.

7.4.2 DMA Transfer Error

A DMA transfer error leads to the generation of a DMA transfer error interrupt (DMAERR).

A DMA transfer error is detected independently for the DMAC channels and the DTS, but the DMA transfer error interrupt (DMAERR) is common to the DMAC and the DTS.

7.4.2.1 Operation of a DMAC When DMA Transfer Error Occurs

When DMA transfer error occurs in a DMAC, the transfer error flag (DCSTn.ER) in the DMAC transfer status register of the channel with the DMA transfer error. The DMAC error register (DMACER) shows the transfer error flags of all 16 DMAC channels.

While the transfer error flag of a channel is set, a new DMA cycle is not executed if the transfer error case DMA transfer disable setting (DTCTn.ESE) bit is set. On the other hand, a DMA cycle is executed regardless of the value of the transfer error flag if the transfer error case DMA transfer disable setting (DTCTn.ESE) bit is cleared.

If you want to abort the DMA transfer by the channel where a DMA transfer error occurred, follow the procedure to abort DMA transfer by the DMAC channel.

If DMA transfer error occurs during the read cycle of a DMA cycle, the write cycle is not executed. If DMA transfer error occurs during the write cycle of a DMA cycle, the validity of the write is not guaranteed.

Regardless of whether DMA transfer error occurs in the read cycle or write cycle of a DMA cycle, the source address, destination address, transfer count, and address reload count registers are updated.

7.4.2.2 Operation of a DTS When DMA Transfer Error Occurs

When DMA transfer error occurs in a DTS, the DTS error flag (DTSER1.DTSER) in the DTS error register is set, and the DTS channel number with the DMA transfer error is stored in the DTS error channel (DTSER1.DTSERCH) in the same register.

If DMA transfer error occurs in a single transfer, a TI write back is executed to finish the DMA cycle.

If DMA transfer error occurs in the middle of a block transfer and the transfer error case DMA transfer abort setting (DTTCTnnn.ESE) is set, the remaining DMA cycles in the block transfer are not executed, but a TI write back is executed to finish the DMA cycle. At the same time, the DTS transfer status (DTSSTS.DTSACT) bit in the DTS status register is cleared. If DMA transfer error occurs during a block transfer and the setting to abort the DMA transfer at the time of a transfer error (DTTCTnnn.ESE) is cleared, the block transfer continues regardless of the DMA transfer error.

If DMA transfer error occurs during the read cycle of a DMA cycle, the write cycle is not executed. If DMA transfer error occurs during the write cycle of a DMA cycle, the validity of the write is not guaranteed.

Regardless of whether DMA transfer error occurs in the read cycle or write cycle of a DMA cycle, the source address, destination address, transfer count, and address reload count registers are updated, and the TI is updated by a TI write back.

If the DTS error flag in the DTS error register is set, a TI fetch is executed when the DTS accepts a DMA transfer request for the channel with the same channel number as the one stored in the DTS error channel. If, as a result of the TI fetch, the setting to abort the DMA transfer at the time of a transfer error (DTTCTnnn.ESE) is found to be set, a DMA cycle and a TI write back are not executed. If the setting to abort the DMA transfer at the time of a transfer error (DTTCTnnn.ESE) is cleared, DMA transfer is executed.

If the DTS error flag in the DTS error register is set, DMA transfer is executed when the DTS accepts a DMA transfer request for a channel with a channel number other than the one stored in the DTS error channel.

7.4.3 DTSRAM Error

There are two types of DTSRAM errors detected in the DTSRAM read access: 1-bit ECC error and 2-bit ECC error.

If a 1-bit ECC error is detected during a TI fetch, error corrected data is used, and DMA transfer continues. If a 1-bit ECC error is detected during DTS channel register access from software, error corrected data is returned as read data. In either case, the DTSRAM 1-bit error flag (DTSER2.RAMSED) in the DTS error register 2 is set, and the address of the error location in the DTSRAM is stored to the DTSRAM 1-bit error address (DTSER2.RAMSEDAD).

In addition, the error is notified to the ECM.

If a 2-bit ECC error is detected during a TI fetch, handling of the DMA transfer request is terminated without executing a DMA cycle and TI write back. If a 2-bit ECC error is detected during DTS channel register access from software, peripheral bus error is notified. In either case, the DTSRAM 2 bit error flag (DTSER2.RAMDED) in the DTS error register 2 is set, and the address of the error location in the DTSRAM is stored to the DTSRAM 2 bit error address (DTSER2.RAMDEDAD). In addition, the error is notified to the ECM.

7.5 Reliability Function

7.5.1 Overview

In this product, DMA is a resource used by multiple masters (CPU1 or PCU). In order for DMA to support multi-core configuration, the following reliability functions are offered.

- Register access protection function
- Master information inherit function

7.5.2 Register Access Protection Function

This product is designed to assign each DMA channel to CPU1 or PCU.

The register access protection function allows access to the transfer information of each DMA channel from the master (CPU1 or PCU) assigned to the channel but prohibits access from other masters.

The register access protection function enables you, for example, to prevent the settings of the channel from being read or updated by masters other than the one assigned to the channel.

7.5.2.1 Identifying the Accessing Master

DMA identifies a master based on the ID of the accessing CPU (PEID), and whether the CPU is in supervisor mode (PSW.UM = 0) or user mode (PSW.UM = 1) .

7.5.2.2 Master Access

Master access includes the following two types.

- Special master access (CPU1 supervisor mode (UM = 0))
- General master access (accesses other than special master access)

In special master access, access to all registers is allowed.

In general master access, access to the following registers is allowed.

- The following global registers

  DMACER, DTSER1, DTSER2, and DTSSTS
- Channel registers of the channels assigned by the channel assignment. (For details, see **Section 7.5.2.3, Channel Assignment**.)

In general master access, access to registers other than the above is not allowed.

7.5.2.3 Channel Assignment

To each channel, DMA can assign a master (CPU1 or PCU) so that the master is allowed to use the channel. Channel assignment is configured in the channel master setting register (DMnnCM in the case of a DMAC and DTSnnnCM in the case of a DTS) in supervisor mode (UM = 0) by CPU1.

In general master access, the master assigned to a channel by channel assignment is allowed to access the channel registers of the channel. If the channel registers of a channel is accessed by a master other than the master assigned to the channel, the access is called illegal access. For information about illegal access, see **Section 7.5.2.4, Illegal Access**.

7.5.2.4 Illegal Access

DMA handles the following access as illegal access.

(a) General master access to the global registers
Except the following registers: DMACER, DTSER1, DTSER2, and DTSSTS

(b) General master access to the channel registers of a channel by a master other than the master assigned to the channel

DMA's actions against illegal access are as follows.

For both cases (a) and (b),

- Write access is ignored.
- Read access returns 0 as read data.

Only for the case (b),

- The information about the illegal access is stored in a register access protection violation register. The DMAC0, DMAC1, and DTS have their own register access protection violation registers (DM0CMV, DM1CMV, and DTSCMV respectively).
- The ECM is notified of DMAVIOL (illegal DMA access).

Only the special master can access the register access protection violation registers. The special master can check whether illegal access has occurred by checking the register access protection violation registers periodically.

In addition, it is recommended that, when a master tries to use DMA and configures transfer information in the channel registers, the master should check whether the configuration has been successfully completed without illegal access by, for example, reading back the settings.

7.5.3 Master Information Inherit Function

In this product, DMA access inherits master information that is equivalent to the master information of the CPU1 or PCU assigned to the DMA channel.

The master information that is output from DMA is as in **Table 7.6**.

Table 7.6 Master Information That Is Output from DMA

Meaning	Value that is output from DMA
UM	Same as the UM bit value in the channel master setting register
SPID	Same as the SPID bit value in the channel master setting register
PEID	Same as the PEID bit value in the channel master setting register
DMA access	1

7.5.4 Other Reliability Functions

7.5.4.1 Restriction on the Next Channel in the Chain

The reliability function limits the channels you can select as the next channel in the chain.

When you use the chain function, the channel master settings of a channel and its next channel in the chain must be the same.

The chain function is designed so that a channel and its next channel in the chain are managed by the same master.

When DMA detects that different masters are assigned to a channel and its next channel in the chain, it is deemed illegal and the chain function is suppressed. More specifically, when DMA tries to execute the chain function, DMA compares the chain master settings of the channel and its next channel in the chain, and if the settings are the same for PEID and UM, the chain function is allowed and a chain request is sent to the next channel. If the settings are not the same for PEID and UM, a chain request is not sent.

7.6 Setting Up DMA Transfer

7.6.1 Overview of Setting Up DMA

Table 7.7 Channel Assignment (1/2)

No.	Master that configures the setting	Description	Register		Necessity of the setting
1	Special master (supervisor mode (UM = 0) of CPU1)	Overall DMA operation setting	DTSPR0 to DTSPR7	DTS channel priority setting register	Mandatory (if a DTS is used)
2			DM00CM to DM17CM	DMAC channel master setting register	Mandatory (if a DMAC is used)
3			DTS0CM to DTS127CM	DTS channel master setting register	Mandatory (if a DTS is used)
4		Status clear	DTSERC	DTS error clear register	Recommended
5			CMVC	Channel protection violation clear register	Recommended
6	Master assigned to the DMAC channel	Channel setting	DSAn	DMAC source address register	Mandatory
7			DDAn	DMAC destination address register	Mandatory
8			DTCn	DMAC transfer count register	Mandatory
9			DTCTn	DMAC transfer control register	Mandatory
10			DRSAn	DMAC reload source address register	Mandatory if the reload function is used
11			DRDAn	DMAC reload destination address register	Mandatory if the reload function is used
12			DRTCn	DMAC reload transfer count register	Mandatory if the reload function is used
13			DTCCn	DMAC transfer count compare register	Mandatory if the transfer count match interrupt is used
14			DTFRn	DTFR setting register	Mandatory
15		Status clear	DCSTCn	DMAC transfer status clear register	Mandatory
16			DTFRRQCn	DTFR transfer request clear register	Recommended
17		Channel operation enable	DCENn	DMAC channel operation enable setting register	Mandatory

Table 7.7 Channel Assignment (2/2)

No.	Master that configures the setting	Description	Register		Necessity of the setting
18	Master assigned to the DTS channel	Channel setting	DTSAnnn	DTS source address register	Mandatory
19			DTDAnnn	DTS destination address register	Mandatory
20			DTTCnnn	DTS transfer count register	Mandatory
21			DTTCTnnn	DTS transfer control register	Mandatory
22			DTRSAnnn	DTS reload source address register	Mandatory if the reload function is used
23			DTRDAnnn	DTS reload destination address register	Mandatory if the reload function is used
24			DTRTCnnn	DTS reload transfer count register	Mandatory if the reload function is used
25			DTTCCnnn	DTS transfer count compare register	Mandatory if the transfer count match interrupt is used
26		Status clear	DTFSCnnn	DTSFSL transfer request clear register	Recommended
27		Transfer request enable	DTFSLnnn	DTSFSL operation setting register	Mandatory

7.6.2 Setting Up the Overall DMA Operation

You need to set up the overall DMA operation before you start using DMA.

To configure the overall DMA operation, the special master (supervisor mode (UM = 0) of CPU1) needs to set up global registers. Global registers can be set up only by special master access. For details, see **Section 7.5, Reliability Function**.

The following registers must be set up to configure the overall DMA operation.

- DTS channel priority setting registers (DTSPRn, n = 0 to 7)
  Those registers configure the priority level of each DTS channel used for DTS channel arbitration.
- DMAC channel master setting registers (DMnnCM)
- DTS channel master setting registers (DTSnnnCM)
  Those registers configure channel assignment. (For details, see **Section 7.5, Reliability Function**.)
  If the DMAC channel master setting registers and the DTS channel master setting registers are not properly set, DMA channel setting and DMA transfer cannot be executed properly.

Also, if errors are detected in the following registers while the overall DMA operation is set up, clearing the errors is recommended.

- DTS error register 1 (DTSER1)
- DTS error register 2 (DTSER2)
- DMAC0 register access protection violation register (DM0CMV)
- DMAC1 register access protection violation register (DM1CMV)
- DTS register access protection violation register (DTSCMV)

7.6.3 Setting Up the DMA Channel Setting

The DMA channel setting defines the transfer information and transfer source for each DMAC and DTS channel.

To configure the DMA channel setting, the master assigned to each channel by the channel assignment needs to set up channel registers.

7.6.3.1 Setting Up the DMAC Channel Setting

Follow the procedure below to set up the DMAC channel setting and use the DMAC.

(1) Disabling the DMAC Channel Operation

If the channel operation enable (DTE) in the DMAC channel operation enable setting register (DCENn) is set, clear the DTE bit to disable the channel operation.

(2) Setting Up the Transfer Information

When you set up the transfer information of the DMAC, the following registers need to be set up.

- DMAC source address register (DSAn)
- DMAC destination address register (DDAn)
- DMAC transfer count register (DTCn)
- DMAC transfer control register (DTCTn)
- DMAC reload source address register (DRSAn)
- DMAC reload destination address register (DRDAn)
- DMAC reload transfer count register (DRTCn)
- DMAC transfer count compare register (DTCCn)

(3) Setting Up the DMA Transfer Request

While setting the transfer information, you need to set up the DMA transfer request selection assignment (DTCTn.DRS) bit in the DMAC transfer control register (DTCTn) to define whether the hardware or software DMA transfer request is used.

You cannot use both the hardware and software DMA transfer requests for the same channel at the same time.

If you use the hardware DMA transfer request, you need to select one source used as the hardware DMA transfer request out of 128 hardware DMA transfer sources using the hardware DMA transfer source selection (DTFRn.REQSEL) in the DTFR setting register. Also, you need to enable the hardware DMA transfer source selection (DTFRn.REQEN) in the same register.

The DTFR may retain a hardware DMA transfer request that came before the hardware DMA transfer source is selected. Clear the hardware DMA transfer request (DTFRRQn.DRQ) retained in the DTFR using the DTFR transfer request clear register (DTFRRQCn) if necessary.

If you use the software DMA transfer request, disable the hardware DMA transfer source selection (DTFRn.REQEN) in the DTFR setting register.

(4) Clearing the Transfer Status

The DMAC transfer status register (DCSTn) may retain the result of the previous DMA transfer. You need to clear the flags in the DMAC transfer status register using the DMAC transfer status clear register (DCSTCn).

(5) Enabling the DMAC Channel Operation

Set the channel operation enable (DCENn.DTE) bit in the DMAC channel operation enable setting register to enable the channel operation.

After the channel operation enable bit is set, the DMAC can accept a DMA transfer request and start DMA transfer.

7.6.3.2 Setting Up the DTS Channel Setting

Follow the procedure below to set up the DTS channel setting and use the DTS.

(1) Disabling the Transfer Request by the DTSFSL

Clear the transfer request enable (DTFSLnnn.REQEN) bit in the DTSFSL operation setting register of the DTS channel you want to set up the channel setting for. This procedure is not mandatory but recommended in order to prevent a DMA transfer request from being sent mistakenly to the DTS channel currently being configured.

It is also recommended to check the DTS status register (DTSSTS) and confirm that DMA transfer is not ongoing for the DTS channel currently being configured.

(2) Setting Up the Transfer Information

When you set up the transfer information of the DTS, the following registers need to be set up to configure the transfer information.

- DTS source address register (DTSAnnn)
- DTS destination address register (DTDAnnn)
- DTS transfer count register (DTTCnnn)
- DTS transfer control register (DTTCTnnn)
- DTS reload source address register (DTRSAnnn)
- DTS reload destination address register (DTRDAnnn)
- DTS reload transfer count register (DTRTCnnn)
- DTS transfer count compare register (DTTCCnnn)

(3) Setting Up the DMA Transfer Request

Unlike a DMAC, a DTS does not care whether a DMA transfer request is a hardware DMA transfer request or software DMA transfer request. A DTS has a transfer request pending bit for each channel in the DTSFSL, and both a hardware and software DMA transfer requests are retained in the same transfer request pending bit (DTFSTnnn.DRQ). Therefore, a DTS has no setting for selecting whether the hardware or software transfer request is used.

The DTSFSL may retain a DMA transfer request that came before the transfer information is set up. Clear the DMA transfer request (DTFSTnnn.DRQ) retained in the DTSFSL if necessary, using the DTSFSL transfer request clear register (DTFSCnnn).

(4) Enabling the Transfer Request by the DTSFSL

Set the transfer request enable (DTFSLnnn.REQEN) bit in the DTSFSL operation setting register to enable the DMA transfer request for the DTS channel.

After the transfer request enable bit for the DTSFSL is set, the DTS can accept a DMA transfer request and start DMA transfer.

7.7 DMA Trigger Source

7.7.1 List of DMA Trigger Sources

The DMA trigger source assignment for DMA channel n is set in the DTFR setting register (DTFRn).

Table 7.8 List of DMA Trigger Sources (1/4)

Note 1. The name of DMA trigger source may be different from that of output signal in each module.

Note 2. When the IRQ interrupt is used as the DMA source, set the external interrupt detection method select bit in the external interrupt control register (EXINTCTL) to high level (01_H).

Note 3. See ***RH850/E1x Flash Memory User's Manual Hardware Interface***.

7.8 DTS Trigger Source

7.8.1 List of DTS Trigger Sources

Table 7.9 shows the DTS trigger source assignment for DTS channel n.

Table 7.9 List of DTS Trigger Sources (1/4)

	Shared with DMACTRG	Function/Module	DMA Trigger Source
DTSTRG[0]	—	OSTM	OSTM0 interrupt (OSTM0TINT)
DTSTRG[1]	—		OSTM1 interrupt (OSTM1TINT)
DTSTRG[2]	—		OSTM2 interrupt (OSTM2TINT)
DTSTRG[3]	—	Reserved	—
DTSTRG[4]	—	ADC	ADI00 ADC0 scan group 0 completion interrupt
DTSTRG[5]	—		ADI01 ADC0 scan group 1 completion interrupt
DTSTRG[6]	—		ADI02 ADC0 scan group 2 completion interrupt
DTSTRG[7]	—		ADI03 ADC0 scan group 3 completion interrupt
DTSTRG[8]	—		ADI04 ADC0 scan group 4 completion interrupt
DTSTRG[9]	—		ADI10 ADC1 scan group 0 completion interrupt
DTSTRG[10]	—		ADI11 ADC1 scan group 1 completion interrupt
DTSTRG[11]	—		ADI12 ADC1 scan group 2 completion interrupt
DTSTRG[12]	—		ADI13 ADC1 scan group 3 completion interrupt
DTSTRG[13]	—		ADI14 ADC1 scan group 4 completion interrupt
DTSTRG[14]	—		ADC0 MPX interrupt (ADMPXI0)
DTSTRG[15]	—		ADC1 MPX interrupt (ADMPXI1)
DTSTRG[16]	—	ASF (AD addition function)	ASI0 ch0 integration completion interrupt
DTSTRG[17]	—		ASI1 ch1 integration completion interrupt
DTSTRG[18]	—		ASI2 ch2 integration completion interrupt
DTSTRG[19]	—		ASI3 ch3 integration completion interrupt

Table 7.10 List of Global Register Addresses (2/2)

Offset Address	Register Symbol	Meaning	Accessed Permission	
			Special Master	General Master
0134_H	DM15CM	DMAC1 channel 5 channel master setting register	√	×
0138_H	DM16CM	DMAC1 channel 6 channel master setting register	√	×
$013C_H$	DM17CM	DMAC1 channel 7 channel master setting register	√	×
0200_H + 4 × [DTS channel number] *1 (0200_H - $03FC_H$)	DTSnnnCM *1	DTS channel nnn channel master setting register *1	√	×

Note 1. [DTS channel number] and “nnn” in the register symbols and meanings are numbers in the range from 000 to 127.

7.9.2 Details of Global Registers

7.9.2.1 DMACTL — DMA Control Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8000$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMA SPD
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.11 DMACTL Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DMASPD	DMA suspension This bit shows whether DMA transfer for all channels is suspended. If a user writes 1 to this bit, DMA transfer for all channels can be suspended. If a user writes 0 to this bit, suspension of DMA transfer for all channels can be cleared. The suspension controlled by this bit is independent from the suspension controlled by the transfer enable bit (DTE) of each DMAC channel and the suspension setting bit (DTSUST) for a DTS. That means, if this bit is 1, all DMA transfers are suspended regardless of the values of the DTE bit of each channel and the DTSUST bit of the DTS. Writing to this bit does not affect the DTE bit of each channel and the DTSUST bit of the DTS. 0: DMA suspension cleared 1: DMA suspension request/DMA suspension ongoing

CAUTION

To suspend or resume currently ongoing DMA transfer by the DTS, the DMA transfer request enable bit (DTFSLnnn.REQEN) must be switched to disable and enable arbitration for the given channel. For details, refer to the notes in **Section 7.3.3, Suspending, Resuming, and Aborting Transfer by the DTS**.

7.9.2.2 DTSCTL1 — DTS Control Register 1

Access: This register can be read/written in 32-bit units.

Address: FFFF 8010_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DTSUST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.12 DTSCTL1 Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DTSUST	DTS suspension This bit shows whether DMA transfer by the DTS is suspended. If a user writes 1 to this bit, DMA transfer by the DTS can be suspended. 0: DTS suspension cleared 1: DTS suspension request/DTS suspension ongoing

CAUTION

To suspend or resume currently ongoing DMA transfer by the DTS, the DMA transfer request enable bit (DTFSLnnn.REQEN) must be switched to disable and enable arbitration for the given channel. For details, refer to the notes in **Section 7.3.3, Suspending, Resuming, and Aborting Transfer by the DTS**.

7.9.2.3 DTSCTL2 — DTS Control Register 2

Access: This register can be read/written in 32-bit units.

Address: FFFF 8014_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DTSTIT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.13 DTSCTL2 Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DTSTIT	DTS transfer abort request While the DTS is suspended, a user can write 1 to this bit to abort the suspended DMA transfer. When the suspended DMA transfer by the DTS is aborted, the DTSSTS.DTSACT bit is cleared to 0. This bit is always read as 0.

7.9.2.4 DTSSTS — DTS Status Register

Access: This register can be read in 32-bit units.

Address: FFFF 8018$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	DTS CYC	DTSACH[6:0]							DTS ACT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.14 DTSSTS Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved
8	DTSCYC	DMA cycle execution state This bit shows whether a DMA cycle is ongoing in the DTS. 0: DMA cycle is not ongoing. 1: DMA cycle is ongoing.
7 to 1	DTSACH[6:0]	DTS transfer channel If there is a channel in the DTS executing DMA transfer, the channel number is shown. If there is no channel in the DTS executing DMA transfer, the channel number of the last DMA transfer is shown.
0	DTSACT	DTS transfer status This bit shows whether there is a channel in the DTS executing DMA transfer. 0: There is a channel in the DTS executing DMA transfer. 1: There is no channel in the DTS executing DMA transfer. If the DTS is put into the suspended state while there is a channel executing DMA transfer, this bit remains 1. If a DTS transfer abort request is made using the DTSCTL2.DTSTIT bit, the suspended DTS transfer is aborted, and this bit is cleared to 0. When DMA transfer error occurs and the DMA transfer is aborted, this bit is cleared.

7.9.2.5 DMACER — DMAC Error Register

Access: This register can be read in 32-bit units.

Address: FFFF 8020$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DM1ER[7:0]								DM0ER[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.15 DMACER Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved
15 to 8	DM1ER[7:0]	DMAC1 DMA transfer error status These bits show the DMA transfer error status of channels 0 through 7 of the DMAC1. Each bit is mapped from the DCSTn.ER bit of each channel of the DMAC1 and is read-only. 0: DMA transfer error is not generated 1: DMA transfer error is generated
7 to 0	DM0ER[7:0]	DMAC0 DMA transfer error status These bits show the DMA transfer error status of channels 0 through 7 of the DMAC0. Each bit is mapped from the DCSTn.ER bit of each channel of the DMAC0 and is read-only. 0: DMA transfer error is not generated 1: DMA transfer error is generated

7.9.2.6 DTSER1 — DTS Error Register 1

Access: This register can be read in 32-bit units.

Address: FFFF 8024$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	DTSERCH[6:0]							—	—	—	—	—	—	DTSERWR	DTSER
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.16 DTSER1 Register Contents

Bit Position	Bit Name	Function
31 to 15	—	Reserved
14 to 8	DTSERCH[6:0]	DTS error channel These bits show the DTS channel number of the first DMA transfer error after the DTSER bit is cleared to 0. These bits are read-only and cannot be cleared.
7 to 2	—	Reserved
1	DTSERWR	DTS DMA transfer error occurring cycle This bit is updated at the same time as setting of the DTS DMA transfer error flag (DTSER), indicating which cycle of read or write the DMA transfer error occurs in. This bit is not updated when a new DMA transfer error occurs after the DTSER bit has been set. If the DTSER bit is cleared, this bit is also cleared. 0: DMA transfer error occurs in read cycle. 1: DMA transfer error occurs in write cycle.
0	DTSER	DTS DMA transfer error flag This bit shows whether DMA transfer error is generated in the DTS. 0: DMA transfer error is not generated 1: DMA transfer error is generated If DMA transfer error is generated in the DTS while this bit is 0, this bit is set, and DTSERCH6-0 retains the DTS channel number of the DMA transfer error. If DMA transfer error is generated in the DTS while this bit is 1, this bit remains 1, and DTSERCH6 to 0 does not change. This bit can be cleared by using the DTSERC register.

7.9.2.7 DTSER2 — DTS Error Register 2

Access: This register can be read in 32-bit units.

Address: FFFF 8028$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 7.17 DTSER2 Register Contents (1/2)

Bit Position	Bit Name	Function
31	RAMDED	DTSRAM 2-bit error flag This bit shows whether the 2-bit error is generated in the read access to the DTSRAM. 0: 2-bit error is not generated in the DTSRAM 1: 2-bit error is generated in the DTSRAM If 2-bit error is generated in the DTSRAM with the read access while this bit is 0, this bit is set, and RAMDEDAD11-0 retains the DTSRAM address of the error. If 2-bit error is generated in the DTSRAM with the read access while this bit is 1, this bit remains 1, and RAMDEDAD11-0 do not change. This bit can be cleared by using the DTSERC register.
30	RAMDEDOV	DTSRAM 2-bit error overflow flag This bit is set when the RAMDED bit is 1 and the 2-bit error occurs in DTSRAM read access whose address is different from that specified by the RAMDEDAD11 to 0 bits. This bit can be cleared by operation of the DTSERC register.
29, 28	—	Reserved
27 to 16	RAMDEDAD [11:0]	DTSRAM 2-bit error address These bits show the DTSRAM address of the first DTSRAM 2-bit error with the read access after the RAMDED bit is cleared to 0. These bits are read-only and cannot be cleared.
15	RAMSED	DTSRAM 1-bit error flag This bit shows whether the 1-bit error is generated in the read access to the DTSRAM. 0: 1-bit error is not generated in the DTSRAM 1: 1-bit error is generated in the DTSRAM If 1-bit error is generated in the DTSRAM with the read access while this bit is 0, this bit is set, and RAMSEDAD11 to 0 retains the DTSRAM address of the error. If 1-bit error is generated in the DTSRAM with the read access while this bit is 1, this bit remains 1, and RAMSEDAD11-0 do not change. This bit can be cleared by using the DTSERC register.
14	RAMSEDOV	DTSRAM 1-bit error overflow flag This bit is set when the RAMSED bit is 1 and the 1-bit error occurs in DTSRAM read access whose address is different from that specified by the RAMSEDAD11 to 0 bits. This bit can be cleared by operation of the DTSERC register.
13, 12	—	Reserved

Table 7.17 DTSER2 Register Contents (2/2)

Bit Position	Bit Name	Function
11 to 0	RAMSEDAD [11:0]	DTSRAM 1-bit error address These bits show the DTSRAM address of the first DTSRAM 1-bit error with the read access after the RAMSED bit is cleared to 0. These bits are read-only and cannot be cleared.

7.9.2.8 DTSERC — DTS Error Clear Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 802C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RAMDEDC	RAMDEDOVC	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 7.18 DTSERC Register Contents

Bit Position	Bit Name	Function
31	RAMDEDC	DTSRAM 2-bit error flag clear If a user writes 1 to this bit, the DTSRAM 2-bit error flag (DTSER2.RAMDED) is cleared. 0 is always read from this bit.
30	RAMDEDOVC	DTSRAM 2-bit error overflow flag clear When the user writes 1 to this bit, the DTSRAM 2-bit error overflow flag (DTSER2.RAMDEDOV) is cleared. The read value of this bit is always 0.
29 to 16	—	Reserved These bits are always read as 0. The write value should be 0.
15	RAMSEDC	DTSRAM 1-bit error flag clear If a user writes 1 to this bit, the DTSRAM 1-bit error flag (DTSER2.RAMSED) is cleared. 0 is always read from this bit.
14	RAMSEDOVC	DTSRAM 1-bit error overflow flag clear When the user writes 1 to this bit, the DTSRAM 1-bit error overflow flag (DTSER2.RAMSEDOV) is cleared. The read value of this bit is always 0.
13 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DTSERC	DTS error flag clear If a user writes 1 to this bit, the DTS DMA error flag (DTSER1.DTSER) is cleared. 0 is always read from this bit.

7.9.2.9 DM0CMV — DMAC0 Register Access Protection Violation Register

Access: This register can be read in 32-bit units.

Address: FFFF 8030_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	MINF[6:1]						—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.19 DM0CMV Register Contents

Bit Position	Bit Name	Function
31 to 23	—	Reserved
22 to 17	MINF[6:1]	Illegal access master information These bits show the accessing master information of the first illegal access after the VF bit is cleared to 0. If illegal access occurs while the VF bit is 1, these bits do not change. These bits are read-only and cannot be cleared. The following master information of the originator of the access is retained in MINF6 to MINF1. MINF6 to 4: The PEID of the originator of the access MINF3, 2: The SPID of the originator of the access MINF1: The UM of the originator of the access
16 to 7	—	Reserved
6 to 4	VCH[2:0]	Illegal access channel These bits show the channel number (0 to 7) of the first illegal access after the VF bit is cleared to 0. If illegal access occurs while the VF bit is 1, these bits do not change. These bits are read-only and cannot be cleared.
3 to 1	—	Reserved
0	VF	Illegal access flag This bit shows whether illegal access occurs in the DMAC0. 0: No illegal access has occurred in the DMAC0 1: Illegal access has occurred in the DMAC0 If illegal access occurs in the DMAC0 while this bit is 0, this bit is set, and MINF6 to 1 and VCH2 to 0 store their respective information. If illegal access occurs in the DMAC0 while this bit is 1, this bit remains 1, and MINF6 to 1 and VCH2 to 0 do not change. This bit can be cleared by using the CMVC register.

7.9.2.10 DM1CMV — DMAC1 Register Access Protection Violation Register

Access: This register can be read in 32-bit units.

Address: FFFF 8034_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7.9.2.14 DTRECCTL — DTSRAM ECC Control Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8080$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEC DIS	ECC DIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 7.31 DTRECCTL Register Contents

Bit Position	Bit Name	Function
31, 30	PROT[1:0]	These bits enable or disable writing to the ECCDIS and SECDIS bits. The written data is not retained. The read value is always 0. These bits should be written when (PROT1, PROT0) = (0, 1)
29 to 2	—	Reserved These bits are always read as 0. The write value should be 0.
1	SECDIS	DTSRAM SEC error correction disable This bit enables or disables SEC error correction when the ECCDIS bit is 0. 1-bit ECC error detection operation is always executed when ECCDIS bit is 0 regardless of the state of this bit. Set (PROT1, PROT0) = (0, 1) at the same time as writing to this bit. 0: Error correction is enabled when the SEC error is detected. 1: Error correction is disabled when the SEC error is detected.
0	ECCDIS	DTSRAM ECC disable This bit enables or disables DTSRAM ECC error detection and correction. Set (PROT1, PROT0) = (0, 1) at the same time as writing to this bit. 0: Error detection and correction are enabled. 1: Error detection and correction are disabled. The encoding function is effective when error detection and correction are disabled

7.9.2.15 DTRERINT — DTSRAM Error Notification Control Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8084_H

Value after reset: 0000 0002_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 7.32 DTRERINT Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should be 0.
1	DEDIE	DTSRAM 2-bit error notification enable This bit enables or disables notification of 2-bit error detection to the ECM when the ECCDIS bit in DTRECCTL is 0. 0: Notification of 2-bit error to ECM is disabled. 1: Notification of 2-bit error to ECM is enabled.
0	SEDIE	DTSRAM 1-bit error notification enable This bit enables or disables notification of 1-bit error detection to the ECM when the ECCDIS bit in DTRECCTL is 0. 0: Notification of 1-bit error to ECM is disabled. 1: Notification of 1-bit error to ECM is enabled.

7.9.2.16 DTRTSCTL — DTSRAM Test Control Register

This register is used for ECC test (self-diagnosis). It enables setting of ECC test mode and selection of ECC data to be written to the DTSRAM.

Access: This register can be read/written in 32-bit units.

Address: FFFF 8094$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECC TST	DAT SEL
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 7.33 DTRTSCTL Register Contents

Bit Position	Bit Name	Function
31, 30	PROT[1:0]	These bits enable or disable writing to the ECCTST and DATSEL bits. The written data is not retained. The read value is always 0. These bits should be written when (PROT1, PROT0) = (0, 1)
29 to 2	—	Reserved These bits are always read as 0. The write value should be 0.
1	ECCTST	DTSRAM ECC Test Mode This bit enables or disables DTSRAM ECC test mode. Set (PROT1, PROT0) = (0, 1) at the same time as writing to this bit. 0: ECC test mode is enabled. 1: ECC test mode is disabled.
0	DATSEL	ECC Test Data Selection This bit is valid when ECCTST is 1 and selects ECC data to be written to the DTSRAM. Set (PROT1, PROT0) = (0, 1) at the same time as writing to this bit. 0: ECC encoded from the written data is used. 1: The value specified by the DTSRAM test write data register (DTRTWDAT) is used.

7.9.2.17 DTRTWDAT — DTSRAM Test Write Data Register

This register is used for ECC test (self-diagnosis). It specifies ECC data to be written to the DTSRAM after ECC test mode is enabled (ECCTST = 1).

Access: This register can be read/written in 32-bit units.

Address: FFFF 8098$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	TWDAT[6:0]

R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.34 DTRTWDAT Register Contents

Bit Position	Bit Name	Function
31 to 7	—	Reserved These bits are always read as 0. The write value should be 0.
6 to 0	TWDAT[6:0]	ECC Test Write Data These bits specify ECC data to be written to the DTSRAM when DTRTSCTL.ECCTST = 1 and DTRTSCTL.DATSEL = 1. Writing to these bits is enabled when DTRTSCTL.ECCTST = 1 When DTRTSCTL.ECCTST = 0, these bits cannot be written and its read value is 0.

7.9.2.18 DTRTRDAT — DTSRAM Test Read Data Register

This register is used for ECC test (self-diagnosis). It reads out ECC data of the DTSRAM after ECC test mode is enabled (ECCTST = 1).

Access: This register can be read in 32-bit units.

Address: FFFF 809C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	TRDAT[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.35 DTRTRDAT Register Contents

Bit Position	Bit Name	Function
31 to 7	—	Reserved
6 to 0	TRDAT[6:0]	ECC Test Read Data These bits retain the last ECC data read out from the DTSRAM when DTRTSCTL.ECCTST = 1. When DTRTSCTL.ECCTST = 0, the read value of these bits is 0.

7.9.2.19 DMnnCM — DMAC Channel Master Setting Register (nn = 00 to 07 and 10 to 17)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8100_H + 4_H × Ch. No. n (n = 0 to 7)
FFFF 8120_H + 4_H × Ch. No. n - 10 (n = 10 to 17)

Value after reset: 0000 0010_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	PEID[2:0]			SPID[1:0]		UM	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 7.36 DMnnCM Register Contents

Bit Position	Bit Name	Function ion
31 to 7	—	Reserved These bits are always read as 0. The write value should be 0.
6 to 4	PEID[2:0]	Channel master PEID setting Specify the PEID information of the master assigned to the channel.
3, 2	SPID[1:0]	Channel master SPID setting Specify the SPID information used by the master assigned to the channel.
1	UM	Channel master UM setting Specifies the UM information of the master assigned to the channel.
0	—	Reserved This bit is always read as 0. The write value should be 0.

CAUTION

DM00CM to DM07CM configure the channel master information of the DMAC0 channel 0 to 7 respectively.

DM10CM to DM17CM configure the channel master information of the DMAC1 channel 0 to 7 respectively.

For information about the functions this register offers, see **Section 7.5, Reliability Function**.

7.9.2.20 DTSnnnCM — DTS Channel Master Setting Register (nnn = 000 to 127)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8200_H + 4_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	PEID[2:0]			SPID[1:0]		UM	—
Value after reset	Undefined															
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMC[15:0]															
Value after reset	Undefined															
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.37 DTS Channel Master Setting Register Contents

Bit Position	Bit Name	Function
31 to 23	—	Reserved When read, the value returned is undefined. The write value should be 0.
22 to 20	PEID[2:0]	Channel master PEID setting Specify the PEID information of the master assigned to the channel.
19, 18	SPID[1:0]	Channel master SPID setting Specify the SPID information used by the master assigned to the channel.
17	UM	Channel master UM setting Specifies the UM information of the master assigned to the channel.
16	—	Reserved When read, the value returned is undefined. The write value should be 0.
15 to 0	CMC[15:0]	Transfer count compare In terms of contents, this field is the same as bits [15:0] of **Section 7.11.3.8, DTTCCnnn — DTS Transfer Count Compare Register**.

CAUTION

DTS000CM to DTS127CM configure the channel master information of the DTS channel 0 to 127 respectively.

For information about the functions this register offers, see **Section 7.5, Reliability Function**.

CAUTION

The 16 low-order bits of this register are shared with the DTS transfer count compare register, one of the DTS channel registers.

If you write to this register, the DTS transfer count compare register is updated as well.

Recommended setup procedure of the DTS channel master setting register

When the special master configures the overall DMA operation, the channel master setting must be configured in bits 22 to 17 in this register, and bits 15 to 0 and the reserved bits (bits 31 to 23 and 16) must be initialized with 0.

When the master assigned to the channel updates the value of the transfer count compare, use the DTS transfer count compare register instead.

Bits 31 to 23 of this register are reserved, but you can read and write those bits. Our recommendation is as follows. When you write to those bits, write 0. When you read from those bits, discard the read value by software.

7.10 DMAC Channel Register

7.10.1 DMAC Channel Register Address

Address = Base address "FFFF 8000_H" + Offset address

Table 7.38 DMAC Channel Register Address

Offset Address	Register Symbol	Meaning	Accessed Permission	
			Special Master	General Master
$0400_H + 40_H \times$ [channel number]	DSAn	DMAC source address	√	√
$0404_H + 40_H \times$ [channel number]	DDAn	DMAC destination address	√	√
$0408_H + 40_H \times$ [channel number]	DTCn	DMAC transfer count	√	√
$040C_H + 40_H \times$ [channel number]	DTCTn	DMAC transfer control	√	√
$0410_H + 40_H \times$ [channel number]	DRSAn	DMAC reload source address	√	√
$0414_H + 40_H \times$ [channel number]	DRDAn	DMAC reload destination address	√	√
$0418_H + 40_H \times$ [channel number]	DRTCn	DMAC reload transfer count	√	√
$041C_H + 40_H \times$ [channel number]	DTCCn	DMAC transfer count compare	√	√
$0420_H + 40_H \times$ [channel number]	DCENn	DMAC channel operation enable setting	√	√
$0424_H + 40_H \times$ [channel number]	DCSTn	DMAC transfer status	√	√
$0428_H + 40_H \times$ [channel number]	DCSTSn	DMAC transfer status set	√	√
$042C_H + 40_H \times$ [channel number]	DCSTCn	DMAC transfer status clear	√	√
$0430_H + 40_H \times$ [channel number]	DTFRn	DTFR setting	√	√
$0434_H + 40_H \times$ [channel number]	DTFRRQn	DTFR transfer request status	√	√
$0438_H + 40_H \times$ [channel number]	DTFRRQCn	DTFR transfer request clear	√	√

Note 1. The [channel number] in the offset addresses and "n" in the register symbols are numbers in the range from 0 to 15, and the correspondence between the channel number n and the channel is as follows.

Channel number n	Channel
0	DMAC0 channel 0
1	DMAC0 channel 1
2	DMAC0 channel 2
3	DMAC0 channel 3
4	DMAC0 channel 4
5	DMAC0 channel 5
6	DMAC0 channel 6
7	DMAC0 channel 7
8	DMAC1 channel 0
9	DMAC1 channel 1
10	DMAC1 channel 2
11	DMAC1 channel 3
12	DMAC1 channel 4
13	DMAC1 channel 5
14	DMAC1 channel 6
15	DMAC1 channel 7

7.10.2 Details of DMAC Channel Registers

The “n” in the register symbols indicates the DMA channel number (n = 0 to 15).

7.10.2.1 DSAn — DMAC Source Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8400_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.39 DSAn Register Contents

Bit Position	Bit Name	Function
31 to 0	SA[31:0]	Source address Specifies the DMA transfer source address. Those bits are updated whenever a DMA cycle is executed. If you read from those bits, the transfer source address for the next DMA cycle is read.

CAUTIONS

1. **It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.**
2. **The address must be set up while the DTE bit is 0.**
3. **DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.)**
   The correct operation is not guaranteed if you select other setting.

Data Size	SA3	SA2	SA1	SA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

7.10.2.2 DDAn — DMAC Destination Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8404_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 7.40 DDAn Register Contents

Bit Position	Bit Name	Function
31 to 0	DA[31:0]	Destination address Specifies the DMA transfer destination address. Those bits are updated whenever a DMA cycle is executed. If you read from those bits, the transfer destination address for the next DMA cycle is read.

CAUTIONS

1. **It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.**
2. **The address must be set up while the DTE bit is 0.**
3. **If transfer error is generated in the read cycle of DMA transfer, the write cycle is not executed, but the destination address is updated.**
4. **DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.)**
   The correct operation is not guaranteed if you select other setting.

Data Size	DA3	DA2	DA1	DA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

7.10.2.3 DTCn — DMAC Transfer Count Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8408_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ARC[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TRC[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.41 DTCn Register Contents

Bit Position	Bit Name	Function
31 to 16	ARC[15:0]	Address reload count Specifies the number of transfers until the address reload when the reload function 2 is used, and also specifies the number of transfers when the block transfer 2 is used. If you read from those bits during DMA transfer, the address reload count for the next DMA cycle is read. When the reload function 2 or block transfer 2 is used, ARC[15:0] bits are decremented by one for every DMA cycle. When the reload function 2 or block transfer 2 is not used, ARC[15:0] bits are not updated. If the value is 0000_H, it means that the number of transfers until the address reload when the reload function 2 is used and the number of transfers when the block transfer 2 is used are 65536.
15 to 0	TRC[15:0]	Transfer count Configures the number of transfers. TRC[15:0] bits are decremented by one whenever a DMA cycle is executed. If you read from those bits, the remaining number of transfers for the next DMA cycle is read. If the reload function is not used, after the last transfer is complete, the value at the completion (0000_H) is retained.

TRC[15:0]	Operation
0000_H	The number of transfers is 65536, or the transfer is complete.
0001_H	The number of transfers or remaining transfers is 1.
:	:
$FFFF_H$	The number of transfers or remaining transfers is 65535.

CAUTIONS

1. **It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.**
2. **If transfer error is generated in the read cycle of DMA transfer, the write cycle is not executed, but the transfer count and the address reload count are updated.**

7.10.2.4 DTCTn — DMAC Transfer Control Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 840C$_H$+ 40$_H$ × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	ESE	DRS	—	—	—	—	—	CHNSEL[2:0]			CHNE[1:0]

Table 7.42 DTCTn Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 28	—	Reserved These bits are always read as 0. The write value should be 0.
27	ESE	Transfer error case DMA transfer disable setting Configures whether a DMA cycle is executed when the DCSTn.ER bit is set due to DMA transfer error. If this bit is cleared to 0, even when the DCSTn.ER bit is set due to DMA transfer error, the following DMA cycles can be executed. If this bit is set to 1, the following DMA cycles are not executed when the DCSTn.ER bit is set due to DMA transfer error. 0: DMA cycles are executed while the DCSTn.ER bit is set. 1: DMA cycles are not executed while the DCSTn.ER bit is set.
26	DRS	DMA transfer request selection assignment Selects the type of DMA transfer requests to be accepted. 0: Software DMA transfer request 1: Hardware DMA transfer request
25 to 21	—	Reserved These bits are always read as 0. The write value should be 0.
20 to 18	CHNSEL[2:0]	Next channel in the chain Specify the next channel in the chain. The next channel must be another channel in the same DMAC. You cannot specify a channel in the different DMAC or in the DTS. You cannot specify the same channel for the next channel (operation is not guaranteed if the setting is made).
17, 16	CHNE[1:0]	Chain enable Select the chain function. 00: Disabled 01: Chain at the last transfer A chain request is generated at the completion of the DMA cycle in which the remaining transfer count is one. 10: (Setting prohibited. Operation is not guaranteed if the setting is made. 11: Always chain A chain request is generated at the completion of every DMA cycle.
15	CCE	Transfer count match interrupt enable If this bit is set, a transfer count match interrupt is generated at the completion of the DMA cycle in which the transfer count compare register and the remaining transfer count have the same value.
14	TCE	Transfer completion interrupt enable If this bit is set, a transfer completion interrupt is generated at the completion of the last transfer.

Table 7.42 DTCTn Register Contents (2/3)

Bit Position	Bit Name	Function
13	MLE	Continuous transfer enable If this bit is set, the DTE bit is not cleared at the completion of DMA transfer. In addition, even if the TC bit is not cleared, DMA transfer starts when there is a DMA transfer request. 0: The DTE bit is cleared at the completion of DMA transfer. In addition, the next DMA transfer can start only after the TC bit is cleared. 1: The DTE bit is not cleared at the completion of DMA transfer. In addition, even if the TC bit is not cleared, DMA transfer starts when there is a DMA transfer request.
12, 11	RLD2M[1:0]	Reload function 2 setting Configure the reload function 2. 00: Reload function 2 is disabled. 01: Reload function 2 is enabled. The source address and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1. 10: Reload function 2 is enabled. The destination address and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1. 11: Reload function 2 is enabled. The source address, destination address, and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1.
10, 9	RLD1M[1:0]	Reload function 1 setting Configure the reload function 1. 00: Reload function 1 is disabled. 01: Reload function 1 is enabled. The source address and transfer count are reloaded at the completion of the DMA cycle in which the remaining transfer count is 1. (If the reload function 2 is enabled, the address reload count is also reloaded.) 10: Reload function 1 is enabled. The destination address and transfer count are reloaded at the completion of the DMA cycle in which the remaining transfer count is 1. (If the reload function 2 is enabled, the address reload count is also reloaded.) 11: Reload function 1 is enabled. The source address, destination address, and transfer count are reloaded at the completion of the DMA cycle in which the remaining transfer count is 1. (If the reload function 2 is enabled, the address reload count is also reloaded.)
8, 7	DACM[1:0]	Destination address count direction Specify the count direction of the destination address. **DACM1 / DACM0 / Direction of Counting** 0 / 0 / Increment 0 / 1 / Decrement 1 / 0 / Fixed 1 / 1 / Setting prohibited (operation not guaranteed)
6, 5	SACM[1:0]	Source address count direction Specify the count direction of the source address. **SACM1 / SACM0 / Direction of Counting** 0 / 0 / **Increment** 0 / 1 / Decrement 1 / 0 / Fixed 1 / 1 / Setting prohibited (operation not guaranteed)

Table 7.42 DTCTn Register Contents (3/3)

<table>
<tr><th>Bit Position</th><th>Bit Name</th><th>Function</th></tr>
<tr><td>4 to 2</td><td>DS[2:0]</td><td>Transfer data size
Specify the transfer data size.
<table>
<tr><th>DS2</th><th>DS1</th><th>DS0</th><th>Transfer Data Size</th></tr>
<tr><td>0</td><td>0</td><td>0</td><td>8 bits</td></tr>
<tr><td>0</td><td>0</td><td>1</td><td>16 bits</td></tr>
<tr><td>0</td><td>1</td><td>0</td><td>32 bits</td></tr>
<tr><td>0</td><td>1</td><td>1</td><td>64 bits</td></tr>
<tr><td>1</td><td>0</td><td>0</td><td>128 bits</td></tr>
<tr><td colspan="3">Other than the above</td><td>Setting prohibited (operation not guaranteed)</td></tr>
</table></td></tr>
<tr><td>1, 0</td><td>TRM[1:0]</td><td>Transfer mode
Specify the DMA transfer mode.
00: Single transfer
01: Block transfer 1 (The number of transfers is specified by the transfer count.)
10: Block transfer 2 (The number of transfers is specified by the address reload count.)
11: Setting prohibited (operation not guaranteed)</td></tr>
</table>

CAUTIONS

1. **While channel operation is enabled (DTE bit = 1), changing the value of the MLE bit from “1” to “0” is only possible (correct operation is not guaranteed when the value of any bit other than the MLE bit is changed).**
2. **Correction operation is not guaranteed when the prohibited setting has been set to a given bit.**

7.10.2.5 DRSAn — DMAC Reload Source Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8410_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 7.45 DRTCn Register Contents

Bit Position	Bit Name	Function
31 to 16	RARC[15:0]	Reload address reload count Specifies the value to be loaded to the address reload count in the transfer count register at the timing of reload when the reload function 2 is used.
15 to 0	RTRC[15:0]	Reload transfer count Specifies the value to be loaded to the transfer count in the transfer count register at the timing of reload when the reload function 1 is used.

7.10.2.8 DTCCn — DMAC Transfer Count Compare Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 841C$_H$ + 40$_H$ × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMC[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.46 DTCCn Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should be 0.
15 to 0	CMC[15:0]	Transfer count compare Configure the transfer count to be compared to the transfer count register. At the completion of the DMA cycle in which the remaining transfer count is the same as the value in this register, the transfer count match flag (DCSTn.CC) in the DMAC transfer status register is set. Furthermore, if the transfer count match interrupt enable (DTCTn.CCE) bit is 1, a transfer count match interrupt is generated. If 0000$_H$ is set, comparison with the transfer count is disabled. In this case, the transfer count match flag in the DMAC transfer status register is never set, and a transfer count match interrupt is never generated.

CAUTION

It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.

7.10.2.9 DCENn — DMAC Channel Operation Enable Setting Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8420_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DTE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.47 DCENn Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DTE	Channel operation enable Specifies whether to enable or disable the transfer operation of the channel. If the DTE bit is 1, DMA transfer starts when there is a DMA transfer request. If the MLE bit is 0, the DTE bit is cleared automatically at the completion of the DMA transfer. In addition, if 0 is written to the DTE bit during DMA transfer, the DMA transfer is suspended. If 1 is written to the DTE bit during suspension, the suspension is cleared and the DMA transfer resumes. 0: Channel operation is disabled/Channel suspended 1: Channel operation is enabled/Channel suspension cleared

7.10.2.10 DCSTn — DMAC Transfer Status Register

Access: This register can be read in 32-bit units.

Address: FFFF 8424_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	ERWR	—	—	CY	ER	—	CC	TC	—	—	DR	SR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.48 DCSTn Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 12	—	Reserved
11	ERWR	DMA Transfer Error occurring cycle This bit is updated at the same time as setting of the DMA transfer error flag (ER), indicating which cycle of read or write the DMA transfer error occurs in. This bit is not updated when a new DMA transfer error occurs after the ER bit has been set. If the ER bit is cleared, this bit is also cleared to 0. 0: DMA transfer error occurs in read cycle. 1: DMA transfer error occurs in write cycle.
10, 9	—	Reserved
8	CY	DMA cycle execution state This bit shows whether a DMA cycle is ongoing in this channel. 0: DMA cycle is not ongoing. 1: DMA cycle is ongoing.
7	ER	Transfer error flag This bit is set when DMA transfer error is generated. If this bit is 1 and the DTCTn.ESE bit is set, a DMA cycle is not executed when a DMA transfer request is generated. 0: No DMA transfer error is generated 1: DMA transfer error is generated
6	—	Reserved
5	CC	Transfer count match flag This bit is set at the completion of the DMA cycle in which the remaining transfer count is the same as the value set in the transfer compare register. 0: No compare match has occurred with the transfer count compare register. 1: Compare match has occurred with the transfer count compare register.
4	TC	Transfer completion flag This bit is set at the completion of the last transfer and shows whether the DMA transfer is complete. If the MLE bit is 0 and this bit is 1, a DMA cycle is not executed when a DMA transfer request is generated. 0: DMA transfer incomplete 1: DMA transfer complete
3, 2	—	Reserved

Table 7.48 DCSTn Register Contents (2/2)

Bit Position	Bit Name	Function
1	DR	Hardware DMA transfer request status This bit shows whether there is a hardware DMA transfer request (DMARQ) from the DTFR. This bit changes regardless of the value of the DTE bit when a hardware DMA transfer request from the DTFR is generated. If the software DMA transfer request is selected by the transfer request selection bit (DRS) in the DMAC transfer control register, this bit is not set even when a hardware DMA transfer request is input from the DTFR. 0: There is no hardware DMA transfer request 1: There is a hardware DMA transfer request
0	SR	Software DMA transfer request flag This bit shows whether there is a software DMA transfer request (DMARQ). This bit is automatically cleared at the completion of the last transfer. A user can set this bit by writing 1 to the SRS bit in the DMAC transfer status set register. In addition, a user can clear this bit by writing 1 to the SRC bit in the DMAC transfer status clear register, but if this is done, the ongoing DMA transfer is aborted and cannot be resumed. 0: There is no software DMA transfer request 1: There is a software DMA transfer request

7.10.2.11 DCSTSn — DMAC Transfer Status Set Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8428_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DRQ
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.52 DTFRRQn Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved
0	DRQ	Hardware DMA transfer request status If this bit is set, it means that a hardware DMA transfer request exists or is retained. • If the hardware DMA transfer request is an edge detection type*1 This bit shows whether a hardware DMA transfer request generated by edge detection is retained. When the DMA transfer request acceptance signal (DMAAKn) from the DMAC is asserted, this bit is automatically cleared. A user can clear this bit by writing 1 to the DTFRRQCn.DRQC bit. • If the hardware DMA transfer request is a level input type*1 This bit shows whether there is a hardware DMA transfer request input. Even when the DMA transfer request acceptance signal (DMAAKn) from the DMAC is asserted, this bit is not automatically cleared. In addition, this bit is not cleared even when a user writes to the DTFRRQCn.DRQC bit. This bit changes regardless of the value of the DTFRn.REQEN bit when a hardware DMA transfer request is generated. 0: There is no hardware DMA transfer request 1: There is a hardware DMA transfer request

Note 1. Whether the hardware DMA transfer request is an edge detection type or level input type depends on the hardware DMA transfer source selected by DTFRn.REQSEL. The hardware DMA transfer request is only an edge detection type.

7.10.2.15 DTFRRQCn — DTFR Transfer Request Clear Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8438_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DRQC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.53 DTFRRQCn Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DRQC	Hardware DMA transfer request clear If the hardware DMA transfer request is an edge detection type*1, a user can clear the DTFRRQn.DRQ bit by writing 1 to this bit. If the hardware DMA transfer request is a level input type*1, the DTFRRQn.DRQ bit cannot be cleared by writing to this bit. 0 is always read from this bit.

Note 1. Whether the hardware DMA transfer request is an edge detection type or level input type depends on the hardware DMA transfer source selected by DTFRn.REQSEL. The hardware DMA transfer request is only an edge detection type.

7.11 DTS Channel Register

7.11.1 Transfer information of the DTS (TI)

7.11.1.1 Structure of the TI

The transfer information of the DTS is called TI. One set of TI consists of 32 bits. 8 sets of TI are assigned for each channel. The 8 sets of TI is called TI-A, TI-B, TI-C, TI-D, TI- E, TI-F, TI-G, and TI-H.

Figure 7.12 shows the structure of the TI.

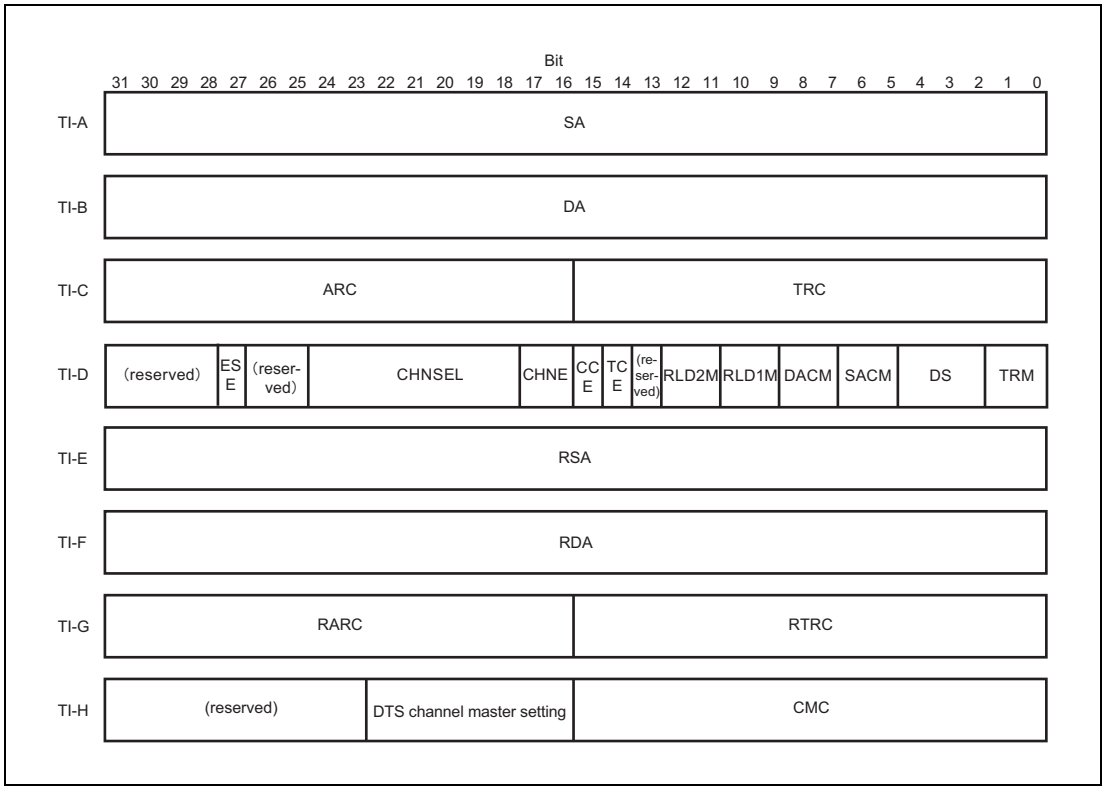

Figure 7.12 Structure of the TI

7.11.1.2 Organization of the TI in the DTSRAM

A user indirectly accesses the DTSRAM by way of the DTS channel registers for each channel and the DTS channel master setting registers.

Therefore, usually, a user does not have to think about the address organization of the TI in the DTSRAM. As an exception, when ECC error occurs while the DTSRAM is read, the address of the ECC error in the DTSRAM is stored to the DTSRAM error register 2 (DTSER2), one of the global registers. In order to know which channel and TI have generated the error, you need to understand the address organization of the TI in the DTSRAM.

Figure 7.13 shows the address organization of the TI in the DTSRAM.

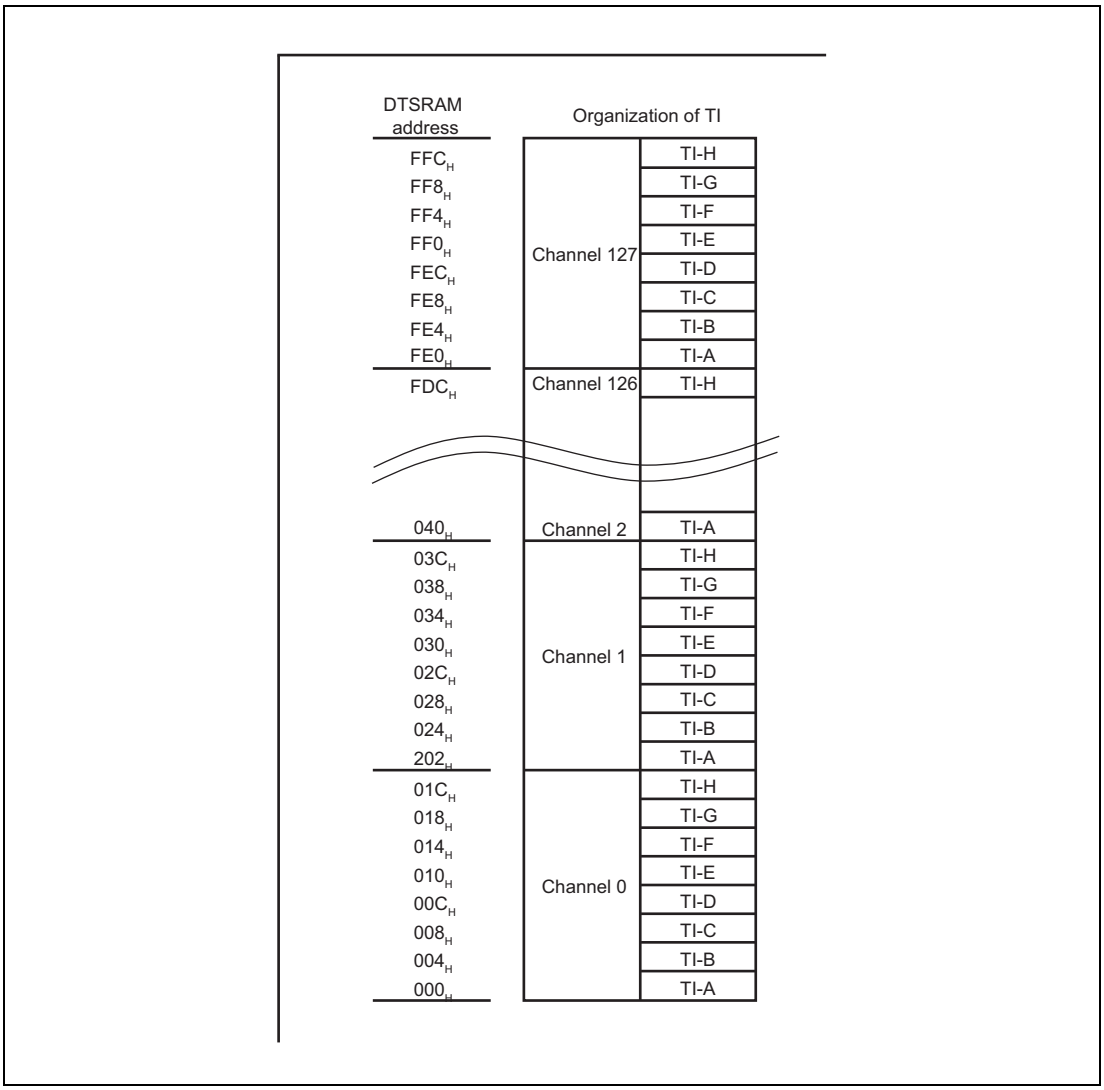

Figure 7.13 Organization of the TI in the DTSRAM

7.11.1.3 Accessing the TI

TI-A can be accessed by way of the DTS source address register (DTSAnnn) for each channel.

TI-B can be accessed by way of the DTS destination address register (DTDAnnn) for each channel.

TI-C can be accessed by way of the DTS transfer count register (DTTCnnn) for each channel.

TI-D can be accessed by way of the DTS transfer control register (DTTCTnnn) for each channel.

TI-E can be accessed by way of the DTS reload source address register (DTRSAnnn) for each channel.

TI-F can be accessed by way of the DTS reload destination address register (DTRDAnnn) for each channel.

TI-G can be accessed by way of the DTS reload transfer count register (DTRTCnnn) for each channel.

TI-H can be accessed by way of the channel master setting register (DTSnnnCM), which is a global register, and the transfer count compare register (DTTCCnnn) for each channel.

7.11.1.4 Caution about accessing the TI

The data of the DTS channel master setting register and the data of the DTS transfer count compare register are stored to the same TI-H.

Access to the DTS channel master setting register (DTSnnnCM) is actually 32-bit access to the whole TI-H. Therefore, when you write to the DTS channel master setting register, the lower 16-bit data, which is the data for the DTS transfer count compare (CMC), is updated at the same time. When you read from the DTS channel master setting register, the value of the DTS transfer count compare (CMC) is read as the lower 16-bit data.

When you read from the DTS transfer count compare register (DTTCCnnn), 32-bit data is read from the TI-H, but only the lower 16-bit data is actually seen in the result of the register read. When you write to the DTS transfer count compare register (DTTCCnnn), lower 16-bit read/modify/write access to the 32-bit TI-H is used. Data in the TI immediately after the reset is undefined. It should be noted that, if you try to write to the DTS transfer count compare register (DTTCCnnn) before setting up the DTS channel master setting register, ECC error may be detected during the read of the read/modify/write access.

Bits 31 to 23 of the TI-H are not used, but you can read and write those bits by accessing the DTS channel master setting register. Our recommendation is as follows. When you write to those bits, write 0. When you read from those bits, discard the read value by software.

After the reset, the values in the DTSRAM, which stores the TI, are undefined. After the reset, if you read TI before you write to the TI, ECC error is generated. Therefore, the first access to the following registers after the reset must be write access. The first access after the reset should never be read access.

- DTS source address register (DTSAnnn)
- DTS destination address register (DTDAnnn)
- DTS transfer count register (DTTCnnn)
- DTS transfer control register (DTTCTnnn)
- DTS reload source address register (DTRSAnnn)
- DTS reload destination address register (DTRDAnnn)
- DTS reload transfer count register (DTRTCnnn)
- Channel master setting registers (DTSnnnCM)

In addition, after the reset, the first access to the DTS transfer count compare register (DTTCCnnn) must be always after write access to the channel master setting register (DTSnnnCM).

You can access the TI from a CPU while the DTS is executing DMA transfer. But if you do so, the following should be noted.

- While a channel is executing DMA transfer, the TI of the channel should not be updated by TI access from a CPU. If this situation happens, the result of the DMA transfer and the contents of the TI may mismatch.
- If TI access is requested from a CPU while a TI fetch or TI write back is executed, the TI access is executed after the completion of the TI fetch or TI write back. If a TI fetch or TI write back is requested while a TI access request from a CPU is processed, the TI fetch or TI write back is executed after the processing of the TI access is complete.

7.11.2 DTS Channel Register Address

Address = Base address "FFFF 9000_H" + Offset address

Offset Address	Register Symbol	Meaning	Accessed Permission	
			Special Master	General Master
$0000_H + 40_H \times$ [channel number]	DTSAnnn	DTS source address	√	√
$0004_H + 40_H \times$ [channel number]	DTDAnnn	DTS destination address	√	√
$0008_H + 40_H \times$ [channel number]	DTTCnnn	DTS transfer count	√	√
$000C_H + 40_H \times$ [channel number]	DTTCTnnn	DTS transfer control	√	√
$0010_H + 40_H \times$ [channel number]	DTRSAnnn	DTS reload source address	√	√
$0014_H + 40_H \times$ [channel number]	DTRDAnnn	DTS reload destination address	√	√
$0018_H + 40_H \times$ [channel number]	DTRTCnnn	DTS reload transfer count	√	√
$001C_H + 40_H \times$ [channel number]	DTTCCnnn	DTS transfer count compare	√	√
$0020_H + 40_H \times$ [channel number]	DTFSLnnn	DTSFSL operation setting	√	√
$0024_H + 40_H \times$ [channel number]	DTFSTnnn	DTSFSL transfer request status	√	√
$0028_H + 40_H \times$ [channel number]	DTFSSnnn	DTSFSL transfer request set	√	√
$002C_H + 40_H \times$ [channel number]	DTFSCnnn	DTSFSL transfer request clear	√	√

Note: The [channel number] in the offset addresses is a number in the range from 0 to 127.
The "nnn" in the register symbols is a 3-digit number in the range from 000 to 127.

7.11.3 Details of DTS Channel Registers

The “nnn” in the register symbols indicates the DTS channel number (nnn = 000 to 127).

7.11.3.1 DTSAnnn — DTS Source Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9000_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

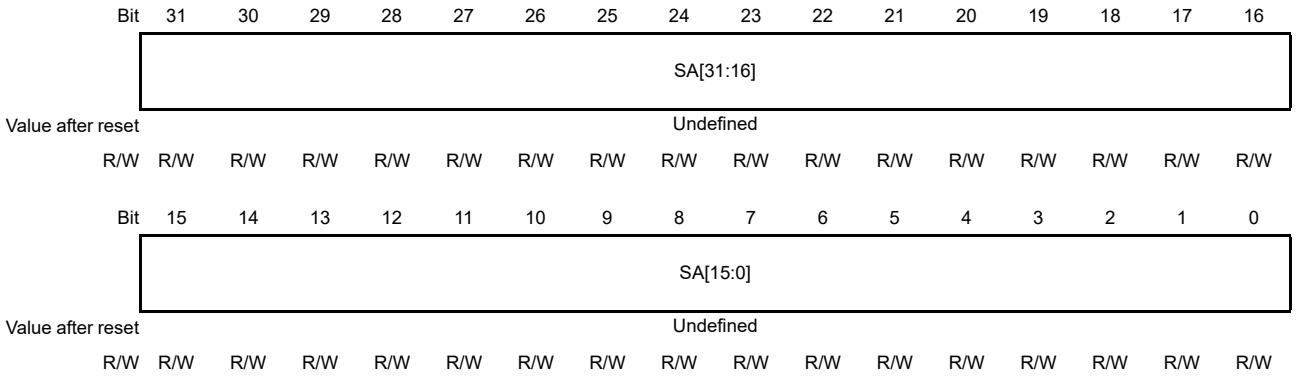

Table 7.54 DTSAnnn Register Contents

Bit Position	Bit Name	Function
31 to 0	SA[31:0]	Source address Specifies the DMA transfer source address. SA[31:0] are updated at the timing of the TI write back and retains the DMA transfer source address for the next DMA transfer.

CAUTION

DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.) The correct operation is not guaranteed if you select other setting.

Data Size	SA3	SA2	SA1	SA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

7.11.3.2 DTDAnnn — DTS Destination Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9004_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DA[31:16]															
Value after reset	Undefined															
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DA[15:0]															
Value after reset	Undefined															
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.55 DTDAnnn Register Contents

Bit Position	Bit Name	Function
31 to 0	DA[31:0]	Destination address Specify the DMA transfer destination address. DA[31:0] are updated at the timing of the TI write back and retains the DMA transfer destination address for the next DMA transfer.

CAUTIONS

1. **If DMA transfer error is generated in the read cycle of DMA transfer, the write cycle is not executed, but the destination address is updated.**
2. **DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.) The correct operation is not guaranteed if you select other setting.**

Data Size	DA3	DA2	DA1	DA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

7.11.3.3 DTTCnnn — DTS Transfer Count Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9008_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ARC[15:0]															
Value after reset	Undefined															
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TRC[15:0]															
Value after reset	Undefined															
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.56 DTTCnnn Register Contents

Bit Position	Bit Name	Function
31 to 16	ARC[15:0]	Address reload count Specify the number of transfers until the address reload when the reload function 2 is used, and also specifies the number of transfers when the block transfer 2 is used. When the reload function 2 or block transfer 2 is used, ARC[15:0] are decremented by one for every DMA cycle and updated at the timing of the TI write back. When the reload function 2 or block transfer 2 is not used, ARC[15:0] are not updated. If 0000_H is set, address reload is disabled. If the value at the start of a DMA cycle is 0000_H, subtraction from the address reload count does not proceed even after the DMA cycle.
15 to 0	TRC[15:0]	Transfer count Configure the number of transfers. TRC[15:0] are decremented by one whenever a DMA cycle is executed. It is updated at the timing of the TI write back. If the reload function is not used, after the last transfer is complete, the value at the completion (0000_H) is retained. If 0000_H is set, DMA transfer is not executed even when a DMA transfer request is accepted.

TRC[15:0]	Operation
0000_H	Transfer is disabled or complete.
0001_H	The number of transfers or remaining transfers is 1.
:	:
$FFFF_H$	The number of transfers or remaining transfers is 65535.

CAUTIONS

1. **If transfer error is generated in the read cycle of DMA transfer, the write cycle is not executed, but the transfer count and the address reload count are updated.**
2. **Unlike a DMAC, "0000_H" in the transfer count of the DTS does not mean "65536 transfers" but means that transfer is disabled or complete.**

7.11.3.4 DTTCTnnn — DTS Transfer Control Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 900C$_H$ + 40$_H$ × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	ESE	—	—	CHNSEL[6:0]							CHNE[1:0]	
Value after reset	Undefined

Value after reset	Undefined															
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.57 DTTCTnnn Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 28	—	Reserved When read, the value returned is undefined. The write value should be 0.
27	ESE	Transfer error case DMA transfer abort setting Specifies whether to abort DMA transfer when DMA transfer error is generated. If this bit is cleared to 0, DMA transfer continues when DMA transfer error is generated. If this bit is set to 1, DMA transfer is aborted when DMA transfer error is generated. 0: DMA transfer continues when DMA transfer error is generated. 1: DMA transfer is aborted when DMA transfer error is generated.
26, 25	—	Reserved When read, the value returned is undefined. The write value should be 0.
24 to 18	CHNSEL[6:0]	Next channel in the chain Specifies the next channel in the chain. The next channel must be another channel in the DTS. You cannot specify a channel in a DMAC. You cannot specify the same channel for the next channel. (If you do, the correct operation is not guaranteed.)
17, 16	CHNE[1:0]	Chain enable Selects the chain function. 00: Disabled 01: Chain at the last transfer A chain request is generated at the completion of the DMA cycle in which the remaining transfer count is one. 10: (Setting prohibited. Operation is not guaranteed if the setting is made.) 11: Always chain A chain request is generated at the completion of every DMA cycle.
15	CCE	Transfer count match interrupt enable If this bit is set, a transfer count match interrupt is generated at the completion of the DMA cycle in which the transfer count compare register and the remaining transfer count have the same value.
14	TCE	Transfer completion interrupt enable If this bit is set, a transfer completion interrupt is generated at the completion of the last transfer.
13	—	Reserved When read, the value returned is undefined. The write value should be 0.

Table 7.57 DTTCTnnn Register Contents (2/3)

Bit Position	Bit Name	Function
12, 11	RLD2M[1:0]	Reload function 2 setting Configures the reload function 2. 00: Reload function 2 is disabled. 01: Reload function 2 is enabled. The source address and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1. 10: Reload function 2 is enabled. The destination address and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1. 11: Reload function 2 is enabled. The source address, destination address, and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1.
10, 9	RLD1M[1:0]	Reload function 1 setting Configures the reload function 1. 00: Reload function 1 is disabled. 01: Reload function 1 is enabled. The source address and transfer count are reloaded at the completion of the DMA cycle in which the remaining transfer count is 1. (If the reload function 2 is enabled, the address reload count is also reloaded.) 10: Reload function 1 is enabled. The destination address and transfer count are reloaded at the completion of the DMA cycle in which the remaining transfer count is 1. (If the reload function 2 is enabled, the address reload count is also reloaded.) 11: Reload function 1 is enabled. The source address, destination address, and transfer count are reloaded at the completion of the DMA cycle in which the remaining transfer count is 1. (If the reload function 2 is enabled, the address reload count is also reloaded.)
8, 7	DACM[1:0]	Destination address count direction Specifies the count direction of the destination address.
6, 5	SACM[1:0]	Source address count direction Specifies the count direction of the source address.
4 to 2	DS[2:0]	Transfer data size Specifies the transfer data size.

DACM1	DACM0	Direction of Counting
0	0	Increment
0	1	Decrement
1	0	Fixed
1	1	Setting prohibited (operation not guaranteed)

SACM1	SACM0	Direction of Counting
0	0	**Increment**
0	1	Decrement
1	0	Fixed
1	1	Setting prohibited (operation not guaranteed)

DS2	DS1	DS0	Transfer Data Size
0	0	0	8 bits
0	0	1	16 bits
0	1	0	32 bits
0	1	1	64 bits
1	0	0	128 bits
Other than the above			Setting prohibited (operation not guaranteed)

Table 7.57 DTTCTnnn Register Contents (3/3)

Bit Position	Bit Name	Function
1, 0	TRM[1:0]	Transfer mode Specifies the DMA transfer mode. 00: Single transfer 01: Block transfer 1 (The number of transfers is specified by the transfer count.) 10: Block transfer 2 (The number of transfers is specified by the address reload count.) 11: Setting prohibited (operation not guaranteed)

CAUTIONS

1. **If forbidden settings are used for some of the bits, the correct operation is not guaranteed.**
2. **Bits 31 to 28, 26, 25, and 13 are unused, but you can read and write those bits. Our recommendation is as follows. When you write to those bits, write 0. When you read from those bits, discard the read value.**

7.11.3.5 DTRSAnnn — DTS Reload Source Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9010_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RSA[31:16]															
Value after reset	Undefined															
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 7.58 DTRSAnnn Register Contents

Bit Position	Bit Name	Function
31 to 0	RSA[31:0]	Reload source address Specify the source address to be reloaded when the reload function 1 or reload function 2 is used.

CAUTION

DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.) The correct operation is not guaranteed if you select other setting.

Data Size	RSA3	RSA2	RSA1	RSA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

7.11.3.6 DTRDAnnn — DTS Reload Destination Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9014_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RDA[31:16]

Value after reset	Undefined															
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.61 DTTCCnnn Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should be 0.
15 to 0	CMC[15:0]	Transfer count compare Configures the transfer count to be compared to the transfer count register. If the transfer count match interrupt enable (DTTCTnnn.CCE) bit in the DTS transfer control register is 1, a transfer count match interrupt is generated at the completion of the DMA cycle in which the remaining transfer count is the same as the value in this register. If 0000$_H$ is set, comparison with the transfer count is disabled. In this case, a transfer count match interrupt is not generated.

CAUTION

This register must be accessed after the DTS channel master setting register is set up.

If you access this register without setting up the DTS channel master setting register after the reset, ECC error may be generated during access to this register.

7.11.3.9 DTFSLnnn — DTSFSL Operation Setting Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9020_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	REQEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.62 DTFSLnnn Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	REQEN	DMA transfer request enable This bit selects whether a DMA transfer request from this channel retained in the DTSFSL is used as a candidate in DTS channel arbitration. 0: A DMA transfer request from this channel is not used as a candidate in DTS channel arbitration. 1: A DMA transfer request from this channel is used as a candidate in DTS channel arbitration. If this bit is 0, even if the DTSFSL retains a DMA transfer request, this channel is not a candidate in DTS channel arbitration inside the DTSFSL, and consequently a DMA transfer request from this channel is not generated.

7.11.3.10 DTFSTnnn — DTSFSL Transfer Request Status Register

Access: This register can be read in 32-bit units.

Address: FFFF 9024_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DRQ
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.63 DTFSTnnn Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved
0	DRQ	DMA transfer request pending This bit shows whether a DMA transfer request of this channel is pending. This bit is set when the hardware transfer source input is detected, or when software writes “1” to the DTFSSnnn.DRQ bit. This bit is automatically cleared when the DTS accepts the DMA transfer request while the DTSFSL is requesting DMA transfer by this channel. Alternatively, software can clear this bit by writing 1 to the DTFSCnnn.DRQC bit. 0: A DMA transfer request is not pending. 1: A DMA transfer request is pending.

7.11.3.11 DTFSSnnn — DTSFSL Transfer Request Set Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9028_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DRQS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 7.64 DTFSSnnn Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DRQS	DMA transfer request set A user can set the DTFSTnnn.DRQ bit by writing 1 to this bit. 0 is always read from this bit.

7.11.3.12 DTFSCnnn — DTSFSL Transfer Request Clear Register

Access: This register can be read/written in 32-bit units.

Address: FFFF $902C_H$ + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DRQC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.65 DTFSCnnn Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DRQC	DMA transfer request clear A user can clear the DTFSTnnn.DRQ bit by writing 1 to this bit. 0 is always read from this bit.

Section 8 Resets

8.1 Features

- The $\overline{\text{RES}}$ pin incorporates a noise canceller.
- The source of a reset can be determined by referring the reset source determination register.
- The CPU can assert reset by setting a register.

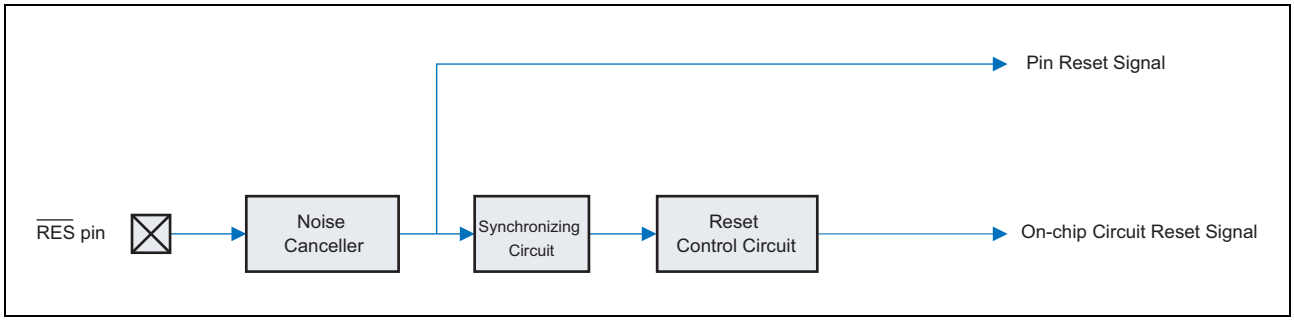

Figure 8.1 Reset Circuit

8.2 Reset State

8.2.1 External Reset State

When a low-level pulse longer than the noise cancel width (t_{RESNCW}) is input to the $\overline{RES}$ pin, external reset is received and this product transits to the external reset state. When external reset is received, individual pins transit to the external reset state. Refer to **Table 2.74, Pin State**, in **Section 2, Pins**, for the state of individual pins during external reset.

The low-level pulse width of the input signal must be longer than t_{RESW6} because the $\overline{RES}$ pin incorporates a noise cancelling circuit. This product transits to the internal reset state by driving the $\overline{RES}$ pin to the high-level after the required low-level period.

CAUTION

Refer to Section 37, Electrical Characteristics, for t_{RESNCW} and t_{RESW6}.

8.2.2 Internal Reset State

When a high-level signal longer than the noise cancel width (t_{RESNCW}) is input to the $\overline{RES}$ pin in the external reset state, this product transits to the internal reset state. Refer to **Table 2.74, Pin State**, in **Section 2, Pins**, for the state of individual pins.

The internal reset state is released in 200µs (max.) after external reset release, and the CPU starts the reset exception process.

CAUTION

Refer to Section 37, Electrical Characteristics for t_{RESNCW}.

8.3 Reset Sources

The following are the reset sources of this product.

Some registers are only initialized by the external reset state. That is, they are only initialized by input of the low level on the $\overline{\text{RES}}$ pin.

However, most registers are initialized by both external and internal reset states. This means that they are initialized by resets from any source.

Regarding sources for the initialization of registers, see the descriptions of the registers in the relevant sections. Where there is no explicit description of the sources for resetting and initializing a register, the register is initialized by both external and internal reset states. That is, such registers are initialized by resets from any source. However, the value after reset of some registers are undefined. Take care since the values of such registers following a reset are not fixed.

Source	Description
When the $\overline{\text{RES}}$ pin is driven to the low level	Transits to the external reset state.
When the reset request is asserted from ECM	Transits to the internal reset state.
When reset is asserted from the debugger (forced reset is issued)	Transits to the external reset state.
When the CPU sets the software reset request register	Transits to the internal reset state

8.4 Register Specifications

8.4.1 List of Registers

Table 8.1 List of Registers

Reset Source Determination

Address	Register Name	Description	Access Width	Value after Reset	Access Protection
FFF8 2800	RESF	Reset source determination register	32	0000 0000_H	
FFF8 2808	RESFC	Reset source clear register	32	0000 0000_H	

Power-On Detection

Address	Register Name	Description	Access Width	Value after Reset	Access Protection
FFF8 AC10	POF	Power-on clear flag register	32	0000 $000X_H$	
FFF8 AC14	POFC	Power-on clear flag clear register	32	0000 0000_H	

Software Reset Control

Address	Register Name	Description	Access Width	Value after Reset	Access Protection
FFF8 AC18	SWRESA	Software Reset Request Register	32	0000 0000_H	PROT1PHCMD

8.4.2 RESF — Reset Source Determination Register

This register determines the reset source.

The flags of this register can be cleared by the RESFC register and can be initialized by an external reset.

The register is initialized only by an external reset. It cannot be initialized by an internal reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit Position	Bit Name	Function
1	RESF1	ECM reset Indicates that a reset event occurred. 0: Event not occurred 1: Event occurred
0	RESF0	Software reset Indicates that a reset event occurred. 0: Event not occurred 1: Event occurred

8.4.3 RESFC — Reset Source Clear Register

This register clears the reset source indicated by the RESF register.

This register is always read as 00_H and can be initialized by an external reset.

The register is initialized only by an external reset. It cannot be initialized by an internal reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	RESFC0	Software reset Clears the status bit. 0: Do not clear 1: Clear

8.4.4 POF — Power-On Clear Flag Register

This register determines whether SYSVCC detects the transition of the power from off to on. The POF flag becomes 1 (cold start) when SYSVCC detects the transition of the power from off to on.

Note that this register does not change even when “0” or “1” is written.

This register becomes 0 when 0 or 1 is written to the POFC bit of the POFC register.

The POF flag does not change even when other reset sources occur while the POF flag has been set to 0 (warm start can be determined).

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 8.5 POFC Register Contents

Bit Position	Bit Name	Function
0	POFC	The POF bit in the POF register is cleared to 0 when 0 or 1 is written to the POFC bit in the POFC register.

8.4.6 SWRESA — Software Reset Request Register

This register generates an internal reset when accessed. A software reset is issued when 1 is written to SWRESA. This register can be protected by the PROT1PHCMD register. This register can be reset by either an internal or external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRESA
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 8.6 SWRESA Register Contents

Bit Position	Bit Name	Function
0	SWRESA	0: — (default) 1: Internal reset enabled (internal reset triggered)

Example) Sequence of writing to register SWRESA

Writing to register SWRESA is only possible with the protection unlock sequence described in Section 11, Clock Controller.

Procedure

1. Write the fixed value (0000 $00A5_H$) to register PROT1PHCMD.
2. Write the setting value (0000 0001_H) to register SWRESA.
3. Write the inverse (FFFF $FFFE_H$) to register SWRESA.
4. Write the new setting value (0000 0001_H) to register SWRESA.

The setting value (0000 0001_H) can only be written to register SWRESA by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting value (0000 0001_H) is not written to register SWRESA, and the PROT1PS.PROTERR bit is set to 1.

In case of failure to follow the sequence, repeat the procedure from the beginning.

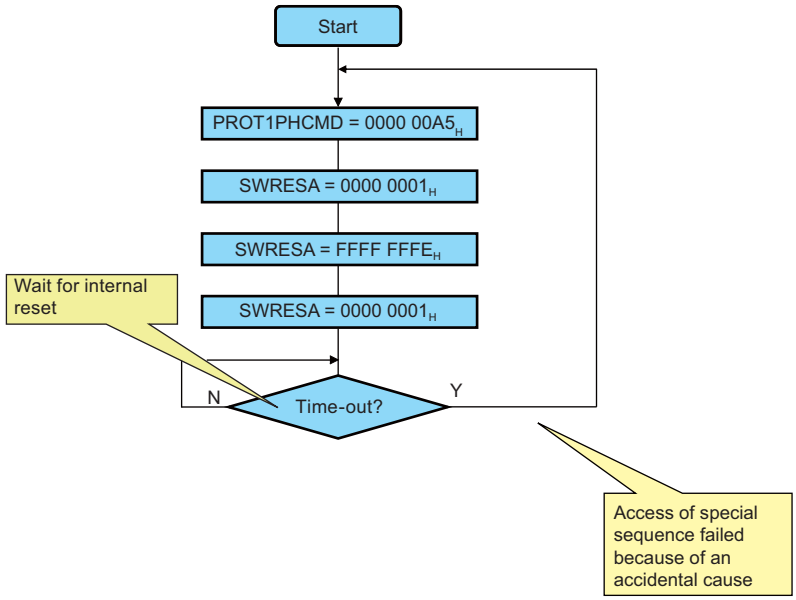
In case of writing to another register during steps 1 to 4 of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*1, writing to the protected register fails and the PROT1PS.PROTERR bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. For the applicable registers, see Section 11.4.10, PROT1PHCMD — Protect 1 Command Register.

8.5 Software Reset



Note: Timeout time should be 5 µs or longer.

Figure 8.2 Flow of Software Reset

8.6 RAM Retention

The values of RAM in retention area are not destroyed by reset.

8.7 Usage Notes

The debug function includes a reset masking function. To prevent unexpected operations of this function, fix the $\overline{\text{TRST}}$ pin to the low level when the debug function is not used.

Section 9 Power Supply Circuit

9.1 Features

- External Pass Transistor (EPT) method

With EPT	Without EPT
Operable with 2-output power management IC (5 V, 3.3 V)	Operable with 3-output power management IC (5 V, 3.3 V, 1.25 V)

- System power supply pins (SYSVCC)
  In the standby state, SYSVCC supplies power to the system logic and retention RAM.

Power Supply Name for Power Supply Pin	Pin Name	Power Supply Voltage in Operation	Uses of Power Supply
SYSVCC		3.0 V to 3.6 V	Power for system logic and retained RAM
VCC		3.0 V to 3.6 V	Power for oscillator, EPT, and flash programming
PLLVCC		3.0 V to 3.6 V	PLL
VDD		1.15 V to 1.35 V	Core power (direct power supply) and stabilizing capacity for core power
EVCC		4.5 V to 5.5 V	Port (5 V)
LVDVCC		3.0 V to 3.6 V	MSC (VccLVDS)
TTLVCC		3.0 V to 3.6 V/4.5 V to 5.5 V	MSC (VccTTL), Port (5 V, 3.3 V)
A0VCC/A1VCC		4.5 V to 5.5 V	Power for SAR AD
	A0VREFH/ A1VREFH	4.5 V to 5.5 V	Reference voltage for SAR AD
ADSVCC		4.5 V to 5.5 V	Power for ΔΣ AD
	ADSVREFH	4.5 V to 5.5 V	Reference voltage for power for ΔΣ AD
	EPTVOUT	—	EPT control for VDD **Note: The voltage is not externally applied.**
	RAMVCL	—	Stabilizing capacity for retained RAM
	ADSVCL	—	Stabilizing capacity for power for ΔΣ AD

For the relationship between the names of power supply pins and the pins, see **Section 37.2.1, Relationship between Power Name and Pin**.

9.2 Example of Connection of Power Management IC

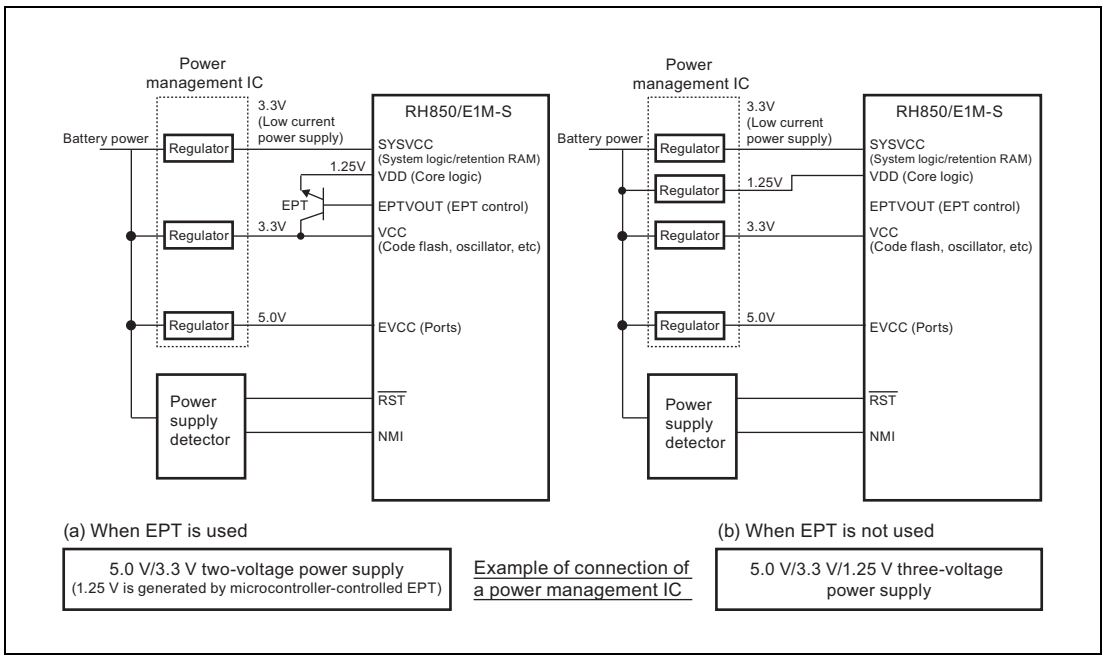


Figure 9.1 Power: Examples of Connection of a Power Management IC

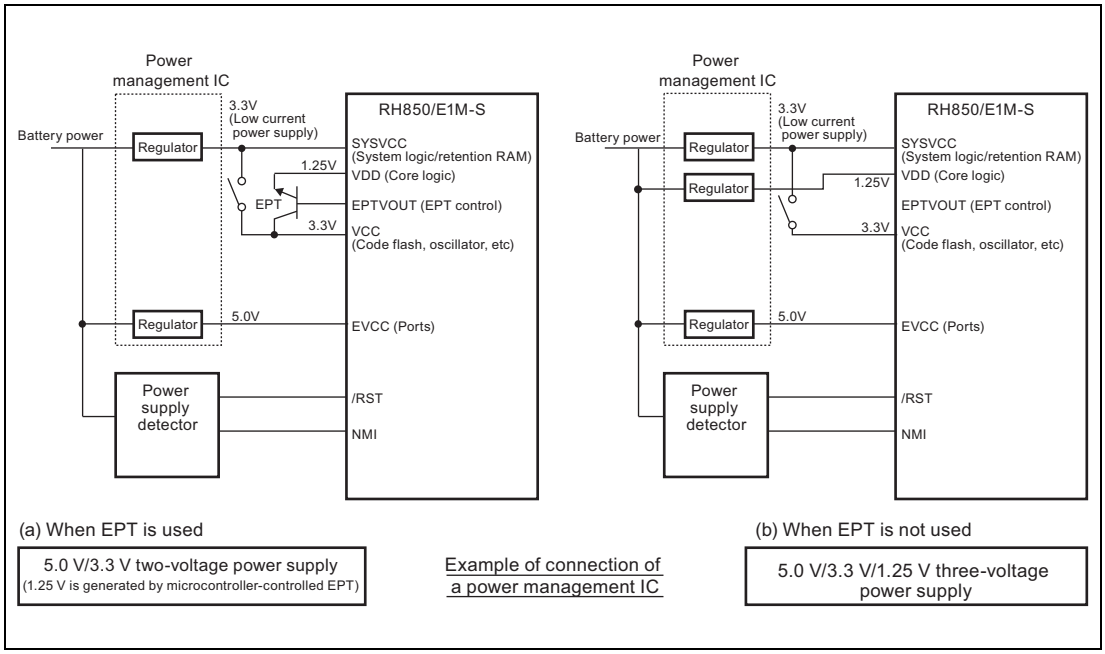

Figure 9.2 Power: Examples of Connection of a Power Management IC, Switched Off

9.3 Power-on Sequence

For details, see **Section 37, Electrical Characteristics**.

9.4 Usage Notes

Handling of power supply pins are described in this section. For handling of unused pins, see **Section 2.5.4, Handling of Unused Pins**.

Power Supply Name for Power Supply Pin	Pin Name	Required Setting	Recommended Handling
SYSVCC		Decoupling capacity: 0.1µF ±30% in total or higher	
VCC		Stabilizing capacity for power: 10µF ±30% or higher	Decoupling capacitor for each pin
PLLVCC			Shared with VCC Decoupling capacitor for each pin
VDD			Same as Guide to Mounting on Boards with an EPT in the following section
EVCC			Connect an external capacitor to suit the conditions of usage.
LVDVCC			Connect an external capacitor to suit the conditions of usage.
TTLVCC			Connect an external capacitor to suit the conditions of usage.
A0VCC/ A1VCC			See the application note separately issued.
	A0VREFH /A1VREFH		See the application note separately issued.
ADSVCC			See the application note separately issued.
	ADSVREFH		See the application note separately issued.
	EPTVOUT	See **Section 2.5.4, Handling of Unused Pins** when EPT is not used. See **Section 9.5, Guide to Mounting on Boards with an EPT** when EPT is used.	
	RAMVCL	Stabilizing capacity for power: 0.1µF ±30%	
	ADSVCL		See the application note separately issued.

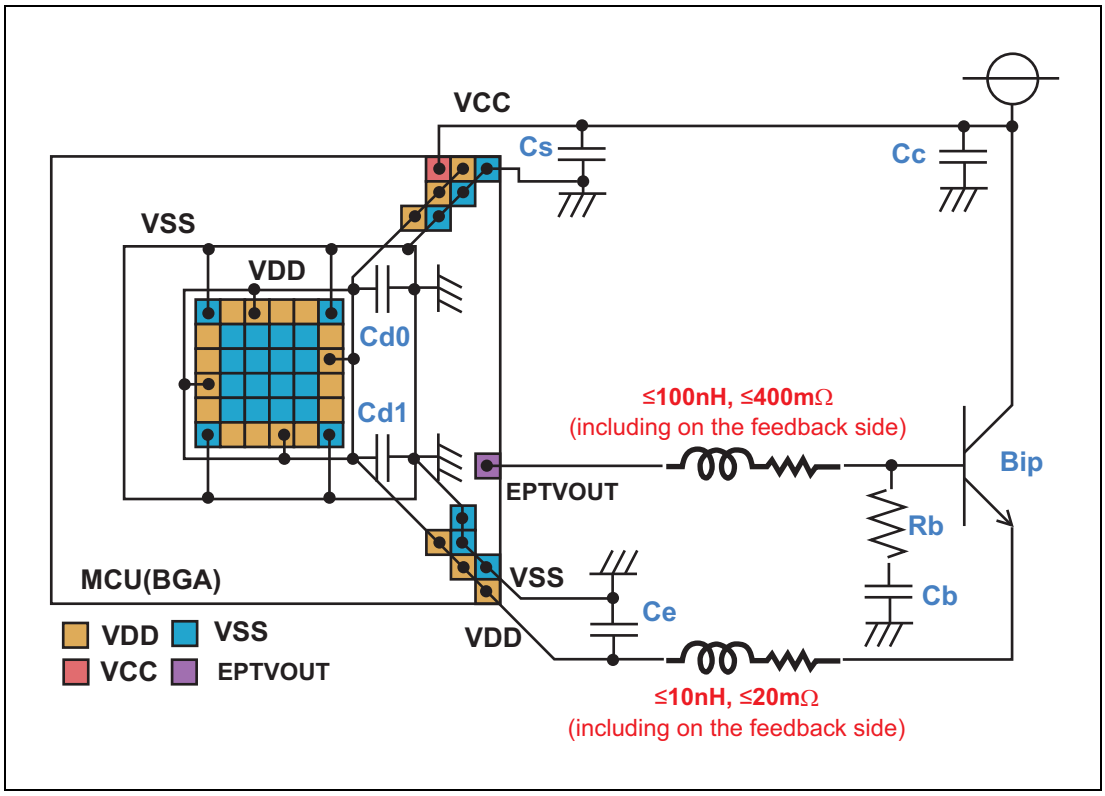
9.5 Guide to Mounting on Boards with an EPT

Comply with the guidelines below in mounting to obtain a VDD within the specified range if you are using a 2SD1899 npn bipolar transistor from Renesas as an EPT to handle the VDD power supply.

However, the guidelines specifically apply when the EPT is that stated above. Using a different transistor will require separate detailed consideration.

9.5.1 BGA

Placement of bypass capacitors: 2 × 2.2 µF if directly below the package and chip; 4.7 µF if drawn out externally to the package



Signal	Spec	Notes
Bip	—	NPN Bip. DC Gain 100 to 400 2SD1899 Renesas
Cc	≥ 5 µF	—
Rb	10Ω ±5%	Resistance tolerance: ±1%, Temperature characteristics: 200ppm/°C, Rated power: ≥ 0.05W
Cb	1 µF ±30%	Capacitance tolerance: ±10%, Temperature characteristics: X7R, X8R, ESR: < 50mΩ
Ce	4.7 µF ±30%	Capacitance tolerance: ±10%, Temperature characteristics: X7R, X8R, ESR: < 50mΩ Dimensions: 2012 *Arranged close to the package
Cdn (n: 0,1)	2.2 µF ±30% ×2	Capacitance tolerance: ±10%, Temperature characteristics: X7R, X8R, ESR: < 50mΩ Dimensions: 1608 *Two arranged directly below the package/chip
Cs	≥ 0.6 µF	ESR: < 50mΩ *Connected just proximal to the place between the VCC and VSS pins. If there is more than one VCC pin, the value in the left is the total capacity of these pins.

CAUTIONS

1. **Values for the parasitic L and R components produced by connection of VSS are based on the assumption that VSS is supplied through a plane of the board (with copper thickness of 35 µm and pitch of at least 1 mm for both VSS and VDD).**
2. **We recommend also forming the pattern for VDD as a plane. If this is impossible, make the wiring patterns as broad as is possible.**

9.5.2 Reference Information

Rough values of the parasitic L and R components for printed circuit boards are listed below.

Width of Wiring Runs (mm)	Inductance (nH/m)	Resistance (mΩ/m)
0.7	621	1210
1	555	913
2	432	571
4	263	257
6	200	183

CAUTION

The values are based on the assumption that VSS is supplied through a plane of the board (with copper thickness of 35 µm and pitch of at least 1 mm for both VSS and VDD).

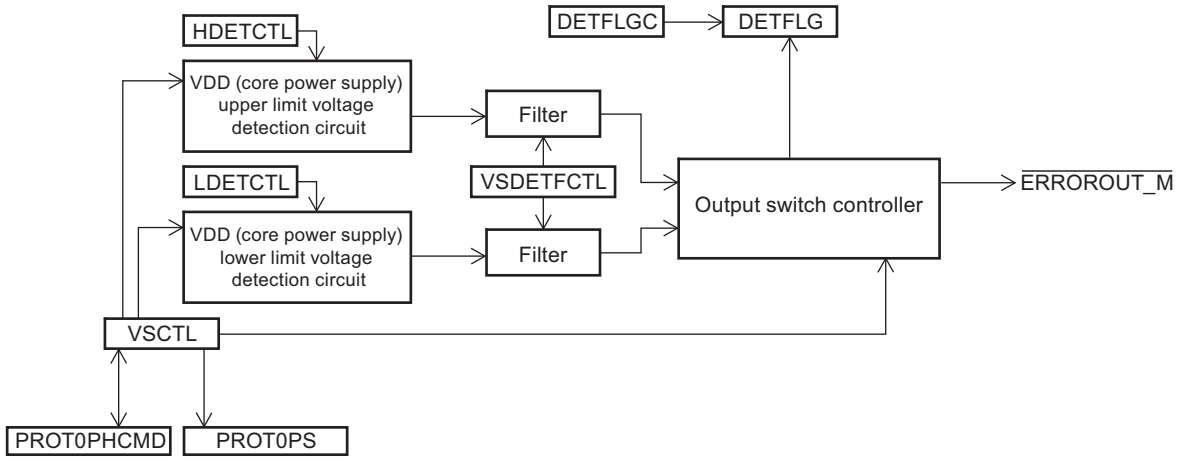
Section 10 Power Supply Voltage Monitor

10.1 Features

- The power supply voltage monitor is used for monitoring the VDD electric potential supplied to the core logic.
- The power supply voltage monitor has H- and L-side voltage detectors, which detect if the VDD is more or less than the specified voltage.
- Writing to the registers which select run or stop of the power supply voltage monitor function should be made in a specific sequence so that they cannot be incorrectly rewritten because of program malfunction and the like.
- If the power supply voltage monitor detects an error, it gives the error notice to external devices outside of LSI.

10.2 Configuration

Figure 10.1 shows the block diagram of the power supply voltage monitor.



Note 1. See **Section 10.3, Register Specifications** for the registers shown in the diagram above.

Figure 10.1 Block Diagram of the Power Supply Voltage Monitor

10.3 Register Specifications

Table 10.1 shows the specifications of registers.

Table 10.1 Register Specifications

Register Name	Abbreviation	R/W	Value After Reset	Address	Access Size
CVM detection flag register	DETFLG	R	0000 0000_H	FFF8 2820_H	32
CVM detection flag clear register	DETFLGC	R/W	0000 0000_H	FFF8 2828_H	32
CVM control register	VSCTL	R/W	0000 0000_H	FFF8 $2C10_H$	32
Upper limit voltage setting register	HDETCTL	R/W	0000 0003_H	FFF8 $2C14_H$	32
Lower limit voltage setting register	LDETCTL	R/W	0000 0003_H	FFF8 $2C18_H$	32
Detection signal filter control register	VSDETFCTL	R/W	0000 0000_H	FFF8 $2C1C_H$	32

10.3.1 DETFLG — CVM Detection Flag Register

This register indicates the detection state of upper/lower limit voltage. This register can only be reset by an external reset signal. This register also can be reset by the DETFLGC register.

Access: This register can be read in 32-bit units.

Address: FFF8 2820$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LDETFLG	HDETFLG
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 10.2 DETFLG Register Contents

Bit Position	Bit Name	Function
1	LDETFLG	Lower Limit Voltage Detection Flag 0: Lower limit voltage has not been detected. 1: Lower limit voltage has been detected.
0	HDETFLG	Upper Limit Voltage Detection Flag 0: Upper limit voltage has not been detected. 1: Upper limit voltage has been detected.

10.3.2 DETFLGC — CVM Detection Flag Clear Register

This register clears the DETFLG register.

Access: This register can be read/written in 32-bit units.
Reading this register always returns 0000 0000_H.

Address: FFF8 2828_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 10.3 DETFLGC Register Contents

Bit Position	Bit Name	Function
1	LDETFLGC	Lower Limit Voltage Detection Flag Clear 0: Lower limit voltage detection flag is not cleared. 1: Lower limit voltage detection flag is cleared.
0	HDETFLGC	Upper Limit Voltage Detection Flag Clear 0: Upper limit voltage detection flag is not cleared. 1: Upper limit voltage detection flag is cleared.

10.3.3 VSCTL — CVM Control Register

This register enables or disables the CVM. This register is protected by the PROT0PHCMD register.

See the description of the PROT0PHCMD register for the details.

This register can only be reset by an external reset signal.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2C10$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	EOUTEN	VSHEN	VSLEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 10.4 VSCTL Register Contents

Bit Position	Bit Name	Function
2	EOUTEN	0: Error output is masked. 1: Error output is not masked.
1	VSHEN	0: Upper limit voltage detection is disabled. 1: Upper limit voltage detection is enabled.
0	VSLEN	0: Lower limit voltage detection is disabled. 1: Lower limit voltage detection is enabled.

It takes 200 µs to start CVM operation after the VSHEN or VSLEN bit is enabled.

10.3.4 HDETCTL — Upper Limit Voltage Setting Register

This register controls the detection level of upper limit voltage. This register can only be reset by an external reset signal.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2C14$_H$

Value after reset: 0000 0003$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VDDREFH1	VDDREFH0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 10.5 HDETCTL Register Contents

Bit Position	Bit Name	Function
1	VDDREFH1	Upper Limit Voltage Detection Level Setting These bits should always be set to 0 when used.
0	VDDREFH0	

VDDREFH1	VDDREFH0	Upper limit voltage detection level
0	0	1.50 V

Setting other than the above is prohibited.

10.3.5 LDETCTL — Lower Limit Voltage Register

This register controls the detection level of lower limit voltage. This register can only be reset by an external reset signal.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2C18$_H$

Value after reset: 0000 0003$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VDDREFL1	VDDREFL0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 10.6 LDETCTL Register Contents

Bit Position	Bit Name	Function
1	VDDREFL1	Lower Limit Voltage Detection Level Setting These bits should always be set to 0 when used.
0	VDDREFL0	

VDDREFL1	VDDREFL0	Lower limit voltage detection level
0	0	0.95 V

Setting other than the above is prohibited.

10.3.6 VSDETFCTL — Detection Signal Filter Control Register

This register controls the width of digital noise filter. This register can only be reset by an external reset signal.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2C1C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DETF1	DETF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 10.7 VSDETFCTL Register Contents

Bit Position	Bit Name	Function
1	DETF1	Digital Noise Filter Width Setting
0	DETF0	

DETF1	DETF0	Digital noise filter width
0	**0**	Bypass the filter.
0	1	Filtering cycle: 16 clk
1	0	Filtering cycle: 32 clk
1	1	Filtering cycle: 64 clk

The sampling clock of the digital noise filter is ROSC (240 KHz).

10.4 Usage

The operation flow from CVM detection condition setting to actual detection is as follows:

1. Set the voltage conditions for H- and L-side voltage detection in the upper and lower voltage limit setting registers (HDETCTL and LDETCTL), respectively. Also set the voltage detection noise filter width in the detection signal filter control register, and complete to set all CVM-related registers. The CVM's H- and L-side enable bits (VSHEN and VSLEN) of the CVM control register (VSCTL) and the error notice to external devices outside of LSI (EOUTEN) are then specified to start operation.
2. When VDD exceeds the specified upper limit voltage, an error signal is output to external devices outside of LSI according to the settings of the EOUTEN bit in the VSCTL register and the upper limit voltage detection flag (the HDETFLG bit in the DETFLG register) is set. When VDD falls below the specified lower limit voltage, an error signal is output to external devices outside of LSI according to the settings of the EOUTEN bit in the VSCTL register and the lower limit voltage detection flag (the LDETFLG bit in the DETFLG register) is set.
3. Check the upper and lower limit voltage detection flags after H- and L-side voltage detection to verify the details of the corresponding detection.

The $\overline{\text{ERROROUT\_M}}$ pin (master) of the error control module (ECM) is also used in common for the CVM error output pin.

When $\overline{\text{ERROROUT\_M}}$ pin output is used in CVM, make related settings under the following procedures.

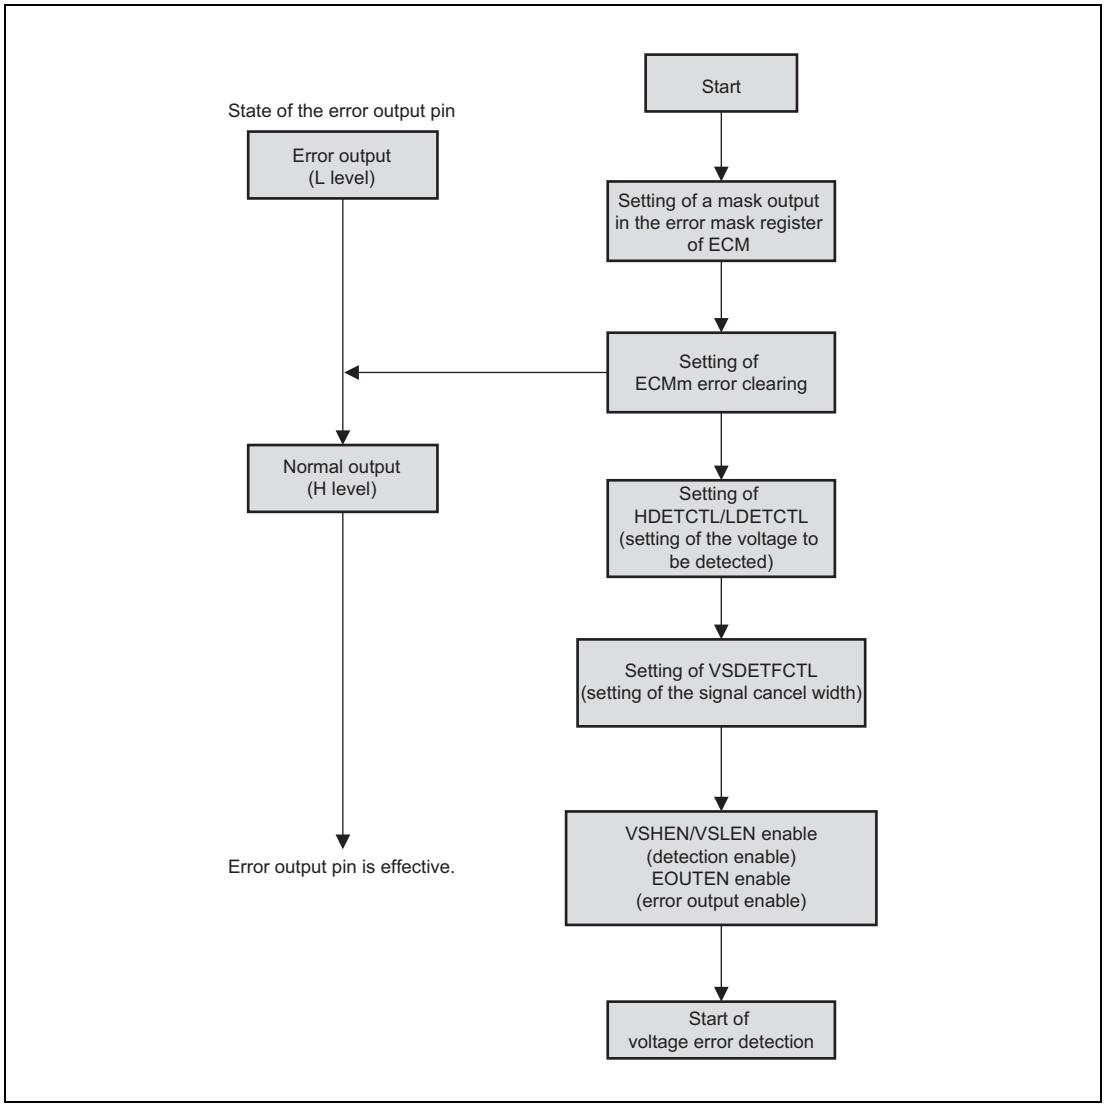

Figure 10.2 Flowchart

10.5 Notes on Usage

- The power supply voltage monitor operates only after release from an external reset. The power supply voltage monitor operation is stopped during an external reset, and various registers are initialized.
- The setting registers and flag registers are only initialized by an external reset. They cannot be initialized by an internal reset requested by the CPU or ECM.

Section 11 Clock Controller

11.1 Features

- An oscillation circuit is included (Main OSC).
- Oscillation at 20 MHz is possible without using external capacitors (only with limited resonators).
- A 20-MHz clock can be input from the EXTAL pin.
  A 20-MHz external clock can be directly input from the EXTAL pin, separately from the main OSC.

CAUTION

XTAL should be an open circuit when an external clock signal is being directly input.

- On-chip PLLs are included and can be used to divide clock frequencies.
- PLL0 is capable of operating as a spread spectrum clock generator (SSCG) for reducing radiated noise.
  The clock signal produced by PLL1 is not frequency modulated (i.e. is a clean clock signal) and so is suitable for use with timers and communications modules.
- The ring oscillator circuits (ROSC) is included.
- Interrupts can be generated when the Main OSC goes outside the frequency range specified by the clock monitor.
- The clock frequencies can be increased stepwise by software for suppressing inrush currents after release from the reset state.
  The division ratios for the CPU clock and the peripheral clocks can be selected with register settings (1/4, 1/2, and 1/1).
- A frequency divided clock set by a 1-MHz clock and a baud rate generator (BRG) can be output from the CK pin.

11.2 Type of Clocks

Table 11.1 shows the list of clocks, **Table 11.2** shows the operation clocks of each functional module, and **Figure 11.1** shows the block diagram of clocks.

Table 11.1 List of Clocks

When operating at 20 MHz input frequency (Main OSC)

Clock Name	Symbol	Clock Frequency: Division Ratio of Divider 0A/ Divider 1A 1/1	1/2	1/4	Remarks
CPU clock	CLK_CPU	320 MHz*1	160 MHz*1	80 MHz*1	PLL0 (SSCG can be selected)
		240 MHz*2	120 MHz*2	60 MHz*2	
High speed peripheral clock	CLK_HSB	80 MHz	40 MHz	20 MHz	
Low speed peripheral clock (peripheral clock)	CLK_LSB	40 MHz	20 MHz	10 MHz	
Unmodulated high speed peripheral clock	CLKC_HSB	80 MHz	40 MHz	20 MHz	PLL1 (SSCG cannot be selected)
Unmodulated low speed peripheral clock	CLKC_LSB	40 MHz	20 MHz	10 MHz	
Low speed ROSC clock	CLK_ROSCL		240 KHz		
ASIC clock (1 MHz clock)	CLKA_ASIC		1 MHz		1/20 X Main OSC
WDTA counter clock	WDTACLKI		250 KHz		1/80 X Main OSC

Note 1. For the products with 320 MHz (max.) CPUs
Note 2. For the products with 240 MHz (max.) CPUs

Table 11.2 Clocks and Functional Modules

Clock Name	Functional Module Name
CPU clock	CPU
High speed peripheral clock	PCU, INTC, DMAC, DTS, CSIH, DFE, FlexRay
Low speed peripheral clock (peripheral clock)	ECM, CRC
Unmodulated high speed peripheral clock	RHSB, ΔΣAD, TSG2, TAPA, PIC
Unmodulated low speed peripheral clock	CAN, LIN, ATU-IV, APA, WDTA*1, OSTM, SCI, AD
Low speed ROSC clock	CLM
WDTA counter clock	WDTA*1

Note 1. The PCLK of the WDTA (the clock on the P-Bus) is the unmodulated low-speed peripheral clock and the operating clock of the WDTA is the WDTA counter clock.

The PCLK mentioned in the section of each function module means the clock frequency listed in the 1/1 division ratio in **Table 11.1**, which corresponds to the clock name listed in **Table 11.2**.

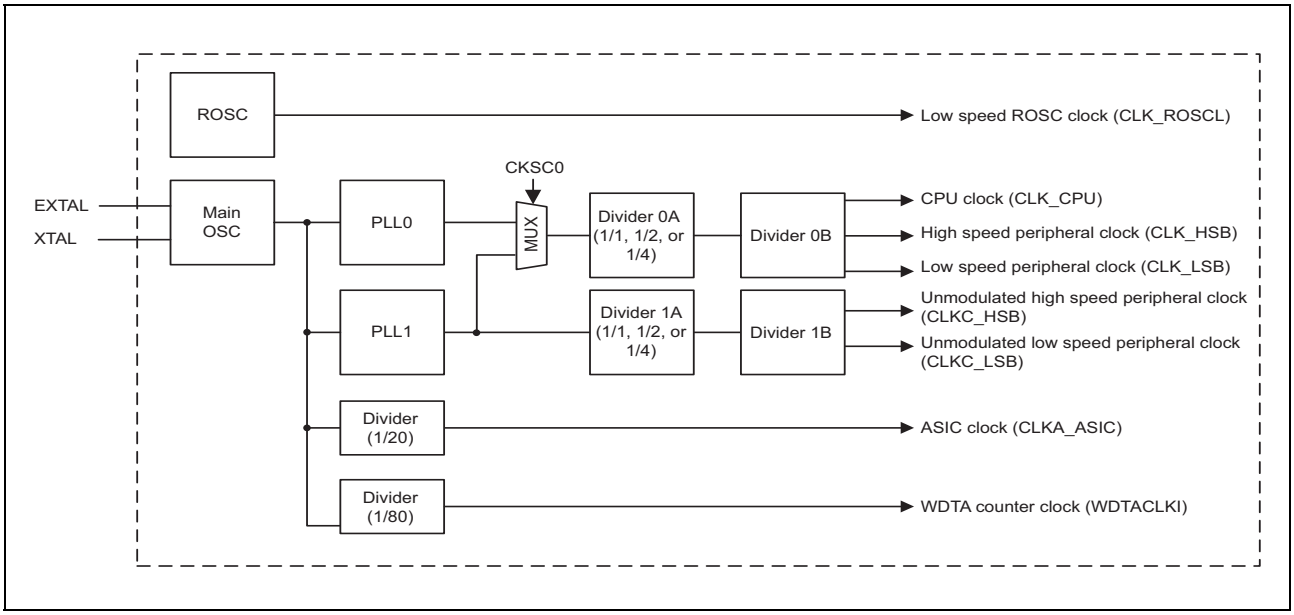

Figure 11.1 Block Diagram of Clock Controller

11.3 Input/Output Pins

Table 11.3 shows the pins related to the clock controller.

Table 11.3 Pins Related to the Clock Controller

Name	Pin Name	Input/Output	Function
External clock	EXTAL	Input	Input of a crystal resonator or external clock
Crystal	XTAL	Output	Connected to a crystal resonator
Clock output	CK	Output	1-MHz clock/BRG output
PLL power	PLLVCC	Input	Power supply for the PLL multiply circuit
PLL ground	PLLVSS	Input	Power supply for the PLL multiply circuit

11.3.1 How to Connect a Crystal Resonator

Figure 11.2 shows how to connect a crystal resonator. When the resonator recommended by the Company is used (the detail information is separately provided), any external component such as a load capacitor and a dumping resistor is not necessarily required for oscillation in general. However, proper operation should be verified under actual conditions prior to use.

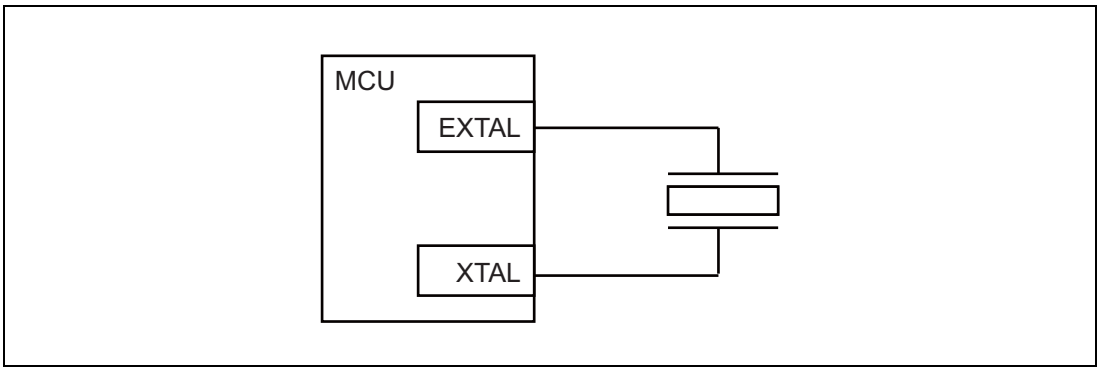

Figure 11.2 Connection Example of Crystal Resonator 1

11.4 Register Specification

11.4.1 List of Registers

Table 11.4 shows the list of registers.

Table 11.4 Registers Related to the Clock Controller

Register Name (abbreviation)	R/W	Value after Reset	Address	Access Size	Access Protection
PLL0 status register (PLL0CLKS)	R	0000 0001_H	FFF8 8004_H	32	
PLL0 control register 1 (PLL0CLKC1)	R/W	0000 0000_H	FFF8 8200_H	32	PROT1PHCMD
Clock 0 selection control register (CKSC0CTL)	R/W	0000 0020_H	FFF8 9000_H	32	PROT1PHCMD
Clock 0 selection active register (CKSC0ACT)	R	0000 0020_H	FFF8 9008_H	32	
Clock 0 division register (CLKD0DIV)	R/W	0000 0004_H	FFF8 8800_H	32	PROT1PHCMD
Clock 0 division status register (CLKD0STAT)	R	0000 0001_H	FFF8 8804_H	32	
Clock 1 selection control register (CKSC1CTL)	R/W	0000 0021_H	FFF8 9040_H	32	PROT1PHCMD
Clock 1 selection active register (CKSC1ACT)	R	0000 0021_H	FFF8 9048_H	32	
Protect 1 command register (PROT1PHCMD)	R/W	0000 0000_H	FFF8 $B000_H$	32	
Protect 1 status register (PROT1PS)	R	0000 0000_H	FFF8 $B004_H$	32	

11.4.2 PLL0CLKS — PLL0 Status Register

This register indicates the state of the PLL0 clock effective, active, or stable.

This register is initialized by either an internal or external reset.

Access: This register can be read in 32-bit units.

Address: FFF8 8004$_H$

Value after reset: 0000 0001$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

1	CLKSTAB	PLL0 Clock Stable State 0: PLL0 is unstable. 1: PLL0 is stable.
0	CLKEN	PLL0 Clock Operating State 0: PLL0 is stopped. 1: PLL0 is operating.

11.4.3 PLL0CLKC1 — PLL0 Control Register 1

This register controls the operation of the spread spectrum clock generator (SSCG) for PLL0.

This register can be set when PLL0 is running.

This register is protected by the PROT1PHCMD register.

This register is initialized by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 8200$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 11.6 PLL0CLKC1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 10	—	Reserved These bits are always read as 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
9	SSMODE1	SSCG Control 0: Modulation disabled 1: Modulation enabled
8	—	Reserved This bit is always read as 0. When writing to this bit, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
7 to 3	SELMFREQ [4:0]	SSCG Cycle Setting The modulation cycle of SSCG can be selected by setting these bits. Selectable settings are as follows: 10000_B : 80.65 kHz 10001_B : 75.76 kHz 10010_B : 69.44 kHz 10011_B : 65.79 kHz 10100_B : 62.50 kHz 10101_B : 59.52 kHz 10110_B : 58.14 kHz 10111_B : 50.00 kHz 11000_B : 41.67 kHz 11001_B : 39.68 kHz 11010_B : 37.31 kHz 11011_B : 33.33 kHz 11100_B : 30.12 kHz 11101_B : 25.00 kHz 11110_B : 20.00 kHz When SSMODE1 is set to 1, do not set a value other than the above.

Table 11.6 PLL0CLKC1 Register Contents (2/2)

Bit Position	Bit Name	Function
2 to 0	SELMPERCENT [2:0]	SSCG Modulation Range Setting The modulation range of SSCG can be selected by setting these bits. Selectable settings are as follows: $1\ 0\ 0_B$: -5.0% Do not set any other value while SSMODE1 is set to 1.

When changing the modulation depth of PLL0, turn off the SSCG and then wait for at least 1.6 ms.

11.4.4 CKSC0CTL — Clock 0 Selection Control Register

This register is used for selection of a clock source for the frequency divider 0A.

This register is protected by the PROT1PHCMD register.

This register is initialized by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 9000_H

Value after reset: 0000 0020_H

5 to 0	CLKACT[5:0]	These bits indicate that switching of an output clock for the frequency divider 1A is completed when their values are the same as those specified in the CKSC[5:0] bits in the CKSC1CTL register. 100001_B: 1/4 of PLL1 100010_B: 1/2 of PLL1 100100_B: 1/1 of PLL1

11.4.10 PROT1PHCMD — Protect 1 Command Register

PROT1PHCMD is a protection command register to start the protection unlocking sequence necessary for access to write-protected registers.

This register is initialized by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 $B000_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 11.13 PROT1PHCMD Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are always read as 0.
7 to 0	PCMD[7:0]	Write protection command register

This register is used in protecting against inadvertent access to write-protected registers, i.e. registers to which writing raises the possibility of serious effects on application systems, such as programs crashing and the like.

Writing to the write-protected registers is only possible with the protection unlock sequence described below.

1. Write the fixed value (0000 $00A5_H$) to register PROT1PHCMD.
2. Write the new setting to the write-protected register. Write the value after a reset to the reserved bits.
3. Write the bitwise inverse of the setting value to the same register as in step 2. Write the inverse of the value after a reset to the reserved bits.
4. Write the new setting to the same register as in step 2. Write the value after a reset to the reserved bits.

A value can only be written to a write-protected register by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting is not written to the write-protected register, and the PROT1PS.PROTERR bit is set to 1. (Although this is not a requirement, you can confirm if the values set in the targeted register was correctly written by checking that the setting of the PROT1PS.PROTERR bit is 0 after step 4.)

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1 to 4 of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*1, writing to the protected register fails and the PROT1PS.PROTERR bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. PROT1PHCMD applies to the registers allocated to the addresses in the range from FFF8 8004_H to FFF8 $B004_H$.
For the register names, register symbols, and module names, see **Appendix, List of Registers**.

11.4.11 PROT1PS — Protect 1 Status Register

PROT1PS is a status register of the protection unlocking sequence. This register indicates whether an error occurs or not in access to write-protected registers.

This register is initialized by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 B004$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 11.14 PROT1PS Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0.
0	PROTERR	Protection Error Flag 0: Protection error does not occur. 1: Protection error occurs.

Operating conditions of the PROTERR bit

[Setting Condition]

Access to a write-protected register without executing the step of the protection unlocking sequence that involves the PROT1PHCMD register

[Clearing Condition]

Writing of 0000 00A5$_H$ to the PROT1PHCMD register (step 1 in the protection unlocking sequence)

11.5 Operation

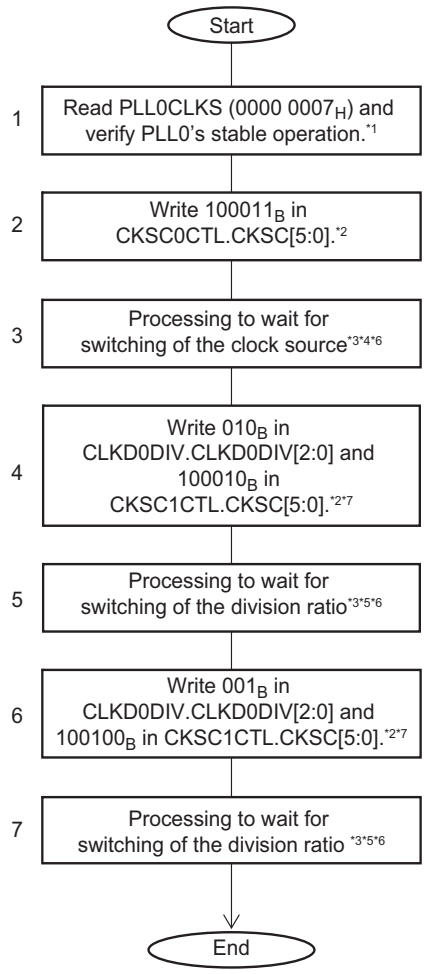
11.5.1 Operation When the Divide Function Is Used

Follow the procedure given below to reduce current fluctuations produced by switching the clock signals during startup (also see **Figure 11.3, Example of Sequence for Shifting the Clock Gear Up**).

1. When a user program is running after release from the reset state, PLL0 or PLL1 will be oscillating and PLL1 will be in use as the internal operating clock. Also, the division ratio of divider 0A is set to 1/4.
   Read the PLL0CLKS register and verify that its value is 07_H, indicating that PLL0 operation is stable.
2. Write 23_H to the CKSC[5:0] bits in CKSC0CTL to select PLL0 as the clock source.
3. When switching the clock source, wait at least 105 or 140 cycles of the CPU clock in the respective cases of products with CPUs having maximum operating frequencies of 240 MHz or 320 MHz . After that, read CKSC0ACT and verify that the value of the CKSC0ACT.CLKACT[5:0] bits is 23_H.
4. Write 010_B to the CLKD0DIV[2:0] bits in CLKD0DIV to select 1/2 as the division ratio for the divider.
5. For switching of the division ratio, wait at least, 105 or 140 cycles of the CPU clock in the respective cases of products with CPUs having maximum operating frequencies of 240 MHz or 320 MHz . Then read CLKD0STAT and verify that the value of the CLKD0SYNC is 1.
6. Write 001_B to the CLKD0DIV[2:0] bits in CLKD0DIV to select 1/1 as the division ratio for the divider.
7. For switching of the division ratio, wait at least 105 or 140 cycles of the CPU clock in the respective cases of products with CPUs having maximum operating frequencies of 240 MHz or 320 MHz . Then read CLKD0STAT and verify that the value of the CLKD0SYNC is 1.

For switching division ratio of the divider 1A on the PLL1, follow the procedures of 4 to 7 above.

Figure 11.3 shows an example of the procedure for switching the clocks (and shifting the clock gear up for both clocks). **Table 11.15** lists the clock frequencies in each step of the process.



Note 1. After release from the reset state, verify that PLL0 operation is stable before executing the sequence to shift the clock gear up. PLL0CLKS = 07_H indicates that PLL0 is stable.

Note 2. The CKSC0CTL and CLKD0DIV registers are protected by the PROT1PHCMD register. Execute the protection unlocking sequence (see the description of the protect 1 command register) when setting these registers.

Note 3. This processing is required because actual switching of the clock source or division ratio from the previous register settings takes time. The processing must produce periods of waiting of at least 105 or 140 cycles of the CPU clock in the respective cases of products with CPUs having maximum operating frequencies of 240 or 320 MHz . The SNOOZE instruction can be used for this purpose; see the RH850G3M User's Manual: Software for details.

Note 4. Verify that the value of the CLKACT[5:0] bits in CKSC0ACT is the same as that specified by the CKSC[5:0] bits in CKSC0CTL after switching the source clock for frequency divider 0A. Similarly, verify that the value of the CLKACT[5:0] bits in CKSC1ACT is the same as that specified by the CKSC[5:0] bits in CKSC1CTL after switching the source clock for frequency divider 1A.

Note 5. Verify that the CLKD0SYNC bit in CLKD0STAT is 1 after changing the division ratio of divider 0A.

Note 6. Switching of clock sources or division ratios produces transient voltage fluctuations which last for a certain time, so measures such as processing to add more cycles of waiting may be required. Whether or not this is the case will depend on evaluation of the actual environment where the LSI chip is used.

Note 7. In the procedure described above, the division ratios of both PLL0 and PLL1 are set at the same time. When minimizing the transient voltage fluctuations during this procedure is crucial, separate the register settings and subsequent periods of waiting for PLL0 and PLL1 to achieve this (which also prolongs the procedure).

Figure 11.3 Example of Sequence for Shifting the Clock Gear Up

Table 11.15 Frequencies in the Process of Shifting the Clock Gear Up

	CLK_CPU					
	Products with 320-MHz (max.) CPUs	Products with 240-MHz (max.) CPUs	CLK_HSB	CLK_LSB	CLKC_HSB	CLKC_LSB
Before Step 1	80	60	20	10	20	10
Between Step 1 and Step 2	80	60	20	10	20	10
Between Step 2 and Step 3	160	120	40	20	40	20
After Step 3	320	240	80	40	80	40

11.6 Notes

Avoid using commands that employ the computing unit, such as FPU operations, while the division ratio is being changed. Increased current fluctuation may make the operation unstable.

11.6.1 Board Design Notes

As shown in **Figure 11.4**, do not cross any other signal lines over the signal lines to the EXTAL and XTAL pins. Induction may inhibit proper oscillation.

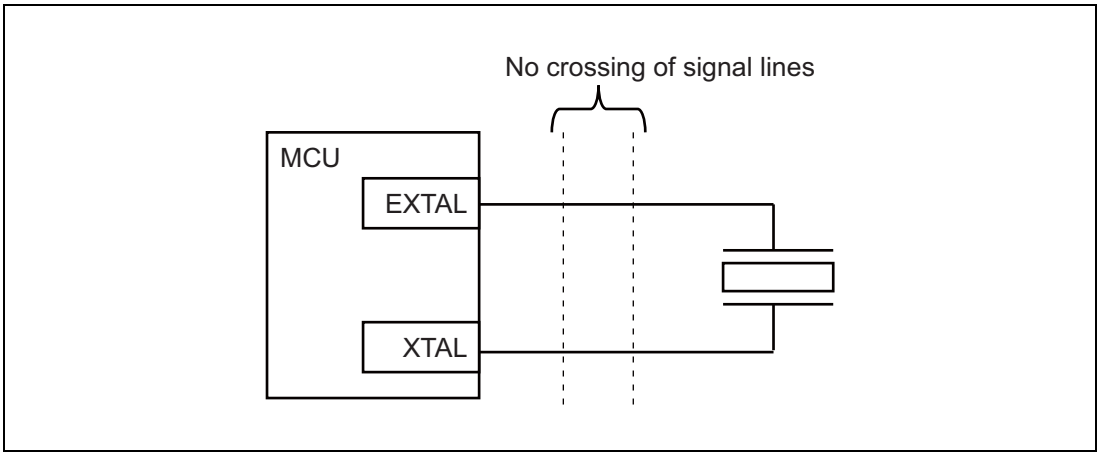


Figure 11.4 Board Design Notes

11.7 ASIC Clock

11.7.1 Features

- ASIC Clock provides a function to select a clock output from the CK pin.
- The frequency-divided clock*2 set by the 1-MHz clock*1 or the baud rate generator (BRG) can be selected through the register settings.
- After release from power-off standby, the 1-MHz clock is output from the CK pin.
- When stop or run of a clock is selected, rewriting to a register should be done in a specific sequence so that the register is not incorrectly rewritten due to program malfunction.

CAUTIONS

1. 1-MHz clock: 1/20 clock of the 20-MHz main OSC

2. BGR (Baud Rate Generator): 1/N clock of the unmodulated low speed peripheral clock (CLKC_LSB)

11.7.2 Configuration

Figure 11.5 shows the diagram of ASIC clock output configuration.

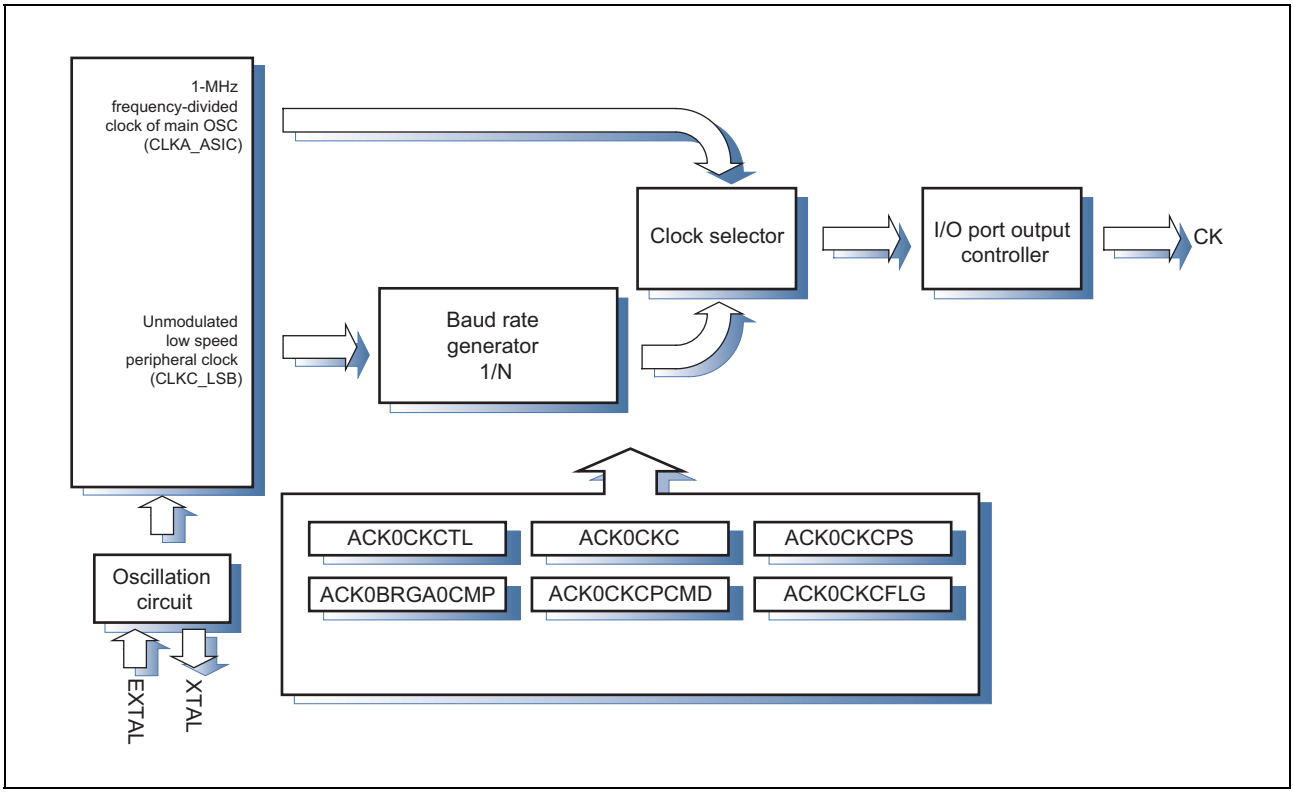

Figure 11.5 Block Diagram of ASIC Clock

11.7.3 Register Specifications

The following shows the specifications of registers.

Table 11.16 Pin Specifications

Register Name	Abbreviation	R/W	Value after Reset	Address	Access Size
Clock control register	ACK0CKC	R/W	01_H	FFC0 4000_H	8
CKC flag register	ACK0CKCFLG	R	01_H	FFC0 4004_H	8
Clock select register	ACK0CKCTL	R/W	00_H	FFC0 4008_H	8
BRGA0 compare register	ACK0BRGA0CMP	R/W	00_H	FFC0 $400C_H$	8
CKC protect command register	ACK0CKCPCMD	W	—	FFC0 4100_H	8
CKC protect status register	ACK0CKCPS	R	00_H	FFC0 4104_H	8

11.7.3.1 ACK0CKC — Clock Control Register

This is an 8-bit register to control the system clock frequency. Therefore, this register can be only written in combination of specific instruction sequences so that it is not incorrectly rewritten due to program malfunction.

Protection of this register can be canceled by writing to the command register (ACK0CKCPCMD).

When a specific register is read out, however, a specific instruction sequence is not required.

Access: This register can be read/written in 8-bit units.

Address: FFC0 4000_H

Value after reset: 01_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	DCLK0
Value after reset	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R/W

Table 11.17 ACK0CKC Register Contents

Bit Position	Bit Name	Description
7 to 1	—	Reserved These bits are always read as 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	DCLK0	Clock Output Control 0: Clock output inhibit mode Output of a clock from the CK pin is prohibited (fixed to low level). Further reduction of power consumption and suppression of radiation noise from the CK pin can be achieved because CK operation is completely stopped. 1: Clock output The clock selected by the ACK0CKCTL is output from the CK pin.

Note 1. Up to three cycles of the clock signal output from the the CK pin (the clock signal selected by ACK0CKCTL) are required to stop clock output to the CK pin after writing 0 to the DCLK0 bit. The clock output stop state can be checked by reading the DCLKF0 bit in the ACK0CKCFLG register.

11.7.3.2 ACK0CKCFLG — CKC Flag Register

The ACK0CKCFLG register indicates the status of clock output control.

Access: This register can be read in 8-bit units.

Address: FFC0 4004_H

Value after reset: 01_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	DCLKF0
Value after reset	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R

Table 11.18 ACK0CKCFLG Register Contents

Bit Position	Bit Name	Description
7 to 1	—	Reserved These bits are always read as 0.
0	DCLKF0	This bit indicates the status of clock output control. 0: Output from the CK pin is stopped. 1: The clock selected by the ACK0CKCTL is output from the CK pin.

11.7.3.3 ACK0CKCTL — Clock Select Register

The ACK0CKCTL is an 8-bit register to select a clock output from the CK pin.

This register can be written in 8-bit units when the DCLKF0 bit in the CKC flag register is 0.

The ACK0CKCTL register is always readable also.

For the DCLKF0 bit, see **Section 11.7.3.2, ACK0CKCFLG — CKC Flag Register**.

Access: This register can be read/written in 8-bit units.

Address: FFC0 4008_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CKSL[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 11.19 ACK0CKCTL Register Contents

Bit Position	Bit Name	Description
7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1, 0	CKSL[1:0]	These bits select a clock output from the CK pin. 00: 1-MHz clock (1/20 clock of the 20-MHz main OSC) 01: BRG (Baud Rate Generator) Setting other than the above is prohibited.

Note 1. Writing to the ACK0CKCTL register (selection of a clock output to the CK pin) can only be performed when the clock output to the CK pin is stopped (the DCLKF0 bit in the ACK0CKCFLG register is 0).

11.7.3.4 ACK0BRGA0CMP — BRGA0 Compare Register

The ACK0BRGA0CMP is a register to store a value to be compared with the baud rate counter.

Access: This register can be read/written in 8-bit units.

Address: FFC0 400C$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	BRGA0CMP[4:0]				
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 11.20 ACK0BRGA0CMP Register Contents

Bit Position	Bit Name	Description
7 to 5	—	Reserved These bits are always read as 0. When writing, always write 0.
4 to 0	BRGA0CMP [4:0]	These bits set a compare value. For the settings, see **Table 11.22, Unmodulated Low Speed Peripheral Clock Frequency (value set in the ACK0BRGA0CMP register and frequency to be output)**.

Note 1. Writing to the ACK0BRGA0CMP register (selection of a value to be compared with the baud rate counter) can only be performed when the clock output to the CK pin is stopped (the DCLKF0 bit in the CKCFLG register is 0).

11.7.3.5 ACK0CKCPCMD — CKC Protect Command Register

The ACK0CKCPCMD register is used to protect against any writing operation to a register that might have a material effect on the application systems. This ensures the systems are not incorrectly stopped due to program malfunction.

The value of the ACK0CKC register can only be rewritten by a sequence specified in advance, and an unauthorized write operation is eliminated.

Access: This register can be written in 8-bit units. The read value is always undefined.

Address: FFC0 4100_H

Value after reset: Undefined

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—
Value after reset	—	—	—	—	—	—	—	—
R/W	W	W	W	W	W	W	W	W

Writing to the ACK0CKC register is only possible with the protection unlock sequence described below.

Procedure

1. Write the fixed value ($A5_H$) to register ACK0CKCPCMD.
2. Write the new setting to register ACK0CKC. Write the value after a reset to the reserved bits.
3. Write the bitwise inverse of the setting value to register ACK0CKC. Write the inverse of the value after a reset to the reserved bits.
4. Write the new setting to register ACK0CKC. Write the value after a reset to the reserved bits.

A value can only be written to register ACK0CKC by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting is not written to the ACK0CKC register, and the ACK0CKCPS.CKCPRERR bit is set to 1. (Although this is not a requirement, you can confirm if the values set in the targeted register was correctly written by checking that the setting of the ACK0CKCPS.CKCPRERR bit is 0 after step 4.)

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1 to 4 of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*1, writing to the protected register fails and the ACK0CKCPS.CKCPRERR bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. "Another register in the same module" indicates a register under the same module name as that containing the write-protected register. For the module names of the registers, see **Appendix, List of Registers**.

11.7.3.6 ACK0CKCPS — CKC Protect Status Register

The ACK0CKCPS is a register to which the CKCPRERR flag indicating a protection error occurrence is allocated.

If the ACK0CKC register is not written to in the correct sequence, including the command register settings, the write operation is not performed on the target register. A protection error then occurs and the status flag (CKCPRERR) is set to 1.

The ACK0CKCPS register is cleared at each start of the specific sequence.

Access: This register can be read in 8-bit units.

Address: FFC0 4104_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CKCPR ERR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 11.21 ACK0CKCPS Register Contents

Bit Position	Bit Name	Description
7 to 1	—	Reserved These bits are always read as 0.
0	CKCPRERR	Protection Error Detection 0: Protection error has not occurred. 1: Protection error has occurred.

11.7.4 Usage

11.7.4.1 CK Pin Output Function

A clock source output from the CK pin can be selected and provided in this function.

1-MHz clock is output from the CK pin during the reset period immediately after release from power-off standby. A clock source output from the CK pin can be selected among the 1-MHz clock and the frequency-divided clocks set by the BRG (Baud Rate Generator) through switching of the ACK0CKCTL register.

- Selectable clock source
  1-MHz clock (1/20 clock of the 20-MHz main OSC) (Initial value)
  BRG (Baud Rate Generator)

11.7.4.2 CK Output Baud Rate Generator Circuit (BRGA)

In the baud rate generator circuit, the unmodulated low speed peripheral clock (CLKC_LSB) is divided and output from the CK pin.

The BRGA0 inverts the CK output in response to a match in comparison between the specified value of the BRGA0CMP[4:0] bit in the ACK0BRGA0CMP register and the value of the baud rate counter.

The CK output is fixed to low when the DCLK0-bit in the ACK0CKC register is set to 0.

Table 11.22 lists the frequencies of unmodulated low speed peripheral clocks that can be set.

Table 11.22 Unmodulated Low Speed Peripheral Clock Frequency (value set in the ACK0BRGA0CMP register and frequency to be output)

BRGA0CMP4	BRGA0CMP3	BRGA0CMP2	BRGA0CMP1	BRGA0CMP0	Output Frequency [MHz]
0	0	0	0	0	1.25
1	0	1	0	0	2.00
1	0	1	0	1	1.90
1	0	1	1	0	1.82
1	0	1	1	1	1.74
1	1	0	0	0	1.67
1	1	0	0	1	1.60
1	1	0	1	0	1.54
1	1	0	1	1	1.48
1	1	1	0	0	1.43
1	1	1	0	1	1.38
1	1	1	1	0	1.33
1	1	1	1	1	1.29

Note 1. Setting other than the above is prohibited.

11.7.4.3 Control Register Rewrite Protect

As shown in **Figure 11.6**, the ACK0CKC register to control the output clock from the CK pin can only be rewritten in a specific sequence due to this protect function. Switching of a clock source is prohibited while a clock is running. The ACK0CKCTL register can only be rewritten when the DCLKF0 bit in the CKC flag register is set to 0.

In addition, rewriting of the compare values is prohibited while the baud rate counter is running. The ACK0BRGA0CMP register can only be rewritten when the DCLKF0 bit in the CKC flag register is set to 0.

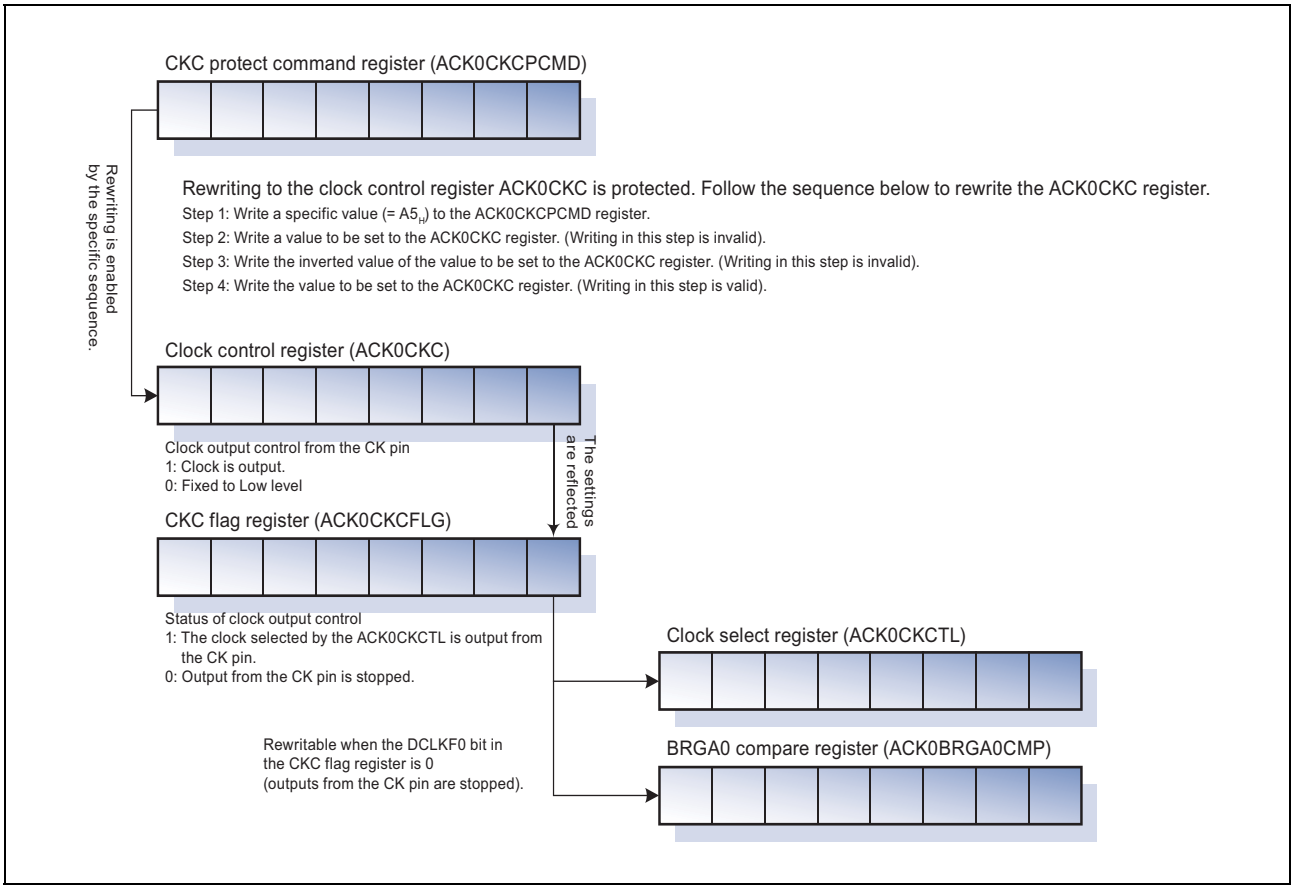

Figure 11.6 Rewriting Protect

11.7.4.4 CK Output Switching Procedure

Follow the procedure below to switch the output clock from the CK pin.

1. Stop an output from the CK pin.

   Rewrite the DCLK0 bit in the clock control register (ACK0CKC) to stop an output from the CK pin.

- Write $A5_H$ to the ACK0CKCPCMD register.
- Write 00_H to the ACK0CKC register.
- Write FF_H to the ACK0CKC register.
- Write 00_H to the ACK0CKC register.

  Read the DCLKF0 bit in the CKC flag register (ACK0CKCFLG) to verify that the output from the CK pin has been stopped.

2. Select a clock source

   Rewrite the CKSL[1:0] bits in the clock selection register (ACK0CKCTL) to select a clock source.
   Also rewrite the BRGA0CMP[4:0] bits in the BRGA0 compare register (ACK0BRGA0CMP) to select a clock cycle for the baud rate generator.

3. Restart an output from the CK pin

   Rewrite the DCLK0 bit in the clock control register (ACK0CKC) to restart an output from the CK pin.

- Write $A5_H$ to the ACK0CKCPCMD register.
- Write 01_H to the ACK0CKC register.
- Write FE_H to the ACK0CKC register.
- Write 01_H to the ACK0CKC register.

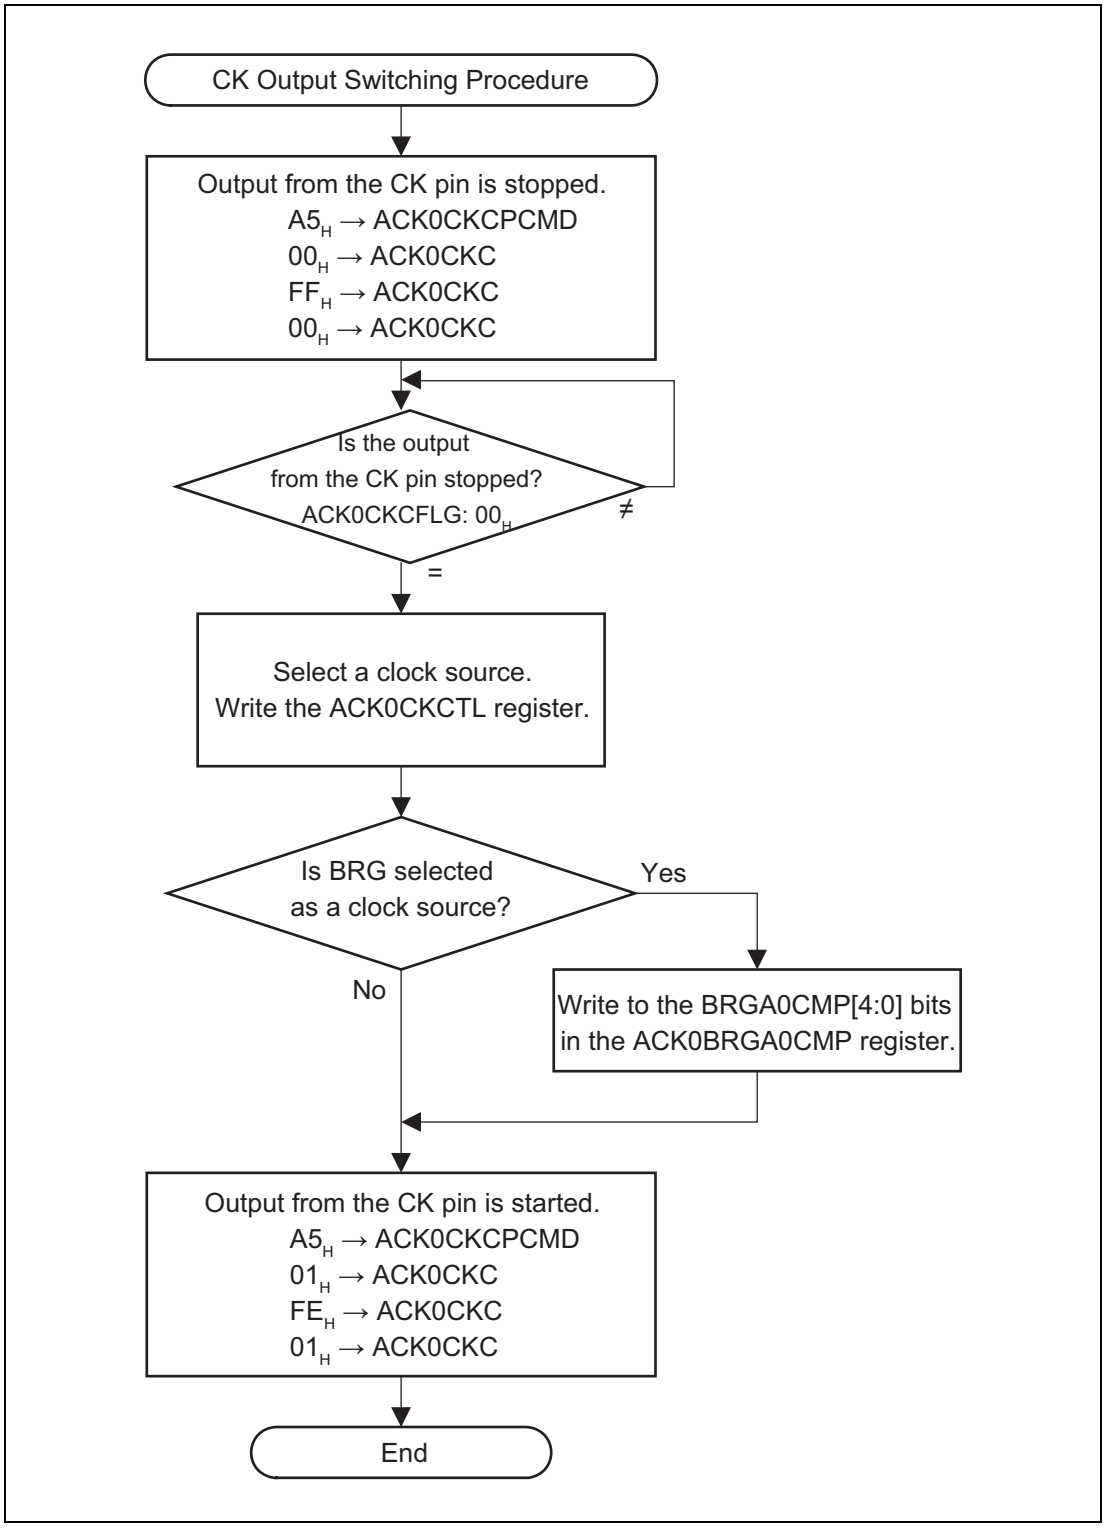

Figure 11.7 CK Output Switching Procedure

Section 12 Standby Controller

This product supports various power-down modes: two modes of power off standby mode and HALT mode, and module standby function that can stop peripheral modules. The power consumption of the LSI can be reduced by selecting a suitable mode for the application.

12.1 Features

12.1.1 Types of Power-Down Mode

Power-down modes are comprised of the modes and function as follows:

- Power off standby mode
  Only RAM retention is possible in this mode. Low leakage is realized by turning off the power outside of the LSI. The oscillation also stops.
  The transition occurs by asserting the $\overline{\text{RES}}$ pin and turning off the power (EVCC).
  The CPU in this state transits to the external reset state by a rising edge of the turned off power and securing the oscillation stabilization time.
- HALT mode
  When the HALT instruction is executed, the CPU transits to HALT mode and stops instruction execution.
  Each CPU can be controlled individually.
  The CPU returns from this state by the occurrence of a reset input, interrupt, or exception.
- Module standby
  This function stops the clock for peripheral macros to reduce the power consumption in accordance with register settings.
  Since peripheral modules are in operation after release from the reset state, it is recommended that the modules not to be used be set to the module stop state before clock gear-up.
  Modules which have been set in the module stop state should not be activated again. In such a case, proper operation cannot be guaranteed.

12.2 Operation

12.2.1 Power Off Standby Mode

The CPU transits to power-off standby mode when EVCC power is set to 0V after driving the $\overline{\text{RES}}$ pin to the low level. In power-off standby mode, leakage current can be reduced because the oscillator is stopped and the core power is turned off. For mid-range and low-end products with the EPT, the EPT controls VDD turn-off.

In power-off standby mode, the data in the RAM can be retained as long as SYSVCC is kept within the specified voltage range.
For the target RAMs, see **Section 35, RAM**.

For recovery from power-off standby mode, restore EVCC and VCC to the specified voltage to allow the CPU to return to the external reset state. Then negate the $\overline{\text{RES}}$ pin after securing the oscillation stabilization time to allow the CPU to return to the normal state.

Refer to **Section 37, Electrical Characteristics**, for the power-off sequences.

12.2.2 Module Standby Function

(1) Transition to the module standby state

Setting each bit in the module standby register to 1 can stop clock supply to each corresponding on-chip peripheral module.

It is recommended that the module standby state be set for power consumption reduction before clock gear-up (while the module is disabled).

The module standby register is protected from unauthorized writing due to incorrect program operation and the like.

For details, see **Section 12.3.6, MSRPCMD — MSR Protection Command Register**.

(2) Release from the module standby state

Set the LSI to the internal reset state for release from the module standby state.

Proper operation cannot be guaranteed when the module standby state which has been already set is released by writing 0 to the module standby register.

12.3 Register List

12.3.1 List of Registers

All registers can be accessed by CPU.

Table 12.1 Register Configuration

Address	Register name	Description	Access Width	Value after Reset	Access protection
FFF8 2C0C	EPTCNT	EPT control register	32	0000 0000_H	PROT0PHCMD
FFF8 3000	PROT0PHCMD	Protection command register	32	0000 0000_H	
FFF8 3004	PROT0PS	Protection command status register	32	0000 0000_H	
FFC0 5000	MSRTSG	Module standby register - TSG2	8	00_H	MSRPCMD
FFC0 5004	MSRTAPA	Module standby register - TAPA	8	00_H	MSRPCMD
FFC0 5008	MSROSTM	Module standby register - OSTM	8	00_H	MSRPCMD
FFC0 500C	MSRWDTA	Module standby register - WDTA	8	00_H	MSRPCMD
FFC0 5010	MSRPIC	Module standby register - PIC	8	00_H	MSRPCMD
FFC0 5014	MSRRCAN	Module standby register - RS-CAN	8	00_H	MSRPCMD
FFC0 5018	MSRFRAY	Module standby register - FlexRay	8	00_H	MSRPCMD

FFC0 5070	MSRPCMD	MSR protection command register	8	—	
FFC0 5074	MSRPS	MSR protection status register	8	00_H	

12.3.2 EPTCNT — EPT Control Register

This register enables or disables the EPT.
This register is protected by the PROT0PHCMD register.
This register can only be reset by an external reset signal.

Access: This register can be read/written in 32-bit units.
Address: FFF8 2C0C
Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EPT CNT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 12.2 EPTCNT Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	EPTCNT	0: EPT is enabled. 1: EPT is disabled.

When the EPT is not used, the EPT control can be powered down by setting 1 in the register above, resulting in power consumption reduction.

12.3.3 PROT0PHCMD — Protection Command Register

This register is used as a special sequence register.

This register can be reset by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 3000

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	PCMD[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12.3 PROT0PHCMD Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved The read value is always 0. When writing, write 0.
7 to 0	PCMD[7:0]	Writing protection command register

Writing to the write-protected registers is only possible with the protection unlock sequence described below.

1. Write the fixed value (0000 $00A5_H$) to register PROT0PHCMD.
2. Write the new setting to the write-protected register. Write the value after a reset to the reserved bits.
3. Write the bitwise inverse of the setting value to the same register as in step 2. Write the inverse of the value after a reset to the reserved bits.
4. Write the new setting to the same register as in step 2. Write the value after a reset to the reserved bits.

A value can only be written to a write-protected register by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting is not written to the write-protected register, and the PROT0PS.PROTERR bit is set to 1. (Although this is not a requirement, but you can confirm if the values set to the targeted register was correctly written by checking that the setting of the PROT0PS.PROTERR bit is 0 after step 4).

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1 to 4 of the sequence, the protection function operates as follows:

Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*1, writing to the protected register fails and the PROT0PS.PROTERR bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence in progress does not lead to failure.

Note 1. PROT0PHCMD applies to the registers allocated to the addresses in the range from FFF8 2410_H to FFF8 3004_H.
For the register names, register symbols, and module names, see Appendix, List of Registers. see **Appendix, List of Registers**.

12.3.4 PROT0PS — Protection Command Status Register

This register is used as a status register of special sequence registers. This register can be reset by either an internal or an external reset signal.

Access: This register can be read in 32-bit units.

Address: FFF8 3004

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PROT ERR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.4 PROT0PS Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved The read value is always 0.
0	PROTERR	Protection error flag

12.3.5 Module Standby Registers

The module standby registers can be read/written in 8-bit units and control each module operation in power-down mode.

12.3.5.1 MSRTSG — Module Standby Register – TSG2

Access: This register can be read/written in 8-bit units.

Address: FFC0 5000

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MS_TSG21	MS_TSG20
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.5 MSRTSG Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
1	MS_TSG21	Setting this bit to 1 stops clock supply to TSG21. 0: TSG21 is operating. 1: Clock supply to TSG21 is stopped.
0	MS_TSG20	Setting this bit to 1 stops clock supply to TSG20. 0: TSG20 is operating. 1: Clock supply to TSG20 is stopped.

12.3.5.2 MSRTAPA — Module Standby Register – TAPA

Access: This register can be read/written in 8-bit units.

Address: FFC0 5004

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MS_TAPA3	MS_TAPA2	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R	R

Table 12.6 MSRTAPA Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
3	MS_TAPA3	Setting this bit to 1 stops clock supply to TAPA3. 0: TAPA3 is operating. 1: Clock supply to TAPA3 is stopped.
2	MS_TAPA2	Setting this bit to 1 stops clock supply to TAPA2. 0: TAPA2 is operating. 1: Clock supply to TAPA2 is stopped.
1, 0	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.

12.3.5.3 MSROSTM — Module Standby Register – OSTM

Access: This register can be read/written in 8-bit units.

Address: FFC0 5008

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	MS_OSTM2	MS_OSTM1	MS_OSTM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 12.7 MSROSTM Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
2	MS_OSTM2	Setting this bit to 1 stops clock supply to OSTM2. 0: OSTM2 is operating. 1: Clock supply to OSTM2 is stopped.
1	MS_OSTM1	Setting this bit to 1 stops clock supply to OSTM1. 0: OSTM1 is operating. 1: Clock supply to OSTM1 is stopped.
0	MS_OSTM0	Setting this bit to 1 stops clock supply to OSTM0. 0: OSTM0 is operating. 1: Clock supply to OSTM0 is stopped.

12.3.5.4 MSRWDTA — Module Standby Register – WDTA

Access: This register can be read/written in 8-bit units.

Address: FFC0 500C

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MS_WDTA1	MS_WDTA0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.8 MSRWDTA Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
1	MS_WDTA1	Setting this bit to 1 stops clock supply to WDTA1. 0: WDTA1 is operating. 1: Clock supply to WDTA1 is stopped.
0	MS_WDTA0	Setting this bit to 1 stops clock supply to WDTA0. 0: WDTA0 is operating. 1: Clock supply to WDTA0 is stopped.

12.3.5.5 MSRPIC — Module Standby Register – PIC

Access: This register can be read/written in 8-bit units.

Address: FFC0 5010

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MS_PIC2	MS_PIC1
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.9 MSRPIC Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
1	MS_PIC2	Setting this bit to 1 stops clock supply to PIC2. 0: PIC2 is operating. 1: Clock supply to PIC2 is stopped.
0	MS_PIC1	Setting this bit to 1 stops clock supply to PIC1. 0: PIC1 is operating. 1: Clock supply to PIC1 is stopped.

12.3.5.6 MSRRCAN — Module Standby Register – RS-CAN

Access: This register can be read/written in 8-bit units.

Address: FFC0 5014

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MS_RCAN
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.10 MSRRCAN Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_RCAN	Setting this bit to 1 stops clock supply to RS-CAN. 0: RS-CAN is operating. 1: Clock supply to RS-CAN is stopped.

12.3.5.7 MSRFRAY — Module Standby Register – FlexRay

Access: This register can be read/written in 8-bit units.

Address: FFC0 5018

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	MS_FRAY	—	—	—	MS_DSAD2_7
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R	R	R/W

Table 12.11 MSRFRAY Register Contents

Bit Position	Bit Name	Function
7 to 5	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
4	MS_FRAY	Setting this bit to 1 stops clock supply to FlexRay. 0: FlexRay is operating. 1: Clock supply to FlexRay is stopped.
3 to1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_DSAD2_7	Setting this bit to 1 stops clock supply to channels 2 to 7 of ΔΣAD. 0: ΔΣAD is operating. 1: Clock supply to channels 2 to 7 is stopped.

12.3.5.8 MSRRLIN — Module Standby Register – RLIN2

Access: This register can be read/written in 8-bit units.

Address: FFC0 501C

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MS_RLIN0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.12 MSRRLIN Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_RLIN0	Setting this bit to 1 stops clock supply to RLIN0. 0: RLIN0 is operating. 1: Clock supply to RLIN0 is stopped.

12.3.5.9 MSRSCI — Module Standby Register – SCI3

Access: This register can be read/written in 8-bit units.

Address: FFC0 5020

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MS_SCI3	MS_SCI2	MS_SCI1	MS_SCI0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 12.13 MSRSCI Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
3	MS_SCI3	Setting this bit to 1 stops clock supply to SCI3. 0: SCI3 is operating. 1: Clock supply to SCI3 is stopped.
2	MS_SCI2	Setting this bit to 1 stops clock supply to SCI2. 0: SCI2 is operating. 1: Clock supply to SCI2 is stopped.
1	MS_SCI1	Setting this bit to 1 stops clock supply to SCI1. 0: SCI1 is operating. 1: Clock supply to SCI1 is stopped.
0	MS_SCI0	Setting this bit to 1 stops clock supply to SCI0. 0: SCI0 is operating. 1: Clock supply to SCI0 is stopped.

12.3.5.10 MSRCSIH — Module Standby Register – CSIH

Access: This register can be read/written in 8-bit units.

Address: FFC0 5024

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MS_CSIH3	MS_CSIH2	MS_CSIH1	MS_CSIH0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 12.14 MSRCSIH Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
3	MS_CSIH3	Setting this bit to 1 stops clock supply to CSIH3. 0: CSIH3 is operating. 1: Clock supply to CSIH3 is stopped.
2	MS_CSIH2	Setting this bit to 1 stops clock supply to CSIH2. 0: CSIH2 is operating. 1: Clock supply to CSIH2 is stopped.
1	MS_CSIH1	Setting this bit to 1 stops clock supply to CSIH1. 0: CSIH1 is operating. 1: Clock supply to CSIH1 is stopped.
0	MS_CSIH0	Setting this bit to 1 stops clock supply to CSIH0. 0: CSIH0 is operating. 1: Clock supply to CSIH0 is stopped.

12.3.5.11 MSRSAD — Module Standby Register – SAR AD

Access: This register can be read/written in 8-bit units.

Address: FFC0 5028

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MS_SARAD1	MS_SARAD0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.15 MSRSAD Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
1	MS_SARAD1	Setting this bit to 1 stops clock supply to SAR-AD1. 0: SAR-AD1 is operating. 1: Clock supply to SAR-AD1 is stopped.
0	MS_SARAD0	Setting this bit to 1 stops clock supply to SAR-AD0. 0: SAR-AD0 is operating. 1: Clock supply to SAR-AD0 is stopped.

12.3.5.12 MSRDAD — Module Standby Register – ΔΣAD

Access: This register can be read/written in 8-bit units.

Address: FFC0 502C

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MS_DSAD
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.16 MSRDAD Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_DSAD	Setting this bit to 1 stops clock supply to ΔΣAD. 0: ΔΣAD is operating. 1: Clock supply to ΔΣAD is stopped.

12.3.5.13 MSRATU — Module Standby Register – ATU-IV

Access: This register can be read/written in 8-bit units.

Address: FFC0 5030

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MS_ATU
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.17 MSRATU Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_ATU	Setting this bit to 1 stops clock supply to ATU. 0: ATU is operating. 1: Clock supply to ATU is stopped.

12.3.5.14 MSRAPA — Module Standby Register – APA

Access: This register can be read/written in 8-bit units.

Address: FFC0 5034

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MS_APA
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.18 MSRAPA Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_APA	Setting this bit to 1 stops clock supply to APA. 0: APA is operating. 1: Clock supply to APA is stopped.

12.3.5.15 MSRDFE — Module Standby Register – DFE

Access: This register can be read/written in 8-bit units.

Address: FFC0 5038

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MS_DFE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.19 MSRDFE Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_DFE	Setting this bit to 1 stops clock supply to DFE. 0: DFE is operating. 1: Clock supply to DFE is stopped.

12.3.5.16 MSRRHSB — Module Standby Register – RHSB

Access: This register can be read/written in 8-bit units.

Address: FFC0 503C

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MS_RHSB1	MS_RHSB0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.20 MSRRHSB Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
1	MS_RHSB1	Setting this bit to 1 stops clock supply to RHSB1. 0: RHSB1 is operating. 1: Clock supply to RHSB1 is stopped.
0	MS_RHSB0	Setting this bit to 1 stops clock supply to RHSB0. 0: RHSB0 is operating. 1: Clock supply to RHSB0 is stopped.

12.3.6 MSRPCMD — MSR Protection Command Register

The MSRPCMD register is used for protection against writing operation to the registers which may have a material effect on the system so that the application system is not incorrectly stopped due to program malfunction and the like.

The values of the module standby registers can be rewritten by a sequence specified in advance and unauthorized writing operation to them is eliminated.

Access: This register can be written in 8-bit units. The read value is undefined.

Address: FFC0 5070

Value after reset: Undefined

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—
Value after reset	—	—	—	—	—	—	—	—
R/W	W	W	W	W	W	W	W	W

Writing to the write-protected registers is only possible with the protection unlock sequence described below.

1. Write the fixed value ($A5_H$) to register MSRPCMD.
2. Write the new setting to the write-protected register. Write the value after a reset to the reserved bits.
3. Write the bitwise inverse of the setting value to the same register as in step 2. Write the inverse of the value after a reset to the reserved bits.
4. Write the new setting to the same register as in step 2. Write the value after a reset to the reserved bits.

A value can only be written to a write-protected register by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting is not written to the write-protected register, and the MSRPS.MSRPRERR bit is set to 1.
(Although this is not a requirement, you can confirm if the values set in the targeted register was correctly written by checking that the setting of the MSRPS.MSRPRERR bit is 0 after step 4.)

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1 to 4 of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*1, writing to the protected register fails and the MSRPS.MSRPRERR bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. “Another register in the same module” indicates a register under the same module name as that containing the write-protected register. For the module names of the registers, see **Appendix, List of Registers**.

12.3.7 MSRPS — MSR Protection Status Register

The MSRPS register is the one to which the MSRPRERR flag indicating a protection error occurrence is allocated.

When an operation to write to the module standby register is not performed in a correct sequence including command register settings, such writing to the target register does not proceed. A protection error occurs and the status flag (MSRPRERR) is set to 1.

Access: This register can be read in 8-bit units.

Address: FFC0 5074

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MSRPRERR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 12.21 MSRPS Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0.
0	MSRPRERR	Protection error detection 0: Protection error does not occur. 1: Protection error occurs.

Section 13 Clocked Serial Interface H (CSIH)

This section contains a generic description of the Clocked Serial Interface H (CSIH).

13.1 CSIH Features

Channels

This microcontroller has the following number of channels of the Clocked Serial Interface H.

Table 13.1 Channels of CSIH

Clocked Serial Interface H	RH850/E1M-S
Number of channels	4
Name	CSIH0, CSIH1, CSIH2, CSIH3

Index n

Throughout this section, the individual channels of a Clocked Serial Interface H is identified by the index “n” (n = 0 to 3), for example, CSIHnCTL0 for the CSIHn control register 0.

Index x

The Clocked Serial Interface H has up to 6 chip select signals. Throughout this section, the individual chip select signals are identified by the index “x”; thus a certain chip select signal is denoted as CSIHnTCSSx. The number of chip select signals for each channel of CSIH is given in the following table.

Table 13.2 Number of CSIH Chip Select Signals

CSIHn Channel	RH850/E1M-S Chip Select Index
CSIH0	CSIH0TCSSx (x = 0 to 5)
CSIH1	CSIH1TCSSx (x = 0 to 3)
CSIH2	CSIH2TCSSx (x = 0 to 3)
CSIH3	CSIH3TCSSx (x = 0 to 3)

Register addresses

All CSIHn register addresses are given as address offsets to the individual base address <CSIHn_base>.
The base address <CSIHn_base> of each CSIHn is listed in the following table.

Table 13.3 Register Base Addresses <CSIHn_base>

CSIHn Channel	<CSIHn_base> Address
CSIH0	FFD8 0000_H
CSIH1	FFD8 2000_H
CSIH2	FFD8 4000_H
CSIH3	FFD8 6000_H

Data consistency check

The following table lists the port pins on which CSIHnTSO pin functions are multiplexed and the availability of data consistency checking. See **Section 13.5.12, Error Detection** for details about data consistency checking.

Table 13.4 CSIHn Data Consistency Checking and Port Pins

CSIHn I/O Port Signal	Function	Alternative Function	Data Consistency Check
CSIH0			
CSIH0TSO	P0_1	ALT_OUT5	Available
CSIH1			
CSIH1TSO	P13_1	ALT_OUT6	Available
CSIH1TSO	P0_7	ALT_OUT6	Available
CSIH2			
CSIH2TSO	P4_8	ALT_OUT6	Available
CSIH2TSO	P0_12	ALT_OUT7	Available
CSIH3			
CSIH3TSO	P4_1	ALT_OUT7	Available
CSIH3TSO	P7_1	ALT_OUT6	Available

13.2 Notes on Pin Combination

CSIH uses multiple pins for one channel and the pins should be used in groups as given in the following table.

Group		CSIHn TSCK	CSIHn TSI	CSIHn TSO	CSIHn TCSS0	CSIHn TCSS1	CSIHn TCSS2	CSIHn TCSS3	CSIHn $\overline{\text{TSSI}}$	CSIHn TRY
CSIH1	A	P0_8	P0_6	P0_7	P0_9	P0_10	P0_11	P0_12	P0_13	P0_14
	B	P13_2	P13_0	P13_1	P13_3	P13_4	—	—	—	—
CSIH2	C	P4_9	P4_7	P4_8	P4_10	P4_11	P4_12	P4_13	P4_3	P4_4
	D	P0_13	P0_11	P0_12	P0_14	P1_0	P1_1	P1_2	P1_3	P1_4
CSIH3	E	P4_2	P4_0	P4_1	P4_3	P4_4	P4_5	P4_6	P4_7	P4_8
	F	P7_2	P7_0	P7_1	P7_3	P7_4	P7_5	P7_6	P7_7	P7_8

13.3 Function Overview

Overview of Functions

- Three-wire serial synchronous data transfer
- Master mode and slave mode selectable
- Multiple slaves configuration plus RCB (Recessive Configuration for Broadcasting) thanks to up to six configurable chip select output signals
- Built-in slave select function (slave select input signal ($\overline{\text{CSIHnTSSI}}$))
- Built-in baud rate generator
- Baud rate adjustable; in slave mode determined by input clock
- Maximum transmission speed:
  - in master mode: PCLK/8: 10 Mbps
  - in slave mode: PCLK/20: 4 Mbps
- Phase of clock and data selectable
- Data transfer with MSB or LSB first selectable
- Transfer data length selectable from 2 to 16 bits in 1-bit units
- EDL (Extended Data Length) function for transferring data with more than 16 bits
- Three selectable transfer modes:
  - transmit-only mode
  - receive-only mode
  - transmit/receive mode
- Built-in handshake function
- Error detection (data consistency check, parity, and overrun)
- Support of job concept
- JOB enable control bit for AUTOSAR is provided
- LBM (Loop Back Mode) function for self-test
- Enforced chip select idle setting

The block diagram shows the main components of the CSIH.

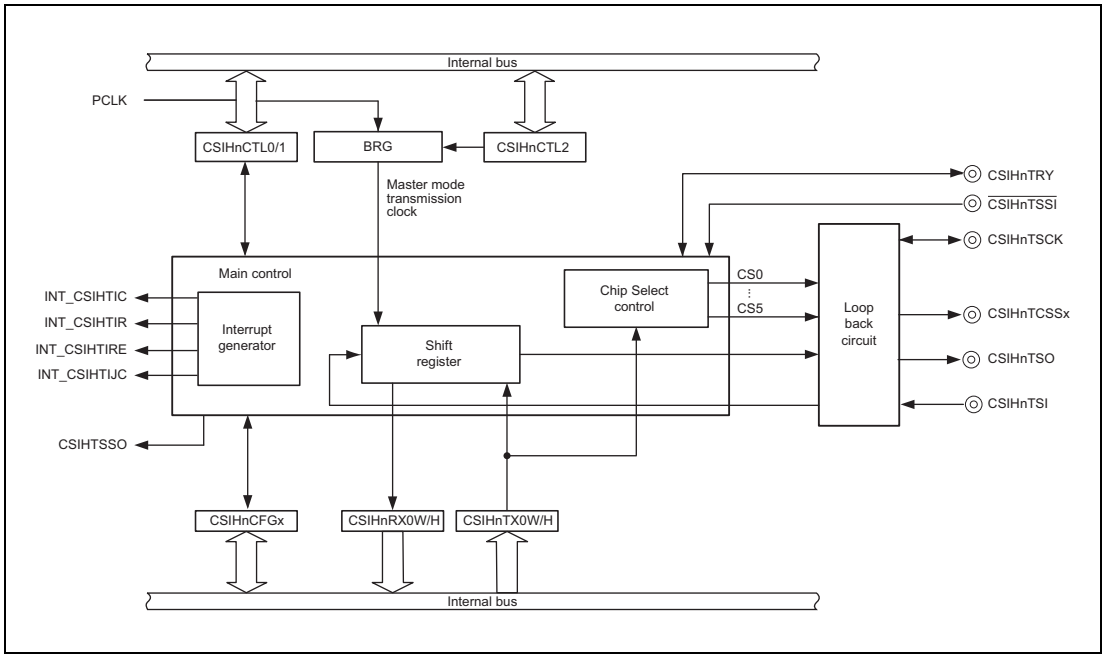

Figure 13.1 CSIH Block Diagram

In master mode, the transmission clock CSIHnTSCK is generated by the built-in baud rate generator (BRG). In slave mode, the transmission clock is provided from an external source.

The loop back circuit disconnects the CSIH completely from the ports and supports internal self-test.

CAUTION

This section describes the following modes:

- **The “operating mode” separates between master and slave mode. In this context, only a master can control and communicate with several slaves (for details see Section 13.5.1, Operating Modes (master/slave)).**
- **The “job mode” is related to the AUTOSAR job concept (for details see Section 13.5.3, Chip Selection (CS) Features, (3) Job concept).**
- **The “data transfer mode” specifies the kind of the communication – transmit-only, receive only, or transmit/receive (for details see Section 13.5.6, Data transfer modes).**

13.4 List of the Usage Notes

Table 13.5 Important Points for Register and Bit Operation (1/2)

Register name	Bit name	Contents
CSIHnCTL0	CSIHnPWR	If this bit is cleared during communication, ongoing communication is aborted.
CSIHnCTL0	CSIHnTXE CSIHnRXE	Do not modify any of these bits while CSIHnCTL0.CSIHnPWR = 0. (These bits and the CSIHnCTL0.CSIHnPWR bit can be modified at the same time.) Do not modify these bits while CSIHnSTR0.CSIHnTSF = 1 because ongoing communication is aborted and operation of this setting is not assured.
CSIHnCTL0	CSIHnJOBE	Do not modify this bit while CSIHnCTL0.CSIHnPWR = 0. This bit is only valid when CSIHnCTL1.CSIHnEDLE = 1. Setting this bit is prohibited in slave mode.
CSIHnCTL0	CSIHnMBS	Do not modify this bit while CSIHnCTL0.CSIHnPWR = 0. (This bit and the CSIHnCTL0.CSIHnPWR bit can be modified at the same time.) Modification of this bit is only allowed while CSIHnSTR0.CSIHnTSF = 0.
CSIHnCTL1	CSIHnCKR	Modification of the value of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. If CS is not used, use this bit instead of CSIHnCFG0-5.CSIHnCKPx. CSIHnCFG0-5.CSIHnCKP must be set to 0. This bit must be used in slave mode.
CSIHnCTL1	CSIHnSLIT CSIHnCSL7-0 CSIHnDCS CSIHnCSRI CSIHnEDLE CSIHnHSE	Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0.
CSIHnCTL1	CSIHnJE CSIHnLBM	Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. Setting these bits prohibited in slave mode.
CSIHnCTL1	CSIHnSSE	Modification of the value of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. Setting this bit to 1 is prohibited in master mode.
CSIHnCTL1	CSIHnSIT	Modification of the value of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. This bit is only valid in master mode. In slave mode, no delay is generated.
CSIHnCTL2	CSIHnPRS2-0	Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. Max baud rate configuration is as follows. • Master mode: PCLK/8 • Slave mode: PCLK/20
CSIHnSTR0	CSIHnTSF	Writing is prohibited. Only reading is effective.
CSIHnSTR0	CSIHnDCE CSIHnPE CSIHnOVE	These bits are Initialized when CSIHnCTL0.CSIHnPWR = 0 →1 or CSIHnCTL0.CSIHnPWR = 1 → 0.
CSIHnCFGx	CSIHnBRSSx1-0 CSIHnRCBx CSIHnIDLx CSIHnIDx2-0 CSIHnHDx3-0 CSIHnINx3-0 CSIHnSPx3-0	Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. Set these bits to 0 in slave mode.
CSIHnCFGx	CSIHnPSx1-0 CSIHnDLSx3-0 CSIHnDIRx CSIHnDAPx	Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. In slave mode, the setting of the CSIHnCFG0 is used. Therefore, all these bits of CSIHnCFG 1 to 5 must be set to 0.

Table 13.5 Important Points for Register and Bit Operation (2/2)

Register name	Bit name	Contents
CSIHnCFGx	CSIHnCKPx	Modification of the value of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. Since the CSIHnCTL1.CSIHnCKR bit is used in slave mode, set this bit to 0. If CS is not used, use CSIHnCTL1.CSIHnCKR instead of this bit and this bit must be set to 0.
CSIHnTX0W	CSIHnEOJ	This bit is only available while CSIHnCTL1.CSIHnEDLE = 1. When CSIHnCTL1.CSIHnJE = 0, the value is ignored even if the read value is 1. In slave mode, this bit must be set to “0”.
CSIHnTX0W	CSIHnEDL	This bit is only available while CSIHnCTL1.CSIHnEDLE = 1. When CSIHnCTL1.CSIHnEDLE = 0, the value is ignored even if the read value is 1.
CSIHnTX0W	CSIHnCS7-0	Setting these bits to FF_H is prohibited in master mode. These bits must be set to FE_H in slave mode.
CSIHnTX0W CSIHnTX0H		Write access to these bits is prohibited when CSIHnCTL0.CSIH0TXE = CSIHnCTL0.CSIH0RXE = 0.
CSIHnRX0W CSIHnRX0H		These bits are initialized when CSIHnCTL0.CSIHnPWR = 0 →1 or CSIHnCTL0.CSIHnPWR = 1 → 0.
CSIHnBRSi		Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. The maximum baud rates are determined in combination with the setting of the CSIHnCTL2.PRS2-0 bits and are as follows. • Master mode: PCLK/8 • Slave mode: PCLK/20

13.5 Functional Description

The Clocked Serial Interface uses three signals for communication:

- Transmission clock CSIHnTSCK (output in master mode, input in slave mode)
- Data output signal CSIHnTSO
- Data input signal CSIHnTSI

Additional signals are available for external control and monitoring.

- $\overline{\text{CSIHnTSSI}}$: Slave select input signal
- CSIHnTRY: Handshake signal
- CSIHnTCSSx: Chip select signals

Data transmission is bit-wise and serial, and synchronous to the transmission clock.

The following table shows the most important registers for setting up the CSIH.

Table 13.6 Main Registers of CSIH

Register	Function
CSIHnCTL0	Enables/disables transmission clock, and permits/ prohibits data transmission and data reception. Defines end-of-job behavior and enables/disables buffering (bypass of the buffer).
CSIHnCTL1	Controls options like interrupt timing, extended data length, job feature, data consistency check, loop-back mode, handshake, etc.
CSIHnCTL2	Selects master/slave mode, and the baud rate of the internal generator (BRG) in master mode
CSIHnBRSi	Registers to configure the baud rate for each chip select signal
CSIHnCFGx	Registers to configure the communication protocol for each chip select signal

13.5.1 Operating Modes (master/slave)

For a particular CSIH module, the master or slave mode determines the source of the serial clock.

(1) Master mode

In master mode, the serial transmission clock is generated by the internal baud rate generator (BRG) and provided to the slave(s) by signal CSIHnTSCK.

Master mode is enabled by setting CSIHnCTL2.CSIHnPRS[2:0] to any value other than but 111_B. In master mode, the BRG frequency can be set by combining the CSIHnCTL2.CSIHnPRS[2:0] bits and the CSIHnBRSi.CSIHnBRSi[11:0] bits.

Chip select signals

In master mode, one or several chip select signals can be used. If several slaves are connected to the master, the chip select signals can be used to address one or several of the slaves. Only a selected slave is then enabled for communication.

The communication protocol and additional parameters are stored separately for each chip select signal. This makes it possible to adapt the data transfer individually to the requirements of each slave. For details, see **Section 13.5.3, Chip Selection (CS) Features**.

Clock default setting

The default level of CSIHnTSCK depends on the clock inverse bit CSIHnCTL1.CSIHnCKR of CSIHnTSCK: It is high level when CSIHnCTL1.CSIHnCKR = 0, and is low level when CSIHnCTL1.CSIHnCKR = 1.

The example below shows the communication in master mode for a data length of 8 bits, CSIHnCTL1.CSIHnCKR = 0, CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0, and MSB first:

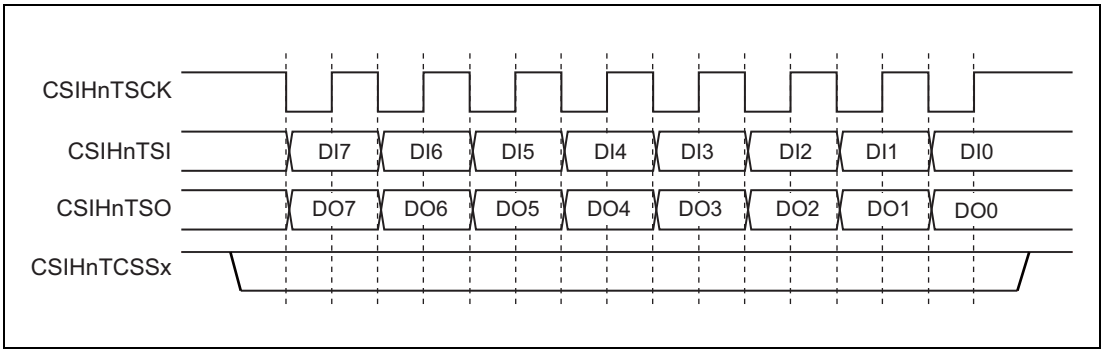

Figure 13.2 Transmission/Receive in Master Mode

(2) Slave mode

In slave mode, another device is the communication master and provides the transmission clock. Send/ receive operation normally starts as soon as a clock signal is detected.

Slave mode is selected by setting the CSIHnCTL2.CSIHnPRS[2:0] bits to 111_B.

In slave mode, the transmission protocol setting of the CSIHnCFG0 register is enabled (setting of the CSIHnCFG1 to CSIHnCFGx registers is disabled).

- CSIHnPS0[1:0]: parity usage
- CSIHnDLS0[3:0]: data length selection
- CSIHnDIR0: data direction
- CSIHnCKP0, CSIHnDAP0: clock and data phase

NOTE

When using slave mode, the baud rate generator (BRG) should be disabled by setting the CSIHnBRSi[11:0] bits in CSIHnBRSi to 000_H.

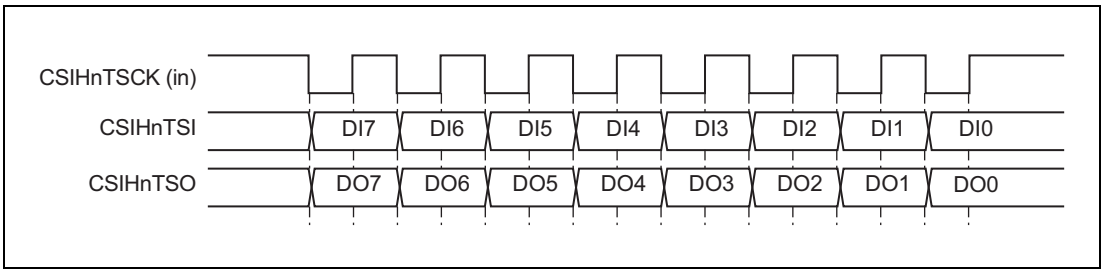

Figure 13.3 Transmission/Receive in Slave Mode

13.5.2 Master/Slave Connections

(1) One master and one slave

The following figure illustrates the connections between one master and one slave.

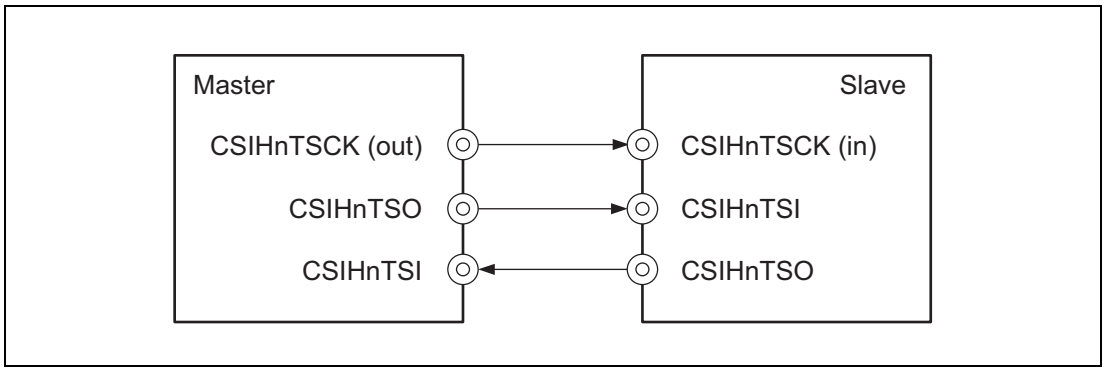

Figure 13.4 Direct Master/Slave Connection

(2) One master and multiple slaves

The following figure illustrates the connections between one master and multiple slaves. In this example, the master provides one chip select (CS) signal to each of the slaves. This signal is connected to the slave select input $\overline{\text{CSIHnTSSI}}$ of the slave.

The $\overline{\text{CSIHnTSSI}}$ signal can be enabled/disabled by the CSIHnCTL1.CSIHnSSE bit.

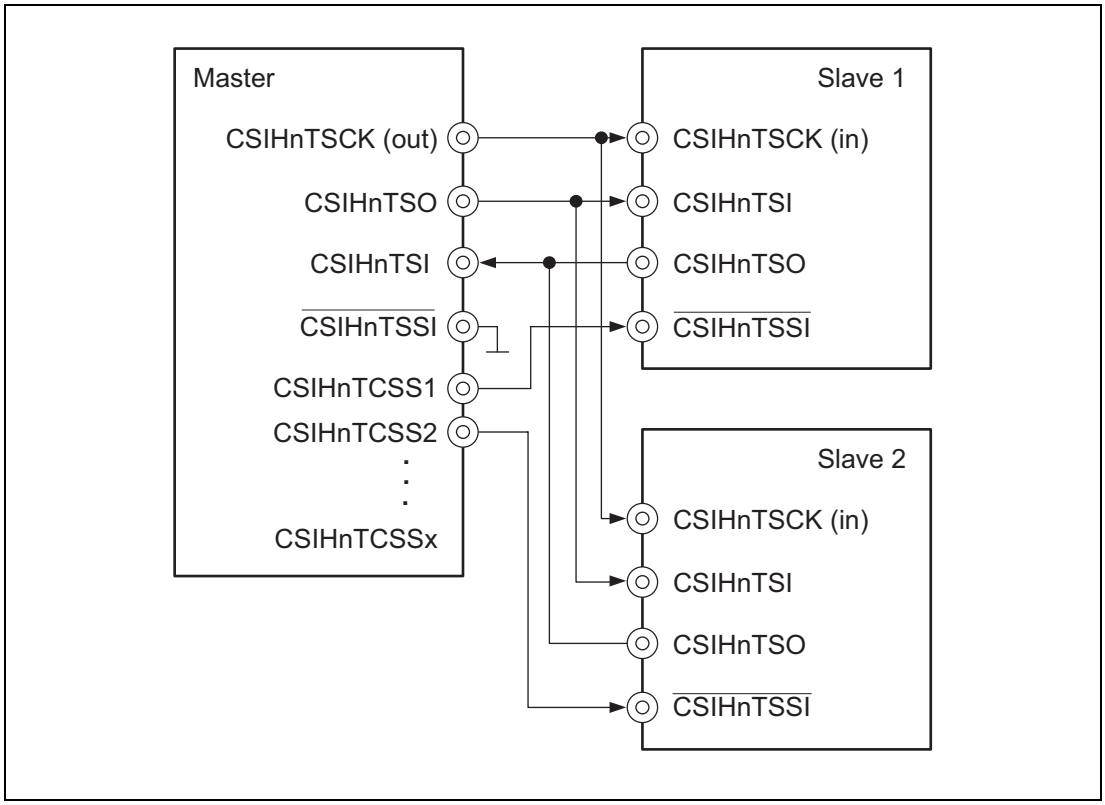

Figure 13.5 Master to Multiple Slaves Connection

By default, the chip select level is active low. That means, a slave is selected (enabled) as a CSIH slave when its $\overline{\text{CSIHnTSSI}}$ signal has low level. However, to adapt the CS to other devices, the output level of each chip select signal can also be programmed to be active high.

If a slave is not selected, it will neither receive nor transmit data. In addition, while transmit-only mode or transmit/receive mode is set (CSIHnCTL0.CSIHnTXE = 1), its output CSIHnTSO of a slave that is not selected is set to input mode in order to avoid interference with the output of another slave that was selected.

13.5.3 Chip Selection (CS) Features

The chip select signal, CSIHnTCSSx can be used by the master to select one or several slaves for communication.

(1) Configuration registers

The parameters for each chip select signal CSIHnTCSSx are defined in the corresponding configuration register CSIHnCFGx. The parameters include the communication protocol and additional CS parameters.

The communication protocol specifies:

- Data length: The number of bits to be sent or received.
- Transfer direction: MSB or LSB first.
- Parity usage: Odd, even, 0 parity or none.
- Clock phase and data phase.

Additional parameters for each chip select signal that is only available in master mode are:

- Prescaler selection of the baud rate generator separately for each chip select signal
- Chip select priority: Separates between “dominant” and “recessive” chip select signals. The priority applies if two or more chip selects signals with different configurations are simultaneously activated for message broadcasting. In this case, the configuration that is set as dominant is used.

The principle is also called “Recessive Configuration for Broadcasting” (RCB).

CAUTION

It is forbidden to specify several chip select signals as dominant with different configurations unless all dominant chip selects have the same configuration.

- Chip select timing:
  - Setup time T_{setup}: The time from setting the CS signal active to starting data output.
  - Inter-data time T_{inter}: The time between data and the next data while the same CS signal is active.
  - Hold time T_{hold}: Hold time of CS active level before changing the CS.
  - Idle time T_{idle}: Inactive time after terminating a CS signal or after every data transfer to the same CSx.

The CS timings of the setup time, the inter-data time, the hold time, and the idle time are illustrated in the figure below. When the CSIHnCFGx.CSIHnIDLx bit is set to 1, idle time is inserted every transfer regardless of the CS signal.

Figure 13.6 provides an example when the default CSIHnTCSS1 and CSIHnTCSS2 signals are active low (CSIHnCTL1.CSIHnCSL1 bit = 0, CSIHnCTL1.CSIHnCSL2 bit = 0). The active level can be specified individually for each CS.

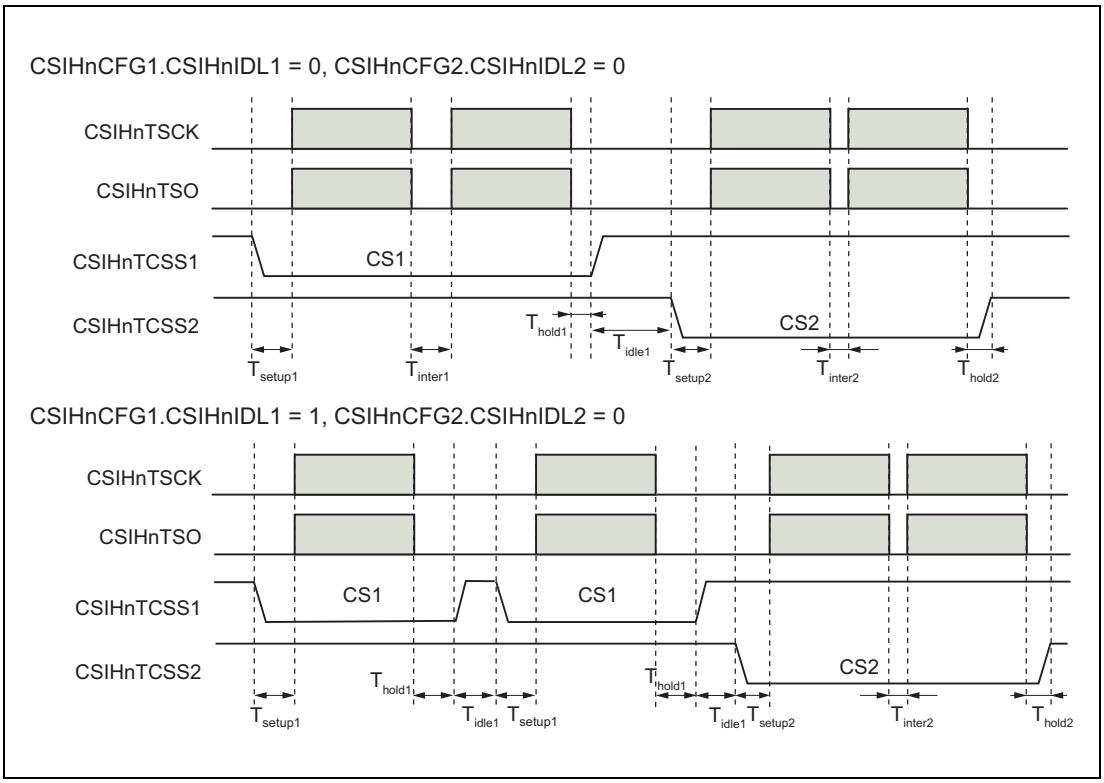

Figure 13.6 Chip Select Timings

Note that each CS signal can have a different value for setup, inter-data time, hold time, and idle time.

A particular chip select signal is activated by setting the appropriate bit in the transmission register CSIHnTX0W.CSIHnCS[7:0].

CSIHnRX0W.CSIHnCS[7:0] in the reception register indicates the chip select signal associated with the received data.

(2) CS example

The following figure shows an example of two consecutive data transmissions.

The first communication uses CS0 to communicate with one single slave. The second enables CS0 and CS1 to broadcast a message to two slaves. The priority of CS0 is set to “recessive: low priority”, the priority of CS1 to “dominant: high priority”.

Therefore, the second communication is conducted by using the CS1 setting specified in the dominant.

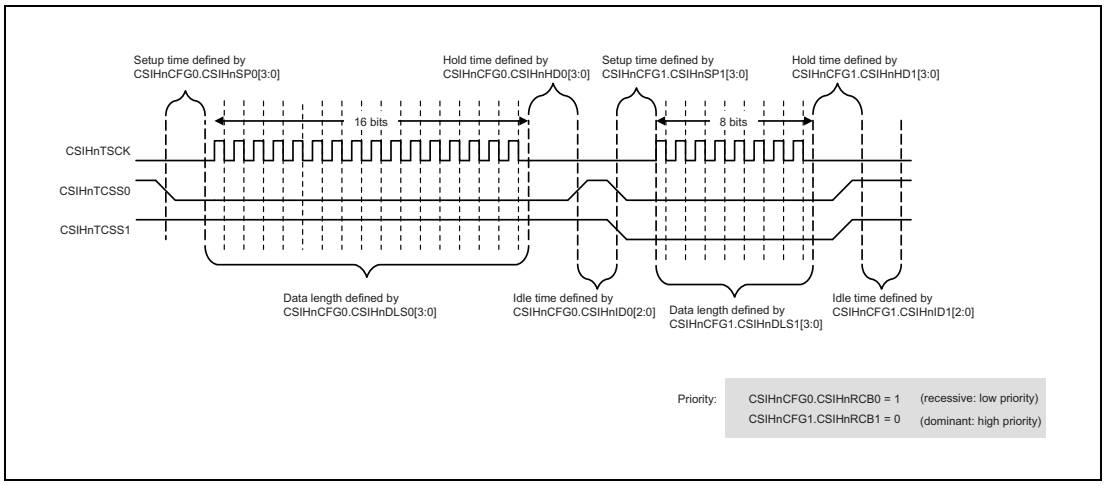

Figure 13.7 Chip Select and RCB Example

(3) Job concept

In terms of CSIH, a job consists of a number of data that are transferred.

Job mode enable

The job mode can only be enabled in master mode. The job mode is enabled and disabled by CSIHnCTL1.CSIHnJE, while the CSIH is disabled by CSIHnCTL0.CSIHnPWR = 0.

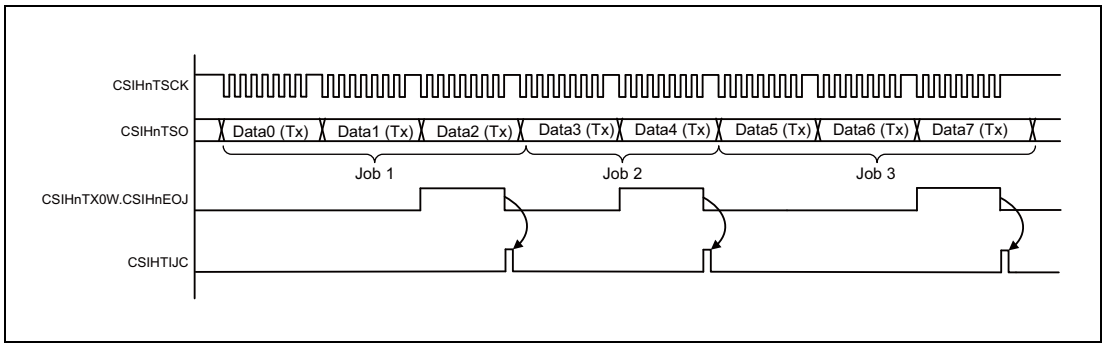

Figure 13.8 Job Examples

A job ends by transmitting data with the end-of-job bit set, i.e. data with CSIHnTX0W.CSIHnEOJ = 1.

A communication stop can be specified to occur after a job has finished. This is done by setting CSIHnCTL0.CSIHnJOBE. When CSIHnJOBE is set, the communication continues until data is sent, for which the CSIHnEOJ bit was set. After this data is sent, the communication is stopped and the job completion interrupt INT_CSIHTIJC is generated.

13.5.4 Chip Select Timing Details

(1) Changing the clock phase

The serial clock level specified by CSIHnCFGx.CSIHnCKPx may be changed when communication is disabled. The minimum value for idle time is 0.5 of a cycle of the transmission clock (CSIHnTSCK) when the clock phases are the same, and one cycle when the phases are different.

If the idle time is set to 0.5 transmission clock periods (in CSIHnCFGx.CSIHnIDx[2:0]) and two consecutive data are sent with different CSIHnCFGx.CSIHnCKPx configuration, the idle time is automatically extended to one period of CSIHnTSCK.

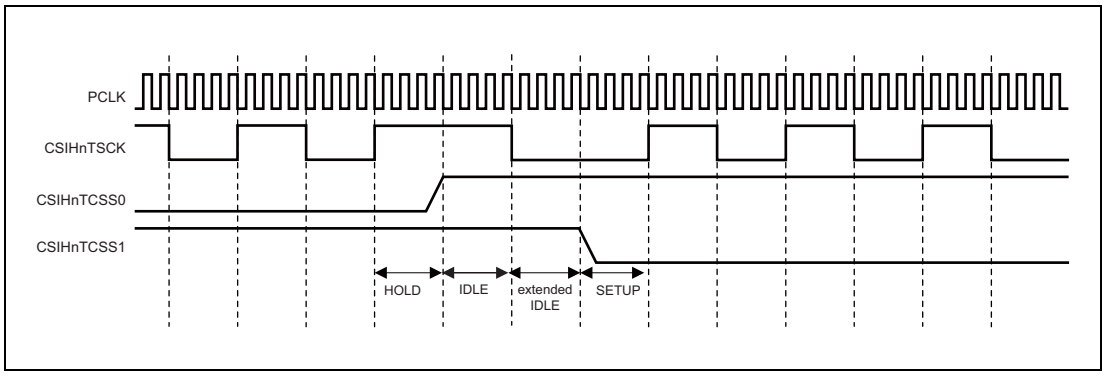

Figure 13.9 Clock Phase Timing
PCLK/8, Thold0 = Tsetup1 = 0 (0.5CSIHnTSCK), Tidle0 = 0 (0.5CSIHnTSCK), CSIHnCFG0.CSIHnCKP0 = 0 (CSIHnTCSS0) → CSIHnCFG1.CSIHnCKP1 = 1 (CSIHnTCSS1)

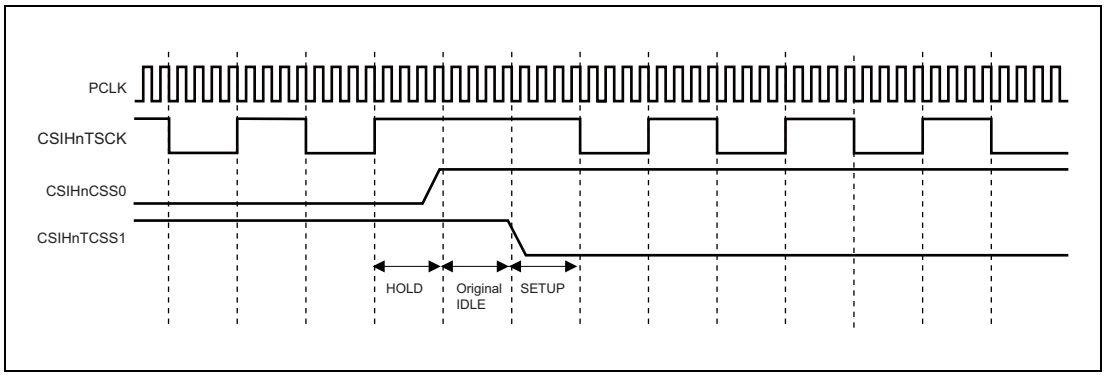

Figure 13.10 Clock Phase Timing
PCLK/8, Thold0 = Tsetup1 = 0 (0.5CSIHnTSCK), Tidle0 = 1 (1CSIHnTSCK), CSIHnCFG0.CSIHnCKP0 = 0 (CSIHnTCSS0) → CSIHnCFG1.CSIHnCKP1 = 1 (CSIHnTCSS1)

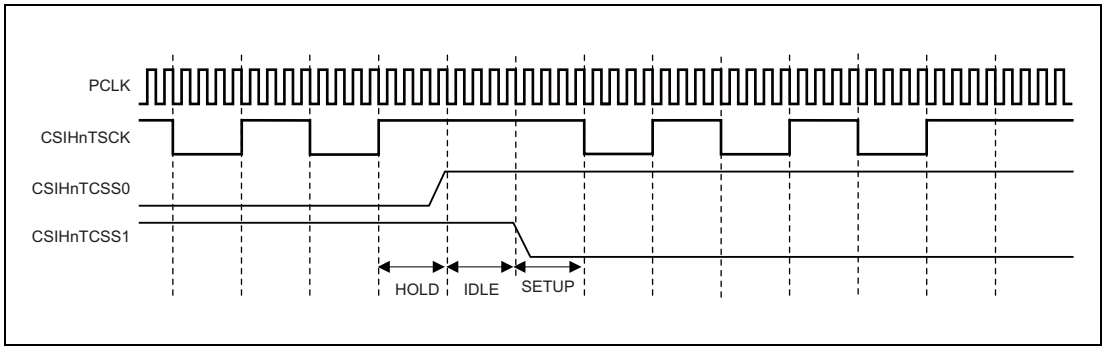

Figure 13.11 Clock Phase Timing
PCLK/8, Thold0 = Tsetup1 = 0 (0.5CSIHnTSCK), Tidle0 = 0 (0.5CSIHnTSCK), CSIHnCFG0.CSIHnCKP0 = 0 (CSIHnTCSS0)→ CSIHnCFG2.CSIHnCKP2 = 0 (CSIHnTCSS2)

(2) Changing the data phase

The CSIHnCFGx.CSIHnDAPx bit is used to define the phase of the data bit that is based on the clock.

The relationship between the CSIHnCFGx.CSIHnDAPx bit and hold/setup period is as followed.

The hold period is the time from the last edge of the serial clock (CSIHnTSCK) to the point where CSIHnTCSSx becomes inactive level.

The setup period is the time from the point where the CSIHnTCSSx becomes active level and to the point where transmit data (CSIHnTSO) is output.

Therefore, there is a 0.5 CSIHnTSCK gap until the edge of the serial clock (CSIHnTSCK) is output due to the setting of CSIHnCFGx.CSIHnDAPx.

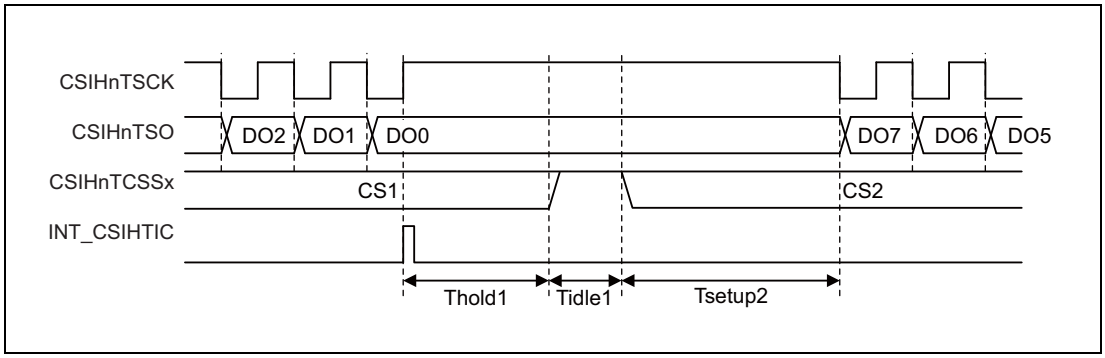

Figure 13.12 Data Phase Timing with CSIHnCFG1.CSIHnCKP1 = 0, CSIHnCFG1.CSIHnDAP1 = 0 and CSIHnCFG2.CSIHnCKP2 = 0, CSIHnCFG2.CSIHnDAP2 = 0

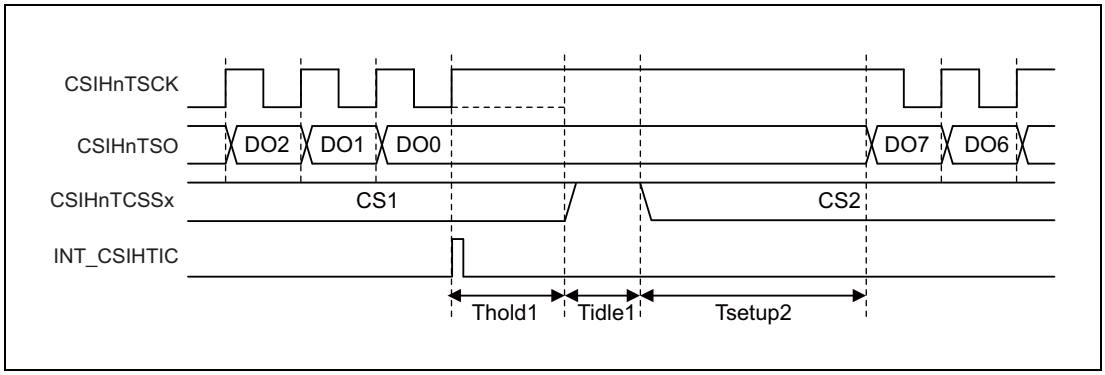

Figure 13.13 Data Phase Timing with CSIHnCFG1.CSIHnCKP1 = 1, CSIHnCFG1.CSIHnDAP1 = 0 and CSIHnCFG2.CSIHnCKP2 = 0, CSIHnCFG2.CSIHnDAP2 = 1

13.5.5 Transmission Clock Selection

In master mode, the transmission baud rate is selectable using the following bits:

- CSIHnCTL2.CSIHnPRS[2:0]
- CSIHnBRSi.CSIHnBRS[11:0]
- CSIHnCFGx.CSIHnBRSSx[1:0]

While the settings in the CSIHnCTL2.CSIHnPRS[2:0] and CSIHnBRSi.CSIHnBRSi[11:0] determine the baud rate of the transmission clock CSIHnTSCK, SIHnCFGx.CSIHnBRSSx[1:0] allows to select a baud rate setting for each chip select signal from the four settings of CSIHnBRS3 to CSIHnBRS0.

The following figure shows a block diagram of the baud rate generator.

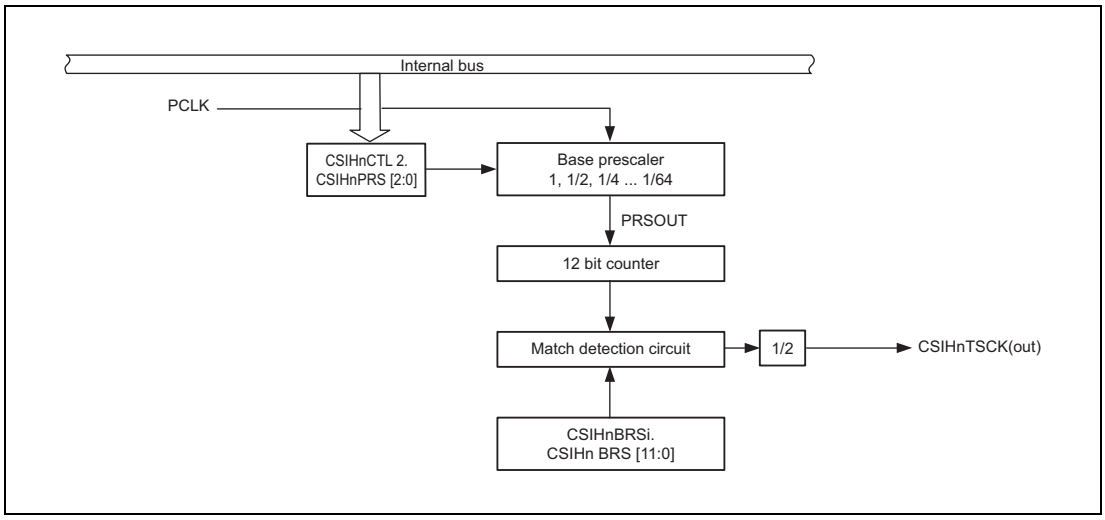

Figure 13.14 Baud Rate Generator Block Diagram

Setting CSIH0BRS[3:0].CSIHnBRS[11:0] to 000_H disables the baud rate generator, and thus all CSIHnTSCK are stopped.

Baud rate calculation

The baud rate is calculated as:

$$CSIHnTSCK = PCLK / (2^m \times k \times 2)$$

Where

m = CSIHnCTL2.CSIHnPRS[2:0] = 0 to 6

k = CSIH0BRSx (x = 0 to 3).CSIHBRS0 11 - 0 = 1 to 4095
(when CSIH0BRSS1 - 0 = 0)
CSIH0BRSx (x = 0 to 3).CSIHBRS1 11 - 0 = 1 to 4095
(when CSIH0BRSS1 - 0 = 1)
CSIH0BRSx (x = 0 to 3).CSIHBRS2 11 - 0 = 1 to 4095
(when CSIH0BRSS1 - 0 = 2)
CSIH0BRSx (x = 0 to 3).CSIHBRS3 11 - 0 = 1 to 4095
(when CSIH0BRSS1 - 0 = 3)

Baud rate limits

When setting the baud rate, please note:

- Maximum acceptable baud rate in master mode is PCLK/8.
- Maximum acceptable baud rate in slave mode is PCLK/20 (must be ensured by the external master).
- Minimum baud rate in both modes is PCLK/524160.

Example

If PCLK = 80 MHz, the maximum baud rate is as follows:

- 10 Mbps (PCLK/8) in master mode
- 4 Mbps (PCLK/20) in slave mode

The minimum baud rate is 152.625 bps (PCLK/524160).

13.5.6 Data transfer modes

(1) Transmit-only mode

Setting CSIHnCTL0.CSIHnTXE = 1 and CSIHnCTL0.CSIHnRXE = 0 puts the CSIH in transmit-only mode.

- Transmission starts when transmit data is written to the CSIHnTX0W or CSIHnTX0H register.

(2) Receive-only mode

Setting CSIHnCTL0.CSIHnTXE = 0 and CSIHnCTL0.CSIHnRXE = 1 puts the CSIH in receive-only mode.

- Receive starts when dummy data is written in the CSIHnTX0W or CSIHnTX0H register.

In slave mode, reception starts as soon as the CSIHnTSCK transmission clock from the master is received. It is not necessary to write data to the CSIHnTX0W or CSIHnTX0H register of the slave.

(3) Transmit/receive mode

Setting CSIHnCTL0.CSIHnTXE = 1 and CSIHnCTL0.CSIHnRXE = 1 puts the CSIH in transmit/receive mode.

- Communication starts when transmit data is written to the CSIHnTX0W or CSIHnTX0H register.

(4) Summary

The following table summarizes this section. It shows how data transfer is started in operating and transfer modes.

Table 13.7 Start of Data Transfer

Operating mode		Transfer mode	
		Transmit-only Transmit/receive	Receive-only
Direct access	Master	Writing to the CSIHnTX0W register or the CSIHnTX0H register	Writing to the CSIHnTX0W register or the CSIHnTX0H register
	Slave	Incoming clock from the master	Incoming clock from the master

13.5.7 Data Length Selection

(1) Data length between 2 and 16 bits

The length of a data packet is selectable for each chip select signal from 2 to 16 bits using CSIHnCFGx.CSIHnDLSx[3:0]. The examples below show the communication with MSB first (CSIHnCFGx.CSIHnDIRx = 0).

Data length = 16 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 0000_B)

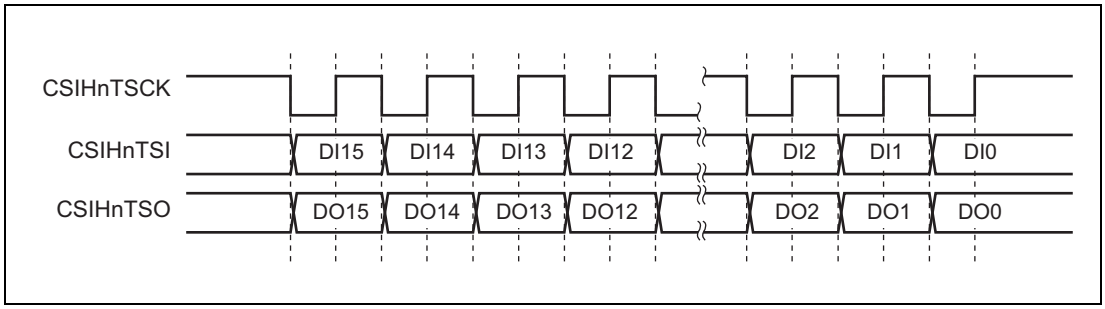

Figure 13.15 16 Bit Data Length, MSB First

Data length = 14 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1110_B):

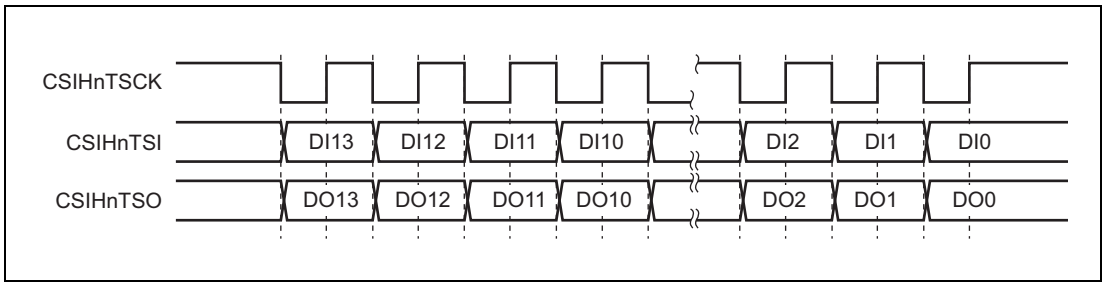

Figure 13.16 14 Bit Data Length, MSB First

(2) Data length greater than 16 bits

If the data to be sent/received exceeds 16 bits, the extended data length (EDL) feature can be used.

The EDL function is enabled by setting the CSIHnCTL1.CSIHnEDLE bit to 1.

The EDL function works as follows:

- The data has to be broken into 16-bit blocks plus remainder. For example, data of 42 bits would be broken into two 16-bit blocks plus 10 bits.
- The bit length of the reminder is set in CSIHnCFGx.CSIHnDLSx[3:0] as data length.
- For transmitting the 16-bit blocks, CSIHnTX0W.CSIHnEDL must be set to 1. In this case, the data written to CSIHnTX0W is sent as a 16-bit data length regardless of the CSIHnCFGx.CSIHnDLSx[3:0] bit setting.
- The transfer is complete after a block with the specified data length (the remainder of data specified with CSIHnTX0W.CSIHnEDL = 0) has been sent.

Example

Example for sending 40-bit data ($123456789A_H$) to CS0:

40 bits are split into two 16 bits and 8 bits.

- Initialize CSIHnCFG0.CSIHnDLS0[3:0] = 8.
- To send $123456789A_H$ with MSB first, write the following sequence to CSIHnTX0W:
  - $20FE\ 1234_H$ (CSIHnTX0W.CSIHnEDL = 1)
  - $20FE\ 5678_H$ (CSIHnTX0W.CSIHnEDL = 1)
  - $00FE\ 009A_H$ (CSIHnTX0W.CSIHnEDL = 0)

The following figure illustrates the timing.

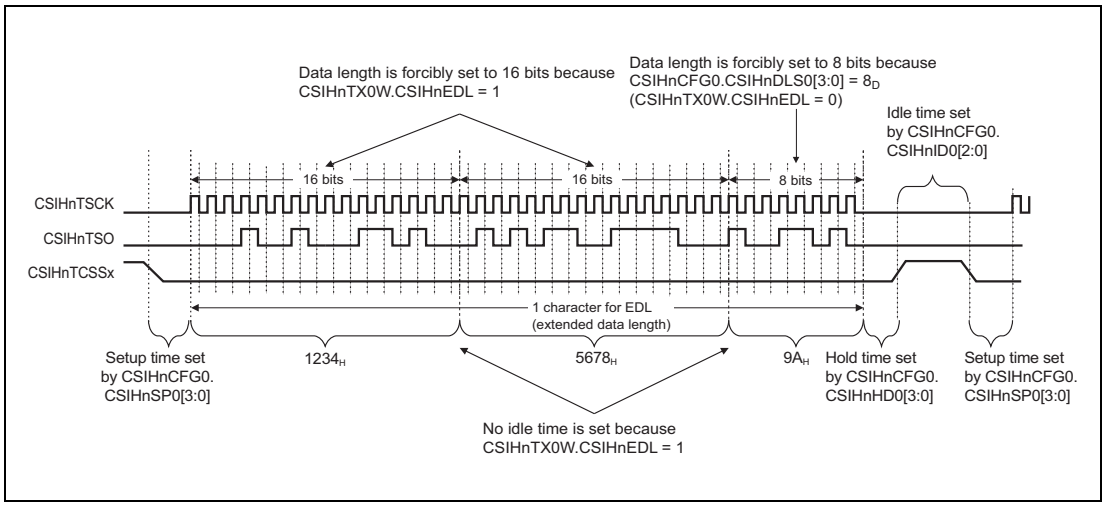

Figure 13.17 EDL Timing Diagram

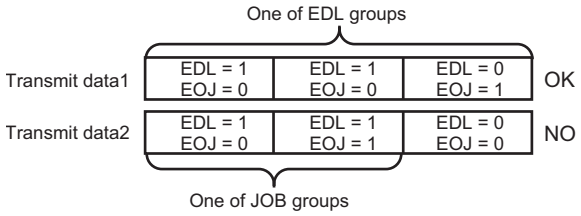
NOTES

1. If parity is enabled, the parity bit is added after the last bit.
2. When extended data length (EDL) mode is used for transmission, use the same chip select signal.
3. To consider the data direction, pay attention to the following example:

   Data to be sent: 123456_H

   MSB first:
   Set CSIHnCFGx.CSIHnDIRx = 0
   Write CSIHnTX0W = 2000 1234_H (EDL bit = 1)
   Write CSIHnTX0W = 0000 0056_H (EDL bit = 0)

   LSB first:
   Set CSIHnCFGx.CSIHnDIRx = 1
   Write CSIHnTX0W = 2000 3456_H (EDL bit = 1)
   Write CSIHnTX0W = 0000 0012_H (EDL bit = 0)
4. When EDL is enabled in job mode (CSIHnCTL1.CSIHnJE = 1 and CSIHnCTL1.CSIHnEDLE = 1), operation is not guaranteed if CSIHnTX0W.CSIHnEOJ is set to 1 while CSIHnTX0W.CSIHnEDL remains 1.



5. EDL mode cannot be used in receive-only mode in slave mode.(CSIHnCTL2.CSIHnPRS[2:0] = 111_B, CSIHnCTL0.CSIHnTXE = 0, CSIHnCTL0.CSIHnRXE = 1)

13.5.8 Serial Data Direction Selection

The serial data direction is selectable for each chip select signal using the CSIHnDIRx bit in the CSIHnCFGx register.

The examples below show communication for a data length of 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).

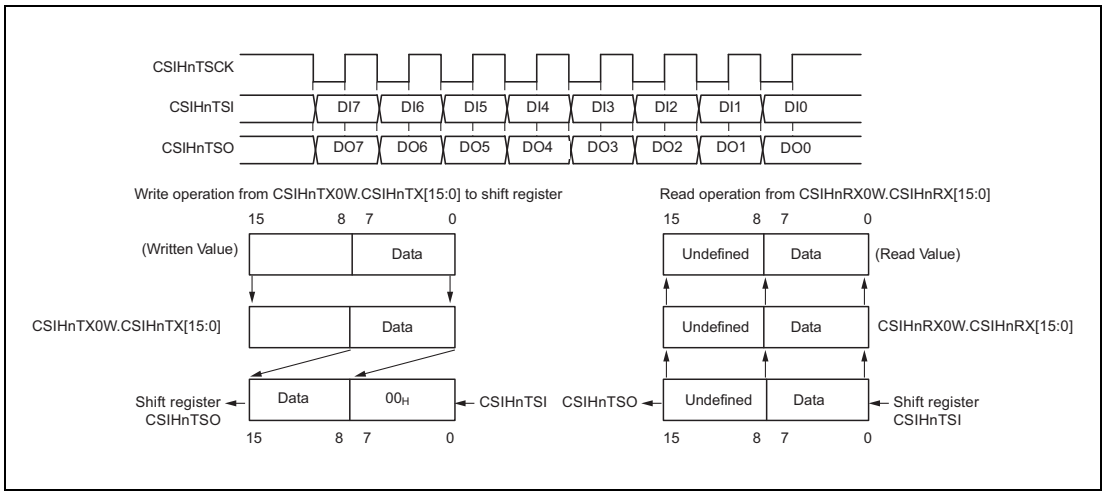


Figure 13.18 Serial Data Direction Select Function - MSB First (CSIHnDIRx = 0)

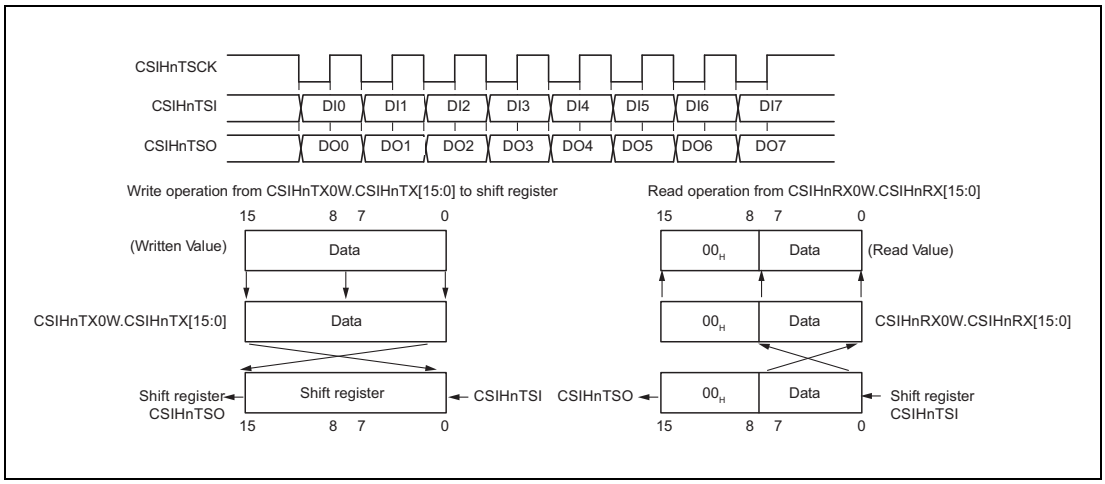

Figure 13.19 Serial Data Direction Select Function - LSB First (CSIHnDIRx = 1)

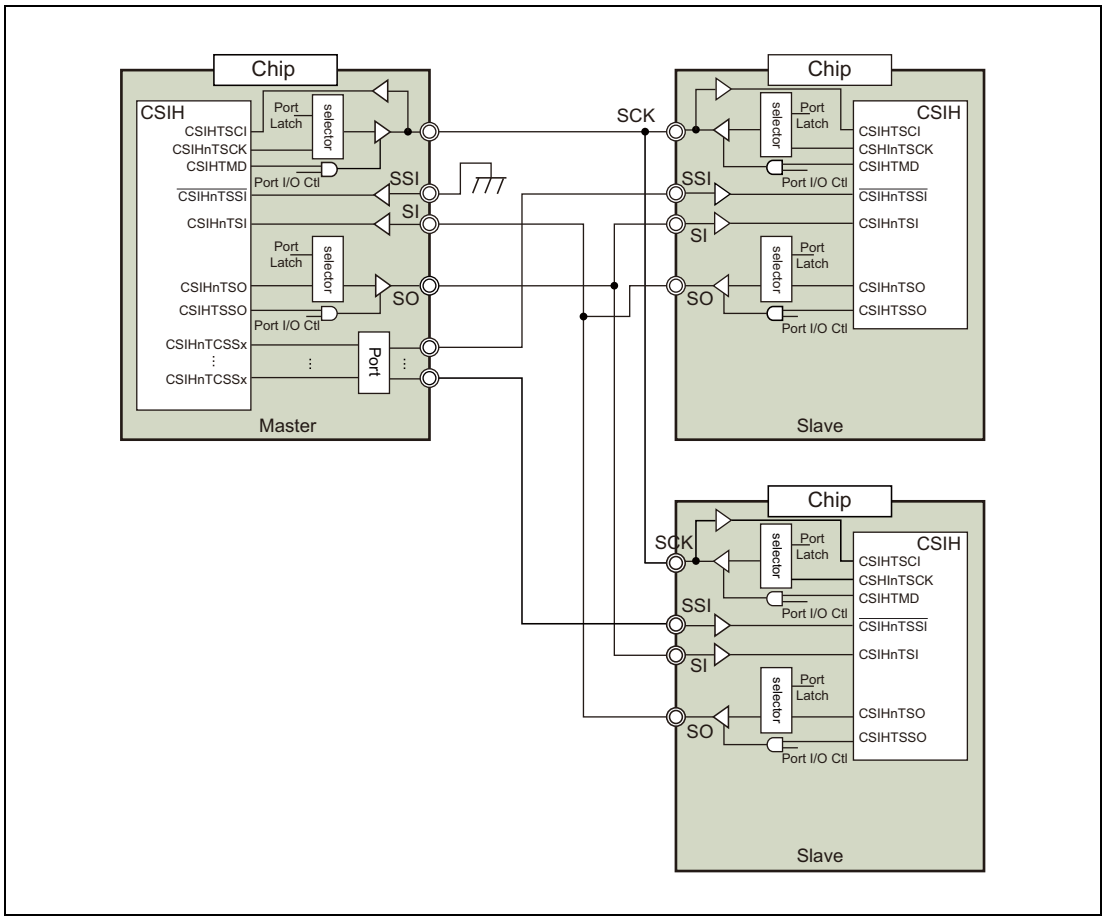
13.5.9 Communication in Slave Mode

(1) System outline



By the slave select function, the CSIH can realize one master and multiple slaves communication. The master chip outputs slave select signal (CSIHnTCSSx) to one of the slave chip. Each slave chip judges itself whether own CSIH is selected target slave or not. If selected, slave chip should control I/O function of SO pin to be an output pin. Then the slave chip can send transmission data to the master chip. If it is not selected as slave chip, SO pin should be an input function to avoid confliction of SO output from other selected slave chip. And also, not selected slave chip doesn't receive any data even if serial clock comes from master chip. By connecting master chip SI pin and multiple SO pins of all slave chips on a board, one master and multiple slaves communication can be realized. Putting level hold circuit to this serial data line is recommended.

(2) Communication timing

The following figure illustrates the communication signals and timings in slave mode.

In slave mode, the data transfer configuration is determined by the CSIHnCFG0 register.

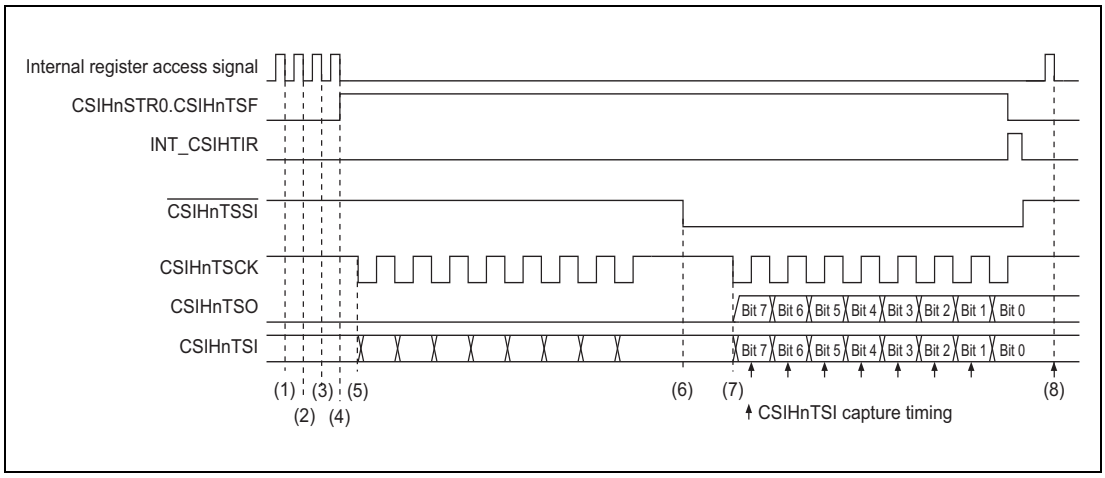


Figure 13.20 Transmit/Receive Communication Timing in Slave Mode

(1) CSIH is put into slave mode by setting CSIHnCTL2.CSIHnPRS[2:0] = 111_B. CSIHnCFG0.CSIHnCKP0 and CSIHnCFG0.CSIHnDAP0 are 0.

(2) The data length is 8 bits (CSIHnCFG0.CSIHnDLS0[3:0] = 1000_B). The data direction is MSB first (CSIHnCFG0.CSIHnDIR0 = 0).

(3) Transmit/receive mode is set (CSIHnCTL0.CSIHnCSIHnPWR = 1, CSIHnCTL0.CSIHnTXE = 1, CSIHnCTL0.CSIHnRXE = 1). Communication start is permitted.

(4) The transfer status flag CSIHnSTR0.CSIHnTSF is automatically set when transfer data is written to the CSIHnTX0W or CSIHnTX0H transmission register.

(5) As long as signal $\overline{\text{CSIHnTSSI}}$ is high, transmission/reception is not started, even if an external transmission clock CSIHnTSCK is applied. Input at CSIHnTSI is ignored.

(6) When $\overline{\text{CSIHnTSSI}}$ falls to low level, indicating that CSIHnTSO is enabled, transmission is enabled.

(7) On detection of the external clock signal CSIHnTSCK, the slave transmits data to CSIHnTSO and simultaneously captures data from CSIHnTSI.

(8) Interrupt INT_CSIHTIR indicates when the reception is complete. The CSIHnRX0W/H register can be read.

(3) Operation of CSIHTSSO

CSIHnPWR	CSIHnTXE	CSIHnRXE	CSIHnSSE	CSIHTSSO
0	—	—	—	H
1	—	—	0	H
	0		1	H
	1		1	Inverse of $\overline{\text{CSIHnTSSI}}$ level

The CSIHTSSO signal is a signal to control the I/O function of the CSIHnTSO pin in case of using the slave select function.

The CSIHnTSO pin is enabled when the CSIHTSSO signal is “High” (the CSIHnTSO pin is being driven).

The CSIHnTSO pin is disabled when the CSIHTSSO signal is “Low” (the CSIHnTSO pin is not being driven).

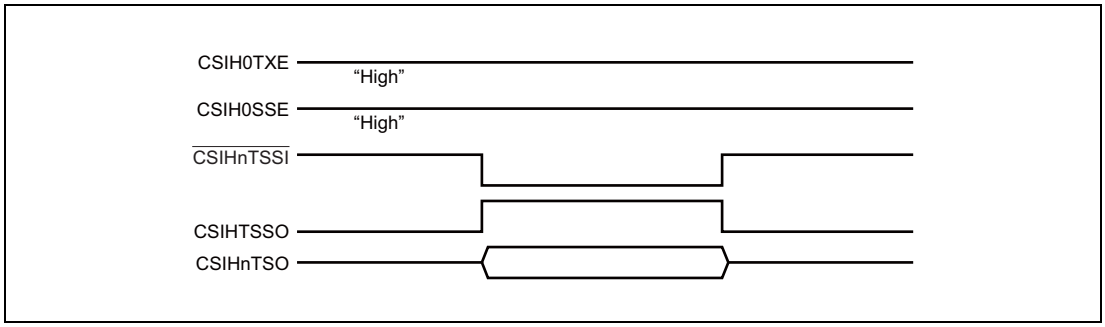

Figure 13.21 Operation of CSIHTSSO

CAUTION

If $\overline{\text{CSIHnTSSI}}$ pin is changed during communication (CSIH0STR0.CSIH0TSF = 1), current communication is not assured.

13.5.10 CSIH interrupt requests

CSIH can generate the following interrupt requests:

- INT_CSIHTIC (communication status interrupt)
- INT_CSIHTIR (reception status interrupt)
- INT_CSIHTIRE (communication error interrupt)
- INT_CSIHTIJC (job completion interrupt)

(1) Overview

The error interrupt INT_CSIHTIRE is generated when an error is detected. The generation of the other interrupts depends on the job mode, and – in case of the job completion interrupt INT_CSIHTIJC –also the operating mode.

The job completion interrupt INT_CSIHTIJC is only generated when job mode is enabled (CSIHnCTL1.CSIHnJE = 1). It is not available in slave mode.

The following table gives an overview.

Table 13.8 Interrupt Generation

Mode	Interrupt	Cause of interrupt	
		Job mode disabled CSIHnCTL1.CSIHnJE = 0	**Job mode enabled CSIHnCTL1.CSIHnJE = 1**
Direct access	INT_CSIHTIC (communication status interrupt)	Single data transfer	Single data transfer (except for job abortion*2)
	INT_CSIHTIR (reception status interrupt)	Data received and CSIHnCTL0.CSIHnRXE = 1	Data received *and* CSIHnCTL0.CSIHnRXE = 1
	INT_CSIHTIRE (communication error interrupt)	Error detected	Error detected
	INT_CSIHTIJC*1 (job completion interrupt)	Not applicable	Job abortion*2

Note 1. INT_CSIHTIJC is not available in slave mode.

Note 2. Job abortion condition: CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1

(2) Interrupt delay

In master mode, all interrupts generated by the master can be delayed by one half period of the transmission clock, CSIHnTSCK. This is not possible in slave mode.

The delay is specified by setting CSIHnCTL1.CSIHnSIT = 1.

The following example illustrates the interrupt delay function, assuming a setting of CSIHnCTL1.CSIHnSIT = 1 (interrupt delay enabled), CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0 (normal clock and data phase), and CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B (data length 8 bits).

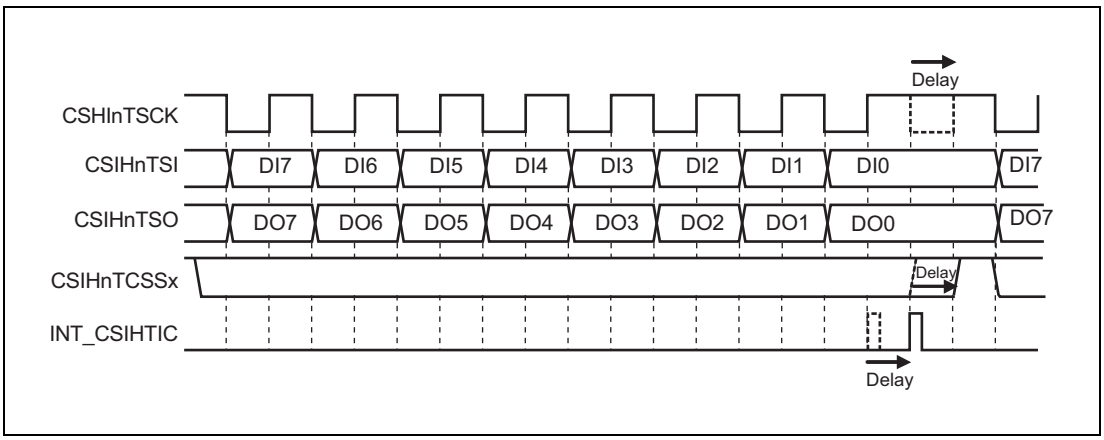

Figure 13.22 Interrupt Delay Function (CSIHnCTL1.CSIHnSIT = 1)

Setting CSIHnCTL1.CSIHnSIT = 1 adds half period delay to the transmission clock. This delays also the end of the present chip select signal (CSIHnTCSSx).

(3) INT_CSIHTIC (communication status interrupt)

Depending and the job mode, this interrupt is generated according to the conditions shown in the following table.

Table 13.9 INT_CSIHTIC Interrupt Generation

	Cause of interrupt	
Memory mode	**Job mode disabled CSIHnCTL1.CSIHnJE = 0**	**Job mode enabled CSIHnCTL1.CSIHnJE = 1**
Direct access	Generated after every data transfer.	Generated after every data transfer, except when the communication was aborted.

INT_CSIHTIC in direct access mode

The examples below show the INT_CSIHTIC behavior in direct access mode.

The examples assume:

- Master mode
- Direct access mode
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Normal INT_CSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

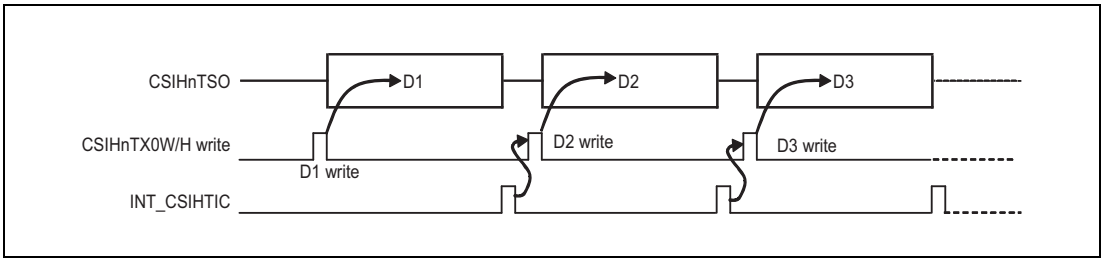

Figure 13.23 Generation of INT_CSIHTIC after Transfer (CSIHnCTL1.CSIHnSLIT = 0)

If job mode is enabled (CSIHnCTL1.CSIHnJE = 1) and a job ends because data is sent with CSIHnTXOW.CSIHnEOJ= 1 and communication stop is requested (CSIHnCTL0.CSIHnJOBE = 1), then INT_CSIHTIC is replaced by the job completion interrupt INT_CSIHTIC.

INT_CSIHTIC can also be set up to occur as soon as the CSIHnTX0W/H register is free for the next data. This is specified by setting CSIHnCTL1.CSIHnSLIT = 1.

The effect is illustrated in the figure below.

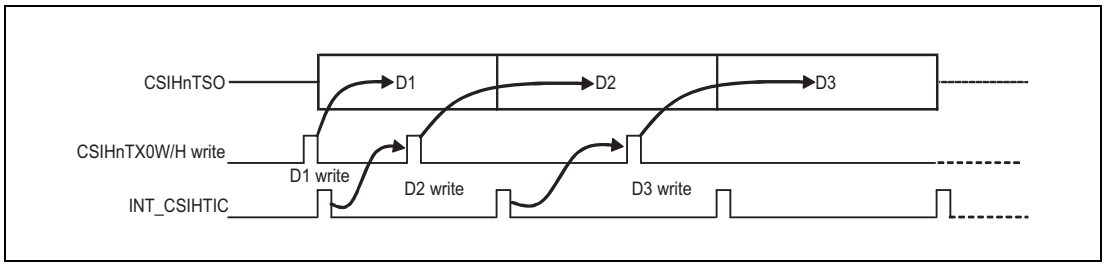

Figure 13.24 Immediate Generation of INT_CSIHTIC (CSIHnCTL1.CSIHnSLIT = 1)

Thus, the new data can be written in advance.

CAUTION

This mode allows faster data transfer but is only available in direct access mode.

INT_CSIHTIC in job mode

The example below shows the INT_CSIHTIC behavior in job mode.

The example assumes:

- Master mode
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Normal INT_CSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

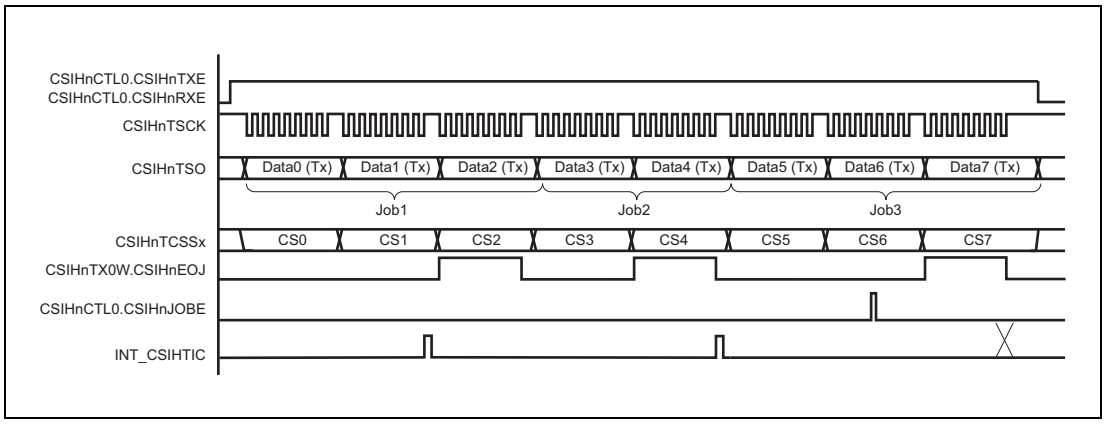

Figure 13.25 Generation of INT_CSIHTIC in Job Mode

The rules for generating INT_CSIHTIC in job mode are shown in the following table.

Table 13.10 Generation of INT_CSIHTIC in Job Mode

CSIHnTX0W. CSIHnEOJ	INT_CSIHTIC
0	Not generated
0	Generated
1	Not generated
1	CSIHnCTL0.CSIHnJOBE = 0: Generated
	CSIHnCTL0.CSIHnJOBE = 1: Not generated, replaced by interrupt INT_CSIHTIJC

(4) INT_CSIHTIR (reception status interrupt)

This interrupt is generated according to the conditions below.

Table 13.11 INT_CSIHTIR Interrupt Generation

Mode	Cause of interrupt	
	Job mode disabled CSIHnCTL1.CSIHnJE = 0	Job mode enabled CSIHnCTL1.CSIHnJE = 1
Direct access	Generated after every data transfer.	

INT_CSIHTIR in direct access mode

The example below shows the INT_CSIHTIR behavior in direct access mode.

The example below assumes:

- Master mode
- Direct access mode
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)

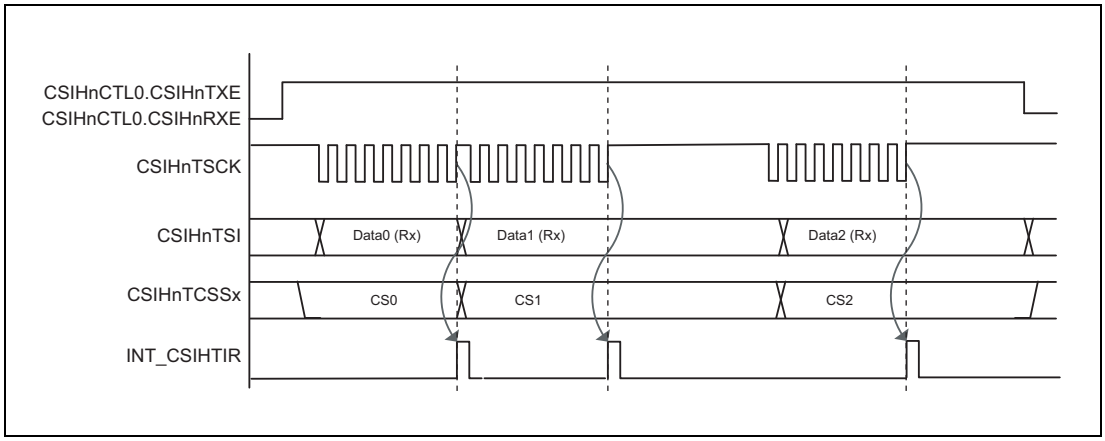

Figure 13.26 Generation of INT_CSIHTIR in Direct Access Memory Mode

(5) INT_CSIHTIRE (communication error interrupt)

This interrupt is generated whenever an error is detected.

For details about generation interruption timing, see **Section 13.5.12, Error Detection**.

Table 13.12 Data Error Types

Error type	Communication status after error interrupt	Comment
Parity error	Interrupt is generated and communication continues	—
Data consistency error	Interrupt is generated and communication continues	—
Overrun error	Interrupt is generated and communication continues	This error interrupt is only generated when CSIHnCTL1.CSIHnHSE = 0 (without handshake) in slave mode.

The type of error that caused the generation of INT_CSIHTIRE is flagged in register CSIHnSTR0.

Additionally a parity error flag and a data consistency error flag are attached to the received data in CSIHnRX0W.

For details about the various error types, see **Section 13.5.12, Error Detection**.

(6) INT_CSIHTIJC (job completion interrupt)

This interrupt supports the handling of jobs. See **Section 13.5.3 (3), Job concept**. This interrupt is only available in master mode.

Job mode is enabled by setting CSIHnCTL1.CSIHnJE = 1. When CSIHnCTL1.CSIHnJE = 0, INT_CSIHTIJC is not generated.

This interrupt is generated according to the condition shown in the following table.

Table 13.13 INT_CSIHTIJC Interrupt Generation

	Interrupt Sources	
Mode	Job mode disabled CSIHnCTL1.CSIHnJE = 0	Job mode enabled CSIHnCTL1.CSIHnJE = 1
Direct access	Not applicable	Indicates that the communication has stopped at the end of a job after a job abortion*1 was triggered

Note 1. Job abortion condition: CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1

13.5.11 Handshake function

CSIH features a handshake function to synchronize the master and the slave devices. This function can be enabled/disabled by the CSIHnCTL1.CSIHnHSE bit. For handshake, the CSIHnTRY signal is used.

The busy timing depends on the setting of the data phase selection bit CSIHnCFGx.CSIHnDAPx.

(1) Slave mode

When CSIHnCTL1.CSIHnHSE = 1 and the slave is busy, the CSIHnTRY signal outputs low level (0). This can happen in the following case:

Case 1: When transmission is not ready (no next transmission data)

Case 2: When reception register is full:

Because the slave is in receive-only or transmit/receive mode but previously received data is still in the CSIHnRX0W/H register, new data cannot be copied from the shift register to CSIHnRX0W/H (CSIHnRX0W/H full condition).

The data length of 8 bits is assumed in the following example.

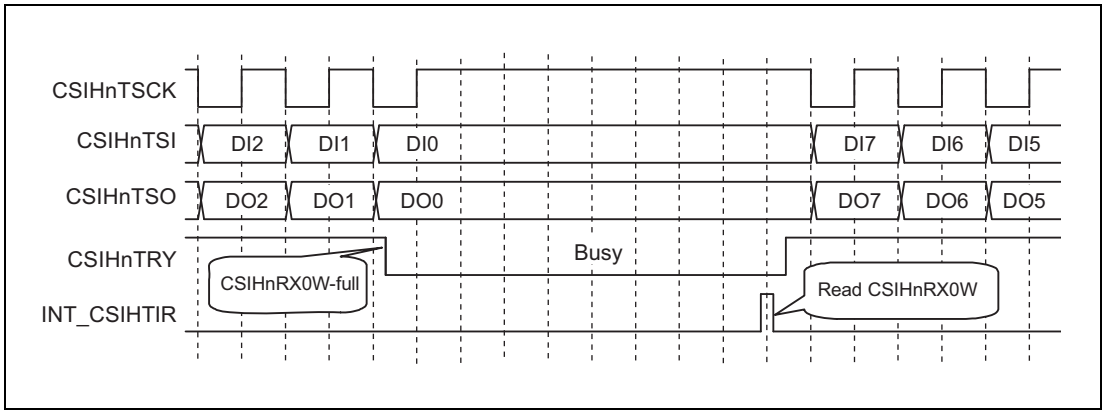

Figure 13.27 Busy Signal from the Slave (Direct Access Mode; CSIHnCFGx.CSIHnDAPx = 0)

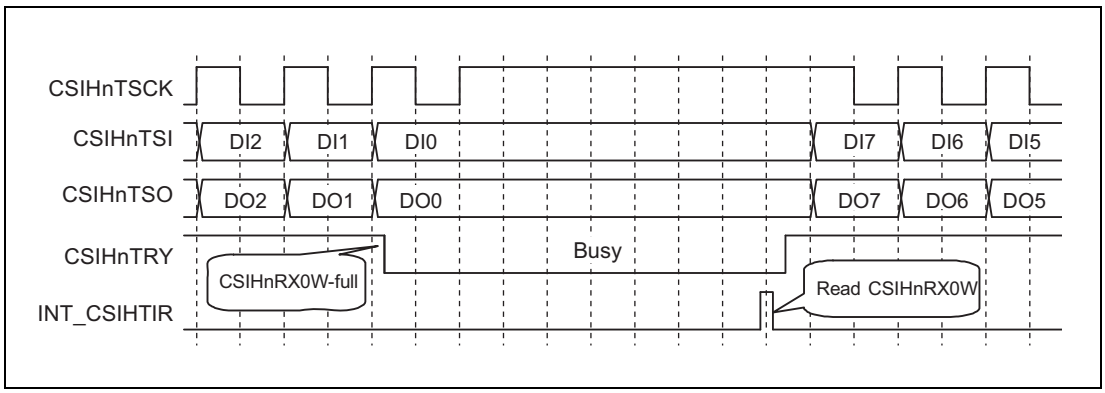

Figure 13.28 Busy Signal from the Slave (CSIHnCFGx.CSIHnDAPx = 1)

(2) Master mode

When the master detects CSIHnTRY being 0 while CSIHnCTL1.CSIHnHSE is 1, the subsequent transfer is put on hold and the master enters the waiting state. It suspends the CSIHnTSCK clock.

The CSIHnTRY level is checked at each half clock cycle of CSIHnTSCK.

The chip select signal is output during the waiting state.

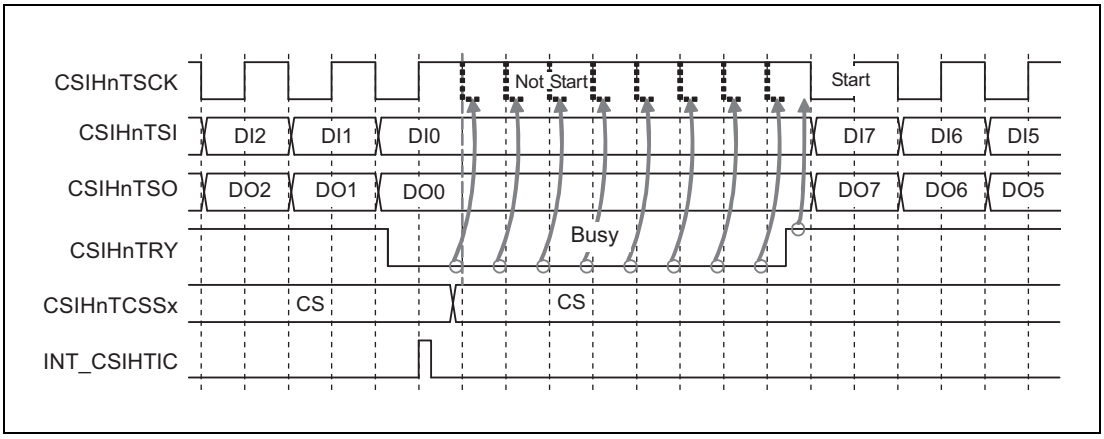

Figure 13.29 Master's Reaction on CSIHnTRY (CSIHnCFGx.CSIHnDAPx = 0)

CSIHnTRYI must be pulled down by the slave before the next transfer starts. When the slave changes the CSIHnTRYI signal to low level during data transfer, the serial clock from the master stops at the completion of data transfer.

The master resumes the communication as soon as CSIHnTRY becomes high level (the slave is "ready").

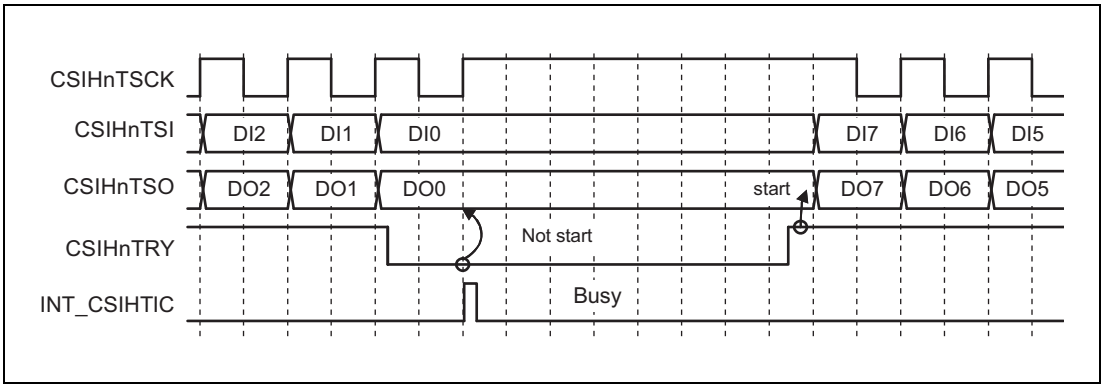

Figure 13.30 Master's Reaction on CSIHnTRY (CSIHnCFGx.CSIHnDAPx = 1)

CAUTIONS

1. **If multiple slaves are connected, the master must only detect the CSIHnTRY signal of the slave it has selected for communication.**
2. **Even when the slave changes the CSIHnTRY signal to low level during a transmission, the transmitting operation is continued until its successful completion.**

13.5.12 Error Detection

CSIH can detect three error types:

- Data consistency error (transmission data)
- Parity error (received data)
- Overrun error (received data)

Check for parity and data consistency can be enabled/disabled individually.

If one of these errors is detected, the interrupt request, INT_CSIHTIRE is generated and the corresponding flags are set.

(1) Data consistency check

The purpose of the data consistency check is to ensure that the data physically sent as output signal is identical to the original data that was copied to the shift register.

The data consistency check can be enabled/disabled by the CSIHnCTL1.CSIHnDCS bit. It is not active if data transmission is disabled (CSIHnCTL0.CSIHnTXE = 0).

When the data consistency check is active, the data transferred from CSIHnTX0W or CSIHnTX0H to the shift register is copied to a separate register. In addition, the physical levels at CSIHnTSO are read back via the CSIHTDCS signal into an own shift register.

After completion of the transmission, the sent data is compared with the original transmission data.

Mismatch is considered as a data consistency error:

- Interrupt INT_CSIHTIRE is generated.
- The CSIHnSTR0.CSIHnDCE bit is set.

Additionally, CSIHnRX0W.CSIHnTDCE of data that contains the error is set.

The data consistency check function is illustrated in the following block diagram.

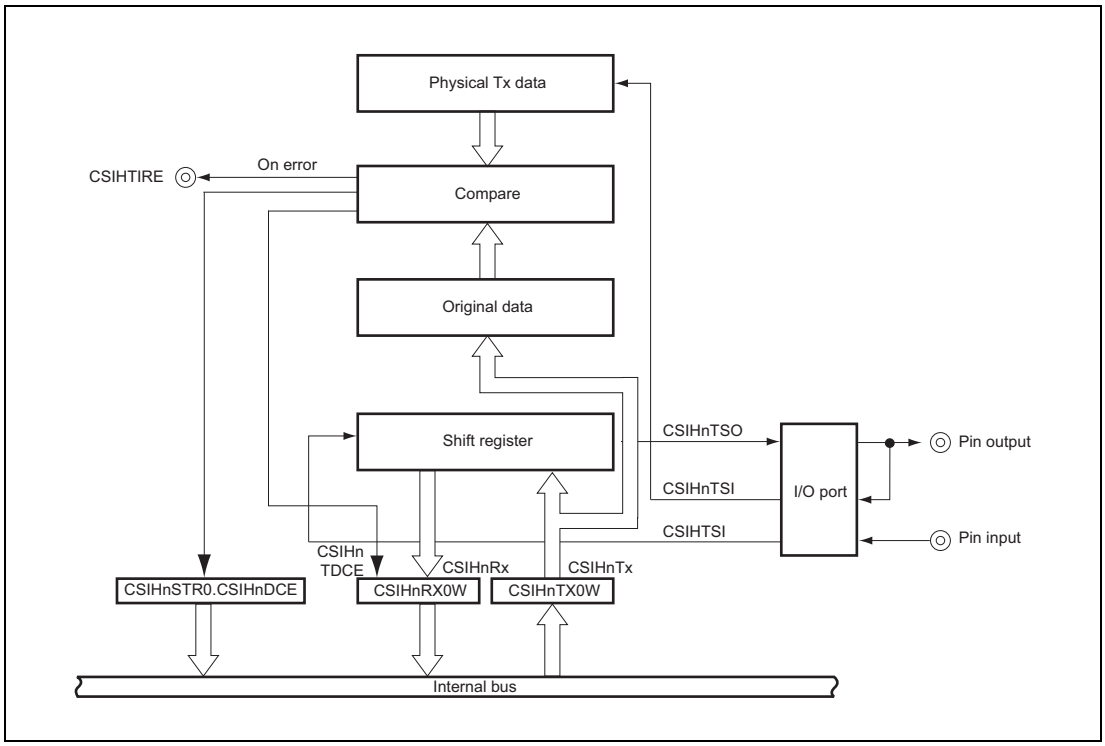

Figure 13.31 Data Consistency Check Functional Block Diagram

(2) Parity check

CSIH can append a parity bit to the last data bit (even if extended data length is used).

The use and type of parity is specified in CSIHnCFGx.CSIHnPSx[1:0].

Parity check is enabled if CSIHnCFGx.CSIHnPSx[1] = 1.

The parity bit is checked after a reception is complete. In case of parity error:

- Interrupt INT_CSIHTIRE is generated.
- The CSIHnSTR0.CSIHnPE bit is set.

Additionally, CSIHnRX0W.CSIHnRPE of data that contains the error is set.

The figure below shows an example.

- Data length is 8 bits.
- The data to be transmitted is 05_H and 35_H.
- Data direction is LSB first.
- Parity type is odd.

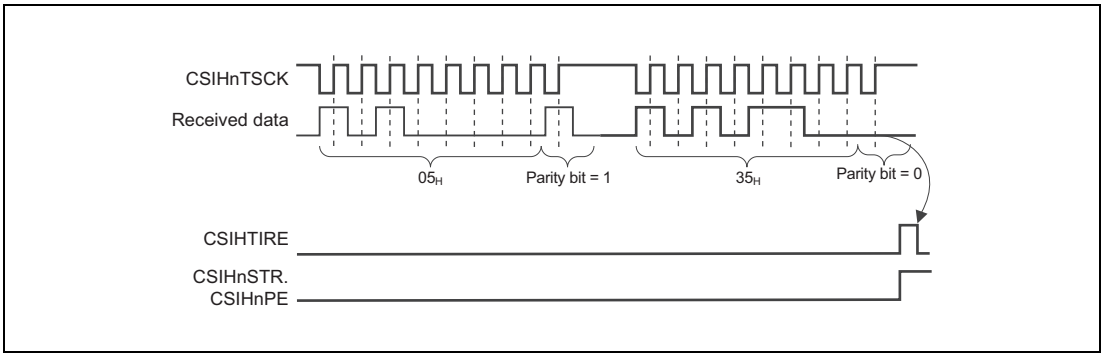

Figure 13.32 Parity Check Example

The parity bit of the first data is 1. There is no parity error, because the total number of ones (including the parity bit) is odd.

The parity bit of the second data is 0. This is detected as a parity error, because the total number of ones (including the parity bit) is even.

If the EDL (extended data length) function is used, the parity bit is added after the last bit of the data.

(3) Overrun error

An overrun error can happen in direct access mode. The overrun error is not generated if data reception is disabled (CSIHnCTL0.CSIHnRXE = 0).

Direct access

In direct access mode, this error occurs when newly received data cannot be transferred from the shift register to the reception register CSIHnRX0W/H. This happens when CSIHnRX0W/H was not read and therefore contains previous reception data.

The following figure illustrates the function.

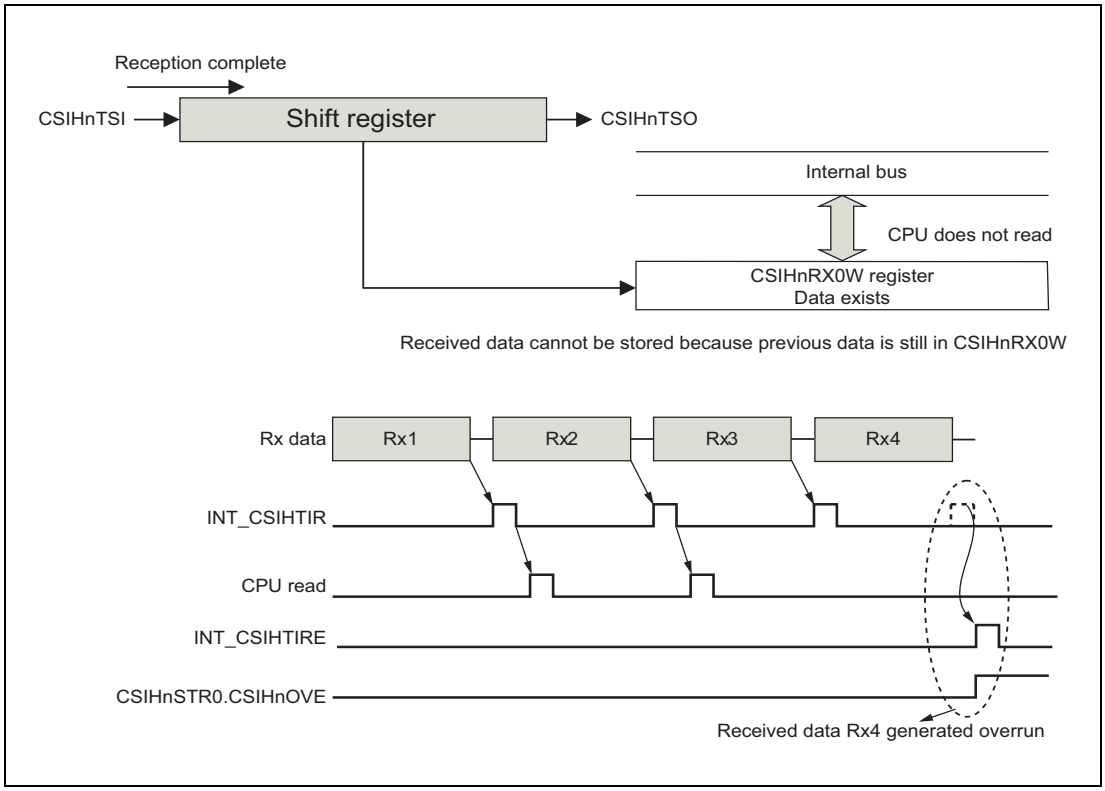

Figure 13.33 Overrun Error Detection in Direct Access

An overrun error causes the following incidents.

- INT_CSIHTIRE interrupt is generated instead of INT_CSIHTIR interrupt
- CSIHnSTR0.CSIHnOVE bit is set
- CSIHnRX0W is rewritten by the received data

NOTE

In slave mode, overrun errors can be avoided by using handshake function. When handshaking is used in slave mode, the receiver (slave) signals the transmitter (master) that the receiver is busy. The transmitter waits until the receiver reads its own register and is ready again.

For details, see **Section 13.5.11, Handshake function**.

13.5.13 Loop-Back Mode

Loop-back mode is a special mode for self-test. This feature is only available in master mode.

When this mode is active (CSIHnCTL1.CSIHnLBM = 1), CSIHnTCSSx is fixed inactive level (the active level is defined by the value of CSIHnCTL1.CSIH0CSLx), and the transmit and receive signals are internally connected, as shown in the figures below. The signals CSIHnTSCK, CSIHnTSO, CSIHnTSI and CSIHnTCSSx are disconnected from the ports. In addition, the CSIHnTSO output level is fixed to low, and CSIHnTSCK is set to the reset level (high) regardless of the value of CSIHnCFGx.CSIHnCKPx register. The rest of CSIH works as in normal operation.

In order to test CSIH, put it in loop-back mode and carry out normal transfer operations. Then check that the received data is the same as the transmitted data.

A loopback test does not affect the destination to which the device is connected.

Table 13.14 Pin Output Level in Loopback Mode

Pin Name	Output Level
CSIHnTSCK(out)	High level
CSIHnTCSSx	Inactive level
CSIHnTSO	Low level (does not depend on the previous values)
Interrupt	Normal function
CSIHnTRY	Normal function (low level)

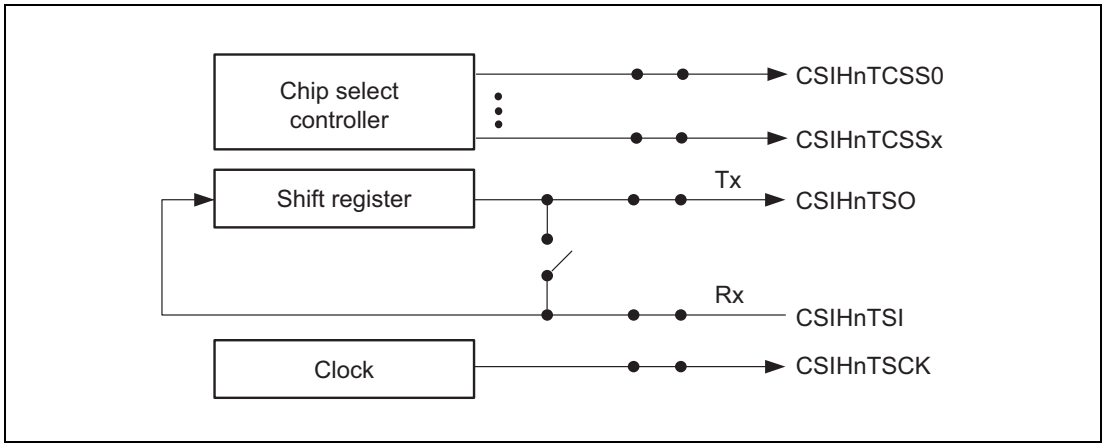

Figure 13.34 Normal Operation

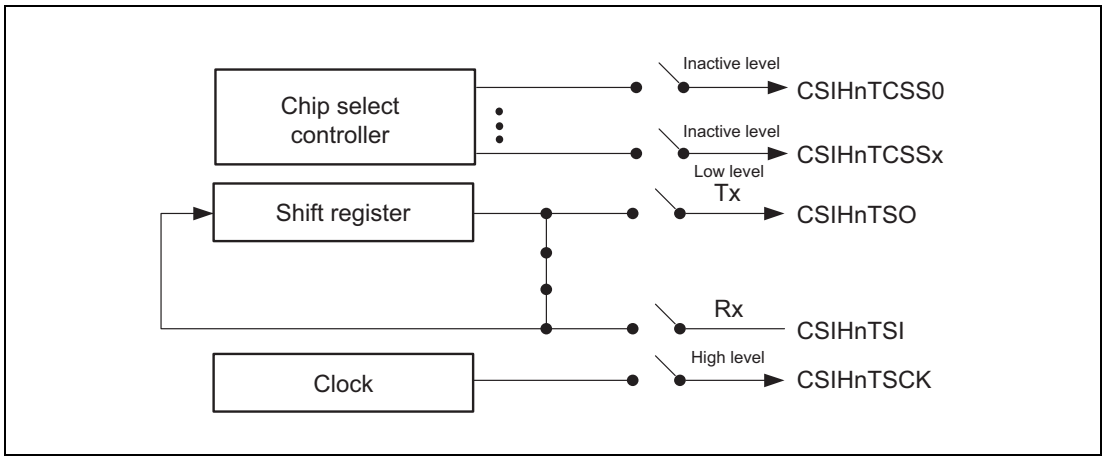

Figure 13.35 Operation in Loop-Back Mode

13.5.14 Enforced Chip Select Idle Setting

The CSIH is able to insert an idle state between the two consecutive transfer data by the setting of CSIHnCFGx.CSIHnIDLx (x: Chip select signal x). Detail is as follows.

1. When CSIHnCFGx.CSIHnIDLx = 0
   If the setting of CSIHnTCSSx for a next transfer data is the same as that for the previous one, an idle state is not inserted and an inter-data time is inserted.
   If the setting of CSIHnTCSSx for a next transfer data is different from the previous one, an idle state is inserted.
2. When CSIHnCFGx.CSIHnIDLx = 1
   An idle state is always inserted even if the setting of CSIHnTCSSx for a next transfer data is the same as that for the previous one.

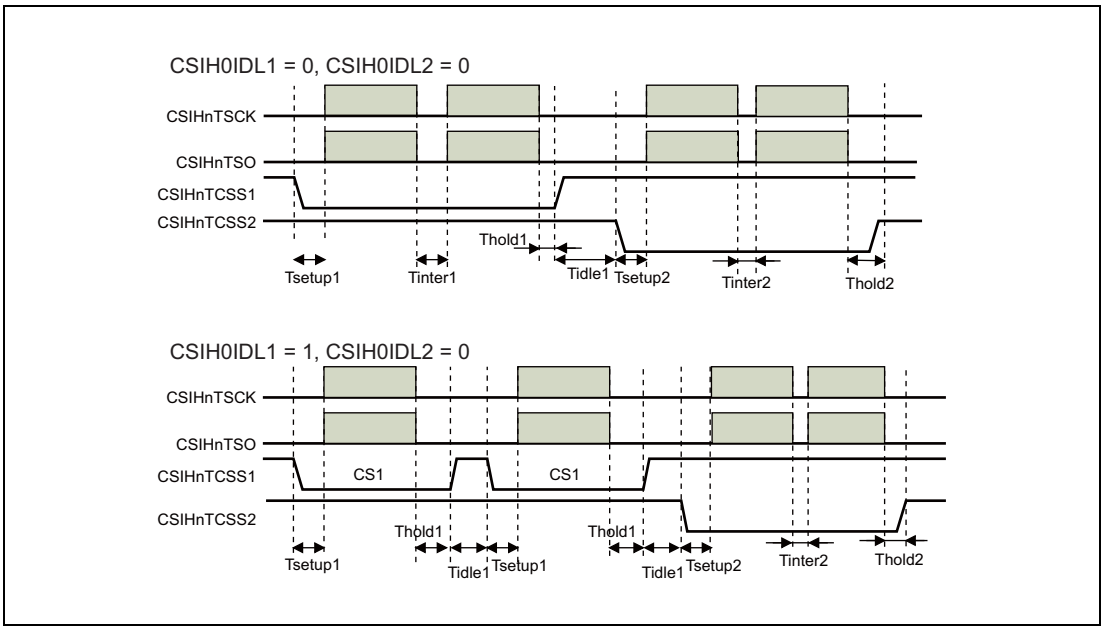

Figure 13.36 Enforced Chip Select Idle Example

13.6 CSIH Control Registers

CSIHn is controlled and operated by means of the registers in the following table.

Table 13.15 CSIH Register Overview

Register name	Shortcut	Address
CSIH control register 0	CSIHnCTL0	<CSIHn_base> + 0000_H
CSIH control register 1	CSIHnCTL1	<CSIHn_base> + 0010_H
CSIH control register 2	CSIHnCTL2	<CSIHn_base> + 0014_H
CSIH status register 0	CSIHnSTR0	<CSIHn_base> + 0004_H
CSIH status clear register 0	CSIHnSTCR0	<CSIHn_base> + 0008_H
CSIH configuration register 0	CSIHnCFG0	<CSIHn_base> + 1044_H
CSIH configuration register 1	CSIHnCFG1	<CSIHn_base> + 1048_H
CSIH configuration register 2	CSIHnCFG2	<CSIHn_base> + $104C_H$
CSIH configuration register 3	CSIHnCFG3	<CSIHn_base> + 1050_H
CSIH configuration register 4	CSIHnCFG4	<CSIHn_base> + 1054_H
CSIH configuration register 5	CSIHnCFG5	<CSIHn_base> + 1058_H
CSIH transmit data register 0 for word access	CSIHnTX0W	<CSIHn_base> + 1008_H
CSIH transmit data register 0 for half word access	CSIHnTX0H	<CSIHn_base> + $100C_H$
CSIH receive data register 0 for word access	CSIHnRX0W	<CSIHn_base> + 1010_H
CSIH receive data register 0 for half word access	CSIHnRX0H	<CSIHn_base> + 1014_H
CSIHn baud rate setting register 0	CSIHnBRS0	<CSIHn_base> + 1068_H
CSIHn baud rate setting register 1	CSIHnBRS1	<CSIHn_base> + $106C_H$
CSIHn baud rate setting register 2	CSIHnBRS2	<CSIHn_base> + 1070_H
CSIHn baud rate setting register 3	CSIHnBRS3	<CSIHn_base> + 1074_H

<CSIHn_base>

The base addresses <CSIHn_base> of the CSIHn are defined in the first part of this section under the key word “Register addresses”.

13.6.1 CSIHnCTL0 — CSIH Control Register 0

This register controls the operation clock and enables/disables transmission/reception and the memory part for transmission and/or reception. It forces the stop of communication at the end of the current job.

Access: This register can be read/written in 8-bit or 1-bit units.

Address: <CSIHn_base> + 0000_H

Value after reset: 00_H This register is initialized by reset operation.

Bit	7	6	5	4	3	2	1	0
	CSIHnPWR	CSIHnTXE	CSIHnRXE	—	—	—	CSIHnJOBE	CSIHnMBS
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R	R/W	R/W

Table 13.16 CSIHnCTL0 Register Contents

Bit Position	Bit Name	Function
7	CSIHnPWR	Controls the operation clock. 0: Stops operation clock. 1: Provides operation clock. Clearing CSIHnPWR to 0 resets the internal circuits, stops operation, and sets CSIH to standby state. No clock is provided to internal circuits. If CSIHnPWR is cleared during communication, ongoing communication is immediately aborted. In this case, communication setting must be started over.
6	CSIHnTXE	Permits or prohibits transmission. 0: Prohibits transmission. 1: Permits transmission.
5	CSIHnRXE	Permits or prohibits reception. 0: Prohibits reception. 1: Permits reception.
4 to 2	—	Reserved When writing, write the value after reset.
1	CSIHnJOBE	Stops communication at the end of the current job (Communication ends if data is written to the transmission buffer when CSIHnTX0W.CSIHnEOJ = 1 (job completion)): 0: Communication stop is not requested. 1: Stops communication. This bit can be used to abort an ongoing job. This bit is cleared to 0 automatically. If this bit is set to 1, the read value is always 0.
0	CSIHnMBS	Enables direct access mode. 0: CSIH transmit/receive operation is prohibited. 1: Direct access mode Write 1 in the CSIHnMBS bit for transmission/reception via the CSIH.

NOTES

1. Do not modify any of CSIHnTXE, CSIHnRXE, CSIHnJOBE, and CSIHnMBS bits while CSIHnPWR = 0.
   Do not modify the CSIHnMBS bit when CSIHnPWR = 1.
   The CSIHnTXE, CSIHnRXE, and CSIHnMBS bits can be modified when the CSIHnPWR bit is changed from 0 to 1.
   To change the CSIHnMBS bit, do so at the same time as when the CSIHnPWR bit is changed from 0 to 1.
2. Do not modify CSIHnTXE, CSIHnRXE, or CSIHnMBS while data transmission is pending or going on, i.e. if CSIHnSTR0.CSIHnTSF = 1.

13.6.2 CSIHnCTL1 — CSIH Control Register 1

This register specifies the interrupt timing and the interrupt delay mode. It enables/disables extended data length control, data consistency check, loop-back mode, handshake functionality, and job mode. It selects the active output level of each chip select signal and the behavior of the chip select signals after the transfer of the final data.

Access: This register can be read/written in 32-bit units.

Address: <CSIHn_base> + 0010_H

Value after reset: $0000\ 0000_H$ This register is initialized by reset operation.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CSIHn CKR	CSIHn SLIT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIHn CSL7	CSIHn CSL6	CSIHn CSL5	CSIHn CSL4	CSIHn CSL3	CSIHn CSL2	CSIHn CSL1	CSIHn CSL0	CSIHn EDLE	CSIHn JE	CSIHn DCS	CSIHn CSRI	CSIHn LBM	CSIHn SIT	CSIHn HSE	CSIHn SSE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

CAUTION

Changing the contents of this register is only permitted when CSIHnCTL0.CSIHnPWR = 0.

Table 13.17 CSIHnCTL1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 18	—	Reserved The write value should be the initial value.
17	CSIHnCKR	CSIHnTSCK Clock Inverting Function 0: Default of CSIHnTSCK is high level. 1: Default of CSIHnTSCK is low level. For details, see **Section 13.6.6, CSIHnCFGx — CSIH Configuration Register x**. **CAUTION** Clear the CSIHnCKPx bit in CSIHnCFGx to 0 when this bit is used without the chip select function.
16	CSIHnSLIT	Selects the timing of interrupt INT_CSIHTIC. 0: Normal interrupt timing (interrupt is generated after the transfer) 1: As soon as the contents of the CSIHnTX0W/H register are transferred to the shift register, an interrupt is generated. For details, see **Section 13.5.10, CSIH interrupt requests**, **(3) INT_CSIHTIC (communication status interrupt)**.
15 to 8	CSIHnCSL[7:0]	Selects the active output level of chip select signal x (CSIHnTCSSx). (n = 0 to 7) 0: Chip select is active low. 1: Chip select is active high. For details, see **Section 13.5.3, Chip Selection (CS) Features**.

Table 13.17 CSIHnCTL1 Register Contents (2/2)

Bit Position	Bit Name	Function
7	CSIHnEDLE	Enables/disables extended data length (EDL) mode. 0: Disables extended data length mode. 1: Enables extended data length mode. For details, see **Section 13.5.7, Data Length Selection**, **(2) Data length greater than 16 bits**.
6	CSIHnJE	Enables/disables job mode. 0: Disables job mode. 1: Enables job mode. For details, see **Section 13.5.3, Chip Selection (CS) Features**, **(3) Job concept**. The CSIHnCTL0.CSIHnJOBE and CSIH0TX0W.CSIH0EOJ bits are enabled only when CSIHnJE = 1. Setting this bit in slave mode is prohibited. **NOTE:** When CSIHnJE = 0, interrupt INTC_CSIHnTIC is generated after one unit of data transmission is completed. When CSIHnJE = 1, interrupt INTC_CSIHnTIC is also generated after one unit of data transmission is completed. In the case of CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1, however, interrupt INTC_CSIHnTIJC is generated instead of INTC_CSIHnTIC.
5	CSIHnDCS	Enables/disables data consistency check. 0: Disables data consistency check. 1: Enables data consistency check. For details, see **Section 13.5.12, Error Detection**, **(1) Data consistency check**.
4	CSIHnCSRI	Defines chip select signal behavior after last data transfer. 0: Chip select signal holds the active level. 1: Chip select signal returns to the inactive level. The last data is determined at the interrupt timing when CSIHnCTL1.CSIHnSLIT is 1.
3	CSIHnLBM	Controls loop-back mode (LBM). 0: Deactivates loop-back mode. 1: Activates loop-back mode. For details, see **Section 13.5.13, Loop-Back Mode**.
2	CSIHnSIT	Selects interrupt delay mode. 0: No delay is generated. 1: Half clock delay is generated for all interrupts. This bit is only valid in master mode. In slave mode, no delay is generated. For details, see **Section 13.5.10, CSIH interrupt requests**, **(2) Interrupt delay**.
1	CSIHnHSE	Enables/disables handshake function. 0: Disables the handshake function. 1: Enables the handshake function. For details refer to **Section 13.5.11, Handshake function**.
0	CSIHnSSE	Enables/disables the slave select function. 0: Input signal $\overline{\text{CSIHnTSSI}}$ is disabled. 1: Input signal $\overline{\text{CSIHnTSSI}}$ is recognized. If the slave select function is not used, this bit must be set to 0 (see also **Section 13.5.2, Master/Slave Connections**).

Details about CSIHnCTL1.CSIHnSSE are shown in the following tables.

Table 13.18 Operation of the Slave Select Function During Receive

CSIHnCTL0. CSIHnRXE	CSIHnCTL1. CSIHnSSE	$\overline{\text{CSIHnTSSI}}$	Receive operation
0	—	—	Receive is prohibited
1	0	—	Possible
1	1	0	Possible
1	1	1	Disabled

Table 13.19 Operation of the Slave Select Function During Transmission

CSIHnCTL0. CSIHnTXE	CSIHnCTL1. CSIHnSSE	$\overline{\text{CSIHnTSSI}}$	Transmit operation
0	—	—	Transmission is prohibited
1	0	—	Possible
1	1	0	Possible
1	1	1	Disabled

13.6.3 CSIHnCTL2 — CSIH Control Register 2

This register selects operating mode and the basic clock value, and specifies the baud rate.

For details see **Section 13.5.5, Transmission Clock Selection**.

Access: This register can be read/written in 16-bit units.

Address: <CSIHn_base> + 0014_H

Value after reset: $E000_H$ This register is initialized by reset operation.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIHnPRS[2:0]			—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

CAUTION

Changing the contents of this register is only permitted when CSIHnCTL0.CSIHnPWR = 0.

Table 13.20 CSIHnCTL2 Register Contents

Bit Position	Bit Name	Function
15 to 13	CSIHnPRS[2:0]	Selects the basic clock (PRSOUT).
12 to 0	—	Reserved When writing, write the value after reset.

CSIHnPRS2	CSIHnPRS1	CSIHnPRS0	Prescaler Section Bits
0	0	0	PCLK (Master mode)
0	0	1	PCLK/2 (Master mode)
0	1	0	PCLK/4 (Master mode)
0	1	1	PCLK/8 (Master mode)
1	0	0	PCLK/16 (Master mode)
1	0	1	PCLK/32 (Master mode)
1	1	0	PCLK/64 (Master mode)
1	1	1	External clock input from CSIHnTSCK (Slave mode)

CAUTION

Max baud rate configuration is as follows.
- Master mode is PCLK/8.
- Slave mode is PCLK/20.

In master mode, the following bits are used to set the transmission baud rate:

CSIHnCTL2.CSIHnPRS2 to 0, CSIHnCFGx.CSIHnBRSSx1 to 0, CSIHnBRSi.CSIHnBRSi11 to 0

In addition, any of the four different baud rate settings that are specified by the CSIHnBRSi (i = 0 to 3).CSIHnBRSi11 to 0 (i = 0 to 3) bit is selected according to the chip select signal. To select the baud rate setting for each chip select signal, use the CSIHnCFGx.CSIHnBRSSx1 to 0 bit.

The following table shows the relationship between CSIHnCFGx.CSIHnBRSSx1 to 0 and CSIHnBRSi (i = 0 to 3).CSIHnBRSi11 to 0 (i = 0 to 3).

CSIHnCFGx CSIHnBRSSx1 to 0	Baud Rate Setting Bits to be Selected
00	CSIHnBRS0.CSIH0BRS0 11 to 0
01	CSIHnBRS1.CSIH0BRS1 11 to 0
10	CSIHnBRS2.CSIH0BRS2 11 to 0
11	CSIHnBRS3.CSIH0BRS3 11 to 0

When the value of CSIHnPRS[2:0] is m, the following table shows the relationship between the baud rate setting (CSIHnBRSi[11:0]) and the baud rate selected by the CSIHnBRSSx[1:0] bits.

CSIHnBRSx11 to 0 (k)	Baud Rate Selection Bits
0	BRG stopped
1	PLCK / (2^m × 1 × 2)
2	PLCK / (2^m × 2 × 2)
3	PLCK / (2^m × 3 × 2)
4	PLCK / (2^m × 4 × 2)
:	:
k	PLCK / (2m × k × 2)
:	:
4095	PLCK / (2^m × 4095 × 2)

13.6.4 CSIHnSTR0 — CSIH Status Register 0

This register indicates the status of CSIH.

Access: This register can be read in 32-bit units.

Address: <CSIHn_base> + 0004_H

Value after reset: $0000\ 0010_H$ This register is initialized by reset operation.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	CSIHn TSF	—	—	—	CSIHn DCE	—	CSIHn PE	CSIHn OVE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 13.21 CSIHnSTR0 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 8	—	Reserved
7	CSIHnTSF	Transfer status flag 0: Idle state 1: Communication is in progress or being prepared. The timing to set or clear this bit is as follows. **Master mode** / **Set by** / **Cleared by** Transmit-only mode, Transmit/receive mode, Receive-only mode: Data is written to a transmit register / Within a half clock of the last serial clock edge **Slave mode** / **Set by** / **Cleared by** Transmit-only mode, Transmit/receive mode: Writing to a transmit register / Within a half clock of the last serial clock edge Receive-only mode: Input timing of CSIHnTSCK
6 to 4	—	Reserved
3	CSIHnDCE	Data consistency check error flag 0: No data consistency error is detected. 1: Data consistency error is detected. This bit is cleared by writing 1 to CSIHnSTCR0.CSIHnDCEC. When this bit is set to 1 and cleared to 0 simultaneously, setting to 1 is prioritized. This bit is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.
2	—	Reserved
1	CSIHnPE	Parity error flag 0: No parity error is detected. 1: Parity error is detected. For details, see **(2) Parity check** in **Section 13.5.12, Error Detection**. This bit is cleared by the CSIHnPEC bit in CSIHnSTCR0. When this bit is set to 1 and cleared to 0 simultaneously, clearing to 0 is prioritized.

Table 13.21 CSIHnSTR0 Register Contents (2/2)

Bit Position	Bit Name	Function
0	CSIHnOVE	Overrun error flag 0: No overrun error is detected. 1: Overrun error is detected. This bit is cleared by writing 1 to CSIHnSTCR0.CSIHnOVEC. When this bit is set to 1 and cleared to 0 simultaneously, setting to 1 is prioritized. This bit is Initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.

13.6.5 CSIHnSTCR0 — CSIH Status Clear Register 0

This register clears the status flags of the CSIHnSTR0 status register.

Access: This register can be read/written in 16-bit units.
When read, the value 0000_H is always returned.

Address: <CSIHn_base> + 0008_H

Value after reset: 0000_H This register is initialized by reset operation.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CSIHn DCEC	—	CSIHn PEC	CSIHn OVEC

Table 13.22 CSIHnSTCR0 Register Contents

Bit Position	Bit Name	Function
15 to 4	—	Reserved When writing, write the value after reset.
3	CSIHnDCEC	Controls the data consistency error flag clear command. 0: No operation. The read value is always 0. 1: Clears the data consistency error flag (CSIHnSTR0.CSIHnDCE).
2	—	Reserved When writing, write the value after reset.
1	CSIHnPEC	Controls the parity error flag clear command. 0: No operation. The read value is always 0. 1: Clears the parity error flag (CSIHnSTR0.CSIHnPE).
0	CSIHnOVEC	Controls the overrun error flag clear command. 0: No operation. The read value is always 0. 1: Clears the overrun error flag (CSIHnSTR0.CSIHnOVE).

13.6.6 CSIHnCFGx — CSIH Configuration Register x

These registers specify for each chip select signal CSIHnTCSSx prescaler, parity, data length, recessive configuration for broadcasting, serial data direction, clock and data phase, idle enforcement configuration, idle time, hold time, inter-data time and setup time.

Slave mode

In slave mode, the transmission protocol setting of the CSIHnCFG0 register is effective.

- CSIHnPS0[1:0]: parity usage
- CSIHnDLS0[3:0]: data length selection
- CSIHnDIR0: data direction
- CSIHnCKP0, CSIHnDAP0: clock and data phase

The settings of the registers other than CSIHnCFG0 are ignored in slave mode.

Access: This register can be read/written in 32-bit units.

Address: CSIHnCFG0: <CSIHn_base> + 1044_H
CSIHnCFG1: <CSIHn_base> + 1048_H
CSIHnCFG2: <CSIHn_base> + $104C_H$
CSIHnCFG3: <CSIHn_base> + 1050_H
CSIHnCFG4: <CSIHn_base> + 1054_H
CSIHnCFG5: <CSIHn_base> + 1058_H

Value after reset: $0000\ 0000_H$ This register is initialized by reset operation.

1110_B	18.0 transmission clock cycles	18.5 transmission clock cycles
1111_B	20.0 transmission clock cycles	20.5 transmission clock cycles

These bits are only available in master mode.

3 to 0	CSIHnSPx[3:0]	Specifies the setup time for chip select signal x in transmission clock cycles.

CSIHn SPx[3:0]	Setup time
0000_B	0.5 transmission clock cycles
0001_B	1.0 transmission clock cycle
0010_B	1.5 transmission clock cycles
0011_B	2.5 transmission clock cycles
0100_B	3.5 transmission clock cycles
0101_B	4.5 transmission clock cycles
0110_B	6.5 transmission clock cycles
0111_B	8.5 transmission clock cycles
1000_B	9.5 transmission clock cycles
1001_B	10.5 transmission clock cycles
1010_B	11.5 transmission clock cycles
1011_B	12.5 transmission clock cycles
1100_B	14.5 transmission clock cycles
1101_B	16.5 transmission clock cycles
1110_B	18.5 transmission clock cycles
1111_B	20.5 transmission clock cycles

These bits are only available in master mode.

13.6.7 CSIHnTX0W — CSIH Transmit Data Register 0 for Word Access

This register stores transmission data. In addition, it specifies the communication interrupt request, the end-of-job, the extended data length, and the chip select activation.

Access: This register can be read/written in 32-bit units.

Address: <CSIHn_base> + 1008_H

Value after reset: Undefined

CAUTIONS

When CSIH0CTL0.CSIH0TXE = CSIH0CTL0.CSIH0RXE = 0 in direct access mode, write access to this register is prohibited.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 13.24 CSIHnTX0W Register Contents (1/2)

Bit position	Bit name	Function
31	—	Reserved When writing, write the value after reset.
30	CSIHnEOJ	Specifies the end of a job. 0: Indicates that the job does not end. The job continues. 1: Indicates end-of-job data. **CAUTION** This bit is only valid when job mode is enabled (CSIHnCTL1.CSIHnJE = 1). This bit must be set to 0 in slave mode.
29	CSIHnEDL	Specifies whether the associated data requires the extended data length (EDL) option. 0: Normal operation 1: Enables the extended data length. The associated data is transmitted as a 16-bit packet. No inter-data time or idle time will be inserted after the data is transmitted. If CSIHnCTL1.CSIHnEDLE = 1 and CSIHnTX0W.CSIHnEDL = 1, the subsequent data must have the same CS selection. If CS is modified for the subsequent data, the correct operation is not assured. **CAUTION** This bit is only available if CSIHnCTL1.CSIHnEDLE = 1.
28 to 24	—	Reserved When writing, write the value after reset.

Table 13.24 CSIHnTX0W Register Contents (2/2)

Bit position	Bit name	Function
23 to 16	CSIHnCSx	Activates one or several chip select signals. 0: Activates chip select x for the associated transmission. 1: Deactivates chip select x for the associated transmission. Setting CSIHnTX0W.CSIHnCS[7:0] = FF_H is prohibited. **CAUTION** If several chip select signals are enabled for broadcasting, the configuration of one with CSIHnCFGx.CSIHnRCBx = 0 (dominant) is used. In this case, all dominant chip select signals must be set to precisely the same value. In slave mode, set the CSIHnCSx bit to FE_H.
15 to 0	CSIHnTX[15:0]	Stores the transmission data.

13.6.8 CSIHnTX0H — CSIH Transmit Data Register 0 for Half Word Access

This register stores the transmission data. This register is the same as bits 15 to 0 of register CSIHnTX0W.

Access: This register can be read/written in 16-bit units.

Address: <CSIHn_base> + $100C_H$

Value after reset: Undefined

CAUTIONS

When CSIH0CTL0.CSIH0TXE = CSIH0CTL0.CSIH0RXE = 0 in direct access mode, write access to this register is prohibited.

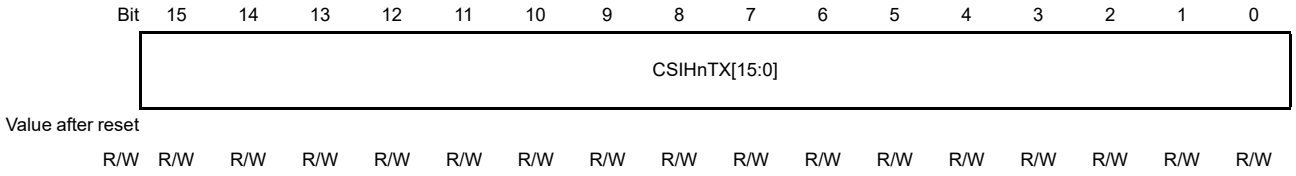

Table 13.25 CSIHnTX0H Register Contents

Bit position	Bit name	Function
15 to 0	CSIHnTX[15:0]	Stores the transmission data.

13.6.9 CSIHnRX0W — CSIH Receive Data Register 0 for Word Access

This register stores the received data.

Access: This register can be read in 32-bit units.

Address: <CSIHn_base> + 1010_H

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

CAUTION

This register can be read in direct access mode and transmit-only buffer mode while CSIHnCTL0.CSIHnPWR = 1.
This register is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.

Table 13.26 CSIHnRX0W Register Contents

Bit position	Bit name	Function
31 to 26	—	Reserved
25	CSIHnRPE	Indicates whether a reception data parity error was detected. 0: No parity error was detected on the associated reception data. 1: A parity error was detected on the associated reception data.
24	CSIHnTDCE	Indicates whether a transmission data consistency error was detected. 0: No consistency error was detected on the associated transmission data. 1: A consistency error was detected on the associated transmission data.
23 to 16	CSIHnCSx	Indicates which chip select signal was activated. 0: Chip select x was activated for the associated reception. 1: Chip select x was deactivated for the associated reception.
15 to 0	CSIHnRX[15:0]	Stores the received data.

13.6.10 CSIHnRX0H — CSIH Receive Data Register 0 for Half Word Access

This register stores the received data. This register is the same as bits 15 to 0 of register CSIHnRX0W.

Access: This register can only be read in 16-bit units.

Address: <CSIHn_base> + 1014_H

Value after reset Undefined

CAUTIONS

This register can be read in direct access mode and transmit-only buffer mode while CSIHnCTL0.CSIHnPWR = 1.

This register is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.

Table 13.27 CSIHnRX0H Register Contents

Bit position	Bit name	Function
15 to 0	CSIHnRX[15:0]	Stores the received data.

13.6.11 CSIHnBRSi — CSIHn Baud Rate Setting Register i

This register sets the baud rate for each chip select signal.

CSIHnCFGx.CSIHnBRSSx1-0 bits, one of the four types of baud rate settings can be selected for each chip select signal.

Access: This register can be read/written in 16-bit units.

Address: CSIHnBRS0: <CSIHn_base> + 1068_H
CSIHnBRS1: <CSIHn_base> + $106C_H$
CSIHnBRS2: <CSIHn_base> + 1070_H
CSIHnBRS3: <CSIHn_base> + 1074_H

Value after reset: 0000_H. This register is initialized by reset operation.

Table 13.28 CSIHnBRSi Register Contents

Bit Position	Bit Name	Function
15 to 12	—	Reserved The write value should be the initial value.
11 to 0	CSIHnBRSi [11:0]	0: BRG stopped 1: PCLK / (2^m × 1 × 2) 2: PCLK / (2^m × 2 × 2) 3: PCLK / (2^m × 3 × 2) 4: PCLK / (2^m × 4 × 2) : k: PCLK / (2^m × k × 2) : 4095: PCLK / (2^m × 4095 × 2) m is the value of CSIHnCTL2.CSIHnPRS[2:0].

13.7 Operating Procedures

13.7.1 Procedures in Direct Access Mode

Two examples for a master are provided, one with job mode disabled, and the other one with job mode enabled.

(1) Transmission/reception in master mode when job mode is disabled

The procedures below are based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = $1000_{B)}$.
- Transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is disabled (CSIHnCTL1.CSIHnJE = 0).
- Normal INT_CSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 1)

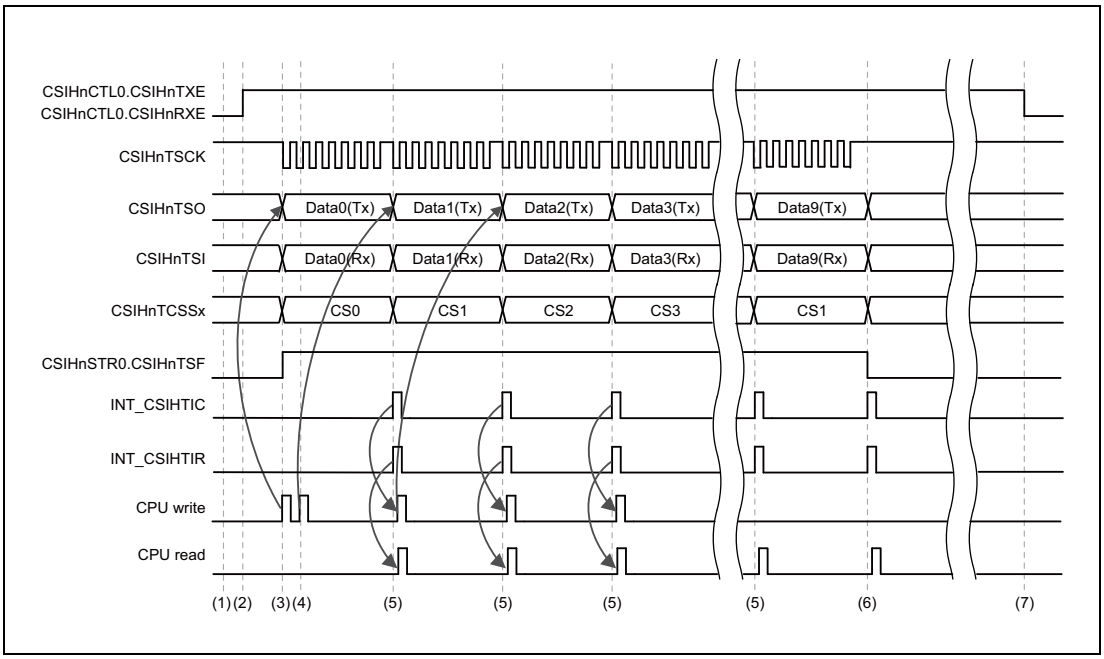

Figure 13.37 Master in Direct Access Mode, CSIHnCTL1.CSIHnJE = 0

Procedure:

(1) Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CS0 to CS3.
Specify the transfer mode and job mode by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.

(2) In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), CSIHnRXE = 1 (permits reception), and CSIHnMBS = 1 (direct access mode).

(3) Write the first data to be sent to the transmission register, CSIHnTX0W. Within the same write operation, activate CS0. Transmission starts automatically when the first data becomes available.

(4) Write the second data to CSIHnTX0W. If required, you can change the CS to address a different device. Writing the second data immediately after the first one avoids unnecessary delays between the data.

(5) After every transmission/reception of a data, the interrupts INT_CSIHTIC and INT_CSIHTIR are generated:
- INT_CSIHTIC indicates that the next data can be written to CSIHnTX0W.
- INT_CSIHTIR indicates that the reception register, CSIHnRX0W must be read.

(6) No more write action is required after completion of data 8. Data 9 (the last packet) has been written in advance.
However, reception register CSIHnRX0W must be read after completion of writing data 8 and 9.

(7) Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.

(2) Transmission/reception in master mode when job mode is enabled

The procedure below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- Transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is enabled (CSIHnCTL1.CSIHnJE = 1).
- Normal INT_CSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 1)
- Two jobs, each of them sends three data.

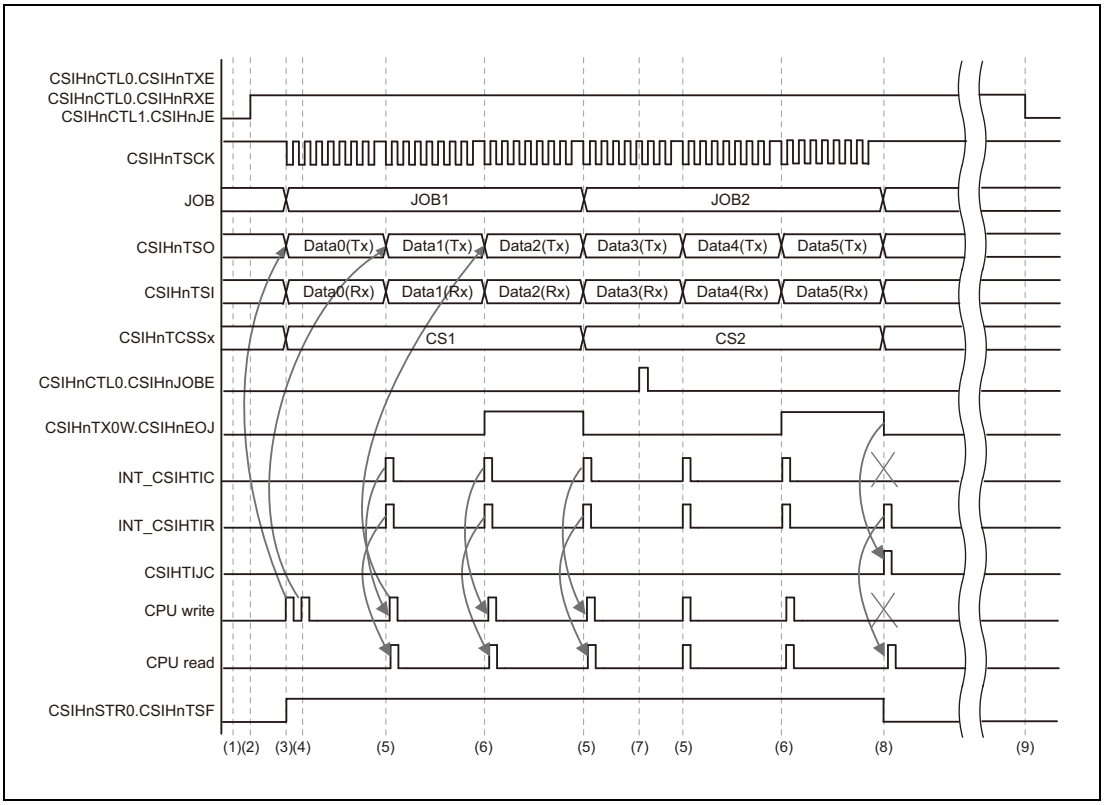

Figure 13.38 Master in Direct Access Mode, CSIHnCTL1.CSIHnJE = 1

Procedure:

(1) Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CS1 and CS2.
Specify the transfer mode and job mode by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.

(2) In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), CSIHnRXE = 1 (permits the reception), and CSIHnMBS = 1 (selects direct access mode).

(3) Write the first data to be sent to the transmission register CSIHnTX0W. Transmission starts automatically when the first data becomes available.
The CSIHnSTR0.CSIHnTSF flag indicates that communication is in progress.

(4) Write the second data to CSIHnTX0W. Writing the second data immediately after the first one avoids unnecessary delays between the data.

(5) After every data transmission/reception, the interrupt requests, INT_CSIHTIC and INT_CSIHTIR are generated.
- INT_CSIHTIC indicates that the next data can be written to CSIHnTX0W.
- INT_CSIHTIR indicates that the reception register, CSIHnRX0W must be read.

(6) Setting CSIHnTX0W.CSIHnEOJ = 1 indicates that the last data of the current job is sent. After that, the next job may begin.

(7) By setting CSIHnCTL0.CSIHnJOBE = 1, communication is forced to stop at the end of the current job (JOB2).

(8) After the forced stop of communication, the interrupt request, INT_CSIHTIC is replaced by INT_CSIHTIJC. INT_CSIHTIR is generated as usual.
The interrupt request, INT_CSIHTIJC indicates a forced stop of communication at the end of the current job.
The interrupt request, INT_CSIHTIC is not generated. Additionally, the transmission data available in the CSIHnTX0W register is not sent.

(9) Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.
To start another transmission without stopping communication, perform steps 3 and later.

Section 14 Serial Communication Interface 3 (SCI3)

14.1 Overview

The serial communication interface 3 (SCI3: Serial Communication Interface 3) can handle two methods of serial communications: asynchronous and clock synchronous serial communications. Asynchronous serial data communications can be carried out with standard asynchronous communication LSIs such as Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA). Asynchronous mode is equipped with a serial communications function between multiple processors (multi-processor communications function).

14.1.1 Features of SCI3

Number of channels

This product contains the serial communication interface 3 for the number of channels shown below.

Table 14.1 Channels of SCI3

Serial Communication Interface 3	RH850/E1M-S
Number of channels	4
Name	SCI3n (n = 0 to 3)

Meaning of “n”

In this section, each channel of the serial communication interface 3 is identified by “n” (n = 0 to 3). For example, a serial mode register is written as SCI3nSMR.

14.1.2 Outline of Functions

- The serial data communication mode can be configured for asynchronous communications or clock synchronous communications.
- Full-duplex communications are available. The independent transmitter unit and receiver unit allow simultaneous transmission and reception. Both the transmitter and the receiver have a double-buffered structure, enabling continuous data transmission and reception.
- An arbitrary bit rate is selectable with the on-chip baud rate generator. An external clock is also selectable as a transmission/reception clock source.
- LSB-first or MSB-first transfer is selectable (except for asynchronous 7-bit data.)
- Interrupt sources: 4 types consisting of transmit-end, transmit-data-empty, receive-data-full, and receive-error. Transmit-data-empty and receive-data-full interrupt sources can activate the DMAC.
- Module stop mode can be configured.
- The bit rate modulation function can reduce errors averagely (even in a high bit rate) by correcting the output of the on-chip baud rate generator (except for the maximum speed in clock synchronous mode).
- The pin level of serial input data can be checked.
- On-chip 6-bit divider (PSC)

14.1.3 Serial Communication Modes

Asynchronous mode

- Data length: 7 bits or 8 bits selectable
- Stop bit length: 1 bit or 2 bits selectable
- Parity: Even parity, odd parity, or none electable
- Receive error detection: Parity error, overrun error, and framing error
- Break detection: A break can be detected by reading a register in the case of a framing error.

Clock synchronous mode

- Data length: 8 bits
- Receive error detection: Overrun error

14.1.4 Block Diagram

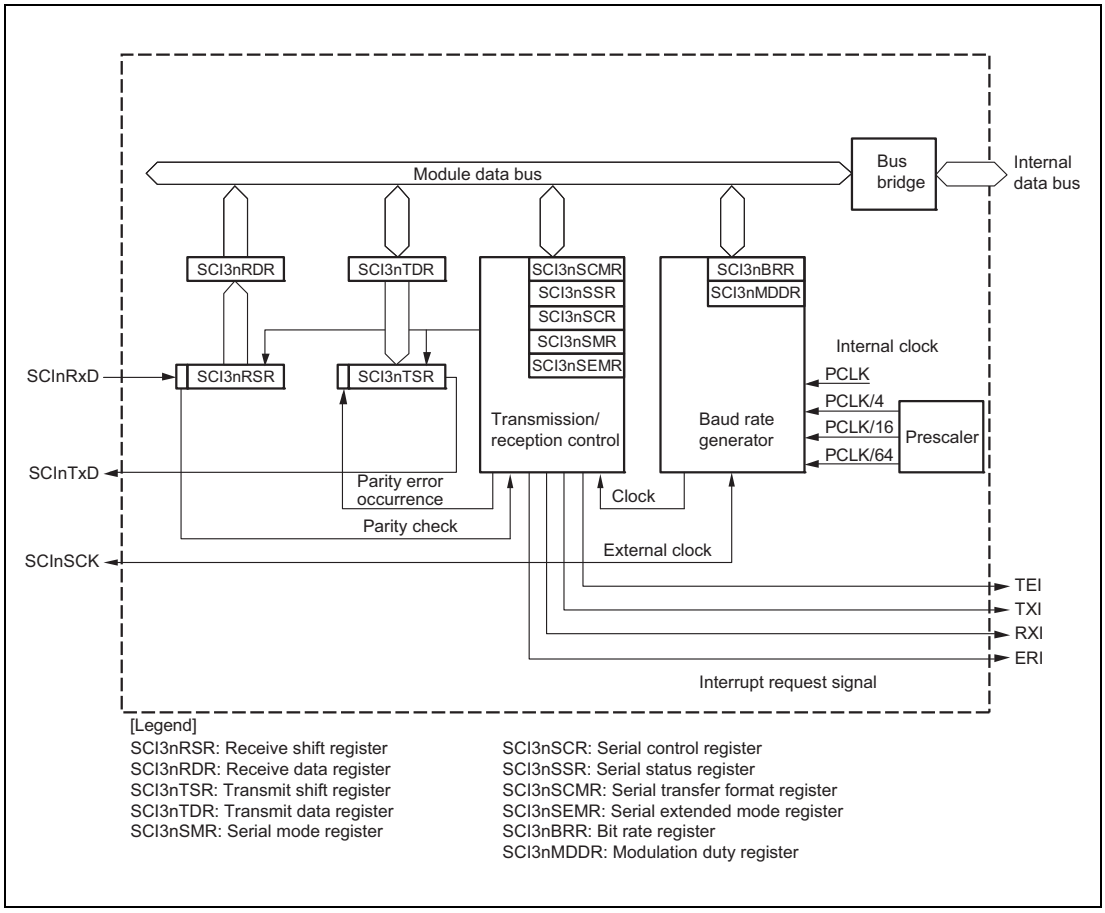

Figure 14.1 SCI3 Block Diagram

14.2 Input/Output Pins

The SCI3 has the input/output pins listed in **Table 14.2**.

Table 14.2 Pin Configuration

Name	Symbol	I/O	Function
Clock input/output pin	SCInSCK	Input	Serial clock input
		Output	Serial clock output
Receive data input pin	SCInRxD	Input	Receive data input
Transmit data output pin	SCInTxD	Output	Transmit data output

14.3 Register Descriptions

SCI3n register addresses are given as offsets from the base address <SCI3n_base>.

The base addresses <SCI3n_base> of each SCI3 are listed in **Table 14.3**.

Table 14.3 Register Base Address <SCI3n_base>

SCI3n Channel	SCI3n_base Address
SCI30	FFD9 0000_H
SCI31	FFD9 1000_H
SCI32	FFD9 2000_H
SCI33	FFD9 3000_H

The SCI3 has the following registers. Some registers have limitations in read/write by the CPU.

CAUTION

SCI3nBRR and SCI3nMDDR are allocated to the same address (relative address 4). The SCI3nMDDRS bit in SCI3nSEMR is used to switch these registers.

Table 14.4 Register Configuration

Register Name	Symbol Note:	Value after Reset	Address	Access Size
Receive shift register	SCI3nRSR	—	—	—
Serial mode register	SCI3nSMR	00_H	<SCI3n_base>+ 0000_H	8
Bit rate register / Modulation duty register	SCI3nBRR/ SCI3nMDDR	FF_H	<SCI3n_base>+ 0004_H	8
Serial control register	SCI3nSCR	00_H	<SCI3n_base>+ 0008_H	8
Transmit data register	SCI3nTDR	FF_H	<SCI3n_base>+ $000C_H$	8
Transmit shift register	SCI3nTSR	—	—	—
Serial status register	SCI3nSSR	84_H	<SCI3n_base>+ 0010_H	8
Receive data register	SCI3nRDR	00_H	<SCI3n_base>+ 0014_H	8
Serial transfer format register	SCI3nSCMR	$F2_H$	<SCI3n_base>+ 0018_H	8
Serial extended mode register	SCI3nSEMR	04_H	<SCI3n_base>+ $001C_H$	8

Note: n = 0 to 3

Relative addresses 4n + 1, 4n + 2, and 4n + 3 (n = 0 to 7) are reserved areas. These areas are always read as 0. Writing is invalid.

14.3.1 SCI3nRSR — Receive Shift Register

SCI3nRSR is a shift register which is used to receive serial data input from the SCInRxD pin and convert it to parallel data. When one frame of data has been received, it is automatically transferred to SCI3nRDR. SCI3nRSR cannot be directly accessed by the CPU.

14.3.2 SCI3nRDR — Receive Data Register

SCI3nRDR is an 8-bit register to store receive data. The initial value of SCI3nRDR is 00_H. When one frame of data has been received, it is transferred from SCI3nRSR to this register allowing SCI3nRSR to receive the next data. SCI3nRSR and SCI3nRDR function as a double-buffer in this way, allowing continuous receive operations. Be sure to check that the RDRF flag in SCI3nSSR is set to 1 before reading SCI3nRDR. SCI3nRDR cannot be written from the CPU.

When the data length is 7 bits, receive data is stored in bit 0 to 6 and bit 7 is fixed to 0 regardless of the SINV bit in SCI3nSCMR.

14.3.3 SCI3nTDR — Transmit Data Register

SCI3nTDR is an 8-bit register to store transmit data. The initial value of SCI3nTDR is FF_H. When SCI3nTSR empty is detected, the transmit data written to SCI3nTDR is transferred to SCI3nTSR and transmission starts. The double-buffered structure of SCI3nTDR and SCI3nTSR allows continuous serial transmission. If the next transmit data has been written to SCI3nTDR when one frame of data is sent, the transmit data is transferred to SCI3nTSR to continue transmission. SCI3nTDR can always be read and written by the CPU. Be sure to check that the TDRE flag in SCI3nSSR is set to 1 before writing transmit data to SCI3nTDR.

14.3.4 SCI3nTSR — Transmit Shift Register

SCI3nTSR is a shift register to transmit serial data. To perform serial data transmission, transmit data written to SCI3nTDR is automatically transferred SCI3nTSR, and is then sent to the SCInTxD pin. SCI3nTSR cannot be directly accessed by the CPU.

14.3.5 SCI3nSMR — Serial Mode Register

SCI3nSMR is a register used to select the transfer format and the clock source for the on-chip baud rate generator.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + 0000_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CM	CHR	PE	PM	STOP	MP	CKS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Note 1. Writable only when TE = RE = 0.

Table 14.5 SCI3nSMR Register Contents

Bit Position	Bit Name	Function
7	CM	Communications Mode 0: Asynchronous mode 1: Clock synchronous mode
6	CHR	Character Length (Valid only in asynchronous mode) 0: Selects 8 bits as the data length. 1: Selects 7 bits as the data length. LSB-first is fixed and the MSB (bit 7) in SCI3nTDR is not transmitted in transmission. In clock synchronous mode, the data length is fixed to 8 bits.
5	PE	Parity Enable (Valid only in asynchronous mode) When this bit is set to 1, a parity bit is added to transmit data and the parity bit is checked in reception. Regardless of the setting of this bit, no parity bit is added or checked in the multi-processor format.
4	PM	Parity Mode (Valid only when PE = 1 in asynchronous mode) 0: Selects even parity. 1: Selects odd parity. When even parity is set, parity bit is added so that the total number of 1 bits in the transmit/receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit is added so that the total number of 1 bits in the transmit/receive character plus the parity bit is odd.
3	STOP	Stop Bit Length (Valid only in asynchronous mode) 0: 1 stop bit for transmission 1: 2 stop bits for transmission In reception, only the first stop bit is checked regardless of the setting of this bit. If the second stop bit is 0, it is treated as the start bit of the next transmission frame.
2	MP	Multi-Processor Mode (Valid only in asynchronous mode) When this bit is set to 1, the multi-processor communication function is enabled. In multi-processor mode, settings of the PE and PM bits are invalid.
1, 0	CKS[1:0]	Clock Select 1, 0 These bits select the clock source for the on-chip baud rate generator. 00: PCLK clock (n = 0) 01: PCLK/4 clock (n = 1) 10: PCLK/16 clock (n = 2) 11: PCLK/64 clock (n = 3) For the relation between the setting of these bits and the baud rate, see **Section 14.3.10, SCI3nBRR — Bit Rate Register**. The character n is the decimal notation of the value of n in **Section 14.3.10, SCI3nBRR — Bit Rate Register**.

14.3.6 SCI3nSCR — Serial Control Register

SCI3nSCR is a register used for the transmission/reception control, interrupt control, and transmission/reception clock source selection listed below. For interrupt requests, see **Section 14.8, Interrupt Sources**.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + 0008_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W*1	R/W*1	R/W	R/W	R/W*2	R/W*2

Note 1. While the CM bit in SCI3nSMR is 1, a value of 1 can be written only when TE = 0 and RE = 0. After the TE or RE bit is set to 1, only 0 can be written to TE and RE. While the CM bit in SCI3nSMR is 0, writing is enabled at any timing.

Note 2. Writable only when TE = 0 and RE = 0. Also, writable at the same time when TE = 0 and RE = 0 are written.

Table 14.6 SCI3nSCR Register Contents (1/2)

Bit Position	Bit Name	Function
7	TIE	Transmit Interrupt Enable When this bit is set to 1, TXI interrupt request is enabled. TXI interrupt request can be cancelled by reading 1 from the TDRE flag and then clearing the flag to 0, or clearing the TIE bit.
6	RIE	Receive Interrupt Enable When this bit is set to 1, RXI and ERI interrupt requests are enabled. RXI and ERI interrupt requests can be cancelled by reading 1 from the RDRF, FER, PER, or ORER flag and then clearing the flag to 0, or clearing the RIE bit.
5	TE	Transmit Enable When this bit is set to 1, transmission is enabled. In this state, serial transmission is started by writing transmit data to SCI3nTDR and clearing the TDRE flag in SCI3nSSR to 0. Be sure to set SCI3nSMR before setting the TE bit to 1 to determine the transmission format. When this bit is set to 0 to disable transmission, the TDRE flag in SCI3nSSR is fixed to 1.
4	RE	Receive Enable When this bit is set to 1, reception is enabled. In this state, serial reception is started by detecting a start bit in asynchronous mode or the input of synchronous clock in clock synchronous mode. Be sure to set SCI3nSMR before setting the RE bit to 1 to determine the reception format. Even if reception is disabled by clearing this bit, the RDRF, FER, PER, and ORER flags are not affected and the previous value is retained.
3	MPIE	Multiprocessor Interrupt Enable (Valid only when MP in SCI3nSMR = 1 in asynchronous mode) When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the RDRF, FER, and ORER flags in SCI3nSSR to 1 is disabled. When the data with the multi-processor bit set to 1 is received, this bit is automatically cleared to 0, and normal reception is resumed. For details, see **Section 14.5, Multi-Processor Communication Function**. When the receive data includes MPB = 0 in SCI3nSSR, the receive data is not transferred from SCI3nRSR to SCI3nRDR, a receive error is not detected, and setting the RDRF, FER, and ORER flags in SCI3nSSR to 1 is disabled. When the receive data includes MPB = 1 in SCI3nSSR, the MPB bit in SCI3nSSR is set to 1, the MPIE bit is automatically cleared to 0, the RXI and ERI interrupt requests are enabled (if the RIE bit in SCI3nSCR is set to 1), and setting the FER and ORER flags to 1 is enabled.

Table 14.6 SCI3nSCR Register Contents (2/2)

Bit Position	Bit Name	Function
2	TEIE	Transmit End Interrupt Enable When this bit is set to 1, TEI interrupt request is enabled. TEI interrupt request can be cancelled by reading 1 from the TDRE flag and then clearing the flag to 0 to clear the TEND flag to 0, or clearing the TEIE bit.
1, 0	CKE[1:0]	Clock Enable 1, 0 These bits select the clock source and the SCInSCK pin function. For asynchronous mode 00: On-chip baud rate generator (The SCInSCK pin functions as an input/output port.) 01: On-chip baud rate generator (The clock with the same frequency as the bit rate is output from the SCInSCK pin.) 1X: Setting prohibited For clock synchronous mode 0X: Internal clock (The SCInSCK pin functions as a clock output pin.) 1X: External clock (The SCInSCK pin functions as a clock input pin.)

Note 1. X: Don’t care

NOTE

When writing to any bit other than the MPIE bit of this register, use a store instruction such that the value of the MPIE bit becomes 0.

Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently set the MPIE bit to 1.

14.3.7 SCI3nSSR — Serial Status Register

SCI3nSSR consists of SCI3 status flags and transfer multi-processor bits.

The TDRE, RDRF, ORER, PER, and FER flags can be cleared only.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + 0010_H

Value after reset: 84_H

Bit	7	6	5	4	3	2	1	0
	TDRE	RDRF	ORER	FER	PER	TEND	MPB	MPBT
Value after reset	1	0	0	0	0	1	0	0
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R	R	R/W

Note 1. Only 0 can be written to clear the flag.

Table 14.7 SCI3nSSR Register Contents (1/2)

Bit Position	Bit Name	Function
7	TDRE	Transmit Data Register Empty Indicates whether or not transmit data exists in SCI3nTDR. [Setting conditions] • When the TE bit in SCI3nSCR is 0 • When the data in SCI3nTDR has been transferred to SCI3nTSR so that new data can be written to SCI3nTDR [Clearing condition] • Writing 0 to TDRE after reading TDRE = 1 When transmit data is written to SCI3nTDR while TE = 1
6	RDRF	Receive Data Register Full Indicates whether or not receive data exists in SCI3nRDR [Setting condition] • When reception finishes successfully and the receive data is transferred from SCI3nRSR to SCI3nRDR [Clearing conditions] • Writing 0 to RDRF after reading RDRF = 1 • When data is read from SCI3nRDR Even when the RE bit in SCI3nSCR is cleared, the RDRF flag is not affected and the previous value is retained. • Note that completing the reception of the next data with the RDRF flag set to 1 will cause an overrun error, resulting in the loss of the receive data.
5	ORER	Overrun Error Indicates that an overrun error has occurred during reception and the reception abended. [Setting condition] • When the next data is received while RDRF = 1 In SCI3nRDR, receive data prior to an overrun error is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be continued. In clock synchronous mode, serial transmission also cannot be continued. [Clearing condition] • Writing 0 to ORER after reading ORER = 1 Even when the RE bit in SCI3nSCR is cleared, the ORER flag is not affected and the previous value is retained.

Table 14.7 SCI3nSSR Register Contents (2/2)

Bit Position	Bit Name	Function
4	FER	Framing Error Indicates that a framing error has occurred during reception in asynchronous mode and the reception abended. [Setting condition] • When the stop bit is 0 In 2-stop-bit mode, only whether the first stop bit is 1 is checked but the second stop bit is not checked. Although the receive data when a framing error has occurred is transferred to SCI3nRDR, the RDRF flag is not set. In addition, while the FER flag is set to 1, the subsequent receive data is not transferred to SCI3nRDR. [Clearing condition] • Writing 0 to FER after reading FER = 1 Even when the RE bit in SCI3nSCR is cleared to 0, the FER flag is not affected and the previous value is retained.
3	PER	Parity Error Indicates that a parity error has occurred during reception in asynchronous mode and the reception abended. [Setting condition] • Although the receive data when a parity error has occurred is transferred to SCI3nRDR, the RDRF flag is not set. In addition, while the PER flag is set to 1, the subsequent receive data is not transferred to SCI3nRDR. [Clearing condition] • Writing 0 to PER after reading PER = 1 Even when the RE bit in SCI3nSCR is cleared to 0, the PER flag is not affected and the previous value is retained.
2	TEND	Transmit End [Setting conditions] • When the TE bit in SCI3nSCR is 0 • When the TDRE flag is 1 while the last bit of a transmit character is being transmitted [Clearing condition] • Writing 0 to the TDRE flag after reading TDRE = 1 • When transmit data is written to SCI3nTDR while TE = 1
1	MPB	Multi-Processor Bit Holds the value of the multi-processor bit in the received frame.
0	MPBT	Multi-Processor Bit Transfer Sets the value of the multi-processor bit to be added to the transmit frame.

14.3.8 SCI3nSCMR — Serial Transfer Format Register

SCI3nSCMR is a register to select transfer format for both asynchronous mode and clock synchronous mode.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + 0018_H

Value after reset: $F2_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	SDIR	SINV	—	—
Value after reset	1	1	1	1	0	0	1	0
R/W	R	R	R	R	R/W*1	R/W*1	R	R

Note 1. Writable only when TE = 0 and RE = 0.

Table 14.8 SCI3nSCMR Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved These bits are always read as 1. When writing, write the value after reset.
3	SDIR	Serial Data Transfer Direction (Valid in asynchronous mode and clock synchronous mode) This bit is used to select the direction of serial/parallel conversion. 0: Transfer with LSB-first 1: Transfer with MSB-first This bit is valid only when the transfer format is 8-bit data. For 7-bit data, LSB-first transfer is used.
2	SINV	Serial Data Invert (Valid in asynchronous mode and clock synchronous mode) This bit is used to invert the transfer data logic level. The SINV bit does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in SCI3nSMR. 0: SCI3nTDR data is transmitted as it is, and receive data is stored in SCI3nRDR as it is. 1: SCI3nTDR data is inverted and transmitted, and receive data is inverted and stored in SCI3nRDR.
1	—	Reserved These bits are always read as 1. When writing, write the value after reset.
0	—	Reserved These bits are always read as 0. When writing, write the value after reset.

14.3.9 SCI3nSEMR — Serial Extended Mode Register

SCI3nSEMR is a register to select a 1-bit period.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + $001C_H$

Value after reset: 04_H

Bit	7	6	5	4	3	2	1	0
	BRME	MDDRS	—	—	ABCS	RXDMON	—	—
Value after reset	0	0	0	0	0	1	0	0
R/W	R/W*1	R/W*1	R	R	R/W*1	R	R	R

Note 1. Writable only when TE = 0 and RE = 0.

Table 14.9 SCI3nSEMR Register Contents

Bit Position	Bit Name	Function
7	BRME	Bit Rate Modulation Enable When this bit is set to 1, the bit rate modulation function is enabled.
6	MDDRS	Modulation Duty Register Select This bit is used to select an accessible register. 0: SCI3nBRR is accessible. 1: SCI3nMDDR is accessible.
5, 4	—	Reserved These bits are always read as 0. When writing to these bits, write the value after reset.
3	ABCS	Asynchronous Reference Clock Select (Valid only in asynchronous mode) This bit is used to select the reference clock for 1-bit period. 0: Operates on the reference clock with a frequency of 16 times the transfer rate. 1: Operates on the reference clock with a frequency of 8 times the transfer rate (double-speed operation).
2	RXDMON	Serial Input Data Monitor This bit indicates the SCInRxD pin state. 0: SCInRxD pin is at the low level. 1: SCInRxD pin is at the high level.
1, 0	—	Reserved These bits are always read as 0. When writing to these bits, write the value after reset.

14.3.10 SCI3nBRR — Bit Rate Register

SCI3nBRR is an 8-bit register to adjust the bit rate. Since each SCI3 channel has an independent baud rate generator, different bit rates can be set for each channel. **Table 14.11** shows the relationship between the setting (N) in SCI3nBRR and the bit rate (B) in normal asynchronous mode and clock synchronous mode. The value after reset of SCI3nBRR is FF_H. SCI3nBRR is allocated at the same address as SCI3nMDDR and is selected when MDDRS in SCI3nSEMR is 0. This register is writable only when TE = 0 and RE = 0.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + 0004_H

Value after reset: FF_H

Bit	7	6	5	4	3	2	1	0
	BRR							
Value after reset	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.10 SCI3nBRR Register Contents

Bit Position	Bit Name	Function
7 to 0	BRR	Baud rate generator setting (0 ≤ N ≤ 255)

Table 14.11 Relationship between Setting N in SCI3nBRR and Bit Rate B

Mode	ABCS Setting	Bit Rate	Mean Error
Asynchronous	0	$B = \frac{\phi \times 10^6}{64 \times 2^{2n-1} \times (N+1)}$	$Error\ (\%) = \{ \frac{\phi \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1 \} \times 100$
	1	$B = \frac{\phi \times 10^6}{32 \times 2^{2n-1} \times (N+1)}$	$Error\ (\%) = \{ \frac{\phi \times 10^6}{B \times 32 \times 2^{2n-1} \times (N+1)} - 1 \} \times 100$
Clock synchronous	—	$B = \frac{\phi \times 10^6}{8 \times 2^{2n-1} \times (N+1)}$	

Note: B: Bit rate (bit/s)
N: SCI3nBRR setting for baud rate generator (0 ≤ N ≤ 255)
ϕ: Operating frequency PCLK (MHz)
n: Determined by the SCI3nSMR setting shown in the following table.

SCI3nSMR Setting		
CKS1	**CKS0**	**n**
0	0	0
0	1	1
1	0	2
1	1	3

Table 14.12 lists sample N settings of the SCI3nBRR register in asynchronous mode. **Table 14.13** lists the maximum settable bit rates.

Table 14.12 Examples of BRR Settings for Bit Rates (Asynchronous Mode)

	Operating Frequency ϕ = 40 (MHz)							
	SCI3nSEMR.ABCS = 0				SCI3nSEMR.ABCS = 1			
Bit Rate (bit/s)	n	N	Actual Bit Rate (bit/s)	Error (%)	n	N	Actual Bit Rate (bit/s)	Error (%)
110	3	177	109.73	–0.25	—	—	—	—
150	3	129	150.24	0.16	3	255	152.59	1.73

14.3.11 SCI3nMDDR — Modulation Duty Register

SCI3nMDDR is a register to correct the bit rate adjusted by SCI3nBRR. The initial value of SCI3nMDDR is FF_H. When the BRME bit in SCI3nSEMR is set to 1, the bit rate generated by the on-chip baud rate generator is corrected to SCI3nMDDR/256 on average. **Table 14.17** shows the relationship between the SCI3nMDDR setting and the bit rate B. SCI3nMDDR is allocated at the same address as SCI3nBRR and is selected when MDDRS in SCI3nSEMR is 1. This register is writable only when TE = 0 and RE = 0. Bit 7 is fixed to 1.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + 0004_H

Value after reset: FF_H

Bit	7	6	5	4	3	2	1	0
	MDDR							
Value after reset	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.16 SCI3nMDDR Register Contents

Bit Position	Bit Name	Function
7 to 0	MDDR	Baud rate generator setting (128 ≤ MDDR ≤ 255)

Table 14.17 Relationship between SCI3nMDDR Setting and Bit Rate B when Bit Rate Modulation Function Is Used

Mode	ABCS Setting	Bit Rate	Mean Error
Asynchronous	0	$B = \frac{\phi \times 10^6}{64 \times 2^{2n-1} \times (256/MDDR) \times (N+1)}$	$Error\ (\%) = \{\frac{\phi \times 10^6}{B \times 64 \times 2^{2n-1} \times (256/MDDR) \times (N+1)} - 1\} \times 100$
	1	$B = \frac{\phi \times 10^6}{32 \times 2^{2n-1} \times (256/MDDR) \times (N+1)}$	$Error\ (\%) = \{\frac{\phi \times 10^6}{B \times 32 \times 2^{2n-1} \times (256/MDDR) \times (N+1)} - 1\} \times 100$
Clock synchronous	—	$B = \frac{\phi \times 10^6}{8 \times 2^{2n-1} \times (256/MDDR) \times (N+1)}$	

Note: B: Bit rate (bit/s)

n: See **Table 14.11, Relationship between Setting N in SCI3nBRR and Bit Rate B**.
SCI3nMDDR:SCI3nMDDR setting (128 ≤ SCI3nMDDR ≤ 255)

14.4 Operation in Asynchronous Mode

Figure 14.2 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communication line is usually held in the mark state (high level). The SCI3 monitors the communication line, and when the SCI3 detects the space state (low level), it recognizes a start bit and starts serial communications. Inside the SCI3, the transmitter and the receiver are independent, enabling full-duplex communications. Both the transmitter and the receiver have a double-buffered structure so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

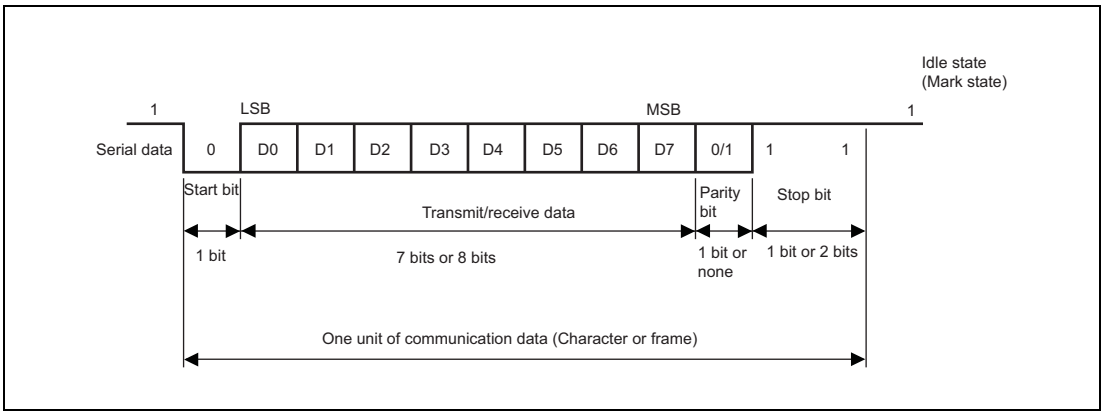

Figure 14.2 Data Format in Asynchronous Serial Communications (Example with 8-Bit Data, Parity, Two Stop Bits)

14.4.1 Transmission/Receive Format

Table 14.18 lists settable transmission/reception formats in asynchronous mode. Any of 12 transmission/reception formats can be selected according to the SCI3nSMR setting. For details of the multi-processor bit, see **Section 14.5, Multi-Processor Communication Function**.

Table 14.18 Serial Transmission/Receive Formats (Asynchronous Mode)

SMR Setting				Serial Transmission/Reception Format and Frame Length
CHR	PE	MP	STOP	1 2 3 4 5 6 7 8 9 10 11 12
0	0	0	0	S 8-bit data STOP
0	0	0	1	S 8-bit data STOP STOP
0	1	0	0	S 8-bit data P STOP
0	1	0	1	S 8-bit data P STOP STOP
1	0	0	0	S 7-bit data STOP
1	0	0	1	S 7-bit data STOP STOP
1	1	0	0	S 7-bit data P STOP
1	1	0	1	S 7-bit data P STOP STOP
0	—	1	0	S 8-bit data MPB STOP
0	—	1	1	S 8-bit data MPB STOP STOP
1	—	1	0	S 7-bit data MPB STOP
1	—	1	1	S 7-bit data MPB STOP STOP

Note: S: Start bit
STOP: Stop bit
P: Parity bit
MPB: Multi-processor bit

14.4.2 Receive Data Sampling Timing and Receive Margin

In asynchronous mode, the SCI3 operates on a reference clock with a frequency of 16 times (8 times for the double-speed mode) the bit rate. In reception, the SCI3 samples the falling edge of the beginning of the start bit (low level) using the reference clock and performs internal synchronization. As shown in **Figure 14.3**, data is latched at the middle of each bit by sampling receive data at the rising edge of the eighth pulse (fourth pulse for the double-speed mode) of the reference clock.

Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\ [\%] \quad \cdots \text{formula (1)}$$

M: Receive margin
N: Ratio of bit rate to clock (N = 16 when ABCS in SCI3nSEMR = 0, N = 8 when ABCS = 1)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 12)
F: Absolute value of clock frequency deviation

Assuming that F (absolute value of clock frequency deviation) = 0, D (duty cycle of clock) = 0.5, and N = 16 in formula (1), the reception margin is obtained by the formula below.

$M = \{0.5 - 1/(2 \times 16)\} \times 100\ [\%] = 46.875\%$

However, this is only the calculated value, and a margin of 20% to 30% should be allowed in system design.

When the bit rate modulation function is used, the reference clock frequency is corrected on average.

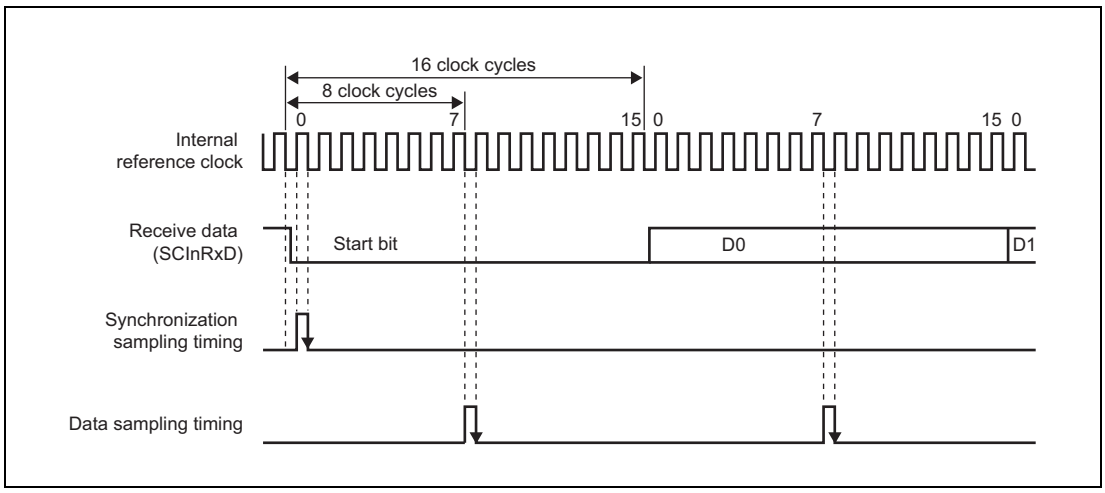

Figure 14.3 Receive Data Sampling Timing in Asynchronous Mode

14.4.3 Clock

An internal clock generated by the on-chip baud-rate generator can be set as the SCI3's transmission/ reception clock according to the settings of the CM bit in SCI3nSMR and the CKE1 and CKE0 bits in SCI3nSCR. When the SCI3 is operated on an internal clock, the clock can be output from the SCInSCK pin.

For details of clock synchronous mode, see **Section 14.6, Operation in Clock Synchronous Mode**.

In asynchronous mode, the frequency of the clock output is equal to the bit rate and the phase is such that the rising edge of the clock comes at the center of the transmit data, as shown in **Figure 14.4**.

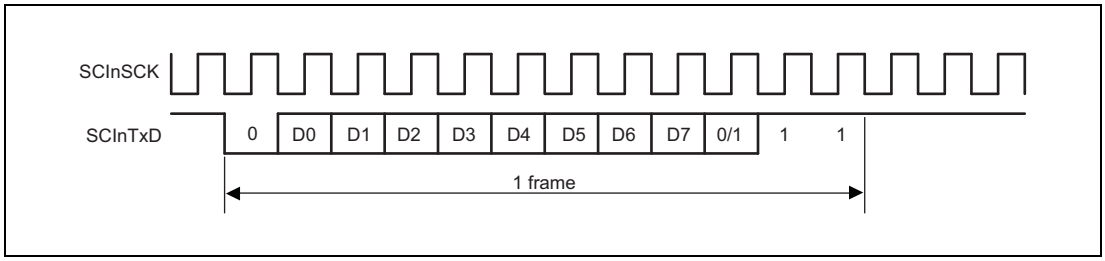

Figure 14.4 Phase Relationship between Output Clock and Transmit Data (Asynchronous Mode)

14.4.4 Double-Speed Operation

In addition to the operation described in **Section 14.4.3, Clock**, double-speed operation is enabled by the setting of the ABCS bit in SCI3nSEMR.

In double-speed operation, the same operation on a clock with a frequency of 16 times the bit rate in normal operation can be conducted on a clock with a frequency of 8 times the bit rate, meaning that the SCI3 operates on a double transfer rate using the same reference clock.

Double-speed operation can be configured with an internal clock generated by the on-chip baud-rate generator.

14.4.5 SCI3 Initialization (Asynchronous Mode)

Before transmitting and receiving data, clear the TE and RE bits in SCI3nSCR and then initialize the SCI3 according to the sample flowchart in **Figure 14.5**. Before changing the operating mode or transfer format, be sure to clear the TE and RE bits to 0. Note that clearing the TE bit to 0 sets the TDRE flag to 1, but clearing the RE bit to 0 initializes neither the RDRF, PER, FER, and ORER flags nor SCI3nRDR.

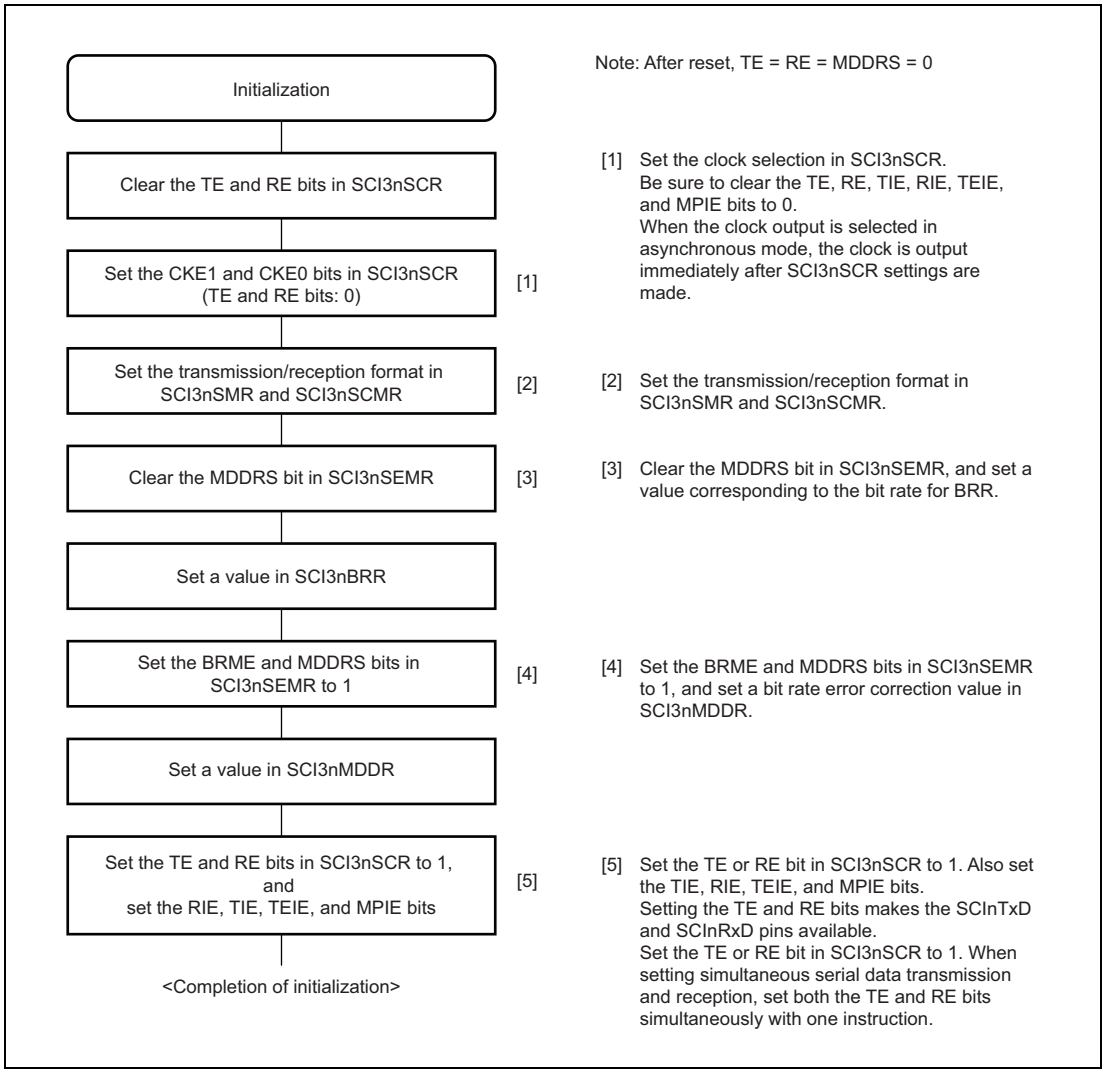

Figure 14.5 Sample Flowchart for SCI3 Initialization

14.4.6 Serial Data Transmission (Asynchronous Mode)

Figure 14.6 shows an example of operation for data transmission in asynchronous mode. In data transmission, the SCI3 operates as described below.

1. When transmit data is written to SCI3nTDR, the TDRE flag is automatically cleared to 0. The SCI3 monitors the TDRE flag in SCI3nSSR. When the flag is cleared, the SCI3 recognizes that data has been written to SCI3nTDR and transfers data from SCI3nTDR to SCI3nTSR. When writing transmit data to SCI3nTDR at a trigger of TXI interrupt request, set the TIE bit to 1 and then set the TE bit to 1 or set both TIE and TE bits simultaneously with one instruction to generate a TXI interrupt request for starting data transfer.
2. Transmission starts after data is transferred from SCI3nTDR to SCI3nTSR and the TDRE flag is set to 1. If the TIE bit in SCI3nSCR is set to 1 at this time, a TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to SCI3nTDR in this TXI interrupt processing routine before transmission of the previously transferred data is completed. When using a TEI interrupt request, write the last transmit data to SCI3nTDR and then clear the TIE bit to 0 and set the TEIE bit to 1.
3. Data is sent from the SCInTxD pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The TDRE flag is checked when the stop bit is output.
5. When the TDRE flag is 0, the next transmit data is transferred from SCI3nTDR to SCI3nTSR. After the stop bit has been sent, transmission of the next frame starts.
6. When the TDRE flag is 1, the TEND flag in SCI3nSSR is set to 1, the stop bit is sent, and then 1 is output to enter the mark state. If the TEIE bit in SCI3nSCR is set to 1 at this time, a TEI interrupt request is generated.

Figure 14.7 shows a sample flowchart for data transmission. **Figure 14.8** shows a sample flowchart for stopping the SCI3 after data transmission.

Supplementary note on operation when data transmission in asynchronous mode is enabled

When the TE bit is set to 1, the high level (preamble) is output for a frame. When transmit data is written to SCI3nTDR while the preamble is output, the data is transferred from SCI3nTDR to SCI3nTSR following the completion of the preamble output.

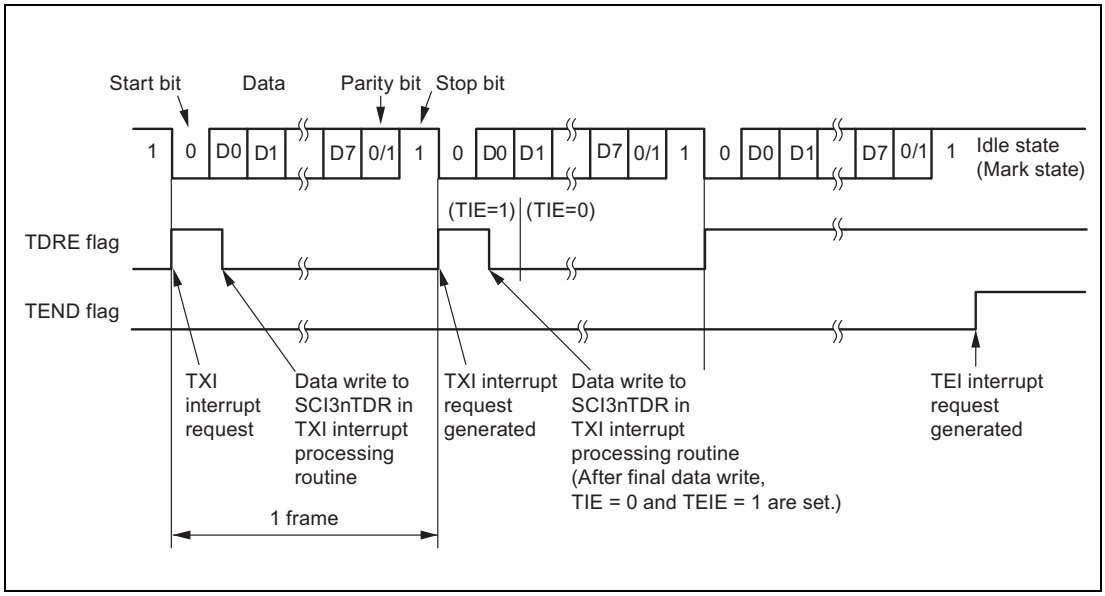

Figure 14.6 Example of Operation for Transmission in Asynchronous Mode (Example with 8-Bit Data, Parity, One Stop Bit)

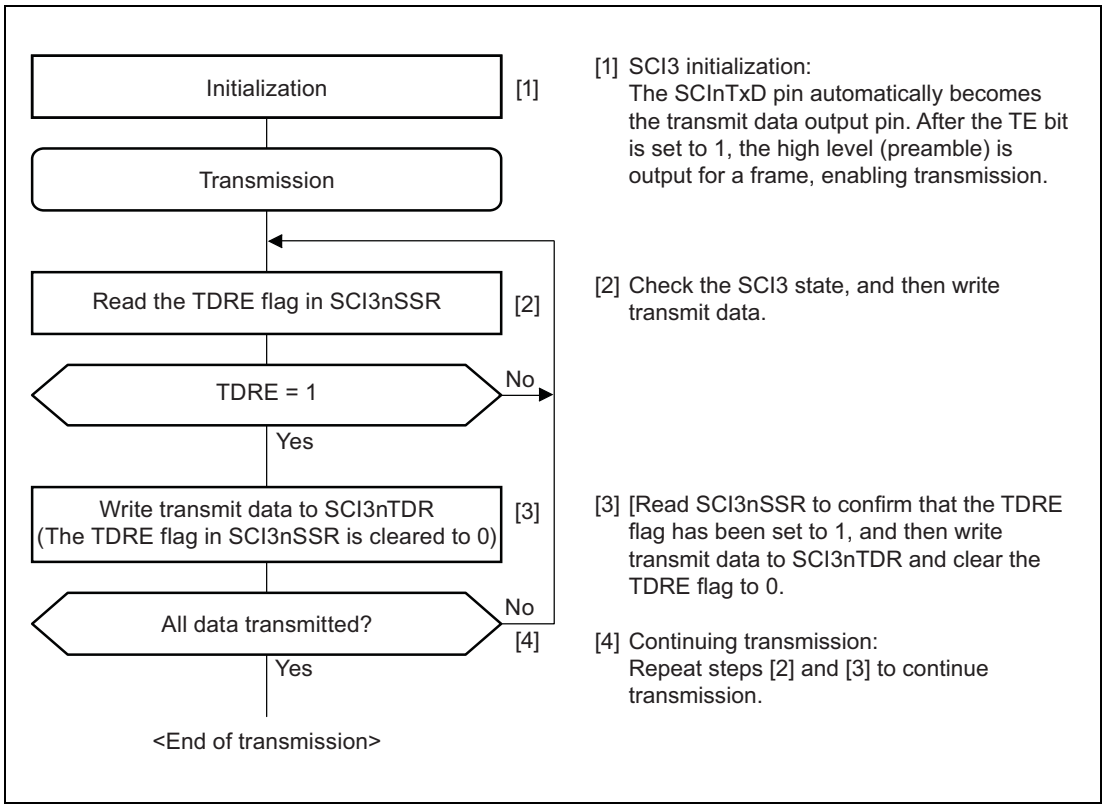

Figure 14.7 Example of Serial Transmission Flowchart

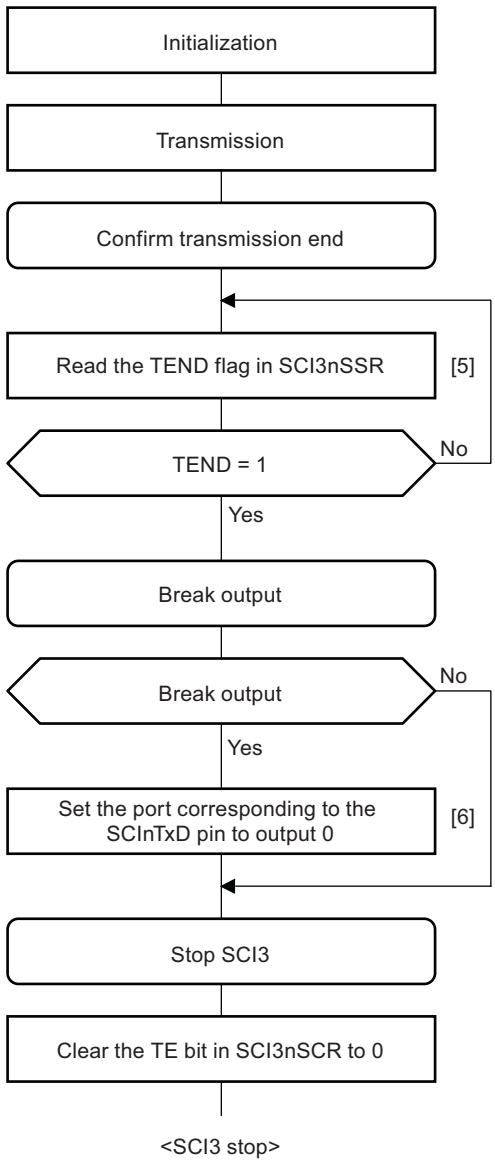

[5] Confirmation of transmission end:
Read the TEND flag in SCI3nSSR to confirm that no data is being transmitted.

[6] To output a break at the end of transmission, set the port corresponding to the SCInTxD pin to port output mode to output the low level (clear the P, PM, and PMC bits to 0), and then clear the TE and RE bits in SCI3nSCR to 0.

Note 1. Clearing the TE bit in SCI3nSCR initializes the SCI3 transmitter and places the SCInTxD pin in the high-impedance state. To retain the serial communications line, switch the SCInTxD pin to port output mode to output the required level before clearing the TE bit to 0.

Figure 14.8 Example Flowchart for Stopping the SCI3 after Serial Transmission

14.4.7 Serial Data Receive (Asynchronous Mode)

Figure 14.9 shows an example of the operation for data reception in asynchronous mode. In data reception, the SCI3 operates as described below.

1. When the SCI3 monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in SCI3nRSR, and checks the parity bit and the stop bit.
2. When an overrun error occurs (the next data has been received with the RDRF flag in SCI3nSSR set to 1), the ORER flag in SCI3nSSR is set to 1. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to SCI3nRDR. The RDRF flag retains the state of being set to 1.
3. When a parity error is detected, the PER flag in SCI3nSSR is set to 1 and receive data is transferred to SCI3nRDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated.
4. When a framing error (when the stop bit is 0) is detected, the FER flag in SCI3nSSR is set to 1 and receive data is transferred to SCI3nRDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated.
5. When reception finishes successfully, the RDRF flag in SCI3nSSR is set to 1 and receive data is transferred to SCI3nRDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to SCI3nRDR in this RXI interrupt processing routine before reception of the next receive data is completed. Reading SCI3nRDR automatically clears the RDRF flag to 0.

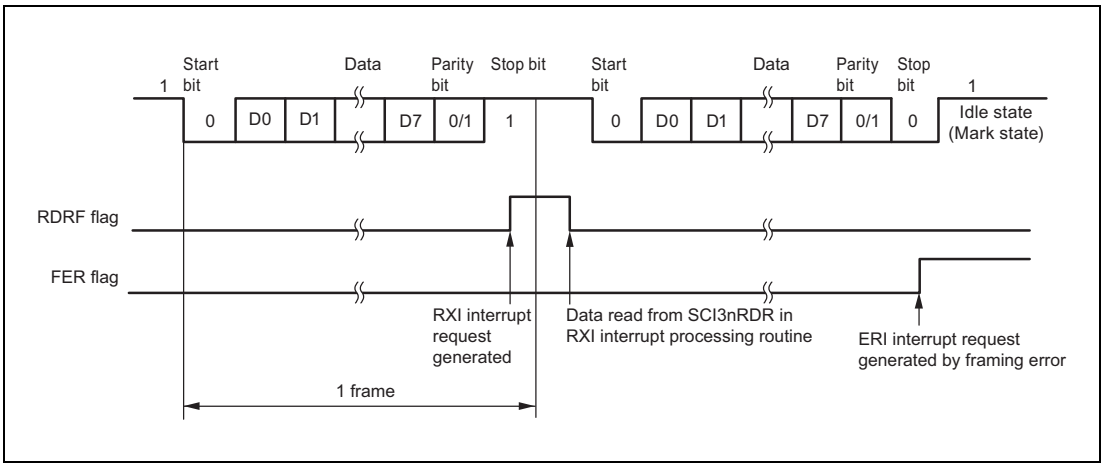

Figure 14.9 Example of Operation for Receive in Asynchronous Mode (Example with 8-Bit Data, Parity, One Stop Bit)

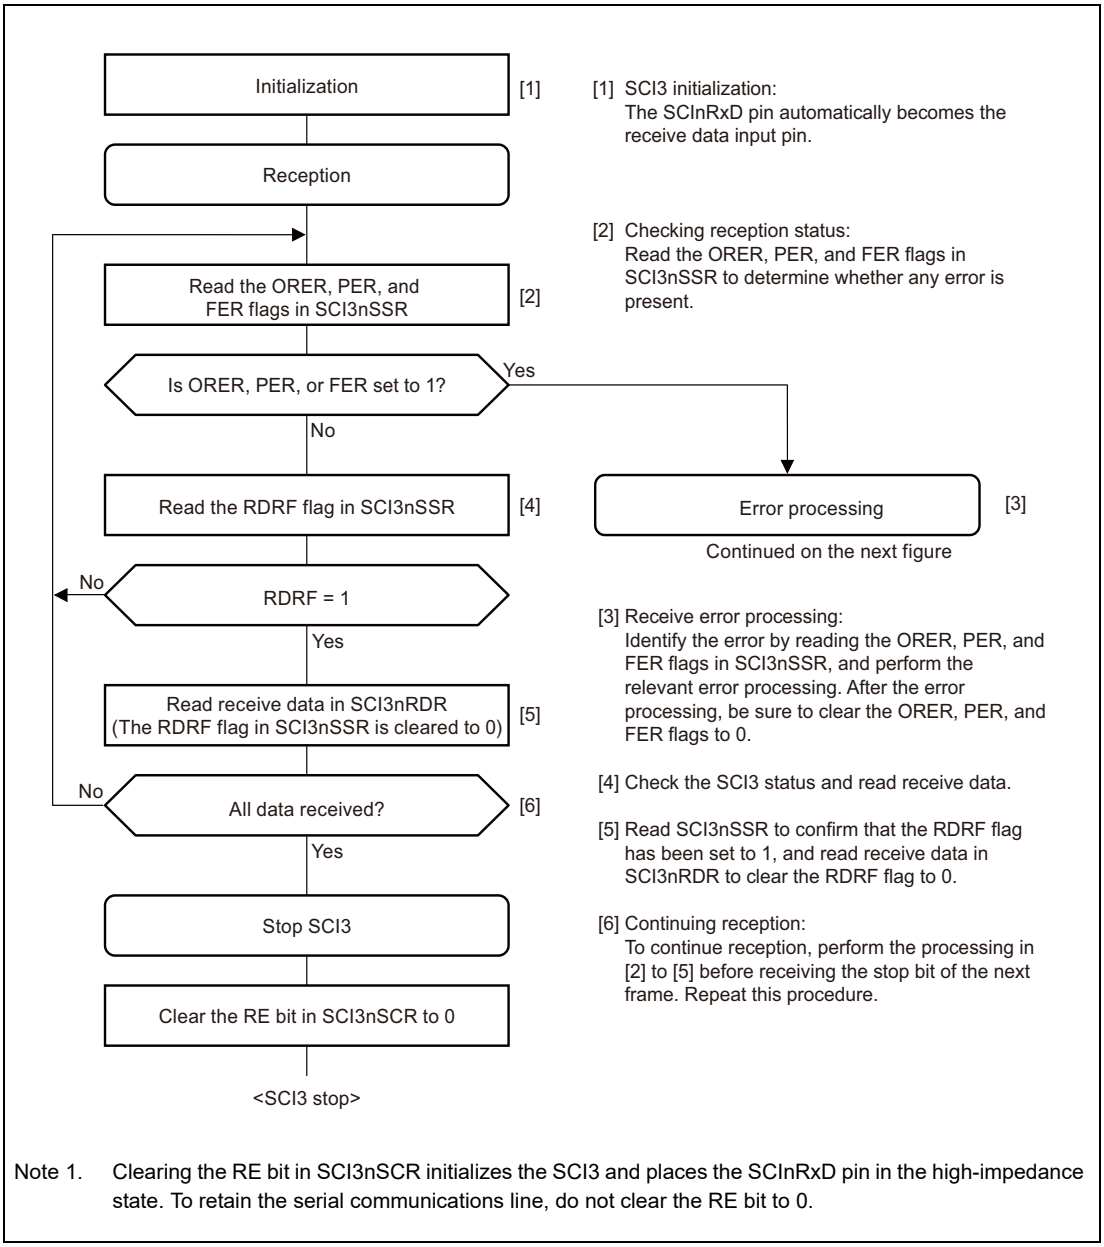
Table 14.19 lists the states of the SCI3nSSR status flags and receive data handling when a receive error is detected. When a receive error is detected, the RDRF flag retains the status before receiving the data. Subsequent data reception is disabled while a receive error flag is set to 1. Accordingly, clear the ORER, FER, PER, and RDRF flags before continuing data reception. **Figure 14.10** shows a sample flowchart for data reception.

Table 14.19 SCI3nSSR Status Flags and Receive Data Handling

SCI3nSSR Status Flags					
RDRF*1	ORER	FER	PER	Receive Data	Receive Status
1	0	0	0	Transferred to SCI3nRDR	Successful reception
0	0	1	0	Transferred to SCI3nRDR	Framing error
0	0	0	1	Transferred to SCI3nRDR	Parity error
0	0	1	1	Transferred to SCI3nRDR	Framing error + parity error
1*	1	0	0	Lost	Overrun error
1*	1	1	0	Lost	Overrun error + framing error
1*	1	0	1	Lost	Overrun error + parity error
1*	1	1	1	Lost	Overrun error + framing error + parity error

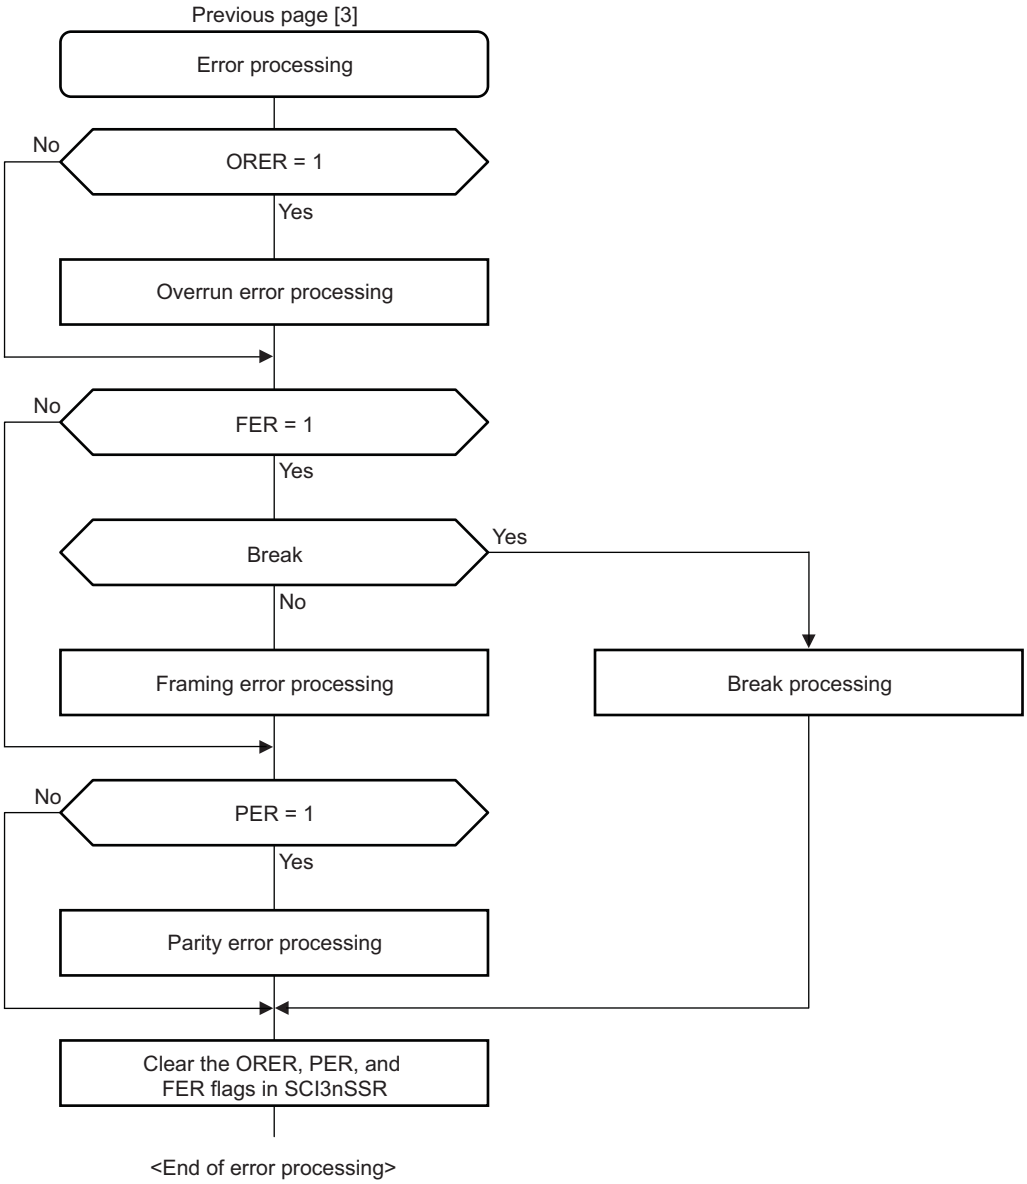
Note 1. In the case of an overrun error, the RDRF flag retains the state before the data reception.

Note: A sign “+” indicates that two or more receive states occur simultaneously in a single reception operation.



Note 1. Clearing the RE bit in SCI3nSCR initializes the SCI3 and places the SCInRxD pin in the high-impedance state. To retain the serial communications line, do not clear the RE bit to 0.

Figure 14.10 Example of Serial Receive Flowchart (1)



Note 1. In the case of a framing error, a break can be detected by reading the value of the RXDMON bit in SCI3nSEMR.

Note 2. After error processing, be sure to clear the ORER, PER, and FER flags to 0. Receive cannot be resumed if either of these flags is set to 1.

Figure 14.11 Example of Serial Receive Flowchart (2)

14.5 Multi-Processor Communication Function

14.5.1 Overview and Sample Connection

Using the multi-processor communication function allows data transmission and reception by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish the ID transmission cycle from the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle. When the multi-processor bit is set to 0, it indicates the data transmission cycle. **Figure 14.12** shows an example of communication between processors by using the multi-processor format. First, a transmitting station sends communication data in which the multi-processor bit (= 1) is added to the ID code of the receiving station. Next, the transmitting station sends communication data in which the multi-processor bit (= 0) is added to the transmit data. Upon receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself. When these IDs match, the receiving station receives communication data that is subsequently transmitted. If these IDs do not match, the receiving station skips communication data until it receives communication data in which the multi-processor bit is set to 1.

To support this function, the SCI3 provides the MPIE bit in SCI3nSCR. When the MPIE bit is set to 1, transfer of receive data from SCI3nRSR to SCI3nRDR, detection of a receive error, and setting the RDRF, FER, and ORER flags in SCI3nSSR are disabled until data in which the multi-processor bit is set to 1 is received. Upon receiving a character in which the multi-processor bit is set to 1, the MPB bit in SCI3nSSR is set to 1 and the MPIE bit is automatically cleared to 0, thus returning to a normal reception operation. When the RIE bit in SCI3nSCR is set to 1 at this time, an RXI interrupt request is generated. While the MPIE bit is cleared to 0, reception operation is conducted regardless of the multi-processor bit value. The multi-processor bit is stored in the MPB bit in SCI3nSSR.

When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the normal asynchronous mode. A clock that is used for multi-processor communications is also the same as the clock used in the normal asynchronous mode.

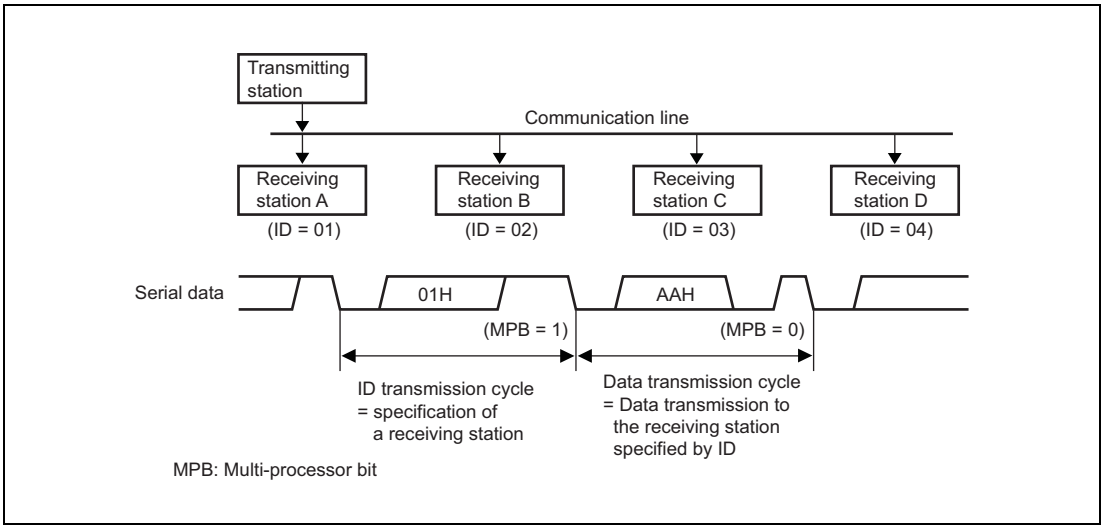


Figure 14.12 Example of Communication Using the Multi-Processor Format (Example of Transmission of Data AA_H to Receiving Station A)

14.5.2 Multi-Processor Serial Data Transmission

Figure 14.13 shows a sample flowchart of multi-processor data processing. In the ID transmission cycle, send the ID with the MPBT bit in SCI3nSSR set to 1. In the data transmission cycle, send data with the MPBT bit in SCI3nSSR cleared to 0. Other operations are the same as operations in asynchronous mode.

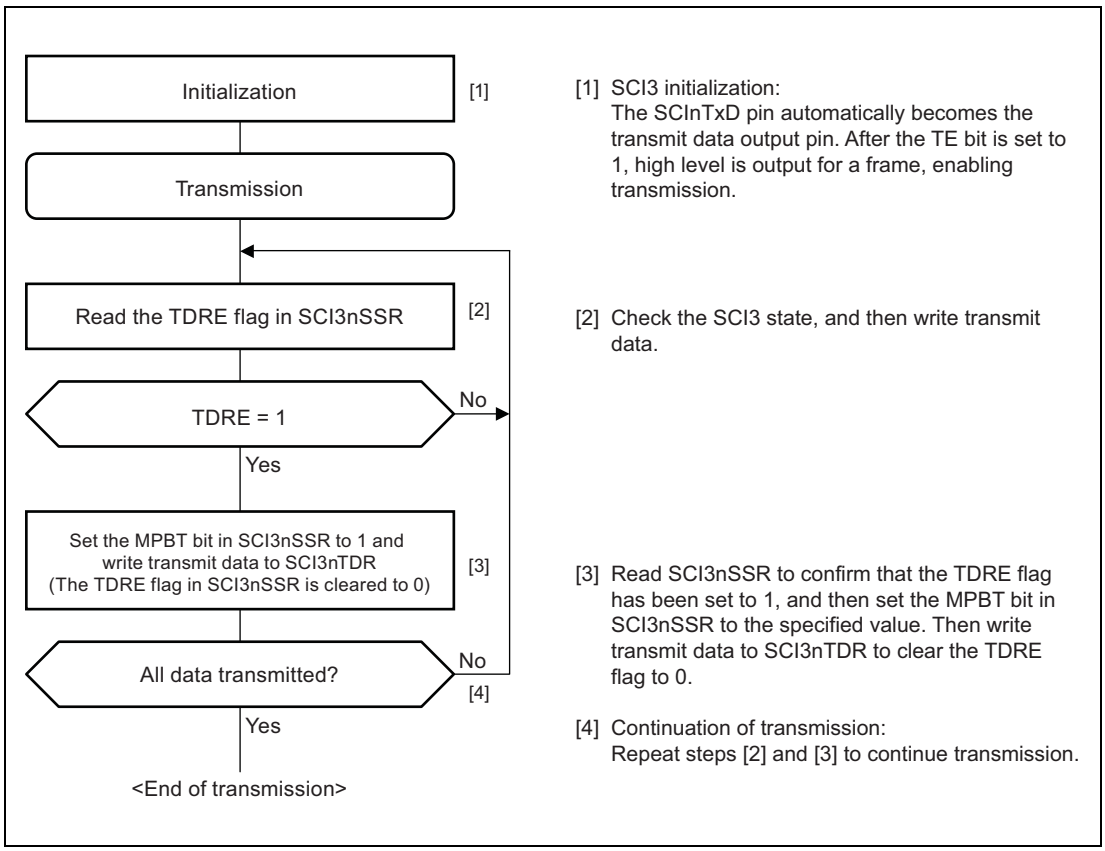

Figure 14.13 Example of Multi-Processor Serial Transmission Flowchart

14.5.3 Multi-Processor Serial Data Receive

Figure 14.15 shows sample flowcharts of multi-processor data reception. When the MPIE bit in SCI3nSCR is set to 1, reading the communication data is skipped until communication data in which the multi-processor bit is set to 1 is received. When communication data in which the multi-processor bit is set to 1 is received, the receive data is transferred to SCI3nRDR. At this time, an RXI interrupt request is generated. Other operations are the same as operations in asynchronous mode. **Figure 14.14** shows an example of operation for reception.

CAUTION

Do not write data to SCI3nSCR when communication data in which the multi-processor bit is set to 1 is received. The MPIE bit may not become the desired state.

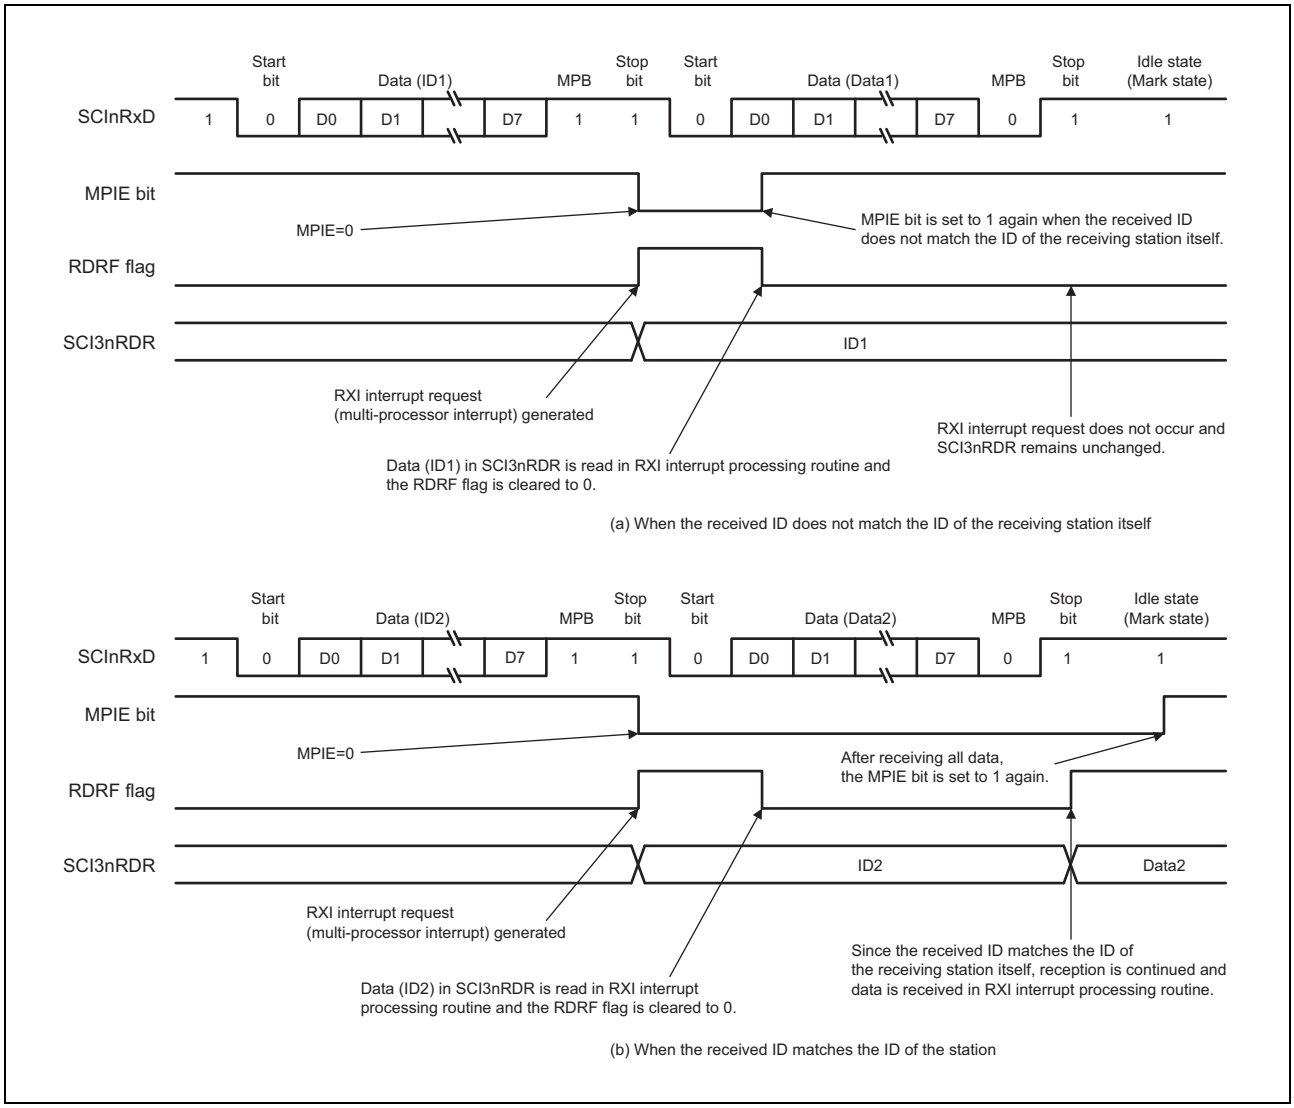

Figure 14.14 Example of SCI3 Receive (8-Bit Data, Multi-Processor Bit, One Stop Bit)

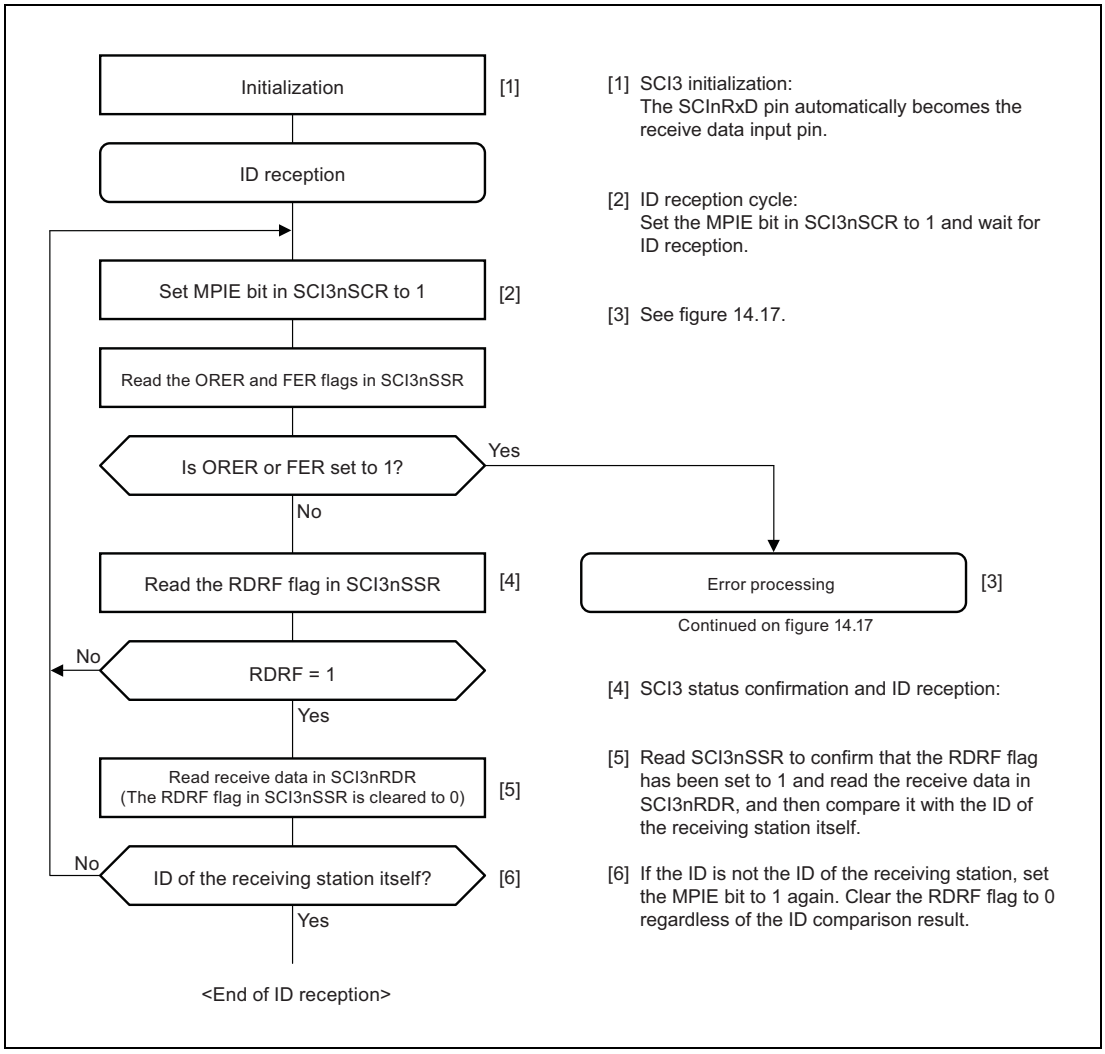

Figure 14.15 Example of Multi-Processor Serial Receive Flowchart (1)

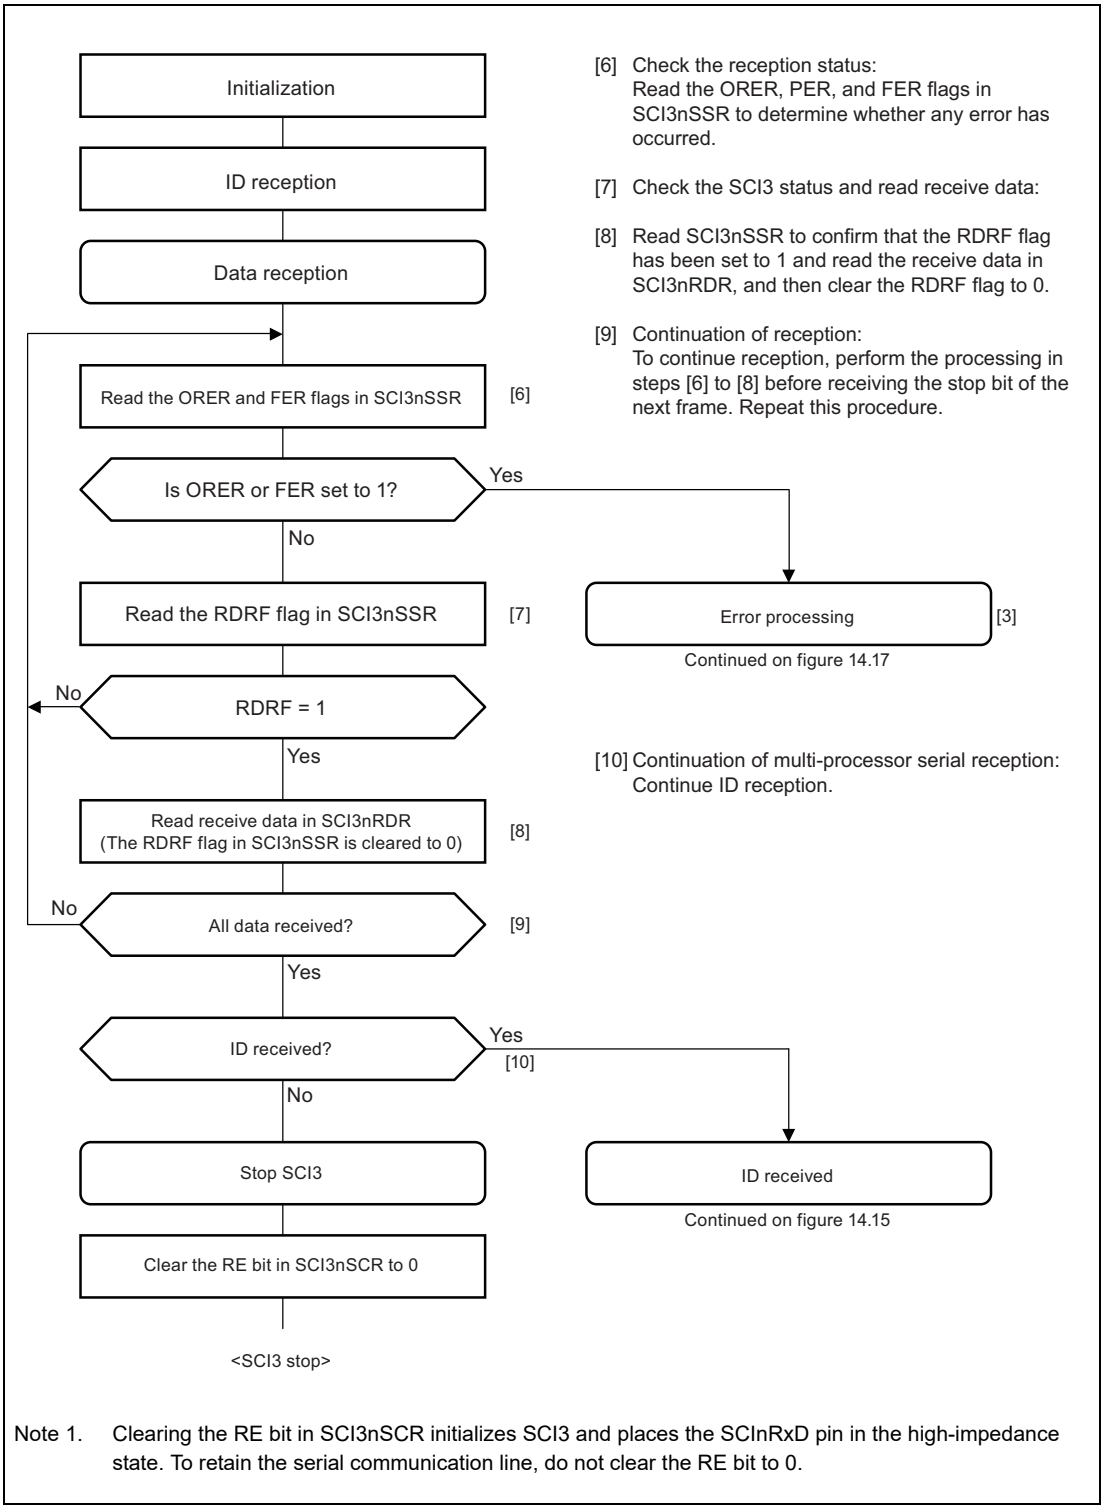
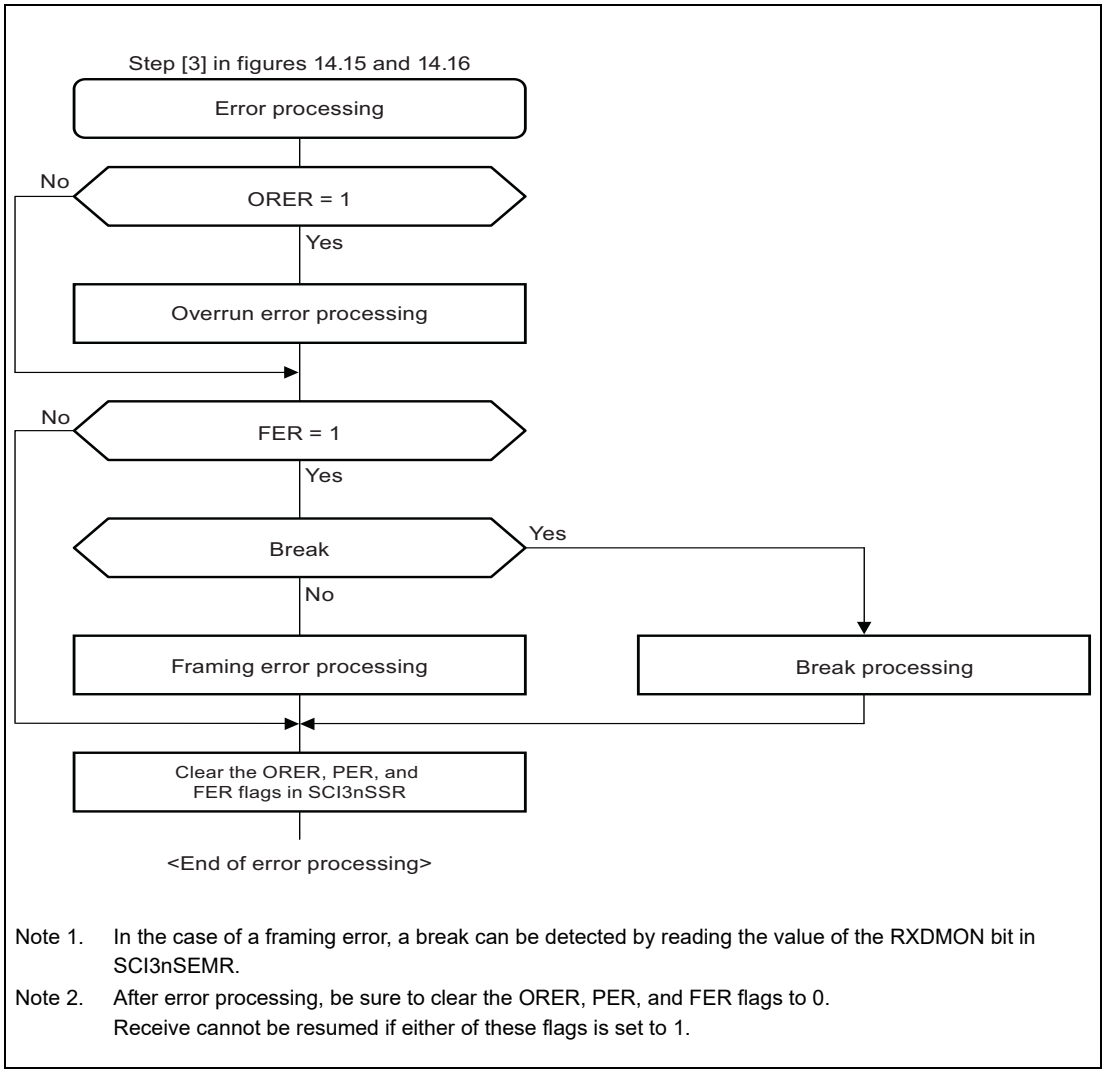


Note 1. Clearing the RE bit in SCI3nSCR initializes SCI3 and places the SCInRxD pin in the high-impedance state. To retain the serial communication line, do not clear the RE bit to 0.

Figure 14.16 Example of Multi-Processor Serial Receive Flowchart (2)



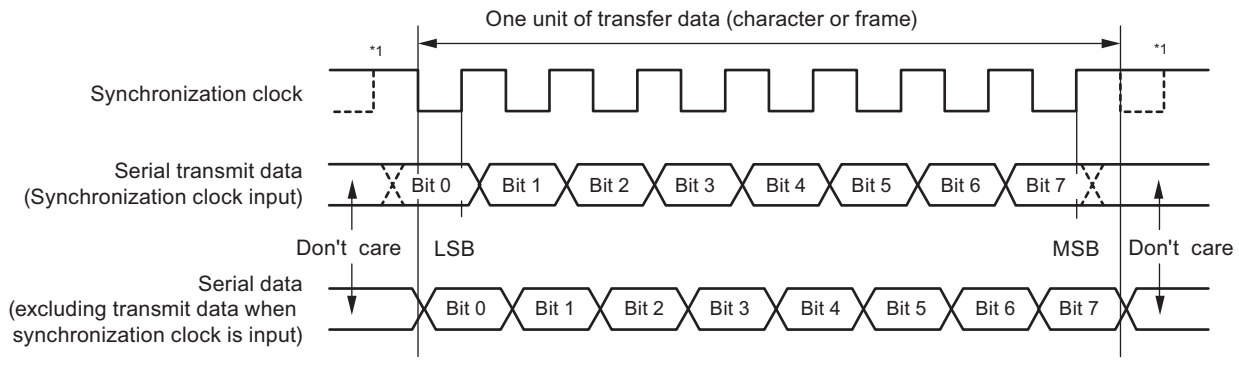
Note 1. In the case of a framing error, a break can be detected by reading the value of the RXDMON bit in SCI3nSEMR.

Note 2. After error processing, be sure to clear the ORER, PER, and FER flags to 0. Receive cannot be resumed if either of these flags is set to 1.

Figure 14.17 Example of Multi-Processor Serial Receive Flowchart (3)

14.6 Operation in Clock Synchronous Mode

Figure 14.18 shows the data format for clock synchronous serial data communication. In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In data transmission with the synchronization clock output, the SCI3 outputs data from one falling edge to the next falling edge of the synchronization clock. In data transmission with the synchronization clock input, the SCI3 outputs the first data (bit 0) after starting transfer immediately after clearing the TDRE bit in SCI3nSSR to 0, and then outputs the next bit data after 2 to 3 ϕ clock cycles from the falling edge of the synchronization clock. In data reception, the SCI3 receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the communication line holds the last-bit output state. In clock synchronous mode, neither parity bit nor multi-processor bit can be added. The transmitter and the receiver are independent in the SCI3, enabling full-duplex communication by using a common clock. Both the transmitter and the receiver have a double-buffered structure so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.



Note 1. Holds a high level except during continuous transmission/reception.

Figure 14.18 Data Format in Clock Synchronous Mode (LSB-First)

14.6.1 Clock

An internal clock generated by the on-chip baud rate generator or an external synchronous clock that is input from the SCInSCK pin can be selected by the setting of the CKE1 and CKE0 bits in SCI3nSCR. When operating the SCI3 on the internal clock, a synchronous clock is output from the SCInSCK pin. Eight pulses of the synchronous clock are output during transfer of one character, and the clock is held high while no data is transferred.

14.6.2 SCI3 Initialization (Clock Synchronous Mode)

Before transmitting and receiving data, clear the TE and RE bits in SCI3nSCR to 0 and then initialize the SCI3 according to the sample flowchart in **Figure 14.19**. To switch the operation between transmission, reception, and transmission/reception, clear the TE and RE bits to 0 and then set these bits to the desired value. Before changing the transfer format, be sure to clear the TE and RE bits to 0. Note that clearing the TE bit to 0 sets the TDRE flag to 1, but clearing the RE bit to 0 initializes neither the RDRF, PER, FER, and ORER flags nor SCI3nRDR.

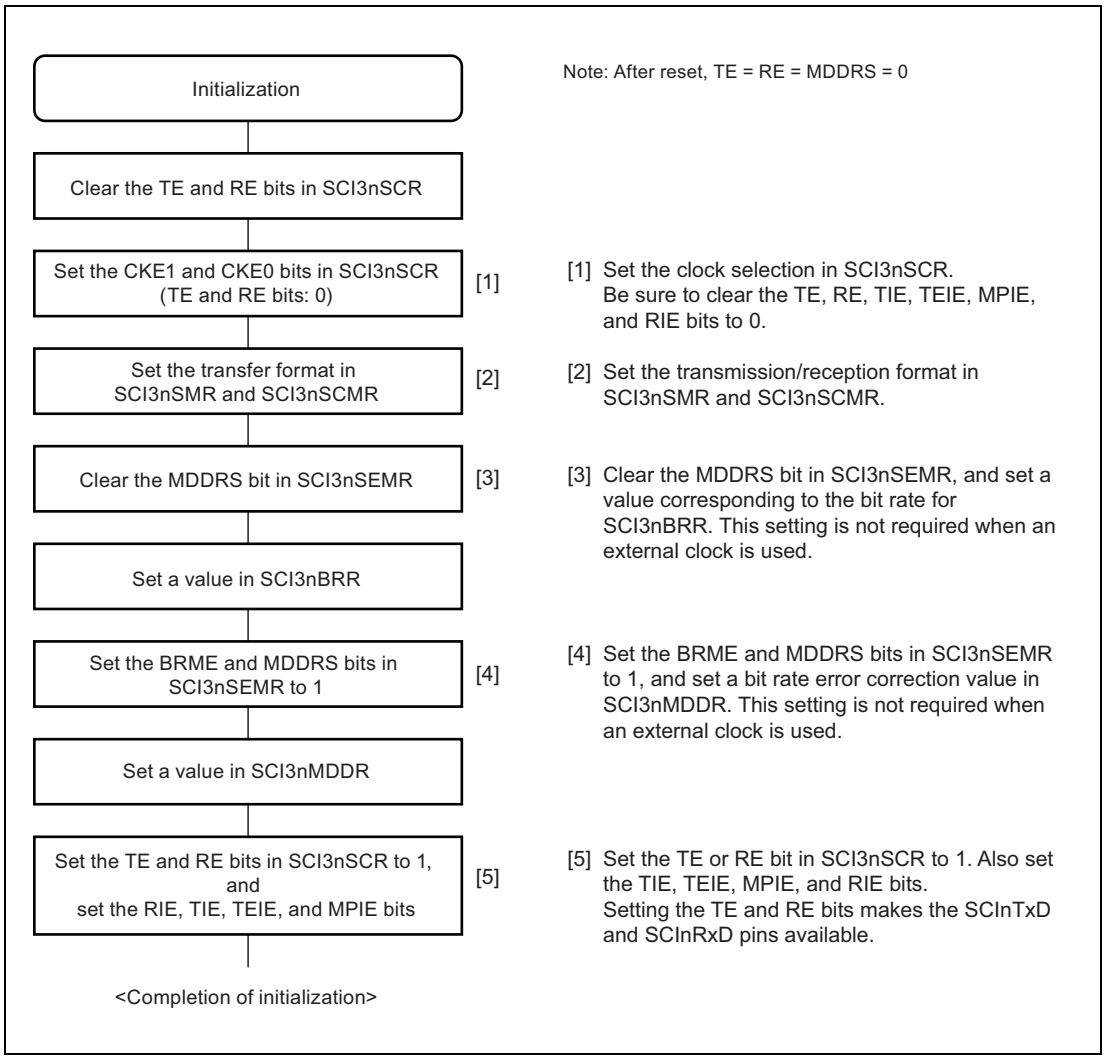


Figure 14.19 Example of SCI3 Initialization Flowchart

14.6.3 Serial Data Transmission (Clock Synchronous Mode)

Figure 14.20 shows an example of the operation for serial transmission in clock synchronous mode. In serial data transmission, the SCI3 operates as described below.

1. When transmit data is written to SCI3nTDR, the TDRE flag is automatically cleared to 0. The SCI3 monitors the TDRE flag in SCI3nSSR. When the flag is cleared, the SCI3 recognizes that data has been written to SCI3nTDR and transfers data from SCI3nTDR to SCI3nTSR, starting output of the first bit when the synchronization clock is input. To write transmit data to SCI3nTDR at a trigger of TXI interrupt request, set the TIE bit to 1 and then set the TE bit to 1 or set both TIE and TE bits simultaneously with one instruction to generate a TXI interrupt request for starting data transfer.
2. Transmission starts after data is transferred from SCI3nTDR to SCI3nTSR, and the TDRE flag is set to 1. When the TIE bit in SCI3nSCR is set to 1 at this time, a TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to SCI3nTDR in this TXI interrupt processing routine before the previously transferred data has been transmitted. When a TEI interrupt request is used, the TIE bit is cleared to 0 after the last transmit data has been written to SCI3nTDR, and the TEIE bit is set to 1.
3. 8-bit data is output from the SCInTxD pin in synchronization with the output clock (when clock output mode has been specified) or in synchronization with the input clock (when external clock has been specified).
4. The SCI3 checks for the TDRE flag at the time of the last bit output.
5. When the TDRE flag is 0, the next transmit data is transferred from SCI3nTDR to SCI3nTSR, and serial transmission of the next frame starts.
6. When the TDRE flag is 1, the TEND flag in SCI3nSSR is set to 1 and the SCInSCK pin retains the output state of the last bit. If the TEIE bit in SCI3nSCR is set to 1 at this time, a TEI interrupt request is generated. The SCInSCK pin is held high.

Figure 14.21 shows a sample flowchart of serial data transmission. Also, **Figure 14.22** shows a sample flowchart for stopping the SCI3 after data transmission. Transmission will not start even if the TDRE flag is cleared while a receive error flag (ORER) is set to 1. Be sure to clear the receive error flags to 0 before starting transmission. Note that clearing the RE bit to 0 does not clear the receive error flags.

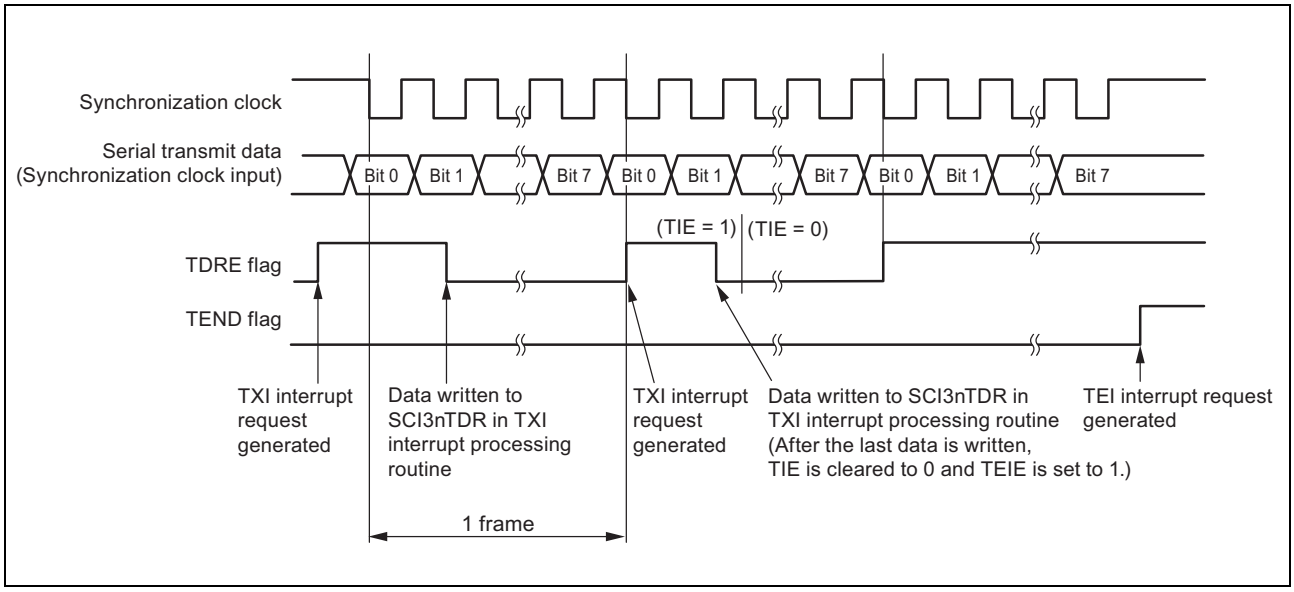

Figure 14.20 Example of Operation for Transmission in Clock Synchronous Mode

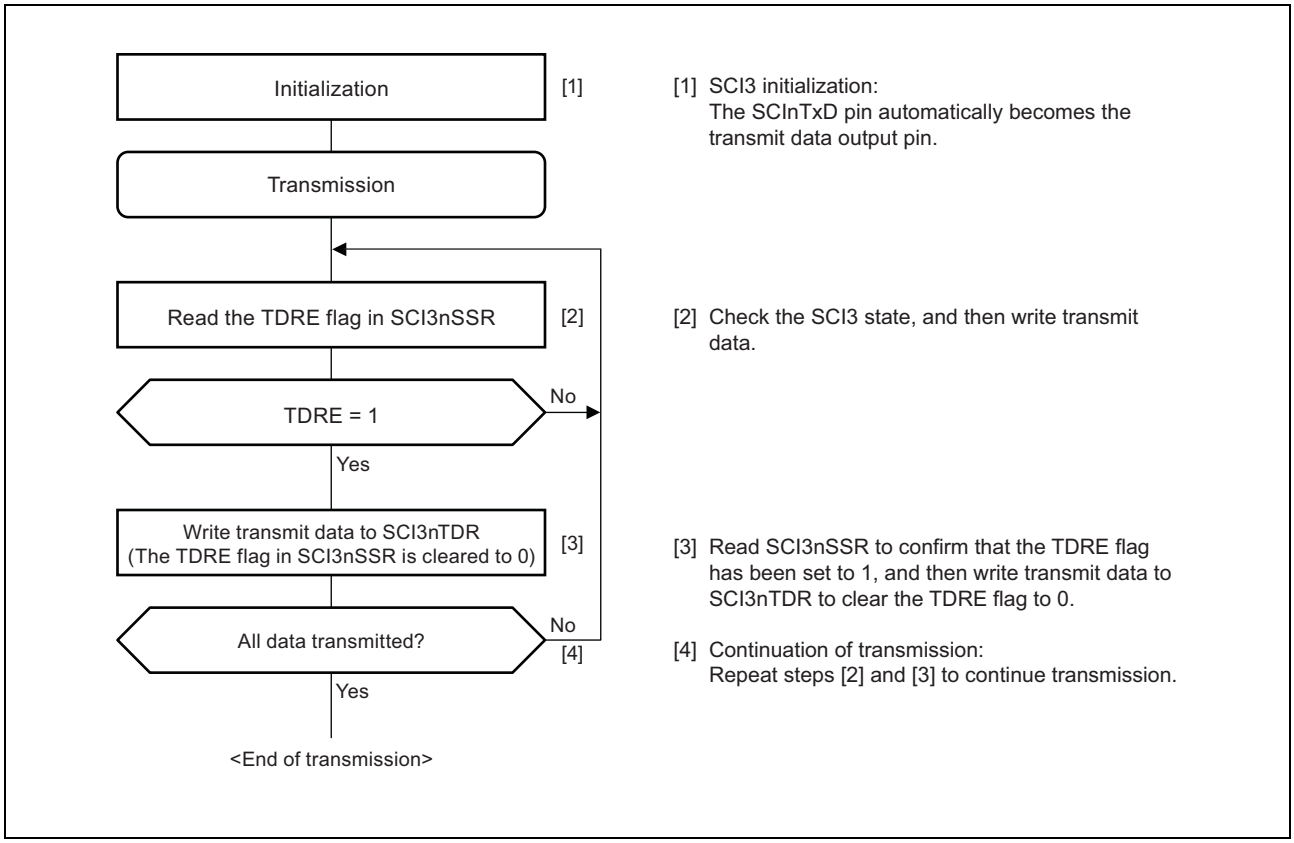

Figure 14.21 Example of Serial Transmission Flowchart

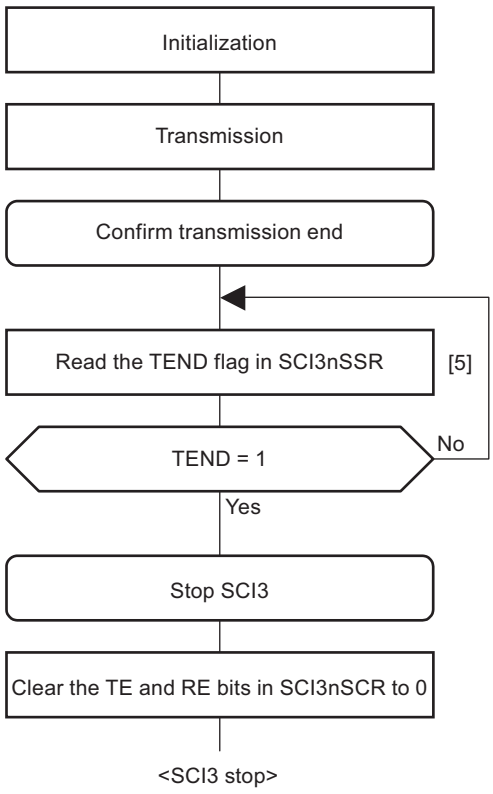

[5] Confirmation of transmission end:
Read the TEND flag in SCI3nSSR to confirm that no data is being transmitted.

Note 1. Clearing the TE and RE bits in SCI3nSCR to 0 initializes SCI3 and places the SCInTxD and SCInRxD pins in the high-impedance state. To retain the serial communications line, switch the SCInTxD pin to port output mode to output the required level before clearing the TE bit to 0. Do not clear the RE bit to 0.

Figure 14.22 Example Flowchart for Stopping the SCI3 after Serial Transmission

14.6.4 Serial Data Receive (Clock Synchronous Mode)

Figure 14.23 shows an example of SCI3 operation for serial reception in clock synchronous mode. In serial data reception, the SCI3 operates as described below.

1. The SCI3 performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores receive data in SCI3nRSR.
2. When an overrun error occurs (the reception of the next data is completed with the RDRF flag in SCI3nSSR set to 1), the ORER flag in SCI3nSSR is set to 1. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to SCI3nRDR. The RDRF flag retains the state of being set to 1.
3. When data has been successfully received, the RDRF flag in SCI3nSSR is set to 1 and the receive data is transferred to SCI3nRDR. When the RIE bit in SCI3nSCR is set to 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to SCI3nRDR in this RXI interrupt processing routine before reception of the next data is completed. Reading SCI3nRDR automatically clears the RDRF flag to 0.

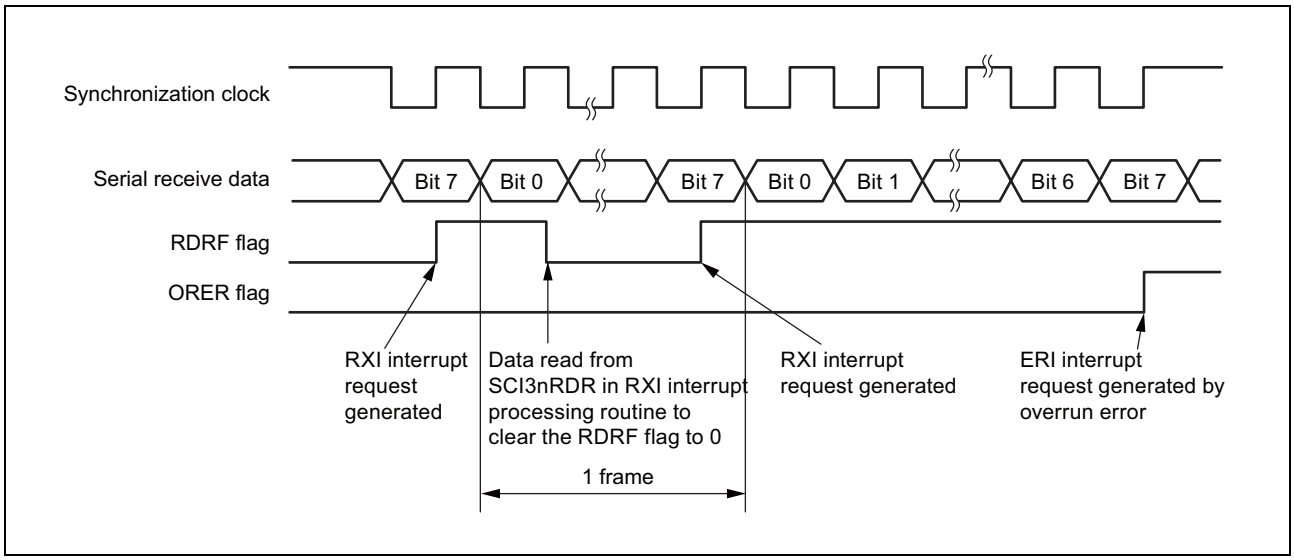

Figure 14.23 Example of SCI3 Operation for Receive

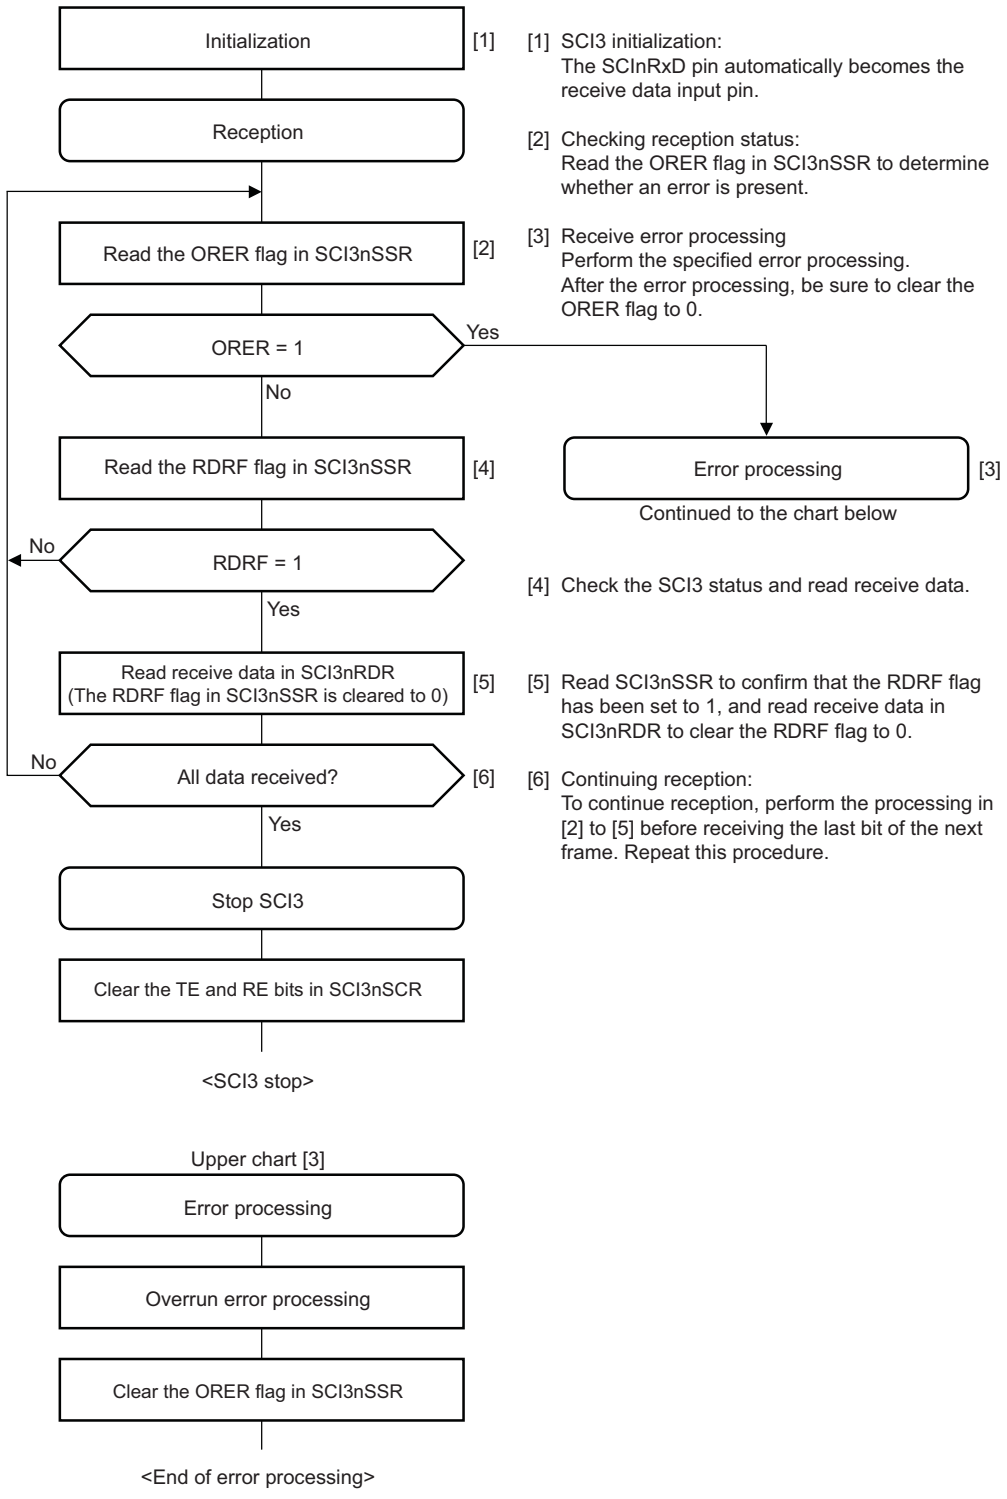
Subsequent transmission and reception are disabled with a receive error flag set to 1. Therefore, be sure to clear the ORER, FER, PER, and RDRF flags before continuing reception. **Figure 14.24** shows an example of flowchart for data reception.



Note 1. Clearing the TE and RE bits in SCI3nSCR initializes the SCI3 and places the SCInTxD and SCInRxD in the high-impedance state. To retain the serial communications line, switch the SCInTxD pin to port output mode to output the required level before clearing the TE bit to 0. Do not clear the RE bit to 0.

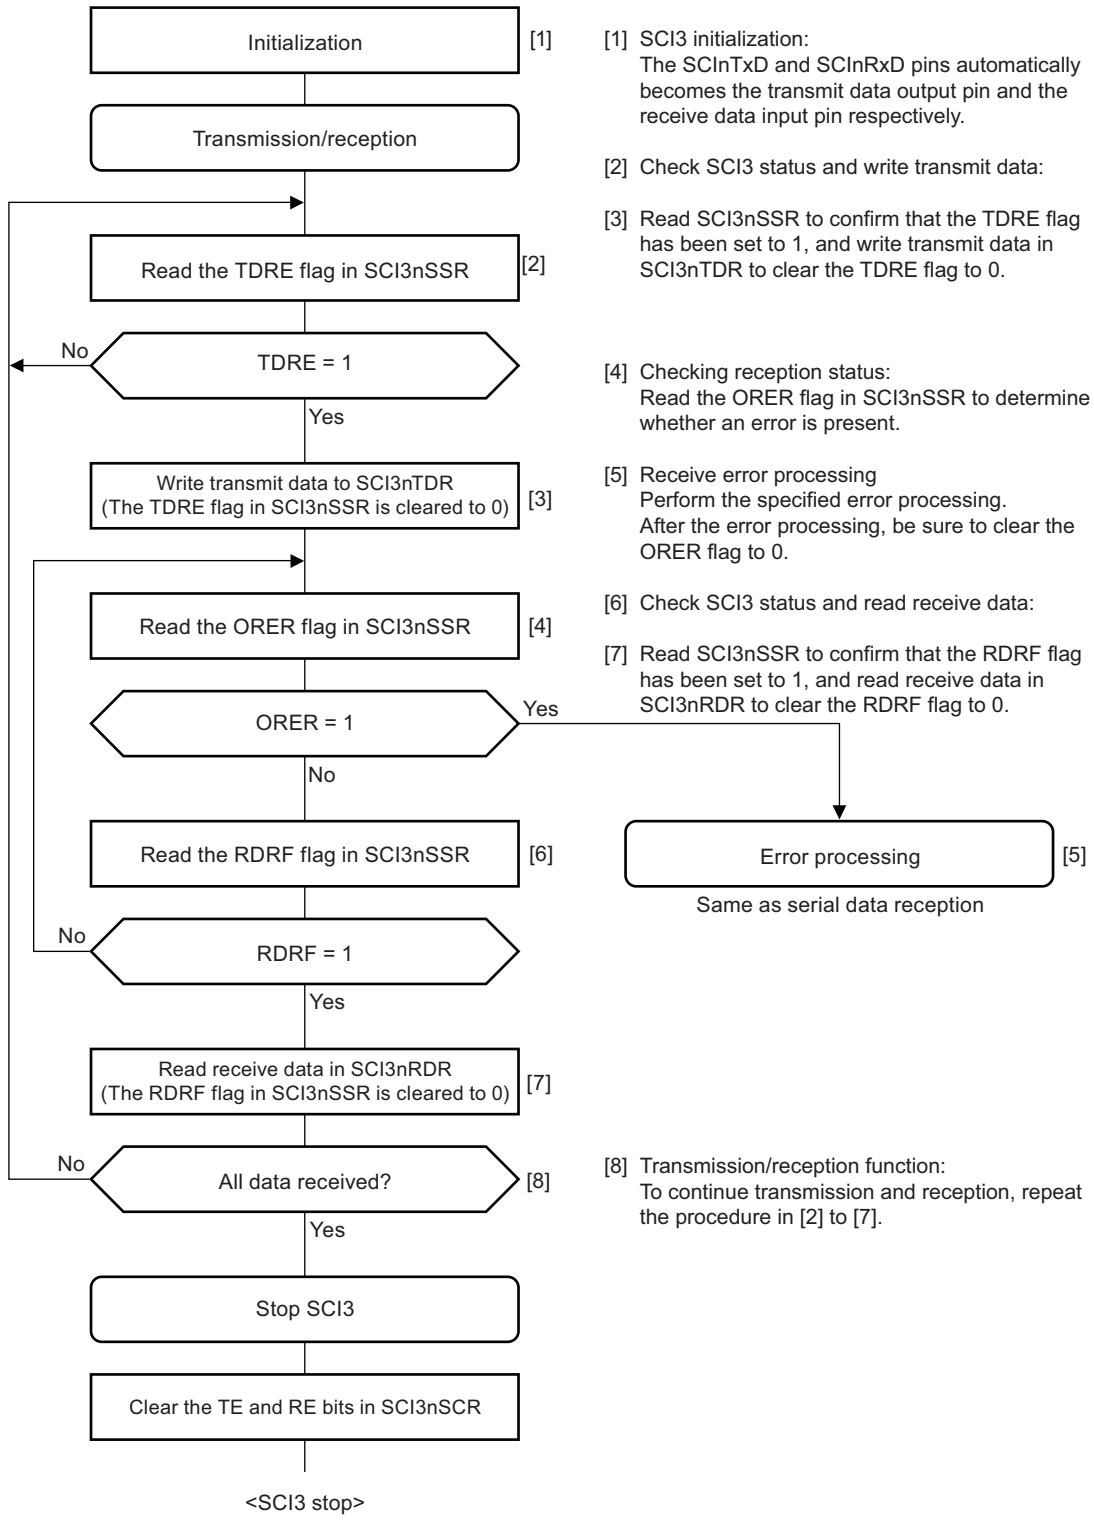
Note 2. After error processing, be sure to clear the ORER, PER, and FER flags to 0. Receive cannot be resumed if either of these flags is set to 1.

Figure 14.24 Example of Serial Receive Flowchart

14.6.5 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

Figure 14.25 shows a sample flowchart for simultaneous data transmit and receive operations. After the SCI3 is initialized, perform the following procedure for simultaneous data transmit and receive operations.

1. To change transmit mode to simultaneous transmit and receive mode, check that the SCI3 has finished transmission and the TDRE and TEND flags are set to 1. Then clear the TE bit to 0 and then set the TE and RE bits to 1 with a single instruction.
2. To change receive mode to simultaneous transmit and receive mode, check that the SCI3 has finished reception and clear the RE bit to 0. Then check that the RDRF and error flags (ORER, FER, and PER) are cleared to 0 and then set the TE and RE bits to 1 with a single instruction.



Note 1. Clearing the TE and RE bits in SCI3nSCR initializes the SCI3 and places the SCInTxD and SCInRxD pins in the high-impedance state. To retain the serial communications line, switch the SCInTxD pin to port output mode to output the required level before clearing the TE bit to 0. Do not clear the RE bit to 0.

Figure 14.25 Example of Simultaneous Serial Transmission and Receive Flowchart

14.7 Bit Rate Modulation Function

The bit rate modulation function corrects a bit rate by averagely enabling the internal clocks specified by the CKS1 and CKS0 bits in SCI3nSMR for the number specified by SCI3nMDDR out of 256 clocks.

Figure 14.26 shows an example of asynchronous mode in which ϕ clock is selected with the CKS1 and CKS0 bits, SCI3nBRR is set to 0, and SCI3nMDDR is set to 160. In this example, the reference clock cycle is corrected to 256/160 on average and the bit rate is corrected to 160/256. Note that the pulse widths of the internal reference clock expand or contract for the amount of the selected internal clocks because there is a deviation in the enabling of the internal clocks.

Do not use this function with the maximum speed settings (CKS1 and CKS0 bits = 0 in SCI3nSMR, CKE1 bit = 0 in SCI3nSCR, and SCI3nBRR = 0) for clock synchronous mode.

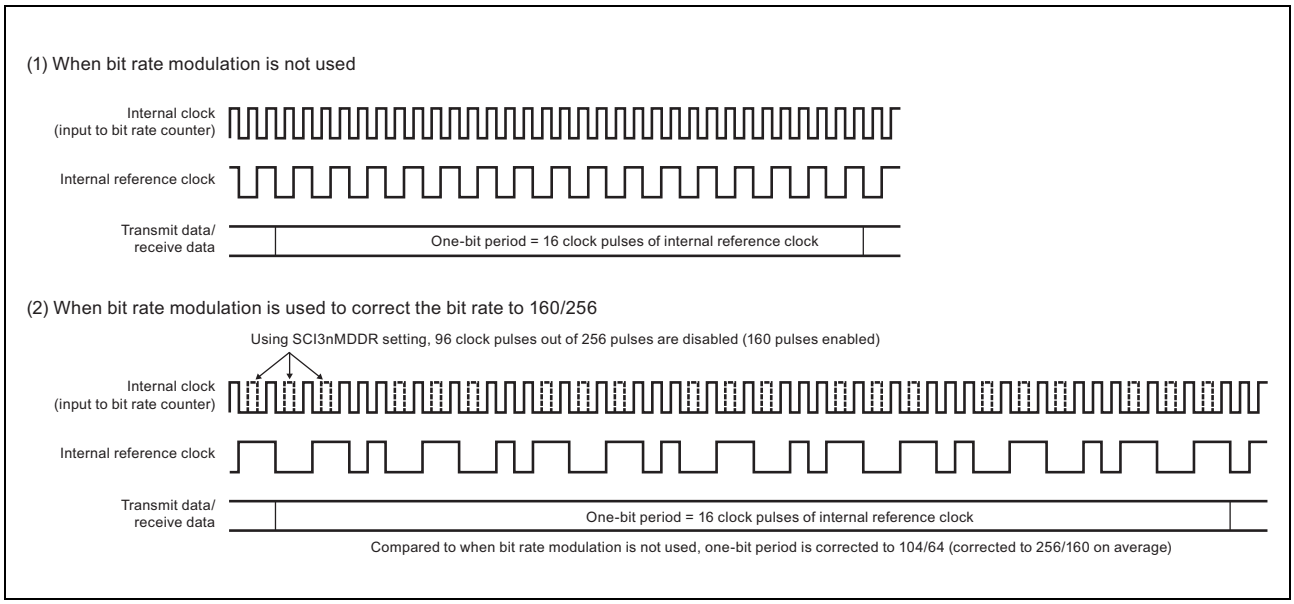


Figure 14.26 Example of Internal Reference Clock when the Bit Rate Modulation Function is Used

14.8 Interrupt Sources

Table 14.20 lists interrupt sources. Each interrupt source outputs an individual interrupt request signal. These interrupt sources can be enabled independently with the enable bit in SCI3nSCR.

A TXI interrupt request is generated when the TDRE flag in SCI3nSSR is set to 1. A TEI interrupt request is generated when the TEND flag in SCI3nSSR is set to 1. A TXI interrupt request can activate the DMAC to handle data transfer. The TDRE flag is automatically cleared to 0 when data is transferred using the DMAC.

CAUTION

The TDRE and TEND flags cannot be cleared to 0 while the TE bit in SCI3nSCR is 0. Since the TEND flag is the level interrupt request flag for a TEI interrupt, do not set the TEIE bit in SCI3nSCR to 1 while the TE bit is 0.

An RXI interrupt request is generated when the RDRF flag in SCI3nSSR is set to 1. An ERI interrupt is generated when either of the ORER, PER, and FER flags in SCI3nSSR is set to 1. An RXI interrupt request can activate the DMAC to handle data transfer. The RDRF flag is automatically cleared to 0 when data is transferred using the DMAC.

A TEI interrupt request is generated when the TEND flag is set to 1 with the TEIE bit set to 1.

CAUTION

If a TEI interrupt request and a TXI interrupt request are generated at the same time, the TXI interrupt request is accepted first. Note that clearing the TDRE flag to 0 at this time in the TXI interrupt processing routine also clears the TEND flag to 0 automatically, disabling the branch to the TEI interrupt processing routine.

Table 14.20 SCI3 Interrupt Sources

Name	Interrupt Source	Interrupt Flag	DMAC Activation	DTS Activation
ERI	Receive error	ORER, FER, PER	Not possible	Not possible
RXI	Receive data full	RDRF	Possible	Not possible
TXI	Transmit data empty	TDRE	Possible	Not possible
TEI	Transmit end	TEND	Not possible	Not possible

14.9 Usage Notes

14.9.1 Break Detection and Processing

A break can be detected by reading the RXDMON bit in SCI3nSEMR when detecting a framing error. Since all inputs from the SCInRxD pin are 0 in the break state, the FER flag is set to 1 and the PER flag may also be set to 1. The SCI3 also continues data reception after it receives a break. For this reason, note that the FER flag is set to 1 again even after the FER flag is cleared to 0.

14.9.2 Mark State and Break Output

While the TE bit is 0 (transmission/reception disabled), the SCInTxD pin can output any level by switching the SCInTxD pin to a general output port. This allows the SCInTxD pin to be the mark state or break output during data transmission.

14.9.3 Receive Error Flags and Transmit Operations in Clock Synchronous Mode

During the clock synchronous simultaneous data transmit/receive operation, transmission cannot be started when a receive error flag (ORER) is set to 1, even if the TDRE flag is cleared to 0. Be sure to clear the receive error flags to 0 before starting transmission. Note that the receive error flags cannot be cleared to 0 even by clearing the RE bit to 0.

14.9.4 Relationship between Writing to SCI3nTDR and the TDRE Flag

The TDRE flag in SCI3nSSR is a status flag indicating that transmit data in SCI3nTDR has been transferred to SCI3nTSR. The TDRE flag is set to 1 when the SCI3 transfers data from SCI3nTDR to SCI3nTSR.

Data can be written to SCI3nTDR regardless of the status of the TDRE flag. However, writing new data to SCI3nTDR while the TDRE flag is 0 will make the data stored in SCI3nTDR lost because it has not been transferred to SCI3nTSR. Therefore, make sure to check that the TDRE flag is set to 1 before writing transmit data to SCI3nTDR.

14.9.5 Restrictions on Using an External Clock for Transmission in Clock Synchronous Mode

When using an external synchronization clock, clear the TDRE flag to 0 and then input a transmission clock (**Figure 14.27**). Also in continuous transmission mode, clear the TDRE flag to 0 and then input a transmission clock for the next frame.

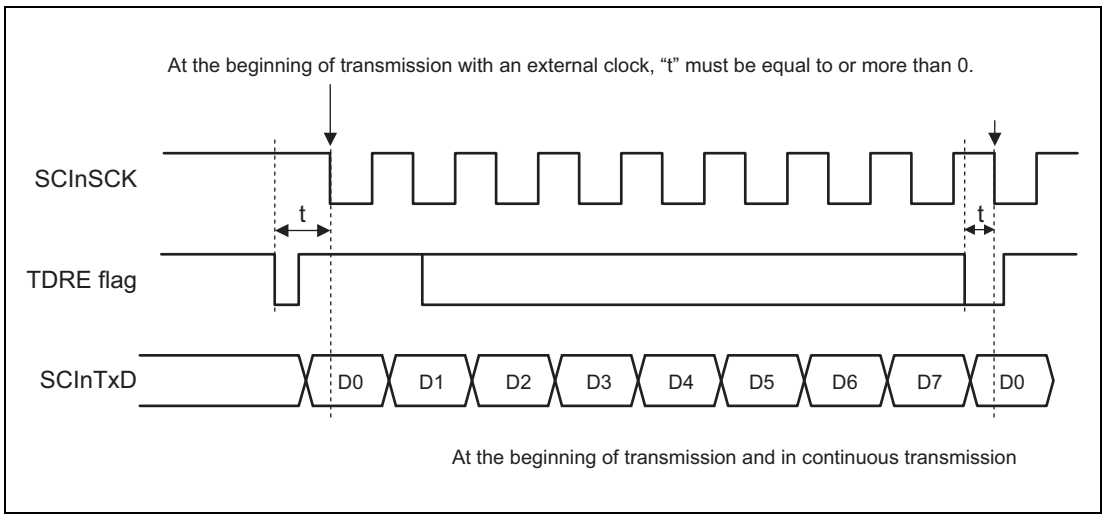

Figure 14.27 Restrictions on Using an External Clock for Transmission in Clock Synchronous Mode

14.9.6 External Clock Input in Clock Synchronous Mode

For the external SCInSCK clock input in clock synchronous mode, see **Section 37.3.7, SCI3/ FLSCI3 Timing**.

Section 15 LIN Master Interface (RLIN2)

This section contains a generic description of the LIN master interface (RLIN2).
The first part of this section describes all RH850/E1M-S specific properties, such as the number of units, register base addresses, etc.

The remainder of the section describes the functions and registers of RLIN2.

15.1 Overview of RH850/E1M-S RLIN2

15.1.1 Units and Channels

This microcontroller has the following number of RLIN2 units and channels.

Table 15.1 Units

Product	RH850/E1x
Units	1
Name	RLIN21n (n = 0)

Table 15.2 Unit Configurations and Channels

Unit Name RLIN21n	Channels per Unit	Unit Channel Number	Channel Name RLIN2m
RLIN210	1	0	RLIN20

Table 15.3 Index

Index	Meaning
n	Throughout this section, the individual RLIN2 units are identified by the index “n” (n = 0).
m	Throughout this section, the individual channels are identified by the index “m” (m = 0).
i	Throughout this section, the individual channels of units that configure RLIN2 are identified by the index “i” (i = 0).
b	Throughout this section, the individual data buffers implemented in RLIN2 are identified by the index “b” (b = 1 to 8).

For example, RLN21nGLWBR are the LIN wake-up baud rate select registers, which are the global registers of RLN21nmLiMD are the LIN mode registers, which are the channel registers.

15.1.2 Register Base Addresses

RLIN2 base addresses are listed in the following table.

RLIN2 register addresses are given as offsets from the base addresses in general.

Table 15.4 Register Base Addresses

Base Address Name	Base Address
<RLIN210_base>	FFCE 0000_H

15.1.3 Clock Supply

RLIN2 clock is listed in following table.

Table 15.5 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
RLIN21n	pclk (P-bus clock)	CLK_LSB (low-speed peripheral clock)
	clkc (LIN communication clock source)	CLKC_LSB (unmodulated low-speed peripheral clock)

15.1.4 Interrupt Request

RLIN2 interrupt requests are listed in the following table.

Table 15.6 Interrupt Requests

Unit Interrupt Name	Outline	Interrupt Number
INTRLIN0	Transmission complete interrupt/ reception complete interrupt/ error detection interrupt (RLIN210 interrupt)	429

15.1.5 Reset Sources

RLIN2 reset sources are listed in the following table. RLIN2 is initialized by these reset sources.

Table 15.7 Reset Sources

Unit Name	Reset Source
RLIN21n	Any reset source

15.1.6 External Input/Output Signals

External input/output signals of RLIN2 are listed below.

Table 15.8 I/O Signals of RLIN2n

Unit Signal Name	Outline	Alternative Port Pin Signal
RLIN210		
RLIN20RX	RLIN210 receive data input	LRX0
RLIN20TX	RLIN210 transmit data output	LTX0

15.2 Function

15.2.1 Functional Overview

The LIN master interface is a hardware LIN communication controller that complies to LIN Specification Package Revision 1.3, 2.0, 2.1, 2.2, and SAEJ2602 (SEP 2005), and automatically performs frame communication and error determination.

Table 15.9 gives the LIN master interface specifications and **Figure 15.1** shows a block diagram of the LIN master interface.

Table 15.9 LIN Master Interface Specifications

Item		Specifications
Channel count		1 channel
LIN communication function	Protocol	LIN Specification Package Revision 1.3, 2.0, 2.1, 2.2, and SAEJ2602 (SEP 2005)
	Variable frame structure	• Break transmission width: 13 to 28 Tbits • Break delimiter transmission width: 1 to 4 Tbits • Inter-byte space (header): 0 to 7 Tbits (space between Sync field and ID field)*1 • Response space: 0 to 7 Tbits*1 • Inter-byte space: 0 to 3 Tbits (space between data bytes in response area) • Transmission wake-up: 1 to 16 Tbits
	Checksum	• Automatic operation for both transmission and reception • Classic or enhanced selectable (for each frame)
	Response field data byte count	Variable from 0 to 8 bytes
	Frame communication modes	• Mode in which header transmission and response transmission/reception is started with a single transmission start request • Mode in which header transmission and response transmission are started with separate transmission start requests (frame separate mode)
	Wake-up transmission and reception	LIN wake-up mode provided • Wake-up transmission (1 to 16 Tbits) • Wake-up reception Low-level width of input signals measured
	Status	• Successful frame/wake-up transmission • Successful header transmission • Successful frame/wake-up reception*2 • Successful data 1 reception • Error detection • Operation mode (LIN reset mode, LIN wake-up mode, LIN operation mode, LIN self-test mode)
	Error status	• Bit error • Checksum error • Frame timeout error • Physical bus error • Framing error
	Baud rate selection	Baud rate conforming to the LIN specifications generated using baud rate generator
	Test mode	Self-test mode for user evaluation
	Interrupt function	• Successful frame/wake-up transmission • Successful frame/wake-up reception*2 • Error detection These three logical OR of these three operations events is are the interrupt sources (INTRLINm) for each channel.

Note 1. Since the same register is used for setting, the inter-byte space (header) = response space.

Note 2. For wake-up reception, the low level width of the input signal is indicated.

15.2.2 Block Diagram

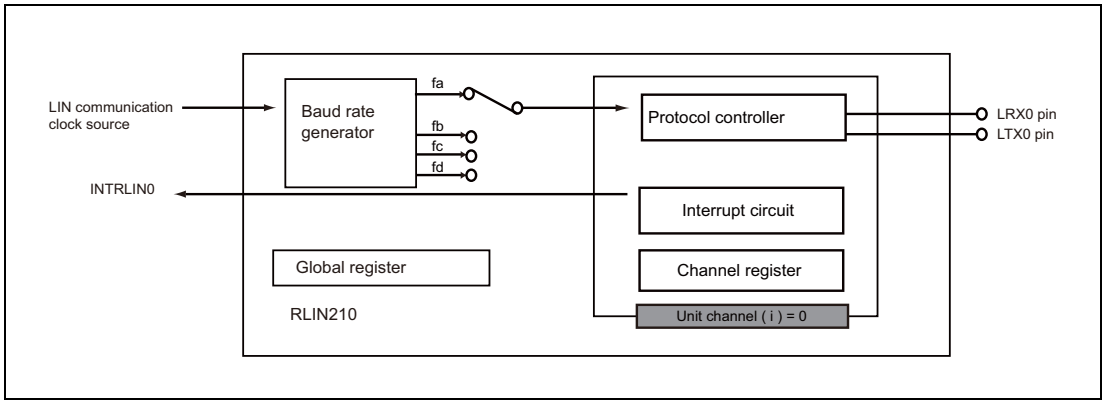

Figure 15.1 LIN Master Interface Block Diagram

15.3 Registers

The registers of the LIN master interface are configured with global registers and channel registers. As the global registers are allocated for each unit, they can be set respectively in units. As the channel registers are allocated for each channel, they can be controlled respectively in channels.

15.3.1 List of Registers

RLIN2 registers are listed in the following table.

For information on <RLIN21n_base>, see **Section 15.1.2, Register Base Addresses**.

Table 15.10 LIN Master Interface Registers Overview

Module name	Register name	Shortcut	Address
Global registers			
RLN21nG	LIN wake-up baud rate select register	RLN21nGLWBR	<RLIN21n_base> + 01_H
RLN21nG	LIN baud rate prescaler 0 register	RLN21nGLBRP0	<RLIN21n_base> + 02_H
RLN21nG	LIN baud rate prescaler 1 register	RLN21nGLBRP1	<RLIN21n_base> + 03_H
RLN21nG	LIN self test control register	RLN21nGLSTC	<RLIN21n_base> + 04_H
Channel registers			
RLN21nm	LIN mode register	RLN21nmLiMD	<RLIN21n_base> + 08_H
RLN21nm	LIN break field configuration register	RLN21nmLiBFC	<RLIN21n_base> + 09_H
RLN21nm	LIN space configuration register	RLN21nmLiSC	<RLIN21n_base> + $0A_H$
RLN21nm	LIN wake-up configuration register	RLN21nmLiWUP	<RLIN21n_base> + $0B_H$
RLN21nm	LIN interrupt enable register	RLN21nmLiIE	<RLIN21n_base> + $0C_H$
RLN21nm	LIN error detection enable register	RLN21nmLiEDE	<RLIN21n_base> + $0D_H$
RLN21nm	LIN control register	RLN21nmLiCUC	<RLIN21n_base> + $0E_H$
RLN21nm	LIN transmission control register	RLN21nmLiTRC	<RLIN21n_base> + 10_H
RLN21nm	LIN mode status register	RLN21nmLiMST	<RLIN21n_base> + 11_H
RLN21nm	LIN status register	RLN21nmLiST	<RLIN21n_base> + 12_H
RLN21nm	LIN error status register	RLN21nmLiEST	<RLIN21n_base> + 13_H
RLN21nm	LIN data field configuration register	RLN21nmLiDFC	<RLIN21n_base> + 14_H
RLN21nm	LIN ID buffer register	RLN21nmLiIDB	<RLIN21n_base> + 15_H
RLN21nm	LIN check sum buffer register	RLN21nmLiCBR	<RLIN21n_base> + 16_H
RLN21nm	LIN data buffer 1 register	RLN21nmLiDBR1	<RLIN21n_base> + 18_H
RLN21nm	LIN data buffer 2 register	RLN21nmLiDBR2	<RLIN21n_base> + 19_H
RLN21nm	LIN data buffer 3 register	RLN21nmLiDBR3	<RLIN21n_base> + $1A_H$
RLN21nm	LIN data buffer 4 register	RLN21nmLiDBR4	<RLIN21n_base> + $1B_H$
RLN21nm	LIN data buffer 5 register	RLN21nmLiDBR5	<RLIN21n_base> + $1C_H$
RLN21nm	LIN data buffer 6 register	RLN21nmLiDBR6	<RLIN21n_base> + $1D_H$
RLN21nm	LIN data buffer 7 register	RLN21nmLiDBR7	<RLIN21n_base> + $1E_H$
RLN21nm	LIN data buffer 8 register	RLN21nmLiDBR8	<RLIN21n_base> + $1F_H$

15.3.2 Global Registers

15.3.2.1 RLN21nGLWBR — LIN Wake-up Baud Rate Select Register

Access: This register can be read/written in 8-bit units.

Address: <RLIN21n_base> + 01_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	LWBR0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 15.11 RLN21nGLWBR Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	The write value should be the value after reset.
0	LWBR0	Wake-up Baud Rate Select 0: In LIN wake-up mode, the clock specified by the LCKS bit setting in the RLN21nmLiMD register is used. (when LIN1.3 is used) 1: In LIN wake-up mode, the clock fa is used regardless of the setting of the LCKS bit of the RLN21nmLiMD register. (When LIN2.x is used)

Set the RLN21nGLWBR register when all channels in the same unit are in LIN reset mode (while the OMM0 bit in the RLN21nmLiMST register is 0).

LWBR0 Bit (Wake-up Baud Rate Select)

When LIN Specification Package Revision 1.3 is used, set the LWBR0 bit in the RLN21nGLWBR register to 0. This allows the 2.5-Tbit or longer low-level width of the input signal to be measured. When LIN Specification Package Revision 2.x is used, set the LWBR0 bit to 1.

With this setting, fa is selected as the LIN system clock (fLIN) during LIN wake-up mode regardless of the setting of the LCKS bit in the RLN21nmLiMD register (the LCKS bit is not changed) and the 2.5-Tbit or longer low-level width of the input signal to be measured.

Setting the baud rate to 19200 bps while fa is selected allows the 130µs or longer low-level width of the input signal to be detected during LIN wake-up mode regardless of the setting of the LCKS bit in the RLN21nmLiMD register.

15.3.2.2 RLN21nGLBRP0 — LIN Baud Rate Prescaler 0 Register

Access: This register can be read/written in 8-bit units

Address: <RLIN21n_base> + 02_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LBRP0[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.12 RLN21nGLBRP0 Register Contents

Bit Position	Bit Name	Function
7 to 0	LBRP0[7:0]	Assuming that the value set in this register is N (0 to 255), the baud rate prescaler 0 divides the frequency of the LIN communication clock source by N + 1. Setting Range: 00_H to FF_H

Set the RLN21nGLBRP0 register when all channels in the same unit are in LIN reset mode (while the OMM0 bit in the RLN21nmLiMST register is 0).

The value set in this register is used to control the frequency of baud rate clock source fa, fb, and fc.

Assuming that the value set in this register is N, the baud rate prescaler 0 divides the frequency of the LIN communication clock source by N+1.

15.3.2.3 RLN21nGLBRP1 — LIN Baud Rate Prescaler 1 Register

Access: This register can be read/written in 8-bit units.

Address: <RLIN21n_base> + 03_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LBRP1[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.13 RLN21nGLBRP1 Register Contents

Bit Position	Bit Name	Function
7 to 0	LBRP1[7:0]	Assuming that the value set in this register is M (0 to 255), the baud rate prescaler 1 divides the frequency of the LIN communication clock source by M+1. Setting Range: 00_H to FF_H

Set the RLN21nGLBRP1 register when all channels in the same unit are in LIN reset mode (while the OMM0 bit in the RLN21nmLiMST register is 0).

The value set in this register is used to control the frequency of baud rate clock source fd.

Assuming that the value set in this register is M, the baud rate prescaler 1 divides the frequency of the LIN communication clock source by M+1.

15.3.2.4 RLN21nGLSTC — LIN Self-Test Control Register

This register is used to unlock protection of LIN self-test mode.

Set the RLN21nGLSTC register when all channels in the same unit are while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

For making transition to LIN self-test mode, refer to **Section 15.15, LIN Self-Test Mode**.

Access: This register can be read/written in 8-bit units.

Address: <RLIN21n_base> + 04_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LSTM[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Note 1. Writing is ignored in modes other than LIN reset mode.

Table 15.14 RLN21nGLSTC Register Contents

Bit Position	Bit Name	Function
7 to 0	LSTM	LIN Self-Test Mode 0: The module is not in LIN self-test mode*1 1: The module is in LIN self-test mode.*2 Writing $A7_H$, 58_H, and 01_H successively to the RLN21nGLSTC register places the module into LIN self-test mode. Setting other than the above is prohibited. If any other value is set, the read value is undefined.

Note 1. For leaving LIN self-test mode, see **Section 15.15.4, Terminating LIN Self-Test Mode**. When LIN self-test mode is terminated, 00_H is read.

Note 2. See **Section 15.15.1, Change to LIN Self-Test Mode** for how to change to LIN self-test mode. When transition to LIN self-test mode is completed, 01_H is read.

15.3.3 Channel Registers

15.3.3.1 RLN21nmLiMD — LIN Mode Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiMD: <RLIN21n_base> + 08_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	LCKS[1:0]		—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R	R

Table 15.15 RLN21nmLiMD Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	The write value should be the value after reset.
3, 2	LCKS[1:0]	LIN System Clock Select b3 b2 0 0: fa (Clock generated by baud rate prescaler 0) 0 1: fb (1/2 clock generated by baud rate prescaler 0) 1 0: fc (1/8 clock generated by baud rate prescaler 0) 1 1: fd (1/2 clock generated by baud rate prescaler 1)
1, 0	Reserved	These bits are always read as 0. The write value should always be 0.

Set the RLN21nmLiMD register while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

LCKS[1:0] Bits (LIN System Clock Select)

The LCKS bits select the clock to be input to the protocol controller.
With 00_B set, the protocol controller is provided with fa (clock generated by baud rate prescaler 0).
With 01_B set, the protocol controller is provided with fb (1/2 clock generated by baud rate prescaler 0).
With 10_B set, the protocol controller is provided with fc (1/8 clock generated by baud rate prescaler 0).
With 11_B set, the protocol controller is provided with fd (1/2 clock generated by baud rate prescaler 1).
When the LWBR0 bit in the RLN21nGLWBR is 1 (when LIN 2.x is used) and the RLN21nmLiMST register is 01_H (LIN wake-up mode), regardless of the setting of the LWBR0 bit, fa is input to the protocol controller (LCKS bit is not changed).

15.3.3.2 RLN21nmLiBFC — LIN Break Field Configuration Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiBFC: <RLIN21n_base> + 09_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	BDT[1:0]		BLT[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.16 RLN21nmLiBFC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	The write value should be the value after reset.
5, 4	BDT[1:0]	Transmission Break Delimiter (High Level) Width Setting b5 b4 0 0: 1 Tbit 0 1: 2 Tbits 1 0: 3 Tbits 1 1: 4 Tbits
3 to 0	BLT[3:0]	Transmission Break (Low Level) Width Setting b3 b0 0 0 0 0: 13 Tbits 0 0 0 1: 14 Tbits 0 0 1 0: 15 Tbits : 1 1 1 0: 27 Tbits 1 1 1 1: 28 Tbits

Set the RLN21nmLiBFC register while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

Some combinations of the set values result in the length of a frame exceeding the timeout time. Set the appropriate values in this register.

BDT[1:0] Bits (Transmission Break Delimiter (High Level) Width Setting)

This bit is used to set the break high level width of transmission frame header.
1 Tbit to 4 Tbits can be set.

BLT[3:0] Bits (Transmission Break (Low Level) Width Setting

This BLT bits set the break low level width of transmission frame header.
13 Tbits to 28 Tbits can be set.

15.3.3.3 RLN21nmLiSC — LIN Space Configuration Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiSC: <RLIN21n_base> + $0A_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	IBS[1:0]		—	IBHS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R/W	R/W	R/W

Table 15.17 RLN21nmLiSC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	The write value should be the value after reset.
5, 4	IBS[1:0]	Inter-Byte Space Select b5 b4 0 0: 0 Tbit 0 1: 1 Tbit 1 0: 2 Tbits 1 1: 3 Tbits
3	Reserved	The write value should be the value after reset.
2 to 0	IBHS[2:0]	Inter-Byte Space (Header)/Response Space Select b2 b0 0 0 0: 0 Tbit 0 0 1: 1 Tbit 0 1 0: 2 Tbits 0 1 1: 3 Tbits 1 0 0: 4 Tbits 1 0 1: 5 Tbits 1 1 0: 6 Tbits 1 1 1: 7 Tbits

Set the RLIN21nmLiSC register while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

Some combinations of the set values result in the length of a frame or a response exceeding the timeout time. Set the appropriate values in this register.

IBS[1:0] Bits (Inter-Byte Space Select)

The IBS bits set the width of the inter-byte space of the transmission frame response field.
0 Tbit to 3 Tbits can be set.
These bits are enabled only during response transmission; these are disabled during response reception.

IBHS[2:0] Bits (Inter-Byte Space (Header)/Response Space Select)

The IBHS bits set the width of the inter-byte space (header) of the transmission frame header field and the response space.
0 Tbit to 7 Tbits can be set.
The response space setting is enabled only during response transmission; setting is disabled during response reception.
The inter-byte space (header) is equal to the response space.

15.3.3.4 RLN21nmLiWUP — LIN Wake-up Configuration Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiWUP: <RLIN21n_base> + $0B_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	WUTL[3:0]				—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 15.18 RLN21nmLiWUP Register Contents

Bit Position	Bit Name	Function
7 to 4	WUTL[3:0]	Wake-up Transmission Low level Width Select b7 b4 0 0 0 0: 1 Tbit 0 0 0 1: 2 Tbits 0 0 1 0: 3 Tbits 0 0 1 1: 4 Tbits : 1 1 0 0: 13 Tbits 1 1 0 1: 14 Tbits 1 1 1 0: 15 Tbits 1 1 1 1: 16 Tbits
3 to 0	Reserved	The write value should be the value after reset.

Set the RLN21nmLiWUP register while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

WUTL[3:0] Bits (Wake-up Transmission Low level Width Select)

The WUTL bits set the low level width of the wake-up signal transmission.
1 Tbit to 16 Tbits can be set.

When the LWBR0 bit in the RLN21nGLWBR is 1 (when LIN 2.x is used), regardless of the setting of the the LCKS bit in the RLN21nmLiMD register, fa is selected as the LIN system clock (fLIN) (LCKS bit is not changed).

15.3.3.5 RLN21nmLiIE — LIN Interrupt Enable Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiIE: <RLIN21n_base> + $0C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	ERRIE	FRCIE	FTCIE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 15.19 RLN21nmLiIE Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	The write value should be the value after reset.
2	ERRIE	Error Detection Interrupt Request Enable 0: Disables error detection interrupt request. 1: Enables error detection interrupt request.
1	FRCIE	Successful Frame/Wake-up Reception Interrupt Request Enable 0: Disables successful frame/wake-up reception interrupt request. 1: Enables successful frame/wake-up reception interrupt request.
0	FTCIE	Successful Frame/Wake-up Transmission Interrupt Request Enable 0: Disables successful frame/wake-up transmission interrupt request. 1: Enables successful frame/wake-up transmission interrupt request.

Set the RLN21nmLiIE register while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

ERRIE Bit (Error Detection Interrupt Request Enable)

The ERRIE bit enables or disables interrupt request generation upon detection of an error.
With 0 set, the interrupt request is not generated when the ERR flag in the RLN21nmLiST register is set to 1.
With 1 set, the interrupt request is generated when the ERR flag in the RLN21nmLiST register is set to 1.
Error sources can be the bit error, physical bus error, frame timeout error, framing error, and checksum error.
Detection of the bit error, physical bus error, frame/response timeout error, and framing error can be enabled or disabled using the RLN21nmLiEDE register.

FRCIE Bit (Successful Frame/Wake-up Reception Interrupt Request Enable)

The FRCIE bit enables or disables interrupt request generation upon successful reception of a frame or a wake-up signal (counting of low level width of the input signal).
With 0 set, the interrupt request is not generated when the FRC flag in the RLN21nmLiST register is set to 1.
With 1 set, the interrupt request is generated when the FRC flag in the RLN21nmLiST register is set to 1.

FTCIE Bit (Successful Frame/Wake-up Transmission Interrupt Request Enable)

The FTCIE bit enables or disables interrupt request generation upon successful transmission of a frame or a wake-up signal.
With 0 set, the interrupt request is not generated when the FTC flag in the RLN21nmLiST register is set to 1.
With 1 set, the interrupt request is generated when the FTC flag in the RLN21nmLiST register is set to 1.

15.3.3.6 RLN21nmLiEDE — LIN Error Detection Enable Register

Access: This register can be read/written in 8-bit units

Address: RLN21nmLiEDE: <RLIN21n_base> + $0D_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	FERE	FTERE	PBERE	BERE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 15.20 RLN21nmLiEDE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	The write value should be the value after reset.
3	FERE	Framing Error Detection Enable 0: Disables framing error detection. 1: Enables framing error detection.
2	FTERE	Frame Timeout Error Detection Enable 0: Disables frame timeout error detection. 1: Enables frame timeout error detection.
1	PBERE	Physical Bus Error Detection Enable 0: Disables physical bus error detection. 1: Enables physical bus error detection.
0	BERE	Bit Error Detection Enable 0: Disables bit error detection. 1: Enables bit error detection.

Set the RLN21nmLiEDE register while the OMM0 bit in the RLN21nmLiMST register is 0_B (in LIN reset mode).

FERE Bit (Framing Error Detection Enable)

The FERE bit enables or disables detection of the framing error.
With 0 set, the framing error is not detected.
With 1 set, the framing error is detected.
When this bit is set to 1, the detection result is indicated in the FER flag in the RLN21nmLiEST register.
For details of the framing error, refer to **Section 15.14, Error Status**.

FTERE Bit (Frame Timeout Error Detection Enable)

The FTERE bit enables or disables detection of the frame timeout error.
With 0 set, the frame timeout error is not detected.
With 1 set, the frame timeout error is detected.
When this bit is set to 1, the detection result is indicated in the FTER flag in the RLN21nmLiEST register.
Do not use the timeout error if response data of 9 bytes or more is to be transmitted or received.
For details of the frame timeout error, refer to **Section 15.14, Error Status**.

PBERE Bit (Physical Bus Error Detection Enable)

The PBERE bit enables or disables detection of the physical bus error.
With 0 set, the physical bus error is not detected.
With 1 set, the physical bus error is detected.
When this bit is set to 1, the detection result is indicated in the PBER flag in the RLN21nmLiEST register.
For details of the physical bus error, refer to **Section 15.14, Error Status**.

BERE Bit (Bit Error Detection Enable)

The BERE bit enables or disables detection of the bit error.
With 0 set, the bit error is not detected.
With 1 set, the bit error is detected.
When this bit is set to 1, the detection result is indicated in the BER flag in the RLN21nmLiEST register.
For details of the bit error, refer to **Section 15.14, Error Status**.

15.3.3.7 RLN21nmLiCUC — LIN Control Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiCUC: <RLIN21n_base> + $0E_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OM1	OM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 15.21 RLN21nmLiCUC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	The write value should be the value after reset.
1	OM1	LIN Mode Select 0: LIN wake-up mode 1: LIN operation mode
0	OM0	LIN Reset 0: LIN reset mode 1: Release from LIN reset mode

Set the RLN21nmLiCUC register to 01_H to cause a transition to LIN wake-up mode after release from LIN reset mode, and set the register to 03_H to cause a transition to LIN operation mode.

In LIN self-test mode, set the RLN21nmLiCUC register to 03_H after a transition to LIN self-test mode is completed.

After a value is written to this register, confirm that the value written is actually indicated in the RLN21nmLiMST register before writing another value.

OM1 Bit (LIN Mode Select)

The OM1 bit selects the specific LIN operation mode (either LIN wake-up mode or LIN operation mode) after release from LIN reset mode.
Setting this bit to 0 causes a transition to LIN wake-up mode.
Setting this bit to 1 causes a transition to LIN operation mode.
This bit is valid only when the OMM0 bit in the RLN21nmLiMST register is 1.
Writing a value to this bit is disabled while the FTS bit in the RLN21nmLiTRC register is 1.

OM0 Bit (LIN Reset)

The OM0 bit selects either a transition to LIN reset mode or release from LIN reset mode.
Setting this bit to 0 causes a transition to LIN reset mode.
Setting this bit to 1 leads to release from LIN reset mode.

15.3.3.8 RLN21nmLiTRC — LIN Transmission Control Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiTRC: <RLIN21n_base> + 10_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	RTS	FTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 15.22 RLN21nmLiTRC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	The write value should be the value after reset.
1	RTS	Response Transmission Start 0: Response transmission is stopped in frame separate mode. 1: Response transmission is started in frame separate mode.
0	FTS	Frame Transmission/Wake-up Transmission/Reception Start 0: Frame Transmission/wake-up transmission/reception is stopped. 1: Frame Transmission/wake-up transmission/reception is started.

RTS Bit (Response Transmission Start)

Set the RTS bit to 1 in frame separate mode after header transmission is started (FTS bit is 1) and response transmission data is ready. Once set, this bit is automatically cleared to 0 upon completion of frame communication or transition to LIN reset mode.
Only 1 can be written to this bit; 0 cannot be written.
To write 1 to this bit, write 02_H to the RLN21nmLiTRC register using the store instruction.
Writing a value to this bit is disabled when the OMM0 bit is 0 (in LIN reset mode).
Do not write 1 to this bit when the OMM0 bit is 0 (in LIN wakeup mode).
Writing a value to this bit is disabled when the FTS bit is 0 (frame transmission or wake-up transmission/reception is halted).

FTS Bit (Frame Transmission/Wake-up Transmission/Reception Start)

Set the FTS bit to 1 to start frame/wake-up transmission.
Also set this bit to 1 to allow wake-up reception (counting of the low level width of the input signal).
Only 1 can be written to this bit; 0 cannot be written.
Writing a value to this bit is disabled when the OMM0 bit is 0 (in LIN reset mode). This bit is set to 0 upon completion of frame or wake-up communication and transition to LIN reset mode.

15.3.3.9 RLN21nmLiMST — LIN Mode Status Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiMST: <RLIN21n_base> + 11_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OMM1	OMM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 15.23 RLN21nmLiMST Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read.
1	OMM1	LIN Mode Status Monitor 0: The LIN master interface is in LIN wake-up mode. 1: The LIN master interface is in LIN operation mode.
0	OMM0	LIN Reset Status Monitor 0: The LIN master interface is in LIN reset mode. 1: The LIN master interface is not in LIN reset mode.

OMM1 Bit (LIN Mode Status Monitor)

The OMM1 bit indicate the current operating mode. The OMM0 bit value is invalid while this bit is 0_B (in LIN reset mode).

OMM0 Bit (LIN Reset Status Monitor)

The OMM0 bit indicates the current operating mode.

15.3.3.10 RLN21nmLiST — LIN Status Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiST: <RLIN21n_base> + 12_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	HTRC	D1RC	—	—	ERR	—	FRC	FTC
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R/W	R/W

Table 15.24 RLN21nmLiST Register Contents

Bit Position	Bit Name	Function
7	HTRC	Successful Header Transmission Flag 0: Header transmission has not been completed. 1: Header transmission has been completed.
6	D1RC	Successful Data 1 Reception Flag 0: Data 1 reception has not been completed. 1: Data 1 reception has been completed.
5, 4	Reserved	The write value should be the value after reset.
3	ERR	Error Detection Flag 0: No error has been detected. 1: Error has been detected.
2	Reserved	The write value should be the value after reset.
1	FRC	Successful Frame/Wake-up Reception Flag 0: Frame or wake-up reception has not been completed. 1: Frame or wake-up reception has been completed.
0	FTC	Successful Frame/Wake-up Transmission Flag 0: Frame or wake-up transmission has not been completed. 1: Frame or wake-up transmission has been completed.

The RLN21nmLiST register is automatically cleared to 00_H upon transition to LIN reset mode and start of the next communication (the FTS bit in the RLN21nmLiTRC register is 1).

In LIN reset mode, writing to the register is disabled.

In LIN reset mode, the register retains 00_H.

Writing to this register is prohibited while the FTS bit in the RLN21nmLiTRC register is 1 (frame transmit or wake-up transmission/reception is started)

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

HTRC Flag (Successful Header Transmission Flag)

Only 0 can be written to the HTRC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The HTRC flag is set to 1 upon completion of header transmission, but an interrupt request is not generated. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode.

D1RC Flag (Successful Data 1 Reception Flag)

Only 0 can be written to the D1RC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The D1RC flag is set to 1 upon completion of data 1 reception. Here, an interrupt request is not generated. To clear the bit to 0 before the next communication, write 0 to the bit in LIN operation mode.

ERR Flag (Error Detection Flag)

The ERR flag is set to 1 upon detection of an error (at least one of the RLN21nmLiEST flags is 1). Here, an interrupt request is generated if the ERRIE bit in the RLN21nmLiIE register is 1 (interrupt request is enabled). To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the CSER, FER, FTER, PBER, and BER flags in the RLN21nmLiEST register in LIN operation mode or LIN wake-up mode. This clears the ERR flag to 0.

FRC Flag (Successful Frame/Wake-up Reception Flag)

Only 0 can be written to the FRC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The FRC flag is set to 1 upon completion of frame or wake-up reception. Here, an interrupt request is generated if the FRCIE bit in the RLN21nmLiIE register is 1 (interrupt request is enabled). To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

FTC Flag (Successful Frame/Wake-up Transmission Flag)

Only 0 can be written to the FTC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The FTC flag is set to 1 upon completion of frame or wake-up transmission. Here, an interrupt request is generated if the FTCIE bit in the RLN21nmLiIE register is 1 (interrupt request is enabled). To clear the bit to 0 before the next communication(the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

15.3.3.11 RLN21nmLiEST — LIN Error Status Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiEST: <RLIN21n_base> + 13_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	CSER	—	FER	FTER	PBER	BER
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R	R/W	R/W	R/W	R/W

Table 15.25 RLN21nmLiEST Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	The write value should be the value after reset.
5	CSER	Checksum Error Flag 0: Checksum error has not been detected. 1: Checksum error has been detected.
4	Reserved	The write value should be the value after reset.
3	FER	Framing Error Flag 0: Framing error has not been detected. 1: Framing error has been detected.
2	FTER	Frame Timeout Error Flag 0: Frame timeout error has not been detected. 1: Frame timeout error has been detected.
1	PBER	Physical Bus Error Flag 0: Physical bus error has not been detected. 1: Physical bus error has been detected.
0	BER	Bit Error Flag 0: Bit error has not been detected. 1: Bit error has been detected.

The RLN21nmLiEST register is automatically cleared to 00_H upon transition to LIN reset mode and start of the next communication (the FTS bit in the RLN21nmLiTRC register is 1).

In LIN reset mode, writing to the register is disabled and the register retains 00_H.

When the FTS bit in the RLN21nmLiTRC register is 1 (frame transmission or wake-up transmission/ reception is started), do not write a value to this register.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

CSER Flag (Checksum Error Flag)

Only 0 can be written to the CSER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The CSER flag is set to 1 upon checksum error detection. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode.

FER Flag (Framing Error Flag)

When the FERE bit in the RLN21nmLiEST register is 1 (flaming error detection is enabled) and a flaming error is detected, 1 is written. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode.

FTER Flag (Frame Fimeout Error Flag)

Only 0 can be written to the FTER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The FTER flag is set to 1 when the FTERE bit in the RLN21nmLiEDE register is 1 (frame timeout error detection enable) and the frame timeout error is detected. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode.

PBER Flag (Physical Bus Error Flag)

Only 0 can be written to the PBER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The PBER flag is set to 1 when the PBERE bit in the RLN21nmLiEDE register is 1 (physical bus error detection enable) and the physical bus error is detected. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

BER Flag (Bit Error Flag)

Only 0 can be written to the BER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The BER flag is set to 1 when the BERE bit in the RLN21nmLiEDE register is 1 (bit error detection enable) and the bit error is detected. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

15.3.3.12 RLN21nmLiDFC — LIN Data Field Configuration Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiDFC: <RLIN21n_base> + 14_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	FSM	CSM	RFT	RFDL[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.26 RLN21nmLiDFC Register Contents

Bit Position	Bit Name	Function
7	Reserved	The write value should be the value after reset.
6	FSM	Frame Separate Mode Select 0: Frame separate mode is not set. 1: Frame separate mode is set.
5	CSM	Checksum Select 0: Classic checksum mode 1: Enhanced checksum mode
4	RFT	Response Field Communication Direction Select 0: Reception 1: Transmission
3 to 0	RFDL[3:0]	Response Field Length Select b3 b0 0 0 0 0: 0 bytes (+ checksum) 0 0 0 1: 1 byte (+ checksum) 0 0 1 0: 2 bytes (+ checksum) : 0 1 1 1: 7 bytes (+ checksum) 1 0 0 0: 8 bytes (+ checksum) Settings other than the above are prohibited.

Set the RLN21nmLiDFC register when the FTS bit in the RLN21nmLiTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

FSM Bit (Frame Separate Mode Select)

The FSM bit sets the response transmission mode.

With 0 set, frame separate mode is not selected. In this case, after header transmission is started (the FTS bit in the RLN21nmLiTRC register is 1), response is transmitted/received without the RTS bit in the RLN21nmLiTRC register being set.

With 1 set, frame separate mode is selected. When the RTS bit in the RLN21nmLiTRC register is set to 1 during header transmission, response is transmitted after header transmission is completed.

Header transmission is successfully completed (the HTRC bit in the RLN21nmLiST register is 1).

Response transmission is requested (the RTS bit in the RLN21nmLiTRC register is 1).

For response reception (the RFT bit is 0), set the FSM bit to 0.
When causing a transition to LIN self-test mode, set this bit to 0 before transition.
For details of frame separate mode, refer to **Section 15.11.1, Transmission of LIN Frames**.

CSM Bit (Checksum Select)

The CSM bit sets the checksum mode.
With 0 set, classic checksum mode is selected.
With 1 set, enhanced checksum mode is selected.
When the frame timeout error is used (the FTERE bit in the RLN21nmLiEDE register is 1), the specific timeout time depends on the setting of this bit. For details of the bit error, refer to **Section 15.14, Error Status**.

RFT Bit (Response Field Communication Direction Select)

The RFT bits set the direction of the response field communication and wake-up signal.
With 0 set, reception is performed in the response field. In LIN wake-up mode, wake-up reception is performed (low level width of the input signal is counted).
With 1 set, transmission is performed in the response field. In LIN wake-up mode, wake-up transmission is performed.

RFDL[3:0] Bits (Response Field Length Select)

The RFDL bits set the length of the response field data.
The data length can be 0 to 8 bytes excluding the checksum size.

15.3.3.13 RLN21nmLiIDB — LIN ID Buffer Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiIDB: <RLIN21n_base> + 15_H

Value after reset: Undefined

Bit	7	6	5	4	3	2	1	0
	IDP1	IDP0	ID[5:0]					
Value after reset	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.27 RLN21nmLiIDB Register Contents

Bit Position	Bit Name	Function
7	IDP1	Parity Setting (P1) Sets the parity bits (P1) to be transmitted in the ID field.
6	IDP0	Parity Setting (P0) Sets the parity bits (P0) to be transmitted in the ID field.
5 to 0	ID[5:0]	ID Setting Sets the 6-bit ID value to be transmitted in the ID field.

Set the RLN21nmLiIDB register when the FTS bit in the RLN21nmLiTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

In LIN self-test mode, this register operates as follows:

Write the value to be transmitted to the register before communication. After flame transmission is completed (after loopback), the inverse of the value transmitted can be read from the register.

For details of LIN self-test mode, see **Section 15.15, LIN Self-Test Mode**.

IDP Bits (Parity Setting)

The IDP bits set the parity bits (P0 and P1) to be transmitted in the ID field of the LIN frame. IDP0 is P0 and IDP1 is P1. Since parity is not automatically calculated, set the calculation result. Note that if the erroneous result is set, it is transmitted as is.

ID Bits (ID Setting)

The ID bit sets the 6-bit ID value to be transmitted in the ID field of the LIN frame.

15.3.3.14 RLN21nmLiCBR — LIN Checksum Buffer Register

Access: This register can be read/written in 8-bit units.
However, this register can be read/written in 8-bit units in LIN self-test mode.

Address: RLN21nmLiCBR: <RLIN21n_base> + 16_H

Value after reset: Undefined

Bit	7	6	5	4	3	2	1	0
	CKSM[7:0]							
Value after reset	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.28 RLN21nmLiCBR Register Contents

Bit Position	Bit Name	Function
7 to 0	CKSM[7:0]	Holds the checksum value transmitted or received.

In LIN operation mode, this register operates as follows:

- When the RFT bit in the RLN21nmLiDFC register is 1 (transmission):
  The value transmitted can be read from the register. Read the value after transmission is completed.
  Writing to this register is invalid.
- When the RFT bit in the RLN21nmLiDFC register is 0 (reception):
  The value received can be read from the register. Read the value after reception is completed.
  Writing to this register is invalid.

In LIN self-test mode, this register operates as follows:

- When the RFT bit in the RLN21nmLiDFC register is 1 (transmission):
  The inverse of the value received can be read from the register after frame transmission/reception completion (after loop-back).
  Writing to this register is invalid.
- When the RFT bit in the RLN21nmLiDFC register is 0 (reception):
  The value to be received should be written to the register before communication.
  The inverse of the value received can be read from the register after frame transmission/reception is completed (after loop-back).

See **Section 15.15, LIN Self-Test Mode** for the details on LIN self-test mode.

Set the RLN21nmLiCBR register when the FTS bit in the RLN21nmLiTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

15.3.3.15 RLN21nmLiDBRb — LIN Data Buffer b Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiDBR1: <RLIN21n_base> + 18_H, RLN21nmLiDBR2: <RLIN21n_base> + 19_H, RLN21nmLiDBR3: <RLIN21n_base> + $1A_H$, RLN21nmLiDBR4: <RLIN21n_base> + $1B_H$, RLN21nmLiDBR5: <RLIN21n_base> + $1C_H$, RLN21nmLiDBR6: <RLIN21n_base> + $1D_H$, RLN21nmLiDBR7: <RLIN21n_base> + $1E_H$, RLN21nmLiDBR8: <RLIN21n_base> + $1F_H$

Value after reset: Undefined

Bit	7	6	5	4	3	2	1	0
	LDB[7:0]							
Value after reset	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.29 RLN21nmLiDBRm (m = 1 to 8) Register Contents

Bit Position	Bit Name	Function
7 to 0	LDB[7:0]	Sets the data to be transmitted or allows the received data to be read. Setting Range: 00_H to FF_H

- For response transmission:

  The RLN21nmLiDBRm registers set the data to be transmitted in the response field.
  Use these registers with the following settings.

  – RFT in RLN21nmLiDFC register is 1 (transmission)
  – FSM in RLN21nmLiDFC register is 0 (not frame separate mode)
  – FTS bit in RLN21nmLiTRC register is 0 (frame transmission or wake-up transmission/ reception is halted)

  or

  – RFT in RLN21nmLiDFC register is 1 (transmission)
  – FSM in RLN21nmLiDFC register is 1 (frame separate mode)
  – RTS in RLN21nmLiTRC register is 0 (response transmission is halted)

- For response reception:

  The RLN21nmLiDBRm registers hold the data received in the response field.
  The received data is overwritten. If an error is detected, the data prior to reception interruption is stored in the register.

  Do not read these registers when the FTS bit is 1 (frame transmission or wake-up transmission/ reception is started)

In LIN self-test mode, these registers operate as follows:

The value to be transmitted should be written to the registers before communication.

The inverse of the value received can be read from the register after frame transmission/reception completion (after loop back).

See **Section 15.15, LIN Self-Test Mode** for the details on the LIN self-test mode.

15.4 Interrupt Sources

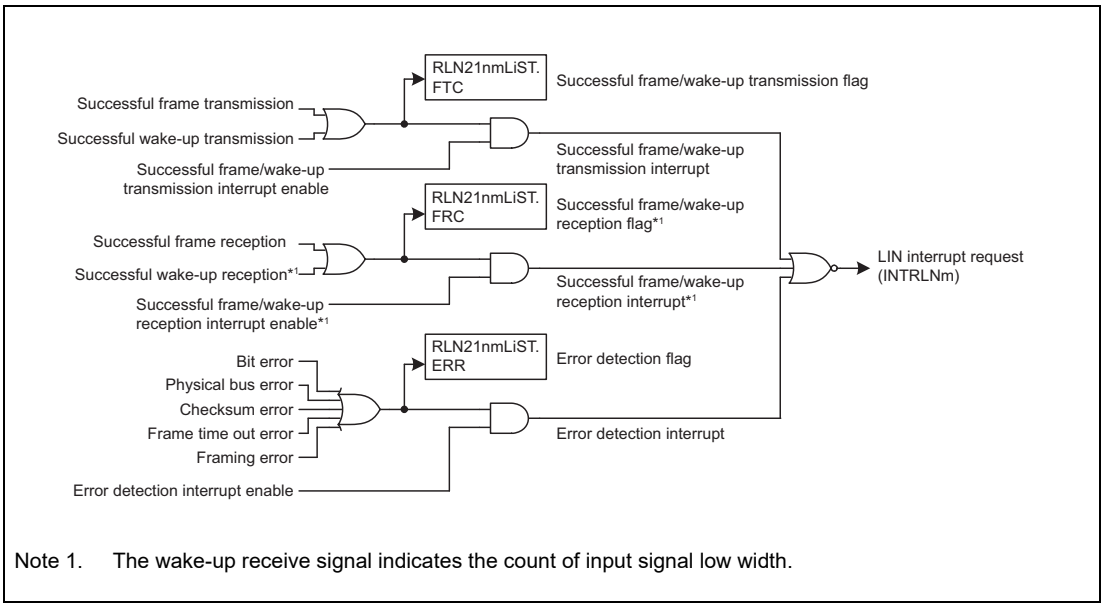
The LIN interrupts are interrupt requests generated by the LIN master interface.

There are three interrupt factors for each channel; frame/wake-up transmission completion, frame/wake-up reception completion, and error detection.

The interrupt request from three interrupt states, frame/wake-up transmit completion, frame/wake-up reception completion, and error detection, is ORed to be one interrupt request “LIN interrupt”.

The respective interrupt request is output when the corresponding flag in the RLN21nmLiST register is set to 1 while the corresponding bit in the RLN21nmLiIE register is 1 (interrupt enabled). However, if an interrupt is requested when the corresponding flag in the RLN21nmLiST register has been set to 1, it is ignored. Therefore, clear the corresponding flag to 0 to enable the interrupt.

Figure 15.2 shows a block diagram of the LIN interrupt.



Note 1. The wake-up receive signal indicates the count of input signal low width.

Figure 15.2 LIN Interrupt Block Diagram

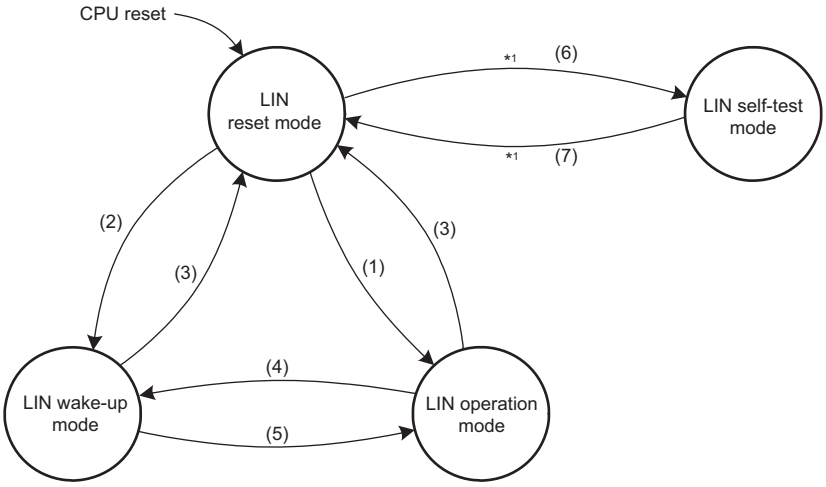
15.5 Modes

The LIN Master Interface provides the following four modes, depending upon the specific function to be performed:

- LIN reset mode
- LIN operation mode
- LIN wake-up mode
- LIN self-test mode

The transition of the operating modes except LIN self-test mode is controlled independently for respective channels.

Figure 15.3 shows mode transitions. **Table 15.30** describes mode transition conditions. **Table 15.31** lists operations available in each mode.



Note 1. See **Section 15.15, LIN Self-Test Mode** for the details.

Figure 15.3 Mode Transitions

Table 15.30 Transition Condition of Each Mode

	Mode transition			Transition condition
1	LIN reset mode	→	LIN operation mode	RLN21nmLiCUC.OM1, OM0 = 11_B
2	LIN reset mode	→	LIN wake-up mode	RLN21nmLiCUC.OM1, OM0 = 01_B
3	LIN wake-up mode LIN operation mode	→	LIN reset mode	RLN21nmLiCUC.OM0 = 0_B
4	LIN operation mode	→	LIN wake-up mode	RLN21nmLiCUC.OM1, OM0 = 01_B
5	LIN wake-up mode	→	LIN operation mode	RLN21nmLiCUC.OM1, OM0 = 11_B
6	LIN reset mode	→	LIN self-test mode	See **Section 15.15, LIN Self-Test Mode**.
7	LIN self-test mode	→	LIN reset mode	See **Section 15.15, LIN Self-Test Mode**.

Table 15.31 Operations Available in Each Mode

LIN operation mode	LIN wake-up mode	LIN self-test mode
Header transmission Response transmission Response reception Error detection	Wake-up transmission Wake-up reception Error detection	Self test

Whether a transition has been made to LIN reset mode, the LIN mode, or the UART mode can be verified by reading the OMM1 and OMM0 bits in the RLN21nmLiMST register.

For a description of the LIN self-test mode, see **Section 15.15, LIN Self-Test Mode**.

15.6 LIN Reset Mode

Setting the OM0 bit in the RLN21nmLiCUC register to 0_B (LIN reset mode) causes a transition to LIN reset mode. The change to LIN reset mode can be verified by determining that the OMM0 bit in the RLN21nmLiMST register has been set to 0_B (LIN reset mode). In this mode, the LIN communication stops.

From LIN reset mode, transitions to LIN operation mode, LIN wake-up mode, and LIN self-test mode can be made.

When the mode changes to LIN reset mode, the following registers are initialized to their reset values, and as long as LIN reset mode is in effect, they retain their value after resets.

- RLN21nmLiTRC register
- RLN21nmLiST register
- RLN21nmLiEST register

The following registers retain their previous values even when a transition to LIN reset mode is made:

- RLN21nGLWBR register
- RLN21nGLBRP0 register
- RLN21nGLBRP1 register
- RLN21nmLiMD register
- RLN21nmLiBFC register
- RLN21nmLiSC register
- RLN21nmLiWUP register
- RLN21nmLiIE register
- RLN21nmLiEDE register
- RLN21nmLiDFC register
- RLN21nmLiIDB register
- RLN21nmLiCBR register
- RLN21nmLiDBRb register

15.7 LIN Operation Mode

In LIN operation mode, frame processing (header transmission, header reception, response transmission, response reception, and error detection) can be performed.

During a transition from LIN reset mode to LIN mode, setting the OM1 and OM0 bits in the RLN21nmLiCUC register to 11_B changes the mode to LIN operation mode, changing the OMM1 and OMM0 bits in the RLN21nmLiMST register to 11_B. Communication settings should be performed after the RLN21nmLiMST register has become 11_B.

15.8 LIN Wake-up Mode

In LIN wake-up mode, wake-up signal processing (wake-up transmission, wake-up reception, and error detection) can be performed.

During a transition from LIN reset mode to LIN mode, setting the OM1 and OM0 bits in the RLN21nmLiCUC register to 01_B changes the mode to LIN wake-up mode, changing the OMM1 and OMM0 bits in the RLN21nmLiMST register to 01_B. Communication settings should be performed after the RLN21nmLiMST register has become 01_B.

15.9 Header Transmission/Response Transmission/Response Reception

15.9.1 Header Transmission

Figure 15.4 shows the operation of the LIN master interface (LIN master mode) in header transmission. **Table 15.32** provides processing in header transmission.

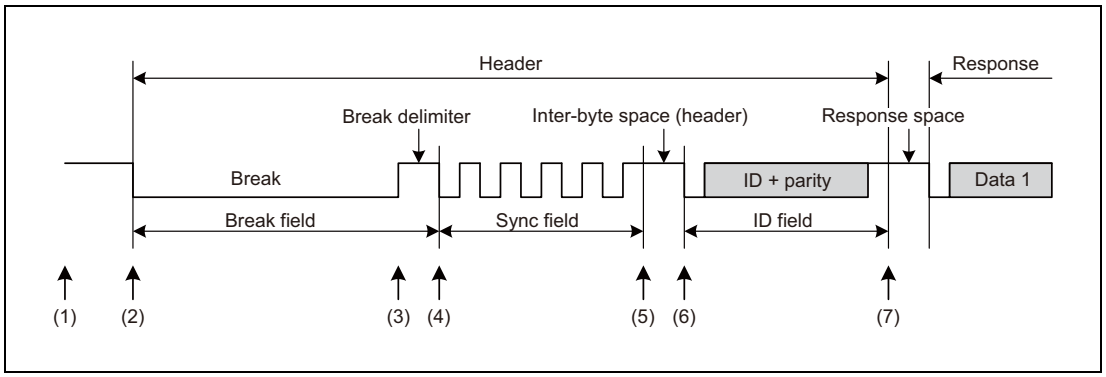


Figure 15.4 Operation in Header Transmission

Table 15.32 Processing in Header Transmission

	Software processing	LIN Master Interface processing
(1)	• Sets a baud rate • Enables interrupt • Enables error detection • Sets frame configuration parameters • Changes LIN operation mode • Sets information on the frame to be transmitted (ID, parity, data length, response direction, Checksum method, and transmission data)	Waits for the setting of the FTS bit in the RLN21nmLiTRC register to 1 by software (idle).
(2)	Sets the FTS bit in the RLN21nmLiTRC register to 1 (frame transmission or wake-up transmission/reception started)	Transmits a break.
(3)	Waits for an interrupt request	Transmits a break delimiter.
(4)		Transmits a sync field (55_H).
(5)		Transmits an inter-byte space (header).
(6)		Transmits an ID field.
(7)		Sets a successful header transmission flag.

NOTE

For information about error detection, refer to **Section 15.14, Error Status**.

15.9.2 Response Transmission

Figure 15.5 shows the operation of the LIN Master Interface (LIN master mode) in response transmission. **Table 15.33** provides processing in response transmission.

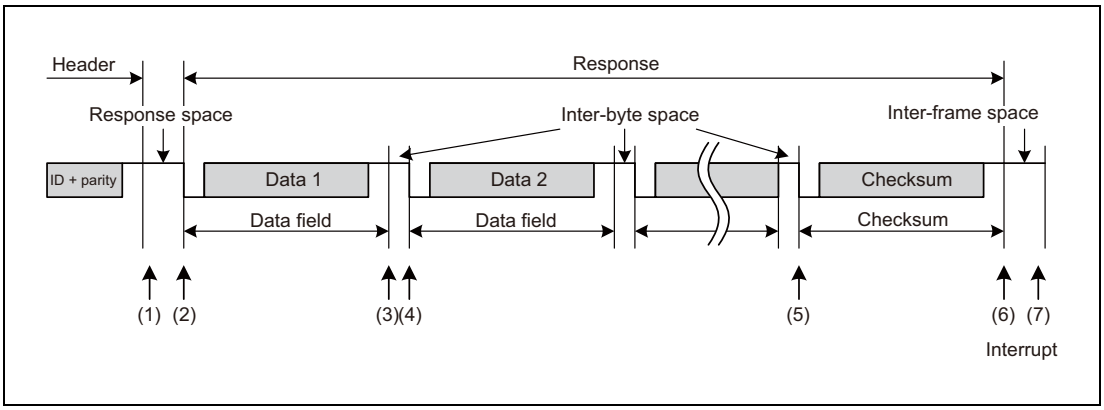

Figure 15.5 Operation in Response Transmission

Table 15.33 Processing in Response Transmission

	Software processing	LIN Master Interface processing
(1)	(When in frame separate mode) • Sets the RTS bit in the RLN21nmLiTRC register to 1 (response transmission started) (When not in frame separate mode) • Waits for an interrupt request	(When in frame separate mode) • Waits for the setting of the RTS bit in the RLN21nmLiTRC register to 1 by software (1 is output during this time). • When the bit is set to 1, sends a response space. (When not in frame separate mode) • Sends a response space.
(2)	Waits for an interrupt request	Transmits the data 1.
(3)		Transmits an inter-byte space.
(4)		• Transmits the data 2. • Transmits an inter-byte space • Transmits the data 3. • Transmits an inter-byte space (Repeats the transmission of inter-byte spaces as many times as the data length specified in bits RFDL[3:0] in the RLN21nmLiDFC register.) : :
(5)		Transmits the checksum.
(6)		• Sets a successful frame/wake-up transmission flag. • Sets the FTS bit in the RLN21nmLiTRC register to 0 (frame transmission or wake-up transmission/reception stopped) (When in frame separate mode). • Sets the RTS bit in the RLN21nmLiTRC register to 0 (response transmission stopped).
(7)	• Processing after communication Checks the RLN21nmLiST register, and clears flags.	Idle

NOTE

For information about error detection, refer to **Section 15.14, Error Status**.

15.9.3 Response Reception

Figure 15.6 shows the operation of the LIN master interface (LIN master mode) on response reception. **Table 15.34** provides processing in response reception.

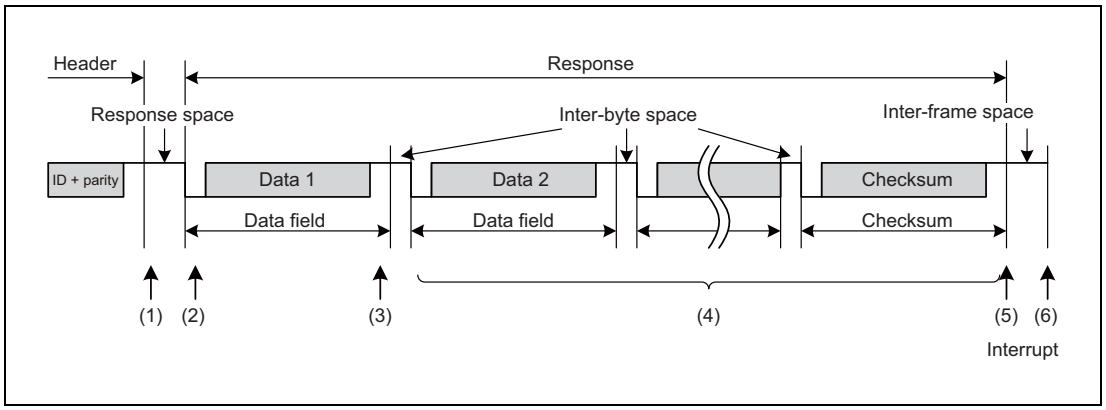

Figure 15.6 Operation in Response Reception

Table 15.34 Processing in Response Reception

	Software processing	LIN Master Interface processing
(1)	Waits for an interrupt request (no processing).	Waits for detection of a start bit.
(2)	Waits for an interrupt request.	Receives the data 1 when the start bit is detected.
(3)		Sets the successful data 1 reception flag.
(4)		• Receives the data 2 when the start bit is detected. • Receives the data 3 when the start bit is detected. Repeats the transmission of inter-byte spaces as many times as the data length specified in bits RFDL[3:0] in the RLN21nmLiDFC register.) ⋮ • Receives the checksum when the start bit is detected.
(5)		• Determines the checksum. • Sets the successful frame/wake-up reception flag. • Sets the FTS bit in the RLN21nmLiTRC register to 0 (frame transmission or wake-up transmission/reception stopped).
(6)	• Processing after communication Reads the received data. Checks the RLN21nmLiST register, and clears flags.	Idle

NOTE

For information about error detection, refer to **Section 15.14, Error Status**.

15.10 Data Transmission/Reception

15.10.1 Data Transmission

One bit of data is transmitted per 1 Tbit.

The data that is transmitted returns to the reception data input pin via the LIN transceiver. The received data and the transmitted data are compared bit by bit, and the results are stored in the BER flag in the RLN21nmLiEST register (see **Section 15.14, Error Status**).

In LIN Master interface, the sampling point for received data, 1 Tbit is generated to be 16fLIN, and thus is at the 13th clock cycle (81.25% position).

Figure 15.7 shows an example of data transmission timing.

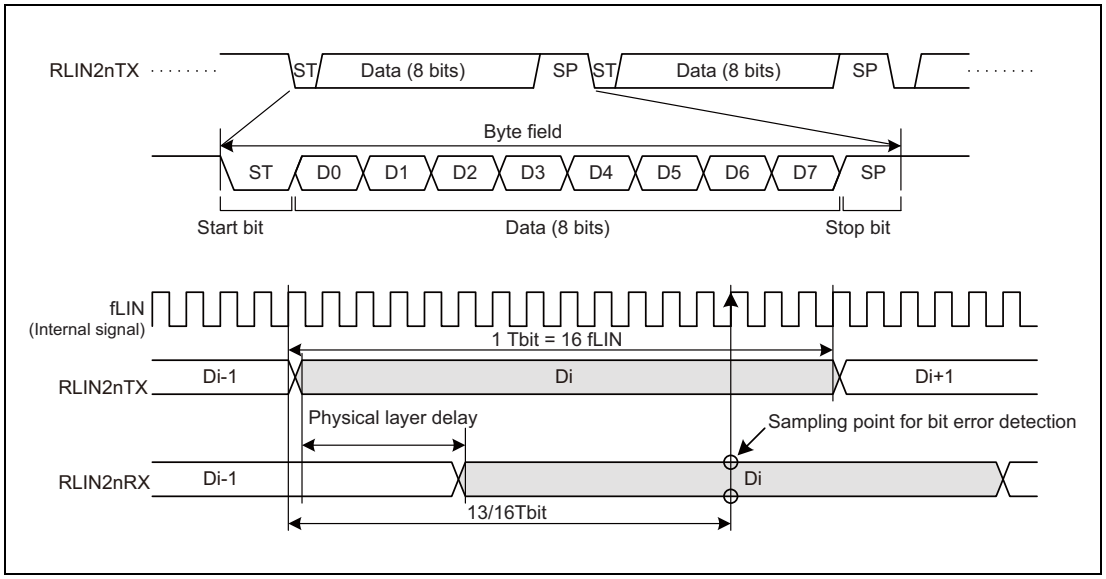

Figure 15.7 Example of Data Transmission Timing

15.10.2 Data Reception

Data reception is performed by using the synchronized RLIN2nRX signal (an internal signal) that is the input from the LRX0 pin synchronized with the LIN system clock (fLIN).

The byte field is synchronized at the falling edge of the start bit for the synchronized RLIN2nRX signal. After the falling edge is detected, sampling is performed again 0.5 Tbit later, and the falling edge is recognized as a start bit if the synchronized RLIN2nRX signal is low level. The falling edge is not recognized as a start bit if the RLIN2nRX signal after the clearing of the resetting is low-level-fixed or if a high level is detected on re-sampling.

After the start bit is detected, the system samples 1 bit per Tbit.

Figure 15.8 shows an example of data reception timing.

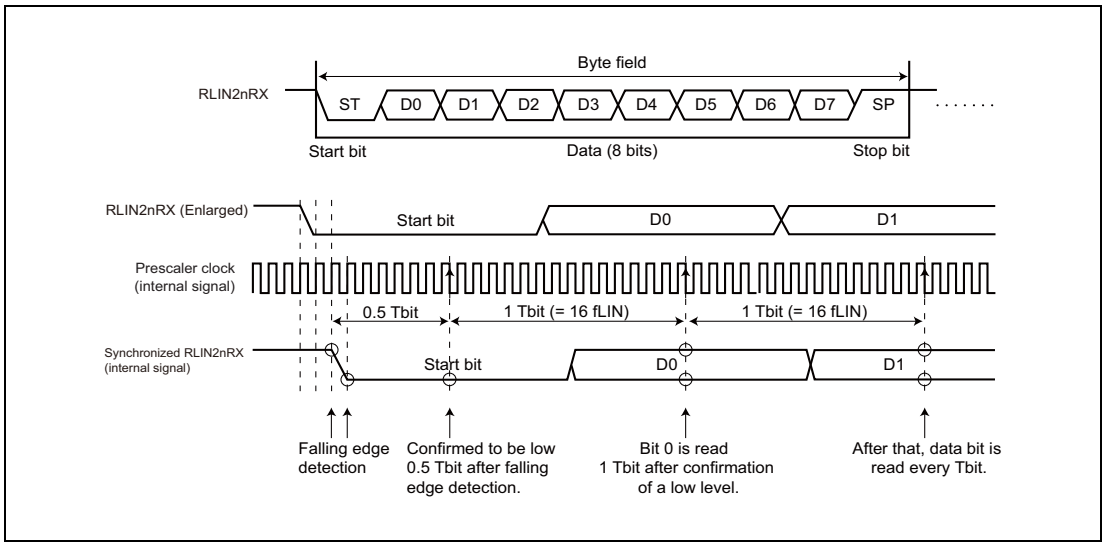

Figure 15.8 Example of Data Reception Timing

15.11 Transmit/Receive Data Buffering

This section explains the buffer processing that takes place when the LIN Master Interface sends or receives data continuously.

15.11.1 Transmission of LIN Frames

For an 8-byte transmission, the contents stored in registers RLN21nmLiDBR1 to RLN21nmLiDBR8 are sequentially transmitted to data areas 1 to 8 of the LIN frame. In the case of a 4-bytes transmission, the contents stored in registers RLN21nmLiDBR1 to RLN21nmLiDBR4 are transmitted to data areas 1 to 4 of the LIN frame, but the contents of registers RLN21nmLiDBR5 to RLN21nmLiDBR8 are not transmitted. The transmitted checksum data is stored in the RLN21nmLiCBR register.

Figure 15.9 depicts the LIN transmission processing and the required buffer.

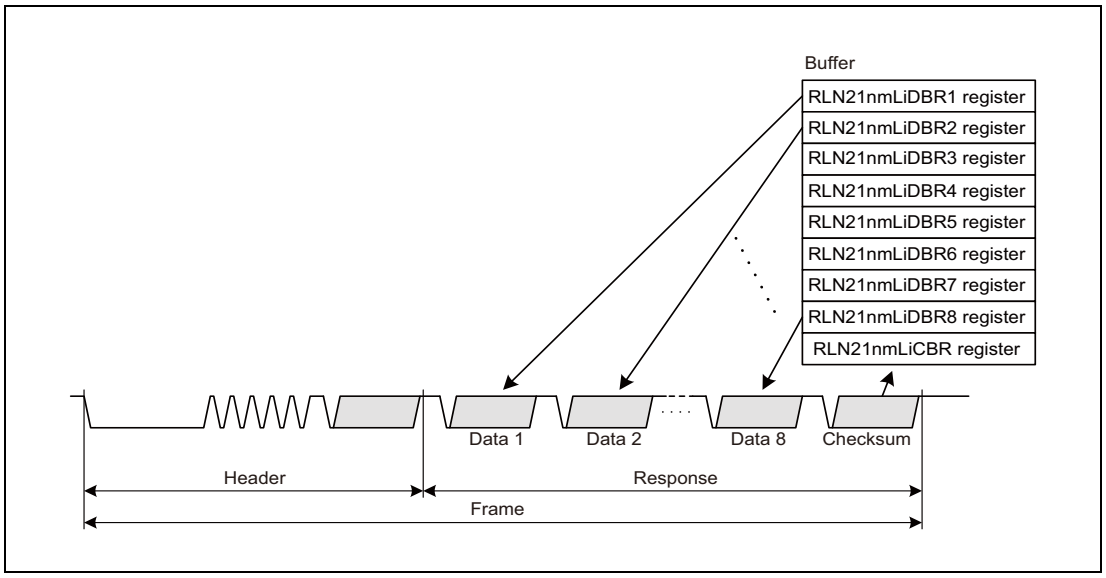

Figure 15.9 LIN Transmission Processing and Required Buffer

(1) Frame Separate Mode

Setting the FSM bit in the RLN21nmLiDFC register to 1 turns on the frame separate mode.

In frame separate mode, a header and a response are transmitted when prompted by separate transmission start requests.

When the transmission of a header is finished, the HTRC flag in the RLN21nmLiST register turns 1 (successful header transmission).

15.11.2 Reception of LIN Frames

For an 8-byte reception, the contents of data areas 1 to 8 of the LIN frame is stored in registers RLN21nmLiDBR1 to RLN21nmLDBR8, respectively, upon receipt of a stop bit. In the case of a 4-byte reception, the contents of data areas 1 to 4 of the LIN frame are stored in registers RLN21nmLiDBR1 to RLN21nmLiDBR4, respectively; however, no data is stored in registers RLN21nmLiDBR5 to RLN21nmLiDBR8. Also, the received checksum data is stored in the RLN21nmLiCBR register.

Figure 15.10 depicts the LIN reception processing and the required buffer.

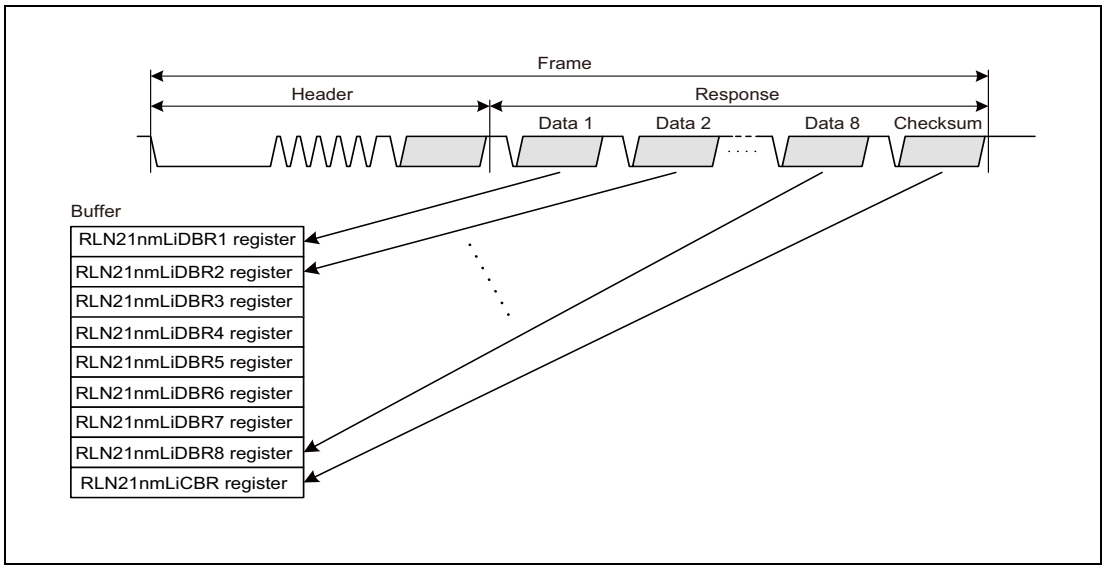

Figure 15.10 LIN Reception Processing and Required Buffer

(1) Reception of Data 1

When the reception of the first byte of data is finished, the D1RC flag in the RLN21nmLiST register turns 1 (successful data 1 reception).

15.12 Wake-up Transmission/Reception

The wake-up transmission/reception can be used in LIN wake-up mode.

15.12.1 Wake-up Transmission

In LIN wake-up mode, setting the RFT bit in the RLN21nmLiDFC register to 1 (transmission) and the FTS bit in the RLN21nmLiTRC register to 1 (frame transmission or wake-up transmission/reception started) causes a wake-up signal to be output from the output pin. The low level width of the wake-up signal should be set using the WUTL[3:0] bits in the RLN21nmLiWUP register.

However, when the setting of the LWBR0 bit in the RLN21nGLWBR register is 1 (if LIN2.x is in use), the width at low level of the LIN system clock (fLIN) becomes that of fa regardless of the setting of LCKS bits in the RLN21nmLiMD register. Setting the bit rate when 19200 bps is selected as fa and setting the WUTL[3:0] bits in the RLN21nmLiWUP register to 0100_B (5 Tbits) enables output of a signal with width at low level of 260 µs in LIN wakeup mode regardless of the setting of LCKS bits in the RLN21nmLiMD register.

If a wake-up low is output without any error, the FTC flag in the RLN21nmLiST register turns 1 (successful frame or wake-up transmission); when the FTCIE bit in the RLN21nmLiIE register is 1 (successful frame/wakeup transmission interrupt enabled), an interrupt request is generated.

If an error is detected, wake-up transmission is suspended and the error flag of the detected error (PBER flag or BER flag in the RLN21nmLiEST register) is set to 1 (detection of a physical bus error or bit error).

Figure 15.11 shows the wake-up transmission timing.

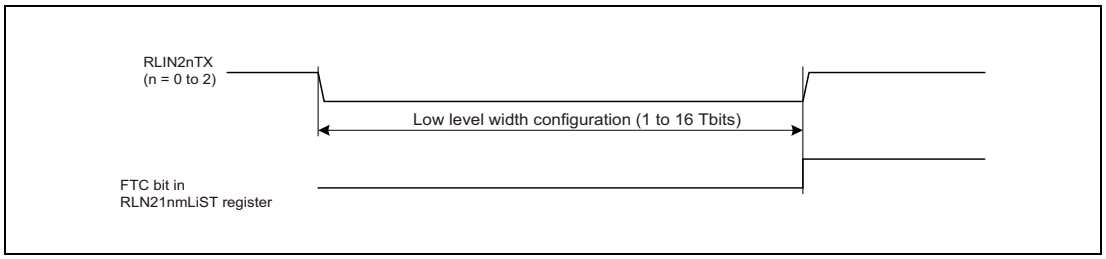

Figure 15.11 Wake-up Transmission Timing

15.12.2 Wake-up Reception

The detection of a wake-up signal involves the use of an input signal low level width count function.

The input signal low level width count function measures the low level width of the input signal to the LRX0 pin, using the same sampling point as data reception. This allows the 2.5-Tbit or longer low-level width of the input signal of fLIN to be measured.

When LIN Specification Package Revision 1.3 is used, set the LWBR0 bit in the RLN21nmGLWBR register to 0. When LIN Specification Package Revision 2.x is used, set the RLN21nmGLWBR register to 1.

When LWBR0 bit is set to 1, regardless of the setting of the LCKS bit in the RLN21nmLiMD register, fa is selected as the LIN system clock (fLIN) (the LCKS bit is not changed).

Setting the baud rate to 19200 bps while fa is selected allows the 130µs or longer low-level width of the input signal to be detected during LIN wake-up mode regardless of the setting of the RLN21nmLiMD register.

When using this function, in LIN wake-up mode set the RFT bit in the RLN21nmLiDFC register to 0 (reception), and the FTS bit in the RLN21nmLiTRC register to 1 (frame transmission or wake-up transmission/reception a started).

When the low level width to be measured is reached, the FRC flag in the RLN21nmLiST register turns 1 (successful frame/wake-up reception). If the FRCIE bit in the RLN21nmLiIE register is 1 (successful frame or wake-up reception interrupt enabled), an interrupt request is generated.

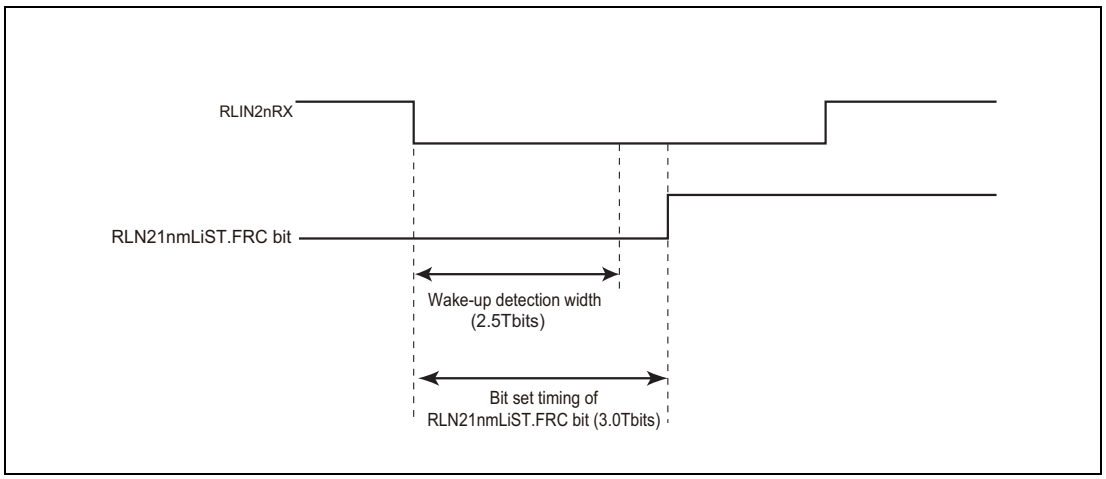

Figure 15.12 Input Signal Low Level Count Function

15.12.3 Wakeup Collision

If the master node and the slave node transmit wakeup signals simultaneously, a collision will occur on the LIN bus, though a collision of wakeup signals is not detected in the LIN master interface.

15.13 Status

During LIN mode operation, the LIN Master Interface can detect seven types of statuses.

The three statuses, successful frame/wake-up transmission, successful frame/wake-up reception, error detection, scan generate interrupt requests.

Table 15.35 shows the types of statuses available.

Table 15.35 Types of Statuses

Status	Status Set Condition	Status Clear Condition	Operation Mode Capable of Status Detection	Corresponding Bit	Interrupt
Reset	After the OM0 bit in the RLN21nmLiCUC register is set to not-LIN–reset-mode, if actually the LIN Master Interface is cleared from LIN reset mode.	After the OM0 bit in the RLN21nmLiCUC register is set to LIN reset mode, if actually the LIN Master Interface enters LIN reset mode.	All modes	OMM0 bit in RLN21nmLiMST register	—
Operation mode	After the OM1 bit in the RLN21nmLiCUC register is set to LIN operation mode, if actually the LIN Master Interface enters LIN operation mode.	After the OM1 bit in the RLN21nmLiCUC register is set to LIN wake-up mode, if actually the LIN Master Interface enters LIN wake-up mode.	• LIN operation mode • LIN wake-up mode	OMM1 bit in RLN21nmLiMST register	—
Frame/wake-up transmission end	When a frame (header transmission + response transmission), a wake-up signal, or a data group is transmitted successfully.	• When another communication is started • When cleared by software • After transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	FTC flag in RLN21nmLiST register	√
Frame/wake-up reception end	When a frame (header transmission + response reception), a wake-up signal, or a data group is received successfully.	• When another communication is started • When cleared by software • After transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	FRC flag in RLN21nmLiST register	√
Error detection	If any of the PRER flag, CSER flag, FER flag, FTER flag, PBER flag, and BER flags in the RLN21nmLiEST register turns 1 (error detected).	• When another communication is started • When cleared by software *1 • After transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	ERR flag in RLN21nmLiST register	√
Data 1 reception end	The RFT bit in the RLN21nmLiDFC register is 0 (reception) and the first byte of the response field is received.*2	• When another communication is started • When cleared by software • After transition to LIN reset mode	LIN operation mode	D1RC flag in RLN21nmLiST register	—
Header reception end	When a header field is transmitted successfully.	• When another communication is started • When cleared by software • After transition to LIN reset mode	LIN operation mode	HTRC flag in RLN21nmLiST register	—

Note 1. In LIN operation mode, the ERR flag in the RLN21nmLiST register is cleared to 0 by writing 0 to the CSER flag, FER flag, FER flag, FTER flag, PBER flag or BER flags in the RLN21nmLiEST register.

Note 2. Not detected when the RFDL [3:0] bits in the RLN21nmLiDFC register are 0000_B (0-byte + checksum).

15.14 Error Status

15.14.1 Types of Error Status

The LIN Master Interface can detect five types of error status in LIN master mode. The condition of these error statuses can be checked by means of the corresponding bits in the RLN21nmLiEST register.

All error statuses represent interrupt events.

Table 15.36 shows the types of error status.

Table 15.36 Types of Error Status

Status	Error Detection Condition	Operation Mode Capable of Error Detection	Commu-nication	Enable/ Disable Detection	Corresponding Bit
Bit error	The transmitted data and the data on the LIN bus monitored by the receive pin do not match *1	• LIN operation mode • LIN wake-up mode	Suspended	√	BER flag in RLN21nmLiEST register
Physical bus error	• LIN bus is detected to be high level when sending a break • LIN bus is detected to be low level when sending a break delimiter • LIN bus is detected to be high level when sending a wake-up	• LIN operation mode • LIN wake-up mode	Suspended	√	PBER flag in RLN21nmLiEST register
Timeout error	A frame or response transmission/reception does not terminate within a given time*2	LIN operation mode	Suspended	√	FTER flag in RLN21nmLiEST register
Framing error	In response field reception, a stop bit of each data byte is low level	LIN operation mode	Suspended	√	FER flag in RLN21nmLiEST register
Checksum error	In response field reception, the result of checksum test gives an error	LIN operation mode	—	—	CSER flag in RLN21nmLiEST register

Note 1. If a bit error is detected, processing is stopped after a stop bit is sent. If a bit error is detected in a non-data area, such as an inter-byte space, the transmission is suspended immediately after the bit which had the error is sent. If a bit error is detected during the transmission of a wake-up, the transmission of the wake-up is suspended after the bit which had the error is sent.

Note 2. The timeout time depends on the response field data length (the RFDL 3:0] bits in the RLN21nmLiDFC register) and the checksum selection (the CSM bit in the RLN21nmLiDFC register), and this can be calculated according to the following formula:
On classic selection (when the CSM bit in RLN21nmLiDFC is 0): Timeout time = 49 + (number of data bytes + 1) × 14 [Tbit]
On enhanced selection (when the CSM bit in RLN21nmLiDFC is 1): Timeout time = 48 + (number of data bytes + 1) × 14 [Tbit]

The aforementioned timeout time is a time greater than the TFRAME_MAX of LIN Specification Package Revision 1.3 on classic selection, or the TFRAME_MAX of LIN Specification Package Revision 2.x on enhanced selection.

The error status is cleared when the next communication is started, by software, or at a transition to LIN reset mode.

15.14.2 Target Time Area for Error Detection

Figure 15.13 shows the time domain in which the LIN master interface performs monitoring for error detection.

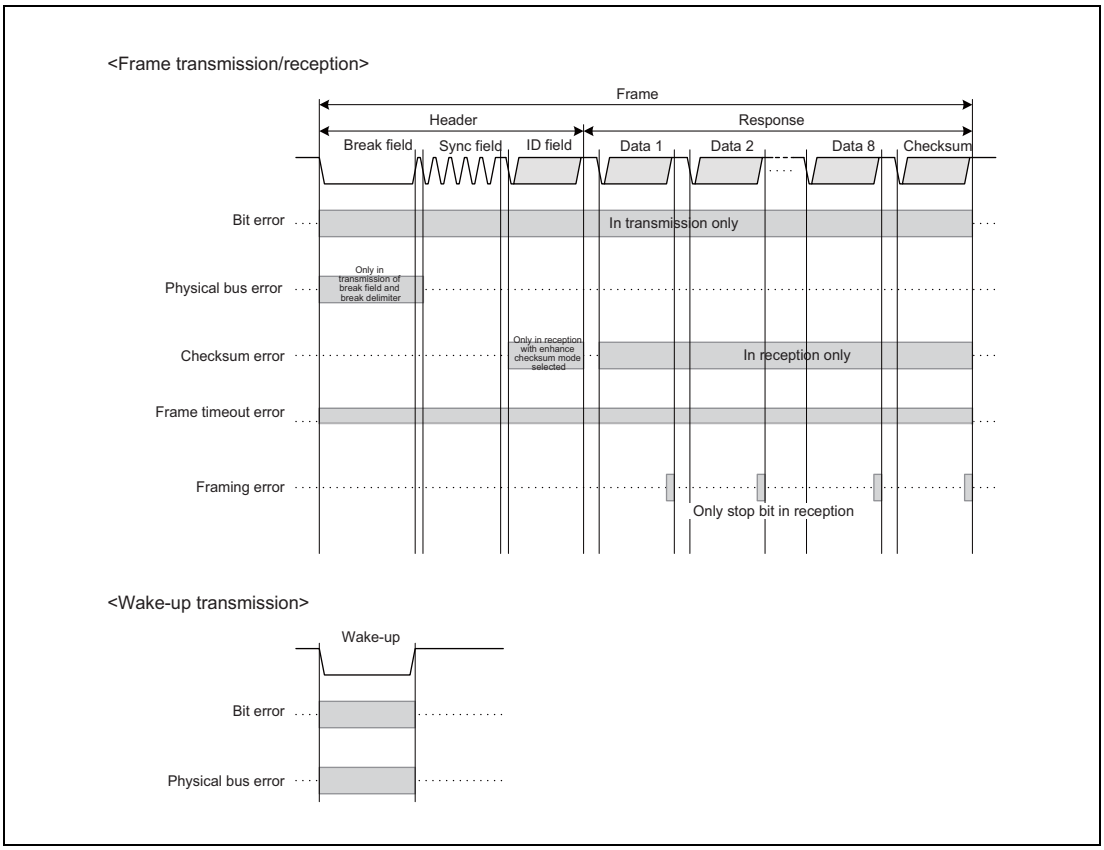

Figure 15.13 Target Time Area for Error Detection

15.15 LIN Self-Test Mode

The LIN Master Interface provides LIN self-test mode. When LIN self-test mode is turned on, RLIN2nTX and RLIN2nRX are disconnected from the external pin, and the internal RLIN2nTX and RLIN2nRX are connected. Thus, the frame transmitted from RLIN2nTX is returned to the internal RLIN2nRX (loop back).

The functions of the LIN self-test mode operate in the following conditions:

- LIN self-test mode (transmission): header transmission and response transmission
- LIN self-test mode (reception): header reception and response reception

In LIN self-test mode, the operation is at the fastest baud rate, regardless of the setting of the baud rate generator. Regardless of the setting of the baud rate related registers, the baud rate operates at the LIN communication clock source/16 [bps].

In LIN self-test mode, the following functions are not supported:

- LIN Wake-up function
- Frame separate mode

Do not use above functions.

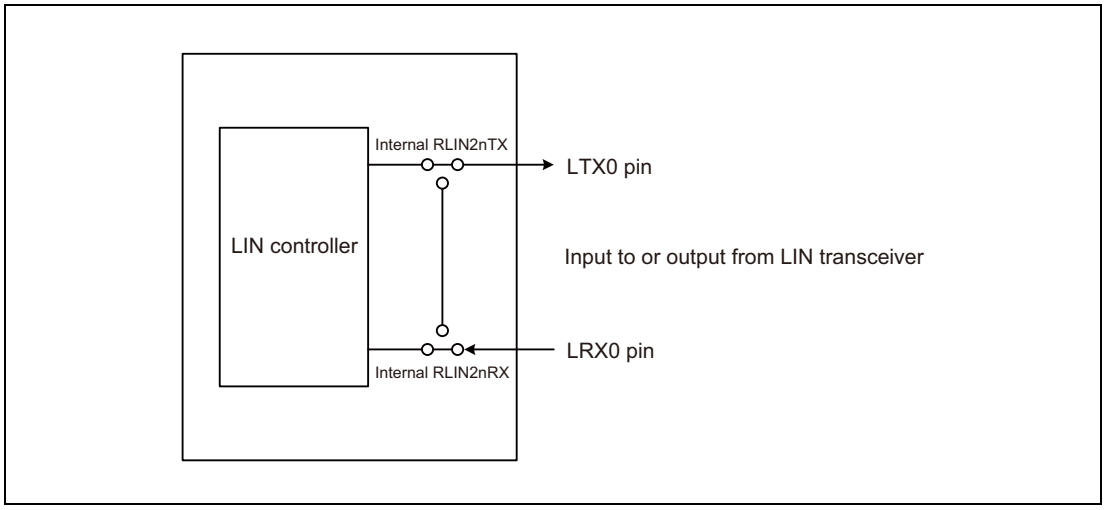

Figure 15.14 Connection in LIN Reset Mode, LIN Wake-Up Mode, and LIN Operation Mode

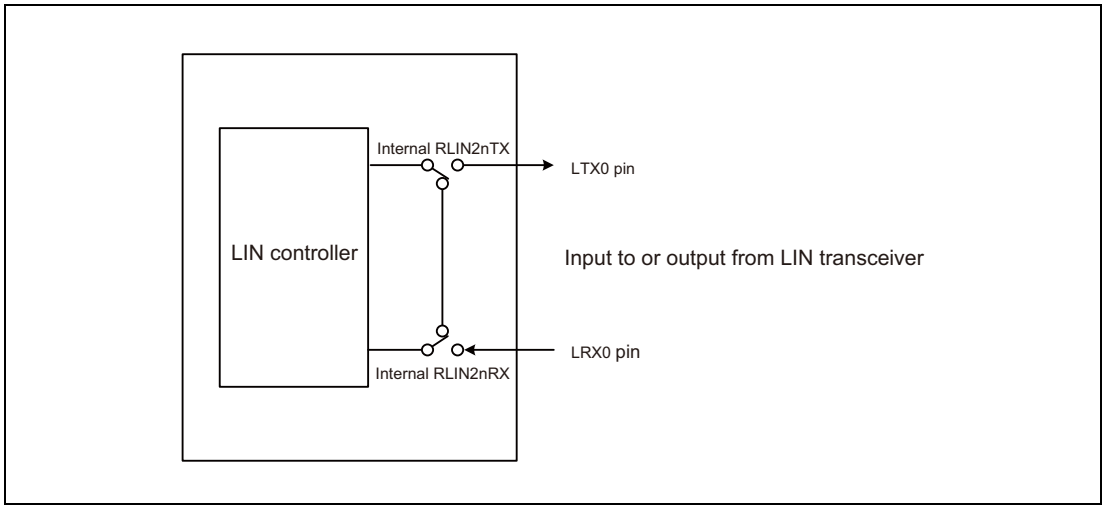

Figure 15.15 Connection in LIN Self-Test Mode

15.15.1 Change to LIN Self-Test Mode

Writing to the RLN21nGLSTC register enables LIN self-test mode.

The RLN21nGLSTC register becoming 01_H indicates that the mode is transit to LIN self-test mode.

When changing to LIN self-test mode, be sure to execute a specific sequence. In that sequence, information must be written three times consecutively to the LIN self-test control register, as follows:

- Change to LIN reset mode regarding all channels in the unit.
  Set the OM0 bit in the RLN21nmLiCUC register to 0 (LIN reset mode).
  Read the OMM0 bit in the RLN21nmLiMST register; verify that it is 0 (LIN reset mode).
- 1st write: RLN21nGLSTC register = $1010\ 0111_B$ ($A7_H$)
- 2nd write: RLN21nGLSTC register = $0101\ 1000_B$ (58_H)
- 3rd write: RLN21nGLSTC register = $0000\ 0001_B$ (01_H)
- Verify the transition to LIN self-test mode
  Read the RLN21nGLSTC register; verify that it is 01_H (LIN self-test mode).

If the key of the first write ($A7_H$) is written twice by mistake, the transition to LIN self-test mode is suspended. The above sequence should be retried from the step of first write. In addition, if a write to another LIN-related register in the same unit is performed during transition to LIN self-test mode (three consecutive write operations to the RLN21nGLSTC register), the transition is also suspended.

15.15.2 Transmission in LIN Self-Test Mode

To execute a self-test on transmission, perform the procedure below:

- Set the baud rate related registers
  RLN21nGLBRP0 register = xxxx $xxxx_B$ *1
  RLN21nGLBRP1 register = xxxx $xxxx_B$ *1
  RLN21nmLiMD register = 0000 $xx00_B$ *1
- Set interrupt enable register and error enable related registers
  RLN21nmLiIE register = 0000 $0xxx_B$ *2
  RLN21nmLiEDE register = 0000 $xxxx_B$
- Set the break field and space related registers.
  RLN21nmLiBFC register = 00xx $xxxx_B$
  RLN21nmLiSC register = 00xx $0xxx_B$
- Release from the LIN reset mode
  Write 11_B to the OM1 and OM0 bits in the RLN21nmLiCUC register, and check that the OMM1 and OMM0 bits in the RLN21nmLiMST register are 11_B.
- Set the transmit frame related registers.
  RLN21nmLiDFC register = 00x1 $xxxx_B$
  RLN21nmLiIDB register = xxxx $xxxx_B$
  RLN21nmLiDBR1 to RLN21nmLiDBR8 registers = xxxx $xxxx_B$
- Header transmission → response transmission started
  Set the FTS bit in the RLN21nmLiTRC register to 1 (frame transmission or wake-up transmission/reception started).
  The LIN self-test mode (transmission) is executed. In this mode, interrupt are generated, and status and error status are also updated. The checksum is automatically calculated by the LIN master interface.
  To suspend the LIN self-test mode (transmission) while it is running, set the OM0 bit in the RLN21nmLiCUC register to 0 (LIN reset mode), which causes a transition to the LIN reset mode.
- When the transmission is completed, the inverse of the looped-back frame data is stored in the RLN21nmLiIDB, RLN21nmLiDBRb, and RLN21nmLiCBR registers (the data is inverted before being stored because the transmitted value should be compared with the looped-back value). Then, the FTS bit in the RLN21nmLiTRC register is cleared.
- If the transmission fails to complete due to an error, the applicable error flag is set and the FTS bit in the RLN21nmLiTRC register is cleared.

NOTE

x: Don't care

Note 1. The following register settings are not reflected to the operation of the LIN self-test mode. The LCKS bit in the RLN21nGLBRP0 register, RLN21nGLBRP1 register, and RLN21nmLiMD register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupt**.

15.15.3 Reception in LIN Self-Test Mode

To execute a self-test on LIN master transmission, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.
  RLN21nGLBRP0 register = xxxx $xxxx_B$ *1
  RLN21nGLBRP1 register = xxxx $xxxx_B$ *1
  RLN21nmLiMD register = 0000 $xx00_B$ *1
- Set the interrupt enable and error enable related registers.
  RLN21nmLiIE register = 0000 $0xxx_B$ *2
  RLN21nmLiEDE register = 0000 $xxxx_B$
- Set the break field and space related registers.
  RLN21nmLiBFC register = 00xx $xxxx_B$
  RLN21nmLiSC register = 00xx $0xxx_B$ *1
- Release from the LIN reset mode
  Write 11_B to the OM1 and OM0 bits in the RLN21nmLiCUC register, and check that the OMM1 and OMM0 bits in the RLN21nmLiMST register are 11_B.
- Set the receive frame related registers.
  RLN21nmLiDFC register = 00x0 $xxxx_B$
  RLN21nmLiIDB register = xxxx $xxxx_B$
  RLN21nmLiDBR1 to RLN21nmLiDBR8 registers = xxxx $xxxx_B$
  RLN21nmLiCBR register = xxxx $xxxx_B$
  Since the checksum value to be transmitted is not automatically calculated, set the calculation value to the RLN21nmLiCBR register. If an incorrect checksum is set at this time, the checksum error can be tested.
- Header transmission → response reception started
  Set the FTS bit in the RLN21nmLiTRC register to 1 (frame transmission or wake-up transmission/reception started).
  The LIN self-test mode (reception) is executed. In this mode, interrupt are generated, and status and error status are also updated.
  To suspend the LIN self-test mode (reception) while it is running, set the OM0 bit in the RLN21nmLiCUC register to 0 (LIN reset mode), which causes a transition to the LIN reset mode.
- When the reception is completed, the inverse of the looped-back frame data is stored in the RLN21nmLiIDB, RLN21nmLiDBRb, and RLN21nmLiCBR registers (the data is inverted before being stored because the set value should be compared with the looped-back value). Then, the FTS bit in the RLN21nmLiTRC register is cleared.
- If the reception fails to complete due to an error, the applicable error flag is set and the FTS bit in the RLN21nmLiTRC register is cleared.

NOTE

x: Don't care

Note 1. The following register settings are not reflected to the operation of the LIN self-test mode. The LCKS bit in the RLN21nGLBRP0 register, the RLN21nGLBRP1 register, and the RLN21nmLiMD register, and the IBS bit and IBHS bit (response space only) in the RLN21nmLiSC register.
Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupt**.

15.15.4 Terminating LIN Self-Test Mode

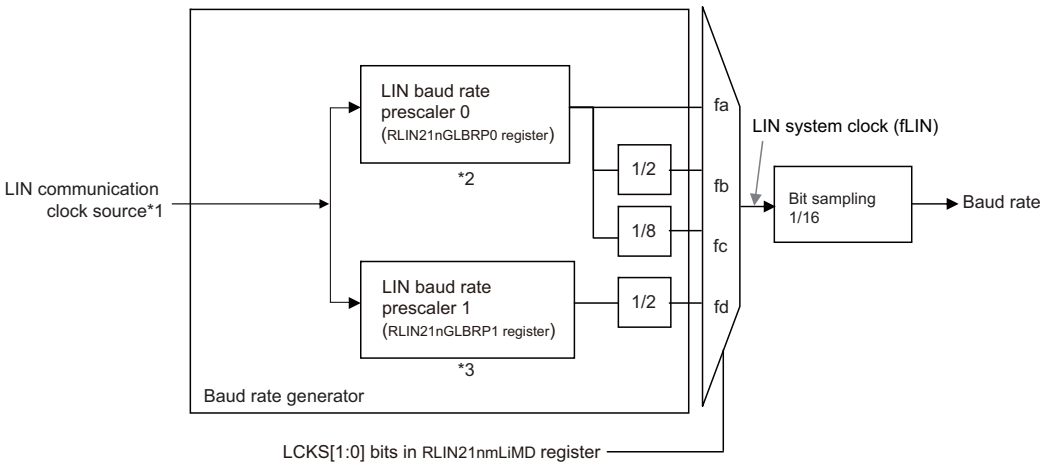
To terminate LIN self-test mode, perform the procedure below:

- All the channels in the unit make a transition to LIN reset mode
  Write 0 to the OM0 bit in the RLN21nmLiCUC register to make a transition to LIN reset mode. However, if the OMM1 and OMM0 bits in the RLN21nmLiMST register are not "11_B" in any channels of the unit after the transition to LIN self-test mode, write "11_B" to the OM1 and OM0 bits in the RLN21nmLiCUC register in any one channel. Check that the OMM1 and OMM0 bits in the RLN21nmLiMST register are set to "11_B", and then make a transition to LIN reset mode.
- Verify release from LIN self-test mode.
  Read the RLN21nGLSTC register; confirm that it is 00_H (not in LIN self-test mode)
- Verify the transition to LIN reset mode.
  Read the OMM0 bit in the RLN21nmLiMST register; verify that it is 0 (LIN reset mode).

15.16 Baud Rate Generator

The LIN system clock (fLIN) is the clock that is made by dividing the LIN communication clock source by the baud rate generator, and the bit rate is made by dividing that clock by 16. The inverse of this bit rate is the bit time (Tbit).

Figure 15.16 shows a block diagram of baud rate generation.



Note 1. For the LIN communication clock source, refer to **Section 11, Clock Controller**
Note 2. According to the RLN21nGLBRP0 register, the clock frequency is divided by N + 1 (N = 0 to 255).
Note 3. According to the RLIN21nGLBPR1 register, the clock frequency is divided by M + 1 (M = 0 to 255).

Figure 15.16 Block Diagram of Baud Rate Generation in LIN Master Mode

Set the LIN communication clock source to the range from 40 MHz.

By setting the RLN21nGLBRP0 register so that fa is 307200 Hz (= 19200 × 16), the resulting bit rates are fa = 19200 × 16, fb = 9600 × 16 and fc = 2400 × 16. These bit rates are frequency-divided by 16 in the bit timing generator, enabling bit rates of 19200 bps, 9600 bps and 2400 bps to be generated. Also, by setting the RLN21nGLBRP1 register so that fd is 166672 Hz (= 10417 × 16), the resulting bit rate is fd = 10417 × 16. This bit rate is frequency-divided by 16 in the bit timing generator, enabling 10417 bps to be generated.

The formula for baud rate is as shown below.

Baud rate:

= {Frequency of LIN communication clock source} / ((RLN21nGLBRP0) + 1) / 16 [bps] (When fa is selected)

= {Frequency of LIN communication clock source} / ((RLN21nGLBRP0) + 1) / 2 / 16 [bps] (When fb is selected)

= {Frequency of LIN communication clock source} / ((RLN21nGLBRP0) + 1) / 8 / 16 [bps] (When fc is selected)

= { Frequency of LIN communication clock source } / ((RLN21nGLBRP1) + 1) / 2 / 16 [bps] (When fd is selected)

Table 15.37 shows examples of baud rate (19200, 10417, 9600, and 2400 bps) generation and also the corresponding errors.

Table 15.37 Examples of Baud Rate (19200, 10417, 9600, and 2400 bps) Generation

LIN Communication Clock Source	Baud Rate Generator 0 (N+1) Frequency-Divided	Baud Rate Generator 1 (M+1) Frequency-Divided	System Clock	Baud Rate	Error
40MHz	130	—	fa	19230.77	+0.16%
	—	120	fd	10416.67	-0.003%
	130	—	fb	9615.38	+0.16%
	130	—	fc	2403.85	+0.16%

Section 16 CAN Interface (RS-CAN)

16.1 Overview of RS-CAN

16.1.1 Number of Units

This microcontroller incorporates the following number of units of the CAN interface (RS-CAN).

Table 16.1 Number of Units

	RS-CAN
Number of units	1
Name	RS-CANn (n = 0)

Table 16.2 Index

Index	
n	In this section, the unit of RS-CAN is identified by “n” (n = 0). For example, a global control register of RS-CAN0 is written as RSCAN0GCTR.
m	In this section, the channel number of RS-CAN is identified by “m” (m = 0 to 3). For example, a channel m status register is written as RSCAN0mSTS (m = 0 to 3).
j	In this section, a register related to reception rule table is identified by “j” (j = 0 to 15). For example, a reception rule ID register is written as RSCAN0GAFLIDj (j = 0 to 15).
k	In this section, the number of transmit/reception FIFO buffer is identified by “k” (k = 0 to 11). For example, a transmit/reception FIFO buffer configuration/control register is written as RSCAN0CFCCk (k = 0 to 14).
x	In this section, the number of reception FIFO is identified by “x” (x = 0 to 7). For example, a reception FIFO buffer status register is written as RSCAN0RFSTSx (x = 0 to 7).
q	In this section, the number of reception buffer is identified by “q” (q = 0 to 63). For example, a reception buffer ID register is written as RSCAN0RMIDq (q = 0 to 63).
p	In this section, the number of transmission buffer is identified by “p” (p = 0 to 63). For example, a transmission buffer control register is written as RSCAN0TMCp (p = 0 to 63).
r	In this section, the number of RAM test for CAN is identified by “r” (r = 0 to 63). For example, a RAM test page access register is written as RSCAN0RPGACCr (r = 0 to 63).
y	In another case, y is used to identify. For example, a reception buffer new data register is written as RSCAN0RMNDy (y = 0 to 1).

The RS-CAN has four channels.

Table 16.3 Number of Channels

Unit Name	Number of Channels	Channel Name
RS-CAN0	4	CANm (m = 0 to 3)

16.1.2 Register Base Address

The base addresses of registers in RS-CAN are described in the list below.

All Access to RS-CAN register addresses are given as address offsets to the base address.

Table 16.4 Register Base Address

Base Address Name	Base Address
<RS-CAN0_base>	FFD0 0000_H

16.1.3 Clock Supply

The clocks listed below are supplied to the RS-CAN.

Table 16.5 RS-CAN Clock Supply

Unit	Clock for the Unit	Clock Supply Name
RS-CAN0	pclk	CLK_HSB (High speed peripheral clock)
	clkc	CLKC_LSB (Unmodulated low speed peripheral clock)
	clk_xincan	Main OSC

16.1.4 Interrupt and DMA / DTS

RS-CAN can generate the interrupt requests described in the list below.

Table 16.6 Interrupt Request

Interrupt Name	Functions	Number of Interrupts
Global interrupt		
—	Receive FIFOm interrupt	412
—	Global error interrupt	413
Channel CAN0 interrupt		
—	CAN0 transmit/receive FIFO successful reception interrupt (when reception mode, gateway mode)	414
—	CAN0 error interrupt	415
—	CAN0 transmission interrupt	416
Channel CAN1 interrupt		
—	CAN1 transmit/receive FIFO successful reception interrupt (when reception mode, gateway mode)	417
—	CAN1 error interrupt	418
—	CAN1 transmission interrupt	419
Channel CAN2 interrupt		
—	CAN2 transmit/receive FIFO successful reception interrupt (when reception mode, gateway mode)	420
—	CAN2 error interrupt	421
—	CAN2 transmission interrupt	422
Channel CAN3 interrupt		
—	CAN3 transmit/receive FIFO successful reception interrupt (when reception mode, gateway mode)	423
—	CAN3 error interrupt	424
—	CAN3 transmission interrupt	425

16.1.5 Reset Sources

RS-CAN is initialized by the reset sources described in the following table.

Table 16.7 Reset Sources

Unit name	Reset Sources
RS-CAN0	All reset sources

16.1.6 External I/O Signals

The external I/O signals of RS-CAN are listed below.

Table 16.8 External I/O Signals

Unit Signal Name	Features	Signal Names Shared with Port Pins
Rxm (m = 0 to 3)	Receive data input pin of CAN communication function	CRX0, CRX1, CRX2, CRX3
Txm (m = 0 to 3)	Transmit data output pin of CAN communication function	CTX0, CTX1, CTX2, CTX3

16.2 Overview

16.2.1 Functional Outline

The RH850/E1M-S incorporates one unit of CAN interface (RS-CAN) mounting four channels (CAN0 to CAN3) of the Controller Area Network (RS-CAN) module conforming to the ISO11898-1 specifications.

Table 16.9 shows the RS-CAN module specifications. **Figure 16.1** shows the RS-CAN module block diagram.

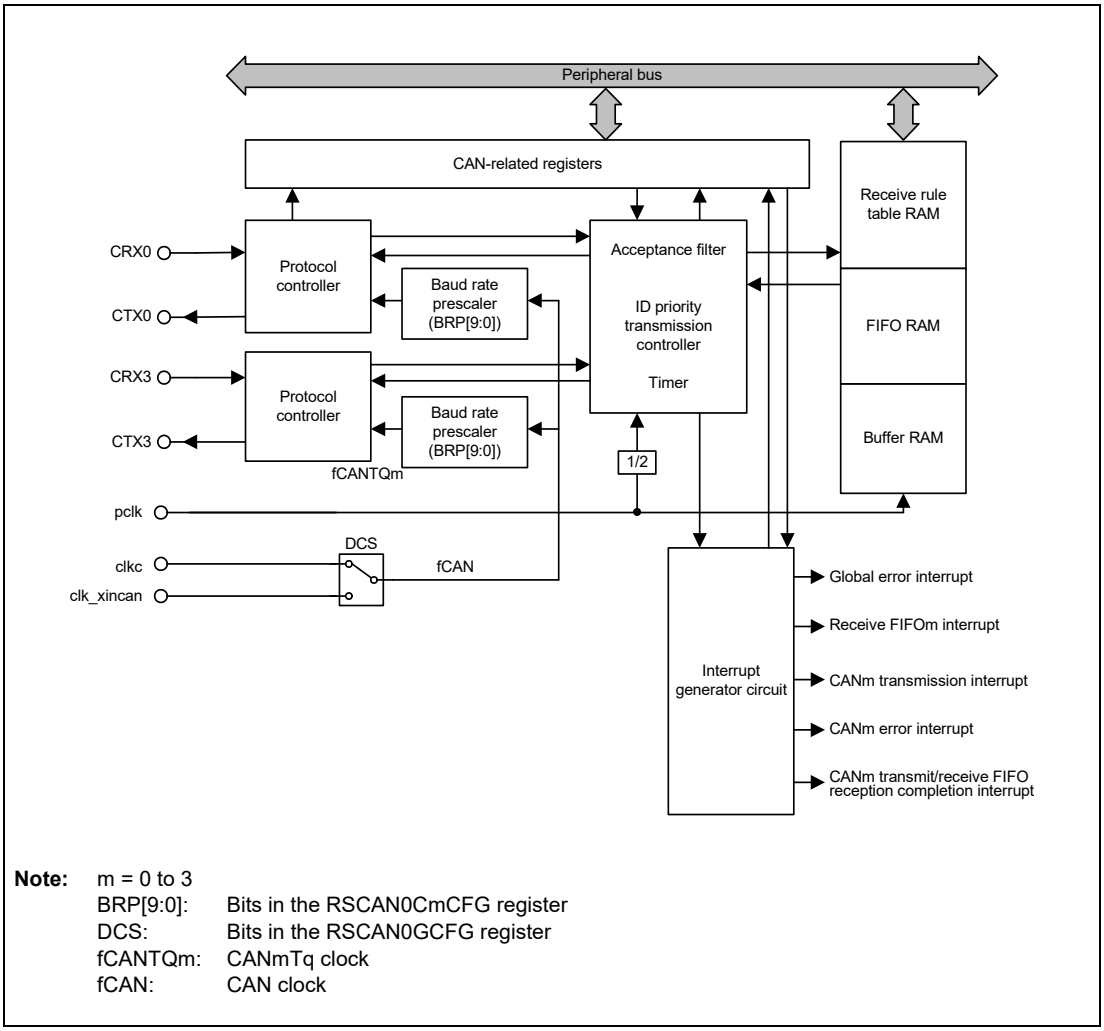
Table 16.9 RS-CAN Module Specifications (1/2)

Item	Specification
Number of channels	4
Protocol	ISO11898-1 compliant
Communication speed	• Up to 1 Mbps $\text{Communication speed (CANn bit time clock)} = \frac{1}{\text{CANm bit time}}$ CANm bit time = CANmTq × Tq count per bit $\text{CANmTq} = \frac{\text{(BRP[9:0] bits in the RCAN0mCFG register + 1)}}{\text{fCAN}}$ m = 0 to 3 Tq: Time quantum fCAN: Frequency of CAN clock (selected by the DCS bit in the RSCAN0GCFG register)
Buffer	320 buffers in total • Individual buffers: 64 buffers (16 buffers ×4 channels) Transmit buffer: 16 buffers per channel Transmit queue: Single queue per channel (shared with the transmit buffer; up to 16 buffers allocatable) • Shared buffers: 256 buffers for all channels Receive buffer: 0 to 64 buffers for all channels Receive FIFO buffer: 8 FIFO buffers for all channels (up to 128 buffers allocatable to each) Transmit/receive FIFO buffer: 3 FIFO buffers per channel (up to 128 buffers allocatable to each)
Receive function	• Receives data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be received. • Sets interrupt enable/disable for each FIFO. • Mirror function (CAN mode receives its own transmitted message.) • Timestamp function (to record message reception time as a 16-bit timer value)
Receive filter function	• Selects receive messages according to 256 receive rules. • Sets the number of receive rules (0 to 128) for each channel. • Acceptance filter processing: Sets ID and mask for each receive rule. • DLC filter processing: Sets DLC check value for each acceptance rule.
Receive message transfer function	• Routing function to transfer receive messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Receive buffer, receive FIFO buffer, and/or transmit/receive FIFO buffer • Label addition function Stores label information together with the message in a receive buffer and FIFO buffer.
Transmission function	• Transmits data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be transmitted. • Sets interrupt enable/disable for each transmit buffer and transmit/receive FIFO buffer. • Selects ID priority transmission or transmit buffer number priority transmission. • Transmit request can be aborted (possible to confirm with a flag) • One-shot transmission function

Table 16.9 RS-CAN Module Specifications (2/2)

Item	Specification
Interval transmission function	Transmit messages at intervals (transmit mode or gateway mode of transmit/receive FIFO buffers)
Transmit queue function	Transmits all stored messages according to the ID priority.
Transmit history function	Stores the history information of transmitted messages.
Gateway function	A received message is automatically routed to a different channel.
Bus off recovery mode selection	Selects the method for returning from bus off state. • ISO11898-1 compliant • Automatic entry to channel halt mode at bus-off entry • Automatic entry to channel halt mode at bus-off end • Entry to channel halt mode by program request • Transition to the error-active state by program request (forcible return from bus-off)
Error status monitoring	• Monitors CAN protocol errors (stuff error, form error, ACK error, CRC error, bit error, ACK delimiter error, and bus dominant lock). • Detects error status transitions (error warning, error passive, bus off entry, and bus off recovery) • Reads the error counter. • Monitors DLC errors.
Interrupt source	14 sources • Global Interrupts (2 sources) Receive FIFO interrupt Global error interrupt • Channel interrupts (3 sources/channel) CANm transmission interrupt (m = 0 to 3) – CANm transmission complete interrupt – CANm transmission abort interrupt – CANm transmit/receive FIFO transmission complete interrupt (in transmit mode, gateway mode) – CANm transmit history interrupt – CANm transmit queue interrupt CANm transmit/receive FIFO reception complete interrupt (in receive mode, gateway mode) CANm error interrupt
CAN stop mode	Reduces power consumption by stopping clock supply to the RS-CAN module.
CAN clock source	Clkc or clk_xincan selectable
Test function	Test function for user evaluation • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback) • RAM test (read/write test) • Inter-channel communication test

16.2.2 Block Diagram



Note: m = 0 to 3
BRP[9:0]: Bits in the RSCAN0CmCFG register
DCS: Bits in the RSCAN0GCFG register
fCANTQm: CANmTq clock
fCAN: CAN clock

Figure 16.1 RS-CAN Module Block Diagram

16.3 Register Descriptions

16.3.1 Register List

RS-CAN is controlled and operated by the following registers.

Table 16.10 List of RS-CAN Module Registers (1/21)

Register Name	Symbol	Value after Reset	Address	Access Size
Channel 0 configuration register	RSCAN0C0CFG	0000 0000$_H$	<RS-CAN0_base> + 0000$_H$	8, 16, 32
Channel 0 control register	RSCAN0C0CTR	0000 0005$_H$	<RS-CAN0_base> + 0004$_H$	8, 16, 32
Channel 0 status register	RSCAN0C0STS	0000 0005$_H$	<RS-CAN0_base> + 0008$_H$	8, 16, 32
Channel 0 error flag register	RSCAN0C0ERFL	0000 0000$_H$	<RS-CAN0_base> + 000C$_H$	8, 16, 32
Channel 1 configuration register	RSCAN0C1CFG	0000 0000$_H$	<RS-CAN0_base> + 0010$_H$	8, 16, 32
Channel 1 control register	RSCAN0C1CTR	0000 0005$_H$	<RS-CAN0_base> + 0014$_H$	8, 16, 32
Channel 1 status register	RSCAN0C1STS	0000 0005$_H$	<RS-CAN0_base> + 0018$_H$	8, 16, 32
Channel 1 error flag register	RSCAN0C1ERFL	0000 0000$_H$	<RS-CAN0_base> + 001C$_H$	8, 16, 32
Channel 2 configuration register	RSCAN0C2CFG	0000 0000$_H$	<RS-CAN0_base> + 0020$_H$	8, 16, 32
Channel 2 control register	RSCAN0C2CTR	0000 0005$_H$	<RS-CAN0_base> + 0024$_H$	8, 16, 32
Channel 2 status register	RSCAN0C2STS	0000 0005$_H$	<RS-CAN0_base> + 0028$_H$	8, 16, 32
Channel 2 error flag register	RSCAN0C2ERFL	0000 0000$_H$	<RS-CAN0_base> + 002C$_H$	8, 16, 32
Channel 3 configuration register	RSCAN0C3CFG	0000 0000$_H$	<RS-CAN0_base> + 0030$_H$	8, 16, 32
Channel 3 control register	RSCAN0C3CTR	0000 0005$_H$	<RS-CAN0_base> + 0034$_H$	8, 16, 32
Channel 3 status register	RSCAN0C3STS	0000 0005$_H$	<RS-CAN0_base> + 0038$_H$	8, 16, 32
Channel 3 error flag register	RSCAN0C3ERFL	0000 0000$_H$	<RS-CAN0_base> + 003C$_H$	8, 16, 32
Global configuration register	RSCAN0GCFG	0000 0000$_H$	<RS-CAN0_base> + 0084$_H$	8, 16, 32
Global control register	RSCAN0GCTR	0000 0005$_H$	<RS-CAN0_base> + 0088$_H$	8, 16, 32
Global status register	RSCAN0GSTS	0000 000D$_H$	<RS-CAN0_base> + 008C$_H$	8, 16, 32
Global error flag register	RSCAN0GERFL	0000 0000$_H$	<RS-CAN0_base> + 0090$_H$	8, 16, 32
Global timestamp counter register	RSCAN0GTSC	0000 0000$_H$	<RS-CAN0_base> + 0094$_H$	16, 32
Global acceptance filter list entry control register	RSCAN0GAFLECTR	0000 0000$_H$	<RS-CAN0_base> + 0098$_H$	8, 16, 32
Global acceptance filter list configuration register 0	RSCAN0GAFLCFG0	0000 0000$_H$	<RS-CAN0_base> + 009C$_H$	8, 16, 32
Receive buffer number register	RSCAN0RMNB	0000 0000$_H$	<RS-CAN0_base> + 00A4$_H$	8, 16, 32
Receive buffer new data register 0	RSCAN0RMND0	0000 0000$_H$	<RS-CAN0_base> + 00A8$_H$	8, 16, 32
Receive buffer new data register 1	RSCAN0RMND1	0000 0000$_H$	<RS-CAN0_base> + 00AC$_H$	8, 16, 32
Receive FIFO buffer configuration/control register 0	RSCAN0RFCC0	0000 0000$_H$	<RS-CAN0_base> + 00B8$_H$	8, 16, 32
Receive FIFO buffer configuration/control register 1	RSCAN0RFCC1	0000 0000$_H$	<RS-CAN0_base> + 00BC$_H$	8, 16, 32
Receive FIFO buffer configuration/control register 2	RSCAN0RFCC2	0000 0000$_H$	<RS-CAN0_base> + 00C0$_H$	8, 16, 32
Receive FIFO buffer configuration/control register 3	RSCAN0RFCC3	0000 0000$_H$	<RS-CAN0_base> + 00C4$_H$	8, 16, 32
Receive FIFO buffer configuration/control register 4	RSCAN0RFCC4	0000 0000$_H$	<RS-CAN0_base> + 00C8$_H$	8, 16, 32
Receive FIFO buffer configuration/control register 5	RSCAN0RFCC5	0000 0000$_H$	<RS-CAN0_base> + 00CC$_H$	8, 16, 32
Receive FIFO buffer configuration/control register 6	RSCAN0RFCC6	0000 0000$_H$	<RS-CAN0_base> + 00D0$_H$	8, 16, 32
Receive FIFO buffer configuration/control register 7	RSCAN0RFCC7	0000 0000$_H$	<RS-CAN0_base> + 00D4$_H$	8, 16, 32
Receive FIFO buffer status register 0	RSCAN0RFSTS0	0000 0001$_H$	<RS-CAN0_base> + 00D8$_H$	8, 16, 32
Receive FIFO buffer status register 1	RSCAN0RFSTS1	0000 0001$_H$	<RS-CAN0_base> + 00DC$_H$	8, 16, 32
Receive FIFO buffer status register 2	RSCAN0RFSTS2	0000 0001$_H$	<RS-CAN0_base> + 00E0$_H$	8, 16, 32
Receive FIFO buffer status register 3	RSCAN0RFSTS3	0000 0001$_H$	<RS-CAN0_base> + 00E4$_H$	8, 16, 32
Receive FIFO buffer status register 4	RSCAN0RFSTS4	0000 0001$_H$	<RS-CAN0_base> + 00E8$_H$	8, 16, 32
Receive FIFO buffer status register 5	RSCAN0RFSTS5	0000 0001$_H$	<RS-CAN0_base> + 00EC$_H$	8, 16, 32
Receive FIFO buffer status register 6	RSCAN0RFSTS6	0000 0001$_H$	<RS-CAN0_base> + 00F0$_H$	8, 16, 32
Receive FIFO buffer status register 7	RSCAN0RFSTS7	0000 0001$_H$	<RS-CAN0_base> + 00F4$_H$	8, 16, 32
Receive FIFO buffer pointer control register 0	RSCAN0RFPCTR0	0000 0000$_H$	<RS-CAN0_base> + 00F8$_H$	8, 16, 32

Table 16.10 List of RS-CAN Module Registers (2/21)

Register Name	Symbol	Value after Reset	Address	Access Size
Receive FIFO buffer pointer control register 1	RSCAN0RFPCTR1	0000 0000$_H$	<RS-CAN0_base> + 00FC$_H$	8, 16, 32
Receive FIFO buffer pointer control register 2	RSCAN0RFPCTR2	0000 0000$_H$	<RS-CAN0_base> + 0100$_H$	8, 16, 32
Receive FIFO buffer pointer control register 3	RSCAN0RFPCTR3	0000 0000$_H$	<RS-CAN0_base> + 0104$_H$	8, 16, 32
Receive FIFO buffer pointer control register 4	RSCAN0RFPCTR4	0000 0000$_H$	<RS-CAN0_base> + 0108$_H$	8, 16, 32
Receive FIFO buffer pointer control register 5	RSCAN0RFPCTR5	0000 0000$_H$	<RS-CAN0_base> + 010C$_H$	8, 16, 32
Receive FIFO buffer pointer control register 6	RSCAN0RFPCTR6	0000 0000$_H$	<RS-CAN0_base> + 0110$_H$	8, 16, 32
Receive FIFO buffer pointer control register 7	RSCAN0RFPCTR7	0000 0000$_H$	<RS-CAN0_base> + 0114$_H$	8, 16, 32
Transmit/receive FIFO buffer configuration/control register 0	RSCAN0CFCC0	0000 0000$_H$	<RS-CAN0_base> + 0118$_H$	8, 16, 32
Transmit/receive FIFO buffer configuration/control register 1	RSCAN0CFCC1	0000 0000$_H$	<RS-CAN0_base> + 011C$_H$	8, 16, 32
Transmit/receive FIFO buffer configuration/control register 2	RSCAN0CFCC2	0000 0000$_H$	<RS-CAN0_base> + 0120$_H$	8, 16, 32
Transmit/receive FIFO buffer configuration/control register 3	RSCAN0CFCC3	0000 0000$_H$	<RS-CAN0_base> + 0124$_H$	8, 16, 32
Transmit/receive FIFO buffer configuration/control register 4	RSCAN0CFCC4	0000 0000$_H$	<RS-CAN0_base> + 0128$_H$	8, 16, 32
Transmit/receive FIFO buffer configuration/control register 5	RSCAN0CFCC5	0000 0000$_H$	<RS-CAN0_base> + 012C$_H$	8, 16, 32

	Transmit buffer 16 × m + 10
	Transmit buffer 16 × m + 11
	Transmit buffer 16 × m + 12
	Transmit buffer 16 × m + 13
	Transmit buffer 16 × m + 14
	Transmit buffer 16 × m + 15

Table 16.12 Transmit/Receive FIFO Buffer k Assigned for Each Channel

	CANm
Transmit/receive FIFO buffer k	Transmit/receive FIFO buffer 3 × m + 0
	Transmit/receive FIFO buffer 3 × m + 1
	Transmit/receive FIFO buffer 3 × m + 2

Table 16.13 Transmit Buffer p Linked to Transmit/Receive FIFO Buffer by the Set Value of CFTML[3:0] Bits

Set value of CFTML[3:0] bit	Transmit buffer p linked to transmit/receive FIFO buffer
0000_B	Transmit buffer 16 × m + 0
0001_B	Transmit buffer 16 × m + 1
0010_B	Transmit buffer 16 × m + 2
0011_B	Transmit buffer 16 × m + 3
0100_B	Transmit buffer 16 × m + 4
0101_B	Transmit buffer 16 × m + 5
0110_B	Transmit buffer 16 × m + 6
0111_B	Transmit buffer 16 × m + 7
1000_B	Transmit buffer 16 × m + 8
1001_B	Transmit buffer 16 × m + 9
1010_B	Transmit buffer 16 × m + 10
1011_B	Transmit buffer 16 × m + 11
1100_B	Transmit buffer 16 × m + 12
1101_B	Transmit buffer 16 × m + 13
1110_B	Transmit buffer 16 × m + 14
1111_B	Transmit buffer 16 × m + 15

Table 16.14 Transmit Buffer p Assigned for Transmit Queue for Each Channel

Set Value of TXQDC[3:0] Bits	Transmit Buffer p Assigned for Transmit Queue
0000_B	Should not be set.
0001_B	Should not be set.
0010_B	Transmit buffer 16 × m + 15 to 16 × m + 13
0011_B	Transmit buffer 16 × m + 15 to 16 × m + 12
0100_B	Transmit buffer 16 × m + 15 to 16 × m + 11
0101_B	Transmit buffer 16 × m + 15 to 16 × m + 10
0110_B	Transmit buffer 16 × m + 15 to 16 × m + 9
0111_B	Transmit buffer 16 × m + 15 to 16 × m + 8
1000_B	Transmit buffer 16 × m + 15 to 16 × m + 7
1001_B	Transmit buffer 16 × m + 15 to 16 × m + 6
1010_B	Transmit buffer 16 × m + 15 to 16 × m + 5
1011_B	Transmit buffer 16 × m + 15 to 16 × m + 4
1100_B	Transmit buffer 16 × m + 15 to 16 × m + 3
1101_B	Transmit buffer 16 × m + 15 to 16 × m + 2
1110_B	Transmit buffer 16 × m + 15 to 16 × m + 1
1111_B	Transmit buffer 16 × m + 15 to 16 × m + 0

16.3.2 Register Details

16.3.2.1 RSCAN0CmCFG — Channel Configuration Register (m = 0 to 3)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0000_H + (m × 0010_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	SJW[1:0]		—	TSEG2[2:0]			TSEG1[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

19 to 16	TSEG1 [3:0]	Time Segment 1 Control b19 b18 b17 b16 0 0 0 0: Setting prohibited 0 0 0 1: Setting prohibited 0 0 1 0: Setting prohibited 0 0 1 1: 4Tq 0 1 0 0: 5Tq 0 1 0 1: 6Tq 0 1 1 0: 7Tq 0 1 1 1: 8Tq 1 0 0 0: 9Tq 1 0 0 1: 10Tq 1 0 1 0: 11Tq 1 0 1 1: 12Tq 1 1 0 0: 13Tq 1 1 0 1: 14Tq 1 1 1 0: 15 Tq 1 1 1 1: 16 Tq
15 to 10	—	Reserved These bits are always read as 0. When writing, write 0.
9 to 0	BRP [9:0]	Prescaler Division Ratio Set When these bits are set to P (0 to 1023), the baud rate prescaler divides fCAN by P+1.

Modify the RSCAN0CmCFG register in channel reset mode or channel halt mode. Set this register before making a transition to channel communication mode. For setting bit timing, see **Section 16.5.1, Initial Settings**.

SJW[1:0] Bits

These bits are used to specify a Tq value for the resynchronization jump width. A value of 1 Tq to 4 Tq can be set. Set a value equal to or smaller than the value of the TSEG2 bits.

TSEG2[2:0] Bits

These bits are used to specify a Tq value for the length of phase buffer segment 2 (PHASE_SEG2).

A value of 2 Tq to 8 Tq can be set.

Set a value smaller than the value of the TSEG1 bits.

TSEG1[3:0] Bits

These bits are used to specify a Tq value for the total length of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1).

A value of 4 Tq to 16 Tq can be set.

BRP[9:0] Bits

The CANmTq clock (fCANTQm) is obtained by dividing the CAN clock (fCAN) by the baud rate prescaler ((BRP[9:0] bits + 1). One clock cycle of the CANmTq clock is 1 time quantum (Tq).

16.3.2.2 RSCAN0CmCTR — Channel Control Register (m = 0 to 3)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0004_H + (m × 0010_H)

Value after reset: 0000 0005_H

7 to 4	—	Reserved These bits are always read as 0. When writing, write 0.
3	RTBO	Forcible Return from Bus-off When this bit is set to 1, forcible return from the bus off state is made. This bit is always read as 0.
2	CSLPR	Channel Stop Mode 0: Other than channel stop mode 1: Channel stop mode
1,0	CHMDC[1:0]	Mode Select b1 b0 0 0: Channel communication mode 0 1: Channel reset mode 1 0: Channel halt mode 1 1: Setting prohibited

CTMS[1:0] Bits

These bits are used to select a communication test mode. Modify these bits in channel halt mode. These bits are set to 0 in channel reset mode.

CTME Bit

Setting this bit to 1 enables communication test mode. Modify this bit in channel halt mode. This bit is set to 0 in channel reset mode.

ERRD Bit

This bit is used to control display mode of bits 14 to 8 in the RSCAN0CmERFL register.

When this bit is cleared to 0, only the flags of the first error are set to 1. If two or more errors occur first, all the flags of detected errors are set to 1.

When this bit is set to 1, all the flags of errors that have occurred are set to 1 regardless of the error occurrence order.

Modify this bit in channel reset mode or channel halt mode.

BOM[1:0] Bits

These bits are used to select a bus off recovery mode of the RS-CAN module.

When the BOM[1:0] bits are set to 00_B, return from the bus off state is compliant with the CAN specifications. That is, the RS-CAN module reenters the CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. A bus off recovery interrupt request is generated at the time of return from the bus off state. If the CHMDC[1:0] bits are set to 10_B (channel halt mode) before recessive bits are detected 128 times, the RS-CAN module does not transition to channel halt mode until recessive bits are detected 128 times.

When the RS-CAN module reaches the bus off state when the BOM[1:0] bits are set to 01_B, the CHMDC[1:0] bits in the RSCAN0CmCTR register (m = 0 to 3) are set to 10_B and the RS-CAN module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits in the RSCAN0CmSTS register are cleared to 00_H.

When the RS-CAN module reaches the bus off state when the BOM[1:0] bits are set to 10_B, the CHMDC[1:0] bits are set to 10_B and the RS-CAN module transitions to channel halt mode after return from the bus off state (11 consecutive recessive bits are detected 128 times). A bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H.

When the BOM[1:0] bits are set to 11_B and the CHMDC[1:0] bits are set to 10_B while the RS-CAN module is in the bus off state, the RS-CAN module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H. However, if 11 consecutive recessive bits are detected 128 times and the RS-CAN module has recovered to the error active state from the bus off state before the CHMDC[1:0] bits are set to 10_B, a bus off recovery interrupt request is generated.

When the RS-CAN module transitions to channel halt mode (at bus off entry when the BOM[1:0] bits are 01_B or at bus off end when the BOM[1:0] bits are 10_B), if the CHMDC[1:0] bits are written by a program at the same time, writing by a program takes precedence. Modify BOM[1:0] bits in channel reset mode.

TAIE Bit

When transmit abort of the transmit buffer is completed with the TAIE bit set to 1, an interrupt request is generated. Modify this bit in channel reset mode.

ALIE Bit

When the ALF flag in the RSCAN0CmERFL register is set to 1 with the ALIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

BLIE Bit

When the BLF flag in the RSCAN0CmERFL register is set to 1 with the BLIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

OLIE Bit

When the OVLF flag in the RSCAN0CmERFL register is set to 1 with the OLIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

BORIE Bit

When the BORF flag in the RSCAN0CmERFL register is set to 1 with the BORIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

BOEIE Bit

When the BOEF flag in the RSCAN0CmERFL register is set to 1 with the BOEIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

EPIE Bit

When the EPF flag in the RSCAN0CmERFL register is set to 1 with the EPIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

EWIE Bit

When the EWF flag in the RSCAN0CmERFL register is set to 1 with the EWIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

BEIE Bit

When the BEF flag in the RSCAN0CmERFL register is set to 1 with the BEIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

RTBO Bit

Setting this bit to 1 (forcible return from the bus off state) in the bus off state returns the state forcibly from the bus off state to the error active state. This bit is automatically cleared to 0. Setting this bit to 1 clears the TEC[7:0] and REC[7:0] bits in the RSCAN0CmSTS register to 00_H and also clears the BOSTS flag in the RSCAN0CmSTS register to 0 (not in bus off state). The other registers remain unchanged. No bus off recovery interrupt request due to return from the bus off state is generated. Use this bit only when the BOM[1:0] bits in the RSCAN0CmCTR register are 00_B (ISO11898-1 compliant).

A delay of up to 1 CAN bit time occurs after the RTBO bit is set to 1 until the RS-CAN module transitions to the error active state. Set this bit to 1 in channel communication mode.

CSLPR Bit

Setting this bit to 1 places the channel in channel stop mode.

Clearing this bit to 0 makes the channel leave from channel stop mode.

Do not rewrite this bit in channel communication mode or in channel halt mode.

CHMDC[1:0] Bits

These bits are used to select a channel mode (channel communication mode, channel reset mode, or channel halt mode). For details, see **Section 16.4.2.6, Channel Modes**. Setting the CSLPR bit to 1 in channel reset mode allows transition to channel stop mode. Do not set these bits to 11_B. When the RS-CAN module has transitioned to channel halt mode by the setting of the BOM[1:0] bits, the CHMDC[1:0] bits automatically becomes 10_B.

16.3.2.3 RSCAN0CmSTS — Channel Status Register (m = 0 to 3)

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0008_H + (m × 0010_H)

Value after reset: 0000 0005_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TEC[7:0]								REC[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.17 RSCAN0CmSTS Register Contents

Bit Position	Bit Name	Function
31 to 24	TEC [7:0]	The transmit error counter (TEC) can be read.
23 to 16	REC [7:0]	The receive error counter (REC) can be read.
15 to 8	—	Reserved These bits are always read as 0.
7	COMSTS	Communication Status Flag 0: Communication is not ready. 1: Communication is ready.
6	RECSTS	Receive Status Flag 0: Bus idle, in transmission, or bus off state 1: In reception
5	TRMSTS	Transmit Status Flag 0: Bus idle or in reception 1: In transmission or bus off state
4	BOSTS	Bus Off Status Flag 0: Not in bus off state 1: In bus off state
3	EPSTS	Error Passive Status Flag 0: Not in error passive state 1: In error passive state
2	CSLPSTS	Channel Stop Status Flag 0: Not in channel stop mode 1: In channel stop mode
1	CHLTSTS	Channel Halt Status Flag 0: Not in channel halt mode 1: In channel halt mode
0	CRSTSTS	Channel Reset Status Flag 0: Not in channel reset mode 1: In channel reset mode

TEC[7:0] Bits

These bits indicate the transmit error counter value. For transmit error counter increment/decrement conditions, see the *CAN specification (ISO11898-1)*.

These bits are cleared to 0 in channel reset mode.

REC[7:0] Bits

These bits indicate the receive error counter value. For receive error counter increment/decrement conditions, see the *CAN specification (ISO11898-1)*.

These bits are cleared to 0 in channel reset mode.

COMSTS Flag

This flag indicates that communication is ready.

This flag becomes 1 when the RS-CAN module has detected 11 consecutive recessive bits after it has transitioned from channel reset mode or channel halt mode to channel communication mode. This flag is cleared to 0 in channel reset mode or channel halt mode.

RECSTS Flag

This flag is set to 1 when reception has started, and is cleared to 0 when the bus has become idle or transmission has started.

TRMSTS Flag

This flag is set to 1 when transmission has started, and is cleared to 0 when the bus has become idle or reception has started. This flag remains 1 in the bus off state.

BOSTS Flag

This flag is set to 1 when the TEC[7:0] value exceeds 255 and the RS-CAN module has entered the bus off state (TEC[7:0] value > 255), and is cleared to 0 when the RS-CAN module has exited the bus off state.

EPSTS Flag

This flag is set to 1 when the TEC[7:0] or REC[7:0] value exceeds 127 and the RS-CAN module has entered the error passive state (128 ≤ TEC[7:0] value ≤ 255 or 128 ≤ REC[7:0] value), and is cleared to 0 when the RS-CAN module has exited the error passive state or has entered channel reset mode.

CSLPSTS Flag

This flag is set to 1 when the RS-CAN module has transitioned to channel stop mode, and is cleared to 0 when the RS-CAN module has returned from channel stop mode.

CHLTSTS Flag

This flag is set to 1 when the RS-CAN module has transitioned to channel halt mode, and is cleared to 0 when the RS-CAN module has exited channel halt mode.

CRSTSTS Flag

This flag is set to 1 when the RS-CAN module has transitioned to channel reset mode, and is cleared to 0 when the RS-CAN module has transitioned to channel communication mode or channel halt mode. This flag remains 1 if the RS-CAN module transitions from channel reset mode to channel stop mode.

16.3.2.4 RSCAN0CmERFL — Channel Error Flag Register (m = 0 to 3)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $000C_H$ + (m × 0010_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	CRCREG[14:0]														
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	ADERR	B0ERR	B1ERR	CERR	AERR	FERR	SERR	ALF	BLF	OVLF	BORF	BOEF	EPF	EWF	BEF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.18 RSCAN0CmERFL Register Contents (1/2)

Bit Position	Bit Name	Function
31	—	Reserved This bit is always read as 0. When writing, write 0.
30 to 16	CRCREG[14:0]	CRC Calculation Data A CRC value calculated based on the transmitted message or received message is indicated.
15	—	Reserved This bit is always read as 0. When writing, write 0.
14	ADERR	ACK Delimiter Error Flag 0: No ACK delimiter error is detected. 1: ACK delimiter error is detected.
13	B0ERR	Dominant Bit Error Flag 0: No dominant bit error is detected. 1: Dominant bit error is detected.
12	B1ERR	Recessive Bit Error Flag 0: No recessive bit error is detected. 1: Recessive bit error is detected.
11	CERR	CRC Error Flag 0: No CRC error is detected. 1: CRC error is detected.
10	AERR	ACK Error Flag 0: No ACK error is detected. 1: ACK error is detected.
9	FERR	Form Error Flag 0: No form error is detected. 1: Form error is detected.
8	SERR	Stuff Error Flag 0: No stuff error is detected. 1: Stuff error is detected.
7	ALF	Arbitration Lost Flag 0: No arbitration lost is detected. 1: Arbitration lost is detected.
6	BLF	Bus Lock Flag 0: No channel bus lock is detected. 1: Channel bus lock is detected.

Table 16.18 RSCAN0CmERFL Register Contents (2/2)

Bit Position	Bit Name	Function
5	OVLF	Overload Flag 0: No overload is detected. 1: Overload is detected.
4	BORF	Bus Off Recovery Flag 0: No bus off recovery is detected. 1: Bus off recovery is detected.
3	BOEF	Bus Off Entry Flag 0: No bus off entry is detected. 1: Bus off entry is detected.
2	EPF	Error Passive Flag 0: No error passive is detected. 1: Error passive is detected.
1	EWF	Error Warning Flag 0: No error warning is detected. 1: Error warning is detected.
0	BEF	Bus Error Flag 0: No channel bus error is detected. 1: Channel bus error is detected.

See the *CAN specification (ISO11898-1)* if you want to check error occurrence conditions. To clear each flag of this register, write 0 by the program. These flags cannot be set to 1 by the program. If any of these flags becomes 1 at the timing when the program writes 0 to the flag, the flag is set to 1. Each flag is cleared to 0 in channel reset mode.

As for bits 14 to 8 in the RSCAN0CmERFL register, if an error is detected with all flags of bits 14 to 8 set to 0 when the ERRD bit in the RSCAN0CmCTR register is set to 0 (only the first error information is displayed), the corresponding flag is set to 1.

CRCREG[14:0] Flags

When the CTME bit in the RSCAN0CmCTR register is set to 1 (communication test mode is enabled), the CRC value calculated based on the transmitted or received message can be read. When the CTME bit is set to 0 (communication test mode is disabled), these bits are always read as 0.

ADERR Flag

This flag is set to 1 when a form error has been detected in the ACK delimiter during transmission.

B0ERR Flag

This flag is set to 1 when a recessive bit has been detected even though a dominant bit was transmitted.

B1ERR Flag

This flag is set to 1 when a dominant bit has been detected even though a recessive bit was transmitted.

CERR Flag

This flag is set to 1 when a CRC error has been detected.

AERR Flag

This flag is set to 1 when an ACK error has been detected.

FERR Flag

This flag is set to 1 when a form error has been detected.

SERR Flag

This flag is set to 1 when a stuff error has been detected.

ALF Flag

This flag is set to 1 when an arbitration lost has been detected.

BLF Flag

This flag is set to 1 when 32 consecutive dominant bits have been detected on the CAN bus in channel communication mode. After that, the detection processing restarts at either timing below.

- A recessive bit is detected after the BLF bit has been modified from 1 to 0.
- The RS-CAN module transitions to channel reset mode and returns to channel communication mode after the BLF bit has been modified from 1 to 0.

OVLF Flag

This flag is set to 1 when the overload frame transmit condition has been detected when performing reception or transmission.

BORF Flag

This flag is set to 1 when 11 consecutive recessive bits have been detected 128 times and the RS-CAN module returns from the bus off state. However, this flag is not set to 1 if the RS-CAN module returns from the bus off state in either of the following cases before 11 consecutive recessive bits are detected 128 times.

- The CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 01_B (channel reset mode).
- The RTBO bit in the RSCAN0CmCTR register is set to 1 (forcible return from the bus off state).
- The BOM[1:0] bits in the RSCAN0CmCTR register are set to 01_B (transition to channel halt mode at bus off entry).
- The CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 10_B (channel halt mode) before 11 consecutive recessive bits are detected 128 times with the BOM[1:0] bits set to 11_B (transition to channel halt mode upon a request from the program during bus off).

BOEF Flag

This flag is set to 1 when the state becomes bus off state (TEC[7:0] value > 255). This flag is also set to 1 when the state becomes bus off state with the BOM[1:0] bits in the RSCAN0CmCTR register (m = 0 to 3) set to 01_B (transition to channel halt mode at bus off entry).

EPF Flag

This flag becomes 1 when the RS-CAN module becomes error passive state (REC[7:0] or TEC[7:0] value > 127). This flag becomes 1 only when the REC[7:0] or TEC[7:0] value exceeds 127 for the first time. Therefore, if the program writes 0 to this flag with the REC[7:0] or TEC[7:0] value remaining over 127, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 127 or less and then either the REC[7:0] or TEC[7:0] value exceeds 127 again.

EWF Flag

This flag is set to 1 only when the REC[7:0] or TEC[7:0] value exceeds 95 for the first time. Therefore, if the program writes 0 to this flag with the REC[7:0] or TEC[7:0] value remaining over 95, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 95 or less and then either the REC[7:0] or TEC[7:0] value exceeds 95 again.

BEF Flag

This flag is set to 1 when any one of the ADERR, B0ERR, B1ERR, CERR, AERR, FERR, and SERR flags in the RSCAN0CmERFL register is set to 1.

NOTE

When writing 0 to flags of this register, write 0 to corresponding flags and 1 to other flags by using a store instruction. Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently clear the flags.

16.3.2.5 RSCAN0GCFG — Global Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0084_H

Value after reset: $0000\ 0000_H$

Bit Position	Bit Name	Function
31 to 16	ITRCP[15:0]	Interval Timer Prescaler Set When these bits are set to q, the peripheral function clock A is divided by q. When using interval timer, setting 0000_H is prohibited.
15 to 13	TSBTCS[1:0]	Timestamp Clock Source Select b15 b14 b13 0 0 0 : Channel 0 bit time clock 0 0 1 : Channel 1 bit time clock 0 1 0 : Channel 2 bit time clock 0 1 1 : Channel 3 bit time clock 1 0 0 : Setting prohibited 1 0 1 : Setting prohibited 1 1 0 : Setting prohibited 1 1 1 : Setting prohibited
12	TSSS	Timestamp Source Select 0: pclk/n2*1 1: Bit time clock is used as the source clock of the timestamp counter.
11 to 8	TSP[3:0]	Timestamp Clock Source Division b11 b10 b9 b8 0 0 0 0 : Not divided 0 0 0 1 : Divided by 2 0 0 1 0 : Divided by 4 0 0 1 1 : Divided by 8 0 1 0 0 : Divided by 16 0 1 0 1 : Divided by 32 0 1 1 0 : Divided by 64 0 1 1 1 : Divided by 128 1 0 0 0 : Divided by 256 1 0 0 1 : Divided by 512 1 0 1 0 : Divided by 1024 1 0 1 1 : Divided by 2048 1 1 0 0 : Divided by 4096 1 1 0 1 : Divided by 8192 1 1 1 0 : Divided by 16384 1 1 1 1 : Divided by 32768
7 to 5	—	Reserved These bits are always read as 0. When writing, write 0.
4	DCS	CAN Clock Source Select 0: clkc 1: clk_xincan*2

Table 16.19 RSCAN0GCFG Register Contents (2/2)

Bit Position	Bit Name	Function
3	MME	Mirror Function Enable 0: Mirror function is disabled. 1: Mirror function is enabled.
2	DRE	DLC Replacement Enable 0: DLC replacement is disabled. 1: DLC replacement is enabled.
1	DCE	DLC Check Enable 0: DLC check is disabled. 1: DLC check is enabled.
0	TPRI	Transmit Priority Select 0: ID priority 1: Transmit buffer number priority

Note 1. Set TSBTCS[2:0] to 000_B before select pclk/2 as the timestamp count source.
Note 2. Set the CAN clock frequency to be pclk/2 or below.

Modify the RSCAN0GCFG register in global reset mode.

ITRCP[15:0] Bits

These bits are used to set a clock source division value of the interval timer for FIFO buffers. For details, see **Section 16.4.4.6, Interval Transmission Function**.

TSBTCS[2:0] Bits

When the TSSS bit is 1, these bits are used to select the channel of the bit time clock that will be the clock source of the timestamp counter.

TSSS Bit

This bit is used to select a clock source of the timestamp counter.

TSP[3:0] Bits

These bits specify the prescaler used to divide the clock source (selected by the TSBTCS[2:0] and TSSS bits) to generate the timestamp counter clock signal.

DCS Bit

When this bit is set to 0, clkc is used as the clock source of the CAN clock (fCAN).

When this bit is set to 1, the main clock is used as the clock source of the CAN clock.

Set the frequency of CAN clock (fCAN) at 1/2 of pclk.

MME Bit

Setting this bit to 1 makes the mirror function available.

DRE Bit

When the DRE bit is set to 1, the DLC value of the receive rule is stored in the buffer instead of the DLC value of the received message after the DLC value has passed through the DLC filter. In this case, a value of 00_H is stored in the data byte that exceeds the DLC value of the receive rule.

When the DCE bit is set to 1 (DLC check is enabled), the DLC replacement function is available.

DCE Bit

Setting this bit to 1 makes the DLC check function available. Set the GAFLDLC[3:0] bits in the RSCAN0GAFLP0j register to 0000_B before clearing the DCE bit in the RSCAN0GCFG register to 0.

TPRI Bit

This bit is used to set the transmit priority.

When this bit is set to 0, ID priority is selected and the transmit priority complies with the CAN bus arbitration rule (ISO11898-1 specifications). When this bit is set to 1, transmit buffer number priority is selected and the lowest-numbered transmit buffer among those specified for transmission takes precedence.

While the transmit queue is in use, clear this bit to 0.

16.3.2.6 RSCAN0GCTR — Global Control Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0088_H

Value after reset: $0000\ 0005_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSRST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.20 RSCAN0GCTR Register Contents

Bit Position	Bit Name	Function
31 to 17	—	Reserved These bits are always read as 0. When writing, write 0.
16	TSRST	Timestamp Counter Reset Setting the TSRST bit to 1 resets the timestamp counter. This bit is always read as 0.
15 to 11	—	Reserved These bits are always read as 0. When writing, write 0.
10	THLEIE	Transmit History Buffer Overflow Interrupt Enable 0: Transmit history buffer overflow interrupt is disabled. 1: Transmit history buffer overflow interrupt is enabled.
9	MEIE	FIFO Message Lost Interrupt 0: FIFO message lost interrupt is disabled. 1: FIFO message lost interrupt is enabled.
8	DEIE	DLC Error Interrupt Enable 0: DLC error interrupt is disabled. 1: DLC error interrupt is enabled.
7 to 3	—	Reserved These bits are always read as 0. When writing, write 0.
2	GSLPR	Global Stop Mode 0: Other than global stop mode 1: Global stop mode
1, 0	GMDC[1:0]	Global Mode Select b1 b0 0 0: Global operating mode 0 1: Global reset mode 1 0: Global test mode 1 1: Setting prohibited

TSRST Bit

This bit is used to reset the timestamp counter. When this bit is set to 1, the RSCAN0GTSC register is cleared to 0000_H.

THLEIE Bit

When the THLEIE bit is set to 1 and the THLES flag in the RSCAN0GERFL register is set to 1, an interrupt request is generated. Modify this bit in global reset mode.

MEIE Bit

When the MEIE bit is set to 1 and the MES flag in the RSCAN0GERFL register is set to 1, an interrupt request is generated. Modify this bit in global reset mode.

DEIE Bit

When the DEIE bit is set to 1 and the DEF flag in the RSCAN0GERFL register is set to 1, an interrupt request is generated. Modify this bit in global reset mode.

GSLPR Bit

Setting this bit to 1 places the RS-CAN module in global stop mode.

Clearing this bit to 0 makes the RS-CAN module leave from global stop mode.

Do not modify this bit from 0 to 1 in global operation mode or global test mode.

GMDC[1:0] Bits

These bits are used to select a mode of the entire RS-CAN module (global operating mode, global reset mode, or global test mode). For details, see **Section 16.4.2.1, Global Modes**. Setting the GSLPR bit to 1 in global reset mode makes the RS-CAN module transition to global stop mode.

16.3.2.7 RSCAN0GSTS — Global Status Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $008C_H$

Value after reset: 0000 $000D_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	GRAM INIT	GSLP STS	GHLT STS	GRST STS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.21 RSCAN0GSTS Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved These bits are always read as 0.
3	GRAMINIT	CAN RAM Initialization Status Flag 0: CAN RAM initialization is completed. 1: CAN RAM initialization is ongoing.
2	GSLPSTS	Global Stop Status Flag 0: Not in global stop mode 1: In global stop mode
1	GHLTSTS	Global Test Status Flag 0: Not in global test mode 1: In global test mode
0	GRSTSTS	Global Reset Status Flag 0: Not in global reset mode 1: In global reset mode

GRAMINIT Flag

This flag indicates the initialization status of the CAN RAM.

This flag is set to 1 after the MCU has been reset, and is cleared to 0 when CAN RAM initialization is completed.

GSLPSTS Flag

This flag is set to 1 when the RS-CAN module has transitioned to global stop mode, and is cleared to 0 when the RS-CAN module has returned from global stop mode.

GHLTSTS Flag

This flag is set to 1 when the RS-CAN module has transitioned to global test mode, and is cleared to 0 when the RS-CAN module has exited global test mode.

GRSTSTS Flag

This flag is set to 1 when the RS-CAN module has transitioned to global reset mode, and is cleared to 0 when the RS-CAN module has exited global reset mode. This flag remains 1 if the RS-CAN module has transitioned from global reset mode to global stop mode.

16.3.2.8 RSCAN0GERFL — Global Error Flag Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0090_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	THLES	MES	DEF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.22 RSCAN0GERFL Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved The read value is undefined. When writing, write 0.
2	THLES	Transmit History Buffer Overflow Status Flag 0: No transmit history buffer overflow is present. 1: A transmit history buffer overflow is present.
1	MES	FIFO Message Lost Status Flag 0: No FIFO message lost error is present. 1: A FIFO message lost error is present.
0	DEF	DLC Error Flag 0: No DLC error is present. 1: A DLC error is present.

All flags in the RSCAN0GERFL register are cleared to 0 in global reset mode.

THLES Flag

The THLES flag is set to 1 when any one of the THLELT flags in the RSCAN0THLSTSm register (m = 0 to 3) is set to 1.

This flag is cleared to 0 when the THLELT flags of all channels are set to 0.

MES Flag

The MES flag is set to 1 when any one of the RFMLT flags in the RSCAN0RFSTSx register (x = 0 to 7) or the CFMLT flags in the RSCAN0CFSTSk register (k = 0 to 11) is set to 1.

This flag is cleared to 0 when all the RFMLT flags and CFMLT flags are set to 0.

DEF Flag

The DEF flag is set to 1 when an error has been detected during the DLC check. This flag can be cleared to 0 by writing 0 by the program.

16.3.2.9 RSCAN0GTINTSTS0 — Global TX Interrupt Status Register 0

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0460_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	THIF3	CFTIF3	TQIF3	TAIF3	TSIF3	—	—	—	THIF2	CFTIF2	TQIF2	TAIF2	TSIF2
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R*1	R*1	R*1	R*1	R*1	R	R	R	R*1	R*1	R*1	R*1	R*1

	—	—	—	THIF1	CFTIF1	TQIF1	TAIF1	TSIF1	—	—	—	THIF0	CFTIF0	TQIF0	TAIF0	TSIF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R*1	R*1	R*1	R*1	R*1	R	R	R	R*1	R*1	R*1	R*1	R*1

Note 1. The bit is automatically cleared in global reset or channel reset mode.

Table 16.23 RSCAN0GTINTSTS0 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 29	—	Reserved These bits are always read as 0. When writing, write 0.
28	THIF3	TX History List Interrupt Channel 3 0: Channel 3 TX history list interrupt flag is not set. 1: Channel 3 TX history list interrupt flag is set.
27	CFTIF3	COM FIFO TX Mode Interrupt Flag Channel 3 0: Channel 3 COM FIFO TX mode interrupt flag is not set. 1: Channel 3 COM FIFO TX mode interrupt flag is set.
26	TQIF3	TX Queue Interrupt Flag Channel 3 0: Channel 3 TX queue interrupt flag is not set. 1: Channel 3 TX queue interrupt flag is set.
25	TAIF3	TX Abort Interrupt Flag Channel 3 0: Channel 3 TX abort interrupt flag is not set. 1: Channel 3 TX abort interrupt flag is set.
24	TSIF3	Transmit Buffer Interrupt Status Flag Channel 3 0: Channel 3 Transmit successful completion interrupt flag is not set. 1: Channel 3 Transmit successful completion interrupt flag is set.
23 to 21	—	Reserved These bits are always read as 0. When writing, write 0.
20	THIF2	TX History List Interrupt Channel 2 0: Channel 2 TX history list interrupt flag is not set. 1: Channel 2 TX history list interrupt flag is set.
19	CFTIF2	COM FIFO TX Mode Interrupt Flag Channel 2 0: Channel 2 COM FIFO TX mode interrupt flag is not set. 1: Channel 2 COM FIFO TX mode interrupt flag is set.
18	TQIF2	TX Queue Interrupt Flag Channel 2 0: Channel 2 TX queue interrupt flag is not set. 1: Channel 2 TX queue interrupt flag is set.
17	TAIF2	TX Abort Interrupt Flag Channel 2 0: Channel 2 TX abort interrupt flag is not set. 1: Channel 2 TX abort interrupt flag is set.
16	TSIF2	TX Success Interrupt Flag Channel 2 0: Channel 2 TX successful completion interrupt flag is not set. 1: Channel 2 TX successful completion interrupt flag is set.

Table 16.23 RSCAN0GTINTSTS0 Register Contents (2/2)

Bit Position	Bit Name	Function
15 to 13	—	Reserved These bits are always read as 0. When writing, write 0.
12	THIF1	TX History List Interrupt Channel 1 0: Channel 1 TX history list interrupt flag is not set. 1: Channel 1 TX history list interrupt flag is set.
11	CFTIF1	COM FIFO TX Mode Interrupt Flag Channel 1 0: Channel 1 COM FIFO TX mode interrupt flag is not set. 1: Channel 1 COM FIFO TX mode interrupt flag is set.
10	TQIF1	TX Queue Interrupt Flag Channel 1 0: Channel 1 TX queue interrupt flag is not set. 1: Channel 1 TX queue interrupt flag is set.
9	TAIF1	Transmit Buffer Abort Interrupt Status Flag Channel 1 0: Channel 1 Transmit buffer abort interrupt flag is not set. 1: Channel 1 Transmit buffer abort interrupt flag is set.
8	TSIF1	TX Success Interrupt Flag Channel 1 0: Channel 1 TX successful completion interrupt flag is not set. 1: Channel 1 TX successful completion interrupt flag is set.
7 to 5	—	Reserved These bits are always read as 0. When writing, write 0.
4	THIF0	TX History List Interrupt Channel 0 0: Channel 0 TX history list interrupt flag is not set. 1: Channel 0 TX history list interrupt flag is set.
3	CFTIF0	COM FIFO TX Mode Interrupt Flag Channel 0 0: Channel 0 COM FIFO TX mode interrupt flag is not set. 1: Channel 0 COM FIFO TX mode interrupt flag is set.
2	TQIF0	TX Queue Interrupt Flag Channel 0 0: Channel 0 TX queue interrupt flag is not set. 1: Channel 0 TX queue interrupt flag is set.
1	TAIF0	Transmit Buffer Abort Interrupt Flag Channel 0 0: Channel 0 Transmit buffer abort interrupt flag is not set. 1: Channel 0 Transmit buffer abort interrupt flag is set.
0	TSIF0	TX Success Interrupt Flag Channel 0 0: Channel 0 TX successful completion interrupt flag is not set. 1: Channel 0 TX successful completion interrupt flag is set.

Note 1. These bits are automatically cleared in global reset mode or channel reset mode.

TSIFm Bit

When the RSCAN0TMIECy.TMIE bit is set to 1 (transmit buffer interrupt is enabled) and corresponding RSCAN0TMSTSp.TMTRF[1:0] flags are set to 10_B (transmission has been completed, without transmit abort request) or 11_B (transmission has been completed, with transmit abort request), the TSIFm bit becomes 1.

The TSIFm flag becomes 0 by setting 00_B to all the TMTRF[1:0] flags which satisfy the condition to lead TSIFm = 1. The TSIFm flag also becomes 0 by setting the TMIE bit to 0.

TAIFm Bit

When RSCAN0CmCTR.TAIE bit is set to 1 (transmit abort interrupt is enabled) and the RSCAN0TMSTSp.TMTRF[1:0] flags are 01_B (transmit abort has been completed), the TAIFm bit becomes 1.

The TAIFm flag becomes 0 by setting 00_B to all the TMTRF[1:0] flags of which transmit abort has been completed.

TQIFm Bit

When the RSCAN0TXQCCm.TXQIE bit is set to 1 (transmit queue interrupt is enabled) and the RSCAN0TXQSTSm.TXQIF bit is set to 1 (a transmit queue interrupt request is present), the TQIFm bit becomes 1.

When the RSCAN0TXQSTSm.TXQIF bit (transmit queue interrupt request) is set to 0, the TQIFm bit becomes 0. The TQIFm flag also becomes 0 by setting the TXQIE bit to 0.

CFTIFm Bit

When the RSCAN0CFCCk.CFTXIE bit is set to 1 (transmit/receive FIFO transmission interrupt is enabled) and the RSCAN0CFSTSk.CFTXIF bit is set to 1 (a transmit/receive FIFO transmission interrupt request is present), the CFTIFm bit becomes 1.

The CFTIFm bit becomes 0 by setting all the RSCAN0CFSTSk.CFTXIF bits to 0. The CFTIFm flag also becomes 0 by setting the CFTXIE bit to 0.

THIFm Bit

When the RSCAN0THLCCm.THLIE bit is set to 1 (transmit history interrupt is enabled) and the RSCAN0THLSTSm.THLIF bit is set to 1 (a transmit history interrupt request is present), the THIFm bit becomes 1.

The THIFm bit becomes 0 by setting the RSCAN0THLSTSm.THLIF bit to 0. The THIFm flag also becomes 0 by setting the THLIE bit to 0.

16.3.2.10 RSCAN0GTSC — Global Timestamp Counter Register

Access: This register can be read in 16- or 32-bit units.

Address: <RS-CAN0_base> + 0094_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.24 RSCAN0GTSC Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0.
15 to 8	TS[15:0]	Timestamp value The timestamp counter value can be read. Counter value: 0000_H to $FFFF_H$

TS[15:0] Bits

When the TS[15:0] bits are read, the read value shows the timestamp counter (16-bit free-running counter) value at that time. The TS[15:0] value at the time when the SOF of the received message is detected is stored in the receive buffer or the FIFO buffer. The timestamp counter is initialized in global reset mode.

Start timing and stop timing of the timestamp counter depend on the count source.

- When the TSSS bit value in the RSCAN0GCFG register is 0 (pclk):
  The timestamp counter starts counting when the RS-CAN module has transitioned to global operating mode. This counter stops counting when the RS-CAN module has transitioned to global stop mode or global test mode.
- When the TSSS bit value in the RSCAN0GCFG register is 1 (CANm bit time clock):
  The timestamp counter starts counting when the corresponding channel has transitioned to channel communication mode. This counter stops counting when the corresponding channel has transitioned to channel reset mode or channel halt mode.

16.3.2.11 RSCAN0GAFLECTR — Receive Rule Entry Control Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0098_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.25 RSCAN0GAFLECTR Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved These bits are always read as 0. When writing, write 0.
8	AFLDAE	Receive Rule Table Write Enable 0: Writing to the receive rule table is disabled. 1: Writing to the receive rule table is enabled.
7 to 5	—	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	AFLPN [4:0]	Receive Rule Table Page Number Configuration A page number can be selected from a range of page 0 (00000_B) to page 15 (01111_B).

AFLDAE Bit

Setting this bit to 0 disables data writing to the receive rule table. After data writing to the receive rule table is completed, set this bit to 0 to disable writing to the receive rule table. The receive rule table can be read regardless of the value of this bit.

Set the AFLDAE bit to 1 in global reset mode.

AFLPN[4:0] Bits

These bits are used to set the page number of the receive rule table. Sixteen receive rules can be set per page.

Set these bits to a value within a range of 00000_B to 01111_B.

16.3.2.12 RSCAN0GAFLCFG0 — Receive Rule Configuration Register 0

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $009C_H$

Value after reset: $0000\ 0000_H$

Bit Position	Bit Name	Function
31 to 24	RNC0[7:0]	Number of Channel 0 Rules The number of rules for channel 0
23 to 16	RNC1[7:0]	Number of Channel 1 Rules The number of rules for channel 1
15 to 8	RNC2[7:0]	Number of Channel 2 Rules The number of rules for channel 2
7 to 0	RNC3[7:0]	Number of Channel 3 Rules The number of rules for channel 3

Modify the RSCAN0GAFLCFG0 register in global reset mode.

Up to "64 × (number of channels)" rules can be registered to the receive rule tables in the entire module. The number of receive rules per channel should meet the following conditions.

- The maximum number of rules per channel is 128.
- The total of the number of rules allocated to each channel is not larger than the number of rules permitted to the entire module.

RNC0[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 0 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

RNC1[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 1 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

RNC2[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 2 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

RNC3[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 3 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

16.3.2.13 RSCAN0GAFLIDj — Receive Rule ID Register (j = 0 to 15)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0500_H + (j × 0010_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLIDE	GAFLRTR	GAFLLB	GAFLID[28:16]

Table 16.27 RSCAN0GAFLIDj Register Contents

Bit Position	Bit Name	Function
31	GAFLIDE	IDE Select 0: Standard ID 1: Extended ID
30	GAFLRTR	RTR Select 0: Data frame 1: Remote frame
29	GAFLLB	Receive Rule Target Message Select 0: When a message transmitted from another CAN node is received 1: When a message transmitted from own node is received
28 to 0	GAFLID[28:0]	ID Set Set the ID of the receive rule. For the standard ID, set the ID in bits b10 to b0 and set bits b28 to b11 to 0.

Modify the RSCAN0GAFLIDj register in global reset mode when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (writing to the receive rule table is enabled).

GAFLIDE Bit

This bit is used to select the ID format (standard ID or extended ID) of the receive rule. This bit is compared with the IDE bit in the received message during the acceptance filter processing.

GAFLRTR Bit

This bit is used to select the frame format (data frame or remote frame) of the receive rule. This bit is compared with the RTR bit in the received message during the acceptance filter processing.

GAFLLB Bit

Setting this bit to 0 causes data processing to be performed using the receive rule when a message transmitted from another CAN node is received.

Setting this bit is to 1 when the mirror function is used causes data processing to be performed using the receive rule when a message transmitted from the own CAN node is received.

GAFLID[28:0] Bits

These bits are used to set the ID field of the receive rule. The ID set by these bits is compared with the ID in the received message during the acceptance filter processing.

16.3.2.14 RSCAN0GAFLMj — Receive Rule Mask Register (j = 0 to 15)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0504_H + (j × 0010_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.28 RSCAN0GAFLMj Register Contents

Bit Position	Bit Name	Function
31	GAFLIDEM	IDE Mask 0: The IDE bit is not compared. 1: The IDE bit is compared.
30	GAFLRTRM	RTR Mask 0: The RTR bit is not compared. 1: The RTR bit is compared.
29	—	Reserved This bit is always read as 0. When writing, write 0.
28 to 0	GAFLIDM [28:0]	ID Mask 0: The corresponding ID bit is not compared. 1: The corresponding ID bit is compared.

Modify the RSCAN0GAFLMj register in global reset mode when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (writing to the receive rule table is enabled).

GAFLIDEM Bit

When this bit is set to 1, filter processing is performed only for messages of the ID format specified by the GAFLIDE bit of the RSCAN0GAFLIDj register.

When this bit is set to 0, it is regarded that all received messages have matched the specified ID. To set the GAFLIDEM bit to 0, set the GAFLIDM[28:0] bits to all 0 at the same time.

GAFLRTRM Bit

This bit is used to mask the RTR bit of the receive rule.

GAFLIDM[28:0] Bits

These bits are used to mask the corresponding ID bits of the receive rule.

16.3.2.15 RSCAN0GAFLP0j — Receive Rule Pointer 0 Register (j = 0 to 15)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0508_H + (j × 0010_H)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.29 RSCAN0GAFLP0j Register Contents

Bit Position	Bit Name	Function
31 to 28	GAFLDLC [3:0]	Receive Rule DLC Set b31 b30 b29 b28 0 0 0 0 : DLC check is disabled. 0 0 0 1 : 1 data byte 0 0 1 0 : 2 data bytes 0 0 1 1 : 3 data bytes 0 1 0 0 : 4 data bytes 0 1 0 1 : 5 data bytes 0 1 1 0 : 6 data bytes 0 1 1 1 : 7 data bytes 1 X X X : 8 data bytes
27 to 16	GAFLPTR [11:0]	Receive Rule Label Set Set the 12-bit label information.
15	GAFLRMV	Receive Buffer Enable 0: No receive buffer is used. 1: A receive buffer is used.
14 to 8	GAFLRMDP [6:0]	Receive Buffer Number Select Set the receive buffer number to store received messages.
7 to 0	—	Reserved These bits are always read as 0. When writing, write 0.

Modify the RSCAN0GAFLP0j register in global reset mode when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (writing to the receive rule table is enabled).

GAFLDLC[3:0] Bits

These bits are used to set the minimum data length necessary for receiving messages. If the data length of a message that is being filtered is equal to or larger than the value set by the GAFLDLC[3:0] bits, the message passes the DLC check. Setting these bits to 0000_B disables the DLC check function, allowing messages with any data length to pass the DLC check.

GAFLPTR[11:0] Bits

These bits are used to set a 12-bit label to be attached to messages that have passed through the filter. A label is attached when a message is stored in the receive buffer or the FIFO buffer.

GAFLRMV Bit

When this bit is set to 1, received messages that have passed through the filter are stored in the receive buffer selected by the GAFLRMDP[6:0] bits.

GAFLRMDP[6:0] Bits

These bits are used to select the number of a receive buffer that stores received messages having passed through the filter when the GAFLRMV bit is set to 1. Set these bits to a value smaller than the value set by the NRXMB[7:0] bits in the RSCAN0RMNB register.

16.3.2.16 RSCAN0GAFLP1j — Receive Rule Pointer 1 Register (j = 0 to 15)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $050C_H$ + (j × 0010_H)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	GAFLFDP[19:16]

Table 16.30 RSCAN0GAFLP1j Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved These bits are always read as 0. When writing, write 0.
19 to 0	GAFLFDP [19:0]	FIFO Buffer y Select (y = 0 to 19) y = 0 to 7 0: Transmit FIFO buffer y is not selected. 1: Transmit FIFO buffer y is selected. y = 8 to 19 0: Transmit/receive FIFO buffer y-8 is not selected. 1: Transmit/receive FIFO buffer y-8 is selected.

Modify the RSCAN0GAFLP1j register in global reset mode when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (receive rule table write is enabled).

GAFLFDP [19:0] Bits

These bits are used to specify FIFO buffers that store received messages having passed through the filter. Up to eight FIFO buffers are selectable. However, when the GAFLRMV bit in the RSCAN0GAFLP0j register is set to 1 (a receive buffer is used), up to seven FIFO buffers are selectable. Selectable buffers are receive FIFO buffers and the transmit/receive FIFO buffers for which the CFM[1:0] bits in the RSCAN0CFCCk register are set to 00_B (receive mode) or 10_B (gateway mode).

16.3.2.17 RSCAN0RMNB — Receive Buffer Number Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $00A4_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.31 RSCAN0RMNB Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are always read as 0. When writing, write 0.
7 to 0	NRXMB [7:0]	Receive Buffer Number Configuration Set the number of receive buffers. Set a value of 0 to 64.

Modify the RSCAN0RMNB register in global reset mode.

NRXMB[7:0] Bits

These bits are used to set the total number of receive buffers of the entire RS-CAN module. The maximum value is “16 × (number of channels)”.

Setting these bits to all 0 makes receive buffers unavailable.

16.3.2.18 RSCAN0RMNDy — Receive Buffer New Data Register y (y = 0, 1)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $00A8_H$ + (y × 0004_H)

Value after reset: $0000\ 0000_H$

Table 16.32 RSCAN0RMNDy Register Contents

Bit Position	Bit Name	Function
31 to 16	RMNSq	Receive Buffer Reception Complete Flag q (q = y × 32 + 31 to y × 32 + 16) 0: Receive buffer q contains no new message. 1: Receive buffer q contains a new message.
15 to 0	RMNSq	Receive Buffer Reception Complete Flag q (q = y × 32 + 15 to y × 32 + 0) 0: Receive buffer q contains no new message. 1: Receive buffer q contains a new message.

Write 0 to the RSCAN0RMNDy register in global operating mode or global test mode.

RMNSq Flags (q = 0 to 63)

Each flag is set to 1 when a process starts to store a message in the corresponding receive buffer.

To clear these flags to 0, write 0 by the program. In this case, write 0 to bits to be cleared and write 1 to other bits using the store instruction. Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently clear the flags. These bits cannot be set to 0 while a message is being stored. Time for storing a message is 10 pclk clock cycles.

These flags are cleared to 0 in global reset mode.

16.3.2.19 RSCAN0RMIDq — Receive Buffer ID Register (q = 0 to 63)

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0600_H + (q × 0010_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.33 RSCAN0RMIDq Register Contents

Bit Position	Bit Name	Function
31	RMIDE	Receive Buffer IDE 0: Standard ID 1: Extended ID
30	RMRTR	Receive Buffer RTR 0: Data frame 1: Remote frame
29	—	Reserved This bit is always read as 0.
28 to 0	RMID [28:0]	Receive Buffer ID Data The standard ID or extended ID of received message can be read. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.

RMIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive buffer.

RMRTR Bit

This bit indicates the frame format (data frame or remote frame) of the message stored in the receive buffer.

RMID[28:0] Bits

These bits indicate the ID of the message stored in the receive buffer.

16.3.2.20 RSCAN0RMPTRq — Receive Buffer Pointer Register (q = 0 to 63)

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0604_H + (q × 0010_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.34 RSCAN0RMPTRq Register Contents

Bit Position	Bit Name	Function
31 to 28	RMDLC [3:0]	Receive Buffer DLC Data b31 b30 b29 b28 0 0 0 0: No data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes
27 to 16	RMPTR [11:0]	Receive Buffer Label Data Label information of the received message can be read.
15 to 0	RMTS [15:0]	Receive Buffer Timestamp Data Timestamp value of the received message can be read.

RMDLC[3:0] Bits

These bits indicate the data length of the message stored in the receive buffer.

RMPTR[11:0] Bits

These bits indicate the label information of the message stored in the receive buffer.

RMTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the receive buffer.

16.3.2.21 RSCAN0RMDF0q — Receive Buffer Data Field 0 Register (q = 0 to 63)

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0608_H + (q × 0010_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMDB3[7:0]								RMDB2[7:0]

Table 16.37 RSCAN0RFCCx Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. When writing, write 0.
15 to 13	RFIGCV [2:0]	Receive FIFO Interrupt Request Timing Select b15 b14 b13 0 0 0: When FIFO is 1/8 full. 0 0 1: When FIFO is 2/8 full. 0 1 0: When FIFO is 3/8 full. 0 1 1: When FIFO is 4/8 full. 1 0 0: When FIFO is 5/8 full. 1 0 1: When FIFO is 6/8 full. 1 1 0: When FIFO is 7/8 full. 1 1 1: When FIFO is full.
12	RFIM	Receive FIFO Interrupt Source Select 0: An interrupt occurs when the condition set by the RFIGCV[2:0] bits is met. 1: An interrupt occurs each time a message has been received.
11	—	Reserved This bit is always read as 0. When writing, write 0.
10 to 8	RFDC [2:0]	Receive FIFO Buffer Depth Configuration b10 b9 b8 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages 1 1 0: 64 messages 1 1 1: 128 messages
7 to 2	—	Reserved These bits are always read as 0. When writing, write 0.
1	RFIE	Receive FIFO Interrupt Enable 0: Receive FIFO interrupt is disabled. 1: Receive FIFO interrupt is enabled.
0	RFE	Receive FIFO Buffer Enable 0: No receive FIFO buffer is used. 1: Receive FIFO buffers are used.

RFIGCV[2:0] Bits

These bits are used to select the timing of generating a receive FIFO interrupt request when the RFIM bit is set to 0. An interrupt request is generated when the number of stored messages reaches the specified ratio (in eighths) of the storable messages set by the RFDC[2:0] bits.

When the RFDC[2:0] bits are set to 001_B (4 messages), set the RFIGCV[2:0] bits to 001_B, 011_B, 101_B, or 111_B. Modify these bits in global reset mode.

RFIM Bit

This bit is used to select a FIFO interrupt source. Modify this bit in global reset mode.

RFDC[2:0] Bits

These bits are used to select the number of messages that can be stored in a single receive FIFO buffer. If these bits are set to 000_B, do not use any receive FIFO buffer. Modify these bits in global reset mode.

RFIE Bit

Setting the RFIE bit to 1 enables receive FIFO interrupts. Modify this bit with the RFE bit set to 0 (no receive FIFO buffer is used).

RFE Bit

Setting the RFE bit to 1 makes receive FIFO buffers available. Clearing this bit to 0 sets the RFEMP flag in the RSCAN0RFSTSx register to 1 (the receive FIFO buffer contains no unread message (buffer empty)). Modify this bit in global operating mode or global test mode.

16.3.2.24 RSCAN0RFSTSx — Receive FIFO Buffer Status Register (x = 0 to 7)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $00D8_H$ + (x × 0004_H)

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFMC[7:0]								—	—	—	—	RFIF	RFMLT	RFFLL	RFEMP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.38 RSCAN0RFSTSx Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. When writing, write 0.
15 to 8	RFMC[7:0]	Receive FIFO Unread Message Counter The number of unread messages stored in the receive FIFO buffer is displayed.
7 to 4	—	Reserved These bits are always read as 0. When writing, write 0.
3	RFIF	Receive FIFO Interrupt Request Flag 0: No receive FIFO interrupt request is present. 1: A receive FIFO interrupt request is present.
2	RFMLT	Receive FIFO Message Lost Flag 0: No receive FIFO message is lost. 1: A receive FIFO message is lost.
1	RFFLL	Receive FIFO Buffer Full Status Flag 0: The receive FIFO buffer is not full. 1: The receive FIFO buffer is full.
0	RFEMP	Receive FIFO Buffer Empty Status Flag 0: The receive FIFO buffer contains unread messages. 1: The receive FIFO buffer contains no unread message (buffer empty).

RFMC[7:0] Flags

These flags indicate the number of unread messages in the receive FIFO buffer. These flags become 00_H when the RFE bit in the RSCAN0RFCCx register is set to 0.

RFIF Flag

This flag is set to 1 when the conditions for receive FIFO interrupt request generation set by the RFIGCV[2:0] bits and the RFIM bit in the RSCAN0RFCCx register are satisfied. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode.

RFMLT Flag

This flag is set to 1 if it is attempted to store a new message when the receive FIFO buffer is full. In this case, the new message is discarded.

This flag is cleared to 0 in global reset mode or by writing 0 to this flag.

Modify this bit in global operating mode or global test mode.

RFFLL Flag

This flag is set to 1 when the number of messages stored in the receive FIFO buffer matches the FIFO buffer depth set by the RFDC[2:0] bits in the RSCAN0RFCCx register.

If the number of messages stored in the receive FIFO buffer becomes smaller than the FIFO buffer depth set by the RFDC[2:0] bits, this flag is cleared to 0. This flag is also cleared to 0 when the RFE bit in the RSCAN0RFCCx register is set to 0 (no receive FIFO buffer is used) or in global reset mode.

RFEMP Flag

This flag is set to 1 when all messages in the receive FIFO buffer have been read. This flag is also set to 1 when the RFE bit in the RSCAN0RFCCx register is 0 or in global reset mode.

This flag is cleared to 0 when even a single received message has been stored in the receive FIFO buffer.

NOTE

To clear the RFMLT or RFIF flag to 0, use a store instruction to write “0” to the given flag and “1” to the other flags. Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently clear the flags.

16.3.2.25 RSCAN0RFPCTRx — Receive FIFO Buffer Pointer Control Register (x = 0 to 7)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $00F8_H$ + (x × 0004_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.39 RSCAN0RFPCTRx Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When writing, write 0.
7 to 0	RFPC [7:0]	Receive FIFO Pointer Control When FF_H is written to these bits, the read pointer moves to the next unread message in the receive FIFO buffer.

RFPC[7:0] Bits

When FF_H is written to the RFPC[7:0] bits, the read pointer moves to the next unread message in the receive FIFO buffer. At this time, the RFMC[7:0] (receive FIFO unread message counter) value in the RSCAN0RFSTSx register is decremented by 1. Read the RSCAN0RFID, RSCAN0RFPTR, RSCAN0RFDF0, and RSCAN0RFDF1 registers to read messages in the receive FIFO buffer, and then write FF_H to the RFPC[7:0] bits.

Write FF_H to these bits when the RFE bit in the RSCAN0RFCCx register is set to 1 (receive FIFO buffers are used) and the RFEMP flag in the RSCAN0RFSTSx register is 0 (the receive FIFO buffer contains unread messages).

16.3.2.26 RSCAN0RFIDx — Receive FIFO Buffer Access ID Register (x = 0 to 7)

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $0E00_H$ + (x × 0010_H)

Value after reset: $0000\ 0000_H$

28 to 0	RFID [28:0]	Receive FIFO Buffer ID Data The standard ID or extended ID of received message can be read. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.

RFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive FIFO buffer.

RFRTR Bit

This bit indicates the frame format (data frame or remote frame) of the message stored in the receive FIFO buffer.

RFID[28:0] Bits

These bits indicate the ID of the message stored in the receive FIFO buffer.

16.3.2.27 RSCAN0RFPTRx — Receive FIFO Buffer Access Pointer Register (x = 0 to 7)

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $0E04_H$ + (x × 0010_H)

Value after reset: $0000\ 0000_H$

15 to 0	RFTS [15:0]	Receive FIFO Buffer Timestamp Data Timestamp value of the received message can be read.

RFDLC[3:0] Bits

These bits indicate the data length of the message stored in the receive FIFO buffer.

RFPTR[11:0] Bits

These bits indicate the label information of the message stored in the receive FIFO buffer.

RFTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the receive FIFO buffer.

16.3.2.28 RSCAN0RFDF0x — Receive FIFO Buffer Access Data Field 0 Register (x = 0 to 7)

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $0E08_H$ + (x × 0010_H)

Value after reset: $0000\ 0000_H$

Table 16.44 RSCAN0CFCCk Register Contents (2/2)

Bit Position	Bit Name	Function
12	CFIM	Transmit/Receive FIFO Interrupt Source Select 0: • Receive mode / gateway mode When the number of received messages reaches the condition set by the CFIGCV[2:0] bits, a FIFO reception interrupt request is generated. • Transmit mode / gateway mode When the buffer becomes empty upon completion of message transmission, a FIFO transmission interrupt request is generated. 1: • Receive mode / gateway mode A FIFO reception interrupt request is generated each time a message has been received. • Transmit mode / gateway mode A FIFO transmission interrupt request is generated each time a message has been transmitted.
11	—	Reserved This bit is always read as 0. When writing, write 0.
10 to 8	CFDC [2:0]	Transmit/Receive FIFO Buffer Depth Configuration b10 b9 b8 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages 1 1 0: 64 messages 1 1 1: 128 messages
7 to 3	—	Reserved These bits are always read as 0. When writing, write 0.
2	CFTXIE	Transmit/Receive FIFO Transmission Interrupt Enable 0: Transmit/receive FIFO transmission interrupt is disabled. 1: Transmit/receive FIFO transmission interrupt is enabled.
1	CFRXIE	Transmit/Receive FIFO Reception Interrupt Enable 0: Transmit/receive FIFO reception interrupt is disabled. 1: Transmit/receive FIFO reception interrupt is enabled.
0	CFE	Transmit/Receive FIFO Buffer Enable 0: No transmit/receive FIFO buffer is used. 1: Transmit/receive FIFO buffers are used.

CFITT[7:0] Bits

These bits are used to set a message transmission interval for continuous message transmission from a transmit/receive FIFO buffer whose CFM[1:0] bits are set to 01_B (transmit mode) or 10_B (gateway mode).

Clear the CFE bit to 0 (no transmit/receive FIFO buffer is used) before modifying the CFITT[7:0] bits.

CFTML[3:0] Bits

These bits are used to set the number of the transmission buffer to be linked to the transmission and reception FIFO buffers when the CFM[1:0] bits are set to 01B (transmission mode) or 10B (gateway mode). Three transmission and reception FIFO buffers are available per channel and channel number m to which FIFO buffer k is allocated is the integer part of the quotient k/3. The number p of the transmission buffer to be linked to FIFO buffer k will be (16 × m) + CFTML[3:0].

For the relationship between transmission and reception FIFO buffer k and transmission buffer p, see **Table 16.11** and **Table 16.12**.

Setting the CFDC[2:0] bits to 001_B or greater enables the setting of the CFTML[3:0] bits.

Do not make a link to the transmission queue of the same channel or any transmission buffer allocated to the transmission queue. Modify these bits in global reset mode.

CFITR Bit

This bit is enabled when the CFITSS bit is 0.

When this bit is 0, the interval timer clock source is selected as the pclk/2 divided by the value of the ITRCP [15:0] bits of the RSCAN0GCFG register.

When this bit is 1, the interval timer clock source is selected as the pclk/2 divided by (ITRCP [15:0] bits × 10) of the RSCAN0GCFG register.

Modify this bit with the CFE bit set to 0 (no transmit/receive FIFO buffer is used).

CFITSS Bit

When this bit is 0, the clock selected by the CFITR bit is the count source of the interval timer.
When this bit is 1, the bit time clock of the channel that is liked to FIFO is the count source of the interval timer.

Modify this bit with the CFE bit set to 0 (no transmit/receive FIFO buffer is used).

CFM[1:0] Bits

These bits are used to select a transmit/receive FIFO mode. Modify these bits in global reset mode.

CFIGCV[2:0] Bits

These bits are used to select the timing of generating a transmit/receive FIFO reception interrupt request when the CFM[1:0] bits are set to 00_B (receive mode) or 10_B (gateway mode) and the CFIM bit is set to 0. An interrupt request is generated when the number of stored messages reaches the specified ratio (in eighths) of the storable messages set by the CFDC[2:0] bits.

When the CFDC[2:0] bits are set to 001_B (4 messages), set the CFIGCV[2:0] bits to 001_B, 011_B, 101_B, or 111_B.

Modify this bit in global reset mode.

CFIM Bits

This bit is used to select a transmit/receive FIFO interrupt source. Modify this bit in global reset mode.

CFDC[2:0] Bit

These bits are used to set the number of messages that can be stored in a single transmit/receive FIFO buffer. If no transmit/receive FIFO buffer is used, set these bits to 000_B. Modify these bits in global reset mode.

CFTXIE Bit

When this bit is set to 1 and the CFTXIF flag in the CFSTSk register becomes 1, a transmit/receive FIFO transmission interrupt request is generated.

Modify this bit with the CFE bit set to 0 (no transmit/receive FIFO buffer is used).

CFRXIE Bit

When this bit is set to 1 and the CFTXIF flag in the RSCAN0CFSTSk register becomes 1, a transmit/receive FIFO reception interrupt request is generated.

Modify this bit with the CFE bit set to 0.

CFE Bit

Setting this bit to 1 makes transmit/receive FIFO buffers available.

When this bit is set to 0 in transmit mode or gateway mode, if a message in the transmit/receive FIFO buffer is being transmitted or to be transmitted next, the transmit/receive FIFO buffer becomes empty after completion of transmission, CAN bus error detection, or arbitration lost. In other cases or in receive mode, the transmit/receive FIFO buffer becomes empty immediately.

This bit is cleared to 0 when the following conditions are met.

- Receive mode: Global reset mode
- Transmit mode or gateway mode: Channel reset mode

Modify this bit in the following mode.

- Receive mode: Global operating mode or global test mode
- Transmit mode or gateway mode: Channel communication mode or channel halt mode

16.3.2.31 RSCAN0CFSTSk — Transmit/Receive FIFO Buffer Status Register (k = 0 to 11)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0178_H + (k × 0004_H)

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CFMC[7:0]								—	—	—	CFTXIF	CFRXIF	CFMLT	CFFLL	CFEMP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.45 RSCAN0CFSTSk Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. When writing, write 0.
15 to 8	CFMC [7:0]	Transmit/Receive FIFO Message Counter The number of messages stored in the transmit/receive FIFO buffer is indicated.
7 to 5	—	Reserved These bits are always read as 0. When writing, write 0.
4	CFTXIF	Transmit/Receive FIFO Transmission Interrupt Request Flag 0: No transmit/receive FIFO transmission interrupt request is present. 1: A transmit/receive FIFO transmission interrupt request is present.
3	CFRXIF	Transmit/Receive FIFO Reception Interrupt Request Flag 0: No transmit/receive FIFO reception interrupt request is present. 1: A transmit/receive FIFO reception interrupt request is present.
2	CFMLT	Transmit/Receive FIFO Message Lost Flag 0: No transmit/receive FIFO message is lost. 1: A transmit/receive FIFO message is lost.
1	CFFLL	Transmit/Receive FIFO Buffer Full Status Flag 0: The transmit/receive FIFO buffer is not full. 1: The transmit/receive FIFO buffer is full.
0	CFEMP	Transmit/Receive FIFO Buffer Empty Status Flag 0: The transmit/receive FIFO buffer contains messages. 1: The transmit/receive FIFO buffer contains no message (buffer empty).

CFMC[7:0] Bits

The CFMC[7:0] bits indicate the following values that depend on the setting of the CFM[1:0] bits in the RSCAN0CFCCk register.

- When CFM[1:0] value is 01_B (transmit mode): Number of untransmitted messages in the buffer
- When CFM[1:0] value is 00_B (receive mode): Number of unread received messages in the buffer
- When CFM[1:0] value is 10_B (gateway mode): Number of untransmitted received messages in the buffer

These bits are cleared to 0 when any of the following conditions is met.

- When CFM[1:0] value is 00_B: global reset mode
- When CFM[1:0] value is 01_B or 10_B: channel reset mode

CFTXIF Flag

The CFTXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] value is 01_B or 10_B and the source selected by the CFIM bit in the RSCAN0CFCCk register occurred.

The CFTXIF flag is set to 0 when any of the following conditions is met.

- When 0 is written in the CFTXIF flag.
- When the CFM[1:0] value is 00_B: global reset mode
- When the CFM[1:0] is 01_B or 10_B: channel reset mode

This flag is set to 0 in global operation mode or global reset mode.

CFRXIF Flag

The CFRXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] value is 00_B or 10_B and the source selected by the CFIM bit in the RSCAN0CFCCk register occurred.

The CFRXIF flag is set to 0 when any of the following conditions is met.

- When 0 is written in the CFRXIF flag.
- When the CFM[1:0] value is 00_B: global reset mode
- When the CFM[1:0] is 01_B or 10_B: channel reset mode

This flag is set to 0 in global operation mode or global reset mode.

CFMLT Flag

The CFMLT flag is set to 1 when any of the following conditions is met.

- When transmit or receive FIFO buffer is full, and a new message is stored in this register. In this case, a new message is terminated.

The CFMLT flag is set to 0 when any of the following conditions is met.

- When 0 is written in the CFMLT flag.
- When the CFM[1:0] value is 00_B: global reset mode
- When the CFM[1:0] is 01_B or 10_B: channel reset mode

This flag is set to 0 in global operation mode or global reset mode.

CFFLL Flag

The CFFLL flag is set to 1 when any of the following conditions is met.

- When the number of messages stored in the transmit and receive FIFO buffer is equal to the FIFO buffer stages set by the CFDF[2:0] bits

The CFFLL flag is set to 0 when any of the following conditions is met.

- When the number of messages stored in the transmit and receive FIFO buffer is smaller than the FIFO buffer stages set by the CFDF[2:0] bits.
- When the CFE bit is 0 (no transmit/receive FIFO buffer is used): Not during transmit abort
- When the CFM[1:0] value is 00_B: global reset mode
- When the CFM[1:0] is 01_B or 10_B: channel reset mode

CFEMP Flag

The CFEMP flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] value is 00_B: All messages have been read or global reset mode.
- When the CFM[1:0] value is 01_B or 10_B: All messages have been transmitted or channel reset mode.
- When the CFE bit is 0 (no transmit/receive FIFO buffer is used): Not during transmit abort

The CFEMP flag is cleared to 0 when any of the following conditions is met.

- When the CFM[1:0] value is 00_B or 10_B: Any one of received messages has been stored in the transmit/receive FIFO buffer.
- When the CFM[1:0] value is 01_B: A value FF_H has been written to the RSCAN0CFPCTRk register after data was written to the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers.

NOTE

To clear the CFTXIF, CFRXIF, and CFMLT flags to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using a store instruction, set 1 to other flags. Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently clear the flags.

16.3.2.32 RSCAN0CFPCTRk — Transmit/Receive FIFO Buffer Pointer Control Register (k = 0 to 11)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $01D8_H$ + (k × 0004_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CFPC[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 16.46 RSCAN0CFPCTRk Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When writing, write 0.
7 to 0	CFPC [7:0]	Transmit/Receive FIFO Pointer Control • Receive mode: Writing FF_H to these bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. • Transmit mode: Writing FF_H to these bits moves the write pointer to the next stage of the transmit/receive FIFO buffer. • Gateway mode: Setting prohibited

CFPC[7:0] Bits

- Receive mode (CFM[1:0] value in the RSCAN0CFCCk register is 00_B):
  Writing FF_H to the CFPC[7:0] bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value (transmit/receive FIFO message counter) in the RSCAN0CFSTSk register is decremented by 1. Read the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers to read messages in the transmit/receive FIFO buffer, and then write FF_H to the CFPC[7:0] bits.
  Write FF_H to these bits when the CFE bit in the RSCAN0CFCCk register is set to 1 (transmit/receive FIFO buffers are used) and the CFEMP flag in the RSCAN0CFSTSk register is 0 (the transmit/receive FIFO buffer contains messages).
- Transmit mode (CFM[1:0] value in the RSCAN0CFCCk register is 01_B):
  Writing FF_H to the CFPC[7:0] bits stores the data written to the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers in the transmit/receive FIFO buffer and moves the write pointer to the next stage of the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value is incremented by 1. Write transmit messages to the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers and then write FF_H to the CFPC[7:0] bits.
  Write FF_H to these bits when the CFE bit in the RSCAN0CFCCk register is set to 1 and the

CFFLL flag in the RSCAN0CFSTSk register is 0 (the transmit/receive FIFO buffer is not full).

- Gateway mode (CFM[1:0] value in the RSCAN0CFCCk register is 10_B):
  Setting prohibited

16.3.2.33 RSCAN0CFIDk — Transmit/Receive FIFO Buffer Access ID Register (k = 0 to 11)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $0E80_H$ + (k × 0010_H)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.47 RSCAN0CFIDk Register Contents

Bit Position	Bit Name	Function
31	CFIDE	Transmit/Receive FIFO Buffer IDE bit 0: Standard ID 1: Extended ID
30	CFRTR	Transmit/Receive FIFO Buffer RTR bit 0: Data frame 1: Remote frame
29	THLEN	Transmit History Data Store Enable bit This bit is valid only when the CFM[1:0] value is 01_B (transmit mode). 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.
28 to 0	CFID [28:0]	Transmit/Receive FIFO Buffer ID Data • When CFM[1:0] value is 01_B (transmit mode): Set standard ID or extended ID. For standard ID, write an ID to bits b10 to b0 and write 0 to bits b28 to b11. • When CFM[1:0] value is 00_B (receive mode): Standard ID or extended ID in the received message can be read. For standard ID, read bits b10 to b0. Bits b28 to b11 are read as 0.

This register is writable only when the CFM[1:0] value of the RSCAN0CFCCk register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, set the ID format of the message to be transmitted from the transmit/receive FIFO buffer.

CFRTR Bit

This bit indicates the data format (data frame or remote frame) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, set the data format of the message to be transmitted from the transmit/receive FIFO buffer.

THLEN Bit

When this bit is set to 1, the transmit history data (label information, buffer number, and buffer type) of transmitted messages is stored in the transmit history buffer after transmission is completed.

This bit is enabled when the CFM[1:0] value is 01_B (transmit mode).

CFID[28:0] Bits

These bits indicate the ID of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B.

When the CFM[1:0] value is 01_B, set the ID of the message to be transmitted from the transmit/receive FIFO buffer.

16.3.2.34 RSCAN0CFPTRk — Transmit/Receive FIFO Buffer Access Pointer Register (k = 0 to 11)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $0E84_H$ + (k × 0010_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.48 RSCAN0CFPTRk Register Contents

Bit Position	Bit Name	Function
31 to 28	CFDLC [3:0]	Transmit/Receive FIFO Buffer DLC Data b31 b30 b29 b28 0 0 0 0 : 0 data bytes 0 0 0 1 : 1 data byte 0 0 1 0 : 2 data bytes 0 0 1 1 : 3 data bytes 0 1 0 0 : 4 data bytes 0 1 0 1 : 5 data bytes 0 1 1 0 : 6 data bytes 0 1 1 1 : 7 data bytes 1 X X X : 8 data bytes
27 to 16	CFPTR [11:0]	Transmit/Receive FIFO Buffer Label Data • When CFM[1:0] value is 01_B (transmit mode): Set the label information to be stored in the transmit history buffer. Only CFPTR[7:0] bits are valid. • When CFM[1:0] value is 00_B (receive mode): The label information of the received message can be read.
15 to 0	CFTS [15:0]	Transmit/Receive FIFO Buffer Timestamp Data These bits are valid only when the CFM[1:0] value is 00_B (receive mode). The timestamp value of the received message can be read.

This register is writable only when the CFM[1:0] value of the RSCAN0CFCCk register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFDLC[3:0] Bits

These bits indicate the data length of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, set the data length of the message to be transmitted from the transmit/receive FIFO buffer. If 9-byte or more data length is set, 8-byte data is transmitted.

CFPTR[11:0] Bits

These bits indicate the label information attached to the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, the CFPTR[7:0] value is stored in the transmit history buffer when message transmission has been completed.

CFTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the transmit/receive FIFO buffer.

These bits are valid when the CFM[1:0] value is 00_B.

16.3.2.35 RSCAN0CFDF0k — Transmit/Receive FIFO Buffer Access Data Field 0 Register (k = 0 to 11)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $0E88_H$ + (k × 0010_H)

Value after reset: $0000\ 0000_H$

8	CF0EMP	
7	RF7EMP	Receive FIFO Buffer Empty Status Flag 0: Receive FIFO buffer x contains an unread message. 1: Receive FIFO buffer x contains no unread message. (x = 0 to 7)
6	RF6EMP	
5	RF5EMP	
4	RF4EMP	
3	RF3EMP	
2	RF2EMP	
1	RF1EMP	
0	RF0EMP	

The RSCAN0FESTS register is set to $007F\ FFFF_H$ in global reset mode.

CFkEMP Flag (k = 0 to 11)

The CFkEMP flag is set to 1 when the CFEMP flag in the RSCAN0CFSTSk register is set to 1 (the transmit/receive FIFO buffer contains no message). When the CFEMP flag is cleared to 0 (the transmit/receive FIFO buffer contains messages), the CFkEMP flag is cleared to 0.

RFxEMP Flag (x = 0 to 7)

The RFxEMP flag is set to 1 when the RFEMP flag in the RSCAN0RFSTSx register is set to 1 (the receive FIFO buffer contains no unread message). When the RFEMP flag is cleared to 0 (the receive FIFO buffer contains unread messages), the RFxEMP flag is cleared to 0.

16.3.2.38 RSCAN0FFSTS — FIFO Full Status Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $023C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3	RF3FLL	
2	RF2FLL	
1	RF1FLL	
0	RF0FLL	

The RSCAN0FFSTS register is cleared to $0000\ 0000_H$ in global reset mode.

CFkFLL Flag (k = 0 to 11)

The CFkFLL flag is set to 1 when the CFFLL flag in the RSCAN0CFSTSk register is set to 1 (the transmit/receive FIFO buffer is full). When the CFFLL flag is cleared to 0, the CFkFLL flag is cleared to 0 (the transmit/receive FIFO buffer is not full).

RFxFLL Flag (x = 0 to 7)

The RFxFLL flag is set to 1 when the RFFLL flag in the RSCAN0RFSTSx register is set to 1 (the receive FIFO buffer is full). When the RFFLL flag is cleared to 0 (the receive FIFO buffer is not full), the RFxFLL flag is cleared to 0.

16.3.2.39 RSCAN0FMSTS — FIFO Message Lost Status Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0240_H

Value after reset: $0000\ 0000_H$

5	RF5MLT	
4	RF4MLT	
3	RF3MLT	
2	RF2MLT	
1	RF1MLT	
0	RF0MLT	

The RSCAN0FMSTS register is cleared to $0000\ 0000_H$ in global reset mode.

CFkMLT Flag (k = 0 to 11)

The CFkMLT flag is set to 1 when the CFMLT flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO message is lost). When the CFMLT flag is cleared to 0, the CFkMLT flag is cleared to 0.

RFxMLT Flag (x = 0 to 7)

The RFxMLT flag is set to 1 when the RFMLT flag in the RSCAN0RFSTSx register is set to 1 (a receive FIFO message is lost). When the RFMLT flag is cleared to 0, the RFxMLT flag is cleared to 0.

16.3.2.40 RSCAN0RFISTS — Receive FIFO Buffer Interrupt Flag Status Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0244_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.54 RSCAN0RFISTS Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are always read as 0.
7	RF7IF	Receive FIFO Buffer Interrupt Request Status Flag 0: No receive FIFO buffer x interrupt request is present. 1: A receive FIFO buffer x interrupt request is present. (x = 0 to 7)
6	RF6IF	
5	RF5IF	
4	RF4IF	
3	RF3IF	
2	RF2IF	
1	RF1F	
0	RF0F	

The RSCAN0RFISTS register is cleared to $0000\ 0000_H$ in global reset mode.

RFxIF Flag (x = 0 to 7)

The RFxIF flag is set to 1 when the RFIF flag in the RSCAN0RFSTSx register is set to 1 (a receive FIFO interrupt request is present). When the RFIF flag is cleared to 0, the RFxIF flag is cleared to 0.

16.3.2.41 RSCAN0CFRISTS — Transmit/Receive FIFO Buffer Reception Interrupt Flag Status Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0248_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.55 RSCAN0CFRISTS Register Contents

Bit Position	Bit Name	Function
31 to 12	—	Reserved These bits are always read as 0.
11	CF11RXIF	Transmit/Receive FIFO Buffer Reception Interrupt Request Status Flag 0: No transmit/receive FIFO buffer k reception interrupt request is present. 1: A transmit/receive FIFO buffer k reception interrupt request is present. (k = 0 to 11)
10	CF10RXIF	
9	CF9RXIF	
8	CF8RXIF	
7	CF7RXIF	
6	CF6RXIF	
5	CF5RXIF	
4	CF4RXIF	
3	CF3RXIF	
2	CF2RXIF	
1	CF1RXIF	
0	CF0RXIF	

The RSCAN0CFRISTS register is cleared to $0000\ 0000_H$ in global reset mode.

CFxRXIF Flag (x = 0 to 11)

The CFxRXIF flag is set to 1 when the CFRXIF flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO reception interrupt request is present). When the CFRXIF flag is cleared to 0, the CFxRXIF flag is cleared to 0.

16.3.2.42 RSCAN0CFTISTS — Transmit/Receive FIFO Buffer Transmission Interrupt Flag Status Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $024C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.56 RSCAN0CFTISTS Register Contents

Bit Position	Bit Name	Function
31 to 12	—	Reserved These bits are always read as 0.
11	CF11TXIF	Transmit/Receive FIFO Buffer Transmission Interrupt Request Status Flag 0: No transmit/receive FIFO buffer k transmission interrupt request is present. 1: A transmit/receive FIFO buffer k transmission interrupt request is present. (k = 0 to 11)
10	CF10TXIF	
9	CF9TXIF	
8	CF8TXIF	
7	CF7TXIF	
6	CF6TXIF	
5	CF5TXIF	
4	CF4TXIF	
3	CF3TXIF	
2	CF2TXIF	
1	CF1TXIF	
0	CF0TXIF	

The RSCAN0CFTISTS register is cleared to $0000\ 0000_H$ in global reset mode.

CFkTXIF Flag (k = 0 to 11)

The CFkTXIF flag is set to 1 when the CFTXIF flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO transmission interrupt request is present). When the CFTXIF flag is cleared to 0, the CFkTXIF flag is cleared to 0.

16.3.2.43 RSCAN0TMCp — Transmit Buffer Control Register (p = 0 to 63)

Access: This register can be read/written in 8 bits/unit

Address: <RS-CAN0_base> + 0250_H + (p × 0001_H)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	TMOM	TMTAR	TMTR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W*1	R/W*1

Note 1. The only effective value for writing to this bit is 1, which sets the bit. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.57 RSCAN0TMCp Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Reserved These bits are always read as 0. When writing, write 0.
2	TMOM	One-Shot Transmission Enable 0: One-shot transmission is disabled. 1: One-shot transmission is enabled.
1	TMTAR	Transmit Abort Request 0: Transmit abort is not requested. 1: Transmit abort is requested.
0	TMTR	Transmit Request 0: Transmission is not requested. 1: Transmission is requested.

When the RSCAN0TMCp register meets any of the following conditions, set it to 00_H.

- The RSCAN0TMCp register (p = m × 16 + of the CFTML[3:0] value) corresponds to the transmit buffer number selected by the CFTML[3:0] bits in the RSCAN0CFCCk register.
- The RSCAN0TMCp register (p = (m × 16 + 15) to (m × 16 + 15 the TXQDC[3:0] value)) corresponds to the transmit buffer allocated to the transmit queue by the TXQDC[3:0] bits in the RSCAN0TXQCCm register (m = 0 to 3).

Bits in the RSCAN0TMCp register are cleared to all 0 in channel reset mode. Modify the RSCAN0TMCp register in channel communication mode or channel halt mode.

TMOM Bit

Setting this bit to 1 enables one-shot transmission. If transmission fails, retransmission defined in the CAN protocol is not performed.

Modify the TMOM bit when the TMTRM flag in the RSCAN0TMSTSp register is set to 0. To set the TMOM bit to 1, also set the TMTR bit together.

TMTAR Bit

Setting this bit to 1 generates a transmit abort request for the message stored in the transmit buffer. However, a message that is being transmitted or to be transmitted next cannot be aborted.

When the TMTR bit is set to 1, the TMTAR bit can be set to 1.

The TMTAR bit is cleared to 0 when any of the following conditions is set. It is not cleared to 0 by writing 0 by the program.

- Transmission has been completed.
- Transmit abort has been completed.
- An error or arbitration lost has been detected.

If this bit becomes 0 at the timing when the program writes 1 to this bit, this bit becomes 0.

TMTR Bit

Setting this bit to 1 transmits the message stored in the transmit buffer.

The TMTR bit is cleared to 0 when any of the following conditions is met. It is not cleared to 0 by writing 0 by the program.

- Transmission has been completed.
- Transmit abort has been completed by setting the TMTAR bit to 1.
- An error or arbitration lost has been detected with the TMOM bit set to 1.

Set the TMTR bit to 1 when the TMTRF[1:0] flag in the RSCAN0TMSTSp register is 00_B.

16.3.2.44 RSCAN0TMSTSp — Transmit Buffer Status Register (p = 0 to 63)

Access: This register can be read/written in 8-bit units.

Address: <RS-CAN0_base> + $02D0_H$ + (p × 0001_H)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R

Table 16.58 RSCAN0TMSTSp Register Contents

Bit Position	Bit Name	Function
7 to 5	—	Reserved These bits are always read as 0. When writing, write 0.
4	TMTARM	Transmit Buffer Transmit Abort Request Status Flag 0: No transmit abort request is present. 1: A transmit abort request is present.
3	TMTRM	Transmit Buffer Transmit Request Status Flag 0: No transmit request is present. 1: A transmit request is present.
2,1	TMTRF[1:0]	Transmit Buffer Transmit Result Flag b2 b1 0 0: Transmission is in progress or no transmit request is present. 0 1: Transmit abort has been completed. 1 0: Transmission has been completed (without transmit abort request). 1 1: Transmission has been completed (with transmit abort request).
0	TMTSTS	Transmit Buffer Transmit Status Flag 0: Transmission is not in progress. 1: Transmission is in progress.

The RSCAN0TMSTSp register is cleared to all 0 in channel reset mode.

TMTARM Flag

The TMTARM flag is set to 1 when the TMTAR bit in the RSCAN0TMCp register is set to 1, and is cleared to 0 when the TMTAR bit is set to 0.

TMTRM Flag

The TMTRM flag is set to 1 when the TMTR bit in the RSCAN0TMCp register is set to 1, and is cleared to 0 when the TMTR bit is set to 0.

TMTRF[1:0] Flag

This flag indicates the result of transmission from the transmit buffer.

00_B: Transmission is in progress or no transmit request is present.

01_B: Transmission from the transmit buffer was aborted.

10_B: Transmission has been completed with the TMTAR bit in the RSCAN0TMCp register set to 0 (transmit abort is not requested).

11_B: Transmission has been completed with the TMTAR bit in the RSCAN0TMCp register set to 1 (transmit abort is requested).

Write 00_B to the TMTRF[1:0] flag in channel communication mode or channel halt mode. Do not write any value other than 00_B to this flag.

TMTSTS Flag

This flag is set to 1 when transmission from the transmit buffer starts, and is cleared to 0 when transmission from the transmit buffer has been completed or stopped due to a bus error or arbitration lost.

16.3.2.45 RSCAN0TMTRSTSy — Transmit Buffer Transmit Request Status Register y (y = 0, 1)

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0350_H + (y × 0004_H)

Value after reset: $0000\ 0000_H$

Table 16.59 RSCAN0TMTRSTSy Register Contents

Bit Position	Bit Name	Function
31 to 16	TMTRSTSp	Transmit Buffer Transmit Request Status Flag p (p = y × 32 + 31 to y × 32 + 16) 0: No transmit request is present. 1: A transmit request is present.
15 to 0	TMTRSTSp	Transmit Buffer Transmit Request Status Flag p (p = y × 32 + 15 to y × 32 + 0) 0: No transmit request is present. 1: A transmit request is present.

TMTRSTSp Flags (p = 0 to 63)

These flags indicate the status of the TMTR bit in the RSCAN0TMCp register.

When the TMTR bit is set to 1 (transmission is requested), the corresponding TMTRSTSp flag is set to 1.

The corresponding TMTRSTSp flag is cleared to 0 when the TMTR bit is set to 0 (transmission is not requested) or in channel reset mode.

Table 16.60 shows the bit allocation.

Table 16.60 TMTRSTSp Bit Allocation (1/2)

Table 16.61 RSCAN0TMTARSTSy Register Contents

Bit Position	Bit Name	Function
31 to 16	TMTARSTSp	Transmit Buffer Transmit Abort Request Status Flag p (p = y × 32 + 31 to y × 32 + 16) 0: No transmit abort request is present. 1: A transmit abort request is present.
15 to 0	TMTARSTSp	Transmit Buffer Transmit Abort Request Status Flag p (p = y × 32 + 15 to y × 32 + 0) 0: No transmit abort request is present. 1: A transmit abort request is present.

TMTARSTSp Flags (p = 0 to 63)

These flags indicate the status of the TMTAR bit in the RSCAN0TMCp register.

When the TMTAR bit is set to 1 (transmit abort is requested), the corresponding TMTARSTSp flag is set to 1.

The corresponding TMTARSTSp flag is cleared to 0 when the TMTAR bit is set to 0 (transmit abort is not requested) or in channel reset mode.

Table 16.62 shows the bit allocation.

Table 16.67 RSCAN0TMIECy Register Contents

Bit Position	Bit Name	Function
31 to 16	TMIEp	Transmit Buffer Interrupt Enable bits p (p = y × 32 + 31 to y × 32 + 16) 0: Transmit buffer interrupt is disabled. 1: Transmit buffer interrupt is enabled.
15 to 0	TMIEp	Transmit Buffer Interrupt Enable bits p (p = y × 32 + 15 to y × 32 + 0) 0: Transmit buffer interrupt is disabled. 1: Transmit buffer interrupt is enabled.

TMIEp Bits (p = 0 to 63)

When any of these bits is set to 1 and the corresponding transmission has been completed, a transmit buffer interrupt request is generated.

Modify these bits when the TMTRM flag in the corresponding RSCAN0TMSTSp register is 0 (no transmit request is present).

Write 0 to the bits corresponding to the transmit buffers linked to transmit/receive FIFO buffers or the transmit buffers allocated to the transmit queue.

Table 16.68 shows the bit allocation.

Table 16.69 RSCAN0TMIDp Register Contents

Bit Position	Bit Name	Function
31	TMIDE	Transmit Buffer IDE 0: Standard ID 1: Extended ID
30	TMRTR	Transmit Buffer RTR 0: Data frame 1: Remote frame
29	THLEN	Transmit History Data Store Enable 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.
28 to 0	TMID [28:0]	Transmit Buffer ID Data Set standard ID or extended ID. For standard ID, write an ID to bits b10 to b0 and write 0 to bits b28 to b11.

Modify this register when the TMTRM bit in the corresponding RSCAN0TMSTSp register is set to 0 (no transmit request is present). If this register is linked to any transmit/receive FIFO buffer, do not write data to this register. Write data only to the transmit buffer p (p = m × 16 + 15) when this register is allocated to the transmit queue.

TMIDE Bit

This bit is used to set the ID format of the message to be transmitted from the transmit buffer.

TMRTR Bit

This bit is used to set the data format of the message to be transmitted from the transmit buffer.

THLEN Bit

Setting this bit to 1 stores a transmitted message in the transmit history buffer after transmission is completed.

TMID[28:0] Bits

These bits are used to set the ID of the message to be transmitted from the transmit buffer.

16.3.2.51 RSCAN0TMPTRp — Transmit Buffer Pointer Register (p = 0 to 63)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 1004_H + (p × 0010_H)

Value after reset: $0000\ 0000_H$

Table 16.70 RSCAN0TMPTRp Register Contents

Bit Position	Bit Name	Function
31 to 28	TMDLC [3:0]	Transmit Buffer DLC Data b31 b30 b29 b28 0 0 0 0: 0 data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 x x x: 8 data bytes
27 to 24	—	Reserved These bits are always read as 0. When writing, write 0.
23 to 16	TMPTR [7:0]	Transmit Buffer Label Data Set the label information to be stored in the transmit history buffer.
15 to 0	—	Reserved These bits are always read as 0. When writing, write 0.

Modify this register when the TMTRM bit in the corresponding RSCAN0TMSTSp register is set to 0 (no transmit request is present). If this register is linked to any transmit/receive FIFO buffer, do not write data to this register. Write data only to the transmit buffer p (p = m × 16 + 15) when this register is allocated to the transmit queue.

TMDLC[3:0] Bits

These bits are used to set the data length of the message to be transmitted from the transmit buffer when the TMRTR bit in the RSCAN0TMIDp register is set to 0 (data frame). If a 9-byte (or more) data length is set, 8-byte data is transmitted.

When the TMRTR bit is set to 1 (remote frame), set the data length of a requested message.

TMPTR[7:0] Bits

When message transmission has been completed, the TMPTR[7:0] value is stored in the transmit history buffer.

16.3.2.52 RSCAN0TMDF0p — Transmit Buffer Data Field 0 Register (p = 0 to 63)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 1008_H + (p × 0010_H)

Value after reset: $0000\ 0000_H$

Table 16.72 RSCAN0TMDF1p Register Contents

Bit Position	Bit Name	Function
31 to 24	TMDB7 [7:0]	Transmit Buffer Data Byte 7
23 to 16	TMDB6 [7:0]	Transmit Buffer Data Byte 6
15 to 8	TMDB5 [7:0]	Transmit Buffer Data Byte 5
7 to 0	TMDB4 [7:0]	Transmit Buffer Data Byte 4 Set transmit buffer data.

Modify this register when the TMTRM bit in the corresponding RSCAN0TMSTSp register is set to 0 (no transmit request is present). If this register is linked to any transmit/receive FIFO buffer, do not write data to this register. Write data only to the transmit buffer p (p = m × 16 + 15) when this register is allocated to the transmit queue.

16.3.2.54 RSCAN0TXQCCm — Transmit Queue Configuration/Control Register (m = 0 to 3)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $03A0_H$ + (m × 0004_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.73 RSCAN0TXQCCm Register Contents

Bit Position	Bit Name	Function
31 to 14	—	Reserved These bits are always read as 0. When writing, write 0.
13	TXQIM	Transmit Queue Interrupt Source Select bit 0: When the buffer becomes empty upon completion of message transmission, a transmit queue interrupt source occurs. 1: A transmit queue interrupt source occurs each time a message has been transmitted.
12	TXQIE	Transmit Queue Interrupt Enable 0: Transmit queue interrupt is disabled. 1: Transmit queue interrupt is enabled.
11 to 8	TXQDC [3:0]	Transmit Queue Depth Configuration Setting these bits to g (g = 2 to 15) makes the “g + 1” transmit queue available. Setting these bits to 0 disables the transmit queue. Setting these bits to 1 is prohibited.
7 to 1	—	Reserved These bits are always read as 0. When writing, write 0.
0	TXQE	Transmit Queue Enable 0: The transmit queue is not used. 1: The transmit queue is used.

TXQIM Bit

This bit is used to select a transmit queue interrupt source. Modify this bit in channel reset mode.

TXQIE Bit

When the TXQIE bit is set to 1 and the source selected by the TXQIM bit occurs, an interrupt request is generated.

Set the TXQE bit to 0 when modifying the TXQIE bit.

TXQDC[3:0] Bits

These bits are used to set the number of transmit buffers to be allocated to the transmit queue. Transmit buffers are allocated to the transmit queues in the descending order of buffer numbers from (m × 16 + 15) to (m × 16 + 0). For an example of buffer allocation, see **Table 16.9**. Modify these bits only in the channel reset mode.

TXQE Bit

Setting this bit to 1 makes the transmit queue available. Modify this bit in channel communication mode or channel halt mode. This bit is cleared to 0 in channel reset mode.

Set the TXQDC[3:0] bits to 0010_B or more before setting the TXQE bit to 1.

16.3.2.55 RSCAN0TXQSTSm — Transmit Queue Status Register (m = 0 to 3)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $03C0_H$ + (m × 0004_H)

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQIF	TXQFLL	TXQEMP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.74 RSCAN0TXQSTSm Register Contents

Bit Position	Bit Name	Function
31 to 13	—	Reserved These bits are always read as 0. When writing, write 0.
12 to 8	—	The read value is the undefined. When writing, write 0.
7 to 3	—	The read value is 0. When writing, write 0.
2	TXQIF	Transmit Queue Interrupt Request Flag 0: No transmit queue interrupt request is present. 1: A transmit queue interrupt request is present.
1	TXQFLL	Transmit Queue Full Status Flag 0: The transmit queue is not full. 1: The transmit queue is full.
0	TXQEMP	Transmit Queue Empty Status Flag 0: The transmit queue contains messages. 1: The transmit queue contains no message (transmit queue empty).

TXQIF Flag

The TXQIF flag is set to 1 when the source set by the TXQIM bit in the RSCAN0TXQCCm register has occurred.

The TXQIF flag is cleared to 0 in channel reset mode or by writing 0 to this flag. This flag is not cleared to 0 by setting the TXQE bit in the RSCAN0TXQCCm register to 0 (the transmit queue is not used).

TXQFLL Flag

The TXQFLL flag is set to 1 when the number of messages set for the transmit queue matches the transmit queue depth set by the TXQDC[3:0] bits in the RSCAN0TXQCCm register.

This flag is cleared to 0 in any of the following cases.

- The number of messages set for the transmit queue is smaller than the transmit queue depth set by the TXQDC[3:0] bits.
- In channel reset mode

TXQEMP Flag

The TXQEMP flag is cleared to 0 when even a single message is set for the transmit queue.

This flag is set to 1 in any of the following cases.

- The TXQE bit is set to 0 (the transmit queue is not used).
- The transmit queue becomes empty.
- In channel reset mode

16.3.2.56 RSCAN0TXQPCTRm — Transmit Queue Pointer Control Register (m = 0 to 3)

Access: This register can be written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $03E0_H$ + (m × 0004_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.75 RSCAN0TXQPCTRm Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When writing, write 0.
7 to 0	TXQPC [7:0]	Transmit Queue Pointer Control Writing FF_H to these bits moves the write pointer of the transmit queue to the next queue.

TXQPC[7:0] Bits

Writing FF_H to the TXQPC[7:0] bits moves the write pointer to the next transmit queue and generates a transmit request of the message. Write transmit messages to the RSCAN0TMIDp, RSCAN0TMPTRp, RSCAN0TMDF0p, and RSCAN0TMDF1p registers (p = m × 16 + 15) before writing FF_H to the TXQPC[7:0] bits.

Write FF_H when the TXQE bit in the RSCAN0TXQCCm register is 1 (the transmit queue is used) and the TXQFLL flag in the RSCAN0TXQSTSm register is 0 (not full).

16.3.2.57 RSCAN0THLCCm — Transmit History List Configuration/Control Register (m = 0 to 3)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0400_H + (m × 0004_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Table 16.76 RSCAN0THLCCm Register Contents

Bit Position	Bit Name	Function
31 to 11	—	Reserved These bits are always read as 0. When writing, write 0.
10	THLDTE	Transmit History Target Buffer Select 0: Entry from transmit/receive FIFO buffers and transmit queue 1: Entry from transmit buffers, transmit/receive FIFO buffers, and transmit queue
9	THLIM	Transmit History Interrupt Source Select 0: When 12 sets of data have been stored in the transmit history buffer 1: When a single set of transmit history data has been stored
8	THLIE	Transmit History Interrupt Enable 0: Transmit history interrupt is disabled. 1: Transmit history interrupt is enabled.
7 to 1	—	Reserved These bits are always read as 0. When writing, write 0.
0	THLE	Transmit History Buffer Enable 0: Transmit history buffer is not used. 1: Transmit history buffer is used.

THLDTE Bit

When this bit is set to 0, the transmit history data of messages transmitted from transmit/receive FIFO buffers and the transmit queue is stored in the transmit history buffer. When this bit is set to 1, the transmit history data of messages transmitted from transmit buffers, transmit/receive FIFO buffers, and the transmit queue is stored in the transmit history buffer.

Modify this bit only in channel reset mode.

THLIM Bit

This bit is used to select a transmit history interrupt source.

Modify this bit only in channel reset mode.

THLIE Bit

When the THLIE bit is set to 1 and the source selected by the THLIM bit has occurred, a transmit history interrupt request is generated. Modify the THLIE bit with the THLE bit set to 0.

THLE Bit

Setting this bit to 1 makes the transmit history buffer available. When data transmission from the buffer selected by the THLDTE bit has been completed, the transmit history data of the transmitted messages is stored in the transmit history buffer.

Modify this bit in channel communication mode or channel halt mode.

16.3.2.58 RSCAN0THLSTSm — Transmit History List Status Register (m = 0 to 3)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0420_H + (m × 0004_H)

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	THLMC[4:0]					—	—	—	—	THLIF	THLELT	THLFLL	THL EMP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.77 RSCAN0THLSTSm Register Contents

Bit Position	Bit Name	Function
31 to 13	—	Reserved These bits are always read as 0. When writing, write 0.
12 to 8	THLMC [4:0]	Transmit History Buffer Unread Data Counter These bits indicate the number of unread data sets stored in the transmit history buffer.
7 to 4	—	Reserved These bits are always read as 0. When writing, write 0.
3	THLIF	Transmit History Interrupt Request Flag 0: No transmit history interrupt request is present. 1: A transmit history interrupt request is present.
2	THLELT	Transmit History Buffer Overflow Flag 0: Transmit history buffer overflow has not occurred. 1: Transmit history buffer overflow has occurred.
1	THLFLL	Transmit History Buffer Full Status Flag 0: Transmit history buffer is not full. 1: Transmit history buffer is full.
0	THLEMP	Transmit History Buffer Empty Status Flag 0: Transmit history buffer contains unread data. 1: Transmit history buffer contains no unread data (buffer empty).

THLMC[4:0] Bits

These bits indicate the number of unread data sets stored in the transmit history buffer.

THLIF Flag

The THLIF flag is set to 1 when the interrupt source set by the THLIM bit in the RSCAN0THLCCm register has occurred.

This flag is cleared to 0 in channel reset mode or by writing 0 to this flag by the program.

THLELT Flag

The THLELT flag is set to 1 when it is attempted to store new transmit history data while the transmit history buffer is full. In this case, the new data is discarded. This flag becomes 0 in channel reset mode or by writing 0 to this flag.

THLFLL Flag

The THLFLL flag is set to 1 when 16 data sets have been stored in the transmit history buffer, and is cleared to 0 when the number of data sets stored in the transmit history buffer has decreased to less than 16. This bit is also cleared to 0 in channel reset mode or when the THLE bit in the RSCAN0THLCCm register is set to 0 (transmit history buffer is not used).

THLEMP Flag

The THLEMP flag is cleared to 0 when even a single set of transmit history data has been stored in the transmit history buffer.

This flag is set to 1 when all the data in the transmit history buffer has been read. This flag is also set to 1 in channel reset mode or when the THLE bit in the RSCAN0THLCCm register is set to 0 (transmit history buffer is not used).

NOTE

To clear the THLIF and THLELT flags to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using a store instruction, set 1 to other flags. Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently clear the flags.

16.3.2.59 RSCAN0THLACCm — Transmit History List Access Register (m = 0 to 3)

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 1800_H + (m × 0004_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.78 RSCAN0THLACCm Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0.
15 to 8	TID[7:0]	Label Data The label information of stored data can be read.
7	—	Reserved This bit is always read as 0. When writing, write 0.
6 to 3	BN[3:0]	Buffer Number Data The buffer number of transmit source (transmit buffer, transmit/receive FIFO or transmit queue) can be read.
2 to 0	BT[2:0]	Buffer Type Data b2 b1 b0 0 0 1: Transmit buffer 0 1 0: Transmit/receive FIFO buffer 1 0 0: Transmit queue

TID[7:0] Bits

These bits indicate the label information of transmit history data stored in the transmit history buffer.

BN[3:0] Bits

These bits indicate the transmit source buffer number of transmit history data stored in the transmit history buffer.

BT[2:0] Bits

These bits indicate the transmit source buffer type of transmit history data stored in the transmit history buffer.

16.3.2.60 RSCAN0THLPCTRm — Transmit History List Pointer Control Register (m = 0 to 3)

Access: This register can be written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0440_H + (m × 0004_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	THLPC[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 16.79 RSCAN0THLPCTRm Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When writing, write 0.
7 to 0	THLPC [7:0]	Transmit History List Pointer Control Writing FF_H to these bits moves the read pointer to the next unread data in the transmit history buffer.

THLPC[7:0] Bits

When the THLPC[7:0] bits are set to FF_H, the read pointer moves to the next data in the transmit history buffer. At this time, the THLMC[4:0] (transmit history buffer unread data counter) value in the RSCAN0THLSTSm register is decremented by 1. After reading the RSCAN0THLACCm register, write FF_H to the THLPC[7:0] bits.

Write FF_H to the THLPC[7:0] bits when the THLE bit in the RSCAN0THLCCm register is set to 1 (transmit history buffer is used) and the THLEMP flag in the RSCAN0THLSTSm register is 0.

16.3.2.61 RSCAN0GTSTCFG — Global Test Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 0468_H

Value after reset: $0000\ 0000_H$

Table 16.80 RSCAN0GTSTCFG Register Contents

Bit Position	Bit Name	Function
31 to 23	—	Reserved These bits are always read as 0. When writing, write 0.
22 to 16	RTMPS [6:0]	RAM Test Page Configuration Set a value within a range of page 0 (00_H) to page 47 ($2F_H$).
15 to 4	—	Reserved These bits are always read as 0. When writing, write 0.
3	C3ICBCE	CAN3 Inter-Channel Communication Test Enable 0: CAN3 inter-channel communication test is disabled. 1: CAN3 inter-channel communication test is enabled.
2	C2ICBCE	CAN2 Inter-Channel Communication Test Enable 0: CAN2 inter-channel communication test is disabled. 1: CAN2 inter-channel communication test is enabled.
1	C1ICBCE	CAN1 Inter-Channel Communication Test Enable 0: CAN1 inter-channel communication test is disabled. 1: CAN1 inter-channel communication test is enabled.
0	C0ICBCE	CAN0 Inter-Channel Communication Test Enable 0: CAN0 inter-channel communication test is disabled. 1: CAN0 inter-channel communication test is enabled.

Modify the RSCAN0GTSTCFG register in global test mode.

RTMPS[6:0] Bits

These bits are used to set the RAM test target page number for RAM test. Set a value from 00_H to $2F_H$.

C3ICBCE Bit

Setting this bit to 1 enables channel 3 inter-channel communication test.

C2ICBCE Bit

Setting this bit to 1 enables channel 2 inter-channel communication test.

C1ICBCE Bit

Setting this bit to 1 enables channel 1 inter-channel communication test.

C0ICBCE Bit

Setting this bit to 1 enables channel 0 inter-channel communication test.

16.3.2.62 RSCAN0GTSTCTR — Global Test Control Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + $046C_H$

Value after reset: $0000\ 0000_H$

2	RTME	RAM Test Enable 0: RAM test is disabled. 1: RAM test is enabled.
1	—	Reserved These bits are always read as 0. When writing, write 0.
0	ICBCTME	Inter-Channel Communication Test Enable 0: Inter-channel communication test is disabled. 1: Inter-channel communication test is enabled.

RTME Bit

Setting this bit to 1 enables RAM test. Modify this bit in global test mode.

1. Set the GMDC[1:0] bits in the RSCAN0GCTR register to 10_B (global test mode).
2. Set the RTME bit to 1.
3. Check that the RTME bit is set to 1.

ICBCTME Bit

When this bit is set to 1, a communication test is enabled between the channels for which the CmICBCE bit (m = 0 to 3) in the RSCAN0GTSTCFG register has been set to 1. Modify the ICBCTME bit only in global test mode.

16.3.2.63 RSCAN0GLOCKK — Global Lock Key Register

Access: This register can be written in 16, 32 bits/unit

Address: <RS-CAN0_base> + $047C_H$

Value after reset: $0000\ 0000_H$.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LOCK[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1

Note 1. Writing to these bits is effective only when the RS-CAN module is in global test mode.

Table 16.82 RSCAN0GLOCKK Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are read as an undefined value. When writing, write 0.
15 to 0	LOCK[15:0]	Lock Key These bits are key bits to release protection of test mode.

The RSCAN0GLOCKK register is a write-only register to release protection of special test bits. For protection released data, **Section 16.5.4.2, Procedure for Releasing the Protection**.

LOCK[15:0] Bits

Writing the protection release data to the LOCK[15:0] bits in succession enables writing 1 to the RTME bit in the GTSTCTR register.

After the protection has been released, writing to the I/O register area of CAN (<RS-CAN0_base> + 0000_H to <RS-CAN0_base> + $04FF_H$), excluding the RAM, enables the protection again.

Reading from the register of the CAN I/O register area or reading from/wring to other areas does not enable the protection.

16.3.2.64 RSCAN0RPGACCr — RAM Test Page Access Register (r = 0 to 63)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RS-CAN0_base> + 1900_H + (r × 0004_H)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RDTA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDTA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.83 RSCAN0RPGACCr Register Contents

Bit Position	Bit Name	Function
31 to 0	RDTA [31:0]	RAM Data Test Access Data can be read and written in CAN RAM.

Modify the RSCAN0RPGACCr register in global test mode with the RTME bit in the RSCAN0GTSTCTR register set to 1 (RAM test is enabled).

The RSCAN0RPGACCr register is readable and writable when the RTME bit is set to 1.

16.4 Functions

16.4.1 Interrupt Sources

The RS-CAN module has 14 interrupts that are grouped into global interrupts and channel interrupts.

- Global interrupts (2 interrupts):
  - Receive FIFO interrupt
  - Global error interrupt
- Channel interrupts (3 interrupts per channel):
  CANm transmission interrupt (m = 0 to 3)
  - CANm transmission complete interrupt
  - CANm transmission abort interrupt
  - CANm transmit/receive FIFO transmission complete interrupt (in transmit mode or gateway mode)
  - CANm transmit history interrupt
  - CANm transmit queue interrupt

  CANm transmit/receive FIFO reception complete interrupt (in receive mode or gateway mode)

  CANm error interrupt

When an interrupt request is generated, the corresponding interrupt request flag is set to 1 (interrupt request present). In that case, when the interrupt enable bit is 1 (enabling interrupts), an interrupt request is output from the RS-CAN module. (Generation of interrupts also depends on the interrupt control register settings of the interrupt controller.)

Setting the interrupt request flag to 0 (no interrupt request present) or setting the interrupt enable bit to 0 (disabling interrupts) clears the interrupt request. The interrupt request is kept being output until the interrupt request flag is cleared.

Table 16.84 lists the CAN interrupt sources. **Figure 16.2** shows the CAN global interrupt block diagram, and **Figure 16.3** shows the CAN channel interrupt block diagram.

Table 16.84 List of CAN Interrupt Sources

		Interrupt Source	Corresponding Interrupt Request Flag	Corresponding Interrupt Enable Bit
Global interrupts	Receive FIFO	Receive FIFO 0	RFIF flag in the RSCAN0RFSTS0 register	RFIE bit in the RSCAN0RFCC0 register
		Receive FIFO 1	RFIF flag in the RSCAN0RFSTS1 register	RFIE bit in the RSCAN0RFCC1 register
		Receive FIFO 2	RFIF flag in the RSCAN0RFSTS2 register	RFIE bit in the RSCAN0RFCC2 register
		Receive FIFO 3	RFIF flag in the RSCAN0RFSTS3 register	RFIE bit in the RSCAN0RFCC3 register
		Receive FIFO 4	RFIF flag in the RSCAN0RFSTS4 register	RFIE bit in the RSCAN0RFCC4 register
		Receive FIFO 5	RFIF flag in the RSCAN0RFSTS5 register	RFIE bit in the RSCAN0RFCC5 register
		Receive FIFO 6	RFIF flag in the RSCAN0RFSTS6 register	RFIE bit in the RSCAN0RFCC6 register
		Receive FIFO 7	RFIF flag in the RSCAN0RFSTS7 register	RFIE bit in the RSCAN0RFCC7 register
	Global error		DEF flag in the RSCAN0GERFL register MES flag in the RSCAN0GERFL register THLES flag in the RSCAN0GERFL register	DEIE bit in the RSCAN0GCTR register MEIE bit in the RSCAN0GCTR register THLEIE bit in the RSCAN0GCTR register
Channel interrupts (m = 0 to 3)	CANm transmit	CANm transmit complete	TMTRF[1:0] flag in the RSCAN0TMSTSp register	TMIE bit in the RSCAN0TMIECy register
		CANm transmit abort	TMTRF[1:0] flag in the RSCAN0TMSTSp register	TAIE bit in the RSCAN0CmCTR register
		CANm transmit/ receive FIFO transmit complete	CFTXIF flag in the RSCAN0CFSTSk register	CFTXIE bit in the RSCAN0CFCCk register
		CANm transmit queue	TXQIF flag in the RSCAN0TXQSTSm register	TXQIE bit in the RSCAN0TXQCCm register
		CANm transmit history	THLIF flag in the RSCAN0THLSTSm register	THLIE bit in the RSCAN0THLCCm register
	CANm transmit/receive FIFO reception complete		CFRXIF flag in the RSCAN0CFSTSk register	CFRXIE bit in the RSCAN0CFCCk register
	CANm error		• BEF flag in the RSCAN0CmERFL register • ALF flag in the RSCAN0CmERFL register • BLF flag in the RSCAN0CmERFL register • OVLF flag in the RSCAN0CmERFL register • BORF flag in the RSCAN0CmERFL register • BOEF flag in the RSCAN0CmERFL register • EPF flag in the RSCAN0CmERFL register • EWF flag in the RSCAN0CmERFL register	• BEIE bit in the RSCAN0CmCTR register • ALIE bit in the RSCAN0CmCTR register • BLIE bit in the RSCAN0CmCTR register • OLIE bit in the RSCAN0CmCTR register • BORIE bit in the RSCAN0CmCTR register • BOEIE bit in the RSCAN0CmCTR register • EPIE bit in the RSCAN0CmCTR register • EWIE bit in the RSCAN0CmCTR register

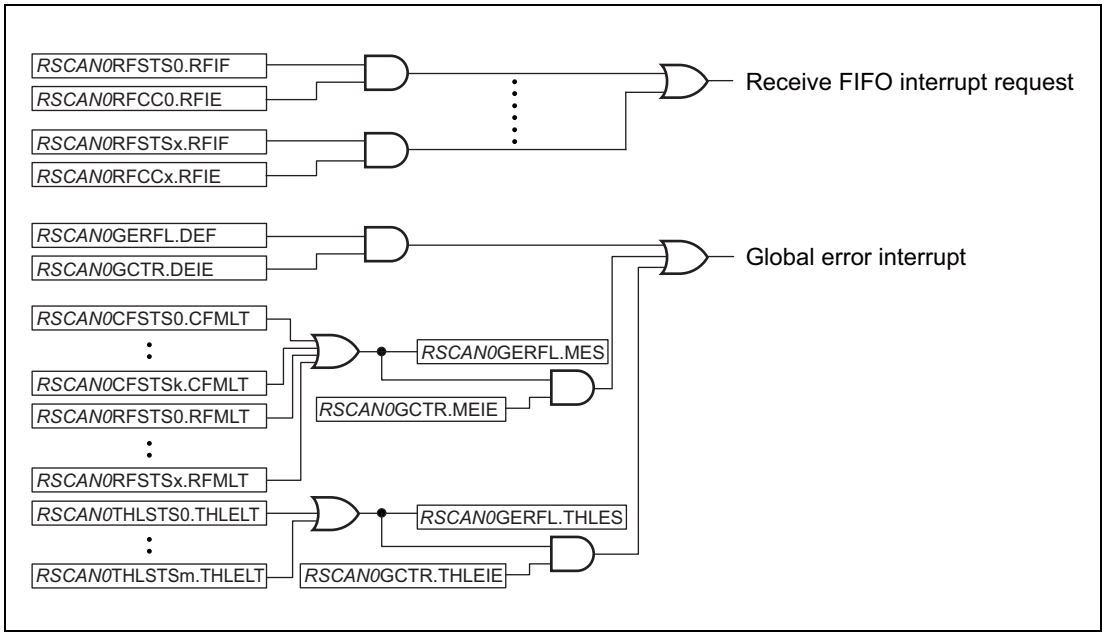

Figure 16.2 CAN Global Interrupt Block Diagram

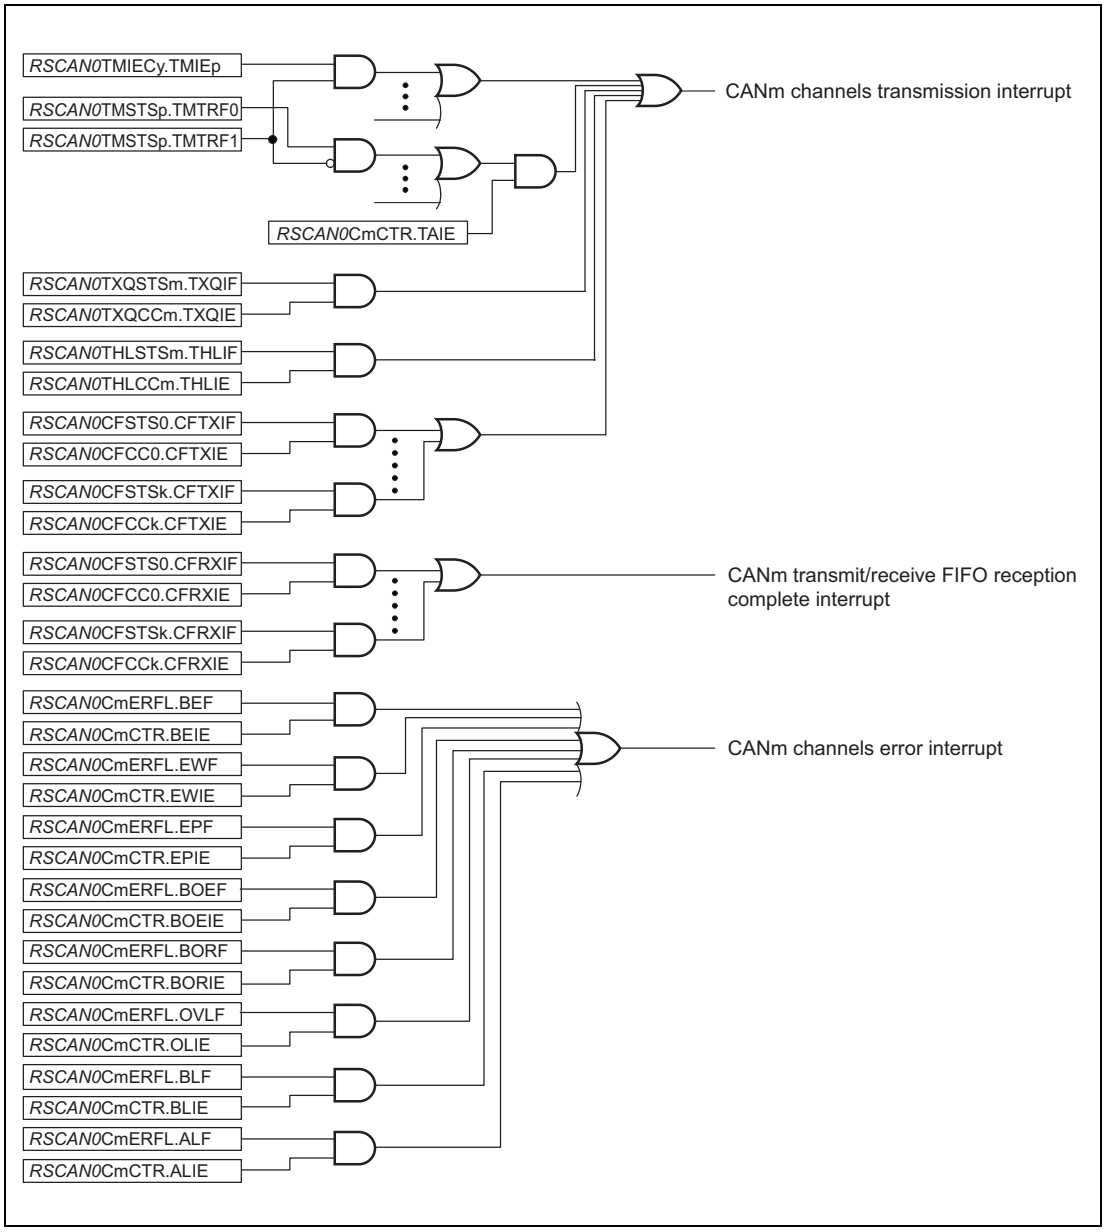

Figure 16.3 CAN Channel Interrupt Block Diagram

16.4.2 CAN Modes

The RS-CAN module has four global modes to control entire RS-CAN module status and four channel modes to control individual channel status. Details of global modes are described in **Section 16.4.2.1, Global Modes**, and details of channel modes are described in **Section 16.4.2.6, Channel Modes**.

- Global stop mode: Stops clocks of the entire module to achieve low power consumption.
- Global reset mode: Performs initial settings for the entire module.
- Global test mode: Performs test settings and performs RAM test.
- Global operating mode: Makes the entire module operable.
- Channel stop mode: Stops the channel clock.
- Channel reset mode: Performs initial settings for the channel.
- Channel halt mode: Stops CAN communication and performs channel test.
- Channel communication mode: Performs CAN communication.

16.4.2.1 Global Modes

Figure 16.4 shows the transitions of global modes.

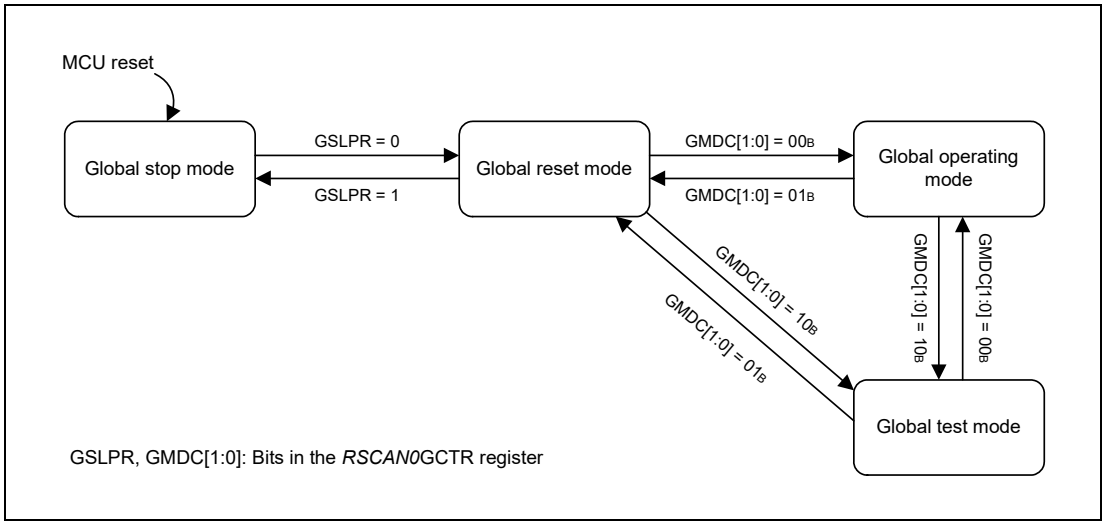

Figure 16.4 Transitions of Global Modes

Channel modes may transition in accordance with transitions of global modes. **Table 16.85** shows the transitions of channel modes depending on the global mode setting (GMDC[1:0] bits and GSLPR bit).

Table 16.85 Transitions of Channel Modes Depending on Global Mode Setting (GMDC[1:0] and GSLPR Bits)

Channel Mode before Setting	Channel Mode after Setting			
	GMDC[1:0] = 00_B GSLPR = 0 (Global Operating)	GMDC[1:0] = 10_B GSLPR = 0 (Global Test)	GMDC[1:0] = 01_B GSLPR = 0 (Global Reset)	GMDC[1:0] = 01_B GSLPR = 1 (Global Stop)
Channel communication	Channel communication	Channel halt	Channel reset	Transition prohibited
Channel halt	Channel halt	Channel halt	Channel reset	Transition prohibited
Channel reset	Channel reset	Channel reset	Channel reset	Channel stop
Channel stop	Channel stop	Channel stop	Channel stop	Channel stop

Note: GMDC[1:0], GSLPR: Bits in the RSCAN0GCTR register

Table 16.86 shows the transition time between each global mode.

Table 16.86 Transition Time of Global Mode

Mode before Transition	Mode after Transition	Maximum Transition Time
Global stop	Global reset	3 clocks of pclk
Global reset	Global stop	3 clocks of pclk
Global reset	Global test	10 clocks of pclk
Global reset	Global operation	10 clocks of pclk
Global test	Global reset	3 clocks of pclk
Global test	Global operation	3 clocks of pclk
Global operation	Global reset	3 clocks of pclk
Global operation	Global test	2 times of CAN frame*1

Note 1. CAN frame time of the channel whose communication speed is lowest among the channels in use.

16.4.2.2 Global Stop Mode

In global stop mode, the CAN clocks do not run and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained. In global stop mode, only the clock for CPU writing to the GSLPR bit is running.

After the MCU is reset, the RS-CAN module transitions to global stop mode. Setting the GSLPR bit in the RSCAN0GCTR register to 1 (in global stop mode) in global reset mode sets the CSLPR bit in each of the RSCAN0CmCTR register to 1 (channel stop mode). If all channels are forcibly caused to transition to channel stop mode, the RS-CAN module transitions to global stop mode. The GSLPR bit should not be modified in global operating mode and global test mode.

16.4.2.3 Global Reset Mode

In global reset mode, RS-CAN module settings are performed. When the RS-CAN module transitions to global reset mode, some registers are initialized. **Table 16.89** and **Table 16.90** list the registers to be initialized.

Setting the GMDC[1:0] bits in the RSCAN0GCTR register to 01_B sets the CHMDC[1:0] bits in each of the RSCAN0CmCTR register (m = 0 to 3) to 01_B (channel reset mode). If all channels are forcibly caused to transition to channel reset mode, the RS-CAN module transitions to global reset mode. Channels that are already in channel reset mode or channel stop mode do not transition (because the CHMDC[1:0] bits have already been set to 01_B).

16.4.2.4 Global Test Mode

In global test mode, settings for test-related registers are performed. When the RS-CAN module transitions to global test mode, all CAN communications are disabled.

Setting the GMDC[1:0] bits in the RSCAN0GCTR register to 10_B sets the CHMDC[1:0] bits in each of the RSCAN0CmCTR register to 10_B (channel halt mode). If all channels are forcibly caused to transition to channel halt mode, the RS-CAN module transitions to global test mode. Channels that are in channel stop mode, channel reset mode, or channel halt mode do not transition.

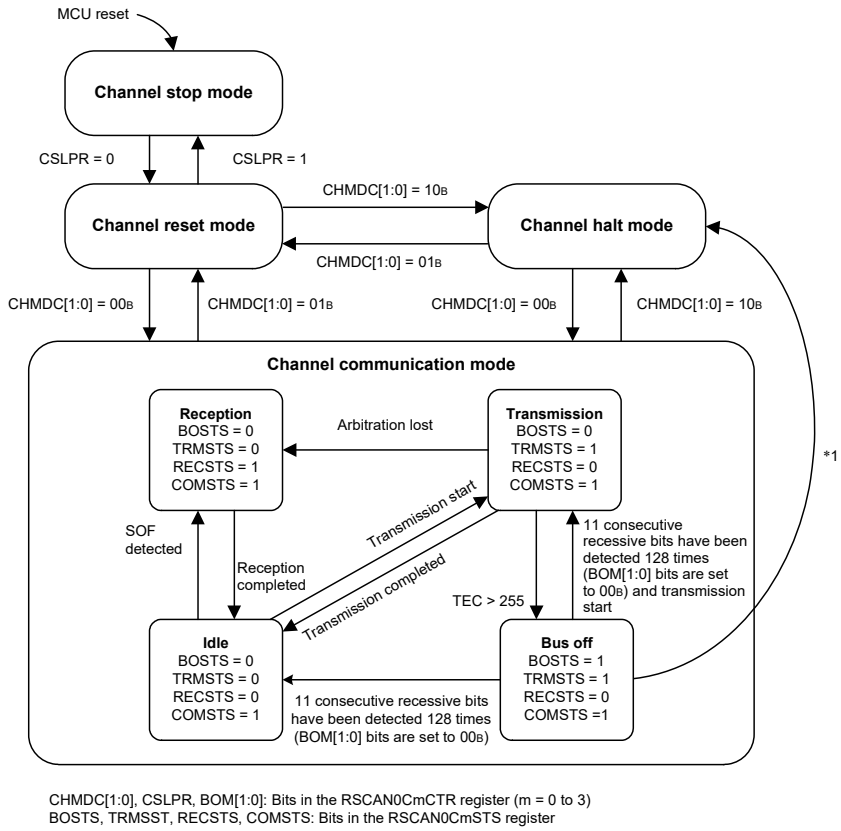
16.4.2.5 Global Operating Mode

In global operating mode, entire RS-CAN module operates.

When the GMDC[1:0] bits in the RSCAN0GCTR register are set to 00_B, the RS-CAN module transitions to global operating mode.

16.4.2.6 Channel Modes

Figure 16.5 shows a channel mode state transition chart. **Table 16.87** shows transition time between channel modes.



Note 1. Timing of transition from bus off state to channel halt mode
When BOM[1:0] = 01_B: Transition to channel halt CHMDC when TEC exceeds 255
When BOM[1:0] = 10_B: Transition to channel halt CHMDC when 11 consecutive recessive bits have been detected 128 times
When BOM[1:0] = 11_B: Transition to channel halt CHMDC when the CHMDC[1:0] bits are set to 10_B

Figure 16.5 Channel Mode State Transition Chart

Table 16.87 Transition Time of Channel Mode (m = 0 to 3)

Mode before Transition	Mode after Transition	Maximum Transition Time
Channel stop	Channel reset	3 clocks of pclk
Channel reset	Channel stop	3 clocks of pclk
Channel reset	Channel Halt	3 CANm bit time
Channel reset	Channel communication	2 CANm bit time
Channel Halt	Channel reset	3 clocks of pclk
Channel Halt	Channel communication	3 CANm bit time
Channel communication	Channel reset	3 clocks of pclk
Channel communication	Channel Halt	2 times of CANm frame

16.4.2.7 Channel Stop Mode

In channel stop mode, clocks are not supplied to channels and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained.

Each channel enters channel stop mode after the MCU is reset. The channel transitions to channel stop mode when the CSLPR bit in the RSCAN0CmCTR register (m = 0 to 3) is set to 1 (channel stop mode) in channel reset mode. The CSLPR bit should not be modified in channel communication mode and channel halt mode.

16.4.2.8 Channel Reset Mode

In channel reset mode, channel settings are performed. When a channel transitions to channel reset mode, some channel-related registers are initialized. **Table 16.89** lists the registers to be initialized.

When the CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 01_B (channel reset mode) during CAN communication, communication is terminated before it is completed and the channel transitions to channel reset mode. **Table 16.88** shows the operation when the CHMDC[1:0] bits are set to 01_B (channel reset mode) during CAN communication.

16.4.2.9 Channel Halt Mode

In channel halt mode, settings for test-related registers of channels are performed. When a channel transitions to channel halt mode, CAN communication of the channel stops.

Table 16.88 shows operation when the CHMDC[1:0] bits are set to 10_B (channel halt mode) during CAN communication.

Table 16.88 Operation When a Channel Transitions to Channel Reset Mode/Channel Halt Mode

Mode	During Reception	During Transmission	Bus Off State
Channel reset (CHMDC[1:0] = "01_B")	Transitions to channel reset mode before reception is completed.*1	Transitions to channel reset mode before transmission is completed.*1	Transitions to channel reset mode before bus off recovery is completed.
Channel halt*3 (CHMDC[1:0] = "10_B")	Transitions to channel halt mode after reception is completed.*2	Transitions to channel halt mode after transmission is completed.	[When BOM[1:0] = 00_B] Transitions to channel halt mode (CHMDC[1:0] = 10_B) only after bus off recovery. [When BOM[1:0] = 01_B] Transitions to channel halt mode automatically when the condition for transition to bus off state is met. [When BOM[1:0] = 10_B] Transitions to channel halt mode automatically after bus off recovery is completed. [When BOM[1:0] = 11_B] Transitions to channel halt mode immediately after the CHMDC[1:0] bits are set to 10_B before bus off recovery is completed.

Note 1. To allow transition to channel reset mode after communication is completed, set the CHMDC[1:0] bits to 10_B and confirm that communication has been completed and transition to channel halt mode has been made, and then set the CHMDC[1:0] bits to 01_B.

Note 2. While the CAN bus is locked at the dominant level, transition to channel halt mode is not made. In that case, enter channel reset mode. The CAN bus status can be confirmed with the BLF flag of the RSCAN0CmERFL register that becomes 1 when dominant lock is detected.

Note 3. When the transition from channel reset mode to channel wait mode is to be made, set the RSCAN0CmBCFG register in channel reset mode and then shift to channel wait RSCAN0CmCFG.

16.4.2.10 Channel Communication Mode

In channel communication mode, CAN communication is performed. Each channel is in the following communication states during CAN communication.

- Idle : Neither reception nor transmission is in progress.
- Reception : Receiving a message sent from another node.
- Transmission : Transmitting a message.
- Bus off : Isolated from CAN communication.

When the CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 00_B, the channel transitions to channel communication mode. After that, when 11 consecutive recessive bits have been detected, the COMSTS flag in the RSCAN0CmSTS register (m = 0 to 3) is set to 1 (communication is ready) and transmission and reception are enabled on the CAN network as an active node. At this time, transmission and reception of messages can be started.

16.4.2.11 Bus Off State

A channel transitions to the bus off state according to the transmit/receive error counter increment/ decrement rules of the CAN specifications. How to return from the bus off state is set by the BOM[1:0] bits in the RSCAN0CmCTR register.

- When BOM[1:0] = 00_B:
  Bus off recovery is compliant with the CAN specification. After 11 consecutive recessive bits have been detected 128 times, a channel returns from the bus off state to the CAN communication ready state (error active state). At that time, the TEC[7:0] and REC[7:0] bits in the RSCAN0CmSTS register are initialized to 00_H , the BORF flag in the RSCAN0CmERFL register is set to 1 (bus off recovery is detected), and a bus off recovery interrupt request is generated. When the CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 10_B (channel halt mode) in the bus off state, the channel transitions to channel halt mode after completion of bus off recovery (11 consecutive recessive bits have been detected 128 times).
- When BOM[1:0] = 01_B:
  When a channel transitions to the bus off state, the CHMDC[1:0] bits are set to 10_B and the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H but the BORF flag is not set to 1 and a bus off recovery interrupt request is not generated.
- When BOM[1:0] = 10_B:
  When a channel has transitioned to the bus off state, the CHMDC[1:0] bits are set to 10_B. After completion of bus off recovery (11 consecutive recessive bits have been detected 128 times), the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H and the BORF flag is set to 1, and bus off recovery interrupt request is generated.
- When BOM[1:0] = 11_B:
  When the CHMDC[1:0] bits are set to 10_B in the bus off state, the channel transitions to channel halt mode before bus off recovery is completed. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H but the BORF flag is not set to 1. And bus off recovery interrupt request is not generated.
  However, the BORF flag becomes 1, and bus off recovery interrupt request is generated if a RS-CAN module transitions to error active state (by detecting 128 times of 11 consecutive recessive bits) before CHMDC[1:0] bits are set to 10_B.

If the channel transitions to channel halt mode by the RS-CAN module simultaneously when the program writes a value to the CHMDC[1:0] bits, writing by the program takes precedence. An automatic transition to channel halt mode when the BOM[1:0] bits are set to 01_B or 10_B is made only when the CHMDC[1:0] bits are 00_B (channel communication mode).

Furthermore, setting the RTBO bit in the RSCAN0CmCTR register to 1 allows forcible return from the bus off state. As soon as the RTBO bit is set to 1, the state changes to the error active state. After 11 consecutive recessive bits have been detected, the RS-CAN module becomes ready for communication. In this case, the BORF flag is not set to 1 and the TEC[7:0] and REC[7:0] bits are initialized to 00_H. Write 1 to the RTBO bit when the BOM[1:0] value is 00_B. If you write 1 to the RTBO bit in any other cases than the buss off state, writing is ignored and the RTBO bit becomes 0 immediately.

Table 16.89 Registers Initialized in Global Reset Mode or Channel Reset Mode

Register	Bit / Flag
RSCAN0CmCTR register	CTMS[1:0], CTME, CHMDC[1:0]
RSCAN0CmSTS register	CHLTSTS, EPSTS, BOSTS, TRMSTS, RECSTS, COMSTS, REC[7:0], TEC[7:0]
RSCAN0CmERFL register	CRCREG[14:0], ADERR, B0ERR, B1ERR, CERR, AERR, FERR, SERR, ALF, BLF, OVLF, BORF, BOEF, EPF, EWF, BEF
RSCAN0CFCCk register	When transmit/receive FIFO buffer is in transmit mode or gateway mode: CFE
RSCAN0CFSTSk register	When transmit/receive FIFO buffer is in transmit mode or gateway mode: CFMC[7:0], CFFLL, CFEMP, CFMLT, CFRXIF, CFTXIF
RSCAN0CFTISTS register	CFkTXIF
RSCAN0TMCp register	TMOM, TMTAR, TMTR
RSCAN0TMSTSp register	TMTARM, TMTRM, TMTRF[1:0], TMTSTS
RSCAN0TMTRSTSy register	TMTRSTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TMTARSTSy register	TMTARSTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TMTCSTSy register	TMTCSTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TMTASTSy register	TMTASTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TXQCCm register	TXQE
RSCAN0TXQSTSm register	TXQIF, TXQFLL, TXQEMP
RSCAN0THLCCm register	THLE
RSCAN0THLSTSm register	THLMC[4:0], THLIF, THLELT, THLFLL,THLEMP
RSCAN0GTINTSTS0 register	TSIFm, TAIFm, TQIFm, CFTIFm, THIFm (m = 0 to 3)

Table 16.90 Registers Initialized Only in Global Reset Mode

Register	Bit / Flag
RSCAN0GSTS register	GHLTSTS
RSCAN0GERFL register	THLES, MES, DEF
RSCAN0GTSC register	TS[15:0]
RSCAN0RMNDy register	RMNSq
RSCAN0RFCCx register	RFE
RSCAN0RFSTSx register	RFMC[7:0], RFIF, RFMLT, RFFLL, RFEMP
RSCAN0CFCCk register	When transmit/receive FIFO buffer is in receive mode: CFE
RSCAN0CFSTSk register	When transmit/receive FIFO buffer is in receive mode: CFMC[7:0], CFFLL, CFEMP, CFTXIF, CFRXIF, CFMLT
RSCAN0FESTS register	CFkEMP, RFxEMP
RSCAN0FFSTS register	CFkFLL, RFxFLL
RSCAN0FMSTS register	CFkMLT, RFxMLT
RSCAN0RFISTS register	RFxIF
RSCAN0CFRISTS register	CFkRXIF
RSCAN0GTSTCFG register	RTMPS[6:0], C0ICBCE, C1ICBCE, C2ICBCE, C3ICBCE
RSCAN0GTSTCTR register	RTME, ICBCTME

16.4.3 Function for Reception

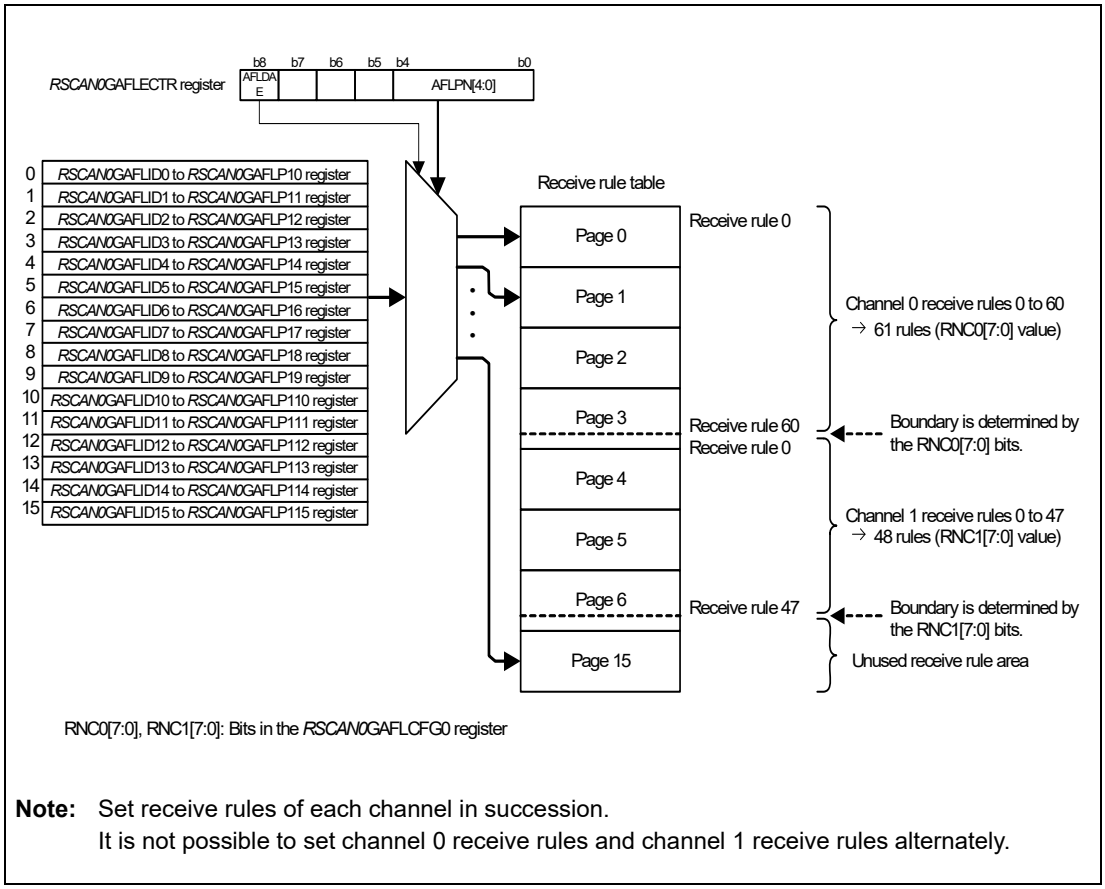
There are two reception types.

- Reception by receive buffers:
  Zero to 64 receive buffers can be shared by all channels. Since messages stored in receive buffers are overwritten at each reception, the latest received data can always be read.
- Reception by receive FIFO buffers and transmit/receive FIFO buffers (receive mode):
  Eight receive FIFO buffers can be shared by all channels and three dedicated transmit/receive FIFO buffers are provided for each channel. Messages of the number specified by the buffer depth can be stored in FIFO buffers and can be read sequentially from the oldest.

16.4.3.1 Data Processing Using the Receive Rule Table

Data processing using the receive rule table allows selected messages to be stored in the specified buffer. Data processing includes acceptance filter processing, DLC filter processing, routing processing, label addition processing, and mirror function processing.

Up to 128 receive rules can be registered per channel and up to “64 × number of channels” receive rules can be registered in the entire module. (Up to 256 receive rules can be registered in this module that has four channels.) Set receive rules for each channel. No receive rule can be shared with other channels. If receive rules are not set, no message can be received. **Figure 16.6** illustrates how receive rules are registered, giving an example using 2 channels of RS-CAN.



Note: Set receive rules of each channel in succession.
It is not possible to set channel 0 receive rules and channel 1 receive rules alternately.

Figure 16.6 Entry of Receive Rules (in the case of setting channel 0,1)

Each receive rule consists of 16 bytes of the RSCAN0GAFLIDj, RSCAN0GAFLMj, RSCAN0GAFLP0j, and RSCAN0GAFLP1j registers (j = 0 to 15). The RSCAN0GAFLIDj register is used to set GAFLID, GAFLIDE bit, GAFLRTR bit, and the mirror function. The RSCAN0GAFLMj register is used to set mask. The RSCAN0GAFLP0j register is used to set label information to be added, DLC value, and destination receive buffer. The RSCAN0GAFLP1j register is used to set a destination FIFO buffer. Up to 16 receive rules can be set per page.

16.4.3.2 Acceptance Filter Processing

In the acceptance filter processing, the ID data, IDE bit, and RTR bit in a received message are compared with the ID data, IDE bit, and RTR bit set in the receive rule of the corresponding channel. When all these bits match, the message passes through the acceptance filter processing. Bits set to 0 (bits are not compared) in the RSCAN0GAFLMj register are not compared and are regarded as matched.

Check begins with the lowest-numbered receive rule. When all the bits to be compared in a received message match the bits set in the receive rule or when all the receive rules are compared without any match, filter processing stops. If there is no matching receive rule, the received message is not stored in the receive buffer or FIFO buffer.

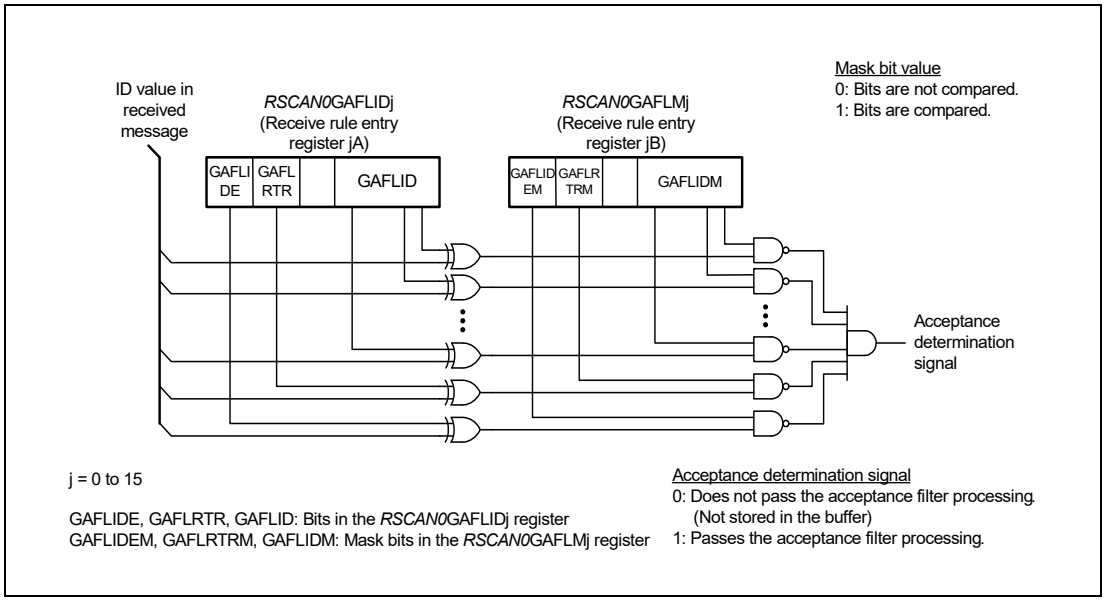


Figure 16.7 Acceptance Filter Function

16.4.3.3 DLC Filter Processing

When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), DLC filter processing is added to messages that passed through the acceptance filter processing. When the DLC value in a message is equal to or larger than the DLC value set in the receive rule, the message passes through the DLC filter processing.

When a message has passed through the DLC filter processing with the DRE bit in the RSCAN0GCFG register set to 0 (DLC replacement is disabled), the DLC value of the received message is stored in the buffer. In this case, all the data bytes in the received message are stored in the buffer.

When a message has passed through the DLC filter processing with the DRE bit in the RSCAN0GCFG register set to 1 (DLC replacement is enabled), the DLC value of the receive rule is stored in the buffer instead of the DLC value of the received message. In this case, a value of 00_H is written to data bytes that are larger than the DLC value of the receive rule.

When the DLC value of the received message is smaller than that of the receive rule, the message does not pass through the DLC filter processing. In this case, the message is not stored in the receive buffer or the FIFO buffer and the DEF flag in the RSCAN0GERFL register is set to 1 (a DLC error is present).

16.4.3.4 Routing Processing

Messages that passed through the acceptance filter processing and the DLC filter processing are stored in receive buffers, receive FIFO buffers, or transmit/receive FIFO buffers set to receive mode or gateway mode. Message storage destination is set by the GAFLRMV and GAFLRMDP[6:0] bits in the RSCAN0GAFLP0j register (j = 0 to 15) and by the RSCAN0GAFLP1j register. Messages that passed through the acceptance filter processing and the DLC filter processing can be stored in up to 8 buffers.

16.4.3.5 Label Addition Processing

It is possible to add 12-bit label information to messages that passed through the filter processing and store them in buffers. This label information is set in the GAFLPTR[11:0] bits of the RSCAN0GAFLP0j register.

16.4.3.6 Mirror Function Processing

The mirror function allows reception of messages transmitted from the own CAN node. The mirror function is made available by setting the MME bit in the RSCAN0GCFG register to 1 (mirror function is enabled).

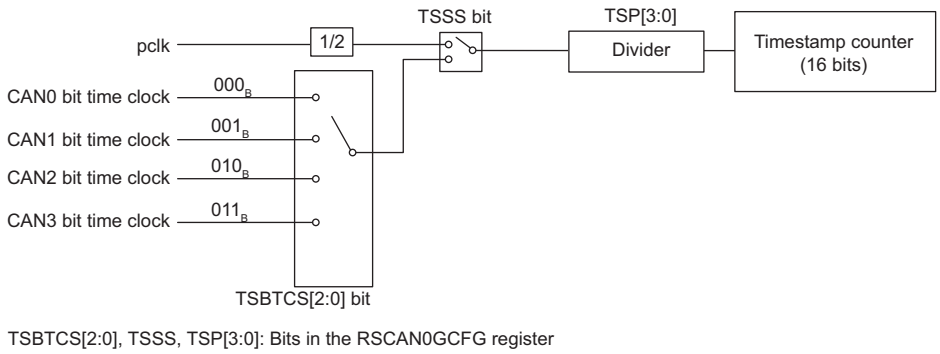
When the mirror function is in use, receive rules for which the GAFLLB bit in the RSCAN0GAFLIDj register is set to 0 are applied to the data processing for messages received from other CAN nodes. When messages transmitted from the own CAN node are received, receive rules for which the GAFLLB bit is set to 1 are used for data processing.

16.4.3.7 Timestamp

The timestamp counter is a 16-bit free-running counter used for recording the message receive time. The timestamp counter value is fetched at the timing of the start-of-frame (SOF) of a message and is then stored in a receive buffer or a FIFO buffer together with the message ID and data. pclk/2 or CANm bit time clock (m = 0 to 3) is selectable as a timestamp counter clock source by the TSBTCS[2:0] bits in the RSCAN0GCFG register. The clock obtained by dividing the selected clock source by the TSP[3:0] value of the RSCAN0GCFG register is used as the count source of the timestamp counter.

When the CANm bit time clock is used as a clock source, the timestamp counter stops when the corresponding channel transitions to channel reset mode or channel halt mode. When pclk/2 is used as a clock source, the timestamp function is not affected by channel mode.

The timestamp counter value is reset to 0000_H by setting the TSRST bit in the RSCAN0GCTR register to 1.



TSBTCS[2:0], TSSS, TSP[3:0]: Bits in the RSCAN0GCFG register

Note: When specifying pclk as the timestamp counter count source, set bits TSBTCS[2:0] to 000_B.

Figure 16.8 Timestamp Function Block Diagram

16.4.4 Transmission Functions

There are three types of transmission.

- Transmission using transmit buffers:
  Each channel has 16 buffers.
- Transmission using transmit/receive FIFO buffers (transmit mode):
  Each channel has three FIFO buffers. Up to 128 messages can be saved in a single FIFO buffer. Each FIFO buffer is used with a link to a transmit buffer. Only the message to be transmitted next in a FIFO buffer becomes a target of transmit priority determination. Messages are transmitted sequentially on a first-in, first-out basis.
- Transmission using transmit queues:
  Up to 16 transmit buffers per channel can be allocated to transmit queues. Transmit buffer number (16 x m) + 15 is used as a common access window. Transmit buffers are allocated to transmit queues in descending order of buffer numbers. All messages in transmit queues, which are targets of priority determination, are transmitted in the order of ID numbers.

Figure 16.9 shows the allocation of transmit queues and transmit/receive FIFO buffer link.

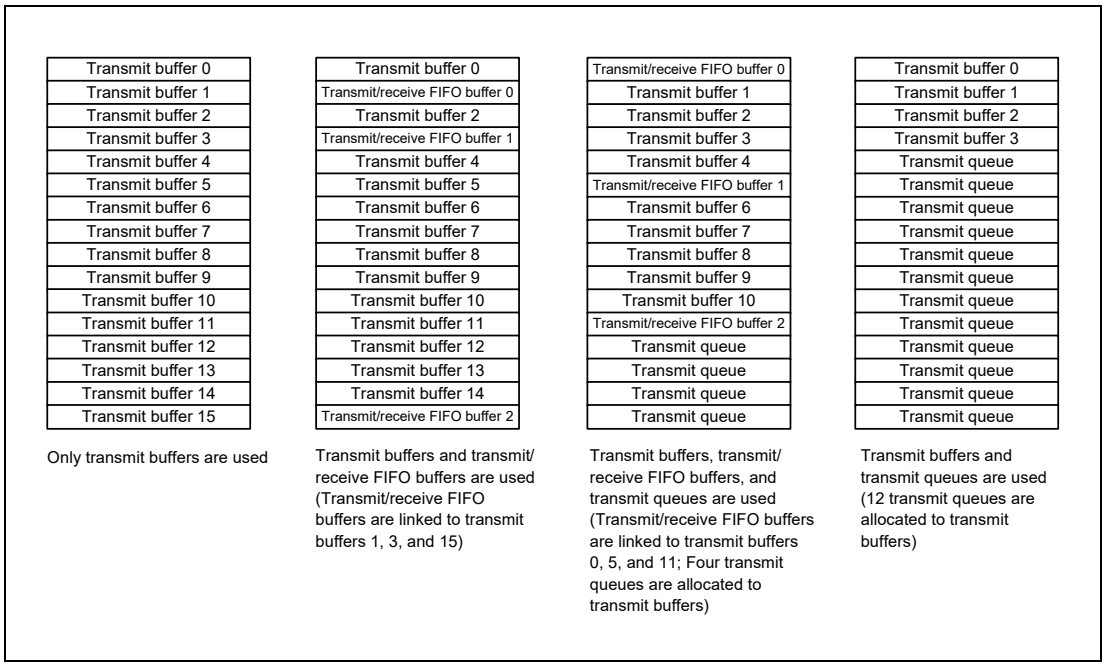


Figure 16.9 Allocation of Transmit Queues and Transmit/Receive FIFO Buffer Links

16.4.4.1 Transmit Priority Determination

If transmit requests are issued from multiple buffers or queues in the same channel, transmit priority is determined.

The priority is determined by using one of the following methods.

- ID priority (TPRI bit = 0)
- Transmit buffer number priority (TPRI bit = 1)

The setting of the TPRI bit in the RSCAN0GCFG register is effective in all CAN channels.

When the TPRI bit is set to 0, messages are transmitted according to the priority of stored message IDs. Priority of IDs conforms to the CAN bus arbitration specification defined in the CAN specification. Targets of priority determination are IDs of messages placed in transmit buffers, transmit/receive FIFO buffers (set to transmit mode or gateway mode), and transmit queues. When one or more transmit queues are used, select the ID priority method. When transmit/receive FIFO buffers are used, the oldest message in a FIFO buffer becomes a target of priority determination. When a message is being transmitted from a transmit/receive FIFO buffer, the next message in the same FIFO buffer becomes a target of priority determination. When transmit queues are used, all messages in transmit queues are targets of priority determination. If the same ID is set for two or more buffers, the buffer with a lower number takes precedence.

When the TPRI bit is set to 1, the message in the transmit buffer whose number is the lowest among buffers having transmit requests is transmitted first. When transmit/receive FIFO buffers are linked to transmit buffers, transmit priority is determined according to the linked transmit buffer numbers.

When messages are retransmitted due to an arbitration lost or an error, transmit priority determination is made again regardless of the TPRI bit.

16.4.4.2 Transmission Using Transmit Buffers

Setting the transmit request bit (TMTR bit in the RSCAN0TMCp register) of a transmit buffer to 1 (transmission is requested) allows transmission of data frames or remote frames.

Transmit result is shown by the TMTRF[1:0] flag in the corresponding RSCAN0TMSTSp register (p = 0 to 63). When transmit completes successfully, the TMTRF[1:0] flag is set to 10_B (transmission has been completed (without transmit abort request)) or 11_B (transmission has been completed (with transmit abort request)).

16.4.4.3 Transmit Abort Function

Setting the TMTAR bit in the RSCAN0TMCp register to 1 (transmit abort is requested) cancels the transmit request from a transmit buffer for which the TMTRM bit in the RSCAN0TMSTSp register is set to 1 (a transmit request is present). When transmit abort is completed, the TMTRF[1:0] flag of the RSCAN0TMSTSp register is set to 01_B (transmit abort has been completed) and the transmit request is canceled (clearing the TMTRM bit to 0).

A message that is being transmitted or a message to be transmitted next according to the transmit priority determination cannot be aborted. However, if an arbitration lost or an error has occurred while a message for which the TMTAR bit is set to 1 is being transmitted, retransmission is not performed.

16.4.4.4 One-Shot Transmission Function (Retransmission Disabling Function)

When the TMOM bit of the RSCAN0TMCp register is set to 1 (one-shot transmission is enabled), transmission is performed only once. Even if an arbitration lost or an error occurs, retransmission is not performed.

One-shot transmission result is shown by the TMTRF[1:0] flag in the corresponding RSCAN0TMSTSp register. When one-shot transmission completes successfully, the TMTRF[1:0] flag is set to 10_B or 11_B. When an arbitration lost or an error has occurred, the TMTRF[1:0] flag is set to 01_B (transmit abort has been completed).

16.4.4.5 Transmission Using FIFO Buffers

A single transmit/receive FIFO buffer can save as many messages as specified by the CFDC[2:0] bits of the RSCAN0CFCCk register (k = 0 to 11). Messages are transmitted sequentially on a first-in, first out basis.

Transmit/receive FIFO buffers are linked to transmit buffers selected by the CFTML[3:0] bits in the RSCAN0CFCCk register. When the CFE bit of the RSCAN0CFCCk register is set to 1 (transmit/receive FIFO buffers are used), transmit/receive FIFO buffers become targets of transmit priority determination. Priority determination is applied only to the message to be transmitted next in a FIFO buffer.

When the CFE bit is set to 0 (no transmit/receive FIFO buffer is used), the CFEMP flag is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)) at the timing below.

- The transmit/receive FIFO buffer becomes empty immediately when the message in it is not being transmitted or is not to be transmitted next.
- The transmit/receive FIFO buffer becomes empty after transmission completion, CAN bus error detection, or arbitration lost when the message in it is being transmitted or to be transmitted next.

When the CFE bit is cleared to 0, all messages in transmit/receive FIFO buffers are lost and messages cannot be stored in FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

16.4.4.6 Interval Transmission Function

To transmit messages continuously from the same transmit/receive FIFO buffer that is set to transmit mode or gateway mode, message transmission interval time can be set.

Immediately after the first message has been transmitted successfully from the FIFO buffer with the CFE bit set to 1 in the RSCAN0RSCAN0CFCCk register, the interval timer starts counting (after EOF7 of the CAN protocol). After that, when the interval time has passed, the next message is transmitted. The interval timer stops in channel reset mode or by clearing the CFE bit to 0.

The interval time is set by the CFITT[7:0] bits in the RSCAN0CFCCk register. When the interval timer is not used, set the CFITT[7:0] bits to 00_H.

Select an interval timer count source by the CFITR and CFITSS bits in the RSCAN0CFCCk register. When the CFITR and CFITSS bits are set to 00_B, the clock obtained by dividing pclk/2 by the ITRCP[15:0] value is used as a count source. When the CFITR and CFITSS bits are set to 10_B, 10 clocks obtained by dividing pclk/2 by the ITRCP[15:0] value are used as a count source. When the CFITR and CFITSS bits are set to $x1_B$, the CANm bit time clock is used as a count source.

The interval time is calculated by the following formulae where m is the ITRCP[15:0] value and n is the CFITT[7:0] value.

- When CFITR and CFITSS bits are 00_B (fPBA is the frequency of pclk):

$$\frac{1}{fPBA} \times 2 \times m \times n$$

- When CFITR and CFITSS bits are 10_B:

$$\frac{1}{fPBA} \times 2 \times m \times 10 \times n$$

- When CFITR and CFITSS bits are $x1_B$ (fCANBIT is the frequency of CANm bit time clock):

$$\frac{1}{fCANBIT} \times n$$

Figure 16.10 shows the interval timer block diagram.

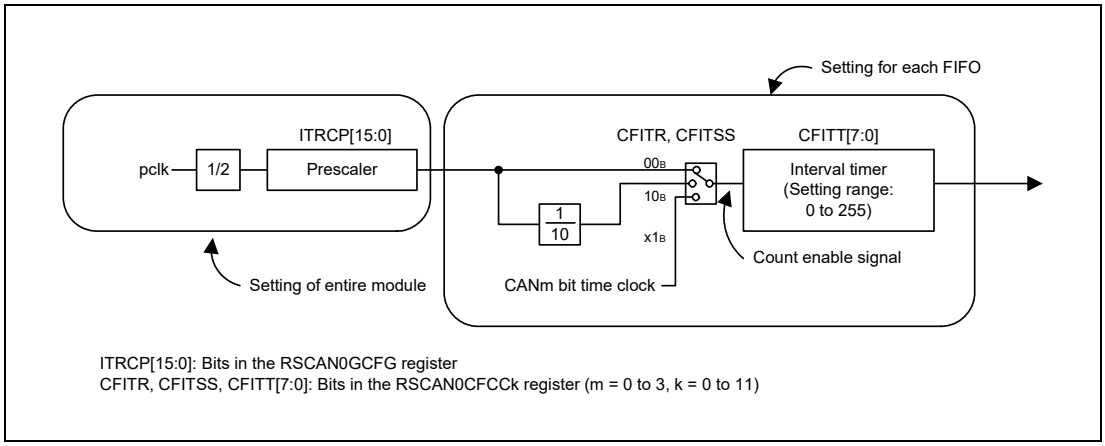

Figure 16.10 Interval Timer Block Diagram

Figure 16.11 shows the interval timer timing chart.

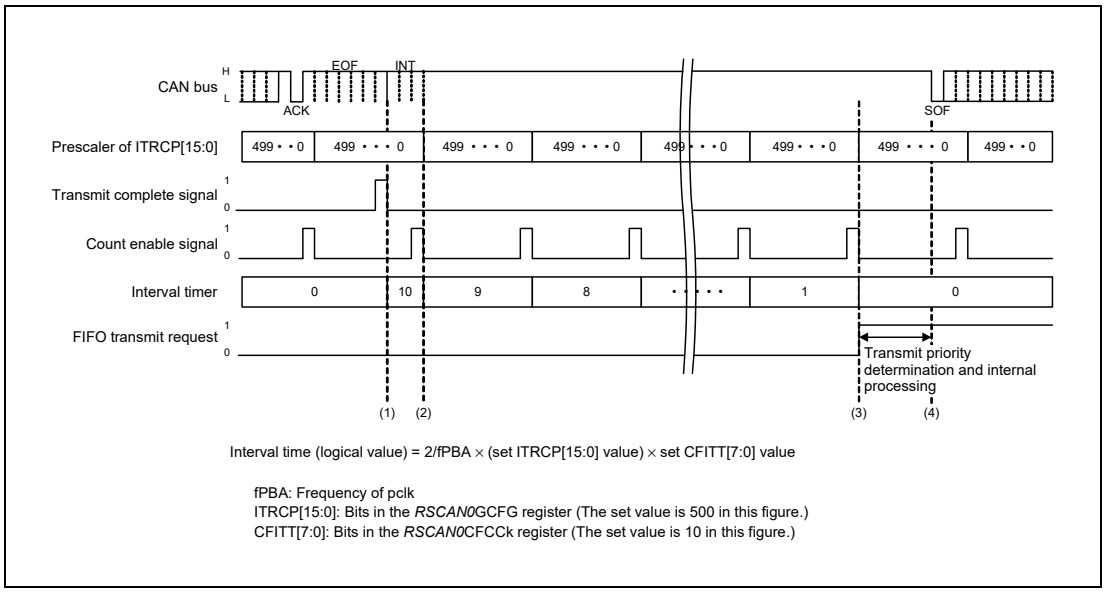

Figure 16.11 Interval Timer Timing Chart

1. The interval timer starts counting upon completion of transmission. Since the prescaler is not initialized at the time of transmission completion, the first interval time has a margin of error of up to one interval timer count.
2. The interval timer is decremented by 1 by the next count enable signal.
3. When the interval timer has decreased to 0, the transmit/receive FIFO buffer issues a transmit request.
4. When the transmit/receive FIFO buffer is determined for the next transmission by the priority determination, it starts transmitting data. Transmission starts usually with a delay of three CANm bit time clock cycles or less from the issue of transmit request.
   Transmission start may delay up to 504 pclk clock cycles if several internal processing including receive filter processing, message routing, and transmit priority determination are performed at all channels.

16.4.4.7 Transmission Using Transmit Queues

Three to sixteen buffers are allocated to a transmit queue for each channel, and the transmit buffer (16 × m) + 15 is used as a common access window.

All messages in a transmit queue are targets of transmit priority determination and are transmitted in the ID priority order regardless of the storing order. If two messages having the same ID are stored in a transmit queue, these messages are not always be transmitted in the storing order in the transmit queue.

Setting the TXQE bit in the RSCAN0TXQCCm register to 0 disables transmit queues. When the TXQE bit is set to 0, the TXQEMP flag in the RSCAN0TXQSTSm register is set to 1 (the transmit queue contains no message (transmit queue empty)) at the timing below.

- The transmit queue becomes empty immediately when the message in it is not being transmitted or is not to be transmitted next.
- The transmit queue becomes empty after transmission completion, CAN bus error detection, or arbitration lost when the message in it is being transmitted or to be transmitted next.

When the TXQE bit is cleared to 0, all messages in transmit queues are lost and messages cannot be stored in transmit queues. Confirm that the TXQEMP flag is set to 1 before setting the TXQE bit to 1 again.

16.4.4.8 Transmit History Function

Information of transmitted messages can be stored in the transmit history buffer. Each channel has a single transmit history buffer that can contain 16 sets of transmit history data.

A message transmit source buffer type can be selected by the THLDTE bit in the RSCAN0THLCCm register. Whether to store transmit history data for each message can be set by the THLEN bit in the RSCAN0CFIDk register (k = 0 to 11).

Storing the transmit history data may be delayed by up to 144 pclk clock cycles after successful completion of transmission.

- Buffer type 001_B: Transmit buffer
  010_B: Transmit/receive FIFO buffer
  100_B: Transmit queue
- Buffer number Number assigned to source transmit buffer, transmit queue, or transmit/receive FIFO buffer. This number depends on buffer types. See **Table 16.91**.
- Label data Label information of transmitted message

Table 16.91 Transmit History Data Buffer Numbers

Buffer type / Buffer No.	001_B	010_B	100_B
0000_B	Transmit buffer 16 × m + 0	Numbers of transmit buffers linked to transmit/receive FIFO buffers by the CFTML[3:0] bits in the RSCAN0CFCCk register (k = 0 to 11)	Numbers of transmit buffers allocated to the transmit queue that performed transmission
0001_B	Transmit buffer 16 × m + 1		
0010_B	Transmit buffer 16 × m + 2		
0011_B	Transmit buffer 16 × m + 3		
0100_B	Transmit buffer 16 × m + 4		
0101_B	Transmit buffer 16 × m + 5		
0110_B	Transmit buffer 16 × m + 6		
0111_B	Transmit buffer 16 × m + 7		
1000_B	Transmit buffer 16 × m + 8		
1001_B	Transmit buffer 16 × m + 9		
1010_B	Transmit buffer 16 × m + 10		
1011_B	Transmit buffer 16 × m + 11		
1100_B	Transmit buffer 16 × m + 12		
1101_B	Transmit buffer 16 × m + 13		
1110_B	Transmit buffer 16 × m + 14		
1111_B	Transmit buffer 16 × m + 15		

Label data is used to identify each message. A unique label data can be added to each message transmitted from a transmit buffer, transmit queue, or transmit/receive FIFO buffer.

Transmit history data can be read from the RSCAN0THLACCm register. If it is attempted to store new transmit history data while the buffer is full, the buffer overflows and the new data is discarded.

16.4.5 Gateway Function

When a transmit/receive FIFO buffer is set to gateway mode, received massages can be transmitted from an arbitrary channel without CPU intervention.

When a transmit/receive FIFO buffer for which the CFM[1:0] bits of the RSCAN0CFCCk register are set to 10_B (gateway mode) is selected by the RSCAN0GAFLP1j register, messages that passed through the filter processing of the receive rule are stored in the specified transmit/receive FIFO buffer and are automatically transmitted from the buffer.

Messages stored in a transmit/receive FIFO buffer are transmitted sequentially on a first-in, first-out basis. Only the message to be transmitted next becomes a target of transmit priority determination.

Transmit/receive FIFO buffers in the gateway mode are disabled by setting the CFE bit in the RSCAN0CFCCk register to 0. When the CFE bit is set to 0, the CFEMP flag becomes 1 at the timing below.

- The transmit/receive FIFO buffer becomes empty immediately when the message in it is not being transmitted or is not to be transmitted next.
- The transmit/receive FIFO buffer becomes empty after transmission completion, CAN bus error detection, or arbitration lost when the message in it is being transmitted or to be transmitted next.

When the CFE bit is cleared to 0, all messages in transmit/receive FIFO buffers are lost and messages can no longer be stored in transmit/receive FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

16.4.6 Test Function

The test function is classified into communication tests and global tests.

- Communication tests: Performed for each channel.
  - Standard test mode
  - Listen-only mode
  - Self-test mode 0 (external loopback mode)
  - Self-test mode 1 (internal loopback mode)
- Global tests: Performed in entire module
  - RAM test (read/write test)
  - Inter-channel communication test

16.4.6.1 Standard Test Mode

Standard test mode allows CRC test.

16.4.6.2 Listen-Only Mode

Listen-only mode allows reception of data frames and remote frames. Only recessive bits are transmitted on the CAN bus, and the ACK bit, overload flag, and active error flag are not transmitted.

Listen-only mode is available for detecting the communication speed.

Do not make a transmit request from any buffer or queue in listen-only mode.

Figure 16.12 shows the connection when listen-only mode is selected.

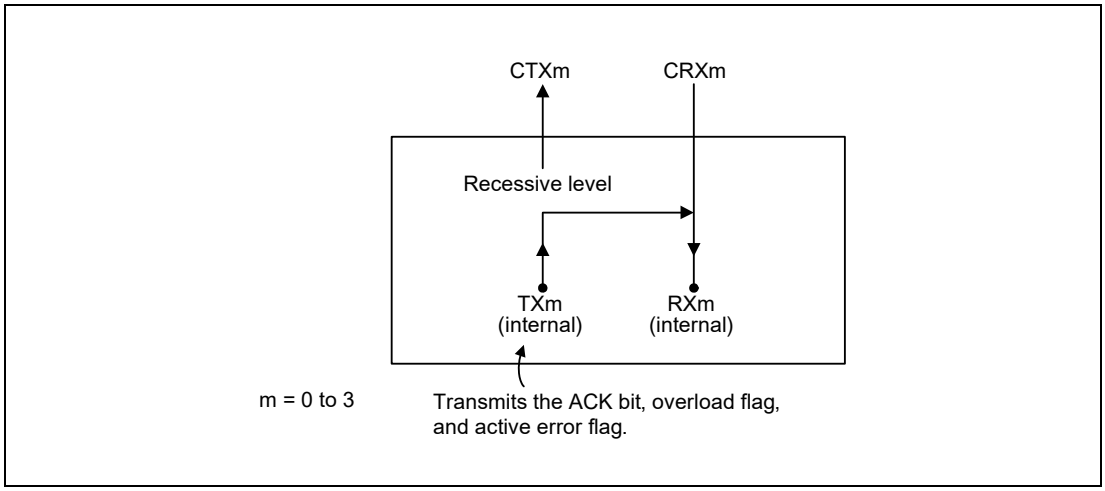

Figure 16.12 Connection When Listen-Only Mode is Selected

16.4.6.3 Self-Test Mode (Loopback Mode)

In self-test mode, messages transmitted from a channel are compared with the receive rule of the same channel. Messages are stored in a buffer if they have passed through the filter processing. Messages transmitted from other CAN nodes are compared only with the receive rule for which the GAFLLB bit in the RSCAN0GAFLIDj register (j = 0 to 15) is set to 0 (when a message transmitted from another CAN node is received).

If the mirror function and self-test mode are both enabled, the self-test mode setting takes precedence.

16.4.6.4 Self-Test Mode 0 (External Loopback Mode)

Self-test mode 0 is used to perform a loopback test within a channel including the CAN transceiver.

In self-test mode 0, transmitted messages are handled as messages received through the CAN transceiver and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.

Figure 16.13 shows the connection when self-test mode 0 is selected.

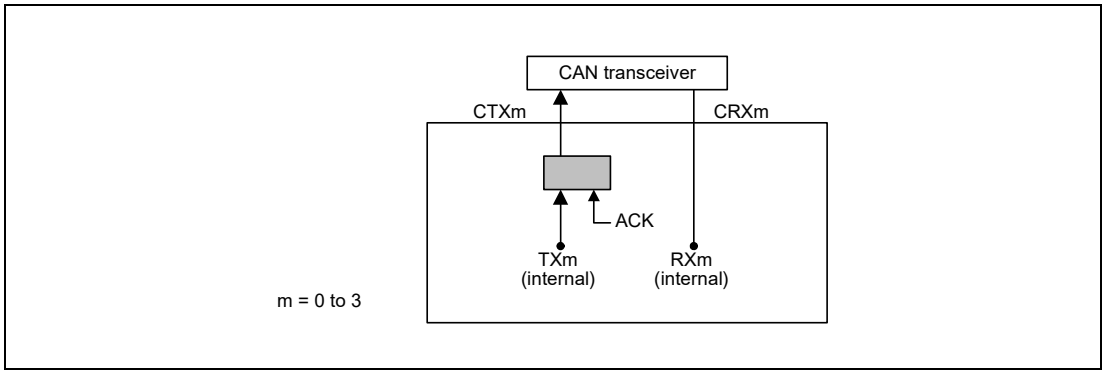

Figure 16.13 Connection When Self-Test Mode 0 is Selected

16.4.6.5 Self-Test Mode 1 (Internal Loopback Mode)

In self-test mode 1, transmitted messages are handled as received messages and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.

In self-test mode 1, internal feedback from the internal TXm pin (m = 0 to 3) to the internal RXm pin is performed. The external CRXm pin input is isolated. The external CTXm pin outputs only recessive bits.

Figure 16.14 shows the connection when self-test mode 1 is selected.

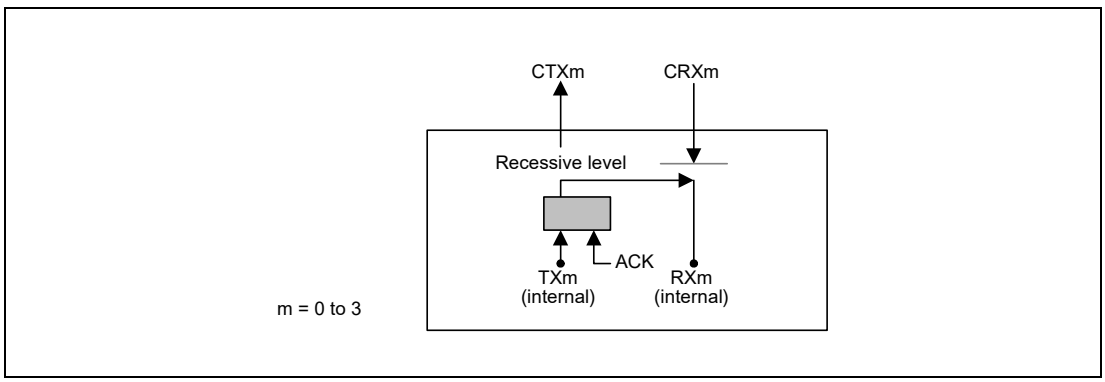

Figure 16.14 Connection When Self-Test Mode 1 is Selected

16.4.6.6 RAM Test

The RAM test function allows accesses to all CAN RAM addresses. RAM initialization which is performed after resetting the MCU does not initialize all CAN RAM areas.

When the RAM test function is used, the RAM is divided into pages of 256 bytes each. A RAM test page is selected by the RTMPS[6:0] bits in the RSCAN0GTSTCFG register. Data in the set page can be read from and written to the RSCAN0RPGACCr register (r = 0 to 63). The available total RAM size is 12160 bytes ($2F80_H$).

16.4.6.7 Inter-Channel Communication Test

The inter-channel communication test function allows communication test by internally and mutually connecting CAN channels. During this test, channels are isolated from the external CAN bus.

Before starting data transmission/reception in channel communication mode, make transmission/reception settings for each channel. Channels not included in the test must be placed in channel halt mode.

Figure 16.15 shows the connection for inter-channel communication test.

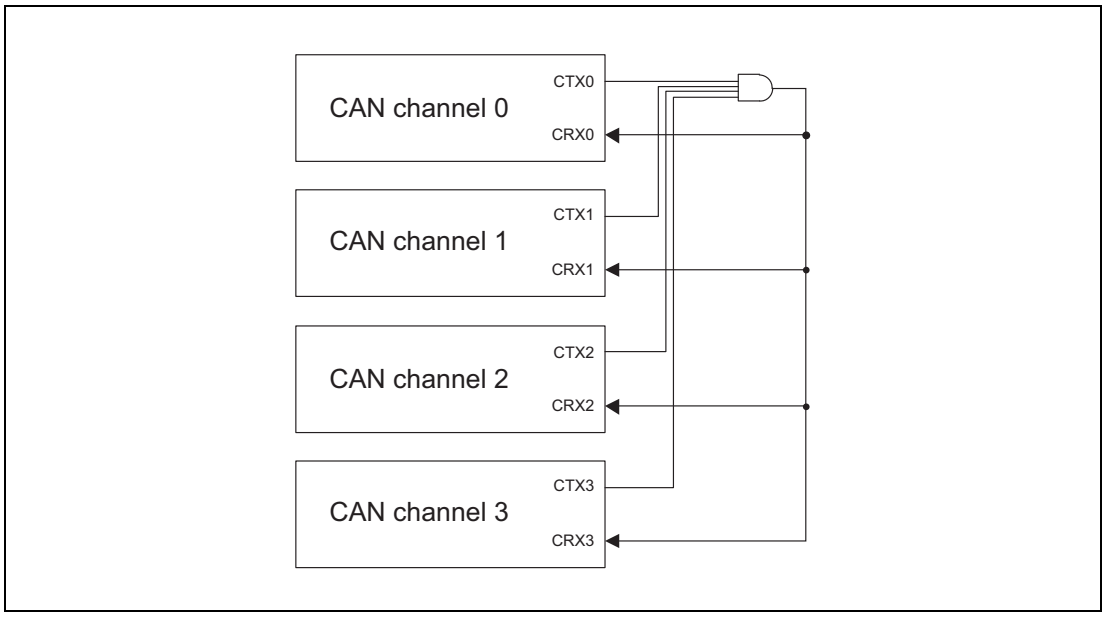

Figure 16.15 Connection for Inter-Channel Communication Test

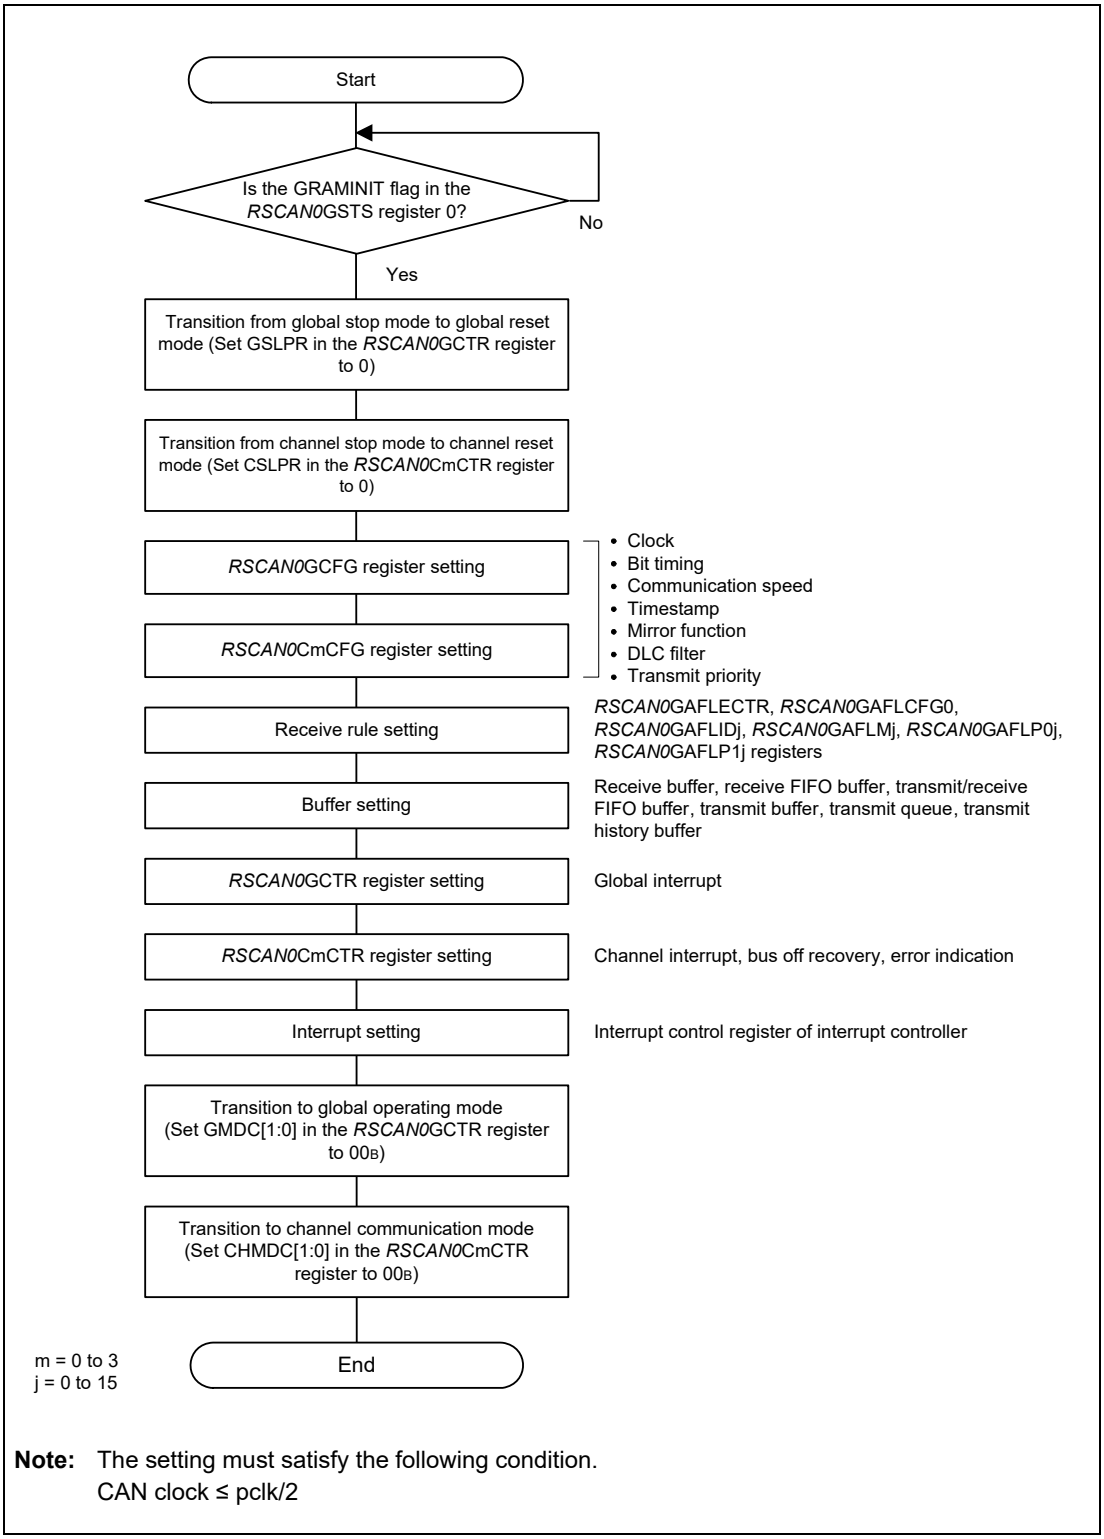
16.5 Procedures

16.5.1 Initial Settings

The RS-CAN module initializes the CAN RAM after the MCU is reset. The RAM initialization time is 6082 cycles/pclk. The GRAMINIT flag in the RSCAN0GSTS register is set to 1 (CAN RAM initialization is ongoing) during the RAM initialization and is cleared to 0 (CAN RAM initialization is finished) when the initialization is completed. Configure CAN settings after the GRAMINIT flag is cleared to 0. **Figure 16.16** shows the CAN setting procedure after the MCU is reset.



Note: The setting must satisfy the following condition.
CAN clock ≤ pclk/2

Figure 16.16 CAN Setting Procedure after the MCU is Reset

16.5.1.1 Clock Setting

Set the CAN clock (fCAN) which is the clock source of the RS-CAN module. Select clkc or clk_xincan by the DCS bit in the RSCAN0GCFG register.

16.5.1.2 Bit Timing Setting

In the CAN protocol, one bit of a communication frame consists of three segments: SS, TSEG1, and TSEG2. Of these, the two segments, TSEG1 and TSEG2 can be set by the RSCAN0CmCFG register for each channel. Sample point timing can be determined by setting these two segments. This timing can be adjusted in units of 1 Time Quantum (referred to as Tq hereinafter). 1 Tq equals to one CANmTq clock cycle. The CANmTq clock is obtained by dividing the clock selected with the DCS bit of the RSCAN0GCFG register by the value of the BRP[9:0] bits of the RSCAN0CmCFG register.

Figure 16.17 shows the bit timing chart. **Table 16.92** shows an example of bit timing setting.

SS = 1 Tq fixed
Set TSEG1 to a range of 4 Tq to 16 Tq
Set TSEG2 to a range of 2 Tq to 8 Tq
Set SJW to a range of 1 Tq to 4 Tq
Set SS + TSEG1 + TSEG2 to a range of 8 Tq to 25 Tq
TSEG1 > TSEG2 ≥ SJW

- SS (synchronization segment):
  The SS is a segment that performs synchronization by monitoring the edge from recessive to dominant bits in the Interframe Space.
  Interframe Space consists of Intermission, Suspend Transmission, and Bus Idle. All nodes can start transmission during Bus Idle.
- TSEG1 (Time segment 1):
  TSEG1 is a segment that absorbs physical delay on the CAN network. The physical delay on the CAN network is twice of the total of the delay on the CAN bus, the delay in the input comparator, and the delay in the output driver.
- TSEG2 (Time segment 2):
  TSEG2 is a segment that compensates phase error due to an error in frequency.
- SJW (Resynchronization jump width)
  The SJW is a length to extend or reduce time segment to compensate an error in phase due to phase error.

Figure 16.17 Bit Timing Chart

Table 16.92 Example of Bit Timing Setting

1 Bit	Set Value (Tq)				Sampling Point (%) Note: See Figure 16.17.
	SS	TSEG1	TSEG2	SJW	
20Tq	1	12	7	1	65.00
	1	13	6	1	70.00

16.5.1.3 Communication Speed Setting

Set the CAN communication speed for each channel using the fCAN, baud rate prescaler division value (BRP[9:0] bits in the RSCAN0CmCFG register), and Tq count of one bit time.

Figure 16.18 shows the CAN clock control block diagram, and **Table 16.93** shows an example of the communication speed setting.

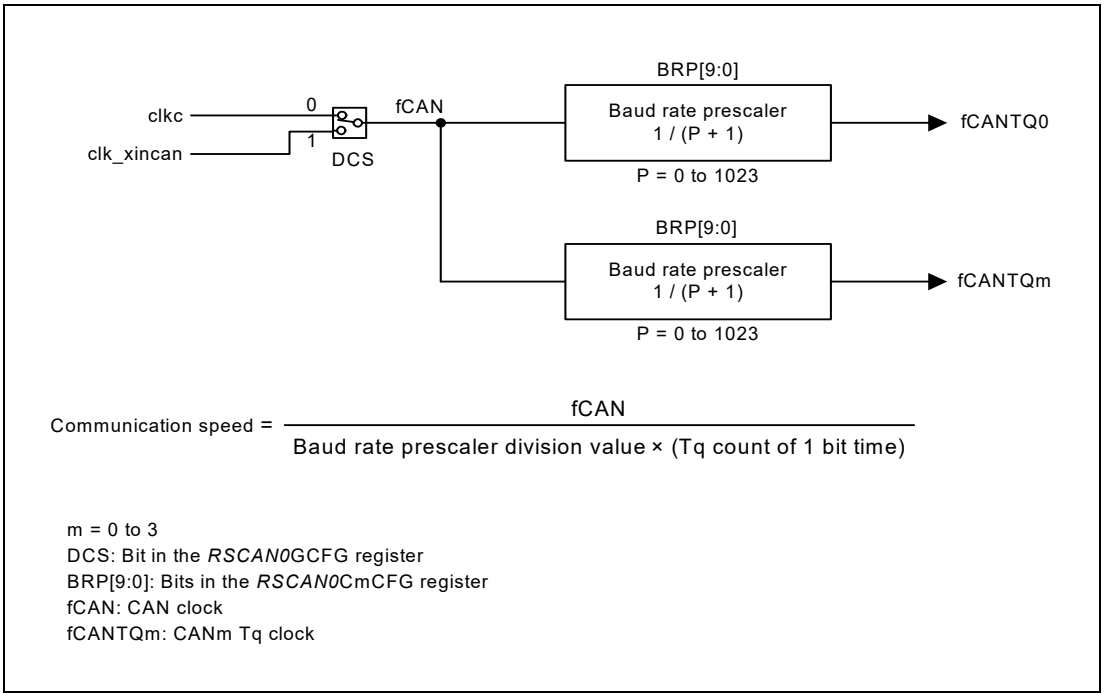


Figure 16.18 CAN Clock Control Block Diagram

Table 16.93 Example of Communication Speed Setting

fCAN / Communication speed	40 MHz
1 Mbps	8 Tq (5) 20 Tq (2)
500 Kbps	8 Tq (10) 20 Tq (4)
250 Kbps	8 Tq (20) 20 Tq (8)

Note: Values in ( ) are baud rate prescaler division values.

16.5.1.4 Receive Rule Setting

Receive rules can be set using receive rule-related registers.

Up to 16 receive rules can be registered per page. Specify pages 0 to 15 by the AFLPN[4:0] bits in the RSCAN0GAFLECTR register. Use the AFLDAE bit to enable or disable writing to the receive rule table.

Figure 16.19 shows the receive rule setting procedure.

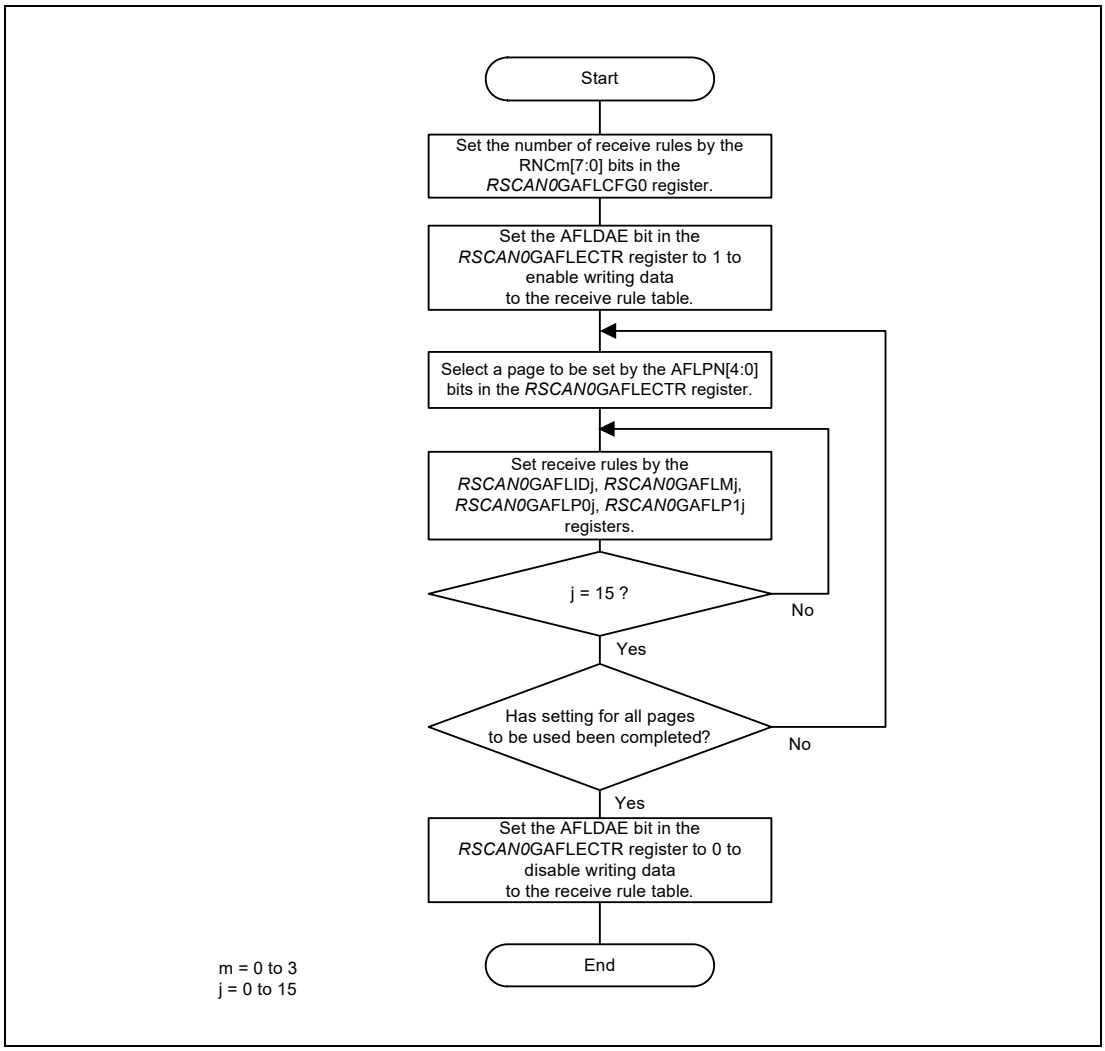

Figure 16.19 Receive Rule Setting Procedure

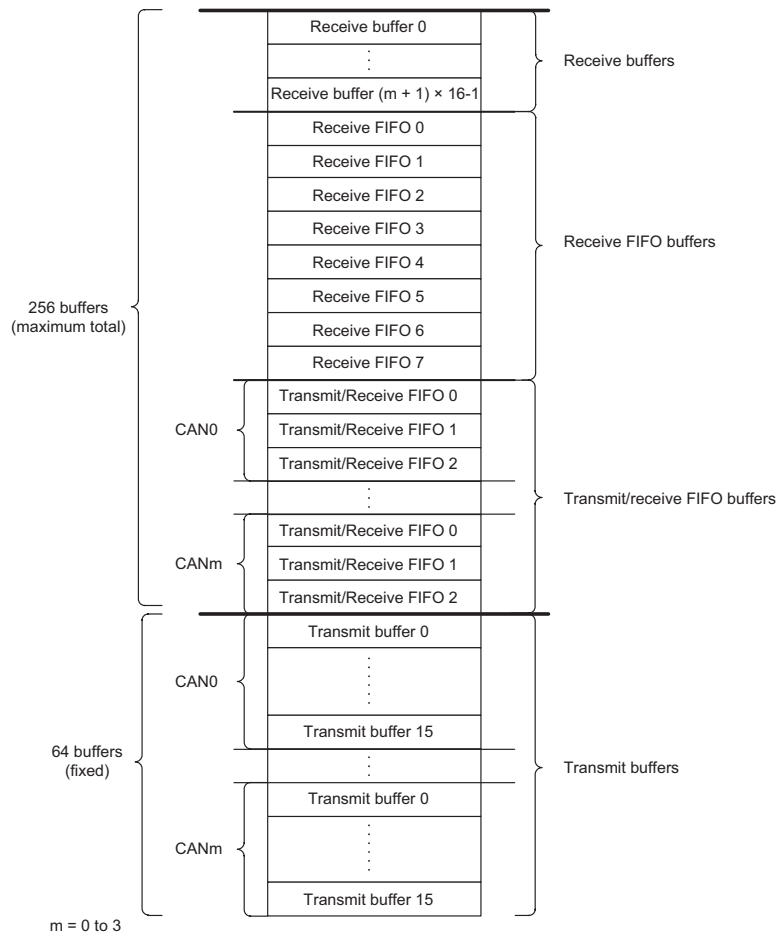
16.5.1.5 Buffer Setting

Set sizes and interrupt sources of buffers. For transmit/receive FIFO buffers that are set to transmit mode, set transmit buffers to be linked.

Figure 16.20 shows the buffer configuration. **Figure 16.21** shows the buffer setting procedure.



Note: Receive buffers, receive FIFO buffers, transmit/receive FIFO buffers, and transmit buffers are located in succession.

Figure 16.20 Buffer Configuration

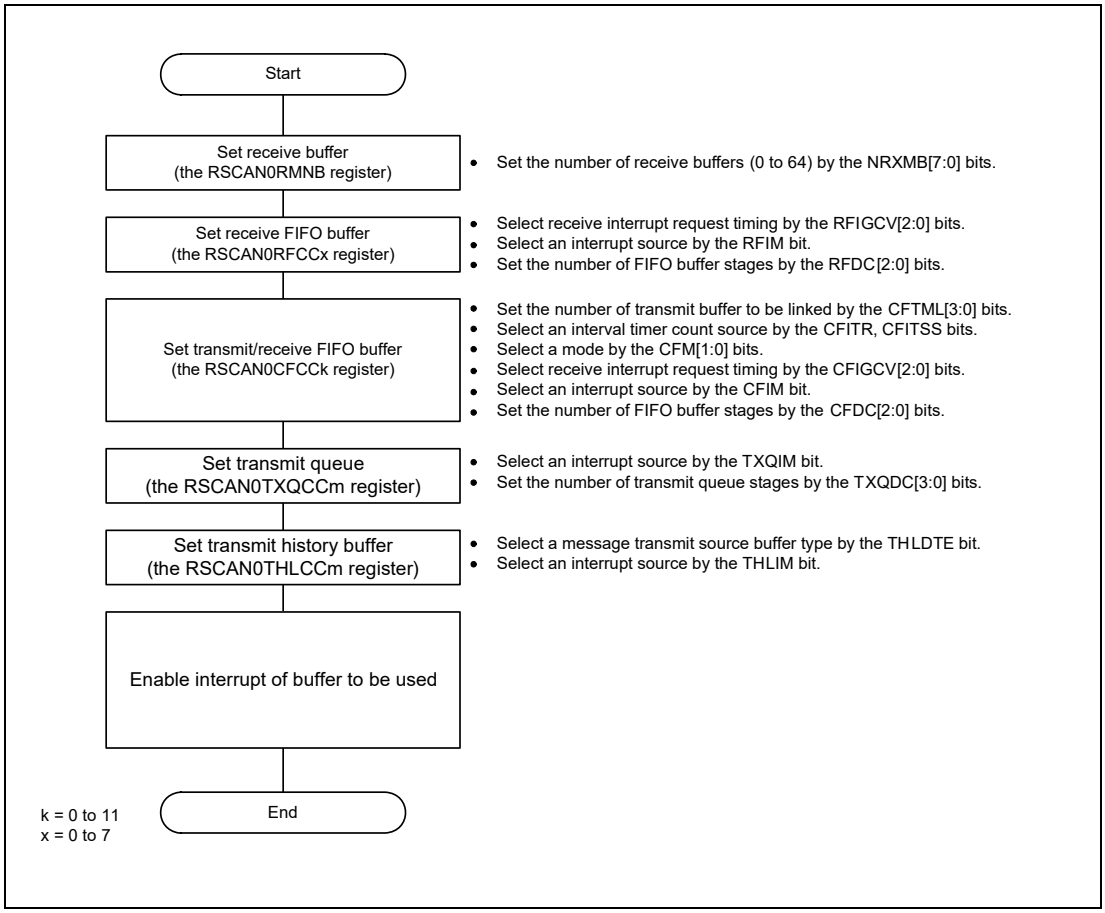


Figure 16.21 Buffer Setting Procedure

16.5.2 Procedure for Reception

16.5.2.1 Receive Buffer Reading Procedure

When the processing to store received messages in a receive buffer starts, the RMNSq flag in the RSCAN0RMNDy register (y = 0, 1, q = 0 to 63) is set to 1 (receive buffer q contains a new message). Messages can be read from the RSCAN0RMIDq, RSCAN0RMPTRq, RSCAN0RMDF0q, and RSCAN0RMDF1q registers. If the next message has been received before the current message is read from the receive buffer, the message is overwritten.

Figure 16.22 shows the receive buffer reading procedure.

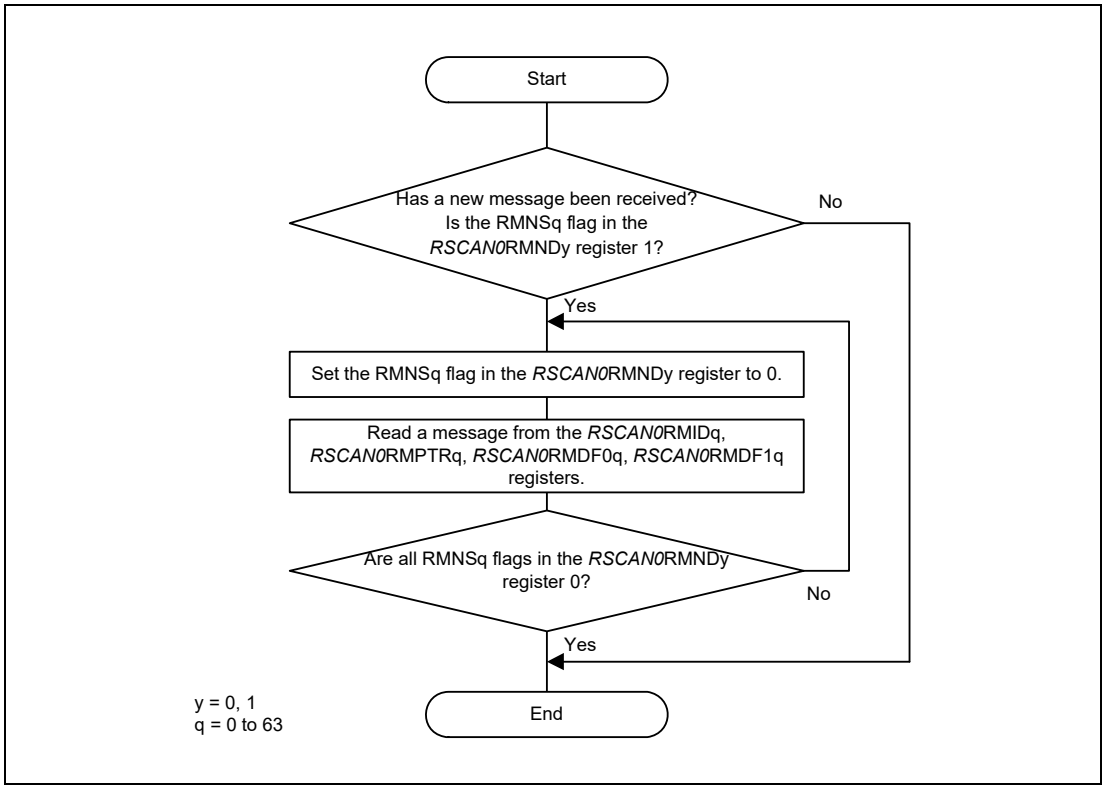

Figure 16.22 Receive Buffer Reading Procedure

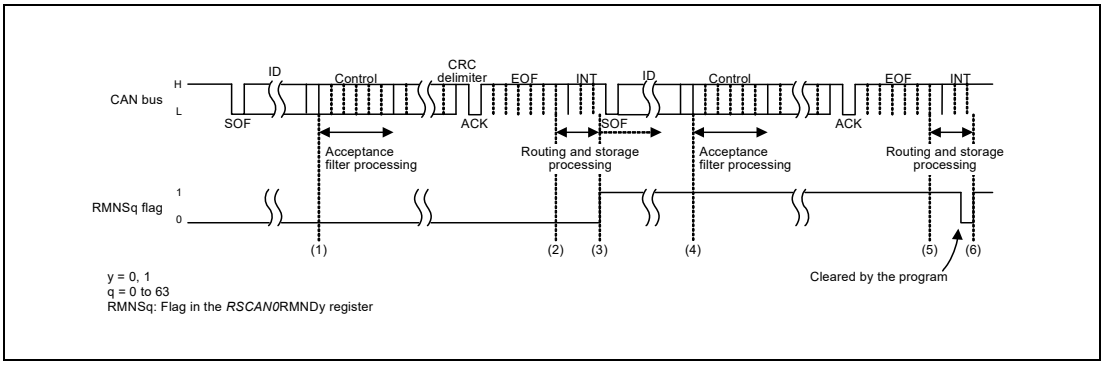

Figure 16.23 Receive Buffer Reception Timing Chart

(1) When the ID field of a message has been received, the acceptance filter processing starts.

(2) When the message matches the receive rule of the corresponding channel and has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(3) When the message has passed through the DLC filter processing, the processing to store the message in the specified receive buffer starts.
When the message storage processing starts, the RMNSq flag in the corresponding RSCAN0RMNDy register is set to 1 (receive buffer n contains a new message). If any other channels are performing filter processing or transmit priority determination processing, the routing processing and the storage processing may be delayed.

(4) When the ID field of the next message has been received, the acceptance filter processing starts.

(5) When the message matches the receive rule of the corresponding channel and has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(6) When the corresponding RMNSq flag is cleared to 0 (receive buffer n contains no new message), this flag is set to 1 again when the message storage processing starts. If the RMNSq flag remains 1, a new message is overwritten in the receive buffer. The RMNSq flag cannot be cleared to 0 during storage of messages.

16.5.2.2 FIFO Buffer Reading Procedure

When received messages have been stored in one or more receive FIFO buffers or transmit/receive FIFO buffers that are set to receive mode or gateway mode, the corresponding message count display counter (RFMC[7:0] bits in the RSCAN0RFSTSx register (x = 0 to 7) or CFMC[7:0] bits in the RSCAN0CFSTSk register (k = 0 to 11)) is incremented by 1. At this time, if the RFIE bit (receive FIFO interrupt is enabled) in the RSCAN0RFCCx register or the CFRXIE bit (transmit/receive FIFO reception interrupt is enabled) in the RSCAN0CFCCk register is set to 1, an interrupt request is generated. Received messages can be read from the RSCAN0RFIDx, RSCAN0RFPTRx, RSCAN0RFDF0x, and RSCAN0RFDF1x registers (receive FIFO buffers) or the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers (transmit/receive FIFO buffers). Messages in FIFO buffers can be read sequentially on a first-in, first-out basis.

When the message count display counter value matches the FIFO buffer depth (a value set by the RFDC[2:0] bits in the RSCAN0RFCCx register or the CFDC[2:0] bits in the RSCAN0CFCCk register), the RFFLL or CFFLL flag is set to 1 (the receive FIFO buffer is full.).

When all messages have been read out of the FIFO buffer, the RFEMP flag in the RSCAN0RFSTSx register or the CFEMP flag in the RSCAN0CFSTSk register is set to 1 (the receive FIFO buffer contains no unread message (buffer empty)).

If the RFE bit or the CFE bit is cleared to 0 (no receive FIFO buffer is used) with the interrupt request flag (RFIF flag in the RSCAN0RFSTSx register or CFRXIF flag in the RSCAN0CFSTSk register) set to 1 (a receive FIFO interrupt request is present), the interrupt request flag is not automatically cleared to 0. Clear the interrupt request flag to 0 by the program.

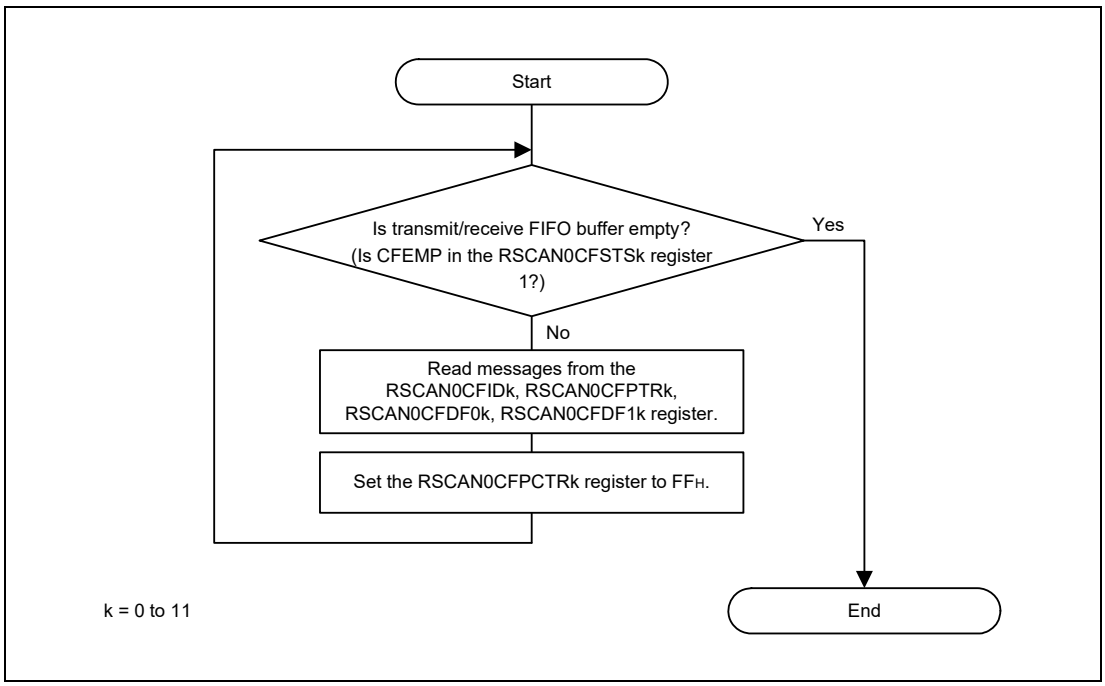

Figure 16.24 Transmit/Receive FIFO Buffer Reading Procedure

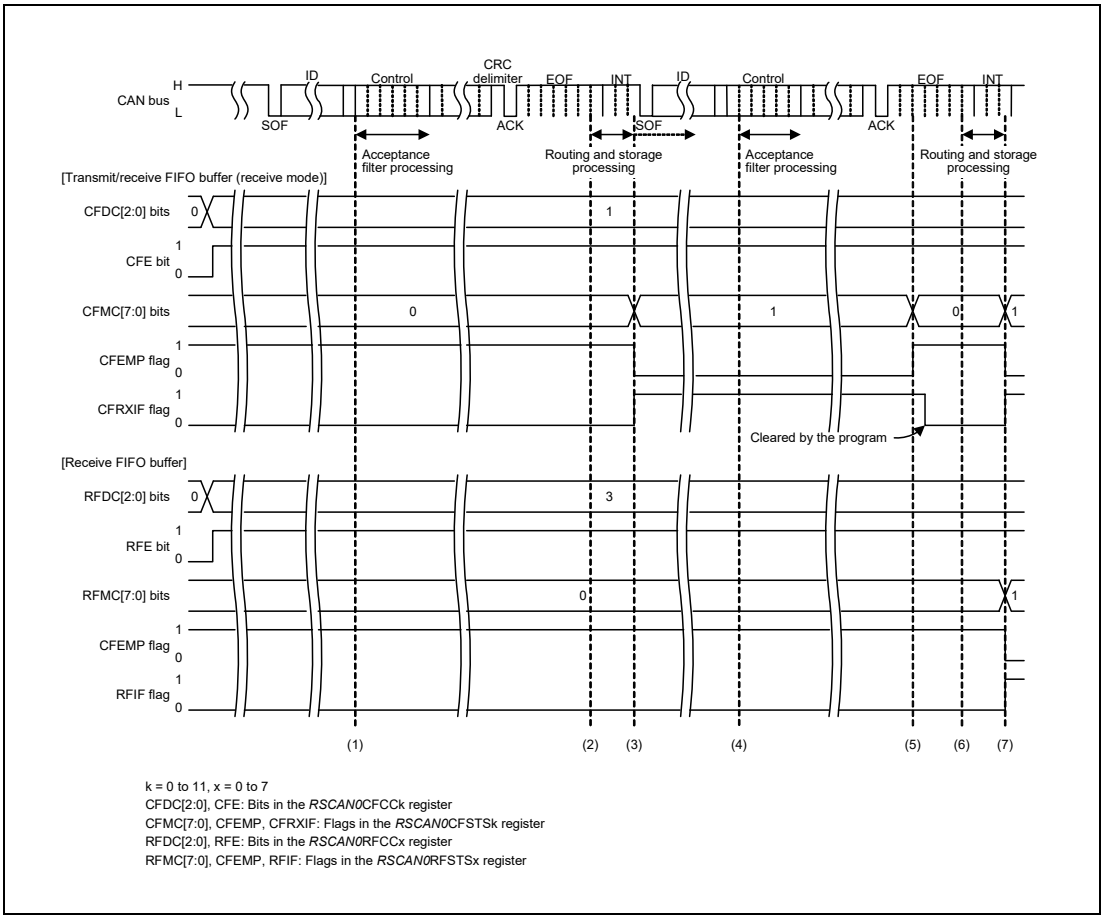

Figure 16.25 FIFO Buffer Receive Timing Chart

(1) When the ID field of a message has been received, the acceptance filter processing starts.

(2) When the message matches the receive rule of the corresponding channel and has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(3) When the message has passed through the DLC filter processing and the CFE value in the RSCAN0CFCCk register is 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] value in the RSCAN0CFCCk register is 001_B or more, the message is stored in the transmit/receive FIFO buffer that is set to receive mode. The CFMC[7:0] value in the RSCAN0CFSTSk register is incremented by 1 and becomes 01_H. When the CFIM bit in the RSCAN0CFCCk register is set to 1 (a FIFO reception interrupt request is generated each time a message has been received), the CFRXIF flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO reception interrupt request is present). The CFRXIF flag can be cleared to 0 by the program.

(4) When the ID field of the next message has been received, the acceptance filter processing starts.

(5) Read received messages from the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers and write FF_H to the RSCAN0CFPCTRk register. Thereby the CFMC[7:0] value in the RSCAN0CFSTSk register is decremented by 1 and become 00_H, and the CFEMP flag in the RSCAN0CFSTSk register becomes 1 (the transmit/receive FIFO buffer contains no message (buffer empty)).

(6) When the message matches the receive rule of the corresponding channel and has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(7) The message having passed through the DLC filter process is stored in the transmit/receive FIFO buffer which is set to receive mode, when the CFE bit is set to 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] bits are set to 001_B or more. The CFMC[7:0] value is incremented by 1 to 01H. When the CFIM bit is set to 1 (an interrupt occurs each time a message has been received), the CFRXIF flag is set to 1 (a transmit/receive FIFO reception interrupt request is present). The message is stored in the receive FIFO buffer when the RFE bit in the RSCAN0RFCCx register is set to 1 (receive FIFO buffers are used.) and RFDC[2:0] bits in the RSCAN0RFCCx register are set to 001B or more. The RFMC[7:0] value in theRSCAN0RFSTSx register is incremented by 1 to 01H. When the RFIM bit in the RSCAN0RFCCx register are set to 1 (an interrupt occurs each time a message has been received), the RFIF flag in the RSCAN0RFSTSx register is set to 1 (a receive FIFO interrupt request is present).

16.5.3 Transmission Procedure

16.5.3.1 Procedure for Transmission from Transmit Buffers

Figure 16.26 shows the procedure for transmission from transmit buffers.

Figure 16.27 shows a timing chart where messages are transmitted from two transmit buffers in the same channel and transmission has been successfully completed. **Figure 16.28** shows a timing chart where messages are transmitted from two transmit buffers in the same channel and transmit abort has been completed.

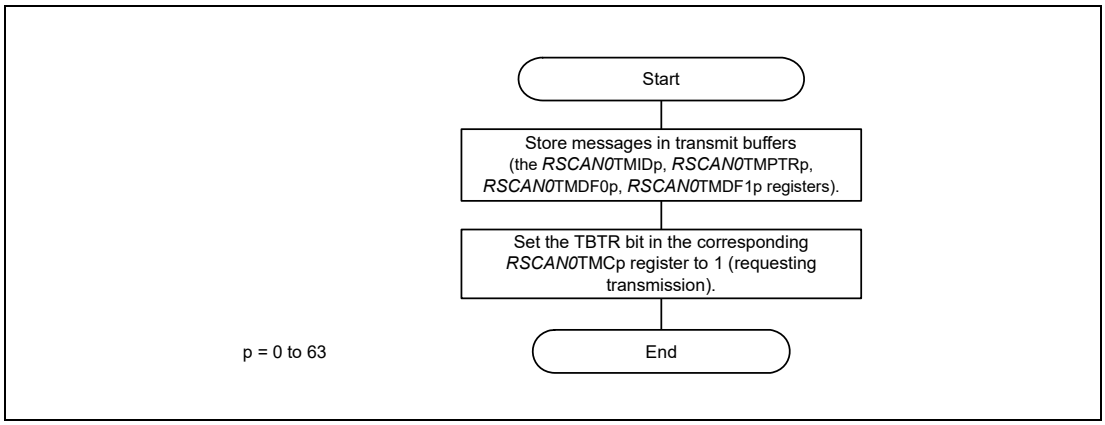

Figure 16.26 Procedure for Transmission from Transmit Buffers

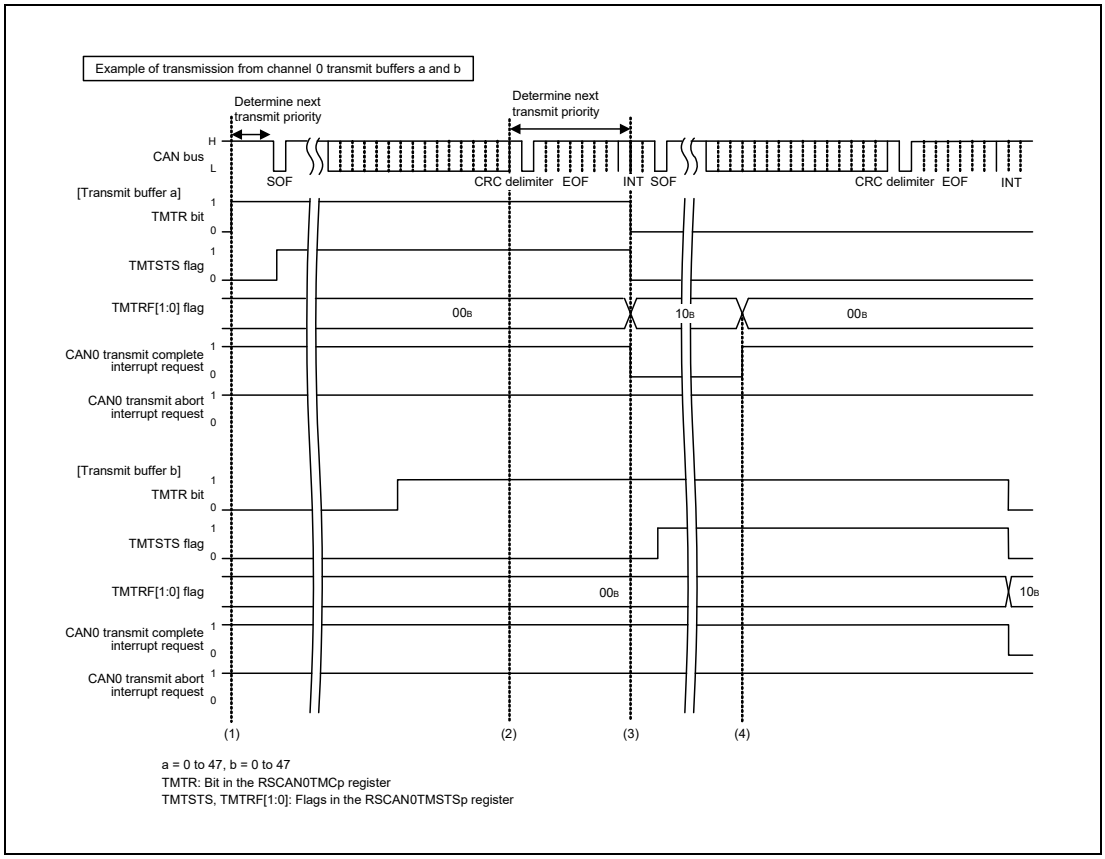

Figure 16.27 Transmit Buffer Transmission Timing Chart (Transmission Completed Successfully)

(1) When the TMTR bit in the RSCAN0TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmit buffer. If transmit buffer a is determined to be the highest-priority transmit buffer, the TMTSTS flag in the corresponding RSCAN0TMSTSa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.

(2) When a transmit request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission. Some delay may occur in the determination time if any other channels are performing the transmit priority determination processing. However, it does not affect the transmission interval because the determination will be completed before bit 3 of intermission.

(3) When transmit completes successfully, the TMTRF[1:0] flag in the RSCAN0TMSTSa register is set to 10_B (transmission has been completed (without transmit abort request)) and the TMTSTS flag and the TMTR bit in the RSCAN0TMSTSa register are cleared to 0. When the TMIEa bit in the RSCAN0TMIEC0 register is 1 (transmit buffer interrupt is enabled), a CAN0 transmit complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B (transmission is in progress or no transmit request is present).

(4) Before starting the next transmission, set the TMTRF[1:0] flag to 00_B. Write the next message to the transmit buffer, and then set the TMTR bit to 1 (transmission is requested). The TMTR bit can be set to 1 only when the TMTRF[1:0] flag value is 00_B.

If an arbitration lost has occurred after transmission started, the TMTSTS flag is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC delimiter to search for the highest-priority transmit buffer. If an error has occurred during transmission or after arbitration lost, the priority determination processing is reexecuted during transmission of an error frame.

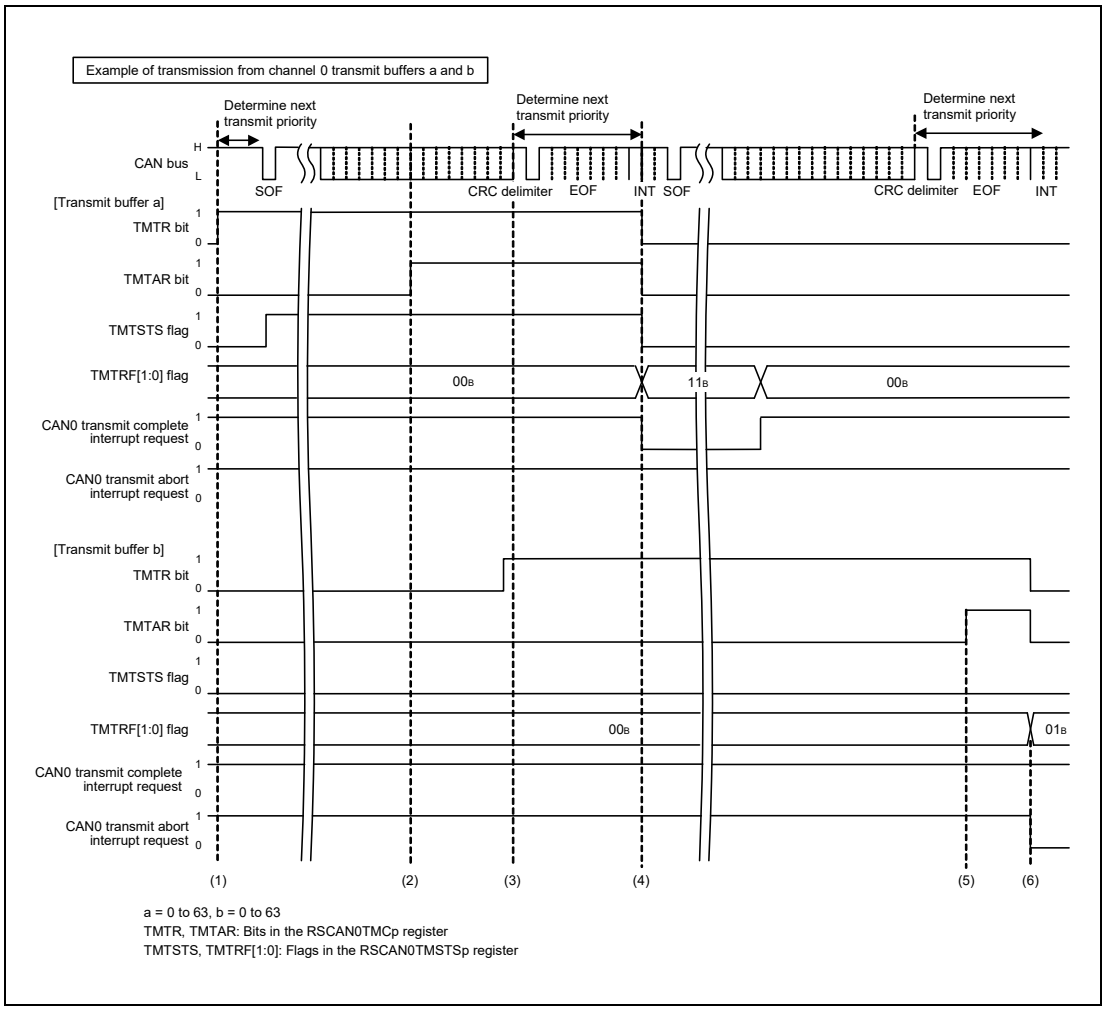

Figure 16.28 Transmit Buffer Transmission Timing Chart (Transmit Abort Completed)

(1) When the TMTR bit in the RSCAN0TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmit buffer. If transmit buffer a is determined to be the highest-priority transmit buffer, the TMTSTS flag in the corresponding RSCAN0TMSTSa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.

(2) When the transmit buffer is determined for the next transmission or is in progress of transmission, message transmission is not aborted unless an error or arbitration lost occurs even if the TMTAR bit is set to 1 (transmit abort is requested).

(3) The priority determination starts with the CRC delimiter for the next transmission. In this timing chart, buffer b is not selected as the next transmit buffer. Some delay may occur in the determination time if any other channels are performing the transmit priority determination processing. However, it does not affect the transmission interval because the determination will be completed before bit 3 of intermission.

(4) When transmit completes successfully, the TMTRF[1:0] flag in the RSCAN0TMSTSa register is set to 11_B (transmission has been completed (with transmit abort request)) and the TMTSTS flag and the TMTR bit in the RSCAN0TMCa register are cleared to 0. When the TMIEa bit in the RSCAN0TMIEC0 register is 1 (transmit buffer interrupt is enabled), a CAN0 transmit complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B (transmission is in progress or no transmit request is present).

(5) When another CAN node is transmitting data on the CAN bus (TMTSTS flag = 0), the TMTR bit cannot be cleared to 0 if the TMTAR bit is set to 1 while the corresponding channel is determining transmit priority.

(6) After the internal processing time has passed, the transmission is terminated and the TMTRF[1:0] flag is set to 01_B. When the transmit buffer is neither transmitting data nor selected as the next transmit buffer and when priority determination is not being made, an abort request is immediately accepted and the TMTRF[1:0] flag is set to 01_B. At this time, the TMTR and TMTAR bits are cleared to 0. When transmit abort is completed with the TAIE bit in the RSCAN0CmCTR register set to 1 (transmit abort interrupt is enabled), an interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B.

If an arbitration lost has occurred after the CAN channel started transmission, the TMTSTS bit is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC delimiter to search for the highest-priority transmit buffer. If an error has occurred during transmission or after arbitration lost, the priority determination processing is reexecuted during transmission of an error frame.

16.5.3.2 Procedure for Transmission from Transmit/Receive FIFO Buffers

Figure 16.29 shows the procedure for transmission from transmit/receive FIFO buffers.

Figure 16.30 shows a timing chart where messages are transmitted from two transmit/receive FIFO buffers in the same channel and transmission has been successfully completed. **Figure 16.31** shows a timing chart where messages are transmitted from two transmit/receive FIFO buffers in the same channel and transmit abort has been completed.

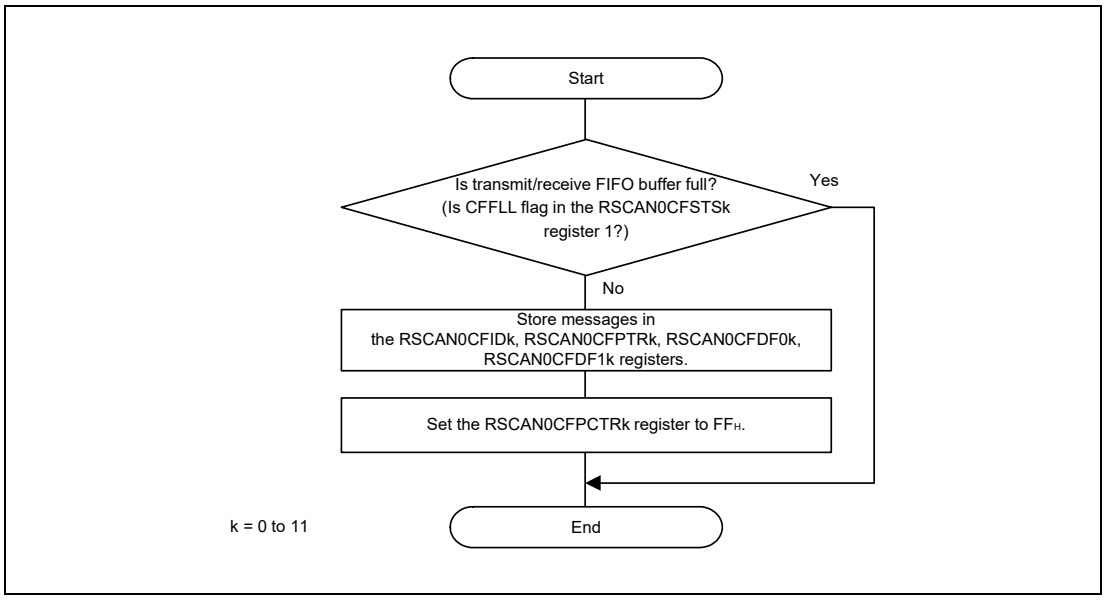

Figure 16.29 Procedure for Transmission from Transmit/Receive FIFO Buffers

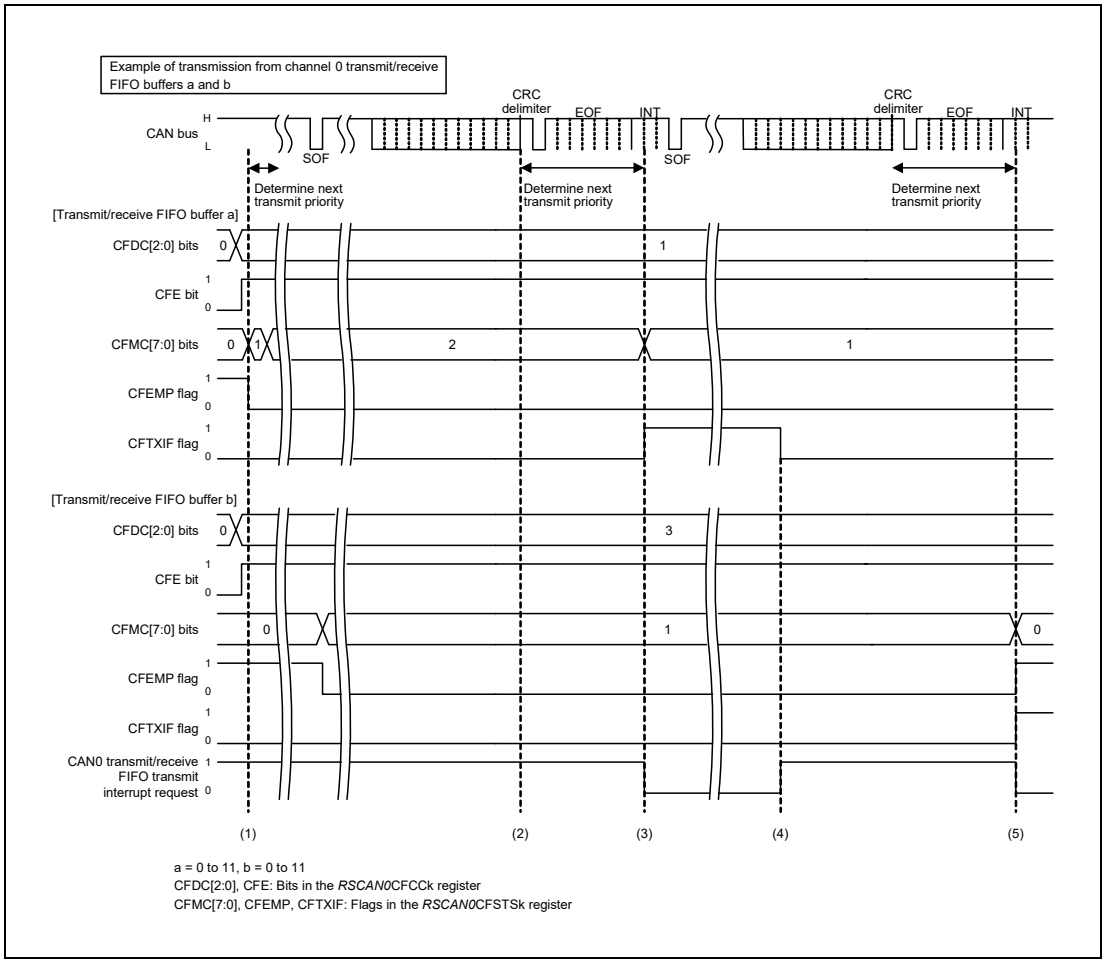

Figure 16.30 Transmit/Receive FIFO Buffer Transmission Timing Chart (Transmission Completed Successfully)

(1) While the CAN bus is idle, the priority determination processing starts to determine the highest-priority transmit message when the CFE bit in the RSCAN0CFCCa register is 1 (transmit/receive FIFO buffers are used), the CFDC[2:0] value in the RSCAN0CFCCa register is 001_B (4 messages) or more, and the CFMC[7:0] value in the RSCAN0CFSTSa register is 01_H or more. When the highest-priority transmit message has been determined, transmission of the message starts. In this figure, the message is transmitted from transmit/receive FIFO buffer a of channel 0.

(2) When a transmit request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission. Some delay may occur in the determination time if any other channels are performing the transmit priority determination processing. However, it does not affect the transmission interval because the determination will be completed before bit 3 of intermission.

(3) When transmit completes successfully, the CFMC[7:0] value in the RSCAN0CFSTSa register is decremented by 1. Setting the CFIM bit in the RSCAN0CFCCa register to 1 (a FIFO transmission interrupt request is generated each time a message has been transmitted) sets the CFTXIF flag in the RSCAN0CFSTSk register to 1 (a transmit/receive FIFO transmission interrupt request is present).

(4) The CFTXIF flag can be cleared by the program.

(5) Message transmission from transmit/receive FIFO buffer b of channel 0 has been completed and the CFMC[7:0] value in the RSCAN0CFSTSb register is decremented by 1. The CFMC[7:0] bits

are cleared to 00_H and therefore the CFEMP flag in the RSCAN0CFSTSk register is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)).

Transmission is continued until the CFEMP flag is set to 1. It is possible to continuously store transmit messages in FIFO buffers until the CFFLL flag in the RSCAN0CFSTSa register and RSCAN0CFSTSb register are set to 1 (the transmit/receive FIFO buffer is full).

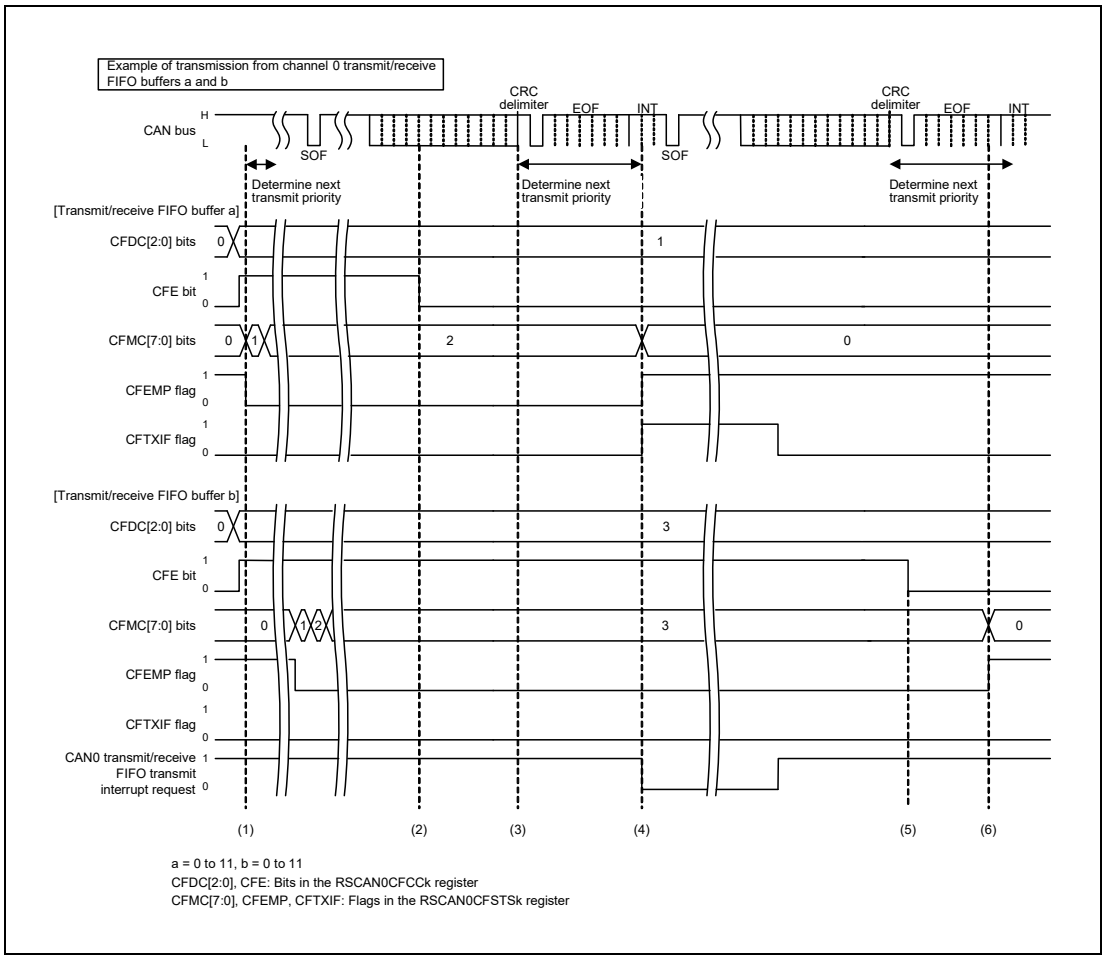

Figure 16.31 Transmit/Receive FIFO Buffer Transmission Timing Chart (Transmit Abort Completed)

(1) While the CAN bus is idle, the priority determination processing starts to determine the highest-priority transmit message when the CFE bit in the RSCAN0CFCCa register (a = 0 to 11) is 1 (transmit/receive FIFO buffers are used), the CFDC[2:0] value in the RSCAN0CFCCa register is 001_B (4 messages) or more, and the CFMC[7:0] value in the RSCAN0CFSTSa register is 01_H or more. When the highest-priority transmit message has been determined, transmission of the message starts. In this figure, the message is transmitted from transmit/receive FIFO buffer a of channel 0.

(2) When transmission is in progress or the transmit/receive FIFO buffer is determined for the next transmission, message transmission is not aborted unless an error or arbitration lost occurs even if the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).

(3) When a transmit request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission. In this figure, transmit/receive FIFO buffer b is not selected as a buffer for the next transmission. Some delay may occur in the determination time if any other channels are performing the transmit priority determination processing. However, it does not affect the transmission interval because the determination will be completed before bit 3 of intermission.

(4) When transmit completes successfully, the CFMC[7:0] value is cleared to 00_H. Setting the CFIM bit to 1 (a FIFO transmission interrupt request is generated each time a message has been transmitted) sets the CFTXIF flag in the RSCAN0CFSTSa register to 1 (a transmit/receive FIFO transmission interrupt request is present). The CFTXIF flag can be cleared by the program.

(5) If another CAN node on the CAN bus is transmitting data (not from transmit/receive FIFO buffer b), transmit/receive FIFO buffers cannot be disabled immediately even if the CFE bit in the RSCAN0CFCCb register is cleared to 0 (no transmit/receive FIFO buffer is used) during transmit priority determination. (The CFEMP flag in the RSCAN0CFSTSb register is not set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)) immediately.)

(6) After the internal processing time has passed, transmit/receive FIFO buffers are disabled and the CFMC[7:0] bits in the RSCAN0CFSTSb register are cleared to 00_H and the CFEMP flag is set to 1. When the transmit/receive FIFO buffer is neither transmitting data nor selected as the next transmit buffer and when priority determination is not in progress, the transmit/receive FIFO buffer is immediately disabled. (The CFMC[7:0] bits are cleared to 00_H and the CFEMP flag is set to 1.)

16.5.3.3 Procedure for Transmission from the Transmit Queue

Figure 16.32 shows the procedure for transmission from the transmit queue.

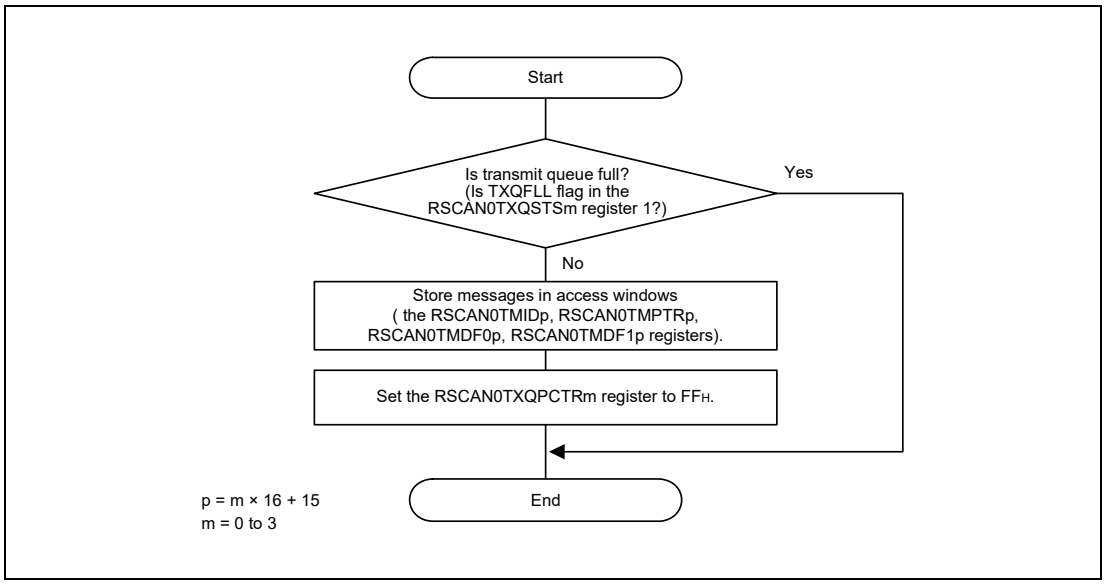

Figure 16.32 Procedure for Transmission from the Transmit Queue

16.5.3.4 Transmit History Buffer Reading Procedure

Transmit history data can be read from the RSCAN0THLACCm register. The next data can be accessed by writing FF_H to the corresponding RSCAN0THLPCTRm register (m = 0 to 3) after reading a set of data. **Figure 16.33** shows the transmit history buffer reading procedure.

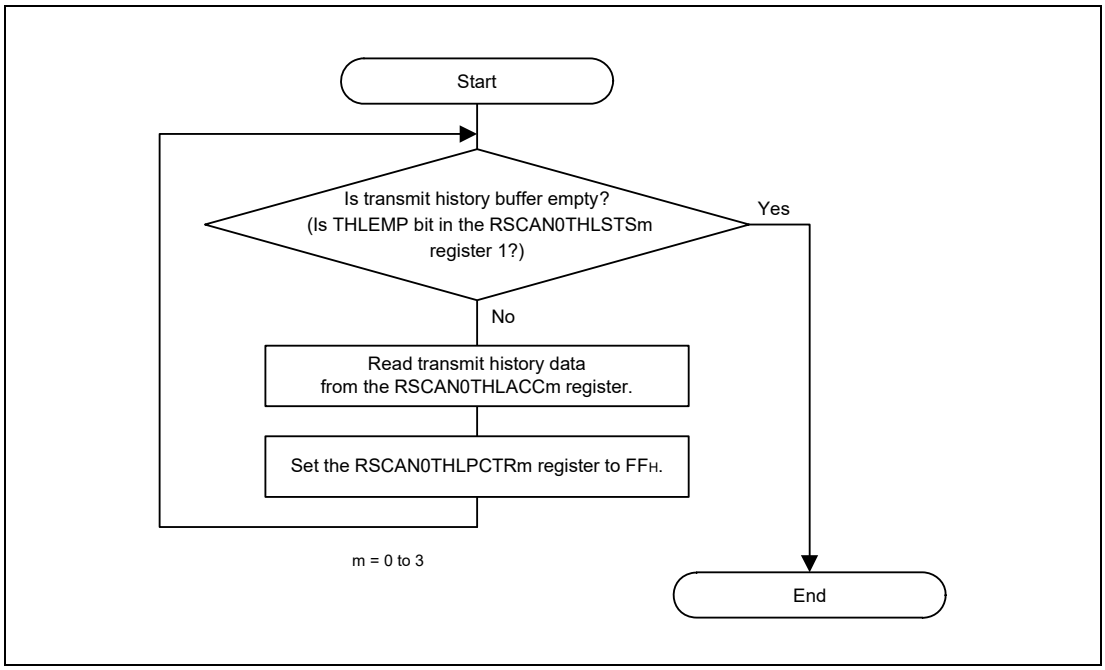

Figure 16.33 Transmit History Buffer Reading Procedure

16.5.4 Test Settings

16.5.4.1 Self-Test Mode Setting Procedure

Self-test mode allows communication test on a channel basis by receiving messages transmitted from the own node.

Figure 16.34 shows the self-test mode setting procedure.

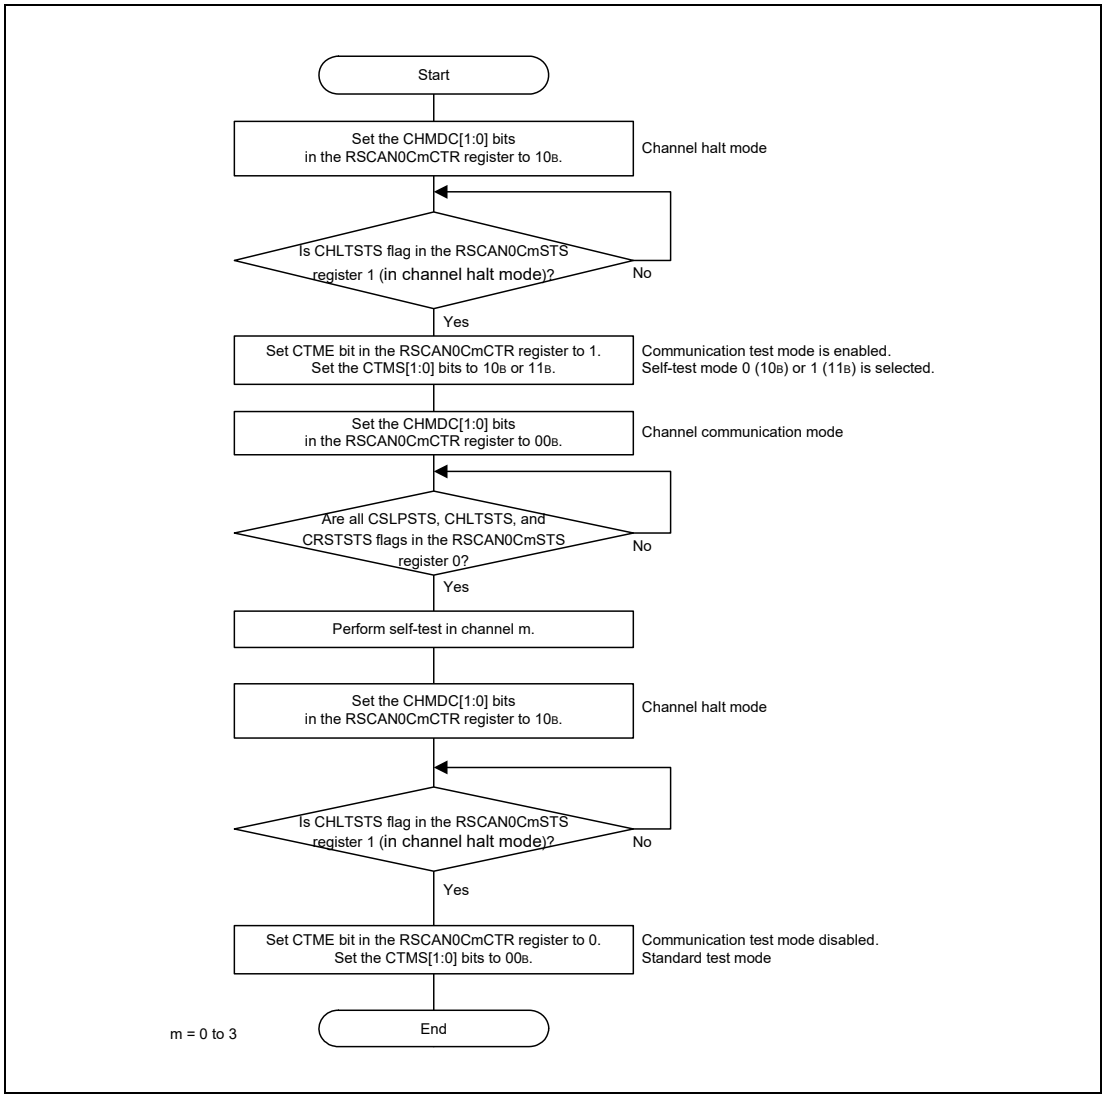

Figure 16.34 Self-Test Mode Setting Procedure

16.5.4.2 Procedure for Releasing the Protection

Since the global test function in **Table 16.94** is protected, write the protection release data 1 and release data 2 in succession to the LOCK[15:0] bits in the RSCAN0GLOCKK register, then set the target test bit to 1.

Table 16.94 Protection Release Data for Test Function

Test Function	Protection Release Data 1	Protection Release Data 2	Target Bit
RAM test	7575_H	$8A8A_H$	RTME bit in the RSCAN0GTSTCTR register

If an incorrect value is written to the LOCK[15:0] bits, restart from writing the protection release data 1. **Figure 16.35** shows the procedure for releasing the protection.

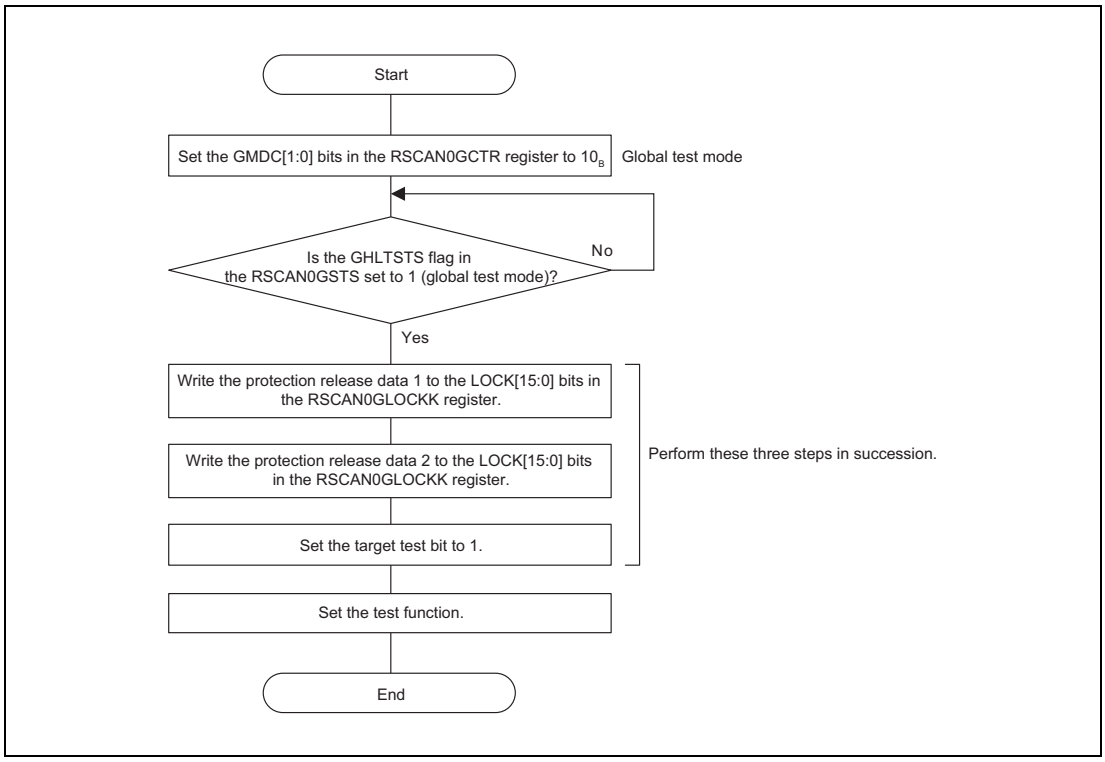

Figure 16.35 Protection Release Procedure

16.5.4.3 RAM Test Setting Procedure

RAM tests include CAN RAM read/write test. The read/write test verifies that data written to the RAM is read correctly. Before closing the RAM test, write 0000 0000_H to all pages of the CAN RAM.

Figure 16.36 shows the RAM test setting procedure.

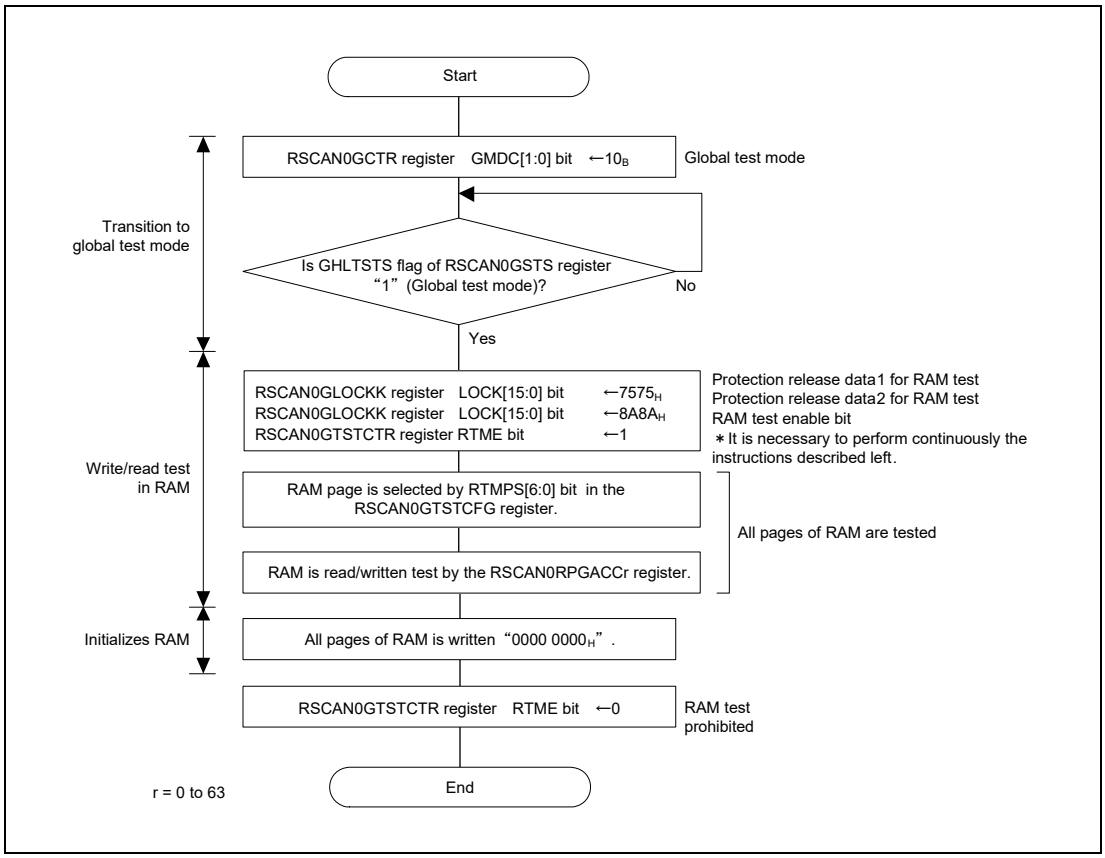

Figure 16.36 RAM Test Setting Procedure

16.5.4.4 Inter-Channel Communication Test Setting Procedure

Communication test can be performed by transmitting and receiving data between different channels.

Figure 16.37 shows the inter-channel communication test setting procedure.

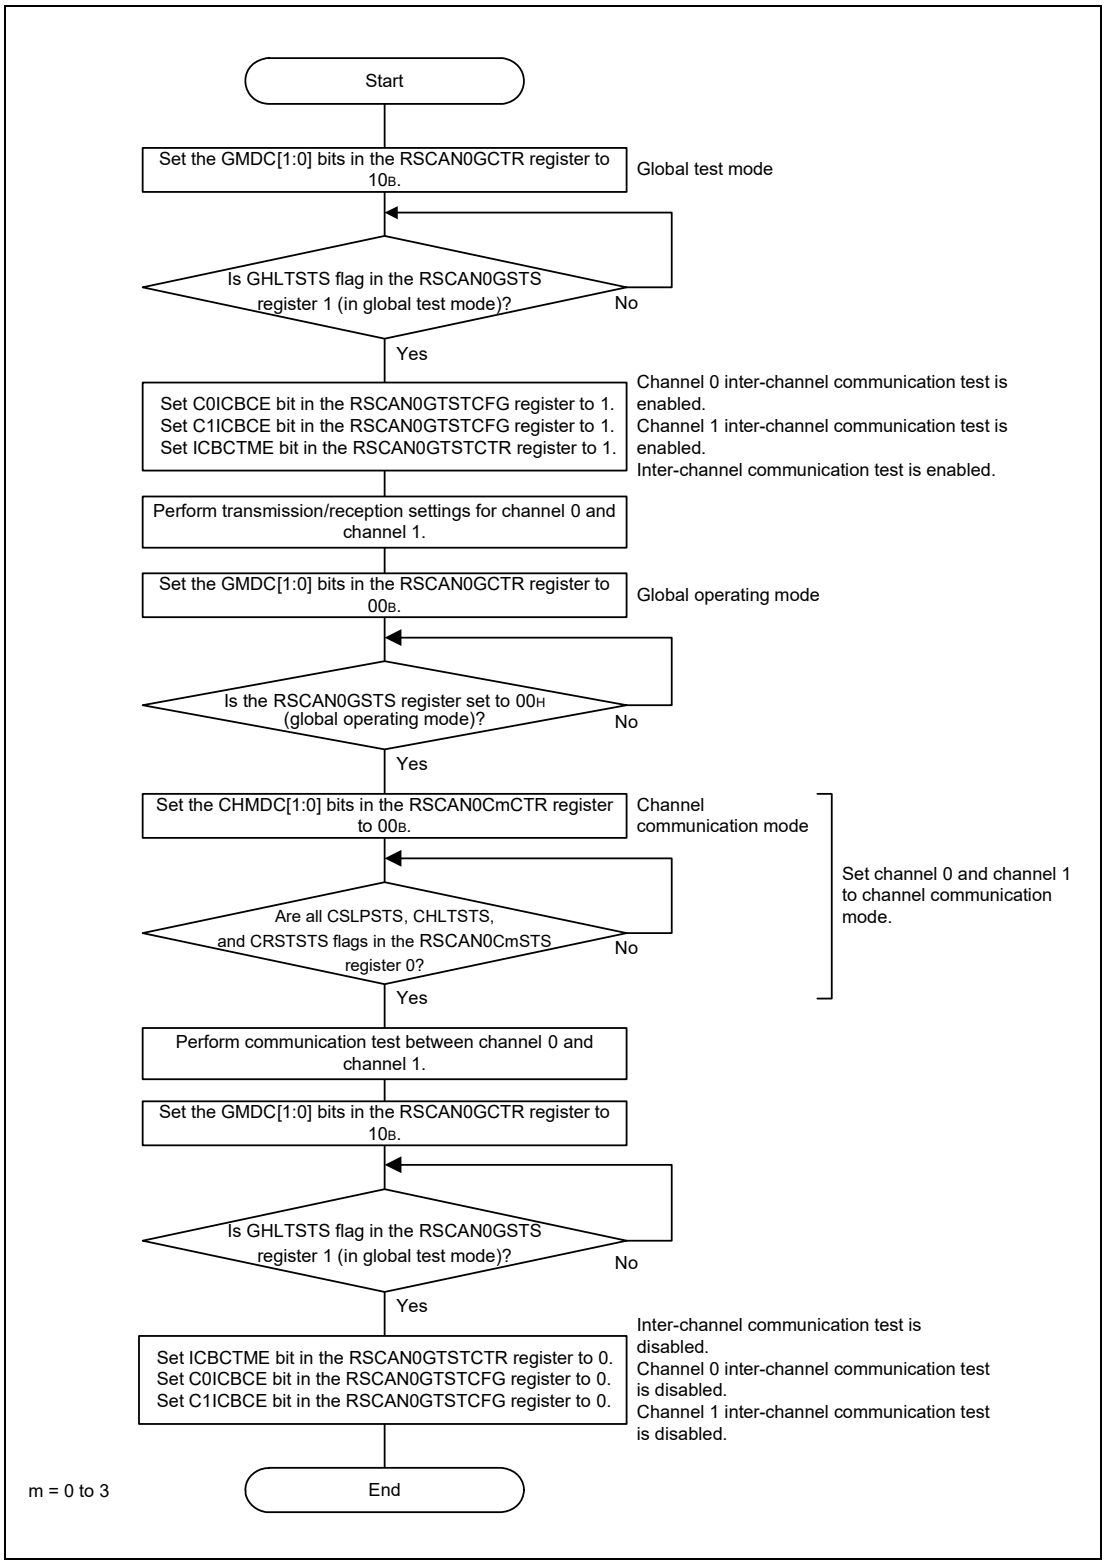

Figure 16.37 Inter-Channel Communication Test Setting Procedure

16.6 Notes on the RS-CAN Module

- When changing a global mode, check the GSLPSTS, GHLTSTS, and GRSTSTS flags in the RSCAN0GSTS register for transitions. When changing a channel mode, check the CSLPSTS, CHLTSTS, and CRSTSTS flags in the RSCAN0CmSTS register (m = 0 to 3) for transitions.
- The acceptance filter processing checks receive rules sequentially in ascending order from the lowest rule number. If the same ID, IDE bit, or RTR bit value is set in multiple receive rules, the lowest-numbered receive rule is used to pass the received message through the acceptance filter processing. If the message does not pass through the subsequent DLC filter processing, the data processing is terminated without returning to the acceptance filter processing and the message is not stored in the buffer.
- When linking transmit buffers to transmit/receive FIFO buffers or allocating transmit buffers to transmit queues, set the control register (RSCAN0TMCp register) of the corresponding transmit buffer to 00_H. The status register (RSCAN0TMSTSp register) of the corresponding transmit buffer should not be used. Flags in other status registers (RSCAN0TMTRSTS0, RSCAN0TMTRSTS1, RSCAN0TMTARSTS0, RSCAN0TMTARSTS1, RSCAN0TMTCSTS0, RSCAN0TMTCSTS1, RSCAN0TMTASTS0, and RSCAN0TMTASTS1 registers), which correspond to transmit buffers linked to transmit/receive FIFO buffers or allocated to transmit queues, remain unchanged. Set the enable bit in the corresponding interrupt enable register (RSCAN0TMIEC0, RSCAN0TMIEC1 register) to 0 (transmit buffer interrupt is disabled).
- Do not allocate transmit buffers that are linked to transmit/receive FIFO buffers to transmit queues.
- Only a single transmit/receive FIFO buffer can be linked to a transmit buffer. Do not link two or more transmit/receive FIFO buffers to the same transmit buffer.
- When the CANm bit time clock is selected as a timestamp counter clock source, the timestamp counter stops when the corresponding channel has transitioned to channel reset mode or channel halt mode.
- If an attempt is made to store a new message when the receive FIFO buffer and the transmit/receive FIFO buffer are full, the new message is discarded. Before attempting to store a new message in the transmit/receive FIFO buffer or the transmit queue, check that the transmit/receive FIFO buffer or the transmit queue is not full.
- The values of unused receive buffers (the RSCAN0RMIDq, RSCAN0RMPTRq, RSCAN0RMDF0q, and RSCAN0RMDF1q registers), receive FIFO buffer access registers (the RSCAN0RFIDx, RSCAN0RFPTRx, RSCAN0RFDF0x, and RSCAN0RFDF1x registers) and transmit/receive FIFO buffer access registers (RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers) become undefined once they exit the global reset mode to enter the global operation mode or global test mode.

Section 17 FlexRay

17.1 FlexRay Module

The FlexRay IP-module performs communication according to the FlexRay protocol specification v2.1. With maximum specified sample clock the bitrate is 10 MBit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

17.1.1 Overview

For communication on a FlexRay network, individual message buffers with up to 254 data bytes are configurable. The message storage consists of a single-ported Message RAM that holds up to 128 message buffers. All functions concerning the handling of messages are implemented in the message handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay channel protocol controllers and the message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the FlexRay IP-module can be accessed directly by an external host via the module's host interface. These registers are used to control/configure/monitor the FlexRay channel protocol controllers, message handler, global time unit, system universal control, frame and symbol processing, network management, interrupt control, to access the message RAM via input/output buffer; and to control the data transfer between the message RAM and the local RAM/global RAM.

The FlexRay IP-module supports the following features:

Item	Specification
Communication	Conformance with FlexRay protocol specification v2.1
Data transfer rate	Up to 10 Mbit/s on each channel
Data link layer clock frequency	80 MHz
Input/output pins per channel	TxD, RxD, ExEN
FlexRay channels	2 (channel A and B)
Message buffer	Up to 128 message buffers configurable
	Configuration of message buffers with different payload lengths possible
	Each message buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO
	Filtering for slot counter, cycle counter, and channel
Message RAM	8 Kbytes of message RAM for storage of e.g.
	128 message buffers with max. 48 byte data section
	Up to 30 message buffers with 254 byte data section
FIFO	One configurable receive FIFO
Message buffer access	By host CPU via input and output buffer Input buffer: Holds message to be transferred to the message RAM Output buffer: Holds message read from the message RAM
	By data transfer function Input transfer: Message buffer content is transferred from local RAM/global RAM to message RAM on CPU request Output transfer: Message buffer content is transferred from message RAM to local RAM/global RAM automatically
Network management	Supported
Interrupts	Maskable module interrupts
Timer	Two absolute timers One relative timer One stop watch timer

17.1.2 Terms and Abbreviations

The following terms and abbreviations are used throughout this section.

Abbreviation	Meaning
AP	Action Point
BD	Bus Driver
BSS	Byte Start Sequence
CAS	Collision Avoidance Symbol
CC	Communication Controller
CHI	Controller Host Interface
CIF	Host CPU Interface Block
CRC	Cyclic Redundancy Check
FES	Frame End Sequence
FSS	Frame Start Sequence
FIFO	First In First Out
FSM	Finite State Machine
FSP	Frame and Symbol Processing Block
FTM	Fault Tolerant Midpoint
GIF	Generic Interface Block
GTU	Global Time Unit Block
IBF	Input Buffer
INT	Interrupt Control Block
MBF	Message (Buffer) RAM
MHD	Message Handler Block
MT	Macrotick
MTS	Media Access Test Symbol
NCT	Network Communication Time
NEM	Network Management Block
NIT	Network Idle Time
NM	Network Management
OBF	Output Buffer
PE	Protocol Engine
POC	Protocol Operation Control
PRT	Protocol Controller Block
SDL	Specification and Description Language
SUC	System Universal Control Block
TBF	Transient Buffer
TDMA	Time Division Multiple Access (media access method)
TRH	Transfer Handler
TSS	Transmission Start Sequence
TT-D	Time Triggered Distributed synchronization (protocol mode)
URAM	User RAM (RAM used to store FlexRay messages, message buffers, settings, and states)
µT	Microtick
WUP	Wakeup Pattern
WUS	Wakeup Symbol

17.1.3 Block Diagram

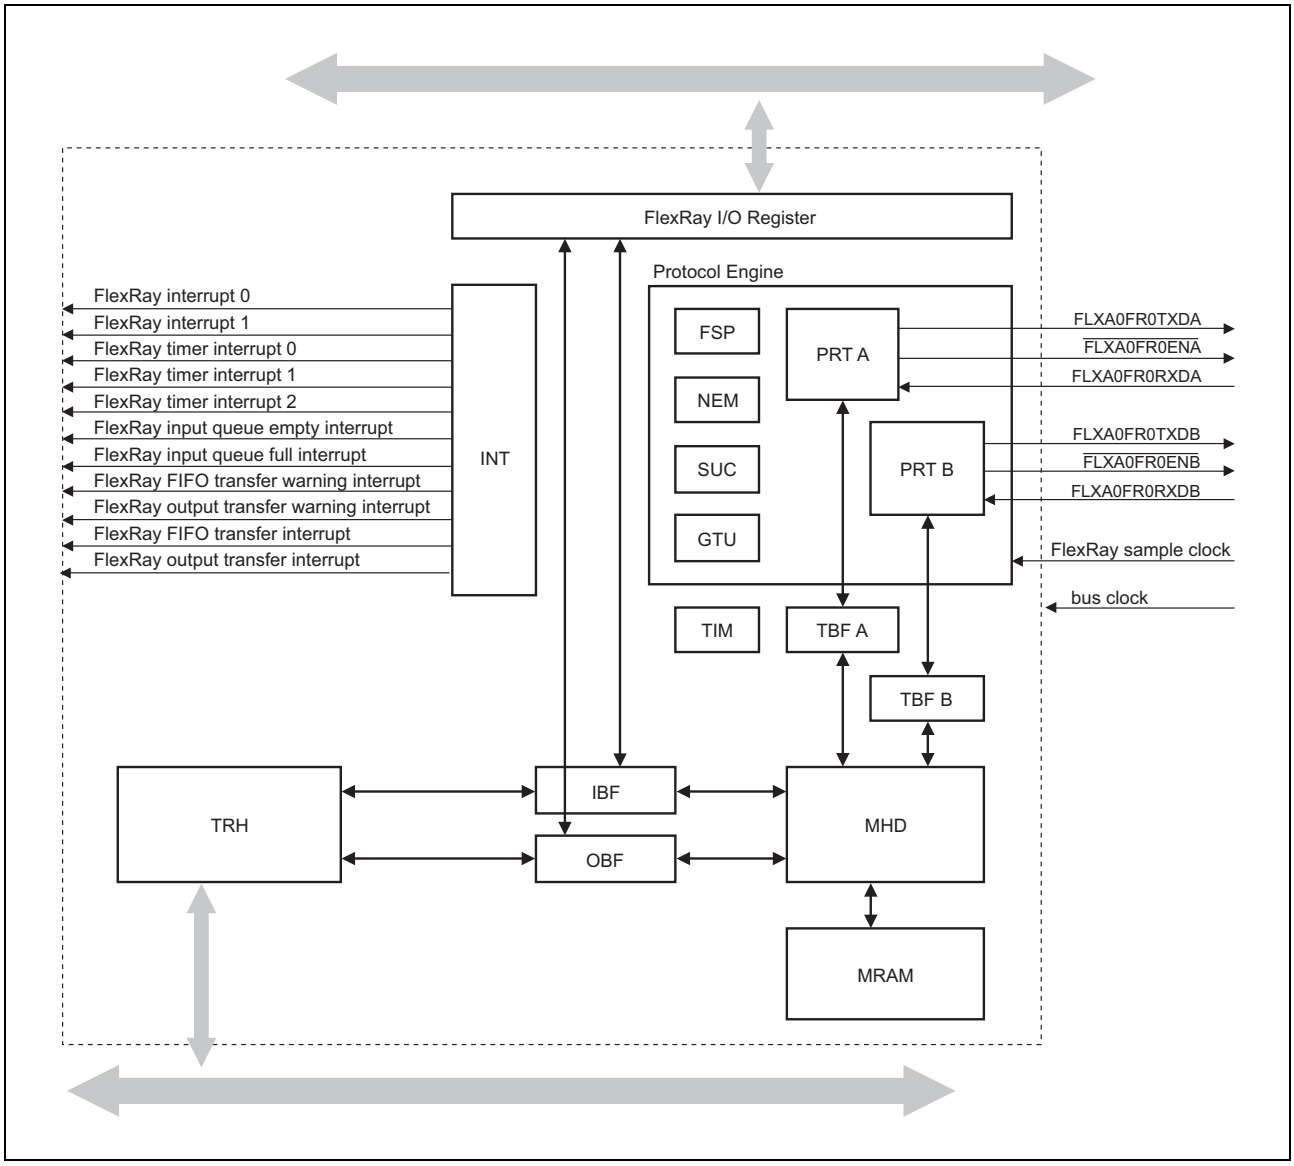

Figure 17.1 FlexRay IP Block Diagram

Input Buffer (IBF)

For write access to the message buffers configured in the message RAM, the host can write the header and data section for a specific message buffer to the input buffer. The message handler then transfers the data from the input buffer to the selected message buffer in the message RAM.

Output Buffer (OBF)

For read access to a message buffer configured in the message RAM the message handler transfers the selected message buffer to the output buffer. After the transfer has completed, the host can read the header and data section of the transferred message buffer from the output buffer.

Message Handler (MHD)

The FlexRay message handler controls data transfers between the following components:

- Input/output buffer and message RAM
- Temporary buffer RAMs of the two FlexRay protocol controllers and message RAM

Message RAM (MRAM)

The message RAM consists of a single-ported RAM that store up to 128 FlexRay message buffers together with the related configuration data (header and data partition).

Temporary Buffer RAM (TBF A/B)

Stores the data section of two complete messages.

FlexRay Channel Protocol Controller (PRT A/B)

The FlexRay channel protocol controllers consist of shift register and FlexRay protocol FSM. They are connected to the temporary buffer RAMs for intermediate message storage and to the physical layer via bus driver BD.

They perform the following functionality:

- Control and check of bit timing
- Reception/transmission of FlexRay frames and symbols
- Check of header CRC
- Generation/checking of frame CRC
- Interfacing to bus driver

Global Time Unit (GTU)

The global time unit performs the following functions:

- Generation of microtick
- Generation of macrotick
- Fault tolerant clock synchronization by FTM algorithm
  - Rate correction
  - Offset correction
- Cycle counter
- Timing control of static segment
- Timing control of dynamic segment (minislotting)
- Support of external clock correction

System Universal Controller(SUC)

The system universal controller controls the following functions:

- Configuration
- Wakeup
- Startup
- Normal Operation
- Passive Operation

Frame and Symbol Processing (FSP)

The frame and symbol processing controls the following functions:

- Checks the correct timing of frames and symbols
- Tests the syntactical and semantical correctness of received frames
- Sets the slot status flags

Network Management (NEM)

Handles the network management vector.

Interrupt Control (INT)

The interrupt controller performs the following functions:

- Provides error and status interrupt flags
- Enable/disable interrupt sources
- Assignment of interrupt sources to one of the two general module interrupt lines
- Enable/disable module interrupt lines

Timer (TIM)

The timer module includes the following macrotick timer:

- Two absolute timers
- One relative timer
- One stop watch timer

Transfer Handler (TRH)

Handles the data transfer between local RAM/global RAM and FlexRay module.

The Transfer Handler supports the following transfer types:

- Transfer of buffer configuration data from the local RAM/global RAM to the message RAM
- Transfer of payload data for transmit buffer from the local RAM/global RAM to the message RAM
- Transfer of buffer configuration data and payload data for transmit buffer from the local RAM/global RAM to the message RAM
- Automatic transfer of payload data from receive buffer to the local RAM/global RAM upon frame reception
- Automatic transfer of payload data, buffer configuration data and message buffer status data from receive buffer to the local RAM/global RAM upon frame reception
- Automatic transfer of buffer configuration data and message buffer status data from the dedicated transmit/receive buffer to the local RAM/global RAM in response to slot status update
- Manual transfer of payload data, buffer configuration data and message buffer status data from the dedicated transmit/receive buffer to the local RAM/global RAM

17.2 Programmer's Model

17.2.1 Register Map

The FlexRay module allocates an address space as shown in **Table 17.2**.

Within this specification the "values after reset" refers to the microcontroller's HW reset. For registers in the address range 0010_H to $0FFF_H$ the "value after reset" is also applicable when the SW reset (using FLXA0FROC.OE) is applied.

The addresses in this specification are listed as offsets from a base address. The base address ERAY must thus be added to the addresses listed in **Table 17.1**. In addition, PE1 accesses the FlexRay registers in a range defined by a different base address (top address in **Table 17.1**) to that for access by the PCU (bottom address in **Table 17.1**). For access from the PCU, "FLXA0" in the register symbol should be replaced by "FLXA0PCU" and the base address becomes that given against "FlexRay (from PCU)" in **Table 17.1**. However, the registers have the same functions.

Table 17.1 Base Address <ERAY>

Base Address	ERAY (User)
FlexRay	$1002\ 0000_H$
FlexRay (from PCU)	$FC02\ 0000_H$

Table 17.2 FlexRay Register Map (1/3)

Register Name	Symbol	Value after Reset	Address	Access Size
FlexRay operation control register	FLXA0FROC	$0000\ 0000_H$	<ERAY> + 0004_H	8, 16, 32
FlexRay operation status register	FLXA0FROS	$0000\ 0000_H$	<ERAY> + $000C_H$	8, 16, 32
FlexRay lock register	FLXA0FRLCK	$0000\ 0000_H$	<ERAY> + $001C_H$	8, 16, 32
FlexRay error interrupt register	FLXA0FREIR	$0000\ 0000_H$	<ERAY> + 0020_H	8, 16, 32
FlexRay status interrupt register	FLXA0FRSIR	$0000\ 0000_H$	<ERAY> + 0024_H	8, 16, 32
FlexRay error interrupt line select	FLXA0FREILS	$0000\ 0000_H$	<ERAY> + 0028_H	8, 16, 32
FlexRay status interrupt line select	FLXA0FRSILS	$0303\ FFFF_H$	<ERAY> + $002C_H$	8, 16, 32
FlexRay error interrupt enable set register	FLXA0FREIES	$0000\ 0000_H$	<ERAY> + 0030_H	8, 16, 32
FlexRay error interrupt enable reset register	FLXA0FREIER	$0000\ 0000_H$	<ERAY> + 0034_H	8, 16, 32
FlexRay status interrupt enable set register	FLXA0FRSIES	$0000\ 0000_H$	<ERAY> + 0038_H	8, 16, 32
FlexRay status interrupt enable reset register	FLXA0FRSIER	$0000\ 0000_H$	<ERAY> + $003C_H$	8, 16, 32
FlexRay interrupt line enable register	FLXA0FRILE	$0000\ 0000_H$	<ERAY> + 0040_H	8, 16, 32
FlexRay timer 0 configuration register	FLXA0FRT0C	$0000\ 0000_H$	<ERAY> + 0044_H	8, 16, 32
FlexRay timer 1 configuration register	FLXA0FRT1C	$0002\ 0000_H$	<ERAY> + 0048_H	8, 16, 32
FlexRay stop watch register 1	FLXA0FRSTPW1	$0000\ 0000_H$	<ERAY> + $004C_H$	8, 16, 32
FlexRay stop watch register 2	FLXA0FRSTPW2	$0000\ 0000_H$	<ERAY> + 0050_H	8, 16, 32
FlexRay SUC configuration register 1	FLXA0FRSUCC1	$0C40\ 1080_H$	<ERAY> + 0080_H	8, 16, 32
FlexRay SUC configuration register 2	FLXA0FRSUCC2	$0100\ 0504_H$	<ERAY> + 0084_H	8, 16, 32
FlexRay SUC configuration register 3	FLXA0FRSUCC3	$0000\ 0011_H$	<ERAY> + 0088_H	8, 16, 32
FlexRay NEM configuration register	FLXA0FRNEMC	$0000\ 0000_H$	<ERAY> + $008C_H$	8, 16, 32

FlexRay GTU configuration register 11	FLXA0FRGTUC11	0000 0000$_H$	<ERAY> + 00C8$_H$	8, 16, 32
FlexRay CC status vector register	FLXA0FRCCSV	0010 4000$_H$	<ERAY> + 0100$_H$	8, 16, 32
FlexRay CC error vector register	FLXA0FRCCEV	0000 0000$_H$	<ERAY> + 0104$_H$	8, 16, 32
FlexRay slot counter value register	FLXA0FRSCV	0000 0000$_H$	<ERAY> + 0110$_H$	8, 16, 32
FlexRay macrotick and cycle counter value register	FLXA0FRMTCCV	0000 0000$_H$	<ERAY> + 0114$_H$	8, 16, 32
FlexRay rate correction value register	FLXA0FRRCV	0000 0000$_H$	<ERAY> + 0118$_H$	8, 16, 32
FlexRay offset correction value register	FLXA0FROCV	0000 0000$_H$	<ERAY> + 011C$_H$	8, 16, 32
FlexRay sync frame status register	FLXA0FRSFS	0000 0000$_H$	<ERAY> + 0120$_H$	8, 16, 32
FlexRay symbol window and NIT status register	FLXA0FRSWNIT	0000 0000$_H$	<ERAY> + 0124$_H$	8, 16, 32
FlexRay aggregated channel status register	FLXA0FRACS	0000 0000$_H$	<ERAY> + 0128$_H$	8, 16, 32
FlexRay even sync ID register n (n=1 to 15)	FLXA0FRESIDn (n = 1 to 15)	0000 0000$_H$	<ERAY> + 0130$_H$ to <ERAY> + 0168$_H$ (<ERAY> + 0130$_H$ + (n-1)*4)	8, 16, 32
FlexRay odd sync ID register n (n=1 to 15)	FLXA0FROSIDn (n = 1 to 15)	0000 0000$_H$	<ERAY> + 0170$_H$ to <ERAY> + 01A8$_H$ (<ERAY> + 0170$_H$ + (n-1)*4)	8, 16, 32
FlexRay network management vector register n (n = 1 to 3)	FLXA0FRNMVn (n = 1 to 3)	0000 0000$_H$	<ERAY> + 01B0$_H$ to <ERAY> + 01B8$_H$ (<ERAY> + 01B0$_H$ + (n-1)*4)	8, 16, 32
FlexRay message RAM configuration register	FLXA0FRMRC	0180 0000$_H$	<ERAY> + 0300$_H$	8, 16, 32
FlexRay FIFO rejection filter register	FLXA0FRFRF	0180 0000$_H$	<ERAY> + 0304$_H$	8, 16, 32
FlexRay FIFO rejection filter mask register	FLXA0FRFRFM	0000 0000$_H$	<ERAY> + 0308$_H$	8, 16, 32
FlexRay FIFO critical level register	FLXA0FRFCL	0000 0080$_H$	<ERAY> + 030C$_H$	8, 16, 32
FlexRay message handler status register	FLXA0FRMHDS	0000 0080$_H$	<ERAY> + 0310$_H$	8, 16, 32
FlexRay last dynamic transmit slot register	FLXA0FRLDTS	0000 0000$_H$	<ERAY> + 0314$_H$	8, 16, 32
FlexRay FIFO status register	FLXA0FRFSR	0000 0000$_H$	<ERAY> + 0318$_H$	8, 16, 32
FlexRay message handler constraints flags register	FLXA0FRMHDF	0000 0000$_H$	<ERAY> + 031C$_H$	8, 16, 32
FlexRay transmission register i (i = 1 to 4)	FLXA0FRTXRQi (i = 1 to 4)	0000 0000$_H$	<ERAY> + 0320$_H$ to <ERAY> + 032C$_H$ (<ERAY> + 0320 $_H$ + (i-1)*4)	8, 16, 32
FlexRay new data register i (i = 1 to 4)	FLXA0FRNDATi (i = 1 to 4)	0000 0000$_H$	<ERAY> + 0330$_H$ to <ERAY> + 033C$_H$ (<ERAY> + 0330$_H$ + (i-1)*4)	8, 16, 32
FlexRay message buffer status changed register i (i = 1 to 4)	FLXA0FRMBSCi (i = 1 to 4)	0000 0000$_H$	<ERAY> + 0340$_H$ to <ERAY> + 034C$_H$ (<ERAY> + 0340$_H$ + (i-1)*4)	8, 16, 32

Table 17.2 FlexRay Register Map (3/3)

Register Name	Symbol	Value after Reset	Address	Access Size
FlexRay write data section register n (n = 1 to 64)	FLXA0FRWRDSn (n = 1 to 64)	0000 0000_H	<ERAY> + 0400_H to <ERAY> + $04FC_H$ (<ERAY> + 0400_H + (n-1)*4)	8, 16, 32
FlexRay write header section register 1	FLXA0FRWRHS1	0000 0000_H	<ERAY> + 0500_H	8, 16, 32
FlexRay write header section register 2	FLXA0FRWRHS2	0000 0000_H	<ERAY> + 0504_H	8, 16, 32
FlexRay write header section register 3	FLXA0FRWRHS3	0000 0000_H	<ERAY> + 0508_H	8, 16, 32
FlexRay input buffer command mask register	FLXA0FRIBCM	0000 0000_H	<ERAY> + 0510_H	8, 16, 32
FlexRay input buffer command request register	FLXA0FRIBCR	0000 0000_H	<ERAY> + 0514_H	8, 16, 32
FlexRay read data section register n (n = 1 to 64)	FLXA0FRRDDSn (n = 1 to 64)	0000 0000_H	<ERAY> + 0600_H to <ERAY> + $06FC_H$ (<ERAY> + 0600_H + (n-1)*4)	8, 16, 32
FlexRay read header section register 1	FLXA0FRRDHS1	0000 0000_H	<ERAY> + 0700_H	8, 16, 32
FlexRay read header section register 2	FLXA0FRRDHS2	0000 0000_H	<ERAY> + 0704_H	8, 16, 32
FlexRay read header section register 3	FLXA0FRRDHS3	0000 0000_H	<ERAY> + 0708_H	8, 16, 32
FlexRay message buffer status register	FLXA0FRMBS	0000 0000_H	<ERAY> + $070C_H$	8, 16, 32
FlexRay output buffer command mask register	FLXA0FROBCM	0000 0000_H	<ERAY> + 0710_H	8, 16, 32
FlexRay output buffer command request register	FLXA0FROBCR	0000 0000_H	<ERAY> + 0714_H	8, 16, 32
FlexRay input transfer configuration register	FLXA0FRITC	0000 0000_H	<ERAY> + 0800_H	8, 16, 32
FlexRay output transfer configuration register	FLXA0FROTC	0000 0000_H	<ERAY> + 0804_H	8, 16, 32
FlexRay input pointer table base address register	FLXA0FRIBA	0000 0000_H	<ERAY> + 0808_H	8, 16, 32
FlexRay FIFO pointer table base address register	FLXA0FRFBA	0000 0000_H	<ERAY> + $080C_H$	8, 16, 32
FlexRay Output pointer table base address register	FLXA0FROBA	0000 0000_H	<ERAY> + 0810_H	8, 16, 32
FlexRay input queue control register	FLXA0FRIQC	0000 0000_H	<ERAY> + 0814_H	8, 16, 32
FlexRay user input transfer request register	FLXA0FRUIR	0000 0000_H	<ERAY> + 0818_H	8, 16, 32
FlexRay user output transfer request register	FLXA0FRUOR	0000 0000_H	<ERAY> + $081C_H$	8, 16, 32
FlexRay input transfer status register	FLXA0FRITS	0000 0000_H	<ERAY> + 0820_H	8, 16, 32
FlexRay output transfer status register	FLXA0FROTS	0000 0000_H	<ERAY> + 0824_H	8, 16, 32
FlexRay access error status register	FLXA0FRAES	0000 0000_H	<ERAY> + 0828_H	8, 16, 32
FlexRay access error address register	FLXA0FRAEA	0000 0000_H	<ERAY>+ $082C_H$	8, 16, 32
FlexRay message data available register i (i = 0 to 3)	FLXA0FRDAi (i = 0 to 3)	0000 0000_H	<ERAY> + 0830_H to <ERAY> + $083C_H$ (<ERAY> + 0830_H + i*4)	8, 16, 32
FlexRay H-Bus configuration register	FLXA0FRAHBC	0000 0000_H	<ERAY> + 0840_H	8, 16, 32
FlexRay timer 2 configuration register	FLXA0FRT2C	0000 0000_H	<ERAY> + 0844_H	8, 16, 32

17.2.2 FlexRay Operation Register

17.2.2.1 FLXA0FROC — FlexRay Operation Control Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	T2IE	T1IE	T0IE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 17.3 FLXA0FROC Register Contents

Bit Position	Bit Name	Function
31 to 19	—	Reserved These bits are always read as 0. When writing, always write 0.
18	T2IE	Timer 2 Interrupt Enable 0: Disabled 1: Enabled
17	T1IE	Timer 1 Interrupt Enable 0: Disabled 1: Enabled
16	T0IE	Timer 0 Interrupt Enable 0: Disabled 1: Enabled
15 to 8	—	Reserved These bits are always read as 0. When writing, always write 0.
7	OEP	Operation Enable Bit Protection 0: OE bit is unprotected 1: OE bit is protected
6 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	BEC	Byte Endian Control 0: Little endian 1: Big endian
0	OE	Operation Enable 0: Operation stopped SW reset 1: Operation Enabled

(1) FLXA0FROC.T2IE

Timer 2 Interrupt enable

This bit controls the timer 2 interrupt.

0: Disabled

No interrupt will be requested and the timer 2 interrupt line will be released if pending.

1: Enabled

Timer 2 interrupt will be asserted when FLXA0FROTS.T2IS is ‘1’.

(2) FLXA0FROC.T1IE

Timer 1 Interrupt enable

The user should only set this bit to ‘1’ when timer 1 interrupt is not enabled in the FlexRay Status interrupt enable register (FLXA0FRSIES.TI1E should be ‘0’).

This bit controls the timer 1 interrupt.

0: Disabled

No interrupt will be requested and the timer 1 interrupt line will be released if pending.

1: Enabled

Timer 1 interrupt will be asserted when FLXA0FROTS.T1IS is ‘1’.

(3) FLXA0FROC.T0IE

Timer 0 Interrupt enable

The user should only set this bit to ‘1’ when timer 0 interrupt is not enabled in the FlexRay Status interrupt enable register (FLXA0FRSIES.TI0E should be ‘0’).

This bit controls the timer 0 interrupt.

0: Disabled

No interrupt will be requested and the timer 0 interrupt line will be released if pending.

1: Enabled

Timer 0 interrupt will be asserted when FLXA0FROTS.T0IS is ‘1’.

(4) FLXA0FROC.OEP

Operation Enable Bit Protection

This bit protects against unintended write access to the OE bit.

0: OE bit is unprotected

Write access to the OE bit is enabled

1: OE bit is protected

Write access to the OE bit is disabled

(5) FLXA0FROC.BEC

Byte Endian Control

The user should only change this bit when FLXA0FROS.OS is ‘1’.

This bit controls the byte order on reading and writing the FlexRay network management vector register (FLXA0FRNMVn), FlexRay write data section (FLXA0FRWRDSn) and FlexRay read data section (FLXA0FRRDDSn). This bit also controls the byte order when reading or writing FlexRay payload data using the data transfer function.

For details about the byte alignment please refer to **Section 17.3.17, Byte Alignment**.

0: Little endian

Byte alignment in FLXA0FRNMVn, FLXA0FRWRDSn and FLXA0FRRDDSn is in little endian style.

1: Big endian

Byte alignment in FLXA0FRNMVn, FLXA0FRWRDSn and FLXA0FRRDDSn is in big endian style.

(6) FLXA0FROC.OE

Operation Enable

The user can only write to this bit when FLXA0FROC.OEP is ‘0’.

The user should only write this bit with ‘0’ when FLXA0FROS.OS is ‘1’.

The user should only write this bit with ‘1’ when FLXA0FROS.OS is ‘0’ and the FlexRay sample clock is enabled.

This bit controls the operation state and serves the software reset of the FlexRay module. The operation status bit (FLXA0FROS.OS) indicates whether the FlexRay module is in reset state or not.

0: Operation stopped SW reset

Forcibly moves the FlexRay module to its reset state, whatever the state of the FlexRay module is.

1: Operation Enabled

Reset state of the FlexRay module is released.

17.2.2.2 FLXA0FROS — FlexRay Operation Status Register

Do not rewrite this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $000C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	T2IS	T1IS	T0IS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.4 FLXA0FROS Register Contents

Bit Position	Bit Name	Function
31 to 19	—	Reserved These bits are always read as 0. When writing, always write 0.
18	T2IS	Timer 2 Interrupt Status 0: Timer 2 has not matched the conditions configured in the FLXA0FRT2C register 1: Timer 2 matched the conditions configured in the FLXA0FRT2C register
17	T1IS	Timer 1 Interrupt Status 0: Timer 1 has not matched the conditions configured in the FLXA0FRT1C register 1: Timer 1 matched the conditions configured in the FLXA0FRT1C register
16	T0IS	Timer 0 Interrupt Status 0: Timer 0 has not matched the conditions configured in the FLXA0FRTOC register 1: Timer 0 matched the conditions configured in the FLXA0FRT0C register
15 to 1	—	Reserved These bits are always read as 0. When writing, always write 0.
0	OS	Operation Status 0: Operation disabled, reset state 1: Operation enabled

(1) FLXA0FROS.T2IS

Timer 2 Interrupt Status

Writing ‘0’ has no effect on the bit value.

This bit represents that Timer 2 has matched the state configured in FLXA0FRT2C register.

If enabled in FLXA0FROC.T2IE the timer 2 interrupt is generated when FLXA0FROS.T2IS is ‘1’.

[Clearing condition]

This bit is cleared by writing ‘1’ to FLXA0FROS.T2IS.

This bit is cleared when FLXA0FROS.OS changes from ‘1’ to ‘0’.

[Setting condition]

This bit is set when Timer 2 matches the state configured in FLXA0FRT2C register.

(2) FLXA0FROS.T1IS

Timer 1 Interrupt Status

Writing ‘0’ has no effect on the bit value.

This bit represents that Timer 1 has matched the state configured in FLXA0FRT1C register.

If enabled in FLXA0FROC.T1IE the timer 1 interrupt is generated when FLXA0FROS.T1IS is ‘1’.

[Clearing condition]

This bit is cleared by writing ‘1’ to FLXA0FROS.T1IS.

This bit is cleared when FLXA0FROS.OS changes from ‘1’ to ‘0’.

[Setting condition]

This bit is set when Timer 1 matches the state configured in FLXA0FRT1C register.

(3) FLXA0FROS.T0IS

Timer 0 Interrupt Status

Writing ‘0’ has no effect on the bit value.

This bit represents that the Timer 0 has matched the state configured in FLXA0FRT0C register.

If enabled in FLXA0FROC.T0IE the timer 1 interrupt is generated when FLXA0FROS.T0IS is ‘1’.

[Clearing condition]

This bit is cleared by writing ‘1’ to FLXA0FROS.T0IS.

This bit is cleared when FLXA0FROS.OS changes from ‘1’ to ‘0’.

[Setting condition]

This bit is set when Timer 0 matches the state configured in FLXA0FRT0C register.

(4) FLXA0FROS.OS

Operation Status

This bit represents if the FlexRay module is in the reset or the operation state.

When FLXA0FROS.OS is ‘0’ the FlexRay module gets initialized and registers mapped to the address area ERAY + 0010_H to ERAY + $0FFF_H$ cannot be accessed; read access from these registers will return undefined data.

When FLXA0FROS.OS is ‘1’ it is possible to access to the address area ERAY + 0010_H to ERAY + $0FFF_H$ and to perform FlexRay communication.

When FLXA0FROS.OS changes from ‘0’ to ‘1’ all registers in the address range ERAY + 0010_H to ERAY + $0FFF_H$ are set to the “Values after reset”.

[Clearing condition]

When FLXA0FROC.OE is set to ‘0’, It takes up to two peripheral bus clock cycles until FLXA0FROS.OS is set to ‘0’.

[Setting condition]

When FLXA0FROC.OE is set to ‘1’ it takes up to four peripheral clock cycles of the clock with the lower frequency out of the FlexRay sample clock and peripheral bus clock until FLXA0FROS.OS is set to ‘1’.

17.2.3 Special Registers

17.2.3.1 FLXA0FRLCK — FlexRay Lock Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $001C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CLK[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17.5 FLXA0FRLCK Register Contents

Bit	Symbol	Function
31 to 8	—	Reserved These bits are always read as 0. When writing, always write 0.
7 to 0	CLK[7:0]	Configuration Lock Key

(1) FLXA0FRLCK.CLK

Configuration Lock Key

The lock register is write-only. Reading the register will return $0000\ 0000_H$.

To leave CONFIG state by writing FLXA0FRSUCC1.CMD (command READY), the write operation has to be directly preceded by two write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the configuration lock key and the write access to the FLXA0FRSUCC1 register, the CC remains in CONFIG state and the sequence has to be repeated.

First write:FLXA0FRLCK.CLK = “1100 1110” (CE_H)

Second write:FLXA0FRLCK.CLK = “0011 0001” (31_H)

Third write:FLXA0FRSUCC1.CMD

NOTE

In case that the host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no “dummy accesses” e.g. to the remaining register bytes/words are inserted by the compiler.

17.2.4 Interrupt Registers

17.2.4.1 FLXA0FREIR — FlexRay Error Interrupt Register

Do not rewrite this register using bit-manipulation instruction.

The flags are set when the CC detects one of the listed error conditions. The flags remain set until the host clears them.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0020_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

24	EDB	Error Detected on Channel B Flag 0: No error detected on channel B 1: Error detected on channel B
23 to 19	—	Reserved These bits are always read as 0. When writing, always write 0.
18	TABA	Transmission Across Boundary Channel A Flag 0: No transmission across slot boundary detected on channel A 1: Transmission across slot boundary detected on channel A
17	LTVA	Latest Transmit Violation Channel A Flag 0: No latest transmit violation detected on channel A 1: Latest transmit violation detected on channel A
16	EDA	Error Detected on Channel A Flag 0: No error detected on channel A 1: Error detected on channel A
15 to 12	—	Reserved These bits are always read as 0. When writing, always write 0.
11	MHF	Message Handler Constraints Flag 0: No message handler failure detected 1: Message handler failure detected

Table 17.6 FLXA0FREIR Register Contents (2/2)

Bit Position	Bit Name	Function
10	IOBA	Illegal Output Buffer Access Flag 0: No illegal host access to output buffer occurred 1: Illegal host access to output buffer occurred
9	IIBA	Illegal Input Buffer Access Flag 0: No illegal host access to input buffer occurred 1: Illegal host access to input buffer occurred
8	EFA	Empty FIFO Access Flag 0: No host access to empty FIFO occurred 1: Host access to empty FIFO occurred
7	RFO	Receive FIFO Overrun Flag 0: No receive FIFO overrun detected 1: A receive FIFO overrun has been detected
6	AERR	Access Error Flag 0: Access error is not detected. 1: Access error is detected.
5	CCL	CHI Command Locked Flag 0: CHI command accepted 1: CHI command not accepted
4	CCF	Clock Correction Failure Flag 0: No clock correction error 1: Clock correction failed
3	SFO	Sync Frame Overflow Flag 0: Number of received sync frames <= FLXA0FRGTUC2.SNM 1: More sync frames received than configured by FLXA0FRGTUC2.SNM
2	SFBM	Sync Frames Below Minimum Flag 0: Sync node: 1 or more sync frames received, non-sync node: 2 or more sync frames received 1: Less than the required minimum of sync frames received
1	CNA	Command Not Accepted Flag 0: CHI command accepted 1: CHI command not accepted
0	PEMC	POC Error Mode Changed Flag 0: Error mode has not changed 1: Error mode has changed

(1) FLXA0FREIR.TABB

Transmission Across Boundary Channel B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing ‘1’ to it.

The flag signals to the host that a transmission across a slot boundary occurred for channel B.

(2) FLXA0FREIR.LTVB

Latest Transmit Violation Channel B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing ‘1’ to it.

The flag signals a latest transmit violation on channel B to the host.

(3) FLXA0FREIR.EDB

Error Detected on Channel B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing ‘1’ to it.

This bit is set whenever one of the flags FLXA0FRACS.SEDB, FLXA0FRACS.CEDB, FLXA0FRACS.CIB, FLXA0FRACS.SBVB changes from ‘0’ to ‘1’.

(4) FLXA0FREIR.TABA

Transmission Across Boundary Channel A Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

The flag signals to the host that a transmission across a slot boundary occurred for channel A.

(5) FLXA0FREIR.LTVA

Latest Transmit Violation Channel A Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

The flag signals a latest transmit violation on channel A to the host.

(6) FLXA0FREIR.EDA

Error Detected on Channel A Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This bit is set whenever one of the flags FLXA0FRACS.SEDA, FLXA0FRACS.CEDA, FLXA0FRACS.CIA, FLXA0FRACS.SBVA changes from ‘0’ to ‘1’.

(7) FLXA0FREIR.MHF

Message Handler Constraints Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

The flag signals a message handler constraints violation condition. It is set whenever one of the flags FLXA0FRMHDF.SNUA, FLXA0FRMHDF.SNUB, FLXA0FRMHDF.FNFA, FLXA0FRMHDF.FNFB, FLXA0FRMHDF.TBFA, FLXA0FRMHDF.TBFB, FLXA0FRMHDF.WAHP changes from ‘0’ to ‘1’.

(8) FLXA0FREIR.IOBA

Illegal Output Buffer Access Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set by the CC when the host requests the transfer of a message buffer from the message RAM to the output buffer while FLXA0FROBCR.OBSYS is set to ‘1’.

(9) FLXA0FREIR.IIBA

Illegal Input Buffer Access Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set by the CC when the host wants to modify a message buffer via input buffer and one of the following conditions applies:

1. The CC is not in CONFIG or DEFAULT_CONFIG state and the host writes to the input buffer command request register to modify the
   - Header section of message buffer 0, 1 if configured for transmission in key slot
   - Header section of static message buffers with buffer number < FLXA0FRMRC.FDB while FLXA0FRMRC.SEC = “01”
   - Header section of any static or dynamic message buffer while FLXA0FRMRC.SEC = “1x”
   - Header and/or data section of any message buffer belonging to the receive FIFO
2. The host writes to any register of the input buffer while FLXA0FRIBCR.IBSYH is set to ‘1’.

(10) FLXA0FREIR.EFA

Empty FIFO Access Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set by the CC when the host requests the transfer of a message from the receive FIFO via output buffer while the receive FIFO is empty.

(11) FLXA0FREIR.RFO

Receive FIFO Overrun Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

The flag is set by the CC when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. The actual state of the FIFO is monitored in register FLXA0FRFSR.

(12) FLXA0FREIR.AERR

Access Error flag

Writing 0 in this bit has no effect.

This bit is cleared when writing ‘1’ to it.

Notifies of an access error.

When the AMR, ATBF1, or ATBF2 bit in the FLXA0FRMHDS register changes from 0 to 1, this bit is set to 1.

(13) FLXA0FREIR.CCL

CHI Command Locked Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

The flag signals that the write access to the CHI command vector FLXA0FRSUCC1.CMD was not successful because the execution of the previous CHI command has not yet completed. In this case bit FLXA0FREIR.CNA is also set to ‘1’.

(14) FLXA0FREIR.CCF

Clock Correction Failure Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set at the end of the communication cycle whenever one of the following errors occurred:

- Missing offset and/or rate correction
- Clock correction limit reached

The clock correction status is monitored in registers FLXA0FRCCEV and FLXA0FRSFS. A failure may occur during startup, therefore bit FLXA0FREIR.CCF should be set to “0” after the CC entered NORMAL_ACTIVE state.

(15) FLXA0FREIR.SFO

Sync Frame Overflow Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

It is set to “1” when either the number of sync frames received during the last communication cycle or the total number of different sync frame IDs received during the last double cycle exceeds the maximum number of sync frames as defined by FLXA0FRGTUC2.SNM.

(16) FLXA0FREIR.SFBM

Sync Frames Below Minimum Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to “1” at the end of a cycle if the number of sync frames received during the last communication cycle was below the limit required for rate or offset correction term calculation (i.e. missing offset and/or missing rate correction). The clock correction status is monitored in FLXA0FRCCEV and FLXA0FRSFS.

This flag may be set to “1” during startup. Therefore this flag should be set to “0” by the host after the CC entered NORMAL_ACTIVE state.

(17) FLXA0FREIR.CNA

Command Not Accepted Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

The flag signals that the write access to the CHI command vector FLXA0FRSUCC1.CMD was not successful because the requested command was not valid in the actual POC state, or because the CHI command was locked (CCL = ‘1’).

(18) FLXA0FREIR.PEMC

POC Error Mode Changed Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to “1” whenever the error mode signaled by FLXA0FRCCEV.ERRM has changed.

17.2.4.2 FLXA0FRSIR — FlexRay Status Interrupt Register

Do not rewrite this register using bit-manipulation instruction.

The flags are set when the CC detects one of the listed events. The flags remain set until the host clears them.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0024_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.7 FLXA0FRSIR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 26	—	Reserved These bits are always read as 0. When writing, always write 0.
25	MTSB	MTS Received on Channel B Flag (vSS!ValidMTSB) 0: No MTS symbol received on channel B 1: MTS symbol received on channel B
24	WUPB	Wakeup Pattern Channel B Flag 0: No wakeup pattern received on channel B 1: Wakeup pattern received on channel B
23 to 18	—	Reserved These bits are always read as 0. When writing, always write 0.
17	MTSA	MTS Received on Channel A Flag (vSS!ValidMTSA) 0: No MTS symbol received on channel A 1: MTS symbol received on channel A
16	WUPA	Wakeup Pattern Channel A Flag 0: No wakeup pattern received on channel A 1: Wakeup pattern received on channel A
15	SDS	Start of Dynamic Segment Flag 0: Dynamic segment not yet started 1: Dynamic segment started
14	MBSI	Message Buffer Status Interrupt Flag 0: No message buffer status change of message buffer with MBI = ‘1’ 1: Message buffer status of at least one message buffer with MBI = ‘1’ has changed
13	SUCS	Startup Normal End Flag 0: No startup completed successfully 1: Startup completed successfully
12	SWE	Stop Watch Event Flag 0: No Stop Watch Event 1: Stop Watch Event occurred
11	TOBC	Transfer Output Buffer Completed Flag 0: No transfer completed 1: Transfer between message RAM and output buffer completed

Table 17.7 FLXA0FRSIR Register Contents (2/2)

Bit Position	Bit Name	Function
10	TIBC	Transfer Input Buffer Completed Flag 0: No transfer completed 1: Transfer between input buffer and message RAM completed
9	TI1	Timer Interrupt 1 Flag 0: No timer interrupt 1 1: Timer interrupt 1 occurred
8	TI0	Timer Interrupt 0 Flag 0: No timer interrupt 0 1: Timer interrupt 0 occurred
7	NMVC	Network Management Vector Changed Flag 0: No change in the network management vector 1: Network management vector changed
6	RFCL	Receive FIFO Critical Level Flag 0: Receive FIFO below critical level 1: Receive FIFO critical level reached
5	RFNE	Receive FIFO Not Empty Flag 0: Receive FIFO is empty 1: Receive FIFO is not empty
4	RXI	Receive Interrupt Flag 0: No ND flag of a receive buffer with MBI = ‘1’ has been set to ‘1’ 1: At least one ND flag of a receive buffer with MBI = 1 has been set to 1
3	TXI	Transmit Interrupt Flag 0: No frame transmitted from a transmit buffer with MBI = ‘1” 1: At least one frame was transmitted from a transmit buffer with MBI = ‘1’
2	CYCS	Cycle Start Interrupt Flag 0: No communication cycle started 1: Communication cycle started
1	CAS	Collision Avoidance Symbol Flag 0: No bit pattern matching the CAS symbol received 1: Bit pattern matching the CAS symbol received
0	WST	Wakeup Status Flag 0: Wakeup status unchanged 1: Wakeup status changed

(1) FLXA0FRSIR.MTSB

MTS Received on Channel B Flag (vSS!ValidMTSB)

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

Media Access Test Symbol (MTS) received on channel B during the preceding symbol window.

Updated by the CC for each channel at the end of the symbol window.

(2) FLXA0FRSIR.WUPB

Wakeup Pattern Channel B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to “1” when a wakeup pattern was received on channel B in either of the following states:

- WAKEUP
- READY
- STARTUP

(3) FLXA0FRSIR.MTSA

MTS Received on Channel A Flag (vSS!ValidMTSA)

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

Media Access Test Symbol (MTS) received on channel A during the preceding symbol window.

Updated by the CC for each channel at the end of the symbol window.

(4) FLXA0FRSIR.WUPA

Wakeup Pattern Channel A Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to “1” when a wakeup pattern was received on channel A in either of the following states:

- WAKEUP
- READY
- STARTUP

(5) FLXA0FRSIR.SDS

Start of Dynamic Segment Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set by the CC when the dynamic segment starts.

(6) FLXA0FRSIR.MBSI

Message Buffer Status Interrupt Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set by the CC when the message buffer status FLXA0FRMBS has changed and if bit MBI of that message buffer is “1” (see **Table 17.100**).

(7) FLXA0FRSIR.SUCS

Startup Normal End Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set whenever a startup completed successfully and the CC entered NORMAL_ACTIVE state.

(8) FLXA0FRSIR.SWE

Stop Watch Event Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set after a stop watch activation when the actual cycle counter and macrotick value are stored in the Stop Watch register (see **Section 17.2.5.4, FLXA0FRSTPW1 — FlexRay Stop Watch Register 1**).

(9) FLXA0FRSIR.TOBC

Transfer Output Buffer Completed Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set whenever a transfer from the message RAM to the output buffer has completed and FLXA0FROBCR.OBSYS has been reset by the message handler.

(10) FLXA0FRSIR.TIBC

Transfer Input Buffer Completed Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set whenever a transfer from input buffer to the message RAM has completed and FLXA0FRIBCR.IBSYS has been reset by the message handler.

(11) FLXA0FRSIR.TI1

Timer Interrupt 1 Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set whenever timer 1 matches the conditions configured in register FLXA0FRT1C.

FlexRay timer interrupt 1 is generated when the T1IE bit in the FLXA0FROC register is effective.

(12) FLXA0FRSIR.TI0

Timer Interrupt 0 Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set whenever timer 0 matches the conditions configured in register FLXA0FRT0C.

FlexRay timer interrupt 0 is generated when the T0IE bit in the FLXA0FROC register is effective.

(13) FLXA0FRSIR.NMVC

Network Management Vector Changed Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This is set when a change in the Network Management Vector occurs.

(14) FLXA0FRSIR.RFCL

Receive FIFO Critical Level Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set when the receive FIFO fill level FLXA0FRFSR.RFFL is equal or greater than the critical level as configured by FLXA0FRFCL.CL.

(15) FLXA0FRSIR.RFNE

Receive FIFO Not Empty Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set when a received valid frame was stored into the empty receive FIFO. The current state of the receive FIFO can be read in register FLXA0FRFSR.

(16) FLXA0FRSIR.RXI

Receive Interrupt Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set whenever the set condition of a message buffers ND flag is fulfilled (see **Section 17.2.9.6, FLXA0FRNDATi — FlexRay New Data Register i (i = 1 to 4)**), and if bit MBI of that message buffer is set to 1 (see **Table 17.100**).

(17) FLXA0FRSIR.TXI

Transmit Interrupt Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set at the end of frame transmission if bit MBI in the respective message buffer is set to 1 (see **Table 17.100**).

(18) FLXA0FRSIR.CYCS

Cycle Start Interrupt Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to “1” every time a communication cycle starts.

(19) FLXA0FRSIR.CAS

Collision Avoidance Symbol Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set during STARTUP state when a CAS or an expected CAS was received.

(20) FLXA0FRSIR.WST

Wakeup Status Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set when FLXA0FRCCSV.WSV changes to a value other than UNDEFINED.

17.2.4.3 FLXA0FREILS — FlexRay Error Interrupt Line Select Register

The FlexRay error interrupt line select register assigns an interrupt generated by a specific error interrupt flag from register FLXA0FREIR to one of the two modules interrupt lines (FlexRay interrupt 0 or FlexRay interrupt 1).

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0028_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

17.2.4.4 FLXA0FRSILS — FlexRay Status Interrupt Line Select Register

The FlexRay status interrupt line select register assign an interrupt generated by a specific status interrupt flag from register FLXA0FRSIR to one of the two module interrupt lines (FlexRay interrupt 0, FlexRay interrupt 1).

Access: This register can be read/written in 8-, 16-, or 32-bit units.

17.2.4.5 FLXA0FREIES — FlexRay Error Interrupt Enable Set Register

The settings in the FlexRay error interrupt enable set register (FLXA0FREIES) and FlexRay error interrupt enable reset register (FLXA0FREIER) determine which status changes in the FlexRay error interrupt register will result in an interrupt.

The enable bits are set by writing to FLXA0FREIES and reset by writing to FLXA0FREIER. Reading from both addresses will result in the same value.

Writing '0' has no effect on the bit value.

Writing a '1' sets the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0030_H

Value after reset: $0000\ 0000_H$

17.2.4.6 FLXA0FREIER — FlexRay Error Interrupt Enable Reset Register

The settings in the FlexRay error interrupt enable set register (FLXA0FREIES) and FlexRay error interrupt enable reset register (FLXA0FREIER) determine which status changes in the FlexRay error interrupt register will result in an interrupt.

The enable bits are set by writing to FLXA0FREIES and reset by writing to FLXA0FREIER. Reading from both addresses will result in the same value.

Writing '0' has no effect on the bit value.

Writing a '1' clears the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

17.2.4.7 FLXA0FRSIES — FlexRay Status Interrupt Enable Set Register

The settings in the FlexRay status interrupt enable set register (FLXA0FRSIES) and FlexRay status interrupt enable reset register (FLXA0FRSIER) determine which status changes in the FlexRay status interrupt register will result in an interrupt.

The enable bits are set by writing to FLXA0FRSIES and reset by writing to FLXA0FRSIER. Reading from both addresses will result in the same value.

Writing '0' has no effect on the bit value.

Writing a '1' sets the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

17.2.4.8 FLXA0FRSIER — FlexRay Status Interrupt Enable Reset Register

The settings in the FlexRay status interrupt enable set register (FLXA0FRSIES) and FlexRay status interrupt enable reset register (FLXA0FRSIER) determine which status changes in the FlexRay status interrupt register will result in an interrupt.

The enable bits are set by writing to FLXA0FRSIES and reset by writing to FLXA0FRSIER. Reading from both addresses will result in the same value.

Writing '0' has no effect on the bit value.

Writing a '1' clears the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

17.2.4.9 FLXA0FRILE — FlexRay Interrupt Line Enable Register

Each of the two module interrupt lines (FlexRay interrupt 0, FlexRay interrupt 1) can be enabled or disabled separately by programming bit FLXA0FRILE.EINT0 and FLXA0FRILE.EINT1.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0040_H

Value after reset: $0000\ 0000_H$

17.2.5 FlexRay Timer Registers

17.2.5.1 FLXA0FRT0C — FlexRay Timer 0 Configuration Register

This register is an absolute timer. It specifies the point in time when a FlexRay timer 0 interrupt occurs as the values of cycle count and macrotick (MT). When the FlexRay timer 0 passes, FLXA0FRSIR.TI0 and FLXA0FROS.T0IS are set to '1'. A timer 0 interrupt then occurs while the FLXA0FROC.T0IE bit is effective.

NOTE

The configuration of timer 0 is compared against the macrotick counter value, there is no separate counter for timer 0.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0044_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.15 FLXA0FRT0C Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 16	T0MO[13:0]	Timer 0 Macrotick Offset Timer 0 macrotick offset
15	—	Reserved This bit is always read as 0. When writing, always write 0.
14 to 8	T0CC[6:0]	Timer 0 Cycle Code timer 0 cycle code
7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	T0MS	Timer 0 Mode Select 0: Single-shot mode 1: Continuous mode
0	T0RC	Timer 0 Run Control 0: Timer 0 halted 1: Timer 0 running

(1) FLXA0FRT0C.T0MO

Timer 0 Macrotick Offset

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXA0FRT0C.T0RC to ‘0’.

Configures the macrotick offset from the beginning of the communication cycle where the interrupt is to occur. The FlexRay timer 0 interrupt occurs at this offset for each cycle of the cycle set.

(2) FLXA0FRT0C.T0CC

Timer 0 Cycle Code

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXA0FRT0C.T0RC to ‘0’.

The 7-bit timer 0 cycle code determines the cycle set used for generation of the FlexRay timer 0 interrupt. For details about the configuration of the cycle code, see **Section 17.3.8.2, Cycle Counter Filtering**.

(3) FLXA0FRT0C.T0MS

Timer 0 Mode Select

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXA0FRT0C.T0RC to ‘0’.

Configures the timer run mode. In Single-shot mode the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(4) FLXA0FRT0C.T0RC

Timer 0 Run Control

Timer 0 can be activated (set FLXA0FRT0C.T0RC to ‘1’) when the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state.

Timer 0 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

17.2.5.2 FLXA0FRT1C — FlexRay Timer 1 Configuration Register

This register is a relative timer. After the specified number of macroticks (MT) has expired, a FlexRay timer 1 interrupt is asserted. When the FlexRay timer 1 passes, FLXA0FRSIR.TI1 and FLXA0FROS.T1IS are set to '1'. A timer 1 interrupt then occurs while the FLXA0FROC.T1IE bit is effective.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0048_H

Value after reset: $0002\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	T1MS	Timer 1 Mode Select 0: Single-shot mode 1: Continuous mode
0	T1RC	Timer 1 Run Control 0: Timer 1 halted 1: Timer 1 running

(1) FLXA0FRT1C.T1MC

Timer 1 Macrotick Count

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXA0FRT1C.T1RC to ‘0’.

Valid values are 2 to 16383 MT in continuous mode

Valid values are 1 to 16383 MT in single-shot mode

When the configured macrotick count is reached the FlexRay timer 1 interrupt is generated.

(2) FLXA0FRT1C.T1MS

Timer 1 Mode Select

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXA0FRT1C.T1RC to ‘0’.

Configures the timer run mode. In Single-shot mode the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(3) FLXA0FRT1C.T1RC

Timer 1 Run Control

Timer 1 can be activated (set FLXA0FRT1C.T1RC to ‘1’) as long as the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state.

Timer 1 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

17.2.5.3 FLXA0FRT2C — FlexRay Timer 2 Configuration Register

29 to 16	T2MO[13:0]	Timer 2 Macrotick Offset Timer 2 macrotick offset
15	—	Reserved This bit is always read as 0. When writing, always write 0.
14 to 8	T2CC[6:0]	Timer 2 Cycle Code Timer 2 cycle code
7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	T2MS	Timer 2 Mode Select 0: Single-shot mode 1: Continuous mode
0	T2RC	Timer 2 Run Control 0: Timer halted 1: Timer running

(1) FLXA0FRT2C.T2MO

Timer 2 Macrotick Offset

Write 0 to the FLXA0FRT2C.T2RC bit and halt the timer before changing the value of the timer.

Configures the macrotick offset from the beginning of the communication cycle where the timer 2 interrupt is generated. The timer 2 interrupt is generated at this offset for each cycle of the cycle set.

(2) FLXA0FRT2C.T2CC

Timer 2 Cycle Code

Before reconfiguration of the timer, the timer has to be halted first by writing 0 to bit FLXA0FRT2C.T2RC.

Configures the cycle set which generates timer 2 interrupt with the 7-bit timer 2 cycle code. For details, see **Section 17.3.8.2, Cycle Counter Filtering**.

(3) FLXA0FRT2C.T2MS

Timer 2 Mode Select

Before reconfiguration of the timer, the timer has to be halted first by writing 0 to bit FLXA0FRT2C.T2RC.

Configures the timer run mode. In single-shot mode, the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(4) FLXA0FRT2C.T2RC

Timer 2 Run Control

Timer 2 can be operated when the POC is in NORMAL_ACTIVE or NORMAL_PASSIVE state. (set FLXA0FRT2C.T2RC to ‘1’)

Timer 2 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

17.2.5.4 FLXA0FRSTPW1 — FlexRay Stop Watch Register 1

The stop watch is activated by the following trigger events.

- FlexRay interrupt 0 or FlexRay interrupt 1
- Writing bit FLXA0FRSTPW1.SSWT to '1'

With the macrotick counter increment following next to the stop watch activation the actual cycle counter and macrotick values are captured in register FLXA0FRSTPW1 while the slot counter values for channel A and B are captured in register FLXA0FRSTPW2.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $004C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.18 FLXA0FRSTPW1 Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 16	SMTV[13:0]	Stop Watch Captured Macrotick Value Stop watch captured macrotick value
15, 14	—	Reserved These bits are always read as 0. When writing, always write 0.
13 to 8	SCCV[5:0]	Stop Watch Captured Cycle Counter Value Stop watch captured cycle counter value
7	—	Reserved This bit is always read as 0. When writing, always write 0.
6	EINT1	Enable FlexRay Interrupt 1 Trigger 0: Stop watch trigger by FlexRay interrupt 1 disabled 1: FlexRay interrupt 1 event triggers stop watch
5	EINT0	Enable FlexRay Interrupt 0 Trigger 0: Stop watch trigger by FlexRay interrupt 0 disabled 1: FlexRay interrupt 0 event triggers stop watch
4	—	Reserved This bit is always read as 0. When writing, always write 0.
3	SSWT	Software Stop Watch Trigger 0: Software trigger reset 1: Stop watch activated by software trigger
2	EDGE	Stop Watch Trigger Edge Select 0: Falling edge 1: Rising edge

Table 17.18 FLXA0FRSTPW1 Register Contents (2/2)

Bit Position	Bit Name	Function
1	SWMS	Stop Watch Mode Select 0: Single-shot mode 1: Continuous mode
0	ESWT	Enable Hardware Stop Watch Trigger 0: Stop watch trigger disabled 1: Stop watch trigger enabled

(1) FLXA0FRSTPW1.SMTV

Stop Watch Captured Macrotick Value

State of the macrotick counter when the stop watch event occurred.

(2) FLXA0FRSTPW1.SCCV

Stop Watch Captured Cycle Counter Value

State of the cycle counter when the stop watch event occurred.

(3) FLXA0FRSTPW1.EINT1

Enable FlexRay Interrupt 1 Trigger

Enables stop watch trigger by FlexRay interrupt 1 when FLXA0FRSTPW1.ESWT = ‘1’.

(4) FLXA0FRSTPW1.EINT0

Enable FlexRay Interrupt 0 Trigger

Enables stop watch trigger by FlexRay interrupt 0 when FLXA0FRSTPW1.ESWT = ‘1’.

(5) FLXA0FRSTPW1.SSWT

Software Stop Watch Trigger

Bits FLXA0FRSTPW1.ESWT and FLXA0FRSTPW1.SSWT cannot be set to ‘1’ simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

Writing 1 in this bit activates the stop watch. This bit is reset to ‘0’ after the cycle count and slot count, and macrotick (MT) value are stored in the FlexRay stop watch register.

(6) FLXA0FRSTPW1.EDGE

Stop Watch Trigger Edge Select

(7) FLXA0FRSTPW1.SWMS

Stop Watch Mode Select

(8) FLXA0FRSTPW1.ESWT

Enable Stop Watch Trigger

Bits FLXA0FRSTPW1.ESWT and FLXA0FRSTPW1.SSWT cannot be set to ‘1’ simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

If enabled, a FlexRay interrupt 0 event or a FlexRay interrupt 1 event activates the stop watch.

In single-shot mode, this bit is reset to ‘0’ after the cycle count and slot count, and macrotick (MT) value are stored in the FlexRay stop watch register.

17.2.5.5 FLXA0FRSTPW2 — FlexRay Stop Watch Register 2

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0050_H

Value after reset: $0000\ 0000_H$

Table 17.19 FLXA0FRSTPW2 Register Contents

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26 to 16	SSCVB[10:0]	Stop Watch Captured Slot Counter Value Channel B
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	SSCVA[10:0]	Stop Watch Captured Slot Counter Value Channel A

(1) FLXA0FRSTPW2.SSCVB

Stop Watch Captured Slot Counter Value Channel B

State of the slot counter for channel B when the stop watch event occurred.

(2) FLXA0FRSTPW2.SSCVA

Stop Watch Captured Slot Counter Value Channel A

State of the slot counter for channel A when the stop watch event occurred.

17.2.6 CC Control Registers

This section describes the registers provided by the CC to allow the host to control the operation of the CC. The FlexRay protocol specification requires the host to write application configuration data in CONFIG state only. Please consider that the configuration registers are not locked for writing in DEFAULT_CONFIG state.

The configuration data is reset when DEFAULT_CONFIG state is entered from reset. To change POC state from DEFAULT_CONFIG to CONFIG state the host has to apply CHI command CONFIG. If the host wants the CC to leave CONFIG state, the host has to execute the lock release sequence as described in **Section 17.2.3.1, FLXA0FRLCK — FlexRay Lock Register**.

17.2.6.1 FLXA0FRSUCC1 — FlexRay SUC Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0080_H

Value after reset: $0C40\ 1080_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.20 FLXA0FRSUCC1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	—	Reserved These bits are always read as 0. When writing, always write 0.
27	CCHB	Connected to Channel B Configures pChannels 0: Node not connected to channel B 1: Node connected to channel B (default after reset)
26	CCHA	Connected to Channel A Configures pChannels 0: Node not connected to channel A 1: Node connected to channel A (default after reset)
25	MTSB	Select Channel B for MTS Transmission 0: Channel B disabled for MTS transmission 1: Channel B selected for MTS transmission
24	MTSA	Select Channel A for MTS Transmission 0: Channel A disabled for MTS transmission 1: Channel A selected for MTS transmission
23	HCSE	Halt due to Clock Sync Error Configures pAllowHaltDueToClock 0: CC will enter or remain in NORMAL_PASSIVE 1: CC will enter HALT state
22	TSM	Transmission Slot Mode Configures pSingleSlotEnabled 0: ALL Slot Mode 1: SINGLE Slot Mode (default after hard reset)

Table 17.20 FLXA0FRSUCC1 Register Contents (2/2)

Bit Position	Bit Name	Function
21	WUCS	Wakeup Channel Select Configures pWakeupChannel 0: Send wakeup pattern on channel A 1: Send wakeup pattern on channel B
20 to 16	PTA[4:0]	Passive to Active Configure pAllowPassiveToActive
15 to 11	CSA[4:0]	Cold Start Attempts Configure gColdStartAttempts
10	—	Reserved This bit is always read as 0. When writing, always write 0.
9	TXSY	Transmit Sync Frame in Key Slot Configure pKeySlotUsedForSync 0: No sync frame transmission in key slot, node is neither sync nor coldstart node 1: Key slot used to transmit sync frame, node is sync node
8	TXST	Transmit Startup Frame in Key Slot Configure pKeySlotUsedForStartup 0: No startup frame transmission in key slot, node is non-coldstarter 1: Key slot used to transmit startup frame, node is leading or following coldstarter
7	PBSY	POC Busy Flag 0: POC not busy, FLXA0FRSUCC1.CMD writeable 1: POC is busy, FLXA0FRSUCC1.CMD locked
6 to 4	—	Reserved These bits are always read as 0. When writing, always write 0.
3 to 0	CMD[3:0]	CHI Command Vector 0000: command_not_accepted 0001: CONFIG 0010: READY 0011: WAKEUP 0100: RUN 0101: ALL_SLOTS 0110: HALT 0111: FREEZE 1000: SEND_MTS 1001: ALLOW_COLDSTART 1010: RESET_STATUS_INDICATORS 1100: CLEAR_RAMS others: reserved

(1) FLXA0FRSUCC1.CCHB

Connected to Channel B

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Configures whether the node is connected to channel B (pChannels).

(2) FLXA0FRSUCC1.CCHA

Connected to Channel A

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Configures whether the node is connected to channel A (pChannels).

(3) FLXA0FRSUCC1.MTSB

Select Channel B for MTS Transmission

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

FLXA0FRSUCC1.MTSB may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to FLXA0FRSUCC1 register is directly preceded by the unlock sequence for the Configuration Lock Key as described in **Section 17.2.3.1, FLXA0FRLCK — FlexRay Lock Register**. This may be combined with CHI command SEND_MTS. If both bits FLXA0FRSUCC1.MTSA and FLXA0FRSUCC1.MTSB are set to '1' an MTS symbol will be transmitted on both channels when requested by writing FLXA0FRSUCC1.CMD = "1000".

The bit selects channel B for MTS symbol transmission.

(4) FLXA0FRSUCC1.MTSA

Select Channel A for MTS Transmission

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

FLXA0FRSUCC1.MTSA may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to FLXA0FRSUCC1 register is directly preceded by the unlock sequence for the Configuration Lock Key as described in **Section 17.2.3.1, FLXA0FRLCK — FlexRay Lock Register**. This may be combined with CHI command SEND_MTS. If both bits FLXA0FRSUCC1.MTSA and FLXA0FRSUCC1.MTSB are set to '1' an MTS symbol will be transmitted on both channels when requested by writing FLXA0FRSUCC1.CMD = "1000".

The bit selects channel A for MTS symbol transmission.

(5) FLXA0FRSUCC1.HCSE

Halt due to Clock Sync Error

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Controls the transition to HALT state due to a clock synchronization error (pAllowHaltDueToClock).

(6) FLXA0FRSUCC1.TSM

Transmission Slot Mode

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Selects the initial transmission slot mode (pSingleSlotEnabled).

In SINGLE slot mode the CC may only transmit in the preconfigured key slot. The key slot ID is configured in the header section of message buffer 0 respectively message buffers 0 and 1 depending on bit FLXA0FRMRC.SPLM.

In case FLXA0FRSUCC1.TSM = '1', message buffer 0 respectively message buffers 0,1 can be (re)configured in DEFAULT_CONFIG or CONFIG state only. In ALL slot mode the CC may transmit in all slots.

FLXA0FRSUCC1.TSM is a configuration bit which can only be set or reset by the host.

The CC changes to ALL slot mode when the host successfully applied the ALL_SLOTS command by writing FLXA0FRSUCC1.CMD = "0101" in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. The actual slot mode is monitored by FLXA0FRCCSV.SLM.

(7) FLXA0FRSUCC1.WUCS

Wakeup Channel Select

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

With this bit the host selects the channel on which the CC sends the Wakeup pattern (pWakeupChannel).

(8) FLXA0FRSUCC1.PTA

Passive to Active Condition Setting

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 31 even/odd cycle pairs.

Defines the number of consecutive even/odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state (pAllowPassiveToActive).

If set to “00000” the CC is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

(9) FLXA0FRSUCC1.CSA

Cold Start Attempt Count Setting

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Must be identical in all nodes of a cluster.

Valid values are 2 to 31.

Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node (gColdStartAttempts).

(10) FLXA0FRSUCC1.TXSY

Transmit Sync Frame in Key Slot

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit sync frames (pKeySlotUsedForSync).

NOTE

The protocol requires that both bits FLXA0FRSUCC1.TXST and FLXA0FRSUCC1.TXSY are set for coldstart nodes.

(11) FLXA0FRSUCC1.TXST

Transmit Startup Frame in Key Slot

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit startup frames (pKeySlotUsedForStartup).

NOTE

The protocol requires that both bits FLXA0FRSUCC1.TXST and FLXA0FRSUCC1.TXSY are set for coldstart nodes.

(12) FLXA0FRSUCC1.PBSY

POC Busy

Signals that the POC is busy and cannot accept a command from the host. FLXA0FRSUCC1.CMD is locked against write accesses.

Set to '1' after reset during initialization of internal RAM blocks.

(13) FLXA0FRSUCC1.CMD

CHI Command Vector

The host may write any CHI command at any time, but certain commands are enabled only in certain POC states. If a command is not enabled, it will not be executed, the CHI command vector FLXA0FRSUCC1.CMD will be reset to "0000" = command_not_accepted, and flag FLXA0FREIR.CNA will be set to '1'.

In general the host must check FLXA0FRSUCC1.PBSY before writing a new CHI command.

In case the previous CHI command has not yet completed, FLXA0FREIR.CCL is set to '1' together with FLXA0FREIR.CNA; the CHI command needs to be repeated.

Except for HALT state, a POC state change command applied while the CC is already in the requested POC state neither causes a state change nor will FLXA0FREIR.CNA be set.

Reading FLXA0FRSUCC1.CMD shows whether the last CHI command was accepted. The actual POC state is monitored by FLXA0FRCCSV.POCS.

- command_not_accepted

  FLXA0FRSUCC1.CMD is reset to "0000" due to one of the following conditions:

  – Illegal command applied by the host
  – Host applied command to leave CONFIG state without preceding config lock key
  – Host applied new command while execution of the previous host command has not completed
  – Host writes command_not_accepted

When FLXA0FRSUCC1.CMD is reset to "0000", FLXA0FREIR.CNA is set to '1', and enabled, an interrupt is generated.

Commands which are not accepted are not executed.

CONFIG

Go to POC state CONFIG when called in POC states DEFAULT_CONFIG, or READY. When called in HALT state the CC transits to POC state DEFAULT_CONFIG. When called in any other state, FLXA0FRSUCC1.CMD will be reset to "0000" = command_not_accepted.

READY

Go to POC state READY when called in POC states CONFIG, NORMAL_ACTIVE, NORMAL_PASSIVE, STARTUP, or WAKEUP. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

WAKEUP

Go to POC state WAKEUP when called in POC state READY. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

RUN

Go to POC state STARTUP when called in POC state READY. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

ALL_SLOTS

Leave SINGLE slot mode and go to ALL-SLOTS mode after successful startup/integration at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

HALT

Set halt request FLXA0FRCCSV.HRQ to ‘1’ and go to POC state HALT at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

FREEZE

Set the freeze status indicator FLXA0FRCCSV.FSI to ‘1’ and go to POC state HALT immediately. Can be called from any state.

SEND_MTS

Send single MTS symbol during the next following symbol window on the channel configured by FLXA0FRSUCC1.MTSA, FLXA0FRSUCC1.MTSB, when called in POC state NORMAL_ACTIVE after CC entered ALL slot mode (FLXA0FRCCSV.SLM = “11”). When called in any other state, or when called while a previously requested MTS has not yet been transmitted, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

ALLOW_COLDSTART

The command resets FLXA0FRCCSV.CSI to enable the node to become leading coldstarter. When called in states DEFAULT_CONFIG, CONFIG, or HALT, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted. To become leading coldstarter it is also required that both FLXA0FRSUCC1.TXST and FLXA0FRSUCC1.TXSY are set.

RESET_STATUS_INDICATORS

Resets status flags FLXA0FRCCSV.FSI, FLXA0FRCCSV.HRQ, FLXA0FRCCSV.CSNI, and FLXA0FRCCSV.CSAI to their default values. Can be called in POC states READY and STARTUP. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

CLEAR_RAMS

Sets FLXA0FRMHDS.CRAM to '1' when called in DEFAULT_CONFIG or CONFIG state. When called in any other state, FLXA0FRSUCC1.CMD will be reset to "0000" = command_not_accepted.

FLXA0FRMHDS.CRAM is also set to '1' when the CC leaves reset. By setting FLXA0FRMHDS.CRAM all internal RAM blocks are initialized to zero. During the initialization of the RAMs, FLXA0FRSUCC1.PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS.

The initialization of the internal RAM block requires 2048 bus clock cycles. There should be no host access to input buffer or output buffer during initialization of the internal RAM blocks after reset or after assertion of CHI command CLEAR_RAMS.

Before asserting CHI command CLEAR_RAMS, confirm that no transfer between message RAM and input buffer or output buffer or the temporary buffer RAMs is ongoing and that the data transfer handler is disabled (FLXA0FRITS.ITS = 0 and FLXA0FROTS.OTS = 0). This command also resets the message buffer status registers FLXA0FRMHDS, FLXA0FRLDTS, FLXA0FRFSR, FLXA0FRMHDF, FLXA0FRTXRQ1/2/3/4, FLXA0FRNDAT1/2/3/4, and FLXA0FRMBSC1/2/3/4.

NOTES

1. All accepted commands with exception of CLEAR_RAMS and SEND_MTS will cause a change of the POC state in the FlexRay domain after at most 8 cycles of the slower of the two clocks "bus clock" and "FlexRay", assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time frame. Reading register FLXA0FRCCSV will show data that is additionally delayed by synchronization from the FlexRay domain to the bus clock domain. The maximum additional delay is 12 cycles of the slower of the two clocks "bus clock" and "FlexRay".
2. When a terminal restarts transfer as a leading coldstart node after transfer was stopped by using the FREEZE or READY command, the startup frame may not be transmitted in cycle 0. This depends on the internal state of the FlexRay module. This phenomenon occurs when the startup frame is set in a slot with a number from 1 to 7.
   This phenomenon does not occur in a coldstart after a hardware reset.
   Even if this phenomenon does occur, a second try of the coldstart will succeed.
   While the coldstart time will be prolonged, this phenomenon does not otherwise affect a coldstart of the FlexRay system.
   To avoid this phenomenon, allocate the Startup/Sync frame to static slot 8 or a slot with a higher number.

Table 17.21 below references the CHI commands from the FlexRay Protocol Specification (Section 2.2.1.1, Table 2.2) to the FlexRay CHI command vector FLXA0FRSUCC1.CMD.

Table 17.21 Reference to CHI Host Command Summary from FlexRay Protocol Specification

CHI Command	Where Processed (POC States)	CHI Command Vector CMD
ALL_SLOTS	POC: normal active, POC: normal passive	ALL_SLOTS
ALLOW_COLDSTART	All except POC: default config, POC: config, POC: halt	ALLOW_COLDSTART
CONFIG	POC: default config, POC: ready	CONFIG
CONFIG_COMPLETE	POC: config	Unlock sequence & READY
DEFAULT_CONFIG	POC: halt	CONFIG
FREEZE	All	FREEZE
HALT	POC: normal active, POC: normal passive	HALT
READY	All except POC: default config, POC: config, POC: ready, POC: halt	READY
RUN	POC: ready	RUN
WAKEUP	POC: ready	WAKEUP

17.2.6.2 FLXA0FRSUCC2 — FlexRay SUC Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0084_H

Value after reset: $0100\ 0504_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.22 FLXA0FRSUCC2 Register Contents

Bit Position	Bit Name	Function
31 to 28	—	Reserved These bits are always read as 0. When writing, always write 0.
27 to 24	LTN[3:0]	Listen Timeout Noise Configure (gListenNoise - 1)
23 to 21	—	Reserved These bits are always read as 0. When writing, always write 0.
20 to 0	LT[20:0]	Listen Timeout Configure pdListenTimeout

(1) FLXA0FRSUCC2.LTN

Listen Timeout Noise

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 16.

FLXA0FRSUCC2.LTN must be configured identical in all nodes of a cluster.

Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of pdListenTimeout.

NOTE

The wakeup/startup noise timeout is calculated as follows:

pdListenTimeout × gListenNoise = FLXA0FRSUCC2.LT × (FLXA0FRSUCC2.LTN + 1)

(2) FLXA0FRSUCC2.LT

Listen Timeout

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1284 to 1283846 µT.

Configures wakeup/startup listen timeout in µT.

17.2.6.3 FLXA0FRSUCC3 — FlexRay SUC Configuration Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0088_H

Value after reset: $0000\ 0011_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are always read as 0. When writing, always write 0.
7 to 4	WCF[3:0]	Maximum Without Clock Correction Fatal (condition for transition to HALT state) Configure gMaxWithoutClockCorrectionFatal
3 to 0	WCP[3:0]	Maximum Without Clock Correction Passive (condition for transition to NORMAL_PASSIVE state) Configure gMaxWithoutClockCorrectionPassive

(1) FLXA0FRSUCC3.WCF

Maximum Without Clock Correction Fatal (condition for transition to HALT state)

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

Setting must be identical in all nodes of a cluster.

Defines the number of consecutive even/odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE or NORMAL_PASSIVE to HALT state.

NOTE

The transition to HALT state is prevented if FLXA0FRSUCC1.HCSE is not set.

(2) FLXA0FRSUCC3.WCP

Maximum Without Clock Correction Passive (transition to NORMAL_PASSIVE state)

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

Setting must be identical in all nodes of a cluster.

Defines the number of consecutive even/odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE to NORMAL_PASSIVE state.

17.2.6.4 FLXA0FRNEMC — FlexRay NEM Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $008C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 17.24 FLXA0FRNEMC Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved These bits are always read as 0. When writing, always write 0.
3 to 0	NML[3:0]	Network Management Vector Length Configure gNetworkManagementVectorLength

(1) FLXA0FRNEMC.NML

Network Management Vector Length

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 12 bytes.

The configured length must be identical in all nodes of a cluster.

These bits configure the length of the NM vector.

17.2.6.5 FLXA0FRPRTC1 — FlexRay PRT Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0090_H

Value after reset: $084C\ 0633_H$

Bit Position	Bit Name	Function
31 to 26	RWP[5:0]	Repetitions of Tx Wakeup Pattern Configure pWakeupPattern
25	—	Reserved This bit is always read as 0. When writing, always write 0.
24 to 16	RXW[8:0]	Wakeup Symbol Receive Window Length Configure gdWakeupSymbolRxWindow
15, 14	BRP[1:0]	Baud Rate Prescaler Configure gdSampleClockPeriod and pSamplesPerMicrotick 00 = 10 Mbps 01 = 5 Mbps 10 = 2.5 Mbps 11 = 2.5 Mbps
13, 12	SPP[1:0]	Strobe Point Position Configure Strobe point position 00 = Sample 5 01 = Sample 4 10 = Sample 6 11 = Sample 5
11	—	Reserved This bit is always read as 0. When writing, always write 0.
10 to 4	CASM[6:0]	Collision Avoidance Symbol Max Configure gdCASRxLowMax
3 to 0	TSST[3:0]	Transmission Start Sequence Transmitter Configure gdTSSTransmitter

(1) FLXA0FRPRTC1.RWP

Repetitions of Tx Wakeup Pattern

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 63.

Configures the number of repetitions (sequences) of the Tx wakeup symbol.

(2) FLXA0FRPRTC1.RXW

Wakeup Symbol Receive Window Length

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 76 to 301 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the received wakeup pattern.

(3) FLXA0FRPRTC1.BRP

Baud Rate Prescaler

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

The Baud Rate Prescaler configures the baud rate on the FlexRay bus. The baud rates listed below are valid with a sample clock set to 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate.

00 = 10 MBit/s

gdSampleClockPeriod = 12.5 ns = 1 * ‘sample clock’

pSamplesPerMicrotick = 2 (1 µT = 25 ns)

01 = 5 MBit/s

gdSampleClockPeriod = 25 ns = 2 * ‘sample clock’

pSamplesPerMicrotick = 1 (1 µT = 25 ns)

10, 11 = 2.5 MBit/s

gdSampleClockPeriod = 50 ns = 4 * ‘sample clock’

pSamplesPerMicrotick = 1 (1 µT = 50 ns)

(4) FLXA0FRPRTC1.SPP

Strobe Point Position

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by FLXA0FRPRTC1.SPP.

NOTE

The current revision 2.1 of the FlexRay protocol requires that FLXA0FRPRTC1.SPP = “00”. The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.

(5) FLXA0FRPRTC1.CASM

Collision Avoidance Symbol Max

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

CASM6 is fixed to '1'.

Valid values are 67 to 99 bit times.

Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS).

(6) FLXA0FRPRTC1.TSST

Transmission Start Sequence Transmitter

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 3 to 15 bit times.

Must be identical in all nodes of a cluster.

Configures the duration of the Transmission Start Sequence (TSS) in terms of bit times (1 bit time = 4 µT = 100ns at 10 Mbps).

17.2.6.6 FLXA0FRPRTC2 — FlexRay PRT Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0094_H

Value after reset: $0F2D\ 0A0E_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 24	TXL[5:0]	Wakeup Symbol Transmit Low Configure gdWakeupSymbolTxLow
23 to 16	TXI[7:0]	Wakeup Symbol Transmit Idle Configure gdWakeupSymbolTxIdle
15, 14	—	Reserved These bits are always read as 0. When writing, always write 0.
13 to 8	RXL[5:0]	Wakeup Symbol Receive Low Configure gdWakeupSymbolRxLow
7, 6	—	Reserved These bits are always read as 0. When writing, always write 0.
5 to 0	RXI[5:0]	Wakeup Symbol Rx Idle Configure gdWakeupSymbolRxIdle

(1) FLXA0FRPRTC2.TXL

Wakeup Symbol Transmit Low

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 15 to 60 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the low phase of the wakeup symbol.

(2) FLXA0FRPRTC2.TXI

Wakeup Symbol Transmit Idle

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 45 to 180 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the idle phase of the wakeup symbol.

(3) FLXA0FRPRTC2.RXL

Wakeup Symbol Receive Low

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 10 to 55 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the low phase of the received wakeup symbol.

(4) FLXA0FRPRTC2.RXI

Wakeup Symbol Rx Idle

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 14 to 59 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the idle phase of the received wakeup symbol.

17.2.6.7 FLXA0FRMHDC — FlexRay MHD Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0098_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 29	—	Reserved These bits are always read as 0. When writing, always write 0.
28 to 16	SLT[12:0]	Start of Latest Transmit Configure pLatestTx
15 to 7	—	Reserved These bits are always read as 0. When writing, always write 0.
6 to 0	SFDL[6:0]	Static Frame Data Length Configure gPayloadLengthStatic

(1) FLXA0FRMHDC.SLT

Start of Latest Transmit

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7981 minislots.

Configures the maximum minislot value allowed before inhibiting frame transmission in the dynamic segment of the cycle. There is no transmission in dynamic segment if FLXA0FRMHDC.SLT is set to zero.

(2) FLXA0FRMHDC.SFDL

Static Frame Data Length

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 127.

The payload length must be identical in all nodes of a cluster.

Configures the cluster-wide payload length for all frames sent in the static segment in double bytes.

17.2.6.8 FLXA0FRGTUC1 — FlexRay GTU Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $00A0_H$

Value after reset: $0000\ 0280_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.28 FLXA0FRGTUC1 Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved These bits are always read as 0. When writing, always write 0.
19 to 0	UT[19:0]	Microtick per Cycle Configure pMicroPerCycle

(1) FLXA0FRGTUC1.UT

Microtick per Cycle

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 640 to 640000 µT.

Configures the duration of the communication cycle in microticks.

17.2.6.9 FLXA0FRGTUC2 — FlexRay GTU Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $00A4_H$

Value after reset: $0002\ 000A_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.29 FLXA0FRGTUC2 Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved These bits are always read as 0. When writing, always write 0.
19 to 16	SNM[3:0]	Sync Node Max
15, 14	—	Reserved These bits are always read as 0. When writing, always write 0.
13 to 0	MPC[13:0]	Macrotick Per Cycle Configure gMacroPerCycle

(1) FLXA0FRGTUC2.SNM

Sync Node Max

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 15.

Must be identical in all nodes of a cluster.

Maximum number of frames within a cluster with sync frame indicator bit SYN set to ‘1’.

(2) FLXA0FRGTUC2.MPC

Macrotick Per Cycle

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 10 to 16000 MT.

The cycle length must be identical in all nodes of a cluster.

Configures the duration of one communication cycle in macroticks.

17.2.6.10 FLXA0FRGTUC3 — FlexRay GTU Configuration Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $00A8_H$

Value after reset: $0202\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.30 FLXA0FRGTUC3 Register Contents

Bit Position	Bit Name	Function
31	—	Reserved This bit is always read as 0. When writing, always write 0.
30 to 24	MIOB[6:0]	Macrotick Initial Offset Channel B Configure pMacroInitialOffset[B]
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	MIOA[6:0]	Macrotick Initial Offset Channel A Configure pMacroInitialOffset[A]
15 to 8	UIOB[7:0]	Microtick Initial Offset Channel B Configure pMicroInitialOffset[B]
7 to 0	UIOA[7:0]	Microtick Initial Offset Channel A Configure pMicroInitialOffset[A]

(1) FLXA0FRGTUC3.MIOB

Macrotick Initial Offset Channel B

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

Must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration.

(2) FLXA0FRGTUC3.MIOA

Macrotick Initial Offset Channel A

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

Must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration.

(3) FLXA0FRGTUC3.UIOB

Microtick Initial Offset Channel B

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 240 µT.

Configures the number of microticks between the actual time reference point on channel B and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation [B] and therefore has to be set for each channel independently.

(4) FLXA0FRGTUC3.UIOA

Microtick Initial Offset Channel A

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 240 µT.

Configures the number of microticks between the actual time reference point on channel A and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation [A] in the FLXA0FRGTUC5 register and therefore has to be set for each channel independently.

17.2.6.11 FLXA0FRGTUC4 — FlexRay GTU Configuration Register 4

For details about configuration of FLXA0FRGTUC4.NIT and FLXA0FRGTUC4.OCS, see **Section 17.3.2.5, Configuration of NIT Start and Offset Correction Start**.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $00AC_H$

Value after reset: $0008\ 0007_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	OCS[13:0]

Table 17.31 FLXA0FRGTUC4 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 16	OCS[13:0]	Offset Correction Start Configure (gOffsetCorrectionStart - 1)
15, 14	—	Reserved These bits are always read as 0. When writing, always write 0.
13 to 0	NIT[13:0]	Network Idle Time Start Configure (gMacroPerCycle -gdNIT - 1)

(1) FLXA0FRGTUC4.OCS

Offset Correction Start

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 8 to 15998 MT.

For cluster consisting of E-Ray implementations only, it is sufficient to program FLXA0FRGTUC4.OCS = FLXA0FRGTUC4.NIT + 1.

Must be identical in all nodes of a cluster.

Determines the start of the offset correction within the NIT phase, calculated from start of cycle.

(2) FLXA0FRGTUC4.NIT

Network Idle Time Start

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 7 to 15997 MT.

Must be identical in all nodes of a cluster.

Configures the starting point of the Network Idle Time NIT at the end of the communication cycle expressed in terms of macroticks from the beginning of the cycle. The start of NIT is recognized if Macrotick = gMacroPerCycle -gdNIT -1 and the increment pulse of Macrotick is set.

17.2.6.12 FLXA0FRGTUC5 — FlexRay GTU Configuration Register 5

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $00B0_H$

Value after reset: $0E00\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.32 FLXA0FRGTUC5 Register Contents

Bit Position	Bit Name	Function
31 to 24	DEC[7:0]	Decoding Correction Configure pDecodingCorrection
23 to 21	—	Reserved These bits are always read as 0. When writing, always write 0.
20 to 16	CDD[4:0]	Cluster Drift Damping Configure pClusterDriftDamping
15 to 8	DCB[7:0]	Delay Compensation Channel B Configure pDelayCompensation[B]
7 to 0	DCA[7:0]	Delay Compensation Channel A Configure pDelayCompensation[A]

(1) FLXA0FRGTUC5.DEC

Decoding Correction

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 14 to 143 µT.

Configures the decoding correction value in microticks used to determine the primary time reference point.

(2) FLXA0FRGTUC5.CDD

Cluster Drift Damping

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 20 µT.

Configures the cluster drift damping value in microticks used in clock synchronization to minimize accumulation of rounding errors.

(3) FLXA0FRGTUC5.DCB

Delay Compensation Channel B

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 µT.

Used to compensate for reception delays on channel B. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied.

(4) FLXA0FRGTUC5.DCA

Delay Compensation Channel A

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 µT.

Used to compensate for reception delays on channel A. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied.

17.2.6.13 FLXA0FRGTUC6 — FlexRay GTU Configuration Register 6

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $00B4_H$

Value after reset: $0002\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26 to 16	MOD[10:0]	Maximum Oscillator Drift Configure pdMaxDrift
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	ASR[10:0]	Accepted Startup Range Configure pdAcceptedStartupRange

(1) FLXA0FRGTUC6.MOD

Maximum Oscillator Drift

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 µT.

Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in µT.

(2) FLXA0FRGTUC6.ASR

Accepted Startup Range

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 1875 µT.

Number of microticks constituting the expanded range of measured deviation for startup frames during integration.

17.2.6.14 FLXA0FRGTUC7 — FlexRay GTU Configuration Register 7

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $00B8_H$

Value after reset: $0002\ 0004_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.34 FLXA0FRGTUC7 Register Contents

Bit Position	Bit Name	Function
31 to 26	—	Reserved These bits are always read as 0. When writing, always write 0.
25 to 16	NSS[9:0]	Number of Static Slots Configure gNumberOfStaticSlots
15 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9 to 0	SSL[9:0]	Static Slot Length Configure gdStaticSlot

(1) FLXA0FRGTUC7.NSS

Number of Static Slots

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1023.

The number of static slots must be identical in all nodes of a cluster.

Configures the number of static slots in a cycle.

(2) FLXA0FRGTUC7.SSL

Static Slot Length

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 4 to 659 MT.

The static slot length must be identical in all nodes of a cluster.

Configures the length of a static slot in macroticks.

17.2.6.15 FLXA0FRGTUC8 — FlexRay GTU Configuration Register 8

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $00BC_H$

Value after reset: $0000\ 0002_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.35 FLXA0FRGTUC8 Register Contents

Bit Position	Bit Name	Function
31 to 29	—	Reserved These bits are always read as 0. When writing, always write 0.
28 to 16	NMS[12:0]	Number of Minislots Configure gNumberOfMinislots
15 to 6	—	Reserved These bits are always read as 0. When writing, always write 0.
5 to 0	MSL[5:0]	Minislot Length Configure gdMinislot

(1) FLXA0FRGTUC8.NMS

Number of Minislots

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7986.

The number of minislots must be identical in all nodes of a cluster.

Configures the number of minislots within the dynamic segment of a cycle.

(2) FLXA0FRGTUC8.MSL

Minislot Length

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 63 MT.

The minislot length must be identical in all nodes of a cluster.

Configures the length of a minislot in macroticks.

17.2.6.16 FLXA0FRGTUC9 — FlexRay GTU Configuration Register 9

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $00C0_H$

Value after reset: $0000\ 0101_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.36 FLXA0FRGTUC9 Register Contents

Bit Position	Bit Name	Function
31 to 18	—	Reserved These bits are always read as 0. When writing, always write 0.
17, 16	DSI[1:0]	Dynamic Slot Idle Phase Configure gdDynamicSlotIdlePhase
15 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12 to 8	MAPO[4:0]	Minislot Action Point Offset Configure gdMinislotActionPointOffset
7, 6	—	Reserved These bits are always read as 0. When writing, always write 0.
5 to 0	APO[5:0]	Action Point Offset Configure gdActionPointOffset

(1) FLXA0FRGTUC9.DSI

Dynamic Slot Idle Phase

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 2 Minislots.

Must be identical in all nodes of a cluster.

Configures the duration of the dynamic slot idle phase in the number of minislots. The duration has to be greater or equal than the idle detection time.

(2) FLXA0FRGTUC9.MAPO

Minislot Action Point Offset

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 31 MT.

Must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within the minislots of the dynamic segment.

(3) FLXA0FRGTUC9.APO

Action Point Offset

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 63 MT.

Must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within static slots and symbol window.

17.2.6.17 FLXA0FRGTUC10 — FlexRay GTU Configuration Register 10

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $00C4_H$

Value after reset: $0002\ 0005_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15, 14	—	Reserved These bits are always read as 0. When writing, always write 0.
13 to 0	MOC[13:0]	Maximum Offset Correction Configure pOffsetCorrectionOut

(1) FLXA0FRGTUC10.MRC

Maximum Rate Correction

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 µT.

Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The CC checks only the internal rate correction value against the maximum rate correction value (absolute value).

(2) FLXA0FRGTUC10.MOC

Maximum Offset Correction

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 5 to 15266 µT.

Holds the maximum permitted offset correction value (absolute value) to be applied by the internal clock synchronization algorithm (absolute value). The CC checks only the internal offset correction value against the maximum offset correction value.

17.2.6.18 FLXA0FRGTUC11 — FlexRay GTU Configuration Register 11

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $00C8_H$

Value after reset: $0000\ 0000_H$

7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1, 0	EOCC[1:0]	External Offset Correction Control Configure vExternOffsetControl 00: External offset correction is prohibited. 01: External offset correction is prohibited. 10: Subtract 11: Add

(1) FLXA0FRGTUC11.ERC

External Rate Correction

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 µT.

Holds the external rate correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted or added from or to the calculated rate correction value. The value is applied during NIT.

(2) FLXA0FRGTUC11.EOC

External Offset Correction

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 µT.

Holds the external offset correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted or added from or to the calculated offset correction value. The value is applied during NIT.

(3) FLXA0FRGTUC11.ERCC

External Rate Correction Control

Should be modified only outside NIT (Network Idle Time).

By writing to FLXA0FRGTUC11.ERCC the external rate correction is enabled as specified below.

00 = External rate correction is prohibited.

01 = External rate correction is prohibited.

10 = Subtract

External rate correction value subtracted from calculated rate correction value

11 = Add

External rate correction value added to calculated rate correction value

(4) FLXA0FRGTUC11.EOCC

External Offset Correction Control

Should be modified only outside NIT (Network Idle Time).

By writing to FLXA0FRGTUC11.EOCC the external offset correction is enabled as specified below.

00 = External offset correction is prohibited.

01 = External offset correction is prohibited.

10 = Subtract

External offset correction value subtracted from calculated offset correction value

11 = Add

External offset correction value added to calculated offset correction value

17.2.7 CC Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the CC between two accesses (non-atomic read accesses).

17.2.7.1 FLXA0FRCCSV — FlexRay CC Status Vector Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0100_H

Value after reset: $0010\ 4000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.39 FLXA0FRCCSV Register Contents

Bit	Symbol	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 24	PSL[5:0]	POC Status Log Flags Status of FLXA0FRCCSV.POCS immediately before entering HALT state.
23 to 19	RCA[4:0]	Remaining Coldstart Attempts Flags Indicate vRemainingColdstartAttempts
18 to 16	WSV[2:0]	Wakeup Status Flags Indicate vPOC!WakeupStatus
15	—	Reserved This bit is always read as 0. When writing, always write 0.
14	CSI	Cold Start Inhibit Flag Indicates vColdStartInhibit 0: Cold starting of node enabled 1: Cold starting of node disabled
13	CSAI	Coldstart Abort Indicator Flag
12	CSNI	Coldstart Noise Indicator Flag Indicates vPOC!ColdstartNoise
11, 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9, 8	SLM[1:0]	Slot Mode Flags Indicate vPOC!SlotMode 00: SINGLE 01: reserved 10: ALL_PENDING 11: ALL
7	HRQ	Halt Request Flag Indicates vPOC!CHIHaltRequest
6	FSI	Freeze Status Indicator Flag Indicates vPOC!Freeze
5 to 0	POCS[5:0]	Protocol Operation Control Status Flags

(1) FLXA0FRCCSV.PSL

POC Status Log Flags

Set the value of FLXA0FRCCSV.POCS immediately before entering HALT state.

Set to HALT when FREEZE command is applied during HALT state and FLXA0FRCCSV.FSI is not already set i.e. the HALT state was not reached by FREEZE command.

Reset to "000000_B" when leaving HALT state.

(2) FLXA0FRCCSV.RCA

Remaining Coldstart Attempts Flags

Indicates the number of remaining coldstart attempts (vRemainingColdstartAttempts).

The initial value of FLXA0FRCCSV.RCA during CONFIG and DEFAULT_CONFIG state is also FLXA0FRSUCC1.CSA.

The RUN command resets this counter to the maximum number of coldstart attempts as configured by FLXA0FRSUCC1.CSA.

(3) FLXA0FRCCSV.WSV

Wakeup Status Flags

Indicates the status of the current wakeup attempt (vPOC!WakeupStatus).

Reset to “0” when entering Wakeup state, by CHI command RESET_STATUS_INDICATORS, or by transition from DEFAULT_CONFIG to CONFIG state

000 = UNDEFINED

Wakeup not yet executed by the CC.

001 = RECEIVED_HEADER

Set when the CC finishes wakeup due to the reception of a frame header without coding violation on either channel in WAKEUP_LISTEN state.

010 = RECEIVED_WUP

Set when the CC finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in WAKEUP_LISTEN state.

011 = COLLISION_HEADER

Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid header on either channel.

100 = COLLISION_WUP

Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel.

101 = COLLISION_UNKNOWN

Set when the CC stops wakeup by leaving WAKEUP_DETECT state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid frame header.

110 = TRANSMITTED

Set when the CC has successfully completed the transmission of the wakeup pattern.

111 = reserved

(4) FLXA0FRCCSV.CSI

Cold Start Inhibit Flag

Indicates that the node is disabled from cold starting (vColdStartInhibit).

The flag is set to “1” whenever the POC enters READY state due to CHI command READY.

The flag has to be reset under control of the host by CHI command ALLOW_COLDSTART (FLXA0FRSUCC1.CMD = “1001”).

(5) FLXA0FRCCSV.CSAI

Coldstart Abort Indicator Flag

Coldstart aborted.

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(6) FLXA0FRCCSV.CSNI

Coldstart Noise Indicator Flag

Indicates that the cold start procedure occurred under noisy conditions (vPOC!ColdstartNoise).

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(7) FLXA0FRCCSV.SLM

Slot Mode Flags

Indicates the actual slot mode of the POC (vPOC!SlotMode) in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE.

Default value is SINGLE. Changes to ALL, depending on FLXA0FRSUCC1.TSM.

In NORMAL_ACTIVE or NORMAL_PASSIVE state the CHI command ALL_SLOTS will change the slot mode from SINGLE over ALL_PENDING to ALL.

Set FLXA0FRSUCC1.TSM to SINGLE except for NORMAL_ACTIVE or NORMAL_PASSIVE.

(8) FLXA0FRCCSV.HRQ

Halt RequestFlag

Indicates that a request from the host has been received to halt the POC at the end of the communication cycle (vPOC!CHIHaltRequest).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(9) FLXA0FRCCSV.FSI

Freeze Status Indicator Flag

Indicates that the POC has entered the HALT state due to CHI command FREEZE or due to an error condition requiring an immediate POC halt (vPOC!Freeze).

Reset by transition from HALT to DEFAULT_CONFIG state.

(10) FLXA0FRCCSV.POCS

Protocol Operation Control Status Flag

Indicates the actual state of operation of the CC Protocol Operation Control

00 0000 = DEFAULT_CONFIG state

00 0001 = READY state

00 0010 = NORMAL_ACTIVE state

00 0011 = NORMAL_PASSIVE state

00 0100 = HALT state

00 0110…00 1110 = reserved

00 1111 = CONFIG state

Indicates the actual state of operation of the POC in the wakeup path

01 0000 = WAKEUP_STANDBY state

01 0001 = WAKEUP_LISTEN state

01 0010 = WAKEUP_SEND state

01 0011 = WAKEUP_DETECT state

Indicates the actual state of operation of the POC in the startup path

10 0000 = STARTUP_PREPARE state

10 0001 = COLDSTART_LISTEN state

10 0010 = COLDSTART_COLLISION_RESOLUTION state

10 0011 = COLDSTART_CONSISTENCY_CHECK state

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.40 FLXA0FRCCEV Register Contents

Bit Position	Bit Name	Function
31 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12 to 8	PTAC[4:0]	Passive to Active Count Indicate vAllowPassiveToActive
7, 6	ERRM[1:0]	Error Mode Flags Indicates vPOC!ErrorMode 00: ACTIVE 01: PASSIVE 10: COMM_HALT 11: reserved
5, 4	—	Reserved These bits are always read as 0. When writing, always write 0.
3 to 0	CCFC[3:0]	Clock Correction Failed Counter Indicate vClockCorrectionFailed

(1) FLXA0FRCCEV.PTAC

Passive to Active Count

Indicates the number of consecutive even/odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from NORMAL_PASSIVE state to NORMAL_ACTIVE state. The transition takes place when FLXA0FRCCEV.PTAC equals FLXA0FRSUCC1.PTA -1.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(2) FLXA0FRCCEV.ERRM

Error Mode Flags

Indicates the actual error mode of the POC (vPOC!ErrorMode).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(3) FLXA0FRCCEV.CCFC

Clock Correction Failed Counter

Indicates the clock correction failed counter of the POC (vClockCorrectionFailed).

The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active.

The Clock Correction Failed Counter is reset to '0' at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active.

The Clock Correction Failed Counter stops at 15.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

17.2.7.3 FLXA0FRSCV — FlexRay Slot Counter Value Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0110_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	SCCB[10:0]

Table 17.41 FLXA0FRSCV Register Contents

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26 to 16	SCCB[10:0]	Slot Counter Channel B Indicates vSlotCounter[B]
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	SCCA[10:0]	Slot Counter Channel A Indicates vSlotCounter[A]

(1) FLXA0FRSCV.SCCB

Slot Counter Channel B

Current slot counter value on channel B (vSlotCounter[B]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FRSCV.SCCA

Slot Counter Channel A

Current slot counter value on channel A (vSlotCounter[A]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.4 FLXA0FRMTCCV — FlexRay Macrotick and Cycle Counter Value Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0114_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.42 FLXA0FRMTCCV Register Contents

Bit Position	Bit Name	Function
31 to 22	—	Reserved These bits are always read as 0. When writing, always write 0.
21 to 16	CCV[5:0]	Cycle Counter Value Indicates vCycleCounter
15, 14	—	Reserved These bits are always read as 0. When writing, always write 0.
13 to 0	MTV[13:0]	Macrotick Value Indicates vMacrotick

(1) FLXA0FRMTCCV.CCV

Cycle Counter Value

Current cycle counter value (vCycleCounter). The value is incremented by the CC at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FRMTCCV.MTV

Macrotick Value

Current macrotick value (vMacrotick). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.5 FLXA0FRRCV — FlexRay Rate Correction Value Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0118_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.43 FLXA0FRRCV Register Contents

Bit Position	Bit Name	Function
31 to 12	—	Reserved These bits are always read as 0. When writing, always write 0.
11 to 0	RCV[11:0]	Rate Correction Value Flags Indicates vRateCorrection

(1) FLXA0FRRCV.RCV

Rate Correction Value Flags

Indicates internal rate correction value (vRateCorrection/ two's complement) before limitation. If the FLXA0FRRCV.RCV value exceeds the limits defined by FLXA0FRGTUC10.MRC, flag FLXA0FRSFS.RCLR is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

NOTE

The external rate correction value is added to the limited rate correction value.

17.2.7.6 FLXA0FROCV — FlexRay Offset Correction Value Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + $011C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	OCV[18:16]

Table 17.44 FLXA0FROCV Register Contents

Bit Position	Bit Name	Function
31 to 19	—	Reserved These bits are always read as 0. When writing, always write 0.
18 to 0	OCV[18:0]	Offset Correction Value Flags Indicate vOffsetCorrection

(1) FLXA0FROCV.OCV

Offset Correction Value Flags

Indicate offset correction value (vOffsetCorrection/ two's complement) before limitation. If the FLXA0FROCV.OCV value exceeds the limits defined by FLXA0FRGTUC10.MOC, flag FLXA0FRSFS.OCLR is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

NOTE

The external offset correction value is added to the limited offset correction value.

17.2.7.7 FLXA0FRSFS — FlexRay Sync Frame Status Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0120_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	RCLR	MRCS	OCLR	MOCS

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VSBO[3:0]				VSBE[3:0]				VSAO[3:0]				VSAE[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.45 FLXA0FRSFS Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved These bits are always read as 0. When writing, always write 0.
19	RCLR	Rate Correction Limit Reached Flag 0: Rate correction below limit 1: Rate correction limit reached
18	MRCS	Missing Rate Correction Signal Flag 0: Rate correction signal valid 1: Missing rate correction signal
17	OCLR	Offset Correction Limit Reached Flag 0: Offset correction below limit 1: Offset correction limit reached
16	MOCS	Missing Offset Correction Signal Flag 0: Offset correction signal valid 1: Missing offset correction signal
15 to 12	VSBO[3:0]	Valid Sync Frames Channel B, odd communication cycle
11 to 8	VSBE[3:0]	Valid Sync Frames Channel B, even communication cycle
7 to 4	VSAO[3:0]	Valid Sync Frames Channel A, odd communication cycle
3 to 0	VSAE[3:0]	Valid Sync Frames Channel A, even communication cycle

(1) FLXA0FRSFS.RCLR

Rate Correction Limit Reached Flag

The rate correction limit reached flag signals to the host, that the rate correction value has exceeded its limit as defined by FLXA0FRGTUC10.MRC10 - MRC0. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(2) FLXA0FRSFS.MRCS

Missing Rate Correction Signal Flag

The missing rate correction flag signals to the host, that no rate correction calculation can be performed because no pairs of even/odd sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(3) FLXA0FRSFS.OCLR

Offset Correction Limit Reached Flag

The offset correction limit reached flag signals to the host, that the offset correction value has exceeded its limit as defined by FLXA0FRGTUC10.MOC. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(4) FLXA0FRSFS.MOCS

Missing Offset Correction Signal Flag

The missing offset correction flag signals to the host, that no offset correction calculation can be performed because no sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(5) FLXA0FRSFS.VSBO

Valid Sync Frames Channel B, odd communication cycle

These bits are only valid when FLXA0FRSUCC1.CCHB is ‘1’.

Holds the number of valid sync frames received on channel B in the odd communication cycle. If transmission of sync frames is enabled by FLXA0FRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(6) FLXA0FRSFS.VSBE

Valid Sync Frames Channel B, even communication cycle

These bits are only valid when FLXA0FRSUCC1.CCHB is ‘1’.

Holds the number of valid sync frames received on channel B in the even communication cycle. If transmission of sync frames is enabled by FLXA0FRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(7) FLXA0FRSFS.VSAO

Valid Sync Frames Channel A, odd communication cycle

These bits are only valid when FLXA0FRSUCC1.CCHA is ‘1’.

Holds the number of valid sync frames received on channel A in the odd communication cycle. If transmission of sync frames is enabled by FLXA0FRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(8) FLXA0FRSFS.VSAE

Valid Sync Frames Channel A, even communication cycle

These bits are only valid when FLXA0FRSUCC1.CCHA is ‘1’.

Holds the number of valid sync frames received on channel A in the even communication cycle. If transmission of sync frames is enabled by FLXA0FRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

17.2.7.8 FLXA0FRSWNIT — FlexRay Symbol Window and NIT Status Register

Symbol window related status information is updated by the CC at the end of the symbol window for each channel. NIT related status information is updated by the CC at the end of the NIT for each channel.

During startup the status data is not updated.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0124_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.46 FLXA0FRSWNIT Register Contents (1/2)

Bit Position	Symbol	Function
31 to 12	—	Reserved These bits are always read as 0. When writing, always write 0.
11	SBNB	Slot Boundary Violation during NIT Channel B Flag 0: No slot boundary violation detected 1: Slot boundary violation during NIT detected on channel B
10	SENB	Syntax Error during NIT Channel B Flag 0: No syntax error detected 1: Syntax error during NIT detected on channel B
9	SBNA	Slot Boundary Violation during NIT Channel A Flag 0: No slot boundary violation detected 1: Slot boundary violation during NIT detected on channel A
8	SENA	Syntax Error during NIT Channel A Flag 0: No syntax error detected 1: Syntax error during NIT detected on channel A
7	MTSB	MTS Received on Channel B Flag 0: No MTS symbol received on channel B 1: MTS symbol received on channel B
6	MTSA	MTS Received on Channel A Flag 0: No MTS symbol received on channel A 1: MTS symbol received on channel A
5	TCSB	Transmission Conflict in Symbol Window Channel B Flag 0: No transmission conflict detected 1: Transmission conflict in symbol window detected on channel B
4	SBSB	Slot Boundary Violation in Symbol Window Channel B Flag 0: No slot boundary violation detected 1: Slot boundary violation during symbol window detected on channel B
3	SESB	Syntax Error in Symbol Window Channel B Flag 0: No syntax error detected 1: Syntax error during symbol window detected on channel B

Table 17.46 FLXA0FRSWNIT Register Contents (2/2)

Bit Position	Symbol	Function
2	TCSA	Transmission Conflict in Symbol Window Channel A Flag 0: No transmission conflict detected 1: Transmission conflict in symbol window detected on channel A
1	SBSA	Slot Boundary Violation in Symbol Window Channel A Flag 0: No slot boundary violation detected 1: Slot boundary violation during symbol window detected on channel A
0	SESA	Syntax Error in Symbol Window Channel A Flag 0: No syntax error detected 1: Syntax error during symbol window detected on channel A

(1) FLXA0FRSWNIT.SBNB

Indicates a Slot Boundary Violation during NIT Channel B Flag (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FRSWNIT.SENB

Indicates a Syntax Error during NIT Channel B Flag (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXA0FRSWNIT.SBNA

Indicates a Slot Boundary Violation during NIT Channel A Flag (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(4) FLXA0FRSWNIT.SENA

Indicates a Syntax Error during NIT Channel A Flag (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

(5) FLXA0FRSWNIT.MTSB

Indicates a MTS Received on Channel B Flag (vSS!ValidMTSB).

Media Access Test symbol received on channel B during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to ‘1’, also interrupt flag FLXA0FRSIR.MTSB is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) FLXA0FRSWNIT.MTSA

Indicates a MTS Received on Channel A Flag (vSS!ValidMTSA).

Media Access Test symbol received on channel A during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to ‘1’, also interrupt flag FLXA0FRSIR.MTSA is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) FLXA0FRSWNIT.TCSB

Indicates a Transmission Conflict in Symbol Window Channel B Flag (vSS!TxConflictB).

Reset when leaving CONFIG state or when entering STARTUP state.

(8) FLXA0FRSWNIT.SBSB

Indicates a Slot Boundary Violation in Symbol Window Channel B Flag (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(9) FLXA0FRSWNIT.SESB

Indicates a Syntax Error in Symbol Window Channel B Flag (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(10) FLXA0FRSWNIT.TCSA

Indicates a Transmission Conflict in Symbol Window Channel A Flag (vSS!TxConflictA).

Reset when leaving CONFIG state or when entering STARTUP state.

(11) FLXA0FRSWNIT.SBSA

Indicates a Slot Boundary Violation in Symbol Window Channel A Flag (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(12) FLXA0FRSWNIT.SESA

Indicates a Syntax Error in Symbol Window Channel A Flag (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.9 FLXA0FRACS — FlexRay Aggregated Channel Status Register

Do not rewrite this register using bit-manipulation instruction.

The aggregated channel status provides the host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception.

The aggregated channel status also includes status data from the symbol window and the network idle time.

The status data is updated (set) after each slot and aggregated until it is reset by the host.

During startup the status data is not updated.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0128_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12	SBVB	Slot Boundary Violation on Channel B Flag 0: No slot boundary violation observed 1: Slot boundary violation(s) observed on channel B
11	CIB	Communication Indicator Channel B Flag 0: No valid frame(s) received in slots containing any additional communication 1: Valid frame(s) received on channel B in slots containing any additional communication
10	CEDB	Content Error Detected on Channel B Flag 0: No frame with content error received 1: Frame(s) with content error received on channel B
9	SEDB	Syntax Error Detected on Channel B Flag 0: No syntax error observed 1: Syntax error(s) observed on channel B
8	VFRB	Valid Frame Received on Channel B Flag 0: No valid frame received 1: Valid frame(s) received on channel B
7 to 5	—	Reserved These bits are always read as 0. When writing, always write 0.
4	SBVA	Slot Boundary Violation on Channel A Flag 0: No slot boundary violation observed 1: Slot boundary violation(s) observed on channel A

Table 17.47 FLXA0FRACS Register Contents (2/2)

Bit Position	Bit Name	Function
3	CIA	Communication Indicator Channel A Flag 0: No valid frame(s) received in slots containing any additional communication 1: Valid frame(s) received on channel A in slots containing any additional communication
2	CEDA	Content Error Detected on Channel A Flag 0: No frame with content error received 1: Frame(s) with content error received on channel A
1	SEDA	Syntax Error Detected on Channel A Flag 0: No syntax error observed 1: Syntax error(s) observed on channel A
0	VFRA	Valid Frame Received on Channel A Flag 0: No valid frame received 1: Valid frame(s) received on channel A

(1) FLXA0FRACS.SBVB

Slot Boundary Violation on Channel B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.EDB is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FRACS.CIB

Communication Indicator Channel B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

One or more valid frames were received on channel B in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.EDB is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

NOTE

The set condition of the flag FLXA0FRACS.CIB is also fulfilled if there is only one single frame in the slot and the slot boundary at the end of the slot is reached during the frames channel idle recognition phase.

(3) FLXA0FRACS.CEDB

Content Error Detected on Channel B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

One or more frames with a content error were received on channel B in any static or dynamic slot during the observation period.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.EDB is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

(4) FLXA0FRACS.SEDB

Syntax Error Detected on Channel B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel B.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.EDB is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

(5) FLXA0FRACS.VFRB

Valid Frame Received on Channel B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

One or more valid frames were received on channel B in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) FLXA0FRACS.SBVA

Slot Boundary Violation on Channel A Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

Slot boundary violations were observed on channel A at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.EDB is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) FLXA0FRACS.CIA

Communication Indicator Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

One or more valid frames were received on channel A in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame, and had one of syntax error, content error, or slot boundary violation.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.EDB is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

NOTE

The set condition of the flag FLXA0FRACS.CIA is also fulfilled if there is only one single frame in the slot and the slot boundary at the end of the slot is reached during the frames channel idle recognition phase.

(8) FLXA0FRACS.CEDA

Content Error Detected on Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

One or more frames with a content error were received on channel A in any static or dynamic slot during the observation period.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.EDB is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

(9) FLXA0FRACS.SEDA

Syntax Error Detected on Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel A.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.EDB is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

(10) FLXA0FRACS.VFRA

Valid Frame Received on Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

One or more valid frames were received on channel A in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.10 FLXA0FRESIDn — FlexRay Even Sync ID Register n (n = 1 to 15)

Registers FLXA0FRESID1 to FLXA0FRESID15 hold the frame IDs of the sync frames received in even communication cycles used for clock synchronization up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register FLXA0FRESID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an even communication cycle, register FLXA0FRESID1 holds the respective sync frame ID as configured in message buffer 0 and flags FLXA0FRESID1.RXEA, FLXA0FRESID1.RXEB are set. The value is updated during the NIT of each even communication cycle.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0130_H to ERAY + 0168_H (ERAY + 0130_H + (n-1)*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.48 FLXA0FRESIDn (n = 1 to 15) Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. When writing, always write 0.
15	RXEB	Received/Configured Even Sync ID on Channel B Flag 0: No sync frame received on channel B or node not configured to transmit sync frames 1: Sync frame received on channel B or node configured to transmit sync frames
14	RXEA	Received/Configured Even Sync ID on Channel A Flag 0: No sync frame received on channel A or node not configured to transmit sync frames 1: Sync frame received on channel A or node configured to transmit sync frames
13 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9 to 0	EID[9:0]	Even Sync ID Flags (vsSyncIDListA,B even)

(1) FLXA0FRESIDn.RXEB

Received/Configured Even Sync ID on Channel B Flag

Signals that a sync frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot indicated by the FLXA0FRESID1.EID.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FRESIDn.RXEA

Received/Configured Even Sync ID on Channel A Flag

Signals that a sync frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot indicated by the FLXA0FRESID1.EID.

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXA0FRESIDn.EID

Even Sync ID Flags (vsSyncIDListA, B even)

Sync frame ID even communication cycle

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.11 FLXA0FROSIDn — FlexRay Odd Sync ID Register n (n = 1 to 15)

Registers FLXA0FROSID1 to FLXA0FROSID15 hold the frame IDs of the sync frames received in odd communication cycles used for clock synchronization up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register FLXA0FROSID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an odd communication cycle, register FLXA0FROSID1 holds the respective sync frame ID as configured in message buffer 0 and flags FLXA0FROSID1.RXOA and FLXA0FROSID1.RXOB are set. The value is updated during the NIT of each odd communication cycle.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0170_H to ERAY + $01A8_H$ (ERAY + 0170_H + (n-1)*4)

Value after reset: $0000\ 0000_H$

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.49 FLXA0FROSIDn Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. When writing, always write 0.
15	RXOB	Received/Configured Odd Sync ID on Channel B Flag 0: No sync frame received on channel B or node not configured to transmit sync frames 1: Sync frame received on channel B or node configured to transmit sync frames
14	RXOA	Received/Configured Odd Sync ID on Channel A Flag 0: No sync frame received on channel A or node not configured to transmit sync frames 1: Sync frame received on channel A or node configured to transmit sync frames
13 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9 to 0	OID[9:0]	Odd Sync ID Flags (vsSyncIDListA,B odd)

(1) FLXA0FROSIDn.RXOB

Received/Configured Odd Sync ID on Channel B Flag

Signals that a sync frame corresponding to the stored odd sync ID was received on channel B or that the node is configured to be a sync node with key slot = FLXA0FROSID1.OID.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FROSIDn.RXOA

Received/Configured Odd Sync ID on Channel A Flag

Signals that a sync frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = FLXA0FRISID1.OID.

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXA0FROSIDn.OID

Odd Sync ID Flags (vsSyncIDListA,B odd)

Sync frame ID odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.12 FLXA0FRNMVn — FlexRay Network Management Vector Register n (n = 1 to 3)

The three network management registers hold the accrued NM vector (see **Section 17.3.7, Network Management**).

The CC updates the NM vector at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state.

NMVn-bytes exceeding the configured NM vector length are not valid.

For information about the byte alignment of the received NM vector in this register see **Section 17.3.17, Byte Alignment**.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + $01B0_H$ to ERAY + $01B8_H$ (ERAY + $01B0_H$ + (n-1)*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NM[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NM[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.50 FLXA0FRNMVn Register Contents

Bit Position	Bit Name	Function
31 to 0	NM[31:0]	NM Vector the three network management vector registers hold the accrued NM vector (configurable 0 to 12 bytes). The NM vector to be held is generated by bit-wise logic OR for each NM vector received on each channel (valid static frames with PPI = '1') (see **Section 17.3.7, Network Management**). For information about the byte alignment of the received NM vector in this register, see **Section 17.3.17, Byte Alignment**. NMVn-bytes exceeding the configured NM vector length are not valid. The register contents are updated at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state. These bits are cleared when leaving CONFIG state or when entering STARTUP state.

17.2.8 Message Buffer Control Registers

17.2.8.1 FLXA0FRMRC — FlexRay Message RAM Configuration Register

The message RAM configuration register defines the number of message buffers assigned to the static segment, dynamic segment, and FIFO.

The message RAM can be divided into up three different areas; static buffer area, static and dynamic buffer area, FIFO area. If present, the static buffer area is starting at message buffer 0.

The start of the static and dynamic buffer area is configured by FLXA0FRMRC.FDB. FLXA0FRMRC.FDB defines the end of the static buffer area. If no static buffer area is present, the static and dynamic buffer area starts at message buffer 0.

The start of the FIFO area is configured by FLXA0FRMRC.FFB. FLXA0FRMRC.FFB defines the end of the previous area, which can be either the static buffer area or the static and dynamic buffer area.

If no static buffer area and no static and dynamic buffer area is present, the FIFO area starts at message buffer 0.

With FLXA0FRMRC.LCB, the end of the last configured area is configured which can be the static buffer area, the static and dynamic buffer area, or the FIFO area.

Figure 17.2 shows an example configuration of the message RAM where all there areas are configured.

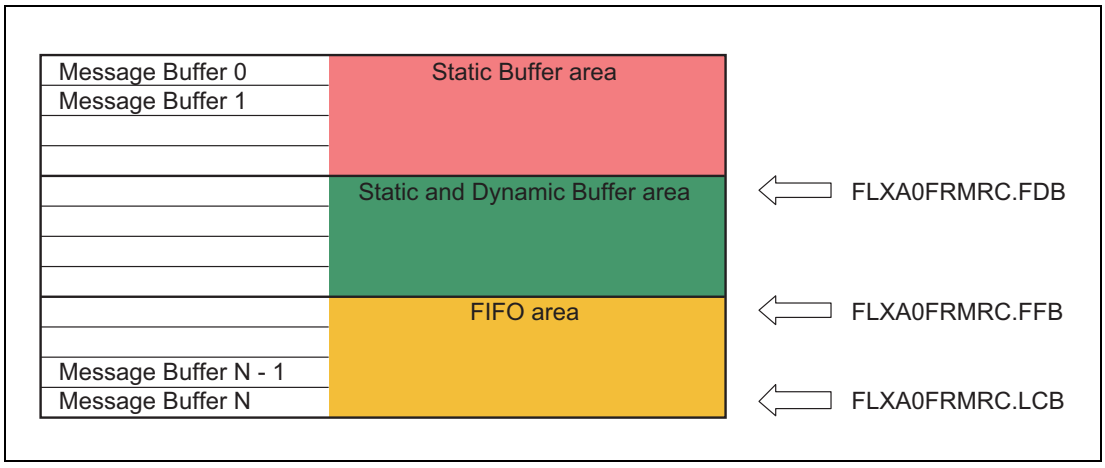

Figure 17.2 Message RAM Organization

NOTES

1. In case the node is configured as sync node (FLXA0FRSUCC1.TXSY = ‘1’) or for single slot mode operation (FLXA0FRSUCC1.TSM = ‘1’), message buffer 0 and 1 are reserved for sync frames or single slot frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation message buffer 0 and 1 are treated like all other message buffers.
2. The maximum number of header sections is 128. This means a maximum of 128 message buffers can be configured. The maximum length of a data section is 254 bytes. The length of the data section can be configured separately for each message buffer. For details see **Section 17.3.13, Message RAM**.
3. In case two or more message buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the “static buffers” or at the beginning of the “static + dynamic buffers” section.

4. The FlexRay protocol specification requires that each node has to send a frame in its key slot. Therefore at least message buffer 0 is reserved for transmission in the key slot. Due to this requirement a maximum number of 127 message buffers can be assigned to the FIFO. Nevertheless, a non-protocol-conforming configuration without a transmission slot in the static segment would still be operational.
5. The payload length and the length of the data section need to be configured identical for all message buffers belonging to the FIFO via FLXA0FRWRHS2.PLC and FLXA0FRWRHS3.DP. When the CC is not in DEFAULT_CONFIG or CONFIG state reconfiguration of message buffers belonging to the FIFO is locked.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0300_H

Value after reset: $0180\ 0000_H$

Table 17.51 FLXA0FRMRC Register Contents

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26	SPLM	Sync Frame Payload Multiplex 0: Writing to message buffer 0 is prohibited. 1: Writing to message buffer 0 or 1 is prohibited.
25, 24	SEC[1:0]	Secure Buffers 00: Writing is enabled for all buffers. 01: Writing is prohibited to static buffer and FIFO, limited transmission 10: Writing is prohibited for all buffers. 11: Writing is prohibited for all buffers, limited transmission
23 to 16	LCB[7:0]	Last Configured Buffer 0 to 127: Number of message buffers is FLXA0FRMRF.LCB + 1 128: No message buffer configured
15 to 8	FFB[7:0]	First Buffer of FIFO 0: All message buffers assigned to the FIFO 1 to 127: Message buffers from FLXA0FRMRC.FFB to FLXA0FRMRC.LCB assigned to the FIFO 128: No message buffer configured
7 to 0	FDB[7:0]	First Dynamic Buffer 0: No group of message buffers exclusively for the static segment configured 1 to 127: Message buffers 0 to FLXA0FRMRC.FDB - 1 reserved for static segment 128: No dynamic message buffers configured

(1) FLXA0FRMRC.SPLM

Sync Frame Payload Multiplex

The user can only write to this bit when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

This bit is only enabled if the node is configured as sync node (FLXA0FRSUCC1.TXSY = ‘1’) or for single slot mode operation (FLXA0FRSUCC1.TSM = ‘1’).

When this bit is set to ‘1’, message buffers 0 and 1 are dedicated for sync frame transmission with separate payload data on channel A and B.

When this bit is set to ‘0’, sync frames are transmitted from message buffer 0 with the same payload data on all channels configured. Note that the channel filter configuration for message buffer 0 and message buffer 1 are selected according to this SPLM bit setting.

(2) FLXA0FRMRC.SEC

Secure Buffer

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

These bits are disabled when the CC is in DEFAULT_CONFIG or CONFIG state.

For temporary unlocking, see **Section 17.3.13.4, Host Handling of Access Errors**.

00 = Writing is enabled for any buffers.

Reconfiguration of message buffers enabled with numbers < FLXA0FRMRC.FFB enabled

Exception: In nodes configured for sync frame transmission or for single slot mode operation, writing to message buffer 0 (and if FLXA0FRMRC.SPLM = '1', also message buffer 1) is prohibited.

01 = static buffers locked, FIFO locked, limited transmission

Reconfiguration of message buffers with numbers < FLXA0FRMRC.FDB and with numbers ≥ FLXA0FRMRC.FFB locked and transmission of message buffers for static segment with numbers ≥ FLXA0FRMRC.FDB disabled

10 = all buffers locked

Writing to any message buffers is prohibited.

11 = Writing to any buffers is prohibited.

Reconfiguration of all message buffers locked and transmission of message buffers for static segment with numbers ≥ FLXA0FRMRC.FDB disabled

(3) FLXA0FRMRC.LCB

Last Buffer Setting

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (FLXA0FRMRC.FDB < 128), the user should configure FLXA0FRMRC.LCB ≥ FLXA0FRMRC.FDB.

When a FIFO area is configured (FLXA0FRMRC.FFB < 128), the user should configure FLXA0FRMRC.LCB ≥ FLXA0FRMRC.FFB.

(4) FLXA0FRMRC.FFB

FIFO First Buffer Setting

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (FLXA0FRMRC.FDB < 128), the user should configure FLXA0FRMRC.FFB > FLXA0FRMRC.FDB.

(5) FLXA0FRMRC.FDB

First Dynamic Buffer Setting

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

17.2.8.2 FLXA0FRFRF — FlexRay FIFO Rejection Filter Register

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, frame ID, and cycle count of the incoming frames are compared. Together with the FIFO Rejection Filter Mask Register this register determines whether a message is rejected by the FIFO.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0304_H

Value after reset: $0180\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	RNF	RSS	CYF[6:0]						
Value after reset	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0

R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17.52 FLXA0FRFRF Register Contents

Bit Position	Bit Name	Function
31 to 25	—	Reserved These bits are always read as 0. When writing, always write 0.
24	RNF	Reject Null Frames 0: Null frames are stored in the FIFO 1: Reject all null frames
23	RSS	Reject in Static Segment 0: FIFO also used for static segment 1: Reject messages in static segment
22 to 16	CYF[6:0]	Cycle Counter Filter
15 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12 to 2	FID[10:0]	Frame ID Filter 0 to 2047: Frame ID filter values
1, 0	CH[1:0]	Channel Filter 00: receive on both channels 01: receive only on channel B 10: receive only on channel A 11: Receive prohibited

(1) FLXA0FRFRF.RNF

Reject Null Frame

The user can only write to this bit when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

If this bit is set to ‘1’, received null frames are not stored in the FIFO.

(2) FLXA0FRFRF.RSS

Reject in Static Segment

The user can only write to this bit when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

If this bit is set to '1', the FIFO is used only for the dynamic segment.

(3) FLXA0FRFRF.CYF

Cycle Counter Filter

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles that are not specified by FLXA0FRFRF.CYF, all frames are rejected. For details about the configuration of the cycle counter filter see **Section 17.3.8.2, Cycle Counter Filtering**.

(4) FLXA0FRFRF.FID

Frame ID Filter

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Determines the frame ID to be rejected by the FIFO. With the additional configuration of register FLXA0FRFRFM, the corresponding frame ID filter bits are ignored. When FLXA0FRFRFM.MFID is zero, a frame ID filter value of zero means that there is no frame ID to be rejected.

(5) FLXA0FRFRF.CH

Channel Filter

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

If reception on both channels is configured, also in static segment always both frames (from channel A and B) are stored in the FIFO, even if they are identical.

17.2.8.3 FLXA0FRFRFM — FlexRay FIFO Rejection Filter Mask Register

The FlexRay FIFO Rejection Filter Mask Register specifies frame ID filter bits relevant to rejection filtering. If a bit is set to '1', it indicates that the corresponding bit in the FLXA0FRFRF register will not be considered for rejection filtering.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0308_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.53 FLXA0FRFRFM Register Contents

Bit Position	Bit Name	Function
31 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12 to 2	MFID[10:0]	Mask Frame ID Filter 0: Corresponding frame ID filter bit is used for rejection filtering 1: Ignore corresponding frame ID filter bit.
1, 0	—	Reserved These bits are always read as 0. When writing, always write 0.

(1) FLXA0FRFRFM.MFID

Mask Frame ID Filter

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

17.2.8.4 FLXA0FRFCL — FlexRay FIFO Critical Level Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $030C_H$

Value after reset: $0000\ 0080_H$

Table 17.54 FLXA0FRFCL Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are always read as 0. When writing, always write 0.
7 to 0	CL[7:0]	Critical Level Setting Critical level setting

(1) FLXA0FRFCL.CL

Critical Level Setting

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

When the receive FIFO fill level FLXA0FRFSR.RFFL is equal or greater than the critical level configured by FLXA0FRFCL.CL, the receive FIFO critical level flag FLXA0FRFSR.RFCL is set to 1.

If FLXA0FRFCL.CL is programmed to values > 128, bit FLXA0FRFSR.RFCL is never set to 1.

17.2.9 Message Buffer Status Registers

17.2.9.1 FLXA0FRMHDS — FlexRay Message Handler Status Register

Do not rewrite this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0310_H

Value after reset: $0000\ 0080_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.55 FLXA0FRMHDS Register Contents

Bit Position	Bit Name	Function
31	—	Reserved This bit is always read as 0. When writing, always write 0.
30 to 24	MBU[6:0]	Message Buffer Updated Flags
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	MBT[6:0]	Message Buffer Transmitted Flags
15	—	Reserved This bit is always read as 0. When writing, always write 0.
14 to 8	FMB[6:0]	Faulty Message Buffer Number Flags
7	CRAM	Internal RAM Clear Flag 0: No execution of the CHI command CLEAR_RAMS 1: Execution of the CHI command CLEAR_RAMS ongoing
6	MFMB	Multiple Faulty Message Buffer Detection Flag 0: No additional faulty message buffer 1: Additional faulty message buffer was detected while the FMBD flag is set to 1.
5	FMBD	Faulty Message Buffer Detection Flag 0: No faulty message buffer 1: Message buffer referenced by FLXA0FRMHDS.FMB holds faulty data with a parity error.
4	ATBF2	Temporary Buffer RAM B Access Error Flag 0: No access error 1: Access error occurred when reading the RAM B.
3	ATBF1	Temporary Buffer RAM A Access Error Flag 0: No access error 1: Access error occurred when reading the RAM A.
2	AMR	Message RAM Access Error Flag 0: No access error 1: Access error occurred when reading the message RAM.
1, 0	—	Reserved These bits are always read as 0. When writing, always write 0

(1) FLXA0FRMHDS.MBU

Message Buffer Updated Flags

These flags indicate the number of message buffer that was updated last by the CC. For this message buffer the respective ND and/or MBC flag in the FLXA0FRNDAT1/2/3/4 registers and the FLXA0FRMBSC1/2/3/4 registers are also set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) FLXA0FRMHDS.MBT

Message Buffer Transmitted Flags

These flags indicate the number of last successfully transmitted message buffer.

If the message buffer is configured for single-shot mode, the respective TXR flag in the FLXA0FRTXRQ1/2/3/4 registers are reset to ‘0’.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) FLXA0FRMHDS.FMB

Faulty Message Buffer Number Flags

These flags indicate that an access error occurred when reading from the message buffer referenced by FLXA0FRMHDS.FMB.

The value of this flag is only valid whenever one of AMR flag, ATBF1 flag, ATBF2 flag, or FMBD flag in the FLXA0FRMHDS register is set to 1.

This flag is not updated while the FLXA0FRMHDS.FMBD flag is 1.

This flag is cleared by the CHI command CLEAR_RAMS.

(4) FLXA0FRMHDS.CRAM

Internal RAM Clear Flag

This flag indicates that the CHI command CLEAR_RAMS is ongoing (all bits of the message RAM, input buffer, output buffer and temporary buffer RAM are written to ‘0’).

This flag is set by the CHI command CLEAR_RAMS.

(5) FLXA0FRMHDS.MFMB

Multiple Faulty Message Buffer Detection Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing ‘1’ to it.

This bit indicates that an additional faulty message buffer was detected while the FMBD flag is set.

This bit is cleared by the CHI command CLEAR_RAMS.

(6) FLXA0FRMHDS.FMBD

Faulty Message Buffer Detection Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing ‘1’ to it.

This bit indicates that the message buffer referenced by FLXA0FRMHDS.FMB holds faulty data due to an access error.

This bit is cleared by the CHI command CLEAR_RAMS.

(7) FLXA0FRMHDS.ATBF2

Temporary Buffer RAM B Access Error Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing ‘1’ to it.

This flag indicates that an access error occurred when reading the temporary buffer RAM B.

NOTE

When this flag changes from ‘0’ to ‘1’, the AERR bit in the FLXA0FREIR register is set to ‘1’. This flag can be reset by the CHI command CLEAR_RAMS.

(8) FLXA0FRMHDS.ATBF1

Temporary Buffer RAM A Access Error Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing ‘1’ to it.

This flag indicates that an access error occurred when reading the temporary buffer RAM A.

NOTE

When this flag changes from ‘0’ to ‘1’, the AERR bit in the FLXA0FREIR register is set to ‘1’. This flag can be reset by the CHI command CLEAR_RAMS.

(9) FLXA0FRMHDS.AMR

Message RAM Access Error Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing ‘1’ to it.

This flag indicates that an access error occurred when reading the message RAM.

NOTE

When this flag changes from ‘0’ to ‘1’, the AERR bit in the FLXA0FREIR register is set to ‘1’. This flag can be reset by the CHI command CLEAR_RAMS.

17.2.9.2 FLXA0FRLDTS — FlexRay Last Dynamic Transmit Slot Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0314_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	LDTB[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.56 FLXA0FRLDTS Register Contents

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26 to 16	LDTB[10:0]	Last Dynamic Transmission Channel B Flags
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	LDTA[10:0]	Last Dynamic Transmission Channel A Flags

(1) FLXA0FRLDTS.LDTB

Last Dynamic Transmission Channel B Flags

Store the value of vSlotCounter at the time of the last frame transmission on channel B in the dynamic segment.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) FLXA0FRLDTS.LDTA

Last Dynamic Transmission Channel A Flags

Store the value of vSlotCounter at the time of the last frame transmission on channel A in the dynamic segment.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

17.2.9.3 FLXA0FRFSR — FlexRay FIFO Status Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0318_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFFL[7:0]								—	—	—	—	—	RFO	RFCL	RFNE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.57 FLXA0FRFSR Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. When writing, always write 0.
15 to 8	RFFL[7:0]	Receive FIFO Fill Level Flags
7 to 3	—	Reserved These bits are always read as 0. When writing, always write 0.
2	RFO	Receive FIFO Overrun Flag 0: No receive FIFO overrun is detected 1: A receive FIFO overrun has been detected
1	RFCL	Receive FIFO Critical Level Flag 0: Receive FIFO is below critical level 1: Receive FIFO critical level is reached
0	RFNE	Receive FIFO Not Empty Flag 0: Receive FIFO is empty 1: Receive FIFO is not empty

(1) FLXA0FRFSR.RFFL

Receive FIFO Fill Level Flags

Indicate the number of FIFO buffers filled with new data not yet read by the host. Maximum value is 128.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) FLXA0FRFSR.RFO

Receive FIFO Overrun Flag

The flag is set to ‘1’ by the CC when a receive FIFO overrun is detected.

When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, interrupt flag FLXA0FREIR.RFO is set to ‘1’.

The flag is cleared when the FIFO is read.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) FLXA0FRFSR.RFCL

Receive FIFO Critical Level Flag

This flag is set to ‘1’ when the receive FIFO fill level FLXA0FRFSR.RFFL is equal or greater than the critical level as configured by FLXA0FRFCL.CL.

When FLXA0FRFSR.RFCL changes from ‘0’ to ‘1’ bit FLXA0FRSIR.RFCL is set to ‘1’, and if enabled, an interrupt is generated.

The flag is cleared by the CC as soon as FLXA0FRFSR.RFFL drops below FLXA0FRFCL.CL.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(4) FLXA0FRFSR.RFNE

Receive FIFO Not Empty Flag

This flag is set to ‘1’ by the CC when a received valid frame (data or null frame depending on rejection mask) was stored in the FIFO. In addition, interrupt flag FLXA0FRSIR.RFNE is set to ‘1’.

The bit is reset to ‘0’ after the host has read all messages from the FIFO.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

17.2.9.4 FLXA0FRMHDF — FlexRay Message Handler Constraints Flags Register

Do not rewrite this register using bit-manipulation instruction.

Some constraints exist for the message handler regarding bus clock frequency, message RAM configuration, and FlexRay bus traffic. To simplify software development, constraints violations are reported by setting flags in the FLXA0FRMHDF.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $031C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.58 FLXA0FRMHDF Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved These bits are always read as 0. When writing, always write 0.
8	WAHP	Write Attempt to Header Partition Flag 0: No write attempt to header partition 1: A write attempt to header partition
7	TNSB	Transmission Not Started Channel B Flag 0: No transmission not started on channel B 1: Transmission not started on channel B
6	TNSA	Transmission Not Started Channel A Flag 0: No transmission not started on channel A 1: Transmission not started on channel A
5	TBFB	Temporary Buffer Access Failure B Flag 0: No TBF B access failure 1: TBF B access failure
4	TBFA	Temporary Buffer Access Failure A Flag 0: No TBF A access failure 1: TBF A access failure
3	FNFB	Find Sequence Not Finished Channel B Flag 0: No find sequence not finished for channel B 1: Find sequence not finished for channel B
2	FNFA	Find Sequence Not Finished Channel A Flag 0: No find sequence not finished for channel A 1: Find sequence not finished for channel A
1	SNUB	Status Not Updated Channel B Flag 0: No overload condition occurred when updating MBS for channel B 1: Message buffer status (FLXA0FRMBS) for channel B not updated
0	SNUA	Status Not Updated Channel A Flag 0: No overload condition occurred when updating MBS for channel A 1: Message buffer status (FLXA0FRMBS) for channel A not updated

(1) FLXA0FRMHDF.WAHP

Write Attempt to Header Partition Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

Outside DEFAULT_CONFIG and CONFIG state this flag is set to ‘1’ when the message handler tries to write message data into the header partition of the message RAM due to faulty configuration of a message buffer. The write attempt is not executed, to protect the header partition from unintended write accesses.

When this flag changes from ‘0’ to ‘1’ in addition interrupt flag FLXA0FREIR.MHF is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) FLXA0FRMHDF.TNSB Flag

Transmission Not Started Channel B

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to ‘1’ when the message handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.MHF is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) FLXA0FRMHDF.TNSA

Transmission Not Started Channel A Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set when the message handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.MHF is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(4) FLXA0FRMHDF.TBFB

Temporary Buffer Access Failure B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to ‘1’ when a read or write access to TBF B requested by PRT (protocol controller) B could not complete within the specified time.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.MHF is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(5) FLXA0FRMHDF.TBFA

Temporary Buffer Access Failure A Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to ‘1’ by the CC when a read or write access to TBF A requested by PRT A could not complete within the specified time.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.MHF is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(6) FLXA0FRMHDF.FNFB

Find Sequence Not Finished Channel B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to ‘1’ when the message handler, due to overload condition, was not able to finish a find sequence (scan of message RAM for matching message buffer).

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.MHF is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(7) FLXA0FRMHDF.FNFA

Find Sequence Not Finished Channel A Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to ‘1’ when the message handler, due to overload condition, was not able to finish a find sequence (scan of message RAM for matching message buffer).

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.MHF is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(8) FLXA0FRMHDF.SNUB

Status Not Updated Channel B Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to ‘1’ when the message handler, due to overload condition, was not able to update a message buffer's status MBS.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.MHF is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(9) FLXA0FRMHDF.SNUA

Status Not Updated Channel A Flag

Writing ‘0’ has no effect on the bit value.

This bit is cleared when writing a ‘1’ to it.

This flag is set to ‘1’ when the message handler, due to overload condition, was not able to update a message buffer's status MBS.

When this flag changes from ‘0’ to ‘1’, interrupt flag FLXA0FREIR.MHF is set to ‘1’.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

17.2.9.5 FLXA0FRTXRQi — FlexRay Transmission Request i (i = 1 to 4)

The four registers reflect the state of the TXR flags of all configured message buffers. The flags are evaluated for transmit buffers only. If the number of configured message buffers is less than 128, the remaining TXR flags have no meaning.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0320_H to ERAY to $032C_H$ (ERAY + 0320_H + (i-1)*4)

Value after reset: $0000\ 0000_H$

Table 17.59 FLXA0FRTXRQi Register Contents

Bit Position	Bit Name	Function
31 to 0	TXRo	Transmission Request Flag o

(1) FLXA0FRTXRQi.TXRo (o = (i-1)*32 to (i*32-1))

Transmission Request Flag o

If the flag is set to ‘1’, the respective message buffer is ready for transmission or transmission of this message buffer is in progress.

In single-shot mode the flags are reset to ‘0’ after transmission has completed.

This bit is cleared by the CHI command CLEAR_RAMS.

17.2.9.6 FLXA0FRNDATi — FlexRay New Data Register i (i = 1 to 4)

The four registers reflect the state of the ND flags of all configured message buffers. ND flags belonging to transmit buffers have no meaning. If the number of configured message buffers is less than 128, the remaining ND flags have no meaning.

Access: This register can be read only in 8-, 16-, or 32-bit units.

Address: ERAY + 0330_H to ERAY + $033C_H$ (ERAY + 0330_H + (i-1)*4)

Table 17.60 FLXA0FRNDATi Register Contents

Bit Position	Bit Name	Function
31 to 0	NDn	New Data Flag n

(1) FLXA0FRNDATi.NDn (n = (i-1)*32 to (i*32-1))

New Data Flag n

The flags are set to ‘1’ when a valid received data frame matches the message buffer’s filter configuration, independent of the payload length received or the payload length configured for that message buffer.

The flags are not set to ‘1’ after reception of null frames except for message buffers belonging to the receive FIFO.

An ND flag is reset to ‘0’ when the header section of the corresponding message buffer is reconfigured or when the data section has been transferred to the output buffer.

Reset when leaving CONFIG state or when entering STARTUP state.

This bit is cleared by the CHI command CLEAR_RAMS.

17.2.9.7 FLXA0FRMBSCi — FlexRay Message Buffer Status Changed Register i (i = 1 to 4)

The four registers reflect the state of the MBC flags of all configured message buffers. If the number of configured message buffers is less than 128, the remaining MBC flags have no meaning.

Access: This register can be read only in 8-, 16-, or 32-bit units.

Address: ERAY + 0340_H to ERAY + $034C_H$ (ERAY + 0340_H + (i-1)*4)

Value after reset: $0000\ 0000_H$

Table 17.61 FLXA0FRMBSCi (i = 1 to 4) Register Contents

Bit Position	Bit Name	Function
31 to 0	MBCm	Message Buffer Status Changed Flag m

(1) FLXA0FRMBSCi.MBCm (m = (i-1)*32 to (i*32-1))

Message Buffer Status Changed Flag m

Indicates whether the message handler has changed one of the status flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB in the header section (see **Section 17.2.11.5, FLXA0FRMBS — FlexRay Message Buffer Status Register** and **Section 17.3.13.1, Header Partition** of the respective message buffer.

An MBC flag is reset to '0' when the header section of the corresponding message buffer is reconfigured or when it has been transferred to the output buffer.

Reset when leaving CONFIG state or when entering STARTUP state.

This bit is cleared by the CHI command CLEAR_RAMS.

17.2.10 Input Buffer

The input buffer (IBF) has a double structure of IBF host and IBF shadow. While the host can write to IBF host, the transfer to the message RAM is done from IBF shadow. The input buffer holds the header and data sections to be transferred to the selected message buffer in the message RAM. It is used to configure the message buffers in the message RAM and to update the data sections of transmit buffers.

When updating the header section of a message buffer in the message RAM from the input buffer, the message buffer status as described in **Section 17.2.11.5, FLXA0FRMBS — FlexRay Message Buffer Status Register** is automatically reset to 0.

The header sections of message buffers belonging to the receive FIFO can only be configured or reconfigured when the CC is in DEFAULT_CONFIG or CONFIG state. For those message buffers, only the payload length and the data pointer can be configured via FLXA0FRWRHS2.PLC and FLXA0FRWRHS3.DP. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask registers.

The data transfer between input buffer (IBF) and message RAM is described in detail in **Section 17.3.12.2, Host Access to Message RAM**.

These registers cannot be written when the input data transfer function shown in **Section 17.3.16.1, Input Data Transfer** is used and the FLXA0FRITS.ITS bit is 1.

17.2.10.1 FLXA0FRWRDSn — FlexRay Write Data Section Register n (n = 1 to 64)

This register holds the data words to be transferred to the data section of the specified message buffer. The number of data words (DWn) written to the message RAM is defined by the payload length configured in the FLXA0FRWRHS2.PLC bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0400_H to ERAY + $04FC_H$(ERAY + 0400_H + (n-1)*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.62 FLXA0FRWRDSn Register Contents

Bit Position	Bit Name	Function
31 to 0	MD[31:0]	Message Data

(1) FLXA0FRWRDSn.MD

Message Data Bits

For information about the byte alignment of the message data in this register see **Section 17.3.17, Byte Alignment**.

NOTE

1. **In case FLXA0FRWRHS2.PLC specifies an odd payload length, the remaining message data bytes are unused.**
2. **When writing to FLXA0FRWRDSn, each 32-bit word has to be filled up by access in a single 32- bit unit, in two consecutive 16-bit units, or in four consecutive 8-bit units before transfer from the input buffer to the message RAM will start. If not all bytes of a 32- bit word have been written by the host (8- or 16-bit access only), FLXA0FRWRDSn holds partly undefined data.**
   Reset by the CHI command CLEAR_RAMS.

17.2.10.2 FLXA0FRWRHS1 — FlexRay Write Header Section Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0500_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.63 FLXA0FRWRHS1 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29	MBI	Message Buffer Interrupt 0: The corresponding message buffer interrupt is disabled 1: The corresponding message buffer interrupt is enabled
28	TXM	Transmission Mode 0: Continuous mode 1: Single-shot mode
27	PPIT	Payload Preamble Indicator Transmit 0: Payload Preamble Indicator is set to ‘0’ 1: Payload Preamble Indicator is set to ‘1’
26	CFG	Message Buffer Direction Configuration 0: The corresponding buffer is configured as receive buffer 1: The corresponding buffer is configured as transmit buffer
25,24	CH[1:0]	Channel Filter Control
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	CYC[6:0]	Cycle Code
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	FID[10:0]	Frame ID

(1) FLXA0FRWRHS1.MBI

Message Buffer Interrupt Enable

This bit enables the receive/transmit interrupt for the corresponding message buffer.

After a dedicated receive buffer has been updated by the message handler, flag FLXA0FRSIR.RXI and/or FLXA0FRSIR.MBSI are set to '1'. After a transmission has completed, flag FLXA0FRSIR.TXI is set to '1'.

(2) FLXA0FRWRHS1.TXM

Transmission Mode Setting

This bit selects transmit mode of the corresponding message buffer. For transmit mode, see **Section 17.3.9.3, Transmit Buffers**.

(3) FLXA0FRWRHS1.PPIT

Payload Preamble Indicator Transmit

This bit is used to control the state of the Payload Preamble Indicator in transmit frames in transmit frames of the corresponding message buffer.

If the bit is set to '1' in a static message buffer, the respective message buffer holds network management information.

If the bit is set to '1' in a dynamic message buffer, the first two bytes of the payload segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay frames is not supported by the FlexRay module, but can be done by the host.

(4) FLXA0FRWRHS1.CFG

Message Buffer Direction Configuration

This bit is used to configure the corresponding buffer as transmit buffer or as receive buffer. For message buffers belonging to the receive FIFO the bit is disabled.

If an unused area of at least 32 bits is not allocated at the start of the data partition, set this bit to 1 to select allocation of the data section of the message buffer as a transmission buffer immediately following (after the last buffer of) the header partition.

(5) FLXA0FRWRHS1.CH

Channel Filter Control

The 2-bit channel filtering field associated with each buffer serves as a filter for receive buffers, and as a control field for transmit buffers.

CH[1:0]	Transmit Buffer transmit frame on	Receive Buffer store frame received from
00	Transmission prohibited	ignore frame
01	channel A	channel A
10	channel B	channel B
11	both channels (static segment only)	channel A or B (store first semantically valid frame; static segment only)

NOTE

If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to '1', no transmission nor reception of frames is performed. (same function as CH = "00")

(6) FLXA0FRWRHS1.CYC

Cycle Code

The 7-bit cycle code determines the cycle set used for cycle counter filtering.

For details about the configuration of the cycle code **Section 17.3.8.2, Cycle Counter Filtering**.

(7) FLXA0FRWRHS1.FID

Frame ID

Frame ID of the selected message buffer. The frame ID defines the slot number for transmission/ reception of the respective message.

Message buffers with frame ID = ‘0’ are considered as invalid.

17.2.10.3 FLXA0FRWRHS2 — FlexRay Write Header Section Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0504_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	PLC[6:0]

Table 17.64 FLXA0FRWRHS2 Register Contents

Bit Position	Bit Name	Function
31 to 23	—	Reserved These bits are always read as 0. When writing, always write 0.
22 to 16	PLC[6:0]	Payload Length Configured
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	CRC[10:0]	Header CRC (vRF!Header!HeaderCRC) Receive Buffer: Configuration is not required Transmit Buffer: Header CRC is configured

(1) FLXA0FRWRHS2.PLC

Payload Length Configured

Length of data section (number of 2-byte words) as configured by the host.

During static segment the static frame payload length as configured by FLXA0FRMHDC.SFDL defines the payload length for all static frames. If the payload length configured by FLXA0FRWRHS2.PLC is shorter than this value padding bytes are inserted to ensure that frames have proper physical length. The padding pattern is "0000_H" (see **Section 17.3.9.3, Transmit Buffers**).

(2) FLXA0FRWRHS2.CRC

Header CRC (vRF!Header!HeaderCRC)

Setting of the receive buffer is not required.

Transmitting of the message buffer needs the header CRC calculation and setting.

For calculation of the header CRC, the payload length of the frame to be sent has to be considered. In static segment the payload length of all frames is configured by FLXA0FRMHDC.SFDL.

17.2.10.4 FLXA0FRWRHS3 — FlexRay Write Header Section Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0508_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	DP[10:0]	Data Pointer

(1) FLXA0FRWRHS3.DP

Data Pointer

Configures the pointer to the first 32-bit word of the data section of the addressed message buffer in the message RAM.

17.2.10.5 FLXA0FRIBCM — FlexRay Input Buffer Command Mask Register

Configures how the message buffer in the message RAM selected by register FLXA0FRIBCR is updated. When IBF host and IBF shadow are swapped, also mask bits FLXA0FRIBCM.LHSH, FLXA0FRIBCM.LDSH, and FLXA0FRIBCM.STXRH are swapped with bits FLXA0FRIBCM.LHSS, FLXA0FRIBCM.LDSS, and FLXA0FRIBCM.STXRS.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0510_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	STXRS	LDSS	LHSS

Table 17.66 FLXA0FRIBCM Register Contents

Bit Position	Bit Name	Function
31 to 19	—	Reserved These bits are always read as 0. When writing, always write 0.
18	STXRS	Transmission Request Shadow Set Flag 0: Reset TXR flag 1: Set TXR flag, transmit buffer released for transmission (operation ongoing or finished)
17	LDSS	Data Section Shadow Load Flag 0: Data section is not updated 1: Data section is transferred (transfer ongoing or finished)
16	LHSS	Header Section Shadow Load Flag 0: Header section is not updated 1: Header is transferred (transfer ongoing or finished)
15 to 3	—	Reserved These bits are always read as 0. When writing, always write 0.
2	STXRH	Transmission Request Host Set Flag 0: Reset TXR flag 1: Set TXR flag, transmit buffer released for transmission
1	LDSH	Data Section Host Load Flag 0: Data section is not updated 1: Data section is transferred
0	LHSH	Header Section Host Load Flag 0: Header section is not updated 1: Header is transferred

(1) FLXA0FRIBCM.STXRS

Transmission Request Shadow Set Flag

(2) FLXA0FRIBCM.LDSS

Data Section Shadow Load Flag

(3) FLXA0FRIBCM.LHSS

Header Section Shadow Load Flag

(4) FLXA0FRIBCM.STXRH

Transmission Request Host Set Flag

If this bit is set to '1', the TXR flag for the selected message buffer is set in the FLXA0FRTXRQ1/2/3/4 registers to release the message buffer for transmission. In single-shot mode the flag is cleared after transmission has completed.

TXR is enabled for transmit buffers only.

(5) FLXA0FRIBCM.LDSH

Data Section Host Load Flag

(6) FLXA0FRIBCM.LHSH

Header Section Host Load Flag

17.2.10.6 FLXA0FRIBCR — FlexRay Input Buffer Command Request Register

When the host writes the number of the target message buffer in the message RAM to FLXA0FRIBCR.IBRH,

IBF host and IBF shadow are switched. In addition the message buffer numbers stored under FLXA0FRIBCR.IBRH and FLXA0FRIBCR.IBRS are also switched (see **Section 17.3.12.2 (1), Data Transfer from Input Buffer to Message RAM**).

With this write operation, the FLXA0FRIBCR.IBSYS is set to '1'. The message handler then starts to transfer the contents of IBF shadow to the message buffer in the message RAM selected by FLXA0FRIBCR.IBRS.

After the transfer between IBF shadow and the message RAM has completed, FLXA0FRIBCR.IBSYS is set back to '0' and the next transfer to the message RAM may be started by the host by writing the respective target message buffer number to FLXA0FRIBCR.IBRH.

If a write access to FLXA0FRIBCR.IBRH occurs while FLXA0FRIBCR.IBSYS is '1', FLXA0FRIBCR.IBSYH is set to '1'. After completion of the ongoing data transfer from IBF Shadow to the message RAM, IBF host and IBF shadow are switched, FLXA0FRIBCR.IBSYH is reset to '0'. FLXA0FRIBCR.IBSYS remains set to '1', and the next transfer to the message RAM is started. In addition the message buffer numbers stored under FLXA0FRIBCR.IBRH and FLXA0FRIBCR.IBRS are also switched.

Any write access to an input buffer register while both FLXA0FRIBCR.IBSYS and FLXA0FRIBCR.IBSYH are set to '1' will cause the error flag FLXA0FREIR.IIBA to be set to '1'. In this case, this write access has no effect and the input buffer will not be changed.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0514_H

Value after reset: $0000\ 0000_H$

Table 17.67 FLXA0FRIBCR Register Contents (1/2)

Bit Position	Bit Name	Function
31	IBSYS	Input Buffer Busy Shadow Flag 0: Transfer between IBF shadow and message RAM completed 1: Transfer between IBF shadow and message RAM in progress
30 to 23	—	Reserved These bits are always read as 0. When writing, always write 0.
22 to 16	IBRS[6:0]	Input Buffer Request ShadowFlags
15	IBSYH	Input Buffer Busy Host Flag 0: No request pending 1: Request while transfer between IBF shadow and message RAM in progress

Table 17.67 FLXA0FRIBCR Register Contents (2/2)

Bit Position	Bit Name	Function
14 to 7	—	Reserved These bits are always read as 0. When writing, always write 0.
6 to 0	IBRH[6:0]	Input Buffer Request Host

(1) FLXA0FRIBCR.IBSYS

Input Buffer Busy Shadow Flag

Set to ‘1’ after writing FLXA0FRIBCR.IBRH.

This bit indicates transmitting between the IBF shadow and the message RAM is ongoing.

When the transfer between IBF shadow and the message RAM has completed, FLXA0FRIBCR.IBSYS is set back to ‘0’.

(2) FLXA0FRIBCR.IBRS

Input Buffer Request Shadow Flags

Number of the target message buffer actually updated or lately updated.

(3) FLXA0FRIBCR.IBSYH

Input Buffer Busy Host Flag

Set to ‘1’ by writing FLXA0FRIBCR.IBRH while FLXA0FRIBCR.IBSYS is still ‘1’.

This bit indicates transmitting between the IBF shadow and the message RAM is ongoing.

After the ongoing transfer between IBF shadow and the message RAM has completed, the FLXA0FRIBCR.IBSYH is set back to ‘0’.

(4) FLXA0FRIBCR.IBRH

Input Buffer Request Host

Selects the target message buffer in the message RAM for data transfer from input buffer.

17.2.11 Output Buffer

The output buffer has a double structure of output buffer host and output buffer shadow and is used to read out message buffers from the message RAM. While the host can read from OBF host, the message handler transfers the selected message buffer from message RAM to output buffer shadow. The data transfer between message RAM and OBF is described in **Section 17.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

These registers cannot be written when the output data transfer function shown in **Section 17.3.16.2, Output Data Transfer**, in output data transfer is used and the FLXA0FROTS.OTS bit is 1.

17.2.11.1 FLXA0FRRDDSn — FlexRay Read Data Section Register n (n = 1 to 64)

These registers hold the data words read from the data section of the specified message buffer. The number of data word read from the message RAM is defined by the payload length configured in the FLXA0FRRDHS2.PLC bit.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0600_H to ERAY + $06FC_H$ (ERAY + 0600_H + (n-1)*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.68 FLXA0FRRDDSn Register Contents

Bit Position	Bit Name	Function
31 to 0	MD[31:0]	Message Data Flags

(1) FLXA0FRRDDSn.MD

Message Data Flags

For information about the byte alignment of the data words in this register, see **Section 17.3.17, Byte Alignment**.

NOTE

In case FLXA0FRWRHS2.PLC specifies an odd payload length, the remaining message data bytes are unused.

Reset by the CHI command CLEAR_RAMS.

17.2.11.2 FLXA0FRRDHS1 — FlexRay Read Header Section Register 1

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0700_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.69 FLXA0FRRDHS1 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29	MBI	Message Buffer Interrupt Enable Flag
28	TXM	Transmission Mode Flag
27	PPIT	Payload Preamble Indicator Transmit Flag
26	CFG	Message Buffer Direction Configuration Bit Flag
25, 24	CH[1:0]	Channel Filter Control Flag
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	CYC[6:0]	Cycle Code
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	FID[10:0]	Frame ID

(1) FLXA0FRRDHS1.MBI

Message Buffer Interrupt Enable Flag

Values as configured by the host via FLXA0FRWRHS1.MBI.

In case that the message buffer read from the message RAM belongs to the receive FIFO, this bit is set to ‘0’.

(2) FLXA0FRRDHS1.TXM

Transmission Mode Flag

Values as configured by the host via FLXA0FRWRHS1.TXM.

In case that the message buffer read from the message RAM belongs to the receive FIFO, this bit is set to ‘0’.

(3) FLXA0FRRDHS1.PPIT

Payload Preamble Indicator Transmit Flag

Values as configured by the host via FLXA0FRWRHS1.PPIT.

In case that the message buffer read from the message RAM belongs to the receive FIFO, this bit is set to ‘0’.

(4) FLXA0FRRDHS1.CFG

Message Buffer Direction Configuration Flag

Values as configured by the host via FLXA0FRWRHS1.CFG.

In case that the message buffer read from the message RAM belongs to the receive FIFO, this bit is set to ‘0’.

(5) FLXA0FRRDHS1.CH

Channel Filter Control Flag

Values as configured by the host via FLXA0FRWRHS1.CH.

In case that the message buffer read from the message RAM belongs to the receive FIFO, these bits are set to ‘0’.

(6) FLXA0FRRDHS1.CYC

Cycle Code

Values as configured by the host via FLXA0FRWRHS1.CYC.

In case that the message buffer read from the message RAM belongs to the receive FIFO, these bits are set to ‘0’.

(7) FLXA0FRRDHS1.FID

Frame ID

Values as configured by the host via FLXA0FRWRHS1.FID

In case that the message buffer read from the message RAM belongs to the receive FIFO, these bits are holding the received frame ID.

17.2.11.3 FLXA0FRRDHS2 — FlexRay Read Header Section Register 2

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0704_H

Value after reset: $0000\ 0000_H$

CAUTION

For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area FLXA0FRWRHS2 is updated from data frames only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	PLR[6:0]							—	PLC[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	CRC[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.70 FLXA0FRRDHS2 Register Contents

Bit Position	Bit Name	Function
31	—	Reserved This bit is always read as 0. When writing, always write 0.
30 to 24	PLR[6:0]	Receive Frame Payload Length Flags (vRF!Header!Length)
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	PLC[6:0]	Configured Payload Length Flags
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	CRC[10:0]	Header CRC Flags (vRF!Header!HeaderCRC)

(1) FLXA0FRRDHS2.PLR

Receive Frame Payload Length Flags (vRF!Header!Length)

Payload length (vRF!Header!Length) value updated from received data frames (exception: To be updated even through null frames are received in the message buffer specified to the receive FIFO).

(2) FLXA0FRRDHS2.PLC

Configured Payload Length Flags

Length of data section (number of 2-byte words) as configured by the host.

(3) FLXA0FRRDHS2.CRC

Header CRC Flags (vRF!Header!HeaderCRC)

Receive Buffer: Header CRC (vRF!Header!HeaderCRC) updated from received data frames

Transmit Buffer: Header CRC configured by the host

(4) Data storage

When a message is stored into a message buffer the following processes with respect to payload length received and payload length configured are implemented:

FLXA0FRRDHS2.PLR > FLXA0FRRDHS2.PLC:

The payload data stored in the message buffer is truncated to the payload length configured if FLXA0FRRDHS2.PLC even or else truncated to FLXA0FRRDHS2.PLC + 1.

FLXA0FRRDHS2.PLR <= FLXA0FRRDHS2.PLC:

The received payload data is stored into the message buffers data section. The remaining data bytes of the data section as configured by FLXA0FRRDHS2.PLC are filled with undefined value.

FLXA0FRRDHS2.PLR = zero:

The message buffer's data section is filled with undefined value.

FLXA0FRRDHS2.PLC = zero:

No data section is configured in the message buffer. No data is stored into the message buffer's data section.

NOTE

1. **The message RAM is organized in 4-byte words. When received data is stored into a message buffer's data section, the number of 2-byte data words written into the message buffer is FLXA0FRRDHS2.PLC rounded to the next even value.**
2. **FLXA0FRRDHS2.PLC should be configured identical for all message buffers belonging to the receive FIFO.**
   For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area FLXA0FRWRHS2 is updated from data frames only.

17.2.11.4 FLXA0FRRDHS3 — FlexRay Read Header Section Register 3

NOTE

For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area FLXA0FRWRHS3 is updated from data frames only.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0708_H

Value after reset: $0000\ 0000_H$

Table 17.71 FLXA0FRRDHS3 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29	RES	Reserved Bit Indicator Flag (vRF!Header!Reserved)
28	PPI	Payload Preamble Indicator Flag (vRF!Header!PPIndicator)
27	NFI	Null Frame Indicator Flag (vRF!Header!NFIndicator) 0 = Up to now no data frame has been stored into the respective message buffer 1 = At least one data frame has been stored into the respective message buffer
26	SYN	Sync Frame Indicator Flag (vRF!Header!SyFIndicator) 0: The received frame is not a sync frame 1: The received frame is a sync frame
25	SFI	Startup Frame Indicator Flag (vRF!Header!SuFIndicator) 0: The received frame is not a startup frame 1: The received frame is a startup frame
24	RCI	Received on Channel Indicator Flag (vSS!Channel) 0: Frame received on channel B 1: Frame received on channel A
23, 22	—	Reserved These bits are always read as 0. When writing, always write 0.
21 to 16	RCC[5:0]	Receive Cycle Count (vRF!Header!CycleCount)
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	DP[10:0]	Data Pointer Flags

(1) FLXA0FRRDHS3.RES

Reserved Bit Indicator Flag (vRF!Header!Reserved)

Reflects the value of the received reserved bit. The reserved bit is transmitted as ‘0’.

(2) FLXA0FRRDHS3.PPI

Payload Preamble Indicator Flag (vRF!Header!PPIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained in the payload segment of the received frame.

0 = The payload segment of the received frame does not contain a network management vector nor a message ID

1 = Static segment: contains network management vector is included in the first part of the payload
Dynamic segment: contains message ID is included in the first part of the payload

(3) FLXA0FRRDHS3.NFI

Null Frame Indicator Flag (vRF!Header!NFIndicator)

Is set to ‘1’ after storage of the first received data frame.

(4) FLXA0FRRDHS3.SYN

Sync Frame Indicator Flag (vRF!Header!SyFIndicator)

A sync frame is indicated by the sync frame indicator.

(5) FLXA0FRRDHS3.SFI

Startup Frame Indicator Flag (vRF!Header!SuFIndicator)

A startup frame is indicated by the startup frame indicator.

(6) FLXA0FRRDHS3.RCI

Received on Channel Indicator Flag (vSS!Channel)

Indicates the channel from which the received data frame was taken to update the respective receive buffer.

(7) FLXA0FRRDHS3.RCC

Receive Cycle Count (vRF!Header!CycleCount)

Cycle counter value updated from received data frame is read.

(8) FLXA0FRRDHS3.DP

Data Pointer Flags

This flag indicates the position of the first 32-bit word of the data section of the addressed message buffer in the message RAM.

The bit value is the same as that set in the FLXA0FRWRHS3.DP bit.

17.2.11.5 FLXA0FRMBS — FlexRay Message Buffer Status Register

The message buffer status is updated by the CC with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the message buffer.

The flags are updated only when the CC is in NORMAL_ACTIVE or NORMAL_PASSIVE state.

If only one channel (A or B) is assigned to a message buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a message buffer, the channel-specific status flags of both channels are updated.

The message buffer status is updated only when the slot counter reached the configured frame ID and when the cycle counter filter matched. When the host updates a message buffer via input buffer, all FLXA0FRMBS flags are reset to zero independent of which FLXA0FRIBCM bits are set or not.

For details about receive/transmit filtering see **Section 17.3.8, Filtering and Masking**, **Section 17.3.9, Transmit Process** and **Section 17.3.10, Receive Process**.

Whenever the message handler changes one of the flags FLXA0FRMBS.VFRA, FLXA0FRMBS.VFRB, FLXA0FRMBS.SEOA, FLXA0FRMBS.SEOB, FLXA0FRMBS.CEOA, FLXA0FRMBS.CEOB, FLXA0FRMBS.SVOA, FLXA0FRMBS.SVOB, FLXA0FRMBS.TCIA, FLXA0FRMBS.TCIB, FLXA0FRMBS.ESA, FLXA0FRMBS.ESB, FLXA0FRMBS.MLST, FLXA0FRMBS.FTA, FLXA0FRMBS.FTB the respective message buffer's MBC flag in registers FLXA0FRMBSC1/2/3/4 is set.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + $070C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29	RESS	Reserved Bit Status Flag (vRF!Header!Reserved)
28	PPIS	Payload Preamble Indicator Status Flag (vRF!Header!PPIndicator) 0: PPI indicator set to ‘0’ 1: PPI indicator set to ‘1’
27	NFIS	Null Frame Indicator Status Flag (vRF!Header!NFIndicator) 0: Received frame is a null frame 1: Received frame is not a null frame
26	SYNS	Sync Frame Indicator Status Flag (vRF!Header!SyFIndicator) 0: No sync frame received 1: The received frame is a sync frame

Table 17.72 FLXA0FRMBS Register Contents (2/2)

Bit Position	Bit Name	Function
25	SFIS	Startup Frame Indicator Status Flag (vRF!Header!SuFIndicator) 0: No startup frame received 1: The received frame is a startup frame
24	RCIS	Received Channel Indicator Status Flag (vSS!Channel) 0: Frame received on channel B 1: Frame received on channel A
23, 22	—	Reserved These bits are always read as 0. When writing, always write 0.
21 to 16	CCS[5:0]	Cycle Count Status Flags
15	FTB	Frame Transmitted on Channel B Flag 0: No data frame transmitted on channel B 1: Data frame transmitted on channel B
14	FTA	Frame Transmitted on Channel A Flag 0: No data frame transmitted on channel A 1: Data frame transmitted on channel A
13	—	Reserved This bit is always read as 0. When writing, always write 0.
12	MLST	Message Lost Flag 0: No message lost 1: Unprocessed message was overwritten
11	ESB	Empty Slot Channel B Flag 0: Bus activity detected in the assigned slot on channel B 1: No bus activity detected in the assigned slot on channel B
10	ESA	Empty Slot Channel A Flag 0: Bus activity detected in the assigned slot on channel A 1: No bus activity detected in the assigned slot on channel A
9	TCIB	Transmission Conflict Indication Channel B Flag (vSS!TxConflictB) 0: No transmission conflict occurred on channel B 1: Transmission conflict occurred on channel B
8	TCIA	Transmission Conflict Indication Channel A Flag (vSS!TxConflictA) 0: No transmission conflict occurred on channel A 1: Transmission conflict occurred on channel A
7	SVOB	Slot Boundary Violation Observed on Channel B Flag (vSS!BViolationB) 0: No slot boundary violation observed on channel B 1: Slot boundary violation observed on channel B
6	SVOA	Slot Boundary Violation Observed on Channel A Flag (vSS!BViolationA) 0: No slot boundary violation observed on channel A 1: Slot boundary violation observed on channel A
5	CEOB	Content Error Observed on Channel B Flag (vSS!ContentErrorB) 0: No content error observed on channel B 1: Content error observed on channel B
4	CEOA	Content Error Observed on Channel A Flag(vSS!ContentErrorA) 0: No content error observed on channel A 1: Content error observed on channel A
3	SEOB	Syntax Error Observed on Channel B Flag (vSS!SyntaxErrorB) 0: No syntax error observed on channel B 1: Syntax error observed on channel B
2	SEOA	Syntax Error Observed on Channel A Flag (vSS!SyntaxErrorA) 0: No syntax error observed on channel A 1: Syntax error observed on channel A
1	VFRB	Valid Frame Received on Channel B Flag (vSS!ValidFrameB) 0: No valid frame received on channel B 1: Valid frame received on channel B
0	VFRA	Valid Frame Received on Channel A Flag (vSS!ValidFrameA) 0: No valid frame received on channel A 1: Valid frame received on channel A

(1) FLXA0FRMBS.RESS

Reserved Bit Status Flag (vRF!Header!Reserved)

Reflects the state of the received reserved bit. The reserved bit is transmitted as ‘0’.

For receive buffers (FLXA0FRWRHS1.CFG = ‘0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(2) FLXA0FRMBS.PPIS

Payload Preamble Indicator Status Flag (vRF!Header!PPIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.

For receive buffers (FLXA0FRWRHS1.CFG = ‘0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

0 = PPI indicator set to ‘0’
The payload segment of the received frame does not contain a network management vector or a message ID

1 = PPI indicator set to ‘1’
Static segment: contains network management vector at the beginning of the payload
Dynamic segment: contains message ID at the beginning of the payload

(3) FLXA0FRMBS.NFIS

Null Frame Indicator Status Flag (vRF!Header!NFIndicator)

If set to ‘0’ the payload segment of the received frame contains no usable data.

For receive buffers (FLXA0FRWRHS1.CFG = ‘0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(4) FLXA0FRMBS.SYNS

Sync Frame Indicator Status Flag (vRF!Header!SyFIndicator)

A sync frame is indicated by the sync frame indicator.

For receive buffers (FLXA0FRWRHS1.CFG = ‘0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(5) FLXA0FRMBS.SFIS

Startup Frame Indicator Status Flag (vRF!Header!SuFIndicator)

The startup frame indicator specifies a startup frame.

For receive buffers (FLXA0FRWRHS1.CFG = ‘0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(6) FLXA0FRMBS.RCIS

Received Channel Indicator Status Flag (vSS!Channel)

Indicates the channel on which the frame was received.

For receive buffers (FLXA0FRWRHS1.CFG = ‘0’) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(7) FLXA0FRMBS.CCS

Cycle Count Status Flag

Actual cycle count at a status update is read.

(8) FLXA0FRMBS.FTB

Frame Transmitted on Channel B Flag

Indicates that this node has transmitted a data frame in the configured slot on channel B.

NOTE

The FlexRay protocol specification requires that FLXA0FRMBS.FTB can only be reset by the host. Therefore the Cycle Count Status FLXA0FRMBS.CCS for this bit is only valid for the cycle where the bit is set to ‘1’.

(9) FLXA0FRMBS.FTA

Frame Transmitted on Channel A Flag

Indicates that this node has transmitted a data frame in the configured slot on channel A.

NOTE

The FlexRay protocol specification requires that FLXA0FRMBS.FTA can only be reset by the host. Therefore the Cycle Count Status FLXA0FRMBS.CCS for this bit is only valid for the cycle where this bit is set to ‘1’.

(10) FLXA0FRMBS.MLST

Message Lost Flag

The flag is set in case the host did not read the message before the message buffer was updated from a received data frame.

Not affected by reception of null frames except for message buffers belonging to the receive FIFO. The flag is reset to ‘0’ by a host write to the message buffer via IBF or when a new message is stored into the message buffer after the message buffers ND flag was reset to ‘0’ by reading out the message buffer via OBF.

(11) FLXA0FRMBS.ESB

Empty Slot Channel B Flag

In an empty slot, the bus is in idle state. This means that any frame transmission is not detected. This state can be checked in static and dynamic slots.

(12) FLXA0FRMBS.ESA

Empty Slot Channel A Flag

In an empty slot, the bus is in idle state. This means that any frame transmission is not detected. This state can be checked in static and dynamic slots.

(13) FLXA0FRMBS.TCIB

Transmission Conflict Indication Channel B Flag (vSS!TxConflictB)

A transmission conflict indication is set to ‘1’ if a transmission conflict has occurred on channel B.

(14) FLXA0FRMBS.TCIA

Transmission Conflict Indication Channel A Flag (vSS!TxConflictA)

A transmission conflict indication is set if a transmission conflict has occurred on channel A.

(15) FLXA0FRMBS.SVOB

Slot Boundary Violation Observed on Channel B Flag (vSS!BViolationB)

A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B.

(16) FLXA0FRMBS.SVOA

Slot Boundary Violation Observed on Channel A Flag (vSS!BViolationA)

A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A.

(17) FLXA0FRMBS.CEOB

Content Error Observed on Channel B Flag (vSS!ContentErrorB)

A content error was observed in the assigned slot on channel B.

(18) FLXA0FRMBS.CEOA

Content Error Observed on Channel A Flag (vSS!ContentErrorA)

A content error was observed in the assigned slot on channel A.

(19) FLXA0FRMBS.SEOB

Syntax Error Observed on Channel B Flag (vSS!SyntaxErrorB)

A syntax error was observed in the assigned slot on channel B.

(20) FLXA0FRMBS.SEOA

Syntax Error Observed on Channel A Flag (vSS!SyntaxErrorA)

A syntax error was observed in the assigned slot on channel A.

(21) FLXA0FRMBS.VFRB

Valid Frame Received on Channel B Flag (vSS!ValidFrameB)

This flag is set to “1” when a valid frame was received on channel B.

(22) FLXA0FRMBS.VFRA

Valid Frame Received on Channel A Flag (vSS!ValidFrameA)

This flag is set to “1” when a valid frame was received on channel A.

17.2.11.6 FLXA0FROBCM — FlexRay Output Buffer Command Mask Register

This register configures how the output buffer is updated from the message buffer in the message RAM selected by FLXA0FROBCR.OBRS.

Mask bits FLXA0FROBCM.RDSS and FLXA0FROBCM.RHSS are copied to the register internal storage when a message RAM transfer is requested by FLXA0FROBCR.REQ.

When OBF host and OBF shadow are switched, mask bits FLXA0FROBCM.RDSH and FLXA0FROBCM.RHSH are switched with the register internal storage to keep them attached to the respective output buffer transfer.

The data transfer between output buffer and message RAM is described in detail in **Section 17.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

CAUTION

After the transfer of the header section from the message RAM to OBF shadow has completed, the message buffer status changed flag MBC of the selected message buffer in the FLXA0FRMBSC1/2/3/4 registers is cleared. After the transfer of the data section from the message RAM to OBF shadow has completed, the new data flag ND of the selected message buffer in the FLXA0FRNDAT1/2/3/4 registers is cleared.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0710_H

Value after reset: $0000\ 0000_H$

Header Section Host Read Flag

(3) FLXA0FROBCM.RDSS

Data Section Shadow Read Flag

(4) FLXA0FROBCM.RHSS

Header Section Shadow Read Flag

17.2.11.7 FLXA0FROBCR — FlexRay Output Buffer Command Request Register

After setting bit FLXA0FROBCR.REQ to '1' while FLXA0FROBCR.OBSYS is '0', FLXA0FROBCR.OBSYS is automatically set to '1', FLXA0FROBCR.OBRS is copied to the register internal storage, mask bits FLXA0FROBCM.RDSS and FLXA0FROBCM.RHSS are copied to register FLXA0FROBCM internal storage, and the transfer of the message buffer selected by FLXA0FROBCR.OBRS from the message RAM to OBF shadow is started. When the transfer between the message RAM and OBF shadow has completed, this is signaled by setting FLXA0FROBCM.OBSYS back to '0'.

By setting bit FLXA0FROBCR.VIEW to '1' while FLXA0FROBCR.OBSYS is '0', OBF host and OBF shadow are switched. Additionally mask bits FLXA0FROBCM.RDSH and FLXA0FROBCM.RHSH are switched with the register FLXA0FROBCM internal storage to keep them attached to the respective output buffer transfer. FLXA0FROBCR.OBRH signals the number of the message buffer currently accessible by the host.

If bits FLXA0FROBCR.REQ and FLXA0FROBCR.VIEW are set to '1' with the same write access while FLXA0FROBCR.OBSYS is '0', FLXA0FROBCR.OBSYS is automatically set to '1' and OBF shadow and OBF host are switched. Additionally mask bits FLXA0FROBCM.RDSH and FLXA0FROBCM.RHSH are switched with the registers internal storage to keep them attached to the respective output buffer transfer. Afterwards FLXA0FROBCR.OBRS is copied to the register internal storage, and the transfer of the selected message buffer from the message RAM to OBF shadow is started. While the transfer is ongoing the host can read the message buffer transferred by the previous transfer from OBF host. When the current transfer between message RAM and OBF shadow has completed, this is signaled by setting FLXA0FROBCR.OBSYS back to '0'.

Any write access to FLXA0FROBCR[15:8] while FLXA0FROBCR.OBSYS is set to '1' will cause the error flag FLXA0FREIR.IOBA to be set to '1'. In this case, this write access has no effect and the output buffer will not be changed.

The data transfer between output buffer and message RAM is described in detail in **Section 17.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0714_H

Value after reset: $0000\ 0000_H$

Table 17.74 FLXA0FROBCR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 23	—	Reserved Flags These bits are always read as 0. When writing, always write 0.
22 to 16	OBRH[6:0]	Output Buffer Request Host

Table 17.74 FLXA0FROBCR Register Contents (2/2)

Bit Position	Bit Name	Function
15	OBSYS	Output Buffer Busy Shadow Flag 0: No transfer in progress 1: Transfer between message RAM and OBF shadow in progress
14 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9	REQ	Request Message RAM Transfer 0: No request 1: Transfer to OBF shadow requested
8	VIEW	View Shadow Buffer 0: No action 1: Switch OBF shadow and OBF host
7	—	Reserved This bit is always read as 0. When writing, always write 0.
6 to 0	OBRS[6:0]	Output Buffer Request Shadow

(1) FLXA0FROBCR.OBRH

Output Buffer Request Host Flags

Indicate number of message buffer currently accessible by the host via FLXA0FRRDHS[1...3], FLXA0FRMBS, and FLXA0FRRDDS[1...64].

By writing FLXA0FROBCR.VIEW to ‘1’, OBF host is switched and the transferred message buffer is accessible by the host.

(2) FLXA0FROBCR.OBSYS

Output Buffer Busy Shadow Flag

Sets to ‘1’ after setting bit FLXA0FROBCR.REQ. When the transfer between the message RAM and OBF shadow has completed, FLXA0FROBCR.OBSYS is set back to ‘0’.

(3) FLXA0FROBCR.REQ

Request Message RAM Transfer

Only writeable while FLXA0FROBCR.OBSYS = ‘0’.

Requests transfer of message buffer addressed by FLXA0FROBCR.OBRS from message RAM to OBF shadow.

(4) FLXA0FROBCR.VIEW

View Shadow Buffer

Only writeable while FLXA0FROBCR.OBSYS = ‘0’.

Toggles between OBF shadow and OBF host.

(5) FLXA0FROBCR.OBRS

Output Buffer Request Shadow

Only writeable while FLXA0FROBCR.OBSYS = ‘0’.

Indicate number of source message buffer to be transferred from the message RAM to OBF shadow.

If the number of the first message buffer of the receive FIFO is written to this register, the message buffer addressed by the GET Index (GIDX, see **Section 17.3.11, FIFO Function**) is transferred to OBF shadow.

17.2.12 Data Transfer Control Register

17.2.12.1 FLXA0FRITC — FlexRay Input Transfer Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0800_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.75 FLXA0FRITC Register Contents

Bit Position	Bit Name	Function
31 to 23	—	Reserved These bits are always read as 0. When writing, always write 0.
22 to 16	ITM[6:0]	Input Queue Table Max These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue.
15 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9	IQEIE	Input Queue Empty Interrupt Enable 0: Disabled 1: Enabled
8	IQFIE	Input Queue Full Interrupt Enable 0: Disabled 1: Enabled
7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	IQHR	Input Queue Halt Request 0: Input queue run request 1: Input queue halt request
0	ITE	Input Transfer Enable 0: Operation Disable request 1: Operation Enable request

(1) FLXA0FRITC.ITM

Input Queue Table Max

The user can only write to this bit when FLXA0FRITS.ITS is ‘0’.

These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue.

Valid values are 00_H (1 queue entry) to $7F_H$ (128 queue entries).

Note that each entry requires two long words in the input pointer table.

(2) FLXA0FRITC.IQEIE

Input Queue Empty Interrupt Enable

This bit controls the input queue empty interrupt.

0: Disabled
No interrupt will be requested and the input queue empty interrupt will be not generated.

1: Enabled
Input queue empty interrupt will be generated when FLXA0FRITS.IQEIS is ‘1’.

(3) FLXA0FRITC.IQFIE

Input Queue Full Interrupt Enable

This bit controls the input queue full interrupt.

0: Disabled
No interrupt will be requested and the input queue full interrupt will be not generated.

1: Enabled
Input queue full interrupt will be generated when FLXA0FRITS.IQFIS is ‘1’.

(4) FLXA0FRITC.IQHR

Input Queue Halt Request

The IQHR bit should not be set to ‘1’ when FLXA0FRITS.ITS is ‘0’.

This bit requests a halt of the input queue.

The status of the halt request is shown in the FLXA0FRITS.IQH register.

Refer to **Section 17.3.16.1 (5), Halting the input queue** about usage of this bit.

0: Input queue run request
The input queue resumes their operation.

1: Input queue halt request
The input queue gets halted. An active input transfer will be completed but no further transfer request will start.

(5) FLXA0FRITC.ITE

Input Transfer Enable

The user should only set this bit to ‘1’ when FLXA0FRIBCR.IBSYS is ‘0’.

The user should only set this bit to ‘0’ when FLXA0FRITC.IQHR ‘0’. Otherwise committed input transfers get lost.

This bit controls the operation mode of the input transfer queue.

The operation status of the input transfer queue function is shown in FLXA0FRITS.ITS.

Refer to **Section 17.3.16.1 (1), Activation and deactivation** about usage of this bit.

0: Operation Disable request
The input transfer queue gets disabled when it becomes empty.

1: Operation Enable request
The input transfer queue gets enabled. Input data structures are transferred to the FlexRay internal message RAM.

17.2.12.2 FLXA0FROTC — FlexRay Output Transfer Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0804_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	—	—	—	—	FWIE	OWIE	FIE	OIE	—	—	—	—	—	—	OTCS	OTE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Table 17.76 FLXA0FROTC Register Contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved These bits are always read as 0. When writing, always write 0.
20 to 16	FTM[4:0]	FIFO Table Max Configure the number of FIFO entries the output transfer handler is capable to maintain in the local RAM/global RAM.
15 to 12	—	Reserved These bits are always read as 0. When writing, always write 0.
11	FWIE	FIFO Transfer Warning Interrupt Enable 0: Disabled 1: Enabled
10	OWIE	Output Transfer Warning Interrupt Enable 0: Disabled 1: Enabled
9	FIE	FIFO Transfer Interrupt Enable 0: Disabled 1: Enabled
8	OIE	Output Transfer Interrupt Enable 0: Disabled 1: Enabled
7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	OTCS	Output Transfer Condition Select 0: New data only mode 1: New data and status changed mode
0	OTE	Output Transfer Enable 0: Operation Disable request 1: Operation Enable request

(1) FLXA0FROTC.FTM

FIFO Table Max

The user can only write to these bits when FLXA0FROTS.OTS is ‘0’.

These bits configure the number of FIFO entries the output transfer handler is capable to maintain in the local RAM/global RAM.

Valid values are 00_H (1 FIFO entry) to $1F_H$ (32 FIFO entries).

(2) FLXA0FROTC.FWIE

FIFO transfer Warning Interrupt Enable

This bit controls the FIFO transfer warning interrupt.

0: Disabled
No interrupt will be requested and the FIFO transfer warning interrupt will be not generated.

1: Enabled
FIFO transfer warning interrupt will be generated when FLXA0FROTS.FWIS is ‘1’.

(3) FLXA0FROTC.OWIE

Output Transfer Warning Interrupt Enable

This bit controls the output transfer warning interrupt.

0: Disabled
No interrupt will be requested and the output transfer warning interrupt will be not generated.

1: Enabled
Output transfer warning interrupt will be generated when FLXA0FROTS.OWIS is ‘1’.

(4) FLXA0FROTC.FIE

FIFO Transfer Interrupt Enable

This bit controls the FIFO transfer interrupt.

0: Disabled
No interrupt will be requested and the FIFO transfer interrupt will be not generated.

1: Enabled
FIFO transfer interrupt will be generated when FLXA0FROTS.FIS is ‘1’.

(5) FLXA0FROTC.OIE

Output Transfer Interrupt Enable

This bit controls the output transfer interrupt.

0: Disabled
No interrupt will be requested and the output transfer interrupt will be not generated.

1: Enabled
Output transfer interrupt will be generated when FLXA0FROTS.OTIS is ‘1’.

(6) FLXA0FROTC.OTCS

Output Transfer Condition Select

The user can only write to this bit when FLXA0FROTS.OTS is '0'.

This bit controls the output transfer condition.

0: New data only mode
The ND bits in the FLXA0FRNDATi registers are used to detect a transfer condition for dedicated receive buffer

1: New data and status changed mode
The ND bits in the FLXA0FRNDATi registers and the MBC bits in the FLXA0FRMBSCi register are used to detect a transfer condition for dedicated transmit and receive buffer

(7) FLXA0FROTC.OTE

Output Transfer Enable

The user should only set this bit to '1' when FLXA0FROBCR.OBSYS is '0'.

This bit controls the operation mode of the output transfer function.

The operation status of the output buffer transfer function is shown in FLXA0FROTS.OTS.

Refer to **Section 17.3.16.2 (1), Activation and deactivation** about usage of this bit.

0: Operation Disable request
The output buffer transfer gets disabled.
An active message buffer transfer will be completed but no further transfer will start.

1: Operation Enable request
The output buffer transfer gets enabled. Message buffers are transferred from the FlexRay internal message RAM to output data structures.

The user should not change the E-Ray message RAM configuration by writing to the FLXA0FRMRC register.

17.2.12.3 FLXA0FRIBA — FlexRay Input Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0808_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ITA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17.77 FLXA0FRIBA Register Contents

Bit Position	Bit Name	Function
31 to 0	ITA[31:0]	Input Table Base Address These bits configure the base address of the input pointer table.

(1) FLXA0FRIBA.ITA

Input Table Base Address

The user can only write to these bits when FLXA0FRITS.ITS is ‘0’.

The address should be 32 bit aligned, thus the bits FLXA0FRIBA.ITA[1:0] are always ‘0’.

These bits configure the base address of the input pointer table.

The table is used for the input transfer queue transferring message buffers from the local RAM/global RAM into the FlexRay internal message RAM.

The size of the input queue is configured in FLXA0FRITC.ITM.

Note that each entry requires two long words in the input pointer table.

17.2.12.4 FLXA0FRFBA — FlexRay FIFO Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $080C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FTA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 17.78 FLXA0FRFBA Register Contents

Bit Position	Bit Name	Function
31 to 0	FTA[31:0]	FIFO Pointer Table Base Address These bits configure the base address of the FIFO pointer table.

(1) FLXA0FRFBA.FTA

FIFO Pointer Table Base Address

The user can only write to these bits when FLXA0FROTS.OTS is ‘0’.

The address should be 32 bit aligned, thus the bits FLXA0FRFBA.FTA[1:0] are always ‘0’.

These bits configure the base address of the FIFO pointer table.

The table is used for message buffers transferred from the FlexRay internal FIFO to the local RAM/ global RAM.

The size of the FIFO is configured in FLXA0FROTC.FTM.

17.2.12.5 FLXA0FROBA — FlexRay Output Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0810_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OTA[31:16]

Table 17.79 FLXA0FROBA Register Contents

Bit Position	Bit Name	Function
31 to 0	OTA[31:0]	Output Pointer Table Base Address These bits configure the base address of the output pointer table.

(1) FLXA0FROBA.OTA

Output Pointer Table Base Address

The user can only write to these bits when FLXA0FROTS.OTS is ‘0’.

The address should be 32 bit aligned, thus the bits FLXA0FROBA.OTA[1:0] are always ‘0’.

These bits configure the base address of the output pointer table.

The table is used for message buffers transferred from the FlexRay internal message RAM to the local RAM/global RAM.

The size of the table depends on the utilization of the FlexRay internal message RAM and can have up to 128 entries.

17.2.12.6 FLXA0FRIQC — FlexRay Input Queue Control Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0814_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	IMBNR[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 17.80 FLXA0FRIQC Register Contents

Bit Position	Bit Name	Function
31 to 7	—	Reserved These bits are always read as 0. When writing, always write 0.
6 to 0	IMBNR[6:0]	Input Message Buffer Number Message buffer number added to the input queue

(1) FLXA0FRIQC.IMBNR

Input Message Buffer Number

The user can only write to these bits when FLXA0FRITS.IQFP is ‘0’.

The user should not write to this register when FLXA0FRITS.ITS is '0' or when FLXA0FRITC.ITE is ‘0’.

These bits are read as “0”.

This value specifies the message buffer added to the input queue.

The number has to be identical to FLXA0FRWRHS4.IMBNR (see **Section 17.3.16.1 (3), Input pointer table**) of the input pointer table.

The address to the input data structure has to be provided in the input pointer table at the put index (FLXA0FRITS.IPIDX) before writing to this register.

Writing to this register increments the input put index (FLXA0FRITS.IPIDX).

17.2.12.7 FLXA0FRUIR — FlexRay User Input Transfer Request Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0818_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 17.81 FLXA0FRUIR Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are always read as 0. When writing, always write 0.
7 to 0	UIDX[7:0]	User Requested Input Index Input pointer table index requested for input transfer

(1) FLXA0FRUIR.UIDX

User Requested Input Index

The user can only write to these bits when FLXA0FRITS.UIRP is ‘0’.

The user should not write to this register when FLXA0FRITS.ITS is ‘0’.

The user should not write to this register when FLXA0FRITS.UIRP is ‘1’.

The user should not write to this register when FLXA0FRITS.IQH is ‘1’.

The user should only write FLXA0FRITC.ITM + 1 to this register.

This value configures the user input pointer table index requested for input transfer.

The address to the input data structure has to be provided in the input pointer table at the index UIDX before writing to this register.

When writing to this register, the requested input data structure will be transferred from input data structure position to the FlexRay internal message RAM.

In opposite to queued input transfers, the related DA flag in the FLXA0FRDA register is not affected by the user input transfer.

17.2.12.8 FLXA0FRUOR — FlexRay User Output Transfer Request Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + $081C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	URDS	—	—	UMBNR[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17.82 FLXA0FRUOR Register Contents

Bit Position	Bit Name	Function
31 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9	URDS	User Request Read Data Section 0: Data section is not transferred 1: Data section is transferred
8, 7	—	Reserved These bits are always read as 0. When writing, always write 0.
6 to 0	UMBNR[6:0]	User Requested Output Message Buffer Number Message buffer number requested for output transfer

(1) FLXA0FRUOR.URDS

User Request Read Data Section

The user can only write to this bit when FLXA0FROTS.UORP is ‘0’.

The user should not write to this register when FLXA0FROTS.OTS is ‘0’.

The user should not write to this register when FLXA0FROTS.UORP is ‘1’.

0: Data section is not transferred
The data section of the message buffer selected by the bits UMBNR is not requested

1: Data section is transferred
The data section of the message buffer selected by the bits UMBNR is requested

(2) FLXA0FRUOR.UMBNR

User Requested output Message Buffer Number

The user can only write to these bits when FLXA0FROTS.UORP is ‘0’.

The user should not write to this register when FLXA0FROTS.OTS is ‘0’.

The user should not write to this register when FLXA0FROTS.UORP is ‘1’.

The user should restrict this bit to dedicated receive and transmit buffers when the FlexRay module is not in the CONFIG state.

When writing to this register, the header sections and the optional data section (configurable by URDS) of the requested message buffer will be transferred from the FlexRay internal message RAM to the output data structure position defined by the output structure data pointer in the output pointer table.

17.2.12.9 FLXA0FRAHBC — FlexRay H-Bus Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0840_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.83 FLXA0FRAHBC Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved These bits are always read as 0. When writing, always write 0.
3 to 0	HPROT[3:0]	Protection Control

(1) FLXA0FRAHBC.HPROT

Protection Control

The user should only write to this register when FLXA0FRITS.ITS is ‘0’ and when FLXA0FROTS.OTS is ‘0’.

This register configures the value assigned to the H-Bus protection control signal.

17.2.13 Data Transfer Status Register

17.2.13.1 FLXA0FRITS — FlexRay Input Transfer Status Register

Do not rewrite this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0820_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.84 FLXA0FRITS Register Contents

Bit Position	Bit Name	Function
31	—	Reserved This bit is always read as 0. When writing, always write 0.
30 to 24	IGIDX[6:0]	Input Queue Get Index Represents the get index of the input pointer table
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	IPIDX[6:0]	Input Queue Put Index Represents the put index of the input pointer table
15 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12	IQFP	Input Queue Full Condition Pending 0: Entries in the input queue are available 1: All entries in the input queue are occupied
11, 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9	IQEIS	Input Queue Empty Interrupt Status 0: No input queue empty condition detected 1: Input queue empty condition detected
8	IQFIS	Input Queue Full Interrupt Status 0: No input queue full condition detected 1: Input queue full condition detected
7 to 3	—	Reserved These bits are always read as 0. When writing, always write 0.
2	UIRP	User Input Transfer Request Pending 0: No user input transfer request pending 1: User input transfer request pending
1	IQH	Input Queue Halted 0: Input queue not halted 1: Input queue halted
0	ITS	Input Transfer Status 0: Disabled 1: Enabled

(1) FLXA0FRITS.IGIDX

Input Queue Get Index

These bits are only valid when FLXA0FRITS.IQH is ‘1’

These bits represent the input pointer index the input queue handler will transfer next.

Valid values are 00_H to FLXA0FRITC.ITM.

The get index is incremented when the input data structure has been transferred from the local RAM/ global RAM and the related DA flag in the FLXA0FRDA register is cleared.

The index is set to 00_H when FLXA0FRITS.ITS changes from ‘0’ to ‘1’.

(2) FLXA0FRITS.IPIDX

Input Queue Put Index

These bits represent the index where the next input data structure pointer in the input pointer table should be stored.

Valid values are 00_H to FLXA0FRITC.ITM.

After reaching the maximum value the put index continues from 00_H.

The index is incremented when writing to FLXA0FRIQC.IMBNR.

The index is set to 00_H when FLXA0FRITS.ITS changes from ‘0’ to ‘1’.

(3) FLXA0FRITS.IQFP

Input Queue Full Condition Pending

This bit represents that the input queue is full.

There should be no further input transfer requests, by writing to FLXA0FRIQC.IMBNR, as long as FLXA0FRITS.IQFP is ‘1’.

[Clearing condition]

This bit is cleared when there is one free entry in the input queue.

[Setting condition]

This bit is set when all entries in the input queue are occupied.

(4) FLXA0FRITS.IQEIS

Input Queue Empty Interrupt Status

Writing ‘0’ has no effect on the bit value.

If enabled in FLXA0FRITC.IQEIE the input queue empty interrupt is generated when FLXA0FRITS.IQEIS is ‘1’.

[Clearing condition]

This bit is cleared when writing a ‘1’ to FLXA0FRITS.IQEIS.

This bit is cleared when FLXA0FRITS.ITS changes from ‘0’ to ‘1’.

[Setting condition]

This bit is set when all pending input transfers have been processed and consequently the input queue becomes empty.

(5) FLXA0FRITS.IQFIS

Input Queue Full Interrupt Status

Writing ‘0’ has no effect on the bit value.

If enabled in FLXA0FRITC.IQFIE the input queue full interrupt is generated when FLXA0FRITS.IQFIS is ‘1’.

This flag is intended as interrupt status flag. It does not represent the current input queue status; for this status refer to FLXA0FRITS.IQFP.

[Clearing condition]

This bit is cleared when writing a ‘1’ to FLXA0FRITS.IQFIS.

This bit is cleared when FLXA0FRITS.ITS changes from ‘0’ to ‘1’.

[Setting condition]

This bit is set when all entries in the input queue are occupied.

(6) FLXA0FRITS.UIRP

User Input Transfer Request Pending

This bit represents that a user input transfer is still pending.

There should be no further write access to FLXA0FRUIR.UIDX when this bit is ‘1’.

[Clearing condition]

This bit is cleared when the user input transfer request is processed by the input transfer handler.

[Setting condition]

This bit is set when writing to FLXA0FRUIR.UIDX.

(7) FLXA0FRITS.IQH

Input Queue Halted

This bit represents the status of the input queue.

There should be no further write access to FLXA0FRUIR.UIDX when this bit is ‘1’.

[Clearing condition]

This bit is cleared when FLXA0FRITC.IQHR is set to ‘0’.

[Setting condition]

This bit is set immediately when the FLXA0FRITC.IQHR is set to ‘1’ and there is no ongoing input transfer.

This bit is set only after an ongoing input transfer has been completed and FLXA0FRITC.IQHR is set to ‘1’.

(8) FLXA0FRITS.ITS

Input Transfer Status

This bit represents the status of the input queue handler.

While this bit is '1', there should be no read or write access to the address area ERAY + 0400_H to ERAY + $05FF_H$ and there should be no CLEAR_RAMS command applied to FLXA0FRSUCC1.CMD.

The input transfer queue indexes and related status flags are set to '0' when FLXA0FRITS.ITS changes from '0' to '1'.

[Clearing condition]

This bit is cleared immediately when FLXA0FRITC.ITE is set to '0' and there are no pending input transfers

This bit is cleared after all pending requests have been processed and FLXA0FRITC.ITE is '0'.

[Setting condition]

This bit is set when FLXA0FRITC.ITE is set to '1'.

17.2.13.2 FLXA0FROTS — FlexRay Output Transfer Status Register

Do not rewrite this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0824_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.85 FLXA0FROTS Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 24	FFL[5:0]	FIFO Fill Level Represent the number of unprocessed output FIFO structures
23 to 21	—	Reserved These bits are always read as 0. When writing, always write 0.
20 to 16	FGIDX[4:0]	FIFO Get Index Represent the get index in the FIFO pointer table
15	FWP	FIFO Transfer Warning Condition Pending 0: No FIFO transfer warning condition pending 1: FIFO transfer warning condition pending
14	OWP	Output Transfer Warning Condition Pending 0: No output transfer warning condition pending 1: Output transfer warning condition pending
13	FDA	FIFO Data Available 0: No available FIFO structures 1: FIFO structures available at current FLXA0FROTS.FGIDX index
12	—	Reserved This bit is always read as 0. When writing, always write 0.
11	FWIS	FIFO Transfer Warning Interrupt Status 0: No FIFO transfer warning condition detected 1: FIFO transfer warning condition detected
10	OWIS	Output Transfer Warning Interrupt Status 0: No output transfer warning condition detected 1: Output transfer warning condition detected
9	FIS	FIFO Transfer Interrupt Status 0: No FIFO structure updated in local RAM/global RAM 1: FIFO structure updated in local RAM/global RAM
8	OTIS	Output Transfer Interrupt Status 0: No output structure updated in local RAM/global RAM 1: Output structure updated in local RAM/global RAM
7 to 3	—	Reserved These bits are always read as 0. When writing, always write 0.

Table 17.85 FLXA0FROTS Register Contents (2/2)

Bit Position	Bit Name	Function
2	UORP	User Output Transfer Request Pending 0: No user output transfer request pending 1: User output transfer request pending
1	—	Reserved This bit is always read as 0. When writing, always write 0.
0	OTS	Output Transfer Status 0: Disabled 1: Enabled

(1) FLXA0FROTS.FFL

FIFO Fill Level

These bits represent the number of available output FIFO structures in the local RAM/global RAM.

Valid values are 00_H to FLXA0FROTC.FTM + 1.

The value 00_H represents that the FIFO is empty.

The value FLXA0FROTC.FTM + 1 represents that the FIFO is full and no further FIFO transfers will be done.

These bits are incremented when a FIFO data structure has been transferred from the FlexRay internal FIFO into the local RAM/global RAM.

The FIFO fill level is decremented when the user releases a FIFO data structure in the local RAM/global RAM by writing '1' to FLXA0FROTS.FDA.

The FIFO fill level is set to 00_H when the bit FLXA0FROTS.OTS changes from '0' to '1'.

(2) FLXA0FROTS.FGIDX

FIFO Get Index

These bits represent the index where the current output data structure pointer in the FIFO pointer table is available for reading.

Valid values are 00_H to FLXA0FROTC.FTM.

After reaching the maximum value the get index continues from 00_H.

The index is incremented when a FIFO data structure is released by writing '1' to FLXA0FROTS.FDA.

The index is set to 00_H when FLXA0FROTS.OTS changes from '0' to '1'.

(3) FLXA0FROTS.FWP

FIFO Transfer Warning Condition Pending

This bit represents the FIFO transfer warning condition.

[Clearing condition]

This bit is cleared when there are free output data structures (FLXA0FROTS.FFL ≤ FLXA0FROTC.FTM).

This bit is cleared when the FLXA0FROTS.OTS changes from '0' to '1'.

[Setting condition]

This bit is set when the output transfer handler detects a transfer condition for FIFO message buffers but there are no free output data structures (FLXA0FROTS.FFL = FLXA0FROTC.FTM + 1).

(4) FLXA0FROTS.OWP

Output Transfer Warning Condition Pending

This bit represents the output transfer warning condition.

[Clearing condition]

This bit is cleared, when all output structure pointers that have a pending output handler transfer condition detected, are released (for dedicated transmit and receive message buffers or a user output transfer request).

[Setting condition]

This bit is set when the output transfer handler detects a transfer condition (for dedicated transmit and receive message buffers or a user output transfer request) but the related output structure pointer was not yet released by the application (data available flag is still set to ‘1’).

This bit is set when the output transfer handler detects a transfer condition for dedicated transmit and receive message buffers but there is a pending input transfer for the same message buffer (data available flag is set to ‘1’ due to the input transfer request).

(5) FLXA0FROTS.FDA

FIFO Data Available

Writing '0' has no effect on the bit value.

When this bit is ‘1’, the next valid output data structure is available.

The related data structure pointer is in the FIFO pointer table at FLXA0FROTS.FGIDX.

Writing ‘1’ to FLXA0FROTS.FDA

- increments FLXA0FROTS.FGIDX and
- decrements the FIFO fill level (FLXA0FROTS.FFL)

If there are still unprocessed data structures, FLXA0FROTS.FDA remains ‘1’.

[Clearing condition]

This bit is cleared when writing ‘1’ to FLXA0FROTS.FDA and the FIFO fill level becomes 00_H.

This bit is cleared when the FLXA0FROTS.OTS changes from ‘0’ to ‘1’.

[Setting condition]

This bit is set when there is at least one FIFO data structure available in the local RAM/global RAM.

(6) FLXA0FROTS.FWIS

FIFO Transfer Warning Interrupt Status

Writing '0' has no effect on the bit value.

If the FLXA0FROTC.FWIE is enabled, the FIFO transfer warning interrupt is generated when FLXA0FROTS.FWIS is ‘1’.

[Clearing condition]

This bit is cleared when writing a ‘1’ to FLXA0FROTS.FWIS.

This bit is cleared when the bit FLXA0FROTS.OTS changes from ‘0’ to ‘1’.

[Setting condition]

This bit is set when the output transfer handler detects a transfer condition for FIFO message buffers but there are no free output data structures (FLXA0FROTS.FFL = FLXA0FROTC.FTM + 1).

(7) FLXA0FROTS.OWIS

Output Transfer Warning Interrupt Status

Writing ‘0’ has no effect on the bit value.

If enabled in FLXA0FROTC.OWIE the FIFO transfer warning interrupt is generated when FLXA0FROTS.OWIS is ‘1’.

[Clearing condition]

This bit is cleared when writing a ‘1’ to FLXA0FROTS.OWIS.

This bit is cleared when the bit FLXA0FROTS.OTS changes from ‘0’ to ‘1’.

[Setting condition]

This bit is set when the output transfer handler detects a transfer condition (for dedicated transmit and receive message buffers or a user output transfer request) but the related output structure pointer was not yet released by the application (data available flag is still set to ‘1’).

This bit is set when the output transfer handler detects a transfer condition for dedicated transmit and receive message buffers but there is a pending input transfer for the same message buffer (data available flag is set to ‘1’ due to the input transfer request).

(8) FLXA0FROTS.FIS

FIFO Transfer Interrupt Status

Writing ‘0’ has no effect on the bit value.

If enabled in FLXA0FROTC.FIE the FIFO transfer interrupt is generated when FLXA0FROTS.FIS is ‘1’.

[Clearing condition]

This bit is cleared when writing a ‘1’ to FLXA0FROTS.FIS.

This bit is cleared when the bit FLXA0FROTS.OTS changes from ‘0’ to ‘1’.

[Setting condition]

This bit is set when a FIFO data structure is updated by the transfer handler or the FFL bit changes from 00_H to 01_H.

(9) FLXA0FROTS.OTIS

Output Transfer Interrupt Status

Writing ‘0’ has no effect on the bit value.

If enabled in FLXA0FROTC.OIE the output transfer interrupt is generated when FLXA0FROTS.OTIS is ‘1’.

[Clearing condition]

This bit is cleared when writing a ‘1’ to FLXA0FROTS.OTIS.

This bit is cleared when the bit FLXA0FROTS.OTS changes from ‘0’ to ‘1’.

[Setting condition]

This bit is set when an output data structure is updated by the transfer handler (from a dedicated transmit or receive message buffer or by a user output transfer request).

(10) FLXA0FROTS.UORP

User Output Transfer Request Pending

This bit represents that a user output transfer is still pending.

There should be no further write access to FLXA0FRUOR.UMBNR when this bit is ‘1’.

[Clearing condition]

This bit is cleared when the user output transfer request is processed by the output transfer handler.

This bit is cleared when the bit FLXA0FROTS.OTS changes from ‘0’ to ‘1’.

[Setting condition]

This bit is set when writing to FLXA0FRUOR.UMBNR.

(11) FLXA0FROTS.OTS

Output Transfer Status

This bit represents the status of the output transfer handler.

While this bit is ‘1’, no read or write access to the address area ERAY + 0600_H to ERAY + $07FF_H$ cannot be made and no CLEAR_RAMS command to the FLXA0FRSUCC1.CMD cannot be provided.

While this bit is ‘1’, the user cannot change the E-Ray message RAM configuration by writing to the FLXA0FRMRC register.

The output hander transfer indexes and related status flags are set to ‘0’ when FLXA0FROTS.OTS changes from ‘0’ to ‘1’.

[Clearing condition]

This bit is cleared immediately when FLXA0FROTC.OTE is set to ‘0’ and there are no ongoing output transfers.

This bit is cleared after an ongoing transfer has been completed and FLXA0FROTC.OTE is ‘0’.

[Setting condition]

This bit is set when FLXA0FROTC.OTE is set to ‘1’.

17.2.13.3 FLXA0FRAES — FlexRay Access Error Status Register

Do not rewrite this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0828_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	MAE	FAE	OAE	IAE	EIDX[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Table 17.86 FLXA0FRAES Register Contents

Bit Position	Bit Name	Function
31 to 12	—	Reserved These bits are always read as 0. When writing, always write 0.
11	MAE	Multiple Access Errors 0: No multiple access errors occurred 1: Multiple access errors occurred
10	FAE	FIFO Transfer Access Error 0: No access error occurred during FIFO transfer 1: Access error occurred during FIFO transfer
9	OAE	Output Transfer Access Error 0: No access error occurred during output transfer 1: Access error occurred during output transfer
8	IAE	Input Transfer Access Error 0: No access error occurred during input transfer 1: Access error occurred during input transfer
7 to 0	EIDX[7:0]	Error Index Data structure pointer index number

(1) FLXA0FRAES.MAE

Multiple Access Errors

Writing ‘0’ has no effect on the bit value.

This bit represents that there were multiple access errors during a data transfer.

[Clearing condition]

This bit is cleared when writing a ‘1’ to FLXA0FRAES.MAE.

[Setting condition]

This bit is set when one of the bits FLXA0FRAES.FAE, FLXA0FRAES.OAE or FLXA0FRAES.IAE are set and

- an access to an protected address occurred during a FIFO data transfer or
- an access to an protected address occurred during an output data transfer or
- an access to an protected address occurred during an input data transfer

(2) FLXA0FRAES.FAE

FIFO Transfer Access Error

Writing ‘0’ has no effect on the bit value.

This bit represent that there was an access error during a FIFO data transfer.

[Clearing condition]

This bit is cleared when writing a ‘1’ to FLXA0FRAES.FAE.

[Setting condition]

This bit is set when a local RAM/global RAM access error was detected during a FIFO transfer and the bits FLXA0FRAES.OAE, FLXA0FRAES.IAE and FLXA0FRAES.MAE are ‘0’.

(3) FLXA0FRAES.OAE

Output Transfer Access Error

Writing ‘0’ has no effect on the bit value.

This bit represent that there was an access error during an output data transfer.

[Clearing condition]

This bit is cleared when writing a ‘1’ to FLXA0FRAES.OAE.

[Setting condition]

This bit is set when a local RAM/global RAM access error was detected during an output transfer and the bits FLXA0FRAES.FAE, FLXA0FRAES.IAE and FLXA0FRAES.MAE are ‘0’.

(4) FLXA0FRAES.IAE

Input Transfer Access Error

Writing '0' has no effect on the bit value.

This bit represent that there was an access error during an input data transfer.

[Clearing condition]

This bit is cleared when writing a ‘1’ to FLXA0FRAES.IAE.

[Setting condition]

This bit is set when a local RAM/global RAM access error was detected during an output transfer and the bits FLXA0FRAES.OAE, FLXA0FRAES.FAE and FLXA0FRAES.MAE are ‘0’.

(5) FLXA0FRAES.EIDX

Error Index

This value is only valid when one of the bits FLXA0FRAES.FAE, FLXA0FRAES.OAE or FLXA0FRAES.IAE is ‘1’.

When the bit FLXA0FRAES.FAE is ‘1’, FLXA0FRAES.EIDX holds the used FIFO put index when an access error has occurred.

When the bit FLXA0FRAES.OAE is ‘1’, FLXA0FRAES.EIDX holds the input pointer table get index used when an access error occurred during an input transfer or when the user request an input transfer.

When the bit FLXA0FRAES.IAE is ‘1’, FLXA0FRAES.EIDX holds the used input pointer table get index when an access error has occurred.

These bits are updated when one of the bits FLXA0FRAES.FAE, FLXA0FRAES.OAE or FLXA0FRAES.IAE is changing from ‘0’ to ‘1’.

17.2.13.4 FLXA0FRAEA — FlexRay Access Error Address Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + $082C_H$

Value after reset: $0000\ 0000_H$

Table 17.87 FLXA0FRAEA Register Contents

Bit Position	Bit Name	Function
31 to 0	AEA[31:0]	Access Error Address Address in the local RAM/global RAM when an access error has occurred

(1) FLXA0FRAEA.AEA

Access Error Address

This value is only valid when one of the bits FLXA0FRAES.FAE, FLXA0FRAES.OAE or FLXA0FRAES.IAE is ‘1’.

These bits represent the address of the access error indicated in the FLXA0FRAES register.

These bits are updated when one of the bits FLXA0FRAES.FAE, FLXA0FRAES.OAE or FLXA0FRAES.IAE is changing from ‘0’ to ‘1’.

17.2.13.5 FLXA0FRDAi — FlexRay Message Data Available Register i (i = 0 to 3)

Do not rewrite this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0830_H to ERAY + $083C_H$ (ERAY + 0830_H + i*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.88 FLXA0FRDAi Register Contents

Bit Position	Bit Name	Function
31 to 0	DAb	Data Available b 0: No data available for destination 1: Data available for destination

(1) FLXA0FRDAi.DAb (b = i*32 to ((i + 1)*32)-1)

Data Available b

The user should not write a ‘1’ to bits that are ‘0’.

To maintain the status of input transfers, the user should not clear bits related to input transfers.

This register is used for input and output transfers.

Each flag corresponds to a FlexRay message buffer.

[Clearing condition]

Input transfer:

This bit is cleared when the input data structure has been transferred from the local RAM/global RAM. The data structure and the data structure pointer can be changed when the related flag is ‘0’.

Output transfer:

This bit is cleared when writing a ‘1’ to it.

[Setting condition]

Input transfer:

This bit is set when the corresponding message buffer number has been written to FLXA0FRIQC.IMBNR.

As long as this bit is ‘1’, the input data structure and the data structure pointer corresponding to this input transfer request should not be changed.

Output transfer:

This bit is set when the output data structure corresponding to this message buffer has been updated.

As long as this bit is ‘1’, the data structure is stable; no further update of the data structure will be done by the output handler. While this bit is ‘1’, the application can change the output data structure pointer in the output pointer table for this message buffer number.

17.3 Functional Description

This chapter describes the FlexRay implementation together with the related FlexRay protocol features. More information about the FlexRay protocol itself can be found in the FlexRay protocol specification.

17.3.1 FlexRay Module Operation Control

17.3.1.1 FlexRay Module Enable

After hardware reset or after the FlexRay module has been disabled (following **Section 17.3.1.2, FlexRay Module Disable**) the FlexRay module is in the reset state (FLXA0FROS.OS is '0') and the clocks of the FlexRay core module are disabled.

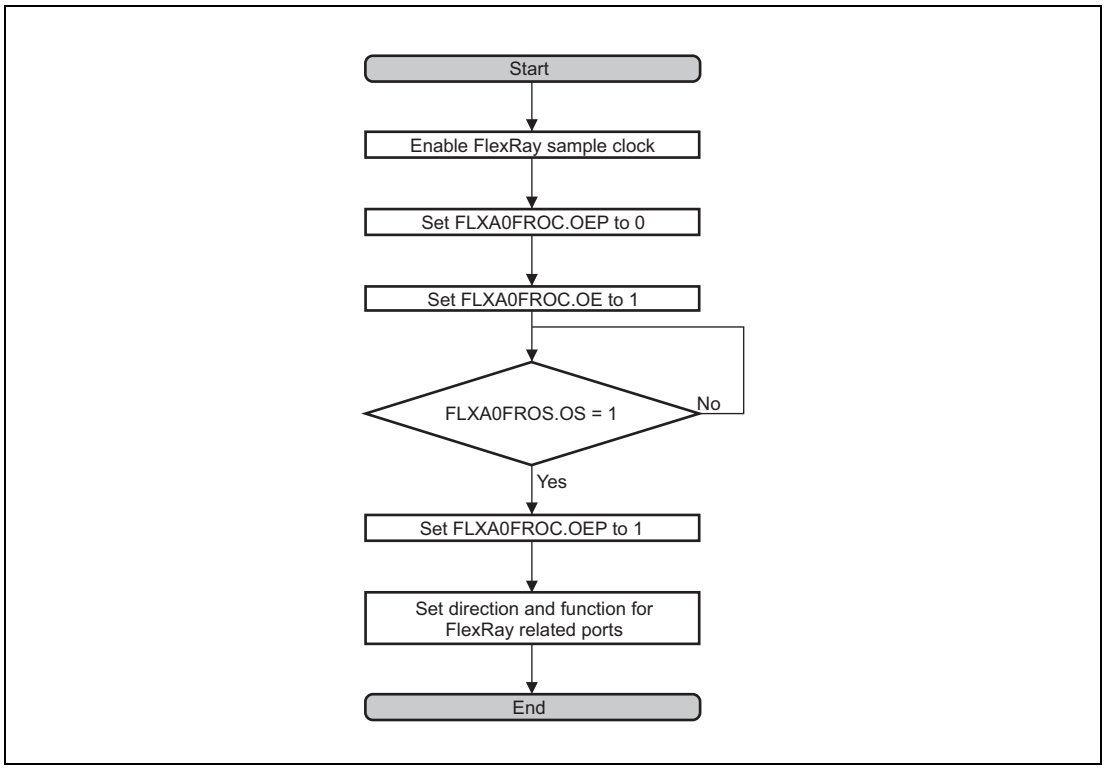

Figure 17.3 FlexRay Enable Flow

17.3.1.2 FlexRay Module Disable

The FlexRay module can be disabled at any time. However, it is recommended to disable the FlexRay module using the FLXA0FROC.OE register only when the FlexRay module is in HALT, CONFIG or DEFAULT_CONFIG state. Resetting the FlexRay module in any other state will terminate any ongoing FlexRay communication.

If the data transfer function is used, it is also required to disable this function before disabling the FlexRay module (see **Section 17.3.16.1 (1), Activation and deactivation** for suspending input transfer function and **Section 17.3.16.2 (2), Output transfer data structure** for suspending output transfer).

The following flow should be executed to disable the FlexRay module.

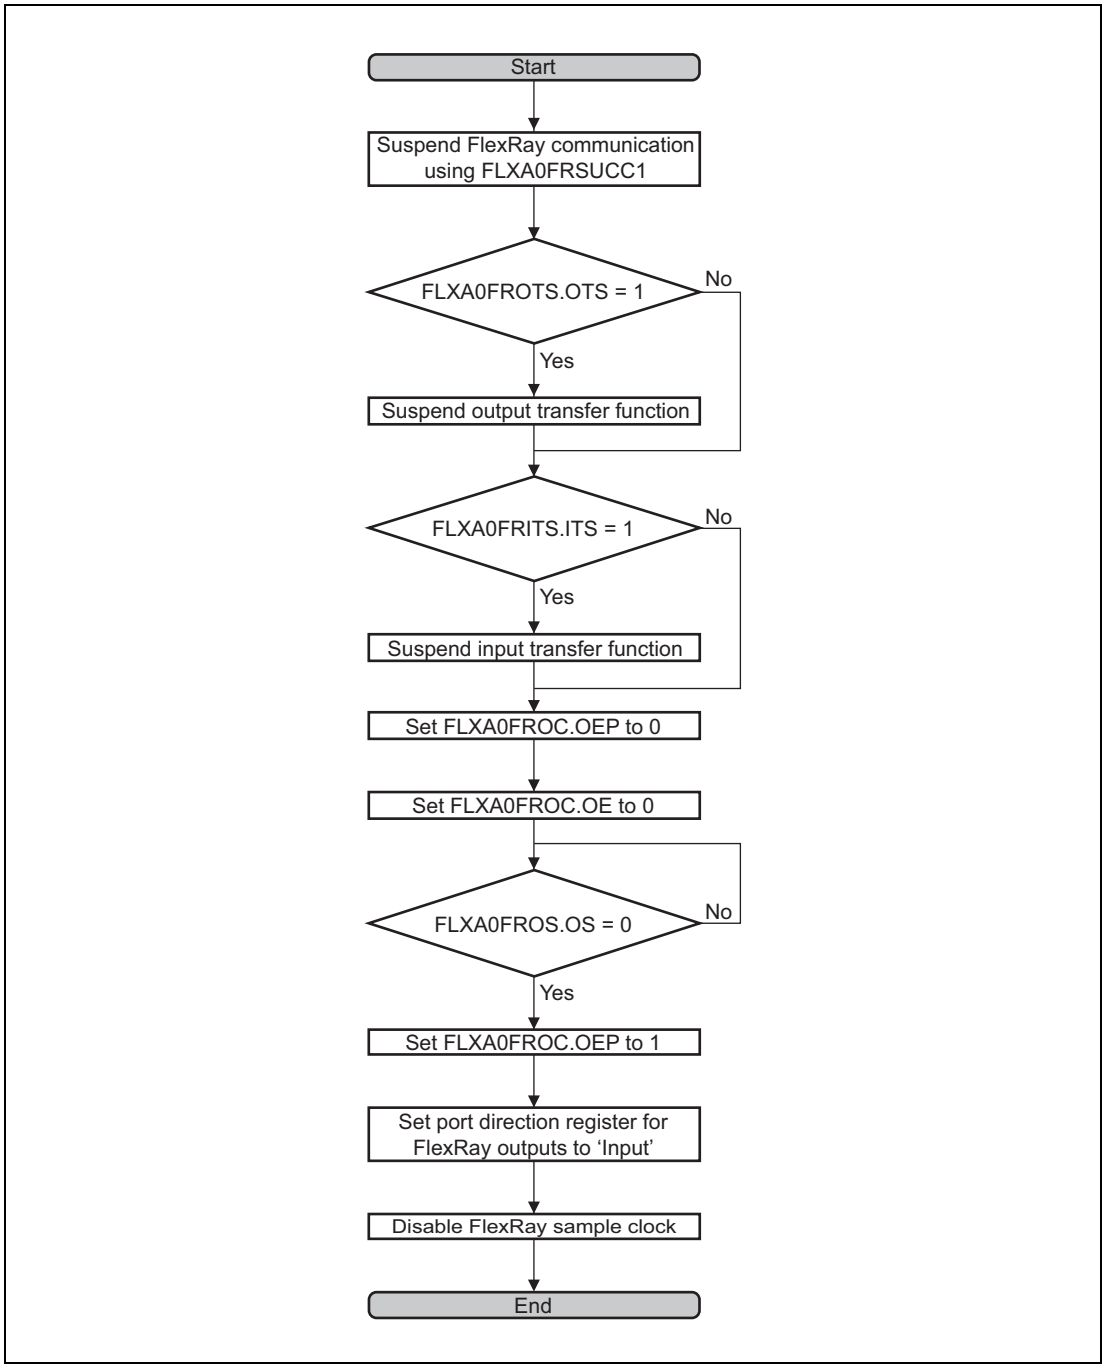

Figure 17.4 FlexRay Disable Flow

17.3.2 Communication Cycle

Communication on FlexRay networks is based on frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to set up the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

A FlexRay communication cycle consists of the following four elements:

- Static Segment
- Dynamic Segment (optional)
- Symbol Window (optional)
- Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized macrotick.

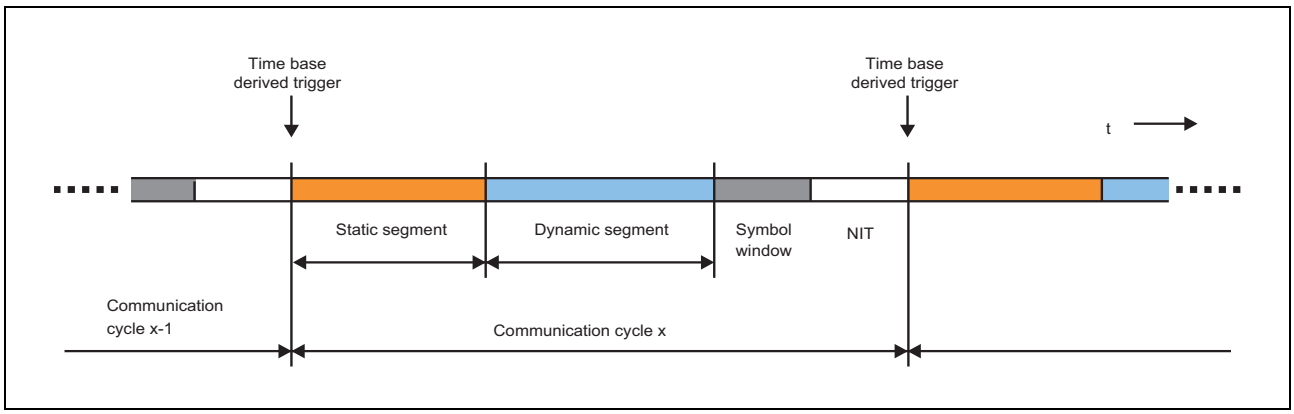

Figure 17.5 Structure of Communication Cycle

17.3.2.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of frame transmission at action point of the respective static slot
- Payload length same for all frames on both channels

Parameters:

Number of Static Slots (FRGTUC7.NSS)

Static Slot Length (FRGTUC7.SSL)

Payload Length Static (FRMHDC.SFDL)

Action Point Offset (FRGTUC9.APO)

17.3.2.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters:

Number of Minislots (FLXA0FRGTUC8.NMS)

Minislot Length (FLXA0FRGTUC8.MSL)

Minislot Action Point Offset (FLXA0FRGTUC9.MAPO)

Start of Latest Transmit (last minislot) (FLXA0FRMHDC.SLT)

17.3.2.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are sent in NORMAL_ACTIVE state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Parameters:

Symbol Window Action Point Offset (FLXA0FRGTUC9.APO) (same as for static slots)

Network Idle Time Start (FLXA0FRGTUC4.NIT)

17.3.2.4 Network Idle Time (NIT)

During network idle time the CC has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple macroticks after offset correction start
- Perform cluster cycle related tasks

Parameters:

Network Idle Time Start Position Setting (FLXA0FRGTUC4.NIT)

Offset Correction Start Position Setting (FLXA0FRGTUC4.OCS)

17.3.2.5 Configuration of NIT Start and Offset Correction Start

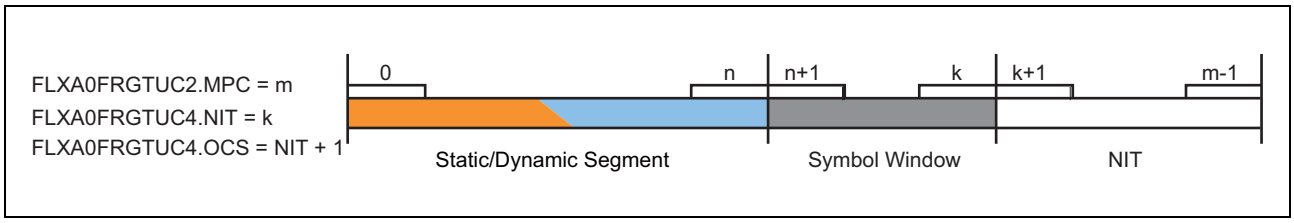

Figure 17.6 Configuration of NIT Start and Offset Correction Start

The number of macroticks per cycle gMacroPerCycle is assumed to be m. It is configured by programming FRGTUC2.MPC = m.

The static/dynamic segment starts with macrotick 0 and ends with macrotick n:

n = static segment length + dynamic segment offset + dynamic segment length - 1MT

n = gNumberOfStaticSlots o gdStaticSlot + dynamic segment offset + gNumberOfMinislots o gdMinislot - 1 MT

The static segment length is configured by FLXA0FRGTUC7.SSL and FLXA0FRGTUC7.NSS.

The dynamic segment length is configured by FLXA0FRGTUC8.MSL and FLXA0FRGTUC8.NMS.

The dynamic segment offset is:

If gdActionPointOffset ≤ gdMinislotActionPointOffset:

dynamic segment offset = 0 MT

Else if gdActionPointOffset > gdMinislotActionPointOffset:

dynamic segment offset = gdActionPointOffset -gdMinislotActionPointOffset

The NIT starts with macrotick k+1 and ends with the last macrotick of cycle m-1. It has to be configured by setting FLXA0FRGTUC4.NIT = k.

For the FlexRay module the offset correction start is required to be FLXA0FRGTUC4.OCS ≥ FLXA0FRGTUC4.NIT + 1 = k+1.

The length of symbol window results from the number of macroticks between the end of the static/ dynamic segment and the beginning of the NIT. It can be calculated by the number of macroticks (k - n).

17.3.3 Communication Modes

The FlexRay Protocol Specification defines the Time-Triggered Distributed (TT-D) mode.

17.3.3.1 Time-triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- Pure static: Minimum 2 or more static slots + symbol window (optional)
- Mixed static/dynamic: Minimum 2 or more static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes needs to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each startup frame must be a sync frame, therefore all coldstart nodes are sync nodes.

17.3.4 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received sync frames from other nodes.

17.3.4.1 Global Time

Activities in a FlexRay node, including communication, are based on the concept of a global time. It is the clock synchronization mechanism that differentiates the FlexRay cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (macrotick counter).

Cluster specific:

- Macrotick (MT) = basic unit of time measurement in a FlexRay network, a macrotick consists of an integer number of microticks (µT)
- Cycle length = duration of a communication cycle in units of macroticks (MT)

17.3.4.2 Local Time

Internally, nodes time their behavior with microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a microtick (µT).

Node specific:

- Oscillator clock → prescaler → microtick (µT)
- µT = basic unit of time measurement in a CC, clock correction is done in units of → µTs
- Cycle counter + macrotick counter = nodes local view of the global time

17.3.4.3 Synchronization Process

Clock synchronization is performed by means of sync frames. Only preconfigured nodes (sync nodes) are allowed to send sync frames. In a two-channel cluster a sync node has to send its sync frame on both channels.

For synchronization in FlexRay the following constraints have to be considered:

- Max. one sync frame per node in one communication cycle
- Max. 15 sync frames per cluster in one communication cycle
- Every node has to use a preconfigured number of sync frames (FLXA0FRGTUC2.SNM) for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization, the time difference between expected and observed arrival time of sync frames received during the static segment is measured. In a two channel cluster, the sync node has to be configured to send sync frames on both channels. The calculation of correction terms is done during NIT (offset: every cycle, rate: every odd cycle) by using an FTM algorithm. For details see FlexRay protocol specification, chapter 8.

(1) Offset (phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during NIT of every communication cycle
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values
- Correction value is a signed integer number of µTs
- Correction done in odd numbered cycles, distributed over the macroticks beginning at offset correction start up to cycle end (end of NIT) to shift nodes next start of cycle (MTs lengthened or shortened)

(2) Rate (frequency) Correction

- Pairs of deviation values measured and stored in even/odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during NIT of odd numbered cycles
- Cluster drift damping is performed using global damping value
- Checked against limit values
- Correction value is a signed integer number of µTs
- Distributed over macroticks comprising the next even/odd cycle pair (MTs lengthened or shortened)

(3) Sync Frame Transmission

Sync frame transmission is only possible from buffer 0 and 1. Message buffer 1 may be used for sync frame transmission in case that sync frames should have different payloads on the two channels. In this case bit FLXA0FRMRC.SPLM has to be programmed to ‘1’.

Message buffers used for sync frame transmission have to be configured with the key slot ID and can be (re)configured in DEFAULT_CONFIG or CONFIG state only. For nodes transmitting sync frames FLXA0FRSUCC1.TXSY must be set to ‘1’.

(4) External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset/rate correction value is a signed integer
- External offset/rate correction value is added to calculated offset/rate correction value
- Aggregated offset/rate correction term (external + internal) is not checked against configured limits

17.3.5 Error Handling

The implemented error handling concept is intended to ensure that, in case of a lower layer protocol error in one single node, communication between non-affected nodes can be maintained. In some cases, higher layer program activity is required for the CC to resume normal operation. A change of the error handling state will set FLXA0FREIR.PEMC to '1' and may trigger an interrupt to the host if enabled. The actual error mode is signaled by FLXA0FRCCEV.ERRM.

Table 17.89 Error Modes of The POC (Degradation Model)

Error Mode	Activity
ACTIVE	Full operation, State: NORMAL_ACTIVE The CC is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers FLXA0FREIR and FLXA0FRSIR.
PASSIVE	Reduced operation, State: NORMAL_PASSIVE, CC self-rescue allowed The CC stops transmitting frames and symbols, but received frames are still processed. Clock synchronization mechanisms are continued based on received frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers FLXA0FREIR and FLXA0FRSIR.
COMM_HALT	Operation halted, State: HALT, CC self rescue not allowed The CC stops frame and symbol processing, clock synchronization processing, and the macrotick generation. The host has still access to error and status information by reading the error and status interrupt flags from registers FLXA0FREIR and FLXA0FRSIR. The bus drivers are disabled.

17.3.5.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the "maximum without clock correction passive" limit defined by FLXA0FRSUCC3.WCP, the POC transits from NORMAL_ACTIVE to NORMAL_PASSIVE state. When it reaches the "maximum without clock correction fatal" limit defined by FLXA0FRSUCC3.WCF, it transits from NORMAL_ACTIVE or NORMAL_PASSIVE to HALT state.

The Clock Correction Failed Counter FLXA0FRCCEV.CCFC allows the host to monitor the duration of the inability of a node to compute clock correction terms after the CC passed protocol startup phase. It will be incremented by one at the end of any odd communication cycle during which either the missing offset correction FLXA0FRSFS.MOCS or the missing rate correction FLXA0FRSFS.MRCS flag is set to '1'.

The Clock Correction Failed Counter is reset to zero at the end of an odd communication cycle if neither the missing offset correction FLXA0FRSFS.MOCS nor the missing rate correction FLXA0FRSFS.MRCS flag is set to '1'.

The Clock Correction Failed Counter stops incrementing when the "maximum without clock correction fatal" value FLXA0FRSUCC3.WCF is reached (i.e. incrementing the counter at its maximum value will not cause it to wrap around back to zero). The Clock Correction Failed Counter is initialized to zero when the CC enters READY state or when NORMAL_ACTIVE state is entered.

NOTE

The transition to HALT state is prevented if FLXA0FRSUCC1.HCSE is not set to '1'.

17.3.5.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from NORMAL_PASSIVE to NORMAL_ACTIVE state. FLXA0FRSUCC1.PTA defines the number of consecutive even/odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state. If FLXA0FRSUCC1.PTA is set to zero the CC is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

17.3.5.3 HALT Command

In case the host wants to stop FlexRay communication of the local node, it can bring the CC into HALT state by asserting the HALT command. This can be done by writing FLXA0FRSUCC1.CMD = “0110”. In order to shut down communication on an entire FlexRay network, a higher layer protocol is required to assure that all nodes apply the HALT command at the same time.

The POC state from which the transition to HALT state took place can be read from FLXA0FRCCSV.PSL.

When called in NORMAL_ACTIVE or NORMAL_PASSIVE state the POC transits to HALT state at the end of the current cycle. When called in any other state FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted and bit FLXA0FREIR.CNA is set to ‘1’. If enabled an interrupt to the host is generated.

17.3.5.4 FREEZE Command

In case the host detects a severe error condition it can bring the CC into HALT state by asserting the FREEZE command. This can be done by writing FLXA0FRSUCC1.CMD = “0111”. The FREEZE command triggers the entry of the HALT state immediately regardless of the actual POC state.

The POC state from which the transition to HALT state took place can be read from FLXA0FRCCSV.PSL.

CAUTION

When a terminal restarts transfer as a leading coldstart node after transfer was stopped by using the FREEZE or READY command, the startup frame may not be transmitted in cycle 0. This depends on the internal state of the FlexRay module. This phenomenon occurs when the startup frame is set in a slot with a number from 1 to 7. This phenomenon does not occur in a coldstart after a hardware reset.
Even if this phenomenon does occur, a second try of the coldstart will succeed. While the coldstart time will be prolonged, this phenomenon does not otherwise affect a coldstart of the FlexRay system.
To avoid this phenomenon, allocate the Startup/Sync frame to static slot 8 or a slot with a higher number.

17.3.6 Communication Controller States

17.3.6.1 Communication Controller State Diagram

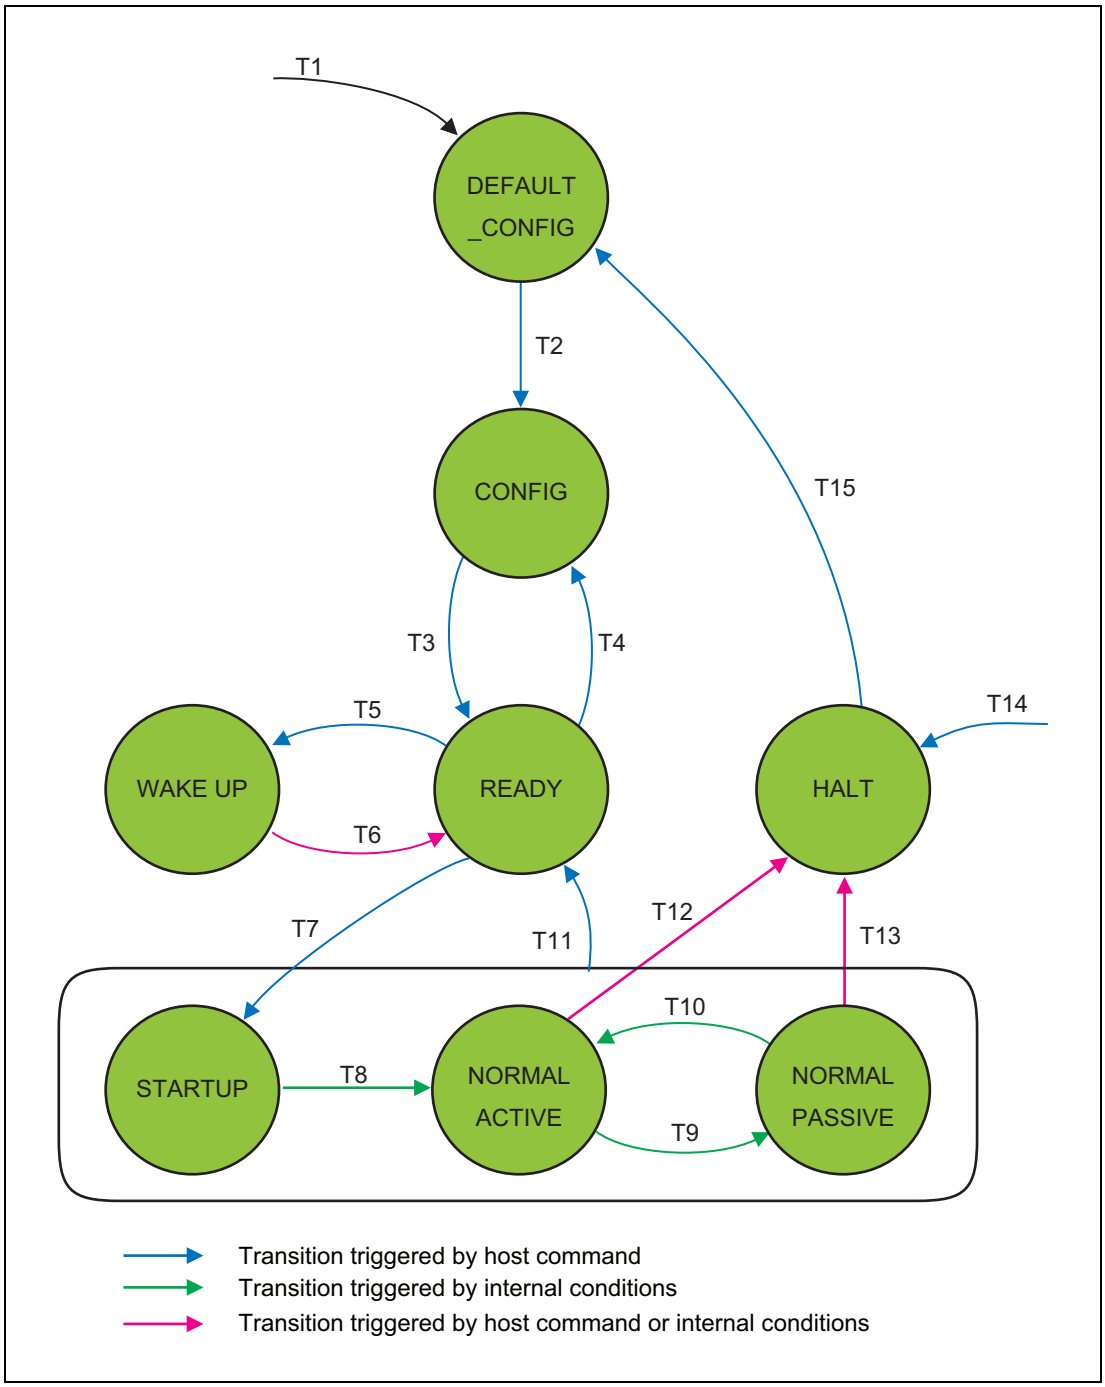

Figure 17.7 Overall state diagram of FlexRay communication controller

State transitions are controlled by reset, FLXA0FR0RXDA, FLXA0FR0RXDB, by the POC state machine, and by the CHI command vector FLXA0FRSUCC1.CMD.

The CC transits from all states to HALT state after application of the FREEZE command (FLXA0FRSUCC1.CMD = “0111”).

Table 17.90 State Transitions of FlexRay Overall State Machine

T#	Condition	From	To
1	Reset	All States	DEFAULT_CONFIG
2	Command CONFIG, FLXA0FRSUCC1.CMD = “0001”	DEFAULT_CONFIG	CONFIG
3	Unlock sequence followed by command READY, FLXA0FRSUCC1.CMD = “0010”	CONFIG	READ
4	Command CONFIG, FLXA0FRSUCC1.CMD = “0001”	READY	CONFIG
5	Command WAKEUP, FLXA0FRSUCC1.CMD = “0011”	READY	WAKEUP
6	Complete transmission of wakeup pattern or received WUP or received frame header or wakeup collision or command READY, FLXA0FRSUCC1.CMD = “0010”	WAKEUP	READY
7	Command RUN, FLXA0FRSUCC1.CMD = “0100”	READY	STARTUP
8	Successful STARTUP	STARTUP	NORMAL_ACTIVE
9	Clock Correction Failed counter reached Maximum Without Clock Correction Passive limit configured by FLXA0FRSUCC3.WCP	NORMAL_ACTIVE	NORMAL_PASSIVE
10	Number of valid correction terms reached the Passive to Active limit configured by FLXA0FRSUCC1.PTA	NORMAL_PASSIVE	NORMAL_ACTIVE
11	Command READY, FLXA0FRSUCC1.CMD = “0010”	STARTUP, NORMAL_ACTIVE, NORMAL_PASSIVE	READY
12	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by FLXA0FRSUCC3.WCF when bit FLXA0FRSUCC1.HCSE set to ‘1’ or command HALT, FLXA0FRSUCC1.CMD = “0110”	NORMAL_ACTIVE	HALT
13	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by FLXA0FRSUCC3.WCF when bit FLXA0FRSUCC1.HCSE set to ‘1’ or command HALT, FLXA0FRSUCC1.CMD = “0110”	NORMAL_PASSIVE	HALT
14	Command FREEZE, FLXA0FRSUCC1.CMD = “0111”	All States	HALT
15	Command CONFIG, FLXA0FRSUCC1.CMD = “0001”	HALT	DEFAULT_CONFIG

17.3.6.2 DEFAULT_CONFIG State

In DEFAULT_CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The CC enters this state

- When the reset is applied (HW reset or SW reset)
- When exiting from HALT state

To leave DEFAULT_CONFIG state the host has to write FLXA0FRSUCC1.CMD = “0001”. The CC then transits to CONFIG state.

17.3.6.3 CONFIG State

In CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the CC configuration.

The CC enters this state

- When exiting from DEFAULT_CONFIG state
- When exiting from READY state

When the state has been entered via HALT and DEFAULT_CONFIG state, the host can analyze status information and configuration. Before leaving CONFIG state, the host has to assure that the configuration is fault-free.

To leave CONFIG state, the host has to perform the unlock sequence as described is **Section 17.2.3.1, FLXA0FRLCK — FlexRay Lock Register**. Directly after unlocking the CONFIG state the host has to write FLXA0FRSUCC1.CMD to enter the next state.

NOTE

Status bits FLXA0FRMHDS[14:0], registers FLXA0FRTXRQ1/2/3/4, and status data stored in the message RAM are not affected by the transition of the POC from CONFIG to READY state.

When the CC is in CONFIG state it is also possible to bring the CC into a power saving mode by halting the module clocks (bus clock and sample clock). To do this the host has to assure that all message RAM transfers have finished before turning off the clocks.

17.3.6.4 READY State

After unlocking CONFIG state and writing FLXA0FRSUCC1.CMD = “0010” the CC enters READY state. From this state the CC can transit to WAKEUP state and perform a cluster wake-up or to STARTUP state to perform a coldstart or to integrate into a running cluster.

The CC enters this state

- When exiting from CONFIG, WAKEUP, STARTUP, NORMAL_ACTIVE, or NORMAL_PASSIVE state by writing FLXA0FRSUCC1.CMD = “0010” (READY command).

The CC exits from this state

- To CONFIG state by writing FLXA0FRSUCC1.CMD = “0001” (CONFIG command)
- To WAKEUP state by writing FLXA0FRSUCC1.CMD = “0011” (WAKEUP command)
- To STARTUP state by writing FLXA0FRSUCC1.CMD = “0100” (RUN command)

Internal counters and the CC status flags are reset when the CC enters STARTUP state.

NOTE

Status bits FLXA0FRMHDS[14:0], registers FLXA0FRTXRQ1/2/3/4, and status data stored in the message RAM are not affected by the transition of the POC from READY to STARTUP state.

17.3.6.5 WAKEUP State

The description below is intended to help configuring wake-up for the FlexRay IP-module. A detailed description of the wake-up procedure together with the respective SDL diagrams can be found in the FlexRay protocol specification, section 7.1.

The CC enters this state

- When exiting from READY state by writing FLXA0FRSUCC1.CMD = “0011” (WAKEUP command).

The CC exits from this state to READY state

- After complete non-aborted transmission of wakeup pattern
- After WUP reception
- After detecting a WUP collision
- After reception of a frame header
- By writing FLXA0FRSUCC1.CMD = “0010” (READY command)

The cluster wakeup must precede the communication startup in order to ensure that all nodes in a cluster are awake. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an external wakeup source.

The host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the CC and configures bus guardian (if available) and CC to perform the cluster wakeup. The CC provides to the host the ability to transmit a special wakeup pattern on each of its available channels separately. The CC needs to recognize the wakeup pattern only during WAKEUP state.

Wakeup can be performed on only one channel at a time. The host has to configure the wakeup channel while the CC is in CONFIG state by writing FLXA0FRSUCC1.WUCS. The CC ensures that ongoing communication on this channel is not disturbed. The CC cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup, the CC returns to READY state and signals the change of the wakeup status to the host by setting flag FLXA0FRSIR.WST. The wakeup status vector can be read from FLXA0FRCCSV.WSV. If a valid wakeup pattern was received also either flag FLXA0FRSIR.WUPA or flag FLXA0FRSIR.WUPB is set to ‘1’.

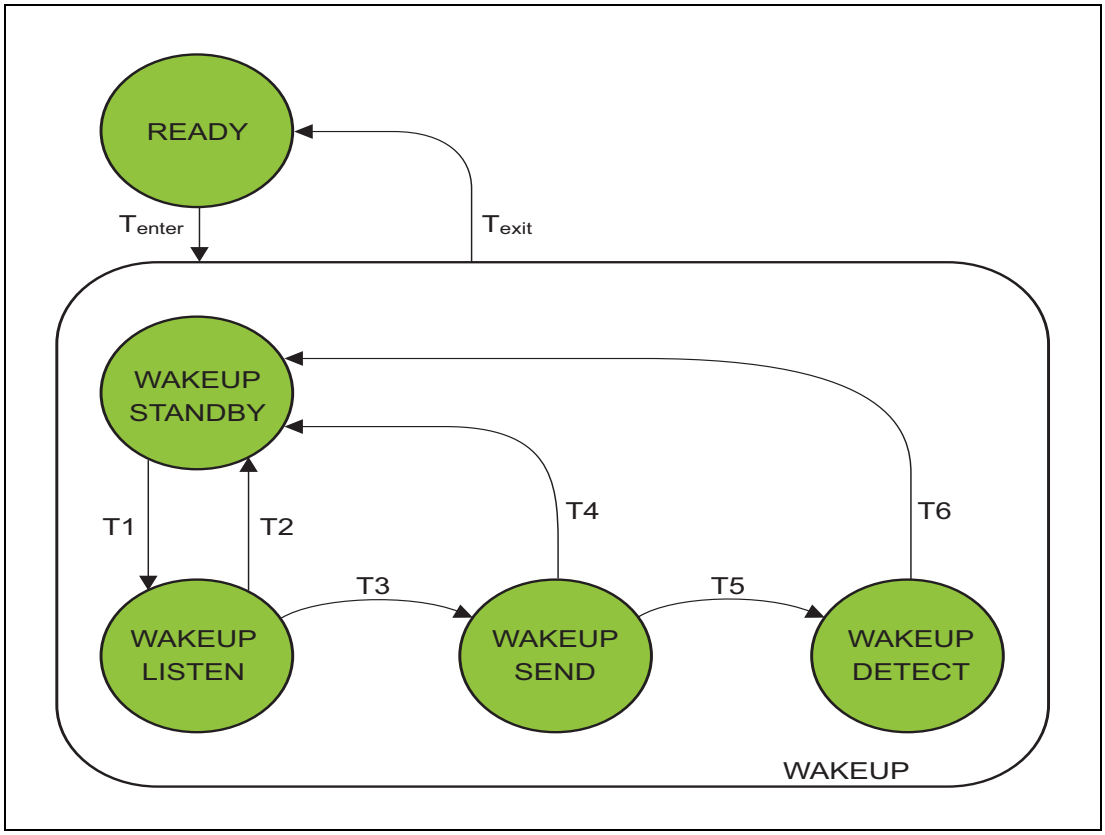

Figure 17.8 Structure of POC State WAKEUP

Table 17.91 State Transitions WAKEUP

T#	Condition	From	To
enter	Host commands change to WAKEUP state by writing FLXA0FRSUCC1.CMD = “0011” (WAKEUP command)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to WAKEUP_LISTEN state	WAKEUP_STANDBY	WAKEUP_LISTEN
2	Received WUP on wakeup channel selected by bit FLXA0FRSUCC1.WUCS or frame header on either available channel	WAKEUP_LISTEN	WAKEUP_STANDBY
3	Timer event	WAKEUP_LISTEN	WAKEUP_SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_SEND	WAKEUP_STANDBY
5	Collision detected	WAKEUP_SEND	WAKEUP_DETECT
6	Wakeup timer expired or WUP detected on wakeup channel selected by bit FLXA0FRSUCC1.WUCS or frame header received on either available	WAKEUP_DETECT	WAKEUP_STANDBY
exit	Wakeup completed (after T2 or T4 or T6) or host commands change to READY state by writing FLXA0FRSUCC1.CMD = “0010” (READY command). This command also resets the wakeup FSM to WAKEUP_STANDBY state	WAKEUP	READY

The WAKEUP_LISTEN state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters listen timeout FLXA0FRSUCC2.LT and listen timeout noise FLXA0FRSUCC2.LTN. Listen timeout enables a fast cluster wakeup in case of a noise free environment, while listen timeout noise enables wakeup under more difficult conditions regarding noise interference.

In WAKEUP_SEND state the CC transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the host has to bring the CC into STARTUP state by CHI command RUN.

In WAKEUP_DETECT state the CC attempts to identify the reason for the wakeup collision detected in WAKEUP_SEND state. The monitoring is limited by the expiration of listen timeout as configured by FLXA0FRSUCC2.LT. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a frame header indicating ongoing communication, causes the direct transition to READY state. Otherwise WAKEUP_DETECT is left after expiration of listen timeout; in this case the reason for wakeup collision is unknown.

The host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay Protocol Specification recommends that two different CCs shall awake the two channels.

(1) Host activities

The host must coordinate the wakeup of the two channels and must decide whether or not to wake a specific channel. The sending of the wakeup pattern is initiated by the host. The wakeup pattern is detected by the remote BDs and signaled to their local hosts respectively.

Wakeup procedure controlled by host (single-channel wakeup):

- Configure the CC in CONFIG state
  - Select wakeup channel by programming bit FLXA0FRSUCC1.WUCS
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command CC to enter READY state
- Command CC to start wakeup on the configured channel by writing FLXA0FRSUCC1.CMD = “0011”
  - CC enters WAKEUP
  - CC returns to READY state and signals status of wakeup attempt to the host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node:
  - In a dual channel cluster wait for WUP on the other channel
  - Reset coldstart inhibit flag FLXA0FRCCSV.CSI by writing FLXA0FRSUCC1.CMD = “1001” (ALLOW_COLDSTART command)
- Command CC to enter startup by writing FLXA0FRSUCC1.CMD = “0100” (RUN command)

Wakeup procedure triggered by BD:

- Wakeup recognized by BD
- BD triggers power-up of host (if required)
- BD signals wakeup event to host
- Host configures its local CC
- If necessary, host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands CC to enter STARTUP state by writing FLXA0FRSUCC1.CMD = “0100” (RUN command)

(2) Wakeup pattern (WUP)

The wakeup pattern (WUP) is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by registers FLXA0FRPRTC1 and FLXA0FRPRTC2.

- Single channel wakeup, wakeup symbol may not be sent on both channels at the same time
- Wakeup symbol collision resilient for at least two sending nodes (two overlapping wakeup symbols always recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by FLXA0FRPRTC2.TXL
- Wakeup symbol idle time used to listen for activity on the bus, configured by FLXA0FRPRTC2.TXI
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by FLXA0FRPRTC1.RWP (2 to 63 repetitions)
- Wakeup symbol receive window length configured by FLXA0FRPRTC1.RXW
- Wakeup symbol receive low time configured by FLXA0FRPRTC2.RXL
- Wakeup symbol receive idle time configured by FLXA0FRPRTC2.RXI

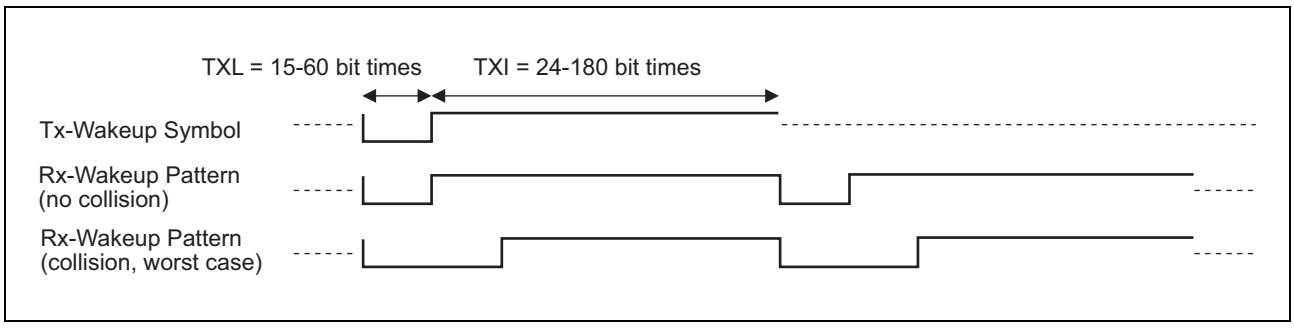

Figure 17.9 Timing of Wakeup Pattern

17.3.6.6 STARTUP State

This section describes configuration of startup for the FlexRay module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the FlexRay protocol specification, section 7.2.

Any node entering STARTUP state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

The required time for complete wake-up and configuration vary for each node and star. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup frames. Startup frames are both sync frames and null frames during startup.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter NORMAL_ACTIVE state via following paths. (see **Figure 17.10**):

- Coldstart path initiating the schedule synchronization (Leading coldstart node)
- Coldstart path joining other coldstart nodes (Following coldstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has bits FLXA0FRSUCC1.TXST and FLXA0FRSUCC1.TXSY set to ‘1’. Message buffer 0 holds the key slot ID which defines the slot number where the startup frame is send. In the frame header of the startup frame the startup frame indicator bit is set to ‘1’.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each startup frame must also be a sync frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by FLXA0FRSUCC1.CSA.

A non-coldstart node requires at least two startup frames from distinct nodes for integration.

It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start integration via the integration path as soon as they receive sync frames from which to derive the TDMA schedule information. During integration, the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

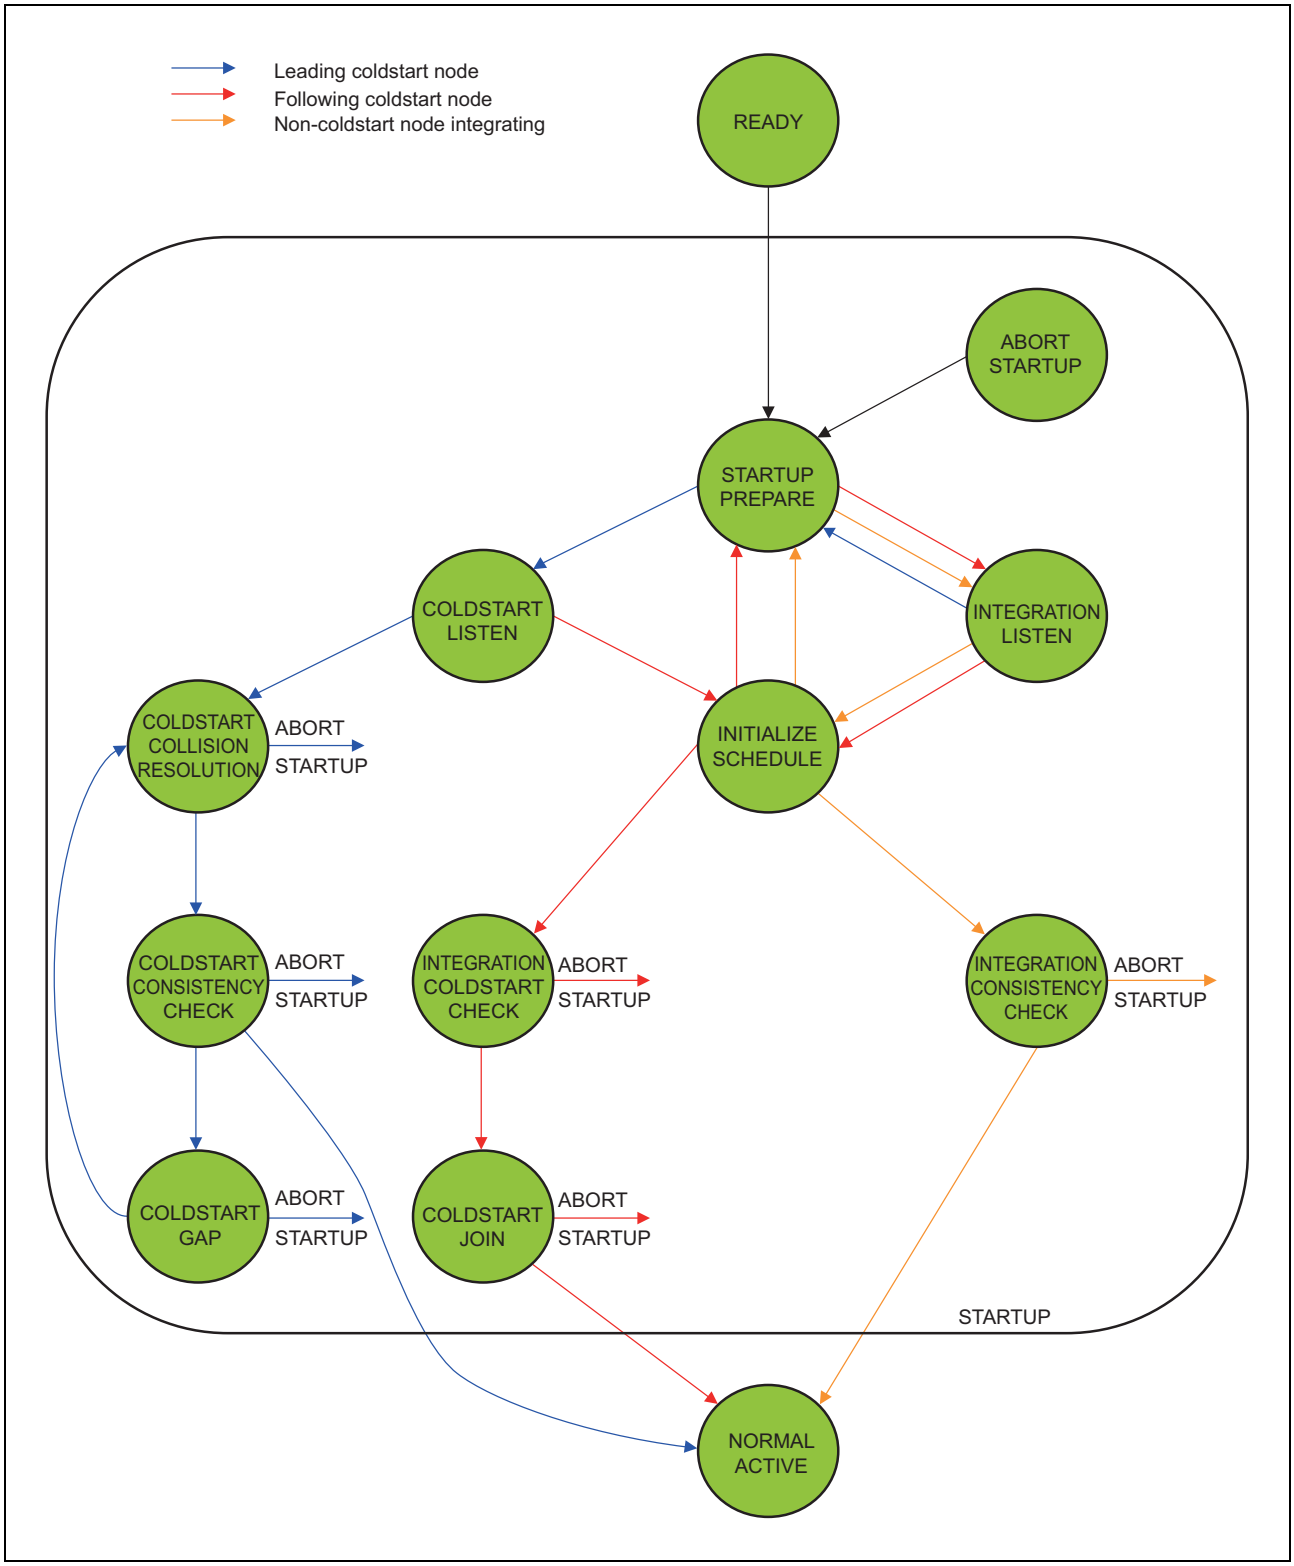

Figure 17.10 State Diagram Time-triggered Startup

(1) Coldstart Inhibit Mode

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit FLXA0FRCCSV.CSI is set to '1', the node is not allowed to initialize the cluster communication, i.e. entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit FLXA0FRCCSV.CSI is set to '1' whenever the POC enters READY state. The bit has to be cleared by issuing the CHI command ALLOW_COLDSTART (FLXA0FRSUCC1.CMD = "1001") by a program.

(2) Startup Timeouts

The CC supplies two different µT timers supporting two timeout values, startup timeout and startup noise timeout. The two timers are started when the CC enters the COLDSTART_LISTEN state. The expiration of either of these timers causes the node to leave the initial sensing phase (COLDSTART_LISTEN state) with the intention of starting up communication.

NOTE

The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values FLXA0FRSUCC2.LT and FLXA0FRSUCC2.LTN.

(a) Startup Timeout

The startup timeout limits the monitoring time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others. The startup timer is configured by programming FLXA0FRSUCC2.LT (see **Section 17.2.6.2, FLXA0FRSUCC2 — FlexRay SUC Configuration Register 2**).

The startup timeout is:

pdListenTimeout = FLXA0FRSUCC2.LT

The startup timer is restarted upon:

- Entering the COLDSTART_LISTEN state
- Both channels reaching idle state while in COLDSTART_LISTEN state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the COLDSTART_LISTEN state
- When the COLDSTART_LISTEN state is left

Once the startup timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

(b) Startup Noise Timeout

At the same time the startup timer is started for the first time (transition from STARTUP_PREPARE state to COLDSTART_LISTEN state), the startup noise timer is started. This additional timeout is used to improve reliability of the startup procedure in the presence of noise. The startup noise timeout is configured by programming FLXA0FRSUCC2.LTN (see **Section 17.2.6.2, FLXA0FRSUCC2 — FlexRay SUC Configuration Register 2**).

The startup noise timeout is:

pdListenTimeout * gListenNoise = FLXA0FRSUCC2.LT * (FLXA0FRSUCC2.LTN + 1)

The startup noise timer is restarted upon:

- Entering the COLDSTART_LISTEN state
- Reception of correctly decoded headers or CAS symbols while the node is in COLDSTART_LISTEN state

The startup noise timer is stopped when the COLDSTART_LISTEN state is left.

Once the startup noise timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer will not be restarted when random channel activity is detected, this timeout defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

(3) Path of Leading Coldstart Node (initiating coldstart)

When a coldstart node enters COLDSTART_LISTEN, it listens to its attached channels.

If no communication is detected, the node enters the COLDSTART_COLLISION_RESOLUTION state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup frame. Since each coldstart node may perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a frame header during these four cycles, it re-enters the COLDSTART_LISTEN state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup frames.

After four cycles in COLDSTART_COLLISION_RESOLUTION state, the node that initiated the coldstart enters the COLDSTART_CONSISTENCY_CHECK state. It collects all startup frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid startup frame pair, the node leaves COLDSTART_CONSISTENCY_CHECK and enters NORMAL_ACTIVE state.

The number of coldstart attempts that a node is allowed to perform is configured by FLXA0FRSUCC1.CSA. The number of remaining coldstarts attempts can be read from FLXA0FRCCSV.RCA. The number of remaining coldstart attempts is reduced by one for each attempted coldstart. A node may enter the COLDSTART_LISTEN state only if this value is two or larger and it may enter the COLDSTART_COLLISION_RESOLUTION state only if this value is one or larger. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

(4) Path of Following Coldstart Node (responding to Leading Coldstart Node)

When a coldstart node enters the COLDSTART_LISTEN state, it tries to receive a valid pair of startup frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid startup frame has been received the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_COLDSTART_CHECK state is entered.

In INTEGRATION_COLDSTART_CHECK state, it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still valid. The node collects all sync frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient frames from the same node it has integrated on, the COLDSTART_JOIN state is entered.

In COLDSTART_JOIN state following coldstart nodes begin to transmit their own startup frames and continue to do so in subsequent cycles. Thereby, the leading coldstart node and the nodes joining it can check if their schedules match with each other. If the clock correction signals any error, the node aborts the integration attempt. If a node in this state sees at least one valid startup frame during all even cycles in this state and at least one valid startup frame pair during all double cycles in this state, the node leaves COLDSTART_JOIN state and enters NORMAL_ACTIVE state. Thereby it leaves STARTUP at least one cycle after the node that initiated the coldstart.

(5) Path of Non-Coldstart Node

When a non-coldstart node enters the INTEGRATION_LISTEN state, it listens to its attached channels.

As soon as a valid startup frame has been received, the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_CONSISTENCY_CHECK state is entered.

In INTEGRATION_CONSISTENCY_CHECK state the node verifies that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) are sending startup frames that agree with the node's own schedule. Clock correction is activated, and if any errors are signaled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup frames or the startup frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid startup frame pairs or the startup frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup frames are received within an even cycle, or less than two valid startup frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to detect two valid startup frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

17.3.6.7 NORMAL_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering STARTUP via coldstart path) and one additional node have entered the NORMAL_ACTIVE state, the startup phase for the cluster has finished. In the NORMAL_ACTIVE state, all configured messages are scheduled for transmission. This includes all data frames as well as the sync frames. Rate and offset measurement is started in all even cycles (even/odd cycle pairs required).

In NORMAL_ACTIVE state, the CC supports regular communication functions.

- The CC performs transmissions and reception on the FlexRay bus as configured
- Clock synchronization is running
- The host interface is operational

The CC exits from that state to

- HALT state by writing FLXA0FRSUCC1.CMD = “0110” (HALT command, at the end of the current cycle)
- HALT state by writing FLXA0FRSUCC1.CMD = “0111” (FREEZE command, immediately)
- HALT state due to change of the error state from ACTIVE to COMM_HALT
- NORMAL_PASSIVE state due to change of the error state from ACTIVE to PASSIVE
- READY state by writing FLXA0FRSUCC1.CMD = “0010” (READY command)

17.3.6.8 NORMAL_PASSIVE State

NORMAL_PASSIVE state is entered from NORMAL_ACTIVE state when the error state changes from ACTIVE to PASSIVE.

In NORMAL_PASSIVE state, the node is able to receive all frames (node is fully synchronized and performs clock synchronization). Contrary to the NORMAL_ACTIVE state, the node does not actively participate in communication, i.e. neither symbols nor frames are transmitted.

In NORMAL_PASSIVE state

- The CC performs reception on the FlexRay bus
- The CC does not transmit any frames or symbols on the FlexRay bus
- Clock synchronization is running
- The host interface is operational

The CC exits from this state to

- HALT state by writing FLXA0FRSUCC1.CMD = “0110” (HALT command, at the end of the current cycle)
- HALT state by writing FLXA0FRSUCC1.CMD = “0111” (FREEZE command, immediately)
- HALT state due to change of the error state from PASSIVE to COMM_HALT
- NORMAL_ACTIVE state due to change of the error state from PASSIVE to ACTIVE. The transition takes place when FLXA0FRCCEV.PTAC equals FLXA0FRSUCC1.PTA - 1
- To READY state by writing FLXA0FRSUCC1.CMD = “0010” (READY command)

17.3.6.9 HALT State

In this state all communication (reception and transmission) is stopped.

The CC enters this state

- By writing FLXA0FRSUCC1.CMD = “0110” (HALT command) while the CC is in NORMAL_ACTIVE or NORMAL_PASSIVE state
- By writing FLXA0FRSUCC1.CMD = “0111” (FREEZE command) from all states
- When exiting from NORMAL_ACTIVE state because the FLXA0FRSUCC1.HCSE is set to ‘1’ and the clock correction failed counter reached the “maximum without clock correction fatal” limit.
- When exiting from NORMAL_PASSIVE state because the FLXA0FRSUCC1.HCSE is set to ‘1’ and the clock correction failed counter reached the “maximum without clock correction fatal” limit.

The CC exits from this state to DEFAULT_CONFIG state

- By writing FLXA0FRSUCC1.CMD = “0001” (CONFIG command)

When the CC enters HALT state, all configuration and status data is maintained for analyzing purposes.

When the host writes FLXA0FRSUCC1.CMD = “0110” (HALT command), the CC sets bit FLXA0FRCCSV.HRQ to ‘1’ and enters HALT state at the next end of cycle.

When the host writes FLXA0FRSUCC1.CMD = “0111” (FREEZE command), the CC enters HALT state immediately and sets bit FLXA0FRCCSV.FSI to ‘1’.

The POC state from which the transition to HALT state took place can be read from FLXA0FRCCSV.PSL.

17.3.7 Network Management

The accrued Network Management (NM) vector can be read from registers FLXA0FRNMV1…3. The CC performs a bit-wise OR operation over all NM vectors out of all received valid NM frames with the Payload Preamble Indicator (PPI) bit set. Only static frames may be configured to hold NM information. The CC updates the NM vector at the end of each cycle. The length of the NM vector can be configured from 0 to 12 bytes by FLXA0FRNEMC.NML. The NM vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay frames with the PPI bit set as '1', bit PPIT in the header section of the respective transmit buffer has to be set to '1' via FLXA0FRWRHS1.PPIT. In addition the host has to write the NM information to the data section of the respective transmit buffer.

The evaluation of the NM vector has to be done by the application running on the host.

Section 17.3.17, Byte Alignment, for byte alignment of the received NM vector in registers FLXA0FRNMV1 to FLXA0FRNMV3.

NOTES

1. In case a message buffer is configured for transmission/reception of network management frames, the payload length configured in header 2 of that message buffer should be equal or greater than the length of the NM vector configured by FLXA0FRNEMC.NML.
2. When the CC transits to HALT state, the cycle count is not incremented and therefore the NM vector is not updated. In this case FLXA0FRNMV1…3 holds the value from the cycle before.

17.3.8 Filtering and Masking

Filtering is done by comparison of the configuration of assigned message buffers against actual slot and cycle counter values and channel ID (channel A, B). A message buffer is only updated/transmitted if the required matches occur.

Filtering is done on:

- Slot Counter
- Cycle Counter
- Channel ID

The following filter combinations for acceptance/transmit filtering are allowed:

- Slot Counter + Channel ID
- Slot Counter + Cycle Counter + Channel ID

All configured filters must match in order to store a received message in a message buffer.

NOTE

For the FIFO the acceptance filter is configured by the FIFO Rejection Filter (FLXA0FRFRF) and the FIFO Rejection Filter Mask (FLXA0FRFRFM).

A message will be transmitted in the time slot corresponding to the configured frame ID on the configured channel(s). If cycle counter filtering is enabled, the configured cycle filter value must also match.

17.3.8.1 Slot Counter Filtering

Every transmit and receive buffer contains a frame ID stored in the header section. This frame ID is compared against the actual slot counter value in order to assign receive and transmit buffers to the corresponding slot.

If two or more message buffers are configured with the same frame ID and channel ID, and if they have a matching cycle counter filter value for the same slot, then the message buffer with the lowest message buffer number is used.

17.3.8.2 Cycle Counter Filtering

Cycle counter filtering is based on the concept of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in header section 1 of each message buffer.

If message buffer 0 or 1 is configured to hold the startup/sync frame or the single slot frame by bits FLXA0FRSUCC1.TXST, FLXA0FRSUCC1.TXSY, and FLXA0FRSUCC1.TSM, cycle counter filtering for message buffer 0 or 1 shall be disabled.

NOTE

Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay network is not allowed.

The set of cycle numbers belonging to a cycle set is determined as described in **Table 17.92**.

Table 17.92 Definition of Cycle Set

Cycle Code	Matching Cycle Counter Values
0b000000x	All Cycles
0b000001c	Every second Cycle at (Cycle Count) mod2 = c
0b00001cc	Every fourth Cycle at (Cycle Count) mod4 = cc
0b0001ccc	Every eighth Cycle at (Cycle Count) mod8 = ccc
0b001cccc	Every sixteenth Cycle at (Cycle Count) mod16 = cccc
0b01ccccc	Every thirty-second Cycle at (Cycle Count) mod32 = ccccc
0b1cccccc	Every sixty-fourth Cycle at (Cycle Count) mod64 = cccccc

Table 17.93 below gives some examples for valid cycle sets to be used for cycle counter filtering.

Table 17.93 Examples for Valid Cycle Sets

Cycle Code	Matching Cycle Counter Values
0b0000011	1-3-5-7-…. -63
0b0000100	0-4-8-12-…. -60
0b0001110	6-14-22-30-…. -62
0b0011000	8-24-40-56
0b0100011	3-35
0b1001001	9

The received message is stored only if the cycle counter value of the cycle during which the message is received matches an element of the receive buffer's cycle set. Channel ID and frame ID must also be matched.

The frame is transmitted when the cycle code set in the transmit buffer matches the current cycle counter value. Channel ID and frame ID must also be matched.

17.3.8.3 Channel ID Filtering

There is a 2-bit channel filtering control field (CH) located in the header section of each message buffer in the message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see **Table 17.94**).

Table 17.94 Channel Filtering Configuration

CH[1:0]	**Transmit Buffer** transmit frame	**Receive Buffer store valid receive frame**
11	on both channels (static segment only)	received on channel A or B (store first semantically valid frame, static segment only)
10	on channel B	received on channel B
01	on channel A	received on channel A
00	Transmission prohibited	ignore frame

The contents of a transmit buffer is transmitted on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be set up for transmission on both channels (CH = “11”).

Valid received frames are stored if they are received on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a receive buffer may be setup for reception on both channels (CH = “11”).

NOTE

If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to ‘1’, no frames are transmitted resp. received frames are ignored (same function as CH = “00”).

17.3.8.4 FIFO Filtering

For FIFO filtering registers FLXA0FRFRF and FLXA0FRFRFM are used. The FIFO filter consists of channel filter FLXA0FRFRF.CH, frame ID filter FLXA0FRFRF.FID, and cycle counter filter FLXA0FRFRF.CYF. Registers FLXA0FRFRF and FLXA0FRFRFM can be configured in DEFAULT_CONFIG or CONFIG state only. The filter configuration in the header section of message buffers belonging to the FIFO is ignored.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by FLXA0FRFRF.CYF, all frames are rejected.

A valid received frame is stored in the FIFO if channel ID, frame ID, and cycle counter are not rejected by FLXA0FRFRF and FLXA0FRFRFM register settings, and if there is no matching dedicated receive buffer.

17.3.9 Transmit Process

17.3.9.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the frame ID corresponding to the next sending slot is selected for transmission.

The data section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the input buffer has to be started by writing to the input buffer command request register (FLXA0FRIBCR) latest at this time.

17.3.9.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest frame ID) is selected next. In the dynamic segment different slot counter sequences on channel A and channel B are possible (concurrent sending of different frame IDs on both channels).

The data section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the input buffer has to be started by writing to the input buffer command request register (FLXA0FRIBCR) latest at this time.

The start of latest transmit configured by FLXA0FRMHDC.SLT defines the maximum minislot value allowed before inhibiting new frame transmission in the dynamic segment of the current cycle.

17.3.9.3 Transmit Buffers

FlexRay message buffers can be configured as transmit buffers by programming bit CFG in the header section of the corresponding message buffer to ‘1’ via FLXA0FRWRHS1.

There exist the following possibilities to assign a transmit buffer to the CC channels:

- Static segment: channel A or channel B,
  channel A and channel B
- Dynamic segment: channel A or channel B

Message buffer 0 and 1 are dedicated to hold the startup frame, the sync frame, or the designated single slot frame as configured by FLXA0FRSUCC1.TXST, FLXA0FRSUCC1.TXSY, and FLXA0FRSUCC1.TSM respectively. In this case, they can be reconfigured in DEFAULT_CONFIG or CONFIG state only. This ensures that any node transmits at most one startup/sync frame per communication cycle. Transmission of startup/sync frames from other message buffers is not possible.

All other message buffers configured for transmission in static or dynamic segment are reconfigurable during runtime depending on the configuration of FLXA0FRMRC.SEC (see **Section 17.3.12.1, Reconfiguration of Message Buffers**). Due to the structure of the data partition in the message RAM (to be referenced by data pointer), reconfiguration of the configured payload length and the data pointer in the header section of a message buffer may lead to erroneous configurations.

If a message buffer is reconfigured (header section updated) during runtime, it may happen that this message buffer is not send out in the corresponding communication cycle.

The CC does not have the capability to calculate the header CRC. The header CRC needs to be provided to all transmit buffers by a program. If network management is required, the host has to set the PPIT bit in the header section of the respective message buffer to ‘1’ and write the network management information to the data section of the message buffer (see **Section 17.3.7, Network Management**).

The payload length field configures the payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by

FLXA0FRMHDC.SFDL, the CC generates padding bytes to ensure that frames have proper physical length. The padding pattern is "0000_H".

NOTE

In case of an odd payload length (PLC = 1,3,5,...), the application has to write zero to the last 16 bit of the message buffers data section to ensure that the padding pattern is "0000_H".

Each transmit buffer provides a transmission mode flag TXM that allows the host to configure the transmission mode for the transmit buffer. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode.

In single-shot mode the CC resets the respective TXR flag to '0' after transmission has completed. Now the host may update the transmit buffer.

In continuous mode, the CC does not reset the respective transmission request flag TXR to '0' after successful transmission. In this case a frame is sent out each time the filter criteria match. The TXR flag can be reset to '0' by the host by writing the respective message buffer number to the FLXA0FRIBCR register while bit FLXA0FRIBCM.STXRH is set to '0'.

If two or more transmit buffers meet the filter criteria simultaneously, the transmit buffer with the lowest message buffer number will be transmitted in the respective slot.

17.3.9.4 Frame Transmission

The following steps are required to prepare a message buffer for transmission:

- Configure the transmit buffer in the message RAM via FLXA0FRWRHS1, FLXA0FRWRHS2, and FLXA0FRWRHS3
- Write the data section of the transmit buffer via FLXA0FRWRDSn
- Transfer the configuration and message data from input buffer to the message RAM by writing the number of the target message buffer to register FLXA0FRIBCR
- If configured in register FLXA0FRIBCM, the transmission request flag TXR for the respective message buffer will be set as soon as the transfer has completed, and the message buffer is ready for transmission.
- Check whether the message buffer has been transmitted by checking the respective TXR bit (TXR = '0') in the FLXA0FRTXRQ1/2/3/4 registers (single-shot mode only).

After transmission has completed, the respective TXR flag in the FLXA0FRTXRQ1/2/3/4 register is reset to '0' (single-shot mode), and, if bit MBI in the header section of the message buffer is set to '1', flag FLXA0FRSIR.TXI is set to '1'. If enabled, an interrupt is generated.

17.3.9.5 Null Frame Transmission

If in static segment the host does not set the transmission request flag to ‘1’ before transmit time, the CC transmits a null frame with the null frame indication bit set to '0' and the payload data set to zero.

In the following cases the CC transmits a null frame:

- If the message buffer with the lowest message buffer number matching the filter criteria does not have its transmission request flag set to ‘1’(TXR = ‘0’) .
- No transmit buffer configured for the slot has a cycle counter filter that matches the current cycle. In this case, no message buffer status FLXA0FRMBS is updated.

Null frames are not transmitted in the dynamic segment.

17.3.10 Receive Process

17.3.10.1 Dedicated Receive Buffers

Some FlexRay message buffers can be configured as dedicated receive buffers by programming bit CFG in the header section of the respective message buffer to ‘0’ via FLXA0FRWRHS1.

The following possibilities exist to assign a receive buffer to the CC channels:

- Static segment: channel A or channel B,
  channel A and channel B (the CC stores the first semantically valid frame)
- Dynamic segment: channel A or channel B

The CC transfers the payload data of valid received messages from the shift register of the FlexRay channel protocol controller (channel A or B) to the receive buffer with the matching filter configuration. A receive buffer stores all frame elements except the frame CRC.

All message buffers configured for reception in static or dynamic segment are reconfigurable during runtime depending on the configuration of FLXA0FRMRC.SEC (see **Section 17.3.12.1, Reconfiguration of Message Buffers**). If a message buffer is reconfigured (header section updated) during runtime, it may happen that in the respective communication cycle a received message is lost.

If two or more receive buffers meet the filter criteria simultaneously, the receive buffer with the lowest message buffer number is updated with the received message.

17.3.10.2 Frame Reception

The following steps are required to prepare a dedicated message buffer for reception:

- Configure the receive buffer in the message RAM via FLXA0FRWRHS1, FLXA0FRWRHS2, and FLXA0FRWRHS3
- Transfer the configuration from input buffer to the message RAM by writing the number of the target message buffer to register FLXA0FRIBCR

Once these steps are performed, the message buffer functions as an active receive buffer and participates in the internal acceptance filtering process which takes place every time the CC receives a message. The first matching receive buffer is updated from the received message.

If a valid payload segment was stored in the data section of a message buffer, the respective ND flag in the FLXA0FRNDAT1/2/3/4 registers is set to ‘1’, and, if bit MBI in the header section of that message buffer is set to ‘1’, flag FLXA0FRSIR.RXI is set to ‘1’. If enabled, an interrupt is generated.

In case that bit ND was already set to ‘1’ when the message handler updates the message buffer, bit FLXA0FRMBS.MLST of the respective message buffer is set to ‘1’ and the unprocessed message data is lost.

If a frame was not received, or if a null frame or a corrupted frame was received in a slot, the data section of the message buffer configured for this slot is not updated. In this case only the respective message buffer status FLXA0FRMBS is updated.

When the message handler changed the message buffer status FLXA0FRMBS in the header section of a message buffer, the respective MBC flag in the FLXA0FRMBSC1/2/3/4 registers is set to ‘1’, and if bit MBI in the header section of that message buffer is set, flag FLXA0FRSIR.MBSI is set to ‘1’. If enabled an interrupt is generated.

If the payload length of a received frame PLR is longer than the value programmed by PLC in the header section of the respective message buffer, the data field stored in the message buffer is truncated to that length.

To read a receive buffer from the message RAM via the output buffer, proceed as described in **Section 17.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

NOTE

The ND and MBC flags are automatically cleared by the message handler when the payload data and the header of a received message have been transferred to the output buffer, respectively.

17.3.10.3 Null Frame Reception

The payload segment of a received null frame is not copied into the matching dedicated receive buffer. If a null frame has been received, only the message buffer status FLXA0FRMBS of the matching message buffer is updated from the received null frame. All bits in header 2 and 3 of the matching message buffer remain unchanged. They are updated from received data frames only.

When the message handler changed the message buffer status FLXA0FRMBS in the header section of a message buffer, the respective MBC flag in the FLXA0FRMBSC1/2/3/4 register is set to ‘1’, and if bit MBI in the header section of that message buffer is set to ‘1’, flag FLXA0FRSIR.MBSI is set to ‘1’. If enabled, an interrupt is generated.

17.3.11 FIFO Function

17.3.11.1 Description

Some message buffers can be configured as a cyclic First-In-First-Out (FIFO) buffer. The group of message buffers belonging to the FIFO is contiguous in the register map starting with the message buffer referenced by FLXA0FRMRC.FFB and ending with the message buffer referenced by FLXA0FRMRC.LCB. Up to 127 message buffers can be assigned to the FIFO.

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case, frame ID, payload length, receive cycle count, and the message buffer status FLXA0FRMBS of the addressed FIFO message buffer are overwritten with frame ID, payload length, receive cycle count, and the status from the received frame. It indicates that the FIFO is not empty when the RFNE flag in the FLXA0FRSIR register is set to '1', the receive FIFO fill level FLXA0FRFSR.RFFL is equal or greater than the critical level configured by FLXA0FRSIR.RFCL bit when FLXA0FRFCL.RFCL bit is 1, and A FIFO overrun has been detected when FLXA0FREIR.RFO is 1, respectively. If enabled, interrupts are generated.

If null frames are not removed by the FIFO rejection filter, the null frames will be treated like data frames when they are stored into the FIFO.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received, it is written into the message buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available message buffer. If the PIDX register is incremented past the highest numbered message buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) message buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next message buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a message buffer belonging to the FIFO to the output buffer. The PUT Index Register and the GET Index Register are not accessible by the host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message overwrites the oldest message in the FIFO. This will set FIFO overrun flag FLXA0FREIR.RFO to ‘1’.

When the PUT index (PIDX) differs from the GET index (GIDX), it indicates that the FIFO is not empty. In this case flag FLXA0FRSIR.RFNE is set to ‘1’. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in **Figure 17.11** for a three message buffer FIFO.

The programmable FlexRay FIFO Rejection Filter (FLXA0FRFRF) defines a filter pattern for messages to be rejected. The FIFO filter consists of channel filter, frame ID filter, and cycle counter filter. If bit FLXA0FRFRF.RSS is set to ‘1’, all messages received in the static segment are rejected by the FIFO. If bit FLXA0FRFRF.RNF is set to ‘1’, received null frames are not stored in the FIFO.

The FlexRay FIFO Rejection Filter Mask (FLXA0FRFRFM) specifies which bits of the frame ID filter in the FIFO Rejection Filter register are marked 'don't care' for rejection filtering.

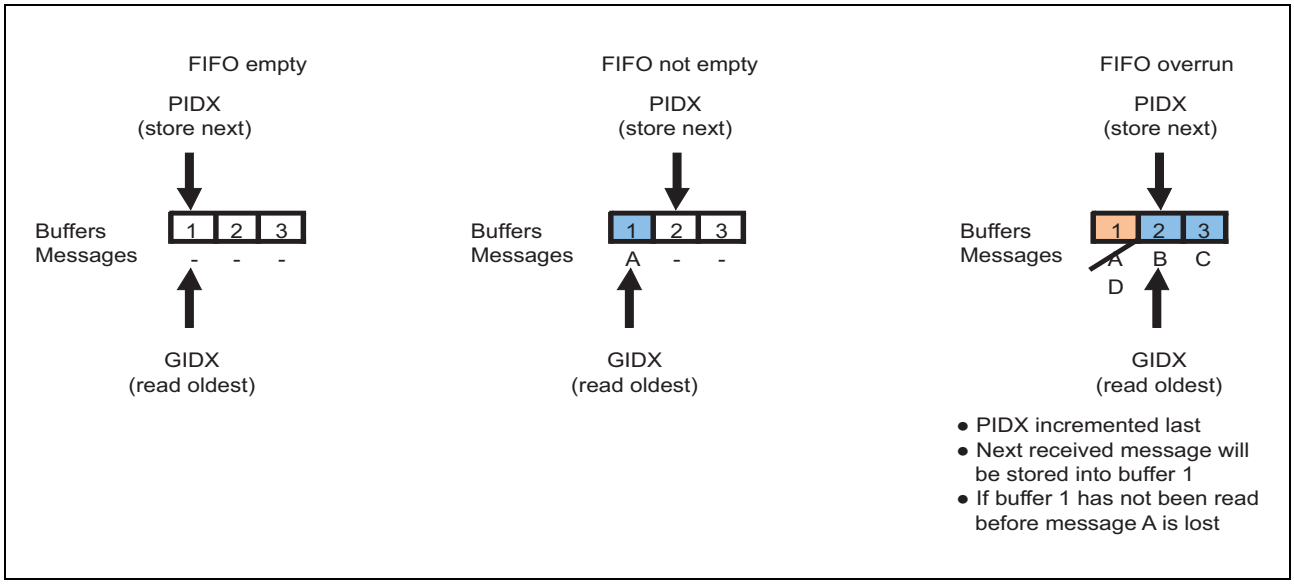

Figure 17.11 FIFO Status: Empty, Not Empty, Overrun

17.3.11.2 Configuration of the FIFO

(Re)configuration of message buffers belonging to the FIFO is only possible when the CC is in DEFAULT_CONFIG or CONFIG state. While the CC is in DEFAULT_CONFIG or CONFIG state, the FIFO function is not available.

For all message buffers belonging to the FIFO the payload length configured need to be programmed to the same value via FLXA0FRWRHS2.PLC. The data pointer to the first 32-bit word of the data section of the respective message buffer in the message RAM has to be configured via FLXA0FRWRHS3.DP.

All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask registers. The values configured in the header sections of the message buffers belonging to the FIFO, with exception of DP and PLC, have no meaning.

NOTES

1. It is recommended to program the MBI bits of the message buffers belonging to the FIFO to ‘0’ via FLXA0FRWRHS1.MBI to avoid generation of RX interrupts.
2. If the payload length of a received frame is longer than the value programmed by FLXA0FRWRHS2.PLC in the header section of the respective message buffer, the data field stored in a message buffer of the FIFO is truncated to that length.

17.3.11.3 Access to the FIFO

(1) When the output buffer is used:

For FIFO access outside DEFAULT_CONFIG and CONFIG state, the host has to trigger a transfer from the message RAM to the output buffer by writing the number of the first message buffer of the FIFO (referenced by FLXA0FRMRC.FFB) to the register FLXA0FROBCR. The message handler then transfers the message buffer addressed by the GET index register (GIDX) to the output buffer. After this transfer the GET index register (GIDX) is incremented.

(2) When the data transfer function is used:

The message received in FIFO can be transferred to the local RAM/global RAM by using the output data transfer function. For the output data transfer function, see **Section 17.3.16.2, Output Data Transfer**.

17.3.12 Message Handling

The message handler controls data transfers between the input/output buffer and the message RAM and between the message RAM and the two temporary buffers.

Access to the message buffers stored in the message RAM is done under control of the message Handler state machine. This avoids conflicts between accesses of the two FlexRay channel protocol controllers and the host to the message RAM.

Frame IDs of message buffers assigned to the static segment have to be in the range from 1 to FLXA0FRGTUC7.NSS. Frame IDs of message buffers assigned to the dynamic segment have to be in the range from FLXA0FRGTUC7.NSS + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

Access of the host to the message buffer contents using the input or output buffer function is described in this subsection. Access to the message buffer contents using the data transfer function is mentioned in **Section 17.3.16, Usage of Data Transfer**.

17.3.12.1 Reconfiguration of Message Buffers

In case that an application needs to handle with more than 128 different messages, static and dynamic message buffers can be reconfigured during FlexRay operation. This is done by updating the header section of the respective message buffer via input buffer registers FLXA0FRWRHS1…3.

Reconfiguration has to be enabled via control bits FLXA0FRMRC.SEC in the message RAM Configuration register.

If a message buffer has not been transmitted/updated from a received frame before reconfiguration starts, the respective message is lost.

The point in time when a reconfigured message buffer is ready for transmission/reception according to the reconfigured frame ID depends on the actual state of the slot counter when the update of the header section has completed. Therefore it may happen that a reconfigured message buffer is not transmitted/updated from a received frame in the cycle where it was reconfigured.

The message RAM is scanned according to **Table 17.95** below.

Table 17.95 Scan of Message RAM

Start of Scan in Slot	Scan for Slots
1	2…15, 1 (next cycle)
8	16…23, 1 (next cycle)
16	24…31, 1 (next cycle)
24	32…39, 1 (next cycle)
…	…

A message RAM scan is terminated with the start of NIT regardless whether it has completed or not. The scan of the message RAM for slots 2 to 15 starts at the beginning of slot 1 of the actual cycle. The scan of the message RAM for slot 1 is done in the cycle before by checking in parallel to each scan of the message RAM whether there is a message buffer configured for slot 1 of the next cycle.

The number of the first dynamic message buffer is configured by FLXA0FRMRC.FDB. In case a message RAM scan starts while the CC is in dynamic segment, the scan starts with the message buffer number configured by FLXA0FRMRC.FDB.

In case a message buffer should be reconfigured to be used in slot 1 of the next cycle, the followings have to be considered:

- If the message buffer to be reconfigured for slot 1 is part of the “Static Buffers”, it will only be detected if it is reconfigured before the last message RAM scan in the static segment of the actual cycle evaluates this message buffer.
- If the message buffer to be reconfigured for slot 1 is part of the “Static + Dynamic Buffers”, it will be detected if it is reconfigured before the last message RAM scan in the actual cycle evaluates this message buffer.
- The start of NIT terminates the message RAM scan. In case the message RAM scan has not evaluated the reconfigured message buffer by this point in time, the message buffer will not be considered for the next cycle.

NOTE

Reconfiguration of message buffers may lead to the loss of messages and therefore has to be performed very carefully. In the worst case (reconfiguration in consecutive cycles), a message buffer may never be transmitted or may not be updated from a received frame.

17.3.12.2 Host Access to Message RAM

The message transfer between input buffer and message RAM as well as between message RAM and output buffer is triggered by the host by writing the number of the target and source message buffer to be accessed to FLXA0FRIBCR or FLXA0FROBCR register.

The FLXA0FRIBCM and FLXA0FROBCM registers can be used to write/read header and data section of the selected message buffer separately.

If bit FLXA0FRIBCM.STXR is set to = '1', the transmission request flag TXR of the selected message buffer is automatically set to '1' after the message buffer has been updated. If bit FLXA0FRIBCM.STXR is reset to '0', the transmission request flag TXR of the selected message buffer is reset. This can be used to stop transmission from message buffers operated in continuous mode.

Input buffer (IBF) and output buffer (OBF) are built up as a double buffer structure. One half of this double buffer structure is accessible by the host (IBF host or OBF host), while the other half (IBF shadow or OBF shadow) is accessed by the message handler for data transfers between IBF/OBF and message RAM.

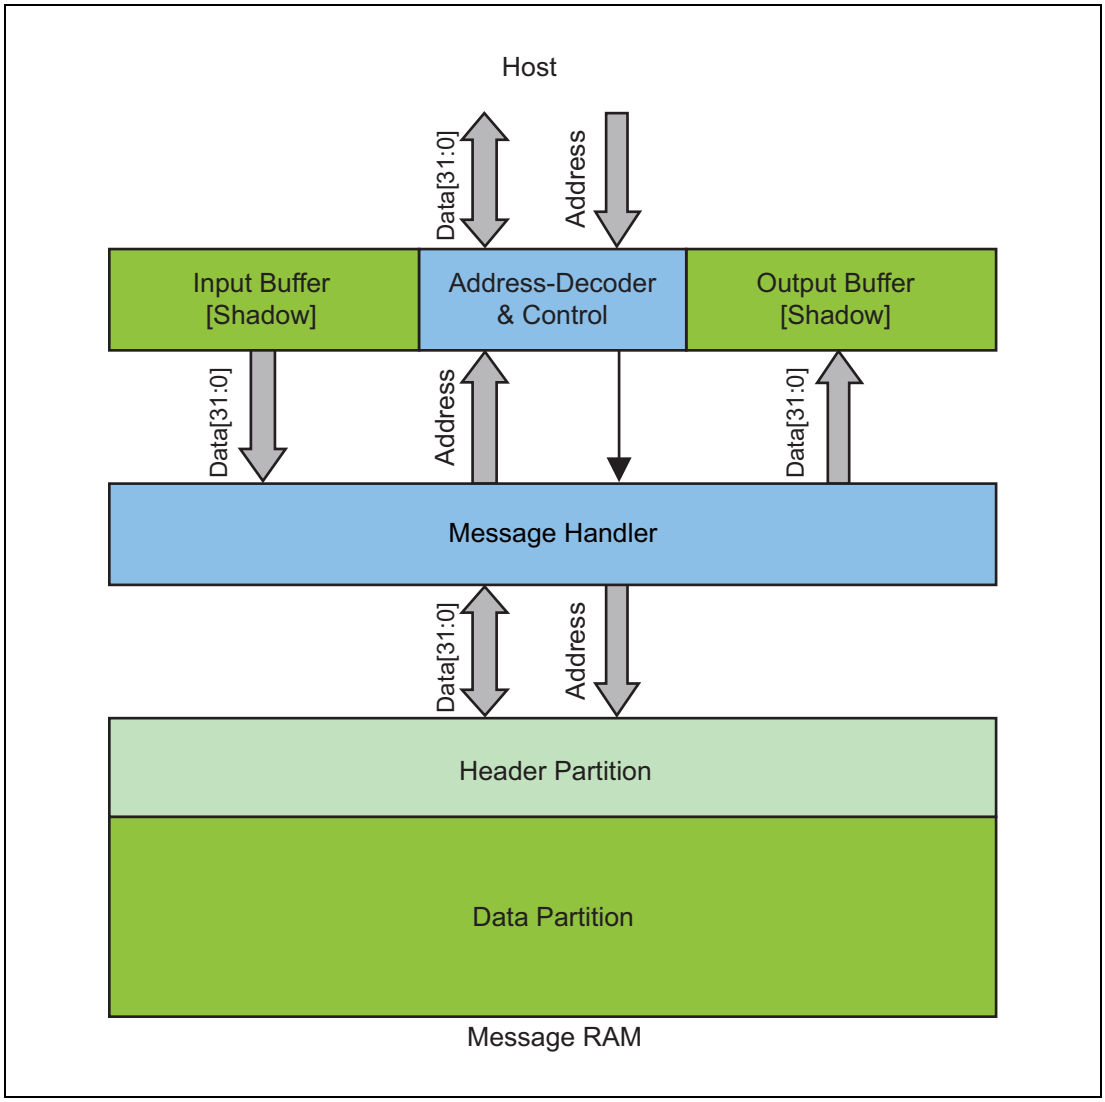

Figure 17.12 Host Access to Message RAM

(1) Data Transfer from Input Buffer to Message RAM

To configure or update a message buffer in the message RAM, the host has to write the data to FLXA0FRWRDSn and the header to FLXA0FRWRHS1…3. The specific action is selected by configuring the FlexRay input buffer command mask register FLXA0FRIBCM.

When the host writes the number of the target message buffer in the message RAM to FLXA0FRIBCR.IBRH, IBF host and IBF shadow are switched (see **Figure 17.13**).

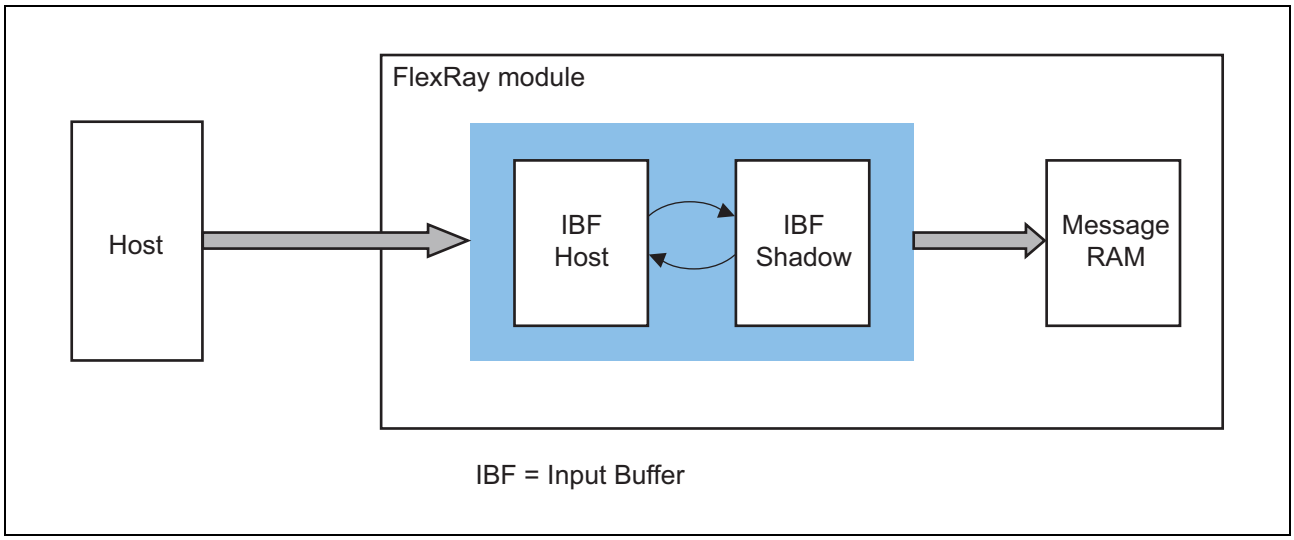

Figure 17.13 Double Buffer Structure Input Buffer

In addition the bits in the FLXA0FRIBCM and FLXA0FRIBCR registers are also switched while they hold the value in each IBF section (see **Figure 17.14**).

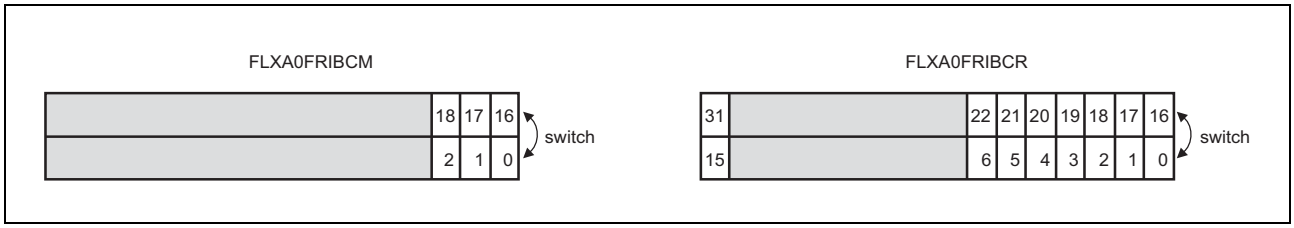

Figure 17.14 Switching of FLXA0FRIBCM and FLXA0FRIBCR Bits

With this write operation, bit FLXA0FRIBCR.IBSYS is set to ‘1’. The message handler then starts to transfer the contents of IBF shadow to the message buffer in the message RAM selected by FLXA0FRIBCR.IBRS.

While the message handler transfers the data from IBF shadow to the target message buffer in the message RAM, the host can write the next message to IBF host. After the transfer between IBF shadow and the message RAM has completed, bit FLXA0FRIBCR.IBSYS is set back to ‘0’ and the next transfer to the message RAM may be started by the host by writing the respective target message buffer number to FLXA0FRIBCR.IBRH.

If a write access to FLXA0FRIBCR.IBRH is made while FLXA0FRIBCR.IBSYS is ‘1’, FLXA0FRIBCR.IBSYH is set to ‘1’. After completion of the ongoing data transfer from IBF shadow to the message RAM, IBF host and IBF shadow are switched, FLXA0FRIBCR.IBSYH is reset to ‘0’, FLXA0FRIBCR.IBSYS remains set to ‘1’, and the next transfer to the message RAM is started. In addition the message buffer numbers stored under FLXA0FRIBCR.IBRH and FLXA0FRIBCR.IBRS and the command mask flags are also switched.

Example of an 8/16/32-bit host access sequence:

Configure or update n-th message buffer via IBF

- Wait until FLXA0FRIBCR.IBSYH is reset
- Write data section to FLXA0FRWRDSn
- Write header section to FLXA0FRWRHS1…3
- Write command mask: set FLXA0FRIBCM.STXRH, FLXA0FRIBCM.LDSH, FLXA0FRIBCM.LHSH
- Demand data transfer to target message buffer: write FLXA0FRIBCR.IBRH

Configure or update (n + 1)th message buffer via IBF

- Wait until FLXA0FRIBCR.IBSYH is reset
- Write data section to FLXA0FRWRDSn
- Write header section to FLXA0FRWRHS1…3
- Write command mask: write FLXA0FRIBCM.STXRH, FLXA0FRIBCM.LDSH, FLXA0FRIBCM.LHSH
- Demand data transfer to target message buffer: write FLXA0FRIBCR.IBRH

NOTE

Any write access to IBF while FLXA0FRIBCR.IBSYH is ‘1’ will set error flag FLXA0FREIR.IIBA to ‘1’. In this case the write access is ignored.

Table 17.96 Assignment of FLXA0FRIBCM Bits

Pos.	Access	Bit	Function
18	r	STXRS	Set Transmission Request Shadow Flag (ongoing or finished)
17	r	LDSS	Load Data Section Shadow Flag (ongoing or finished
16	r	LHSS	Load Header Section Shadow Flag (ongoing or finished)
2	r/w	STXRH	Set Transmission Request Host
1	r/w	LDSH	Load Data Section Host
0	r/w	LHSH	Load Header Section Host

Table 17.97 Assignment of FLXA0FRIBCR Bits

Pos.	Access	Bit	Function
31	r	IBSYS	IBF Busy Shadow Flag, signals ongoing transfer from IBF Shadow to message RAM
22…16	r	IBRS	IBF Request Shadow Flag, number of message buffer currently or lately updated
15	r	IBSYH	IBF Busy Host Flag, transfer request pending for message buffer referenced by IBRH
6…0	r/w	IBRH	IBF Request Host, number of message buffer to be updated next

(2) Data Transfer from Message RAM to Output Buffer

To read a message buffer from the message RAM, the host has to write to register FLXA0FROBCR to trigger the data transfer as configured in FLXA0FROBCM. After the transfer has completed, the host can read the transferred data from FLXA0FRRDDSn, FLXA0FRRDHS1…3, and FLXA0FRMBS.

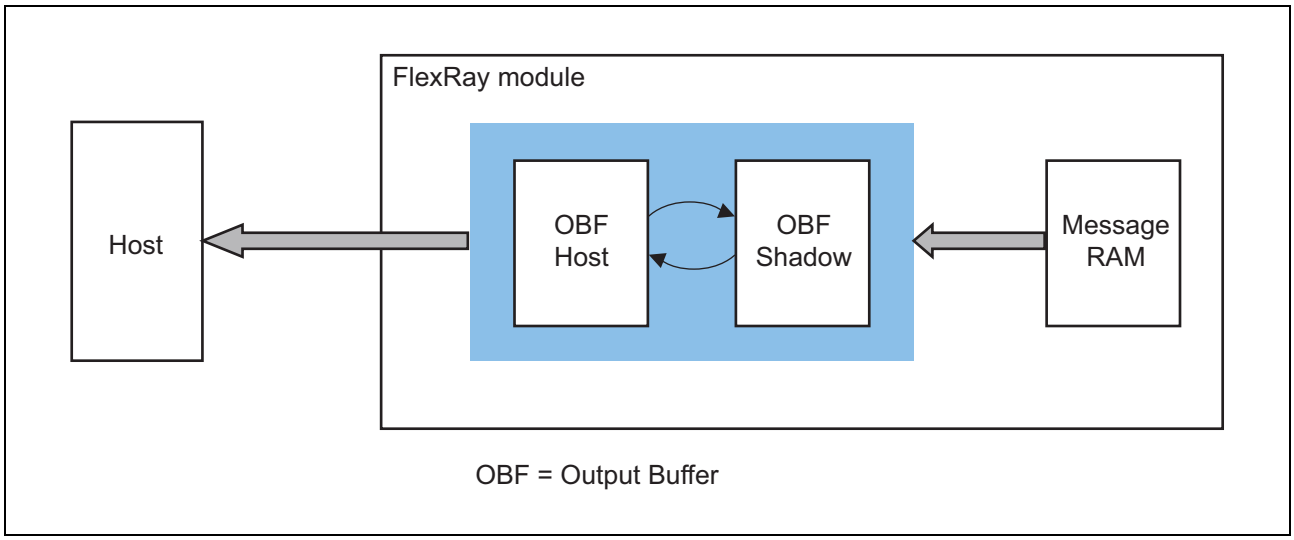

Figure 17.15 Double Buffer Structure Output Buffer

OBF host and OBF shadow as well as bits FLXA0FROBCM.RHSS, FLXA0FROBCM.RDSS, FLXA0FROBCM.RHSH, FLXA0FROBCM.RDSH and bits FLXA0FROBCR.OBRS, FLXA0FROBCR.OBRH are switched under control of bits FLXA0FROBCR.VIEW and FLXA0FROBCR.REQ.

Writing bit FLXA0FROBCR.REQ to ‘1’ copies bits FLXA0FROBCM.RHSS, FLXA0FROBCM.RDSS and bits FLXA0FROBCR.OBRS to an internal memory (see **Figure 17.16**).

After setting FLXA0FROBCR.REQ to ‘1’, FLXA0FROBCR.OBSYS is set to ‘1’, and the transfer of the message buffer selected by FLXA0FROBCR.OBRS from the message RAM to OBF shadow is started. After the transfer between the message RAM and OBF shadow has completed, the FLXA0FROBCR.OBSYS bit is set back to ‘0’. Bits FLXA0FROBCR.REQ and FLXA0FROBCR.VIEW can only be set to ‘1’ while FLXA0FROBCR.OBSYS is ‘0’.

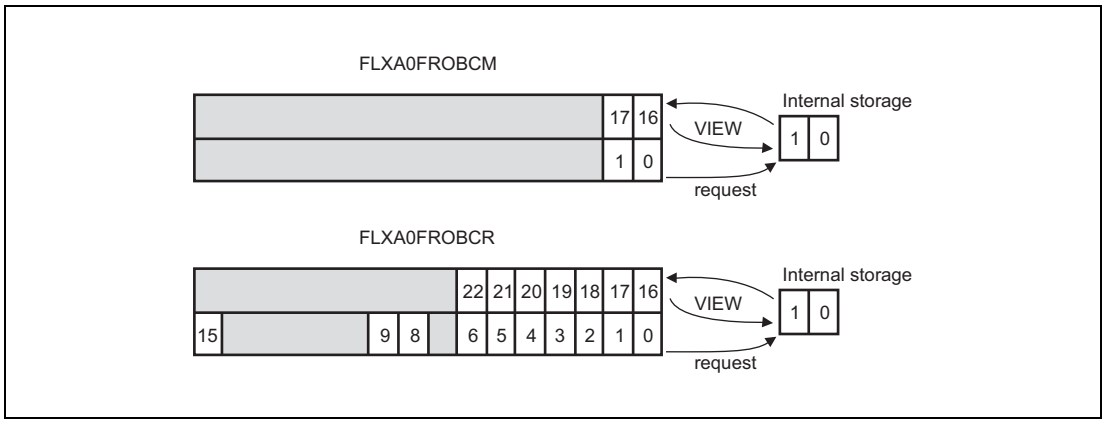

Figure 17.16 Switching of FLXA0FROBCM and FLXA0FROBCR Bits

OBF host and OBF shadow are switched by setting bit FLXA0FROBCR.VIEW to ‘1’ while bit FLXA0FROBCR.OBSYS is ‘0’ (see **Figure 17.15**).

In addition bits FLXA0FROBCR.OBRH and bits FLXA0FROBCM.RHSH, FLXA0FROBCM.RDSH are switched with the registers internal memory thus assuring that the message buffer number stored in FLXA0FROBCR.OBRH and the mask configuration stored in FLXA0FROBCM.RHSH, FLXA0FROBCM.RDSH matches the transferred data stored in OBF host (see **Figure 17.16**).

Now the host can read the transferred message buffer from OBF host while the message handler transfers the next message from the message RAM to OBF shadow.

If bits REQ and VIEW are set to ‘1’ with the same write access while FLXA0FROBSYS is ‘0’, FLXA0FROBSYS is automatically set to ‘1’ and OBF shadow and OBF host are switched. Additionally mask bits FLXA0FROBCM.RDSH and FLXA0FROBCM.RHSH are switched with the registers internal storage to keep them attached to the respective output buffer transfer. Afterwards FLXA0FROBCR.OBRS is copied to the register internal storage, mask bits FLXA0FROBCM.RDSS and FLXA0FROBCM.RHSS are copied to register FLXA0FROBCM internal memory, and the transfer of the selected message buffer from the message RAM to OBF shadow is started. While the transfer is ongoing the host can read the message buffer transferred by the previous transfer from OBF host. When the current transfer between message RAM and OBF shadow has completed, completion of the transfer is notified by setting FLXA0FROBCR.OBSYS back to ‘0’.

Example of an 8/16/32-bit host access to a single message buffer:

If a single message buffer has to be read out, two separate write accesses to FLXA0FROBCR.REQ and FLXA0FROBCR.VIEW are necessary:

- Wait until FLXA0FROBCR.OBSYS is reset
- Write output buffer command mask FLXA0FROBCM.RHSS, FLXA0FROBCM.RDSS
- Request transfer of message buffer to OBF shadow by writing FLXA0FROBCR.OBRS and FLXA0FROBCR.REQ (in case of and 8-bit host interface, FLXA0FROBCR.OBRS has to be written before FLXA0FROBCR.REQ).
- Wait until FLXA0FROBCR.OBSYS is reset
- Toggle OBF shadow and OBF host by writing FLXA0FROBCR.VIEW = ‘1’
- Read out transferred message buffer by reading FLXA0FRRDDSn, FLXA0FRRDHS1…3, and FLXA0FRMBS

Example of an 8/16/32-bit host access sequence:

Request transfer of 1st message buffer to OBF shadow

- Wait until FLXA0FROBCR.OBSYS is reset
- Write output buffer command mask FLXA0FROBCM.RHSS, FLXA0FROBCM.RDSS for 1st message buffer
- Request transfer of 1st message buffer to OBF shadow by writing FLXA0FROBCR.OBRS and FLXA0FROBCR.REQ (in case of an 8-bit host interface, FLXA0FROBCR.OBRS has to be written before FLXA0FROBCR.REQ).

Toggle OBF shadow and OBF host to read out 1st transferred message buffer and request transfer of 2nd message buffer:

- Wait until FLXA0FROBCR.OBSYS is reset to ‘0’

- Write output buffer command mask FLXA0FROBCM.RHSS, FLXA0FROBCM.RDSS for 2nd message buffer
- Toggle OBF shadow and OBF host and start transfer of 2nd message buffer to OBF shadow simultaneously by writing FLXA0FROBCR.OBRS of 2nd message buffer, FLXA0FROBCR.REQ, and FLXA0FROBCR.VIEW (in case of and 8-bit host interface, FLXA0FROBCR.OBRS has to be written before FLXA0FROBCR.REQ and FLXA0FROBCR.VIEW).
- Read out 1st transferred message buffer by reading FLXA0FRRDDSn, FLXA0FRRDHS1…3, and FLXA0FRMBS

…

Demand access to last requested message buffer without a request of another message buffer:

- Wait until FLXA0FROBCR.OBSYS is reset to ‘0’
- Demand access to last transferred message buffer by writing FLXA0FROBCR.VIEW
- Read out last transferred message buffer by reading FLXA0FRRDDSn, FLXA0FRRDHS1…3, and FLXA0FRMBS

Table 17.98 Assignment of FLXA0FROBCM Bits

Pos.	Access	Bit	Function
17	r	RDSH	Data Section Accessible
16	r	RHSH	Header Section Accessible
1	r/w	RDSS	Read Data Section Shadow
0	r/w	RHSS	Read Header Section Shadow

Table 17.99 Assignment of FLXA0FROBCR Bits

Pos.	Access	Bit	Function
22…16	r	OBRH	OBF Host Transfer Request Flag, number of message buffer accessible
15	r	OBSYS	OBF Busy Shadow Flag, signals ongoing transfer from message RAM to OBF shadow
9	r/w	REQ	Request transfer from message RAM to OBF shadow
8	r/w	VIEW	View OBF Shadow, swap OBF shadow and OBF host
6…0	r/w	OBRS	OBF Request Shadow, number of message buffer for next request

17.3.12.3 FlexRay Protocol Controller Access to Message RAM

The two temporary buffers (TBF A and TBF B) are used to buffer the data for transfer between the two FlexRay protocol controllers and the message RAM.

Each temporary buffer is build up as a double buffer, and able to store two complete FlexRay messages. There is always one buffer assigned to the corresponding protocol controller while the other one is accessible by the message handler.

If e.g. the message handler writes the next message to be sent to temporary buffer Tx, the FlexRay channel protocol controller can access temporary buffer Rx to store the message it is actually receiving. During transmission of the message stored in temporary buffer Tx, the message handler transfers the last received message stored in temporary buffer Rx to the message RAM (if it passes acceptance filtering) and updates the corresponding message buffer.

Data transfers between the temporary buffers and the shift registers of the FlexRay channel protocol controllers are done in words of 32 bit. This enables the use of a 32 bit shift register regardless of the length of the FlexRay messages.

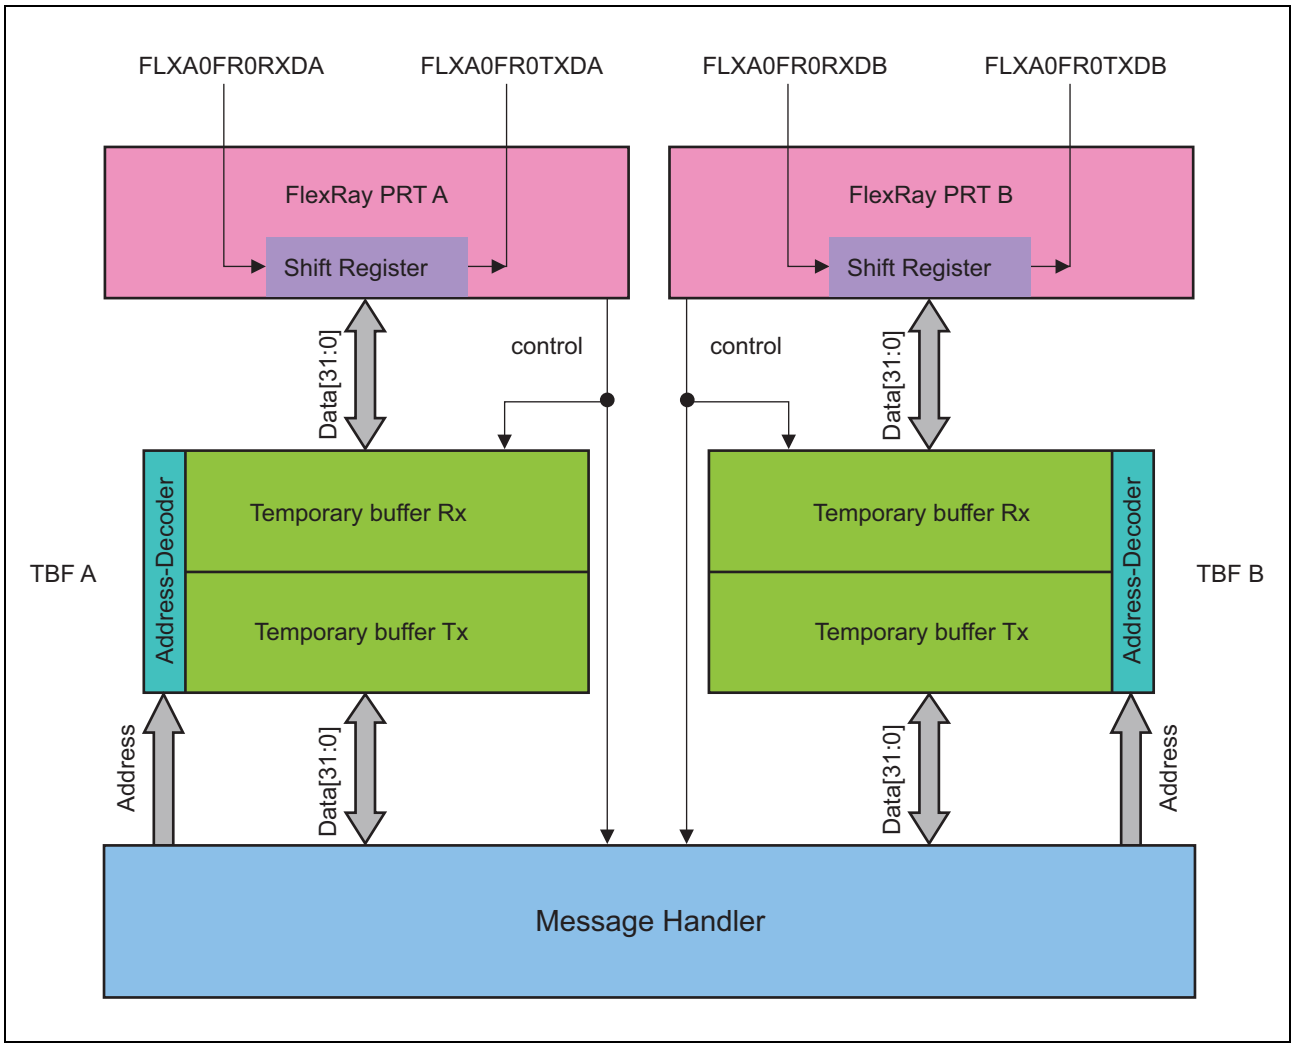

Figure 17.17 Access to Temporary Buffers

17.3.13 Message RAM

To avoid conflicts between host access to the message RAM and FlexRay message reception/ transmission, the host cannot directly access the message buffers in the message RAM. These accesses are handled via the input and output buffers. The Message RAM is able to store up to 128 message buffers depending on the configured payload length.

The message RAM is able to store up to 2048 32-bit words. To achieve the required flexibility with respect to different numbers of data bytes per FlexRay frame (0…254), the message RAM has a structure as shown in **Figure 17.18**.

When the message buffer of the data section to be allocated after the header partition is set as a reception buffer (by setting the FLXAnFRWRHS1.CFG bit to 0) or as a reception FIFO buffer, set an unused area of at least 32 bits at the start of the data section. In this case, the data partition can be started from the nth word in the message RAM where n calculated from (the setting of the FLXAnFRMRC.LCB[7:0] bits + 1) × 4 + 1.

When the message buffer of the data section to be allocated after the header partition is set as a transmission buffer (by setting the FLXAnFRWRHS1.CFG bit to 1), the data partition can be started from the nth word in the message RAM where n calculated from (the setting of the FLXAnFRMRC.LCB[7:0] bits + 1) × 4.

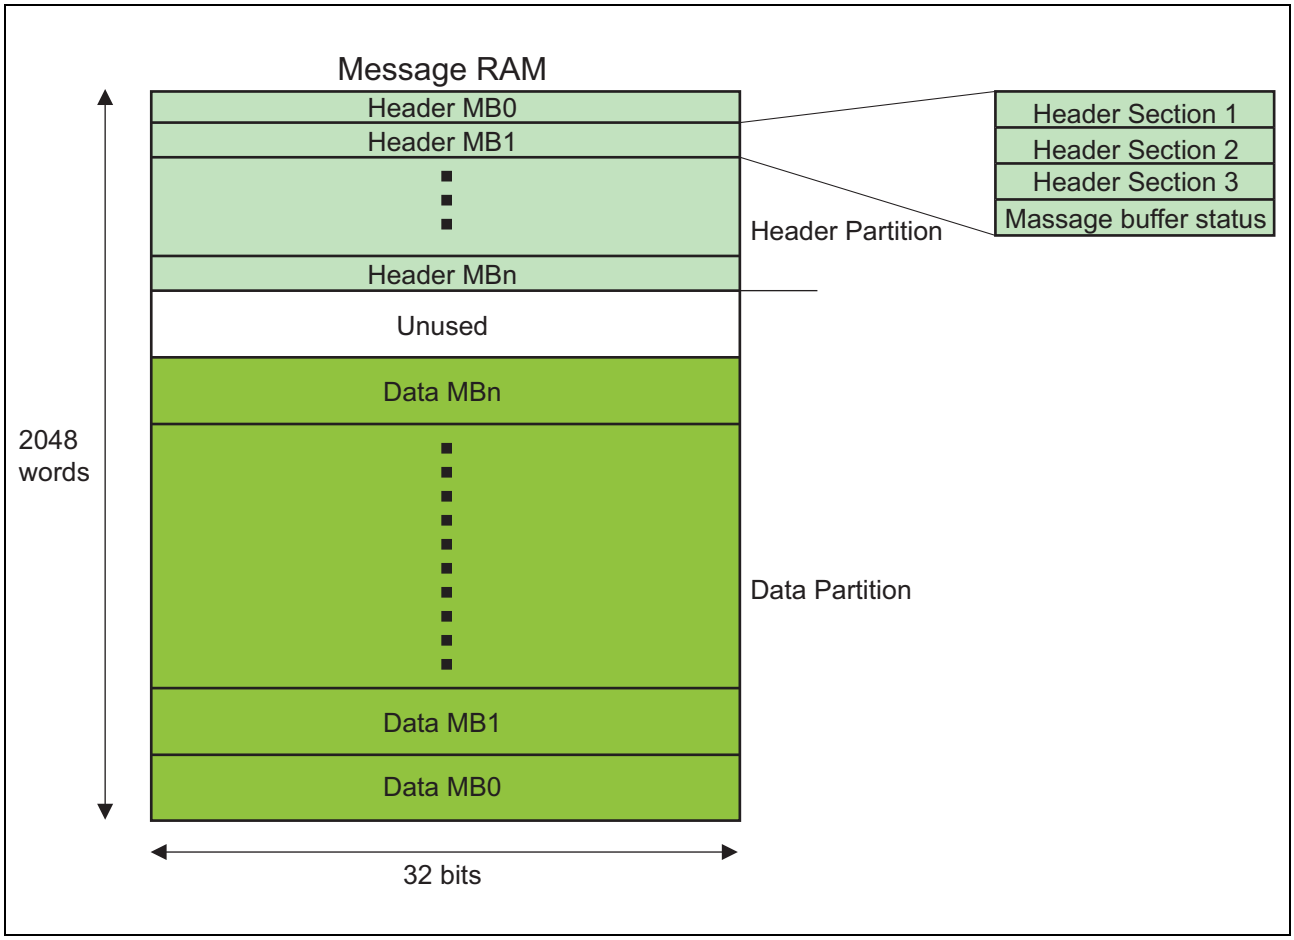

Figure 17.18 Configuration Example of Message Buffers in the Message RAM

Header Partition

Stores header sections of the configured message buffers:

- Supports a maximum of 128 message buffers
- Each message buffer has a header section of four 32-bit words
- Header 3 of each message buffer holds the 11-bit data pointer to the respective data section in the data partition

Data Partition

Flexible storage of data sections with different length. Some maximum values are:

- 30 message buffers with 254 byte data section each
- Or 56 message buffers with 128 byte data section each
- Or 128 message buffers with 48 byte data section each

NOTE

The total size of the header partition and data partition must be set less than 2048 32-bit words.

17.3.13.1 Header Partition

The elements used for configuration of a message buffer as well as the actual message buffer status are stored in the header partition of the message RAM as listed in **Table 17.100** below. Configuration of the header sections of the message buffers is done via IBF (FLXA0FRWRHS1…3). Read access to the header sections is done via OBF (FLXA0FRRDHS1…3 + FLXA0FRMBS). The data pointer has to be calculated to define the starting point of the data section for the corresponding message buffer in the data partition of the message RAM. The data pointer should not be modified during runtime. For message buffers belonging to the receive FIFO (re)configuration is possible in DEFAULT_CONFIG or CONFIG state only.

The header section of each message buffer occupies four 32-bit words in the header partition of the message RAM. The header of message buffer 0 starts with the first word in the message RAM.

For transmit buffers the Header CRC has to be calculated by the host.

The followings are updated from received valid data frames only:
Payload Length Received (PLR bit), Receive Cycle Count (RCC bit), Received on Channel Indicator (RCI bit), Startup Frame Indicator (SFI bit), Sync Frame Indicator (SYN bit), Null Frame Indicator (NFI bit), Payload Preamble Indicator (PPI bit), and Reserved Bit (RES).

17.3.13.2 Data Partition

The data partition of the message RAM stores the data sections of the message buffers configured for reception/transmission as defined in the header partition. The number of data bytes for each message buffer can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay protocol controllers and the message RAM as well as between the host interface and the message RAM, the physical width of the message RAM is set to 4 bytes.

The data partition starts after the last word of the header partition. When configuring the message buffers in the message RAM the programmer has to assure that the data pointers point to addresses within the data partition. **Table 17.101** below shows an example how the data sections of the configured message buffers can be stored in the data partition of the message RAM.

The beginning and the end of a message buffer's data section is determined by the data pointer and the payload length configured in the message buffer's header section, respectively. This enables a flexible usage of the available RAM space for storage of message buffers with different data length.

If the size of the data section is an odd number of 2-byte words, the remaining 16 bits in the last 32-bit word are unused (see **Table 17.101** below).

Table 17.101 Example for Structure of the Data Partition in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

17.3.13.3 Message Data Integrity Check

A data integrity checking mechanism is implemented in the FlexRay core to assure the integrity of the data stored in the related RAM. Each RAM has a checksum generator and checker attached as shown in **Figure 17.19**.

When data is written to a RAM, the local checksum generator generates the checksum. The checksum is stored together with the respective data word. The checksum is checked each time a data word is read from a RAM.

If a checksum error is detected, the respective access error flag is set. The access error flags FLXA0FRMHDS.AMR, FLXA0FRMHDS.ATBF1, FLXA0FRMHDS.ATBF2 and the faulty message buffer indicators FLXA0FRMHDS.FMBD, FLXA0FRMHDS.MFMB, FLXA0FRMHDS.FMB are located in the FlexRay message handler status register. These single access error flags control the error interrupt flag FLXA0FREIR.AERR.

Figure 17.19 shows the data paths between the input buffer, temporary buffer and message RAM.

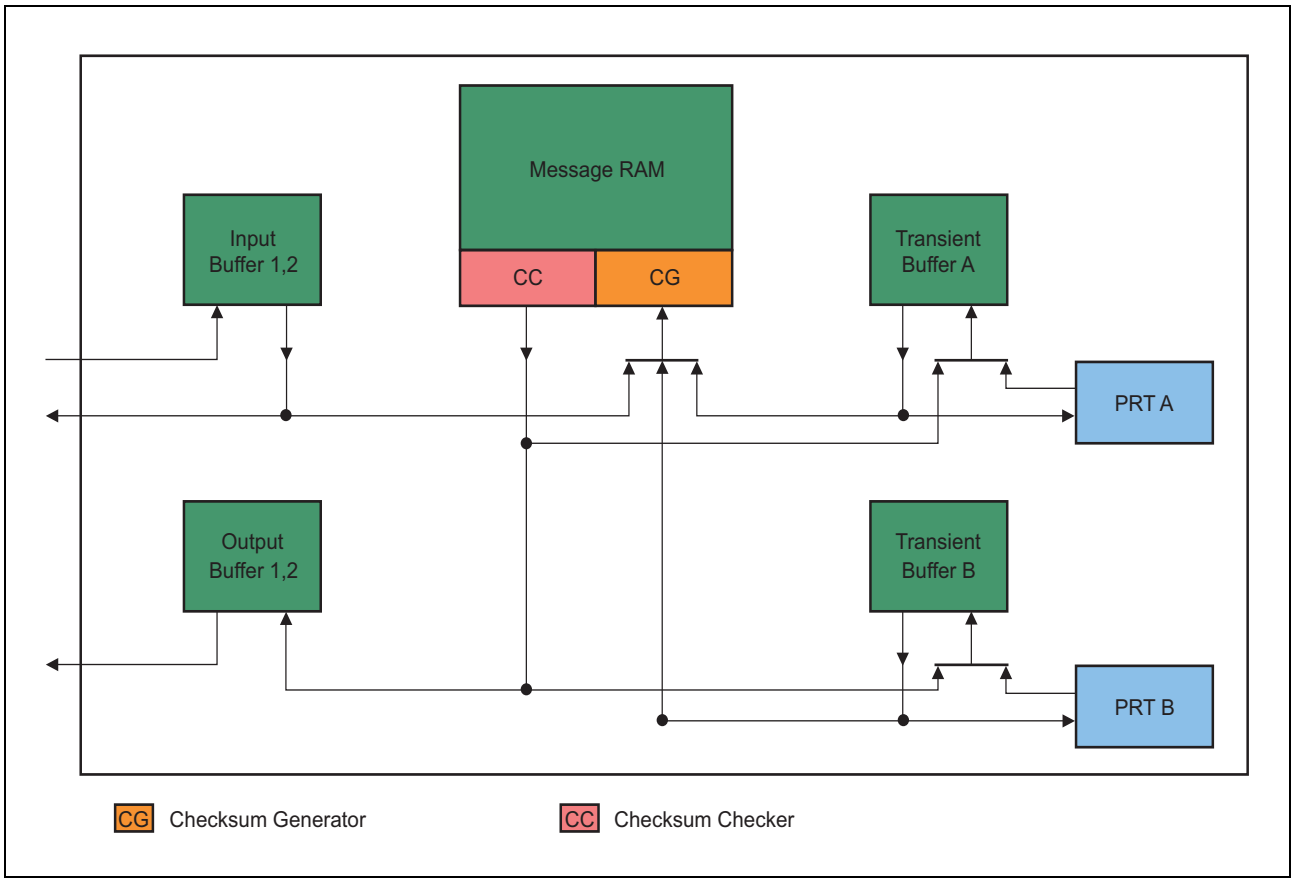

Figure 17.19 Checksum Generation and Check

When an access error has been detected the following actions will be performed:

In all cases:

- The respective access error flag in FLXA0FRMHDS register is set
- The access error flag FLXA0FREIR.AERR is set and, if enabled, a module interrupt to the host will be generated.

Additionally in specific cases:

(1) Access error during data transfer from input buffer 1 or 2 to message RAM when reading header section of respective message buffer from message RAM:

- FLXA0FRMHDS.AMR is set.
- FLXA0FRMHDS.FMBD bit is set to indicate that there is an error in the message buffer to which FLXA0FRMHDS.FMB points.
- FLXA0FRMHDS.FMB indicates the number of the message buffer which has an error.
- The data section of the corresponding message buffer is not updated.
- Transmit buffer: Transmission request for the corresponding message buffer is not set.

(2) Access error during scan of header sections in message RAM:

- FLXA0FRMHDS.AMR is set.
- FLXA0FRMHDS.FMBD bit is set to indicate that there is an error in the message buffer to which FLXA0FRMHDS.FMB points.
- FLXA0FRMHDS.FMB indicates the number of the message buffer which has an error.
- The message buffer is ignored (skipped).

(3) Access error during data transfer from message RAM to temporary buffer 1 or 2:

- FLXA0FRMHDS.AMR is set.
- FLXA0FRMHDS.FMBD bit is set to indicate that there is an error in the message buffer to which FLXA0FRMHDS.FMB points.
- FLXA0FRMHDS.FMB indicates the number of the message buffer which has an error.
- Frame is not transmitted. After the frame CRC is set to 0, the frame which is being transmitted is invalidated.

(4) Access error during data transfer from temporary buffer 1 or 2 to message RAM when reading header section of respective message buffer from message RAM:

- FLXA0FRMHDS.AMR is set.
- FLXA0FRMHDS.FMBD bit is set to indicate that there is an error in the message buffer to which FLXA0FRMHDS.FMB points.
- FLXA0FRMHDS.FMB indicates the number of the message buffer which has an error.
- The data section of the corresponding message buffer is not updated.

(5) Access error during data transfer from message RAM to output buffer:

- The access error flag FLXA0FRMHDS.AMR is set.
- FLXA0FRMHDS.FMBD bit is set to indicate that there is an error in the message buffer to which FLXA0FRMHDS.FMB points.
- FLXA0FRMHDS.FMB indicates the number of the message buffer which has an error.

(6) Access error during a data transfer from temporary buffer 1 or 2 to protocol controller 1 or 2:

- FLXA0FRMHDS.ATBF1 and FLXA0FRMHDS.ATBF2 bits are set.
- After the frame CRC is set to 0, the frame which is being transmitted is invalidated.

(7) Access error during data transfer from temporary buffer 1 or 2 to message RAM when reading temporary buffer 1 or 2:

- FLXA0FRMHDS.ATBF1 and FLXA0FRMHDS.ATBF2 bits are set.
- FLXA0FRMHDS.FMBD bit is set to indicate that there is an error in the message buffer to which FLXA0FRMHDS.FMB points.
- FLXA0FRMHDS.FMB indicates the number of the message buffer which has an error.

(8) Access error during data read of temporary buffer RAM 1 or 2:

- When an access error occurs while the message handler read a frame with network management information (PPI = '1') from temporary buffer RAM 1 or 2, the corresponding network management vector registers FLXA0FRNMV1 to 3 are not updated from this frame.

17.3.13.4 Host Handling of Access Errors

Access error caused by temporary bit flips can be fixed by:

(1) Self-healing

Access errors located in the data section of message RAM, temporary buffer RAM A or temporary buffer RAM B is overwritten with the next write access to the disturbed bit(s) caused by host access or by FlexRay communication.

(2) CLEAR_RAMS Command

The POC command CLEAR_RAMS initializes the message RAM to zero, when called in the DEFAULT_CONFIG or CONFIG state.

(3) Temporary Unlocking of Header Section

An access error in the header section of a locked message buffer can be fixed by a transfer from the input buffer to the locked buffer header section. For this transfer, the write access to the FLXA0FRIBCR (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state (see **Section 17.2.3.1, FLXA0FRLCK — FlexRay Lock Register**).

For that single transfer the message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by FLXA0FRMRC.SEC, and will be updated with new data.

17.3.14 Interrupts

In general, interrupts provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the CC, a frame is received or transmitted, a configured timer interrupt is activated, or a stop watch event occurred. This enables the host to react very quickly on specific error conditions, status changes, or timer events. On the other hand, too many interrupts can cause the host to miss deadlines required by the application. Therefore the CC supports enable and disable controls for each individual interrupt source separately.

An interrupt may be triggered when

- An error was detected
- A status flag is set to '1'
- A timer reaches a configured value
- A message transfer from input buffer to message RAM or from message ram to output buffer has completed
- A message transfer from the local RAM/global RAM to message RAM or from message RAM to local RAM/global RAM has completed
- A stop watch event occurred

Tracking status and generating interrupts when a status change or an error occurs are two independent tasks. Regardless of whether an interrupt is enabled or not, the corresponding status is tracked and indicated by the CC. The host has access to the actual status and error information by reading registers FLXA0FREIR, FLXA0FRSIR, FLXA0FROS, FLXA0FROTS and FLXA0FRITS.

The general purpose interrupt lines to the host, FlexRay Interrupt 0, FlexRay Interrupt 1, are controlled by the enabled interrupts in FLXA0FREIES and FLXA0FRSIES. In addition each of the two interrupt lines can be enabled or disabled separately by programming bit FLXA0FRILE.EINT0 and FLXA0FRILE.EINT1.

The input data transfer interrupt lines to the host, FlexRay input queue empty interrupt, FlexRay input queue full interrupt, are controlled by the enabled interrupts in FLXA0FRITS. In addition each of the input data transfer interrupts can be enabled or disabled separately by programming the related bits in FLXA0FRITC.

The output data transfer interrupt lines to the host, FlexRay FIFO transfer warning interrupt, FlexRay output transfer warning interrupt, FlexRay FIFO transfer interrupt, FlexRay output transfer interrupt, are controlled by the enabled interrupts in FLXA0FROTS. In addition each of the output data transfer interrupts can be enabled or disabled separately by programming the related bits in FLXA0FROTC.

The three timer interrupts lines to the host are controlled by the enabled interrupts in FLXA0FROS. In addition, each of the interrupt lines can be enabled or disabled separately by programming bit FLXA0FROC.T0IE, FLXA0FROC.T1IE and FLXA0FROC.T2IE.

When a transfer between IBF/OBF and the message RAM has completed, bit FLXA0FRSIR.TIBC or FLXA0FRSIR.TOBC is set to '1'.

17.3.16 Usage of Data Transfer

A mechanism is implemented to allow storage of FlexRay messages directly into the local RAM/global RAM (user RAM) and have transfers between the FlexRay internal message RAM and the local RAM/global RAM and vice versa with minimum CPU support. The data in the local RAM/global RAM should be indexed by data structure pointers located in data pointer tables stored in the local RAM/global RAM.

Data transfer from the local RAM/global RAM to the FlexRay internal message RAM (input transfer) needs to be initiated by the application. These transfers can be used to configure message buffers or to update transmit data.

A data transfer from the FlexRay internal message RAM to the local RAM/global RAM (output transfer) is initiated automatically by a reception into a receive message buffer or FlexRay internal FIFO or by a change in the slot status. It can be initiated also by a specific user transfer request.

The input and output data transfer can be activated independently. When the input data transfer is activated the application should not directly access message buffers using the FlexRay input buffer. When the output data transfer is activated the application cannot directly access message buffers using the FlexRay output buffer.

17.3.16.1 Input Data Transfer

When the automatic input data transfer function is enabled, committed input data structures are transferred from the local RAM/global RAM to the FlexRay internal message RAM with minimum CPU support.

(1) Activation and deactivation

The input data transfer function should be activated before usage. The activation of the input transfer handler initializes the input queue put index (FLXA0FRITS.IPIDX) and get index (FLXA0FRITS.IGIDX) to zero. In addition, set the interrupt status flags in the FLXA0FRITS register (IQEIS and IQFIS) to '0'.

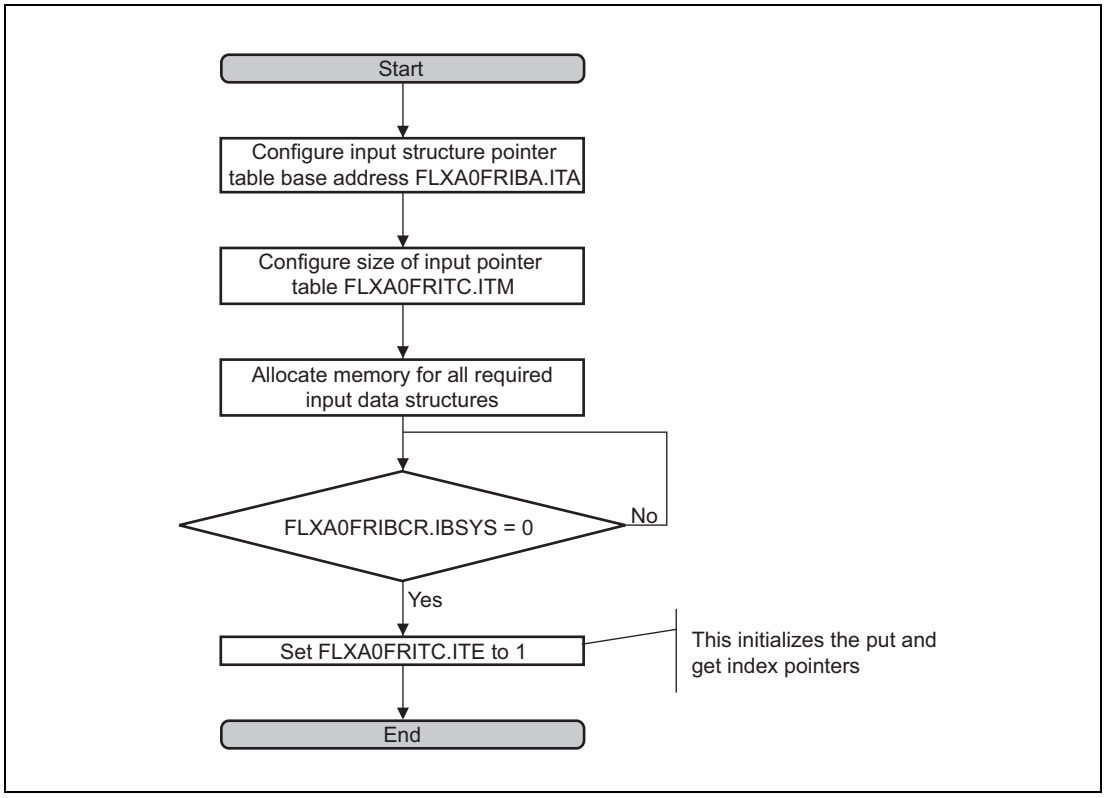

Figure 17.20 Input Transfer Enable Flow

A deactivation request of the input transfer function can be made at any time. The input queue put index and the input queue status are maintained independently from the input transfer function state.

Before the transfer function is disabled (status indicated by FLXA0FRITS.ITS), user requested input transfers and all committed input transfers will be completed.

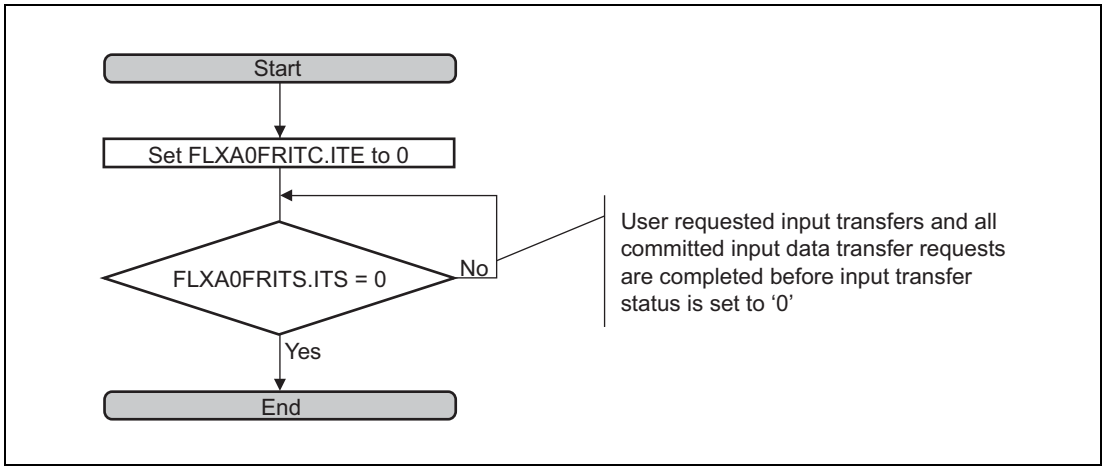

Figure 17.21 Input Transfer Disable Flow

(2) Input data structure

The application has to reserve a location in the local RAM/global RAM to provide the content for message buffer configuration (input data structure).

The location of this input data structure needs to also be defined by an input data structure pointer located in the local RAM/global RAM.

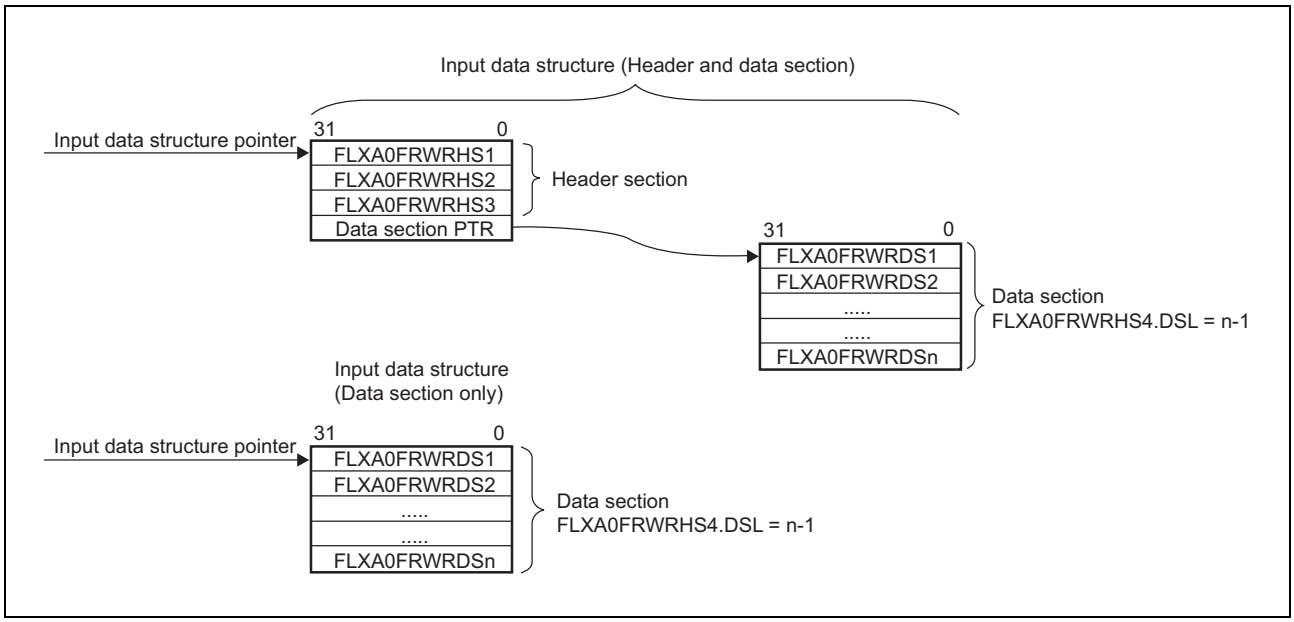

Figure 17.22 Input Data Structure

In general the input data structure consists of two sections, the header and the data section.

The header section consists of FLXA0FRWRHS1, FLXA0FRWRHS2, FLXA0FRWRHS3 and the data section pointer.

For bit alignment and bit function in the header section, see **Section 17.3.13.1, Header Partition**.

Depending on the settings in the control field (FLXA0FRWRHS4) located in the input pointer table, the data structure pointer is a reference to the address of FLXA0FRWRHS1 or FLXA0FRWRDS1. The data structure pointer has to be aligned to a 32 bit address.

If the bit LHS in the address related to FLXA0FRWRHS4 is set to ‘1’ it is required to provide a valid header section. In this case FLXA0FRWRHS1 is the first element of the data structure.

If the bit LHS in the address related to FLXA0FRWRHS4 is set to ‘0’ a header section is not required. In this case FLXA0FRWRDS1 is the first element of the data structure.

If the bit LDS in the address related to FLXA0FRWRHS4 is set to ‘1’ it is required to provide a valid data section. The pointer to the data section is a reference to the address of the first payload long word (FLXA0FRWRDS1) and has to be aligned to a 32 bit address.

If the bit LDS in the address related to FLXA0FRWRHS4 is set to '0' a data section is not required. The data section pointer is not evaluated by the input handler.

The byte order for the FlexRay payload data in the input data structure is determined by FLXA0FROC.BEC. For information about the payload data alignment within the data section, refer to **Section 17.3.13.2, Data Partition** and **Section 17.3.17, Byte Alignment**.

The length of the data section and the size to be allocated in the local RAM/global RAM depend on the configuration of the bits DSL in the address related to FLXA0FRWRHS4.

For the transfer into the FlexRay core internal message RAM the number of 16 bit words configured by FLXA0FRWRHS2.PLC is used. The application has to ensure that a proper number of data words are provided in the local RAM/global RAM. In case the buffer is configured by FLXA0FRWRHS2.PLC to hold an odd payload length, the application has to write zero to the last 16 bit of the payload section to ensure that the padding data is all zero.

(3) Input pointer table

To transfer data from the input data structures located in the local RAM/global RAM to the FlexRay internal message RAM, the related input data structure pointer and control field need to be added to the input pointer table which is located in the local RAM/global RAM.

The location of the first element of this table is identified by the input pointer table base address (FLXA0FRIBA.ITA). This base address has to be aligned to a 32 bit address.

The maximum number of input requests that can be queued is defined by the Input queue Table Max register (FLXA0FRITC.ITM).

Each Input pointer table entry requires two long words. The required address range of the input pointer table for the queued transfer requests can be calculated by

Input pointer table size (byte) = (((FLXA0FRITC.ITM + 1) × 2) × 4

Equation 1

The input pointer entry for the user requested input transfer should be added after the end of the input pointer table.

The pointer table index related to this entry and hence the number to be written to FLXA0FRUIR.UIDX, is FLXA0FRITC.ITM+1. The address in the input pointer table related to the user requested input transfer (user input address) can be calculated by

User input address = FLXA0FRIBA.ITA + Input pointer table size

Equation 2

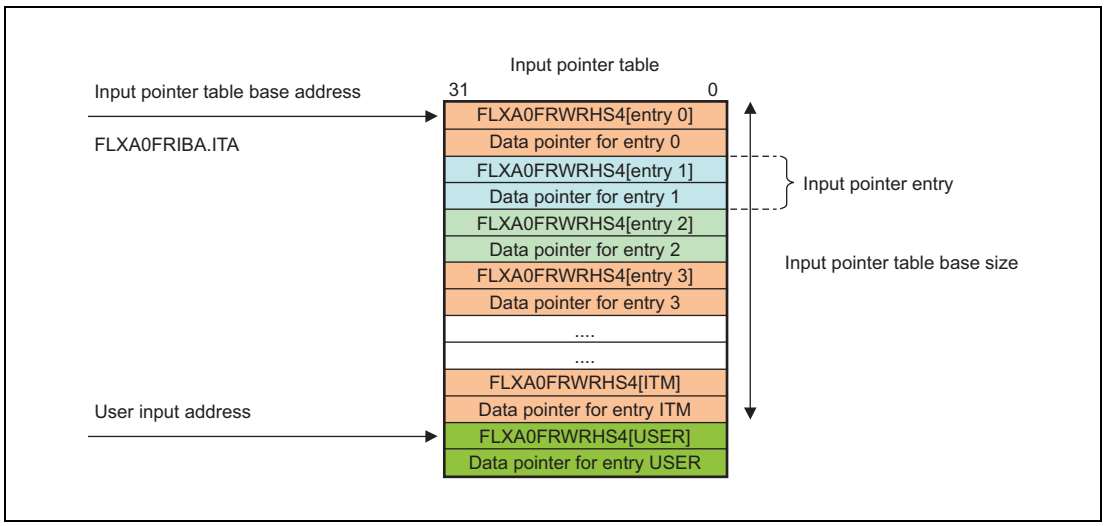

Figure 17.23 Input Pointer Table

The input pointer table holds the control field FLXA0FRWRHS4 and the pointers to the local RAM/ global RAM location where the message buffer content (header section and/or data section) is stored.

The application has to write FLXA0FRWRHS4 and the input data structure pointer at the addresses in the input pointer table related to the put index position before a transfer request is initiated.

FLXA0FRWRHS4:

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	DSL[5:0]					
Value after reset																
R/W																

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	INV	STR	LDS	LHS	—	IMBNR[6:0]						
Value after reset																
R/W																

Table 17.103 FLXA0FRWRHS4 Register Contents

Bit Position	Bit Name	Function
31 to 22	—	Reserved The read value is undefined. When writing, always write 0.
21 to 16	DSL	Data Section Length Specifies the length of the data section in terms of 32 bit values.
15 to 12	—	Reserved The read value is undefined. When writing, always write 0.
11	INV	Invalidate Entry 0: The data structure is valid and will be transferred to the FlexRay internal message RAM. 1: The data structure is invalid. FlexRay internal message RAM is not updated using this input pointer entry.
10	STR	Set Transmission Request 0: The bit FLXA0FRTXRQx.TXR for the message buffer selected by the bits IMBNR is set to ‘0’. No data from this message buffer is transmitted. 1: The bit FLXA0FRTXRQx.TXR for the message buffer selected by the bits IMBNR is set to ‘1’ to release the message buffer for transmission The application should not set the bit STR to ‘1’ for receive buffers.
9	LDS	Load Data Section 0: No update of data section 1: Data section for the message buffer selected by the bits IMBNR is updated.
8	LHS	Load Header Section 0: No update of header section 1: Header section for the message buffer selected by the bits IMBNR is updated.
7	—	Reserved The read value is undefined. When writing, always write 0.
6 to 0	IMBNR	Message Buffer Number Update Select the target message buffer number in the FlexRay internal message RAM for transfer.

Note that the LHS bit cannot be set for protected message buffers.

The bit LDS defines if the data section of the message buffer selected by the bits IMBNR is updated.

If LDS is set to ‘1’, (DSL + 1) 32-bit words of payload data are transferred from the local RAM/global RAM to the message buffer selected by the bits IMBNR.

If LDS is set to ‘0’, no payload data is transferred from the local RAM/global RAM.

Note that the payload transferred is independent from the configured payload length (bits PLC in the address related to FLXA0FRWRHS2).

The bit INV can be used to invalidate a transmitted data structure. This bit should be only used to cancel the transfer of committed data structures when the input queue is halted (see **Section 17.3.16.1 (5), Halting the input queue**).

When this bit is set to ‘1’, the message buffer number IMBNR is not updated. When the bit is set to '0', the message buffer number IMBNR is updated.

(4) Transfer function of input data structure

To use the input data structure transfer function, the input transfer has to be activated (see **Section 17.3.16.1 (1), Activation and deactivation**). The activation process requires the setup of the input pointer table (see **Section 17.3.16.1 (3), Input pointer table**) in order to specify the source location (input data structures) for the data structures to be transferred. When the input transfer is enabled the get index pointer is initialized to zero.

All FlexRay internal message buffers can be updated using the input transfer queue which is built in the input pointer table. The application has to write the pointer and control field (table entry) to the data structure to be transferred into the input pointer table. For that purpose the application has to maintain a put index for the input pointer table that indicates where the pointer has to be written to.

To transmit this table entry to the input handler, the application has to write the target message buffer number to the input queue control register (FLXA0FRIQC.IMBNR). Afterwards the application increments the application internal put index.

By writing to the input queue control register the data available flag (FLXA0FRDAi.DA[IMBNR]) is automatically set to ‘1’. The input transfer handler also maintains the put index pointer in the status register (FLXA0FRITS.IPIDX).

In case the input queue is full (number of queued input transfer requests is equal to the input queue table size), FLXA0FRITS.IQFP and FLXA0FRITS.IQFIS are set to ‘1’. The input queue full condition pending flag (FLXA0FRITS.IQFP) changes from ‘1’ to ‘0’ when there are entries in the input queue available, whereby the input queue full interrupt status flag (FLXA0FRITS.IQFIS) needs to be cleared by the application.

The application cannot make any further write access to the bit IMBNR in the FLXA0FRIQC register as long as the bit IQFP in the FLXA0FRITS register is ‘1’.

In case the input queue becomes empty (number of queued input transfer requests changes to zero) FLXA0FRITS.IQEIS is set to ‘1’.

The input queue empty interrupt status flag (FLXA0FRITS.IQEIS) needs to be cleared by the application.

The transfer of the input data structures to the FlexRay message RAM is controlled by a get index pointer which is handled inside the FlexRay module and flagged in FLXA0FRITS.IGIDX. Note that the index is referring to the input entry, but not the address offset in the input pointer table.

If the input queue is not empty, the transfer handler reads the input pointer table entry of the transfer queue and starts the transfer of the input data structure from the address the input pointer is referring to. When all required data words are transferred to the FlexRay module, the data available flag for the transferred message buffer number is set to ‘0’ and the get index in the transfer handler is incremented by one.

In case of an invalidated data structure (see **Section 17.3.16.1 (5), Halting the input queue**) no FlexRay internal message buffer is updated and the related data available flag is automatically set to ‘0’. The change of the data available flag can be used to confirm the cancellation a transmit request.

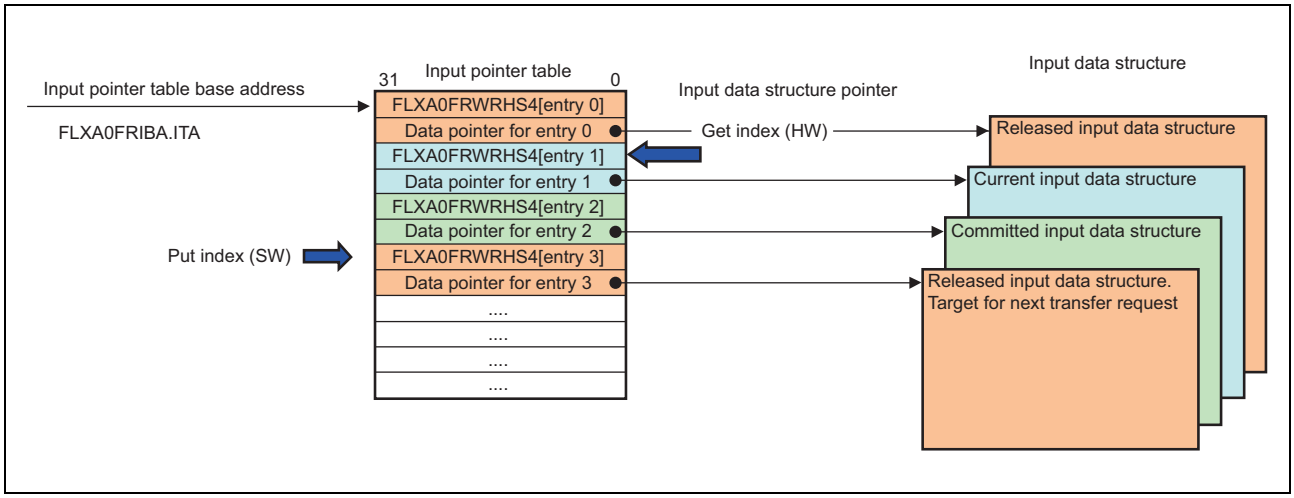

Figure 17.24 Input Pointer Table

Receive message buffers can be also configured using the input data transfer by setting up the required header sections and mark only the header section (FLXA0FRWRHS4.LDS = '0', FLXA0FRWRHS4.LHS = '1') to be updated in the FlexRay module.

The C-code below should be handled as an example of how the input queue could be handled in SW.

```
// Add the message block 'blk' into the FlexRay Tx queue
// If leng = -1, HS and DS is updated, else only DS
// Return 1, if the queue is full
int flex_add_transmit_block(int mbnr, int setTxReq, int leng,
t_is_block *blk)
{
    int mode;

    //ckeck if resource is free
    if (FRITS.IQFP != 0) return 1;

    mode  = (setTxReq << 10) + 0x20; /*load DS */
    if (leng == -1) {
        leng = (blk->hs2.plc+1) / 2; /* number of 32 bit word */
        mode |= 0x10; /* load HS + DS */
    }

    //add to input queue
    flex_tx_table[flex_tx_pidx*2+0] = blk;/* add the pointer */
    flex_tx_table[flex_tx_pidx*2+1] = (leng << 16) +mode + mbnr;

    //increment SW put index
    if (++flex_input_pidx == FLEX_INPUT_TABLE_MAX) flex_input_pidx = 0;

    //activate transmission
    FRIQC = mbnr;

    //done
    return 0;
}
```

(5) Halting the input queue

Committed data structures cannot be removed, but can be invalidated or updated when the input queue is halted.

To cancel data structures already committed to the input queue, the queue can be halted by writing a '1' to FLXA0FRITC.IQHR.

After the ongoing input transfer has been completed the queue is halted and FLXA0FRITS.IQH changes from '0' to '1'.

To invalidate an entry of the input queue, FLXA0FRWRHS4.INV has to be set to '1'. All other bits in FWRHS4 cannot be changed.

Following flow shall be used to analyze whether a transmitted message has been already transferred to the FlexRay internal message RAM or not.

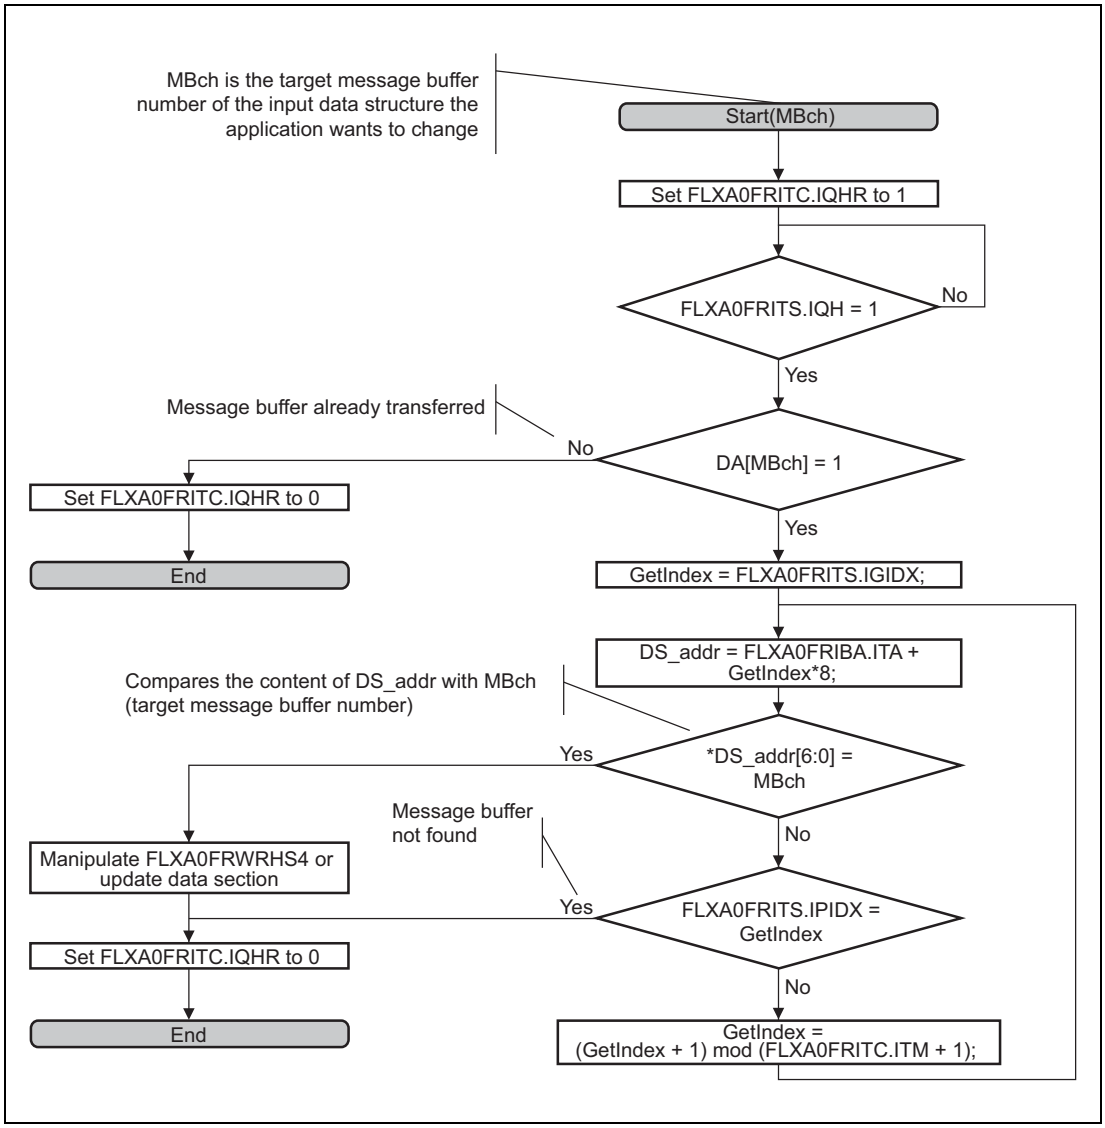

Figure 17.25 Input Table Analysis

In case the message buffer was already transferred to the FlexRay internal message RAM, the user input transfer request can be used to bypass the actual queue and update the required message buffer (see **Section 17.3.16.1 (6), Transfer function of user requested input transfers**).

(6) Transfer function of user requested input transfers

To use this function, the input transfer has to be activated (see **Section 17.3.16.1 (1), Activation and deactivation**).

The application is capable, by using FLXA0FRUIR.UIDX, to request a transfer of an input data structure. The user input transfer request is executed first.

The application has to write the pointer and control field (table entry) to the data structure to be transferred into the input pointer table. Add the table entry for the user input transfer request after the end of the input pointer table (see **Section 17.3.16.1 (3), Input pointer table**).

To transmit this table entry to the input handler, the application has to write the index (FLXA0FRITC.ITM + 1) to the user input transfer request register (FLXA0FRUIR.UIDX).

By writing to the user input transfer request register, the user input transfer request pending flag (FLXA0FRITS.UIRP) is automatically set to ‘1’.

As long this flag is ‘1’, the application cannot make any further user input transfer requests.

The user input transfer request pending flag (FLXA0FRITS.UIRP) changes from ‘1’ to ‘0’ when the requested input transfer is completed. Subsequently, next the pending transfers are processed.

17.3.16.2 Output Data Transfer

When the output data transfer function is enabled, received messages (either in dedicated message buffers or in the FlexRay receive FIFO) are transferred to the local RAM/global RAM by the output data handler. The output data handler can also transfer the message buffer content to the local RAM/ global RAM on application request. When enabled the output handler is also capable to initiate a transfer when the message buffer status has changed.

(1) Activation and deactivation

The output data transfer function should be activated before usage. The activation of the output transfer hander will initialize the FIFO put and get index pointer and FIFO fill level (FLXA0FROTS.FGIDX and FLXA0FROTS.FFL) to zero, set the bits FLXA0FROTS.FDA, FLXA0FROTS.OWP, FLXA0FROTS.FWP and FLXA0FROTS.UORP to ‘0’. Also the interrupt status flags FLXA0FROTS.OTIS, FLXA0FROTS.FIS, FLXA0FROTS.OWIS and FLXA0FROTS.FWIS) are set to ‘0’.

The activation has no effect on the data available flags (FLXA0FRDAi.DA) which are related to the dedicated buffers; these flags have to be cleared by the application.

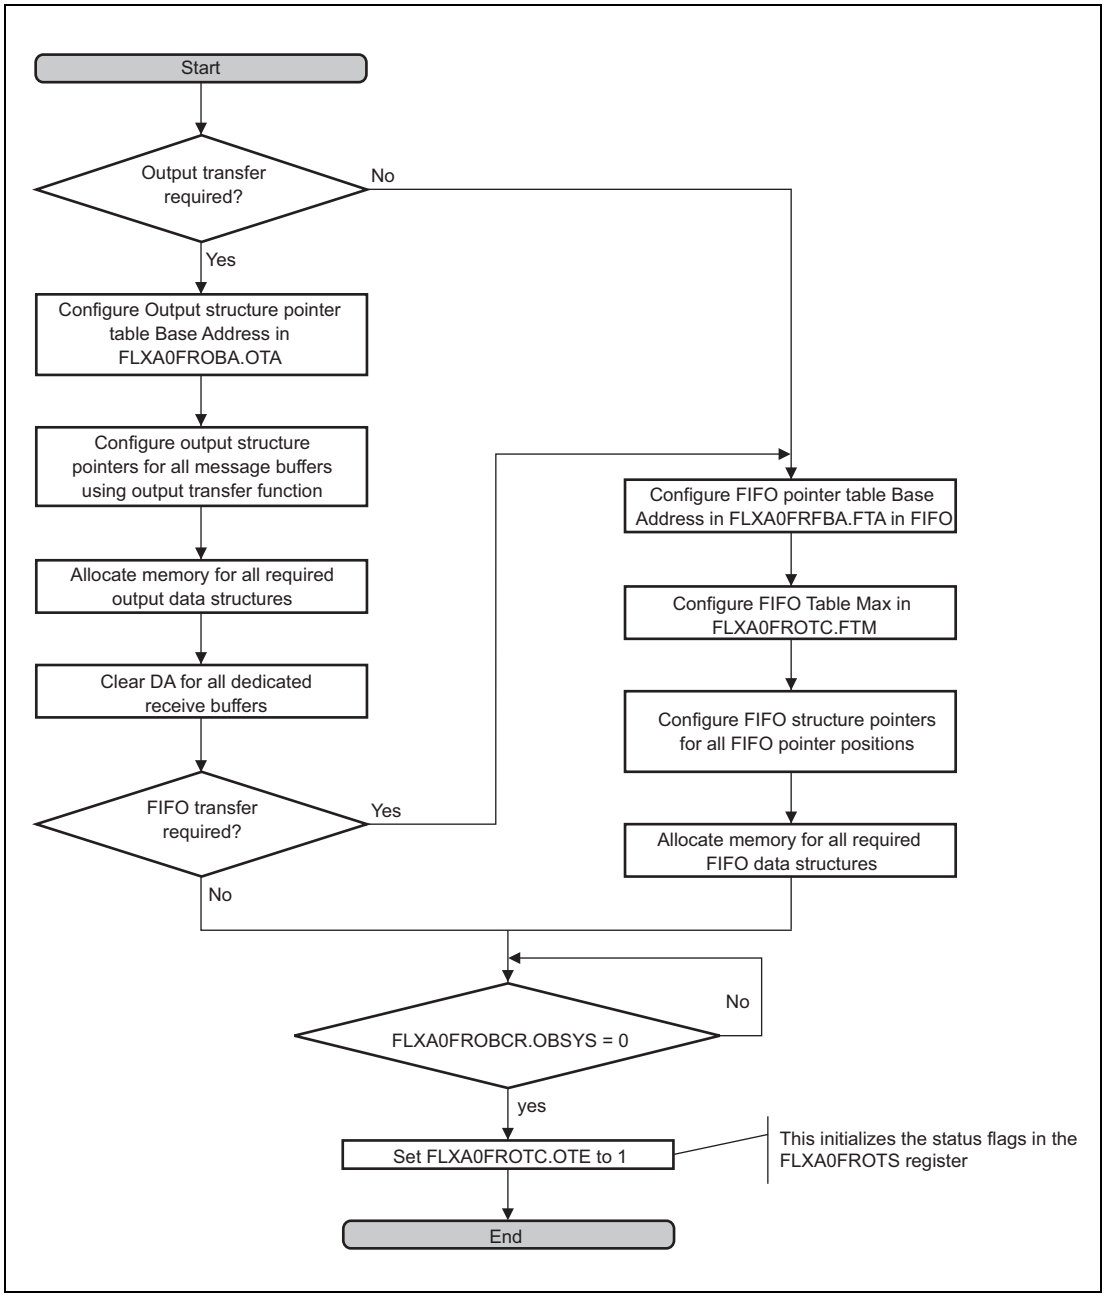

Figure 17.26 Output Transfer Enable Flow

A deactivation request of the output data transfer function can be made at any time. An ongoing transfer will be completed and the completion of this transfer will be flagged. During this time FLXA0FROTS.OTS remains ‘1’.

When FLXA0FROTS.OTS changes from ‘1’ to ‘0’, the output transfer function is deactivated. The data available status flags and the FIFO get index are still maintained when the output transfer function is disabled.

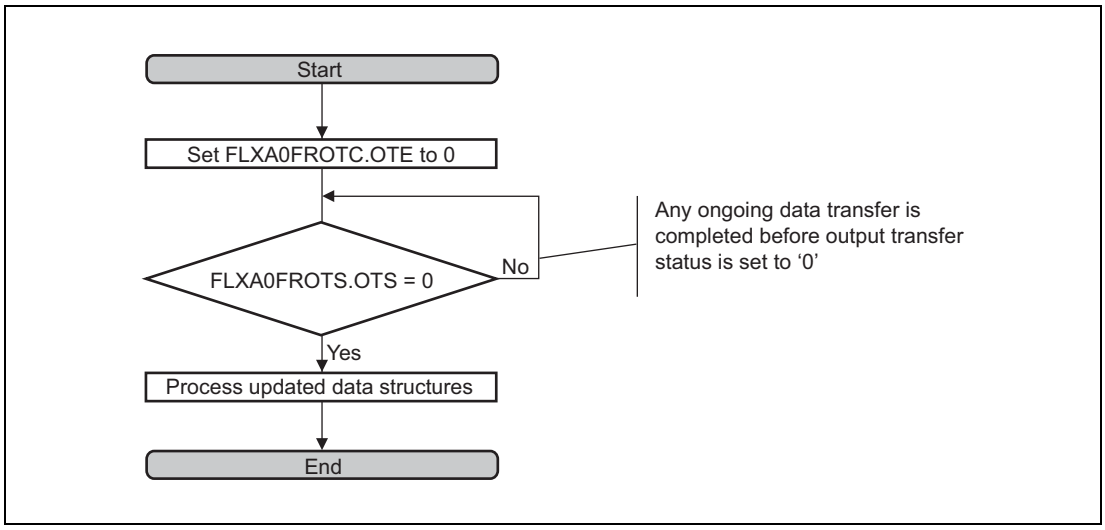

Figure 17.27 Output Transfer Disable Flow

(2) Output transfer data structure

The data in the local RAM/global RAM is stored in an output data structure. The location of the output data structures are determined by output data structure pointers also located in the local RAM/global RAM. The output data structure and indexing is visualized in **Figure 17.28**.

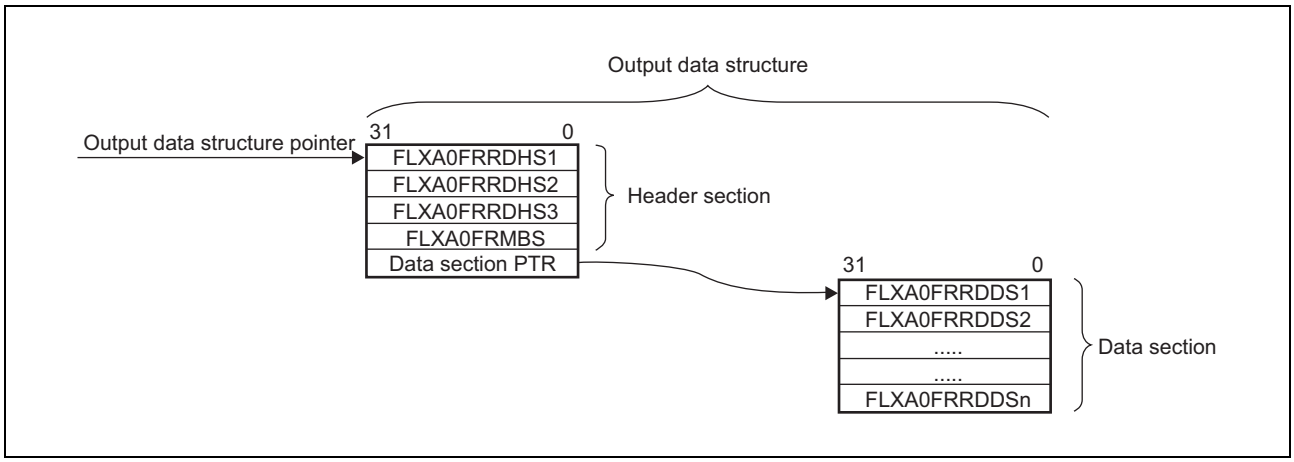

Figure 17.28 Output Data Structure

The output data structure consists of two sections, the header and data section. The header section consists of FLXA0FRRDHS1, FLXA0FRRDHS2, FLXA0FRRDHS3, FLXA0FRMBS and the data section pointer. FLXA0FRRDHS1 is the first element of the structure and has to be aligned to a 32 bit address. The data structure pointer is a reference to the address of FLXA0FRRDHS1. For information about the bit alignment and bit function within the header section, refer to **Section 17.3.13.1, Header Partition**.

FLXA0FRRDDS1 is the first element of the data section. The data section pointer is a reference to the address of FLXA0FRRDDS1 and has to be aligned to a 32 bit address. The byte order for the FlexRay payload data in the output data structure is determined by the bit BEC in the FLXA0FROC register. For information about the payload data alignment within the data section, refer to **Section 17.3.13.2, Data Partition**.

The length of the data section and the total structure size to be allocated in the local RAM/global RAM depend on the configured payload length (FLXA0FRRDHS2.PLC) of the related message buffer. In case the configured payload length is an odd number of words or the received payload length (FLXA0FRRDHS2.PLR) is shorter than the configured payload length, the remaining data words in the local RAM/global RAM are unused and cannot be used by the application.

The output data structure is unique for all three kinds of output transfers. In case only the header section is transferred, the data section pointer is not evaluated by the output handler and the data section remains unchanged.

(3) Output pointer table

For the output data transfer function, the application needs to set up an output pointer table in the local RAM/global RAM. The location of the first element of this table must be programmed into the output pointer table base address (FLXA0FROBA.OTA). This base address has to be aligned to a 32 bit address.

The size of the output pointer table is defined by the maximum of: the last configured dedicated message buffer and the highest message buffer number which will be used for the user output transfer request.

The output pointer table holds pointers (output data structure pointers) to the local RAM/global RAM location where a memory space is reserved for the target message buffer content (header section and data section).

There is a fixed linear relationship between the address of the entries in the output pointer table and the number of the related message buffers (see **Figure 17.29**): the output pointer table starts with the entry for message buffer number 0 at the address configured in FLXA0FROBA.OTA and continues in ascending order for each following message buffer number, by 32 bit aligned address (e.g. message buffer 1 at address OTA + 4, message buffer 2 at address OTA + 8, etc.) for all possible message buffers.

When a set ND bit is the only transfer condition (FLXA0FROTC.OTCS is set to 0), only message buffers configured as a dedicated receive buffer or that will be used for user output transfer requests need have valid pointer entries.

When a set ND bit or a set MBC bit is the transfer condition (FLXA0FROTC.OTCS is set to 1), all dedicated receive buffer and dedicated transmit buffers need to have valid pointer entries.

(4) FIFO output pointer table

The FlexRay module internal FIFO can be extended by a queued buffer structure in the local RAM/ global RAM.

If the FlexRay module internal FIFO is used, the application needs to set up the FIFO output pointer table. The location of the first element of this table is identified by the FIFO pointer table base address (FLXA0FRFBA.FTA). This base address has to be aligned to a 32 bit address.

The size of the FIFO pointer table and hence the maximum number of messages that can be added to the queue, is defined by FIFO Table Max (FLXA0FROTC.FTM).

The FIFO pointer table holds pointers (output data structure pointers) to the local RAM/global RAM location where a memory space is reserved the target message buffer content (header section and data section). For each table entry a data pointer shall be configured in this table.

(5) Transfer function of dedicated message buffers

To use this transfer function, the output transfer has to be activated (see **Section 17.3.16.2 (1), Activation and deactivation**). The activation process requires to set up the output pointer table (see **Section 17.3.16.2 (3), Output pointer table**) in order to specify the destination location (output data structures) for the data to transfer. **Figure 17.29** shows how the output pointer table references the output data structures.

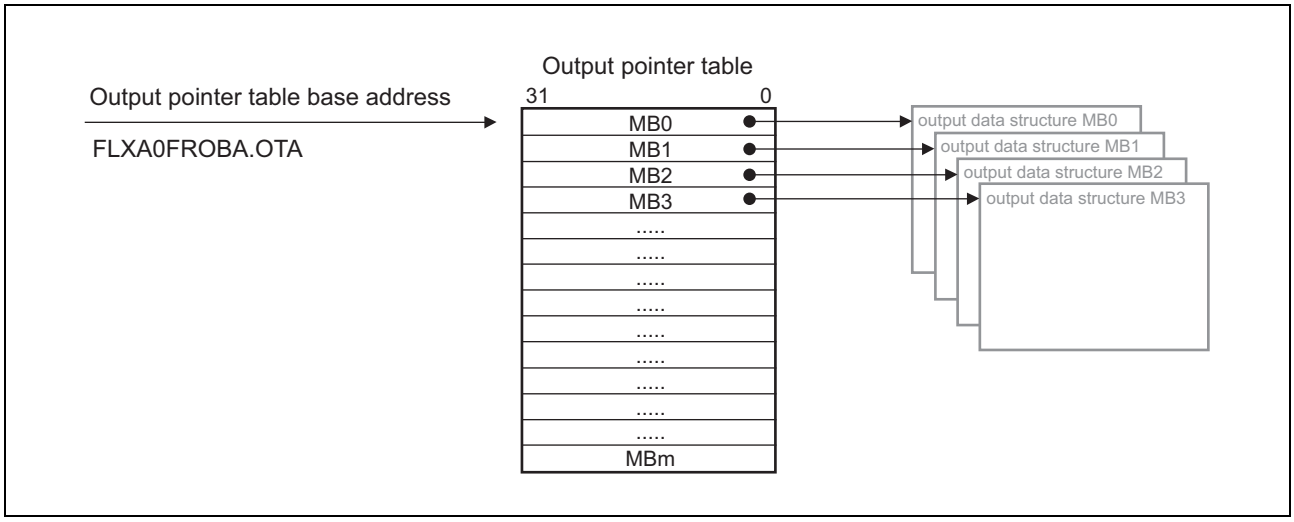

Figure 17.29 Output Data Structure and Indexing

With FLXA0FROTC.OTCS the output transfer condition can be selected between the ‘New data only mode’ and the ‘New data and status changed mode’.

In the ‘New data only mode’, an output data transfer is initiated when a valid FlexRay data frame has been stored into a dedicated receive buffer which causes the related ND flag in the FLXA0FRNDATi register to set. The ND flag in the FLXA0FRNDATi register is automatically set to ‘0’ during the transfer procedure. The header section is also transferred and hence the MBC flag in the FLXA0FRMBSCi register is set to ‘0’.

In the ‘New data and status changed mode’, an output data transfer is initiated as described in the ‘New data only mode’. In addition an output data transfer is initiated when only the message buffer status has been changed which causes the related MBC flag in the FLXA0FRMBSCi register to be set. In this case only the header section is transferred. The flag in the register is automatically set to ‘0’ during the transfer procedure.

After transferring the message buffer data from the FlexRay internal message RAM to the output data structure, the corresponding data available flag in the FLXA0FRDAi (i = 0 to 3) registers is set to ‘1’. The update of the output data structure is also flagged by the setting of the output transfer interrupt status flag (FLXA0FROTS.OTIS).

As long as the data available flag remains ‘1’, the corresponding output data structure will not be updated.

In the case

- the data available flag is ‘1’ and a valid received message was stored or
- when FLXA0FROTC.OTCS is ‘1’ and the message buffer status was updated,

The output transfer warning interrupt flag (FLXA0FROTS.OWIS) is set to ‘1’ notifying the application that new data is available but the output data structure transfer cannot be processed. In addition FLXA0FROTS.OWP is set to ‘1’ that continuously flags that status of the output transfer warning condition.

If a valid receive message in the FlexRay internal message RAM is overwritten by an additional receive message, the message lost flag (FLXA0FRMBS.MLST) is set to ‘1’. This flag can be evaluated after the message buffer has been transferred into an output data structure.

The following sections describe how output data structures can be handled.

(a) Data section copy method

One option is to copy the information from the output data structure to a different location of the local RAM/global RAM and then to release the output data structure by clearing the related data enable flag. The application can use the copied information for further processing.

The C-code below is an example showing how output data structures could be handled in SW.

```
// Get copy of one output structure block (FlexRay Rx or user transfer)
// Return -1 if the buffer has no valid data (DA = "0") else the used
payload size
int flex_copy_output_block(unsigned mbnr, void *target_hs, void
*target_ds)
{
    unsigned long *this_FRDA, mask;
    int size;

    //ckeck if data of MB is available
    this_FRDA = (&FRDA0) + ((mbnr >> 5) & 0x03);
    mask = 1 << (mbnr & 0x1f)
    if ((*this_FRDA & mask) == 0) return -1;

    //calculate the real MB size min(PLC, PLR)
    size = flex_output_table[mbnr]->hs2.f.plr;
    if (size > flex_output_table[mbnr]->hs2.f.plc)
        size = flex_output_table[mbnr]->hs2.f.plc;

    //copy header and data to target location
    if (target_hs != NULL)
        memcpy(flex_output_table[mbnr], target_hs, 4*4);
    if (target_ds != NULL)
        memcpy(flex_output_table[mbnr]->dsptr, target_ds, 2*size);

    //acknowledge reception
    *this_FRDA = mask;      /* clear by writing a "1" */

    //done
    return size;
}
```

(b) Data structure pointer method

A different option is to modify the output data structure pointer in the output pointer table and to release the output data structure by clearing the related data enable flag. The changed output data pointer should refer to a free data structure. The application needs to use the old data structure for further processing.

The C-code below is an example showing how output data structures could be handled in SW.

```
// Get one output structure block (FlexRay Rx or user transfer)
// The returned block is replaced by a free output structure
// Return the block or NULL if the buffer has no valid data (DA = "0")
t_os_block *flex_get_output_block(unsigned mbnr, t_os_block *free_blk)
{
    t_os_block *this_blk;
    unsigned long *this_FRDA, mask;

    //ckeck if data of MB is available
    this_FRDA = (&FRDA1) + ((mbnr >> 5) & 0x03);
    mask = 1 << (mbnr & 0x1f);
    if ((*this_FRDA & mask) == 0) return NULL;

    //get pointer from output table and replace it by free location
    this_blk = flex_output_table[mbnr];
    flex_output_table[mbnr] = free_blk;

    //acknowledge reception
    *this_FRDA = mask;      /* clear by writing a "1" */

    //done
    return this_blk;
}
```

(c) Data section pointer method

A third option is to modify the data section pointer in the output data structure and to release the output data structure by clearing the related data enable flag. The changed data section pointer should refer to a free memory area. The application should use the old data section for further processing by forwarding the data section pointer.

The C-code below is an example showing how output data structures could be handled in SW.

```
// Get one data section block (FlexRay Rx or user transfer)
// The returned data section block is replaced by a free data section
area
// Return the block or NULL if the buffer has no valid data  (DA = "0")
t_ds_block *flex_get_datasection_block(unsigned mbnr, t_ds_block
*free_blk)
{
    t_os_block *this_blk;
    unsigned long *this_FRDA, mask;
    unsigned long this_os_ptr;

    //ckeck if data of MB is available
    this_FRDA = (&FRDA1) + ((mbnr >> 5) & 0x03);
    mask = 1 << (mbnr & 0x1f);
    if ((*this_FRDA & mask) == 0) return NULL;

    //get base address from output table
    this_os_ptr = (unsigned long)flex_output_table[mbnr];

    //get pointer from output data section and replace it by free
location
    this_blk = (t_os_block*)(this_os_ptr + 20);
    (t_os_block*)(this_os_ptr + 20) = free_blk;

    //acknowledge reception
    *this_FRDA = mask;      /* clear by writing a "1" */

    //done
    return this_blk;
}
```

(6) Transfer function of FIFO message buffers

To use this buffer transfer function, the output transfer has to be activated (see **Section 17.3.16.2 (1), Activation and deactivation**). The activation process requires the setup of the FIFO pointer table (see **Section 17.3.16.2 (4), FIFO output pointer table**) in order to specify a location in the local RAM/global RAM reserved for the storage of the required output data structures.

A FIFO data transfer is initiated when a valid FlexRay data frame has been stored in the FlexRay internal FIFO.

After transfers from the internal FIFO to the output data structure, the FIFO interrupt status flag (FLXA0FROTS.FIS) and FLXA0FROTS.FDA are set to '1'. The bit FLXA0FROTS.FIS can be used as an interrupt source. The bit FLXA0FROTS.FDA indicates that the FIFO is not empty.

Up to FLXA0FROTS.FTM output structures configured in the register can be queued.

The transfer to the extended FIFO buffer structure is controlled by index pointers. This put index is controlled by the FIFO transfer handler and is incremented after transferring a message to the output data structure. The FIFO reception handler also maintains a get index which is flagged in FLXA0FROTS.FGIDX. The value of this get index is known by the application by either reading the status or maintaining a software variable. The get index (initially set to the zero) is incremented by one when the application releases the oldest entry of the FIFO queue by writing '1' to FLXA0FROTS.FDA. By comparing the put index and the get index, the FIFO handler acquires the current fill level of the queued buffer structure.

The current FIFO fill level is set in FLXA0FROTS.FFL. When FLXA0FROTS.FDA is '1', there is at least one entry in the FIFO queue.

In case the queued buffer structure in the local RAM/global RAM is full (FLXA0FROTS.FFL = FLXA0FROTC.FTM + 1), no further transfers are initialized, new messages remain in the FlexRay internal FIFO and the FIFO transfer warning interrupt status flag (FLXA0FROTS.FWIS) is set to '1'.

In case the FlexRay internal FIFO structure becomes full, messages in the FlexRay internal FIFO structure will be overwritten. The related status flags and configuration registers of the FlexRay core module are used to generate desired warning notifications.

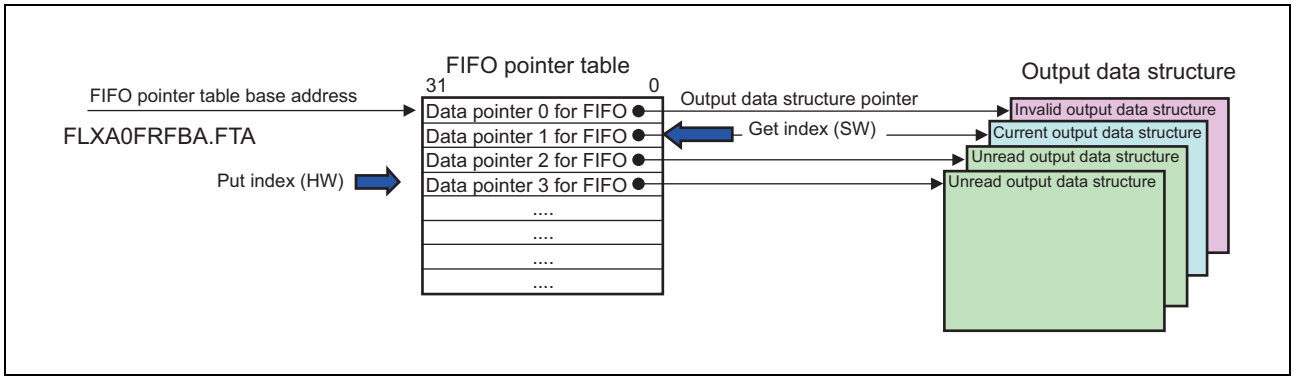

Figure 17.30 FIFO Pointer Table

The following code illustrates a good example of handling the extended FIFO. The function flex_get_fifo_block ( ) assumes that there is a global variable flex_fifo_gidx which is initialized to zero when the output transfer is enabled. Using this variable, a read access to FLXA0FROTS.FGIDX becomes redundant. The constant FLEX_FIFO_MAX is used to configure FLXA0FROTC.FTM. When getting an output structure from the FIFO queue for further processing, its pointer is replaced by an empty output data structure given as parameter.

```
// Get one output structure block from the FlexRay Rx FIFO
// The returned block is replaced by a free output structure
// Return the block or NULL if FIFO is empty
t_os_block *flex_get_fifo_block(t_os_block *free_blk)
{
    t_os_block_ptr this_blk;

    //ckeck if data in FIFO is available
    if (FROTS.FDA == 0) return NULL;

    //get pointer from FIFO table and replace it by free location
    this_blk = flex_fifo_table[flex_fifo_gidx];
    flex_fifo_table[flex_fifo_gidx] = free_blk;

    //increment SW get index
    if (++flex_fifo_gidx == FLEX_FIFO_MAX) flex_fifo_gidx = 0;

    //acknowledge FIFO reception
    FROTS.FDA = 1;      /* clear by writing a "1" */

    //done
    return this_blk;
}
```

(7) Transfer function of user output transfer requests

To use this transfer function, the output transfer has to be activated (see **Section 17.3.16.2 (1), Activation and deactivation**). The activation process requires to set up the output pointer table (see **Section 17.3.16.2 (3), Output pointer table**) in order to specify the location in the local RAM/ global RAM reserved for the transfer of the data (output data structures).

The application can, by using FLXA0FRUOR.UMBNR, request a transfer of dedicated message buffer to an output data structure. Except in CONFIG state, message buffers which are part of the FlexRay internal FIFO cannot be requested.

The header section is always transferred to the output data structure. The transfer of the data section can be enabled by setting FLXA0FRUOR.URDS to '1'. The selected message buffer content is stored in the output data structure location determined by the pointers in the output pointer table.

The data available status and transfer blocking by the DA bits in the FLXA0FRDAi register is also used for the user requested transfers. Therefore, the DA bit in the FLXA0FRDAi register related to the requested buffer number (FLXA0FRUOR.UMBNR) needs to be released before making the transfer request.

After writing to FLXA0FRUOR.UMBNR, the bit FLXA0FROTS.UORP is set to '1' to indicate that there is a pending user transfer request. When the transfer has been processed the bit FLXA0FROTS.UORP is set to '0', the bit FLXA0FROTS.OTIS is set to '1' and the DA bit in the FLXA0FRDAi register related to the requested buffer number (FLXA0FRUOR.UMBNR) is set to '1'.

User output transfer requests cannot be queued. The application needs to check the bit FLXA0FROTS.UORP before writing to FLXA0FRUOR.UMBNR.

User output transfer requests cannot be made for message buffers which are pending in the input transfer queue.

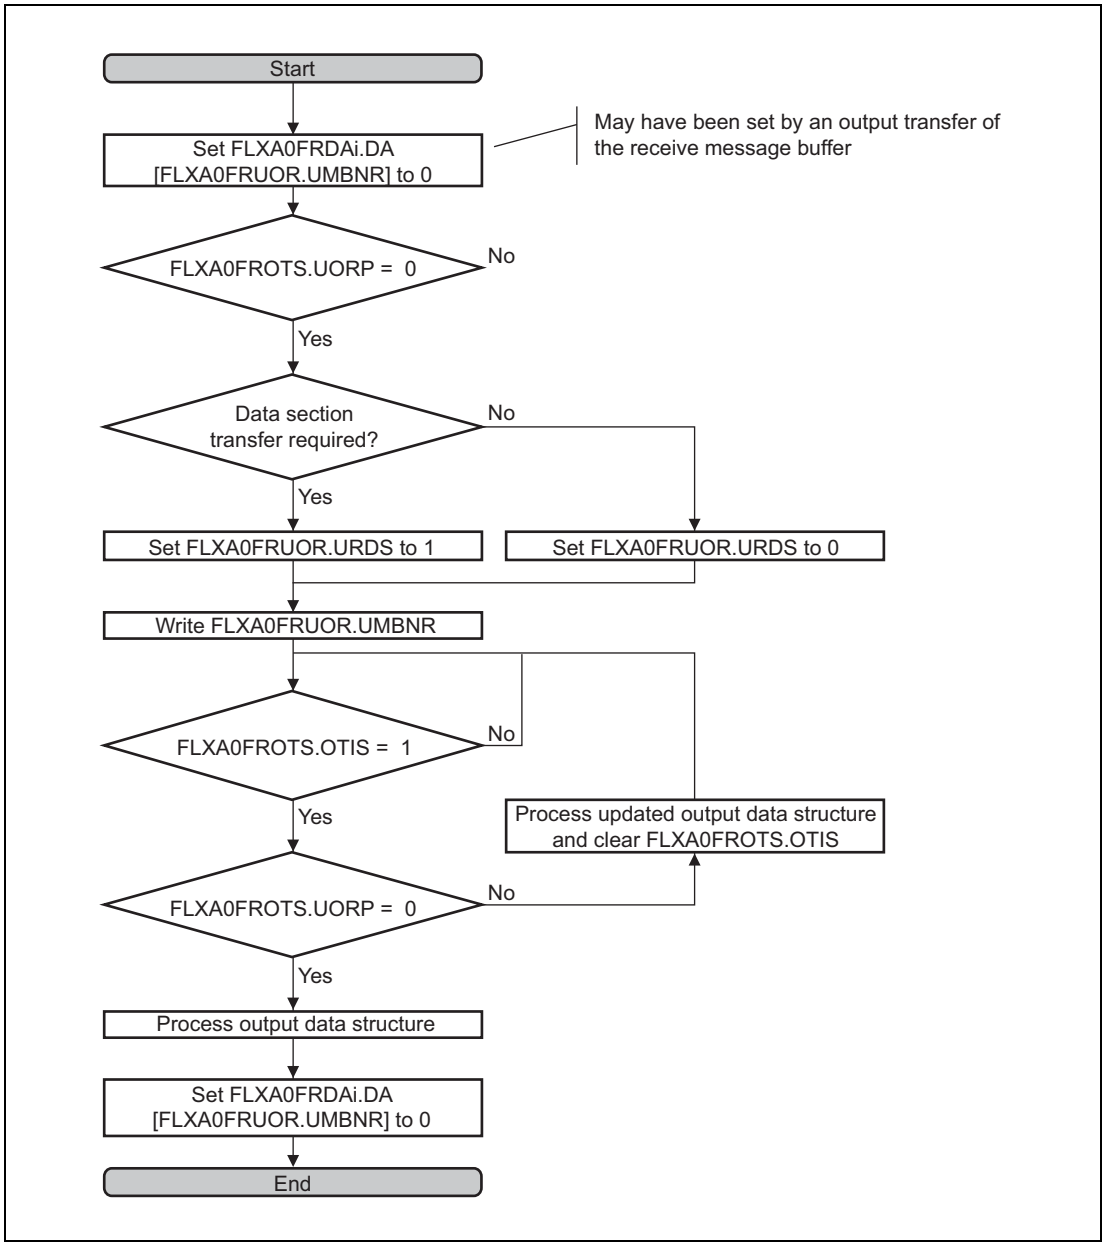

Figure 17.31 User Output Transfer Request Flow

Note that it may be possible that the data structure addressed by a user request is being updated due to a receive message buffer update (which causes the bit DA in the FLXA0FRDAi register being set). This DA flag setting inhibits the user output transfer request. Therefore, polling FLXA0FROTS.UORP is not a secure method to identify when the transfer of a requested message buffer has been completed. The bits FLXA0FROTS.OTIS or the DA bit in the FLXA0FRDAi register can be used instead. The exact flow depends on the software architecture.

17.3.16.3 Data Structure Transfer Scheduling

Cyclically the different types of transfer requests are checked. In order to guarantee a certain transfer time, the different types of transfers have different priorities.

Use requested input transfers that have highest priority followed by the transfer of data structures to be transmitted into the active input transfer queue. No new output transfer will be started as long as there is a pending input transfer request.

The three output transfer request types are checked in a specific order:

(1) All dedicated message buffers in ascending order

When FLXA0FROTC.OTCS is set to ‘0’, set flags in the FLXA0FRNDATn register are causing a transfer of the message buffer to the output data structure if the destination area is free (DA bit in the FLXA0FRDAi register is ‘0’).

When FLXA0FROTC.OTCS is set to ‘1’, set flags in the FLXA0FRNDATn register or set flags in the FLXA0FRMBSCn register are causing a transfer of the message buffer to the output data structure if the destination area is free (DA bit in the FLXA0FRDAi register is ‘0’).

(2) FlexRay internal FIFO

When the FlexRay internal FIFO is not empty and there is a free destination area, one FIFO message is transferred into the output data structure addressed by the FIFO pointer table.

(3) User output request

If there is a pending user output transfer request, one message buffer is transferred into the corresponding output data structure.

The check sequence is suspended when an input transfer is generated.

17.3.16.4 Behavior in Case of Data Transfer Access Error

The memory areas accessed by the data transfer function may be protected by a memory protection unit (MPU). When the MPU flags an access to a protected address caused by an input or output transfer, an access error event is generated and the related bit in the FLXA0FRAES register is set.

The ongoing transfer is immediately terminated but completed transfers are processed and may generate further access errors. Any following access errors are only flagged in FLXA0FRAES.MAE. The other status flags are not updated.

(1) Access error during input transfer

When an access error occurs during an input transfer:

- The ongoing transfer is immediately terminated. The FlexRay internal message RAM will not be updated
- The address, the FlexRay module intended to access to, is written in the FLXA0FRAEA register
- FLXA0FRAES.IAE is set to '1'
- The input pointer table index is flagged in FLXA0FRAES.EIDX
- In case of a normal input transfer the transfer related DA bit in the FLXA0FRDAi register is set to '0'
- In case of a user input transfer request FLXA0FRITS.UIRP is set to '0'

With the given status information, the application is able to identify and correct the faulty data structure.

In addition the application needs to clear the input access error flag (FLXA0FRAES.IAE).

(2) Access error during output transfer

When an access error occurs during an output transfer:

- The ongoing transfer is immediately terminated but the update of the data structure may be started.
- The address, the FlexRay module intended to access to, is written in the FLXA0FRAEA register
- FLXA0FRAES.OAE is set to '1'
- The output pointer table index is flagged in FLXA0FRAES.EIDX
- In case of a normal output transfer, the related DA flag in the FLXA0FRDAi register remains '0' and no output transfer interrupt is generated
- In case of a user output transfer request, FLXA0FROTS.UORP is set to '0'

With the given status information, the application is able to identify and correct the faulty data structure. The data structure in the local RAM/global RAM cannot be treated as valid.

In addition the application needs to clear the output access error flag (FLXA0FRAES.OAE).

The FlexRay module internal transfer of the message buffer is completed before the local RAM/global RAM access error is detected. The output transfer cannot be resumed. To avoid loss of data, the application can perform a user output transfer request of this message buffer to a correct local RAM/ global RAM location.

(3) Access error during FIFO transfer

When an access error occurs during an FIFO transfer:

- The ongoing transfer is immediately terminated
- The address, the FlexRay module intended to access to, is written in the FLXA0FRAEA register
- FLXA0FRAES.FAE is set to '1'
- The FIFO pointer table index is written in FLXA0FRAES.EIDX
- The FIFO index pointer is not changed and hence the FIFO status flags are unchanged

With the given status information, the application is able to identify and correct the faulty data structure.

In addition, the application needs to clear the FIFO access error flag (FLXA0FRAES.FAE).

The data in the local RAM/global RAM cannot be treated as valid and is not released to the application. The message cannot be recovered.

17.3.16.5 Behaviors in Case of RAM Read Errors

The FlexRay internal message RAM has an ECC checking mechanism. In case an uncorrectable RAM read error occurs, the application has to analyze the status in the FLXA0FRMHDS register and redo as described in **Section 17.3.16.3, Data Structure Transfer Scheduling**. The input and output transfer handler redoes also on these errors detected in the message RAM when the error is related to an active transfer.

In addition, temporary buffer RAM A and temporary buffer RAM B have an ECC checking mechanism as well.

An uncorrectable RAM read errors does not affect the data transfer functionality but have to be handled as described in **Section 17.3.13.1 (4), Message Buffer Status FLXA0FRMBS (word 3)**.

In all cases, data causing a read error is never transferred to the local RAM/global RAM. If there is no recovery available in the application, the message is lost.

(1) Read error during transfer from TBF to MBF

This internal transfer is performed for each valid FlexRay message received.

A read error can only occur when the header section in the FlexRay message RAM (see read error flags in FLXA0FRMHDS) is read. In this case, the message buffer needs to be re-configured.

For dedicated receive message buffers, the related ND flag in the FLXA0FRNDATi register will not be set. Consequently the affected message buffer will not be transferred to the output data structure.

For the FlexRay internal FIFO buffers, the ND flag in the FLXA0FRNDATi register is not set, but the FlexRay internal FIFO put index is incremented. Due to this, a transfer procedure from the FlexRay internal FIFO buffer to the output buffer is started. However, if the read error is still present in the header section, updating of the output data structure will not start (see **Section 17.3.16.5 (2), Read error during transfer from MBF to OBF**); thus the data in the local RAM/global RAM remains correct.

Note that the correction or any other reconfiguration of FIFO related to message buffers, while there are pending FIFO transfers, may result in incorrect data in the local RAM/global RAM. It is strongly recommended to deactivate the output data transfer before starting the reconfiguration and flush the FlexRay internal FIFO before reactivation of the output data transfer.

(2) Read error during transfer from MBF to OBF

This internal transfer is performed for every output data transfer (dedicated reception, FIFO, user requested).

A read error can occur in the header and data section (see read error flags in FLXA0FRMHDS). In both cases, the message gets lost. If the error is located in the header section, the message buffer needs to be re-configured. If the error is located in the data section, the error is corrected with the next data section update.

When a read error occurs during the transfer from the message RAM to the output buffer, the output data structure will not be updated and the data enable bit will not be set to '1'. The FIFO put index and the FIFO fill level are not changed also. In case of user output transfer request, FLXA0FROTS.UORP is set to '0' even if there was no update of the output data structure.

(3) Read error during transfer from IBF to MBF

This internal transfer is performed for every input data transfer.

A read error can occur only when the header section requested (the bit LHS in FLXA0FRWRHS4 is set to "0") cannot be updated due to the reading of the header section from the message RAM (see read error flags in FLXA0FRMHDS). In this case, the message buffer needs to be re-configured.

When a read error occurs during the input data transfer, the actually transferred message in the input queue is lost.

(4) Message RAM read errors

Read errors when reading the header section are flagged in the FLXA0FRMHDS register.

Depending on the buffer type and set buffer protection, the message buffer may not be reconfigured.

The input transfer function cannot be used to reconfigure a locked message buffer using the method described in **Section 17.3.13.4 (3), Temporary Unlocking of Header Section**.

Before reconfiguring a locked buffer, the user needs to disable the input transfer function and the output transfer function.

17.3.16.6 Data Transfer Timings

The transfer timing between the local RAM/global RAM and the FlexRay internal message buffers is composed of two elements. The first element is the FlexRay core internal transfer time between the interface buffer and the message RAM. The second element is the transfer time required between the local RAM/global RAM and the interface buffer.

The concept of the input- and output handler allows only one active transfer between the local RAM/ global RAM and input buffer as well as only one active transfer between the input buffer and the message RAM. In case two requests are made at the same time, the input transfer task is handled at first.

Due to this concept constrains the calculation of transfer times does not consider a parallel transfer but the worst case scenario whereby an output transfer is started only after all input transfers are completed.

(1) FlexRay core internal transfer time

The number of clock cycles required for a transfer is set in FlexRay core module clock cycles (bus clock). The transfer time differs between the input and output transfer.

The time required for a transfer between the interface buffer and the FlexRay internal message RAM is given by [ERAY_ADD]

$$cycles_{req\_MHD[PL]} = (numberOfConcurrentTasks) * (setupTime + (DataWords_{req[PL]}) + 75)$$

Equation 3

The number of data words (32 bit) can be calculated by

$$DataWords_{req[PL]} = 4 + floor\left(\frac{PLC + 1}{2}\right)$$

Equation 4

Whereby 4 is the number of header section words (32 bit) which needs to be always accessed even if the header section is not updated.

As there can be in total three parallel tasks in the FlexRay internal message handler but the number of concurrent tasks is unknown, not only for a worst case consideration the number of concurrent tasks must be set to 3. Beside the setup time and the number of words to be transferred a message handler internal delay time of 75 bus clock cycles must be added. The maximum number of payload to be transferred is in worst case 64.

The worst case for an input transfer is different from the worst case for an output transfer.

For an input transfer the setup time required is 6 bus clock cycles and therefore

$$cycles_{req\_MHD\_input[64]} = 3 * (6 + 68 + 75) = 447$$

Equation 5 Message hander internal input transfer time (longest case)

For an output transfer the setup time required is 2 bus clock cycles and therefore

$$cycles_{req\_MHD\_output[64]} = 3 * (2 + 68 + 75) = 435$$

Equation 6 message handler internal output transfer time (longest case)

(2) System bus transfer time

The number of bus clock cycles required for a transfer is written in bus clock cycles and is identical for all kind of transfers between the local RAM/global RAM and the FlexRay module.

The time required by the transfer handler for a transfer between the local RAM/global RAM and the FlexRay interface buffer is given by

$$cycles_{req\_SB[PL]} = throughput * (systemTime + DataWords_{req[PL]}) + setupTime$$

Equation 7 General system bus transfer time formula

The number of payload words (32 bit) can be calculated by using Equation 4.

The throughput depends on the utilization of the system bus and depends on the application. However, the data transfer handler has the highest priority for accessing the local RAM/global RAM and the data throughput factor can be assumed as XXXX even in worst case scenarios. The system time (read of the data pointer from local RAM/global RAM) can be set to 1 in all cases. The transfer setup time can be set to 3 in all cases.

Therefore, the system bus transfer time (given in bus clock cycles) is given by

$$cycles_{req\_SB[64]} = throughput * (2 + 68) + 3 = XXXX * (2 + 68) + 3$$

Equation 8 System bus transfer time (longest case)

In addition to the system bus transfer time, a FlexRay module internal processing time needs to be taken into account. The number of clock cycles required for the internal processing time required is given in FlexRay core module clock cycles (bus clock) and is different between input transfers and output transfers but can be treated as constants.

$$cycles_{req\_THD\_input} = 2 + 4 = 6$$

Equation 9

Whereby 2 cycles are required to initiate the FlexRay module internal transfer from the input buffer to the message RAM. In addition 4 internal processing cycles are required.

$$cycles_{req\_THD\_output} = 3 + 4 = 7$$

Equation 10

Whereby 3 cycles are required to initiate the FlexRay module internal transfer from the input buffer to the message RAM. In addition 4 internal processing cycles are required.

(3) Summary required input transfer time

The worst case time (as a function of the transferred payload) required to transfer data between the local RAM/global RAM to the FlexRay internal message buffer can be calculated by

$$t\_input_{[PL]} = t\_chi * (cycles_{req\_THD\_input} + cycles_{req\_MHD\_input[PL]}) + t\_sys * (cycles_{req\_SB[PL]})$$

$$t\_input_{[PL]} = t\_chi * \left(6 + 3 * \left[81 + DataWords_{[PL]}\right]\right) + t\_sys * \left(throughput * \left[2 + DataWords_{[PL]}\right] + 3\right)$$

Equation 11 input transfer time

With

$$t\_sys = \left(f(sysclk)\right)^{-1}$$

and

$$t\_chi = \left(f(clkp2\_flx)\right)^{-1}$$

(4) Summary required output transfer time

The worst case time (as a function of the transferred payload) required to transfer data from the FlexRay internal message buffer to the local RAM/global RAM can be calculated by

$$t\_output_{[PL]} = t\_chi * (cycles_{req\_THD\_output} + cycles_{req\_MHD\_output[PL]}) + t\_sys * (cycles_{req\_SB[PL]})$$
$$t\_output_{[PL]} = t\_chi * \left(7 + 3 * \left\lceil 77 + DataWords_{[PL]} \right\rceil\right) + t\_sys * \left(throughput * \left\lceil 2 + DataWords_{[PL]} \right\rceil + 3\right)$$

Equation 12 Output transfer time

With

$$t\_sys = \left(f(sysclk)\right)^{-1}$$

and

$$t\_chi = \left(f(clkp2\_flx)\right)^{-1}$$

17.3.17 Byte Alignment

The alignment of the bytes received by the FlexRay protocol and the alignment of the bytes required by the application may be different. The FlexRay module provides with FLXA0FROC.BEC a byte alignment function to support different byte ordering styles.

Figure 17.32 shows the payload byte alignment in a FlexRay frame.

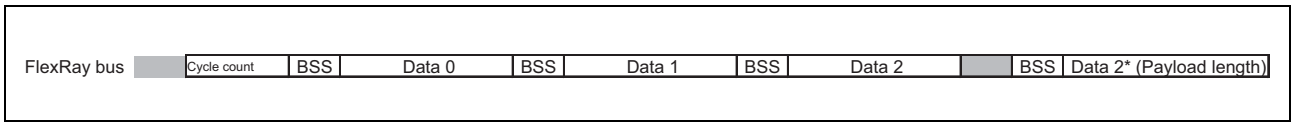

Figure 17.32 Byte Alignment on the FlexRay Bus

17.3.17.1 Little Endian Alignment

When FLXA0FROC.BEC is '0', the byte alignment is set to Little Endian.

(1) FLXA0FRNMVn (n = 1 to 3)

The byte alignment of the NMV bytes is as below.

Bit	31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
FLXA0FRNMV1	Data 3		Data 2		Data 1		Data 0	
FLXA0FRNMV2	Data 7		Data 6		Data 5		Data 4	
FLXA0FRNMV3	Data 11		Data 10		Data 9		Data 8	

(2) FLXA0FRWRDSn (n = 1 to 64)

The byte alignment for the message payload in the FlexRay input buffer and the input data structure is as below.

FLXA0FRWRDSn.MD[7:0] = $Data_{4n-4}$

FLXA0FRWRDSn.MD[15:8] = $Data_{4n-3}$

FLXA0FRWRDSn.MD[23:16] =$Data_{4n-2}$

FLXA0FRWRDSn.MD[31:24] = $Data_{4n-1}$

Transmission order on the FlexRay bus is FLXA0FRWRDSn.MD[7:0], FLXA0FRWRDSn.MD [15:8], FLXA0FRWRDSn.MD [23:16], FLXA0FRWRDSn.MD [31:24] with the most significant bit (MSB) transmitted first.

(3) FLXA0FRRDDSn (n = 1 to 64)

The byte alignment for the message payload in the FlexRay output buffer and the output data structure is as below.

FLXA0FRRDDSn.MD[7:0] = $Data_{4n-4}$

FLXA0FRRDDSn.MD[15:8] = $Data_{4n-3}$

FLXA0FRRDDSn.MD[23:16] =$Data_{4n-2}$

FLXA0FRRDDSn.MD[31:24] = $Data_{4n-1}$

Transmission order on the FlexRay bus is FLXA0FRRDDSn.MD[7:0], FLXA0FRRDDSn.MD[15:8], FLXA0FRRDDSn.MD[23:16], FLXA0FRRDDSn.MD[31:24] with the most significant bit (MSB) transmitted first.

17.3.17.2 Big Endian Alignment

When FLXA0FROC.BEC is '1', the byte alignment is set to Big Endian.

(1) FLXA0FRNMVn (n = 1 to 3)

The byte alignment of the NMV bytes is as below.

Bit	31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
FLXAnFRNMV1	Data 0		Data 1		Data 2		Data 3	
FLXAnFRNMV2	Data 4		Data 5		Data 6		Data 7	
FLXAnFRNMV3	Data 8		Data 9		Data 10		Data 11	

(2) FLXA0FRWRDSn (n = 1 to 64)

The byte alignment for the message payload in the FlexRay input buffer and the input data structure is as below.

FLXA0FRWRDSn.MD[7:0] = $Data_{4n-1}$

FLXA0FRWRDSn.MD[15:8] = $Data_{4n-2}$

FLXA0FRWRDSn.MD[23:16] =$Data_{4n-3}$

FLXA0FRWRDSn.MD[31:24] = $Data_{4n-4}$

Transmission order on the FlexRay bus is FLXA0FRWRDSn.MD[31:24], FLXA0FRWRDSn.MD[23:16], FLXA0FRWRDSn.MD[15:8], and FLXA0FRWRDSn.MD[7:0] with the most significant bit (MSB) transmitted first.

(3) FLXA0FRWRDSn (n = 1 to 64)

The byte alignment for the message payload in the FlexRay output buffer and the output data structure is as below.

FLXA0FRRDDSn.MD[7:0] = $Data_{4n-1}$

FLXA0FRRDDSn.MD[15:8] = $Data_{4n-2}$

FLXA0FRRDDSn.MD[23:16] =$Data_{4n-3}$

FLXA0FRRDDSn.MD[31:24] = $Data_{4n-4}$

Transmission order on the FlexRay bus is FLXA0FRWRDSn.MD[7:0], FLXA0FRWRDSn.MD [15:8], FLXA0FRWRDSn.MD [23:16], FLXA0FRWRDSn.MD [31:24] with the most significant bit (MSB) transmitted first.

Section 18 Renesas High-Speed Bus (RHSB)

18.1 Overview

18.1.1 Features of RHSB

Channels: This microcontroller has the following number of channels of the Renesas high-speed bus (RHSB).

Table 18.1 Channels of RHSB

Renesas High-Speed Bus	RH850/E1M-S
Instance	2
Name	RHSB0, RHSB1

Chip select index: The Renesas high-speed bus has up to 2 chip select signals. Throughout this section, the individual chip select signals are identified by the index “x”, thus a given chip select signal is denoted as RHSBjCSDx (j = 0, 1).

The number of chip select signals for each channel of RHSBj is given in the following table.

Table 18.2 RHSB Chip Select Index

RHSB instance	RH850/E1M-S
RHSB0	RHSB0CSDx (x = 0, 1)
RHSB1	RHSB1CSDx (x = 0, 1)

Upstream serial input index: The Renesas high-speed bus has up to 2 upstream serial input signals. Throughout this section, the individual upstream serial input signals are identified by the index “x”, thus a upstream serial input signal is denoted as RHSBjSIx (j = 0, 1).

The number of upstream serial input signals for each channel of RHSBj is given in the following table.

Table 18.3 RHSB Upstream Serial Input Index

RHSB Channels	RH850/E1M-S
RHSB0	RHSB0SIx (x = 0, 1)
RHSB1	RHSB1SIx (x = 0, 1)

18.1.2 Module Overview

This section describes the features of this Renesas high-speed bus (RHSB). The RHSB is designed to be used as a master node for up to 4 Microsecond Bus Channels. It is designed to be compliant to MSC 1.0 (BOSCH/Infineon, July 2003) specification and to MSC 1.0.0 (IPextreme, July 27, 2007).

18.1.2.1 Downstream Channel Communication Functions

Downstream communication

- Synchronous serial transmission
- Clock phase is selectable and clock activity is configurable during passive phases
- Configurable repetition period is independent from data frame length (1 to 512_D bits (data bit))
- Configurable downstream bit rate to be $f_{DW} = f_{PE}/x$ with x = (2, 4, 5, 8, 16, 32, 64, 128, 256). f_{PE} is typically 80 MHz.
- Indication of the status of ongoing downstream transmission, for evaluation purpose

Up to 2 slaves are supported with this individual configuration

- Active level of the chip select and data bits
- Selection bit for data frame present/not present
- Length of assertion time (0 to 7_D bits) and of de-assertion time (0 to 7_D bits)

Downstream data frame

- Each data frame (1 to 64 bits) is composed by 1 to 4 DFTEs with individual length
- The user can define for each bit of a DFTE an individual source (e.g. timer input, data register)
- The frame passive phase after each data frame is configurable from 1 to 64 bits
- Three transmission modes to schedule data transmission

Downstream command frame

- Command frame transmission with/without request of remote data
- Dedicated register is available defining 1 to 32 bits for command frame transmission
- Three different methods to insert command frames into the data frame schedule

Emergency function

- Handling of emergency condition can be enabled/disabled
- Emergency condition is identified by an input pin of the MCU with programmable active level
- Emergency input is selectable between level or edge sensitive
- After transmission of an emergency frame data transmission can be stopped automatically
- Emergency data transmission DFTE bits are individually programmable through a dedicated register

18.1.2.2 Upstream Channel Communication Functions

Upstream communication

- Asynchronous serial reception
- Automatic selection of slave configuration when applying a command frame with data request
- Timeout detection can be activated to monitor slave response on a command frame with data request
- Status indication of ongoing upstream reception transmission, for evaluation purpose

Up to 2 slaves are supported for upstream communication with individual configuration

- Active level of data line
- Frame with 8 or 12 data bits, even or odd parity bit, and 2 or 3 stop bits
- Upstream bit rate derived from downstream bit rate ($f_{UP} = f_{DW}/2^x$ with x = 3 to 9; results in /8 to /512)

Upstream status of up to 2 slaves

- Valid data received
- Data lost (overrun of data register)
- Timeout error
- Receive error (parity bit error or stop bit error)

18.1.2.3 Interrupts

The RHSB module has 9 sources for interrupt requests. 5 interrupts are downstream related, 4 interrupts are upstream related. These requests are grouped to 5 physical interrupt request lines.

There is an individual interrupt enable bit and an individual interrupt status bit for each interrupt source.

18.1.2.4 DMA Support

The RHSB module supports an update of the downstream data registers by downstream data DMA transfer. The ‘Data frame transmission started’ interrupt is used to trigger this transfer.

The RHSB module supports an update of the downstream command data registers by downstream command DMA transfer. Command frame transmission done' interrupt is used to trigger this transfer.

The RHSB module supports an automatic transfer of valid received data by upstream DMA. The ‘Receive Data’ interrupt is used to trigger this transfer.

18.1.2.5 Other Features

The RHSB module supports a test mode for key-on test. In this test mode a simple check of the data path is possible by loop back of downstream transmission to the upstream reception.

18.1.2.6 Caution

This product supports only the driving ability with the setting of high as the output buffer characteristics of pins (driving ability) for chip select signal of the RHSB. For setting of output buffer characteristics, see **Table 2.25, PUCCn Register Contents**.

18.1.3 Block Diagram

Figure 18.1 shows a top level block diagram of the RHSB module.

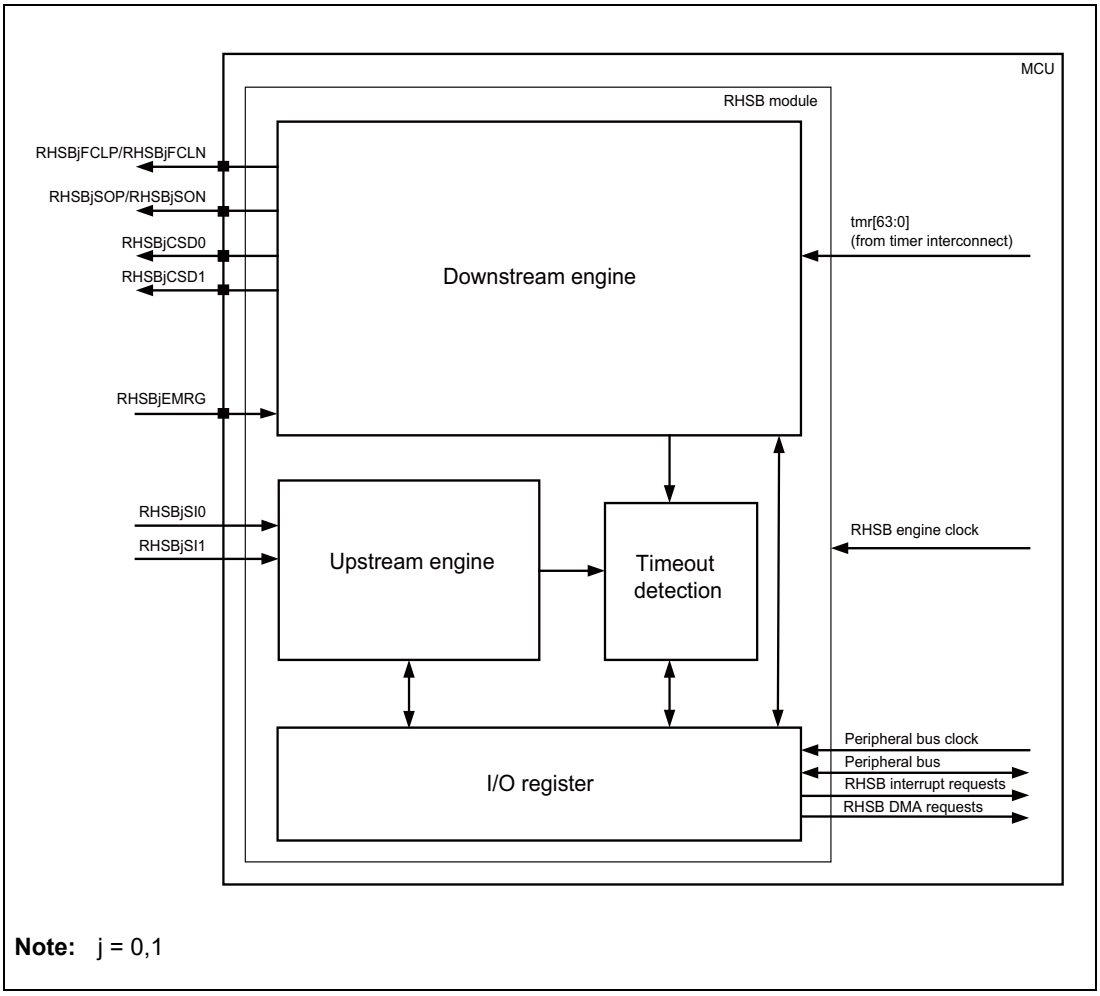

Figure 18.1 Top Level Block Diagram

The tmr[63:0] bits of the timer correspond to the ATU-IV and APA selected by the XBAR. For details of the XBAR, see **Section 18.7, Cross Bar (XBAR)**.

18.2 Register Descriptions

This section describes in detail the I/O registers of the RHSB module.

In case of a concurrent update of the same register bit, RHSB module write (hardware write) has higher priority than CPU write (software write).

18.2.1 I/O Registers Overview

The RHSB address range starts from <RHSBj_base> + 00_H and ends at <RHSBj_base> + $7F_H$.

The base address <RHSBj_base> is shown in **Table 18.4**.

The register map of a RHSB module is shown in **Table 18.5**.

Table 18.4 Base Address <RHSBj_base>

RHSBj	RHSBj_base
RHSB0	FFEE 0000_H
RHSB1	FFEE 1000_H

The RHSB module remains in reset while RHSBjGC.RHSBjOPS is RESET.

The values shown in **Table 18.5** and in the I/O registers description under 'Values after Reset' are related to this reset state.

For further information about the RHSB operation modes please refer to **Section 18.3, Operation States**.

The module specific base address of a RHSB module needs to be added to each of the specified offset addresses.

Table 18.5 I/O Registers Address Map (1/2)

Register Name	Symbol *1	Value after Reset	Address	Access Size
Global configuration register	RHSBjGC	0000 0000_H	<RHSBj_base> + 00_H	32, 16, 8
Module status register	RHSBjMSR	0001 0000_H	<RHSBj_base> + 08_H	32, 16, 8
Downstream configuration register	RHSBjDCR	0011 $FF00_H$	<RHSBj_base> + 10_H	32, 16
Data element configuration register	RHSBjDEC	0000 0000_H	<RHSBj_base> + 14_H	32, 16, 8
Slave device configuration register i (i = 0)	RHSBjSDCi	0000 0000_H	<RHSBj_base> + 18_H + 4*i	32, 16
Data element bit assignment register m (m = 0 to 3)	RHSBjDEBAm	0000 0000_H	<RHSBj_base> + 20_H + 4*m	32, 16
Emergency bit enable register i (i = 0, 1)	RHSBjEBEi	0000 0000_H	<RHSBj_base> + 30_H + 4*i	32, 16
Downstream transmission control register	RHSBjDTC	0000 0000_H	<RHSBj_base> + 38_H	32, 16, 8
Downstream command data register	RHSBjDCD	0000 0000_H	<RHSBj_base> + $3C_H$	32, 16
Downstream data register i (i = 0, 1)	RHSBjDDRi	0000 0000_H	<RHSBj_base> + 40_H + 4*i	32, 16
Downstream emergency data register i (i = 0, 1)	RHSBjDEDi	0000 0000_H	<RHSBj_base> + 48_H + 4*i	32, 16
Upstream configuration register	RHSBjUCR	0000 1800_H	<RHSBj_base> + 50_H	32, 16, 8
Upstream channel configuration register	RHSBjUCC	0F0F $0F0F_H$	<RHSBj_base> + 54_H	32, 16, 8
Upstream channel selection register	RHSBjUCS	0000 0000_H	<RHSBj_base> + 58_H	32, 16, 8
Upstream data read register	RHSBjUDR	0000 0000_H	<RHSBj_base> + $5C_H$	32, 16, 8
Upstream data register i (i = 0, 1)	RHSBjUDi	0000 0000_H	<RHSBj_base> + 60_H + 4*i	32, 16, 8
Upstream status summary register	RHSBjUSS	0000 0000_H	<RHSBj_base> + 70_H	32, 16, 8
Interrupt control register	RHSBjIC	0000 0000_H	<RHSBj_base> + 74_H	32, 16, 8
Interrupt status register	RHSBjIS	0000 0000_H	<RHSBj_base> + 78_H	32, 16, 8

Table 18.5 I/O Registers Address Map (2/2)

Register Name	Symbol *1	Value after Reset	Address	Access Size
Downstream configuration register for period 1	RHSBjDCR1	0000 0000_H	<RHSBj_base> + $7C_H$	32, 16, 8

Note 1. j = 0, 1

The access size mentioned in **Table 18.5** is obligatory for write accesses. In addition all registers are readable by 8, 16 and 32 bit access.

The user should not access the registers marked as reserved in **Table 18.5**.

The user should not write bits to a value specified as 'invalid' in the I/O registers description.

18.2.2 Legend

This section explains the module state dependent abbreviations used for the I/O registers description in **Section 18.2.3, Description of the Registers in the Common Controller** to **Section 18.2.6, Interrupt Registers**.

Conditions:

- R/W: Bit is readable and writable
- R: Read-only bit; the user cannot write to this bit

Indexes used for register and register bit names

i: Universal index

m: Index related to DFTE m

n: Index related to slave n

Reserved bits:

- Always read as 0
- Writing to these bits has no effect (hardware protection)

18.2.3 Description of the Registers in the Common Controller

18.2.3.1 RHSBjGC — Global Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + 00_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	RHSBj DCDE	RHSBj DDE	RHSBj UDE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RHSBjOPS[1:0]

Table 18.6 RHSBjGC Register Contents

Bit Position	Bit Name	Function
31 to 19	—	Reserved These bits are always read as 0. The write value should be always 0.
18	RHSBjDCDE	Downstream Command DMA Request Enable 0_B: Downstream command DMA request is disabled. 1_B: Downstream command DMA request is enabled.
17	RHSBjDDE	Downstream Data DMA Request Enable 0_B: Downstream data DMA request is disabled. 1_B: Downstream data DMA request is enabled.
16	RHSBjUDE	Upstream DMA Request Enable 0_B: Upstream DMA request is disabled. 1_B: Upstream DMA request is enabled.
15 to 2	—	Reserved These bits are always read as 0. The write value should be always 0.
1, 0	RHSBjOPS[1:0]	Operation Status 00_B: RESET state 01_B: CONFIG state 10_B: ACTIVE state 11_B: TEST state

(1) RHSBjGC.RHSBjDCDE — Downstream Command DMA Request Enable

The user should not set this bit to 1_B when RHSBjIS.RHSBjCTF is used as interrupt source (RHSBjIC.RHSBjCTIE is 1_B).

This bit defines if the downstream command data register (RHSBjDCD) and downstream transmission control register (RHSBjDTC) are updated by downstream DMA transfer and command data are transferred to slaves when RHSBjIS.RHSBjCTF is 1_B.

For details about downstream command DMA refer to **Section 18.6.2, DMA Usage for Downstream Command Transmission**.

(2) RHSBjGC.RHSBjDDE — Downstream Data DMA Enable

The user should not set this bit to 1_B when RHSBjIS.RHSBjDTSF is used as interrupt source (RHSBjIC.RHSBj DTSIE is 1_B).

This bit defines if the downstream data registers (RHSBjDDRi) are updated by downstream DMA transfer when RHSBjIS.RHSBjDTSF is 1_B.

For details about downstream data DMA refer to **Section 18.6.1, DMA Usage for Downstream Data Transmission**.

(3) RHSBjGC.RHSBjUDE — Upstream DMA Enable

The user should not set this bit to 1_B when RHSBjIS.RHSBjDRF is used as interrupt source (RHSBjIC.RHSBjDRIE is 1_B).

This bit defines if the upstream data register (RHSBjUDR) is transferred by upstream DMA when RHSBjIS.RHSBjDRF is 1_B.

For details about upstream DMA refer to **Section 18.6.3, DMA Usage for Upstream Data Reception**.

(4) RHSBjGC.RHSBjOPS — Operation Status

The user cannot write 11_B (TEST) to these bits while RHSBjGC.RHSBjOPS is 00_B or 10_B.

The user cannot write 10_B (ACTIVE) to these bits while RHSBjGC.RHSBjOPS is 00_B or 11_B.

These bits define the current operation state of the RHSB module.

Refer to **Section 18.3, Operation States**.

18.2.3.2 RHSBjMSR — Module Status Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + 08_H

Value after reset: 0001 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	RHSBjDFA[2:0]			—	—	—	—	—	—	—	RHSBj TPS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RHSBj UFA
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.7 RHSBjMSR Register Contents

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. The write value should be always 0
26 to 24	RHSBjDFA[2:0]	Downstream Frame Activity 000_B: Inter-frame passive or disabled 001_B: Passive phase of data frame 010_B: Active phase of command frame 011_B: Passive phase of command frame 100_B: Active phase of data frame (DFTE0) 101_B: Active phase of data frame (DFTE1) 110_B: Active phase of data frame (DFTE2) 111_B: Active phase of data frame (DFTE3)
23 to 17	—	Reserved These bits are always read as 0. The write value should be always 0
16	RHSBjTPS	Transmission Period Status 0_B: Period 0 1_B: Period 1
15 to 1	—	Reserved These bits are always read as 0. The write value should be always 0
0	RHSBjUFA	Upstream Frame Activity 0_B: Upstream is idle 1_B: Upstream frame decoding is ongoing

(1) Downstream Frame Activity (RHSBjMSR.RHSBjDFA)

These bits indicate details of the downstream frame transmission. These bits are only valid when the downstream communication rate is equal to or falls below 5 megabits per second.

DTFE being transferred is flagged for the active phase of a data frame. A flag is placed in the slave select bit (assert phase or deassert phase) as a part of related DFTE.

[Changing conditions]

These bits are updated when the downstream communication phase changes.

These bits are updated when the number of DFTE used for transmission changes.

These bits are set to 000_B when entering CONFIG state.

(2) Transmission Period Status (the RHSBjTPS bit in RHSBjMSR)

This bit is only valid in multi-period repetition mode.

This bit counts and specifies the transmission period.

This bit starts to operate from 0_B when a transmission starts.

[Changing condition]

When multi-period repetition mode is selected, this bit is updated at the timing of time tick.

[Setting conditions]

When a user writes 1_B to the RHSBjDTE bit in RHSBjDTC, reading the value of this bit returns 1_B.

When the emergency function enable bit (the RHSBjEE bit in RHSBjDCR) is set to 11_B, reading the value of this bit returns 1_B.

When entering the CONFIG state, reading the value of this bit returns 1_B.

(3) Upstream Frame Activity (RHSBjMSR.RHSBjUFA)

This bit represents that the upstream decoder has detected a start bit and a frame is currently decoded.

[Clearing condition]

This bit is set to 0_B when the upstream decoder leaves RX-Active state.

[Setting condition]

This bit is set to 1_B when the upstream decoder enters RX-Active state.

18.2.4 Downstream (Tx) Registers

18.2.4.1 RHSBjDCR — Downstream Configuration Register

Access: This register can be read/written in 16- or 32-bit units.

Address: <RHSBj_base> + 10_H

Value after reset: 0011 $FF00_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31, 30	RHSBjSLS[1:0]	Sequence Length Setting 00_B: 1 DFTE (DFTE0) 01_B: 2 DFTEs (DFTE0, DFTE1) 10_B: 3 DFTEs (DFTE0 to DFTE2) 11_B: 4 DFTEs (DFTE0 to DFTE3)
29 to 24	RHSBjDFP[5:0]	Data Frame Passive Length Length of the data frame passive phase
23 to 20	RHSBjDBR[3:0]	Downstream Bit Rate 0_D: Invalid 1_D: $f_{DW} = f_{PE}/2$ 2_D: Invalid 3_D: $f_{DW} = f_{PE}/4$ 4_D: $f_{DW} = f_{PE}/5$ 5_D: Invalid 6_D: Invalid 7_D: $f_{DW} = f_{PE}/8$ 8_D: $f_{DW} = f_{PE}/16$ 9_D: $f_{DW} = f_{PE}/32$ 10_D: $f_{DW} = f_{PE}/64$ 11_D: $f_{DW} = f_{PE}/128$ Others: $f_{DW} = f_{PE}/256$
19, 18	RHSBjCIM[1:0]	Command Frame Insertion Method 00_B: Time-slot method 01_B: Immediate method 10_B: Best-effort method 11_B: Invalid
17	RHSBjCTD	Command Frame Transmission Delay 0_B: No restriction 1_B: Transmission of consecutive command frames prevented
16 to 8	RHSBjREP[8:0]	Repetition Period Length Length of the data frame repetition period
7	RHSBjCLP	Clock Line Phase 0_B: Change on rising edge 1_B: Change on falling edge

Table 18.8 RHSBjDCR Register Contents (2/2)

Bit Position	Bit Name	Function
6	RHSBjCAC	Clock Active Control 0_B: Clock is inactive during the passive phases 1_B: Clock is always active
5, 4	RHSBjEE[1:0]	Emergency Enable 00_B: Emergency condition detection disabled 01_B: Emergency condition detection enabled and automatic stop disabled 10_B: Invalid 11_B: Emergency condition detection enabled and automatic stop enabled
3	RHSBjEIM	Emergency Input Mode 0_B: Edge sensitive 1_B: Level sensitive
2	RHSBjEIP	Emergency Input Polarity 0_B: Active level is high / Rising edge 1_B: Active level is low / Falling edge
1, 0	RHSBjDMS[1:0]	Downstream Mode Select 00_B: Single-period repetition mode 01_B: Triggered mode 10_B: Multi-period repetition mode 11_B: Invalid

(1) Sequence Length Setting (RHSBjDCR.RHSBjSLS)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define the number of DFTEs used to assemble one downstream data frame.

(2) Data Frame Passive Length (RHSBjDCR.RHSBjDFP)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define the length of the frame passive phase (1 to 64_D bits) for data frames.

That is, when these bits are 0_D, the frame passive phase has the length of 1_D bit.

Note that a frame passive phase of 1_D bit is not valid according MSC specification.

(3) Downstream Bit Rate (RHSBjDCR.RHSBjDBR)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define how the downstream bit rate is derived from the f_{PE} clock.

(4) Command Frame Insertion Method (RHSBjDCR.RHSBjCIM)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines how a command frame is inserted into an ongoing downstream schedule.

The following methods are available.

Time-slot method:

Command frame transmission is delayed to be handled within the defined repetition period. The repetition period is not affected by command frame transmission.

Immediate method:

Command frame transmission is handled as soon as possible. The prepetition period can be re-adjusted in case of command frame transmission.

Best-effort method:

Command frame transmission is handled as soon as possible with minimum impact to the data frame transmission. The repetition period is not affected by command frame transmission.

(5) Command Frame Transmission Delay (RHSBjDCR.RHSBjCTD)

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines if the command frame transmission is restricted to have at least one data frame between two command frames.

(6) Repetition Period Length (RHSBjDCR.RHSBjREP)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define the length of repetition period (1 to 512_D bits) used for downstream communication in single-period repetition mode and multi-period repetition mode.

That is, when these bits are 0_D the repetition period is 1_D bit.

Please refer to **Section 18.4.1.3, Downstream Modes (2) Repetition mode (Single-period repetition, Multi-period repetition)** for details.

(7) Clock Line Phase (RHSBjDCR.RHSBjCLP)

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines if the serial data line (RHSBjSOP, RHSBjSON (j = 0, 1)) and the chip select lines (RHSB0CSD0-1, RHSB1CSD0-1) are changing with the rising or falling edge of the serial clock line (RHSBjFCLP, RHSBjFCLN (j = 0, 1)).

(8) Clock Active Control (RHSBjDCR.RHSBjCAC)

This bit defines the activity of the downstream serial clock line (RHSBjFCLP, RHSBjFCLN (j = 0, 1)) during the passive phases. During active phases the clock is always active.

(9) Emergency Input Enable (RHSBjDCR.RHSBjEE)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits enable the emergency function of the RHSB module.

In addition these bits define if the data transmission is stopped after an emergency frame has been transmitted.

(10) Emergency Input Mode (RHSBjDCR.RHSBjEIM)

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines how the emergency condition is derived from the external emergency signal (RHSBjEMRG (j = 0, 1)).

(11) Emergency Input Polarity (RHSBjDCR.RHSBjEIP)

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines the active level of the external emergency signal (RHSBjEMRG(j = 0, 1)).

(12) Downstream Mode Select (RHSBjDCR.RHSBjDMS)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define the timing mode of the downstream channel.

18.2.4.2 RHSBjDCR1 — Downstream Configuration Register for Period 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + $7C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.9 RHSBjDCR1 Register Contents

Bit Position	Bit Name	Function
31, 30	RHSBjSLS1[1:0]	Sequence Length Setting for Period 1 00_B: 1 DFTE (DFTE0) 01_B: 2 DFTEs (DFTE0, DFTE1) 10_B: 3 DFTEs (DFTE0 to DFTE2) 11_B: 4 DFTEs (DFTE0 to DFTE3)
29 to 0	—	Reserved These bits are always read as 0. The write value should be always 0

(1) Sequence Length Setting for Period 1 (RHSBjDCR1.RHSBjSLS1)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define the number of DFTEs used to assemble one downstream data frame.

These bits are available only in multi-period repetition mode. RHSBjDCR1.RHSBjSLS1 value should be equal to or smaller than RHSBjDCR.RHSBjSLS value.

18.2.4.3 RHSBjDEC — Data Element Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + 14_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.10 RHSBjDEC Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. The write value should be always 0
29, 28	RHSBjSSD0 [1:0]	Slave Selected for DFTE0 Slave selected when transmitting DFTE0
27 to 24	RHSBjNDB0 [3:0]	Number of Data Bits 0 Number of data bits used from DFTE0
23, 22	—	Reserved These bits are always read as 0. The write value should be always 0
21, 20	RHSBjSSD1 [1:0]	Slave Selected for DFTE1 Slave selected when transmitting DFTE1
19 to 16	RHSBjNDB1 [3:0]	Number of Data Bits 1 Number of data bits used from DFTE1
15, 14	—	Reserved These bits are always read as 0. The write value should be always 0
13, 12	RHSBjSSD2 [1:0]	Slave Selected for DFTE2 Slave selected when transmitting DFTE2
11 to 8	RHSBjNDB2 [3:0]	Number of Data Bits 2 Number of data bits used from DFTE2
7, 6	—	Reserved These bits are always read as 0. The write value should be always 0
5, 4	RHSBjSSD3 [1:0]	Slave Selected for DFTE3 Slave selected when transmitting DFTE3
3 to 0	RHSBjNDB3 [3:0]	Number of Data Bits 3 Number of data bits used from DFTE3

(1) Slave Selected for DFTEm (RHSBjDEC.RHSBjSSDm) (m = 0 to 3)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define which slave is addressed by downstream frame transmission element m (DFTEm). Setting 10_B and 11_B is prohibited.

(2) Number of Data Bits m (RHSBjDEC.RHSBjNDBm) (m = 0 to 3)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define the number of bits (1 to 16) used from DFTEm for data frame transmission.

That is, when these bits are 0_D, 1 bit from DFTEm is transmitted.

18.2.4.4 RHSBjSDCi — Slave Device Configuration Register i (i = 0)

Access: This register can be read/written in 16- or 32-bit units.

Address: <RHSBj_base> + 18_H + 4_H × i

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note 1. n = 2 * i (for bits 31 to 16)

Note 2. n = 2 * i + 1 (for bits 15 to 0)

Table 18.11 RHSBjSDCi Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. The write value should be always 0.
26 to 24	RHSBjAPLn[2:0]	Assertion Phase Length Assertion phase length for slave 0
23, 22	—	Reserved These bits are always read as 0. The write value should be always 0.
21	RHSBjCSLPn	Chip Select Line Polarity Chip select line polarity for slave 0 0_B: Active high 1_B: Active low
20	RHSBjSOLPn	Serial Out Line Polarity Serial out line polarity for slave 0 0_B: Inversion disabled 1_B: Inversion enabled
19	RHSBjCPSn	Content Phase Selection Bit Enable Content phase selection bit enable for slave 0 0_B: No selection bit is present 1_B: Selection bit is present
18 to 16	RHSBjDPLn[2:0]	Deassertion Phase Length Deassertion phase length for slave 0
15 to 11	—	Reserved These bits are always read as 0. The write value should be always 0.
10 to 8	RHSBjAPLn[2:0]	Assertion Phase Length Assertion phase length for slave 1
7, 6	—	Reserved These bits are always read as 0. The write value should be always 0.
5	RHSBjCSLPn	Chip Select Line Polarity Chip select line polarity for slave 1 0_B: Active high 1_B: Active low
4	RHSBjSOLPn	Serial Out Line Polarity Serial out line polarity for slave 1 0_B: Inversion disabled 1_B: Inversion enabled

Table 18.11 RHSBjSDCi Register Contents (2/2)

Bit Position	Bit Name	Function
3	RHSBjCPSn	Content Phase Selection Bit Enable Content phase selection bit enable for slave 1 0_B: No selection bit is present 1_B: Selection bit is present
2 to 0	RHSBjDPLn[2:0]	Deassertion Phase Length Deassertion phase length for slave 1

(1) Assertion Phase Length (RHSBjSDCi.RHSBjAPLn) (n = 0, 1)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define the assertion phase (0 to 7_D bits) used for frames transmitted to slave n. If these bits are 0_D no assertion phase is present.

(2) Chip Select Line Polarity (RHSBjSDCi.RHSBjCSLPn) (n = 0, 1)

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines the polarity of the chip select line (RHSBjCSDn (n = 0, 1)) for slave n.

(3) Serial Out Line Polarity (RHSBjSDCi.RHSBjSOLPn) (n = 0, 1)

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines the inversion of the serial data line (RHSBjSOP, RHSBjSON (j = 0, 1)) when slave n is selected.

(4) Content Phase Selection Bit enable (RHSBjSDCi.RHSBjCPSn) (n = 0, 1)

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines if there is a selection bit in data frames transmitted to slave n.

Note that in command frames the selection bit is always present.

(5) Deassertion Phase Length (RHSBjSDCi.RHSBjDPLn) (n = 0, 1)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define the deassertion phase (0 to 7_D bits) used for frames transmitted to slave n. If these bits are 0_D no deassertion phase is present.

18.2.4.5 RHSBjDEBAm — Data Element Bit Assignment Register m (m = 0 to 3)

Access: This register can be read/written in 16- or 32-bit units.

Address: <RHSBj_base> + 20_H + 4_H × m

Value after reset: 0000 0000_H

13, 12	RHSBjDSS6 [1:0]	Data Source Select 6 Data source select for bit 6 in DFTEm
11, 10	RHSBjDSS5 [1:0]	Data Source Select 5 Data source select for bit 5 in DFTEm
9, 8	RHSBjDSS4 [1:0]	Data Source Select 4 Data source select for bit 4 in DFTEm
7, 6	RHSBjDSS3 [1:0]	Data Source Select 3 Data source select for bit 3 in DFTEm
5, 4	RHSBjDSS2 [1:0]	Data Source Select 2 Data source select for bit 2 in DFTEm
3, 2	RHSBjDSS1 [1:0]	Data Source Select 1 Data source select for bit 1 in DFTEm
1, 0	RHSBjDSS0 [1:0]	Data Source Select 0 Data source select for bit 0 in DFTEm

(1) Data Source Select i (RHSBjDEBAm.RHSBjDSSi) (i = 0 to 15)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define the data source of bit i in RHSBjDFTEm.

00_B: Bit from timer input is selected

01_B: Inverted bit from timer input is selected

10_B: Bit from downstream data register RHSBjDDR0 or RHSBjDDR1 is selected

11_B: Invalid

Please refer to **Section 18.4.1.6, Data Frame Assembling** for details about the bit selection and the bit mapping.

18.2.4.6 RHSBjEBEi — Emergency Bit Enable Register i (i = 0, 1)

Access: This register can be read/written in 16- or 32-bit units.

Address: <RHSBj_base> + 30_H + 4_H × i

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RHSBjEBE[15 + 32*i:8 + 32*i]								RHSBjEBE[7 + 32*i:32*i]

Table 18.13 RHSBjEBEi Register Contents

Bit Position	Bit Name	Function
31 to 24	RHSBjEBE[15 + 32*i:8 + 32*i]	Emergency Bit Enable Emergency Enable of DFTE i*2 (DFTE0, DFTE2) 0_B: Emergency function for this bit is disabled 1_B: Emergency function for this bit is enabled
23 to 16	RHSBjEBE[7 + 32*i:32*i]	
15 to 8	RHSBjEBE[31 + 32*i:24 + 32*i]	Emergency Bit Enable Emergency Enable of DFTE 1+i*2 (DFTE1, DFTE3) 0_B: Emergency function for this bit is disabled 1_B: Emergency function for this bit is enabled
7 to 0	RHSBjEBE[23 + 32*i:16 + 32*i]	

(1) Emergency Bit Enable (RHSBjEBEi.RHSBjEBE)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define if the emergency function is enabled for a data frame bit.

Each bit enables the emergency function for the corresponding bit in a RHSBjDFTE.RHSBjDFTE0 is controlled by RHSBjEBE0[31:16], RHSBjDFTE1 by RHSBjEBE0[15:0], RHSBjDFTE2 by RHSBjEBE1[31:16] and RHSBjDFTE3 by RHSBjEBE1[15:0].

Please refer to **Section 18.4.1.6, Data Frame Assembling** for details.

18.2.4.7 RHSBjDTC — Downstream Transmission Control Register

Do not rewrite this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + 38_H

Value after reset: 0000 0000_H

Table 18.14 RHSBjDTC Register Contents

Bit Position	Bit Name	Function
31 to 29	—	Reserved These bits are always read as 0. The write value should be always 0.
28 to 24	RHSBjNCB[4:0]	Number of Command Bits Number of bits used for command frame transmission
23, 22	—	Reserved These bits are always read as 0. The write value should be always 0.
21, 20	RHSBjSSCF [1:0]	Slave Selection for Command Frame 00_B: Command is send to slave 0 01_B: Command is send to slave 1 10_B: Setting prohibited 11_B: Setting prohibited.
19, 18	—	Reserved These bits are always read as 0. The write value should be always 0.
17, 16	RHSBjCTR [1:0]	Command Transmission Request 00_B: No request 01_B: Requests a command which does not requires a response from the receive slave. 10_B: Invalid 11_B: Requests a command which requires a response from the receive slave.
15 to 2	—	Reserved These bits are always read as 0. The write value should be always 0.
1	RHSBjTSR	Transmission Stop Request 0_B: No action 1_B: Request pending
0	RHSBjDTE	Data Transmission Enable 0_B: Disabled 1_B: Enabled

(1) Number of Command Bits (RHSBjDTC.RHSBjNCB)

The user can write to these bits only if RHSBjDTC.RHSBjCTR is 00_B.

The user should not write to these bits if downstream command DMA is enabled (RHSBjGC.RHSBjDCDE is 1_B).

These bits define the number of bits (1 to 32) used from RHSBjDCD register for command frame transmission.

That is, when these bits are 0_D, 1 bit from the RHSBjDCD register is transmitted.

(2) Slave Selection for Command Frame (RHSBjDTC.RHSBjSSCF)

The user can write to these bits only if RHSBjDTC.RHSBjCTR is 00_B.

The user should not write to these bits if downstream command DMA is enabled (RHSBjGC.RHSBjDCDE is 1_B).

These bits define the slave addressed for command frame transmission.

(3) Command Transmission Request (RHSBjDTC.RHSBjCTR)

The user cannot write to these bits if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

The user cannot write 11_B to these bits if RHSBjUCS.RHSBjBSY is 1_B.

The user can write to these bits only if RHSBjDTC.RHSBjCTR is 00_B.

The user should not write to these bits if downstream command DMA is enabled (RHSBjGC.RHSBjDCDE is 1_B).

These bits are used to request a command frame transmission.

[Changing conditions]

These bits are set to 00_B when a command frame has been transmitted.

These bits are set to 00_B when entering the CONFIG state.

(4) Transmission Stop Request (RHSBjDTC.RHSBjTSR)

The user can only write 1_B to this bit.

The user cannot set this bit to 1_B if RHSBjDTC.RHSBjDTE is 0_B.

This bit defines if the data transmission should be stopped when there is no ongoing data frame transmission.

[Clearing conditions]

This bit is set to 0_B when data transmission is disabled (RHSBjDTC.RHSBjDTE is 0_B).

(5) Data Transmission Enable (RHSBjDTC.RHSBjDTE)

The user cannot write to this bit if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

The user can only write 1_B to this bit.

This bit defines if the data frame transmission is enabled.

[Clearing conditions]

This bit is set to 0_B when there is a transmission stop request (RHSBjDTC.RHSBjTSR is 1_B) and this request has been processed.

This bit is set to 0_B when emergency condition detection and automatic stop is enabled

(RHSBjDCR.RHSBjEE is 11_B) and an emergency frame has been transmitted.

This bit is set to 0_B when the CONFIG state is entered.

18.2.4.8 RHSBjDCD — Downstream Command Data Register

Access: This register can be read/written in 16- or 32-bit units.

Address: <RHSBj_base> + $3C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RHSBjCB[31:24]								RHSBjCB[23:16]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 18.15 RHSBjDCD Register Contents

Bit Position	Bit Name	Function
31 to 0	RHSBjCB[31:0]	Command Bit These bits define the data for command frame transmission

(1) Command Bit (RHSBjDCD.RHSBjCB)

The user can write to these bits only if RHSBjDTC.RHSBjCTR is 00_B.

The user should not write to these bits if downstream command DMA is enabled (RHSBjGC.RHSBjDCDE is 1_B).

These bits define the data bits used to assemble command frames.

The transmission order is LSB first.

Please refer to **Section 18.4.1.7, Command Frame Assembling** for details.

18.2.4.9 RHSBjDDRi — Downstream Data Register i (i = 0, 1)

Access: This register can be read/written in 16- or 32-bit units.

Address: <RHSBj_base> + 40_H + 4_H × i

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RHSBjDB[15 + 32*i:8 + 32*i]								RHSBjDB[7 + 32*i:32*i]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RHSBjDB[31 + 32*i:24 + 32*i]								RHSBjDB[23 + 32*i:16 + 32*i]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.16 RHSBjDDRi Register Contents

Bit Position	Bit Name	Function
31 to 16	RHSBjDB[15 + 32*i:32*i]	Data Bit These bits define the data of DFTE i*2 (DFTE0, DFTE2)
15 to 0	RHSBjDB[31 + 32*i:16 + 32*i]	Data Bit These bits define the data of DFTE 1+i*2 (DFTE1, DFTE3)

(1) Data Bit (RHSBjDDRi.RHSBjDB)

The user can write to these bits only if RHSBjIS.RHSBjDTSF is 1_B or only if RHSBjDTC.RHSBjDTE is 0_B.

If the user writes to these bits in other cases, write action are ignored and write data are disappeared.

The user should not write to these bits if downstream data DMA is enabled (RHSBjGC.RHSBjDDE is 1_B).

These bits define the data bits of the RHSBjDFTEs used to assemble data frames.

The transmission order of each RHSBjDFTE is LSB first.

RHSBjDFTE0 is assembled from RHSBjDDR0[31:16], RHSBjDFTE1 from RHSBjDDR0[15:0], RHSBjDFTE2 from RHSBjDDR1[31:16] and RHSBjDFTE3 from RHSBjDDR1[15:0].

Please refer to **Section 18.4.1.6, Data Frame Assembling** for details.

Whether or not writing to which bit of RHSBjDDRi can be a trigger of downstream transmission depends on RHSBjDCR.RHSBjSLS (the number of DFTE to be used).

For detail, see **Section 18.4.1.10, Data Update and Data Frame Transmission Request**.

18.2.4.10 iRHSBjDEDi — Downstream Emergency Data Register (i = 0, 1)

Access: This register can be read/written in 16- or 32-bit units.

Address: <RHSBj_base> + 48_H + 4_H × i

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.17 RHSBjDEDi Register Contents

Bit Position	Bit Name	Function
31 to 16	RHSBjEB[15 + 32*i:32*i]	Emergency Data Bit These bits define the emergency data of DFTE i*2 (DFTE0, DFTE2)
15 to 0	RHSBjEB[31 + 32*i:16 + 32*i]	Emergency Data Bit These bits define the emergency data of DFTE 1+i*2 (DFTE1, DFTE3)

(1) Emergency Data Bit (RHSBjDEDi.RHSBjEB)

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define the bits of the RHSBjDFTEs used to assemble data frames under emergency condition.

RHSBjDFTE0 is assembled from RHSBjDED0[31:16], RHSBjDFTE1 from RHSBjDED0[15:0], RHSBjDFTE2 from RHSBjDED1[31:16] and RHSBjDFTE3 from RHSBjDED1[15:0].

Please refer to **Section 18.4.1.6, Data Frame Assembling** for details.

18.2.5 Upstream (Rx) Registers

18.2.5.1 RHSBjUCR — Upstream Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + 50_H

Value after reset: 0000 1800_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	RHSBjRTO[4:0]					—	—	—	—	RHSBj UE	RHSBj TOE	RHSBj UMS	RHSBj FSM
Value after reset	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 18.18 RHSBjUCR Register Contents

Bit Position	Bit Name	Function
31 to 13	—	Reserved These bits are always read as 0. The write value should be always 0.
12 to 8	RHSBjRTO[4:0]	Receive Timeout Period Timeout period in U bit
7 to 4	—	Reserved These bits are always read as 0. The write value should be always 0.
3	RHSBjUE	Upstream Enable 0_B: Disabled 1_B: Enabled
2	RHSBjTOE	Timeout Enable 0_B: Disabled 1_B: Enabled
1	RHSBjUMS	Upstream Mode Select 0_B: Dedicated mode 1_B: Shared mode
0	RHSBjFSM	Frame Storing Method 0_B: Normal storing method 1_B: Addressed storing method For details, refer to **Section 18.4.2.4, Frame Storing**.

(1) Receive Timeout Period (RHSBjUCR.RHSBjRTO)

These bits define the number of nominal upstream bit times before the timeout counter expires.

That is, when these bits are 24_D (18_H), the timeout period has a length of 25 U bits.

(2) Upstream Enable (RHSBjUCR.RHSBjUE)

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines if reception on the upstream channels is enabled.

(3) Timeout Enable (RHSBjUCR.RHSBjTOE)

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines if the timeout function is enabled.

(4) Upstream Mode Select (RHSBjUCR.RHSBjUMS)

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines how the slaves are connected to the serial input lines of the RHSB module.

(5) Frame Storing Method (RHSBjUCR.RHSBjFSM)

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines where the result of upstream decoding is stored.

18.2.5.2 RHSBjUCC — Upstream Channel Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + 54_H

Value after reset: 0F0F 0F0F$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RHSBj UFT0	RHSBj SBN0	RHSBj ILP0	RHSBj PC0	RHSBjUBR0[3:0]				RHSBj UFT1	RHSBj SBN1	RHSBj ILP1	RHSBj PC1	RHSBjUBR1[3:0]			
Value after reset	0	0	0	0	1	1	1	1	0	0	0	0	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	1	1	1	1	0	0	0	0	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.19 RHSBjUCC Register Contents

Bit Position	Bit Name	Function
31	RHSBjUFT0	Upstream Frame Type Defines if upstream frame on channel 0 uses an 8-bit or 12-bit data format
30	RHSBjSBN0	Stop Bit Number Defines if upstream frame on channel 0 uses 2 or 3 stop bit format
29	RHSBjILP0	Serial Input Line Polarity Defines if the serial input line of channel 0 (RHSBjSI0) is inverted
28	RHSBjPC0	Parity Control Defines if upstream frame on channel 0 uses even or odd parity
27 to 24	RHSBjUBR0 [3:0]	Upstream Bit Rate Defines the upstream bit rate used for channel 0
23	RHSBjUFT1	Upstream Frame Type Defines if upstream frame on channel 1 uses an 8-bit or 12-bit data format
22	RHSBjSBN1	Stop Bit Number Defines if upstream frame on channel 1 uses 2 or 3 stop bit format
21	RHSBjILP1	Serial Input Line Polarity Defines if the serial input line of channel 1 (RHSBjSI1) is inverted
20	RHSBjPC1	Parity Control Defines if upstream frame on channel 1 uses even or odd parity
19 to 16	RHSBjUBR1 [3:0]	Upstream Bit Rate Defines the upstream bit rate used for channel 1
15 to 0	—	Reserved These bits are always read as their initial values. The write value should always be the initial one.

(1) RHSBjUCC.RHSBjUFTn — Upstream Frame Type

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines the number of data bits of an upstream frame received on channel n.

0_B: 8-bit data field format

1_B: 12-bit data field format (including 4 bit address)

(2) RHSBjUCC.RHSBjSBNn — Stop Bit Number

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines the number of stop bits of an upstream frame received on channel n.

0_B: 2 stop bits format

1_B: 3 stop bits format

(3) RHSBjUCC.RHSBjILPn — Serial Input Line Polarity

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines if two is an inversion of the serial input line of channel n.

0_B: Inversion disabled

1_B: Inversion enabled

Note when RHSBjUCR.RHSBjUMS is shared mode, RHSBjILP0 is used for all four channels (RHSBjILP1 are ignored).

(4) RHSBjUCC.RHSBjPCn — Parity Control

The user can write to this bit only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

This bit defines the parity bit interpretation of an upstream frame received on channel n.

0_B: Even parity

1_B: Odd parity

(5) RHSBjUCC.RHSBjUBRn — Upstream Bit Rate

The user can write to these bits only if RHSBjGC.RHSBjOPS is 01_B (CONFIG).

These bits define the relation from upstream to downstream bit rate for channel n.

0_D: Setting prohibited

1_D: Setting prohibited

2_D: Setting prohibited

3_D: $f_{UP} = f_{DW}/8$

4_D: $f_{UP} = f_{DW}/16$

5_D: $f_{UP} = f_{DW}/32$

6_D: $f_{UP} = f_{DW}/64$

7_D: $f_{UP} = f_{DW}/128$

8_D: $f_{UP} = f_{DW}/256$

Others: $f_{UP} = f_{DW}/512$

Not all combinations of upstream and downstream bit rate are valid. Please refer to **Section 18.4.2.5, Upstream Bit Rates** for details.

18.2.5.3 RHSBjUCS — Upstream Channel Selection Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + 58_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RHSBj BSY	—	—	—	—	—	RHSBjACC[1:0]		—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.20 RHSBjUCS Register Contents

Bit Position	Bit Name	Function
31	RHSBjBSY	Busy 0_B: Configuration ready 1_B: Processing configuration change
30 to 26	—	Reserved These bits are always read as 0. The write value should be always 0.
25, 24	RHSBjACC[1:0]	Active Channel Configuration 00_B: Configuration given for channel 0 01_B: Configuration given for channel 1 10_B: Setting prohibited 11_B: Setting prohibited
23 to 0	—	Reserved These bits are always read as 0. The write value should be always 0.

(1) RHSBjUCS.RHSBjBSY — Busy

This bit represents that the RHSB module is processing the change of active channel configuration.

[Clearing conditions]

This bit is set to 0_B when the change of active channel configuration has been processed.

This bit is set to 0_B when entering the CONFIG state.

[Setting conditions]

This bit is set to 1_B when RHSBjUCS.RHSBjACC changes and RHSBjGC.RHSBjOPS is not 01_B (CONFIG).

This bit is set to 1_B when leaving the CONFIG state.

(2) RHSBjUCS.RHSBjACC — Active Channel Configuration

The user cannot write to these bits if RHSBjUCS.RHSBjBYS is 1_B.

The user should not write to these bits after starting a command transmission with upstream data request (by setting RHSBjDTC.RHSBjCTR to 11_B) until the upstream reception has been completed. The exact period where an upstream reception is expected, is application specific.

These bits define the channel configuration specified in RHSBjUCC register to be used for upstream reception. In dedicated mode (RHSBjUCR.RHSBjUMS = 0_B) these bits also define the serial input line.

Note that an ongoing reception is aborted and the timeout detection is deactivated when these bits are changing.

[Changing condition]

These bits are updated to the value of RHSBjDTC.RHSBjSSCF when the user requests a command transmission with upstream data request by setting RHSBjDTC.RHSBjCTR to 11_B.

18.2.5.4 RHSBjUDR — Upstream Data Read Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + $5C_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RHSBjNDS[0:1]		—	—	—	—	RHSBjLUD[1:0]		—	—	—	RHSBj DL	RHSBj TO	RHSBj FERR	RHSBj PERR	RHSBj ND
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	RHSBjEDF[3:0]				RHSBjDF[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.21 RHSBjUDR Register Contents

Bit Position	Bit Name	Function
31	RHSBjNDS0	New Data Summary 0_B: No new reception of a fault free frame on upstream channel 0 1_B: New frame received without fault on upstream channel 0
30	RHSBjNDS1	New Data Summary 0_B: No new reception of a fault free frame on upstream channel 1 1_B: New frame received without fault on upstream channel 1
29 to 26	—	Reserved These bits are always read as 0. The write value should be always 0.
25, 24	RHSBjLUD[1:0]	Last Updated Data 00_B: UD0 (channel 0) 01_B: UD1 (channel 1)
23 to 21	—	Reserved These bits are always read as 0. The write value should be always 0.
20	RHSBjDL	Data Lost 0_B: No data lost situation detected 1_B: Data lost situation detected
19	RHSBjTO	Timeout Detected 0_B: No timeout situation detected 1_B: Timeout situation detected
18	RHSBjFERR	Frame Error 0_B: No stop bit error detected 1_B: Stop bit error detected
17	RHSBjPERR	Parity Error 0_B: No parity error detected 1_B: Parity error detected
16	RHSBjND	New Data 0_B: No new reception of a fault free frame 1_B: New frame received without fault
15 to 12	—	Reserved These bits are always read as 0. The write value should be always 0.
11 to 8	RHSBjEDF[3:0]	Extended Data Field 4-bit extended data field of last received frame
7 to 0	RHSBjDF[7:0]	Data Field 8-bit data field of last received frame

The user should not read the RHSBjUDR register when upstream DMA is enabled (RHSBjGC.RHSBjUDE is 1_B).

Note that reading this register sets RHSBjIS.RHSBjDRF to 0_B and sets RHSBjUDi.RHSBjND of channel i to 0_B. The channel number i is shown by RHSBjUDR.RHSBjLUD.

(1) RHSBjUDR.RHSBjNDS — New Data Summary

These bits represent the value of RHSBjUDi.RHSBjND from channel i (i = 0, 1).

[Changing condition]

This bit is updated when RHSBjUDi.RHSBjND changes.

(2) RHSBjUDR.RHSBjLUD — Last Updated Data

These bits represent the number of Upstream Data register (RHSBjUDi) where the last data update occurred.

[Changing condition]

This bit is updated when the set condition of one of the RHSBjUDi.RHSBjND bits is fulfilled.

(3) RHSBjUDR.RHSBjDL — Data Lost

This bit represents the value of RHSBjUDi.RHSBjDL from channel i. The channel number i is shown by RHSBjUDR.RHSBjLUD.

[Changing condition]

This bit is updated when RHSBjUDR.RHSBjLUD or RHSBjUDi.RHSBjDL (with i = RHSBjUDR.RHSBjLUD) change.

(4) RHSBjUDR.RHSBjTO — Timeout Detected

This bit represents the value of RHSBjUDi.RHSBjTO from channel i. The channel number i is shown by RHSBjUDR.RHSBjLUD.

[Changing condition]

This bit is updated when RHSBjUDR.RHSBjLUD or RHSBjUDi.RHSBjTO (with i = RHSBjUDR.RHSBjLUD) change.

(5) RHSBjUDR.RHSBjFERR — Frame Error

This bit represents the value of RHSBjUDi.RHSBjFERR from channel i. The channel number i is shown by RHSBjUDR.RHSBjLUD.

[Changing condition]

This bit is updated when RHSBjUDR.RHSBjLUD or RHSBjUDi.RHSBjFERR (with i = RHSBjUDR.RHSBjLUD) change.

(6) RHSBjUDR.RHSBjPERR — Parity Error

This bit represents the value of RHSBjUDi.RHSBjPERR from channel i. The channel number i is shown by RHSBjUDR.RHSBjLUD.

[Changing condition]

This bit is updated when RHSBjUDR.RHSBjLUD or RHSBjUDi.RHSBjPERR (with i = RHSBjUDR.RHSBjLUD) change.

(7) RHSBjUDR.RHSBjND — New Data

This bit represents the value of RHSBjUDi.RHSBjND from channel i. The channel number i is shown by RHSBjUDR.RHSBjLUD.

[Changing condition]

This bit is updated when RHSBjUDR.RHSBjLUD or RHSBjUDi.RHSBjND (with i = RHSBjUDR.RHSBjLUD) change.

(8) RHSBjUDR.RHSBjEDF — Extended Data Field

This bit represents the value of RHSBjUDi.RHSBjEDF from channel i. The channel number i is shown by RHSBjUDR.RHSBjLUD.

[Changing condition]

This bit is updated when RHSBjUDR.RHSBjLUD or RHSBjUDi.RHSBjEDF (with i = RHSBjUDR.RHSBjLUD) change.

(9) RHSBjUDR.RHSBjDF — Data Field

This bit represents the value of RHSBjUDi.RHSBjDF from channel i. The channel number i is shown by RHSBjUDR.RHSBjLUD.

[Changing condition]

This bit is updated when RHSBjUDR.RHSBjLUD or RHSBjUDi.RHSBjDF (with i = RHSBjUDR.RHSBjLUD) change.

18.2.5.5 RHSBjUDi — Upstream Data Register i (i = 0, 1)

Do not clear the RHSBjDL, RHSBjTO, RHSBjFERR, RHSBjPERR, and RHSBjND bits in this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + 60_H + 4_H × i

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.22 RHSBjUDi Register Contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved These bits are always read as 0. The write value should be always 0.
20	RHSBjDL	Data Lost 0_B: No data lost situation detected 1_B: Data lost situation detected
19	RHSBjTO	Timeout Detected 0_B: No timeout situation detected 1_B: Timeout situation detected
18	RHSBjFERR	Frame Error 0_B: No stop bit error detected 1_B: Stop bit error detected
17	RHSBjPERR	Parity Error 0_B: No parity error detected 1_B: Parity error detected
16	RHSBjND	New Data 0_B: No valid data available 1_B: Valid data available
15 to 12	—	Reserved These bits are always read as 0. The write value should be always 0.
11 to 8	RHSBjEDF[3:0]	Extended Data Field 4-bit extended data field of received frame
7 to 0	RHSBjDF[7:0]	Data Field 8-bit data field of received frame

(1) RHSBjUDi.RHSBjDL — Data Lost

The user can only write 0_B to this bit.

This bit represents that a fault free frame was received on channel i while the RHSBjND bit in this register is 1_B.

[Clearing condition]

This bit is set to 0_B when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B when the set condition of ND fulfilled while the ND bit in this register is 1_B.

(2) RHSBjUDi.RHSBjTO — Timeout Detected

The user can only write 0_B to this bit.

This bit represents that there was no valid reception, after a command frame transmission with upstream data request, within the timeout period.

[Clearing condition]

This bit is set to 0_B when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B when the timeout counter expires and RHSBjUCS.RHSBjACC is indexing this channel.

(3) RHSBjUDi.RHSBjFERR — Frame Error

The user can only write 0_B to this bit.

This bit represents that a frame with stop bit error was received on channel i.

[Clearing condition]

This bit is set to 0_B when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B after an upstream reception with at least one faulty stop bit.

(4) RHSBjUDi.RHSBjPERR — Parity Error

The user can only write 0_B to this bit.

This bit represents that a frame with parity error was received on channel i.

[Clearing condition]

This bit is set to 0_B when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B after an upstream reception with faulty parity bit.

(5) RHSBjUDi.RHSBjND — New Data

The user can only write 0_B to this bit.

This bit represents that RHSBjUDi.RHSBjEDF and RHSBjUDi.RHSBjDF containing valid data received on channel i.

[Clearing conditions]

This bit is set to 0_B when there is a read access to the RHSBjUDR and RHSBjUDR.RHSBjLUD is indexing this channel.

This bit is set to 0_B when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B after an upstream reception without parity and without stop bit errors.

(6) RHSBjUDi.RHSBjEDF — Extended Data Field

These bits represent the 4-bit extended data field bits of received message.

When using an 8-bit data format, these bits are undefined.

[Changing condition]

These bits are updated when the set condition of RHSBjND is fulfilled.

(7) RHSBjUDi.RHSBjDF — Data Field

These bits represent the 8 bit data field of received message.

[Changing condition]

These bits are updated when the set condition of RHSBjND is fulfilled.

18.2.5.6 RHSBjUSS — Upstream Status Summary Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + 70_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	RHSBj DL0	RHSBj TO0	RHSBj FERR0	RHSBj PERR0	RHSBj ND0	—	—	—	RHSBj DL1	RHSBj TO1	RHSBj FERR1	RHSBj PERR1	RHSBj ND1

Table 18.23 RHSBjUSS Register Contents

Bit Position	Bit Name	Function
31 to 29	—	Reserved These bits are always read as 0. The write value should be always 0.
28	RHSBjDL0	Data Lost Data lost indication of channel 0 (RHSBjUD0.RHSBjDL).
27	RHSBjTO0	Timeout Detected Time out indication of channel 0 (RHSBjUD0.RHSBjTO).
26	RHSBjFERR0	Frame Error Frame error indication of channel 0 (RHSBjUD0.RHSBjFERR).
25	RHSBjPERR0	Parity Error Parity error indication of channel 0 (RHSBjUD0.RHSBjPERR).
24	RHSBjND0	New Data New data indication of channel 0 (RHSBjUD0.RHSBjND).
23 to 21	—	Reserved These bits are always read as 0. The write value should be always 0.
20	RHSBjDL1	Data Lost Data lost indication of channel 1 (RHSBjUD1.RHSBjDL).
19	RHSBjTO1	Timeout Detected Timeout indication of channel 1 (RHSBjUD1.RHSBjTO).
18	RHSBjFERR1	Frame Error Frame error indication of channel 1 (RHSBjUD1.RHSBjFERR).
17	RHSBjPERR1	Parity Error Parity error indication of channel 1 (RHSBjUD1.RHSBjPERR).
16	RHSBjND1	New Data New data indication of channel 1 (RHSBjUD1.RHSBjND).
15 to 13	—	Reserved These bits are always read as 0. The write value should be always 0.
12 to 8	—	Reserved These bits are always read as 0.
7 to 5	—	Reserved These bits are always read as 0. The write value should be always 0.
4 to 0	—	Reserved These bits are always read as 0.

(1) RHSBjUSS.RHSBjDLi — Data Lost

This bit represents the value of RHSBjUDi.RHSBjDL from channel i.

0_B: No data lost situation detected

1_B: Data lost situation detected

[Changing condition]

This bit is updated when RHSBjUDi.RHSBjDL changes.

(2) RHSBjUSS.RHSBjTOi — Timeout Detected

This bit represents the value of RHSBjUDi.RHSBjTO from channel i.

0_B: No timeout situation detected

1_B: Timeout situation detected

[Changing condition]

This bit is updated when RHSBjUDi.RHSBjTO changes.

(3) RHSBjUSS.RHSBjFERRi — Frame Error

This bit represents the value of RHSBjUDi.RHSBjFERR from channel i.

0_B: No stop bit error detected

1_B: Stop bit error detected

[Changing condition]

This bit is updated when RHSBjUDi.RHSBjFERR changes.

(4) RHSBjUSS.RHSBjPERRi — Parity Error

This bit represents the value of RHSBjUDi.RHSBjPERR from channel i.

0_B: No parity error detected

1_B: Parity error detected

[Changing condition]

This bit is updated when RHSBjUDi.RHSBjPERR changes.

(5) RHSBjUSS.RHSBjNDi — New Data

This bit represents the value of RHSBjUDi.RHSBjND from channel i.

0_B: No valid data available

1_B: Valid data available

[Changing condition]

This bit is updated when RHSBjUDi.RHSBjND changes.

18.2.6 Interrupt Registers

18.2.6.1 RHSBjIC — Interrupt Control Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + 74_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.24 RHSBjIC Register Contents

Bit Position	Bit Name	Function
31 to 28	—	Reserved These bits are always read as 0. The write value should be always 0.
27	RHSBjDLIE	Data Lost Interrupt Enable 0_B: Disabled 1_B: Enabled
26	RHSBjTOIE	Timeout Detected Interrupt Enable 0_B: Disabled 1_B: Enabled
25	RHSBjUEIE	Upstream Error Interrupt Enable 0_B: Disabled 1_B: Enabled
24	RHSBjDRIE	Data Received Interrupt Enable 0_B: Disabled 1_B: Enabled
23 to 21	—	Reserved These bits are always read as 0. The write value should be always 0.
20	RHSBjTSIE	Transmission Started Interrupt Enable 0_B: Disabled 1_B: Enabled
19	RHSBjETIE	Emergency Frame Transmission Done Interrupt Enable 0_B: Disabled 1_B: Enabled
18	RHSBjCTIE	Command Frame Transmission Done Interrupt Enable 0_B: Disabled 1_B: Enabled
17	RHSBjDTIE	Data Frame Transmission Done Interrupt Enable 0_B: Disabled 1_B: Enabled
16	RHSBjDTSIE	Data Frame Transmission Started Interrupt Enable 0_B: Disabled 1_B: Enabled
15 to 0	—	Reserved These bits are always read as 0. The write value should be always 0.

(1) RHSBjIC.RHSBjDLIE — Data Lost Interrupt Enable

While this bit is 1_B, an interrupt will be generated if RHSBjIS.RHSBjDLF is 1_B.

(2) RHSBjIC.RHSBjTOIE — Timeout Detected Interrupt Enable

While this bit is 1_B, an interrupt will be generated if RHSBjIS.RHSBjTOF is 1_B.

(3) RHSBjIC.RHSBjUEIE — Upstream Error Interrupt Enable

While this bit is 1_B, an interrupt will be generated if RHSBjIS.RHSBjUEF is 1_B.

(4) RHSBjIC.RHSBjDRIE — Data Received Interrupt Enable

The user should not set this bit to 1_B when the upstream DMA support is enabled (RHSBjGC.RHSBjUDE is 1_B).

While this bit is 1_B, an interrupt will be generated if RHSBjIS.RHSBjDRF is 1_B.

(5) RHSBjIC.RHSBjTSIE — Transmission Started Interrupt Enable

While this bit is 1_B, an interrupt will be generated if RHSBjIS.RHSBjTSF is 1_B.

(6) RHSBjIC.RHSBjETIE — Emergency Frame Transmission Done Interrupt Enable

While this bit is 1_B, an interrupt will be generated if RHSBjIS.RHSBjETF is 1_B.

(7) RHSBjIC.RHSBjCTIE — Command Frame Transmission Done Interrupt Enable

The user should not set this bit to 1_B when the downstream command DMA transfer is enabled (RHSBjGC.RHSBjDCDE is 1_B).

While this bit is 1_B, an interrupt will be generated if RHSBjIS.RHSBjCTF is 1_B.

(8) RHSBjIC.RHSBjDTIE — Data Frame Transmission Done Interrupt Enable

While this bit is 1_B, an interrupt will be generated if RHSBjIS.RHSBjDTF is 1_B.

(9) RHSBjIC.RHSBjDTSIE — Data Frame Transmission Started Interrupt Enable

The user should not set this bit to 1_B when the downstream data DMA support is enabled (RHSBjGC.RHSBjDDE is 1_B).

While this bit is 1_B, an interrupt will be generated if RHSBjIS.RHSBjDTSF is 1_B.

18.2.6.2 RHSBjIS — Interrupt Status Register

Do not clear each bit in this register using bit-manipulation instruction

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <RHSBj_base> + 78_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	RHSBj DLF	RHSBj TOF	RHSBj UE	RHSBj DRF	—	—	—	RHSBj TSF	RHSBj ETF	RHSBj CTF	RHSBj DTF	RHSBj DTSF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

	—	—	—	—	—	—	—	RHSBj ERF	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Table 18.25 RHSBjIS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	—	Reserved These bits are always read as 0. The write value should be always 0.
27	RHSBjDLF	Data Lost Flag 0_B: No data lost situation detected 1_B: Data lost situation detected
26	RHSBjTOF	Timeout Detected Flag 0_B: No timeout situation detected 1_B: Timeout situation detected
25	RHSBjUEF	Upstream Error Flag 0_B: No receive error detected 1_B: Receive error detected
24	RHSBjDRF	Data Received Flag 0_B: No reception of new valid data 1_B: Reception of new valid data
23 to 21	—	Reserved These bits are always read as 0. The write value should be always 0.
20	RHSBjTSF	Transmission Started Flag 0_B: No transmission started 1_B: Transmission has been started
19	RHSBjETF	Emergency Frame Transmission Done Flag 0_B: No emergency transmission 1_B: Emergency frame has been transmitted
18	RHSBjCTF	Command Frame Transmission Done Flag 0_B: No command frame transmission 1_B: Command frame has been transmitted
17	RHSBjDTF	Data Frame Transmission Done Flag 0_B: No data frame transmission 1_B: Data frame has been transmitted
16	RHSBjDTSF	Data Frame Transmission Started Flag 0_B: No data transmission has been started 1_B: Data transmission has been started
15 to 9	—	Reserved These bits are always read as 0. The write value should be always 0.

Table 18.25 RHSBjIS Register Contents (2/2)

Bit Position	Bit Name	Function
8	RHSBjERF	Emergency Signal Rising Flag 0_B No edge detected 1_B Edge detected
7 to 0	—	Reserved These bits are always read as 0. The write value should be always 0.

(1) RHSBjIS.RHSBjDLF — Data Lost Flag

The user can only write 0_B to this bit.

This bit represents that data lost has been detected on at least one channel.

[Clearing conditions]

This bit is set to 0_B when all RHSBjUDi.RHSBjDL (i = 0, 1) flags are 0_B.

This bit is set to 0_B when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B when the set condition of at least one of these flags (RHSBjUDi.RHSBjDL with i = 0, 1) is fulfilled.

(2) RHSBjIS.RHSBjTOF — Timeout Detected Flag

The user can only write 0_B to this bit.

This bit represents that there was no valid reception requested by a command frame transmission within the timeout period.

[Clearing condition]

This bit is set to 0_B when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B when the timeout counter expires.

(3) RHSBjIS.RHSBjUEF — Upstream Error Flag

The user can only write 0_B to this bit.

This bit represents that a frame with parity or stop bit error was received.

[Clearing conditions]

This bit is set to 0_B when all RHSBjUDi.RHSBjFERR (i = 0, 1) and all RHSBjUDi.RHSBjPERR (i = 0, 1) flags are 0_B.

This bit is set to 0_B when entering the CONFIG state.

[Setting conditions]

This bit is set to 1_B when the set condition of at least one of these flags (RHSBjUDi.RHSBjFERR with i = 0, 1) is fulfilled.

This bit is set to 1_B when the set condition of at least one of these flags (RHSBjUDi.RHSBjPERR with i = 0, 1) is fulfilled.

(4) RHSBjIS.RHSBjDRF — Data Received Flag

The user can only write 0_B to this bit.

The user should not set this bit to 0_B when upstream DMA is enabled (RHSBjGC.RHSBjUDE is 1_B).

This bit represents that at least one RHSBjUDi register is updated with new valid data.

[Clearing conditions]

This bit is set to 0_B when all RHSBjUDi.RHSBjND (i = 0, 1) flag are 0_B.

This bit is set to 0_B when there is a read access to RHSBjUDR.

This bit is set to 0_B when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B when the set condition of at least one of these flags (RHSBjUDi.RHSBjND with i = 0, 1) is fulfilled.

(5) RHSBjIS.RHSBjTSF — Transmission Started Flag

The user can only write 0_B to this bit.

This bit indicates that a command or data frame transmission has been started.

[Clearing condition]

This bit is set to 0_B when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B when a new frame transmission starts.

(6) RHSBjIS.RHSBjETF — Emergency Frame Transmission Done Flag

The user can only write 0_B to this bit.

This bit indicates that a data frame assembled under emergency condition has been transmitted.

[Clearing condition]

This bit is set to 0_B when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B when an emergency frame has been transmitted.

(7) RHSBjIS.RHSBjCTF — Command Frame Transmission Done Flag

The user can only write 0_B to this bit.

The user should not set this bit to 0_B when downstream command DMA transfer is enabled (RHSBjGC.RHSBjDCDE is 1_B).

This bit indicates that a command frame has been transmitted.

[Clearing conditions]

This bit is set to $0_B$when a new command frame transmission is requested.

This bit is set to $0_B$when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B when a command frame has been transmitted.

(8) RHSBjIS.RHSBjDTF — Data Frame Transmission Done Flag

The user can only write 0_B to this bit.

This bit indicates that a data frame has been transmitted.

[Clearing conditions]

This bit is set to 0_B when last active portions of the downstream data registers (RHSBjDDRi) are written (please refer to **Section 18.4.1.10, Data Update and Data Frame Transmission Request**).

This bit is set to 0_B when entering the CONFIG state.

[Setting condition]

This bit is set to 1_B when a data frame has been transmitted.

(9) RHSBjIS.RHSBjDTSF — Data Frame Transmission Started Flag

The user can only write 0_B to this bit.

The user should not set this bit to 0_B when downstream data DMA is enabled (RHSBjGC.RHSBjDDE is 1_B).

This bit indicates that a data frame transmission has been started.

When this bit is 0_B, data frame transmission is disabled or the downstream data registers (RHSBjDDRi) contain pending transmit data.

When this bit is 1_B, data frame transmission has been started. The downstream data registers can be updated to define the data for the next data frame.

[Clearing conditions]

This bit is set to 0_B when last active portions of the downstream data registers (RHSBjDDRi) are written (please refer to **Section 18.4.1.10, Data Update and Data Frame Transmission Request**).

This bit is set to 0_B when data frame transmission gets disabled (RHSBjDTC.RHSBjDTE changes from 1_B to 0_B).

This bit is set to 0_B when entering the CONFIG state.

[Setting conditions]

This bit is set to 1_B when a data frame transmission starts.

This bit is set to 1_B when data frame transmission gets enabled (RHSBjDTC.RHSBjDTE changes from 0_B to 1_B) and RHSBjDCR.RHSBjDMS is 01_B (TRIGGERED).

(10) RHSBjIS.RHSBjERF — Emergency Signal Rising Flag

The user can only write 0_B to this bit.

This bit indicates that an edge to the active level of the external emergency signal (RHSBjEMRG (j = 0, 1)) has been detected.

[Clearing condition]

This bit is set to 0_B when entering the CONFIG state.

[Setting conditions]

This bit is set to 1_B when a transition from inactive to active level of the emergency signal has been detected while RHSBjGC.RHSBjOPS is ACTIVE or TEST.

This bit is set to 1_B when there is an active level of the emergency signal when leaving the CONFIG state.

18.3 Operation States

After the release of MCU's hardware reset, the RHSB module is in RESET state. The user can trigger changes of the operation state by writing the target state to RHSBjGC.RHSBjOPS.

The current operation state is indicated by RHSBjGC.RHSBjOPS.

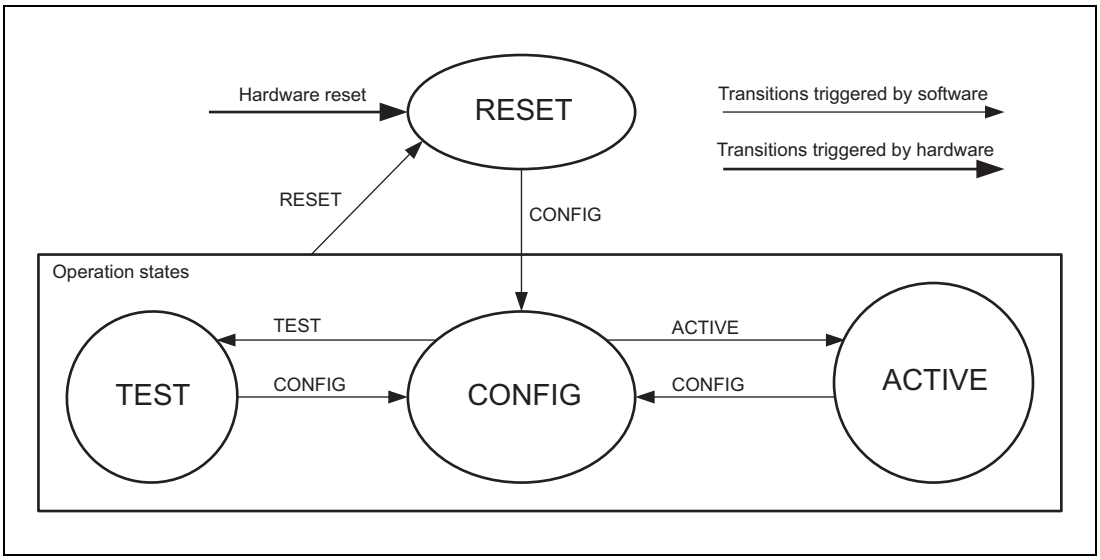

Figure 18.2 Module State Transitions

Figure 18.2 illustrates the implemented operation states and the possible state transitions. The RESET state can be entered from all operation states (TEST, CONFIG, ACTIVE).

18.3.1 Operation State Description

18.3.1.1 RESET State

The RESET state is considered as the power down and reset state of the RHSB module. All internal clocks are stopped to reduce the power consumption. All configuration, control and status registers are reset.

The user can only write to RHSBjGC.RHSBjOPS to leave the RESET state. All other registers are reset and writing to these registers does not have any effect.

18.3.1.2 CONFIG State

Within the CONFIG state the user has write access to all registers to define the module configuration.

18.3.1.3 ACTIVE State

In the ACTIVE state the RHSB module is able to perform up- and downstream communication.

Upstream communication can only be used in ACTIVE state when this function is enabled by RHSBjUCR.RHSBjUE.

Downstream communication can be individually enabled and disabled during ACTIVE and TEST state in the RHSBjDTC register.

18.3.1.4 TEST State

The TEST state is intended to support key-on testing and fault localization. By loop-back the downstream data to the upstream channel, the RHSB internal data paths can be checked.

Refer to **Section 18.4.4, Test Mode Operation** for details and restrictions of this mode.

18.3.2 Activation of the RHSB Module (Leaving RESET State)

To leave the RESET state this flow should be used. The flow assumes that the peripheral bus clock and the RHSB engine clock are already enabled.

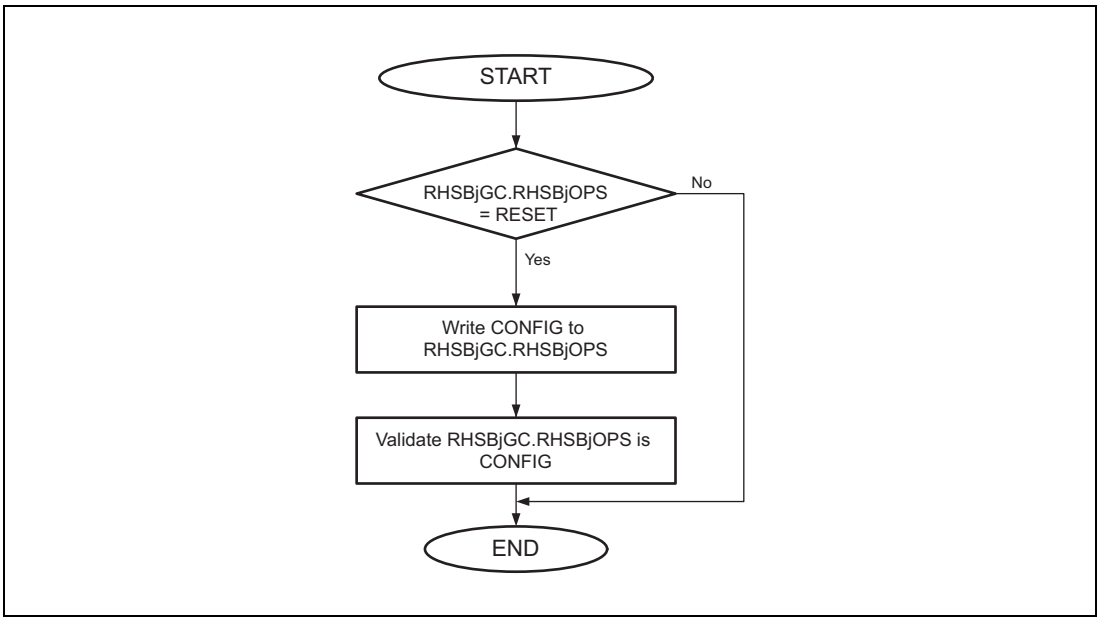

Figure 18.3 Software Flow to Leave RESET State

Note that port function and direction registers of the MCU needs to be configured before the RHSB module can perform active operation. To prevent invalid levels on the downstream chip select lines, it is recommended to define the correct active level for these lines before setting the MCU pin function to the RHSB.

18.3.3 Deactivation of the RHSB Module (Entering RESET State)

To enter the RESET state this flow should be used. Once this flow is executed the peripheral bus clock and the RHSB engine clock can be disabled; the function of the MCU ports can be changed.

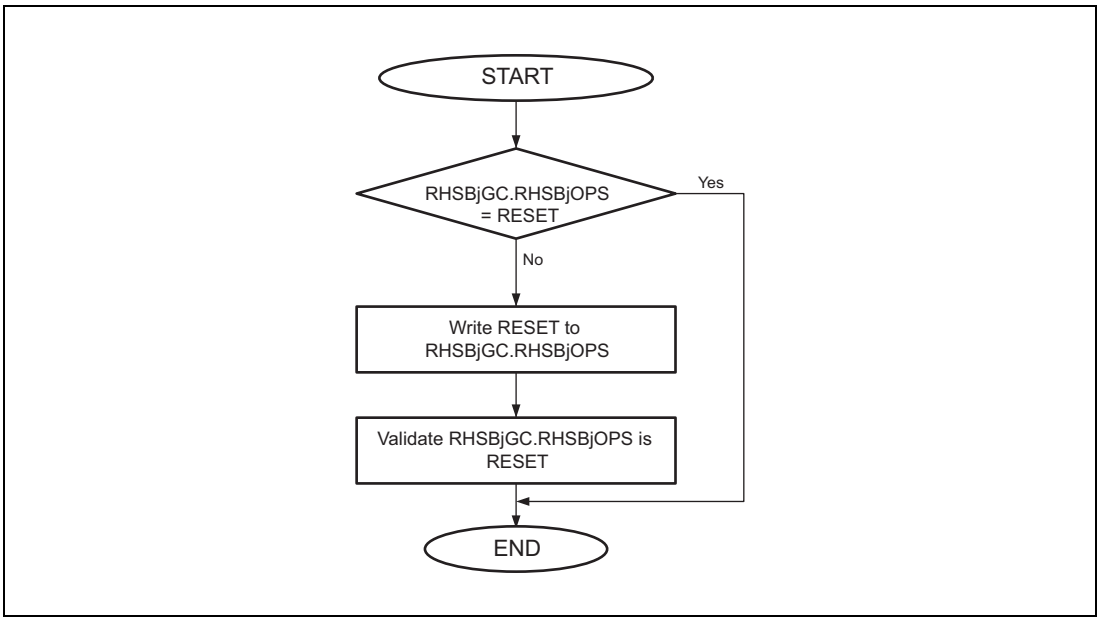

Figure 18.4 Software Flow to Enter RESET State

If the module enters the RESET state, ongoing transmission will be aborted, ongoing reception is lost and the RHSB output lines are changed to their reset levels.

Note when using the flow mentioned in **Figure 18.5**, it is possible to enter RESET state without influencing an ongoing transmission.

18.3.4 Changing between Operation States (ACTIVE, CONFIG, TEST)

Changing the operation state of the RHSB module is triggered by writing the target state to RHSBjGC.RHSBjOPS. The successful processing of the state transition is observable in RHSBjGC.RHSBjOPS.

18.3.5 Leaving ACTIVE State without Interrupting Ongoing Transmission

When the ACTIVE state is left, an ongoing transmission is aborted. This may result in an invalid reception on the downstream receiver side (slave).

Using this flow, interruption of an ongoing transmission can be prevented when changing the operation state to CONFIG or RESET.

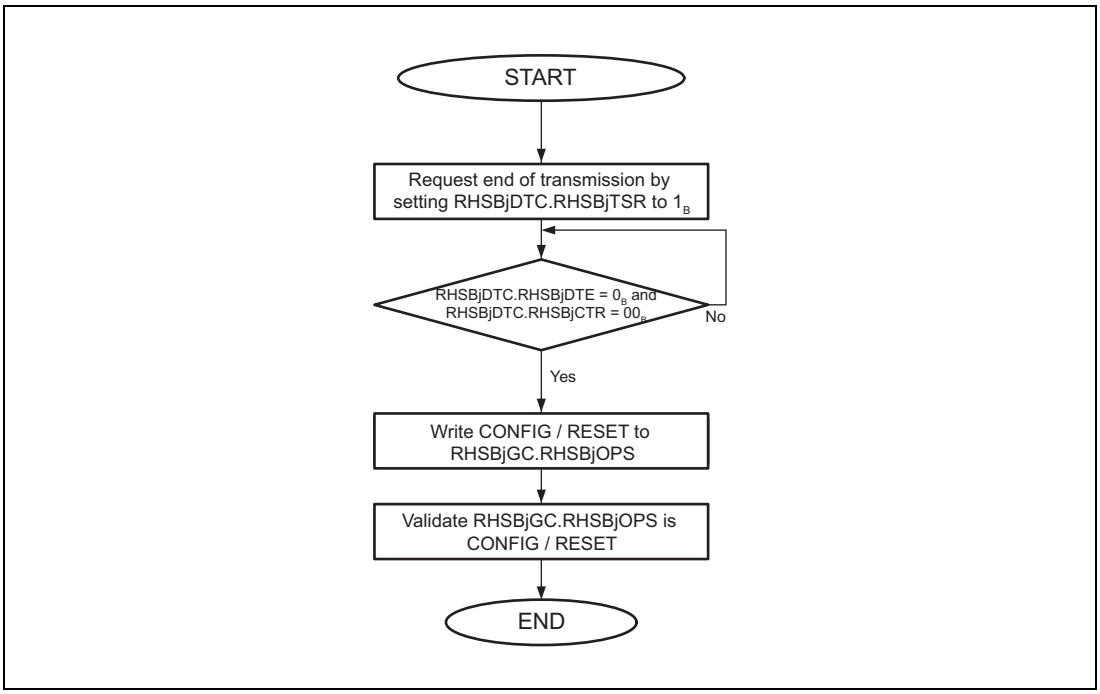

Figure 18.5 Software Flow to Leave ACTIVE/TEST State without Interruption of Ongoing Transmissions

The same flow can be used to leave the TEST state.

18.4 RHSB operations

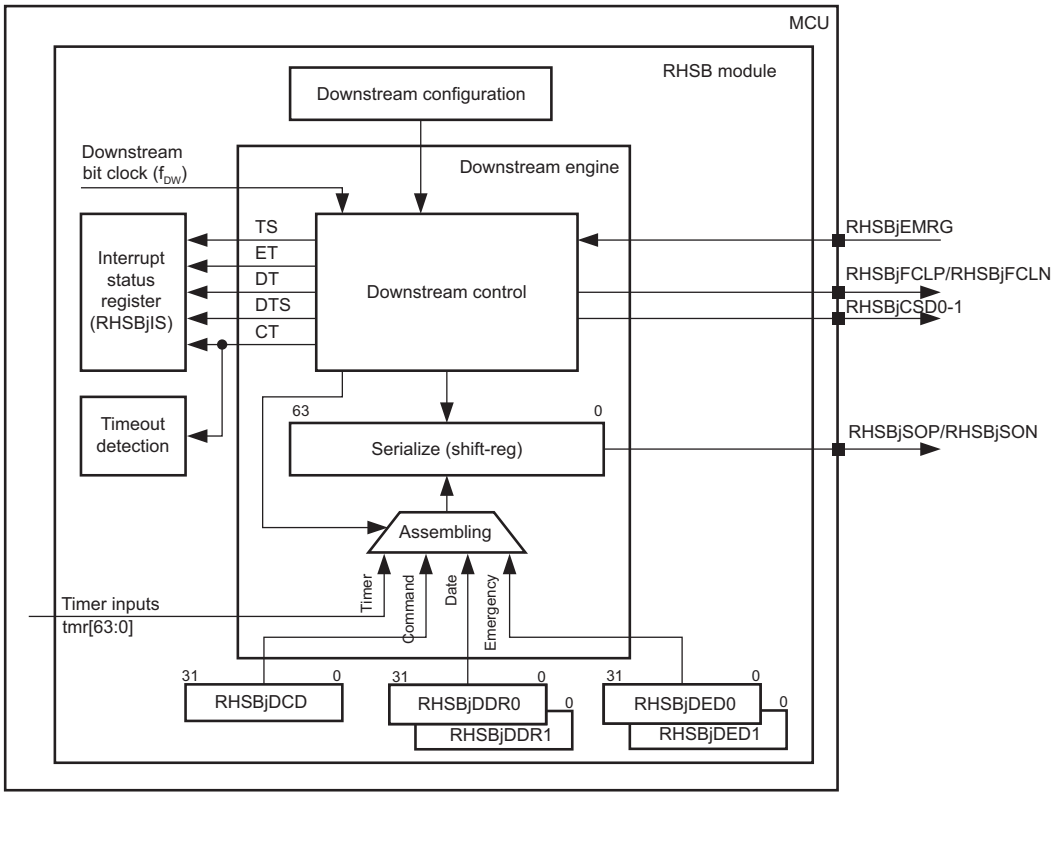
18.4.1 Downstream Communication

The RHSB module uses for downstream communication the synchronous serial transmission.

In addition to the synchronous serial frame, the downstream communication defines a set of communication phases to serve up to two slaves by one frame and to define a repetition period for cyclic transmission.

There are different modes and configuration parameters available to schedule the downstream communication according the application requirements. This downstream configuration is defined by the registers described in **Section 18.2.4, Downstream (Tx) Registers**.

The diagram in **Figure 18.6** illustrates the functional blocks of the downstream engine. The detailed downstream communication is explained in this section.



Note: j = 0,1

Figure 18.6 Downstream Block Diagram

Downstream Configuration

This block represents the downstream related configuration parameters and the downstream control interface handled by the application software.

Downstream Control

This block provides the main function of the downstream engine. It schedules the transmission, controls the frame assembling, generates the downstream communication signals (RHSBjFCLP/ RHSBjFCLN (j = 0, 1), RHSBjCSD0-1 (j = 0, 1)) and triggers the downstream related status flags in the RHSBjIS register.

Serialize

The shift register captures the assembled data at frame start and provides the downstream phase related information to the serial data line (RHSBjSOP/RHSBjSON (j = 0, 1)) of the downstream interface.

Assembling

This multiplexing logic selects the data source for each data bit.

18.4.1.1 Downstream Communication Phases

The downstream communication is composed of different phases.

These phases are used by the RHSB module.

Active phases:

- Assertion phase: The serial data line is invalid
  This optional phase allows the selected slave to get prepared for the content phase.
- Content phase: The serial data line is valid
  During this phase content is transmitted to the selected slave.
- Deassertion phase: The serial data line is invalid
  Optional phase after content is transmitted to the selected slave.

Passive phases:

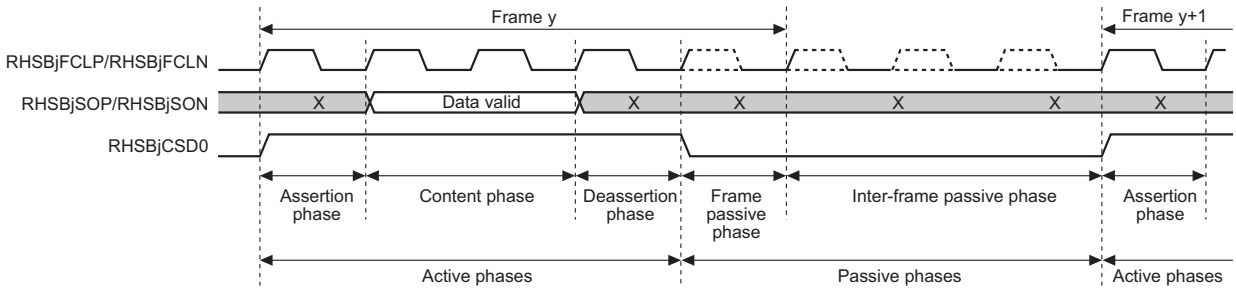
- Frame passive phase:
  This phase is part of each frame and defines a minimum time of inactivation before the next frame starts.
- Inter-frame passive phase:
  This phase describes the time, where no frame is transmitted (bus is idle).
  An inter-frame passive phase occurs, depending on the downstream mode and the downstream configuration.

A frame consists of the active phases and the frame passive phase.

Figure 18.7 illustrates the phases of downstream communication. The frame shown in this figure addresses one slave (slave 0). The mode dependent clock during the passive phases is shown by dotted lines. All phases, including the optional ones, are shown in the ordering used for transmission.

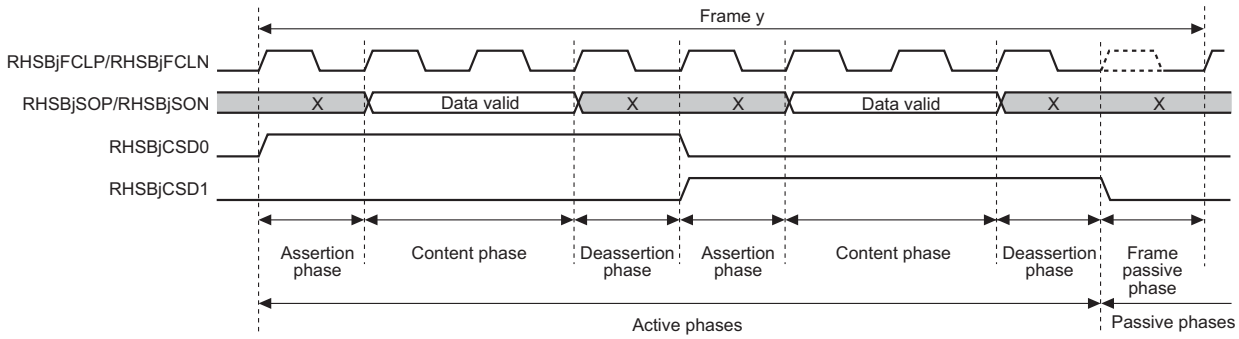
Figure 18.8 illustrates the phases of downstream communication of a frame addressing two slaves (slave 0 and slave 1). The optional assertion and deassertion phases are individually configurable for each slave.

In **Figure 18.7** and **Figure 18.8**, the select signal of the slaves are configured as active high; the clock line phase is set to rising edge.



Note: j = 0,1

Figure 18.7 Downstream Communication Phases



Note: j = 0,1

Figure 18.8 Downstream Communication Phases of a Frame Addressing Two Slaves

For evaluation purpose the user can monitor the communication phases by reading RHSBjMSR. Note that this function is not available for all downstream bit rates.

18.4.1.2 Frame Dependent Flagging

Figure 18.9 illustrates the RHSB internal processing flow of command and data frame transmission. The scheduling when a command or data frame is transmitted is mode dependent and explained in **Section 18.4.1.3, Downstream Modes**.

The flows described in **Figure 18.8** are used as macros in the mode description of **Section 18.4.1.3, Downstream Modes**.

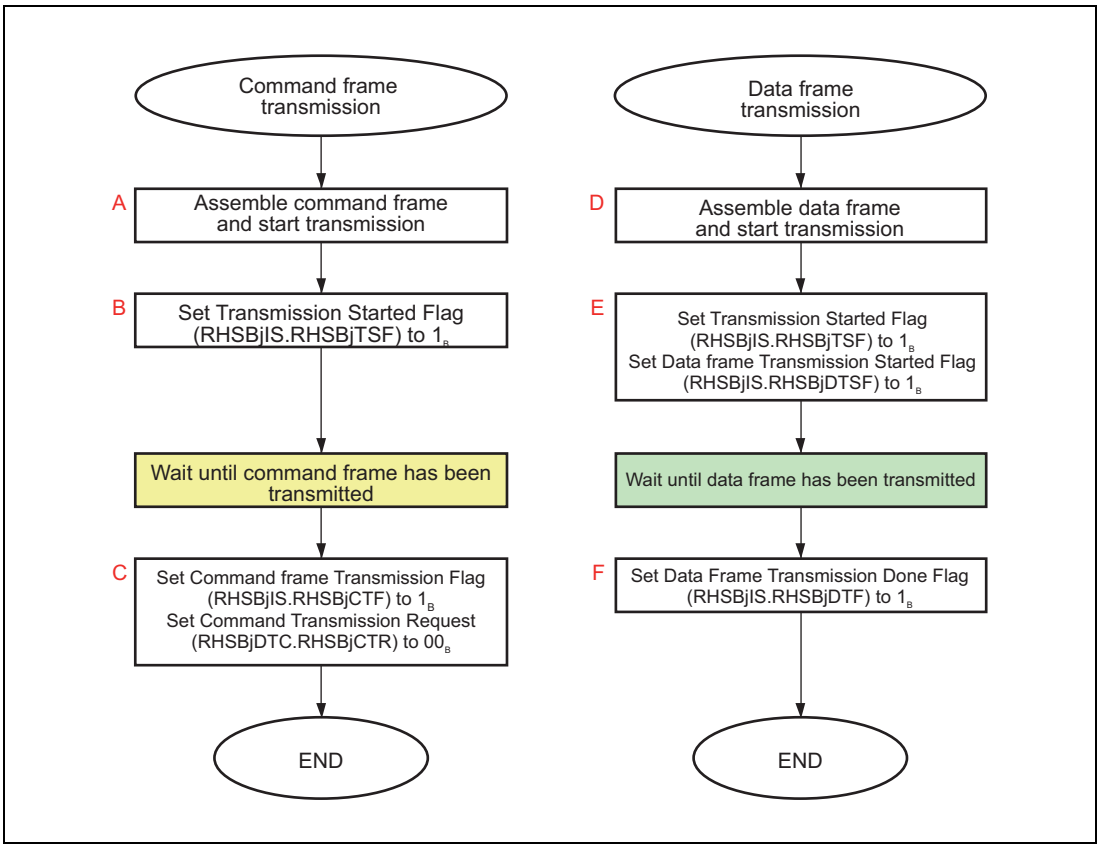


Figure 18.9 Internal Transmission Processing of Command and Data Frames

The flagging related to command and data frame transmission is illustrated in **Figure 18.10**. A gray background illustrates values which depend on previous user interaction but have no influence to the transmission.

In triggered mode RHSBjIS.RHSBjDTSF is always 0_B immediately before a data frame transmission starts. In other modes the value can be 0_B or 1_B.

The timing marks A to F refer to the marks in **Figure 18.9**.

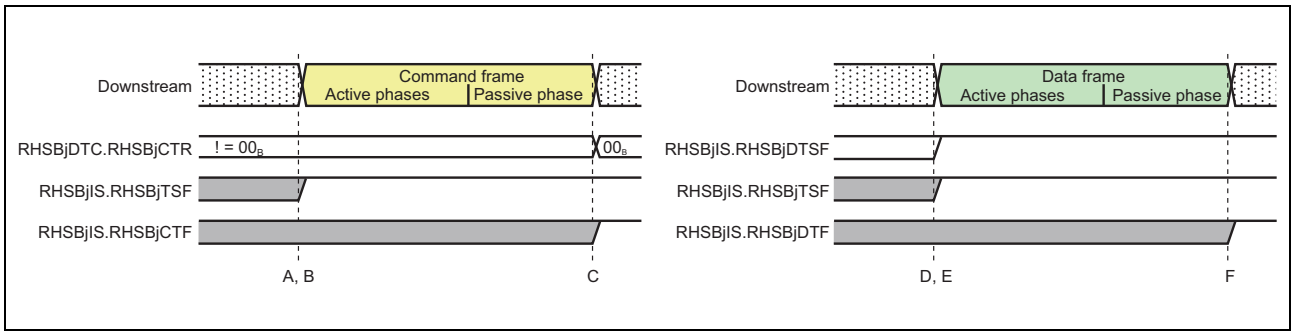

Figure 18.10 Command and Data Frame Related Flagging

When an emergency frame is transmitted, the RHSBjIS.RHSBjETF is rising at the same time as RHSBjIS.RHSBjDTF (timing F).

18.4.1.3 Downstream Modes

The RHSB module supports different downstream transmission modes which can be selected during CONFIG state.

These modes are available and can be configured in RHSBjDCR.RHSBjDMS:

- Triggered mode
  The RHSB module starts downstream communication immediately on user request (software triggered).
- Single-period repetition mode
  The RHSB module starts downstream communication in a defined repetition period. The cyclic transmission is independent from user interaction.
- Multi-period repetition mode
  The RHSB module starts downstream communication in two defined repetition periods. The cyclic transmission is independent from user interaction.

In all modes transmission of data frames is only possible when the data transmission is enabled by setting RHSBjDTC.RHSBjDTE to 1_B.

Except in triggered mode it is recommended to initialize the downstream data registers with valid data before enabling the data transmission because a data frame transmission is immediately started when RHSBjDTC.RHSBjDTE changes from 0_B to 1_B.

The RHSB module is able to transmit command frames independent from the downstream mode and whether data transmission is enabled or not.

(1) Triggered mode

In this mode transmission of data frames is triggered by the user. Each trigger starts the transmission of one data frame.

There is no repetition period defined for this mode, the transmission is controlled by the software execution timing.

These configuration parameters are ignored in triggered mode:

- Command frame insertion mode (RHSBjDCR.RHSBjCIM)
- Command frame transmission delay (RHSBjDCR.RHSBjCTD)
- Repetition period length (RHSBjDCR.RHSBjREP)

A data frame transmission is triggered when RHSBjIS.RHSBjDTSF is 0_B. This bit can be cleared by writing 0_B to RHSBjIS.RHSBjDTSF (keep data unchanged) or by updating the downstream data registers (RHSBjDDRi). Please refer to **Section 18.4.1.10, Data Update and Data Frame Transmission Request** for details about data update and data frame transmission request.

The flow shown in **Figure 18.11** assumes that the RHSB module is in triggered mode and that the data transmission is enabled.

The details about command and data frame transmission (colored ovals) are shown in **Figure 18.9**.

The flow is started when the following configuration is applied:

- RHSBjGC.RHSBjOPS is ACTIVE
- RHSBjDCR.RHSBjDMS is triggered
- RHSBjDTC.RHSBjDTE is 1_B

The flow is immediately aborted when the RHSB module leaves the ACTIVE state.

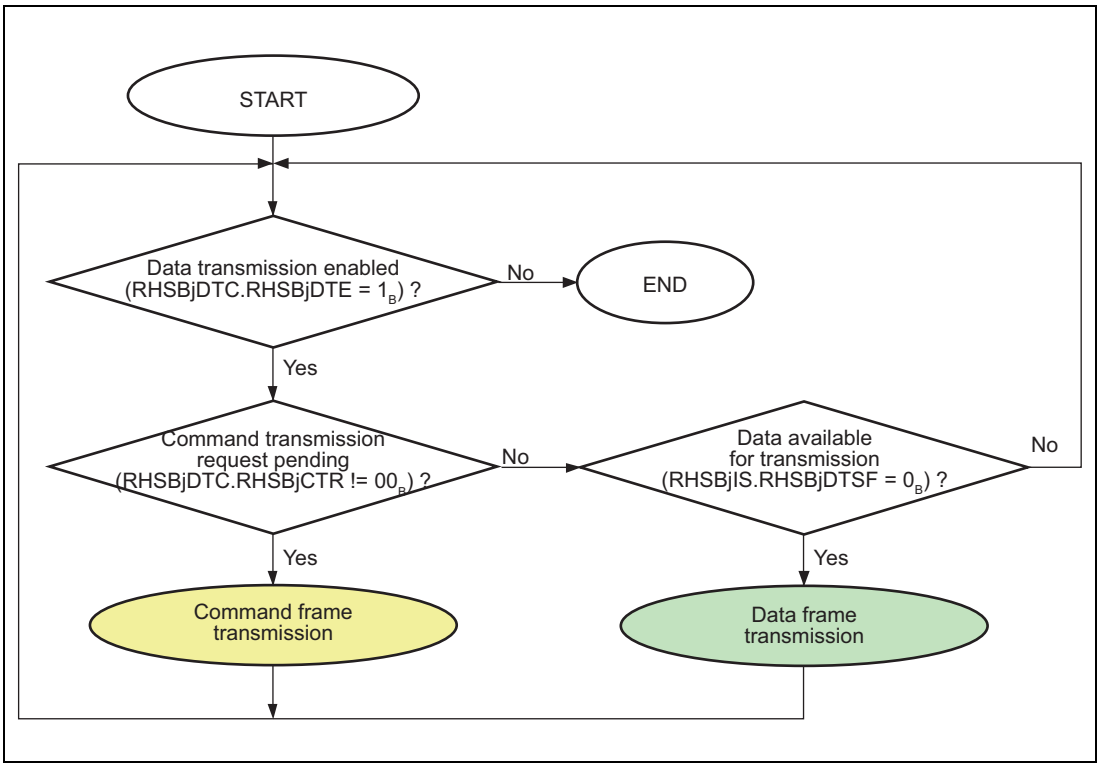

Figure 18.11 Internal Transmission Processing in Triggered Mode when Data Transmission is Enabled

Figure 18.12 illustrates the downstream communication in case of concurrent command and data frame transmission requests. If there is a pending request when a frame transmission ends, the next frame is transmitted immediately.

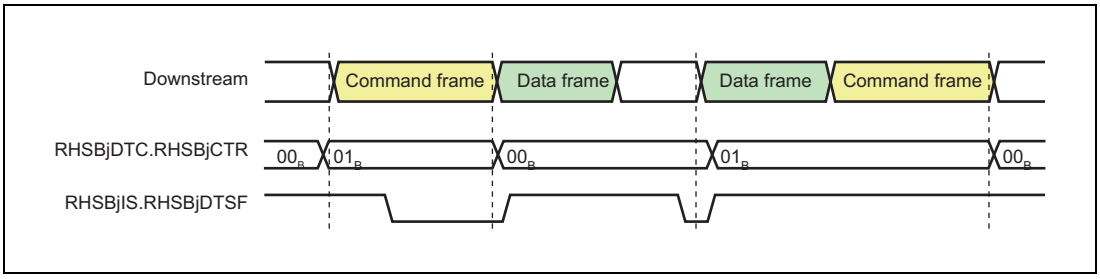

Figure 18.12 Example of Concurrent Command/Data Transmission Requests in Triggered Mode

(a) Command frame transmission in triggered mode

Command frame transmission has higher priority than data frame transmission as shown in the transmission processing figure. The user needs to schedule data and command frame transmission to be consistent with the requirements of the application.

When the data transmission is disabled (RHSBjDTC.RHSBjDTE = 0_B) a command frame is immediately transmitted when the request is pending. This command frame transmission is not controlled by the internal transmission processing as shown in **Figure 18.11**.

(2) Repetition mode (Single-period repetition, Multi-period repetition)

In this mode transmission of data frames is done periodically.

A periodical time tick defines the repetition period of the cyclic data transmission.

The fixed repetition period used in this mode is controlled by the RHSB module.

By RHSBjDTC.RHSBjDTE and RHSBjDTC.RHSBjTSR the user can start and stop the cyclic data transmission in repetition mode. The RHSB module ensures that disabling of data transmission will not interrupt an ongoing transmission.

In repetition mode the trigger of data frame transmission is independent from RHSBjIS.RHSBjDTSF.

However the values from the downstream data registers (RHSBjDDRi) are used to assemble the transmission data.

(a) Repetition period definition

The repetition period is defined by RHSBjDCR.RHSBjREP. The minimum repetition period should be at least the data frame length.

When the repetition period is bigger than the data frame length, there is an inter-frame passive phase between two data frames as illustrated in **Figure 18.13**.

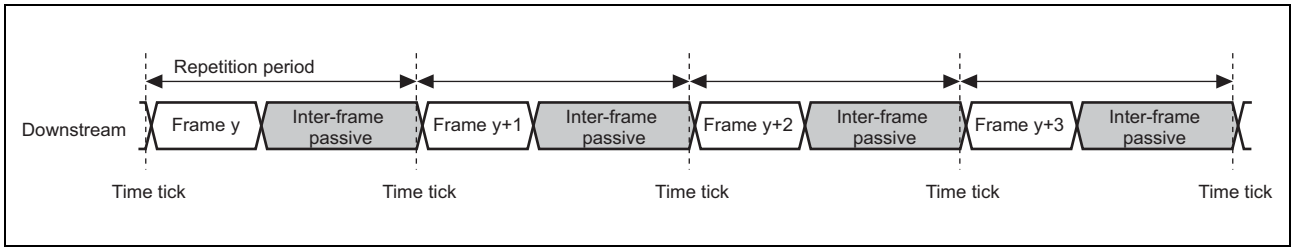

Figure 18.13 Transmission Timing in Repetition Mode

The length of a data frame can be calculated as sum of these configuration parameters:

- Assertion phase length (RHSBjSDCi.RHSBjAPLn) of all addressed slaves
- Data frame selection bit (RHSBjSDCi.RHSBjCPSn) of all addressed slaves
- Deassertion phase length (RHSBjSDCi.RHSBjDPLn) of all addressed slaves
- Number of data bits (RHSBjDEC.RHSBjNDBm) of all used DFTEs (RHSBjDCR.RHSBjSLS and RHSBjDCR1.RHSBj.SLS1 (multi-period repetition mode))
- Data frame passive phase length (RHSBjDCR.RHSBjDFP)

The user should not configure a repetition period (RHSBjDCR.RHSBjREP) less than 8 peripheral bus clock cycles. As example: With a typical peripheral bus clock (CLK_LSB) frequency of 40 MHz, this results in a minimal repetition period of 0.2 µs.

The transmission period count in single-period repetition mode holds “period 0” and that in multi-period repetition mode toggles between “period 0” and “period 1” repeatedly as illustrated in **Figure 18.13**.

The sequence length in single-period repetition mode is defined by RHSBjDCR.RHSBjSLS for period 0. The sequence length in multi-period repetition mode is defiled by RHSBjDCR.RHSBjSLS for period 0 and RHSBjDCR1.RHSBjSLS1 for period 1.

(b) Command frame transmission

Command frame transmission has higher priority than data frame transmission. Depending on the configuration parameter RHSBjDCR.RHSBjCTD transmission of consecutive command frames can be prevented.

Different command frame insertion methods are available. They differ in the strategy for the case when a command frame is transmitted and how data transmission is affected by command frame insertion. All insertion methods (controlled by RHSBjDCR.RHSBjCIM) are explained in detailed in **18.4.1.3 (3) Command frame insertion methods in single-period repetition mode**.

(3) Command frame insertion methods in single-period repetition mode

In Single-Period REPETITION mode, a request for command transmission comes asynchronously with respect to the repetition period. The RHSB module supports different strategies controlled by RHSBjDCR.RHSBjCIM, on how to insert command frames into the repetition schedule.

If data transmission is disabled (RHSBjDTC.RHSBjDTE is 0_B), a command frame is immediately transmitted when the request is pending. In addition the restriction about consecutive command frames (RHSBjDCR.RHSBjCTD is 1_B) is ignored.

(a) Time-slot method

When this method is selected, the RHSB module processes command and data frames aligned to the time ticks. The command frames substitute data frames within the repetition period.

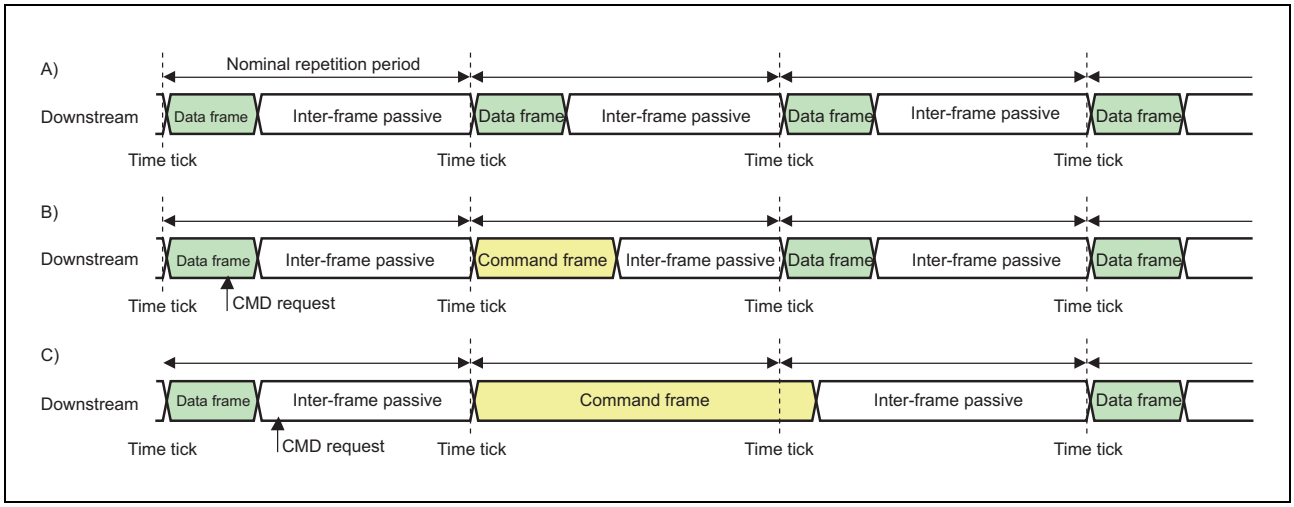

Figure 18.14 Examples of Command Insertion Using Time-Slot Method

Scenario A) shows a schedule with no command requests.

Scenario B) shows command frame insertion where the length of the command frame is less or equal to the repetition period. One data frame is substituted.

Scenario C) shows command frame insertion where the length of the command frame is greater than the repetition period. Two data frames are substituted.

(b) Immediate method

When this method is selected, the RHSB module processes a command frame transmission request as soon as possible (immediately during inter-frame passive phase or when a data frame ends). The command frame transmission is not aligned to the repetition period.

If a data frame transmission cannot be started at the origin time tick because a command frame has broken the repetition period, the data transmission is processed as soon as possible. The repetition period is re-adjusted.

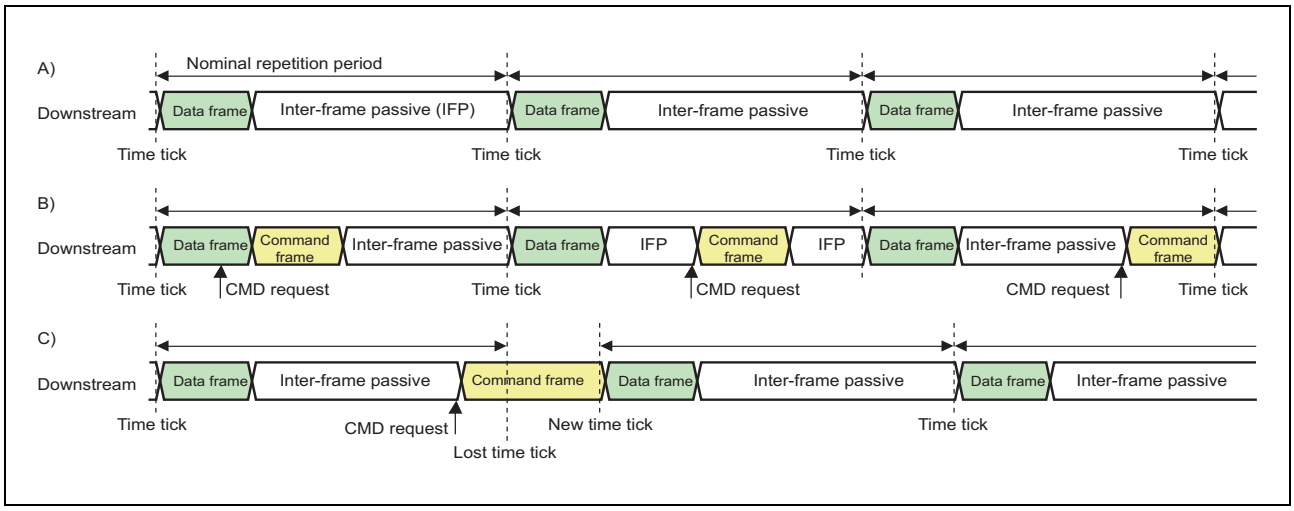

Figure 18.15 Examples of Command Insertion Using Immediate Method

Scenario A) shows a schedule with no command requests.

Scenario B) shows command frame insertion which is not breaking the repetition period (three examples).

Scenario C) shows command frame insertion which is breaking the repetition period. The original time tick for the data frame is lost. When the command frame transmission ends, the time base is re-adjusted, a new time tick is generated and data frame transmission is immediately stated.

It is possible to insert more than one command frame between two data frames if this is allowed from the configuration. Also in this case a re-adjust of the repetition period happens if a command frame brakes the repetition period.

(c) Best-effort method

When this method is selected, the RHSB module starts command frame transmission only

- at the end of a data frame transmission or
- when the command frame transmission will end within the inter-frame passive phase.

The repetition time grid is not adjusted when using the best-effort insertion method.

If the command frame is shorter or equal to the inter-frame passive phase, command frame transmission has no influence to the data frame transmission (see case B in **Figure 18.18**). If possible from configuration, more than one command frame can be transmitted during the repetition period.

If the command frame is longer than the inter-frame passive phase, command frame transmission influences the data frame transmission (see case C in **Figure 18.18**). The data transmission is processed as soon as possible.

If a data frame transmission is influenced by another data frame (shifted by command frame transmission), the data frame is not processed (see case D in **Figure 18.18**).

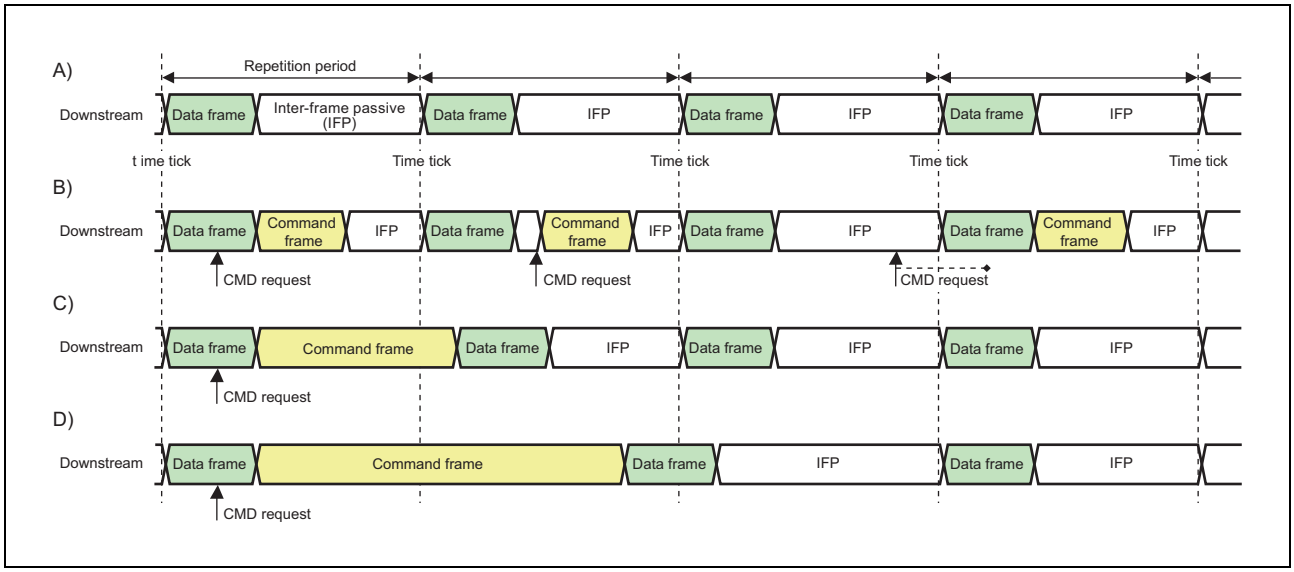

Figure 18.16 Examples of Command Insertion Using Best-Effort Method

Scenario A) shows a schedule with no command requests.

Scenario B) shows command frame insertion where the command frames are shorter or equal to the inter-frame passive length (three examples). In the third example the command frame is shifted after the next data frame, because it would influence the data transmission.

Scenario C) shows command frame insertion where the command frames are longer than the inter-frame passive length. The delayed data frame has no influence to the next data frame.

Scenario D) shows command frame insertion where the command frames are longer than the inter-frame passive length. The delayed data frame influences to the next data frame.

18.4.1.4 Command Frame Insertion Methods in Multi-Period Repetition Mode

In the Multi-Period repetition mode, a request for command transmission comes asynchronously with respect to the repetition period.

(1) Best-effort method

Multi-Period repetition mode supports only Best-effort method. When this method is selected, the RHSB module starts command frame transmission only

- at the end of a data frame transmission in period 1.

The repetition time grid is not adjusted when using the best-effort insertion method.

If the command frame is shorter or equal to the inter-frame passive phase in period 1, command frame transmission has no influence to the data frame transmission (see case B, C, D, E, F and G in **Figure 18.17**). If possible from configuration, more than one command frame can be transmitted during the repetition period.

If the command frame is longer than the inter-frame passive phase, command frame transmission influences the data frame transmission (see case H in **Figure 18.17**). The transferred command and data are not guaranteed.

If a data frame transmission is influenced by another data frame (shifted by command frame transmission), the data frame is not processed (see case I in **Figure 18.17**). The transferred command and data are not guaranteed.

The processing of the best-effort method is also mentioned in transmission processing flows as shown in **Figure 18.17**.

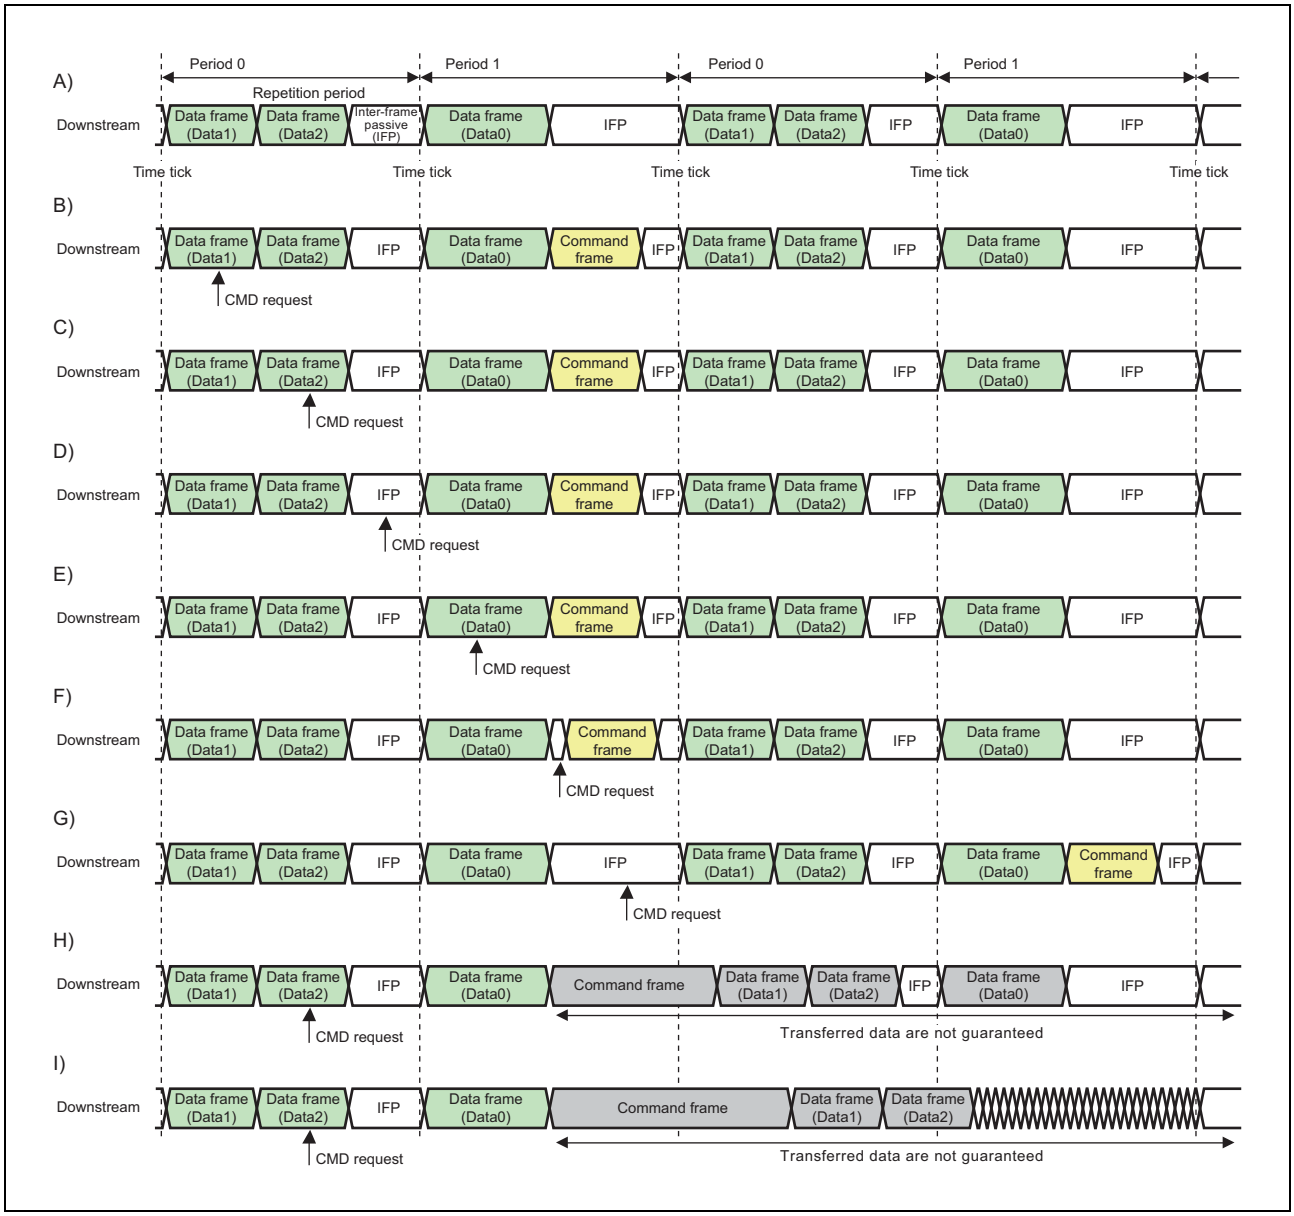

Figure 18.17 Examples of Command Insertion Using Best-Effort Method in Multi-Period Repetition Mode

Scenario A) shows a schedule with no command requests.

Scenario B, C, D) shows command frame insertion when a command request comes in period 0. The command frame is shifted after the end of data frame in period 1.

Scenario E) shows command frame insertion when a command request comes at a data frame in period 1. The command frame is shifted after the end of data frame in period 1.

Scenario F) shows command frame insertion when a command request comes at an inter-frame passive phase and the command length is shorter than the rest of the inter-frame passive length.

Scenario G) shows command frame insertion when a command request comes at an inter-frame passive phase and the command length is longer than the rest of the inter-frame passive length.

Scenarios H) and I) show command frame insertion where the command frame length is longer than the inter-frame passive length. This setting is prohibited. Transferred data after the command frame are not guaranteed until the user writes RHSBjDTC.RHSBjTSR to 1_B.

18.4.1.5 Physical Frame Format

(1) Clock line

The serial clock line (RHSBjFCLP/RHSBjFCLN (j = 0, 1)) provides the timing information from the MSC master to the MSC slave modules. The clock line and the clock phase are common for all slaves.

The user can configure by setting RHSBjDCR.RHSBjCLP whether the serial data line (RHSBjSOP/RHSBjSON (j = 0, 1)) and the chip select lines (RHSBjCSD0-1 (j = 0, 1)) are changing their values with rising edge or falling edge of the serial clock line (RHSBjFCLP/RHSBjFCLN (j = 0, 1)).

Note that RHSBjDCR.RHSBjCLP is directly influencing the level on the serial clock line (RHSBjFCLP/RHSBjFCLN (j = 0, 1)).

The user is able to configure the serial clock activity by RHSBjDCR.RHSBjCAC anytime. The RHSB module guarantees a glitch free clock signal on the serial clock line (RHSBjFCLP/RHSBjFCLN (j = 0, 1)).

The configuration given by RHSBjDCR.RHSBjCAC is not affecting the clock activity during the active phases; for a proper downstream communication the clock is required during active phases. RHSBjDCR.RHSBjCAC is only affecting the clock activity during the passive phases; for downstream communication the clock is not required during passive phases.

An active serial clock line may be required in some applications by a connected slave (e.g. if a slave uses the downstream clock to handle the upstream communication).

(2) Individual slave configuration

For each slave the user can independently program in CONFIG state:

- The active level of the chip select line (RHSBjSDCi.RHSBjCSLPn)
- The active level of the serial data line (RHSBjSDCi.RHSBjSOLPn)
- The assertion phase length (RHSBjSDCi.RHSBjAPLn)
- The deassertion phase length (RHSBjSDCi.RHSBjDPLn)
- The presence of a selection bit in data frames (RHSBjSDCi.RHSBjCPSn)

Note that the active level configuration for the chip select lines is directly visible at the outputs of the RHSB module.

(3) Downstream frame encoding

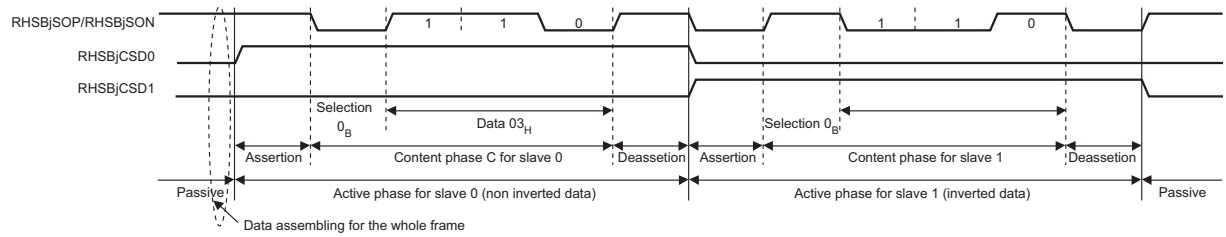
The selection bit is 0_B for data frames and 1_B for command frames.

The serial data line (RHSBjSOP/RHSBjSON (j = 0, 1)) is specified as 'invalid' for the assertion and deassertion phases; the RHSB module is transmitting 1_B during these phases. Note that the level on the serial data line depends on the individual slave configuration (RHSBjSDCi.RHSBjSOLPn).

An enabled inversion of the serial data line happens as long as slave n is selected.

The inversion of the serial data line is only configurable for active phases; the RHSB module sets serial data line (RHSBjSOP/RHSBjSON (j = 0, 1)) to high level during passive phases independent from RHSBjSDCi.RHSBjSOLPn.

Figure 18.18 illustrates a data frame encoding in case of two slaves with active high chip select lines. The frame transmits a data word of 3 bits (value is 03_H) to slave 0 and to slave 1. The configuration of both slaves is identical except that the data line for the slave 1 is inverted.



Note: j = 0,1

Figure 18.18 Frame Encoding Example

The RHSB module assembles the downstream frame directly before the transmission starts (as marked in **Figure 18.18**). This assembling timing is independent from the downstream mode (RHSBjDCR.RHSBjDMS) and the frame type (command/data frame).

18.4.1.6 Data Frame Assembling

A data frame is a stream of un-correlated bits sent to up to 4 slaves. There is an individual chip select line for each slave indicating which content is for which slave. Two chip select signals are not simultaneously active. Only one chip select signal can be activated at a time.

A data frame is composed by up to 4 Downstream Frame Transmission Elements (DFTEs).

The number of DFTEs used is defined by RHSBjDCR.RHSBjSLS.

For each DFTE the user can configure:

- The slave assigned to (RHSBjDEC.RHSBjSSDm)
- Presence of an optional selection bit in each content phase (RHSBjSDCi.RHSBjCPSn)
- The number of used data bits (RHSBjDEC.RHSBjNDBm)

If a slave needs more than one DFTE, the user should assign consecutive DFTEs to the same slave. These DFTEs are combined into one content phase.

Note that it is possible to assign nonconsecutive DFTEs to the same slave (e.g. DFTE0 and DFTE2); in this case each DFTE defines its own content phase.

The DFTEs are always placed in ascending order inside a data frame. Because the DFTE/slave assignment is free configurable, the ordering of slave selection is not restricted by the fixed DFTE order.

(1) Data source configuration

For each bit of a DFTE the user can configure independently the data source by setting RHSBjDEBAm.RHSBjDSSn as:

- Timer input (tmr)
- Timer input inverted
- Downstream data register

The relation between DFTEs and the data sources is shown in **Figure 18.29**. The diagram in **Figure 18.19** illustrates this relation for one bit and includes the emergency case.

For details about the mapping of timer inputs please refer to **Section 18.7, Cross Bar (XBAR)**.

Table 18.26 Relation of DFTEs and Data Sources

	Timer Input	Data Input	Bit Assignment	Emergency Data	Emergency Enable
DFTE0[15:0]	tmr[15:0]	DDR0[31:16]	DEBA0[31:0]	DED0[31:16]	EBE0[31:16]
DFTE1[15:0]	tmr[31:16]	DDR0[15:0]	DEBA1[31:0]	DED0[15:0]	EBE0[15:0]
DFTE2[15:0]	tmr[47:32]	DDR1[31:16]	DEBA2[31:0]	DED1[31:16]	EBE1[31:16]
DFTE3[15:0]	tmr[63:48]	DDR1[15:0]	DEBA3[31:0]	DED1[15:0]	EBE1[15:0]

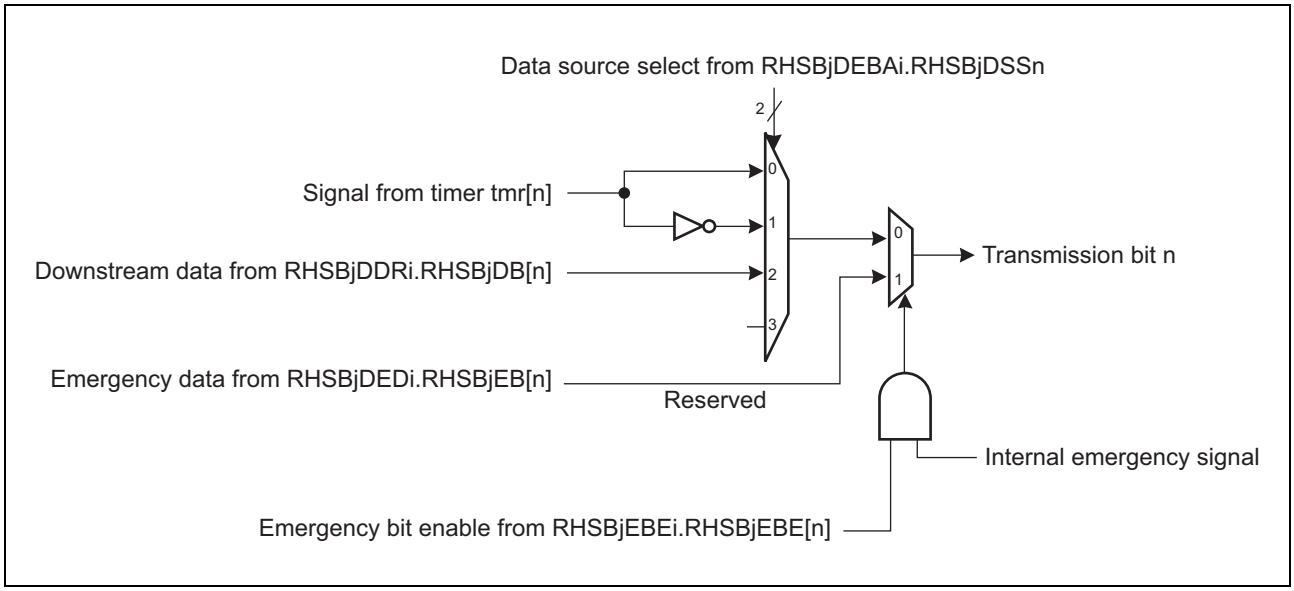


Figure 18.19 Data Source Selection for One Bit of a DFTE

The 'transmission bit n' signal in **Figure 18.19** represents the value of bit n. This signal is used by the RHSB module to assemble the content of a data frame when starting the data frame transmission.

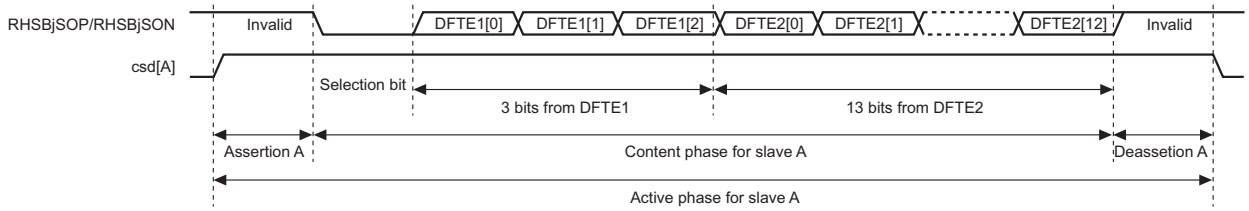
(2) Data frame DFTE mapping

Table 18.27 shows all possible configurations of data bits available for each slave depending on the number of used slaves. The slaves are named A to D to illustrate that there is no dependency between the DFTEs and slave number. If there is a range of assigned DFTEs given, these DFTEs have to be consecutive.

Table 18.27 Combinations of DFTEs and Data Bits Assignments to Slaves

Number of Slaves	Slave A Bits	Slave B Bits	Slave C Bits	Slave D Bits	DFTE Assignment
1 slave (A)	1 to 64	—	—	—	1 to 4 DFTEs to slave A
2 slaves (A, B)	1 to 48	1 to 16	—	—	1 to 3 DFTEs to slave A 1 DFTE to slave B
2 slaves (A, B)	1 to 32	1 to 32	—	—	1 to 2 DFTEs to slave A 1 to 2 DFTEs to slave B

Figure 18.20 shows an example of a downstream frame to be transmitted to slave A assembled from DFTE1 and DFTE2. The slave device A is configured in RHSBjSDCi register as: RHSBjAPLn = 1, RHSBjCSLPn = 0, RHSBjSOLPn = 0, RHSBjCPSn = 1, RHSBjDPLn = 1 (active high, assertion and deassertion phase of 1_D bit, selection bit is present). For DFTE1 3 data bits are configured (RHSBjDEC.RHSBjNDB1 = 2), for DFTE2 13 data bits are configures (RHSBjDEC.RHSBjNDB2 = 12).



Note: j = 0,1

Figure 18.20 Example Bit Mapping when Combining Two DFTEs

18.4.1.7 Command Frame Assembling

The command frame is a stream of correlated bits sent to one slave. There is only one content phase available in a command frame.

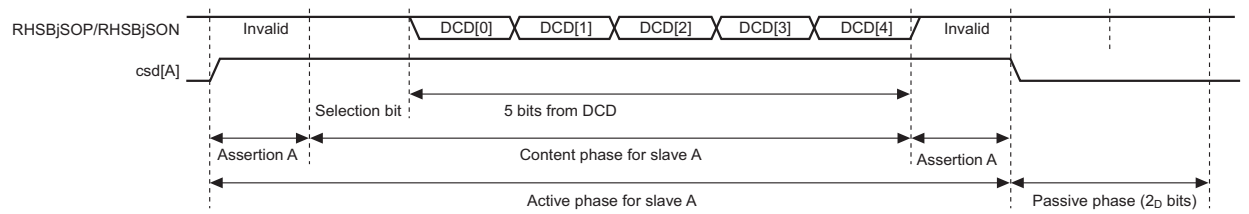
The content phase of a command frame always contains a selection bit.

The number of data bits which are sent in the content phase from the RHSBjDCD register is configurable from 1 to 32 bits. This number can be changed individually for each command frame transmission by RHSBjDTC.RHSBjNCB.

The frame passive phase of command frames is fixed to 2_D bits.

The length of assertion and deassertion phase depends on the slave device configuration in RHSBjSDCi register as used for data frames.

Figure 18.21 shows an example of a command frame with 5 bits (RHSBjDTC.RHSBjNCB = 4) to be transmitted to slave A. The slave device A is configured in RHSBjSDCi register as: RHSBjAPLn = 1, RHSBjCSLPn = 0, RHSBjSOLPn = 0, RHSBjDPLn = 1 (active high, assertion and deassertion phase of 1_D bit).



Note: j = 0,1

Figure 18.21 Command Frame Bit Mapping

18.4.1.8 Emergency Function

The emergency function of the RHSB modules supports an automatic transmission of pre-defined data to slaves in case of emergency. The emergency function controls only the content of data frames; the scheduling of data transmission is not affected.

The external emergency signal (RHSBjEMRG (j = 0, 1)) which is available as primary input pin of the MCU, is evaluated to derive the emergency condition.

The emergency function can be globally enabled/disabled using RHSBjDCR.RHSBjEE. Additionally, the user can individually select via RHSBjEBEi.RHSBjEBE for each bit of each DFTE if there should any action taken in an emergency case.

When the RHSB module detects the emergency condition, the data source of the selected DFTE bits is forced to the corresponding value defined in the downstream emergency data registers (RHSBjDEDi). This selection is illustrated in **Figure 18.19**.

To use the emergency function, the user should:

- configure the active level of the emergency signal (RHSBjDCR.RHSBjEIP),
- configure the mode indicating how the emergency condition is derived from the emergency signal (RHSBjDCR.RHSBjEIM),
- enable the emergency function and define the usage of automatic stop capability (RHSBjDCR.RHSBjEE),
- select the action in an emergency case for the individual DFTE bits (RHSBjEBEi.RHSBjEBE),
- define the emergency data for the individual DFTE bits (RHSBjDEDi.RHSBjEB).

Figure 18.22 illustrates how the emergency condition (internal emergency signal) is derived from the level of the external emergency signal (RHSBjEMRG (j = 0, 1)). The RHSB module requires stable levels on the external emergency signal which are longer than three peripheral bus clock cycles (CLK_LSB).

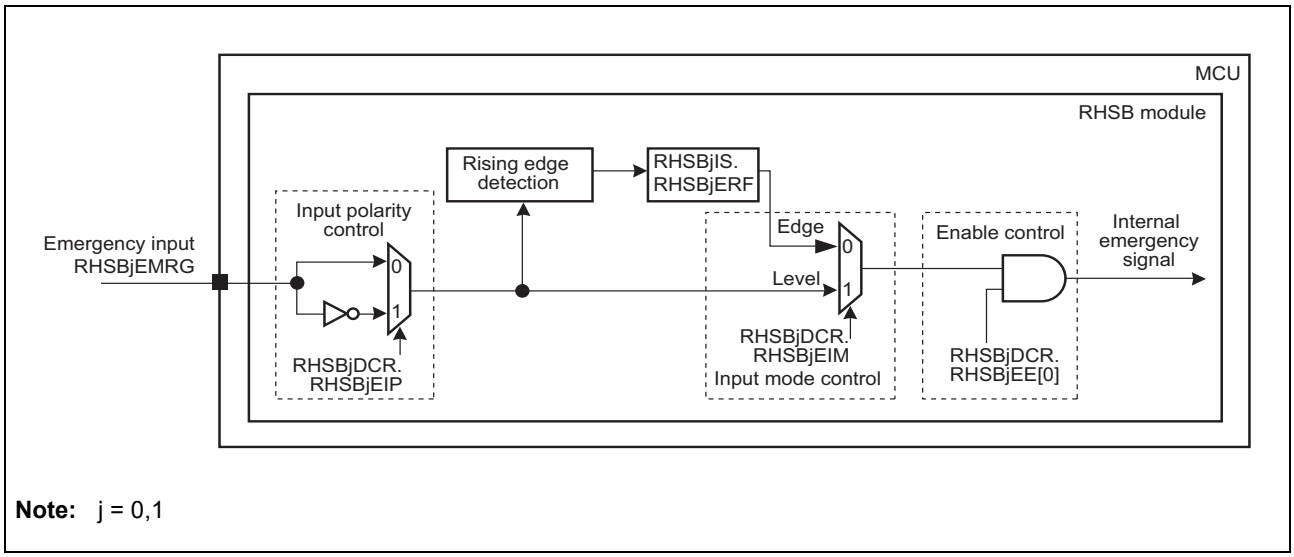


Figure 18.22 Detection of Emergency Condition

The RHSB module uses the internal emergency signal when assembling a data frame. To transmit an emergency frame the internal emergency signal has to be active at assembling time (when the data frame starts).

Even if the emergency function is not used (RHSBjDCR.RHSBjEE is 00_B), the user can read RHSBjIS.RHSBjERF to get informed about the emergency case detection.

(1) Edge sensitive input mode

The emergency input mode is edge sensitive when RHSBjDCR.RHSBjEIM is 0_B

When the RHSB module detects an edge where the external emergency signal goes active, the RHSBjIS.RHSBjERF flag is set to 1_B.

This flag needs to be cleared by the user.

When using the edge sensitive input mode, the user has to ensure that the RHSBjIS.RHSBjERF flag is 1_B until an emergency frame is transmitted. The RHSBjIS.RHSBjETF flag indicates that the emergency frame has been transmitted.

Note that an edge will be detected when the ACTIVE state is entered while there is an active level at the external emergency signal.

(2) Level sensitive input mode

The emergency input mode is level sensitive when RHSBjDCR.RHSBjEIM is 1_B.

When using the level sensitive input mode, the user has to ensure that the external emergency signal is on the active level for one repetition period or longer in single-period repetition mode or for two repetition periods or longer in multi-period repetition mode. If shorter, the RHSB module may not detect emergency.

(3) Automatic stop function

When the emergency function is enabled by RHSBjDCR.RHSBjEE, the user defines if the data transmission should be automatically stopped after the transmission of the first emergency frame.

When RHSBjDCR.RHSBjEE is set to 01_B (emergency condition detection enabled, no stop), the automatic stop function is inactive. The RHSB module transmits emergency frames as long as the emergency condition (see **Figure 18.22**) is true.

When the emergency condition changes to false, the RHSB module continues with transmission of normal data frames.

When RHSBjDCR.RHSBjEE is set to 11_B (emergency condition detection and automatic stop enabled), the RHSB module transmits exactly one emergency frame in single-period repetition mode or the RHSB module transmits one or two emergency frames in multi-period repetition mode when the emergency condition is true.

After transmitting the emergency frame to all slaves, the data transmission is automatically stopped (RHSBjDTC.RHSBjDTE changes to 0_B) after period 0 as illustrated in **Figure 18.23**. Independent from the downstream mode (RHSBjDCR.RHSBjDMS) no data transmission is possible until the user enables this by setting DTC.DTE to 1_B. After setting DTC.DTE to 1_B, the RHSB module restarts transmission of DFTE0 data from period 0.

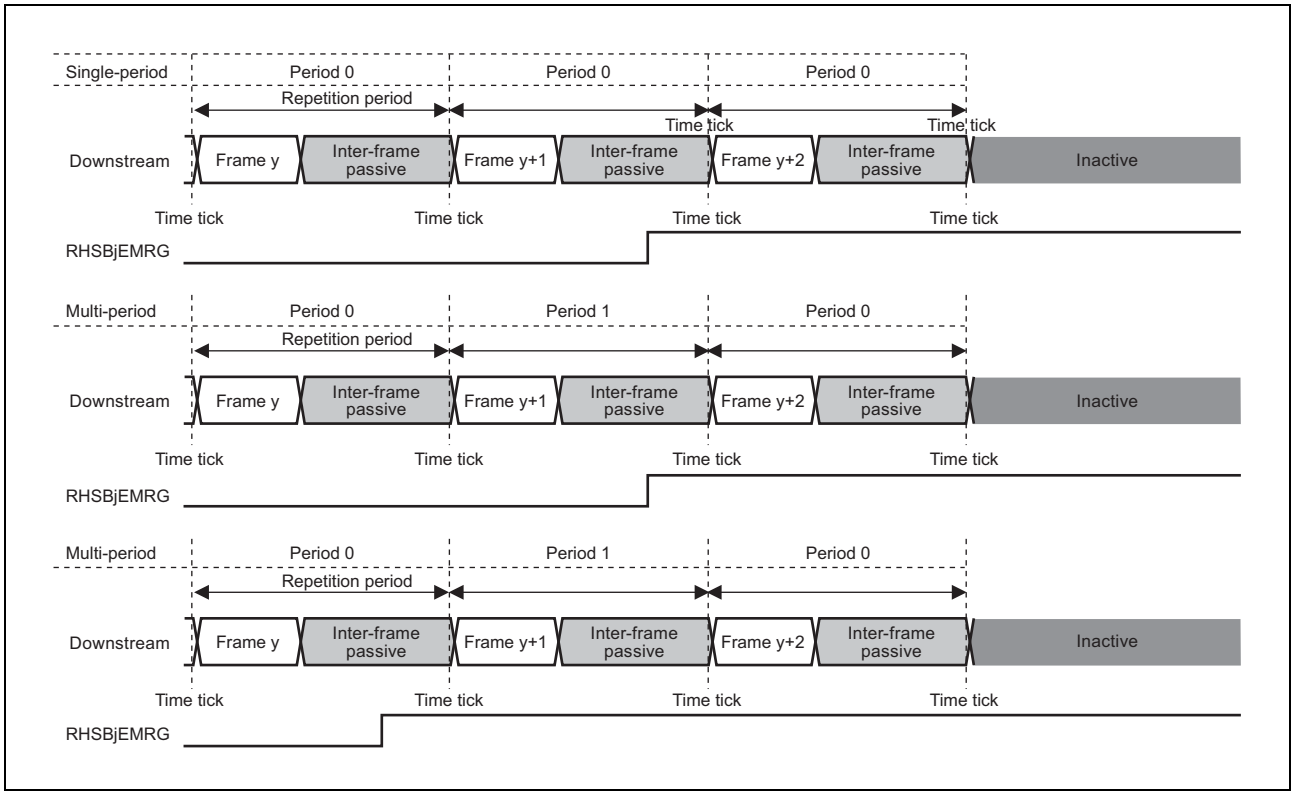

Figure 18.23 Automatic Stop Function in Repetition Mode

18.4.1.9 Downstream Bit Rates

The downstream bit rate (f_{DW}) is derived from the RHSB engine clock source frequency (f_{PE}).

With the divider value x defined by RHSBjDCR.RHSBjDBR, the downstream bit rate can be calculated as function of the RHSB engine clock source frequency:

$f_{DW} = f_{PE} / x$

With f_{PE} of 80 MHz these downstream bit rates can be achieved.

Table 18.28 Possible Downstream Bit Rates with a RHSB Engine Clock Source of 80 MHz

RHSBjDCR.RHSBjDBR	1	3	4	7	8	9	10	11	12
x	2	4	5	8	16	32	64	128	256
Bit rate	40 Mbit/s	20 Mbit/s	16 Mbit/s	10 Mbit/s	5 Mbit/s	2.5 Mbit/s	1.25 Mbit/s	625 Kbit/s	312.5 Kbit/s

When the divider value x is odd, the duty cycle of the clock signals on the serial clock line (RHSBjFCLP/RHSBjFCLN) will not be 50%. In this case, the first phase of the clock signal becomes 1 clock cycle longer than that of f_{PE}.

Example: When x is 5 and RHSBjDCR.RHSBjCLP is 0_B, the widths at high and low level of the clock signal are 3 cycles of f_{PE} and 2 cycles of f_{PE}, respectively. When x is 5 and RHSBjDCR.RHSBjCLP is 1_B, the widths at low and high level of the clock signal are 3 cycles of f_{PE} and 2 cycles of f_{PE}, respectively.

18.4.1.10 Data Update and Data Frame Transmission Request

By setting RHSBjIS.RHSBjDTSF to 0_B, the user acknowledges the data transmission start event and informs the RHSB module that new data is available.

RHSBjIS.RHSBjDTSF can be set to 0_B by two strategies:

- Writing the RHSBjIS.RHSBjDTSF flag directly to 0_B
  - Data configured in RHSBjDDRi is used for the next transmission
- Writing to RHSBjDDRi register (by the user or by DMA)
  - New data written to RHSBjDDRi is used for the next transmission

The write DDRi method allows an optimized transmission flow because it automatically sets RHSBjIS.RHSBjDTSF to 0_B and hence starts the transmission.

It depends on the configuration parameter RHSBjDCR.RHSBjSLS (number of used DFTEs) when a write to a RHSBjDDRi triggers a transmission.

- RHSBjDCR.RHSBjSLS is 00_B (1 DFTE is used): writing to RHSBjDDR0[31:16] (DFTE0)
- RHSBjDCR.RHSBjSLS is 01_B (2 DFTEs are used): writing to RHSBjDDR0[15:0] (DFTE1)
- RHSBjDCR.RHSBjSLS is 10_B (3 DFTEs are used): writing to RHSBjDDR1[31:16] (DFTE2)
- RHSBjDCR.RHSBjSLS is 11_B (4 DFTEs are used): writing to RHSBjDDR1[15:0] (DFTE3)

Even if DCR1.SLS1(number of used DFTEs for period 1) is available in multi-period repetition mode, it depends on the configuration parameter DCR.SLS (number of used DFTEs) when a write to a DDRi triggers a transmission. If DCR1.SLS1 is smaller than DCR.SLS, the user should write dummy data to DDRi defined by DCR.SLS.

- DCR.SLS is 00_B (1 DFTEs is used): writing to DDR0[31:16] (DFTE0)
- DCR.SLS is 01_B (2 DFTEs are used): writing to DDR0[15:0] (DFTE1)
- DCR.SLS is 10_B (3 DFTEs are used): writing to DDR1[31:16] (DFTE2)
- DCR.SLS is 11_B (4 DFTEs are used): writing to DDR1[15:0] (DFTE3)

The data frame transmission started flag (RHSBjIS.RHSBjDTSF) is set to 1_B when the assembling has been performed at the start of the data frame transmission.

RHSBjIS.RHSBjDTSF equal to 1_B indicates that a data frame transmission has been started and so the downstream data registers can be written with new transmit data.

In addition the RHSBjIS.RHSBjDTSF is set to 1_B when data transmission is initially enabled by RHSBjDTC.RHSBjDTE to prevent a data frame transmission without explicit software trigger.

Updating RHSBjDDRi while a data frame is transmitted is not affecting the ongoing transmission but it requests an additional data transmission.

As there is write protection of the downstream data registers (RHSBjDDRi) while there is new data pending for transmission, it is guaranteed, that written downstream data is transmitted at least one time.

(1) Scheduling of Downstream Data Update

The user can update the downstream data by using the following as a trigger.

- Data Frame Transmission Started
  New data can be supplied timely. In this case, RHSBjIS.RHSBjDTSF is used as a trigger.

- Data Frame Transmission Done
  New data is supplied upon completion of data frame transmission. In this case, RHSBjIS.RHSBjDTF is used as a trigger.

Writing to the RHSBjDDRi, the RHSBjIS.RHSBjDTSF and RHSBjIS.RHSBjDTF are cleared. It is recommendable to use only one of them as a trigger of downstream data update.

18.4.1.11 Command Frame Transmission Request

The transmission of command frames is always triggered when the user writes to RHSBjDTC.RHSBjCTR. On each request the transmission of one command frame is started. The method for how command frames are inserted into the downstream communication depends on the selected mode and a set of configuration parameters; for details refer to the detailed mode description.

When RHSBjDTC.RHSBjCTR is set to a value not equal to 00_B, a command frame transmission is scheduled. After completion of the command frame transmission, RHSBjDTC.RHSBjCTR is automatically set to 00_B and the user is able to set a new request.

18.4.2 Upstream Communication

The RHSB module uses for upstream communication the asynchronous serial reception.

There are two upstream channels available to connect up to two slaves with the RHSB module. Only one channel can be selected as active channel at the same time. Any activity on the not selected channels is ignored.

It is possible to receive consecutive upstream frames sent on the same serial input line.

Reception of upstream communication is only supported when the user has enabled this function by setting RHSBjUCR.RHSBjUE to 1_B in CONFIG state.

The diagram in **Figure 18.24** illustrates the functional blocks of the upstream engine. The detailed upstream communication is explained in this section.

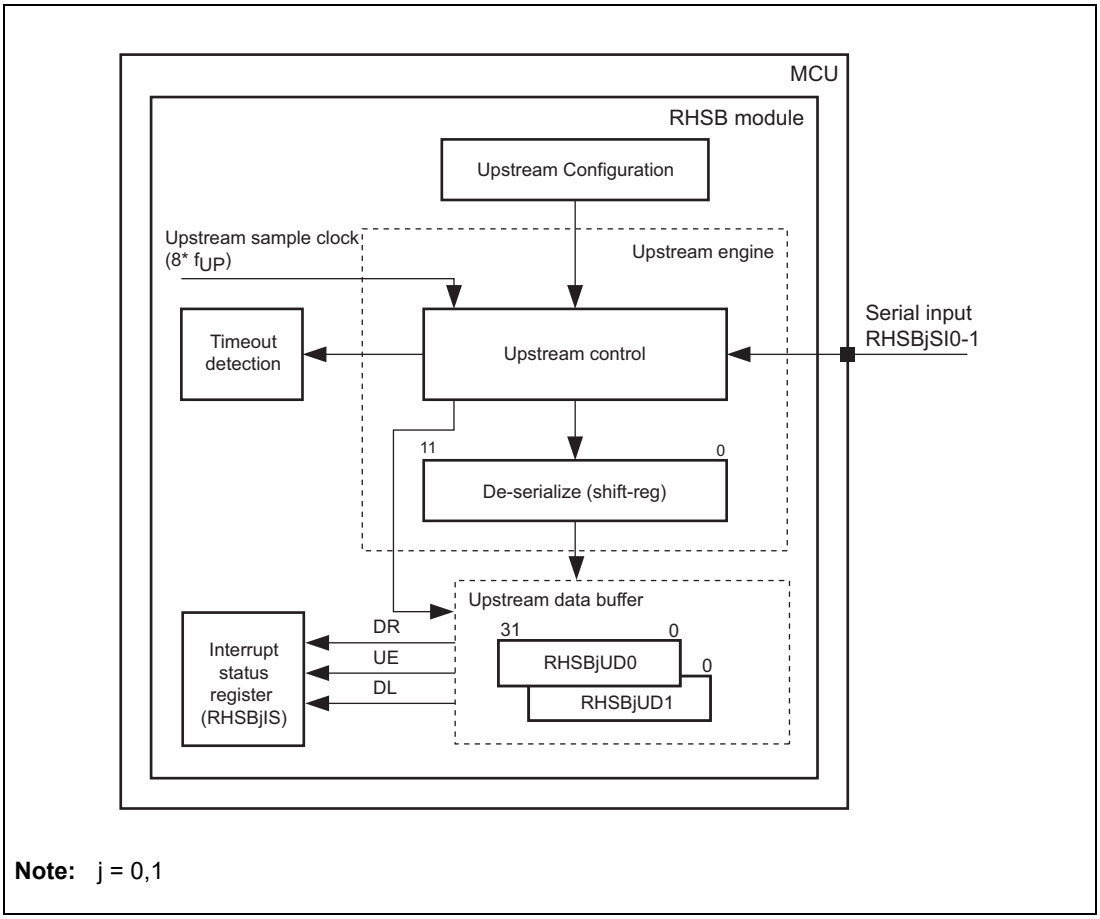

Figure 18.24 Upstream Block Diagram

Upstream Configuration

This block represents the upstream related configuration parameters and the upstream control interface handled by the application software.

Upstream Control

This block provides the main function of the upstream engine. It selects the active serial data input line (RHSBjSI0-1 (j = 0, 1)) and the corresponding configuration, provides the start bit detection, schedules the sampling and observes the frame syntax. In addition this block controls the storage of the received information in the upstream data registers (RHSBjUDi) and provides the required decoding status.

De-serialize

The shift register stores the received payload and provides this information for storage in the upstream data registers.

Upstream Data Buffer

This block includes the upstream data registers and the control logic to select one RHSBjUDi for updating. In addition the upstream related status flags in the RHSBjIS register are controlled by this block.

18.4.2.1 Upstream Modes

The RHSB module has two upstream modes with different methods for how the slaves are connected to the serial input lines. These upstream modes can be configured by RHSBjUCR.RHSBjUMS:

- Dedicated input mode
  - Each slave is connected to an individual serial input line.
  - The active serial input line is selected by RHSBjUCS.RHSBjACC.
- Shared input mode
  - All slaves are connected on the serial input line 0.
  - The active serial input line is always line 0 independently of the value in RHSBjUCS.RHSBjACC.

Note when using the Shared input mode, the unused serial input lines are not required to be configured as RHSB inputs in the MCU port function registers.

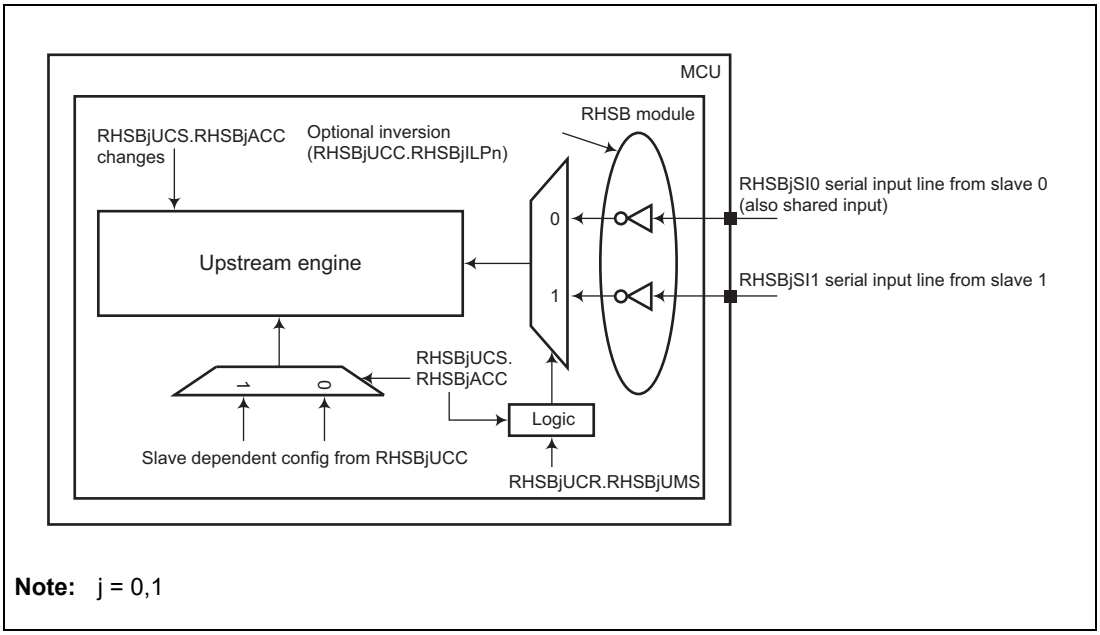

Figure 18.25 Slave Connection and Selection for Upstream Communication

Figure 18.25 illustrates how the serial input lines are connected to the upstream engine. The shown 'Logic' ensures that in shared mode always input line 0 is used, independent from the value of RHSBjUCS.RHSBjACC. The shown 'RHSBjUCS.RHSBjACC changes' information is used by the upstream engine to abort an ongoing reception when the selected channel changes.

18.4.2.2 Individual Slave Configuration

The RHSB module supports for each slave an individual upstream configuration. The usage of different channel configurations is independent from the upstream mode (RHSBjUCR.RHSBjUMS). For each channel the user can program via the RHSBjUCC register:

- The frame type (8 or 12 bit format)
- The number of stop bits (2 or 3)
- The parity type (even or odd)
- The upstream bit rate (please refer to **Section 18.4.2.5, Upstream Bit Rates** for details)

The serial input line polarity is independent from RHSBjUCS.RHSBjACC. The inversion function configured by RHSBjUCC.RHSBjILPn is fixed and assigned to a serial input line n. Thus, RHSBjUCC.RHSBjILP0 is used for all two channels in shared input mode.

The configuration used by the upstream engine to decode upstream frame is defined by RHSBjUCS.RHSBjACC.

There are two ways to change the active upstream configuration:

- Direct request for configuration change by writing to RHSBjUCS.RHSBjACC.
- Request of a command transmission with upstream data request by writing RHSBjDTC.RHSBjCTR to 11_B.

18.4.2.3 Frame Format Types

The RHSB module supports two frame types for upstream communication which only differs in the number of data bits (8 or 12 bit). Other configuration options are not influenced by the frame type.

When the parity type is even, the number of 1_B bits inside the parity covered area is even (0, 2, 4, 6, 8, 10 and 12).

When the parity type is odd, the number of 1_B bits inside the parity covered area is odd (1, 3, 5, 7, 9, 11 and 13).

Figure 18.26 and **Figure 18.27** show an upstream frame with non-inverted data line.

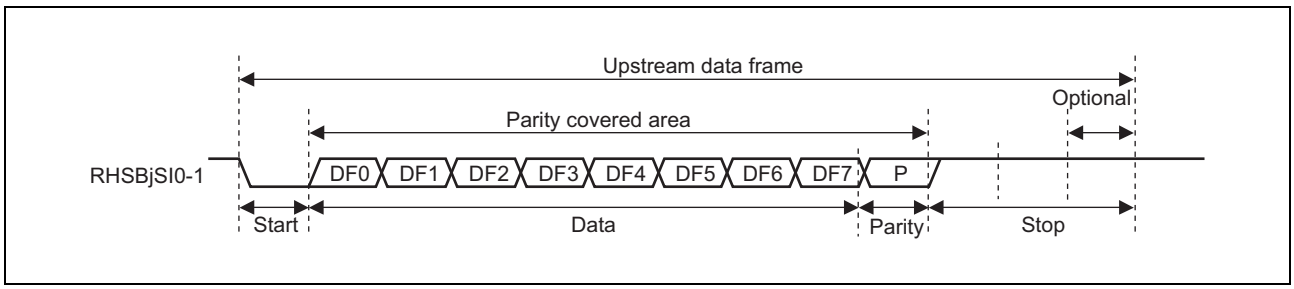

Figure 18.26 Upstream Frame Format with 8 Data Bits (12 or 13 Bit Frame)

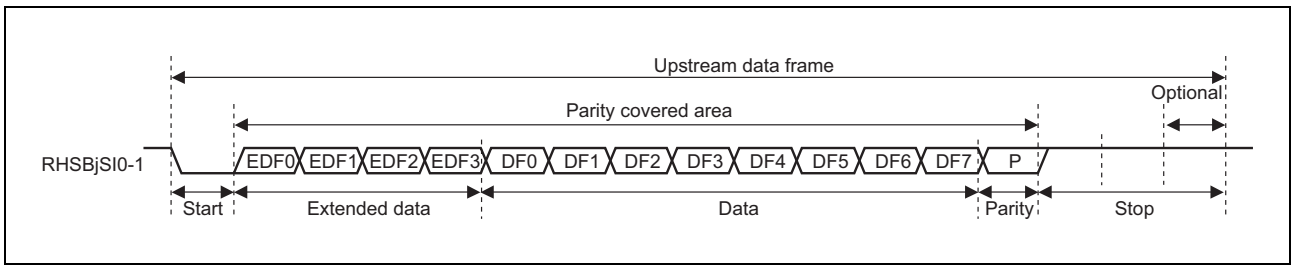

Figure 18.27 Upstream Frame Format with 12 Data Bits (16 or 17 Bit Frame)

18.4.2.4 Frame Storing

The RHSB module offers two upstream data registers (RHSBjUDi) where the upstream engine stores its decoding results. There are two methods selectable in RHSBjUCR.RHSBjFSM defining how the RHSBjUDi is selected for updating.

Note that the decoding of an ongoing reception is aborted when RHSBjUCS.RHSBjACC changes. In this case no decoding result is stored.

(1) Normal storage method

This method is used when RHSBjUCR.RHSBjFSM is 0_B.

The storage strategy is identical for frames of 8-bit and 12-bit format.

The active channel configuration (RHSBjUCS.RHSBjACC) defines the upstream data register to store the decoding results. The target can be identified by this relation:

- when RHSBjUCS.RHSBjACC is 00_B, RHSBjUD0 is updated
- when RHSBjUCS.RHSBjACC is 01_B, RHSBjUD1 is updated

(2) Addressed storage method

This method is used when RHSBjUCR.RHSBjFSM is 1_B.

When the frame type is configured as 8-bit format, the target is always RHSBjUD0.

When the frame type is configures as 12-bit format, the target depends on the received extended data field (EDF, see **Figure 18.27**). The target can be identified by this relation:

- when RHSBjEDF[3:2] is 00_B, RHSBjUD0 is updated
- when RHSBjEDF[3:2] is 01_B, RHSBjUD1 is updated

Note also in case of a faulty reception (parity or stop bit error detected) the received extended data field is used to identify the target for updating the error flags.

18.4.2.5 Upstream Bit Rates

The upstream bit rate (f_{UP}) is derived from the downstream bit rate (f_{DW}).

The bit rate is configured for each channel individually by RHSBjUCC.RHSBjUBRn.

With (x = RHSBjUCC.RHSBjUBRn) the upstream bit rate used by channel n can be calculated as a function of the downstream bit rate such that:

$f_{UP} = f_{DW} / 2^x$

Because the RHSB module samples each upstream bit 8 times, the maximal upstream bit rate is 1/8 of the RHSB engine clock source frequency ($f_{PE}/8$). However, set this RHSB module to 16-frequency division at 5 MHz or lower.

18.4.2.6 Update of Decoding Status

The upstream engine updates one of the RHSBjUDi registers after the decoding of an upstream frame has been completed (after the last stop bit).

When the decoder has detected a parity or stop bit error, the related error flags (RHSBjFERR or RHSBjPERR or both) are set in the corresponding RHSBjUDi register.

When the decoder has not detected parity nor stop bit errors, this frame is judged as a valid frame and these parts of the corresponding RHSBjUDi are updated:

- New data flag (RHSBjND) is set to 1_B
- Data field (RHSBjDF) is updated
- Extended data field (RHSBjEDF) is updated in case of 12-bit frames
- Data lost flag (RHSBjDL) is set to 1_B if the new data flag was already 1_B

18.4.3 Timeout Detection

The concept of timeout detection realized by the RHSB module is linked to the concept of “command transmission with data request”. The concept assumes this flow:

Step 1: Master requests data from slave x by sending a command frame.

Step 2: Slave x answers the master by sending the requested data on the upstream channel.

From an application point of view the master expects to receive an answer from slave x within a certain period (timeout period). This expectation is processed by the timeout detection function.

To use the timeout detection function the user should enable the upstream reception (RHSBjUCR.RHSBjUE is 1_B) and should enable the timeout function (RHSBjUCR.RHSBjTOE is 1_B).

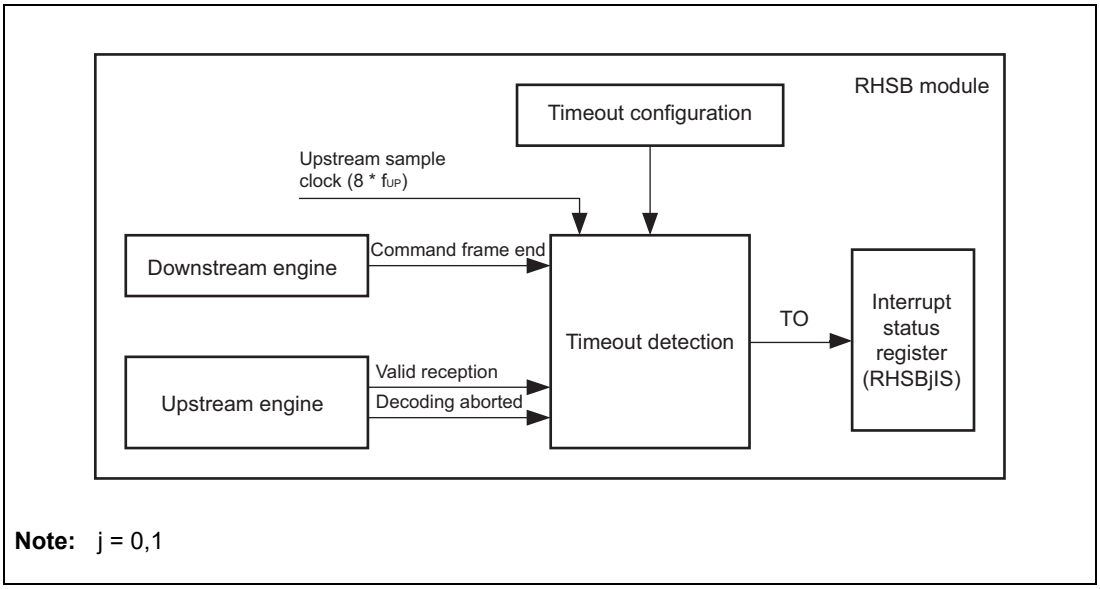

Figure 18.28 Timeout Block Diagram

The diagram in **Figure 18.28** illustrates the scope of timeout detection block. It is controlled by the downstream and upstream engine. The timeout detection controls RHSBjIS.RHSBjTOF. The detection of a timeout has no influence to an ongoing reception.

Note that the timeout detection cannot distinguish between the reception due to the request and other receptions. For example if the shared input mode configuration is used and two slaves are transmitting upstream frames during the timeout period. The user has to ensure that in fault free operation only one upstream reception can happen during the timeout period.

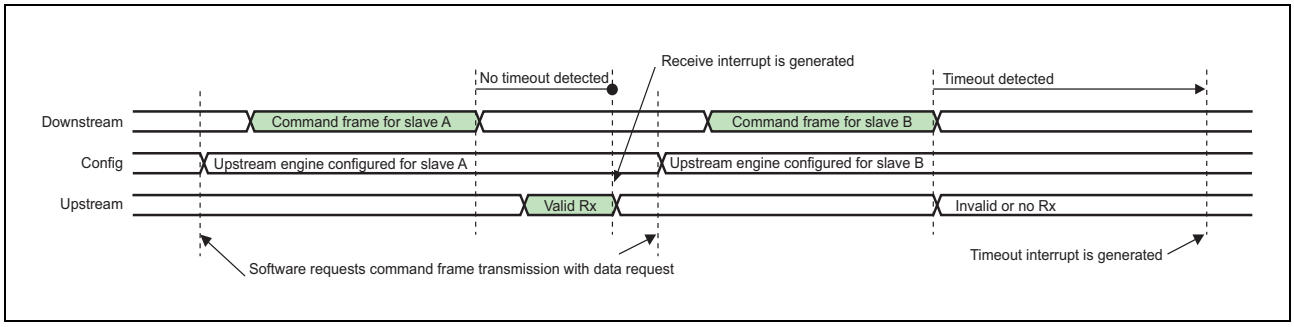

Figure 18.29 Example of Timeout Detection

The example shown in **Figure 18.29** illustrates the principle timing of the timeout detection.

In the first case the user issues a command frame transmission with data request for slave A. The downstream configuration is updated, and then a command frame is scheduled for transmission. After the end of transmission the timeout period starts. The valid response of the slave is decoded before the timeout period ends.

In the second case the user issues a command frame transmission with data request for slave B. In this case the timeout period ends before a valid response was decoded.

18.4.3.1 Command Transmission with Remote Data Request

To perform a command transmission with data request the user has to follow this flow:

- Writing the command data to the RHSBjDCD register
- Define the target slave by writing to RHSBjDTC.RHSBjSSCF
- Request command transmission with data request by writing 11_B to RHSBjDTC.RHSBjCTR

Writing of the command to RHSBjDRC.RHSBjCTR triggers in the RHSB module to carry out these actions:

- Update of the active slave configuration (RHSBjUCS.RHSBjACC) with the target slave number (RHSBjDTC.RHSBjSSCF)
- Abort an ongoing reception if the active slave changes
- Transmit the command frame on the downstream channel
- Start timeout counter when the command transmission has been completed

When there is a valid reception on the upstream channel, the RHSB module judges the remote data request as handled and the timeout counter is stopped.

When there is no valid reception on the upstream channel before the timeout counter elapses, the remote data request is judged as failed and the timeout is flagged by setting RHSBjUDi.RHSBjTO and RHSBjIS.RHSBjTOF to 1_B.

18.4.3.2 Timeout Detection Details

The timeout counter uses the nominal upstream bit time for timeout detection. The timeout counter is not influenced by possible resynchronization effects during start bit decoding.

The timeout counter is initialized to the value (RHSBjUCR.RHSBjRTO + 1)*8 (U bit), when the command frame transmission has been completed (end of frame passive phase).

The timeout counter is decremented with every sample period (U bit/8) used by the decoder according to the active slave configuration (RHSBjUCC.RHSBjUBRn).

The timeout counter stops when:

- there is a valid reception decoded on the upstream channel or
- the timeout counter elapse or
- the decoding is aborted (e.g. by changing the RHSBjUCS.RHSBjACC)

Note that there is no synchronization between the downstream frame passive phase end and the upstream sample points. Thus, the first timeout counter decrement can happen between 1_D bit and 1 U bit/8.

18.4.4 Test Mode Operation

The RHSB module is able to support key-on tests when RHSBjGC.RHSBjOPS is TEST.

Aim of the test mode is to transmit data on the downstream channel and receive the same data as an upstream frame. Because the upstream engine can only decode UART-like frames, such pattern needs to be emulated within the SPI-like downstream frame.

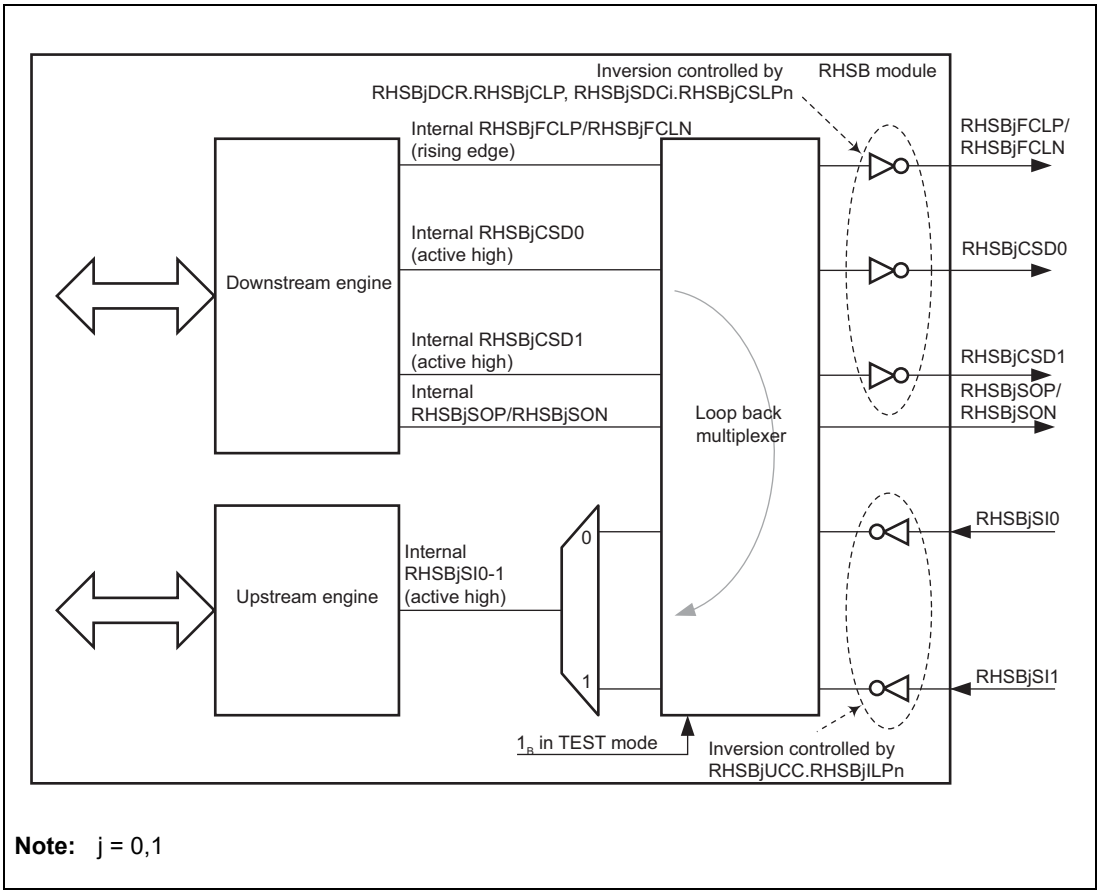
Since the downstream and upstream paths in the RHSB module are independent, the test mode allows good test coverage of all RHSB flags.

While the test mode is active, the serial input lines are disconnected from the upstream engine and the outputs are driven with fixed levels:

- the serial output line (RHSBjSOP/RHSBjSON) is driven with a high level
- the serial clock line (RHSBjFCLP/RHSBjFCLN) is driven with a level depending on the clock line phase (low level when RHSBjDCR.RHSBjCLP is 0_B)
- the chip select lines (RHSBjCSD0-1) are driven with a level depending on the chip select line polarity (low level when RHSBjSDCi.RHSBjCSLPn is 0_B)

Figure 18.30 illustrates the details about the position of the loop-back multiplexer. Only the inversion of the downstream data (RHSBjSDCi.RHSBjSOLPn) is influencing the test mode; all other inversions are out of scope.

The loop-back multiplexer connects the internal serial data (RHSBjSOP/RHSBjSON) signal to one upstream channel. The channel is selected by an active internal chip select. Thus, all two upstream channels can be checked.



Note: j = 0,1

Figure 18.30 Loop-Back Connection in Test Mode

The test mode should be carried out under the following conditions:

- The downstream bit rate divider should be fDW = f_{PE}/8 (this results in the maximum bit rate of 10 MBit/s when using 80 MHz RHSB engine clock source frequency). The user should set RHSBjDCR.RHSBjDBR to 7_D.
- The upstream bit rate should be equal to the downstream bit rate ($f_{UP} = f_{DW}$). The user should set RHSBjUCC.RHSBjUBRn to 0_D for all two upstream channels.

18.4.4.1 Test Mode Data Generation

Figure 18.31 shows an example of how the bits of a command frame are received by the upstream channel. The example uses non inverted downstream data without assertion/deassertion phases and assumes a 12-bit format with two stop bits.

On the downstream data line a command frame is transmitted for slave 1, the receiver has to be connected to the same slave by setting UCS.ACC to 01_B.

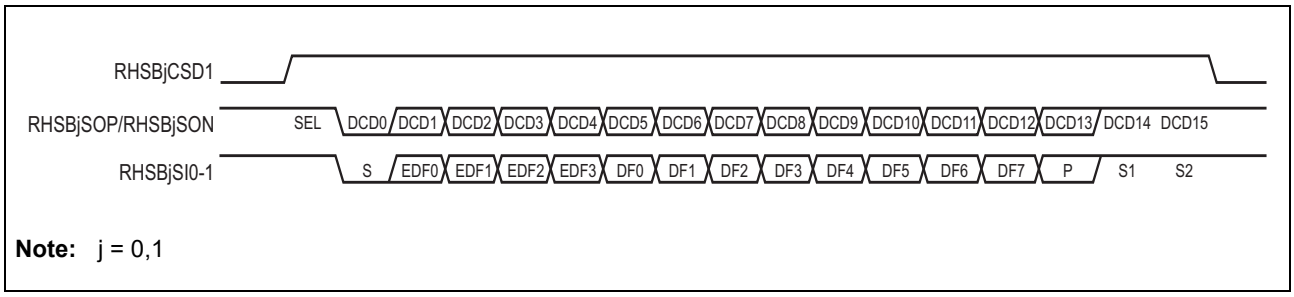


Figure 18.31 Example of How a Command Frame is Received by the Upstream Engine

By writing pattern into the RHSBjDCD register the user is able to check the parity logic and the stop bit error detection. In addition it is possible to check all 32 bits of the RHSBjDCD register, the command length configuration, the assertion/deassertion phase lengths and the data inversion.

Similar checks are also possible with data frames. Note that only the data for the select slave is received, even if multiple slaves are addressed in the data frame.

18.5 Interrupts

The RHSB module has 9 sources which can be used for interrupt request generation.

The interrupt status flags are cleared by the user when writing the flags to 0_B. Writing a 1_B has no effect. For some interrupt flags there are additional functional clear conditions defined to allow an optimized software flow. These interrupt flags are marked by * in the interrupt source lists in **Section 18.5.1** and **Section 18.5.2**.

When the RHSB module is in the RESET state or CONFIG state, an interrupt request is not generated.

18.5.1 Downstream Related Interrupts (Transmission)

Interrupt line 0

Data frame transmission started (RHSBjDTSF) *

Data frame transmission done (RHSBjDTF) *

Interrupt line 1

Command frame transmission done (RHSBjCTF) *

Transmission started (RHSBjTSF)

Interrupt line 2

Emergency frame transmission done (RHSBjETF)

18.5.2 Upstream Related Interrupts (Reception)

Interrupt line 3

Data received (RHSBjDRF) *

Interrupt line 4

Upstream error (RHSBjUEF) *

Timeout detected (RHSBjTOF)

Data lost (RHSBjDLF) *

By reading the RHSBjUSS register the user gets informed about the complete upstream status.

18.5.3 Interrupt Request Details

There is an individual interrupt status flag in the RHSBjIS register (RHSBjIS.RHSBjxF) and an individual interrupt enable bit in the RHSBjIC register (RHSBjIC.RHSBjxIE) for each interrupt source (x).

The function of the interrupt status is independent form the interrupt enable. The interrupt enable controls only if an interrupt request is made to the MCU's interrupt controller.

Figure 18.32 illustrates how an interrupt request is generated and the realization of the interrupt grouping.

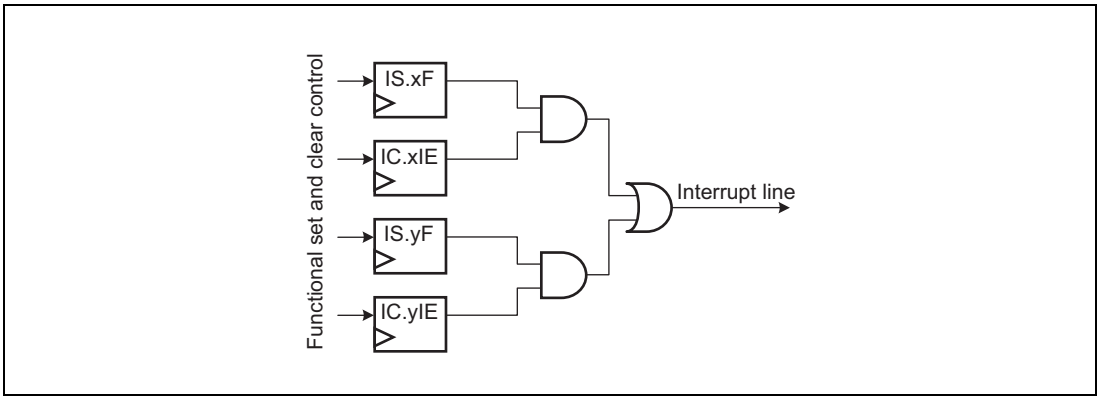

Figure 18.32 Interrupt Grouping (Example of Two Interrupts x and y)

18.6 DMA Capability

18.6.1 DMA Usage for Downstream Data Transmission

The downstream data DMA function is intended to serve applications where pre-calculated data tables are stored in the memory (RAM or FLASH) defining the pattern the RHSB module has to transfer to slaves.

A downstream data DMA transfer is started when RHSBjIS.RHSBjDTSF is 1_B and DMA is enabled by RHSBjGC.RHSBjDDE.

The user should not use RHSBjIS.RHSBjDTSF as interrupt source (RHSBjIC.RHSBjDTSIE should be set to 0_B) when using downstream data DMA. In addition the user should not write to the downstream data registers (RHSBjDDRi) nor set RHSBjIS.RHSBjDTSF to 0_B.

In **Figure 18.33**, case 1 shows normal DMA transfer of downstream data for transmission. In case 2, the DMAC is not able to supply downstream data within the repetition cycle, the DMAC retransmits the last data that it wrote. Accordingly, define a repetition cycle that is longer than the time the DMAC will take to supply the downstream data.

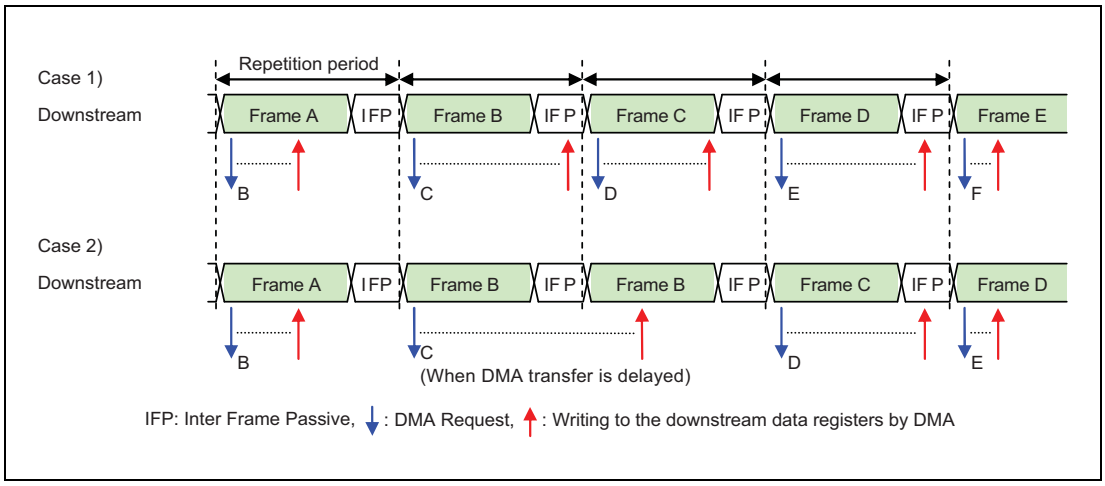

Figure 18.33 Downstream Data DMA Timing

18.6.1.1 Configuring and Enabling Flow to Use Downstream data DMA

These configurations should be done during CONFIG state:

- Set RHSBjDCR.RHSBjDMS to 01_B (triggered mode)
- Set RHSBjIC.RHSBjDTSIE to 0_B
- Set all other configuration parameters according to the application requirements
- Configure the DMA controller to serve the required data to the RHSB module
  - Target in the RHSB module is the RHSBjDDR0 register
  - Number of transferred data words depends on RHSBjDCR.RHSBjSLS

These actions can be done in ACTIVE state according to the application requirements:

- Write initial data to RHSBjDDRi registers

  - The first DMA transfer after setting RHSBjDTC.RHSBjDTE to 1_B is requested after a data frame with this initial data has been transmitted

- Enable or disable the downstream data transmission by setting RHSBjDTC.RHSBjDTE or RHSBjDTC.RHSBjTSR to 1_B.
- Enable or disable the downstream data DMA function (RHSBjGC.RHSBjDDE)

While the downstream data DMA is enabled, RHSBjIS.RHSBjDTSF equal to 1_B indicates a pending DMA transfer.

18.6.1.2 Data Layout in Memory for Downstream Data DMA

The layout of the data to be transferred from the memory to the RHSBjDDRi registers of the RHSB module depends on the data frame configuration in RHSBjDCR.RHSBjSLS.

Because the DMA request (RHSBjIS.RHSBjDTSF) is cleared by writing to the downstream data registers (RHSBjDDRi), the user has to ensure that the transferred amount of data fits to the required data for transmission (refer to **Section 18.4.1.10, Data Update and Data Frame Transmission Request** for details about the request mapping). The RHSB module allows writing more than the required data to the RHSBjDDRi registers. Therefore, there is no functional restriction when the DMA controller supports only 32 bit transfers.

Note when using 16 bit transfers the user has to ensure that the upper part (bits [31:16]) of the downstream data registers are written first.

18.6.2 DMA Usage for Downstream Command Transmission

The downstream command DMA function is intended to serve applications where command data tables are stored in the memory (RAM or FLASH) the RHSB module has to transfer to slaves.

A downstream command DMA transfer is started when RHSBjIS.RHSBjCTF is 1_B and DMA is enabled by RHSBjGC.RHSBjDCDE.

The user should not use RHSBjIS.RHSBjCTF as interrupt source (RHSBjIC.RHSBjCTIE should be set to 0_B) when using downstream command DMA. In addition the user should not write to the downstream command data register (RHSBjDCD) nor downstream transmission control register (RHSBjDTC) nor set RHSBjIS.RHSBjCTF to 0_B.

18.6.2.1 Configuring and Enabling Flow to Use Downstream Command DMA

These configurations should be done during CONFIG state:

- Set RHSBjIC.RHSBjCTIE to 0_B
- Set all other configuration parameters according to the application requirements
- Configure the DMA controller to serve the required data to the RHSB module
  - Targets in the RHSB module are the RHSBjDCD register and RHSBjDTC register
  - Number of transferred command bits depends on RHSBjDTC.RHSBjNCB

These actions can be done in ACTIVE state according to the application requirements:

- Write command data to RHSBjDCD register and configuration parameters to RHSBjDTC register
- Enable or disable the downstream command DMA function (RHSBjGC.RHSBjDCDE)

While the downstream command DMA is enabled, RHSBjIS.RHSBjCTF equal to 1_B indicates a pending DMA transfer.

18.6.2.2 Command Data Layout in Memory for Downstream Command DMA

The layout of the command data to be transferred from the memory to the RHSBjDCD register of the RHSB module depends on the command frame configuration in RHSBjDTC.RHSBjNCB.

Because the DMA request (RHSBjIS.RHSBjCTF) is cleared by writing to the command transmission request (RHSBjDTC.RHSBjCTR), the user has to ensure that the transferred amount of command data fits to the required command for transmission. The RHSB module allows writing more than the required data to the RHSBjDCD register. Therefore, there is no functional restriction when the DMA controller supports only 32 bit transfers.

Note when using 16 bit transfers the user has to ensure that the upper part (bits [31:16]) of the downstream command data register is written first.

18.6.3 DMA Usage for Upstream Data Reception

The upstream DMA function is intended to store a set of upstream frames into the memory.

An upstream DMA transfer is started when RHSBjIS.RHSBjDRF is 1_B and DMA is enabled by RHSBjGC.RHSBjUDE.

The user should not use RHSBjIS.RHSBjDRF as interrupt source (RHSBjIC.RHSBjDRIE should be set to 0_B) when using upstream DMA. In addition the user should not read from the upstream data read registers (RHSBjUDR) nor set an RHSBjUDi.RHSBjND to 0_B nor set RHSBjIS.RHSBjDRF to 0_B.

When the DMA controller is not able to process the new received data timely, a received message might be lost because it is no longer available in the RHSBjUDR (even if still available in the related RHSBjUDi). The software gets informed about the overrun by the RHSBjUDR.RHSBjNDS bits and about a data lost by RHSBjUDi.RHSBjDL.

18.6.3.1 Configuring and Enabling Flow to Use Upstream DMA

These configurations should be done during CONFIG state:

- Set RHSBjUCR.RHSBjUE to 1_B
- Set RHSBjIC.RHSBjDRIE to 0_B
- Set all other configuration parameters according to the application requirements
- Configure the DMA controller to serve the required data to the RHSB module
  - Source in the RHSB module is RHSBjUDR
  - Number of transferred data (8, 16, 32 bits) depends on the application requirements

These actions can be done in ACTIVE state according to the application requirements:

- Request data from the slaves (e.g. by command frame)
- Enable or disable the upstream DMA function (RHSBjGC.RHSBjUDE)
- Evaluate the upstream error interrupts to handle upstream problems

While the upstream DMA is enabled, RHSBjIS.RHSBjDRF equal to 1_B indicates a pending DMA transfer.

18.6.3.2 Data Layout in Memory for Upstream DMA

The DMA transfer should only use the RHSBjUDR as source for the DMA transfer. It depends on the application requirements whether all 32 bits of the RHSBjUDR are transferred to the memory or only a part (8 or 16 bits).

When the DMA controller reads from the RHSBjUDR, the related new data flag in an RHSBjUDi register is set to 0_B. In addition RHSBjIS.RHSBjDRF is set to 0_B. Note that the error flags in the RHSBjUDi registers are not touched by the DMA transfer.

18.7 Cross Bar (XBAR)

18.7.1 Overview

XBAR is configured of the following functions.

- RHSB XBAR

The RHSB XBAR selects signals from the ATU-IV and APA with the multiplexer and outputs arbitrary signals to the RHSB. The RHSB has two channels , each of which has a XBAR. Each XBAR has four 16-bit sub XBARs. To output signals to the RHSB is specified by setting the MSBiCRjH and MSBiCRjL bits. RHSB0 and RHSB1 select the different signals in XBAR, where i = 0 for RHSB0 and i = 1 for RHSB1.

18.7.2 Module Configuration

18.7.2.1 RHSB XBAR Configuration

The RHSB cross bar is selection logic that connects between ATU- IV and RHSB. The RHSB cross bar has four 16-bit sub XBARs for each RHSB channel.

18.7.3.2 RHSBGiCRjH — Microsecond Bus Control Register H

RHSBGiCRjH is a 32-bit readable/writable register that selects upper bits of signals to be output to the RHSB from signals received from the ATU and APA. This register supports ATU timer C, timer D, timer E, and APA signals.

Do not change the setting of bits in this register while the ATU timer C, timer D, timer E, or APA is working.

RHSBGiCRjH can be read and written in byte units.

RHSBGiCRjH is initialized to 0000 0000_H by a reset.

i = 0, 1 (number of RHSB channels)

j = 0 to 3 (number of sub XBARs)

18.7.3.3 RHSBGiCRjL — Microsecond Bus Control Register L

RHSBGiCRjL is a 32-bit readable/writable register that selects lower bits of signals to be output to the RHSB from signals received from the ATU and APA. This register supports ATU timer C, timer D, timer E, and APA signals.

Do not change the setting of bits in this register while the ATU timer C, timer D, timer E, or APA is working.

RHSBGiCRjL can be read and written in byte units.

RHSBGiCRjL is initialized to 0000 0000_H by a reset.

i = 0, 1 (number of RHSB channels)

j = 0 to 3 (number of sub XBARs)

18.7.4 Summary of Operation

Signals received from the ATU-IV and APA are selected by the multiplexer and arbitrary signals are output to the RHSB. The RHSB has two channels , each of which has a XBAR. Each XBAR has four 16-bit sub XBAR. Output to the RHSB can be selected as shown in **Table 18.33** by changing each bit in RHSBGiCRjH and RHSBGiCRjL. Different signals are selected by the cross bar in RHSB0 and RHSB1. RHSB0 supports i = 0 and RHSB1 supports i = 1.

Section 19 Window Watchdog Timer (WDTA)

19.1 Features

Channels

This product has two channels of the window watchdog timer.

Table 19.1 Channels of WDTA

Window Watchdog Timer	
Number of Channels	2
Name	WDTA0, WDTA1

Meaning of n

Throughout this section, the individual channels of a window watchdog timer A are identified by the index “n” (n = 0, 1), for example, WDTAnWDTE for the WDTAn enable register.

Register address

All WDTAn register addresses are given as address offsets from the individual base address <WDTAn_base>.

The register base address of each WDTAn is listed in **Table 19.2**.

Table 19.2 Register Base Addresses of WDTAn

WDTAn	<WDTAn_base> Address
WDTA0	FFED 0000_H
WDTA1	FFED 1000_H

Clock supply

The window watchdog timer A provides WDTATCKI and PCLK as the clock inputs.

Table 19.3 Clock Supply of Window Watchdog Timer A

WDTAn	Clock Name for the Unit	Supplied Clock Name
WDTA0	WDTATCKI	WDTACLKI
	PCLK	CLKC_LSB (non-modulated low speed peripheral clock)
WDTA1	WDTATCKI	WDTACLKI
	PCLK	CLKC_LSB (non-modulated low speed peripheral clock)

Interrupts and reset outputs

The interrupts and reset outputs of the WDTAn are listed in **Table 19.4**.

Table 19.4 WDTA Interrupts and Reset Outputs

WDTAn Signal	Function	Connected to
WDTAnTRES	Watchdog reset output signal	ECM
WDTAnTIT	Interval timer interrupt	INTC

19.2 Overview

19.2.1 Functional Overview

The WDTA has the following functions:

- Selection of the operating mode after release from reset using the option byte
  Starting/stopping of the counter after the WDTA is reset, enabling or disabling of 75% interrupt requests, the window-open period, and overflow time can be selected.
- WDTA trigger function
  Writing an activation code to the WDTA trigger register starts WDTA and restarts the counter.
- 75% interrupt request signals
  An interrupt request signal can be generated when the WDTA counter reaches 75% of the overflow interval time (this function can be enabled or disabled by the setting of WDTAnMD.WDTAnWIE).
- Window function
  The period during which writing to the WDTA trigger register is valid (window-open period) can be set. Writing to the WDTA trigger register at a time outside the window-open period causes an error.
- WDTA error detection
  When an error is detected, the WDTAnTRES signal indicates the error to the ECM. For details about the error sources, refer to **Section 19.5.3, Error Detection.**

19.2.2 Block Diagram

Figure 19.1 shows the main components of the WDTA.

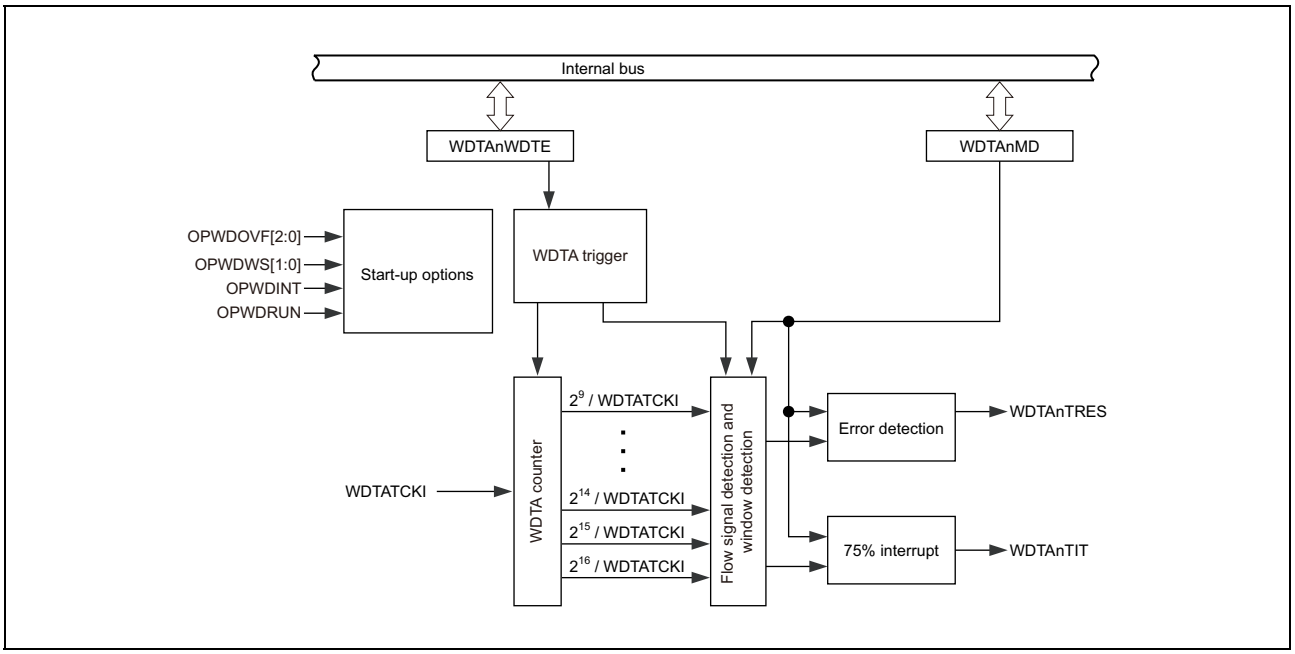

Figure 19.1 Block Diagram of the WDTA

19.3 Registers

The WDTA is controlled and operated by the following registers.

19.3.1 Registers Overview

The following shows the list of registers and the memory address of WDTAn (n = 0, 1).

For the base addresses, see **Table 19.2**.

The actual address can be obtained by adding the offset shown in the table to this base address.

Register Name	Function	R/W	Value after Reset	Access Width			Address
				8	16	32	
WDTAnWDTE	WDTA enable register	R/W	$2C_H$*1	√	—	—	<WDTAn_base> + 0000_H
WDTAnMD	WDTA mode register	R/W	$7F_H$*2	√	—	—	<WDTAn_base> + $000C_H$

Note 1. This value in the WDTA0WDTE register depends on the optional setting value. Refer to **Section 19.3.1.1, WDTAnWDTE — WDTA Enable Register**.

Note 2. This value in the WDTA0MD register depends on the optional setting value. Refer to **Section 19.3.1.2, WDTAnMD — WDTA Mode Register**.

19.3.1.1 WDTAnWDTE — WDTA Enable Register

This register is the WDTA start control and trigger register.

Writing AC_H to this register generates a WDTA trigger and starts or restarts the WDTA counter. See **Section 19.5.2, WDTA Trigger**, for details.

The only value that can be written to this register is AC_H.

Access: This register can be read/written in 8-bit units.

Address: <WDTAn_base> + 0000_H

Value after reset: (1) WDTA0
The value after reset depends on the settings of OPWDRUN. The initial state of OPWDRUN at shipment is OPWDRUN = 0_B. Therefore, the register value after reset of WDTA0 at shipment is $2C_H$.
(2) WDTA1
The register value after reset is also $2C_H$.
See **Section 33.10, Option Bytes** for details of OPWDRUN settings. These registers are initialized by any reset sources.
