Table 19.5 WDTAnWDTE Register Contents

Bit Position	Bit Name	Function
7 to 0	WDTAnRUN [7:0]	Writing a fixed activation code (AC_H) generates a WDTA trigger to control WDTAn count start and restart. Writing a value other than AC_H generates an error. After WDTAn starts, it cannot be stopped.

The value of bit WDTAnRUN[7] after reset depends on other start-up options as listed below.

Table 19.6 WDTAnRUN[7] Value after Reset

Start-Up Options	
OPWDRUN	**WDTAnRUN[7] Value after Reset**
1	1
0	0

19.3.1.2 WDTAnMD — WDTA Mode Register

This register specifies the overflow interval time, enabling or disabling of the 75% interrupt, and the window-open period.

It can be updated only once after reset release and before the first trigger. The updated value is effective after the next WDTA trigger.

Updating this register after the first WDTA trigger has been generated leads to error detection, but the read value of this register can be written without generating an error.

Access: This register can be read/written in 8-bit units.

Address: <WDTAn_base> + $000C_H$

Value after reset: (1) WDTA0
The value after reset depends on the settings of OPWDOVF2-0, OPWDINT, and OPWDWS1-0. The values of OPWDOVF2-0, OPWDINT, and OPWDWS1-0 are set to 1_B because the initial state of WDTA0 set by the option byte at shipment is the same as that of WDTA1. Therefore, the register value after reset of WDTA0 at shipment is $7F_H$.
(2) WDTA1
The register value after reset is also $7F_H$.

It is initialized by any reset sources.

0	1	50%
1	0	75%
1	1	100%

19.4 Interrupt Sources

The WDTA detects the state of the WDTA counter value or illegal accesses to the WDTA-related registers, and generates an interrupt request. A WDTA interrupt request is described below.

(1) WDTAnTIT (WDTA timer count 75% interrupt request)
An interrupt request signal is generated at 75% of the counter overflow time of the WDTA timer. An interrupt request signal can be enabled or disabled by using the WDTA mode register (WDTAnMD).

19.5 Functional Description

19.5.1 WDTA after Reset Release

19.5.1.1 Start modes

The WDTA provides two modes for the counter start after release from the reset state:

- Software trigger start mode (for WDTA0 and WDTA1)
  The counter value remains 0000_H after reset release.
  The counter is started with the first WDTA trigger.
- Default start mode (only for WDTA0)
  The counter starts automatically after release from the reset state. However, default start mode is disabled in serial programming mode even if OPWDRUN is set to 1_B for the star-up options.

WDTA1 is fixed to software trigger start mode, and cannot be set by the option byte.

19.5.1.2 Start mode selection (only for WDTA0)

The start mode can be selected by the start-up options.

The start mode selection is listed in **Table 19.8**.

Table 19.8 Start Mode Selection

Start-Up Options		
OPWDRUN	**Reset Type**	**Start Mode**
0	Ignored	Software trigger
1		Default

19.5.1.3 WDTA settings after reset release

The WDTA settings are as follows between reset release and the first trigger:

Function	Setting after WDTA0 is Reset	Setting after WDTA1 is Reset
Start mode	Specified by start-up options	Software trigger mode
Overflow interval time	Specified by start-up options	2^{16}/WDTATCKI
75% interrupt mode	Specified by start-up options	75% interrupt enabled
Window-open period	Specified by start-up options	100%

Change WDTA settings

The setting of the WDTA mode register (WDTAnMD) is effective when the first WDTA trigger is generated (writing an activation code to WDTAnWDTE). Change the setting of the WDTAnMD register before a WDTA trigger is generated.

Setting of the WDTA by using WDTAnMD is possible only once. If the value set for WDTAnMD is changed after a WDTA trigger is generated, an error occurs. However, an error does not occur if the same value has been set.

19.5.1.4 Default start mode timing (only for WDTA0)

The default start mode timing and the changes to the WDTA settings are illustrated in **Figure 19.2**.

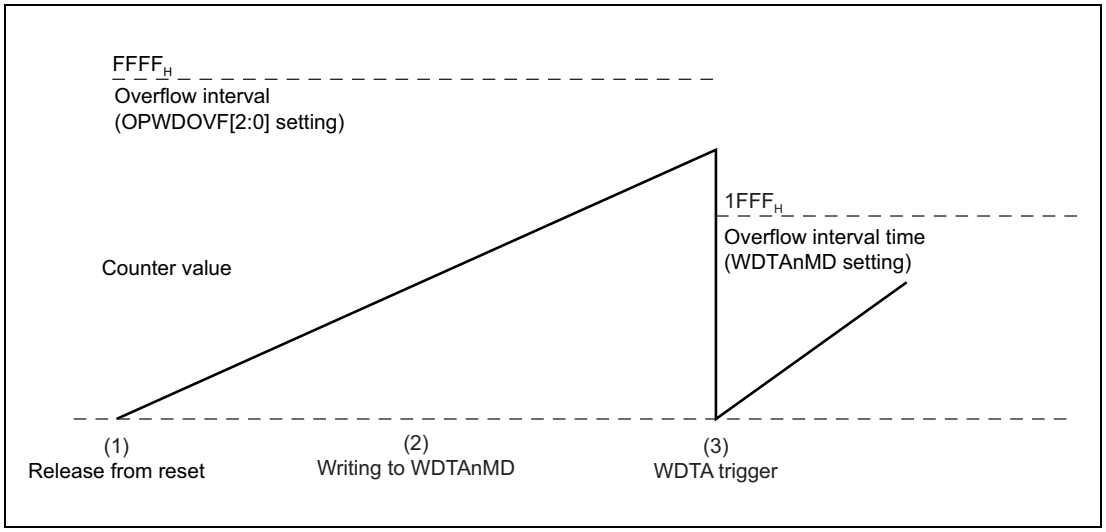

Figure 19.2 Timing Diagram of WDTA Start in Default Start Mode

The timing diagram in **Figure 19.2** shows the following behaviors:

(1) In default start mode, the WDTA counter starts after release from the reset state. The overflow interval time after release from the reset state is set by start-up options.

Example: Overflow interval time after release from the reset state
$= 2^{16}$/WDTATCKI (OPWDOVF[2:0] = 111_B)

(2) WDTAnMD is set before a WDTA trigger is generated. Note, however, that the setting is not applied immediately.

(3) Write to the WDTA trigger register before the WDTA counter overflows.
The WDTAnMD setting is applied due to the WDTA trigger.

Example: Overflow interval time after a WDTA trigger is generated
$= 2^{13}$/WDTATCKI

19.5.1.5 Software trigger start mode timing (common to WDTA0 and WDTA1)

The software trigger start mode timing and the changes to the WDTA settings are illustrated in **Figure 19.3**.

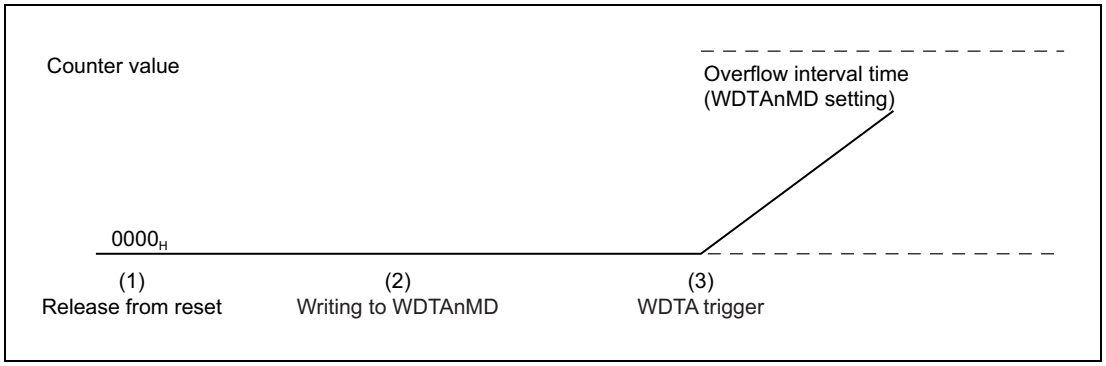

Figure 19.3 Timing Diagram of WDTA Start in Software Trigger Start Mode

The timing diagram in **Figure 19.3** shows the following behaviors:

(1) After release from the reset state, the counter remains 0000_H until the first WDTA trigger.
The overflow interval time is set by using the start-up options, but it does not have any effect.

(2) WDTAnMD is set before the first WDTA trigger. However, the settings are not applied immediately.

(3) The WDTA counter starts at the first WDTA trigger.
The overflow interval time and other settings specified in WDTAnMD are applied.

19.5.2 WDTA Trigger

Writing a special value called an activation code to the WDTA enable register (WDTAnWDTE) leads to generation of a WDTA trigger.

The WDTA trigger has the following functions:

- Starting the WDTA counter in software trigger start mode
- Restarting the WDTA counter
- WDTA mode setting by the WDTAnMD register (only for the first WDTA trigger after release from the reset state)

The WDTA can be triggered by writing a fixed activation code to the trigger register.

Table 19.9 Trigger Register and Activation Code

Type of Activation Code	Trigger Register	Activation Code
Fixed	WDTAnWDTE	AC_H

19.5.3 Error Detection

The WDTA detects an overflow of the WDTA counter and illegal operations as an error.

The conditions for error detection are:

- WDTA counter overflow
- Wrong activation code is written to the WDTA trigger register.
- Writing to the trigger register at the time outside the window-open period
- When an attempt is made to change the setting value of the WDTA mode register WDTAnMD after the first WDTA trigger has been generated
- When updating the setting value of the WDTA mode register WDTAnMD twice before the first WDTA trigger is generated

19.5.4 WDTA Error Mode

When an error is detected, the WDTAnTRES signal indicates the error to the ECM.

Figure 19.4 shows generation of a reset when the counter overflows and default start mode is selected.

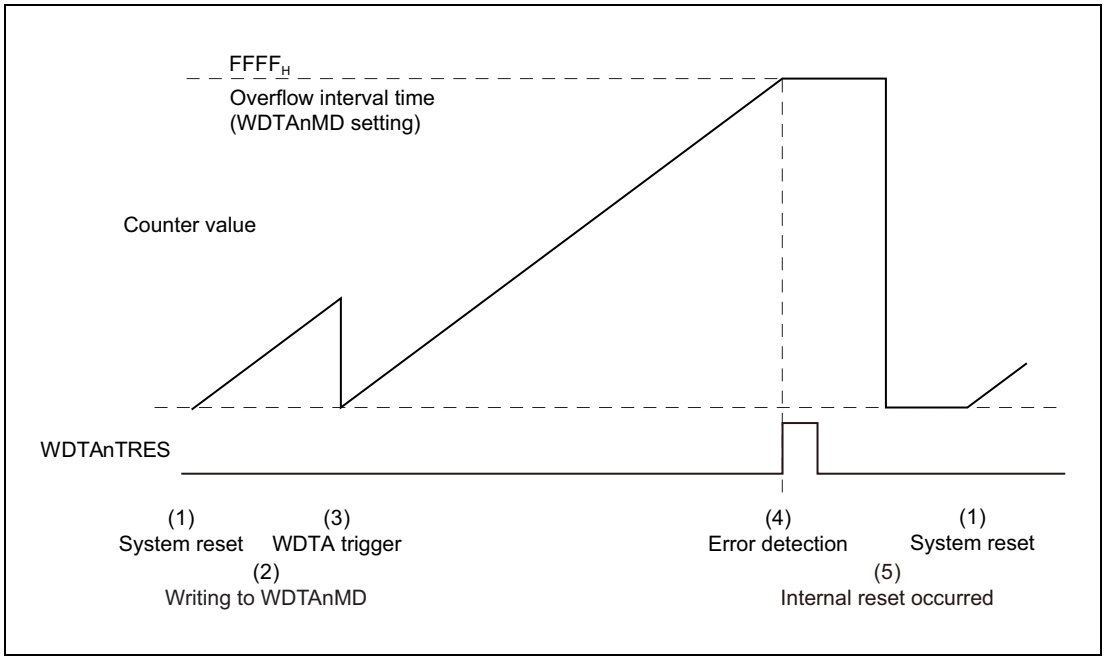

Figure 19.4 Timing Diagram of WDTA Internal Reset Generation

The timing diagram in **Figure 19.4** shows the following behaviors:

(1) In default start mode, the WDTA counter starts after release from the reset state. The overflow interval time after release from the reset state is set by using start-up options.

(2) WDTAnMD is set before a WDTA trigger is generated.
In this case, 2^{16}/WDTATCKI is set for the overflow interval time.

(3) The WDTAnMD setting is applied due to the WDTA trigger.

(4) If the counter overflows, an error is detected and the WDTAnTRES signal indicates the error to the ECM. The counter value remains unchanged until an internal reset occurs.

(5) If an internal reset occurs due to the ECM and other sources, the counter is cleared and stopped until release from the reset state.

19.5.5 75% Interrupt Request Signals

When the WDTA counter reaches 75% of the time set for the overflow interval, an interrupt request WDTAnTIT is generated.

By use of WDTAnMD.WDTAnWIE this function can be enabled or disabled afterwards.

Figure 19.5 shows the 75% interrupt request generation under following conditions:

- Default start mode is selected.
- 75% interrupt request is enabled after the first WDTA trigger is generated.
- WDTA overflow interval time: 2^{16}/WDTATCKI.

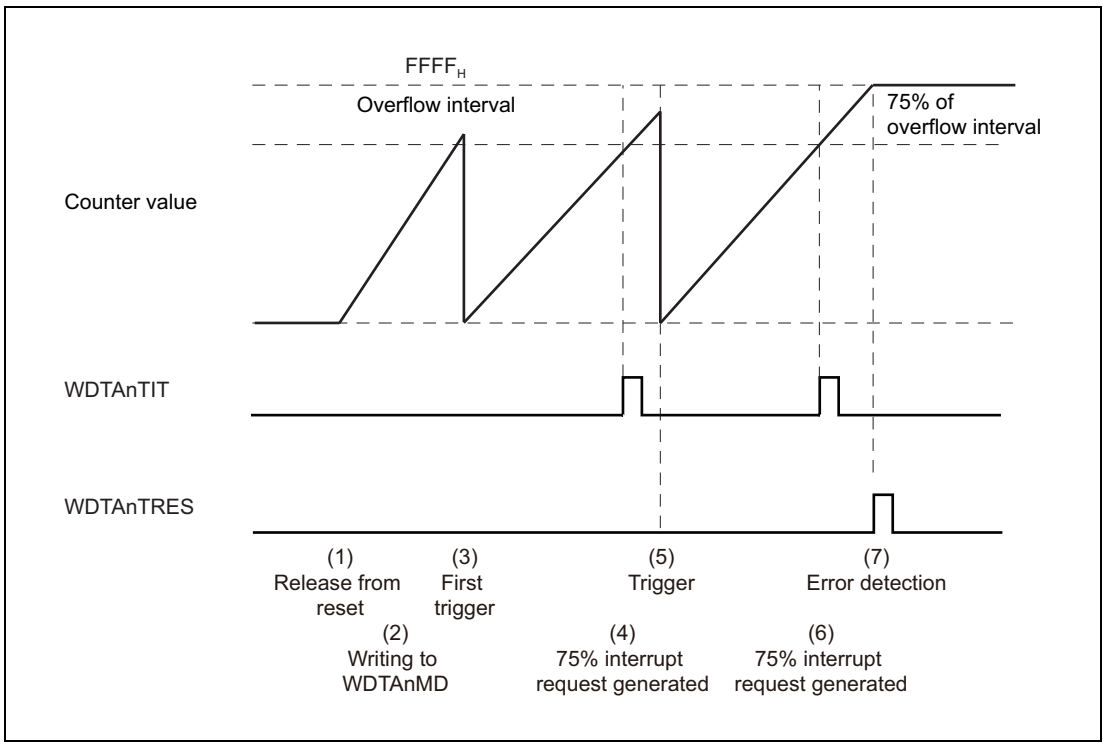

Figure 19.5 Timing Diagram of WDTA 75% Interrupt Request Signals

(1) In default start mode, the WDTA counter starts after release from the reset state. The overflow interval time period after release from the reset state is set by using the start-up options.

(2) WDTAnMD is set before the WDTA trigger is generated. In this figure, 2^{16}/WDTATCKI is set as the overflow interval time period.

(3) The WDTAnMD setting is applied at the WDTA trigger.

(4) When the WDTA counter reaches 75% of the set overflow interval time, an interrupt request WDTAnTIT is generated.

(5) The counter restarts at the WDTA trigger.

(6) When the WDTA counter reaches 75% of the set overflow interval time, an interrupt request WDTAnTIT is generated.

(7) When the counter overflows, an error is detected and the WDTAnTRES signal indicates the error to the ECM. The counter value remains unchanged until an internal reset occurs.

19.5.6 Window Function

The period when a WDTA trigger is valid (window-open period) can be set.
If the window-open period is set to the value less than 100%, an error occurs by the WDTA trigger generated at the time outside the window-open period. The window-open period after release from the reset state is 100%. The period is set to the value set in the WDTAnMD.WDTAnWS[1:0] after the first WDTA trigger is generated.

Figure 19.6 shows window function operations under the following conditions.

- Default start mode is selected.
- The 25% window open period is valid (WDTAnWS[1:0] = 00_B) after the first WDTA trigger.
- WDTA overflow interval time period: 2^{16}/WDTATCKI

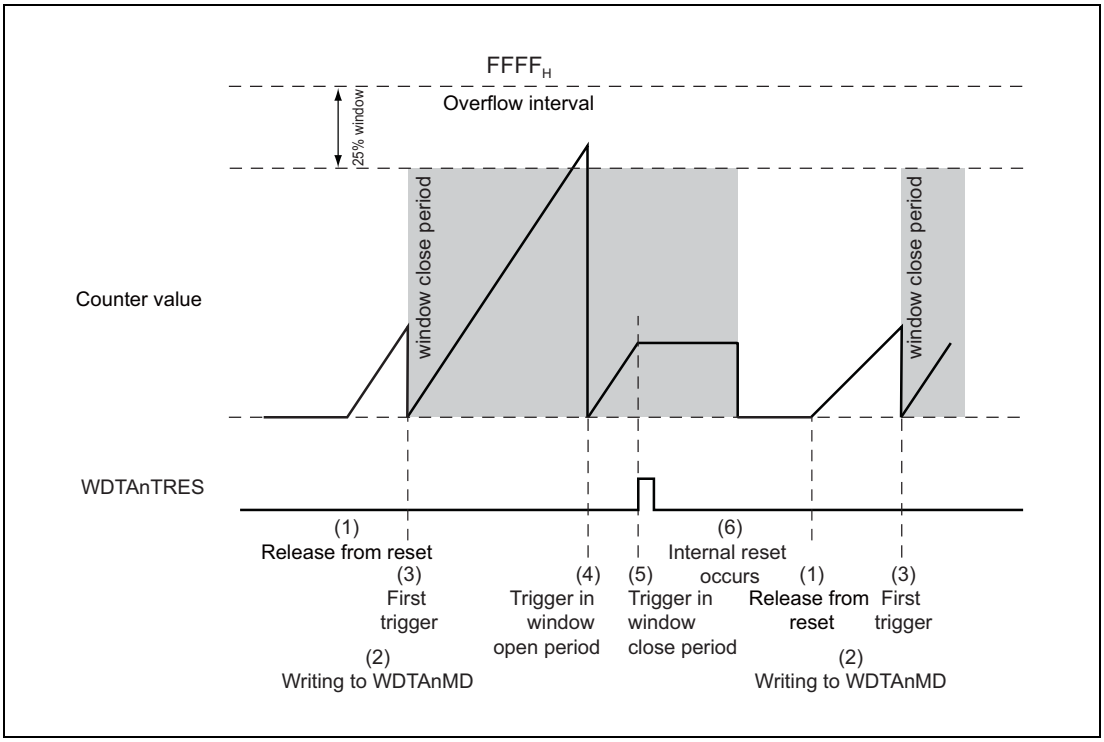

Figure 19.6 Timing Diagram of WDTA Window Function

(1) In default start mode, the WDTA counter starts after release from the reset state. The overflow interval time period after release from the reset state is set by using the start-up options.

(2) WDTAnMD is set before the WDTA trigger is generated. In this figure, 2^{16}/WDTATCKI is set as the overflow interval time period.

(3) The WDTAnMD setting is applied at the WDTA trigger.

(4) The WDTA counter restarts at the WDTA trigger during the window open period.

(5) An error is detected at the WDTA trigger during the window close period, and then the WDTAnTRES signal indicates the error to the ECM. The counter value remains unchanged until an internal reset occurs.

(6) If an internal reset occurs due to the ECM and other sources, the counter is cleared and stopped until release from the reset state.

Section 20 OS Timer (OSTM)

20.1 Functional Overview

The OS timer has the following features.

- Two operating modes
  - Interval timer mode
  - Free-running comparison mode
- Simultaneous starting of multiple channels of the OS timer (timer synchronization of PIC1)
- Interrupt and DTS notification when counting by the counter is started, restarted, or ends.
- Notifying the ECM of errors when an OSTMn (n = 1 only) interrupt occurs.
- Generation of output waveform from the $\overline{\text{ERROROUT\_M}}$ and $\overline{\text{ERROROUT\_C}}$ pins with the OSTM0TTOUT signal of OSTM0 when ECM is in dynamic mode.
- Module standby can be set for each channel (see **Section 12, Standby Controller**, for details).Features of OSTM

20.1.1 Features

Channels

This product has the following number of channels of the OS timer.

Table 20.1 Channels of OS Timer

	OS Timer
Number of channels	3
Name	OSTMn

Meaning of n

Throughout this section, the individual channels of the OS timer are identified by the index “n” (n = 0 to 2), for example, OSTMnTO for the OS timer n output register.

Register address

All OS timer register addresses are given as address offsets from the individual base addresses <OSTMn_base>.

The register base address of each OSTMn is listed in the following table.

Table 20.2 Register Base Addresses

OSTMn	<OSTMn_base> Address
OSTM0	FFEC 0000_H
OSTM1	FFEC 1000_H
OSTM2	FFEC 2000_H

Interrupts

The OS timers can generate the following interrupt requests.

Table 20.3 OSTMn Interrupt Requests

OSTMn Signal	Function	Connected to
OSTM0TINT	OSTM0 interrupt	Interrupt controller INTC
OSTM1TINT	OSTM1 interrupt	Interrupt controller INTC, ECM for error inputs
OSTM2TINT	OSTM2 interrupt	Interrupt controller NTC

20.2 Registers

The OS timers are controlled and operated by the following registers.

20.2.1 Registers Overview

The list of OSTMn (n = 0 to 2) registers and the memory addresses are as follows.

For the base addresses, see **Table 20.2**.

Register Name	Function	R/W	Value after Reset	Access Unit (bit)			Address
				8	16	32	
OSTMnCMP	OSTM compare register	R/W	0000 0000_H	—	—	√	<OSTMn_base> + 00_H
OSTMnCNT	OSTM counter register	R	FFFF $FFFF_H$	—	—	√	<OSTMn_base> + 04_H
OSTMnTO	OSTM output register	R/W	00_H	√	—	—	<OSTMn_base> + 08_H
OSTMnTOE	OSTM output enable register	R/W	00_H	√	—	—	<OSTMn_base> + $0C_H$
OSTMnTE	OSTM count enable status register	R	00_H	√	—	—	<OSTMn_base> + 10_H
OSTMnTS	OSTM count start trigger register	W	00_H	√	—	—	<OSTMn_base> + 14_H
OSTMnTT	OSTM count stop trigger register	W	00_H	√	—	—	<OSTMn_base> + 18_H
OSTMnCTL	OSTM control register	R/W	00_H	√	—	—	<OSTMn_base> + 20_H

20.2.2 Details of OSTM Registers

20.2.2.1 OSTMnCMP — OSTM Compare Register

Depending on the mode of operation, this register holds the start value for the down-counter or the value for comparison with that of the counter.

Access: This register can be read/written in 32-bit units.

Address: <OSTMn_base>

Value after reset: 0000 0000_H
This register is initialized by a reset from any source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OSTMnCMP[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.4 OSTMnCMP Register Contents

Bit Position	Bit Name	Function
31 to 0	OSTMnCMP [31:0]	• In interval timer mode: Start value of the down-counter • In free-running comparison mode: Value for comparison

20.2.2.2 OSTMnCNT — OSTM Counter Register

This register indicates the counter value of the timer.

Access: This register can be read in 32-bit units.

Address: OSTMn_base> + 4_H

Value after reset: FFFF FFFF$_H$
This register is initialized by a reset from any source.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OSTMnCNT[31:16]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OSTMnCNT[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Table 20.5 OSTMnCNT Register Contents

Bit Position	Bit Name	Function
31 to 0	OSTMnCNT [31:0]	32-bit counter value

Table 20.6 lists the correspondence among the operating mode, counting direction, and start value.

The start value indicates the value to be read after the operating mode is changed.

Table 20.6 Correspondence between Operating Mode, Counting Direction and Start Value

Timer Operating Mode	OSTMnCTL.OSTMnMD1	Counting Direction	Start value
Interval timer mode	0 *1	Down	FFFF FFFF$_H$
Free-running comparison mode	1	Up	0000 0000$_H$

Note 1. Value after reset

20.2.2.3 OSTMnTO — OSTM Output Register

The OSTM output register is used to specify and read the level of an OSTMnTTOUT output signal. The setting of this register is only valid in OSTM0 (n = 0).

Access: This register can be read/written in 8-bit units. Writing can only proceed when the software control mode is selected (OSTMnTOE.OSTMnTOE = 0).

Address: <OSTMn_base> + 8_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTO
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 20.7 OSTMnTO Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	OSTMnTO	This bit specifies/reads the level of an OSTMnTTOUT output signal 0: Low level 1: High level

20.2.2.4 OSTMnTOE — OSTM Output Enable Register

The OSTM output enable register specifies OSTMnTTOUT output mode. The setting of this register is only valid in OSTM0 (n = 0).

Access: This register can be read/written in 8-bit units.

Address: <OSTMn_base> + C_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTOE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 20.8 OSTMnTOE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	OSTMnTOE	This bit specifies the OSTMnTTOUT output mode. 0: Software control mode: The level corresponding to the setting of OSTMnTO.OSTMnTO is output to OSTMnTTOUT. 1: Timer-output toggling mode: OSTMnTTOUT output is toggled whenever an OSTMnTINT interrupt request is generated.

20.2.2.5 OSTMnTE — OSTM Count Enable Status Register

This register indicates the state of the counter.

Access: This register can be read in 8-bit units.

Address: <OSTMn_base> + 10_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 20.9 OSTMnTE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read.
0	OSTMnTE	This bit indicates whether the counter is operating or stopped. 0: Counter is stopped. 1: Counter is operating. This bit is set to 1 in response to OSTMnTS.OSTMnTS being set to 1, or to the OSTMnTSST signal (when timer synchronization of PIC1 is in use) becoming 1. This bit is reset to 0, if the OSTMnTT.OSTMnTT bit is set to 1.

NOTE

When OSTMnTE = 0, the counter retains its value.

If the counter is restarted,

- It restarts counting down from the value in the OSTMnCMP register in interval timer mode, or
- It restarts counting up from the counter value 0000 0000_H in free-running comparison mode.

20.2.2.6 OSTMnTS — OSTM Count Start Trigger Register

This register starts the counter.

Access: This register can be written in 8-bit units. It is always read as 00_H.

Address: <OSTMn_base> + 14_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 20.10 OSTMnTS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	OSTMnTS	This bit starts the counter. 0: This setting is invalid. 1: Starts the counter and sets OSTMnTE.OSTMnTE = 1. • In interval timer mode, a forced restart is executed if this bit is set while OSTMnTE.OSTMnTE = 1. • In free-running comparison mode, setting this bit is ignored as long as OSTMnTE.OSTMnTE = 1.

20.2.2.7 OSTMnTT — OSTM Count Stop Trigger Register

This register stops the counter.

Access: This register can be written in 8-bit units. It is always read as 00_H.

Address: <OSTMn_base> + 18_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSTMnTT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 20.11 OSTMnTT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	OSTMnTT	Stops the counter. 0: This setting is invalid. 1: Stops the counter and clears the OSTMnTE.OSTMnTE bit.

20.2.2.8 OSTMnCTL — OSTM Control Register

This register specifies the operating mode for the counter and controls enabling/disabling of OSTMnTINT interrupt requests when counting starts.

Access: This register can be read/written in 8-bit units. Writing to this register is only possible if the counter is disabled (OSTMnTOE.OSTMnTOE = 0).

Address: <OSTMn_base> + 20_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OSTMnMD1	OSTMnMD0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 20.12 OSTMnCTL Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	OSTMnMD1	Specifies the operating mode for the counter. 0: Interval timer mode 1: Free-running comparison mode
0	OSTMnMD0	Controls enabling/disabling of OSTMnTINT interrupt requests when counting starts. 0: Disables the interrupts when counting starts. 1: Enables the interrupts when counting starts.

20.3 Functional Description

Each OS timer is a 32-bit timer/counter.

The settings for operating mode specify the direction of counting (up or down) and the generation of interrupt requests.

20.3.1 Block Diagram

The following block diagram shows the main components of OSTMn.

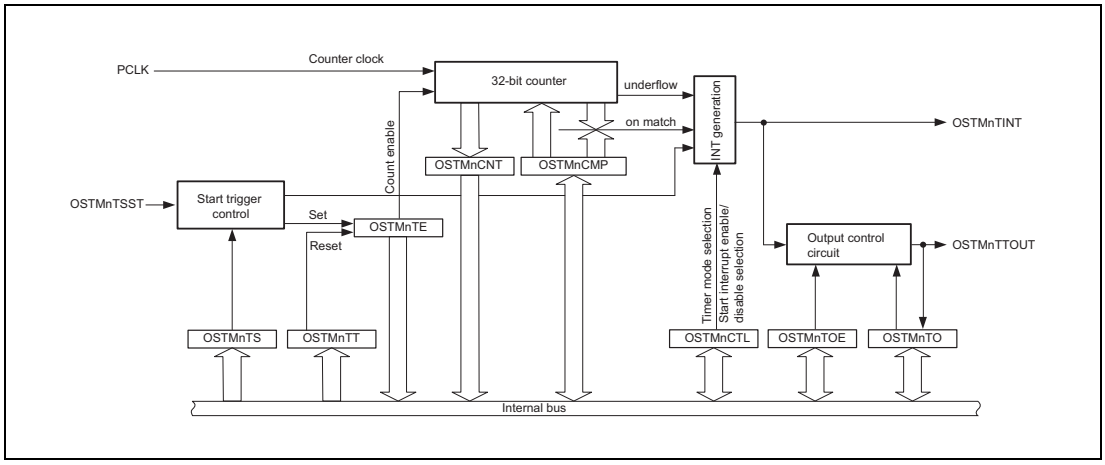

Figure 20.1 Block Diagram of OSTMn

20.3.2 Counter Clock

The counter clock PCLK of OSTMn is CLKC_LSB (non-modulated low speed peripheral clock).

20.3.3 Output Modes (only for OSTM0)

The OSTMn has the following output modes. The mode is selected by the setting of the OSTMnTOE.OSTMnTOE bit.

- Software control mode (the OSTMnTOE.OSTMnTOE bit is 0): The value set in the OSTMnTO.OSTMnTO bit is output to OSTMnTTOUT.
- Timer-output toggling mode (the OSTMnTOE.OSTMnTOE bit is 1): The OSTMnTTOUT output is toggled each time an OSTMnTINT request is generated.

Both output modes are illustrated in the following figure.

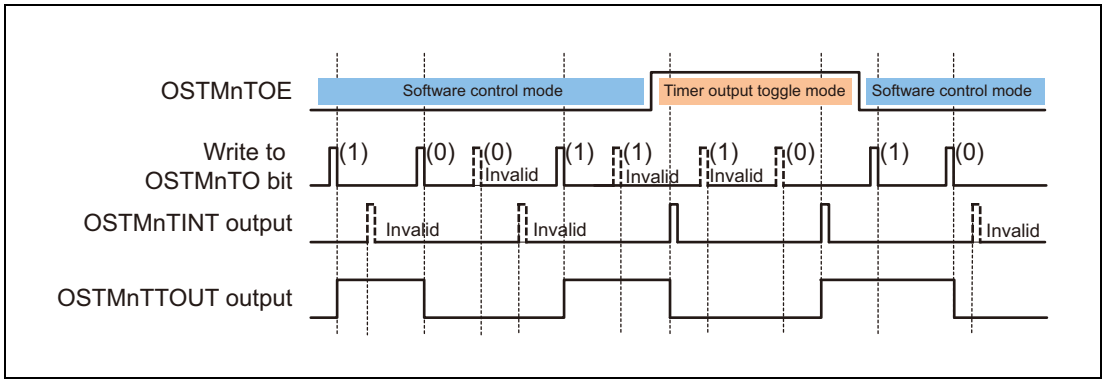

Figure 20.2 Timing Diagram of Output Modes

The above timing diagram shows the following operations.

- In software control mode, the level of the OSTMnTTOUT output changes in accord with the value set in the OSTMnTO.OSTMnTO bit.
- In timer-output toggling mode, the value of the OSTMnTO.OSTMnTO bit and level of the OSTMnTTOUT output are toggled each time an OSTMnTINT interrupt request is generated.

20.3.4 Interrupt Request Generation

An OSTMnTINT interrupt request is generated whenever the counter reaches 0000 0000_H (in interval timer mode) or matches the comparison value (in free-running comparison mode).

An interrupt request can also be generated on starting and restarting of the counter. This is controlled by the OSTMnCTL.OSTMnMD0 bit.

Since OSTMnTINT triggers toggling of the OSTMnTTOUT output in timer output toggling mode (OSTMnTOE.OSTMnTOE is 1), the setting of the OSTMnCTL.OSTMnMD0 bit also affects the output (OSTMnTTOUT).

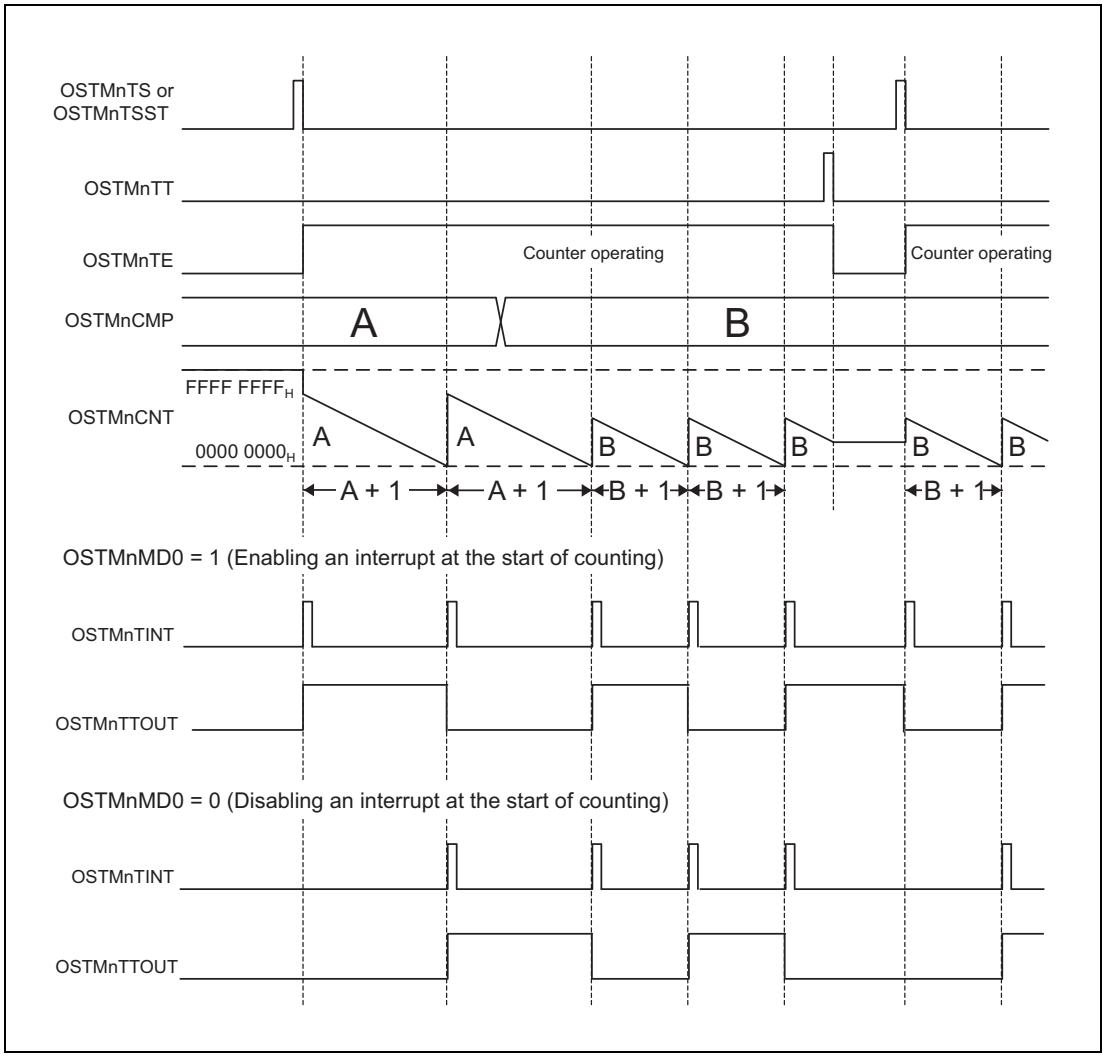

Figure 20.3 Generating an Interrupt when Counting Starts (Interval Timer Mode)

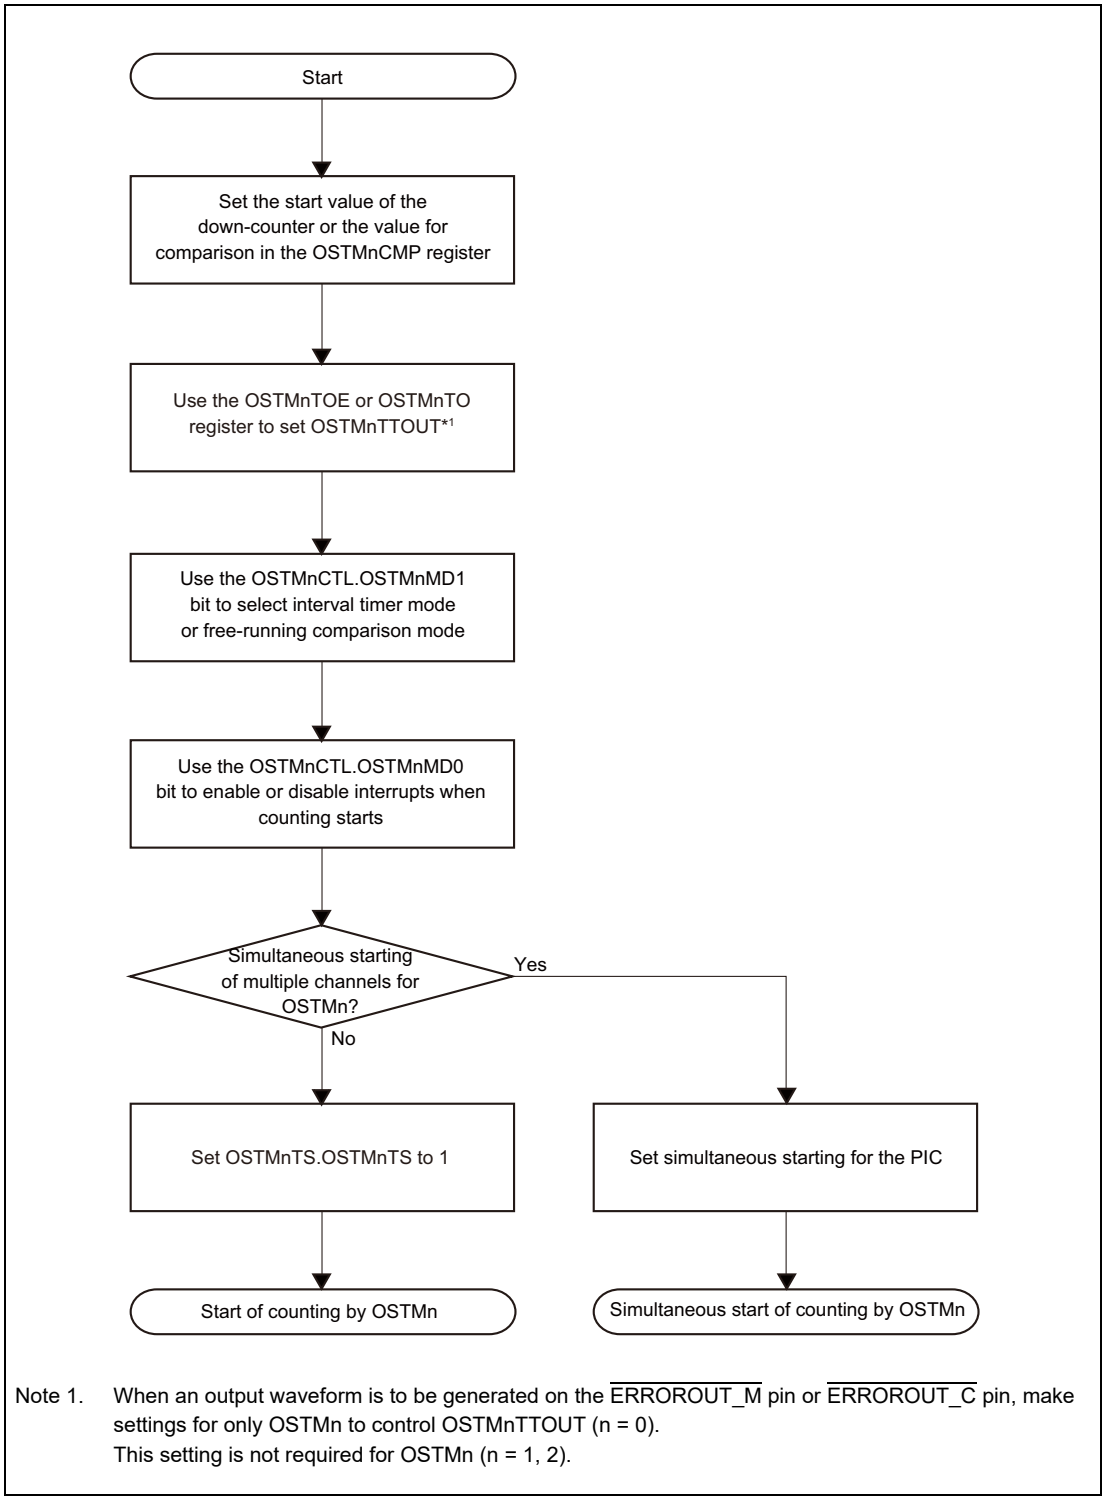
20.3.5 Starting and Stopping the Timer

The OS timer is started and stopped as follows.

Starting the timer

Figure 20.4 shows the flow of starting the counter of OSTMn. For details of the operations of the timer in interval timer mode and free-running timer mode in the given step of the figure, see the descriptions of interval timer mode and free-running comparison mode.



Note 1. When an output waveform is to be generated on the $\overline{\text{ERROROUT\_M}}$ pin or $\overline{\text{ERROROUT\_C}}$ pin, make settings for only OSTMn to control OSTMnTTOUT (n = 0).
This setting is not required for OSTMn (n = 1, 2).

Figure 20.4 Flow of Starting the OS Timer

Stopping the timer

Setting the OSTMnTT.OSTMnTT bit to 1 stops the timer.

This also clears the OSTMnTE.OSTMnTE status flag bit.

Timer Synchronization (PIC1)

The OSTMnTSST signal can be used to start multiple timers at the same time. For detailed connections, refer to **Section 25, Peripheral Interconnection (PIC)**.

20.3.6 Interval Timer Mode

Select the interval timer mode when an OS timer is to be used as a reference timer for generating interrupt requests at a fixed interval.

20.3.6.1 Basic Operation in Interval Timer Mode

In interval timer mode, the timer counts down from the value specified in the OSTMnCMP register. An OSTMnTINT interrupt request is generated when the counter reaches 0000 0000_H.

Select interval timer mode by setting OSTMnCTL.OSTMnMD1 = 0.

New values can be written to the OSTMnCMP register at any time. If it is rewritten during count operation, the counter loads the new OSTMnCMP value when the next 0000 0000_H is reached.

Cycles of OSTMnTINT and OSTMnTTOUT output

The cycles of OSTMnTINT and OSTMnTTOUT output are as follows.

- OSTMnTINT generation cycle = Counter-clock cycle × (OSTMnCMP + 1)
- OSTMnTTOUT output cycle = OSTMnTINT generation period × 2

The following figure shows the basic operation of OSTMn in interval timer mode with counter-start interrupts enabled.

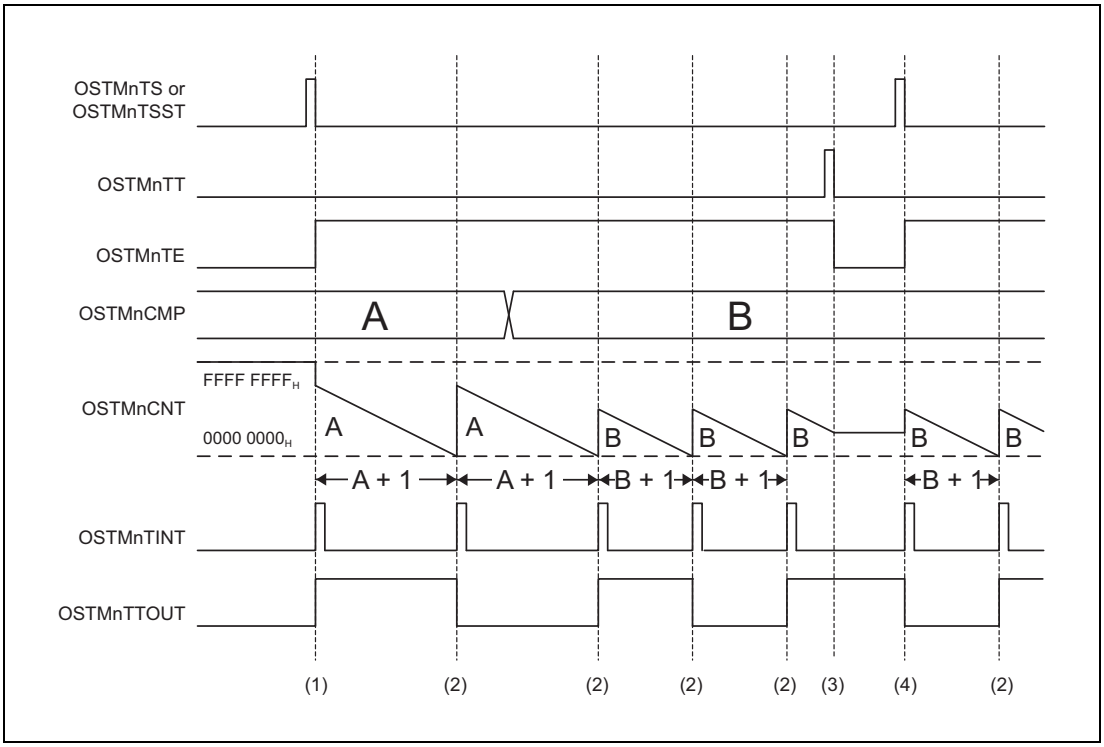


Figure 20.5 Timing Diagram of OSTMn in Interval Timer Mode

The timing diagram above shows the following:

(1) The counter starts counting when OSTMnTS.OSTMnTS = 1 or OSTMnTSST = 1. The OSTMnTE.OSTMnTE bit is set to indicate enabling of the counter.
The counter starts counting-down from the value of OSTMnCMP.
If OSTMnCTL.OSTMnMD0 is 1, OSTMnTINT interrupt requests are generated at the start of

counting and the OSTMnTTOUT signal is toggled. The OSTMnCNT register contains the current value as the counter.

(2) When the counter reaches 0000 0000_H, an OSTMnTINT interrupt request is generated and the OSTMnTTOUT signal is toggled. The counter loads the new start value from OSTMnCMP and continues counting down.

(3) When the counter is stopped (OSTMnTT.OSTMnTT = 1), the OSTMnTE.OSTMnTE bit is cleared to indicate disabling of the counter. The counter retains its current value until it is restarted.

(4) When counting is restarted (OSTMnTS.OSTMnTS = 1, or OSTMnTSST = 1), the counter loads the new start value from OSTMnCMP and starts counting down.

Forced restart

The counter is forcibly restarted by setting OSTMnTS.OSTMnTS = 1 or by transitions of the OSTMnTSST signal from 0 to 1 (when timer synchronization of PIC1 is in use) during counting. The counter loads the initial value from the OSTMnCMP register and continues counting down.

CAUTION

If the OSTMnTS.OSTMnTS bit for a desired channel is set to 1 while simultaneous starting of multiple channels of the timer is in progress, the individual channels are forcibly restarted, so synchronous operation between the channels is not guaranteed. If simultaneous starting of the PIC is used while multiple channels of the timer start individually, the timers set for simultaneous starting are forcibly restarted at the same time.

The counter loads the start value from the OSTMnCMP register and continues counting down.

The following figure shows a timing diagram in interval timer mode, with counter-start interrupts enabled (OSTMnCTL.OSTMnMD0 = 1), and in timer output toggling mode, where OSTMnTTOUT is toggled (OSTMnTOE.OSTMnTOE = 1).

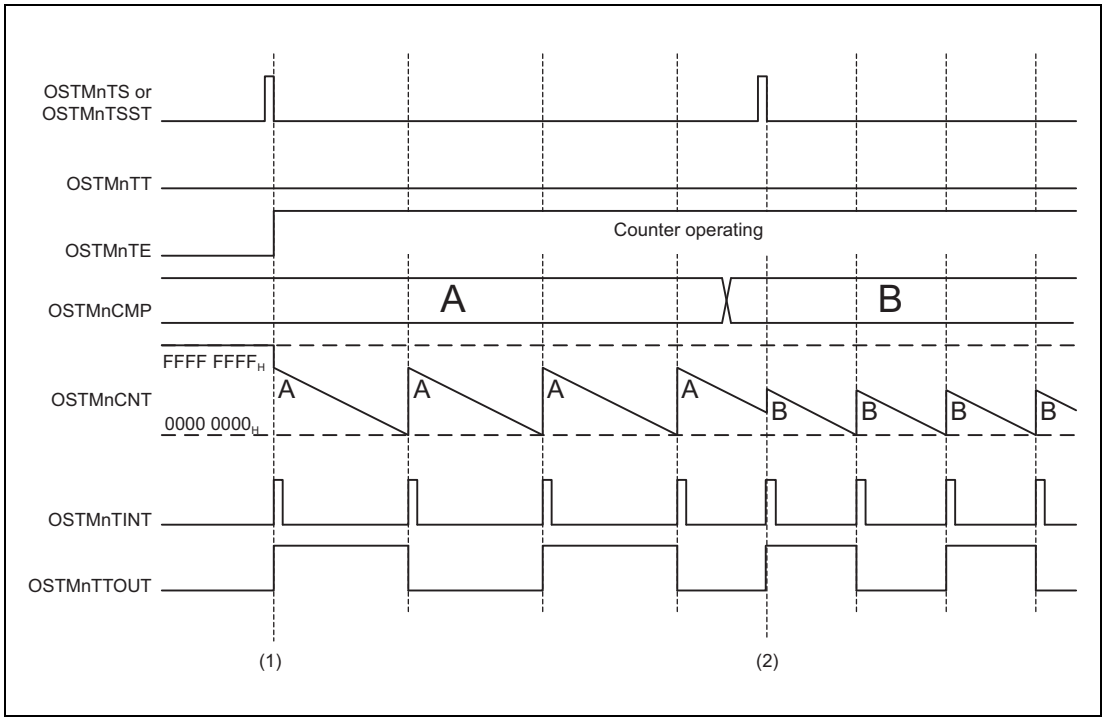

Figure 20.6 Timing Diagram of Forced Restart in Interval Timer Mode

Operations shown in the above timing diagram are as follows.

(1) The counter is started and stopped as described under **Figure 20.5, Timing Diagram of OSTMn in Interval Timer Mode**.

(2) Setting OSTMnTS.OSTMnTS = 1 or OSTMnTSST = 1 restarts the counter while counting is in progress (i.e. while OSTMnTE.OSTMnTE = 1).
The counter immediately restarts counting down, starting with the current value of OSTMnCMP. When OSTMnCTL.OSTMnMD0 = 1, an OSTMnTINT interrupt request is generated when counting starts and the OSTMnTTOUT signal is toggled.

20.3.6.2 Operation when OSTMnCMP = 0000 0000_H

When OSTMnCMP = 0000 0000_H, the OS timer behaves as follows.

- If the counter is enabled, the OSTMnTINT interrupt request will always be set to 1. However, the timer (OSTMnTTOUT) output signal can still be used. Timer (OSTMnTTOUT) output using timer output toggling mode results in OSTMnTTOUT being toggled on every cycle of the counter clock.

The following figure shows operations of the OSTMn when OSTMnCMP = 0000 0000_H, the counter start interrupt is enabled (OSTMnCTL.OSTMnMD0 = 1), and the timer is in timer output toggling mode, where OSTMnTTOUT is toggled (OSTMnTOE.OSTMnTOE = 1).

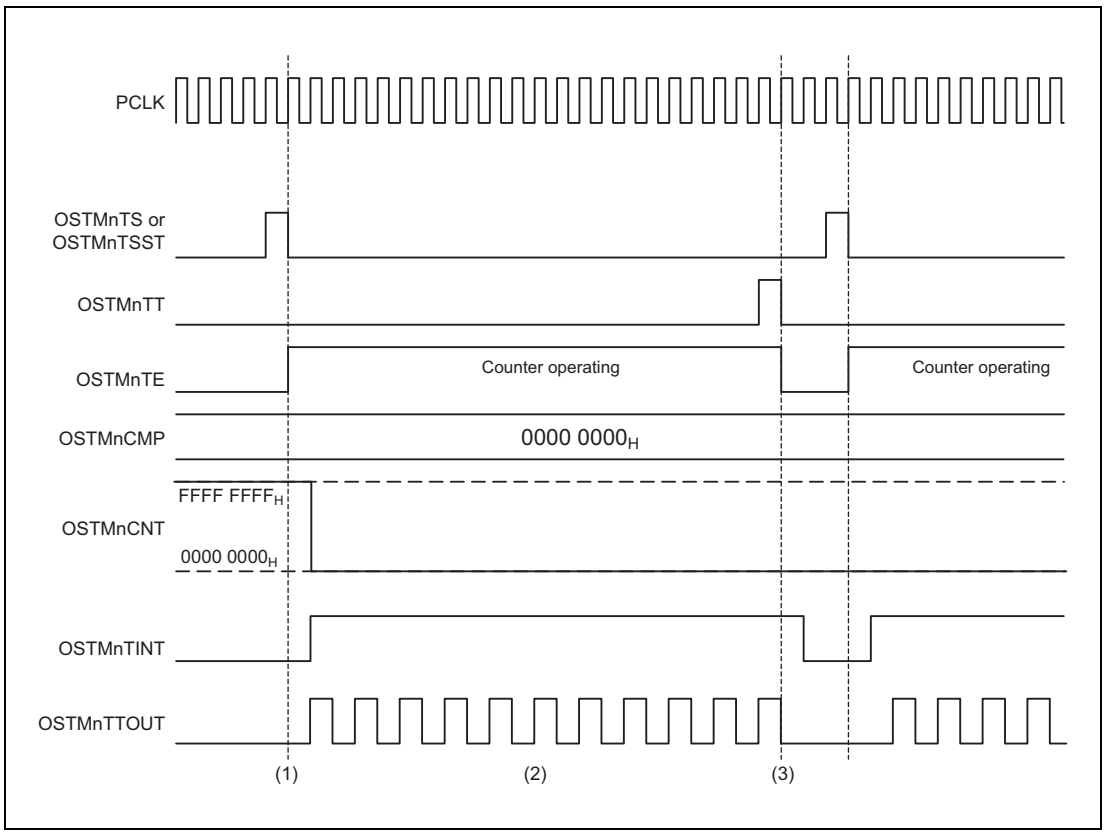

Figure 20.7 Timing Diagram when OSTMnCMP = 0000 0000_H in Interval Timer Mode

The timing diagram above shows the following operations:

(1) The counter is reloaded with the value in OSTMnCMP as soon as it starts counting, so the value 0000 0000_H is retained in OSTMnCMP.

(2) While the OSTMnTINT interrupt request signal is continuously asserted, OSTMnTTOUT is toggled (in **Figure 20.7**, OSTMnTINT is fixed to the high level because PCLK is selected as the counter clock).

(3) After the counter stops, the OSTMnTINT interrupt request signal is deasserted and the output level of the OSTMnTTOUT signal is maintained.

When an interrupt is prohibited when the counter starts, 1 clock cycle of the counter clock is not generated at the start timing of the counter.

20.3.7 Free-Running Comparison Mode

20.3.7.1 Basic Operation in Free-Running Comparison Mode

In free-running comparison mode, the counter counts up from 0000 0000_H to FFFF $FFFF_H$. An OSTMnTINT interrupt request is output when the current value of the counter matches the value of the OSTMnCMP register. The free-running comparison mode is selected by setting the OSTMnCTL.OSTMnMD1 bit to 1.

New values can be written to the OSTMnCMP register at any time.

The following figure shows the basic operation of OSTMn in free-running compare mode with the start of counting enabled (OSTMnCTL.OSTMnMD0 = 1) and with the timer in timer output toggling mode, where OSTMnTTOUT is toggled (OSTMnTOE.OSTMnTOE = 1).

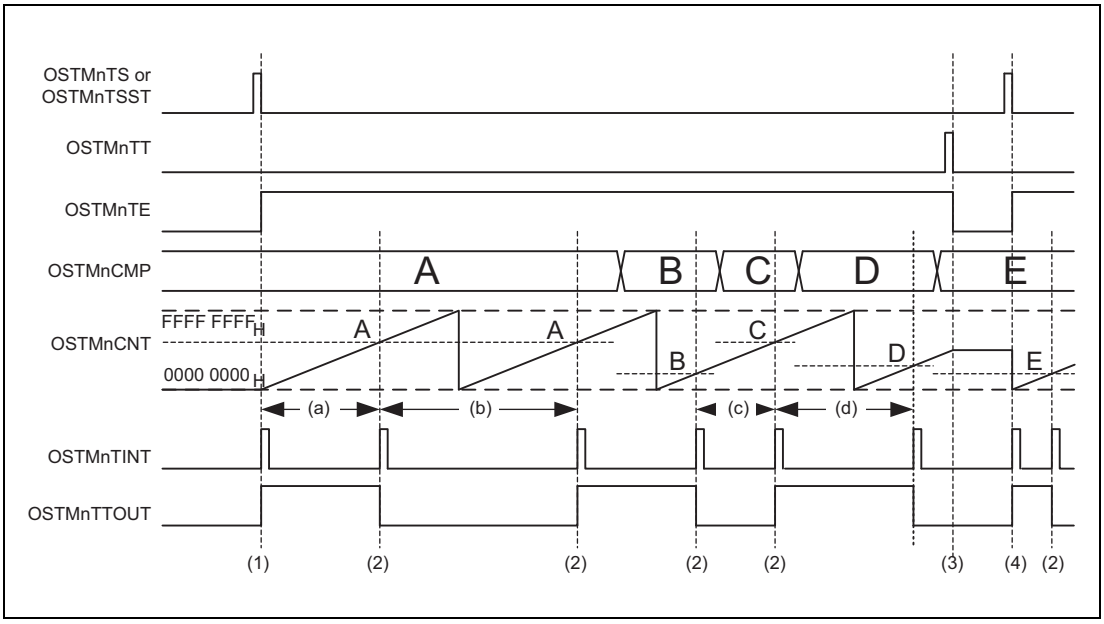

Figure 20.8 Timing Diagram of OSTMn in Free-Running Comparison Mode

The timing diagram above shows the following:

(1) The counter starts counting when OSTMnTS.OSTMnTS = 1, or when OSTMnTSST = 1. The OSTMnTE.OSTMnTE bit is set to indicate enabling of the counter. The counter counts up from 0000 0000_H to FFFF $FFFF_H$. The OSTMnCNT register is the counter, so it contains the current value. When the OSTMnCTL.OSTMnMD0 set to 1, the interrupt request OSTMnTINT is generated when the counting starts.

(2) When the current counter value matches the value in the OSTMnCMP register, an OSTMnTINT interrupt request is generated and the OSTMnTTOUT signal is toggled.

(3) When the counter is stopped (OSTMnTT.OSTMnTT = 1), the OSTMnTE.OSTMnTE bit is cleared to indicate disabling of the counter.
The counter retains its current value until it is restarted.

(4) Counting by the counter restarts from 0000 0000_H when OSTMnTS.OSTMnTS = 1, or when OSTMnTSST = 1.

OSTMnTINT Period

The OSTMnTINT generation period is different at the start of counting and depends on the old and new comparison values if OSTMnCMP is rewritten during operation.

Table 20.13 Timing of OSTMnTINT Generation

Old value for comparison	New value for comparison	Counter value at time of rewriting	Period of OSTMnTINT Generation	Label in timing diagram
Counter starts			(A + 1) × counter clock period	(a)
A	A	No rewriting	(FFFF FFFF$_H$ + 1) × counter clock period	(b)
B	C > B	B < counter value < C	(C - B) × counter clock period	(c)
C	D < C	Counter value > D,C	(FFFF FFFF$_H$ - C + D + 1) × counter clock period	(d)

Forced restart

Forced restarting does not proceed during counting even if the OSTMnTS.OSTMnTS bit is set, or if OSTMnTSST is high when the simultaneous start trigger is in use. The counter ignores the attempted setting and continues counting.

20.3.7.2 Operation when OSTMnCMP = 0000 0000$_H$

The following figure shows the operation of OSTMn when OSTMnCMP = 0000 0000$_H$, counter-start interrupts are enabled (OSTMnCTL.OSTMnMD0 = 1) and the timer is in timer output toggling mode, where OSTMnTTOUT is toggled (OSTMnTOE.OSTMnTOE = 1).

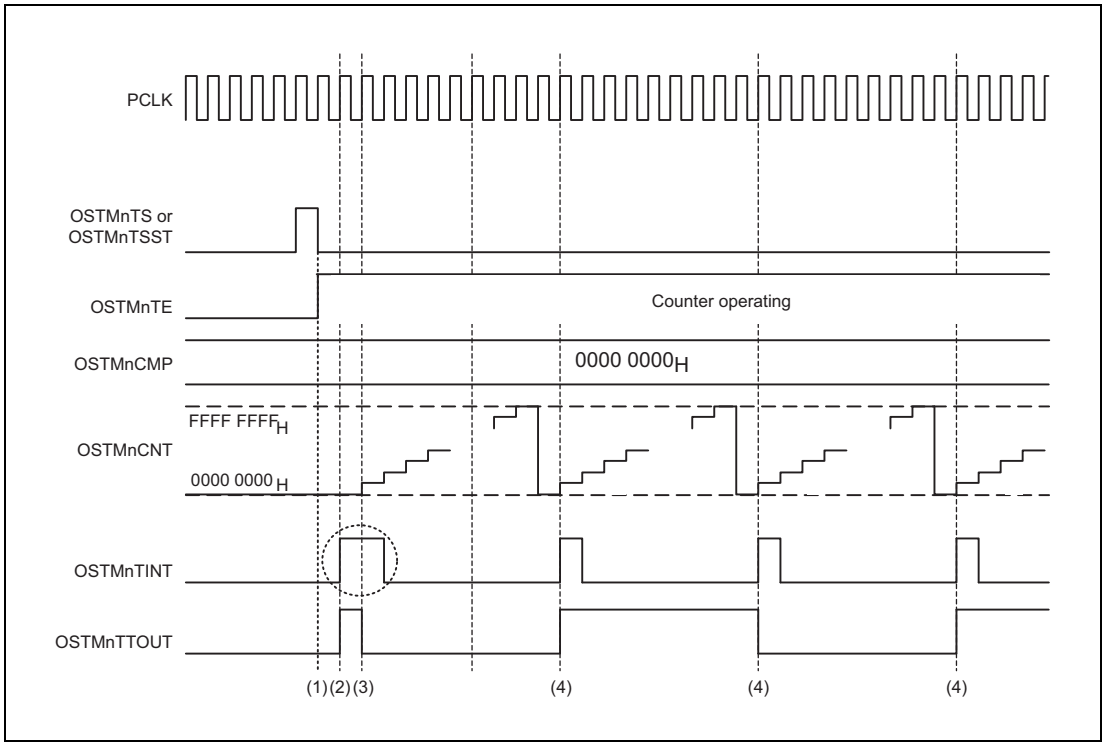

Figure 20.9 Timing Diagram when OSTMnCMP = 0000 0000$_H$ in Free-Running Comparison Mode

The timing diagram above shows the following operations.

(1) Once the counter starts, it counts up from 0000 0000$_H$ to FFFF FFFF$_H$.

(2) An OSTMnTINT interrupt request is generated when counting starts and the OSTMnTTOUT signal is toggled.

(3) If the current counter value matches OSTMnCMP, the interrupt request OSTMnTINT is generated.
If OSTMnCMP = 0000 0000$_H$ in the above case, OSTMnTINT is generated over two clock cycles and the OSTMnTTOUT signal is toggled.

(4) For every (FFFF FFFF$_H$ + 1) clock cycles the OSTMnTINT interrupt request signal is asserted and the OSTMnTTOUT signal is toggled.

When an interrupt is prohibited when the counter starts, 1 clock cycle of the counter clock is not generated at the start timing of the counter.

Section 21 Advanced Timer Unit IV (ATU-IV)

21.1 Overview

The ATU-IV has the following features.

- Processing of up to 166 pulse input/output signals
- 297 interrupt sources can be generated. This enables to activate the general direct memory access controller (DMAC), and interrupt processing by the CPU.
- Equipped with a function to output pulses to A/D and DFE (64 pulses to ADC (16 for timer C, 40 for timer D, and 8 for timer G), 48 pulses to ΔΣAD (40 for timer D and 8 for timer G), and 40 pulses to DFE (40 for timer D))
- On-chip 4-channel prescaler provided, which generates four types of clocks by dividing on-chip peripheral clock (PCLK) by 1/1 to 1/1024
- Each channel for a timer can select a count source from among four divided clocks generated by prescaler, two external clocks, and angle clock generated by timer B.
- Pin output values of timer C, D, and E can be selected by the RHSB cross bar and then output as data to the RHSB.
- Counter values of timer D and G can be selected by the APA input selector and then output as reference data to the APA. Timer D counter compare match, counter underflow, pin output signals of timer D, and timer G counter compare match can be output as event input signals to the APA.
- Timer A has a 32-bit free-run counter and seven 32-bit input capture registers. Features are shown below.
  - Detection by rising edges, falling edges, or both edges
  - Activating the DMAC at the capture timing
  - Noise canceling function for each external input pin with maximum length of 0.21 s or noise cancelling function using the angle clock
  - The level of each external input pin can be read or captured.
  - A capture interrupt request and a counter overflow interrupt request can be generated.
  - Settings for noise cancellation mode can be made in subblock/channel units.
  - Signals after noise cancellation can be sent to external input pins of timer F.
- Timer B consists of three subblocks: an edge-interval measuring block, frequency-multiplied clock generator, and frequency-multiplied clock signal corrector.
- The edge-interval measuring block is provided with a 32-bit input edge-interval measuring timer, three output compare and input capture registers, six edge-interval time measured value recording registers, seven edge-interval time measured value history registers, 8-bit event counter, and output compare register. This provides the following operations:
  - Capture by edges of external event input (rising edge, falling edge, or both edges are selectable)
  - Capture by event compare match of external event input
  - Automatic event counter clear by event compare match
  - Capture interrupt and compare match interrupt (edge-interval compare match, event compare match)

  - Captures event counter values individually by detection of seven external event inputs from timer A.

- The frequency-multiplied clock generator is provided with 24-bit reload counter, reload register, 20-bit multiplied clock counter, 26-bit multiplied clock counter, capture register and output compare register. This provides the following operations:
  - Reloadable counting of values captured by edge-interval measuring block with arbitrary number (1 to 4095)
  - Reloadable down-count values can be modified by event compare match of the edge-interval measuring block.
  - Internal clock generated by the underflow of the reload counter can be used as input of 20-bit multiplied clock counter and 26-bit multiplied clock counter.
  - The 20-bit multiplied clock counter value can be captured by an edge input of external input event.
  - An interrupt request for compare match between 20-bit multiplied clock counter and output compare register and an interrupt request for comparison between 26-bit multiplied clock counter and capture register can be generated.
- Frequency-multiplied clock signal corrector is provided with 20-bit correcting event counter, 20-bit correcting multiplied clock counter, multiplied-and-corrected clock generating counter, and correcting counter clearing register. This provides the following operations:
  - Frequency-multiplied correcting clock that serves as the count source for other timers can be generated based on the read count in frequency-multiplied clock generator.
  - The free-running counter of timer D can be cleared by compare match (enabling or disabling this function selectable) between multiplied-and-corrected clock generating counter and correcting counter clearing register.
  - The correcting event counter can be automatically cleared at the event compare match timing due to an external input event of the edge-interval measuring block.
  - Additionally corrected multiplied-and-corrected clock 2 (AGCKM2) can be output to the multiplied-and-corrected clock (AGCKM).
- Timer C consists of eight subblocks that have the same functions. Each subblock consists of four channels. Each subblock is provided with a 32-bit free-running counter, four 32-bit general registers, four 32-bit compare match registers, and a 32-bit upper-limit value setting register. This provides the following operations:
  - Input capture or output compare is selectable
  - Detection edge for input capture is selectable from among rising edge, falling edge, or both edges.
  - When timer C is used as input capture, capturing is possible at the timing of event output 1, 2A, and 2B from timer A.
  - Noise canceling function with maximum length of 0.21 s or noise cancelling function using the angle clock for each external input pin
  - Selectable noise canceling mode per sub-block or channel
  - 1, 0, or toggle can be output by a compare match.
  - Three PWM waveforms can be output for each subblock in PWM mode.
  - Input capture/compare match interrupt and overflow interrupt can be generated. Input capture/compare match interrupts activate DMAC.

  - One-shot pulse mode can be output.
  - Upper-limit value setting function for 32-bit counters

- Timer D consists of 10 subblocks that have the same function Each subblock is provided with two 32-bit free running counters, an offset base register, an output value register, and an output setting register, and four channels. Each channel is provided with two 32-bit output compare registers, two range comparison value setting registers, two input capture registers, a 32-bit down-counter for outputting one-shot pulse, and two 32-bit upper-limit value setting registers. This provides the following operations:
  - Enables to start down-counter by software. One-shot pulse can also be generated.
  - Compare match between compare match register and general register can be used as the start trigger for down-counter. One-shot pulse with offset can also be generated.
  - Compare match in compare match register can stop down-counter and forcibly cut off one-shot pulse output.
  - Compare match between compare match register and general register can be output.
  - Compare match range can be set by the range comparison value setting register (range compare function).
  - Compare match in compare match register can be used as a trigger and the count number can be captured by input capture register.
  - Free run value can be captured triggered by timer A
  - Provided with counter clearing function from timer B
  - Generation of 80 compare match interrupts, 20 counter overflow interrupts, and 40 underflow interrupts. The 24 compare match interrupts and 20 underflow interrupts correspond to DMAC activation.
  - Output pulses that show interrupts of compare match A or compare match B for A/D activation. (20 for each)
  - Output waveform can be inverted.
  - The value set in the output value register can be output from each pin by the output setting register.
  - Timer D counter compare match, counter underflow, and pin output signal of timer D can be output as event output to the APA (subblock 0).
  - Free-running counter value can be output as reference data to the APA (subblock 0).
  - Upper-limit value setting function for 32-bit counters
- Timer E consists of seven subblocks that have the same function. Each subblock consists of four channels. Each channel is provided with 24-bit free running counter, duty cycle setting register, cycle setting register, duty cycle reload register, and cycle reload register. This provides the following operations:
  - PWM output with programmable cycle time and duty cycle ranging from 0 to 100%
  - Switchable between on-state and off-state duty modes
  - Values in duty cycle reload register/cycle reload register can be transferred to duty cycle setting register/cycle setting register at every cycle.
  - Writing $000\ 0000_H$ to the 24 higher-order bits of the counter can forcibly end PWM cycle and start new PWM cycle.
  - PWM output can be blocked by shutoff input.

  - 28 interrupt requests can be output at each cycle for cycle match interrupt requests and duty match interrupt request (Channel 0 of each subblock supports for DMAC activation by cycle match)

- Timer F consists of 16 subblocks. Each subblock is provided with two 32-bit counters, a 16-bit counter, three (for all subblocks) 32-bit general registers, and a 16-bit general register. This provides the following operations:
  - Detection by rising edge, falling edge or both edges
  - TIA00 to TIA06 signals of timer A after noise cancellation can be used as external input signals.
  - Noise canceling function for each external pin with maximum length of 0.21 s or noise cancelling function using the angle clock.
  - Selectable noise canceling mode per sub-block or channel
  - Seven operation modes: edge counting in a specified period, effective edge interval counting, measurement of time during high/low input, measurement of PWM input waveform timing, rotation speed/pulse measurement, up/down event count, and four-time multiplication event count.
  - Activates DMAC by input capture interrupt request
  - Overflow interrupt generation
  - A compare match interrupt request can be generated in PWM input waveform measurement mode or rotation speed/pulse measurement mode.
  - Settings for noise cancellation mode can be made in channel units.
- Timer G consists of 10 subblocks that have the same function. Each channel is provided with a 32-bit free-run counter and output compare register. This provides the following operations:
  - A compare match trigger event can be output and used as A/D activation/interrupt request trigger and event output to the APA.
  - Activates DMAC by compare match interrupt request
  - Free-running counter value can be output as reference data to the APA (subblock 0).
- Timer H consists of a pair of 16-bit counter and 16-bit compare match register, and a 32-bit counter. This provides the following operations:
  - Measurement of time ranging from 1 to 2^{26} times of peripheral internal clock (PCLK) using a 16-bit counter and a 16-bit compare match register. Can be output as compare match interrupt.
  - Equipped with a 32-bit counter to count the compare match occurrence.
- Timer J consists of 6 subblocks that have the same function. Each channel is provided with a 32-bit counter, output compare register, and nine-stage FIFO register. This provides the following operations:
  - Detection by rising edge, falling edge or both edges
  - Noise canceling function with maximum length of 0.21 s or noise cancelling function using the angle clock for each external input pin.
  - Selectable noise canceling mode per sub-block
  - Capture the counter value in FIFO register (edge input interval) when detecting edges on external input pin.
  - Activates DMAC at the timing when FIFO is full.
  - Controls FIFO's effective capture time using compare match register
  - FIFO full interrupt, counter overflow, and FIFO overflow interrupt can be generated.

21.1.1 Configuration of ATU-IV

ATU-IV consists of nine timer blocks (timer A to timer J), prescalers, and a controller. The timer blocks have different functions and each can operate independently; timer blocks can also be linked via the clock bus. Each timer block consists of one or more timer subblocks and each subblock has one or more channels. (See **Table 21.1, Block Configuration for ATU-IV**, and **Section 21.1.2, ATU-IV Registers**).

Table 21.1 Block Configuration for ATU-IV

Modules	Blocks	Subblock	Remarks
ATU-IV			
	Common controller unit		
	Prescaler		Total number of channels: 4

21.1.2 ATU-IV Registers

Addresses of the ATU-III registers are shown below. To access the registers, the following procedure should be followed.

1. When writing to reserved bits, always write 0.
2. There are restrictions on register write access size for some registers. Be careful when making a write access with a bit width smaller than the register bit width. For details, see the description of each register.

The following shows address allocation of ATU-IV registers.

Common Controller Registers (FFE6 0000_H to FFE6 $007F_H$)

Address	b31 +3 b24	b23 +2 b16	b15 +1 b8	b7 +0 b0	Page

21.1.3 ATU-IV Input/Output Signals

Common Controller

Symbol	I/O	Number of Bits	Function
TCLKA	Input	1	Input pin for the external clock on signal line 4 of the clock bus
TCLKB	Input	1	Input pin for the external clock on signal line 5 of the clock bus

Prescaler

Not provided

Timer A

Symbol	I/O	Number of Bits	Function
TIA00 to TIA06	Input	7	Input pins for input-capture triggers for timer A channels

Timer B

Not provided

Timer C

Symbol	I/O	Number of Bits	Function
TIOC00 - 03 to TIOC70 - 73	Input	32	Input pins for input-capture triggers and output pins for output-compare signals of timer C (one each for channels 0 to 3 in subblocks C0 to C7)

Timer D

Symbol	I/O	Number of Bits	Function
TOD00A - 03A to TOD90A - 93A*1	Output	40	Output pins for compare-match signals of timer D (one each for channels 0 to 3 in subblocks D0 to D9)
TOD00B - 03B to TOD90B - 93B*1	Output	40	Output pins for one-shot pulses of timer D (one each for channels 0 to 3 in subblocks D0 to D9)

Note 1. The subblock D9 is used to activate the A/D and DFE and has no external input/output pin.

Timer E

Symbol	I/O	Number of Bits	Function
POE0 to POE5	Input	6	Timer E (subblocks E0 to E5) shutoff input * Shared with TIF0A to TIF2A and TIF0B to TIF2B
TOE00 - 03 to TOE60 - 63	Output	28	Output pins for PWM signals of timer E (one each for channels 0 to 3 in subblocks E0 to E6)

Timer F

Symbol	I/O	Number of Bits	Function
TIF0A to TIF2A TIF3 to TIF15	Input	16	Input pins for event signals for subblocks F0 to F15 of timer F TIF0A to TIF2A: Input pins for subblocks F0 to F2 TIF3 to TIF15: Input pins for subblocks F3 to F15
TIF0B to TIF2B	Input	3	Input pins for event signals for subblocks F0 to F2 of timer F

Timer G

Not provided

Timer H

Not provided

Timer J

Symbol	I/O	Number of Bits	Function
TIJ0 to TIJ5	Input	6	Input pins for input-capture triggers for subblocks of timer J

21.1.4 Clock Supply

The clock supply for ATU-IV is listed in the following table.

Clock for the Unit	Supply Clock Name
Pϕ, PCLK, pclk	CLKC_LSB (non-modulated low speed peripheral clock)

21.2 Common Controller

21.2.1 Operation

The common controller controls the ATU-IV module as a whole. For example, it enables and disables the prescalers and timer counters for timers A to J and controls the clock bus.

Clock Bus

The clock bus consists of seven signal lines used to distribute the source signals for counting (counter enabling signals) to the timer channels. The timer counters on each of the channels run in synchronization with the internal peripheral clock (Pϕ).

The following table shows the signals which are available for input on the clock bus.

Bit Number of Clock Bus	Input Signals
6	Timer B output (AGCKM2)
5	Output signal from timer B (angle clock) or external input clock B (TCLKB)
4	External input clock A (TCLKA)
3	Output signal from prescaler 3
2	Output signal from prescaler 2
1	Output signal from prescaler 1
0	Output signal from prescaler 0

21.2.2 Register Description of Common Controller

21.2.2.1 ATUENR — ATU-IV Master Enable Register

Access: 8-bit and 16-bit accessible

Address: FFE6 0000_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 21.2 ATUENR Register Contents

Bit Position	Bit Name	Function
15 to 10	—	These bits are not used. Fix these bits to 0.
9	TJE	Timer J Enable 0: Timer J counter operation disabled 1: Timer J counter operation enabled
8	THE	Timer H Enable 0: Timer H counter operation disabled 1: Timer H counter operation enabled
7	TGE	Timer G Enable 0: Timer G counter operation disabled 1: Timer G counter operation enabled
6	TFE	Timer F Enable 0: Timer F counter operation disabled 1: Timer F counter operation enabled
5	TEE	Timer E Enable 0: Timer E counter operation disabled 1: Timer E counter operation enabled
4	TDE	Timer D Enable 0: Timer D counter operation disabled 1: Timer D counter operation enabled
3	TCE	Timer C Enable 0: Timer C counter operation disabled 1: Timer C counter operation enabled
2	TBE	Timer B Enable 0: Timer B counter operation disabled 1: Timer B counter operation enabled
1	TAE	Timer A Enable 0: Timer A counter operation disabled 1: Timer A counter operation enabled
0	PSCE	Prescaler Enable 0: Prescaler counter operation disabled 1: Prescaler counter operation enabled

ATUENR is a 16-bit readable/writable register. This register is used to enable and disable the prescalers and the individual blocks in ATU-IV. Setting an enable bit to 1 enables the corresponding block. Clearing the bit to 0 disables the corresponding block. Even when the enable bit is cleared to 0, the registers of these blocks remain accessible.

Timers can be synchronized by simultaneously setting multiple bits to 1.

(1) TJE — Timer J Enable

Enables and disables counter operation of timer J.

When this bit is set to 1, the timer J counter starts working. When this bit is cleared to 0, the timer J counter stops working. When the counter is disabled, its value is retained. When this bit is again set to 1, the counter resumes counting from the retained value.

However, the corresponding bit in the timer J start register must also be set to 1 to enable the operation of either of the subblock counters.

(2) THE — Timer H Enable

Enables and disables counter operation of timer H.

When this bit is set to 1, the timer H counter starts working. When this bit is cleared to 0, the timer H counter stops working. When the counter is disabled, its value is retained. When this bit is again set to 1, the counter resumes counting from the retained value.

(3) TGE — Timer G Enable

Enables and disables counter operation of timer G.

When this bit is set to 1, the timer G counter starts working. When this bit is cleared to 0, the timer G counter stops working. When the counter is disabled, its value is retained. When this bit is again set to 1, the counter resumes counting from the retained value.

However, the corresponding bit in the timer G start register must also be set to 1 to enable the operation of either of the subblock counters.

(4) TFE — Timer F Enable

Enables and disables counter operation of timer F.

When this bit is set to 1, the timer F counter starts working. When this bit is cleared to 0, the timer F counter stops working. When the counter is disabled, its value is retained. When this bit is again set to 1, the counter resumes counting from the retained value.

However, the corresponding bit in the timer F start register must also be set to 1 to enable the operation of either of the subblock counters.

(5) TEE — Timer E Enable

Enables and disables counter operation of timer E.

When this bit is set to 1, the timer E counter starts working. When this bit is cleared to 0, the timer E counter stops working. When the counter is disabled, its value is retained. When this bit is again set to 1, the counter resumes counting from the retained value.

However, the corresponding bit in the timer E start register must also be set to 1 to enable the operation of either of the subblock counters.

(6) TDE — Timer D Enable

Enables and disables counter operation of timer D.

When this bit is set to 1, the timer D counter starts working. When this bit is cleared to 0, the timer D counter stops working. When the counter is disabled, its value is retained. When this bit is again set to 1, the counter resumes counting from the retained value.

However, the corresponding bit in the timer D start register must also be set to 1 to enable the operation of either of the subblock counters.

(7) TCE — Timer C Enable

Enables and disables counter operation of timer C.

When this bit is set to 1, the timer C counter starts working. When this bit is cleared to 0, the timer C counter stops working. When the counter is disabled, its value is retained. When this bit is again set to 1, the counter resumes counting from the retained value.

However, the corresponding bit in the timer C start register must also be set to 1 to enable the operation of either of the subblock counters.

(8) TBE — Timer B Enable

Enables and disables counter operation of timer B.

When this bit is set to 1, the timer B counter starts working. When this bit is cleared to 0, the timer B counter stops working. When the counter is disabled, its value is retained. When this bit is again set to 1, the counter resumes counting from the retained value.

(9) TAE — Timer A Enable

Enables and disables counter operation of timer A.

When this bit is set to 1, the timer A counter starts working. When this bit is cleared to 0, the timer A counter stops working. When the counter is disabled, its value is retained. When this bit is again set to 1, the counter resumes counting from the retained value.

(10) PSCE — Prescaler Enable

Enables and disables the prescaler counters.

When this bit is set to 1, the prescaler counter starts working. When this bit is cleared to 0, the prescaler counter stops working. When the prescaler counters are disabled, the counter values are retained. Once the bit is set to 1 again, the counter resumes counting from the retained value.

21.2.2.2 CBCNT — Clock Bus Control Register

Access: 8-bit accessible

Address: FFE6 0002_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	CB4EG[1:0]		—	CB5SEL	CB5EG[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R/W	R/W	R/W

Table 21.3 CBCNT Register Contents

Bit Position	Bit Name	Function
7, 6	—	These bits are not used. Fix these bits to 0.
5, 4	CB4EG[1:0]	Clock Bus 4 Edge Select These bits specify the edge sense for external input clock (TCLKA) to be output on signal line 4 of the clock bus. 00: Neither edge of the external clock is sensed 01: Rising edges of the external clock are sensed 10: Falling edges of the external clock are sensed 11: Both rising and falling edges of the external clock are sensed
3	—	This bit is not used. Fix this bit to 0.
2	CB5SEL	Clock Bus 5 Source Select This bit specifies the clock to be output on signal line 5 of the clock bus. 0: External input clock B (TCLKB) 1: Multiplied-and-corrected clock output by Timer B
1, 0	CB5EG[1:0]	Clock Bus 5 Edge Select These bits specify the edge sense for external input clock to be output on signal line 5 of the clock bus when CB5S is cleared to 0. 00: Neither edge of the external clock is sensed 01: Rising edges of the external clock are sensed 10: Falling edges of the external clock are sensed 11: Both rising and falling edges of the external clock are sensed

CBCNT is an 8-bit readable/writable register that selects the source of the clock signal to be supplied on signal line 5 of the clock bus and the effective edge of the external clock signal (only applies to line 5 when the externally input clock is selected).

(1) CB4EG[1:0] — Clock Bus 4 Edge Select

These bits select the edge sense for externally input clock A (TCLKA). The clock signal is output on signal line 4 of the clock bus. Counters for which signal line 4 of the clock bus has been selected as the source for counting count on the edge selected by these bits.

(2) CB5SEL — Clock Bus 5 Source Select

Selects the source of the clock to be output on signal line 5 of the clock bus.

(3) CB5EG[1:0] — Clock Bus 5 Edge Select

These bits select the edge sense for external input clock B (TCLKB). The clock signal is output on signal line 5 of the clock bus. Counters for which signal line 5 of the clock bus has been selected as the source for counting count on the edge selected by these bits.

The setting of these bits is only valid when the TCLKB signal is selected as the source for line 5 of the clock bus. When the angle clock is selected as the source for line 5 of the clock bus, the setting of these bits is ignored.

21.2.2.3 NCMR — Noise Cancellation Mode Register

Access: 8-bit accessible

Address: FFE6 0003_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NCCSEL	—	—	NCMSEL	NCMJ	NCMF	NCMC	NCMA
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Table 21.4 NCMR Register Contents

Bit Position	Bit Name	Function
7	NCCSEL	Noise Canceler Counter Clock Select This bit selects the clock for counting by the noise cancelers. 0: PCLK divided by 128 is used as the counter clock 1: PCLK is used as the counter clock
6, 5	—	These bits are not used. Fix these bits to 0.
4	NCMSEL	Noise Cancellation Mode Select This bit selects minimum time-at-level cancellation mode or level accumulation cancellation mode. 0: Minimum time-at-level cancellation mode 1: Level accumulation cancellation mode
3	NCMJ	Timer J Noise Cancellation Mode This bit specifies the operating mode of the timer J noise canceler. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (when NCMSEL = 0) Level accumulation cancellation mode (when NCMSEL = 1)
2	NCMF	Timer F Noise Cancellation Mode This bit specifies the operating mode of the timer F noise canceler. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (when NCMSEL = 0) Level accumulation cancellation mode (when NCMSEL = 1)
1	NCMC	Timer C Noise Cancellation Mode This bit specifies the operating mode of the timer C noise canceler. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (when NCMSEL = 0) Level accumulation cancellation mode (when NCMSEL = 1)
0	NCMA	Timer A Noise Cancellation Mode This bit specifies the operating mode of the timer A noise canceler. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (when NCMSEL = 0) Level accumulation cancellation mode (when NCMSEL = 1)

NCMR is an 8-bit readable/writable register that selects the mode and clock to drive the counter for of the noise canceler in each of timers A, C, F, and J.

In premature-transition cancellation mode, subsequent changes to the input signal level are ignored if they come within a given period of a detected change. That is, level changes within a certain period of an initial one are treated as noise.

In minimum time-at-level cancellation mode, the first and subsequent level changes are ignored unless the input signal level remains the same over a given period. Level changes occurring within a shorter period are considered to indicate an unstable signal, and such signals are treated as noise.

In level accumulation cancellation mode, input signal levels are accumulated and the input level is regarded to have reached 0 or 1 when the accumulation result becomes 0 or the specified value.

The period is set by noise canceler registers in each of the applicable blocks (i.e. in timers A, C, F, and J) and is counted by a noise canceler counter.

Outline of noise canceling operation (example of TIA00 input signal of timer A) is shown in **Figure 21.1** (in premature-transition cancellation mode), **Figure 21.2** (in minimum time-at-level cancellation mode), and **Figure 21.3** (in level accumulation cancellation mode).

Each timer (A, C, F, and J) detects the edge of a signal that has passed through the noise canceler. **Figure 21.1**, **Figure 21.2**, and **Figure 21.3** show an example of detecting the rising edge of a signal that has passed through the noise canceler.

(1) NCCSEL — Noise Canceler Counter Clock Select

Selects the clock for counting by the noise cancelers. Either of the internal peripheral clock (PCLK) divided by 128 or the internal peripheral clock can be selected. The default setting is the clock divided by 128. The same counter clock must be used for all timers other than timer A. In the case of timer A, the clock signal on clock-bus line 5 is also available. For setting the counter clock, see the description of the TIOR2A register in timer A.

(2) NCMSEL — Noise Cancellation Mode Select

Noise cancellation mode when each noise cancellation mode bit (NCMA, NCMC, NCMF, or NCMJ) is set to 1 can be set to premature-transition cancellation mode or level accumulation cancellation mode.

(3) NCMJ — Noise Canceler Counter Clock Select

Selects the noise cancellation mode for timer J. A different operating mode cannot be set for each channel of timer J.

(4) NCMF — Timer F Noise Cancellation Mode

Selects the noise cancellation mode for timer F. A different operating mode cannot be set for each channel of timer F. The mode of operation is not individually selectable for each channel of Timer F. To make per-channel settings, start by setting this bit to 0 as the setting for Timer F as a unit, and then set noise cancellation mode channel registers 1F (NCMCR1F) and 2F (NCMCR2F).

(5) NCMC — Timer C Noise Cancellation Mode

Selects the noise cancellation mode for timer C. A different operating mode cannot be set for each channel of timer C.

(6) NCMA — Timer A Noise Cancellation Mode

Selects the noise cancellation mode for timer A. A different operating mode cannot be set for each channel of timer A.

Modes of operation are individually selectable for each channel of Timer A. To make per-channel settings, start by setting this bit to 0 as the setting for Timer A as a unit, and then set noise cancellation mode channel register 1A (NCMCR1A) and 2A (NCMCR2A).

Table 21.5 to **Table 21.7** are truth tables for settings that determine the noise cancellation mode.

Table 21.5 Settings that Determine Noise Cancellation Modes for Timer A

Channel Enable	Filter Mode		Channel Register			
TIOR2A. NCEAx	NCMR. NCMA	NCMR. NCMSEL	NCMCR1A. NCM1Ax	NCMCR2A. NCM2Ax	Mode of Cancellation	Unit of Filtering
0	—	—	—	—	Filter invalid	—
1	0	(–)	0	(–)	Premature-transition	Each subblock/ channel
1	0	(–)	1	0	Minimum time-at-level	Each channel
1	0	(–)	1	1	Level accumulation	Each channel
1	1	(0)	—	—	Minimum time-at-level	Each subblock
1	1	1	—	—	Level accumulation	Each subblock

Note 1. x = 0 to 6

Note 2. A noise canceler enable bit Ax (NCEAx) can be set per channel.

Methods of setting noise cancellation for timer A according to the unit of filtering (precondition: channel enable = 1)

- Settings for individual channels:
  After setting the noise cancellation mode bit (NCMA) in the noise cancellation mode register (NCMR) to 0, set even one of the noise cancellation mode channel setting bits (NCM1Ax) in noise cancellation mode channel register 1A (NCMCR1A) of timer A to 1.
- Setting for all channels:
  Set the noise cancellation mode bit (NCMA, the same bit as in “Settings for individual channels” above) in the noise cancellation mode register (NCMR) to 1 or set all of the noise cancellation mode channel setting bits (NCM1Ax) in noise cancellation mode channel register 1A (NCMCR1A) to 0.

Table 21.6 Settings That Determine Noise Cancellation Modes for Timer C

Channel Enable	Filter Mode		Channel Register			
NCCRCx. NCECx	NCMR. NCMC	NCMR. NCMSEL	NCMCR1C. NCM1Cx	NCMCR2C. NCM2Cx	Mode of Cancellation	Unit of Filtering
0	—	—	—	—	Filter invalid	—
1	0	(–)	0	(–)	Premature-transition	Each subblock/ channel
1	0	(–)	1	0	Minimum time-at-level	Each channel
1	0	(–)	1	1	Level accumulation	Each channel
1	1	(0)	—	—	Minimum time-at-level	Each subblock
1	1	1	—	—	Level accumulation	Each subblock

Note 1. x = 0 to 7

Note 2. A noise canceler enable bit Cx (NCECx) can be set for each channel.

Methods of setting noise cancellation for timer C according to the unit of filtering (precondition: channel enable = 1)

- Settings for individual channels:
  After setting the noise cancellation mode bit (NCMC) in the noise cancellation mode register (NCMR) to 0, set even one of the noise cancellation mode channel setting bits (NCM1Cx) in noise cancellation mode channel register 1C (NCMCR1C) of timer C to 1.
- Settings for all channels:
  Set the noise cancellation mode bit (NCMC, the same bit as in “Settings for individual channels” above) in the noise cancellation mode register (NCMR) to 1 or set all of the noise cancellation mode channel setting bits (NCM1Cx) in noise cancellation mode channel register 1C (NCMCR1C) to 0.

Table 21.7 Settings that Determine Noise Cancellation Modes for Timer F

Channel Enable	Filter Mode		Channel Register			
NCCRF. NCEFx	NCMR. NCMF	NCMR. NCMSEL	NCMCR1F. NCM1Fx	NCMCR2F. NCM2Fx	Mode of Cancellation	Unit of Filtering
0	—	—	—	—	Filter invalid	—
1	0	(–)	0	(–)	Premature-transition	Each subblock/ channel
1	0	(–)	1	0	Minimum time-at-level	Each channel
1	0	(–)	1	1	Level accumulation	Each channel
1	1	(0)	—	—	Minimum time-at-level	Each subblock
1	1	1	—	—	Level accumulation	Each subblock

Note 1. x = 0 to 15

Note 2. A noise canceler enable bit Fx (NCEFx) can be set per channel.

Methods of setting noise cancellation for timer F according to the unit of filtering (precondition: channel enable = 1)

- Settings for individual channels: After setting the noise cancellation mode bit (NCMF) in the noise cancellation mode register (NCMR) to 0, set even one of the noise cancellation mode channel setting bits (NCM1Fx) in noise cancellation mode channel register 1F (NCMCR1F) of timer F to 1.
- Setting for all channels: Set the noise cancellation mode bit (NCMF, the same bit as in “Settings for individual channels” above) in the noise cancellation mode register (NCMR) to 1 or set all of the noise cancellation mode channel setting bits (NCM1Fx) in noise cancellation mode channel register 1F (NCMCR1F) to 0.

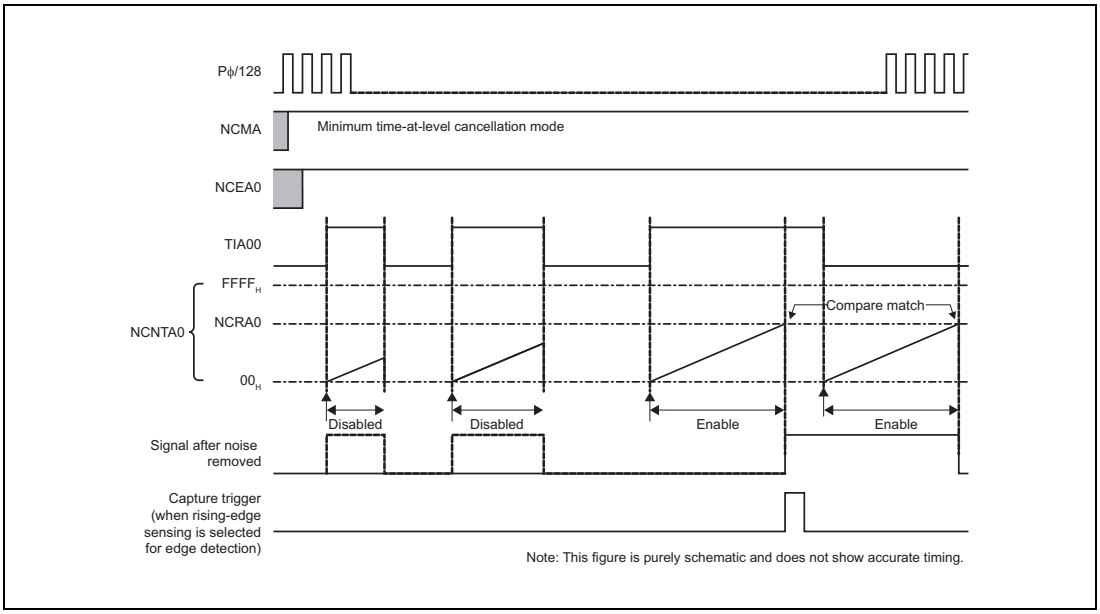

Figure 21.2 Outline of Noise Canceling Operation in Minimum Time-at-Level Cancellation Mode

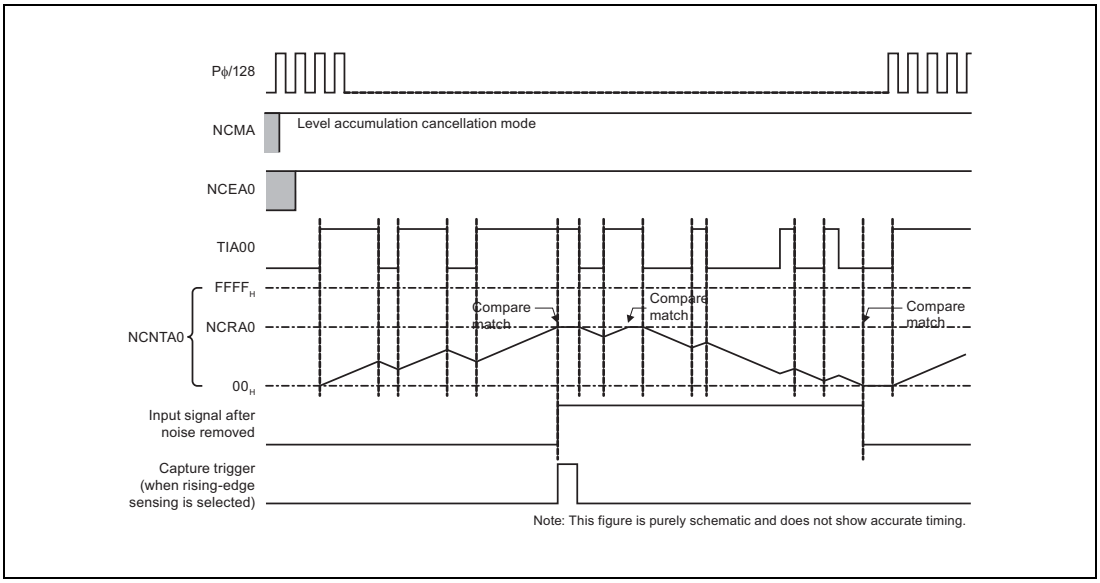

Figure 21.3 Outline of Noise Canceling Operation in Level Accumulation Cancellation Mode

21.3 Prescaler

21.3.1 Operation

ATU-IV includes four general prescalers and a prescaler for the noise-canceler clock.

The general prescalers are implemented as 10-bit down-counters, in which the prescaled clock signals are derived by frequency-dividing the peripheral clock (PCLK) by N ($1 \leq N \leq 1024$). The generated clock signals are supplied to the individual timers via the clock bus. The prescalers for each of the channels operate independently.

The prescaler for the noise-canceler clock is implemented as a 7-bit down-counter. This generates a clock signal by frequency-dividing the peripheral clock (PCLK) by 128. The clock signal thus generated is supplied to the noise cancelers of timers A, C, F, and J.

A clock signal derived by frequency-dividing the peripheral clock frequency by 128 can be selected for the noise canceler clock by the NCCSEL bit in NCMR of the common controller. No other division ratios are available.

The down-counters of the prescalers are initialized to 0000_H by a reset.

21.3.2 Register Description of Prescalers

21.3.2.1 PSCRx — Prescaler Registers x (x = 0 to 3)

Access: 16-bit accessible, but 8-bit inaccessible

Table 21.8 PSCR Register Contents

Bit Position	Bit Name	Function
15 to 10	—	These bits are not used. Fix these bits to 0.
9 to 0	PSCx[9:0]	Division Ratio These bits specify the division ratio for the corresponding prescaler.

Note: x = 0 to 3

Prescaler registers x are 16-bit readable/writable registers, each of which holds a division ratio for one of the four prescalers.

When the value in prescaler register x is changed, the prescaler updates the value on its underflow.

Settable values range from 000_H to $3FF_H$.

The division ratio is obtained from the following expression.

$$\text{Division ratio of prescaler} = \frac{1}{\text{PSCx[9:0]} + 1} \quad \text{(Settable value: 1/1 to 1/1024)}$$

A duty cycle of 50% is not guaranteed for the clock-signal outputs of the prescalers. Instead, the high level is output in one cycle of the PCLK clock and the low level is output in the remaining cycles within the prescaled period.

21.3.3 Details of Operation

21.3.3.1 Starting Prescalers

The prescalers start operating when the PSCE bit in the ATU-IV master enable register is set to 1 and generates a clock with a frequency given by the division ratio in the PSCx bits. While a prescaler is operating, the high level is output for one cycle of the PCLK clock each time the corresponding prescaler counter underflows.

When the setting in the PSCx bits is changed during operation, the division ratio of the output clock is updated on the first subsequent counter underflow.

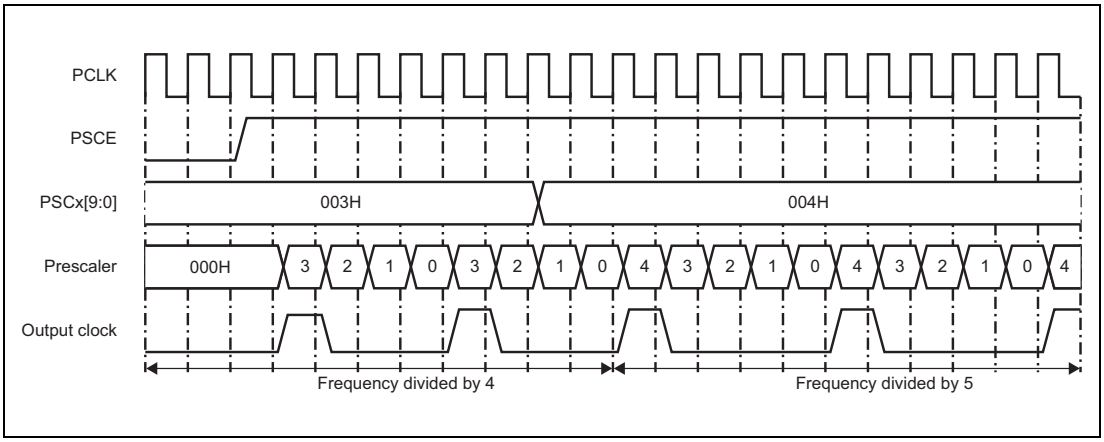

Figure 21.4 Starting Prescaler

21.3.3.2 Stopping and Restarting Operation

The prescaler stops operating when the PSCE bit in the ATU-IV master enable register is cleared to 0. The clock signal stays at the low level while the prescaler is stopped.

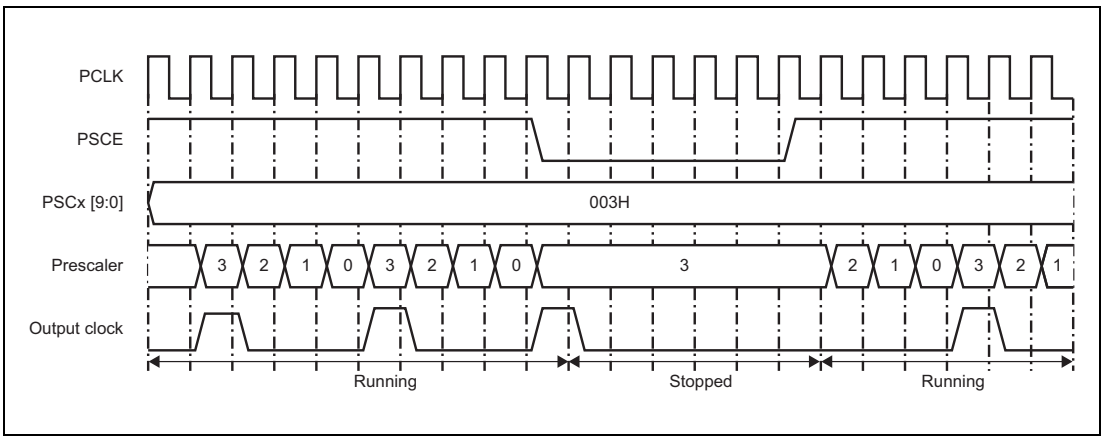

Figure 21.5 Stopping Prescaler

21.4 Timer A

21.4.1 Operation

Timer A includes a 32-bit free-running counter A (TCNTA) and seven 32-bit input capture registers Ax (ICRA0 to ICRA6). TCNTA is a free-running up counter. An interrupt request can be output when the counter overflows.

Seven input capture registers A0 to A6 (ICRA0 to ICRA6) capture the value of free-running counter A (TCNTA) on an assertion of the corresponding external input signal (TIA00 to TIA06). The rising or falling edge, or both edges, can be selected as the trigger for capture. The edge selection is made timer I/O control register 1A (TIOR1A). The interrupt is requested or the A-DMAC is activated at the same timing as capturing.

Noise on the external input signals can be removed by the noise canceler. The pin level of these external signal input pins (TIA00 to TIA06) after noise cancellation can be read and captured. The pin level is captured at the timing of the OCRB6 interrupt request signal from timer B. Input pin (TIA00 to TIA06) signals after noise cancellation can be output as input signals to timer F. Signals on pins TIA00 to TIA06 can be output to timer B, C or D as event signals after noise has been removed and their edges have been extracted. One of TIA00 to 06, or a combination with an input edge are selectable for output to timer B as an event signal (event output 1). Seven event signals TIA00 to 06 are output (event outputs 1B to 1H) to timer B to be used as the capture trigger of the event counter B1(TCNTB1). One of seven event signals TIA00 to 06 or an event signal which is a combination of several input edges is output (event output 2A and 2B) to timer D0 to D9 respectively to be used as the capture trigger of timer offset base registers OSBRD0 to OSBRD 9. The signals of these event output 1 and event output 2A and 2B can be used as the input capture trigger of timer C.

The capture register value can be transferred by the DMAC by activating the DMAC at the capture timing.

Figure 21.6 is a block diagram of timer A.

TCR1A is an 8-bit readable/writable register that sets the event output generated from external input signals (TIA00 to TIA02) and the counter clock.

TCR1A is initialized to 00_H by a reset.

(1) EVOSEL2A — Event Output 2A Select

Selects the signal for output on event output 2A as the externally input signal TIA01 or TIA02 (signals after the noise cancellation and edge detection). In timers D0 to D9, the event output 2A signal can be used as a capture trigger for the corresponding timer-offset base registers Dx (OSBRD0 to OSBRD9).

Timer C can use this event output 2A signal as a capture trigger.

(2) EVOSEL2B — Event Output 2B Select

Selects the signal for output on event output 2B as the externally input signal TIA01 or TIA02 (signals after the noise cancellation and edge detection). In timer D0 to D9, the event output 2B signal can be used as a capture trigger for the corresponding timer-offset base register Dx (OSBRD0 to OSBRD9).

Timer C can use this event output 2B signal as a capture trigger.

(3) EVOSEL1 — Event Output 1 Select

These bits select the signal for output on event output 1 as one of the externally input signal TIA00 to TIA02 (signals after the noise cancellation and edge detection). In timer B, the event output 1 signal can be used as an event output 1 to timer B and timer C. Furthermore, input edge combinations of TIA00 and TIA01, TIA00 and TIA02, TIA01 and TIA02, and TIA00, TIA01, and TIA02 can be output together as an event output 1 to timer B and timer C.

(4) CKSELA — Clock Select A

These bits select the signal on one of clock-bus lines 0 to 5 as the clock signal for counting. The signal on lines 0 to 3 have been frequency-divided by prescalers 0 to 3, respectively. Clock-bus line 4 supplies externally input clock A (TCLKA). Clock-bus line 5 supplies externally input clock B (TCLKB) or the multiplied-and-corrected clock output by timer B.

Stop timer A before making or changing the counter-clock selection.

CAUTION

The edge of an external input clock is detected before it is output on a clock bus. When using external input clock A or B, select the edge to be detected by setting the edge select bit in the clock bus control register (CBCNT).

21.4.2.2 TCR2A — Timer Control Register 2A

Access: 8-bit accessible

Address: FFE6 0202_H

6 to 0	EVOSELE1	Event Output 1 Extension Select These bits select the combination of inputs (TIA00 to 06) to be output as an event. b6: 0: TIA06 input edge is not output 1: TIA06 input edge is output b5: 0: TIA05 input edge is not output 1: TIA05 input edge is output b4: 0: TIA04 input edge is not output 1: TIA04 input edge is output b3: 0: TIA03 input edge is not output 1: TIA03 input edge is output b2: 0: TIA02 input edge is not output 1: TIA02 input edge is output b1: 0: TIA01 input edge is not output 1: TIA01 input edge is output b0: 0: TIA00 input edge is not output 1: TIA00 input edge is output

(1) EVOSELE1E — Event Output 1 Extension Select Enable

Event Output 1 Extension Select Enable (EVOSELE1E) is an 8-bit readable/writable register to enable or disable the event output 1 extension selection.

EVOSELE1E is initialized to 00_H by a reset.

(2) EVOSELE1 — Event Output 1 Extension Select Register

Event Output 1 Extension Select register (EVOSELE1) is an 8-bit readable/writable register to set event output 1 of external input edges TIA00 to TIA06 when EVOSELE1E is enabled.

EVOSELE1 is initialized to 00_H by a reset.

Any one of external input signals TIA00 to TIA06 (signals after noise cancellation and edge detection) or combination of these input edges can be output to timer B or timer C as event 1 by the settings of this register.

When this function is enabled, event output selection specified by TCR1A is disabled.

21.4.2.3 TCR3A — Timer Control Register 3A

Access: 8-bit accessible

Address: FFE6 0204_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	EVOSELE2AE	EVOSELE2A						
Value after reset	0	0	0	0	0	0	0	0

6 to 0	EVOSELE2A	Event Output 2A Extension Select These bits select the combination of inputs (TIA00 to 06) to be output as an event. b6: 0: TIA06 input edge is not output 1: TIA06 input edge is output b5: 0: TIA05 input edge is not output 1: TIA05 input edge is output b4: 0: TIA04 input edge is not output 1: TIA04 input edge is output b3: 0: TIA03 input edge is not output 1: TIA03 input edge is output b2: 0: TIA02 input edge is not output 1: TIA02 input edge is output b1: 0: TIA01 input edge is not output 1: TIA01 input edge is output b0: 0: TIA00 input edge is not output 1: TIA00 input edge is output

(1) EVOSELE2AE — Event Output 2A Extension Select Enable

Event Output 2A Extension Select Enable (EVOSELE2AE) is an 8-bit readable/writable register to enable or disable the event output 2A extension selection. EVOSELE2AE is initialized to 00_H by a reset.

(2) EVOSELE2A — Event Output 2A Extension Select Register

Event Output 2A Extension Select register (EVOSELE2A) is an 8-bit readable/writable register to set event output 2A of external input edges TIA00 to TIA06 when EVOSELE2AE is enabled.

EVOSELE2A is initialized to 00_H by a reset.

Any one of external input signals TIA00 to TIA06 (signals after noise cancellation and edge detection) or combination of these input edges can be output as event 2A by the settings of this register. Timer D0 to timer D9 can use this event 2A signal as the capture trigger of timer offset base registers Dx (OSBRD0 to OSBRD9).

Timer C can use this event output 2A signal as a capture trigger.

When this function is enabled, event output selection specified by TCR1A is disabled.

21.4.2.4 TCR4A — Timer Control Register 4A

Access: 8-bit accessible

Address: FFE6 0206_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	EVOSELE2BE	EVOSELE2B						
Value after reset	0	0	0	0	0	0	0	0

Table 21.12 TCR4A Register Contents

Bit Position	Bit Name	Function
7	EVOSELE2BE	Event Output 2B Extension Enable 0: Event output 2B extension selection is disabled. 1: Event output 2B extension selection is enabled.
6 to 0	EVOSELE2B	Event Output 2B Extension Select These bits select the combination of inputs (TIA00 to 06) to be output as an event. b6: 0: TIA06 input edge is not output 1: TIA06 input edge is output b5: 0: TIA05 input edge is not output 1: TIA05 input edge is output b4: 0: TIA04 input edge is not output 1: TIA04 input edge is output b3: 0: TIA03 input edge is not output 1: TIA03 input edge is output b2: 0: TIA02 input edge is not output 1: TIA02 input edge is output b1: 0: TIA01 input edge is not output 1: TIA01 input edge is output b0: 0: TIA00 input edge is not output 1: TIA00 input edge is output

(1) EVOSELE2BE — Event Output 2B Extension Select Enable

Event Output 2B Extension Select Enable (EVOSELE2BE) is an 8-bit readable/writable register to enable or disable the event output 2B extension selection.

EVOSELE2BE is initialized to 00_H by a reset.

(2) EVOSELE2B — Event Output 2B Extension Select Register

Event Output 2B Extension Select register (EVOSELE2B) is an 8-bit readable/writable register to set event output 2B of external input edges TIA00 to TIA06 when EVOSELE2BE is enabled.

EVOSELE2B is initialized to 00_H by a reset.

Any one of external input signals TIA00 to TIA06 (signals after noise cancellation and edge detection) or a combination of them can be output as event 2B with input edge by the settings of this register. Timer D0 to timer D9 can use this event 2B signal as the capture trigger of timer-offset base registers Dx (OSBRD0 to OSBRD9).

Timer C can use this event output 2B signal as a capture trigger.

When this function is enabled, event output selection specified by TCR1A is disabled.

21.4.2.5 NCMCR1A — Noise Cancellation Mode Channel Register 1A

2	NCM1A2	Noise Cancellation Mode of Channel 2 Specify the operation mode of noise canceler in channel 2. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (When NCMA = 0 and NCM2A2 = 0) 1: Level accumulation cancellation mode (When NCMA = 0 and NCM2A2 = 1)
1	NCM1A1	Noise Cancellation Mode of Channel 1 Specify the operation mode of noise canceler in channel 1. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (When NCMA = 0 and NCM2A1 = 0) 1: Level accumulation cancellation mode (When NCMA = 0 and NCM2A1 = 1)
0	NCM1A0	Noise Cancellation Mode of Channel 0 Specify the operation mode of noise canceler in channel 0. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (When NCMA = 0 and NCM2A0 = 0) 1: Level accumulation cancellation mode (When NCMA = 0 and NCM2A0 = 1)

NCMCR1A is an 8-bit readable/writable register that selects the operation mode of noise canceler for each channel unit.

In premature-transition cancellation mode, after an input signal level change is detected, any input signal level change in the specified period is ignored. This mode regards a signal level change in the specified period as noise after the first level change is detected.

In level accumulation cancellation mode, input signal levels are accumulated and the input level is regarded to have reached 0 or 1 when the accumulation result becomes 0 or the specified value.

Each period is specified by the noise canceler register of each channel and the noise canceler counter measures time.

Outline of noise canceling operation (example of TIA00 input signal of timer A) is shown in **Figure 21.1** (in premature-transition cancellation mode), **Figure 21.2** (in minimum time-at-level cancellation mode), and **Figure 21.3** (in level accumulation cancellation mode).

Each channel detects the edge of a signal that has passed through the noise canceler. **Figure 21.1**, **Figure 21.2**, and **Figure 21.3** show an example of detecting the rising edge of a signal that has passed through the noise canceler.

(1) NCM1A6 — Noise Cancellation Mode of Channel 6

Specify the operating mode of noise canceler in channel 6.

(2) NCM1A5 — Noise Cancellation Mode of Channel 5

Specify the operation mode of noise canceler in channel 5.

(3) NCM1A4 — Noise Cancellation Mode of Channel 4

Specify the operation mode of noise canceler in channel 4.

(4) NCM1A3 — Noise Cancellation Mode of Channel 3

Specify the operation mode of noise canceler in channel 3.

(5) NCM1A2 — Noise Cancellation Mode of Channel 2

Specify the operation mode of noise canceler in channel 2.

(6) NCM1A1 — Noise Cancellation Mode of Channel 1

Specify the operation mode of noise canceler in channel 1.

(7) NCM1A0 — Noise Cancellation Mode of Channel 0

Specify the operation mode of noise canceler in channel 0.

CAUTIONS

1. **This register is only effective when the NCMA bit of the noise cancellation mode register (NCMR) in the common control unit is 0. Furthermore, when the corresponding channel bit (NCM1Ax) in this register is set to 1, the mode can be set to premature-transition cancellation mode, minimum time-at-level cancellation mode, or level accumulation cancellation mode according to the state of the corresponding channel bit in the noise cancellation mode channel register 2A (NCMCR2A).**
2. **x is 0 to 6.**

Table 21.14 shows the truth table for setting the noise cancellation mode.

Table 21.14 Truth Table for Noise Cancellation Modes of Timer A

Channel Enable	Filter Mode		Channel Register			
TIOR2A. NCEAx	NCMR. NCMA	NCMR. NCMSEL	NCMCR1A. NCM1Ax	NCMCR2A. NCM2Ax	Mode of Cancellation	Unit of Filtering

1	0	(—)	1	0	Minimum time-at-level	Each channel
1	0	(—)	1	1	Level accumulation	Each channel
1	1	(0)	—	—	Minimum time-at-level	Each subblock
1	1	1	—	—	Level accumulation	Each subblock

Note 1. x = 0 to 6

Note 2. An enable bit (NCEAx) can be set per channel.

Methods of setting noise cancellation for timer A according to the unit of filtering (precondition: channel enable = 1)

- Settings for individual channels:
  After setting the noise cancellation mode bit (NCMA) in the noise cancellation mode register (NCMR) to 0, set even one of the noise cancellation mode channel setting bits (NCM1Ax) in noise cancellation mode channel register 1A (NCMCR1A) of timer A to 1.
- Setting for all channels:
  Set the noise cancellation mode bit (NCMA, the same bit as in “Settings for individual channels” above) in the noise cancellation mode register (NCMR) to 1 or set all of the noise cancellation mode channel setting bits (NCM1Ax) in noise cancellation mode channel register 1A (NCMCR1A) to 0.

1	NCM2A1	Noise Cancellation Mode 2 of Channel 1 Specify the operation mode of noise canceler in channel 1. 0: Minimum time-at-level cancellation mode (When NCMA = 0 and NCM1A1 = 1) 1: Level accumulation cancellation mode (When NCMA = 0 and NCM1A1 = 1)
0	NCM2A0	Noise Cancellation Mode 2 of Channel 0 Specify the operation mode of noise canceler in channel 0. 0: Minimum time-at-level cancellation mode (When NCMA = 0 and NCM1A0 = 1) 1: Level accumulation cancellation mode (When NCMA = 0 and NCM1A0 = 1)

NCMCR2A is an 8-bit readable/writable register that selects the operation mode of noise canceler for each channel unit.

In level accumulation cancellation mode, input signal levels are accumulated and the input level is regarded to have reached 0 or 1 when the accumulation result becomes 0 or the specified value.

Each period is specified by the noise canceler register of each channel and the noise canceler counter measures time.

Outline of noise canceling operation (example of TIA00 input signal of timer A) is shown in **Figure 21.1** (in premature-transition cancellation mode) and **Figure 21.3** (in level accumulation cancellation mode).

Each channel detects the edge of a signal that has passed through the noise canceler. **Figure 21.1** and **Figure 21.3** show an example of detecting the rising edge of a signal that has passed through the noise canceler.

(1) NCM2A6 — Noise Cancellation Mode 2 of Channel 6

Specify the operating mode of noise canceler in channel 6.

(2) NCM2A5 — Noise Cancellation Mode 2 of Channel 5

Specify the operation mode of noise canceler in channel 5.

(3) NCM2A4 — Noise Cancellation Mode 2 of Channel 4

Specify the operation mode of noise canceler in channel 4.

(4) NCM2A3 — Noise Cancellation Mode 2 of Channel 3

Specify the operation mode of noise canceler in channel 3.

(5) NCM2A2 — Noise Cancellation Mode 2 of Channel 2

Specify the operation mode of noise canceler in channel 2.

(6) NCM2A1 — Noise Cancellation Mode 2 of Channel 1

Specify the operation mode of noise canceler in channel 1.

(7) NCM2A0 — Noise Cancellation Mode 2 of Channel 0

Specify the operation mode of noise canceler in channel 0.

CAUTIONS

1. **This register is only effective when the NCMA bit in the noise cancellation mode register (NCMR) in the common control unit is 0 and the corresponding channel bit (NCM1Ax) in noise cancellation mode channel register 1A (NCMCR1A) of timer A is set to 1.**
2. **x = 0 to 6**

Table 21.16 shows the truth table for setting the noise cancellation mode.

Table 21.16 Truth Table for Noise Cancellation Modes of Timer A

Channel Enable	Filter Mode		Channel Register

Methods of setting noise cancellation for timer A according to the unit of filtering (precondition: channel enable = 1)

- Settings for individual channels:
  After setting the noise cancellation mode bit (NCMA) in the noise cancellation mode register (NCMR) to 0, set even one of the noise cancellation mode channel setting bits (NCM1Ax) in noise cancellation mode channel register 1A (NCMCR1A) of timer A to 1.
- Setting for all channels:
  Set the noise cancellation mode bit (NCMA, the same bit as in “Settings for individual channels” above) in the noise cancellation mode register (NCMR) to 1 or set all of the noise cancellation mode channel setting bits (NCM1Ax) in noise cancellation mode channel register 1A (NCMCR1A) to 0.

Timer I/O Control Register 1A (TIOR1A) is a 16-bit readable/writable register that sets the edge of external inputs (TIA00 to TIA06) to be detected.

TIOR1A is initialized to 0000_H by a reset.

(1) IOA0 to 6 — I/O Control A0 to 6

These bits select the edge of external inputs (TIA00 to TIA06) that is to be extracted for use in input-capture triggering. When these bits are set to 00_B, input capturing is not performed. When the bit is set to 01, 10 or 11, the contents of free-running counter A0 to A5 (TCNTA) are transferred to input capture register A0 to A6 (ICRA0 to ICRA6) on detection of the selected edge from one of the external inputs.

Edge extraction is synchronized with the PCLK clock. Make sure that the frequency of the Pφ clock is at least twice the frequency of the external input signal. Otherwise, edge extraction will not be performed correctly.

Edge extraction is performed for signals that have passed through the noise canceler. When the noise canceler is disabled, the selected edge is simply extracted from the external inputs (TIA00 to TIA06). When the noise canceler is enabled, the selected edge is extracted from the signals after noise removal.

The edge detection signals of TIA00 to TIA06 are directly output to event output 1B to 1H. TIA00 corresponds to event output 1B, TIA01 to event output 1C, TIA02 to event output 1D, TIA03 to event output 1E, TIA04 to event output 1F, TIA05 to event output 1G, and TIA06 to event output 1H respectively.

Furthermore, the edge extracted here is output to other timer modules by setting the event output 1 and event output 2 select bits (EVOSEL1, EVOSEL2) in TCR1A, the event output 1 extension select bit in TCR2A, the event output 2A extension select bit in TCR3A, and the event output 2B extension select bit in TCR4A. (Signals to be output after edge extraction are generated in positive logic.)

0	NCEA0	Noise Canceler Enable A0 0: Noise cancelers for TIA00 are disabled 1: Noise cancelers for TIA00 are enabled

Timer I/O Control Register 2A (TIOR2A) is a 32-bit readable/writable register that selects the noise canceler clock and enables and disables the noise cancelers for externally input signals (TIA00 to TIA06).

TIOR2A is initialized to 0000 0000_H by a reset.

(1) NCKGA0 to 6 — Noise Canceler Clock Select G A0 to 6

These bits select the count source clock of noise canceler counters A0 to 6 (NCNTGA0 to 6).

The noise canceler count clock selected by the noise canceler clock select bits (NCKA0 to 6) or AGCK1 can be selected as the count source clock.

(2) NCKA0 to 6 — Noise Canceler Clock Select A0 to 6

These bits select the count source clock of noise canceler counter A0 to 6 (NCNTA0 to 6).

The noise canceler count clock or the signal on clock-bus line 5 can be selected as the signal for counting. Either the Pϕ clock frequency divided by 128 or the Pϕ clock can be selected as the noise canceler count clock by setting the NCCSEL bit of the common controller.

(3) NCEA0 to 6 — Noise Canceler Enable A0 to 6

These bits enable and disable the noise cancelers for externally input signals (TIA00 to TIA06).

When a level change on externally input signals TIA00 to TIA06 is detected while this bit is set to 1, it is processed in premature-transition cancellation mode, minimum time-at-level cancellation mode, or level accumulation cancellation mode depending on the setting in the noise cancellation mode register (NCMR) of the common controller, noise cancellation mode channel register 1A (NCMCR1A) of timer A, or noise cancellation mode channel register 2A (NCMCR2A) of timer A.

In premature-transition cancellation mode, when a level change of the externally input signal is detected, the change is output as the signal whose noise is removed and the corresponding noise canceler counter (NCNTA0 to NCNTA6) is started for counting up. Subsequent level changes are masked until the value in the counter reaches the value in the noise canceler register (NCRA0 to NCRA6). The level of the externally input signal is output as the signal following noise cancellation at the time of the match in comparison.

When these bits are cleared while the counter (NCNTA0 to NCNTA6) is being incremented, counting continues until the values in the counter and the noise canceler register match. The subsequent level changes are also masked over this period.

In minimum time-at-level cancellation mode, when a level change of the externally input signal is detected, the corresponding noise canceler counter (NCNTA0 to NCNTA6) is started for counting up. If subsequent level changes are not detected until the value in the counter reaches the value in the noise canceler register (NCRA0 to NCRA6), the previously accepted level change is output as the signal following noise cancellation at the time of the match in comparison. When the subsequent level change is detected before the values in the counter and noise canceler register match, all the changes are treated as noise. Therefore the signal whose noise is removed is not changed.

When these bits are cleared while the counter (NCNTA0 to NCNTA6) is being incremented, counting continues until the values in the counter and the noise canceler register match or a level change on the externally input signal is detected.

In level accumulation cancellation mode, the corresponding noise canceler counter A0 to A6 (NCNTA0 to NCNTA6) increments or decrements according to the input signal level. It increments at the input high level and decrements at the input low level. Up-counting continues until the noise canceler counter value matches the noise canceler register A0 to A6 (NCRA0 to NCRA6) value. Down-counting continues until the noise canceler counter becomes 00_H.

If the counter is counting up, the noise canceler output is updated to 1 in response to a match in comparison (NCRA0 to NCRA6). If the counter is counting down, the noise canceler output is updated to 0 in response to a match in comparison (00_H).

In minimum time-at-level cancellation mode and premature-transition cancellation mode, level changes are always detected by Pϕ regardless of the selected noise-canceler clock. In level accumulation cancellation mode, input level sampling is performed by the clock selected by the noise canceler clock select bits A0 to A6 (NCKA0 to NCKA6).

For examples of operation in each cancellation mode, see **Figure 21.1**, **Figure 21.2**, and **Figure 21.3**.

21.4.2.9 TSRA — Timer Status Register A

Access: 8-bit accessible

Address: FFE6 0208_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	OVFA	ICFA6	ICFA5	ICFA4	ICFA3	ICFA2	ICFA1	ICFA0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.19 TSRA Register Contents

Bit Position	Bit Name	Function
7	OVFA	Overflow Flag A 0: Indicates that TCNTA has not overflowed 1: Indicates that TCNTA has overflowed
6	ICFA6	Input Capture Flag A6 0: No input capture has occurred 1: Input capture has occurred
5	ICFA5	Input Capture Flag A5 0: No input capture has occurred 1: Input capture has occurred
4	ICFA4	Input Capture Flag A4 0: No input capture has occurred 1: Input capture has occurred
3	ICFA3	Input Capture Flag A3 0: No input capture has occurred 1: Input capture has occurred
2	ICFA2	Input Capture Flag A2 0: No input capture has occurred 1: Input capture has occurred
1	ICFA1	Input Capture Flag A1 0: No input capture has occurred 1: Input capture has occurred
0	ICFA0	Input Capture Flag A0 0: No input capture has occurred 1: Input capture has occurred

The timer status register A (TSRA) is an 8-bit read-only register that indicates occurrence of overflow of the free-running counter A (TCNTA) and input capture of input capture registers A0 to A6 (ICRA0 to ICRA6).

These status flags indicate occurrence of an interrupt request, and can be cleared to 0 by setting the corresponding bit in timer status clear register A (TSCRA). When an interrupt source occurs while one of these flags is set to 1, an interrupt request is generated again. Even if flag clear by the corresponding timer status clear register conflicts with flag setting due to occurrence of an interrupt source, an interrupt request is generated.

TSRA is initialized to 00_H by a reset.

(1) OVFA — Overflow Flag A

Indicates that free-running counter A (TCNTA) has overflowed.

This flag indicates that an overflow occurred in TCNTA when this bit are read as 1. This flag can be set neither to 1 nor 0 by software.

- Setting (to 1) condition
  When TCNTA overflows (transition from FFFF $FFFF_H$ to 0000 0000_H)
- Clearing (to 0) condition
  When OVFCA in timer status clear register A (TSCRA) is set to 1

(2) ICFA0 to 6 — Input Capture Flag A0 to 6

These bits indicate that the value in free-running counter A (TCNTA) has been captured by input capture register A0 to 6 (ICRA0 to ICRA6). When one of these bits is read as 1, the value in TCNTA has been stored in the corresponding ICRA.

These bits can be set neither to 1 nor 0 by software.

- Setting (to 1) condition
  When TCNTA is transferred to ICRA0 to ICRA6 on assertion of the input capture signal (TIA00 to TIA06)
- Clearing (to 0) condition
  When ICFCA0 to ICFCA6 in timer status clear register A (TSCRA) are set to 1

21.4.2.10 TSCRA — Timer Status Clear Register A

Access: 8-bit accessible
Writing 0 is disabled. If 1 is written to this register, data is not retained. This register is always read as 0.

Address: FFE6 020A$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	OVFCA	ICFCA6	ICFCA5	ICFCA4	ICFCA3	ICFCA2	ICFCA1	ICFCA0
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.20 TSCRA Register Contents

Bit Position	Bit Name	Function
7	OVFCA	Overflow Flag Clear A Enable 0: Disabled (Initial value) 1: OVFA in the timer status register A (TSRA) is cleared to 0.
6	ICFCA6	Input Capture Flag Clear A6 Enable 0: Disabled (Initial value) 1: ICFA6 in the timer status register A (TSRA) is cleared to 0.
5	ICFCA5	Input Capture Flag Clear A5 Enable 0: Disabled (Initial value) 1: ICFA5 in the timer status register A (TSRA) is cleared to 0.
4	ICFCA4	Input Capture Flag Clear A4 Enable 0: Disabled (Initial value) 1: ICFA4 in the timer status register A (TSRA) is cleared to 0.
3	ICFCA3	Input Capture Flag Clear A3 Enable 0: Disabled (Initial value) 1: ICFA3 in the timer status register A (TSRA) is cleared to 0.
2	ICFCA2	Input Capture Flag Clear A2 Enable 0: Disabled (Initial value) 1: ICFA2 in the timer status register A (TSRA) is cleared to 0.
1	ICFCA1	Input Capture Flag Clear A1 Enable 0: Disabled (Initial value) 1: ICFA1 in the timer status register A (TSRA) is cleared to 0.
0	ICFCA0	Input Capture Flag Clear A0 Enable 0: Disabled (Initial value) 1: ICFA0 in the timer status register A (TSRA) is cleared to 0.

TSCRA is an 8-bit readable/writable register to set clearing of flags at occurrence of an overflow or input capture.

TSCRA can be read and written only in 8-bit units, but this register is always read as 0.

TSCRA is initialized to 00$_H$ by a reset.

(1) OVFCA — Overflow Flag Clear A Enable

Writing 1 to this bit while overflow flag A (OVFA) in the timer status register A (TSRA) is set to 1 clears OVFA to 0. This bit is always read as 0.

(2) ICFCA6 — Input Capture Flag Clear A6 Enable

Writing 1 to this bit while input capture flag A6 (ICFA6) in the timer status register A (TSRA) is set to 1 clears ICFA6 to 0. This bit is always read as 0.

(3) ICFCA5 — Input Capture Flag Clear A5 Enable

Writing 1 to this bit while input capture flag A5 (ICFA5) in the timer status register A (TSRA) is set to 1 clears ICFA5 to 0. This bit is always read as 0.

(4) ICFCA4 — Input Capture Flag Clear A4 Enable

Writing 1 to this bit while input capture flag A4 (ICFA4) in the timer status register A (TSRA) is set to 1 clears ICFA4 to 0. This bit is always read as 0.

(5) ICFCA3 — Input Capture Flag Clear A3 Enable

Writing 1 to this bit while input capture flag A3 (ICFA3) in the timer status register A (TSRA) is set to 1 clears ICFA3 to 0. This bit is always read as 0.

(6) ICFCA2 — Input Capture Flag Clear A2 Enable

Writing 1 to this bit while input capture flag A2 (ICFA2) in the timer status register A (TSRA) is set to 1 clears ICFA2 to 0. This bit is always read as 0.

(7) ICFCA1 — Input Capture Flag Clear A1 Enable

Writing 1 to this bit while input capture flag A1 (ICFA1) in the timer status register A (TSRA) is set to 1 clears ICFA1 to 0. This bit is always read as 0.

(8) ICFCA0 — Input Capture Flag Clear A0 Enable

Writing 1 to this bit while input capture flag A0 (ICFA0) in the timer status register A (TSRA) is set to 1 clears ICFA0 to 0. This bit is always read as 0.

21.4.2.11 ICRAx — Input Capture Registers Ax (x = 0 to 6)

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0240_H (ICRA0)
FFE6 0260_H (ICRA1)
FFE6 0280_H (ICRA2)

Table 21.21 ICRAx Register Contents

Bit Position	Bit Name	Function
31 to 0	ICAx	Input Capture Ax These bits hold 32-bit input capture value.

Note: x is an integer of 0 to 6.

Input capture registers A0 to A6 (ICRA0 to ICRA6) are 32-bit read-only registers only for input capture. No value can be written to these registers.

Input capture-dedicated registers detect an external input capture signal (TIA00 to TIA06) and store the free-running counter A (TCNTA) value. The DMAC can be activated at this input capture timing. At this time, the corresponding bit in the timer status register A (TSRA) is set to 1.

The input capture signal edge to be extracted is set by the I/O control bits in the timer I/O control register 1A (TIOR1A).

ICRA0 to ICRA6 can be read only in 32-bit units. Do not read these registers in 16-bit or 8-bit units.

ICRA0 to ICRA6 are initialized to 0000 0000_H by a reset.

21.4.2.12 TCNTA — Free-Running Counter A

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0220$_H$

Value after reset: 0000 0000$_H$

Table 21.22 TCNTA Register Contents

Bit Position	Bit Name	Function
31 to 0	CNTA	Timer Count A These bits hold the counter value in 32-bit units.

TCNTA is a 32-bit readable/writable register that counts on the signal output by the prescaler via the clock bus, externally input clock signal, or multiplied-and-corrected signal output by timer B.

Timer A is started for counting up by setting the TAE bit in the ATU-IV master enable register (ATUENR) to 1. The clock input to the counter is selected by setting the clock select bit (CKSELA) in timer control register 1A (TCR1A).

When TCNTA overflows (FFFF FFFF$_H$ to 0000 0000$_H$), an overflow interrupt is generated and the overflow flag (OVFA) in timer status register A (TSRA) is set to 1.

TCNTA can be read and written only in 32-bit units. Do not read or write TCNTA in 16-bit or 8-bit units.

TCNTA is initialized to 0000 0000$_H$ by a reset.

21.4.2.13 TILRA — Timer Input Signal Level Register A

Access: 8-bit accessible

Bit Position	Bit Name	Function
7	—	This bit is not used. Fix this bit to 0.
6 to 0	CTIAL0x	Capture Pin Level Register only for reading the TIA0x pin level capture

The timer input signal level capture register A (TILCRA) is an 8-bit read-only register that can capture and hold external input signal pin (TIA00 to TIA06) levels after noise cancellation.

Pin level is captured when TCNTB6 of timer B matches OCRB6 regardless of the setting of the IREGB6 bits in TICRB of timer B.

TILCRA can be read only in 8-bit units.

TILCRA is initialized to 00$_H$ by a reset.

21.4.2.15 NCNTAx — Noise Canceler Counters Ax (x = 0 to 6)

Table 21.25 NCNTA Register Contents

Bit Position	Bit Name	Function
15 to 0	NCNTAx	Noise Canceler Count Ax 16-bit count value

Note: x is an integer of 0 to 6.

NCNTA0 to NCNTA6 are 8-bit readable/writable registers that are started for counting up by an assertion of externally input signals (TIA00 to TIA06) as a trigger when the noise cancelers are enabled by setting the noise canceler enable bit (NCEA6 to NCEA0) in timer I/O control register 2A (TIOR2A) to 1. In level accumulation cancellation mode, these registers increment or decrement according to the external input level. The count clock for the noise cancelers or clock bus 5 is selectable as a count source by the noise canceler clock select bits (NCKA0 to NCKA6) in TIOR2A.

NCNTA0 to NCNTA6 can be read and written only in 16-bit units.

NCNTA0 to NCNTA6 are initialized to 00_H by a reset.

According to the settings of the noise cancellation mode select bit (NCMSEL) and the timer A noise cancellation mode bit (NCMA) in the noise cancellation mode register (NCMR) in the common control unit, the noise cancellation mode bits (NCM1Ax) in noise cancellation mode channel register 1A (NCMCR1A) of timer A, and the noise cancellation mode bits (NCM2Ax) in noise cancellation mode channel register 2A (NCMCR2A), these registers operate in premature-transition cancellation mode, minimum time-at-level cancellation mode, or level accumulation cancellation mode.

- Premature-transition cancellation mode

  When a level change of the externally input signal (TIA00 to TIA06) is detected while bits NCEA0 to NCEA6 are set to 1 and NCNTA0 to NCNTA6 are stopped, NCNTA0 to NCNTA6 are started for counting up. These counters are cleared to 0000_H and stopped on the first edge of the PCLK after the value in NCNTA0 to NCNTA6 matches the value in noise canceler registers A0 to A6 (NCRA0 to NCRA6).

  NCNTA0 to NCNTA6 are incremented regardless of the TAE bits in the ATU-IV master enable register (ATUENR).

The first change is output as the signal whose noise is removed and the edge is to be extracted. Subsequent level changes are masked until the value in the counter reaches the value in the noise canceler register (NCRA0 to NCRA6). The level of the externally input signal is output as the signal following noise cancellation at the time of the match in comparison.

When the NCEA bits are cleared to 0 while the counter (NCNTA0 to NCNTA6) is being incremented, counting continues until the values in the counter and the noise canceler register match. The subsequent level changes are also masked over this period.

- Minimum time-at-level cancellation mode

  When a level change of the externally input signal (TIA00 to TIA06) is detected while bits NCEA6 to NCEA0 are set to 1 and NCNTA0 to NCNTA6 are stopped, NCNTA0 to NCNTA6 are started for counting up. These counters are cleared to 0000_H and stopped on the first edge of the PCLK after the value in NCNTA0 to NCNTA6 matches the value in noise canceler registers A0 to A6 (NCRA0 to NCRA6) or after the level of the externally input signal (TIA00 to TIA06) is changed during count operation.

  NCNTA0 to NCNTA6 are incremented regardless of the TAE bits in the ATU-IV master enable register (ATUENR).

  When a change in the level of an externally input signal is detected, the corresponding noise canceler counter (NCNTA0 to NCNTA6) starts counting up. If subsequent level changes are not detected until the value in the counter reaches the value in the noise canceler register (NCRA0 to NCRA6), the previously accepted level change is output as the signal following noise cancellation at the time of the match in comparison between the counter and noise canceler register. When a subsequent level change is detected before the values in the counter and noise canceler register match, the signal is treated as noise. The output signal from which noise has been removed is not changed in this case.

  When the NCEA bits are cleared to 0 while the counter (NCNTA0 to NCNTA6) is being incremented, counting continues until the values in the counter and the noise canceler register match or a change in the level of the externally input signal is detected.

- Level accumulation cancellation mode

  While NCEA0 to NCEA6 bits are set to 1, NCNTA0 to NCNTA6 increment or decrement according to the input signal level. When the input level is high, NCNTA0 to NCNTA6 increment. When the counter value matches the noise canceler register A0 to A6 (NCRA0 to NCRA6) value, up-counting stops on the next PCLK. When the input level is low, NCNTA0 to NCNTA6 decrement. When the counter value reaches 0000_H, down-counting stops on the next PCLK.

  NCNTA0 to NCNTA6 count regardless of the TAE bit value in the ATU-IV master enable register (ATUENR).

  When the counter value matches the NCRA0 to NCRA6 value during up-counting, the noise canceler output is updated to 1. When the counter value reaches 0000_H during down-counting, the noise canceler output is updated to 0.

  When the NCEA bit is cleared during counting, the noise canceler counter stops working and the value changes from the noise canceler output to the input signal level at that time.

  For this reason, note that when clearing the NCEA bit in level accumulation cancellation mode, edge detection may be made at this changeover.

21.4.2.16 NCRAx — Noise Canceler Registers Ax (x = 0 to 6)

Access: 16-bit accessible but 8-bit inaccessible

Table 21.26 NCRAx Register Contents

Bit Position	Bit Name	Function
15 to 0	NCTAx	Noise Canceler Count Ax TIA0x noise cancellation period (16-bit comparison value)

Note: x is an integer of 0 to 6.

NCRA0 to NCRA6 are 16-bit readable/writable registers that set the upper limitations of noise cancel counters Ax (NCNTA0 to NCNTA6). For example, when the noise canceler is driven by the PCLK divided by 128 and these registers are set to FFFF$_H$, a pulse whose width is 0.21 s (when PCLK is 40 MHz) can be treated as noise.

According to the settings of the noise cancellation mode select bit (NCMSEL) and the timer A noise cancellation mode bit (NCMA) in the noise cancellation mode register (NCMR) in the common control unit, the noise cancellation mode bits (NCM1Ax) in noise cancellation mode channel register 1A (NCMCR1A) of timer A, and the noise cancellation mode bits (NCM2Ax) in noise cancellation mode channel register 2A (NCMCR2A), these registers operate in premature-transition cancellation mode, minimum time-at-level cancellation mode, or level accumulation cancellation mode.

- Premature-transition cancellation mode

  While NCNTAx is in count operation, the level change of the subsequent input signal is masked. Values of NCNTAx and NCRAx are constantly compared. When these values match, the NCNTAx count value is cleared on the next PCLK, the counter stops, and the input signal mask is canceled.

- Minimum time-at-level cancellation mode

  While NCNTA0 to NCNTA6 are in count operation, noise canceler processing waiting state is entered. Values in NCNTA0 to NCNTA6 and NCRA0 to NCRA6 are constantly compared. When these values match, the NCNTA0 to NCNTA6 count value is cleared on the next PCLK, the counter stops, and at the same time the noise canceler outputs the input signal that has passed through the noise canceling processing.

- Level accumulation cancellation mode

  While NCNTA0 to NCNTA6 are in up-count operation, values of NCNTA0 to NCNTA6 and NCRA0 to NCRA6 are compared. When these values match, the NCNTA0 to NCNTA6 stop up-counting on the next PCLK. While NCNTA0 to NCNTA6 are in down-count operation, the NCNTA0 to NCNTA6 value is compared with 0000_H.

  NCRA0 to NCRA6 can be read and written only in 16-bit units.

  NCRA0 to NCRA6 are initialized to 0000_H by a reset.

21.4.3 Detailed Operation

21.4.3.1 Operation of Noise Canceler

The noise canceller has three operating modes. Settings for the noise cancellation mode register (NCMR) in the common controller and of noise cancellation mode channel register 1A (NCMCR1A) and noise cancellation mode channel register 2A (NCMCR2A) of timer A select premature-transition cancellation mode, minimum time-at-level cancellation mode, or level accumulation cancellation mode.

Figure 21.7 shows an example of operations for noise cancellation in premature-transition cancellation mode, and **Figure 21.9** shows an example of operations for noise cancellation in minimum time-at-level cancellation mode. These figures show the situation where the settings are for detection of edges and for the edges to be rising in the signal input to TIA00.

In premature-transition cancellation mode, counting by noise cancellation counter Ax (NCNTAx) starts in response to a change in the level of the input signal as a trigger. At the same time as counting starts, its change in the level of the input signal is output as the signal after noise cancellation.

Counting continues until the value in the counter matches that in noise cancellation register Ax (NCRAx). All changes in the level of the input signal are ignored over this period and are not output in the signal following processing for noise cancellation.

The level being input at the time the value of the counter has matched that of the noise cancellation register is then output as the signal following processing for noise cancellation. Accordingly, note that the levels following processing for noise cancellation are changed on the compare match when the input levels at the start of counting (level following a change of level) and on the compare match differ.

Figure 21.8 shows an example of noise cancellation for two type of input waveforms in premature-transition cancellation mode.

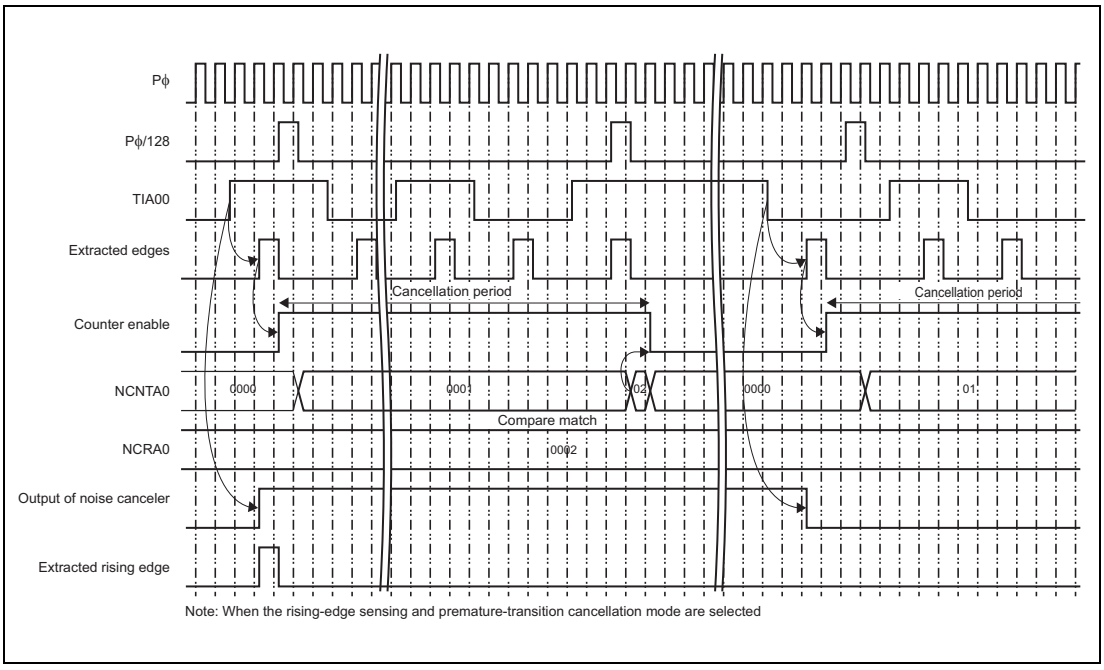

Figure 21.7 Example of Noise Cancellation in Premature-Transition Cancellation Mode

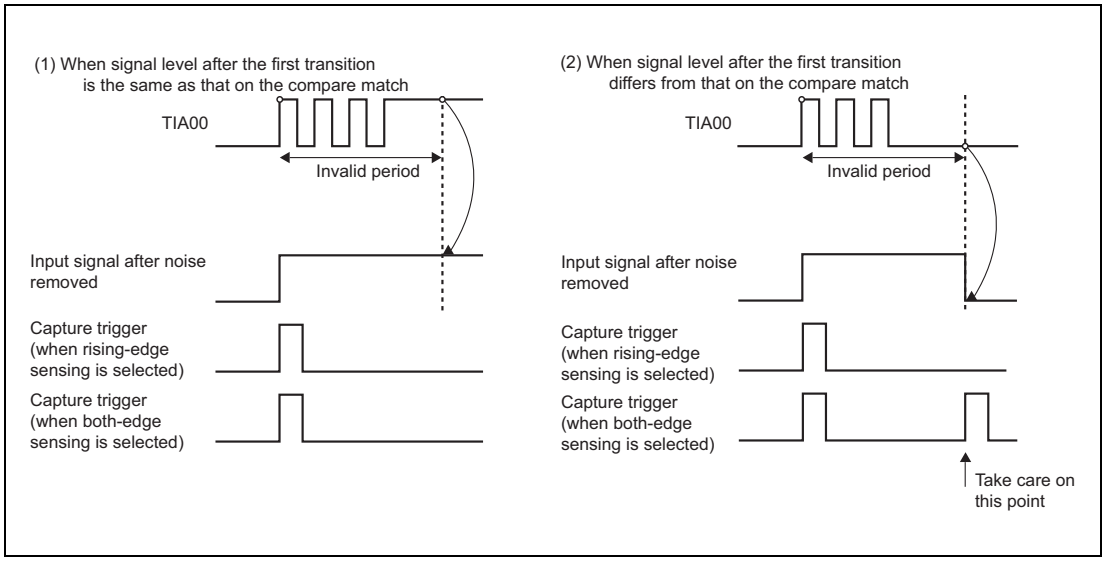

Figure 21.8 Example of Noise Cancellation in Premature-Transition Cancellation Mode for Two Types of Input Waveforms

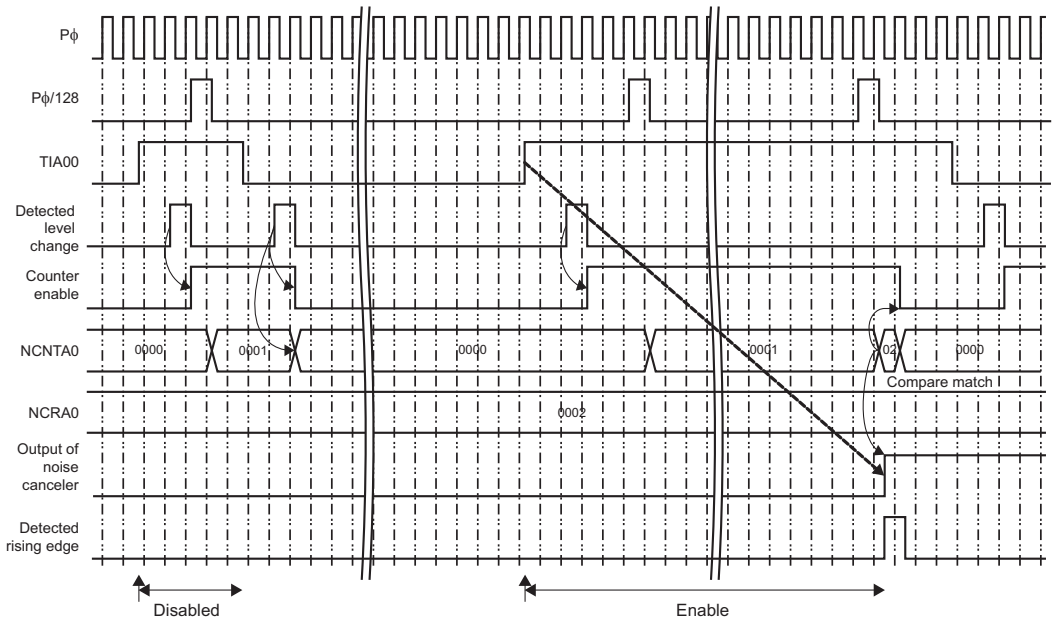
In minimum time-at-level cancellation mode, counting by noise cancellation counter Ax (NCNTAx) starts in response to a change in the level of the input signal as a trigger. Counting continues until the value counted matches that of the noise cancellation register Ax (NCRAx) or until the level of the input signal changes.

When the value of the counter matches that of the noise cancellation register, a change in the level of the input at the start of counting is output as the signal following noise cancellation. If the level of the input signal changes before the values of the counter and of the noise cancellation register match, its change and the change of level from that when counting started are deemed to be noise, and are not output in the signal following noise cancellation.

Figure 21.10 shows an example of shows an example of operations for noise cancellation in level accumulation cancellation mode. These figures show the situation where the settings are for detection of edges and for the edges to be rising in the signal input to TIA00.

In level accumulation cancellation mode, whether noise cancellation counter Ax (NCNTAx) counts up or down depends on the level of the input signal. If the counter is counting up, this continues until the value counted matches that of noise cancellation register Ax (NCNTAx), or if it is counting down, this continues until the value counted matches 0000_H.

Updating of the output of the noise canceller proceeds when there are matches in comparison. When the value of the counter matches that of NCRAx during up-counting, the noise canceller output value is updated to 1, and when the value of the counter matches 0000_H during down-counting, the noise canceller output value is updated to 0.



Note: Rising-edge sensing and minimum time-at-level cancellation mode are selected in this example.

Figure 21.9 Example of Noise Cancellation in Minimum Time-at-Level Cancellation mode

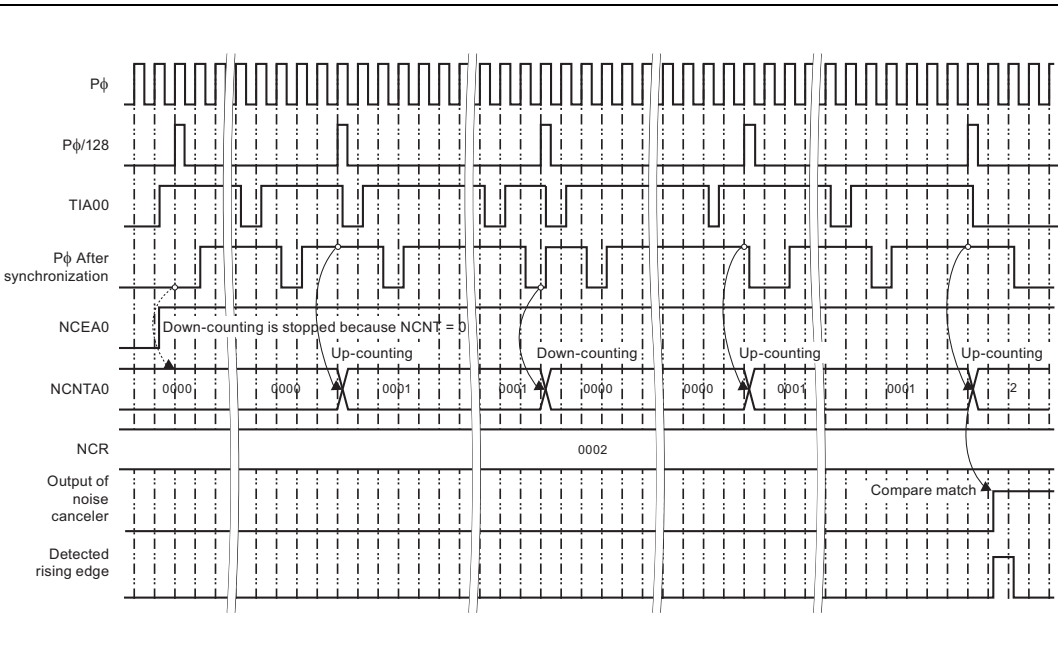


Figure 21.10 Example of Noise Cancellation in Level Accumulation Cancellation Mode

21.4.3.2 Operation of Free-Running Counter

Free-running counter A (TCNTA) is started for counting up by setting the TAE bit in ATU-IV master enable register (ATUENR) to 1. When TCNTA overflows (from FFFF FFFF$_H$ to 0000 0000$_H$), the OVFA bit in timer status register A (TSRA) is set to 1. An interrupt request is issued to the CPU at the time. After overflow, TCNTA continues counting up from 0000 0000$_H$.

When the TAE bit in ATU-IV master enable register (AUTENR) is cleared to 0, TCNTA is stopped but is not cleared. By setting the TAE bit to 1 again, TCNTA is resumed from the value when stopped.

TCNTA can be written during operation and writing takes priority over counting. After that, TCNTA is started from the written value. Regardless of the clock driving the counter, the write access is completed in two cycles of the PCLK clock.

CAUTION

The prescalers run regardless of the TAE bit and are not synchronized with the timing at which the TAE bit is set. Therefore, the time from when the TAE bit is set to when TCNTA is incremented for the first time is less than the cycle of the clock of TCNTA.

Figure 21.11 shows an example of free-running counter A (TCNTA) operation.

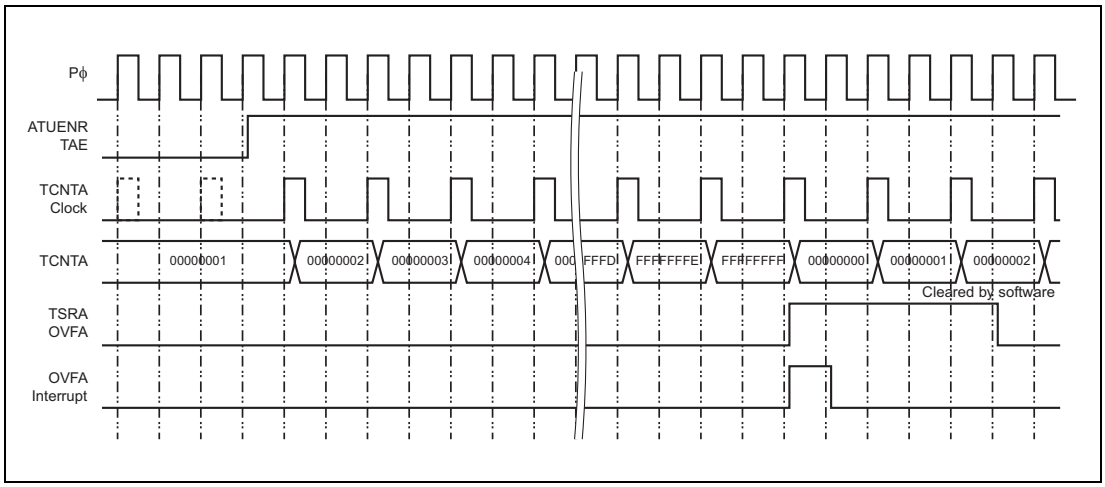

Figure 21.11 Example of Free-Running Counter A (TCNTA) Operation: Overflow Timing

21.4.3.3 Input Capture

Input capture is performed by input capture registers A0 to A6 (ICRA0 to ICRA6) when input capture is enabled in bits IOA6 to IOA0 in timer I/O control register 1A (TIOR1A). ICRA0 to ICRA6 capture the value in free-running counter A (TCNTA) by an edge of externally input signals (TIA00 to TIA06).

Noise on the signals can be removed by the noise cancelers. TCNTA is started for counting up by setting the TAE bit in ATU-IV master enable register (ATUENR). When an edge is input on the corresponding signal, the bit in timer status register (TSRA) is set to 1 and the value in TCNTA is transferred to ICRA. The rising or falling edge, or both edges can be selected. At this time, it is also possible to output an interrupt request to the CPU, and start DMA transfer.

When input capture registers and free-running counter A (TCNTA) are written simultaneously, ICRA0 to ICRA6 capture the previous value stored in TCNTA.

Figure 21.12 shows an example of input capture when the edges to be sensed are rising edges for TIA00, falling edges for TIA01, and both edges for TIA02.

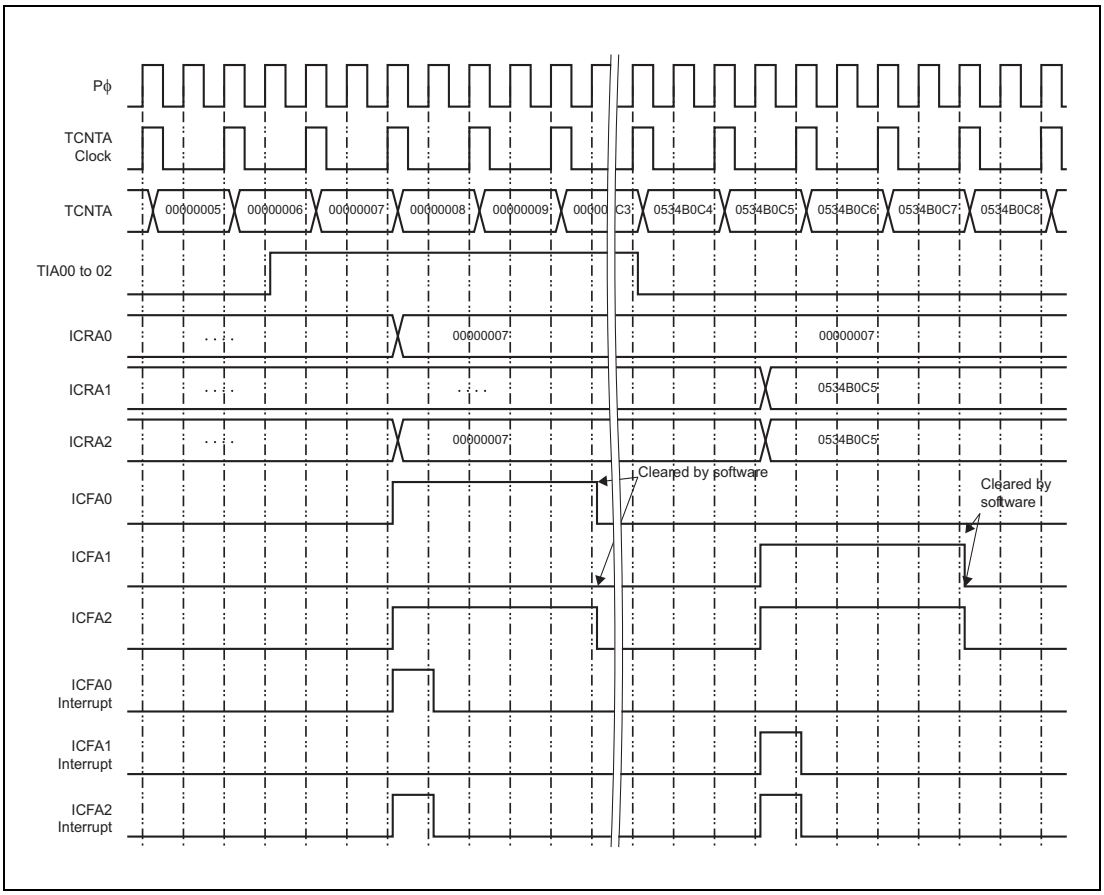

Figure 21.12 Example of Input Capture of Timer A

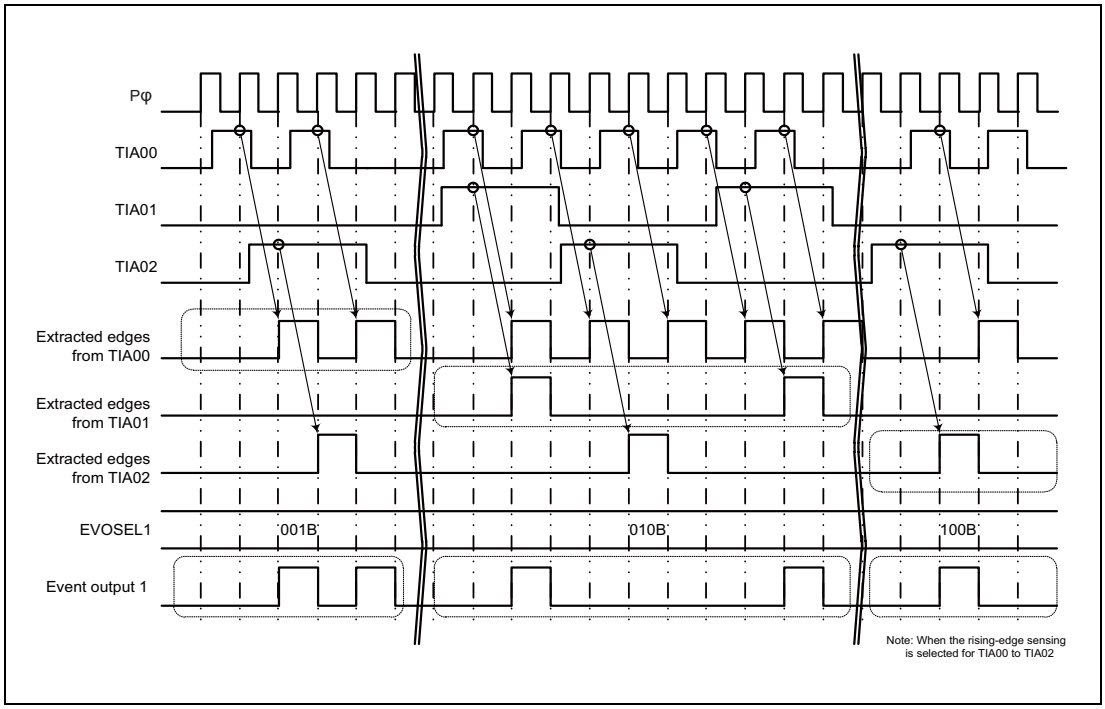

Figure 21.13 Example of TIA00 to TIA02 Event Output

By setting the EVOSEL1 bit in timer control register 1A (TCR1A), any one of edges of external input pins TIA00 to TIA02 can be detected and signals after noise cancellation can be output to timer B and timer C as an event. Furthermore, either TIA01 or TIA02 (signal after edge detection and noise cancellation) can be output to timer C and timer D as an event by setting the EVOSEL2 bit and EVOSEL2B bit. In addition, any one of external input pins TIA00 to TIA06 or a combination of them (signals after edge detection and noise cancellation) can be output as an event to timer B and timer C by setting the EVOSELE1E and EVOSELE1 bits in timer control register 2A (TCR2A). Any one of external input pins TIA00 to TIA06 or a combination of them (signals after edge detection and noise cancellation) can be output as an event to timer C and timer D by setting the EVOSELE2AE and EVOSELE2A bits in timer control register 3A (TCR3A) and the EVOSELE2BE and EVOSELE2B bits in timer control register 4A (TCR4A).

Figure 21.13 shows an example of event output operation in case EVOSEL1 is set to 001_B (TIA00 input edge output), 010_B (TIA01 input edge output), and 100_B (TIA02 input edge output).

21.4.3.4 Pin Level Capture Operation

Levels of the external input pins (TIA00 to TIA06) after noise cancellation can be read from the timer input signal level register A (TILRA). Furthermore, the value of the timer input signal level registerA (TILRA) can be captured to the timer input signal level capture register A (TILCRA). The value is captured from TILRA to TILCRA by the missing-tooth detection trigger at the timing of compare match between TCNTB6 and OCRB6 of timer B. **Figure 21.14** shows an example of operation of the TILRA register and the TILCRA capture triggered by missing-tooth detection when signals are input to TIA00 to TIA06.

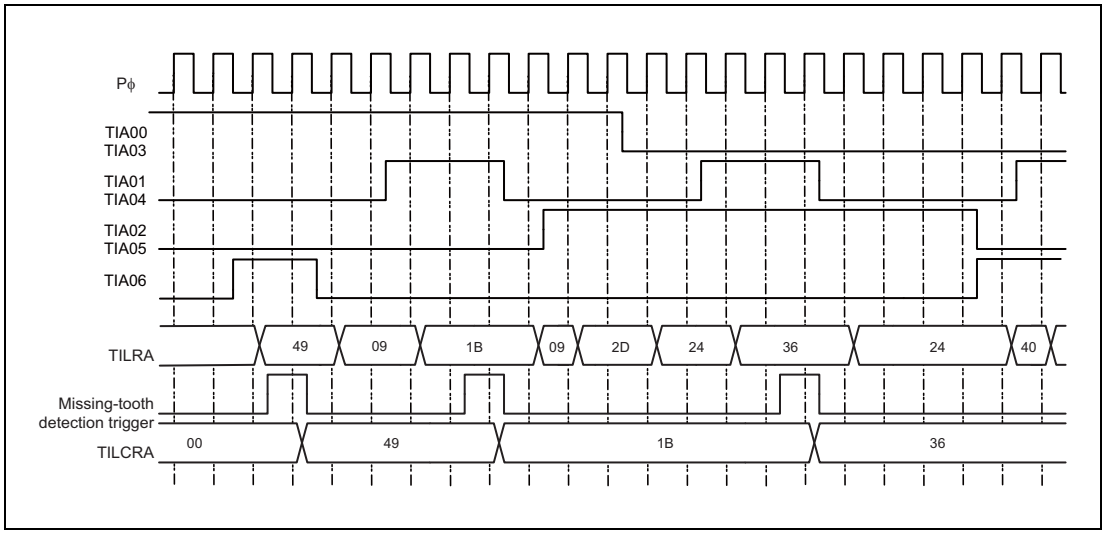

Figure 21.14 Example of TILCRA Capture Operation

21.4.3.5 DMA Transfer

Setting the DMAC allows it to be activated by input capture operation of timer A.

21.5 Timer B

21.5.1 Operation

Timer B generates a multiplied-and-corrected clock signal based on an external-event input and supplies the generated signal to other timers. Timer B consists of an edge-interval measuring block, frequency-multiplying clock generator, and corrector for the frequency-multiplied clock signal.

Edge-Interval Measuring Block

The edge-interval measuring block measures the intervals between edges of external-event signals input via timer A (TCNTB0, ICRB0). Interrupt requests can be issued for the CPU in response to matches between edge interval measuring counter B0 (TCNTB0) and output compare register B0 (OCRB0). TCNTB0 can also be captured in ICRB2 via ICRB1 on matches between event counter B1 (TCNTB1) and output compare register B1 (OCRB1). Counting by TCNTB1 is driven by the external-event input. This provides a way to measure the intervals between multiple event inputs. Although TCNTB0 is cleared every event input, ICRB1 keeps a running total of the TCNTB0 value. ICRB2 latches the running totals on compare matches of the event counter. Furthermore, it is also possible to set the value of the event counter B1 (TCNTB1) that uses an external event input as a count source to 01_H by the CLRB1 bit(TCNTB1 clear bit) in the timer control register B (TCRB) at the next external event input timing after an event compare match with OCRB10. Furthermore, up to seven capture values (ICRB0) can be retained in record registers B-1 to 6 (RECRB1 to RECRB6) at the external input event timing. Values retained in ICRB0 and RECRB1 to RECRB6 can be backed up in record backup registers B 0 to 6 (RBURB0 to RBURB6) on event compare match between the event counter B1 (TCNTB1) and OCRB12.

In the edge-interval measuring block, the event counter B1(TCNTB1) value is captured for the event counter B1(TCNTB1) at occurrence of any of seven external event input signals 1_B to 1_H that are input via timer A (ICRB30 to ICRB36). The event counter B1(TCNTB1) is not cleared at occurrence of any of external event input signals 1_B to 1_H.

Frequency-Multiplied Clock Generator

The frequency-multiplied clock generator generates a clock signal obtained by frequency-multiplying an external-event input signal by a value from 1 to 4095.

In the edge-interval measuring block, down-counting (TCNTB2) with reload (RLDB) is performed for the capture value (ICRB0) in the input edge-interval measuring counter B0 (TCNTB0). Down-counting is performed by the set division ratio value specified in the PIMR select register. In addition to PIMR1, a division ratio value of PIMR2 can be selected by an event compare match between the event counter B1 (TCNTB1) in the edge-interval measuring block and OCRB11. When the down counter underflows, the multiplied clock (AGCK1) signal is asserted.

TCNTB6 is a measuring counter using the multiplied clock as a source clock, and an interrupt request to the CPU can be output due to the compare match with OCRB6. ICRB6 is a capture register, and this TCNTB6 value is captured when an external event input occurs.

TCNTB6M is a measuring counter using the multiplied clock as a source clock. The up-count value can be set within a range from 0 to less than 4 in units of 1/64. When an external event input occurs, the TCNTB6M value is compared with the ICRB6 value. When the TCNTB6M value is smaller than the ICRB6 value, an interrupt request to the CPU can be output.

Frequency-Multiplied Clock Signal Corrector

The multiplied clock signal (AGCK1) needs to be corrected when two consecutive edge intervals differ significantly, since the earlier interval is referred to in calculating the multiplier for the current interval. The frequency-multiplied clock signal corrector generates a multiplied-and-corrected clock signal (AGCKM) by using three correcting counters (TCNTB3 to TCNTB5) and correcting counter clearing register B (TCCLRB). Output of the clock signal thus produced on clock-bus line 5 can be selected by using the clock-bus control register (CBCNT). Other timers can then use this clock as a source for counting. For the automatic up-counting function that continues counting until the multiplied-and-corrected clock generating counter B5 (TCNTB5) value matches the correcting counter clear register B (TCCLRB) value when the multiplied-and-corrected clock (AGCKM) is generated, whether to enable or disable this function is selectable. Furthermore, the correcting counter B3 (TCNTB3) can be automatically cleared by the CLRB3 bit (TCNTB3 clear bit) in the timer control register B (TCRB) at the timing of an event compare match between the event counter B1 (TCNTB1) in the edge-interval measuring block and OCRB10 or between the correcting event counter B3 (TCNTB3) and OCRB8.

Setting ACRTRG in the AGCKM2 correction enable setting register (ACRTRGB) to 1 corrects the multiplied-and-corrected clock (AGCKM). The multiplied-and-corrected clock 2 (AGCKM2) corrected from AGCKM is output by operation of the internal AGCKM2 counter according to the AGCKM2 correction clock count setting register (ACRVALRB).

The internal AGCKM2 counter keeps operating even in the break state caused by the debugger during counting. To stop counting of the internal AGCKM2 counter, set ACRCLR in the AGCKM2 correction clear setting register (ACRCLRB) to 1.

Figure 21.15 is a block diagram of timer B.

TCRB is an 8-bit readable/writable register that allows you to select a count source for the input edge interval measuring counter B0 (TCNTB0) and the reload counter B2 (TCNTB2), select whether to clear the TCNTB1 and TCNTB3 values at the time of a match in comparison between TCNTB1 and OCRB10 or of that between TCNTB6 and OCRB6, and to select a pulse interval multiplier.

TCRB can be read and written in 8-bit units.

TCRB is initialized to 00_H by a reset.

(1) CKSELB — Clock Select B

These bits select the clock driving TCNTB0 and TCNTB2 from clock-bus lines 0 to 3, which are clock signals divided by prescalers 0 to 3. The counters are incremented on the rising edge of the selected clock.

To select the clock, stop timer B operation.

(2) PIMRSEL — Pulse Interval Multiplier Select

By setting the PIMRSEL bit to 1 while TCNTB1 matches OCRB11, PIMR2 is selected for down-count values to be loaded to reload register B (RLDB) or for down-count values of TCNT2B. In other cases, PIMR1 is selected. However, PIMR1 is always used for adding the TCNTB3 value.

While the PIMRSEL bit is 0, PIMR1 is always used.

(3) CLRB1 — TCNTB1 Clear

Setting the TCNTB1 clear bit (CLRB1) to 1 clears the TCNTB1 value at the timing of the first event input after a match in comparison between TCNTB1 and OCRB10 or between TCNTB6 and OCRB6 for the CLRB1SEL setting condition.

(4) CLRB3 — TCNTB3 Clear

Setting the TCNTB3 clear bit (CLRB3) to 1 clears the TCNTB3 value in synchronization with the first PCLK after a match in comparison between TCNTB1 and OCRB10, between TCNTB6 and OCRB6, or between TCNTB3 and OCRB8 for the CLRB3SEL setting condition.

(5) CLRB1SEL — TCNTB1 Clear Select

Setting the TCNTB1 clear select bit (CLRB1SEL) sets the TCNTB1 clearing condition. When CLRB1SEL is 0, TCNTB1 can be cleared in response to a match in comparison between TCNTB1 and OCRB10. When CLRB1SEL is 1, TCNTB1 can be cleared in response to a match in comparison between TCNTB6 and OCRB6.

(6) CLRB3SEL — TCNTB3 Clear Select

Setting the TCNTB1 clear select bit (CLRB3SEL) sets TCNTB3 clearing condition. When CLRB3SEL is 00, TCNTB3 can be cleared in response to a match in comparison between TCNTB1 and OCRB10. When CLRB3SEL is 01, TCNTB3 can be cleared in response to a match in comparison between TCNTB6 and OCRB6. When CLRB3SEL is 10, TCNTB3 can be cleared in response to a match in comparison between TCNTB3 and OCRB8.

Table 21.28 TIORB Register Contents

Bit Position	Bit Name	Function
7	LDSEL	Loading Data Select 0: ICRB0 value is used to calculate the data to be loaded to TCNTB2 and RLDB. 1: LDB value is used to calculate the data to be loaded to TCNTB2 and RLDB.
6	CTCNTB5	Count Control B5 0: TCNTB5 is in operation 1: TCNTB5 is stopped
5	EVCNTB	Event Control B 0: Disables the externally input events 1: Enables the externally input events
4	LDEN	Load Enable 0: TCNTB2 and RLDB are updated on ICEB0 input capture 1: TCNTB2 and RLDB are not updated on ICEB0 input capture
3	CCS	Counter Correction Select 0: TCNTB4 is in operation when TCNTB3 = TCNTB4 1: TCNTB4 is stopped when TCNTB3 = TCNTB4
2, 1	—	These bits are not used. Fix these bits to 0.
0	IOB6	I/O Control B6 0: Compare match between TCNTB6 and OCRB6 is disabled 1: Compare match between TCNTB6 and OCRB6 is enabled

TIORB is an 8-bit readable/writable register that selects the source of the frequency-multiplied clock and enables and disables the externally input signals, loading data, and correcting frequency multiplied clock. TIORB also controls multiplied-and-corrected clock generating counter B5 (TCNTB5) and output compare register B6 (OCRB6).

TIORB can be read and written in 8-bit units.

TIORB is initialized to 00_H by a reset.

(1) LDSEL — Loading Data Select

Selects the register to be loaded to reload counter B2 (TCNTB2) and to be used for calculating data to be loaded to reload register B (RLDB) from ICRB0 or LDB.

(2) CTCNTB5 — Count Control B5

Selects whether the multiplied-and-corrected clock generating counter B5 (TCNTB5) is enabled or stopped.

Setting this bit to 1 stops TCNTB5 and the multiplied-and-corrected clock to be output to other timers. Even if the counter is stopped, it is not cleared. Clearing this bit to 0 resumes TCNTB5 and multiplied-and-corrected clock.

(3) EVCNTB — Event Control B

Disables and enables the externally input events. Clearing this bit to 0 disables the input. Setting this bit to 1 enables the input with which input capture or generating the multiplied-and-corrected clock signal.

(4) LDEN — Load Enable

Selects whether to update the input capture register B0 (ICRB0) value, the reload counter B2 (TCNTB2) value, and the reload register B (RLDB) value at the input capture of the input edge interval measuring counter B0 (TCNTB0).

(5) CCS — Counter Correction Select

Selects whether or not correcting multiplied clock counter B4 (TCNTB4) is stopped when TCNTB3 = TCNTB4.

(6) IOB6 — I/O Control B6

Enables and disables compare match between TCNTB6 and OCRB6. When this bit is cleared to 0, compare match between TCNTB6 and OCRB6 is disabled. When it is set to 1, compare match between TCNTB6 and OCRB6 is enabled. At this time, an interrupt request is output to the CPU in response to a match in comparison.

21.5.2.3 TSRB — Timer Status Register B

Access: 8-bit and 16-bit accessible

Address: FFE6 0404_H

Value after reset: 0000_H

Table 21.29 TSRB Register Contents

Bit Position	Bit Name	Function
15 to 10	—	These bits are not used. Fix these bits to 0.
9	CMFB6E	Compare Match Flag B6E 0: Function is not selected or there are no matches in comparison. 1: A match in comparison has occurred under the condition set for IREGB6E in TICRB.
8	CMFB6M	Compare Match Flag B6M 0: The TCNTB6M value is the ICRB6 value or larger. 1: When the TCNTB6M value is smaller than ICRB6, the next event input occurs.
7	—	This bit is not used. Fix these bits to 0.
6	CMFB12	Compare Match Flag B12 0: There are no matches in comparison. 1: A match in comparison has occurred.
5	CMFB11	Compare Match Flag B11 0: No input capture has occurred. 1: Input capture has occurred.
4	CMFB10	Compare Match Flag B10 0: There are no matches in comparison. 1: A match in comparison has occurred.
3	CMFB6	Compare Match Flag B6 0: There are no matches in comparison. 1: A match in comparison has occurred.
2	CMFB1	Compare Match Flag B1 0: There are no matches in comparison. 1: A match in comparison has occurred.
1	ICFB0	Input Capture Flag B0 0: No input capture has occurred. 1: Input capture has occurred.
0	CMFB0	Compare Match Flag B0 0: There are no matches in comparison. 1: A match in comparison has occurred.

The timer status register B (TSRB) is a 16-bit read-only register that indicates occurrence of input capture and compare match. These status flags indicate occurrence of an interrupt request, and can be cleared to 0 by setting the corresponding bit in timer status clear register B (TSCRB). When an interrupt source occurs while one of these flags is set to 1, an interrupt request is generated again. Even if flag clear by the corresponding timer status clear register conflicts with flag setting due to occurrence of an interrupt source, an interrupt request is generated.

Supplement: Even if a match in comparison between TNTB6 and OCRB6 occurs while the CMFB6 flag is set, the CMFB6 bit does not generate OCRB6 compare match interrupt.

TSRB can be read and written only in 8-bit or 16-bit units.

TSRB is initialized to 0000_H by a reset.

(1) CMFB6E — Compare Match Flag B6E

This status flag indicates that both (or one of) CMFB6 and CMFB6M flags have been set by the setting for IREGB6E in the timer interrupt control register B (TICRB). When 1 is read from this flag, it shows that both (or one of) CMFB6 and CMFB6M flags have been set. This flag cannot be set to 1 or 0 by the software.

- Setting (to 1) condition
  When a CMFB6E interrupt request has occurred by the setting of IREGB6E in the timer interrupt control register B (TICRB). For details, see the description of the setting for IREGB6E in TICRB.
- Clearing (to 0) condition
  Writing 1 to CMFCB6E in timer status clear register B (TSCRB)

(2) CMFB6M — Compare Match Flag B6M

This status flag indicates that the multiplied clock counter B6M (TCNTB6M) value was smaller than the input capture register B6 (ICRB6) value at the external input event timing. When 1 is read from this flag, the TCNTB6M value is not larger than the ICRB6 value and the next event input has occurred. This flag cannot be set to 1 or 0 by the software.

- Setting (to 1) condition
  When the TCNTB6M count value does not exceed the ICRB6 value and the next event input has occurred
- Clearing (to 0) condition
  Writing 1 to CMFCB6M in timer status clear register B (TSCRB)

(3) CMFB12 — Compare Match Flag B12

This status flag indicates occurrence of a match in comparison with output compare register B12 (OCRB12). When 1 is read from this flag, it shows that a match in comparison has occurred in CMFB12. This flag cannot be set to 1 or 0 by the software.

- Setting (to 1) condition
  When the TCNTB1 count value matches the OCRB12 value and the next PCLK has occurred
- Clearing (to 0) condition
  Writing 1 to CMFCB12 in timer status clear register B (TSCRB)

(4) CMFB11 — Compare Match Flag B11

This status flag indicates occurrence of a match in comparison with output compare register B11 (OCRB11). When 1 is read from this flag, it shows that a match in comparison has occurred in CMFB11. This flag cannot be set to 1 or 0 by the software.

- Setting (to 1) condition
  When the TCNTB1 count value matches the OCRB11 value and the next PCLK has occurred
- Clearing (to 0) condition
  Writing 1 to CMFCB11 in timer status clear register B (TSCRB)

(5) CMFB10 — Compare Match Flag B10

This status flag indicates occurrence of a match in comparison with output compare register B10 (OCRB10). When 1 is read from this flag, it shows that a match in comparison has occurred in CMFB10. This flag cannot be set to 1 or 0 by the software.

- Setting (to 1) condition
  When the TCNTB1 count value matches the OCRB10 value and the next PCLK has occurred
- Clearing (to 0) condition
  Writing 1 to CMFCB10 in timer status clear register B (TSCRB)

(6) CMFB6 — Compare Match Flag B6

This status flag indicates occurrence of a match in comparison with output compare register B6 (OCRB6). When 1 is read from this flag, it shows that a match in comparison has occurred in CMFB6. This flag cannot be set to 1 or 0 by the software.

This flag is automatically cleared to 0 in response to a match in comparison with OCRB7 only when IREGB6 in TICRB is set to 10.

- Setting (to 1) condition
  When the TCNTB6 count value matches the OCRB6 value and the next AGCK1 has occurred with compare match enabled by the IOB6 bit in timer I/O control register B (TIORB)
- Clearing (to 0) condition
  - Writing 1 to CMFCB6 in timer status clear register B (TSCRB)
  - Automatically cleared to 0 in response to a match in comparison with OCRB7 when IREGB6 = 10.

(7) CMFB1 — Compare Match Flag B1

This status flag indicates occurrence of a match in comparison with output compare register B1 (OCRB1). When 1 is read from this flag, it shows that a match in comparison has occurred in CMFB1. This flag cannot be set to 1 or 0 by the software.

- Setting (to 1) condition
  When the TCNTB1 count value matches the OCRB1 value and the next PCLK has occurred
- Clearing (to 0) condition
  Writing 1 to CMFCB1 in timer status clear register B (TSCRB)

(8) ICFB0 — Input Capture Flag B0

This status flag indicates occurrence of an input capture of input capture register B0 (ICRB0). When 1 is read from this flag, it shows that an input capture has occurred in ICRB0. This flag cannot be set to 1 or 0 by the software.

- Setting (to 1) condition
  When the TCNTB0 value has been transferred to ICRB0 at an input capture trigger due to an external event
- Clearing (to 0) condition
  Writing 1 to ICFCB0 in timer status clear register B (TSCRB)

(9) CMFB0 — Compare Match Flag B0

This status flag indicates occurrence of a match in comparison with output compare register B0 (OCRB0). When 1 is read from this flag, it shows that a match in comparison has occurred in CMFB0. This flag cannot be set to 1 or 0 by the software.

- Setting (to 1) condition
  When the TCNTB0 count value matches the OCRB0 value and the next clock set by the prescaler has occurred
- Clearing (to 0) condition
  Writing 1 to CMFCB0 in the timer status clear register B (TSCRB)

21.5.2.4 TSCRB — Timer Status Clear Register B

Access: 8-bit and 16-bit accessible
Writing 0 is disabled. When 1 is written to this register, data is not retained. This register is always read as 0.

Address: FFE6 0406_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 21.30 TSCRB Register Contents

Bit Position	Bit Name	Function
15 to 10	—	These bits are not used. Fix these bits to 0.
9	CMFCB6E	Compare Match Flag Clear B6E Enable 0: Disabled (Initial value) 1: CMFB6E in timer status register B (TSRB) is cleared to 0.
8	CMFCB6M	Compare Match Flag Clear B6M Enable 0: Disabled (Initial value) 1: CMFB6M in timer status register B (TSRB) is cleared to 0.
7	—	This bit is not used. Fix these bits to 0.
6	CMFCB12	Compare Match Flag Clear B12 Enable 0: Disabled (Initial value) 1: CMFB12 in timer status register B (TSRB) is cleared to 0.
5	CMFCB11	Compare Match Flag Clear B11 Enable 0: Disabled (Initial value) 1: CMFB11 in timer status register B (TSRB) is cleared to 0.
4	CMFCB10	Compare Match Flag Clear B10 Enable 0: Disabled (Initial value) 1: CMFB10 in timer status register B (TSRB) is cleared to 0.
3	CMFCB6	Compare Match Flag Clear B6 Enable 0: Disabled (Initial value) 1: CMFB6 in timer status register B (TSRB) is cleared to 0.
2	CMFCB1	Compare Match Flag Clear B1 Enable 0: Disabled (Initial value) 1: CMFB1 in timer status register B (TSRB) is cleared to 0.
1	ICFCB0	Input Capture Flag Clear B0 Enable 0: Disabled (Initial value) 1: ICFB0 in timer status register B (TSRB) is cleared to 0.
0	CMFCB0	Compare Match Flag Clear B0 Enable 0: Disabled (Initial value) 1: CMFB0 in timer status register B (TSRB) is cleared to 0.

The timer status clear register B (TSCRB) is a 16-bit readable/writable register to set clearing of flags at occurrence of an input capture or compare match.

TSCRB can be read and written only in 16-bit units, but this register is always read as 0.

TSCRB is initialized to 0000_H by a reset.

(1) CMFCB6E — Compare Match Flag Clear B6E Enable

Writing 1 to this bit while the compare match flag B6E (CMFB6E) in timer status register B (TSRB) is set to 1 clears CMFB6E to 0. This bit is always read as 0.

(2) CMFCB6M — Compare Match Flag Clear B6M Enable

Writing 1 to this bit while the compare match flag B6M (CMFB6M) in timer status register B (TSRB) is set to 1 clears CMFB6M to 0. This bit is always read as 0.

(3) CMFCB12 — Compare Match Flag Clear B12 Enable

Writing 1 to this bit while the compare match flag B12 (CMFB12) in timer status register B (TSRB) is set to 1 clears CMFB12 to 0. This bit is always read as 0.

(4) CMFCB11 — Compare Match Flag Clear B11 Enable

Writing 1 to this bit while the compare match flag B11 (CMFB11) in timer status register B (TSRB) is set to 1 clears CMFB11 to 0. This bit is always read as 0.

(5) CMFCB10 — Compare Match Flag Clear B10 Enable

Writing 1 to this bit while the compare match flag B10 (CMFB10) in timer status register B (TSRB) is set to 1 clears CMFB10 to 0. This bit is always read as 0.

(6) CMFCB6 — Compare Match Flag Clear B6 Enable

Writing 1 to this bit while the compare match flag B6 (CMFB6) in timer status register B (TSRB) is set to 1 clears CMFB6 to 0. This bit is always read as 0.

(7) CMFCB1 — Compare Match Flag Clear B1 Enable

Writing 1 to this bit while the compare match flag B1 (CMFB1) in timer status register B (TSRB) is set to 1 clears CMFB1 to 0. This bit is always read as 0.

(8) ICFCB0 — Input Capture Flag Clear B0 Enable

Writing 1 to this bit while the input capture flag B0 (ICFB0) in timer status register B (TSRB) is set to 1 clears ICFB0 to 0. This bit is always read as 0.

(9) CMFCB0 — Compare Match Flag Clear B0 Enable

Writing 1 to this bit while the compare match flag B0 (CMFB0) in timer status register B (TSRB) is set to 1 clears CMFB0 to 0. This bit is always read as 0.

21.5.2.5 TICRB — Timer Interrupt Control Register B

Access: 8-bit accessible

Address: FFE6 0408_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	IREGB6E		IREGB6	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 21.31 TICRB Register Contents

Bit Position	Bit Name	Function
7 to 4	—	These bits are not used. Fix these bits to 0.
3, 2	IREGB6E	Interrupt Enable Edge B6E 00: No interrupt request is output. 01: An interrupt request is output when CMFB6 is enabled and then CMFB6M is enabled or when CMFB6M is enabled and then CMFB6 is enabled (AND condition). 10: An interrupt request is output when CMFB6 or CMFB6M is enabled (OR condition) 11: Setting prohibited
1, 0	IREGB6	Interrupt Enable Edge B6 00: An interrupt request is output when CMFB6 is enabled. 01: An interrupt request is output at the next external event input timing after CMFB6 is enabled. 10: An interrupt request is output at the second external event input timing after CMFB6 is enabled. However, no interrupt request is output if compare match B7 occurs before the second external event is input. 11: Setting prohibited

The timer interrupt control register B (TICRB) is an 8-bit readable/writable register to control the compare match interrupt request output timing.

TICRB can be read and written only in 8-bit units.

TICRB is initialized to 00_H by a reset.

(1) IREGB6E — Interrupt Enable Edge B6E

These bits select conditions for CMFB6E interrupt request output of TSRB.

Operation of these bits is disabled if these bits are set to 00.

While these bits are set to 01, an interrupt request is output at the external event input timing at the time when CMFB6M is enabled while a CMFB6 interrupt by the IREGB6 setting is present or at the timing of a CMFB6 interrupt request by the IREGB6 setting with CMFB6M enabled (AND condition). If CMFB6 is cleared even after a CMFB6 interrupt has occurred, no CMFB6E interrupt request is output even while CMFB6M is enabled. Otherwise, if CMFB6M is cleared even while CMFB6M is enabled, a CMFB6 interrupt request by the IREGB6 setting occurs but no CMFB6E interrupt request is output.

While these bits are set to 10, an interrupt request is output when a CMFB6 interrupt by the IREGB6 setting occurs or when CMFB6M is enabled (OR condition). Note that, if the CMFB6 interrupt request timing by the IREGB6 setting differs from the CMFB6M interrupt request timing, respective interrupt requests occur.

However, if the CMFB6 interrupt request timing matches the CMFB6M interrupt request timing, an interrupt request occurs once.

Do not modify these bits while the counter is working or the CMFB6 or CMFB6M bit in TSRB is set to 1. If these bits are modified, this register does not function correctly.

(2) IREGB6 — Interrupt Enable Edge B6

These bits select CMFB6 interrupt request output timing of TSRB. While these bits are set to 00, a CMFB6 interrupt request is output when CMFB6 is enabled. While these bits are set to 01, an interrupt request is output at the first external event input timing after CMFB6 is enabled.

While these bits are set to 10, an interrupt request is output at the second external event input timing after CMFB6 is enabled. However, if compare match B7 occurs during the period of waiting for the second external event input, CMFB6 is automatically cleared and no interrupt request is output even if the second external event is input.

Do not modify these bits while the counter is working or the CMFB6 bit in TSRB is set to 1. If these bits are modified, this register does not function correctly.

21.5.2.6 TCNTB0 — Edge Interval Measuring Counter B0

Access: 32-bit accessible but 8-bit/16-bit in accessible

Address: FFE6 0480_H

Value after reset: $0000\ 0001_H$

Table 21.32 TCNTB0 Register Contents

Bit Position	Bit Name	Function
31 to 0	CNTB0	Edge Interval Count These bits store 32-bit counter value

TCNTB0 is a 32-bit readable/writable register that functions as a counter driven by the clock selected in the clock select bit B (CKSELB) of timer control register B (TCRB). TCNTB0 is cleared to $0000\ 0001_H$ on input capture by an externally input event.

TCNTB0 is started when the timer B enable bit (TBE) in ATU-IV master enable register (ATUENR) is set to 1. Clearing the TBE bit to 0 stops the counting but the counter value is not cleared.

TCNTB0 can be read and written only in 32-bit units. Do not make 8-bit or 16-bit accesses to TCNTB0.

TCNTB0 is initialized to $0000\ 0001_H$ by a reset.

21.5.2.7 ICRB0 — Input Capture Register B0

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0484_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.33 ICRB0 Register Contents

Bit Position	Bit Name	Function
31 to 0	ICB0	Input Capture B0 These bits store 32-bit captured value.

ICRB0 is a 32-bit read-only register that is loaded with the value in TCNTB0 when an externally input event is detected. At this time, bit ICFB0 in timer status register B (TSRB) is set to 1.

An interrupt request can be output to the CPU at this ICRB0 input capture timing. TCNTB0 is cleared to $0000\ 0001_H$.

ICRB0 can be read only in 32-bit units. Do not read ICRB0 in 8-bit or 16-bit units.

ICRB0 is initialized to $0000\ 0000_H$ by a reset.

21.5.2.8 RECRBx— Record Registers Bx (x = 1 to 6)

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0488_H (RECRB1)
FFE6 $048C_H$ (RECRB2)
FFE6 0490_H (RECRB3)
FFE6 0494_H (RECRB4)

Table 21.34 RECRB1 to RECRB6 Register Contents

Bit Position	Bit Name	Function
31 to 0	RECRB1-6	Record Register B1 to B6 32-bit event capture value

Record registers B1 to B6 (RECRB1 to RECRB6) are 32-bit registers that capture the ICRB0 value at the timing of external event input (event 1 input). Each time an external event is input, the ICRB0 value is captured by shifting the ICRB0 value to RECRB1, the RECRB1 value to RECRB2, and the RECBR2 value to RECRB3. Thus up to seven past TCNT0B values can be retained in ICRB0 and RECRB1 to RECRB6.

RECRB1 to RECRB6 can be read and written only in 32-bit units.

To initialize these registers, write $0000\ 0000_H$ to them.

RECRB1 to RECRB6 are initialized to $0000\ 0000_H$ by a reset.

21.5.2.9 RBURBx — Record Backup Registers Bx (x = 0 to 6)

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 $04A0_H$ (RBURB0)
FFE6 $04A4_H$ (RBURB1)
FFE6 $04A8_H$ (RBURB2)

Table 21.35 RBURB0 to RBURB6 Register Contents

Bit Position	Bit Name	Function
31 to 0	RBURB0-6	Record Backup Registers B0 to B6 32-bit event capture backup value

Record backup registers B0 to B6 (RBURB0 to RBURB6) are 32-bit registers that back up values of ICRB0 and RECRB1 to RECRB6 in this register at the timing of event compare match between the event counter B1 (TCNTB1) and OCRB12.

The ICRB0 value is retained in RBURB0, the RECRB1 value in RBURB1, the RECRB2 value in RBURB2, the RECRB3 value in RBURB3, the RECRB4 value in RBURB4, the RECRB5 value in RBURB5, and the RECRB6 value is retained in RBURB6.

RBURB0 to RBURB6 can be read and written only in 32-bit units.

RBURB0 to RBURB6 are initialized to 0000 0000_H by a reset.

21.5.2.10 ICRB3x — Input Capture Registers B3x (x = 0 to 6)

Access: 8-bit accessible

Address: FFE6 $04D8_H$ (ICRB30)
FFE6 $04D9_H$ (ICRB31)
FFE6 $04DA_H$ (ICRB32)
FFE6 $04DB_H$ (ICRB33)
FFE6 $04DC_H$ (ICRB34)
FFE6 $04DD_H$ (ICRB35)
FFE6 $04DE_H$ (ICRB36)

Table 21.36 ICRB30 to ICRB 36 Register Contents

Bit Position	Bit Name	Function
7 to 0	ICRB30-36	Input Capture Registers B30 to B36 8-bit event capture value

Input capture registers B30 to B36 (ICRB30 to ICRB36) are 8-bit read-only registers. In the edge-interval measuring block, the event counter B1 (TCNTB1) value is captured at occurrence of any of seven external event inputs 1_B to 1_H that are input via timer A (ICRB30 to ICRB36). The event counter B1 (TCNTB1) is not cleared at occurrence of any of external event inputs 1_B to 1_H.

ICRB30 to ICRB36 can be read only in 8-bit units.

ICRB30 to ICRB36 are initialized to 00_H by a reset.

21.5.2.11 OCRB0 — Output Compare Register B0

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 04BC$_H$

Value after reset: FFFF FFFF$_H$

Table 21.37 OCRB0 Register Contents

Bit Position	Bit Name	Function
31 to 0	OCB0	Output Compare B0 These bits store 32-bit data to be compared with TCNTB0.

The output compare register B0 (OCRB0) is a 32-bit readable/writable register that is constantly compared with the input edge interval measuring counter B0 (TCNTB0). When the OCRB0 value matches the TCNTB0 value, an interrupt request due to this compare match can be output to the CPU and the CMFB0 bit in timer status register B (TSRB) is set to 1.

OCRB0 can be read and written only in 32-bit units. Do not make 8-bit or 16-bit accesses to OCRB0.

OCRB0 is initialized to FFFF FFFF$_H$ by a reset.

21.5.2.12 TCNTB1 — Event Counter B1

Access: 8-bit accessible

Address: FFE6 04C4$_H$

Value after reset: 00$_H$

Table 21.38 TCNTB1 Register Contents

Bit Position	Bit Name	Function
7 to 0	CNTB1	Event Count B1 These bits store 8-bit counter value.

The event counter B1 (TCNTB1) is an 8-bit readable/writable register that counts an external event. According to the setting for the CLRB1 and CLRB1SEL bits in the timer control register B (TCRB), the TCNTB1 value can be cleared to 01$_H$ at the next event input timing after a match in comparison between TCNTB1 and OCRB10 or between TCNTB6 and OCRB6 occurs.

When the TBE bit of the ATU-IV master enable register (ATUENR) is set to 1, the event counter is incremented every time the active level of an external event signal is input.

TCNTB1 can be read and written only in 8-bit units.

TCNTB1 is initialized to 00$_H$ by a reset.

21.5.2.13 OCRB1 — Output Compare Register B1

Access: 8-bit accessible

Address: FFE6 04C6$_H$

Value after reset: FF$_H$

Table 21.39 OCRB1 Register Contents

Bit Position	Bit Name	Function
7 to 0	OCB1	Output Compare B1 These bits store 8-bit data to be compared.

The output compare register B1 (OCRB1) is an 8-bit readable/writable register that is constantly compared with the event counter B1 (TCNTB1). When the OCRB1 value matches the TCNTB1 value, an interrupt request can be output to the CPU and the CMFB1 bit in timer status register B (TSRB) is set to 1 on the next PCLK.

The input capture register B1 (ICRB1) value is transferred to input capture register B2 (ICRB2) and ICRB1 is cleared at this compare match timing.

OCRB1 can be read and written only in 8-bit units.

OCRB1 is initialized to FF$_H$ by a reset.

21.5.2.14 OCRB10 — Output Compare Register B10

Access: 8-bit accessible

Address: FFE6 04C8$_H$

Value after reset: FF$_H$

Bit	7	6	5	4	3	2	1	0
	OCB10

Table 21.40 OCRB10 Register Contents

Bit Position	Bit Name	Function
7 to 0	OCB10	Output Compare B10 These bits store 8-bit data to be compared.

The output compare register B10 (OCRB10) is an 8-bit readable/writable register that is constantly compared with the event counter B1 (TCNTB1). When the OCRB10 value matches the TCNTB1 value, an interrupt request can be output to the CPU and the CMFB10 bit in timer status register B (TSRB) is set to 1 on the next PCLK.

According to the setting for the CLRB1 and CLRB1SEL bits in timer control register B (TCRB), the TCNTB1 value can be cleared to 01$_H$ at the next event input timing after this compare match occurs. Furthermore, according to the setting for the CLRB3 and CLRB3SEL bits in timer control register B (TCRB), the TCNTB3 value can be cleared to 0000 0000$_H$ at the next PCLK timing after this compare match occurs.

OCRB10 can be read and written only in 8-bit units.

OCRB10 is initialized to FF$_H$ by a reset.

21.5.2.15 OCRB11 — Output Compare Register B11

Access: 8-bit accessible

Address: FFE6 04CA$_H$

Value after reset: FF$_H$

Bit	7	6	5	4	3	2	1	0
	OCB11

Table 21.41 OCRB11 Register Contents

Bit Position	Bit Name	Function
7 to 0	OCB11	Output Compare B11 These bits store 8-bit data to be compared.

The output compare register B11 (OCRB11) is an 8-bit readable/writable register. According to the setting for the PIMRSEL bit in timer control register B (TCRB), this register can operate by using PIMR2 for down-count values to be loaded to RLDB and for down-count values of TCNTB2 during a compare match between TCNTB1 and OCRB11. PIMR1 is always used for up-count values of TCNTB3.

When the TCNTB1 value matches the OCRB11 value, an interrupt request due to this compare match can be output to the CPU and the CMFB11 bit in timer status register B (TSRB) is set to 1 on the next PCLK.

OCRB11 can be read and written only in 8-bit units.

OCRB11 is initialized to FF$_H$ by a reset.

21.5.2.16 OCRB12 — Output Compare Register B12

Access: 8-bit accessible

Address: FFE6 04CC$_H$

Value after reset: FF$_H$

Bit	7	6	5	4	3	2	1	0
	OCB12							
Value after reset	1	1	1	1	1	1	1	1

Table 21.42 OCRB12 Register Contents

Bit Position	Bit Name	Function
7 to 0	OCB12	Output Compare B12 These bits store 8-bit data to be compared.

The output compare register B12 (OCRB12) is an 8-bit readable/writable register. Values of ICRB0 and RECRB1 to RECRB6 can be backed up in RBURB0 to RBURB6 at the timing of event compare match between the event counter B1 (TCNTB1) and this register.

When the TCNTB1 value matches the OCRB12 value, an interrupt request due to this compare match can be output to the CPU and the CMFB12 bit in timer status register B (TSRB) is set to 1 on the next PCLK.

OCRB12 can be read and written only in 8-bit units.

OCRB12 is initialized to FF$_H$ by a reset.

21.5.2.17 ICRB1 — Input Capture Register B1

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 04D0$_H$

Value after reset: 0000 0000$_H$

Table 21.45 LDB Register Contents

Bit Position	Bit Name	Function
31 to 24	—	These bits are not used. Fix these bits to 0.
23 to 0	LDVAL	Load Value These bits store 24-bit data to be loaded to TCNTB2 and RLDB.

LDB is a 32-bit readable/writable register that is mapped to the lower-order 24 bits on a 32-bit boundary. The lower 24 bits are available.

When the LDSEL bit in timer I/O control register B (TIORB) is set to 1, the value in this register is loaded to reload counter B2 (TCNTB2) and reload register B (RLDB).

LDB can be read and written only in 32-bit units. Do not make 16-bit accesses to LDB.

LDB is initialized to $0000\ 0000_H$ by a reset.

21.5.2.20 RLDB — Reload Register B

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0504$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RLDVAL															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Table 21.46 RLDB Register Contents

Bit Position	Bit Name	Function
31 to 8	RLDVAL	Reload Value These bits store 24-bit reload value.
7 to 0	—	These bits are not used. Fix these bits to 0.

RLDB is a 32-bit readable/writable register that is aligned with a longword boundary. The upper 24 bits are available.

This register is updated when the externally input event is detected while the LDEN bit in timer I/O control register B (TIORB) is cleared to 0.

The value in input capture register B0 (ICRB0) or load register B (LDB) minus the value in the PIMR bits in PIM is used for updating. According to the setting for the PIMRSEL bit in timer control register B (TCRB) and a compare match between TCNTB1 and OCRB11, PIMR2 is used as the PIMR value. In other cases, PIMR1 is used as the PIMR value. ICRB0 or LDB is set by the LDSEL bit in TIORB. For subtraction on ICRB0 and PIMR, the lower 24 bits of ICRB0 and PIM which is zero-extended.

The value in this register is added to the value in TCNTB2 on the first counter clock after the value in bits reload count B2 (CNTB2) is equal to or less than the value in the pulse interval multiplier register (PIM).

RLDB can be read and written only in 32-bit units. Do not make 8-bit or 16-bit accesses to RLDB.

RLDB is initialized to 0000 0000$_H$ by a reset.

An initial value should be set before starting this function. For details on the operation, see **Section 21.5.3.2, Frequency-Multiplied Clock Generator**.

21.5.2.21 TCNTB2 — Reload Counter B2

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0508_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CNTB2															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CNTB2								—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Table 21.47 TCNTB2 Register Contents

Bit Position	Bit Name	Function
31 to 8	CNTB2	Reload Counter B2 These bits store 24-bit reload counter value.
7 to 0	—	These bits are not used. Fix these bits to 0.

TCNTB2 is a down counter mapped to 24 bits in a 32-bit readable and writable register and functions as a counter driven by the clock selected by the clock selection B bits (CKSELB0 to CKSELB2) in timer control register B (TCRB). Each decrementation by the value set in the pulse interval multiplier register (PIMR). According to the setting for the PIMRSEL bit in timer control register B (TCRB) and in response to a compare match between TCNTB1 and OCRB11, PIMR2 is used as the PIMR value. In other cases, PIMR1 is used as the PIMR value.

TCNTB2 starts counting when the TBE bit in the ATU-IV master enable register (ATUENR) is set to 1. Even if the TBE bit is cleared to 0, this counter is not cleared.

The TCNTB2 value is updated when the externally input event is detected while the LEDN bit in timer I/O control register B (TIORB) is cleared to 0.

The value in input capture register B0 (ICRB0) or load register B (LDB) is used for updating.

ICRB0 or LDB can be set by the LDSEL bit in TIORB.

The value in reload register B (RLDB) is added to the value stored in this counter on the first counter clock cycle after the value in this counter is equal to or less than the value in PIM. The frequency-multiplied clock (AGCK1) is output as a train of single pulses equal in width to the cycle of the Pϕ clock on reloading.

TCNTB2 can be read and written only in 32-bit units. Do not make 8-bit or 16-bit accesses to TCNTB2.

TCNTB2 is initialized to $0000\ 0000_H$ by a reset.

An initial value should be set before starting this function. For details on the operation, see **Section 21.5.3.2, Frequency-Multiplied Clock Generator**.

21.5.2.22 PIMR1 — Pulse Interval Multiplier Register 1

Access: 16-bit accessible but 8-bit inaccessible

Address: FFE6 050C$_H$

Value after reset: 0001$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	PIM1											
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.48 PIMR1 Register Contents

Bit Position	Bit Name	Function
15 to 12	—	These bits are not used. Fix these bits to 0.
11 to 0	PIM1	Pulse Interval Multiplier 1 These bits set the multiplication ratio for the frequency-multiplied clock. The settable value ranges from 1 to 4095.

PIMR1 is a 16-bit readable/writable register that sets the multiplication ratio of the externally input event for generation of the frequency-multiplied clock.

The settable value ranges from 1 (001$_H$) to 4095 (FFF$_H$). Do not set the PIM bits to 000$_H$. If the PIM bits are set to 000$_H$ operation cannot be guaranteed.

The value in this register is used in various registers: as the step size in decrementation of reload counter B2 (TCNTB2); for calculation of the value to be input to reload register B (RLDB); and for calculation of the value to be input to corrected event counter B3 (TCNTB3). However, when a match in comparison between TCNTB1 and OCRB11 occurs with the PIMRSEL bit in timer control register B (TCRB) set to 1, PIMR2 is used to calculate the TCNTB2 down-count value and the RLDB input value. PIMR1 is always used to calculate the TCNTB3 input value.

PIMR1 can be read and written only in 16-bit units. Do not make 8-bit accesses to PIMR1.

PIMR1 is initialized to 0001$_H$ by a reset.

21.5.2.23 PIMR2 — Pulse Interval Multiplier Register 2

Access: 16-bit accessible but 8-bit inaccessible

Address: FFE6 050E$_H$

Value after reset: 0001$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	PIM2											
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.49 PIMR2 Register Contents

Bit Position	Bit Name	Function
15 to 12	—	These bits are not used. Fix these bits to 0.
11 to 0	PIM2	Pulse Interval Multiplier 2 These bits set the multiplication ratio for the frequency-multiplied clock. The settable value ranges from 1 to 4095.

The pulse interval multiplier register 2 (PIMR2) is a 16-bit readable/writable register that is mapped to the lower 12 bits. PIMR2 sets the multiplication ratio of the frequency-multiplied clock when tooth is missing.

The settable value ranges from 1 (001$_H$) to 4095 (FFF$_H$). Do not set the PIM2 bits to 000$_H$. If the PIM2 bits are set to 000$_H$, operation cannot be guaranteed.

By setting the PIMRSEL bit in timer control register B (TCRB), the reload counter B2 (TCNTB2) performs down-counting with the set PIMR2 value (PIM2) (not with the PIMR1 value) while the TCNTB1 value is equal to the OCRB11 value. The PIMR2 value is also used to calculate the reload register B (RLDB) input value, but is not used to calculate the correction event counter B3 (TCNTB3) input value. The multiplication ratio of the frequency-multiplied clock at missing tooth is corrected by setting a value of (N (number of missing teeth) + 1) times for the PIMR1 value. When the number of missing teeth is 2, for example, a value of (PIMR1 value × 3) is set for PIMR2.

PIMR2 can be read and written only in 16-bit units. Do not make 8-bit accesses to PIMR2.

PIMR2 is initialized to 0001$_H$ by a reset.

21.5.2.24 TCNTB6 — Multiplied Clock Counter B6

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0510_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CNTB6

Table 21.50 TCNTB6 Register Contents

Bit Position	Bit Name	Function
31 to 12	CNTB6	Frequency-Multiplied Clock Counter B6 These bits store 20-bit counter value driven by the frequency-multiplied clock
11 to 0	—	These bits are not used. Fix these bits to 0.

The multiplied clock counter B6 (TCNTB6) is a 20-bit up-counter mapped in the 32-bit readable/writable register. TCNTB6 performs up-counting on the frequency-multiplied clock (AGCK1). This counter is cleared to 00000_H when the external input event is detected.

TCNTB6 starts counting when the TBE bit in the ATU-IV master enable register (ATUENR) is set to 1. Even if the TBE bit is cleared to 0 and counting up is stopped, the counter value is not cleared.

TCNTB6 can be read and written only in 32-bit units. Do not make 16-bit accesses to TCNTB6.

TCNTB6 is initialized to $0000\ 0000_H$ by a reset.

21.5.2.25 ICRB6 — Input Capture Register B6

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0514_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ICB6

Table 21.51 ICRB6 Register Contents

Bit Position	Bit Name	Function
31 to 12	ICB6	Input Capture B6 20-bit input capture value
11 to 0	—	These bits are not used. Fix these bits to 0.

The input capture register B6 (ICRB6) is a 32-bit read-only register that is mapped to upper 20 bits. No value can be written to this register.

When an external event input is detected, ICRB6 stores the TCNTB6 value at the next clock (Pϕ) timing. The value stored in ICRB6 is compared with the TCNTB6M value at the next external event input timing. When the ICRB6 value is larger than the TCNTB6M value, an interrupt request can be output.

ICRB6 can be read only in 32-bit units.

ICRB6 is initialized to $0000\ 0000_H$ by a reset.

21.5.2.26 RARB6 — Multiplication Setting Register B6

Access: 8-bit accessible

Address: FFE6 0518$_H$

Value after reset: 40$_H$

Bit	7	6	5	4	3	2	1	0

Table 21.52 RARB6 Register Contents

Bit Position	Bit Name	Function
7 to 0	RARB6	Multiplication Setting Register B6 These bits set the TCNTB6M count value.

The multiplication setting register B6 (RARB6) is an 8-bit readable/writable register to set an up-count value of the frequency-multiplied clock counter B6M (TCNTB6M). RARB6 handles the lower 6 bits as fixed point. A multiplication of 1 to 3.984375 can be set with a resolution of 1/64.

RARB6 can be read and written only in 8-bit units.

RARB6 is initialized to 40$_H$ by a reset.

21.5.2.27 TCNTB6M — Frequency-Multiplied Clock Counter B6M

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 051C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.53 TCNTB6M Register Contents

Bit Position	Bit Name	Function
31 to 6	CNTB6M	Frequency-Multiplied Clock Counter B6M 26-bit frequency-multiplied clock count value
5 to 0	—	These bits are not used. Fix these bits to 0.

The frequency-multiplied clock counter B6M (TCNTB6M) is a 32-bit readable/writable register (up-counter) that is mapped to upper 26 bits. TCNTB6M performs count-up operation with a count value of multiplication that is set in multiplication setting register B6 (RARB6) for the frequency-multiplied clock (AGCK1). TCNTB6M handles the lower 6 bits (b11 to b6) as fixed point, and can count within a range of 1 to 1048575.984375 with a resolution of 1/64. Each time an external event is input, the TCNTB6M value is compared with the ICRB6 value. When ICRB6 is larger than TCNTB6M, an interrupt request can be output. TCNTB6M is initialized to 0000 0000$_H$ at the first clock (Pϕ) timing after occurrence of an external event input.

Setting the TBE bit in the ATU-IV master enable register (ATUENR) to 1 starts counting by this counter. Clearing the TBE bit to 0 stops counting but the counter value is not cleared.

TCNTB6M can be read and written only in 32-bit units. Do not make 8-bit or 16-bit accesses to TCNTB6M.

TCNTB6M is initialized to 0000 0000$_H$ by a reset.

21.5.2.28 OCRB6 — Output Compare Register B6

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0520_H

Value after reset: FFFF $F000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OCB6															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 21.54 OCRB6 Register Contents

Bit Position	Bit Name	Function
31 to 12	OCB6	Output Compare B6 These bits store 20-bit data to be compared.
11 to 0	—	These bits are not used. Fix these bits to 0.

OCRB6 is a 32-bit readable/writable register in which output compare B6 (OCB6) is mapped to upper 20 bits in 32 bits. Whether to perform compare match between multiplied-clock counter B6 and OCRB6 can be selected by the IOB6 setting of timer I/O control register B (TIORB).

The OCRB6 value is compared with the TCNTB6 value. When input of the frequency-multiplied clock signal (AGCK1) leads to the values matching, a missing tooth detection trigger is generated, which leads to setting of the CMFB6 bit in timer status register B (TSRB) to 1 and can also cause the output of an interrupt request for the CPU.

According to the setting for the CLRB1 and CLRB1SEL bits in the timer control register B (TCRB) and this compare match occurrence, the TCNTB1 value can be cleared to 01_H at the next event input timing. Furthermore, according to the setting for the CLRB3 and CLRB3SEL bits in the timer control register B (TCRB) and this compare match occurrence, the TCNTB3 value can be cleared to $0000\ 0000_H$ at the next PCLK timing.

OCRB6 can be read and written only in 32-bit units. Do not make 8-bit or 16-bit accesses to OCRB6.

OCRB6 is initialized to FFFF $F000_H$ by a reset.

21.5.2.29 OCRB7 — Output Compare Register B7

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0524_H

Value after reset: FFFF $F000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.55 OCRB7 Register Contents

Bit Position	Bit Name	Function
31 to 12	OCB7	Output Compare B7 These bit store 20-bit data to be compared.
11 to 0	—	These bits are not used. Fix these bits to 0.

OCRB7 is a 32-bit readable/writable register in which output compare B7 (OCB7) is mapped to upper 20 bits in 32 bits.

The OCRB7 value is compared with the TCNTB6 value. When the frequency-multiplied clock (AGCK1) is input with these values matching, a compare match occurs. When the IREGB6 bits in timer interrupt control register B (TICRB) are set to 10, the CMFB6 bit in timer status register B (TSRB) is cleared to 0 at an occurrence of this compare match.

There is no status flag or interrupt request that indicates occurrence of a compare match of OCRB7.

OCRB7 can be read and written only in 32-bit units. Do not make 16-bit accesses to OCRB7.

OCRB7 is initialized to FFFF $F000_H$ by a reset.

21.5.2.30 TCNTB3 — Correcting Event Counter B3

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0580$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CNTB3															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.56 TCNTB3 Register Contents

Bit Position	Bit Name	Function
31 to 12	CNTB3	Correcting Event Counter B3 These bits store 20-bit event count value.
11 to 0	—	These bits are not used. Fix these bits to 0.

The correcting event counter B3 (TCNTB3) is a 20-bit up-counter mapped in the 32-bit readable/writable register.

TCNTB3 transfers its counter value to the correcting multiplied-clock counter B4 (TCNTB4) at the external event input timing, and then starts up-counting. The pulse interval multiplier register 1 (PIMR1) value is used for up-counting (CNTB3+ = PIM1). The pulse interval multiplier register 2 (PIMR2) value is not used for up-counting of TCNTB3.

TCNTB3 starts counting when the TBE bit in the ATU-IV master enable register (ATUENR) is set to 1. Even if the TBE bit is cleared to 0, the counter value is not cleared. According to the settings for the CLRB3 and CLRB3SEL bits in the timer control register B (TCRB), the TCNTB3 value can be cleared to 0000 0000$_H$ at the first PCLK timing after a compare match between TCNTB1 and OCRB10, TCNTB6 and OCRB6, or TCNTB3 and OCRB8.

TCNTB3 can be read and written only in 32-bit units. Do not make 8-bit or 16-bit accesses to TCNTB3.

TCNTB3 is initialized to 0000 0000$_H$ by a reset.

21.5.2.31 OCRB8 — Output Compare Register B8

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0594$_H$

Value after reset: FFFF F000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OCB8															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.57 OCRB8 Register Contents

Bit Position	Bit Name	Function
31 to 12	OCB8	Output Compare B8 20-bit comparison value
11 to 0	—	These bits are not used. Fix these bits to 0.

OCRB8 is a 32-bit readable/writable register in which output compare B8 (OCB8) bits are mapped to the upper 20 bits.

The OCRB8 value is compared with the TCNTB3 value. When TCNTB3 clear (due to a compare match between OCRB8 and TCNTB3) is enabled by bit 4 and bit 3 in the timer control register B (TCRB), the TCNTB3 value is cleared to 0 at the first PCLK timing after a compare match between the OCRB8 value and the TCNTB3 value. OCRB8 has no compare match status flag or interrupt.

OCRB8 can be read and written only in 32-bit units. Do not read or write it in 16-bit units.

OCRB8 is initialized to FFFF F000$_H$ by a reset.

21.5.2.32 TCNTB4 — Multiplied-and-Corrected Clock Counter B4

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0584_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.58 TCNTB4 Register Contents

Bit Position	Bit Name	Function
31 to 12	CNTB4	Multiplied-and-Corrected Clock Counter B4 These bits store 20-bit frequency-multiplied clock count value.
11 to 0	—	These bits are not used. Fix these bits to 0.

The multiplied-and-corrected clock counter B4 (TCNTB4) is a 20-bit up-counter mapped in the 32-bit readable/writable register.

The value in TCNTB3 is loaded to this counter when the externally input event is detected.

This up-counter is driven by the frequency-multiplied clock (AGCK1) output by reload counter B2 (TCNTB2) and is cleared to 00000_H when the externally input event is detected while CNTB3 = 00000_H.

When the values in this counter and TCNTB3 match with the CCS bit in timer I/O control register B (TIORB) set to 1, counting is stopped. When the CCS bit is set to 0, counting is continued.

TCNTB4 starts counting when the TBE bit in the ATU-IV master enable register (ATUENR) is set to 1. Even if the TBE bit is cleared to 0 and counting is stopped, the counter value is not cleared.

TCNTB4 can be read and written only in 32-bit units. Do not make 16-bit accesses to TCNTB4.

TCNTB4 is initialized to $0000\ 0000_H$ by a reset.

21.5.2.33 TCNTB5 — Multiplied-and-Corrected Clock Generating Counter B5

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0588$_H$

Value after reset: 0000 1000$_H$

Table 21.59 TCNTB5 Register Contents

Bit Position	Bit Name	Function
31 to 12	CNTB5	Multiplied-and-Corrected Clock Generation Count B5 These bit store 20-bit multiplied-and-corrected clock count value.
11 to 0	—	These bits are not used. Fix these bits to 0.

The multiplied-and-corrected clock generating counter B5 (TCNTB5) is a 20-bit up-counter mapped in the 32-bit readable/writable register.

This counter is enabled by the TBE bit in ATU-IV master enable register (ATUENR) and the count control B5 bit (CTCNTB5). Incrementation of this counter is driven by the PCLK as long as the counter value is less than the value in multiplied-and-corrected clock counter B4 (TCNTB4). Incrementation is stopped when the counter value matches the value in correcting counter clearing register (TCCLRB).

The value in this counter is corrected and cleared when the externally input event is detected while CNTB3 = 00000$_H$ or bit TCCLFSB in the correcting counter clearing flag set register B (TCCLFSRB) is set to 1. The value for the clearing depends on the counter value.

- When the counter value is equal to the value in TCCLRB
  This counter is cleared to 0000 1000$_H$. The corrected counter clear flag register B (TCCLFRB) retains 0.
- When the counter value is not equal to the value in TCCLRB
  Incrementation continues until the counter value reaches the value in TCCLRB and then TCNTB5 is cleared to 0000 1000$_H$.

Every incrementation of this counter, a single pulse of the multiplied-and-corrected clock (AGCKM) is output. The clock can be output on clock-bus line 5 by setting the CB5SEL bit in clock bus control register (CBCNT) to 1. The output of the clock is temporarily stopped by altering the setting in bit CTCNTB5 in the TIORB during counting.

TCNTB5 can be read and written only in 32-bit units. Do not make 16-bit accesses to TCNTB5.

TCNTB5 is initialized to 0000 1000$_H$ by a reset.

An initial value should be set before starting this function. For details on the operation, see **Section 21.5.3.3, Frequency-Multiplied Clock Signal Corrector**.

21.5.2.34 TCCLFRB — Correcting Counter Clear Flag Register B

Access: 8-bit accessible
Address: FFE6 058C$_H$
Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TCCLFB
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.60 TCCLFRB Register Contents

Bit Position	Bit Name	Function
7 to 1	—	These bits are not used. Fix these bits to 0.
0	TCCLFB	Correcting Counter Clear Flag B 0: TCNTB5 is not automatically counting up (Initial value). 1: TCNTB5 is automatically counting up until it matches the TCCLRB value.

The correcting counter clear flag register B (TCCLFRB) is an 8-bit read-only register that indicates whether the function of correcting TCNTB5 (the automatic up-counting function that continues counting until TCNTB5 = TCCLRB) is enabled or disabled.

TCCLFRB can be read only in 8-bit units.

TCCLFRB is initialized to 00$_H$ by a reset.

(1) TCCLFB — Correcting Counter Clear Flag B

This status flag shows that the function of correcting TCNTB5 is enabled and the automatic up-counting function continues until TCNTB5 = TCCLRB. When 1 is read from this flag, it shows that TCNTB5 is automatically up-counting until TCNTB5 = TCCLRB. This flag cannot be set to 1 or 0 by the software.

- Setting (to 1) conditions
  - Writing 1 to TCCLFSB in the correcting counter clear flag setting register B (TCCLFSRB)
  - When an external event is input with TCNTB3 = 00000$_H$ and TCNTB5 ≠ TCCLRB while TCNTB5 is automatically up-counting until it reaches the TCCLRB value
- Clearing (to 0) conditions
  - Writing 1 to TCCLFCB in the correcting counter clear flag clearing register B (TCCLFCRB)
  - When TCNTB5 value has reached the TCCLRB value after counting with the TCCLFB bit set to 1, the TCNTB5 value has matched the TCCLRB value, and TCNTB5 has been cleared to 0000 1000$_H$

21.5.2.35 TCCLFSRB — Correcting Counter Clear Flag Setting Register B

Access: 8-bit accessible
Writing 0 is disabled. If 1 is written to this register, data is not retained. This register is always read as 0.

Address: FFE6 058D$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TCCLFSB
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 21.61 TCCLFSRB Register Contents

Bit Position	Bit Name	Function
7 to 1	—	These bits are not used. Fix these bits to 0.
0	TCCLFSB	Correcting Counter Clear Flag Set B 0: Disabled 1: TCCLFB in correcting counter clear flag register B (TCCLFRB) is set to 1.

The correcting counter clear flag setting register B (TCCLFSRB) is an 8-bit readable/writable register.

TCCLFSRB can be read and written only in 8-bit units, but it is always read as 0.

TCCLFSRB is initialized to 00$_H$ by a reset.

(1) TCCLFSB — Correcting Counter Clear Flag Set B

Writing 1 to TCCLFSB sets TCCLFB in the correcting counter clear flag register B (TCCLFRB) to 1 to enable automatic up-counting until the TCNTB5 matches the TCCLRB value. When TCCLFSB is set to 1 while TCCLFB is 1, TCCLFB holds 1. When TCCLFSB is set to 1 while TCNTB5 = TCCLRB, TCNTB5 is cleared to 0000 1000$_H$ and TCCLFB holds 0. When writing 0 to this flag is attempted, the writing is ignored.

21.5.2.36 TCCLFCRB — Correcting Counter Clear Flag Clearing Register B

Access: 8-bit accessible
Writing 0 is disabled. If 1 is written to this register, data is not retained. This register is always read as 0.

Address: FFE6 058E$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TCCLFCB
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 21.62 TCCLFCRB Register Contents

Bit Position	Bit Name	Function
7 to 1	—	These bits are not used. Fix these bits to 0.
0	TCCLFCB	Correcting Counter Clear Flag Clear B 0: Disabled 1: TCCLFB in correcting counter clear flag register B (TCCLFRB) is cleared to 0.

The correcting counter clear flag clearing register B (TCCLFCRB) is an 8-bit readable/writable register.

TCCLFCRB can be read and written only in 8-bit units, but it is always read as 0.

TCCLFCRB is initialized to 00$_H$ by a reset.

(1) TCCLFCB — Correcting Counter Clear Flag Clear B

Writing 1 to TCCLFCB sets TCCLFB in the correcting counter clear flag register B (TCCLFRB) to 0 to inhibit automatic up-counting until the TCNTB5 matches the TCCLRB value and enter the up-count state of TCNTB5 at the time when TCNTB4 > TCNTB5. If this conflicts with the condition for setting the TCCLFB bit when TCNTB3 = 0 and an event input has occurred, clearing by writing this register is prioritized. If TCCLFB is cleared when it is 0, TCCLFB holds 0. When writing 0 to this flag is attempted, the writing is ignored.

21.5.2.37 TCCLRB — Correcting Counter Clearing Register B

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0590_H

Value after reset: $0000\ 0000_H$

Bit Position	Bit Name	Function
31 to 12	CCLRB	Correcting Counter Clear B These bits store 20-bit correcting counter clear value.
11 to 0	—	These bits are not used. Fix these bits to 0.

The correcting counter clearing register B (TCCLRB) is a 32-bit readable/writable register mapped to upper 20 bits in 32 bits.

TCCLRB is constantly compared with TCNTB5. When they match, TCNTB5 is stopped and a counter clearing trigger is output to timer D. TCNT1Dx and TCNT2Dx in timer D are separately cleared by setting the corresponding counter clearing enable bit in timer control register Dx (TCRDx).

TCCLRB can be read and written only in 32-bit units. Do not make 8/16-bit accesses to TCCLRB.

TCCLRB is initialized to $0000\ 0000_H$ by a reset.

21.5.2.38 ACRTRGB — AGCKM2 Correction Enable Setting Register

Access: 8-bit accessible
Writing 0 is disabled. If 1 is written to these bits, data is not retained. These bits are always read as 0.

Address: FFE6 05A0$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ACRTRG

Bit Position	Bit Name	Function
7 to 1	—	These bits are not used. Fix these bits to 0.
0	ACRTRG	AGCKM2 Correction Enable 0: Disabled 1: AGCKM2 correction is enabled.

The AGCKM2 correction enable setting register (ACRTRGB) is an 8-bit readable/writable register.

When the ACRTRG bit is set to 1, the number of correction clocks is corrected according to the specification of the ACRVALRB register.

Then the AGCKM2 output corrected based on AGCKM from the input timer B external event (AGCK) is generated.

Write-access to the AGCKM2 correction enable setting register (ACRTRGB) is enabled only when ACRST is 00$_B$.

When ACRST is not 00$_B$, write-access to this register is disabled.

ACRTRGB can be read and written only in 8-bit units.

ACRTRGB is initialized to 00$_H$ by a reset.

21.5.2.39 ACRCLRB — AGCKM2 Correction Clear Setting Register

Access: 8-bit accessible
Writing 0 is disabled. If 1 is written to these bits, data is not retained. These bits are always read as 0.

Address: FFE6 05A1$_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ACRCLR
Value after reset	0	0	0	0	0	0	0	0

The AGCKM2 correction status register (ACRSTRB) is an 8-bit readable register.

The ACRST bit is used to check the AGCKM1 correction status.

ACRSTRB can be read only in 8-bit units.

ACRSTRB is initialized to 00$_H$ by a reset.

21.5.2.41 ACRVALRB — AGCKM2 Correction Clock Count Setting Register

Access: 16-bit accessible but 8-bit/32-bit inaccessible

Address: FFE6 05A4$_H$

Value after reset: 0000$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ACRSIGN	ACRVAL[14:0]

Table 21.67 ACRVALRB Register Contents

Bit Position	Bit Name	Function
15	ACRSIGN	AGCKM2 Correction Clock Count Sign 0: The number of correction clocks (ACRVAL[14:0] value) is treated as a positive value. 1: The number of correction clocks (ACRVAL[14:0] value) is treated as a negative value.
14 to 0	ACRVAL[14:0]	AGCKM2 Correction Clock Count These bits specify the number of AGCKM2 correction clocks. AGCKM2 is corrected for the number of clocks indicated by the ACRSIGN bit and these bits. (Positive value: high level is output additionally, Negative value: AGCKM high level is masked to low level and is output as AGCKM2.)

The AGCKM2 correction clock count setting register (ACRVALRB) is a 16 bit readable/writable register.

This register generates AGCKM2 output corrected based on AGCKM according to the set value of the AGCKM2 correction clock count setting register (ACRVALRB).

The AGCKM2 correction counter starts counting from the set ACRVALB value and continues down-counting until 0001$_H$ is detected.

When ACRVALB is set to 0000$_H$, the counter decrements as 0000$_H$ → 7FFF$_H$ → 7FFE$_H$ → 7FFD$_H$ → … → 0001$_H$.

ACRVALRB can be read and written only in 16-bit units.

ACRVALRB is initialized to 0000$_H$ by a reset.

21.5.3 Detailed Operation

21.5.3.1 Edge Interval Measuring Function and Edge Input Stopping Function

For timer B, input-capture and compare-match operations are unconditionally performed with 32-bit input capture register B0 (ICRB0) and 32-bit output compare register B0 (OCRB0), respectively. These registers are connected to input edge-interval measuring counter B0 (TCNTB0).

Operation of timer B is started by setting the TBE bit in the ATU-IV master enable register (ATUENR).

ICRB0 captures the TCNTB0 value when an event (the AGCK signal) is input via timer A. At the same time, TCNTB0 is set to 0000 0001_H. An interrupt request can be output to the CPU at this capture timing. This enables measurement of the time of edge-to-edge interval.

The value captured in ICRB0 is transferred to the frequency-multiplied clock generating block to be used as an input value to the reload counter B2 (TCNTB2) and the reload register B (RLDB). Furthermore, up to six captured values (ICRB0) can be retained in the record registers B1 to B6 (RECRB1 to RECRB6) at the external input event timing. Values retained in ICRB0 and RECRB1 to RECRB6 are backed up in the record backup registers B0 to B6 (RBURB0 to RBURB6) at the timing of B12 (OCRB12) event compare match between TCNTB1 and the output compare register B12 (OCRB12).

When TCNTB0 reaches the value set in OCRB0, an interrupt request due to this compare match can be output. This interrupt indicates that active edge input has stopped for at least time equivalent to the setting in OCRB0.

Figure 21.16 shows input-capture and compare-match operation of TCNTB0.

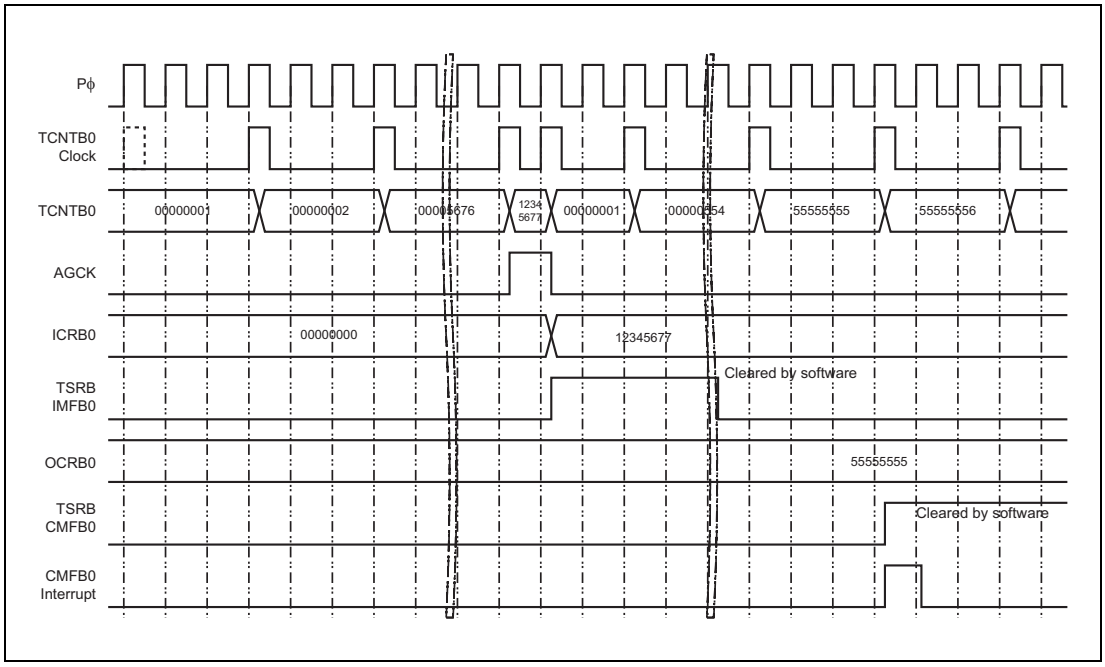

Figure 21.16 Input-Capture and Compare-Match Operation of TCNTB0

Event counter B1 (TCNTB1) counts the input of signals indicating external events (AGCK). When a predetermined value is set in output compare register B1 (OCRB1) and TCNTB1 reaches that value, a compare-match occurs. When a value is set in output compare register B10 (OCRB10) by the setting of the TCNTB1 clear setting bit (CLRB1) in the timer control register B (TCRB), TCNTB1 can be cleared at the first event input timing after an event compare match between TCNTB1 and OCRB10. Furthermore, by the setting of the TCNTB3 clear setting bit (CLRB3SEL) in the timer control register

B (TCRB), TCNTB3 can be cleared at a compare match between TCNTB1 and OCRB10. Input capture register B2 (ICRB2) can capture input capture register B1 (ICRB1) at the timing of a compare match between TCNTB1 and OCRB1. This compare match makes it possible to output an interrupt request to the CPU, allowing detection of edge input stop of external event. In addition, event counter B1 (TCNTB1) has a function for compare match with output compare register B11 (OCRB11). When the pulse interval multiplier select bit (PIMRSELR) is set to 1, TCNTB1 can operate by using PIMR2 for down-count values to be loaded to RLDB and for down-count values of TCNTB2 at a compare match between TCNTB1 and OCRB11. When the TCNTB1 value matches the OCRB11 value, an interrupt request due to this compare match can be output to the CPU.

The external event signal (AGCK) drives the capturing of TCNTB0 values in ICRB1. Moreover, latching of ICRB1 in ICRB2 on matches between TCNTB1 and OCRB1 can also be selected. This enables the measurement of multiple edge-to-edge intervals.

Registers ICRB30 to ICRB 36 capture the TCNTB1 value by using the external event input 1B to 1H as a trigger. ICRB30 corresponds to external event input 1B and ICRB31 to ICRB36 correspond to respective external event input 1C to 1H.

Figure 21.17 shows compare-match operation of TCNTB1 and capture operation of ICRB1 and ICRB2, and **Figure 21.18** shows capture operation of TCNTB1 and ICRB3x.

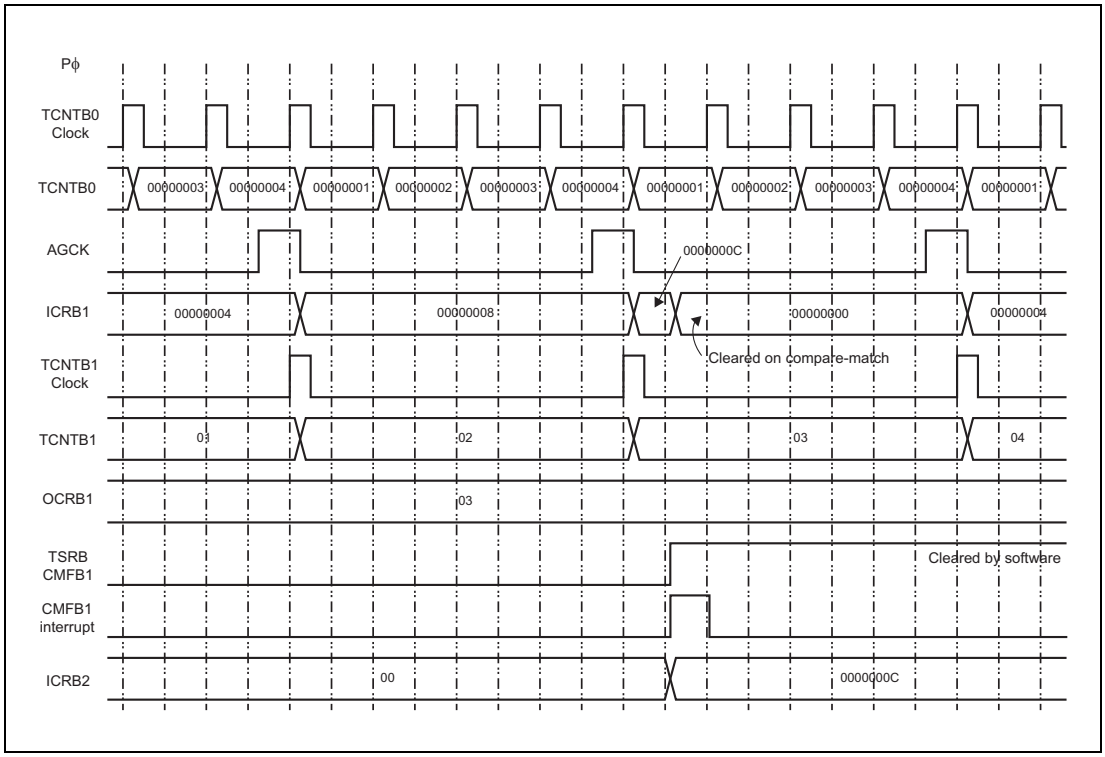

Figure 21.17 Compare-Match Operation of TCNTB1 and Capture Operation of ICRB1 and ICRB2

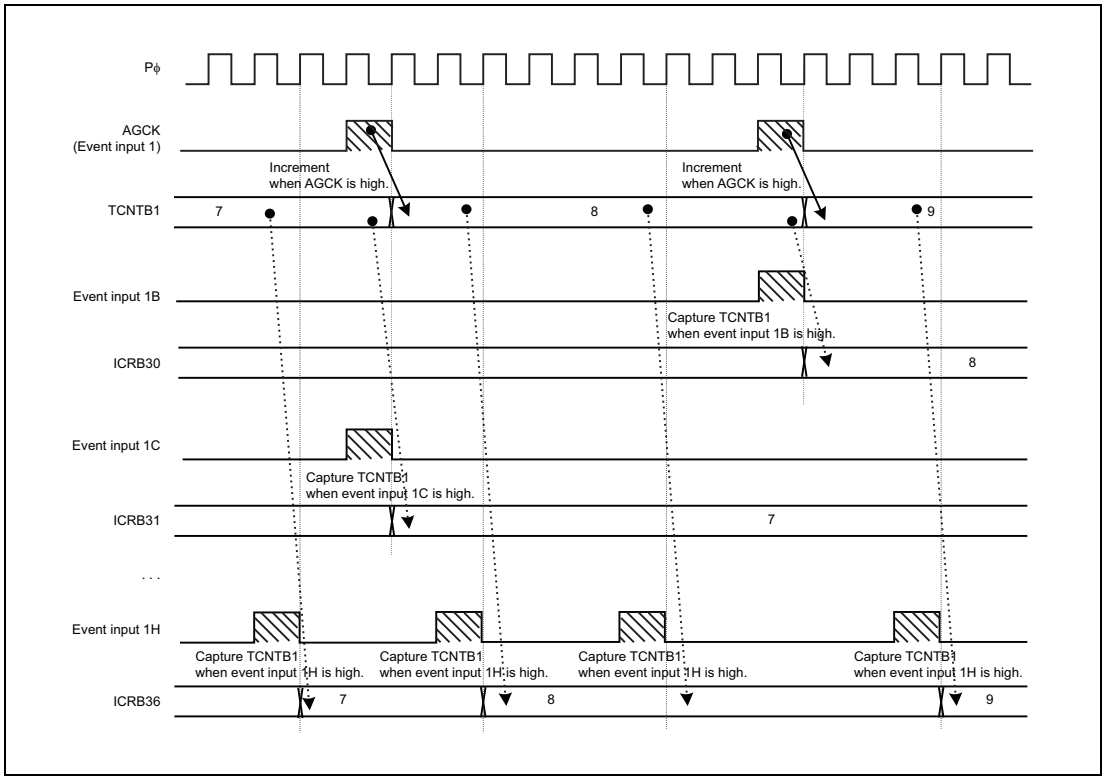

Figure 21.18 Count Operation of TCNTB1 and Capture Operation of ICRB3x

21.5.3.2 Frequency-Multiplied Clock Generator

The frequency-multiplied clock generator generates a clock signal (AGCK1) for use within timer B. The cycle of this clock signal is obtained by dividing the intervals between selected transitions of the external-event input (AGCK) by the value in the pulse interval multiplier register (PIMR1 or PIMR2).

When the LDEN bit in the TIORB is 0, On the selected transition of the external-event input signal, the lower 24 bits of the value captured in ICRB0 of the edge-interval measuring block are transferred to 24-bit reload counter B2 (TCNTB2). At the same time, the value transferred to TCNTB2 minus the value in PIMR (PIM1 or PIM2) is transferred to 24-bit reload register B (RLDB). When the LDEN bit in the TIORB is 1, the values of TCNTB2 and RLDB are not updated on ICRB0 input capture.

When the LDSEL bit in timer I/O control register B (TIORB) is set to 1, the value in load register B (LDB) instead of that in ICRB0 can be transferred to TCNTB2 and RLDB. When the pulse interval multiplier select bit (PIMRSELR) is set to 1, the above operation is performed using the PIMR2 value instead of PIMR1 value while TCNTB1 matches OCRB11.

24-bit reload counter B2 (TCNTB2) is driven to count down by the clock selected by the CKSELB bits in timer control register B (TCRB). Each decrementation is by the value set in PIMR (TCNTB2- = PIM). When the value in the down counter is less than or equal to that of the PIM bits, RLDB is automatically read out into TCNTB2 and added to the count value (TCNTB2 + the RLDB value) and , which again starts to count down. A single pulse of the multiplied clock signal (AGCK1) is output in synchronization with the reloading of TCNTB2. The pulse width is equal to the cycle of the PCLK.

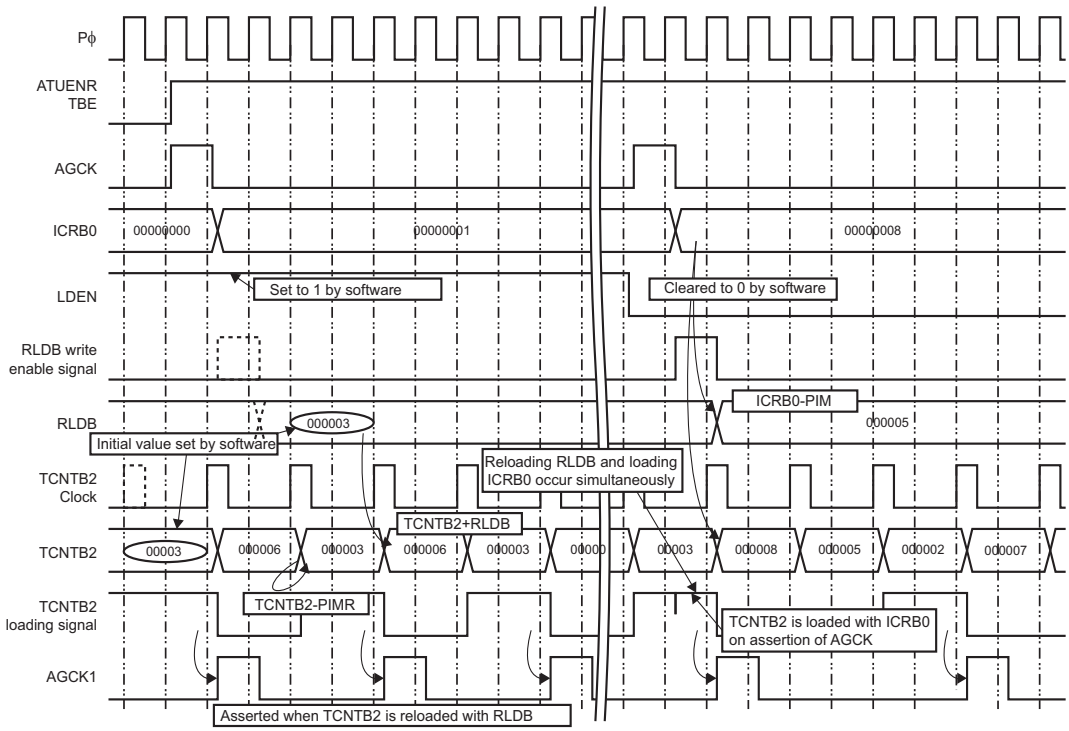
Compare match operation by frequency-multipiled clock (AGCK1) can be performed by using 20-bit output compare register B6 (OCRB6) and 20-bit frequency-multiplied clock counter B6 (TCNTB6).

Incrementaion of TCNTB6 on the assertion of AGCK1 is unconditional. The values in TCNTB6 and output compare register B6 (OCRB6) are tested for matches, and an interrupt request will be generated to the CPU when the values match. The IREGB6 bits in TICRB can be set so that the interrupt is generated on the match, on the first AGCK pulse (external event) after the match, or on the second AGCK pulse (external event) after the match.

When an external event input (AGCK) is detected, ICRB6 stores the TCNTB6 value at the next clock (Pϕ) timing. The frequency-multiplied clock counter B6M (TCNTB6M) performs count-up operation with a count value of multiplication that is set in multiplication setting register B6 (RARB6) for the frequency-multiplied clock (AGCK1). Each time an external event (AGCK) is input, the TCNTB6M value is compared with the ICRB6 value. When the ICRB6 value is larger than the TCNTB6M value as a result of comparison, an interrupt request can be output.

Since AGCK1 is generated with reference to the previous edge-to-edge interval, if two consecutive edge intervals differ significantly, the clock will not be generated correctly. To correct this error, AGCK1 is corrected by the frequency-multiplied clock signal corrector, whose description is provided in the next section, and is to be converted into AGCKM.

Figure 21.19 and **Figure 21.20** show counting operations with reloading and output of the frequency-multiplied clock and **Figure 21.21** and **Figure 21.22** show the generation of interrupt requests on matches between TCNTB6 and CMFB6, enabled or disabled by the setting in IREG. **Figure 21.23** shows the Switching Timing of PIMR1 and PIMR2. **Figure 21.24**. shows comparison of TCNTB6M and ICRB6 operations and interrupt request output.



Note: When LDSEL = 0_B and PIM = '003_H' (multiplying by 3)

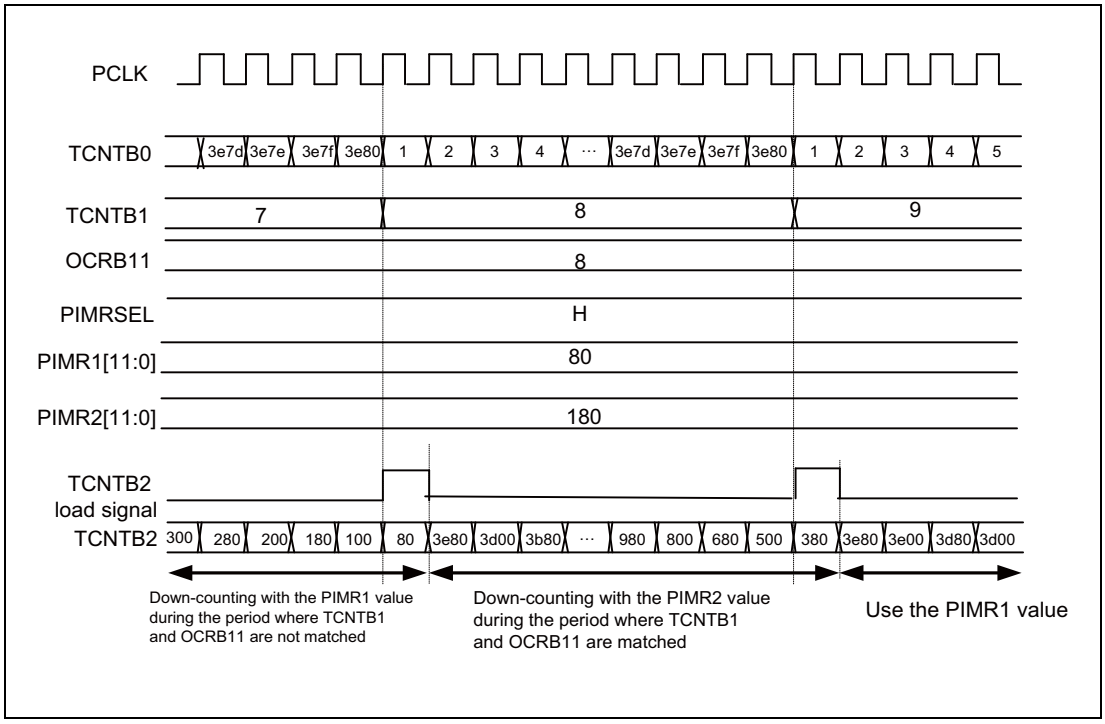

Figure 21.23 Switch Timing between PIMR1 and PIMR2

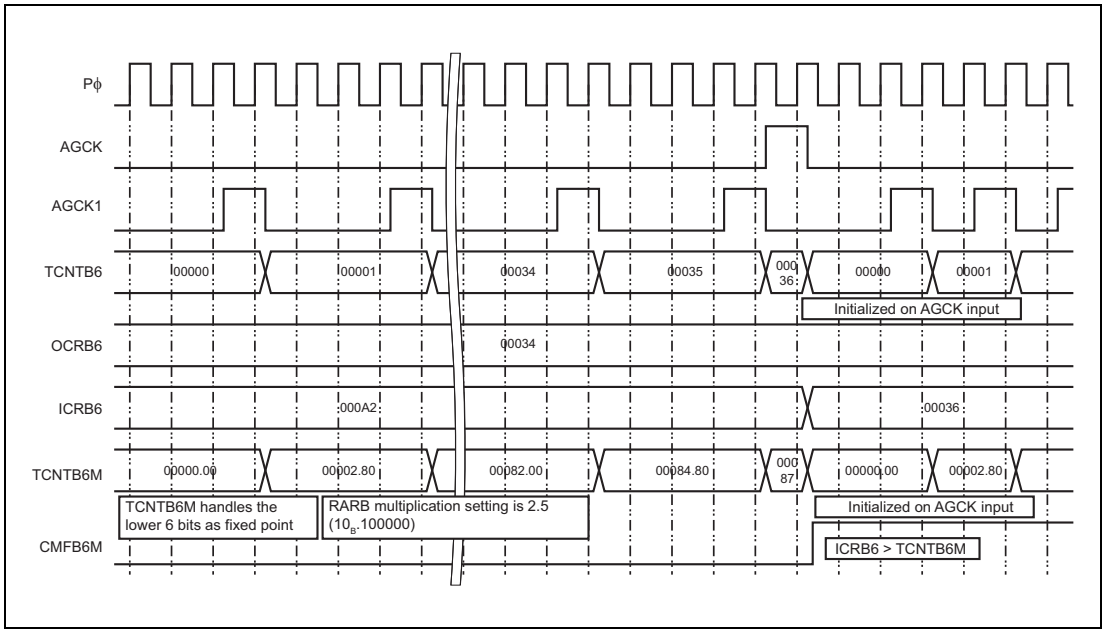

Figure 21.24 Example of Operations of TCNTB6M and ICRB6

21.5.3.3 Frequency-Multiplied Clock Signal Corrector

The frequency-multiplied clock signal which is generated by dividing the intervals between external event inputs by the multiplication ratio set in the PIM bits in PIMR can be corrected by using 20-bit correcting event counter B3 (TCNTB3), 20-bit multiplied-and-corrected clock counter B4 (TCNTB4), 20-bit multiplied-and-corrected clock generating counter B5 (TCNTB5), and correcting counter clearing register B (TCCLRB).

TCNTB3 is a 20-bit up-counter that is driven by the external event input (AGCK). On the selected transition of the AGCK signal, the value in TCNTB3 is transferred to TCNTB4, after which TCNTB3 is incremented by the value in the PIM bits (TCNTB3+ = PIM). According to the setting for the CLRB3SEL bit (TCNTB3 clear select bit) in the timer control register B (TCRB), TCNTB3 can be cleared by a compare match between TCNTB1 and OCRB10, between TCNTB6 and OCRB6, or between TCNTB3 and OCRB8.

TCNTB4 is a 20-bit up-counter that is driven by the multiplied clock signal (AGCK1). TCNTB3 is loaded to TCNTB4 with the AGCK input as a trigger, and incrementation of TCNTB4 is driven by the AGCK1 input.

The counter correcting select bit (CCS) in TIORB controls counting by TCNTB4; that is, it selects whether or not counting stops when TCNTB3 = TCNTB4.

TCNTB5 is a 20-bit up-counter that is driven by the PCLK clock, meaning that it operates at a high speed. TCNTB5 is constantly compared with TCNTB4 and is incremented as long as its value is lower than that in TCNTB4. Each time TCNTB5 is actually incremented, it produces a single pulse whose width is equal to one cycle of the PCLK clock. pulse of the peripheral clock signal, namely the multiplied-and -corrected clock signal (AGCKM), for which output on clock-bus line 5 can be selected by bit CB5SEL in the clock bus control register (CBCNT). The AGCKM signal is then available on clock-bus line 5 as a source to drive counting by other timers.

As state above, TCNTB5 is not incremented when its value is greater that in TCNTB4 (for example, after TCNTB3 has been loaded to TCNTB4), TCNTB5 can also be disabled by the count control B5 (CTCNTB5) bit in timer I/O control register B (TIORB). This halts the output of the AGCKM signal.

As long as its value is lower than TCNTB4, TCNTB5 is incremented until it reaches the value in correcting counter clearing register B (TCCLRB). This function allows you to check the automatic up-count status by using correcting counter clear flag register B (TCCLFRB). It also allows you to set automatic up-count operation status by using the correcting counter clear setting register (TCCLFSRB) and the correcting counter clear flag clearing register (TCCLFCRB). Incrementation of TCNTB5 then stops, regardless of the relation between its value and that of TCNTB4. In addition, timer counters 1Dx and 2Dx of timer D (TCNT1Dx and TCNT2Dx) can be separately cleared by this match as a trigger when the corresponding counter clearing enable bit (C1CEDx/C2CEDx) in timer control register Dx (TCRDx) is set to 1.

TCNTB4 is unconditionally cleared to 0000 0000_H when a pulse of the external-event signal (AGCK) is input while TCNTB3 = 0000 0000_H. TCNTB5 is unconditionally set to 0000 1000_H when a pulse of the external-event signal (AGCK) is input while TCNTB3 = 0000 0000_H.

However, when TCNTB5 has not reached TCCLRB, TCNTB5 is incremented until it reaches TCCLRB. After that, it is set to 0000 1000_H.

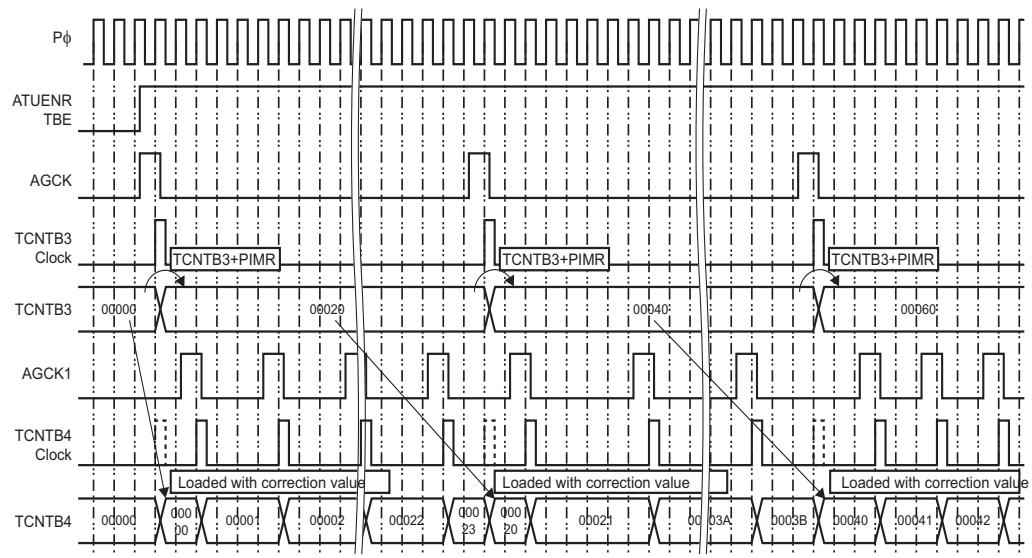
Figure 21.25 shows operations of TCNTB3 and TCNTB4, **Figure 21.26** shows operation when TCNTB5 is being started up, **Figure 21.27** shows TCNTB5 operation with correction at the end of a cycle, and **Figure 21.28** shows TCNTB5 operation with no correction at the end of a cycle.

The multiplied-and-corrected clock 2 (AGCKM2) is generated and output for the multiplied-and-corrected clock (AGCKM) by setting the correction enable trigger bit (ACRTRG) to 1. In the case of

positive logic (+) correction for AGCKM, AGCKM2 extends the active time of AGCKM. In the case of negative logic (–) correction, AGCKM2 masks the active time of AGCKM.

Generation of AGCKM2 is controlled by ACRSTRB, and the correction time is controlled by the internal down-counter.

AGCKM2 is generated as follows: AGCKM2 correction is started (ACRSTRB = 10_B) by detection of a timer B external event (AGCK) after correction enable trigger bit (ACRTRG) is set to 1 (ACRSTRB = 01_B). **Figure 21.29** shows AGCKM2 Operation (Positive Logic) and **Figure 21.30** shows AGCKM2 Operation (Negative Logic).



Note: When PIM = '020_H' (multiplying by 32)

21.6 Timer C

21.6.1 Operation

The timer C block is a general-purpose timer consisting of eight subblocks having the same function.

Each timer C subblock can achieve the following functions.

- Input capture and output compare matches
- Choice of rising edge, falling edge, or both edge sensing as the edge of input capture trigger signal
- Capturing at the timing of event output 1, 2A, or 2B from timer A when used as input capture
- Output of a waveform on compare match. Choice of a logical one, a logical zero, a toggled output, or a one-shot pulse output by setting a register
- Output of an interrupt request and a DMA request on capture or compare match
- Output of an interrupt request on timer counter overflow
- Clearing timer counter Cx (TCNTCx) on compare match (two types)
  - The counter can be cleared on compare match of GRCx0 in PWM mode (not supported by GRCx1 to GRCx3)
  - When the counter upper-limit setting function is used in any mode other than PWM mode, the counter can be cleared on compare match of CUCRCx.
- Output of forced compare match by setting the forced compare match bit
- Noise canceling function (noise canceler count clock or clock bus 5 selectable)

Timer C subblock consists of a 32-bit timer counter Cx (TCNTCx) , four 32-bit timer general registers Cxy (GRCxy), four 32-bit output compare registers Cxy (OCRCxy), a 32-bit counter upper-limit setting compare register Cx (CUCRCx), and controller. The timer general registers Cxy (GRCxy) can be used for input capture/compare match operations and input capture trigger input and output compare output signals (TIOCxy) are available.

The initial output value on the TIOCxy pin is 0 for output compare operation. During operation, the previous state is reflected.

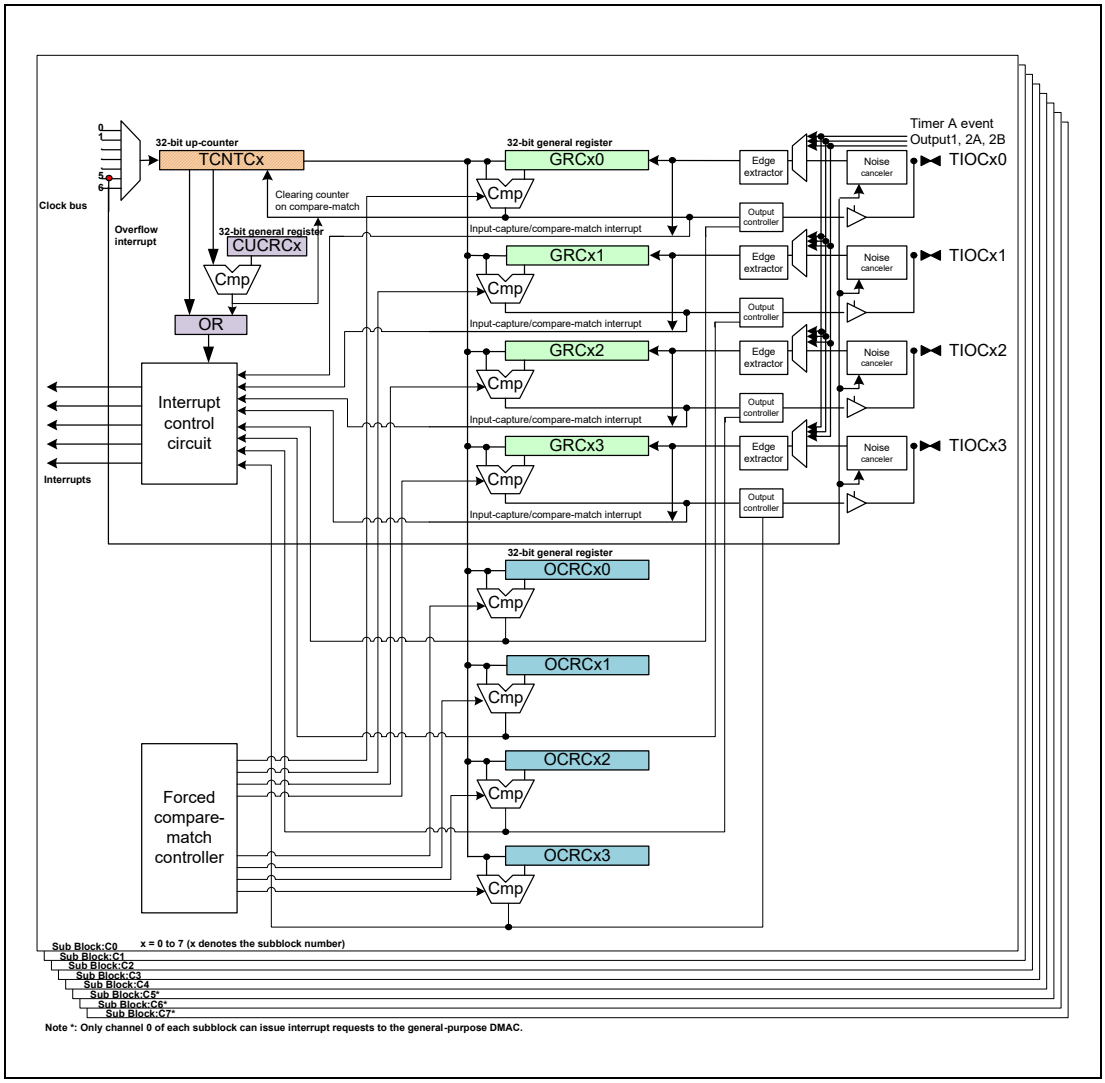

Figure 21.31 Block Diagram of Timer C

21.6.2 Timer C Registers

21.6.2.1 TSTRC — Timer Start Register C

Access: 8-bit accessible

Address: FFE6 0600_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	STRC7	STRC6	STRC5	STRC4	STRC3	STRC2	STRC1	STRC0
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.68 TSTRC Register Contents

Bit Position	Bit Name	Function
7	STRC7	Counter C7 Start 0: TCNTC7 is disabled 1: TCNTC7 is enabled
6	STRC6	Counter C6 Start 0: TCNTC6 is disabled 1: TCNTC6 is enabled
5	STRC5	Counter C5 Start 0: TCNTC5 is disabled 1: TCNTC5 is enabled
4	STRC4	Counter C4 Start 0: TCNTC4 is disabled 1: TCNTC4 is enabled
3	STRC3	Counter C3 Start 0: TCNTC3 is disabled 1: TCNTC3 is enabled
2	STRC2	Counter C2 Start 0: TCNTC2 is disabled 1: TCNTC2 is enabled
1	STRC1	Counter C1 Start 0: TCNTC1 is disabled 1: TCNTC1 is enabled
0	STRC0	Counter C0 Start 0: TCNTC0 is disabled 1: TCNTC0 is enabled

Note 1. Start bits are provided for subblocks C0 to C7 respectively.

TSTRC is an 8-bit readable/writable register that enables and disables timer counter Cx (TCNTCx) in eight subblocks Cx (x = 0 to 7). When the both the STRC bits in this register and the TCE bit in ATU-IV master enable register (ATUENR) are set to 1, counting is enabled.

TSTRC is initialized to 00_H by a reset.

(1) STRCx — Counter Cx Start

These bits enable and disable timer counter Cx (TCNTCx) in a subblock.

When bit STRCx is cleared to 0, TCNTCx is stopped. While TCNTCx is stopped, the previous counter value is retained and TCNTCx is resumed from the value when this bit is set to 1 again.

Even if the counter Cx start bit is set to 1, counting does not start unless the timer Cx master enable bit in the ATU-IV control register is set to 1.

CAUTION

The prescalers run regardless of this bit and are not synchronized with the timing at which this bit is set. Therefore, the time from when this bit is set to 1 until TCNTCx is incremented for the first time is less than the cycle time of the clock of TCNTCx.

21.6.2.2 NCCRCx — Noise Canceler Control Register Cx (x = 0 to 7)

Access: 8-bit accessible

Address: FFE6 0604_H (NCCRC0)

Table 21.69 NCCRCx Register Contents

Bit Position	Bit Name	Function
7 to 4	NCKCxy	Noise Canceler Clock Select These bits select the count source clock for noise canceler counter Cxy (NCNTCxy).
3 to 0	NCECxy	Noise Canceler Enable Cxy These bits set the TIOCxy input noise canceling function.

Note: (x = 0, 1, 2, 3, 4, 5, 6, 7) (y = 0, 1, 2, 3)

Cx (NCCRCx) is an 8-bit readable/writable register. The noise cancellation is performed on the input capture trigger signal input from pin TIOCxy in subblock Cx by setting this register. Three modes are available in noise cancellation and can be switched by the NCMC bit in the noise cancel mode register (NCMR). Noise canceler count clock or clock bus 5 can be selected as the count source by the noise canceler clock select bits (NCKCxy) in this register.

NCCRCx is initialized to 00_H by a reset.

(1) NCKCxy — Noise-Canceler Clock Select

These bits select the count source clock of noise canceler counter Cxy (NCNTCxy).

NCKCxy	Description
0	Noise canceler count clock (Pϕ or Pϕ/128) is selected as the count source clock of NCNTCxy (Initial value).
1	Clock bus 5 is selected as the count source clock of NCNTCxy.

Note: (x = 0, 1, 2, 3, 4, 5, 6, 7) (y = 0, 1, 2, 3)

Noise canceler count clock or clock bus 5 is selectable as the count source clock. As the noise canceler count clock, a clock of Pϕ or Pϕ/128 can be selected by the NCCSEL bit in the common control unit.

(2) NCECxy — Noise Canceler Enable Cxy

These bits enable or disable the noise canceling function for input/output pins TIOCx0 to TIOCx3 of subblock Cx.

NCECxy	Description	
0	The TIOCxy input noise canceling function is disabled	(Initial value).
1	The TIOCxy input noise canceling function is enabled.	

Note: (x = 0, 1, 2, 3, 4, 5, 6, 7) (y = 0, 1, 2, 3)

When a change in input signal level from TIOCxy is detected with these bits set to 1, processing for premature-transition cancellation mode, minimum time-at-level cancellation mode, or level accumulation cancellation mode starts according to the settings of the noise cancellation mode register (NCMR) and the noise canceler clock select bit (NCKC) in the common control unit.

In premature-transition cancellation mode:

When a level change of the externally input signal is detected, the change is output as the signal whose noise is removed and the corresponding noise canceler counter (NCNTCxy) is started for counting up. Subsequent level changes are masked until the value in the counter reaches the value in the noise canceler register (NCRCxy). The level of the externally input signal is output on this compare match.

When these bits are cleared to 0 while the counter (NCNTCxy) is being incremented, counting continues until the values in the counter and the noise canceler register match. The subsequent level changes are also masked over this period.

In minimum time-at-level cancellation mode:

When a level change of the externally input signal is detected, the corresponding noise canceler counter (NCNTCxy) is started for counting up. If subsequent level changes are not detected until the value in the counter reaches the value in the noise canceler register (NCRCxy), the previously accepted level change is output as the signal whose noise is removed on compare match of the counter and noise canceler register.

When the subsequent level change is detected before the values in the counter and noise canceler register match, all the changes are treated as noise. Therefore the signal whose noise is removed is not changed.

When these bits are cleared to 0 while the counter (NCNTCxy) is being incremented, counting continues until the values in the counter and the noise canceler register match or a level change on the externally input signal is detected.

In level accumulation cancellation mode:

The corresponding noise canceler counter Cxy (NCNTCxy) is started for counting up or down according to the input signal level (high level: up-count, low level: down-count). Up-count continues until the noise canceler counter value matches the noise canceler register Cxy (NCRCxy) value. Down-count continues until the noise canceler counter value reaches 0000_H. When a compare match (NCRCxy) occurs during up-counting, the noise canceler output is updated to 1. When a compare match (0000_H) occurs during down-counting, the noise canceler output is updated to 0.

In minimum time-at-level cancellation mode and premature-transition cancellation mode, clock Pϕ is always used to detect input signal level changes regardless of the selected noise canceler clock. In level

accumulation cancellation mode, the clock selected by the noise canceler clock select Cxy bits (NCKCxy) is used for sampling the input level.

For details on operations in each mode, see **Figure 21.1**, **Figure 21.2** and **Figure 21.3**.

21.6.2.3 TCRCx — Timer Control Registers C (x = 0 to 7)

Access: 8-bit/16-bit accessible

Note 1. Writing 0 is disabled. If 1 is written to these bits, data is not retained. These bits are always read as 0.

Table 21.70 TCRCx Register Contents

Bit Position	Bit Name	Function
15 to 12	FOCMCxy	Forced Output Compare Match Cxy Forced compare match is performed by output compare register Cxy (OCRCxy).
11 to 9	—	Not used. These bits are read as 0. When writing, always write 0.
8	CLRCx	TCNTCx Clear Cx Enables or disables clearing of timer counters.
7 to 4	FCMCxy	Forced Compare Match Cxy Forced compare match is performed by timer general register Cxy (GRCxy).
3	PWMx0	PWM Mode Whether to operate subblock Cx in PWM mode is selected.
2 to 0	CKSELCx[2:0]	Clock Select The count clock is selected from clock bus 0 to 6.

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7
y = 0, 1, 2, 3: Corresponding to general registers Cx0, Cx1, Cx2, and Cx3

The timer control registers Cx (TCRCx) are 8-bit/16-bit readable/writable registers that select the counter clock for subblocks C0 to C7, set operating mode, set forced compare matches, and enable/disable clearing of timer counters.

(1) CKSELCx[2:0] — TCNTCx Clock Select

These bits select the counter clock of subblock Cx.

Timer counters Cx (TCNTCx) in subblock Cx are driven by the clock selected in these bits.

CKSELCx			Description	
0	0	0	Counters are driven by clock-bus line 0	(initial value)
0	0	1	Counters are driven by clock-bus line 1	
0	1	0	Counters are driven by clock-bus line 2	
0	1	1	Counters are driven by clock-bus line 3	
1	0	0	Counters are driven by clock-bus line 4	
1	0	1	Counters are driven by clock-bus line 5	
1	1	0	Counters are driven by clock-bus line 6	
1	1	*	Reserved	

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7

(2) PWMx0 — PWM Mode

Setting this bit to 1 makes subblock Cn operate in PWM mode. In PWM mode, TCNTCn is cleared on compare match between TCNTCn and timer general register Cx0 (GRCx0). The setting of this bit is valid when GRCn0 functions as a compare match register.

When general register GRCxm (m = 1 to 3) functions as a compare match register, aIOCx0 setting value in the TIORCx is output to its output pins (TIOCx1, TIOCx2, TIOCx3) at the timing of clearing of the TCNTCx.

PWM output from pins TIOCx1 to TIOCx3 is enabled by setting a PWM cycle in GRCx0 and setting a duty cycle in GRCx1 to GRCx3.

CAUTION

To make the subblock operate in PWM mode, further setting is needed. Select the compare match (IOCxy[3:2] = 00_B) by the IOCxy bits in timer I/O control register Cx (TIORCx) for GRCx0 and GRCx1 to GRCx3 (for PWM output). Set IOCxy[1:0] to 01_B or 10_B.

The active polarity of PWM can be specified by the IOCxy[1:0] bits.

PWMx0	Description	
0	0: Subblock Cx does not operate in PWM mode	(initial value)
1	1: Subblock Cx operates in PWM mode	

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7

When TCNTCx matches GRCn0 while this bit is set to 1, the counter is cleared to 0000 0000_H. However, when clearing the counter on compare match and incrementation occur simultaneously, TCNTCx is set to 0000 0001_H. This occurs when TCNTCx is driven by the clock whose frequency is equal to the Pϕ clock.

In PWM mode, do not set from GRCx0 to GRCx3 to 0000 0000_H. If GRCx0 is set to 0000 0000_H, note that compare match occurs at illegal cycles.

(3) FCMxy — Forced Compare Match Cxy

Setting these bits to 1 generates forced compare match when a general register (Cxy) is used for compare match.

FCMCxy	Description
0	No forced compare match is disabled on timer general register Cxy (GRCxy) (Initial value)
1	Forced compare match generated on general register Cxy (GRCxy)

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7,
y = 0, 1, 2, 3: Corresponding to general registers Cx0, Cx1, Cx2, and Cx3

Setting the FCMCxy bit to 1 sets the IMFCxy bit (compare match flag) in TSRCx (timer status register Cx) to 1 and outputs a compare match interrupt to the CPU. Even when the IMFCxy bit is set to 1, a compare match interrupt is output. Furthermore, TIOCxy output data also changes as in the case of compare match. This operation is performed only once when the FCMCxy bit is set to 1. Writing 0 to these bits is disabled. If 1 is written to these bits, data is not retained. These bits are always read as 0.

When both PWMx0 bit and FCMCx0 bit are set to 1, the counter is cleared and the set IOCx0 value is output to TIOCxy due to forced compare match. Then, TCNTCx starts counting from 0000 0000_H. (Counter clear due to compare match is enabled only for channel 0 in each subblock.)

(4) CLRCx — TCNTCx Clear Cx

Setting the TCNTCx clear bit Cx to 1 clears the TCNTCx value at the first clock after a compare match between timer counter Cx (TCNTCx) and counter upper-limit setting compare register Cx (CUCRCx).

CLRCx	Description
0	CUCRCx compare match is not used to clear TCNTCx. (Initial value)
1	CUCRCx compare match is used to clear TCNTCx

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7 and timer counter Cx

The upper-limit setting function (CLRCx = 1) can be set in any mode other than PWM mode (PWMx0 = 0).

When the upper-limit setting function (CLRCx = 1) is set in PWM mode (PWMx0 = 1), timer counter Cx (TCNTCx) is cleared in cycles other than the PWM cycle, which sets the PWM output undefined.

(5) FOCMCxy — Forced Output Compare Match Cxy

When the output compare register Cxy (OCRCxy) is used as a compare match register, a compare match is forcibly generated by setting FOCMCxy to 1.

FOCMCxy	Description
0	Forced compare match is disabled for the output compare register Cxy (OCRCxy). (Initial value)
1	Forced compare match is generated in the output compare register Cxy (OCRCxy).

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7
y = 0, 1, 2, 3: Corresponding to output compare registers Cx0 to Cx3

Setting the FOCMCxy bit to 1 sets the OCMFCxy bit (compare match flag) in TSRCx (timer status register Cx) to 1 and outputs a compare match interrupt to the CPU. Even when the OCMFCxy bit is 1, a compare match interrupt is generated and the output from TIOCxy changes as when a compare match occurs. This operation is performed only once when 1 is written to this bit. Writing 0 is disabled. If 1 is written to this bit, data is not retained. This bit is always read as 0.

21.6.2.4 TSRCx — Timer Status Registers Cx (x = 0 to 7)

Access: 8-bit/16-bit accessible
Writing 0 is disabled. If 1 is written to these bits, data is not retained. These bits are always read as 0.

Address: FFE6 0626_H (TSRC0)
FFE6 $06A6_H$ (TSRC1)
FFE6 0726_H (TSRC2)
FFE6 $07A6_H$ (TSRC3)

Table 21.71 TSRCx Register Contents

Bit Position	Bit Name	Function
15 to 12	—	Not used. These bits are read as 0. When writing, always write 0.
11 to 8	OCMFCxy	Output Compare Match Flag Cxy 1: A compare match has occurred by the OCRCxy register. 0: No compare match has occurred by the OCRCxy register. (Initial value)
7 to 3	—	These bits are not used. Fix these bits to 0.
4	OVFCx	Overflow Flag Cx 1: An overflow has occurred. 0: No overflow has occurred.
3 to 0	IMFCxy	Input Capture/Compare Match Flag Cxy 1: Input capture and compare match by the GRCxy register have occurred. 0: No input capture or compare match by the GRCxy register has occurred.

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7
y = 0, 1, 2, 3: Corresponding to channels 0 to 3

Timer Status Registers Cx (TSRCx) are 8-bit/16-bit read-only registers that indicate occurrence of overflow of timer counter Cx (TCNTCx) in subblocks Cx (x = 0 to 7) and input capture and compare match of timer general registers Cxy (GRCxy, y = 0 to 3), and output compare match of output compare registers Cxy (OCRCxy, y = 0 to 3).

These status flags indicate occurrence of an interrupt request. These flags can be cleared by setting corresponding bits in the timer status clear register Cx (TSCRCx). If an interrupt source occurs with one of these flags set to 1, an interrupt request is generated again. Even when clearing a flag by using the corresponding timer status clear register Cx conflicts with setting the flag due to occurrence of an interrupt source, an interrupt request is generated.

TSRCx is initialized to 0000_H by a reset.

(1) OCMFCxy — Output Compare Match Flag Cxy

This status flag indicates occurrence of an output compare match of the output compare register Cxy (OCRCxy). This flag cannot be set to 1 or 0 by the software. Setting and clearing conditions are described below.

OCMFCxy	Description
0	[Clearing condition: compare match mode/input capture mode/one-shot pulse mode] Writing 1 to OCMFCCxy in timer status clear register Cx (TSCRCx).
1	[Setting conditions: compare match mode/input capture mode] • When the TCNTCx value is equal to the OCRCxy value • Writing 1 to FOCMCxy (forced output compare match bit) in TCRCx [Setting conditions: one-shot pulse mode] • When the TCNTCx value is equal to the OCRCxy value while one-shot pulse is output • Writing 1 to FOCMCxy (forced output compare match bit) in TCRCx while one-shot pulse is output

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7
y = 0, 1, 2, 3: Corresponding to channels 0 to 3

The next output compare processing is enabled even when the output compare match flag (OCMFCxy) is 1 (the flag is not cleared). At this time, 1 is overwritten to OCMFCxy.

Even if the output compare match status is cleared while the TCNTCx and OCMFCxy values are equal after an output compare match is detected, no status is set newly.

OCMFCxy and IMFCxy shares the same interrupt. Output of interrupt for one or both bits is enabled by setting the timer interrupt enable register Cx (TIERCx).

(2) OVFCx — Overflow Flag Cx

Indicates whether or not TCNTCx has overflowed. This flag cannot be set to 1 or 0 by software.

OVFCx	Description
0	[Clearing condition] Writing 1 to OVFCCx in timer status clear register Cx (TSCRCx) (Initial value)
1	[Setting condition] • When the TCNTCx value overflows (FFFF FFFF$_H$ to 0000 0000$_H$) • When the counter is cleared with the upper-limit setting function enabled

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7

The overflow flag is set to 1 when the up-count clock is input with TCNTCx set to FFFF FFFF$_H$ or at the next PCLK clock after the counter value matches the upper-limit setting register value with the upper-limit setting function enabled. When writing 0000 0000$_H$ to TCNTCx or

TCNTCx is started from 0000 0000$_H$, this bit is not set to 1.

When writing to TCNTCx at the same time as incrementation while it is FFFF FFFF$_H$, this bit is set to 1. However, TCNTCx is started from the written value.

(3) IMFCxy — Input Capture/Compare Match Flag Cxy

These bits indicate whether or not input capture and compare match between timer general register Cxy (GRCxy) and TCNTCx has occurred. This flag cannot be set to 1 or 0 by software. Setting and clearing conditions are shown below.

IMFCxy	Description
0	[Clearing conditions: compare match mode/input capture mode/one-shot pulse mode] Writing 1 to IMFCCxy in timer status clear register Cx (TSCRCx)
1	[Setting condition: input capture mode] • When GRCxy functions as an input capture register and the value in TCNTCx is transferred to GRCxy on an assertion of the input capture signal [Setting conditions: output compare mode] • When GRCxy functions as a compare match register and the values in TCNTCx and GRCxy match • When the forced compare match bit (FCMCxy) in TCRCx is set to 1 [Setting conditions: one-shot pulse output mode] • When the TCNTCx value is equal to the GRCxy after (or at the same time when) a compare match of OCRCxy is generated while one-shot pulse is output • When the forced compare match bit (FCMCxy) in TCRCx is set to 1 after (or at the same time when) a compare match of OCRCxy is generated while one-shot pulse is output

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7
y = 0, 1, 2, 3: Corresponding to channels 0 to 3

Even if these bits are set to 1 meaning that the flag has not been cleared, another input capture or output compare signal can be input. A value of 1 is written to these bits.

Even if the compare match flag is cleared to 0 while TCNTCx = IMFCxy after the match in comparison is detected, these bits are not set to 1.

OCMFCxy and IMFCxy shares the same interrupt. Output of interrupt for one or both bits is enabled by setting the timer interrupt enable register Cx (TIERCx).

Bit Position	Bit Name	Function
15 to 12	—	These bits are not used. These bits are read as 0.
11	OCMFCCx3	Output Compare Match Flag Clear Cx3 Enable 0: Disabled (Initial value) 1: OCMFCx3 in timer status register Cx (TSRCx) is cleared to 0.
10	OCMFCCx2	Output Compare Match Flag Clear Cx2 Enable 0: Disabled (Initial value) 1: OCMFCx2 in timer status register Cx (TSRCx) is cleared to 0.
9	OCMFCCx1	Output Compare Match Flag Clear Cx1 Enable 0: Disabled (Initial value) 1: OCMFCx1 in timer status register Cx (TSRCx) is cleared to 0.
8	OCMFCCx0	Output Compare Match Flag Clear Cx0 Enable 0: Disabled (Initial value) 1: OCMFCx0 in timer status register Cx (TSRCx) is cleared to 0.
7 to 5	—	These bits are not used. Fix these bits to 0.
4	OVFCCx	Overflow Flag Clear C Enable 0: Disabled (Initial value) 1: OVFCx in timer status register Cx (TSRCx) is cleared to 0.
3	IMFCCx3	Input Capture Flag Clear C3 Enable 0: Disabled (Initial value) 1: IMFCx3 in timer status register Cx (TSRCx) is cleared to 0.
2	IMFCCx2	Input Capture Flag Clear C2 Enable 0: Disabled (Initial value) 1: IMFCx2 in timer status register C (TSRCx) is cleared to 0.
1	IMFCCx1	Input Capture Flag Clear C1 Enable 0: Disabled (Initial value) 1: IMFCx1 in timer status register Cx (TSRCx) is cleared to 0.
0	IMFCCx0	Input Capture Flag Clear C0 Enable 0: Disabled (Initial value) 1: IMFCx0 in timer status register Cx (TSRCx) is cleared to 0.

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7

TSCRCx is an 8-bit/16-bit readable/writable register to set clearing of flags at occurrence of an overflow or input capture or compare match.

This register is always read as 0.

TSCRCx is initialized to 0000_H by a reset.

(1) OCMFCCx3 — Output Compare Match Flag Clear Cx3 Enable

Writing 1 to this register while the compare match flag (OCMFCx3) in the timer status register Cx (TSRCx) is set to 1 clears OCMFCx3 to 0. This bit is always read as 0.

(2) OCMFCCx2 — Output Compare Match Flag Clear Cx2 Enable

Writing 1 to this register while the compare match flag (OCMFCx2) in the timer status register Cx (TSRCx) is set to 1 clears OCMFCx2 to 0. This bit is always read as 0.

(3) OCMFCCx1 — Output Compare Match Flag Clear Cx1 Enable

Writing 1 to this register while the compare match flag (OCMFCx1) in the timer status register Cx (TSRCx) is set to 1 clears OCMFCx1 to 0. This bit is always read as 0.

(4) OCMFCCx0 — Output Compare Match Flag Clear Cx0 Enable

Writing 1 to this register while the compare match flag (OCMFCx0) in the timer status register Cx (TSRCx) is set to 1 clears OCMFCx0 to 0. This bit is always read as 0.

(5) OVFCCx — Overflow Flag Clear Cx Enable

Writing 1 to this bit while overflow flag Cx (OVFCx) in the timer status register Cx (TSRCx) is set to 1 clears OVFCx to 0. This bit is always read as 0.

(6) IMFCCx3 — Input Capture Flag Clear Cx3 Enable

Writing 1 to this bit while input capture flag Cx3 (IMFCx3) in the timer status register Cx (TSRCx) is set to 1 clears IMFCx3 to 0. This bit is always read as 0.

(7) IMFCCx2 — Input Capture Flag Clear Cx2 Enable

Writing 1 to this bit while input capture/compare match flag Cx2 (IMFCx2) in the timer status register Cx (TSRCx) is set to 1 clears IMFCx2 to 0. This bit is always read as 0.

(8) IMFCCx1 — Input Capture Flag Clear Cx1 Enable

Writing 1 to this bit while input capture/compare match flag Cx1 (IMFCx1) in the timer status register Cx (TSRCx) is set to 1 clears IMFCx1 to 0. This bit is always read as 0.

(9) IMFCCx0 — Input Capture Flag Clear Cx0 Enable

Writing 1 to this bit while input capture/compare match flag Cx0 (IMFCx0) in the timer status register Cx (TSRCx) is set to 1 clears IMFCx0 to 0. This bit is always read as 0.

21.6.2.6 TIORCx — Timer I/O Control Registers Cx (x = 0 to 7)

Table 21.73 TIORCx Register Contents

Bit Position	Bit Name	Function
15 to 0	IOCxy[3:0]	Settings of timer general register Cxy (GRCxy) functions, input capture and compare match, edge to be extracted at input capture, and output value at compare match

Note: x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7
y = 0, 1, 2, 3: Corresponding to channels 0 to 3

(1) IOCxy[3:0] — I/O Control bit

IOCxy					
[3]	[2]	[1]	[0]		Function
0	0	0	0	Compare match mode GRCxy is used as output compare register. OCRCxy is used as output compare register.	Compare match by GRCxy disabled (Initial value) Compare match by OCRCxy enabled
0	0	0	1		A value of 0 is output at compare match by GRCxy Compare match by OCRCxy enabled
0	0	1	0		A value of 1 is output at compare match by GRCxy Compare match by OCRCxy enabled
0	0	1	1		Toggle output at compare match by GRCxy Compare match by OCRCxy enabled
0	1	0	0	Input capture mode GRCxy is used as input capture register. OCRCxy is used as output compare register.	Input capture disabled Compare match by OCRCxy enabled
0	1	0	1		Capturing at the rising edge of TIOCxy Compare match by OCRCxy enabled
0	1	1	0		Capturing at the falling edge of TIOCxy Compare match by OCRCxy enabled
0	1	1	1		Capturing at the rising edge and falling edge of TIOCxy Compare match by OCRCxy enabled
1	0	0	0	One-shot pulse mode GRCxy and OCRCxy are used as output compare register for one-shot.*2	Compare match of OCRCxy and GRCxy disabled A value of 0 is output from TIOCxy output (active high)
1	0	0	1		Compare match of OCRCxy and GRCxy disabled A value of 1 is output from TIOCxy output (active low)
1	0	1	0		A value of 0 is output from TIOCxy output until occurrence of a compare match of OCRCxy, a value of 1 is output from TIOCxy output from occurrence of a compare match of OCRCxy until occurrence of a compare match of GRCxy, and then a value of 0 is output from TIOCxy output at occurrence of a compare match of GRCxy (active high). *1
1	0	1	1		A value of 1 is output from TIOCxy output until occurrence of a compare match of OCRCxy, a value of 0 is output from TIOCxy output from occurrence of a compare match of OCRCxy until occurrence of a compare match of GRCxy, and then a value of 1 is output from TIOCxy output at occurrence of a compare match of GRCxy (active low) *1
1	1	0	0	Input capture mode GRCxy is used as input capture register. OCRCxy is used as output compare register.	Input capture disabled Compare match by OCRCxy enabled
1	1	0	1		Capturing by timer A event output 1 Compare match by OCRCxy enabled
1	1	1	0		Capturing by timer A event output 2A Compare match by OCRCxy enabled
1	1	1	1		Capturing by timer A event output 2B Compare match by OCRCxy enabled

Note: x = 0, 1, 2, 3, 4, 5, 6, 7) (y = 0, 1, 2, 3)

Note 1. If a compare match by OCRCxy and a compare match by GRCxy occur at the same time, the compare match by GRCxy takes precedence.

Note 2. Before selecting one-shot pulse mode (IOCxy[3:2] = 10_B), set the PWMX0 bit to 0. It is prohibited to set PWMX0 bit to 1.

The IOCxy[3:2] bits are used to set operating mode (compare match mode, input capture mode, or one-shot pulse mode). Change operating mode (IOCxy[3:2]) while the counter is not working.

Disable compare match and input capture (by setting IOCxy[1:0] to 00_B) before switching output mode for compare match mode (IOCxy[3:2] = 00_B) or switching edge detection/trigger for input capture mode (IOCxy[3:2] = 01_B or 11_B).

Change operating mode to one-shot pulse mode (IOCxy[3:2] = 10_B) and change active polarity (IOCxy[1:0]) in one-shot pulse mode (IOCxy[3:2] = 10_B) while the counter is not working.

When one-shot pulse mode (IOCxy[3:2] = 10_B) is used, initialize the external pins (TIOCxy) by forced compare match Cxy (FCMCxy) after operating mode is set, and then start counting.

21.6.2.7 TCNTCx — Timer Counters Cx (x = 0 to 7)

Timer counter Cx (TCNTCx) is 32-bit readable/writable registers driven by the input clock. These counters can be read from and written to while they are being run.

Timer counter Cx (TCNTCx) is started for counting by setting the bit in timer start register C (TSTRC) to 1. The clock signal is selected by the clock select bit (CKSEL) in timer control register Cx (TCRCx). A timer overflow causes an overflow interrupt request to be output to the CPU. TCNTCx is initialized to $0000\ 0000_H$ by a reset.

21.6.2.8 GRCxy — General Registers Cxy

(x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

These timer general registers Cxy (GRCxy) are 32-bit readable/writable registers that function as the input capture register or output compare register. These functions are switched by setting timer I/O control register Cx (TIORCx).

While a timer general register Cx is used as an input capture register, it detects an external input capture signal, stores the TCNTCx value, and outputs an input capture interrupt request to the CPU and a start request to the DMA. At this time, the IMFCxy bit in timer status register Cx (TSRCx) is set to 1. The edge to be detected is selected by TIORCx.

Input capture is performed even if the counter is stopped (the TCE bit in ATUENR is cleared to 0 or the STRCx bit in TSTRC is cleared to 0). The value in the counter stopped is loaded to GRCxy.

If these registers function as the output compare register for compare match, the values in GRCxy and the timer counter Cx (TCNTCx) are constantly compared. When these values match, TIOCxy output is changed according to the method (0 output, 1 output, or toggle output) specified in TIORCx, a compare match interrupt request is output to the CPU, and a start request is output to the DMA. At this time, the IMFCxy bit in the timer status register Cx (TSRCx) is set to 1. Initially, logical zero is output on the TIOCxy pin (immediately after a reset or output compare modes are switched). During operation, the previous value is output.

If these registers function as the output compare register for one-shot pulse output, one-shot pulse output starts by writing to GRCxy. Set OCRCxy before writing to GRCxy.

When one-shot pulse output starts, the values in GRCxy and timer counter Cx (TCNTCx) are compared after the match in comparison with OCRCxy is detected (or when GRCxy = OCRCxy).

Compare match of GRCxy inactivates one-shot pulse (compare match with OCRCxy activates one-shot pulse) and the IMFCxy bit in the timer status register Cx (TSRCx) is set to 1.

Once the one-shot pulse is output, another output is not performed until new value is set to GRCxy. Also, the IMFCxy bit in the timer status register Cx (TSRCx) is not changed.

When these registers are used as output compare registers for compare match or one-shot pulse output, if the counter upper-limit setting function (see **Section 21.6.3.5, Counter Upper-Limit Setting Function**) is in use with clock-bus line 5 or 6, or with a division ratio of 1/1 selected for the prescaler, the timer counter counts between 1 and the value of CUCRCx and the counter value may not become $0000\ 0000_H$. Therefore, do not set these registers to $0000\ 0000_H$ in such cases.

GRCxy is initialized to $FFFF\ FFFF_H$ by a reset.

21.6.2.9 NCNTCxy — Noise Canceler Counters Cxy

(x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Table 21.74 NCNTCxy Register Contents

Bit Position	Bit Name	Function
15 to 0	NCNTCxy	Noise Cancel Count Cxy These bits store a 16-bit count value

Noise Canceler counters Cxy (NCNTCx0 to x3) are 8-bit readable/writable registers.

NCNTCx0 to x3 are started by the external input pins (TIOCx0 to TIOCx3) as triggers when the noise canceler is enabled by the noise cancel enable bit (NCECx0 to x3) in timer I/O control register Cx (TIORCx). In level accumulation cancellation mode, these counters increment or decrement according to the external input level. Up-count or down-count after operation start is performed in synchronization with the noise canceler count clock or clock bus 5 supplied from the prescaler.

NCNTCxy continues counting regardless of the settings in the timer C enable bit (TCE) in ATU-IV master enable register (ATUENR) and in TSTRC (regardless of the TCNTCx).

NCNTCxy operates in one of three modes (premature-transition cancellation mode, minimum time-at-level cancellation mode, or level accumulation cancellation mode) according to the settings of the noise cancellation mode select bit (NCMSEL) and the timer C noise cancellation mode bit (NCMC) in the noise cancellation mode register (NCMR) in the common control unit.

- Premature-transition cancellation mode
  When a level change of the externally input signal (TIOCxy) is detected while bit NCECxy is set to 1 and NCNTCxy is stopped, NCNTCxy is started for counting up. This counter is cleared to 0000_H and stopped on the first edge of the PCLK after the value in NCNTCxy matches the value in noise cancel register Cxy (NCRCxy).
  NCNTCxy is incremented regardless of the TCE bit in ATUENR.
  The first change is output as the signal whose noise is removed and the edge is to be extracted. Subsequent level changes are masked until the value in the counter reaches the value in the noise cancel register (NCRCxy). The level of the externally input signal is output on this compare match.

  When the NCECxy bit is cleared to 0 while the counter (NCRCxy) is being incremented, counting continues until the values in the counter and the noise canceler register match. The subsequent level changes are also masked over this period.

- In minimum time-at-level cancellation mode
  When a level change of the externally input signal (TIOCxy) is detected while the NCECxy bit is set to 1 and NCNTxy is stopped, NCNTxy is started for counting up. This counter is cleared to 0000_H and stopped on the first edge of the PCLK after the value in NCNTxy matches the value in noise cancel registers Cxy (NCRCxy) or after the level of the externally input signal (TIOCxy) is changed.
  NCNTxy is incremented regardless of the TCE bits in ATUENR.
  When a level change of the externally input signal is detected, the corresponding noise canceler counter (NCNTxy) is started for counting up. If subsequent level changes are not detected until the value in the counter reaches the value in the noise canceler register (NCRCxy), the previously accepted level change is output as the signal whose noise is removed on compare match of the counter and noise canceler register. When the subsequent level change is detected before the values in the counter and noise canceler register match, all the changes is treated as noise. Therefore the signal whose noise is removed is not changed.
  When the NCECxy bits are cleared to 0 while the counter (NCNTCxy) is being incremented, counting continues until the values in the counter and the noise canceler register match or a level change on the externally input signal is detected.

- In level accumulation cancellation mode
  When the NCECxy bit is 1, NCNTCxy increments or decrements according to the input signal level. input While the input level is high, NCNTCxy increments. When the counter value matches the noise cancel register Cxy (NCRCxy) value, up-counting stops on the next PCLK. While the input level is low, NCNTCxy decrements. When the counter value reaches 0000_H, down-counting stops on the next PCLK.
  NCNTCxy counts regardless of the TCE bit value in the ATU-IV master enable register (ATUENR).
  When the counter value matches the NCRCxy value during up-counting, the noise canceler output is updated to 1. When the counter value reaches 0000_H during down-counting, the noise canceler output is updated to 0.
  When the NCECxy bit is cleared during counting, the noise canceler counter stops working and the value changes from the noise canceler output to the input signal level at that time. For this reason, note that when clearing the NCECxy bit in level accumulation cancellation mode, edge detection may be made at this changeover.
  NCNTCxy is initialized to 0000_H by a reset.

21.6.2.10 NCRCxy — Noise Canceler Registers Cxy

(x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 16-bit accessible but 8-bit inaccessible

Address: FFE6 0672_H + (80_H * x) (NCRCx0)
FFE6 0676_H + (80_H * x) (NCRCx1)
FFE6 $067A_H$ + (80_H * x) (NCRCx2)

Table 21.75 NCRCxy Register Contents

Bit Position	Bit Name	Function
15 to 0	NCRCxy	Noise Canceling Time Cxy TIOCxy noise canceling period (16-bit comparison value)

Noise cancel resisters Cxy (NCSCx0 to Cx3) are 16-bit readable/writable registers that are provided in each subblock and set the upper limitations of noise cancel counters Cxy (NCNTCx0 to Cx3).

When PCLK/128 clock is selected as a noise canceler clock, noise with maximum length of 0.21 s (at PCLK = 40 MHz) can be canceled when this register is set to $FFFF_H$.

NCSCx0 to NCSCx3 operate in one of three modes (premature-transition cancellation mode, minimum time-at-level cancellation mode, or level accumulation cancellation mode) according to the settings of the noise cancellation mode select bit (NCMSEL) and the timer C noise cancellation mode bit (NCMC) in the noise cancellation mode register (NCMR) in the common control unit.

(1) Premature-Transition Cancellation Mode

While NCNTCxy is in count operation, the level change of the subsequent input signal is masked. Values in NCNTCxy and NCRCxy are always compared. If a compare match occurs, the value in NCNTCxy is cleared on the next PCLK, the count operation is stopped, and the masking of the input signal is canceled.

(2) In Minimum Time-at-Level Cancellation Mode

While NCNTCxy is in count operation, noise canceler processing waiting state is entered. Values in NCNTCxy and NCRCxy are always compared. If a compare match occurs, the value in NCNTCxy is cleared on the next PCLK, the count operation is stopped, and at the same time the noise canceler outputs the input signal that has passed through the noise canceling processing.

(3) In Level Accumulation Cancellation Mode

While NCNTCxy is counting up, the NCNTCxy value is compared with the NCRCxy value. When a compare match occurs, NCNTCxy stops up-counting on the next PCLK. While NCNTCxy is counting down, the NCNTCxy value is compared with 0000_H.

NCRCx0 to NCRCx3 can be read and written only in 16-bit units.

NCRCx0 to NCRCx3 are initialized to 0000_H by a reset.

21.6.2.11 OCRCxy — Output Compare Registers Cxy

(x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 0650_H + (80_H * x) + (4_H * y)

Value after reset: FFFF $FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OCRCxy[31:16]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OCRCxy[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Output compare registers Cxy (OCRCxy) are 32-bit readable/writable registers that function as an output compare register.

These registers are used as a compare register in modes other than one-shot pulse mode.

The values in OCRCxy and timer counter Cx (TCNTCx) are always compared. When these values match, a compare match interrupt request and DMA activation request are output to the CPU. At this time, the OCMFCxy bit in the timer status register Cx (TSRCx) is set to 1.

If these registers function as the output compare register for one-shot pulse output, one-shot pulse output starts by writing to GRCxy. Set OCRCxy before writing to GRCxy.

When one-shot pulse output starts, the values in OCRCxy and timer counter Cx (TCNTCx) are compared.

Compare match with OCRCxy activates one-shot pulse (compare match with GRCxy inactivates one-shot pulse) and the OCMFCxy bit in the timer status register Cx (TSRCx) is set to 1.

Once the one-shot pulse is output, another output is not performed until new value is set to GRCxy. Also, the OCMFCxy bit in the timer status register Cx (TSRCx) is not changed.

When these registers are used as output compare registers for compare match or one-shot pulse output, if the counter upper-limit setting function (see **Section 21.6.3.5, Counter Upper-Limit Setting Function**) is in use with clock-bus line 5 or 6, or with a division ratio of 1/1 selected for the prescaler, the timer counter counts between 1 and the value of CUCRCx and the counter value may not become 0000 0000_H. Therefore, do not set these registers to 0000 0000_H in such cases.

OCRCxy is initialized to FFFF $FFFF_H$ by a reset.

21.6.2.12 TIERCx — Timer Interrupt Enable Registers Cx

(x = 0, 1, 2, 3, 4, 5, 6, 7: Corresponding to subblocks C0 to C7)

Access: 8-bit/16-bit accessible

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Counter upper-limit value compare registers Cx (CUCRCx) are 32-bit readable/writable registers that has a function to be compared with the timer counter Cx (TCNTCx). Matching in the comparison between this register and the timer counter Cx (TCNTCx) is enabled by setting the TCNTCx clear bit Cx (CLRCx) in the timer control register Cx (TCRCx) to 1.

The timer counter Cx (TCNTCx) is cleared to 0000 0000$_H$ in response to a match in comparison between the timer counter Cx (TCNTCx) and counter upper-limit setting compare register Cx (CUCRCx). If this match in comparison occurs at the same time as counting up by the timer counter Cx (TCNTCx), the timer counter Cx (TCNTCx) is cleared to 0000 0001$_H$.

The OVFCx bit in timer status register Cx (TSRCx) is set to 1 and an overflow interrupt is output on compare match between the timer counter Cx (TCNTCx) and counter upper-limit setting compare register Cx (CUCRCx).

Do not set CUCRCx to 0000 0000$_H$. Note that if CUCRCx is set to 0000 0000$_H$, a compare match occurs at incorrect intervals.

NOTE

The upper-limit setting function (CLRCx = 1) can be set in modes other than PWM mode (PWMx0 = 0).

5	NCM1C5	Subblock 5 Noise Cancellation Mode This bit specifies the operating mode of subblock 5 noise canceler. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (When NCMC = 0 and NCM2C5 = 0) 1: Level accumulation cancellation mode (When NCMC = 0 and NCM2C5 = 1)
4	NCM1C4	Subblock 4 Noise Cancellation Mode This bit specifies the operating mode of subblock 4 noise canceler. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (When NCMC = 0 and NCM2C4 = 0) 1: Level accumulation cancellation mode (When NCMC = 0 and NCM2C4 = 1)
3	NCM1C3	Subblock 3 Noise Cancellation Mode This bit specifies the operating mode of subblock 3 noise canceler. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (When NCMC = 0 and NCM2C3 = 0) 1: Level accumulation cancellation mode (When NCMC = 0 and NCM2C3 = 1)
2	NCM1C2	Subblock 2 Noise Cancellation Mode This bit specifies the operating mode of subblock 2 noise canceler. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (When NCMC = 0 and NCM2C2 = 0) 1: Level accumulation cancellation mode (When NCMC = 0 and NCM2C2 = 1)
1	NCM1C1	Subblock 1 Noise Cancellation Mode This bit specifies the operating mode of subblock 1 noise canceler. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (When NCMC = 0 and NCM2C1 = 0) 1: Level accumulation cancellation mode (When NCMC = 0 and NCM2C1 = 1)
0	NCM1C0	Subblock 0 Noise Cancellation Mode This bit specifies the operating mode of subblock 0 noise canceler. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (When NCMC = 0 and NCM2C0 = 0) 1: Level accumulation cancellation mode (When NCMC = 0 and NCM2C0 = 1)

The noise cancellation mode channel register 1C is an 8-bit readable/writable register used to select an operating mode of noise canceler in each channel.

Premature-transition cancellation mode detects a change in input signal level, and then ignores changes in input signal level within the specified time period. Changes in input signal level within the specified time period after the first level change are regarded as noise in this mode.

Level accumulation cancellation mode accumulates input signal levels and regards that the input level has reached 0 or 1 when the accumulation result becomes 0 or the specified value.

Each period is specified by the noise cancellation register in each channel, and the noise cancellation counter measures the time.

Figure 21.1, **Figure 21.2**, and **Figure 21.3** show schematics of noise cancellation operation (example of TIA00 input of timer A) in premature-transition cancellation mode, minimum time-at-level cancellation mode, and level accumulation cancellation mode, respectively.

Edge detection is made for signals that have passed through the noise canceler in each channel. **Figure 21.1**, **Figure 21.2**, and **Figure 21.3** show examples of rising-edge detection of signals that have passed through the noise canceler.

(1) NCM1C7 — Subblock 7 Noise Cancellation Mode

This bit specifies the operating mode of subblock 7 noise canceler.

(2) NCM1C6 — Subblock 6 Noise Cancellation Mode

This bit specifies the operating mode of subblock 6 noise canceler.

(3) NCM1C5 — Subblock 5 Noise Cancellation Mode

This bit specifies the operating mode of subblock 5 noise canceler.

(4) NCM1C4 — Subblock 4 Noise Cancellation Mode

This bit specifies the operating mode of subblock 4 noise canceler.

(5) NCM1C3 — Subblock 3 Noise Cancellation Mode

This bit specifies the operating mode of subblock 3 noise canceler.

(6) NCM1C2 — Subblock 2 Noise Cancellation Mode

This bit specifies the operating mode of subblock 2 noise canceler.

(7) NCM1C1 — Subblock 1 Noise Cancellation Mode

This bit specifies the operating mode of subblock 1 noise canceler.

(8) NCM1C0 — Subblock 0 Noise Cancellation Mode

This bit specifies the operating mode of subblock 0 noise canceler.

CAUTIONS

1. **Setting this register is enabled only when the NCMC bit in the noise cancellation mode register (NCMR) of the common controller is 0. Furthermore, in case the noise cancellation mode bit of corresponding channel (NCM1Cx) in this register is set to 1, the mode can be set to premature-transition cancellation mode or minimum time-at-level cancellation mode depending on the status of the corresponding channel bit in the noise cancellation mode channel register 2C (NCMCR2C).**
2. **x = 0 to 7**

Table 21.78 shows the truth table for settings that determine noise cancellation modes.

Note 1. x = 0 to 7

Note 2. An enable bit (NCECx) can be set for each channel.

Setting when each channel is the unit of filtering of timer C (precondition: channel enable = 1)

- Setting each channel

  When the noise cancellation mode bit (NCMC) in the noise cancellation mode register (NCMR) is set to 0 and any of the noise cancellation mode channel setting bits (NCM1C*) in the noise cancellation mode channel register 1C (NCMCR1C) of timer C is set to 1

- Setting all channels

  When the noise cancellation mode bit (NCMC) in the noise cancellation mode register (NCMR) is 1 in the description of “Setting each channel” above or when all of the noise cancellation mode channel setting bits (NCM1Cx) in the noise cancellation mode channel register 1C (NCMCR1C) are set to 0 in the description of “Setting each channel” above

21.6.3 Operation

21.6.3.1 Input Capture Mode — Input Capture Function

Timer general registers Cxy (GRCxy) of timer C performs input capture when an edge is input from the corresponding external pin (TIOCxy) or an event output (event 1, 2A, or 2B) from timer A is input by setting input capture in timer I/O control registers Cx (TIORCx).

The timer counter Cx (TCNTCx) starts up-counting by setting the timer start register C (TSTRC). When an edge of the corresponding external pin of GRCxy is input or an event output from timer A is input, the corresponding bit (IMFCxy) in the timer status register Cx (TSRCx) is set to 1 and the counter value is transferred to GRCxy. After a changed edge of TIOCxy has been extracted and then two internal operating clock (PCLK) cycles have passed, the interrupt output changes. Input capture flags (IMFCxy bits in TSRCx) can be cleared by writing 1 to the corresponding clear bit in the timer status clear register Cx (TSCRCx).

An edge to be input can be selected from rising edge, falling edge, and both edges according to the setting of the IOC bit in the TIORCx register.

Furthermore, an interrupt request can be output to the CPU at the input capture timing and DMA transfer can be activated.

The output compare register Cxy (OCRCxy) and timer counter Cx (TCNTCx) are compared.

When the values in OCRCxy and TCNTCx match, the bit (OCMFCxy) in timer status register Cx (TSRCx) corresponding to OCRCxy is set.

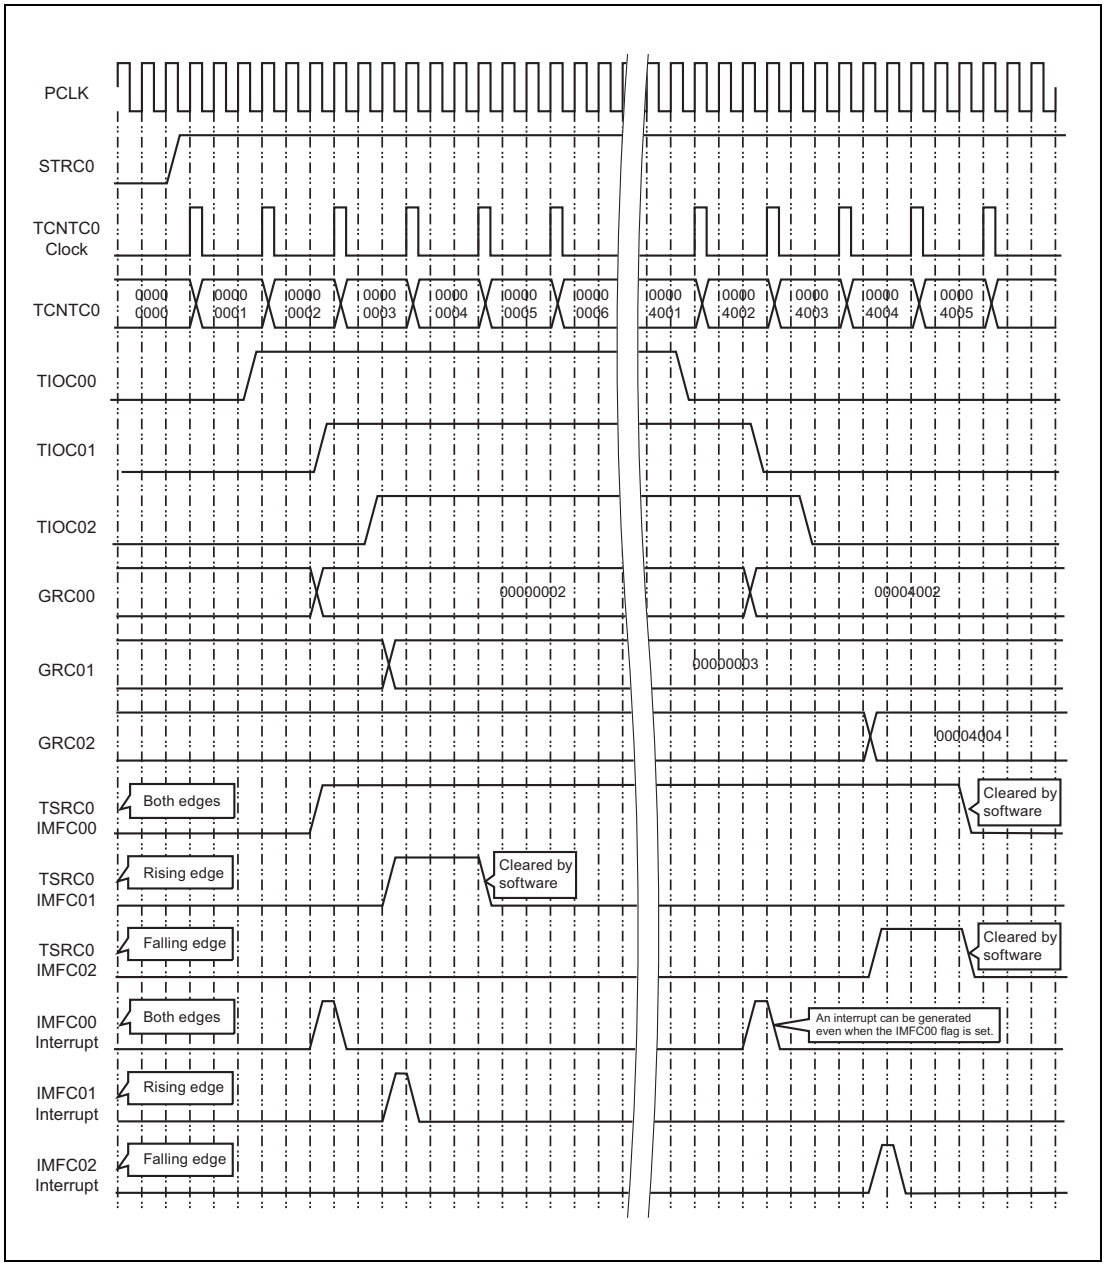

Figure 21.32 Operation Example of Input Capture

Figure 21.32 shows an operation example of input capture in subblock C0. In this example, the both edges on pin TIOC00, the rising edge on pin TIOC01, and the falling edge on TIOC02 are selected.

Input capture is performed even if TCNTCx is stopped (when the TCE bit in ATUENR or bit STRCx is cleared to 0). The counter value of the TCNTCx stopped is captured in GRCxy.

21.6.3.2 Compare Match Mode — Compare Match Function

Timer general registers Cxy (GRCxy) of timer C output compare match from the corresponding external pin (TIOCxy) by setting compare match operation in timer I/O control registers Cx (TIORCx).

Timer counter Cx (TCNTCx) is started for counting up by setting a bit in timer start register C (TSTRC) to 1. Set the value in GRCxy before starting the counter. When the values in GRCxy and TCNTCn match, a bit corresponding to GRCxy in timer status register Cx (TSRCx) is set and a waveform is output on external pin TIOCxy.

The compare match flag is set and the signal level on pin TIOCnm is changed on the first edge of the PCLK immediately after compare match between GRCnm and TCNTCx. Compare match flags (IMFCxy bits in TSRCx) can be cleared to 0 by writing 1 to the corresponding clear bit in the timer status clear register Cx (TSCRCx).

A logical one, a logical zero, or a toggled output can be selected for the signal to be output on pin TIOCxy.

An interrupt request can be output to the CPU at occurrence of a compare match.

and DMA transfer can be activated.

The output compare register Cxy(OCRCxy) is compared with the timer counter Cx(TCNTCx). When the values of OCRCxy and TCNTCx are matched, the (OCMFCxy) bit in the timer status register Cx (TSRCx) corresponding to OCRCxy is set.

Figure 21.33 shows an operation example of compare match. In this example, a toggled output on GRC00, a logical one output on GRC01, and a logical zero output on GRC02 are externally output. A value of 004004 is set for GRC0y, which changes the TIOC0y output on the next PCLK after compare match with the TCNTC0 value.

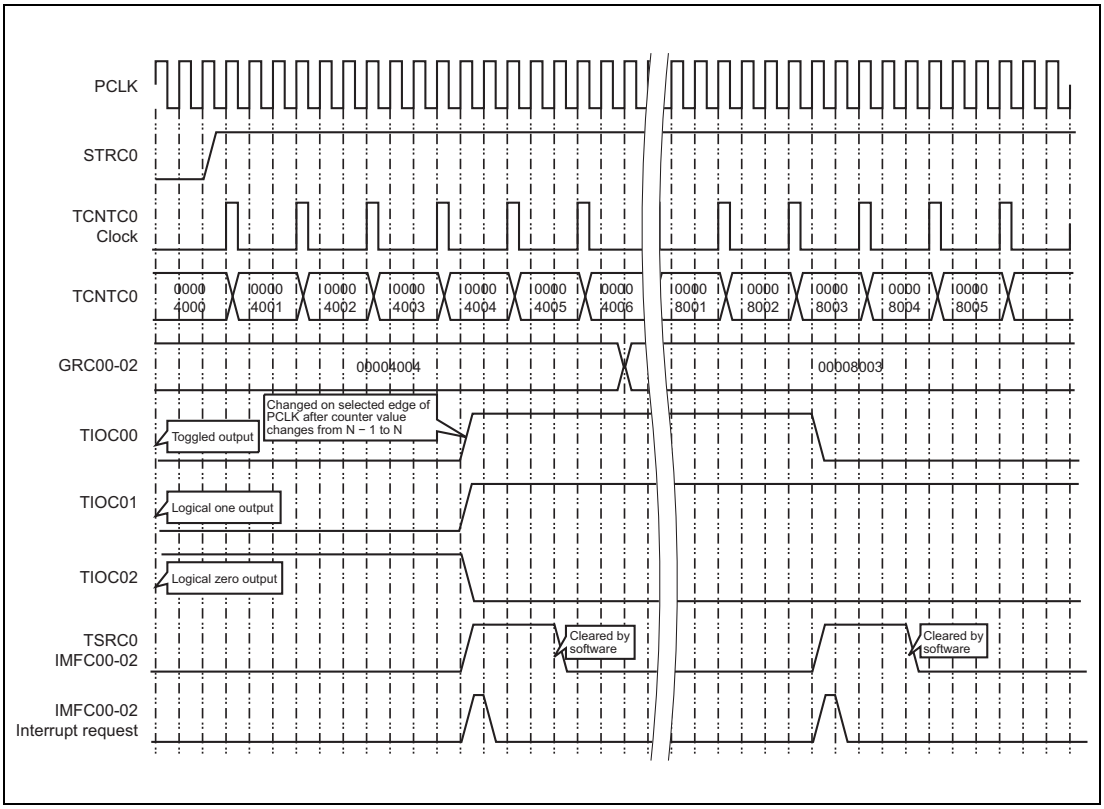

Figure 21.33 Operation Example of Compare Match

By setting a forced compare match bit (FMCMxy) in timer control register Cx (TCRCx), compare match can be generated even if TCNTCx has not matched GRCxy. The compare match flag and the signal level on pin TIOCxy are changed on the first edge of the PCLK after bit FCMCxy is set to 1.

The match in comparison is detected when any of the following occurs.

- When the values in TCNTCx and GRCxy match (forced compare match is OFF)
- When the forced compare match bit (bit FCMCxy in TCRCx) is changed from 0 to 1
- When the values in TCNTCx and GRCxy match because a counter is cleared on compare match of GRCx0

The compare match flag and the signal level on pin TIOCxy is changed on the first edge of the PCLK after bit FCMCxy is set to 1. Make sure that the compare match operation is selected by bits IOCxy[2:0] in TIORCx before starting operation. The match in comparison is not detected; when GRCxy is set to the same value as TCNTCx; when the compare match operation is selected after setting the forced compare match bit to 1.

The match in comparison is detected regardless of the counter operating state. Even if the counter is stopped, compare match occurs when the condition is satisfied.

When the compare match status flag is cleared before GRCxy and TCNTCx are changed (such as before counting while the counter has been stopped), the match in comparison is not detected.

The output compare register Cxy (OCRCxy) and timer counter Cx (TCNTCx) are compared.

When the values in OCRCxy and TCNTCx match, the bit (OCMFCxy) in timer status register Cx (TSRCx) corresponding to OCRCxy is set.

21.6.3.3 PWM Function

Setting bit PWMx0 in timer control register Cx (TCRCx) to 1 makes channels 1 to 3 in each subblock function as PWM timers with the same frequency. In PWM mode, GRCx0 as a cycle setting register and GRCx1 to GRCx3 as duty cycle setting registers are used. External pins TIOCx1 to TIOCx3 corresponding GRCx1 to GRCx3 are used to output PWM signals. To use them as PWM signal outputs, select the compare match operation by bits IOCxy in TIORCx as well as setting bit PWMx0 so that GRCn0 to GRCn3 function as compare match registers. Furthermore, the active polarity of the PWM waveform can be set by the IOCxy[0] bit in TIORCx (IOCxy[0] = 0: Active high, 1: Active low)

Figure 21.34 shows the PWM operation setting procedure

Timer counter Cx (TCNTCx) is started by setting timer start register C (TSTRC). When the value in TCNTCx reaches the value in the cycle setting register (GRCx0), compare match occurs and the bit in timer status register Cx (TSRCx) is set to 1. At this time, TCNTCx is cleared and a signal is output on external pins TIOCx1 to TIOCx3 according to bit IOCx0 in PWM mode. The output signal levels on pin TIOCx0 depend on bit IOCx0.

When the value in TCNTCx reaches the value in the duty cycle setting register (GRCx1 to GRCx3), the bit in timer status register Cx (TSRCx) is set to 1 and a signal is output on external pins TIOCx1 to TIOCx3 according to bits IOCx1 to IOCx3.

When the same value is set in the cycle and duty cycle setting registers, priority is given to bit IOCx0 corresponding to the cycle setting register.

Figure 21.35 shows an operation example of block C0 in PWM mode.

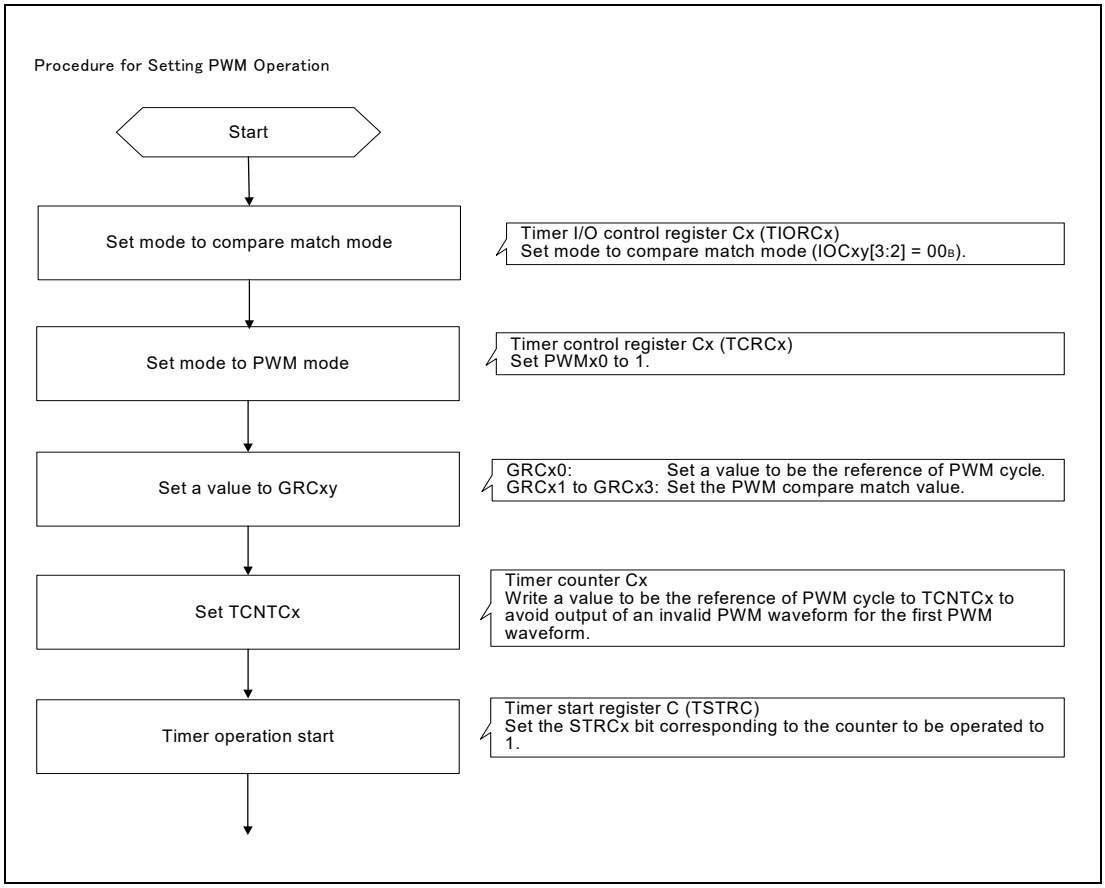

Figure 21.34 PWM Operation Setting Procedure

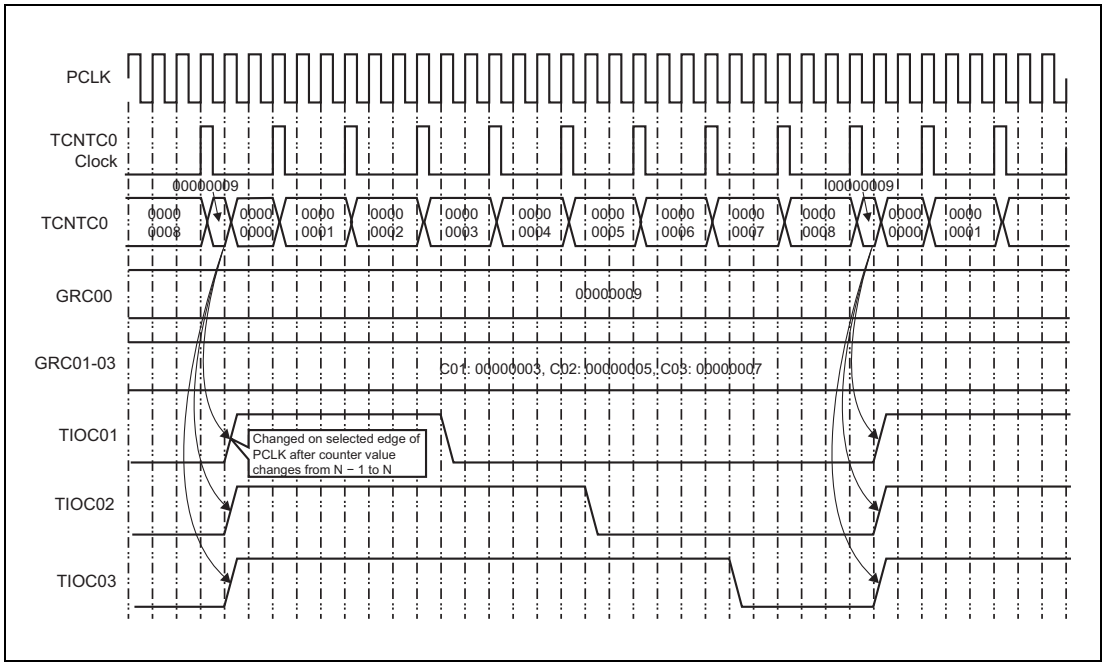

Figure 21.35 Operation Example of PWM Mode

21.6.3.4 One-Shot Pulse Mode — One-Shot Pulse Function

By setting the PWMx0 bits in timer control register Cx (TCRCx) to 0_B and setting the IOCxy[3:2] bits in timer I/O control register Cx (TIORXCx) to 10_B, one-shot pulses are output from the corresponding external pin (TIOCxy).

Setting the timer start register C (TSTRC) starts up-count of the timer counter Cx (TCNTCx).

In one-shot pulse mode, a one-shot pulse is output at a trigger of write access to the GRCxy register.

After the write access to the GRCxy register, a compare match interrupt is output on compare match between timer counter Cx (TCNTCx) and OCRCxy register, set the external pin (TIOCxy) to active level, a compare match interrupt is output on compare match between timer counter Cx (TCNTCx) and GRCxy register, and then reset the external pin (TIOCxy) to inactive level. When a single one-shot pulse output has been completed after an access to the GCRxy register, no interrupt occurs until the next write access to the GCRxy register is made and the external pin (TIOCxy) retains inactive level.

When one-shot pulse mode (IOCxy[3:2] = 10_B) is used, initialize the external pin (TIOCxy) by forced compare match Cxy (FCMCxy) after operating mode is set, and then start counting.

If one-shot pulse mode is activated without initializing the external pin (TIOCxy) to inactive level, output level becomes unstable.

To cancel one-shot pulse mode after a value is written to the GRCxy register, write 1 to forced compare match Cxy (FCMCxy) and forced output compare match Cxy (FOCMCxy) simultaneously.

Figure 21.36 shows an example of one-shot pulse mode operation in block C0.

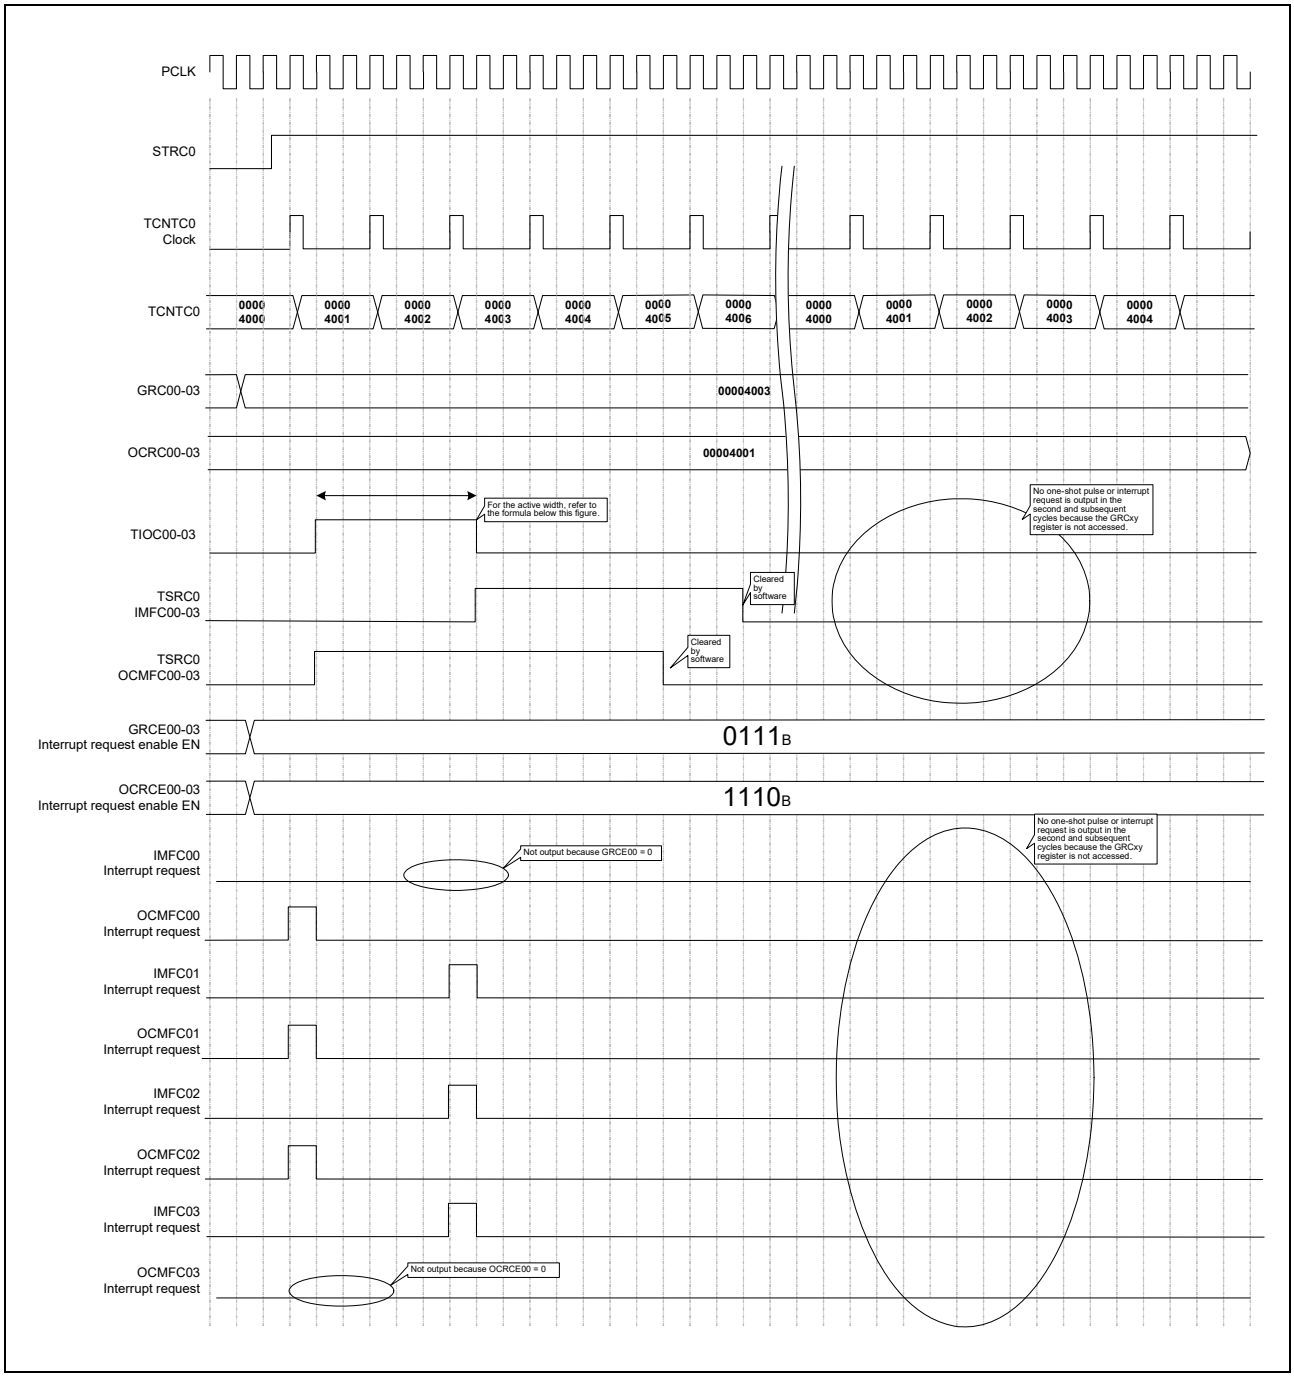

Figure 21.36 One-Shot Pulse Mode Operation

The active width of one-shot pulse can be obtained from the following formula.

GRCxy = OCRCxy:

One-shot pulse (active) width = 0

GRCxy > OCRCxy:

One-shot pulse (active) width = GRCxy[31:0] – OCRCxy[31:0]

GRCxy < OCRCxy:

- Upper-limit setting function is off

  One-shot pulse (active) width = (FFFF $FFFF_H$ – OCRCxy[31:0]) + (GRCxy[31:0] + 1)

- Upper-limit setting function is on

  One-shot pulse (active) width = (CUCRCx – OCRCxy[31:0]) + GRCxy[31:0]

IMFC and OCMFC shares one interrupt request signal though described separately in the above figure.

To output a one-shot pulse in the second and subsequent cycles, be sure to confirm that the previously set one-shot pulse output has been completed, and then set GRCxy and OCRCxy in the second and subsequent cycles. If the GRCxy or OCRCxy register value is modified before the one-shot pulse output has been completed, the modified value is reflected to the ongoing one-shot-pulse output.

21.6.3.5 Counter Upper-Limit Setting Function

The timer counter Cx (TCNTCx) upper-limit value in each subblock can be changed by the counter upper-limit setting compare register Cx (CUCRCx) to perform interval operation. To enable the counter upper-limit setting function, set the CLRCx bit in the timer control register Cx (TCRCx) to 1.

Figure 21.43 shows an example of operation with the counter upper-limit setting function of block C0 enabled.

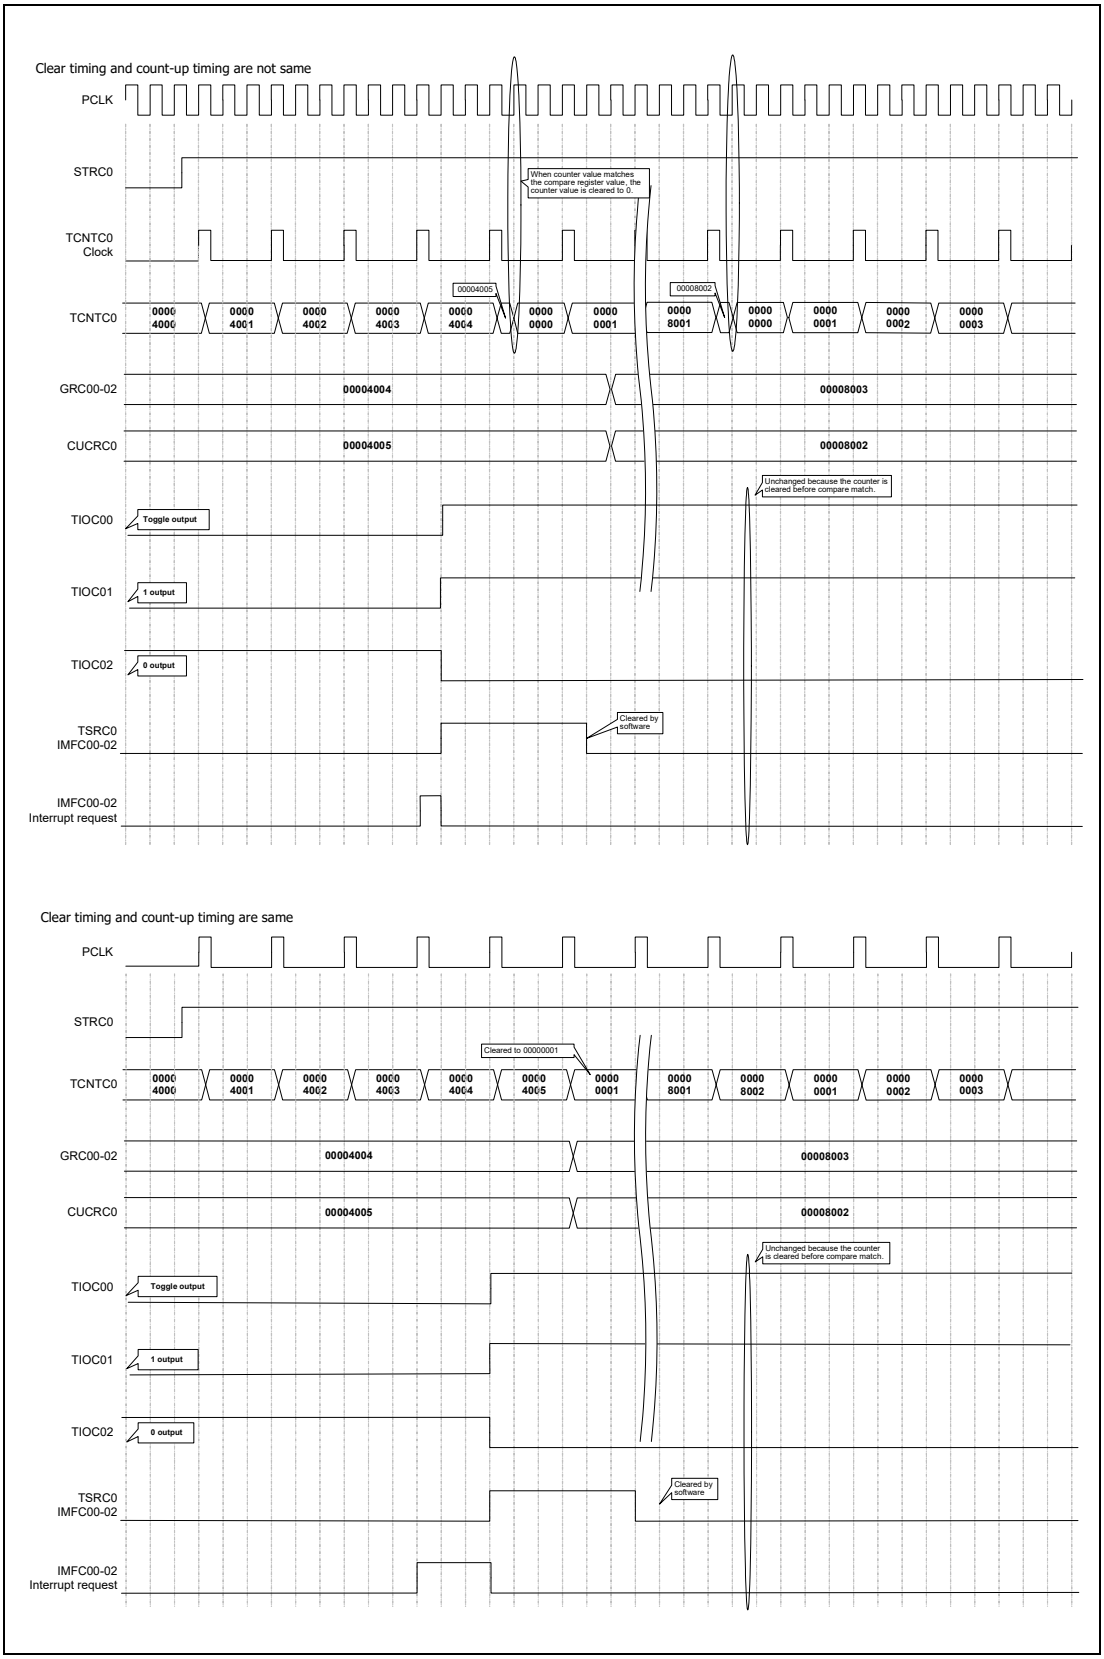

Figure 21.43 Example of Upper-Limit Setting Function Operation

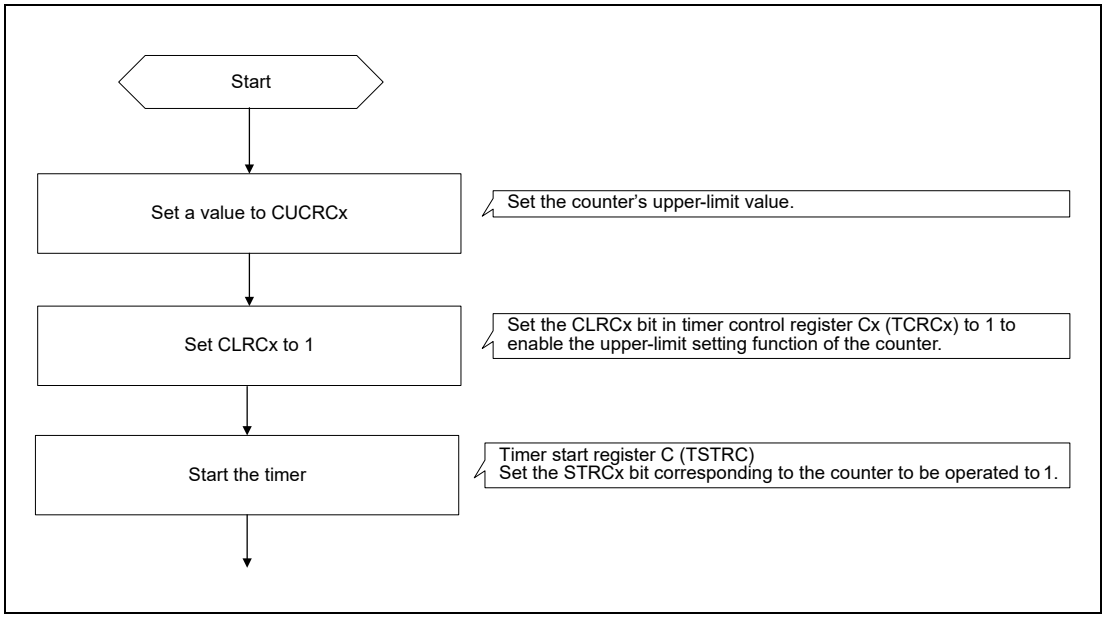

Figure 21.44 Counter Upper-Limit Setting Function Setting Procedure

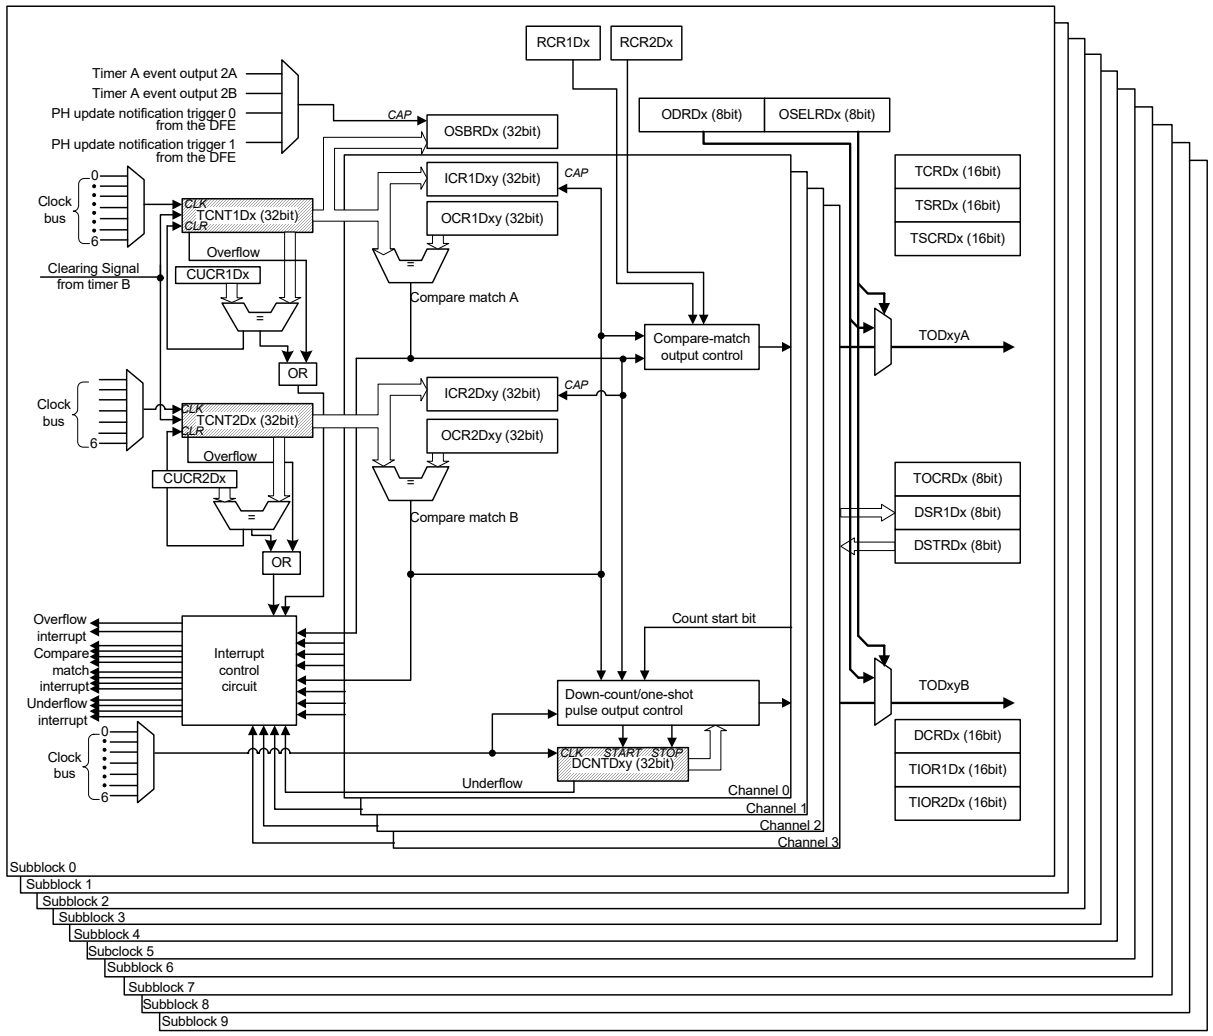
21.7 Timer D

21.7.1 Operation Overview

Timer D consists of ten subblocks that output one-shot pulses.

Timer D has the following functions.

- A compare match between the counter and output compare register is generated.
  Compare match A by compare match of TCNT1Dx and OCR1Dxy and compare match B by compare match of TCNT2Dx and OCR2Dxy are generated respectively.
- Down counter is started on compare match A or B of the output compare register or writing to the counter start bit in the down-counter start register. A one-shot pulse with an offset can be output.
- The output waveform can be forcibly shutoff regardless of the down-counter value by compare match B of the compare match register. If compare match A or counter start bit writing occurs concurrently with compare match B, output shutoff takes precedence.
- The input capture register enables to capture the TCNT2Dx value using compare match A as a trigger and the TCNT1Dx value using compare match B as a trigger.
- Pulse indicating that compare match A or B has been detected for A/D converter activation can be output. (40 lines supported by subblocks D0, D2, D4, D6, and D9)
- Interrupt requests can be output on compare matches A and B (80 lines supported).
- Range compare function by the compare match register is enabled according to the range comparison value setting register.
- When the upper-limit setting function of the timer counter 1Dx (TCNT1Dx) is enabled, the counter can be cleared on compare match of CUCR1Dx.
- When the upper-limit setting function of the timer counter 2Dx (TCNT2Dx) is enabled, the counter can be cleared on compare match of CUCR2Dx.
- Interrupt requests (20 in total) can be output on counter overflow: ten outputs from TCNT1Dx and ten outputs from TCNT2Dx.
- Interrupt requests can be output on down-counter underflow (40 lines supported). A DMA transfer request can be issued for the DMAC. (20 lines for DMA transfer requests supported by down counters in subblocks D0 to D4)
- Offset base register can capture the counter value by a trigger signal from timer A and a PH notification trigger from DFE
- Clearing TCNT1Dx and TCNT2Dx is possible by a clear signal issued from timer B.
- The value configured in the output value register can be output from pins according to the output setting register.
- Reference data and events can be output to APA. The counter values of TCNT1D0 and TCNT2D0 can be output as reference data. For selection of output values, see **Section 22.5.8, APA Input Selector**. Compare match A, compare match B, down counter underflow, TOD0yA, and TOD0yB of subblock 0 can be output as event outputs.



Note: x = 0 to 9 (number of Subblock), y = 0 to 3 (number of channel)

Figure 21.45 Block Diagram of Timer D

Figure 21.45 is a block diagram of timer D. Components of timer D subblock Dx include two range compare setting registers (RCR1Dx and RCR2Dx), two 32-bit timer counters 1Dx, 2Dx (TCNT1Dx and TCNT2Dx), one offset base register Dx (OSBRDx), one output value register Dx (ORDx), one output setting register Dx (OSELRDx), eight output compare registers 1Dxy, 2Dxy (OCR1Dxy and OCR2Dxy), four timer down-counters Dxy (DCNTDxy), two counter upper-limit setting registers Dx (CUCRDx), eight input capture registers 1Dxy, 2Dxy (ICR1Dxy and ICR2Dxy), and a controller. Each channel includes two output pins; TODxyA for compare match output and TODxyB for one-shot pulse output. (Output pins are supported by subblocks D0 to D8.)

TODxyA and TODxyB are output a level of 0 as a default.

A trigger for activating the A/D converter can be output to the on compare matches A and B.

21.7.2 Registers Related to Timer D

21.7.2.1 TSTRD — Timer Start Register D

Access: 8-bit/16-bit accessible

Address: FFE6 1000_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 21.81 TSTRD Register Contents

Bit Position	Bit Name	Function
15 to 10	—	Not used. This bit is always read as 0. These bits are read as 0. When writing, always write 0.
9	STRD9	Counter D9 Start 0: TCNT1D9, TCNT2D9, and DCNTD9y are disabled 1: TCNT1D9, TCNT2D9, and DCNTD9y are enabled
8	STRD8	Counter D8 Start 0: TCNT1D8, TCNT2D8, and DCNTD8y are disabled 1: TCNT1D8, TCNT2D8, and DCNTD8y are enabled
7	STRD7	Counter D7 Start 0: TCNT1D7, TCNT2D7, and DCNTD7y are disabled 1: TCNT1D7, TCNT2D7, and DCNTD7y are enabled
6	STRD6	Counter D6 Start 0: TCNT1D6, TCNT2D6, and DCNTD6y are disabled 1: TCNT1D6, TCNT2D6, and DCNTD6y are enabled
5	STRD5	Counter D5 Start 0: TCNT1D5, TCNT2D5, and DCNTD5y are disabled 1: TCNT1D5, TCNT2D5, and DCNTD5y are enabled
4	STRD4	Counter D4 Start 0: TCNT1D4, TCNT2D4, and DCNTD4y are disabled 1: TCNT1D4, TCNT2D4, and DCNTD4y are enabled
3	STRD3	Counter D3 Start 0: TCNT1D3, TCNT2D3, and DCNTD3y are disabled 1: TCNT1D3, TCNT2D3, and DCNTD3y are enabled
2	STRD2	Counter D2 Start 0: TCNT1D2, TCNT2D2, and DCNTD2y are disabled 1: TCNT1D2, TCNT2D2, and DCNTD2y are enabled
1	STRD1	Counter D1 Start 0: TCNT1D1, TCNT2D1, and DCNTD1y are disabled 1: TCNT1D1, TCNT2D1, and DCNTD1y are enabled
0	STRD0	Counter D0 Start 0: TCNT1D0, TCNT2D0, and DCNTD0y are disabled 1: TCNT1D0, TCNT2D0, and DCNTD0y are enabled

Note: A start bit is provided for each subblock D0 to D9. (y = 0, 1, 2, 3: Correspond to Dx0 to Dx3.)

Timer start register D (TSTRD) is a 16-bit register that can read and write upper 8 bits as TSTRDH and lower 8 bits as TSTRDL. This register is set to enable or disable two timer counters 1Dx and 2Dx (TCNT1Dx and TCNT2Dx) and timer down counters Dxy (DCNTDxy) in nine subblocks Dx (x = 0 to

9). When the count Dx start bit and the TDE bit in the ATU-IV control register (ATUENR) are both set to 1, the counters are started.

When TSTRD is reset, it is initialized to 0000_H.

(1) STRDx — Counter Dx Start Bit

These bits enable and disable timer counters 1Dx and 2Dx (TCNT1Dx, TCNT2Dx) and timer down counters Dxy (DCNTDxy).

When this bit is cleared to 0, TCNT1Dx, TCNT2Dx, and DCNTDxy stop operation. The counter value is retained while the counter is stopped. When this bit is set to 1 again, the counter is restarted from the value.

Even if the counter Dx start bit is set to 1, counting does not start unless the master enable of timer Dx is set to 1 by the ATU-IV control register.

CAUTION

The prescalers run regardless of this counter Dx start bit and are not synchronized with the timing at which this bit is set. Therefore, the time from when this bit is set to when TCNT1Dx and TCNT2Dx are incremented for the first time is less than the cycle of the clock of TCNT1Dx and TCNT2Dx.

21.7.2.2 TCRDx — Timer Control Registers Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit and 16-bit accessible

Address: FFE6 1100_H + (100_H * x)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 21.82 TCRDx Register Contents

Bit Position	Bit Name	Function
15	—	Not used. This bit is always read as 0. This bit is always read as 0. When writing, always write 0.
14	OBREDx	Timer Offset Base Register Enable Enables and disables input capture to the offset base register.
13	C2CEDx	Counter 2 Clear Enable Enables and disables a timer counter 2 clearing request from timer B.
12	C1CEDx	Counter 1 Clear Enable Enables and disables a timer counter 1 clearing request from timer B.
11	CLR2Dx	TCNT2Dx Clear Setting Enables and disables clearing the timer counter.
10 to 8	CKSEL2Dx[2:0]	TCNT2Dx Clock Select These bits select the TCNT2Dx counting-up clock from clock-bus lines 0 to 6.
7	CLR1Dx	TCNT1Dx Clear Setting Enables and disables clearing the timer counter.
6 to 4	CKSEL1Dx[2:0]	TCNT1Dx Clock Select These bits select the TCNT1Dx counting-up clock from clock-bus lines 0 to 6.
3	—	Not used. This bit is always read as 0. When writing, always write 0.
2 to 0	DCSELDx[2:0]	DCNTDxy Clock Select These bits select the DCNTDxy counting-down clock from clock-bus lines 0 to 6.

Timer control registers Dx (TCRDx) are 16-bit readable/writable registers that select the counter clocks in subblock Dx for 32-bit timer counter 1Dx (TCNT1Dx), 32-bit timer counter 2Dx (TCNT2Dx), and 32-bit timer down counter Dxy (DCNTDxy) from clock-bus lines 0 to 6. These registers also enable and disable capture of the timer offset base register, counter clearing requests from timer B for TCNT1Dx and TCNT2Dx, and clearing timer counters 1Dx (TCNT1Dx) and 2Dx (TCNT2Dx).

(1) OBREDx — Timer Offset Base Register Enable

This register enables and disables input capture to timer offset base register Dx (OSBRDx). When this bit is set to 1, the value in TCNT1Dx is captured by OSBRDx in the PCLK cycles following cycles in which the input signal selected by the TICTSELDx register is asserted. When the pulse width of the event 2A or 2B signal from timer A exceeds one cycle of PCLK, the counter value is captured on every clock cycle while the signal is at the active level.

OBREDx	Function	
0	Input capture by OSBRDx is enabled	(Initial value)
1	Input capture by OSBRDx is disabled	

(2) C2CEDx — Counter 2 Clear Enable

Enables and disables clearing the counter value in TCNT2Dn by timer B.

When an edge of the counter clearing signal output from timer B is detected while this bit is set to 1, TCNT2Dx is cleared ($0000\ 0000_H$) in the following timing. When the rising edge of the clearing signal is detected in the cycle in which TCNT2Dx is counted up, the counter is cleared on the counting up timing. When the rising edge of the clearing signal is detected in other than the TCNT2Dx counting-up cycle, the counter is cleared on the first counting up timing after edge detection.

The counter clearing signal is ignored with this bit set to the initial value.

C2CEDx	Function	
0	TCNT2Dx clearing signal from timer B is disabled	(Initial value)
1	TCNT2Dx clearing signal from timer B is enabled	

(3) C1CEDx — Counter 1 Clear Enable

Enables and disables clearing the value in TCNT1Dx by timer B.

When an edge of the counter clearing signal output from timer B is detected while this bit is set to 1, TCNT1Dx is cleared ($0000\ 0000_H$) in the following timing. When the rising edge of the clearing signal is detected in the cycle in which TCNT1Dx is counted up, the counter is cleared on the counting up timing. When the rising edge of the clearing signal is detected in other than the TCNT1Dx counting-up cycle, the counter is cleared on the first counting up timing after edge detection.

The counter clearing signal is ignored with this bit set to the initial value.

C1CEDx	Function	
0	TCNT1Dx clearing signal from timer B is disabled	(Initial value)
1	TCNT1Dx clearing signal from timer B is enabled	

(4) CLR2Dx — TCNT2Dx Clear

Setting the TCNT2Dx clear bit to 1 clears ($0000\ 0000_H$) the TCNT2Dx value at the first clock after a compare match between timer counter 2Dx (TCNT2D) and counter upper-limit setting compare register 2Dx (CUCR2Dx).

If there is a conflict with TCNT2Dx count up, it is cleared to $0000\ 0001_H$.

CLR2Dx	Function	
0	CUCR2Dx compare match is not used to clear the TCNT2Dx value.	(Initial value)
1	CUCR2Dx compare match is used to clear the TCNT2Dx value.	

When the CLR2Dx bit is set to 1, set the range comparison value setting register 2Dx (RCR2Dx) to 00_H.

(5) CKSEL2Dx[2:0] — TCNT2Dx Clock Select

These bits select the TCNT2Dx counting-up clock.

CKSEL2Dx				
[2]	[1]	[0]	Function	
0	0	0	Incrementation of TCNT2Dx is driven by clock-bus line 0.	(Initial value)
0	0	1	Incrementation of TCNT2Dx is driven by clock-bus line 1.	
0	1	0	Incrementation of TCNT2Dx is driven by clock-bus line 2.	
0	1	1	Incrementation of TCNT2Dx is driven by clock-bus line 3.	
1	0	0	Incrementation of TCNT2Dx is driven by clock-bus line 4.	
1	0	1	Incrementation of TCNT2Dx is driven by clock-bus line 5.	
1	1	0	Incrementation of TCNT2Dx is driven by clock-bus line 6.	
1	1	*	Reserved	

(6) CLR1Dx — TCNT1Dx Clear

The TCNT1Dx value is cleared to $0000\ 0000_H$ by setting the TCNT1Dx clear bit to 1 at the first clock after a compare match between timer counter 1Dx (TCNT1Dx) and counter upper-limit setting compare register 1Dx (CUCR1Dx). If there is a conflict with TCNT1Dx count up, it is cleared to $0000\ 0001_H$.

CLR1Dx	Function	
0	CUCR1Dx compare match is not used to clear the TCNT1Dx value.	(Initial value)
1	CUCR1Dx compare match is used to clear the TCNT1Dx value.	

When the CLR1Dx bit is set to 1, set the range comparison value setting register 1Dx (RCR1Dx) to 00_H.

(7) CKSEL1Dx[2:0] — TCNT1Dx Clock Select

These bits select the TCNT1Dn counting-up clock.

CKSEL1Dx				
[2]	[1]	[0]	Function	
0	0	0	Incrementation of TCNT1Dx is driven by clock-bus line 0.	(Initial value)
0	0	1	Incrementation of TCNT1Dx is driven by clock-bus line 1.	
0	1	0	Incrementation of TCNT1Dx is driven by clock-bus line 2.	
0	1	1	Incrementation of TCNT1Dx is driven by clock-bus line 3.	

CKSEL1Dx			
[2]	[1]	[0]	Function
1	0	0	Incrementation of TCNT1Dx is driven by clock-bus line 4.
1	0	1	Incrementation of TCNT1Dx is driven by clock-bus line 5.
1	1	0	Incrementation of TCNT1Dx is driven by clock-bus line 6.
1	1	*	Reserved

(8) DCSELDx[2:0] — DCNTDxy Clock Select

These bits select the clock signal to drive counting down by the 32-bit timer down counter Dxy (DCNTDxy) of the Dx sub-block.

DCSELDx				
[2]	[1]	[0]	Function	
0	0	0	Decrementation of DCNTDxy is driven by clock-bus line 0.	(Initial value)
0	0	1	Decrementation of DCNTDxy is driven by clock-bus line 1.	
0	1	0	Decrementation of DCNTDxy is driven by clock-bus line 2.	
0	1	1	Decrementation of DCNTDxy is driven by clock-bus line 3.	
1	0	0	Decrementation of DCNTDxy is driven by clock-bus line 4.	
1	0	1	Decrementation of DCNTDxy is driven by clock-bus line 5.	
1	1	0	Decrementation of DCNTDxy is driven by clock-bus line 6.	
1	1	*	Reserved	

Note: Channels 0 to 3 of a subblock share a common counter clock.

Output of one-shot pulse (TODxyB) is synchronized with the clock selected in these bits.

21.7.2.3 TIOR1Dx — Timer I/O Control Registers 1Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit and 16-bit accessible

Address: FFE6 1104_H + (100_H * x)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OSSDx3		OSSDx2		OSSDx1		OSSDx0		IOADx3		IOADx2		IOADx1		IOADx0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.83 TIOR1Dx Register Contents

Bit Position	Bit Name	Function
15 to 8	OSSDx3 to OSSDx0	Compare Match Output Source Select These bits select the output level on the compare match output pin (TODxyA). The output is controlled by compare match A, compare match B, or both matches.
7 to 0	IOADx3 to IOADx0	I/O Control A These bits select the function of the output compare register 1Dxy (OCR1Dxy).

TIOR1Dx are 16-bit readable/writable registers that select the source of compare match output (TODxyA), enable and disable compare match of OCR1Dxy, and set the output level on pin TODxyA on compare match A.

TIOR1Dx is initialized to 0000_H by a reset.

(1) OSSDxy[1:0] — Compare Match Output Source Select

OSSDxy		
[1]	[0]	Function
0	0	No TODxyA pin output (Initial value)
0	1	Output level on TODxyA depends on the I/O control bit A on compare match A
1	0	Output level on TODxyA depends on the I/O control bit B on compare match B
1	1	Output level on TODxyA depends on the I/O control bit A or B on compare match A or B, respectively

These bits select the output level on the compare match output pin (TODxyA). The output is controlled by compare match A, compare match B, or both matches.

Either of compare matches A and B is used as a start/stop trigger of timer down counter Dxy (DCNTDxy), and the other one is used as a trigger of compare match output. In addition, both of compare matches A and B are used to control the output, with one as a trigger of an assertion of the output and the other as a trigger of a negation of the output, enabling a one-shot pulse to be output from pin TODxyA.

When both matches are used as a trigger of the output and they occur at the same time, priority is given to compare match B and the output level depends on the IOBxy bit in TIOR2Dx.

A level of 0 is output on TODxyA as a default. While these bits are set to 00_B, the output level on TODxyA is not changed even if compare match A or B occurs.

(2) IOADxy[1:0] — I/O Control A

IOADxy		
[1]	[0]	Function
0	0	Compare match is not performed (Initial value)
0	1	Output level on compare match is 0
1	0	Output level on compare match is 1
1	1	Output level on compare match is toggled

These bits select the function of the output compare register 1Dxy (OCR1Dxy).

When these bits are set to 00_B, compare match between OCR1Dxy and timer counter 1Dx (TCNT1Dx) is not performed. Otherwise, the compare match is performed. An interrupt request is issued on compare match. AD conversion trigger is also issued (only for subblocks D0, D2, D4, D6, and D9).

If compare match A is selected by the compare match output source select bit (OSSDxy), a signal is output on pin TODxyA according to the IOADxy bits (only subblocks D0 to D9).

21.7.2.4 TIOR2Dx — Timer I/O Control Register 2Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit and 16-bit accessible

Address: FFE6 1106_H + (100_H * x)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	IOBDx3			—	IOBDx2			—	IOBDx1			—	IOBDx0		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Table 21.84 TIOR2Dx Register Contents

Bit Position	Bit Name	Function
15, 11, 7, 3	—	Not used. These bits are always read as 0. When writing, always write 0.
14 to 12, 10 to 8, 6 to 4, 2 to 0	IOBDx3 to IOBDx0	I/O Control B Sets permission/prohibition of the output compare register 2Dxy (OCR2Dxy), and the compare match output value.

The timer I/O Control Register 2Dx (TIOR2Dx) is a 16-bit readable/writable register.

This register has bits to set the functions of the output compare registers 2Dxy(OCR2Dxy). This can enable/disable compare match and can set the output level on pin TODxyA on compare match B.

TIOR2Dx is initialized to 0000_H by a reset.

(1) IOBDxy[2:0] — I/O Control B

IOBDxy			Function		
[2]	[1]	[0]			
0	0	0	Selects compare match output of OCR2Dxy.	Compare match is disabled	(Initial value)
0	0	1		Output level on compare match is 0	
0	1	0		Output level on compare match is 1	
0	1	1		Output level on compare match is toggled	
1	0	0	Reserved	Setting prohibited	
1	0	1		Setting prohibited	
1	1	0		Setting prohibited	
1	1	1		Setting prohibited	

These bits enable and disable of compare match of the output compare register 2Dxy (OCR2Dxy) and select the TODxyA pin output value on the compare match B.

When TIOR2Dx is used as the compare match register (IOBDxy[2] = 0) and the IOBDxy[1:0] bits are set to 00B, compare match between GRDxy and timer counter 2Dx (TCNT2Dx) is not performed. Otherwise, the compare match is performed. At this time, an interrupt request is issued to CPU by compare match. An AD interrupt conversion trigger is also issued (only for subblock D0, D2, D4, D6, D9).

When compare match B is selected as the output source in the compare match output source select bit (OSSDxy), a signal is output on pin TODxyA according to the IOBDxy bits.

21.7.2.5 OSELRDx — Line Select Register Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit accessible

Address: FFE6 1111_H + (100_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	OSELBDx3	OSELBDx2	OSELBDx1	OSELBDx0	OSELADx3	OSELADx2	OSELADx1	OSELADx0
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.85 OSELRDx Register Contents

Bit Position	Bit Name	Function
7 to 4	OSELBDxy	Output Selection B 0: TODxyB provides normal output. 1: TODxyB provides the value of the output value register.
3 to 0	OSELADxy	Output Selection A 0: TODxyA provides normal output. 1: TODxyA provides the value of the output value register.

The output selection register Dx (OSELRDx) is an 8-bit readable/writable register.

It determines whether to output the value of output value register from the pins (TODxyA and TODxyB).

OSELRDx is initialized to 00_H by a reset.

(1) OSELA (B) Dxy — Output Setting Bits A (B) xy

Writing 1 to this bit outputs the value of the output value register to TODxyA (or TODxyB) pin. Setting of the timer I/O control register 1Dx and 2Dx (TIOR1Dx and TIOR2Dx), setting of the timer output control register Dx (TOCRDx), or one-shot pulse output by the timer downcounter Dxy has no effect on the output value.

When this bit is set to 0, the TODxyA (TODxyB) pin outputs according to the settings of the timer I/O control register 1Dx and 2Dx (TIOR1Dx and TIOR2Dx), and settings of the one-shot pulse output by the timer output control register Dx (TOCRDx).

21.7.2.6 ODRDx — Output Value Register Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit accessible

Address: FFE6 1112_H + (100_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	ODBDx3	ODBDx2	ODBDx1	ODBDx0	ODADx3	ODADx2	ODADx1	ODADx0
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.86 ODRDx Register Contents

Bit Position	Bit Name	Function
7 to 4	ODBDxy (y = 3, 2, 1, 0: corresponding channel 0 to 3)	Output Value B Sets the value to be output to TODxyB.
3 to 0	ODADxy (y = 3, 2, 1, 0: corresponding channel 0 to 3)	Output Value A Sets the value to be output to TODxyA.

The output value register Dx (ODRDx) is an 8-bit readable/writable register.

When a bit of the output selection register Dx (OSELRDx) is set to 1, the corresponding ODRDx value is issued from respective pins (TODxyA and TODxyB).

ODRDx is initialized to 00_H by a reset.

21.7.2.7 DSTRDx — Down Counter Start Register Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit accessible

Address: FFE6 1108_H + (100_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	DSTDx3	DSTDx2	DSTDx1	DSTDx0
Value after reset	0	0	0	0	0*1	0*1	0*1	0*1
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Note 1. Value 0 cannot be written. If 1 is written to these bits, data is not retained. This bit is always read as 0.

Table 21.87 DSTRDx Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Not used. These bits are always read as 0. The write value should always be 0. When writing, always write 0.
3 to 0	DSTDxy	Down Counter Start 0: No operation 1: Timer down counters Dxy (DCNTDx3-Dx0) are started

The down counter starting register Dx (DSTRDx) is an 8-bit readable/writable register. This register has a start bit for the down counter. Writing a value to the bit by software starts down counting.

DSTRDx is initialized to 00_H by a reset.

(1) DSTDxy — Down Counter Start Dxy

Setting these bits to 1 makes timer down counter Dxy (DCNTDxy) start. The setting in these bits is always valid and regardless of the start trigger setting in the down counter control register. When compare match B and writing 1 to these bits occurs at the same time if the down counter is set so that it is stopped on compare match B (compare match A or B), compare match B (compare match A or B) takes priority and the down counter is not started.

When DCNTDxy = $0000\ 0000_H$, writing 1 to these bits has no effect.

21.7.2.8 DSR1Dx — Down Counter Status Registers 1Dx

Table 21.88 DSR1Dx Register Contents

Bit Position	Bit Name	Function
7 to 4	DWFDxy	Down Count Wait Flag Dxy 0: Down count compare match start wait status has not occurred. 1: Down count compare match start wait status has occurred.
3 to 0	DSFDxy	Down Counter Status Flag Dxy 0: Down counter is disabled 1: Down counter is enabled

The down count status register 1Dx (DSR1Dx) is an 8-bit read-only register. This register has a flag that indicates the status of the timer down counter Dxy (DCNTDxy).

DSR1Dx is initialized to 00_H by a reset.

(1) DWFDxy — Down Count Wait Flag Dxy

These bits are flags that indicate whether timer down count Dxy (DCNTDxy) is in the count start wait status. This flag is valid only when compare match A and B is set for the count start trigger by TRGSELDxy bits in the control register Dx (DCRDx). This flag is not set to 1 in other settings.

When compare match A and B is set as a count start trigger and DWFDxy is 0, if compare match A or compare match B occurs, DWFDxy is set to 1. When a compare match (compare match B if DWFDxy is set to 1 on compare match A) of a source different from setting DWFDxy to 1 occurs, it is recognized as a count start trigger and down-counting starts. At this time, the DWFDxy value is cleared to 0.

Even when a compare match of the same source as setting DWFDxy to 1 occurs, the DWFDxy value remains 1 and is not recognized as a count start trigger.

If compare match A and compare match B occur simultaneously, it is immediately recognized as a count start trigger. Therefore, this flag does not enter the down count wait status and DWFDxy is not set to 1.

This flag is read-only flag and cannot be set to 1 or cleared to 0 by the software.

- Setting condition
  - When compare match A or compare match B has occurred while TRGSELDxy in the down counter control register Dx (DCRDx) is 110_B
- Clearing conditions
  - When DWFDxy is set to 1 on compare match A and compare match B has occurred while DWFDxy is 1
  - When DWFDxy is set to 1 on compare match B and compare match A has occurred while DWFDxy is 1
  - Writing 1 to DWFCDxy in the down count status clear register Dx (DSCRDx)

(2) DSFDxy — Down Counter Status Flag Dxy

These bits indicate enabling/disabling of timer down counter Dxy (DCNTDxy). When these bits are read as 1, the counter operation is enabled. If the TDE bit of ATUENR is 1 and the STRDx bit of TSTRD is 1, the counter is running.

When these bits are read as 0, the counter operation is disabled, so counting cannot be in progress.

This flag is a read-only flag; it cannot be set to 1 or cleared to 0 by software.

- Setting conditions
  - When writing 1 to the down count start bit in the down count starting register Dx (DSTRDx)
  - When the condition set as the down counter start trigger is satisfied (compare match A or B)
- Clearing conditions
  - When the down counter is stopped by underflow
  - When the condition to stop the down counter (compare match B)

These flags are set regardless of the settings of the TDE bit in ATUENR and the STRDx bit in TSTRD.

Accordingly, if the TDE bit and the STRDx bit are not set to enable counting, the down counter is not actually running even if these bits indicate that counting is enabled.

Clearing proceeds in synchronization with the down-count clock.

21.7.2.9 DSR2Dx — Down Count Status Register 2Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit accessible

Address: FFE6 $110B_H$ + (100_H * x)

Value after reset: 00_H

Table 21.89 DSR2Dx Register Contents

Bit Position	Bit Name	Function
7 to 0	DWRFDxy[1:0]	Down Count Wait Record Flag Dxy 00: No compare match 01: Down-counting starts on compare match A. 10: Down-counting starts on compare match B. 11: Down-counting starts on simultaneous occurrence of compare match A and compare match B.

Down count status registers 2Dx (DSR2Dx) are 8-bit read-only registers.

The DWRFDxy register is a flag that indicates the condition for starting count operation of the timer down counter Dxy (DCNTDxy).

The status is updated when the timer down counter Dxy (DCNTDxy) starts counting.

When the down count start condition is “A and B”, the down count start (compare match occurring later) condition is retained in the status register. When down-counting is started by the down count start register Dx (DSTRDx), the status register keeps retaining the previous value.

DSR2Dx is initialized to 00_H by a reset.

- Clearing (to 00_B) condition
  Writing 1 to DWRFCDxy in the down count status clear register Dx (DSCRDx)

21.7.2.10 DSCRDx — Down Count Status Clear Register Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Table 21.90 DSCRDx Register Contents

Bit Position	Bit Name	Function
7 to 4	DWFCDxy	Down Count Wait Flag Clear Enable Dxy 0: Disabled (Initial value) 1: DWFDxy in the down count status register 1Dx (DSR1Dx) is cleared to 0.
3 to 0	DWRFCDxy	Down Count Wait Record Flag Clear Enable Dxy 0: Disabled (Initial value) 1: DWRFDxy in the down count status register 2Dx (DSR2Dx) is cleared to 0.

The down count status clear register Dx (DSCRDx) is an 8-bit readable/writable register that sets clearing of the flag on compare match when setting compare match A and B for the down count status registers 1Dx, 2Dx (DSR1Dx and DSR2Dx).

DSCRDx is initialized to 00_H by a reset.

(1) DWFCDxy — Down Count Wait Flag Clear Enable Dxy

These bits set clearing the flag that is set by occurrence of down count wait of the down count status register 1Dx (DSR1Dx).

Setting each of these bits to 1 clears the down count wait flag Dxy (DWFDxy) in the down count status register 1Dx (DSR1Dx). These bits are always read as 0.

(2) DWRFCDxy — Down Count Wait Record Flag Clear Enable Dxy

These bits set clearing of the flag that is set by occurrence of down count wait of the down count status register 2Dx (DSR2Dx).

Setting each of these bits to 1 clears the down count wait record flag Dx (DWRFDxy) and the down count wait A flag Dxy (DWRFDxy) in the down count status register 2Dx (DSR2Dx). These bits are always read as 0.

21.7.2.11 DCRDx — Down Counter Control Registers Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Table 21.91 DCRDx Register Contents

Bit Position	Bit Name	Function
15 to 0	TRGSELDx3 to TRGSELDx0	Down Counter Start/Stop Trigger Select Compare match A and compare match B can be set as the start or stop condition for counting of the timer down counter Dxy (DCNTDxy).

Down counter control registers Dx (DCRDx) are 16-bit readable/writable registers that starts the timer down counter Dxy (DCNTDxy). Compare match A, compare match B, compare match A or B, or compare match A and B can be set as a starting or stopping trigger of timer down counters Dxy (DCNTDxy).

DCRDx is initialized to 0000_H by a reset. To change the TRGSELDxy bit, stop the counter. Otherwise operation cannot be guaranteed.

(1) TRGSELDxy — Down Counter Start/Stop Trigger Select Bits Dxy

TRGSELDxy				Function	
[3]	[2]	[1]	[0]	Counter start trigger	Counter stop trigger
0	0	0	0	No trigger	No trigger (Initial value)
0	0	0	1	No trigger	Compare match B
0	0	1	0	Compare match A	No trigger
0	0	1	1	Compare match A	Compare match B
0	1	0	0	Compare match B	No trigger
0	1	0	1	Setting prohibited	Setting prohibited
0	1	1	0	Compare match A and B	No trigger
0	1	1	1	Setting prohibited	Setting prohibited
1	0	0	0	Setting prohibited	Setting prohibited
1	0	0	1	No trigger	Compare match A or B
1	0	1	0	Compare match A or B	No trigger
1	0	1	1	Compare match A or B	Compare match A or B
1	1	0	0	Setting prohibited	Setting prohibited
1	1	0	1	Setting prohibited	Setting prohibited
1	1	1	0	Setting prohibited	Setting prohibited
1	1	1	1	Setting prohibited	Setting prohibited

The trigger sources to start and stop the timer down counter Dxy (DCNTDxy) can be selected by these TRGSELDxy bits. Compare match A, compare match B, compare match A or B, or compare match A and B can be set as a trigger to start counting.

Compare match B or compare match A or B can be set as a trigger to stop counting. In case of compare matches A and B, the counter starts counting down when both compare match A and compare match B are satisfied (compare match A and compare match B need not necessarily occur at the same time).

The counter can also be started by writing 1 to the down counter start bit. The trigger source is always valid regardless of the setting of the TRGSELDxy bits.

If the trigger sources to start and stop the down counter occur at the same time, stopping the counter is given priority.

CAUTION

When an underflow and compare match A occur simultaneously while TRGSELDxy is 1010_B, an underflow interrupt is not generated and the underflow flag is not set to 1. When a count start trigger and a compare match A occur simultaneously when the timer down counter Dxy (DCNTDxy) stops with 0000 0000_H while TRGSELDxy is 1010_B, an underflow interrupt is not generated and the underflow flag is not set to 1.

In this case, to execute software processing for underflow occurrence, write the underflow interrupt flag to 1 (EICz.EIRFz = 1) only when the down counter is stopped (DSR1Dx.DSFDxy = 0) and the underflow interrupt flag of the interrupt controller is 0 (EICz.EIRFz = 0).

21.7.2.12 TSRDx — Timer Status Registers Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Table 21.92 TSRDx Register Contents

Bit Position	Bit Name	Function
15, 14	—	Not used. These bits are always read as 0. When writing, always write 0.
13	OVF2Dx	Overflow Flag 2Dx 0: TCNT2Dx has not overflowed 1: TCNT2Dx has overflowed
12	OVF1Dx	Overflow Flag 1Dx 0: TCNT1Dx has not overflowed 1: TCNT1Dx has overflowed
11 to 8	UDFDx3 to UDFDx0	Underflow Flag Dx3-Dx0 0: DCNTDxy has not underflowed 1: DCNTDxy has underflowed
7 to 4	CMFADx3 to CMFADx0	Compare Match A Flag Dx3-Dx0 0: Compare match A has not occurred 1: Compare match A has occurred
3 to 0	CMFBDx2 to CMFBDx0	Compare Match B Flag Dx3-Dx0 0: Compare match B has not occurred 1: Compare match B has occurred

The timer status register Dx (TSRDx) is a 16-bit read-only register. This register indicates overflow of two timer counters 2Dx, 1Dx (TCNT2Dx and TCNT1Dx) of subblock Dx (x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9), underflow of the timer down counters Dxy (DCNTDxy) of channels 0 to 3, and compare match of the output compare registers 1Dxy, 2Dxy (OCRD1xy and OCR2Dxy). If an interrupt source takes effect when this flag is set, an interrupt request is made again. An interrupt request is made even if there is a conflict between clearing by the corresponding timer status clear register and setting by an interrupt source.

Overflow flags 2 and 1 as well as underflow flags and compare match flags A and B can be cleared by setting the corresponding bits of the timer status clear register Dx (TSCRDx). Each of compare match A and B can use 20 pulse outputs (subblocks D0, D2, D4, D6, and D9) as the AD conversion trigger. TSRDx is initialized to 0000_H by a reset.

(1) OVF2Dx — Overflow Flag 2Dx

OVF2Dx	Function
0	[Clearing condition] When 1 is written to the OVFC2Dx bit of the timer status clear register Dx (TSCRDx). (Initial value)
1	[Setting condition] • When TCNT2Dx overflowed (from FFFF FFFF$_H$ to 0000 0000$_H$) • When the counter is cleared with the upper-limit setting function enabled

Indicates whether or not timer counter 2Dx (TCNT2Dx) has overflowed. If the reading value of this flag is 1, it means that an overflow in TCNT2Dx has occurred. This flag cannot be set to 1 by software. The overflow flag is set when the count-up clock is input while TCNT2Dx is FFFF FFFF$_H$ or at the first clock after the counter value matches the upper-limit setting register value with the upper-limit setting function enabled. Writing 0000 0000$_H$ to TCNT2Dx or starting TCNT2Dx from an initial value of 0000 0000$_H$ has no effect on this bit.

When writing to TCNT2Dx at the same time as incrementation while it is FFFF FFFF$_H$, this bit is set to 1. However, TCNT2Dx is updated with the written value, but not 0000 0000$_H$.

When an assertion of counter clearing signal from timer B and overflow due to count up occur, overflow does not occur.

Simultaneous occurrence of counter clearing by timer B and counter clearing with the upper-limit setting function enabled is detected as an overflow.

(2) OVF1Dx — Overflow Flag 1Dx

OVF1Dx	Function
0	[Clearing condition] When 1 is written to the OVFC1Dx bit of the timer status clear register Dx (TSCRDx). (Initial value)
1	[Setting condition] • When TCNT1Dx overflowed (from FFFF FFFF$_H$ to 0000 0000$_H$) • When the counter is cleared with the upper-limit setting function enabled

Indicates whether or not timer counter 1Dx (TCNT1Dx) has overflowed. If the reading value of this flag is 1, it means that an overflow in TCNT1Dx has occurred. This flag cannot be set to 1 by software. The overflow flag is set when the count-up clock is input while TCNT1Dx is FFFF FFFF$_H$ or at the first clock after the counter value matches the upper-limit setting register value with the upper-limit setting function enabled. Writing 0000 0000$_H$ to TCNT1Dx or starting TCNT1Dx from an initial value of 0000 0000$_H$ has no effect on this bit.

When writing to TCNT1Dn at the same time as incrementation while it is FFFF FFFF$_H$, this bit is set to 1.

However, TCNT1Dx is updated with the written value, but not 0000 0000$_H$. When an assertion of counter clearing signal from timer B and an overflow by counting up occur simultaneously, the overflow is not detected. Simultaneous occurrence of counter clearing by timer B and counter clearing with the upper-limit setting function enabled is detected as an overflow

(3) UDFDxy — Underflow Flag Dxy

UDFDxy	Function
0	[Clearing condition] When 1 is written to the UDFCDxy bit of the timer status clear register Dx (TSCRDx). (Initial value)
1	[Setting condition] When DCNTDxy underflowed (decremented while DCNTDxy = 0000 0000_H)

This flag is a status flag that indicates underflow of subblock Dx and down counter Dxy of channel y. If the reading value of this flag is 1, it means that DCNTDxy had an underflow. These flags cannot be set to 1 by software.

This bit is set to 1 when DCNTDxy is to be decremented while it is 0000 0000_H. DCNTDxy holds 0000 0000_H on underflow. Writing FFFF $FFFF_H$ to DCNTDxy has no effect on these bits.

These bits are initialized to 0 by a reset. Although DCNTDxy is initialized to 0000 0000_H, these flags do not indicate underflow because DCNTDxy has not started. For details on control of DCNTDxy, see descriptions of timer D down counters.

(4) CMFADxy — Compare Match A Flag Dxy

CMFADxy	Function
0	[Clearing condition] When 1 is written to the CMFCADxy bit of the timer status clear register Dx (TSCRDx). (Initial value)
1	[Setting condition] When the values in timer counter 1Dx (TCNT1Dx) and the output compare register 1Dxy (OCR1Dxy) match while operation of compare match with OCR1Dxy is enabled

These bits indicate whether or not compare match between the output compare register 1Dxy (OCR1Dxy) and TCNT1Dx has occurred. If the reading value of this flag is 1, it means that a compare match occurs between TCNT1Dx and OCR1Dxy. This flag cannot be set to 1 by software.

When operation of compare match between OCRDxy and TCNT1Dx is enabled by the setting in timer I/O control register 1Dx (TIOR1Dx), compare match operation is performed regardless of the state of TCNT1Dx. These bits are set to 1 on the first edge of the PCLK after the values in TCNT1Dx and OCR1Dxy match. Even if these compare match flags are cleared to 0 by software while TCNT1Dx = OCR1Dxy after the match in comparison is detected, these bits are not set to 1 again.

A single pulse, signaling detection of compare match A, whose width is equal to the cycle of the PCLK is output to activate the A/D converter (supported by 20 channels in subblocks D0, D2, D4, D6, D9).

If TCNT1Dx matches OCR1Dxy again before the status flag is cleared, the compare match A is detected and the status flag is rewritten with 1.

(5) CMFBDxy — Compare Match B Flag Dxy

CMFBDxy	Function
0	[Clearing condition] When 0 is written to the CMFCBDxy bit of the timer status clear register Dx (TSCRDx). (Initial value)
1	[Setting condition] When the values in timer counter 2Dx (TCNT2Dx) and output compare register 2Dxy (OCR2Dxy) match while operation of compare match with OCR2Dxy is enabled

These bits indicate whether or not compare match between the output compare register 2Dxy (OCR2Dxy) and TCNT2Dx has occurred. If the reading value of this flag is 1, it means that a compare match of TCNT2Dx and OCR2Dxy has happened. This flag cannot be set to 1 by software.

When operation of compare match between OCR2Dxy and TCNT2Dx is enabled by the setting in timer I/O control register 2Dx (TIOR2Dx), compare match operation is performed regardless of the state of TCNT2Dx. These bits are set to 1 on the first edge of the Pϕ clock after the values in TCNT2Dx and OCR2Dxy match.

Even if these compare match flags are cleared to 0 by software while TCNT2Dx = OCR2Dxy after the match in comparison is detected, these bits are not set to 1 again.

A single pulse, signaling detection of compare match B, whose width is equal to the cycle of the PCLK is output to activate the A/D converter (supported by 20channels in subblocks D0, D2, D4, D6, D9).

If TCNT2Dx matches OCR2Dxy again before the status flag is cleared, the compare match B is detected and the status flag is rewritten with 1.

21.7.2.13 TSCRDx — Timer Status Clear Register Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit access and 16-bit access are possible.
Value 0 cannot be written. The value is not retained when 1 is written. This bit is always read as 0.

Address: FFE6 $110E_H$ + (100_H * x)

Value after reset: 0000_H

Table 21.93 TSCRDx Register Contents

Bit Position	Bit Name	Function
15, 14	—	Not used. These bits are always read as 0. When writing, always write 0.
13	OVFC2Dx	Overflow Flag Clear Enable 2Dx 0: Disabled (Initial value) 1: Clears OVF2Dx of timer status register Dx (TSRDx) to 0.
12	OVFC1Dx	Overflow Flag Clear Enable 1Dx 0: Disabled (Initial value) 1: Clears OVF1Dx of timer status register Dx (TSRDx) to 0.
11 to 8	UDFCDx3 to UDFCDx0	Underflow Flag Clear Enable Dx3-Dx0 0: Disabled (Initial value) 1: Clears UDFDx3-UDFDx0 of timer status register Dx (TSRDx) to 0.
7 to 4	CMFCADx3 to CMFCADx0	Compare Match A Flag Clear Enable Dx3-Dx0 0: Disabled (Initial value) 1: Clears CMFADx3-CMFADx0 of timer status register Dx (TSRDx) to 0.
3 to 0	CMFCBDx3 to CMFCBDx0	Compare Match B Flag Clear Enable Dx3-Dx0 0: Disabled (Initial value) 1: Clears CMFBDx3-CMFBDx0 of timer status register Dx (TSRDx) to 0.

The timer status clear register Dx (TSCRDx) is a 16-bit readable/writable register. This register specifies the flag clearing at the time of overflow of two 32-bit up-counters (TCNT2Dx and TCNT1Dx), compare match of TCNT1Dx and the output compare register 1Dxy (OCR1Dxy), and compare match of TCNT2Dx and the output compare register 2Dxy (OCR2Dxy).

When TSCRDx is reset, it is initialized to 0000_H.

(1) OVFC2Dx — Overflow Flag Clear Enable 2Dx

This bit specifies flag clearing at the time of overflow of the timer counter 2Dx (TCNT2Dx).

Setting this bit enables clearing of the overflow flag 2Dx (OVF2Dx) of the timer status register Dx (TSRDx). This bit is always read as 0.

OVFC2Dx	Function	
0	Disabled	(Initial value)
1	Clears OVF2Dx to 0.	

(2) OVFC1Dx — Overflow Flag Clear Enable 1Dx

This bit specifies flag clearing at the time of overflow of the timer counter 1Dx (TCNT1Dx).

Setting this bit enables clearing of overflow flag 1Dx (OVF1Dx) of the timer status register Dx (TSRDx). This bit is always read as 0.

OVFC1Dx	Function	
0	Disabled	(Initial value)
1	Clears OVF1Dx to 0.	

(3) UDFCDxy — Underflow Flag Clear Enable Dxy

This bit specifies flag clearing at the time of underflow of the timer down counter Dxy (DCNTDxy).

Setting this bit enables clearing of the underflow flag Dxy (UDFDxy) of the timer status register Dx (TSRDx). This bit is always read as 0.

UDFCDxy	Function	
0	Disabled	(Initial value)
1	Clears UDFDxy to 0.	

(4) CMFCADxy — Compare Match A Flag Clear Enable Dxy

This flag specifies flag clearing at the time of compare match of the output compare register 1Dxy (OCR1Dxy). Setting this bit enables clearing of the compare match A flag Dxy (CMFADxy) of the timer status register Dx (TSRDx). This bit is always read as 0.

CMFCADxy	Function	
0	Disabled	(Initial value)
1	Clears CMFADxy to 0.	

(5) CMFCBDxy — Compare Match B Flag Clear Enable Dxy

This flag specifies flag clearing at the time of compare match of the output compare register 2Dxy (OCR2Dxy). Setting this bit enables clearing of the compare match B flag Dxy (CMFBDxy) of the timer status register Dx (TSRDx). This bit is always read as 0.

CMFCBDxy	Function	
0	Disabled	(Initial value)
1	Clears CMFBDxy to 0.	

21.7.2.14 TOCRDx — Timer Output Control Registers Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Table 21.94 TOCRDx Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Not used. These bits are always read as 0. When writing, always write 0.
1	TONEBDx	Output Inversion Select TODxyB 0: Output level is not inverted 1: Output level is inverted
0	TONEADx	Output Inversion Select TODxyA 0: Output level is not inverted 1: Output level is inverted

The timer output control register Dx (TOCRD0 to TOCRD9) is an 8-bit readable/writable register. This register specifies whether to invert signals of the output pins TODxyA and TODxyB of each subblock Dx.

When this register is reset, it is initialized to 00_H.

(1) TONEBDx, TONEADx — Output Inversion Select Dx

Specifies whether to invert the output from TODxy and TODxyA.

TONEBDx	Function	
0	Normal output from the output pin (TODxyB)	(Initial value)
1	Inverted output from the output pin (TODxyB)	

TONEADx	Function	
0	Normal output from the output pin (TODxyA)	(Initial value)
1	Inverted output from the output pin (TODxyA)	

Signals on pins TODxyA and TODxyB are inverted on the first edge of the PCLK after the output inversion select Dx bit is set to 1.

This function is not affected by the operating state of timer counters 1Dx and 2Dx (TCNT1Dx, TCNT2Dx).

The TONEBDx bit controls four outputs (TODx0B, TODx1B, TODx2B, TODx3B) in a single subblock. The TONEADx bit controls four outputs (TODx0A, TODx1A, TODx2A, TODx3A) in a single subblock. These bits cannot control individual signals independently (channel control is not available).

Output levels on pins TODxyA and TODxyB are initialized to a level of 0 (when TONEADx = 0 and TONEBDx = 0).

21.7.2.15 OSBRDx — Timer Offset Base Registers Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9)

Access: 32-bit read access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 1118$_H$ + (100$_H$ * x)

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OSBRD[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PSBRD[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. This register does not accept write access.

Timer offset base registers Dx (OSBRDx) are 32-bit read only registers that are used only for input capture. The timer counter 1Dx (TCNT1Dx) value is captured and stored by a trigger signal from timer A and PH update notification triggers 0 and 1 from DFE.

The trigger signal from timer A is selectable from TIA00 to TIA06, and PH update notification triggers 0 and 1 from DFE as external input signals are selectable in the timer input capture trigger select register Dx (TICTSELDx). For details, see **Section 21.4.2.1, TCR1A — Timer Control Register 1A** and **Section 21.7.2.16, TICTSELDx — Timer Input Capture Trigger Select Register Dx**.

When this register is reset, it is initialized to 0000 0000$_H$.

21.7.2.16 TICTSELDx — Timer Input Capture Trigger Select Register Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9)

Access: 8-bit accessible

Address: FFE6 1114_H + (100_H * x)

Value after reset: $0X_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TIDSELDx[1:0]	
Value after reset	0	0	0	0	0	0	0	*1
R/W	R	R	R	R	R	R	R/W	R/W

Note 1. This bit varies with the subblocks.
x = 0 to 2: 0
x = 3 to 9: 1

The timer input capture trigger select register Dx (TICTSELDx) is an 8-bit readable/writable register.

This register is used to select event 2A or 2B from timer A and PH update notification triggers 0 and 1 from DFE as external input signals, and to capture the TCNT1Dx counter value in the OSBRDx register.

Table 21.95 TICTSELDx Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Not used. These bits are read as 0. When writing, always write 0.
1, 0	TIDSELDx[1:0]	00: Event 2A 01: Event 2B 10: PH update notification trigger 0 from the DFE 11: PH update notification trigger 1 from the DFE

21.7.2.17 TCNT1Dx — Timer Counter 1Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 1120_H + (100_H * x)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCNT1D[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Timer counters 1Dx (TCNT1Dx) are 32-bit readable/writable registers driven by the clock selected in the CKSEL1Dx[2:0] bits in timer control register Dx (TCRDx). These counters are started by setting the bit in timer start register D (TSTRD) to 1.

An overflow interrupt request can be issued to CPU when the timer overflows.

The overflow flag 1Dx (OVF1Dx) of the timer status register Dx (TSRDx) is set to 1. When this register is reset, it is initialized to 0000 0000_H.

21.7.2.18 TCNT2Dx — Timer Counter 2Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 1124_H + (100_H * x)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCNT2D[31:16}															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCNT2D[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Timer counters 2Dx (TCNT2Dx) are 32-bit readable/writable registers driven by the clock selected in the CKSEL2Dx[2:0] bits in timer control register Dx (TCRDx). These counters are started by setting the bit in timer start register D (TSTRD) to 1.

An overflow interrupt request can be issued to CPU when the timer overflows.

The overflow flag 2Dx (OVF2Dx) of the timer status register Dx (TSRDx) is set to 1. When this register is reset, it is initialized to 0000 0000_H.

21.7.2.19 CUCR1Dx — Counter Upper-Limit Setting Compare Register 1Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9)

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 1128_H + (100_H * x)

Value after reset: FFFF $FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CUCR1D[31:16]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CUCR1D[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

The counter upper-limit setting compare register 1Dx (CUCR1Dx) is a 32-bit readable/writable register that has a function for comparison with the TCNT1Dx counter. Compare match between this register and the TCNT1Dx counter is enabled by setting the TCNT1Dx clear setting bit (CLR1Dx) in the timer control register Dx (TCRDx) to 1. The TCNT1Dx counter value is cleared to 0000 0000_H on compare match between timer counter 1Dx (TCNT1Dx) and counter upper-limit setting compare register 1Dx (CUCR1Dx). When this compare match and count up of the timer counter 1Dx (TCNT1Dx) occur simultaneously, the timer counter 1Dx (TCNT1Dx) is cleared to 0000 0001_H.

The OVF1Dx bit in timer status register Dx (TSRDx) is set to 1 and an overflow interrupt is output on compare match between timer counter 1Dx (TCNT1Dx) and counter upper-limit setting compare register 1Dx (CUCR1Dx).

The overflow interrupt output width is one clock width of PCLK.

OCR1Dxy compare match by the counter upper-limit setting compare register 1Dx (CUCR1Dx) occurs when CUCR1Dx ≥ OCR1Dxy.

Do not set CUCR1Dx to 0000 0000_H. Note that if CUCR1Dx is set to 0000 0000_H, a compare match occurs at incorrect intervals.

21.7.2.20 CUCR2Dx — Counter Upper-Limit Setting Compare Register 2Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9)

Access: 32-bit accessible but 8-bit/16-bit inaccessible

Address: FFE6 $112C_H$ + (100_H * x)

Value after reset: $FFFF\ FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CUCR2D[31:16]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CUCR2D[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

The counter upper-limit setting compare register 2Dx (CUCR2Dx) is a 32-bit readable/writable register that has a function for comparison with the TCNT2Dx timer counter. Compare match between this register and the TCNT2Dx counter is enabled by setting the TCNT2Dx clear setting bit (CLR2Dx) in the timer control register Dx (TCRDx) to 1. The TCNT2Dx counter value is cleared to $0000\ 0000_H$ on compare match between the timer counter 2Dx (TCNT2Dx) and counter upper-limit setting compare register 2Dx (CUCR2Dx).When this compare match and count up of the timer counter 2Dx (TCNT2Dx) occur simultaneously, the timer counter 2Dx (TCNT2Dx) is cleared to $0000\ 0001_H$.

The OVF2Dx bit in timer status register Dx (TSRDx) is set to 1 and an overflow interrupt is output on compare match between the timer counter 2Dx (TCNT2Dx) and counter upper-limit setting compare register 2Dx (CUCR2Dx).

The overflow interrupt output width is one clock width of PCLK.

OCR2Dxy compare match by the counter upper-limit setting compare register 2Dx (CUCR2Dx) occurs when CUCR2Dx ≥ OCR2Dxy.

Do not set CUCR2Dx to $0000\ 0000_H$. Note that if CUCR2Dx is set to $0000\ 0000_H$, a compare match occurs at incorrect intervals.

21.7.2.21 OCR1Dxy — Output Compare Registers 1Dxy

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 1140_H + (100_H * x) + (20_H * y)

Value after reset: FFFF $FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	OC1D[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

OCR1Dxy are 32-bit readable/writable registers.

OCR1Dxy is constantly compared with the timer counter 1Dx (TCNT1Dx). When compare match operation is selected by bit IOADxy in TIOR1Dx, the compare match A flag (CMFADxy) in TSRDx is set to 1 on the first edge of the PCLK after the values in TCNT1Dx and OCR1Dxy match. When compare match A is selected by an output source select bit, a signal is output to pin TODxyA on compare match.

When compare match A is selected as a down counter starting trigger by the TRGSELDxy bit in DCRDxy, DCNTDxy is ready to be counted down on compare match A.

When the down counter (DCNTDxy) is ready, it is started in synchronization with the down counter clock. At this time, a one-shot pulse can be output on pin TODxyB. If compare match A and down-counter stop trigger are output at the same time, output is disabled without any pulse.

When TCNT1Dx overflows to change from FFFF $FFFF_H$ to 0000 0000_H and OCRDxy is set to 0000 0000_H, the match in comparison is detected.

If the counter upper-limit setting function (see **Section 21.7.3.2, Counter Upper-Limit Setting Function**) is in use with clock-bus line 5 or 6, or with a division ratio of 1/1 selected for the prescaler, the timer counter counts between 1 and the value of CUCR1Dx and the counter value may not become 0000 0000_H. Therefore, do not set these registers to 0000 0000_H in such cases.

An interrupt can be issued to CPU by a compare match A detection. Subblocks 0, 2, 4, 6, and 9 can issue AD start triggers.

When the range compare function is enabled (RCR1Dx is not 0), the TCNT1Dx value at the compare match timing is stored in OCR1Dxy.

This register is initialized to FFFF $FFFF_H$ by a reset.

21.7.2.22 RCR1Dx — Range Comparison Value Setting Register 1Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9)

Access: 8-bit accessible

Address: FFE6 1130_H + (100_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	RC1D[4:0]				
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

The range comparison value setting register 1Dx (RCR1Dx) is an 8-bit readable/writable register.

According to the setting of this register, if the TCNT1Dx value is within the range of OCR1Dxy ≤ TCNT1Dx ≤ (OCR1Dxy + the value of the range specified by RCR1Dx) when writing to OCR1Dxy, a compare match A between OCR1Dxy and TCNT1Dx is generated. RCR1Dx is initialized to 00_H by a reset.

This function is enabled when RCR1Dx is set to a value other than 00_H, and is judged only when a value is written to OCR1Dxy.

When setting the TCNT1Dx clear 1Dx bit (CLR1Dx) to 1, set RCR1Dx to 00_H.

The following table shows ranges that can be set as range compare values (power of 2 (excluded only when RCR1Dx = 0)).

RCR1Dx[4:0]	Selectable Range	Note
00000	None	Range compare disable (Initial value)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OC2D[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

OCR2Dxy are 32-bit readable/writable registers.

OCR2Dxy is always compared with timer counter T2Dx (CNT2Dx), and if the IOBDxy bit of the TIOR2Dx register permits compare match, a match of TCNT2Dx and OCR2Dxy values is detected. If the OSSDxy bit specifies compare match B as the output source, the compare match is output to the TODxyA pin at the next PCLK cycle.

When compare match B is selected as a down counter starting trigger by the TRGSELDxy bit in DCRDx, DCNTDxy is ready to be counted down on compare match B.

When the down counter (DCNTDxy) is ready, it is started in synchronization with the down counter clock. At this time, a one-shot pulse can be output on pin TODxyB. If compare match A and down-counter stop trigger are output at the same time, output is disabled without any pulse.

If the TRGSELDxy bit of DCRDx specifies compare match B as the down count stop trigger, detection of compare match B disables down counting. At the next down-counting clock cycle, the down counter is cleared to 0 and TODxyB output (one-shot pulse) is negated.

When TCNT2Dx overflows to change from FFFF $FFFF_H$ to 0000 0000_H and OCR2Dxy is set to 0000 0000_H, the match in comparison is detected.

If the counter upper-limit setting function (see **Section 21.7.3.2, Counter Upper-Limit Setting Function**) is in use with clock-bus line 5 or 6, or with a division ratio of 1/1 selected for the prescaler, the timer counter counts between 1 and the value of CUCR2Dx and the counter value may not become 0000 0000_H. Therefore, do not set these registers to 0000 0000_H in such cases.

An interrupt can be issued to CPU by compare match B detection. Subblocks 0, 2, 4, 6, and 9 can issue AD start triggers.

When the range compare function is enabled (RCR2Dx is not 0), the TCNT2Dx value at the compare match timing is stored in OCR2Dxy.

This register is initialized to FFFF $FFFF_H$ by a reset.

21.7.2.24 RCR2Dx — Range Comparison Value Setting Register 2Dx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9)

Access: 8-bit accessible

Address: FFE6 1134_H + (100_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	RC2D[4:0]				
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

The range comparison value setting register 2Dx (RCR2Dx) is a 5-bit readable/writable register.

According to the setting of this register, if the TCNT2Dx value is within the range of OCR2Dxy ≤ TCNT2Dx ≤ (OCR2Dxy + the value of the range specified by RCR2Dx) when writing to OCR2Dxy, a compare match B between OCR2Dxy and TCNT2Dx is generated. RCR2Dx is initialized to 00_H by a reset.

This function is enabled when RCR2Dx is set to a value other than 00_H, and is judged only when a value is written to OCR2Dxy.

When setting the TCNT2Dx clear 2Dx bit (CLR2Dx) to 1, set RCR2Dx to 00_H.

The following table shows ranges that can be set as range compare values (power of 2 (excluded only when RCR2Dx = 0)).

RCR2Dx[4:0]	Selectable Range	Note
00000	None	Range compare is invalid (Initial value)
00001	2^1-1	—
00010	2^2-1	—
00011	2^3-1	—
00100	2^4-1	—
00101	2^5-1	—
00110	2^6-1	—
00111	2^7-1	—
01000	2^8-1	—

The input capture register 1Dxy (ICR1Dxy) is a 32-bit read-only register, and its initial value is 0000 0000_H. This register captures the counter value of TCNT1Dx into ICR1Dxy triggered by compare match B.

When ICR1Dxy is reset, it is initialized to 0000 0000_H.

21.7.2.26 ICR2Dxy — Input capture register 2Dxy

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 1154_H + (100_H * x) + (20_H * y)

Value after reset: 0000 0000_H

The input capture register 2Dxy (ICR2Dxy) is a 32-bit read-only register, and its initial value is 0000 0000_H. This register captures the counter value of TCNT2Dx in ICR2Dxy triggered by compare match A.

When ICR2Dxy is reset, it is initialized to 0000 0000_H.

21.7.2.27 DCNTDxy — Timer Down Counters Dxy

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks D0 to D9, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 1158_H + (100_H * x) + (20_H * y)

Value after reset: 0000 0000_H

Timer down counters Dxy (DCNTDxy) are 32-bit readable/writable registers driven by the clock selected in the DCSELDx[2:0] bits in timer control register Dx (TCRDx).

DCNTDxy is controlled by the down counter control register Dx (DCRDx). Down-counting is started when compare match A, compare match B, compare match A or B, or compare match A and B is detected or when the DSTDxy bit in the DSTRDx register is set to 1. While the down counter is enabled, it is decremented every input of the down counter clock. Counting can be stopped by an underflow of DCNTDxy, detection of compare match B, or detection of compare match A or B. When the decrementing is stopped by an underflow, a down counter underflow interrupt request and a DMA transfer request can be issued.

Decrementation is enabled; on the first edge of the PCLK (the same as compare match A) after the values in TCNT1Dx and OCRDxy match; on the first edge of the PCLK (the same as compare match B) after the values in TCNT2Dx and OCR2Dxy match; on the first edge of the PCLK after the DSTDxy bit is set to 1. Decrementation is enabled until DCNTDxy underflows or until the first edge of the PCLK (the same as compare match A) after the values in TCNT1Dx and OCR2Dxy or the first edge of the PCLK (the same as compare match B) after the values in TCNT2Dx and OCR2Dxy match. The down counter is decremented every input of the down counter clock while it is enabled.

Once DCNTDxy is enabled, it remains enabled until DCNTDxy underflow, compare match B, or compare match A or B (if selected as a count stop trigger) is detected. While it is enabled, another counter starting trigger or writing 1 to DSTDxy bit has no effect on the enabled state of the counter.

When compare match B or compare match A or B (if selected as a count stop trigger) is detected, the counter is stopped on the first edge of the down counter clock and then cleared to 0000 0000_H. If a down count start trigger (compare match A or writing 1 to DSTDxy) and a down count stop trigger (compare match B) are detected at the same time, the count stop trigger takes priority. The counter is not decremented and no signal on pin TODxyB is output. Moreover, When no down counter clock is input during the time between enabled state due to compare match A or writing 1 to DSTDxy and counter stop state due to compare match B, the counter stops without performing down-count. The counter stops down-counting in the down-count stop state regardless of that the DCNTDxy value is 0000 0000_H.

If a value other than 0000 0000_H is set in DCNTDxy after decrementation is terminated by underflow, the counter is not decremented until the counter stopping source is activated. When the DCNTDxy value is 0000 0000_H and the down-count clock is not input at the beginning of down-counting, only flags in the down count status register 2Dx (DSR2Dx) are updated without performing down-counting. A count down stop interrupt (due to DCNTDxy = 0000 0000_H) is generated at the next down-count clock. The down-count status flag Dxy (DSFDxy) in the down count status register 1Dx (DSR1Dx) retains 1 until an interrupt occurs.

This is initialized to 0000 0000_H by a reset.

21.7.3 Operation

Timer D consists of 10 subblocks. Each block has two range compare setting registers (RCR1Dx and RCR2Dx), two 32-bit timer counters 1Dx, 2Dx (TCNT1Dx and TCNT2Dx), one timer offset base register Dx (OSBRDx), one output value register (ODRDx), one output select register (OSELRDx), and four channels described below.

Each channel consists of the output compare register 1Dxy (OCR1Dxy) to which TCNT1Dx is compared, the output compare register 2Dxy (OCR2Dxy) to which TCNT2Dx is compared, one timer down counter Dxy (DCNTDxy), two upper-limit setting registers Dxy (CUCR1Dx, CUCR2Dx) for two counters, and two input capture registers (ICR1Dxy and ICR2Dxy).

One-shot pulse can be output from timer D. By using compare match A, compare match B, compare match A or B, (or compare match A and B) as a start trigger of a down-counter, one-shot pulse with an offset can also be output.

Setting the TDE bit in ATUENR and bit STRDx in timer start register D (TSTRD) to 1 makes two timer counters 1Dx, 2Dx (TCNT1Dx and TCNT2Dx) in subblock Dx start operation.

The down-counter is started by any of four (five) sources; setting the DSTDxy bit in the down count start register Dx (DSTRDx) to 1, compare match A, compare match B, compare match A or B, (and compare match A and B) that are set by the TRGSELDxy bit in the down counter control register Dx (DCRDx). When any of these triggers occurs, DCNTDxy driven by the down counter clock is started.

The down counter is stopped on an underflow of the down counter and compare match B or A or B selected by bit TRGSELxy. The down counter is stopped immediately after it underflows (the counter is to be decremented when the value is $0000\ 0000_H$). It is stopped and cleared to $0000\ 0000_H$ on the first edge of the down counter clock after the trigger is detected.

For compare match A between TCNT1Dx and OCR1Dxy and compare match B between TCNT2Dx and OCR2Dxy are set to 1 on the first edge of the PCLK after the compare match. A compare match interrupt request is issued to CPU triggered by the compare match. According to the settings of range comparison value setting registers (RCR1Dx and RCR2Dx), a compare match A between OCR1Dxy and TCNT1Dx can be generated if the TCNT1Dx value is within the range of OCR1Dxy ≤ TCNT1Dx ≤ (OCR1Dxy + the value of the range specified by RCR1Dx) when writing to OCR1Dxy, and a compare match B between OCR2Dxy and TCNT2Dx can be generated if the TCNT2Dx value is within the range of OCR2Dxy ≤ TCNT2Dx ≤ (OCR2Dxy + the value of the range specified by RCR2Dx) when writing to OCD2Dxy.

Furthermore, the counter value of TCNT2Dx is captured into ICR2Dxy triggered by compare match A and the counter value of TCNT1Dx is capture into ICR1Dxy triggered by compare match B. The CMFADxy and CMFBDxy bits in TSRDx are set to 1 in synchronization with PCLK in the occurrence of compare match.

A signal on pin TODxyA is output when the output source selected in the OSSDxy bit in timer I/O control register 1Dx (TIOR1Dx) is activated. For example, assume that compare match A is selected. A signal level set by the IOAxy bit is output on pin TODxyA on the first edge of the PCLK after the compare match between TCNT1Dx and OCR1Dxy.

Output of the one-shot pulse is synchronized with the down counter clock in a way similar to the down counter operation. The four (five) counter starting sources are synchronized with the PCLK, a signal on pin TODxyB is output on the first edge of the down counter clock after the source is activated. Underflow of the down counter, which is a counter stopping source, is synchronized with the down counter clock and compare match B and compare match A or B is synchronized with the PCLK. As to negation timing, the TODxyB signal is negated in synchronization with underflow and on the first edge of the down counter clock after the compare match B or A or B.

Output Pin	Assertion Timing	Negation Timing	Initial Value
TODxyB	On the first edge of the down counter clock after the counter starting source is activated	On the first edge of the down counter clock after compare match or on DCNTDxy underflow	0 (inverted depending on TOCRDx)

Note: If an assertion and a negation occur simultaneously, the negation takes priority.

The initial values output on pins TODxyA and TODxyB are 0. However, the output level can be inverted by setting timer output control register Dx (TOCRDx). Setting bit TONEADx to 1 makes pin TODxyA in subblock Dn inverted and setting bit TONEBDx to 1 makes pin TODxyB in subblock Dx inverted. By setting the output select register Dx (OSELRDx), the value of the corresponding output value register Dx (ODRDx) can be output to pins (TODxyA and TODxyB).

To set the clocks for TCNT1Dx, TCNT2Dx, or DCNTDxy or values in registers such as DCNTDxy, OCR1Dxy, and OCR2Dxy while TCNT1Dx or TCNT2Dx is in operation, note that the value to be set may lead to malfunction. For example, while setting the compare match value, the counter value may exceed the value to be set.

Figure 21.46 shows an operation example of one-shot pulse output for channel 0 in subblock D0.

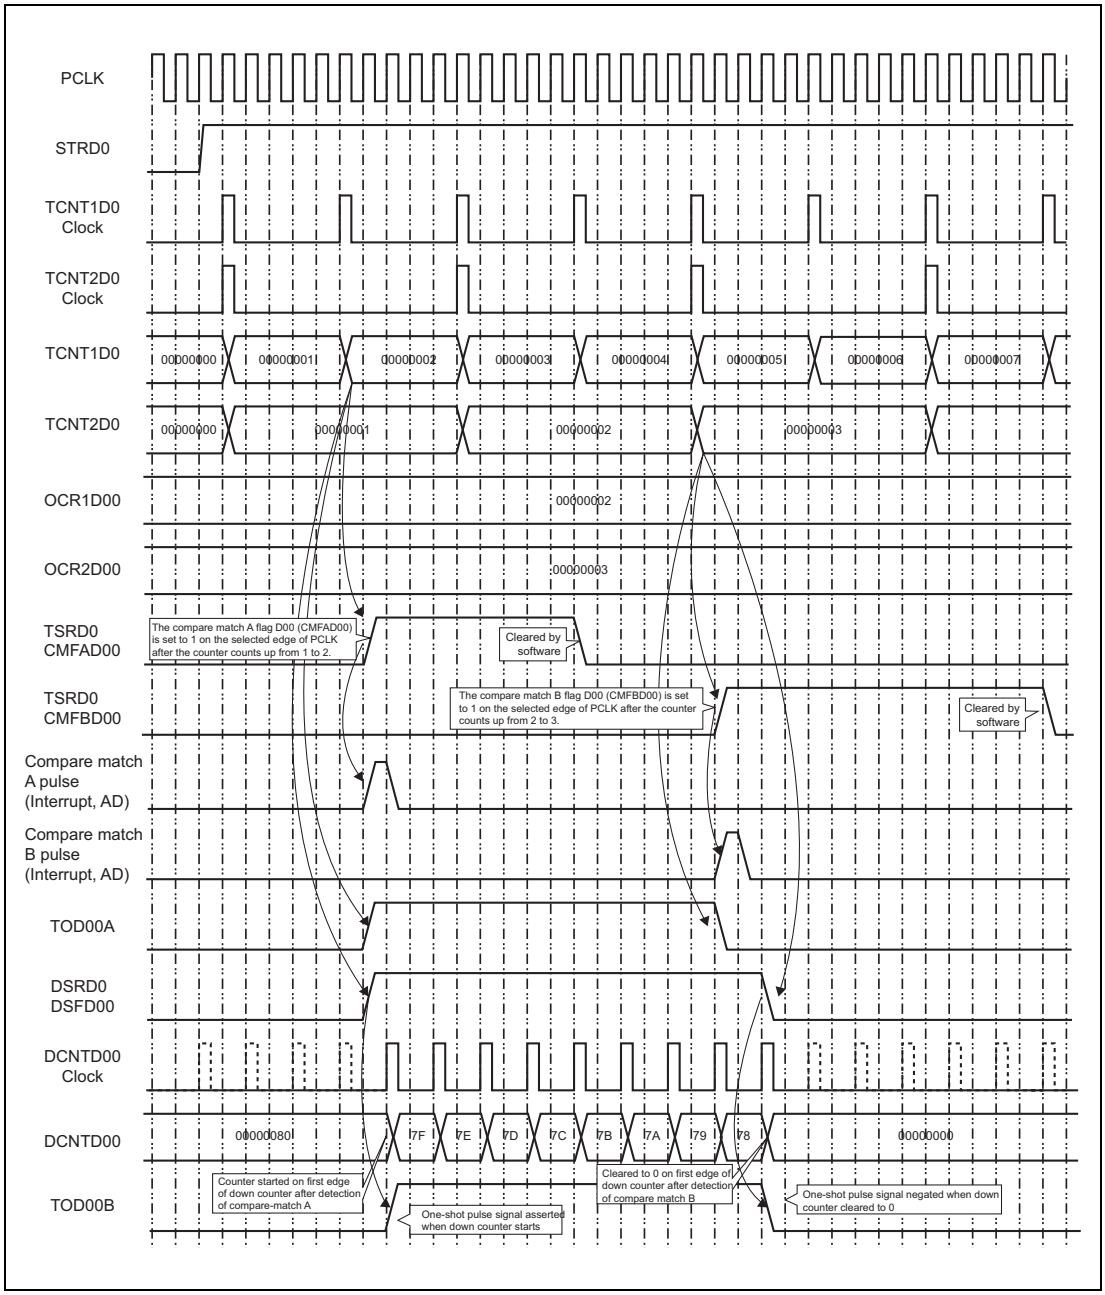

Figure 21.46 Operation Example of One-Shot Pulse Output (1) (Counting Started on Compare Match A and Stopped on Compare Match B)

Figure 21.46 shows operations of the down counter when the counter is started on compare match A and is stopped on compare match B. It also shows the assertion and negation of a one-shot pulse. Compare match A as the counter starting trigger and compare match B as the counter stopping trigger are set by the TRGSELD00 bits in DCRD0. Both matches are selected as the source of the output signal by the OSSD00 bits in TIOR1D0 and output levels are set by the IOAD00 and IOBD00 bits. A logical one for compare match A and a logical zero for compare match A are selected.

TCNT1D0 and TCNT2D0 are started for counting up on the first edge of the counter clock after the counter Dn start bit in timer start register D (TSTRD) is set to 1. If TCNT1D0 coincides with the output compare register (OCR1D00), compare match A occurs at the next PCLK cycle. At this time, the counter value of TCNT2Dx is captured in ICR2Dxy. In addition, a compare match interrupt request is issued to CPU triggered by compare match A. The compare match A flag D00 (CMFAD00) is set to 1.

At the same time, TOD00A outputs 1 and the down count status flag (DSFD00) is also set to 1, entering the down counter enabled state. This down count enabled state continues until detection of compare match B or under flow of DCNTD00. Input of the down counter clock during this state decrements DCNTD00. TOD00B outputs 1 from the time of the first down counter clock input.

If TCNT2D0 coincides with the output compare register (OCR2D00), compare match B occurs at the next PCLK cycle. At this time, the counter value of TCNT1Dx is captured into ICR1Dxy. In addition, a compare match interrupt request is issued to CPU triggered by compare match B. The compare match B flag D00 (CMFBD00) is set to 1. At this time, a level of 0 is output on pin TOD00A. The down counter is cleared and a one-shot pulse (TOD00B) is terminated.

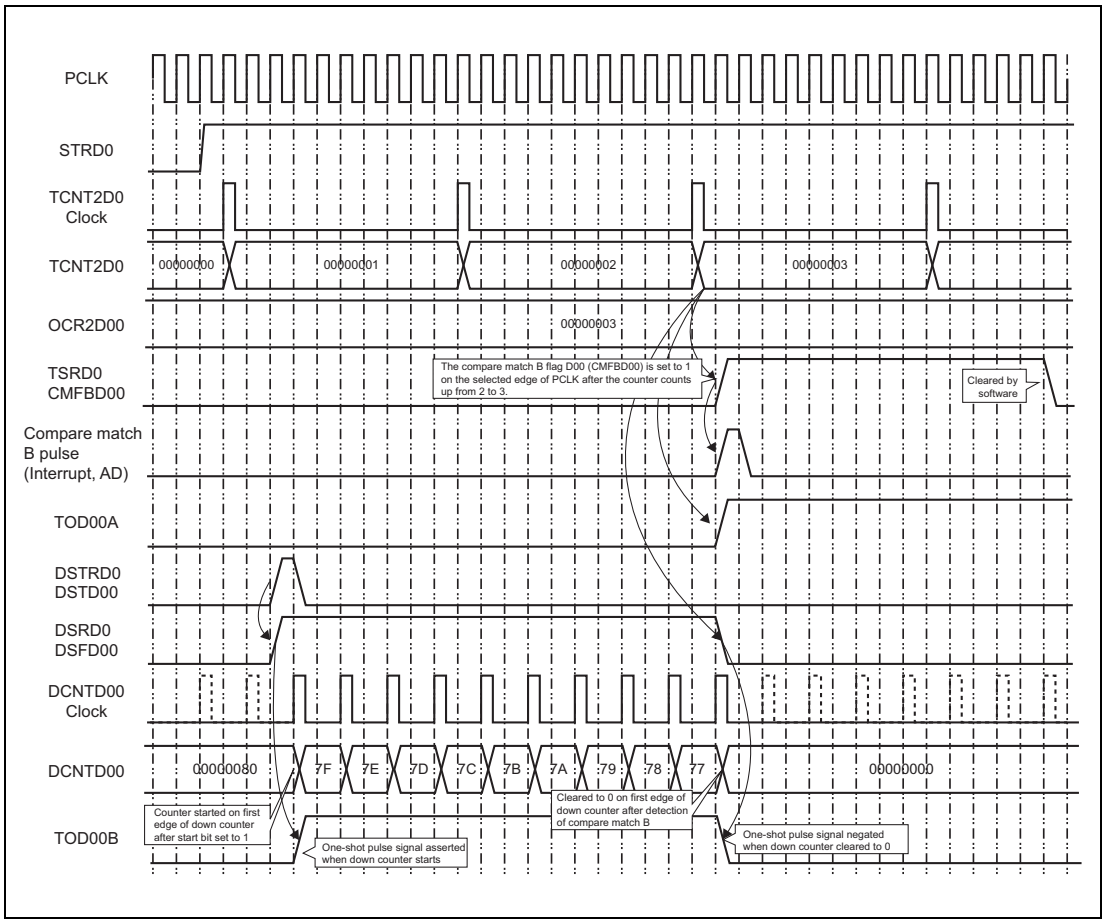

Figure 21.47 Operation Example of One-Shot Pulse Output (2) (Counting Started by Writing 1 to Counter Starting Bit and Stopped on Compare Match B)

Figure 21.47 shows an operation example when the down counter is started by writing 1 to the down counter starting bit. In this example, the counter starting trigger is not selected and compare match B is selected as the counter stopping trigger (TRGSELD00 in DCRD0). The source of the output signal is compare match B (OSSD00 in TIOR1D0) and logical one is output (IOBD00 in TIOR1D0).

Figure 21.48 shows an operation example of a one-shot pulse output for channel 0 in subblock D0. Setting the DSTD00 bit in the down counter starting register D0 (DSTRD0) sets the down counter status flag (DSFD00) to 1. This makes the down counter ready for counting down. DCNTD00 is started on the first edge of the down counter clock after DSFD00 is set to 1. At this time, a level of 1 is output on pin TOD00B.

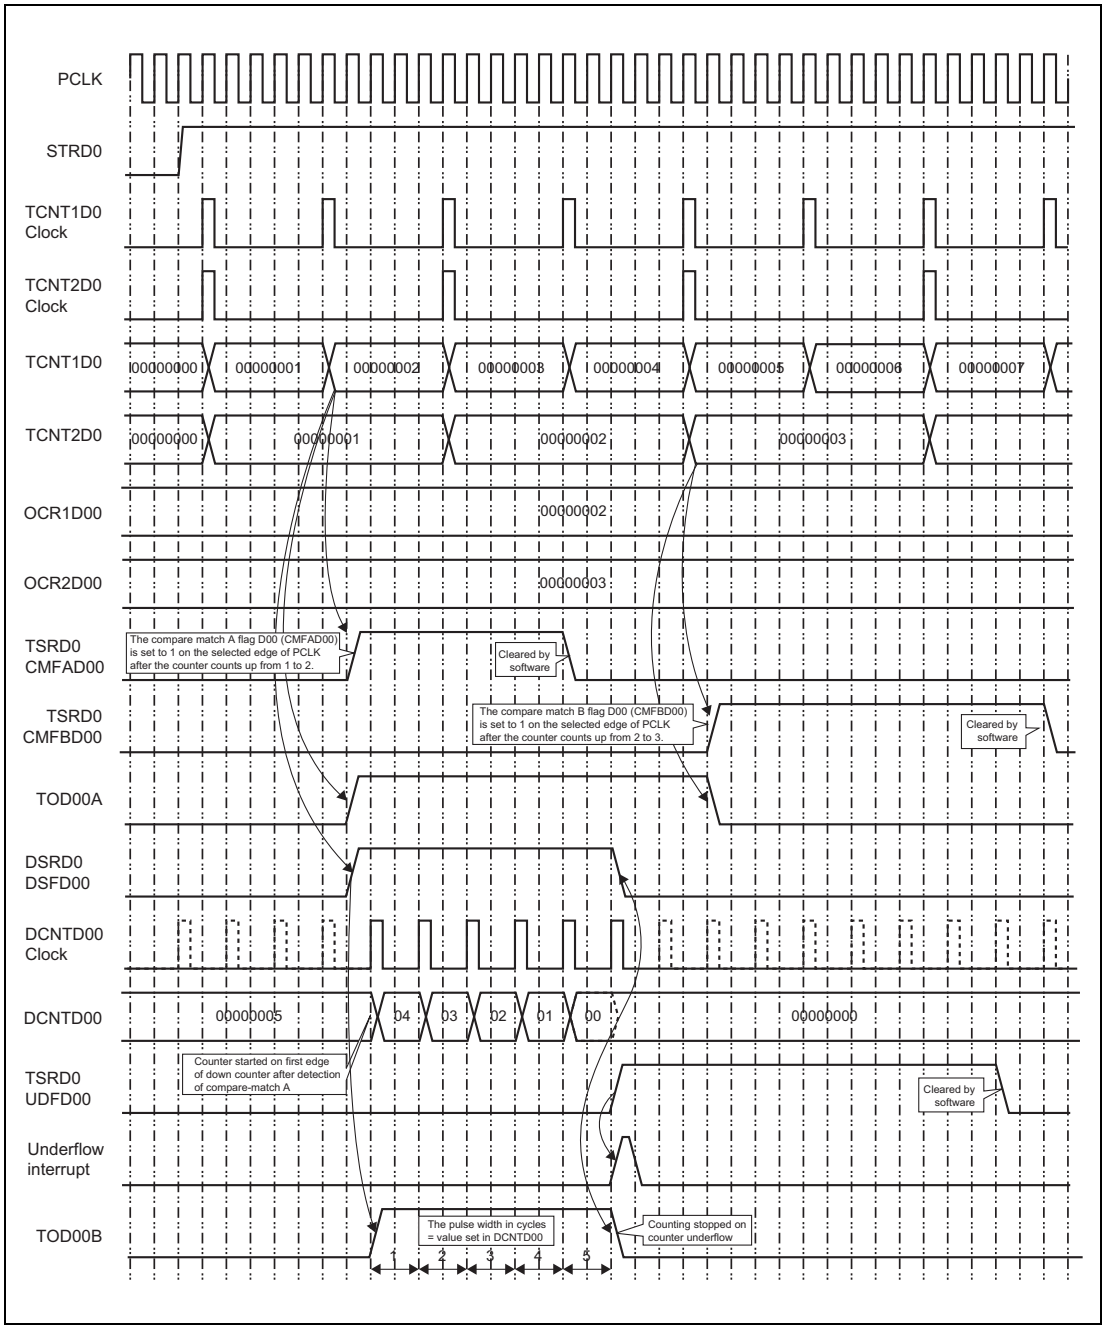

Figure 21.48 Operation Example of One-Shot Pulse Output (3) (Underflow Occurs)

Figure 21.48 shows an operation example when a one-shot pulse is terminated on underflow. In this example, compare match A as the counter starting trigger is selected and the counter stopping trigger is not selected (TRGSELD00 in DCRD0). Both compare matches A and B as the source of the output signal (OSSD00 in TIOR1D0) are selected. Output levels of 1 for compare match A (IOAD00) and 0 for compare match B (IOBD00) are selected.

Underflow is detected and the underflow flag D00 (UDFD00) in TSRD0 is set on the first edge of the down counter clock after the value in timer down counter Dxy (DCNTD00) is 000 000_H. At the same time, the one-shot pulse output is terminated. The width of the pulse output on pin TOD00B is equal to the value set in DCNTD00 before counting down.

21.7.3.1 Range Comparison Function

Figure 21.49 shows the operation of compare match occurrence using the range compare function according to the setting of the range comparison value setting register 1Dx (RCR1Dx).

If TCNT1Dx is larger than the output compare register 1Dxy (OCR1Dxy) value when writing to OCR1Dxy, a compare match A between OCR1Dxy and TCNT1Dx can be generated if the TCNT1Dx value is within the range of OCR1Dxy ≤ TCNT1Dx ≤ (OCR1Dxy + the value of the range specified by RCR1Dx).

At this time, the TCNT1Dx value is captured into OCR1Dxy.

The range comparison value setting register 2Dx (RCR2Dx) behaves similarly to TCNT2Dx.

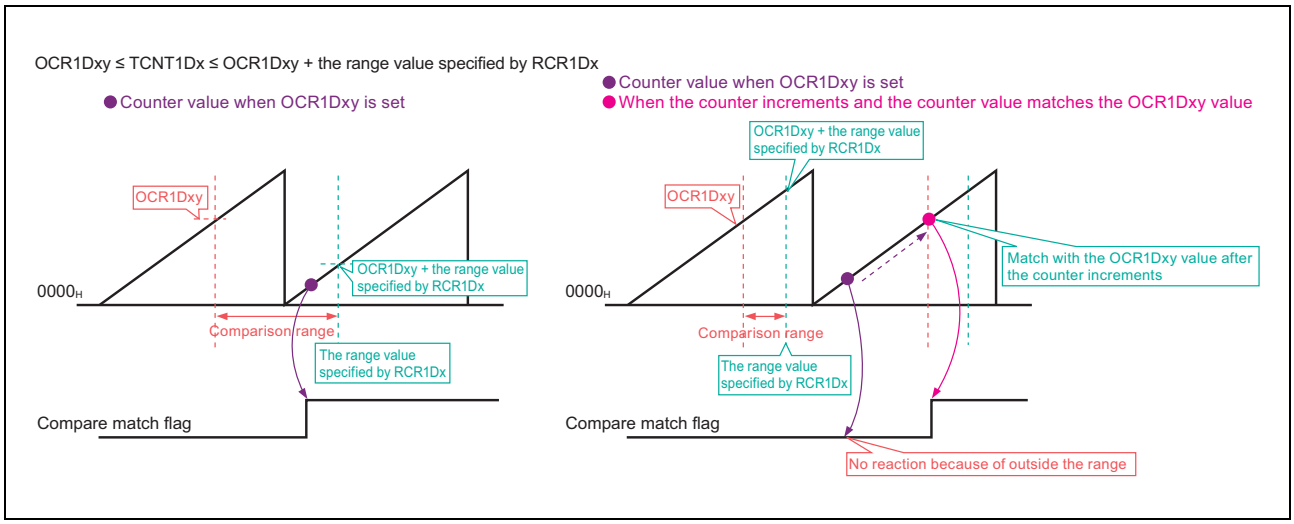

Figure 21.49 Operation of the Range Comparison Function

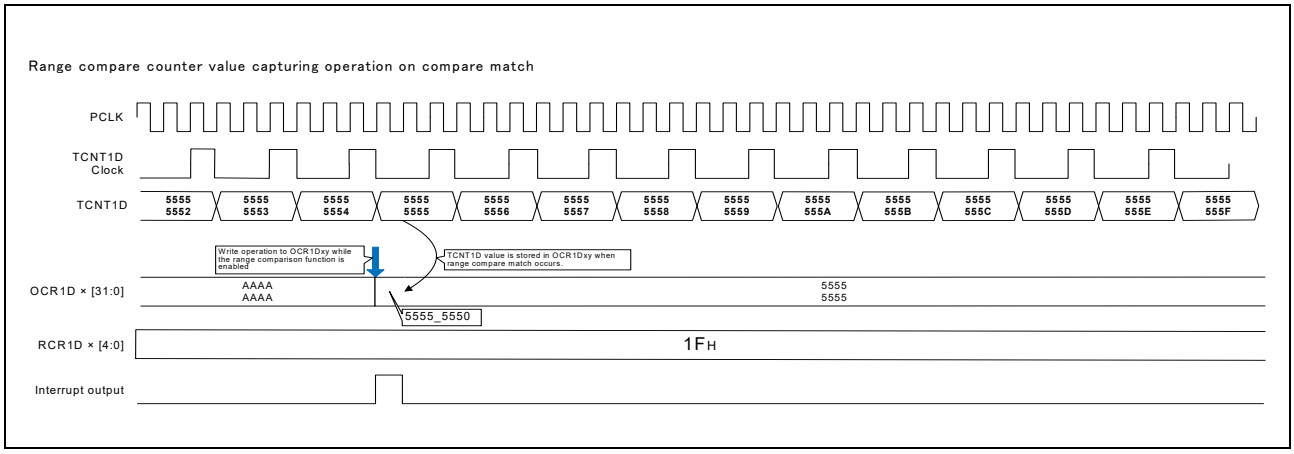

Figure 21.50 Range Compare Counter Value Capturing Operation

21.7.3.2 Counter Upper-Limit Setting Function

According to the setting for the counter upper-limit setting compare register 1Dx (CUCR1Dx), the upper-limit value of the timer counter 1Dx (TCNT1Dx) in each subblock can be modified to change the one-shot pulse cycle. To enable the counter upper-limit setting function, the CLR1Dx bit in the timer control register Dx (TCRDx) must be set to 1.

According to the setting for the counter upper-limit setting compare register 2Dx (CUCR2Dx), the upper-limit value of the timer counter 2Dx (TCNT2Dx) in each subblock can be modified to change the one-shot pulse cycle. To enable the counter upper-limit setting function, the CLR1Dx bit in the timer control register Dx (TCRDx) must be set to 1.

Figure 21.51 shows an example of operation when the counter upper-limit setting function in block D1 is enabled.

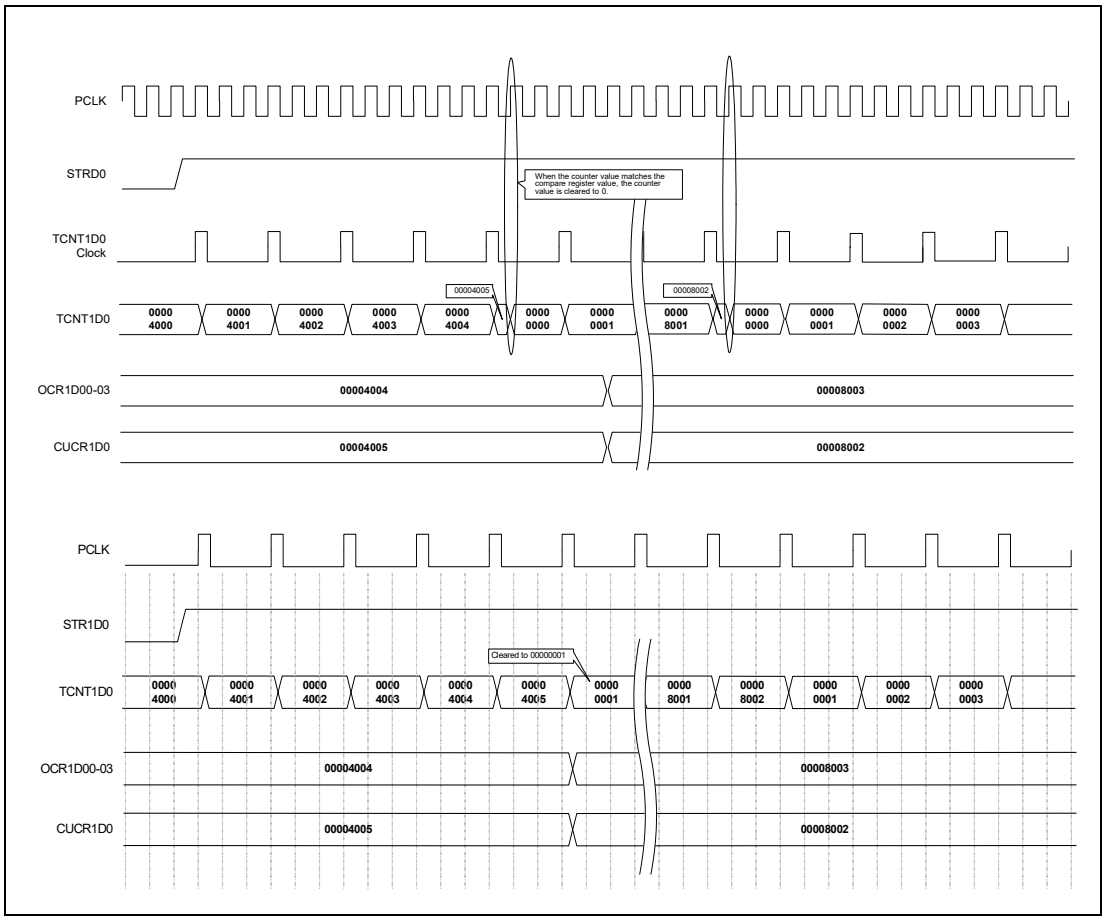

Figure 21.51 Operation of the Counter Upper-Limit Setting Function

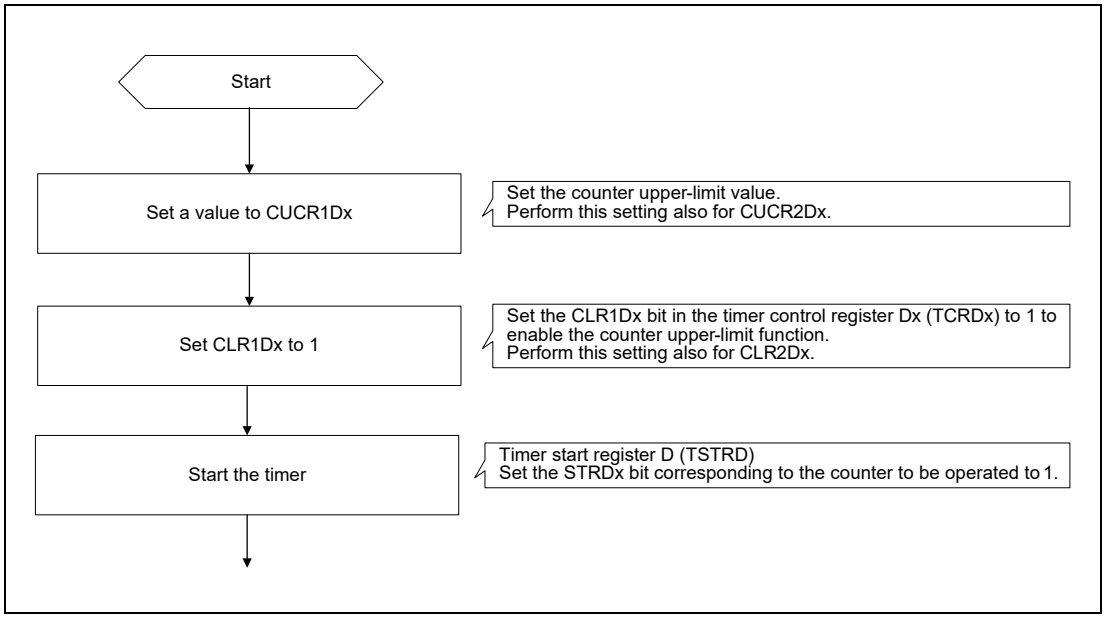

Figure 21.52 Counter Upper-Limit Function Setting Procedure

21.7.3.3 Capture Function

The input capture registers 1Dxy (ICR1Dxy) and 2Dxy (ICR2Dxy) capture the values counted by timer counters 1Dx (TCNT1Dx) and 2Dx (TCNT2Dx) in response to the compare match B and compare match A triggers, respectively. Capture proceeds on the rising edges of the pulses produced by matches.

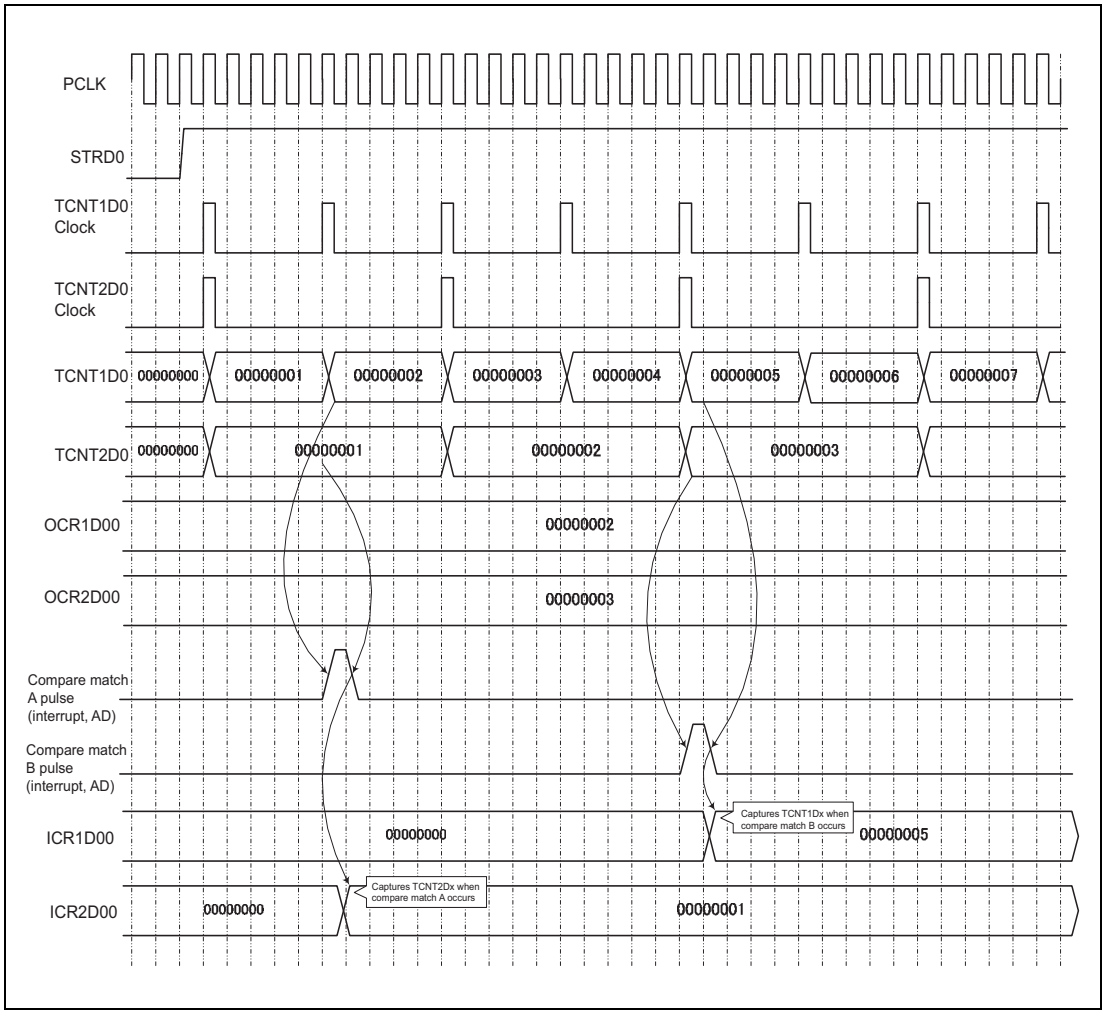

Figure 21.53 Capture Operation for Input Capture Registers 1Dxy and 2Dxy (ICR1Dxy, ICR2Dxy)

21.8 Timer E

21.8.1 Operation Overview

The timer E block is a PWM output timer that consists of seven timer E subblocks.

Timer E subblocks realize the following features:

- Output of waveform with a duty cycle of 0 to 100% by setting cycle-setting register and duty cycle-setting register
- The values of the cycle-setting and duty-cycle-setting registers are updated every PWM cycle. The values in the cycle reload register and duty cycle reload register are reloaded as update data. The reloading function can be enabled and disabled.
- Writing $000\ 000_H$ to the 24 higher-order bits of the counter can forcibly end PWM cycle.
- The shutoff input pins (POEx) shut off the PWM output. (They can also be used as the timer F input pins.) This feature is supported by subblocks E0 to E5. Subblock E6 does not support this feature.
- On-state duty (active-high output) and off-state duty (active-low output) modes available
- Interrupt requests can be issued on cycle match (compare match between cycle setting register and timer counter), that is, interrupts are issued every cycle.
- Cycle matches of channel 0 can be used as DMAC activation interrupts.
- Compare matches of the duty cycle setting register generate interrupt requests periodically.

A timer E subblock Ex consists of 4 channels. Components of each channel include a 24-bit timer counter (TCNTExy), a 24-bit cycle-setting register (CYLRExy), a 24-bit duty-cycle-setting register (DTRExy), a 24-bit cycle reload register Exy (CRLDExy), a 24-bit duty-load register (DRLDExy), and a controller.

Subblocks E0 to E5 has a shutoff input pin (POEx), and each channel of each subblock has a PWM output pin (TOExy). (The initial value of TOExy: 0)

POEx can also be used as TIF0A to TIF2A and TIF0B to TIF2B of timer F. For timer E, signals of TIF0A to TIF2A and TIF0B to TIF2B that have been processed by a noise canceler are used, which means that their noise canceler feature can be used. To use the noise canceler for the shutoff input signal of the PWM output shutoff feature, the timer F noise canceler setting is necessary as well as the timer E setting. For more about the setting, see **Section 21.9, Timer F**.

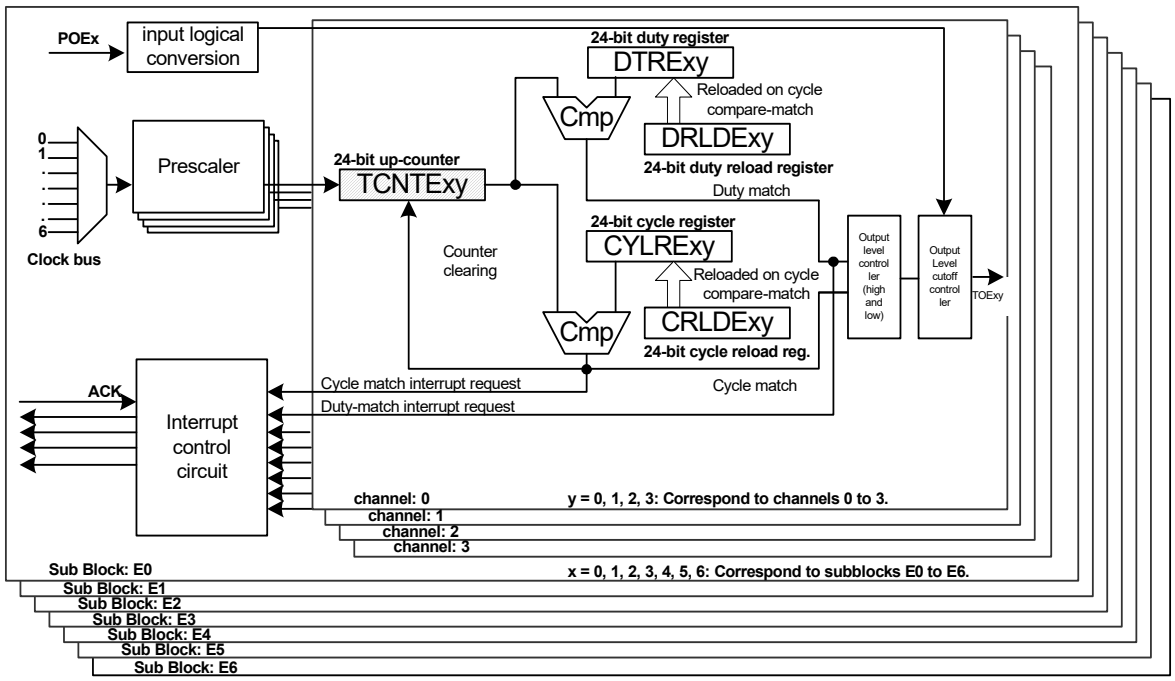
Table 21.96 shows the correspondence between TIF0A/B to TIF2A/B and POEx.

Table 21.96 Correspondence Between Timer F Primary Inputs and Timer E Shutoff Inputs

Timer F Primary Inputs	Timer E Shutoff Inputs
TIF0A	POE0
TIF1A	POE1
TIF2A	POE2
TIF0B	POE3
TIF1B	POE4
TIF2B	POE5

Be noted that the timer F measurement signals become the shutoff input signals when TIF0A/B to TIF2A/B are used as POEx inputs and the corresponding timer F subblocks are operated simultaneously.

Figure 21.54 is a block diagram of timer E.



Note: Interrupt requests to general DMA is supported only for channel 0 of each subblock. POEx input is supported only for subblock 0 to 5.

Figure 21.54 Block Diagram of Timer E

21.8.2 Registers Related to Timer E

21.8.2.1 TSTRE — Timer Start Register E

Access: 8-bit access is possible.

Address: FFE6 2000_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	STRE6	STRE5	STRE4	STRE3	STRE2	STRE1	STRE0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.97 TSTRE Register Contents

Bit Position	Bit Name	Function
7	—	Not used. This bit is always read as 0. This bit is read as 0. When writing, always write 0.
6	STRE6	Subblock E6 Start 0: Subblock E6 is disabled 1: Subblock E6 is enabled
5	STRE5	Subblock E5 Start 0: Subblock E5 is disabled 1: Subblock E5 is enabled
4	STRE4	Subblock E4 Start 0: Subblock E4 is disabled 1: Subblock E4 is enabled
3	STRE3	Subblock E3 Start 0: Subblock E3 is disabled 1: Subblock E3 is enabled
2	STRE2	Subblock E2 Start 0: Subblock E2 is disabled 1: Subblock E2 is enabled
1	STRE1	Subblock E1 Start 0: Subblock E1 is disabled 1: Subblock E1 is enabled
0	STRE0	Subblock E0 Start 0: Subblock E0 is disabled 1: Subblock E0 is enabled

TSTRE controls subblocks E0 to E6.

The timer E counters run when the timer E enable bit (TEE) in the ATU-IV master enable register (ATUENR), timer start register E (TSTRE), and subblock starting register E (SSTRE) must be set.

When this register is reset, it is initialized to 00_H.

CAUTION

To synchronize timer operation for all channels in the subblock, do not use the SSTREx register; instead, use the TSTRE register to enable or disable operation for each subblock.

21.8.2.2 SSTREx — Subblock Starting Registers Ex

(x = 0, 1, 2, 3, 4, 5, 6: Corresponding to subblocks E0 to E6, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit access is possible.

Address: FFE6 2100_H + (100_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	SSTREx3	SSTREx2	SSTREx1	SSTREx0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 21.98 SSTREx Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Not used. These bits are always read as 0. These bits are read as 0. When writing, always write 0.
3	SSTREx3	Counter Ex3 Start 0: Counter of channel 3 in subblock Ex is disabled 1: Counter of channel 3 in subblock Ex is enabled
2	SSTREx2	Counter Ex2 Start 0: Counter of channel 2 in subblock Ex is disabled 1: Counter of channel 2 in subblock Ex is enabled
1	SSTREx1	Counter Ex1 Start 0: Counter of channel 1 in subblock Ex is disabled 1: Counter of channel 1 in subblock Ex is enabled
0	SSTREx0	Counter Ex0 Start 0: Counter of channel 0 in subblock Ex is disabled 1: Counter of channel 0 in subblock Ex is enabled

The subblock starting registers E0 to E6 (SSTRE0 to SSTRE6) are 8-bit readable/writable registers. These registers control stop/start of timer counters of 4 channels of each subblock. This control is effective only for subblocks enabled by the timer start register E (TSTRE).

When SSTRE0 to SSTRE6 are reset, they are initialized to 00_H.

(1) SSTRExy — Counter Exy Start bit

Enables and disables timer counter Exy (TCNTExy).

SSTRExy	Function	
0	Counting of TCNTExy is disabled.	(Initial value)
1	Counting of TCNTExy is enabled.	

When this bit is cleared to 0, TCNTExy is disabled. TCNTExy retains the previous value while it is stopped. When this bit is set to 1 again, TCNTExy is resumed from the retained value.

Even if the counter Exy start bit is set to 1, counting does not start unless the master enable of timer Ex is set to 1 by the ATU-IV control register.

CAUTION

The prescalers run regardless of the counter Exy start bit and are not synchronized with the timing at which TCNTExy is started. Therefore, the time from when the counter Enm start bit is set to when TCNTExy is incremented for the first time is less than the cycle of the clock of TCNTE.

21.8.2.3 PSCREx — Prescaler Registers Ex

(x = 0, 1, 2, 3, 4, 5, 6: Correspond to subblocks E0 to E6.)

Access: 8-bit access is possible.

Address: FFE6 2104_H + (100_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	PSCEx[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 21.99 PSCREx Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Not used. Fix these bits to 0.
2 to 0	PSCEx[2:0]	Division Ratio These bits store the division ratio of the prescaler.

Prescaler registers E are 8-bit readable/writable registers.

Each subblock of timer E has one prescaler that divides the frequency of the clock supplied via the clock bus. The register sets the division ratio of the prescalers.

When the value in prescaler register E (PSCRE) is changed, the prescaler updates the value on its underflow. Timer counter E (TCNTExy) (y = 0 to 3) in the same block is driven by the clock output from prescaler Ex.

The settable value in prescaler register E (PSCRE) ranges from 0_H to 7_H. The division ratio is given below.

$$\text{Division ratio of prescaler} = \frac{1}{\text{PSCEx[2:0]} + 1} \quad \text{(Settable value: 1/1 to 1/8)}$$

A duty cycle of 50% for the prescaler E output clock is not guaranteed. The high level width is equal to the cycle of the PCLK and a low level is output in the remaining cycle of the prescaler E output clock.

Prescaler Ex runs when the TEE bit in the ATU-IV master enable register (ATUENR) and the subblock Ex start bit (STREx) in timer start register E (TSTRE) are both set to 1.

21.8.2.4 PSCCRExy — Prescaler Channel Registers Exy

(x = 0, 1, 2, 3, 4, 5, 6: Corresponding to subblocks E0 to E6, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit access is possible.

Address: FFE6 2118_H + (100_H * x) + y

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	PSCCExy[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.100 PSCCRExy Register Contents

Bit Position	Bit Name	Function
7 to 0	PSCCExy[7:0]	Division Ratio These bits store the division ratio of the prescaler.

Prescaler channel registers Exy are 8-bit readable/writable registers.

Each channel of timer E has one prescaler that divides the frequency of the clock supplied via the clock bus. The register sets the division ratio of the prescalers.

When the value in prescaler channel register Exy is changed, the prescaler updates the value on its underflow. Timer counter E (TCNTExy) (y = 0 to 3) in the same channel is driven by the clock output from prescaler Exy.

The settable value in prescaler channel register Exy ranges from 00_H to FF_H. The division ratio is given below.

$$\text{Division ratio of prescaler} = \frac{1}{\text{PSCCExy[7:0]} + 1} \quad \text{(Settable value: 1/1 to 1/256)}$$

A duty cycle of 50% for the prescaler Exy output clock is not guaranteed. The high level width is equal to the cycle of the PCLK and a low level is output in the remaining cycle of the prescaler E output clock.

Prescaler Exy runs when the TEE bit in the ATU-IV timer enable register (ATUENR) and the subblock Ex start bit (STREx) in timer start register E (TSTRE) are both set to 1. The setting of the counter Exy start bit (SSTRExy) in the subblock start register Ex (SSTREx) does not affect operation of the prescaler Exy.

21.8.2.5 TCREx — Timer Control Register Ex

(x = 0, 1, 2, 3, 4, 5, 6: Corresponding to subblocks E0 to E6, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit access is possible.

Address: FFE6 2108_H + (100_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	PSCSEL	—	—	—	—	CKSELEx[2:0]		
Value after reset	0	0	0	0	0	0	0	0

Table 21.101 TCREx Register Contents

Bit Position	Bit Name	Function
7	PSCSEL	Prescaler Select 0: These bits select the prescaler registers Ex (PSCREx: 3-bit settings for subblock units). 1: These bits select the prescaler channel registers Exy (PSCRExy: 8 bit settings for channel units).
6 to 3	—	Not used. These bits are always read as 0. When writing, always write 0.
2 to 0	CKSELEx[2:0]	TCNTExy Clock Select These bits select the counter clock of prescaler E from clock-bus lines 0 to 6.

Timer control registers Ex (TCREx) are 8-bit readable/writable registers that select the counter clock of prescaler E from clock-bus lines 0 to 6. 16-bit timer counter Exy (TCNTExy) is driven by the clock output from prescaler E.

(1) PSCSEL — Prescaler Select

The prescaler can be selected in subblock units or in channel units.
This selection makes a difference in the range of division ratios that can be selected for the prescaler.

(2) CKSELEx[2:0] — Subblock Ex Clock Select

The subblock Ex clock select (CKSELEx) selects the count source of the prescaler of subblock Ex.

CKSELEx				
[2]	[1]	[0]	Function	
0	0	0	Clock-bus line 0 is selected as counter clock of prescaler E	(Initial value)
0	0	1	Clock-bus line 1 is selected as counter clock of prescaler E	
0	1	0	Clock-bus line 2 is selected as counter clock of prescaler E	
0	1	1	Clock-bus line 3 is selected as counter clock of prescaler E	
1	0	0	Clock-bus line 4 is selected as counter clock of prescaler E	
1	0	1	Clock-bus line 5 is selected as counter clock of prescaler E	
1	1	0	Clock-bus line 6 is selected as counter clock of prescaler E.	
1	1	1	Reserved	

21.8.2.6 RLDCREx — Reload Control Registers Ex

(x = 0, 1, 2, 3, 4, 5, 6: Corresponding to subblocks E0 to E6, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit access is possible.

Address: FFE6 $210A_H$ + (100_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	RLDENEx3	RLDENEx2	RLDENEx1	RLDENEx0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 21.102 RLDCREx Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Not used. These bits are always read as 0. When writing, always write 0.
3 to 0	RLDENEx3 to RLDENEx0	Reload Enable Ex3-Ex0 0: Reload function on cycle match is disabled 1: Reload function on cycle match is enabled

Reload control registers Ex (RLDCREx) are 8-bit readable/writable registers. RLDENExy enables and disables the reload function.

When RLDCREx is reset, it is initialized to 00_H.

(1) RLDENExy — Reload Enable Exy

If the reload feature is enabled by setting this bit to 1, the value of the cycle reload register Exy (CRLDExy) is set to the cycle-setting register, and the value of the duty reload register Exy (DRLDExy) is set to the duty cycle setting register at the time of cycle matches of the timer counter Exy (TCNTExy) and the cycle-setting register Exy (CYLRExy).

21.8.2.7 POECREx — Output Shutoff Control Register Ex

(x = 0, 1, 2, 3, 4, 5, 6: Corresponding to subblocks E0 to E6, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 16-bit access is supported. 8-bit access is prohibited.

Address: FFE6 $210C_H$ + (100_H * x)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	POECRKEY[7:0]								—	—	—	POEPOLx	POEENx3	POEENx2	POEENx1	POEENx0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	(W)*1	(W)*1	(W)*1	(W)*1	(W)*1	(W)*1	(W)*1	(W)*1	R	R	R	R/W	R/W	R/W	R/W	R/W

Note 1. Values written to the write key code are not retained.

Table 21.103 POECREx Register Contents

Bit Position	Bit Name	Function
15 to 8	POECRKEY[7:0]	Write Key Code $9C_H$: Values of POEENxy and POEPOLx can be changed. Other than $9C_H$: Values of POEENxy and POEPOLx cannot be changed.
7 to 5	—	Not used. These bits are always read as 0. When writing, always write 0.
4	POEPOLx	Shutoff Input Active Level Selection 0: Shutoff input is L active. 1: Shutoff input is H active.
3	POEENx3	Output Shutoff Enable/Disable 0: Output shutoff is disabled. 1: Output shutoff is enabled.
2	POEENx2	
1	POEENx1	
0	POEENx0	

Output shutoff register Ex (POECREx) is a 16-bit readable/writable register. To write a value to this register, the data to be written must be provided and the write key code must be set in bits 15-8. This feature is not supported for subblock 6 because there is no POE6 input. Do not enable the output shutoff enable/disable bits (POEEN60 to POEEN63) for POECRE6.

POECREx is initialized to 0000_H by a reset.

(1) POECRKEY — Write Key Code

This code controls the write permission for bits POEENxy (y = 0 to 3) and POEPOLx. Setting is required to bits 15-8 as well as the data to be written to bits POEENxy (y = 0 to 3) and POEPOLx. Data written to these bits is not retained; Value 00_H is always returned when being read.

(2) POEPOLx — Shutoff Input Active Level Selection

Controls the active level of the shutoff input (POEx). The setting of this bit applies to all channels of the subblock.

(3) POEENxy — Output Shutoff Enable/Disable

Controls disable/enable of the output shutoff feature. This bit can be set for each channel.

21.8.2.8 SOLVLEx — Output Shutoff Level Setting Register Ex

(x = 0, 1, 2, 3, 4, 5, 6: Corresponding to subblocks E0 to E6)

Access: 8-bit access is possible.

Address: FFE6 $210E_H$ + (100_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	PWMSLVx3	PWMSLVx2	PWMSLVx1	PWMSLVx0
Value after reset	0	0	0	0	0	0	0	0

Table 21.104 SOLVLEx Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Not used. These bits are always read as 0. When writing, always write 0.
3	PWMSLVx3	Output Level H/L Selection 0: L level is output to TOEx when output is shutoff. 1: H level is output to TOEx when output is shutoff.
2	PWMSLVx2	
1	PWMSLVx1	
0	PWMSLVx0	

The output shutoff level setting register Ex (SOLVLEx) is an 8-bit readable/writable register. When SOLVLEx is reset, it is initialized to 00_H.

(1) PWMSLVxy — Output Level H/L Selection

This bit specifies the output level of TOExy in the output shutoff state.

21.8.2.9 TSREx — Timer Status Registers E

(x = 0, 1, 2, 3, 4, 5, 6: Corresponding to subblocks E0 to E6, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit access and 16-bit access are possible.

Address: FFE6 2110_H + (100_H * x)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	DMF Ex3	DMF Ex2	DMF Ex1	DMF Ex0	OVF Ex3	OVF Ex2	OVF Ex1	OVF Ex0	CMF Ex3	CMF Ex2	CMF Ex1	CMF Ex0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.105 TSREx Register Contents

Bit Position	Bit Name	Function
15 to 12	—	Not used. These bits are always read as 0. When writing, always write 0.
11 to 8	DMFEx3-DMFEx0	Duty Match Flags Ex3-Ex0 0: No duty match has occurred. 1: A Duty match has occurred.
7 to 4	OVFEx3-OVFEx0	Overflow Flags Ex3-Ex0 0: Counter E has not overflowed 1: Counter E has overflowed
3 to 0	CMFEx3-CMFEx0	Cycle Match Flags Ex3-Ex0 0: Cycle match has not occurred 1: Cycle match has occurred

The timer status register Ex (TSREx) is a 16-bit read-only register. In subblocks E0 to E6, these registers indicate occurrence of compare match (cycle match) of cycle-setting registers Exy (CYLRExy) and timer counters Exy (TCNTExy), compare match (duty match) of duty cycle setting registers Exy (DTRExy) and timer counters Exy (TCNTExy), and overflow of TCNTExy.

The overflow flag is the status flag for indicating the occurrence of overflow. It does not generate interrupts. The cycle match flag and the duty match flag are status flags for requesting interrupts. Interrupts can be issued by setting the corresponding bits of the TIEREx register. Setting the corresponding flags issues interrupt requests. To cancel an interrupt request, clear this flag by the timer status clear register Ex (TSCREx). Setting a bit of the timer status clear register Ex (TSCREx) clears the corresponding flag. Cycle matches of channel 0 can issue transfer requests to DMAC. DMA transfer requests are issued upon cycle matches regardless of the setting of this bit.

When TSREx is reset, it is initialized to 0000_H.

(1) DMFExy — Duty Match Flag Exy

DMFExy	Function
0	[Clearing condition] When 1 is written to the DMFCExy bit of the timer status clear register Ex (TSCREx). (Initial value)
1	[Setting condition] When the counter clock is input in the condition where the timer counter Exy (TCNTExy) value coincides with the duty cycle setting register Exy (DTRExy) value.

This flag cannot be set to 1 or 0 by software. The next duty match can be processed even if DMFExy is 1 (even if the flag is not cleared). 1 is overwritten to these bits.

(2) CMFExy — Cycle Match Flag Exy

CMFExy	Function
0	[Clearing conditions] When 1 is written to the CMFCExy bit of the timer status clear register Ex (TSCREx). (Initial value)
1	[Setting condition] When timer counter Exy (TCNTExy) is incremented while it is the same value as cycle setting register Exy (CYLRExy)

These bits cannot be set to 1 or 0 by software. Even if these bits are 1, meaning that the flag has not been cleared, the next cycle match and DMA transfer request can be input. In this case, 1 is rewritten to these bits.

(3) OVFExy — Overflow Flag Exy

OVFExy	Function
0	[Clearing condition] When 1 is written to the OVFCExy bit of the timer status clear register Ex (TSCREx). (Initial value)
1	[Setting condition] When the 24 higher-order bits of the timer counter Exy (TCNTExy) value changes from FFF FFF_H to 000 000_H

This flag cannot be set to 1 or 0 by software. The next cycle match and DMA transfer can work even if CMFExy is 1 (even if the flag is not cleared). 1 is overwritten to these bits.

These bits are set to 1 when timer counter Exy (TCNTExy) overflows. This flag cannot be set to 1 or 0 by software.

Overflow occurs when the 24 higher-order bits of the timer counter Exy is incremented while it is FFF FFF_H. Writing 000 000_H to the 24 higher-order bits of the timer counter Exy has no effect on these bits.

When writing a value to the 24 higher-order bits of the timer counter and incrementation occur simultaneously while the counter is FFF FFF_H, the overflow flag is set to 1 but the counter value is changed to the written value instead of 000000_H.

No interrupt corresponds to these flags. As to cycle match, since the 24 higher-order bits of the counter is cleared to 000 001_H, overflow will not occur. However, it may occur when the value in the cycle setting register is changed during counter in operation.

When overflow and cycle match occur simultaneously, overflow is not detected (the 24 higher-order bits of the counter is incremented while it is FFF FFF_H and the 24 higher-order bits of CYLRExy is FFF FFF_H). In this case, only the cycle match is handled. If the 24 higher-order bits of the counter value is 000 001_H and the reload function is enabled, cycle reload or duty-cycle reload is performed. The above operation applies for the case when an overflow and a duty match occur simultaneously.

21.8.2.10 TSCREx — Timer Status Clear Register Ex

(x = 0, 1, 2, 3, 4, 5, 6: Corresponding to subblocks E0 to E6, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit access and 16-bit access are possible.
Value 0 cannot be written. The value is not retained when 1 is written. These bits are always read as 0.

Address: FFE6 2112_H + (100_H * x)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	DMFCEx3	DMFCEx2	DMFCEx1	DMFCEx0	OVFCEx3	OVFCEx2	OVFCEx1	OVFCEx0	CMFCEx3	CMFCEx2	CMFCEx1	CMFCEx0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.106 TSCREx Register Contents

Bit Position	Bit Name	Function
15 to 12	—	Not used. These bits are always read as 0. When writing, always write 0.
11 to 8	DMFCExy	Duty Match Flag Clear Enable Exy 0: Disabled (Initial value) 1: Clears DMFExy of timer status register Ex (TSREx) to 0.
7 to 4	OVFCExy	Overflow Flag Clear Enable Exy 0: Disabled (Initial value) 1: Clears OVFExy of timer status register Ex (TSREx) to 0.
3 to 0	CMFCExy	Cycle Match Flag Clear Enable Exy 0: Disabled (Initial value) 1: Clears CMFExy of timer status register Ex (TSREx) to 0.

The timer status clear register Ex (TSCREx) is a 16-bit readable/writable register. This register specifies flag clearing in the events of overflow of timer counters Exy (TCNTExy), cycle match of TCNTExy and cycle-setting registers Exy (CYLRExy), and duty match of TCNTExy and duty cycle setting registers Exy (DTRExy).

TSCREx is readable/writable in 16-bit units. Value 0 is always returned when being read.

When TSCREx is reset, it is initialized to 0000_H.

(1) DMFCExy — Duty Match Flag Clear Enable Exy

This flag specifies flag clearing at the time of duty match of TCNTExy and the duty cycle setting register Exy (DTRExy).

Setting this bit enables clearing of the duty match flag (DMFExy) of the timer status register Ex (TSREx). This bit is always read as 0.

DMFCExy	Function
0	Disabled (Initial value)
1	Clears DMFExy of timer status register Ex (TSREx) to 0.

(2) OVFCExy — Overflow Flag Clear Enable Exy

This bit specifies flag clearing at the time of overflow of the timer counter Exy (TCNTExy).

Setting this bit enables clearing of the overflow flag Exy (OVFExy) of the timer status register Ex (TSREx). This bit is always read as 0.

OVFCExy	Function
0	Disabled (Initial value)
1	Clears OVFExy of timer status register Ex (TSREx) to 0.

(3) CMFCExy — Cycle Match Flag Clear Enable Exy

This flag specifies flag clearing at the time of cycle match of TCNTExy and the cycle-setting register Exy (CYLRExy).

Setting this bit enables clearing of the cycle match flag Exy (CMFExy) of the timer status register Ex (TSREx). This bit is always read as 0.

CMFCExy	Function
0	Disabled (Initial value)
1	Clears CMFExy of timer status register Ex (TSREx) to 0.

21.8.2.11 TIEREx — Timer Interrupt Enable Registers Ex

(x = 0, 1, 2, 3, 4, 5, 6: Correspond to subblocks E0 to E6, y = 0, 1, 2, 3: Corresponding to channels 0 to 3.)

Access: 8-bit access and 16-bit access are possible.

Address: FFE6 2116_H + (100_H * x)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	DME Ex3	DME Ex2	DME Ex1	DME Ex0	—	—	—	—	CME Ex3	CME Ex2	CME Ex1	CME Ex0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 21.107 TIEREx Register Contents

Bit Position	Bit Name	Function
15 to 12	—	Not used. These bits are always read as 0. When writing, always write 0.
11 to 8	DMEEx3-DMEEx0	Duty match interrupt enable Ex3-Ex0 Specifies enable/disable of interrupt requests issued by duty match flags DMFExy.
7 to 4	—	Not used. These bits are always read as 0. When writing, always write 0.
3 to 0	CMEEx3-CMEEx0	Cycle Match Interrupt Enable Ex3-Ex0 Specifies enable/disable of interrupt requests issued by cycle match flags CMFExy.

The timer interrupt enable register Ex (TIEREx) is a 16-bit readable/writable register. This register controls enable/disable of interrupts triggered by compare match (cycle match) of the cycle-setting register Exy (CYLRExy) and TCNTExy and compare match (duty match) of the duty cycle setting register Exy (DTRExy) and TCNTExy.

When TIEREx is reset, it is initialized to 0000_H.

(1) DMEExy — Duty Match Interrupt Enable Exy

This flag specifies enable/disable of interrupt requests triggered by duty match of DTExy.

Setting this bit enables interrupts issued by the duty match flag (DMFExy) of the timer status register Ex (TSREx).

DMEExy	Function
0	Interrupts by DMFExy is disabled. (Initial value)
1	Interrupts by DMFExy is enabled.

(2) CMEExy — Cycle Match Interrupt Enable Exy

This flag specifies enable/disable of interrupt requests triggered by cycle matches of CYLExy.

CMEExy	Function
0	Interrupts by CMFExy is disabled.(Initial value)
1	Interrupts by CMFExy is enabled.

CAUTION

Interrupt requests by cycle match (CMFExy) and duty match (DMFExy) of timer subblock Ex are issued as the logical sum of CMFExy and DMFExy. Whether the interrupt request is triggered by a cycle match or a duty match of the counter can be determined by referencing TSREx. Clear the corresponding interrupt request flag of TSREx when processing the interrupt. The interrupt request will be repeated if the flag is not cleared.

21.8.2.12 TOCREx — Timer Output Control Registers Ex

(x = 0, 1, 2, 3, 4, 5, 6: Corresponding to subblocks E0 to E6, y = 0, 1, 2, 3: Corresponding to channels 0 to 3)

Access: 8-bit access is possible.

Address: FFE6 2114_H + (100_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TONEEx3	TONEEx2	TONEEx1	TONEEx0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 21.108 TOCREx Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Not used. These bits are always read as 0. When writing, always write 0.
3 to 0	TONEExy	TOExy Output Inversion Select Inversion setting of the TOExy output signal (on-state duty/off-state duty selection)

Timer output control registers Ex (TOCRE0 to TOCRE6) are 8-bit readable/writable registers that select whether or not a signal on the output pin TOExy in each subblock Ex is inverted.

When this register is reset, it is initialized to 00_H.

(1) TONEExy — TOExy Output Inversion Select

These bits select whether or not a signal on the PWM output pin (TOE) is inverted.

TONEExy	function	
0	Normal output from the output pin (TOExy)	(Initial value)
1	Inverted output from the output pin (TOExy)	

The output signal is inverted on the first edge of the PCLK after duty modes are switched by the timer output control register. The operating state of the timer counter Exy (TCNTExy) has no effect on the mode switching.

The initial level on the PWM output pin is low (TONEExy = 0).

21.8.2.13 TCNTExy — Timer Counters Exy

(x = 0, 1, 2, 3, 4, 5, 6: Correspond to subblocks E0 to E6. y = 0, 1, 2, 3: Correspond to channels 0 to 3.)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 2124$_H$ + (100$_H$ * x) + (20$_H$ * y)

Value after reset: 0000 0100$_H$

Timer counters Exy (TCNTExy) are 24-bit readable/writable registers allocated in channel y of subblock Ex. When the 8 lower-order bits are read, 0 is always read. When writing to these bits, always write 0. These registers are started by setting the TEE bit in the ATU-IV master enable register (ATUENR), the subblock Ex start bit (STREx) in the timer start register E (TSTRE), and the counter Exy start bit (SSTRExy) in subblock starting register Ex (SSTREx).

The counter clock is selected by the TCNTEx clock select bits (CKSELEx[2:0]) in timer control register x (TCREx), and 2nd prescaler register Ex (PSCREx) of timer E.

The 24 higher-order bits of these counters are initialized to 000 001$_H$ on cycle match with cycle setting register Exy (CYLRExy). For example, when the value of the 24 higher-order bits in the cycle setting register is N and the 24 higher-order bits of the counter value is to be incremented from N to N + 1, the counter value is changed to 1. This enables counting from 1 to N and PWM pulses with the cycle time of N is produced.

The 24 higher-order bits of these counters can count from 000 001$_H$ to FFF FFF$_H$ (when the value of the 24 higher-order bits of the cycle setting register is FFF FFF$_H$).

When writing 000 000$_H$ to the 24 higher-order bits of these counters, a PWM cycle is terminated and a new PWM cycle is started in the next clock cycle. While the 24 higher-order bits of the counter value holds 000 000$_H$, the PWM output retains the previous value and outputs a level of 1 at the beginning of the new cycle. When the PWM cycle is terminated before duty cycle match, the duty cycle for that PWM cycle is 100% (1 is always output), that is, a level of 0 will not be output between PWM cycles. For details on writing 000 000$_H$ to the 24 higher-order bits of these counters, see **Figure 21.56** and **Figure 21.57**.

When TCNTExy or CYLRExy is rewritten during the counter in operation, a cycle match may not occur even if the value of the 24 higher-order bits of the counter reaches FFF FFF$_H$. In this case, the 24 higher-order bits of the counter value is changed from FFF FFF$_H$ to 000000$_H$ in the next counter clock cycle. A PWM cycle is terminated in a way similar to writing 0000$_H$. The 24 higher-order bits of the counter value is incremented to 000 001$_H$ and a new PWM cycle is started.

When the reload function is enabled, reloading of the cycle or duty cycle is also performed.

When the 24 higher-order bits of TCNTExy is reset, it is initialized to 000 001$_H$.

21.8.2.14 CYLRExy — Cycle-Setting Registers Exy

(x = 0, 1, 2, 3, 4, 5, 6: Correspond to subblocks E0 to E6. y = 0, 1, 2, 3: Correspond to channels 0 to 3.)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 2128$_H$ + (100$_H$ * x) + (20$_H$ * y)

Value after reset: FFFF FF00$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CYLRExy															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

CYLRExy are 24-bit readable/writable registers that store the cycle of PWM. The settable value of the 24 higher-order bits ranges from 000 001$_H$ to FFF FFF$_H$.

When the 8 lower-order bits are read, 0 is always read. When writing to these bits, always write 0.

The value in CYLREnm is constantly compared with the value in the timer counter Exy (TCNTExy). When they match, the 24 higher-order bits of TCNTExy is cleared to 000 001$_H$. When the RLDENxy bit in the reload control register Ex (RLDCREx) is set to 1, the values in the cycle reload register Exy (CRLDExy) and duty cycle reload register Exy (DRLDExy) are transferred to cycle-setting register Exy (CYLRExy) and duty cycle setting register Exy (DTRExy). Writing 000 000$_H$ to the 24 higher-order bits of TCNTExy can forcibly end PWM cycle and start the same reloading as above at the next clock cycle.

Interrupt request to CPU and transfer request to DMAC (only channel 0) can be made by a compare match (cycle match) of the cycle-setting register. Do not make, however, an interrupt request and a transfer request to DMAC simultaneously.

To rewrite to CYLRExy during TCNTExy in operation, note that the value to be set may lead to malfunction. When TCNTExy in operation is rewritten, a cycle match between TCNTExy and DTRExy may not be detected and TCNTExy continues to be incremented even if the counter value exceeds the value in CYLRExy. In this case, unwanted PWM waveforms are output.

When the 24 higher-order bits of CYLRExy is reset, it is initialized to FFF FFF$_H$.

21.8.2.15 DTRExy — Duty Cycle Setting Registers Exy

(x = 0, 1, 2, 3, 4, 5, 6: Correspond to subblocks E0 to E6. y = 0, 1, 2, 3: Correspond to channels 0 to 3.)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 212C$_H$ + (100$_H$ * x) + (20$_H$ * y)

Value after reset: FFFF FF00$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DTREXy															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DTREXy								—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

DTREXy are 24-bit readable/writable registers that store the duty cycle of PWM. The settable value of the 24 higher-order bits ranges from 000 000$_H$ to FFF FFF$_H$.

When the 8 lower-order bits are read, 0 is always read. When writing to these bits, always write 0.

The value in DTREXy is constantly compared with the value in timer counter Exy (TCNTExy). When they match, the output level on the pin for the corresponding channel becomes 0. When the values in CYLREXy and TCNTExy match while the RLDENxy bit is set to 1, the value in DRLDExy is reloaded to DTREXy. Writing 000 000$_H$ to the 24 higher-order bits of TCNTExy can forcibly end PWM cycle and start the same reloading as above at the next clock cycle.

Interrupt requests to CPU can be issued by compare match (duty matches) of the duty cycle setting register.

The settable value of the 24 higher-order bits in DTREXy ranges from 0 to the value in CYLREXy. When 0 is set, the duty cycle is 0% and the same value as CYLREXy is set, the duty cycle is 100%. DTREXy must be set to the value less than CYLREXy.

To rewrite to DTREXy during TCNTExy in operation, note that the value to be set may lead to malfunction. When TCNTExy in operation is rewritten, a duty cycle match may not be detected. In this case, unwanted PWM waveforms may be output.

When the 24 higher-order bits of DTREXy is reset, it is initialized to FFF FFF$_H$.

21.8.2.16 CRLDExy — Cycle Reload Registers Exy

(x = 0, 1, 2, 3, 4, 5, 6: Correspond to subblocks E0 to E6. y = 0, 1, 2, 3: Correspond to channels 0 to 3.)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 2130_H + (100_H * x) + (20_H * y)

Value after reset: FFFF $FF00_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CRLDExy

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Cycle reload registers Exy (CRLDExy) are 24-bit readable/writable register, and the 24 higher-order bits in this register can be set to 000 001_H to FFF FFF_H as the cycle of PWM outputs.

When the 8 lower-order bits are read, 0 is always read. When writing to these bits, always write 0.

When the reload function is enabled, the value in this register is transferred to the cycle-setting register Exy (CYLRExy) on cycle match.

Writing 000 000_H to the 24 higher-order bits of TCNTExy can forcibly end PWM cycle and start the same reloading as above at the next clock cycle.

When the 24 higher-order bits of CRLDExy is reset, it is initialized to FFF FFF_H.

21.8.2.17 DRLDExy — Duty Cycle Reload Registers Exy

(x = 0, 1, 2, 3, 4, 5, 6: Correspond to subblocks E0 to E6. y = 0, 1, 2, 3: Correspond to channels 0 to 3.)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 2134$_H$ (100$_H$ * x) + (20$_H$ * y)

Value after reset: FFFF FF00$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DRLDExy

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Duty cycle reload registers Exy (DRLDExy) are a 24-bit readable/writable register, and the 24 high-order bits in this register can be set to 000 000$_H$ to FFF FFF$_H$ as the duty cycle.

When the 8 lower-order bits are read, 0 is always read. When writing to these bits, always write 0.

When the reload function is enabled, the value in this register is transferred to the duty cycle-setting register Exy (DTRExy) on cycle match.

Writing 000 000$_H$ to the 24 higher-order bits of TCNTExy can forcibly end PWM cycle and start the same reloading as above at the next clock cycle.

When the 24 higher-order bits of DRLDExy is reset, it is initialized to FFF FFF$_H$.

21.8.3 Operation Description

Timer E consists of 24-bit timer counter Exy (TCNTExy), 24-bit cycle-setting register Exy (CYLRExy), 24-bit duty cycle setting register Exy (DTRExy), 24-bit cycle reload register Exy (CRLDExy), and 24-bit duty cycle reload register Exy (DRLDExy). Timer E can be used as a PWM timer.

TCNTExy starts counting up when a channel is selected by subblock starting register Ex (SSTREx) after a subblock is selected by timer start register E (TSTRE). A logical zero level is output on pin TOExy on the first edge of the counter clock after TCNTExy matches duty cycle setting register Exy (DTRExy), or a logical one level is output on pin TOExy on the first edge the counter clock after TCNTExy matches cycle setting register Exy (CYLRExy). After a match with the cycle setting register, the 24 higher-order bits of the counter is set to $000\ 001_H$ on the next counter clock edge and starts counting up again.

Subsequently duty-cycle and cycle match are repeated, producing a PWM output on pin TOExy.

However, externally output level retains an initial value of 0 for one cycle which is from starting up the counter to the first cycle match.

The settable PWM cycle ranges from $000\ 001_H$ to $FFF\ FFF_H$. The settable duty cycle ranges from 0% to 100%. When the duty cycle setting register is set to $000\ 000_H$, the output level is 0 and remains unchanged (duty cycle = 0%). When the values in duty cycle setting register and cycle setting register are the same, the output level is 1 and remains unchanged (duty cycle = 100%). The value in duty cycle setting register must be equal to or less than the value in cycle setting register.

An interrupt request can be generated per cycle by a compare match (cycle match) of the cycle register. The cycle match of channel 0 can be used as a DMA transfer request. As shown in **Figure 21.55**, a DMA transfer request becomes 1 PCLK pulse output.

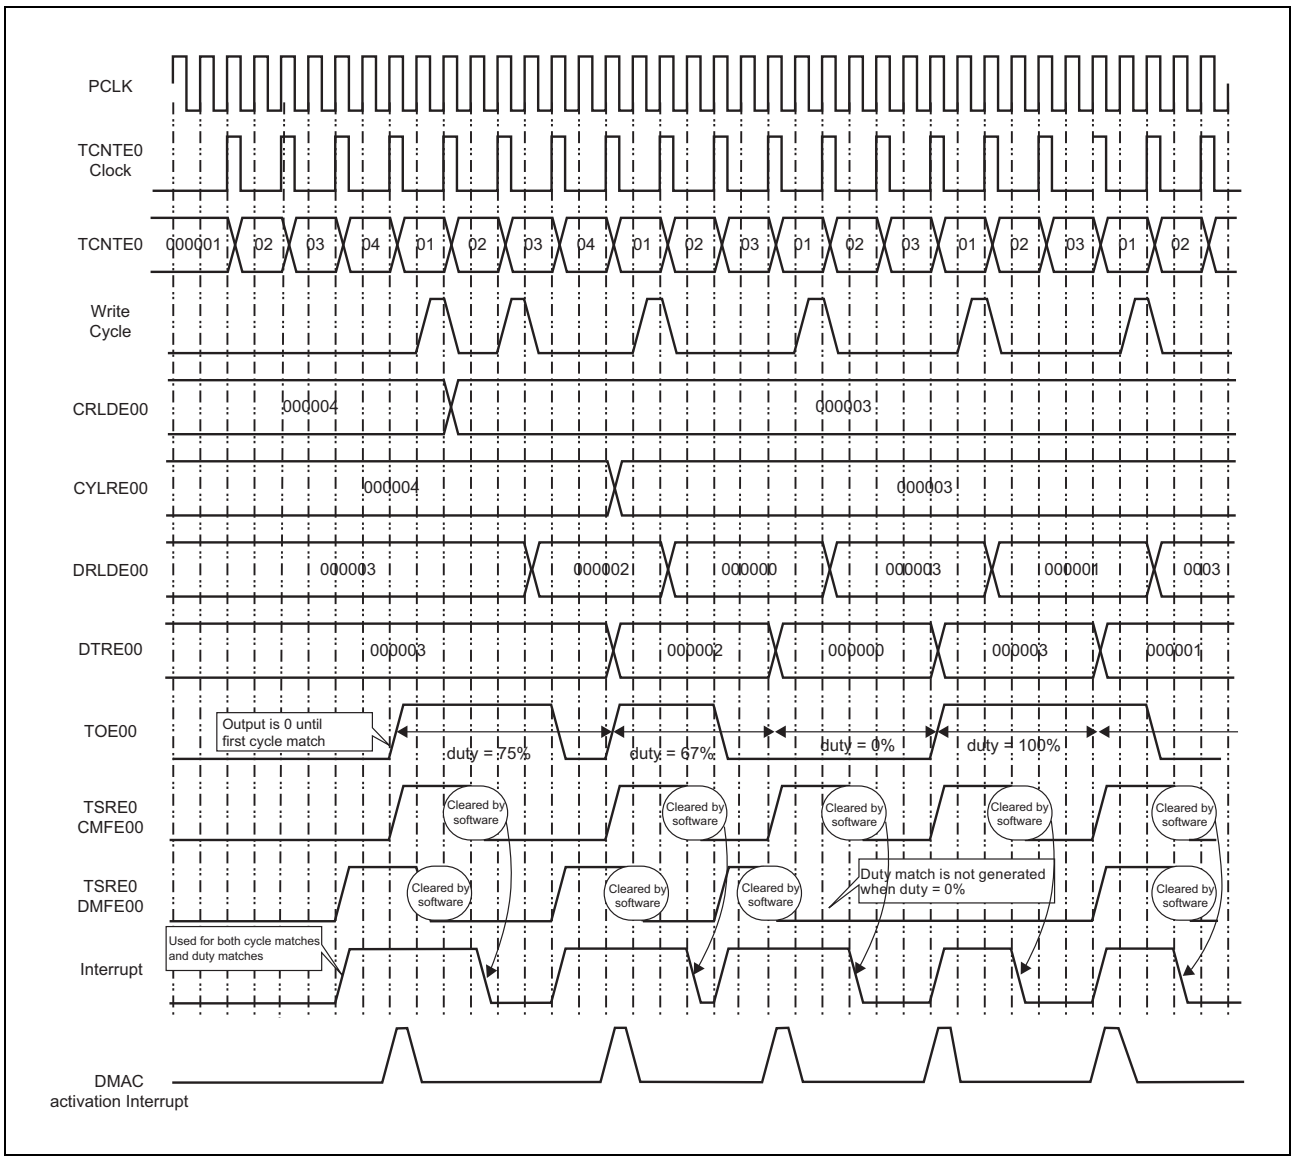

Figure 21.55 Operation of PWM (1)

The duty cycle setting and cycle setting registers have respective reload registers. When the values in the up-counter and cycle-setting register match, the values in the duty cycle reload and cycle reload registers are loaded to the duty cycle setting and cycle setting registers. The loaded data is updated in the next PWM cycle after loading. The reload function is enabled and disabled by the reload enable bit Exy (RLDENExy) in the reload control register Ex (RLDCREx).

In timer E, a PWM output cycle is terminated by writing $000\ 000_H$ to the 24 higher-order bits of the timer counter Exy (TCNTExy). The value of the 24 higher-order bits of the counter is changed from $000\ 000_H$ to $000\ 001_H$ on the next counter clock and the counter is restarted. When the 24 higher-order bits of the counter value is changed, the values in the duty cycle reload and cycle reload registers are loaded to the duty cycle setting and cycle setting registers.

Figure 21.55 illustrates the operation of the PWM timer of channel 0, block E0.

The figure illustrates an operation in which the duty is changed from 75% to 67%, 0%, and to 100% in every cycle.

Figure 21.56 shows the PWM output cycle terminated by writing 000 000_H to the 24 higher-order bits of the counter and the counter restarted.

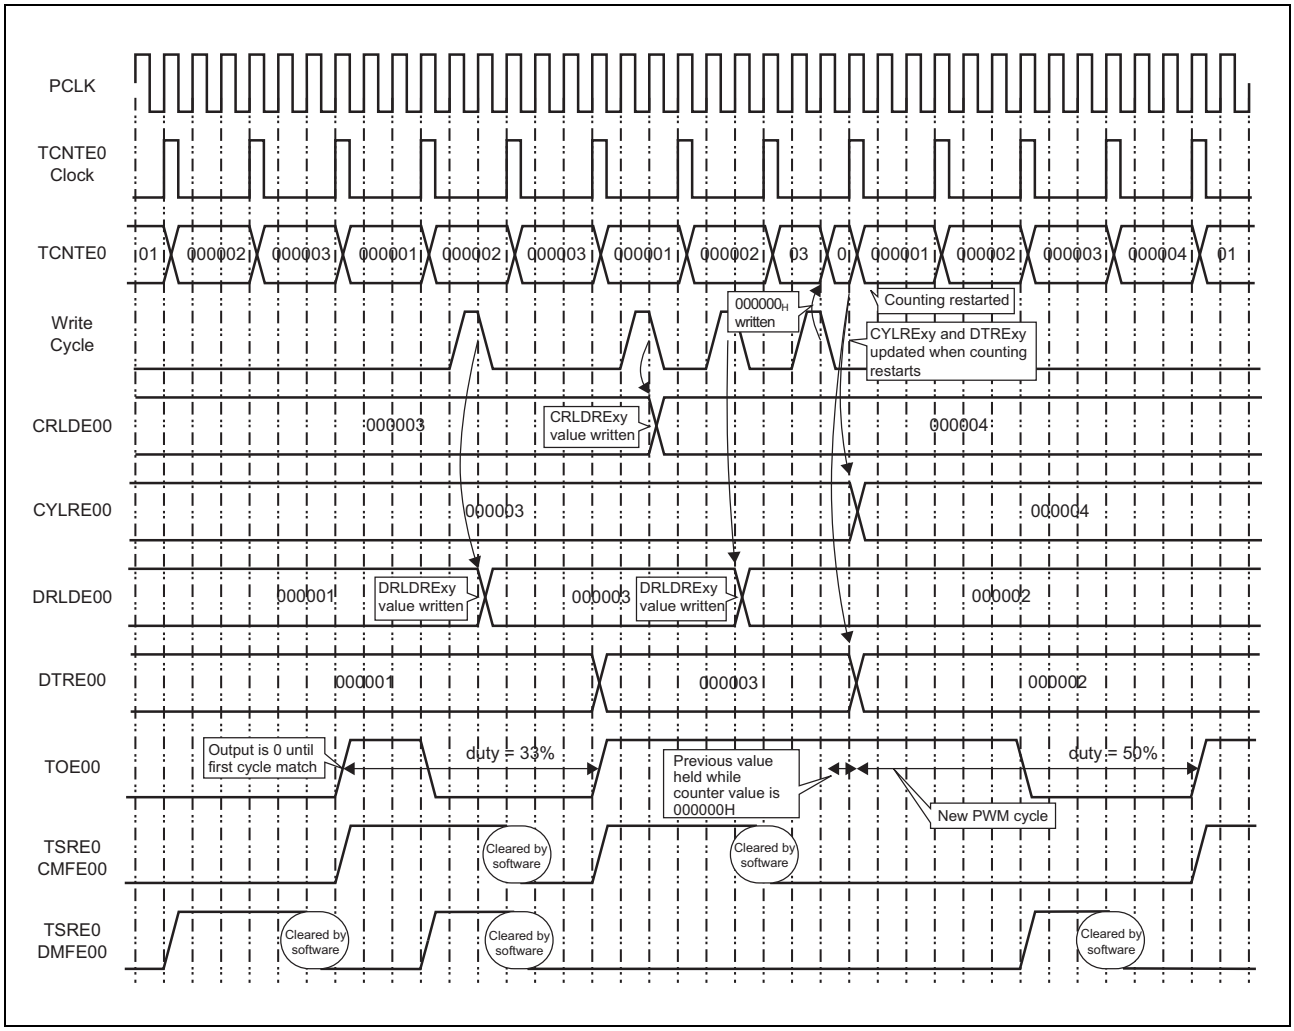

Figure 21.56 Operation of PWM (2)

Writing 000 000_H to the 24 higher-order bits of the counter changes the 24 higher-order bits values of the counter to 000 000_H. The output waveform (TOE00) does not change. If the reload feature is enabled, an input of counter clock after writing 000 000_H to the 24 higher-order bits transfers the values of the cycle reload register and the duty reload register to the cycle-setting register and the duty cycle setting register. At the same time, counting starts and PWM output also starts.

A waveform is output in off-state duty (active-low output) mode by selecting the off-state duty mode in timer output control register Ex (TOCREx). The output waveform on pin TOExy is inverted on the next PCLK cycle after setting.

Figure 21.57 shows an example of a waveform when switching on- and off-state duty modes. By selecting the off-state duty mode before the counter is started, the initial output level on the PWM output pin TOE00 is 1. After the counter started until the first cycle match, the level on pin TOE00 retains 1. On the following cycle match and duty cycle match, the output levels are alternated.

When the PWM cycle is forcibly terminated by writing 000 000_H to the 24 higher-order bits of the counter, TOE00 retains the previous value. At the timing in which the 24 higher-order bits of the counter is incremented to 000 001_H, a new PWM cycle is started.

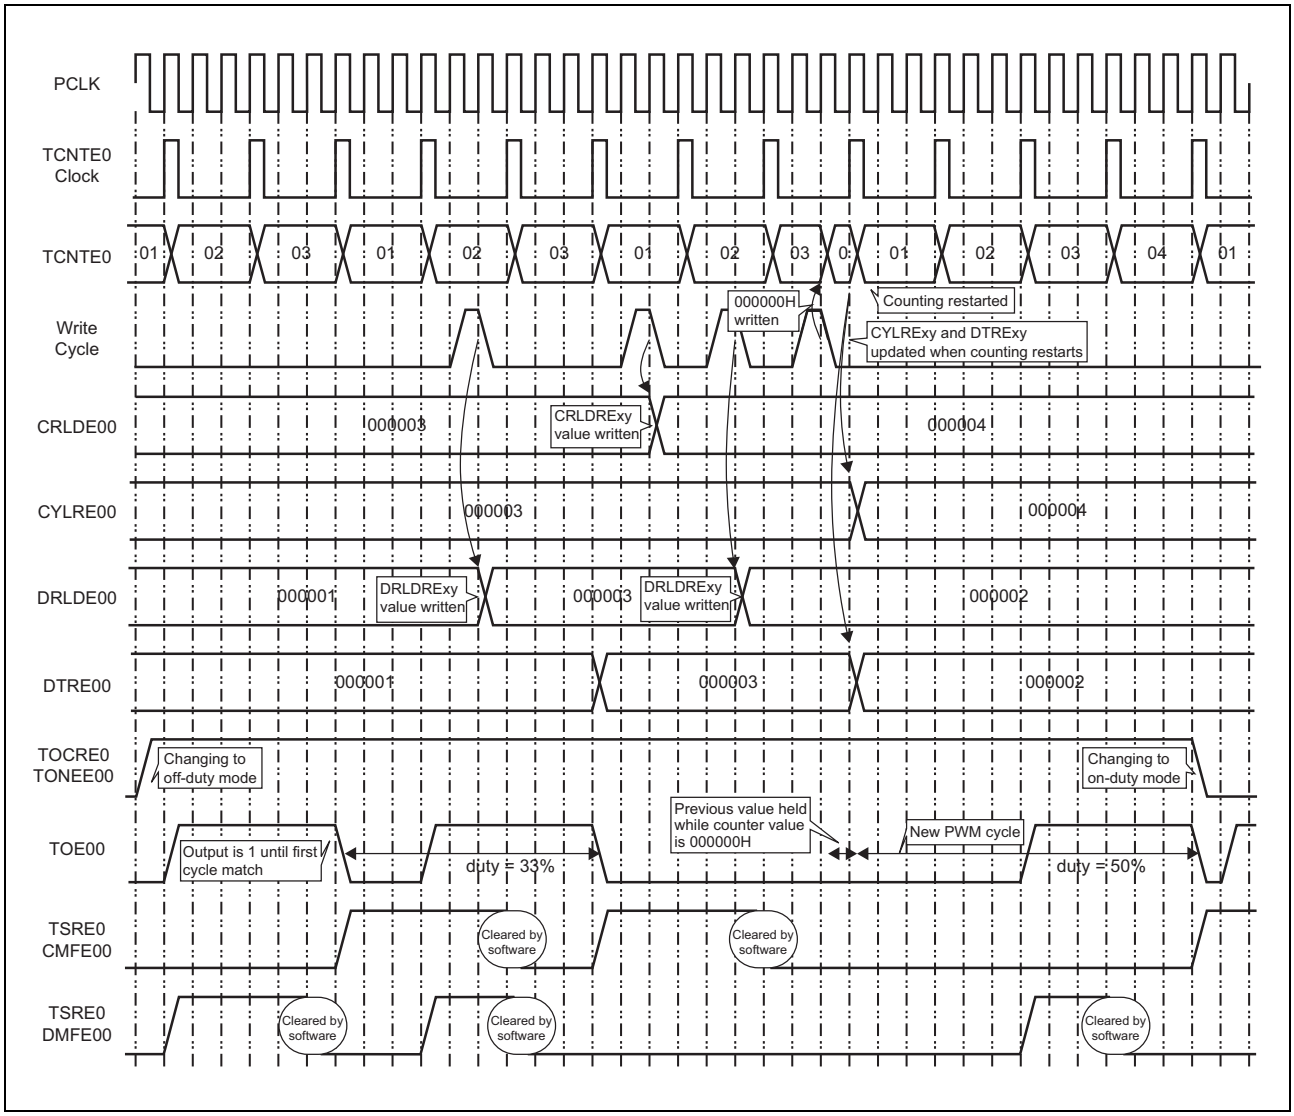

Figure 21.57 Operation of PWM (3)

Figure 21.58 illustrates the output waveform when PWM output is shutoff. PWM output is shutoff if the output shutoff enable/disable selection bit (POEENxy) of the output-shutoff control register Ex (POECREx) is enabled and shutoff input (POEx) is enabled during a duty period (between a cycle match in the previous PWM cycle to a duty match). POEx being enabled during non-duty period does not trigger a shutoff. During an output shutoff period, the signal is output to TOExy at the level specified by the output level H/L selection bit (PWMSLVxy) of the output shutoff setting register Ex (SOLVLEx). This output level is not affected by the inversion setting (on-state/off-state duty) of the corresponding bit of the timer output control register Ex (TOCREx).

The state of output shutoff is released if POEx is disabled at the time of a cycle match. The state of PWM output being shutoff continues to the next cycle match if POEx is in the enabled state at the above-mentioned timing.

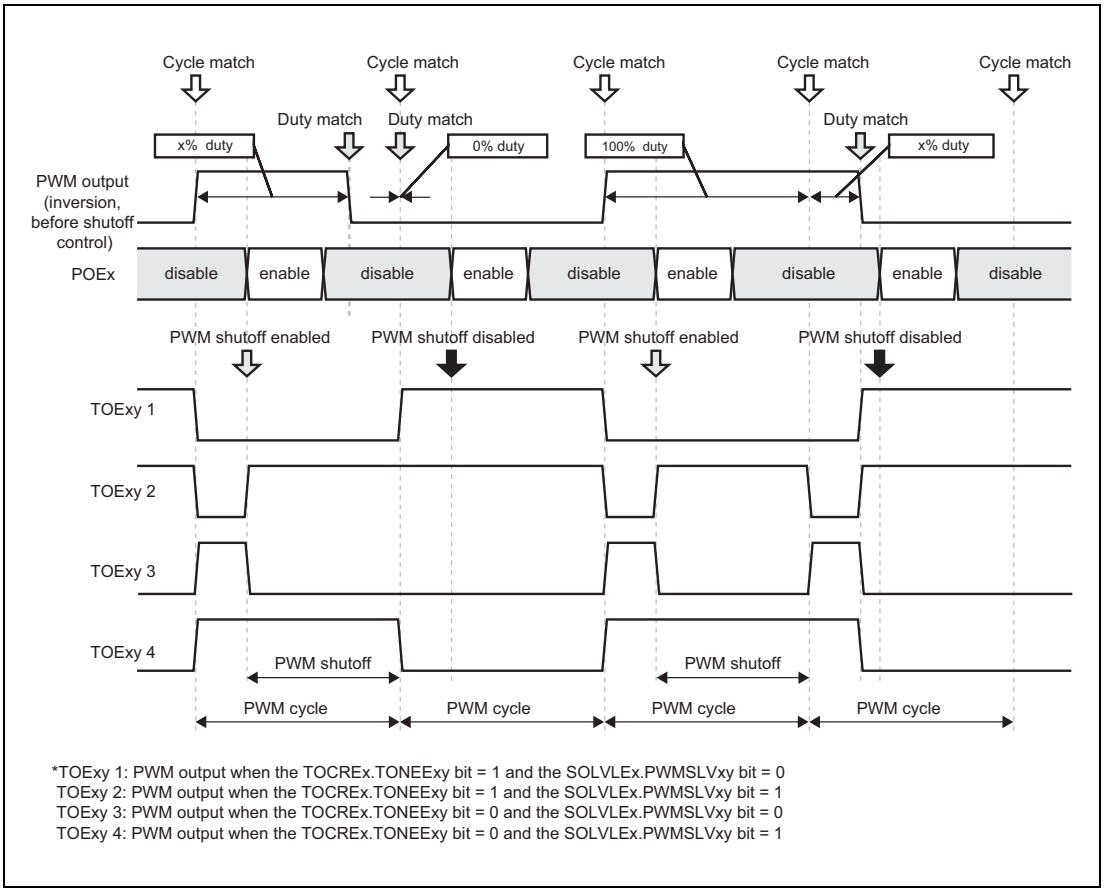

Figure 21.58 Example of PWM Output shutoff

21.9 Timer F

21.9.1 Operation Overview

The timer F block consists of 16 timer F subblocks.

Timer F subblocks realize the following features:

- Edge counting in a specified period:
  Counts the number of edges input to the external input pin (TIFxA or TIFx)
- Effective edge interval counting:
  Measures time until a specified number of edges is input to the external pin (TIFxA or TIFx).
- Measurement of time during high/low input levels:
  Measures a total amount of time when a high or low level is input to the external input pin (TIFxA or TIFx). The duration of measurement is designated as the number of pulses input to the external pin.
- Measurement of PWM input waveform timing:
  Measures the off-duty period and cycle time of the PWM waveform input to the external pin (TIFxA or TIFx). The duration of measurement is designated as the number of PWM cycles input to the external pin.
- Rotation speed/pulse measurement (for the subblock 3 to 15 only):
  Every time an edge is input to the external pin (TIFx), the following values are retained edge count, time stamp at edge input, edge input interval (cycle), and high/low input level immediately before input.
- Up/down event count (for the subblock 0 to 2 only):
  TIFnA of the two external pins (TIFxA, TIFxB) is used to count as the count source. TIFnB switches between up-counting and down-counting.
- Four-time multiplication event count (for the subblock 0 to 2 only):
  Counting operation is executed using two external input pins (TIFxA, TIFxB) as the count sources. Signals in the pins switch between up-counting and down-counting.

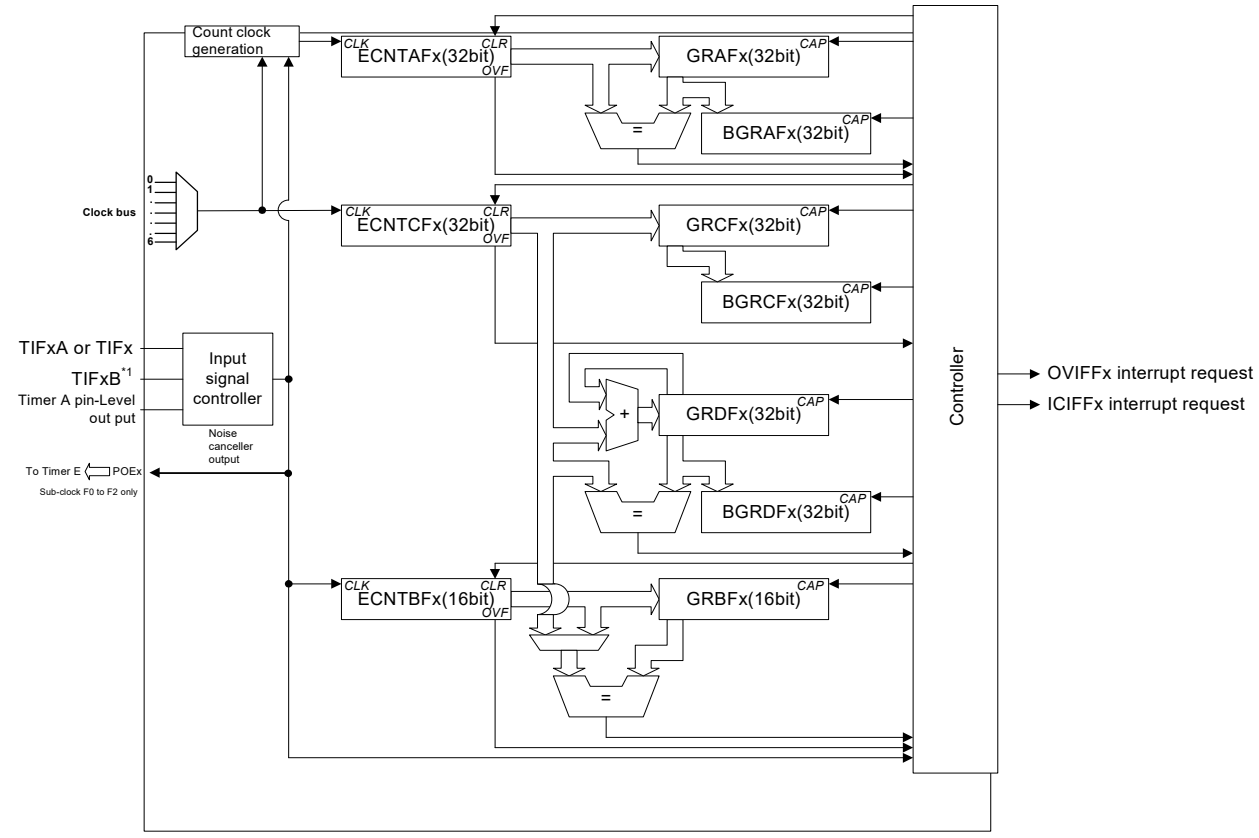
Input signals from the external input pins TIFxA or TIFx and TIFxB can be subject to the noise cancellation function using the input cancellation function. Noise-canceled signals from TIA00 to TIA06 of timer A can be used instead of external signal input pin TIFxA or TIFx.

Inputs of TIF0A to TIF2A and TIF0B and TIF2B can also be used as inputs (shutoff inputs) for POE0 to POE5 of timer E. For the correspondence between TIFxA/B and POEx, see **Table 21.96** of timer E.

Note that, if any of TIF0A to TIF2A and TIF0B to TIF2B is used as a shutoff input of timer E, the shutoff input becomes the measurement target of the corresponding timer F subblock.

Configuration

Figure 21.59 is a block diagram of timer F. Subblocks 0 to 2 of timer F have two external inputs (TIFxA and TIFxB) and the other subblocks have one external input (TIFx), two 32-bit counters (ECNTAFx and ECNTCFx), three 32-bit generic registers (GRAFx, GRCFx, and GRDFx), three 32-bit backup registers (BGRAFx, BGRCFx, and BGRDFx), a 16-bit up/down counter (ENCTBFx), a 16-bit generic register (GRBFx), an input processor (edge detection and noise canceler), and a controller.



Note 1. TIFxB is for subblocks 0 to 2 only.

Figure 21.59 Block Diagram of Subblocks of Timer F

NOTE

For the correspondence between TIFxA/B and POEx, see **Table 21.96** of timer E.

Interrupt request

The timer F can output two types of interrupts totaling 32 interrupts.

- OVFFx interrupt requests (16 interrupts ($0 \leq x \leq 15$)): An interrupt is output when one of the three counters (ECNTAFx, ECNTBFx, ECNTCFx) in the subblock Fx has overflown or underflown (only in ECNTBFx). They can also be used as compare match interrupts in PWM input waveform measurement mode and “rotation speed/pulse measurement” mode. To which counter the interrupt belongs can be known by referring to the timer status register F (ISRF). This request is received by the INTC block and the designated processing is performed.
- ICFFx interrupt requests (16 interrupts ($0 \leq x \leq 15$)): The interrupt is output when a count value capturing in the timer subblock Fx occurs. This request is received by the DMAC block or INTC. DMA transfer by DMAC enables to transfer captured data obtained by using compare match as a trigger to the on-chip RAM or perform designated processing by interrupt request. For details on DMA transfer by DMAC, see **Section 7, DMA**.

21.9.2 Registers Related to Timer F

21.9.2.1 TSTRF — Timer Start Register F

Access: 8-bit access, 16-bit access is possible.

Address: FFE6 3000_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	STRF 15	STRF 14	STRF 13	STRF 12	STRF 11	STRF 10	STRF 9	STRF 8	STRF 7	STRF 6	STRF 5	STRF 4	STRF 3	STRF 2	STRF 1	STRF 0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.109 TSTRF Register Contents

Bit Position	Bit Name	Function
15 to 0	STRF15 to STRF0	Timer F start 0: Stops counting of ECNTAFx, ECNTBFx, and ECNTCFx. 1: Permits counting of ECNTAFx, ECNTBFx, and ECNTCFx.

Note: x is an integer from 0 to 15.

TSTRF is a 16-bit readable/writable register that specifies whether to operate or stop each subblock (timer F0 to F15) in the timer F. Count operation is not executed unless TFE bit in ATUIV master enable register (ATUENR) is enabled even if the start bit in timer F is set to enable the count operation.

When TSTRF is reset, it is initialized to 0000_H.

(1) STRFx — Counter F Start

These bits specify whether to operate or stop two time counters (ECNTAFx, ECNTCFx) in subblocks (F0 to F15) of timer F and event counter Fx (ECNTBFx). When this bit is cleared to 0, ECNTAFx, ECNTBFx, and ECNTCFx stop operation. Counter value is retained at stop state. When this bit is set to 1 once again, the operation starts at the retained value.

Count operation is not executed unless TFE bit in ATU-IV master enable register (ATUENR) is enabled even if the start bit in timer F is set enable the count operation.

CAUTION

The prescaler is operating regardless of the setting of the counter F start bit, and not initialized at the start of counter. Therefore, during the time between the activation and the start of actual count operation by the above counter, hardware-related uncertainty shorter than the period of selected count source (resolution) accompanies

21.9.2.2 NCMCR1F — Noise Cancellation Mode Channel Register 1F

Access: 8-bit access and 16-bit access are possible.

Address: FFE6 3004_H

Value after reset: 0000_H

Table 21.110 NCMCR1F Register Contents

Bit Position	Bit Name	Function
15 to 0	NCM1F 15 to NCM1F 0	Noise Cancel Mode Specifies the operation mode of the noise canceler of channel x. 0: Premature-transition cancellation mode 1: Minimum time-at-level cancellation mode (when NCMF = 0 and NCM2Fx = 0) Level accumulation cancellation mode (when NCMF = 0 and NCM2Fx = 1)

Note: x stands for the subblock number (channel number) of 0 to 15.

NCMCR1F is a 16-bit readable/writable register that selects the mode of operation of the noise canceller for each channel unit.

In the premature-transition cancellation mode, after a change in the level of the input signal has been detected, further changes in the level of the input signal that occur within a specified period are ignored. That is, changes with a specified period after each initial level change are regarded as noise in this mode.

In minimum time-at-level cancellation mode, the first and subsequent level changes are ignored unless the input signal level remains the same over a given period. Level changes occurring within a shorter period are considered to indicate an unstable signal, and such signals are treated as noise.

In level accumulation cancellation mode, input signal levels are accumulated until it reaches 0 or the specified value, at which time the input level is considered to have reached to 0 or 1. The period is set by noise canceler registers in each of the applicable blocks and is counted by a noise canceler counter.

Figure 21.1 illustrates the premature-transition cancellation mode, and **Figure 21.3** illustrates overview of the noise cancellation operation (TIA00 input of timer A) in level accumulation cancellation mode. Each channel detects edges in signals that have been processed by the noise canceler. **Figure 21.1** and **Figure 21.3** illustrate the cases when rising edges are detected in signals processed by the noise canceler.

(1) NCM1Fx — Channel n noise cancellation mode

Specify the operation mode of noise canceller in channel x.

CAUTION

This register is effective only when the NCMF bit of the noise cancel mode register (NCMR) of the common controller is set to 0. The channel mode when the corresponding bit (NCM1Fx) of this register is set to 1 can be set to minimum time-at-level cancellation mode or level accumulation cancellation mode depending on the setting of the corresponding bit of the noise cancel mode channel register 2F (NCMCR2F). Note: x is from 0 to 15.

Table 21.111 Noise Cancel Mode Correspondence of Timer F

Channel Enable	Filter Mode		Channel Register			
NCCRF. NCEFx	NCMR. NCMF	NCMR. NCMSEL	NCMCR1F. NCM1Fx	NCMCR2F. NCM2Fx	Operation Mode	Filter Unit
0	—	—	—	—	Filter disabled	—
1	0	(—)	0	(—)	Premature-transition	Each subblock/ channel
1	0	(—)	1	0	Minimum time-at-level	Each channel
1	0	(—)	1	1	Level accumulation	Each channel
1	1	(0)	—	—	Minimum time-at-level	Each subblock
1	1	1	—	—	Level accumulation	Each subblock

Note 1. x is from 0 to 15.

Note 2. A noise canceller enable bit Fx (NCEFx) can be set for each channel.

Setting when timer F filtering is made for each channel (Prerequisites: channel enable = 1)

- Each channel setting: When the noise cancel mode bit (NCMF) of the noise cancel mode register (NCMR) is set to 0 and any one of the noise cancel mode setting bits (NCM1Fx) of the noise cancel mode channel register 1F (NCMCR1F) of timer F is set to 1.
- All channel setting: Same as the above description except that the noise cancel mode bit of the noise cancel mode register is set to 1. Or, in the above description, all noise cancel mode setting bits (NCM1Fx) of the noise cancel mode channel register 1F (NCMCR1F) are set to 0.

21.9.2.3 NCMCR2F — Noise Cancellation Mode Channel Register 2F

Access: 8-bit access, and 16-bit access are possible.

Address: FFE6 3008_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 21.112 NCMCR2F Register Contents

Bit Position	Bit Name	Function
15 to 0	NCM2F15 to NCM2F0	Noise Cancel Mode Specifies the operation mode of the noise canceler of channel x. 0: Minimum time-at-level cancellation mode (when NCMF = 0 and NCM1Fx = 1) 1: Level accumulation cancellation mode (when NCMF = 0 and NCM1Fx = 1)

Note: x stands for the subblock number (channel number) of 0 to 15.

Noise cancel mode channel register 2F is a 16-bit readable/writable register, which selects the operation mode of the noise canceler for each channel. In level accumulation cancellation mode, input signal levels are accumulated until it reaches 0 or the specified value, at which time the input level is considered to have reached to 0 or 1.

Intervals are specified by the noise cancel register of each channel, and the time is measured by the noise cancel counter.

Figure 21.1 illustrates the premature-transition cancellation mode, and **Figure 21.3** illustrates overview of the noise cancellation operation (TIA00 input of timer A) in level accumulation cancellation mode. Each channel detects edges in signals that have been processed by the noise canceler. **Figure 21.1** and **Figure 21.3** illustrate the cases when rising edges are detected in signals processed by the noise canceler.

(1) NCM2Fx — Channel n noise cancellation mode

Specify the operation mode of noise canceller in channel x.

CAUTION

This register is effective only when the NCMF bit of the noise cancel mode register (NCMR) of the common controller is set to 0. The channel mode when the corresponding bit (NCM1Fx) of this register is set to 1 can be set to the minimum time-at-level cancellation mode or the level accumulation cancellation mode depending on the setting of the corresponding bit of the noise cancel mode channel register 2F (NCMCR2F). Note: x is from 0 to 15.

The following table indicates the true/false conditions of the noise cancel mode.

Table 21.113 Noise Cancel Mode Correspondence of Timer F

Channel Enable	Filter Mode		Channel Register			
NCCRF. NCEFx	NCMR. NCMF	NCMR. NCMSEL	NCMCR1F. NCM1Fx	NCMCR2F. NCM2Fx	Operation Mode	Filter Unit
0	—	—	—	—	Filter disabled	—
1	0	(—)	0	(—)	Premature-transition	All channels/Each channel
1	0	(—)	1	0	Minimum time-at-level	Each channel
1	0	(—)	1	1	Level accumulation	Each channel
1	1	(0)	—	—	Minimum time-at-level	All channels
1	1	1	—	—	Level accumulation	All channels

Note 1. x is from 0 to 15.

Note 2. A noise canceler enable bit Fx(NCEFx) can be set for each channel.

Setting when timer F filtering is made for each channel (Prerequisites: channel enable = 1)

- Each channel setting: When the noise cancel mode bit (NCMF) of the noise cancel mode register (NCMR) is set to 0 and any one of the noise cancel mode setting bits (NCM1Fx) of the noise cancel mode channel register 1F (NCMCR1F) of timer F is set to 1.
- All channel setting: Same as the above description except that the noise cancel mode bit of the noise cancel mode register is set to 1. Or, in the above description, all noise cancel mode setting bits (NCM1Fx) of the noise cancel mode channel register 1F (NCMCR1F) are set to 0.

21.9.2.4 NCCRF — Noise Canceller Control Register F

Access: 8-bit access and 16-bit access are possible.

Address: FFE6 300C$_H$

Value after reset: 0000$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NCEF 15	NCEF 14	NCEF 13	NCEF 12	NCEF 11	NCEF 10	NCEF 9	NCEF 8	NCEF 7	NCEF 6	NCEF 5	NCEF 4	NCEF 3	NCEF 2	NCEF 1	NCEF 0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.114 NCCRF Register Contents

Bit Position	Bit Name	Function
15 to 0	NCEFx	Noise Canceler Enable Fx (NCEFx) 0: The noise cancel feature of TIFxA or TIFx and TIFxB is disabled. 1: The noise cancel feature of TIFxA or TIFx and TIFxB is enabled.

Note: x is an integer from 0 to 15.

The noise canceler control register F (NCCRF) is a 16-bit readable/writable register that specifies enable/disable of the noise canceler feature of each subblock (timer F0 to timer F15) of timer F.

When NCCRF is reset, it is initialized to 0000$_H$.

(1) NCEFx — Noise Canceller Enable Fx

Specify to enable/disable the noise canceller in each subblock. Regarding the subblocks 2 to 0, each subblock has noise cancellers TIFxA and TIFxB but enabling/disabling these cancellers cannot be specified independently. Setting the NCEFx bit to 1 enables each noise canceller in TIFxA and TIFxB.

If the noise cancel feature is enabled, upon detection of a level change of the input signal of external input TIFxA, TIFx, or TIFxB, the settings in the noise cancel mode register (NCMR) of common controller, noise cancel mode channel register 1F (NCMCR1F) of timer F, and nose cancel mode channel register 2F (NCMCR2F) of timer F start operation by selecting an operation mode from premature-transition cancellation mode, minimum time-at-level cancellation mode, and level accumulation cancellation mode.

In premature-transition cancellation mode, when the input signal level change is detected, the change is output as the signal that has passed through noise canceling.

Simultaneously, corresponding noise canceler counters FAx, FBx(NCNTFA15 to NCNTFA0 and NCNTFB2 to NCNTFB0) start up-counting. The input signal level change is masked until a compare match occurs between the value in the noise canceler counter and the values in the noise cancel register (NCRFA15 to NCRFA0 and NCRFB2 to NCRFB0). When a compare match occurs, the input signal level at this moment is output as the signal after noise canceling.

When these bits are cleared to 0 while NCNTFAx and NCNTFBx are in count operation, the count operation continues until a compare match occurs and the level change of the corresponding external input (TIFxA or TIFx and TIFxB) is kept being masked.

In minimum time-at-level cancellation mode, when the level change of the input signal is detected, the corresponding noise canceler counter FAx, FBx (NCNTFA15 to NCNTFA 0 and NCNTFB2 to NCNTFB0) starts up-counting. If a level change of input signal is not detected during the period until a compare match occurs between the value in the noise canceler counter and the values in the noise cancel register (NCRFA15 to NCRFA0 and NCRFB2 to NCRFB0), the level change at the compare match is output as the signal after a noise cancellation. If a noise change is detected, this change is regarded as noise and the noise canceller does not change the signal after a noise cancel regarding that no level change of input signal occurred.

When these bits are cleared to 0 while NCNTFAx and NCNTFBx are in count operation, the count operation continues to keep noise canceling processing until a compare match or input signal change occurs.

In level accumulation cancellation mode, the input signal level determines the up/down counting of the corresponding noise cancel counters FAx, FBx (NCNTFA0 to NCNTFA15 and NCNTFB0 to NCNTFB2). Up-counting is made with high-level input, down-counting is made with low-level inputs. Up-count continues until a compare match between the noise cancel counter and the noise cancel registers (NCRFA0 to NCRFA15 and NCRFB0 to NCRFB2), and down-count continues until the noise cancel counter matches $*0000_H$. If an up-counting results in a compare match (NCRFA0 to NCRFA15 and NCRFB0 to NCRFB2), the noise canceler output is updated to 1. If a down-counting results in a compare match (0000_H), the noise canceler output is updated to 0.

In minimum time-at-level cancellation mode and premature-transition cancellation mode, level change detection is always made by Pϕ regardless of the selected noise cancel clock. In level accumulation cancellation mode, the sampling of the input level is made by the noise canceler clock (Pϕ or Pϕ /128).

For an operating example in cancel mode, see **Figure 21.1**, **Figure 21.2** and **Figure 21.3**.

21.9.2.5 PVFCRF — Private Function Control Register F

Access: 16-bit access is possible.

Address: FFE6 3010_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PVFCRKEY[7:0]								—	—	—	—	—	—	GRDFCMEN	BKCRWEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R	R	R	R	R	R	R/W	R/W

Note 1. Values written to the write key code are not retained.

Table 21.115 PVFCRF Register Contents

Bit Position	Bit Name	Function
15 to 8	PVFCRKEY [7:0]	Write Key Code $C9_H$: GRDFCMEN and BKCRWEN values can be changed. Other than $C9_H$: GRDFCMEN and BKCRWEN values cannot be changed.
7 to 2	—	Not used. These bits are always read as 0. Fix these bits to 0.
1	GRDFCMEN	GRDFx Compare Match Enable 0: GRDFx compare match feature is disabled in PWM input waveform measurement mode. 1: GRDFx compare match feature is enabled in PWM input waveform measurement mode.
0	BKCRWEN	Backup Control Register Fx Write Enable 0: The BKCRFx register is not writable. 1: The BKCRFx register is writable.

Note: x is an integer from 0 to 15.

The private function control register F (PVFCRF) is a 16-bit readable/writable register. To write a value to this register, write key code setting is required to bits 15 to 8 as well as the data to be written.

When PVFCRF is reset, it is initialized to 0000_H.

(1) PVFCRKEY — Write Key Code

This code controls the write permission for bits GRDFCMEN and BKCRWEN. Setting is required to bits 15 to 8 as well as the data to be written to bits GRDFCMEN and BKCRWEN. Data written to this bit is not retained; Value 00_H is always returned when being read.

(2) GRDFCMEN — GRDFx Compare Match Enable

Controls enable/disable of the compare match of time measurement counter CFx (ECNTCFx) and general register DFx (GRDFx). This bit takes effect in PWM input waveform mode, and is ignored in other modes. (GRDFx compare match feature is disabled.)

The setting of this bit is applied to all subblocks of timer F. Subblock-individual setting is not possible.

(3) BKCRWEN — Backup Control Register Fx Write Enable

Controls write permission to the backup control register Fx (BKCRFx) The setting of this bit is applied to all subblocks of timer F. Subblock-individual setting is not possible.

21.9.2.6 TCR1Fx — Timer Control Registers 1Fx

(x = 0 to 15: Correspond to subblocks F0 to F15.)

Access: 8-bit access is possible.

Address: FFE6 3040_H + (40_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CKSELFx[2:0]			MDFx[2:0]			EGSELFx[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.116 TCR1Fx Register Contents

Bit Position	Bit Name	Function
7 to 5	CKSELFx[2:0]	Clock Select Fx Specify the clock sources for the time counters (ECNTAFx, ECNTCFx). 000: Clock bus 0 001: Clock bus 1 010: Clock bus 2 011: Clock bus 3 100: Clock bus 4 101: Clock bus 5 110: Clock bus 6 111: Reserved
4 to 2	MDFx[2:0]	Timer Operation Mode Fx Specify the operation mode for the corresponding subblocks Fx. 000: Edge counting in a specified period 001: Effective edge interval counting 010: Measurement of time during high/low input levels 011: Reserved 100: Measurement of PWM input waveform timing 101: Rotation speed/pulse measurement 110: Up/down event count 111: Four-time multiplication event count
1, 0	EGSELFx[1:0]	Edge Select Fx Specify the edge sense mode of TIFxA, TIFx, or TIA00-06 input. 00: Edge detection disabled 01: Rising edge 10: Falling edge 11: Both edges

Timer control registers 1Fx (TCR1F0 to TCR1F15) are 8-bit readable/writable registers that specify the operation mode of the subblocks F0 to F15.

When TCR1F0 to TCR1F15 are reset, they are initialized to 00_H.

(1) CKSELFx — Clock Select Fx

Specify the clock sources for the two time counters (ECNTAFn, ECNTCFn) in the subblocks F0 to F15.

Setting these bits to a value from 000_B to 110_B selects the corresponding clock bus (0 to 6) as the clock source. Do not specify 111_B. If specified, the operation is not guaranteed.

(2) MDFx — Timer Operation Mode Fx

Specify the operation mode for the timer subblocks F0 to F15. There are seven modes: up/down event count, four-time multiplication event count, edge counting in a specified period, effective edge interval counting, measurement of time during high/low input levels, measurement of PWM input waveform timing, and rotation speed/pulse measurement.

Do not set rotation speed/pulse measurement for subblocks other than 3 to 15.

(3) EGSELFx — Edge Select Fx

Specifies the event input (TIFxA or TIFx) of timer subblock F0 to F15 and the edge sense mode of pin inputs (TIA00 to 06) from timer A. Edge detection is done for signals that have passed through the noise canceller. Therefore, edge detection is done to the external input (TIFxA or TIFx, TIFxB) if the noise cancel function is disabled, and to signals after noise cancel if the noise cancel function is enabled. Noise cancellation for TIA00 to TIA06 input signals is in accord with the setting of noise cancellation for timer A.

While measurement of time during high/low input levels is specified, when this bit selects the falling edge, measurement of time during high level is specified. When this bit selects the rising edge, measurement of time during low level is specified. Do not select both edges.

While measurement of PWM input waveform timing and rotation speed/pulse measurement are specified, when this bit selects the rising edge, the period between the two rising edges is regarded as the PWM cycle and the low level period is regarded as the off-duty period. If the falling edge is selected, the period between the two falling edges is regarded as the PWM cycle and the high-level period is regarded as the off-duty period. Do not select both edges.

When up/down event count mode and four-time multiplication event count mode are specified, be sure to designate both the rising and falling edges. If otherwise selected, the operation is not guaranteed.

CAUTION

TIFxB pin is available only when up/down event count and four-time multiplication event count are specified. TIFxB operates always detecting both the rising and falling edges. In other modes, TIFxB does not detect edges.

21.9.2.7 TCR2Fx — Timer Control Registers 2Fx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 8-bit access is possible.

Address: FFE6 3042_H + (40_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	EISELEFx	—	—	—	—	EISELFx		
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R/W	R/W	R/W

Table 21.117 TCR2Fx Register Contents

Bit Position	Bit Name	Function
7 to 5	EISELEFx	Event Input Selection Enable Ex 0: Selects TIFxA or TIFx. 1: Selects the signal processed by noise canceling of TIA.
6 to 3	—	Not used. Fix these bits to 0.
2 to 0	EISELFx	Event Input Selection Ex 000: Selects the signal of TIA00 of timer A processed by noise canceling. 001: Selects the signal of TIA01 of timer A processed by noise canceling. 010: Selects the signal of TIA02 of timer A processed by noise canceling. 011: Selects the signal of TIA03 of timer A processed by noise canceling. 100: Selects the signal of TIA04 of timer A processed by noise canceling. 101: Selects the signal of TIA05 of timer A processed by noise canceling. 110: Selects the signal of TIA06 of timer A processed by noise canceling. 111: Setting not permitted.

The timer control register 2Fx (TCR2Fx) is an 8-bit readable/writable register that specifies the event input of each subblock (timer F0 to timer F15) of timer F.

When TCR2F0 to TCR2F15 are reset, they are initialized to 00_H.

(1) EISELEFx — Event Input Selection Enable Fx

Selects an event input for each subblock (timer F0 to timer F15) included in timer F.

By setting this bit, noise-canceled signals from TIA00 to TIA06 of timer A can be used as the event input instead of external input pin TIFxA or TIFx.

(2) EISELFx — Event Input Selection Fx

When EISELEFx is set to 1, noise-canceled signal TIA00 to TIA06 of timer A can be selected as the event input for each subblock (timer F0 to timer F15) included in timer F.

Do not specify 111_B. If specified, the operation is not guaranteed.

21.9.2.8 TIERFx — Timer Interrupt Enable Registers Fx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 8-bit access is possible.

Address: FFE6 3047_H + (40_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	OVECFx	OVEBFx	OVEAFx	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R

Table 21.118 TIERFx Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Not used. These bits are always read as 0. When writing, always write 0.
3	OVECFx	Overflow Interrupt Enable CFx 0: Interrupt by OVFCFx disabled 1: Interrupt by OVFCFx enabled
2	OVEBFx	Overflow Interrupt Enable BFx 0: Interrupt by OVFBFx disabled 1: Interrupt by OVFBFx enabled
1	OVEAFx	Overflow Interrupt Enable AFx 0: Interrupt by OVFAFx disabled 1: Interrupt by OVFAFx enabled
0	—	Not used. This bit is always read as 0. These bits are always read as 0. Fix this bit to 0.

Timer interrupt enable registers Fx (TIERF0 to TIERF15) are 8-bit readable/writable registers that specify whether to enable or disable the interrupt corresponding to the status flag of the timer status register Fx (TSRFx).

When TIERF0 to TIERF15 are reset, they are initialized to 00_H.

(1) Overflow Interrupt Enable AFx

Specifies whether to enable or disable the interrupt by OVFAFx to the status corresponding to the overflow of the time measurement counter AFx (ECNTAFx).

(2) Overflow Interrupt Enable BFx

Specifies whether to enable or disable the interrupt by OVFBFx to the status corresponding to the overflow/underflow of the event counter Fx (ECNTBFx).

(3) Overflow Interrupt Enable CFx

This flag specifies whether to permit or prohibit interrupt requests of the state (OVFCFx) corresponding to overflow of timer measurement counter CFx (ECNTCFx) (when it is in PWM input waveform measurement mode and the GRDFCMEN bit of the PVFCRF register is 0), corresponding to compare match of ECNTCFx and GRDFx (when it is in PWM input waveform measurement mode and the GRDFCMEN bit of the PVFCRF register is 1), or corresponding to compare match of ECNTCFx and GRBFx (rotation speed/pulse measurement mode).

CAUTION

The overflow of interrupt of the timer subblock Fx is requested as the logical sum of the interrupts OVFAFx, OVFBFx, and OVFCFx. By referring to TSRFx, which counter generated the interrupt by overflow or underflow can be known. Clear the corresponding interrupt request flag of TSRFx when processing the interrupt. The interrupt request will be repeated if the flag is not cleared

21.9.2.9 BKCRFx — Backup Control Register Fx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 8-bit access is possible.

Address: FFE6 3044_H + (40_H * x)

Value after reset: 00_H

[Subblocks F00 to F02]

Bit	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R	R	R	R/W	R

[Subblocks F03 to F15]

Bit	7	6	5	4	3	2	1	0
	—	BKENAFx	BKENCFx	BKENDFx	—	ARSWAFx	ARSWCFx	ARSWDFx
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W*2	R/W*2	R/W*2	R	R/W*2	R/W*2	R/W*2

Table 21.119 BKCRFx Register Contents

Bit Position	Bit Name	Function
7	—	Not used. This bit is always read as 0. When writing, always write 0.
6	BKENAFx*1	Backup Enable A Saving GRAFx in BGRAFx when CDRFx is read 0: Not saved 1: Saved
5	BKENCFx	Backup Enable C Saving GRCFx in BGRCFx when CDRFx is read 0: Not saved 1: Saved
4	BKENDFx*1	Backup Enable D Saving GRDFx in BGRDFx when CDRFx is read 0: Not saved 1: Saved
3	—	Not used. This bit is always read as 0. When writing, always write 0.
2	ARSWAFx*1	Mapping to Access Register Switching A To FFE6 3054_H + (40_H * x), 0: GRAFx is mapped. 1: BGRAFx is mapped.
1	ARSWCFx	Mapping to Access Register Switching C To FFE6 3064_H + (40_H * x), 0: GRCFx is mapped. 1: BGRCFx is mapped.
0	ARSWDFx*1	Mapping to Access Register Switching D To FFE6 3064_H + (40_H * x), 0: GRDFx is mapped. 1: BGRDFx is mapped.

Note 1. BKENAFx, BKENDFx, ARSWAFx, and ARSWDFx exist only in subblocks F03 to F15. Nothing is deployed in F00 to F02. These bits are always read as 0. Writing value must always be 0.

Note 2. Writing to this register is permitted only when the BKCRWEN bit of the PVFCRF register is 1.

The backup control register Fx (BKCRF00 to BKCRF15) is an 8-bit readable/writable register.

Writing to BKCRF00 to BKCRF15 is permitted only when the BKCRWEN bit of the private function control register F (PVFCRF) is 1.

When BKCRF00 to BKCRF15 are reset, they are initialized to 00_H.

(1) BKENAFx, BKENCFx, and BKENDFx — Backup Enable A, C, and D

These bits permit or prohibit value saving of GRAFx to BGRAFx, GRCFx to BGRCFx, and GRDFx to BGRDFx when capture output register Fx (CDRFx) is read.

(2) ARSWAFx, ARSWCFx, and ARSWDFx — Access Register Switching A, C, and D

These bits specify whether BGRAFx is mapped instead of GRAFx to address FFE6 $3054_H + (40_H * x)$, whether BGRCFx is mapped instead of GRCFx to address FFE6 $3064_H + (40_H * x)$, and whether BGRDFx is mapped instead of GRDFx to address FFE6 $3068_H + (40_H * x)$.

CAUTION

Setting of this register always takes effect regardless of the operation mode. Value saving and mapping change are performed even for registers that do not operate in some operation mode.

21.9.2.10 TSRFx — Timer Status Registers Fx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 8-bit access is possible.

Address: FFE6 3045_H + (40_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	OVFCFx	OVFBFx	OVFAFx	ICFFx
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.120 TSRFx Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Not used. These bits are always read as 0. When writing, always write 0.
3	OVFCFx	Overflow/Compare Match Flag CFx 0: No overflow in ECNTCFx 1: ECNTCFx overflows
2	OVFBFx	Overflow Flag BFx 0: No overflow or underflow in ECNTBFx 1: ECNTBFx overflows or underflows
1	OVFAFx	Overflow Flag AFx 0: No overflow in ECNTAFx 1: ECNTAFx overflows
0	ICFFx	Input Capture Flag Fx 0: Input capture is not detected in the subblock Fx 1: Input capture in subblock Fx detected

Timer status registers Fx (TSRF0 to TSRF15) are 8-bit readable/writable registers that indicate overflows in the time counters A and C, overflow or underflow in the event counter, and input capture occurrence.

These flags are status flags that indicate occurrence of an interrupt request. For overflow flags AFx, BFx, and CFx (OVFAx, OVFBx, and OVFCx), interrupt requests can be issued by setting the TIERFx register. Setting a bit of the timer status clear register Fx (TSCRFx) clears the corresponding flag.

For input capture flag Fx (ICFFx), an interrupt request is made again If an interrupt source takes effect while this flag is set. An interrupt request is issued even in cases of contention between clearing by the corresponding timer status clear register and setting by an interrupt source.

For overflow flags, an interrupt request is issued when the corresponding flag is set by setting the corresponding bit of timer interrupt enable register Fx (TIERFx). To cancel an interrupt request, clear this flag by the timer status clear register Fx (TSCRFx).

When TSRF00 to TSRF15 are reset, they are initialized to 00_H.

(1) ICFFx — Input Capture Flag Fx

By this bit, the detection state of input capture and compare match in the subblock Fx (F0 to F15) can be monitored. This flag cannot be set to 1 or 0 by software.

- Setting condition
  When input capture is detected in the subblock Fx.
- Clearing condition
  When 1 is written to ICFCFx of the timer status clear register Fx (TSCRFx).

(2) OVFAFx — Overflow Flag AFx

By this flag, overflow of the time counter AFx (ECNTAFx) can be monitored. This flag cannot be set to 1 or 0 by software.

- Setting condition
  When ECNTAFx overflows (FFFF $FFFF_H \rightarrow 0000\ 0000_H$)
- Clearing condition
  When 1 is written to OVFCAFx of the timer status clear register Fx (TSCRFx).

(3) OVFBFx — Overflow Flag BFx

By this flag, overflow or underflow of the event counter Fx (ECNTBFx) can be monitored. This flag cannot be set to 1 or 0 by software.

- Setting condition
  When ECNTBFx overflows ($FFFF_H \rightarrow 0000_H$) or underflows ($0000_H \rightarrow FFFF_H$)
- Clearing condition
  When 1 is written to OVFCBFx of the timer status clear register Fx (TSCRFx).

(4) OVFCFx — Overflow Flag CFx

Values of this flag indicate different conditions depending on the operation mode and the setting of the GRDFx compare match enable bit (GRDFCMEN) of the private function control register F (PVFCRF). When the PWM input waveform measurement mode is set, value 0 of the GRDFCMEN bit makes this flag indicate an overflow of time measurement counter CFx (ECNTCFx), and value 1 of the GRDFCMEN bit makes this flag indicate a compare match of ENCTCFx and GRDFx. In “rotation speed/pulse measurement” mode, this flag indicates a compare match of ECNTCFx and GRBFx regardless of the GRDFCMEN bit setting.

This flag cannot be set to 1 or 0 by software.

- Setting condition
  Measurement of PWM input waveform timing mode
  [GRDFCMEN = 0]
  When the value of ECNTCFx has overflown (from FFFF $FFFF_H$ to 0000 0000_H)
  [GRDFCMEN = 1]
  When the values of ECNTCFx and GRDFx coincide.
  Rotation speed/pulse measurement mode
  When ECNTCFx and GRDFx (the value of zero extension to the 16 lower-order bits) coincide
- Clearing condition
  When 1 is written to OVFCCFx of the timer status clear register Fx (TSCRFx).

21.9.2.11 TSCRFx — Timer Status Clear Register Fx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 8-bit access is possible.
Value 0 cannot be written. The value is not retained when 1 is written. These bits are always read as 0.

Address: FFE6 3046_H + (40_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	OVFCCFx	OVFCBFx	OVFCAFx	ICFCFx
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 21.121 TSCRFx Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Not used. Fix these bits to 0.
3	OVFCCFx	Overflow Flag Clear CFx 0: Disabled (Initial value) 1: Clears OVFCFx of timer status register Fx (TSRFx) to 0.
2	OVFCBFx	Overflow Flag Clear BFx 0: Disabled (Initial value) 1: Clears OVFBFx of timer status register Fx (TSRFx) to 0.
1	OVFCAFx	Overflow Flag Clear AFx 0: Disabled (Initial value) 1: Clears OVFAFx of timer status register Fx (TSRFx) to 0.
0	ICFCFx	Input Capture Flag Clear Fx 0: Disabled (Initial value) 1: Clears ICFFx of timer status register Fx (TSRFx) to 0.

The timer status clear register Fx (TSCRF00 to TSCRF15) is an 8-bit readable/writable register. This register specifies flag clearing in the events of an overflow of time measurement counter A or C, an overflow or an underflow of an event counter, and an input capture occurrence.

TSCRFx is readable/writable only in 8-bit units. This register is always read as 0.

When TSCRFx is reset, it is initialized to 00_H.

(1) OVFCCFx — Overflow Flag Clear CFx

When overflow flag CFx (OVFCFx) of timer status register Fx (TSRFx) is set to 1, writing 1 to this register clears OVFCFx to 0. This register is always read as 0.

(2) OVFCBFx — Overflow Flag Clear BFx

When overflow flag BFx (OVFBFx) of timer status register Fx (TSRFx) is set to 1, writing 1 to this register clears OVFBFx to 0. This register is always read as 0.

(3) OVFCAFx — Overflow Flag Clear AFx

When overflow flag AFx (OVFAFx) of timer status register Fx (TSRFx) is set to 1, writing 1 to this register clears OVFAFx to 0. This register is always read as 0.

(4) ICFCFx — Input Capture Flag Clear Fx

When input capture flag Fx (ICFFx) of timer status register Fx (TSRFx) is set to 1, writing 1 to this register clears ICFFx to 0. This register is always read as 0.

21.9.2.12 ECNTAFx — Timer Measurement Counters AFx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 3050_H + (40_H * x)

Value after reset: 0000 0000_H

Table 21.122 ECNTAFx Register Contents

Bit Position	Bit Name	Function
31 to 0	ECNTAFx	Time Measurement Count AFx Up-counter A

ECNTAF0 to ECNTAF15 are 32-bit readable/writable registers. This register is readable/writable only in 32-bit units. Do not write or read 8-bit or 16-bit data for this register.

This register, with one provided to each subblock, executes up-count operation using the input clock. One clock bus from clock buses 0 to 6 can be selected as the input clock according to the setting of the corresponding control register. The input clocks for ECNTAFx and ECNTCFx are the same. Clock source cannot be set independently.

When clearing the counter is done at the countup timing, ECNTAFx is cleared to 0000 0001_H, and to 0000 0000_H in other cases.

When ECNTAF0 to ECNTAF15 are reset, they are initialized to 0000 0000_H.

21.9.2.13 ECNTBFx — Event Counters Fx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 16-bit access is supported. 8-bit access is prohibited.

Address: FFE6 3058_H + (40_H * x)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.123 ECNTBFx Register Contents

Bit Position	Bit Name	Function
15 to 0	ECNTBFx	Event Count Fx Up/down counter

Event counters Fx (ECNTBF0 to ECNTBF15) are 16-bit readable/writable registers. This register, with one provided to each subblock, executes up-count/downcount operation using the input clock. The input clock is given two external input pins (TIFxA, TIFxB) for subblocks 0 to 2 and one external input TIFx for the other subblocks. The external pin and edge used to count differs according to the setting of the corresponding control register (operation mode and edge select).

The input clock in each mode is listed in **Table 21.124**.

When clearing the counter is done at the count-up timing, ECNTBFx is cleared to 0001_H, and to 0000_H in other cases.

When ECNTBF0 to ECNTBF15 are reset, they are initialized to 0000_H.

Table 21.124 Event Counter Input Clocks and Count Edges for Each Operation Mode of Timer

Operation Mode	Input Clock	Count Edge
Edge counting in a specified period	TIFxA or TIFx	Selectable by EGSELFx
Effective edge interval counting	TIFxA or TIFx	Selectable by EGSELFx
Measurement of time during high/ low input levels	TIFxA or TIFx	Selectable by EGSELFx (other than both edges)
Measurement of PWM input waveform timing	TIFxA or TIFx	Selectable by EGSELFx (other than both edges)
Rotation speed/pulse measurement	TIFx	Selectable by EGSELFx (other than both edges)
Up/down event count	TIFxA (Count direction is specified by TIFnB level)	Both rising/falling edges
Four-time multiplication event count	TIFxA, TIFxB	Both rising/falling edges

21.9.2.14 ECNTCFx — Time measurement Counters CFx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 3060_H + (40_H * x)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.125 ECNTCFx Register Contents

Bit Position	Bit Name	Function
31 to 0	ECNTCFx	Time Counter CFx Up-counter C

Timer counters CFx (ECNTCF00 to ECNTCF15) are 32-bit readable/writable registers. They are up-counters. This register is readable/writable only in 32-bit units. Do not write or read 8-bit or 16-bit data for this register.

This register, with one provided to each subblock, is enabled only in measurement of PWM input waveform timing and rotation speed/pulse measurement modes. This register does not execute count operation in other modes.

This register executes up-count operation using the input clock. One clock bus from clock buses 0 to 6 can be selected as the input clock according to the setting of the corresponding control register. The input clocks for ECNTAFx and ECNTCFx are the same. Clock source cannot be set independently.

The timing of external input and the count value clearing by a compare match with ECNTBFx are synchronized with the count clock of ECNTCFx. At this time, ECNTCFx is cleared to 0000 0001_H.

When ECNTCF0 to ECNTCF15 are reset, they are initialized to 0000 0000_H.

21.9.2.15 GRAFx — General Registers AFx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 3054_H + (40_H * x)

Value after reset: FFFF $FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.126 GRAFx Register Contents

Bit Position	Bit Name	Function
31 to 0	GRAFx	General Registers AFx Input capture value or output compare match value for the time counter A.

General registers AFx (GRAF00 to GRAF15) are 32-bit readable/writable registers. This register is readable/writable only in 32-bit units. Do not write or read 8-bit or 16-bit data for this register. This register, with one provided to each subblock, has two functions such as input capture register and output compare register for the time measurement counter AFx (ECNTAFx).

Do not set GRAFx to $0000\ 0000_H$ to function this register as the compare match register. Note that if $0000\ 0000_H$ is set, incorrect measurement may occur.

When GRAF00 to GRAF15 are reset, they are initialized to FFFF $FFFF_H$.

GRAF03 to GRAF15 are mapped to target addresses and become readable and writable when the ARSWAFx bit of backup control register Fx (BKCRFx) is 0 (initial value: 0).

21.9.2.16 BGRAFx — Backup Register AFx

(x = 3 to 15: Correspond to subblocks F3 to F15.)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 3054$_H$ + (40$_H$ * x)

Value after reset: FFFF FFFF$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.127 BGRAFx Register Contents

Bit Position	Bit Name	Function
31 to 0	BGRAFx[31:0]	When the BKENAFx bit of BKCRFx is 1, this register retains the value of general register AFx (GRAFx) at the time of reading the capture output register Fx (CDRFx).

Backup register AFx (BGRAF03 to BGRAF15) is a 32-bit read-only register. One instance of this register is provided for each of subblock 03 to subblock 15. If the BKENAFx bit of backup control register Fx (BKCRFx) is 1, this register retains the content of general register AFx (GRAFx) when capture output register Fx (CDRFx) is read.

When BGRAF03 to BGRAF15 are reset, they are initialized to FFFF FFFF$_H$.

BGRAFx is mapped to target addresses and becomes readable when the ARSWAFx bit of backup control register Fx (BKCRFx) is 1 (initial value: 0).

21.9.2.17 GRBFx — General Registers BFx

(x = 0 to 15: Correspond to subblocks F0 to F15.)

Access: 16-bit access is possible. 8-bit access is prohibited.

Address: FFE6 305C$_H$ + (40$_H$ * x)

Value after reset: FFFF$_H$

Table 21.129 GRCFx Register Contents

Bit Position	Bit Name	Function
31 to 0	GRCFx	General Registers CFx Input capture value for the time counter C

General register CFx (GRCF00 to GRCF15) is a 32-bit readable/writable register, and can be read from and written to in 32-bit units. Do not write or read 8-bit or 16-bit data for this register.

This register, with one provided to each subblock, has a function as the input capture register for the time measurement counter CFx (ECNTCFx). Triggered by a compare match between ECNTBFx and GRBx (in measurement of PWM input waveform timing mode) or edge input of the TIFx pin (in rotation speed/pulse measurement mode), ECNTCFx count number is taken in at the next ECNTCFx up-count timing. These registers are valid only in measurement of PWM input waveform timing or rotation speed/pulse measurement mode. Capture operation is not executed in other modes.

When GRCF00 to GRCF15 are reset, they are initialized to FFFF $FFFF_H$.

GRCF00 to GRCF15 are mapped to target addresses and become readable and writable when the ARSWCFx bit of backup control register Fx (BKCRFx) is 0 (initial value: 0).

21.9.2.19 BGRCFx — Backup Register CFx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 3064_H + (40_H * x)

Value after reset: FFFF $FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 0	GRDFx	General Register DFx In PWM input waveform measurement mode: Compare match value of time measurement counter C In “rotation speed/pulse measurement” mode: (only for x = 3 to 15) accumulated value of time measurement counter C

General registers DFx (GRDF00 to GRDF15) are 32-bit readable/writable registers that can be read and written only in 32-bit units.

Do not read or write these registers in 16 bit or 8-bit units.

This register is provided individually for subblocks F00 to 15. This register operates differently depending on the subblock. For subblocks F00 to F02, this register works only in PWM input waveform measurement mode. This register does not work in other modes.

For subblocks F03 to F15, this register works in PWM input waveform measurement mode and in “rotation speed/pulse measurement” mode. This register does not work in other modes.

In PWM input waveform measurement mode, this register works as a compare match register, and is always compared with the value of time measurement counter CFx (ECNTCFx). If the values of both registers coincide, the OVFCFx bit of timer status register Fx (TSRFx) is set to 1 at the next Pϕ clock cycle. To make this register work as a compare match register, the GRDFCMEN bit of PVFCRF must be set. In rotation speed/pulse measurement mode, this register works as an input capture register. Triggered by an edge input of the TIFx pin, this register takes and accumulates the value of time measurement counter Cx (ECNTCFx) at the next cycle of ECNTCFx increment.

When GRDF00 to GRDF15 are reset, they are initialized to FFFF $FFFF_H$.

GRDF03 to GRDF15 are mapped to target addresses and become readable and writable when the ARSWDFx bit of backup control register Fx (BKCRFx) is 0 (initial value: 0).

21.9.2.21 BGRDFx — Backup Register DFx

(x = 3 to 15: Corresponding to subblocks F3 to F15)

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 3068_H + (40_H * x)

Value after reset: FFFF $FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BGRDFx[31:16]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BGRDFx[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.132 BGRDFx Register Contents

Bit Position	Bit Name	Function
31 to 0	BGRDFx[31:0]	When the BKENDFx bit of BKCRFx is 1, this register retains the value of general register DFx (GRDFx) at the time of reading the capture output register Fx (CDRFx).

Backup register DFx (BGRDF03 to BGRDF15) is a 32-bit read-only register. This register is readable only in 32-bit units. Do not read this register in 8-bit or 16-bit units.

One instance of this register is provided for each of subblock F03 to subblock F15. If the BKENDFx bit of backup control register Fx (BKCRFx) is 1, this register retains the content of general register DFx (GRDFx) when capture output register Fx (CDRFx) is read.

When BGRDF03 to BGRDF15 are reset, they are initialized to FFFF $FFFF_H$.

BGRDFxis mapped to target addresses and becomes readable when the ARSWDFx bit of backup control register Fx (BKCRFx) is 1 (initial value: 0).

21.9.2.22 CDRFx — Capture Output Registers Fx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 32-bit access is possible.
8-bit access and 16-bit access are prohibited.

Address: FFE6 306C$_H$ + (40$_H$ * x)

Value after reset*1: 0000 FFFF$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CDRFx															
Value after reset*1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CDRFx															
Value after reset*1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. The value after a reset is 0000 FFFF$_H$ since the timer operation mode after a reset is “edge counting in a specified period” (i.e., the MDFx bit in the TCR1Fx register = 000$_B$).

Table 21.133 CDRFx Register Contents

Bit Position	Bit Name	Function
31 to 0	CDRFx	Capture Output Register Fx Data retained in GRAFx, GRBFx, or ECNTBFx is read depending on the operation mode. Edge count mode: GRBFx Edge input interval measurement mode: GRAFx Input high period measurement mode: GRAFx Input low period measurement mode: GRAFx PWM input waveform measurement mode: GRAFx Rotation speed/pulse measurement mode: ECNTBFx Up/down count mode: GRBFx Four-time multiplication event count mode: GRBFx

The capture output register is a 32-bit read-only register. This register is provided to each subblock. When this register is read, values in GRAFx, GRBFx, or ECNTBFx is read according to the operation mode. A 16-bit value in GRBFx and ECNTBFx are read from the 16 lower-order bits in CDRFx. In this case, the 16 higher-order bits in CDRFx are read as 0.

Registers corresponding to various modes are listed below. Writing to these registers are ignored.

Edge count mode: GRBFx

Edge input interval measurement mode: GRAFx

Input high period measurement mode: GRAFx

Input low period measurement mode: GRAFx

PWM input waveform measurement mode: GRAFx

Rotation speed/pulse measurement mode: ECNTBFx

Up/down count mode: GRBFx

Four-time multiplication event count mode: GRBFx

When CDRF0 to CDRF15 are reset, they are initialized to FFFF FFFF$_H$.

Depending on the setting of bits BKENAFx, BKENCFx, and BKENDFx of backup control register Fx (BKCRFx), reading CDRFx triggers value saving from general register AFx (GRAFx) to backup general register AFx (BGRAFx), from general register CFx (GRCFx) to backup general register CFx (BGRCFx), and from general register DFx (GRDFx) to backup general register DFx (BGRDFx). For more information, see the sections on backup general registers corresponding to individual general registers.

21.9.2.23 NCNTFAx — Noise Canceler Counters FAx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 16-bit access is supported. 8-bit access is prohibited.

Address: FFE6 3048_H + (40_H * x)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NCNTFAx															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.134 NCNTFAx Register Contents

Bit Position	Bit Name	Function
15 to 0	NCNTFAx	Noise Cancel Counter FAx 16-bit count value

Noise canceler counters registers FAx (NCNTFAx) are 16-bit readable/writable registers.

When the noise canceler is enabled by noise canceler control register F (NCCRF) and the operation mode is premature-transition cancellation mode or minimum time-at-level cancellation mode, a level change of external input pin TIFxA or TIFx triggers the up-count operation ticked by the noise canceler counter clock provided by the prescaler. In level accumulation cancellation mode, up/down counting is performed based on the external input level.

NCNTFAx is readable/writable only in 16-bit units.

When NCNTFAx is reset, it is initialized to 0000_H. One of the three different operation modes, which are premature-transition cancellation mode, minimum time-at-level cancellation mode, and level accumulation cancellation mode, takes place depending on the setting of the noise cancel mode selection bit (NCMSEL) and the timer F noise cancel mode bit (NCMF) of the noise cancel mode register (NCMR) of the common controller, as well as on a couple of timer F bits, which are the noise cancel mode bit (NCM1Fx) of the noise cancel mode channel register 1F (NCMCR1F) and the noise cancel mode bit (NCM2Fx) of the noise cancel mode channel register 2F (NCMCR2F).

- Premature-transition cancellation mode
  NCNTFAx starts up-count operation triggered by the level change of input signal in TIFxA or TIFx under the condition that the NCEFx bit is set to 1 and NCNTFAx is not in count operation. When the count number matches the value in the noise cancel register FAx (NCRFAx), this register stops the count operation, clearing the count value to 0000_H synchronizing with the next PCLK. NCNTFAx executes the count operation regardless of the setting of the TFE bit in the ATU-IV master enable register (ATUENR).
  A level change at the start of count operation is output as it is as the signal that passed through the noise canceling operation. Although this signal is the subject of edge detection, the signal does not change because any input level change is masked until the count number matches the value of NCRFAx.
  Even if the NCEFx bit is cleared during the count operation, the count operation continues until the count number matches the value of NCRFAx. The input signal is masked during all that time.

- Minimum time-at-level cancellation mode
  NCNTFAx starts up-count operation triggered by the level change of input signal in TIFxA or TIFx under the condition that the NCEFx bit is set to 1 and NCNTFAx is not in count operation.
  When the level change of the input signal occurs during the count operation or the count number matches the value in the noise cancel register FAx (NCRFAx), this register stops the count operation, clearing the count value to 0000_H synchronizing with the next PCLK.
  NCNTFAx executes the count operation regardless of the setting of the TFE bit in the ATU-IV master enable register (ATUENR).
  Signals that passed through the noise canceling operation can change only when the count number matches the value of NCRFAx according to the level change at the count start. If the count operation stops before the count number matches the value of NCRFAx, signals that passed through the noise canceling operation do not change because the level changes at the start or stop of counting are masked.
  Even if the NCEFx bit is cleared during the count operation, the count operation and noise canceling processing continue until a compare match occurs or the level of the input signal changes.

- Level accumulation cancellation mode
  When the NCEFx bit is set to 1, NCNTFAx performs up or down counting depending on the input signal level. Up-counting is performed when the input level is high, and if the counter value coincides with NCRFAx, the up-counting stops at the next PCLK cycle. Down-counting is performed when the input level is low, and if the counter value coincides with 0000_H, the down-counting stops at the next PCLK cycle.
  Counting of NCNTFAx is performed regardless of the setting of the TFE bit of the ATU-IV master enable register (ATUENR).
  If up-counting results in a compare match of NCRFAx, the noise canceler output is updated to 1. If down-counting results in a compare match with 0000_H, the noise canceler output is updated to 0.
  If the NCEFx bit is cleared when counting is in progress, the noise cancel counter stops counting, and the value is changed from the noise canceler output to the current input signal level. Be noted that clearing the NCEFx bit in level accumulation cancellation mode might cause an edge detection due to this value change.

21.9.2.24 NCNTFBx — Noise Canceler Counters FBx

(x = 0 to 2: Correspond to subblocks F0 to F2.)

Access: 16-bit access is supported. 8-bit access is prohibited.

Address: FFE6 304C$_H$ + (40$_H$ * x)

Value after reset: 0000$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NCNTFBx															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.135 NCNTFBx Register Contents

Bit Position	Bit Name	Function
15 to 0	NCNTFBx	Noise Cancel Counter FBx 16-bit count value

Noise cancel counters FBx (NCNTFBx) are 16-bit readable/writable registers. These registers are available only in up/down event count mode and 4-time multiplication event count mode.

When the noise canceler is enabled by noise canceler control register F (NCCRF) and the operation mode is premature-transition cancellation mode or minimum time-at-level cancellation mode, a level change of external input pin TIFxB triggers the up-count operation ticked by the noise canceler counter clock provided by the prescaler. In level accumulation cancellation mode, up/down counting is performed based on the external input level.

NCNTFBx is readable/writable only in 16-bit units.

When NCNTFBx is reset, it is initialized to 0000$_H$.

One of the three different operation modes, which are premature-transition cancellation mode, minimum time-at-level cancellation mode, and level accumulation cancellation mode, takes place depending on the setting of the noise cancel mode selection bit (NCMSEL) and the timer F noise cancel mode bit (NCMF) of the noise cancel mode register (NCMR) of the common controller, as well as on a couple of timer F bits, which are the noise cancel mode bit (NCM1Fx) of the noise cancel mode channel register 1F (NCMCR1F) and the noise cancel mode bit (NCM2Fx) of the noise cancel mode channel register 2F (NCMCR2F).

- Premature-transition cancellation mode
  NCNTFBx starts upcount operation triggered by the level change of input signal in TIFxB under the condition that the NCEFx bit is set to 1 and NCNTFBx is not in count operation. When the count number matches the value in the noise cancel register FBx (NCRFBx), this register stops the count operation, clearing the count value to 0000$_H$ synchronizing with the next PCLK. NCNTFBx executes the count operation regardless of the setting of the TFE bit in the ATU-IV master enable register (ATUENR).
  A level change at the start of count operation is output as it is as the signal that passed through the noise canceling operation. Although this signal is the subject of edge detection, the signal does not change because any input level change is masked until the count number matches the value of NCRFBx.
  Even if the NCEFx bit is cleared during the count operation, the count operation continues until the count number matches the value of NCRFBx. The input signal is masked during all that time.

- Minimum time-at-level cancellation mode
  NCNTFBx starts upcount operation triggered by the level change of input signal in TIFxB under the condition that the NCEFx bit is set to 1 and NCNTFBx is not in count operation. When the level change of the input signal occurs during the count operation or the count number matches the value in the noise cancel register FBx (NCRFBx), this register stops the count operation, clearing the count value to 0000_H synchronizing with the next PCLK.
  NCNTFBx executes the count operation regardless of the setting of the TFE bit in the ATU-IV master enable register (ATUENR).
  Signals that passed through the noise canceling operation can change only when the count number matches the value of NCRFBx, according to the level change at the count start. If the count operation stops before the count number matches the value of NCRFBx, signals that passed through the noise canceling operation do not change because the level changes at the start or stop of counting are masked.
  Even if the NCEFx bit is cleared during the count operation, the count operation and noise canceling processing continue until a compare match occurs or the level of the input signal changes.

- Level accumulation cancellation mode
  When the NCEFx bit is set to 1, NCNTFBx performs up or down counting depending on the input signal level. Up-counting is performed when the input level is high, and if the counter value coincides with NCRFBx, the up-counting stops at the next PCLK cycle. Down-counting is performed when the input level is low, and if the counter value coincides with 0000_H, the down-counting stops at the next PCLK cycle.
  Counting of NCNTFBx is performed regardless of the setting of the TFE bit of the ATU-IV master enable register (ATUENR).
  If an up-count results in a compare match of NCRFBx, the noise canceler output is updated to 1. If down-counting results in a compare match with 0000_H, the noise canceler output is updated to 0.
  If the NCEFx bit is cleared when counting is in progress, the noise cancel counter stops counting, and the value is changed from the noise canceler output to the current input signal level.
  Be noted that clearing the NCEFx bit in level accumulation cancellation mode might cause edge detection due to this value change.

21.9.2.25 NCRFAx — Noise Cancel Registers FAx

(x = 0 to 15: Corresponding to subblocks F0 to F15)

Access: 16-bit access is supported. 8-bit access is prohibited.

Address: FFE6 304A$_H$ + (40$_H$ * x)

Value after reset: 0000$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NCTFAx															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.136 NCRFAx Register Contents

Bit Position	Bit Name	Function
15 to 0	NCTFAx	Noise Cancel Time FAx TIFxA or TIFx noise cancel period (16-bit compare value)

Noise cancel registers FAx (NCRFAx) are 16-bit readable/writable registers that set the upper limit of the noise canceler counter FAx (NCNTFAx). When a period of 128 PCLK cycles is selected as the noise cancel clock, setting of FFFF$_H$ can cancel noise for maximum of 0.21 second period (when PCLK = 40 MHz).

One of the three different operation modes, which are premature-transition cancellation mode, minimum time-at-level cancellation mode, and level accumulation cancellation mode, takes place depending on the setting of the noise cancel mode selection bit (NCMSEL) and the timer F noise cancel mode bit (NCMF) of the noise cancel mode register (NCMR) of the common controller, as well as on a couple of timer F bits, which are the noise cancel mode bit (NCM1Fx) of the noise cancel mode channel register 1F (NCMCR1F) and the noise cancel mode bit (NCM2Fx) of the noise cancel mode channel register 2F (NCMCR2F).

- Premature-transition cancellation mode
  While NCNTFAx is in count operation, the level change of the subsequent input signal is masked. Values in NCNTFAx and NCRFAx are always compared. If a compare match occurs, these registers clear the value in NCNTFAx synchronizing with the next PCLK, stop the count operation, and cancel the masking of the input signal.
- Minimum time-at-level cancellation mode
  While NCNTFAx is in count operation, noise canceler processing waiting state is entered. Values in NCNTFAx and NCRFAx are always compared. If a compare match occurs, these registers clear the value in NCNTFAx synchronizing with the next PCLK, stop the count operation, and then cancel the masking of the input signal and the noise canceler outputs the input signal that has passed through the noise canceling processing.
- Level accumulation cancellation mode
  When NCNTFAx up-counting is in progress, values of CNTFAx and NCRFAx are compared. When a compare match occurs, the up-counting of NCNTFAx stops at the next PCLK cycle. When NCNTFAx down-counting is in progress, NCNTFAx is compared with 0000$_H$.

NCRFAx is readable/writable only in 16-bit units.

When NCRFAx is reset, it is initialized to 0000$_H$.

21.9.2.26 NCRFBx — Noise Cancel Registers FBx

(x = 0 to 2: Correspond to subblocks F0 to F2.)

Access: 16-bit access is supported. 8-bit access is prohibited.

Address: FFE6 304E$_H$ + (40$_H$ * x)

Value after reset: 0000$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NCTFBx

	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.137 NCRFBx Register Contents

Bit Position	Bit Name	Function
15 to 0	NCTFBx	Noise Cancel Time FBx TIFxB noise cancel period (16-bit compare value)

Noise cancel registers FBx (NCRFBx) are 16-bit readable/writable registers that set the upper limit of the noise canceler counter FBx (NCNTFBx). When a period of 128 PCLK cycles is selected as the noise cancel clock, setting of FFFF$_H$ can cancel noise for maximum of 0.21 second period (when PCLK = 40 MHz). This register is effective only during up/down counting and the four-time multiplication event count mode.

One of the three different operation modes, which are premature-transition cancellation mode, minimum time-at-level cancellation mode, and level accumulation cancellation mode, takes place depending on the setting of the noise cancel mode selection bit (NCMSEL) and the timer F noise cancel mode bit (NCMF) of the noise cancel mode register (NCMR) of the common controller, as well as on a couple of timer F bits, which are the noise cancel mode bit (NCM1Fx) of the noise cancel mode channel register 1F (NCMCR1F) and the noise cancel mode bit (NCM2Fx) of the noise cancel mode channel register 2F (NCMCR2F).

- Premature-transition cancellation mode
  While NCNTFBx is in count operation, the level change of the subsequent input signal is masked. Values in NCNTFBx and NCRFBx are always compared. If a compare match occurs, these registers clear the value in NCNTFBx synchronizing with the next PCLK, stop the count operation, and cancel the masking of the input signal.
- Minimum time-at-level cancellation mode
  While NCNTFBx is in count operation, noise canceler processing waiting state is entered. Values in NCNTFBx and NCRFBx are always compared. If a compare match occurs, these registers clear the value in NCNTFBx synchronizing with the next PCLK, stop the count operation. Simultaneously the noise canceler outputs the input signal that has passed through noise canceling processing.
- Level accumulation cancellation mode
  When NCNTFBx up-counting is in progress, values of CNTFBx and NCRFBx are compared. When a compare match occurs, the up-counting of NCNTFBx stops at the next PCLK cycle. When NCNTFBx down-counting is in progress, NCNTFBx is compared with 0000$_H$.

NCRFBx is readable/writable only in 16-bit units.

When NCRFBx is reset, it is initialized to 0000$_H$.

21.9.3 Detailed Operation Description

21.9.3.1 Edge Counting in a Given Time

When a period over which edges are counted is set in GRAFx, the number of edges within the period is obtained in GRBFx. When no edge is detected within the period, 0 is set to GRBFx. The period set to count is equivalent to the cycle of the ECNTAFx clock (GRAFx value). Operation of the timer Fx is described below. **Figure 21.60** shows an operation example. In this example, eight edges are input to 12 cycles of the count source clock. Timer counter ECNTAFx and event counter ECNTBFx are driven by the ECNTAFx and ECNTBFx clocks, respectively.

- ECNTAFx: Measures time using one of the clock buses 0 to 6. When a compare match is detected, the count value is cleared synchronized with the next PCLK.
- ECNTBFx: Counts edges of the signals provided from TIFxA or TIFx input. Edge types subject to count can be selected from among rising, falling, or both edges. The example given here counts the falling edges. A delay of two cycles in TIFxA or TIFx occurs because of synchronization processing. When a compare match in ECNTAFx is detected, the count number is cleared synchronized with the next PCLK. In a case where edges subject to count are given simultaneously at a count clearing by a compare match, both operations are regarded to be done in one cycle, setting the count value to 0001_H. **Figure 21.61** shows an example of this.
- GRAFx: Functions as the compare match register for ECNTAFx. A compare match is detected when the count values in ECNTAFx and GRAFx agree.
- GRBFx: Functions as the capture register for ECNTBFx. When a compare match in ECNTAFx is detected, this register captures the ECNTBFx count number synchronizing with the next PCLK.
- Compare match interrupt request output: After compare match detection of ECNTAFx, a compare match interrupt request is issued to CPU at the next PCLK cycle.
- DMA transfer request output: After compare match detection of ECNTAFx, a DMA transfer request is issued to DMAC at the next PCLK cycle.
- ICFFn flag: After detecting a compare match in ECNTAFx, sets the ICFFx flag synchronized with the next PCLK.
- ECNTCFx, GRCFx, GRDFx: Do not function

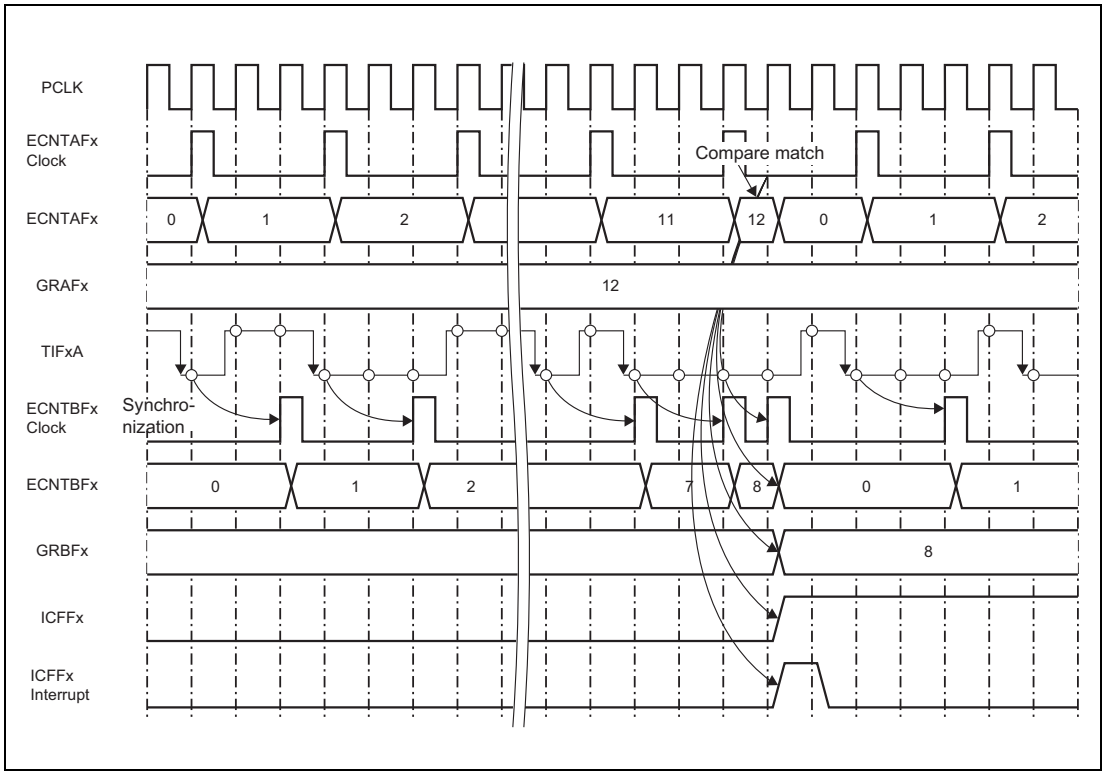

Figure 21.60 Operation Example of Edge Count in a Given Time

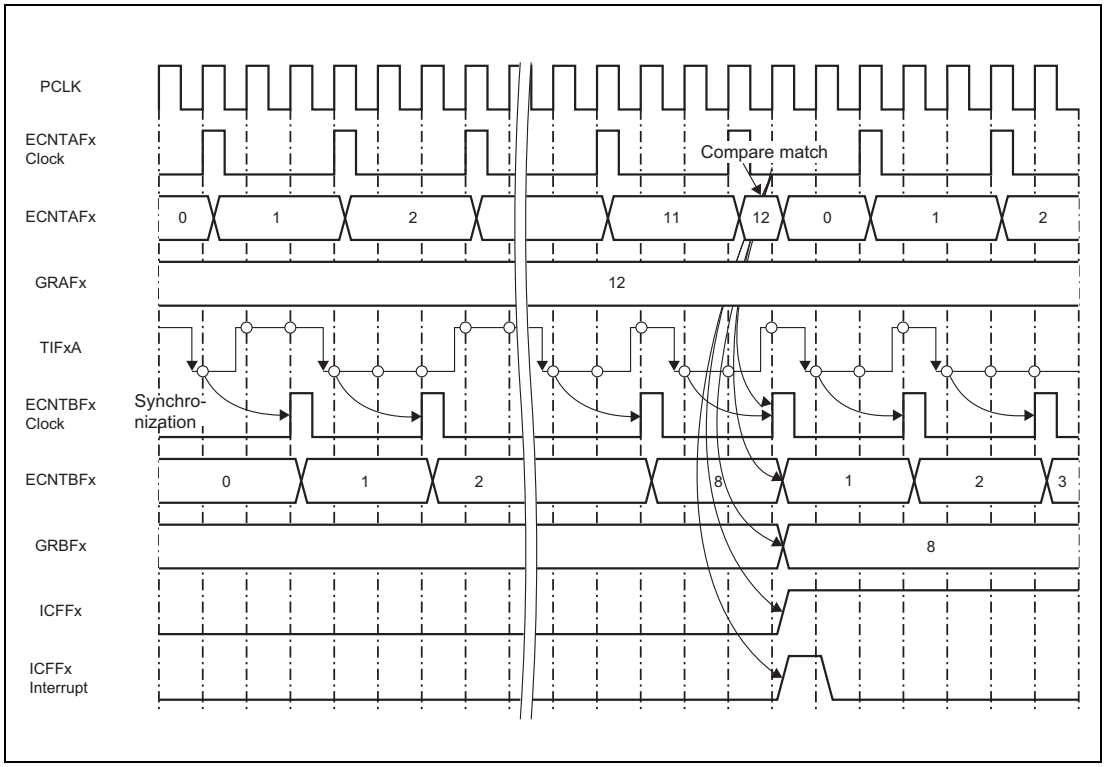

Figure 21.61 Operation Example 2 of Edge Count in a Given Time (Same Timing as Compare Match and Event)

21.9.3.2 Effective Edge Interval Counting

When a number of edges are set in GRBFx, the time necessary to count these edges is notified to GRAFx. The average of input edge intervals is obtained by dividing the time by the number of edges. The outcome is given as the unit of the ECNTAFx count source clock (GRAFx). Operation of the timer Fx is described below. **Figure 21.62** shows an operation example. In this example, 13 cycles of the counter clock are needed to detect 12 input edges. Timer counter ECNTAFx and event counter ECNTBFx are driven by the ECNTAFx and ECNTBFx clocks, respectively.

- ECNTAFx: Measures time using one of the clock buses 0 to 6. When a compare match between ECNTBFx and GRBFx is detected, the count value is cleared synchronized with the next ECNTAFx clock. Since ECNTAFx count clear occurs at the same time with countup, the cleared value becomes 0000 0001_H.
- ECNTBFx: Counts edges provided from TIFxA or TIFx. Edge types subject to count can be selected from among rising, falling, or both edges. The example given here counts the falling edges. A delay of two cycles in TIFxA or TIFx occurs because of synchronization processing. When a compare match is detected, the count number is cleared synchronized with the next PCLK.
- GRAFx: Functions as the capture register for ECNTAFx. When a compare match in ECNTBFx is detected, this register captures the ECNTAFx count number synchronizing with the next ECNTAFx clock.
- GRBFx: Functions as the compare match register for ECNTBFx. A compare match is detected when the count values in ECNTBFx and GRBFx agree.
- Compare match interrupt request: After a compare match detection of ECNTBFx, a compare match interrupt request is issued to CPU at the next “ECNTAFx Clock” cycle.
- DMA transfer request output: After a compare match detection of ECNTBFx, a DMA transfer request is issued to DMAC at the next “ECNTAFx Clock” cycle.
- ICFFx: After detecting a compare match in ECNTBFx, sets the ICFFx flag synchronized with the next ECNTAFx clock.
- ECNTCFx GRCFx GRDFx: Do not function.

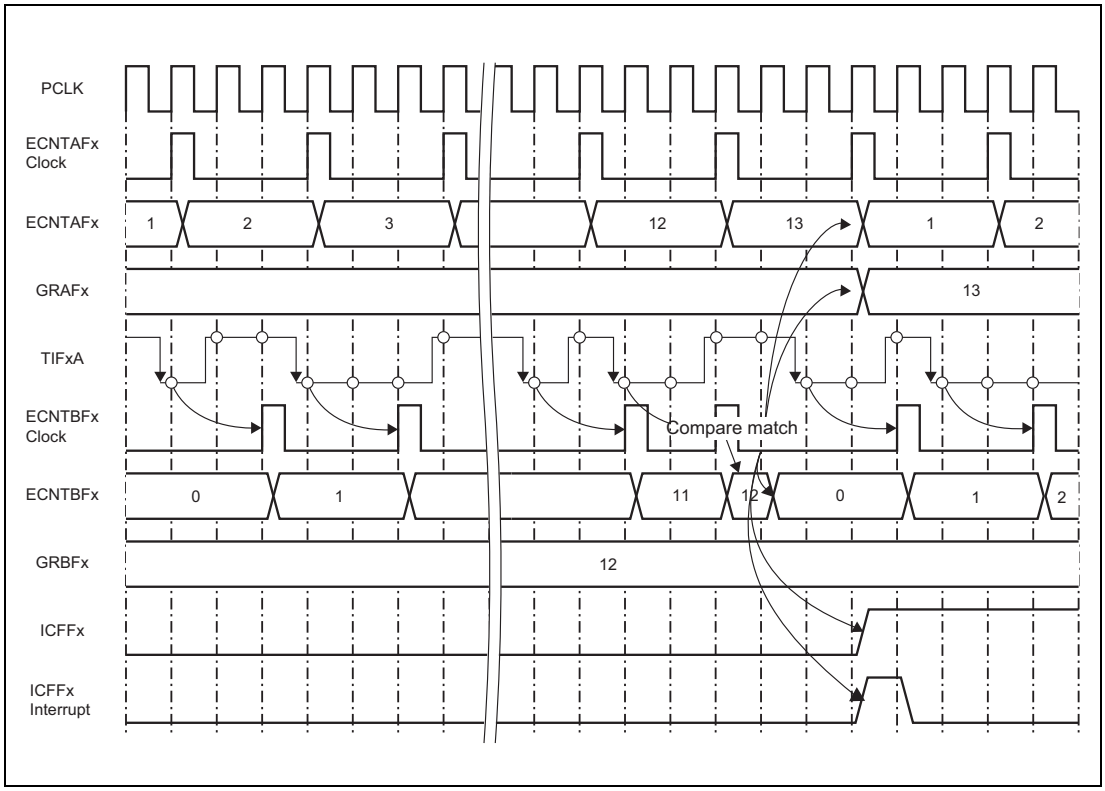

Figure 21.62 Operation Example of Effective Edge Interval Counting

21.9.3.3 Measurement of Time during High/Low Input Levels

Measures the time while TIFxA or TIFx is driven high or low. The time obtained is indicated using the ECNTAFx clock source as the standard. The width of the measurement time is specified to GRBFx in the form of the pulse number provided for TIFxA or TIFx (GRBFx value). Operation of the timer F is described below. **Figure 21.63** shows an operation example. This is the example in which the high level periods of the three pulses are measured as nine count source cycles. Timer counter ECNTAFx and event counter ECNTBFx are driven by the ECNTAFx and ECNTBFx clocks, respectively.

- ECNTAFx: Executes up-count using one of the clock buses 0 to 6 as a count source and TIFxA or TIFx level as enable. Therefore, the time period in which TIFxA or TIFx is in high level (EGSELFx = 2, falling edge selected), or TIFxA or TIFx is in low level (EGSELFx = 1, rising edge selected) is measured. After detecting a compare match in ECNTBFx, this register clears the count number synchronizing with the next count source clock. If TIFxA or TIFx is driven high (EGSELFx = 2) or low (EGSELFx = 1) at clearing count by the compare match, the count value becomes $0000\ 0001_H$. **Figure 21.64** is an example of this.
- ECNTBFx: Counts the falling edge of the signal from the TIFxA or TIFx input. Rising or falling edge is selectable to be counted. The operation example shows counting of the TIFxA or TIFx falling edge. A delay of two cycles occurs because of synchronization processing. When a compare match is detected, the count number is cleared synchronized with the next PCLK.
- GRAFx: Functions as the capture register for ECNTAFx. When a compare match in ECNTBFx is detected, this register captures the ECNTAFx count number synchronizing with the next ECNTAFx clock.
- GRBFx: Functions as the compare match register for ECNTBFx. A compare match is detected when the count number in ECNTBFx and GRBFx agree.
- Compare match interrupt request: After a compare match detection of ECNTBFx, a compare match interrupt request is issued to CPU at the next “ECNTAFx Clock” cycle.
- DMA transfer request output: After a compare match detection of ECNTBFx, a DMA transfer request is issued to DMAC at the next “ECNTAFx Clock” cycle.
- ICFFx: After detecting a compare match in ECNTBFx, sets the ICFFx flag synchronized with the next ECNTAFx clock.
- ECNTCFx, GRCFx, GRDFx: Do not function.

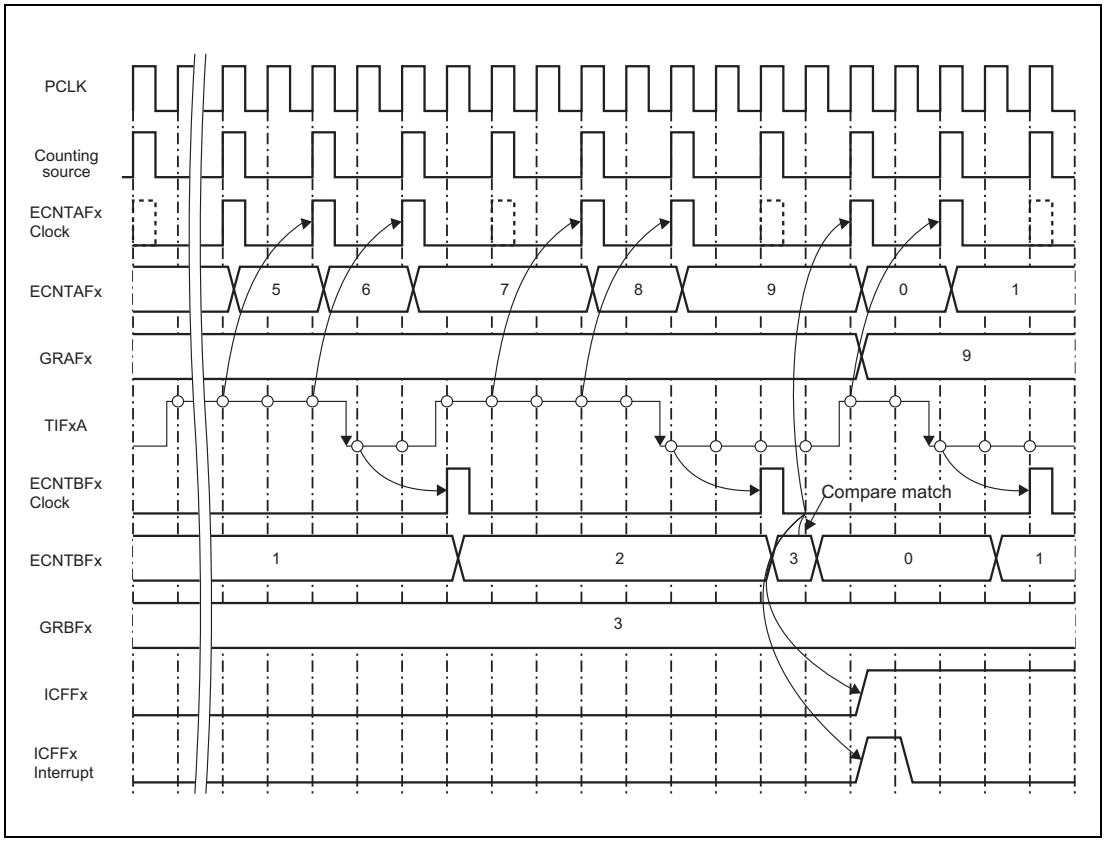

Figure 21.63 Operation Example of Measurement of Time during High Input Levels

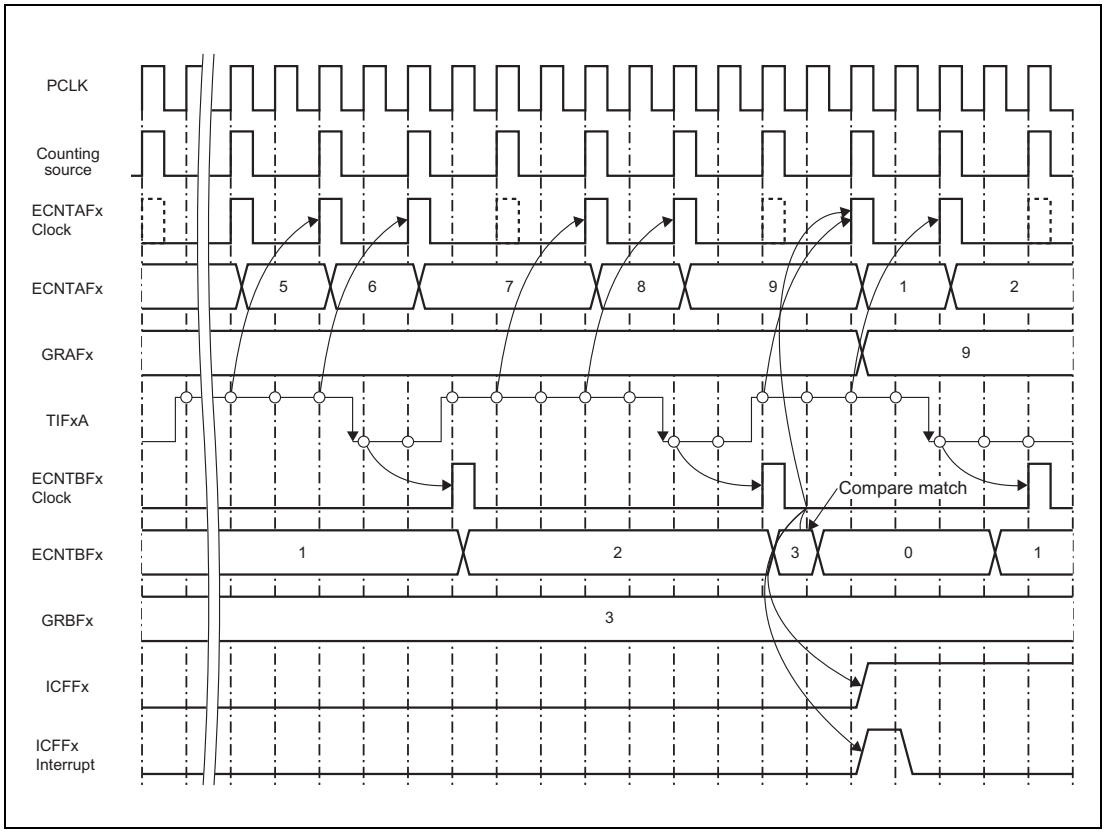

Figure 21.64 Operation Example of Measurement of Time during High Input Levels (TIFxA is in High Level When Capture is in Operation)

21.9.3.4 Measurement of PWM Input Waveform Timing

Measures the off-duty (non-active) period and cycle time of the PWM waveform input to TIFxA or TIFx. The off-duty period is measured as the period of either the high or low level input on TIFxA or TIFx, and the PWM cycle is measured as the interval between two rising or falling edges. Both are measured concurrently. The measured time is expressed in the number of cycles of the clock source for ECNTAFx. The duration of the measurement is set in GRBFx, which is specified as the number of PWM pulses input to TIFxA or TIFx.

Compare match is possible for the number of PWM cycles. A compare match can issue an interrupt request to CPU.

Operation of timer F is described below. **Figure 21.65** shows an operation example. This is the example in which two PWM cycles in PWM waveform are measured as six counter clock cycles and the off-duty period (low-level period) is measured as four counter clock cycles.

The clocks for ECNTAFx, ECNTBFx, and ECNTCFx in this example provide the timing of counting or clearing operation of the time counter ECNTAFx, event counter ECNTBFx, and ECNTCFx, respectively.

- ECNTAFx: Executes up-count using one of the clock buses 0 to 6 as a count source and TIFxA or TIFx input level as enable. Therefore, the time period in which TIFxA or TIFx is in high level (EGSELFx = 2, falling edge selected), or TIFxA or TIFx is in low level (EGSELFx = 1, rising edge selected) is measured. After detecting a compare match in ECNTBFx, this register clears the count number synchronizing with the next count source clock. If TIFxA or TIFx is driven high (EGSELFx = 2) or low (EGSELFx = 1) at clearing count by the compare match, the count value becomes $0000\ 0001_H$. The operation example shows measurement of low level.
- ECNTBFx: Counts the edge of the signal from the TIFxA or TIFx input. Rising or falling edge is selectable to be counted. The operation example shows counting of the rising edge. A delay of two cycles occurs because of synchronization processing. When a compare match is detected, the count number is cleared synchronized with the next PCLK.
- GRAFx: Functions as the capture register for ECNTAFx. When a compare match in ECNTBFx is detected, this register captures the ECNTAFx count number synchronizing with the next ECNTAFx clock.
- GRBFx: Functions as the compare match register for ECNTBFx. A compare match is detected when the count number in ECNTBFx and GRBFx agree.
- ECNTCFx: Measures time using the same count source as ECNTAFx. This register clears the count number synchronizing with the next ECNTAFx clock after detecting a compare match in ECNTBFx. Since ECNTCFx count clear occurs at the same time with countup, the cleared value is $0000\ 0001_H$. A compare match with GRDFx does not clear ECNTCFx, and the counting continues.
- GRCFx: Functions as the capture register for ECNTCFx. This register captures the ECNTCFx count number synchronizing with the next ECNTAFx clock after detecting a compare match in ECNTBFx.
- Input capture interrupt request: After a compare match detection of ECNTBFx, an input capture interrupt request is issued to CPU at the next “ECNTAFx Clock” cycle.
- DMA transfer request output: After a compare match detection of ECNTBFx, a DMA transfer request is issued to DMAC at the next “ECNTAFx Clock” cycle.
- ICFFx: After detecting a compare match in ECNTBFx, sets the ICFFx synchronized with the next ECNTAFx clock.

- GRDFx: This register works as a compare match register of ECNTCFx. A compare match occurs when the ECNTCFx count coincides with GRDFx. (Effective when the GRDFCMEN bit of the private function control register F (PVFCRF) is 1.)
- Overflow interrupt request output: After a compare match detection of ECNTCFx, an overflow interrupt request is issued to CPU at the next PCLK cycle. (Effective when the GRDFCMEN bit of the private function control register F (PVFCRF) is 1.)
- OVFCFx: After detection of a compare match of ECNTCFx, OVFCFx is set at the next PCLK cycle. (Effective when the GRDFCMEN bit of the private function control register F (PVFCRF) is 1.)

Therefore, ECNTBFx (GRBFx) and ECNTAFx (GRAFx) are operating in measurement of time during low input levels mode and ECNTBFx (GRBFx) and ECNTCFx (GRCFx) are operating in effective edge interval counting mode.

The measured values in PWM input waveform measurement mode are saved in two 32-bit registers: GRAFx and GRCFx. Be noted that, when reading these two registers, a capture might occur in the period between reading one register and reading the other register, resulting in reading incorrect measurements (for example, when an interrupt request was processed in between).

Reading values from backup registers would provide two consistent values. For details, see **Section 21.9.3.9, Simultaneous Access of Multiple Registers**.

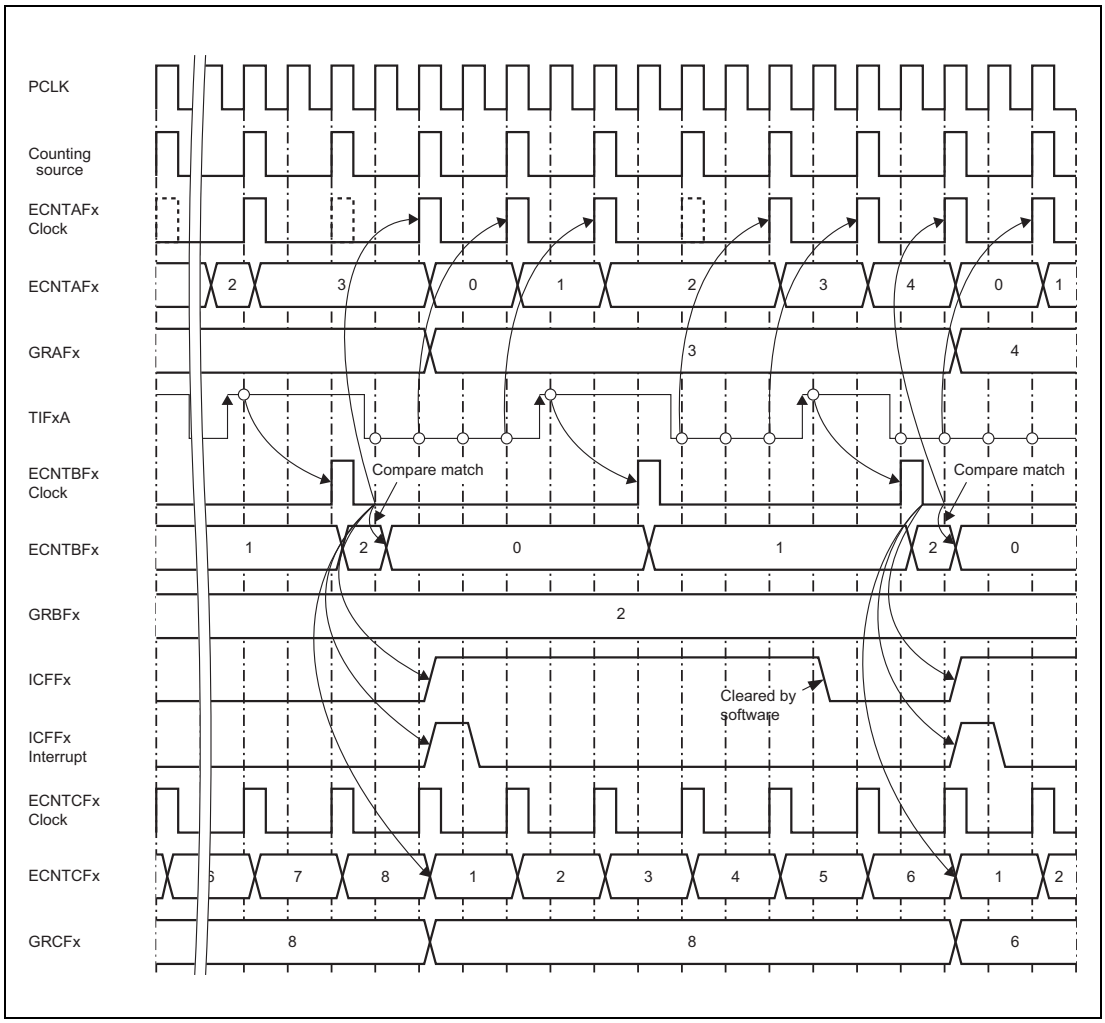

Figure 21.65 Operation Example of Measurement of PWM Input Waveform Timing

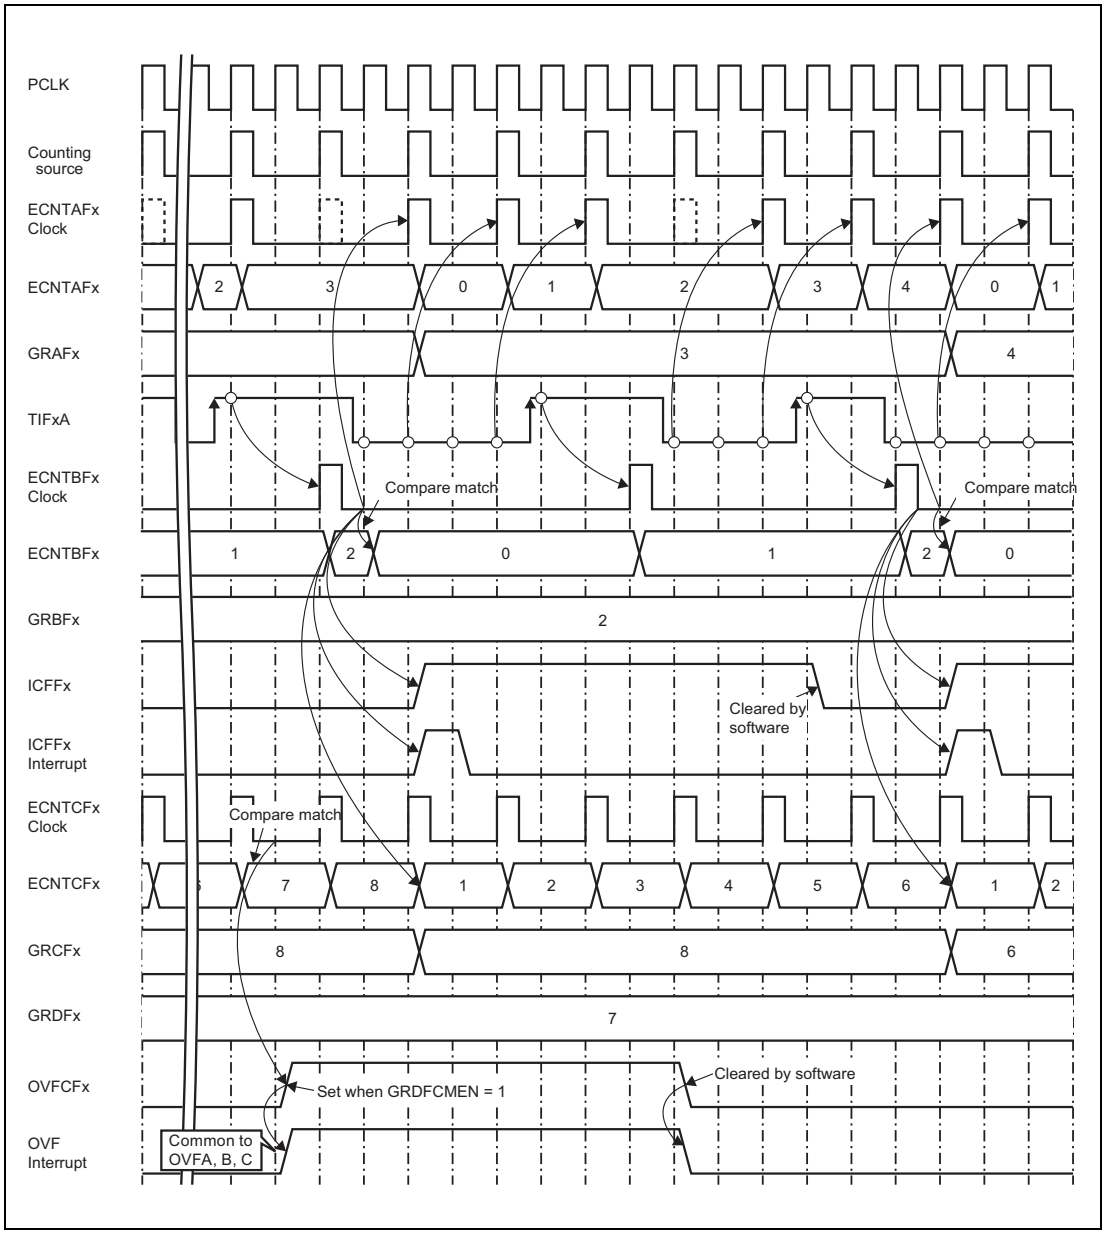

Figure 21.66 Operation Example of Measurement of PWM Input Waveform Timing

21.9.3.5 Rotation Speed/Pulse Measurement

Measures the number of edges input to TIFx, the edge input time (time stamp), the off-duty period in the PWM waveform that emerges between the last input edge and the edge this time, and PWM cycle time.

The time obtained is expressed using the ECNTAFx clock source as the standard. The maximum interval of edge input can be set to GRBFx, which enables to output an interrupt request if the edge input interval exceeds the maximum value.

At this moment, the timer F operates as shown below. **Figure 21.67** shows an example of operation. The ECNTAFx clock, ECNTBFx clock, and ECNTCFx clock show the timing of count operation or clearing for the time counter ECNTAFx, event counter ECNTBFx, and ECNTCFx, respectively.

- ECNTAFx: Executes up-count using one of the clock buses 0 to 6 as a count source and TIFx input level as enable. Therefore, the time period in which TIFx is in high level (EGSELFx = 2, falling edge selected), or TIFx is in low level (EGSELFx = 1, rising edge selected) is measured. After inputting the edge to TIFx, this register clears the count number synchronizing with the next count source clock. If TIFx is driven high (EGSELFx = 2) or low (EGSELFx = 1) at clearing count by the compare match, the count value becomes $0000\ 0001_H$.
- ECNTBFx: Counts the edge of the signal from the TIFx input. Rising or falling edge is selectable to be counted. The operation example shows counting of the falling edge. A delay of two cycles occurs because of synchronization processing.
- GRAFx: Functions as the capture register for ECNTAFx. This register captures the ECNTAFx count number synchronizing with the next ECNTAFx clock after inputting the edge to TIFx.
- GRBFx: Functions as the capture register for ECNTCFx. When the ECNTCFx count and the value in the 16 lower-order bits in GRBFx extended with 0 match, this register detects a compare match and set the OVFCFx to 1.
- ECNTCFx: Measures time using the same count source as ECNTAFx. This register clears the count number synchronizing with the next ECNTAFx clock after inputting the edge to TIFx. Since ECNTCFx count clear occurs in the same timing, the cleared value is $0000\ 0001_H$.
- GRCFx: Functions as the capture register for ECNTCFx. This register captures the ECNTCFx count number synchronizing with the next ECNTAFx clock after inputting the edge to TIFx.
- GRDFx: Functions as the capture register for ECNTCFx. This register captures the ECNTAFx, whose number being accumulated to GRDFx, synchronizing with the next ECNTAFx clock after inputting the edge to TIFx. The value to be added is the ECNTCFx value before clearing. (Capture value: GRDFx+ = ECNTCFx).
- Input capture interrupt request output: After an edge input to TIFx, an input capture interrupt request is issued to CPU at the next “ECNTAFx Clock” cycle.
- DMA transfer request output: After an edge input to TIFx, a DMA transfer request is issued to DMAC at the next “ECNTAFx Clock” cycle.
- ICFFx: Sets the ICFFx synchronizing with the next ECNTAFx clock after inputting the edge to TIFx.
- Overflow interrupt request output: An overflow interrupt request is issued to CPU at the next PCLK cycle during which values of ECNTCFx and GRBFx coincide (zero extension of 16 lower-order bits).
- OVFCFx flag: Sets the OVFCFx synchronizing with the next PCLK after the values in ECNTCFx and GRBFx (zero extension of 16 lower-order bits) match.

At the time of an input capture interrupt request, reading ECNTBFx, GRAFx, GRCFx, and GRDFx provides the number of edges, the off-state duty cycle, the PWM cycle, and the edge input time, respectively.

The capture timing of GRAFx, GRCFx, and GRDFx synchronizes with the count clock of ECNTAFx. Note that if the edge input cycle is shorter than the ECNTAFx count clock cycle, incorrect measurement may occur.

The measured values in “rotation speed/pulse measurement” mode are saved in three 32-bit registers GRAFx, GRCFx, and GRDFx. Be noted that, when reading these three registers, a capture might occur in the period between reading one register and reading another register, resulting in reading incorrect measurements (for example, when an interrupt request was processed in between).

Reading values from backup registers would provide three consistent values. For details, see **Section 21.9.3.9, Simultaneous Access of Multiple Registers**.

CAUTION

Do not set this mode for subblocks other than 03 to 15.

Figure 21.67 Operation Example of Rotation Speed/Pulse Measurement

21.9.3.6 Up/Down Event Count

This register uses the TIFxA pin, one of the two external input pins (TIFxA, TIFxB), as the count source, and TIFxB switches upcount to and from downcount. If a count period is designated to GRAFx the count number after designation can be obtained in GRBFx. The counting period is the period of ECNTAFx count source clock (GRAFx value).

At this moment, the timer F operates as shown below. **Figure 21.68** shows an example of operation. The ECNTAFx clock and ECNTBFx clock show the timing that time counter ECNTAFx and event counter ECNTBFx execute the count operation or clearing, respectively.

- ECNTAFx: Measures time using one of the clock buses 0 to 6. When a compare match is detected, the count value is cleared synchronized with the next PCLK.
- ECNTBFx: Upcount/downcount operation is performed at both rising and falling edges of TIFxA. Count direction is determined by the TIFxB input level. (See **Table 21.138**.) Because of synchronization processing, a delay of two cycles occurs in TIFxA and TIFxB.
- GRAFx: Functions as the compare match register for ECNTAFx. A compare match is detected when the count number in ECNTAFx and GRAFx agree.
- GRBFx: Functions as the capture register for ECNTBFx. When a compare match in ECNTAFx is detected, this register captures the ECNTBFx count number synchronizing with the next PCLK.
- Input capture interrupt request output: After compare match detection of ECNTAFx, an interrupt request is issued to CPU at the next PCLK cycle.
- DMA transfer request output: After compare match detection of ECNTAFx, a DMA transfer request is issued to DMAC at the next PCLK cycle.
- ICFFx: After detecting a compare match in ECNTAFx, sets the ICFFx flag synchronized with the next PCLK.
- ECNTCFx, GRCFx, GRDFx: Do not function

Table 21.138 Count Direction in Up/Down Event Count Mode

	Count Direction	
Input	**Upcount**	**Downcount**
TIFxA		
TIFxB	Low	High

CAUTION

Always set this mode only in subblock 0 to subblock 2.

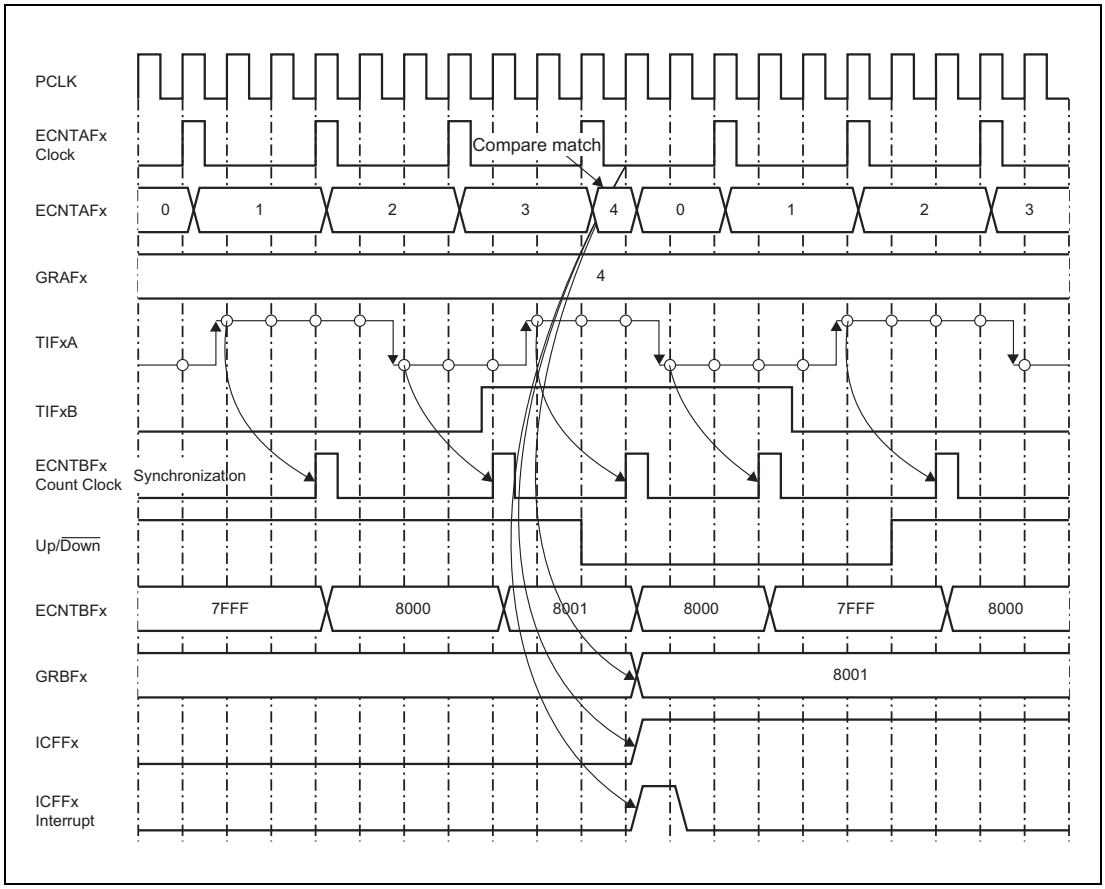

Figure 21.68 Operation Example of Up/Down Event Count

21.9.3.7 Four-time Multiplication Event Count

The count operation is executed using the external two input pins (TIFxA, TIFxB) as the count sources. Upcount or downcount is switched according to their input states. If a count period is designated to GRAFx, the count number after designation can be obtained in GRBFx. The counting period is the period of ECNTAFx count source clock (GRAFx value).

At this moment, the timer F operates as shown below. **Figure 21.69** shows an example of operation. The ECNTAFx clock and ECNTBFx clock show the timing that time counter ECNTAFx and event counter ECNTBFx execute the count operation or clearing, respectively.

- ECNTAFx: Measures time using one of the clock buses 0 to 6. When a compare match is detected, the count value is cleared synchronized with the next PCLK.
- ECNTBFx: Upcount/downcount operation is performed at both rising and falling edges of TIFxA and TIFxB respectively. Count direction is determined by the other signal input level. (See **Table 21.139**). Because of synchronization processing, a delay of two cycles occurs in TIFxA and TIFxB.
- GRAFx: Functions as the compare match register for ECNTAFx. A compare match is detected when the count number in ECNTAFx and GRAFx agree.
- GRBFx: Functions as the capture register for ECNTBFx. When a compare match in ECNTAFx is detected, this register captures the ECNTBFx count number synchronizing with the next PCLK.
- Input capture interrupt request output: After a compare match detection of ECNTAFx, an input capture interrupt request is issued to CPU at the next PCLK cycle.
- DMA transfer request output: After compare match detection of ECNTAFx, a DMA transfer request is issued to DMAC at the next PCLK cycle.
- ICFFx: After detecting a compare match in ECNTAFx, sets the ICFFx synchronized with the next PCLK.
- ECNTCFx, GRCFx, GRDFx: Do not function

Table 21.139 Count Direction in Four-time Multiplication Event Count Mode

Input	Count Direction							
	Upcount				Downcount			
TIFxA	High		Low		High		Low	
TIFxB		High		Low		Low		High

CAUTION

Always set this mode only in subblock 0 to subblock 2.

Note: Operation when edge inputs in TIFxA and TIFxB are detected simultaneously is not guaranteed. The interval between edge inputs in TIFnA and TIFnB must be at least 1.5 cycles (PCLK).

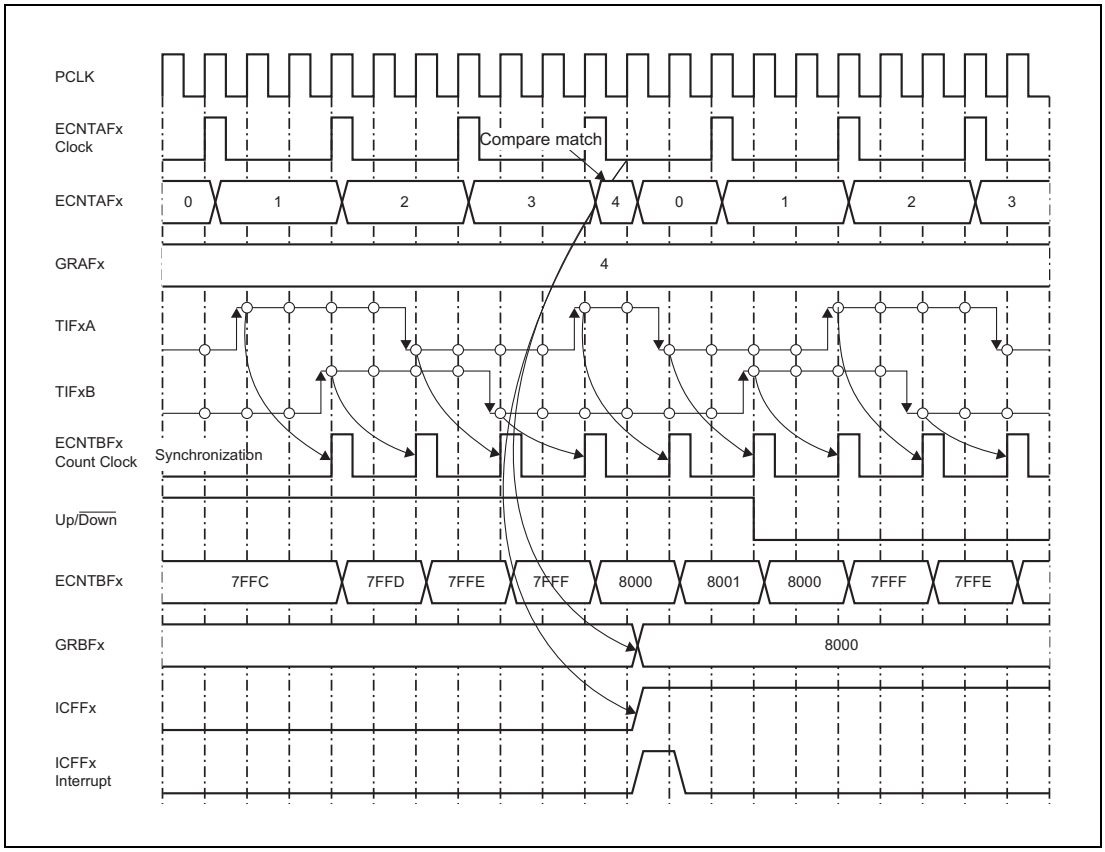

Figure 21.69 Operation Example of Four-time Multiplication Event Count Overflow/ Underflow

21.9.3.8 Overflow and Underflow

Counter clearing of FFFF $FFFF_H$ (ECNTAFx and ECNTCFx) to 0000 0000_H (ECNTAFx and ECNTCFx) or $FFFF_H$ (ECNTBFx) to 0000_H (ECNTBFx) causes overflow detection. In this case, the overflow flag is reset and an overflow interrupt request is issued as soon as the counter value becomes 0000 0000_H (or 0000_H). (A figure is omitted.) When an overflow of ECNTAFx is detected, OVFAFx is set and an overflow A interrupt request is issued. When an overflow of ECNTBFx is detected, OVFBFx is set and an overflow B interrupt request is issued. When an overflow of ECNTCFx is detected, OVFCFx is set and an overflow C interrupt request is issued.

An underflow is detected when the counter value changes from 0000_H (ECNTBFx) to $FFFF_H$ (ECNTBFx). In this case, OVFBFx is reset and an overflow interrupt request is issued as soon as the counter value becomes $FFFF_H$. (A figure is omitted.) OVFBFx is also set. An underflow occurs only with ECNTBFx, in which case an overflow B interrupt request is issued.

21.9.3.9 Simultaneous Access of Multiple Registers

In PWM input waveform measurement mode and rotation speed/pulse measurement mode, saving register values of measurement results to backup registers provides multiple register values of the same time point. When the CDRFx register is read, register values are saved from GRAFx to BGRAFx, from GRCFx to BGRCFx, and from GRDFx to BGRDFx.

For saving general register values to backup registers and for reading data from backup registers, the backup control register Fx (BKCRFx) must be set. For details, see the section above explaining backup control registers.

With the above method in PWM input waveform measurement mode, reading CDRFx and then BGRCFx (in the order of DMAC transfer access) provides the PWM cycle and the duty time of the same time point. In “rotation speed/pulse measurement” mode, reading CDRFx and then BGRAFx, BGRCFx, and BGRDFx provides data of the same time point.

21.10 Timer G

21.10.1 Operation Overview

The timer G block consists of 10 timer G subblocks.

A timer G subblock reads the input clock, and when a predetermined time period has passed, generates a pulse signal of one PCLK cycle period. The generated signals can be used as activation of the AD conversion device and interrupt request triggers. By a DMAC setting, the interrupt requests can be used as triggers of DMA transfer. An input clock can be selected for the counter from the seven clocks on the clock bus. The counter value of free-run counter TCNTG0 can be output as reference data for APA. For selection of output values, see **Section 22.5.8, APA Input Selector**.

Configuration

Timer G subblock includes one 32-bit counter (TCNTGx), one compare match register (OCRGx), and a controller.

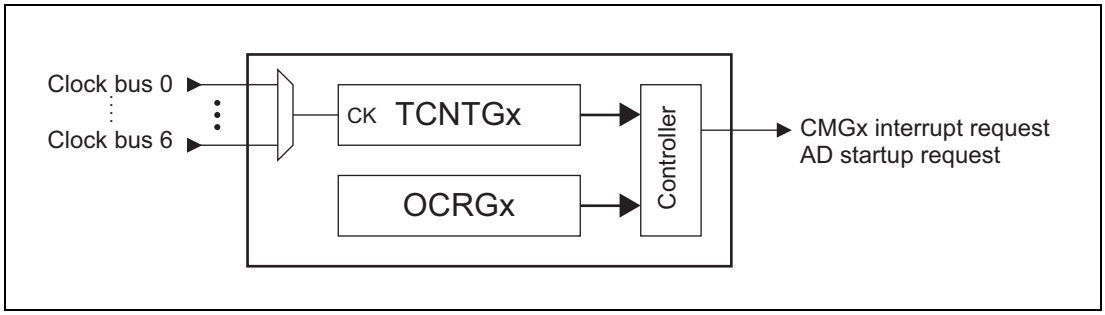

Figure 21.70 Timer G Configuration

Interrupt request

Timer G can issue 10 interrupt requests as described below.

- An interrupt request is issued upon compare match detection at timer subblock Gx. These requests are received by AD, DMAC, and the interrupt request controller, and they perform their processing according to individual settings.

21.10.2 Registers Related to Timer G

21.10.2.1 TSTRG — Timer Start Register G

Access: 8-bit /16-bit access is possible.

Address: FFE6 3900_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	STRG9	STRG8	STRG7	STRG6	STRG5	STRG4	STRG3	STRG2	STRG1	STRG0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.140 TSTRG Register Contents

Bit Position	Bit Name	Function
15 to 10	—	Not used. These bits are always read as 0. When writing, always write 0.
9 to 0	STRG9 to STRG0	Counter G Start 0: TCNTGx is disabled 1: TCNTGx is enabled

Note: x is an integer from 0 to 9.

The timer start register G (TSTRG) is a 16-bit register.

The 8 higher- and lower-order bits can be read and written as a TSTRGH register and a TSTRGL register respectively. This register specifies whether to start or stop each subblock (timer G0 to timer G9) included in timer G. The counting is not performed if the TGE bit of the ATU-IV control register (ATUENR) is not enabled even if the start bit of timer G permits counting.

When TSTRG is reset, it is initialized to 0000_H.

(1) STRGx — Counter G Start

These bits enable and disable timer counter Gx (TCNTGx) (G0 to G9) in the subblocks.

When these bits are cleared to 0, TCNTGx is stopped. While TCNTGx is stopped, it retains the previous value. When these bits are set to 1, TCNTGx is resumed from the previous value. TCNTGx runs when these bits and the TGE bit in ATUENR are both set to 1.

CAUTION

The prescalers run regardless of the counter G start bit and are not synchronized with the timing at which TCNTG is started. Therefore, the time from when the counter G start bit is set to when TCNTG is incremented for the first time is less than the cycle of the clock of TCNTG.

21.10.2.2 TCRGx — Timer Control Register Gx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks G0 to G9)

Access: 8-bit access is possible.

Address: FFE6 3910_H + (10_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	CKSELGx[2:0]			—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R	R	R	R

Table 21.141 TCRGx Register Contents

Bit Position	Bit Name	Function
7	—	Not used. This bit is always read as 0. When writing, always write 0.
6 to 4	CKSELGx[2:0]	Clock Select Gn These bits select the clock source of timer counter Gx (TCNTGn) of subblock. 000: Clock-bus line 0 001: Clock-bus line 1 010: Clock-bus line 2 011: Clock-bus line 3 100: Clock-bus line 4 101: Clock-bus line 5 110: Clock-bus line 6 111: Reserved
3 to 0	—	Not used. These bits are always read as 0. When writing, always write 0.

Timer control registers Gx (TCRG0 to TCRG9) are 8-bit readable/writable registers that set the operating mode of each subblock of timer G (G0 to G9).

When TCRG0 to TCRG9 are reset, they are initialized to 00_H.

(1) CKSELGx — Clock Select Gx

These bits select the clock source of timer counter Gx (TCNTGx) of subblocks (G0 to G9). Setting these bits to a value from 000 to 110 selects a clock source from clock bus 0 to clock bus 6.

However, do not set to 111. If set, operation cannot guaranteed.

21.10.2.3 TSRGx — Timer Status Registers Gx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks G0 to G9)

Access: 8-bit access is possible.

Address: FFE6 3912_H + (10_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OVFGx	CMFGx
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.142 TSRGx Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Not used. These bits are always read as 0. When writing, always write 0.
1	OVFGx	Overflow Flag Gx 1: TCNTGx has overflowed 0: TCNTGx has not overflowed
0	CMFGx	Compare Match Flag Gx 1: Compare match has occurred in subblocks Gx 0: Compare match has not occurred in subblocks Gx

Timer status registers Gx (TSRG0 to TSRG9) are 8-bit readable/writable registers that measure the time and indicate occurrence of event counter overflow and compare match.

The overflow flag is the status flag for indicating the occurrence of overflow. It does not generate interrupts. The compare match flag is a status flag that indicates occurrence of an interrupt request. Setting a bit of the timer status clear register Gx (TSCRGx) clears the corresponding flag. If an interrupt source takes effect when this flag is set, an interrupt request is made again. An interrupt request is issued even in cases of contention between clearing by the corresponding timer status clear register and setting by an interrupt source.

When TSRG0 to TSRG9 are reset, they are initialized to 00_H.

(1) OVFGx — Overflow Flag Gx

Indicates whether or not timer counter Gx (TCNTGx) has overflowed. This bit cannot be set to 1 or 0 by software.

- Setting condition
  When TCNTGx overflowed (from FFFF $FFFF_H$ to 0000 0000_H)
- Clearing condition
  Writing 1 to OVFCGx in timer status clear register (Gx (TSCRGX))

(2) CMFGx — Compare Match Flag Gx

Indicates whether or not a compare match has occurred in subblocks Gx (G0 to G9). This flag cannot be set to 1 or 0 by software.

- Setting condition
  When compare match occurred in subblocks Gx
- Clearing conditions
  When 1 is written to CMFCGx of the timer status clear register Gx (TSCRGx).

21.10.2.4 TSCRGx — Timer Status Clear Register Gx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks G0 to G9)

Access: 8-bit access is possible.

Address: FFE6 3913_H + (10_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OVFCGx	CMFCGx
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Note 1. Value 0 cannot be written. The value is not retained when 1 is written. These bits are always read as 0.

Table 21.143 TSCRGx Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Not used. These bits are always read as 0. When writing, always write 0.
1	OVFCGx	Overflow Flag Clear Gx Enable 0: Disabled (Initial value) 1: Writes 0 to OVFGx
0	CMFCGx	Compare Match Flag Clear Gx Enable 0: Disabled (Initial value) 1: Writes 0 to CMFGx

TSCRG is an 8-bit readable/writable register, which clears flags when compare match occur.

TSCRG is readable/writable only in 8-bit units. This register is always read as 0.

When TSCRG is reset, it is initialized to 00_H.

(1) OVFCGx — Overflow Flag Clear Gx Enable

When overflow flag Gx (OVFGx) of timer status register Gx (TSRGx) is set to 1, writing 1 to this register clears OVFGx to 0. This register is always read as 0.

(2) CMFCGx — Compare Match Flag Clear Gx Enable

When compare match flag Gx (CMFGx) of timer status register Gx (TSRGx) is set to 1, writing 1 to this register clears CMFGx to 0. This register is always read as 0.

21.10.2.5 TCNTGx — Timer Counters Gx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks G0 to G9)

Access: 32-bit access is possible. 8-bit access and 16-bit access are prohibited.

Address: FFE6 3914_H + (10_H * x)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.144 TCNTGx Register Contents

Bit Position	Bit Name	Function
31 to 0	TCNTGx[31:0]	Timer Counter Gx These bits store the up-counter value.

Timer counters Gx (TCNTGx) are 32-bit readable/writable registers. These registers are provided one for each subblock and are incremented by the clock selected in the corresponding control register. Lines 0 to 6 of the clock bus can be selected as the input clock.

These counter values are compared with the value in compare match register Gx (OCRGx). When they match, Compare match flag (CMFGx bit in TSRGx register) is set and the counter value is cleared to 0000 0000_H in the next PCLK cycle. If counter clearing by compare match and incrementation occur simultaneously, TCNTGx is initialized to 0000 0001_H. This occurs when TCNTGx is driven by the clock whose frequency is equal to the PCLK. An interrupt request can be issued to CPU by detection of a compare match.

When TCNTGx is reset, it is initialized to 0000 0000_H.

21.10.2.6 OCRGx — Compare Match Registers Gx

(x = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9: Corresponding to subblocks G0 to G9)

Access: 32-bit access is possible. 8-bit access and 16-bit access are prohibited.

Address: FFE6 3918$_H$ + (10$_H$ * x)

Value after reset: FFFF FFFF$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.145 OCRGx Register Contents

Bit Position	Bit Name	Function
31 to 0	OCRGx[31:0]	Compare Match Gx These bits set the compare match value.

Compare match registers Gx (OCRGx) are 32-bit readable/writable registers. These registers are provided one for each subblock and function as the output compare register for timer counter Gx. A compare match can trigger an interrupt request to CPU or a DMA transfer request.

Do not set OCRGx to 0000 0000$_H$. If 0000 0000$_H$ is set, compare matches occur at unwanted cycles.

When OCRGx is reset, it is initialized to FFFF FFFF$_H$.

21.10.3 Detailed Operation Description

Specifying a time period in OCRGx generates a positive logical pulse of one PCLK cycle when the specified period has passed. The initial value of the output signal is 0. The counting period is specified based on the clock source of TCNTGx. The generated signals can be output to the AD conversion device for AD activation and interrupt request triggers.

The compare match flag Gx (CMFGx) of the timer status register Gx (TSRGx) is set when a compare match occurs. Compare match can trigger a DMA activation request to DMAC and an interrupt request to CPU.

Figure 21.71 illustrates the operation example. “TCNTGx Clock” here is an imaginary signal indicating the timing of counting and clearing of counter TCNTGx.

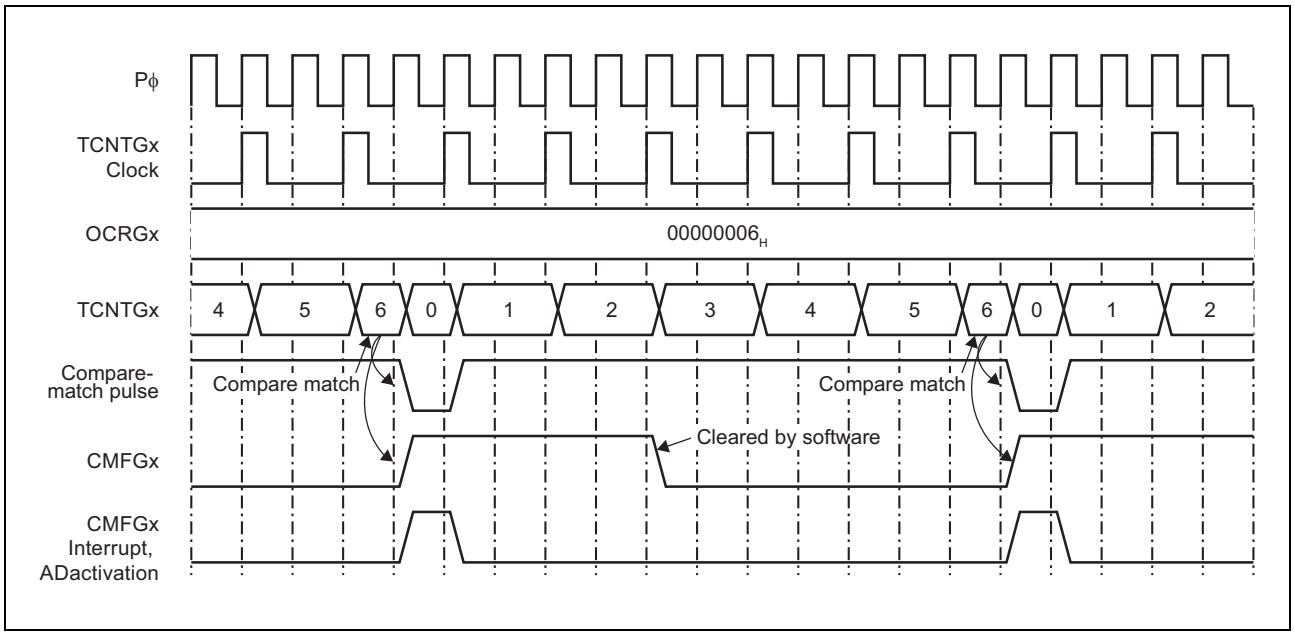

Figure 21.71 Operation Example of Counter and Compare Match

21.11 Timer H

21.11.1 Operation Overview

Timer H is a counter that measures a given time repeatedly.

Timer counter 1H (TCNT1H) is a 16-bit up-counter driven by the clock selected from seven lines of the clock bus. When the value in TCNT1H reaches the value in compare register 1H (OCR1H), it is cleared to 0000_H and is incremented again.

Timer counter 2H (TCNT2H) is a 32-bit counter that is incremented on compare match between TCNT1H and OCR1H, meaning that the counter counts the compare match.

Interrupt requests can be issued when TCNT2H is incremented.

Configuration

Timer H consists of one 16-bit timer counter 1H (TCNT1H), one compare match register 1_H (OCR1H), one 32-bit timer counter 2H (TCNT2H), and controller.

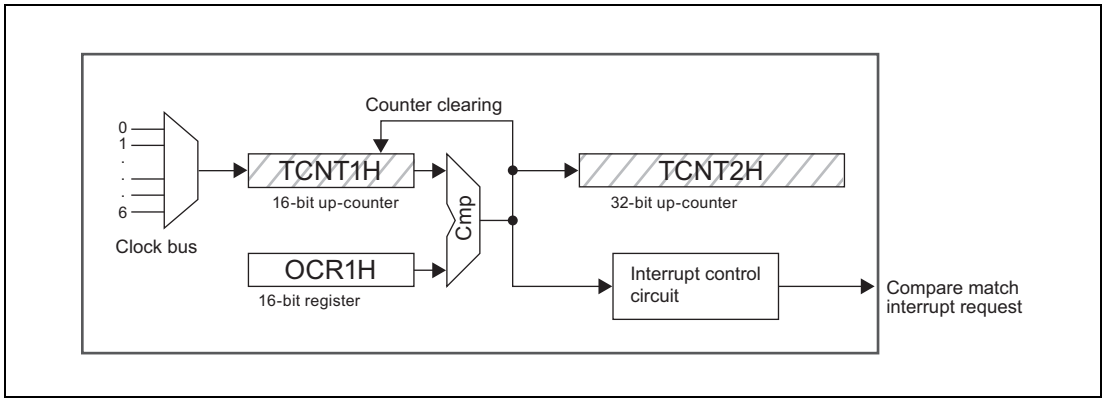

Figure 21.72 Block Diagram of Timer H Configuration

Interrupt request

Timer H can issue 1 interrupt requests as described below.

- Compare match interrupt request (1): Interrupt requests are issued on compare match between TCNT1H and OCR1H.

21.11.2 Registers Related to Timer H

21.11.2.1 TCRH — Timer Control Register H

Access: 8-bit access is possible.

Address: FFE6 0100_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	CKSELH[2:0]			—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R	R	R	R

Table 21.146 TCRH Register Contents

Bit Position	Bit Name	Function
7, 3, 2	—	Not used. This bit is always read as 0. When writing, always write 0.
6 to 4	CKSELH[2:0]	These bits select the source of the clock of 16-bit timer counter 1H (TCNT1H). 000: Clock-bus line 0 001: Clock-bus line 1 010: Clock-bus line 2 011: Clock-bus line 3 100: Clock-bus line 4 101: Clock-bus line 5 110: Clock-bus line 6 111: Reserved
3 to 0	—	Not used. These bits are always read as 0. When writing, always write 0.

Timer control register H (TCRH) is an 8-bit readable/writable register. This register selects a count source for a 16-bit timer counter 1H (TCNT1H).

When TCRH is reset, it is initialized to 00_H.

(1) CKSELH — Clock Select H

These bits select the source of the clock of 16-bit timer counter 1H (TCNT1H).

Setting these bits to a value from 000 to 110 selects a clock source from clock bus 0 to clock bus 6. Do not set these bits to 111. If these values are set, the timer might not work properly.

21.11.2.2 TSRH — Timer Status Register H

Access: 8-bit access is possible.

Address: FFE6 0102_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	OVF2H	OVF1H	CMFH
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.147 TSRH Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Not used. These bits are always read as 0. When writing, always write 0.
2	OVF2H	Overflow Flag 2H 1: TCNT2H has overflowed 0: TCNT2H has not overflowed
1	OVF1H	Overflow Flag 1H 1: TCNT1H has overflowed 0: TCNT1H has not overflowed
0	CMFH	Compare Match Flag H 1: Compare match between TCNT1H and OCR1H has occurred 0: Compare match between TCNT1H and OCR1H has not occurred

The timer status register H (TSRH) is an 8-bit read-only register.

This register indicates compare match of a 16-bit timer counter 1H (TCNT1H) and a compare match register (OCR1H), overflow of TCNT1H, and overflow of a 32-bit timer counter (TCNT2H).

These flags are status flags indicating overflow and compare match, and can be cleared by setting the corresponding bits of the timer status clear register H (TSCRH). If an interrupt source takes effect when this flag is set, an interrupt request is made again. An interrupt request is issued even in cases of contention between clearing by the corresponding timer status clear register and setting by an interrupt source.

When TSRH is reset, it is initialized to 00_H.

(1) OVF2H — Overflow Flag 2H

Indicates whether or not timer counter 2H (TCNT2H) has overflowed. This flag cannot be set to 1 or 0 by software.

OVF2H	Function
0	[Clearing condition] When 1 is written to OVFC2H of timer status clear register H (TSCRH) (Initial value)
1	[Setting condition] TCNT2H has overflowed (from FFFF FFFF$_H$ to 0000 0000$_H$)

Writing 0000 0000$_H$ to TCNT2H or starting TCNT2H up from the initial value (0000 0000$_H$) has no effect on this bit. When writing a value to the counter and incrementation occur simultaneously while the counter is FFFF FFFF$_H$, the overflow flag is set to 1 but the counter value is changed to the written value instead of 0000 0000$_H$.

(2) OVF1H — Overflow Flag 1H

Indicates whether or not timer counter 1H (TCNT1H) has overflowed. This flag cannot be set to 1 or 0 by software.

OVF1H	Function
0	[Clearing condition] When 1 is written to OVFC1H of timer status clear register H (TSCRH) (Initial value)
1	[Setting condition] TCNT1H has overflowed (from FFFF$_H$ to 0000$_H$)

Writing 0000$_H$ to TCNT1H or starting TCNT1H up from the initial value (0000$_H$) has no effect on this bit When writing a value to the counter and incrementation occur simultaneously while the counter is FFFF, the overflow flag is set to 1 but the counter value is changed to the written value instead of 0000 0000$_H$.

(3) CMFH — Compare Match Flag H

Indicates whether or not compare match between TCNT1H and OCR1H has occurred. This flag cannot be set to 1 or 0 by software.

CMFH	Function
0	[Clearing condition] When 1 is written to CMFCH of timer status clear register H (TSCRH) (Initial value)
1	[Setting condition] When the values in TCNT1H and OCR1H match

While CMFH is set to 1, meaning that the flag has not been cleared, the next compare match can be detected. In this case, 1 is rewritten to this bit.

21.11.2.3 TSCRH — Timer Status Clear Register H

Access: 8-bit access is possible.
Value 0 cannot be written. The value is not retained when 1 is written. These bits are always read as 0.

Address: FFE6 0103_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	OVFC2H	OVFC1H	CMFCH
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 21.148 TSCRH Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Not used. Fix these bits to 0.
2	OVFC2H	Overflow Flag Clear 2h Enable 0: Disabled (Initial value) 1: Writes 0 to OVF2H.
1	OVFC1H	Overflow Flag Clear 1h Enable 0: Disabled (Initial value) 1: Writes 0 to OVF1H.
0	CMFCH	Compare Match Flag Clear H Enable 0: Disabled (Initial value) 1: Writes 0 to CMFH.

TSCRH is an 8-bit readable/writable register, which clears flags when compare matches occur.

TSCRH is readable/writable only in 8-bit units. This register is always read as 0.

When TSCRH is reset, it is initialized to 00_H.

(1) OVFC2H — Overflow Flag Clear 2H Enable

When overflow flag 2H (OVF2H) of timer status register H (TSRH) is set to 1, writing 1 to this register clears OVF2H to 0. This register is always read as 0.

(2) OVFC1H — Overflow Flag Clear 1H Enable

When overflow flag 1H (OVF1H) of timer status register H (TSRH) is set to 1, writing 1 to this register clears OVF1H to 0. This register is always read as 0.

(3) CMFCH — Compare Match Clear H Enable

When compare match flag H (CMFH) of timer status register H (TSRH) is set to 1, writing 1 to this register clears CMFH to 0. This register is always read as 0.

21.11.2.4 TCNT1H — Timer Counter 1H

Access: 16-bit access is possible. 8-bit access is prohibited.

Address: FFE6 0104_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 21.149 TCNT1H Register Contents

Bit Position	Bit Name	Function
15 to 0	TCNT1H[15:0]	Timer Counter 1H 16-bit up-counter

TCNT1H is a 16-bit readable/writable register. 8-bit access is prohibited.

TCNT1H run when the THE bit in the ATU-IV master enable register (ATUENR) and is incremented by the clock selected in timer control register H (TCRH). Overflow flag 1H (OVF1H) in timer status register H (TSRH) is set to 1 when TCNT1H overflows (from $FFFF_H$ to 0000_H)

The value in TCNT1H is constantly compared with the value in compare match register 1H (OCR1H). When they match, the CMFH bit in TSRH is set to 1 and TCNT1H is cleared to 0000_H in the next PCLK cycle.

However, if counter clearing by compare match and incrementation occur simultaneously, TCNT1H is cleared to 0001_H. This occurs when TCNT1H is driven by the clock whose frequency is equal to the PCLK. An interrupt request can be issued to CPU by detection of a compare match.

At the same time as compare match, timer counter 2H (TCNT2H) is incremented.

When TCNT1H is reset, it is initialized to 0000_H.

21.11.2.5 OCR1H — Compare Match Register 1H

Access: 16-bit access is possible. 8-bit access is prohibited.

Address: FFE6 0106$_H$

Value after reset: FFFF$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OCR1H[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.150 OCR1H Register Contents

Bit Position	Bit Name	Function
15 to 0	OCR1H[15:0]	Timer Counter 1H These bits specify the compare match value.

OCR1H is a 16-bit readable/writable register that function as the output compare register for timer counter 1H (TCNT1H). Compare match occurs at the following cycles.

Cycle of compare match = cycle of the TCNT1H counter clock (selected in the CKSELH bit in TCRH) × value in OCR1H

TCNT2H is incremented at this cycle. An interrupt request is issued to CPU.

Do not set OCR1H to 0000$_H$. If set, compare match occurs at unwanted cycles.

When this register is reset, it is initialized to FFFF$_H$.

21.11.2.6 TCNT2H — Timer Counter 2H

Access: 32-bit access is supported. 8-bit access and 16-bit access are prohibited.

Address: FFE6 0108$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TCNT2H															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCNT2H															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.151 TCNT2H Register Contents

Bit Position	Bit Name	Function
31 to 0	TCNT2H	Timer Counter 2H These bits store the 32-bit counter value.

Timer counter 2H (TCNT2H) is a 32-bit readable/writable register. Do not write or read 16-bit or 8-bit data for this register.

This register is incremented by compare match between a 16-bit timer counter 1H (TCNT1H) and a compare match register 1H (OCR1H).

TCNT2H runs when the THE bit in the ATU-IV master enable register (ATUENR).

When TCNT2H overflowed (FFFF FFFF$_H$ → 0000 0000$_H$), the overflow flag 2H (OVF2H) in the timer status register H (TSRH) is set to 1.

When TCNT2H is reset, it is initialized to 0000 0000$_H$.

21.11.3 Operation Description

Compare match occurs and the compare match flag (CMFH) is set to 1 when a time set in the compare match register 1H (OCR1H) has elapsed. At this time, the timer counter 2H (TCNT2H) is incremented and the timer counter 1H (TCNT1H) is cleared to 0000_H.

The TCNT1H counter clock is selected by TCRH. TCNT1H and TCNT2H run when the THE bit in ATUENR is set to 1. If the THE bit is cleared to 0 while the counters are in operation, TCNT1H and TCNT2H are stopped and retain the counter value unchanged. When the THE bit is set to 1, the counters are resumed from the retained value.

A compare match of compare match register 1H (OCR1H) can issue an interrupt request to CPU.

Figure 21.73 shows an operation example of timer H. In this example, the TCNT1H counter clock is an ideal signal to show counter operation or clearing operation timing.

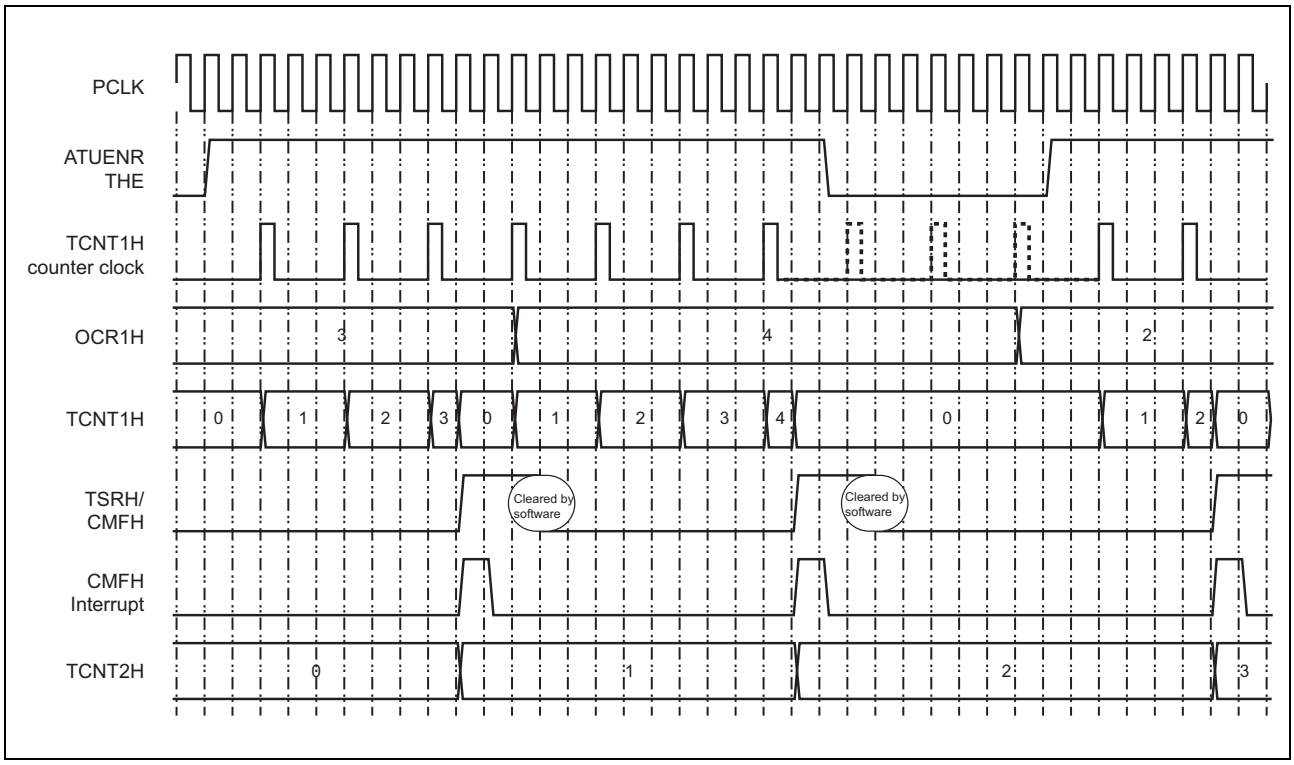

Figure 21.73 Operations of Timer H

21.12 Timer J

21.12.1 Operation Overview

The timer J block consists of 6 subblocks.

A timer J subblock counts the input clock to measure a predetermined time period repeatedly.

A 32-bit counter (TCNTJx) performs counting by a clock selected from seven clock buses. TCNTJx is cleared by the input edge of the TIJx pin. Timer J also has nine 32-bit FIFO registers which latch the value in TCNTJx every edge input. When the FIFO becomes full, DMAC activation or an interrupt request can be issued.

The validity period of the FIFO registers can be set to the period from a compare match of the compare match register (OCRJx) to the time when the FIFO registers become full.

Noise of the externally input signals (TIJx) can be removed by the input noise cancellation function.

Configuration

Timer J subblock includes one 32-bit counter (TCNTJx), one compare match register Jx (OCRJx), nine 32-bit FIFO registers, input signal controller (edge extractors and noise cancelers), and controller.

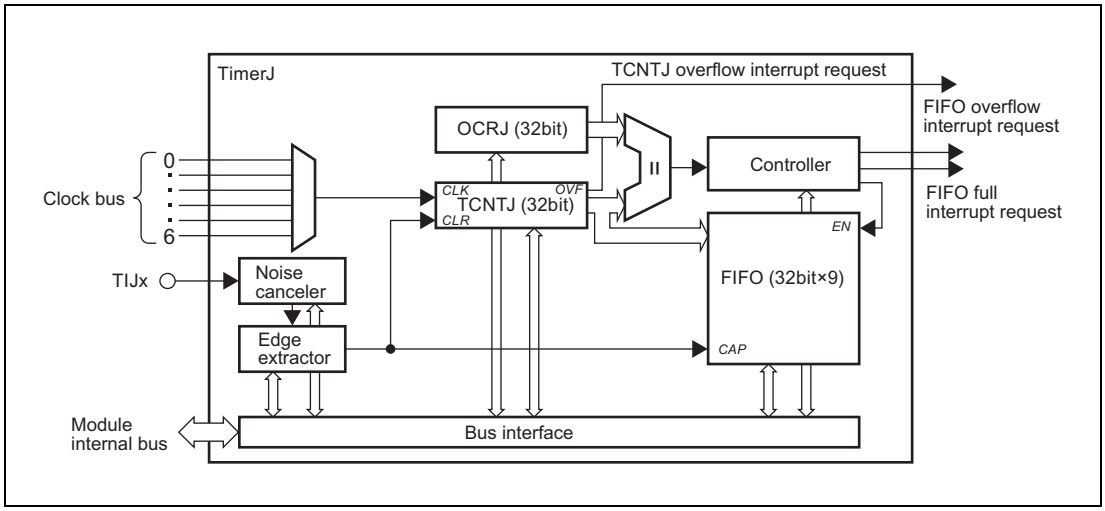

Figure 21.74 Block Diagram of Timer J

21.12.2 Registers Related to Timer J

21.12.2.1 TSTRJ — Timer Start Register J

Access: 8-bit access is possible.

Address: FFE6 3C00$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	STRJ5	STRJ4	STRJ3	STRJ2	STRJ1	STRJ0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.152 TSTRJ Register Contents

Bit Position	Bit Name	Function
7, 6	—	Not used. These bits are always read as 0. When writing, always write 0.
5 to 0	STRJ5 to STRJ0	Counter Jn Start 0: Counting of TCNTJn is stopped 1: Counting of TCNTJn is enabled

Note: x is an integer from 0 to 5.

Timer start register J (TSTRJ) is an 8-bit readable/writable register that enables and disables the subblocks (timer Jx) of timer J. Timer J counters run when the counter J start bit (STRJ) and timer J enable bit (TJE) in the ATU-IV master enable register (ATUENR) are both set to 1.

When TSTRJ is reset, it is initialized to 00$_H$.

(1) STRJx — Counter J Start

This bit specifies whether to enable or disable the timer counter Jx (TCNTJx) of timer subblock Jx.

When this bit is cleared to 0, TCNTJx stops operation. When stopped, the counter value is retained. Counting starts from the retained value when this bit is set to 1 again.

Even if the counter J start bit is set to 1, counting does not start unless the TJE bit of the ATU-IV enable register is set.

CAUTION

The prescalers run regardless of the counter J start bit and are not synchronized with the timing at which the TCNTJx is started. Therefore, the time from when the THE bit is set to when TCNTJx is incremented for the first time is less than the cycle of the clock of TCNTJx.

21.12.2.2 TCRJx — Timer Control Registers Jx

(x = 0, 1, 2, 3, 4, 5: Corresponding to subblocks J0 to J5)

Access: 8-bit access is possible.

Address: FFE6 3C20$_H$ + (20$_H$ * x)

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	CKSELJx[2:0]			—	NCEJx	IOJx	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Table 21.153 TCRJx Register Contents

Bit Position	Bit Name	Function
7, 3	—	Not used. These bits are always read as 0. When writing, always write 0.
6 to 4	CKSELJx	Clock Select Jx Specify the clock source of the timer counter Jx (TCNTJx). 000: Clock bus 0 001: Clock bus 1 010: Clock bus 2 011: Clock bus 3 100: Clock bus 4 101: Clock bus 5 110: Clock bus 6 111: Reserved
2	NCEJx	Noise Canceler Enable Jx 0: Disables the noise canceler of the TIJx input. 1: Enables the noise canceler of the TIJx input.
1, 0	IOJx	I/O Control Jx 00: Input capture of TIJx is disabled. 01: Input capture is made with TIJx rises. 10: Input capture is made with TIJx falls. 11: Input capture is made with TIJx rises and falls.

Timer control registers Jx (TCRJx) are 8-bit readable/writable registers that select operation modes of each subblock (timer Jx).

When TCRJ is reset, it is initialized to 00$_H$.

(1) CKSELJx — Clock Select Jx

These bits select the clock source of timer counter Jx (TCNTJx) of subblock. Setting these bits to a value from 000 to 110 selects a clock source from clock bus 0 to clock bus 6. However, do not set to 111. If set, operation cannot guaranteed.

(2) NCEJx — Noise Canceler Enable Jx

These bits enable and disable the noise cancelers for externally input signals (TIJx)

If a level change of external input TIJx is detected after this bit is set to 1, the setting of the noise cancel mode register (NCMR) of the common controller determines the operation mode to be started from the following modes: premature-transition cancellation mode, minimum time-at-level cancellation mode, and level accumulation cancellation mode.

- In premature-transition cancellation mode

When a level change of the externally input signal is detected, the change is output as the signal whose noise is removed and the corresponding noise canceler counter Jx (NCNTJx) is started for counting up. Subsequent level changes are masked until the value in the counter reaches the value in the noise canceler register Jx (NCRJx). The level of the externally input signal is output on this compare match.

When these bits are cleared to 0 while the counter (NCNTJx) is being incremented, counting continues until the values in the counter and the noise canceler register match. The subsequent level changes are also masked over this period.

- In minimum time-at-level cancellation mode

When a level change of the externally input signal is detected, the corresponding noise canceler counter Jx (NCNTJx) is started for counting up. If subsequent level changes are not detected until the value in the counter reaches the value in the noise canceler register Jx (NCRJx), the previously accepted level change is output as the signal whose noise is removed on compare match of the counter and noise canceler register. When the subsequent level change is detected before the values in the counter and noise canceler register match, all the changes are treated as noise. Therefore the signal whose noise is removed is not changed.

When these bits are cleared to 0 while the counter Jx (NCNTJx) is being incremented, counting continues until the values in the counter and the noise canceler register match or a level change on the externally input signal is detected.

In level accumulation cancellation mode, the input signal level determines the up/down counting of the corresponding noise cancel counters Jx (NCNTJx). Up-counting is made with high-level input, down-counting is made with low-level input. Up-count continues until a compare match between the noise cancel counter and noise cancel register Jx (NCRJx), and down-count continues until the noise cancel counter matches $*0000_H$. If an up-count results in a compare match (NCRJx), the noise canceler output is updated to 1. If a down-count results in a compare match (0000_H), the noise canceler output is updated to 0.

In minimum time-at-level cancellation mode and premature-transition cancellation mode, level change detection is always made by P regardless of the selected noise cancel clock. In level accumulation cancellation mode, the sampling of the input level is made by the noise canceler clock.

For details on operations in each mode, see **Figure 21.1, Figure 21.2** and **Figure 21.3**.

(3) IOJx — I/O Control Jx

These bits select edges to be detected for input capture triggers. When these bits are set to 00, input capture is not made. When they are set to 01, 10, or 11, detection of the selected edge transfers the value of timer counter Jx (TCNTJx) to the corresponding FIFO register Jx (FIFOJx).

Edges are extracted from the signal after noise removal.

When the noise canceler is disabled, the selected edge is simply extracted from the external inputs (TIJx). When the noise canceler is enabled, the selected edge is extracted from the signals after noise removal.

Edge extraction is synchronized with the PCLK. Make sure that the frequency of the PCLK is at least twice the frequency of the external input signal. Otherwise, edge extraction will not be performed correctly.

21.12.2.3 FCRJx — FIFO Control Registers Jx

(x = 0, 1, 2, 3, 4, 5: Corresponding to subblocks J0 to J5)

Access: 8-bit access is possible.

Address: FFE6 3C21$_H$ + (20$_H$ * x)

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	FIFOENJx	—	FVCRENJx	FRSTJx	—	—	FDFTRGJx	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R/W	R/W*1	R	R	R/W	R/W

Note 1. Value 0 cannot be written. The value is not retained when 1 is written. These bits are always read as 0.

Table 21.154 FCRJx Register Contents

Bit Position	Bit Name	Function
6, 3, 2	—	Not used. These bits are always read as 0. When writing, always write 0.
7	FIFOENJx	FIFO Register Enable Jn Enables and disables FIFO register Jx (FIFOJx) 0: FIFO Jx is disabled 1: FIFO Jx is enabled
5	FVCRENJx	FIFO Enable Control Enable Jx Specifies whether to control the enabled period of FIFO registers. 0: FIFO is not enabled on OCRJx compare match 1: FIFO is enabled until it becomes full after OCRJx compare match
4	FRSTJx	FIFO Data Register Reset Jx Invalidates the data in the FIFO register, and resets it to the idle state. 0: No operation 1: FIFO is reset
1, 0	FDFTRGJx	FIFO Data Full Trigger Jx Specifies the number of data items that determines the setting of FDFFJx of the timer J status register. 00: 9 01: 6 10: 4 11: 2

FIFO control registers Jx (FCRJx) are 8-bit readable/writable registers that control FIFO of each subblock (timer J0 and timer J1). When FCRJx is reset, it is initialized to 00$_H$.

(1) FIFOENJx — FIFO Register Enable Jx

Enables and disables FIFO register Jx (FIFOJx) in subblocks J0 and J1. When this bit is set to 1 and the FIFO is disabled, even if an edge is input on pin TIJx, the value in TCNTJx is not latched in FIFO. However when FVCRENJx is set to 1, even if this bit (FIFOENJx) is 0, the value in TCNTJx is latched in the FIFO every input edge until FIFO becomes full (data count that fills FIFO full by the FDFTRGJx bit can be set) after compare match on OCRJx. When FVCRENJx = 1 and FIFOENJx = 1, the setting of FIFOENJx takes precedence.

(2) FVCRENJx — FIFO Enable Control Enable Jx

When FIFOENJx = 1 and FIFOENJx = 0, the FIFO is temporarily enabled until it becomes full (the threshold level can be set by FDFTRGJx) after compare match between timer counter Jx (TCNTJx) and compare match register Jx (OCRJx). Note that the FIFO is always enabled regardless of this bit when bit FIFOENJx is set to 1.

(3) FRSTJx — FIFO Data Register Reset Jx

When FRSTJx is set to 1, data capture by the FIFO buffer is disabled, after which the FIFO buffer is emptied and FDNRJx is reset while the FIFO is empty. However, the FDFFJx and FDOVFJx flags which have been set to 1 are not cleared. And the TSRJx.FVLDFJx is not also cleared.

(4) FDFTRGJx — FIFO Data Full Trigger Jx

These bits set the number of data words which is the threshold for setting the FDFFJx flag in the timer J status register Jx (TSRJx). When the FIFO is enabled and the number of data words in it has reached the trigger count, the FDFFJx bit is set to 1. When the FIFO is enabled on compare match between TCNTJx and OCRJx while FIFOENJx = 0 and FVCRENJx = 1, and then the number of data words has reached the trigger count, the FIFO is disabled.

CAUTION

When setting FCRJx to 20_H, read 9 captured values from the FIFOJx register during FIFO full interrupt handling, then reset the FIFO register (by writing 1 to the FRSTJx bit of the register) and clear the FIFO full interrupt request flag to 0*.

*** The procedure for clearing the FIFO full interrupt request flag to 0 is described below.**

1. **Write 0 to the FIFO full interrupt request flag of the interrupt controller (EIRFx bit in the EICx register).**
2. **Dummy-read the above register.**
3. **Execute an SYNCP instruction.**

21.12.2.4 TSRJx — Timer Status Register Jx

(x = 0, 1, 2, 3, 4, 5: Corresponding to subblocks J0 to J5)

Access: 8-bit access is possible.

Address: FFE6 3C22$_H$ + (20$_H$ * x)

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	FVLDFJx	CMFJx	OVFJx	FDOVFJx	FDFFJx
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.155 TSRJx Register Contents

Bit Position	Bit Name	Function
7 to 5	—	Not used. Fix these bits to 0.
4	FVLDFJx	FIFO Status Flag Jx 0: FIFO is not enabled 1: FIFO is enabled
3	CMFJx	Compare Match Flag Jx 0: Compare match between OCRJx and TCNTJx has not occurred 1: Compare match between OCRJx and TCNTJx has occurred
2	OVFJx	Overflow Flag Jx 0: TCNTJn has not overflowed 1: TCNTJn has overflowed
1	FDOVFJx	FIFO Data Overflow Flag Jx 0: Data in the FIFO is normal 1: Another capture has occurred while nine words of data was in the FIFO
0	FDFFJx	FIFO Data Full Flag Jx 0: Number of data words in FIFO is less than the value in FDFTRGJn 1: Number of data words in FIFO is equal to or exceeds the value in FDFTRGJn

Timer status registers Jx (TSRJx) are 8-bit readable/writable registers that indicate occurrence of overflow on timer counter Jx (TCNTJx), and compare match on compare register Jn (OCRJx). In addition, there are flags that indicate that the FIFO has overflowed and the number of data in the FIFO exceeds the trigger count.

The FIFO status flag and the compare match flag are status flags that indicate the status of FIFO and occurrence of timer compare matches. It does not generate interrupts. The overflow flag, FIFO data overflow flag, and FIFO data full flag are status flags for occurrence of interrupt requests. Setting a bit of the timer status clear register Jx (TSCRJx) clears the corresponding flag. If an interrupt source takes effect when this flag is set, an interrupt request is made again. An interrupt request is issued even in cases of contention between clearing by the corresponding timer status clear register and setting by an interrupt source.

When TSRJ is reset, it is initialized to 00$_H$.

(1) FVLDFJx — FIFO Status Flag Jx

Indicates whether the FIFO is enabled or disabled. This bit cannot be set or cleared by software.

When this bit is 1, the corresponding FIFO register Jx (FIFOJx) is enabled. The value in TCNTJx is latched in the FIFO on the edge of the TIJx pin.

When FIFOENJx = 1, this bit is always set to 1. When FIFOENJx = 0 and FVCRENJx = 1, FVLDFJx becomes 1 on compare match between TCNTJx and OCRJx. When the FIFO becomes full (matches the number of data set by FDFTRGJx), FVLDFJx is cleared to 0. When FIFOENJx = 0 and FVCRENJx = 0, this bit is always 0.

- Setting conditions

1. When FIFOENJx is set to 1
2. When FIFOENJx is 0, FVCRENJx is 1, and OCRJx compare match occurred

- Clearing conditions

1. When FIFOENJx is cleared to 0
2. When FIFOENJx is 0, FVCRENJx is 1, and the number of data words in FIFO exceeds the value set in FDFTRGJx

(2) CMFJx — Compare Match Flag Jx

Indicates that compare match between TCNTJx and OCRJx has occurred. When this bit is 1, compare match on compare match register Jx (OCRJx) has occurred. This bit cannot be set to 1 or 0 by software.

- Setting condition
  When the values in TCNTJx and OCRJx match
- Clearing condition
  When 1 is written to CMFCJx of timer status clear register Jx (TSCRJx).

(3) OVFJx — Overflow Flag Jx

Indicates that timer counter Jx (TCNTJx) has overflowed. When this bit is 1, timer counter Jx (TCNTJx) has overflowed. This bit cannot be set to 1 or 0 by software.

- Setting condition
  When TCNTJx has overflowed (from FFFF $FFFF_H$ to 0000 0000_H)
- Clearing condition
  When 1 is written to OVFCJx of the timer status clear register Jx (TSCRJx).

(4) FDOVFJx — FIFO Data Overflow Flag Jx

Indicates that another capture has occurred while nine words of data was in the FIFO. When this bit is 1, FIFOJx has overflowed and captured data is lost. This bit cannot be set to 1 or 0 by software.

- Setting condition
  When another capture has occurred while nine words of data was in the FIFO
- Clearing condition
  When 1 is written to FDOVFCJx of the timer status clear register Jx (TSCRJx).

(5) FDFFJx — FIFO Data Full Flag Jx

Indicates that the number of data words (TCNTJx counter values) captured in the FIFO is equal to or exceeds the value set in the FDFTRGJn bits in the FIFO control register Jx (FCRJx).

When this bit is 1, the number of data words captured in the FIFO is equal to or exceeds the set value and the captured data is ready to be read.

This bit cannot be set to 0 or 1 by software.

- Setting condition
  When the number of data words in FIFO has reached the value in FTRGJx
- Clearing condition
  When 1 is written to FDDFFCJx of the timer status clear register Jx (TSCRJx).
  However, the data in FIFOJn must be read to make the number of data words in the FIFO less than the value set in the FDFTRGJn bits.

21.12.2.5 TSCRJx — Timer Status Clear Register Jx

(x = 0, 1, 2, 3, 4, 5: Corresponding to subblocks J0 to J5)

Access: 8-bit access is possible.
Value 0 cannot be written. The value is not retained when 1 is written. These bits are always read as 0.

Address: FFE6 $3C23_H$ + (20_H * x)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	CMFCJx	OVFCJx	FDOVFCJx	FDFFCJx
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 21.156 TSCRJx Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Not used. Fix these bits to 0.
3	CMFCJx	Compare Match Flag Clear Jx Enable 0: Disabled (Initial value) 1: Writes 0 to CMFJx
2	OVFCJx	Overflow Flag Clear Jx Enable 0: Disabled (Initial value) 1: Writes 0 to OVFJx
1	FDOVFCJx	FIFO Overflow Flag Clear Jx Enable 0: Disabled (Initial value) 1: Writes 0 to FDOVFJx.
0	FDFFCJx	FIFO Table Full Flag Clear Jx Enable 0: Disabled (Initial value) 1: Writes 0 to FDFFJx.

Timer status clear register Jx (TSCRJx) is an 8-bit readable/writable register that specifies clearing of flags upon occurrence of compare match, overflow, overflow of FIFO registers, and data full.

TSCRJx is readable/writable only in 8-bit units. This register is always read as 0.

When TSCRJx is reset, it is initialized to 00_H.

(1) CMFCJx — Compare Match Flag Clear Jx Enable

When compare match flag Jx (CMFJx) of the timer status register Jx (TSRJx) is set to 1, writing 1 to this register clears CMFJx to 0. This register is always read as 0.

(2) OVFCJx — Overflow Flag Clear Jx Enable

When overflow flag Jx (OVFJx) of the timer status register Jx (TSRJx) is set to 1, writing 1 to this register clears OVFJx to 0. This register is always read as 0.

(3) FDOVFCJx — FIFO Overflow Flag Clear Jx Enable

When FIFO overflow flag Jx (FDOVFJx) of the timer status register Jx (TSRJx) is set to 1, writing 1 to this register clears FDOVFJx to 0. This register is always read as 0.

(4) FDFFCJx — FIFO Table Full Flag Clear Jx Enable

When FIFO data full flag Gx (FDFFJx) of the timer status register Jx (TSRJx) is set to 1, writing 1 to this register clears FDFFJx to 0. By reading data captured in FIFOJx, the data saved in the FIFO register must be made less than the amount specified by the FDFTRGJx bit.

21.12.2.6 TCNTJx — Timer Counter Jx

(x = 0, 1, 2, 3, 4, 5: Corresponding to subblocks J0 to J5)

Access: 32-bit access is possible. 8-bit access and 16-bit access are prohibited.

Address: FFE6 3C24$_H$ + (20$_H$ * x)

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.157 TCNTJx Register Contents

Bit Position	Bit Name	Function
31 to 0	TCNTJx	Timer Counter Jx These bits store the up-counter value.

Timer counters Jx (TCNTJx) are 32-bit readable/writable registers. These registers are provided one for each subblock and when the STRJx bit in the TSTRJ register is 1, these registers are incremented by the clock selected from lines 0 to 6 of the clock bus depending on the control register. The counter value is cleared to 0000 0000$_H$ by the edge of pin TIJx. Only when contention between clearing by the edge input of pin TIJx and timing of count-up occurs, TCNTJx is cleared to 0000 0001$_H$.

An overflow interrupt request can be issued to CPU when the timer counter overflows.

When TCNTJx are reset, they are initialized to 0000 0000$_H$.

21.12.2.7 OCRJx — Compare Match Registers Jx

(x = 0, 1, 2, 3, 4, 5: Corresponding to subblocks J0 to J5)

Access: 32-bit access is possible. 8-bit access and 16-bit access are prohibited.

Address: FFE6 $3C28_H$ + (20_H * x)

Value after reset: $FFFF\ FFFF_H$

Table 21.158 OCRJx Register Contents

Bit Position	Bit Name	Function
31 to 0	OCRJx	Compare Match Jx These bits store the compare match value.

Compare match registers OCRJx are 32-bit readable/writable registers. These registers are provided one for each subblock and function as output compare registers for timer counter Jx (TCNTJx).

When OCRJ0 to OCRJ5 are reset, they are initialized to $FFFF\ FFFF_H$.

When FIFOENJx and FVCRENJx in FIFO control register Jx (FCRJx) is 0 and 1, and STRJx bit in the TSTRJ register is 1, respectively, the FIFO is enabled (FVLDFJx is set to 1) on TCNTJx and OCRJx compare match.

21.12.2.8 FIFOJx — FIFO Registers Jx

(x = 0, 1, 2, 3, 4, 5: Corresponding to subblocks J0 to J5)

Access: 32-bit access is possible. 8-bit access and 16-bit access are prohibited.

Address: FFE6 3C2C$_H$ + (20$_H$ * x)

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.159 FIFOJx Register Contents

Bit Position	Bit Name	Function
31 to 0	FIFODJx	FIFO Data Jn These bits store the FIFO register data.

FIFO registers Jx (FIFOJx) are 32-bit read-only registers. These register are provided one for each subblock and can store nine words of data of timer counter Jx (TCNTJx). FIFOJx can be read but cannot be written by the CPU. If FIFOJx in which no data is captured is read, the read value is undefined.

If FIFO registers hold nine pieces of capture data (when FDNRJx is 9), an occurrence of capture can issue an interrupt request of FIFO data overflow to CPU. At this time, the new captured data is lost. If another capture occurs while nine words of data is captured in the FIFO, the latest data is lost. Secure the free area by reading the FIFO before another capture has occurred (FDNRJx is equal to or less than 9).

21.12.2.9 FDNRJx — FIFO Data Count Registers Jx

(x = 0, 1, 2, 3, 4, 5: Corresponding to subblocks J0 to J5)

Access: 8-bit access is possible.

Address: FFE6 3C30$_H$ + (20$_H$ * x)

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	FDNJx			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.160 FDNRJx Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Not used. Fix these bits to 0.
3 to 0	FDNJx	FIFO Data Count Jx These bits indicate the number of data words captured in the FIFO. The value ranges from 0$_H$ to 9$_H$. 0$_H$ indicates no data is in the FIFO and 9$_H$ indicates that FIFOJx is full with the captured data.

Note 1. This register is a read-only register. Writing to this register is ignored.

FIFO data count registers Jx (FDNRJx) are 8-bit read-only registers. These registers are provided one for each subblock and indicate the number of data words in FIFOJx which stores captured data. This register cannot be written to.

This register is incremented by 1 every capture in FIFO and is decremented by 1 every read from FIFO (one-data read).

When the FIFO is reset by the FRSTJx bit in FIFO control register Jx (FCRJx), the value in this register is also cleared to 0$_H$.

21.12.2.10 NCNTJx — Noise Canceler Counters Jx

(x = 0, 1, 2, 3, 4, 5: Corresponding to subblocks J0 to J5)

Access: 16-bit access is possible. 8-bit access is prohibited.

Address: FFE6 $3C34_H$ + (20_H * x)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NCNTJx															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.161 NCNTJx Register Contents

Bit Position	Bit Name	Function
15 to 0	NCNTJx	Noise Canceler Counter Jx These bits store the 16-bit counter value.

Noise cancel counters Jx (NCNTJx) are 16-bit readable/writable registers.

These registers are incremented by an assertion of the input signals (TIJx) as triggers when the noise canceler function is enabled by the noise canceler enable bits (NCEJx) in timer control register Jx (TCRJx). These registers are driven by the noise canceler counter clock, which is supplied by the prescaler. In level accumulation cancellation mode, up/down counting is performed based on the external input level.

NCNTJx is readable/writable only in 16-bit units. When NCNTJx is reset, it is initialized to 0000_H. One of the three different operation modes, which are premature-transition cancellation mode, minimum time-at-level cancellation mode, and level accumulation cancellation mode, takes place depending on the setting of the noise cancel mode selection bit (NCMSEL) and timer J noise cancel mode bit (NCMF) of the noise cancel mode register (NCMR) of the common controller.

- In premature-transition cancellation mode
  When the NCEJx bit is 1, NCNTJx is stopped, and a level change on pin TIJx is detected, NCNTJx is started for counting up. The counter is cleared to 0000_H and stopped on the first edge of the PCLK after the counter value matches the value in noise canceler register Jx (NCRJx). NCNTJx is incremented regardless of the TJE bit in the ATU-IV master enable register (ATUENR).
  The level change at the start of counting is output as the signal after noise removal and its edge is to be extracted. However, since subsequent level changes are masked, the noise removal signal is not changed. When the values in the counter and NCRJx match, the input signal level at this time is output as the noise removal signal.
  When NCEJx bits are cleared to 0 while the counter is being incremented, counting continues until the values in the counter and the noise canceler register match. The subsequent level changes are also masked over this period.

- In minimum time-at-level cancellation mode
  When the NCEJx bit is 1, NCNTJx is stopped, and a level change on pin TIJx is detected, NCNTJx is started for counting up. If subsequent level change is detected or the values in the counter and the noise canceler register Jx (NCRJx) match, the counter is cleared to 0000_H and stopped on the next PCLK cycle.
  NCNTJx is incremented regardless of the TJE bit in the ATU-IV master enable register (ATUENR).
  The signal after noise removal is changed only on compare match between the counter and NCRJx in synchronization with the level change at the start of counting. When the counter is stopped before the compare match, level changes at the start and stop of counting are masked and the signal after noise removal is not changed.
  When the NCEJx bit is cleared during the counter in operation, counting continues until compare match or a level change on the pin is detected.

- Level accumulation cancellation mode
  When the NCEJx bit is set to 1, NCNTJx performs up or down counting depending on the input signal level. Up-counting is performed when the input level is high, and if the counter value coincides with noise cancel register Jx (NCRJx), the up-counting stops at the next PCLK cycle. Down-counting is performed when the input level is low, and if the counter value coincides with 0000_H, the down-counting stops at the next PCLK cycle.
  Counting of NCNTJx is performed regardless of the setting of the TJE bit of the ATU-IV master enable register (ATUENR).
  If an up-count results in a compare match of NCRJx, the noise canceler output is updated to 1. If a down-count results in a compare match with 0000_H, the noise canceler output is updated to 0.
  If the NCEJx bit is cleared during counting operation, the noise cancel counter stops counting, and the value is changed from the noise canceler output to the current input signal level.
  Be noted that clearing the NCEJx bit in level accumulation cancellation mode might cause an edge detection due to this value change.

21.12.2.11 NCRJx — Noise Cancel Registers Jx

(x = 0, 1, 2, 3, 4, 5: Corresponding to subblocks J0 to J5)

Access: 16-bit access is supported. 8-bit access is prohibited.

Address: FFE6 $3C36_H$ + (20_H * x)

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NCTJx															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.162 NCRJx Register Contents

Bit Position	Bit Name	Function
15 to 0	NCTJx	Noise Cancellation Time Jn These bits store the 16-bit TIJx noise cancellation time.

Noise cancel registers Jx (NCRJx) are 8-bit readable/writable registers that set the upper limitation of the noise cancel counters Jx (NCNTJx). When a period of 128 PCLK cycles is selected as the noise cancel clock, setting of $FFFF_H$ can cancel noise for maximum of 0.21 second period (when PCLK = 40 MHz).

One of the three different operation modes, which are premature-transition cancellation mode, minimum time-at-level cancellation mode, and level accumulation cancellation mode, takes place depending on the setting of the noise cancel mode selection bit (NCMSEL) and timer J noise cancel mode bit (NCMF) of the noise cancel mode register (NCMR) of the common controller.

- Premature-transition cancellation mode
  While NCNTJx counting is in progress, level changes of succeeding input signals are masked. Values of NCNTJx and NCRJx are always compared. If a compare match occurs, the NCNTJx counter value is cleared, the counting is stopped, and the input signal mask is removed at the next PCLK cycle.
- Minimum time-at-level cancellation mode
  While NCNTJx counting is in progress, the noise canceler processing is waited for. Values of NCNTJx and NCRJx are always compared. If a compare match occurs, the NCNTJx counter value is cleared, the counting is stopped, and the noise canceler starts to output noise-canceled signals at the next PCLK cycle.
- Level accumulation cancellation mode
  When up-counting of NCNTJ1 and NCNTJ0 is in progress, values of NCNTJx and NCRJx are compared. When a compare match occurs, the up-counting of NCNTJx stops at the next PCLK cycle. When NCNTJx down-counting is in progress, NCNTJx is compared with 0000_H.

NCRJx is readable/writable only in 16-bit units.

When NCRJx is reset, it is initialized to 0000_H.

21.12.3 Operation description

The TCNTJx counter clock is selected by the TCRJx register from the clock-bus lines. When the TJE bit in ATUENR and the STRJx bit in TSTR is set to 1, TCNTJx can be operated. TCNTJx is cleared to 0000 0000_H by the input edge of pin TIJx. Only when contention between clearing by the edge input of pin TIJx and count-up timing occurs, TCNTJx is cleared to 0000 0001_H.

For the edge detection, the rising, falling, or both edge sensing can be selected by the IOJx bit in TCRJx.

When the FIFOEN bit in FCRFJx is set to 1, FIFOJx captures the TCNTJx counter value by the input edge of pin TIJx. The number of data captured in the FIFO is indicated in FDNRx.

When FIFOJx has taken data in a quantity equal to or larger than the number of data set in the FDFTRGJx bit of FCRJx, a FIFO data full interrupt request to CPU and a DMA transfer request to DMAC can be issued. FDFFJx of TSRJx is set to 1.

When FIFOENJx = 0, FVCRENJx = 1, and compare match between TCNTJx and OCRJn occurs, FIFOJx is enabled (FVLDFJx in TSRJx is 1). Under these conditions, when the number of data captured in FIFOJx exceeds the value set in the FDFTRGJx bits in FCRJx, FIFOJx is disabled.

Operation examples for subblock 0 are shown below. The TCNTJ0 counter clock is an ideal signal to show the counting and clearing timing of TCNTJ0.

In **Figure 21.75**, falling edge sensing is selected, FIFOEN = 1, FDFTRGJx = 11_B, and FDFFJx is set by the input edge.

In **Figure 21.76**, falling edge sensing is selected, FIFOEN = 0, FVCRENJx = 1, FDFTRGJx = 00_B and FDFFx is set by the input edge.

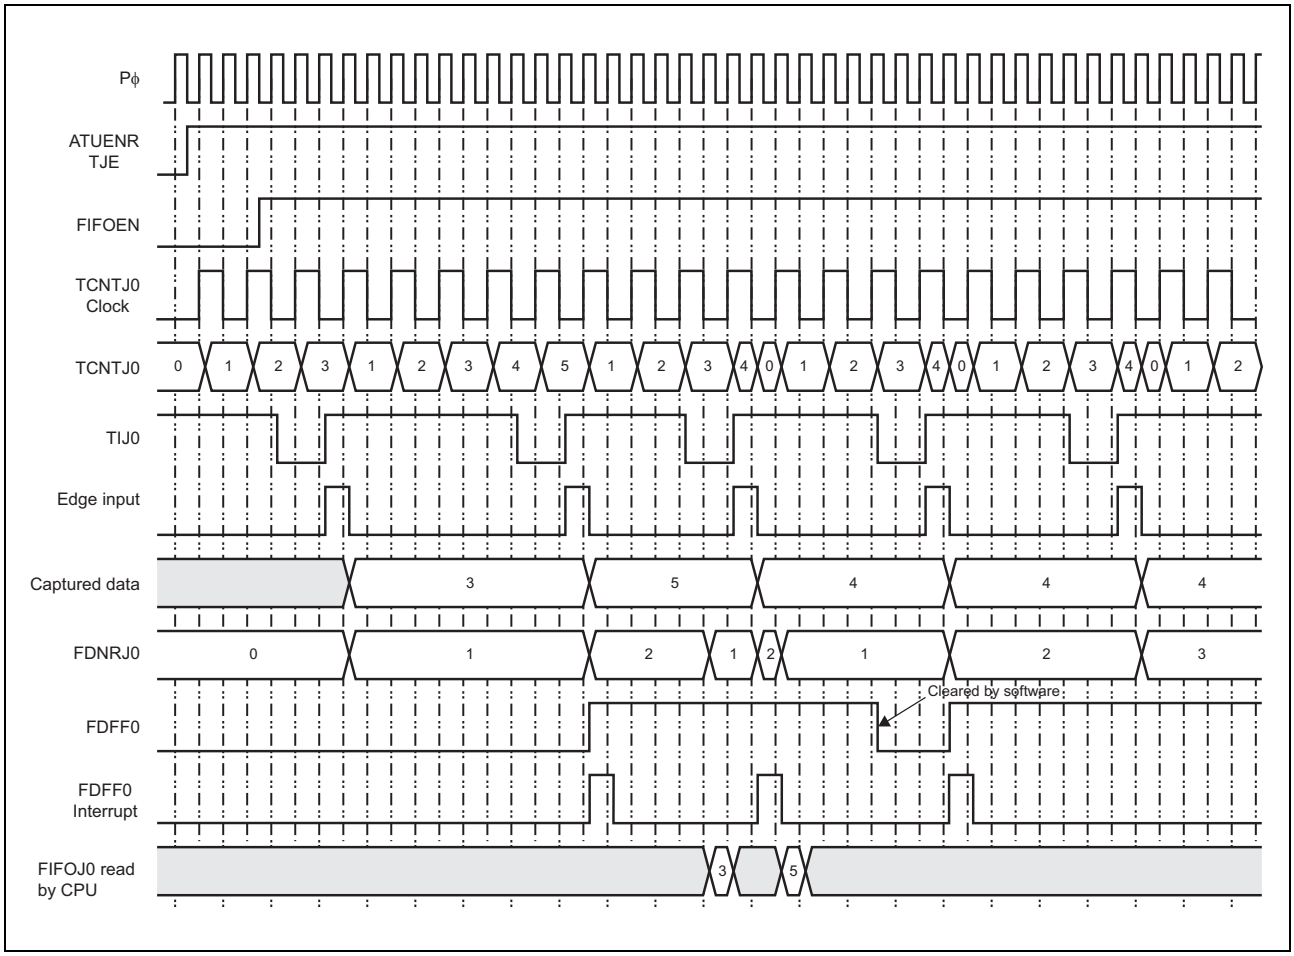

Figure 21.75 Operation Example of Timer J (1)

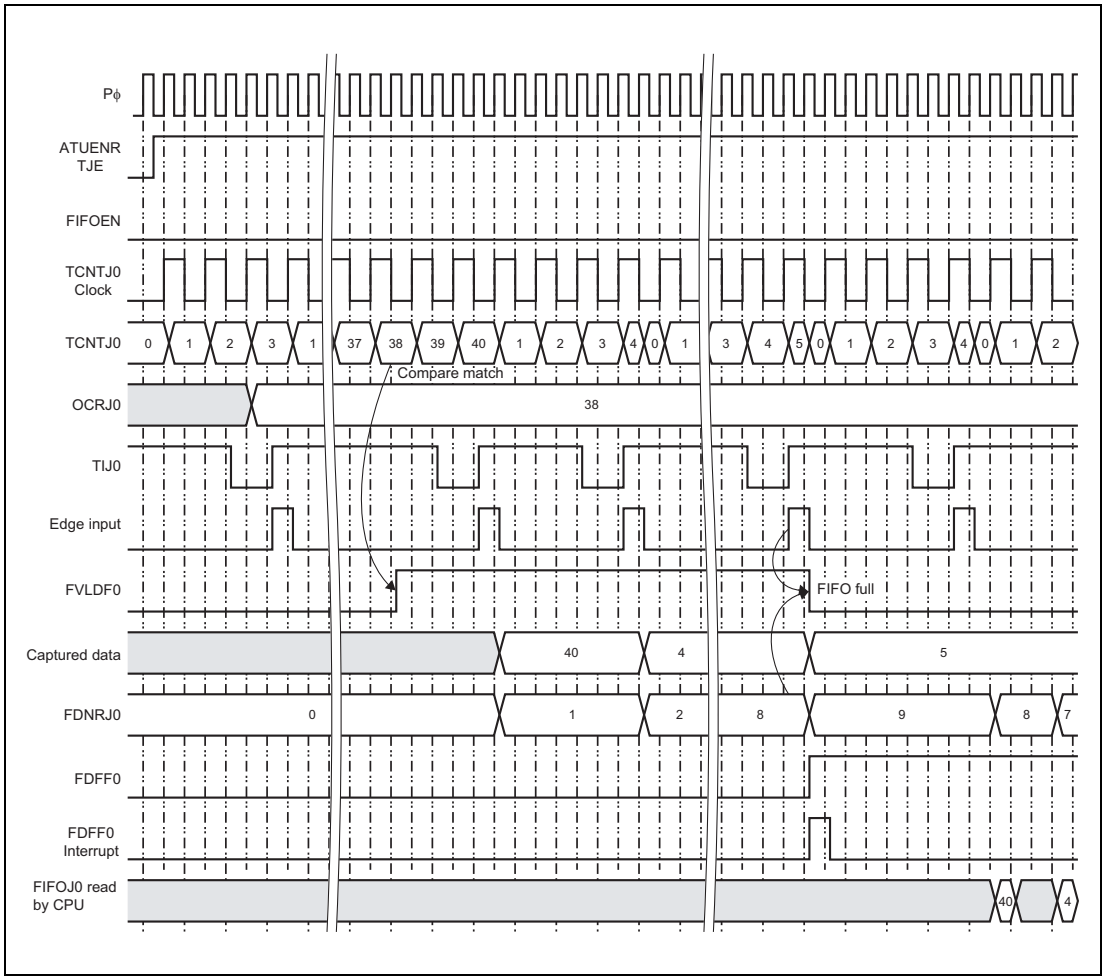

Figure 21.76 Operation Example of Timer J (2)

21.13 Automatic Switching of DMA and AD Requests

21.13.1 Overview of Operation

This function controls trigger signals to be output to DMA and SAR-AD. There are three trigger signals (data DMA trigger, count DMA trigger, and SAR-AD trigger signals) described below.

(1) DMA trigger for data — Data DMA trigger

Data DMA trigger signals include AD skipping DMA transfer request 0 and AD skipping DMA transfer request 1.

The data DMA trigger can be selected from AGCK1 from timer B, timer G sub-block G1, G2 compare interrupt output (timer G1 compare interrupt or timer G2 compare interrupt), DFE filter completion signal, ADC0 scan group 0 to 4 end interrupt (ADC0 scan group 0 end interrupt, ADC0 scan group 1 end interrupt, ADC0 scan group 2 end interrupt, ADC0 scan group 3 end interrupt, or ADC0 scan group 4 end interrupt), and output stop. One of the two data DMA trigger signals is output, and the DMA output to output the trigger is switched at the comparison timing of TCNT1D0 and OCR1D00 of timer D.

(2) DMA trigger for the number of times — Count DMA trigger

Count DMA trigger signals include AD skipping DMA transfer request 2 and AD skipping DMA transfer request 3.

The count DMA trigger can be selected from AGCK of timer A, timer G sub-block G3 compare interrupt output (timer G3 compare interrupt), and output stop. One of the two count DMA trigger signals is output, and the DMA output to output the trigger is switched at the comparison timing of TCNT1D0 and OCR1D00 of timer D.

(3) SAR-AD trigger

SAR-AD trigger signals include the SAR-AD trigger.

The SAR-AD trigger can be selected from AGCK1 from timer B, timer G sub-block G1, G2 compare interrupt output (timer G1 compare interrupt or timer G2 compare interrupt), and output stop.

21.13.2 DMA/AD Requests Auto-Switching Registers

21.13.2.1 TRGSRDMA0 — Trigger Status Register DMA0

Access: 8-bit accessible, but 16-bit/32-bit inaccessible

Address: FFE6 $00C0_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OUTSRDMA0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.163 TRGSRDMA0 Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Not used
0	OUTSRDMA0	0: AD skipping DMA transfer request 0 is selected 1: AD skipping DMA transfer request 1 is selected

Trigger status register DMA0 is an 8-bit read-only register that indicates the selected request: data AD skipping DMA transfer request 0 or AD skipping DMA transfer request 1.

21.13.2.2 TRGSELDMA00 — Trigger Select Register DMA00

Access: 8-bit accessible, but 16-bit/32-bit inaccessible

Address: FFE6 00C4$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	INSELDMA00			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 21.164 TRGSELDMA00 Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Not used
3 to 0	INSELDMA00	0000: Output stop (output is fixed to 0) 0001: AGCK1 is selected. 0010: Timer G sub-block G1 compare interrupt signal (CMFG1 interrupt) is selected. 0011: Timer G sub-block G2 compare interrupt signal (CMFG2 interrupt) is selected. 0100: DFE filter completion signal is selected. 0101: Setting prohibited 0110: Setting prohibited 0111: Setting prohibited 1000: ADC0 scan group 0 end interrupt is selected. 1001: ADC0 scan group 1 end interrupt is selected. 1010: ADC0 scan group 2 end interrupt is selected. 1011: ADC0 scan group 3 end interrupt is selected. 1100: ADC0 scan group 4 end interrupt is selected. 1101: Setting prohibited 1110: Setting prohibited 1111: Setting prohibited

This register is an 8-bit readable/writable register that selects the signal to be output to the data AD skipping DMA transfer request 0. This register can be modified during operation. The settings are valid immediately after this register is modified.

21.13.2.3 TRGSELDMA01 — Trigger Select Register DMA01

Access: 8-bit accessible, but 16-bit/32-bit inaccessible

Address: FFE6 00C6$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	INSELDMA01			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 21.165 TRGSELDMA01 Register Contents

Bit Position	Bit Name	Function

1, 0	INSELDMA11	00: Output stop (output is fixed to 0) 01: AGCK is selected. 10: Timer G sub-block G3 compare interrupt signal (CMFG3 interrupt) is selected. 11: Setting prohibited

This register is an 8-bit readable/writable register that selects the signal to be output to the count AD skipping DMA transfer request 3. This register can be modified during operation. The settings are valid immediately after this register is modified.

21.13.3 Details of Operation

The following describes the operation and block diagram of each trigger.

21.13.3.1 Data DMA Trigger

Figure 21.77 shows the data DMA trigger selection circuit.

The signal to be output to the data DMA trigger output pin (AD skipping DMA transfer request 0) is selected by the INSELDMA00[3:0] bits in TRGSELDMA00.

The signal to be output to the data DMA trigger output pin (AD skipping DMA transfer request 1) is selected by the INSELDMA01[3:0] bits in TRGSELDMA01.

The data DMA trigger output pin outputs only AD skipping DMA transfer request 0 when the DMA select signal is low, and only AD skipping DMA transfer request 1 when the DMA select signal is high. Since ADC0 scan group 0 end interrupt to ADC0 scan group 4 end interrupt are asynchronous input signals, a synchronization circuit is provided.

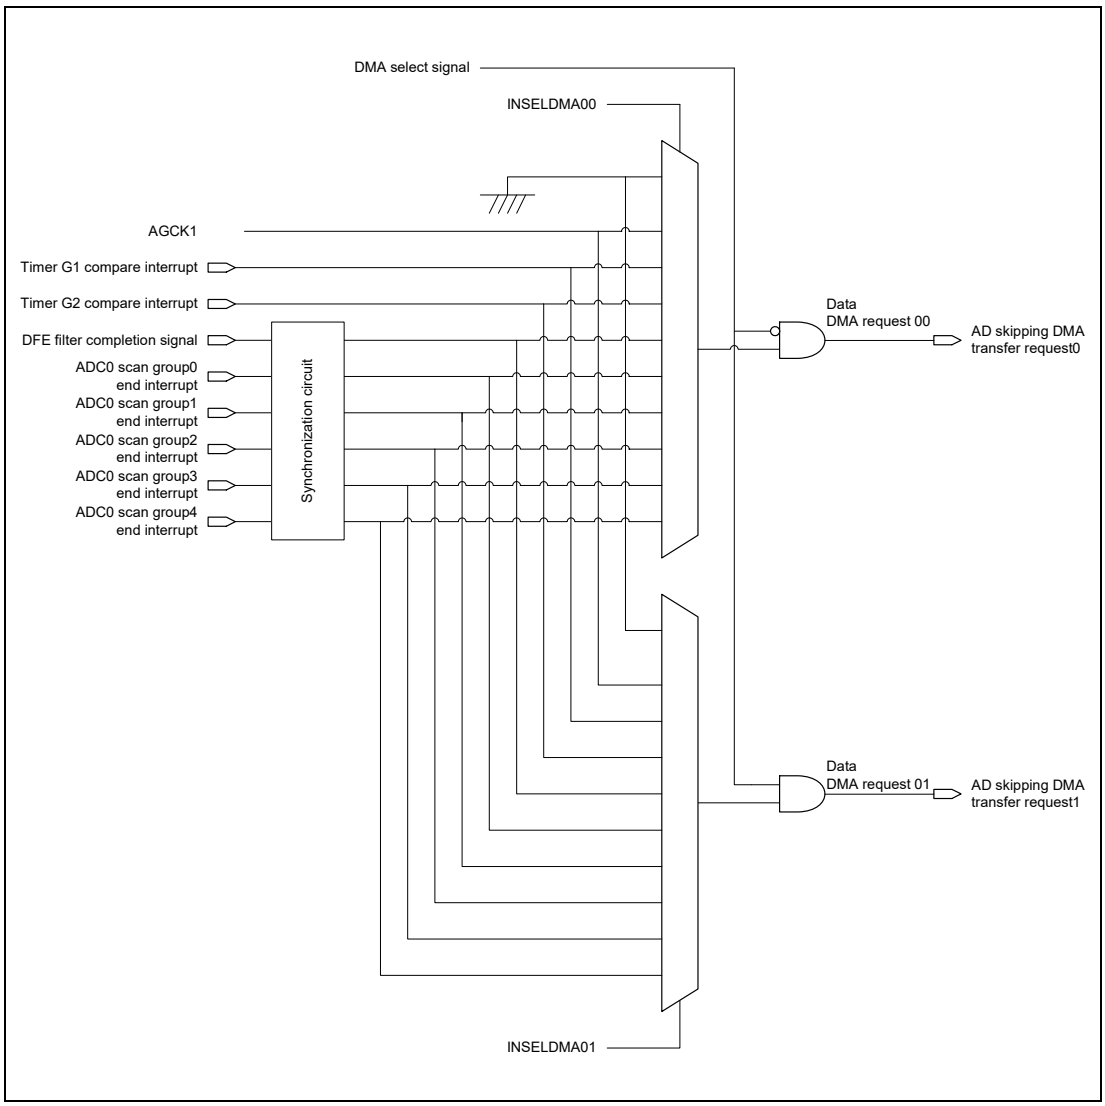

Figure 21.77 Data DMA Trigger Selection Circuit

21.13.3.2 Count DMA Trigger

Figure 21.78 shows the count DMA trigger selection circuit.

The signal to be output to the count DMA trigger output pin (AD skipping DMA transfer request 2) is selected by the INSELDMA10[1:0] bits in TRGSELDMA10.

The signal to be output to the count DMA trigger output pin (AD skipping DMA transfer request 3) is selected by the INSELDMA11[1:0] bits in TRGSELDMA11.

The count DMA trigger output pin outputs only AD skipping DMA transfer request 2 when the DMA select signal is low, and only AD skipping DMA transfer request 3 when the DMA select signal is high.

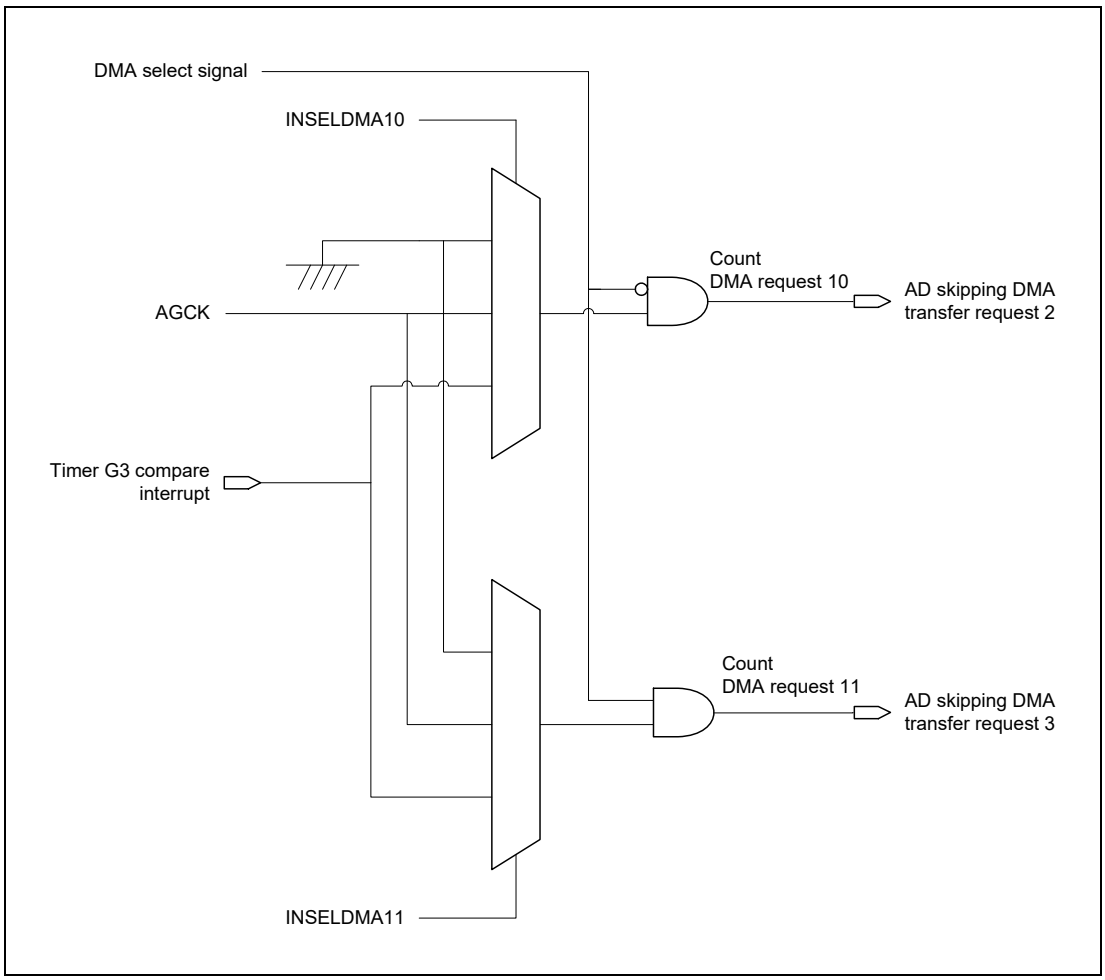

Figure 21.78 Count DMA Trigger Selection Circuit

21.13.3.3 SAR-AD Trigger

Figure 21.79 shows the SAR-AD trigger selection circuit.

The signal to be output to the SAR-AD trigger output pin is selected by the INSELAD[1:0] bits in TRGSELAD.

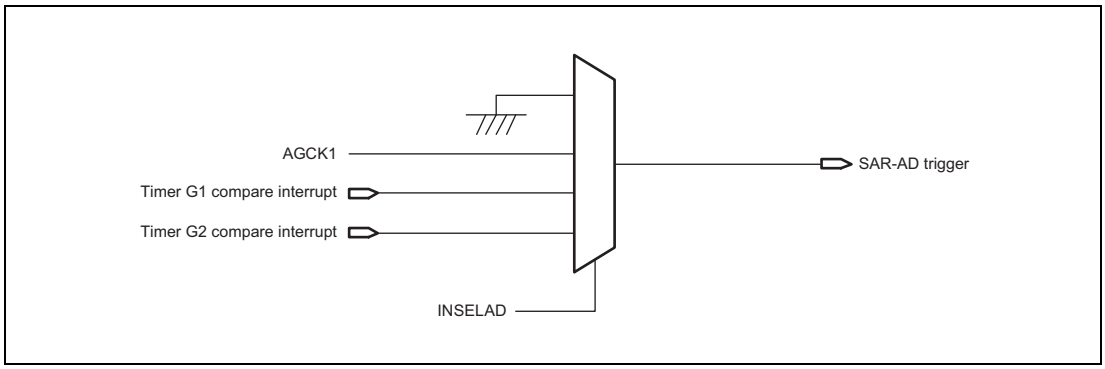

Figure 21.79 SAR-AD Trigger Selection Circuit

Figure 21.80 shows the trigger output timing chart.

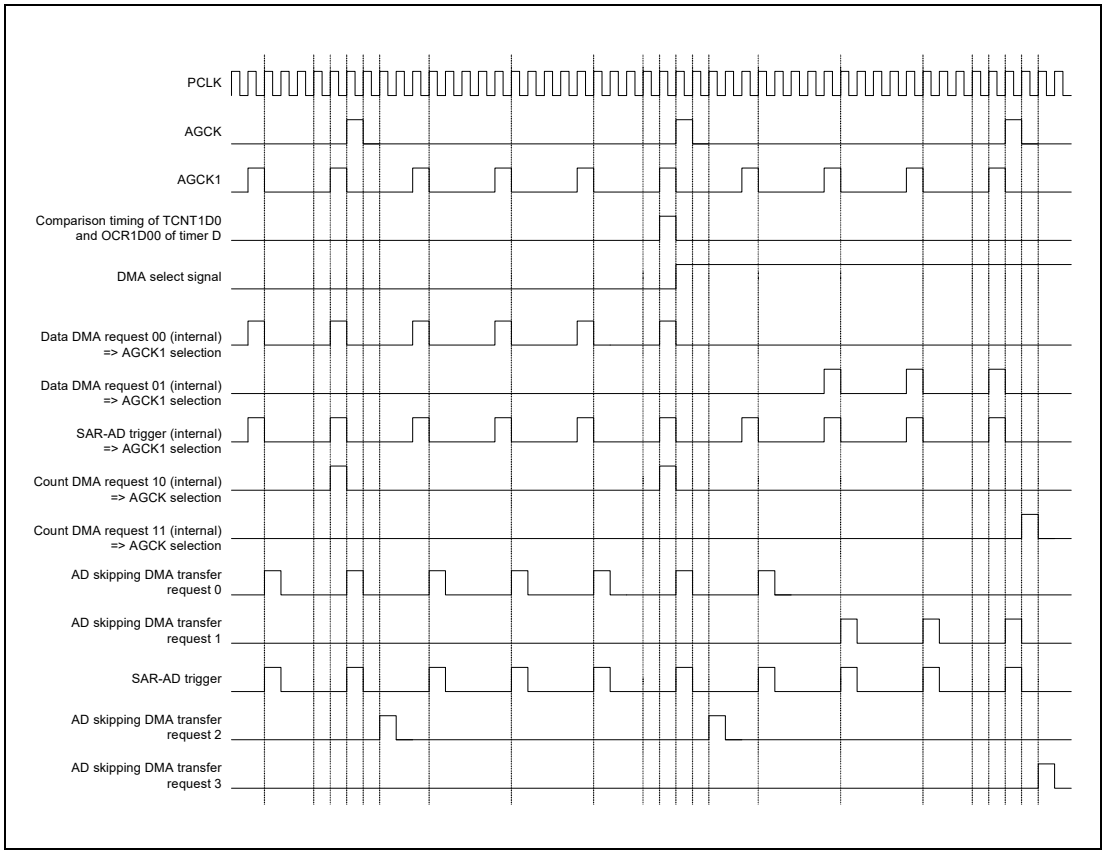

Figure 21.80 DMA/AD Trigger Timing Chart

21.14 Usage Notes

In ATU-IV, status register (TSR) flags deployed in different timers are status flags indicating occurrences of compare match, overflow, underflow, and input capture. In the condition that the status flag is set to 1, an occurrence of compare match, overflow, underflow, or input capture retains the status flag value of 1, and issues an interrupt request to CPU. To find out whether an interrupt request has been made properly, the corresponding flag on the “INTC” side needs to be checked. Be noted that if two interrupt conditions occur in succession in a period shorter than a PCLK cycle, an interrupt request is generated for the first interrupt condition, but not for the subsequent one.

Note that contention and operation described below occur during ATU-IV operation.

21.14.1 Input Capture Contention

21.14.1.1 Contention between Writing to General Register and Input Capture

When writing to a general register occurs simultaneously with input capture, writing takes priority (**Figure 21.81**). However, an input capture interrupt request is issued, and if input capture status is provided, the input capture flag is set. The waveforms in the right half of **Figure 21.81** indicate a case in which writing occurs one PCLK cycle prior to input capture.

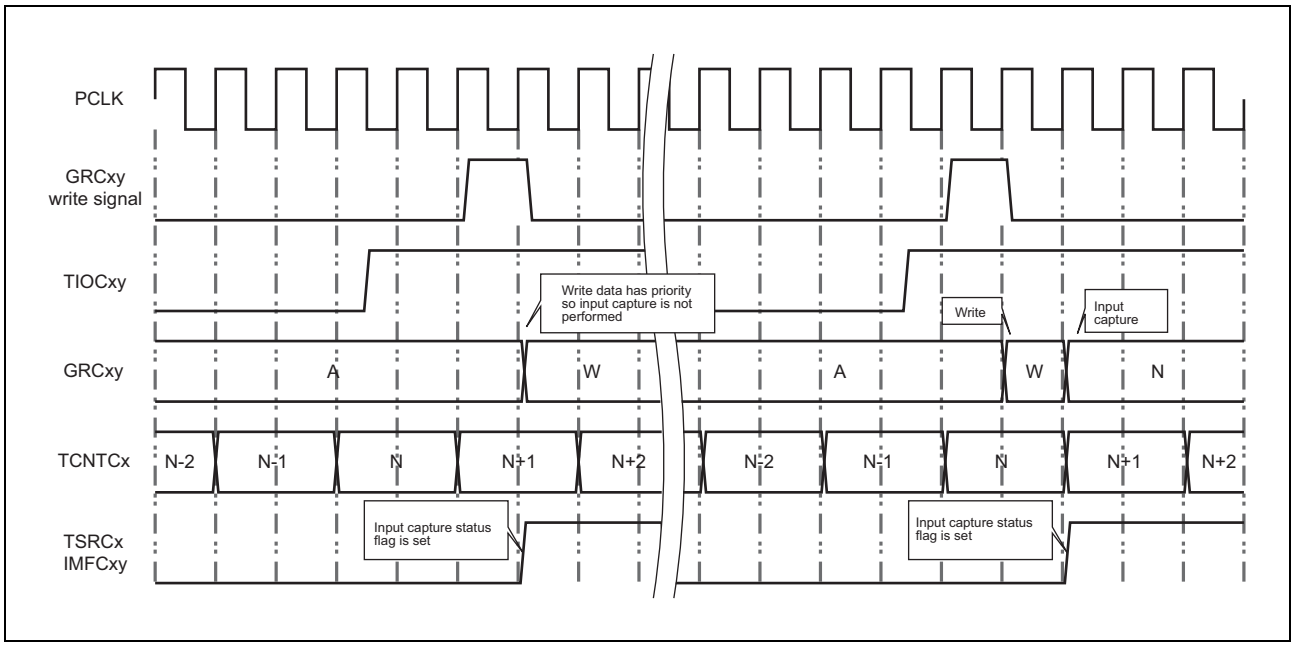

Figure 21.81 Contention between Writing to GRCxy and Input Capture

Timer	Counter (Whose Value is Captured)	Capture Register	Status
Timer C	TCNTCx	GRCxy	IMFCxy
Timer F	ECNTAFx	GRAFx	ICFFx
	ECNTBFx	GRBFx	
	ECNTCFx	GRCFx	
	ECNTCFx + GRDFx	GRDFx	

21.14.1.2 Contention between Writing to Counter and Input Capture

When writing to a counter occurs simultaneously with input capture, the value immediately before writing is captured (**Figure 21.82**). The waveforms in the right half of **Figure 21.82** indicate a case in which writing occurs one PCLK cycle prior to input capture, so the written value is captured.

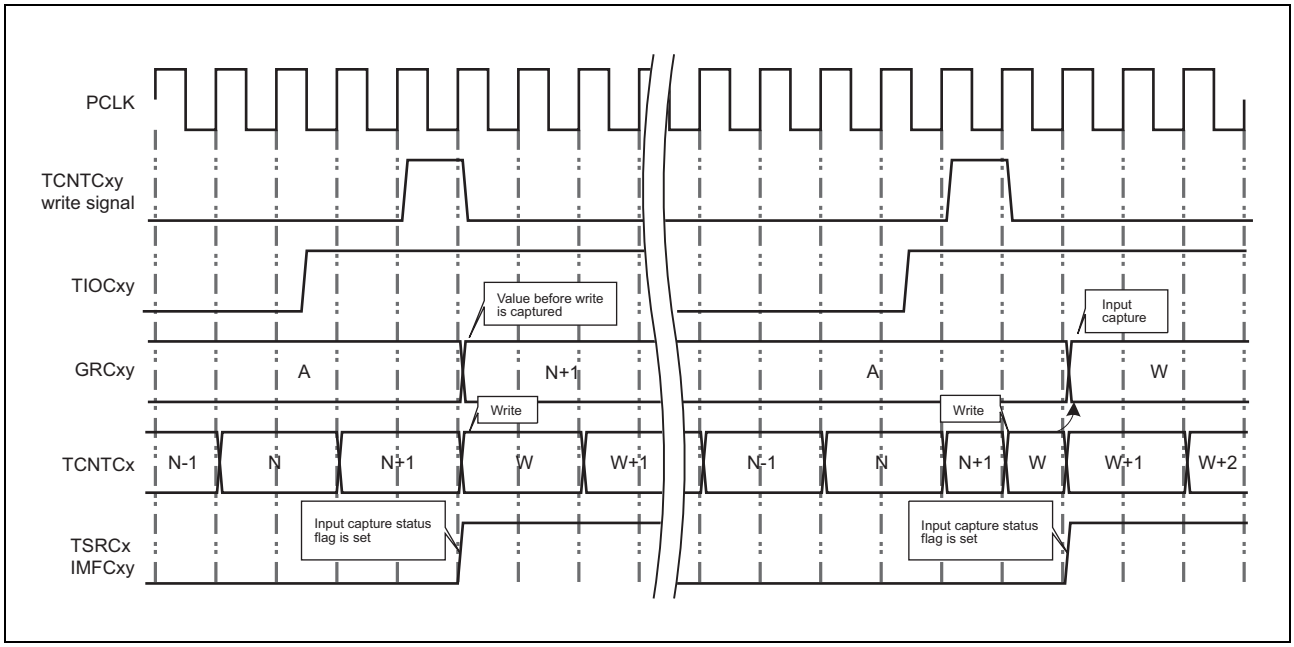

Figure 21.82 Contention between Writing to TCNTCx and Input Capture

Target Timer	Counter (Whose Value is Captured)	Capture Register	Status
Timer A	TCNTAx	ICRAx	ICFAx
Timer B	TCNTB0	ICRB0	ICFB0
	TCNTB0 + ICRB1	ICRB1	
	TCNTB6	ICRB6	
Timer C	TCNTCx	GRCxy	IMFCxy
Timer D	TCNT1Dx	OSBRDx	
	TCNT1Dx	ICR1Dxy	
	TCNT2Dx	ICR2Dxy	
Timer F	ECNTAFx	GRAFx	ICFFx
	ECNTBFx	GRBFx	
	ECNTCFx	GRCFx	
	ECNTCFx + GRDFx	GRDFx	
Timer J	TCNTJx	FIFOJx	(FDOVFJx, FDFFJx)

21.14.1.3 Contention between Setting and Clearing of Input Capture Status Flag

Flag clearing by a timer status clear register takes priority over flag setting by an input capture. The left half of **Figure 21.83** shows an example where an input capture and a flag clearing occur simultaneously, and the flag is cleared. In contrast with this, the waveforms in the right half of **Figure 21.83** indicate an example in which input capture is performed immediately after the flag has been cleared.

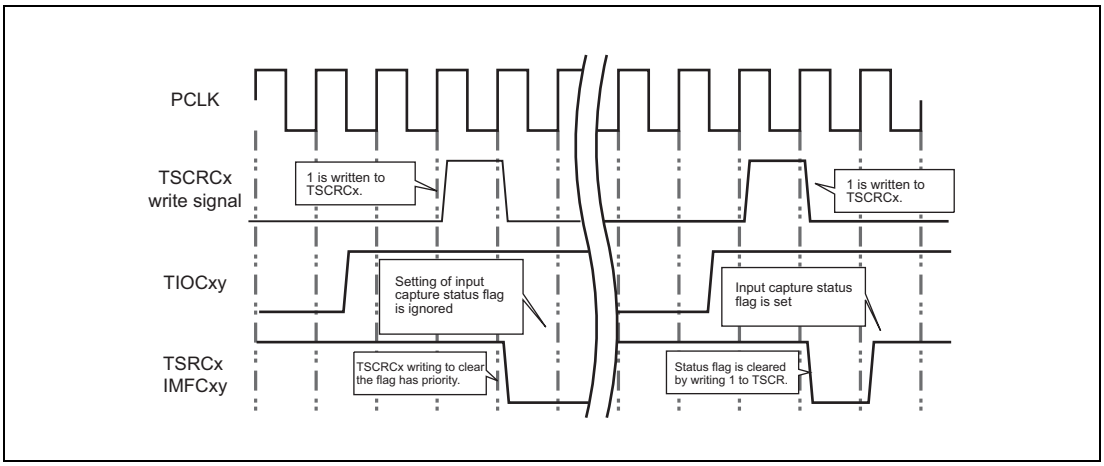

Figure 21.83 Contention between Status Clearing by Writing 1 to Status Clear Register and Input Capture

	Flag
Timer A	ICFAx
Timer B	ICFB0
Timer C	IMFCxy
Timer F	ICFFx
Timer J	(FDOVFJx, FDFFJx)

21.14.2 Compare Match Contention

21.14.2.1 Contention between Writing to Compare-Match General Register and Compare Match

Contention between writing to a register provided with the compare match function and compare match is described here with timer C used as an example. If writing takes place after the values of GRCxy and TCNTCx coincide (left half of **Figure 21.84**), a compare match interrupt request is issued, and the compare match status is set. If GRCxy and TCNTCx do not coincide in any cycles (right half of **Figure 21.84**), no compare match is detected.

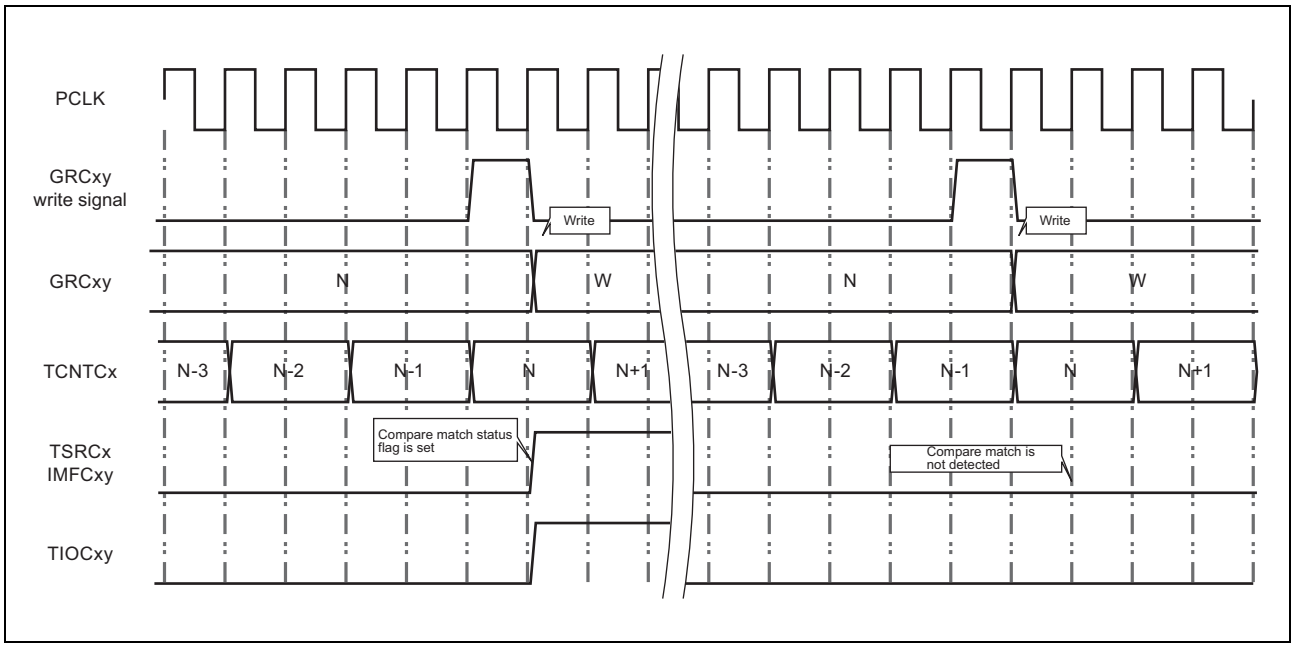

Figure 21.84 Contention between Writing to GRCxy and Compare Match

Timer	Counter	Compare Match Register	Status
Timer B	TCNTB1	OCRB1	CMFB1
	TCNTB1	OCRB10	CMFB10
	TCNTB1	OCRB11	CMFB11
	TCNTB1	OCRB12	CMFB12
Timer C	TCNTCx	GRCxy	IMFCxy
Timer D	TCNT1Dx	OCR1Dxy	CMFADxy
	TCNT2Dx	OCR2Dxy	CMFBDxy
Timer F	ECNTAFx	GRAFx	—
	ECNTBFx	GRBFx	—
	ECNTCFx	GRBFx	OVFCFx
		GRDFx	OVFCFx
Timer G	TCNTGx	OCRGx	CMFGx
Timer H	TCNT1H	OCR1H	CMFH
Timer J	TCNTJx	OCRJx	CMFJx

Timing of compare match B0 and compare match B6 of timer B and the cycle match of timer E differ from the timing of these compare matches. For details, see **Section 21.14.2.2, Contention between Writing to CYLRExy and Cycle Match of TCNTExy**.

21.14.2.2 Contention between Writing to CYLRExy and Cycle Match of TCNTExy

Operation when writing to CYLRExy occurs simultaneously with compare match (cycle match) with TCNTExy is shown below. As shown in **Figure 21.85**, if writing to CYLRExy takes place at the time of cycle match counter clearing, TCNTExy is cleared as in the case of normal cycle match, a cycle match interrupt request is issued, and the cycle match status and PWM output are changed. The waveforms in the right half of **Figure 21.85** show an example in which CYLRExy is written to before the counter is cleared. In this case, no cycle match is detected and TCNTExy continues to be incremented.

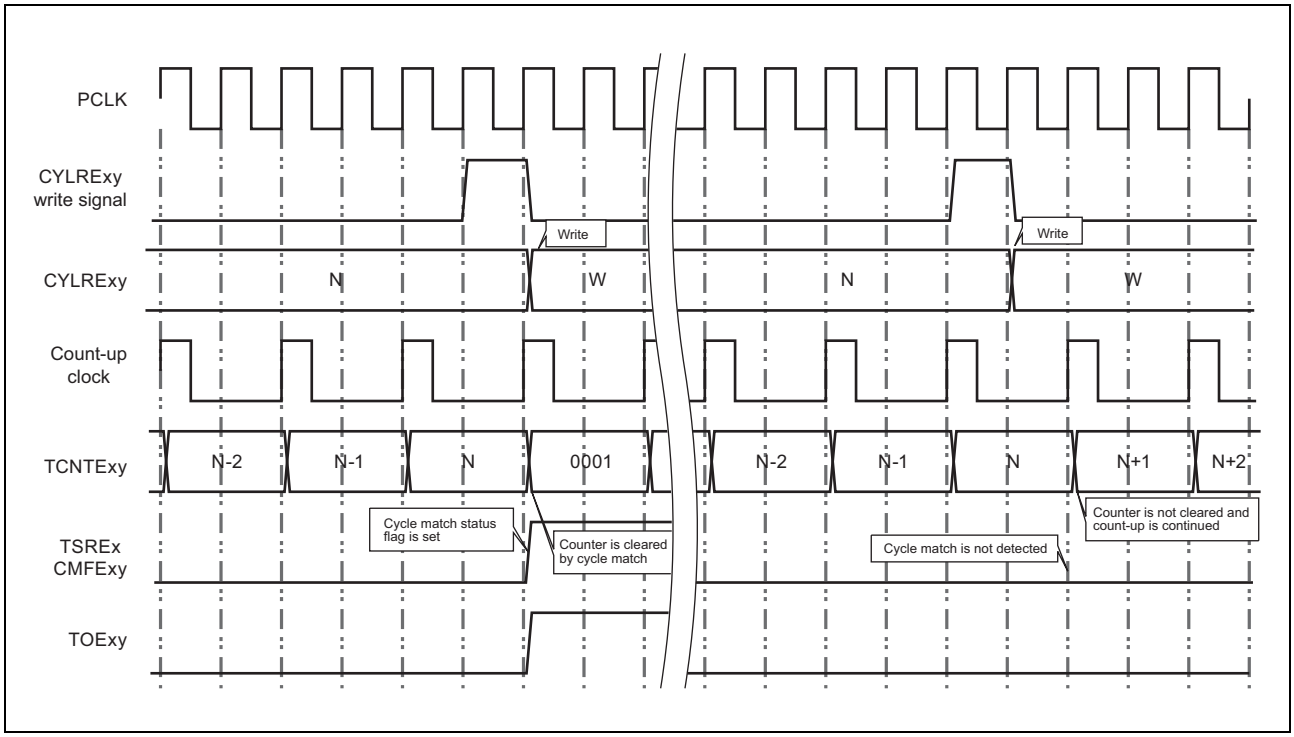

Figure 21.85 Contention between Writing to CYLRExy and Cycle Match

Timer	Counter	Compare (Cycle) Match Register	Status
Timer B	TCNTB0	OCRB0	CMFB0
	TCNTB6	OCRB6/OCRB7	CMFB6
	TCNTB6M	ICRB6	CMFB6M
Timer E	TCNTExy	CYLRExy	CMFExy

21.14.2.3 Contention between Writing to DTRExy and Cycle Match of TCNTExy

The operation is the same as the case of contention between writing to CYLRExy and cycle matches with TCNTExy described above.

21.14.2.4 Contention between Writing to Counter and Compare Match

Contention between writing to a counter and compare match is described below. If writing takes place after the compare match register and the counter coincide (left half of **Figure 21.86**), a compare match interrupt request is issued, and the compare match status is set. If the compare match register and the counter do not coincide in any cycles (right half of **Figure 21.86**), a compare match interrupt request is not is issued, and the match in comparison is not detected.

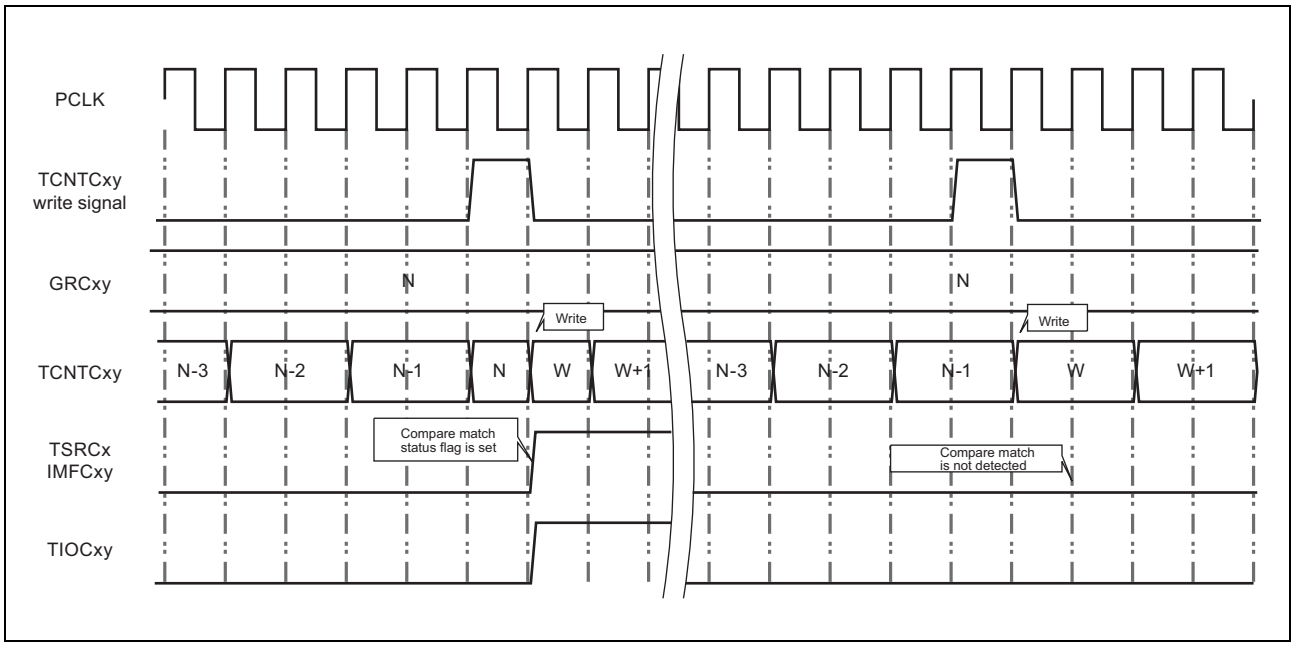

Figure 21.86 Contention between Writing to TCNTCx and Compare Match

Timer	Counter	Compare Match Register	Status
Timer B	TCNTB1	OCRB1	CMFB1
Timer C	TCNTCx	GRCxy	IMFCxy
Timer D	TCNT1Dx	OCR1Dxy	CMFADxy
	TCNT2Dx	OCR2Dxy	CMFBDxy
Timer F	ECNTAFx	GRAFx	—
	ECNTBFx	GRBFx	—
	ECNTCFx	GRBFx	OVFCFx
		GRDFx	OVFCFx
Timer G	TCNTGx	OCRGx	CMFGx
Timer H	TCNT1H	OCR1H	CMFH
Timer J	TCNTJx	OCRJx	CMFJx

Timing of compare match B0 and compare match B6 of timer B and the cycle match of timer E differ from the timing of these compare matches. For details, see **Section 21.14.2.6, Contention between Writing to TCNTExy and Counter Clearing by Cycle Match**.

21.14.2.5 Contention between Writing to Counter and Counter Clearing by Compare Match

The waveforms shown here are for when the function to clear a counter by compare match is enabled. If writing to a counter and counter clearing by compare match occur simultaneously, the counter is not cleared and the write takes precedence (left half of **Figure 21.87**). However, a compare match interrupt request is issued, and the compare match status is set. The waveforms in the right half of **Figure 21.87** show a case in which writing to TCNTCx is one PCLK cycle later.

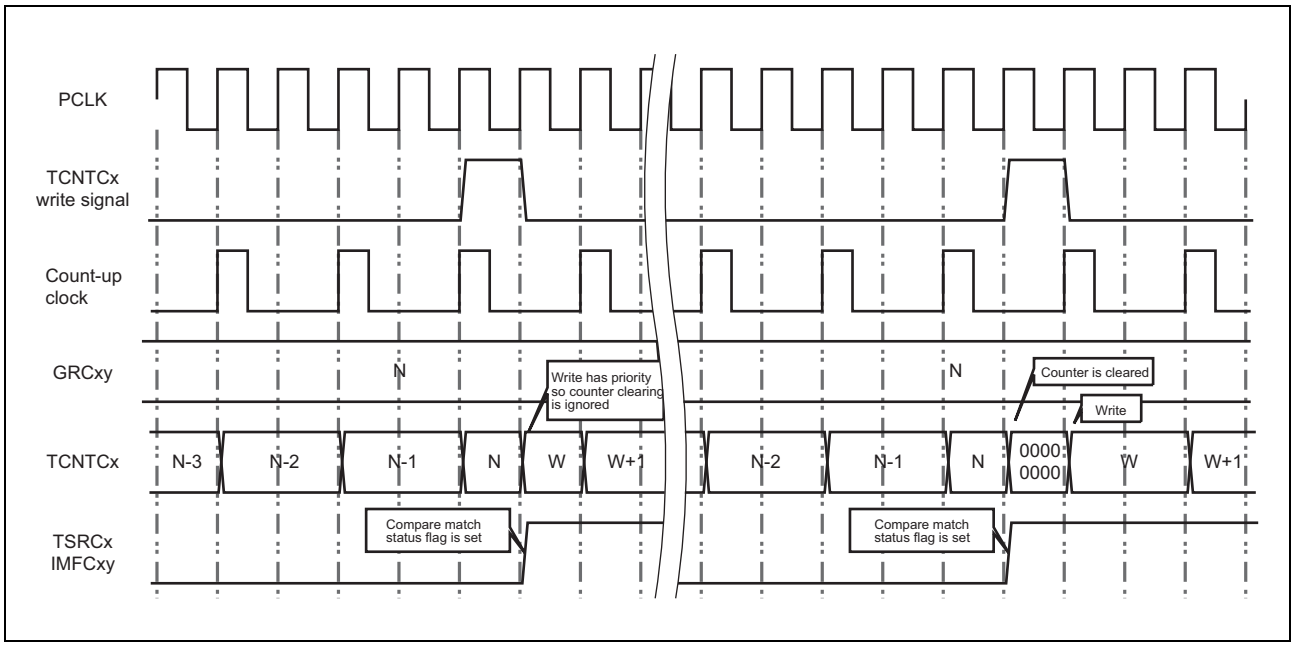

Figure 21.87 Contention between Writing to TCNTCx and Counter Clearing by Compare Match

Timer	Counter	Compare Match Register	Status
Timer C	TCNTCx	GRCxy	IMFCxy
	TCNTCx	CUCRCx	OVFCx
Timer D	TCNT1Dx	CUCR1Dx	OVF1Dx
	TCNT2Dx	CUCR2Dx	OVF2Dx
Timer F	ECNTAFx	GRAFx	—
	ECNTBFx	GRBFx	—
Timer G	TCNTGx	OCRGx	CMFGx
Timer H	TCNT1H	OCR1H	CMFH

21.14.2.6 Contention between Writing to TCNTExy and Counter Clearing by Cycle Match

When writing to TCNTExy occurs simultaneously with counter clearing by cycle match, the counter is not cleared and TCNTExy is written to. However, a cycle match interrupt request is issued, the cycle match status is set, and reload of the cycle-setting register and the duty cycle setting register are performed (right half of **Figure 21.88**). PWM waveform output at the time of cycle match is also performed.

The waveforms in the left half of **Figure 21.88** show operation when writing is performed one PCLK cycle earlier than the count-up clock.

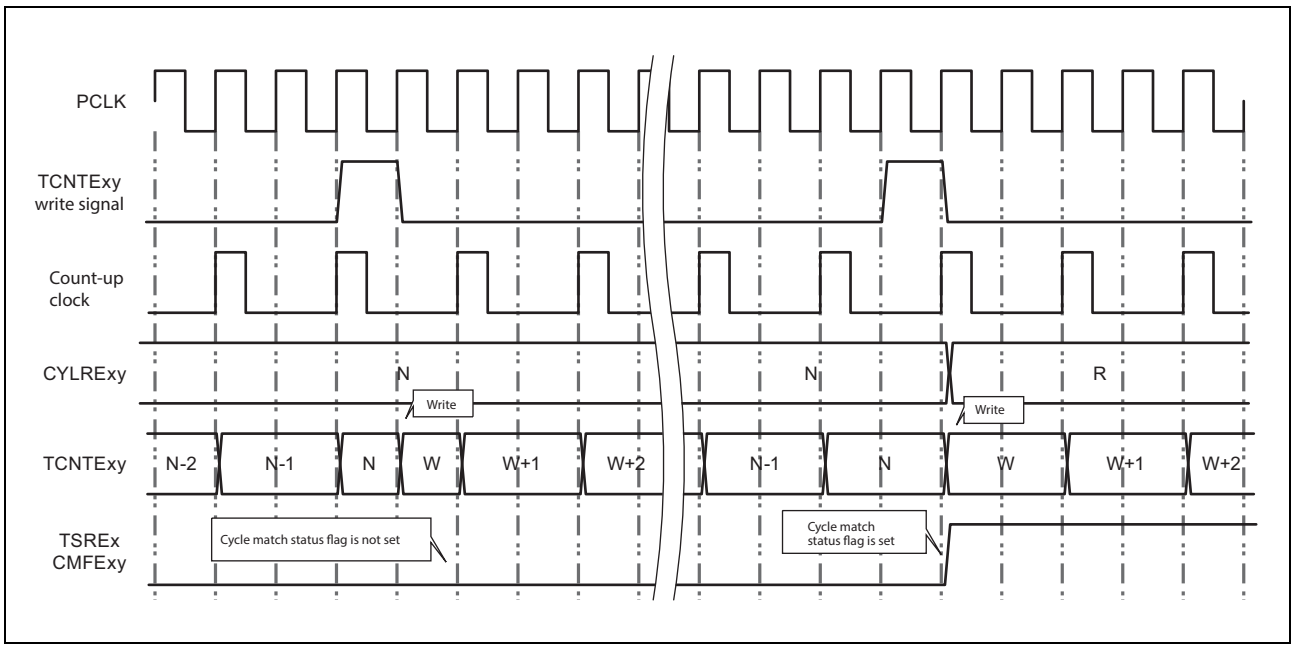

Figure 21.88 Contention between Writing to TCNTExy and Counter Clearing by Cycle Match

Timer	Counter	Compare (Cycle) Match Register	Status
Timer B	TCNTB0	OCRB0	CMFB0
	TCNTB6	OCRB6/OCRB7	CMFB6
	TCNTB6M	ICRB6	CMFB6M
Timer E	TCNTExy	CYLRExy	CMFExy

21.14.2.7 Contention between Setting and Clearing of Compare Match Status Flag

Flag clearing by a timer status clear register takes priority over flag setting by compare match (left half of **Figure 21.89**). The right half of **Figure 21.89** illustrates the case where a compare match occurs just after flag clearing.

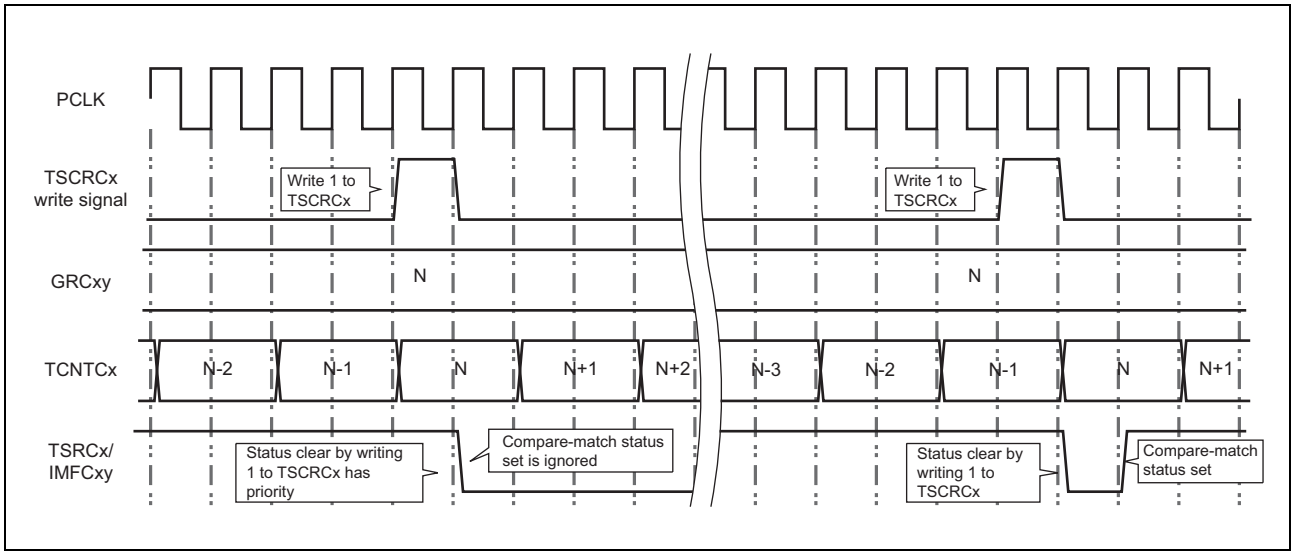

Figure 21.89 Contention between Setting and Clearing of Compare Match Status Flag

Timer	Counter	Compare Match Register	Status
Timer B	TCNTB1	OCRB1	CMFB1
	TCNTB1	OCRB10	CMFB10
	TCNTB1	OCRB11	CMFB11
	TCNTB1	OCRB12	CMFB12
Timer C	TCNTCx	GRCxy	IMFCxy
Timer D	TCNT1Dx	OCR1Dxy	CMFADxy
	TCNT2Dx	OCR2Dxy	CMFBDxy
Timer F	TCNTCFx	GRDFx	OVFCFx
Timer G	TCNTGx	OCRGx	CMFGx
Timer H	TCNT1H	OCR1H	CMFH
Timer J	TCNTJx	OCRJx	CMFJx

Timing of compare match B0 and compare match B6 of timer B and the cycle match of timer E differ from the timing of these compare matches. For details, see **Section 21.14.2.8, Contention between Setting of Cycle Match Status Flag and Writing 1 to the Status Clear Register**.

21.14.2.8 Contention between Setting of Cycle Match Status Flag and Writing 1 to the Status Clear Register

If setting of the cycle match flag (cycle match) and clearing of the flag by the timer status clear register occurs simultaneously, clearing of the flag takes priority. The left half of **Figure 21.90** illustrates an example where flag setting by cycle match and flag clearing by the timer status clear register occur simultaneously. The waveforms in the right half of **Figure 21.90** show an example in which the flag is cleared one PCLK cycle earlier than flag setting.

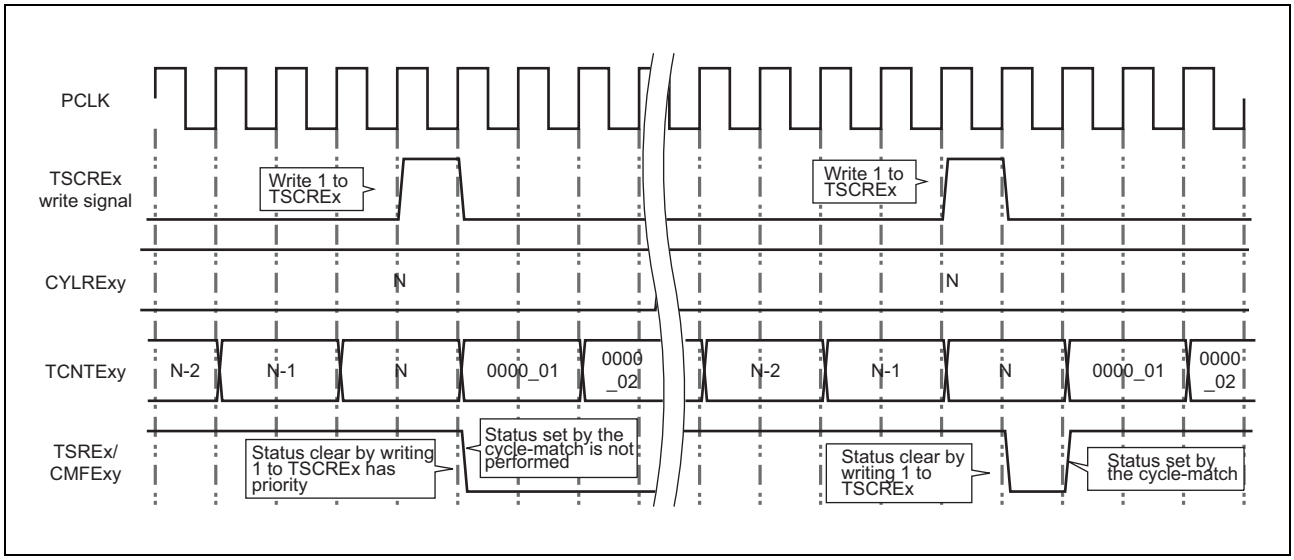

Figure 21.90 Contention between Cycle Match and Cycle Match Status Clear by Writing 1 to the Status Clear Register

Timer	Counter	Compare (Cycle) Match Register	Status
Timer B	TCNTB0	OCRB0	CMFB0
	TCNTB6	OCRB6	CMFB6
	TCNTB6M	ICRB6	CMFB6M
Timer E	TCNTExy	CYLRExy	CMFExy

21.14.2.9 Contention between Detection of 1H Compare Match and Disabling of Counter by ATUENR Setting

When compare match between TCNT1H and OCR1H is detected at the same time a counter enable bit (each bit in ATUENR) is changed to 0, compare match is detected but TCNT2H is not incremented (the left side of **Figure 21.91**). Thereafter, even though a counter enable bit is set to 1, TCNT2H is not incremented until the next compare match occurs.

The waveforms in the right half of **Figure 21.91** show an example in which a counter enable bit is changed to 0 one PCLK cycle after compare match has been detected.

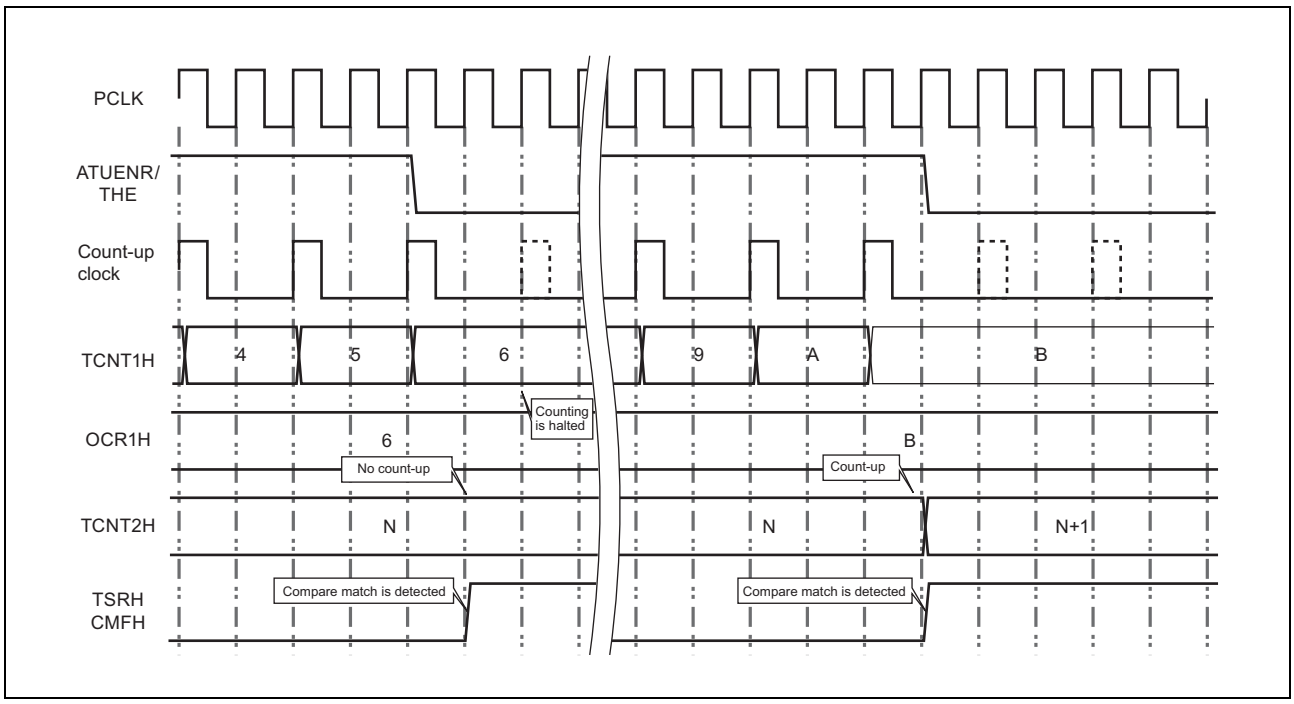

Figure 21.91 Contention between Compare Match Detection and Disabling of Counter

Timer	Counter	Compare Match Register	Status
Timer H	TCNT1H	OCR1H	CMFH

21.14.2.10 Contention between Writing 0 to TCNTExy and Cycle Match

Operation when writing 0 to the 24 higher-order bits of TCNTExy occurs simultaneously with cycle match is shown below. The waveforms in the left half of **Figure 21.92** show a case in which 000 000_H is written to the 24 higher-order bits of TCNTExy at the same time the 24 higher-order bits of TCNTExy is to be cleared to 000 001_H due to cycle match. A cycle match interrupt request is issued and the cycle match status is set, but PWM output does not start because zero writing takes priority. The waveforms in the middle of the figure indicate a case in which 0 is written to the 24 higher-order bits of TCNTExy one PCLK cycle after the counter has been cleared by cycle match. Cycle match detection and PWM output are restarted at the timing the 24 higher-order bits of the TCNTExy counter value changes from N to 1. In contrast with this, the waveforms in the right half of the figure show an example in which 0 is written one PCLK before detection of cycle match. In this case, neither cycle match is detected nor PWM output restarted, and the previous state is retained.

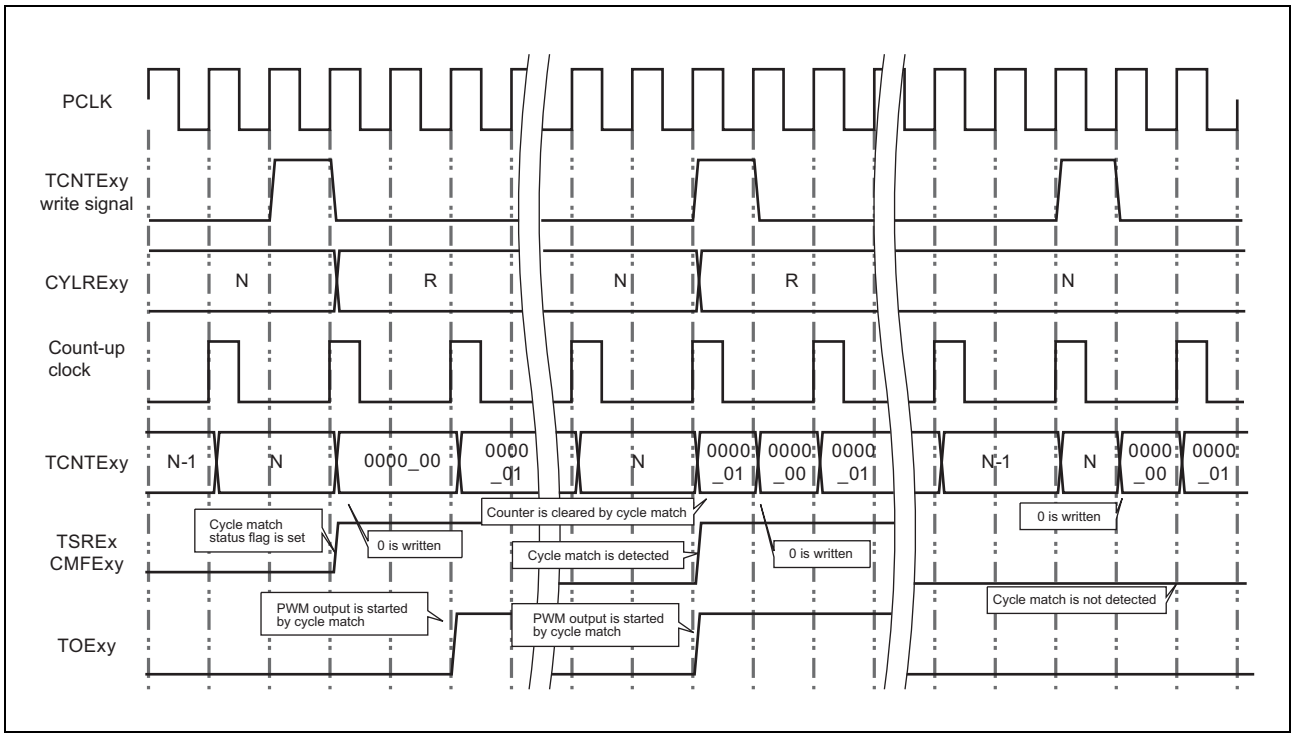

Figure 21.92 Contention between Writing 0 to TCNTExy and Cycle Match

21.14.3 Load/Reload Contention

21.14.3.1 Contention between Data Transfer and Writing to Transfer Destination Register

Contention between data transfer between registers and a peripheral bus write to the transfer destination register is described below. When data transfer occurs simultaneously with writing to the transfer destination register, writing takes priority and the attempt of data transfer is ignored. **Figure 21.93** shows contention between reload to CYLRExy of timer E and writing to it. As shown by the waveforms in the left half of the figure, if writing to CYLRExy occurs at the same timing as cycle reload, writing takes priority. The waveforms in the right half of the figure indicate a case in which CYLRExy is written to immediately after cycle reload.

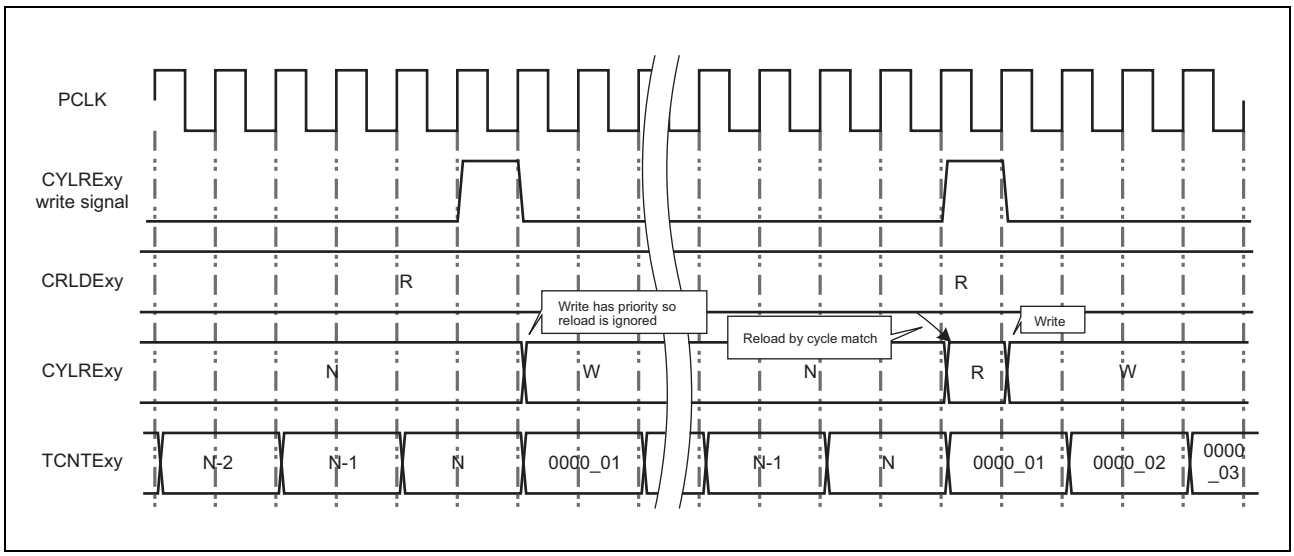

Figure 21.93 Contention between Writing to CYLRExy and Cycle Reload

Timer	Transfer Data	Transfer Destination Register	Transfer Timing
Timer B	ICRB0 LDB TCNTB2 – PIMR TCNTB2 + RLDB	TCNTB2	External event
	ICRB0 – PIMR LDB – PIMR	RLDB	External event
	TCNTB3 + PIMR	TCNTB3	External event
	TCNTB3	TCNTB4	External event
Timer E	CRLDExy	CYLRExy	Cycle match
	DRLDExy	DTRExy	Cycle match

21.14.3.2 Contention between Data Transfer and Writing to Transfer Source Register

Contention between data transfer between registers and a peripheral bus write to the transfer source register is described below. When data transfer occurs simultaneously with writing to the transfer source register, the value prior to writing is transferred. At the same time, the value of the transfer source register is modified. Operation when writing to CRLDExy occurs at the timing of cycle reload is shown below. If writing to CRLDExy occurs at the same timing as cycle reload (waveforms in the left half of **Figure 21.94**), the value immediately before writing is reloaded. On the other hand, the waveforms in the right half of the figure show an example in which CRLDExy is written to one cycle earlier than cycle reload.

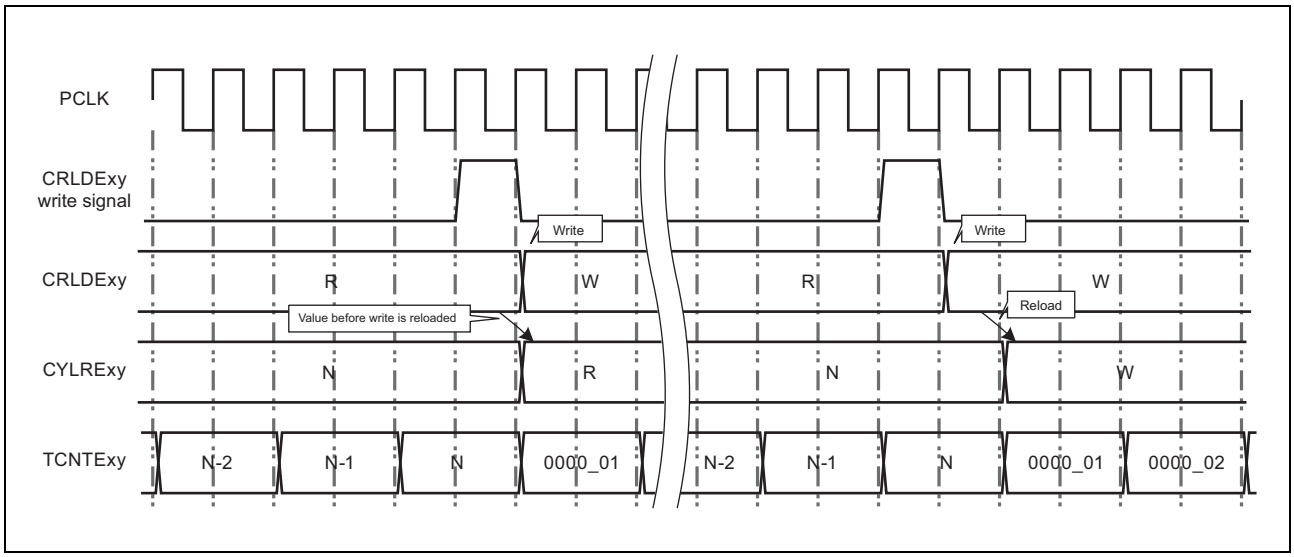

Figure 21.94 Contention between Writing to CRLDExy and Cycle Reload

Timer	Transfer Source Register	Transferred Value	Transfer Destination Register	Transfer Timing
Timer B	LDB	LDB – PIMR	RLDB	External event
		LDB	TCNTB2	External event
	PIMR	ICRB0 – PIMR LDB – PIMR	RLDB	External event
		TCNTB2 – PIMR	TCNTB2	External event

21.14.4 Counter Contention

21.14.4.1 Contention between Writing to Counter and Count-Up/Count-Down

When writing to a counter occurs simultaneously with incrementation/decrementation of the counter, the write operation takes priority. The attempt to increment/decrement the value is ignored and incrementation/decrementation recommences from the new value on the next counter clock.

21.14.4.2 Contention between Count-Up and Counter Clearing

When incrementation of a counter occurs simultaneously with clearing of the counter, the counter is not cleared to 0 but cleared to 1.

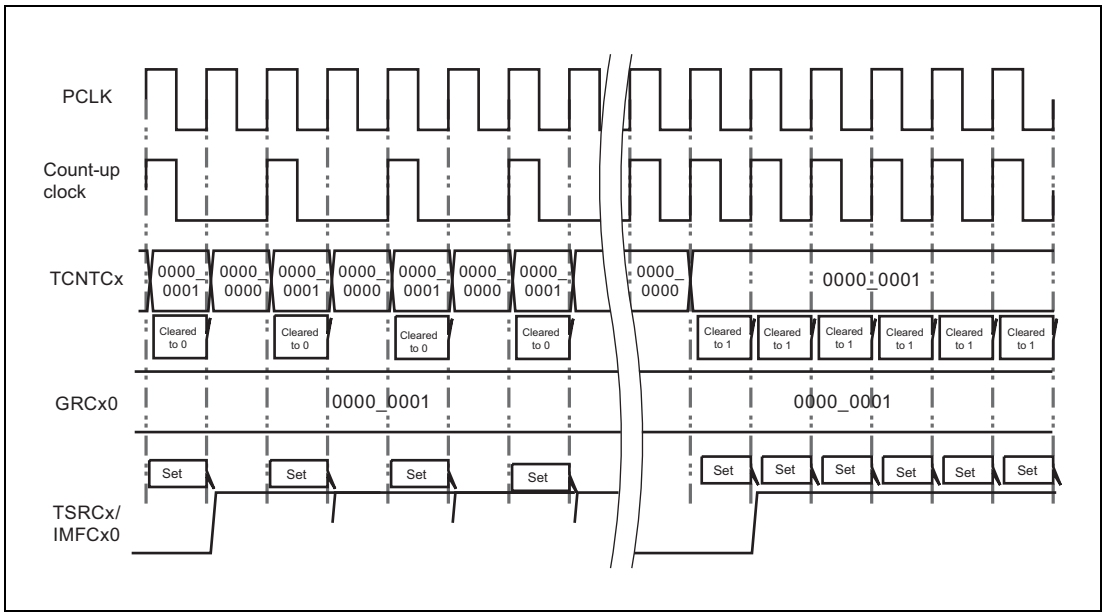

Figure 21.95 Simultaneous Occurrence of Count-Up and Counter Clearing

Timer	Counter	Compare Match Register	Remarks
Timer C	TCNTCx	GRCx0	Only when PWMx0 = 1
	TCNTCx	CUCRCx	Only when PWMx0 = 0, CLRCx = 1 = 1
Timer D	TCNT1Dx	CUCR1Dx	Only when CLR1Dx = 1
	TCNT2Dx	CUCR2Dx	Only when CLR2Dx = 1
Timer F	ECNTAFx	GRAFx	Only when MDFx = 000, 110, or 111
	ECNTBFx	GRBFx	Only when MDFx = 001, 010, or 100
Timer G	TCNTGx	OCRGx	
Timer H	TCNT1H	OCR1H	

21.14.4.3 Contention between Writing to Counter and Overflow

When counter overflow occurs simultaneously with writing to TCNTCx, writing to TCNTCx takes priority. However, an overflow interrupt request is issued, and the overflow status is set (left half of **Figure 21.96**). If the timing for writing to the counter is earlier than incrementation of the counter (waveforms in the right half of the figure), the overflow status flag is not set.

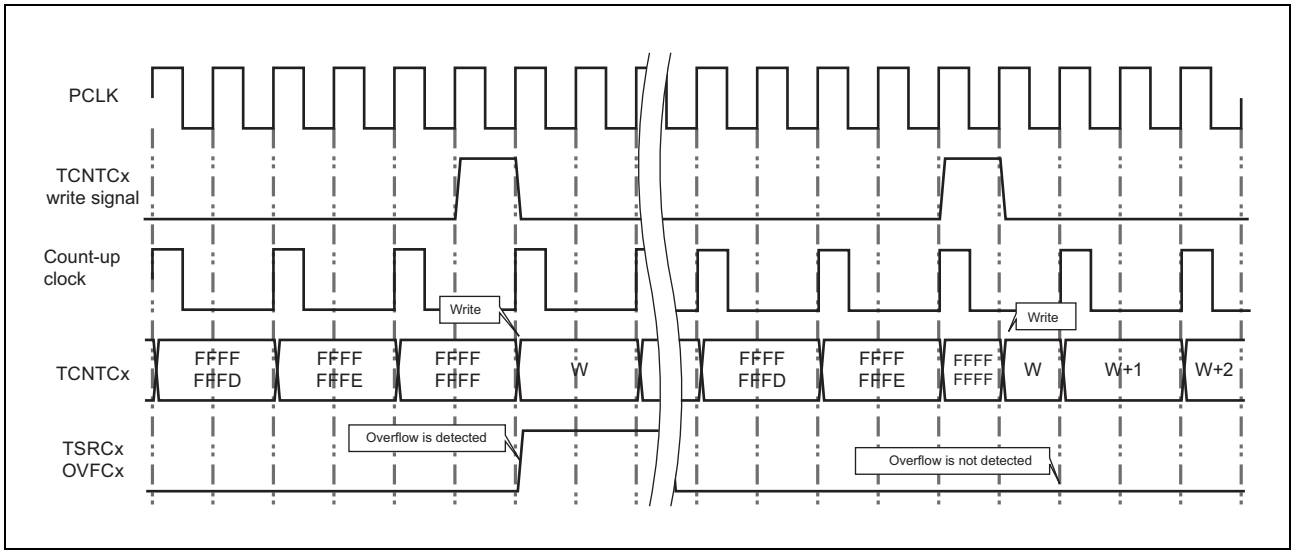

Figure 21.96 Contention between Writing to TCNTCx and Counter Clearing on Overflow

Timer	Counter	Status
Timer A	TCNTA	OVFA
Timer C	TCNTCx	OVFCx
Timer D	TCNT1Dx	OVF1Dx
	TCNT2Dx	OVF2Dx
Timer E	TCNTExy	OVFExy
Timer F	ECNTAFx	OVFAFx
	ECNTBFx	OVFBFx
	ECNTCFx	OVFCFx
Timer G	TCNTGx	OVFGx
Timer H	TCNT1H	OVF1H
	TCNT2H	OVF2H
Timer J	TCNTJx	OVFJx

21.14.4.4 Contention between Setting and Clearing of Overflow Status Flag

When clearing and setting of the overflow status flag occur simultaneously, clearing takes priority. Illustrated below is an example where status flag setting by an overflow of the counter value (FFFF $FFFF_H$ to 0000 0000_H) and flag clearing by the timer status clear register occur simultaneously (left half of **Figure 21.97**). The waveforms in the right half of the figure show the way the overflow status flag is set again immediately after the status flag has been cleared.

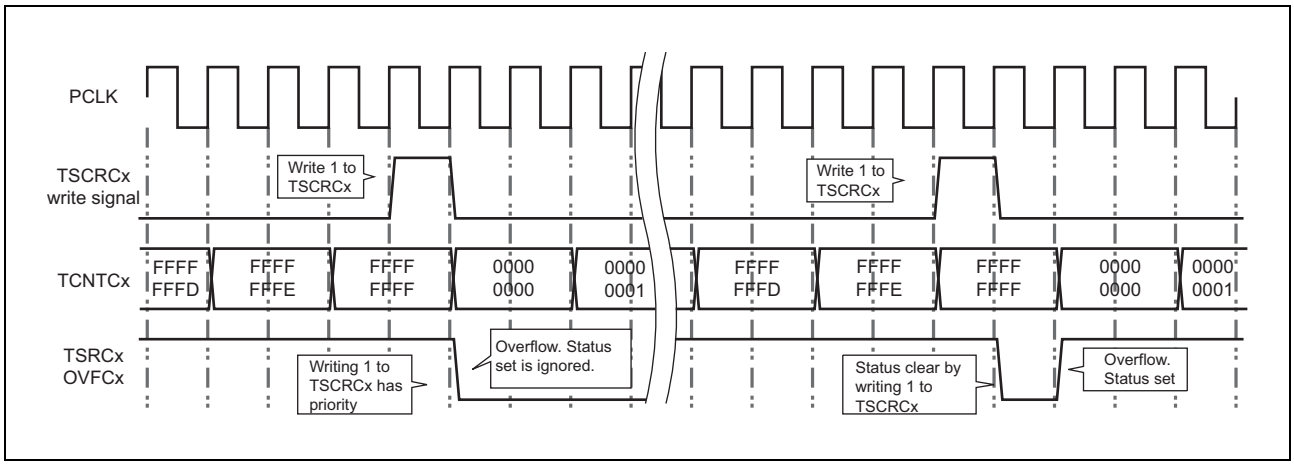

Figure 21.97 Contention between Setting and Clearing of Overflow Status Flag

Timer	Counter	Status
Timer A	TCNTA	OVFA
Timer C	TCNTCx	OVFCx
Timer D	TCNT1Dx	OVF1Dx
	TCNT2Dx	OVF2Dx
Timer E	TCNTExy	OVFExy
Timer F	ECNTAFx	OVFAFx
	ECNTBFx	OVFBFx
	ECNTCFx	OVFCFx
Timer G	TCNTGx	OVFGx
Timer H	TCNT1H	OVF1H
	TCNT2H	OVF2H
Timer J	TCNTJ x	OVFJx

21.14.4.5 Contention between Overflow and Counter Clearing by Compare Match

If the maximum value is set in a compare match register that has the function to clear a counter by compare match and that function is enabled, when the counter reaches its maximum value, the counter is cleared. At this time, an overflow interrupt request is not issued even if the counter clock is 1/1PCLK, so that an overflow is not detected.

Examples using TCNT1H and OCR1H of timer H are shown in **Figure 21.98**. With $FFFF_H$ set in OCR1H, a case in which the count-up clock is not PCLK × 1/1 (waveforms in the left half of the figure) and a case in which the count-up clock is PCLK × 1/1 (waveforms in the right half of the figure) are shown.

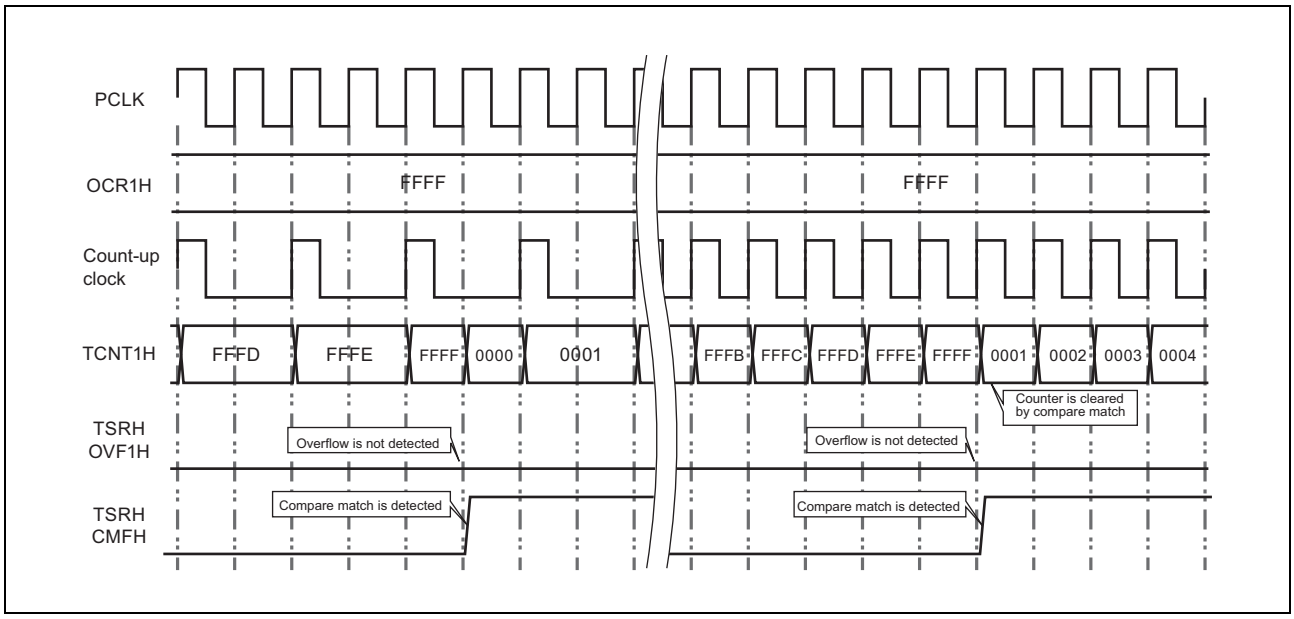

Figure 21.98 Contention between TCNT1H Counter Overflow and Compare Match

Timer	Counter	Status	Remarks
Timer C	TCNTCx	OVFCx	Only when PWMn0 = 1
Timer F	ECNTAFx	OVFAFx	Only when MDFx = 000, 110, or 111
	ECNTBFx	OVFBFx	Only when MDFx = 001
Timer G	TCNTGx	OVFGx	
Timer H	TCNT1H	OVF1H	

If the compare match counter clear feature is not provided or is disabled, an overflow interrupt request is issued and the overflow status is set. **Figure 21.99** shows operation when the PWMx0 bit of timer C is 1 (counter clearing is enabled) and when the PWMx0 bit is 0 (counter clearing is disabled).

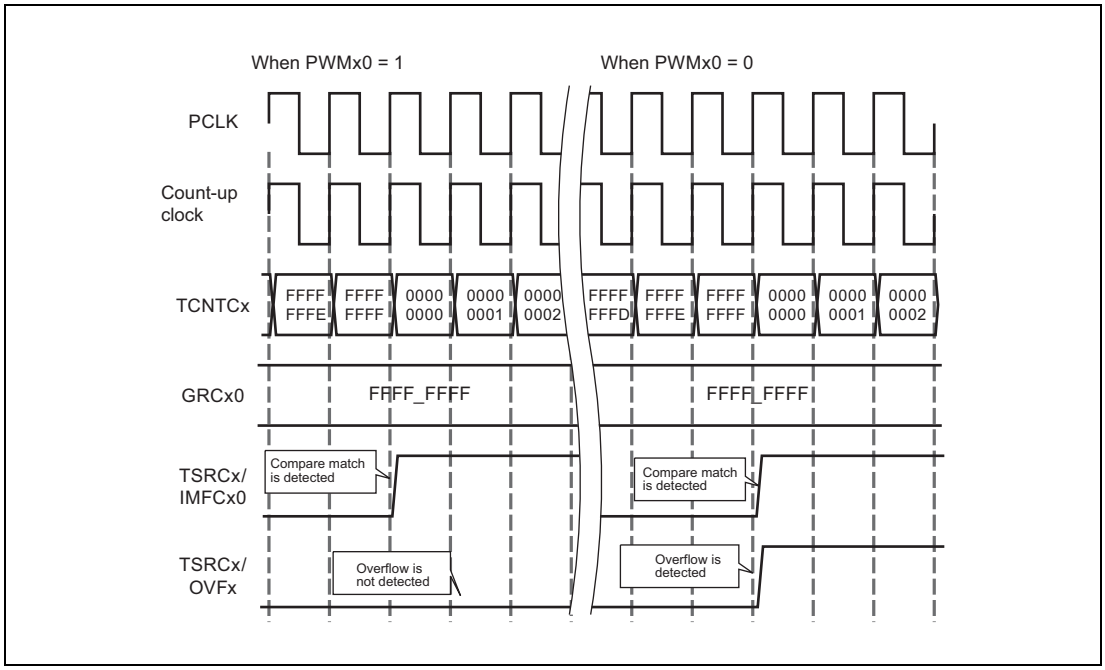

Figure 21.99 Contention between Counter Clearing by Compare Match of Timer C and Overflow (PWMx0 = 1/0)

21.14.5 Contention in Noise Canceler

Contentions in the noise cancelers are described here.

Timer	Counter	Compare Match Register
Timer A	NCNTAx	NCRAx
Timer C	NCNTCxy	NCRCxy
Timer F	NCNTAFx	NCRAFx
	NCNTBFx	NCRBFx
Timer J	NCNTJx	NCRJx

21.14.5.1 Contention between Writing to Noise Canceler Counter and Compare Match with Noise Canceler Register

When writing to NCNT occurs simultaneously with a compare match with NCR, writing takes priority. An example in minimum time-at-level cancellation mode is shown below. In the example in the left half of **Figure 21.100**, since writing prevents compare match from occurring, input capture is also not performed. The example in the right half of the figure shows a case in which writing is performed one PCLK cycle later. In this case, compare match occurs so input capture processing is carried out.

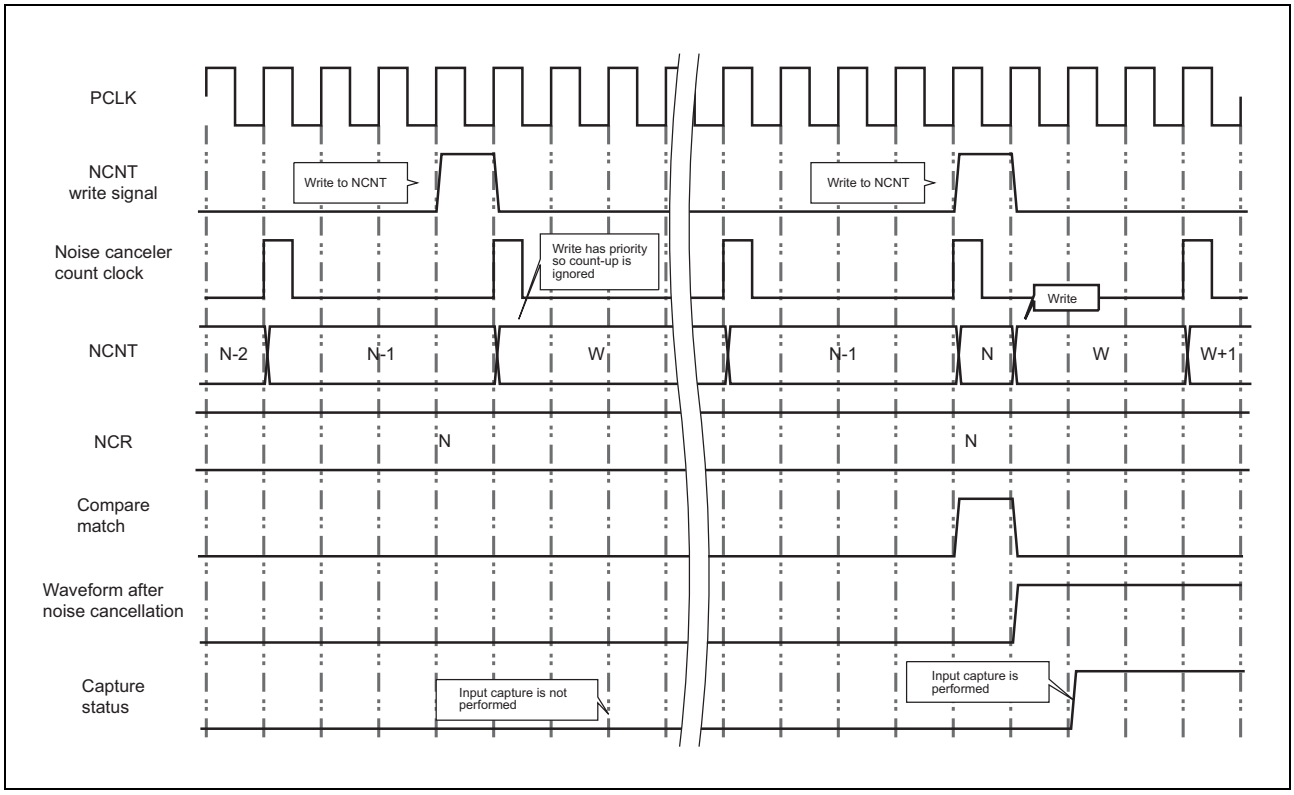

Figure 21.100 Contention between Writing to NCNT and Compare Match of NCN-TNCR (Example in Minimum Time-at-Level Cancellation Mode)

21.14.5.2 Contention between Writing to Noise Canceler Register and Compare Match with Noise Canceler Counter

When writing to NCR occurs simultaneously with a compare match with NCNT, writing takes priority. An example in minimum time-at-level cancellation mode is shown below. In the example in the left half of **Figure 21.101**, since writing prevents compare match from occurring, input capture is also not performed. The example in the right half of the figure shows a case in which writing is performed one PCLK cycle later. In this case, compare match occurs so input capture processing is carried out.

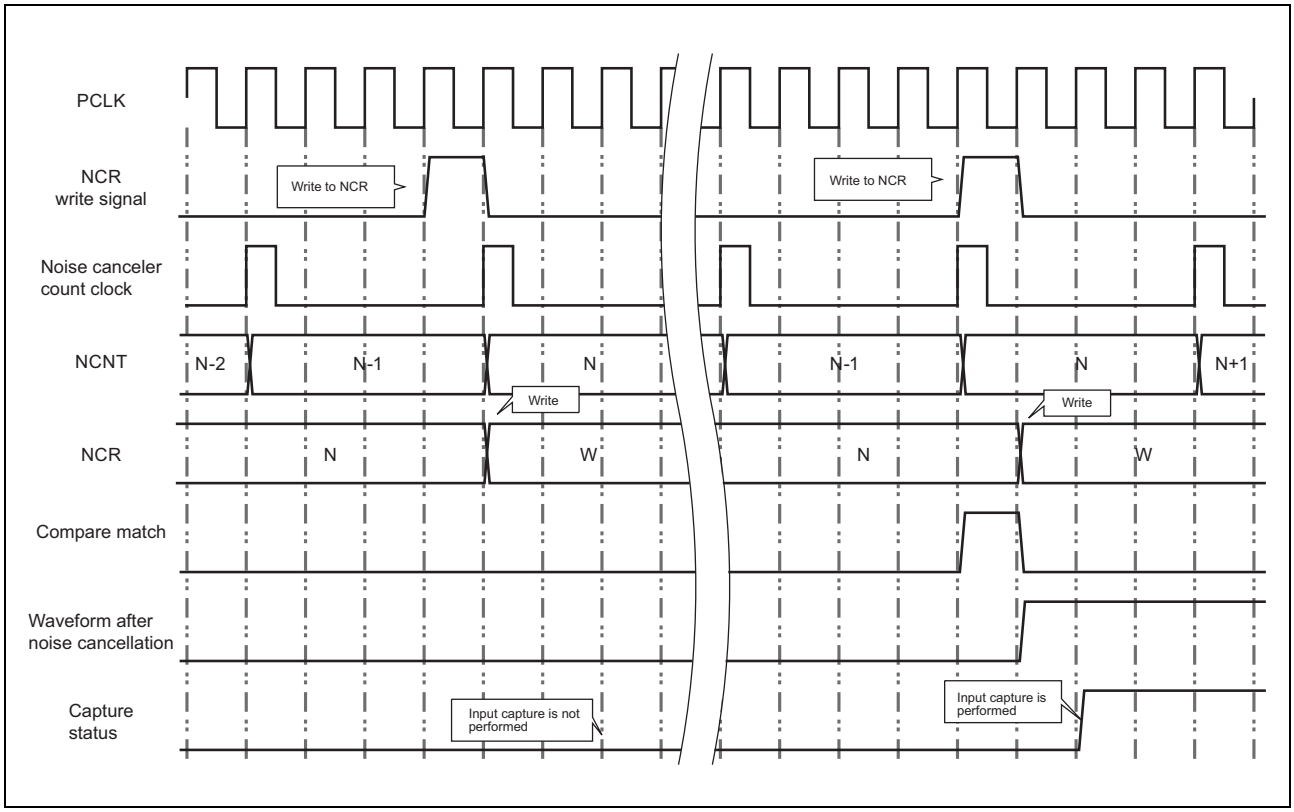

Figure 21.101 Contention between Writing to NCR and Compare Match of NCR-NCNT (Example in Minimum Time-at-Level Cancellation Mode)

21.14.6 Contention in Timer Down Counter Dxy

Contentions in DCNTDxy are described here.

21.14.6.1 Contention between Writing to DCNTDxy Counter and Count-Down

When writing occurs simultaneously with decrementation of the down counter, writing to DCNTDxy is performed. The attempt to decrement the value is ignored and decrementation recommences from the new value on the next count-down clock.

21.14.6.2 Contention between Writing to DCNTDxy Counter and Underflow

When writing to DCNTDxy occurs simultaneously with underflow, writing to DCNTDxy is performed. The example in the left half of **Figure 21.102** shows operation when a count-down clock is input simultaneously with writing to DCNTDxy when the DCNTDxy value is 0000 0000_H. Though the new value is written to DCNTDxy, count-down operation will be halted because underflow is detected. The underflow status flag is set. Figure on the right illustrates the case where data is written to DCNTDxy one cycle before, in which case an underflow interrupt request is not issued, so that an underflow will not be detected.

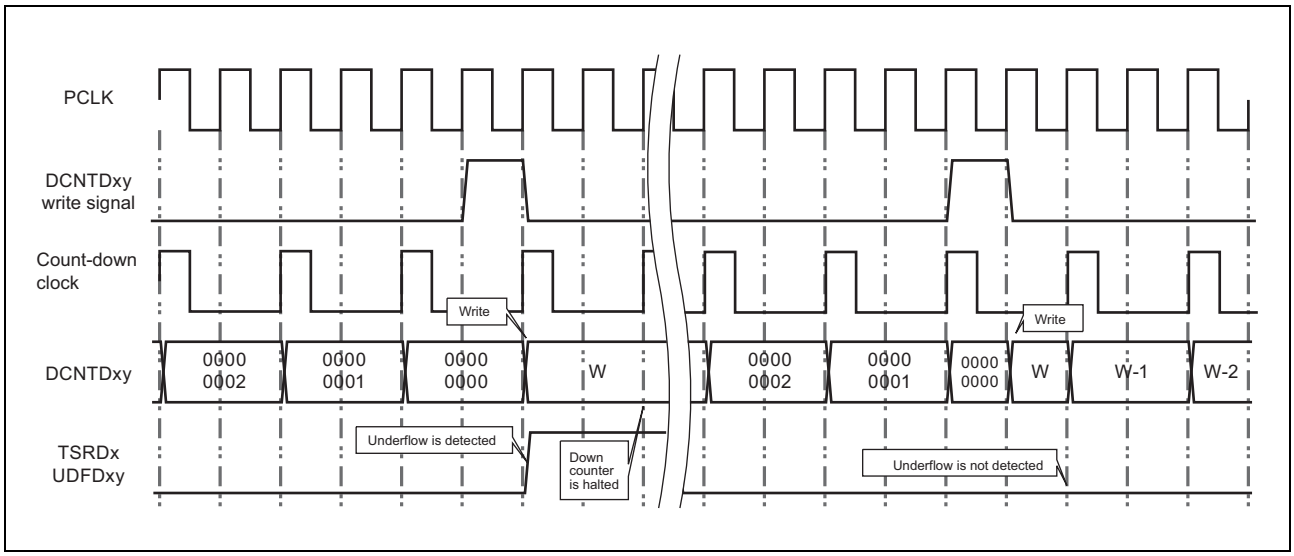

Figure 21.102 Contention between Writing to DCNTDxy and Underflow

21.14.6.3 Counter Stop Trigger — Contention between Writing to DCNTDxy Counter and Compare Match B

When writing to DCNTDxy occurs simultaneously with compare match B, writing to DCNTDxy is performed (if compare match B is selected as a condition to stop the down counter).

An example in which writing to DCNTDxy occurs simultaneously with clearing of the counter by detection of compare match B is shown in the middle of **Figure 21.103**. Counter clearing of DCNTDxy by compare match B is ignored, and writing takes priority. However, the output on TODxyB is turned off due to compare match B, and DCNTDxy halts with the written value retained. The waveforms in the right half of the figure show a case in which the write cycle occurs one PCLK cycle earlier. During the PCLK cycle subsequent to writing to DCNTDxy, the counter is cleared by compare match B. The waveforms in the left half of the figure show an example in which writing is performed immediately after the counter has been cleared by compare match B.

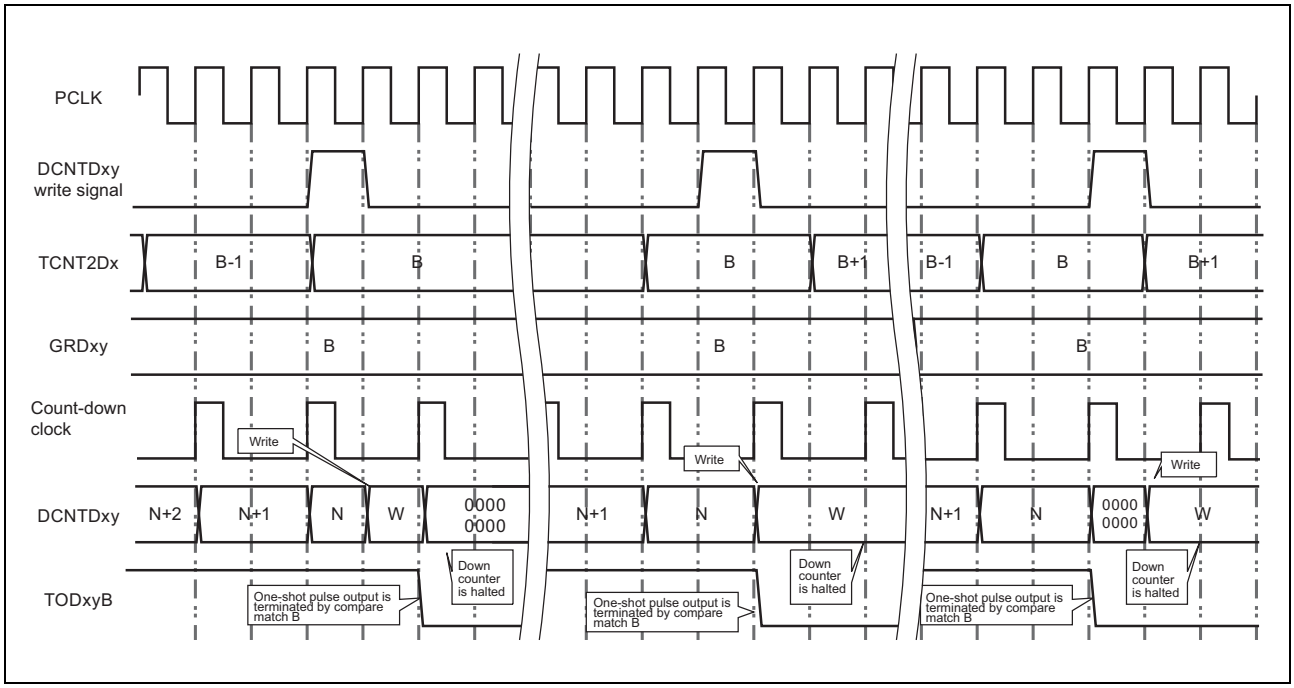

Figure 21.103 Contention between Writing to DCNTDxy and Counter Clearing by Compare Match B

21.14.6.4 Contention between Setting of Underflow Status Flag and Clearing by Writing 1 to Status Clear Register

When flag clearing by the timer status clear register and an underflow occurs simultaneously, flag clearing is performed. Illustrated below is an example where status flag setting by an underflow of DCNTDxy and flag clearing by the timer status clear register occur simultaneously (left half the figure below). The waveforms in the right half of **Figure 21.104** show how the status flag is set again by underflow occurrence immediately after the status flag has been cleared.

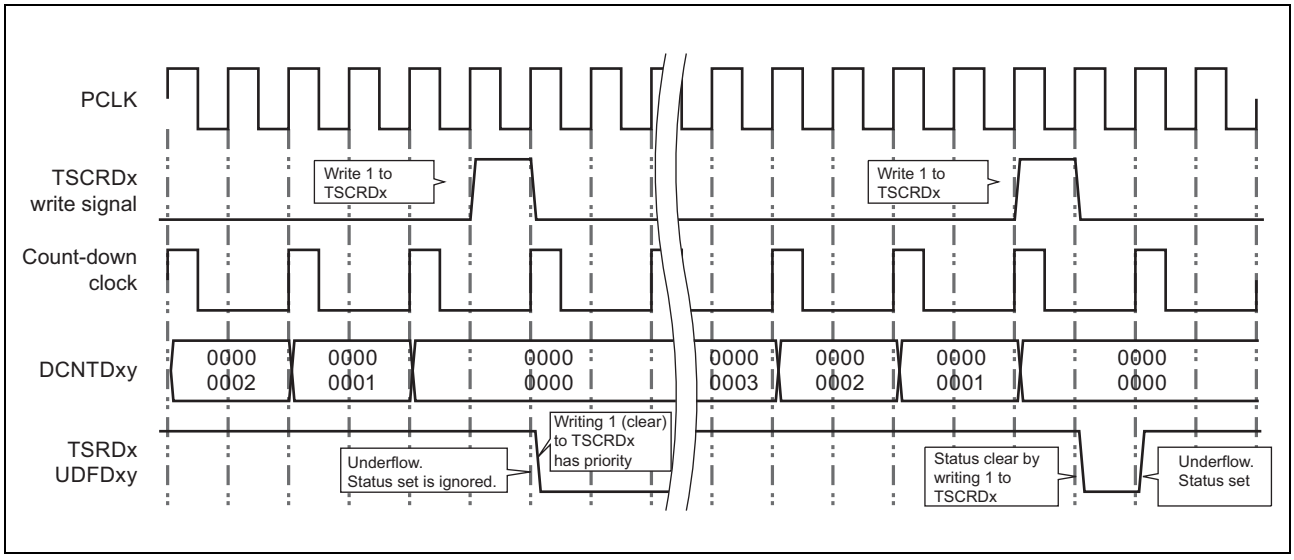

Figure 21.104 Contention between Setting and Clearing of Underflow Status Flag

21.14.6.5 TODxyB Output at Occurrence of Down Counter Start Trigger When Down Counter Value is 0000 0000$_H$

The TODxyB output (one-shot pulse) is not started by down counter underflow.

21.14.6.6 TODxyB Output at Simultaneous Occurrence of Start Trigger and Stop Trigger for Down Counter

When the down counter start trigger occurs simultaneously with the down counter stop trigger, the down counter is cleared to 0 by the stop trigger. In this case, the one-shot pulse output on the TODxyB pin is not started.

Similar to the above case, when the down counter start trigger occurs and then the down counter stop trigger occurs before the first count-down clock is input, the down counter is cleared to 0 without being decremented even once and the one-shot pulse output on the TODxyB pin is not started.

21.14.6.7 Contention between Down Counter Start Trigger and Underflow

When the down counter start trigger occurs simultaneously with underflow, DCNTDxy remains halted at the value of 0000 0000_H (waveforms in the middle of **Figure 21.105**). If the down counter had been in process of decrementing, the TODxyB output is turned off by underflow (waveforms in the left half of the figure). If compare match A occurs while the down counter is halted (DCNTDxy = 0000 0000_H), the TODxyB output is kept negated (waveforms in the right half of the figure). In both cases, the underflow interrupt request and setting of the underflow flag to 1 are performed upon detection of a down count start trigger or at the first cycle of the down count clock after detection.

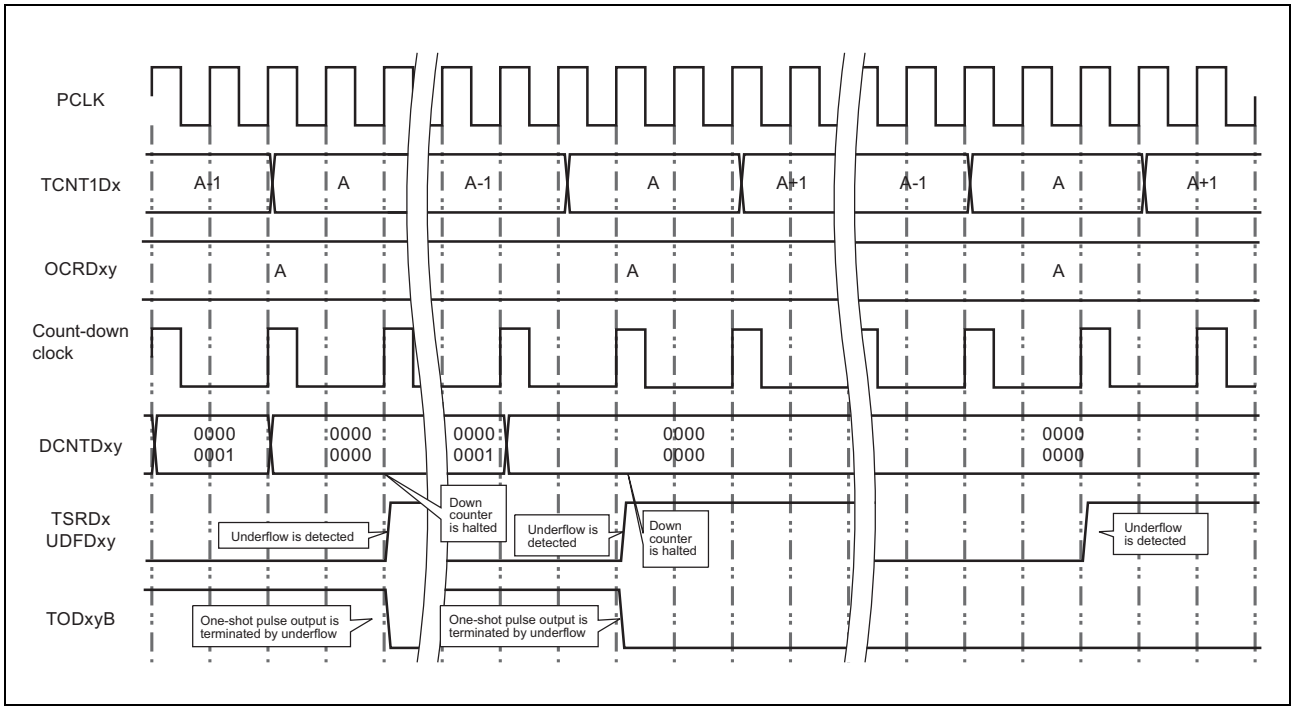

Figure 21.105 Contention between Compare Match A and Underflow

21.14.7 Coordinated Operation of Timers A, B, and D

This section explains the contention between counter clear requests from timer B and TCNT1Dx and TCNT2Dx.

21.14.7.1 Contention Between Counter Clearing of TCNT1Dx and 2Dx and Compare Match

Operation when clearing of the TCNT1Dx/TCNT2Dx counter by a counter clearing signal from timer B occurs simultaneously with compare match is shown below. The waveforms in the left half of **Figure 21.106** show a case in which the counter is cleared prior to compare match. On the other hand, the waveforms in the right half of the figure show a case in which the counter is cleared simultaneously with compare match.

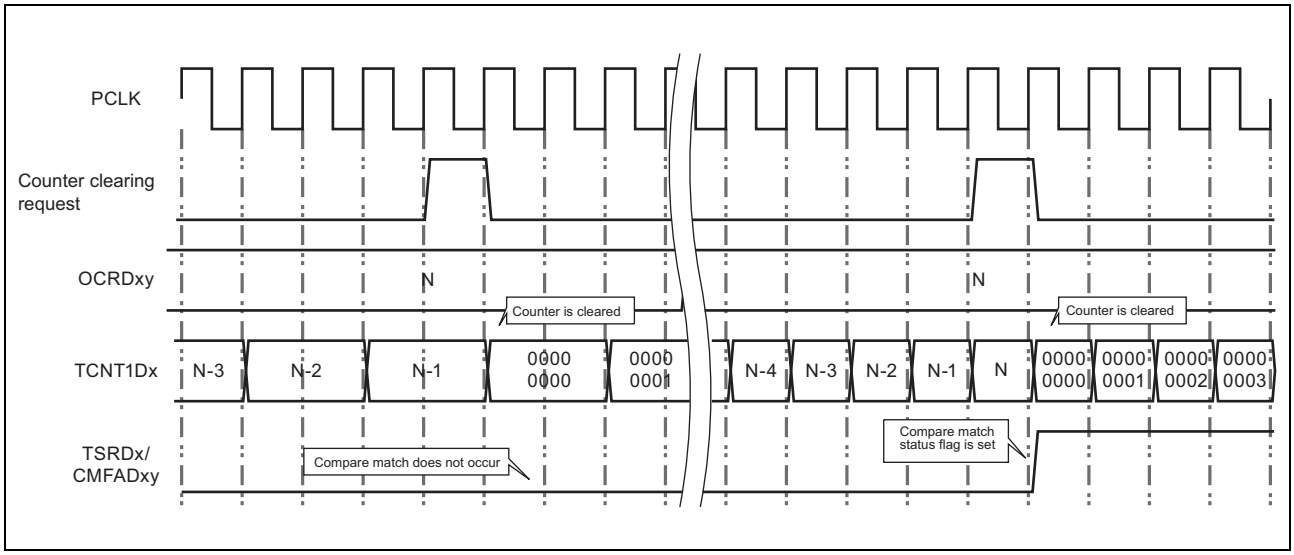

Figure 21.106 Contention between Counter Clearing by Timer B and Compare Match

Timer	Counter	Counter Clearing Source	Compare Match Register	Status
Timer D	TCNT1Dx	TCNT1Dx/TCNT2Dx clearing request from timer B	OCR1Dxy	CMFADxy
	TCNT2Dx		OCR2Dxy	CMFBDxy

21.14.7.2 Contention between TCNT1Dx/TCNT2Dx Counter Overflow and Counter Clearing by Timer B

When writing to TCNT1Dx/TCNT2Dx occurs simultaneously with a counter clearing signal from timer B, the counter is not cleared but writing to the counter is performed (waveforms in the left half of **Figure 21.107**). The waveforms in the right half of the figure show a case in which writing to TCNT1Dx is one PCLK cycle later. This is the same for TCNT2Dx.

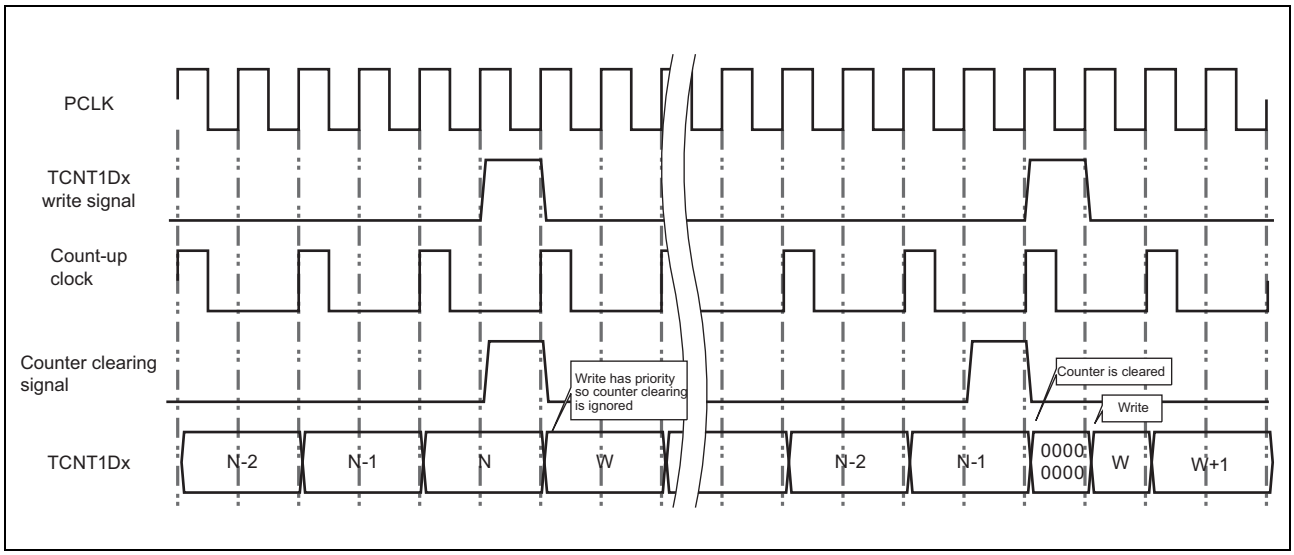

Figure 21.107 Contention between Writing to TCNT1Dx and Counter Clearing

21.14.7.3 Contention between TCNT1Dx/TCNT2Dx Counter Overflow and Counter Clearing by Timer B

When TCNT1Dx overflow by the counting up occurs simultaneously with clearing of TCNT1Dx from timer B, the counter value is cleared to 0000 0000_H by the counter clearing signal. In this case, the overflow status flag is not set (only for when C1CEDx = 1). The same applies to TCNT2Dx overflow.

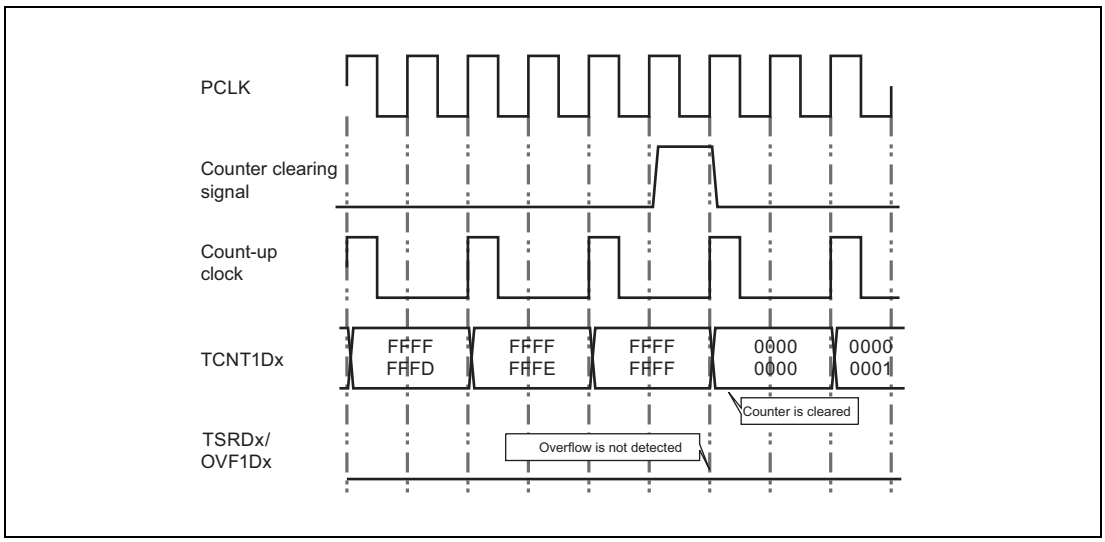

Figure 21.108 Contention between Counter Clearing and Overflow

21.14.7.4 Contention between TCNT1Dx Clearing by Clearing Signal from Timer B and Input Capture to OSBRDx

Operation when clearing of the TCNT1Dx counter by timer B occurs simultaneously with input capture to an offset base register is shown below. When capture and counter clearing occur simultaneously, the counter value before clearing is captured in OSBRDx. At the same time, the TCNT1Dx counter is cleared (waveforms in the left half of **Figure 21.109**).

The waveforms in the right half of the figure show a case in which capture is performed one PCLK cycle after the counter has been cleared and the counter value after clearing is captured in OSBRDx.

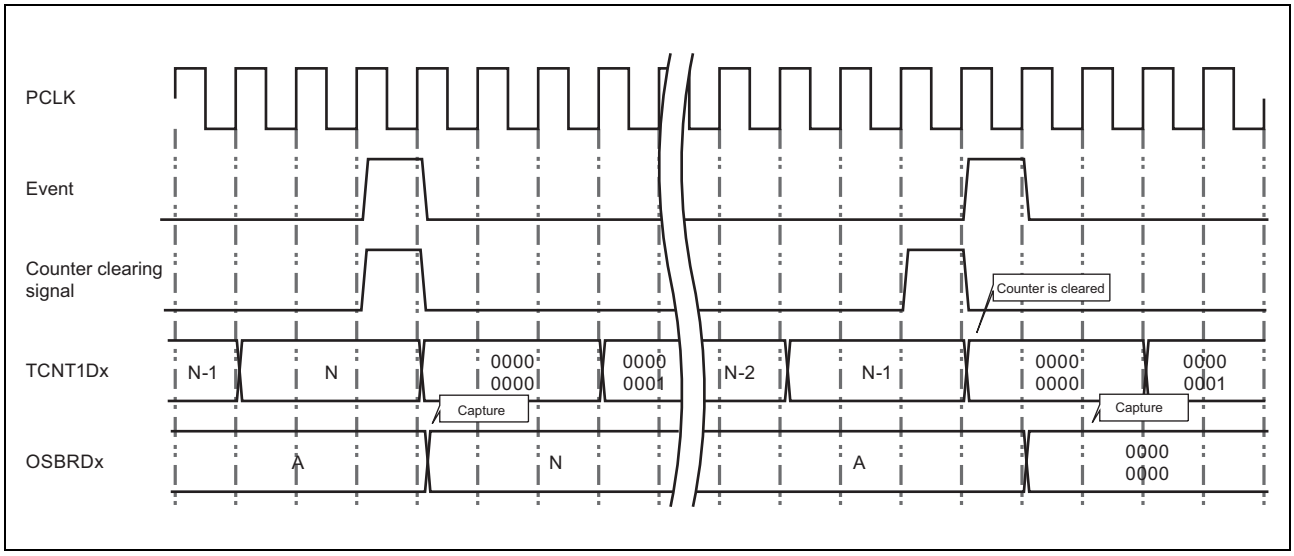

Figure 21.109 Contention between TCNT1Dx Counter Clearing and Input Capture to OSBRDx

21.14.7.5 Contention between Clearing of the Counter to 0 by Timer B and Clearing of the Counter by the Counter Upper-Limit Setting Function

If the signal for clearing the counter to 0 from timer B and clearing by the timer D counter upper-limit setting function are in contention, the former is given priority and is responsible for the counter value becoming 0.

Applicable Timer	Counter	Counter Clearing Source	Compare-Match Register
Timer D	TCNT1Dx	Request for clearing TCNT1Dx from timer B	CUCR1Dx
	TCNT2Dx	Request for clearing TCNT2Dx from timer B	CUCR2Dx

21.14.8 Different Specifications of Operation in Response to a Match in Comparison

Operation in response to a match in comparison differs from timer to timer. Timers have the following three types of operation, according to differences in the time the match in comparison is detected and the condition for detection.

- Type 1
  - The match in comparison is detected in the cycle of PCLK following that in which the values of the timer counter and the compare-match register have matched.
  - Testing for a match in comparison proceeds in every cycle of PCLK.
  - A match in comparison is detected even if it occurs at the time a value is written to the timer counter or the compare-match register.
- Type 2
  - The match in comparison is detected in the cycle of PCLK following that in which the values of the timer counter and the compare-match register have matched.
  - A match in comparison is detected in the cycle of PCLK when the timer counter counts up or down to the matching value.
  - A match in comparison is not detected if it occurs at the time a value is written to the timer counter or the compare-match register.
- Type 3
  - A match in comparison is detected in the next cycle of the counter clock after the values of the timer counter and the compare-match register have matched.
  - Testing for a match in comparison proceeds in every cycle of the counter clock.
  - A match in comparison is not detected if it occurs at the time a value is written to the timer counter or the compare-match register.

Applicable Timer	Counter	Compare-Match Register	Type of Match in Comparison
Timer B	TCNTB0	OCRB0	Type 3
	TCNTB1	OCRB1	Type 1
		OCRB10	Type 1
		OCRB11	Type 1
		OCRB12	Type 1
	TCNTB6	OCRB6	Type 3
		OCRB7	Type 3
	TCNTB3	OCRB8	Type 1
Timer C	TCNTCx	CUCRCx	Type 1
		GRCxy	Type 1
		OCRCxy	Type 1
Timer D	TCNT1Dx	CUCR1Dx	Type 1
		OCR1Dxy	Type 2
	TCNT2Dx	CUCR2Dx	Type 1
		OCR2Dxy	Type 2
Timer E	TCNTExy	CYLRExy	Type 3
		DTRExy	Type 3

Applicable Timer	Counter	Compare-Match Register	Type of Match in Comparison
Timer F	ECNTAFx	GRAFx	Type 1
	ECNTBFx	GRBFx	Type 1
	ECNTCFx	GRCFx	Type 1
		GRDFx	Type 1

Timer H	TCNT1H	OCR1H	Type 1
Timer J	TCNTJx	OCRJx	Type 1

Section 22 Autonomous Pulse Adapter (APA)

The autonomous pulse adapter (APA) enables real-time generation of complex pulse waveforms without intervention by the CPU. Use of APA reduces the workload on the CPU and periphery buses, and coordinates the PWM channels and the reference inputs for pulse generation.

22.1 Overview

Basic functions

- Real-time generation of complex waveforms without intervention by the CPU.
- Built-in calculation device for real-time calculation of pulse width.
- Generation of complex pulse sequences by defining one-shot pulses, which are basic building blocks.
- A one-shot pulse is generated from multiple instances of reference data. Times, angles, and AD conversion values can be combined.
- Pulse sequences can be controlled (can be put to different states) on a real-time basis by event inputs. The manner of control by event inputs can be selected from multiple options (stop of output, transition to the next pulse, output masks, etc.)
- Synchronization of multiple channels by using the same event signal to control the channels.

Reference input

- The following 3 types (11 channels) can be used as reference inputs, each of which has a different time resolution.

CAUTION

SAR-AD cannot be used as APA reference in this product.

Table 22.1 Reference Input

Type	Time Resolution	Number of Channels	Dynamic Range	Remarks
Reference input A	pclk *4	2 (ch.0 and ch.1)	16 bits	External input
Reference input C	pclk *20	8 (ch.2 to ch.9)	16 bits	External input
Reference input S	pclk *20	1 (ch.sw)	16 bits	These registers can be used as reference inputs, and can be read and written by software.

Note: A signal to be used as a reference input must have slower update intervals than time resolutions in **Table 22.1** (If it is faster, APA cannot capture data inside, resulting in data losses.)

Table 22.2 Example of Application (electric current feedback configuration pclk = 40 MHz)

Type	Time Resolution	Channels	Dynamic Range	Reference Used	Connected to	Remarks
Timer	10 MHz (pclk*4)	ch.0, ch.1	16 bits	Reference A *2	ATU (Timer D, Timer G)	ATU output is 32 bits, and 16 bits of them are used. It is used by the register of the APA input selector (see **Section 22.5.8, APA Input Selector**).
ADC	2 MHz (pclk*20)	ch.2 to ch.9	16 bits	Reference C *8	ΔΣ-ADC or SAR-AD	—
Software reference	2 MHz (pclk*20)	ch.sw	16 bits	Reference S *1	—	—

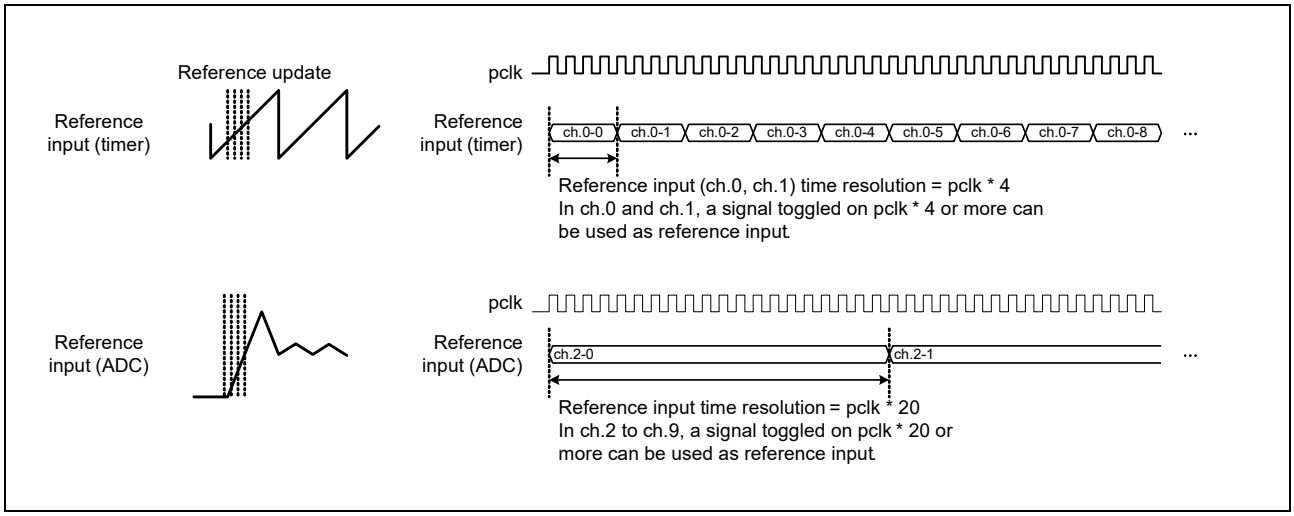

Figure 22.1 Use Conditions of Reference Inputs

Event input

- 32 channels are available
  - Selection of 16 channels is possible from 64 channels of event inputs (including 6 channels of software events).
  - For other 16 channels, PWM output generated by APA can be used as event input.
- Event input to pulse generation channels is performed by time division.

Table 22.3 Event Input

Type	Time Resolution	Number of Channels	Detection Edge	Remarks
Event input	pclk * 1	58	Rise, fall, or rise and fall	—
Software event input	pclk * 1	6	Rise, fall, or rise and fall	These registers can be used as event inputs, and can be read and written by software.

Pulse generation channels

- PWM pulse generation can use 16 channels.
- Each pulse generation channel can have 1 interrupt output channel (16 channels in total).
  - An interrupt cause can be one of the following 5 types: element transition, channel operation completion, on match, off match, and on/off match.
- Pulse generation is realized by setting a set of parameters (called an element). Each parameter specifies a PWM output enabling condition (=, <, or >) for a reference input, a PWM output disabling condition (=, <, or >) for a reference input, or exception processing for an event input.
- Combination of multiple elements can realize a complex pulse sequence.

Table 22.4 Pulse/Interrupt Output

Type	Time Resolution	Number of Channels	Minimum Pulse Width	Remarks
PWM output*1	pclk * 1	16	pclk * 40 (High) pclk * 40 (Low)	The minimum pulse width shown here is applicable when ON/OFF occurs on the match condition specified by an element. If the match status is forcibly changed by exception processing, a shorter pulse width may result from the conflict with a match.
Interrupt output	pclk * 1	16	pclk * 1 (High)	Only one-shot pulse (high) can be output.

Note 1. PWM output matching condition can be specified by an element. A matching condition must satisfy the minimum pulse widths listed in the above table (see **Section 22.5.7.1, Matching Condition Setting 1**). Specifying a matching condition with a pulse width of pclk*40 or shorter might result in an unintended pulse width.

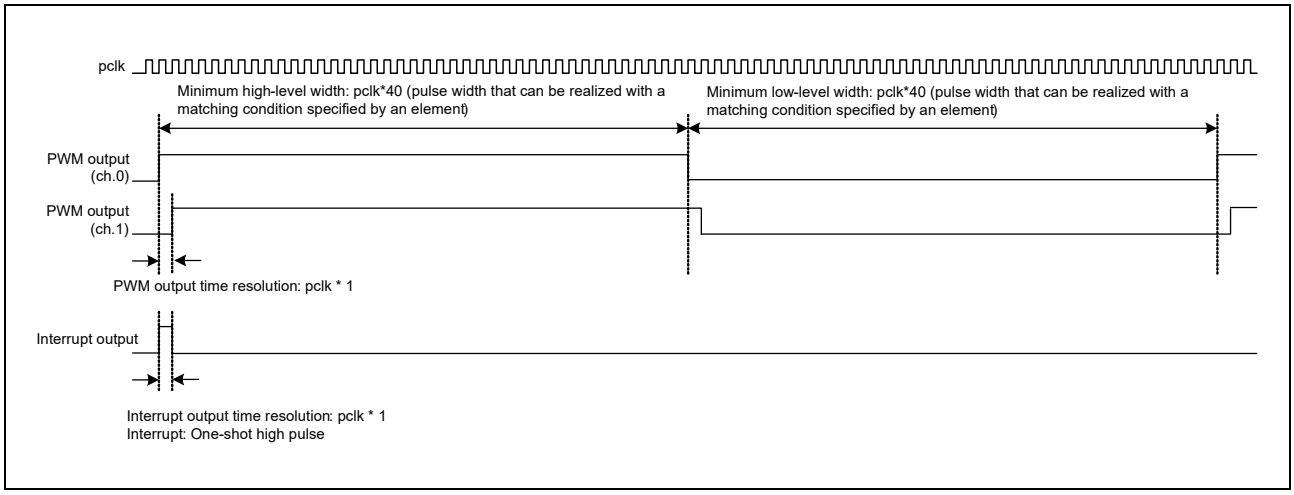

Figure 22.2 Use Condition of Pulse/Interrupt Output

Element RAM Interface

- In APA, 128 elements can be defined.
- A piece of element information can be shared by all pulse generation channels (16 channels). Access from a pulse generation channel to an element RAM is made with time division which is controlled by the event input block.
- Element data is written before a pulse generation channel generates pulses. (through the P-Bus).
- Element data can be read through P-Bus.
- Each element is stored in memory, and can be read and written through the P-Bus. Writing to an element through the P-Bus must be made successively in units of 3 words (32 bits * 3).
- Built-in capability of calculating matching conditions (relative/absolute).

22.2 Terms and Definitions

Table 22.5 lists and defines the terms used in this section.

Table 22.5 List of Terms (1/2)

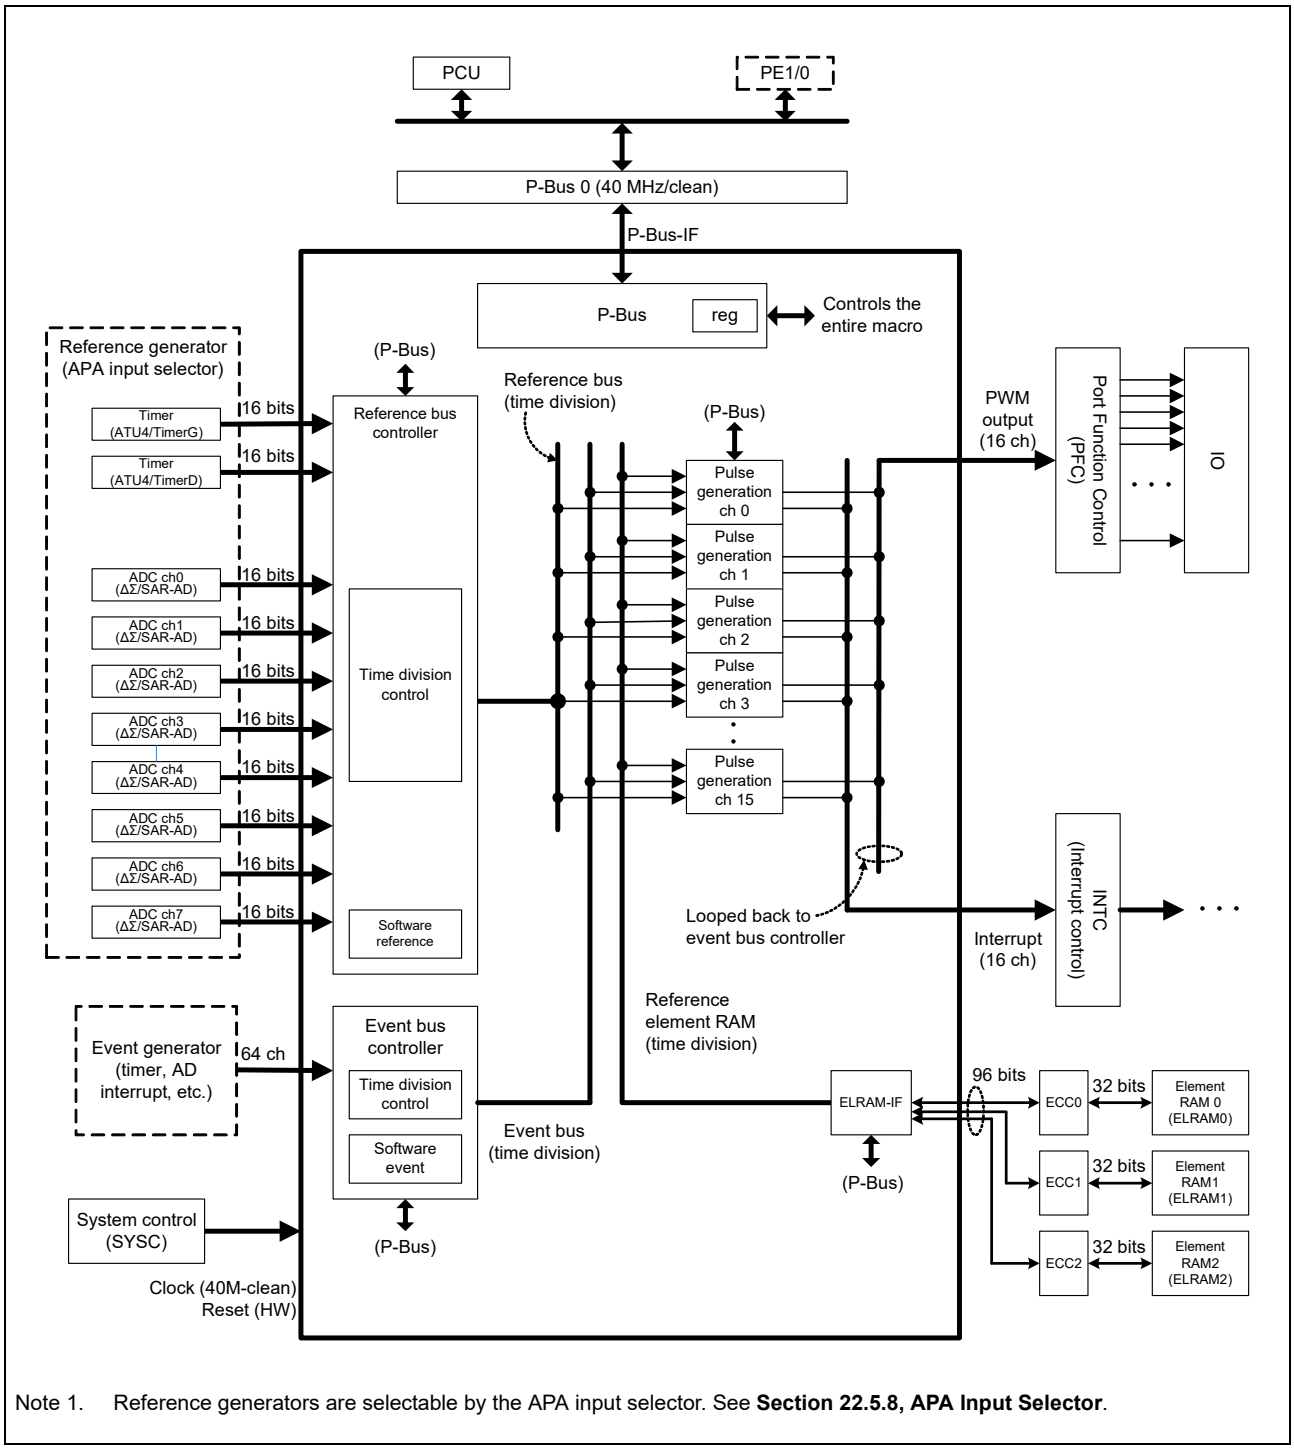
Terms	Definition in This Section
APA	Abbreviation of Autonomous Pulse Adapter. Autonomous pulse control adapter.
External reference	Various data output signals to be referenced for pulse generation such as timers, ADCs, and sensors are referred to as “references” here. The configuration here is intended to allow 16-bit, 10-channel references for each channel. References of different resolutions (frequencies) can coexist.
Software reference	A register area (16 bits) that can be used as a virtual reference through writing data by software. One channel is available.
Reference bus	An APA-internal local bus that multiplexes all 11 reference channels (10 external and 1 software).
Event	A signal that triggers an APA-internal control action is referred to as an “event” here. Examples of events include an interrupt signal from peripheral modules and PWM output signal from APA itself. Events are represented by 1 bit per channel. Up to 32 channels can be used (among which 16 channels can be selected from 64 input channels, and other 16 channels have fixed connection).
Software event	A register area that can be used as a virtual event through writing data by software. 1 bit * 6 channels are available.
Event bus	An APA-internal local bus that connects 32 event channels in a parallel manner (eb_dat_r[31:0]).
Element	A data structure of a set of parameters as conditions for pulse generation. Each pulse generation channel generates pulses in accordance with the setting defined by the referenced element. • An element contains such information as a reference input number (0 to 7), a PWM output enabling condition (=, <, or >), a PWM output disabling condition (=, <, or >), exception processing for an event input, and a pointer to the next element. • An element is deployed in an APA-internal local memory (element RAM), and is configured through the P-Bus before pulse generation. • Each element has a pointer to the next elements, which is used in exception processing (transfer) to control transition to next elements. Combination of multiple elements can realize a complex pulse sequence.
Exception	An operation control of a pulse generation channel is referred to as an “exception” here. • There are six exception types: Postpone, force, restart, transfer, start, and stop, each of which can be assigned with any event as its trigger.
Reference time division	Time division processing that delivers reference inputs to each pulse generation channel (0 to 15).
Reference slot	A unit of time that constitutes the reference time division (= pclk * 1).
Fixed event input	The event input used for the loop back of the PWM output. It can be used as a fixed input.
Selected event input	Event input of 16 channels selected from 64 channels, which are 58 channels of external event inputs and 6 channels of software event inputs. Event inputs that can be used by APA concurrently are 32 channels, which consists of fixed events (16 channels) and selected event inputs (16 channels).
Event time division	Event time division assigns time available for circuits in APA (pulse generation channels, P-Bus) for sharing hardware resources such as the element RAM and the calculation device.
Event slot	A unit of time that constitutes the event time division (= pclk * 1).
Shared cycle	The cycle of event time division. A cycle consists of 20 event slots (pclk * 20).

Table 22.5 List of Terms (2/2)

Terms	Definition in This Section
Pulse generation channel	A circuit that generates a PWM waveform. This type of circuit monitors a set of reference inputs to generate a PWM waveform that satisfies the conditions. Each module has 16 channels, each of which can operate independently.
ON match/OFF match	A match is a state, in which a reference input satisfies the pulse generating condition defined in an element, for generating PWM pulses on a pulse generation channel. A condition for enabling pulses is an ON match, and that for disabling pulses is an OFF match.
ON waiting/OFF waiting	ON waiting is a state in which ON match is being monitored. OFF waiting is a condition in which OFF match is being monitored. ON waiting and OFF waiting are mutually exclusive.
Absolute designation	Absolute designation is the specification of absolute thresholds for matching with references that turn outputs on and off. That is, in absolute designation, the thresholds are directly compared with reference values. The opposite of absolute is relative.
Relative designation	Relative designation is the specification of differences from the reference value at the time the threshold was specified. Outputs are turned on and off when the references reach these differences. The condition takes the form of a difference, so is not directly compared with the reference values (doing this requires converting the differences to absolute thresholds). The opposite of relative is absolute.
Time resolution	Minimum time unit (in terms of clock cycles) of a signal that can be input to or output from APA. For example, when pclk*4 is defined for an input signal (reference input A in **Table 22.1, Reference Input**), APA can process input signals whose period is 4 pclk cycles or more. When pclk*1 is defined for an output signal (PWM output in **Table 22.4, Pulse/Interrupt Output**), the signal will be toggled every pclk cycle.

22.3 Configuration

Figure 22.3 is a block diagram of APA.



Note 1. Reference generators are selectable by the APA input selector. See **Section 22.5.8, APA Input Selector**.

Figure 22.3 APA Block Diagram

Table 22.6 lists the event input sources.

Table 22.6 External Event Sources

External Event Source No.	Function	Remarks
External event sources 0 to 15	APA interrupt output n (m: 0 to 15)	
External event sources 16 to 19	ATU timer D0m compare match A (m: 0 to 3)	
External event sources 20 to 23	ATU timer D0m compare match B (m: 0 to 3)	
External event sources 24 to 27	ATU TOD0mA pin output (m: 0 to 3)	
External event sources 28 to 31	ATU TOD0mB pin output (m: 0 to 3)	
External event sources 32 to 35	ATU Timer D0m down counter underflow (m: 0 to 3)	
External event sources 36 to 43	Timer G compare match interrupt (channel m) (m: 0 to 7)	
External event source 44	2-bit error detection interrupt from the ECC for APA	Outputs of apa_ecc_0, apa_ecc_1, and apa_ecc_2 (1 bit each) are logically ORed to be one bit.
External event sources 45 to 48	Condition match interrupt of DFE channels 6 to 9	
External event sources 49 to 56	Not used	Low-Clamp
External event sources 57	Fixed value input for unused event processing	Low-Clamp See **Section 22.5.7.5, Handling of Unused Exceptions**.

22.4 Control Registers

22.4.1 List of Control Registers

APA registers are arranged on the P-Bus as shown in **Table 22.7**.

Register addresses are given as offsets from the base address FFEB 0000_H.

Table 22.7 Register Map (APA Local) (1/17)

+3	+2	+1	+0	Offset Address
000000_H			APAA0EN	0000
0000 0000_H				0004
APAA0CHEN				0008
0000_H		APAA0CHST		000C
0000 0000_H				0010 to 01FF
0000_H		APAA0RFDT0		0200
0000_H		APAA0RFDT1		0204
0000_H		APAA0RFDT2		0208
0000_H		APAA0RFDT3		020C
0000_H		APAA0RFDT4		0210
0000_H		APAA0RFDT5		0214

22.4.2 Control Register Details (Overall Operation)

Registers explained here configure the overall operation of APA.

Table 22.8 List of Control Registers (Overall Operation)

Offset Address	Symbol	Register Name	Value after Reset	Access Size	Function
0000_H	APAA0EN	APAA0 operation enable register	00_H	8	Enabling APA overall operation
0008_H	APAA0CHEN	APAA0 channel operation enable register	0000_0000_H	32	Enabling all pulse generation channels
$000C_H$	APAA0CHST	APAA0 channel output status register	0000_H	16	Operation status of all pulse generation channels (PWM)
0010_H to $01FF_H$	(N/A)		0000_0000_H	—	Unused area (read-only) **Note:** This area is read as 0 and cannot be modified.

22.4.2.1 APAA0EN — APAA0 Operation Enable Register

This register controls starts and stops of the reference bus and the event bus of APA.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	APAACMENAPAA
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 22.9 APAA0EN Register Contents

Bit Position	Bit Name	Reset Cause	Function
0	APAACMENAPA	PRESETZ	Enabling APA operation. 0: Disabling stops APA 1: Enabling starts APA

Table 22.10 Setting to Enable Each Function

		Function		
Setting Register	Enable Setting	Reference Control	Event Control	Pulse generation channel (0 to 15)
APAA0EN	Writing 1 though the P-Bus	√	√	—
APAA0CHEN[15:0]	Writing 1 though the P-Bus. The setting can be made independently for channels 0 to 15.	—	—	√

NOTES

1. Change of this register must be made while all pulse generation channels (16 channels) are stopped (APAA0CHEN register = 0000 0000_H).
2. Pulse generation channels are not initialized even if this register is cleared to 0. Thus, if APAACMENAPA = low is set before pulse generation channel operation is stopped, unintended PWM waveforms may be output because the pulse generation channel stops with the values retained.
3. For the settings to start and stop operation, see **Section 22.5.7.4, Operation Procedure**.
4. Enabling APA starts reference control and event control operation.

22.4.2.2 APAA0CHEN — APAA0 Channel Operation Enable Register

This register enables all pulse generation channels. Each bit of the APAA0CHEN[15:0] register controls ON/OFF of a pulse generation channel.

Each bit of the APAA0CHEN[15:0] register can be written to only if the corresponding bit of the mask register (APAACMENMSKPGCH[15:0]) is set to 1.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	APAACMENMSKPGCH[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	APAACMENPGCH15	APAACMENPGCH14	APAACMENPGCH13	APAACMENPGCH12	APAACMENPGCH11	APAACMENPGCH10	APAACMENPGCH9	APAACMENPGCH8	APAACMENPGCH7	APAACMENPGCH6	APAACMENPGCH5	APAACMENPGCH4	APAACMENPGCH3	APAACMENPGCH2	APAACMENPGCH1	APAACMENPGCH0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.11 APAA0CHEN Register Contents

Bit Position	Bit Name	Reset Cause	Function
31 to 16	APAACMENMSKPGCH[15:0]	—	Mask writing to APAACMENPGCH[15:0]. Each bit is assigned for control of PGCH15 to PGCH0. 0: Writing to APAACMENPGCH[n] is disabled. 1: Writing to APAACMENPGCH[n] is enabled. **Note:** These bits are read as 0.
15 to 0	APAACMENPGCH[15:0]	PRESETZ	Set On/Off of PGCH. Each bit is assigned for control of PGCH15 to PGCH0. 0: Operation of PGCH15 to PGCH0 is disabled. 1: Operation of PGCH15 to PGCH0 is enabled.

The following examples show the settings to enable or disable the operation of the pulse generation channels (PGCHs).

- Writing 00FF $FFFF_H$: Operation of PGCH7 to PGCH0 is enabled.
- Writing 0000 $00FF_H$: No effect (The registers retain the previous values.)
- Writing FFFF 0000_H: Operation of PGCH15 to PGCH0 is disabled.
- Writing 0000 0000_H: No effect (The registers retain the previous values.)

Table 22.12 shows the correspondence between the bits of APAACMENMSKPGCH[15:0] and APAACMENPGCH[15:0] and PGCHs.

Table 22.12 Bit Correspondence to PGCH

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Corresponding channels	PGCH15	PGCH14	PGCH13	PGCH12	PGCH11	PGCH10	PGCH9	PGCH8	PGCH7	PGCH6	PGCH5	PGCH4	PGCH3	PGCH2	PGCH1	PGCH0

NOTES

1. Event time division must be in operation (the APAA0EN register = 1) when this register is set to 1 with pulse generation channels stopped. If this register is modified when event time division is not in operation (the APAA0EN register = 0), the intended matching comparison is not performed because the reference bus and the event bus do not work.
2. If APAACMENPGCH[n] is changed from 1 to 0 (channel operation enabled → disabled), one or two shared cycles of delay are inserted before the operation is stopped.
3. For the settings to start and stop operation, see **Section 22.5.7.4, Operation Procedure**.
4. For the pin state with APAACMENPGCH[n] = low, see **(5) Channel ON/OFF** in **Section 22.5.4.2, Operation: Matching Comparator**.

22.4.2.3 APAA0CHST — APAA0 Channel Output Status Register

This register monitors the operation status of all pulse generation channels (PWM). Each bit indicates level of the current PWM output pin (APAAEOPWM[15:0]) of each pulse generation channel.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	APAACMSTATPWM15	APAACMSTATPWM14	APAACMSTATPWM13	APAACMSTATPWM12	APAACMSTATPWM11	APAACMSTATPWM10	APAACMSTATPWM9	APAACMSTATPWM8	APAACMSTATPWM7	APAACMSTATPWM6	APAACMSTATPWM5	APAACMSTATPWM4	APAACMSTATPWM3	APAACMSTATPWM2	APAACMSTATPWM1	APAACMSTATPWM0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.13 APAA0CHST Register Contents

Bit Position	Bit Name	Reset Cause	Function
15 to 0	APAACMSTATPWM [15:0]	PRESETZ	Indicate the PWM output level of each pulse generation channel (0 to 15). For the correspondence between each bit and PGCH, see **Table 22.12**.

22.4.3 Control Register Details (Reference Bus)

These registers configure and read information about the operation of the reference bus.

Table 22.14 List of Control Registers (Reference Bus)

Offset Address	Symbol	Register Name	Value after Reset	Access Size	Function
0200_H	APAA0RFDT0	APAA0 reference data register 0	0000_H	16	Reads the value of reference input 0.
0204_H	APAA0RFDT1	APAA0 reference data register 1	0000_H	16	Reads the value of reference input 1.
0208_H	APAA0RFDT2	APAA0 reference data register 2	0000_H	16	Reads the value of reference input 2.
$020C_H$	APAA0RFDT3	APAA0 reference data register 3	0000_H	16	Reads the value of reference input 3.
0210_H	APAA0RFDT4	APAA0 reference data register 4	0000_H	16	Reads the value of reference input 4.
0214_H	APAA0RFDT5	APAA0 reference data register 5	0000_H	16	Reads the value of reference input 5.
0218_H	APAA0RFDT6	APAA0 reference data register 6	0000_H	16	Reads the value of reference input 6.
$021C_H$	APAA0RFDT7	APAA0 reference data register 7	0000_H	16	Reads the value of reference input 7.
0220_H	APAA0RFDT8	APAA0 reference data register 8	0000_H	16	Reads the value of reference input 8.
0224_H	APAA0RFDT9	APAA0 reference data register 9	0000_H	16	Reads the value of reference input 9.
0228_H	APAA0RFSW	APAA0 software reference data register	0000_H	16	Configures the value of the software reference input.
$022C_H$ to $023C_H$	(N/A)		$0000\ 0000_H$	—	Unused area (read-only) **Note:** This area is read as 0 and cannot be modified.
0240_H	APAA0RFMX0	APAA0 reference maximum value setting register 0	$FFFF_H$	16	Sets the maximum value of reference input 0.
0244_H	APAA0RFMX1	APAA0 reference maximum value setting register 1	$FFFF_H$	16	Sets the maximum value of reference input 1.
0248_H to 0264_H	(N/A)		$0000\ 0000_H$	—	Unused area (read-only) **Note:** This area is read as 0 and cannot be modified.
0268_H	APAA0RFMXSW	APAA0 software reference maximum value setting register	$FFFF_H$	16	Sets the maximum value of the software reference input.
$026C_H$ to $03FC_H$	(N/A)		$0000\ 0000_H$	—	Unused area (read-only) **Note:** This area is read as 0 and cannot be modified.

22.4.3.1 APAA0RFDTn — APAA0 Reference Data Registers (n = 0 to 9)

These registers read the value of reference inputs. The value to be read is the latest value that is output on the reference bus.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	APAAREFBDAT[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.15 APAA0RFDTn Register Contents

Bit Position	Bit Name	Reset Cause	Function
15 to 0	APAAREFBDAT[15:0]	PRESETZ	Read the latest data of reference input n. **Note:** This register is effective only when the reference bus is effective (APAACMENAPA = 1). The current value is retained when the reference bus is disabled (APAACMENAPA = 0).

Table 22.16 shows the correspondence between registers and reference inputs.

Table 22.16 Correspondence between APAA0RFDTn Registers and Reference Inputs

		Reference Input
Register	Offset Address	Reference ID
APAA0RFDT0	0200_H	0
APAA0RFDT1	0204_H	1
APAA0RFDT2	0208_H	2
APAA0RFDT3	$020C_H$	3
APAA0RFDT4	0210_H	4
APAA0RFDT5	0214_H	5
APAA0RFDT6	0218_H	6
APAA0RFDT7	$021C_H$	7
APAA0RFDT8	0220_H	8
APAA0RFDT9	0224_H	9

22.4.3.2 APAA0RFSW — APAA0 Software Reference Data Register

This register configures and reads the value of the software reference input.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	APAAREFBDATSW[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.17 APAA0RFSW Register Contents

Bit Position	Bit Name	Reset Cause	Function
15 to 0	APAAREFBDATSW [15:0]	PRESETZ	Software reference input. It is specified as an unsigned value. The set value in this register becomes effective as reference input immediately after completion of writing. However, the setting of this register is reflected in a reference bus output (refb_dat_r[15:0]) when the reference slot is 12_H (see **Section 22.5.2.2, Operation**).

22.4.3.3 APAA0RFMXn — APAA0 Reference Maximum Value Setting Registers (n = 0, 1, sw)

These registers set the maximum values of reference inputs.

These registers are referenced when relative designation is employed for matching conditions (used for overflow processing that might occur when relative designation is converted to absolute designation). Relative destination is available for only references 0, 1, and sw. Absolute destination is only available for references 2 to 9.

CAUTION

When these registers are configured, all pulse generation channels must be stopped (APAACMENPGCH = 0000 0000_H). If any of these registers is configured in other conditions, matching comparison might operate in an unintended manner.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	APAAREFBMAX[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.18 APAA0RFMXn Register Contents

Bit Position	Bit Name	Reset Cause	Function
15 to 0	APAAREFBMAX[15:0]	PRESETZ	Set the maximum value of the software reference input. It is specified as an unsigned value.

Table 22.19 shows the correspondence between registers and reference inputs.

Table 22.19 Correspondence between APAA0RFMXn Registers and Reference Inputs

		Reference Input	
Register	**Offset Address**	**Reference ID**	**Time Resolution**
APAA0RFMX0	0240_H	0	pclk*4
APAA0RFMX1	0244_H	1	pclk*4
APAA0RFMXSW	0268_H	f	pclk*20

If the corresponding reference input is smaller than the dynamic range (16 bits), set any of these registers to a value that the corresponding reference input can take (dynamic range).

If the dynamic range of the reference input and the register value do not coincide, matching might not be obtained in the intended manner when relative designation is employed for matching comparison.

If the source counter value of the corresponding reference input is larger than the dynamic range of APA, care must be taken on the relationship with the reference input value of APA at an overflow of the source counter.

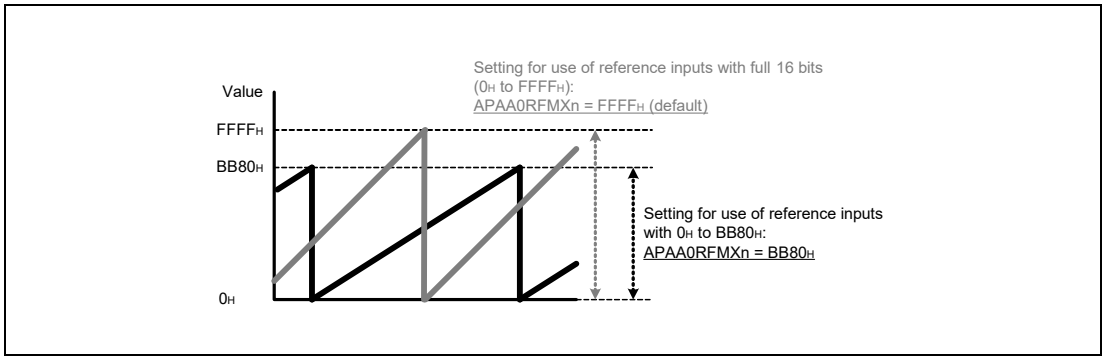

Figure 22.4 Configuration Example of APAA0RFMXn (n = 0/1/sw)

22.4.4 Control Register Details (Event Bus)

These registers configure and read information about the operation of the event buses.

22.4.4.1 APAA0EVSLn — APAA0 Event Select Registers (n = 00 to 15)

These registers select event inputs.

In the event bus, any 16 event inputs can be selected from among 64 channels, which consist of external event sources and software events 5 to 0. These registers configure the selection of event inputs.

Bit	7	6	5	4	3	2	1	0
	—	—	APAAEVSEL[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.21 APAA0EVSLn Register Contents

Bit Position	Bit Name	Reset Cause	Function
5 to 0	APAAEVSEL[5:0]	PRESETZ	Selects an event input. See **Table 22.22.**

CAUTION

When these registers are configured, all pulse generation channels must be stopped (APAACMENPGCH = 0000 0000_H). If any of these registers are configured in other conditions, event detection might operate in a wrong manner.

Table 22.22 shows the correspondence between the setting of APAAEVSEL[5:0] and the event input selection. Events that can be selected by each of APAAEVSEL[5:0] are called selected event inputs. For the correspondence between the setting of APAAEVSEL[5:0] and the event buses within the APA, see **Table 22.23**.

Table 22.22 Correspondence between APAAEVSEL[5:0] Setting and Event Inputs

The internal event buses eb_dat_r[31:0] have the following correspondence.

- eb_dat_r[15:0]: Correspond to PWM outputs n (n = 0 to 15) one by one (fixed event inputs).
- eb_dat_r[31:16]: Event inputs selected with the APAA0EVSL00 to APAA0EVSL 15 settings can be used (selected event inputs).

Table 22.23 Input Sources of Event Bus Signals

Fixed Event Input			Selected Event Input		
Event Bus	**Setting Register**	**Corresponding Pin**	**Event Bus**	**Setting Register**	**Offset Address**

22.4.4.2 APAA0EVSW — APAA0 Software Event Register

This register is the software event register. The value of each of bits APAAEVSW5 to APAAEVSW0 in this register can be used as an event input as it is. Each of bits APAAEVSW5 to APAAEVSW0 can be modified only if the corresponding mask bit (APAAEVSWMSK5 to APAAEVSWMSK0) is set to 1.

The operation option can be set by bits APAAEVSWCFG5 to APAAEVSWCFG0 in the APAA0EVSC register.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	APAAEVSWMSK[5:0]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	W	W	W	W	W	W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	APAAEVSW5	APAAEVSW4	APAAEVSW3	APAAEVSW2	APAAEVSW1	APAAEVSW0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.24 APAA0EVSW Register Contents

Bit Position	Bit Name	Reset Cause	Function
21 to 16	APAAEVSWMSK[5:0]	—	Mask writing to APAAEVSW[5:0]. Each bit is assigned to control each of APAAEVSW[5:0]. 0: Writing to APAAEVSW[n] is disabled. 1: Writing to APAAEVSW[n] is enabled. **Note:** These bits are read as 0.
5 to 0	APAAEVSW[5:0]	PRESETZ (after pclk*1)	The software event. Each bit corresponds to the software event ID (5 to 0). 0: Sets a software event (ID = bit) to low 1: Sets a software event (ID = bit) to high **Note:** The set value in this register becomes effective as an event input immediately after completion of writing. A software event is actually applied as an exception processing request in a pulse generation channel two cycles after completion of writing if the edge is detected (see **Figure 22.23**), and upon completion of writing if the level is detected (see **Figure 22.45**).

The following examples show how software events are configured.

- Writing 003F $003F_H$: All software events of channels 5 to 0 are set to 1 simultaneously.
- Writing 0000 $003F_H$: No effect (no software event)
- Writing 003F 0000_H: All software events of channels 5 to 0 are cleared to 0 simultaneously.
- Writing 0000 0000_H: No effect (The registers retain the previous values.)

22.4.4.3 APAA0EVSC — APAA0 Software Event Setting Register

This register sets the software event.

This register configures the operation options of the software event registers APAA0EVSW5 to 0.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	APAAEVSWCFG5[1:0]		APAAEVSWCFG4[1:0]		APAAEVSWCFG3[1:0]		APAAEVSWCFG2[1:0]		APAAEVSWCFG1[1:0]		APAAEVSWCFG0[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.25 APAA0EVSC Register Contents

Bit Position	Bit Name	Reset Cause	Function
11, 10	APAAEVSWCFG5[1:0]	PRESETZ	Configures the operation of software event register APAAEVSW5. 00: No control 01: One-shot (writing “high” to APAAEVSW5, and returning to “low” after one cycle of pclk) 10: One-shot (writing “low” to APAAEVSW5, and returning to “high” after one cycle of pclk) Others: Setting prohibited.
9, 8	APAAEVSWCFG4[1:0]	PRESETZ	Configures the operation of software event register APAAEVSW4. 00: No control 01: One-shot (writing “high” to APAAEVSW4, and returning to “low” after one cycle of pclk) 10: One-shot (writing “low” to APAAEVSW4, and returning to “high” after one cycle of pclk) Others: Setting prohibited.
7, 6	APAAEVSWCFG3[1:0]	PRESETZ	Configures the operation of software event register APAAEVSW3. 00: No control 01: One-shot (writing “high” to APAAEVSW3, and returning to “low” after one cycle of pclk) 10: One-shot (writing “low” to APAAEVSW3, and returning to “high” after one cycle of pclk) Others: Setting prohibited.
5, 4	APAAEVSWCFG2[1:0]	PRESETZ	Configures the operation of software event register APAAEVSW2. 00: No control 01: One-shot (writing “high” to APAAEVSW2, and returning to “low” after one cycle of pclk) 10: One-shot (writing “low” to APAAEVSW2, and returning to “high” after one cycle of pclk) Others: Setting prohibited.
3, 2	APAAEVSWCFG1[1:0]	PRESETZ	Configures the operation of software event register APAAEVSW1. 00: No control 01: One-shot (writing “high” to APAAEVSW1, and returning to “low” after one cycle of pclk) 10: One-shot (writing “low” to APAAEVSW1, and returning to “high” after one cycle of pclk) Others: Setting prohibited.
1, 0	APAAEVSWCFG0[1:0]	PRESETZ	Configures the operation of software event register APAAEVSW0. 00: No control 01: One-shot (writing “high” to APAAEVSW0, and returning to “low” after one cycle of pclk) 10: One-shot (writing “low” to APAAEVSW0, and returning to “high” after one cycle of pclk) Others: Setting prohibited.

CAUTION

When this register setting is modified, all pulse generation channels must be stopped ($APAA0CHEN = 0000_H$). If this register is modified during the operation of the pulse generation channels, event detection might operate in a wrong manner.

NOTES

When this register is modified to "01_B" or "10_B", the software event APAA0EVSW is set as follows.

1. When the setting of this register is changed to "01_B", the software event APAA0EVSW is set to a low level at the first PCLK after the setting change.
2. When the setting of this register is changed "10_B" the software event APAA0EVSW is set to a high level at the first PCLK after the setting change.

22.4.4.4 APAA0ESTA — APAA0 Event Status Register A

This register monitors the current level (high/low) of each bit of the event bus.

22.4.5.1 APAA0CCGAn — APAA0 Channel Setting Registers An (n = 00 to 15)

These registers are the setting registers for pulse generation channels n (0 to 15).

CAUTIONS

1. Only the APAACHNFSTEL[6:0] bits in this register (APAA0CCGAn) can be modified during operation. When modifying these bits during operation of a pulse generation channel, the previous value must be written to the other bits.
2. Modification of bits other than the APAACHNFSTEL[6:0] bits must be made while a pulse generation channel is stopped (APAA0CHEN.APAACMENPGCH[n] = 0). If a bit other than the APAACHNFSTEL[6:0] bits is modified during operation of a pulse generation channel, it may cause an unintended operation.
3. For the operation when the APAACHNFSTEL[6:0] bits are modified while a pulse generation channel is operating, see **Section 22.5.5.3, Changing Starting Element Number during Operation**.

22.4.5.2 APAA0CCGBn — APAA0 Channel Setting Registers Bn (n = 00 to 15)

These registers are setting registers for pulse generation channels n (0 to 15).

CAUTION

Modification of this register must be made while a pulse generation channel is stopped (APAA0CHEN.APAACMENPGCH[n] = 0).

Modifying this register during operation of a pulse generation channel may cause the channel to operate in an unintended manner.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 22.30 APAA0CCGBn Register Contents (1/2)

Bit Position	Bit Name	Reset Cause	Function
22, 21	APAACHNEGRES[1:0]	PRESETZ	Indicate the effective edge(s) of the event input signal for the exception processing (restart). 00: Rising edge 01: Falling edge 10: Both (rising/falling) edges Others: Setting prohibited.
20 to 16	APAACHNIDRES[4:0]	PRESETZ	Specify the event bus signal to be used for the exception processing (restart). See **Table 22.31** for the correspondence between the values and event bus signals.
15	APAACHNOPSTR	PRESETZ	Option for the operation of the exception processing (start). This bit specifies the behavior of pulse generation channels after the operation is enabled (APAACMENPGCH[n] = 1). 0: Operation starts, triggered by a start exception after the operation is enabled. 1: Operation starts immediately after the operation is enabled. A start exception is not required. **Note:** When this option is set to 1, a stop exception does not stop the operation. (A stop exception stops the operation once, but the operation restarts from the initial element.) In this case, the operation can be stopped by setting the APPA0CHEN register to prohibit the operation.
14, 13	APAACHNEGSTR[1:0]	PRESETZ	Indicate the effective edge(s) of the event input signal for the exception processing (start). 00: Rising edge 01: Falling edge 10: Both (rising/falling) edges Others: Setting prohibited.
12 to 8	APAACHNIDSTR[4:0]	PRESETZ	Specify the event bus signal to be used for the exception processing (Start). See **Table 22.31** for the correspondence between the values and event bus signals.

Table 22.30 APAA0CCGBn Register Contents (2/2)

Bit Position	Bit Name	Reset Cause	Function
6, 5	APAACHNEGSTP[1:0]	PRESETZ	Indicate the effective edge(s) of the event input signal for the exception processing (stop). 00: Rising edge 01: Falling edge 10: Both (rising/falling) edges Others: Setting prohibited.
4 to 0	APAACHNIDSTP[4:0]	PRESETZ	Specify the event bus signal to be used for the exception processing (stop). See **Table 22.31** for the correspondence between the values and event bus signals.

The exception processing (start, stop, transfer, force, restart, and postpone) can use any internal event bus signals. The set value definitions are common to all types of exception processing.

Table 22.31 Correspondence between Exception Processing and Internal Event Bus Signals

Register Set Value	Selected Event	Related Setting (Register)	Register Set Value	Selected Event	Related Setting (Register)

22.4.5.3 APAA0CSTAn — APAA0 Channel Status Registers An (n = 00 to 15)

These registers monitor the channel status data for pulse generation channels n (0 to 15).

CAUTION

All the effective bits in these registers except APAACHNEN and APAAEOPWM take effect only when the reference and event buses are enabled (APAACMENAPA = 1) and the operation of the target channel is enabled (APAA0EN[n] = 1) (this setting is hereinafter described as “channel-enabled setting”).

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 22.34 APAA0CSTAn Register Contents (1/2)

Bit Position	Bit Name	Reset Cause	Function
22 to 16	APAACHNCUREL[6:0]	PRESETZ	Current element number (the element number currently effective for the pulse generation channel) **Note:** The value is retained except when the channel-enabled setting is made.
12 to 8	APAACMPSTAT[4:0]	PRESETZ	Indicate the current operation status of the matching comparator. See **Figure 22.52** and **Figure 22.13**. 00000: disable 00001: dis_wstart 00010: Unused 00011: pre_dis 00100: pre_on_cur 00101: pre_on_init 00110: pre_on_nxt 00111: pre_off 01000: waiton 01001: waiton_tron 01010: forcedoff_troff 01011: on_postponed 01100: waitoff 01101: waitoff_tron 01110: matoff_troff 01111: off_postponed 10000: terminate **Note:** The value is 00000 (disable) except when the channel-enabled setting is made.
5, 4	APAAMATSTAT[1:0]	PRESETZ	Indicate the matching detection status in the matching comparator. 00: Not match (matching is not detected) 01: ON match is detected. 10: OFF match is detected. 11: (Nothing detected) **Note:** The value is 00 (not match) except when the channel-enabled setting is made.

Table 22.34 APAA0CSTAn Register Contents (2/2)

Bit Position	Bit Name	Reset Cause	Function
3	APAATRNSTAT	PRESETZ	Indicates whether the transfer exception is entered (whether element transition upon OFF match is enabled) in the currently effective element. 0: Transfer exception is not entered. 1: Transfer exception is entered. **Note:** The value is 0 (transfer exception not entered) except when the channel-enabled setting is made.
2	APAAPPNSTAT	PRESETZ	Indicates whether the currently effective element is in the Postpone state. 0: Postpone OFF 1: Postpone ON **Note:** The value is 0 (Postpone OFF) except when the channel-enabled setting is made.
1	APAACHNEN	PRESETZ	The operation status of the corresponding pulse generation channel. 0: Disabled: PGCHn (n = 0 to 15) is stopped. 1: Enabled: PGCHn (n = 0 to 15) is in operation. **Note:** The bit contents are identical to those of bits APAACMENPGCH[n] in the APAA0CHEN register, so the same data can be read. The above feature is effective even if the channel-enabled setting is not made.
0	APAAEOPWM	PRESETZ	The operation status of the corresponding pulse generation channel (PWM). This bit indicates the output level of the PWM output pin n of the corresponding pulse generation channel. **Note:** The above feature is effective even if the channel-enabled setting is not made.

Table 22.35 shows the correspondence between the register settings and the pulse generation channels.

Table 22.35 Correspondence between Pulse Generation Channels and Register Settings (APAA0CSTAn)

PGCH15	APAA0CSTA15	$07E8_H$

22.4.5.4 APAA0CSTBn — APAA0 Channel Status Registers Bn (n = 00 to 15)

These registers monitor the element settings for pulse generation channels n (0 to 15).

The values that can be monitored by these registers are element information that is currently effective in the corresponding pulse generation channel, and those values are loaded from the element RAM.

CAUTION

All the effective bits in these registers take effect only when the reference and event buses are enabled (APAACMENAPA = 1) and the operation of the target channel is enabled (APAA0EN[n] = 1) (this setting is hereinafter described as “channel-enabled setting”).

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	APAAELDFINEL	APAAELDCONT	—	—	—	—	—	APAAELDRBIDON[3:0]				APAAELDMCON[1:0]		APAAELDABREON

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.36 APAA0CSTBn Register Contents (1/2)

Bit Position	Bit Name	Reset Cause	Function
29	APAAELDFINEL	PRESETZ	The last element flag. This flag indicates whether the element is the last one. 0: The element is not the last one. 1: The element is the last one. **Note:** The value is retained except when the channel-enabled setting is made.
28	APAAELDCONT	PRESETZ	The element continuation setting. This bit indicates how the currently enabled element operates after an OFF match. 0: Single operation (matching comparison is stopped until transition to the next element.) 1: Continuous operation (the operation returns to ON matching comparison after an OFF match is detected.) **Note:** The value is retained except when the channel-enabled setting is made.
22 to 19	APAAELDRBIDON[3:0]	PRESETZ	Indicate the reference number for ON matching comparison. For the correspondence between the values and the reference numbers, see **Table 22.37**. **Note:** The value is retained except when the channel-enabled setting is made.
18, 17	APAAELDMCON[1:0]	PRESETZ	Indicate the criteria for ON matching comparison. 00: [The specified reference value] == [Comparison baseline APAAELDRBDATON[15:0]] 01: [The specified reference value] > [Comparison baseline APAAELDRBDATON[15:0]] 10: [The specified reference value] < [Comparison baseline APAAELDRBDATON[15:0]] Others: Setting prohibited. **Note:** The value is retained except when the channel-enabled setting is made. The settings of 01 (>) and 10 (<) cannot be used when an overflow is generated at the reference value (the values before and after the overflow cannot be compared properly).

Table 22.36 APAA0CSTBn Register Contents (2/2)

Bit Position	Bit Name	Reset Cause	Function
16	APAAELDABREON	PRESETZ	Indicates whether the specified baseline (APAAELDRBDATON) is interpreted as an absolute value or a relative value for determining the comparison baseline (APAAELDRBDATON) for ON matching comparison. 0: Absolute designation. The specified baseline is interpreted as an absolute value. 1: Relative designation. The baseline is interpreted as the difference from the reference value at the time of the start of matching comparison. However, the relative designation is available only for references 0, 1, and sw. **Note:** The value is retained except when the channel-enabled setting is made.
15 to 0	APAAELDRBDATON[15:0]	PRESETZ	Indicate the comparison baseline for ON match. A comparison baseline is used for actual matching comparison, and has been converted to an absolute value. The value differs depending on the APAAELDRBDATON setting. • APAAELDABREON = 0 (absolute designation) APAAELDRBDATON[15:0] = APAAELMRBDATON[15:0] • APAAELDABREON = 1 (relative designation) APAAELDRBDATON[15:0] = refb_dat_n[15:0] + APAAELMRBDATON[15:0] **Note:** If OFF matching comparison is in progress when these bits are read, or the relative designation is made for the references 2 to 9, the values of these bits are identical to the relatively designated values. APAAELDRBDATON[15:0] = APAAELMRBDATON[15:0] The value is retained except when the channel-enabled setting is made.

For both ON match and OFF match, the correspondence between the compared reference numbers and setting values is as listed in **Table 22.37**. The relative destination is only available for references 0, 1, and sw.

Table 22.37 Comparison between Matching Comparison Setting and Reference Numbers

eln_rbid_on/off Set Value	Reference No.	Reference Name	Time Resolution	Relative Designation
0_H	0	Reference 0	pclk*4	Possible
1_H	1	Reference 1	pclk*4	Possible
2_H	2	Reference 2	pclk*20	Not possible*1
3_H	3	Reference 3	pclk*20	Not possible*1
4_H	4	Reference 4	pclk*20	Not possible*1
5_H	5	Reference 5	pclk*20	Not possible*1
6_H	6	Reference 6	pclk*20	Not possible*1
7_H	7	Reference 7	pclk*20	Not possible*1
8_H	8	Reference 8	pclk*20	Not possible*1
9_H	9	Reference 9	pclk*20	Not possible*1
F_H	f	Software reference	pclk*20	Possible
Others	0	(Interpreted as reference 0)	pclk*4	Possible

Note 1. If the relative designation is set for a reference for which the relative designation is not possible, the setting is ignored (the comparison baseline is the same as that for the absolute designation).

Table 22.38 shows the correspondence between the register settings and pulse generation channels.

Table 22.38 Correspondence between Pulse Generation Channels and Register Settings (APAA0CSTBn)

22.4.5.5 APAA0CSTCn — APAA0 Channel Status Registers Cn (n = 00 to 15)

These registers monitor the element settings for the pulse generation channels n (0 to 15).

The values that can be monitored by these registers are element information that is currently effective in the corresponding pulse generation channel, and those values are loaded from the element RAM.

CAUTION

All the effective bits in these registers take effect only when the reference and event buses are enabled (APAACMENAPA = 1) and the operation of the target channel is enabled (APAA0EN[n] = 1) (this setting is hereinafter described as “channel-enabled setting”).

Table 22.39 APAA0CSTCn Register Contents (1/2)

Bit Position	Bit Name	Reset Cause	Function
22 to 19	APAAELDRBIDOFF[3:0]	PRESETZ	Indicate the reference number for OFF matching comparison. For the correspondence between the values and the reference numbers, see **Table 22.37**. **Note:** The value is retained except when the channel-enabled setting is made.
18, 17	APAAELD_MCOFF[1:0]	PRESETZ	Indicate the condition for OFF matching comparison. 00: [The specified reference value] == [Comparison baseline APAAELDRBDATON[15:0]] 01: [The specified reference value] > [Comparison baseline APAAELDRBDATON[15:0]] 10: [The specified reference value] < [Comparison baseline APAAELDRBDATON[15:0]] Others: Setting prohibited. **Note:** The value is retained except when the channel-enabled setting is made. The settings of 01 (>) and 10 (<) cannot be used when an overflow is generated at the reference value. (The values before and after the overflow cannot be compared properly.)
16	APAAELDABREOFF	PRESETZ	Indicates whether the specified baseline (APAAELDRBDATOFF) is interpreted as an absolute value or a relative value for determining the comparison baseline (APAAELDRBDATOFF) for OFF matching comparison. 0: Absolute designation. The specified baseline is interpreted as an absolute value. 1: Relative designation. The baseline is interpreted as the difference from the reference value at the time of the start of matching comparison. However, the relative designation is available only for references 0, 1, and sw. **Note:** The value is retained except when the channel-enabled setting is made.

Table 22.39 APAA0CSTCn Register Contents (2/2)

Bit Position	Bit Name	Reset Cause	Function
15 to 0	APAAELDRBDATOFF[15:0]	PRESETZ	Indicate the comparison baseline for OFF match. A comparison baseline is used for actual matching comparison, and has been converted to an absolute value. The value differs depending on the APAAELDABREOFF setting. • APAAELDABREOFF = 0 (absolute designation) APAAELDRBDATOFF[15:0] = APAAELMRBDATOFF[15:0] • APAAELDABREOFF = 1 (relative designation) APAAELDRBDATOFF[15:0] = refb_dat_n[15:0] + APAAELMRBDATOFF[15:0] **Note:** If ON matching comparison is in progress when these bits are read, or the relative designation is made for the references 2 to 9, the values of these bits are not converted to absolutely designated values and are identical to the relatively designated values. APAAELDRBDATOFF[15:0] = APAAELMRBDATOFF[15:0] The value is retained except when the channel-enabled setting is made.

Table 22.40 shows the correspondence between the register settings and pulse generation channels.

22.4.5.6 APAA0CSTDn — APAA0 Channel Status Registers Dn (n = 00 to 15)

These registers monitor the element settings for the pulse generation channels n (0 to 15).

The values that can be monitored by these registers are the element information that is currently effective in the corresponding pulse generation channel, and those values are loaded from the element RAM.

CAUTION

All the effective bits in these registers take effect only when the reference and event buses are enabled (APAACMENAPA = 1) and the operation of the target channel is enabled (APAA0EN[n] = 1) (this setting is hereinafter described as “channel-enabled setting”).

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	APAAELDNEXTEL[6:0]							APAAELDOPTRN	APAAELDEGTRN[1:0]		APAAELDIDTRN[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.41 APAA0CSTDn Register Contents (1/2)

Bit Position	Bit Name	Reset Cause	Function
30 to 24	APAAELDNEXTEL[6:0]	PRESETZ	The next element number (00_H to $7F_H$). **Note:** The value is retained except when the channel-enabled setting is made.
23	APAAELDOPTRN	PRESETZ	Option for the operation of the exception processing (Transfer). Indicates whether an element transition is allowed without a Transfer exception in a certain condition. 0: The input of the Transfer exception enables the element transition to occur upon an OFF match. Once the Transfer exception is input, the element transition occurs only for the currently effective elements upon an OFF match. When the element is updated, another Transfer exception must be input. 1: The occurrence of an OFF match automatically triggers transition to next elements. Enabling of the element transition using the Transfer exception is not required. The element transition is given priority over the element continuation setting (APAAELMCONT). **Note:** The value is retained except when the channel-enabled setting is made.
22, 21	APAAELDEGTRN[1:0]	PRESETZ	Indicate the effective edge(s) of the event input signal for the exception processing (Transfer). 00: Rising edge 01: Falling edge 10: Both (rising/falling) edges Others: Setting prohibited. **Note:** The value is retained except when the channel-enabled setting is made.

Table 22.41 APAA0CSTDn Register Contents (2/2)

Bit Position	Bit Name	Reset Cause	Function
20 to 16	APAAELDIDTRN[4:0]	PRESETZ	Specify the event bus signal to be used for the exception processing (transfer). See **Table 22.31** for the correspondence between the values and event bus signals. **Note:** The value is retained except when the channel-enabled setting is made.
15	APAAELDOPFOR	PRESETZ	Option for the operation of the exception processing (force). 0: Next match is forcibly generated. ON waiting → ON match generated + transition to OFF waiting OFF waiting → OFF match forcibly generated + transition to the next state 1: OFF match is forcibly generated. ON waiting → OFF match generated. OFF waiting → ON match generated. **Note:** The value is retained except when the channel-enabled setting is made.
14, 13	APAAELDEGFOR[1:0]	PRESETZ	Indicate the effective edge(s) of the event input signal for the exception processing (force). 00: Rising edge 01: Falling edge 10: Both (rising/falling) edges Others: Setting prohibited. **Note:** The value is retained except when the channel-enabled setting is made.
12 to 8	APAAELDIDFOR[4:0]	PRESETZ	Specify the event bus signal to be used for the exception processing (force). See **Table 22.31** for the correspondence between the values and event bus signals. **Note:** The value is retained except when the channel-enabled setting is made.
5	APAAELDLVPPN	PRESETZ	Indicates the effective level of the event input signal for the exception processing (postpone). 0: Low level 1: High level **Note:** The value is retained except when the channel-enabled setting is made.
4 to 0	APAAELDIDPPN[4:0]	PRESETZ	Specify the event bus signal to be used for the exception processing (postpone). See **Table 22.31** for the correspondence between the values and event bus signals. **Note:** The value is retained except when the channel-enabled setting is made.

Table 22.42 shows the correspondence between the register settings and pulse generation channels.

22.4.6 Details of Elements

These registers configure and read the elements.

There are 128 elements (00_H to $7F_H$) available, and they can be read and written through the P-Bus.

The elements are deployed on the SRAM, so that they cannot be initialized by a reset.

Table 22.43 List of Element Setting Registers

Offset Address	Symbol	Register Name	Value after Reset	Access Size	Function
1000_H	APAA0ELMA000	APAA0 Element Setting Register A0		32	Setting data 0 of element 00
1004_H	APAA0ELMB000	APAA0 Element Setting Register B0		32	Setting data 1 of element 00
1008_H	APAA0ELMC000	APAA0 Element Setting Register C0		32	Setting data 2 of element 00
$100C_H$	(N/A)		$0000\ 0000_H$		Unused area (read-only) **Note:** This area is read as 0 and cannot be modified.
1010_H	APAA0ELMA001	APAA0 Element Setting Register A1		32	Setting data 0 of element 01
1014_H	APAA0ELMB001	APAA0 Element Setting Register B1		32	Setting data 1 of element 01
1018_H	APAA0ELMC001	APAA0 Element Setting Register C1		32	Setting data 2 of element 01
$101C_H$	(N/A)		$0000\ 0000_H$		Unused area (read-only) **Note:** This area is read as 0 and cannot be modified.
(Details of 1020_H to $17DC_H$ are the same as above, so they are omitted here.)					
$17E0_H$	APAA0ELMA126	APAA0 Element Setting Register A126		32	Setting data 0 of element 7E
$17E4_H$	APAA0ELMB126	APAA0 Element Setting Register B126		32	Setting data 1 of element 7E
$17E8_H$	APAA0ELMC126	APAA0 Element Setting Register C126		32	Setting data 2 of element 7E
$17EC_H$	(N/A)		$0000\ 0000_H$		Unused area (read-only) **Note:** This area is read as 0 and cannot be modified.
$17F0_H$	APAA0ELMA127	APAA0 Element Setting Register A127		32	Setting data 0 of element 7F
$17F4_H$	APAA0ELMB127	APAA0 Element Setting Register B127		32	Setting data 1 of element 7F
$17F8_H$	APAA0ELMC127	APAA0 Element Setting Register C127		32	Setting data 2 of element 7F
$17FC_H$	(N/A)		$0000\ 0000_H$		Unused area (read-only) **Note:** This area is read as 0 and cannot be modified.
1800_H to $1FFC_H$	(N/A)		$0000\ 0000_H$		Unused area **Note:** When accessed, the area from 1000_H to $17FC_H$ is read from or written to.

22.4.6.1 APAA0ELMAn — APAA0 Element Setting Registers An (n = 000 to 127)

These registers configure the operation of elements.

CAUTIONS

1. Since the contents of these registers are mapped to the SRAM, they are not initialized by hardware (values after reset are undefined). Therefore, the SRAM must be initialized before the APA starts operating even if an element is not currently used.
2. For writing to and reading from these registers, see **Section 22.5.6.2, Write to Element RAM**, and **Section 22.5.6.3, Read from Element RAM**, respectively.

Table 22.44 APAA0ELMAn Register Contents (1/2)

Bit Position	Bit Name	Reset Cause	Function
29	APAAELMFINEL	(None)	Last element setting. This bit specifies whether the element is to be the last one. 0: The element is not the last one. 1: The element is the last one.
28	APAAELMCONT	(None)	Element continuation setting. This bit specifies how the currently-effective element operates after an OFF match. 0: Single operation (matching comparison is stopped until transition to next elements.) 1: Continuous operation (the operation returns to ON matching comparison after an OFF match is detected.)
22 to 19	APAAELMRBIDON[3:0]	(None)	Specify the reference number for ON matching comparison. For the correspondence between the values and the reference numbers, see **Table 22.37**.
18, 17	APAAELMMCON[1:0]	(None)	Specify the condition for ON matching comparison. Comparison of large and small values is performed by interpreting the reference value as an unsigned number. The specified baseline is converted to an absolute designation format before comparison (see the APAAELDRBDATON[15:0] bits). 00: [Specified reference value] == [Comparison baseline APAAELDRBDATON[15:0]] 01: [Specified reference value] > [Comparison baseline APAAELDRBDATON[15:0]] 10: [Specified reference value] < [Comparison baseline APAAELDRBDATON[15:0]] Others: Setting prohibited

Table 22.44 APAA0ELMAn Register Contents (2/2)

Bit Position	Bit Name	Reset Cause	Function
16	APAAELMABREON	(None)	Indicates whether the specified baseline (APAAELMRBDATON) is interpreted as an absolute value or a relative value for determining the comparison baseline (APAAELMRBDATON) for ON matching comparison. 0: Absolute designation. The specified baseline is interpreted as an absolute value. 1: Relative designation. The baseline is interpreted to specify the difference from the reference value at the time when matching comparison started. Relative designation is valid only for references 0, 1, and sw.
15 to 0	APAAELMRBDATON[15:0]	(None)	Specify the baseline for ON matching comparison. It is specified as an unsigned value.

22.4.6.2 APAA0ELMBn — APAA0 Element Setting Registers Bn (n = 000 to 127)

These registers configure the operation of elements.

CAUTIONS

1. Since the contents of these registers are mapped to the SRAM, they are not initialized by hardware (values after reset are undefined). Therefore, the SRAM must be initialized before the APA starts operating even if an element is not currently used.
2. For writing to and reading from theses registers, see **Section 22.5.6.2, Write to Element RAM**, and **Section 22.5.6.3, Read from Element RAM**, respectively.

Table 22.45 APAA0ELMBn Register Contents

Bit Position	Bit Name	Reset Cause	Function
22 to 19	APAAELMRBIDOFF[3:0]	(None)	Specify the reference number for OFF matching comparison. For the correspondence between the values and the reference numbers, see **Table 22.37**.
18, 17	APAAELMMCOFF[1:0]	(None)	Specify the condition for OFF matching comparison. Comparison of large and small values is performed by interpreting the reference value as an unsigned number. The specified baseline is converted to an absolute designation format before comparison (see the APAAELDRBDATOFF[15:0] bits). 00: [Specified reference value] == [Comparison baseline APAAELDRBDATON[15:0]] 01: [Specified reference value] > [Comparison baseline APAAELDRBDATON[15:0]] 10: [Specified reference value] < [Comparison baseline APAAELDRBDATON[15:0]] Others: Setting prohibited
16	APAAELMABREOFF	(None)	Indicates whether the specified baseline (APAAELMRBDATOFF) is interpreted as an absolute value or a relative value for determining the comparison baseline (APAAELMRBDATOFF) for OFF matching comparison. 0: Absolute designation. The specified baseline is interpreted as an absolute value. 1: Relative designation. The baseline is interpreted to specify the difference from the reference value at the time when matching comparison started. Relative designation is valid only for references 0, 1, and sw.
15 to 0	APAAELMRBDATOFF[15:0]	(None)	Specify the baseline for OFF matching comparison. It is specified as an unsigned value.

22.4.6.3 APAA0ELMCn — APAA0 Element Setting Registers Cn (n = 000 to 127)

These registers configure the operation of elements.

CAUTIONS

1. Since the contents of these registers are mapped to the SRAM, they are not initialized by hardware (values after reset are undefined). Therefore, the SRAM must be initialized before the APA starts operating even if an element is not currently used.
2. For writing to and reading from these registers, see **Section 22.5.6.2, Write to Element RAM**, and **Section 22.5.6.3, Read from Element RAM**.

Table 22.46 APAA0ELMCn Register Contents (1/2)

Bit Position	Bit Name	Reset Cause	Function
30 to 24	APAAELMNEXTEL[6:0]	(None)	Specify the next element number (00_H to $7F_H$).
23	APAAELMOPTRN	(None)	Option for the operation of the exception processing (transfer). Specifies whether an element transition is allowed without a transfer exception in a certain condition. 0: the input of the transfer exception enables the element transition to occur upon an OFF match. Once the transfer exception is input, the element transition occurs only for the currently effective elements upon an OFF match. After the element update, another transfer exception must be input. 1: the occurrence of an OFF match automatically triggers transition to next elements, only when element continuation is disabled (APAAELMCONT = 0). Enabling of the element transition by the transfer exception is not required.
22, 21	APAAELMEGTRN	(None)	Indicate the effective edge(s) of the event input signal for the exception processing (transfer). 00: Rising edge 01: Falling edge 10: Both (rising/falling) edges Others: Setting prohibited.
20 to 16	APAAELMIDTRN[4:0]	(None)	Specify the event bus signal to be used for the exception processing (transfer). See **Table 22.31** for the correspondence between the values and event bus signals.

Table 22.46 APAA0ELMCn Register Contents (2/2)

Bit Position	Bit Name	Reset Cause	Function
15	APAAELMOPFOR	(None)	Option for the operation of for the exception processing (force). 0: Next match is forcibly generated. ON waiting → ON match generated + transition to OFF waiting OFF waiting → OFF match forcibly generated + transition to the next state 1: OFF match is forcibly generated. ON waiting → OFF match generated OFF waiting → ON match generated
14, 13	APAAELMEGFOR	(None)	Indicate the effective edge(s) of the event input signal for the exception processing (Force). 00: Rising edge 01: Falling edge 10: Both (rising/falling) edges Others: Setting prohibited.
12 to 8	APAAELMIDFOR[4:0]	(None)	Specify the event bus signal to be used for the exception processing (force). See **Table 22.31** for the correspondence between the values and event bus signals.
5	APAAELMLVPPN	(None)	Indicates the effective level of the event input assigned to the exception processing (postpone). 0: Low level 1: High level
4 to 0	APAAELMIDPPN[4:0]	(None)	Specify the event bus signal to be used for the exception processing (postpone). See **Table 22.31** for the correspondence between the values and event bus signals.

22.5 Functions

22.5.1 Concept

22.5.1.1 Pulse Generation by APA

The APA generates pulses in the following manner:

- The APA generates the pulse waveforms by continuously comparing the external inputs (references) against a pair of specified criteria: the criterion for making the PWM output ON (ON matching condition) and the criterion for making the PWM output OFF (OFF matching condition). The state in which ON match is awaited and the state in which OFF match is awaited are mutually exclusive.
- There are the following two ways to specify the matching conditions for ON match and OFF match.
  - Absolute designation: The matching condition is specified by a value against which the reference values are directly compared.
  - Relative designation: The matching condition is specified by a relative value variation from the reference value at the time when the matching comparison starts.
- Both cyclic pulses and one-shot pulses can be generated by specifying the matching conditions.
- The pulse generation conditions are specified by data structures called elements. More information on elements will be given below.
- For each APA module, there are 16 channels of the comparison circuit (pulse generation channel), each of which can operate independently.

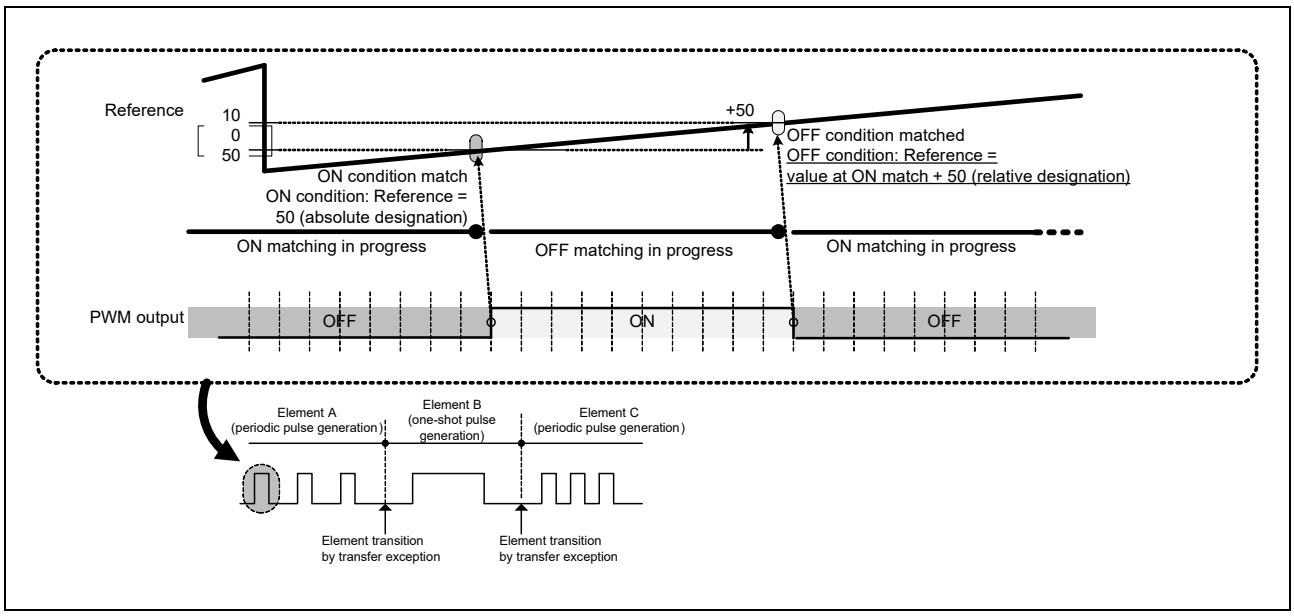

Figure 22.5 Conceptual Diagram of PWM Generation by APA

22.5.1.2 Element

- A data structure of a set of parameters that specify the pulse generation conditions is called an element. Each pulse generation channel loads a specific element, and generates a PWM waveform according to the element contents.
- For data specified for each element, see **Section 22.4.6.1, APAA0ELMAn — APAA0 Element Setting Registers An (n = 000 to 127)**, **Section 22.4.6.2, APAA0ELMBn — APAA0 Element Setting Registers Bn (n = 000 to 127)**, and **Section 22.4.6.3, APAA0ELMCn — APAA0 Element Setting Registers Cn (n = 000 to 127)**.
- A total of 128 elements can be specified, and they can be shared among different pulse generation channels (PGCH0 to PGCH15).
- An element has a pointer to the next elements, and transition to next elements can be controlled by setting conditions (see **Section 22.5.1.3, Exception Processing**). By this mechanism, a single pulse generation channel can use multiple elements, so that a pulse generation channel can generate a complex pulse sequence by combination of elements.

22.5.1.3 Exception Processing

- When a pulse generation channel generates pulses by PWM, the internal operation is controlled by a state machine. A signal that triggers a specific state transition is called exception, and the transition itself is called the exception processing.
- Any event input can be assigned as an exception, and an edge (rising/falling) or a level (high/low) can be assigned for each type of exception processing. Some exception processing types (stop, start, and restart) are defined for each pulse generation channel, and others (transfer, force, and postpone) are defined for each element.
- There are six exceptions processing as listed in **Table 22.47**.

Table 22.47 Exception Processing

Exception Processing	Operation	Assignment to Event Input	Defined for	Remarks
Stop	Stops the matching comparison.	Edge (rising /falling/both)	Pulse generation channel	
Start	Starts the matching comparison.	Edge (rising /falling/both)	Pulse generation channel	ON matching comparison starts based on the setting in the initial element defined for each pulse generation channel.
Restart	Initiate a transition to the initial element.	Edge (rising /falling/both)	Pulse generation channel	ON matching comparison starts based on the setting in the initial element defined for each pulse generation channel.
Transfer	Permits an element transition upon OFF match.	Edge (rising /falling/both)	Element	After a transfer exception input, the permission of element transition upon OFF match is retained. This condition is valid until an element transition occurs (see the option bit APAAELMOPTRN).
Force	Forcibly generates ON match or OFF match.	Edge (rising /falling/both)	Element	By default, the next ON/OFF match is forcibly generated (see the option bit APAAELMOPFOR).
Postpone	Temporarily postpones the operation that normally takes place upon match detection.	Level (high/low)	Element	Postpones the reflection in the PWM output pin, switching ON/OFF conditions and its accompanying element transition, which should normally occur upon a match. Matching comparison itself is in progress, and if there is a match during the Postpone period, a given operation restarts after release from the Postpone state.

22.5.2 Reference Control

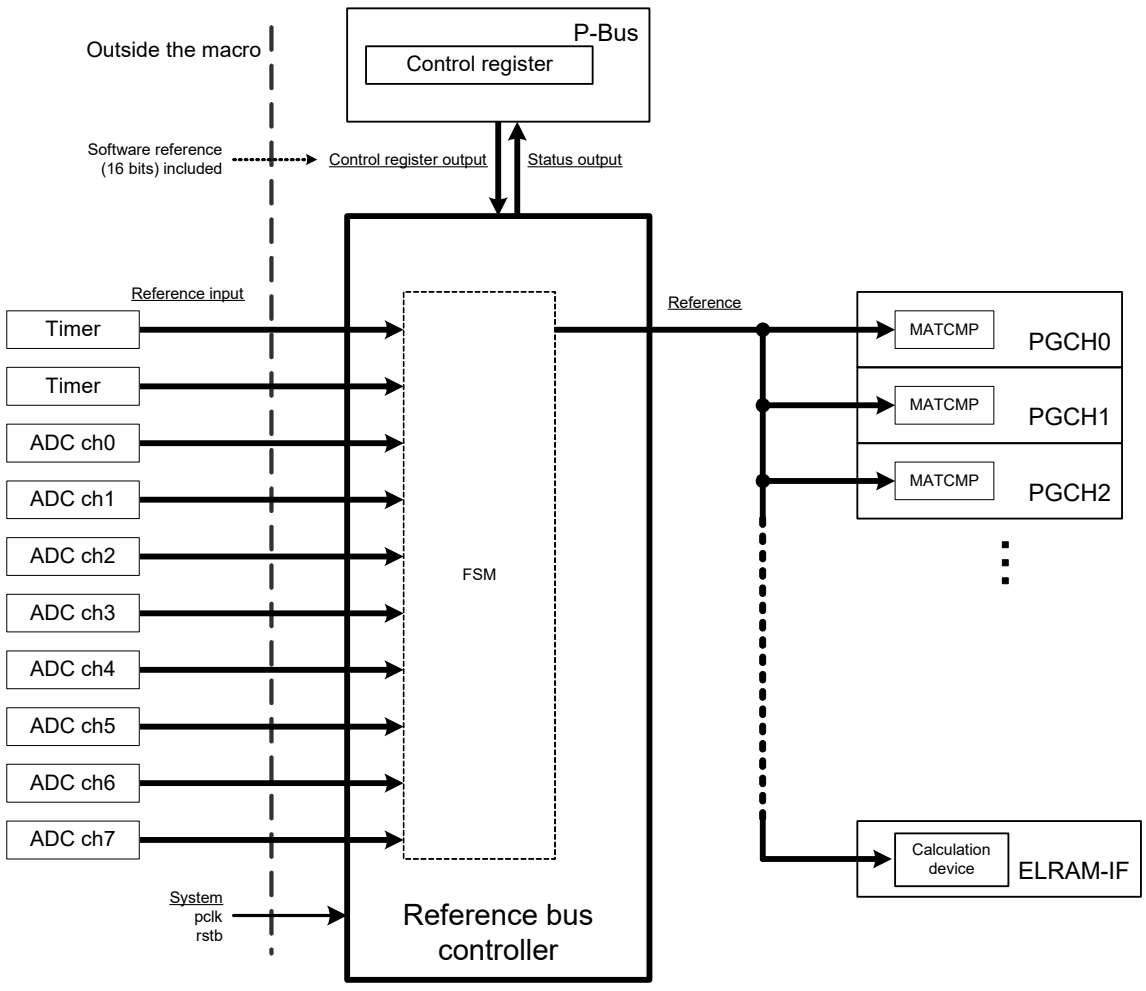
22.5.2.1 Features and Overview of Functions

External reference inputs (and software references) are multiplexed by time division within the APA.

The internal pulse generation channels (PGCH0 to PGCH15) are able to read desired references.

Reference outputs are initialized with the reset input signal PRESETZ or the module operation enable bit APAACMENAPA.

Figure 22.6 shows the circuit configuration.



Note 1. Reference inputs can be selected using the APA input selector. Refer to **Section 22.5.8, APA Input Selector**.

Figure 22.6 Configuration of Reference Control Circuit

22.5.2.2 Operation

All the reference inputs are multiplexed by time division with the following timing. Hereafter in this section, this time division processing is called “reference time division” and the unit time of time division (pclk * 1) is called a “reference slot”. By periodically assigning reference inputs to the reference slots, multiple references of different resolutions can be multiplexed.

Time division of the reference bus is controlled with the timing shown in **Figure 22.7**.

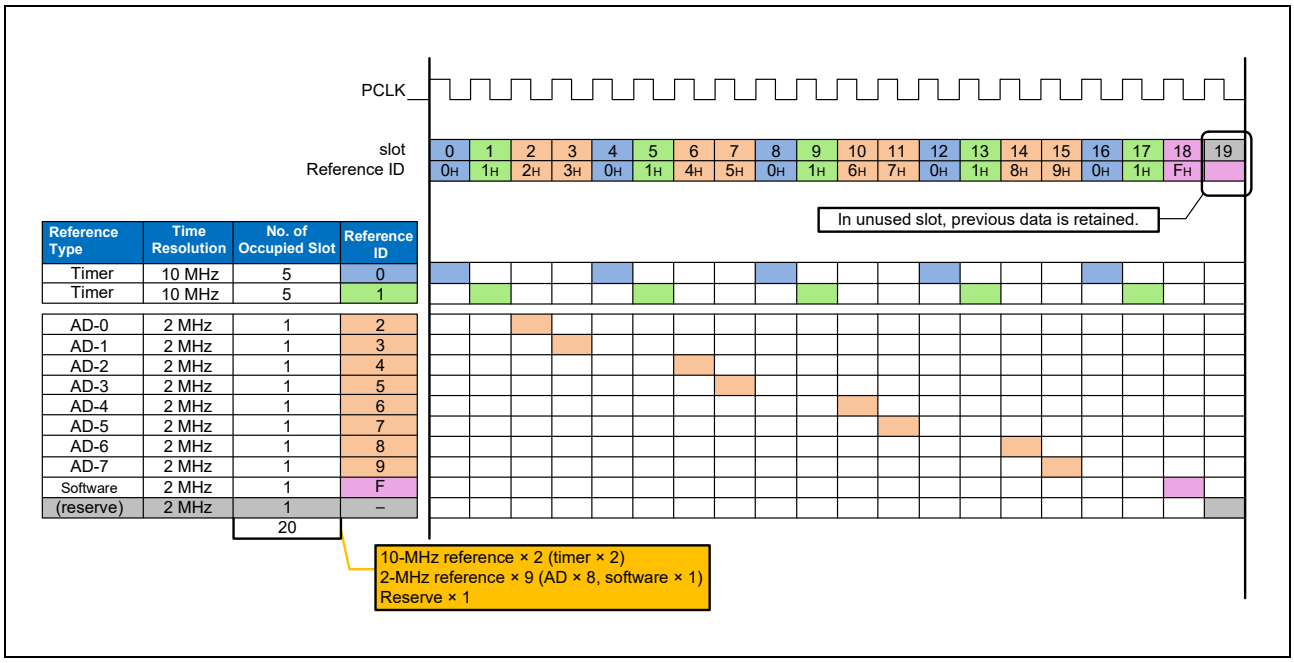


Figure 22.7 Reference Bus Operation

Table 22.48 shows the correspondence between available references and IDs.

Table 22.48 Types of Reference Inputs

Reference ID	Name	Time Resolution	Relative Designation	Reference Frequency Example at pclk=40 MHz
0_H	Reference input 0	pclk*4	Available	10 MHz
1_H	Reference input 1	pclk*4	Available	10 MHz
2_H	Reference input 2	pclk*20	Not available	2 MHz
3_H	Reference input 3	pclk*20	Not available	2 MHz
4_H	Reference input 4	pclk*20	Not available	2 MHz
5_H	Reference input 5	pclk*20	Not available	2 MHz
6_H	Reference input 6	pclk*20	Not available	2 MHz
7_H	Reference input 7	pclk*20	Not available	2 MHz
8_H	Reference input 8	pclk*20	Not available	2 MHz
9_H	Reference input 9	pclk*20	Not available	2 MHz
F_H	Software reference	pclk*20	Available	2 MHz

Note 1. A signal to be connected as a reference input must have slower update cycles than the time resolutions in **Table 22.48**. If it is faster, data will be lost in the reference control circuit, resulting in an unintended operation. For the reference inputs 0 and 1, update cycle can be adjusted with the bit select function of APA input selector described in **Section 22.5.8**.

22.5.3 Event Control

22.5.3.1 Features and Function Overview

The following processing is applied to external event inputs (and internal event inputs):

- Event inputs are selected for internal use. Out of 58 channels of the external event inputs and 6 channels of software events, 16 channels can be selected (these are hereinafter called selected event inputs). PWM outputs (16 channels) generated internally can also be used as event inputs (hereinafter called fixed event inputs).
- Selected event inputs (16 channels) and fixed event inputs (16 channels) are shared on a bus by the internal pulse generation channels (PGCH0 to PGCH15) and the element RAM (ELRAM).
- Time division control signals are generated so that the pulse generation channels (PGCH0 to PGCH15) can share common resources such as the element RAM and the calculation device.
- Event bus outputs are initialized with the reset input signal PRESETZ and the module operation enable bit APAACMENAPA.

Figure 22.8 shows the configuration of the event control circuit.

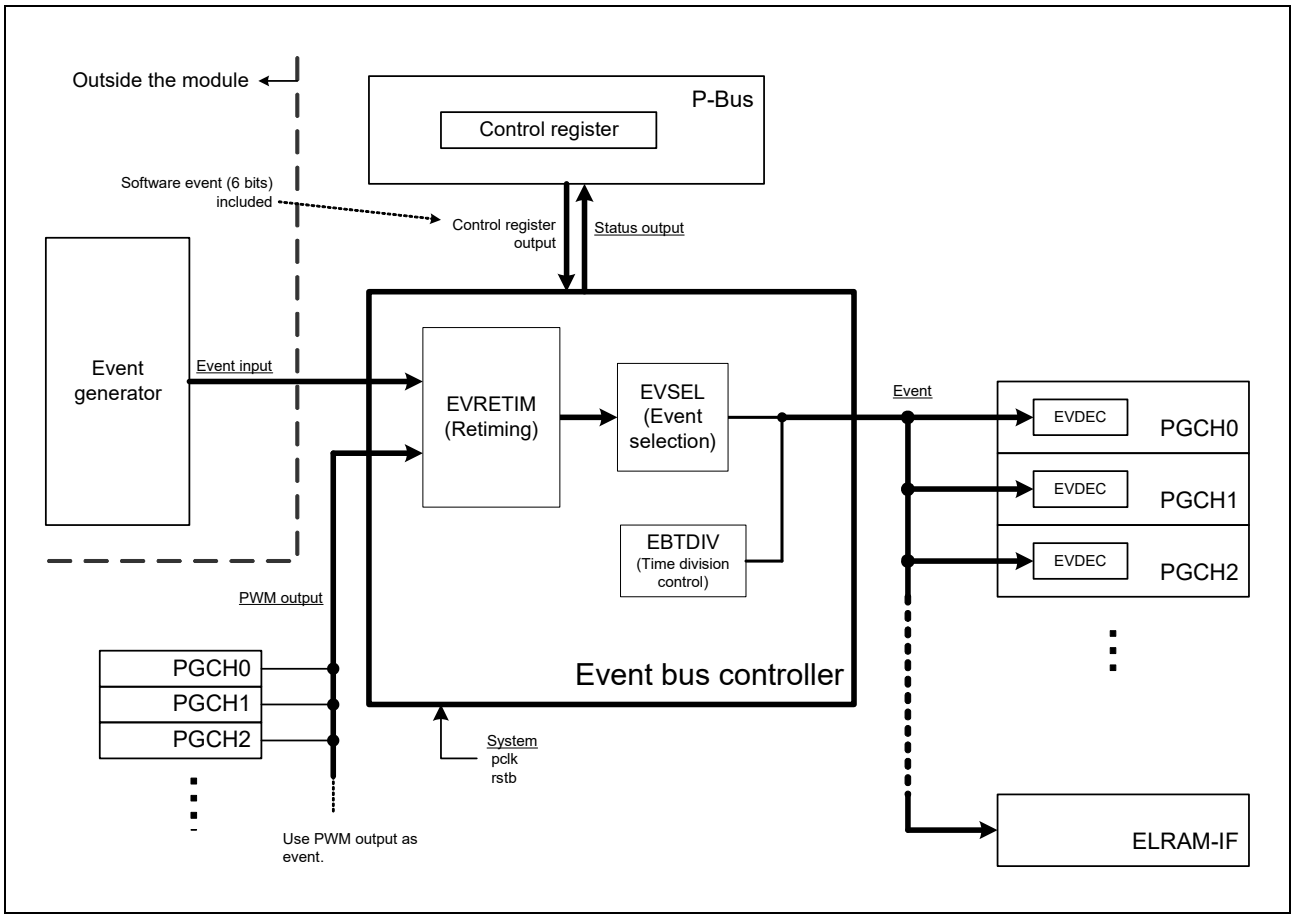

Figure 22.8 Configuration of Event Control Circuit

22.5.3.2 Operation: Selection of Event Inputs

The PWM outputs (16 channels) generated within the APA can be used as events by the pulse generation channels.

Among the 64 channels of the external event inputs (58 channels) and software events (6 channels), 16 channels can be used as events by the pulse generation channels.

Table 22.49 lists the inputs that the event bus can receive.

Table 22.49 Correspondence between Event Inputs and Event Buses

Event Type	Signal Source	Time Resolution	No of Channels	Corresponding Event Bus Bit
Fixed event input	PWM output: PWM outputs 0 to 15 (generated within APA)	pclk * 1	16	eb_dat_r[15:0]
Selected event input	External event input: External event sources 0 to 57, or software event: 6 channels → Selects any 16 channels from 64 channels	pclk * 1	16	eb_dat_r[31:16]

Note 1. A signal to be used as an event input must be slower than the time resolutions in **Table 22.49**. If it is faster, the APA cannot process it as an event input inside, resulting in data losses.

22.5.3.3 Operation: Generation of Time Division Control Signals

An event input is handled as a trigger of an exception processing on a pulse generation channel, in which access to the element RAM and various calculations take place. The APA performs the time division control to assign time to be used by the circuits in the APA (pulse generation channels and P-Bus) for sharing hardware resources such as the element RAM and the calculation device. Hereafter in this section, this time division control is called “event time division”, and a unit (pclk * 1) of time division is called an “event slot”. The event time division works with a cycle of 20 event slots (pclk * 20), which is defined as a “shared cycle”.

The time division control signals are generated with the timing shown in **Figure 22.9**.

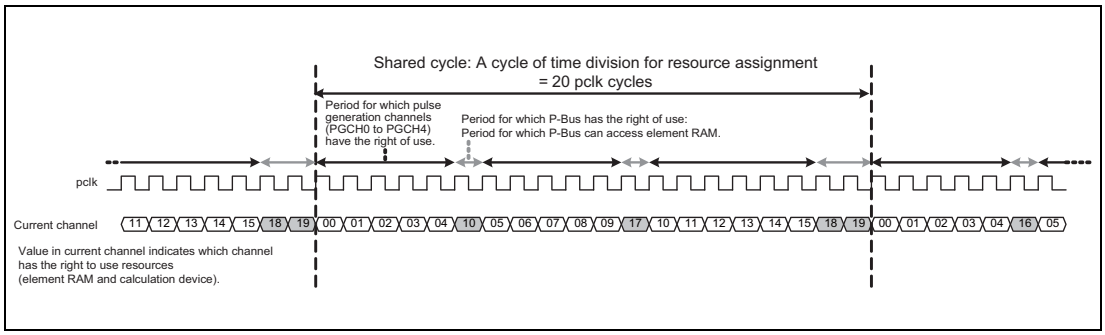

Figure 22.9 Operation of Event Time Division

Based on the current channel value, the APA assigns the access rights to the shared resources (element RAM and calculation device) as shown in **Table 22.50**.

Table 22.50 List of Current Channels and Shared Resource Assignment

Current Channel Value	Meaning	Current Channel Value	Meaning
00_H	PGCH0 can access shared resources.	09_H	PGCH9 can access shared resources.
01_H	PGCH1 can access shared resources.	11_H	P-Bus can access element RAM.
02_H	PGCH2 can access shared resources.	$0A_H$	PGCH10 can access shared resources.
03_H	PGCH3 can access shared resources.	$0B_H$	PGCH11 can access shared resources.
04_H	PGCH4 can access shared resources.	$0C_H$	PGCH12 can access shared resources.
10_H	P-Bus can access element RAM.	$0D_H$	PGCH13 can access shared resources.
05_H	PGCH5 can access shared resources.	$0E_H$	PGCH14 can access shared resources.
06_H	PGCH6 can access shared resources.	$0F_H$	PGCH15 can access shared resources.
07_H	PGCH7 can access shared resources.	12_H	P-Bus can access element RAM.
08_H	PGCH8 can access shared resources.	13_H	P-Bus can access element RAM.

22.5.4 Pulse Generation

22.5.4.1 Features and Overview of Functions

The following processing is applied to outputs of the reference bus and the event bus:

- A pulse generation channel extracts desired reference signals from the reference bus to generate a PWM based on the pulse generation conditions. Pulse generation conditions are expressed in elements.
- A pulse generation channel extracts desired event signals from the event bus, and performs exception processing triggered by these events. Conditions for generating exception processing from events are also expressed by elements.
- Exception processing of different pulse generation channels operates with time division.
- The PWM and INT outputs are initialized using the reset input signal presetz or the pulse generation channel operation enable bits APPACMENPGCH[15:0].

Figure 22.9 shows the configuration of the pulse generation circuit.

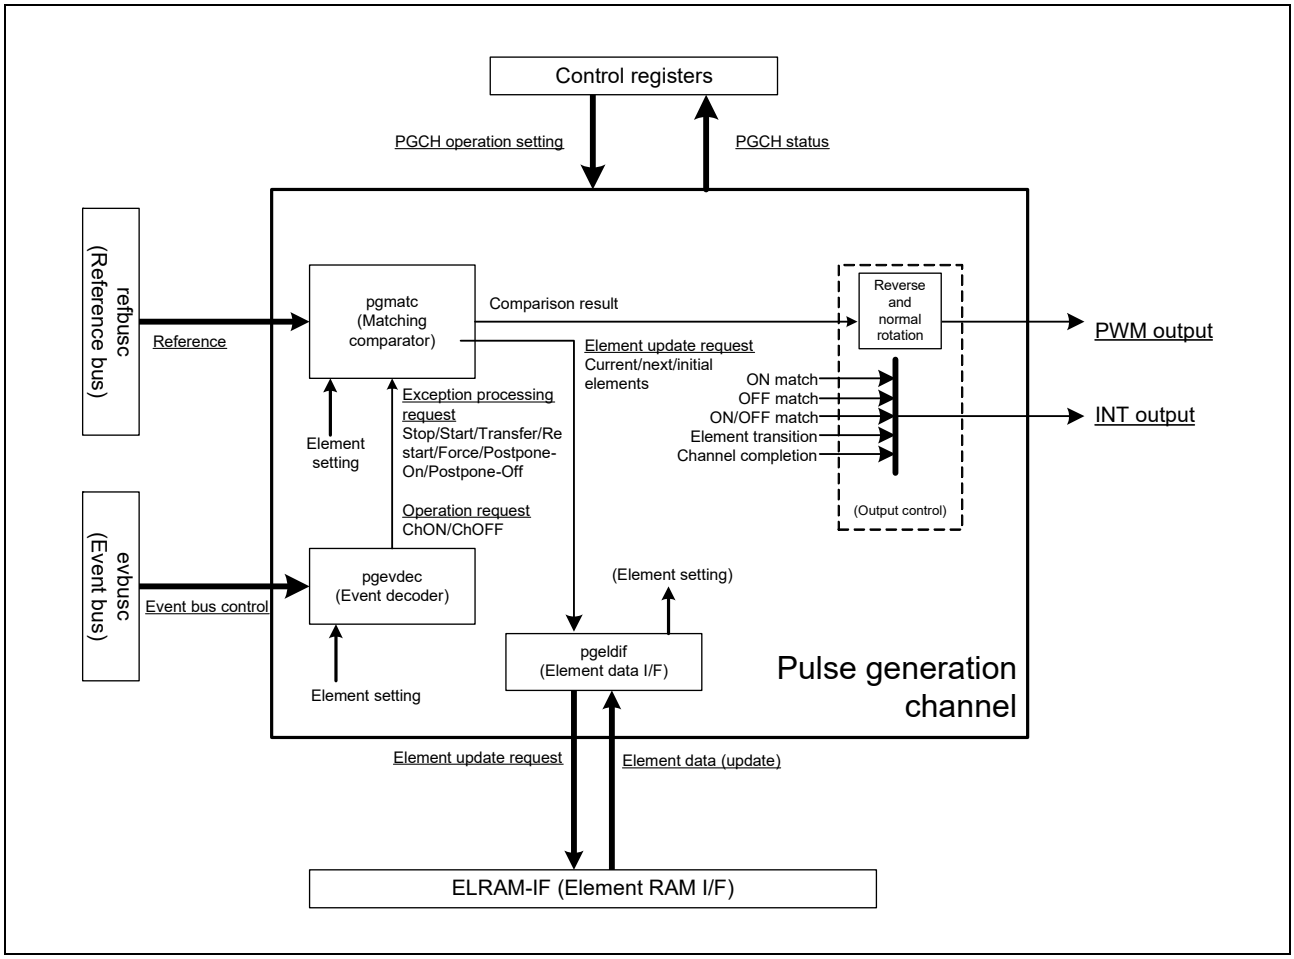

Figure 22.10 Configuration of Pulse Generation Circuit

22.5.4.2 Operation: Matching Comparator

(1) Overview

The matching comparator generates pulses and interrupts by comparing reference inputs with the matching conditions.

Matching comparison is performed according to the parameters defined in the element and the pulse generation channel. Upon a match detection, the pulse generation channel setting (see **22.4.5.1, APAA0CCGAn — APAA0 Channel Setting Registers An (n = 00 to 15)**) and the element setting (see **22.4.6.1, APAA0ELMAn — APAA0 Element Setting Registers An (n = 000 to 127)**) to **22.4.6.3, APAA0ELMCn — APAA0 Element Setting Registers Cn (n = 000 to 127)**) determine issuing of an element update request to the element control module (element RAM-IF).

Table 22.51 PWM Outputs and Interrupt Outputs

Type	Time Resolution	Number of Channels	Minimum Pulse Width	Remarks
PWM output	pclk * 1	16	pclk * 40 (high) pclk * 40 (low)	The minimum pulse width shown here is applicable when ON/OFF occurs on the match condition specified by an element. If the match status is forcibly changed by exception processing, a shorter pulse width may result from the conflict with a match.
Interrupt output	pclk * 1	16	pclk * 1 (high)	Only one-shot pulse (rise) can be output.

Note 1. PWM output matching conditions can be specified by an element. A matching condition must satisfy the minimum pulse widths listed in the above table (see **22.5.7.1, Matching Condition Setting 1**). Specifying a matching condition with a pulse width of pclk*40 or shorter might result in an unintended pulse width.

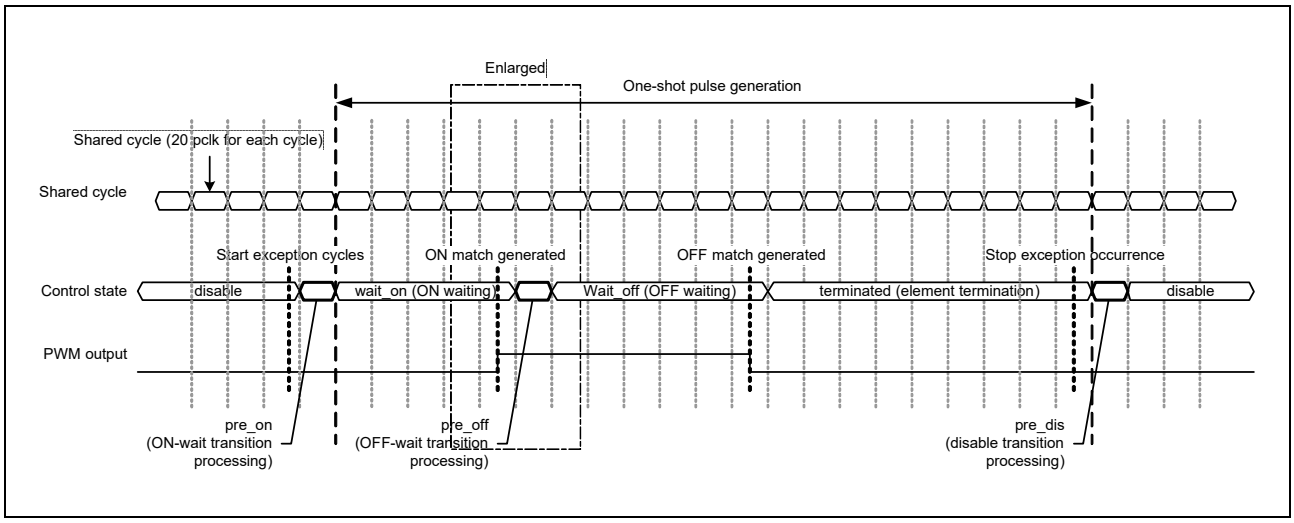

Figure 22.11 Operation of Matching Comparator

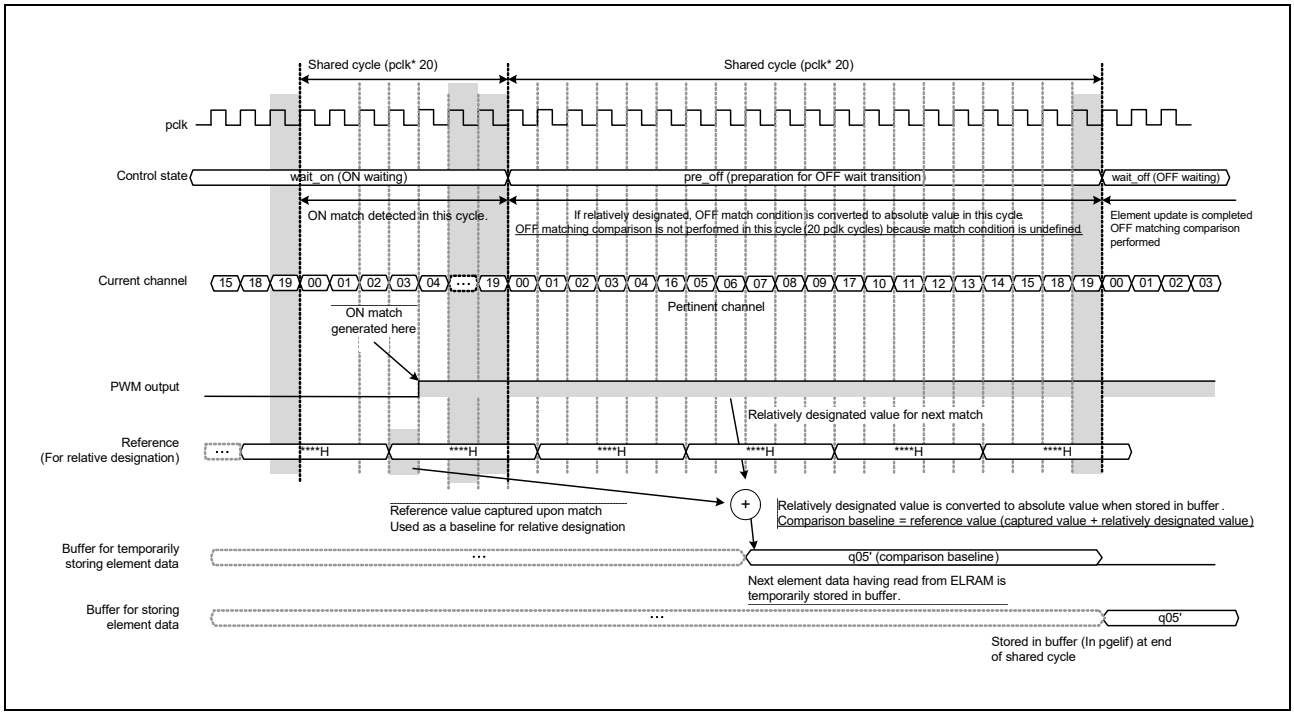

Figure 22.12 Operation of Matching Comparator (Enlarged View)

(2) State Control

The matching comparator controls operation starting/stopping, ON matching comparison, OFF matching comparison, element sequence according to the state control rules below.

- States are controlled every shared cycle (pclk * 20) based on the current channel signal generated from the event bus.
- State control is linked with the matching control described in **(3) Matching control** in this section.
- States of the matching comparator are controlled as shown in the state transition shown in **Figure 22.13**.
- The states shown in **Figure 22.13** include sub-states. For the relationships between the states and sub-states, refer to **Table 22.52** and **Figure 22.13** to **Figure 22.21**.

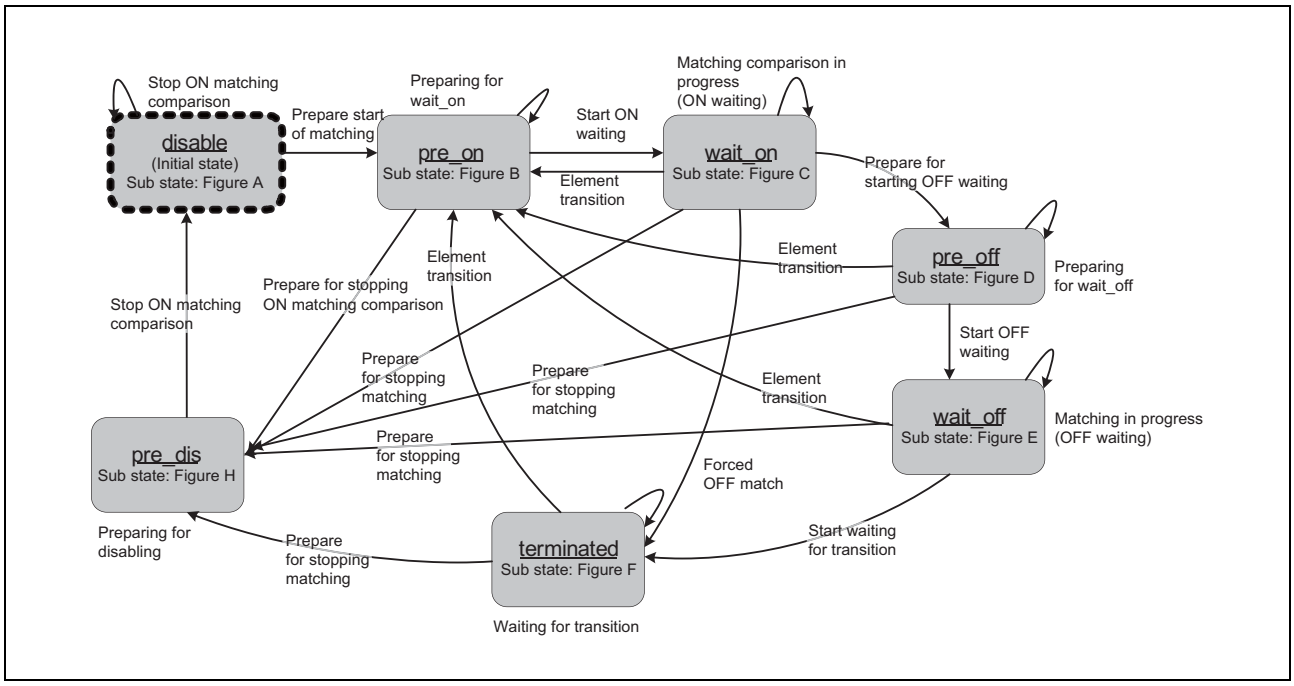

Figure 22.13 State Transition of Matching Comparator

In the matching comparison state, the operation proceeds as described in **Table 22.52**.

Table 22.52 List of States (1/2)

State			Input Condition (left: high priority; right: low priority)							
State	Sub-state	Operation Overview	Channel ON/OFF	Stop exception	Restart exception	Transfer exception	Force exception	Match	Postpone exception	Start exception
disable	disable	State of complete stop, where no matching comparison is made. The initial state of the state machine.	√ (ON only)	×	×	—	—	—	—	×
	dis_wstart	State of matching comparison stop. Operation permission = enabled, and Start/Restart is awaited.	√ (OFF only)	×	√	—	—	—	—	√
pre_on	pre_on_cur	Preparing for transition to ON waiting. Element update (current element) is performed. Matching comparison is not performed. Used when looping in element continuation.	√ (OFF only)	√	√	√	√	—	×	×
	pre_on_init	Preparing for transition to ON waiting. Element update (initial element) is performed. Matching comparison is not performed	√ (OFF only)	√	√	—	—	—	—	×
	pre_on_nxt	Preparing for transition to ON waiting. Element update (next element) is performed. Matching comparison is not performed	√ (OFF only)	√	√	—	—	—	—	×
wait_on	waiton	For ON matching comparison, a match or a Transfer exception input is awaited.	√ (OFF only)	√	√	√	√	√	√	×
	waiton_tron	For On matching comparison, a Transfer has been input. A match is awaited.	√ (OFF only)	√	√	√	√	√	√	×
	forcedoff_troff	For ON matching comparison, a forced OFF match has occurred by a Force exception. A Transfer exception input is awaited.	√ (OFF only)	√	√	√	√	× (OFF match occurs)	√	×
	on_postponed	For ON matching comparison, a Postpone exception has been input. A match occurrence and release from the Postpone state are awaited. ON matching comparison is operating during the Postpone input period, but the PWM pin is not affected, and a state transition is not initiated until release from the Postpone state.	√ (OFF only)	√	√	√	√	√	√	×
pre_off	pre_off	Preparing for transition to OFF waiting. Element update (current element) is performed. Matching comparison is not performed	√ (OFF only)	√	√	√	√	—	×	×

Table 22.52 List of States (2/2)

State			Input Condition (left: high priority; right: low priority)							
State	Sub-state	Operation Overview	Channel ON/OFF	Stop exception	Restart exception	Transfer exception	Force exception	Match	Postpone exception	Start exception
wait_off	waitoff	For OFF matching comparison, a match or a Transfer exception input is awaited.	√ (OFF only)	√	√	√	√	√	√	×
	waitoff_tron	For OFF matching comparison, a Transfer has been input. A match is awaited.	√ (OFF only)	√	√	√	√	√	√	×
	matoff_troff	For OFF matching comparison, a Transfer has not been input and an OFF match has occurred. A Transfer exception is awaited.	√ (OFF only)	√	√	√	√	× (OFF match occurs)	√	×
	off_postponed	For OFF matching comparison, a Postpone exception has been input. A match occurrence and release from the Postpone state are awaited. OFF matching comparison is operating during the Postpone input period, but the PWM pin is not affected and a state transition is not initiated until release from the Postpone state.	√ (OFF only)	√	√	√	√	√	√	×
terminate	terminate	There is no next element to be executed (i.e. the last element has been completed). Matching comparison is not performed, and a Stop or Restart exception is awaited.	√ (OFF only)	√	√	—	—	—	—	×
pre_dis	pre_dis	Preparing for transition to “disable”. The internal status registers are reset (the channel element settings are retained).	×	×	×	—	—	—	—	×

Note: √: Processing is possible.
×: Processing is impossible (occurrence of an input condition is ignored).
—: Processing is impossible (no effective input conditions can occur since definition is impossible in the pertinent state).

For details of the input conditions, refer to the related sections listed below.

- Channel ON/OFF: **(5) Channel ON/OFF** in **Section 22.5.4.2, Operation: Matching Comparator**
- Stop exception: **(1) Stop Exception** in **Section 22.5.4.3, Operation: Event Decoder**
- Restart exception: **(3) Restart Exception** in **Section 22.5.4.3, Operation: Event Decoder**
- Transfer exception: **(4) Transfer Exception** in **Section 22.5.4.3, Operation: Event Decoder**
- Force exception: **(5) Force Exception** in **Section 22.5.4.3, Operation: Event Decoder**
- Matching comparison: **(3) Matching control** in **Section 22.5.4.2, Operation: Matching Comparator**
- Postpone exception: **(6) Postpone Exception** in **Section 22.5.4.3, Operation: Event Decoder**

- Start exception: **(2) Start Exception** in **Section 22.5.4.3, Operation: Event Decoder**

The input conditions shown in **Table 22.52** are enabled at the points in time as shown in **Figure 22.14**.

When more than one input condition is detected, they are processed according to the priority shown in **Table 22.52**.

For details of the input conditions, refer to **Section 22.5.4.3, Operation: Event Decoder**.

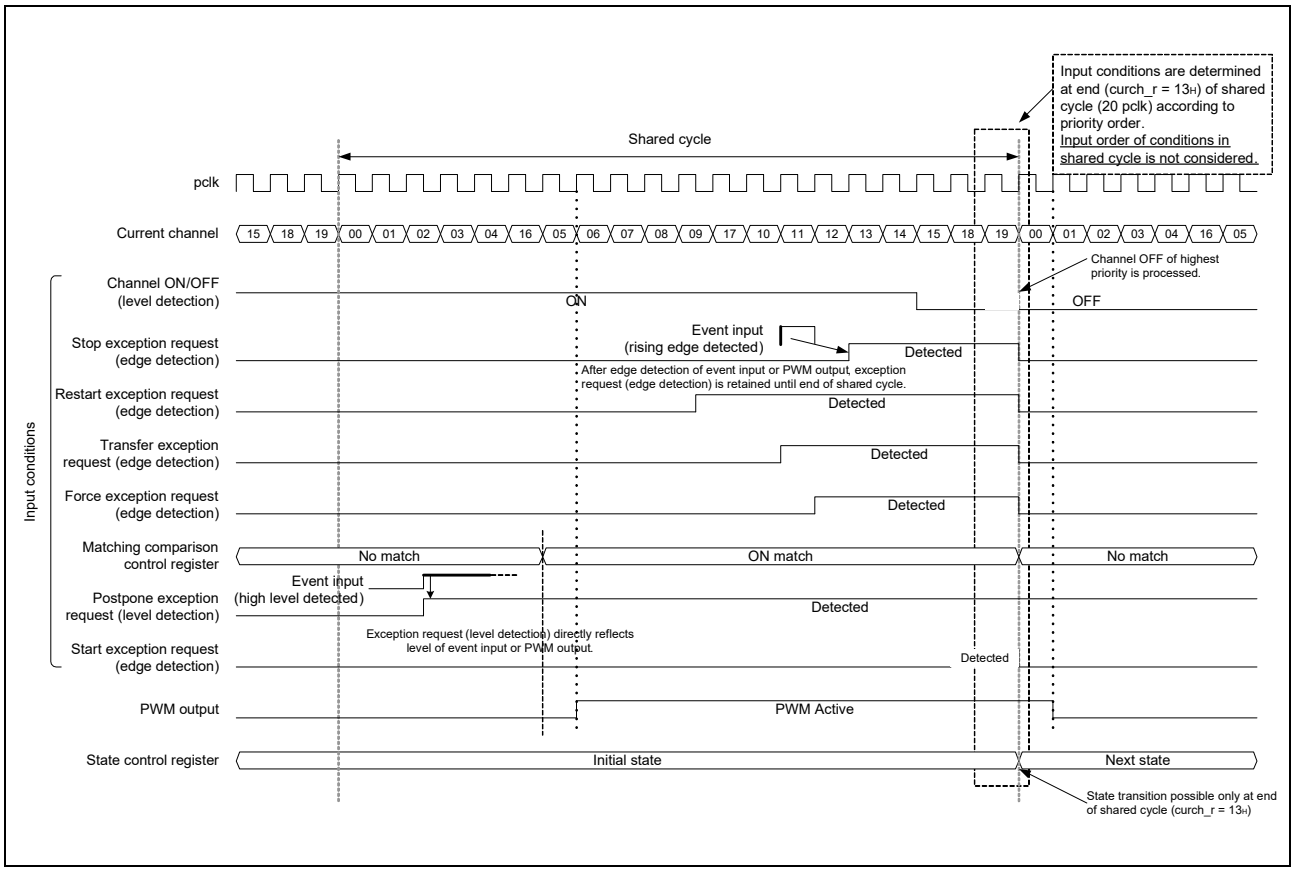

Figure 22.14 Input Condition Determination Timing

Figure 22.15 to **Figure 22.21** show details of each state of the matching comparator.

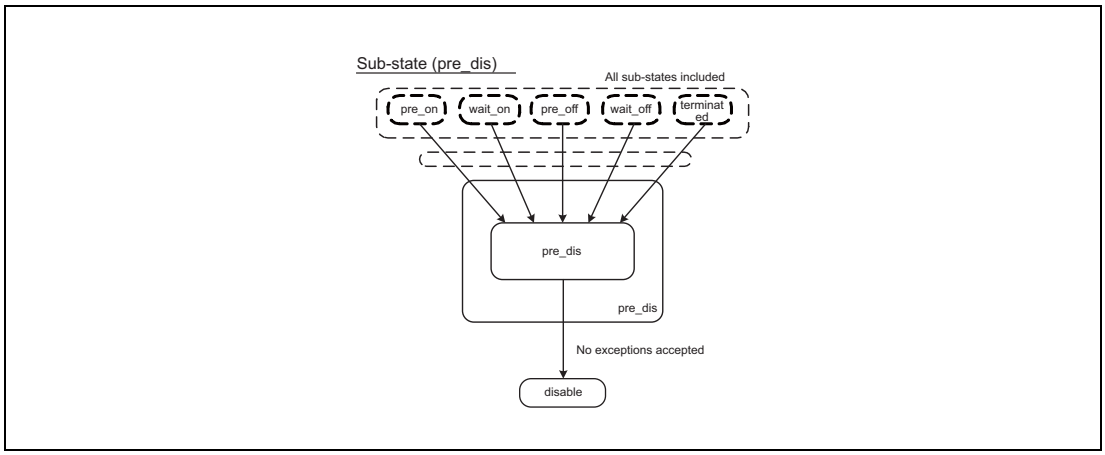

Figure 22.21 Sub-State Transition in pre_dis State (figure G indicated in Figure 22.13, State Transition of Matching Comparator)

(3) Matching control

Matching is controlled based on comparison of the reference inputs with the comparison conditions using the matching comparator. Operations are described in detail below.

- The outputs from the reference bus (reference inputs are time-division multiplexed) are compared to the conditions specified using the matching comparison registers (refer to **Table 22.53** and **Table 22.54**). If all the conditions agree with the reference bus outputs, a match detection is determined and the match control register settings are modified.
- Comparison is linked to state control: only ON matching comparison is performed in the wait_on system states, and only OFF matching comparison is performed in the wait_off system states. ON matching and OFF matching comparison are not performed simultaneously.
- A match is detected only once in a single state and cannot occur more than once.
- The matching comparison conditions are defined for each element.
- With using the Force exception, the match control status can be changed independently of ON matching and OFF matching comparison status. For details of the Force exception, refer to **(5) Force Exception** in **Section 22.5.4.3, Operation: Event Decoder**.

Table 22.53 ON Matching Comparison

Item		Description
Applicable states	4 wait_on system states	ON matching comparison is performed in the following states: waiton, waiton_tron, forcedoff_troff, on_postponed
Comparison condition 1 (reference number)	APAAELDRBIDON[3:0]	Reference number is specified. For the correspondence between the settings and the reference numbers, refer to **Table 22.37**.
Comparison condition 2 (large/small relationship)	APAAELDMCON[1:0]	Whether the reference value is larger, smaller, or equal to the comparison baseline is specified. In comparison of large and small values, the reference value is handled as unsigned. 00_B: [Reference value of specified reference number] == [comparison baseline] 01_B: [Reference value of specified reference number] > [comparison baseline] 10_B: [Reference value of specified reference number] < [comparison baseline]
Comparison condition 3 (comparison baseline)	APAAELDRBDATON[15:0]	Comparison baseline for ON matching comparison is specified as an unsigned value.

In ON matching comparison, when all of the three comparison conditions shown in **Table 22.53** are satisfied, an ON match is detected in the next clock edge. The control signals change as shown in **Table 22.54**.

Table 22.54 Signal Change upon ON Match Occurrence

Item		Description
Match control	APAAMATSTAT[1:0]	Match not detected (00_B) → ON match detected (01_B)
PWM output	APAAEOPWM[X] (X = channel number)	Inactive level → Active level • Active level is specified for each channel using chn_lev register. • Level does not change if ON match is detected in Postpone state.
slotID (register for holding timing information upon match occurrence)	el_slotid_r[4:0]	slotID (reference bus output) upon ON match occurrence is held.

By inputting the Force exception, an ON match detection can be caused independently of the above comparison conditions. For details, refer to **(5) Force Exception** in **Section 22.5.4.3, Operation: Event Decoder**.

Table 22.55 OFF Matching Comparison

Item		Description
Applicable states	4 wait_off system states	OFF matching comparison is performed in the following states: waitoff, waitoff_tron, matoff_troff, off_postponed
Comparison condition 1 (reference number)	APAAELDRBIDOFF[3:0]	Reference number is specified. For the correspondence between the settings and the reference numbers, refer to **Table 22.37**.
Comparison condition 2 (large/small relationship)	APAAELD_MCOFF[1:0]	Whether the reference value is larger, smaller, or equal to the comparison baseline is specified. In comparison of large and small values, the reference value is handled as unsigned. 00_B: [Reference value of specified reference number] == [comparison baseline] 01_B: [Reference value of specified reference number] > [comparison baseline] 10_B: [Reference value of specified reference number] < [comparison baseline]
Comparison condition 3 (comparison baseline)	APAAELDRBDATOFF[15:0]	Baseline for OFF matching comparison. It is specified as an unsigned value.

In OFF matching comparison, when all of the three comparison conditions shown in **Table 22.55** are satisfied, an OFF match is detected in the next clock edge. The control signals change as shown in **Table 22.56**.

Table 22.56 Signal Change upon OFF Match Occurrence

Item		Description
Match control	APAAMATSTAT[1:0]	ON match detected (01_B) → OFF match detected (10_B)
PWM output	APAAEOPWM[X] (X = channel number)	Active level → Inactive level • Active level is specified for each channel using chn_lev register. • Level does not change if OFF match is detected in Postpone state.
slotID (register for holding timing information upon match occurrence)	el_slotid_r[4:0]	slotID (reference bus output) upon OFF match occurrence is held.

By inputting the Force exception, an OFF match detection can be caused independently of the above comparison conditions. For details, refer to **(5) Force Exception** in **Section 22.5.4.3, Operation: Event Decoder**.

Figure 22.22 shows ON match control operations.

This figure is also applicable to OFF match control operations if the comparison conditions for ON match are replaced with those for OFF match.

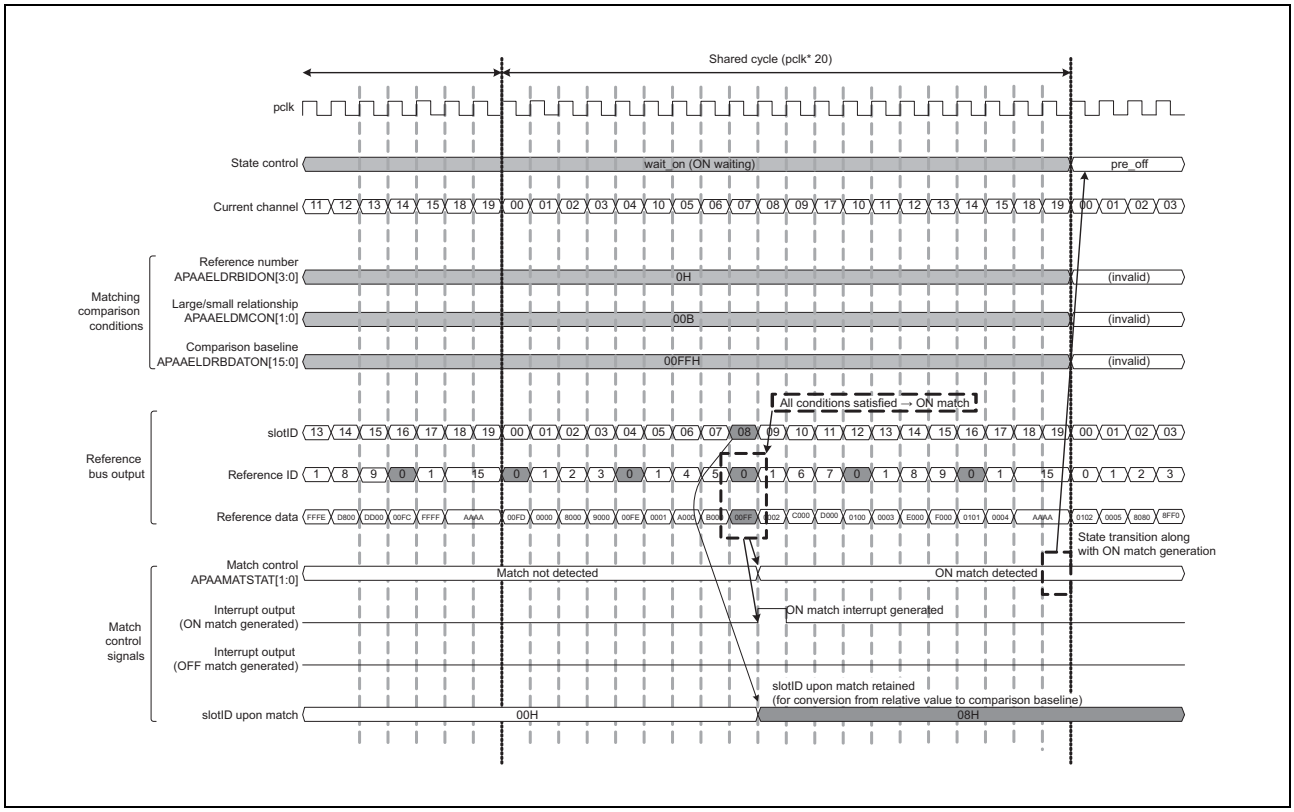

Figure 22.22 ON Match Control Operations

(4) Interrupts

While the matching comparator is operating, an interrupt can be generated on either of the conditions shown in **Table 22.57**.

Interrupts can be independently set using the APAA0CCGAn.APAACHNINTSEL[2:0] bits (n = 0 to 15) for each channel.

Interrupts are output as a one-shot active-high pulse.

Table 22.57 Interrupt Generation Conditions

APAACHNINTSEL[2:0] Setting	Interrupt Generation Condition	Interrupt Generation Timing
000_B	After element transition	An interrupt is generated at a shared cycle boundary after element update (state: pre_on). When element continuation is enabled (APAA0ELMAn.APAAELMCONT = 1), an interrupt is also generated at a shared cycle boundary after pre_on_cur state. Refer to **Figure 22.23**.
001_B	Upon channel operation completion	An interrupt is generated at a shared cycle boundary after last element completion (match or OFF match by Force exception). Refer to **Figure 22.24**.
010_B	Upon ON match	An interrupt is generated upon ON match (match by comparison or Force exception) during ON waiting (state: wait_on). Specifically, an interrupt is output in the following cases. • ON match detection by comparison (refer to **Figure 22.25**) • ON match detection by Force exception (refer to **Figure 22.26**) • Conflict between ON match detection by comparison and ON match detection by Force exception (refer to **Figure 22.27**) • Conflict between ON match detection by comparison and OFF match detection by Force exception (refer to **Figure 22.28**) An interrupt is output also in Postpone state whether ON match occurs or not. Refer to **Figure 22.46**.
011_B	Upon OFF match	An interrupt is generated upon OFF match (match by comparison or Force exception) during OFF waiting (state: wait_off) or upon forced OFF match by Force exception during ON waiting (state: wait_on). Refer to the same figures listed in the description of “Upon ON” description above. As in “Upon ON Match” above, an interrupt is output also in Postpone state.
100_B	Upon either ON match or OFF match	An interrupt is generated simultaneously with PWM assertion/negation upon either ON or OFF match. Refer to the same figures listed in the description of “Upon ON Match” above. As in “Upon ON Match” above, an interrupt is output also in Postpone state.

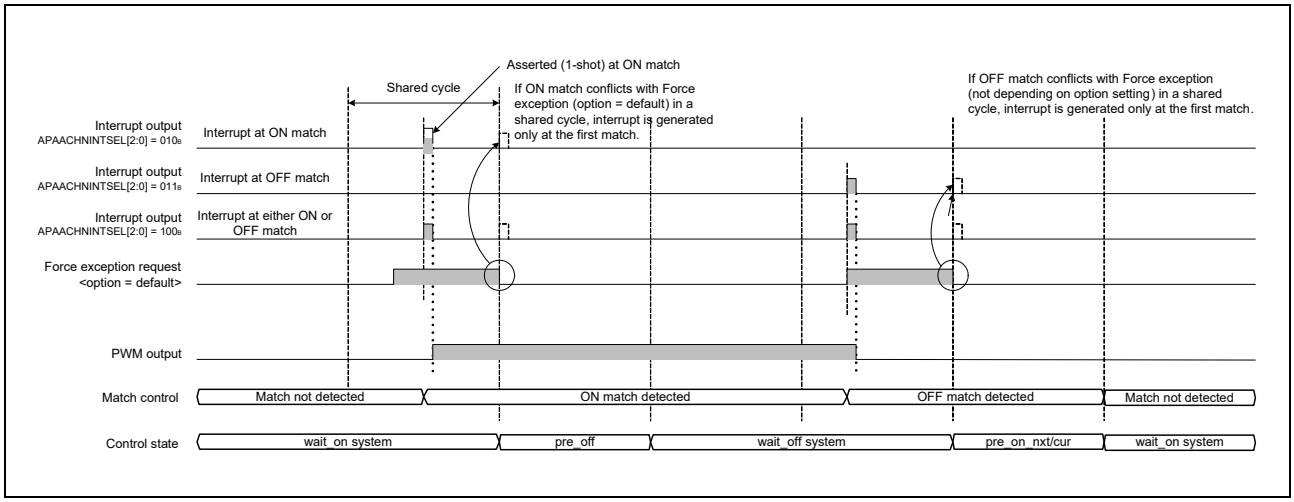

Figure 22.27 Interrupt Generation (upon conflict between match detection by comparison and match detection by Force exception 1/2)

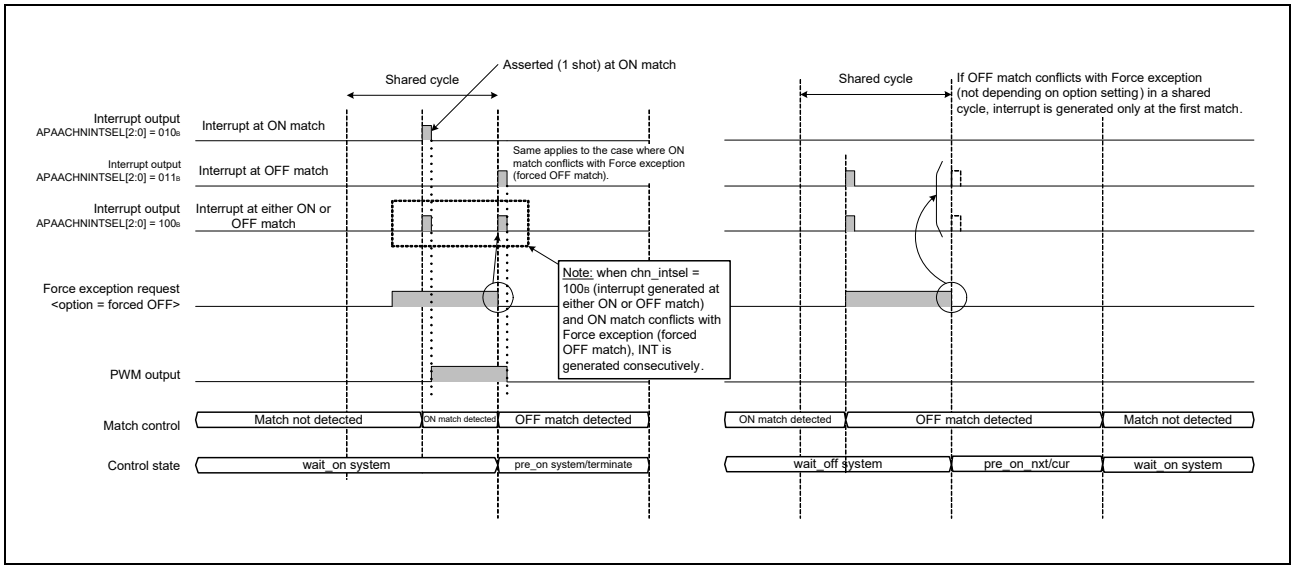

Figure 22.28 Interrupt Generation (upon conflict between match detection by comparison and match detection by Force exception 2/2)

(5) Channel ON/OFF

Channel ON/OFF is an input condition according to the exception processing requests generated by the event decoder, which are described in **Section 22.5.4.3, Operation: Event Decoder**. Channel on/off operations cause the operations shown in **Table 22.57**.

Table 22.58 Channel ON/OFF Operations

Item	Description
Operation (channel ON)	• Channel ON operation is used as the condition input to start the matching comparator in the stop state. • Channel ON operation is valid only in the disable state; it is ignored in the other states. • Channel ON operation does not cause changes in PWM output or interrupt output.
Operation (channel OFF)	• Channel OFF operation is used as the condition input to stop the matching comparator in the operating state. • Channel OFF operation is valid while the channel is operating (in the states other than disable and pre_dis). • Channel OFF operation forcibly causes PWM output to become inactive one pclk cycle after state transition. Here, no interrupt is output.
Assignment	• APAA0CHEN[15:0] register is used for setting. Each bit corresponds to a channel.
Detection type	• Level detection (active high only; active level cannot be selected)
Option	• None
Note	• None

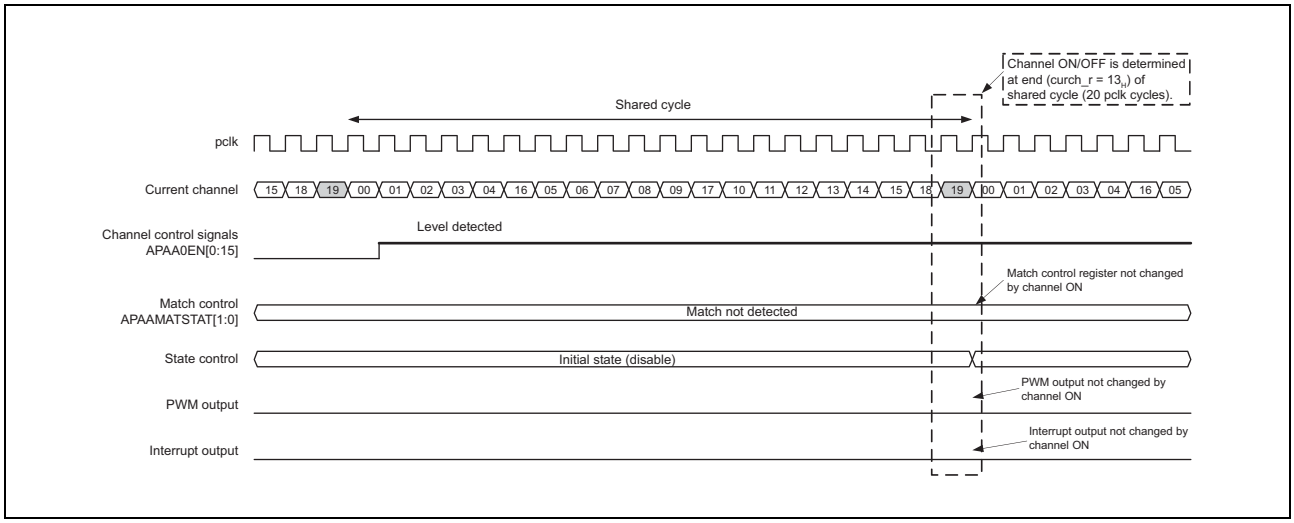

Figure 22.29 Channel ON Acceptance Timing

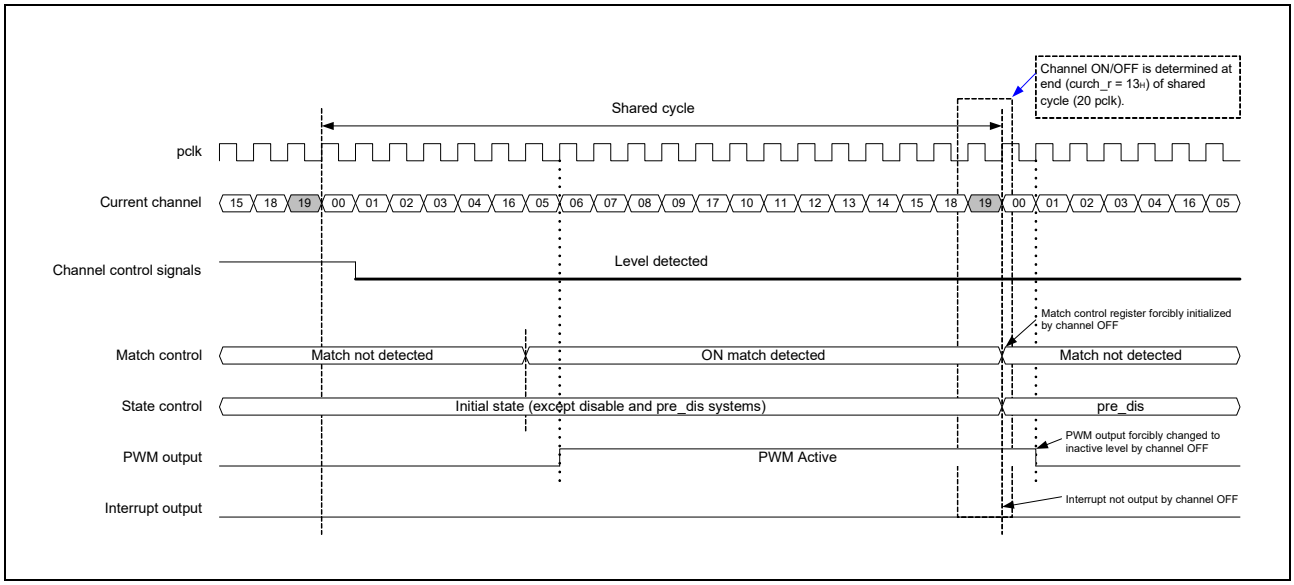

Figure 22.30 Channel OFF Acceptance Timing

22.5.4.3 Operation: Event Decoder

The event decoder generates exception processing requests based on the event bus or PWM outputs generated by the pulse generation channels.

Figure 22.31 and **Figure 22.32** are timing charts of the exception signals.

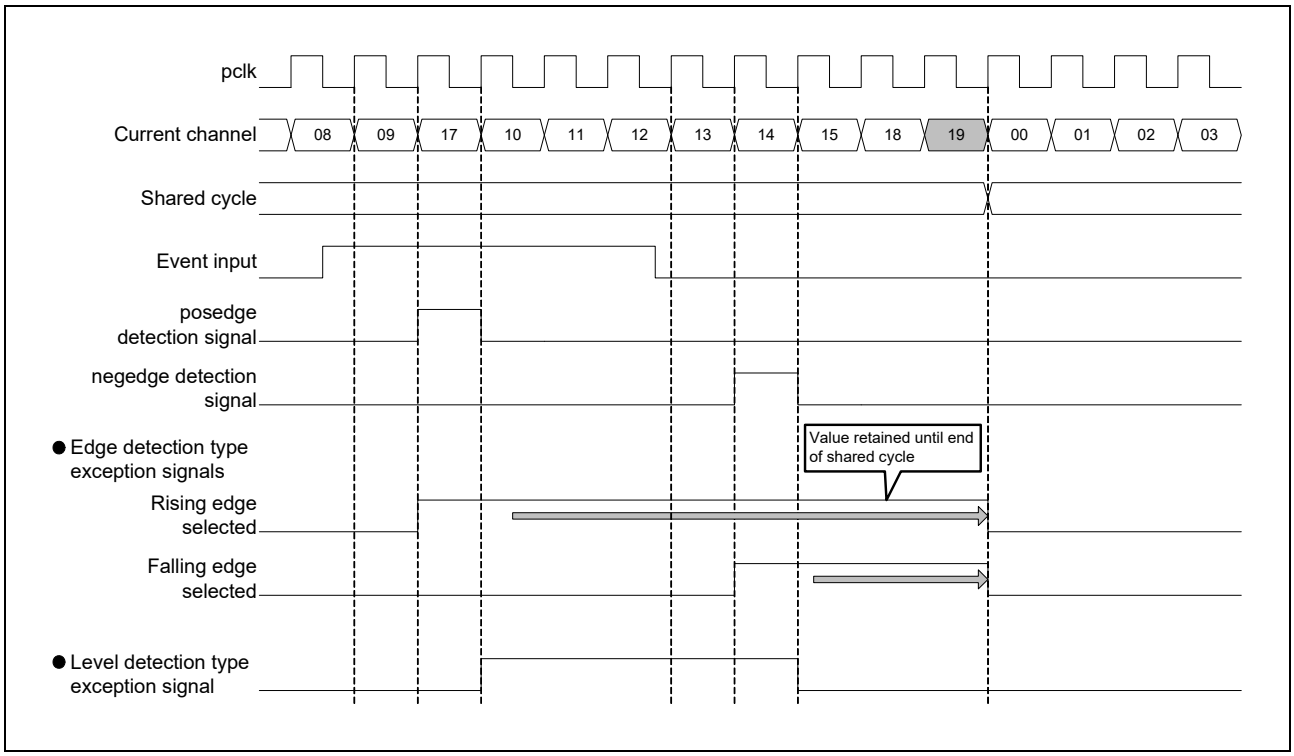

Figure 22.31 Timing Chart of Exception Signals when External Event is Selected

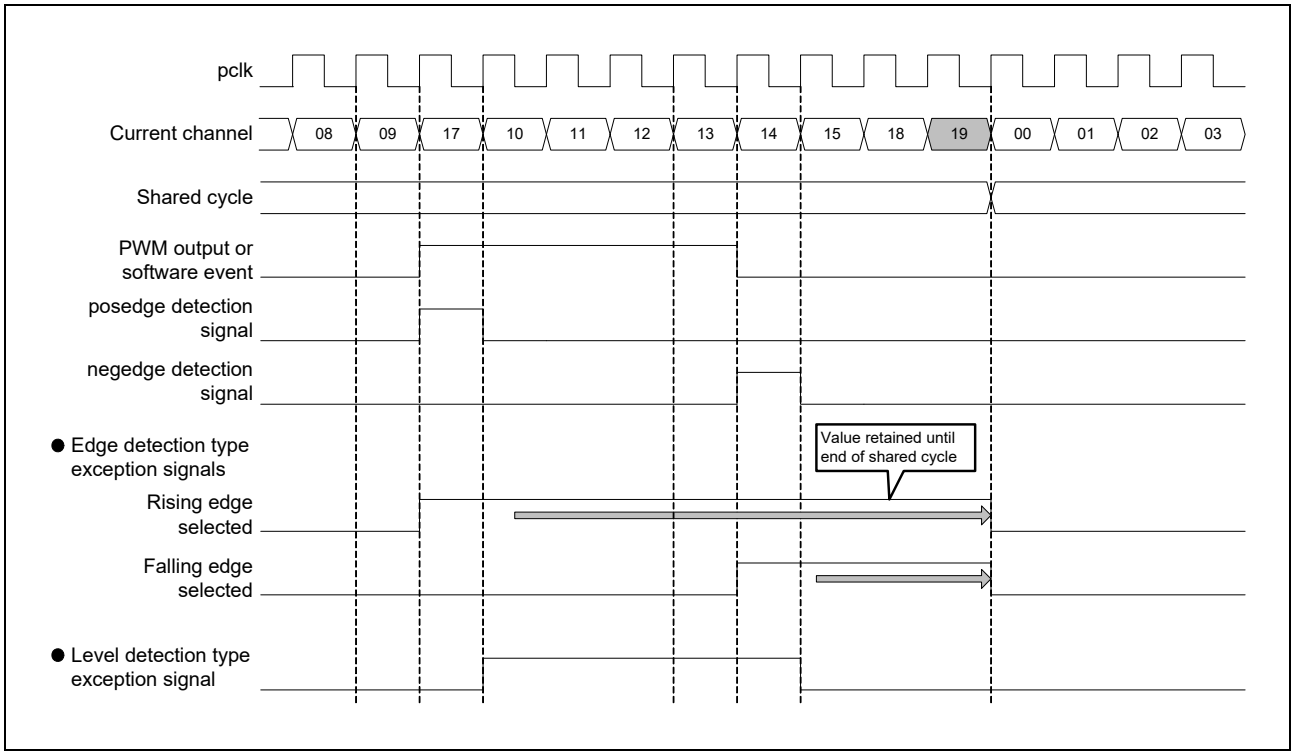

Figure 22.32 Timing Chart of Exception Signals when PWM Output or Software Event is Selected

(1) Stop Exception

The Stop exception processing causes the operations shown in **Table 22.59**.

Table 22.59 Stop Exception Operations

Item	Description
Operation	• Stop exception stops the matching comparator operation. • Stop exception is valid while the matching comparator is operating (valid in states other than disable, dis_wstart, and pre_dis).
Signal change upon exception acceptance	The following signals change simultaneously with state transition (shared cycle boundary). • Match control registers: Initialized (00_B: Match not detected) • PWM output: Inactive level PWM output changes one pclk cycle after state transition because of being F/F output. • Interrupt output: Not changed (low level) • slotID: Initialized (00_H)
Assignment	• Selected from the 32-bit event buses. Refer to **Section 22.5.3.2, Operation: Selection of Event Inputs.** • Separately defined for each pulse generation channel. APAACHNIDSTP[4:0] register is used for setting.
Detection type	• Edge detection (rising edge, falling edge, or both edges) • Separately defined for each pulse generation channel. APAACHNEGSTP[1:0] register is used for setting.
Option	• None
Note	• When Start exception option (APAACHNOPSTR) is valid, a Stop exception does not stop the operation. (A Stop exception stops the operation once, but the operation restarts from the first element.) In this case, the operation can be stopped by setting the APAA0CHEN register to disable the operation of the applicable channel.

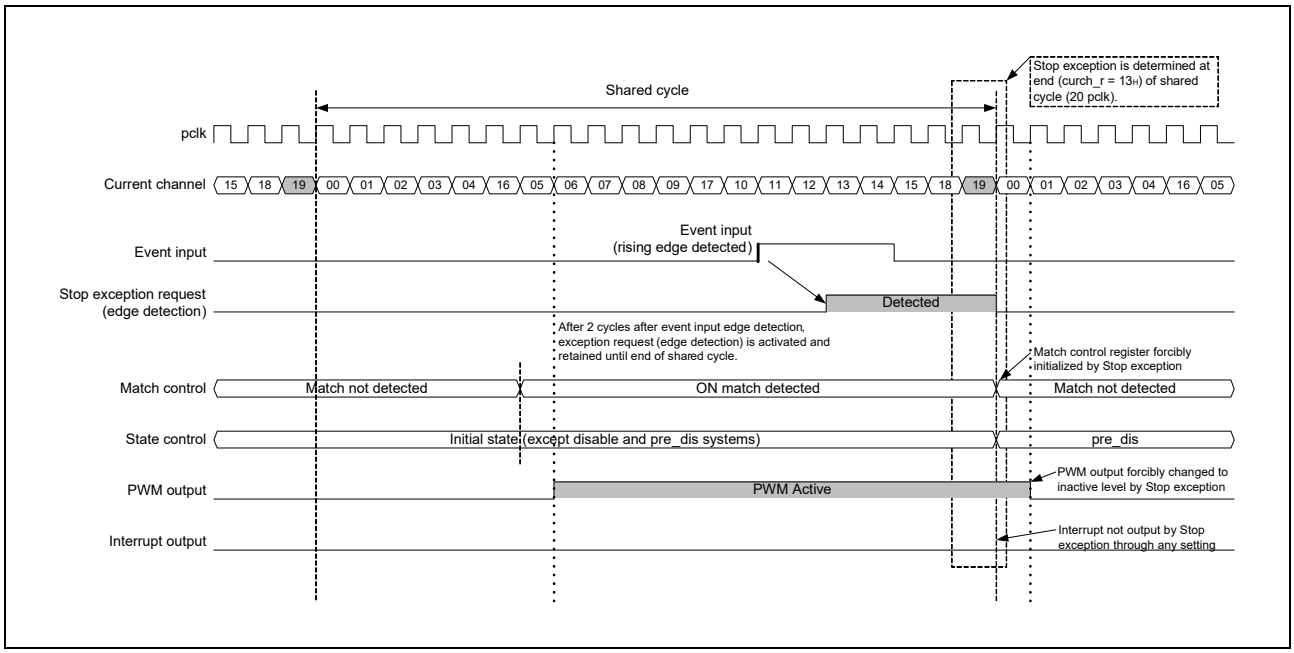

Figure 22.33 Stop Exception Acceptance Timing

(2) Start Exception

The Start exception processing causes the operations shown in **Table 22.60**.

Table 22.60 Start Exception Operations

Item	Description
Operation	• Start exception starts the matching comparator operation. • Start exception is valid only while the matching comparator is stopped and channel operation is enabled (ON) (valid in dis_wstart state).
Signal change upon exception acceptance	No signals change. • Match control registers: Not changed • PWM output: Not changed • Interrupt output: Not changed • slotID: Not changed
Assignment	• Selected from the 32-bit event buses. Refer to **Section 22.5.3.2, Operation: Selection of Event Inputs**. • Separately defined for each pulse generation channel. APAACHNIDSTR[4:0] register is used for setting.
Detection type	• Edge detection (rising edge, falling edge, or both edges) • Separately defined for each pulse generation channel. APAACHNEGSTR[1:0] register is used for setting.
Option	• The Start option (APAACHNOPSTR) is used. – 0: Operation starts triggered by a Start exception after operation is enabled (default) – 1: Operation starts immediately after operation is enabled. Start exception is not required.
Note	• When Start exception option (APAACHNOPSTR) is valid, a Stop exception does not stop the operation. (A Stop exception stops the operation once, but the operation restarts from the first element.) In this case, the operation can be stopped by setting the APAA0CHEN register to disable the operation of the applicable channel.

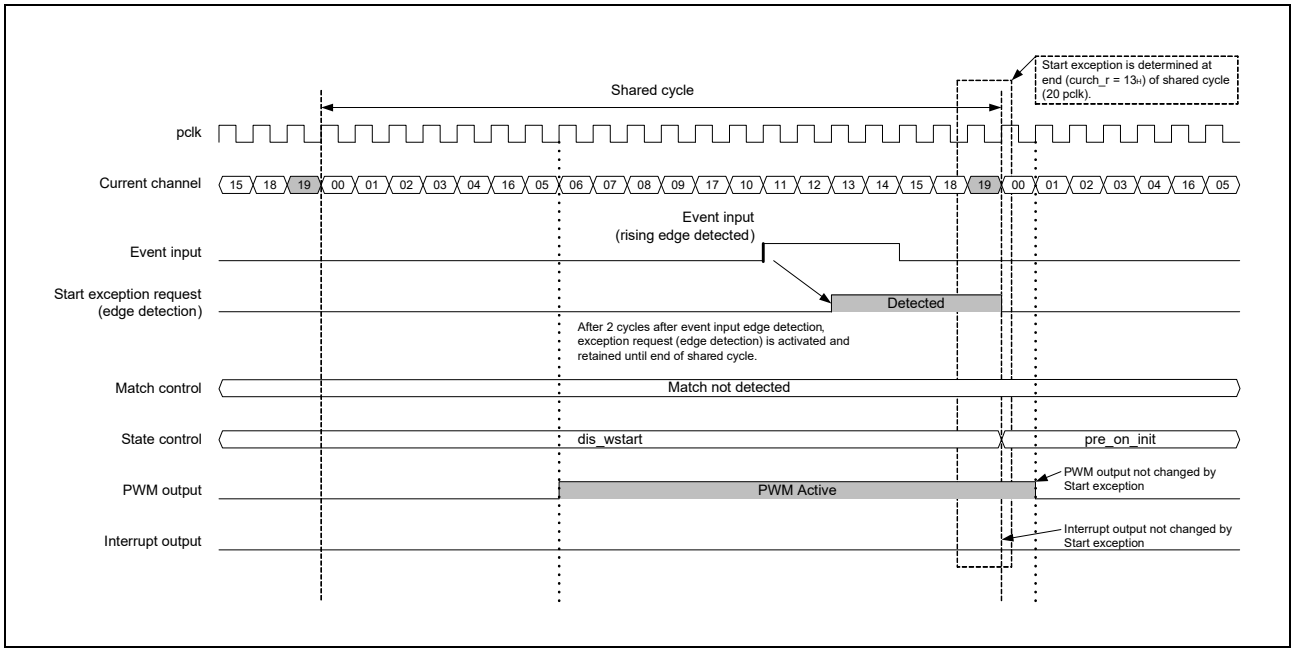

Figure 22.34 Start Exception Acceptance Timing

(3) Restart Exception

The Restart exception processing causes the operations shown in **Table 22.61**.

Table 22.61 Restart Exception Operations

Item	Description
Operation	• Restart exception forcibly initiates transition to the initial element while the matching comparator is operating. • Restart exception is valid only while the matching comparator is not stopped (valid in states other than disable and pre_dis). • When Restart exception is accepted, PWM output is forcibly made inactive simultaneously with state transition. Here, no interrupt is output.
Signal change upon exception acceptance	The following signals change simultaneously with state transition (shared cycle boundary). • Match control registers: Initialized (00_B: Match not detected) • PWM output: Inactive level PWM output changes one pclk cycle after state transition because of being F/F output. • Interrupt output: Not changed (low level) • slotID: Initialized (00_H)
Assignment	• Selected from the 32-bit event buses. Refer to **Section 22.5.3.2, Operation: Selection of Event Inputs**. • Separately defined each pulse generation channel. APAACHNIDRES[4:0] register is used for setting.
Detection type	• Edge detection (rising edge, falling edge, or both edges) • Separately defined for each pulse generation channel APAACHNEGRES[1:0] register is used for setting.
Option	• None
Note	• None

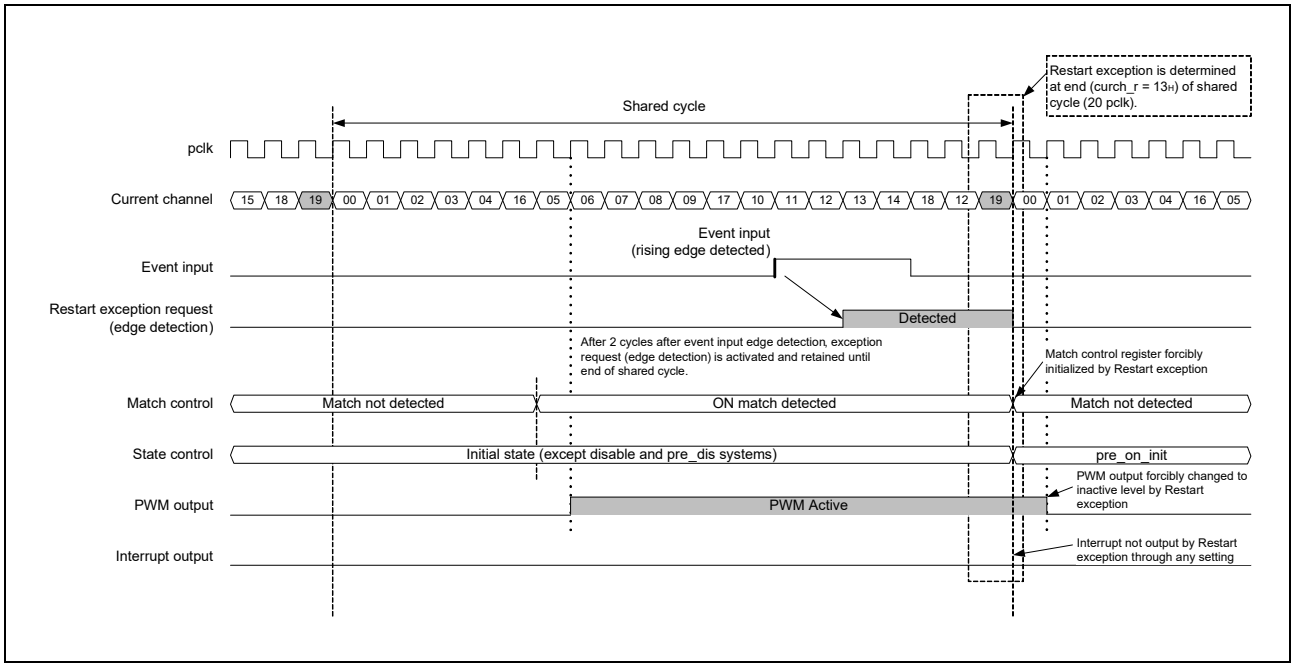

Figure 22.35 Restart Exception Acceptance Timing

(4) Transfer Exception

The Transfer exception processing causes the operations shown in **Table 22.62**.

Table 22.62 Transfer Exception Operations

Item	Description
Operation	• Transfer exception enables state transition upon OFF match. • Transfer exception is valid while ON matching comparison (wait_on system states), OFF matching comparison (wait_off system states), or update to the current element (pre_on_cur and pre_off states) is in progress. • When Transfer exception is accepted with OFF match not yet generated, The Transfer input status flag (APAATRNSTAT register) is set to 1. The value of the APAATRNSTAT register is retained until transition to next elements is initiated and is cleared upon transition to the next elements. • When Transfer exception is accepted with OFF match generated, transition to next elements is initiated. Here, the APAATRNSTAT register is not set.
Signal change upon exception acceptance	The following signals change simultaneously with state transition (shared cycle boundary). • Match control registers: Not changed • PWM output: Not changed • Interrupt output: Not changed (low level) • slotID: Not changed • Transfer input status flag: 0 → 1 (with OFF match not yet generated), or 0 left unchanged (with Transfer exception not yet input before OFF match).
Assignment	• Selected from the 32-bit event buses. Refer to **Section 22.5.3.2, Operation: Selection of Event Inputs**. • Separately defined for each element. APAAELMIDTRN[4:0] register is used for setting.
Detection type	• Edge detection (rising edge, falling edge, or both edges) • Separately defined for each element. APAAELMEGTRN[1:0] register is used for setting.
Option	• The Transfer option (APAAELMOPTRN) is used. – 0: Transfer exception input is required for transition to next elements (default). – 1: Transition to next elements is automatically made upon OFF match (Transfer exception not required).
Note	• Transfer option (APAAELMOPTRN) setting is given priority over element continuation setting (APAAELMCONT); to enable element continuation, clear Transfer option (APAAELMOPTRN) to 0.

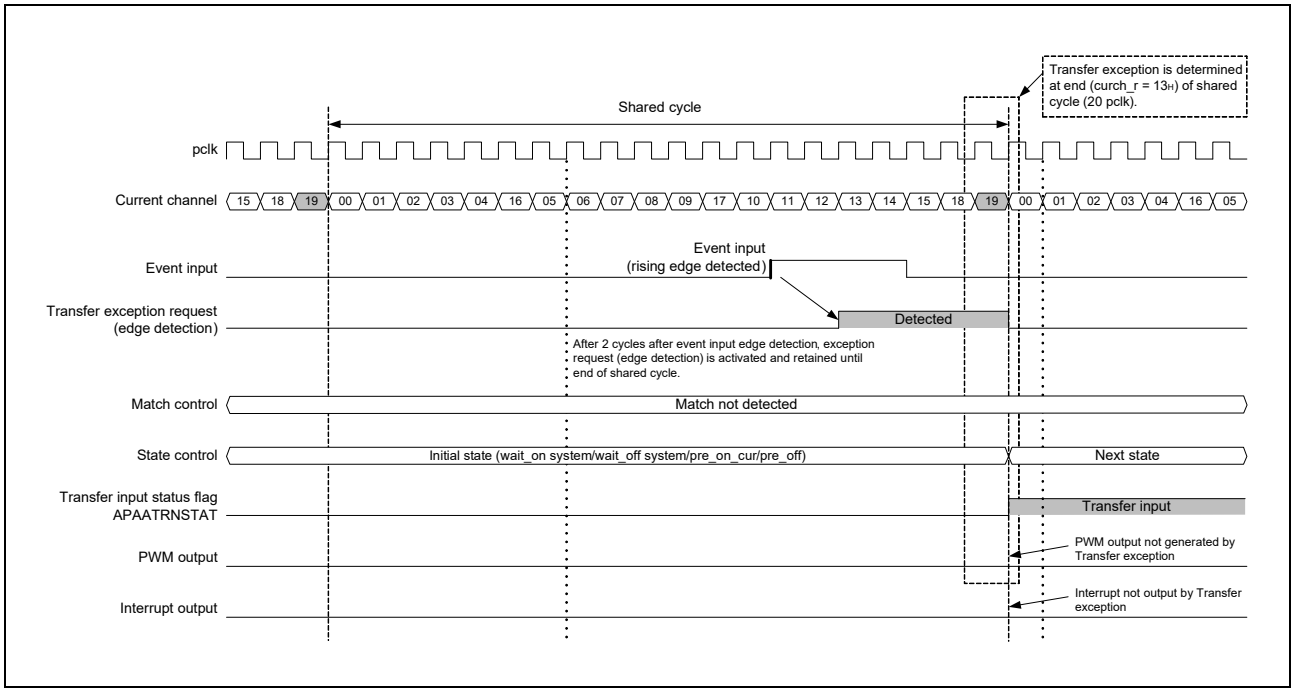

Figure 22.36 Transfer Exception Acceptance Timing

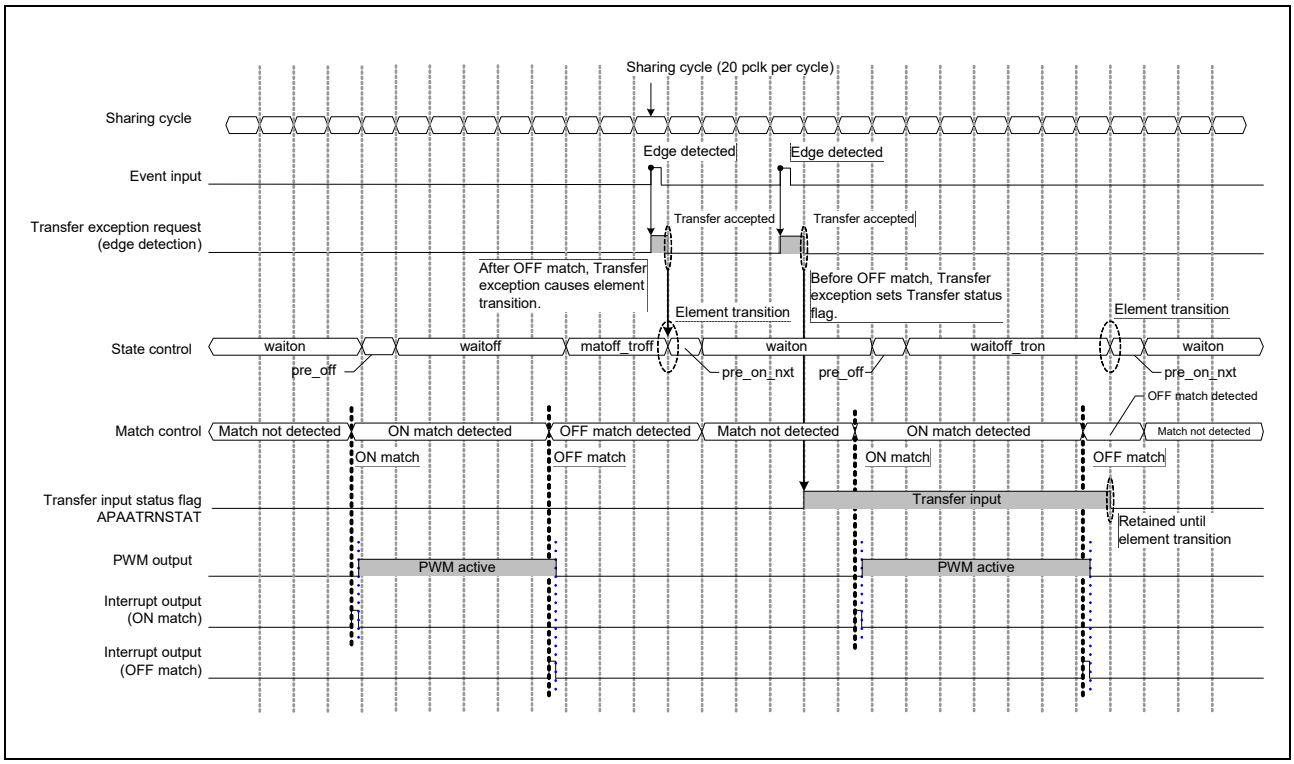

Figure 22.37 Transfer Exception Operation

(5) Force Exception

The Force exception processing causes the operations shown in **Table 22.63**.

Table 22.63 Force Exception Operations (1/2)

Item	Description
Operation	• Force exception forcibly generates a match. • Force exception is valid while ON matching comparison (wait_on system states), OFF matching comparison (wait_off system states), or update to the current element (pre_on_cur and pre_off states) is in progress.
Signal change upon exception acceptance (wait_on system states)	The following signals change simultaneously with state transition (shared cycle boundary). • Case: ON match not yet generated and Force exception (option = default) (refer to **Figure 22.38**) – Match control registers: ON match detected (01_B) – PWM output: Inactive level → active level (not changed in Postpone state) PWM output changes one pclk cycle after state transition because of being F/F output. – Interrupt output: 1-shot active-high pulse is asserted (when ON match interrupt or ON match + OFF match interrupt is set). – slotID: Set to 13_H • Case: ON match not yet generated and Force exception (forced OFF match option) (refer to **Figure 22.39**) – Match control registers: OFF match detected (10_B) – PWM output: Not changed – Interrupt output: 1-shot active-high pulse is asserted (when OFF match interrupt or ON match + OFF match interrupt is set). – slotID: Set to 13_H • Case: ON match generated and Force exception (option = default) (refer to **Figure 22.41**) – Match control registers: Not changed – PWM output: Not changed – Interrupt output: Not changed (low level) – slotID: Set to 13_H • Case: ON match generated and Force exception (forced OFF match option) (refer to **Figure 22.44**) – Match control registers: OFF match detected (10_B) – PWM output: Active level → inactive level (not changed in Postpone state) PWM output changes one pclk cycle after state transition because of being F/F output. – Interrupt output: 1-shot active-high pulse is asserted (when OFF match interrupt or ON match + OFF match interrupt is set). – slotID: Set to 13_H • Case: OFF match generated (Force exception: forced OFF match option) and Force exception (refer to **Figure 22.43**) – Match control registers: Not changed – PWM output: Not changed – Interrupt output: Not changed (low level) – slotID: Set to 13_H

Table 22.63 Force Exception Operations (2/2)

Item	Description
Signal change upon exception acceptance (wait_off system states)	The following signals change simultaneously with state transition (shared cycle boundary). • Case: OFF match not yet generated and Force exception (not depending on option setting) (refer to **Figure 22.40**) – Match control registers: OFF match detected (10_B) – PWM output: Active level → Inactive level (not changed in Postpone state) PWM output changes one pclk cycle after state transition because of being F/F output. – Interrupt output: 1-shot active-high pulse is asserted (when OFF match interrupt or ON match + OFF match interrupt is set). – slotID: Set to 13_H • Case:OFF match generated and Force exception (not depending on option setting) (refer to **Figure 22.42**) – Match control registers: OFF match detected (10_B) – PWM output: Not changed – Interrupt output: Not changed (low level) – slotID: Set to 13_H
Assignment	• Selected from the 32-bit event buses. Refer to **Section 22.5.3.2, Operation: Selection of Event Inputs**. • Separately defined for each element. APAAELMIDFOR[4:0] register is used for setting.
Detection type	• Edge detection (rising edge, falling edge, or both edges) • Separately defined for each element. APAAELMEGFOR[1:0] register is used for setting.
Option	• The Force option (APAAELMOPFOR) is used. – 0: Next match is forcibly generated. ON waiting → ON match is forcibly generated; OFF waiting → OFF match is forcibly generated (default). – 1: OFF match is forcibly generated. ON waiting → OFF match is forcibly generated; OFF waiting → OFF match is forcibly generated.
Note	• None

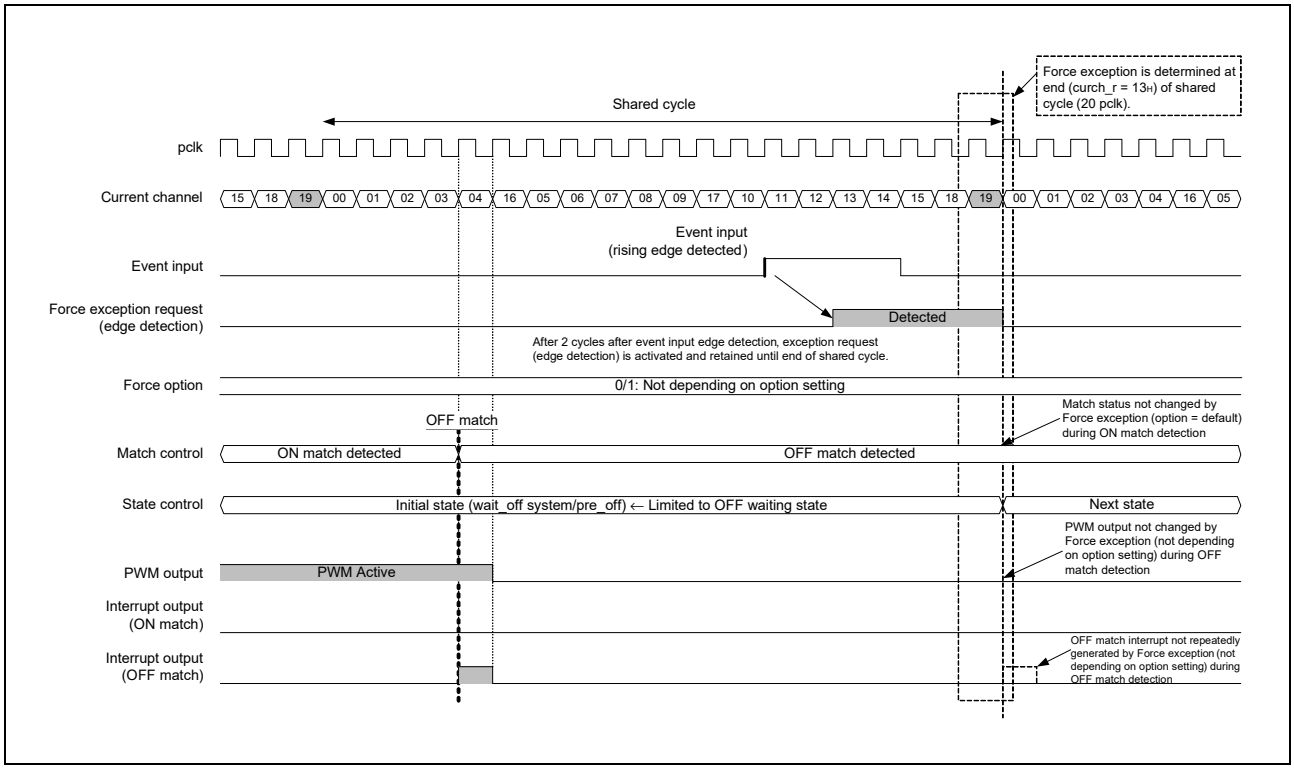

Figure 22.42 Force Exception Operation 5 (Repeated OFF Match Detection 1)

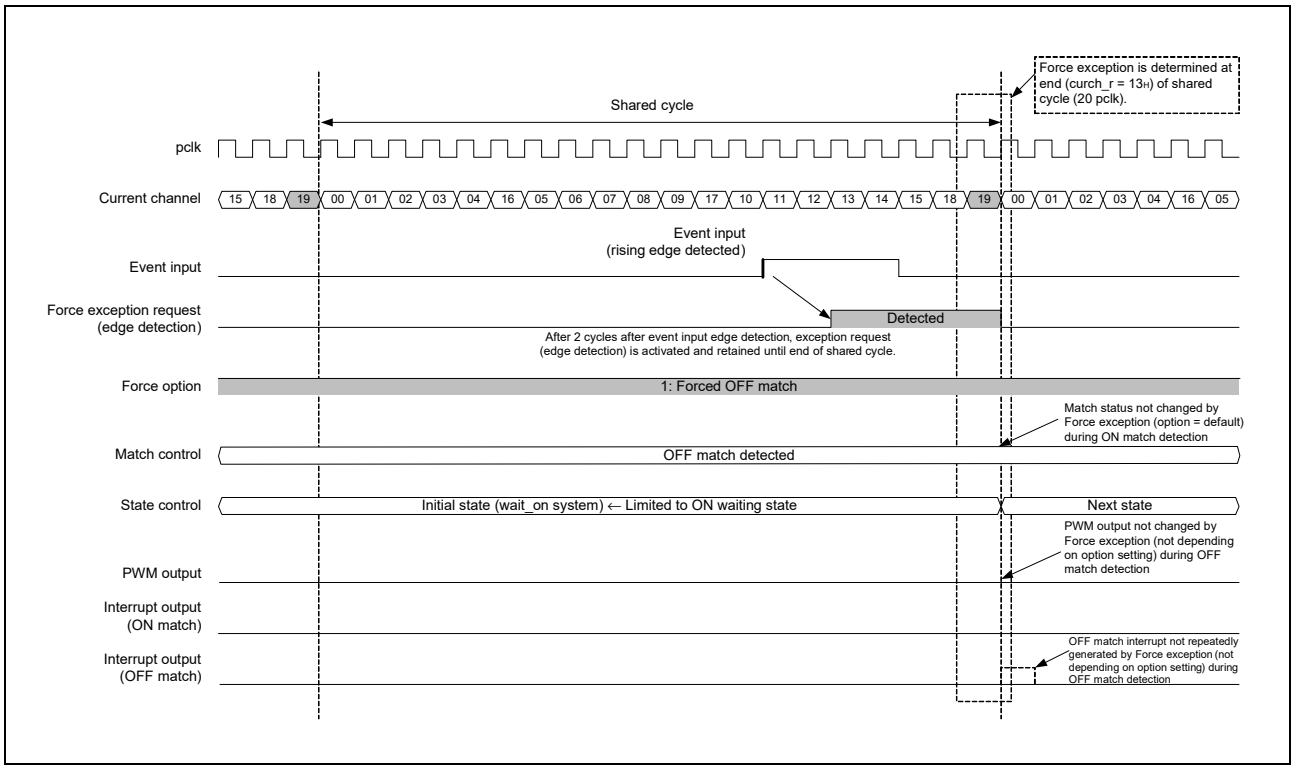

Figure 22.43 Force Exception Operation 6 (Repeated OFF Match Detection 2)

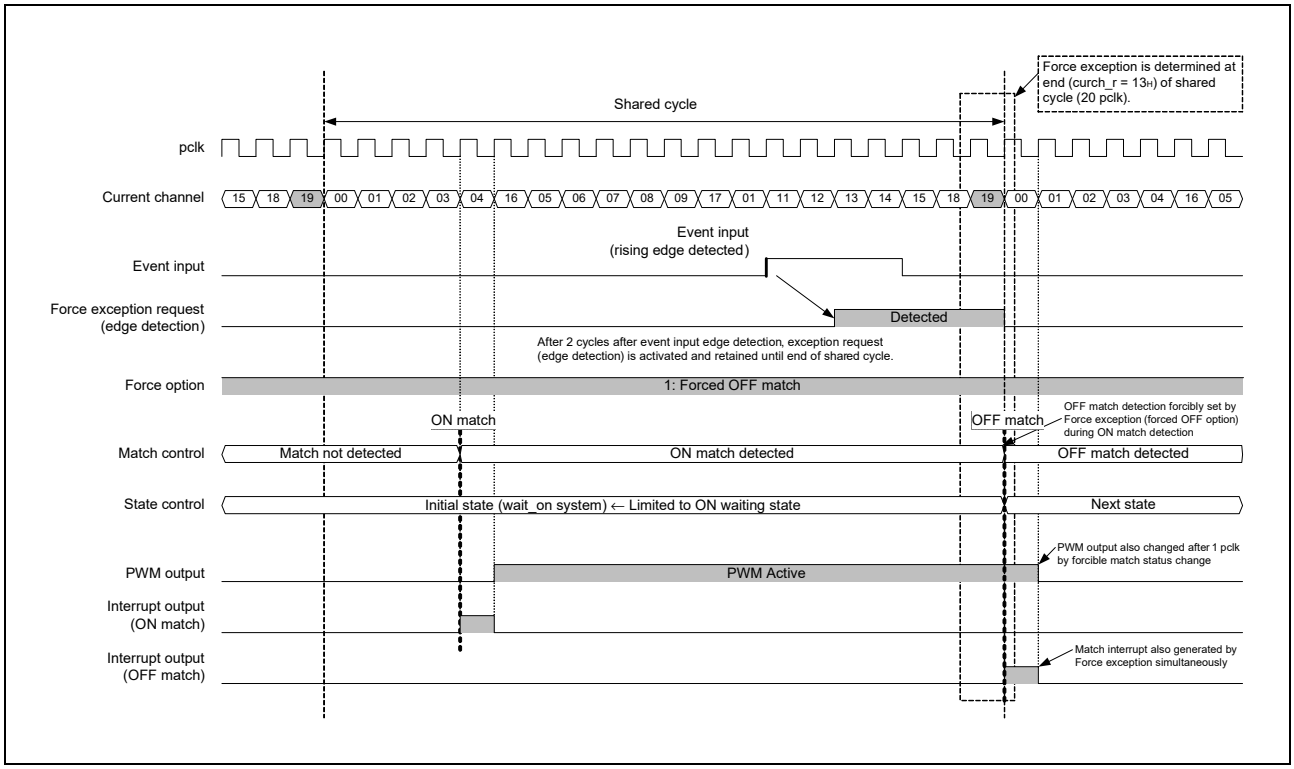

Figure 22.44 Force Exception Operation 7 (Conflict Between ON Match Detection and OFF Match Detection)

(6) Postpone Exception

The Postpone exception processing causes the operations shown in **Table 22.64**.

Table 22.64 Postpone Exception Operations

Item	Description
Operation	• Postpone exception temporarily postpones the operation that should normally takes place upon a match. • Postpone exception is valid while ON matching comparison (wait_on system states) or OFF matching comparison (wait_off system states) is in progress. • When Postpone exception turns active and is accepted as an exception, the Postpone status flag (APAAPPNSTAT register) is set to 1 simultaneously with state transition and the status is retained while the matching comparator is in the Postpone state. When Postpone exception turns inactive, the Postpone state is canceled simultaneously with state transition and the APAAPPNSTAT register is cleared to 0. • While the matching comparator is in the Postpone state, PWM output does not change. However, ON matching comparison or OFF matching comparison continues and PWM output begins to change according to the match status from the next state after Postpone state is canceled. • While Postpone exception is accepted, ON match interrupt or OFF match interrupt is output according to ON/OFF match detection or Force exception input.
Signal change upon exception acceptance	The following signals change simultaneously with state transition (shared cycle boundary). • Match control registers: Not changed • PWM output: Not changed • Interrupt output: Not changed (low level) • slotID: Not changed • Postpone status flag: 0 → 1
Signal change in Postpone state	The following signals change simultaneously with state transition (shared cycle boundary). • Match control registers: Changed according to match/Force • PWM output: Not changed • Interrupt output: Changed according to match/Force • slotID: Changed according to match/Force • Postpone status flag: Not changed (remains 1)
Signal change upon Postpone cancelation	The following signals change simultaneously with state transition (shared cycle boundary). • Match control registers: Changed according to match/Force • PWM output: Changed according to match/Force • Interrupt output: Changed according to match/Force • slotID: Changed according to match/Force • Postpone status flag: 1 → 0
Assignment	• Selected from the 32-bit event buses. Refer to **Section 22.5.3.2, Operation: Selection of Event Inputs**. • Separately defined for each element. APAAELMIDPPN[4:0] register is used for setting.
Detection type	• Level detection (either high or low) • Separately defined for each element. APAAELMLVPPN register is used for setting.
Option	• None
Note	• Since Postpone exception is level-sensitive, the assigned signal (one of event inputs or PWM outputs) needs to be high or low for 1 or more shared cycles (pclk*20). If the input level cannot be retained for the specified duration, the input may fail to be accepted as Postpone exception input.

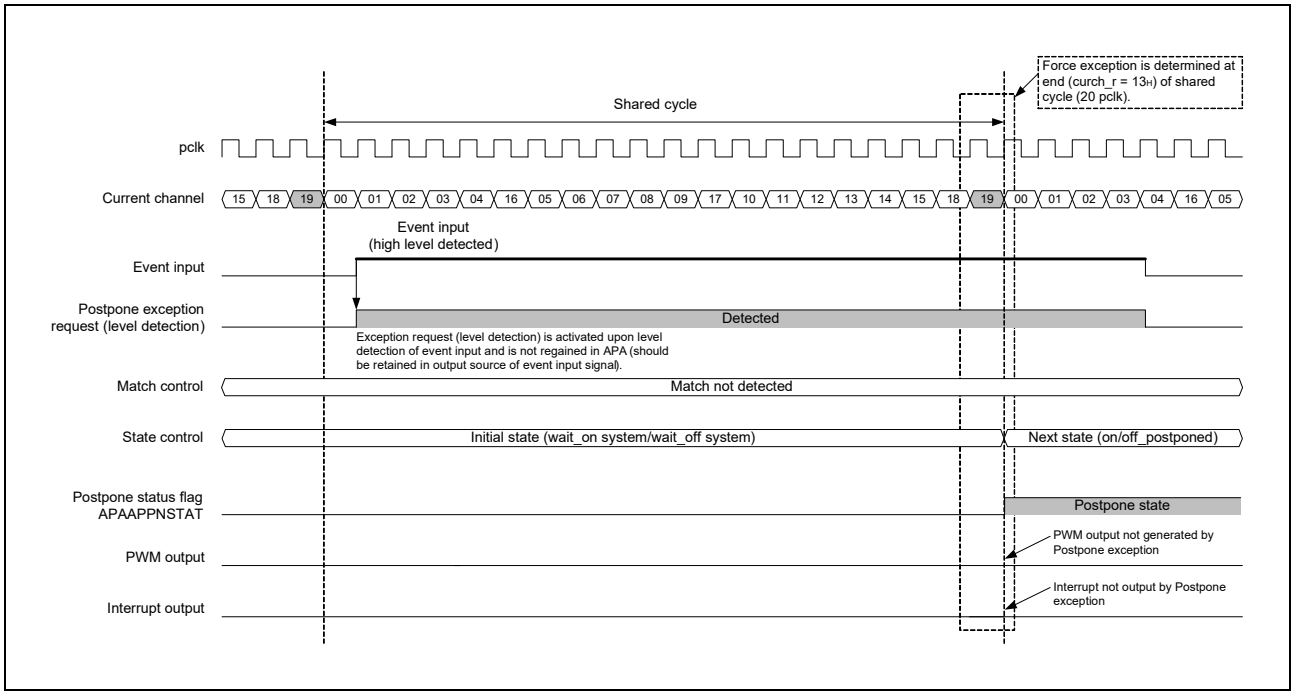

Figure 22.45 Postpone Exception Acceptance Timing

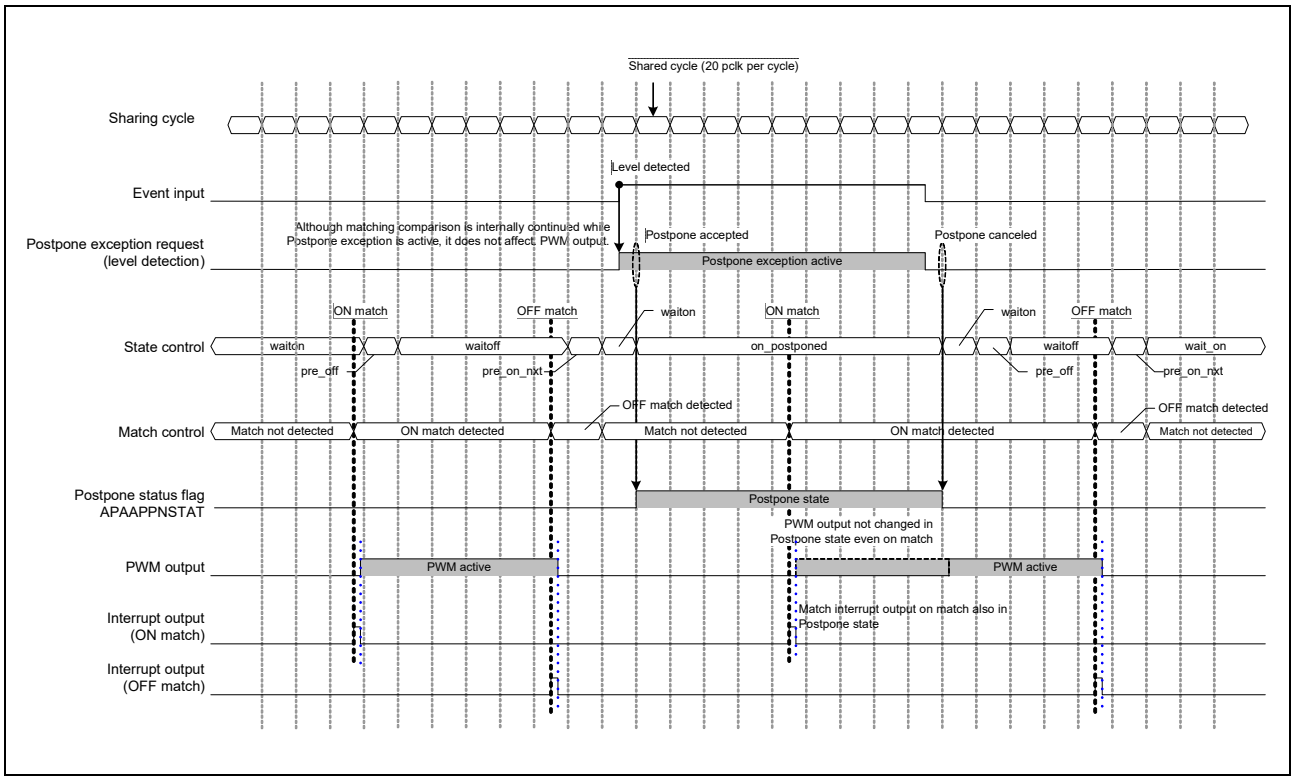

Figure 22.46 Postpone Exception Operation

22.5.4.4 Operation: Conflict between Matching Comparator and Event Decoder

When multiple input conditions shown in **Table 22.64** conflict in the same sharing cycle, the input conditions are handled as follows.

(1) Conflicts involving Channel OFF, Stop Exception, and Restart Exception

Channel OFF, Stop exception, and Restart exception are accepted according to the following priority order.

- Channel OFF > Stop exception > Restart exception

When Channel OFF, Stop exception, or Restart exception conflicts with the other input conditions, only one of the Channel OFF, Stop exception, and Restart exception is accepted according to the above priority order and the other conditions are ignored.

(2) Conflicts involving Start Exception

When Start exception, which is normally accepted only in the dis_wstart state, conflicts with Restart exception, both exceptions are accepted (in this state, Restart exception and Start exception behave in the same way).

In the other states, Start exception is ignored.

(3) Conflicts involving Transfer Exception

When Transfer exception has not yet been accepted in any state in which Transfer exception can be accepted, Transfer exception is accepted independently of the other input conditions (except for Channel OFF, Stop exception, and Restart exception), which affects the pertinent state transition. Here, the other input conditions can also be accepted. Contrarily, when Transfer exception has been accepted in any state in which Transfer exception can be accepted and another Transfer exception is input, it is ignored.

(4) Conflicts involving Match Detection and Force Exception

When Force exception is input in the same sharing cycle in which match is detected, Force exception is ignored.

However, when ON match is detected in the ON waiting state and Force exception (forced OFF option) is input, Force exception (forced OFF option) is accepted (refer to **Figure 22.42**).

When Force exception is input with match not yet detected, Force exception is accepted.

(5) Conflicts involving Postpone Exception (Postpone canceled state → Postpone state)

Postpone exception is accepted when match has not yet been detected and Postpone exception does not conflict with Force exception.

Postpone exception is ignored in the pertinent state when match has not yet been detected or when Force exception is input in conflict with Postpone exception.

(6) Conflicts involving Postpone Exception (Postpone state → Postpone canceled state)

Even when Postpone exception conflicts with match or Force exception, associated operations are completely executed.

22.5.5 Element control

22.5.5.1 Features and Overview of functions

This function generates control signals for the element RAM and the calculation device. In order to allow the elements to be shared by all pulse control channels, the following processing and control are made:

- All element information can be read and written through the P-Bus. Element data can be read and written whenever pulse generation channels are not generating pulses. If pulse generation is in progress, element data can be read and written only during the time when pulse generation channels are not accessing the element RAM. This time period is controlled by the event time division signals generated by the event bus.
- Each pulse generation channel can only read the elements. When an ON match, an OFF match, or exception processing (Transfer, Restart, Force, or Start) is generated in a pulse generation channel, the channel issues an element update request (a read request) to the element RAM. Element update requests align with the time division governed by the event time division signal, so that they are controlled not to conflict with reads and writes through the P-Bus and other pulse generation channels.
- If the next element has a match condition of relative designation, the designated value cannot be compared with the reference input as it is; it needs to be converted to a comparison baseline (absolute value). The element decoder is equipped with the calculation device (addition device) for this conversion. As with the element RAM, this calculation device is shared by different pulse generation channels.

Figure 22.47 shows the configuration of the element control circuit.

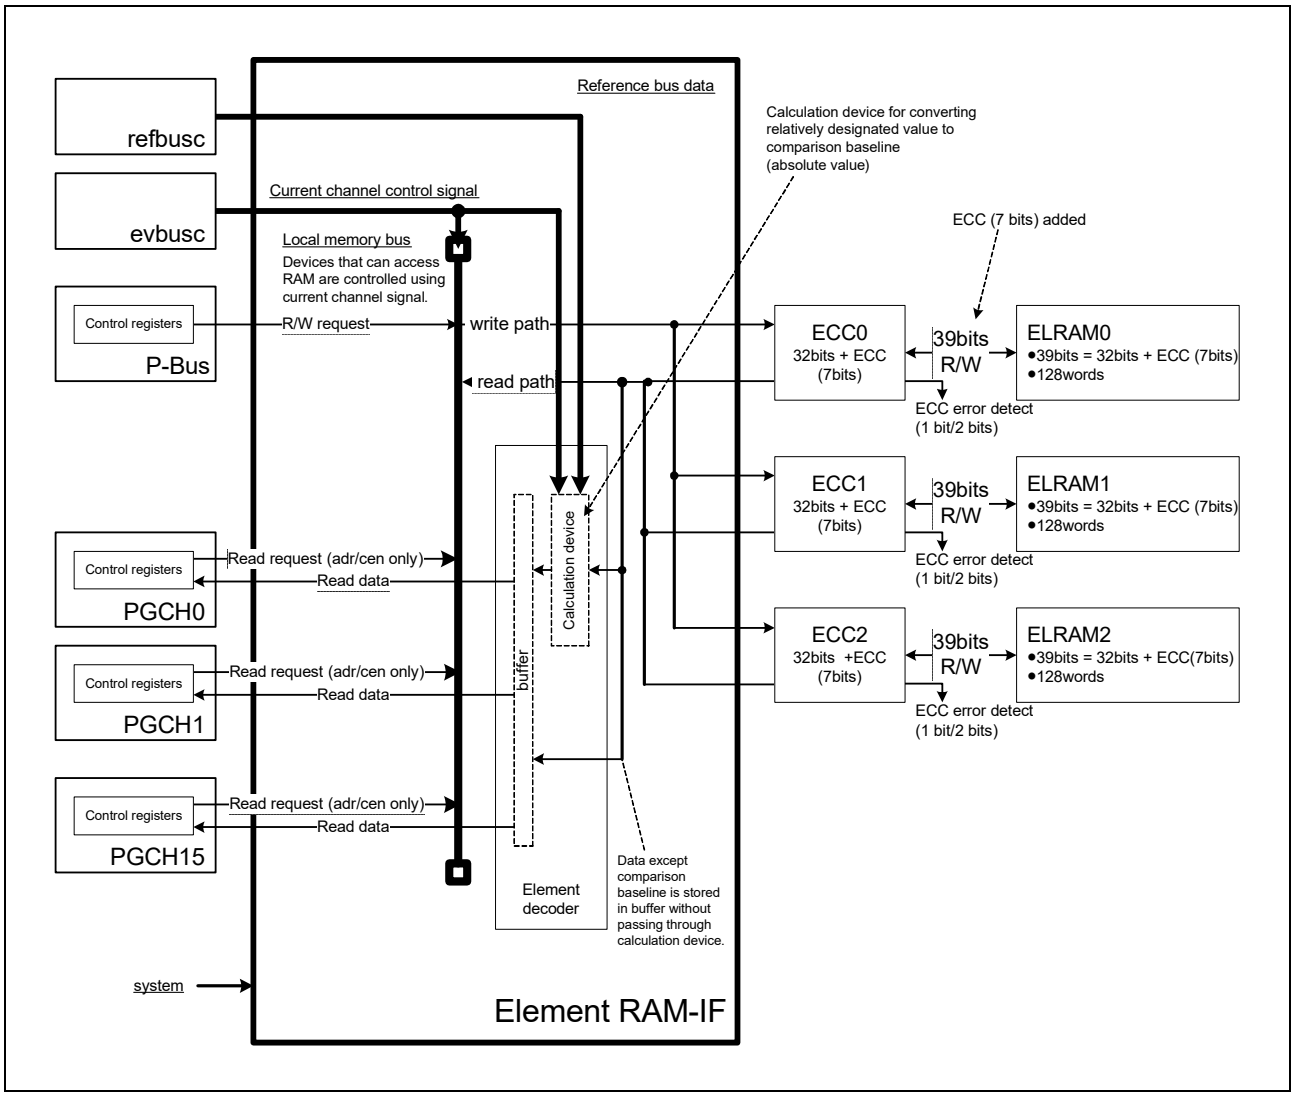

Figure 22.47 Configuration of Element Control Circuit

22.5.5.2 Operation

Access to the element RAM (from the P-Bus or pulse generation channels 0 to 15) is performed using time division as shown in **Figure 22.48**. Access from the P-Bus is held in the wait state until access to the element RAM is enabled.

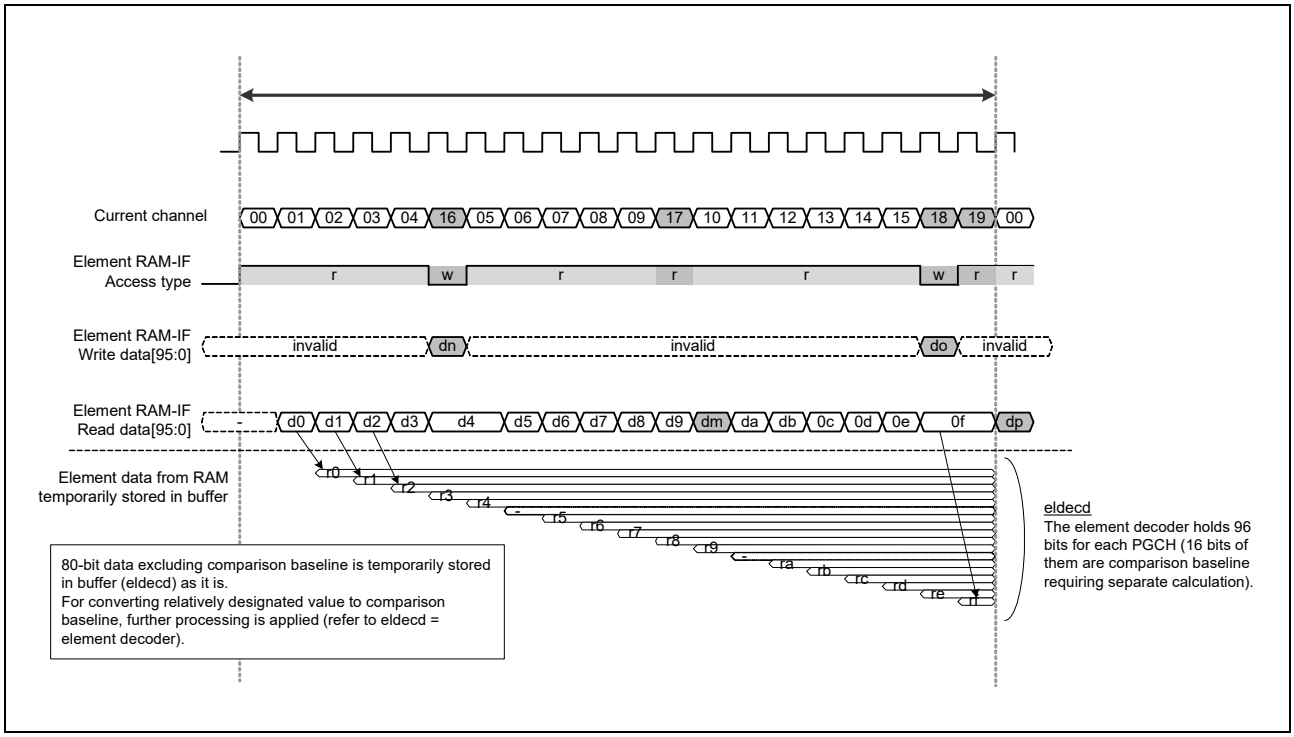

Figure 22.48 Access to Element RAM

22.5.5.3 Changing Starting Element Number during Operation

When the starting element number setting bits APAA0CCGAn.APAACHNFSTEL[6:0] (n = 0 to 15) are modified while a pulse generation channel is operating, the newly set number is applied when the starting element number is referenced to next (pre_on_init state). Therefore, to change the starting element when the starting element number is referenced to next, modify the APAA0CCGAn.APAACHNFSTEL[6:0] (n = 0 to 15) bits before transition to pre_on_init state (refer to **Figure 22.50**). For details of state transition, refer to **(2) State Control** in **Section 22.5.4.2, Operation: Matching Comparator**.

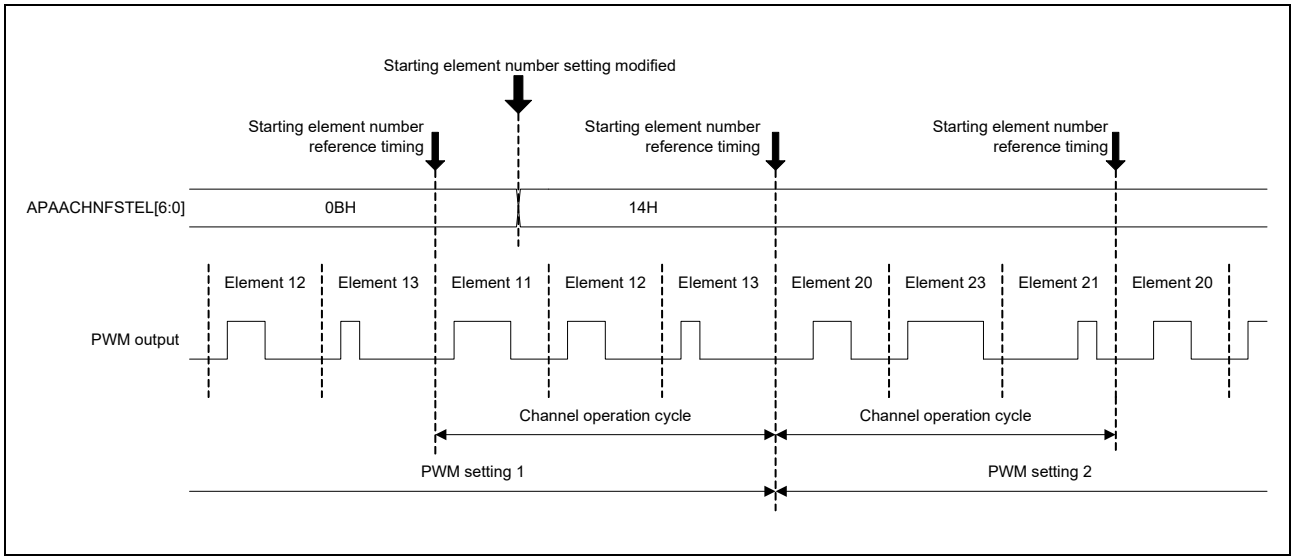

Figure 22.49 Operation Example when Starting Element is Changed during Operation

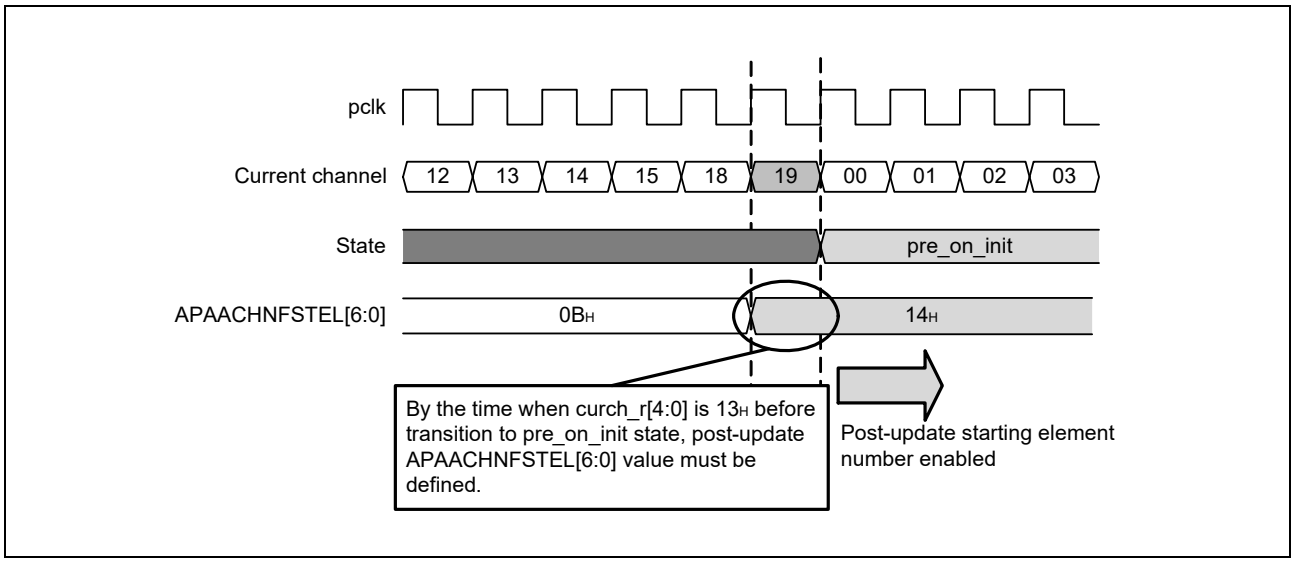

Figure 22.50 Timing of Changing Starting Element Number

Figure 22.51 shows the procedure for modifying both the starting element number and unused element RAM during operation. If this procedure is not followed, pulse generation channels might behave in an unintended way.

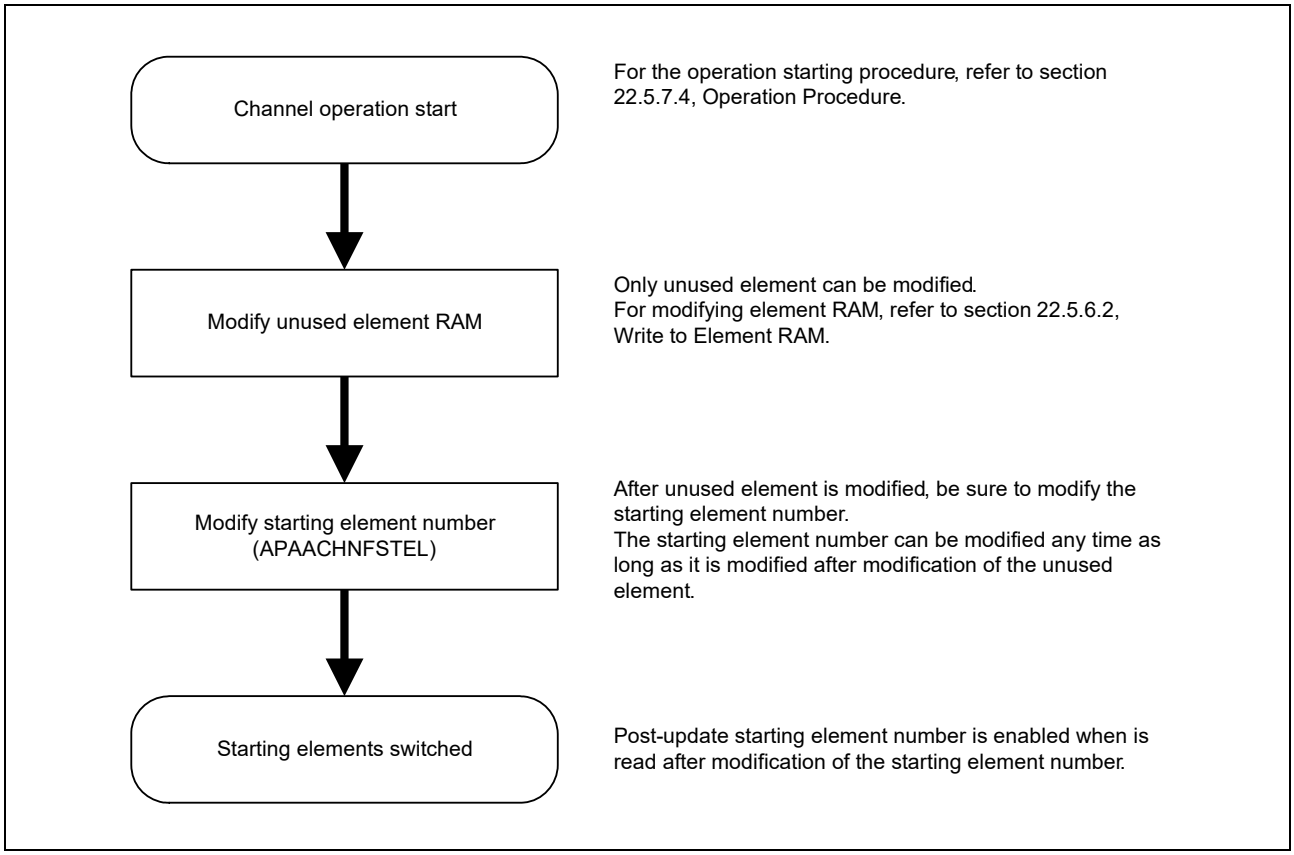

Figure 22.51 Procedure for Changing Starting Element and Unused Element during Operation

22.5.5.4 Operation: Element Decoder

In element update processing triggered by exception processing or a match occurrence, the match condition in the element that is read from the element RAM can be a value of relative designation. By definition, the value of relative designation cannot be compared with the reference input as it is; it must be converted to a comparison baseline (absolute value). The element decoder allows the calculation device used for conversion to be shared by multiple pulse generation channels. It operates as follows:

- Absolutely designated values are not converted.
- In the case of relative comparison, calculation is made based on the specified reference value when a match detection starts.
- In the case of relative designation, the reference input must satisfy the following conditions (**Figure 22.52**):
  - Quasi-monotone increasing waveform (has a “saw” shape).
  - The maximum value is fixed.
- If overflow occurs when converting from the relatively designated value to the comparison baseline, the portion exceeding the maximum value becomes the comparison baseline (**Figure 22.53**). The maximum value should be specified in advance for each reference.
- In the case of relative designation, the maximum value setting (APAA0RFMX0, APAA0RFMX1, APAA0RFMXsw registers) must satisfy the following conditions (**Figure 22.53**):
  - The value of relative designation (APAAELMRBDATON[15:0] or APAAELMRBDATOFF[15:0]) must not exceed the maximum value that the reference input can take.
  - The maximum value must be equal to the maximum value that the corresponding reference input can take. If the source counter value of the corresponding reference input is larger than the dynamic range of APA, care must be taken on the relationship with the reference input value of APA at an overflow of the source counter.
- Relative designation is valid only for references 0, 1, and sw. If relative designation is made for references 2 to 9, the designated value is used as the comparison baseline.

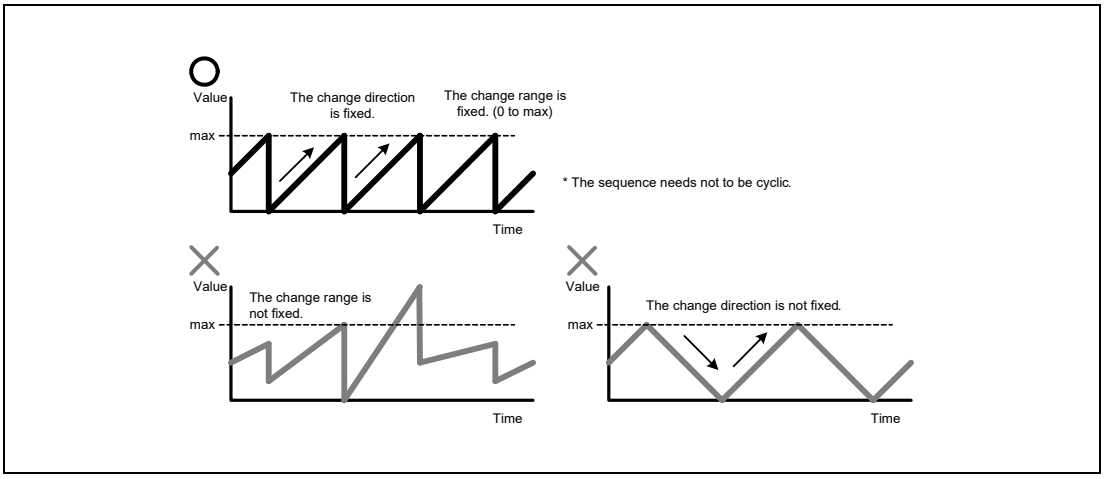

Figure 22.52 Reference Waveform Suitable for Relative Designation

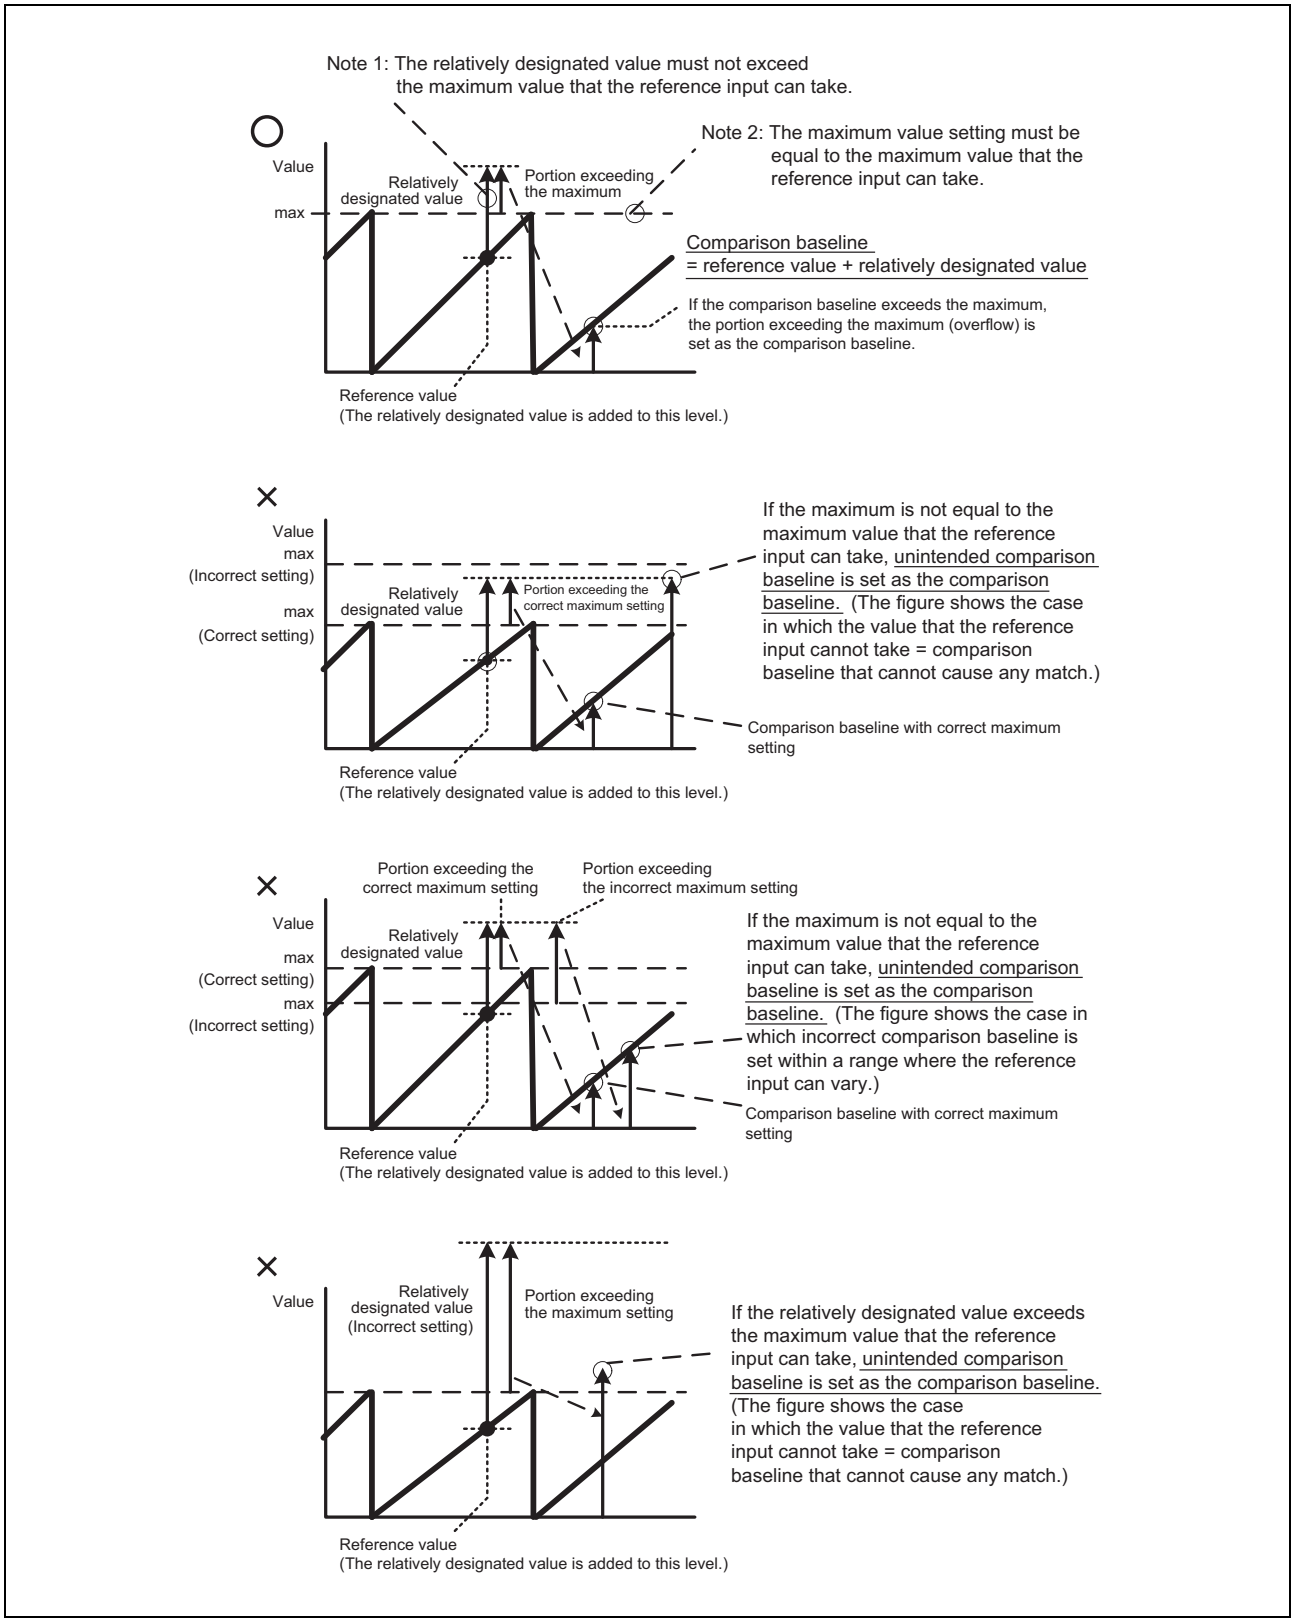

Figure 22.53 Handling of Overflow in Relative Designation

22.5.6 P-Bus-I/F

22.5.6.1 Features and Overview of Functions

The control registers in the APA (refer to **Table 22.8**, **Table 22.14**, **Table 22.20**, **Table 22.27**, and **Table 22.43**) are writable and readable via the P-Bus and the contents of the registers are held in the P-Bus-I/F. The P-Bus-I/F generates the signals to be supplied to sub-modules such as the reference bus and event bus.

22.5.6.2 Write to Element RAM

- Since the element RAM is read also by pulse generation channels, access to RAM is limited to the time in which the element RAM is not used by any pulse generation channel. The element RAM can only be read or written to in the event slots that are not assigned to pulse generation channels according to event time division timing.
- In writing to the element RAM, write 3 words of data continuously (32 low-, 32 middle-, and 32 high-order bits, in this order) to store up element data in the registers, which completes preparation for write access to the element RAM. If the words are written in the wrong order, or the element number is changed or the element RAM is read in the middle of write, unintended data is written.
- After the write preparation is completed, a wait time is produced until an event slot becomes available in which the P-Bus has priority. A wait time length depends on the APAA0EN register setting: 3 PCLK cycles when APAACMENAPA is 0 and 3 to 9 PCLK cycles when APAACMENAPA = 1.
- As soon as an event slot becomes available, data is written to the element RAM (1 cycle).
- Writing data to the registers during operation is possible only for the element not currently used. If data is written for the currently used element, the pulse generation channel in operation might behave in an unintended way.

22.5.6.3 Read from Element RAM

- Similar to write, the element RAM is read according to time division timing from the event bus. (Access is possible only in the event slots in which the element RAM is not used by any pulse generation channel.)
- Data can be read from any location in the element RAM.
- The element data (96 bits) having been read from RAM is stored in the buffer (read buffer). The data is retained until read to another element (or write to the same address read) occurs.
- When accessing the address from which data has not yet stored in the buffer, a wait time is produced until an event slot becomes available in which the P-Bus has priority. A wait time length depends on the APAA0EN register setting: 3 PCLK cycles when APAACMENAPA is 0 and 3 to 9 PCLK cycles when APAACMENAPA = 1.
  When accessing the address from which data has stored in the buffer, no wait time is produced irrespective of the APAACMENAPA setting.

22.5.7 Usage Notes

22.5.7.1 Matching Condition Setting 1

For a condition setting between an ON match and an OFF match, consider the resolution of the reference, and set the matching condition with a pulse width of 2 sharing cycles (pclk * 40) or more.

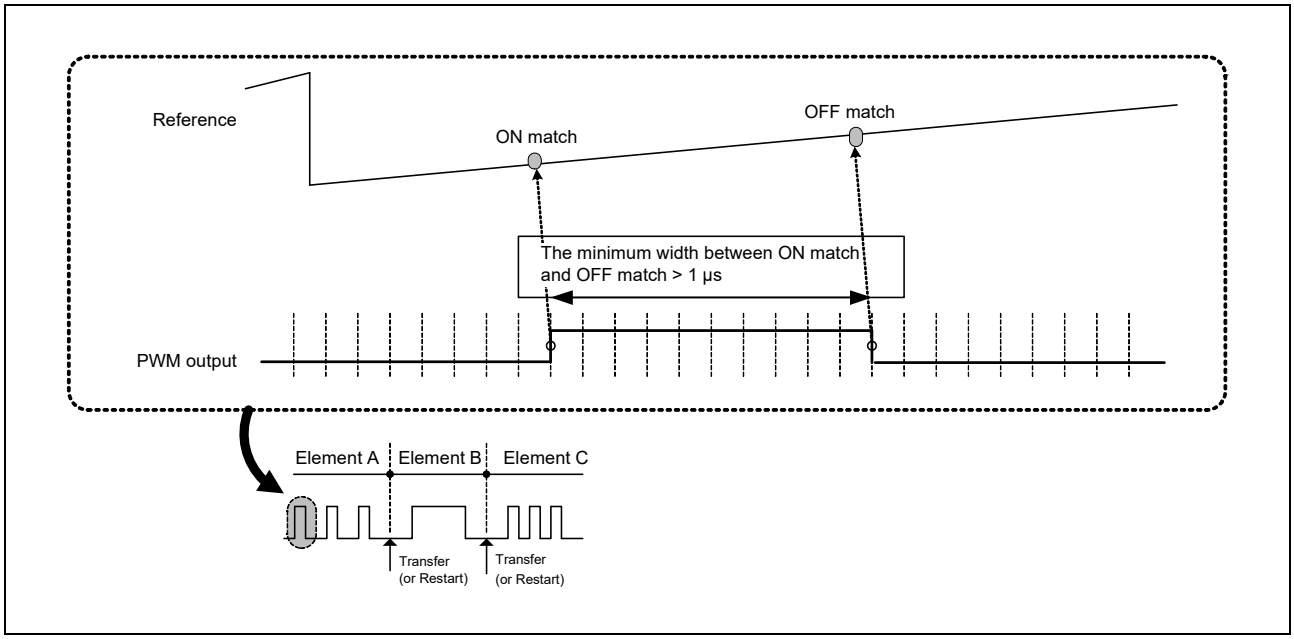

Figure 22.54 Restriction of Matching Condition Setting

22.5.7.2 Matching Condition Setting 2 (ADC Input)

In cases where the reference input takes discrete values (e.g. ADC), matching condition specification (APAAELMMCON[1:0] or APAAELMMCOFF[1:0]) should use “>” or “<“ (because “==” specification might not have matches as expected).

22.5.7.3 Event Input Interval

If the same event input is used for exception processing of multiple elements, the input must have intervals of 1 shared cycle (pclk * 20) or longer. An interval shorter than this length might cause the latter pulse (event input) to be lost.

22.5.7.4 Operation Procedure

In pulse generation using APA, follow the procedure below for generic register setting and element setting. Steps 3 to 8 must be done when the reference bus and event bus are stopped and all pulse generation channels are stopped. (Otherwise unintended operation might be made.)

Table 22.65 Standard Setting and Operation Procedure

Step	Setting Item	Example of Setting and Operation	Remarks
1	a. Reference bus setting	Setting of registers APAA0RFMX0 to sw	
	b. Event bus setting	Setting of registers APAA0EVSL00 to 15, APAA0EVSW, and APAA0EVSC	
	c. Pulse generation channel setting	Setting of registers APAA0CCGAn, APAA0CCGBn	“n” on the left stands for a channel number to be used (0 to 15). All the pulse generation channels to be used are set.
	d. Element RAM setting	Setting of registers APAA0ELMAn, APAA0ELMBn, APAA0ELMCn	“n” on the left stands for the element number to be used (000 to 127). All the elements to be used are set.
2	a. Enabling operation of the reference bus and the event bus	Register APAA0EN = 1	
3	a. Enabling operation of pulse generation channels	Setting of register APAA0CHEN	Setting value = **** (write_mask)_ ****H (channel to be enabled). Set value 1 in the bit that corresponds to the channel to be enabled, and set value 1 in the corresponding bit of write_mask.
4	a. Starting matching comparison	—	Waiting for a Start exception **Note:** When APAA0CCGBn.APAACHNOPSTR is 0, operation starts after a Start exception occurs. A maximum of 20 pclk cycles of wait time are inserted between the event input and operation start.
5	a. Execution of matching comparison	—	Execution of an element
6	a. Ending matching comparison	—	Completion of element execution or suspension due to a Stop exception
7	a. Stopping channel operation	Setting of register APAA0CHEN	Setting value = **** (write_mask)_ ****H (channel to be enabled). Set value 0 in the bit that corresponds to the channel to be enabled, and set value 1 in the corresponding bit of write_mask.
8	a. Confirming stopping of channel operation	Reading of APAA0CSTAn	Stops all pulse generation channels (7 above), waits for 40 pclk or longer, and then read APAA0CSTAn.APAACMPSTAT[4:0] to confirm that the matching comparator is in the disable state.
	b. Stopping operation of the reference bus and the event bus	Register APAA0EN=0	Confirms that all the pulse generation channels are stopped (8-a above) and then sets register APAA0EN to 0.

22.5.7.5 Handling of Unused Exceptions

If any exception should be set so that it is left unused in channel setting or element setting, take measures 1 and 2 described below.

(1) Measure 1: Assigning Unused Exception to Event Input

Handle the unused exception as described below in order to avoid unintended edge detection and level detection.

- Use one of the 64 event input channels (58 external event input channels and six software event input channels) for handling unused exceptions.
- Use one of the 16 event input selector channels exclusively for handling unused exceptions.

NOTE

For the exception input by level (postpone), take care of the level to be enabled when handling unused exception.

(2) Measure 2: Assigning Unused Exception Processing to Event Input for Handling Unused Exceptions

Set the inverted logic of the event input (one channel) and event input selector (one channel), which are assigned using measure 1 above, for the unused exception.

Table 22.66 Setting Example for Avoiding Unintended Exception Processing

Step	Setting Item	Register	Setting Value	Remarks
1	a. Event bus setting	APAA0EVSL12	0000 0039_H	Assign external event source 57 to selected event input 12.
	b. Element RAM setting	APAA0ELMA10	301C $0A00_H$	Reference 3, absolute designation, condition = "< $0A00_H$ " Last element, element continuation
		APAA0ELMB10	001A $0B00_H$	Reference 3, absolute designation, condition = "> $0B00_H$ "
		APAA0ELMC10	7F1C $1C3C_H$	The following is executed as exception processing: • Transfer: External event source 57, rise • Force: External event source 57, rise • Postpone: External event source 57, high → The above 3 exceptions can be disabled.

Note: The table above shows setting examples in cases where Transfer, Force, and Postpone exceptions are not used for element 10. They are based on the standard procedure described in **Section 22.5.7.4, Operation Procedure**.

22.5.7.6 Notes on Interrupt Outputs

On the condition shown below, an interrupt output is continuously generated twice, which results in a single interrupt output. Extra care should be taken in using the setting shown below.

Item	Description
Setting	APAACHNINTSEL[2:0] in APAA0CCGA register are set to 100_B (interrupt output upon either ON match or OFF match).
Condition	Force exception (forced OFF match option) is accepted in 1 pclk cycle after ON match generation, and then OFF match is generated.
Operation	Interrupt output is continuously generated, which results in a single interrupt output.
Remark	Cause of the above operation is that the interrupt generator that generates an interrupt upon either ON match or OFF match is configured so that it generates an interrupt output by performing OR between the ON match interrupt and OFF match interrupt.

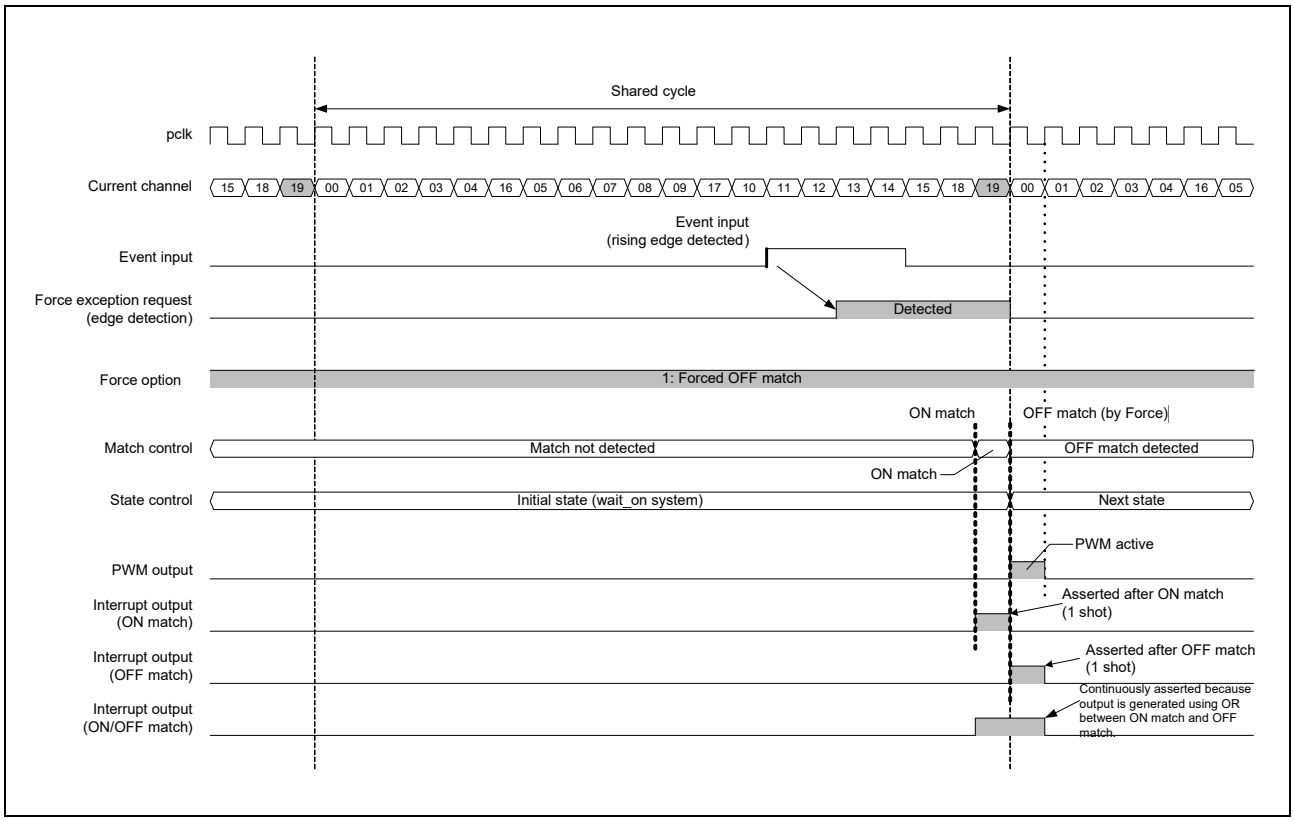

Figure 22.55 Continuous Generation of ON Match Interrupt and OFF Match Interrupt

22.5.8 APA Input Selector

The following sections describe the APA input selector.

22.5.8.1 Block Diagram

Figure 22.56 shows a block diagram of the APA input selector.

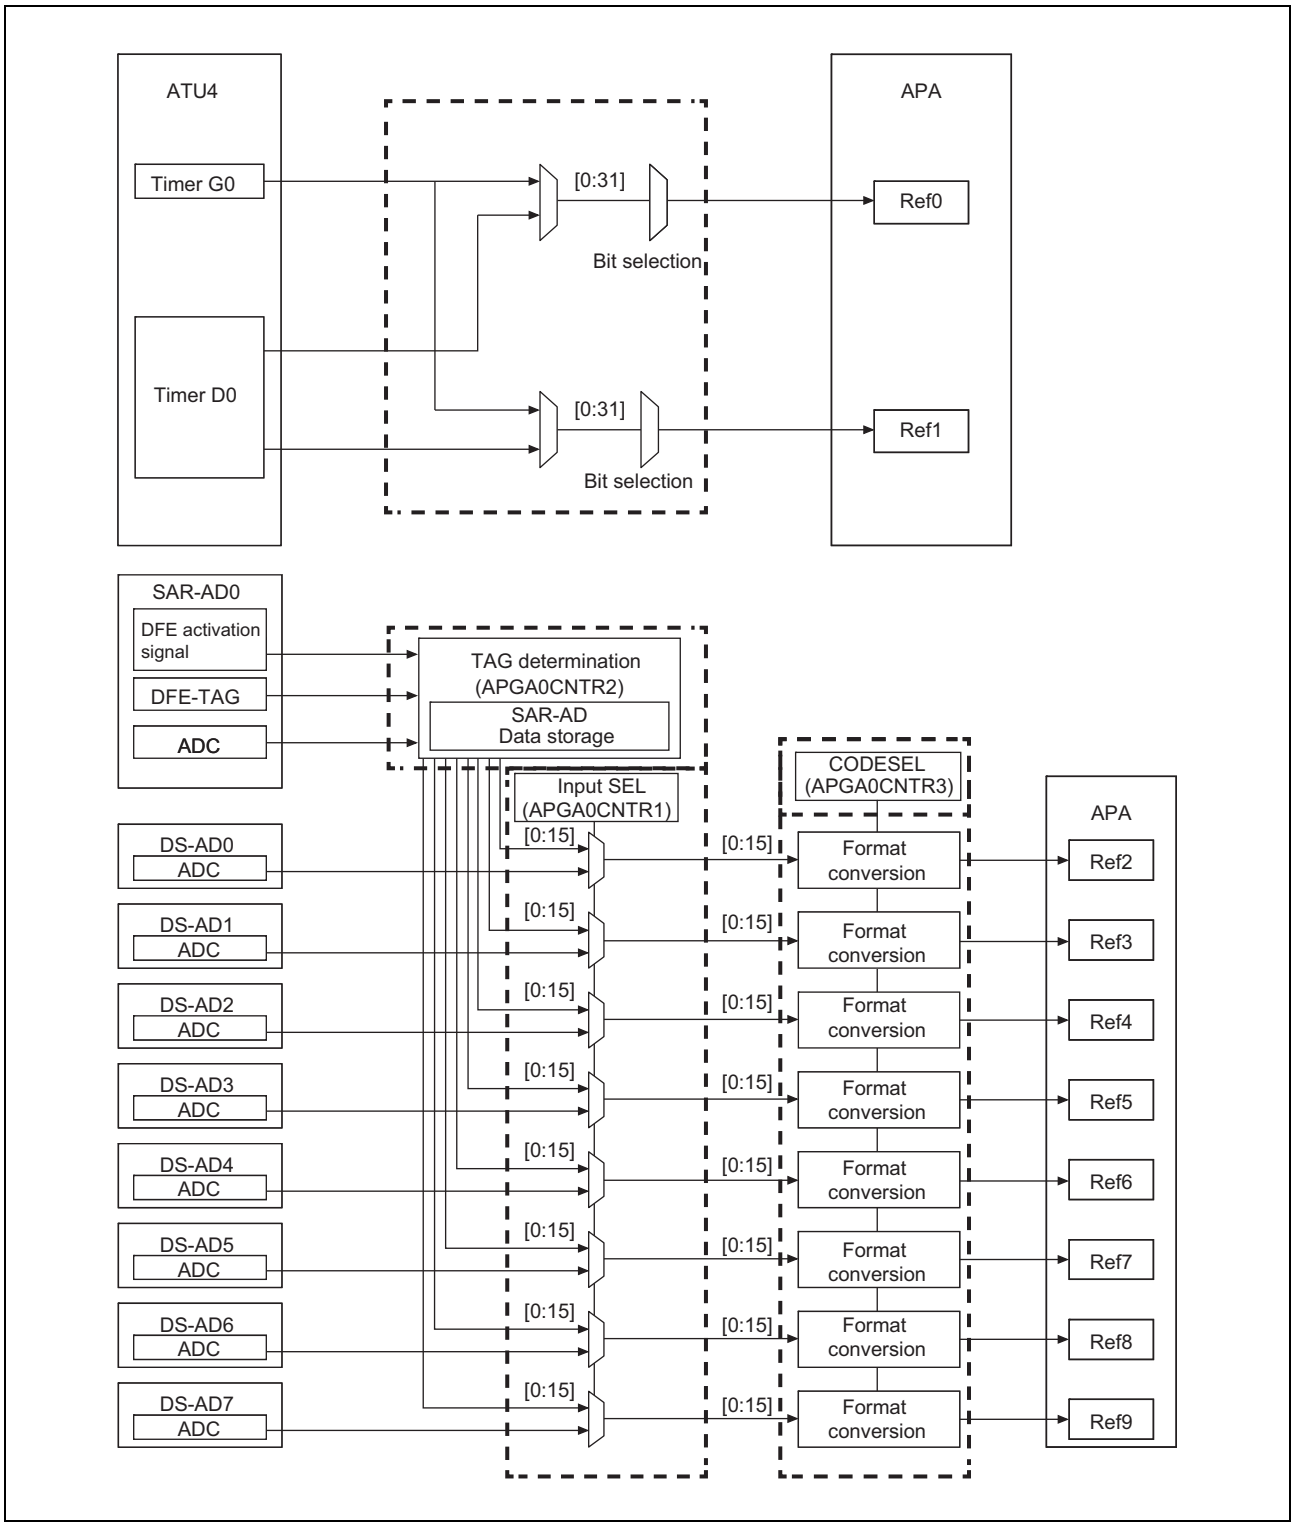

Figure 22.56 Block Diagram of APA Input Selector

22.5.8.2 List of Registers

The addresses of the APA input selector registers are given as offsets from the base address FFED $C000_H$. **Table 22.67** lists the registers.

Table 22.67 APA Input Selector Registers

Offset Address	Symbol	Register Name	Value after Reset	Access Size	Function
0000_H	APGA0CNTR0	APGA0 register control register 0	00_H	8	Selects the counters and bit shift types for ATU-IV to APA connection.
0004_H	APGA0CNTR1	APGA0 register control register 1	00_H	8	Selects DS-AD or SAR-AD0 for reference channels 2 to 5 from AD.
0005_H	APGA0CNTR3	APGA0 register control register 3	FF_H	8	Selects whether to convert the format.
0008_H	APGA0CNTR2	APGA0 register control register 2	$0000\ 0000_H$	32	Selects the channels used for SAR-AD0 (DFE-TAG).

22.5.8.3 Function Details

The following sections describe the functions of the APA input selector modules in detail.

(1) APA Reference Data Selection Control Module

The following describes the functions of the APA reference data selection control module.

- Selects the counter and bit shift types for ATU-IV to APA connection.
- Selects the counter to be output to APA and 16 bits out of the selected counter (32 bits).
- Selects the ATU4 counter to be output to APA reference channels 0 and 1.

Selects either of the following counters for reference channel 0.

- TCNTG0 of ATU-IV timer G
- TCNT1D0 of ATU-IV timer D

Selects either of the following counters for reference channel 1.

- TCNTG0 of ATU-IV timer G
- TCNT2D0 of ATU-IV timer D

The value of each selected counter can be shifted within a range of 0 to 5 bits. 8- and 16-bit shifting is also available.

With APGA0 register control register 0 (APGA0CNTR0), the ATU-IV counter type to be used can be selected. Modifying the register is prohibited while APA is operating.

(a) APGA0CNTR0 — APGA0 Register Control Register 0

Bit	7	6	5	4	3	2	1	0
	REF_SEL1	BIT_SEL1			REF_SEL0	BIT_SEL0		
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.68 APGA0CNTR0 Register Contents

Bit Position	Bit Name	Function
7	REF_SEL1	Selects the counter to be output to the APA reference channel 1. 0: TCNTG0 of ATU timer G 1: TCNT2D0 of ATU timer D
6 to 4	BIT_SEL1	Selects 16 bits to be output to APA reference channel 1. 000: No shift 001: 1-bit shift 010: 2-bit shift 011: 3-bit shift 100: 4-bit shift 101: 5-bit shift 110: 8-bit shift (middle 16 bits) 111: 16-bit shift (upper 16 bits)
3	REF_SEL0	Selects the counter to be output to the APA reference channel 0. 0: TCNTG0 of ATU timer G 1: TCNT1D0 of ATU timer D
2 to 0	BIT_SEL0	Selects 16 bits to be output to APA reference channel 0. 000: No shift 001: 1-bit shift 010: 2-bit shift 011: 3-bit shift 100: 4-bit shift 101: 5-bit shift 110: 8-bit shift (middle 16 bits) 111: 16-bit shift (upper 16 bits)

(2) AD Reference Selection

For APA reference channels 2 to 9 from AD, either DS-AD or SAR-AD0 can be selected and used. The format of the input data is converted. When SAR-AD0 is used, the DFE TAG used by the DFE is read to determine the channels to be used and the data of the specified channels is retained and output.

- Modifying the reference selection is prohibited while APA is operating

(a) APGA0CNTR1 — APGA0 Register Control Register 1

APGA0 register control register 1 (APGA0CNTR1) selects the type of AD to be used.

Bit	7	6	5	4	3	2	1	0
	REF_SEL9	REF_SEL8	REF_SEL7	REF_SEL6	REF_SEL5	REF_SEL4	REF_SEL3	REF_SEL2
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

CAUTION

Since SAR-AD0 cannot be used as APA reference in this product, use this register with its value after a reset, 00_H.

Table 22.69 APGA0CNTR1 Register Contents

Bit Position	Bit Name	Function
7	REF_SEL9	Selects AD data to be input to APA reference channel 9. 0: DS-AD7 1: Data with TAG identical to SAR-AD0 TAG_SEL9
6	REF_SEL8	Selects AD data to be input to APA reference channel 8. 0: DS-AD6 1: Data with TAG identical to SAR-AD0 TAG_SEL8
5	REF_SEL7	Selects AD data to be input to APA reference channel 7. 0: DS-AD5 1: Data with TAG identical to SAR-AD0 TAG_SEL7
4	REF_SEL6	Selects AD data to be input to APA reference channel 6. 0: DS-AD4 1: Data with TAG identical to SAR-AD0 TAG_SEL6
3	REF_SEL5	Selects AD data to be input to APA reference channel 5. 0: DS-AD3 1: Data with TAG identical to SAR-AD0 TAG_SEL5
2	REF_SEL4	Selects AD data to be input to APA reference channel 4. 0: DS-AD2 1: Data with TAG identical to SAR-AD0 TAG_SEL4

0	REF_SEL2	Selects AD data to be input to APA reference channel 2. 0: DS-AD0 1: Data with TAG identical to SAR-AD0 TAG_SEL2

(b) APGA0CNTR2 — APGA0 Register Control Register 2

APGA0 register control register 2 (APGA0CNTR2) specifies the DEF-TAG and indirectly selects the channels to be used for SAR-AD0. The channels to be used for SAR-AD0 are determined based on the DFE-TAG and DFE activation signal. Note that this register does not directly select the channels.

Modifying the register is prohibited while APA is operating.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 22.70 APGA0CNTR2 Register Contents

Bit Position	Bit Name	Function
31 to 28	SARAD0_TAG_SEL9	Selects SAR-AD0 data to be used when REF_SEL9 = 1. Data with DFTAG identical to the specified value is selected.
27 to 24	SARAD0_TAG_SEL8	Selects SAR-AD0 data to be used when REF_SEL8 = 1. Data with DFTAG identical to the specified value is selected.
23 to 20	SARAD0_TAG_SEL7	Selects SAR-AD0 data to be used when REF_SEL7 = 1. Data with DFTAG identical to the specified value is selected.
19 to 16	SARAD0_TAG_SEL6	Selects SAR-AD0 data to be used when REF_SEL6 = 1. Data with DFTAG identical to the specified value is selected.
15 to 12	SARAD0_TAG_SEL5	Selects SAR-AD0 data to be used when REF_SEL5 = 1. Data with DFTAG identical to the specified value is selected.
11 to 8	SARAD0_TAG_SEL4	Selects SAR-AD0 data to be used when REF_SEL4 = 1. Data with DFTAG identical to the specified value is selected.
7 to 4	SARAD0_TAG_SEL3	Selects SAR-AD0 data to be used when REF_SEL3 = 1. Data with DFTAG identical to the specified value is selected.
3 to 0	SARAD0_TAG_SEL2	Selects SAR-AD0 data to be used when REF_SEL2 = 1. Data with DFTAG identical to the specified value is selected.

(3) Conversion of AD Reference Format

Although it is assumed that signed reference data is input from each AD, the APA only handles unsigned data for comparison. Therefore, it is necessary to convert the format of the reference data input from each AD as shown below.

- Hardware inverts the MSB value.

AD Output		APA Input	
Hexadecimal	**Decimal**	**Hexadecimal**	**Decimal**
$7FFF_H$	+32767	$FFFF_H$	65535
|	|	|	|
0001_H	1	8001_H	32769
0000_H	0	8000_H	32768
$FFFF_H$	-1	$7FFF_H$	32767
|	|	|	|
8000_H	-32768	0000_H	0

CAUTION

Zero is always input as a sign of data from SAR-AD (it is necessary to inform the user that the data format should be converted as required). Therefore, in setting elements in the APA, the MSB must always be set in such a manner that the value should be 8000_H or greater.

6	CODE_SEL8	Selects whether to convert a sign of AD data to be input to APA Ref8. 0: Sign is not converted. 1: Sign is converted.
5	CODE_SEL7	Selects whether to convert a sign of AD data to be input to APA Ref7. 0: Sign is not converted. 1: Sign is converted.
4	CODE_SEL6	Selects whether to convert a sign of AD data to be input to APA Ref6. 0: Sign is not converted. 1: Sign is converted.
3	CODE_SEL5	Selects whether to convert a sign of AD data to be input to APA Ref5. 0: Sign is not converted. 1: Sign is converted.
2	CODE_SEL4	Selects whether to convert a sign of AD data to be input to APA Ref4. 0: Sign is not converted. 1: Sign is converted.
1	CODE_SEL3	Selects whether to convert a sign of AD data to be input to APA Ref3. 0: Sign is not converted. 1: Sign is converted.
0	CODE_SEL2	Selects whether to convert a sign of AD data to be input to APA Ref2. 0: Sign is not converted. 1: Sign is converted.

22.5.8.4 Overview of Operations

(1) APA Reference Data Selection Control Module

Figure 22.57 shows a block diagram of the APA reference data selection control module.

Channels 1 and 2 of timer G and timer D input from the ATU-IV timer are controlled using the APGA0CNTR0 register to select the ATU-IV counter to be output to APA reference channel 0 and reference channel 1.

Select the bits considering that the resolution of the reference input to be higher than the count cycle of the counter to be connected.

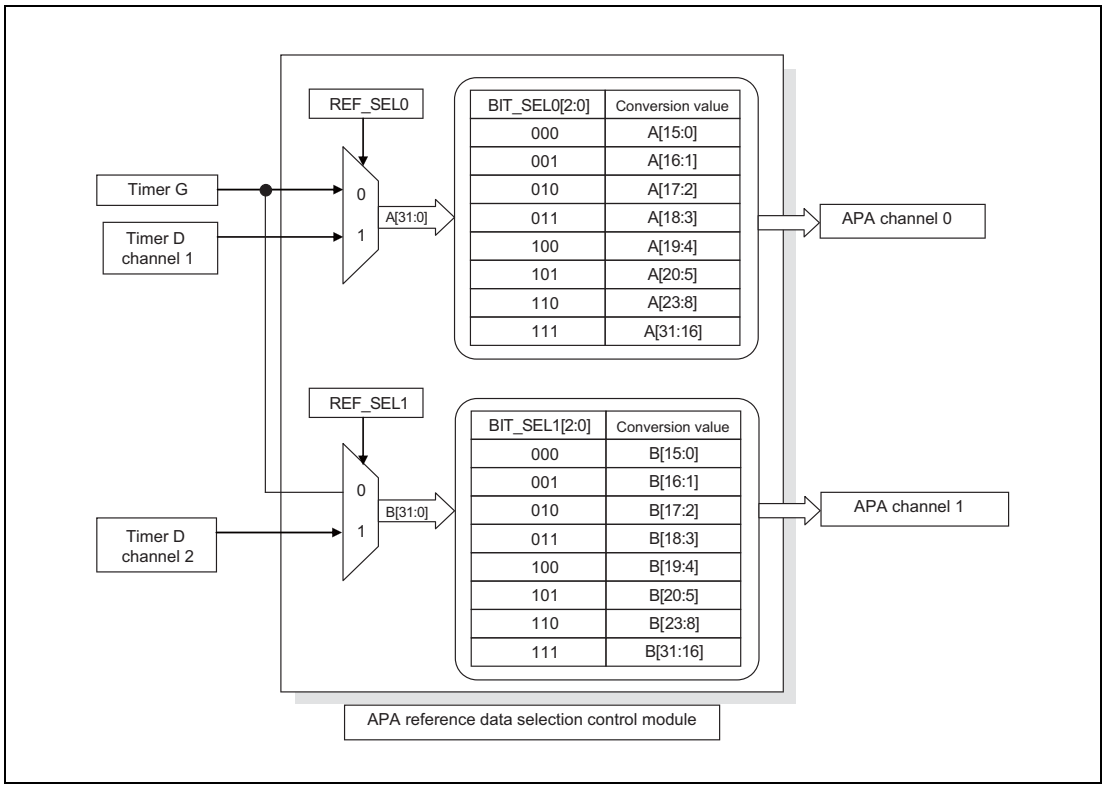

Figure 22.57 Block Diagram of APA Reference Data Selection Control Module

(2) AD Reference Selection

Figure 22.58 and **Figure 22.59** show block diagrams of the APA reference selection functions.

A match between the values set in SARAD0_TAG_SEL9 to SARAD0_TAG_SEL2 in the APGA0CNTR2 register and the AD tag signal (ADC0DFTAG) input from PB0 are checked and confirmed, and which signals to be output as addf_dat9 to addf_dat2 is selected.

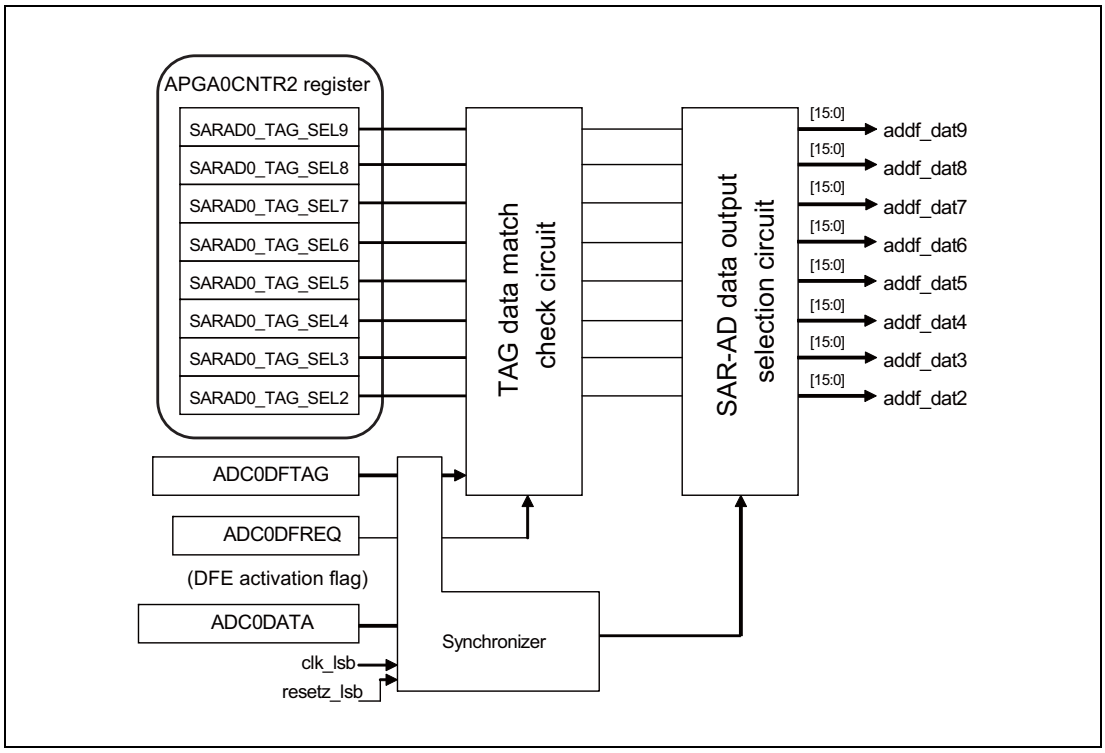

Figure 22.58 Block Diagram of SAR-AD Data Selector

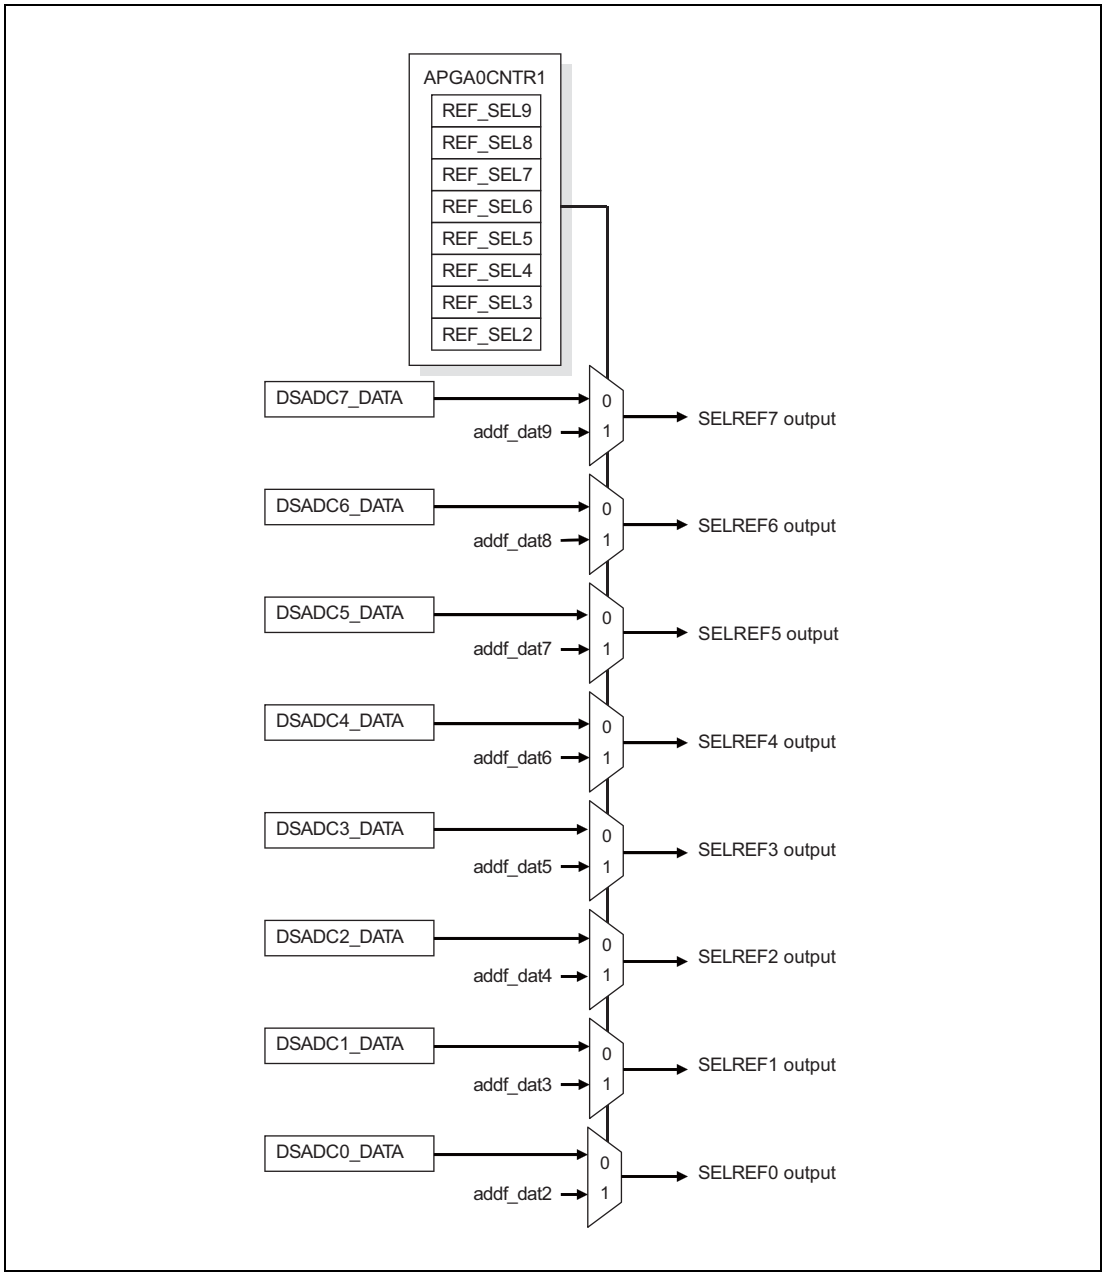

Figure 22.59 Block Diagram of SAR-AD and DA-AD Selector

(3) Conversion of AD Reference Format

Figure 22.60 shows a block diagram of the APA reference format conversion function.

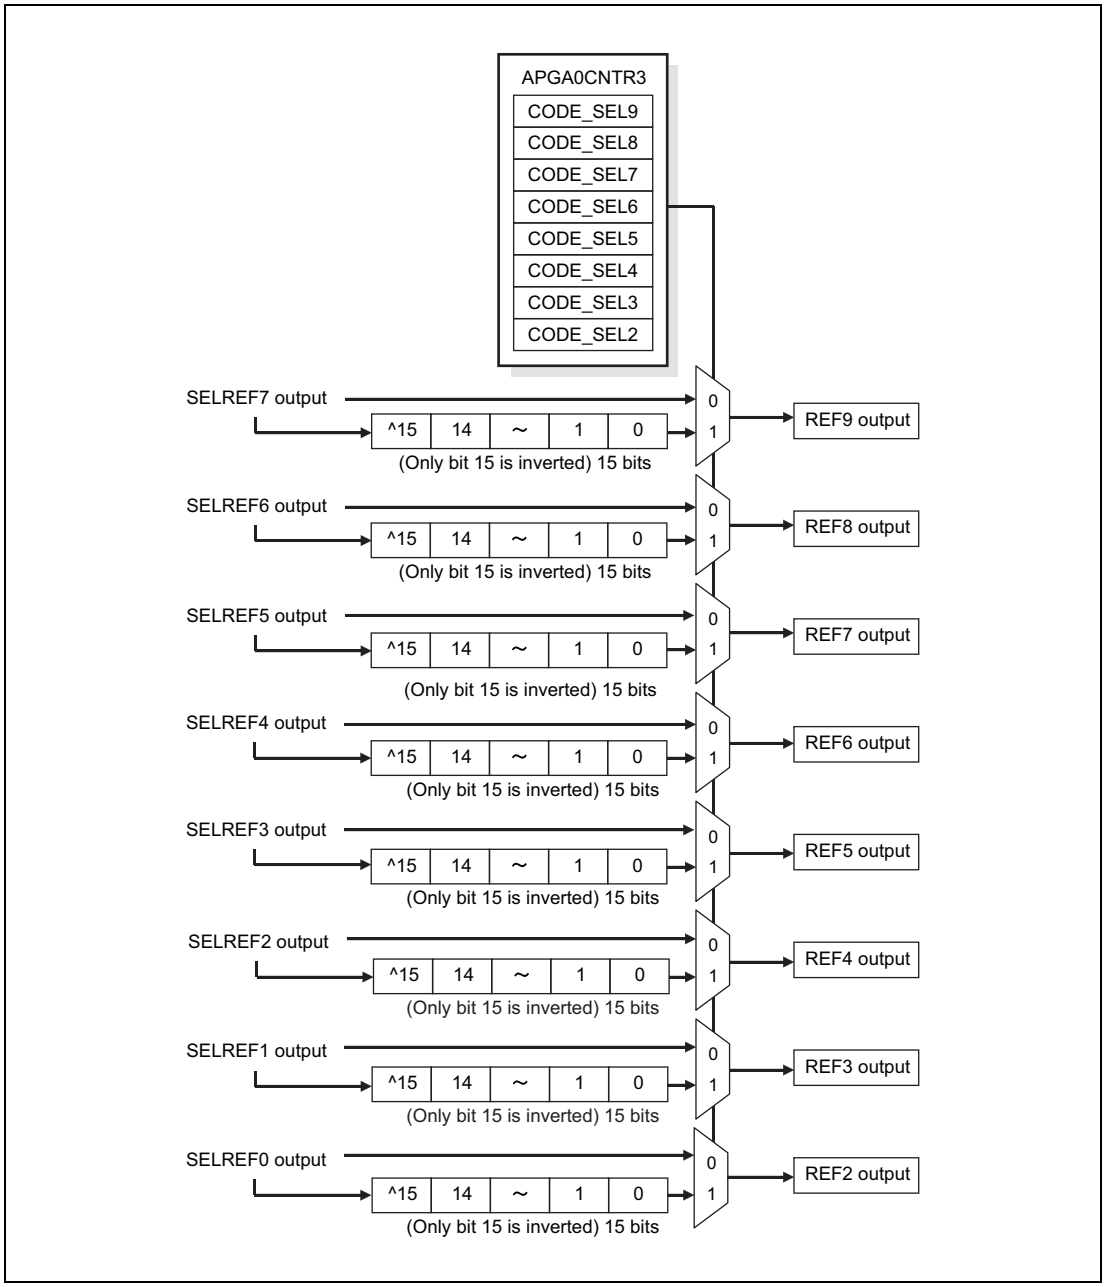

Figure 22.60 Block Diagram of APA Reference Format Conversion Function

Section 23 Motor Control Timer (TSG2)

23.1 Functions of TSG2n

- Channels
  This microcontroller provides two channels of TSG2n (n = 0, 1).

Table 23.1 TSG2 Channels

	TSG2
Number of Channels	2
Name	TSG20, TSG21

Meaning of n

Throughout this section, the TSG2 channels are identified by the index n (n = 0 or 1): for example, TSG2n control register 0 (TSG2nCTL0).

- Register addresses
  TSG2n register addresses are given as offsets from the individual base addresses <TSG2n_base>. **Table 23.2** shows the base addresses of TSG2n.

Table 23.2 TSG2n Register Base Address

TSG2n	<TSG2n_base> Address
TSG20	FFE7 0000_H
TSG21	FFE7 1000_H

- Interrupt requests
  The TSG2n interrupt requests are listed in **Table 23.3**.

Table 23.3 List of TSG2n Interrupt Requests

TSG2n Interrupt Request	Function	Connected to
INTTSG2nI[12:0]	TSG2n compare match interrupt 0 to 12	Interrupt controller (INTC)
INTTSG2nIPEK	TSG2n peak interrupt	Interrupt controller (INTC)
INTTSG2nIVLY	TSG2n trough interrupt	Interrupt controller (INTC)
INTTSG2nIER	TSG2n error interrupt	Interrupt controller (INTC) PIC1
INTTSG2nIWN	TSG2n warning interrupt	Interrupt controller (INTC)

- DMA transfer requests
  The Table below shows TSG2n DMA transfer requests.

Table 23.4 List of TSG2n DMA Transfer Requests

TSG2n Interrupt Request	Function	Connected to
INTTSG2nI[12:11]	TSG2n compare match interrupt 11 to 12	DMA controller (DTS)
INTTSG2nIPEK	TSG2n peak interrupt	DMA controller (DTS)
INTTSG2nIVLY	TSG2n trough interrupt	DMA controller (DTS)

23.2 Functional Overview

The TSG2n is a 16-bit timer counter with various motor control functions.

- Count clock resolution: Minimum 12.5 ns (count clock = 80 MHz)
- Operating mode corresponding to various motor control methods
- Compare registers with reload buffer
- 10-bit dead time counter
  - Dead time counter with reload buffer
  - Independent dead time can be set for positive to inverse phase change and inverse to positive phase change.
- A/D conversion trigger signal generation
  - Three A/D conversion trigger signals can be generated by the compare registers TSG2nDCMP0W and TSG2nDCMP2.
  - Skipping function of A/D conversion trigger signals TSTADT0 and TSTADT1 can be set independently. The skipping ratio can be selected among 1/1, 1/2, 1/4, and 1/8.
  - The dedicated pin (TSOn7) can be used to output the toggle or diagnostic signal set by the TSTADT0 signal and reset by the TSTADT1 signal.
- Interrupt skipping
  - Skipping rate: 1/1 to 1/32
- Forced output stop function
  - Using the TOP function allows the high impedance control of the TSOn1 to TSOn6 pin output.
- Compare value setting
  - Reload (simultaneous rewrite) or anytime rewrite can be selected.
- Reload mode
  - Writing to TSG2nCMP1 enables reload (the reload request flag (TSG2nRSF) is set), and allows simultaneous transfer of the values of multiple registers.
  - Data can be transferred at peak/trough/peak or trough reload timing
  - Reload request flag (TSG2nRSF)
  - Register address assignment allowing DMA transfer
  - Reload skipping
- HT-PWM mode
  - 0 to 100% PWM duty cycle output is possible (with possible dead time reduction).
  - The LSB in the compare register can be used to append an additional pulse to the PWM output during count up, thus improving the output resolution without extra load on software.
- 120-DC control
  - A trigger signal can be generated by an offset in conjunction with the semi-automatic drive function.
- Three-phase encoder function (hall sensor signals can be input).

- Active level of the output pins (TSOn1 to TSOn6) can be set individually.
- Fail-safe function (warning interrupt or error interrupt can be generated)
  - Simultaneous active output detection function for positive and inverse phases.
  - Abnormal input detection function of the three-phase encoder

23.3 Configuration

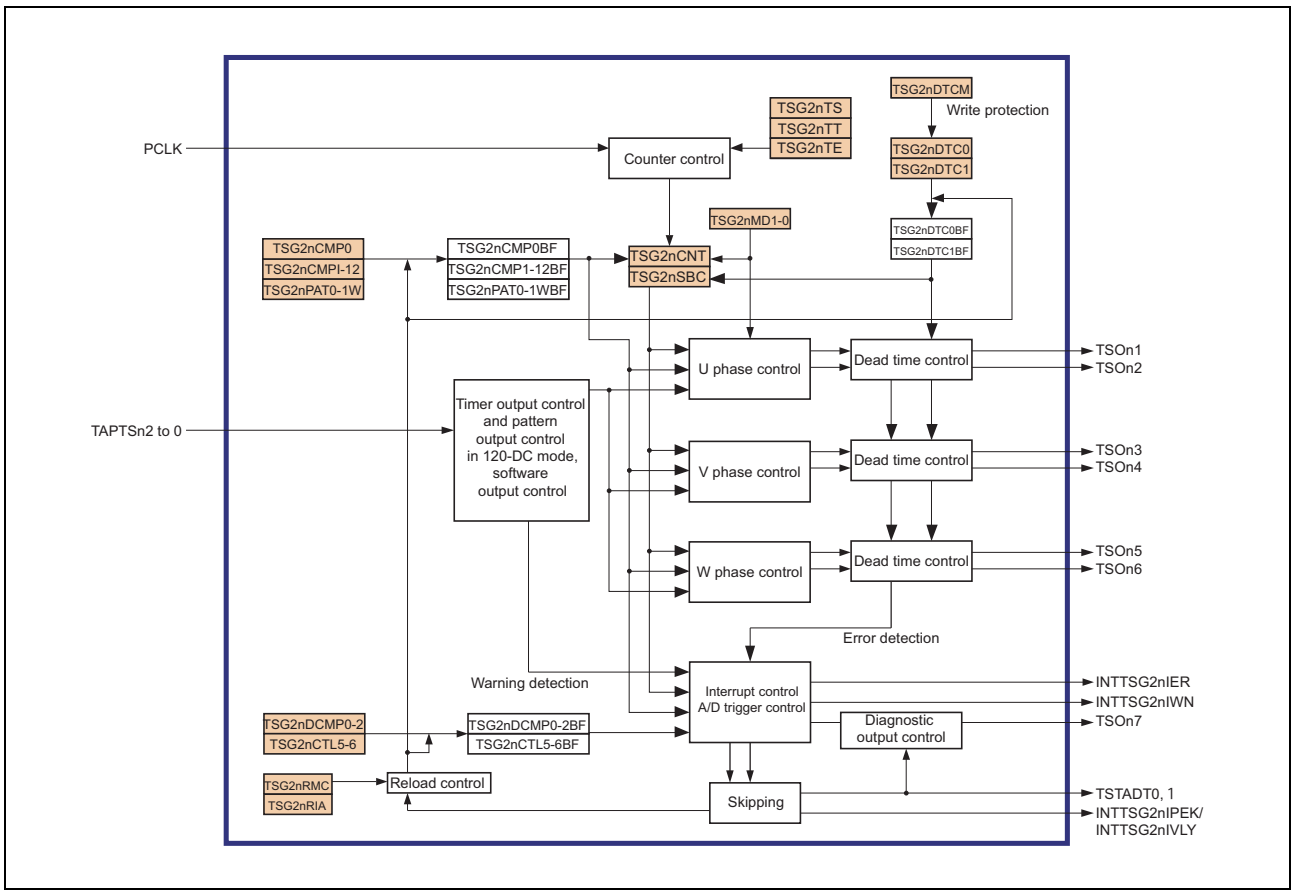

Figure 23.1 Block Diagram of TSG2n

23.4 Registers

This section contains a description of all registers of the TSG2n (n = 0, 1).

23.4.1 List of Registers

The TSG2n (n = 0, 1) registers and addresses are shown in **Table 23.5**.

The base address of TSG20 is FFE7 0000_H and TSG21 is FFE7 1000_H respectively.

For the actual addresses, the offset values shown in the table below are added to the base addresses.

Table 23.5 TSG2n (n = 0, 1) Registers (1/2)

Register Name	Function	R/W	Reset value	Access			Offset address	Dynamic	Reload
				8	16	32			
TSG2nIOC2	TSG2n I/O control register 2	R/W	0000_H	×	√	×	000_H	Enable	Disable

TSG2nVPW	TSG2n V phase period register	R/W	0000_H	×	√	×	$0C0_H$	Enable	Enable
TSG2nWPW	TSG2n W phase period register	R/W	0000_H	×	√	×	$0C4_H$	Enable	Enable
TSG2nIOC0	TSG2n I/O control register 0	R/W	$7E_H$	√	×	×	200_H	Disable	Disable
TSG2nIOC1	TSG2n I/O control register 1	R/W	00_H	√	×	×	204_H	Disable	Disable
TSG2nCTL0	TSG2n control register 0	R/W	00_H	√	×	×	208_H	Disable	Disable
TSG2nCTL1	TSG2n control register 1	R/W	0000_H	×	√	×	$20C_H$	Disable	Disable
TSG2nDTPR	TSG2n dead time protection register	R/W	0000_H	×	√	×	210_H	Disable	Disable

- Dynamic: “Enable” means that registers can be read during TSG2 operation. “Disable” means that the contents of registers cannot be changed during TSG2 operation.
- Reload: “Reload” means that the register is provided with the reload function.

23.4.2 TSG2n Register Details

23.4.2.1 TSG2nCTL0 — TSG2n Control Register 0

This register specifies the pulse width for TSOn7 and operating mode of the TSG2n.

This register can be written only when TSG2nTE = 0 (while macros are stopped).

Access: This register can be read/written in 8-bit units.

Address: TSG20: FFE7 0208_H
TSG21: FFE7 1208_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	TSG2n DWD	—	—	TSG2nMD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R	R/W	R/W

Table 23.6 TSG2nCTL0 Register Contents

Bit Position	Bit Name	Functions
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	TSG2nDWD	TSOn7 Pulse Width Control 0: The TSOn7 pulse width is 8 clock cycles. 1: The TSOn7 pulse width is 16 clock cycles. This bit controls the pulse width of TSOn7 and is valid when TSG2nTGS = 1. (See the description of TSG2nTGS) For the detailed functions, refer to **Section 23.5.4.1 (1), TSOn7 Pin Output Control**.
3, 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TSG2nMD[1:0]	TSG2n Mode Control 00: PWM mode 01: High-accuracy triangle-wave PWM mode 10: Shift pulse PWM mode 11: 120-degree energization control mode These bits are mode control bits of TSG2n. TSG2n has four modes. PWM mode controls six PWM timer outputs. Each timer output is controlled by the two compare registers (set and clear). High-accuracy triangle-wave PWM mode (HT-PWN mode) controls three complementary PWM outputs by using up-count and down-count (triangle-wave count). Shift pulse PWM mode (SP-PWM mode) controls three complementary PWM outputs by using up-count (saw-wave count). 120-degree energization control mode (120-DC mode) controls six PWM outputs by using twelve compare registers, two pattern registers, and six output steps.

23.4.2.2 TSG2nCTL1 — TSG2n Control Register 1

This register controls the error/warning detection and can be written only when TSG2nTE = 0 (while macros are stopped).

Refer to the description of TSG2nSTR2 register and **Section 23.10, Error and Warning Interrupts**.

Access: This register can be read/written in 16-bit units.

Address: TSG20: FFE7 020C$_H$
TSG21: FFE7 120C$_H$

Value after reset: 0000$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 23.7 TSG2nCTL1 Register Contents

Bit Position	Bit Name	Functions
15 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	TSG2nTBA2	TSG2nTBF2 Control 0: Disables TSG2nTBF2 1: Enables TSG2nTBF2
8	TSG2nTBA1	TSG2nTBF1 Control 0: Disables TSG2nTBF1 1: Enables TSG2nTBF1
7	TSG2nTBA0	TSG2nTBF0 Control 0: Disables TSG2nTBF0 1: Enables TSG2nTBF0
6	TSG2nPPC	TSG2nPPF Control 0: Disables TSG2nPPF 1: Enables TSG2nPPF
5	TSG2nPEC	TSG2nPEF Control 0: Disables TSG2nPEF 1: Enables TSG2nPEF
4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3	TSG2nNDC	TSG2nNDF Control 0: Disables TSG2nNDF 1: Enables TSG2nNDF
2	TSG2nPRC	TSG2nPRF Control 0: Disables TSG2nPRF 1: Enables TSG2nPRF
1, 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

23.4.2.3 TSG2nCTL3 — TSG2n Control Register 3

This register controls TSG2n reload /IMWRITE function.

Access: This register can be read/written in 8-bit units.

Address: TSG20: FFE7 0004_H
TSG21: FFE7 1004_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG2n RIA	TSG2n RMC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 23.8 TSG2nCTL3 Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	TSG2nRIA	Reload and INTTSG2nIPEK/INTTSG2nIVLY Adjustment 0: The reload timing is controlled only by TSG2nPRE or TSG2nVRE. 1: The reload timing is adjusted by INTTSG2nIPEK or INTTSG2nIVLY output timing. TSG2nRIA controls reload timing and is valid when TSG2nRMC = 0.
0	TSG2nRMC	Register Mode Control 0: Update the value of registers with reload function when reloading 1: Update the value of registers when written. This function is called “Reload” when TSG2nRMC = 0 and “IMWRITE” (immediate write) when TSG2nRMC = 1

23.4.2.4 TSG2nCTL4 — TSG2n Control Register 4

This register controls INTTSG2nIPEK/INTTSG2nIVLY interrupt function.

Access: This register can be read/written in 32-bit units.

Address: TSG20: FFE7 007C$_H$
TSG21: FFE7 107C$_H$

Table 23.9 TSG2nCTL4 Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is read. When writing, write the value after reset.
8	TSG2nPRE	Reloading by INTTSG2nIPEK Timing Enable Bit 0: Disables reload operation at the peak timing (in HT-PWM mode) Disables reload operation at the PWM cycle timing (in any mode other than HT-PWM mode) 1: Enables reload operation at the peak timing (in HT-PWM mode) Enables reload operation at the PWM cycle timing (in any mode other than HT-PWM mode) When setting TSG2nRMC to 0 in any mode other than HT-PWM mode, reloading does not proceed. Accordingly, when recovery from the abnormal state is required, the setting for IMWRITE function needs to be changed.
7	TSG2nVRE	Reloading by INTTSG2nIVLY Timing Enable Bit 0: Disables reload operation at the trough timing 1: Enables reload operation at the trough timing This bit is only valid in HT-PWM mode.
6	TSG2nPIE	INTTSG2nIPEK Interrupt Enable 0: Masks INTTSG2nIPEK output 1: Does not mask INTTSG2nIPEK output
5	TSG2nVIE	INTTSG2nIVLY Interrupt Enable 0: Masks INTTSG2nIVLY output 1: Does not mask INTTSG2nIVLY output This bit is only valid in HT-PWM mode.
4 to 0	TSG2nRCC [04:00]	Reload Skipping Control 00000: No reload/interrupt skipping 00001: 1 skipping/1 generation out of 2 reloads/interrupts 00010: 2 skippings/1 generation out of 3 reloads/interrupts 00011: 3 skippings/1 generation out of 4 reloads/interrupts | 11110: 30 skippings/1 generation out of 31 reloads/interrupts 11111: 31 skippings/1 generation out of 32 reloads/interrupts

23.4.2.5 TSG2nCTL5 — TSG2n Control Register 5

This register controls A/D conversion trigger (TSTADT0) function.

See **Section 23.9, A/D Conversion Trigger Function**.

Access: This register can be read/written in 16-bit units.

Address: TSG20: FFE7 0008_H
TSG21: FFE7 1008_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 23.10 TSG2nCTL5 Register Contents (1/2)

Bit Position	Bit Name	Function
15 to 12	Reserved	When read, the value after reset is read. When writing, write the value after reset.
11, 10	TSG2nACC [01:00]	TSTADT0 Skipping Control 00: No TSTADT0 skipping 01: 1 skipping/1 trigger output out of 2 A/D source triggers 10: 3 skipping/1 trigger output out of 4 A/D source triggers 11: 7 skipping/1 trigger output out of 8 A/D source triggers When a write access is made, the TSTADT0 skipping counter is simultaneously cleared.
9	TSG2nAT09	TSTADT0 Trigger Control 9 0: Not selected 1: Selects TSG2nSBC peak timing as A/D source trigger. This bit is only valid in HT-PWM mode.
8	TSG2nAT08	TSTADT0 Trigger Control 8 0: Not selected 1: Selects TSG2nSBC trough timing as A/D source trigger. This bit is only valid in HT-PWM mode.
7	TSG2nAT07	TSTADT0 Trigger Control 7 0: Not selected 1: Selects the matching points of TSG2nDCMP2 and TSG2nCNT as A/D source triggers for down-counting by TSG2nCNT. This bit is only valid in HT-PWM mode. In other modes, TSG2nCNT does not count down.
6	TSG2nAT06	TSTADT0 Trigger Control 6 0: Not selected 1: Selects the matching points of TSG2nDCMP2 and TSG2nCNT as A/D source triggers for up-counting by TSG2nCNT.
5	TSG2nAT05	TSTADT0 Trigger Control 5 0: Not selected 1: Selects the matching points of TSG2nDCMP1 and TSG2nCNT as A/D source triggers for down-counting by TSG2nCNT. This bit is only valid in HT-PWM mode. In other modes, TSG2nCNT does not count down.
4	TSG2nAT04	TSTADT0 Trigger Control 4 0: Not selected 1: Selects the matching points of TSG2nDCMP1 and TSG2nCNT as A/D source triggers for up-counting by TSG2nCNT.

Table 23.10 TSG2nCTL5 Register Contents (2/2)

Bit Position	Bit Name	Function
3	TSG2nAT03	TSTADT0 Trigger Control 3 0: Not selected 1: Selects the matching points of TSG2nDCMP0 and TSG2nCNT as A/D source triggers for down-counting by TSG2nCNT. This bit is only valid in HT-PWM mode. In other modes, TSG2nCNT does not count down.
2	TSG2nAT02	TSTADT0 Trigger Control 2 0: Not selected 1: Selects the matching points of TSG2nDCMP0 and TSG2nCNT as A/D source triggers for up-counting by TSG2nCNT.
1	TSG2nAT01	TSTADT0 Trigger Control 1 0: Not selected 1: Selects INTTSG2nIPEK (*) as A/D source trigger. (*) INTTSG2nIPEK is a signal for skipping by TSG2nRCC04 to TSG2nRCC00 bits.
0	TSG2nAT00	TSTADT0 Trigger Control 0 0: Not selected 1: Selects INTTSG2nIVLY (*) as A/D source trigger. This bit is only valid in HT-PWM mode. (*) INTTSG2nIVLY is a signal for skipping by TSG2nRCC04 to TSG2nRCC00 bits

23.4.2.6 TSG2nCTL6 — TSG2n Control Register 6

This register controls A/D conversion trigger (TSTADT1) function.

See **Section 23.9, A/D Conversion Trigger Function**.

Access: This register can be read/written in 16-bit units.

Address: TSG20: FFE7 000C$_H$
TSG21: FFE7 100C$_H$

Value after reset: 0000$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 23.11 TSG2nCTL6 Register Contents (1/2)

Bit Position	Bit Name	Function
15 to 12	Reserved	When read, the value after reset is read. When writing, write the value after reset.
11, 10	TSG2nACC [11:10]	TSTADT1 Skipping Control 00: No TSTADT1 skipping 01: 1 skipping/1 trigger output out of 2 A/D source triggers 10: 3 skipping/1 trigger output out of 4 A/D source triggers 11: 7 skipping/1 trigger output out of 8 A/D source triggers When a write access is made, the TSTADT1 skipping counter is simultaneously cleared.
9	TSG2nAT19	TSTADT1 Trigger Control 9 0:Not selected 1:Selects TSG2nSBC peak timing as A/D source trigger. This bit is only valid in HT-PWM mode.
8	TSG2nAT18	TSTADT1 Trigger Control 8 0: Not selected 1: Selects TSG2nSBC trough timing as A/D source trigger. This bit is only valid in HT-PWM mode.
7	TSG2nAT17	TSTADT1 Trigger Control 7 0: Not selected 1: Selects the matching points of TSG2nDCMP2 and TSG2nCNT as A/D source triggers for down-counting by TSG2nCNT. This bit is only valid in HT-PWM mode. In other modes, TSG2nCNT does not count down.
6	TSG2nAT16	TSTADT1 Trigger Control 6 0: Not selected 1: Selects the matching points of TSG2nDCMP2 and TSG2nCNT as A/D source triggers for up-counting by TSG2nCNT.
5	TSG2nAT15	TSTADT1 Trigger Control 5 0: Not selected 1: Selects the matching points of TSG2nDCMP1 and TSG2nCNT as A/D source triggers for down-counting by TSG2nCNT. This bit is only valid in HT-PWM mode. In other modes, TSG2nCNT does not count down.
4	TSG2nAT14	TSTADT1 Trigger Control 4 0: Not selected 1: Selects the matching points of TSG2nDCMP1 and TSG2nCNT as A/D source triggers for up-counting by TSG2nCNT.

Table 23.11 TSG2nCTL6 Register Contents (2/2)

Bit Position	Bit Name	Function
3	TSG2nAT13	TSTADT1 Trigger Control 3 0: Not selected 1: Selects the matching points of TSG2nDCMP0 and TSG2nCNT as A/D source triggers for down-counting by TSG2nCNT. This bit is only valid in HT-PWM mode. In other modes, TSG2nCNT does not count down.
2	TSG2nAT12	TSTADT1 Trigger Control 2 0: Not selected 1: Selects the matching points of TSG2nDCMP0 and TSG2nCNT as A/D source triggers for up-counting by TSG2nCNT.
1	TSG2nAT11	TSTADT1 Trigger Control 1 0: Selects INTTSG2nIPEK (*) as A/D source trigger. 1: Selects the matching points of TSG2nDCMP2 and TSG2nCNT as A/D source triggers for up-counting by TSG2nCNT. (*) INTTSG2nIPEK is a signal for skipping by TSG2nRCC04 to TSG2nRCC00 bits.
0	TSG2nAT10	TSTADT1 Trigger Control 0 0: Not selected 1: Selects INTTSG2nIVLY (*) as A/D source trigger. This bit is only valid in HT-PWM mode. (*) INTTSG2nIVLY is a signal for skipping by TSG2nRCC04 to TSG2nRCC00 bits

23.4.2.7 TSG2nIOC0 — TSG2n I/O Control Register 0

This register controls the timer output (TSOn1 to TSOn6) function and can be written only when TSG2nTE = 0 (while macros are stopped).

See **Section 23.5.4, List of Outputs in Each Mode**.

Access: This register can be read/written in 8-bit units.

Address: TSG20: FFE7 0200_H
TSG21: FFE7 1200_H

Value after reset: $7E_H$

Bit	7	6	5	4	3	2	1	0

Table 23.12 TSG2nIOC0 Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 1	TSG2nTOEm	0: The TSG2nIOC2 register (TSG2nTOm/TSG2nTOLm bits) can be rewritten by software. 1: The TSG2nIOC2 register (TSG2nTOm/TSG2nTOLm bits) cannot be rewritten by software. (Write access to the TSG2nIOC2 register is ignored.) This register controls write access to TSG2nIOC2 (m = 1, 2, 3, 4, 5, 6).
0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

23.4.2.8 TSG2nIOC1 — TSG2n I/O Control Register 1

This register controls various I/O port functions.

This register can be written only when TSG2nTE = 0 (while macros are stopped).

Access: This register can be read/written in 8-bit units.

Address: TSG20: FFE7 0204_H
TSG21: FFE7 1204_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0

Table 23.13 TSG2nIOC1 Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3	TSG2nEOC	INTTSG2nIER Output Control 0: Fixes the INTTSG2nIER signal to 0. 1: Enables output of the INTTSG2nIER signal.
2	TSG2nWOC	INTTSG2nIWN Output Control 0: Fixes the INTTSG2nIWN signal to 0. 1: Enables to output INTTSG2nIWN signal.
1	TSG2nTGS	TSOn7 Function Selection 0: A/D trigger output mode 1: Diagnostic output mode See **Section 23.5.4.1,(1) TSOn7 Pin Output Control**.
0	TSG2nTOS	TSOn0 Output Status Selection 0: Outputs the TSG2nCNT up/down status (same as TSG2nCUF). 1: Outputs the TSG2nSBC up/down status (same as TSG2nSUF).

23.4.2.9 TSG2nIOC2 — TSG2n I/O Control Register 2

This register controls the timer output (TSOn1 to TSOn6) functions.

See **Section 23.5.4, List of Outputs in Each Mode**.

Access: This register can be read/written in 16-bit units.

Address: TSG20: FFE7 0000_H
TSG21: FFE7 1000_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	TSG2nOL6	TSG2nOL5	TSG2nOL4	TSG2nOL3	TSG2nOL2	TSG2nOL1	—	—	TSG2nTO6	TSG2nTO5	TSG2nTO4	TSG2nTO3	TSG2nTO2	TSG2nTO1	—

Table 23.14 TSG2nIOC2 Register Contents

Bit Position	Bit Name	Function
15	Reserved	When read, the value after reset is read. When writing, write the value after reset.
14 to 9	TSG2nOLm	TSOnm Active Level Control 0: The active level of TSOnm is high. 1: The active level of TSOnm is low. These bits control the active level of TSOnm and thereby the level selector is placed closest to the TSOnm pin. They can be changed when TSG2nTOEn = 0. In this document, TSOnm is described as TSG2nOLm = 0 (m = 1, 2, 3, 4, 5, 6).
8, 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 1	TSG2nTOm	TSOnm Output Buffer Latch 0: TSOnm is at the low level. 1: TSOnm is at the high level. These bits are TSOnm output buffer latches. They can be changed when TSG2nTOEm = 0 (m = 1, 2, 3, 4, 5, 6).
0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

23.4.2.10 TSG2nIOC3 — TSG2n I/O Control Register 3

This register controls timer output (TSOn1 to TSOn6) function.

See **Section 23.5.4, List of Outputs in Each Mode**.

Access: This register can be read/written in 32-bit units.

Address: TSG20: FFE7 0074_H
TSG21: FFE7 1074_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 23.15 TSG2nIOC3 Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 1	TSG2nTOLm	TSOnm 0: Normal set/clear level 1: Reversed set/clear level These bits control the setting and clearing levels of the timer output. A change to an output level is reflected at the time of the next compare match. TSG2nTOLm should not be set to 1 in HT-PWM mode. In this document, TSOnm is described as TSG2nOLm = 0 (m = 1, 2, 3, 4, 5, 6)
0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

23.4.2.11 TSG2nSTR0 — TSG2n Status Register 0

This register indicates TSG2 up-/down-count, reload request, and macro enable statuses.

Access: This register can be read in 8-bit units.

Address: TSG20: FFE7 0010_H
TSG21: FFE7 1010_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TSG2nCUF	TSG2nSUF	TSG2nRSF	TSG2nTE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 23.16 TSG2nSTR0 Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3	TSG2nCUF	TSG2nCNT UP-/Down-Count Status Flag 0: TSG2nCNT is being incremented. 1: TSG2nCNT is being decremented.
2	TSG2nSUF	TSG2nSBC Up-/Down-Count Status Flag 0: TSG2nSBC is being incremented. 1: TSG2nSBC is being decremented. This bit is only valid in HT-PWM mode. (In other mode, it is fixed to 0.)
1	TSG2nRSF	Reload Holding Status Flag 0: No reload request, or reloading is complete. 1: A reload request is generated and waiting for the reload timing. See **Section 23.7.3, Reload Request Flag (TSG2nRSF)**.
0	TSG2nTE	Timer Enable Status Flag 0: The timer is stopped. (Macros are stopped.) 1: The timer is operating.

23.4.2.12 TSG2nSTR1 — TSG2n Status Register 1

This register indicates the direction, reload request and macro enable statuses of TAPTSn2-0.

Access: This register can be read in 8-bit units.

Address: TSG20: FFE7 0014_H
TSG21: FFE7 1014_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TSG2n TSF	TSG2nOPF[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 23.17 TSG2nSTR1 Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3	TSG2nTSF	TAPTSn2-0 Pattern Order Detection Flag 0: Indicates that the rotation order of TAPTSn2-0 is clockwise. 1: Indicates that the rotation order of TAPTSn2-0 is counter-clockwise. See **Section 23.7.5, Pattern Order Detection Flag (TSG2nTSF)** and **Section 23.7.7, Pattern Inversion Detection Flag (TSG2nPRF)**.
2 to 0	TSG2nOPF[2:0]	Timer Output Pattern Flag 000-111: Indicates the timer output pattern status.

23.4.2.13 TSG2nSTR2 — TSG2n Status Register 2

This register indicates the error/warning status.

Access: This register can be read in 16-bit units.

Address: TSG20: FFE7 0018_H
TSG21: FFE7 1018_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG2n TBF2	TSG2n TBF1	TSG2n TBF0	TSG2n PPF	TSG2n PEF	—	TSG2n NDF	TSG2n PRF	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.18 TSG2nSTR2 Register Contents (1/2)

Bit Position	Bit Name	Function
15 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	TSG2nTBF2	Positive/Negative Phase Simultaneous Activation Detection Flag 2 0: No error 1: TSOn5 and TSOn6 are active simultaneously or the setting of the compare register may be incorrect For how to clear this error flag, see the description of the TSG2nTBF0 bit.
8	TSG2nTBF1	Positive/Negative Phase Simultaneous Activation Detection Flag 1 0: No error 1: TSOn3 and TSOn4 are active simultaneously or the setting of the compare register may be incorrect. For how to clear this error flag, see the description of the TSG2nTBF0 bit.
7	TSG2nTBF0	Positive/Negative Phase Simultaneous Activation Detection Flag 0 0: No error 1: TSOn1 and TSOn2 are active simultaneously or the setting of the compare register may be incorrect. This error flag can be cleared in the following two ways. • Write 1 to the TSG2nTBR2-0 bits. • Change TSG2nTE from 0 to 1. See **Section 23.4.2.14, TSG2nSTC — TSG2n Status Clear Trigger Registers**.
6	TSG2nPPF	Input/Output Pattern Phase Difference Detection Flag 0: No error 1: A phase difference detected between the input patterns (TAPTSn2-0) and the output patterns (TSG2nOPF2-0) This warning flag can be cleared in the following two ways. • Write 1 to the TSG2nPPR bit. • Write 1 to TSG2nTS or TSTSST input (timer start or timer restart). See **Section 23.7.8, Pattern Phase Difference Detection Flag (TSG2nPPF)**.
5	TSG2nPEF	Input Pattern (TAPTSn2-0) Error Detection Flag 0: No error 1: Detects that TAPTSn2-0 are all high or low. This warning flag can be cleared in the following two ways. • Write 1 to TSG2nPER bit. • Write 1 to TSG2nTS or TSTSST input (timer start or timer restart). See **Section 23.7.6, Pattern Error Detection Flag (TSG2nPEF)**.
4	Reserved	When read, the value after reset is read. When writing, write the value after reset.

Table 23.18 TSG2nSTR2 Register Contents (2/2)

Bit Position	Bit Name	Function
3	TSG2nNDF	Input Pattern (TAPTSn2-0) Noise Detection Flag 0: No error 1: Detects non-gray code operation of TAPTSn2-0 (the level of TAPTSn2-0 on two or more pins changes simultaneously). This warning flag can be cleared in the following two ways. • Write 1 to the TSG2nNDR bit. • Write 1 to TSG2nTS or TSTSST input (timer start or timer restart). See **Section 23.7.4, Noise Detection Flag (TSG2nNDF)**.
2	TSG2nPRF	Input Pattern (TAPTSn2) Inversion Detection Flag 0: No error 1: Detects inversion of TAPTSn2-0 (detects the change of motor rotation.) This warning flag can be cleared in the following two ways. • Write 1 to the TSG2nPRR bit. • Write 1 to TSG2nTS or TSTSST input (timer start or timer restart). See **Section 23.7.5, Pattern Order Detection Flag (TSG2nTSF)**.
1, 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

23.4.2.14 TSG2nSTC — TSG2n Status Clear Trigger Registers

This register is a trigger register for clearing TSG2nSTR2.

When this register is read, it is always read as "0000_H".

Access: This register can be written in 16-bit units.

Address: TSG20: FFE7 001C$_H$
TSG21: FFE7 101C$_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSG2nTBR2	TSG2nTBR1	TSG2nTBR0	TSG2nPPR	TSG2nPER	—	TSG2nNDR	TSG2nPRR	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	W	W	W	W	W	R	W	W	R	R

Table 23.19 TSG2nSTC Register Contents (1/2)

Bit Position	Bit Name	Function
15 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	TSG2nTBR2	TSG2nTBF2 Clear Trigger 0 write: Invalid 1 write: Clears TSG2nTBF2 to 0. If TSG2nTBF2 is set and 1 is written to TSG2nTBR2 at the same time, the TSG2nTBF2 setting is given priority.
8	TSG2nTBR1	TSG2nTBF1 Clear Trigger 0 write: Invalid 1 write: Clears TSG2nTBF1 to 0. If TSG2nTBF1 is set and 1 is written to TSG2nTBR1 at the same time, the TSG2nTBF1 setting is given priority.
7	TSG2nTBR0	TSG2nTBF0 Clear Trigger 0 write: Invalid 1 write: Clears TSG2nTBF0 to 0. If TSG2nTBF0 is set and 1 is written to TSG2nTBR0 at the same time, the TSG2nTBF0 setting is given priority.
6	TSG2nPPR	TSG2nPPF Clear Trigger 0 write: Invalid 1 write: Clears TSG2nPPF to 0 If TSG2nPPF is set and 1 is written to TSG2nPPR at the same time, the TSG2nPPF setting is given priority.
5	TSG2nPER	TSG2nPEF Clear Trigger 0 write: Invalid 1 write: Clears TSG2nPEF to 0 If TSG2nPEF is set and 1 is written to TSG2nPER at the same time, the TSG2nPEF setting is given priority.
4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3	TSG2nNDR	TSG2nNDF Clear Trigger 0 write: Invalid 1 write: Clears TSG2nNDF to 0 If TSG2nNDF is set and 1 is written to TSG2nNDR at the same time, the TSG2nNDF setting is given priority.
2	TSG2nPRR	TSG2nPRF Clear Trigger 0 write: Invalid 1 write: Clears TSG2nPRF to 0 If TSG2nPRF is set and 1 is written to TSG2nPRR at the same time, the TSG2nPRF setting is given priority.

Table 23.19 TSG2nSTC Register Contents (2/2)

Bit Position	Bit Name	Function
1, 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

23.4.2.15 TSG2nOPT0 — TSG2n Option Register 0

This register configures the option function.

Access: This register can be read/written in 8-bit units.

Address: TSG20: FFE7 0020_H
TSG21: FFE7 1020_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	TSG2n SOC	TSG2n STE	—	TSG2n PSS	TSG2n IDC	TSG2n PSC	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R	R/W	R/W	R/W	R

Table 23.20 TSG2nOPT0 Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	TSG2nSOC	Enables or disables control of the timer output (TSOn1 to TSOn6 pins) by software. 0 : Disables control by software. 1 : Enables control by software. • When TSG2nSOC is set to 1, timer output is switched to the software control/trigger control output pattern specified by TSG2nSPC2 to TSG2nSPC0. The dead time is secured by the dead time counter.
5	TSG2nSTE	Enables or disables control by the pattern output trigger. 0: Disables TAPTSn0 to TAPTSn2 inputs. 1: Enables TAPTSn0 to TAPTSn2 inputs. • TSG2nSTE is valid in 120-DC mode and while software output control function is enabled.
4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3	TSG2nPSS	Selects the pattern output order switch factor. 0: Switching of the pattern output order by TSG2nPSC is not used. 1: Switching of the pattern output order by TSG2nPSC is used.
2	TSG2nIDC	Determines the output pattern from the TSOn1 to TSOn6 pins in combination with the TSG2nIDC, TSG2nSTR1.TSG2nTSF and TSG2nPSC signals. For the timer output order and patterns to be output, see **Figure 23.74** to **Figure 23.77**, Example of Operation in 120-DC Mode, in **Section 23.11.4.5, Operation in 120-DC Mode**.
1	TSG2nPSC	Selects the pattern output order when the semi-automatic cruise function is enabled. 0: Switches the timer output (TSOn1 to TSOn6) in the normal rotation. 1: Switches the timer output (TSOn1 to TSOn6) in the reverse rotation. • If the signal input to TAPTSn0 to TAPTSn2 changes with TSG2n operation being stopped (TSG2nSTR0.TSG2nTE = 0), the TSG2nTRG0.TSG2nTS bit should be set to 1 after matching the input signal change logic with the TSG2nPSC order. • For output order in normal or reverse rotation, see **Section 23.11.4, 120-DC Mode**. Here, normal rotation and reverse rotation refer to the change of output, and they are different from normal rotation and reverse rotation of a motor.
0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

23.4.2.16 TSG2nOPT1 — TSG2n Option Register 1

This register configures the option function.

Access: This register can be read/written in 8-bit units.

Address: TSG20: FFE7 0024_H
TSG21: FFE7 1024_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	TSG2nSPC[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 23.21 TSG2nOPT1 Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2 to 0	TSG2nSPC[2:0]	These bits specify the timer output pattern while software output function is enabled and in 120-DC mode. For the output pattern, see **Section 23.11.5, Software Output Control Function**, and **Section 23.11.4, 120-DC Mode**.

23.4.2.17 TSG2nTRG0 — TSG2n Trigger Register 0

This register is a trigger register for starting the timer.

When this register is read, it is always read as "00_H".

Access: This register can be written in 8-bit units.

Address: TSG20: FFE7 0030_H
TSG21: FFE7 1030_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TSG2nTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 23.22 TSG2nTRG0 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TSG2nTS	Timer Start Trigger 0: Invalid 1: Triggers the start of timer software (setting TSG2nTE = 1) Also, this bit triggers the restart of timer software.

23.4.2.18 TSG2nTRG1 — TSG2n Trigger Register 1

This register controls the stop of the timer.

When this register is read, it is always read as "00_H".

Access: This register can be written in 8-bit units.

Address: TSG20: FFE7 0034_H
TSG21: FFE7 1034_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TSG2nTT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 23.23 TSG2nTRG1 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TSG2nTT	Timer Stop Trigger 0: Invalid 1: Triggers stopping of timer software (TSG2nTE = 0).

23.4.2.19 TSG2nCNT — TSG2n Counter Register

These registers are the main counters for this macro. In HT-PWM mode, TSG2nCNT counts up or down according to triangle-wave control where the counter value is incremented by two until the peak and then decremented by two until the trough. In other modes, the counter is under sawtooth wave control where its value is incremented by one until the peak and then returned to the initial value.

Access: This register can be read in 16-bit units.

Address: TSG20: FFE7 0028_H
TSG21: FFE7 1028_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	16-bit counter															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

[TSG2nCNT Count Value]

Operating Mode	At the Beginning	Minimum Value	Maximum Value
HT-PWM mode	TSG2nDTC0	TSG2nDTC0	TSG2nDTC0+TSG2nCMP0*1
Other modes	0000_H	0000_H	TSG2nCMP0

Note 1. Set a value so that the following condition can be satisfied: TSG2nDTC0 + TSG2nCMP0 < $FFFF_H$.

23.4.2.20 TSG2nSBC — TSG2n Sub-Counter Register

This register is a sub-counter of this macro in HT-PWM mode. In HT-PWM mode, TSG2nCNT counts up or down according to triangle-wave control where the counter value is incremented by two until the peak and then decremented by two until the trough. In addition, this register is provided with a jump function.

Access: This register can be read in 16-bit units.

Address: TSG20: FFE7 002C$_H$
TSG21: FFE7 102C$_H$

Value after reset: 0000$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	16-bit counter															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Operating Mode	At the Beginning	Minimum Value	Maximum Value
HT-PWM mode	TSG2nDTC0	0000$_H$	TSG2nDTC0+TSG2nDTC1+TSG2nCMP0*1
Other modes	0000$_H$	0000$_H$	0000$_H$

Note 1. Set a value so that the following condition can be satisfied: TSG2nDTC0 + TSG2nDTC1 + TSG2nCMP0 < FFFF$_H$.

23.4.2.21 TSG2nCMP0 — TSG2n Compare Register 0

This register is a compare register that specifies the PWM cycle in all modes.

Access: This register can be read/written in 32-bit units.

Address: TSG20: FFE7 0058_H
TSG21: FFE7 1058_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	16-bit compare register															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Operating Mode	At the Beginning	Minimum Value	Maximum Value
HT-PWM mode	TSG2nCMP0*[1]	0002_H	$FFFE_H$
Other modes	TSG2nCMP0 + 1	1 (TSG2nCMP0 = 0000_H)	10000_H (TSG2nCMP0 = $FFFF_H$)

Note 1. In HT-PWM mode, the LSB is ignored because TSG2nCNT is incremented or decremented by 2.

23.4.2.22 TSG2nCMP1W — TSG2n Compare Registers 1 and 2

These registers specify the timer PWM duty in all modes. The 16 high-order bits are called TSG2nCMP2 and the 16 low-order bits are called TSG2nCMP1.

The table below shows the matching operation of TSG2nCNT and the compare registers.

Access: This register can be read/written in 32-bit units.

Address: TSG20: FFE7 0040_H
TSG21: FFE7 1040_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSG2nCMP2 (16-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG2nCMP1 (16-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	PWM Mode	HT-PWM Mode	SP-PWM Mode	120-DC Mode
TSG2nCMP1	TSOn1 clear	TSOn1 clear/ TSOn2 set	Same as on the left	TSOn1, 3, or 5 output PWM is selected by the TSG2nPAT0 register
TSG2nCMP2	TSOn1 set	TSOn1 set/ TSOn2 clear	Same as on the left	TSOn1, 3, or 5 output PWM is selected by the TSG2nPAT0 register

When TSG2nTOEm = 1, the dead time function is enabled in any operating mode. The table above shows the basic functions.

In HT-PWM mode, this is connected with the timing of matches between this register and TSG2nSBC.

In 120-DC mode, the output from TSOn1 to TSOn6 is controlled by TSG2nCMPm, TSG2nPAT0 and TSG2nPAT1.

23.4.2.23 TSG2nCMP5W — TSG2n Compare Registers 5 and 6

These registers specify the timer PWM duty in all modes. The 16 high-order bits are called TSG2nCMP6 and the 16 low-order bits are called TSG2nCMP5.

The table below shows the matching operation of TSG2nCNT and the compare registers.

Access: These registers can be read/written in 32-bit units.

Address: TSG20: FFE7 0044_H
TSG21: FFE7 1044_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSG2nCMP6 (16-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG2nCMP5 (16-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	PWM Mode	HT-PWM Mode	SP-PWM Mode	120-DC Mode
TSG2nCMP5	TSOn3 clear	TSOn3 clear/ TSOn4 set	Same as on the left	TSOn1, 3, or 5 output PWM is selected by the TSG2nPAT0 register
TSG2nCMP6	TSOn3 set	TSOn3 clear/ TSOn4 set	Same as on the left	TSOn1, 3, or 5 output PWM is selected by the TSG2nPAT0 register

When TSG2nTOEm = 1, the dead time function is enabled in any operating mode. The table above shows the basic functions.

In HT-PWM mode, this is connected with the timing of matches between this register and TSG2nSBC.

In 120-DC mode, the output from TSOn1 to TSOn6 is controlled by TSG2nCMPm, TSG2nPAT0 and TSG2nPAT1.

23.4.2.24 TSG2nCMP9W — TSG2n Compare Registers 9 and 10

These registers specify the timer PWM duty in all modes. The 16 high-order bits are called TSG2nCMP10 and the 16 low-order bits are called TSG2nCMP9.

The table below shows the matching operation of TSG2nCNT and the compare registers.

Access: These registers can be read/written in 32-bit units.

Address: TSG20: FFE7 0048_H
TSG21: FFE7 1048_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSG2nCMP10 (16-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG2nCMP9 (16-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	PWM Mode	HT-PWM Mode	SP-PWM Mode	120-DC Mode
TSG2nCMP9	TSOn5 clear	TSOn5 clear/ TSOn6 set	Same as on the left	TSOn1, 3, or 5 output PWM is selected by the TSG2nPAT0 register
TSG2nCMP10	TSOn5 set	TSOn5 set/ TSOn6 clear	Same as on the left	TSOn1, 3, or 5 output PWM is selected by the TSG2nPAT0 register

When TSG2nTOEm = 1, the dead time function is enabled in any operating mode. The table above shows the basic functions.

In HT-PWM mode, this is connected with the timing of matches between this register and TSG2nSBC.

In 120-DC mode, the output from TSOn1 to TSOn6 is controlled by TSG2nCMPm, TSG2nPAT0 and TSG2nPAT1.

23.4.2.25 TSG2nCMP3W — TSG2n Compare Registers 3 and 4

These registers specify the timer PWM duty in all modes. The 16 high-order bits are called TSG2nCMP4 and the 16 low-order bits are called TSG2nCMP3.

The table below shows the matching operation of TSG2nCNT and the compare registers.

Access: These registers can be read/written in 32-bit units.

Address: TSG20: FFE7 004C$_H$
TSG21: FFE7 104C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSG2nCMP4 (16-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG2nCMP3 (16-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	PWM Mode	HT-PWM Mode	SP-PWM Mode	120-DC Mode
TSG2nCMP3	TSOn2 clear	—	—	TSOn2, 4, or 6 output PWM is selected by the TSG2nPAT1 register
TSG2nCMP4	TSOn2 set	—	—	TSOn2, 4, or 6 output PWM is selected by the TSG2nPAT1 register

When TSG2nTOEm = 1, the dead time function is enabled in any operating mode. The table above shows the basic functions.

In HT-PWM mode, this is connected with the timing of matches between this register and TSG2nSBC.

In 120-DC mode, the output from TSOn1 to TSOn6 is controlled by TSG2nCMPm, TSG2nPAT0 and TSG2nPAT1.

23.4.2.26 TSG2nCMP7W — TSG2n Compare Registers 7 and 8

These registers specify the timer PWM duty in any mode. The 16 high-order bits are called TSG2nCMP8 and the 16 low-order bits are called TSG2nCMP7.

The table below shows the matching operation of TSG2nCNT and the compare registers.

Access: These registers can be read/written in 32-bit units.

Address: TSG20: FFE7 0050_H
TSG21: FFE7 1050_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSG2nCMP8 (16-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSG2nCMP7 (16-bit compare register)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	PWM Mode	HT-PWM Mode	SP-PWM Mode	120-DC Mode
TSG2nCMP7	TSOn4 clear	—	—	TSOn2, 4, or 6 output PWM is selected by the TSG2nPAT1 register
TSG2nCMP8	TSOn4 set	—	—	TSOn2, 4, or 6 output PWM is selected by the TSG2nPAT1 register

When TSG2nTOEm = 1, the dead time function is enabled in any operating mode. The table above shows the basic functions.

In HT-PWM mode, this is connected with the timing of matches between this register and TSG2nSBC.

In 120-DC mode, the output from TSOn1 to TSOn6 is controlled by TSG2nCMPm, TSG2nPAT0 and TSG2nPAT1.

23.4.2.27 TSG2nCMP11W — TSG2n Compare Registers 11 and 12

These registers specify the timer PWM duty in any mode. The 16 high-order bits are called TSG2nCMP12 and the 16 low-order bits are called TSG2nCMP11.

The table below shows the matching operation of TSG2nCNT and the compare registers.

Access: These registers can be read/written in 32-bit units.

Address: TSG20: FFE7 0054_H
TSG21: FFE7 1054_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	PWM Mode	HT-PWM Mode	SP-PWM Mode	120-DC Mode
TSG2nCMP11	TSOn6 clear	—	—	TSOn2, 4, or 6 output PWM is selected by the TSG2nPAT1 register
TSG2nCMP12	TSOn6 set	—	—	TSOn2, 4, or 6 output PWM is selected by the TSG2nPAT1 register

When TSG2nTOEm = 1, the dead time function is enabled in any operating mode. The table above shows the basic functions.

In HT-PWM mode, this is connected with the timing of matches between this register and TSG2nSBC.

In 120-DC mode, the output from TSOn1 to TSOn6 is controlled by TSG2nCMPm, TSG2nPAT0 and TSG2nPAT1.

23.4.2.28 TSG2nCMP1-12 — TSG2n Compare Registers 1 to 12

These registers specify the timer PWM duty in all modes. They reflect the address mapping of TSG2nCMP1W, 3W, 5W, 7W, 9W, and 11W, so the function is the same as that of these registers.

Access: These registers can be read/written in 16-bit units.

23.4.2.29 TSG2nDCMP0W — TSG2n Diagnostic Output Compare Registers 0 and 1

These registers diagnose the output function and A/D start trigger timing in all modes. The 16 high-order bits are called TSG2nDCMP1 and the 16 low-order bits are called TSG2nDCMP0. When the value of TSG2nCNT and these registers match, the TSTADT0, TSTADT1, and TSOn7 output pins are controlled.

See **Section 23.9, A/D Conversion Trigger Function** and **Section 23.5.4.1 (1) TSOn7 Pin Output Control**.

Access: These registers can be read/written in 32-bit units.

Address: TSG20: FFE7 005C$_H$
TSG21: FFE7 105C$_H$

23.4.2.30 TSG2nDCMP2 — TSG2n Diagnostic Output Compare Register 2

This register diagnose the output function and A/D start trigger timing in all modes. The 16 low-order bits are called TSG2nDCMP2.

When the value of TSG2nCNT and this register match, the TSTADT0, TSTADT1 and TSOn7 output pins are controlled.

See **Section 23.9, A/D Conversion Trigger Function** and **Section 23.5.4.1 (1) TSOn7 Pin Output Control**.

Access: This register can be read/written in 32-bit units.

111	The high level is held.

23.4.2.32 TSG2nPAT1W — TSG2n Pattern Register 1

This register controls the UT/VT/WT output pattern.

Bits 17 to 15 are for PAT5B; bits 14 to 12 for PAT4B; bits 11 to 9 for PAT3B; bits 8 to 6 for PAT2B; bits 5 to 3 for PAT1B; and bits 2 to 0 for PAT0B.

Access: This register can be read/written in 32-bit units.

Address: TSG20: FFE7 0068_H

110	PWM output set by TSG2nCMP12
111	The high level is held.

23.4.2.33 TSG2nDTC0W — TSG2n Dead Time Compare Register 0

This register is a compare register for the dead time. It controls the period from inverse phase inactivation to positive phase activation. The 10 low-order bits are called TSG2nDTC0.

When the 10-bit dead time compare value is changed, the write protection code must be written to TSG2nPWDATA0. Only when TSG2nPWDATA0 and TSG2nDTPR (TSG2n dead time protection register) match while TSG2nDTCM = 0, the 10-bit dead time compare value can be changed.

During timer operation (TSG2nTE = 1), the register should not be written except by reloading (TSG2nRMC = 0).

Access: This register can be read/written in 32-bit units.

Address: TSG20: FFE7 006C$_H$
TSG21: FFE7 106C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

23.4.2.34 TSG2nDTC1W — TSG2n Dead Time Compare Register 1

This register is a compare register for the dead time. It controls the period from positive phase inactivation to inverse phase activation. The 10 low-order bits are called TSG2nDTC1.

When the 10-bit dead time compare value is changed, the write protection code must be written to TSG2nPWDATA1. Only when TSG2nPWDATA1 and TSG2nDTPR (TSG2n dead time protection register) match while TSG2nDTCM = 0, the 10-bit dead time compare value can be changed.

During timer operation (TSG2nTE = 1), the register should not be written except by reloading (TSG2nRMC = 0).

Access: This register can be read/written in 32-bit units.

Address: TSG20: FFE7 0070_H
TSG21: FFE7 1070_H

Value after reset: 0000 0000_H

23.4.2.35 TSG2nCMPU — TSG2n U Phase Compare Register

This register is used only in HT-PWM mode. Though the function of this register is the same as TSG2nCMP1W (TSG2nCMP1, 2), access to this register requires a specific sequence. In other words, data are written to TSG2nCMPU and then stored in the TSG2nCMP1 and 2 registers. Thereby, only a single write access is required to start the generation of a symmetric triangle wave in PWM mode (see **Figure 23.2**).

When this register is read, the same value as TSG2nCMP1 is read.

Access: This register can be read/written in 16-bit units.

Address: TSG20: FFE7 00B0$_H$
TSG21: FFE7 10B0$_H$

Value after reset: 0000$_H$

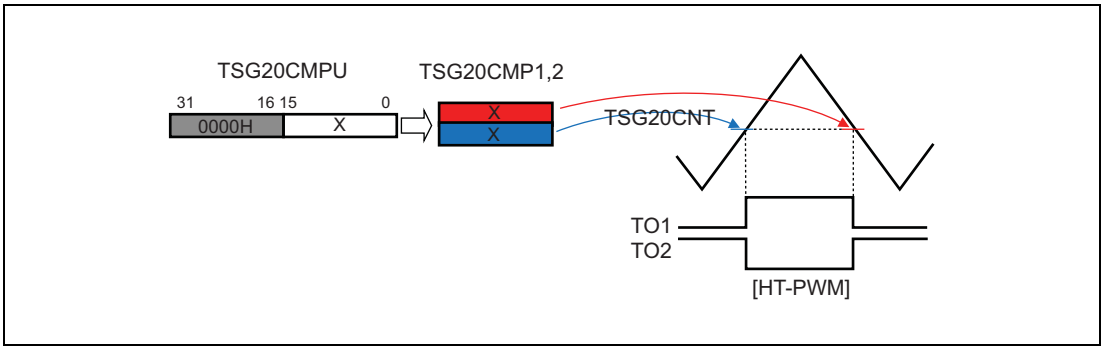

Figure 23.2 TSG2nCMPU Register Access

23.4.2.36 TSG2nCMPV — TSG2n V Phase Compare Register

This register is used only in HT-PWM mode. Though the function of this register is the same as TSG2nCMP5W (TSG2nCMP5, 6), access to this register requires a specific sequence. In other words, data are written to TSG2nCMPV and then stored in the TSG2nCMP 5 and 6 registers. Thereby, only a single write access is required to start the generation of a symmetric triangle wave in PWM mode (see **Figure 23.3**).

When this register is read, the same value as TSG2nCMP5 is read.

Access: This register can be read/written in 16-bit units.

Address: TSG20: FFE7 00B4$_H$
TSG21: FFE7 10B4$_H$

Value after reset: 0000$_H$

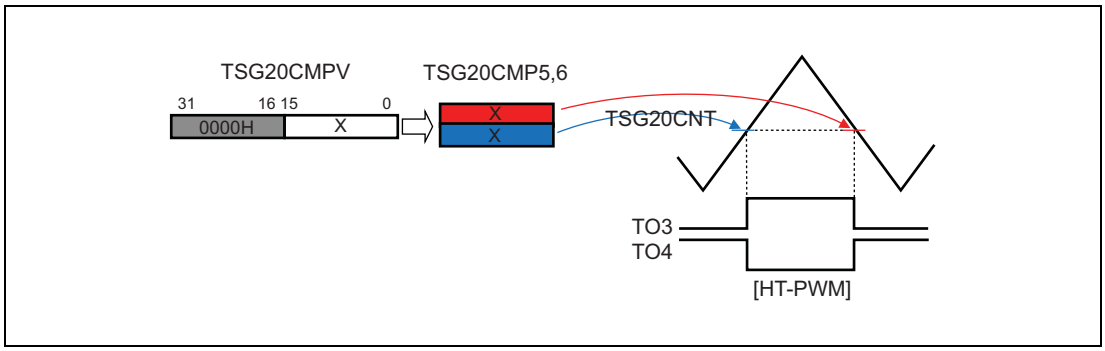

Figure 23.3 TSG2nCMPV Register Access

23.4.2.37 TSG2nCMPW — TSG2n W Phase Compare Register

This register is used only in HT-PWM mode. Though the function of this register is the same as TSG2nCMP9W (TSG2nCMP9,10), access to this register requires a specific sequence. In other words, data are written to TSG2nCMPW and then stored in the TSG2nCMP 9 and 10 registers. Thereby, only a single write access is required to start the generation of a symmetric triangle wave in PWM mode (see **Figure 23.4**).

When this register is read, the same value as TSG2nCMP9 is read.

Access: This register can be read/written in 16-bit units.

Address: TSG20: FFE7 00B8$_H$
TSG21: FFE7 10B8$_H$

Value after reset: 0000$_H$

Bit Position	Bit Name	Function
15	TSG2nDTCM	TSG2nDTC0 and 1 Write Mask 0: Enables rewriting of TSG2nDTC0 and TSG2nDTC1. 1: Disables rewriting of TSG2nDTC0 and TSG2nDTC1.
14 to 0	TSG2nDTPR	Write Protection Code 0000_H-$7FFF_H$: Sets any value from 0000_H to $7FFF_H$.

23.5 Basic Operation

23.5.1 Basic Operation of 16-Bit Counter

The basic operation of the 16-bit counter is described.

Counting start

The 16-bit counter of TSG2n starts counting from the value after reset 0000_H in any mode other than HT-PWM mode.

The counter increments from 0000_H, 0001_H, 0002_H, 0003_H, … in any mode other than HT-PWM mode.

Counter clear

The 16-bit counter is cleared when the counter value and the compare register set value match.

Counter read during counting

In the TSG2n, the 16-bit counter value during counting can be read through TSG2nCNT.

Interrupt operation

In the TSG2n, the following interrupts are generated.

- INTTSG2nI[0]: This interrupt works as a cyclic interrupt when the 16-bit counter value matches the TSG2nDTC0 value in HT-PWM mode. It works as an interrupt on compare match between the 16-bit counter value and the TSG2nCMP0 buffer register value in modes other than HT-PWM mode.
- INTTSG2nI[1]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP1 buffer register.
- INTTSG2nI[2]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP2 buffer register value.
- INTTSG2nI[3]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP3 buffer register value.
- INTTSG2nI[4]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP4 buffer register value.
- INTTSG2nI[5]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP5 buffer register value.
- INTTSG2nI[6]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP6 buffer register value.
- INTTSG2nI[7]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP7 buffer register value.
- INTTSG2nI[8]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP8 buffer register value.
- INTTSG2nI[9]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP9 buffer register value.
- INTTSG2nI[10]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP10 buffer register value.

- INTTSG2nI[11]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP11 buffer register value.
- INTTSG2nI[12]: An interrupt on compare match between the 16-bit counter value and the TSG2nCMP12 buffer register value.
- INTTSG2nIPEK: A peak interrupt when the 16-bit counter switches from incrementing to decrementing.
- INTTSG2nIVLY: A trough interrupt when the 16-bit counter switches from decrementing to incrementing (only in HT-PWM mode)
- INTTSG2nIER: An interrupt on detection of simultaneous activation of the positive phase and inverse phase
- INTTSG2nIWN: A warning detection interrupt

23.5.2 Functions of Compare Registers

The functions of the compare registers in each operating mode are shown in **Table 23.25** to **Table 23.28**.

Table 23.25 Compare Register Functions in Each Mode (1/4)

Operating Mode	TSG2nCMP0	TSG2nCMP1W	TSG2nCMP3W	TSG2nCMP5W

23.5.3 Compare Register Rewrite Operation

The following compare registers are rewritten by reloading (TSG2nCTL3.TSG2nRMC = 0) mode or anytime rewriting (TSG2nCTL3.TSG2nRMC = 1).

The target registers are as follows:

- TSG2nCMP0
- TSG2nCMP1-TSG2nCMP12 (TSG2nCMP1W, TSG2nCMP3W, TSG2nCMP5W, TSG2nCMP7W, TSG2nCMP9W, TSG2nCMP11W)
- TSG2nPAT0W, TSG2nPAT1W
- TSG2nDTC0W, TSG2nDTC1W
- TSG2nDCMP0W, TSG2nDCMP2
- TSG2nCTL4
- TSG2nIOC3

Anytime rewriting

This mode allows direct rewriting of the values of the compare registers. That is, whenever a value is written to the compare register, the written value is reflected immediately.

CAUTION

In anytime rewriting in HT-PWM mode, if rewriting is performed again before a transfer to the buffer register is completed, the written value is not reflected immediately.

If rewriting is performed while the 16-bit counter is counting up, the value is reflected at the next peak timing of the 16-bit sub-counter. If rewriting is performed while the 16-bit counter is counting down, the value is reflected at the next trough timing of the 16-bit sub-counter.

Reloading (simultaneous rewriting)

Writing to TSG2nCMP1 (TSG2nCMP1W, TSG2nCMPU, TSG2nUPW) enables reload (sets the reload request flag (TSG2nSTR0.TSG2nRSF)), and the values of all the target registers are updated simultaneously at the next reload timing (reload).

The reload timing is the peak or trough timing of the 16-bit counter when the TSG2nTRG0.TSG2nTS bit is changed from 0 to 1. Reloading is controlled by TSG2nCTL4.TSG2nPRE and TSG2nVRE.

Writing to any register other than TSG2nCMP1 (TSG2nCMP1W, TSG2nCMPU, TSG2nUPW) does not enable reloading.

Do not write to the registers for reloading until the next reload timing after reloading is enabled by writing to TSG2nCMP1 (TSG2nCMP1W, TSG2nCMPU, TSG2nUPW). The target registers should be rewritten when the reload request flag (TSG2nSTR0.TSG2nRSF) is 0.

Rewriting the registers for reloading by DMA transfer

Some of the registers for reloading can be rewritten by DMA transfer. DMA transfer is performed as follows.

Table 23.29 Example of DMA Transfer Order of Registers for Reloading

Address	Register Name	DMA Transfer Order (Example)
<TSG2n_base1> + 040_H	TSG2nCMP1W	↑
<TSG2n_base1> + 044_H	TSG2nCMP5W	↑
<TSG2n_base1> + 048_H	TSG2nCMP9W	↑
<TSG2n_base1> + $04C_H$	TSG2nCMP3W	↑
<TSG2n_base1> + 050_H	TSG2nCMP7W	↑
<TSG2n_base1> + 054_H	TSG2nCMP11W	↑
<TSG2n_base1> + 058_H	TSG2nCMP0	↑
<TSG2n_base1> + $05C_H$	TSG2nDCMP0W	↑
<TSG2n_base1> + 060_H	TSG2nDCMP2	↑
<TSG2n_base1> + 064_H	TSG2nPAT0W	↑
<TSG2n_base1> + 068_H	TSG2nPAT1W	↑
<TSG2n_base1> + $06C_H$	TSG2nDTC0W	↑
<TSG2n_base1> + 070_H	TSG2nDTC1W	↑

Table 23.30 Duty Setting in HT-PWM Mode

Address	Register Name	DMA Transfer Order (Example)
<TSG2n_base1> + $0B0_H$	TSG2nCMPU	↑
<TSG2n_base1> + $0B4_H$	TSG2nCMPV	↑
<TSG2n_base1> + $0B8_H$	TSG2nCMPW	↑

Table 23.31 Active Width Setting in SP-PWM Mode

Address	Register Name	DMA Transfer Order (Example)
<TSG2n_base1> + $0BC_H$	TSG2nUPW	↑
<TSG2n_base1> + $0C0_H$	TSG2nVPW	↑
<TSG2n_base1> + $0C4_H$	TSG2nWPW	↑

NOTES

1. TSG2nCTL4 and TSG2nIOC3 should be rewritten individually.
2. Since writing to TSG2nCMP1W (including TSG2nCMP1, TSG2nCMPU, and TSG2nUPW) enables reloading, it should be rewritten after all the other registers for reloading have been rewritten (ready to be reloaded).

23.5.3.1 Operation Example of Anytime Rewriting

In this mode, the values written to the compare registers (TSG2nCMP1 to TSG2nCMP12) are transferred to the internal buffer registers immediately, and are compared with the counter value.

The values are transferred to the internal compare buffer registers one clock cycle (PCLK) after being written to the compare registers (TSG2nCMP1 to TSG2nCMP12).

The transfer timing of the TSG2nCMP0 is the peak or trough timing (only in HT-PWM mode) of the 16-bit counter after being written to the compare registers, or at the match timing of the TSG2nCMP0 value with the 16-bit counter value (in any mode other than HT-PWM mode).

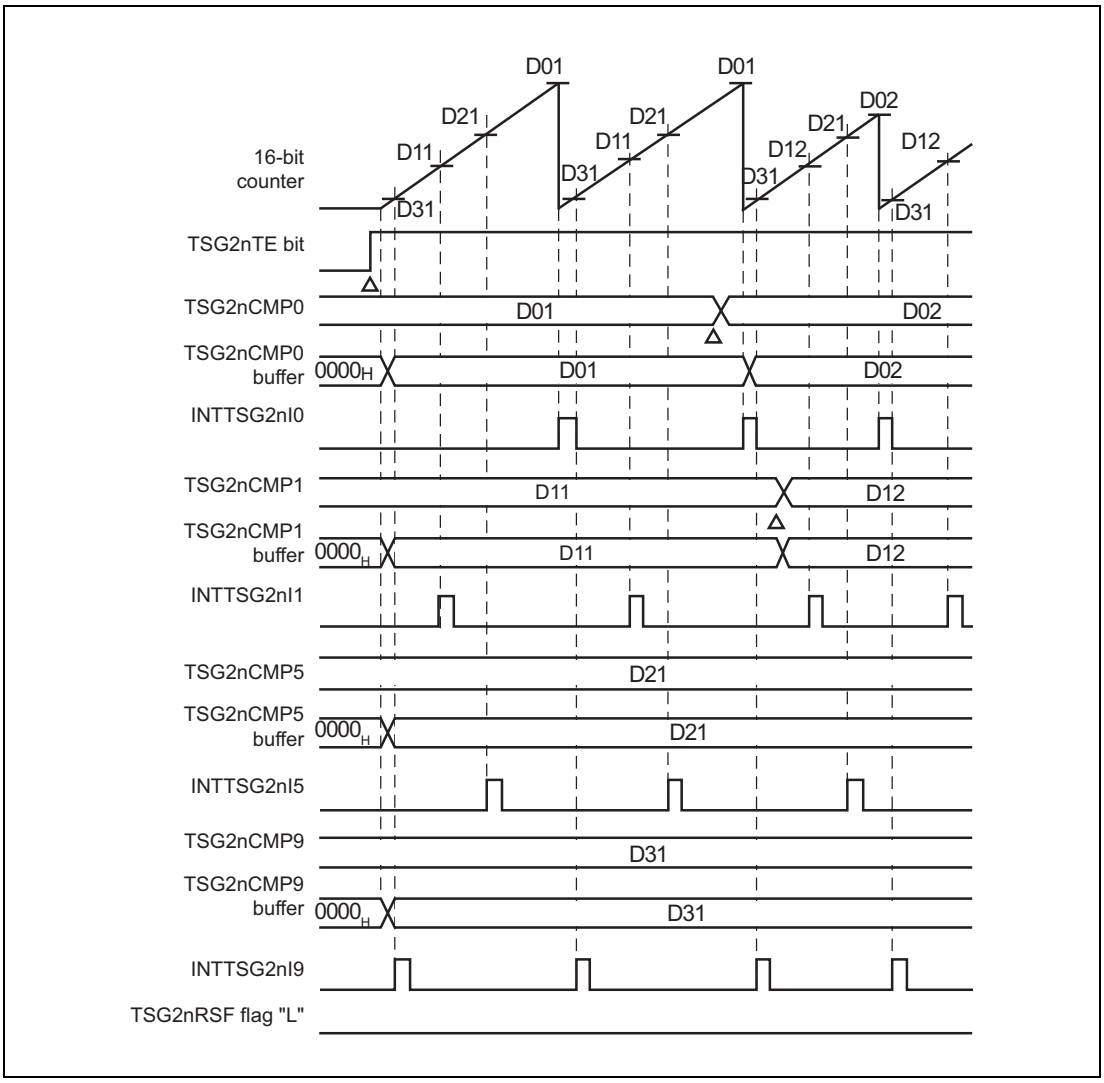

Figure 23.8 Anytime Rewriting Timing (Example in PWM Mode)

NOTES

   D11, D12: TSG2nCMP1setting value (0000_H to $FFFF_H$)
   D21: TSG2nCMP5 setting value (0000_H to $FFFF_H$)
   D31: TSG2nCMP9 setting value (0000_H to $FFFF_H$)
2. Δ: Write access

(1) Data Reflection on PWM by Anytime Rewriting in HT-PWM Mode

In HT-PWM mode, the following output control is performed depending on the timing of anytime rewriting of the compare registers.

- If anytime rewriting is performed after the inverse phase is cleared while the 16-bit counter is counting up (the 16-bit sub-counter is counting up), the positive phase is set if the rewritten value is TSG2nCMPm < TSG2nSBC. The inverse phase is set if the rewritten value is TSG2nCMPm > TSG2nCNT. (The dead time is inserted after clearance of the positive phase and inverse phase.)
- If anytime rewriting is performed after the positive phase is set while the 16-bit counter is counting up (the 16-bit sub-counter is counting up), the positive phase is cleared if the rewritten value is TSG2nCMPm > TSG2nSBC. The positive phase is cleared and the inverse phase is set if the rewritten value is TSG2nCMPm > TSG2nCNT. (The dead time is inserted after clearance of the positive phase and inverse phase.)
- If anytime rewriting is performed before the inverse phase is cleared while the 16-bit counter is counting up (the 16-bit sub-counter is counting up), the inverse phase is cleared if the rewritten value is TSG2nCMPm < TSG2nCNT. The inverse phase is cleared and the positive phase is set if the rewritten value is TSG2nCMPm < TSG2nSBC. (The dead time is inserted after clearance of the positive phase and inverse phase.)
- If anytime rewriting is performed after the positive phase is cleared while the 16-bit counter is counting up (the 16-bit sub-counter is counting down), the inverse phase is set if the rewritten value is TSG2nCMPm > TSG2nCNT. (The dead time is inserted after clearance of the positive phase.)
- If anytime rewriting is performed before the positive phase is cleared while the 16-bit counter is counting up (the 16-bit sub-counter is counting down), the positive phase is cleared if the rewritten value is TSG2nCMPm > TSG2nSBC. The positive phase is cleared and the inverse phase is set if the rewritten value is TSG2nCMPm > TSG2nCNT. (The dead time is inserted after clearance of the positive phase and inverse phase.)
- If anytime rewriting is performed after the positive phase is set while the 16-bit counter is counting up (the 16-bit sub-counter is counting up), the positive phase is cleared if the rewritten value is TSG2nCMPm > TSG2nSBC. The positive phase is cleared and the inverse phase is set if the rewritten value is TSG2nCMPm > TSG2nCNT. (The dead time is inserted after clearance of the positive phase and inverse phase.)
- If anytime rewriting is performed after the positive phase is set while the 16-bit counter is counting down (the 16-bit sub-counter is counting up), the positive phase is cleared if the rewritten value is TSG2nCMPm > TSG2nSBC. (The dead time is inserted after clearance of the positive phase.)
- If anytime rewriting is performed after the positive phase is set while the 16-bit counter is counting down (the 16-bit sub-counter is counting up), the positive phase is cleared if the rewritten value is TSG2nCMPm > TSG2nCNT. The positive phase is cleared and the inverse phase is set if the rewritten value is TSG2nCMPm > TSG2nSBC. (The dead time is inserted after clearance of the positive phase.)

23.5.3.2 Operation Example of Reloading (Simultaneous Rewriting)

The rewritten values of the registers for reloading (TSG2nCMP0 to TSG2nCMP12, TSG2nCTL4, TSG2nIOC3, TSG2nPAT0W, TSG2nPAT1W, TSG2nDTC0W, TSG2nDTC1W, TSG2nDCMP0W, and TSG2nDCMP2) can be transferred to the corresponding buffer registers simultaneously at the reload timing.

The registers should be rewritten when the pertinent reload request flag (TSG2nSTR0.TSG2nRSF) is 0.

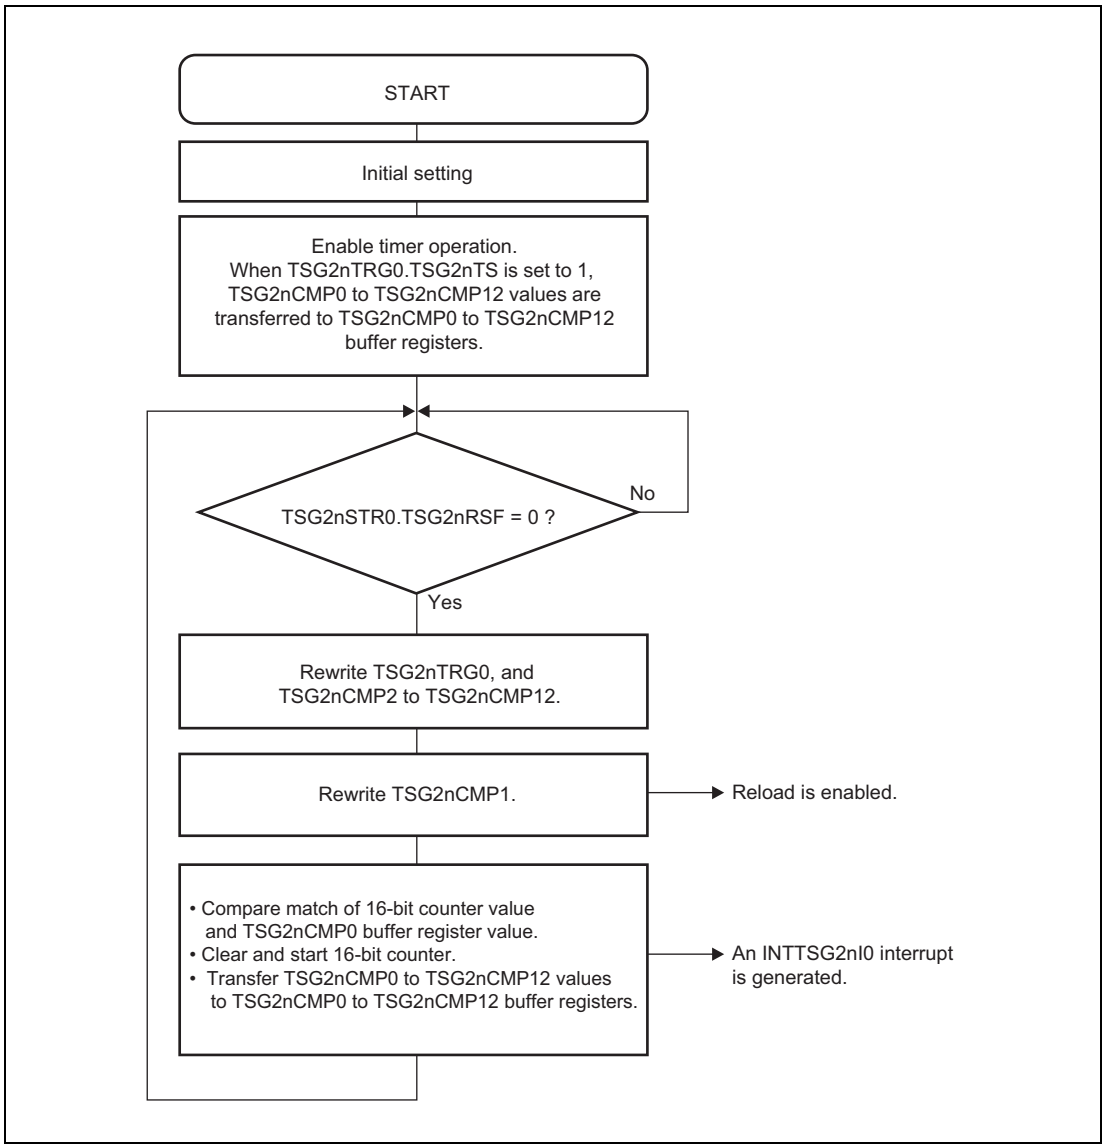

Figure 23.9 Basic Operation Flow of Reloading (Simultaneous Rewriting) (Example of PWM Mode)

CAUTION

Writing to TSG2nCMP1 also enables reloading. Therefore, TSG2nCMP1 should be rewritten after TSG2nCMP0 and TSG2nCMP2 to TSG2nCMP12 registers have been rewritten.

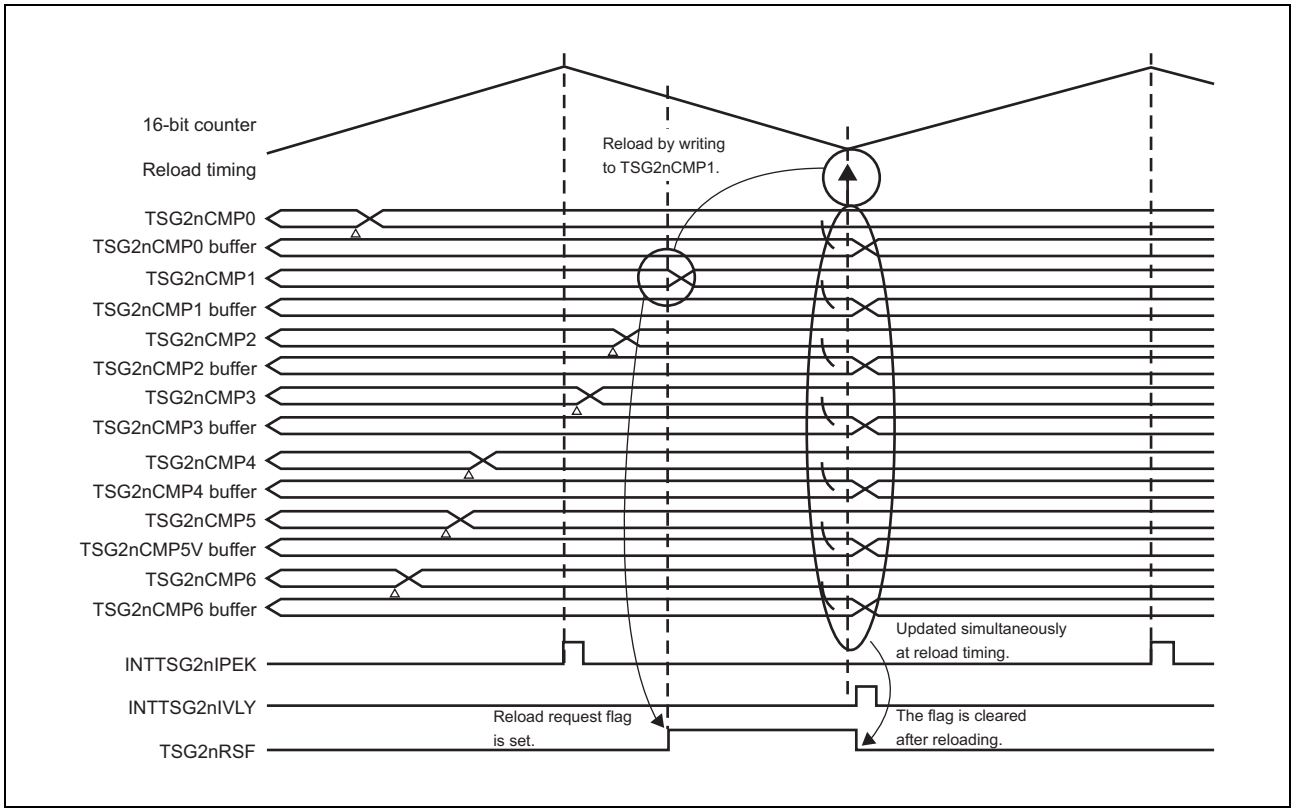

Figure 23.10 Simultaneous Rewriting Timing (1/2) (Example of HT-PWM Mode)

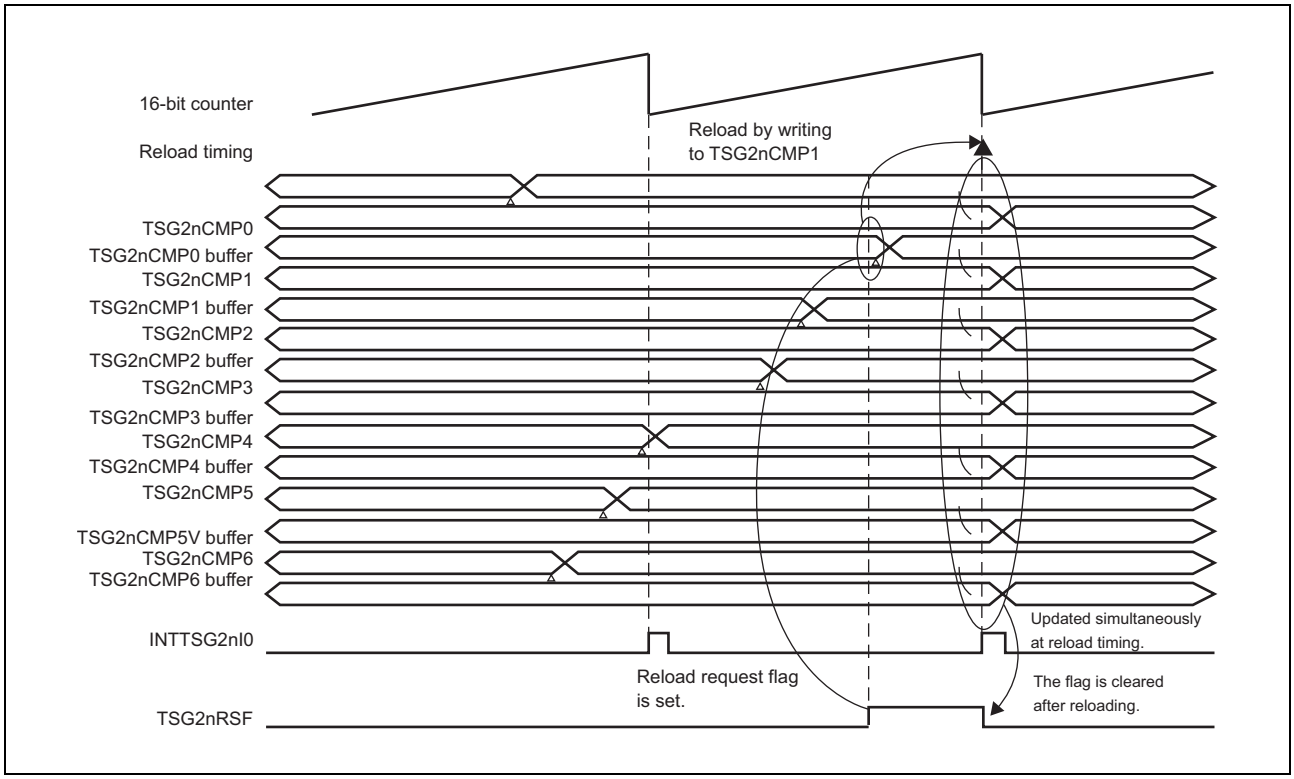

Figure 23.11 Simultaneous Rewriting Timing (2/2) (Example of PWM mode)

(1) Reload Setting Example in Each Mode

Reloading conditions and setting examples are shown below.

Table 23.32 List of Reload Settings (when TSG2nCTL3.TSG2nRIA = 0)

Operating Mode	TSG2nCTL4.TSG2nPRE	TSG2nCTL4.TSG2nVRE	TSG2nCTL4.TSG2nPIE	TSG2nCTL4.TSG2nVIE	TSG2nCTL4.TSG2nRCC04-TSG2nRCC00	Reload

	1	1	1	0	Any value	When INTTSG2nIPEK is generated.
	1	1	1	1	Any value	When INTTSG2nIPEK/ INTTSG2nIVLY is generated.

23.5.4 List of Outputs in Each Mode

23.5.4.1 Timer Output in Each Mode

The list of timer outputs (TSOn0 to TSOn7) in each mode is shown in **Table 23.34** to **Table 23.36**.

Table 23.34 List of Timer Outputs in Each Mode (1/3)

Operating Mode	TSOn0 Pin	TSOn1 Pin	TSOn2 Pin
PWM mode	— (fixed to low.)	Outputs a PWM signal by compare match of TSG2nCMP1W (TSG2nCMP1 and TSG2nCMP2).	Outputs a PWM signal by compare match of TSG2nCMP3W (TSG2nCMP3 and TSG2nCMP4).
HT-PWM mode	Outputs the status indicating whether the 16-bit counter or 16-bit sub-counter is incremented or decremented.	Outputs a positive phase PWM signal (with dead time) by compare match of TSG2nCMP1W (TSG2nCMP1 and TSG2nCMP2).	Outputs an inverse phase PWM signal (with dead time) to the TSOn1 pin.
SP-PWM mode	— (fixed to low.)	Outputs a positive phase PWM signal (with dead time) by compare match of TSG2nCMP1W (TSG2nCMP1 and TSG2nCMP2).	Outputs an inverse phase PWM signal (with dead time) to the TSOn1 pin.
120-DC mode	— (fixed to low.)	Outputs a PWM signal by TSG2nCMP1W (TSG2nCMP1 and TSG2nCMP2), TSG2nCMP5W (TSG2nCMP5 and TSG2nCMP6), and TSG2nCMP9W (TSG2nCMP9 and TSG2nCMP10).	Outputs a PWM signal by TSG2nCMP3W (TSG2nCMP3 and TSG2nCMP4), TSG2nCMP7W (TSG2nCMP7 and TSG2nCMP8), and TSG2nCMP11W (TSG2nCMP11 and TSG2nCMP12).

Table 23.35 List of Timer Outputs in Each Mode (2/3)

Operating Mode	TSOn3 Pin	TSOn4 Pin	TSOn5 Pin
PWM mode	Outputs a PWM signal by compare match of TSG2nCMP5W (TSG2nCMP5 and TSG2nCMP6).	Outputs a PWM signal by compare match of TSG2nCMP7W (TSG2nCMP7 and TSG2nCMP8).	Outputs a PWM signal by compare match of TSG2nCMP9W (TSG2nCMP9 and TSG2nCMP10).
HT-PWM mode	Outputs a positive phase PWM signal (with dead time) by compare match of TSG2nCMP5W (TSG2nCMP5 and TSG2nCMP6).	Outputs an inverse phase PWM signal (with dead time) to the TSOn3 pin.	Outputs a positive phase PWM signal (with dead time) by compare match of TSG2nCMP9W (TSG2nCMP9 and TSG2nCMP10).
SP-PWM mode	Outputs a positive phase PWM signal (with dead time) by compare match of TSG2nCMP5W (TSG2nCMP5 and TSG2nCMP6).	Outputs an inverse phase PWM signal (with dead time) to the TSOn3 pin.	Outputs a positive phase PWM signal (with dead time) by compare match of TSG2nCMP9W (TSG2nCMP9 and TSG2nCMP10).
120-DC mode	Outputs a PWM signal by TSG2nCMP1W (TSG2nCMP1 and TSG2nCMP2), TSG2nCMP5W (TSG2nCMP5 and TSG2nCMP6), and TSG2nCMP9W (TSG2nCMP9 and TSG2nCMP10).	Outputs a PWM signal by TSG2nCMP3W (TSG2nCMP3 and TSG2nCMP4), TSG2nCMP7W (TSG2nCMP7 and TSG2nCMP8), and TSG2nCMP11W (TSG2nCMP11 and TSG2nCMP12).	Outputs a PWM signal by TSG2nCMP1W (TSG2nCMP1 and TSG2nCMP2), TSG2nCMP5W (TSG2nCMP5 and TSG2nCMP6), and TSG2nCMP9W (TSG2nCMP9 and TSG2nCMP10).

Table 23.36 List of Timer Outputs in Each Mode (3/3)

Operating Mode	TSOn6 Pin	TSOn7 Pin
PWM mode	Outputs a PWM signal by compare match of TSG2nCMP11W (TSG2nCMP11 and TSG2nCMP12).	Outputs a diagnostic signal or A/D conversion trigger.
HT-PWM mode	Outputs an inverse phase PWM signal (with dead time) to the TSOn5 pin.	Outputs a diagnostic signal or A/D conversion trigger.
SP-PWM mode	Outputs an inverse phase PWM signal (with dead time) to the TSOn5 pin.	Outputs a diagnostic signal or A/D conversion trigger*1.
120-DC mode	Outputs a PWM signal by TSG2nCMP3W (TSG2nCMP3 and TSG2nCMP4), TSG2nCMP7W (TSG2nCMP7 and TSG2nCMP8), and TSG2nCMP11W (TSG2nCMP11 and TSG2nCMP12).	Outputs a diagnostic signal or A/D conversion trigger*1.

Note 1. For TSOn7, see **Section 23.5.4.1**, **(1) TSOn7 Pin Output Control**.

(1) TSOn7 Pin Output Control

The TSOn7 pin can output an A/D conversion trigger pulse (TSG2nIOC1.TSG2nTGS = 0) or diagnostic signal (TSG2nIOC1.TSG2nTGS = 1). When outputting an A/D conversion trigger pulse, the TSOn7 pin is activated at the rising edge of the TSTADT0 signal, and inactivated at the rising edge of the TSTADT1 signal. When the TSTADT0 signal is detected while the TSOn7 pin is active, the TSOn7 pin remains active. When the TSTADT1 signal is detected while the TSOn7 pin is inactive, the TSOn7 pin remains inactive. If TSTADT0 and TSTADT1 signal triggers occur simultaneously, the TSOn7 pin is inactivated.

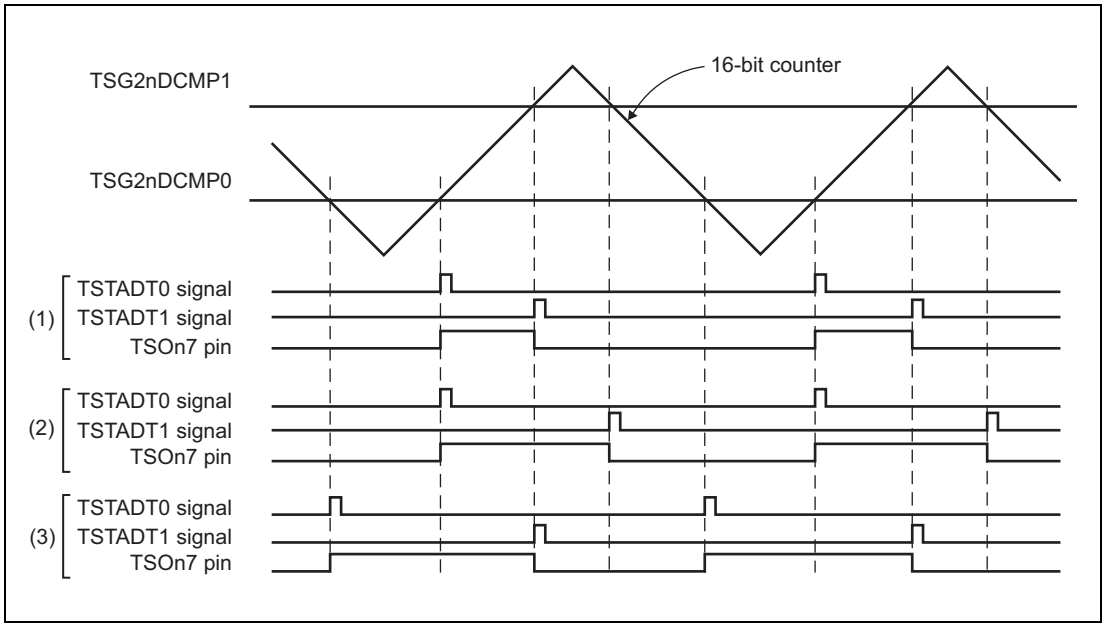

Figure 23.12 Timing Example of A/D Trigger Output by the TSOn7 Pin (TSG2nIOC1.TSG2nTGS = 0)

NOTES

1. When TSG2nDCMP0 < TSG2nDCMP1, TSG2nCTL5 = 0004_H, and TSG2nCTL6 = 0010_H
2. When TSG2nDCMP0 < TSG2nDCMP1, TSG2nCTL5 = 0004_H, and TSG2nCTL6 = 0020_H
3. When TSG2nDCMP0 < TSG2nDCMP1, TSG2nCTL5 = 0008_H, and TSG2nCTL6 = 0010_H
   For TSOn7, see **Section 23.5.4.1 (1) TSOn7 Pin Output Control**.

The TSOn7 pin during diagnostic output outputs the active level with the output width specified by TSG2nCTL0.TSG2nDWD at the match timing of the TSG2nDCMP0 to TSG2nDCMP2 values with the 16-bit counter value. If another match of the TSG2nDCMP0 to TSG2nDCMP2 values with the 16-bit counter value occurs consecutively within the output width specified by TSG2nDWD causing their active level widths to be overlapped, the TSOn7 pin outputs a pulse within 16 clock cycles (PCLK).

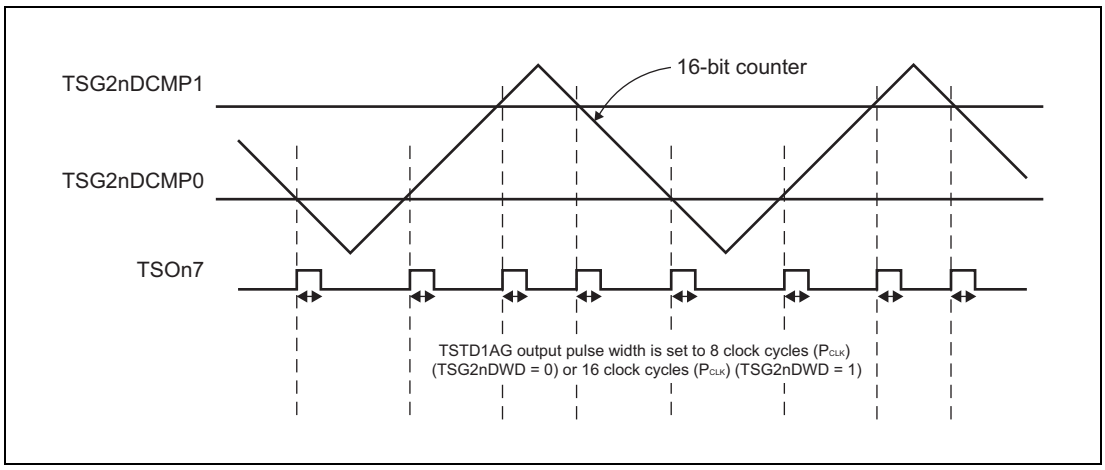

Figure 23.13 Timing Example of Diagnostic Output by the TSOn7 Pin (1) (TSG2nIOC1.TSG2nTGS = 1)

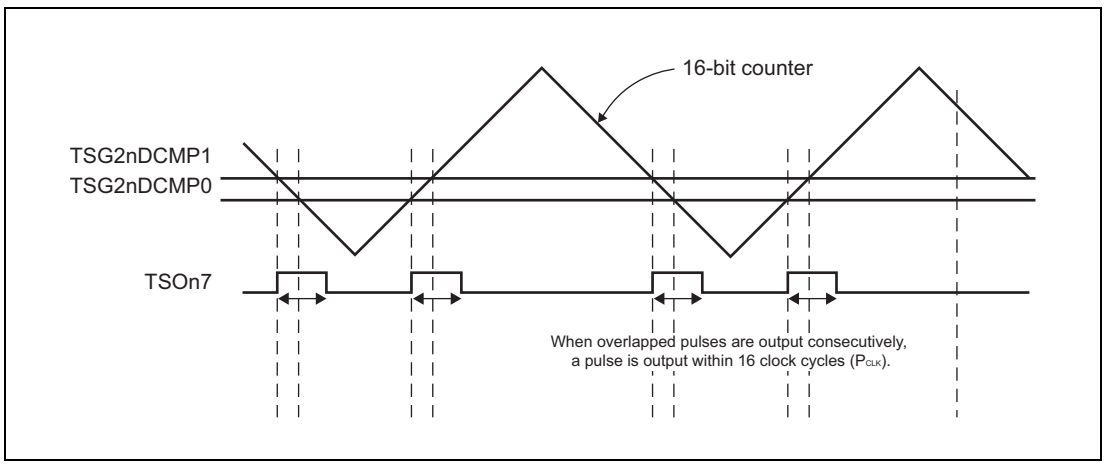

Figure 23.14 Timing Example of Diagnostic Output by the TSOn7 Pin (2) (with Output Width Overlapped)

23.5.4.2 Interrupts in Each Mode

A list of interrupts (INTTSG2nI[0] to INTTSG2nI[12], INTTSG2nIPEK, INTTSG2nIVLY, INTTSG2nIER and INTTSG2nIWN) in each mode is shown in **Table 23.37** to **Table 23.41**.

Table 23.37 List of Interrupts in Each Mode (1/5)

Operating mode	INTTSG2nI[0]	INTTSG2nI[1]	INTTSG2nI[2]	INTTSG2nI[3]
PWM mode	TSG2nCMP0 compare match interrupt	TSG2nCMP1 compare match interrupt*1	TSG2nCMP2 compare match interrupt*1	TSG2nCMP3 compare match interrupt*1
HT-PWM mode	Periodic interrupt	TSG2nCMP1 compare match interrupt*2	TSG2nCMP2 compare match interrupt*2	—
SP-PWM mode	TSG2nCMP0 compare match interrupt	TSG2nCMP1 compare match interrupt*1	TSG2nCMP2 compare match interrupt *1	—
120-DC mode	TSG2nCMP0 compare match interrupt	TSG2nCMP1 compare match interrupt*1	TSG2nCMP2 compare match interrupt*1	TSG2nCMP3 compare match interrupt *1

Note 1. When TSG2nCMP0 < TSG2nCMPm, a compare match interrupt is not generated (m = 1 to 12).
Note 2. When $0000_H \leq$ TSG2nCMPm < TSG2nDTC0, and (TSG2nCMP0 + TSG2nDTC0) < TSG2nCMPm, a compare match interrupt is not generated.

Table 23.38 List of Interrupts in Each Mode (2/5)

Operating mode	INTTSG2nI[4]	INTTSG2nI[5]	INTTSG2nI[6]	INTTSG2nI[7]
PWM mode	TSG2nCMP4 compare match interrupt*1	TSG2nCMP5 compare match interrupt*1	TSG2nCMP6 compare match interrupt*1	TSG2nCMP7 compare match interrupt*1
HT-PWM mode	—	TSG2nCMP5 compare match interrupt*2	TSG2nCMP6 compare match interrupt*2	—
SP-PWM mode	—	TSG2nCMP5 compare match interrupt*1	TSG2nCMP6 compare match interrupt*1	—
120-DC mode	TSG2nCMP4 compare match interrupt*1	TSG2nCMP5 compare match interrupt*1	TSG2nCMP6 compare match interrupt*1	TSG2nCMP7 compare match interrupt*1

Note 1. When TSG2nCMP0 < TSG2nCMPm, a compare match interrupt is not generated (m = 1 to 12).
Note 2. When $0000_H \leq$ TSG2nCMPm < TSG2nDTC0, and (TSG2nCMP0 + TSG2nDTC0) < TSG2nCMPm, a compare match interrupt is not generated.

Table 23.39 List of Interrupts in Each Mode (3/5)

Operating mode	INTTSG2nI[8]	INTTSG2nI[9]	INTTSG2nI[10]	INTTSG2nI[11]
PWM mode	TSG2nCMP8 compare match interrupt*1	TSG2nCMP9 compare match interrupt*1	TSG2nCMP10 compare match interrupt*1	TSG2nCMP11 compare match interrupt*1
HT-PWM mode	—	TSG2nCMP9 compare match interrupt*2	TSG2nCMP10 compare match interrupt*2	—
SP-PWM mode	—	TSG2nCMP9 compare match interrupt*1	TSG2nCMP10 compare match interrupt*1	—
120-DC mode	TSG2nCMP8 compare match interrupt*1	TSG2nCMP9 compare match interrupt*1	TSG2nCMP10 compare match interrupt*1	TSG2nCMP11 compare match interrupt*1

Note 1. When TSG2nCMP0 < TSG2nCMPm, a compare match interrupt is not generated (m = 1 to 12).
Note 2. When $0000_H \leq$ TSG2nCMPm < TSG2nDTC0, and (TSG2nCMP0 + TSG2nDTC0) < TSG2nCMPm, a compare match interrupt is not generated.

Table 23.40 List of Interrupts in Each Mode (4/5)

Operating mode	INTTSG2nI[12]	INTTSG2nIPEK	INTTSG2nIVLY
PWM mode	TSG2nCMP12 compare match interrupt*1	Peak interrupt at the same timing as INTTSG2nI[0]	—
HT-PWM mode	—	Peak interrupt	Trough interrupt
SP-PWM mode	—	Peak interrupt at the same timing as INTTSG2nI[0]	—
120-DC mode	TSG2nCMP12 compare match interrupt*1	Peak interrupt at the same timing as INTTSG2nI[0]	—

Note 1. When TSG2nCMP0 < TSG2nCMPm, a compare match interrupt is not generated (m = 1 to 12).

Table 23.41 List of Interrupts in Each Mode (5/5)

Operating mode	INTTSG2nIER	INTTSG2nIWN
PWM mode	Error interrupt	Warning interrupt
HT-PWM mode	Error interrupt	Warning interrupt
SP-PWM mode	Error interrupt	Warning interrupt
120-DC mode	Error interrupt	Warning interrupt

23.6 Match Interrupt

TSG2n can interrupts include a compare match interrupt (INTTSG2nIm), a peak interrupt (INTTSG2nIPEK), and a trough interrupt (INTTSG2nIVLY). For error interrupt and warning interrupts (INTTSG2nIER and INTTSG2nIWN), see **Section 23.10, Error and Warning Interrupts**.

A periodic interrupt (INTTSG2nI[0]) is generated for each timer cycle. In HTPWM mode, it is generated when the TSG2nDTC0 buffer register value matches with the 16-bit counter value. When the 16-bit counter performs sawtooth wave operation (PWM mode, SP-PWM mode, and 120-DC mode), it is generated after the 16-bit counter value has matched with the TSG2nCMP0 buffer register value.

A compare match interrupt (INTTSG2nIm) is generated on matches between the TSG2nCMPm buffer register value and the 16-bit counter value depending on the compare register to be used in each operating mode (m = 1 to 12).

A peak interrupt (INTTSG2nIPEK) is generated in all modes. In HT-PWM mode, it is generated when the 16-bit counter switches from incrementing to decrementing. When the 16-bit counter performs sawtooth wave operation (PWM mode, SP-PWM mode, and 120-DC mode), it is generated after the 16-bit counter value has matched with the TSG2nCMP0 buffer register value (the same timing as an INTTSG2nI[0] interrupt).

A trough interrupt (INTTSG2nIVLY) is generated when the 16-bit counter switches from decrementing to incrementing in HT-PWM mode.

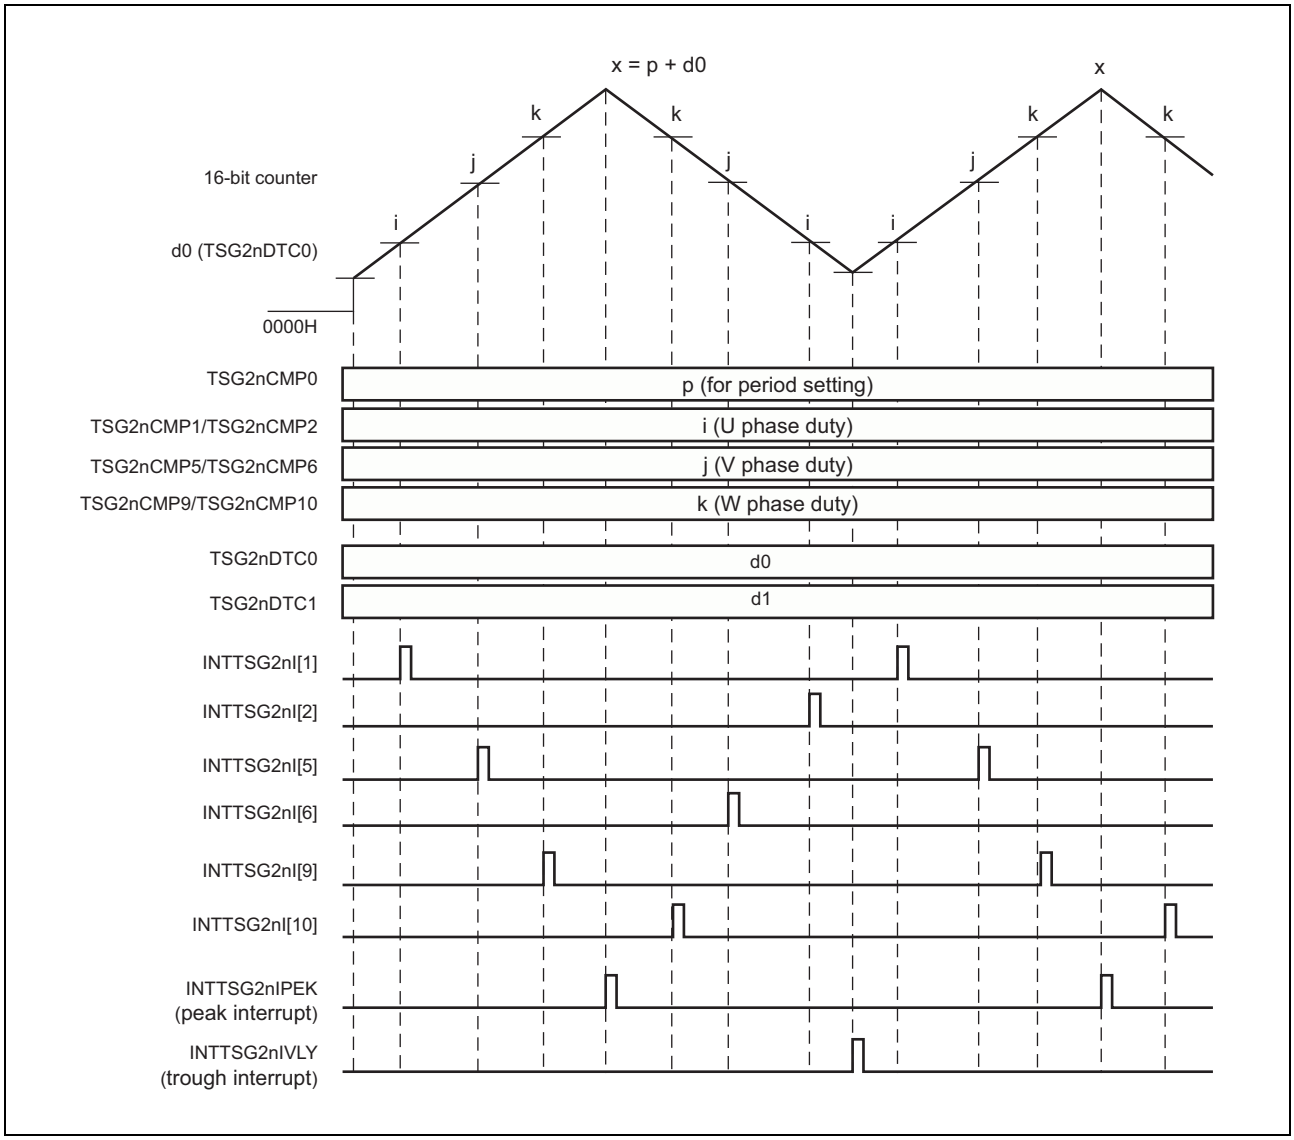

Figure 23.15 Interrupt Generation Example (1/2) (Example of HT-PWM Mode)

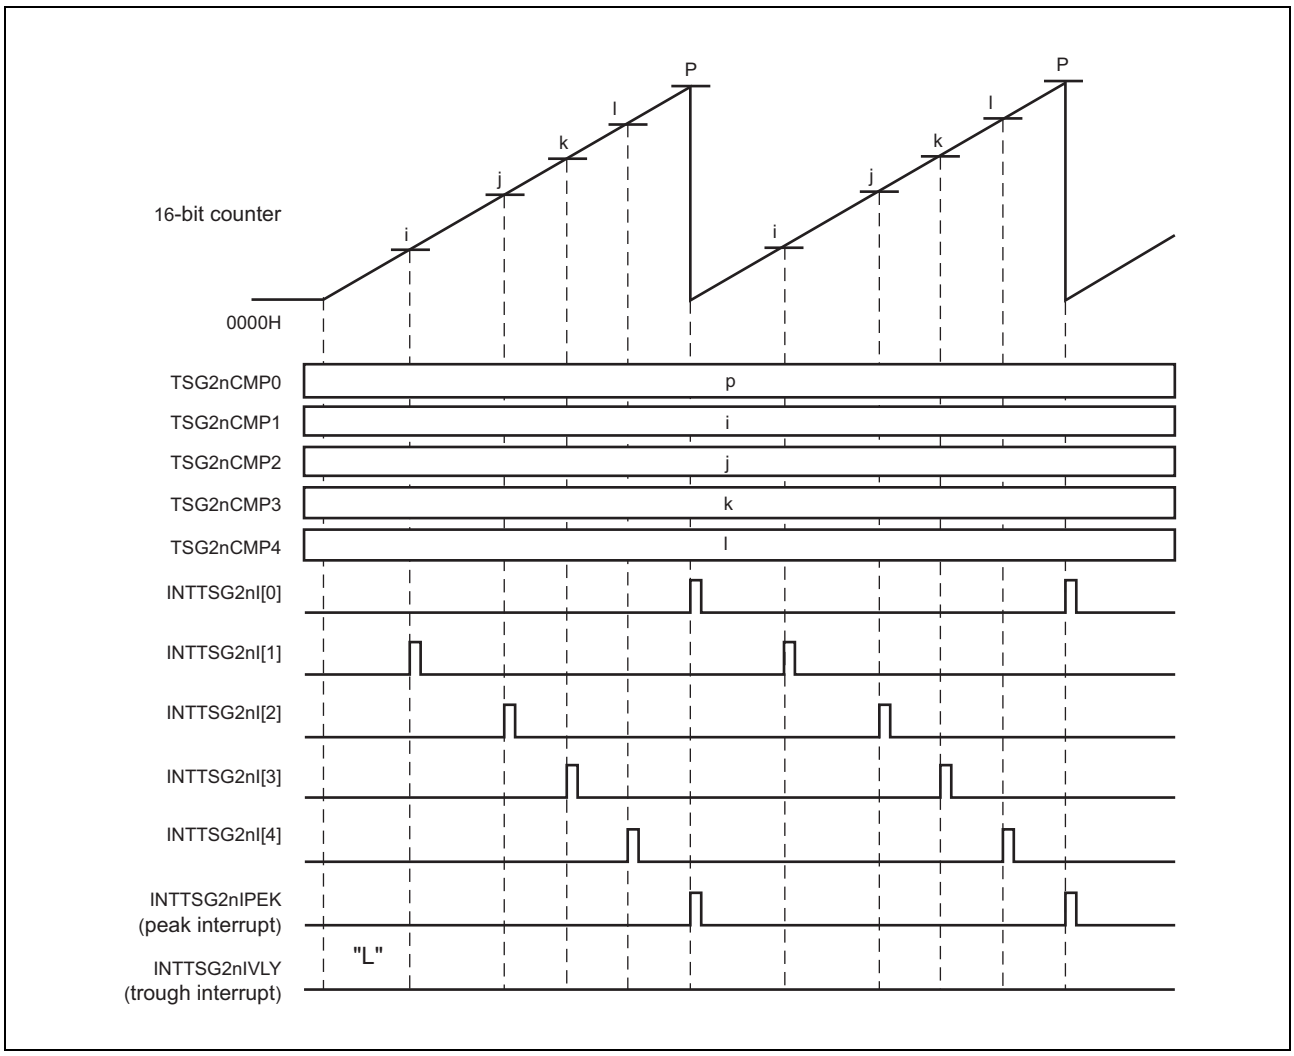

Figure 23.16 Interrupt Generation Example (2/2) (Example of PWM Mode)

23.7 Flags

Table 23.42 List of Flags

No.	Flag Name	Symbol	Register	Operating Mode
(1)	Up-count flag	TSG2nCUF	TSG2nSTR0	HT-PWM mode
		TSG2nSUF	TSG2nSTR0	
(2)	Positive/negative phase simultaneous activation detection flag	TSG2nTBF0-TSG2nTBF2	TSG2nSTR2	All operating modes
(3)	Reload request flag	TSG2nRSF	TSG2nSTR0	All operating modes
(4)	Noise detection flag	TSG2nNDF	TSG2nSTR2	All operating modes
(5)	Pattern order detection flag	TSG2nTSF	TSG2nSTR1	All operating modes
(6)	Pattern error detection flag	TSG2nPEF	TSG2nSTR2	All operating modes
(7)	Pattern inversion detection flag	TSG2nPRF	TSG2nSTR2	All operating modes
(8)	Pattern phase difference detection flag	TSG2nPPF	TSG2nSTR2	All operating modes
(9)	Timer output pattern flag	TSG2nOPF0-TSG2nOPF2	TSG2nSTR1	All operating modes
(10)	Pattern switch detection signal (internal signal)	TSG2nPTE	—	All operating modes

23.7.1 Up-Count Flags (TSG2nCUF and TSG2nSUF)

Name

Up count flag (TSG2nSTR0.TSG2nCUF and TSG2nSUF)

Description

There are following two up-count flags.

TSG2nCUF is an up-/down-count flag of the 16-bit counter.

TSG2nSUF is an up-/down-count flag of the 16-bit sub-counter.

For both TSG2nCUF and TSG2nSUF, 0 indicates incrementing, whereas 1 indicates decrementing.

TSG2nCUF and TSG2nSUF can be used only in HT-PWM mode.

Example of operation

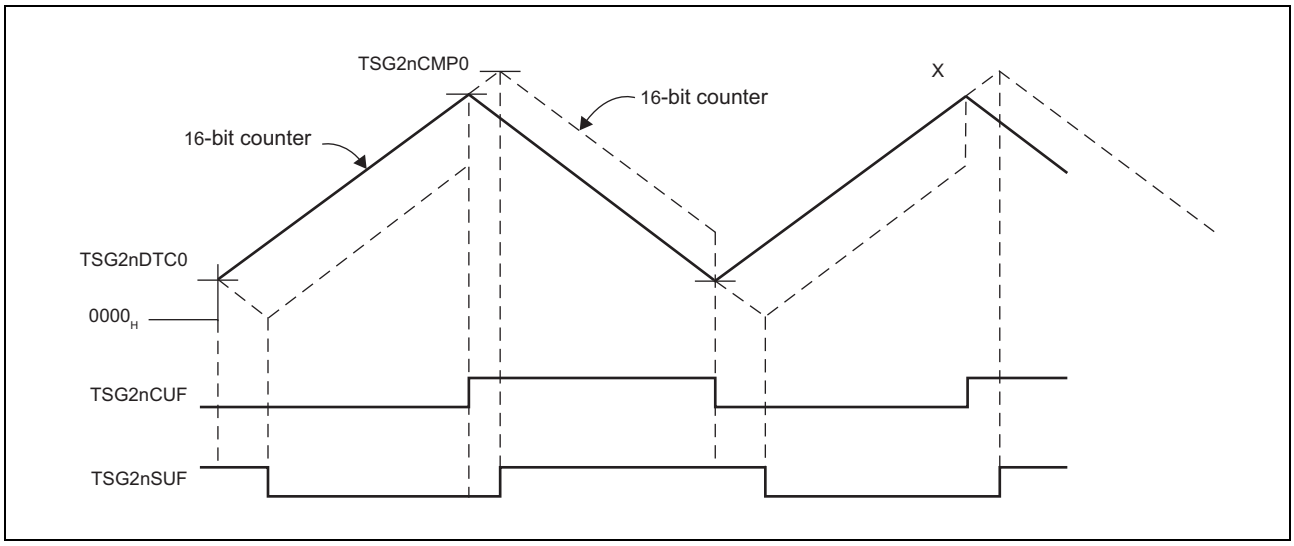

Figure 23.17 Example of Up-Count Flag Operation

NOTES

1. TSG2nCUF is set to the value as below:
   0 (up-count) when TSG2nDTC0 ≤ 16-bit counter ≤ (TSG2nCMP0 + TSG2nDTC0 - 2)
   1 (down-count) when (TSG2nCMP0 + TSG2nDTC0) ≥ 16-bit counter ≥ TSG2nDTC0 + 2
2. TSG2nSUF is set to the value as below:
   0 (up-count) when 0 ≤ 16-bit sub-counter ≤ (TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1 - 2)
   1 (down-count) when (TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1) ≥ 16-bit sub-counter ≥ 2

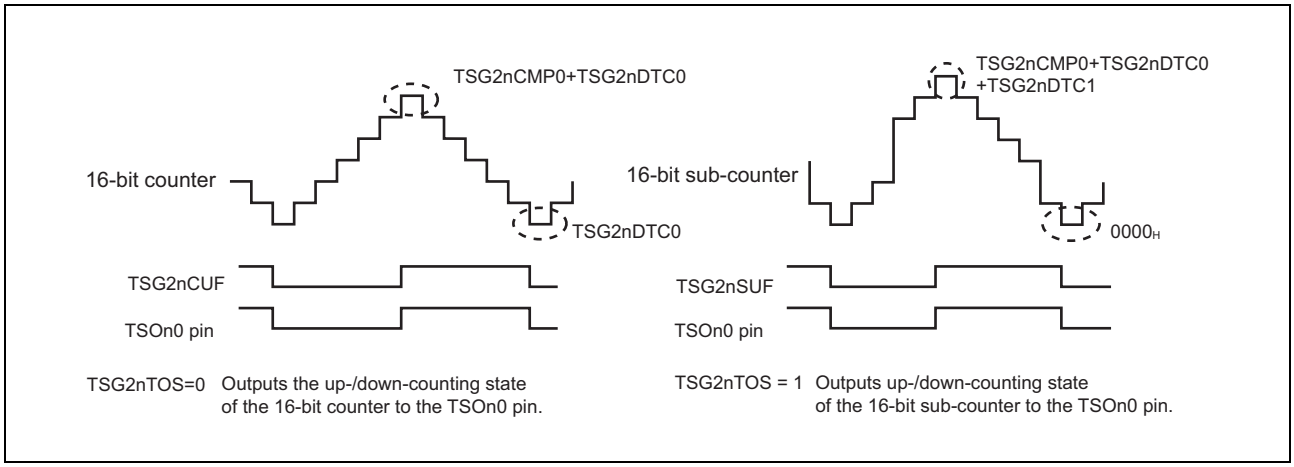

Figure 23.18 TSOn0 Pin Output depending onTSG2nIOC1.TSG2nTOS Setting

Operating mode

TSG2nCUF and TSG2nSUF can be used only in HT-PWM mode.

23.7.2 Positive/Negative Phase Simultaneous Activation Detection Flags (TSG2nTBF0 to TSG2nTBF2)

Name

Positive phase and negative phase simultaneous activation detection flags (TSG2nSTR2.TSG2nTBF0 to TSG2nTBF2 flags)

Description

When any of TSG2nCTL1.TSG2nTBA2 to TSG2nTBA0 is 1, TSG2nTBF0 to TSG2nTBF2 can detect simultaneous activation of the positive and negative phases of TSG2n.

When the simultaneous active state of the positive phase and inverse phase of the TSG2n is detected, the corresponding TSG2nTBF0 to TSG2nTBF2 flags are set to 1, and an error interrupt (INTTSG2nIER) is generated. The flags are cleared when 1 is written to TSG2nSTC.TSG2nTBR0 to TSG2nTBR2, respectively.

Example of operation

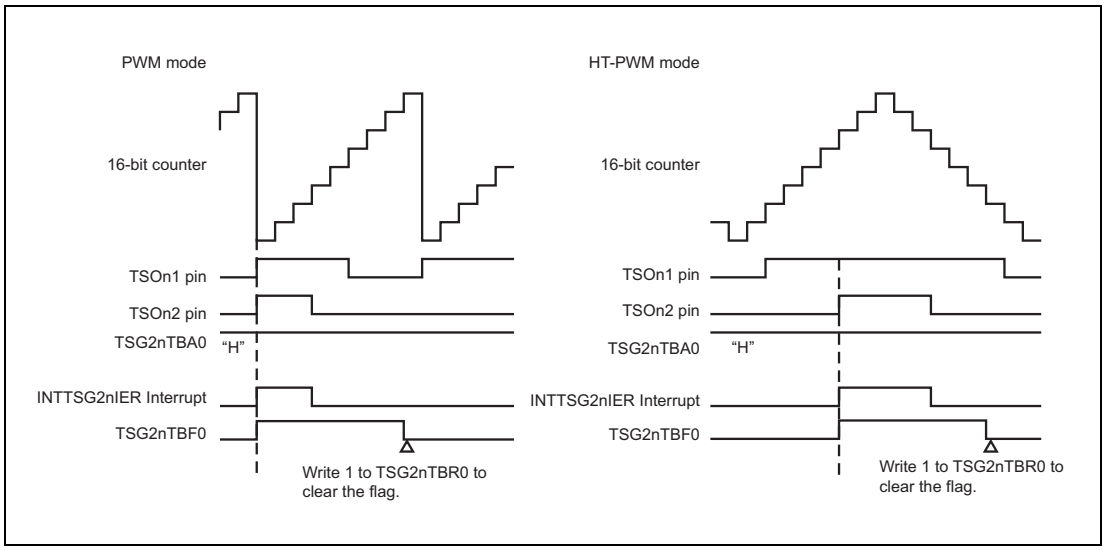

Figure 23.19 Example of Positive /Negative Phase Simultaneous Activation Detection Flag Operation

Operating mode

TSG2nTBF0 to TSG2nTBF2 can be used in all operating modes.

CAUTION

TSG2nTBF0 to TSG2nTBF2 are valid only when TSG2nCTL1.TSG2nTBA0 to TSG2nTBA2 = 1 and TSG2nSTR0.TSG2nTE = 1.

23.7.3 Reload Request Flag (TSG2nRSF)

Name

Reload request flag (TSG2nSTR0.TSG2nRSF)

Description

TSG2nRSF is set to 1 when a reload request is generated (when a value is written to TSG2nCMP1 (TSG2nCMP1W, TSG2nCMPU, TSG2nCPW)), and cleared to 0 when the value is transferred to all the buffer registers.

Example of operation

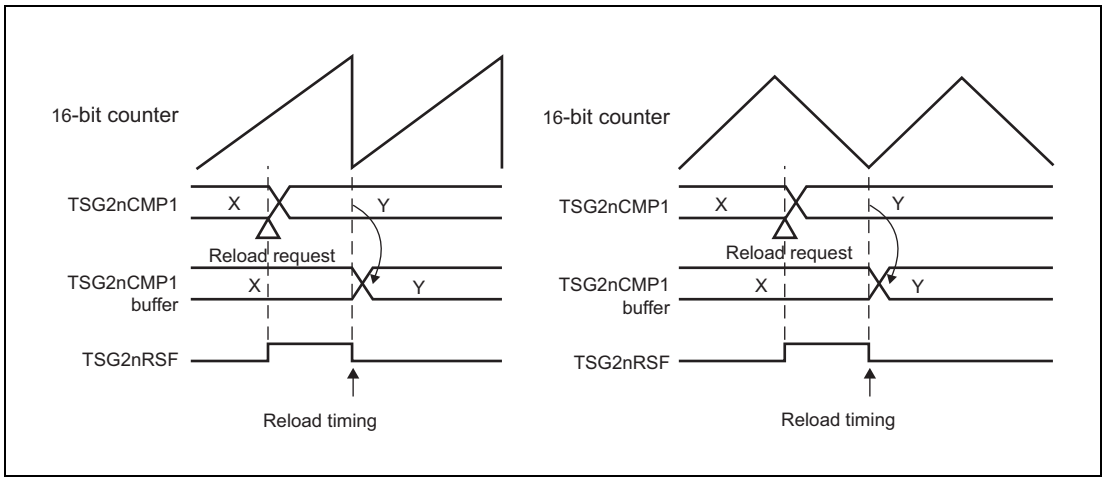

Figure 23.20 Example of Reload Request Flag Operation

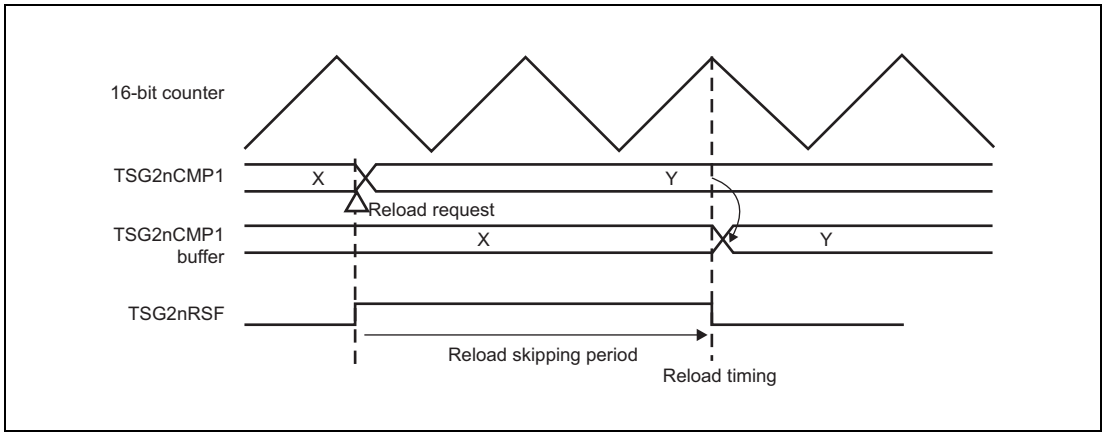

Figure 23.21 Reload Request Flag and Reload Skipping Period

Operating Mode

TSG2nRSF can be used in all operating modes.

23.7.4 Noise Detection Flag (TSG2nNDF)

Name

Noise detection flag (TSG2nSTR2.TSG2nNDF)

Description

TSG2nNDF can detect that two or more pins of TAPTSn2 to TAPTSn0 have changed simultaneously (a noise is generated).

TSG2nNDF is set to 1 when two or more pins of TAPTSn2 to TAPTSn0 have changed simultaneously (a noise is generated), and a warning interrupt (INTTSG2nIWN) is generated. The TSG2nNDF flag is cleared to 0 when 1 is written to the TSG2nSTC.TSG2nNDR bit.

Example of operation

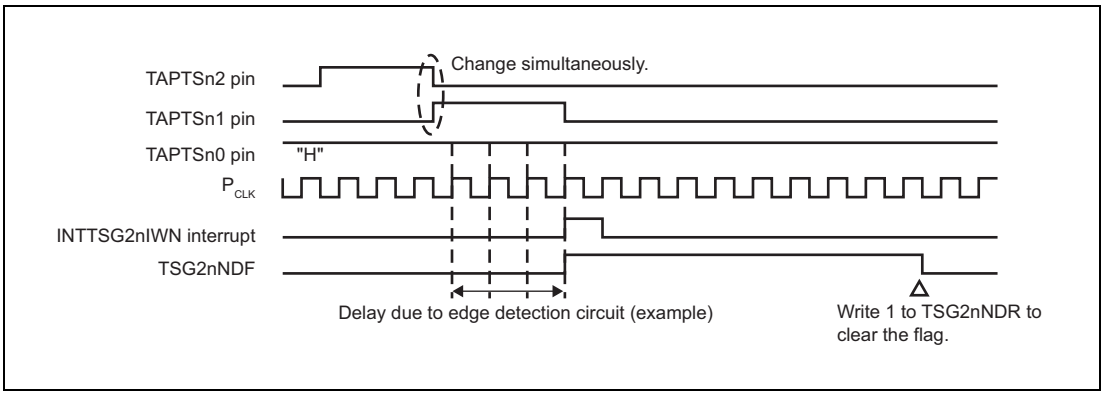

Figure 23.22 Example of Noise Detection Flag Operation

Operating mode

TSG2nNDF can be used in all operating modes.

CAUTION

TSG2nNDF is valid only when TSG2nCTL1.TSG2nNDC = 1 and TSG2nSTR0.TSG2nTE = 1.

23.7.5 Pattern Order Detection Flag (TSG2nTSF)

Name

Pattern order detection flag (TSG2nSTR1.TSG2nTSF)

Description

TSG2nTSF can detect the order of patterns input to the TAPTSn2 to TAPTSn0 pins.

TSG2nTSF is set depending on the values input to the TAPTSn2 to TAPTSn0 pins as shown in the table below.

TSG2nTSF	Values input to TAPTSn2 to TAPTSn0 Pins
0	[1,0,1] → [1,0,0] → [1,1,0] → [0,1,0] → [0,1,1] → [0,0,1]
1	[1,0,1] ← [1,0,0] ← [1,1,0] ← [0,1,0] ← [0,1,1] ← [0,0,1]

Example of operation

23.7.5.1 When Normal Input to TAPTSn2 to TAPTSn0 Pins is Detected

As shown in **Figure 23.23**, if the TAPTSn2 to TAPTSn0 pins change in the normal order, 0 or 1 is set according to the change order at the change timing.

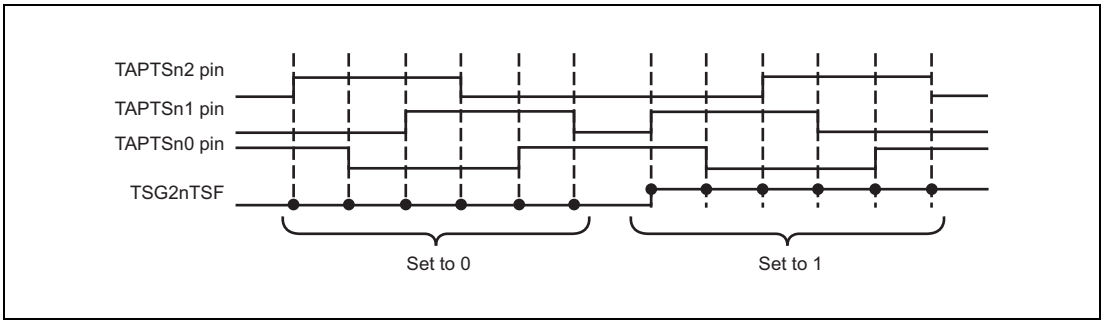

Figure 23.23 Example of Pattern Order Detection Flag Operation (Normal Operation)

23.7.5.2 Detection of Input Pattern Change

Immediately after TSG2n starts operation, the rotation direction cannot be determined. Therefore, TSG2nTSF cannot detect a change (normal or reverse rotation) in the pattern input to the TAPTSn2 to TAPTSn0 pins. To enable detection of a change immediately after the start of operation, TSG2nPSC should be set before operation starts (when TSG2nTE = 0, the TSG2nPSC value is reflected).

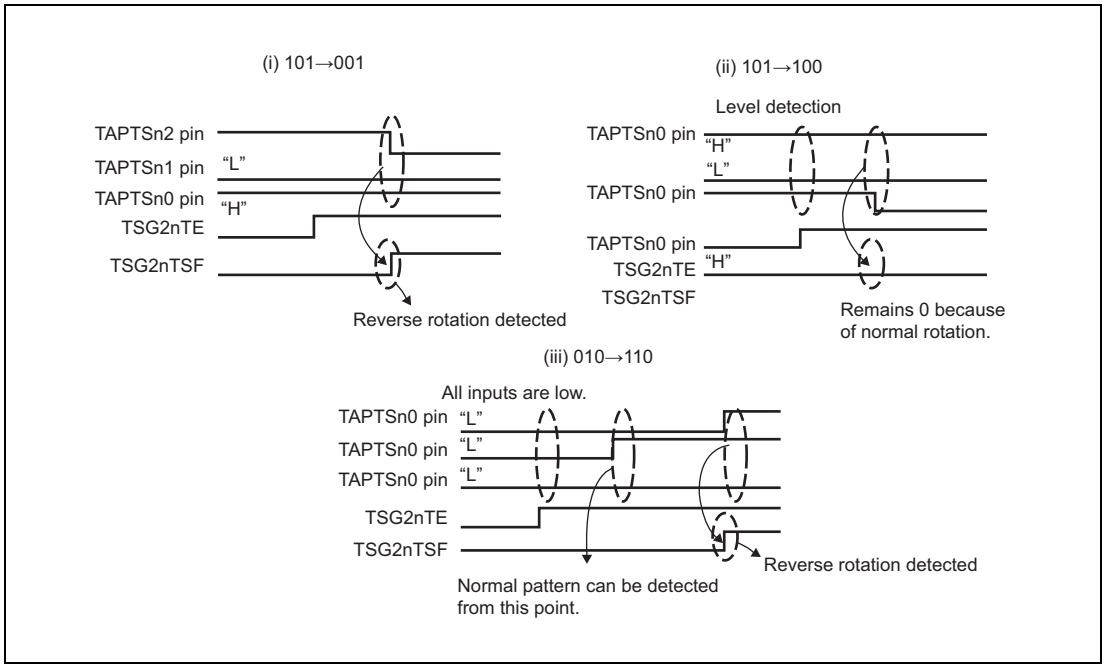

Figure 23.24 Detection of a Change (Normal/Reverse Rotation) in the Pattern Input to TAPTSn2-TAPTSn0 Pins

23.7.5.3 When Abnormal Input to TAPTSn2-TAPTSn0 Pins is Detected

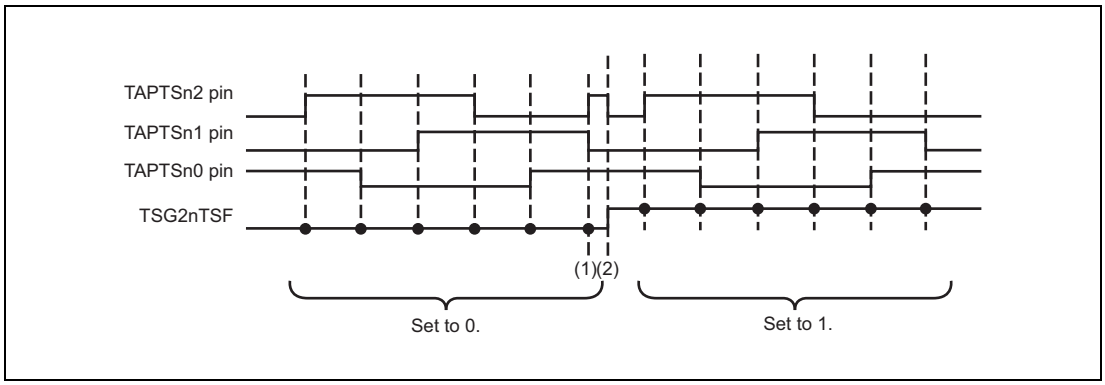

Figure 23.25 Example of Operation when Values Input to Two Pins of TAPTSn2-TAPTSn0 Change (Abnormal Operation)

(1) TSG2nTSF does not change at this point because it expects the input pattern change to {0, 1, 0} or {0, 0, 1} (if values of two pins change, TSG2nTSF does not change).

(2) The TAPTSn2-TAPTSn0 pins are judged to have been changed from {1, 0, 1} to {0, 0, 1}, and TSG2nTSF is set to 1.

Operating Mode

TSG2nTSF can be used in all operating modes.

23.7.6 Pattern Error Detection Flag (TSG2nPEF)

Name

Pattern error detection flag (TSG2nSTR2.TSG2nPEF)

Description

TSG2nPEF can detect that 000 or 111 has been input to the TAPTSn2-TAPTSn0 pins.

TSG2nPEF is set to 1 when the levels of the TAPTSn2-TAPTSn0 pins are 111 or 000, and a warning interrupt (INTTSG2nIWN) is generated. TSG2nPEF is cleared to 0 when 1 is written to TSG2nSTC.TSG2nPER.

Example of operation

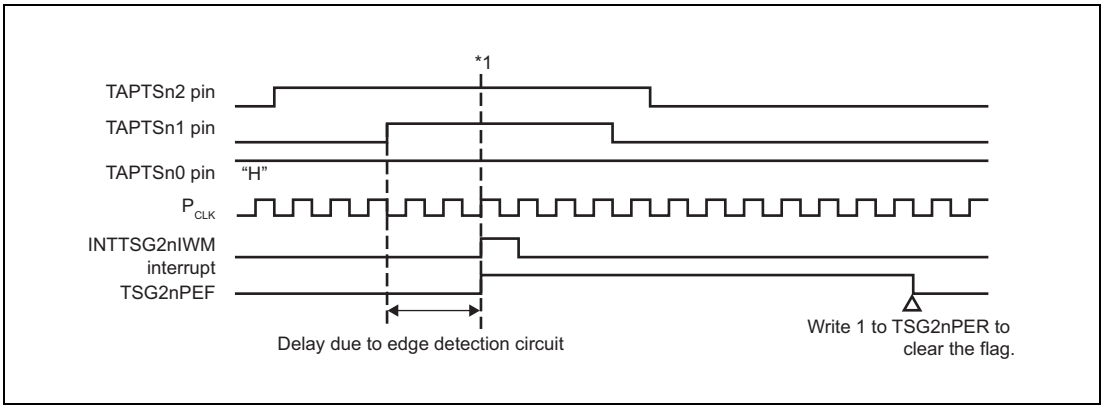

Figure 23.26 Example of Pattern Error Detection Flag Operation (TAPTSn2-TAPTSn0 Pins = 111)

CAUTION

"111" is detected.

Operating mode

TSG2nPEF can be used in all operating modes.

CAUTION

TSG2nPEF is valid only when TSG2nCTL1.TSG2nPEC = 1 and TSG2nSTR0.TSG2nTE = 1.

23.7.7 Pattern Inversion Detection Flag (TSG2nPRF)

Name

Pattern reversal inversion flag (TSG2nSTR2.TSG2nPRF)

Description

TSG2nPRF can detect that the pattern change order of the TAPTSn2 to TAPTSn0 pins have been inverted.

TSG2nPRF is set to 1 when the pattern order detection flag (TSG2nTSF) changes, and a warning interrupt (INTTSG2nIWN) is generated. However, immediately after TSG2nSTR0.TSG2nTE is set to 1, TSG2nPRF is valid at the timing of the second and subsequent change in TAPTSn2 to TAPTSn0 pins. TSG2nPRF is cleared to 0 when 1 is written to the TSG2nSTC.TSG2nPRR bit.

Example of operation

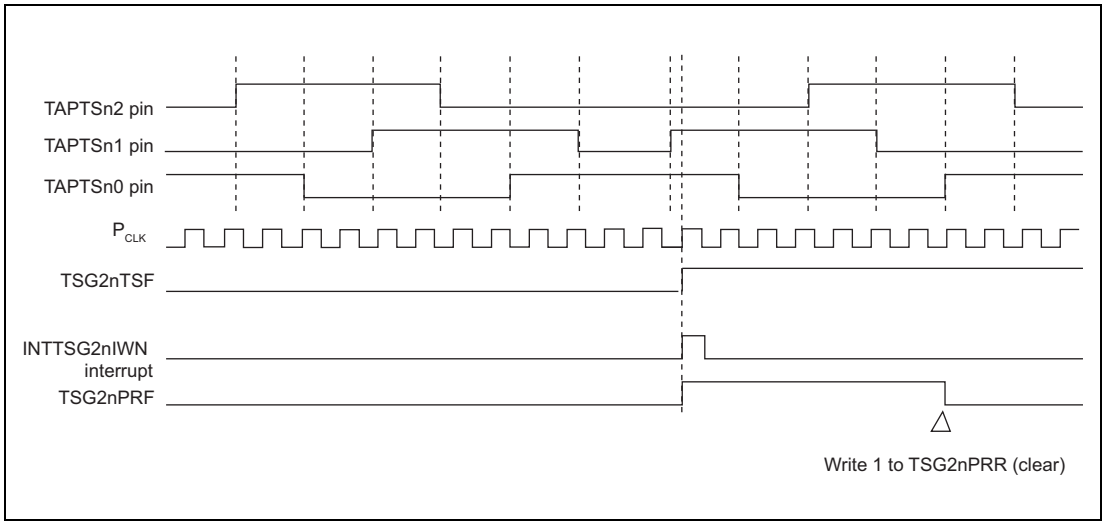

Figure 23.27 Example of Pattern Inversion Detection Flag Operation

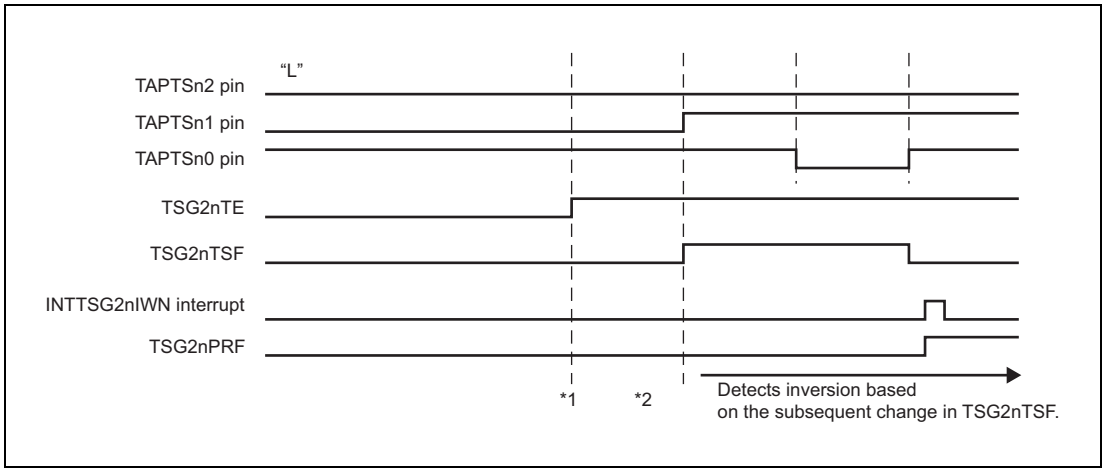

Figure 23.28 Example of Operation immediately after TSG2nTE Flag in TSG2nSTR0 is Set to 1

CAUTIONS

1. **Operation starts.**
2. **If TSG2nTSF is set to 1 by the first change in the TAPTSn2 to TAPTSn0 pins immediately after TSG2nTE is set to 1, inversion is not detected.**

Operating mode

TSG2nPEF can be used in all operating modes.

CAUTION

TSG2nPEF is valid only when TSG2nCTL1.TSG2nPEC = 1 and TSG2nSTR0.TSG2nTE = 1.

23.7.8 Pattern Phase Difference Detection Flag (TSG2nPPF)

Name

Pattern phase difference detection flag (TSG2nSTR2.TSG2nPPF)

Description

TSG2nPPF can detect the phase difference between the input pattern (TAPTSn2-TAPTSn0 pins) and the output pattern (TSG2nSTR1.TSG2nOPF2 to TSG2nOPF0 flags).

TSG2nPPF is set to 1 when the pattern phase difference is detected, and a warning interrupt (INTTSG2nIWN) is generated. TSG2nPPF remains 1 until it is cleared to 0 when 1 is written to TSG2nSTC.TSG2nPPR by software. When the phase difference is detected, TSG2nPPF is set at each operation clock cycle (PCLK). TSG2nPPF should be cleared to 0 when no phase difference occurs.

Table 23.43 Correspondence between Normal Input Patterns and Output Patterns

TAPTSn2-TAPTSn0 pins (input)	“1,0,1”	“1,0,0”	“1,1,0”	“0,1,0”	“0,1,1”	“0,0,1”
TSG2nOPF2-TSG2bOPF0 flags (output)	“0,0,1” “1,0,1” “1,0,0”	“1,0,1” “1,0,0” “1,1,0”	“1,0,0” “1,1,0” “0,1,0”	“1,1,0” “0,1,0” “0,1,1”	“0,1,0” “0,1,1” “0,0,1”	“0,1,1” “0,0,1” “1,0,1”

Example of operation

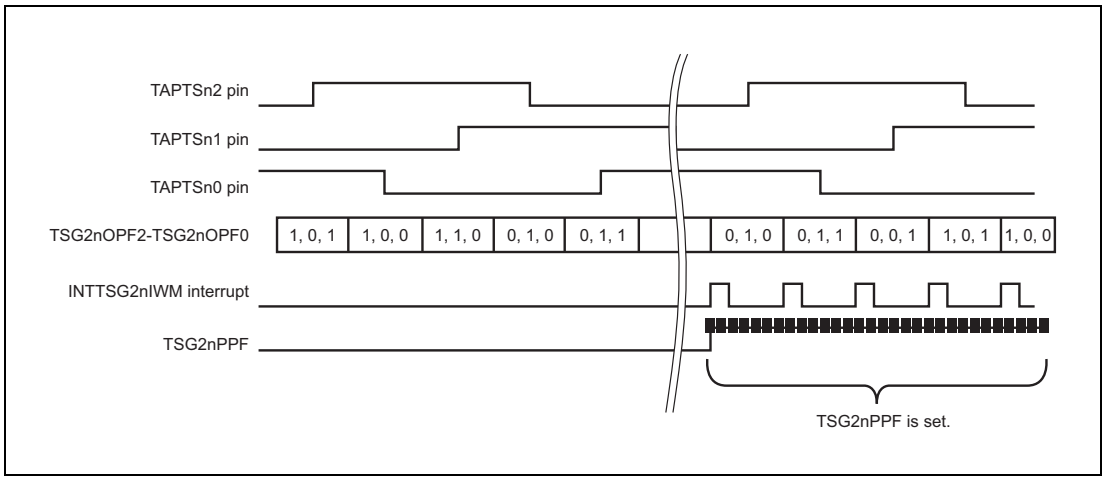

Figure 23.29 Example of Pattern Difference Detection Flag Operation

Operating mode

TSG2nPPF can be used in all operating modes.

CAUTIONS

1. **TSG2nPPF is valid only when TSG2nCTL1.TSG2nPPC = 1 and TSG2nSTR0.TSG2nTE = 1.**
2. **When 000 or 111 is input to the TAPTSn2 to TAPTSn0 pins, or when TSG2nOPF2 to TSG2nOPF0 are set to 000 or 111, TSG2nPPF is not set.**

23.7.9 Timer Output Pattern Flag (TSG2nOPF2-TSG2nOPF0)

Name

Timer output pattern flag (TSG2nSTR1.TSG2nOPF2-TSG2nOPF0)

Description

TSG2nOPF2 to TSG2nOPF0 flags indicate the timer output patterns.

Operating mode

TSG2nOPF2 to TSG2nOPF0 can be used in all operating modes.

23.7.10 Pattern Switch Detection Signal (TSG2nPTE)

Name

Pattern switch detection signal (TSG2nPTE signal)

Description

The TSG2nPTE signal toggles when the input pattern (TAPTSn2-TAPTSn0 pins) changes.

The toggle pattern is determined by the TSG2nPSC bit (TSG2nOPT0.TSG2nPSS = 1).

- TSG2nPSC = 0

		TAPTSn2-TAPTSn0 Pins after Change							
		000	111	101	100	110	010	011	001
Current TAPTSn2-TAPTSn0 pins	000	—	—	—	—	—	—	—	—
	111	—	—	—	—	—	—	—	—

Example of operation

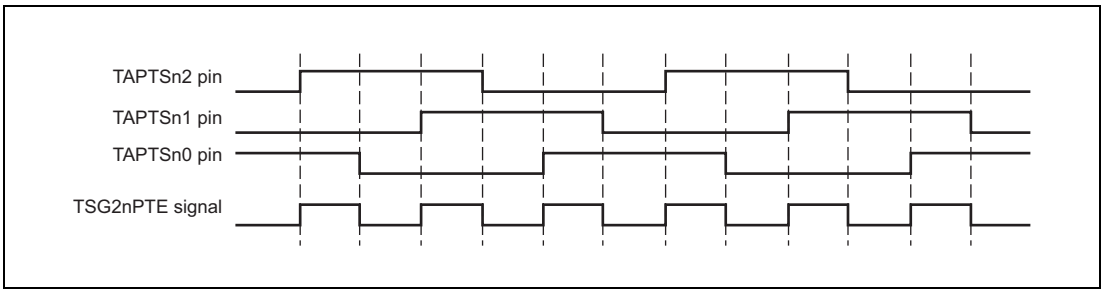

Figure 23.30 Example of Pattern Switch Detection Signal Operation

23.8 Operation of Interrupt Skipping Function

Operation related to the interrupt skipping function is described below.

Peak interrupts (INTTSG2nIPEK) and trough interrupts (INTTSG2nIVLY) can be skipped.

- TSG2nCTL4.TSG2nPIE enables output of the INTTSG2nIPEK interrupt and specifies whether to skip the interrupts.
- TSG2nCTL4.TSG2nVIE enables output of the INTTSG2nIVLY interrupt and specifies whether to skip the interrupts.

When TSG2nCTL3.TSG2nRIA is set to 1 (with reload skipping), reload is executed at the same timing as the interrupt after being skipped.

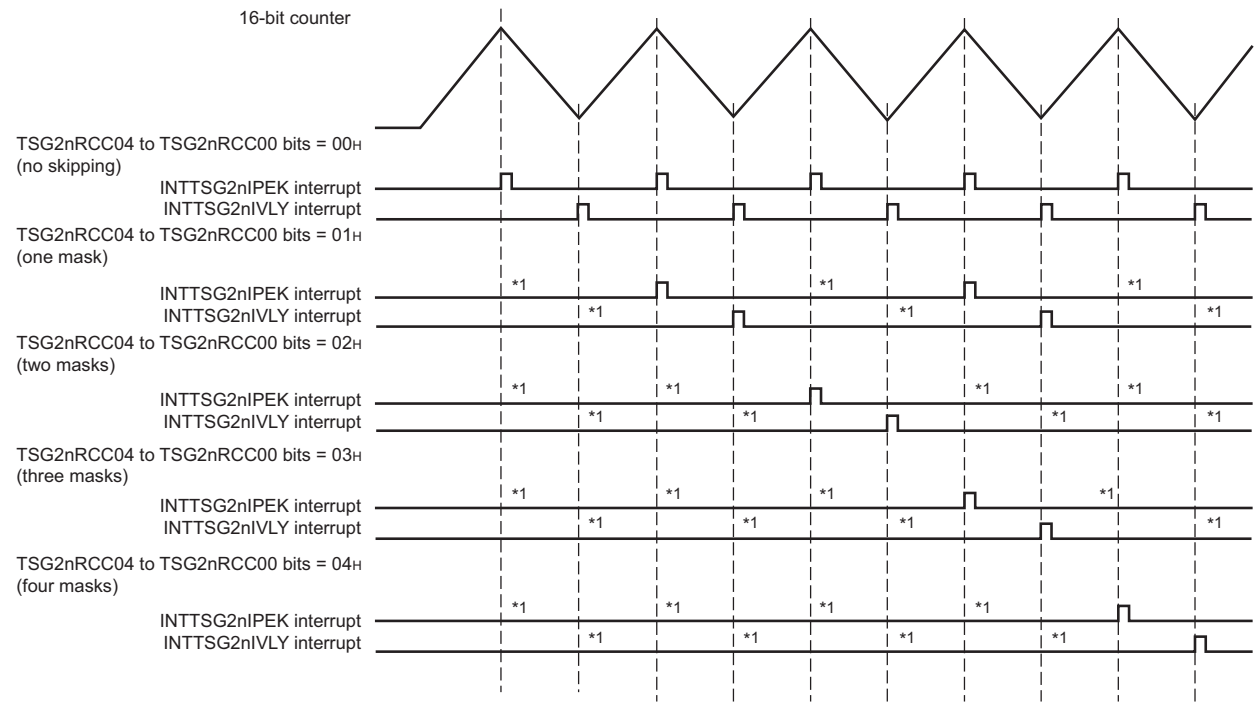
When TSG2nCTL3.TSG2nRIA is set to 0 (without reload skipping), reload is executed at the specified reload timing regardless of interrupt skipping.

CAUTION

When a value is written to TSG2nCTL4, and TSG2nRCC04 to TSG2nRCC00 are transferred to the buffer register, the interrupt skipping counter is cleared. Therefore, when the interrupt skipping function is used, the interrupt interval may be long temporarily. To avoid this, the interrupt skipping count should be changed with the reload timing being set to the interrupts skipped (TSG2nCTL3.TSG2nRIA = 1).

23.8.1 Operation of Interrupt Skipping Function

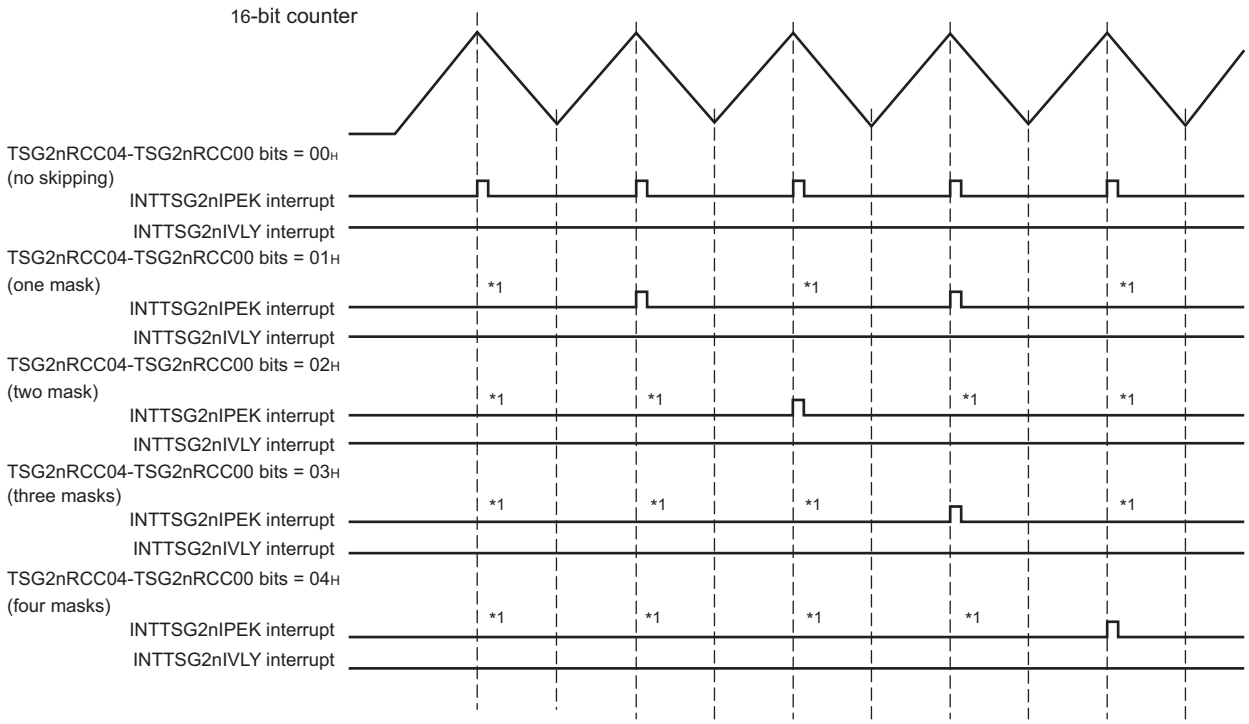
23.8.1.1 Interrupt Skipping Operation when TSG2nPIE = 1 and TSG2nVIE = 1 in TSG2nCTL4 (Peak and Trough Interrupt Generation in HT-PWM Mode)



Note 1. Skipped interrupt request

Figure 23.31 When TSG2nPIE = 1 and TSG2nVIE = 1 in TSG2nCTL4 (Peak and Trough Interrupt Generation in HT-PWM Mode)

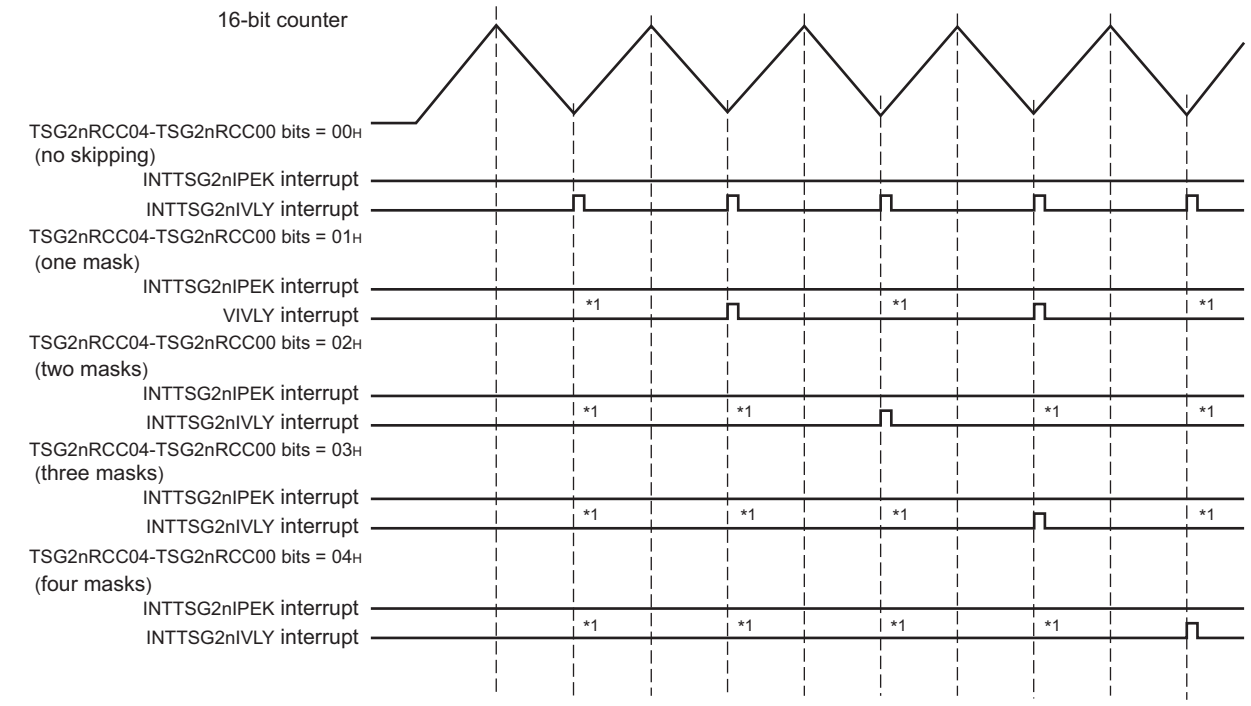
23.8.1.2 Interrupt Skipping Operation when TSG2nPIE = 1 and TSG2nVIE = 0 in TSG2nCTL4 (Generation of Only Peak Interrupts in HT-PWM Mode)



Note 1. Skipped interrupt request

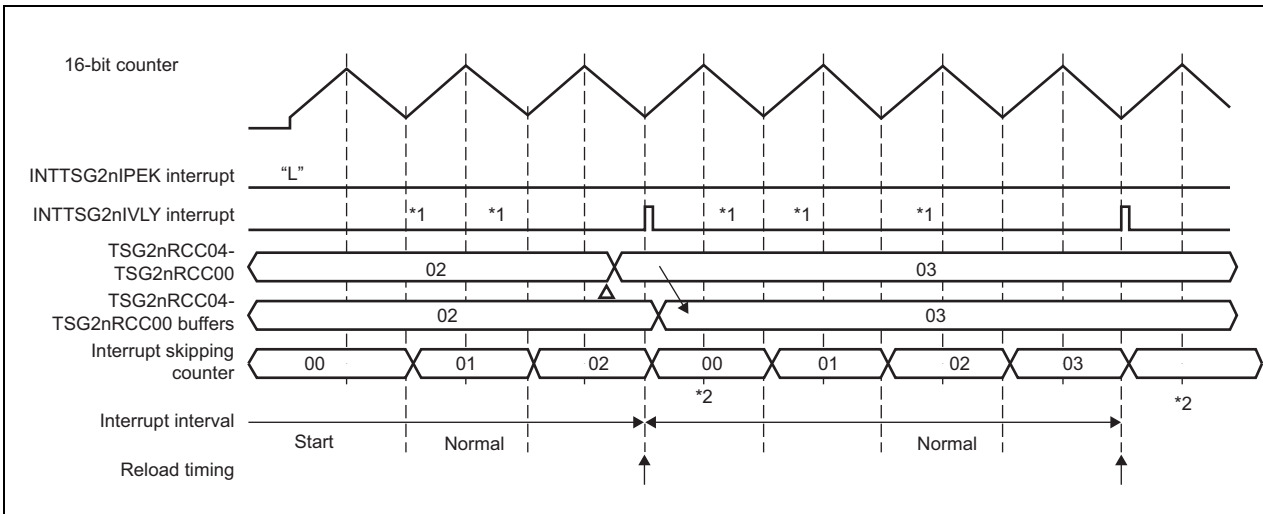
Figure 23.32 When TSG2nPIE = 1 and TSG2nVIE = 0 in TSG2nCTL4 (Generation of Only Peak Interrupts in HT-PWM Mode)

23.8.1.3 Interrupt Skipping Operation when TSG2nPIE = 0 and TSG2nVIE = 1 in TSG2nCTL4 (Generation of Only Trough Interrupts in HT-PWM Mode)



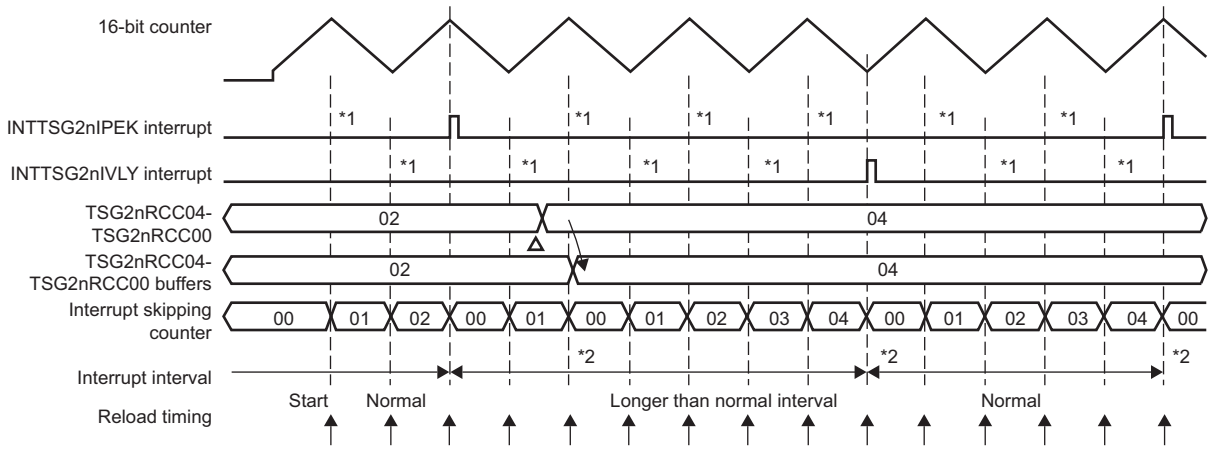
Note 1. Skipped interrupt request

Figure 23.33 When TSG2nPIE = 0 and TSG2nVIE = 1 in TSG2nCTL4 (Generation of Only Trough Interrupts in HT-PWM Mode)



Note 1. Skipped interrupt request
Note 2. Clearing of the interrupt skipping counter

Figure 23.34 When TSG2nRMC = 0 and TSG2nRIA = 1 in TSG2nCTL3 (with Reload Skipping)



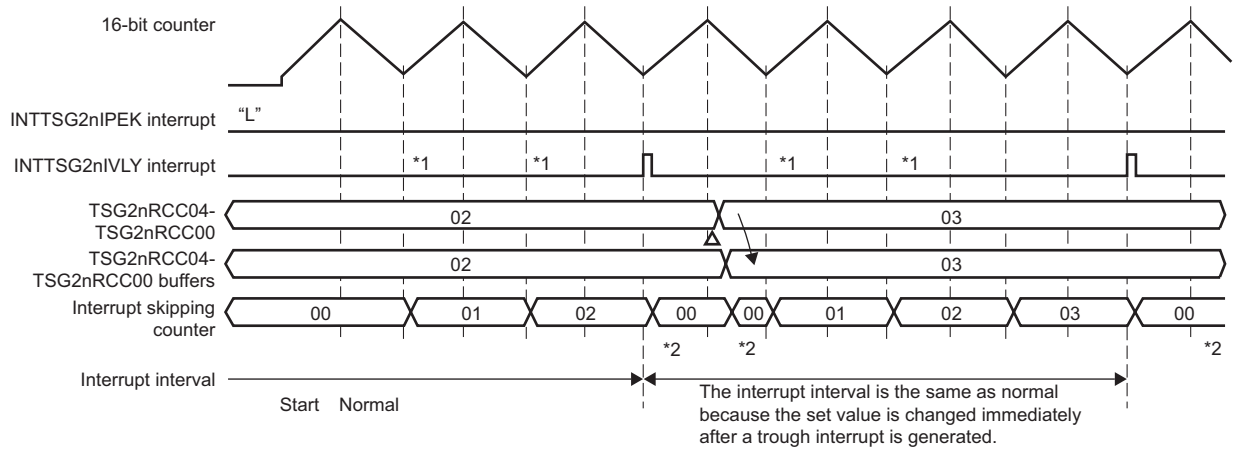
Note 1. Skipped interrupt request

Note 2. Clearing of the interrupt skipping counter

Figure 23.35 When TSG2nRMC = 0 and TSG2nRIA = 0 in TSG2nCTL3 (without Reload Skipping)

CAUTION

The interrupt interval might be longer.



Note 1. Skipped interrupt request
Note 2. Clearing of the interrupt skipping counter

Figure 23.36 When TSG2nRMC = 1 in TSG2nCTL3 (Anytime Rewriting)

CAUTION

The interrupt interval might be longer.

NOTE

After rewriting, the value is reflected immediately regardless of the reload timing. The interrupt skipping counter is cleared when the value is transferred to the TSG2nRCC04 to TSG2nRCC00 buffers, not when the pertinent register is rewritten.

23.8.2 Example of Operation when Peak Interrupt is Generated (in PWM Mode)

Operation related to the interrupt skipping function in PWM mode is described below.

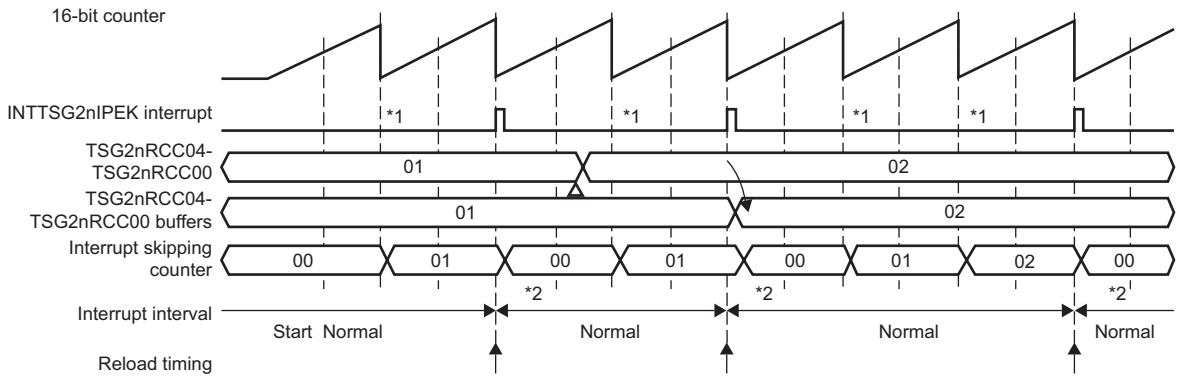
- Trough interrupts (INTTSG2nIPEK) can be skipped. In PWM mode, it is generated on compare match between the TSG2nCMP0 buffer register and the 16-bit counter.
- TSG2nCTL4.TSG2nPIE enables output of the INTTSG2nIVLY interrupt and specifies whether to skip the interrupts.
- The setting of TSG2nCTL4.TSG2nVIE is disabled. At this time, the INTTSG2nIVLY interrupt is not generated.

When TSG2nCTL3.TSG2nRIA is set to 1 (with reload skipping), reload is executed at the same timing as the interrupt after being skipped.

CAUTION

When a value is written to TSG2nCTL4, and TSG2nRCC04 to TSG2nRCC00 are transferred to the buffer register, the interrupt skipping counter is cleared. Therefore, when the interrupt skipping function is used, the interrupt interval may be long temporarily. To avoid this, the interrupt skipping count should be changed with the reload timing being set to the interrupts skipped (TSG2nCTL3.TSG2nRIA = 1).

23.8.2.1 Example of Operation



Note 1. Skipped interrupt request
Note 2. Clearing of the interrupt skipping counter

Figure 23.37 When TSG2nCTL3.TSG2nRMC = 0, TSG2nRIA = 1 and TSG2nCTL4.TSG2nPRE = 1 (Recommended Setting)

NOTE

When TSG2nCTL3.TSG2nRIA = 1, reload is executed at the same timing as the interrupt after being skipped.

23.9 A/D Conversion Trigger Function

A/D conversion trigger operation is described below.

TSG2nDCMP0W and TSG2nDCMP2 are used as compare registers of the A/D conversion trigger function.

23.9.1 A/D Operation of A/D Conversion Trigger

TSG2n has a function to generate A/D conversion start triggers (TSTADT0 and TSTADT1 signals) by selecting any of ten trigger sources as required.

The trigger sources are selected by TSG2nAT09 to TSG2nAT00 in TSG2nCTL5 and TSG2nAT19 to TSG2nAT10 in TSG2nCTL6.

23.9.1.1 TSTADT0/TSTADT1 Signal Output Control (TSG2nCTL5 and TSG2nCTL6)

[Trigger source]

- TSG2nAT00/TSG2nAT10 = 1: A trough interrupt (INTTSG2nIVLY) causes an A/D conversion trigger pulse to be generated.
- TSG2nAT01/TSG2nAT11 = 1: A peak interrupt (INTTSG2nIPEK) causes an A/D conversion trigger pulse to be generated.
- TSG2nAT02/TSG2nAT12 = 1: While the 16-bit counter is counting up, a TSG2nDCMP0 compare match enables A/D conversion trigger to be generated.
- TSG2nAT03/TSG2nAT13 = 1: While the 16-bit counter is counting down, a TSG2nDCMP0 compare match enables A/D conversion trigger to be generated.
- TSG2nAT04/TSG2nAT14 = 1: While the 16-bit counter is counting up, a TSG2nDCMP1 compare match enables A/D conversion trigger to be generated.
- TSG2nAT05/TSG2nAT15 = 1: While the 16-bit counter is counting down, a TSG2nDCMP1 compare match enables A/D conversion trigger to be generated.
- TSG2nAT06/TSG2nAT16 = 1: While the 16-bit counter is counting up, a TSG2nDCMP2 compare match enables A/D conversion trigger to be generated.
- TSG2nAT07/TSG2nAT17 = 1: While the 16-bit counter is counting down, a TSG2nDCMP2 compare match enables A/D conversion trigger to be generated.
- TSG2nAT08/TSG2nAT18 = 1: A trough timing of the 16-bit sub-counter (at a switch from decrementing to incrementing) enables A/D conversion trigger to be generated.
- TSG2nAT09/TSG2nAT19 = 1: A peak timing of the 16-bit sub-counter (at a switch from incrementing to decrementing) enables A/D conversion trigger to be generated.

[Skipping setting]

- TSG2nACC01 and TSG2nACC00, and TSG2nACC11 and TSG2nACC10:Set the skipping rate of the TSTADT0 and TSTADT1 signals, respectively.

All A/D conversion triggers selected by TSG2nAT09 to TSG2nAT00 and TSG2nAT19 to TSG2nAT10 are logically ORed, and the resultant signals are subjected to skipping control specified by TSG2nACC01 and TSG2nACC00, and TSG2nACC11 and TSG2nACC10, and then the TSTADT0 and TSTADT1 signals are generated.

A peak interrupt (INTTSG2nIPEK) and a trough interrupt (INTTSG2nIVLY) selected by TSG2nAT00 and TSG2nAT01, and TSG2nAT10 and TSG2nAT11 are interrupt signals obtained after skipped. Therefore, they are output at the timing according to interrupt skipping control. If the interrupt output is not enabled by TSG2nCTL4.TSG2nPIE and TSG2nVIE, A/D conversion trigger is not output.

TSG2nACC01, TSG2nACC00, and TSG2nAT09 to TSG2nAT00, and TSG2nACC11, TSG2nACC10, and TSG2nAT19 to TSG2nAT10 can be rewritten during timer operation.

If A/D conversion trigger setting bits are rewritten during operation, the rewritten values are reflected on the A/D conversion trigger output status immediately. Such control bits are rewritten at anytime regardless of operating modes. If a write access is made to TSG2nCTL5 and TSG2nCTL6 (including a rewrite of the same value), the A/D conversion trigger skipping counter is cleared and starts counting from zero.

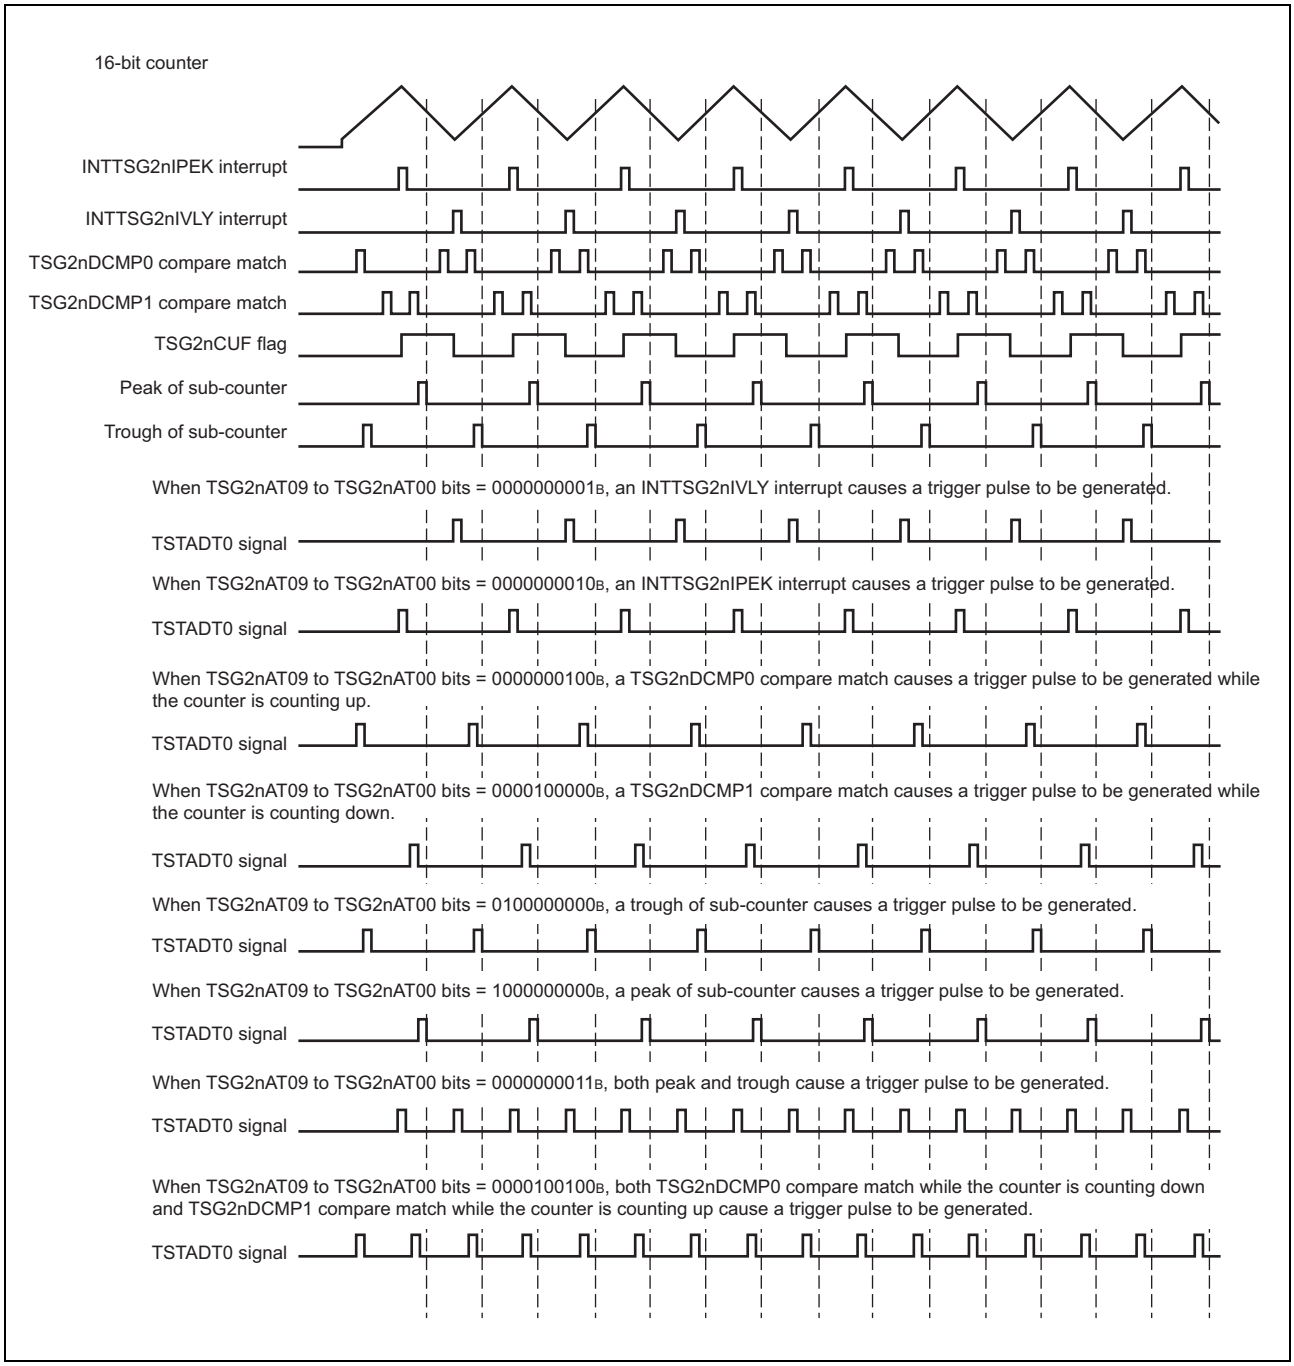


Figure 23.38 When TSG2nPIE = 1, TSG2nVIE = 1, and TSG2nRCC04 to TSG2nRCC00 = 00_B in TSG2nCTL4, and TSG2nACC01 and TSG2nACC00 = 00_B in TSG2nCTL5 (HT-PWM Mode)

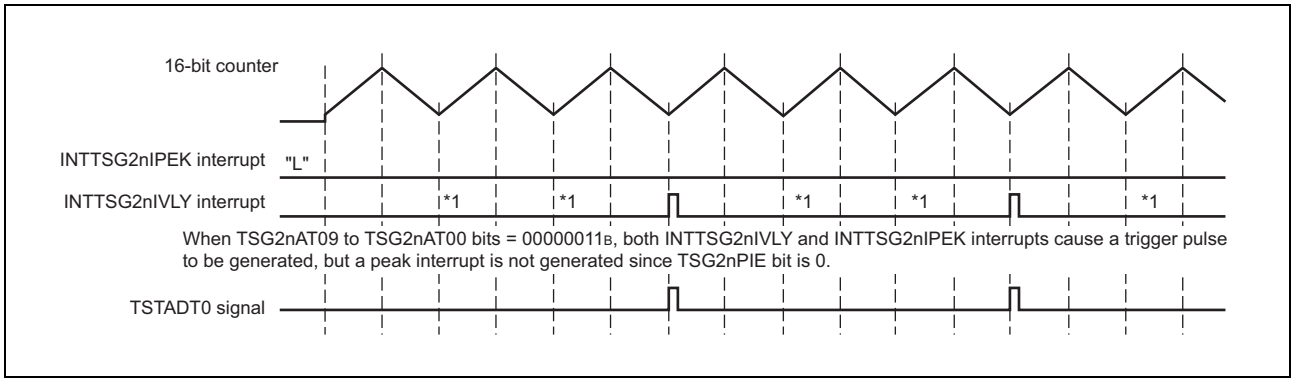

Figure 23.39 When TSG2nPIE = 0, TSG2nVIE = 1, and TSG2nRCC04 to TSG2nRCC00 = 02_B in TSG2nCTL4 and TSG2nACC01 and TSG2nACC00 = 00_B in TSG2nCTL5 (HT-PWM Mode)

Note1. Skipped interrupt request

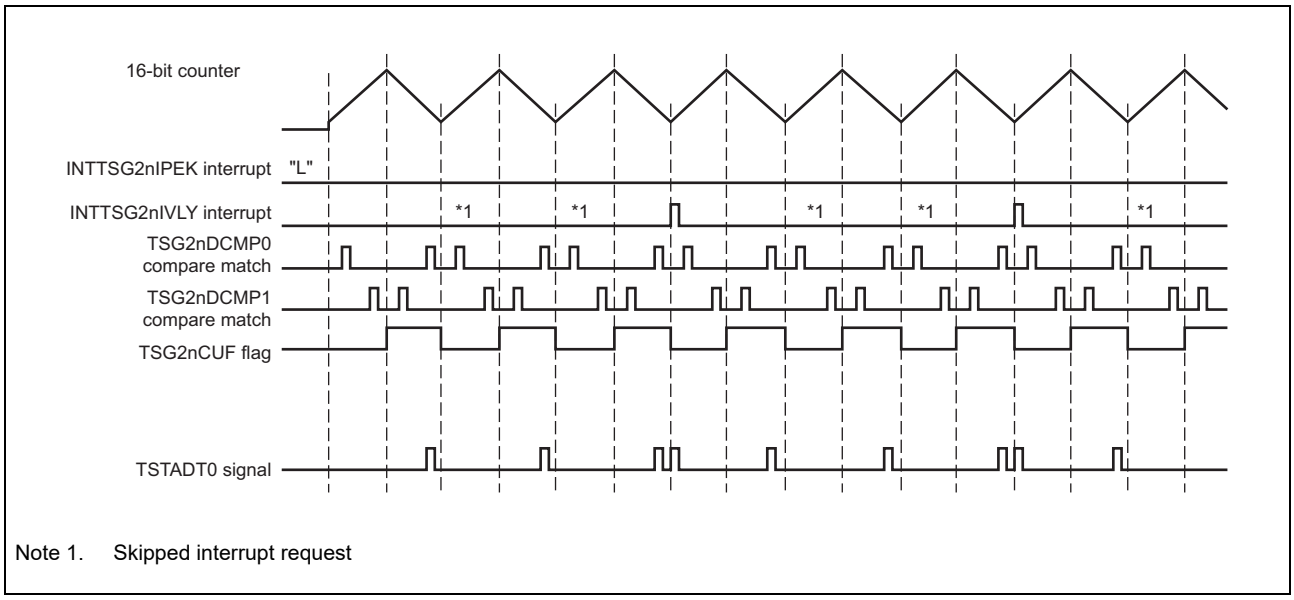

Figure 23.40 When TSG2nPIE = 0, TSG2nVIE = 1, and TSG2nRCC04 to TSG2nRCC00 = 02_B in TSG2nCTL4 and TSG2nACC01 and TSG2nACC00 = 00_B, and TSG2nAT09 to TSG2nAT00 = 0000 1001_B in TSG2nCTL5 (HT-PWM Mode)

23.9.1.2 A/D Conversion Trigger Skipping Function

Example of operation of the A/D conversion trigger skipping function is shown in Figure below.

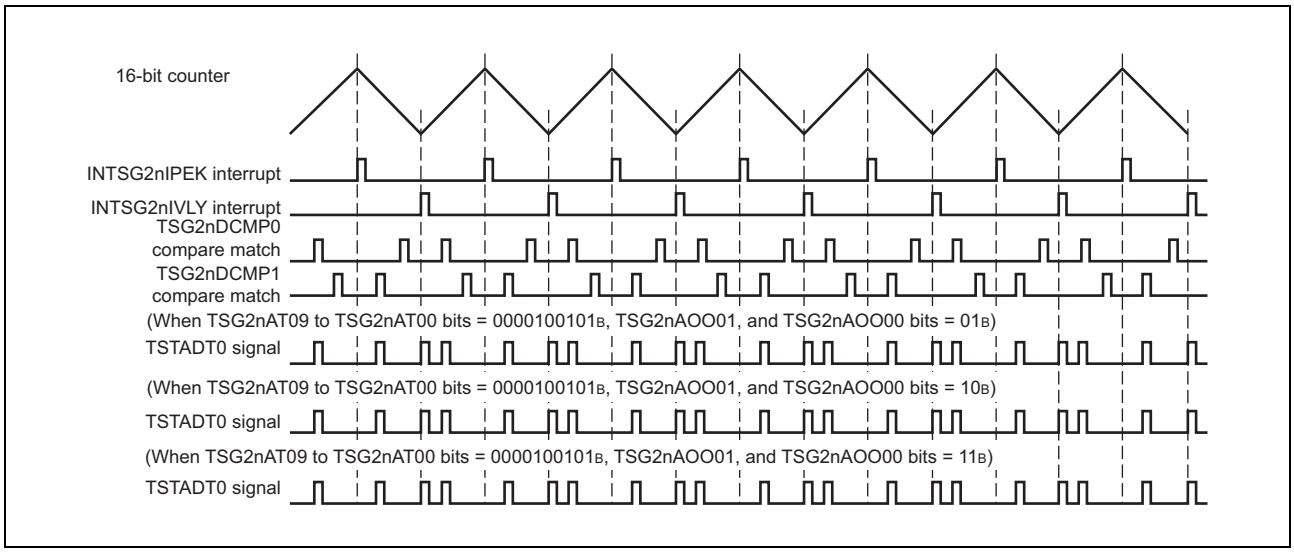

Figure 23.41 Example of Operation of A/D Conversion Trigger Skipping Function

NOTE

Broken-lined pulses indicate A/D conversion trigger pulses skipped by the A/D conversion trigger skipping function.

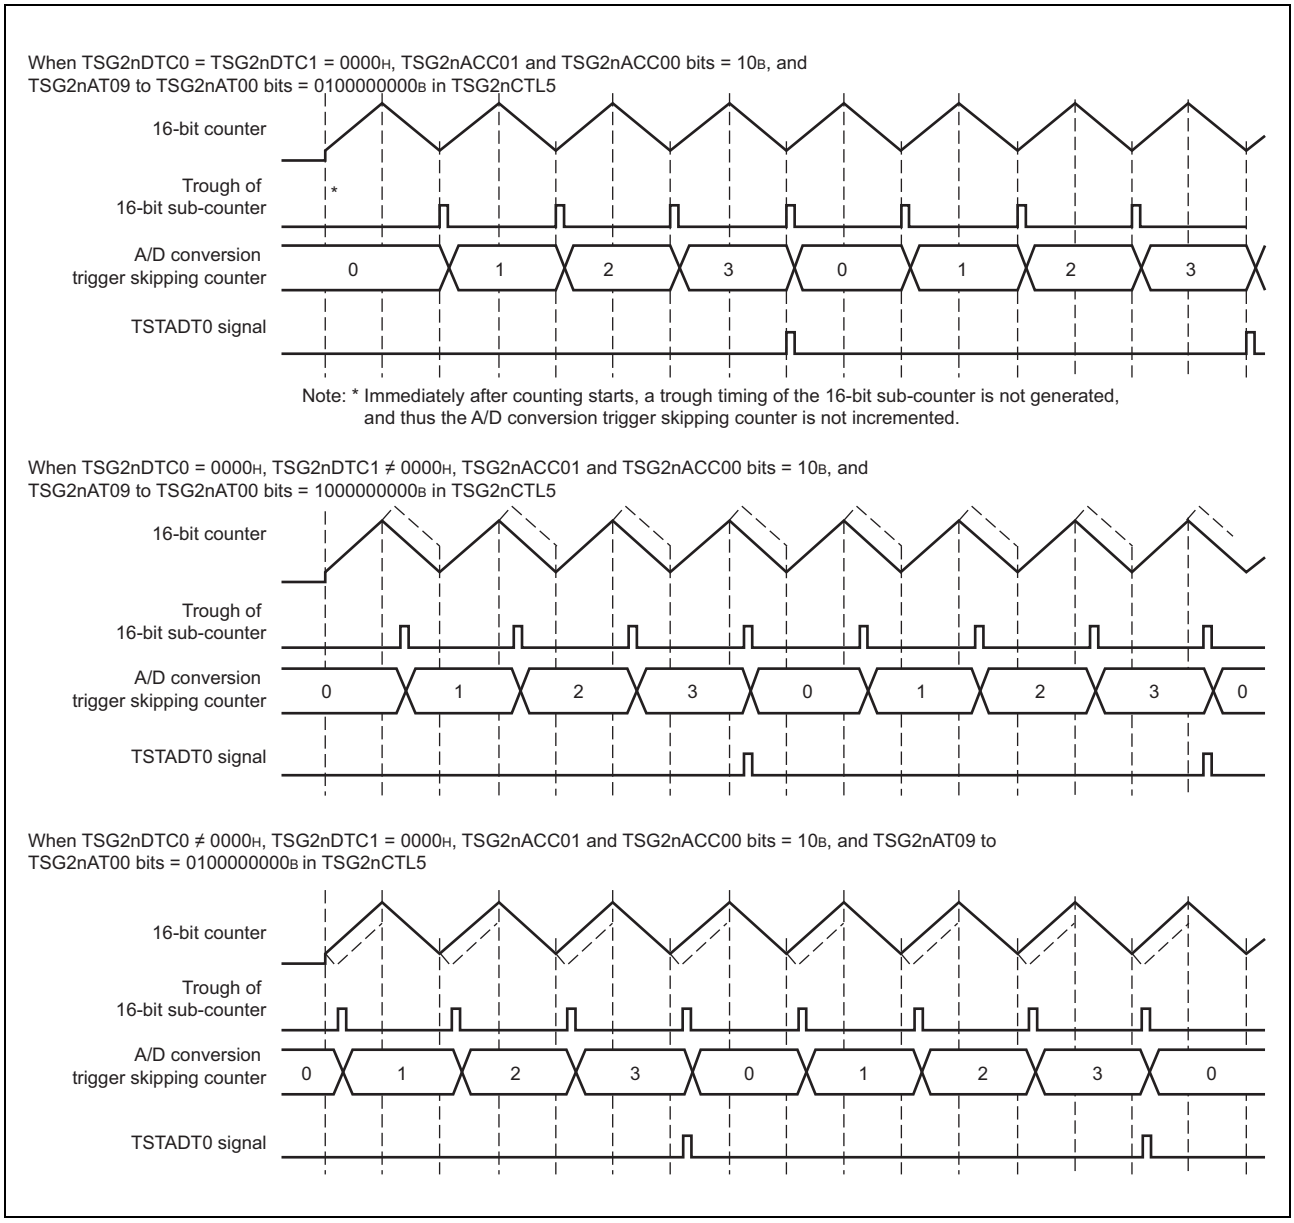

Figure 23.42 Example of Operation of A/D Conversion Trigger Skipping Function

23.9.1.3 Notes on A/D Conversion Trigger

- If the same value is written to TSG2nDCMP0 and TSG2nDCMP1 or TSG2nDCMP2, and the same condition (when the 16-bit counter increments or decrements) is set as the valid A/D conversion trigger, A/D conversion trigger skipping counter is incremented by one and one trigger pulse is output upon a match of the 16-bit counter with these registers.
- In PWM mode, SP-PWM mode, and 120-DC mode, a trough interrupt (INTTSG2nIVLY) is not generated. Only a peak interrupt (INTTSG2nIPEK) is valid.
- In 120-DC mode, when the 16-bit counter is cleared during the carrier period due to switch of the output pattern, the A/D conversion trigger is not generated if TSG2nDCMP2 to TSG2nDCMP0 values do not match with the 16-bit counter value and a peak interrupt (INTTSG2nIPEK) is not generated.

23.10 Error and Warning Interrupts

23.10.1 Error Interrupt Function

If simultaneous activation of the positive and negative phases is detected after the error interrupt function is enabled (TSG2nIOC1.TSG2nEOC = 1), TSG2nSTR2.TSG2nTBF is set, and an error interrupt (INTTSG2nIER) of TSG2n is generated. Whether or not to detect an error of each phase (TSOn1 and TSOn2, TSOn3 and TSOn4, and TSOn5 and TSOn6 pins) can be selected by TSG2nCTL1.TSG2nTBA2 to TSG2nTBA0, respectively.

When an error occurs, outputs of the TSOn1 to TSOn6 pins can be set to high-impedance.

The following table shows whether or not simultaneous activation of the positive and negative phases can be detected in each mode.

Mode	Positive Phase and Negative Phase Simultaneous Active State Detection
PWM mode	Possible
HT-PWM mode	Possible
SP-PWM mode	Possible
120-DC mode	Possible

CAUTION

When an error interrupt is generated, the error status should be canceled within an error interrupt handling. Otherwise, subsequent error interrupts are not generated.

23.10.1.1 PWM Mode and 120-DC Mode

In PWM mode, if TSG2nCMP1 and TSG2nCMP2, and TSG2nCMP3 and TSG2nCMP4 are set so that the TSOn1 and TSOn2 pins output the active level simultaneously, an error interrupt (INTTSG2nIER) is generated. With the same setting, if TSG2nCMP5, TSG2nCMP6, TSG2nCMP7, TSG2nCMP8, TSG2nCMP9, TSG2nCMP10, TSG2nCMP11, and TSG2nCMP12 are set so that the TSOn3 and TSOn4, and TSOn5 and TSOn6 pins output the active level simultaneously, an error interrupt (INTTSG2nIER) is generated.

In 120-DC mode, if TSG2nCMP1, TSG2nCMP2, TSG2nCMP5, TSG2nCMP6, TSG2nCMP9, and TSG2nCMP10, TSG2nCMP3, TSG2nCMP4, TSG2nCMP7, TSG2nCMP8, TSG2nCMP11, and TSG2nCMP12, and TSG2nPAT0W and TSG2nPAT1W are set so that the TSOn1 and TSOn2 pins output the active level simultaneously, an error interrupt (INTTSG2nIER) is generated. With the same setting, the TSOn3 and TSOn4, and TSOn5 and TSOn6 pins also output the active level simultaneously, an error interrupt (INTTSG2nIER) is generated.

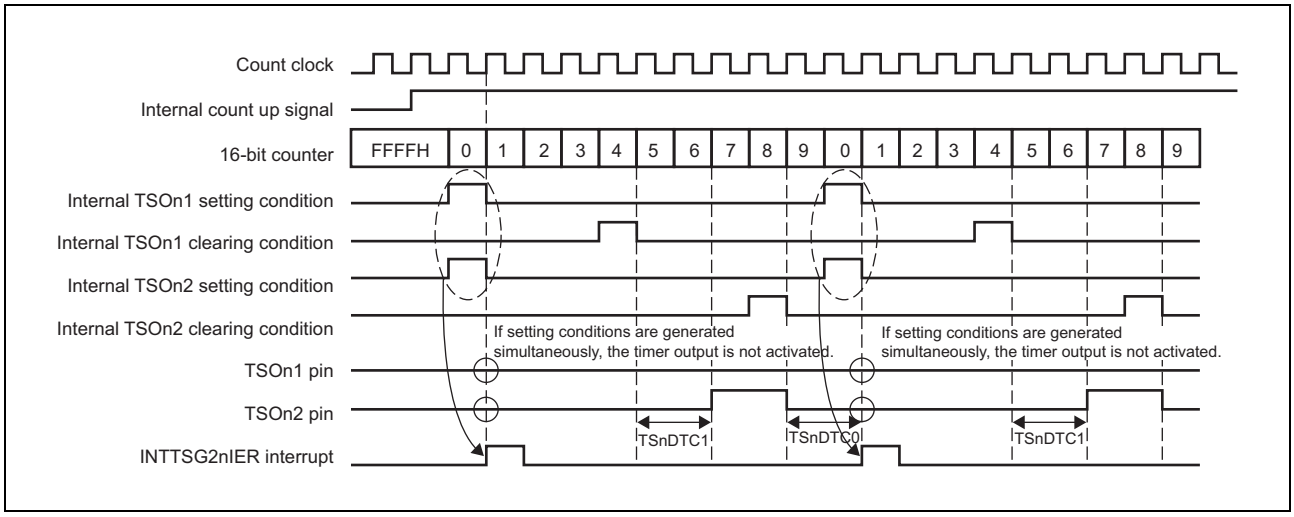

Figure 23.43 Example of Error Interrupt (INTTSG2nIER) Generation (PWM Mode)

NOTE

TSOn3 and TSOn4, and TSOn5 and TSOn6 behave the same.

When the active level of output is switched by operating TSG2nIOC2.TSG2nOL1 and TSG2nOL2, an error interrupt is generated as shown in the figure below.

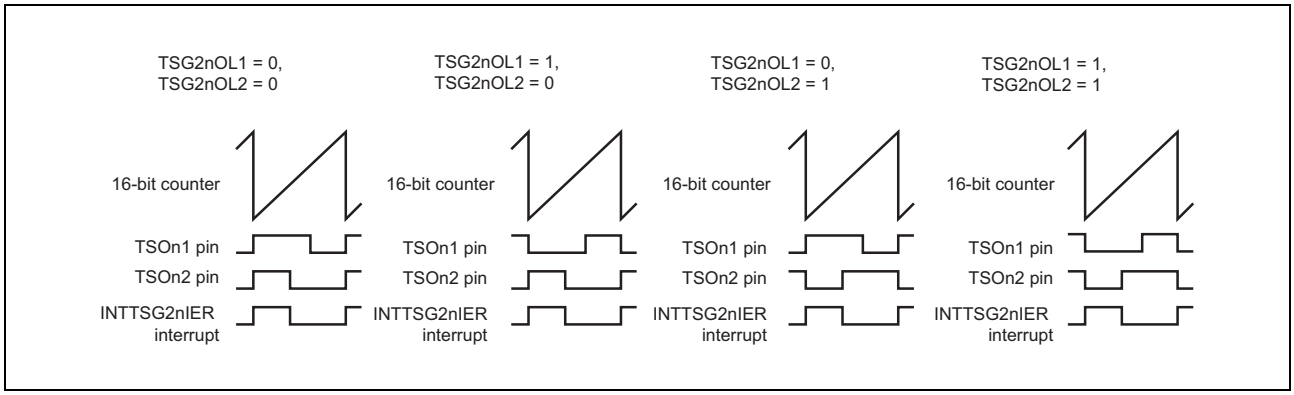

Figure 23.44 Example of Error Interrupt (INTTSG2nIER) Generation for Each Active Level

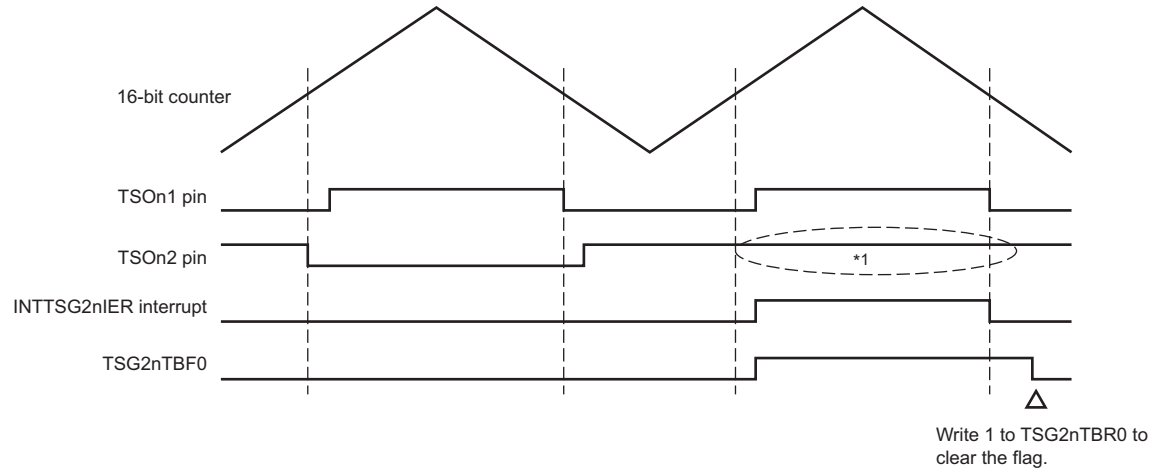
23.10.1.2 HT-PWM Mode and SP-PWM Mode

Either TSG2n dead time setting register 0 or 1 (TSG2nDTC0 or TSG2nDTC1) is 0000_H, an error may occur.

NOTE

If an error occurs when the dead time control function is used (both TSG2nDTC0 and TSG2nDTC1 are not 0000_H), internal circuit failure may occur.



Note 1. TSOn2 pin control circuit failure occurs.

Figure 23.45 Example of Error Interrupt Operation

23.10.2 Warning Interrupt Function

TSG2n has a warning interrupt (INTTSG2nIWN).

Warning interrupt (INTTSG2nIWN) is generated when any of the following conditions is detected.

For details, see **Section 23.7, Flags**.

- When simultaneous change in two or more pins of TAPTSn2-TAPTSn0 is detected
  See **Section 23.7.4, Noise Detection Flag (TSG2nNDF)**.
- When inversion is detected on the TAPTSn2-TAPTSn0
  See **Section 23.7.7, Pattern Inversion Detection Flag (TSG2nPRF)**.
- When 000 or 111 is detected from the TAPTSn2-TAPTSn0 pins
  See **Section 23.7.6, Pattern Error Detection Flag (TSG2nPEF)**.
- When the phase difference between the input pattern (TAPTSn2 to TAPTSn0 pins) and output patterns (TSG2nOPF2 to TSG2nOPF0) is detected
  See **Section 23.7.8, Pattern Phase Difference Detection Flag (TSG2nPPF)**.

23.11 Operating Modes

Table 23.44 List of Modes

TSG2nCTL0 Register		
TSG2nMD1	TSG2nMD0	Timer Modes
0	0	PWM mode
0	1	HT-PWM mode (HT-PWM)
1	0	Shifted-pulse - pulse width modulation mode (SP-PWM)
1	1	120-DC mode

23.11.1 PWM Mode

Overview

A PWM signal is output at the TSOn1 to TSOn6 pins according to set timing/clear timing of TSG2nCMP1 to TSG2nCMP12 registers with the PWM period set in the TSG2nCMP0 register.

Prerequisites

- Set the set timing to the compare register with an even number:
  TSG2nCMP2 (set timing of the TSOn1 output), TSG2nCMP4 (set timing of the TSOn2 output), TSG2nCMP6 (set timing of the TSOn3 output), TSG2nCMP8 (set timing of the TSOn4 output), TSG2nCMP10 (set timing of the TSOn5 output) and TSG2nCMP12 (set timing of the TSOn6 output)
- Set the clear timing to the compare register with an odd number:
  TSG2nCMP1 (clear timing of the TSOn1 output), TSG2nCMP3 (clear timing of the TSOn2 output), TSG2nCMP5 (clear timing of the TSOn3 output), TSG2nCMP7 (clear timing of the TSOn4 output), TSG2nCMP9 (clear timing of the TSOn5 output) and TSG2nCMP11 (clear timing of the TSOn6 output)

Functional description

Set the PWM period and set/clear timing of the TSOn1 to TSOn6 outputs. Set TSG2nTRG0.TSG2nTS = 1 to start the timer counter.

The TSOn1 to TSOn6 outputs are set to the inactive state at the same time the counting begins. The outputs are set to the active state by the match of the buffer registers TSG2nCMP2, TSG2nCMP4, TSG2nCMP6, TSG2nCMP8, TSG2nCMP10, and TSG2nCMP12 with the 16-bit counter.

Next, the TSOn1 to TSOn6 outputs are set to the inactive state by the match of the buffer registers TSG2nCMP1, TSG2nCMP3, TSG2nCMP5, TSG2nCMP7, TSG2nCMP9, and TSG2nCMP11 with the 16-bit counter.

During counting, a compare match interrupt (INTTSG2nI0 to INTTSG2nI12) is generated by the match of the buffer register TSG2nCMP0 to TSG2nCMP12 with the 16-bit counter.

CAUTION

Reload is executed when writing to the TSG2nCMP1 register at TSG2nCTL3.TSG2nRMC = 0. Therefore, even when it is needed to rewrite only the value of the TSG2nCMP0 register, a write operation to the TSG2nCMP1 register is necessary. When only the TSG2nCMP0 register is rewritten, reload is not done.

NOTE

The PWM mode is set when TSG2nCTL0.TSG2nMD1 and TSG2nMD0 = 00_B.

(1) When TSG2nCMP0 and TSG2nCMP1 to TSG2nCMP12 are Not Rewritten during Timer Operation

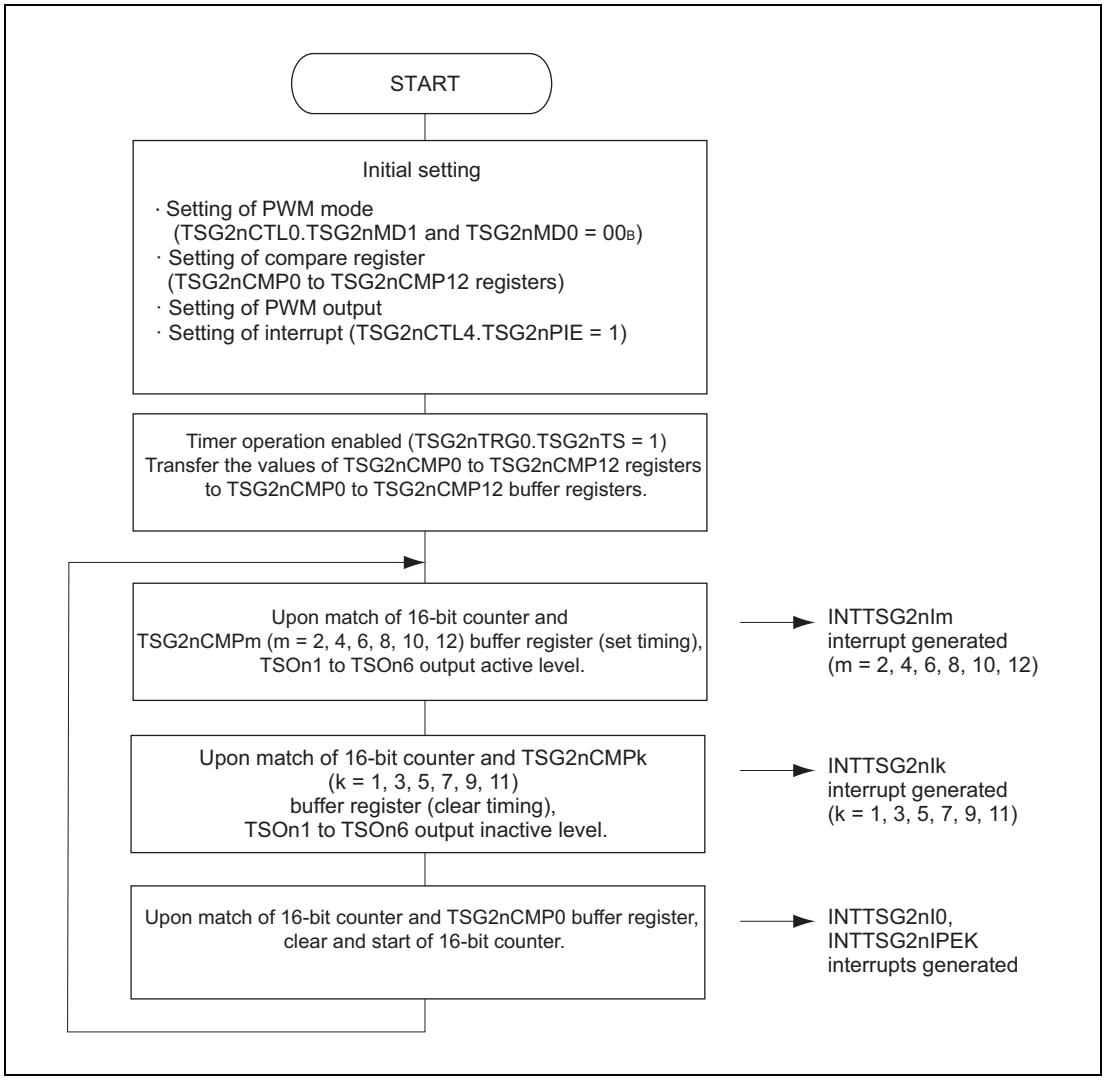


Figure 23.46 Basic Operation Flow of PWM Mode (1/2)

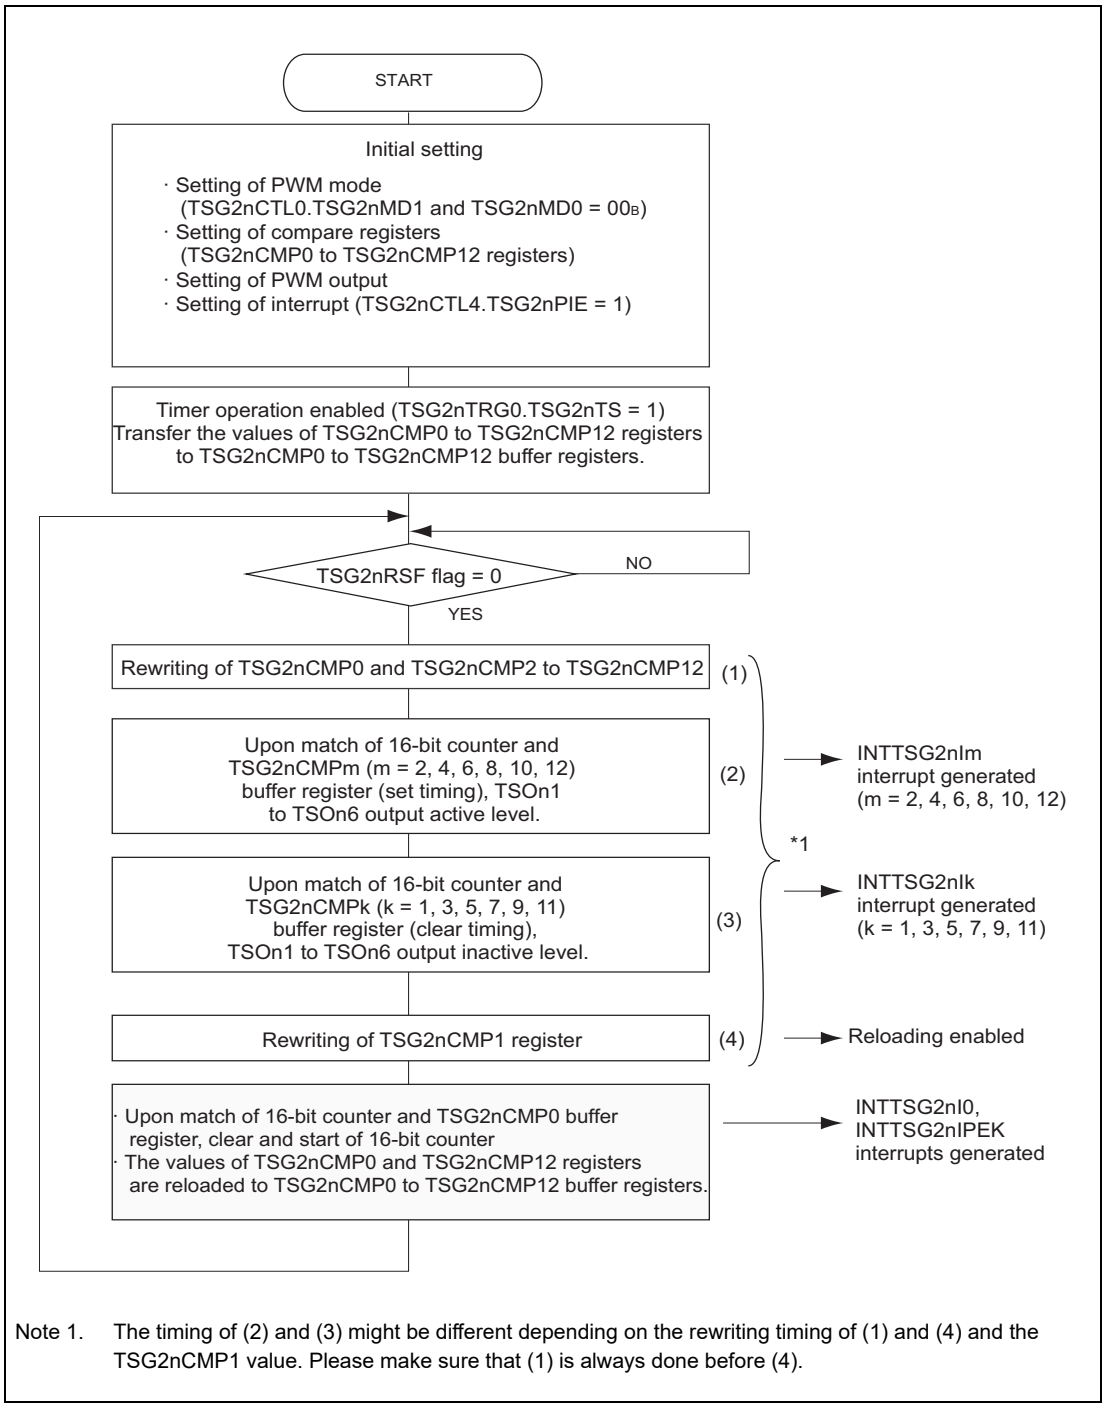
(2) When TSG2nCMP0 and TSG2nCMP1 to TSG2nCMP12 are Rewritten during Timer Operation



Note 1. The timing of (2) and (3) might be different depending on the rewriting timing of (1) and (4) and the TSG2nCMP1 value. Please make sure that (1) is always done before (4).

Figure 23.47 Basic Operation Flow of PWM Mode (2/2)

CAUTION

Please rewrite compare registers after confirming that the reload request flag TSG2nRSF is 0.

23.11.1.1 List of Operations in PWM Mode

Table 23.45 Counter Functions in PWM Mode

Operation		Setting Conditions
16-bit counter	Start	TSG2nTRG0.TSG2nTS = 0 → 1, or a simultaneous start trigger
	Clear	Compare match of TSG2nCMP0 buffer register and 16-bit counter
	Stop	TSG2nTRG1.TSG2nTT = 0 → 1

Table 23.46 Functions of Compare Registers and Dead Time Setting Register in PWM Mode

Register	Rewriting Method	Rewrite during Operation	Function
TSG2nCMP0	Reload/Anytime rewrite	Possible	Setting period
TSG2nCMPm (m = 1 to 12)	Reload/Anytime rewrite	Possible	Setting set/clear timing
TSG2nDCMP0W, TSG2nDCMP2	Reload/Anytime rewrite	Possible	Diagnostic output or A/D conversion trigger
TSG2nDTC0, TSG2nDTC1	Reload	Possible*1	Setting dead time

Note 1. Please refer to **Section 23.11.1.3, Controlling Dead Time in PWM Mode**.

Table 23.47 Timer Output in PWM Mode

Pin	Function
TSOnm (m = 1 to 6)	PWM output by compare match of TSG2nCMPk buffer register and 16-bit counter (k = 1 to 12)
TSOn7	Diagnostic signal output or pulse output by A/D conversion trigger

Table 23.48 Timer Output in PWM Mode

Interrupt	Function
INTTSG2nIm (m = 0 to 12)	Compare match of TSG2nCMPm buffer register and 16-bit counter (m = 0 to 12)
INTTSG2nIER	Error (simultaneous active state of TSOn1 and TSOn2, or TSOn3 and TSOn4, or TSOn5 and TSOn6)
INTTSG2nIVLY	—
INTTSG2nIPEK	Peak interrupt (generated at the same timing as INTTSG2nI0)
INTTSG2nIWN	Warning interrupt

Note: "—" : Not available in PWM mode

Table 23.49 Compare Match Timing in PWM Mode

Compare Match	Timing
TSG2nCMP0	When 16-bit counter changes from TSG2nCMP0 to 0000_H
TSG2nCMPm (m = 1 to 12)	After detecting the match of 16-bit counter and TSG2nCMPm (m = 1 to 12)

Table 23.50 Example of Setting Each Timer Output Condition in PWM Mode

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TSOnm (m = 1 ot 6)	PWM output	(TSG2nCMP0 + 1) × count clock	Output an inactive level throughout one period (duty cycle 0%)	TSG2nCMPm = TSG2nCMP (m + 1) or TSG2nCMP (m + 1) > TSG2nCMP0 (m = 1, 3, 5, 7, 9, 11)
			Output an active level of one count clock in one period	TSG2nCMPm = TSG2nCMP (m + 1) + 1 TSG2nCMP (m + 1) = TSG2nCMPm - 1 (m = 1, 3, 5, 7, 9, 11)
			Output an inactive level of one count clock in one period	TSG2nCMPm = TSG2nCMP (m + 1) - 1 TSG2nCMP (m + 1) = TSG2nCMPm + 1 (m = 1, 3, 5, 7, 9, 11)
			Output an active level throughout one period (duty cycle 100%)	TSG2nCMPm > TSG2nCMP0 TSG2nCMP (m + 1) ≤ TSG2nCMP0 (m = 1, 3, 5, 7, 9, 11)

When only the TSG2nCMP2 register is rewritten and the TSOn1 pin output is used (TSG2nIOC0.TSG2nTOE1 = 1, TSG2nIOC2.TSG2nOL1 = 0)

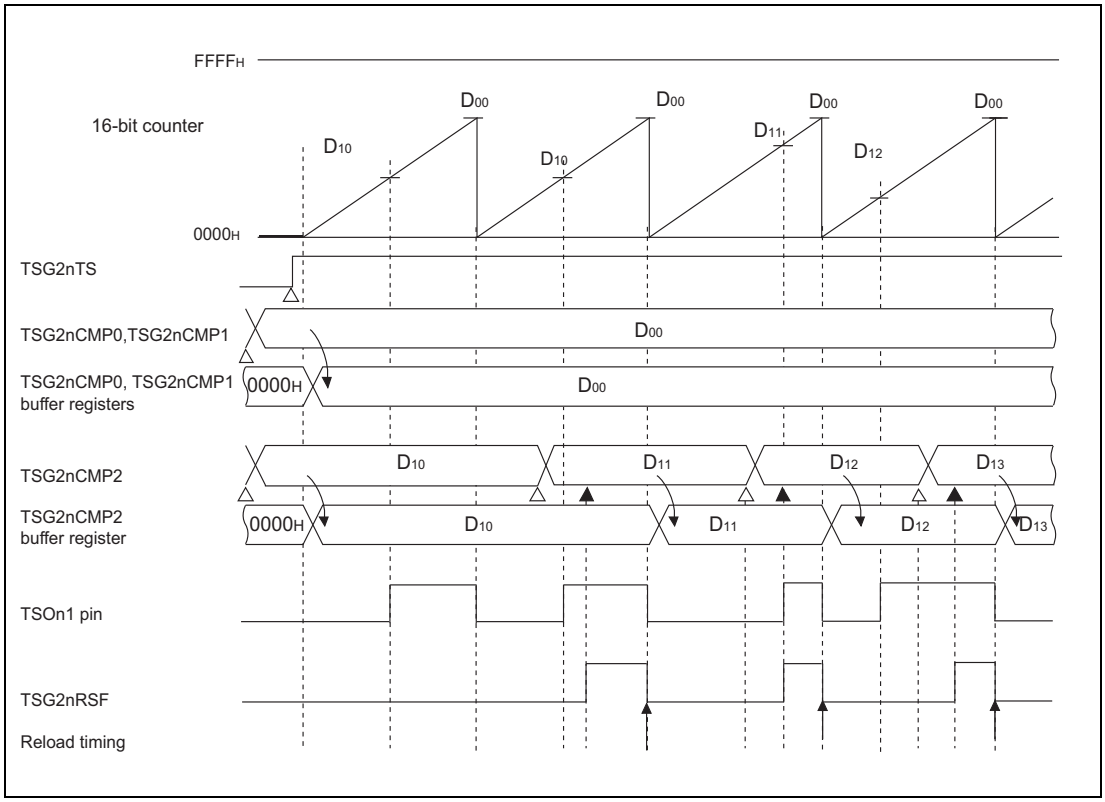


Figure 23.48 Example of Basic Operation Timing in PWM Mode (1/2)

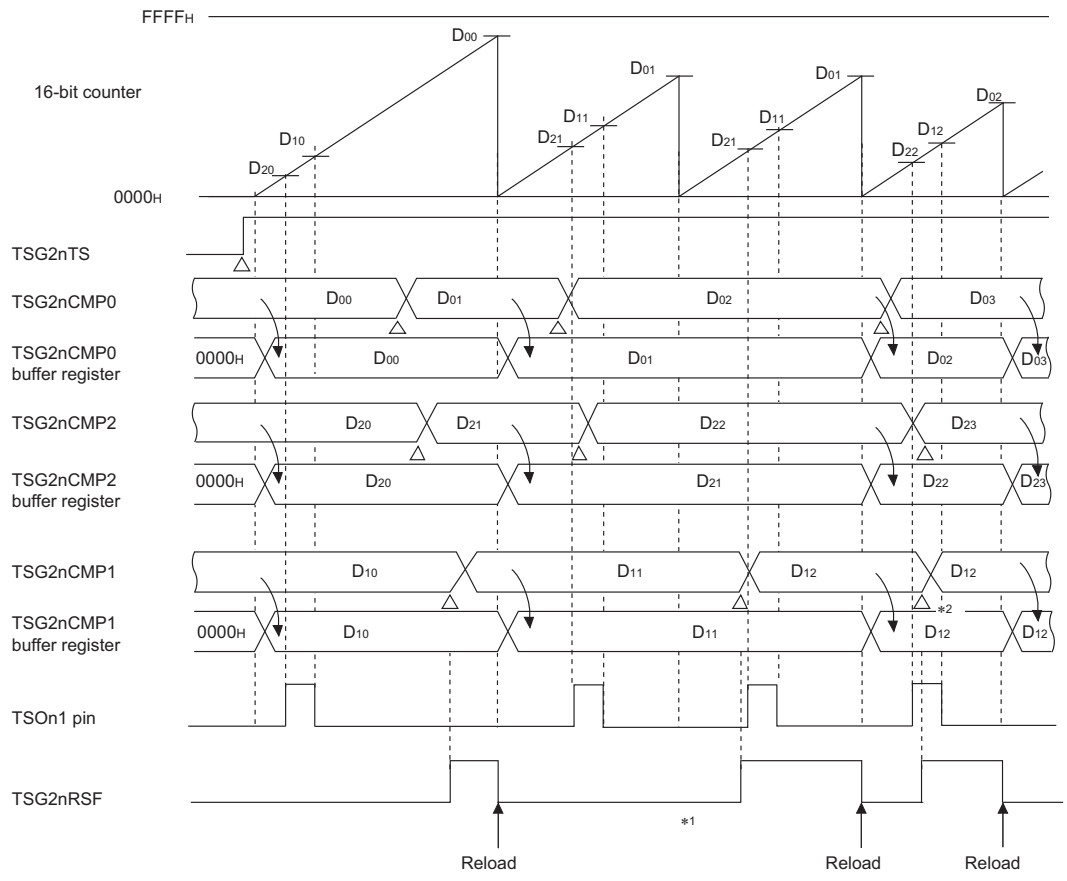
NOTES

1. D00: Set values of TSG2nCMP0 and TSG2nCMP1 (0000_H - $FFFF_H$)
   D10, D11, D12 and D13: Set values of TSG2nCMP2 (0000_H - $FFFF_H$)
2. TSOn1 (PWM duty cycle) = (TSG2nCMP1 - TSG2nCMP2) × count clock
   TSOn1 (PWM period) = (TSG2nCMP0 + 1) × count clock
3. TSOn2 to TSOn6 pins behave similarly to the TSOn1 pin.
4. Δ: Write access
5. ▲: TSG2nCMP1 write access (equivalent).

When the TSG2nCMP0 to TSG2nCMP2 registers are rewritten, and the TSOn1 pin output is used (TSG2nIOC0.TSG2nTOE1 = 1, TSG2nIOC2.TSG2nOL1 = 0)



Note 1. The TSG2nCMP0 buffer register is not reloaded, because the TSG2nCMP1 register was not rewritten.
Note 2. Equivalent writing

Figure 23.49 Example of Basic Operation Timing in PWM Mode (2/2)

NOTES

1. D00, D01, D02, and D03: Set point of TSG2nCMP0 (0000_H - $FFFF_H$)
   D10, D11, D12, and D13: Set point of TSG2nCMP1 (0000_H - $FFFF_H$)
   D20, D21, D22, and D23: Set point of TSG2nCMP2 (0000_H - $FFFF_H$)
2. Outputs from the TSOn2 to TSOn6 pins behave similarly to the TSOn1 pin.
3. Δ: Write access

23.11.1.2 Interrupt/Reload Skipping Function in PWM Mode

By setting TSG2nCTL4.TSG2nPRE and TSG2nPIE to 1 and setting TSG2nRCC04 to TSG2nRCC00 and TSG2nCTL3.TSG2nRIA, the reload and interrupt skipping function can be used.

By setting TSG2nPRE to 1 and setting TSG2nRCC04 to TSG2nRCC00, the interrupt skipping function can be used.

23.11.1.3 Controlling Dead Time in PWM Mode

By setting the dead time in the TSG2nDTC0 and TSG2nDTC1 registers in PWM mode, it is possible to control the dead time. The dead time is controlled according to the switch timing of the TSOn1 and TSOn2 pin outputs, the TSOn3 and TSOn4 pin outputs, and the TSOn5 and TSOn6 pin outputs.

Table 23.51 Dead Time in PWM Mode

Switch Timing	Dead Time
TSOn1 : High level to low level TSOn2 : Low level to high level	Value of TSG2nDTC1 register
TSOn2 : High level to low level TSOn1 : Low level to high level	Value of TSG2nDTC0 register
TSOn3 : High level to low level TSOn4 : Low level to high level	Value of TSG2nDTC1 register
TSOn4 : High level to low level TSOn3 : Low level to high level	Value of TSG2nDTC0 register
TSOn5 : High level to low level TSOn6 : Low level to high level	Value of TSG2nDTC1 register
TSOn6 : High level to low level TSOn5 : Low level to high level	Value of TSG2nDTC0 register

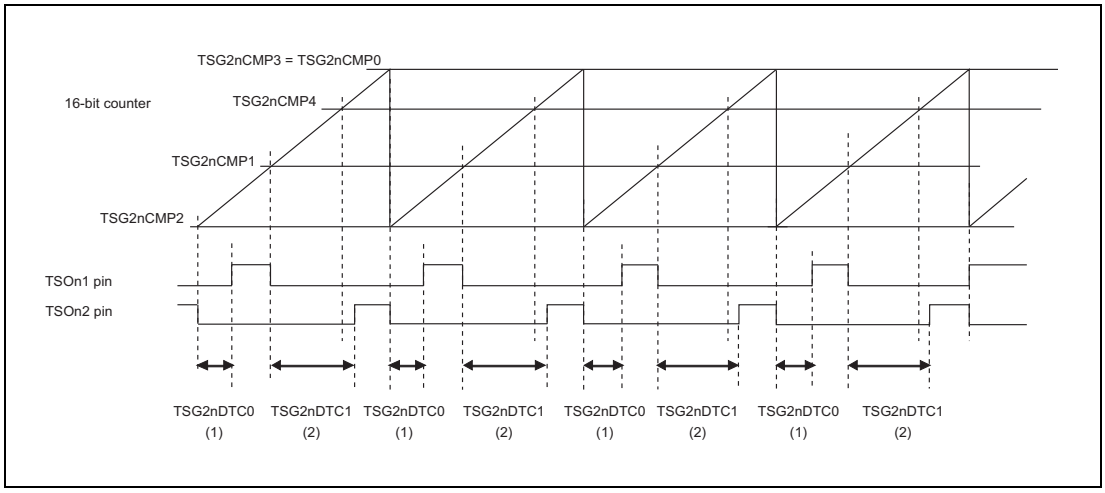


Figure 23.50 Example of Dead Time Control between TSOn1 and TSOn2 Outputs (1/2)

At (1), the dead time counter starts counting at the falling edge of the TSOn2 output. Here, although the 16-bit counter is 0000_H, the TSOn1 output stays inactive because the dead time counter is still operating. The TSOn1 output becomes active at the timing when the dead time count operation ends.

At (2), the dead time counter starts counting at the falling edge of the TSOn1 output. Even after the match of the 16-bit counter and TSG2nCMP4, the TSOn2 output stays inactive because the dead time counter is still operating. The TSOn2 output becomes active at the timing when the dead time count operation ends.

NOTES

1. The TSOn1 and TSOn2 pin outputs are active high.
2. The TSOn3 to TSOn6 pin outputs behave similarly.

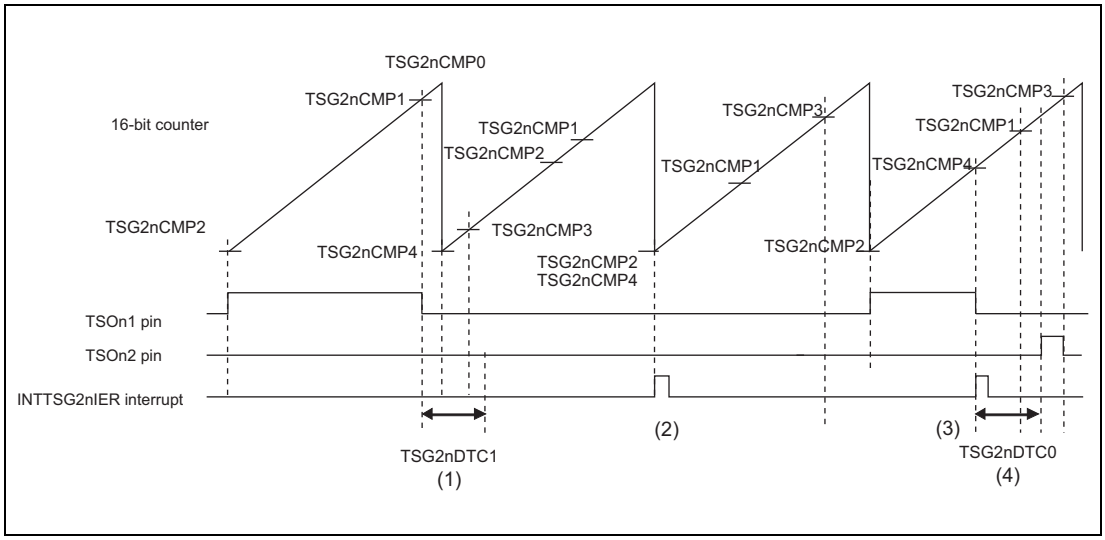

Figure 23.51 Example of Dead Time Control between TSOn1 and TSOn2 Outputs (2/2)

During (1), the dead time counter starts counting at the falling edge of the TSOn1 output. Even after the 16-bit counter reaches 0000_H and the match occurs between the 16-bit counter and TSG2nCMP4, the TSOn2 output stays inactive because the dead time counter is still operating. Moreover, since the TSG2nCMP3 register compare match occurs before the operation of the dead time counter ends, the TSOn2 output stays inactive.

$$TSG2nCMP1 + TSG2nDTC1 \geq TSG2nCMP0 + TSG2nCMP2 \text{ (TSOn2 stays inactive)}$$

$$TSG2nCMP2 + TSG2nDTC0 \geq TSG2nCMP0 + TSG2nCMP1 \text{ (TSOn1 stays inactive)}$$

At (2), the INTTSG2nIER interrupt occurs because the TSG2nCMP2 register and the TSG2nCMP4 register are set so that the TSOn1 and TSOn2 outputs rise simultaneously. Here, the TSOn1 output and the TSOn2 output are inactive.

At (3), compare match with the TSG2nCMP4 register generates an INTTSG2nIER interrupt and both TSOn1 and TSOn2 outputs become inactive.

At (4), the falling edge (inactive) of the TSOn1 output is caused by the simultaneous active state detected and the dead time counter starts counting. After the end of the dead time counter operation, the TSOn2 output becomes active.

NOTES

1. TSOn1 and TSOn2 are set to active high.
2. The TSOn3 to TSOn6 pin outputs behave similarly.

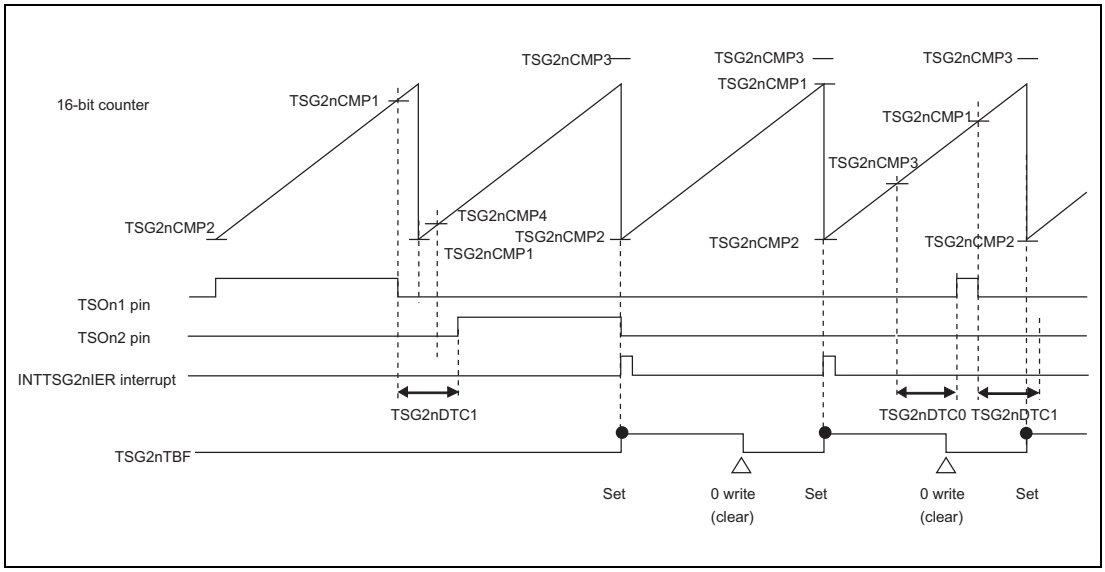

Figure 23.52 Example of 100% Duty Output at Dead Time Control

When the TSOn2 pin is set to duty cycle of 100% (TSG2nCMP3 ≥TSG2nCMP0 + 1), the output of the TSOn1 pin is fixed to a low level. This control is intended to mask the active condition of TSOn1 output since the TSOn2 output is active before the TSOn1 output becomes active. In this case, the INTTSG2nIER interrupt is also generated because TSOn1 and TSOn2 outputs become high simultaneously.

NOTES

1. TSOn1 and TSOn2 are set to active high.
2. The TSOn3 to TSOn6 pin outputs behave similarly.

23.11.1.4 Dead Time Rewriting during Timer Operation in PWM Mode

In PWM mode, it is possible to rewrite TSG2n dead time setting registers TSG2nDTC0 and TSG2nDTC1 while counting. The new settings are active at reload timing. It is not possible to change the dead time setting by rewriting at anytime.

Please enable reloading by writing to the TSG2nCMP1 register.

23.11.2 HT-PWM Mode (High Accuracy Triangular - Pulse Width Modulation Mode)

Overview

In this mode, the 16-bit counter (up/down count by ±2 bits, practically 15 bits) and the 16-bit compare registers (LSB is used to control additional pulse) are used to generate a 6-phase PWM signal.

Prerequisites

- Set the carrier wave period to TSG2nCMP0.
- Set the duty cycle of the voltage data signals of the U phase, V phase, and W phase with TSG2nCMPU, TSG2nCMPV, and TSG2nCMPW (The values set to TSG2nCMPU, TSG2nCMPV, and TSG2nCMPW are reflected immediately to the corresponding TSG2nCMPm (m = 1, 2, 5, 6, 9, 10)).
- Symmetric triangular wave control is described in this section. Please refer to **Section 23.11.2.10, Asymmetric Triangular Wave Control in HT-PWM Mode**, for asymmetric triangular wave control.

Functional description

Set the period of carrier wave and the duty cycle of the U phase, the V phase, and the W phase. Counting up begins when TSG2nTRG0.TSG2nTS is set to 1.

The 16-bit counter counts up from TSG2nDTC0 as the minimum value, and counts down upon the match of the maximum value of TSG2nCMP0 + TSG2nDTC0.

The dead time is set with TSG2nDTC0 and TSG2nDTC1. TSG2nDTC0 sets the dead time of inverse phase (OFF) to positive phase (ON) switch and TSG2nDTC1 sets the dead time of positive phase (OFF) to inverse phase (ON) switch. The 10-bit counters (TSG2nDTT1 to TSG2nDTT3) for dead time generation load the set values of TSG2nDTC0 and TSG2nDTC1 by the compare match of the 16-bit counter and the TSG2nCMPm buffer register (m = 1, 2, 5, 6, 9, 10), and start down-counting.

The INTTSG2nIm interrupts (m = 1, 2, 5, 6, 9, 10) are generated by the compare match of the 16-bit counter with the TSG2nCMP1, TSG2nCMP2, TSG2nCMP5, TSG2nCMP6, TSG2nCMP9, and TSG2nCMP10 buffer registers.

NOTE

The HT-PWM mode is enabled when TSG2nTRG0.TSG2nMD1 and TSG2nMD0 = 01_B.

23.11.2.1 Block Diagram and Basic Timing Chart

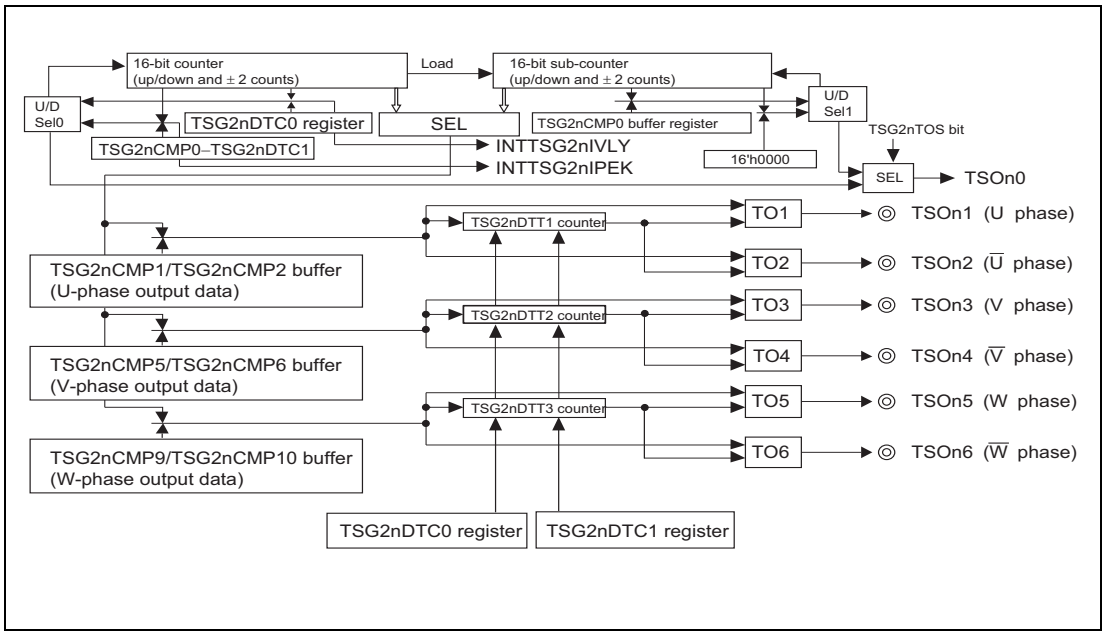

Figure 23.53 Block Diagram in HT-PWM Mode

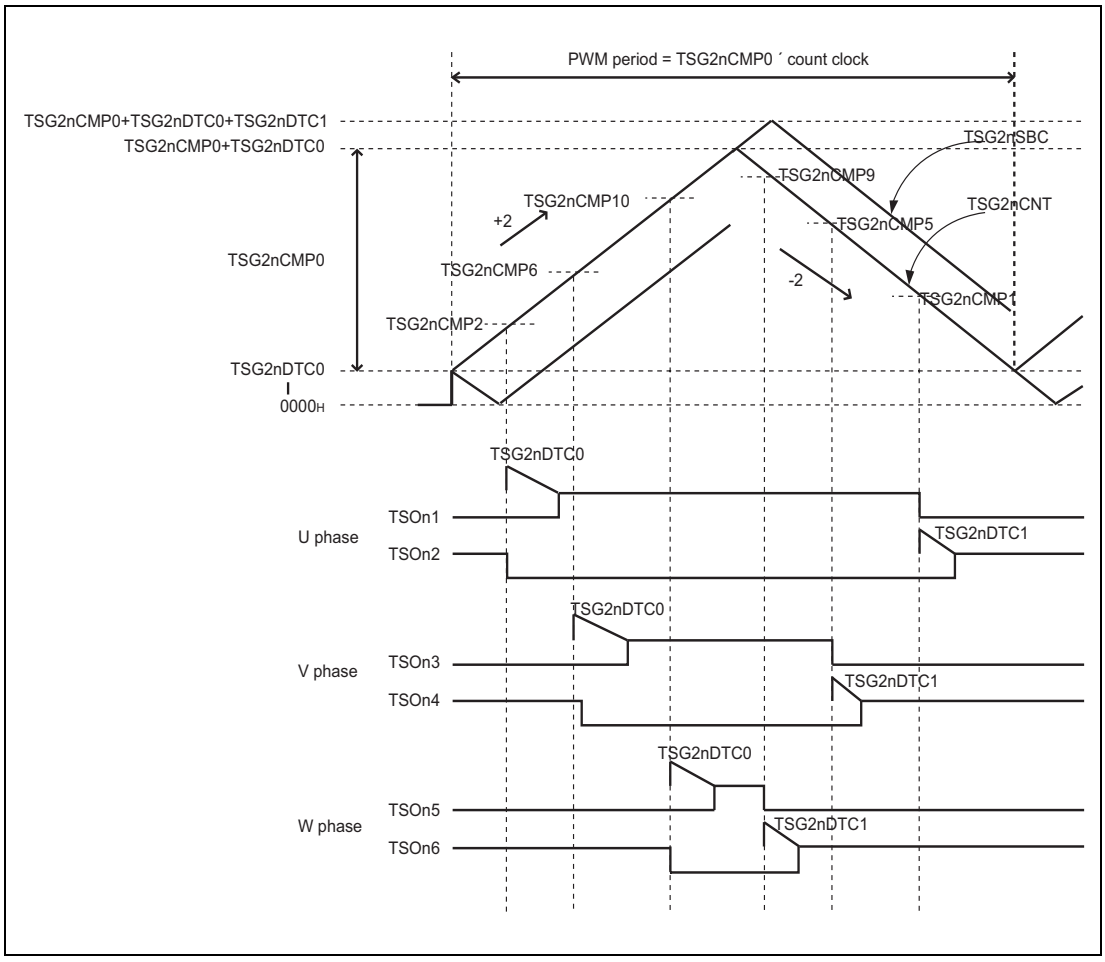

Figure 23.54 Basic Timing in HT-PWM Mode

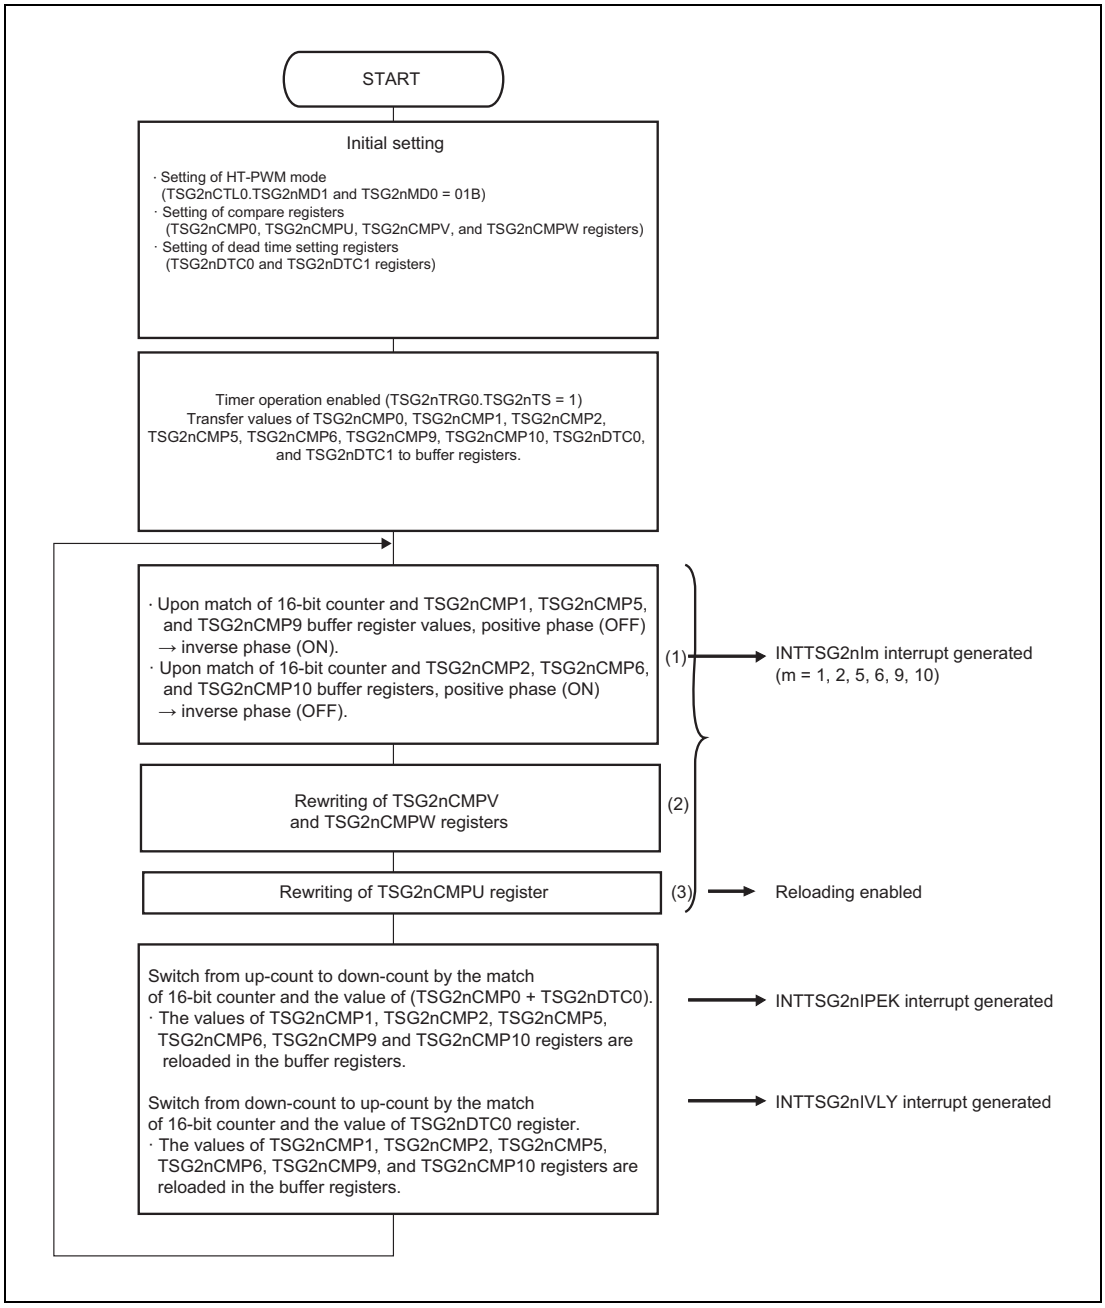

Figure 23.55 Basic Operation Flow in HT-PWM Mode

NOTES

- Write access to TSG2nCMPU (TSG2nCMP1) includes reloading enabling operation. Therefore, (3) must be done after (2).
- The INTTSG2nIPEK interrupt is generated only when TSG2nCTL4.TSG2nPRE = 1.
- The INTTSG2nIVLY interrupt is generated only when TSG2nCTL4.TSG2nVRE = 1.

23.11.2.2 List of HT-PWM Mode Operations

Table 23.52 Counter Function in HT-PWM Mode

Operation		Setting Condition
16-bit counter	Start	TSG2nTRG0.TSG2nTS = 0 → 1 (up count from TSG2nDTC0)
	Up count	Compare match of TSG2nDTC0 buffer register and 16-bit counter
	Down count	Compare match of TSG2nCMP0 + TSG2nDTC0 buffer register and 16-bit counter
	Clear	—
	Stop	TSG2nTRG1.TSG2nTT = 0 → 1
16-bit sub-counter	Start	TSG2nTRG0.TSG2nTS = 0 → 1 (down count from TSG2nDTC0)
	Up count	Underflow
	Down count	Compare match of TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1 buffer register and 16-bit sub-counter
	Load	• TSG2nCMP0 + TSG2nDTC0 when the value of 16-bit counter matches the value of buffer register TSG2nCMP0 + TSG2nDTC0 • TSG2nDTC0 when the value of 16-bit counter matches the value of the buffer register TSG2nDTC0
	Clear	—
	Stop	TSG2nTRG1.TSG2nTT = 0 → 1

Table 23.53 Compare Register and Dead Time Setting Register Functions in HT-PWM Mode

Register	Rewrite Method	Rewrite during Operation	Function
TSG2nCMP0	Reload/Anytime rewrite	Possible	Setting period
TSG2nCMPU	—	Possible	PWM control for U phase
TSG2nCMP1W (TSG2nCMP1, TSG2nCMP2)	Reload/Anytime rewrite		
TSG2nCMPV	—	Possible	PWM control for V phase
TSG2nCMP5W (TSG2nCMP5, TSG2nCMP6)	Reload/Anytime rewrite		
TSG2nCMPW	—	Possible	PWM control for W phase
TSG2nCMP9W (TSG2nCMP9, TSG2nCMP10)	Reload/Anytime rewrite		
TSG2nDCMP0W, TSG2nDCMP2	Reload/Anytime rewrite	Possible	Diagnostic signal output or A/D conversion trigger
TSG2nDTC0, TSG2nDTC1	Reload	Possible conditionally	Period and dead time setting

NOTES

- The values written to TSG2nCMPU, TSG2nCMPV, and TSG2nCMPW registers are set to both the lower and upper 16-bits of the respective TSG2nCMP1W (TSG2nCMP1, TSG2nCMP2), TSG2nCMP5W (TSG2nCMP5, TSG2nCMP6), and TSG2nCMP9W (TSG2nCMP9, TSG2nCMP10) registers.
- Please refer to **(1), TSG2nDTC0 and TSG2nDTC1 Rewriting**, on how to rewrite the TSG2nDTC0 and TSG2nDTC1.

Table 23.54 Timer Output Function in HT-PWM Mode

Pin	Function
TSOn0	Active level output during up count, inactive level output at down count of the 16-bit counter/sub-counter
TSOn1	PWM output with dead time by compare match of TSG2nCMP1 buffer register and 16-bit counter (down count) and compare match of TSG2nCMP2 buffer register and 16-bit counter (up count)
TSOn2	Inverse phase output to TSOn1
TSOn3	PWM output with dead time by compare match of TSG2nCMP5 buffer register and 16-bit counter (down count) and compare match of TSG2nCMP6 buffer register and 16-bit counter (up count).
TSOn4	Inverse phase output to TSOn3
TSOn5	PWM output with dead time by compare match of TSG2nCMP9 buffer register and 16-bit counter (down count) and TSG2nCMP10 buffer register and 16-bit counter (up count).
TSOn6	Inverse phase output to TSOn5
TSOn7	Diagnostic signal output or pulse output by A/D conversion trigger

NOTE

State of TSOn0 output can be switched with TSG2nIOC1.TSG2nTOS.

Table 23.55 Interrupt Request in HT-PWM Mode

Interrupt	Function
INTTSG2nI0	Compare match of TSG2nDTC0 buffer register and 16-bit counter (periodic interrupt)
INTTSG2nIm (m = 1, 2, 5, 6, 9, 10)	Compare match of TSG2nCMPm buffer register and 16-bit counter
INTTSG2nIER	Error interrupt
INTTSG2nIVLY	Trough interrupt
INTTSG2nIPEK	Peak interrupt
INTTSG2nIWN	Warning interrupt

Table 23.56 Compare Match Timing in HT-PWM Mode

Compare Match	Timing
TSG2nCMP0	When 16-bit counter changes from TSG2nCMP0 + TSG2nDTC0 to TSG2nCMP0 + TSG2nDTC0 - 2
TSG2nCMPm (m = 1, 2, 5, 6, 9, 10)	When 16-bit counter changes from TSG2nCMPm to TSG2nCMPm ± 2 (m = 1, 2, 5, 6, 9, 10)

Table 23.57 Example of Setting Each Timer Output Condition in HT-PWM Mode

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TSOn0	Toggle output	TSG2nCMP0 × count clock	Output an active level during up count, and an inactive level during down count	—
TSOn1, TSOn3, TSOn5	PWM output	TSG2nCMP0 × count clock	Output an inactive level throughout one period (0% duty)	TSG2nCMPm = TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1 (m = U, V, W)
			Output an active level of one count clock in one period	TSG2nCMPm = TSG2nCMP0 - 1 (m = U, V, W)
			Output an inactive level of one count clock in one period	TSG2nCMPm = 0001_H (m = U, V, W)
			Active level during all period (100% duty)	TSG2nCMPm = 0000_H (m = U, V, W)
TSOn2, TSOn4, TSOn6	PWM output		Inactive level during all period (0% duty)	TSG2nCMPm = 0000_H (m = U, V, W)
			Output an active level of one count clock in one period	TSG2nCMPm = TSG2nDTC0 + TSG2nDTC1 + 1 (m = U, V, W)
			Output an inactive level of one count clock in one period	TSG2nCMPm = TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1 - 1 (m = U, V, W)
			Active level during all period (100% duty)	TSG2nCMPm = TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1 (m = U, V, W)
TSOn7	Diagnostic signal output or pulse output by A/D conversion trigger	TSG2nCMP0 × count clock	Please refer to **Section 23.9.1, A/D Operation of A/D Conversion Trigger**.	

23.11.2.3 Various Settings of HT-PWM Mode

Mode Setting

HT-PWM can be used when TSG2nCTL0.TSG2nMD1 and TSG2nMD0 are set to 01_B.

Setting timer output

The output pins TSOn1 to TSOn6 are controlled by setting TSG2nIOC0, TSG2nIOC2, and TSG2nIOC3.

The output pin TSOn0 indicates the up/down count status of the 16-bit counter or the 16-bit sub-counter. Switch between the 16-bit sub-counter and the 16-bit counter is done with the TSG2nIOC1.TSG2nTOS bit.

The TSOn7 pin outputs pulses of the diagnostic output or the A/D conversion trigger. Please set it as required.

Enabling error interrupt generation

Error interrupt (INTTSG2nIER) due to the detection of the simultaneous active state of the positive phase and inverse phase is enabled by setting TSG2nIOC1.TSG2nEOC to 1. In HT-PWM mode, with any value set in the compare register, the simultaneous active state of the positive phase and inverse phase is not possible. Please refer to **Section 23.10, Error and Warning Interrupts**, for details.

Setting register rewriting timing with reload function

With TSG2nCTL3.TSG2nRMC, reload (simultaneous rewrite) or rewrite (anytime) is specified for the registers with reload function. The default setting is 0 (reload). To reload, set TSG2nCTL4.TSG2nPRE or TSG2nVRE to 1.

The reload timing is not generated if both the TSG2nPRE and TSG2nVRE bits are set to 0.

When "anytime rewrite" is specified, the unintended output may be generated depending on the rewrite timing.

Setting interrupts and skipping function

Interrupts and the skipping function are set with TSG2nCTL4. TSG2nPIE should be set to 1 when peak interrupt (INTTSG2nIPEK) is necessary and TSG2nVIE to 1 when trough interrupt (INTTSG2nIVLY) is necessary. To use the skipping function for peak/trough interrupts, the TSG2nRCC04 to TSG2nRCC00 must be set.

Setting A/D conversion trigger output

To set A/D conversion trigger 0 (TSTADT0 signal), use TSG2nCTL5.TSG2nAT09 to TSG2nAT00.

With TSG2nAT09 to TSG2nAT00, A/D conversion trigger output is enabled or disabled at the match of 16-bit counter (during up count) with TSG2nDCMP2 to TSG2nDCMP0, the match of the 16-bit counter (during down count) with TSG2nDCMP2 to TSG2nDCMP0, the 16-bit counter peak interrupt (INTTSG2nIPEK), the 16-bit counter trough interrupt (INTTSG2nIVLY), the 16-bit sub-counter peak timing, and 16-bit sub-counter trough timing.

To set A/D conversion trigger 1 (TSTADT1 signal), use TSG2nCTL6.TSG2nAT19 to TSG2nAT10.

To set the match timing of 16-bit counter and TSG2nDCMP2 to TSG2nDCMP0, set the compare value to the pertinent register.

The skipping function can be used for TSTADT0 and the TSTADT1 signals. Use TSG2nACC00, TSG2nACC01 of TSG2nCTL5, TSG2nACC10, and TSG2nACC11 of TSG2nCTL6 to select the skipping rate among 1/1, 1/2, 1/4, and 1/8.

CAUTION

Set TSG2nCTL5, TSG2nCTL6, and TSG2nDCMP2 to TSG2nDCMP0 correctly when using the TSOn7 output for the A/D conversion trigger timing pulse.

Setting dead time

The dead time can be set with TSG2nDTC0 and TSG2nDTC1.

The dead time is calculated by the following expressions:

PCLK × TSG2nDTC0

PCLK × TSG2nDTC1

TSG2nDTC0 can set the time between a change of TSOn2, TSOn4, and TSOn6 to the inactive state and a change of TSOn1, TSOn3, and TSOn5 to the active state, respectively.

TSG2nDTC1 can set the time between a change of TSOn1, TSOn3, TSOn5 to the inactive state and a change of TSOn2, TSOn4, and TSOn6 to the active state, respectively.

TSG2nDTC0 and TSG2nDTC1 can only be set to an even value.

Carrier period

Set the carrier period with TSG2nCMP0 according to the following expression:

TSG2nCMP0 = Carrier period/count clock period (PCLK)

Satisfy the following requirements when setting the TSG2nCMP0 register regarding the dead time:

- TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1 ≤ FFFEH
- TSG2nCMP0 > TSG2nDTC0
- TSG2nCMP0 > TSG2nDTC1
- TSG2nCMP0 > 3 × MAX (TSG2nDTC0, TSG2nDTC1)
- TSG2nCMP0: Even number

NOTES

MAX (A, B) indicates the larger value of A and B.

Duty (PWM width) setting

The duty of the U phase, the V phase, and the W phase is set with TSG2nCMPm (m = U, V, W, or 1, 2, 5, 6, 9, and 10), respectively. The setting range of the compare registers is as follows:

0000_H ≤ TSG2nCMPm ≤ TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1

LSB (least significant bit) of TSG2nCMPU, TSG2nCMPV, and TSG2nCMPW indicates the setting of an additional pulse. When TSG2nCMPU = 0003_H, the change in the inverse phase (TSOn2 output) is done one count clock later compared to the TSG2nCMPU = 0002_H setting (when the 16-bit counter is up-counting). The additional pulse cannot be set to TSG2nCMP1, TSG2nCMP2, TSG2nCMP5, TSG2nCMP6, TSG2nCMP9, or TSG2nCMP10 (only even numbers can be set to these registers).

23.11.2.4 16-Bit Counter Operation in HT-PWM Mode

The 16-bit counter is initialized to 0000_H and the value of TSG2nDTC0 is loaded immediately after starting the TSG2n timer operation (TSG2nTRG0.TSG2nTS = 1). Afterwards, counting is done by +2. After 16-bit counter reaches the value of TSG2nCMP0 + TSG2nDTC0, counting is done by -2.

Figure 23.56 shows 16-bit counter operation.

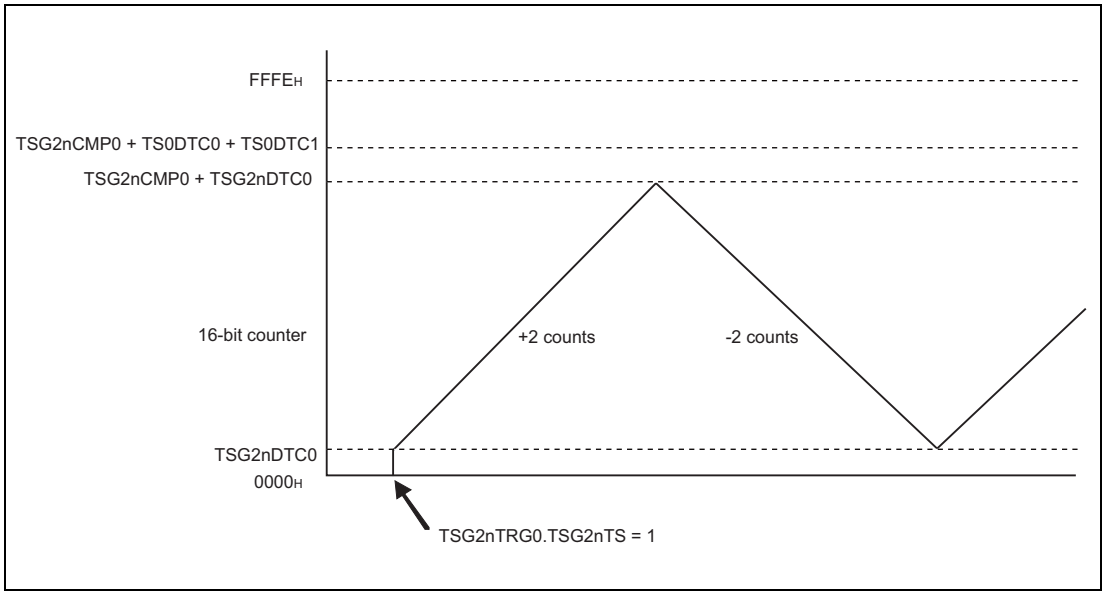

Figure 23.56 Example of 16-Bit Counter Operation in HT-PWM Mode

NOTE

Minimum 16-bit counter value: TSG2nDTC0
Maximum 16-bit counter value: TSG2nCMP0 + TSG2nDTC0
Carrier period : TSG2nCMP0 × count clock period (PCLK)

The 16-bit sub-counter is initialized to 0000_H and the value of TSG2nDTC0 is loaded immediately after starting the TSG2n timer operation (TSG2nTRG0.TSG2nTS = 1). Afterwards, counting by -2 is done until 0000_H is reached and counting by +2 begins. Next, the value of the 16-bit counter is loaded into the 16-bit sub-counter at a change timing of the 16-bit counter into the down count. Counting up by the 16-bit sub-counter continues until the value reaches the value of TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1, and then counting by -2 begins. Similarly, when the 16-bit counter value matches the TSG2nDTC0 value, the 16-bit counter value is loaded to the 16-bit sub-counter and the down count is continued.

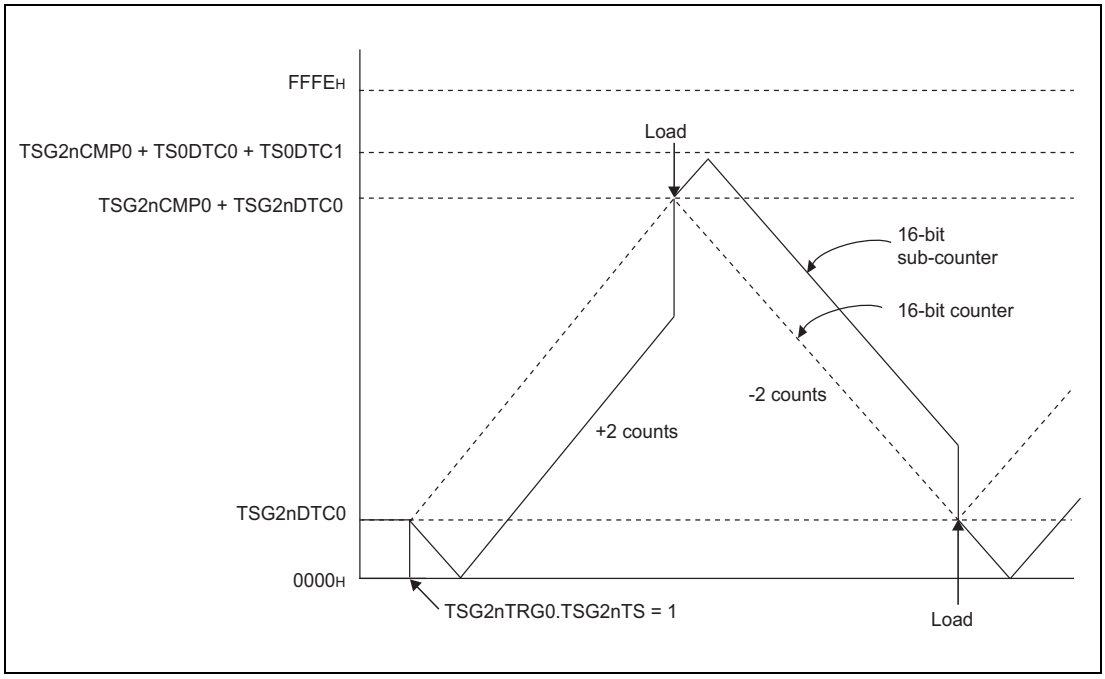

Figure 23.57 Example of 16-bit Sub-Counter Operation in HT-PWM Mode

NOTE

Minimum 16-bit sub-counter value: 0000_H
Maximum 16-bit sub-counter value: TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1

23.11.2.5 Basic Operation of HT-PWM Mode

(1) Example of Timer Output Immediately after the Start of the TSG2n Timer Operation

Figure 23.58 shows the timing chart when TSG2nCMP0 = $000E_H$, TSG2nDTC0 = 0002_H, TSG2nDTC1 = 0004_H and TSG2nCMPU = 0000_H-0014_H (excerpt). In this example, TSG2nIOC2.TSG2nOL1-TSG2nOL6 = 000000_B.

In the case of TSG2nCMPU = TSG2nDTC0, when the initial value of the counter is loaded after TSG2n begins operation (TSG2nTRG0.TSG2nTS = 1), the TSOn2 output is changed to the active level. When TSG2nCMPU = TSG2nDTC0-0001_H, an additional pulse is generated, the TSOn2 output is changed one count clock cycle later compared to the case of TSG2nCMPU = TSG2nDTC0-0002_H.

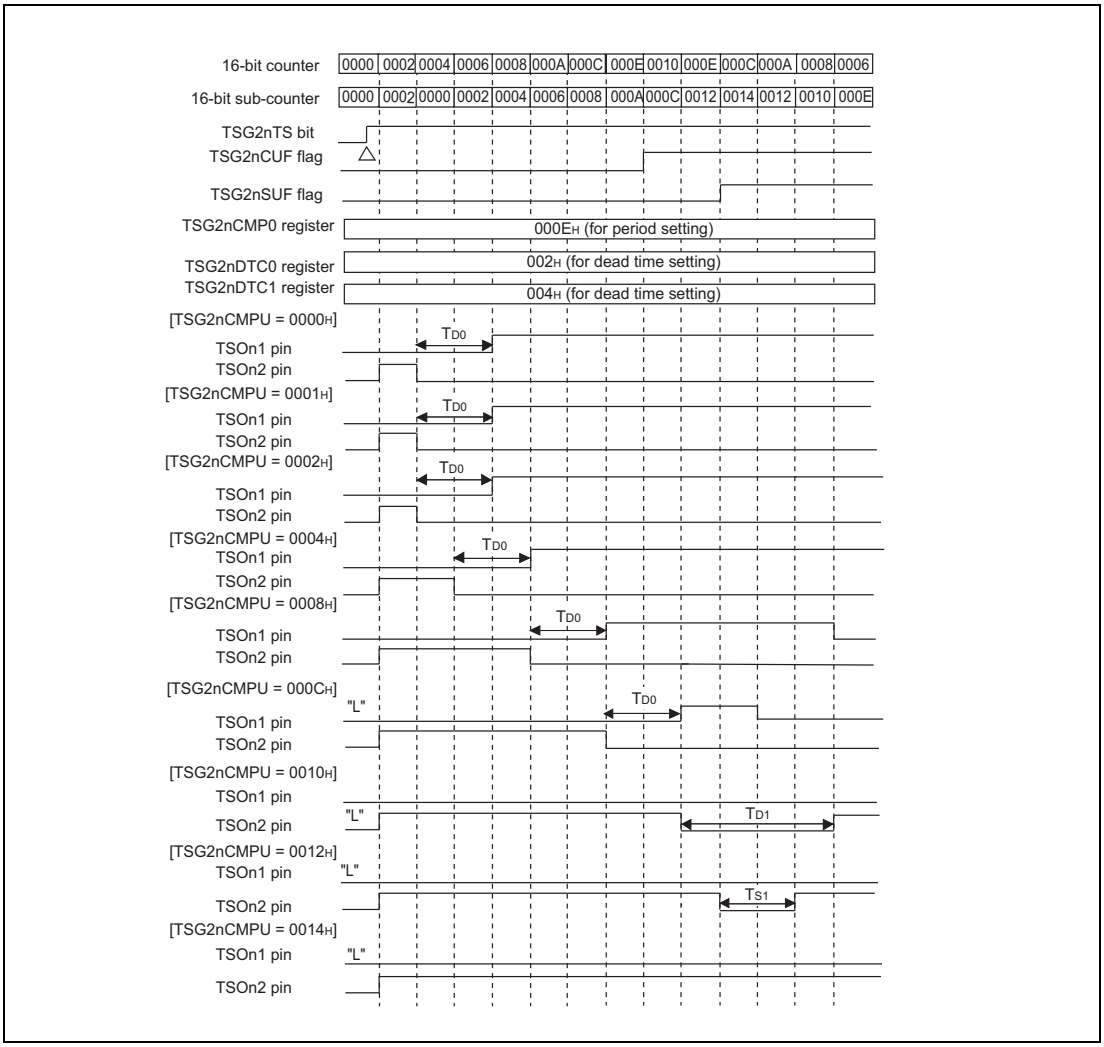

Figure 23.58 Example of Timer Output when TSG2nTS is Set to 1 (Initial) in HT-PWM Mode

NOTES

1. TSG2nCMP0 = $000E_H$, TSG2nDTC0 = 0002_H, TSG2nDTC1 = 0004_H
2. TD0: Time depending on setting of the dead time in the TSG2nDTC0 register
   TD1: Time depending on setting of the dead time in the TSG2nDTC1 register
   TS1: Time decided by compare match of the 16-bit sub-counter and TSG2nCMPU register, when TSG2nCMPU >16-bit counter maximum value
3. Δ: Write access

(2) Example of Timer Output during TSG2n Timer Operation

The figure below shows the timing chart when TSG2nCMP0 = $000E_H$, TSG2nDTC0 = 0002_H, TSG2nDTC1 = 0004_H, and TSG2nCMPU is set to 0000_H-0014_H (excerpt). In this example, TSG2nIOC2.TSG2nOL1-TSG2nOL6 = 000000_B.

The range of the active (high level) width of a positive phase (TSOn1) output is $0000_H \leq$ TSG2nCMPU $\leq$ TSG2nCMP0 (for the additional pulse). The range of the active (high level) width of an inverse phase (TSOn2) output is TSG2nDTC0 + TSG2nDTC1 $\leq$ TSG2nCMPU $\leq$ TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1.

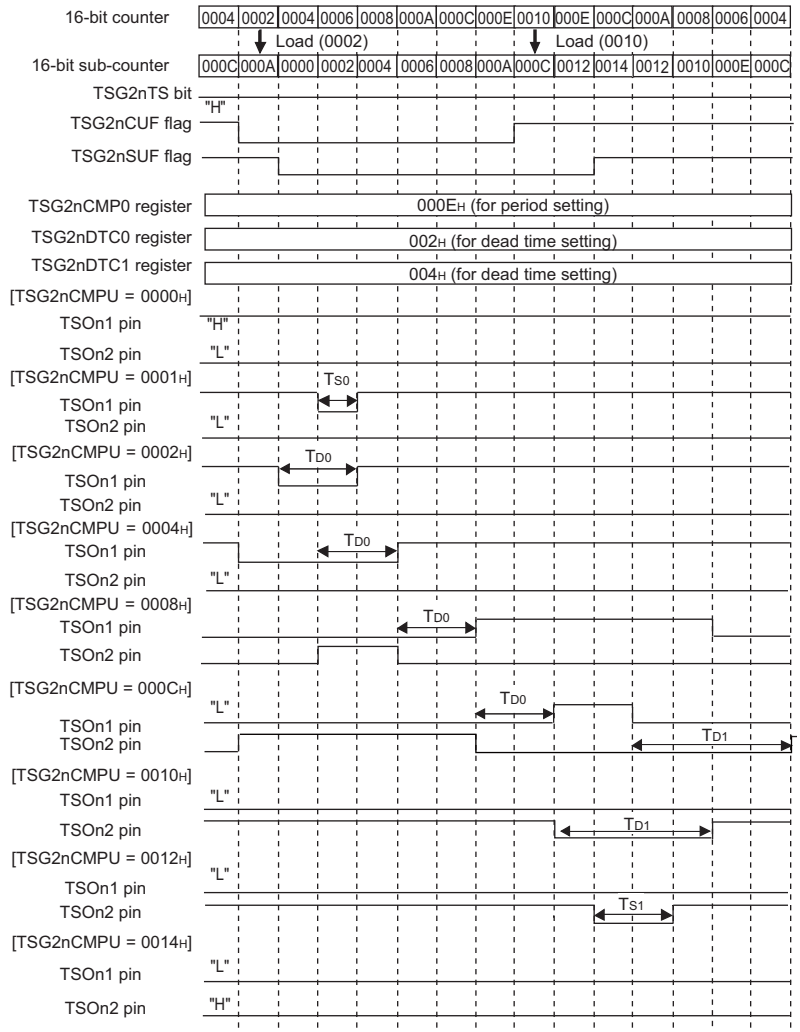

Figure 23.59 Example of Timer Output during TSG2n Operation in HT-PWM Mode

NOTES

1. TSG2nCMP0 = $000E_H$, TSG2nDTC0 = 0002_H, TSG2nDTC1 = 0004_H
2. TD0 : Time depending on setting of the dead time in the TSG2nDTC0 register
   TD1 : Time depending on setting of the dead time in the TSG2nDTC1 register
   TS0 : Time decided by compare match of 16-bit sub-counter and the TSG2nCMPU register, when TSG2nCMPU < 16-bit counter minimum value
   TS1 : Time decided by compare match of the 16-bit sub-counter and the TSG2nCMPU register, when TSG2nCMPU > 16-bit counter maximum value

23.11.2.6 Additional Pulse Control in HT-PWM Mode

The HT-PWM mode can generate an additional pulse by setting 1 to the LSB of the duty setting registers (TSG2nCMPU, TSG2nCMPV, and TSG2nCMPW). This allows more precise control of the pulse duty than standard pulse control.

The following sections describe two examples of pulse output of TSOn1: additional pulse control is used in one example and additional pulse control is not used in another.

(1) Example of Pulse Output when Additional Pulse Control is Used

Figure 23.60 shows the additional pulse control when an odd value is set to TSG2nCMPU.

The arrows and numerical values show the width of the duty cycle of the TSOn1 output in one period.

When the additional pulse control is used as shown in **Figure 23.60**, the width of the output of the TSOn1 (duty cycle) can be set within a range from the width of 12 clock cycles to the width of 0 clock cycles in one-clock-cycle step.

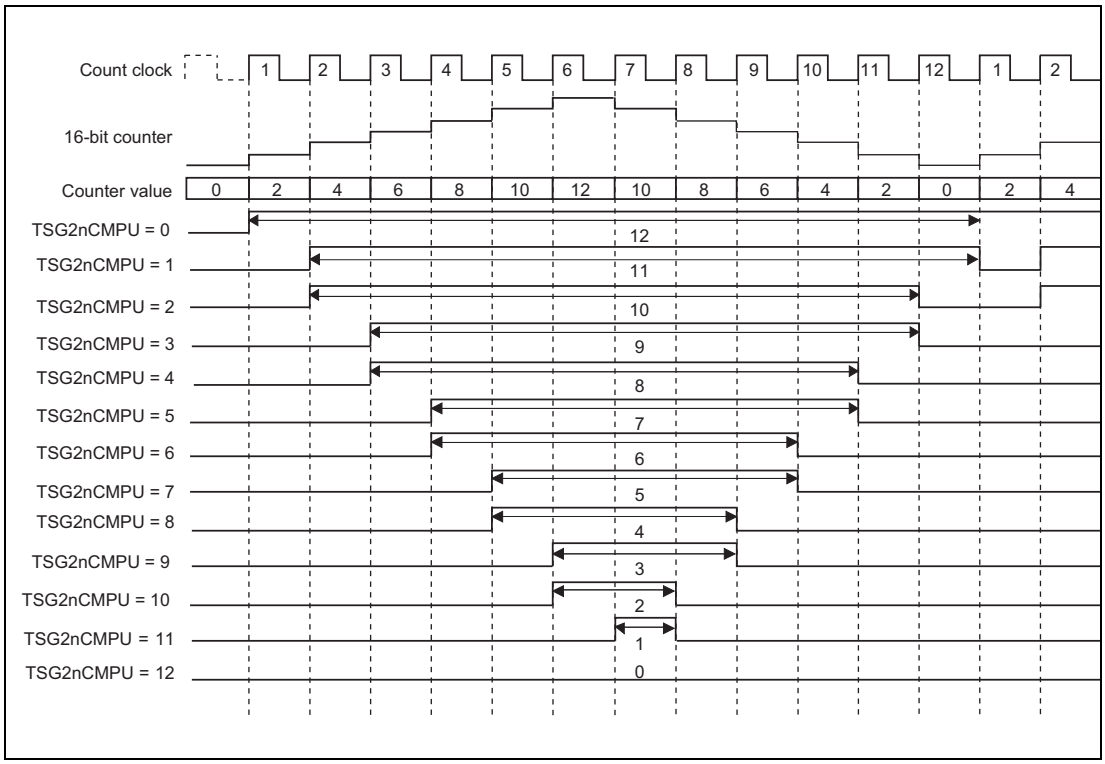

Figure 23.60 Example of TSOn1 Output when Additional Pulse Control is Used in HT-PWM Mode

NOTE

TSG2nCMP0 = 12, TSG2nDTC0 = 0, TSG2nDTC1 = 0

(2) Example of Pulse Output when Additional Pulse Control is Not Used

The arrows and numerical values in **Figure 23.61** show the width of the duty cycle of the TSOn1 output in one period.

When the additional pulse control is not used, the width of the TSOn1 output can be set within a range from the width of 12 clock cycles to the width of 0 clock cycles in two-clock-cycle step. In this case, the change in duty cycle is larger than that in the case when the additional pulse control is used.

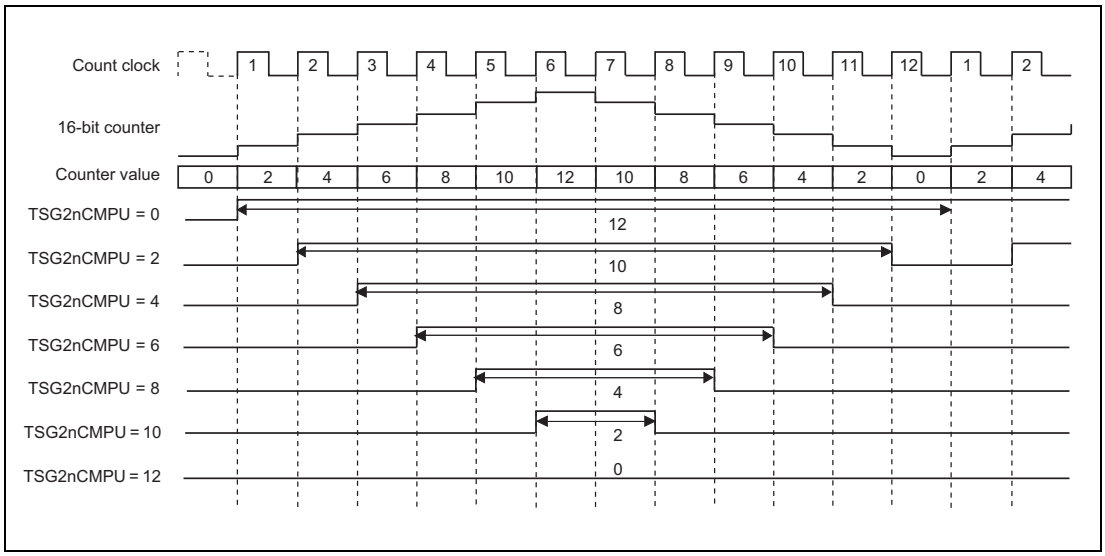

Figure 23.61 Example of Output when Additional Pulse Control is Not Used in HT-PWM Mode

NOTE

TSG2nCMP0 = 12, TSG2nDTC0 = 0, TSG2nDTC1 = 0

23.11.2.7 Dead Time Control in HT-PWM Mode

Duty setting registers are TSG2nCMP1, TSG2nCMP2, TSG2nCMP5, TSG2nCMP6, TSG2nCMP9, and TSG2nCMP10 and registers for setting the period are TSG2nCMP0, TSG2nDTC0, and TSG2nDTC1 in HT-PWM mode. The 6-phase PWM waveform of a variable duty is output by using these registers. To achieve the dead time control, there are two dead time setting registers (TSG2nDTC0 and TSG2nDTC1) and six 10-bit down counters that operate synchronously with the count clock of the 16-bit counter. TSG2nDTC0 is used for setting a dead time from a change of the inverse phase to the inactive state to a change of the positive phase to the active state. TSG2nDTC1 is used for setting a dead time from a change of the positive phase to the inactive state to a change of the inverse phase to the active state.

Figure 23.11 shows the output waveform when TSG2nDTC0 = x and TSG2nDTC1 = y.

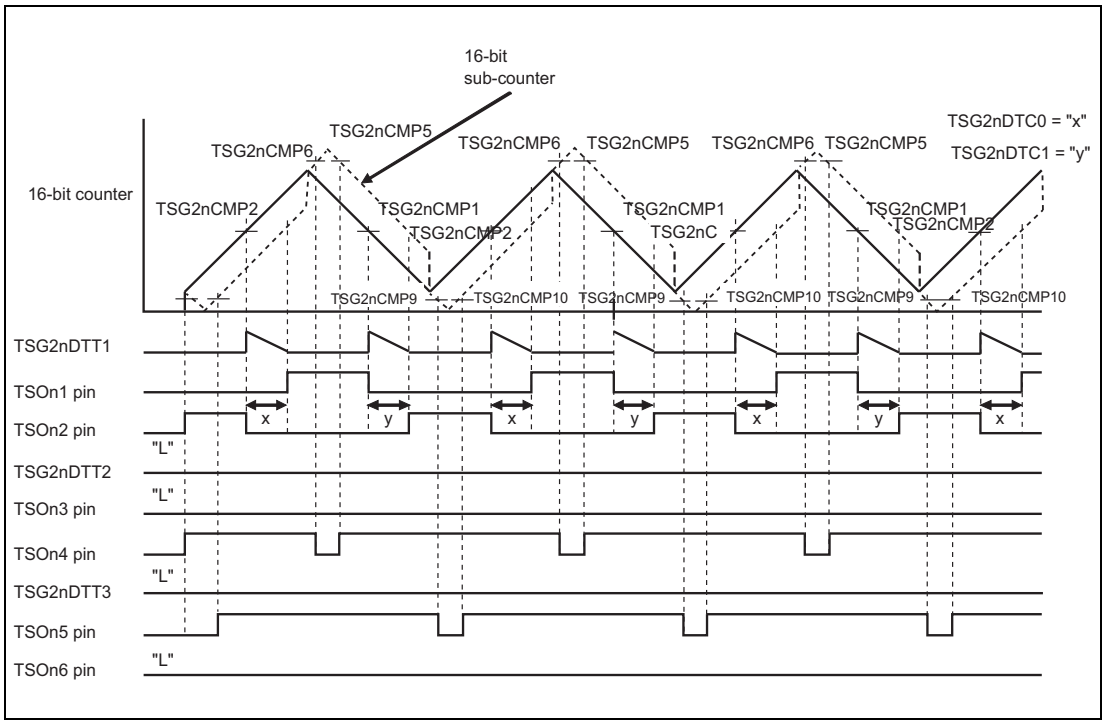

Figure 23.62 Example of Output Waveform with Dead Time in HT-PWM Mode

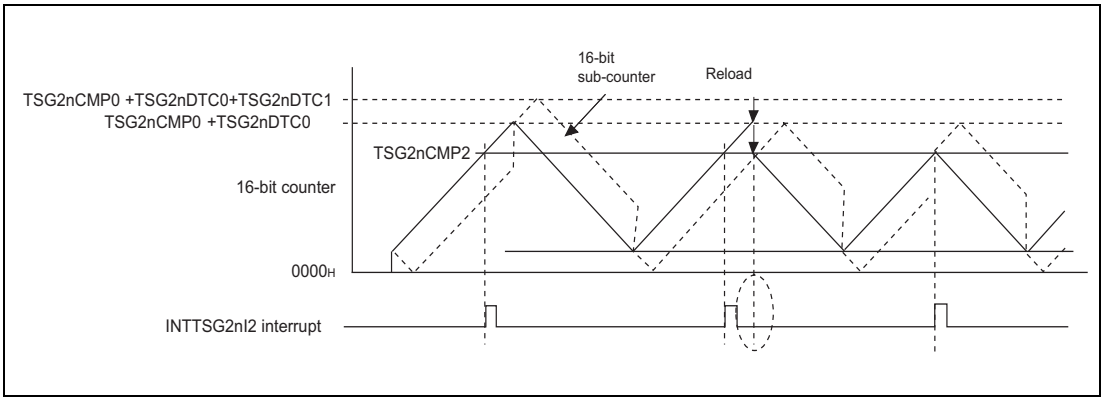
23.11.2.8 Notes Concerning Dead Time Control in HT-PWM Mode

(1) TSG2nDTC0 and TSG2nDTC1 Rewriting

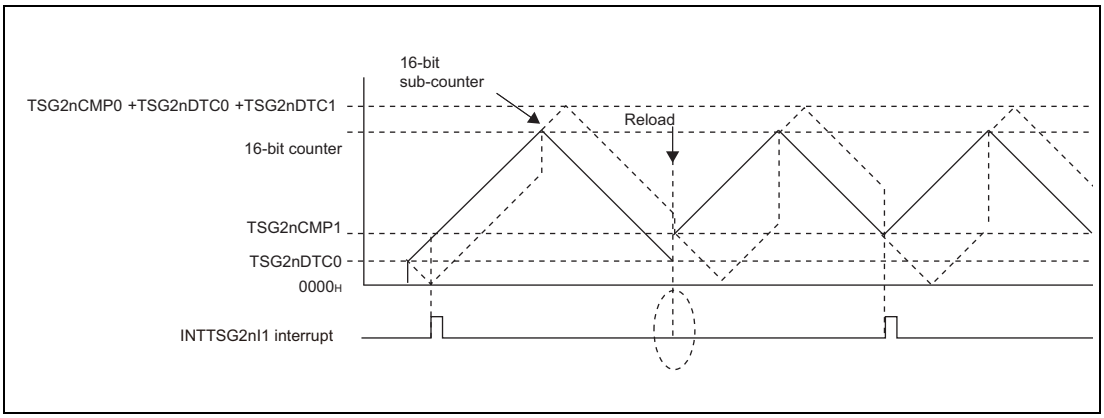
It is possible to rewrite the dead time setting in TSG2nDTC0 and TSG2nDTC1 registers during timer operation.

CAUTIONS

1. **Rewrite TSG2nDTC0 and TSG2nDTC1 when the reload function is used (TSG2nRMC = 0).**
2. **The write protection code check function is applied when TSG2nDTC0 and TSG2nDTC1 are rewritten. Refer to the pertinent register description for details.**
3. **When the TSG2nCMP0 and TSG2nDTC1 are updated at the peak of the 16-bit counter:**
   If the setting of TSG2nCMPm is greater than the updated TSG2nCMP0 + TSG2nDTC0 (new maximum value of the main counter), the match interrupt (INTTSG2nIm) will not be generated immediately after reload (m = 2, 6, 10).



4. **When the TSG2nDTC0 is updated at the trough of the 16-bit counter:**
   If the setting of TSG2nCMPm is less than the updated TSG2nDTC0 (new minimum value of the main counter), the match interrupt (INTTSG2nIm) is not generated immediately after reload (m = 1, 5, 9).



23.11.2.9 Software Output Control Function in HT-PWM Mode

TSG2nOPT0.TSG2nSOC, TSG2nIDC, and TSG2nOPT1.TSG2nSPC2-TSG2nSPC0 are used in HT-PWM mode for software control of timer output control.

As shown in **Figure 23.63**, with TSG2nSTE = 0, the output control is switched immediately when TSG2nSOC is set to 1. If the dead time is set, the period of the dead time is guaranteed. After that, when TSG2nSOC is set to 0, output control is retained. When the reload timing is generated, output control is switched to HT-PWM mode output control.

For details, refer to **Section 23.11.5, Software Output Control Function**.

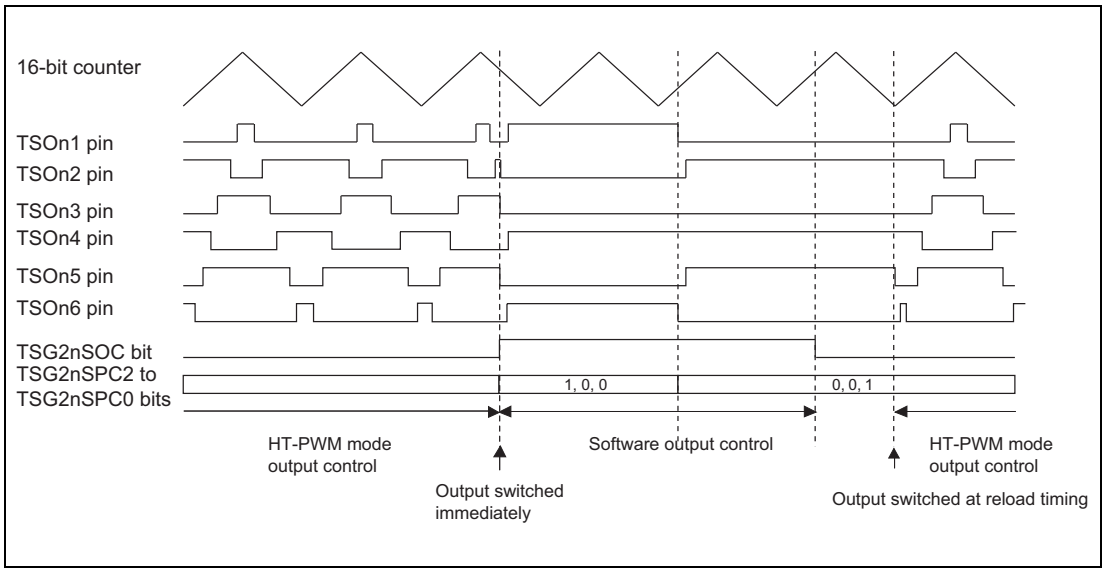


Figure 23.63 Example of Software Output Control Switching in HT-PWM Mode

CAUTION

Use reload (simultaneous rewrite) mode (TSG2nCTL3.TSG2nRMC = 0) when software output control function is used.

(1) Procedure for Software Output Control

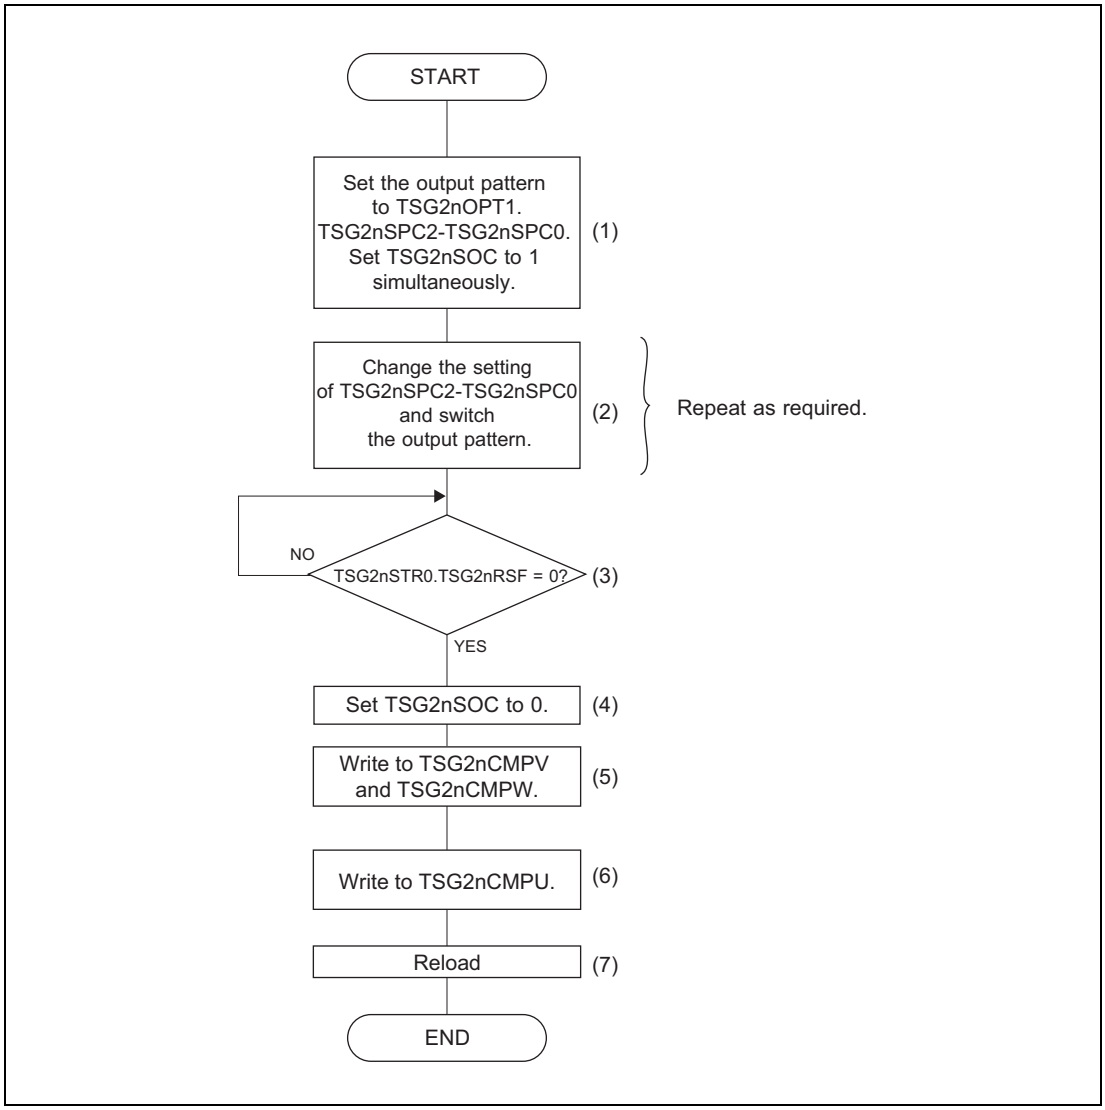

Figure 23.64 Flow of Software Output Control in HT-PWM Mode

The procedure for software output control is described below.

(1) Set the output pattern to the TSG2nOPT1.TSG2nSPC2-TSG2nSPC0. To enable software output control, set TSG2nOPT0.TSG2nSOC to 1 simultaneously.

(2) Change the output pattern setting of the TSG2nSPC2-TSG2nSPC0 to change the timer output. The registers that can be changed during software control are: TSG2nTRG1.TSG2nTT, TSG2nCTL3-TSG2nCTL6, TSG2nOPT0, TSG2nOPT1, TSG2nCMPm (m = 0, 1, 2, 5, 6, 9, 10), TSG2nDTC0, and TSG2nDTC1

(3) Confirm that reload request flag TSG2nSTR0.TSG2nRSF = 0. In case TSG2nRSF = 1, do not proceed to the following step until TSG2nRSF = 0.

(4) By setting TSG2nSOC = 0, the software control starts to be released (it is not released here yet).

(5) After releasing the software output control, set the necessary compare registers. Proceed to the following step when the register setting is not required. Here, change the registers with the reload function.

(6) Write to TSG2nCMPU (TSG2nCMP1) to start reloading.

(7) Reload is executed and software output is released.

CAUTION

Execute reload after executing steps (3), (4), (5), (6), and (7). When reload cannot be executed, the software output cannot be released.

23.11.2.10Asymmetric Triangular Wave Control in HT-PWM Mode

In HT-PWM mode, it is possible to control output by an asymmetric triangular waveform by setting the different timings for setting and clearing the U, V, and W phases.

The following describes the differences of the asymmetric triangular wave control from the symmetric triangular wave control.

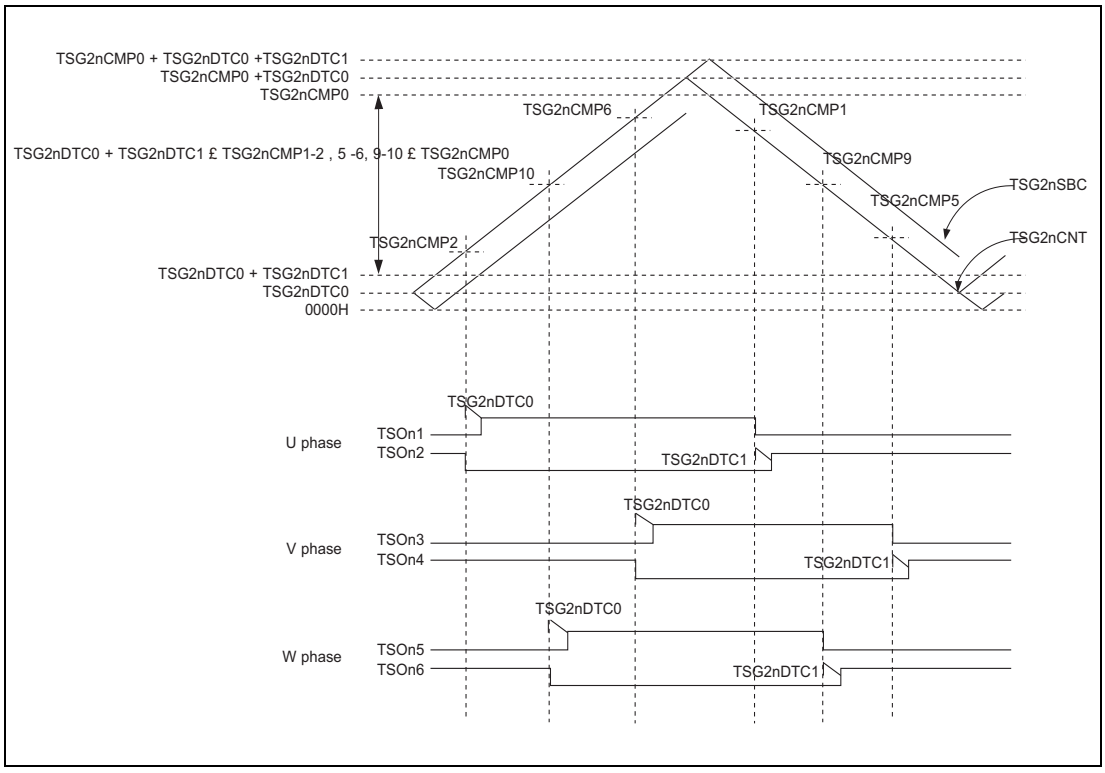
(1) PWM Setting

When a symmetric triangular wave is used, the output control of each of the U phase, V phase, and W phase is done by setting the set timing and the clear timing to the same value to the TSG2nCMPU, TSG2nCMPV, and TSG2nCMPW. When an asymmetric triangular wave is used, the output control of each phase is done by setting TSG2nCMPm as follows (m = 1, 2, 5, 6, 9, 10):

Prerequisites

- The clear timing of PWM of the voltage data signal of U, V and W phases is set with TSG2nCMP1, TSG2nCMP5, and TSG2nCMP9.
- The set timing of PWM of the voltage data signal of U, V, and W phases is set with TSG2nCMP2, TSG2nCMP6, and TSG2nCMP10.
- The set and the clear timings of each phase can also be set with TSG2nCMP1W (TSG2nCMP1 and TSG2nCMP2), TSG2nCMP5W (TSG2nCMP5 and TSG2nCMP6), and TSG2nCMP9W (TSG2nCMP9 and TSG2nCMP10)
- TSG2nCMPm can only be set to an even value (m = 1, 2, 5, 6, 9, 10).

(2) Timer Output



NOTE

When output is controlled by the asymmetric triangular waveform, the following conditions apply to setting of TSG2nCMPm (m = 1, 2, 5, 6, 9, 10):

- TSG2nDTC0 + TSG2nDTC1 ≤ TSG2nCMPm ≤ TSG2nCMP0
- Only when TSG2nCMPm = TSG2nCMP(m+1) or TSG2nCMPm = TSG2nCMP(m+1) + 2, it is possible to set TSG2nCMPm under the condition 0000_H ≤ TSG2nCMPm ≤ TSG2nCMP0 + TSG2nDTC0 + TSG2nDTC1, which also applies to the case in which the symmetric triangular wave is used.

23.11.3 SP-PWM Mode (Shifted-pulse - Pulse Width Modulation Mode)

Overview

In this mode, a 6-phase PWM can be generated using the 16-bit counter and the 16-bit compare registers.

Prerequisites

- The PWM signal cycle is set in TSG2nCMP0.
- The set timings of the U phase, V phase, and W phase are set with TSG2nCMP2, TSG2nCMP6, and TSG2nCMP10, while the clear timings of these phases are set with TSG2nCMP1, TSG2nCMP5, and TSG2nCMP9 (when set timing and clear timing are used for control).
- The set timings of the U phase, V phase, and W phase are set with TSG2nCMP2, TSG2nCMP6, and TSG2nCMP10 while the active periods of these phases are set with TSG2nUPW, TSG2nVPW, and TSG2nWPW.
  The sum of the set values of TSG2nCMP2, TSG2nCMP6, TSG2nCMP10, and the set values of TSG2nUPW, TSG2nVPW, TSG2nWPW are set to TSG2nCMP1, TSG2nCMP5, and TSG2nCMP9 respectively (when set timing and active period are used for control).

Functional description

Set the carrier period and the set timings and duty of U phase, V phase, and W phase. The counting up begins when TSG2nTRG0.TSG2nTS is set to 1.

The 16-bit counter counts up from 0000_H and is cleared by match with TSG2nCMP0.

The dead time is set with TSG2nDTC0 and TSG2nDTC1. TSG2nDTC0 sets the dead time of inverse phase (OFF) to positive phase (ON) switch while TSG2nDTC1 sets that of positive phase (OFF) to inverse phase (ON) switch. The 10-bit counters (TSG2nDTT1 to TSG2nDTT3) for dead time generation load the set values of TSG2nDTC0 and TSG2nDTC1 at compare match of the 16-bit counter with the TSG2nCMPm buffer register (m = 1, 2, 5, 6, 9, 10) and start down-counting.

INTTSG2nIm interrupts (m = 1, 2, 5, 6, 9, 10) are generated by the compare match of the 16-bit counter with the TSG2nCMP1, TSG2nCMP2, TSG2nCMP5, TSG2nCMP6, TSG2nCMP9, and TSG2nCMP10 buffer registers.

NOTES

SP-PWM mode is enabled when TSG2nTRG0.TSG2nMD1 and TSG2nMD0 = 10_B.

23.11.3.1 Basic Timing Chart

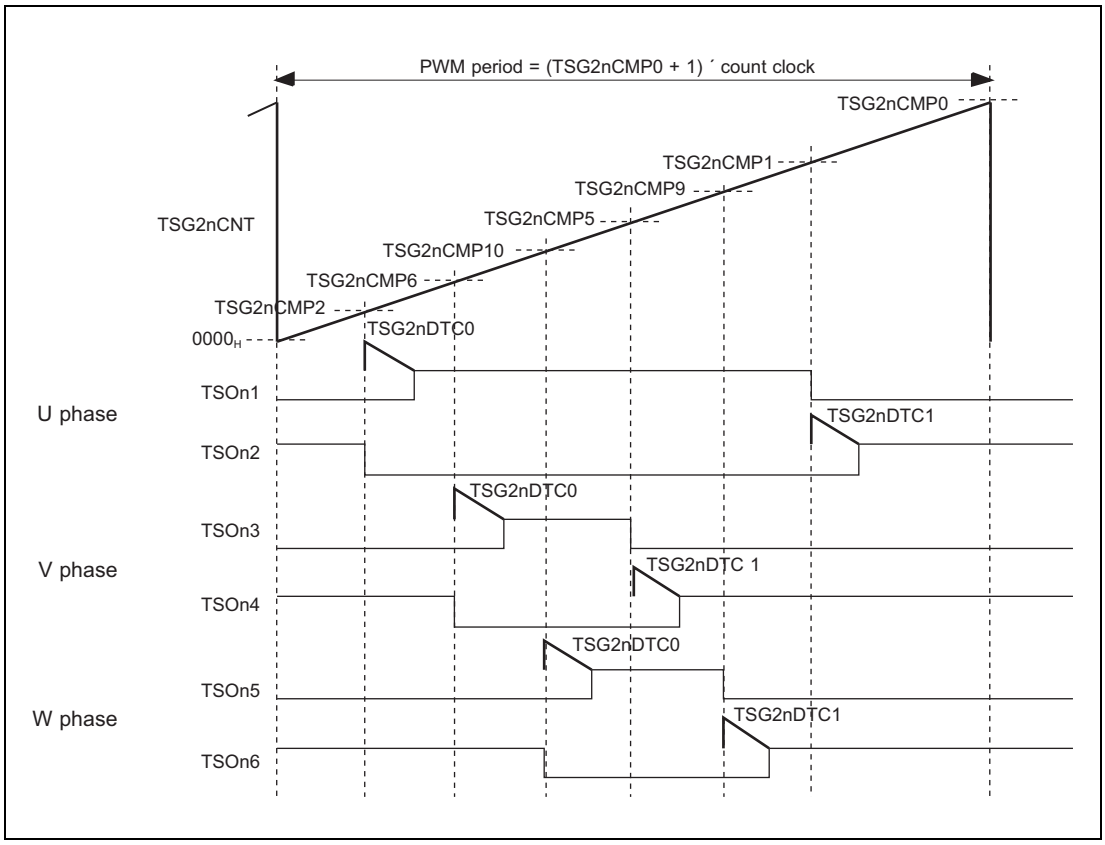


Figure 23.65 Basic Timing in SP-PWM Mode

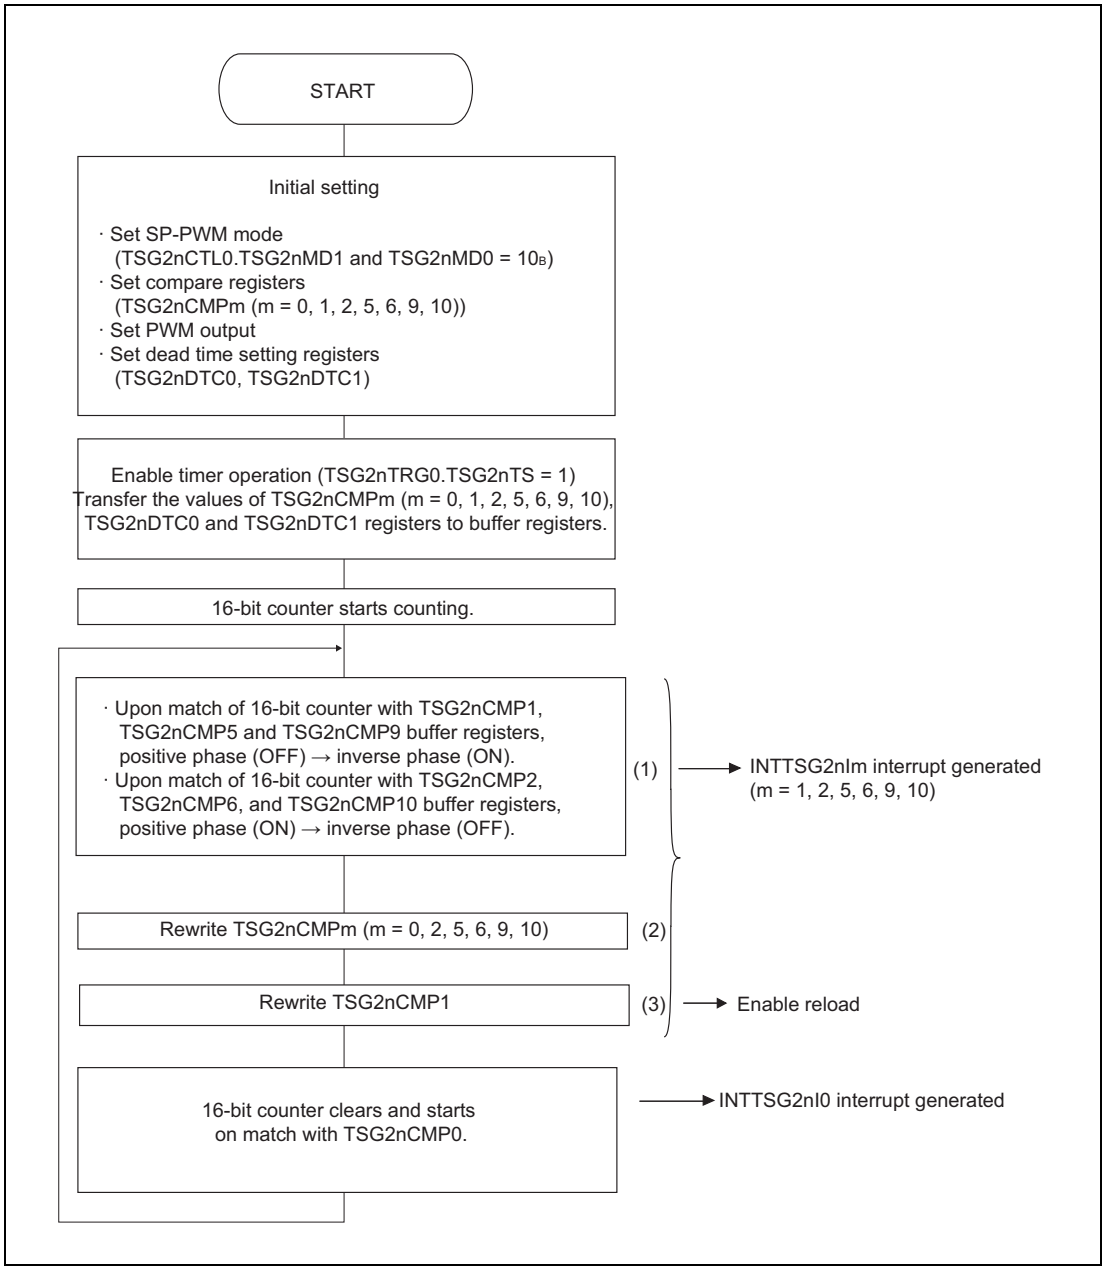

Figure 23.66 Basic Operation Flow in SP-PWM Mode

NOTE

The timing of (1) may be different depending on the rewriting timing of (2) and (3).
Be sure to do step (2) before (3).

23.11.3.2 List of SP-PWM Mode Operations

Table 23.58 Counter Functions in SP-PWM Mode

Operation		Setting Condition
16-bit counter	Start	TSG2nTRG0.TSG2nTS = 0 → 1
	Clear	Compare match of TSG2nCMP0 buffer register with 16-bit counter
	Stop	TSG2nTRG1.TSG2nTT = 0 → 1

Table 23.59 Compare Registers and Dead Time Setting Register Functions in SP-PWM Mode

Register	Rewriting Method	Rewrite during Operation	Function
TSG2nCMP0	Reload/Anytime rewrite	Possible	Setting period
TSG2nUPW	Reload/Anytime rewrite	Possible	PWM control for U phase
TSG2nCMP1W (TSG2nCMP1, TSG2nCMP2)	Reload/Anytime rewrite		
TSG2nVPW	Reload/Anytime rewrite	Possible	PWM control for V phase
TSG2nCMP5W (TSG2nCMP5, TSG2nCMP6)	Reload/Anytime rewrite		
TSG2nWPW,	Reload/Anytime rewrite	Possible	PWM control for W phase
TSG2nCMP9W (TSG2nCMP9, TSG2nCMP10)	Reload/Anytime rewrite		
TSG2nDTC0, TSG2nDTC1	Reload	Possible	Period and dead time
TSG2nDCMP0W, TSG2nDCMP2	Reload/Anytime rewrite	Possible	Diagnostic signal output or A/D conversion trigger

Table 23.60 Output Functions in SP-PWM Mode

Pin	Function
TSOn1	PWM output with dead time by compare match of TSG2nCMP1 buffer register (clear timing) or TSG2nCMP2 buffer register (set timing) with 16-bit counter
TSOn2	Output inverse phase with respect to TSOn1 (with dead time)
TSOn3	PWM output with dead time by compare match of TSG2nCMP5 buffer register (clear timing) or TSG2nCMP6 buffer register (set timing) with 16-bit counter
TSOn4	Output inverse phase with respect to TSOn3 (with dead time)
TSOn5	PWM output with dead time by compare match of the TSG2nCMP9 buffer register (clear timing) or the TSG2nCMP10 buffer register (set timing) with the 16-bit counter
TSOn6	Output inverse phase with respect to TSOn5 (with dead time)
TSOn7	Diagnostic signal output or pulse output by A/D conversion trigger

Table 23.61 Interrupt Requests in SP-PWM Mode

Interrupt	Function
INTTSG2nIm (m = 0, 1, 2, 5, 6, 9, 10)	Compare match of TSG2nCMPm buffer register with 16-bit counter (m = 0, 1, 2, 5, 6, 9, 10)
INTTSG2nIER	Error
INTTSG2nIVLY	—
INTTSG2nIPEK	Peak interrupt (generated at the same timing as INTTSG2nI0)
INTTSG2nIWN	Warning

Table 23.62 Compare Match Timing in SP-PWM Mode

Compare Match	Timing
TSG2nCMP0	When 16-bit counter changes from TSG2nCMP0 to 0000_H
TSG2nCMPm (m = 1, 2, 5, 6, 9, 10)	After match of 16-bit counter and TSG2nCMPm is detected (m = 1, 2, 5, 6, 9, 10)

Table 23.63 Example of Setting Each Timer Output Condition in SP-PWM Mode

			Output Duty	
Pin	**Item**	**Output Period**	**Output Condition**	**Setting Condition**
TSOn1, TSOn3, TSOn5	PWM output	(TSG2nCMP0 + 1) × count clock	Output an inactive level throughout one period (duty 0%)	TSG2nCMPm = TSG2nCMP(m + 1) or TSG2nCMP(m + 1) > TSG2nCMP0 (m = 1, 5, 9)
			Output an active level of one count clock in one period	TSG2nCMPm = TSG2nCMP(m + 1) + 1 TSG2nCMP(m + 1) = TSG2nCMPm - 1 (m = 1, 5, 9)
			Output an inactive level of one count clock in one period	TSG2nCMPm = TSG2nCMP(m + 1) - 1 TSG2nCMP(m + 1) = TSG2nCMPm + 1 (m = 1, 5, 9)
			Output an active level throughout one period (duty 100%)	TSG2nCMPm > TSG2nCMP0 TSG2nCMP(m + 1) ≤ TSG2nCMP0 (m = 1, 5, 9)
TSG2nO2, TSG2nO4, TSG2nO6	PWM output	(TSG2nCMP0 + 1) × count clock	Output an inactive level throughout one period (duty 0%)	TSG2nCMPm = TSG2nCMP(m - 1) or TSG2nCMP(m - 1) > TSG2nCMP0 (m = 2, 6, 10)
			Output an active level of one count clock in one period	TSG2nCMPm = TSG2nCMP(m - 1) - 1 TSG2nCMP(m - 1) = TSG2nCMPm + 1 (m = 2, 6, 10)
			Output an inactive level of one count clock in one period	TSG2nCMPm = TSG2nCMP(m - 1) + 1 TSG2nCMP(m - 1) = TSG2nCMPm - 1 (m = 2, 6, 10)
			Output an active level throughout one period (duty 100%)	TSG2nCMPm > TSG2nCMP0 (m = 2, 6, 10)
TSOn7	Diagnostic signal output or pulse output by A/D conversion trigger	(TSG2nCMP0 + 1) × count clock	Please refer to **Section 23.9, A/D Conversion Trigger Function**.	

23.11.3.3 Various Settings of SP-PWM Mode

Mode Setting

SP-PWM mode is entered by setting TSG2nCTL0.TSG2nMD1-TSG2nMD0 to 10_B.

Setting timer output

The output pins TSOn1-TSOn6 are controlled by setting TSG2nIOC0, TSG2nIOC2, and TSG2nIOC3.

The TSOn7 pin provides output pulse as diagnostic output or analog to digital conversion trigger. The pin should be set as necessary.

Enabling error interrupt generation

Error interrupt (INTTSG2nIER) due to the detection of the simultaneous active state of the positive and inverse phases is enabled by setting TSG2nIOC1.TSG2nEOC to 1. For details, refer to **Section 23.10, Error and Warning Interrupts**.

Setting rewriting timing of register with reload function

With the TSG2nCTL3.TSG2nRMC, reload (simultaneous rewrite) or rewrite (anytime) is specified for the registers with reload function. The default setting is 0 (reload). To reload, set TSG2nCTL4.TSG2nPRE to 1.

No reload timing is generated when TSG2nPRE = 0.

When "anytime rewrite" is specified, the unintended output may be generated depending on the rewrite timing.

Setting analog to digital conversion trigger output

The analog to digital conversion trigger 0 (TSTADT0 signal) is set with TSG2nCTL5.TSG2nAT09 to TSG2nAT00.

TSG2nAT09 to TSG2nAT00 is used to enable or disable the A/D conversion trigger output on timing match of TSG2nDCMP2 to TSG2nDCMP0 with the 16-bit counter (up count).

TSG2nCTL6.TSG2nAT19 to TSG2nAT10 is used to set the analog to digital conversion trigger 1 (TSTADT1 signal).

To set the match timing of the 16-bit counter and TSG2nDCMP2 to TSG2nDCMP0, set the compare value to each register.

The skipping function can be used for TSTADT0 and TSTADT1 signals. TSG2nACC00 and TSG2nACC01 of TSG2nCTL5, and TSG2nACC10 and TSG2nACC11 of TSG2nCTL6 can be used to select the skipping rate among 1/1, 1/2, 1/4, and 1/8.

CAUTIONS

- **Be sure to set TSG2nCTL5, TSG2nCTL6, and TSG2nDCMP2 to TSG2nDCMP0 correctly when the timing pulse of analog to digital conversion trigger is output to TSOn7.**
- **In SP-PWM mode, no trough interrupt (INTTSG2nIVLY) is generated. Therefore, TSG2nCTL5.TSG2nAT00 and TSG2nCTL6.TSG2nAT10 must be set to 0.**
- **In SP-PWM mode, the 16-bit sub-counter does not operate. Therefore, TSG2nAT09, and TSG2nAT08 in TSG2nCTL5, and TSG2nAT19, and TSG2nAT18 in TSG2nCTL6 must be set to 0.**
- **In SP-PWM mode, down counting by the 16-bit counter is not generated. Therefore, TSG2nAT07, TSG2nAT05, and TSG2nAT03 in TSG2nCTL5 and TSG2nAT17, TSG2nAT15, and TSG2nAT13 in TSG2nCTL6 should be set to 0.**

Setting dead time

The dead time can be set with TSG2nDTC0 and TSG2nDTC1.

The dead time is calculated by the following expressions:

PCLK × TSG2nDTC0

PCLK × TSG2nDTC1

TSG2nDTC0 can set the time between a change of TSOn2, TSOn4, and TSOn6 to the inactive state and a change of TSOn1, TSOn3, and TSOn5 to the active state, respectively.

TSG2nDTC1 can set the time between a change of TSOn1, TSOn3, and TSOn5 to the inactive state, and a change of TSOn2, TSOn4, and TSOn6 to the active state, respectively.

Carrier period

Set the carrier period with TSG2nCMP0 according to the following expression:

TSG2nCMP0 = (carrier period/count clock period) - 1

CAUTION

PWM output with 100% duty cannot be produced when TSG2nCMP0 = $FFFF_H$.

Setting duty (PWM width)

The duty of U phase, V phase, and W phase is set with TSG2nCMPm, TSG2nUPW, TSG2nVPW, and TSG2nWPW (m = 1, 2, 5, 6, 9, 10), respectively.

- The set timings of the U phase, V phase, and W phase are set with TSG2nCMP2, TSG2nCMP6, and TSG2nCMP10, and the clear timings are set with TSG2nCMP1, TSG2nCMP5, and TSG2nCMP9. (The set and clear timing setting is used for control.)
- The set timings of U phase, V phase, and W phase is set with TSG2nCMP2, TSG2nCMP6, and TSG2nCMP10 while the active periods of these phases are set with TSG2nUPW, TSG2nVPW, and TSG2nWPW.
  The sum of the set values of TSG2nCMP2, TSG2nCMP6, and TSG2nCMP10, and the set values of TSG2nUPW, TSG2nVPW, and TSG2nWPW are set to TSG2nCMP1, TSG2nCMP5, and TSG2nCMP9 respectively (when set timing and active period are used for control).

23.11.3.4 Dead Time Control in SP-PWM mode

Duty setting registers are TSG2nCMPm (m = 1, 2, 5, 6, 9, 10), TSG2nUPW, TSG2nVPW, and TSG2nWPW and register for setting the period is TSG2nCMP0. The 6-phase PWM waveform of a variable duty is output by using these registers. To achieve the dead time control, there are six 10-bit down counters that operate synchronously with the count clock of the 16-bit counter and two dead time setting registers (TSG2nDTC0 and TSG2nDTC1). TSG2nDTC0 is used for setting a dead time from a change of the inverse phase to the inactive state to a change of the positive phase to the active state. TSG2nDTC1 is used for setting a dead time from a change of the positive phase to the inactive state to a change of the inverse phase to the active state. **Figure 23.67** shows an example of the output waveform.

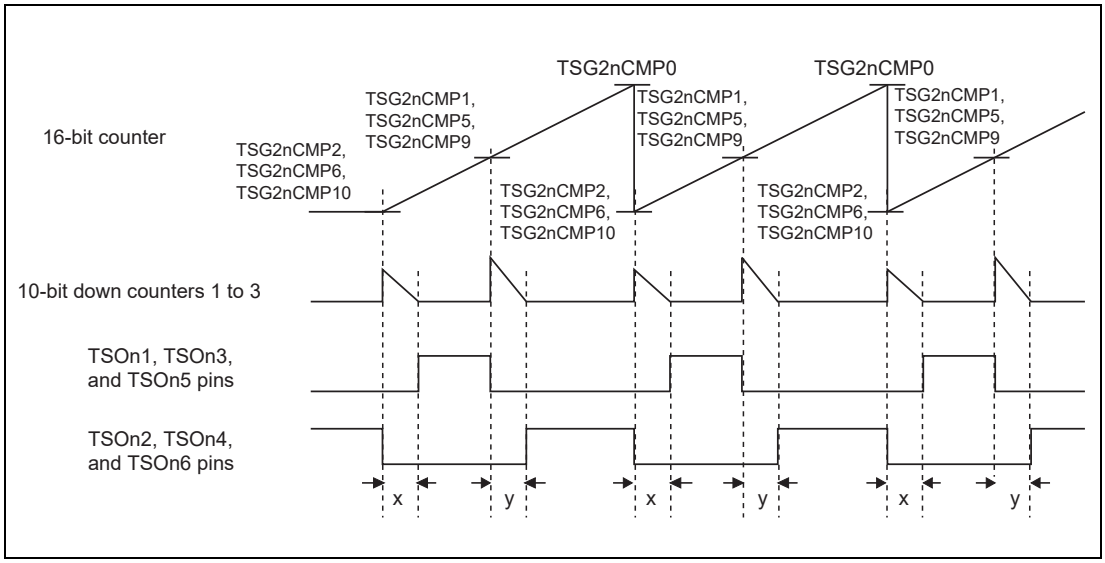

Figure 23.67 Example of Output Waveform in SP-PWM Mode

NOTE

x : TSG2nDTC0 register values

y : TSG2nDTC1 register values

23.11.3.5 Software Output Control Function in SP-PWM Mode

TSG2nOPT0.TSG2nSOC, TSG2nIDC, and TSG2nOPT1.TSG2nSPC2 to TSG2nSPC0 are used to control timer output by software.

As shown in **Figure 23.68**, the output control is switched immediately when TSG2nSOC is set to 1. If the dead time is set, the period of the dead time is guaranteed. After that, when TSG2nSOC is set to 0, output control is retained. When the reload timing is generated, output control is switched to SP-PWM mode output control.

For details, refer to **Section 23.11.5, Software Output Control Function**.

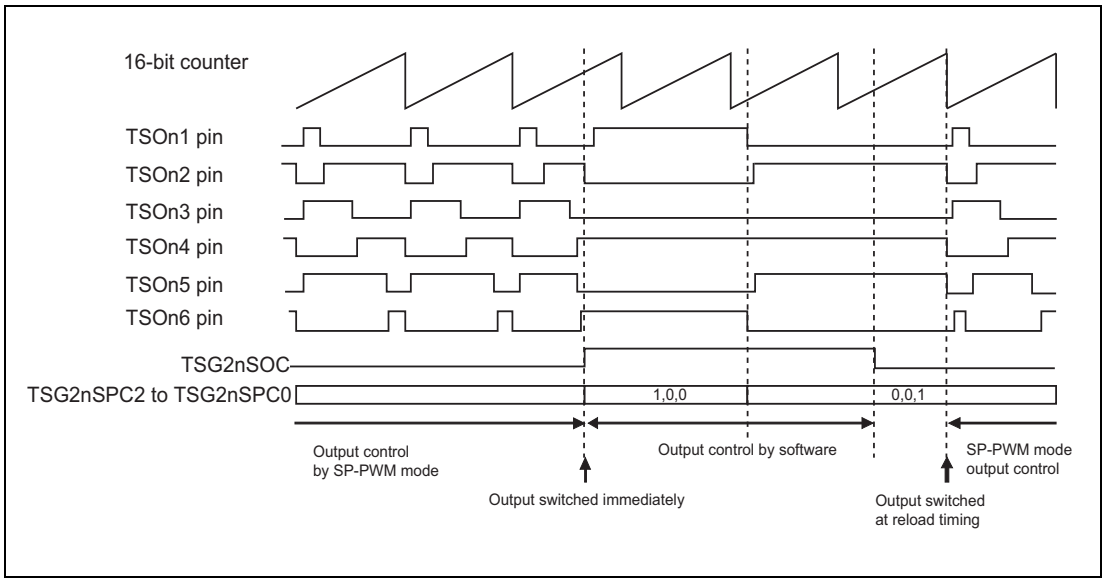

Figure 23.68 Example of Output Control Switching from SP-PWM Mode Control to Software Control

(1) Procedure on Software Output Control Processing

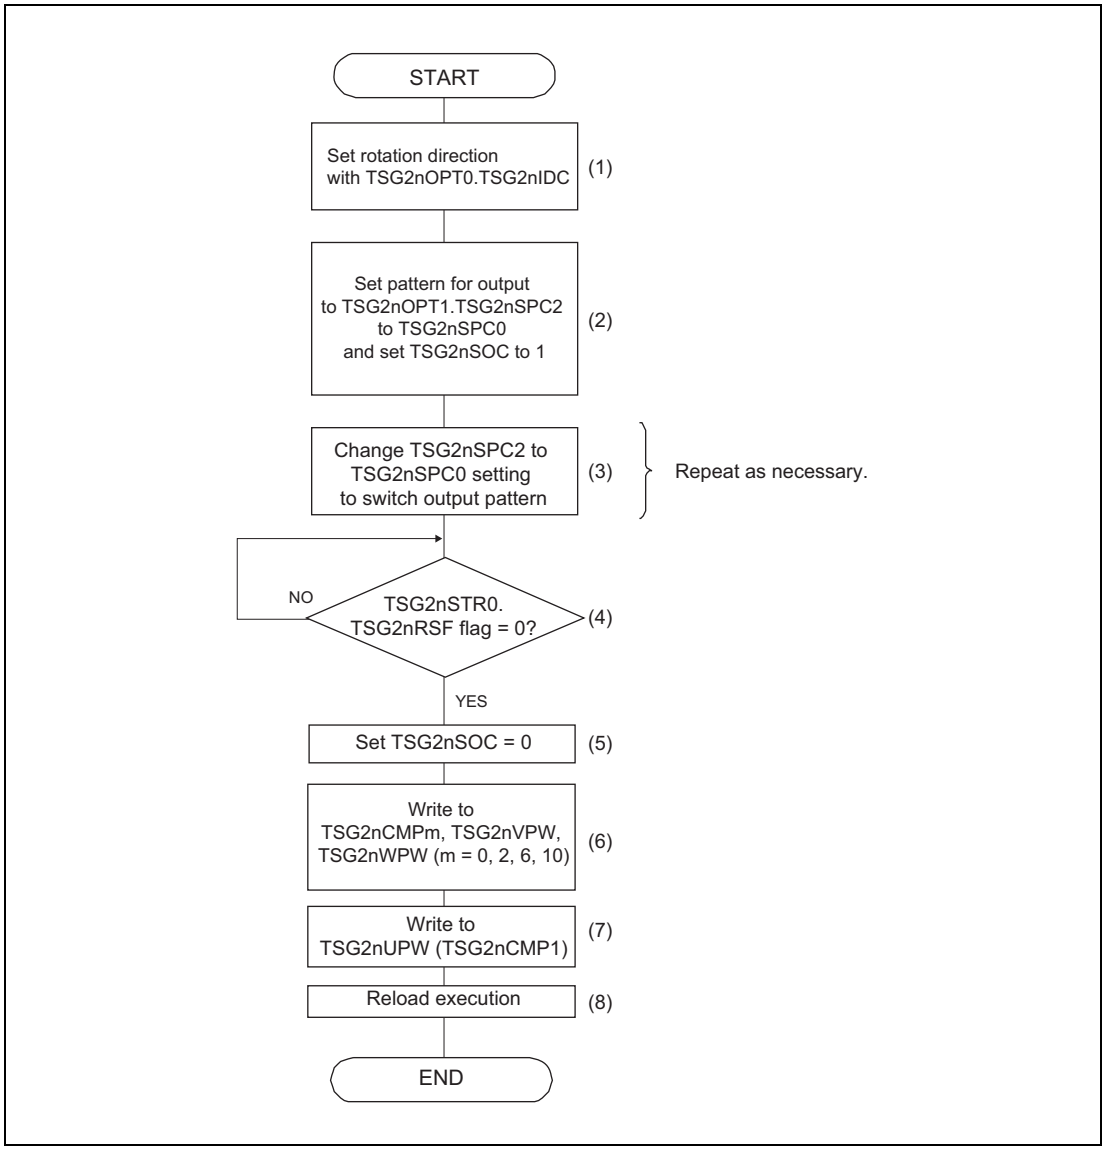

Figure 23.69 Flow of Software Output Control

The procedure for software output control is described below.

(1) Set TSG2nOPT0 to determine the rotation direction. The timer output has a 180-degree phase shift between when TSG2nIDC = 0 and when TSG2nIDC = 1. With the software output control function, the timer output will not change only by rewriting the TSG2nOPT0 bit.

(2) Set the pattern for output to TSG2nOPT1. At the same time, set TSG2nOPT0.TSG2nSOC to 1 to switch to software output control mode.

(3) Change the output pattern setting for TSG2nSPC2-TSG2nSPC0 to change the timer output. During software control mode, the following registers can be modified: TSG2nTRG0.TSG2nTS, TSG2nCTL3-TSG2nCTL6, TSG2nOPT0, TSG2nOPT1, TSG2nCMP0-TSG2nCMP12, TSG2nDTC0, and TSG2nDTC1.

(4) Ensure that the reload request flag TSG2nSTR0.TSG2nRSF is 0. If TSG2nRSF is 1, do not shift to the following procedure until it goes 0.

(5) By clearing TSG2nSOC to 0, software control starts to be released (not yet released here).

(6) After software output control is released, set the compare registers if necessary. Move to the following procedure if no setting is required. In addition, change the registers with the reload function if necessary.

(7) Write TSG2nUPW (TSG2nCMP1) to start reloading.

(8) Reload is executed and software output control is released.

CAUTION

Be sure to execute reload after execution of steps (4), (5), (6), and (7). Unless reload can be executed, software output control cannot be released

23.11.4 120-DC Mode

Overview

In this mode, PWM output period set to TSG2nCMP0 and timer output (TSOn1 to TSOn6) according to the duty cycle set to TSG2nCMP1 to TSG2nCMP12 are controlled with two types of pattern inputs (software output control method and pattern switch method) to perform 120-DC control.

Prerequisites

- Set the PWM period to TSG2nCMP0.
- Set the PWM duty to TSG2nCMP1 to TSG2nCMP12 and set the output pattern to TSG2nPAT0W and TSG2nPAT1W.

Functional description

Set the PWM period, set the duty cycle to individual compare register, and set the pattern to be output to the pattern register. Setting TSG2nTRG0.TSG2nTS to 1 starts counting.

The 16-bit counter starts counting from 0000_H, and is cleared by the match with TSG2nCMP0.

INTTSG2nI1 to INTTSG2nI12 interrupts are generated by a compare match of the 16-bit counter and TSG2nCMP1 to TSG2nCMP12 buffer registers, respectively.

NOTE

120-DC mode is valid when TSG2nCTL0.TSG2nMD1 to TSG2nMD0 are set to 11_B.

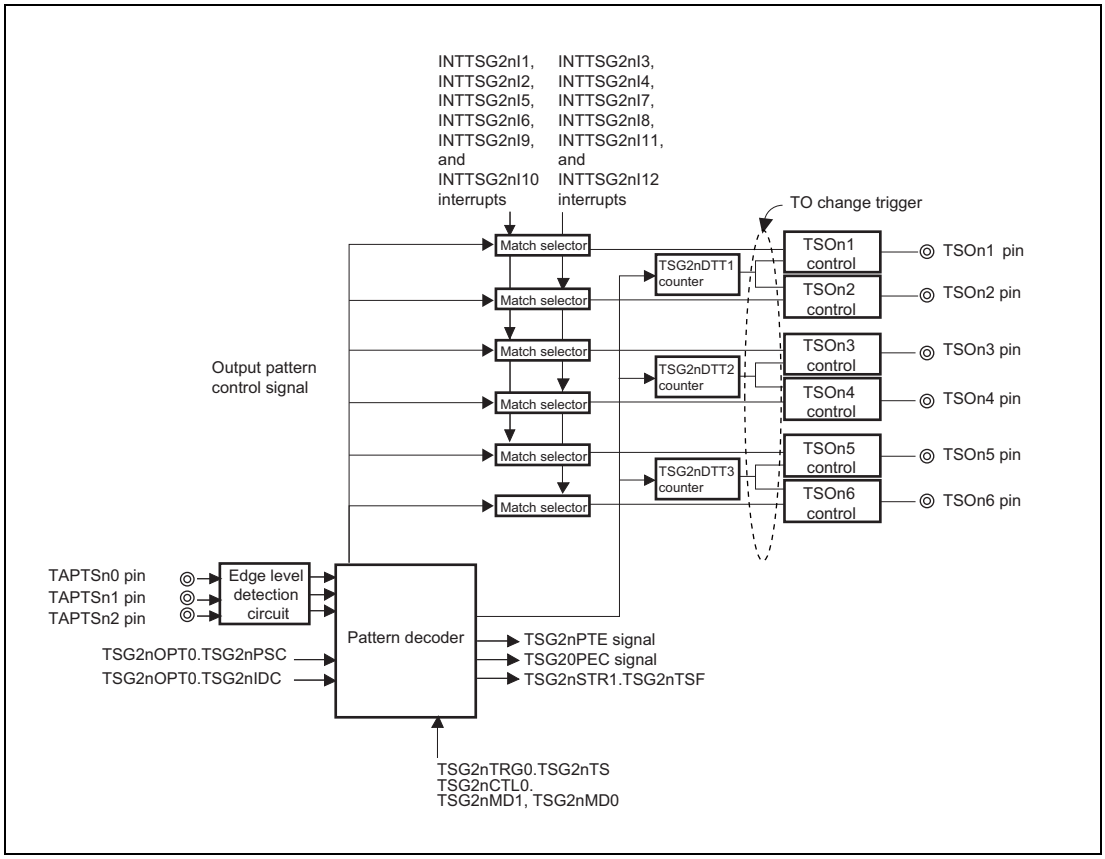

Figure 23.70 Block Diagram in 120-DC Mode

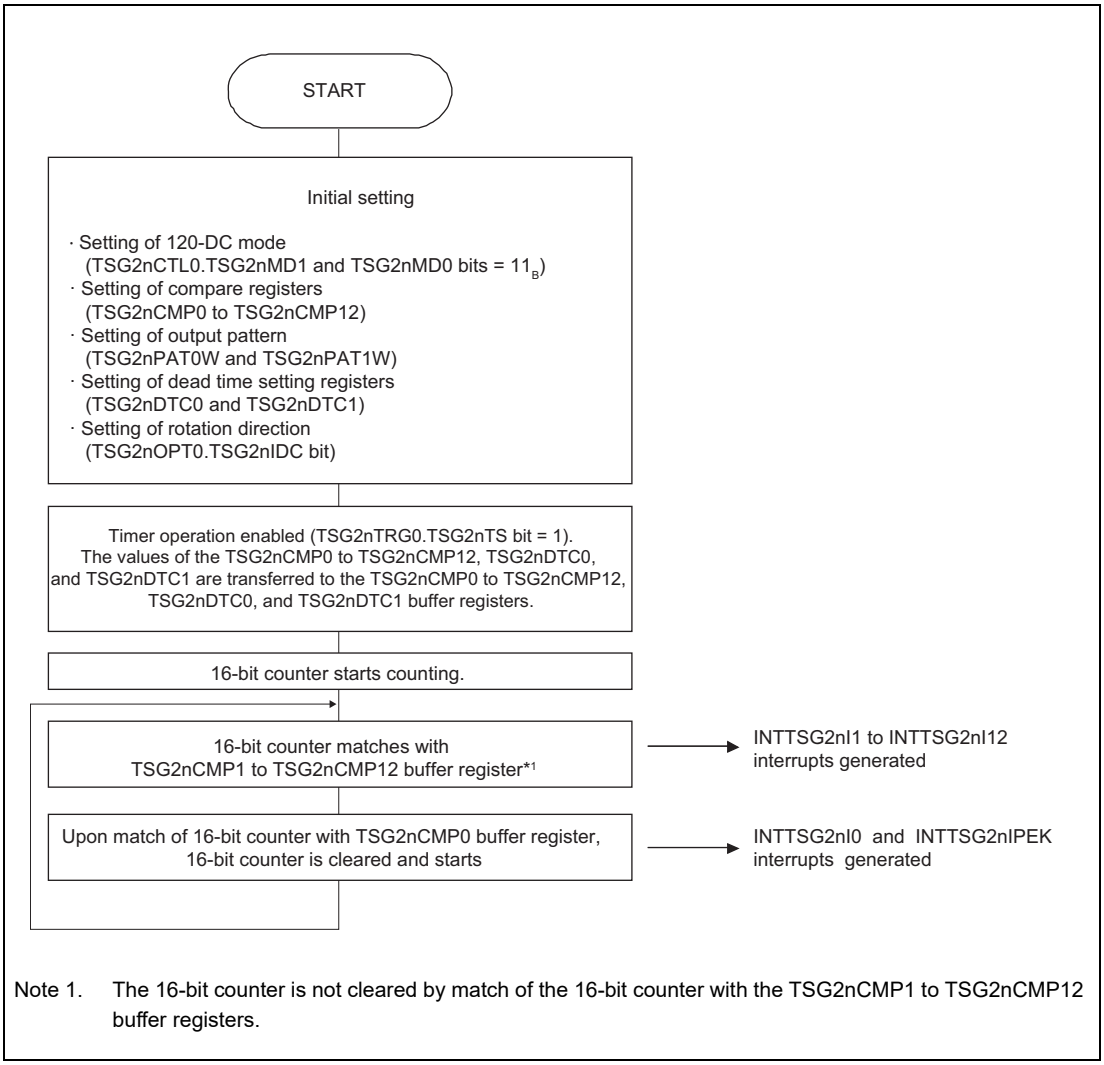

Note 1. The 16-bit counter is not cleared by match of the 16-bit counter with the TSG2nCMP1 to TSG2nCMP12 buffer registers.

Figure 23.71 Basic Operation Flow in 120-DC Mode

23.11.4.1 List of Operations in 120-DC Mode

Table 23.64 Counter Functions in 120-DC Mode

Operation		Setting Condition
16-bit counter	Start	TSG2nTRG0.TSG2nTS = 0 → 1
	Clear	Match of TSG2nCMP0 value and 16-bit counter value, or output pattern switch timing
	Stop	TSG2nTRG1.TSG2nTT = 0 → 1

Table 23.65 Functions of Compare Registers and Dead Time Setting Registers in 120-DC Mode

Register	Rewrite Method	Rewrite during Operation	Function
TSG2nCMP0	Reload	Possible	Setting period
TSG2nCMPm (m = 1 to 12)	Reload	Possible	Setting PWM duty
TSG2nDCMP0W, TSG2nDCMP2	Reload	Possible	Outputting diagnostic signal or setting A/D conversion trigger
TSG2nDTC0, TSG2nDTC1	Reload	Possible	Setting dead time

Table 23.66 Timer Input Function in 120-DC Mode

Pin/Signal	Function
TAPTSn2 to TAPTSn0 pins	Pattern input (3 phases)

Table 23.67 Timer Output Function in 120-DC Mode

Pin/Signal	Function
TSOn1 pin	PWM output (with dead time) by compare match of the TSG2nCMPm buffer register (m = 1, 2, 5, 6, 9, 10) with the 16-bit counter and by selecting output pattern through TSG2nPAT0W setting.
TSOn2 pin	PWM output (with dead time) by compare match of the TSG2nCMPm buffer register (m = 3, 4, 7, 8, 11, 12) and the 16-bit counter and by selecting output pattern through TSG2nPAT1W setting.
TSOn3 pin	PWM output (with dead time) by compare match of the TSG2nCMPm buffer register (m = 1, 2, 5, 6, 9, 10) and the 16-bit counter and by selecting output pattern through TSG2nPAT0W setting.
TSOn4 pin	PWM output (with dead time) by compare match of the TSG2nCMPm buffer register (m = 3, 4, 7, 8, 11, 12) and the 16-bit counter and by selecting output pattern through TSG2nPAT1W setting.
TSOn5 pin	PWM output (with dead time) by compare match of the TSG2nCMPm buffer register (m = 1, 2, 5, 6, 9, 10) and the 16-bit counter and by selecting output pattern through TSG2nPAT0W setting.
TSOn6 pin	PWM output (with dead time) by a compare match of the TSG2nCMPm buffer register (m = 3, 4, 7, 8, 11, 12) and the 16-bit counter and by selecting output pattern through TSG2nPAT1W setting.
TSOn7 pin	Diagnostic signal output or pulse output by A/D conversion trigger
TSG2nPTE signal	Toggle signal by change in input pattern

Table 23.68 Interrupt Requests in 120-DC Mode

Interrupt	Function
INTTSG2nIm (m = 0 to 12)	Compare match of TSG2nCMPm buffer register and 16-bit counter (m = 0 to 12)
INTTSG2nIER	Error
INTTSG2nIVLY	—
INTTSG2nIPEK	Peak interrupt (generated at the same timing as INTTSG2nI0)
INTTSG2nIWN	Warning interrupt

Table 23.69 Compare Match Timing in 120-DC Mode

Compare Match	Timing
TSG2nCMP0	When 16-bit counter changes from TSG2nCMP0 to 0000_H
TSG2nCMPm (m = 1 to 12)	After detecting the match of 16-bit counter and TSG2nCMPm (m = 1 to 12)

Table 23.70 Example of Setting Each Timer Output Condition in 120-DC Mode

			Output Duty	
Pin	Item	Output Period	Output Condition	Setting Condition
TSOnm (m = 1 to 6)	PWM output	(TSG2nCMP0 + 1) × count clock	See **23.11.4.6, List of Output Patterns in 120-DC Mode**.	—
TSOn7	Diagnostic signal output or pulse output by A/D conversion trigger	(TSG2nCMP0 + 1) × count clock	See **23.9, A/D Conversion Trigger Function**.	—

23.11.4.2 Various Settings of 120-DC Mode

Mode setting

120-DC mode can be used by setting TSG2nCTL0.TSG2nMD1 and TSG2nMD0 are set to 11_B.

Setting timer output

The output pins TSOn1 to TSOn6 are controlled by setting TSG2nIOC0, TSG2nIOC2, and TSG2nIOC3.

The TSOn7 pin outputs pulses of the diagnostic output or the A/D conversion trigger. Please set it as required.

Enabling error interrupt generation

With TSG2nIOC1.TSG2nEOC = 1, the error interrupt (INTTSG2nIER) generation is enabled when the simultaneous active state of the positive phase and inverse phase is detected. For details, see **Section 23.10, Error and Warning Interrupts**.

Setting register rewrite timing

Reloading the registers with the reload function is activated with TSG2nCTL3.TSG2nRMC (simultaneous rewrite; default setting is 0 = reload). Set TSG2nCTL4.TSG2nPRE to 1 when reload is used.

The reload timing is not generated if TSG2nPRE is 0.

Setting A/D conversion trigger output

To set A/D conversion trigger 0 (TSG2nADTRG0 signal), use TSG2nCTL5.TSG2nAT09 to TSG2nAT00.

With TSG2nAT09 to TSG2nAT00, A/D conversion trigger output is enabled or disabled at the match of the 16-bit counter and TSG2nDCMP2 to TSG2nDCMP0 (during up count).

To set A/D conversion trigger 1 (TSG2nADTRG1 signal), use TSG2nCTL6.TSG2nAT19 to TSG2nAT10.

To set the match timing of the 16-bit counter and TSG2nDCMP2 to TSG2nDCMP0, set the compare value to the pertinent register.

The skipping function can be used for TSG2nADTRG0 and TSG2nADTRG1 signals. Use TSG2nACC01, TSG2nACC00 of TSG2nCTL5 and TSG2nACC11, and TSG2nACC10 in TSG2nCTL6 to select the skipping rate among 1/1, 1/2, 1/4, and 1/8.

CAUTIONS

- **Set TSG2nCTL5, TSG2nCTL6, and TSG2nDCMP2 to TSG2nDCMP0 correctly when using the TSOn7 output for the A/D conversion trigger timing pulse.**
- **In 120-DC mode, a trough interrupt (INTTSG2nIVLY) is not generated. Therefore, set TSG2nAT00 and TSG2nAT10 in TSG2nCTL5 and TSG2nCTL6 to 0.**
- **In 120-DC mode, the 16-bit sub-counter does not operate. Therefore, set TSG2nAT09, TSG2nAT08, TSG2nAT19, and TSG2nAT18 in TSG2nCTL5 and TSG2nCTL6 to 0.**
- **In 120-DC mode, the 16-bit counter does not decrement. Therefore, set TSG2nAT07, TSG2nAT05, TSG2nAT03, TSG2nAT17, TSG2nAT15, and TSG2nAT13 in TSG2nCTL5 and TSG2nCTL6 to 0.**

Setting dead time

The dead time can be set with TSG2nDTC0 and TSG2nDTC1.

The dead time is calculated by the following expressions:

PCLK × TSG2nDTC0

PCLK × TSG2nDTC1

TSG2nDTC0 can set the time between a change of TSOn2, TSOn4, and TSOn6 to the inactive state and a change of TSOn1, TSOn3, and TSOn5 to the active state, respectively.

TSG2nDTC0 can set the time between a change of TSOn1, TSOn3, and TSOn5 to the inactive state to a change of TSOn2, TSOn4, and TSOn6 to the active state.

Carrier period

Set the carrier period with TSG2nCMP0 according to the following expression:

TSG2nCMP0 = (carrier period/count clock period) - 1

Duty (PWM width) setting

The duty of PWM output is set with TSG2nCMP1 to TSG2nCMP12. The setting range of the compare registers is as follows:

$0000_H \leq$ TSG2nCMPm $\leq$ TSG2nCMP0 + 1

CAUTION

Do not set TSG2nCMPm to TSG2nCMP0 + 1 (m = 1 to 12) only when TSG2nCMP0 + 1 < TSG2nCMPm and TSG2nCMP0 = $FFFF_H$.

Output PWM setting

In 120-DC mode, the output pins TSOn1, TSOn3, and TSOn5 are controlled by TSG2nCMP1, TSG2nCMP2, TSG2nCMP5, TSG2nCMP6, TSG2nCMP9, and TSG2nCMP10, and the output pins TSOn2, TSOn4, TSOn6 are controlled by TSG2nCMP3, TSG2nCMP4, TSG2nCMP7, TSG2nCMP8, TSG2nCMP11, and TSG2nCMP12. The duty cycle of a PWM period (TSG2nCMP0) can be set with TSG2nCMP1 to TSG2nCMP12. Setting TSG2nCMP1 to TSG2nCMP12 to 0000H sets the PWM duty cycle to 0%. Setting TSG2nCMP1 to TSG2nCMP12 to TSG2nCMP0 + 1 value sets the PWM duty cycle to 100%. This allows chopping output control and rectangular wave output control.

23.11.4.3 Control Methods in 120-DC Mode

Control methods in 120-DC mode are listed below.

Control Method	Function
Software output control method	Switches the output pattern according to the TSG2nOPT1.TSG2nSPC2 to TSG2nSPC0 setting made by software.
Pattern switch method	Directly switches the output pattern by the pattern input signal of TAPTSn0 to TAPTSn2.

Setting software output control method

Setting TSG2nOPT0.TSG2nSTE = 0 switches the output pattern by software output control. The TSOn1 to TSOn6 pin output is switched according to TSG2nOPT1.TSG2nSPC2 to TSG2nSPC0.

The output order at the beginning of operation is set with TSG2nOPT0.TSG2nIDC. The output pattern is set with TSG2nOPT0.TSG2nPSC.

Operation of software output control method

The PWM output of TSOn1 to TSOn6 pins (PWM output defined by TSG2nCMP1 to TSG2nCMP12) is selected by TSG2nOPT1.TSG2nSPC2 to TSG2nSPC0 by software. To control the dead time, the dead time counter is activated at the falling edge of the signals in each phase and the dead time is inserted.

The 16-bit counter counts based on the carrier period set in TSG2nCMP0. The 16-bit counter is cleared by match of the 16-bit counter and TSG2nCMP0 or by a write access to TSG2nOPT1.TSG2nSPC2 to TSG2nSPC0.

In this method, the pattern is output, which is decoded using information on the output pattern (TSG2nSPC2 to TSG2nSPC0), the electric current direction control bit (TSG2nOPT0.TSG2nIDC), and the order direction control bit (TSG2nOPT0.TSG2nPSC). **Figure 23.91** shows the timer output when the output pattern is changed by software output control.

Immediately after the operation starts (TSG2nTRG0.TSG2nTS = 1), the output pattern of TSG2nSPC2 to TSG2nSPC0 and the pattern set with TSG2nIDC and TSG2nPSC (TSG2nOPT0.TSG2nPSS = 1) are output.

Setting pattern switch method

Setting TSG2nOPT0.TSG2nSTE to 1 and TSG2nPOT to 0 selects the pattern switch method. The TSOn1 to TSOn6 pin output is changed at the change timing of the TAPTSn2 to TAPTSn0 pins.

The output order at the beginning of operation is set with TSG2nOPT0.TSG2nIDC. The initial output pattern is set with TSG2nOPT0.TSG2nPSC. However, after determining the rotation direction (after the value is set to TSG2nSTR1.TSG2nTSF), the setting of TSG2nPSC is disabled.

Operation of pattern switch method

After level detection is performed for the pins (three inputs from the hall sensor), the level-detected signals are decoded. From the decoding result, the PWM output of TSOn1 to TSOn6 pins (PWM output defined by TSG2nCMP1 to TSG2nCMP12) is selected. To control the dead time, the dead time counter is activated at the falling timing of signals in each phase and the dead time is inserted.

The 16-bit counter counts based on the carrier period set in TSG2nCMP0. The 16-bit counter is cleared by match of the 16-bit counter and TSG2nCMP0 or by a change of the input pattern (TAPTSn2 to TAPTSn0 pins).

In this method, the pattern, which is decoded by using information on input pattern (TAPTSn2 to TAPTSn0), the electric current direction control bit (TSG2nOPT0.TSG2nIDC), and the order direction control bit (TSG2nOPT0.TSG2nPSC), is output. **Figure 23.74** to **Figure 23.77** show the timer output when TAPTSn2 to TAPTSn0 pin inputs change. If input pattern 1 is switched to input pattern 4 due to an abnormal input pattern, the output pattern is switched to the pattern corresponding to the input pattern.

Immediately after the operation starts (TSG2nTRG0.TSG2nTS = 1), the output pattern set with the input level of TAPTSn2 to TAPTSn0 pins, TSG2nIDC, and TSG2nPSC (TSG2nOPT0.TSG2nPSS = 1) is output. After the TSG2nTSF value is determined, the output pattern is determined by TSG2nTSF instead of TSG2nPSC.

CAUTION

When connecting the three-phase pulse input signal to the TAPTSn2 to TAPTSn0 pins, confirm that the three-phase pulse input value and the patterns output from the TSOn1 to TSOn6 pins satisfy the expected conditions.
If the expected conditions are not satisfied, change the connection between the three-phase pulse input signal and the TAPTSn2 to TAPTSn0 pins.

23.11.4.4 Timer Output in 120-DC Mode

In 120-DC mode, the PWM output is controlled with TSG2nPAT0W, TSG2nPAT1W, and TSG2nCMP1 to TSG2nCMP12. TSG2nPAT0W, TSG2nCMP1, TSG2nCMP2, TSG2nCMP5, TSG2nCMP6, TSG2nCMP9, and TSG2nCMP10 are set to control the output of TSOn1, TSOn3, and TSOn5 pins. TSG2nPAT1W, TSG2nCMP3, TSG2nCMP4, TSG2nCMP7, TSG2nCMP8, TSG2nCMP11, and TSG2nCMP12 are set with the output of TSOn2, TSOn4, and TSOn6 pins.

With PWM output control, eight types of output patterns can be selected for each of TSOn1, TSOn3, and TSOn5 pins and TSOn2, TSOn4, and TSOn6 pins.

Table 23.71 TSG2nPAT0W Set Value and Output Control

PATmT Value	Output Control
000	Fixed to low
001	PWM output set with TSG2nCMP1
010	PWM output set with TSG2nCMP2

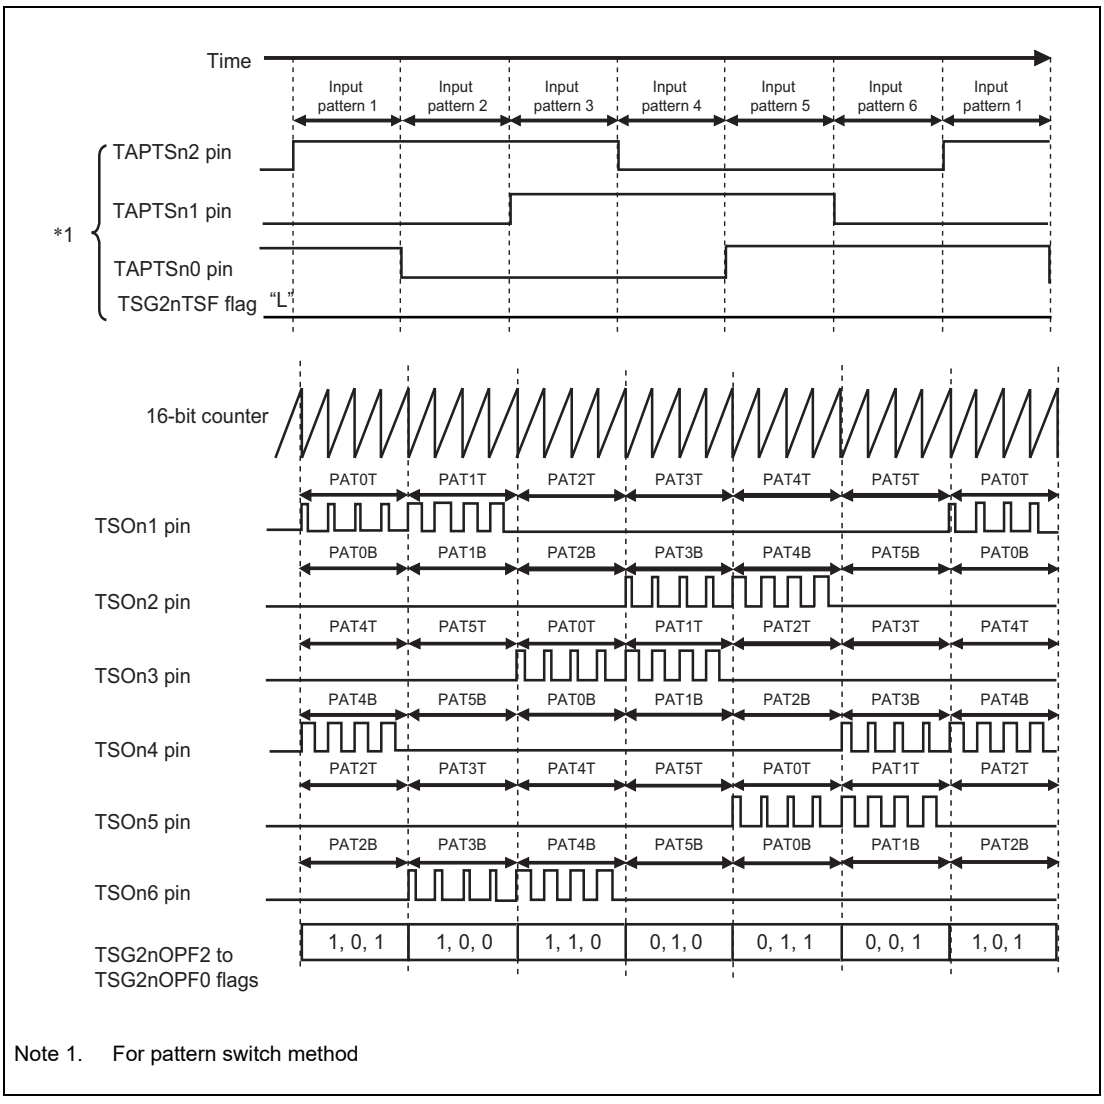
23.11.4.5 Operation in 120-DC Mode

Figure 23.74 to **Figure 23.77** show examples of operation in 120-DC mode.

The TSOn1 to TSOn6 pins detect the input level change of the TAPTSn2 to TAPTSn0 pins, then change the output pattern. The 16-bit counter produces sawtooth waveform, and TSG2nCMP0 to TSG2nCMP12 output PWM signal. The 16-bit counter is cleared to 0000_H each time the counter value matches with TSG2nCMP0 or a change in the TAPTSn2 to TAPTSn0 pins is detected. The timer output pattern is switched each time a change in the TAPTSn2 to TAPTSn0 pins is detected.

NOTE

PAT0T to PAT5T and PAT0B to PAT5B show PWM operation set by TSG2nCMP1 to TSG2nCMP12, respectively.



Note 1. For pattern switch method

23.11.4.7 Operation Start Timing in 120-DC Mode

When pattern switch control is used, the pattern of the TAPTSn2 to TAPTSn0 pins can be detected but rotation direction (TSG2nSTR1.TSG2nTSF) cannot be determined. Therefore, set the rotation direction in TSG2nPSC when TSG2nTE is 0. The TSG2nPSC set value is loaded to TSG2nTSF, and the value can be used for the initial pattern setting.

- TSG2nOPT0.TSG2nSOC = 0, TSG2nPSC = 0, TSG2nIDC = 0

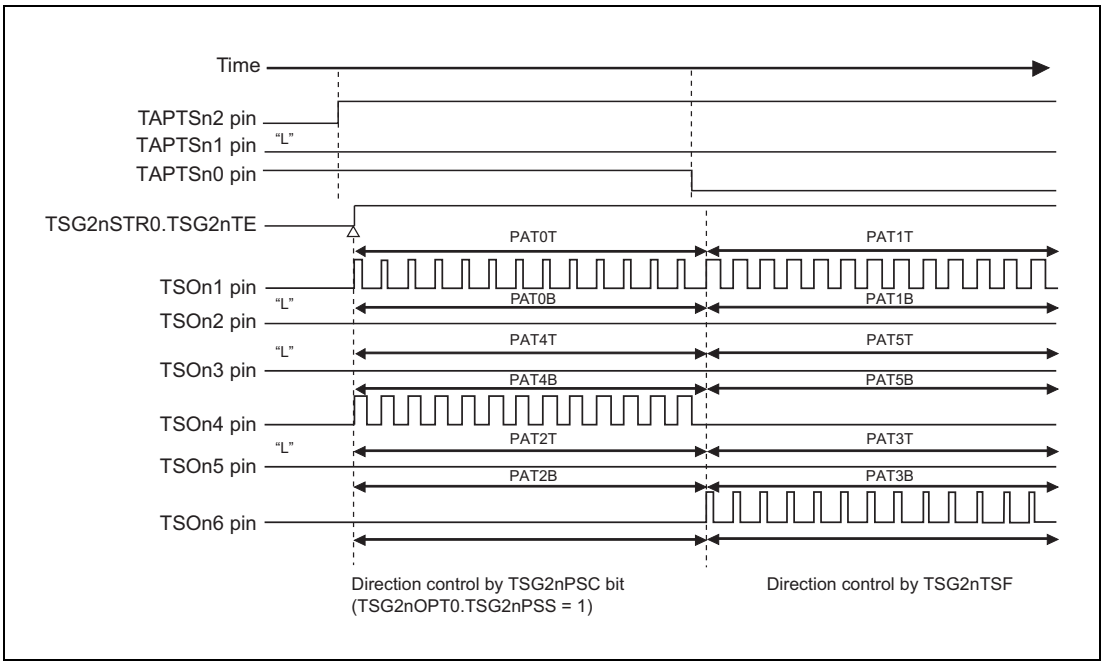

Figure 23.78 Control when Timer Output Starts in Normal Rotation (when Normal Pattern is Input)

- TSG2nOPT0.TSG2nSOC = 0, TSG2nPSC = 1, TSG2nIDC = 1

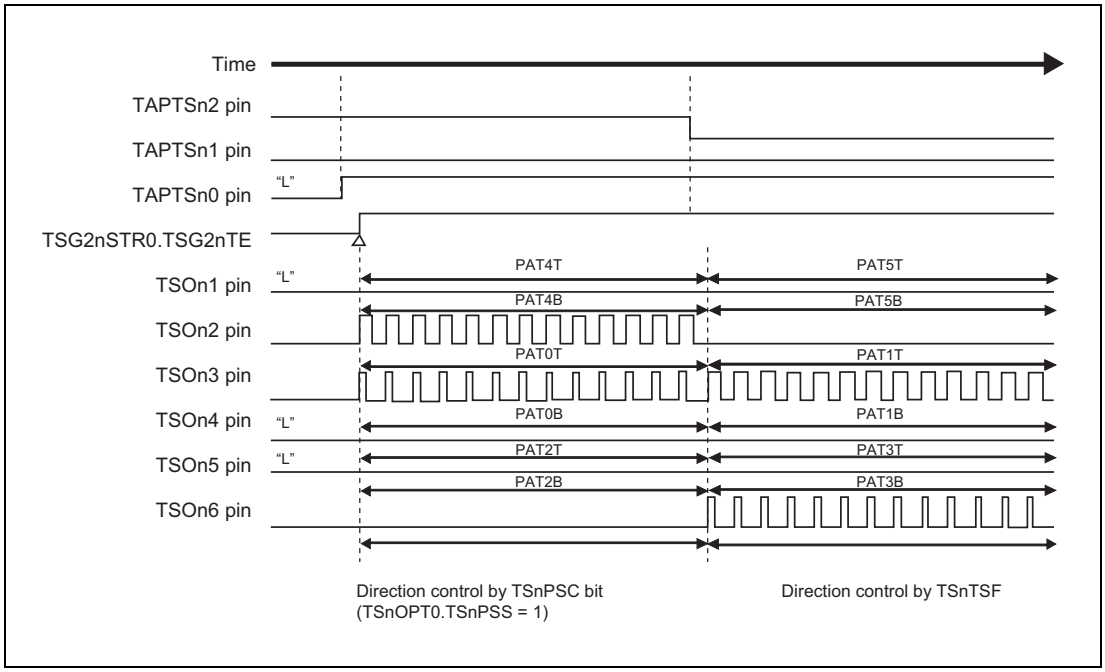

Figure 23.79 Control when Timer Output Starts in Reverse Rotation (when Normal Pattern is Input)

- TSG2nOPT0.TSG2nSOC = 0, TSG2nPSC = 0, TSG2nIDC = 0

- TSG2nOPT0.TSG2nSOC = 0, TSG2nPSC = 1, TSG2nIDC = 1

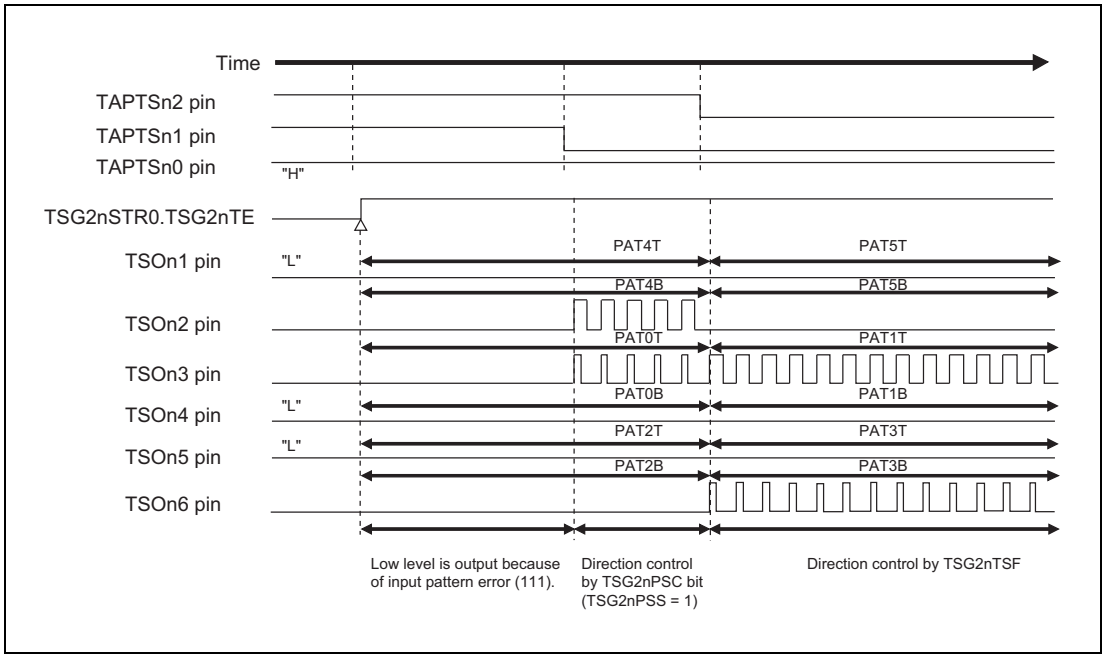

Figure 23.81 Control when Timer Output Starts in Reverse Rotation (when Error Pattern is Input)

23.11.4.8 Output Switch Timing in 120-DC Mode

As shown in **Figure 23.82** to **Figure 23.85**, in 120-DC mode, the external switch timing for output pattern (TAPTSn2 to TAPTSn0 pins) is input irrespective of the 16-bit counter operation. The output is switched to the new pattern by clearing the 16-bit counter using the pattern switch timing signal applied from outside.

In the pattern switch method, if a change in TAPTSn2 to TAPTSn0 pins occurs consecutively within one period, the value edge detected immediately before the period match timing is reflected to PWM output in the following periods.

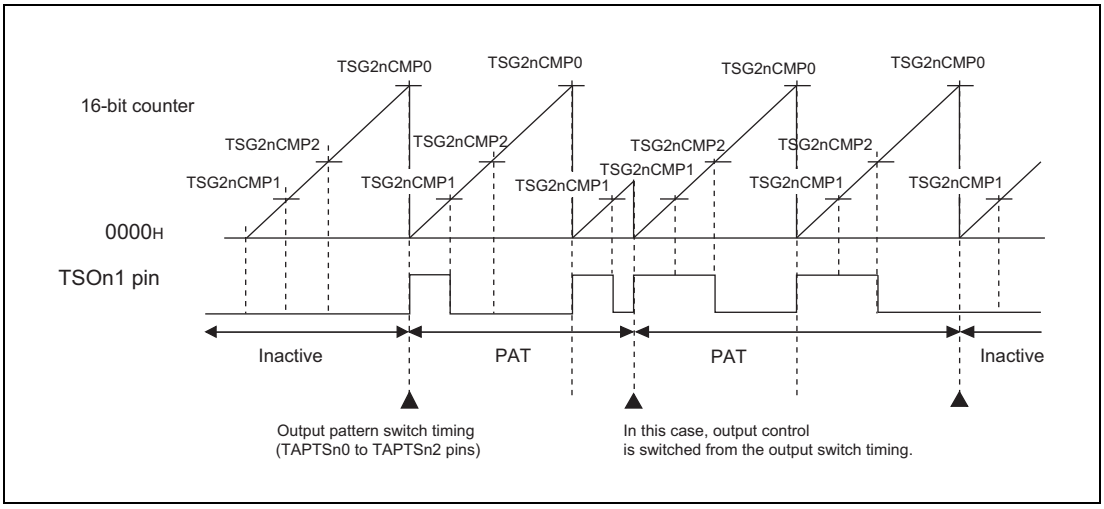

Figure 23.82 Output Switch Example (TAPTSn2 to TAPTSn0 Pins Trigger Input)

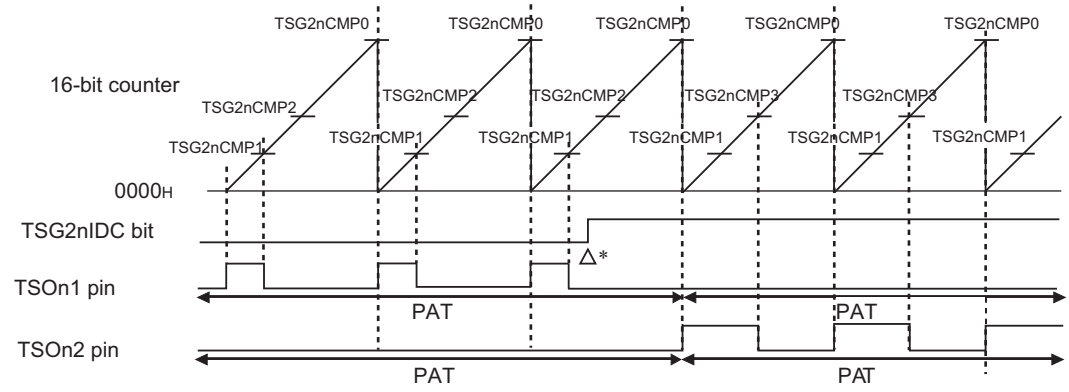
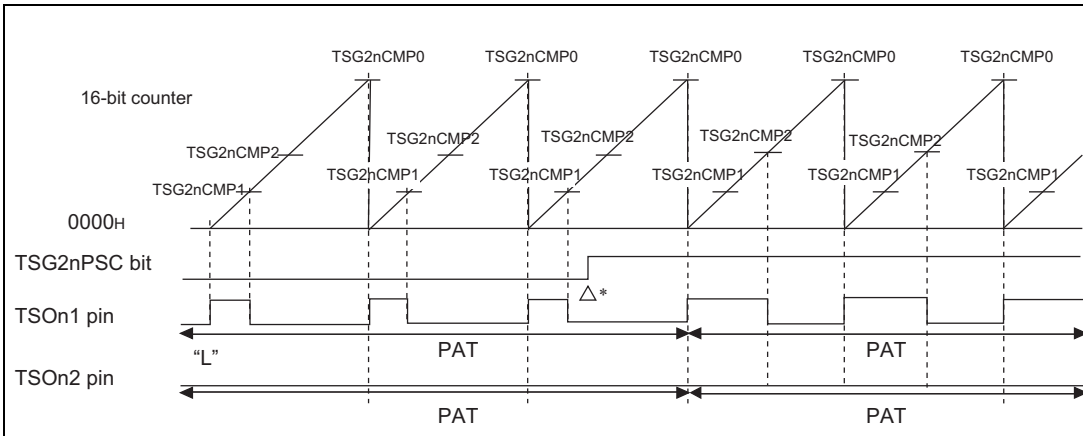


Note 1. When the pattern is switched here, output control is switched in the next period.

Figure 23.83 Output Switch Example (Switched by TSG2nOPT0.TSG2nIDC)

NOTE

If a change in the TAPTSn2 to TAPTSn0 pins occurs by the time the next period when output control is switched by the TSG2nIDC bit, the 16-bit counter is cleared and output control is switched.



Note 1. When the pattern is switched here, output control is switched from the next period.

Figure 23.84 Output Switch Example (Switched by TSG2nOPT0.TSG2nPSC)

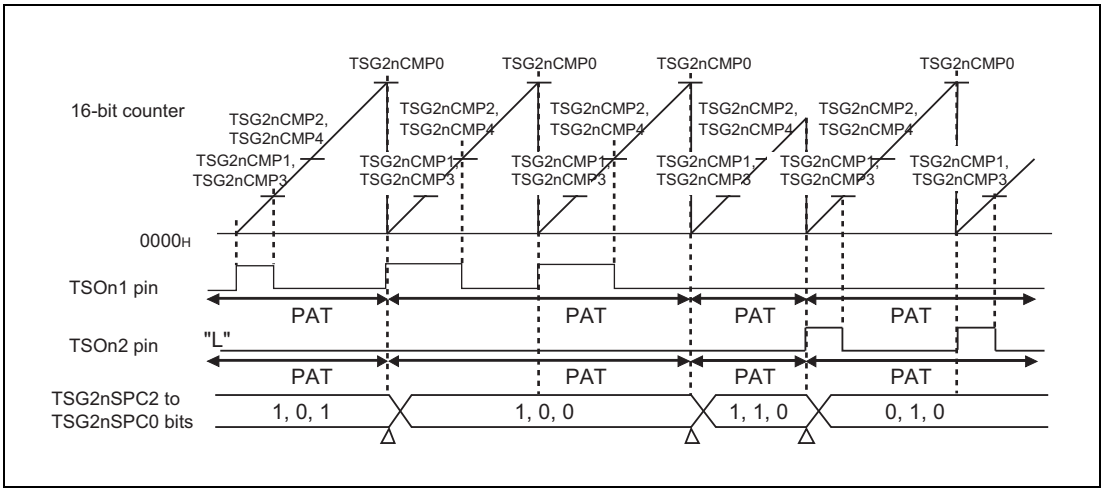


Figure 23.85 Output Switch Example (Switched by TSG2nOPT1.TSG2nSPC2 to TSG2nSPC0)

NOTE

Δ: Write access

23.11.4.9 Compare Register Rewrite Timing in 120-DC Mode

Example of operation when TSG2nCMP1 is reloaded (rewritten simultaneously) is shown below.

Figure 23.86 shows an output example when TSG2nCMP1 is rewritten. After TSG2nCMP1 is changed, data is not transferred to the TSG2nCMP1 buffer register (changed data is not valid) until the next reload timing; therefore, the specified output waveform can be obtained. However, do not write to TSG2nCMP1 again while the reload is suspended (period from when TSG2nCMP1 is changed to when simultaneous rewrite is executed). Be sure to read the reload request flag (TSG2nRSF) to confirm that the flag is 0, and write data to TSG2nCMP1.

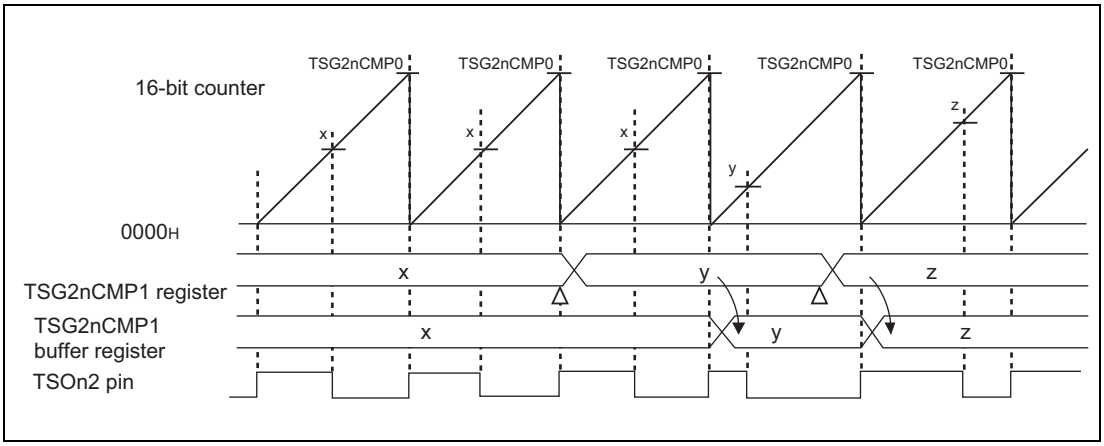

Figure 23.86 Output Example when TSG2nCMP1 is Rewritten

NOTE

Δ: Write access

23.11.4.10 Dead Time Control in 120-DC Mode

In 120-DC mode, the dead time is controlled on falling of each phase, and the dead time is added.

The dead time set in TSG2nDTC1 is inserted on falling of the positive phase, and the dead time set in TSG2nDTC0 is inserted on falling of the inverse phase.

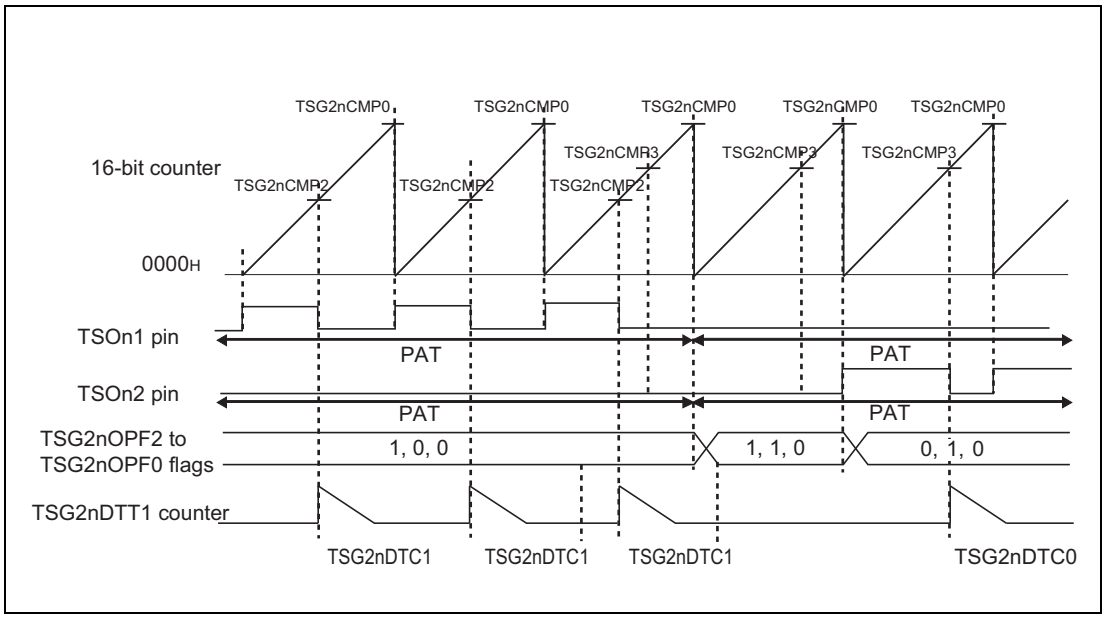

Figure 23.87 Output Switch Example

CAUTION

The dead time control method may affect the timer output. The timer output may not have the specified active level width due to the dead time control under the following conditions:

- When noise is generated on the input pattern in the pattern switch method
- When a change in the input pattern occurs earlier than the PWM period in the pattern switch method
- When switch method is changed
- When the current direction control bit (TSG2nOPT0.TSG2nIDC) is changed
- When the software output control function is used

23.11.4.11 Operation when Noise is Generated in TAPTSn2 to TAPTSn0 Pins in 120-DC Mode

Input to the TAPTSn2 to TAPTSn0 pins is assumed to be the hall sensor signals of the brushless DC motor. Depending on the system, a noise may be generated on the TAPTSn2 to TAPTSn0 pins. Operation when a noise is generated is described below.

For system product design, be sure to insert a noise filter circuit between the hall sensor and the TAPTSn2 to TAPTSn0 pins.

Figure 23.89 shows a case when a noise is generated on the TAPTSn2 to TAPTSn0 pins during operation with the pattern switch method used.

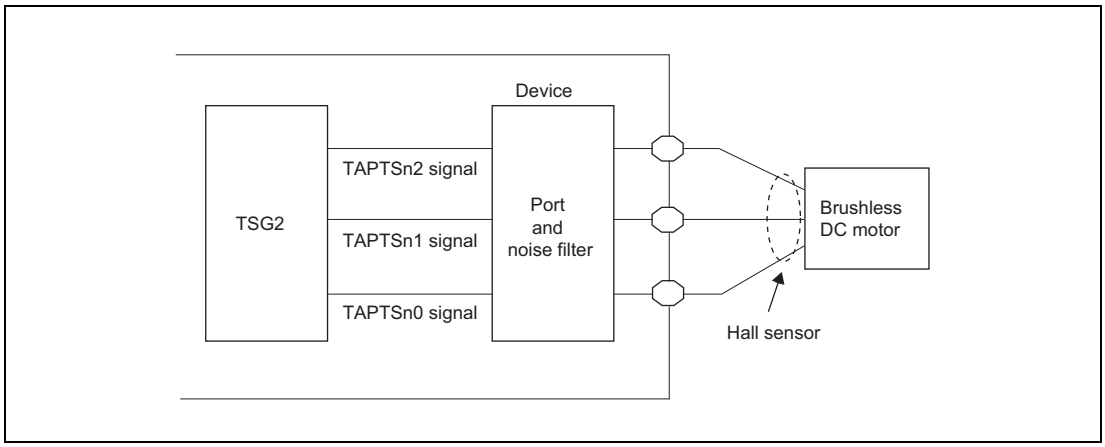

Figure 23.88 Example of Noise Filter Circuit Connection

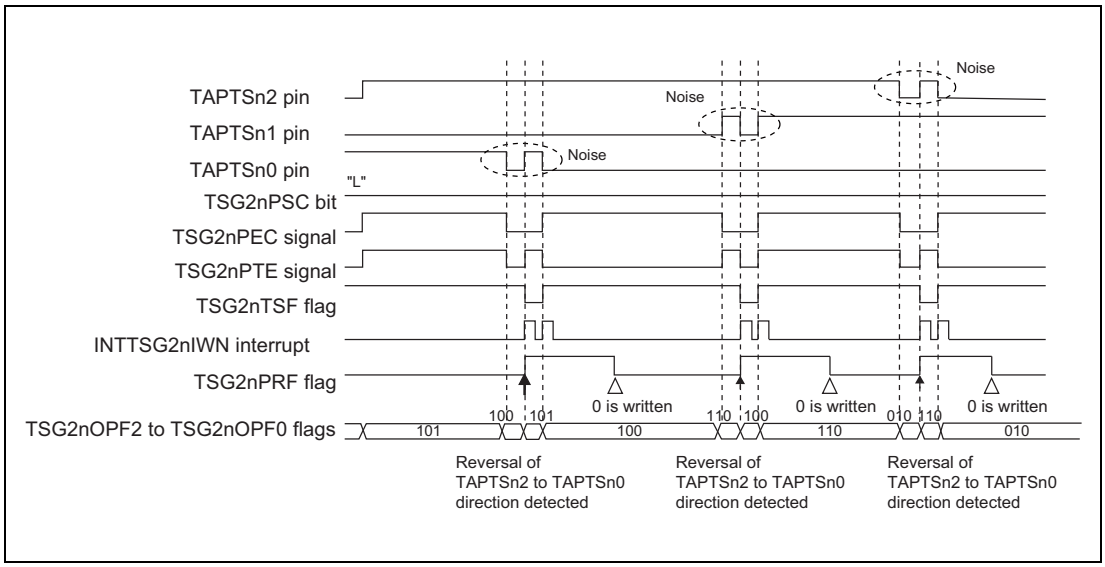

Figure 23.89 Example of Noise Generation at Level Change in TAPTSn2 to TAPTSn0 Pins (Pattern Switch Method)

(1) Change Timing of Input Pattern Change Detection Signal (TSG2nPTE)

- The TSG2nPTE signal toggles when the input pattern (TAPTSn2 to TAPTSn0 pins) changes.

CAUTION

Be sure to specify the rotation direction by TSG2nPSC (TSG2nPSS = 1 in TSG2nOPT0) in TSG2nOPT0.

(when TSG2nPSC = 0)

		TAPTSn2 to TAPTSn0 Pins after Change							
		000	**111**	**101**	**100**	**110**	**010**	**011**	**001**

	011	—	—	—	—	—	Toggle	—	—
	001	—	—	—	—	—	—	Toggle	—

(2) Change Timing of Three-Phase Encode Signal (TSG2nPEC)

- The TSG2nPEC signal toggles when input pattern (TAPTSn2 to TAPTSn0 pins) changes.

		TAPTSn2 to TAPTSn0 Pins after Change							
		000	111	101	100	110	010	011	001
Current TAPTSn2 to TAPTSn0 Pins	000	—	—	—	—	—	—	—	—
	111	—	—	—	—	—	—	—	—
	101	—	—	—	Toggle	—	—	—	Toggle
	100	—	—	Toggle	—	Toggle	—	—	—
	110	—	—	—	Toggle	—	Toggle	—	—
	010	—	—	—	—	Toggle	—	Toggle	—
	011	—	—	—	—	—	Toggle	—	Toggle
	001	—	—	Toggle	—	—	-	Toggle	—

(3) Change Timing of TSOn1 to TSOn6 Pins

- When the pattern switch method is used, the output pattern changes when the input signal of the TAPTSn2 to TAPTSn0 pins changes. The output is also switched when two or more pins change simultaneously.

CAUTION

When the input pattern changes to 000 or 111, the TSOn1 to TSOn6 pins are driven low.

(4) Change Timing of TSG2nTSF Flag

- The TSG2nTSF flag toggles when the input pattern (TAPTSn2 to TAPTSn0 pins) changes.

		TAPTSn2 to TAPTSn0 Pins after Change							
		000	111	101	100	110	010	011	001
Current TAPTSn2 to TAPTSn0 Pins	000	—	—	—	—	—	—	—	—
	111	—	—	—	—	—	—	—	—
	101	—	—	—	0	—	—	—	1
	100	—	—	1	—	0	—	—	—
	110	—	—	—	1	—	0	—	—
	010	—	—	—	—	1	—	0	—
	011	—	—	—	—	—	1	—	0
	001	—	—	0	—	—	—	1	—

(5) Set Timing of TSG2nNDF Flag

- The TSG2nNTF flag is set when two or more pins of the TAPTSn2 to TAPTSn0 pins change simultaneously, and cleared when 1 is written to the TSG2nNDR bit. The TSG2nNDF flag is valid when 1 is set to the TSG2nNDC bit.

(6) Set Timing of TSG2nPRF Flag

- The TSG2nPRF flag is set when the TSG2nTSF flag changes, and cleared when 1 is written to the TSG2nPRR bit. The TSG2nPRF flag is valid when 1 is set to the TSG2nPRC bit.

(7) Set Timing of TSG2nPEF Flag

- The TSG2nPRF flag is set when 000 or 111 is input to the TAPTSn2 to TAPTSn0 pins, and cleared when 1 is written to the TSG2nPER bit. The TSG2nPEF flag is valid when the TSG2nPEC bit is set to 1.

23.11.4.12 Basic Control Flow in 120-DC Mode

In 120-DC mode, there are eight control states as listed in **Table 23.73**.

When TSG2nOPT0.TSG2nSTE = 1, the pattern switch method is used for 120-DC control.

This is defined as fixed phase control. The fixed phase control should be performed considering the factors such as delay from the hall sensor and delay from sensor level detection to timer output. However, acceleration or deceleration can be performed simply by changing the PWM duty.

Table 23.73 Timer Control Status

Status	TSG2nTSF in TSG2nSTR1	TSG2nIDC in TSG2nOPT0	Control
A	0	0	Normal rotation, acceleration, and fixed phase
D	0	1	Normal rotation, deceleration, and fixed phase
E	1	1	Reverse rotation, acceleration, and fixed phase
H	1	0	Reverse rotation, deceleration, and fixed phase

Generally, the state, when the motor rotation stops, is assumed to be a state of the start and the control begins. First the fixed phase control is used to rotate the motor from the stopped state.

State transition is shown in **Figure 23.90**.

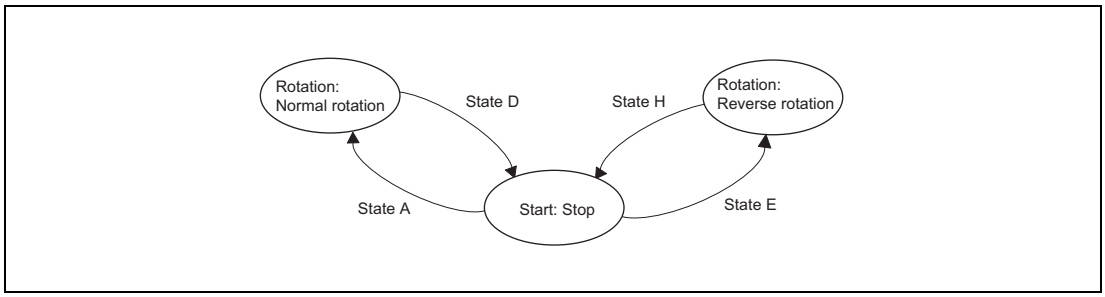

Figure 23.90 State Transition Diagram

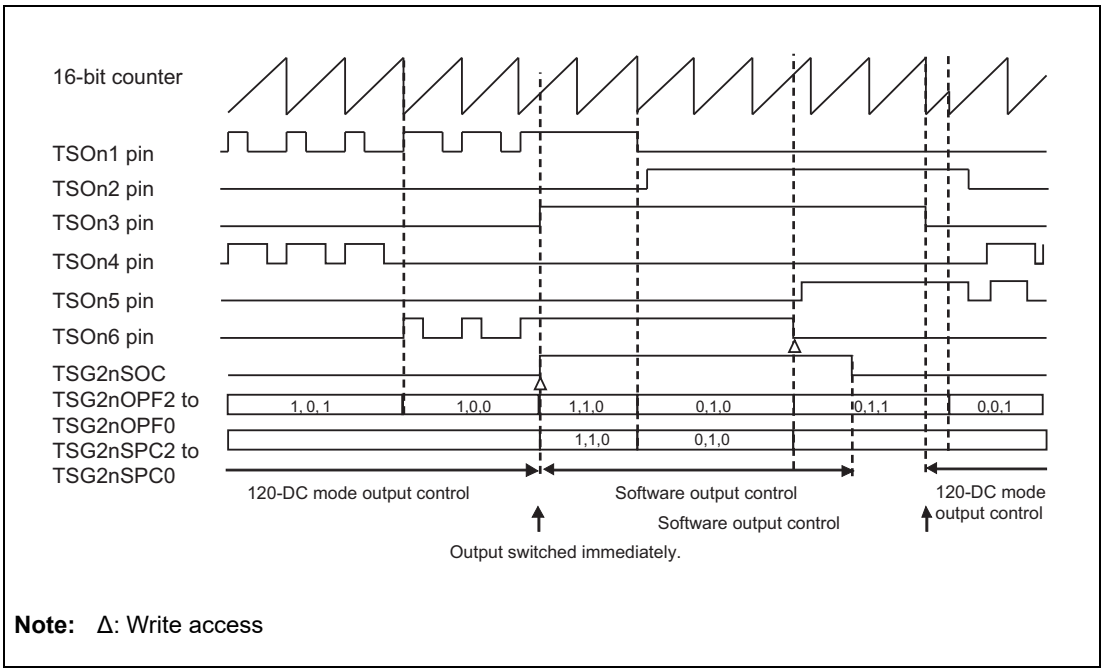
23.11.4.13 Software Output Control Function in 120-DC Mode

TSG2nOPT0.TSG2nSOC and TSG2nIDC, and TSG2nOPT1.TSG2nSPC2 to TSG2nSPC0 are used in 120-DC mode for timer output control by software.

As shown in **Figure 23.91**, the output control is switched immediately when TSG2nSOC is set to 1. If the dead time is set, the period of the dead time period is guaranteed. After that, to switch the output control from software output control to 120-DC control, set TSG2nSOC to 0. At this timing, output control is retained. When the reload timing is generated, output control is switched to 120-DC mode.

For details on software output control function, see **Section 23.11.5, Software Output Control Function**.



Note: Δ: Write access

Figure 23.91 Example of Switching from 120-DC Mode to Software Output Control Function

(1) Procedure for Software Output Control

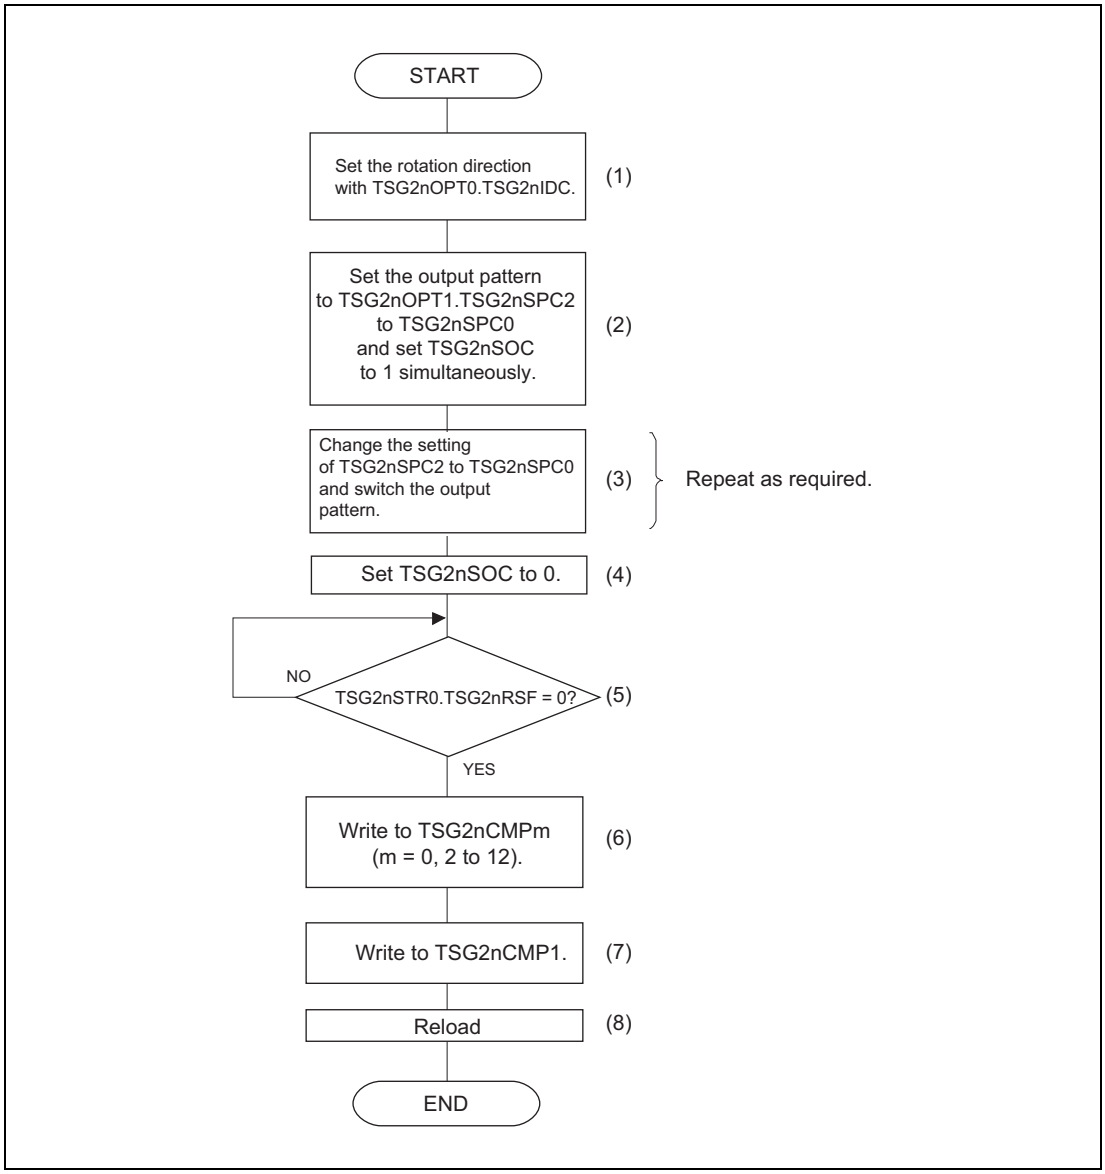


Figure 23.92 Process Flow of Software Output Control

The procedure for software output control is described below.

(1) Set TSG2nIDC to determine the rotation direction. The phase of the timer output with TSG2nIDC = 0 is different by 180 degrees from that with TSG2nIDC = 1. The timer output does not change if only this bit is rewritten using the software output control function. However, if the period match occurs before step (2), the output pattern of 120-DC control changes. So, schedule so as to prevent the period match from occurring before step (2).

(2) Set the output pattern to TSG2nSPC2 to TSG2nSPC0. To enable software output control, set TSG2nSOC to 1 simultaneously.

(3) Change the output pattern setting of TSG2nSPC2 to TSG2nSPC0 to change the timer output. The registers that can be changed during software control are: TSG2nTRG1.TSG2nTT, TSG2nCTL4 to TSG2nCTL6, TSG2nOPT0, TSG2nOPT1, TSG2nCMP0 to TSG2nCMP12, TSG2nDTC0, and TSG2nDTC1.

(4) Confirm that the reload request flag (TSG2nRSF) = 0. If TSG2nRFS = 1, do not proceed to the following step until TSG2nRSF = 0.

(5) By setting TSG2nSOC = 0 the software control starts to be released (it is not released here yet).

(6) After releasing the software output control, set the necessary compare registers. Proceed to the following step when the register setting is not required. Here, change the registers with the reload function.

(7) Write to TSG2nCMP1 to start reloading.

(8) Reload is executed and software output is released.

CAUTION

Execute reload after executing steps (4) to (7). When reload cannot be executed, the software output cannot be released.

23.11.5 Software Output Control Function

Software output control function can be used in HT-PWM mode, SP-PWM mode, and 120-DC mode. This function can switch six output patterns for the TSOn1 to TSOn6 pins using TSG2nOPT0.TSG2nSOC, TSG2nIDC, and TSG2nOPT1.TSG2nSPC2 to TSG2nSPC0.

When TSG2nSOC is switched from 0 to 1, the output control method of the TSOn1 to TSOn6 pins is switched to the software output control immediately. On the contrast, when TSG2nSOC is switched from 1 to 0, the software output control is released at the reload timing.

Table 23.74 Register Description on Software Output Control Function

Register	Setting
TSG2nOPT0.TSG2nSOC	TSG2nSOC = 1
TSG2nOPT0.TSG2nSTE	TSG2nSTE = 0
TSG2nOPT1.TSG2nSPC2 to TSG2nSPC0	Set output patterns listed in **Table 23.75** and **Table 23.76**.
TSG2nOPT0.TSG2nIDC	Set output pattern (rotation direction).

Section 24 Timer Option (TAPA)

24.1 Overview

The timer option (TAPA) is for use with the motor control timer (TSG2) to realize a motor system.

- Asynchronous Hi-Z control to deal with pin input

24.1.1 Basic functions

Channel

This product has the following number of channels of timer option modules.

Table 24.1 Channels of Timer Option Modules

Timer Option	
Number of channels	2
Name	TAPAn (n = 2, 3)

Meaning of n

Throughout this section, the individual channels of the timer option function are identified by the index “n”. For example, TAPAnFLG indicates the TAPAn flag registers (n = 2, 3).

Since TAPA0 and 1 are not used in this product, only TAPA2 and TAPA3 are provided.

Register addresses

All TAPAn register addresses are given as offsets from the given base address, <TAPAn_base>. Each of the TAPAn base addresses is listed in the following table.

Table 24.2 Register Base Address

TAPAn	<TAPAn_base> Address
TAPA2	FFE9 2000_H
TAPA3	FFE9 3000_H

24.2 Registers

TAPAn (n = 2 and 3) is controlled and operated by means of the following registers.

24.2.1 Registers Overview

The list of TAPAn (n = 2 and 3) registers and the memory addresses are shown below.

The base address is FFE9 2000_H for TAPA2 and FFE9 3000_H for TAPA3.

For the actual addresses, the offset values indicated in the following table are added to the base addresses.

Register Name	Function	R/W	Reset Value	Access Unit			Offset Address
				8	16	32	
TAPAnCTL0	TAPAn control register 0	R/W	0000_H	—	√	—	0020_H
TAPAnFLG	TAPAn flag register	R	0000_H	—	√	—	0000_H
TAPAnACWE	TAPAn asynchronous control write enable register	R/W	00_H	√	—	—	0004_H
TAPAnACTS	TAPAn asynchronous control start trigger register	W	00_H	√	—	—	0008_H

24.2.2 TAPAnCTL0 — TAPAn Control Register 0

Control register 0 is used to control Hi-Z.

A value in this register can only be rewritten when TAPAnFLG.TAPAnACE = 0.

Access: This register can be read/written in 16-bit units.

Address: <TAPAn_base> + 20_H

Value after reset: 0000_H
This register is initialized by a reset from any source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	TAPAn DCM	TAPAn DCN	TAPAn DCP	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R

Table 24.3 TAPAnCTL0 Register Contents

Bit Position	Bit Name	Function
15 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	TAPAnDCM	Clearing Condition Specification This control bit specifies the condition for clearing of the Hi-Z control outputs. 0: Manipulation of TAPAnOPHT0 is enabled regardless of the TAPATHASIN signal input level. 1: Manipulation of TAPAnOPHT0 is disabled when the TAPATHASIN input signal is at the active level. Manipulation of TAPAnOPHT0 is enabled when the TAPATHASIN signal input is inactive.
3, 2	TAPAnDCN, TAPAnDCP	Hi-Z Input Edge Selection These control bits specify the effective edge of TAPAnTHASIN.
1, 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

TAPAn DCN	TAPAn DCP	Description
0	0	Does not detect effective edges
0	1	Detects a rising edge as the effective edge (active level = high)
1	0	Detects a failing edge as the effective edge (active level = low)
1	1	Setting is prohibited.

24.2.3 TAPAnFLG — TAPAn Flag Register

This flag register is used to control Hi-Z.

Access: This register can be read/written in 16-bit units.

Address: <TAPAn_base> + 00_H

Value after reset: 0000_H
This register is initialized by a reset from any source.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	TAPAnHOF[2:0]			—	—	—	—	—	—	—	TAPAn ACE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.4 TAPAnFLG Register Contents

Bit Position	Bit Name	Function
15 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10 to 8	TAPAnHOF[2:0]	HZOUTm Output Monitor (m = 0 to 2) These bits monitor the TAPATHZOUTmz output. 0: The TAPATHZOUTmz output is at the high level. 1: The TAPATHZOUTmz output is at the low level.
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TAPAnACE	Asynchronous Hi-Z Control Enable This bit indicates the state of asynchronous Hi-Z control (TAPATHASIN). 0: Asynchronous Hi-Z control is stopped. 1: Asynchronous Hi-Z control is enabled. The conditions for setting and clearing this bit are as follows. Clearing condition: Writing 1 to TAPAnACTT while TAPAnACWE = 1. Setting condition: Writing 1 to TAPAnACTS while TAPAnACWE = 1.

24.2.4 TAPAnACWE — TAPAn Asynchronous Control Write Enable Register

This register enables writing for asynchronous Hi-Z control.

Access: This register can be read/written in 8-bit units.

Address: <TAPAn_base> + 04_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAn ACWE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 24.5 TAPAnACWE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TAPAnACWE	Asynchronous Control Write Enable This is a write-enable bit for asynchronous Hi-Z control. After 1 has been written to this bit, it is automatically cleared to 0 by writing 1 to TAPA0ACTS and TAPA0ACTT. 0: Disables writing to TAPAnACTS and TAPAnACTT. 1: Enables writing to TAPAnACTS and TAPAnACTT.

24.2.5 TAPAnACTS — TAPAn Asynchronous Control Start Trigger Register

This register enables the start trigger for asynchronous Hi-Z control.

Access: This register can be read/written in 8-bit units. This register is always read as 00_H.

Address: <TAPAn_base> + 08_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAn ACTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 24.6 TAPAnACTS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TAPAnACTS	Asynchronous Control Start Trigger This bit enables the start trigger for asynchronous Hi-Z control. The setting of this bit is only valid when TAPAnACWE = 1. 0: Writing 0 to this bit is ignored (no function). 1: Enables asynchronous Hi-Z control if TAPAnACWE = 1.

24.2.6 TAPAnACTT — TAPAn Asynchronous Control Stop Trigger Register

This register enables the stop trigger for asynchronous Hi-Z control.

Access: This register can be read/written in 8-bit units. This register is always read as 00_H.

Address: <TAPAn_base> + $0C_H$

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAn ACTT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 24.7 TAPAnACTT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TAPAnACTT	Asynchronous Control Stop Trigger This bit enables the stop trigger for asynchronous Hi-Z control. The setting of this bit is only valid when TAPAnACWE = 1. 0: Writing 0 to this bit is ignored (no function). 1: Stops asynchronous Hi-Z control if TAPAnACWE = 1.

24.2.7 TAPAnOPHS — TAPAn Hi-Z Start Trigger Register

This register sets the start trigger for a Hi-Z control signal (TAPATHZOUT0Z).

Access: This register can be read/written in 8-bit units. This register is always read as 00_H.

Address: <TAPAn_base> + 14_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAn OPHS0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 24.8 TAPAnOPHS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TAPAnOPHS0	Hi-Z Control Signal Start Trigger 0 This bit sets the start trigger for a Hi-Z control signal. 0: The read value is always 0 and writing 0 to this bit is ignored. 1: Sets the Hi-Z control signal (TAPATHZOUT0Z) to the low level.

24.2.8 TAPAnOPHT — TAPAn Hi-Z Stop Trigger Register

This register sets the stop trigger for a Hi-Z control signal (TAPATHZOUT0Z).

Access: This register can be read/written in 8-bit units. This register is always read as 00_H.

Address: <TAPAn_base> + 18_H

Value after reset: 00_H
This register is initialized by a reset from any source.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAn OPHT0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 24.9 TAPAnOPHT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TAPAnOPHT0	Hi-Z Control Signal Stop Trigger 0 This bit sets the stop trigger for a Hi-Z control signal. 0: The read value is always 0 and writing 0 to this bit is ignored. 1: Sets a Hi-Z control signal (TAPATHZOUT0Z) to the high level.

24.3 Basic Functions

24.3.1 Hi-Z Control Function

24.3.1.1 Purpose of Hi-Z Control Function

Abnormal operation in timer motor-control under CPU control leads to rotation of the externally connected motor also becoming abnormal. In such a case, this function forcibly sets the motor control output to the Hi-Z state, independently of control by the CPU.

24.3.1.2 Overview of Hi-Z Control Function

The following method is available for controlling Hi-Z.

- Asynchronous input Hi-Z control for pin inputs
  - Controls the Hi-Z control output signals TAPATHZOUT0Z (phase U) asynchronously.

24.3.1.3 Hi-Z Control and Its Operation

Function	Operation
Asynchronous Hi-Z control corresponding to pin input	This function detects pin inputs that are asynchronous and forcibly stops TSOn1 to 6 pin output from the corresponding timer module (TSG2) in response. Device outputs become Hi-Z while TAPATHASIN is active and until software sends a stop request.

24.3.2 Asynchronous Hi-Z Control for pin Inputs

24.3.2.1 Basic Operation in Hi-Z Control Asynchronous Inputs

Examples of system configuration are described below.

Hi-Z Control when TAPAnCTL0.TAPAnDCM = 0, TAPAnDCP = 1, and TAPAnDCN = 0

TAPATHZOUT0Z goes to the low level on detection of an effective edge of the asynchronous input (TAPATHASIN).

Output is forcibly stopped (by port control for Hi-Z output) as long as the TAPATHZOUT0Z output is at the low level.

TAPATHZOUT0Z goes to the high level in response to writing 1 to Hi-Z stop trigger 0 (TAPAnOPHT0), regardless of the level of TAPATHASIN.

Hi-Z Control when TAPAnCTL0.TAPAnDCM = 1, TAPAnDCP = 1, TAPAnDCN = 0

TAPATHZOUT0Z goes to the low level in response to detection of an effective edge of the asynchronous input signal (TAPATHASIN).

Output is forcibly stopped (by port control for Hi-Z output) as long as the TAPATHZOUT0Z output is at the low level.

Writing of 1 to Hi-Z stop trigger 0 (TAPAnOPHT0) is ignored as long as the asynchronous input signal (TAPATHASIN) is at the active level (high because TAPAnDCP = 1).

After the asynchronous input signal (TAPATHASIN) is switched to the inactive level (low because TAPAnDCP = 1), TAPATHZOUT0 goes to the high level when 1 is written to Hi-Z stop trigger 0 (TAPAnOPHT0).

24.3.2.2 Software Operations for Asynchronous Input Hi-Z Control

This module allows software control of the output of Hi-Z control signals.

Hi-Z start trigger 0 (TAPAnOPHS0) and Hi-Z stop trigger 0 (TAPAnOPHT0) are used to control TAPATHZOUT0Z.

Operation of the Hi-Z Start Trigger (TAPAnOPHS)

TAPAnDCM	Operation
0/1	Writing 1 to the TAPAnOPHS0 bit places the TAPATHZOUT0Z signal at the low level.

Operation of the Hi-Z Stop Trigger (TAPAnOPHT) during Hi-Z Control in Response to Asynchronous Input

The Hi-Z stop trigger operates as follows.

TAPAnDCM	Operation
0	Writing 1 to the TAPAnOPHT0 bit places the TAPATHZOUT0Z signal at the high level.
1	If TAPATHASIN is at the inactive level, writing 1 to the TAPAnOPHT0 bit places the TAPATHZOUT0Z signal at the high level. If TAPATHASIN is at the active level, writing of 1 to the TAPAnOPHT0 bit is ignored.

24.3.2.3 Operating Procedure Example for Hi-Z Control in Response to Asynchronous Input

An example of the operating procedure for Hi-Z control in response to asynchronous input is as follows (the table only covers settings for the timer option module because this operation does not depend on timer operations).

		Operation	State of TAPA
Restart operation	Initial settings	Setting in the TAPAnCTL0 register. Set TAPAnDCP and TAPAnDCN (input edge selection). Set TAPAnDCM (clearing mode selection).	Hi-Z control in response to asynchronous input is stopped (TAPAnFLG.TAPAnACE = 0).
	Starting operation	Setting in the TAPAnACWE register: Set the TAPAnACWE bit to 1. Setting in the TAPAnACTS register: Set the TAPAnACTS bit to 1.	Writing to the TAPAnACTS bit is enabled. TAPAnFLG.TAPAnACE = 1, enabling Hi-Z control in response to asynchronous input.
	During operation	To start Hi-Z control of an output from the timer: – Control is by the TAPAnOPHS0 bit of TAPA – Control is by the Hi-Z input signal (TAPATHASIN) for TAPA To stop Hi-Z control of output from the timer: – Control is by the TAPAnOPHT0 bit of TAPA (if TAPAnDCM = 0) – TAPAnOPHT0 is used if the Hi-Z input signal for TAPA (TAPATHASIN) is at the inactive level (if TAPAnDCM = 1) The state of TAPA operations can be read from the TAPAnFLG register at all times.	On detection of input of the starting edge of the Hi-Z input signal (TAPATHASIN) or setting of the start trigger bit (TAPAnOPHS0 = 1), the Hi-Z controller switches the TAPATHZOUT0Z pin to low-level output. In accord with the operating mode settings in TAPAnDCM, the Hi-Z controller switches the TAPATHZOUT0Z pins to high-level outputs in response to setting of the stop trigger bit (TAPAnOPHT0 = 1).
	Stopping operation	Setting in the TAPAnACWE register: Set the TAPAnACWE bit to 1. Setting in the TAPAnACTT register. Set the TAPAnACTT bit to 1.	Writing to the TAPAnACTT bit is enabled. TAPAnFLG.ACE = 0, stopping asynchronous Hi-Z control.

Section 25 Peripheral Interconnection (PIC)

25.1 Timer Synchronization and Port Hi-Z Function

25.1.1 Overview

The peripheral interconnection (PIC1) handles synchronous operation using multiple timers and Hi-Z control of ports by working with TAPA.

Table 25.1 describes the overview of the PIC1 specification.

Table 25.1 PIC1 Specification Overview

Item	Description
Timer synchronization	Realizes simultaneous start of any combination of timers (TSG2n and OSTMn).
Port Hi-Z function	Realizes Hi-Z control of ports by working with TAPA.

25.1.2 Registers

Table 25.2 lists the PIC1-related registers.

For information about restrictions on the individual registers and bits, see the register description in the following sections.

Table 25.2 List of PIC1 registers

<Base: FFDD 0000_H>

Register Name	Symbol	Address
Control register EN	PIC1EN	Base + 00_H
Simultaneous start trigger control register	PIC1SST	Base + 04_H
Simultaneous start control register 2	PIC1SSER2	Base + 18_H
Simultaneous start control register 3	PIC1SSER3	Base + $1C_H$
Hi-Z output control register 2	PIC1HIZCEN2	Base + 88_H
Hi-Z output control register 3	PIC1HIZCEN3	Base + $8C_H$

25.1.2.1 PIC1EN — Control Register EN

This register is set when the PIC1 function is used.

Access: This register can be read/written in 8-bit units.

Address: <Base> + 00_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	PIC1EN0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 25.3 PIC1EN Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When writing to these bits, write 0.
0	PIC1EN0	Enables and disables the PIC1 function. 0: disabled 1: enabled

25.1.2.2 PIC1SST — Simultaneous Start Trigger Control Register 0

The PIC1SST register generates start triggers of the timers for which simultaneous start is enabled.

Access: This register can be read/written in 8-bit units.

Address: <Base> + 04_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SYNCTRG
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 25.4 PIC1SST Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When writing to these bits, write 0.
0	SYNCTRG*1	Generates start triggers of the timers for which simultaneous start is enabled. 0: Invalid 1: Generates a trigger of simultaneous start (outputs a pulse of 1-PCLK-cycle).

Note 1. When this bit is read, the result is always 0.

25.1.2.3 PIC1SSER2 — Simultaneous Start Control Register 2

The PIC1SSER2 register permits start triggers of TSG2n. The selected signal is supplied to the TSTSST signal input line of TSG2n.

Access: This register can be read/written in 16-bit units.

Address: <Base> + 18_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PIC1SSER209	PIC1SSER208	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Table 25.5 PIC1SSER2 Register Contents

Bit Position	Bit Name	Function
15 to 10	—	Reserved When writing to these bits, write 0.
9	PIC1SSER209	Permits TSG21 simultaneous start triggers. 0: TSG21 simultaneous start triggers are not permitted. 1: TSG21 simultaneous start triggers are permitted.
8	PIC1SSER208	Permits TSG20 simultaneous start triggers. 0: TSG20 simultaneous start triggers are not permitted. 1: TSG20 simultaneous start triggers are permitted.
7 to 0	—	Reserved When writing to these bits, write 0.

25.1.2.4 PIC1SSER3 — Simultaneous Start Control Register 3

The PIC1SSER3 register permits start triggers of OSTMn. The selected signal is supplied to the OSTMnTSST signal input line of OSTMn (n = 0 to 2).

Access: This register can be read/written in 16-bit units.

Address: <Base> + $1C_H$

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	PIC1SSER302	PIC1SSER301	PIC1SSER300
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 25.6 PIC1SSER3 Register Contents

Bit Position	Bit Name	Function
15 to 3	—	Reserved When writing to these bits, write 0.
2	PIC1SSER302	Permits OSTM2 simultaneous start triggers. 0: OSTM2 simultaneous start triggers are not permitted. 1: OSTM2 simultaneous start triggers are permitted.
1	PIC1SSER301	Permits OSTM1 simultaneous start triggers. 0: OSTM1 simultaneous start triggers are not permitted. 1: OSTM1 simultaneous start triggers are permitted.
0	PIC1SSER300	Permits OSTM0 simultaneous start triggers. 0: OSTM0 simultaneous start triggers are not permitted. 1: OSTM0 simultaneous start triggers are permitted.

25.1.2.5 PIC1HIZCEN2 — Hi-Z Output Control Register 2

The PIC1HIZCEN2 register selects an input signal for Hi-Z output control. The selected signal is supplied to the TAPATHASIN signal input line of TAPA2.

Access: This register can be read/written in 8-bit units.

Address: <Base> + 88_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	PIC1HIZCEN25	—	PIC1HIZCEN23	—	—	PIC1HIZCEN20
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R	R/W	R	R	R/W

Table 25.7 PIC1HIZCEN2 Register Contents

Bit Position	Bit Name	Function
7, 6	—	Reserved When writing to these bits, write 0.
5	PIC1HIZCEN25	Enables or disables Hi-Z output control by the ERROROUTZ signal. 0: Disabled 1: Enabled
4	—	Reserved When writing to these bits, write 0.
3	PIC1HIZCEN23	Enables or disables Hi-Z output control by the INTTSG20IER signal. 0: Disabled 1: Enabled
2 to 1	—	Reserved When writing to these bits, write 0.
0	PIC1HIZCEN20	Enables or disables Hi-Z output control by input to the ESO2 pin. 0: Disabled 1: Enabled

25.1.2.6 PIC1HIZCEN3 — Hi-Z Output Control Register 3

The PIC1HIZCEN3 register selects an input signal for Hi-Z output control. The selected signal is supplied to the TAPATHASIN signal input line of TAPA3.

Access: This register can be read/written in 8-bit units.

Address: <Base> + $8C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	PIC1HIZCEN35	PIC1HIZCEN34	—	—	—	PIC1HIZCEN30
Value after reset	0	0	0	0	0	0	0	0

Table 25.8 PIC1HIZCEN3 Register Contents

Bit Position	Bit Name	Function
7 to 6	—	Reserved When writing to these bits, write 0.
5	PIC1HIZCEN35	Enables or disables Hi-Z output control by the ERROROUTZ signal. 0: Disabled 1: Enabled
4	PIC1HIZCEN34	Enables or disables Hi-Z output control by the INTTSG21IER signal. 0: Disabled 1: Enabled
3 to 1	—	Reserved When writing to these bits, write 0.
0	PIC1HIZCEN30	Enables or disables Hi-Z output control by input to the ESO3 pin. 0: Disabled 1: Enabled

25.1.3 Operation

25.1.3.1 Timer Synchronization

(1) An arbitrary combination of timers (TSG2n and OSTMn) that operate the given operating mode is started simultaneously.

(2) Simultaneous start of the target timers is permitted by setting the corresponding bits of PIC1SSER2 and PIC1SSER3 to 1.

(3) Writing 1 to the SYNCTRG bit of PIC1SST0 simultaneously starts the target timers specified in (2).

(4) Repeating (2) and (3) for the channels that are not yet started allow each of the different target timer groups to be started simultaneously in separate timing.

25.2 Trigger Selection Function (PIC2)

25.2.1 Overview

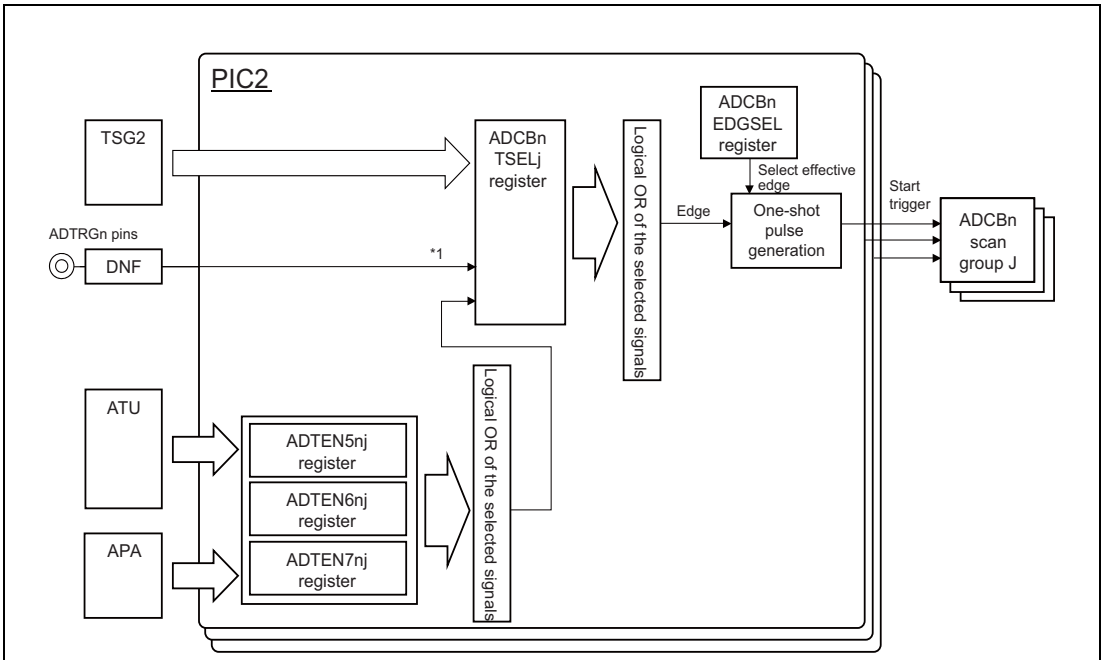
The trigger selection block (PIC2: Peripheral Interconnection-2) selects triggers for the ADC from among signals from the ATU and APA and signals from other internal modules and for starting and stopping ΔΣADC from among internal signals from various timers and other peripheral modules.

Table 25.9 describes the overview of the PIC2 specifications.

Table 25.9 Overview of the PIC2 specifications

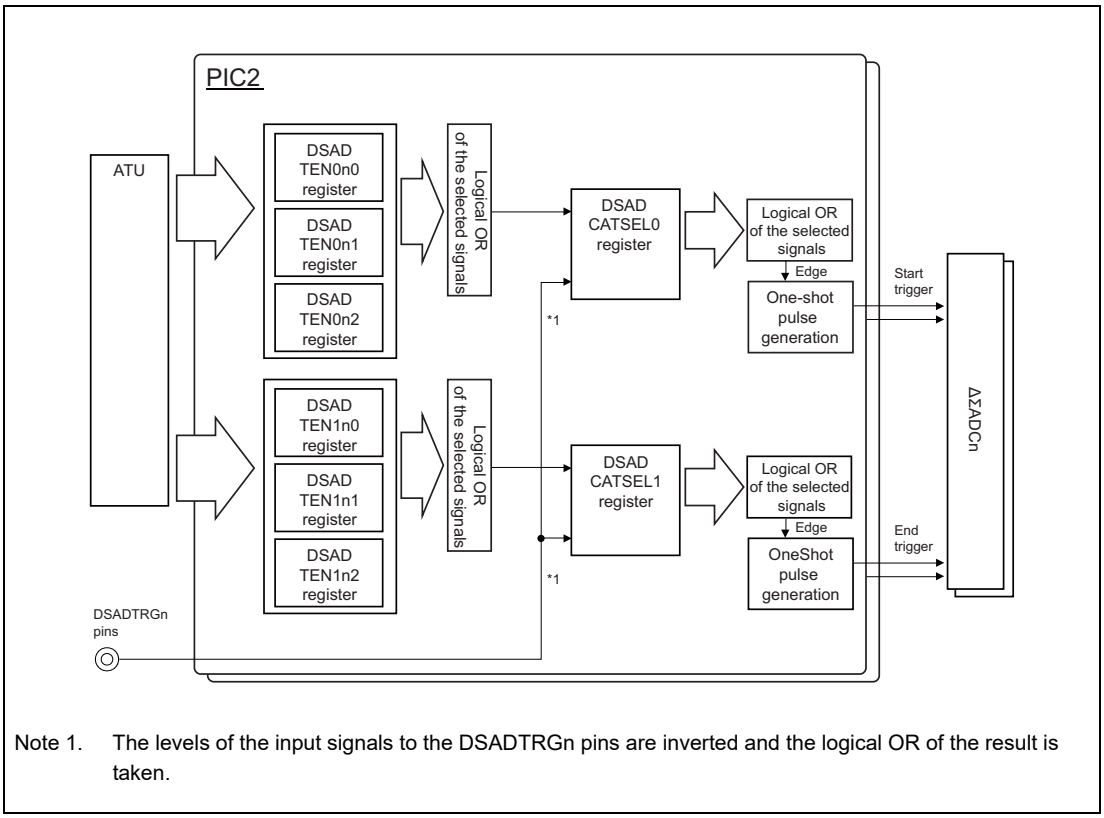
Item	Description
ADC trigger selection function (selection from ATU timers, peripheral IPs, and above described sources)	Selects sources from ATU and APA for ADC.
	Selects an AD trigger from the above selected sources and internal signals from peripheral IPs.
ΔΣADC trigger selection	Selects an AD trigger for ΔΣADC from ATU and external pins.

25.2.2 Block Diagram



Note 1. The levels of the input signals to the ADTRGn pins are inverted and the logical OR of the result is taken.

Figure 25.1 Block Diagram of Trigger Selection Function of ADCBn Scan Group j



Note 1. The levels of the input signals to the DSADTRGn pins are inverted and the logical OR of the result is taken.

Figure 25.2 Block Diagram of Trigger Selection Function of ΔΣADCn

25.2.3 Register

Table 25.10 lists the registers related to PIC2.

For information about restrictions on the individual registers and bits, see the register description in the following sections.

Table 25.10 List of PIC2 Registers (1/3)

<Base: FFDD 1000$_H$>

Register Name	Symbol	Address
ADC trigger selection control register		
A/D converter 0 trigger selection control register 0	PIC2ADCB0TSEL0	Base + 00$_H$

25.2.3.1 PIC2ADCBnTSELj — AD Converter n Trigger Selection Control Register j

The PIC2ADCBnTSELj register selects a trigger for ADCBn scan group j (n = 0, 1; j = 0 to 4).

Access: This register can be read/written in 16- or 32-bit units.

Address: <Base> + 00_H (n = 0, j = 0), <Base> + 04_H (n = 0, j = 1),
<Base> + 08_H (n = 0, j = 2), <Base> + $0C_H$ (n = 0, j = 3),
<Base> + 10_H (n = 0, j = 4), <Base> + 20_H (n = 1, j = 0),
<Base> + 24_H (n = 1, j = 1), <Base> + 28_H (n = 1, j = 2),
<Base> + $2C_H$ (n = 1, j = 3), <Base> + 30_H (n = 1, j = 4)

Value after reset: 0000 0000_H

Table 25.11 PIC2ADCBnTSELj Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved When writing to these bits, write 0.
15	PIC2ADCBnTSELj15	Selects the trigger selected by the PIC2ADTEN5nj, PIC2ADTEN6nj, or PIC2ADTEN7nj register as a trigger source of ADCBn scan group j. 0: Does not select the trigger selected by register PIC2ADTEN5nj, 6nj, or 7nj. 1: Selects the trigger selected by register PIC2ADTEN5nj, 6nj, or 7nj.
14 to 9	—	Reserved When writing to these bits, write 0.
8	PIC2ADCBnTSELj08	Selects the ADTRGn pin as a trigger source of ADCBn scan group j. 0: The ADTRGn pin is not selected. 1: The ADTRGn pin is selected.
7	PIC2ADCBnTSELj07	Selects TSG21TSTADT1 as a trigger source of ADCBn scan group j. (TSG21 TSTADT1 signal) 0: TSG21TSTADT1 is not selected. 1: TSG21TSTADT1 is selected.
6	PIC2ADCBnTSELj06	Selects TSG21TSTADT0 as a trigger source of ADCBn scan group j. (TSG21 TSTADT0 signal) 0: TSG21TSTADT0 is not selected. 1: TSG21TSTADT0 is selected.
5	PIC2ADCBnTSELj05	Selects TSG20TSTADT1 as a trigger source of ADCBn scan group j. (TSG20 TSTADT1 signal) 0: TSG20TSTADT1 is not selected. 1: TSG20TSTADT1 is selected.
4	PIC2ADCBnTSELj04	Selects TSG20TSTADT0 as a trigger source of ADCBn scan group j. (TSG20 TSTADT0 signal) 0: TSG20TSTADT0 is not selected. 1: TSG20TSTADT0 is selected.
3 to 0	—	Reserved When writing to these bits, write 0.

25.2.3.2 PIC2ADCBnEDGSEL — AD Converter n Trigger Edge Selection Control Register

The PIC2ADCBnEDGSEL register selects an effective edge for the one-shot pulse generation circuit which generates an ADCB trigger.

The ADC external pin trigger is input in negative logic, but it is converted to positive logic for trigger source selection. Since edge detection is made for a trigger source after selection, note that the definition of an edge is reversed for an ADC external pin signal. (Setting 00 enables selection of a falling edge of ADC external pin triggers ADTRG0 and ADTRG1).

Access: This register can be read in 16-bit units.

Address: <Base> + $1C_H$ (n = 0), <Base> + $3C_H$ (n = 1)

Value after reset: 0000_H

Table 25.12 PIC2ADCBnEDGSEL Register Contents

Bit Position	Bit Name	Function
15 to 10	—	Reserved When writing to these bits, write 0.
9, 8	PIC2ADCBnEDGSEL98[9:8]	Select an effective edge of ADCBn scan group 4. 00: Rising edge is selected. 01: Falling edge is selected. 10: Both edges are selected. 11: — (setting prohibited)
7, 6	PIC2ADCBnEDGSEL76[7:6]	Select an effective edge of ADCBn scan group 3. 00: Rising edge is selected. 01: Falling edge is selected. 10: Both edges are selected. 11: — (setting prohibited)
5, 4	PIC2ADCBnEDGSEL54[5:4]	Select an effective edge of ADCBn scan group 2. 00: Rising edge is selected. 01: Falling edge is selected. 10: Both edges are selected. 11: — (setting prohibited)
3, 2	PIC2ADCBnEDGSEL32[3:2]	Select an effective edge of ADCBn scan group 1. 00: Rising edge is selected. 01: Falling edge is selected. 10: Both edges are selected. 11: — (setting prohibited)
1, 0	PIC2ADCBnEDGSEL10[1:0]	Select an effective edge of ADCBn scan group 0. 00: Rising edge is selected. 01: Falling edge is selected. 10: Both edges are selected. 11: — (setting prohibited)

25.2.3.3 PIC2ADTEN5nj — AD Converter Trigger Output Control Register 5nj

The PIC2ADTEN5nj register enables a trigger source from ATU timer C compare match, ATU timer G compare match, and ATU DMA request switch function to be selected as an ADCB trigger (n = 0, 1; j = 0 to 4).

Access: This register can be read/written in 16- or 32-bit units.

Address: <Base> + 80_H (n = 0, j = 0), <Base> + 84_H (n = 0, j = 1),
<Base> + 88_H (n = 0, j = 2), <Base> + $8C_H$ (n = 0, j = 3),
<Base> + 90_H (n = 0, j = 4), <Base> + 94_H (n = 1, j = 0),
<Base> + 98_H (n = 1, j = 1), <Base> + $9C_H$ (n = 1, j = 2),
<Base> + $A0_H$ (n = 1, j = 3), <Base> + $A4_H$ (n = 1, j = 4)

Value after reset: $0000\ 0000_H$

Table 25.13 PIC2ADTEN5nj Register Contents (2/3)

Bit Position	Bit Name	Function
24	PIC2ADTEN5nj24	OCRC60 input capture/compare match interrupt (ATU4 timer C subblock 6 channel 0 input capture/compare match interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
23	PIC2ADTEN5nj23	OCRC43 input capture/compare match interrupt (ATU4 timer C subblock 4 channel 3 input capture/compare match interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
22	PIC2ADTEN5nj22	OCRC42 input capture/compare match interrupt (ATU4 timer C subblock 4 channel 2 input capture/compare match interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
21	PIC2ADTEN5nj21	OCRC41 input capture/compare match interrupt (ATU4 timer C subblock 4 channel 1 input capture/compare match interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
20	PIC2ADTEN5nj20	OCRC40 input capture/compare match interrupt (ATU4 timer C subblock 4 channel 0 input capture/compare match interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
19	PIC2ADTEN5nj19	OCRC03 input capture/compare match interrupt (ATU4 timer C subblock 0 channel 3 input capture/compare match interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
18	PIC2ADTEN5nj18	OCRC02 input capture/compare match interrupt (ATU4 timer C subblock 0 channel 2 input capture/compare match interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
17	PIC2ADTEN5nj17	OCRC01 input capture/compare match interrupt (ATU4 timer C subblock 0 channel 1 input capture/compare match interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
16	PIC2ADTEN5nj16	OCRC00 input capture/compare match interrupt (ATU4 timer C subblock 0 channel 0 input capture/compare match interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
15	PIC2ADTEN5nj15	OCRG7 compare match interrupt (ATU4 timer G subblock 7) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
14	PIC2ADTEN5nj14	OCRG6 compare match interrupt (ATU4 timer G subblock 6) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
13	PIC2ADTEN5nj13	OCRG5 compare match interrupt (ATU4 timer G subblock 5) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
12	PIC2ADTEN5nj12	OCRG4 compare match interrupt (ATU4 timer G subblock 4) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
11	PIC2ADTEN5nj11	OCRG3 compare match interrupt (ATU4 timer G subblock 3) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
10	PIC2ADTEN5nj10	OCRG2 compare match interrupt (ATU4 timer G subblock 2) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
9	PIC2ADTEN5nj9	OCRG1 compare match interrupt (ATU4 timer G subblock 1) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.

Table 25.13 PIC2ADTEN5nj Register Contents (3/3)

Bit Position	Bit Name	Function
8	PIC2ADTEN5nj8	OCRG0 compare match interrupt (ATU4 timer G subblock 0) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
7 to 1	—	Reserved When writing to these bits, write 0.
0	PIC2ADTEN5nj0	Output signal from the SAR-AD trigger selection circuit for ATU DMA/AD request auto-switching 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.

25.2.3.4 PIC2ADTEN6nj — AD Converter Trigger Output Control Register 6nj

The PIC2ADTEN6nj register enables a trigger source from APA0 interrupt and ATU timer D compare match A to be selected as an ADCB trigger (n = 0, 1; j = 0 to 4).

Access: This register can be read/written in 32-bit units.

Address: <Base> + $A8_H$ (n = 0, j = 0), <Base> + AC_H (n = 0, j = 1),
<Base> + $B0_H$ (n = 0, j = 2), <Base> + $B4_H$ (n = 0, j = 3),
<Base> + $B8_H$ (n = 0, j = 4), <Base> + BC_H (n = 1, j = 0),
<Base> + $C0_H$ (n = 1, j = 1), <Base> + $C4_H$ (n = 1, j = 2),
<Base> + $C8_H$ (n = 1, j = 3), <Base> + CC_H (n = 1, j = 4)

9	PIC2ADTEN6nj9	OCR1D41 compare match interrupt (ATU4 timer D subblock 4 channel 1 compare match A interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
8	PIC2ADTEN6nj8	OCR1D40 compare match interrupt (ATU4 timer D subblock 4 channel 0 compare match A interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
7	PIC2ADTEN6nj7	OCR1D23 compare match interrupt (ATU4 timer D subblock 2 channel 3 compare match A interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
6	PIC2ADTEN6nj6	OCR1D22 compare match interrupt (ATU4 timer D subblock 2 channel 2 compare match A interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
5	PIC2ADTEN6nj5	OCR1D21 compare match interrupt (ATU4 timer D subblock 2 channel 1 compare match A interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
4	PIC2ADTEN6nj4	OCR1D20 compare match interrupt (ATU4 timer D subblock 2 channel 0 compare match A interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
3	PIC2ADTEN6nj3	OCR1D03 compare match interrupt (ATU4 timer D subblock 0 channel 3 compare match A interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
2	PIC2ADTEN6nj2	OCR1D02 compare match interrupt (ATU4 timer D subblock 0 channel 2 compare match A interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.

Table 25.14 PIC2ADTEN6nj Register Contents (3/3)

Bit Position	Bit Name	Function
1	PIC2ADTEN6nj1	OCR1D01 compare match interrupt (ATU4 timer D subblock 0 channel 1 compare match A interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
0	PIC2ADTEN6nj0	OCR1D00 compare match interrupt (ATU4 timer D subblock 0 channel 0 compare match A interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.

25.2.3.5 PIC2ADTEN7nj — A/D Converter Trigger Output Control Register 7nj

The PIC2ADTEN7nj register enables a trigger source from ATU timer D compare match B to be selected as an ADCB trigger (n = 0, 1; j = 0 to 4).

Access: This register can be read/written in 32-bit units.

Address: <Base> + $D0_H$ (n = 0, j = 0), <Base> + $D4_H$ (n = 0, j = 1), <Base> + $D8_H$ (n = 0, j = 2), <Base> + DC_H (n = 0, j = 3), <Base> + $E0_H$ (n = 0, j = 4), <Base> + $E4_H$ (n = 1, j = 0), <Base> + $E8_H$ (n = 1, j = 1), <Base> + EC_H (n = 1, j = 2), <Base> + $F0_H$ (n = 1, j = 3), <Base> + $F4_H$ (n = 1, j = 4)

Value after reset: $0000\ 0000_H$

Table 25.15 PIC2ADTEN7nj Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 20	—	Reserved When writing to these bits, write 0.
19	PIC2ADTEN7nj19	OCR2D93 compare match interrupt (ATU4 timer D subblock 9 channel 3 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
18	PIC2ADTEN7nj18	OCR2D92 compare match interrupt (ATU4 timer D subblock 9 channel 2 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
17	PIC2ADTEN7nj17	OCR2D91 compare match interrupt (ATU4 timer D subblock 9 channel 1 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
16	PIC2ADTEN7nj16	OCR2D90 compare match interrupt (ATU4 timer D subblock 9 channel 0 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
15	PIC2ADTEN7nj15	OCR2D63 compare match interrupt (ATU4 timer D subblock 6 channel 3 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
14	PIC2ADTEN7nj14	OCR2D62 compare match interrupt (ATU4 timer D subblock 6 channel 2 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
13	PIC2ADTEN7nj13	OCR2D61 compare match interrupt (ATU4 timer D subblock 6 channel 1 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.

Table 25.15 PIC2ADTEN7nj Register Contents (2/2)

Bit Position	Bit Name	Function
12	PIC2ADTEN7nj12	OCR2D60 compare match interrupt (ATU4 timer D subblock 6 channel 0 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
11	PIC2ADTEN7nj11	OCR2D43 compare match interrupt (ATU4 timer D subblock 4 channel 3 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
10	PIC2ADTEN7nj10	OCR2D42 compare match interrupt (ATU4 timer D subblock 4 channel 2 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
9	PIC2ADTEN7nj9	OCR2D41 compare match interrupt (ATU4 timer D subblock 4 channel 1 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
8	PIC2ADTEN7nj8	OCR2D40 compare match interrupt (ATU4 timer D subblock 4 channel 0 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
7	PIC2ADTEN7nj7	OCR2D23 compare match interrupt (ATU4 timer D subblock 2 channel 3 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
6	PIC2ADTEN7nj6	OCR2D22 compare match interrupt (ATU4 timer D subblock 2 channel 2 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
5	PIC2ADTEN7nj5	OCR2D21 compare match interrupt (ATU4 timer D subblock 2 channel 1 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
4	PIC2ADTEN7nj4	OCR2D20 compare match interrupt (ATU4 timer D subblock 2 channel 0 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
3	PIC2ADTEN7nj3	OCR2D03 compare match interrupt (ATU4 timer D subblock 0 channel 3 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
2	PIC2ADTEN7nj2	OCR2D02 compare match interrupt (ATU4 timer D subblock 0 channel 2 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
1	PIC2ADTEN7nj1	OCR2D01 compare match interrupt (ATU4 timer D subblock 0 channel 1 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.
0	PIC2ADTEN7nj0	OCR2D00 compare match interrupt (ATU4 timer D subblock 0 channel 0 compare match B interrupt) 0: Selection of the above signal as an ADCB trigger is disabled. 1: Selection of the above signal as an ADCB trigger is enabled.

25.2.3.6 PIC2DSADTEN0n0 — DSADC Start Trigger Output Control Register n0 (n = 0 to 7)

DSADC start trigger output control register n0 enables a trigger source from ATU timer G compare match to be selected as a trigger for starting ΔΣADC.

Access: This register can be read/written in 16-bit units.

Address: <Base> + 100_H (n = 0), <Base> + 118_H (n = 1),
<Base> + 130_H (n = 2), <Base> + 148_H (n = 3),
<Base> + 160_H (n = 4), <Base> + 178_H (n = 5),
<Base> + 190_H (n = 6), <Base> + $1A8_H$ (n = 7)

Value after reset: 0000_H

Table 25.18 PIC2DSADTEN0n2 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 20	—	Reserved When writing to these bits, write 0.
19	PIC2DSADTEN 0n219	OCR2D93 compare match interrupt (ATU4 timer D subblock 9 channel 3 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
18	PIC2DSADTEN 0n218	OCR2D92 compare match interrupt (ATU4 timer D subblock 9 channel 2 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
17	PIC2DSADTEN 0n217	OCR2D91 compare match interrupt (ATU4 timer D subblock 9 channel 1 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
16	PIC2DSADTEN 0n216	OCR2D90 compare match interrupt (ATU4 timer D subblock 9 channel 0 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
15	PIC2DSADTEN 0n215	OCR2D63 compare match interrupt (ATU4 timer D subblock 6 channel 3 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
14	PIC2DSADTEN 0n214	OCR2D62 compare match interrupt (ATU4 timer D subblock 6 channel 2 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
13	PIC2DSADTEN 0n213	OCR2D61 compare match interrupt (ATU4 timer D subblock 6 channel 1 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
12	PIC2DSADTEN 0n212	OCR2D60 compare match interrupt (ATU4 timer D subblock 6 channel 0 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.

Table 25.18 PIC2DSADTEN0n2 Register Contents (2/2)

Bit Position	Bit Name	Function
11	PIC2DSADTEN 0n211	OCR2D43 compare match interrupt (ATU4 timer D subblock 4 channel 3 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
10	PIC2DSADTEN 0n210	OCR2D42 compare match interrupt (ATU4 timer D subblock 4 channel 2 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
9	PIC2DSADTEN 0n29	OCR2D41 compare match interrupt (ATU4 timer D subblock 4 channel 1 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
8	PIC2DSADTEN 0n28	OCR2D40 compare match interrupt (ATU4 timer D subblock 4 channel 0 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
7	PIC2DSADTEN 0n27	OCR2D23 compare match interrupt (ATU4 timer D subblock 2 channel 3 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
6	PIC2DSADTEN 0n26	OCR2D22 compare match interrupt (ATU4 timer D subblock 2 channel 2 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
5	PIC2DSADTEN 0n25	OCR2D21 compare match interrupt (ATU4 timer D subblock 2 channel 1 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
4	PIC2DSADTEN 0n24	OCR2D20 compare match interrupt (ATU4 timer D subblock 2 channel 0 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
3	PIC2DSADTEN 0n23	OCR2D03 compare match interrupt (ATU4 timer D subblock 0 channel 3 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
2	PIC2DSADTEN 0n22	OCR2D02 compare match interrupt (ATU4 timer D subblock 0 channel 2 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
1	PIC2DSADTEN 0n21	OCR2D01 compare match interrupt (ATU4 timer D subblock 0 channel 1 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.
0	PIC2DSADTEN 0n20	OCR2D00 compare match interrupt (ATU4 timer D subblock 0 channel 0 compare match B interrupt) 0: Selection of the above signal as a ΔΣADCn start trigger is disabled. 1: Selection of the above signal as a ΔΣADCn start trigger is enabled.

25.2.3.9 PIC2DSADTEN1n0 — DSADC Stop Trigger Output Control Register n0 (n = 0 to 7)

DSADC stop trigger output control register n0 enables a trigger source from ATU timer G compare match to be selected as a trigger for stopping ΔΣADC.

Access: This register can be read/written in 16-bit units.

Address: <Base> + $10C_H$ (n = 0), <Base> + 124_H (n = 1), <Base> + $13C_H$ (n = 2), <Base> + 154_H (n = 3), <Base> + $16C_H$ (n = 4), <Base> + 184_H (n = 5), <Base> + $19C_H$ (n = 6), <Base> + $1B4_H$ (n = 7)

Value after reset: 0000_H

Table 25.19 PIC2DSADTEN1n0 Register Contents

Bit Position	Bit Name	Function
15	PIC2DSADTEN1n115	OCRG7 compare match interrupt (ATU4 timer G subblock 7) 0: Selection of the above signal as a ΔΣADCn end trigger is disabled. 1: Selection of the above signal as a ΔΣADCn end trigger is enabled.
14	PIC2DSADTEN1n114	OCRG6 compare match interrupt (ATU4 timer G subblock 6) 0: Selection of the above signal as a ΔΣADCn end trigger is disabled. 1: Selection of the above signal as a ΔΣADCn end trigger is enabled.
13	PIC2DSADTEN1n113	OCRG5 compare match interrupt (ATU4 timer G subblock 5) 0: Selection of the above signal as a ΔΣADCn end trigger is disabled. 1: Selection of the above signal as a ΔΣADCn end trigger is enabled.
12	PIC2DSADTEN1n112	OCRG4 compare match interrupt (ATU4 timer G subblock 4) 0: Selection of the above signal as a ΔΣADCn end trigger is disabled. 1: Selection of the above signal as a ΔΣADCn end trigger is enabled.
11	PIC2DSADTEN1n111	OCRG3 compare match interrupt (ATU4 timer G subblock 3) 0: Selection of the above signal as a ΔΣADCn end trigger is disabled. 1: Selection of the above signal as a ΔΣADCn end trigger is enabled.
10	PIC2DSADTEN1n110	OCRG2 compare match interrupt (ATU4 timer G subblock 2) 0: Selection of the above signal as a ΔΣADCn end trigger is disabled. 1: Selection of the above signal as a ΔΣADCn end trigger is enabled.
9	PIC2DSADTEN1n109	OCRG1 compare match interrupt (ATU4 timer G subblock 1) 0: Selection of the above signal as a ΔΣADCn end trigger is disabled. 1: Selection of the above signal as a ΔΣADCn end trigger is enabled.
8	PIC2DSADTEN1n108	OCRG0 compare match interrupt (ATU4 timer G subblock 0) 0: Selection of the above signal as a ΔΣADCn end trigger is disabled. 1: Selection of the above signal as a ΔΣADCn end trigger is enabled.
7 to 0	—	Reserved When writing to these bits, write 0.

25.2.3.10 PIC2DSADTEN1n1 — DSADC Stop Trigger Output Control Register n1 (n = 0 to 7)

DSADC stop trigger output control register n1 enables a trigger source from ATU timer D compare match A to be selected as a trigger for stopping ΔΣADC.

Access: This register can be read/written in 32-bit units.

Address: <Base> + 110_H (n = 0), <Base> + 128_H (n = 1), <Base> + 140_H (n = 2), <Base> + 158_H (n = 3), <Base> + 170_H (n = 4), <Base> + 188_H (n = 5), <Base> + $1A0_H$ (n = 6), <Base> + $1B8_H$ (n = 7)

3	DSADCATSEL003	Selects the DSADTRG1 pin as a trigger source for starting DSADC1. 0: DSADTRG1 is not selected. 1: DSADTRG1 is selected.
2	DSADCATSEL002	Selects the trigger selected by DSADC start trigger output control register 1j (j = 0 to 2) as a trigger source for starting DSADC1. 0: Does not select the trigger selected by register PIC2DSADTEN01j. 1: Selects the trigger selected by register PIC2DSADTEN01j.
1	DSADCATSEL001	Selects the DSADTRG0 pin as a trigger source for starting DSADC0. 0: DSADTRG0 is not selected. 1: DSADTRG0 is selected.
0	DSADCATSEL000	Selects the trigger selected by DSADC start trigger output control register 0j (j = 0 to 2) as a trigger source for starting DSADC0. 0: Does not select the trigger selected by register PIC2DSADTEN00j. 1: Selects the trigger selected by register PIC2DSADTEN00j.

25.2.3.13 PIC2DSADCATSEL1 — DSADC Trigger Selection Control Register 1

DSADC trigger selection control register 1 selects a trigger for stopping DSADCj (j = 0 to 7).

Access: This register can be read/written in 16-bit units.

Address: <Base> + $1C4_H$

Value after reset: 0000_H

Table 25.23 PIC2DSADCATSEL1 Register Contents (1/2)

Bit Position	Bit Name	Function
15	DSADCATSEL115	Selects the DSADTRG7 pin as a trigger source for stopping DSADC7. 0: DSADTRG7 is not selected. 1: DSADTRG7 is selected.
14	DSADCATSEL114	Selects the trigger selected by DSADC stop trigger output control register 7j (j = 0 to 2) as a trigger source for stopping DSADC7. 0: Does not select the trigger selected by register PIC2DSADTEN07j. 1: Selects the trigger selected by register PIC2DSADTEN07j.
13	DSADCATSEL113	Selects the DSADTRG6 pin as a trigger source for stopping DSADC6. 0: DSADTRG6 is not selected. 1: DSADTRG6 is selected.
12	DSADCATSEL112	Selects the trigger selected by DSADC stop trigger output control register 6j (j = 0 to 2) as a trigger source for stopping DSADC6. 0: Does not select the trigger selected by register PIC2DSADTEN06j. 1: Selects the trigger selected by register PIC2DSADTEN06j.
11	DSADCATSEL111	Selects the DSADTRG5 pin as a trigger source for stopping DSADC5. 0: DSADTRG5 is not selected. 1: DSADTRG5 is selected.
10	DSADCATSEL110	Selects the trigger selected by DSADC stop trigger output control register 5j (j = 0 to 2) as a trigger source for stopping DSADC5. 0: Does not select the trigger selected by register PIC2DSADTEN15j. 1: Selects the trigger selected by register PIC2DSADTEN15j.
9	DSADCATSEL109	Selects the DSADTRG4 pin as a trigger source for stopping DSADC4. 0: DSADTRG4 is not selected. 1: DSADTRG4 is selected.
8	DSADCATSEL108	Selects the trigger selected by DSADC stop trigger output control register 4j (j = 0 to 2) as a trigger source for stopping DSADC4. 0: Does not select the trigger selected by register PIC2DSADTEN14j. 1: Selects the trigger selected by register PIC2DSADTEN14j.
7	DSADCATSEL107	Selects the DSADTRG3 pin as a trigger source for stopping DSADC3. 0: DSADTRG3 is not selected. 1: DSADTRG3 is selected.
6	DSADCATSEL106	Selects the trigger selected by DSADC stop trigger output control register 3j (j = 0 to 2) as a trigger source for stopping DSADC3. 0: Does not select the trigger selected by register PIC2DSADTEN13j. 1: Selects the trigger selected by register PIC2DSADTEN13j.
5	DSADCATSEL105	Selects the DSADTRG2 pin as a trigger source for stopping DSADC2. 0: DSADTRG2 is not selected. 1: DSADTRG2 is selected.
4	DSADCATSEL104	Selects the trigger selected by DSADC stop trigger output control register 2j (j = 0 to 2) as a trigger source for stopping DSADC2. 0: Does not select the trigger selected by register PIC2DSADTEN12j. 1: Selects the trigger selected by register PIC2DSADTEN12j.

Table 25.23 PIC2DSADCATSEL1 Register Contents (2/2)

Bit Position	Bit Name	Function
3	DSADCATSEL103	Selects the DSADTRG1 pin as a trigger source for stopping DSADC1. 0: DSADTRG1 is not selected. 1: DSADTRG1 is selected.
2	DSADCATSEL102	Selects the trigger selected by DSADC stop trigger output control register 1j (j = 0 to 2) as a trigger source for stopping DSADC1. 0: Does not select the trigger selected by register PIC2DSADTEN11j. 1: Selects the trigger selected by register PIC2DSADTEN11j.
1	DSADCATSEL101	Selects the DSADTRG0 pin as a trigger source for stopping DSADC0. 0: DSADTRG0 is not selected. 1: DSADTRG0 is selected.
0	DSADCATSEL100	Selects the trigger selected by DSADC stop trigger output control register 0j (j = 0 to 2) as a trigger source for stopping DSADC0. 0: Does not select the trigger selected by register PIC2DSADTEN10j. 1: Selects the trigger selected by register PIC2DSADTEN10j.

25.2.4 AD Trigger Selection Function

25.2.4.1 ADC Trigger Selection Function

Each of ADCB0 and ADCB1 has 5 scan groups, and provides the ADCB hardware triggers corresponding to each of the scan groups.

The internal trigger signals selected by register PIC2ADCBnTSELj from TSG20, TSG21, the ATU, and APA0 are ORed with the external trigger signal from the pin and the result can be input as the ADCB hardware trigger signal for the pertinent scan group.

Furthermore, of the above triggers, the ATU and APA triggers are selected from among internal signals of the respective timers.

NOTE

One input external ADTRG pin is provided as an external trigger pin for each AD1. The same external pin is allocated to each AD scan group.

- ATU and APA Trigger Selection
  ADCB hardware trigger signals are generated for 5 scan groups per AD, a total of 10 triggers, from the ATU sources (16 sources of ATU timer C compare match, 20 sources of ATU timer D compare match A, 20 sources of ATU timer D compare match B, 8 sources of ATU timer G compare match, and 1 source of ATU DMA switch function, which are selected independently for each scan group) and the APA0 interrupt.

25.2.4.2 ΔΣADC Trigger Selection Function

ΔΣADC has 2 types of hardware trigger: start and stop triggers. Start and stop triggers are obtained by ORing external pin inputs DSADTRGn and signals selected by ATU trigger selection function and can be input as the ΔΣADC hardware trigger signal.

- ATU trigger selection
  One ΔΣADC trigger is generated for each AD from the ATU sources (20 sources of ATU timer D compare match A, 20 sources of ATU timer D compare match B, and 8 sources of ATU timer G compare match).

Section 26 A/D Converter (ADCB)

This LSI has two 12-bit successive approximation A/D converter modules (ADC0 and ADC1).

26.1 Features

The ADC has the following features.

- Analog channels and sample-and-hold function
  A/D conversion is available for 24 ADC0 channels and 24 ADC1 channels (48 channels in total).
  Each of ADC0 and ADC1 has an internal sample-and-hold circuit that enables ADC0 and ADC1 to perform A/D conversion independently.
- Advanced A/D converter
  Resolution: 12 bits
  A/D conversion method: Successive approximation
  Conversion speed: 1.0 µs
- Supporting simultaneous track and hold for up to 4 channels
  ADC0 has a track-and-hold circuit for 2 channels and ADC1 has for 2 channels , supporting simultaneous track and hold for up to 4 channels.
- Supporting five scan groups
  Each ADC has five scan groups. Scan settings can be made independently for each scan group.
- Two scan modes
  Each ADC has two scan modes.
  Multicycle scan mode: Specified number of scans are executed.
  Continuous scan mode: Scans are repeatedly executed without limit.
- Virtual channels
  Each ADC has 40 virtual channels. Analog channels for which A/D conversion is to be made and other accompanying information are set for each virtual channel. By sequentially performing the processing for the virtual channels indicated by the start virtual channel pointer and the end virtual channel pointer in each scan group, scans (which can perform A/D conversion for any analog channels in any order) can be executed.
- Extended physical channels
  Each ADC can extend physical channels by using an external analog multiplexer. Furthermore, an external analog multiplexer for the CSIH interface is available when DMA is used. (One channel can be set for each ADC.)
- Interval function
  The ADC can start scan groups in any cycle by using the A/D timer equipped in the scan groups 3 and 4. This enables scans with intervals inserted.
- A/D-converted value adding function
  The ADC performs A/D conversion sequentially twice or four times for a channel, and stores the addition result in the data register. The addition count can be set for each virtual channel.
  The effect of the moving average filter can be gained by using this result. However, this function does not always ensure that A/D conversion accuracy is improved.
  In addition, using an optional function ASF makes the extended summation function available.
  For details, see **Section 26.11, ADC Summation Function (ASF)**.

- Data registers
  Data registers corresponding to virtual channels are provided.
- Start trigger for each scan group
  Hardware triggers and software triggers can start processing of each scan group. Only scan groups 3 and 4 can start processing by an A/D timer trigger.
- Asynchronous/synchronous suspend and resume function
  A processing for a scan group can interrupt an ongoing processing for another scan group. The priority is as follows:
  Low High
  SG0 < SG1 < SG2 < SG3 < SG4 (SG: Scan group)
  If a request for a higher-priority SG is present while a lower-priority SG is being processed, the lower-priority SG is suspended after the ongoing virtual channel processing is stopped (synchronous suspend) or after the ongoing virtual channel processing is immediately stopped (asynchronous suspend), and then the processing for the higher-priority SG is performed. After the processing for the higher-priority SG is completed, the suspended virtual channel processing of the lower-priority SG resumes.
  Also, you can set as follows: when a higher-priority SG interrupts an SG0 processing, asynchronous suspend occurs, but when a higher-priority SG interrupts a lower-priority SG other than SG0, synchronous suspend occurs.
- Entry to the digital filter engine and the ADC summation function
  A/D-converted values can be directly entered into the digital filter engine (DFE) or the ADC summation function (ASF). Whether to enable or disable entry and a tag used to define the target channel for entry can be set for each virtual channel. Entry to the DEF or entry to the ASF can be set for each scan group.
- Supporting scan end interrupt and DMA transfer
  Each scan group can generate an interrupt request to the INTC and activate the DMAC each time a processing for the virtual channel indicated by the end virtual channel pointer ends or a virtual channel ends.
- Supporting interrupt and DMA transfer for an external analog multiplexer
  The ADC can generate an interrupt request to the INTC and activate the DMAC when the specified virtual channel is started. This enables transfer of the MPX value to an external analog multiplexer in cooperation with an I/O port or CSIH.
- An analog conversion voltage settable
  The A0VREFH pin and the A1VREFH pin can be used to set the voltage range for analog conversion.
- A/D conversion monitor output
  The processing timing of a desired virtual channel can be output to the A/D conversion monitor output pin.
- A wide range of safety functions
  The ADC has various safety functions, including self-diagnosis, pin-level self-diagnosis, wiring-break detection, normality check for analog selection, upper-limit/lower-limit check for data registers, parity check for data registers, overwrite check for data registers, and read and clear function for data registers.

26.2 Configuration

Figure 26.1 and **Figure 26.2** show the block diagrams of ADC, and **Table 26.1** and **Table 26.2** show the pin configuration of ADC.

ADTRG1	ADC1	Input	External trigger pin
ADEND0	ADC0	Output	A/D conversion timing monitor pin
ADEND1	ADC1	Output	A/D conversion timing monitor pin

To ensure reliability of the LSI, the following relationship is required between A0VCC, A1VCC, A0VSS, and A1VSS and VCC and VSS when the ADC is used.

A0VCC = 5V ± 0.5V, A1VCC = 5V ± 0.5V, and A0VSS = A1VSS = VSS

If you do not use the ADC, the following relationship should be satisfied: A0VCC = A1VCC = EVCC, and A0VSS = A1VSS = VSS. The voltage to be applied to analog input pins must be within the following range:

A0VSS ≤ AN0kl (k = 0 to 5, l = 0 to 3) ≤ A0VREFH, and A1VSS ≤ AN1kl (k = 0 to 7, l = 0 to 2) ≤ A1VREFH

Scan group x status register	ADCBmSGSRx	00_H	<ADCm_base> + x × 80_H + $4A4_H$	8
A/D timer initial phase register y	ADCBmADTIPRy	0000 0000_H	<ADCm_base> + y × 80_H + $4A8_H$	32
A/D timer cycle register y	ADCBmADTPRRy	001F $FFFF_H$	<ADCm_base> + y × 80_H + $4AC_H$	32
Scan group x upper limit/lower limit table select register	ADCBmULLMSRx	00_H	<ADCm_base> + x × 80_H + $4B0_H$	8

Note: m = 0, 1; n = 0 to 39; x = 0 to 4; y = 3, 4

26.4 ADC Common Registers

This section describes common registers for ADC0 and ADC1.

26.4.1 ADCB0ADSYNSTCR — A/D Synchronization Start Control Register

ADCB0ADSYNSTCR is an 8-bit write-only register that controls simultaneous start of A/D conversion for scan groups of ADC0 and ADC1. The register bits are always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADSTART
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 26.5 ADCB0ADSYNSTCR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	ADSTART	This bit starts A/D conversion for scan groups of ADC0 and ADC1. Start condition for SGx of ADCm: 1 is written to ADSTART when SGACT for SGx of ADCm is 0 and ADSTARTE is 1. A/D conversion is started simultaneously for the scan groups (of ADC0 and ADC1) for which ADSTARTE has been set to 1.

NOTE

m = 0, 1; x = 0 to 4

26.4.2 ADCB0ADTSYNSTCR — A/D Timer Synchronization Start Control Register

ADCB0ADTSYNSTCR is an 8-bit write-only register that controls simultaneous start of counting by A/D timers of ADC0 and ADC1. The register bits are always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADTSTART
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 26.6 ADCB0ADTSYNSTCR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	ADTSTART	This bit starts counting by the A/D timers of ADC0 and ADC1. Start condition for SGx of ADCm: 1 is written to ADTSTART when ADTACT for A/D timer y of ADCm is 0 and ADTSTARTE is 1. The A/D timers (of ADC0 and ADC1) for which ADTST has been set to 1 start counting simultaneously.

NOTE

m = 0, 1; x = 0 to 4; y = 3, 4

26.5 ADC Specific Registers (Virtual Channel)

26.5.1 ADCBmVCRn — Virtual Channel Register n

ADCBmVCRn is a 16-bit readable/writable register used for each virtual channel. ADCBmVCRn is initialized to 0000_H at a reset.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CNVCLS[2:0]			DFENT	DFTAG[3:0]				ADIE	—	GCTRL[5:0]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 26.7 ADCBmVCRn Register Contents (1/2)

Bit Position	Bit Name	Function
15 to 13	CNVCLS[2:0]	Conversion Type 0_H: Normal A/D conversion 1_H: Hold value A/D conversion 2_H: Execution of the selected T&H (physical channel group selected) 3_H: Self-diagnosis 4_H: Normal A/D conversion in addition mode 5_H: Normal A/D conversion with the MPX 6_H: Normal A/D conversion with the MPX in addition mode Other than above: Setting prohibited
12	DFENT	DFE Entry 0: Entry disabled 1: Entry enabled This bit specifies whether to enable or disable entry to DFE (digital filter engine) or ASF (ADC summation function). Only the scan groups enabled by DFENTSGxE and ASENTSGxE in ADCBmDFASENTSGER are entered. No scan groups are entered for execution of the selected T&H (CNVCLS[2:0] = 2_H) regardless of the DFENT setting.
11 to 8	DFTAG[3:0]	DFE-TAG When entry to DFE is requested, entry is made to the DFE channel for which the same tag with DFTAG[3:0] is set. If this applies to multiple channels, entry is made to multiple channels. When entry to ASF is requested, entry is made to the ASF channel corresponding to DFTAG[3:0]. When entry to ASF is requested, setting of DFTAG[3:0] = B_H to F_H is invalid.
7	ADIE	Virtual Channel End Interrupt Enable 0: ADImx is not output when A/D conversion for virtual channel n ends in SGx 1: ADImx is output when A/D conversion for virtual channel n ends in SGx ADIE in ADCBmSGCRx is independent of ADIE in ADCBmVCRn. For details, see **Section 26.7.16, Scan End Interrupt Request**.
6	—	Reserved This bit is always read as 0. The write value should always be 0.
5 to 0	GCTRL[5:0]	General Control • For normal A/D conversion (CNVCLS[2:0] = 0_H) – GCTRL[4:2]: Physical Channel Group These bits specify a physical channel group. – GCTRL[1:0]: Physical sub-channel These bits specify a physical sub-channel. Always set the other GCTRL bits to 0.

Table 26.7 ADCBmVCRn Register Contents (2/2)

Bit Position	Bit Name	Function
5 to 0	GCTRL[5:0]	General Control (continued) • For hold value A/D conversion (CNVCLS[2:0] = 1_H) – GCTRL[2:0]: Specification of T&H 0_H: Hold value of T&H0 is A/D converted. 1_H: Hold value of T&H1 is A/D converted. Settings other than the above and those described in **Section 26.9.3, Notes when Current is Being Injected**, are prohibited. • For execution of the selected T&H (CNVCLS[2:0] = 2_H) – GCTRL[5:3]: Physical Channel Group These bits specify a physical channel group. – GCTRL[1]: T&H1 Execution 0: Sampling and holding are not executed on T&H1. 1: Sampling and holding of physical sub-channel 1 are executed on T&H1. – GCTRL[0]: T&H0 Execution 0: Sampling and holding are not executed on T&H0. 1: Sampling and holding of physical sub-channel 0 are executed on T&H0. Settings other than the above and those described in **Section 26.9.3, Notes when Current is Being Injected**, are prohibited. • For self-diagnosis (CNVCLS[2:0] = 3_H) – GCTRL[4:0]: Self-diagnostic Voltage Level 10_H: AVREFH × 1 $0C_H$: AVREFH × 3/4 08_H: AVREFH × 1/2 04_H: AVREFH × 1/4 00_H: AVREFH × 0 Other than above : Setting prohibited Always set the other GCTRL bits to 0. • For normal A/D conversion in addition mode (CNVCLS[2:0] = 4_H) – GCTRL[4:2]: Physical Channel Group These bits specify a physical channel group. – GCTRL[1:0]: Physical sub-channel These bits specify a physical sub-channel. Always set the other GCTRL bits to 0. The count specified by ADDNT is reflected as the number of addition times. • For normal A/D conversion with the MPX (CNVCLS[2:0] = 5_H) – GCTRL[4:0]: MPX Channel Setting These bits set the MPX value to be transferred to an external analog multiplexer. The GCTRL[4:0] value is transferred to ADCBmMPXCURR at the start of virtual channel, and an interrupt request (ADMPXIm) or a DMA request is issued. Activating an interrupt or the DMAC and transferring ADCBmMPXCURR to Pn or PSRn of the I/O port or to CSIHnTX0H of CSIH enables transfer of the MPX value to an external analog multiplexer. For details, see **Section 26.7.5, Example of Operation of External Analog Multiplexer**. • For normal A/D conversion with the MPX in addition mode (CNVCLS[2:0] = 6_H) – GCTRL[4:0]: MPX Channel Setting These bits set the MPX value to be transferred to an external analog multiplexer. The GCTRL[4:0] value is transferred to ADCBmMPXCURR at the start of virtual channel, and an interrupt request (ADMPXIm) or a DMA request is issued. Activating an interrupt or the DMAC and transferring ADCBmMPXCURR to Pn or PSRn of the I/O port or to CSIHnTX0H of CSIH enables transfer of the MPX value to an external analog multiplexer. For details, see **Section 26.7.5, Example of Operation of External Analog Multiplexer**. The count specified by ADDNT is reflected as the number of addition times.

CAUTION

To prevent malfunction, ADCBmVCRn should be set while SGACT for all scan groups is 0 (before scan groups are started), ADSTARTE for all scan groups is 0, TRGMD[0] for scan groups 0, 1, and 2 is 0_H, and TRGMD[1:0] for scan groups 3 and 4 is 0_H.

NOTE

m = 0, 1; n = 0 to 39; x = 0 to 4

26.5.2 ADCBmDRn — Data Register n

ADCBmDRn is a 16-bit read-only register that stores an A/D converted value.

ADCBmDRn is provided for each virtual channel, and its format depends on the DFMT setting of ADCBmADCR2 and the ADDNT setting (when CNVCLS[2:0] of ADCBmVCRn = 4_H or 6_H). The format of data transferred to the DFE (Digital Filter Engine), IFC (Integer/Floating-point Conversion module), and ASF (ADC Summation function) also depends on the above settings. ADCBmDRn is cleared to 0000_H when ADCBmDRn or ADCBmDIRn is read or ADCBmDRn is read via the IFC while RDCLRE is set to 1. ADCBmDRi and ADCBmDRi+1 must always be read together as 32-bit data. When the data must be read in 16-bit units, set RDCLRE to 0. Note that ADCBmDIRi+1.WFLG at that time will be cleared by reading ADCBmDRi in 16-bit units. When CNVCLS[2:0] is 2_H, no data is stored in ADCBmDRn. ADCBmDRn is initialized to 0000_H at a reset.

For signed fixed-point format (DFMT = 0)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Convert once	S													0	0	0
Convert twice	S														0	0
Convert 4 times	S															0

↑ Position of decimal point

For signed integer format (DFMT = 1)

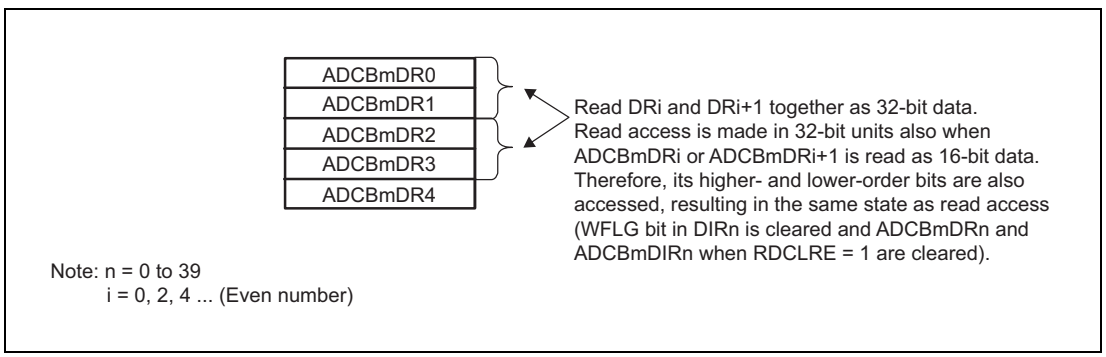
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Convert once	S	S	S	S												
Convert twice	S	S	S													
Convert 4 times	S	S														

↗ Position of decimal point

S	: Sign bit (always 0)
0	: Zero extension

The format setting in ADDNT is valid when CNVCLS[2:0] = 4_H or 6_H.

If CNVCLS[2:0] is not 4_H or 6_H, the format is “convert once.”



NOTE

m = 0, 1; n = 0 to 39; i = 0, 2, 4, ... (Even)

26.5.3 ADCBmDIRn — Data Supplementary Information Register n

ADCBmDIRn is a 32-bit read-only register that stores supplementary information of ADCBmDRn and A/D converted value. ADCBmDIRn is provided for each virtual channel. ADCBmDIRn is cleared to 0000 0000_H when ADCBmDRn or ADCBmDIRn is read or ADCBmDRn is read via the IFC while RDCLRE is set to 1. WFLG is cleared when ADCBmDRn or ADCBmDIRn is read or ADCBmDRn is read via the IFC regardless of the RDCLRE setting. This register must always be read as 32-bit data. ADCBmDRn is read from the lower 16 bits. ADCBmDIRn is initialized to 0000 0000_H at a reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	WFLG	PRTY	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADCBmDRn															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 26.8 ADCBmDIRn Register Contents

Bit Position	Bit Name	Function
31 to 26	—	Reserved These bits are always read as 0. The write value should always be 0.
25	WFLG	Write Flag Setting condition An A/D converted value is stored in ADCBmDRn. Clearing conditions ADCBmDRn or CBmDIRn is rad. ADCBmDRn is read via IFC. This bit is not set when CNVCLS[2:0] = 2_H.
24	PRTY	Parity Parity bit (even parity) for ADCBmDRn This bit is not set when CNVCLS[2:0] = 2_H.
23 to 16	—	Reserved These bits are always read as 0. The write value should always be 0.

NOTE

m = 0, 1; n = 0 to 39

26.5.4 ADCBmADHALTR — AD Halt Register

ADCBmADHALTR is an 8-bit write-only register that halts the ADC. The register bits are always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	HALT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 26.9 ADCBmADHALTR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	HALT	Halt All scan groups and all AD timers are halted and initialized, and the ADC becomes the idle state. Writing 0: Scan groups and timers are not halted. Writing 1: Scan groups and timers are halted.

NOTE

m = 0, 1

26.5.5 ADCBmADCR1 — AD Control Register 1

ADCBmADCR1 is an 8-bit readable/writable register for ADC common control. ADCBmADCR1 is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	SUSMTD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 26.10 ADCBmADCR1 Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	SUSMTD[1:0]	Suspend Method These bits select the suspend method when a higher-priority scan group interrupts a lower-priority scan group. Synchronous suspend: If a request from a higher-priority SG is present while a lower-priority SG is being processed, processing for the lower-priority SG is suspended after the ongoing virtual channel processing is completed, and then processing for the higher-priority SG is executed. After processing for the higher-priority SG is completed, the suspended virtual channel processing for the lower-priority SG is resumed. Asynchronous suspend: If a request from a higher-priority SG is present while a lower-priority SG is being processed, the ongoing virtual channel processing is immediately suspended, and then processing for the higher-priority SG is executed. After processing for the higher-priority SG is completed, the suspended virtual channel processing for the lower-priority SG is resumed. 0_H: Synchronous suspend 1_H: Asynchronous suspend when a higher-priority SG interrupts SG0 Synchronous suspend when a higher-priority SG interrupts a lower-priority SG (except for SG0) 2_H: Asynchronous suspend 3_H: Setting prohibited For details, see **Figure 26.13, Example of Synchronous Suspend and Resume Operation** and **Figure 26.14, Example of Asynchronous Suspend and Resume Operation**.

CAUTION

To prevent malfunction, ADCBmADCR1 should be set while SGACT for all scan groups is 0 (before scan groups are started), ADSTARTE for all scan groups is 0, TRGMD[0] for scan groups 0, 1, and 2 is 0_H, and TRGMD[1:0] for scan groups 3 and 4 is 0_H.

NOTE

m = 0, 1

26.5.6 ADCBmMPXCURCR — MPX Current Control Register

ADCBmMPXCURCR is an 8-bit readable/writable register that controls the ADCBmMPXCURR format. ADCBmMPXCURR is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MSKCFMT[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 26.11 ADCBmMPXCURCR Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	MSKCFMT[3:0]	MSKC Format Specification These bits specify the MSKC[15:0] format of ADCBmMPXCURR. MSKCFMT[3] 0: MSKC[15:12] = 0000 1: MSKC[15:12] = 1111 MSKCFMT[2] 0: MSKC[11:8] = 0000 1: MSKC[11:8] = 1111 MSKCFMT[1] 0: MSKC[7:4] = 0000 1: MSKC[7:4] = 1111 MSKCFMT[0] 0: MSKC[3:0] = 0000 1: MSKC[3:0] = 1111

CAUTION

To prevent malfunction, ADCBmMPXCURCR should be set while SGACT for all scan groups is 0 (before scan groups are started), ADSTARTE for all scan groups is 0, TRGMD[0] for scan groups 0, 1, and 2 is 0_H, and TRGMD[1:0] for scan groups 3 and 4 is 0_H.

NOTE

m = 0, 1

26.5.7 ADCBmMPXCURR — MPX Current Register

ADCBmMPXCURR is a 32-bit read-only register that stores the MPX value for an external analog multiplexer. ADCBmMPXCURR is initialized to 0000 0000_H at a reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MSKC[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MPXCMD[7:0]								—	—	—	MPXCUR[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 26.12 ADCBmMPXCURR Register Contents

Bit Position	Bit Name	Function
31 to 16	MSKC[15:0]	Mask Control The format depends on the MSKCFMT[3:0] setting of ADCBmMPXCURCR. For details, see **Section 26.5.6, ADCBmMPXCURCR — MPX Current Control Register**.
15 to 8	MPXCMD[7:0]	SPI Communication Command Information A command information register to control an external analog multiplexer by using SPI communication. When a virtual channel in which CNVCLS[2:0] in ADCBmVCRn is set to 5_H or 6_H is started, the MPXCMD[7:0] value in ADCBmMPXCMDR is transferred to MPXCMD[7:0] in ADCBmMPXCURR.
7 to 5	—	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	MPXCUR[4:0]	Current MPX Value When a virtual channel for which CNVCLS[2:0] in ADCBmVCRn is set to 5_H or 6_H is started, GCTRL[4:0] in ADCBmVCRn is transferred to MPXCUR[4:0]. At this time, an interrupt request to the INTC or a DMA transfer request is generated. The DMAC transfers ADCBmMPXCURR to Pn or PSRn of the I/O port or to CSIHnTX0H of CSIH, enabling the MPX value to be sent to an external analog multiplexer. When Pn is used, transfer the lower 5 bits. When PSRn is used, transfer the MPX value as a 32-bit value. This enables you to rewrite only the necessary ports by using the format control in MSKC[15:0]. When transferring the value to CSIHnTX0H, transfer the lower 16 bits. For details, see **Section 26.7.5, Example of Operation of External Analog Multiplexer**.

NOTE

m = 0, 1; n = 0 to 39

26.5.8 ADCBmMPXOWR — MPX Optional Wait register

ADCBmMPXOWR is an 8-bit readable/writable register that specifies the wait time to be inserted for an external analog multiplexer. ADCBmMPXOWR is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MPXOW[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 26.13 ADCBmMPXOWR Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	MPXOW[3:0]	MPX Optional Wait These bits specify the wait time to be inserted before A/D conversion is started after a virtual channel for which CNVCLS[2:0] in ADCBmVCRn is 5_H or 6_H is started. 0_H: 0 µs 1_H: 1 µs 2_H: 2 µs 3_H: 3 µs 4_H: 4 µs 5_H: 5 µs 6_H: 6 µs 7_H: 7 µs 8_H: 8 µs 9_H: 9 µs A_H: 10 µs B_H to F_H: Setting prohibited For details, see **Section 26.7.5, Example of Operation of External Analog Multiplexer**.

CAUTION

To prevent malfunction, ADCBmMPXOWR should be set while SGACT for all scan groups is 0 (before scan groups are started), ADSTARTE for all scan groups is 0, TRGMD[0] for scan groups 0, 1, and 2 is 0_H, and TRGMD[1:0] for scan groups 3 and 4 is 0_H.

NOTE

m = 0, 1; n = 0 to 39

26.5.9 ADCBmMPXCMDR — MPX Command Information Register

ADCBmMPXCMDR is an 8-bit readable/writable register that stores SPI communication command information to be transferred to an external analog multiplexer. ADCBmMPXCMDR is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	MPXCMD[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 26.14 ADCBmMPXCMDR Register Contents

Bit Position	Bit Name	Function
7 to 0	MPXCMD[7:0]	SPI Communication Command Information These bits are a register that stores command information for controlling an external analog multiplexer by using the SPI communication. When a virtual channel for which CNVCLS[2:0] in ADCBmVCRn is set to 5_H or 6_H is started, MPXCMD[7:0] in ADCBmMPXCMDR is transferred to MPXCMD[7:0] in ADCBmMPXCURR and it can be read by ADCBmMPXCURR together with MPXCUR[4:0].

NOTE

m = 0, 1 : n = 0 to 39

26.5.10 ADCBmADCR2 — AD Control Register 2

ADCBmADCR2 is an 8-bit readable/writable register for ADC common control. ADCBmADCR2 is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	DFMT	—	—	—	ADDNT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R	R	R/W

Table 26.15 ADCBmADCR2 Register Contents

Bit Position	Bit Name	Function
7 to 5	—	Reserved These bits are always read as 0. The write value should always be 0.
4	DFMT	Data Format 0: Signed fixed-point format 1: Signed integer format This bit specifies the format of data to be transferred to ADCBmDRn, DFE, and ASF. For details of data format, see **Section 26.5.2, ADCBmDRn — Data Register n**.
3 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	ADDNT	Addition Count Select 0: Add twice 1: Add 4 times This register is valid only when CNVCLS[2:0] is 4_H or 6_H.

CAUTION

To prevent malfunction, perform ADCBmADCR2 settings when SGACT of all scan groups is 0 (before scan groups are started), ADSTARTE of all scan groups is 0, TRGMD[0] of scan groups 0, 1, and 2 is 0_H, and TRGMD[1:0] of scan groups 3 and 4 is 0_H.

NOTE

m = 0, 1 : n = 0 to 39

26.5.11 ADCBmDFASENTSGER — DFE/ASF Entry Scan Group Enable Register

ADCBmDFASENTSGER is a 16-bit readable/writable register that enables or disables scan groups to be entered to the DFE and ASF. ADCBmDFASENTSGER is initialized to 0000_H at a reset.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	DFENTSG4E	DFENTSG3E	DFENTSG2E	DFENTSG1E	DFENTSG0E	—	—	—	ASENTSG4E	ASENTSG3E	ASENTSG2E	ASENTSG1E	ASENTSG0E
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 26.16 ADCBmDFASENTSGER Register Contents

Bit Position	Bit Name	Function
15 to 13	—	Reserved These bits are always read as 0. The write value should always be 0.
12 to 8	DFENTSGxE	DFE Entry Scan Group Enable 0: Entry to DFE is disabled when starting SGx. 1: Entry to DFE is enabled when starting SGx. Entry is made in virtual channels for which DFENT in ADCBmVCRn is set to 1.
7 to 5	—	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	ASENTSGxE	ASF Entry Scan Group Enable 0: Entry to ASF is disabled when starting SGx. 1: Entry to ASF is enabled when starting SGx. Entry is made in virtual channels for which DFENT in ADCBmVCRn is set to 1. Use the ASENTSGxE bits by setting one of these bits to 1.

CAUTIONS

1. To prevent malfunction, ADCBmDFASENTSGER should be set while SGACT for all scan groups is 0 (before scan groups are started), ADSTARTE for all scan groups is 0, TRGMD[0] for scan groups 0, 1, and 2 is 0_H, and TRGMD[1:0] for scan groups 3 and 4 is 0_H.
2. Do not set DFENTSGxE or ASENTSGxE for the same scan group to 1. If it is enabled for the same scan group, entry is made to both DFE and ASF of virtual channels for which DFENT in ADCBmVCRn is set to 1 specified for the scan group.

NOTE

m = 0, 1; n = 0 to 39; x = 0 to 4

26.5.12 ADCBmADENDP — A/D Conversion Monitor Virtual Channel Pointer

ADCBmADENDP is an 8-bit readable/writable register that selects a virtual channel that outputs the A/D conversion timing to ADENDm. ADCBmADENDP is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	ENDP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 26.17 ADCBmADENDP Register Contents

Bit Position	Bit Name	Function
7, 6	—	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	ENDP[5:0]	A/D Conversion Monitor Virtual Channel Pointer When the virtual channel selected by ADCBmADENDP is started, a high level is output to ADENDm. When the virtual channel selected by ADCBmADENDP ends, a low level is output.

CAUTION

To prevent malfunction, ADCBmADENDP should be set while SGACT for all scan groups is 0 (before scan groups are started), ADSTARTE for all scan groups is 0, TRGMD[0] for scan groups 0, 1, and 2 is 0_H, and TRGMD[1:0] for scan groups 3 and 4 is 0_H.

NOTE

m = 0, 1

26.5.13 ADCBmSFTCR — Safety Control Register

ADCBmSFTCR is an 8-bit readable/writable register for safety control. ADCBmSFTCR is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	RDCLRE	ULEIE	OWEIE	PEIE	IDEIE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 26.18 ADCBmSFTCR Register Contents

Bit Position	Bit Name	Function
7 to 5	—	Reserved These bits are always read as 0. The write value should always be 0.
4	RDCLRE	Read and Clear Enable 0: ADCBmDRn and ADCBmDIRn are not cleared by reading ADCBmDRn or ADCBmDIRn and by reading ADCBmDRn via the IFC. 1: ADCBmDRn and ADCBmDIRn are cleared by reading ADCBmDRn or ADCBmDIRn and by reading ADCBmDRn via the IFC. **NOTE** WFLG in ADCBmDIRn is cleared by reading ADCBmDRn or ADCBmDIRn and by reading ADCBmDRn via the IFC regardless of the RDCLRE setting.
3	ULEIE	Upper-Limit/Lower-Limit Error Interrupt Enable 0: Disabled 1: Enabled
2	OWEIE	Overwrite Error Interrupt Enable 0: Disabled 1: Enabled
1	PEIE	Parity Error Interrupt Enable 0: Disabled 1: Enabled
0	IDEIE	ID Error Interrupt Enable 0: Disabled 1: Enabled

CAUTION

To prevent malfunction, ADCBmSFTCR should be set while SGACT for all scan groups is 0 (before scan groups are started), ADSTARTE for all scan groups is 0, TRGMD[0] for scan groups 0, 1, and 2 is 0_H, and TRGMD[1:0] for scan groups 3 and 4 is 0_H.

NOTE

m = 0, 1; n = 0 to 39

26.5.14 ADCBmTDCR — Pin-Level Self-Diagnosis Control Register

ADCBmTDCR is an 8-bit readable/writable register that controls the pin-level self-diagnosis. ADCBmTDCR is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	TDE	—	—	—	—	—	TDLV[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R/W	R/W

Table 26.19 ADCBmTDCR Register Contents

Bit Position	Bit Name	Function
7	TDE	Pin-Level Self-Diagnosis 0: Pin-level self-diagnosis is disabled. 1: Pin-level self-diagnosis is enabled. When TDE is set to 1, all analog pins are disconnected from the input buffer. When TDE is set to 0, all analog pins are connected to the input buffer. When TDE is set to 1, the voltage is fixed to the level specified by TDLV[1:0]. Performing A/D conversion in this state and checking the A/D converted value allows diagnosis of the path from an analog pin to the ADC.
6 to 2	—	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	TDLV[1:0]	Pin-Level Self-Diagnosis 0_H: Even numbers of physical channel groups are discharged to AVSS, and odd numbers of physical channel groups are charged to AVSS. 1_H: Even numbers of physical channel groups are charged to AVCC, and odd numbers of physical channel groups are discharged to AVSS. 2_H: Even numbers of physical channel groups are discharged to AVSS, and odd numbers of physical channel groups are charged to 1/2*AVCC. 3_H: Even numbers of physical channel groups are charged to 1/2*AVCC, and odd numbers of physical channel groups are discharged to AVSS.

CAUTION

To prevent malfunction, ADCBmTDCR should be set while SGACT for all scan groups is 0 (before scan groups are started), ADSTARTE for all scan groups is 0, TRGMD[0] for scan groups 0, 1, and 2 is 0_H, and TRGMD[1:0] for scan groups 3 and 4 is 0_H.

NOTE

m = 0, 1

26.5.15 ADCBmODCR — Wiring-break Detection Control Register

ADCBmODCR is an 8-bit readable/writable register that controls wiring-break detection.

ADCBmODCR is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	ODE	—	ODPW[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 26.20 ADCBmODCR Register Contents

Bit Position	Bit Name	Function
7	ODE	Wiring-break Detection Enable 0: Wiring-break is not detected. 1: Wiring-break is detected. When ODE is set to 1, wiring-break detection is enabled for all analog pins. After sampling for A/D conversion ends, analog pins for which A/D conversion is to be performed are discharged with the pulse width specified in ODPW[5:0].
6	—	Reserved This bit is always read as 0. The write value should always be 0.
5 to 0	ODPW[5:0]*1	Wiring-break Detection Pulse Width 04_H: 1 state (of internal clock) 05_H: 2 states (of internal clock) : 13_H: 16 states (of internal clock) 14_H: 17 states (of internal clock)

Note 1. When ODE = 1 (wiring-break detection is enabled), the setting of ODPW[5:0] must be greater than 03_H and less than 15_H.

CAUTIONS

1. To prevent malfunction, ADCBmODCR should be set while SGACT for all scan groups is 0 (before scan groups are started), ADSTARTE for all scan groups is 0, TRGMD[0] for scan groups 0, 1, and 2 is 0_H, and TRGMD[1:0] for scan groups 3 and 4 is 0_H.
2. Do not perform T&H (CNVCLS in ADCBmVCRn is 2_H) or A/D conversion of the hold value (CNVCLS in ADCBmVCRn is 1_H) with wiring-break detection enabled (ODE = 1).

NOTE

m = 0, 1; n = 0 to 39

26.5.16 ADCBmULLMTBR0 to 2 — Upper Limit/Lower Limit Table Register 0 to 2

ADCBmULLMTBR0 to ADCBmULLMTBR2 are 16/32-bit readable/writable registers that set the upper-limit and lower-limit values of an A/D converted value. Specify any of ADCBmULLMTBR0 to ADCBmULLMTBR2 by ULS[1:0] in ADCBmULLMSRx. These registers are initialized to 7FFE 0000_H by a reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ULMTB[15:0]															
Value after reset	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LLMTB[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 26.21 ADCBmULLMTBR Register Contents

Bit Position	Bit Name	Function
31 to 16	ULMTB[15:0]	Upper Limit Table These bits specify the upper-limit value of an A/D converted value. ULE (upper limit/lower limit error) is set when the following condition is met. ULMTB[15:0] < A/D converted value The ULMTB[15:0] format is the signed fixed-point format regardless of the format of ADCBmDRn. If the signed integer format is selected for the ADCBmDRn format, the ADCBmDRn format is replaced with the signed fixed-point format, and then the values are compared. Note that ULMTB[15] and ULMTB[0] are always fixed to 0.
15 to 0	LLMTB[15:0]	Lower Limit Table These bits specify the lower-limit value of an A/D converted value. ULE (upper limit/lower limit error) is set when the following condition is met. LLMTB[15:0] > A/D converted value The LLMTB[15:0] format is the signed fixed-point format regardless of the format of ADCBmDRn. If the signed integer format is selected for the ADCBmDRn format, the ADCBmDRn format is replaced with the signed fixed-point format, and then the values are compared. Note that LLMTB[15] and LLMTB[0] are always fixed to 0.

CAUTION

To prevent malfunction, ADCBmULLMTBR0 to ADCBmULLMTBR2 should be set while SGACT for all scan groups is 0 (before scan groups are started), ADSTARTE for all scan groups is 0, TRGMD[0] for scan groups 0, 1, and 2 is 0_H, and TRGMD[1:0] for scan groups 3 and 4 is 0_H.

NOTE

m = 0, 1; n = 0 to 39; x = 0 to 4

26.5.17 ADCBmECR — Error Clear Register

ADCBmECR is an 8-bit write-only register that controls error clear. The register bits are always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	ULEC	OWEC	PEC	IDEC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	W	W	W	W

Table 26.22 ADCBmECR Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved These bits are always read as 0. The write value should always be 0.
3	ULEC	Upper Limit/Lower Limit Error Clear Writing 0: Not cleared Writing 1: Cleared
2	OWEC	Overwrite Error Clear Writing 0: Not cleared Writing 1: Cleared
1	PEC	Parity Error Clear Writing 0: Not cleared Writing 1: Cleared
0	IDEC	ID Error Clear Writing 0: Not cleared Writing 1: Cleared

NOTE

m = 0, 1

26.5.18 ADCBmULER — Upper Limit/Lower Limit Error Register

ADCBmULER is an 8-bit read-only register that indicates upper limit/lower limit errors.

ADCBmULER is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	ULE	—	ULECAP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 26.23 ADCBmULER Register Contents

Bit Position	Bit Name	Function
7	ULE	Upper Limit/Lower Limit Error 0: No error 1: An error is present. Setting condition The A/D converted value exceeds the range of the specified upper limit/lower limit table. Clearing condition A value of 1 is written to ULEC.
6	—	Reserved This bit is always read as 0. The write value should always be 0.
5 to 0	ULECAP[5:0]	Upper Limit/Lower Limit Error Capture The virtual channel at the time when an upper limit/lower limit error occurred is captured. Capturing condition ULE = 0 and the A/D converted value exceeds the range of the specified upper limit/lower limit table. Clearing condition A value of 1 is written to ULEC.

CAUTION

ADCBmULER is updated when the A/D converted value is written to ADCBmDRn.

NOTE

m = 0, 1; n = 0 to 39

26.5.19 ADCBmOWER — Overwrite Error Register

ADCBmOWER is an 8-bit read-only register that indicates an overwrite error.

ADCBmOWER is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	OWE	—	OWECAP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 26.24 ADCBmOWER Register Contents

Bit Position	Bit Name	Function
7	OWE	Overwrite Error 0: No error 1: An error is present. Setting condition The A/D converted value is written to ADCBmDRn when WFLG = 1. Clearing condition A value of 1 is written to OWEC.
6	—	Reserved This bit is always read as 0. The write value should always be 0.
5 to 0	OWECAP[5:0]	Overwrite Error Capture The virtual channel at the time when an overwrite error occurred is captured. Capturing condition The A/D converted value is written to ADCBmDRn when OWE = 0 and WFLG = 1. Clearing condition A value of 1 is written to OWEC.

CAUTION

ADCBmOWER is updated when the A/D converted value is written to ADCBmDRn.

NOTE

m = 0, 1; n = 0 to 39

26.5.20 ADCBmPER — Parity Error Register

ADCBmPER is an 8-bit read-only register that indicates a parity error. ADCBmPER is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	PE	—	PECAP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 26.25 ADCBmPER Register Contents

Bit Position	Bit Name	Function
7	PE	Parity Error 0: No error 1: An error is present. Setting condition A parity error is detected. Clearing condition A value of 1 is written to PEC.
6	—	Reserved This bit is always read as 0. The write value should always be 0.
5 to 0	PECAP[5:0]	Parity Error Capture The virtual channel at the time when a parity error occurred is captured. Capturing condition A parity error is detected when PE = 0. Clearing condition A value of 1 is written to PEC.

CAUTION

ADCBmPER is updated when ADCBmDRn or ADCBmDIRn is read, but is not updated when ADCBmDRn is read via the IFC.

NOTE

m = 0, 1; n = 0 to 39

26.5.21 ADCBmIDER — ID Error Register

ADCBmIDER is an 8-bit read-only register that indicates an ID error. ADCBmIDER is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	IDE	—	IDECAP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 26.26 ADCBmIDER Register Contents

Bit Position	Bit Name	Function
7	IDE	ID Error 0: No error 1: An error is present. Setting condition The physical channel (ADC0: AN043 and ADC1: AN100 when external multiplexer is specified) specified in ADCBmVCRn does not match the physical channel actually converted. Clearing condition A value of 1 is written to IDEC.
6	—	Reserved This bit is always read as 0. The write value should always be 0.
5 to 0	IDECAP[5:0]	ID Error Capture The virtual channel at the time when an ID error occurred is captured. Capturing condition The physical channel (ADC0: AN043 and ADC1: AN100 when external multiplexer is specified) specified in ADCBmVCRn does not match the physical channel actually converted when IDE = 0. Clearing condition A value of 1 is written to IDEC.

CAUTION

ADCBmIDER is updated when the A/D converted value is written to ADCBmDRn.

NOTE

m = 0, 1; n = 0 to 39

26.6 Scan Group Specific Registers

This section describes registers provided for each scan group.

26.6.1 ADCBmSGSTCRx — Scan Group x Start Control Register

ADCBmSGSTCRx is an 8-bit write-only register that controls the start of scan group x. The register bits are always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SGST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 26.27 ADCBmSGSTCRx Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	SGST	Scan Group Start Condition for starting scan group x: A value of 1 is written to SGST when SGACT = 0

NOTE

m = 0,1; x = 0 to 4

26.6.2 ADCBmADTSTCRy — A/D Timer y Start Control Register

ADCBmADTSTCRy is an 8-bit write-only register that controls the start of A/D timer y. The register bits are always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADTST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 26.28 ADCBmADTSTCRy Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	ADTST	A/D Timer Start Condition for starting A/D timer y: A value of 1 is written to ADTST when ADTACT = 0

NOTE

m = 0, 1; y = 3, 4

26.6.3 ADCBmADTENDCRy — A/D Timer y End Control Register

ADCBmADTENDCRy is an 8-bit write-only register that controls the end of A/D timer y. The register bits are always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADTEND
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 26.29 ADCBmADTENDCRy Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	ADTEND	A/D Timer End Condition for finishing A/D timer y: A value of 1 is written to ADTEND when ADTACT = 1

NOTE

m = 0, 1; y = 3, 4

26.6.4 ADCBmSGCRx — Scan Group x Control Register

ADCBmSGCRx is an 8-bit readable/writable register that controls scan group x. ADCBmSGCRx is initialized to 00_H at a reset.

- When x = 0 to 2

Bit	7	6	5	4	3	2	1	0
	—	ADSTARTE	SCANMD	ADIE	—	—	—	TRGMD[0]
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R	R	R	R/W

Table 26.30 ADCBmSGCRx Register Contents (x = 0 to 2)

Bit Position	Bit Name	Function
7	—	Reserved This bit is always read as 0. The write value should always be 0.
6	ADSTARTE	Scan Group Synchronization Start Enable 0: ADSTART is disabled. 1: ADSTART is enabled.
5	SCANMD	Scan Mode 0: Multicycle scan mode 1: Continuous scan mode In multicycle scan mode, scans are repeated as many times as specified in ADCBmSGMCYCRx. In continuous scan mode, scans are repeated with no limit of times.
4	ADIE	Scan End Interrupt Enable 0: ADImx is not output at the end of scan for SGx. 1: ADImx is output at the end of scan for SGx. ADIE of ADCBmSGCRx is independent of ADIE of ADCBmVCRn. For details, see **Section 26.7.16, Scan End Interrupt Request**.
3 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	TRGMD[0]	Trigger Mode 0_H: Trigger input to SGx is disabled. 1_H: The SGx_TRG hardware trigger is selected for the trigger input to SGx. TRGMD is for enabling or disabling of hardware trigger. Software trigger is always enabled.

- When x = 3 or 4

Bit	7	6	5	4	3	2	1	0
	ADTSTARTE	ADSTARTE	SCANMD	ADIE	—	—	TRGMD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W

Table 26.31 ADCBmSGCRx Register Contents (x = 3 or 4)

Bit Position	Bit Name	Function
7	ADTSTARTE	A/D Timer Synchronization Start Enable 0: ADSTART is disabled. 1: ADSTART is enabled.
6	ADSTARTE	Scan Group Synchronization Start Enable 0: ADSTART is disabled. 1: ADSTART is enabled.
5	SCANMD	Scan Mode 0: Multicycle scan mode 1: Continuous scan mode In multicycle scan mode, scans are repeated as many times as specified in ADCBmSGMCYCRx. In continuous scan mode, scans are repeated with no limit of times.
4	ADIE	Scan End Interrupt Enable 0: ADImx is not output at the end of scan for SGx. 1: ADImx is output at the end of scan for SGx. ADIE of ADCBmSGCRx is independent of ADIE of ADCBmVCRn. For details, see **Section 26.7.16, Scan End Interrupt Request**.
3, 2	—	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	TRGMD[1:0]	Trigger Mode 0_H: Trigger input to SGx is disabled. Trigger input to A/D timer x is disabled. 1_H: SGx_TRG hardware trigger is selected for the trigger input to SGx. Trigger input to A/D timer x is disabled. 2_H: A/D timer trigger x is selected for the trigger input to SGx. Trigger input to A/D timer x is disabled. 3_H: A/D timer trigger x is selected for the trigger input to SGx. The SGx_TRG hardware trigger is selected for the trigger input to A/D timer x. TRGMD is for enabling or disabling of hardware trigger. Software trigger is always enabled.

CAUTIONS

1. To prevent malfunction, SCANMD and ADIE in ADCBmSGCRx should be set while SGACT for scan group x is 0 (before scan groups are started), ADSTARTE for scan group x is 0, and TRGMD for scan group x is 0_H.
2. If a trigger of a lower-priority scan group is input to a scan group for which continuous scan mode is set (SCANMD = 1_H), the trigger is not accepted. Therefore, it is assumed that continuous scan mode is set for scan group 0.

NOTE

m = 0, 1; n = 0 to 39; x = 0 to 4

26.6.5 ADCBmSGVCSPx — Scan Group x Start Virtual Channel Pointer

ADCBmSGVCSPx is an 8-bit readable/writable register that specifies the start pointer of a virtual channel. ADCBmSGVCSPx is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	VCSP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 26.32 ADCBmSGVCSPx Register Contents

Bit Position	Bit Name	Function
7, 6	—	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	VCSP[5:0]*1, *2	Start Virtual Channel Pointer These bits select the virtual channel from which the scan is to be started. When SGx is started, processing for the virtual channels from ADCBmSGVCSPx to ADCBmSGVCEPx is executed.

CAUTIONS

1. ADCBmSGVCSPx must be equal to or less than ADCBmSGVCEPx.
2. To prevent malfunction, ADCBmSGVCSPx should be set while SGACT for scan group x is 0 (before scan groups are started), ADSTARTE for scan group x is 0, and TRGMD for scan group x is 0_H.

NOTE

m = 0, 1; x = 0 to 4

26.6.6 ADCBmSGVCEPx — Scan Group x End Virtual Channel Pointer

ADCBmSGVCEPx is an 8-bit readable/writable register that specifies the end pointer of a virtual channel. ADCBmSGVCEPx is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	VCEP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 26.33 ADCBmSGVCEPx Register Contents

Bit Position	Bit Name	Function
7, 6	—	Reserved These bits are always read as 0. The write value should always be 0.
5 to 0	VCEP[5:0]*1, *2	End Virtual Channel Pointer These bits select the virtual channel at which the scan is to be ended. When SGx is started, processing for the virtual channels from ADCBmSGVCSPx to ADCBmSGVCEPx is executed.

CAUTIONS

1. ADCBmSGVCSPx must be equal to or smaller than ADCBmSGVCEPx.
2. To prevent malfunction, ADCBmSGVCEPx should be set while SGACT for scan group x is 0 (before scan groups are started), ADSTARTE for scan group x is 0, and TRGMD for scan group x is 0_H.

NOTE

m = 0, 1; x = 0 to 4

26.6.7 ADCBmSGMCYCRx — Scan Group x Multicycle Register

ADCBmSGMCYCRx is an 8-bit readable/writable register that specifies the number of scan times in multicycle scan mode. ADCBmSGMCYCRx is initialized to 00_H at a reset.

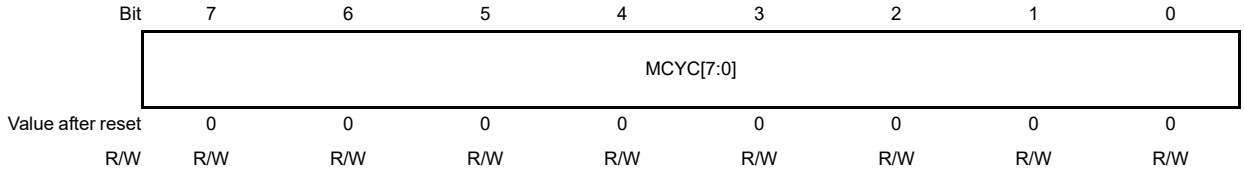


Table 26.34 ADCBmSGMCYCRx Register Contents

Bit Position	Bit Name	Function
7 to 0	MCYC[7:0]	Multicycle Specification These bits specify the number of scan times in multicycle scan mode. Number of scan times = MCYC[7:0] + 1 When SGx is started, scans are repeated for virtual channels from ADCBmSGVCSPx to ADCBmSGVCEPx as many times as specified in ADCBmSGMCYCRx.

CAUTION

To prevent malfunction, ADCBmSGMCYCRx should be set while SGACT for scan group x is 0 (before scan groups are started), ADSTARTE for scan group x is 0, and TRGMD for scan group x is 0_H.

NOTE

m = 0,1; x = 0 to 4

26.6.8 ADCBmSGSRx — Scan Group x Status Register

ADCBmSGSRx is an 8-bit read-only register that indicates the status of scan group x. ADCBmSGSRx is initialized to 00_H at a reset.

- When x = 0 to 2

Bit	7	6	5	4	3	2	1	0

Bit Position	Bit Name	Function
7 to 3	—	Reserved These bits are always read as 0. The write value should always be 0.
2	ADTACT	A/D Timer Status 0: A/D timer x is in idle state. 1: A/D timer x is running.
1	SGACT	Scan Group Status 0: There is no source in SGx. 1: There is a source in SGx.
0	—	Reserved This bit is always read as 0. The write value should always be 0.

NOTE

m= 0, 1; x = 0 to 4

26.6.9 ADCBmADTIPRy — A/D Timer Initial Phase Register y

ADCBmADTIPRy is a 32-bit readable/writable register that sets the initial phase of A/D timer y. ADCBmADTIPRy is initialized to 0000 0000_H at a reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	ADTIP[20:16]

Bit Position	Bit Name	Function
31 to 21	—	Reserved These bits are always read as 0. The write value should always be 0.
20 to 0	ADTIP[20:0]	A/D Timer Initial Phase These bits set the initial phase of A/D timer y. (1) After A/D timer y is started, ADCBmADTIPRy is loaded to A/D timer y and the timer counts down. (2) After A/D timer y becomes 0, A/D timer trigger y is output for one cycle, ADCBmADTPRRy is loaded to A/D timer y, and the timer counts down again. After that, (2) is repeated. For details, see **Section 26.7.8, Example of A/D Timer Operation**.

CAUTION

To prevent malfunction, ADCBmADTIPRy should be set while ADTACT for scan group y is 0 (before A/D timer is started), ADTSTARTE for scan group y is 0, and TRGMD[1:0] for scan group y is not 3_H.

NOTE

m = 0, 1; y = 3, 4

26.6.10 ADCBmADTPRRy — A/D Timer Cycle Register y

ADCBmADTPRRy is a 32-bit readable/writable register that sets the cycle of A/D timer y.
ADCBmADTPRRy is initialized to 001F FFFF$_H$ at a reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	ADTPR[20:16]

R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADTPR[15:0]															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 26.38 ADCBmADTPRRy Register Contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved These bits are always read as 0. The write value should always be 0.
20 to 0	ADTPR[20:0]	A/D Timer Cycle These bits set the cycle of A/D timer y. (1) After A/D timer y is started, ADCBmADTIPRy is loaded to A/D timer y and the timer counts down. (2) After A/D timer y becomes 0, A/D timer trigger y is output for one cycle, ADCBmADTPRRy is loaded to A/D timer y, and the timer counts down again. After that, (2) is repeated. For details, see **Section 26.7.8, Example of A/D Timer Operation**.

CAUTION

To prevent malfunction, ADTPPRy should be set while ADTACT for scan group y is 0 (before A/D timer is started), ADTSTARTE for scan group y is 0, and TRGMD[1:0] for scan group y is not 3$_H$.

NOTE

m = 0, 1; y = 3, 4

26.6.11 ADCBmULLMSRx — Scan Group x Upper Limit/Lower Limit Table Select Register

ADCBmULLMSRx is an 8-bit readable/writable register that controls scan group x. ADCBmSGCRx is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	ULS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 26.39 ADCBmULLMSRx Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	ULS[1:0]	Upper Limit/Lower Limit Table Select 0_H: Neither upper limit nor lower limit is checked. 1_H: Upper limit and lower limit are checked in ADCBmULLMTBR0. 2_H: Upper limit and lower limit are checked in ADCBmULLMTBR1. 3_H: Upper limit and lower limit are checked in ADCBmULLMTBR2. Upper limit and lower limit are checked by using the upper limit/lower limit table selected by ULS[1:0] when storing the A/D converted value in ADCBmDRn.

CAUTION

To prevent malfunction, ADCBmULLMSRx should be set while SGACT for scan group x is 0 (before scan groups are started), ADSTARTE for scan group x is 0, and TRGMD for scan group x is 0_H.

NOTE

m = 0, 1: n = 0 to 39; x = 0 to 4

26.7 Operation

26.7.1 Setting Procedure

26.7.1.1 Initial Settings

A/D conversion of the ADC starts by setting the registers shown in **Figure 26.3**. For trigger input, see **Section 26.7.1.2, Trigger Input Flow**.

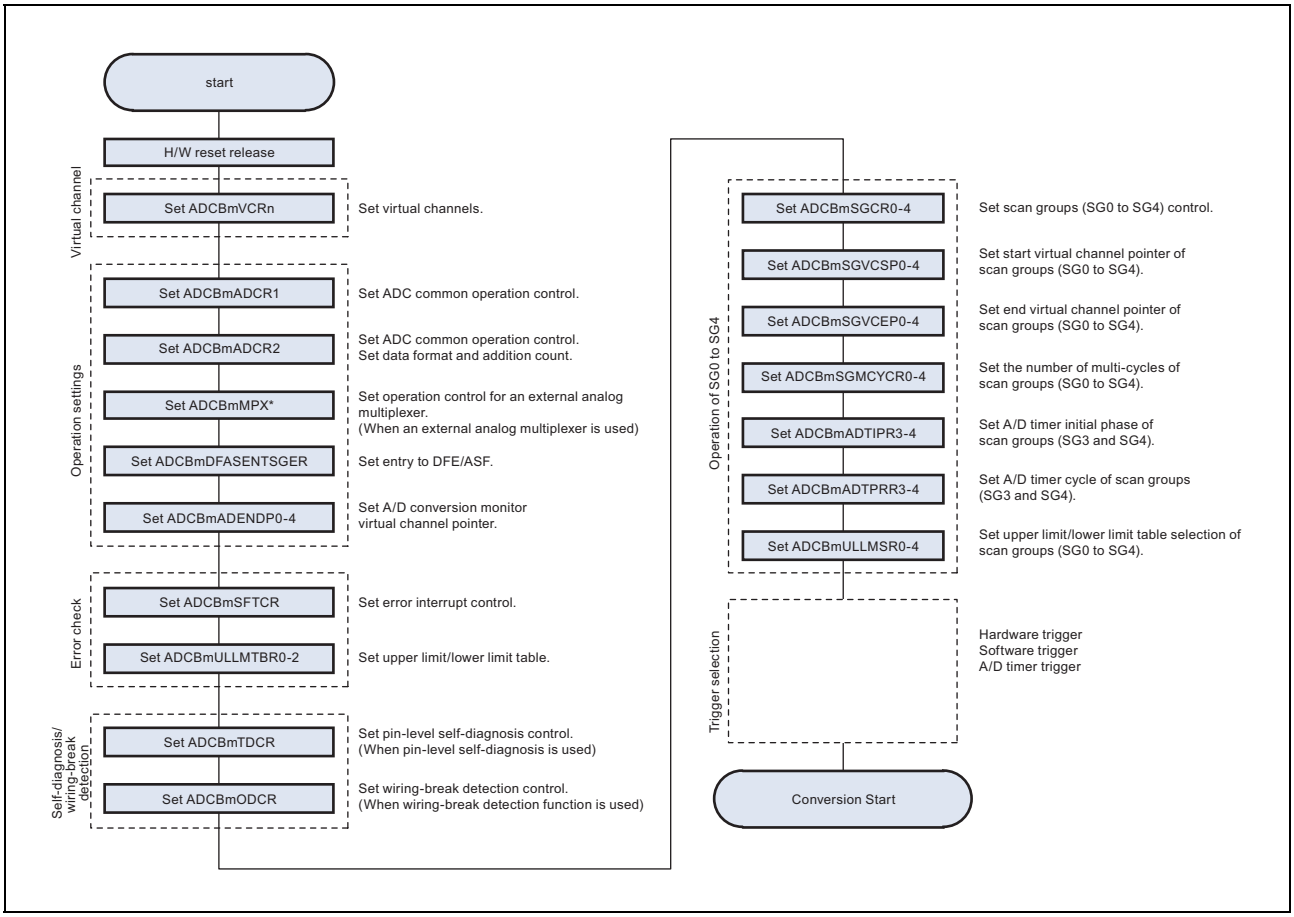

Figure 26.3 Initial Settings

NOTE

m = 0, 1 : n = 0 to 39

26.7.1.2 Trigger Input Flow

A/D conversion start triggers of the ADC include hardware triggers, software triggers, and A/D timer triggers. Scan group x (x = 0 to 4) supports the software trigger specified by ADSTART and SGST (SG0 to SG4), the hardware trigger of SGx_TRG (x = 0 to 4), and the A/D timer trigger (SG3 and SG4).

A/D conversion starts according to the trigger input flows shown in **Figure 26.4** and **Figure 26.5**. For the trigger configuration of SGx_TRG (x = 0 to 4), see **26.7.11, Selection of Trigger Input for a Scan Group**. For the initial settings flow shown in these figures, see **Section 26.7.1.1, Initial Settings**.

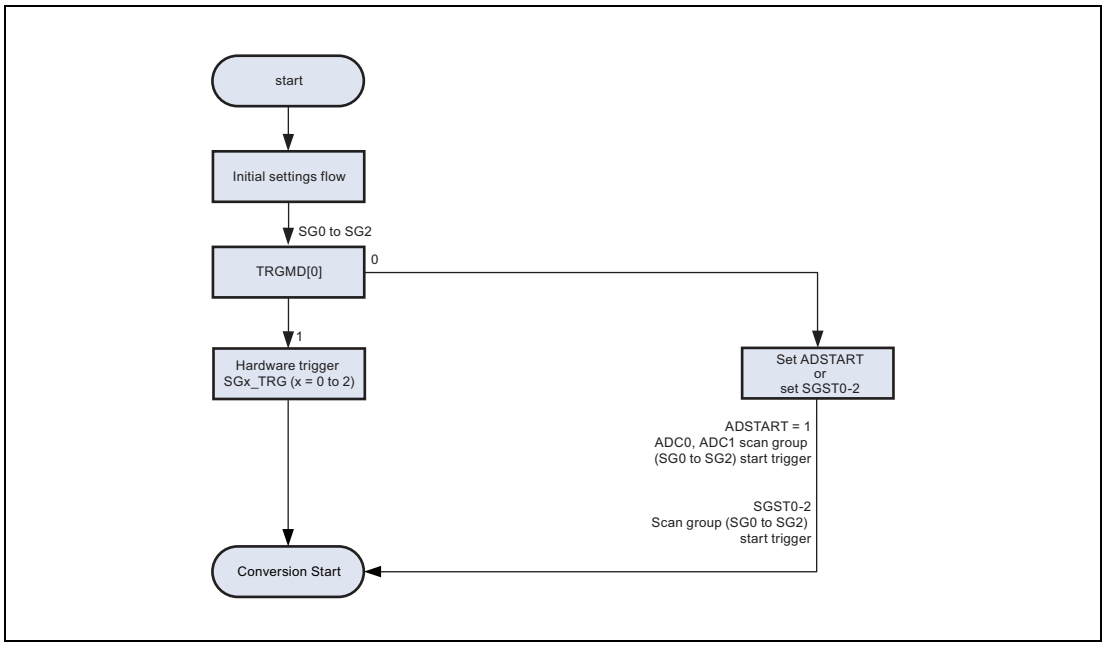

Figure 26.4 Trigger Input Flow (SG0 to SG2)

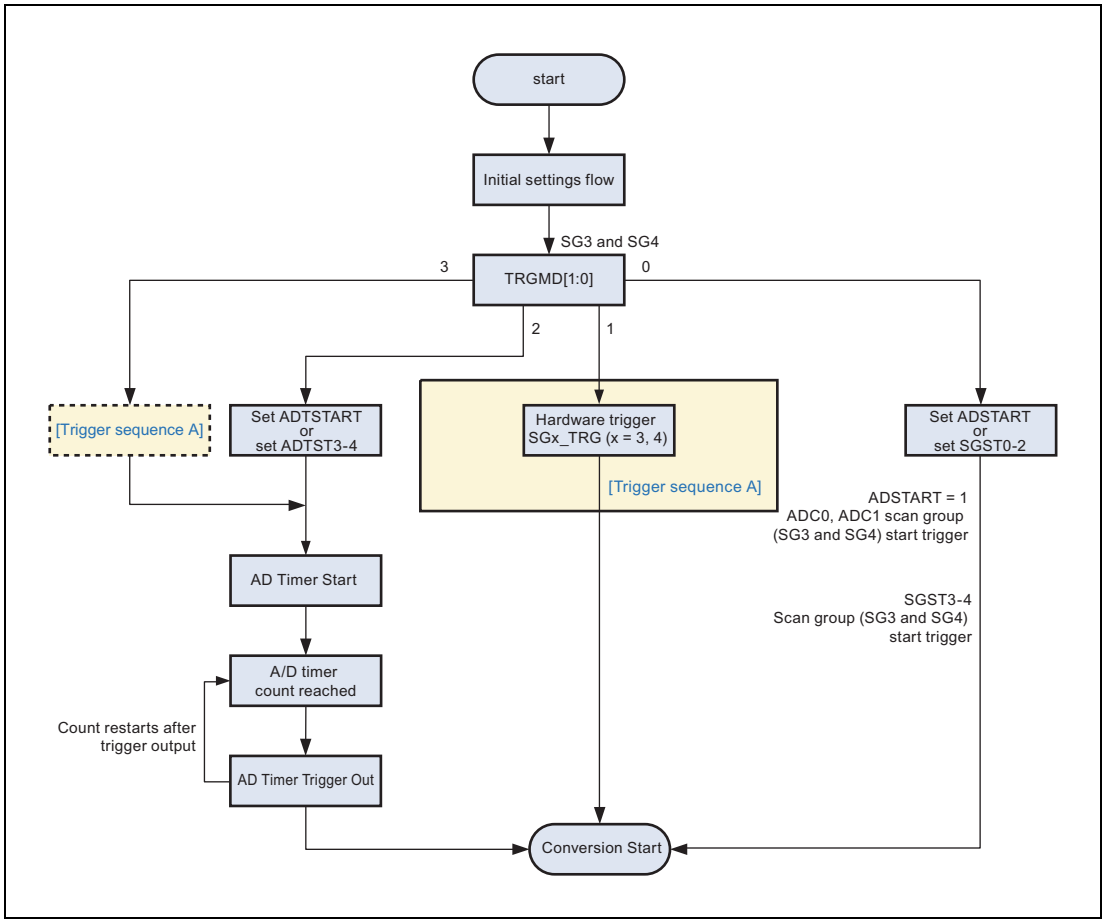

Figure 26.5 Trigger Input Flow (SG3 and SG4)

26.7.1.3 Terminating Procedure

The ADC is forcibly terminated according to the processing flow shown in **Figure 26.6**.

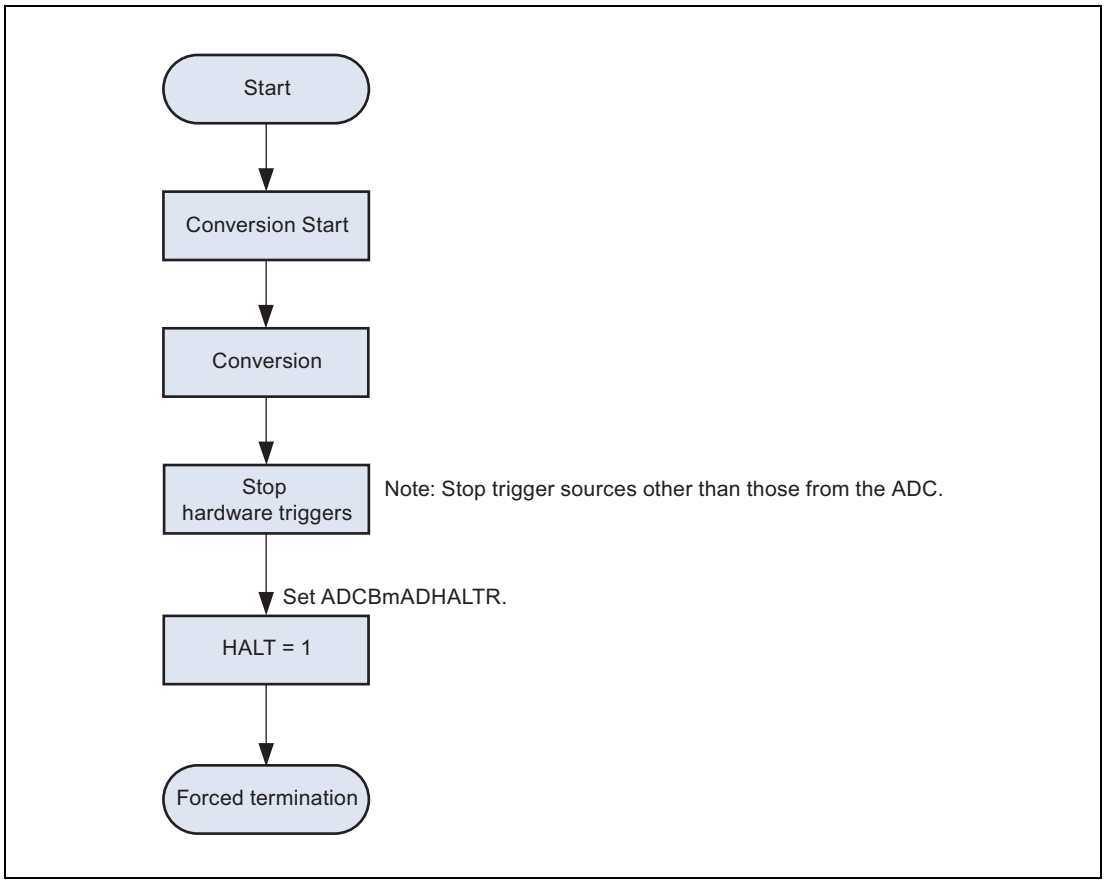

Figure 26.6 Terminating Procedure

NOTE

m = 0, 1

26.7.2 Examples of Normal A/D Conversion Operation

26.7.2.1 Multicycle Scan Mode

The following figure shows an example of operation when converting four virtual channels by 2-cycle scan for scan group 0 in multicycle scan mode by using normal A/D conversion mode (CNVCLS[2:0] = 0_H).

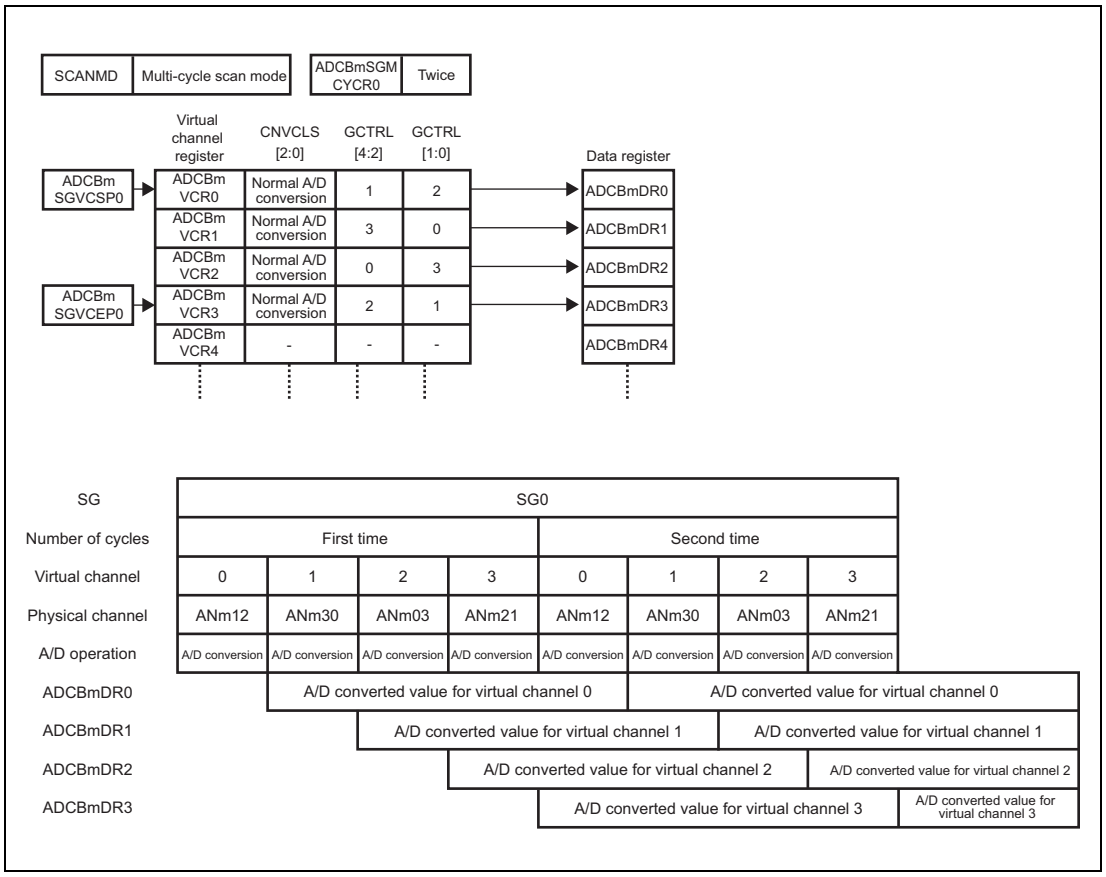

Figure 26.7 Example of Operation in Multicycle Scan Mode

NOTE

m = 0, 1

26.7.2.2 Continuous Scan Mode

Figure 26.8 shows an example of operation when converting four virtual channels for scan group 0 in continuous scan mode by using normal A/D conversion mode (CNVCLS[2:0] = 0_H).

In this mode, if a trigger of a lower-priority scan group is input to a scan group for which continuous scan mode is set (SCANMD = 1_H), the trigger is not accepted. Therefore, it is assumed that continuous scan mode is set for scan group 0.

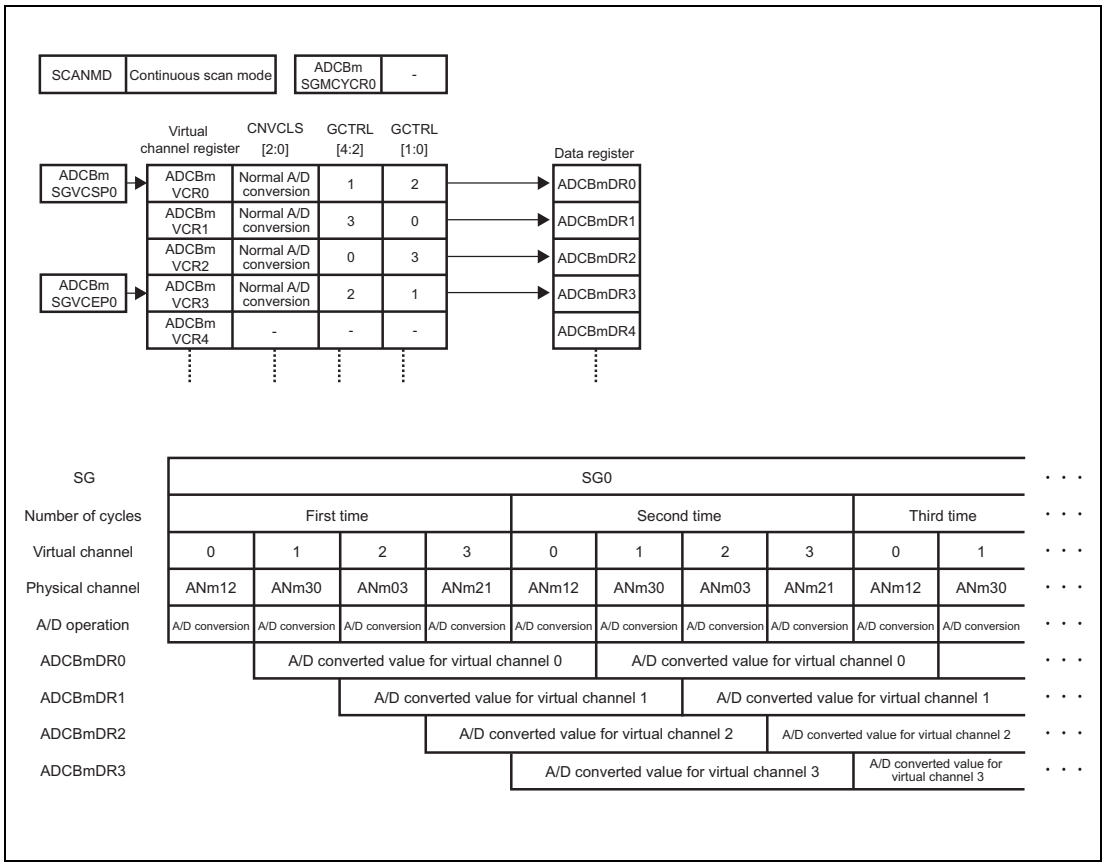

Figure 26.8 Example of Operation in Continuous Scan Mode

NOTE

m = 0, 1

26.7.3 Example of Simultaneous Track-and-Hold Operation

26.7.3.1 Simultaneous Track-and-Hold Operation (Physical Channel Group Selected)

Figure 26.9 shows an example of simultaneous track-and-hold operation when execution of selected T&H (CNVCLS[2:0] = 2_H with physical channel group selected), A/D conversion of the hold value (CNVCLS[2:0] = 1_H), and self-diagnosis (CNVCLS[2:0] = 3_H) are performed.

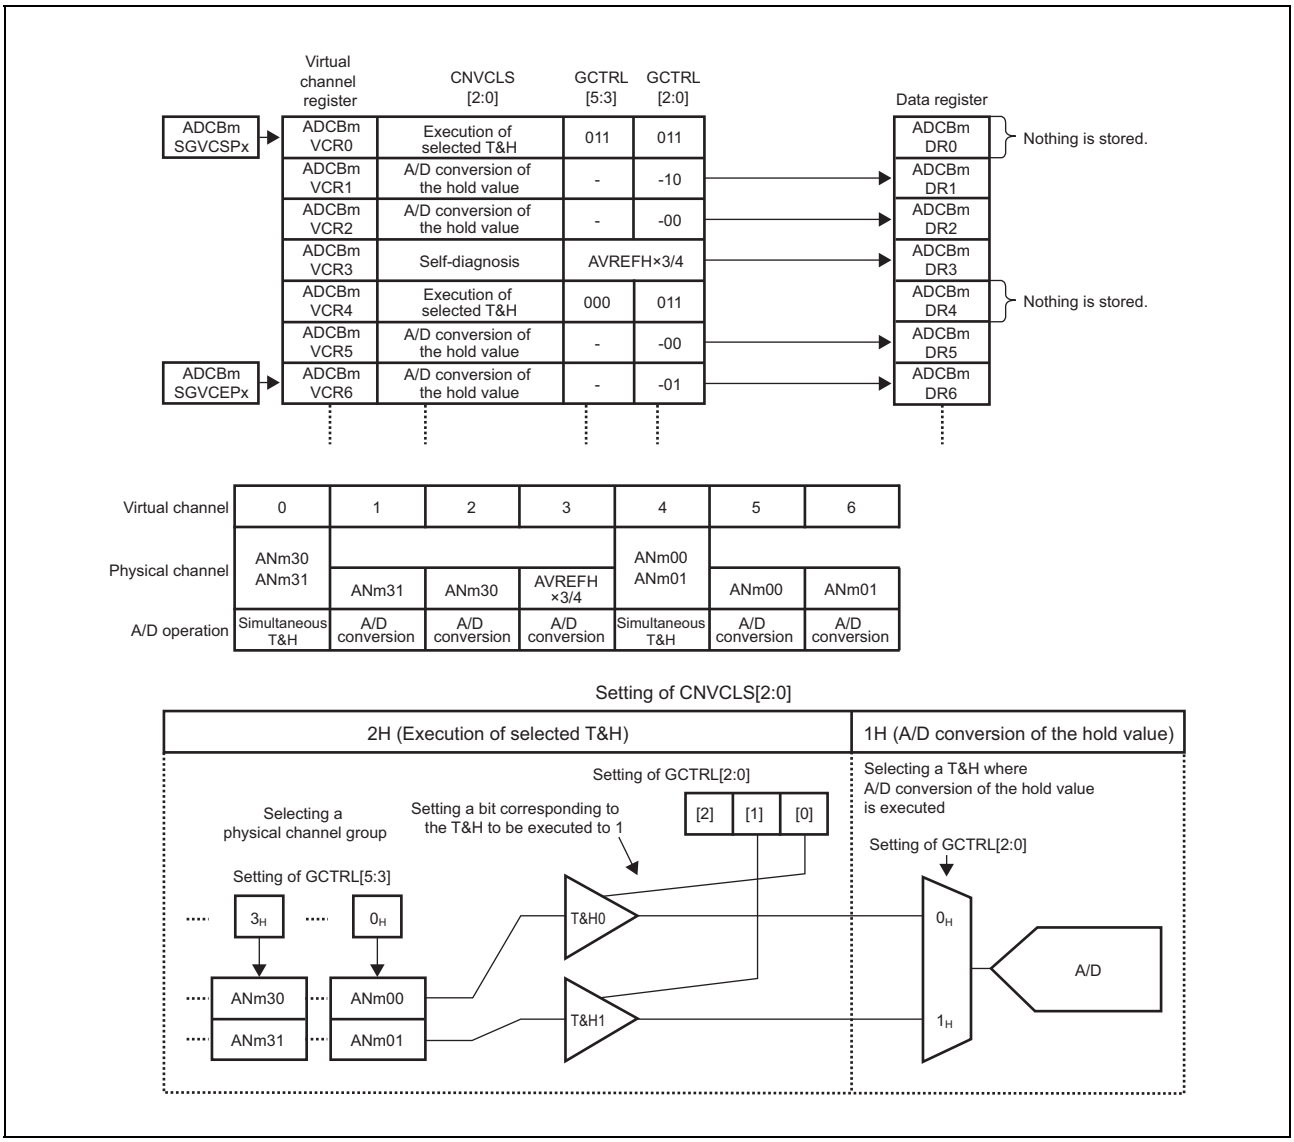

Figure 26.9 Example of Simultaneous Track-and-Hold Operation (Physical Channel Group Selected)

NOTES

m = 0; x = 0 to 4

26.7.4 Example of Normal A/D Conversion Operation in Addition Mode

Figure 26.10 shows an example of operation when converting four virtual channels for scan group 0 by using normal A/D conversion (CLVCLS[2:0] = 4_H) in addition mode.

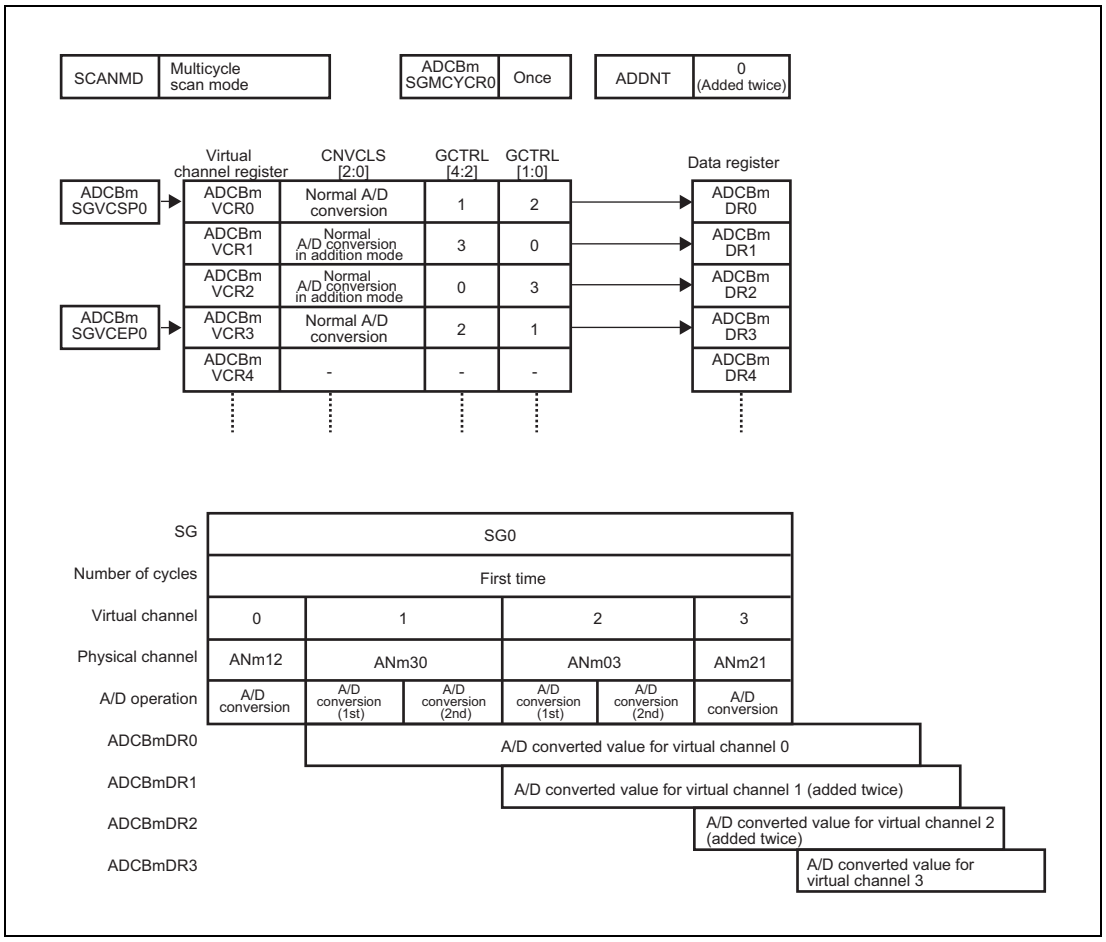

Figure 26.10 Example of Normal A/D Conversion Operation in Addition Mode

NOTE

m = 0, 1

26.7.5 Example of Operation of External Analog Multiplexer

The following shows examples of operation of an external analog multiplexer using normal A/D conversion with the MPX mode (CNVCLS[2:0] = 5_H) or normal A/D conversion in addition mode with the MPX mode (CNVCLS[2:0] = 6_H).

26.7.5.1 Example of Using an External Analog Multiplexer (Port Output)

Figure 26.11 shows an example of port output using an external analog multiplexer.

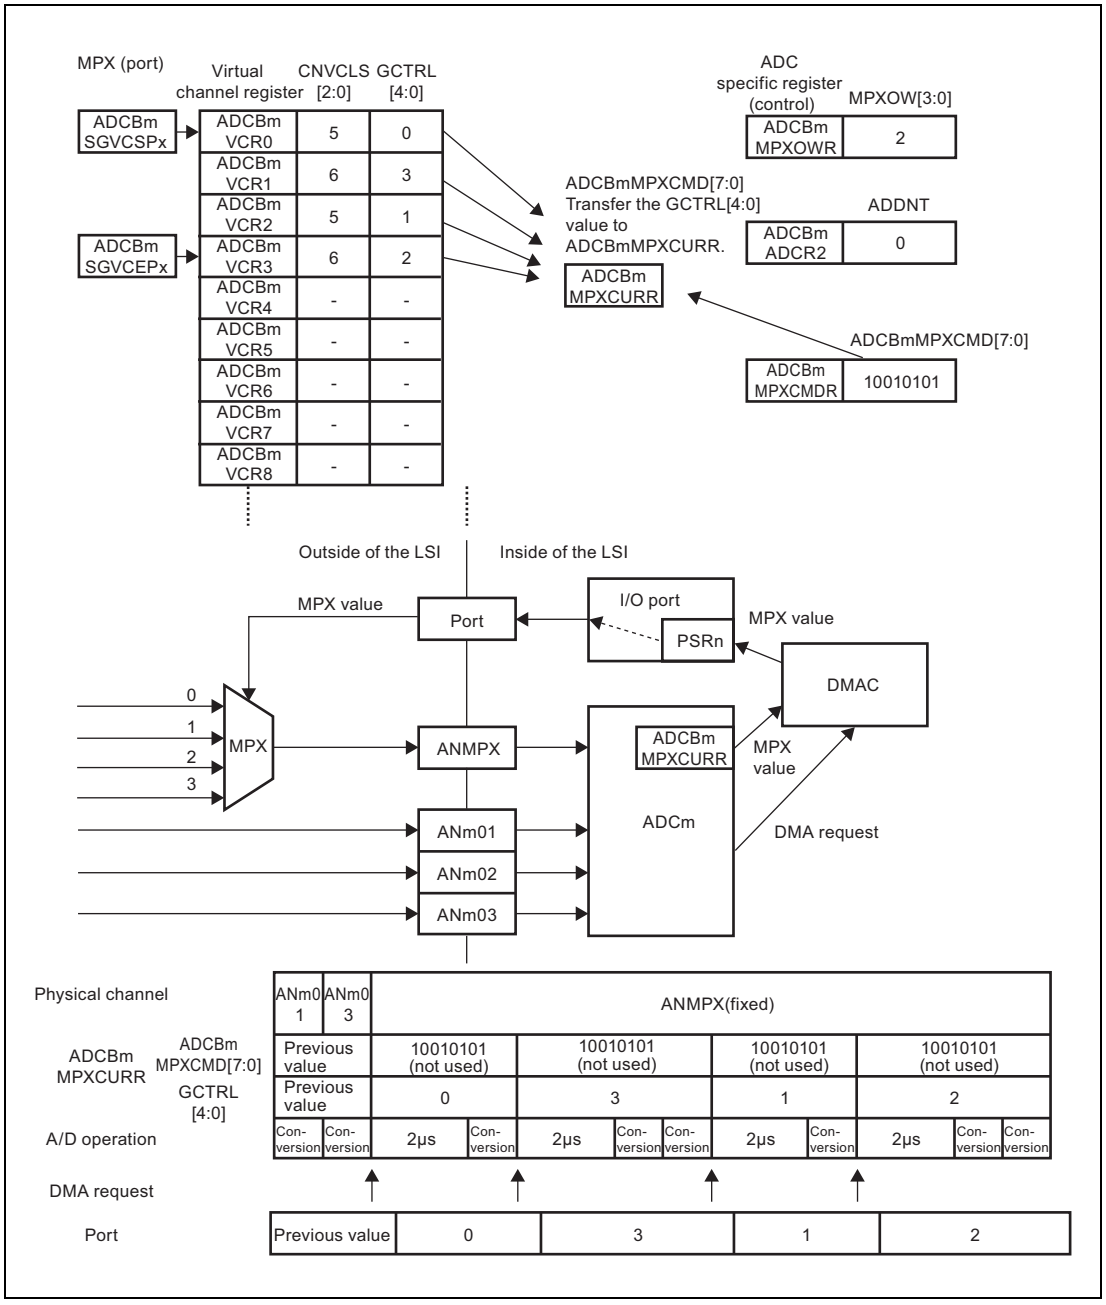

Figure 26.11 Example of Using an External Analog Multiplexer (Port Output)

NOTE

m = 0: ANMPX = AN043; m = 1: ANMPX = AN100; x = 0 to 4

26.7.5.2 Example of Using an External Analog Multiplexer (SPI Output)

Figure 26.12 shows an example of SPI output using an external analog multiplexer.

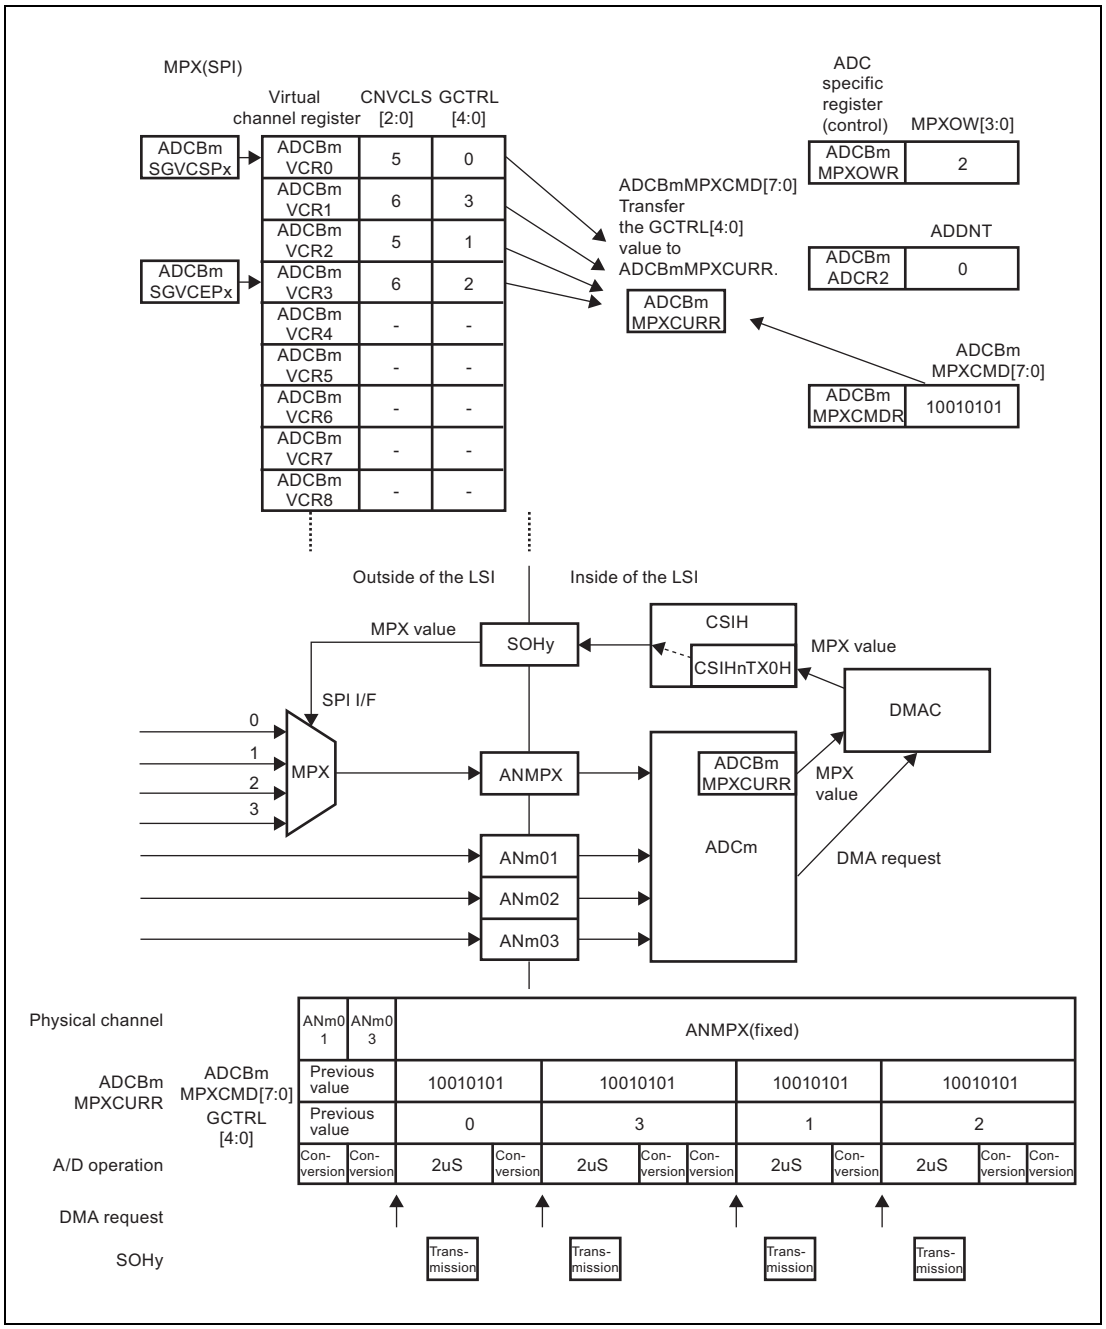

Figure 26.12 Example of Using an External Analog Multiplexer (SPI Output)

NOTE

m = 0: ANMPX = AN043; m = 1: ANMPX = AN100; x = 0 to 4

26.7.6 Example of Synchronous Suspend and Resume Operation

Figure 26.13 shows an example of synchronous suspend and resume operation when a higher-priority SG interrupts a lower-priority SG.

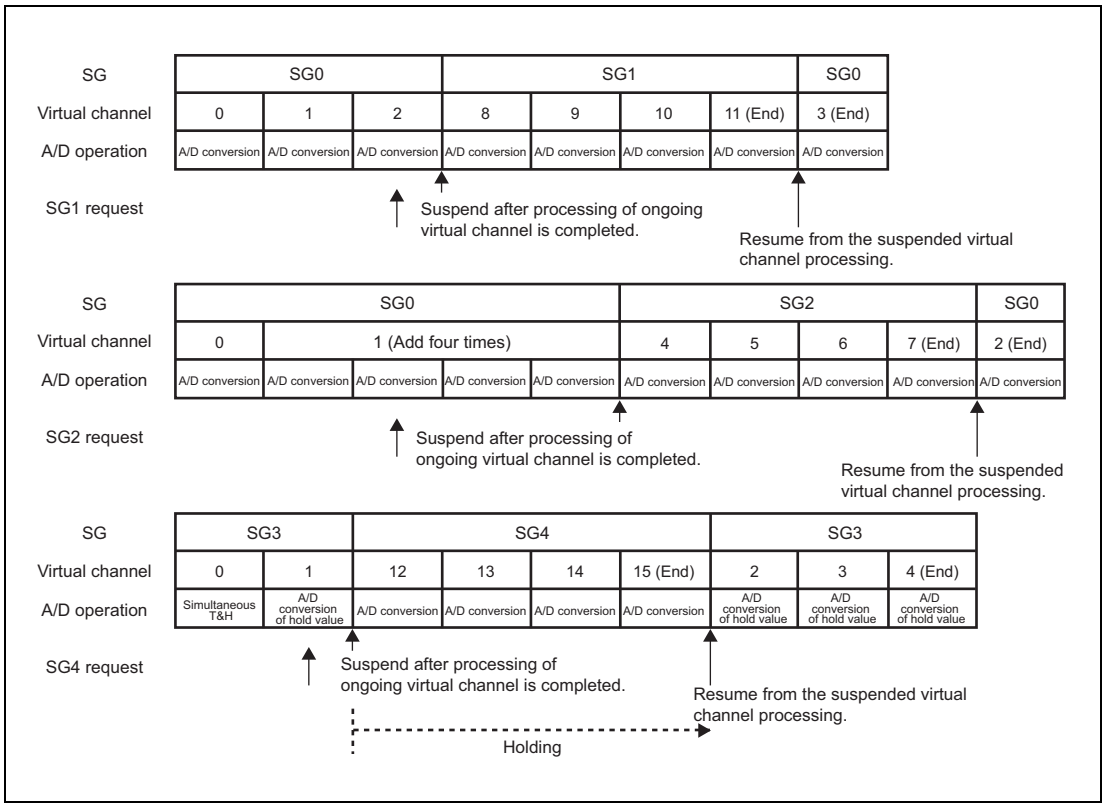

Figure 26.13 Example of Synchronous Suspend and Resume Operation

CAUTION

Priority of scan groups:

Low High

SG0 < SG1 < SG2 < SG3 < SG4

26.7.7 Example of Asynchronous Suspend and Resume Operation

Figure 26.14 shows an example of asynchronous suspend and resume operation when a higher-priority SG interrupts a lower-priority SG.

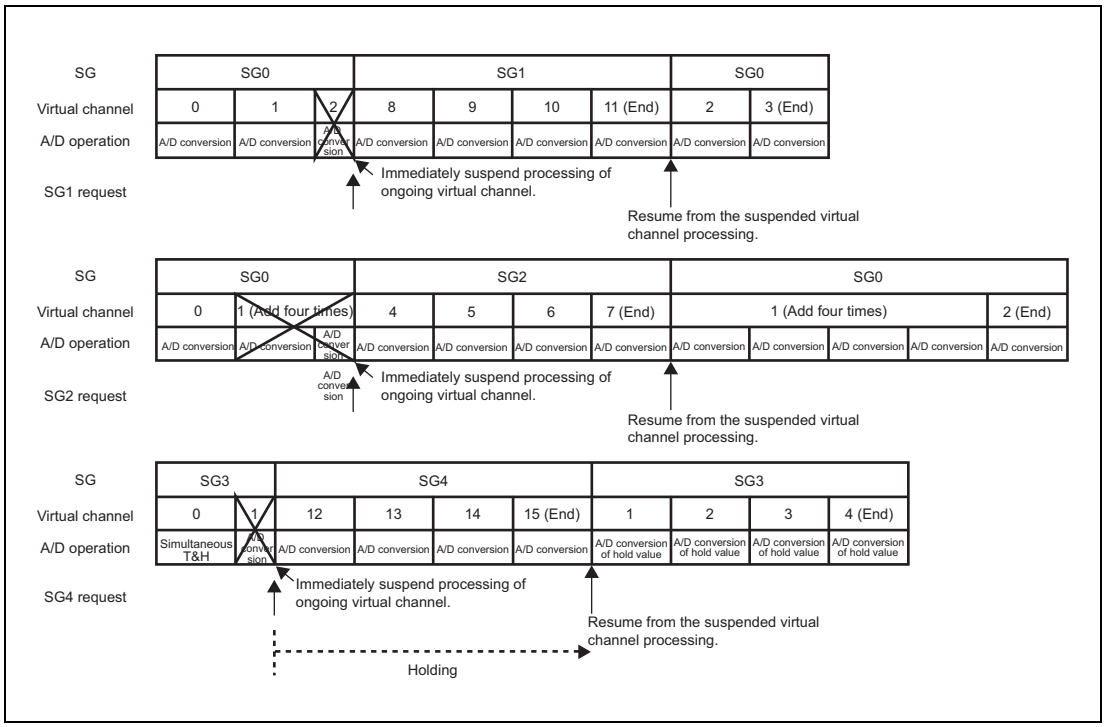

Figure 26.14 Example of Asynchronous Suspend and Resume Operation

CAUTION

Priority of scan groups:

Low High

SG0 < SG1 < SG2 < SG3 < SG4

26.7.8 Example of A/D Timer Operation

Figure 26.15 shows an example of A/D timer operation.

The A/D timer counts in synchronization of the 40-MHz clock.

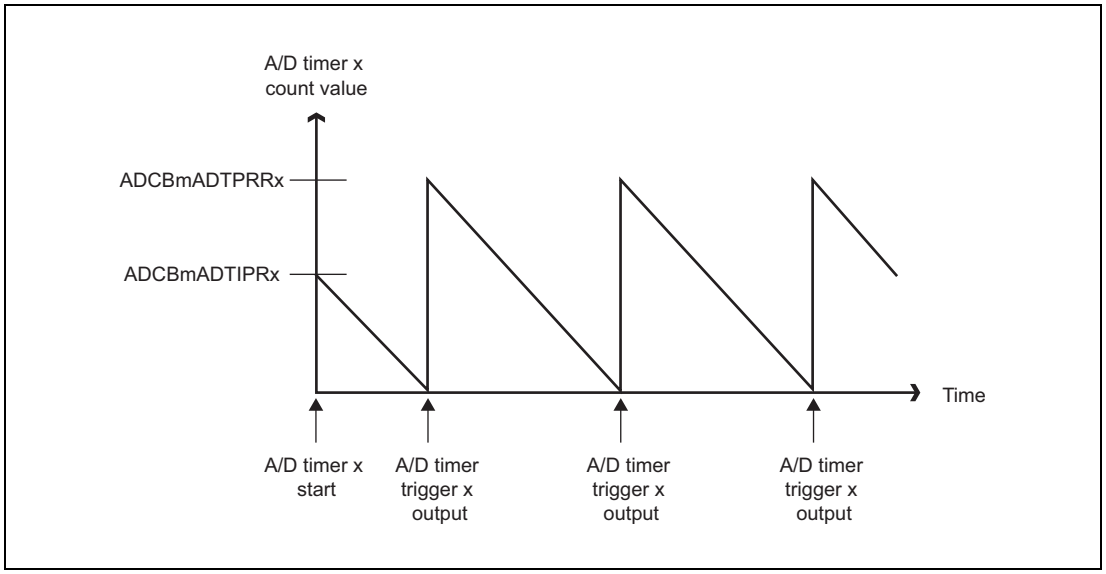

Figure 26.15 Example of A/D Timer Operation

NOTE

m = 0, 1; x = 3, 4

26.7.9 Self-Diagnostic Functions

The ADC is equipped with the following three self-diagnostic functions.

- Pin-level self-diagnosis
- A/D conversion circuit self-diagnosis
- Wiring-break detection self-diagnosis

26.7.9.1 Pin-Level Self-Diagnosis

The pin-level self-diagnosis performs A/D conversion that is set to a different voltage for even-number physical channel groups and odd-number physical channel groups to check an abnormal path from the ANI.

The different voltage setting is made in ADCBmTDCR and can be detected by combination of AVSS, AVCC, and 1/2 × AVCC.

Features and settings of the pin-level self-diagnosis of the ADC are described below.

[Features]

1. Users can select desired physical channels to be tested.
2. AVSS, AVCC, or 1/2AVCC is selectable as a self-diagnosis level.
3. Performing A/D conversion for SG0 to SG4 makes the pin-level self-diagnosis available.

[Settings]

1. Make settings according to the initial settings (**Figure 26.3, Initial Settings**).
2. Set CNVCLS[2:0] in the virtual channel register ADCBmVCRn to 0_H and set GCTRL[4:0] to select desired channels.
3. Set TDE in the pin-level self-diagnosis control register to 1_H and set TDLV[1:0] to specify the desired level of pin-level self-diagnosis.
4. Make other settings required for A/D conversion according to the initial settings (**Figure 26.3, Initial Settings**).
5. Assert SG0 to SG4 trigger signals to perform A/D conversion.

26.7.9.2 A/D Converter Self-Diagnosis

The A/D converter self-diagnosis is used to verify that A/D conversion operates correctly.

The voltage value setting is made in GCTRL[4:0] when CNVCLS[2:0] = 3_H, and can be converted for AVREFH × 1, AVREFH × 3/4, AVREFH × 1/2, AVREFH × 1/4, and AVREFH × 0.

Features and settings of the A/D conversion circuit self-diagnosis are described below.

[Features]

1. AVREFH × 1, AVREFH × 3/4, AVREFH × 1/2, AVREFH × 1/4, or AVREFH × 0 is selectable as a self-diagnosis voltage level.
2. Performing A/D conversion for SG0 to SG4 makes the A/D converter self-diagnosis available.

[Settings]

1. Make settings according to the initial settings (**Figure 26.3, Initial Settings**).
2. Set CNVCLS[2:0] in the virtual channel register ADCBmVCRn to 3_H and set GCTRL[5:0] to specify the desired self-diagnosis voltage level.
3. Make other settings required for A/D conversion according to the initial settings (**Figure 26.3, Initial Settings**).
4. Assert SG0 to SG4 trigger signals to perform A/D conversion.

NOTE

m = 0, 1; n = 0 to 39

Applying A/D converter self-diagnosis to a pin which has handled A/D conversion before A/D converter self-diagnosis while an injection current is flowing may affect the accuracy of the result of conversion. Accordingly, select pins through which a current will not be being injected as targets for A/D converter self-diagnosis.

Example settings are as follows.

CAUTION

Applying a voltage above the power supply voltage or below the ground voltage to a pin will lead to an injection current flowing.

(1) If A/D conversion and A/D converter self-diagnosis proceed in the same SG, select pins through which a current will not be being injected before A/D converter self-diagnosis.

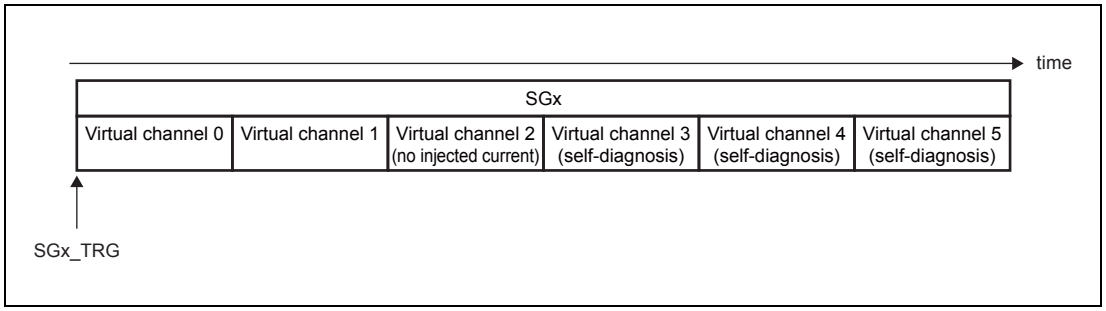

Figure 26.16 Example Setting when A/D Conversion and A/D Converter Diagnosis Proceed in the Same SG

(2) If a scan group has higher priority than a scan group to which A/D converter self-diagnosis is to be applied, the self-diagnosis may be suspended to allow A/D conversion by the higher-priority SG to proceed, and then resumed. If this is the case, select pins*1 through which current will not be being injected at the end of conversion by the high-priority SG.

Note 1. If you cannot determine which pins will not have current being injected, proceed with A/D conversion on an unused pin as an alternative.

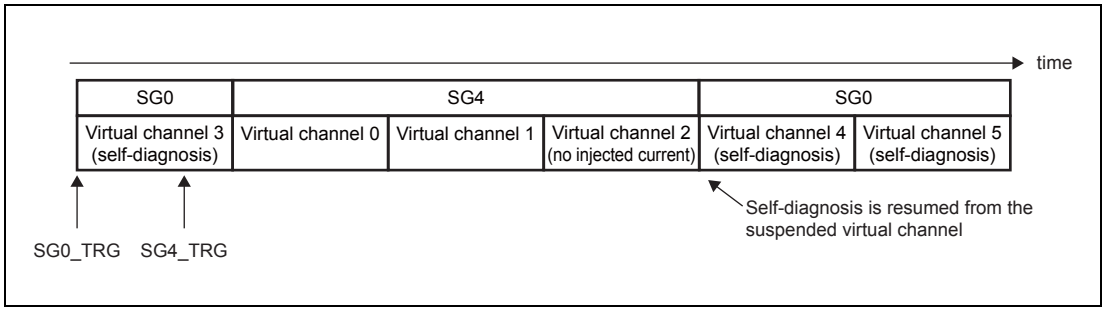

Figure 26.17 Example Setting when a Scan Group has Higher Priority than a Scan Group to which A/D Converter Self-Diagnosis is to be Applied

26.7.9.3 Wiring-Break Detection Self-Diagnosis

The wiring-break detection self-diagnosis detects wiring-break of the ANI. If a wiring-break is present, the conversion result attenuates to approximately 0 V, and an abnormal value is detected in the conversion result. This can be determined as detection of wiring-break.

[Feature]

1. Users can select desired physical channels for which wiring-break is to be detected.

[Settings]

1. Make settings according to the initial settings (**Figure 26.3, Initial Settings**).
2. Set CNVCLS[2:0] in the virtual channel register ADCBmVCRn to 0_H and set GCTRL[5:0] to select desired channels.
3. Set ODE in the wiring-break detection control register to 1_H and set ODPW[5:0] to specify the desired wiring-break detection pulse width.
4. Assert SG0 to SG4 trigger signals to perform A/D conversion.

NOTE

m = 0, 1; n = 0 to 39

26.7.10 Sampling of an Analog Input and Processing Time for a Scan Group

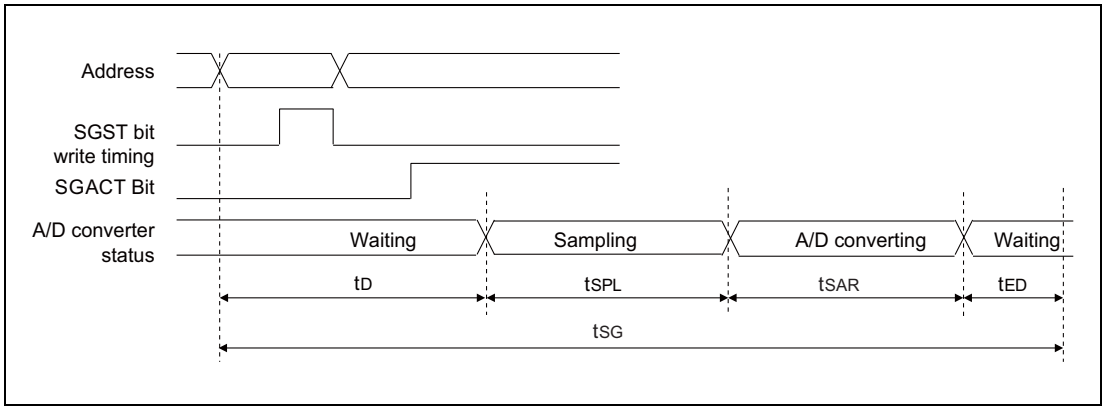

Figure 26.18 Timing Chart of Normal A/D Conversion Operation (Single Conversion)

The track-and-hold circuit is equipped subsequent to the analog input. The ADC has an internal sample-and-hold circuit. After the SGST bit in ADCBmSGCRx is set to 1, the ADC performs sampling after the scan group start delay time (tD) has passed, and then starts successive approximation conversion processing.

Figure 26.18, Timing Chart of Normal A/D Conversion Operation (Single Conversion) shows the operation timing in one-cycle scan for a single virtual channel. The processing time for a scan group (tSG) includes the scan group start delay time (tD), the sampling time (tSPL), the successive approximation conversion processing time (tSAR), and the scan group end delay time (tED). **Table 26.40, Processing Time for a Scan Group** lists the processing time for a scan group.

The processing time for a scan group (tSG) can be obtained from the following formula, where the number of virtual channels is i and the number of multicycles is j in multicycle scan mode:

$$tSG = tD + (tSPL + tSAR) \times i \times j + tED$$

The processing time for the first cycle of scan in continuous scan mode is as follows:

$$tD + (tSPL + tSAR) \times i$$

The processing time for the second (or subsequent) cycle of scan in continuous scan mode is as follows:

$$(tSPL + tSAR) \times i$$

Table 26.40 Processing Time for a Scan Group

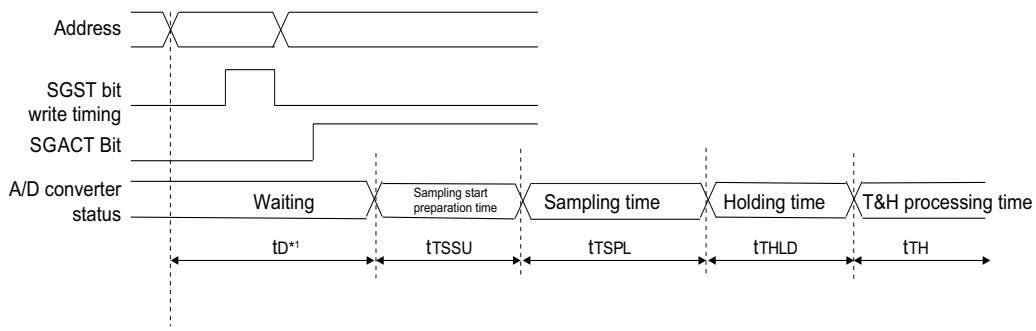
Item	Symbol	Period	Unit
Scan group start delay time	tD	(2 to 4) × Pϕ + 5 × Iϕ	Pϕ (P-Bus clock) Iϕ (Internal clock)
Sampling time	tSPL	18 × Iϕ	Iϕ (Internal clock)
Successive approximation conversion processing time	tSAR	22 × Iϕ	Iϕ (Internal clock)
Scan group end delay time	tED	(2 to 4) × Iϕ + 3 × Pϕ	Pϕ (P-Bus clock) Iϕ (Internal clock)
Scan group processing time	tSG	47 × Iϕ + 5 × Pϕ to 49 × Iϕ + 7 × Pϕ	Pϕ (P-Bus clock) Iϕ (Internal clock)

NOTE

m = 0, 1; x = 0 to 4

"Pϕ" and "Iϕ" in the table respectively represent the low-speed peripheral clock (CLK_LSB) and the non-modulated low-speed peripheral clock (CLKC_LSB).

26.7.10.1 Processing Time for Execution of Selected T&H and A/D Conversion of Hold Value



Note 1. For tD, see **Figure 26.18**.

Figure 26.19 Timing Chart for Operation of Execution of Selected T&H and A/D Conversion of Hold Value

The track-and-hold circuit is equipped subsequent to the analog input. **Table 26.41** shows the specified time period from sampling start to transition to the hold state (tTSPL) and the specified time period from transition to the hold state to A/D conversion start (tTHLD), and also shows the T&H processing time (tTH) when A/D conversion of the hold value is performed in a virtual channel.

Table 26.41 Track-and-Hold Processing Time

Item	Symbol	Period	Unit
Sampling start preparation time	tTSSSU	3	Iϕ (internal clock)
Sampling time	tTSPL	27	Iϕ (internal clock)
Hold time	tTHLD	10	Iϕ (internal clock)
T&H processing time	tTH	40	Iϕ (internal clock)

26.7.11 Selection of Trigger Input for a Scan Group

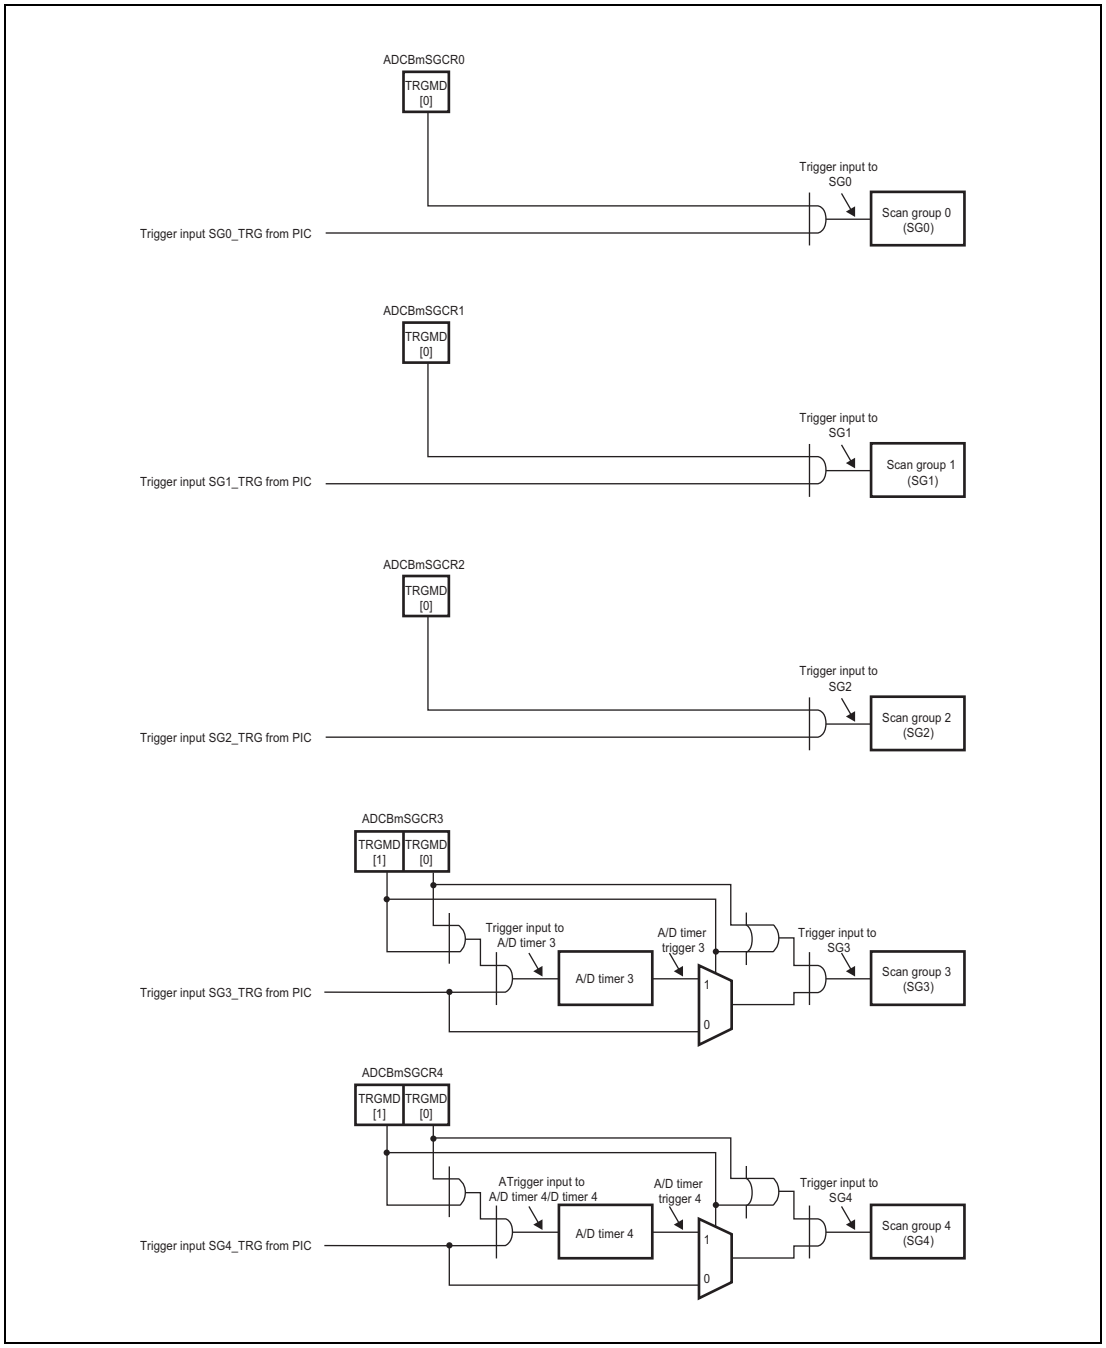


Figure 26.20 Selection of Trigger Input for a Scan Group

NOTE

m = 0, 1

26.7.12 Starting a Scan Group by Using a Hardware Trigger

Scan group x can be started by using an input from hardware trigger SGx_TRG. To start scan group x by an input from hardware trigger SGx_TRG, set TRGMD in ADCBmSGCRx to 1_H. When the selected hardware trigger SGx_TRG is input in this state, SGACT is set to 1. The timing since SGACT is set to 1 until scan group x is started is the same as the timing when SGST is set to 1 by a software trigger.

NOTE

m = 0, 1; x = 0 to 4

26.7.13 Starting a Scan Group by Using an A/D Timer Trigger

Scan group 3 or 4 can be started by using a trigger from A/D timer 3 or 4. To start scan group 3 or 4 by using a trigger from A/D timer 3 or 4, set TRGMD in ADCBmSGCR3 or ADCBmSGCR4 to 2_H. Furthermore, set ADTST of scan group 3 or 4 to 1 to start A/D timer 3 or 4.

When a timer trigger is input in this state, SGACT is set to 1. The timing since SGACT is set to 1 until scan group 3 or 4 is started is the same as the timing when SGST is set to 1 by a software trigger.

NOTE

m = 0, 1

26.7.14 Starting A/D Timer by Using a Hardware Trigger

A/D timer 3 or 4 can be started by using a hardware trigger SG3_TRG or SG4_TRG input. To start A/D timer 3 or 4 by using a hardware trigger SG3_TRG or SG4_TRG input, set TRGMD in ADCBmSGCR3 or ADCBmSGCR4 to 3_H. When the selected external trigger is input in this state, A/D timer 3 or 4 starts. Furthermore, a trigger from A/D timer 3 or 4 starts scan group 3 or 4.

NOTE

m = 0, 1

26.7.15 Monitoring Function by Using the A/D Conversion Monitor Pin

ADENDm can be used to monitor the processing timing of the virtual channel specified by ADCBmADENDP. For details of pin settings, see **Section 2, Pins**.

Figure 26.21 shows the A/D conversion monitor timing.

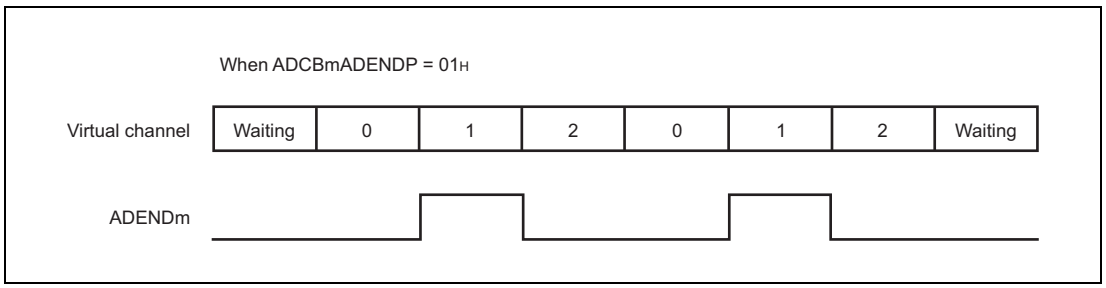

Figure 26.21 A/D Conversion Monitor Timing

CAUTION

If the high-level voltage is output from ADENDm in a lower-priority scan group and a higher-priority scan group suspends (asynchronous suspend) the processing of the lower-priority scan group, the low-level voltage is output from ADENDm. Since the suspended virtual channel processing for the lower-priority scan group resumes after that, the high-level voltage is output again from ADENDm.

NOTE

m = 0, 1

26.7.16 Scan End Interrupt Request

Scan group x can issue a scan end interrupt request (ADImx) to the INTC. When ADIE in ADCBmSGCRx is set to 1, ADImx can be output after the SGx scan ends. When ADIE in ADCBmSGCRx is set to 0, the ADImx output at the end of the SGx scan can be disabled. When ADIE in ADCBmVCRn is set to 1, ADImx can be output when A/D conversion for virtual channel n in SGx ends. When ADIE in ADCBmVCRn is set to 0, the ADImx output at the end of the A/D conversion for virtual channel n in SGx can be disabled. The setting of ADIE in ADCBmSGCRx is independent of the setting of ADIE in ADCBmVCRn.

Example 1) A scan is executed for virtual channel 0 or 1 in SG0 when ADIE in ADCBmSGCR0 is 0, ADIE in ADCBmVCR0 is 1, and ADIE in ADCBmVCR1 is 0.
ADIm0 is output when A/D conversion ends for virtual channel 0.

Example 2) A scan is executed for virtual channel 0 or 1 in SG0 when ADIE in ADCBmSGCR0 is 0, ADIE in ADCBmVCR0 is 1, and ADIE in ADCBmVCR1 is 1.
ADIm0 is output when A/D conversion ends for virtual channel 0 and virtual channel 1.

Example 3) A scan is executed for virtual channel 0 or 1 in SG0 when ADIE in ADCBmSGCR0 is 1, ADIE in ADCBmVCR0 is 0, and ADIE in ADCBmVCR1 is 0.
ADIm0 is output when a scan ends (at the end of A/D conversion for virtual channel 1).
ADIm0 is output at each two cycles (or more) in multicycle scan mode, or each time a scan ends (at the end of A/D conversion for virtual channel 1) in continuous scan mode.

Furthermore, the DMAC can be activated when ADImx occurs.

For the DMAC setting, see **Section 7, DMA**.

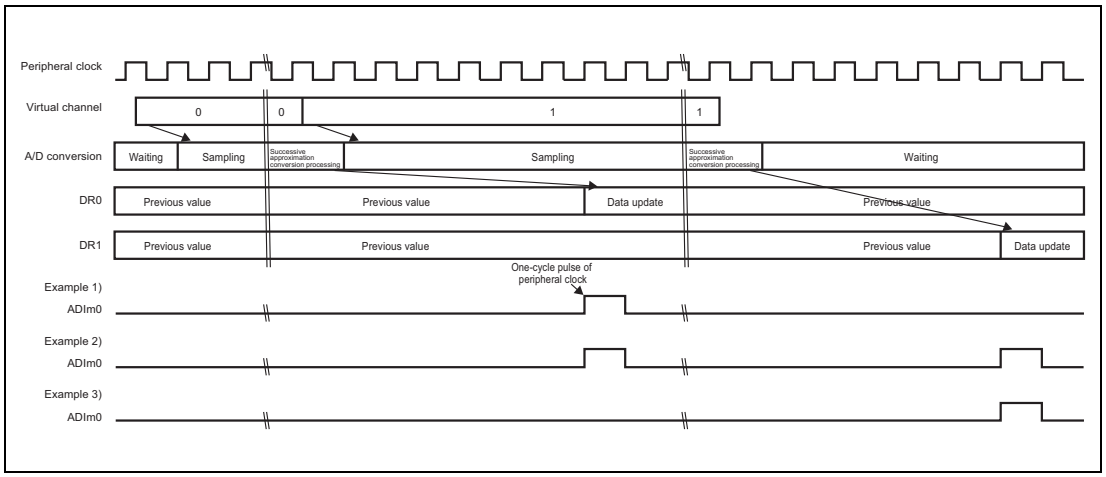

Figure 26.22 Scan Conversion End Interrupt Occurrence Timing

NOTE

m = 0, 1; x = 0 to 4; n = 0 to 39

26.7.17 MPX Interrupt Request

The ADC can issue an MPX interrupt request (ADMPXIm) to the INTC. ADMPXIm is generated when a virtual channel for which CNVCLS[2:0] in ADCBmVCRn is set to 5_H or 6_H is started.

The DMAC can be activated when ADMPXIm occurs.

For the DMAC setting, see **Section 7, DMA**.

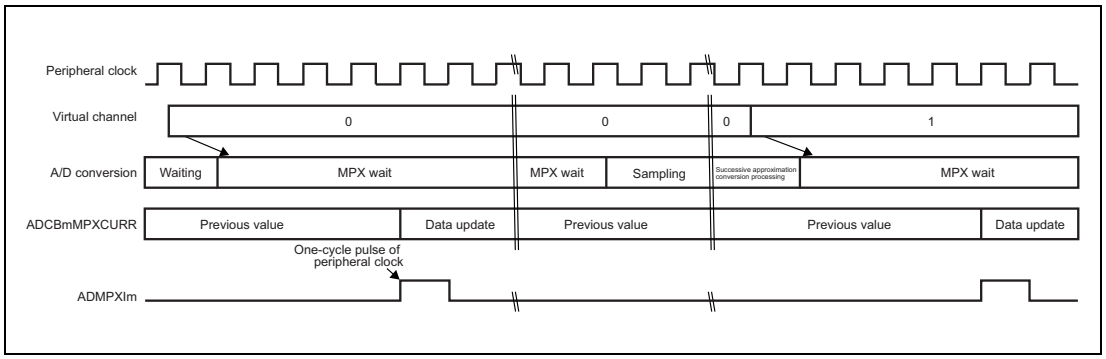

Figure 26.23 Example of an MPX Interrupt Occurrence

NOTE

m = 0, 1; n = 0 to 39

26.7.18 A/D Error Interrupt Request and A/D Parity Error Notification

The ADC can issue an A/D error interrupt request (ADEm) to the INTC and an A/D parity error notification (ADPEm) to the error control module (ECM). For an error source for which ULEIE, OWEIE, and IDEIE in ADCBmSFTCR is set to 1, the OR condition of the error source is issued as ADEm. For an error source for which ULEIE, OWEIE, and IDEIE in ADCBmSFTCR is set to 0, ADEm can be disabled. ADPEm is enabled when PEIE in ADCBmSFTCR is set to 1. ADPEm is disabled when PEIE in ADCBmSFTCR is set to 0.

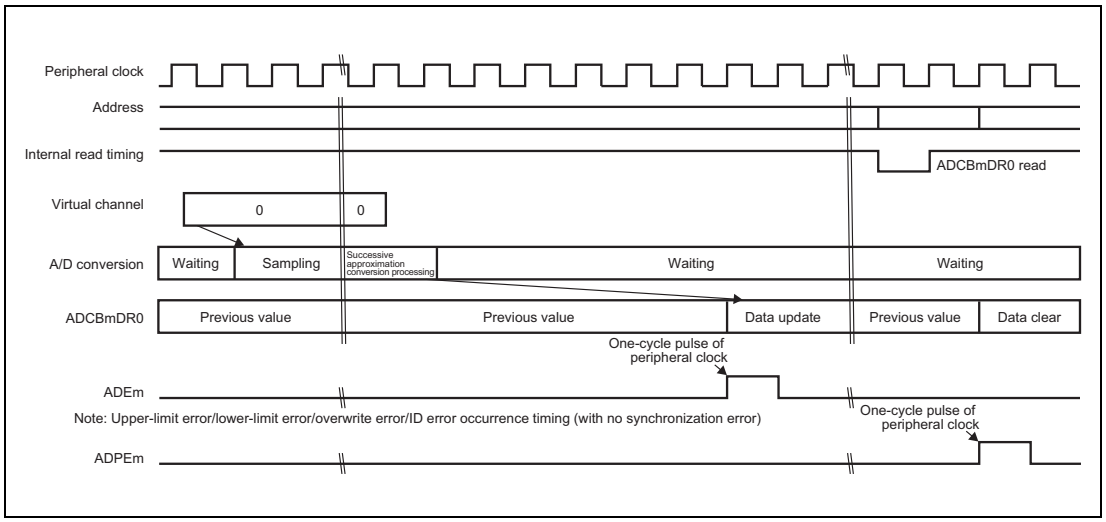

Figure 26.24 Example of an Occurrence of A/D Error Interrupt and A/D Parity Error Notification

NOTES

m = 0, 1

26.7.19 DFE/ASF Entry Function

The ADC can issue a request for entry to the DFE and a request for entry to the ASF for both DFE and ASF to enable entry according to the settings of DFENT in ADCBmVCRn and DFENTSGxE and ASENTSGxE in ADCBmDFASENTSGER. At the same time, the ADC outputs the TAG information and A/D conversion data that are set in DFTAG in ADCBmVCRn. For the format of the output A/D conversion data, see **Section 26.5.2, ADCBmDRn — Data Register n**.

NOTE

m = 0, 1; n = 0 to 39; x = 0 to 4

26.8 Definition of A/D Conversion Accuracy

A/D conversion accuracy is defined below.

- Resolution
  Number of digital output codes of the A/D converter
- Quantization error
  An error essentially contained in A/D converters, which is given as 1/2LSB (**Figure 26.26**).
- Offset error
  Deviation of the analog input voltage value from the ideal A/D conversion characteristics when the digital output changes from the minimum voltage value 000_H to 001_H. However, the quantization error is not included (**Figure 26.26**).
- Full-scale error
  Deviation of the analog input voltage value from the ideal A/D conversion characteristics when the digital output changes from FFE_H to FFF_H. However, the quantization error is not included (**Figure 26.26**).
- DNL (Differential nonlinear error)
  Deviation between the ideal digital output code width (Vq) and the actual digital output code width (Va), which is given as (Va - Vq)/Vq. However, the offset error, the full-scale error, and the quantization error are not included (**Figure 26.26**).
- INL (Integral nonlinear error)
  Deviation of the actual value from the ideal A/D conversion characteristics, from the zero voltage to the full-scale voltage, which is given as an integral of DNL from 000_H to a digital output code. However, the offset error, the full-scale error, and the quantization error are not included (**Figure 26.26**).
- Absolute accuracy
  Deviation between the digital value and the analog input value. The offset error, the full-scale error, the quantization error, DNL, and INL are included (**Figure 26.26**).

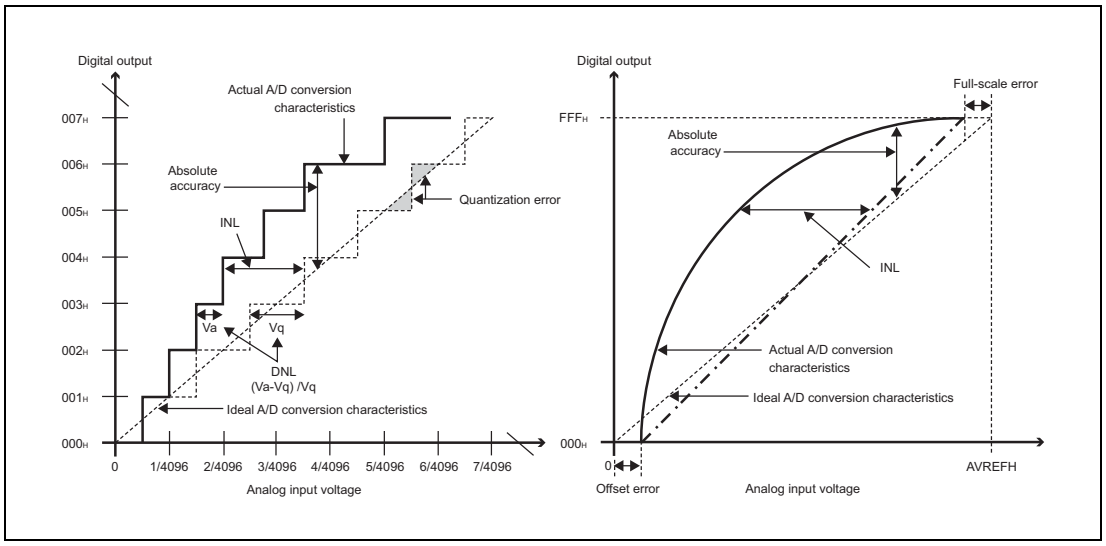

Figure 26.26 Definition of A/D Conversion Accuracy

26.9 Usage Notes

26.9.1 Notes on Using an External Analog Multiplexer

When you use an external multiplexer, observe the following notes so as not to cause system crash.

Except for the exceptions below, set the MPX wait as follows:

- When an MPX value is transferred at a port: Insert a wait of at least 1 µs.
- When an MPX value is transferred with the SPI interface: Insert a wait of at least SPI transmission time + 1 µs.

Exception 1) When an external multiplexer is used for one scan group

When an external multiplexer is used for SG0 with SUSMTD[1:0] set to 1_H, or when an external multiplexer is used for any of SG0 to SG3 with SUSMTD[1:0] set to 2_H, set the MPX wait as follows:

- When an MPX value is transferred at a port: Insert a wait of at least 1 µs.
- When an MPX value is transferred with the SPI interface: Insert a wait of at least SPI transmission time × 2.

Exception 2) When an external multiplexer is used for multiple scan groups

When an external multiplexer is used with SUSMTD[1:0] set to 1_H or 2_H, observe the following notes.

- For the start virtual channel of each scan group, make a setting so as not to use an external multiplexer. (However, for the start virtual channel of the scan group whose priority is lowest among the scan groups for which the external multiplexer is used, a setting to use an external multiplexer does not cause any problem.)
- Up to two scan groups can be transferred with the SPI interface.

Furthermore, set the MPX wait as follows:

- When an MPX value is transferred at a port: Insert a wait of at least 1 µs.
- When an MPX value is transferred with the SPI interface: Insert a wait of at least SPI transmission time × 2.

26.9.2 Notes on Using Analog Input Pins

- Do not perform A/D conversion for an analog pin with both ΔΣADC and SAR-ADC at the same time. Also, do not perform A/D conversion with SAR-ADC for an analog pin that is being selected for digital input. Doing so may degrade the A/D conversion accuracy.

- When a digital input or output signal is multiplexed with an analog input signal, it can also be used as a digital general-purpose input or output pin. Changes in a digital input or output during AD conversion may reduce the precision of conversion. Noise from the operation of digital pins near analog input pins may also reduce the precision of conversion. Notes on how to reduce the effects of digital input and output on the results of AD conversion are given below.

(1) Notes on Analog Input Pins

(a) Place the capacitors of RC circuits as close to the LSI pin as is possible. This reduces the effects of digital inputs and outputs on the precision of conversion. Since the improvement in precision also depends on other conditions of the board, evaluate the situation on the actual board.

(2) Notes on Digital Input and Output Pins near Analog Pins

(a) If digital input through the pin is not essential, disable digital input.

(b) If a digital signal is input to such a pin, the signal should not include overshot or undershot.

(c) Set the voltage to AVCC = EVCC (if an analog pin function is multiplexed with the digital function).
Operation outside the range of -0.3 V AVCC-EVCC 0.3 V may negatively affect the reliability of the chip.

(d) Design the board so that load capacitances connected to output pins to suppress discharge currents are small.

(e) Lower the output driving ability (boosting) of pins that may be affected.

(3) Software Measures against Effects on the Results of Conversion

(a) Use the average of multiple results of AD conversion.

(b) When using multiple consecutive results of ADC conversion, exclude outlying results.

26.9.3 Notes when Current is Being Injected

Proceeding with A/D conversion by using simultaneous track-and-hold while current is being injected may affect the accuracy of A/D conversion.

To avoid the effects of injection current on the accuracy of A/D conversion, make settings according to either of the following descriptions.

CAUTION

Applying a voltage above the power supply voltage or below the ground voltage to a pin will lead to an injection current flowing.

(1) If you are using simultaneous track-and-hold, do not allow current to be injected to pins where this will affect the accuracy of conversion.

Table 26.42 Combination of the T&H Circuits and Pins where Injected Current will Affect the Accuracy of Conversion

Unit	T&H Circuit for Conversion	Pins where Injected Current will Affect the Accuracy of Conversion
ADCB0	T&H Circuit 0	AN000
	T&H Circuit 1	AN001
ADCB1	T&H Circuit 0	AN100
	T&H Circuit 1	AN101

(2) When simultaneous track-and-hold is in use, setting a value other than 00_B to bits 4 and 3 (GCTRL) of the ADCBnVCRj register changes the pins where injected current will affect the accuracy of conversion.
The table below shows the correspondence between settings other than 00_B for bits 4 and 3 (GCTRL) of the ADCBnVCRj register and the pins which are subject to injected current affecting the accuracy of conversion. Follow the table to set bits 4 and 3 (GCTRL) such that the result for pins which may be affected is no applicable pins or use pins to which no injection current is being applied.

Table 26.43 Combination of the T&H Circuits and Pins where Injected Current will Affect the Accuracy of Conversion (the ADCBnVCRj.GCTRL bits are used)

Unit	T&H Circuit for Conversion	Settings Other than 00_B for GCTRL[4:3]	Pins where Injected Current will Affect the Accuracy of Conversion
ADCB0	T&H Circuit 0	11_B	– (no applicable pins)
	T&H Circuit 1	11_B	– (no applicable pins)
ADCB1	T&H Circuit 0	00_B	AN100
		01_B	AN120
		10_B	AN140
		11_B	AN160
	T&H Circuit 1	00_B	AN101
		01_B	AN121
		10_B	AN141
		11_B	AN161

26.10 IFC (Integer/Floating-Point Conversion Module)

The IFC module can read data in the ADC's register data via the IFC and convert it to the floating-point format.

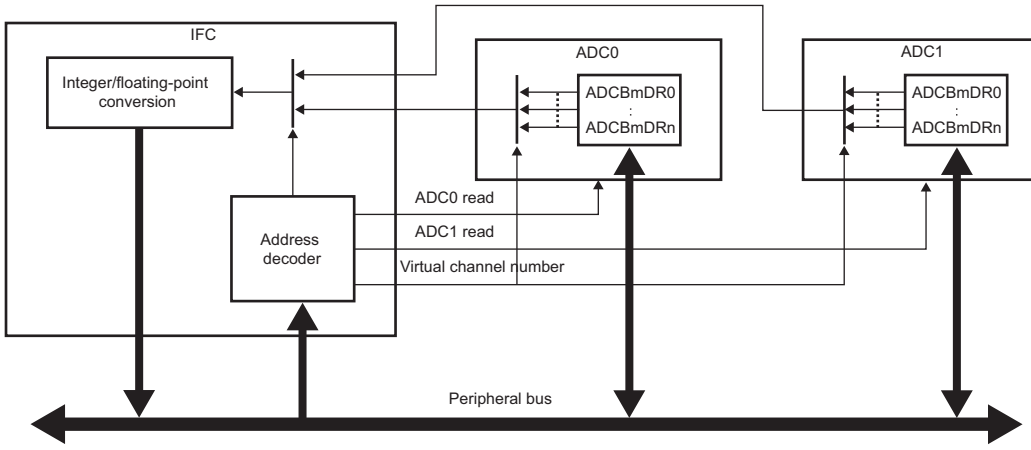
26.10.1 Features

The IFC has the following features:

- Floating-point format: IEEE754 standard single-precision
- Supported registers: Data registers for all virtual channels of the ADC

26.10.2 Configuration

Figure 26.27 illustrates the IFC block diagram.



Note: n = 39

Figure 26.27 IFC Block Diagram

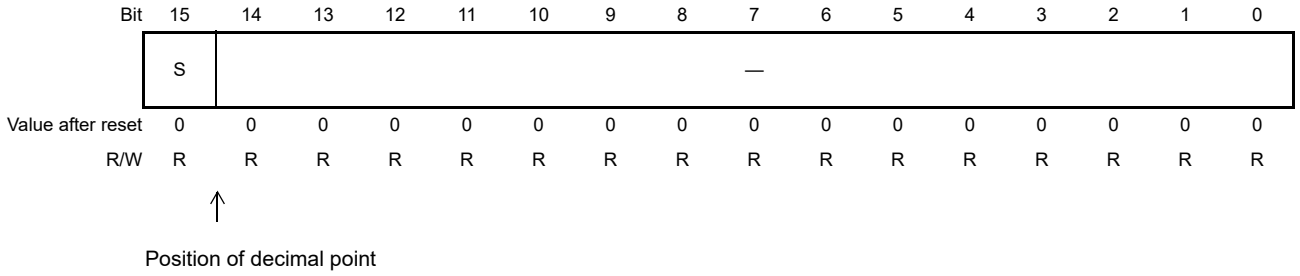
Note: m = 0, 1; n = 0 to 39

26.10.4 Register

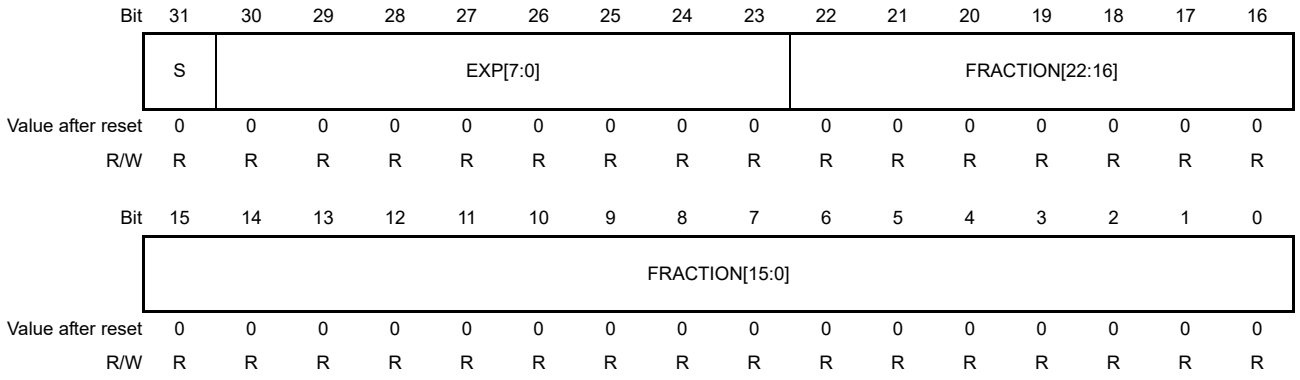
26.10.4.1 FDRmn — Floating-Point Data Register mn

FDRmn is a 32-bit read-only register that can read DRn of ADCm, converting it to the floating-point format. Data in an ADC data register is converted from the signed fixed-point format to the floating-point format. Even data in the signed integer format (DFMT bit in ADCBmADCR2 of ADCm is set to 1) is regarded as data in the signed fixed-point format, and converted to the floating-point format.

Signed fixed-point format



Floating-point format



Bit Position	Bit Name	Function
31	S	Sign bit
30 to 23	EXP[7:0]	Exponent
22 to 0	FRACTION[22:0]	Mantissa

Expression: (-1)^S × 2^ (EXP-127) × (1+ (Fraction × 2^ (-23)))

NOTE

m = 0, 1; n = 0 to 39

26.11 ADC Summation Function (ASF)

The ASF is a function that accumulates the A/D converted value from the ADC the specified number of times, and then stores the total value in a register.

26.11.1 Features

The ASF has the following features:

- Compatible module: ADC0
- Number of accumulation channels: 11
- Entry from ADC:
  Upon receiving an ASF entry request, TAG for DFE, and data for DFE from the ADC, the ASF enters them to each accumulation channel (with the same number as the TAG value for DFE) of the ASF.
- Accumulation data register: 32 bits
- Accumulation end interrupt:
  Each time accumulation for the number of times specified in each channel ends, an interrupt request (ASI0 to ASI10) to the CPU can be generated.

26.11.2 Configuration

Figure 26.28 illustrates the ASF block diagram.

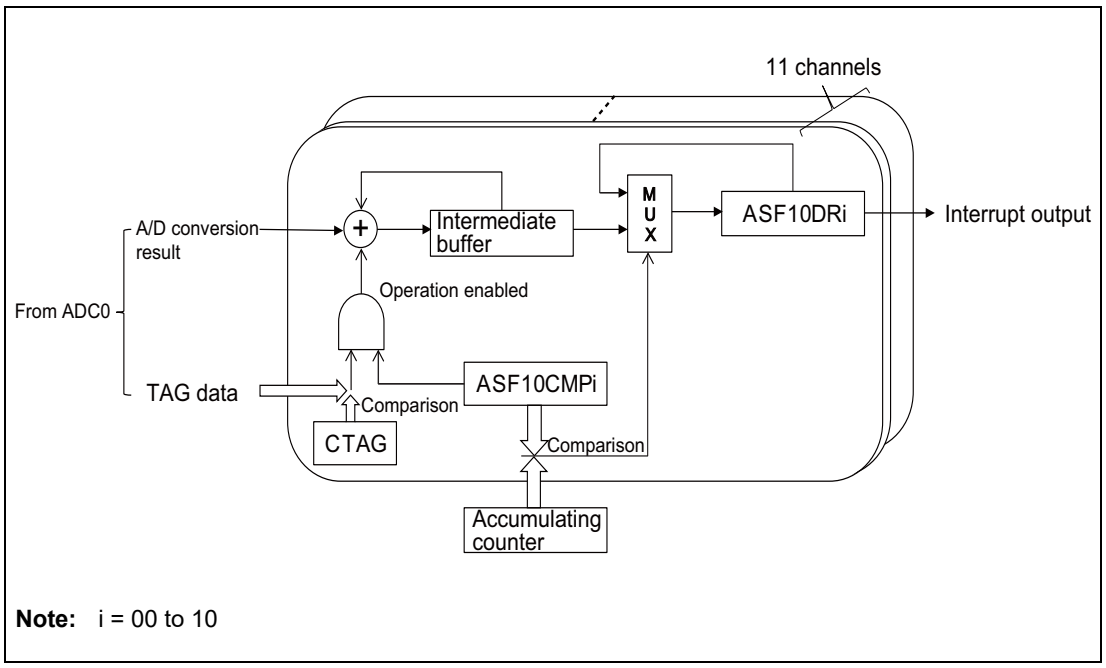


Figure 26.28 Block Diagram of ASF Configuration

Note: n = 0

26.11.4 Registers

26.11.4.1 ASF1nDRi — Accumulation Data Read Register i

ASF1nDRi is a 32-bit read-only register that stores an accumulation value. When ASF1nCNT matches ASF1nCMPi, data in accumulator i is updated to ASF1nDRi. The ASF1nDRi value is retained until the next compare match occurs.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ASF1nDRi[16:1]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ASF1nDRi[0:0]	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

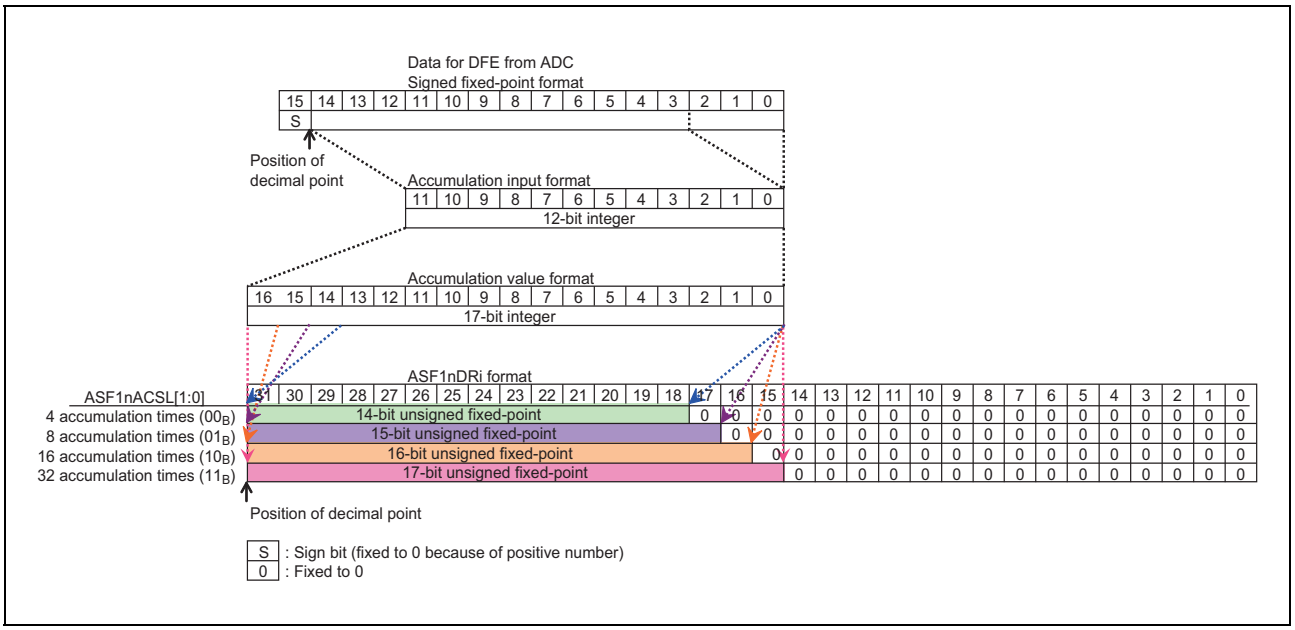
Table 26.48 ASF1nDRi Register Contents

Bit Position	Bit Name	Function
31 to 15	ASF1nDRi [16:0]	Accumulation Data When ASF1nCNT matches ASF1nCMPi, data in accumulator i is updated to ASF1nDRi.

Note: i = 00 to 10 or 0 to 10
n = 0

A 12-bit (bit14 to bit3) value is extracted from the data for DFE from the ADC for use in the input of accumulation as a 12-bit integer. Therefore, even if the valid number of digits of the data for DFE is 13 or 14 bits after addition is performed twice or four times in the ADC, the valid number of digits is regarded as 12 bits and accumulation processing is performed. Even the signed integer format (DFMT = 1 is set in the ADC) is regarded as the signed fixed-point format and accumulation processing is performed. For this reason, when using the ASF function, be sure to disable the ADC's addition function and set DFMT to 0 (signed fixed-point format).

ASF1nDRi is in a format with left-aligned valid bits according to the accumulation count setting out of 17-bit accumulation value. ASF1nDRi is initialized to 0000 0000_H at a reset.



26.11.4.2 ASF1nCMPi — Accumulation Compare Match Register i

ASF1nCMPi is an 8-bit readable/writable register that enables or disables accumulation processing for accumulation channel i and specifies the ASF1nCNT compare match value for updating ASF1nDRi. ASF1nCMPi is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	ASF1nCHEi	—	—	ASF1nCMPi[4:0]				
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Table 26.49 ASF1nCMPi Register Contents

Bit Position	Bit Name	Function
7	ASF1nCHEi	Accumulation Channel i Enable 0: Accumulation is disabled. – Accumulator i is cleared to 0. – ASF1nDRi is not updated. – Accumulation end interrupt i (INT_ACE[i]) is not generated. 1: Accumulation is enabled. – Each time an ASF entry request of TAG for DFE (TAG for DFE = i) that matches accumulation channel i is accepted, the result of sum of data for DFE and accumulator i is stored in accumulator i (accumulation processing for accumulation channel i). – When ASF1nCNT matches ASF1nCMPi, data in accumulator i is updated to ASF1nDRi and accumulator i is cleared to 0 (ASF1nDRi update). – An accumulation end interrupt i (INT_ACE[i]) is generated on compare match.
4 to 0	ASF1nCMPi[4:0]	Accumulation Compare Match When ASF1nCNT matches ASF1nCMPi, data in accumulator i is updated to ASF1nDRi. These bits must not be modified during operation (while ASF1nST = 1).

Note: i = 00 to 10 or 0 to 10
n = 0

CAUTIONS

1. Each time ASF1nCNT[4:0] matches ASF1nCMPi[4:0], the accumulator i value is stored in ASF1nDRi[16:0] and an INT_ACE[i] interrupt is generated.
   Therefore, the first accumulation count in ASF1nDRi[16:0] is not ensured after accumulation processing (where ASF1nST is changed from 0 to 1) is started, or immediately after an accumulation channel (for which ASF1nCHEi is changed from 0 to 1 during accumulation processing) is enabled (the accumulation count is variable).
   For example of operation, see **Section 26.11.5.1, Example of Accumulation Processing Operation**.
2. Set ASF1nCMPi[4:0] to a value less than the accumulation count selected by ASF1nACSL[1:0]. If a value equal to or greater than the accumulation count is set in ASF1nCMPi[4:0], ASF1nCNT[4:0] does not match ASF1nCMPi[4:0], so the ASF1nDRi[16:0] value is not updated.

26.11.4.3 ASF1nCTL0 — Accumulation Counter Control Register 0

ASF1nCTL0 is a 16-bit or 8-bit readable/writable register that sets count-up conditions for ASF1nCNT. ASF1nCTL0 is initialized to 0000_H at a reset.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	ASF1nACSL [1:0]		—	—	—	—	ASF1nCTAG[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 26.50 ASF1nCTL0 Register Contents

Bit Position	Bit Name	Function
9, 8	ASF1nACSL[1:0]	Accumulation Count Select 00_B: 4 times 01_B: 8 times 10_B: 16 times 11_B: 32 times These bits must not be modified during operation (while ASF1nST = 1).
3 to 0	ASF1nCTAG[3:0]	Accumulation Count-Up TAG When an ASF entry request of TAG for DFE that matches ASF1nCTAG is accepted, ASF1nCNT starts count-up. These bits must not be modified during operation (while ASF1nST = 1).

Note: n = 0

26.11.4.4 ASF1nCTL1 — Accumulation Counter Control Register 1

ASF1nCTL1 is an 8-bit readable/writable register that enables (starts) or disables (stops) counting up by ASF1nCNT. ASF1nCTL1 is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ASF1nST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 26.51 ASF1nCTL1 Register Contents

Bit Position	Bit Name	Function
0	ASF1nST	Accumulation Counter Start 0: The accumulation counter and all accumulators are cleared to 0. 1: Counting up and accumulation processing by the accumulation counter are enabled. When an ASF entry request of TAG for DFE that matches ASF1nCTAG is accepted with ASF1nST set to 1, ASF1nCNT starts counting up.

Note: n = 0

26.11.4.5 ASF1nCNT — Accumulation Count Read Register

ASF1nCNT is an 8-bit read-only register that indicates the count value of the accumulation counter. ASF1nCNT is initialized to 00_H at a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	ASF1nCNT[4:0]				
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 26.52 ASF1nCNT Register Contents

Bit Position	Bit Name	Function
4 to 0	ASF1nCNT[4:0]	Accumulation Counter When ASF1nST is set to 1, ASF1nCNT counts up each time an ASF entry request of TAG for DFE that matches ASF1nCTAG is accepted. When ASF1nST is set to 0, ASF1nCNT is cleared to 0. • When ASF1nACSL = 00_B (4 accumulation times) The counter counts up to 3 and then returns to 0. • When ASF1nACSL = 01_B (8 accumulation times) The counter counts up to 7 and then returns to 0. • When ASF1nACSL = 10_B (16 accumulation times) The counter counts up to 15 and then returns to 0. • When ASF1nACSL = 11_B (32 accumulation times) The counter counts up to 31 and then returns to 0.

Note: n = 0

26.11.5 Operation

The summation function ASF accumulates the results of ADC conversion from the ADC, stores the accumulation value in a register, and generates an interrupt request each time accumulation for the specified number of times is completed.

The ASF allows accumulation for up to 11 channels. The number of accumulation times is selectable from 4, 8, 16, and 32. However, the number of accumulation times is common to all channels (it cannot be set individually for each channel). Furthermore, interrupt timing offset is enabled by register setting.

After ASF1nST is set to 1 to enable accumulation processing, the ADC conversion result is added to the accumulation channel that is the same as the TAG value for DFE each time an ASF entry request from the ADC becomes a high level.

The accumulation counter ASF1nCNT[4:0] counts up when TAG for DFE that matches ASF1nCTAG[3:0] is input and an ASF entry request becomes a high level. When ASF1nCTAG [3:0] matches the TAG for DFE and the accumulation count reaches number of accumulation times specified by ASF1nACSL[1:0] - 1, the accumulation counter returns to 1 at an ASF entry request timing.

When ASF1nCMPi[4:0] matches ASF1nCNT[4:0], the accumulation data ASF1nDRi[31:0] is updated and an accumulation end interrupt ASI[i] is generated.

[Setting Procedure]

1. While ASF1nST = 0, set a required value in each of ASF1nACSL[1:0], ASF1nCTAG[3:0], ASF1nCMPi [4:0], and ASF1nCHEi in any order.
2. Set ASF1nST to 1 to enable (start) the accumulation processing operation.
3. Ignore the first accumulation end interrupt ASI[i] (or discard the ASF1nDRi[16:0] read value) because the first accumulation count after accumulation start is variable.
4. Read ASF1nDRi[16:0] required for accumulation end interrupt ASI[i] from the second time, and then read the accumulation value of the ADC conversion result.
5. After the required accumulation value of the ADC conversion results is obtained, set ASF1nST to 0 to finish the accumulation processing.

26.11.5.1 Example of Accumulation Processing Operation

(1) Operation start

Figure 26.29 shows an example of accumulation processing operation for four channels when the number of accumulation times is set to 8 (ASF1nACSL[1:0] = 01_B), ASF1nCTAG[3:0] = 1_H, ASF1nCMP00[4:0] = 00_H, ASF1nCMP01[4:0] = 01_H, ASF1nCMP02[4:0] = 02_H, and ASF1nCMP03[4:0] = 03_H.

In this example, data of TAG (for DFE) = 0_H is always 10, data of TAG (for DFE) = 1_H is always 20, data of TAG (for DFE) = 2_H is always 30, and data of TAG (for DFE) = 3_H is always 40 for convenience.

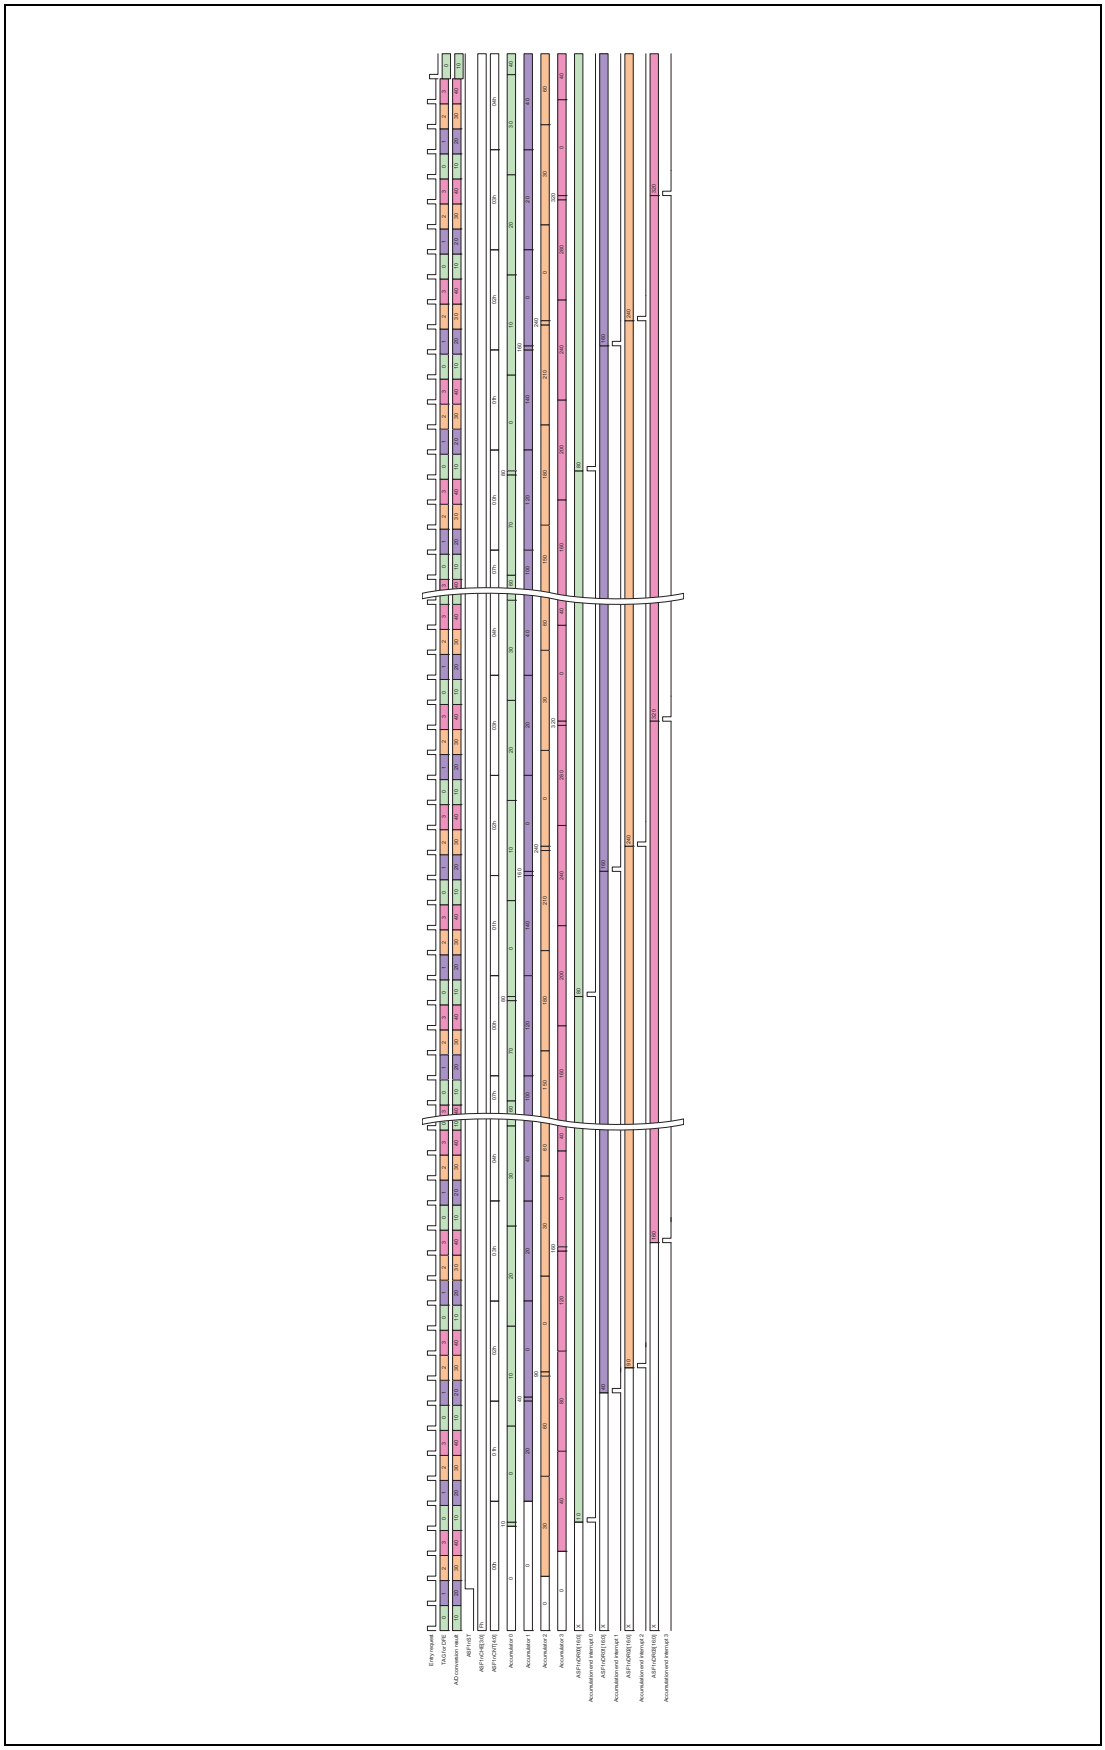


Figure 26.29 Timing of Accumulation Processing Start Operation Example

(2) Operation stop and restart

Figure 26.30 shows an example of accumulation processing stop and restart operation.

When ASF1nST is set to 0, the accumulation counter ASF1nCNT[4:0] and accumulator i are cleared to 0.

Figure 26.30 Timing of Accumulation Processing Stop and Restart Operation Example

(3) Channel stop

Figure 26.31 shows an example of accumulation processing stop and restart operation for an accumulation channel.

When ASF1nCHEi is set to 0, accumulator i is cleared to 0.

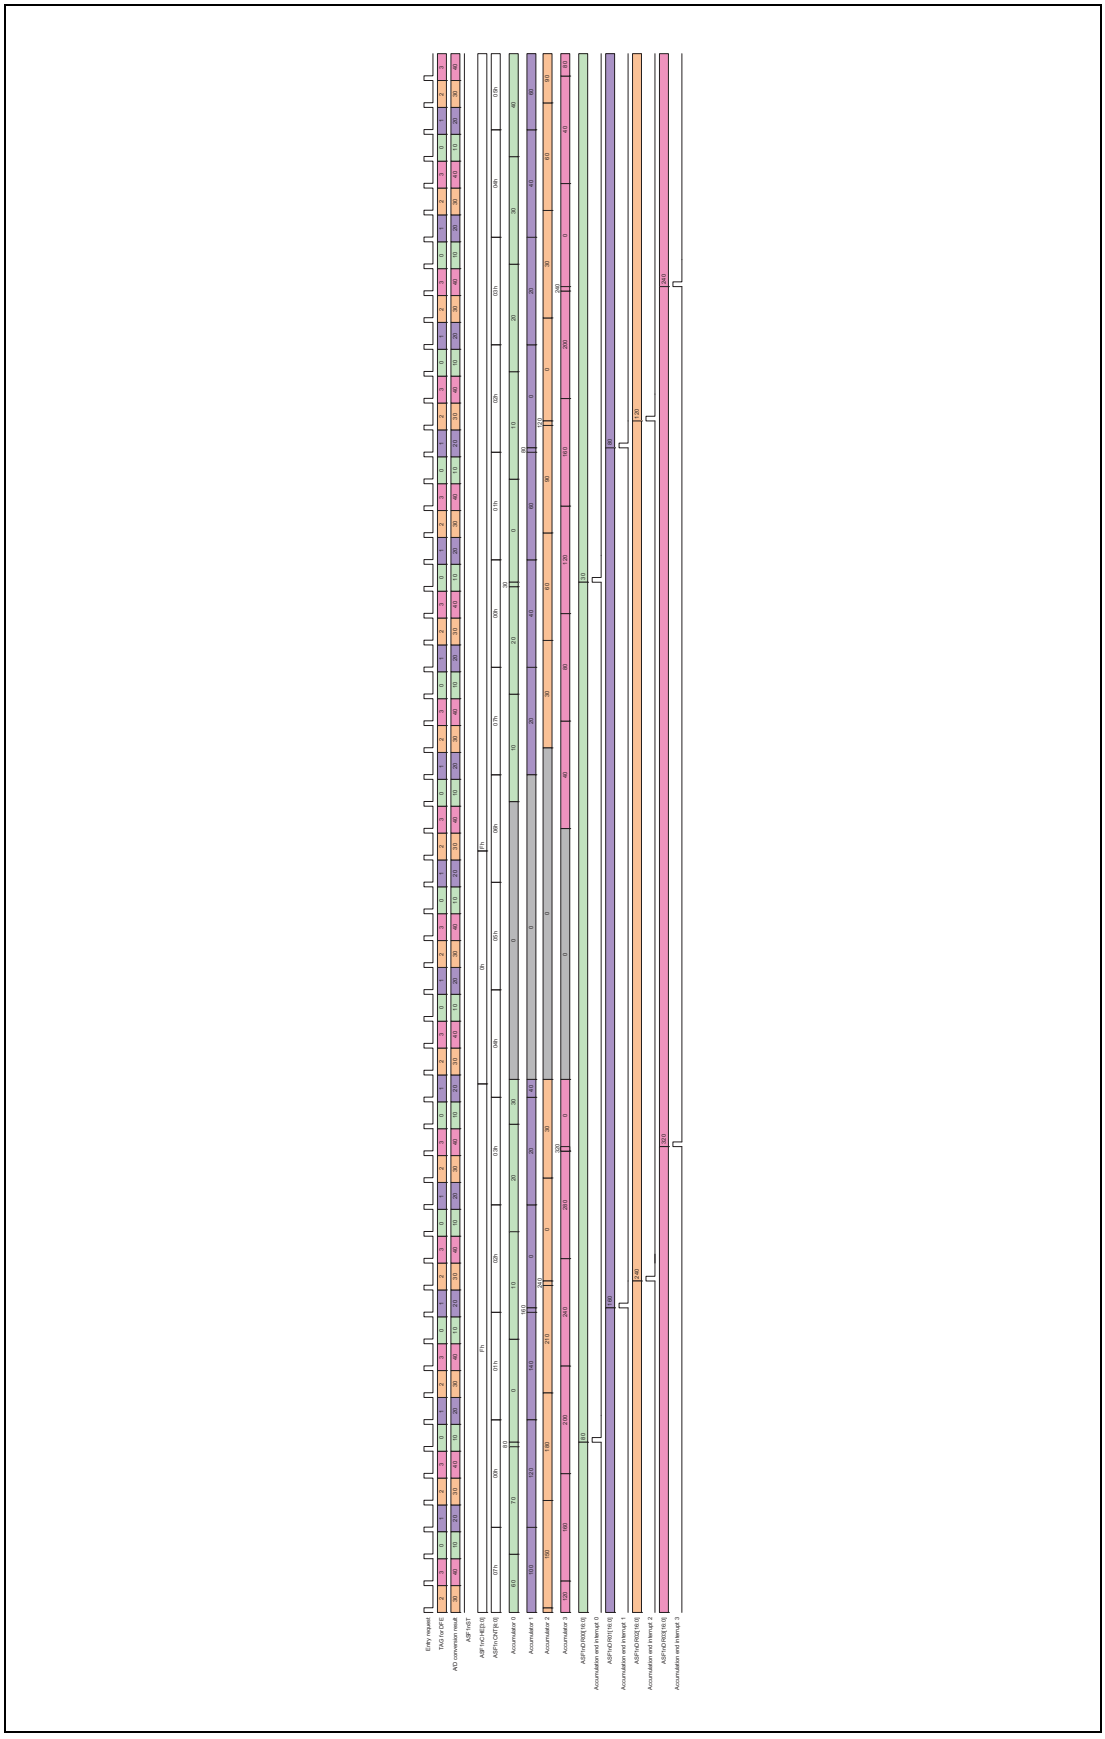

Figure 26.31 Timing of Accumulation Processing Stop Operation Example by ASF1nCHEi

Section 27 Delta-Sigma AD Converter (DS-ADC)

This LSI, provided with eight A/D converter modules (DSADC0 to DSADC7) using the delta-sigma modulation method, consists of a delta-sigma modulator and a digital filter.

27.1 Features

The following describes features of the delta-sigma ADC.

- Analog channels
  Eight channels are provided.
- Enhanced A/D converter
  - Valid bits (analog signal bandwidth):
    13 bits (30 kHz) when Fos = 8 Msps, Fs = 100 ksps (usage example 1)
    13 bits (30 kHz) when Fos = 8 Msps, Fs = 200 ksps (usage example 2)
    13 bits (60 kHz) when Fos = 8 Msps, Fs = 200 ksps (usage example 3)
    8 bits (200 kHz) when Fos = 8 Msps, Fs = 1.6 Msps (usage example 4)
  - A/D conversion method: Delta-sigma modulation method
  - Oversampling rate (Fos): 8 Msps
  - Sampling rate (Fs): 100 ksps, 200 ksps, 1.6 Msps
- Supporting single-ended input and differential input
  Single-ended input or differential input can be selected for each delta-sigma ADC (DSADC0 to DSADC7).
- Input gain function
  Each delta-sigma ADC (DSADC0 to DSADC7) contains a programmable gain amplifier (PGA). A gain of ×1, ×2, ×4, or ×8 is selectable.
- Data register
  A data register corresponding to each delta-sigma ADC (DSADC0 to DSADC7) is contained in the data supplementary information register.
- A/D conversion start trigger
  Each delta-sigma ADC (DSADC0 to DSADC7) can start A/D conversion by software, each timer trigger, or an external trigger (DSADC0 to DSADC7: DSADTRG0 to DSADTRG7).
- A/D conversion end trigger
  Each delta-sigma ADC can terminate A/D conversion by software, each timer trigger, or an external trigger ((DSADC0 to DSADC7: DSADTRG0 to DSADTRG7).
- Entry to the digital filter engine
  A/D converted values can be entered directly in the digital filter engine (DFE).
  Whether to enable or disable DFE entry and TAG to determine channels for entry can be set for each delta-sigma ADC (DSADC0 to DSADC7).
- Supporting DMA transfer based on A/D conversion end timing
  Each time A/D conversion ends, each delta-sigma ADC (DSADC0 to DSADC7) outputs a DMA request on completion of A/D conversion (DSADIm), which can generate DMA request sources (DSADC0 to DSADC7: DSADI0 to DSADI7) to the DMAC or activate the DMAC.
- AD error interrupt request and AD parity error notification
  Each delta-sigma ADC (DSADC0 to DSADC7) can generate an AD error interrupt request

(DSADEm) to the INTC and an AD parity error notification (DSADPEm) to the ECM (error control module).

- Settable analog conversion voltage range
  An analog conversion voltage range can be set using the ADSVREFH pin and the ADSVREFL pin. When performing A/D conversion by using the single-ended input, either ADSVREFL or ADSVREFH/2 is selectable as a common voltage.
- A/D conversion monitor output
  A/D conversion timing can be output to the DSADEND0 to DSADEND7 pins.
- A wide range of safety functions
  A variety of safety functions are provided, such as self-diagnosis of delta-sigma ADC, pin-level self-diagnosis, upper-limit/lower-limit check for data registers, data register parity check for data registers, overwrite check for data registers, and read and clear function for data registers.

27.2 Configuration

Figure 27.1 is a block diagram of the delta-sigma ADC, and **Table 27.1** shows the pin configuration of the delta-sigma ADC.

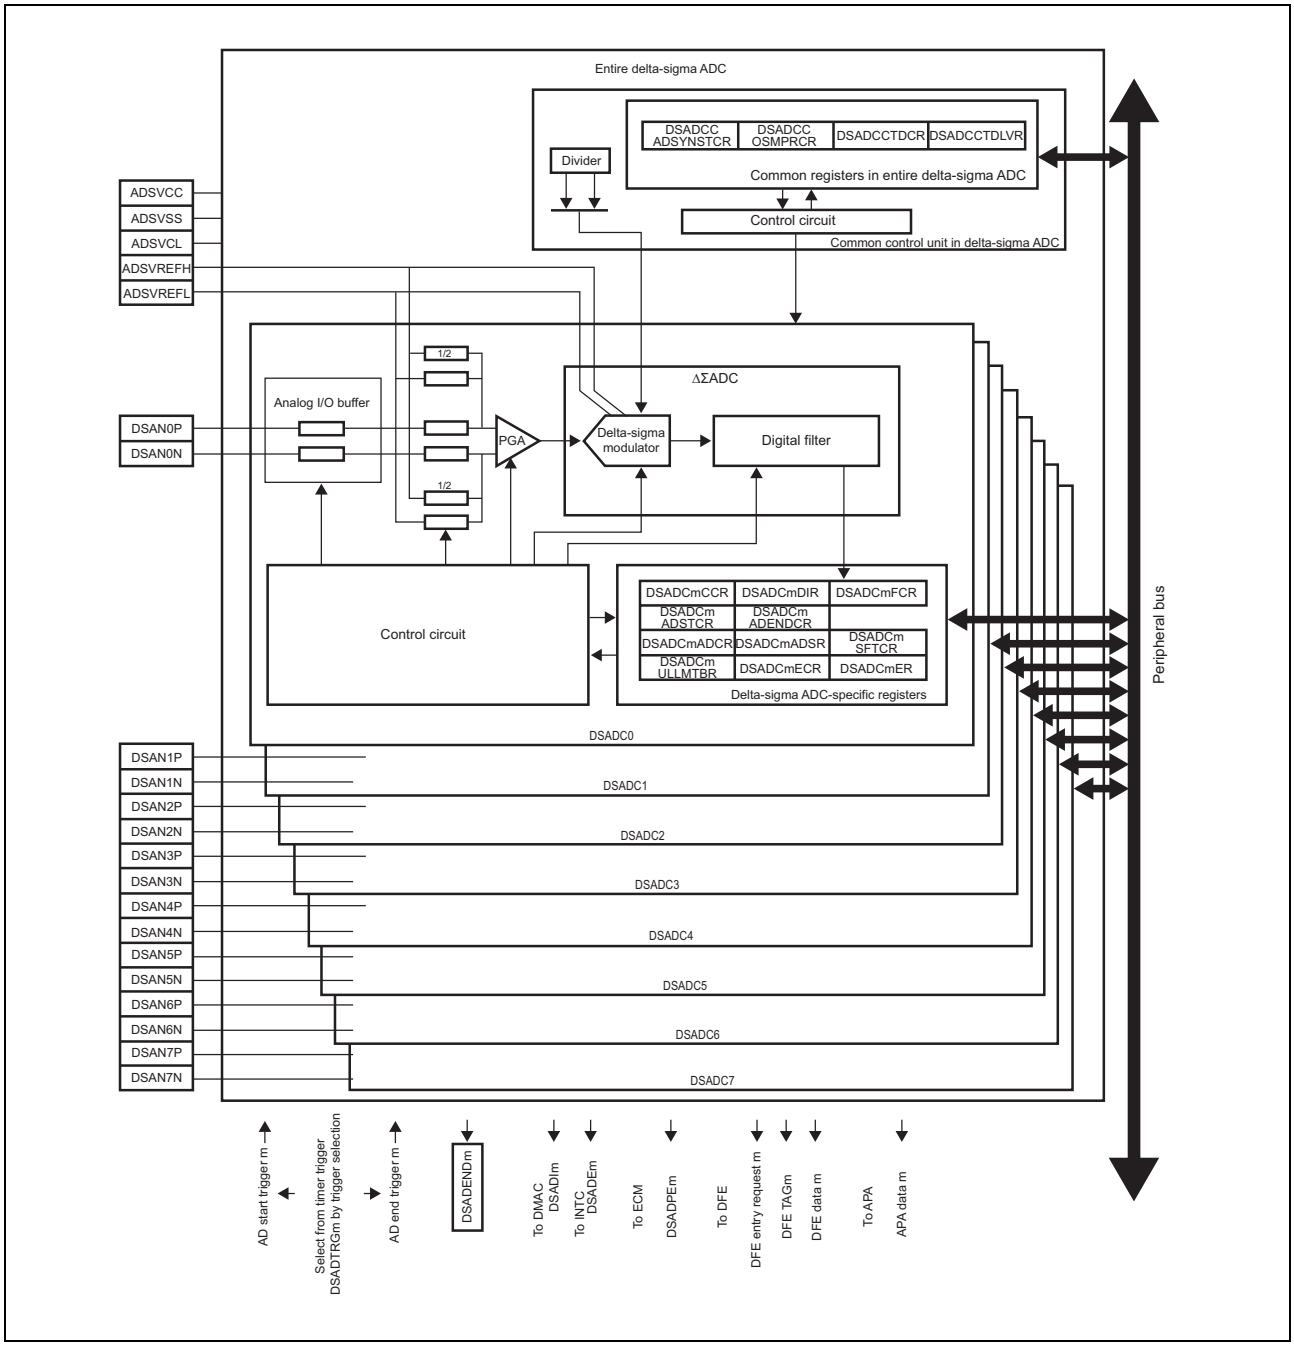

Figure 27.1 Block Diagram of Delta-Sigma ADC

Table 27.1 Delta-Sigma ADC Pin Configuration

Pin Name	I/O	Description
ADSVCC	Input	Analog block power supply pin
ADSVSS	Input	Analog block ground pin
ADSVREFH	Input	Analog block upper reference voltage pin
ADSVREFL	Input	Analog block lower reference voltage pin
ADSVCL	—	Delta-sigma ADC external capacitor pin
DSAN0P	Input	Analog pin 0P
DSAN0N	Input	Analog pin 0N
DSAN1P	Input	Analog pin 1P
DSAN1N	Input	Analog pin 1N
DSAN2P	Input	Analog pin 2P
DSAN2N	Input	Analog pin 2N
DSAN3P	Input	Analog pin 3P
DSAN3N	Input	Analog pin 3N
DSAN4P	Input	Analog pin 4P
DSAN4N	Input	Analog pin 4N
DSAN5P	Input	Analog pin 5P
DSAN5N	Input	Analog pin 5N
DSAN6P	Input	Analog pin 6P
DSAN6N	Input	Analog pin 6N
DSAN7P	Input	Analog pin 7P
DSAN7N	Input	Analog pin 7N
DSADTRG0	Input	External trigger pin (for DSADC0)
DSADTRG1	Input	External trigger pin (for DSADC1)
DSADTRG2	Input	External trigger pin (for DSADC2)
DSADTRG3	Input	External trigger pin (for DSADC3)
DSADTRG4	Input	External trigger pin (for DSADC4)
DSADTRG5	Input	External trigger pin (for DSADC5)
DSADTRG6	Input	External trigger pin (for DSADC6)
DSADTRG7	Input	External trigger pin (for DSADC7)
DSADEND0	Output	A/D conversion timing monitor pin (for DSADC0)
DSADEND1	Output	A/D conversion timing monitor pin (for DSADC1)
DSADEND2	Output	A/D conversion timing monitor pin (for DSADC2)
DSADEND3	Output	A/D conversion timing monitor pin (for DSADC3)
DSADEND4	Output	A/D conversion timing monitor pin (for DSADC4)
DSADEND5	Output	A/D conversion timing monitor pin (for DSADC5)
DSADEND6	Output	A/D conversion timing monitor pin (for DSADC6)
DSADEND7	Output	A/D conversion timing monitor pin (for DSADC7)

To ensure reliability of this LSI, the following relationship is required between ADSVCC and ADSVSS and VCC and VSS when using a delta-sigma ADC.

ADSVCC = 5 V ± 0.5 V, ADSVSS = VSS

When no delta-sigma ADC is used, do not leave the ADSVCC and ADSVSS pins open. The voltage to be applied to analog input pins must be within the following range.

ADSVREFL ≤ DSANkx (k = 0 to 7 x = P, N) ≤ ADSVREFH

27.3 Register Addresses

Table 27.2 Register Base Address (<DSADCcom_base>, <DSADCm_base>)

DSADCcom DSADCm	<DSADCcom_base> address <DSADCm_base> address

Error clear register	DSADCmECR	00_H	<DSADCm_base> + 20_H	8
Error register	DSADCmER	00_H	<DSADCm_base> + 24_H	8
Digital filter FIR control register	DSADCmFCR	00_H	<DSADCm_base> + 28_H	8

NOTE

DSADCcom_base: Common register base address

DSADCm_base: Specific register base address (DSADCm register)

m = 0 to 7

27.4 Common Registers for Delta-Sigma ADC

The following describes registers shared by all delta-sigma ADCs (DSADC0 to DSADC7).

27.4.1 DSADCCADSYNSTCR — AD Synchronization Start Control Register

DSADCCADSYNSTCR is an 8-bit write-only register to control simultaneous start of delta-sigma ADCs. This register is always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADSTART
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 27.4 DSADCCADSYNSTCR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	ADSTART	A/D Conversion Start of Delta-Sigma ADCs Condition for starting A/D conversion of DSADCm by ADSTART A value of 1 is written to ADSTART when ADTACT for DSADCm is 0 and ADSTARTE is 1. Delta-sigma ADCs for which ADSTARTE is set to 1 are activated simultaneously. While the setting of ADACT in DSADCm is 1, writing 1 to this bit is ignored and DSADCm continues A/D conversion in progress. While the setting of ADSTARTE in DSADCm is 0, writing 1 to this bit is ignored and DSADCm does not start A/D conversion. Writing 0 to this bit is ignored.

Note 1. m = 0 to 7

Note 2. It is recommended that ADSTART be written to while ENDTRGE for all the delta-sigma ADCs is 0 considering external trigger.

27.4.2 DSADCCOSMPRCR — Oversampling Rate Control Register

DSADCCOSMPRCR is an 8-bit readable/writable register to control the oversampling rate.
DSADCCOSMPRCR is initialized to 00_H by a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OSMPR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 27.5 DSADCCOSMPRCR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	OSMPR	Oversampling Rate This bit selects the oversampling rate. When a delta-signal ADC is to be used, be sure to set 1_B = 8 MHz. 0: Setting prohibited 1: 8 Msps

CAUTION

To prevent malfunction, DSADCCOSMPRCR should be set while ADACT for all delta-sigma ADCs is 0 (before starting A/D conversion) and STTRGE for all delta-sigma ADCs is 0.

27.4.3 DSADCCTDCR — Pin Level Self-Diagnosis Control Register

DSADCCTDCR is an 8-bit readable/writable register to control self-diagnosis of pin levels.
DSADCCTDCR is initialized to 00_H by a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TDE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 27.6 DSADCCTDCR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	TDE	Pin Level Self-Diagnosis Enable 0: Pin level self-diagnosis is disabled. 1: Pin level self-diagnosis is enabled. Setting TDE to 1 disconnects all analog pins from the input buffer. Clearing TDE to 0 connects all analog pins to the input buffer. When TDE is set to 1, DSANkx is fixed to the level specified by ANkxLV. The route from an analog pin to the delta-sigma ADC can be diagnosed by performing A/D conversion in this state and checking the A/D converted value.

Note 1. k = 0 to 7; x = P, N

CAUTION

To prevent malfunction, DSADCCTDCR should be set while ADACT for all delta-sigma ADCs is 0 (before starting A/D conversion) and STTRGE for all delta-sigma ADCs is 0.

27.4.4 DSADCCTDLVR — Pin Level Self-Diagnosis Level Setting Register

DSADCCTDLVR is a 16-bit readable/writable register to specify the level of pin-level self-diagnosis. DSADCCTDLVR is initialized to 0000_H by a reset.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AN7NLV	AN7PLV	AN6NLV	AN6PLV	AN5NLV	AN5PLV	AN4NLV	AN4PLV	AN3NLV	AN3PLV	AN2NLV	AN2PLV	AN1NLV	AN1PLV	AN0NLV	AN0PLV
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.7 DSADCCTDLVR Register Contents

Bit Position	Bit Name	Function
15 to 0	ANkxLV	Pin Level Self-Diagnosis Level 0: Discharges (ADSVSS) DSANkx. 1: Charges (ADSVCC) DSANkx.

Note 1. k = 0 to 7; x = P, N

CAUTION

To prevent malfunction, DSADCCTDLVR should be set while ADACT for all delta-sigma ADCs is 0 (before starting A/D conversion) and STTRGE for all delta-sigma ADCs is 0.

27.5 Delta-Sigma ADC-Specific Registers

The following describes specific registers of the individual delta-sigma ADCs (DSADC0 to DSADC7).

27.5.1 DSADCmCCR — Channel Control Register (m = 0 to 7)

DSADCmCCR is a 32-bit readable/writable register to control channels. DSADCmCCR is initialized to 0000 0000_H by a reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DFENT	—	DFTAG[3:0]				—	ULS	—	—	—	DSDFTYP	—	—	GAIN[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R	R/W	R	R	R	R/W	R	R	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DFMT[3:0]				—	—	CNVCLS[1:0]		—	—	—	—	GCTRL[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 27.8 DSADCmCCR Register Contents (1/2)

Bit Position	Bit Name	Function
31	DFENT	DFE Entry 0: Not entered 1: Entered This bit selects whether to perform entry to the DFE (digital filter engine).
30	—	Reserved This bit is always read as 0. The write value should always be 0.
29 to 26	DFTAG[3:0]	DFE-TAG These bits are used to perform entry to a channel of the DFE for which TAG identical to the setting of DFTAG[3:0] is set. If TAG matches the setting DFTAG[3:0] for multiple channels, entry to multiple channels is performed.
25	—	Reserved This bit is always read as 0. The write value should always be 0.
24	ULS	Upper-Limit/Lower-Limit Table Select 0: Upper-limit /lower-limit check is not performed. 1: Upper-limit /lower-limit check is performed by DSADCmULLMTBR. When the A/D converted value is stored in DR, upper-limit and lower-limit values are checked using the upper-limit/lower-limit table.
23 to 21	—	Reserved These bits are always read as 0. The write value should always be 0.
20	DSDFTYP	Delta-Sigma ADC Digital Filter Type This bit specifies the digital filter type of delta-sigma ADC. This bit is valid when Fovs = 8 Msps. 0: The digital filter type depends on the DSADCmFCR setting. Set the DSADCmFCR register. 1: Fs = 1.6 Msps; ENOB = 8 bits (usage example 4) Set the DSADCmFCR register to the initial value. (Fs: Sampling rate, ENOB = Valid bits) **CAUTION** ENOB is a value when gain ×1 and differential input are used.
19, 18	—	Reserved These bits are always read as 0. The write value should always be 0.

Table 27.8 DSADCmCCR Register Contents (2/2)

Bit Position	Bit Name	Function
17, 16	GAIN[1:0]	Gain These bits specify the input gain. 0_H: ×1 1_H: ×2 2_H: ×4 3_H: ×8
15 to 12	DFMT[3:0]	Data Format These bits specify the lower bits to be zero-masked (rounded in the -∞ direction). 0_H: Not masked 1_H: Lower 1 bit masked 2_H: Lower 2 bits masked 3_H: Lower 3 bits masked 4_H: Lower 4 bits masked 5_H: Lower 5 bits masked 6_H: Lower 6 bits masked 7_H: Lower 7 bits masked 8_H: Lower 8 bits masked Others: Setting prohibited The setting of these bits is the format of data for DR, DFE, and APA. For details of data format, see **Section 27.5.2, DSADCmDIR — Data Supplementary Information Register (m = 0 to 7)**.
11, 10	—	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	CNVCLS[1:0]	Conversion Type 0_H: Single-ended input, common = ADSVREFL 1_H: Single-ended input, common = ADSVREFH/2 2_H: Differential input 3_H: Self-diagnosis
7 to 4	—	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	GCTRL[3:0]	General-Purpose Control Write 0_H when self-diagnosis is not used (CNVCLS[1:0] ≠ 3_H). When self-diagnosis is used (CNVCLS = 3_H), GCTRL[3:0] are used to select the level of self-diagnosis. 7_H: ADSVREFH ×1 4_H: ADSVREFH ×1/2 0_H: ADSVREFH ×0 C_H: -ADSVREFH ×1/2 8_H: -ADSVREFH ×1 Others: Setting prohibited

CAUTIONS

1. To prevent malfunction, DSADCmCCR should be set while ADACT is 0 (before starting A/D conversion) and STTRGE is 0.
2. The filter type depends on the combination of DSADCCOSMPRCR, DSADCmCCR, and DSADCmFCR settings. Make appropriate settings to suit the purpose, as described in **Section 27.6.2, Setting Filter Type**.

27.5.2 DSADCmDIR — Data Supplementary Information Register (m = 0 to 7)

DSADCmDIR is a 32-bit read-only register to store A/D converted values and information incidental to A/D converted values. DSADCmDIR is cleared to 0000 0000_H by reading it while RDCLRE is set to 1. The WFLG bit is cleared to 0 by reading DSADCmDIR regardless of the setting of the RDCLRE bit. DSADCmDIR is initialized to 0000 0000_H by a reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	WFLG	PRTY	—	—	—	—	—			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DR															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.9 DSADCmDIR Register Contents

Bit Position	Bit Name	Function
31 to 26	—	Reserved These bits are always read as 0. The write value should always be 0.
25	WFLG	Write Flag Setting condition The A/D converted value is stored in DR. Clearing condition DSADCmDIR is read.
24	PRTY	Parity Even parity bit for DR.
23 to 16	—	Reserved These bits are always read as 0. The write value should always be 0.
15 to 0	DR[15:0]	These bits store A/D converted values. For the data format, see **(1), Bits 15 to 0: Data format of DR (data register)**.

(1) Bits 15 to 0: Data format of DR (data register)

AD converted values are stored in DR. **Table 27.10** shows the DR format. The same format applies to data to be transferred to the DFE (digital filter engine) and the APA (autonomous pulse adapter).

Table 27.10 Signed Fixed-Point Format

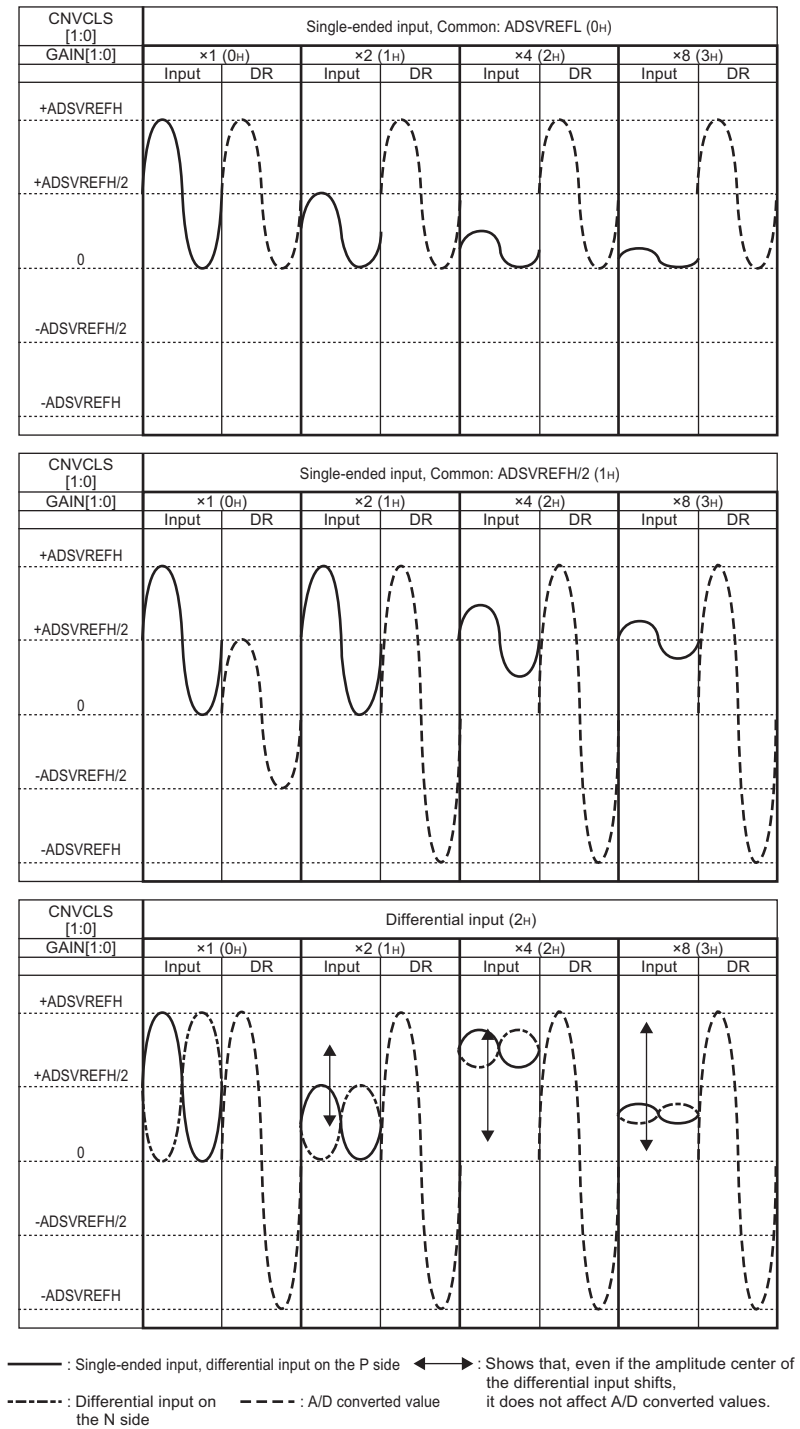

Figure 27.2 Input Range and Conversion Result Range at Each Gain

27.5.3 DSADCmADSTCR — AD Start Control Register (m = 0 to 7)

DSADCmADSTCR is an 8-bit write-only register to control starting delta-sigma ADCs. This register is always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 27.11 DSADCmADSTCR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	ADST	A/D Conversion Start Condition for starting A/D conversion by ADST Writing 1 to ADST when ADACT = 0 While ADACT = 1, writing 1 to this bit is ignored and A/D conversion in progress continues. Writing 0 to this bit is ignored.

Note: It is recommended that ADST be written to while ENDTRGE is 0 considering external trigger.

27.5.4 DSADCmADENDCR — AD Stop Control Register (m = 0 to 7)

DSADCmADENDCR is an 8-bit write-only register to control stopping delta-sigma ADCs. This register is always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADEND
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 27.12 DSADCmADENDCR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	ADEND	A/D Conversion Stop Condition for stopping A/D conversion by ADEND Writing 1 to ADEND when ADACT = 1 Writing 1 to this bit is ignored while ADACT = 0. Writing 0 to this bit is ignored.

Note: It is recommended that ADEND be written to while STTRGE is 0, taking external trigger.

27.5.5 DSADCmADCR — AD Control Register (m = 0 to 7)

DSADCmADCR is an 8-bit readable/writable register to control delta-sigma ADCs. DSADCmADCR is initialized to 00_H by a reset.

Bit	7	6	5	4	3	2	1	0
	—	ADSTARTE	—	ADIE	—	—	ENDTRGE	STTRGE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R	R/W	R	R	R/W	R/W

Table 27.13 DSADCmADCR Register Contents

Bit Position	Bit Name	Function
7	—	Reserved This bit is always read as 0. The write value should always be 0.
6	ADSTARTE	AD Synchronization Start Enable 0: ADSTART is disabled. 1: ADSTART is enabled.
5	—	Reserved This bit is always read as 0. The write value should always be 0.
4	ADIE	A/D Conversion End Interrupt Enable 0: Issuing DSADIm is disabled. 1: Issuing DSADIm is enabled.
3, 2	—	Reserved These bits are always read as 0. The write value should always be 0.
1	ENDTRGE	AD End Trigger Enable 0: AD end trigger m is disabled. 1: AD end trigger m is enabled. Trigger source selection of AD end trigger m is set by the trigger selection function. For details, see **Section 25.2, Trigger Selection Function (PIC2)**.
0	STTRGE	AD Start Trigger Enable 0: AD start trigger m is disabled. 1: AD start trigger m is enabled. Trigger source selection of AD start trigger m is set by the trigger selection function. For details, see **Section 25.2, Trigger Selection Function (PIC2)**.

Note 1. m = 0 to 7

CAUTIONS

1. To prevent malfunction, ADIE in DSADCmADCR should be set while ADACT is 0 (before starting A/D conversion) and STTRGE is 0.
2. To enable module standby, ENDTRGE and STTRGE must be 0. For details, see **Section 27.7.2, Module Standby Function**.

27.5.6 DSADCmADSR — AD Status Register (m = 0 to 7)

DSADCmADSR is an 8-bit read-only register that indicates delta-sigma ADC status. DSADCmADSR is initialized to 00_H by a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADACT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 27.14 DSADCmADSR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	ADACT	A/D Conversion Status 0: No A/D conversion source is present. 1: An A/D conversion source is present. This bit is set when an A/D conversion start source is generated (ADACT = 1) and cleared when an A/D conversion end source is generated (ADACT = 0).

CAUTION

To enable module standby, ADACT must be 0. For details, see **Section 27.7.2, Module Standby Function**.

27.5.7 DSADCmSFTCR — Safety Control Register (m = 0 to 7)

DSADCmSFTCR is an 8-bit readable/writable register associated with safety control.

DSADCmSFTCR is initialized to 00_H by a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	RDCLRE	ULEIE	OWEIE	PEIE	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R

Table 27.15 DSADCmSFTCR Register Contents

Bit Position	Bit Name	Function
7 to 5	—	Reserved These bits are always read as 0. The write value should always be 0.
4	RDCLRE	Read and Clear Enable 0: Reading DSADCmDIR does not clear DSADCmDIR. 1: Reading DSADCmDIR clears DSADCmDIR. **CAUTION** WFLG in DSADCmDIR is cleared by reading DSADCmDIR regardless of the RDCLRE value. To check clearing of the bit in DSADCmDIR by reading DSADCmDIR, read it after waiting for three read access cycles after DSADCmDIR is read. If DSADCmDIR is read without a wait, the value before clearing may be read. Since the relation between the bus clock frequency and the internal clock frequency is 1:2, a latency for clock synchronization will occur.
3	ULEIE	Upper-Limit /Lower-Limit Error Interrupt Enable 0: Disabled 1: Enabled
2	OWEIE	Overwrite Error Interrupt Enable 0: Disabled 1: Enabled
1	PEIE	Parity Error Interrupt Enable 0: Disabled 1: Enabled
0	—	Reserved These bits are always read as 0. The write value should always be 0.

CAUTION

To prevent malfunction, DSADCmSFTCR should be set while ADACT is 0 (before starting A/D conversion) and STTRGE is 0.

27.5.8 DSADCmULLMTBR — Upper-Limit/Lower-Limit Table Register (m = 0 to 7)

DSADCmULLMTBR is a 32-bit readable/writable register to set the upper-limit and lower-limit of A/D converted values. DSADCmULLMTBR is initialized to 7FFF 8000$_H$ by a reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ULMTB[15:0]															
Value after reset	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LLMTB[15:0]															
Value after reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.16 DSADCmULLMTBR Register Contents

Bit Position	Bit Name	Function
31 to 16	ULMTB[15:0]	Upper-Limit Table These bits specify the upper-limit of A/D converted values. When the following condition is met, ULE (upper-limit/lower-limit error) is set. ULMTB[15:0] < A/D converted value The ULMTB[15:0] format is the same as the DR format. Signed upper-limit value (2's complement) is compared. The A/D converted value is compared using the value before it is masked by DFMT[3:0].
15 to 0	LLMTB[15:0]	Lower-Limit Table These bits specify the lower-limit of A/D converted values. When the following condition is met, ULE (upper-limit/lower-limit error) is set. LLMTB[15:0] > A/D converted value The LLMTB[15:0] format is the same as the DR format. Signed lower-limit value (2's complement) is compared. The A/D converted value is compared using the value before it is masked by DFMT[3:0].

CAUTION

To prevent malfunction, DSADCmULLMTBR should be set while ADACT is 0 (before starting A/D conversion) and STTRGE is 0.

27.5.9 DSADCmECR — Error Clear Register (m = 0 to 7)

DSADCmECR is an 8-bit write-only register to control clearing errors. This register is always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	ULEC	OWEC	PEC	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	W	W	W	R

Table 27.17 DSADCmECR Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved These bits are always read as 0. The write value should always be 0.
3	ULEC	Upper-Limit/Lower-Limit Error Clear Writing 0: Does not clear an upper-limit or lower-limit error. Writing 1: Clears an upper-limit or lower-limit error.
2	OWEC	Overwrite Error Clear Writing 0: Does not clear an overwrite error. Writing 1: Clears an overwrite error.
1	PEC	Parity Error Clear Writing 0: Does not clear a parity error. Writing 1: Clears a parity error.
0	—	Reserved These bits are always read as 0. The write value should always be 0.

27.5.10 DSADCmER — Error Register (m = 0 to 7)

DSADCmER is an 8-bit read-only register that indicates an error. DSADCmER is initialized to 00_H by a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	ULE	OWE	PE	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 27.18 DSADCmER Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved These bits are always read as 0. The write value should always be 0.
3	ULE	Upper-Limit /Lower-Limit Error 0: No error occurred. 1: An error occurred. Setting condition The A/D converted value exceeds the specified range of the upper-limit/lower-limit table. Clearing condition Writing 1 to ULEC
2	OWE	Overwrite Error 0: No error occurred. 1: An error occurred. Setting condition The A/D converted value is written to DR when WFLG = 1. Clearing condition Writing 1 to OWEC
1	PE	Parity Error 0: No error occurred. 1: An error occurred. Setting condition A parity error is detected. Clearing condition Writing 1 to PEC
0	—	Reserved This bit is always read as 0. The write value should always be 0.

CAUTIONS

- Bits ULE and OWE are updated when the A/D converted value is written to DSADCmDIR. The PE bit is updated when DSADCmDIR is read.
- When an AD error interrupt request is generated, read DSADCmER in the interrupt exception handling and check bits being set to 1, and then clear them by using corresponding clear bits in DSADCmECR.

If error bits are not cleared and then an error occurs in the next A/D conversion, the following operation takes place, disabling error detection or identification.

1. When the same error (error bit = 1) occurs:
   No AD error interrupt request is sent. The relevant error bit in DSADCmER remains 1.
2. When a different error (error bit = 0) occurs:
   An AD error interrupt request is sent. The error bit set in the previous A/D conversion remains 1 and the relevant error bit in DSADCmER is set to 1.

27.5.11 DSADCmFCR — Digital Filter FIR Control Register (m = 0 to 7)

DSADCmFCR is an 8-bit readable/writable register to control the digital filter FIR. DSADCmFCR is initialized to 00_H by a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	ORT	—	TPVSL[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R/W	R/W	R/W

Table 27.19 DSADCmFCR Register Contents

Bit Position	Bit Name	Function
7 to 5	—	Reserved These bits are always read as 0. The write value should always be 0.
4	ORT	Digital Filter FIR Type Output Rate Select This bit is invalid when TPVSL[2:0] = 0_H (FIR is not used). 0: FIR output rate is halved. 1: FIR output rate is quartered. The output rate of this IP (general filter type) is determined by the combination of the DSADCCOSMPRCR.OSMPR and DSADCmFCR.DSDFTYP settings.
3	—	Reserved This bit is always read as 0. The write value should always be 0.
2 to 0	TPVSL[2:0]	Digital Filter FIR Use and Factor Select These bits are valid when DSADCmCCR.DSDFTYP = 0_H. For the factors, see **Table 27.20**. 0_H: Digital filter FIR is not used. 1_H: Digital filter FIR is used and factor 1 is applied. 2_H: Digital filter FIR is used and factor 2 is applied. 3_H to 7_H: Setting prohibited

CAUTIONS

1. The filter type depends on the combination of DSADCCOSMPRCR, DSADCmCCR, and DSADCmFCR settings. Make appropriate settings to suit the purpose, as described in **Section 27.6.2, Setting Filter Type**.
2. To prevent malfunction, DSADCmFCR should be set while ADACT is 0 (before starting AD conversion) and STTRGE is 0.

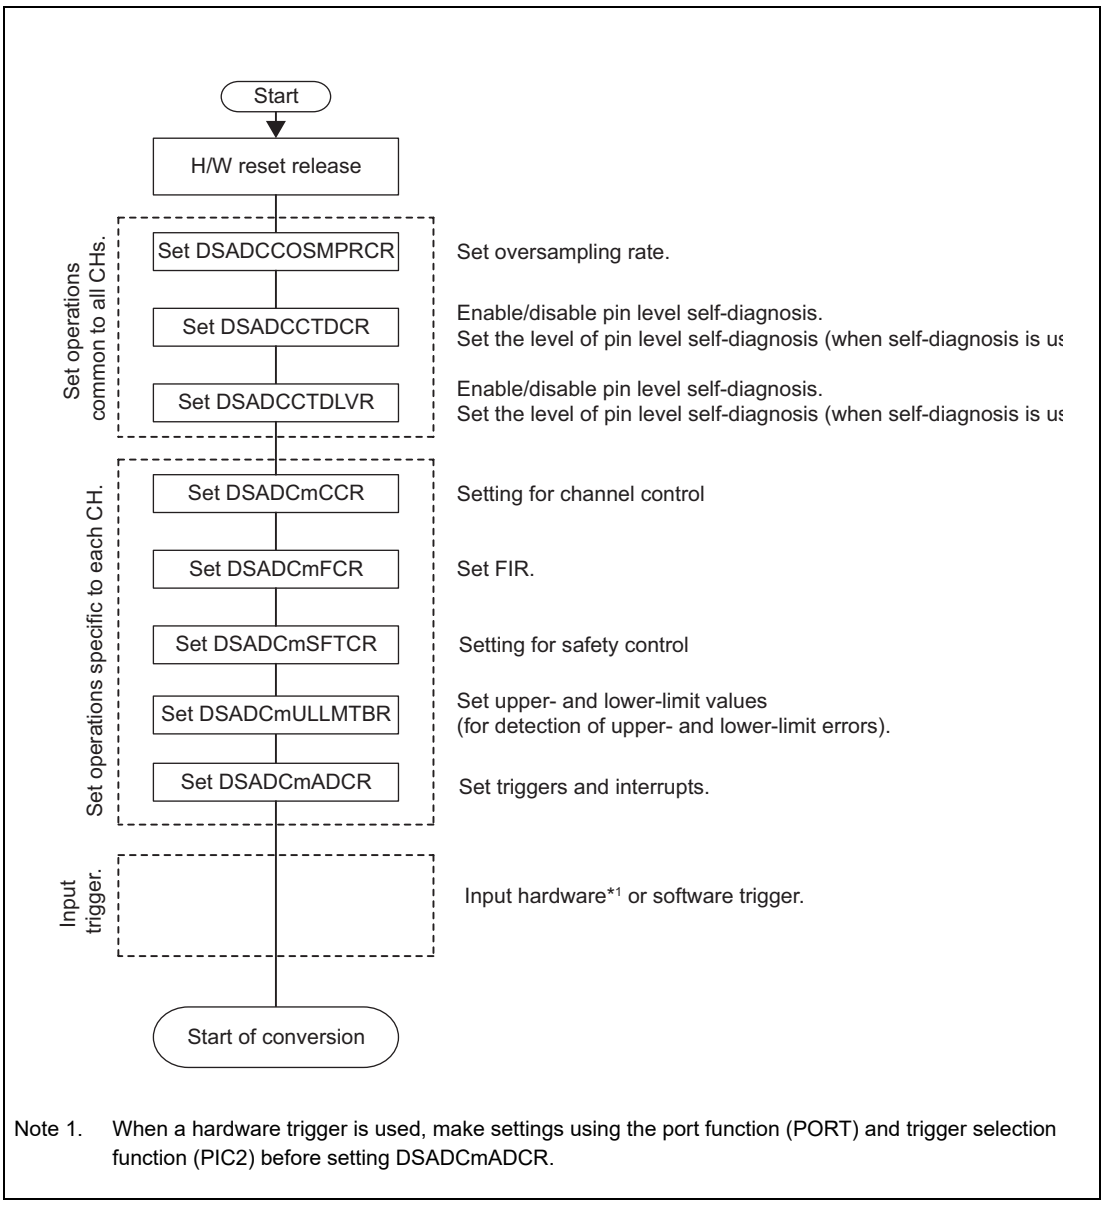
Table 27.20 Digital Filter FIR Factors

No.	Factor 1 (TPVSL = 1_H) BW = 30 kHz at 400 ksps	Factor 2 (TPVSL = 2_H) BW = 60 kHz at 400 ksps
0	681	1649
1	1940	5765
2	3911	10863
3	6089	12706
4	7674	8333
5	7890	101
6	6397	-5597
7	3581	-4689
8	417	349
9	-1978	3549
10	-2889	2155
11	-2320	-1082
12	-913	-2167
13	460	-577
14	1176	1082
15	1105	964
16	556	-170
17	-26	-694
18	-335	-298
19	-332	169
20	-210	228
21	58	-53

27.6 Operation

27.6.1 Initial Setting Flow

The delta-sigma ADC starts AD conversion by setting the registers as shown in **Figure 27.3**.



Note 1. When a hardware trigger is used, make settings using the port function (PORT) and trigger selection function (PIC2) before setting DSADCmADCR.

Figure 27.3 Initial Setting Flow

27.6.2 Setting Filter Type

The filter type depends on the combination of DSADCCOSMPRCR, DSADCmCCR, and DSADCmFCR settings. Make appropriate settings to suit the purpose, based on **Table 27.21**.

Table 27.21 Register Settings for Each Filter Type

Item	Usage Example 1	Usage Example 2	Usage Example 3	Usage Example 4
Target performance				
Fos	8 Msps	8 Msps	8 Msps	8 Msps
Fs	100 ksps	200 ksps	200 ksps	1.6 Msps
BW	30 kHz	30 kHz	60kHz	200 kHz
ENOB	13 bits	13 bits	13 bits	8 bits
Register settings				
DSADCCOSMPRCR.OSMPR	1_H	1_H	1_H	1_H
DSADCmCCR.DSDFTYP	0_H	0_H	0_H	1_H
DSADCmFCR.ORT	1_H	0_H	0_H	0_H
DSADCmFCR.TPVSL[2:0]	1_H	1_H	2_H	0_H

27.6.3 A/D Conversion Time

After the ADST bit in DSADCmADSTCR is set to 1 and then the A/D conversion start delay time (t_D) and the internal stabilization time (t_W) have passed, the delta-sigma ADC starts A/D conversion processing.

Figure 27.4 shows the A/D conversion start and end timing. **Figure 27.5** shows a budget for A/D conversion processing. The first A/D processing time (t_{AD}) includes A/D conversion start delay time (t_D), internal stabilization time (t_W), and digital filter processing delay time (t_{DF}).

The second and subsequent A/D conversion processing time (t_{AD}) is a sampling cycle (t_S). **Table 27.22** shows the A/D conversion processing time.

The following equation is used to calculate A/D conversion processing time (t_{AD}).

$$t_{AD} = t_D + t_W + t_{DF}$$

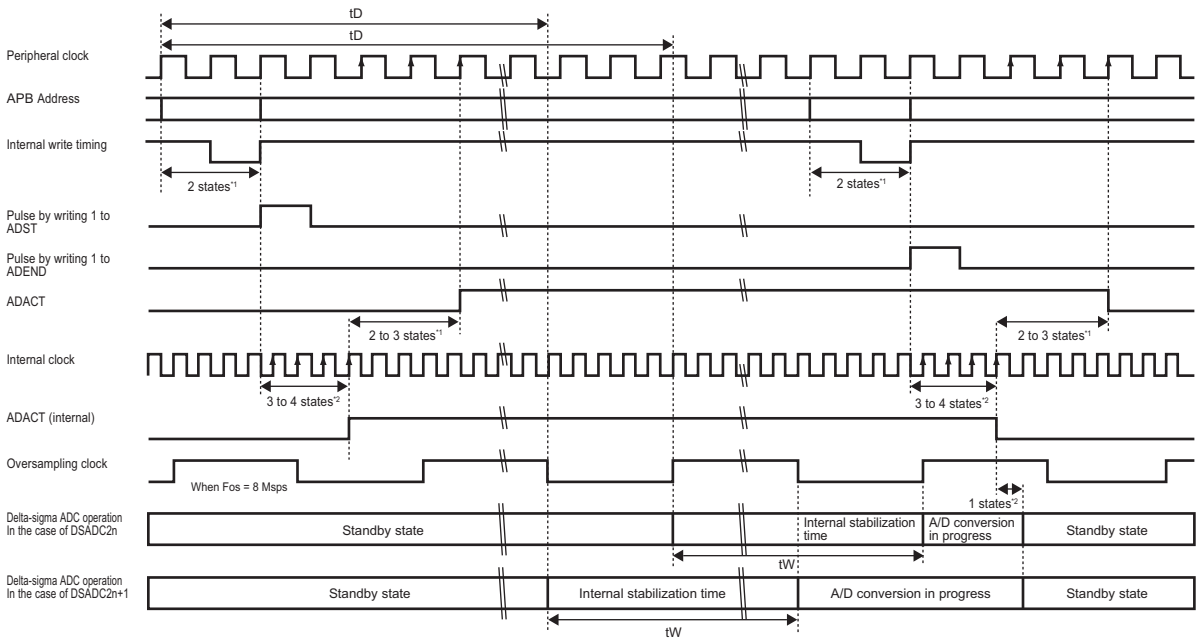
The second and subsequent t_{AD} is given by the following equation.

$$t_{AD} = t_S$$

Table 27.22 A/D Conversion Processing Time (Unit: Pϕ P-Bus Clock (40 MHz))

Item		Usage Example 1	Usage Example 2	Usage Example 3	Usage Example 4
A/D conversion processing time	t_{AD} (first time)	2595.5*1 to 2602.5*1	2595.5*1 to 2602.5*1	2595.5*1 to 2602.5*1	180.5*1 to 187.5*1
A/D conversion start delay time	t_D	16.5*1 to 23.5*1	16.5*1 to 23.5*1	16.5*1 to 23.5*1	16.5*1 to 23.5*1
Internal stabilization time	t_W	10	10	10	10
Digital filter processing delay time	t_{DF}	2569	2569	2569	154
A/D conversion processing time	t_{AD} (second or subsequent time)	400	200	200	25
Sampling cycle	t_S	400	200	200	25

Note 1. These values are for odd-numbered channels. The values for even-numbered channels are plus 2.5 bus clocks.



Note 1. Number of states of the peripheral clock

Note 2. Number of states of the internal clock

Note: n: 0 to 3, Fos: Oversampling rate

Figure 27.4 A/D Conversion Start and End

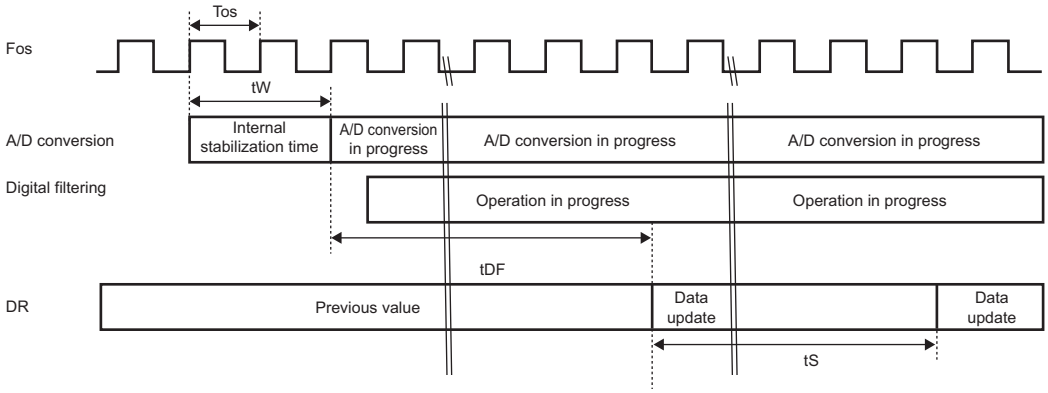


Figure 27.5 Budget for A/D Conversion Processing

27.6.4 Starting A/D Conversion by an External Trigger

DSADCm can be activated by the input of DSADTRGm. To activate DSADCm by DSADTRGm, set pin functions by the pin function controller (PFC) and select a trigger source of AD start trigger m by the trigger selection function. Input a high level to DSADTRGm and then set STTRGE in DSADCmADCR to 1. When a low level is input to DSADTRGm in this state, DSADCm detects a pulse's falling edge and sets ADACT to 1.

DSADCmADSR.ADACT is set to 1 when 3 or 4 internal clock states + 2 or 3 bus clock states have passed after the falling edge of DSADTRGm.

The timing after ADACT is set to 1 until DSADCm is activated is the same as when ADST is set to 1 by the software. For pin function settings, see **Section 2, Pins**. For selecting a trigger source of AD start trigger m, see **Section 25.2, Trigger Selection Function (PIC2)**.

To stop an active DSADCm, set ADEND in DSADCmADENDCR to 1.

27.6.5 Terminating A/D Conversion by an External Trigger

DSADCm can be deactivated by the input of DSADTRGm. To deactivate DSADCm by DSADTRGm, set pin functions by the pin function controller (PFC) and select a trigger source of AD start trigger m by the trigger selection function. Input a high level to DSADTRGm and then set ENDTRGE in DSADCmADCR to 1. When a low level is input to DSADTRGm in this state, DSADCm detects a pulse's falling edge and clears ADACT to 0 to deactivate DSADCm.

ADACT is cleared to 0 when 3 or 4 internal clock states + 2 or 3 bus clock states have passed after the falling edge of DSADTRGm.

For pin function settings, see **Section 2, Pins**. For selecting a trigger source of AD end trigger m, see **Section 25.2, Trigger Selection Function (PIC2)**.

NOTE

m = 0 to 7

27.6.6 Starting A/D Conversion by a Timer Trigger

DSADCm can be activated by a timer trigger. To activate DSADCm by a timer trigger, select a timer trigger as a trigger source of AD start trigger m by the trigger selection function. Then set STTRGE in DSADCmADCR to 1.

When the selected timer trigger is input in this state, ADACT is set to 1. The timing after the ADACT bit is set to 1 until DSADCm is activated is the same as when ADST is set to 1 by software.

For selecting a trigger source of AD start trigger m, see **Section 25.2, Trigger Selection Function (PIC2)**.

To stop an active DSADCm, set ADEND to 1.

NOTE

m = 0 to 7

27.6.7 Terminating A/D Conversion by a Timer Trigger

DSADCm can be deactivated by a timer trigger. To deactivate DSADCm by a timer trigger, select a timer trigger as a trigger source of AD end trigger m by the trigger selection function. Then set ENDTRGE in DSADCmADCR to 1.

When the selected timer trigger is input in this state, ADACT is cleared to 0 to deactivate DSADCm.

For selecting a trigger source of AD end trigger m, see **Section 25.2, Trigger Selection Function (PIC2)**.

NOTE

m = 0 to 7

27.6.8 Monitoring Using the A/D Conversion Monitor Pin

DSADENDm allows monitoring of A/D conversion of DSADCm. For pin settings, see **Section 2, Pins**.

Figure 27.6 shows an example of output from the A/D conversion monitor pin.

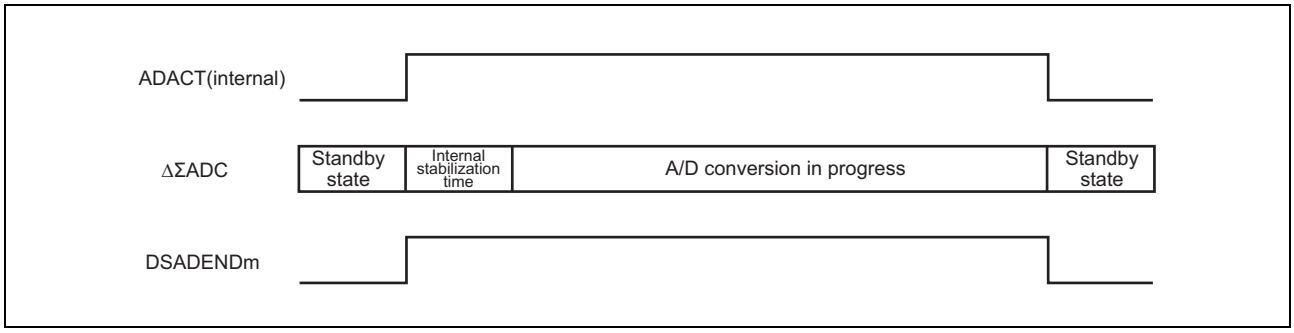

Figure 27.6 Example of A/D Conversion Monitor Pin Output

NOTE

m = 0 to 7

27.6.9 DMA Request Source

The delta-sigma ADC can generate a DMA request source (DSADIm) and send it to the DMAC to activate the DMAC (an interrupt for the INTC is not generated). Setting ADIE in DSADCmADCR to 1 outputs DSADIm at the end of the A/D conversion. Clearing ADIE to 0 disables DSADIm to be output even after the A/D conversion ends.

For settings of the DMAC, see **Section 7, DMA**.

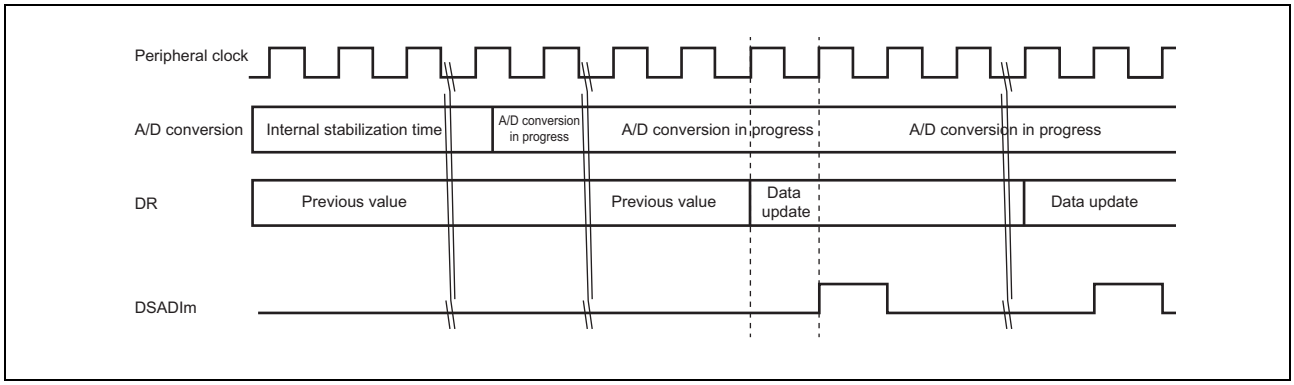

Figure 27.7 Example of DMA Request Source

NOTE

m = 0 to 7

27.6.10 AD Error Interrupt Request and AD Parity Error Notification

The delta-sigma ADC can issue an AD error interrupt request (DSADEm) to the INTC and also can issue an AD parity error notification (DSADPEm) to the error control module (ECM). The OR condition of the error source for which ULEIE and OWEIE in DSADCmSFTCR are set to 1 is issued as DSADEm. DSADEm of the error source being set to 0 can be disabled. Setting PEIE in DSADCmSFTCR to 1 enables DSADPEm, while clearing PEIE to 0 disables DSADPEm.

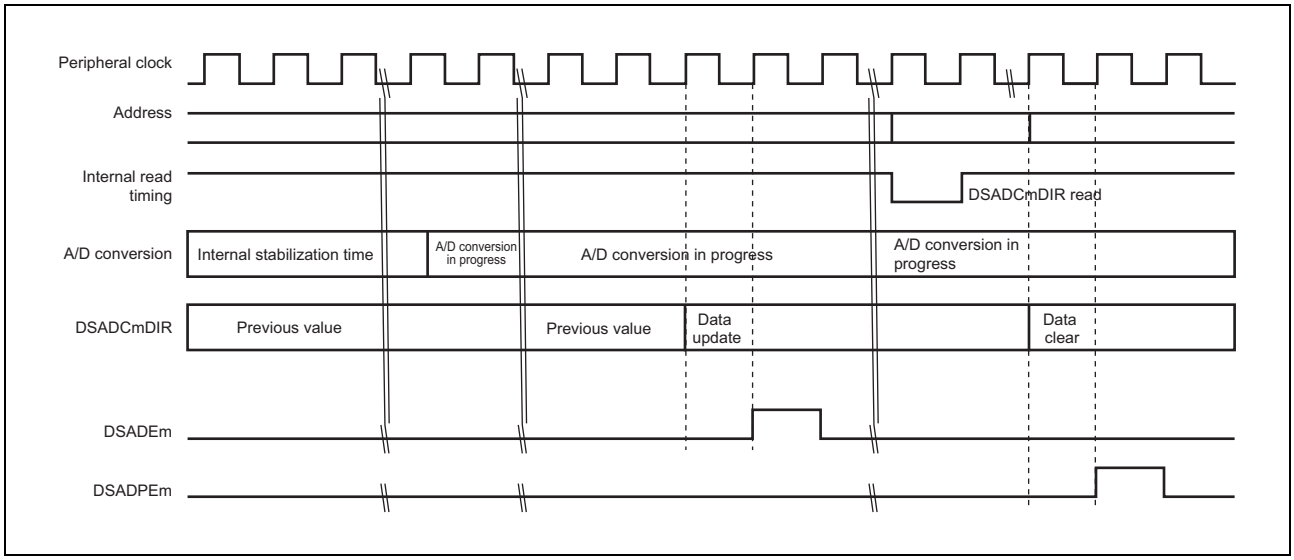

Figure 27.8 Example of Issuing of an AD Error Interrupt and AD Parity Error Notification

NOTE

m = 0 to 7

27.7 Usage Note

27.7.1 Notes on Using Analog Input Pins

Do not perform A/D conversion on the value of the same analog pin simultaneously by the delta-sigma ADC and SAR-ADC. Also, do not allow the delta-sigma ADC to perform A/D conversion on the value of the analog pin currently selected for digital input. It may lead to a deteriorated A/D accuracy.

When the delta-sigma ADC is used with single-ended input, only the analog input pins on the P side of the corresponding channel are used, and thus the analog input pins on the N side can be used for ADC input.

27.7.2 Module Standby Function

The delta-sigma ADC has the module standby function.

Module standby stops clock supply to the common units and all the channels altogether.

In addition, stop the clock for DSADC2 to 7 by setting the MSRFRAY.MS_DSAD2_7 bit of the module standby register.

To prevent malfunction, do not set module standby mode during A/D conversion or while A/D conversion start/end trigger is enabled.

- Before setting module standby mode, set the related channels as follows.
  - ADACT = 0, ENDTRGE = 0, and STTRGE = 0

Section 28 Digital Filter (DFE)

28.1 Overview

28.1.1 Features

- On-chip digital filtering (FIR/IIR) function for 16 channels
- Filter coefficients and data are stored in the on-chip RAM.
- Incorporates an accumulation circuit (for accumulation processing or decimation processing for filtered data) and a PH circuit (for peak hold processing or comparison processing).
- Generates an interrupt request when comparison calculation result is true.
- Inputs converted data from the on-chip A/D converter.

28.1.2 Overall Configuration

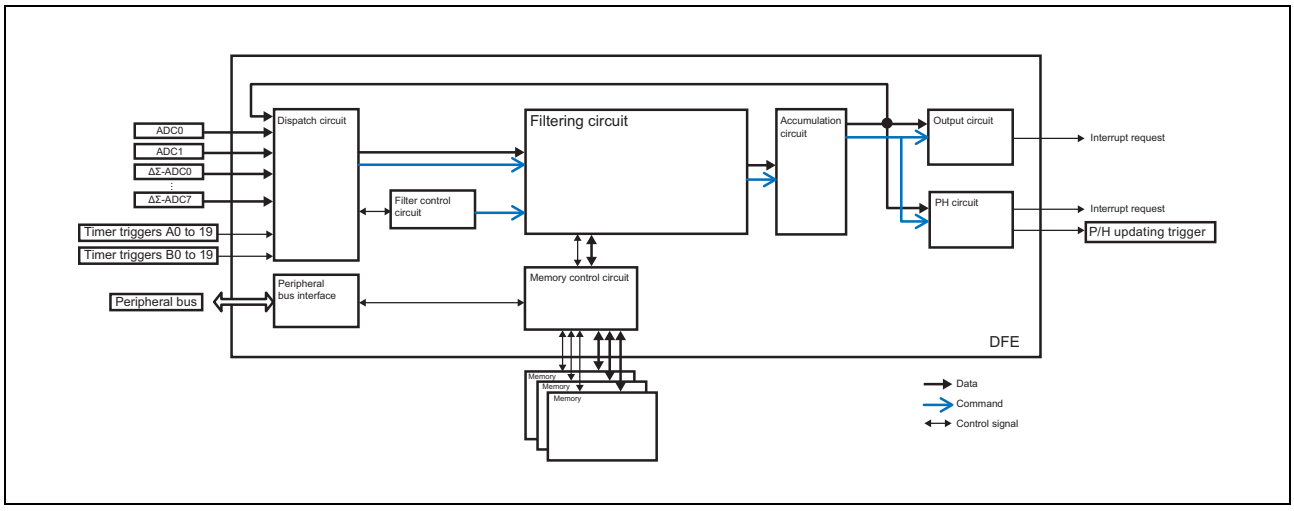

Figure 28.1 Overall Configuration of the DFE

The digital filter engine (DFE) is able to perform 16-channel filter processing on a time-division basis. FIR (up to 32 taps) or IIR (up to 6 stages) is selectable as a filter algorithm. When data is given from the A/D converter through the peripheral bus, the DFE performs FIR/IIR filter processing automatically. In normal mode, all filter processing results are stored in the output data register. In decimation mode, output data is stored in the output data register once every four filter processing, for example. When data is stored in the output data register, an interrupt request can be issued. Furthermore, the digital filter processing result can be input again to the filtering circuit.

28.1.3 Data Format

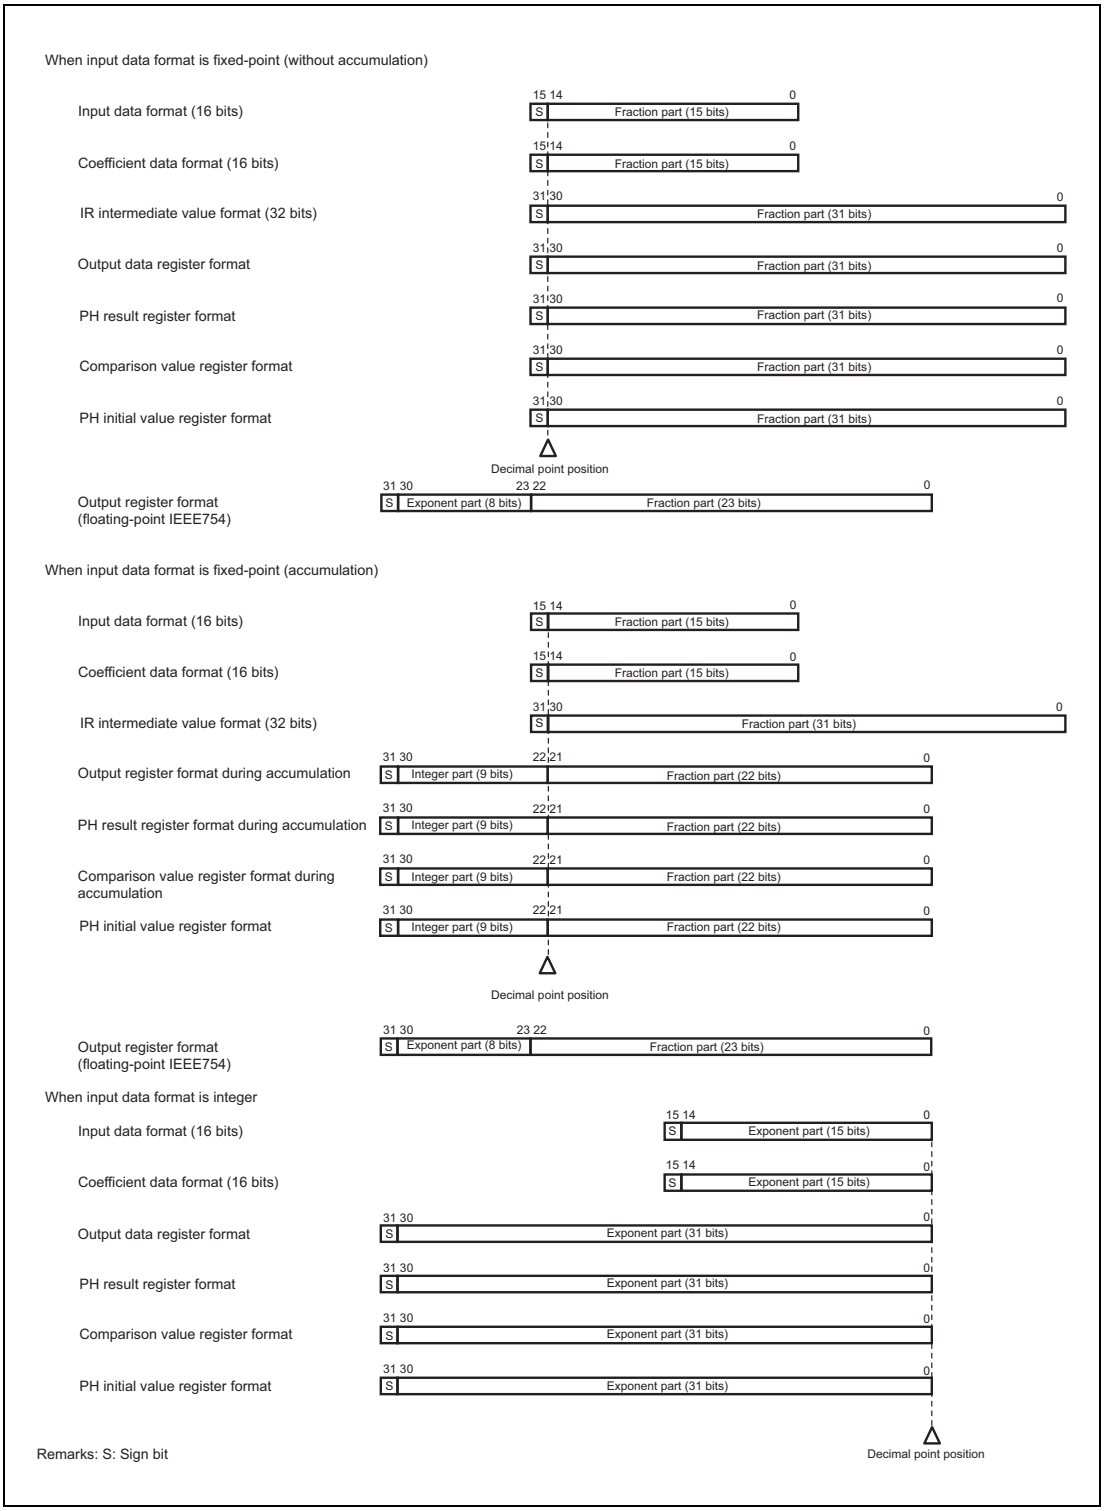

Figure 28.2 Data Format

28.1.4 Filtering Circuit

28.1.4.1 FIR Filter

- Number of taps: Selectable from 8, 16, 24, and 32
- Input data and coefficients: 16-bit signed fixed-point/16-bit integer
- Output data: 32-bit signed fixed-point/32-bit integer
- Product-sum operation accuracy: 32 bits

28.1.4.2 IIR Filter

- Number of secondary biquad stages: Selectable from 1, 2, and 3
- Input data and coefficients: 16-bit signed fixed-point data
- Intermediate data and output data: 32-bit signed fixed-point data
- Product-sum operation accuracy: 32 bits

28.1.5 Dispatch Circuit

The dispatch circuit accepts data to be filtered from the A/D converter and peripheral bus.

It assigns the accepted data to sixteen channels, then selects data to be filtered and outputs that data to the filter circuit. The data that can be input is specified for each channel. **Table 28.1** lists the data that can be input for each channel.

Table 28.1 Data that Can be Input for Each Channel

	ADC		Delta-Sigma AD Converter									
	0	1	0	1	2	3	4	5	6	7	Software	Cascade
CH0	√	√	√	√	√	×	×	×	×	×	√	√
CH1	√	√	√	√	×	√	×	×	×	×	√	√
CH2	√	√	√	√	×	×	√	×	×	×	√	√
CH3	√	√	√	√	×	×	×	√	×	×	√	√
CH4	√	√	√	√	×	×	×	×	√	×	√	√
CH5	√	√	√	√	×	×	×	×	×	√	√	√
CH6	√	√	√	√	√	×	×	×	×	×	√	√
CH7	√	√	√	√	×	√	×	×	×	×	√	√
CH8	√	√	√	√	×	×	√	×	×	×	√	√
CH9	√	√	√	√	×	×	×	√	×	×	√	√
CH10	√	√	√	√	×	×	×	×	√	×	√	√
CH11	√	√	√	√	×	×	×	×	×	√	√	√
CH12	√	√	√	√	√	×	×	×	×	×	√	√
CH13	√	√	√	√	×	√	×	×	×	×	√	√
CH14	√	√	√	√	×	×	√	×	×	×	√	√
CH15	√	√	√	√	×	×	×	√	×	×	√	√

Note: √ : Data can be input; ×: Data cannot be input

28.1.6 Accumulation Circuit

The accumulation circuit allows absolute value calculation, accumulation, and decimation processing for filtering results of all channels. Either accumulation or decimation can be specified.

- Absolute value: The absolute value of each filtering result is calculated.
- Accumulation: Accumulation of filtering results can be obtained. The maximum accumulation count is 511. Filtering results are of the S10.22 format. After accumulation processing for the predetermined number of times has been completed, one accumulation result is sent to the next processing.
- Decimation: Filtering results are decimated. If the decimation count is set to 4, for example, filtering result is output once every four filter processing. The maximum decimation count is 511.

28.1.7 PH Circuit

The PH circuit allows peak hold or comparison calculation for channels 0 to 9. The PH circuit can be linked to the accumulation circuit. For example, when accumulation/decimation is set with a specified count, peak hold processing or comparison calculation is performed on each specified count. When accumulation/decimation is not set, peak hold processing or comparison calculation is performed on each filter processing.

- Peak hold (PH): Peak hold processing of filtering results or accumulation circuit output results is possible. When the peak hold end flag is enabled, an interrupt can be requested. When the peak hold result registers are updated in the selected channels (two channels selectable), the PH update notification can be output.
- Comparison: A filtering result or accumulation circuit output result is compared with the predetermined value (=, <, >, ≥, ≤) and an interrupt can be requested according to condition match.

28.1.8 Output Circuit

In the output circuit, calculation results are stored in the output data register for each channel. When accumulation or decimation is specified, an interrupt can be requested at the same time when data is stored. In the case of input of fixed-point format data, the data format can be converted to the floating-point (IEEE754) format and the data can be stored in the output data register.

28.1.9 Terms

Table 28.2 provides definitions of terms used in this section.

Table 28.2 List of Terms (1/2)

Term	Definition in This Section
DFE operating clock	SSCG 80-MHz clock to be input to the DFE
Filtering circuit	A circuit to perform FIR filtering and IIR filtering
Data to be processed	Data for which the DFE performs filter processing, including data to be input by the AD and peripheral bus and filter processing result re-entry (cascade) data
Software input	Activation of the DFE by writing data to be processed to a register from the CPU or DMA through the peripheral bus
Input data register	A register for writing data to be processed, which is provided for 16 channels
DFE activation signal	DFE processing start signal to be input to the DFE together with data to be processed
AD tag	A tag value to be input to the DFE by the AD together with data to be processed
AD data	Data to be processed to be input to the DFE by the AD
AD input	AD tag or AD data or DFE activation signal to be input by the AD In figures, AD input shows DFE activation signal to be input by the AD.
Channel tag	A tag signal specified by the DFE's control register A, which is provided for each channel
Dispatch	Writing data to be processed to an input data register Dispatch means writing data to the input data register of the matched channel through comparison between channel tag and AD tag signal after processing is started by the DFE activation signal.
Dispatch circuit	A circuit to output filtering target data to the dispatch processing and filtering circuit
Accumulation	Accumulation of filter processing result data in each channel for the count specified in the control register
Decimation	Decimation (thinning) of filter processing result data for the count specified in the control register
Accumulation circuit	A circuit to perform absolute value calculation, accumulation, and decimation for filter processing result data
PH peak hold	Processing to hold the maximum of output data from the accumulation circuit
PH circuit	A circuit to perform PH processing and comparison processing
PH result register	A register that retains the PH processing result value
Output circuit	A circuit to write accumulation circuit output data to the output data register and to convert accumulation circuit output data to floating-point format data and write the data to the output data register
Output data register	A register used to write data after DFE processing is completed, which is provided for 16 channels
Input data overwrite error (DIOW)	An error that occurs when new data is written to the input data register while valid data is contained in the input data register (filter processing waiting state in the DFE, during filter processing, or during accumulation circuit processing)
Output data overwrite error (DOOW)	An error that occurs when new data is written to the output data register while valid data is contained in the output data register (after the DFE has written filter processing result or accumulation processing result to the output data register)
Multiplication error	An error that occurs during execution of 8000_H*8000_H in the filtering circuit
Guard error	A guard bit overflow or underflow error that occurs during execution of accumulation in the filtering circuit
Cascade error	An overflow error that occurs when 32-bit accumulation circuit output data is rounded to 16-bit data when cascade processing is enabled
Absolute value calculation error	An error to be generated when 8000_0000_H is input during calculation of absolute values in the accumulation circuit
Timer trigger	A trigger that is input from the timer.
Software trigger	A trigger generated by writing 1 to the software trigger register from the CPU or DMA

Table 28.2 List of Terms (2/2)

Term	Definition in This Section
Trigger flag	Five flags: accumulation/decimation initialization flag, accumulation/decimation disable flag, PH initialization flag, PH end flag, and filter initialization flag, which are generated by the DFE at a timer trigger, software trigger, or trigger setting register (control register in the DFE)
Accumulation/ decimation initialization flag	A trigger flag that functions as an accumulation initialization flag when accumulation is specified or as a decimation initialization flag when decimation is specified, which is used to initialize the counter in the accumulation circuit.
Accumulation/ decimation disable flag	A trigger flag that functions as an accumulation disable flag when accumulation is specified or as a decimation disable flag when decimation is specified, which stops the counter in the accumulation circuit and disables accumulation processing and decimation processing without updating output data after execution
PH initialization flag	A trigger flag that is enabled when PH is specified, which is used to initialize the counter in the PH circuit.
PH end flag	A trigger flag that is enabled when PH is specified, which is a command to terminate PH processing
Filter initialization flag	A trigger flag to be performed by adding the initialization sequence to initialization for the address pointer used in filter processing and normal filter processing.
Interrupt request	An interrupt to request activation of the interrupt controller, CPU (PCU), or DMA.

28.2 Control Registers

28.2.1 List of Registers

Table 28.3 lists registers and memory addresses of the DFE. All registers are accessible in 8, 16, or 32 bits. 32-bit write access to the coefficient memory is possible, and upper 16-bit or lower 16-bit or 32-bit write access to the data memory is possible.

Table 28.3 List of Control Registers (1/4)

Register address = FFBF 0000$_H$ + <offset address>

Offset Address	Register Name	Function	Access Size	R/W	Value after Reset
0000$_H$	CTLACH0	Control register A (Channel 0)	8, 16, 32	R/W	0000 0000$_H$
0004$_H$	CTLACH1	Control register A (Channel 1)	8, 16, 32	R/W	0000 0000$_H$
0008$_H$	CTLACH2	Control register A (Channel 2)	8, 16, 32	R/W	0000 0000$_H$
000C$_H$	CTLACH3	Control register A (Channel 3)	8, 16, 32	R/W	0000 0000$_H$
0010$_H$	CTLACH4	Control register A (Channel 4)	8, 16, 32	R/W	0000 0000$_H$
0014$_H$	CTLACH5	Control register A (Channel 5)	8, 16, 32	R/W	0000 0000$_H$
0018$_H$	CTLACH6	Control register A (Channel 6)	8, 16, 32	R/W	0000 0000$_H$
001C$_H$	CTLACH7	Control register A (Channel 7)	8, 16, 32	R/W	0000 0000$_H$
0020$_H$	CTLACH8	Control register A (Channel 8)	8, 16, 32	R/W	0000 0000$_H$
0024$_H$	CTLACH9	Control register A (Channel 9)	8, 16, 32	R/W	0000 0000$_H$
0028$_H$	CTLACH10	Control register A (Channel 10)	8, 16, 32	R/W	0000 0000$_H$
002C$_H$	CTLACH11	Control register A (Channel 11)	8, 16, 32	R/W	0000 0000$_H$
0030$_H$	CTLACH12	Control register A (Channel 12)	8, 16, 32	R/W	0000 0000$_H$
0034$_H$	CTLACH13	Control register A (Channel 13)	8, 16, 32	R/W	0000 0000$_H$
0038$_H$	CTLACH14	Control register A (Channel 14)	8, 16, 32	R/W	0000 0000$_H$
003C$_H$	CTLACH15	Control register A (Channel 15)	8, 16, 32	R/W	0000 0000$_H$
0040$_H$	CTLBCH0	Control register B (Channel 0)	8, 16, 32	R/W	0000 0000$_H$
0044$_H$	CTLBCH1	Control register B (Channel 1)	8, 16, 32	R/W	0000 0000$_H$
0048$_H$	CTLBCH2	Control register B (Channel 2)	8, 16, 32	R/W	0000 0000$_H$
004C$_H$	CTLBCH3	Control register B (Channel 3)	8, 16, 32	R/W	0000 0000$_H$
0050$_H$	CTLBCH4	Control register B (Channel 4)	8, 16, 32	R/W	0000 0000$_H$
0054$_H$	CTLBCH5	Control register B (Channel 5)	8, 16, 32	R/W	0000 0000$_H$
0058$_H$	CTLBCH6	Control register B (Channel 6)	8, 16, 32	R/W	0000 0000$_H$
005C$_H$	CTLBCH7	Control register B (Channel 7)	8, 16, 32	R/W	0000 0000$_H$
0060$_H$	CTLBCH8	Control register B (Channel 8)	8, 16, 32	R/W	0000 0000$_H$
0064$_H$	CTLBCH9	Control register B (Channel 9)	8, 16, 32	R/W	0000 0000$_H$

28.2.2 CTLACHn — Control Register A (n = 0 to 15)

This register is used to perform filter processing, control interrupt requests, and set channel tag and cascade tag for each channel.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.4 CTLACHn Register Contents (1/2)

Bit Position	Bit Name	Function
29 to 26	CATAG	Tag Value (Cascade Tag) for Reentering Filter Result (Cascade Input) 0000_B to 1111_B: These bits specify the tag value (CTLACHn.TAG) of the channel to which accumulation circuit output data is to be reentered (cascaded) during execution of cascade.
25, 24	CAEN	Cascade Enable 00_B: Cascade is disabled. Output data of the accumulation circuit is written to the output data register. (Initial value) 01_B: Setting prohibited 10_B: Cascade is enabled. Output data of the accumulation circuit is written to the output data register together with cascade. 11_B: Cascade is enabled. Output data of the accumulation circuit is not written to the output data register.
19 to 16	TAG	Channel Tag 0000_B to 1111_B: When specifying the channel for processing input data from each AD for this channel, set the same value as the AD tag value that is input from the AD. When specifying the input data processing channel when cascade is enabled, set the same value as the tag value (CTLA.CATAG) of the cascade output source. When specifying the software input data processing channel for this channel, set the same value as the tag value (DI.TAG) of software input.
15 to 12	CMD	Filter Processing Select 0000_B: FIR 8TAP (Initial value) 0001_B: FIR 16TAP 0010_B: FIR 24TAP 0011_B: FIR 32TAP 0100_B: Setting prohibited 0101_B: Setting prohibited 0110_B: Setting prohibited 0111_B: Setting prohibited 1000_B: IIR secondary biquad 1 stage 1001_B: IIR secondary biquad 2 stages 1010_B: IIR secondary biquad 3 stages 1011_B to 1111_B: Setting prohibited
8	FMT	Input Data Format Select 0: 16-bit fixed-point (Initial value) 1: 16-bit integer To perform IIR processing, accumulation processing, or floating-point processing, specify 16-bit fixed-point.

Table 28.4 CTLACHn Register Contents (2/2)

Bit Position	Bit Name	Function
6	IEE	Error Interrupt Request Enable 0: An error interrupt request is disabled. (Initial value) 1: An error interrupt request is enabled.
5	IEC	Condition Match Interrupt Request Enable 0: A PH end interrupt request is disabled when PH is specified. (Initial value) When comparison calculation is specified, an interrupt request when the comparison calculation result is true is disabled. (Initial value) 1: A PH end interrupt request is enabled when PH is specified. When comparison calculation is specified, an interrupt request when the comparison calculation result is true is enabled. **CAUTION** PH can be specified only for channels 0 to 9.
4	IEO	Output Data Interrupt Request Enable 0: An output data interrupt when calculation result is written to the output data register is disabled. (Initial value) 1: An output data interrupt when calculation result is written to the output data register is enabled.
0	EN	Channel Enable 0: Channel disabled No processing is performed in this channel. (Initial value) 1: Channel enabled Processing is performed in this channel.

28.2.3 CTLBCHn — Control Register B (n = 0 to 15)

This register is used to set floating-point conversion, absolute value conversion, accumulation/ decimation processing, and PH/comparison processing for each channel. For channels 0 to 9, all the control bits can be set. For channels 10 to 15, bits CTLBCHn.DISB, CTLBCHn.SELB2, CTLBCHn.SELB1, and CTLBCHn.PRCSB are not supported because these channels do not have the PH/comparison processing function.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.5 CTLBCHn Register Contents (1/3)

Bit Position	Bit Name	Function
24	DISB	PH Processing Disable (not supported by channels 10 to 15) 0: Indicates that PH processing is in progress or PH processing is enabled (Initial value) DISB is cleared to 0 when the following condition is satisfied while DISB is 1: – Reset input – The PH initialization flag is enabled by a timer trigger or a software trigger. At this time, DISB is automatically cleared to 0. – 0 is written to DISB by setting the register by the software. When DISB is 0, PH processing is started from the data that is input after CTLBCHn.PRCSB is set to 01_B (PH processing performed) and CTLACHn.EN is set to 1. 1: Indicates that PH processing is disabled DISB is set to 1 when the following condition is satisfied while DISB is 0: – The PH end flag is enabled by a timer trigger or a software trigger. At this time, DISB is automatically set to 1. – 1 is written to DISB by setting the register by the software. When DISB is 1, PH processing is not started until the PH initialization flag is enabled after CTLBCHn.PRCSB is set to 01_B (PH processing performed) and CTLACHn.EN is set to 1. **CAUTION** Writing to the DISB or DISA is prohibited while the CTLACHn.EN bit is 1 or the STCHn.VALID bit is 1.

Table 28.5 CTLBCHn Register Contents (2/3)

Bit Position	Bit Name	Function
16	DISA	Accumulation/Decimation Processing Disable 0: Indicates that accumulation/decimation processing is in progress or accumulation/decimation processing is enabled (Initial value) DISA is cleared to 0 when the following condition is satisfied while DISA is 1: – Reset input – The accumulation/decimation initialization flag is enabled by a timer trigger or a software trigger. At this time, DISA is automatically cleared to 0. – 0 is written to DISA by setting the register by the software. When DISA is 0, accumulation/decimation processing is started from the data that is input after CTLBCHn.PRCSA is set to 01_B (accumulation/decimation processing performed) and CTLACHn.EN is set to 1. 1: Indicates that accumulation/decimation processing is disabled DISA is set to 1 when the following condition is satisfied while DISA is 0: – The accumulation/decimation disable flag is enabled by a timer trigger or a software trigger. At this time, DISA is automatically set to 1. – 1 is written to DISA by setting the register by the software. When DISA is 1, accumulation/decimation processing is not started until the accumulation/decimation initialization flag is enabled after CTLBCHn.PRCSA is set to 01_B (accumulation or decimation processing performed) and CTLACHn.EN is set to 1. **CAUTION** Writing to the DISB or DISA is prohibited while the CTLACHn.EN bit is 1 or the STCHn.VALID bit is 1.
15	PRCSC	Floating-Point Conversion 0: Floating-point conversion is not performed. (Initial value) 1: Floating-point conversion is performed. Fixed-point format (1.31/10.22) is converted to floating-point (IEEE754). This bit must not be set to 1 while the FMT bit in CTLACHn is 1 (integer mode).
14 to 12	SELB2	PH Initialization Value Register Select (not supported by channels 10 to 15) When PH is specified (CTLBCHn.PRCSB = 01_B) 000_B: PHIA register value is selected for the initial value of PH processing. (Initial value) 001_B: PHIB register value is selected for the initial value of PH processing. 010_B: PHIC register value is selected for the initial value of PH processing. 011_B: PHID register value is selected for the initial value of PH processing. 100_B to 111_B: Setting prohibited Comparison Calculation Select (not supported by channels 10 to 15) When comparison is specified (CTLBCHn.PRCSB = 10_B) 000_B: “Equal to (==)” is selected. Calculation of “equal to (==)” for the comparison target register selected by CTLBCHn.SELB1 and PH circuit input data is performed. (Initial value) 001_B: “Equal to or less than (≤)” is selected. Calculation of “equal to or less than (≤)” for the comparison target register selected by CTLBCHn.SELB1 and PH circuit input data is performed. 010_B: “Equal to or more than (≥)” is selected. Calculation of “equal to or more than (≥)” for the comparison target register selected by CTLBCHn.SELB1 and PH circuit input data is performed. 011_B: “Less than (≤)” is selected. Calculation of “less than (<)” for the comparison target register selected by CTLBCHn.SELB1 and PH circuit input data is performed. 100_B: “More than (≥)” is selected. Calculation of “more than (>)” for the comparison target register selected by CTLBCHn.SELB1 and PH circuit input data is performed. 101_B to 111_B: Setting prohibited **CAUTION** PH and comparison calculation can be specified only for channels 0 to 9.

Table 28.5 CTLBCHn Register Contents (3/3)

Bit Position	Bit Name	Function
11, 10	SELB1	Comparison Target Register Select (not supported by channels 10 to 15) 00_B: CPA register value is selected for the comparison calculation target value. (Initial value) 01_B: CPB register value is selected for the comparison calculation target value. 10_B: CPC register value is selected for the comparison calculation target value. 11_B: CPD register value is selected for the comparison calculation target value.
9, 8	PRCSB	PH Circuit Processing Select (not supported by channels 10 to 15) 00_B: Neither PH processing nor comparison calculation processing is performed. (Initial value) 01_B: PH processing is performed. 10_B: Comparison calculation processing is performed. 11_B: Setting prohibited
5, 4	SELA	Accumulation/Decimation Count Register Select 00_B: ACA value is selected for the accumulation/decimation count. (Initial value) 01_B: ACB value is selected for the accumulation/decimation count. 10_B: ACC value is selected for the accumulation/decimation count. 11_B: ACD value is selected for the accumulation/decimation count.
2	ABS	Absolute Value Calculation 0: Absolute value calculation for filter result is not performed. (Initial value) 1: Absolute value calculation for filter result is performed.
1, 0	PRCSA	Accumulation Circuit Processing Select 00_B: Neither accumulation processing nor decimation processing is performed. (Initial value) 01_B: Accumulation processing is performed. 10_B: Decimation processing is performed. 11_B: Setting prohibited

28.2.4 DOCHn — Output Data Register (n = 0 to 15)

This register is used to store the calculation result for each channel after DFE processing has been completed.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 0	PH	PH Result Data These bits show the PH processing calculation result.

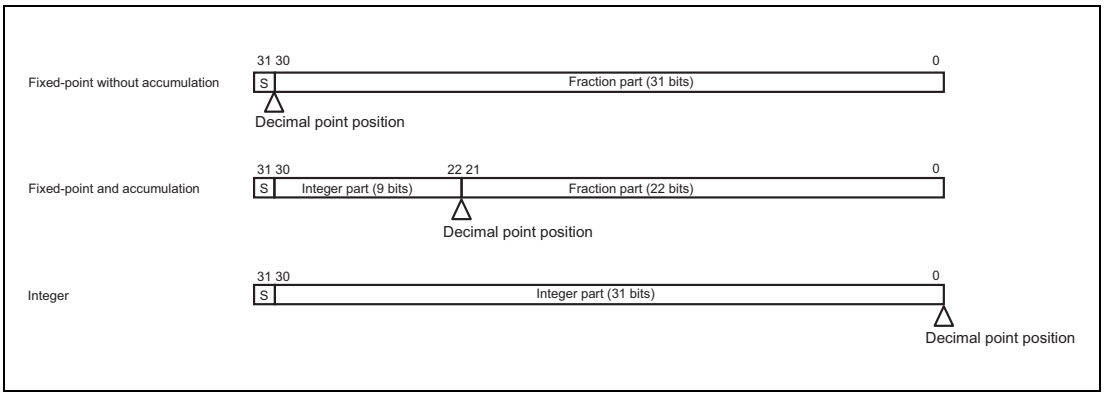

Figure 28.4 Format of PH Result Register Value

28.2.6 STCHn — Status Register (n = 0 to 15)

This register is used to indicate channel status. For channels 0 to 9, all the status bits are valid. For channels 10 to 15, STCHn.CND is not supported because these channels do not have the PH/ comparison processing function.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	VALID	—	—	CND	DOEN	—	—	CER	AER	MER	GER	DOOW	DIOW
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.8 STCHn Register Contents (1/2)

Bit Position	Bit Name	Function
12	VALID	Input Data Register Valid 0: Input data register value is invalid. This indicates that there is no data to be processed. (Initial value) 1: Input data register value is valid. This bit is set to 1 when data to be processed is input to the input data register, and is cleared to 0 when the data has been processed in the accumulation circuit.
9	CND	Condition Match (not supported by channels 10 to 15) When PH is specified (CTLBCHn.PRCSB = 01_B) 0: Initial value Setting CCND in the clear status register to 1 when CLRCND = 1 clears this bit to 0. 1: PH processing completed This bit is set to 1 while CND = 0 or when the PH end flag is executed. When comparison is specified (CTLBCHn.PRCSB = 10_B) 0: Initial value Setting CCND in the clear status register to 1 when CLRCND = 1 clears this bit to 0. 1: Comparison calculation result is true. This bit is set to 1 when the comparison calculation result is true while CND = 0. **CAUTION** PH and comparison calculation can be specified only for channels 0 to 9.
8	DOEN	Output Data Register Valid 0: Indicates that the output data register value is invalid. (Initial value) Setting CDOEN in the clear status register to 1 when CLRDOEN = 1 clears this bit to 0. Reading the DOCHn register when DOEN = 1 clears this bit to 0. 1: Indicates that the output data register value is valid. This bit is set to 1 when the DFE writes the calculation result data to the output data register while CTLBCHn.PRCSA is 01_B (accumulation) or CTLBCHn.PRCSA is 10_B (decimation).
5	CER	Cascade Rounding Error 0: No cascade rounding error is present. (Initial value) Setting CCER in the clear status register to 1 when CLRCER = 1 clears this bit to 0. 1: A cascade rounding error is present. This bit is set to 1 when an overflow occurs when the 32-bit accumulation circuit output data is rounded to 16-bit data when cascade is specified (CTLA.CAEN = 10_B or 11_B).

Table 28.8 STCHn Register Contents (2/2)

Bit Position	Bit Name	Function
4	AER	Absolute Value Calculation Error 0: No absolute value calculation error is present. (Initial value) Setting CAER in the clear status register to 1 when CLRAER = 1 clears this bit to 0. 1: An absolute value calculation error is present. This bit is set to 1 when the accumulation circuit input data is 8000 0000_H when absolute value calculation is specified (CTLB.ABS = 1).
3	MER	Multiplication Error 0: No multiplication error is present. (Initial value) Setting CMER in the clear status register to 1 when CLRMER = 1 clears this bit to 0. 1: A multiplication error is present. This bit is set to 1 when multiplication 8000_H*8000_H is performed in the filtering circuit.
2	GER	Guard Error 0: No guard error is present. (Initial value) Setting CGER in the clear status register to 1 when CLRGER = 1 clears this bit to 0. 1: A guard error is present. This bit is set to 1 when an overflow or underflow occurs when the accumulation result is rounded to 32 bits in the filter circuit.
1	DOOW	Output Data Overwrite Error 0: No output data overwrite error is present. (Initial value) Setting CDOOW in the clear status register to 1 when CLRDOOW = 1 clears this bit to 0. 1: An output data overwrite error is present. This bit is set to 1 when a value is written to the output data register while the output data register contains a valid value (DOEN = 1) while CTLBCHn.PRCSA is 01_B (accumulation) or CTLBCHn.PRCSA is 10_B (decimation).
0	DIOW	Input Data Overwrite Error 0: No input data overwrite is present. (Initial value) Setting CDIOW in the clear status register to 1 when CLRDIOW = 1 clears this bit to 0. 1: An input data overwrite error is present. This bit is set to 1 when a value is written to the input data register while the input data register contains a valid value (VALID = 1).

28.2.7 CLRSTCHn — Clear Status Register (n = 0 to 15)

This register is used to clear the status register. Writing 1 to each clear bit clears the corresponding bit in STCHn to 0. For channels 0 to 9, all the clear bits are valid. For channels 10 to 15, STCHn.CLRCND is not supported because these channels do not have the PH/comparison processing function.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CLRCND	CLRDOEN	—	—	CLRCER	CLRAER	CLRMER	CLRGER	CLRDOOW	CLRDIOW
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.9 CLRSTCHn Register Contents

Bit Position	Bit Name	Function
9	CLRCND	Condition Match Bit Clear (not supported by channels 10 to 15) 0: STCHn.CND is not cleared. (Initial value) 1: STCHn.CND is cleared. When STCHn.CND is cleared, this bit is automatically cleared to 0. This bit is always read as 0.
8	CLRDOEN	Output Data Enable Bit Clear 0: STCHn.DOEN is not cleared. (Initial value) 1: STCHn.DOEN is cleared. When STCHn.DOEN is cleared, this bit is automatically cleared to 0. This bit is always read as 0.
5	CLRCER	Cascade Rounding Error Bit Clear 0: STCHn.CER is not cleared. (Initial value) 1: STCHn.CER is cleared. When STCHn.CER is cleared, this bit is automatically cleared to 0. This bit is always read as 0.
4	CLRAER	Absolute Value Calculation Error Bit Clear 0: STCHn.AER is not cleared. (Initial value) 1: STCHn.AER is cleared. When STCHn.AER is cleared, this bit is automatically cleared to 0. This bit is always read as 0.
3	CLRMER	Multiplication Error Bit Clear 0: STCHn.MER is not cleared. (Initial value) 1: STCHn.MER is cleared. When STCHn.MER is cleared, this bit is automatically cleared to 0. This bit is always read as 0.
2	CLRGER	Guard Error Bit Clear 0: STCHn.GER is not cleared. (Initial value) 1: STCHn.GER is cleared. When STCHn.GER is cleared, this bit is automatically cleared to 0. This bit is always read as 0.
1	CLRDOOW	Output Data Register Overwrite Error Bit Clear 0: STCHn.DOOW is not cleared. (Initial value) 1: STCHn.DOOW is cleared. When STCHn.DOOW is cleared, this bit is automatically cleared to 0. This bit is always read as 0.
0	CLRDIOW	Input Data Register Overwrite Error Bit Clear 0: STCHn.DIOW is not cleared. (Initial value) 1: STCHn.DIOW is cleared. When STCHn.DIOW is cleared, this bit is automatically cleared to 0. This bit is always read as 0.

28.2.8 ERMCHn — Error Mask Register (n = 0 to 15)

This register is used to mask errors.

Bit	7	6	5	4	3	2	1	0
	—	—	MSKCER	MSKAER	MSKMER	MSKGER	MSKDOOW	MSKDIOW
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.10 ERMCHn Register Contents

Bit Position	Bit Name	Function
5	MSKCER	Cascade Rounding Error Bit (STCHn.CER) Mask 0: The cascade rounding error bit (STCHn.CER) is not masked. (Initial value) 1: The cascade rounding error bit (STCHn.CER) is masked.
4	MSKAER	Absolute Value Calculation Error Bit (STCHn.AER) Mask 0: The absolute value calculation error bit (STCHn.AER) is not masked. (Initial value) 1: The absolute value calculation error bit (STCHn.AER) is masked.
3	MSKMER	Multiplication Error Bit (STCHn.MER) Mask 0: The multiplication error bit (STCHn.MER) is not masked. (Initial value) 1: The multiplication error bit (STCHn.MER) is masked.
2	MSKGER	Guard Error Bit (STCHn.GER) Mask 0: The guard error bit (STCHn.GER) is not masked. (Initial value) 1: The guard error bit (STCHn.GER) is masked.
1	MSKDOOW	Output Data Overwrite Error Bit (STCHn.DOOW) Mask 0: The output data overwrite error bit (STCHn.DOOW) is not masked. (Initial value) 1: The output data overwrite error bit (STCHn.DOOW) is masked.
0	MSKDIOW	Input Data Overwrite Error Bit (STCHn.DIOW) Mask 0: The input data overwrite error bit (STCHn.DIOW) is not masked. (Initial value) 1: The input data overwrite error bit (STCHn.DIOW) is masked.

28.2.9 TRGCHn — Trigger Setting Register (n = 0 to 15)

This register is used to set generation of trigger flags by using software triggers or timer triggers. It is prohibited to set both the initialization flag and end flag as a software trigger for the PH processing. Furthermore, it is prohibited to set both the initialization flag and the disable flag as a software trigger for the accumulation/decimation processing. Any operation under prohibited settings is not guaranteed. For channels 10 to 15, bits TRGCHn.PFE, TRGCHn.PE, and TRGCHn.PT are not supported because these channels do not have the PH/comparison processing function.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	PFE		—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AFE		—	—	PE		PT		AE		AT		FE		FT	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.11 TRGCHn Register Contents (1/2)

Bit Position	Bit Name	Function
19, 18	PFE	PH End Flag Trigger Setting (not supported by channels 10 to 15) 00_B: The PH end flag is not generated. (Initial value) 01_B: The PH end flag is generated by a timer trigger. 10_B: The PH end flag is generated by a software trigger. 11_B: Setting prohibited These bits disable both PH initialization flag and PH end flag to be set as a software trigger (Setting both PE and PFE bits in TRGCHn to 10_B is prohibited.) When the PH end flag is generated by a timer trigger (TRGCHn.PFE = 01_B), the PH end flag is automatically selected from among the compare-match B interrupt signals from the ATU4 which correspond to (have the same channel number in the same subblock of timer D as) the timer trigger (one of the 20 compare-match A interrupt signals from timer D of the ATU4) selected by the PH initialization flag timer trigger select bit (TRGCHn.PT).
15, 14	AFE	Accumulation/Decimation Disable Flag Trigger Setting 00_B: The accumulation/decimation disable flag is not generated. (Initial value) 01_B: The accumulation/decimation disable flag is generated by a timer trigger. 10_B: The accumulation/decimation disable flag is generated by a software trigger. 11_B: Setting prohibited These bits disable both accumulation/decimation initialization flag and accumulation/decimation disable flag to be set as a software trigger. (Setting both AE and AFE bits in TRGCHn to 10_B is prohibited.) When the accumulation/decimation disable flag is generated by a timer trigger (TRGCHn.AFE = 01_B), the accumulation/decimation disable flag is automatically selected from among the compare-match B interrupt signals from the ATU4 which correspond to (have the same channel number in the same subblock of timer D as) the timer trigger (one of the 20 compare-match A interrupt signals from timer D of the ATU4) selected by the accumulation/decimation initialization flag timer trigger select bit (TRGCHn.AT).

Table 28.11 TRGCHn Register Contents (2/2)

Bit Position	Bit Name	Function
11, 10	PE	PH Initialization Flag Trigger Setting 00_B: The PH initialization flag is not generated. (Initial value) 01_B: The PH initialization flag is generated by a timer trigger. 10_B: The PH initialization flag is generated by a software trigger. 11_B: Setting prohibited These bits disable both PH initialization flag and PH end flag to be set as a software trigger. (Setting both PE and PFE bits in TRGCHn to 10_B is prohibited.)
9, 8	PT	PH Initialization Flag and PH End Flag Timer Trigger Select (not supported by channels 10 to 15) 00_B: Timer trigger 0 is selected for generating the PH initialization flag and PH end flag. (Initial value) 01_B: Timer trigger 1 is selected for generating the PH initialization flag and PH end flag. 10_B: Timer trigger 2 is selected for generating the PH initialization flag and PH end flag. 11_B: Timer trigger 3 is selected for generating the PH initialization flag and PH end flag. These bits are valid when the PH initialization flag trigger setting bit (TRGCHn.PE) or the PH end flag trigger setting bit (TRGCHn.PFE) is 01_B. Timer triggers 0 to 3 are selected with PITMTRG0 to PITMTRG3 in PITRG.
7, 6	AE	Accumulation/Decimation Initialization Flag Trigger Setting 00_B: The accumulation/decimation initialization flag is not generated. (Initial value) 01_B: The accumulation/decimation initialization flag is generated by a timer trigger. 10_B: The accumulation/decimation initialization flag is generated by a software trigger. 11_B: Setting prohibited These bits disable both accumulation/decimation initialization flag and accumulation/decimation disable flag to be set as a software trigger. (Setting both AE and AFE bits in TRGCHn to 10_B is prohibited.)
5, 4	AT	Accumulation/Decimation Initialization Flag and Accumulation/Decimation Prohibition Flag Timer Trigger Select 00_B: Timer trigger 0 is used for generating the accumulation/decimation initialization flag and accumulation/decimation prohibition flag. (Initial value) 01_B: Timer trigger 1 is used for generating the accumulation/decimation initialization flag and accumulation/decimation prohibition flag. 10_B: Timer trigger 2 is used for generating the accumulation/decimation initialization flag and accumulation/decimation prohibition flag. 11_B: Timer trigger 3 is used for generating the accumulation/decimation initialization flag and accumulation/decimation prohibition flag. These bits are valid when the accumulation/decimation initialization flag trigger setting bit (TRGCHn.AE) or the accumulation/decimation prohibition flag trigger setting bit (TRGCHn.AFE) is 01_B. Timer triggers 0 to 3 are selected with MITMTRG0 to MITMTRG3 in MITRG.
3, 2	FE	Filter Initialization Flag Trigger Setting 00_B: The filter initialization flag is not generated. (Initial value) 01_B: The filter initialization flag is generated by a timer trigger. 10_B: The filter initialization flag is generated by a software trigger. 11_B: Setting prohibited
1, 0	FT	Filter Initialization Flag Timer Trigger Select 00_B: Timer trigger 0 is used for generating the filter initialization flag. (Initial value) 01_B: Timer trigger 1 is used for generating the filter initialization flag. 10_B: Timer trigger 2 is used for generating the filter initialization flag. 11_B: Timer trigger 3 is used for generating the filter initialization flag. Timer triggers 0 to 3 are selected with FITMTRG0 to FITMTRG3 in FITRG.

28.2.10 TRHCHn — Trigger History Register (n = 0 to 15)

This register is used to monitor execution history of software triggers, timer triggers, and trigger flags.

Bit	7	6	5	4	3	2	1	0
	—	—	—	PITS	PETS	MITS	METS	FITS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 28.12 TRHCH Register Contents

Bit Position	Bit Name	Function
4	PITS	PH Initialization Flag Trigger History (not supported by channels 10 to 15) 0: PH initialization flag trigger is not present. (Initial value) This bit is cleared to 0 when execution of the PH initialization flag has been completed while PITS = 1. This bit is also cleared to 0 if EN in CTLACHn is set to 0 and there is no input data which is in DFE processing. 1: This bit is set to 1 when a PH initialization flag trigger occurs.
3	PETS	PH End Flag Trigger History (not supported by channels 10 to 15) 0: PH end flag trigger is not present. (Initial value) This bit is cleared to 0 when execution of the PH end flag has been completed while PETS = 1. This bit is also cleared to 0 if EN in CTLACHn is set to 0 and there is no input data which is in DFE processing. 1: This bit is set to 1 when a PH end flag trigger occurs.
2	MITS	Accumulation/Decimation Initialization Flag Trigger History 0: Accumulation/decimation initialization flag trigger is not present. (Initial value) This bit is cleared to 0 when execution of the accumulation/decimation initialization flag has been completed while MITS = 1. This bit is also cleared to 0 if EN in CTLACHn is set to 0 and there is no input data which is in DFE processing. 1: This bit is set to 1 when an accumulation/decimation initialization flag trigger occurs.
1	METS	Accumulation/Decimation Disable Flag Trigger History 0: Accumulation/decimation disable flag trigger is not present. (Initial value) This bit is cleared to 0 when execution of the accumulation/decimation disable flag has been completed while METS = 1. This bit is also cleared to 0 if EN in CTLACHn is set to 0 and there is no input data which is in DFE processing. 1: This bit is set to 1 when an accumulation/decimation disable flag trigger occurs.
0	FITS	Filter Initialization Flag Trigger History 0: Filter initialization flag trigger is not present. (Initial value) This bit is cleared to 0 when execution of the filter initialization flag has been completed while FITS = 1. This bit is also cleared to 0 if EN in CTLACHn is set to 0 and there is no input data which is in DFE processing. 1: This bit is set to 1 when a filter initialization flag trigger occurs.

28.2.11 CPA to CPD — Comparison Value Setting Registers

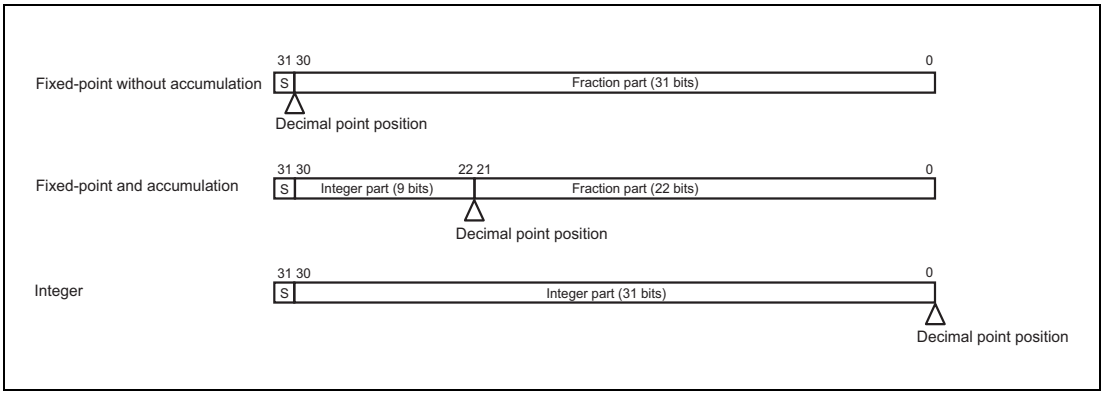
These registers are used to set a comparison calculation target value when comparison calculation is specified.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CP															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CP															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.13 Contents of CPA to CPD Registers

Bit Position	Bit Name	Function
31 to 0	CP	Comparison Value These bits set the comparison value when comparison calculation is specified.



28.2.12 PHIA to PHID — PH Initial Value Setting Registers

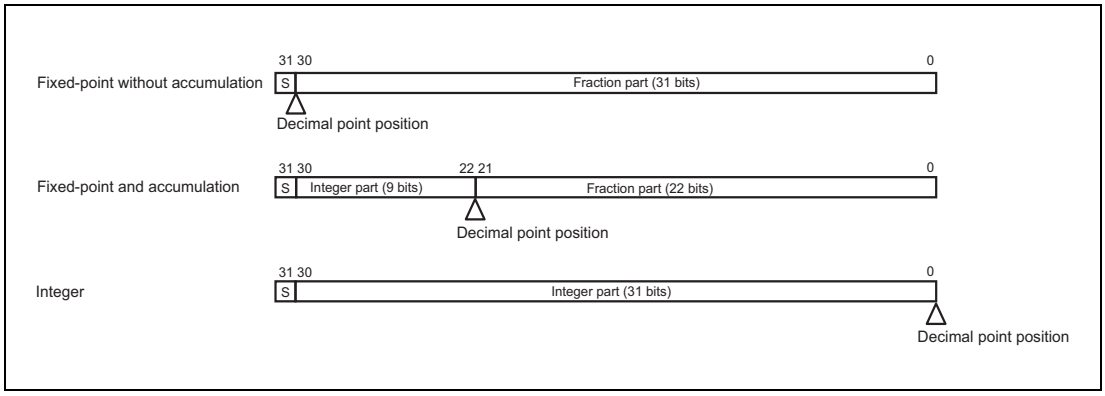
These registers are used to set the PH initial value when PH calculation is specified.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PHI															
Value after reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PHI															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.14 Contents of PHIA to PHID Registers

Bit Position	Bit Name	Function
31 to 0	PHI	PH Initial Value These bits set the PH initial value when PH calculation is specified. Initial value: Negative minimum value (8000 0000_H)



28.2.13 ACA to ACD — Accumulation/Decimation Count Setting Registers

These registers are used to set accumulation count or decimation count when accumulation/decimation is specified. A value of 0 to 511 can be set in these registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	AC								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.15 Contents of ACA to ACD Registers

Bit Position	Bit Name	Function
8 to 0	AC	In the case of accumulation (CTLACHn.PRCSA = 01_B) Accumulation Count Setting Register 000_H: Accumulation processing is not performed.*1 (Initial value) 001_H: Accumulation is performed once. Two filter processing results are added and output from the accumulation circuit. 002_H: Accumulation is performed twice. Three filter processing results are added and output from the accumulation circuit. : $1FF_H$: Accumulation is performed 511 times. 512 filter processing results are added and output from the accumulation circuit. In the case of decimation (CTLACHn.PRCSA = 10_B) Decimation Count Setting Register 000_H: Decimation processing is not performed. (Initial value) 001_H: Decimation is performed once. Filter processing result is output once in two filter processing results. 002_H: Decimation is performed twice. Filter processing result is output once in three filter processing results. : $1FF_H$: Decimation is performed 511 times. Filter processing result is output once in 512 filter processing results.

Note 1. However, since arithmetic right shift is executed during accumulation, the format of data that is input to the accumulation circuit is (1.31) data format to (10.22) data format.

28.2.14 DI — Software Input Data Register

This register is used to input data to be processed (software input) from the CPU or DMA to the DFE through the peripheral bus. A write access to this register activates the DFE.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	TAG			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DI															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.16 DI Register Contents

Bit Position	Bit Name	Function
19 to 16	TAG	Software Input Tag 0_H to F_H: Set the same value as the channel tag (CTLCHn.TAG) to be allocated.
15 to 0	DI	Software Input Data Data to be filtered is set with the input data format of the channel to be allocated. The fixed-point (1.31) format or the integer format is applicable. Set data to be filtered with the data format of the channel to be allocated. (When FMT in CTLCHn is 0, set data with the fixed-point format. When FMT in CTLCHn is 1, set data with the integer format.)

28.2.15 TRG — Software Trigger Register

This register is used to generate a software trigger by writing a value to this register from the CPU or DMA through the peripheral bus.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TRGA
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 28.17 TRG Register Contents

Bit Position	Bit Name	Function
0	TRGA	Software Trigger Generation 0: No software trigger is generated. 1: A software trigger is generated. Writing 1 to this bit generates a software trigger. When a software trigger has occurred, this bit is automatically cleared to 0. This bit is always read as 0.

28.2.16 ST — DFE Status Register

This register is used to indicate DFE status. This register consists of logical OR of the VALID bit and each error bit in STCHn. It is supposed that the CPU uses this register to monitor error channels when the DFE outputs an error interrupt request.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CH15S		CH14S		CH13S		CH12S		CH11S		CH10S		CH9S		CH8S	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CH7S		CH6S		CH5S		CH4S		CH3S		CH2S		CH1S		CH0S	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.18 ST Register Contents

Bit Position	Bit Name	Function
bit 2*n+1-2*n	CHnS	Channel n Status ({STCHn.VALID, | (STCHn.ERR)}) 00_B: Input data register disabled with no error (Initial value) 01_B: Input data register disabled with an error 10_B: Input data register enabled with no error 11_B: Input data register enabled with an error

28.2.17 PITRG — PH Initialization/End Timer Trigger Select Register

This register selects the timer trigger 0 to 3 according to the setting of the PH initialization flag and PH end flag timer trigger select bit (TRGCHn.PT) from among 20 compare matches A and B timer D of the ATU4.

Compare match A is selected for the PH initialization flag while compare match B of the same channel is selected for the PH end flag.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

20 to 16	PITMTRG2	PH Initialization/End Flag Timer Trigger 2 00000_B: Uses compare match A/B (channel 0 in subblock 0) from timer D of the ATU4 as timer trigger 2 (initial value). 00001_B: Uses compare match A/B (channel 1 in subblock 0) from timer D of the ATU4 as timer trigger 2. 00010_B: Uses compare match A/B (channel 2 in subblock 0) from timer D of the ATU4 as timer trigger 2. : 10011_B: Uses compare match A/B (channel 3 in subblock 9) from timer D of the ATU4 as timer trigger 2. 10100_B to 11111_B: Setting prohibited
12 to 8	PITMTRG1	PH Initialization/End Flag Timer Trigger 1 00000_B: Uses compare match A/B (channel 0 in subblock 0) from timer D of the ATU4 as timer trigger 1 (initial value). 00001_B: Uses compare match A/B (channel 1 in subblock 0) from timer D of the ATU4 as timer trigger 1. 00010_B: Uses compare match A/B (channel 2 in subblock 0) from timer D of the ATU4 as timer trigger 1. : 10011_B: Uses compare match A/B (channel 3 in subblock 9) from timer D of the ATU4 as timer trigger 1. 10100_B to 11111_B: Setting prohibited
4 to 0	PITMTRG0	PH Initialization/End Flag Timer Trigger 0 00000_B: Uses compare match A/B (channel 0 in subblock 0) from timer D of the ATU4 as timer trigger 0 (initial value). 00001_B: Uses compare match A/B (channel 1 in subblock 0) from timer D of the ATU4 as timer trigger 0. 00010_B: Uses compare match A/B (channel 2 in subblock 0) from timer D of the ATU4 as timer trigger 0. : 10011_B: Uses compare match A/B (channel 3 in subblock 9) from timer D of the ATU4 as timer trigger 0. 10100_B to 11111_B: Setting prohibited

28.2.18 MITRG — Accumulation/Decimation Initialization/Prohibition Timer Trigger Select Register

This register selects the timer trigger 0 to 3 according to the setting of the accumulation/decimation initialization flag and the accumulation/decimation prohibition flag timer trigger select bit (TRGCHn.AT) from among 20 compare matches A and B from timer D of the ATU4.

Compare match A is selected for the accumulation/decimation initialization flag while compare match B of the same channel is selected for the accumulation/decimation prohibition flag.

Table 28.21 FITRG Register Contents (1/2)

Bit Position	Bit Name	Function
28 to 24	FITMTRG3	Filter Initialization Flag Timer Trigger 3 00000_B: Uses compare match A (channel 0 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 3 (initial value). 00001_B: Uses compare match A (channel 1 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 3. 00010_B: Uses compare match A (channel 2 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 3. 00011_B: Uses compare match A (channel 3 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 3. 00100_B: Uses compare match A (channel 0 in subblock 2) from timer D of the ATU4 as filter initialization flag timer trigger 3. 00101_B: Uses compare match A (channel 1 in subblock 2) from timer D of the ATU4 as filter initialization flag timer trigger 3. 00110_B: Uses compare match A (channel 2 in subblock 2) from timer D of the ATU4 as filter initialization flag timer trigger 3. 00111_B: Uses compare match A (channel 3 in subblock 2) from timer D of the ATU4 as filter initialization flag timer trigger 3. 01000_B: Uses compare match A (channel 0 in subblock 4) from timer D of the ATU4 as filter initialization flag timer trigger 3. 01001_B: Uses compare match A (channel 1 in subblock 4) from timer D of the ATU4 as filter initialization flag timer trigger 3. 01010_B: Uses compare match A (channel 2 in subblock 4) from timer D of the ATU4 as filter initialization flag timer trigger 3. 01011_B: Uses compare match A (channel 3 in subblock 4) from timer D of the ATU4 as filter initialization flag timer trigger 3. 01100_B: Uses compare match A (channel 0 in subblock 6) from timer D of the ATU4 as filter initialization flag timer trigger 3. 01101_B: Uses compare match A (channel 1 in subblock 6) from timer D of the ATU4 as filter initialization flag timer trigger 3. 01110_B: Uses compare match A (channel 2 in subblock 6) from timer D of the ATU4 as filter initialization flag timer trigger 3. 01110_B: Uses compare match A (channel 3 in subblock 6) from timer D of the ATU4 as filter initialization flag timer trigger 3. 10000_B: Uses compare match A (channel 0 in subblock 9) from timer D of the ATU4 as filter initialization flag timer trigger 3. 10001_B: Uses compare match A (channel 1 in subblock 9) from timer D of the ATU4 as filter initialization flag timer trigger 3. 10010_B: Uses compare match A (channel 2 in subblock 9) from timer D of the ATU4 as filter initialization flag timer trigger 3. 10011_B: Uses compare match A (channel 3 in subblock 9) from timer D of the ATU4 as filter initialization flag timer trigger 3. 10100_B to 11111_B: Setting prohibited

Table 28.21 FITRG Register Contents (2/2)

Bit Position	Bit Name	Function
20 to 16	FITMTRG2	Filter Initialization Flag Timer Trigger 2 00000_B: Uses compare match A (channel 0 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 2 (initial value). 00001_B: Uses compare match A (channel 1 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 2. 00010_B: Uses compare match A (channel 2 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 2. : 10011_B: Uses compare match A (channel 3 in subblock 9) from timer D of the ATU4 as filter initialization flag timer trigger 2. 10100_B to 11111_B: Setting prohibited
12 to 8	FITMTRG1	Filter Initialization Flag Timer Trigger 1 00000_B: Uses compare match A (channel 0 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 1 (initial value). 00001_B: Uses compare match A (channel 1 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 1. 00010_B: Uses compare match A (channel 2 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 1. : 10011_B: Uses compare match A (channel 3 in subblock 9) from timer D of the ATU4 as filter initialization flag timer trigger 1. 10100_B to 11111_B: Setting prohibited
4 to 0	FITMTRG0	Filter Initialization Flag Timer Trigger 0 00000_B: Uses compare match A (channel 0 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 0 (initial value). 00001_B: Uses compare match A (channel 1 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 0. 00010_B: Uses compare match A (channel 2 in subblock 0) from timer D of the ATU4 as filter initialization flag timer trigger 0. : 10011_B: Uses compare match A (channel 3 in subblock 9) from timer D of the ATU4 as filter initialization flag timer trigger 0. 10100_B to 11111_B: Setting prohibited

28.2.20 PHUPDCn — PH Update Notification Setting Register n (n = 0, 1)

These registers are used to set a PH result register update notification during PH processing. One of the channels 0 to 9 can be independently selected with PHUPDC0 and PHUPDC1. The set update notification is output to the ATU4.

Bit	7	6	5	4	3	2	1	0
	PHUPDCH				—	—	—	OEPHUPD
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R/W

Table 28.22 PHUPDCn Register Contents

Bit Position	Bit Name	Function
7 to 4	PHUPDCH	PH Result Register Update Notification Channel Select 0_H: It is notified that PH result register has been updated in channel 0. (Initial value) 1_H: It is notified that PH result register has been updated in channel 1. 2_H: It is notified that PH result register has been updated in channel 2. : 9_H: It is notified that PH result register has been updated in channel 9. A_H to F_H: Setting prohibited
0	OEPHUPD	PH Result Register Update Notification Enable 0_B: Notification of PH result register update in the selected channel is disabled. (Initial value) 1_B: Notification of PH result register update in the selected channel is enabled.

28.3 Operation

28.3.1 Overview of Operation

The DFE imports output data from the Delta-Sigma ADC or the ADC (referred to as AD hereafter) and performs filter (FIR or IIR) processing, accumulation/decimation processing, PH/comparison calculation processing, or floating-point conversion processing for the output data.

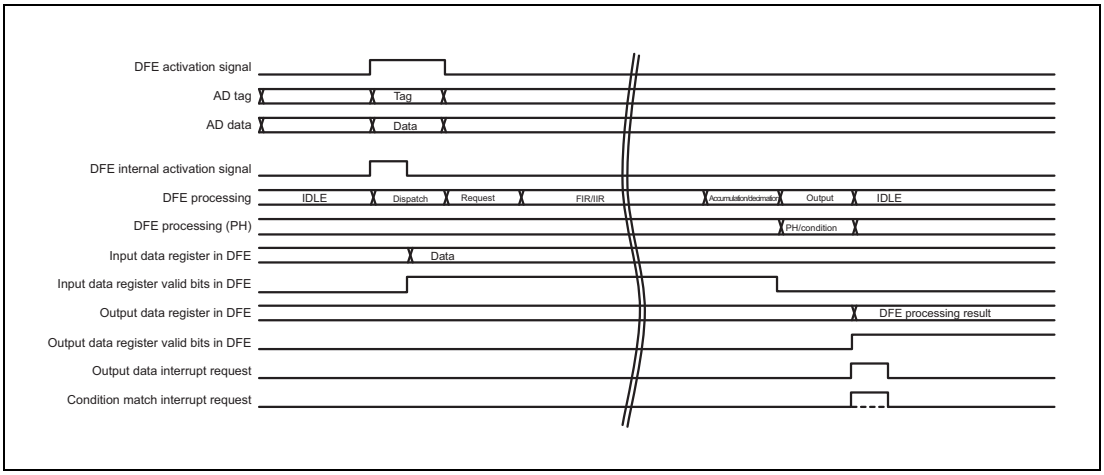

Figure 28.5 Overview of Operation

The AD inputs the DFE activation signal, AD tag, and AD conversion data (AD data) to the DFE. The DFE imports the AD data in the internal input data register to perform dispatch processing, request processing, FIR/IIR processing, accumulation/decimation processing, output processing, or PH/comparison processing, and then writes the DFE processing result to the output data register.

- Dispatch processing:
  The DFE writes data to the input data register of the relevant channel by using the AD tag from the AD and DFE's control register values. Before writing data, the input data register is enabled.
- Request processing:
  The DFE arbitrates FIR/IIR processing target data from the input data register of 16 channels and inputs the filter processing target data to the FIR/IIR processing.
- FIR/IIR processing (filter processing):
  The DFE performs FIR or IIR filter calculation. Coefficient data and intermediate values in the filter calculation are stored in the memory.
- Accumulation/decimation processing:
  The DFE performs accumulation processing or decimation processing for the FIR or IIR processing result. After the accumulation/decimation processing has been completed, the input data register is disabled.
- Output processing:
  The DFE writes the accumulation/decimation processing result to the output data register of the relevant channel. Before writing the result, the output data register is enabled and an output data interrupt request is issued.
- PH/comparison processing:
  The DFE performs PH processing or comparison processing for the accumulation/decimation processing result. In the case of PH processing, a condition match interrupt request is output when

the PH end trigger is enabled. In the case of comparison processing, a condition match interrupt request is output when the comparison calculation result is true.

28.4.6 Setting Control Registers

28.4.6.1 FIR (Fixed-Point)

The following table shows combinations of calculations and cascades that are selectable in the control register A (CTLACHn) and the control register B (CTLBCHn) when FIR and fixed-point format are specified in the control register A. Does not use the cascade function in channels for which accumulation is specified.

Table 28.23 FIR (Fixed-Point)

Input Format	Filter	Accumulation or Decimation	PH or Comparison	Floating-Point Conversion	Execution (Result)	Cascade (Output)*1
Fixed-point (1.15)	FIR	Accumulation	PH	Conversion specified	OK (floating-point)	NO
				Conversion not specified	OK (10.22)	NO
			Comparison	Conversion specified	OK (floating-point)	NO
				Conversion not specified	OK (10.22)	NO
			Not specified	Conversion specified	OK (floating-point)	NO
				Conversion not specified	OK (10.22)	NO
		Decimation	PH	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)
			Comparison	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)
			Not specified	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)
		Not specified	PH	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)
			Comparison	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)
			Not specified	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)

Note 1. Setting is prohibited for NO combinations. For OK combinations, set fixed-point as an input data format of cascade destination channels.

28.4.6.2 FIR (Integer)

The following table shows combinations of calculations and cascades that are selectable in the control register A (CTLACHn) and the control register B (CTLBCHn) when FIR and integer format are specified in the control register A. When integer is specified, only the FIR filter processing can be performed. Do not specify floating-point conversion.

Table 28.24 FIR (Integer)

Input Format	Filter	Accumulation or Decimation	PH or Comparison	Floating-Point Conversion	Execution (Result)*1	Cascade (Output)*2
Integer (16-bit integer)	FIR	Accumulation	PH	Conversion specified	NO	NO
				Conversion not specified	NO	NO
			Comparison	Conversion specified	NO	NO
				Conversion not specified	NO	NO
			Not specified	Conversion specified	NO	NO
				Conversion not specified	NO	NO
		Decimation	PH	Conversion specified	NO	OK (16-bit integer)
				Conversion not specified	OK (32-bit integer)	OK (16-bit integer)
			Comparison	Conversion specified	NO	OK (16-bit integer)
				Conversion not specified	OK (32-bit integer)	OK (16-bit integer)
			Not specified	Conversion specified	NO	OK (16-bit integer)
				Conversion not specified	OK (32-bit integer)	OK (16-bit integer)
		Not specified	PH	Conversion specified	NO	OK (16-bit integer)
				Conversion not specified	OK (32-bit integer)	OK (16-bit integer)
			Comparison	Conversion specified	NO	OK (16-bit integer)
				Conversion not specified	OK (32-bit integer)	OK (16-bit integer)
			Not specified	Conversion specified	NO	OK (16-bit integer)
				Conversion not specified	OK (32-bit integer)	OK (16-bit integer)

Note 1. Setting is prohibited for NO combinations.

Note 2. Setting is prohibited for NO combinations. For OK combinations, set integer as an input data format of cascade destination channels.

28.4.6.3 IIR (Fixed-Point)

The following table shows combinations of calculations and cascades that are selectable in the control register A (CTLACHn) and the control register B (CTLBCHn) when IIR and fixed-point format are specified in the control register A. When IIR is specified, only fixed-point format filter processing can be performed. When accumulation is specified, specification of cascade is prohibited.

Table 28.25 IIR

Input Format	Filter	Accumulation or Decimation	PH or Comparison	Floating-Point Conversion	Execution (Result)	Cascade (Output) *1
Fixed-point (1.15)	IIR	Accumulation	PH	Conversion specified	OK (floating-point)	NO
				Conversion not specified	OK (10.22)	NO
			Comparison	Conversion specified	OK (floating-point)	NO
				Conversion not specified	OK (10.22)	NO
			Not specified	Conversion specified	OK (floating-point)	NO
				Conversion not specified	OK (10.22)	NO
		Decimation	PH	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)
			Comparison	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)
			Not specified	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)
		Not specified	PH	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)
			Comparison	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)
			Not specified	Conversion specified	OK (floating-point)	OK (1.15)
				Conversion not specified	OK (1.31)	OK (1.15)

Note 1. Setting is prohibited for NO combinations. For OK combinations, set fixed-point as an input data format of cascade destination channels.

28.4.7 Trigger Control

28.4.7.1 Timer Trigger Input

The DFE uses 40 signals from timer D of the ATU4: compare-match A interrupts xy and compare-match B interrupts xy (x = 0, 2, 4, 6, 9; y = 0 to 3) as timer triggers.

Four compare-match A interrupt signals can be selected for each of three trigger flag functions (accumulation/decimation initialization flag, PH initialization flag, and filter initialization flag) with the PH initialization timer trigger select register (PITRG), accumulation/decimation initialization timer trigger select register (MITRG), and filter initialization timer trigger select register (FITRG). The selected signals are allocated to timer triggers 0 to 3 for each flag function.

Then, compare-match B interrupt signals with the same number as the compare-match A interrupt signals selected for the accumulation/decimation initialization flag are automatically allocated to the accumulation/decimation disable flag timer triggers 0 to 3.

Also, compare-match B interrupt signals with the same number as the compare-match A interrupt signals selected for the PH initialization flag are automatically allocated to the PH end flag timer triggers 0 to 3.

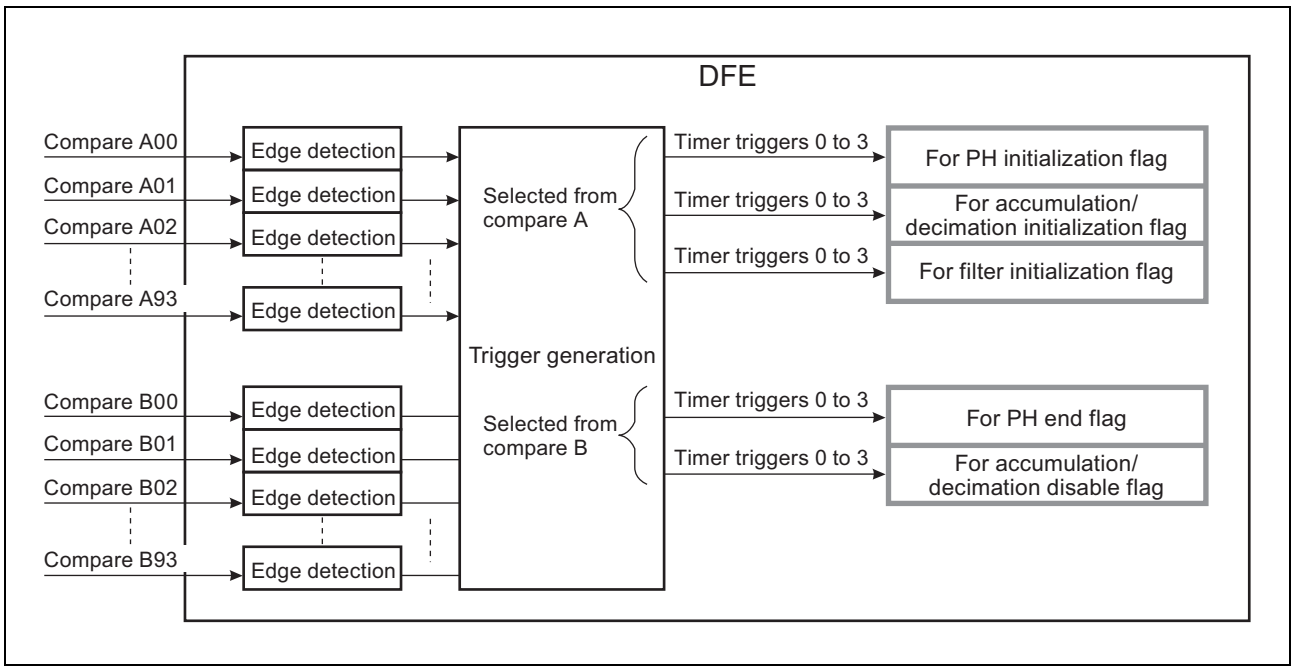

Figure 28.13 Timer Trigger Input

28.4.7.2 Trigger Flag Functions

When the channel enable bit (CTLACHn.EN) is 1, the DFE can generate flags of the following five functions for each channel by using software triggers, timer triggers 0 to 3 that are allocated to the trigger functions, and the trigger setting register (TRGCHn). (These flags are referred to as trigger flags hereafter.)

The accumulation/decimation processing is set with CTLBCHn.PRCSA, and the PH processing is set with CTLBCHn.PRCSB.

Whether the accumulation/decimation processing and PH processing are enabled or disabled can be checked by CTLBn.DISA and CTLBn.DISB, respectively. Before the DFE starts processing, in other words, when the channel is disabled (CTLACHn.EN = 0) and there is no data to be processed (STCHn.VALID = 0), CTLBn.DISA and CTLBn.DISB can be set to enable or disable processing.

For details, see **Section 28.2.3, CTLBCHn — Control Register B (n = 0 to 15)**.

Table 28.26 Trigger Flags

Flag Name	Description
Accumulation/decimation initialization flag	When the accumulation/decimation initialization flag is enabled by timer triggers or software triggers specified for each channel while accumulation/decimation processing is in progress or in the enabled or disabled state, the DFE initializes the counter of the accumulation circuit and performs accumulation/decimation processing for the subsequent input data.
Accumulation/decimation disable flag	When the accumulation/decimation disable flag is enabled by timer triggers or software triggers specified for each channel while accumulation/decimation processing is in progress or in the enabled state, the DFE disables accumulation/decimation processing for the subsequent input data. To enable accumulation/decimation processing again, enable the accumulation/decimation initialization flag.
PH initialization flag	When the PH initialization flag is enabled by timer triggers or software triggers specified for each channel while PH processing is in progress or in the enabled or disabled state, the DFE compares the next input data with the PH initialization value setting register value, not with a PH processing result as before, and after that the DFE compares the subsequent data with the PH processing result.
PH end flag	When the PH end flag is enabled by timer triggers or software triggers specified for each channel while PH processing is in progress or in the enabled state, the DFE disables PH processing for the subsequent input data. The PH end interrupt can be output when the PH end flag is enabled. To enable PH processing again, enable the PH initialization flag.
Filter initialization flag	When the filter initialization flag is enabled by timer triggers or software triggers specified for each channel, the DFE initializes the filter processing address pointer and performs FIR/IIR processing from the initial value.

Note 1. When timer triggers are used for the accumulation/decimation disable flag or PH end flag, timer triggers 0 to 3 are automatically allocated as described in **Section 28.4.7.1, Timer Trigger Input**.

Note 2. The PH initialization flag and PH end flag are only supported by channels 0 to 9.

Timer triggers and software triggers can be allocated to trigger flags for each channel. Timer triggers for accumulation/decimation disable flag and PH end flag are automatically allocated. Details of trigger flag operation are described in the sections of the accumulation circuit, PH circuit, and filtering circuit, respectively.

Table 28.27 Example of Trigger Flag Settings

	Accumulation/ Decimation Initialization Flag	Accumulation/ Decimation Disable Flag	PH Initialization Flag	PH Disable Flag	Filter Initialization Flag
Channel 0	Timer trigger 0 (compare A0)	Compare B0 is automatically allocated according to the timer trigger selection.	None	None	Timer trigger 3
Channel 1	None	None	Timer trigger 2 (compare A9)	Compare B9 is automatically allocated according to the timer trigger selection.	Software trigger
...	...	...	...	...	...
Channel 9	Timer trigger 3 (compare A5)	Compare B5 is automatically allocated according to the timer trigger selection.	None	None	None
Channel 10	Timer trigger 1	Software trigger	Not supported	Not supported	Timer trigger 0
...	...	...	...	...	...
Channel 15	None	None	Not supported	Not supported	None

Trigger flags are valid for data that is input after a software trigger or timer trigger is generated.

If timer trigger 0 is set for the accumulation initialization flag in channel 0, for example, accumulation processing is initialized for the first input data in channel 0 after a timer trigger is generated.

To process the same data in multiple channels, the trigger flag settings should be the same to keep consistency in processed data.

For example, when data input from the AD0 is specified for channels 0 and 1 and the accumulation initialization flag is used, the same accumulation initialization flag timer trigger should be set for both channels 0 and 1.

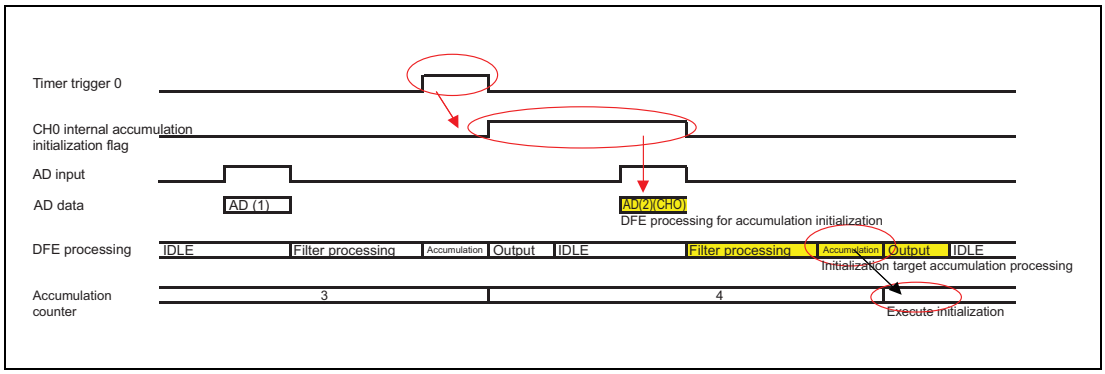

Figure 28.14 Example of Trigger Flag Operation

28.4.7.3 Trigger Flag Functions and Processing

Table 28.28 shows the relationship between the trigger flag functions and processing.

Table 28.28 Trigger Flag Functions and Processing

Register Setting		Trigger Flag Function		Input Data Processing after Trigger Flag is Enabled			
		Accumulation/ decimation	PH	Output data write	Output data interrupt	Condition match interrupt	PH update notification
Accumulation/ decimation disabled	PH/comparison disabled	Flag is invalid	Flag is invalid	Provided	Not provided	Not provided	Not provided
	PH performed	Flag is invalid	Enabled	Provided	Not provided	Not provided	Provided
			Disabled	Provided	Not provided	Not provided*	Not provided
	Comparison performed	Flag is invalid	Flag is invalid	Provided	Not provided	Provided	Not provided
Accumulation/ decimation performed	PH/comparison disabled	Enabled	Flag is invalid	Provided	Provided	Not provided	Not provided
		Disabled	Flag is invalid	Not provided	Not provided	Not provided	Not provided
	PH performed	Enabled	Enabled	Provided	Provided	Not provided	Provided
			Disabled	Provided	Provided	Not provided*1	Not provided
		Disabled	Flag is invalid	Not provided	Not provided	Not provided	Not provided
	Comparison performed	Enabled	Flag is invalid	Provided	Provided	Provided	Not provided
		Disabled	Flag is invalid	Not provided	Not provided	Not provided	Not provided

Note 1. The interrupt is output when the PH end flag is enabled.

When accumulation/decimation processing and PH/comparison processing are used in the same channel with the accumulation/decimation count specified, PH processing is performed on each specified count.

If accumulation/decimation processing is disabled by the trigger flag function, PH/comparison processing is not performed, either. Do not input software triggers or timer triggers for the trigger flag function for PH initialization and PH end trigger flag functions to a channel with accumulation/ decimation processing disabled.

28.4.8 Input Data Control

The DFE allows AD input (from Delta-Sigma AD0 to AD7 and ADC0/ADC1), cascade input (to perform filter calculation of the DFE's filter calculation result again), and software input (by the CPU or DMA).

28.4.8.1 AD Input

The DFE compares the tag value (channel tag hereafter) set in the TAG bits in CTLACHn for each channel and the AD tag input from the AD, and performs processing in the channel that has the matched tag value. This function allows single piece of AD data to be input to processing in multiple channels.

28.4.8.2 Cascade Input

The DFE has a cascade input function to input filter processing result again. This cascade input function performs rounding processing for 32-bit accumulation circuit output data to 16-bit data, and then performs filter processing again. In integer mode, when the accumulation circuit output data is a positive value and the 16 high-order bits contain a valid value, the output data is rounded to a 16-bit positive maximum value ($7FFF_H$). When the accumulation circuit output data is a negative value and the 16 high-order bits contain a valid value, the output data is rounded to a 16-bit negative minimum value (8000_H). If rounding of both positive and negative values occurs, the cascade rounding error flag is set to 1. In fixed-point mode, the accumulation circuit output data is added to 0000 8000_H and rounding processing is performed. As a result of this addition, if an overflow occurs in 32-bit positive value, the added data is rounded to a positive maximum value ($7FFF_H$) and the cascade rounding error flag is set.

The CAEN bits in the control register CTLACHn can control enabling or disabling the cascade input function and enabling or disabling the output data register mask function.

Table 28.29 CAEN Flag Function

CAEN Bits	Description
00_B	Cascade input is disabled. Calculation result is written to the output data register. (Initial value)
01_B	Setting prohibited
10_B	Cascade input is enabled. Calculation result is written to the output data register.
11_B	Cascade input is enabled. Calculation result is not written to the output data register.

When cascade input is enabled, the cascade input destination channel is specified by using the tag value for cascade (cascade tag hereafter). The cascade tag is set by the CATAG bits in CTLACHn. The DFE compares the cascade tag with the channel tag, and performs cascade input filter processing in the channel where the tags matched. The following figures show operations when cascade input is enabled.

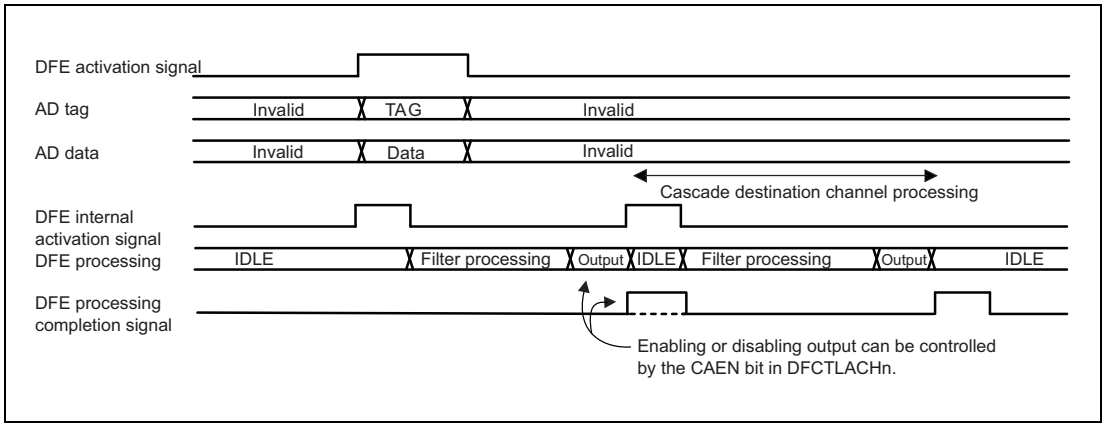

Figure 28.15 Cascade Input Processing (Normal Processing)

When cascade input is enabled and decimation is specified, a decimation result becomes cascade input data. When decimation count is set to 4, for example, the data after filter processing of the fourth AD input becomes cascade input data.

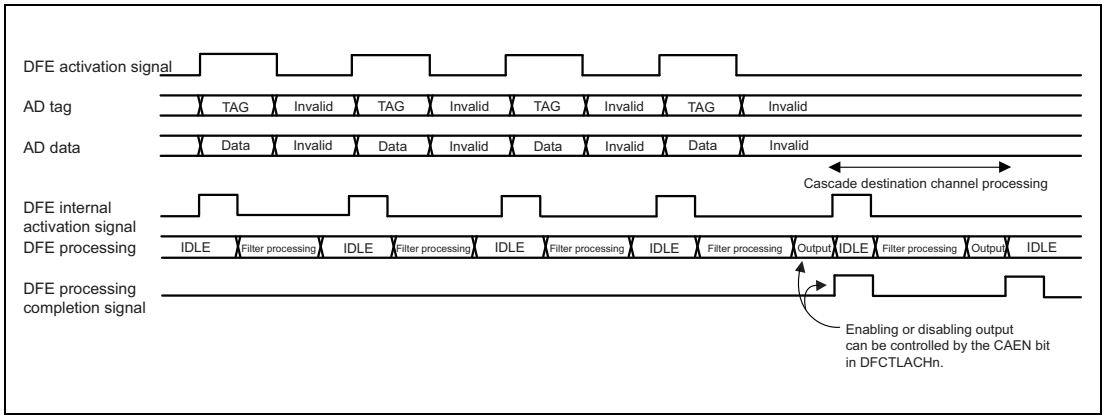

Figure 28.16 Cascade Input Processing (Decimation: 4 Times)

28.4.8.3 Software Input

The DFE has a function to input DFE processing target data through the peripheral bus by using the CPU or DMA. (This function is referred to as software input function hereafter.) DFE processing can be started by writing filter processing target data and a tag value to the software input data register (DI) from the peripheral bus.

28.4.8.4 Dispatch

A channel to be processed is selected by activation signals of AD input (Delta-Sigma AD and ADC), cascade input, and software input and the channel tag, and then processing target data is written to the input data register of each channel. This processing is called dispatch.

After processing target data is written to the input data register, the input data register is enabled until the accumulation circuit processing is completed. If new data is written for the same channel while the input data register is enabled, the data is overwritten causing an input data overwrite error (DIOW).

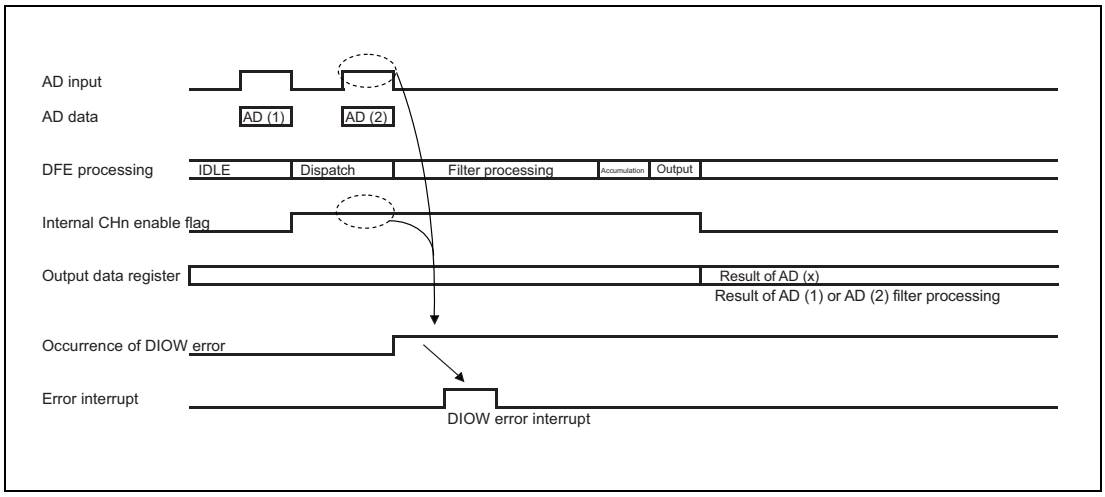

Figure 28.17 Input Data Overwrite (DIOW) Error

When the input data register of each channel is enabled, filter processing target data is arbitrated. The highest priority is given to the processing for channel 0, the second highest priority is given to the processing for channel 1, and the lowest priority is given to the processing for channel 15. The input data register value of arbitrated channels is input to the filtering circuit where FIR/IIR processing is applied to the input data register value according to the control register value.

If the same data is set for multiple channels, processing is also performed for all of the specified channels in the channel priority order. If the trigger flag function is enabled, it is not applied until the next input data processing.

For example, if the same input data is set for multiple channels and the accumulation processing is set and the same accumulation/decimation disable trigger is set for the channels, the accumulation is not disabled until the next input data processing if any unprocessed channel exists when the disable trigger is input.

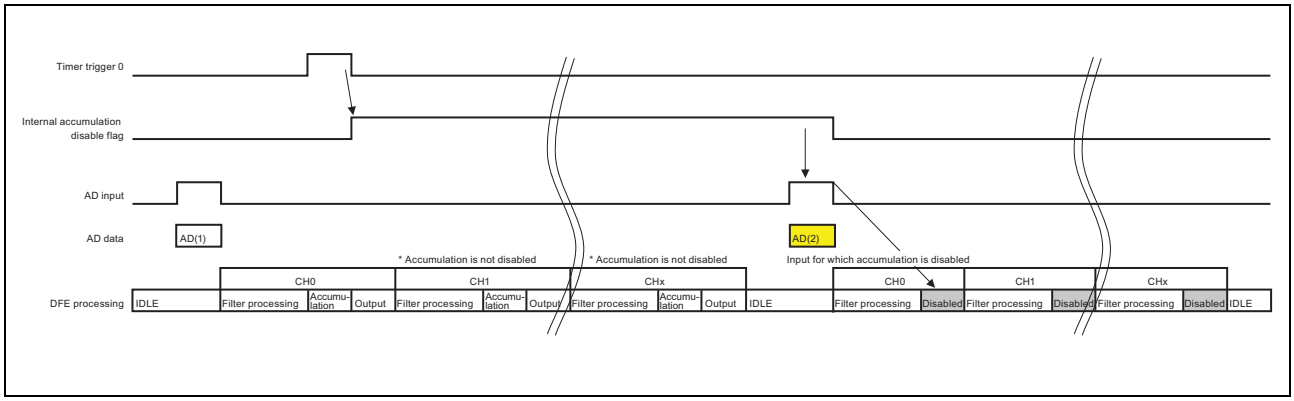

Figure 28.18 Processing when the Same Input Data is Set for Multiple Channels

28.4.9 Filtering Circuit

The filtering circuit accepts a request from channel 0 to channel 15 selected in the dispatch circuit, and starts FIR or IIR filter processing. Another request cannot be accepted during execution of filter processing. Upon completion of processing in the accumulation circuit, the DFE accepts a new request. Coefficients required for filtering are stored in the coefficient memory and input data to be used for FIR processing and intermediate data to be used for IIR processing are stored in the data memory. These memory areas are allocated for each channel.

28.4.9.1 FIR

Figure 28.19 shows the FIR filter configuration.

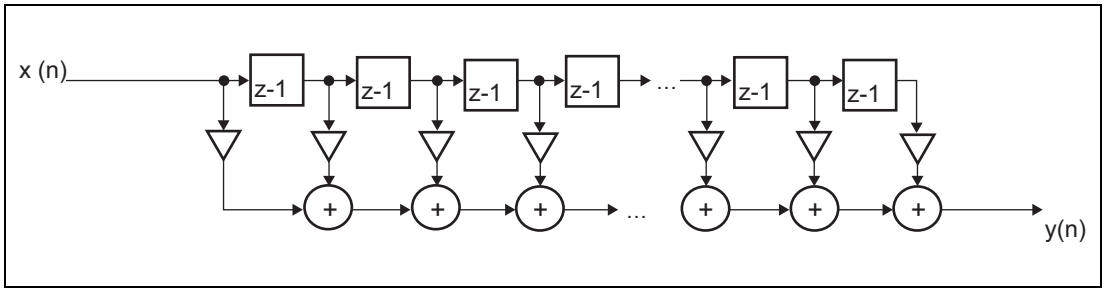

Figure 28.19 FIR Filter Configuration

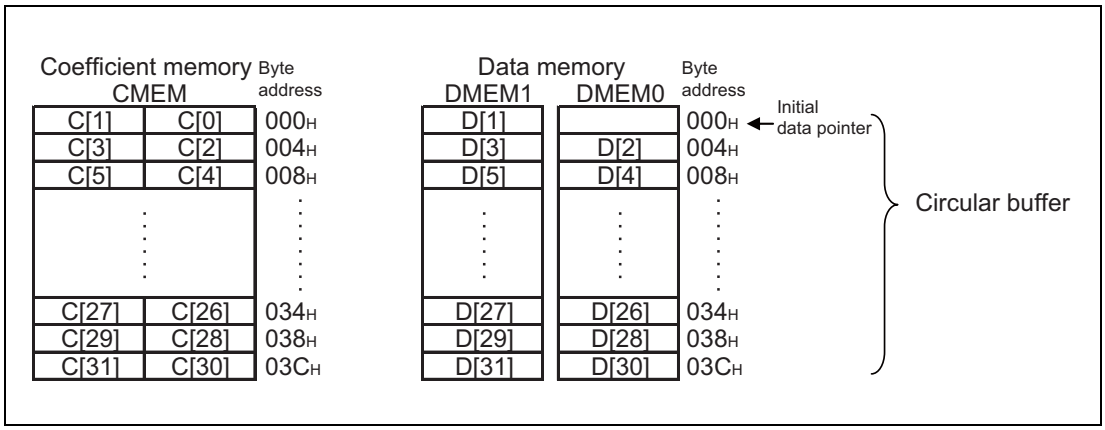

Figure 28.20 Memory Configuration for FIR Filter (32TAP Selected)

Before starting FIR filter processing, set values for the coefficient memory and data memory buffer areas. For 8-tap FIR, set coefficient values to be used for coefficient memory C[0] to C[7] and set the circular buffer area in the data memory to 0000_H.

While the filter processing initialization flag is enabled, the DFE writes 0 to circular buffers of the number of taps, and then starts the FIR processing. In the case of 8-tap FIR, for example, the DFE writes 0 to circular buffers of D[0] to D[7] and then starts FIR processing.

28.4.9.2 IIR (Single Stage)

Figure 28.21 shows the IIR filter configuration (single stage).

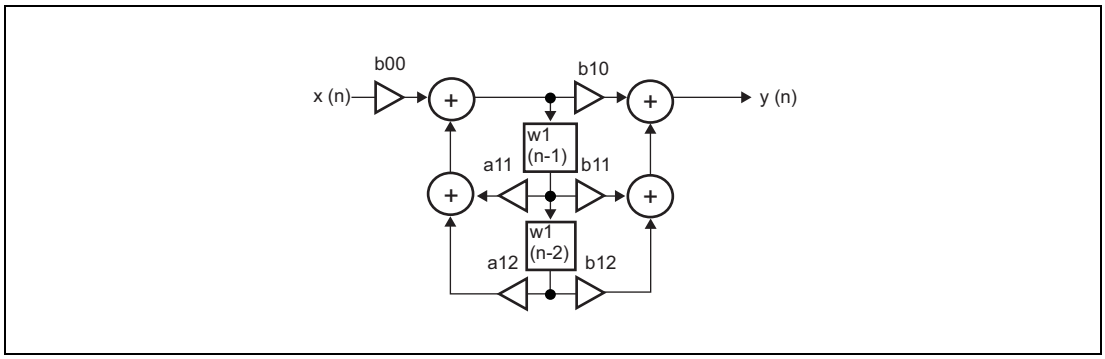

Figure 28.21 IIR Filter Configuration (Single Stage)

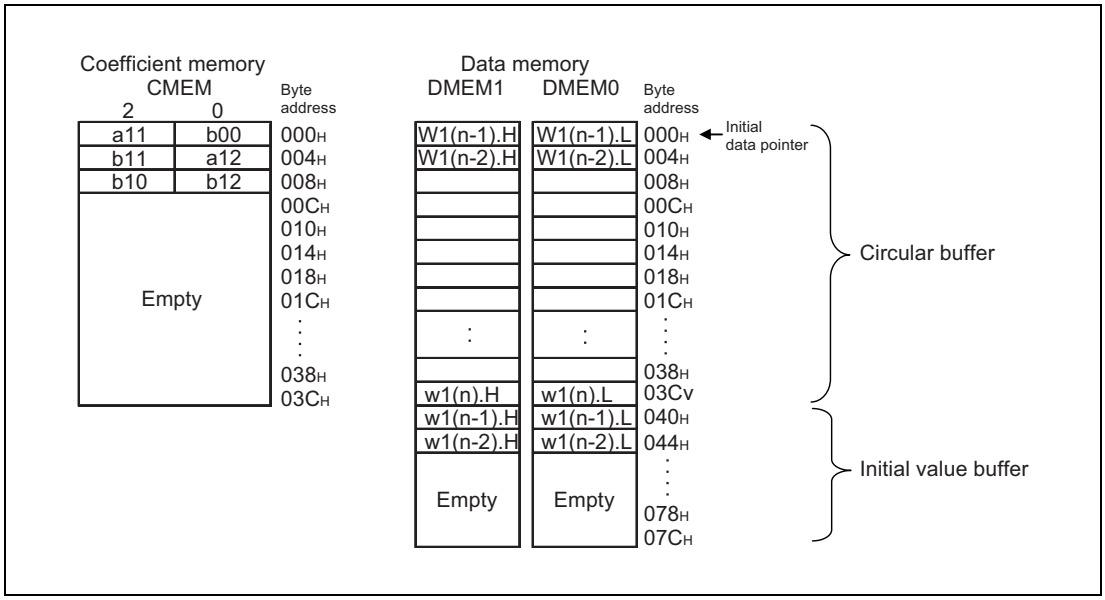

Figure 28.22 Memory Configuration for IIR Filter (Single Stage)

Before starting IIR filter processing, set values for the coefficient memory and data memory buffer areas. Set the intermediate value data for the circular buffer area and the initial value buffer area in the data memory.

While the filter processing initialization flag is enabled, the DFE initializes the data pointer of the circular buffer to 0, writes the intermediate value data stored in the initial value buffer to the relevant circular buffer, and then performs IIR processing.

28.4.9.3 IIR (Two Stages)

Figure 28.23 shows the IIR filter configuration (two stages).

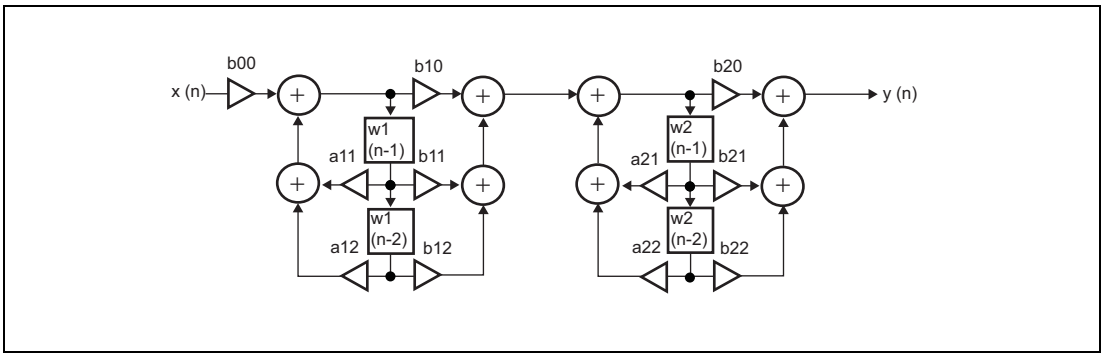

Figure 28.23 IIR Filter Configuration (Two Stages)

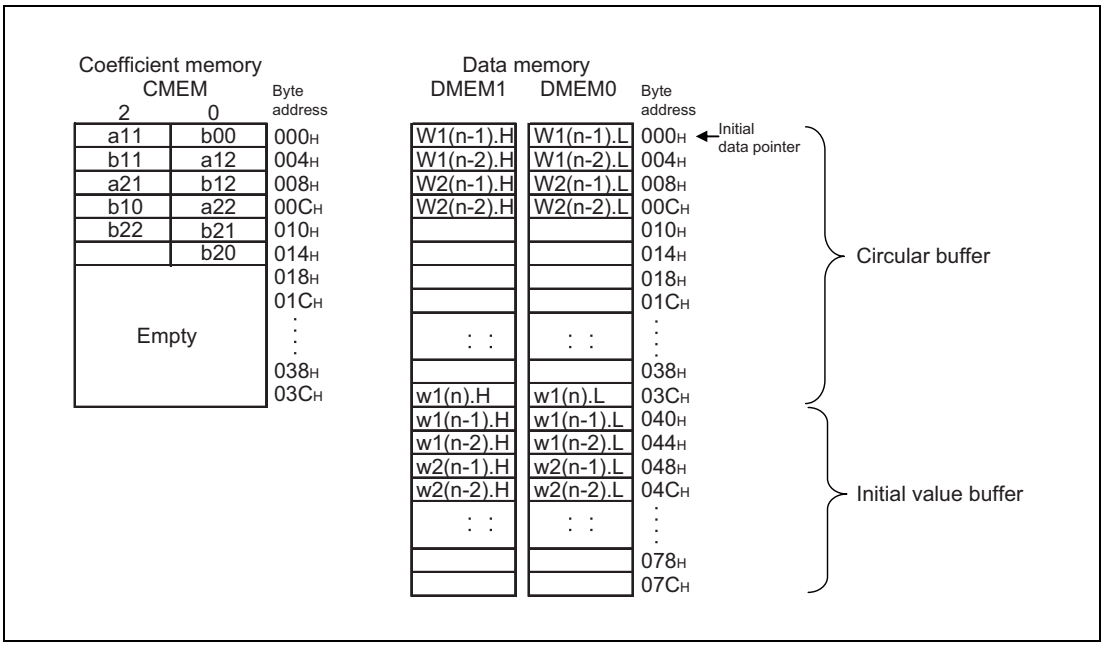

Figure 28.24 Memory Configuration for IIR Filter (Two Stages)

Before starting IIR filter processing, set values for the coefficient memory and data memory buffer areas. Set the intermediate value data for the circular buffer area and the initial value buffer area in the data memory.

While the filter processing initialization flag is enabled, the DFE initializes the data pointer of the circular buffer to 0, writes the intermediate value data stored in the initial value buffer to the relevant circular buffer, and then performs IIR processing.

28.4.9.4 IIR (Three Stages)

Figure 28.25 shows the IIR filter configuration (three stages).

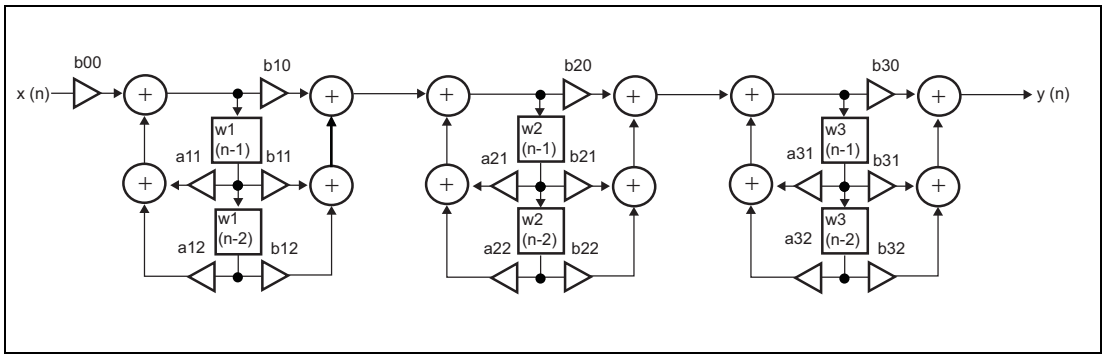

Figure 28.25 IIR Filter Configuration (Three Stages)

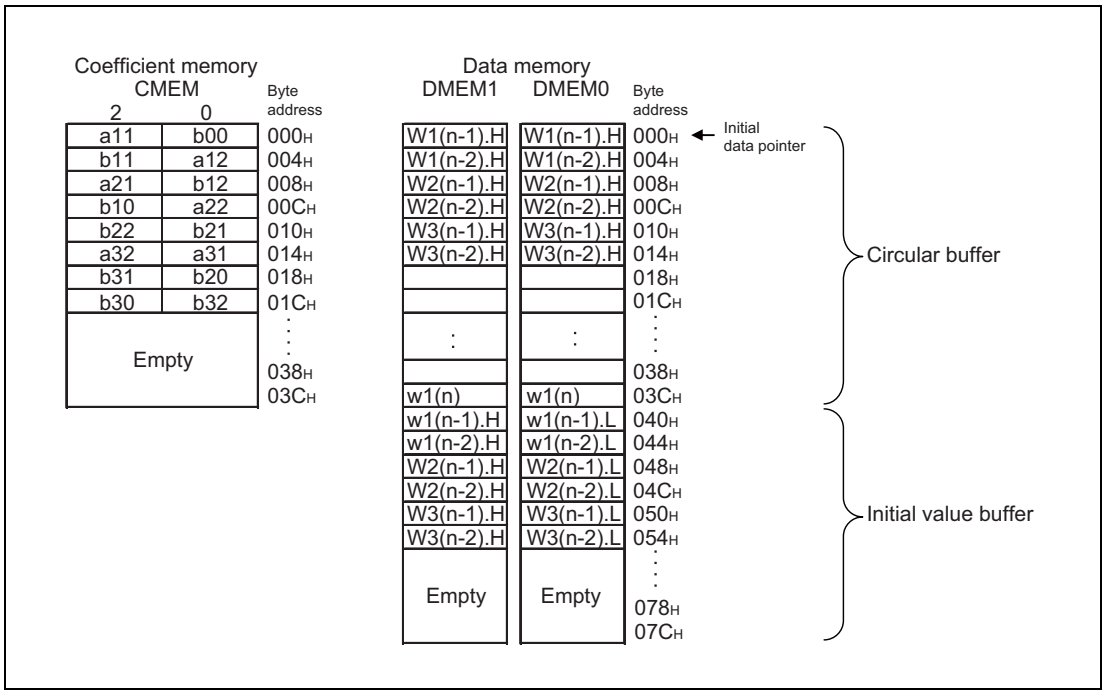

Figure 28.26 Memory Configuration for IIR Filter (Three Stages)

Before starting IIR filter processing, set values for the coefficient memory and data memory buffer areas. Set the intermediate value data for the circular buffer area and the initial value buffer area in the data memory.

While the filter processing initialization flag is enabled, the DFE initializes the data pointer of the circular buffer to 0, writes the intermediate value data stored in the initial value buffer to the relevant circular buffer, and then performs IIR processing.

28.4.9.5 Errors in Filtering Circuit

If multiplication of 8000_H*8000_H is performed by the multiplier, a multiplication error occurs and the multiplication error flag is set to 1.

To prevent an overflow in the multiplication result addition processing, six guard bits are provided. To round data with guard bits to 32 bits, rounding operation is performed. When guard bits contain a valid value after the rounding operation, the error flag is set to 1. This error is called guard bit error.

When the calculation result is larger than the 32-bit positive maximum value ($7FFF\_FFFF_H$), saturation processing is performed for $7FFF\_FFFF_H$. When the calculation result is smaller than the 32-bit negative minimum value (8000_0000_H), saturation processing is performed for 8000_0000_H.

28.4.10 Accumulation Circuit

The accumulation circuit has a function to perform absolute value conversion, accumulation processing, or decimation processing for the filter processing result data that is output from the filtering circuit and to output the processing result data to the output circuit and the PH circuit. When the cascade function is used, the accumulation circuit sends the accumulation circuit output data to the dispatch circuit.

28.4.10.1 Absolute Value Calculation

The filter processing result data that is output from the filtering circuit is converted to an absolute value. When the ABS bit in CTLBCHn is 1, absolute value conversion is performed. When the ABS bit is 0, absolute value conversion is not performed. If the filter processing result data that is output from the filtering circuit is 8000_0000_H, an absolute value error is generated. The absolute value conversion result at this time is $7FFF\_FFFF_H$.

28.4.10.2 Summary of Accumulation Processing

In the accumulation processing, the filter processing result data that is input to the accumulation circuit is right shifted (9 bits) arithmetically, and then this filter processing result data is added to the filter processing result data that has been input for each channel.

The data format after the accumulation processing is (10.22). Accumulation processing can be performed up to 511 times. After processing for the specified accumulation processing count has been completed, accumulation processing is performed again.

When the PRCSA bits in CTLBCHn are 01_B, accumulation processing is performed. Specify the accumulation processing count by the SELA bits in CTLBCHn by selecting one of the four accumulation/decimation count setting registers (ACA to ACD).

28.4.10.3 Operation of Accumulation Processing

Operation of accumulation processing is explained using an example when ACA = 000_H, ACB = 001_H/ ACC = 002_H, and CTLBCHn.PRCSA = 01_B.

When the SELA bits in CTLBCHn are 00_B, ACA is selected and accumulation processing is performed with an accumulation count set value of 0.

The 9-bit arithmetic right-shift result data (DADD (1)) from the filter processing result data (D (1)) is written to the output data register and an output data interrupt request is issued.

In accumulation processing with an accumulation count set value of 0, one-time filter processing result is right shifted (9 bits) arithmetically without addition processing and an interrupt request is issued. This processing is repeated subsequently.

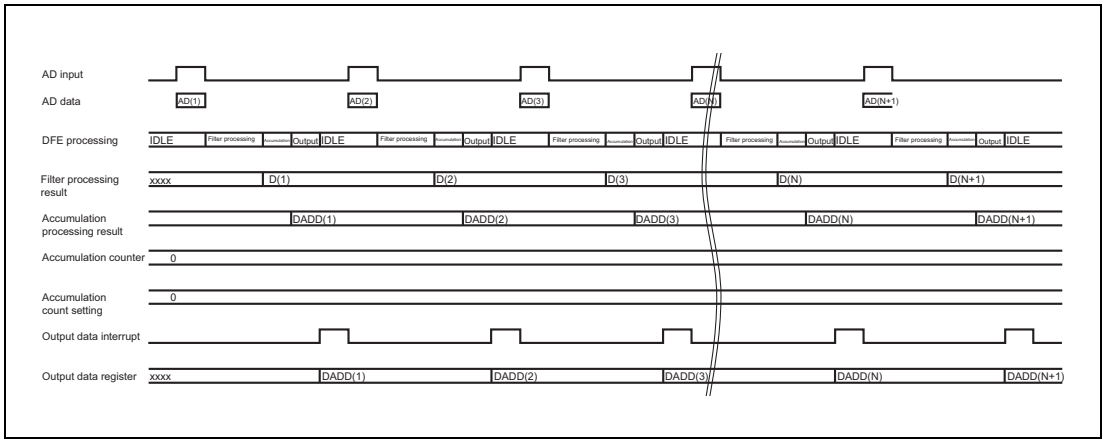

Figure 28.27 Accumulation Processing (Set Count Value = 0)

When the SELA bits in CTLBCHn are 01_B, the ACB register is selected and accumulation processing is performed with a set accumulation count value of 1.

When the filter processing result data (D (1)) is input to the accumulation circuit, the 9-bit arithmetic right-shift result data (DADD (1)) from the filter processing result data (D (1)) is written to the accumulator. After that, when the filter processing result data (D (2)) is input to the accumulation circuit, the filter processing result data (D (2)) is right shifted (9 bits) arithmetically (DADD (2)) and this data is added to the accumulator value (DADD (1)). The addition result (DADD (1) + DADD (2)) is written to the output data register. After this writing has been completed, an output data interrupt request is issued.

When the accumulation count is set to 1, 9-bit arithmetic right shift is made for two filter processing results and these results are added, and then an interrupt request is issued once. This processing is repeated subsequently.

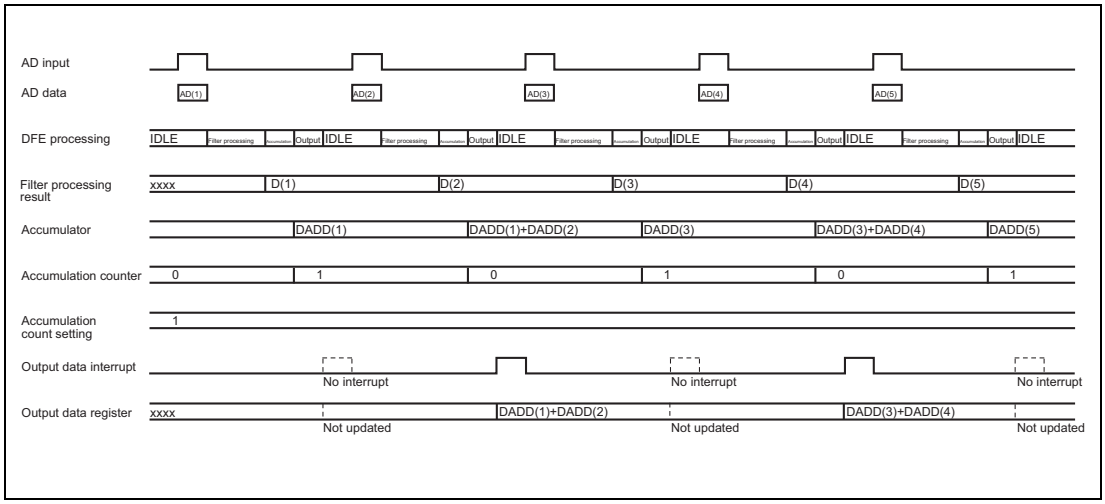

Figure 28.28 Accumulation Processing (Set Count Value = 1)

When the SELA bits in CTLBCHn are 10_B, the ACC register is selected and accumulation processing is performed with a set accumulation count value of 2.

When the filter processing result data (D (1)) is input to the accumulation circuit, the 9-bit arithmetic right-shift result data (DADD (1)) from the filter processing result data (D (1)) is written to the accumulator. After that, when the filter processing result data (D (2)) is input to the accumulation

circuit, the filter processing result data (D (2)) is right shifted (9 bits) arithmetically (DADD (2)) and this data is added to the accumulator value (DADD (1)). The addition result (DADD (1) + DADD (2)) is written to the accumulator again. Next, when the filter processing result data (D (3)) is input to the accumulation circuit, the filter processing result data (D (3)) is right shifted (9 bits) arithmetically (DADD (3)) and this data is added to the accumulator value (DADD (1) + DADD (2)). The addition result (DADD (1) + DADD (2) + DADD (3)) is written to the output data register. After this writing has been completed, an output data interrupt request is issued.

When the accumulation count is set to 2, 9-bit arithmetic right shift is made for three filter processing results and these results are added, and then an interrupt request is issued once. This processing is repeated subsequently.

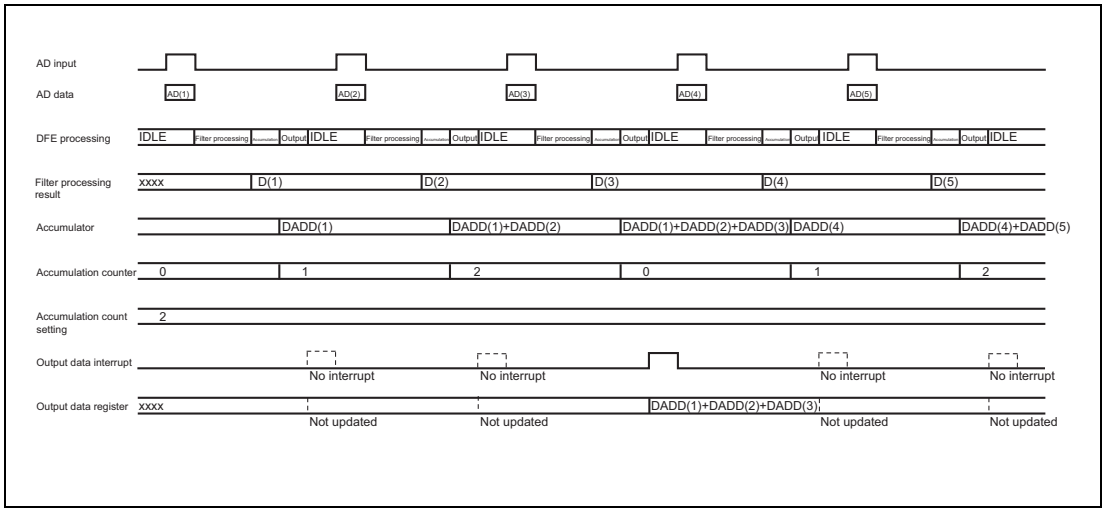

Figure 28.29 Accumulation Processing (Set Count Value = 2)

28.4.10.4 Operation of Accumulation Processing (with Trigger Flag)

The following describes operation of accumulation processing when the accumulation initialization flag and the accumulation disable flag are enabled.

When the accumulation initialization flag is enabled by a timer trigger or a software trigger while accumulation is specified (PRCSA = 01_B in CTLBCHn), the accumulation counter is initialized and accumulation processing is performed as the first data of the accumulation processing in the DFE‘s accumulation processing of the immediately following target channel.

In case the accumulation initialization flag is enabled and the accumulation count is set to 2, for example, when data (D (3)) is input to the accumulation circuit third time, the 9-bit arithmetic right-shift (DADD (3)) from the third data (D (3)) is written to the accumulator. The accumulation result value (DADD (1) + DADD (2)) is overwritten.

The data (D (4)) that is input next to the accumulation circuit is added to the data (D (5)) that is input after that to the accumulation circuit. Three accumulation results ((DADD (3) + DADD (4) + DADD (5)) are written to the output data register after the accumulation initialization flag is enabled, and an output data interrupt request is issued.

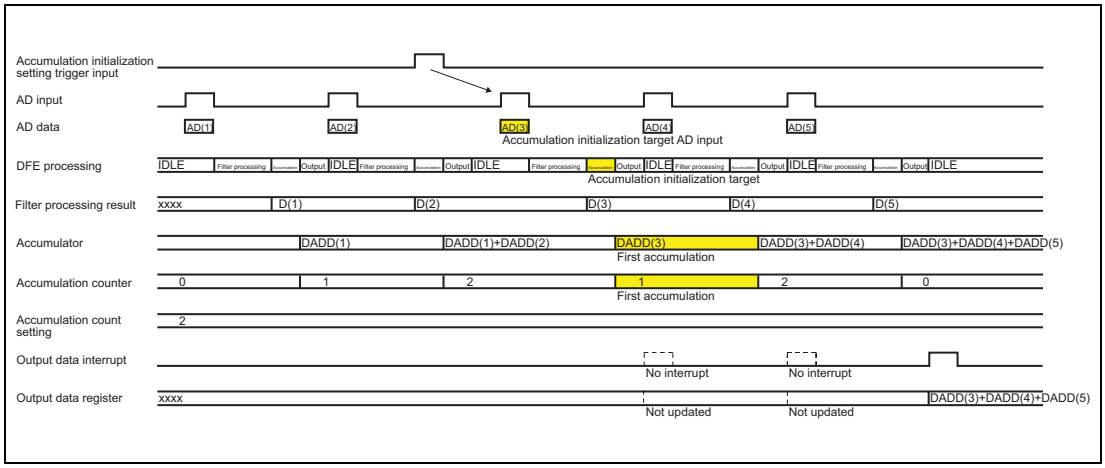

Figure 28.30 Accumulation Processing (with the Initialization Flag Enabled)

When the accumulation disable flag is enabled by a timer trigger or a software trigger while accumulation is specified (PRCSA = 01_B in CTLBCHn), the DFE's accumulation processing of the immediately following target channel is not performed and the internal accumulation disable flag is asserted. No accumulation is performed in the subsequent processing.

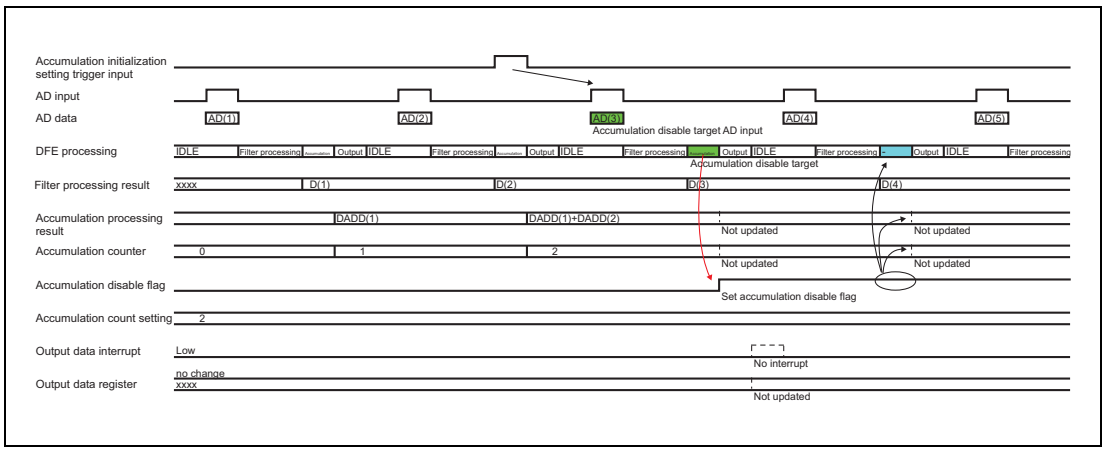

Figure 28.31 Accumulation Processing (with the Accumulation Disable Flag Enabled)

To perform accumulation processing again while the accumulation disable flag is asserted, enable the accumulation initialization flag.

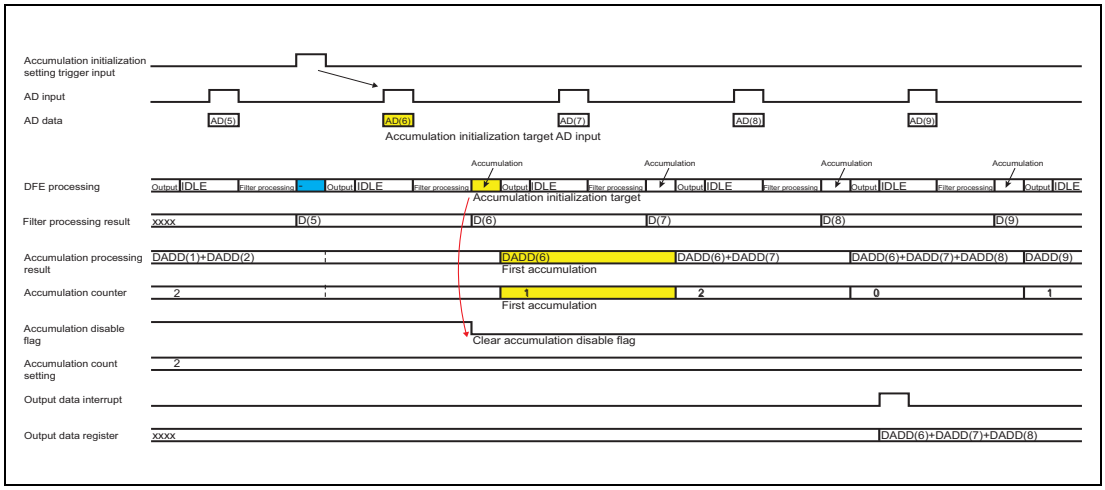

Figure 28.32 Accumulation Processing (Disable to Enable)

28.4.10.5 Summary of Decimation Processing

In the decimation processing, filter processing result data that is input to the accumulation circuit is decimated. The decimation processing count can be set to up to 511. (Data is output once every 512 times.) After processing for the specified decimation count has been completed, decimation processing is performed again.

When the PRCSA bits in CTLBCHn are 10_B, decimation processing is performed. Specify the decimation processing count by the SELA bits in CTLBCHn by selecting one of the four accumulation/decimation count setting registers (ACA to ACD).

28.4.10.6 Operation of Decimation Processing

Operation of decimation processing is explained using an example when ACA = 0_H, ACB = 1_H, ACC = 2_H, and PRCSA bits in CTLBCHn = 10_B.

When the SELA bits in CTLBCHn are 00_B, ACA is selected and decimation processing is performed with a decimation count set value of 0.

In decimation processing with a decimation count set value of 0, one-time filter processing result is output as it is and an interrupt request is issued. This processing is repeated subsequently.

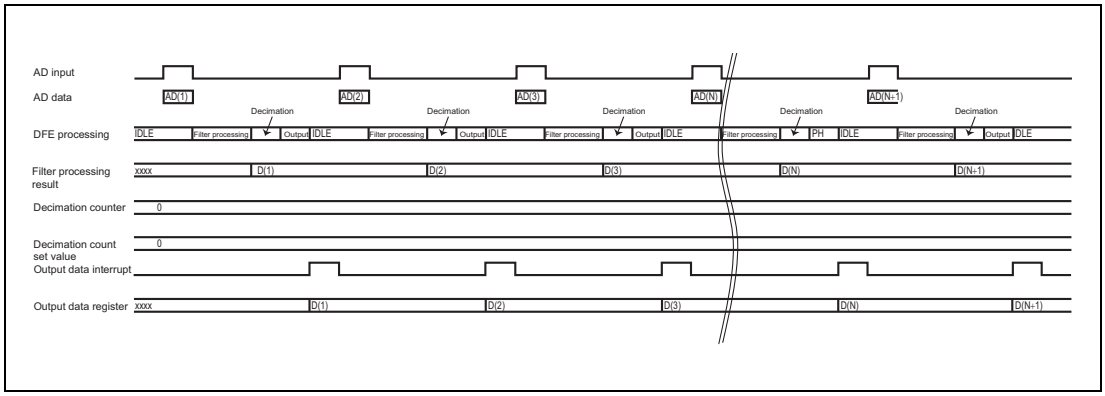

Figure 28.33 Decimation Processing (Set Count Value = 0)

When the SELA bits in CTLBCHn are 01_B, the ACB register is selected and decimation processing is performed with a set decimation count value of 1.

When the filter processing result data (D (1)) is input to the accumulation circuit, the decimation counter is incremented. At this time, the accumulation circuit does not output the input filter processing result data (D (1)) to the output circuit because the decimation counter value differs from the set decimation count value.

After that, when the filter processing result data (D (2)) is input to the accumulation circuit, the accumulation circuit outputs the input filter processing result data (D (2)) to the output circuit because the decimation counter value is equal to the set decimation count value. The output circuit writes the data (D (2)) that is input from the accumulation circuit to the output data register and issues an output data interrupt request.

When the decimation count is set to 1, an interrupt request is issued once in two filter processings. This processing is repeated subsequently.

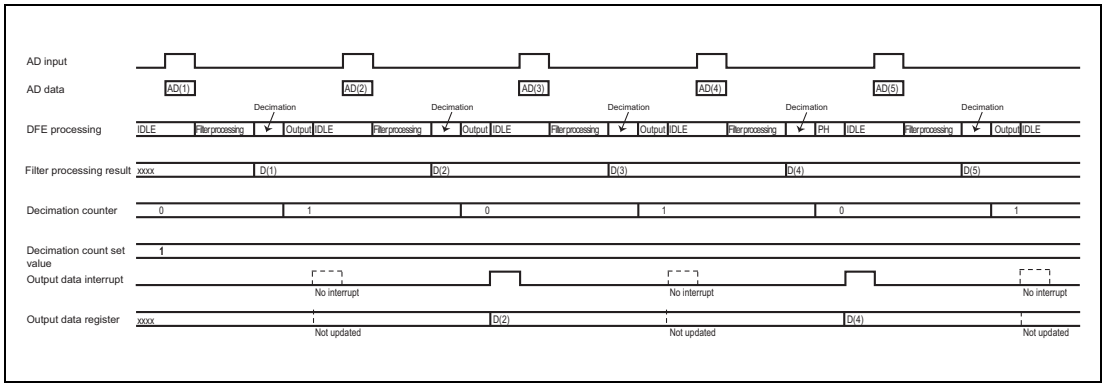

Figure 28.34 Decimation Processing (Set Count Value = 1)

When the SELA bits in CTLBCHn are 10_B, the ACC register is selected and decimation processing is performed with a set decimation count value of 2.

When the filter processing result data (D (1)) is input to the accumulation circuit, the decimation counter is incremented. At this time, the accumulation circuit does not output the input filter processing result data (D (1)) to the output circuit because the decimation counter value differs from the set decimation count value.

Then, when the filter processing result data (D (2)) is input to the accumulation circuit, the decimation counter is incremented. At this time, the accumulation circuit does not output the input filter processing result data (D (2)) to the output circuit because the decimation counter value differs from the set decimation count value.

After that, when the filter processing result data (D (3)) is input to the accumulation circuit, the accumulation circuit outputs the input filter processing result data (D (3)) to the output circuit because the decimation counter value is equal to the set decimation count value. The output circuit writes the data (D (3)) that is input from the accumulation circuit to the output data register and issues an output data interrupt request.

When the decimation count is set to 2, an interrupt request is issued once in three filter processings. This processing is repeated subsequently.

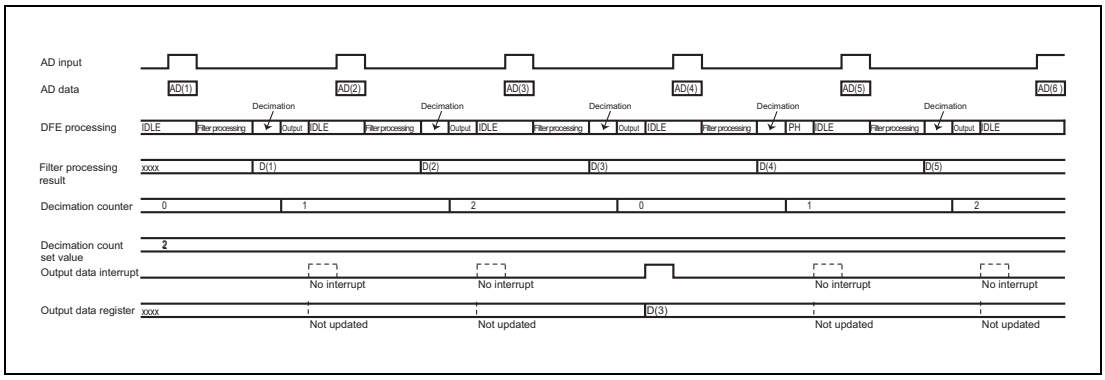

Figure 28.35 Decimation Processing (Set Count Value = 2)

28.4.10.7 Operation of Decimation Processing (with Trigger Flag)

The following describes operation of decimation processing when the decimation initialization flag and the decimation disable flag are enabled. When the decimation initialization flag is enabled by a timer trigger or a software trigger while decimation is specified (PRCSA = 10_B in CTLBCHn), the decimation counter is initialized and decimation processing is performed as the first data of the decimation processing in the DFE's decimation processing of the immediately following target channel.

In case the decimation initialization flag is enabled and the decimation count is set to 2, for example, when data (D (3)) is input to the accumulation circuit third time, the third data (D (3)) is not output from the accumulation circuit, but is processed as the first input data. Subsequently, the accumulation circuit does not output data (D (4)) that is input next to the accumulation circuit as usual, but outputs data (D (5)) that is input after that to the output circuit.

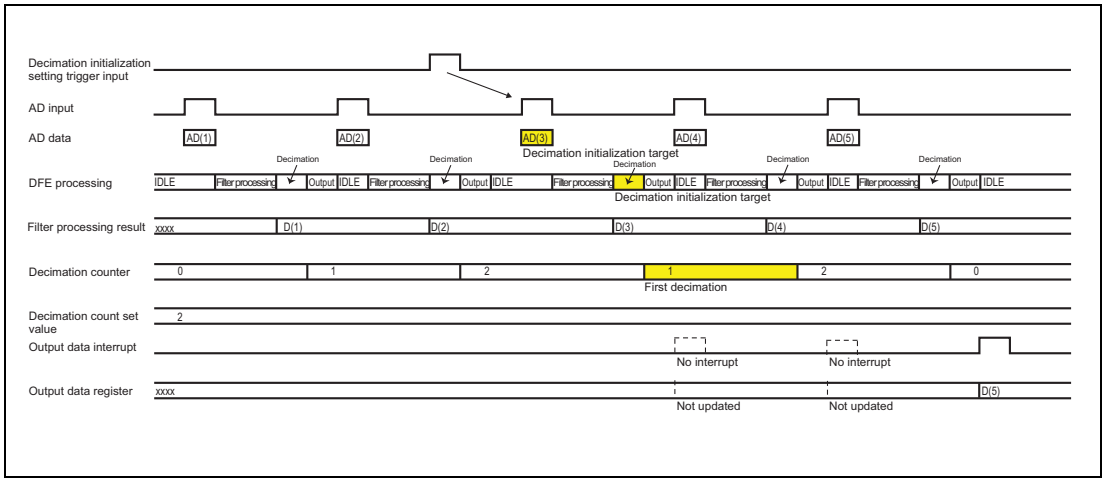

Figure 28.36 Decimation Processing (with the Initialization Flag Enabled)

When decimation is specified (PRCSA = 10_B in CTLBCHn) and the decimation disable flag is enabled, the internal decimation disable flag is asserted. In the subsequent processing, the decimation counter is disabled. While decimation is disabled, no output data interrupt request is issued.

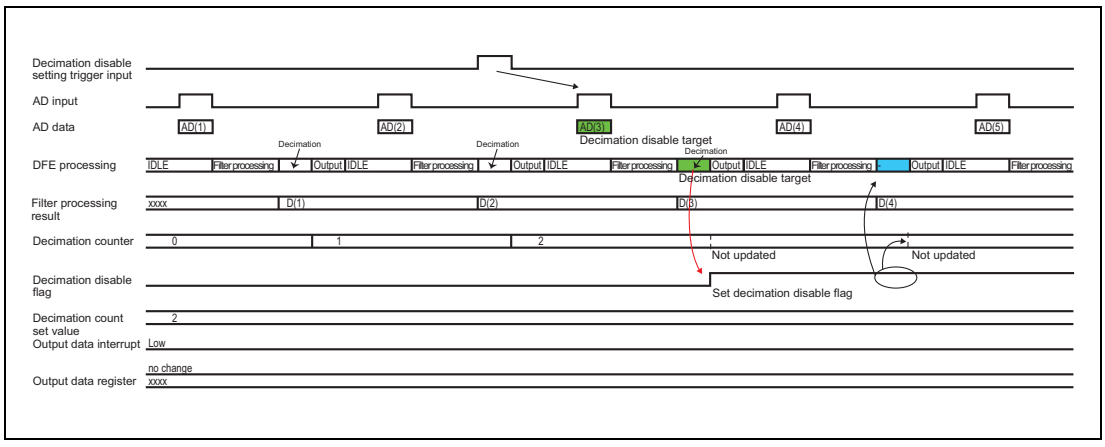

Figure 28.37 Decimation Processing (with the Decimation Disable Flag Enabled)

To perform decimation processing again while the internal decimation disable flag is asserted, enable the decimation initialization flag.

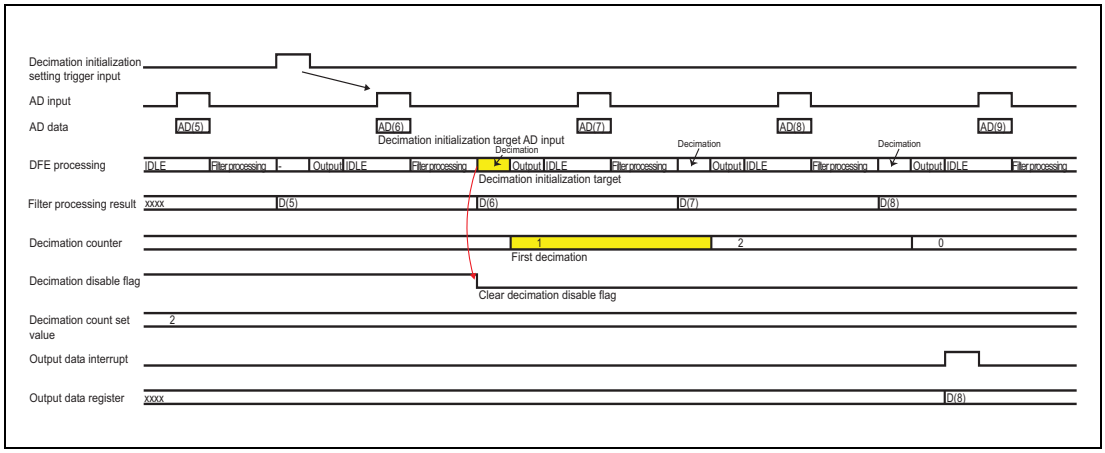

Figure 28.38 Decimation Processing (Disable to Enable)

28.4.11 PH Circuit

The PH circuit performs PH processing or comparison processing for data that is output from the accumulation circuit. When the accumulation/decimation count is specified, PH processing is performed on each specified count.

In PH processing, PH results are written to the PH result register. A condition match interrupt is generated at the end of PH processing. In comparison processing, accumulation circuit output data is compared with the value of the comparison target register. When the comparison result is true, a condition match interrupt is generated.

28.4.11.1 Summary of PH Processing

In PH processing, data that is input to the PH circuit is compared with the data that has been input to the PH circuit for each channel, and the larger value is written to the PH result register as a PH result. The PH initial value can be selected by using the SELB2 bits in CTLBCHn. Once PH processing starts, it is performed continuously until the PH processing end flag is enabled. After the PH processing flag is enabled, PH processing of data that is input to the PH circuit is not restarted until the PH initialization flag is enabled.

28.4.11.2 Operation of PH processing

Operation of PH processing is explained using an example when PRCSB = 01_B (PH specified) in CTLBCHn.

For the first input data to the target channel, PH processing is performed using the PH initial value register value and PH circuit input data value. After that, PH processing is performed using the PH result register value and PH circuit input data value.

During PH processing, when the PH initialization flag is enabled, the next input data for the target channel is compared with the PH initial value register value, not with the PH result register value.

When the PH end flag is enabled, PH processing is terminated.

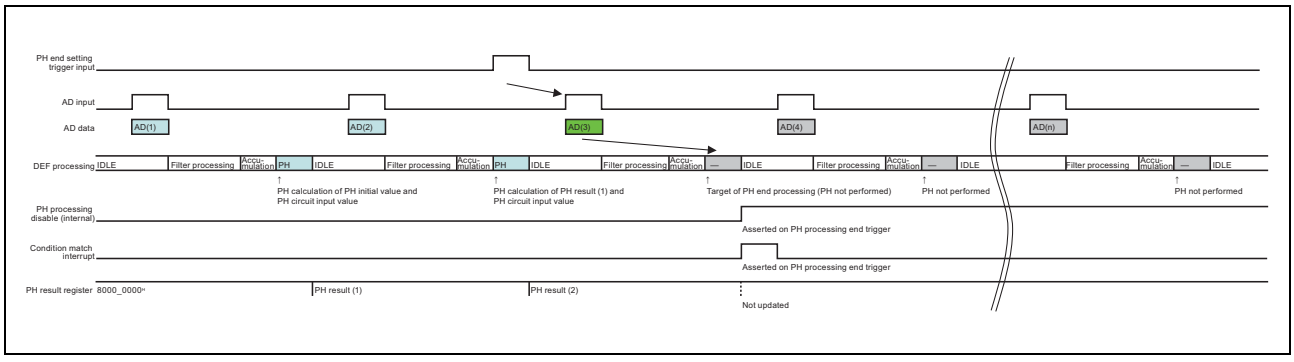

Figure 28.39 PH Processing (from PH Processing Start to PH End Flag)

NOTE

n = 0 to 9

To restart PH processing, enable the PH initialization flag.

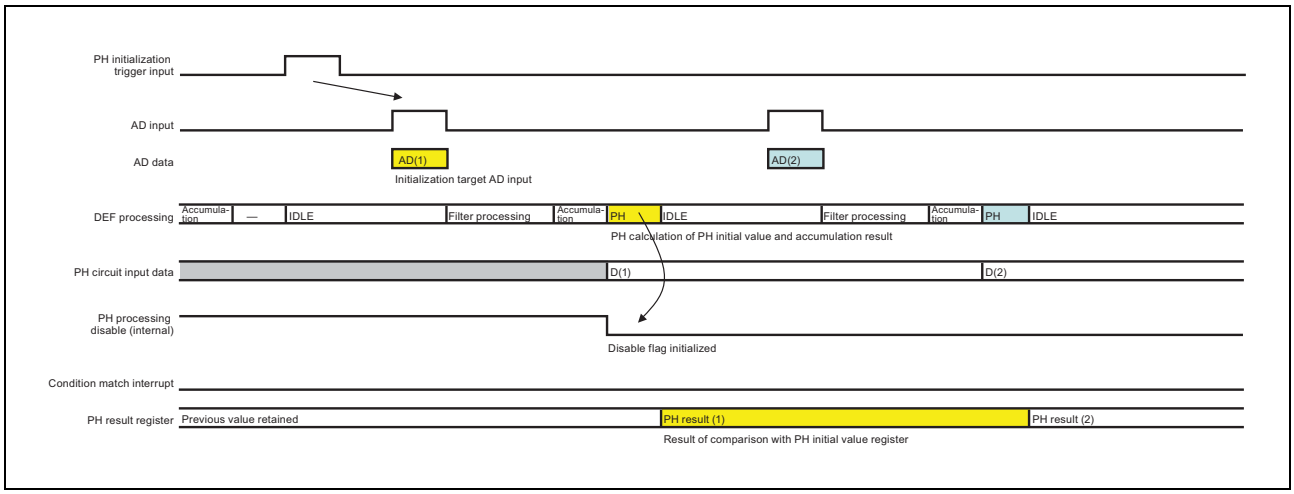

Figure 28.40 PH Processing (PH Initialization Enabled during PH Processing is Disabled)

28.4.11.3 Comparison

In comparison processing, the PH circuit input data is compared with the value of comparison target registers (CPA to CPD) for each channel. When the comparison result is true, the CND flag (condition match flag) is asserted and a condition match interrupt request is issued. Comparison processing is not affected by trigger flags. When the PRCSB bits in CTRLCHn are 10_B, comparison processing is performed.

The following comparison calculations can be performed.

Comparison	Description
Equal to (= =)	“Equal to (= =)” calculation is performed between the PH circuit input data and the selected value to be compared. When the comparison result is “equal to,” it is true.
Equal to or less than (≤)	“Equal to or less than (≤)” calculation is performed between the PH circuit input data and the selected value to be compared. When the comparison result is “equal to or less than,” it is true.
Equal to or more than (≥)	“Equal to or more than (≥)” calculation is performed between the PH circuit input data and the selected value to be compared. When the comparison result is “equal to or more than,” it is true.
Less than (<)	“Less than (<)” calculation is performed between the PH circuit input data and the selected value to be compared. When the comparison result is “less than,” it is true.
More than (>)	“More than (>)” calculation is performed between the PH circuit input data and the selected value to be compared. When the comparison result is “more than,” it is true.

Once the comparison calculation result is true and the condition match bit (CND in STCHn) is set to 1, the condition match bit remains 1 even if the subsequent comparison calculation result is false. Use the clear status register to clear the condition match bit to 0.

NOTE

n = 0 to 9

28.4.12 Output Circuit

28.4.12.1 Floating-Point Conversion Circuit

This circuit performs IEEE754 floating-point conversion of (1.31) format data that is input to the output circuit and (10.22) format data after accumulation. Specify floating-point conversion processing by setting the PRCSC bit in the control register B (CTLBCHn) to 1_B.

28.4.12.2 Output Register Circuit

The output register circuit has 32-bit registers for 16 channels. Input calculation result data or floating-point conversion result is written to the output register for each channel.

When a result of calculation with CTLBCHn.PRCSA = 01_B (accumulation) or CTLBCHn.PRCSA = 10_B (decimation) is written to an output register, the DOEN bit in STCHn is set and an interrupt request is generated. When filter processing is performed with CTLBCHn.PRCSA = 00_B, the filtering result is stored in an output register but the DOEN bit is not set and no interrupt is output.

To perform filter processing without accumulation/decimation and output an interrupt, set the PRCSA bit in CTLBCHn to 10_B (decimation) and set the decimation count to 0.

The DOEN flag in STCHn is automatically cleared to 0 by reading the output register. If another calculation result is written to the output data register with the DOEN flag in STCHn set to 1, the value in the output data register is overwritten. At this time, the DOOW bit in STCHn is set to 1.

The DOEN bit in STCHn is cleared to 0 by reading DOCHn (output data register) from the peripheral bus or setting the CLRDOOW bit in CLRSTCHn to 1.

28.4.13 Status Register

The DFE has a status register for each channel. The status register indicates the status shown below. Each flag except VALID can be cleared by using the corresponding clear status register. Only the DOEN flag can be automatically cleared by reading the output data register in addition to the clear status register.

Table 28.30 Status Register

Name	Description
VALID	Input Data Register Valid This bit is set to 1 when the input data register contains a valid value. This bit is cleared to 0 by a reset or at completion of accumulation/decimation processing.
CND	Condition Match This bit is set to 1 at the end of PH processing when PH is specified. This bit is also set to 1 when the comparison calculation result is true when comparison calculation is specified.
DOEN	Output Data Register Enable This bit is set to 1 when a calculation result with CTLBCHn.PRCSA = 01_B (accumulation) or CTLBCHn.PRCSA = 10_B (decimation) is written to an output register.
DIOW	Input Data Overwrite Error This bit is set to 1 when the input data register is overwritten during processing for the relevant channel. This bit is also set to 1 when the input data register in processing is overwritten by another input data with the same tag.
DOOW	Output Data Overwrite Error This bit is set to 1 when another calculation result is written while the output data register contains valid data.
MER	Multiplication Error This bit is set to 1 when calculation 8000_H*8000_H is performed in the filtering circuit.
GER	Guard Error This bit is set to 1 when a rounding error (48 bits to 32 bits) occurs in the filtering circuit.
CER	Cascade Rounding Error This bit is set to 1 when a rounding error (32 bits to 16 bits) occurs during execution of cascade input.
AER	Absolute Value Error This bit is set to 1 when absolute value calculation of 8000 0000_H is performed during absolute value calculation in the accumulation circuit.

28.4.14 Error Mask Registers

Functions of error mask registers are shown below. Masked error factors are excluded from error interrupt request conditions.

When the multiplication error mask flag is set to 1 in channel 0, for example, the multiplication error flag is not set to 1 even if a multiplication error occurs in channel 0. No error interrupt request is output in this case.

Table 28.31 Error Mask Registers

Flag	Description
MSKDIOW	Input data error (DIOW) mask bit
MSKDOOW	Output data error (DOOW) mask bit
MSKMER	Multiplication error (MER) mask bit
MSKGER	Guard error (GER) mask bit
MSKAER	Absolute value error (AER) mask bit
MSKCER	Cascade rounding error (CER) mask bit

28.4.15 Interrupt Requests

The DFE has 16 interrupt requests for output data for each channel, 10 condition match interrupt requests for each channel, and an error interrupt request.

28.4.15.1 Output Data Interrupt Requests

When a calculation result with CTLBCHn.PRCSA = 01_B (accumulation) or CTLBCHn.PRCSA = 10_B (decimation) is written to an output register, an output data interrupt request is output. (When the PRCSA is 00_B, a calculation result is written to an output data register but no interrupt is output.)

Interrupt requests corresponding to each channel can be output.

Interrupt request output can be controlled by using the IEO bit in the control register A.

Figure 28.41 shows the relationship between the DOEN bit in STCHn and an output data interrupt request.

Writing a DFE processing result with CTLBCHn.PRCSA = 01_B (accumulation) or CTLBCHn.PRCSA = 10_B (decimation) to an output data register sets the DOEN bit in STCHn to 1. The DOEN bit in STCHn is cleared to 0 by reading the DOCHn register by the software or by setting the CLRDOEN bit in CLRSTCHn to 1.

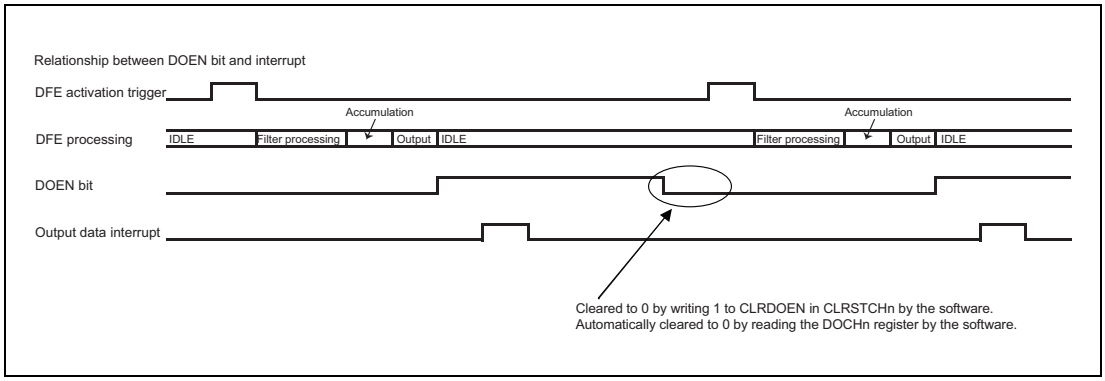

Figure 28.41 Relationship between DOEN Bit and an Interrupt

When the DOEN bit in STCHn is not cleared by the software, an output data interrupt request is not output even if data is rewritten to the output data register. If the output data register value is overwritten, the DOOW bit in STCHn is set to 1.

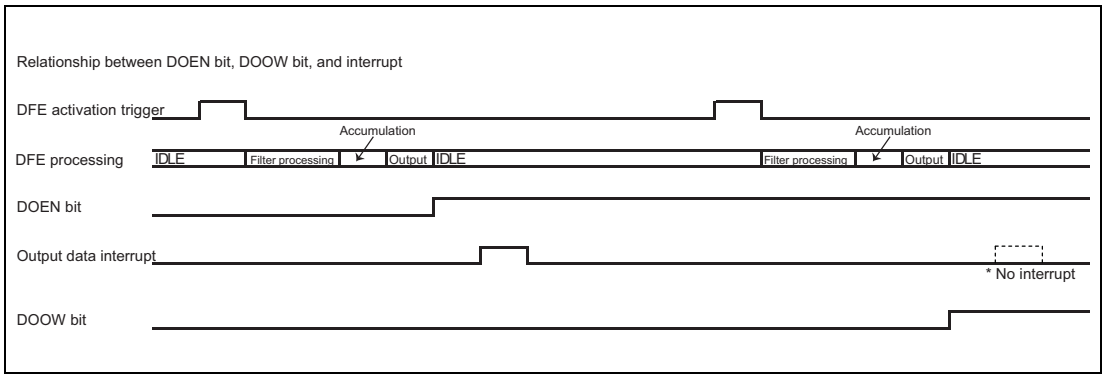

Figure 28.42 Relationship among DOEN Bit, DOOW Bit, and an Interrupt

28.4.15.2 Condition Match Interrupt Request

When the PH end trigger flag is enabled during PH processing, a condition match interrupt request indicating completion of PH processing is output. When comparison calculation result is true during comparison calculation, a condition match interrupt request is output. These requests share an interrupt. This interrupt request is given to channels 0 to 9.

Interrupt request output can be controlled by using the IEC flag in the control register A.

Figure 28.43 shows the relationship between the CND bit in the status register (STCHn (n = 0 to 9)) and condition match interrupt request. When the PH end flag is enabled, a condition match interrupt request is issued in the same timing.

The DISB bit (PH processing disable bit) in CTLBCHn disables PH processing in the same way as the enabling of the PH end flag, but does not output a condition match interrupt. In addition, even if a PH end trigger is input with PH processing, no condition match interrupt is output.

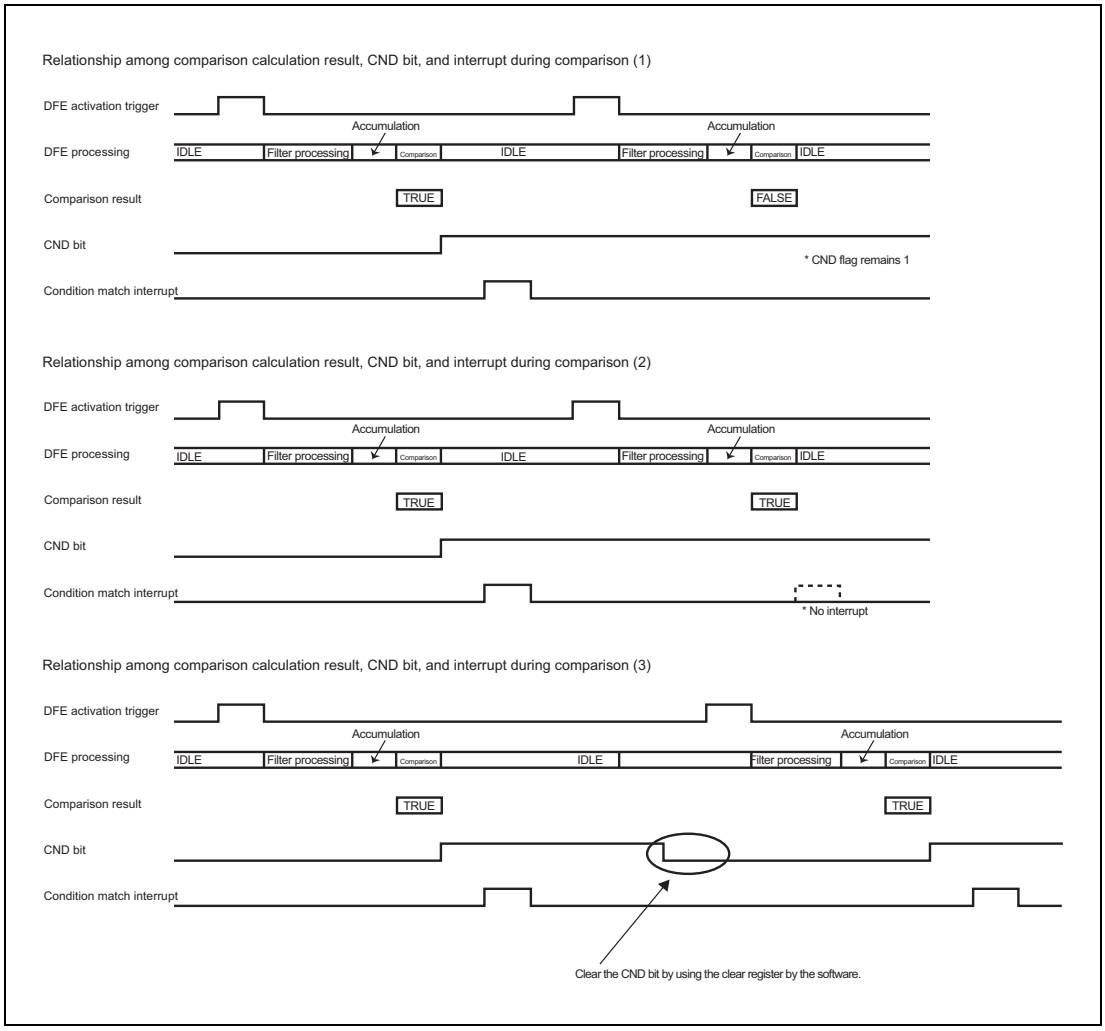

Figure 28.43 Relationship between CND Bit and Condition Match Interrupt Request

NOTE

n = 0 to 9

28.4.15.3 Error Interrupt Requests

An interrupt is generated as logical OR of errors of all channels. Error interrupt request output can be controlled for each channel.

For example, in case error interrupt requests for channel 0 to channel 7 are enabled and error interrupt requests for channel 8 to channel 15 are masked, if an error occurs in any of channels 0 to 7, an error interrupt request is output. However, if an error occurs in any of channels 8 to 15 in this state, no error interrupt request is output.

The following figure shows the relationship between error bit and error interrupt request. Since an error interrupt is generated as logical OR of error factors, another error interrupt due to a new error factor is not output while an error interrupt request is already present. After an error interrupt was output and the error bit has been cleared by the clear register, if the error bit is set again, an error interrupt is output.

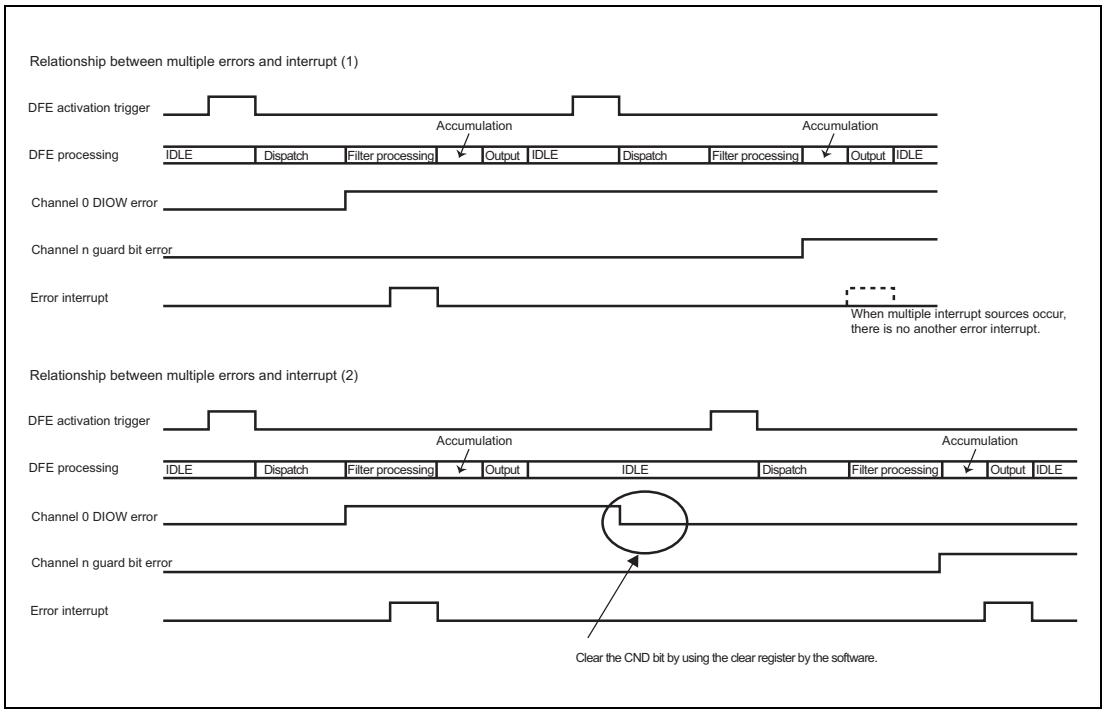

Figure 28.44 Relationship between Error Bit and Error Interrupt

28.5 Notes and Restrictions

28.5.1 Processing Time

28.5.1.1 Processing Time for One Channel

The DFE performs a single-time processing of FIR or IIR in a maximum of 0.8 µs when there is no memory access competition. If memory access competition occurs, the processing time is a maximum of 1.1 µs.

28.5.1.2 Termination Processing Time

When the EN bit in CTLACH is set to 0, the DEF performs processing for all the input data that has been accepted and terminates processing. The maximum processing time up to the termination is obtained by “the number of channels for which input data has been accepted (number of channels for which processing has not been done) x processing time”. For example, if five channels have not been processed, the termination processing time is a maximum of 5.5 µs.

28.5.2 DFE Activation Input Interval

An interval of DFE activation signal inputs should be a minimum of 0.8 µs if there is no memory access competition or a minimum of 1.1 µs if memory competition occurs.

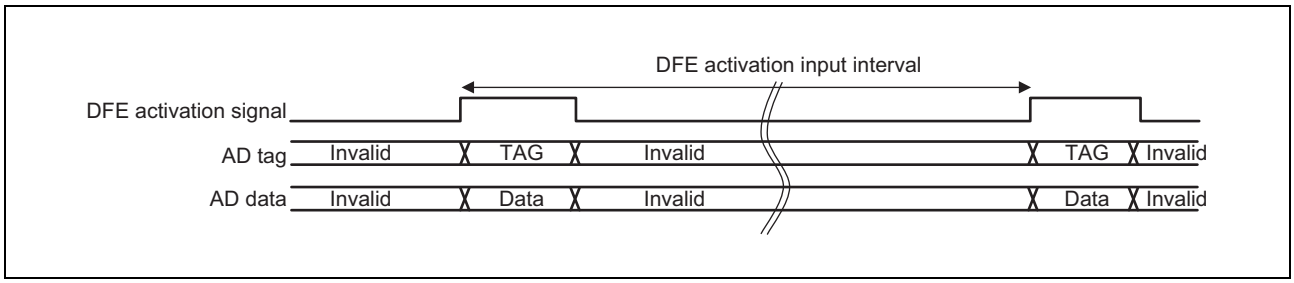

Figure 28.45 DFE Activation Input Interval (AD Input)

28.5.3 DFE Processing Time

The following two tables list the DFE processing time, i.e. the cycle from inputting a startup trigger from the AD to getting the next startup trigger on the same channel acceptable.

Table 28.32 Processing Time of FIR and IIR (Normal Cases)

		Time
FIR (normal case)	8TAP	240 ns
	16TAP	300 ns
	24TAP	350 ns
	32TAP	400 ns
IIR (normal case)	Secondary biquad 1 stage	310 ns
	Secondary biquad 2 stages	400 ns
	Secondary biquad 3 stages	490 ns

Table 28.33 Processing Time of FIR and IIR (with Initialization)

		Time
FIR (with initialization)	8TAP	310 ns
	16TAP	410 ns
	24TAP	520 ns
	32TAP	630 ns
IIR (with initialization)	Secondary biquad 1 stage	400 ns
	Secondary biquad 2 stages	570 ns
	Secondary biquad 3 stages	750 ns

Access by the CPU to the coefficient memory or data memory during DFE processing increases the total time for processing. When the frequency of the DFE operating clock is 80 MHz, the processing time increases by 25 ns per memory access.

28.5.4 Trigger Input

The following figure shows an example of supposed input of timer triggers 0 to 3 and a software trigger. When timer trigger 0 is used, for example, it is supposed that the DFE activation signal is input once or more times and timer trigger 0 is input again after the trigger flag function is enabled by the timer trigger 0 input.

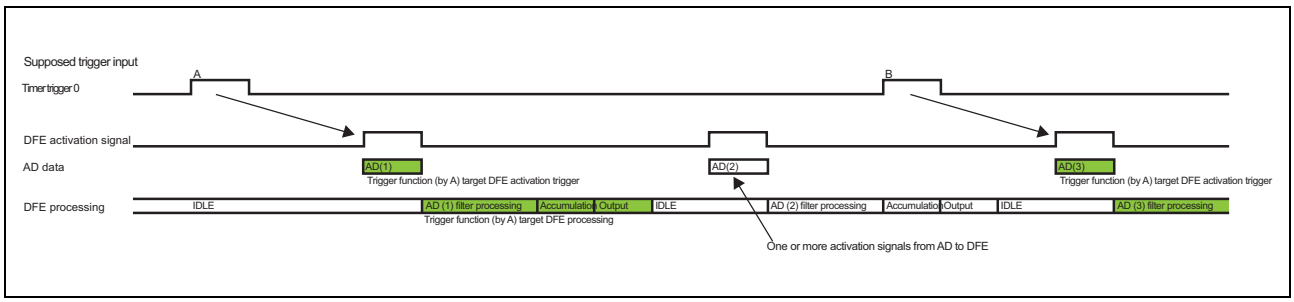

Figure 28.46 Example of Trigger Input

When a timer trigger or a software trigger is input, the corresponding flag is enabled on completion of the DFE processing. Then the flag is cleared to accept the next trigger. However, the latter trigger is not enabled when it is input before the former trigger flag is completely cleared. Therefore, successive inputs of a timer trigger or a software trigger are prohibited.

In the example below, the trigger function by B is not enabled in some cases.

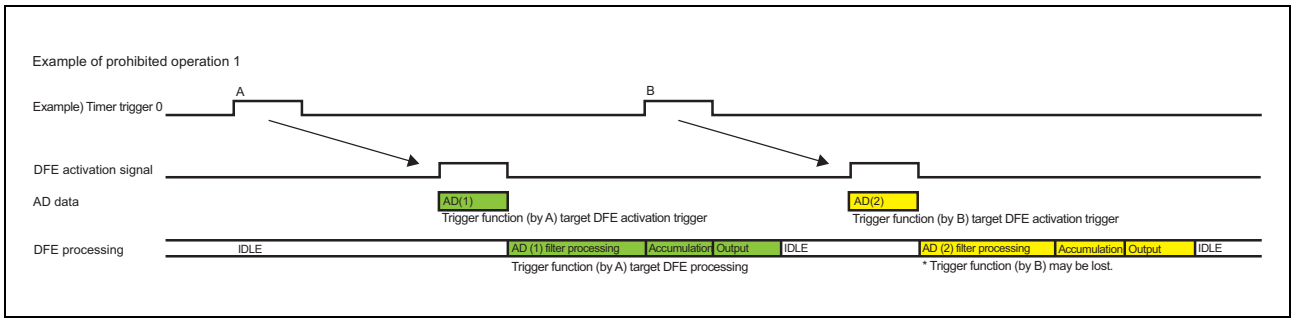

Figure 28.47 Operation in which the Same Trigger is Prohibited 1

Before a timer trigger or a software trigger is input and the DFE activation signal is input, the same timer trigger or software trigger must not be input again. In the example below, the trigger function by A and the trigger function by B are enabled only for AD (2).

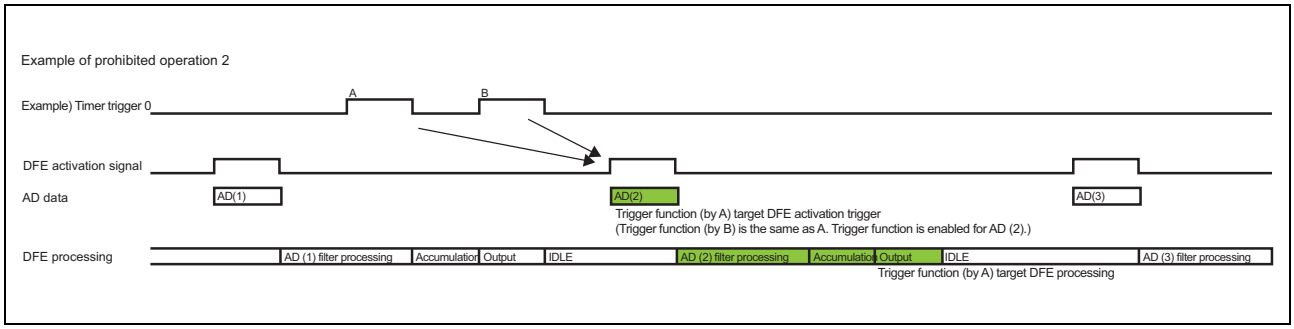

Figure 28.48 Operation in which the Same Trigger is Prohibited 2

28.5.5 Channel Tag and AD Tag

If a tag value (AD tag) that the AD inputs to the DFE and a tag value (channel tag) that the software sets for the DFE are different, correct processing is disabled. For example, the AD inputs an AD tag value of 0001_B to the DFE and there is no channel with a DFE's channel tag value 0001_B, the DFE does not perform filter processing.

28.5.6 Input Data Format and Calculation Restrictions

Restrictions on available calculations are provided for the DFE. For details, see **Section 28.4.6, Setting Control Registers**.

28.5.7 Restrictions on Cascade Processing

Cascade processing is a function to round 32-bit accumulation circuit output data to 16-bit data to be input data of other channels. The following restrictions are provided for cascade processing. Observe these restrictions together with the descriptions in **Section 28.4.6, Setting Control Registers**.

1. When cascade is enabled, do not set the same value for cascade tag and channel tag in the same channel. Assign a channel that is different from the channel for which cascade is specified as a cascade destination channel. If the same tag value is set, the filter processing result is input to the same channel again and calculation is repeated.
2. When cascade is enabled, the data format of cascade enabled channels must be the same as the data format of cascade destination channels. For example, when the fixed-point input format is specified for cascade enabled channels, also specify the fixed-point input format for cascade destination channels.
3. Cascade input can be enabled for up to 15 channels in 16 channels. If cascade input is enabled for all channels, calculation is repeated for filter calculation results that are input in cascade.
4. The CAEN bits in the control register A (CTLACHn) must not be set to 01_B.
5. When PH processing and comparison processing are enable, PH processing and comparison processing are performed for 32-bit data.
6. No floating-point conversion result can be a cascade input.
7. When enabling the cascade function of two or more channels and selecting a single cascade destination channel, pay attention to the priority of channels. Specify cascade channels so that higher priority is given to cascade destination channels than cascade enabled channels. To enable the cascade function of channel 1 and channel 2 and select the same cascade destination for channel 1 and channel 2, for example, specify channel 0 as a cascade destination channel.

28.5.8 Operation when a Channel is Disabled

While the channel enable bit (CTLACHn.EN) is set to 0, filter processing is not activated even if the AD tag value that is input from the AD is equal to the channel tag value.

In addition, timer trigger input of the trigger flag function specified for the channel and software trigger input are not accepted.

When the channel enable bit (CTLACHn.EN) is set to 0 from 1, data to be processed that was input before this bit is set to 0 is processed.

At this time, if a trigger for the trigger flag function is input before the channel enable bit is set to 0, the trigger flag function is enabled for the data to be processed.

When the channel enable bit (CTLACHn.EN) is 1, input trigger for the trigger flag function is held until AD data is input and the trigger flag function is enabled for the data to be processed (trigger held).

After the channel enable bit (CTLACHn.EN) is set to 0 from 1, the held trigger is cleared if there is no data to be processed.

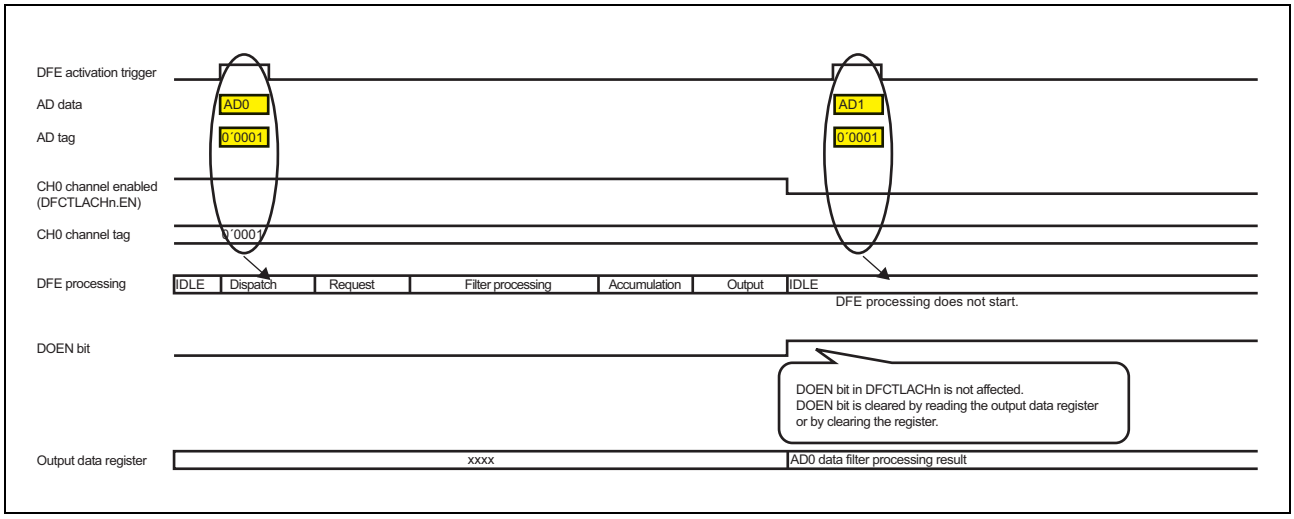

Figure 28.49 EN Bit and DOEN Bit

Even if the channel enable bit (CTLACHn.EN) is cleared to 0, the status register is not cleared. Clear the status register by the software as needed.

If the channel enable bit is set to 1 from 0 to restart the DFE processing.

- Accumulation/decimation counter starts at 0 in the same way as the first DFE processing after a reset.
- Comparison with the initial value register value is performed during the first PH processing, and comparison with the PH result register value is performed during the subsequent processing.

28.5.9 Restrictions on Memory Access

8-bit or 16-bit write access to the coefficient memory is prohibited. Write data to the coefficient memory in 32 bits. 8-bit write access to data memory 0 and data memory 1 is prohibited. Write data to data memory 0 and data memory 1 in 16 bits.

If a prohibited access is made, data may be broken. In the case of the coefficient memory, word data (32 bits) including a byte-write address may be broken. In the case of data memory 0 and data memory 1, half-word data (16 bits) including a byte-write address may be broken.

28.5.10 Restrictions on Trigger Setting Registers

A software trigger must not be used to set both the accumulation/decimation initialization and the accumulation/decimation disable setting. Operation is not guaranteed if this setting is made.

A software trigger must not be used to set both the PH initialization and the PH end setting. Operation is not guaranteed if this setting is made.

28.5.11 Setting of PH Processing Disable Bit and Accumulation/Decimation Processing Disable Bit

When the EN bit in CTLACHn and VALID bit in STCHn are both 0, the DISB bit (PH processing disable bit) in CTLBCHn and DISA bit (accumulation/decimation processing disable bit) in CTLBCHn can be set by software.

To disable PH processing by writing 1 to the DISB bit in CTLBCHn, set the PRCSB bit in CTLBCHn to 01_B (for PH processing). To disable accumulation/decimation processing by writing 1 to the DISA bit in CTLBCHn, set the PRCSA bit to 01_B (for accumulation processing) or 10_B (for decimation processing).

Section 29 Safety

29.1 Overview

This section describes the failure detection functions provided to detect the LSI failures in the early stage. Here, the failures include both the recoverable transient failures such as software errors of a memory and the unrecoverable permanent failures.

This microcontroller was developed to meet the requirements for a Safety Element out of Context (SEooC) as described in the ISO26262. Contact our sale office for the details regarding the development process and safety organization.

The following lists the failure detection functions provided by this LSI.

ECC and EDC

Detect failures of memories and data transfer paths; correct some types of failures.

Lockstep

Detects failures of the CPU1 in the early stage.

NOTE

The lockstep function is disabled during debugging.

Failures are not detected even when the failure detection function is used.

Memory Protection

Detects erroneous access to memories and peripheral circuits to protect the data in these elements against erroneously access.

MISG

Monitors write access to a specific address by the CPU or PCU, generates the signatures based on the written data, and automatically compares the generated signatures with each other.

Clock Monitor

Monitors the clock operation to detect abnormal operation.

BIST

Detects failures of the failure detection function itself.

Error Control Module (ECM)

Monitors various failure detection states in the LSI and defines the operation to be carried out upon failure detection.

29.2 ECC and EDC

29.2.1 Overview

29.2.1.1 ECC

This product incorporates ECC for the following memories. The ECC enables detection and correction of errors of the data retained in the memories. The ECC also enables detection and correction of errors produced between the ECC encoder and memories; and memories and ECC decoder.

Table 29.1 ECC Overview

Applicable Memory	Applicable Data Width [bits]	Operation upon Error Detection				Failure Insertion
		Detection/ Correction	Notice to ECM	Error Status	Address Capture	
Code flash	128	SEC-DED	Possible	Possible	Possible	Possible
Data flash Local RAM (CPU1) Local RAM (PCU) Global RAM	32	SEC-DED	Possible	Possible	Possible	Possible
Instruction cache (data)	64	SEC-DED	Possible	Possible	Possible	Possible
Instruction cache (tag)	32	SED-DED	Possible	Possible	Possible	Possible
RAM for DTS	32	SEC-DED	Possible	Possible	Possible	Possible
Peripheral RAM (32 bits)	32	SEC-DED	Possible	Possible	Possible	Possible
Peripheral RAM (16 bits)	16	SEC-DED	Possible	Possible	Possible	Possible

Applicable Data Width

ECC encoding is applied to the data of the shown width. If narrower data is to be written, the following processes are required. Here, ECC is also checked when data is read out in (1).

(1) Read data to which ECC encoding is applied, including data to be rewritten.

(2) Replace data to be rewritten.

(3) Write back the data generated in (2).

Detection/Correction

SEC-DED: 1-bit errors can be detected and corrected, and 2-bit errors can only be detected.

SED-DED: 1-bit errors and 2-bit errors can only be detected.

Notice to ECM

An error detected can be notified to the ECM (error control module).

Error Status

The status of an error detected is retained.

Address Capture

The address of an error detected is retained.

Failure Insertion

An ECC error can be intentionally caused to enable self-diagnosis of the ECC decoder operation.

29.2.1.2 Address Parity

This product incorporates address parity for the following memories. The address parity enables detection of errors during address decoding. The EDC also enables detection of errors produced at addresses between the parity encoder and memories.

Table 29.2 Address Parity Overview

Applicable Memory	Parity Bit	Notice to ECM	Error Status	Address Capture	Failure Insertion
Code flash	1 bit	Possible	Possible	Possible	Possible
Local RAM (CPU1)	2 bits*1	Possible	Possible	Possible	Possible
Global RAM	1 bit	Possible	Possible	Possible	Possible

Note 1. The parity bits corresponding to the written address are written to two locations in the memory. When they are compared to the parity bits corresponding to the read address and errors are detected at both of the two parity bits stored in the memory, it is handled as an address parity error. When an error is detected only at one of the parity bits, it is handled as a parity bit error.

29.2.1.3 Data Parity

This product incorporates data parity for the particular data transfer. The data EDC enables detection of errors of the transferred data. For details, refer to **Section 29.2.11, Data Parity for Data Transfer Paths**.

29.2.2 Code Flash ECC and Address Parity

29.2.2.1 Overview

The code flash ECC is summarized in the table below.

Table 29.3 Overview of Code Flash ECC

Item	Description
ECC error detection and correction	ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected. • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). In the state after reset, detection of a 2-bit error and detection and correction of a 1-bit error will be notified while the function is enabled.
Address parity	Address parity check can be either enabled or disabled. Address parity is checked during data read. In the state after reset, this function is enabled.
Error notification	Upon occurrence of an ECC error or parity error, the ECM is notified of the error. **ECC Error:** • Error notification can be either enabled or disabled upon detection of a 2-bit ECC error. • Error notification can be either enabled or disabled upon detection of a 1-bit ECC error. In the state after reset, error notification is enabled upon detection of a 2-bit ECC error, and error notification is disabled upon detection of a 1-bit ECC error. **Parity Error:** • Error notification can be either enabled or disabled upon detection of an address parity error. In the state after reset, error notification is enabled upon detection of an address parity error. The error notification signal is issued to the ECM, where a 2-bit ECC error and an address parity error are handled as one source, and a 1-bit ECC error is handled as one source.
Error status	A status register is provided, which indicates the statuses of 2-bit ECC error detection, 1-bit ECC error detection, and address parity error detection. If an error occurs while no error status flag is set, the corresponding status is set. The error status flag can be cleared using the clear register.
Address capture	If an ECC error or a parity error occurs while no error status flag is set, the address at which the associated error has occurred is captured. The address is captured when a 2-bit ECC error, a 1-bit ECC error, or an address parity error is detected. The error status flag serves as the enable bit of the capture address.
Self-diagnosis	Data in the ROM and the ECC and address parity bits can all be read directly. Desired values can also be written to the ROM and to the ECC and address parity bits.
Others	The ECM can initiate a transition to the safe state in response to the detection of a 2-bit ECC error during the fetching of an instruction.

The ECC decoder and address parity generator are provided each for the read ports (CPU1, PCU, and interconnect) connected to the code flash interface. The address parity checker is provided in the access controller near the code flash. For details, see **Figure 29.1**.

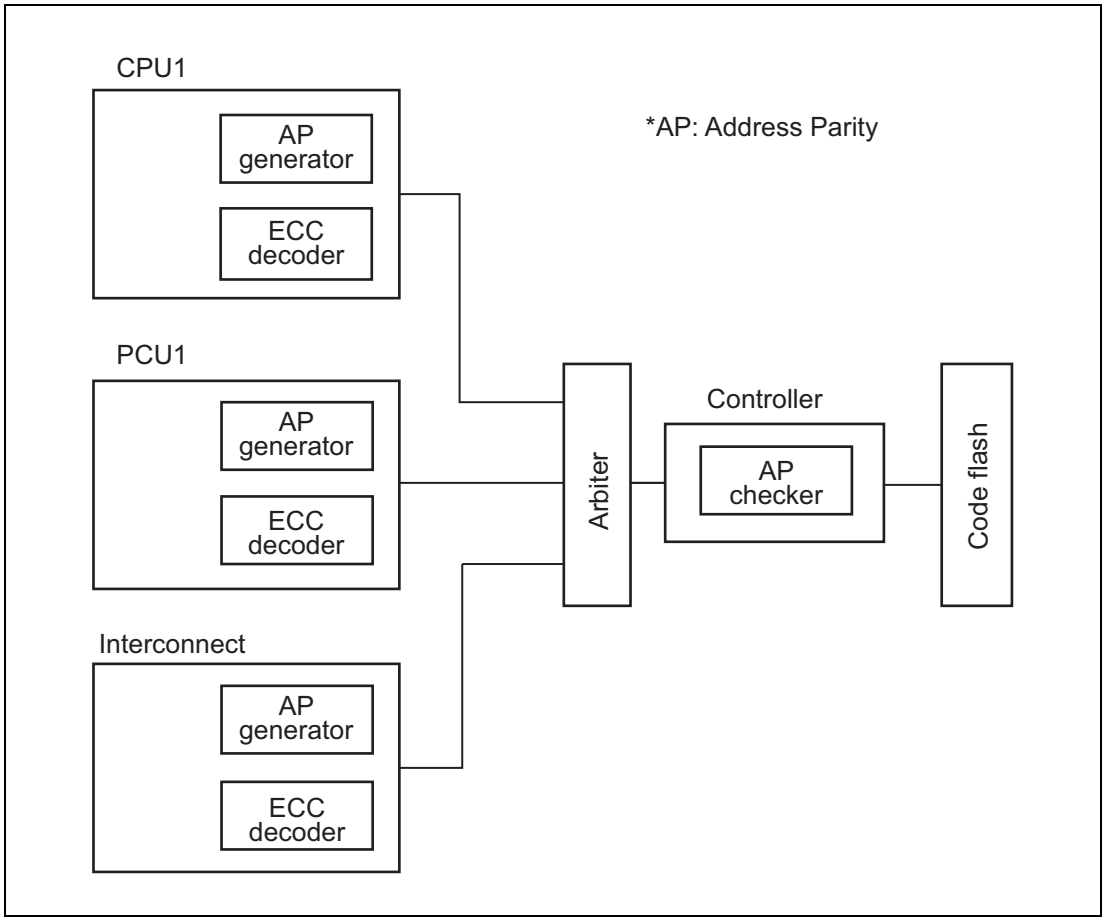

Figure 29.1 ECC and Address Parity of Code Flash

29.2.2.2 List of Registers

Table 29.4 List of Registers

Address	Symbol*1	Register Name	R/W	Value after Reset	Access Size
FFC6 2000_H	CFAPCTL	Code flash address parity control register	R/W	0000 0000_H	16/32
FFC6 2200_H	CFECCCTL_VCI	Code flash ECC control register (VCI)	R/W	0000 0000_H	16/32
FFC6 2204_H	CFERRINT_VCI	Code flash error information control register (VCI)	R/W	0000 0006_H	8/16/32
FFC6 2208_H	CFSTCLR_VCI	Code flash status clear register (VCI)	W	0000 0000_H	8/16/32
FFC6 $220C_H$	CFOVFSTR_VCI	Code flash error count overflow status register (VCI)	R	0000 0000_H	8/16/32
FFC6 2210_H	CF1STERSTR_VCI	Code flash 1st error status register (VCI)	R	0000 0000_H	8/16/32
FFC6 2250_H	CF1STEADR0_VCI	Code flash 1st error address register (VCI)	R	0000 0000_H	8/16/32
FFC6 2350_H	CFSTSTCTL_VCI	Code flash sub test control register (VCI)	R/W	0000 0000_H	16/32
FFC6 2400_H	CFECCCTL_PE1	Code flash ECC control register (PE1)	R/W	0000 0000_H	16/32
FFC6 2404_H	CFERRINT_PE1	Code flash error information control register (PE1)	R/W	0000 0006_H	8/16/32
FFC6 2408_H	CFSTCLR_PE1	Code flash status clear register (PE1)	W	0000 0000_H	8/16/32
FFC6 $240C_H$	CFOVFSTR_PE1	Code flash error count overflow status register (PE1)	R	0000 0000_H	8/16/32
FFC6 2410_H	CF1STERSTR_PE1	Code flash 1st error status register (PE1)	R	0000 0000_H	8/16/32
FFC6 2450_H	CF1STEADR0_PE1	Code flash 1st error address register (PE1)	R	0000 0000_H	8/16/32
FFC6 2550_H	CFSTSTCTL_PE1	Code flash sub test control register (PE1)	R/W	0000 0000_H	16/32
FFC6 2800_H	CFECCCTL_PCU	Code flash ECC control register (PCU)	R/W	0000 0000_H	16/32
FFC6 2804_H	CFERRINT_PCU	Code flash error information control register (PCU)	R/W	0000 0006_H	8/16/32
FFC6 2808_H	CFSTCLR_PCU	Code flash status clear register (PCU)	W	0000 0000_H	8/16/32
FFC6 $280C_H$	CFOVFSTR_PCU	Code flash error count overflow status register (PCU)	R	0000 0000_H	8/16/32
FFC6 2810_H	CF1STERSTR_PCU	Code flash 1st error status register (PCU)	R	0000 0000_H	8/16/32
FFC6 2850_H	CF1STEADR0_PCU	Code flash 1st error address register (PCU)	R	0000 0000_H	8/16/32
FFC6 2950_H	CFSTSTCTL_PCU	Code flash sub test control register (PCU)	R/W	0000 0000_H	16/32

Note 1. The registers with symbols "_VCI", "_PE1", and "_PCU" as suffixes are provided to the particular ECC controllers: the registers with "_VCI" are provided to the ECC controller for access from the system interconnect 1 to the code flash, the registers with "_PE1" are provided to the ECC controller for access from the CPU1, and the registers with "_PCU" are provided to the ECC controller for access from the PCU.

29.2.2.3 Details of Registers

(1) CFAPCTL — Code Flash Address Parity Control Register

CFAPCTL enables or disables address parity check. Set the PROT[1:0] bits to 01_B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	APTESTB	APTESTA	APARIDIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 29.5 CFAPCTL Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	PROT[1:0]	These bits enable writng to this register. The read value is 0.
13 to 3	—	Reserved These bits are always read as 0. The write value should also be 0.
2	APTESTB	Address Parity Checker (Bank B) Test Sets the address parity checker to test mode. When APTESTB = 1, the parity generated by the address parity generator is inverted.
1	APTESTA	Address Parity Checker (Bank A) Test Sets the address parity checker to test mode. When APTESTA = 1, the parity generated by the address parity generator is inverted.
0	APARIDIS	Address Parity Check Disable Enables or disables address parity check by the address parity circuit. 0: Enables address parity check. 1: Disables address parity check.

(2) CFECCCTL_VCI/_PE1/_PCU — Code Flash ECC Control Register

CFECCCTL enables or disables ECC error detection and correction and 1-bit error correction. Set the PROT[1:0] bits to 01_B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	SECDIS	ECCDIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 29.6 CFECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	SECDIS	1-Bit Error Correction Disable Enables or disables 1-bit error correction when ECC error detection and correction are enabled. 0: Enables correction of the 1-bit error detected. 1: Disables correction of the 1-bit error detected.
0	ECCDIS	ECC Disable Enables or disables ECC error detection and correction. 0: Enables ECC error detection and correction. 1: Disables ECC error detection and correction.

(3) CFERRINT_VCI/_PE1/_PCU — Code Flash Error Information Control Register

CFERRINT enables or disables generation of the error notification signal to the ECM upon detection of a 2-bit ECC error, a 1-bit ECC error, or an address parity error.

CFERRINT is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	APEIE	DEDIE	SEDIE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 29.7 CFERRINT Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved These bits are always read as 0. The write value should also be 0.
2	APEIE	Address Parity Error Notification Enable Enables or disables generation of the error notification signal upon detection of an address parity error when address parity check is enabled. 0: Disables notification of the address parity error. 1: Enables notification of the address parity error.
1	DEDIE	2-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 2-bit ECC error. 1: Enables notification of the 2-bit ECC error.
0	SEDIE	1-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 1-bit ECC error. 1: Enables notification of the 1-bit ECC error.

(4) CFSTCLR_VCI/_PE1/_PCU — Code Flash Status Clear Register

CFSTCLR clears the error flags in the error status register (CF1STERSTR), the overflow flag in the error count overflow status register (CFOVFSTR), and the error address register (CF1STEADR). CFSTCLR is a write-only register and is always read as 0.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STCLR0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 29.8 CFSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	STCLR0	Error Overflow Flag Clear Writing 1 to this bit clears the APEF0, DEDF0, and SEDF0 flags in CF1STERSTR; ERROVF0 flag in CFOVFSTR; and CF1STEADR0.

(5) CFOVFSTR_VCI/_PEI/_PCU — Code Flash Error Count Overflow Status Register

CFOVFSTR monitors occurrence of error count overflow. If the second error occurs after the first error (= while any of the error flags in the error status register is set), the flag in this register is set. However, if the second error is identical to the first error (both the source and address are same), this flag is not set. ERROVF is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in CFSTCLR.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ERROVF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.9 CFOVFSTR Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	ERROVF0	Error Overflow Flag This flag is set if the second error occurs while any of the error flags (APEF0, DEDF0, and SEDF0) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.

(6) CF1STERSTR_VCI/_PE1/_PCU — Code Flash 1st Error Status Register

CF1STERSTR monitors occurrence of the first error. An error status flag is set if an error occurs while the error flag is 0. Note, however, that the corresponding error flag is also set if a 2-bit ECC error or an address parity error occurs in subsequent access as long as only the 1-bit ECC error flag is set at the time.

If more than one error is detected for a given memory access, all the corresponding error flags are set. CF1STERSTR is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in CFSTCLR.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	APEF0	DEDF0	SEDF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.10 CF1STERSTR Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved These bits are always read as 0. The write value should also be 0.
2	APEF0	Address Parity Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting the STCLR0 bit to 1 in CFSTCLR. Setting condition: An address parity error has occurred while the error flags DEDF0 and APEF0 are 0.
1	DEDF0	2-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting the STCLR0 bit to 1 in CFSTCLR. Setting condition: A 2-bit ECC error has occurred while the error flags DEDF0 and APEF0 are 0.
0	SEDF0	1-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting the STCLR0 bit to 1 in CFSTCLR. Setting condition: A 1-bit ECC error has occurred while the error flags DEDF0, SEDF0, and APEF0 are 0.

(7) CF1STEADR0_VCI/_PE1/_PCU — Code Flash 1st Error Address Register

CF1STEADR0 holds the address at which an error has occurred.

The error address is set if an error occurs while all the error flags are 0 in CF1STERSTR. The address is updated if a 2-bit ECC error or an address parity error occurs while the 1-bit ECC error flag is set as the first error. Once a 2-bit ECC error or an address parity error occurs, the address is not updated.

EADR[24:4] of this register correspond to bits [24:4] of the real address. The real address can be calculated by appending the higher-order address bits [31:25] as a base address.

CF1STEADR0 is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in CFSTCLR.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	EADR[24:16]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EADR[15:4]												—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.11 CF1STEADR0 Register Contents

Bit Position	Bit Name	Function
31 to 25	—	Reserved These bits are always read as 0. The write value should also be 0.
24 to 4	EADR[24:4]	1st Error Address These bits monitor the address of the first error. The error address is set if an error occurs while all the error flags are 0 in CF1STERSTR. The address is updated if a 2-bit ECC error or an address parity error occurs while the 1-bit ECC error flag is set as the first error. Once a 2-bit ECC error or an address parity error occurs, the address is not updated.
3 to 0	—	Reserved These bits are always read as 0. The write value should also be 0.

(8) CFSTSTCTL_VCI/PE1/PCU — Code Flash Sub-Test Control Register

CFSTSTCTL is used for the ECC test (self-diagnosis). This register is dedicated for the code flash. After ECC test mode is enabled by setting ECCTST = 1, the ECC and address parity bits can be read directly. Set the PROT[1:0] bits to 01_B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.12 CFSTSTCTL_VCI/PE1/PCU Registers Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 1	—	Reserved These bits are always read as 0. The write value should also be 0
0	ECCTST	ECC Test After ECC test mode is enabled by setting ECCTST = 1, the ECC and address parity bits can be read directly.

Correctly reading instructions from the code flash access port is not possible while ECC test mode is selected (ECCTST = 1). While the access port for the CPU or PCU is set to test mode (including during changes to the value of the ECCTST bit), the CPU or PCU must run a program from the local RAM or global RAM and must not fetch instructions from the code flash memory.

The CPU has a small data buffer. If an old value remains in this buffer, the correct value cannot be read even when the ECCTST bit is switched. When switching the ECCTST bit, be sure to clear the data buffer. For how to clear the data buffer, see **Section 3, CPU System**.

From the code flash access port with ECC test mode selected, access must be made by reading 4 bytes aligned to 16n address. The results of code flash reading are as follows:

Table 29.13 Results of Code Flash Reading

Bit Position	Contents
31 to10	Always 0
9	Address parity bit
8 to 0	ECC bits

29.2.2.4 Test Function

Through appropriate register setting, the code flash data, ECC bits, and address parity bit can be read out.

(1) Reading Code Flash Data

(1) Set the ECCDIS bit in the code flash ECC control register to 1 to disable ECC error detection and correction.

(2) When ECCDIS = 1, neither error detection nor correction proceeds when the code flash is read; the data output from the code flash is read unchanged.

How to exit this test mode:

(1) Set the ECCDIS bit in the code flash ECC control register to 0 to enable ECC error detection and correction.

(2) Reading the ECC and Address Parity Bits

(1) Set the ECCDIS bit in the code flash ECC control register to 1 to disable ECC error detection and correction.

(2) Set the ECCTST bit in the code flash sub-test control register to 1 to set test mode.

(3) When the code flash is read, the ECC and address parity bits are read instead of the code flash data.

How to exit this test mode:

(1) Set the ECCDIS bit in the code flash ECC control register to 0 to enable ECC error detection and correction.

(2) Set the ECCTST bit in the code flash sub-test control register to 0 to set normal mode.

(3) Self-Diagnosis

Self-diagnosis of the ECC decoder and address parity decoder for the access ports is possible by writing incorrect data to the code flash memory beforehand (fault injection) and then reading this data. A 1- or 2-bit ECC error or an address parity error fault can be injected by generating correct ECC bits and address parity bit once and inverting only the appropriate bits.

For details on programming of the code flash, refer to the *RH850/E1x Flash Memory User's Manual: Hardware Interface*.

(4) Self-Diagnosis of the ECC and Address Parity for Code Flash Memory

Data for generating a 1-bit ECC error, 2-bit ECC error, or address parity error has been written to the area from 0100 $A000_H$ to 0100 $A8CF_H$ in advance for the self-diagnosis of the ECC and address parity for code flash memory, and read access to the area can intentionally generate an error to allow self-diagnosis of the operation of the ECC and address parity.

The tables below lists the addresses written with the error-generating code.

Table 29.14 Code Flash Diagnosis Code

Address	Description
0100 $A000_H$ to 0100 $A08F_H$	1-bit ECC error generation (ECC code area walking)
0100 $A090_H$ to 0100 $A88F_H$	1-bit ECC error generation (data area walking)
0100 $A8B0_H$ to 0100 $A8BF_H$	2-bit ECC error generation
0100 $A8C0_H$ to 0100 $A8CF_H$	Address parity error generation

29.2.3 Data Flash ECC

29.2.3.1 Overview

The data flash ECC is summarized in the table below.

Table 29.15 Overview of Data Flash ECC

Item	Description
ECC error detection and correction	ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected. • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, neither error detection nor correction is carried out. In the state after reset, this function is enabled, and 1-bit error detection and correction and 2-bit error detection and notification are carried out.
Error notification	Upon occurrence of an ECC error, the ECM is notified of the error. **ECC Error:** • Error notification can be either enabled or disabled upon detection of a 2-bit ECC error. • Error notification can be either enabled or disabled upon detection of a 1-bit ECC error. In the state after reset, error notification is enabled upon detection of a 2-bit ECC error, and error notification is disabled upon detection of a 1-bit ECC error. The error notification signal is output, where a 2-bit ECC error is handled as one source, and a 1-bit ECC error is handled as one source.
Error status	A status register is provided, which indicates the statuses of 2-bit ECC error detection and 1-bit ECC error detection. If an error occurs while no error status flag is set, the corresponding status is set. The error status flag can be cleared using the clear register.
Address capture	If an ECC error occurs while no error status flag is set, the address at which the associated error has occurred is captured. The address is captured when a 2-bit ECC error or a 1-bit ECC error is detected. The error status flag serves as the enable bit of the capture address.
Self-diagnosis	Data in the ROM and the ECC bits can be read directly. Desired values can be written as ROM data and to the ECC bits.

29.2.3.2 List of Registers

(1) List of ECC Modules

Table 29.16 List of Modules

Name of ECC Modules and Register Base Address			
Master Side		Checker Side	
Module Name	Base Address <Base_addr>	Module Name	Base Address <Base_addr>
ECCEEP	FFC6 $2C00_H$	ECCEEPC	FFC6 $2E00_H$

(2) List of Registers

Each ECC module has the registers shown in the following table.

Table 29.17 List of Registers

Symbol	Register Name	R/W	Value after Reset	Address	Access Size		
					8	16	32
DFECCCTL	Data flash ECC control register	R/W	0000_H	<Base_addr>		√	
DFERSTR	Data flash error status register	R	00_H	<Base_addr> + 04_H	√		
DFERSTC	Data flash error status clear register	W	00_H	<Base_addr> + 08_H	√		
DFOVFSTR	Data flash error overflow status register	R	00_H	<Base_addr> + $0C_H$	√		
DFOVFSTC	Data flash error overflow status clear register	W	00_H	<Base_addr> + 10_H	√		
DFERRINT	Data flash error notification control register	R/W	02_H	<Base_addr> + 14_H	√		
DFEADR	Data flash 1st error address register	R	$0000\ 0000_H$	<Base_addr> + 18_H			√
DFTSTCTL	Data flash test control register	R/W	0000_H	<Base_addr> + $1C_H$		√	

(3) DFECCCTL — Data Flash ECC Control Register

DFECCCTL enables or disables ECC error detection and correction and 1-bit error correction.

This register is initialized by an internal reset or an external reset.

Set the PROT[1:0] bits to 01_B when writing to this register.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	SECDIS	ECCDIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 29.18 DFECCCTL Register Contents

Bit Position	Bit Name	Function
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 2	—	Reserved
1	SECDIS	1-Bit Error Correction Disable Enables or disables 1-bit error correction when ECC error detection and correction are enabled. 0: Enables correction of the 1-bit error detected. 1: Disables correction of the 1-bit error detected.
0	ECCDIS	ECC Disable Enables or disables ECC error detection and correction. In the initial state, ECC error detection and correction are enabled. 0: Enables ECC error detection and correction. 1: Disables ECC error detection and correction.

(4) DFERSTR — Data Flash Error Status Register

DFERSTR monitors occurrence of errors.

DFERSTR is initialized by an internal reset, an external reset, or setting the clear bit in the data flash error status clear register.

The SEDF bit is set if a 1-bit ECC error is detected while ECC error detection and correction are enabled, and the DEDF bit is set if a 2-bit ECC error is detected.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	DEDF	SEDF
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 29.19 DFERSTR Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved
1	DEDF	2-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting 1 to the ERRCLR bit in DFERSTC. Setting condition: A 2-bit ECC error has occurred while the error flags DEDF and SEDF are 0.
0	SEDF	1-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting 1 to the ERRCLR bit in DFERSTC. Setting condition: A 1-bit ECC error has occurred while the error flags DEDF and SEDF are 0.

(5) DFERSTC — Data Flash Error Status Clear Register

DFERSTC clears the error flags in the data flash error status register. DFERSTC is a write-only register and is always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ERRCLR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 29.20 DFERSTC Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved
0	ERRCLR	SEDF/DEDF Flag Clear Writing 1 to this bit clears the SEDF/DEDF flag.

(6) DFOVFSTR — Data Flash Error Overflow Status Register

DFOVFSTR monitors occurrence of data flash error overflow. The ERROVF flag is cleared by an internal reset, an external reset, or setting the ERROVFCLR bit to 1 in DFOVFSTC.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ERROVF
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 29.21 DFOVFSTR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved
0	ERROVF	Error Overflow Flag This flag is set if an ECC error occurs while the error address register is full.

(7) DFOVFSTC — Data Flash Error Overflow Status Clear Register

DFOVFSTC clears the data flash error overflow flag. Setting the ERROVFCLR bit to 1 clears this flag.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ERROVFCLR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 29.22 DFOVFSTC Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved
0	ERROVFCLR	Error Overflow Flag Clear Writing 1 to this bit clears the ERROVF flag. This bit is always read as 0.

(8) DFERRINT — Data Flash Error Notification Control Register

DFERRINT enables or disables generation of the error notification signal upon detection of a 2-bit ECC error or a 1-bit ECC error.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	DEDIE	SEDIE
Value after reset	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 29.23 DEFRRINT Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved
1	DEDIE	2-Bit ECC Error Notification Control Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 2-bit ECC error. 1: Enables notification of the 2-bit ECC error.
0	SEDIE	1-Bit ECC Error Notification Control Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 1-bit ECC error. 1: Enables notification of the 1-bit ECC error.

(9) DFEADR — Data Flash 1st Error Address Register

DFEADR holds the address at which an ECC error has occurred while both of the SEDF and DEDF bits in the data flash error status register are 0.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	DFEADR[20:16]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DFEADR[15:2]														—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.24 DFEADR Register Contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved
20 to 2	DFEADR[20:2]	ECC Error Address These bits are read-only and used to monitor the address at which an ECC error has occurred.
1, 0	—	Reserved

(10) DFTSTCTL — Data Flash Test Control Register

DFTSTCTL is used for the ECC test. After ECC test mode is enabled by setting ECCTST = 1, the ECC bits can be read.

Set PROT[1:0] bits to 01_B when writing to this register.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	—	ECCTST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 29.25 DFTSTCTL Register Contents

Bit Position	Bit Name	Function
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	ECCTST	ECC Test Sets ECC test mode.

29.2.3.3 Test Function

Data in the ROM and the ECC bits can be read through the setting of the data flash test control register (DFTSTCTL).

(1) Reading the ROM Data

(1) Set the ECCDIS bit in the data flash ECC control register to 1 to disable ECC error detection and correction.

(2) When ECCDIS = 1, neither error detection nor correction proceeds when the data flash is read; the data output from the data flash is read unchanged.

How to exit this test mode:

(1) Set the ECCDIS bit in the data flash ECC control register to 0 to enable ECC error detection and correction.

(2) Reading the ECC Data

(1) Set the ECCDIS bit in the data flash ECC control register to 1 to disable ECC error detection and correction.

(2) Set the ECCTST bit in the data flash control register to 1 to set test mode.

(3) When the data flash is read, the 7 lower-order bits of read data are read as ECC data.

How to exit this test mode:

(1) Set the ECCDIS bit in the data flash ECC control register to 0 to enable ECC error detection and correction.

(2) Set the ECCTST bit in the data flash control register to 0 to set normal mode.

(3) Self-Diagnosis

Self-diagnosis of the ECC decoder is possible by writing incorrect data to the data flash memory beforehand (fault injection) and then reading this data. A 1- or 2-bit ECC error fault can be injected by generating correct ECC bits once and inverting only the appropriate bits.

For details on programming of the data flash, refer to "*RH850/E1x Flash Memory User's Manual: Hardware Interface*".

29.2.4 Local RAM (CPU1) ECC and Address Parity

29.2.4.1 Overview

The local RAM ECC of CPU1 is summarized in the table below.

Table 29.26 Overview of Local RAM ECC of CPU1

Item	Description
ECC error detection and correction	ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected. • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, neither error detection nor correction is carried out. In the state after reset, the ECC function is enabled; 1-bit error detection and correction and 2-bit error detection and notification are carried out.
Address parity	Address parity check can be either enabled or disabled. During data write, a parity bit generated based on the written address is written simultaneously with the write data. At this time, the same parity bit is written to two locations in the RAM. During read, comparison is performed between a parity bit generated based on the read address and a parity bit read from the RAM. The error decoding specifications are shown in **Table 29.27 Address Parity Definitions**. In the state after reset, this function is enabled.
Error notification	Upon occurrence of an ECC error or address parity error, the ECM is notified of the error. **ECC Error:** • Error notification can be either enabled or disabled upon detection of a 2-bit ECC error. • Error notification can be either enabled or disabled upon detection of a 1-bit ECC error. In the state after reset, notification of the 2-bit error is enabled and notification of the 1-bit error is disabled. **Parity Error:** • Error notification can be either enabled or disabled upon detection of an address parity error. • Error notification can be either enabled or disabled upon detection of a parity bit error. In the state after reset, notification of the address parity error is enabled and notification of the parity bit error is disabled. The error notification signal is output, where a 2-bit ECC error and an address parity error are handled as one source, and a 1-bit ECC error and a parity bit error are handled as one source.
Error status	A status register is provided, which indicates the statuses of 2-bit ECC error detection, 1-bit ECC error detection, and address parity error detection. If an error occurs while no error status flag is set, the corresponding status is set. The error status flag can be cleared using the clear register.
Self-diagnosis	Desired values can be written as RAM data and to the ECC and address parity bits. The RAM data and the ECC and address parity bits can be read directly.

The definitions of the address parity error during read accesses are shown in the table below.

Table 29.27 Address Parity Definitions

RAM Macro Parity Bit 1	RAM Macro Parity Bit 2	Read Address Parity	Error Determination and Error Name
0	0	0	No error
0	0	1	Address parity error
0	1	0	Parity bit error
0	1	1	Parity bit error
1	0	0	Parity bit error
1	0	1	Parity bit error
1	1	0	Address parity error
1	1	1	No error

CPU1 is capable of simultaneously writing or reading up to 128 bits of data at a time to or from the local RAM. Meanwhile, ECC and address parity bits are provided for each 32 bits of data and the locations for storage of each 32-bit data segment are referred to as banks 0 to 3. Addresses for the lowest-order bits (i.e., for the LSB side of the data) are for bank 0, while addresses for the highest-order bits (i.e., for the MSB side of the data) are for bank 3.

The relationship between addresses and banks is described below.

Table 29.28 Relationship between Addresses and Bank Numbers

Lower 4 Bits of Address (Hexadecimal Notation)	F_H to C_H	B_H to 8_H	7_H to 4_H	3_H to 0_H
Bank number	Bank 3	Bank 2	Bank 1	Bank 0

29.2.4.2 List of Registers

Table 29.29 List of Registers

Address	Symbol	Register Name	R/W	Value after Reset	Access Size
FFC6 5000$_H$	LRAPCTL_PE1	Local RAM address parity control register (PE1)	R/W	0000 0000$_H$	16/32
FFC6 5004$_H$	LRTSTCTL_PE1	Local RAM test control register	R/W	0000 0000$_H$	16/32

FFC6 5408$_H$	LRSTCLR_PE1	Local RAM status clear register (PE1)	W	0000 0000$_H$	8/16/32
FFC6 540C$_H$	LROVFSTR_PE1	Local RAM error count overflow status register (PE1)	R	0000 0000$_H$	8/16/32
FFC6 5410$_H$	LR1STERSTR_PE1	Local RAM 1st error status register (PE1)	R	0000 0000$_H$	8/16/32

29.2.4.3 Details of Registers

(1) LRAPCTL_PE1 — Local RAM Address Parity Control Register

LRAPCTL enables or disables address parity check. Set PROT[1:0] bits to 01_B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	—	APARIDIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 29.30 LRAPCTL Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	APARIDIS	Address Parity Check Disable Enables or disables address parity check by all the address parity circuits (bank 0 to bank 3). 0: Enables address parity check. 1: Disables address parity check.

(2) LRTSTCTL_PE1 — Local RAM Test Control Register

This register is used for the ECC test (self-diagnosis) and address parity checker test (self-diagnosis). After ECC test mode is enabled by setting ECCTST = 1, desired values can be written to the ECC and address parity bits. The DATSEL bit is used to select RAM data or the ECC and address parity bits.

By setting address parity test mode (APTESTi = 1; i = 0, 1, 2, 3), the parity to be input to the address parity checker is inverted. Set PROT[1:0] bits to 01_B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.31 LRTSTCTL_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 6	—	Reserved These bits are always read as 0. The write value should also be 0.
5	APTEST3	Address Parity Checker (Bank 3) Test Sets the address parity checker to test mode. When APTEST3 = 1, the parity generated through the address parity generator is inverted.
4	APTEST2	Address Parity Checker (Bank 2) Test Sets the address parity checker to test mode. When APTEST2 = 1, the parity generated through the address parity generator is inverted.
3	APTEST1	Address Parity Checker (Bank 1) Test Sets the address parity checker to test mode. When APTEST1 = 1, the parity generated through the address parity generator is inverted.
2	APTEST0	Address Parity Checker (Bank 0) Test Sets the address parity checker to test mode. When APTEST0 = 1, the parity generated through the address parity generator is inverted.
1	ECCTST	ECC Test After ECC test mode is enabled by setting ECCTST = 1, the ECC and address parity bits can be read directly.
0	DATSEL	Data Select This bit is valid when ECCTST = 1. This bit selects the RAM bit which can be accessed when writing. 0: RAM data is selected. 1: The ECC bits and address parity bit are selected.

Note 1. When ECC test mode for the local RAM is enabled (ECCTST = 1), access to the local RAM should be accessed in 4-byte units.

(3) LRTDATBFn_PE1 — Local RAM Test Data Read Buffer n (n = 0, 1)

In ECC test mode (self-diagnosis), the ECC and address parity bits can be read. If the local RAM is read while ECCTST = 1 in the local RAM test control register LRTSTCTL, reading from the local RAM reads out the ECC and address parity bits, and these bits are stored in this buffer.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.32 LRTDATBFn_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 25	—	Reserved These bits are always read as 0. The write value should also be 0.
24 to 16	LRTDATBF	These bits are valid when ECCTST = 1 (selecting test mode) in the local RAM test control register. When reading from the corresponding bank in the local RAM, the ECC bits for the local RAM (bank (2n + 1)) and the address parity bit are respectively stored in LRTDATBF[22:16] and LRTDATBF[24:23].
15 to 9	—	Reserved These bits are always read as 0. The write value should also be 0.
8 to 0	LRTDATBF	These bits are valid when ECCTST = 1 (selecting test mode) in the local RAM test control register. When reading from the corresponding bank in the local RAM, the ECC bits for the local RAM (bank (2n)) and the address parity bit are respectively stored in LRTDATBF[6:0] and LRTDATBF[8:7].

(4) LRECCCTL_PE1 — Local RAM ECC Control Register

LRECCCTL enables or disables ECC error detection and correction and 1-bit error correction. Set PROT[1:0] bits to 01B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	SECDIS	1-Bit Error Correction Disable Enables or disables 1-bit error correction when ECC error detection and correction are enabled. 0: Enables correction of the 1-bit error detected. 1: Disables correction of the 1-bit error detected.
0	ECCDIS	ECC Disable Enables or disables ECC error detection and correction. 0: Enables ECC error detection and correction. 1: Disables ECC error detection and correction.

(5) LRERRINT_PE1 — Local RAM Error Information Control

LRERRINT enables or disables generation of the error notification signal to the ECM upon detection of a 2-bit ECC error, a 1-bit ECC error, an address parity error, or a parity bit error.

LRERRINT is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 4	—	Reserved These bits are always read as 0. The write value should also be 0.
3	PBEIE	Parity Bit Error Notification Enable Enables or disables generation of the error notification signal upon detection of a parity bit error when address parity check is enabled. 0: Disables notification of the parity bit error. 1: Enables notification of the parity bit error.
2	APEIE	Address Parity Error Notification Enable Enables or disables generation of the error notification signal upon detection of an address parity error when address parity check is enabled. 0: Disables notification of the address parity error. 1: Enables notification of the address parity error.
1	DEDIE	2-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 2-bit ECC error. 1: Enables notification of the 2-bit ECC error.
0	SEDIE	1-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 1-bit ECC error. 1: Enables notification of the 1-bit ECC error.

(6) LRSTCLR_PE1 — Local RAM Status Clear Register

LRSTCLR clears the error flags in the error status register (LR1STERSTR) and the overflow flag in the error count overflow status register (LROVFSTR). LRSTCLR is a write-only register and is always read as 0.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	W	W	W	W

Table 29.35 LRSTCLR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved These bits are always read as 0. The write value should also be 0.
3	STCLR3	Error Overflow Flag Clear (for bank 3) Writing 1 to this bit clears the PBEF3, APEF3, DEDF3, and SEDF3 flags in LR1STERSTR; and ERROVF3 flag in LROVFSTR.
2	STCLR2	Error Overflow Flag Clear (for bank 2) Writing 1 to this bit clears the PBEF2, APEF2, DEDF2, and SEDF2 flags in LR1STERSTR; and ERROVF2 flag in LROVFSTR.
1	STCLR1	Error Overflow Flag Clear (for bank 1) Writing 1 to this bit clears the PBEF1, APEF1, DEDF1, and SEDF1 flags in LR1STERSTR; and ERROVF1 flag in LROVFSTR.
0	STCLR0	Error Overflow Flag Clear (for bank 0) Writing 1 to this bit clears the PBEF0, APEF0, DEDF0, and SEDF0 flags in LR1STERSTR; and ERROVF0 flag in LROVFSTR.

(7) LROVFSTR_PE1 — Local RAM Error Count Overflow Status Register

LROVFSTR monitors occurrence of error overflow. If the second error occurs after the first error (= while any of the error flags in the error status register is set), the flag in this register is set. However, if the second error is identical to the first error (both the source and address are same), this flag is not set. ERROVF is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in LRSTCLR.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.36 LROVESTR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved These bits are always read as 0. The write value should also be 0.
3	ERROVF3	Error Overflow Flag (for bank 3) This flag is set if the second error occurs while any of the error flags (PBEF3, APEF3, DEDF3, and SEDF3) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.
2	ERROVF2	Error Overflow Flag (for bank 2) This flag is set if the second error occurs while any of the error flags (PBEF2, APEF2, DEDF2, and SEDF2) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.
1	ERROVF1	Error Overflow Flag (for bank 1) This flag is set if the second error occurs while any of the error flags (PBEF1, APEF1, DEDF1, and SEDF1) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.
0	ERROVF0	Error Overflow Flag (for bank 0) This flag is set if the second error occurs while any of the error flags (PBEF0, APEF0, DEDF0, and SEDF0) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.

(8) LR1STERSTR_PE1 — Local RAM 1st Error Status Register

LR1STERSTR monitors occurrence of the first error. Errors are detected and the states are updated independently for each bank.

An error status flag is set if an error occurs while all error flags for the given bank are 0. Note, however, that the corresponding error flag is also set if a 2-bit ECC error or an address parity error occurs in subsequent access as long as only the 1-bit ECC error flag or parity bit error flag is set at the time.

If more than one error is detected for a given memory access, all the corresponding error flags are set. LR1STERSTR is cleared by an internal reset, an external reset, or setting 1 to the STCLR bit in LRSTCLR.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.37 LR1STERSTR_PE1 Register Contents

Bit Position	Bit Name	Function
7+8n:4+8n	—	Reserved These bits are always read as 0. The write value should also be 0.
3+8n	PBEFn	Parity Bit Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting 1 to the STCLRn bit in LRSTCLR. Setting condition: A parity bit error has occurred while all the error flags PBEFn, APEFn, DEDFn, and SEDFn are 0.
2+8n	APEFn	Address Parity Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting 1 to the STCLRn bit in LRSTCLR. Setting condition: An address parity error has occurred while the error flags DEDFn and APEFn are 0. **NOTE** This flag is set equally for read and write; the error generation source is not considered.
1+8n	DEDFn	2-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting 1 to the STCLRn bit in LRSTCLR. Setting condition: A 2-bit ECC error has occurred while the error flags DEDFn and APEFn are 0.
0+8n	SEDFn	1-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting 1 to the STCLRn bit in LRSTCLR. Setting condition: A 1-bit ECC error has occurred while all the error flags PBEFn, APEFn, DEDFn, and SEDF are 0.

Note 1. n = 0 to 3, where “n” denotes a bank number.

29.2.4.4 Test Function

Through appropriate register setting, desired values can be written as RAM data and to the ECC and address parity bits. Also, data in the RAM and the ECC and address parity bits can all be read.

(1) Writing RAM Data

(a) Set the ECCTST bit in the local RAM test control register to 1 to set test mode.

(b) Set the corresponding DATSEL bit in the local RAM test control register to 0 to select RAM data for access when writing.

(c) When data is written to the local RAM, only the RAM data can be modified without updating the ECC bits.

How to exit this test mode:

(a) Set the ECCTST bit in the local RAM test control register to 0 to disable test mode (normal mode).

(2) Reading RAM Data

(a) Set the ECCDIS bit in the local RAM ECC control register to 1 to disable ECC error detection and correction.

(b) Read the local RAM. Since neither error detection nor correction proceeds when the local RAM is read, the RAM data is read unchanged.

How to exit this test mode:

(a) Set the ECCDIS bit in the local RAM ECC control register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC and Address Parity Bits

(a) Set the ECCTST bit in the local RAM test control register to 1 to set test mode.

(b) Set the corresponding DATSEL bit in the local RAM test control register to 1 to select the ECC bits and the address parity bit for access when writing.

(c) When data is written to the local RAM, only the ECC and address parity bits can be modified without updating the RAM data. At that time, bit[6:0] and bit[8:7] are respectively written to the ECC bits and to the address parity bit.

NOTE

Writing desired values to the RAM data and the address parity bit should be in order of 1) writing the RAM data and then 2) writing the address parity bit.
When writing desired values to the RAM data and ECC bits, you can start either by writing to the RAM data or ECC bits.

How to exit this test mode:

(a) Set the ECCTST bit in the local RAM test control register to 0 to disable test mode (normal mode).

(4) Reading the ECC and Address Parity Bits

(a) Set the ECCTST bit in the local RAM test control register to 1 to set test mode.

(b) When the local RAM is read, the ECC and address parity bits are stored in the bank corresponding to local RAM test data read buffer 0 or local RAM test data read buffer 1.

How to exit this test mode:

(a) Set the ECCTST bit in the local RAM test control register to 0 to disable test mode (normal mode).

(5) Self-Diagnosis of the ECC Check Function

Desired values can be written to the RAM data and/or ECC bits by following the procedure described in (1) or (3) above. Therefore, a fault can be injected by, for example, inverting appropriate bits of the RAM data and/or ECC bits. After that, self-diagnosis of the ECC decoder is possible by reading the local RAM in normal mode and checking the result of error correction or detection.

(6) Self-Diagnosis of the Address Parity Check Function

Self-diagnosis is enabled by following either of the two procedures below.

(a) Setting APTESTi (i = 0, 1, 2, 3) in the local RAM test control register to 1 inverts the result of address parity generation for the corresponding bank. That is, a fault can be injected to the address parity generator. Writing to the corresponding bank in the local RAM in this state and checking the result of parity error detection allows self-diagnosis of the address parity check function in writing.

(b) Desired data can be written to the address parity bit through the procedure described in (3) above. This enables injection of a 1-bit or 2-bit fault to the address parity bit by inverting the address parity bit. After that, self-diagnosis of the address parity bit checking function for reading is possible by reading the local RAM in normal mode and checking the result of parity error detection.

29.2.5 Local RAM (PCU) ECC

29.2.5.1 Overview

The local RAM ECC of PCU is summarized in the table below.

Table 29.38 Overview of Local RAM ECC of PCU

Item	Description
ECC error detection and correction	ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected. • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, neither error detection nor correction is carried out. In the state after reset, the ECC function is enabled; 1-bit error detection and correction and 2-bit error detection and notification are carried out.
Address parity	None
Error notification	Upon occurrence of an ECC error, the ECM is notified of the error. **ECC Error:** • Error notification can be either enabled or disabled upon detection of a 2-bit ECC error. • Error notification can be either enabled or disabled upon detection of a 1-bit ECC error. In the state after reset, notification of 2-bit error is enabled and notification of 1-bit error is disabled. The error notification signal is output, where a 2-bit ECC error is handled as one source and a 1-bit ECC error is handled as one source.
Error status	A status register is provided, which indicates the statuses of 2-bit ECC error detection and 1-bit ECC error detection. If an error occurs while no error status flag is set, the corresponding status is set. The error status flag can be cleared using the clear register.
Address capture	If an ECC error occurs while no error status flag is set, the address at which the associated error has occurred is captured. The address is captured when a 2-bit ECC error or a 1-bit ECC error is detected. The error status flag serves as the enable bit of the capture address.
Self-diagnosis	Desired values can be written as RAM data and to the ECC bits. Data in the RAM and the ECC bits can be read directly.

29.2.5.2 List of Registers

Table 29.39 List of Registers

Address	Symbol	Register Name	R/W	Value after Reset	Access Size
FFC6 5800$_H$	LRECCCTL_PCU	Local RAM ECC control register (PCU)	R/W	0000 0000$_H$	16/32

FFC6 58B8$_H$	LRTDATBF0_PCU	Local RAM test data read buffer (PCU)	R	0000 0000$_H$	32

29.2.5.3 Details of Registers

(1) LRECCCTL_PCU — Local RAM ECC Control Register

LRECCCTL enables or disables ECC error detection and correction and 1-bit error correction. Set PROT[1:0] bits to 01B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 29.40 LRECCCTL_PCU Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	SECDIS	1-Bit Error Correction Disable Enables or disables 1-bit error correction when ECC error detection and correction are enabled. 0: Enables correction of the 1-bit error detected. 1: Disables correction of the 1-bit error detected.
0	ECCDIS	ECC Disable Enables or disables ECC error detection and correction. 0: Enables ECC error detection and correction. 1: Disables ECC error detection and correction.

(2) LRFSTERSTR_PCU — Local RAM 1st Error Status Register

LRFSTERSTR monitors occurrence of the first error.

An error status bit is set if an error occurs while the error flag is 0. Note, however, that the corresponding error flag is also set if a 2-bit ECC error occurs in subsequent access as long as only the 1-bit ECC error flag is set at the time.

LRFSTERSTR is cleared by an internal reset or an external reset, or by setting the FSTERRCLR0 bit in LRSTCLR to 1.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 29.41 LRFSTERSTR_PCU Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	DEDF0	2-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting 1 to the FSTERRCLR0 bit in LRSTCLR. Setting condition: A 2-bit ECC error has occurred while the error flag DEDF0 is 0.
0	SEDF0	1-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting 1 to the FSTERRCLR0 bit in LRSTCLR. Setting condition: A 1-bit ECC error has occurred while the error flags DEDF0 and SEDF0 are 0.

(3) LRSTCLR_PCU — Local RAM Error Status Clear Register

LRSTCLR clears the error flags in the local RAM 1st error status register (LRFSTERSTR). LRSTCLR is a write-only register and is always read as 0.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	FSTERRCLR0	1st Error Status Register Clear Writing 1 to this bit clears the error flags in the 1st error status register.

(4) LROVFSTR_PCU — Local RAM Overflow Status Register

LROVFSTR monitors occurrence of local RAM error overflow. ERROVF0 is cleared by an internal reset, an external reset, or setting the ERROVFCLR0 bit to 1 in LROVFSTC.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

31 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	ERROVF0	Error Overflow Flag This flag is set if the second error occurs while any of the error flags (DEDF0 and SEDF0) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.

(5) LROVFSTC_PCU — Local RAM Overflow Status Clear Register

LROVFSTC clears the local RAM error overflow flag. Setting the ERROVFCLR0 bit to 1 clears the flag.

LROVFSTC is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	ERROVFCLR0	Error Overflow Flag Clear Writing 1 to this bit clears the ERROVF0 flag. This bit is always read as 0.

(6) LRFSTEADR0_PCU — Local RAM 1st Error Address Register 0

LRFSTEADR0 holds the address at which an ECC error has occurred. LRFSTEADR0[21:2] of this register correspond to bits [21:2] of the real address. The real address can be calculated by appending the higher-order address bits [31:22] as a base address.

LRFSTEADR0 is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	LRFSTEADR0[21:16]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.45 LRFSTEADR0_PCU Register Contents

Bit Position	Bit Name	Function
31 to 22	—	Reserved These bits are always read as 0. The write value should also be 0.
21 to 2	LRFSTEADR0 [21:2]	1st Error Address These bits are read-only and used to monitor the address of the first error. The address is updated under the following conditions: • When error source for the retained address is SEDF A 1-bit error has occurred on the same address -> The address is not overwritten. A 1-bit error has occurred on a different address -> The address is not overwritten. A 2-bit error has occurred -> The address is overwritten. • When error source for the retained address is DEDF A 1-bit error has occurred -> The address is not overwritten. A 2-bit error has occurred on the same address -> The address is not overwritten. A 2-bit error has occurred on a different address -> The address is not overwritten.
1, 0	—	Reserved These bits are always read as 0. The write value should also be 0.

(7) LRERRINT_PCU — Local RAM Error Information Control Register

LRERRINT enables or disables generation of the error notification signal to the ECM upon detection of a 2-bit ECC error or a 1-bit ECC error.

LRERRINT is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 29.46 LRERRINT_PCU Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	DEDIE	2-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 2-bit ECC error. 1: Enables notification of the 2-bit ECC error.
0	SEDIE	1-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 1-bit ECC error. 1: Enables notification of the 1-bit ECC error

(8) LRTSTCTL_PCU — Local RAM Test Control Register

This register is used for the ECC test (self-diagnosis). After ECC test mode is enabled by setting ECCTST = 1, desired values can be written to the ECC bits. The DATSEL bit is used to select the RAM data or ECC bits. Set PROT[1:0] bits to 01_B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 29.47 LRTSTCTRL_PCU Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	ECCTST	ECC Test After ECC test mode is enabled by setting ECCTST = 1, the ECC bits can be read directly.
0	DATSEL	Data Select This bit is valid when ECCTST = 1. This bit selects the RAM bit which can be accessed when writing. 0: RAM data is selected. 1: The ECC bits are selected.

Note 1. When ECC test mode for the local RAM is enabled (ECCTST = 1), access to the local RAM should be accessed in 4-byte units.

(9) LRTDATBF0_PCU — Local RAM Test Data Read Buffer 0

In ECC test mode (self-diagnosis), the ECC bits can be read. If the local RAM is read while ECCTST = 1 in the local RAM test control register LRTSTCTL, reading from the local RAM reads out the ECC bits, and these bits are stored in this buffer.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 29.48 LRTDATBF0_PCU Register Contents

Bit Position	Bit Name	Function
31 to 7	—	Reserved These bits are always read as 0. The write value should also be 0.
6 to 0	LRTDATBF	These bits are valid when ECCTST = 1 (selecting test mode) in the local RAM test control register. When reading from the local RAM, the ECC bits are stored in LRTDATBF[6:0].

29.2.5.4 Test Function

For the test function and procedures for self-diagnosis, see the section on the local RAM (for the CPU). However, since the local RAM for the PCU does not have an address parity facility, ignore the description of address parity.

29.2.6 Global RAM ECC and Address Parity

29.2.6.1 Overview

The global RAM ECC is summarized in the table below.

Table 29.49 Overview of Global RAM ECC

Item	Description
ECC error detection and correction	ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected. • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, neither error detection nor correction is carried out. In the state after reset, the ECC function is enabled, and 1-bit error detection and correction and 2-bit error detection and notification are carried out.
Address parity	Address parity check can be either enabled or disabled. During data write, a parity bit generated based on the written address is written simultaneously with the write data. At this time, the parity bit is written to only one location in the RAM. During data read, comparison is performed between a parity bit generated based on the read address and a parity bit read from the memory. In the state after reset, this function is enabled.
Error notification	Upon occurrence of an ECC error or address parity error, the ECM is notified of the error. **ECC Error:** • Error notification can be either enabled or disabled upon detection of a 2-bit ECC error. • Error notification can be either enabled or disabled upon detection of a 1-bit ECC error. In the state after reset, error notification is enabled upon detection of a 2-bit ECC error, and error notification is disabled upon detection of a 1-bit ECC error. Parity Error: • Error notification can be either enabled or disabled upon detection of an address parity error. In the state after reset, error notification is enabled upon detection of an address parity error. The error notification signal is output, where a 2-bit ECC error and an address parity error are handled as one source, and a 1-bit ECC error is handled as one source.
Error status	A status register is provided, which indicates the statuses of 2-bit ECC error detection, 1-bit ECC error detection, and address parity error detection. If an error occurs while no error status flag is set, the corresponding status is set. The error status flag can be cleared using the clear register.
Address capture	If an ECC error or a parity error occurs while no error status flag is set, the address at which the associated error has occurred is captured. The address is captured when a 2-bit ECC error, a 1-bit ECC error, or an address parity error is detected. The error status flag serves as the enable bit of the capture address.
Self-diagnosis	Desired values can be written as RAM data and to the ECC and address parity bits. Data in the RAM and the ECC and address parity bits can be read directly.

The ECC encoder and decoder and the address parity generator are provided for the access ports (CPU1 and interconnect) that are connected to the global RAM. Separate address checkers are provided for bank A and bank B of the global RAM. Also, the ECC decoder and ECC encoder for RMW processing* are provided for each of bank A and bank B. See **Figure 29.2**.

- RMW processing

  Bit manipulation instructions, 2-byte writing and 1-byte writing are executed in three steps: 1) reading of 32-bit data; 2) generation of write data by replacement of (modifying) the predetermined data; and 3) writing of 32-bit data. In this section, such operations are referred to as read-modify-write (RMW) processing. RMW processing for the global RAM proceeds in the controller for each bank.

  In RWM processing, the ECC is decoded for the read operation in step 1), while the ECC is encoded for the write operation in step 3).

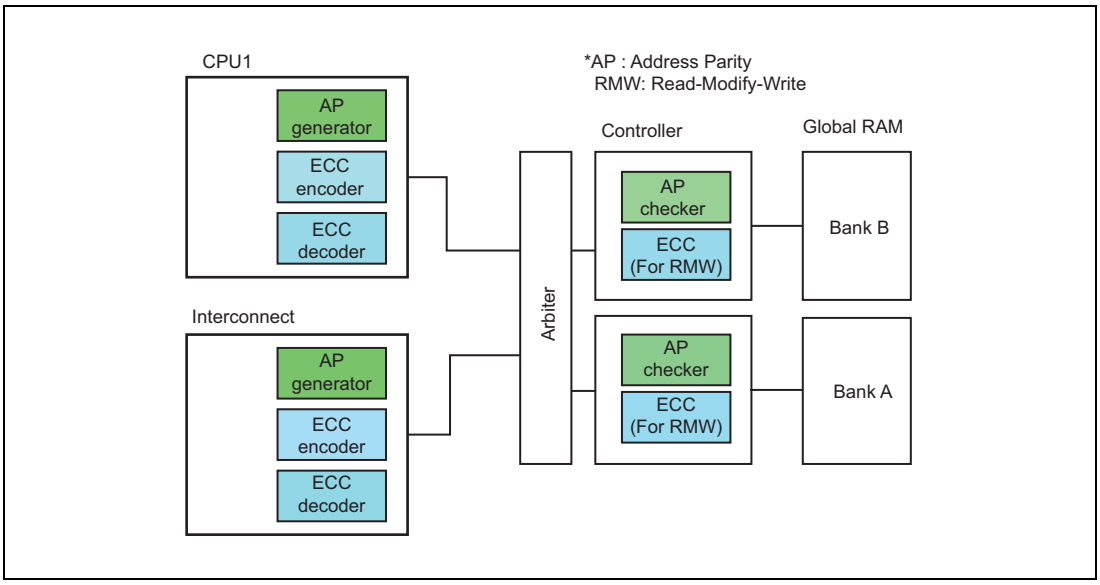

Figure 29.2 ECC of Global RAM and Address Parity

Up to 64 bits of data can be simultaneously read from or written to the global RAM. Meanwhile, the ECC and address parity are provided for each 32-bit data. That is, two each of the ECC decoder, ECC encoder, ECC circuit (for RMW), and address parity checker in **Figure 29.2** are provided, one for the 32 higher-order bits and the other for the 32 lower-order bits.

Table 29.50 Address and Corresponding ECC Circuit

Lower 3 Bits of the Address	7_H to 4_H	3_H to 0_H
Corresponding ECC circuit	Upper 32 bits	Lower 32 bits

NOTE

In the local RAM (CPU1), the locations for storage of data for units of the ECC are referred to as banks 0 to 3. Since the global RAM is divided into banks A and B with the address FEF0 0000_H as the boundary, banks A and B are respectively referred to as the 32 higher-order bits and the 32 lower-order bits to reduce confusion.

29.2.6.2 List of Registers

Table 29.51 List of Registers

Address	Symbol*[1]	Register Name	R/W	Value after Reset	Access Size
FFC6 4000$_H$	GRECCCTL_GRAMC	Global RAM ECC control register (GRAMC)	R/W	0000 0000$_H$	16/32

FFC6 420C$_H$	GROVFSTR_VCI	Global RAM error count overflow status register (VCI)	R	0000 0000$_H$	8/16/32
FFC6 4210$_H$	GR1STERSTR_VCI	Global RAM 1st error status register (VCI)	R	0000 0000$_H$	8/16/32
FFC6 4250$_H$	GR1STEADR0_VCI	Global RAM 1st error (lower 32-bit data) address register (VCI)	R	0000 0000$_H$	8/16/32
FFC6 4254	GR1STEADR1_VCI	Global RAM 1st error (upper 32-bit data) address register (VCI)	R	0000 0000$_H$	8/16/32
FFC6 4400$_H$	GRECCCTL_PE1	Global RAM ECC control register (PE1)	R/W	0000 0000$_H$	16/32
FFC6 4404$_H$	GRERRINT_PE1	Global RAM error information control register (PE1)	R/W	0000 0006$_H$	8/16/32
FFC6 4408$_H$	GRSTCLR_PE1	Global RAM status clear register (PE1)	W	0000 0000$_H$	8/16/32
FFC6 440C$_H$	GROVFSTR_PE1	Global RAM error count overflow status register (PE1)	R	0000 0000$_H$	8/16/32
FFC6 4410$_H$	GR1STERSTR_PE1	Global RAM 1st error status register (PE1)	R	0000 0000$_H$	8/16/32
FFC6 4450$_H$	GR1STEADR0_PE1	Global RAM 1st error (lower 32-bit data) address register (PE1)	R	0000 0000$_H$	8/16/32
FFC6 4454$_H$	GR1STEADR1_PE1	Global RAM 1st error (upper 32-bit data) address register (PE1)	R	0000 0000$_H$	8/16/32

Note 1. In the register symbols, "*_VCI" and "*_PE1" indicate the registers provided for the ECC controllers for each of the access ports. Specifically, "_VCI" and "_PE1" indicate the control registers for access to the Global RAM from system interconnect 1 and to the Global RAM from CPU1, respectively. "_GRAMC" is a common control register for all access ports.

29.2.6.3 Details of Registers

(1) GRECCCTL_GRAMC — Global RAM ECC Control Register

GRECCCTL is the ECC and address parity control register shared by Global RAMs. GRECCCTL enables or disables address parity check and specifies ECC processing for Read-Modify-Write (RMW) processing. Set PROT[1:0] bits to 01_B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	APARIDIS	SECDIS	ECCDIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 29.52 GRECCCTL_GRAMC Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 3	—	Reserved These bits are always read as 0. The write value should also be 0.
2	APARIDIS	Address Parity Check Disable Enables or disables address parity check. In the initial state, the parity check is enabled. 0: Enables address parity check. 1: Disables address parity check.
1	SECDIS	1-Bit Error Correction Disable for RMW Enables or disables 1-bit error correction when ECC error detection and correction are enabled. 0: Enables correction of the 1-bit error detected. 1: Disables correction of the 1-bit error detected.
0	ECCDIS	ECC Disable for RMW Enables or disables ECC error detection and correction. In the initial state, ECC error detection and correction are enabled. 0: Enables ECC error detection and correction. 1: Disables ECC error detection and correction. **NOTE** The encoding function is enabled even though the error detection and correction are disabled.

(2) GRTSTCTL — Global RAM Test Control Register

This register is used for the ECC test (self-diagnosis) and address parity checker test (self-diagnosis). After ECC test mode is enabled by setting ECCTST = 1, desired values can be written to the ECC and address parity bits. The DATSEL0 or DATSEL1 bit is used to select the RAM data or the ECC and address parity bits. Also, input and output by the ECC decoder in the Global RAM controller can be controlled for testing (self-diagnosis).

By setting address parity test mode (APTESTi = 1; i = 0, 1, 2, 3), the parity to be input to the address parity checker is inverted. Set PROT[1:0] bits to 01_B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.53 GRTSTCTL Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 8	—	Reserved These bits are always read as 0. The write value should also be 0.
7	APTEST3	Address Parity Checker (Bank B, 32 Higher-Order Bits) Test Sets the address parity checker to test mode. When APTEST3 = 1, the parity generated through the address parity generator is inverted.
6	APTEST2	Address Parity Checker (Bank B, 32 Lower-Order Bits) Test Sets the address parity checker to test mode. When APTEST2 = 1, the parity generated through the address parity generator is inverted.
5	APTEST1	Address Parity Checker (Bank A, 32 Higher-Order Bits) Test Sets the address parity checker to test mode. When APTEST1 = 1, the parity generated through the address parity generator is inverted.
4	APTEST0	Address Parity Checker (Bank A, 32 Lower-Order Bits) Test Sets the address parity checker to test mode. When APTEST0 = 1, the parity generated through the address parity generator is inverted.
3	ECCTST	ECC Test After ECC test mode is enabled by setting ECCTST = 1, the ECC and address parity bits can be read directly.
2	DECINEN	RMW ECC Decoder Error Injection Enable This bit is valid when ECCTST = 1. This bit enables input of the value in the ECC decoder input buffer register to the ECC decoder for use in updating of data at the time of RMW access. 0: The value in the ECC decoder input buffer is not input. 1: The value in the ECC decoder input buffer is input.

Table 29.53 GRTSTCTL Register Contents (2/2)

Bit Position	Bit Name	Function
1, 0	DATSEL	Read Buffer Storage Data Select 0 and 1 These bits are valid when ECCTST = 1. These bits select the value to be stored in the read buffer GRTDATBFn, and the value to be written to each field. 00: – GRTDATBFn: When reading involves an RMW cycle, the ECC and address parity bits are stored. – Global RAM: When writing involves an RMW cycle, the data area that is updated depends on the unit of access and the location accessed. The ECC bits are not updated. 01: – GRTDATBFn: When reading involves an RMW cycle, the ECC and address parity bits are stored. – Global RAM: When writing involves an RMW cycle, only the ECC and address parity bits are updated. The data area is not updated. 10: – GRTDATBFn: When access is RMW, this register holds the result of ECC decoding for the data read out in the read portion of the RMW cycle. Its value is not updated in the case of access that is not RMW. – Global RAM: Operates in the same way as in normal operating mode (i.e. when ECCTST = 0). 11: – GRTDATBFn: When access is RMW, this register holds the result of ECC decoding for use in the updating of data at the time of RMW access. Its value is not updated in the case of access that is not RMW. – Global RAM: Operates in the same way as in normal operating mode (i.e. when ECCTST = 0). In any case, the result of reading by the CPU, DMAC, etc. is the same value as would normally be read out.

(3) GRTDATBFn — Global RAM Test Data Read Buffer n (n = 0 to 3)

In test mode (ECCTST = 1), data in the RAM, the ECC bits, address parity bit, and ECC decoder output can all be read. When the RAM is read, the value selected by the DATSEL1 or DATSEL0 bit of the global RAM test control register is stored in this buffer.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.54 GRTDATBFn Register Contents

Bit Position	Bit Name	Function
31 to 0	GRTDATBF	These bits are valid when while ECCTST = 1 (selecting test mode) in the global RAM test control register. When (DATSEL1, DATSEL0) = (0, 0) or (0, 1) When reading from the RAM, the ECC bits and the address parity bit are respectively stored in GRTDATBF[6:0] and GRTDATBF[7]. 0 is stored in GRTDATBF[31:8]. When (DATSEL1, DATSEL0) = (1, 0) When access is RMW, the output data from the ECC decoder for reading (after updating) are stored in GRTDATBF[31:0]. When (DATSEL1, DATSEL0) = (1, 1) When access is RMW, the output data from the ECC decoder for updating (after updating) are stored in GRTDATBF[31:0].

n = 0: Bank A, 32 lower-order bits
n = 1: Bank A, 32 higher-order bits
n = 2: Bank B, 32 lower-order bits
n = 3: Bank B, 32 higher-order bits

(4) GRECCCTL_VCI/_PE1 — Global RAM ECC Control Register

GRECCCTL enables or disables ECC error detection and correction and 1-bit error correction. Set PROT[1:0] bits to 01_B when writing to this register.

The setting of this register is used for accesses through the respective access port.

This register is initialized by an internal reset or an external reset.

15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	SECDIS	1-Bit Error Correction Disable Enables or disables 1-bit error correction when ECC error detection and correction are enabled. 0: Enables correction of the 1-bit error detected. 1: Disables correction of the 1-bit error detected.
0	ECCDIS	ECC Disable Enables or disables ECC error detection and correction. 0: Enables ECC error detection and correction. 1: Disables ECC error detection and correction.

(5) GRDECINBF0 — Global RAM ECC Decoder Input Data Buffer 0

This register holds input data for the ECC decoder to use in updating the data at the time of RMW access. The value of this register is treated by the ECC decoder as if it were 32 bits of data from RAM.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.56 GRDECINBF0 Register Contents

Bit Position	Bit Name	Function
31 to 0	GRDECINBF0	These bits are valid when ECCTST = 1 (selecting test mode) in the global RAM test control register. When DECINEN = 1, the value of this register is input to the ECC decoder as data for use in updating in response to the execution of an RMW instruction. The value is treated as if it were 32 bits of data from RAM. This register is common to banks A and B and provides the values for both the 32 higher-order bits and the 32 lower-order bits.

(6) GRDECINBF1 — Global RAM ECC Decoder Input Data Buffer 1

This register holds input data for the ECC decoder to use in updating the data at the time of RMW access. The value of this register is treated by the ECC decoder as if it were 7 bits of data from ECC.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 7	—	Reserved These bits are always read as 0. The write value should also be 0.
6 to 0	GRDECINBF1	These bits are valid when ECCTST = 1 (selecting test mode) in the global RAM test control register. When DECINEN = 1, the value of this register is input to the ECC decoder as data for use in updating in response to the execution of an RMW instruction. The value is treated as if it were 7 bits of data from ECC. This register is common to banks A and B and provides the values for both the 32 higher-order bits and the 32 lower-order bits.

(7) GRERRINT_VCI/_PE1 — Global RAM Error Information Control Register

GRERRINT enables or disables generation of the error notification signal to the ECM upon detection of a 2-bit ECC error, a 1-bit ECC error, or an address parity error.

The setting of this register is used for accesses through the respective access port.

GRERRINT is initialized by an internal reset or an external reset.

31 to 3	—	Reserved These bits are always read as 0. The write value should also be 0.
2	APEIE	Address Parity Error Notification Enable Enables or disables generation of the error notification signal upon detection of an address parity error when address parity check is enabled. 0: Disables notification of the address parity error. 1: Enables notification of the address parity error.
1	DEDIE	2-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 2-bit ECC error. 1: Enables notification of the 2-bit ECC error.
0	SEDIE	1-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 1-bit ECC error. 1: Enables notification of the 1-bit ECC error.

(8) GRSTCLR_VCI/_PE1 — Global RAM Status Clear Register

GRSTCLR clears the error flags in the error status register (GR1STERSTR), the overflow flag in the error count overflow status register (GROVFSTR), and the error address register (GR1STEADR). GRSTCLR is a write-only register and is always read as 0.

The setting of this register is used for accesses through the respective access port.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	STCLR1	Error Overflow Flag Clear (for the upper 32-bit data) Writing 1 to this bit clears the EXDEDF1, EXSEDF1, APEF1, DEDF1, and SEDF1 flags in GR1STERSTR; ERROVF1 flag in GROVFSTR; and GR1STEADR1.
0	STCLR0	Error Overflow Flag Clear (for the lower 32-bit data) Writing 1 to this bit clears the EXDEDF0, EXSEDF0, APEF0, DEDF0, and SEDF0 flags in GR1STERSTR; ERROVF0 flag in GROVFSTR; and GR1STEADR0.

(9) GROVFSTR_VCI/PE1 — Global RAM Error Count Overflow Status Register

GROVFSTR monitors occurrence of error overflow. If the second error occurs after the first error (= while any of the error flags in the error status register is set), the flag in this register is set. However, if the second error is identical to the first error (both the source and address are same), this flag is not set. ERROVF is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in GRSTCLR.

The setting of this register is used for accesses through the respective access port.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 29.60 GROVFSTR_VCI/PE1 Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	ERROVF1	Error Overflow Flag (for the upper 32-bit data) This flag is set if the second error occurs while any of the error flags (EXDEDF1, EXSEDF1, APEF1, DEDF1, and SEDF1) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.
0	ERROVF0	Error Overflow Flag (for the lower 32-bit data) This flag is set if the second error occurs while any of the error flags (EXDEDF0, EXSEDF0, APEF0, DEDF0, and SEDF0) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.

(10) GR1STERSTR_VCI/PE1 — Global RAM 1st Error Status Register

GR1STERSTR monitors occurrence of the first error. Errors are detected and the states are updated independently for the higher- and lower-order 32 bits.
An error status flag is set if an error occurs while all error flags for the higher-order or the lower-order bits are 0. Note, however, that the corresponding error flag is also set if a 2-bit ECC error or an address parity error occurs in subsequent access as long as only the 1-bit ECC error flag is set at the time.

If more than one error is detected for a given memory access, all the corresponding error flags are set. GR1STERSTR is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in GRSTCLR.

The setting of this register is used for accesses through the respective access port.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 29.61 GR1STERSTR_VCI/PE1 Register Contents (1/2)

Bit Position	Bit Name	Function
7+8n 6+8n	—	Reserved These bits are always read as 0. The write value should also be 0.
5+8n	EXDEDFn	2-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting the STCLRn bit to 1 in GRSTCLR. Setting condition: A 2-bit ECC error has occurred while the error flags EXDEDFn, APEFn, and DEDFn are 0 (during RMW processing for Global RAM).
4+8n	EXSEDFn	1-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting the STCLRn bit to 1 in GRSTCLR. Setting condition: A 1-bit ECC error has occurred while the error flags EXDEDFn, EXSEDFn, APEFn, DEDFn, and SEDFn are 0 (during RMW processing for Global RAM).
3+8n	—	Reserved These bits are always read as 0. The write value should also be 0.
2+8n	APEFn	Address Parity Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting the STCLRn bit to 1 in GRSTCLR. Setting condition: An address parity error has occurred while the error flags EXDEDFn, APEFn, and DEDFn are 0. **NOTE** This flag is set equally for read and write; the error generation source is not considered.

Table 29.61 GR1STERSTR_VCI/PE1 Register Contents (2/2)

Bit Position	Bit Name	Function
1+8n	DEDFn	2-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting the STCLRn bit to 1 in GRSTCLR. Setting condition: A 2-bit ECC error has occurred while the error flags EXDEDFn, APEFn, and DEDFn are 0.
0+8n	SEDFn	1-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting the STCLRn bit to 1 in GRSTCLR. Setting condition: A 1-bit ECC error has occurred while the error flags EXDEDFn, EXSEDFn, APEFn, DEDFn, and SEDFn are 0.

Note 1. n = 0, 1, n = 0 represents the 32 lower-order bits and n = 1 represents the 32 higher-order bits.

(11) GR1STEADRn_VCI/PE1 — Global RAM 1st Error Address Register n (n = 0, 1)

GR1STEADRn holds the address at which an error has occurred.

The error address is set if an error occurs while all the error flags are 0 in GR1STERSTR. The address is updated if a 2-bit ECC error or an address parity error occurs while the 1-bit ECC error flag is set as the first error. Once a 2-bit ECC error or an address parity error occurs, the address is not updated.

EADR[20:0] of this register correspond to bits [20:0] of the real address. The real address can be calculated by appending the higher-order address bits [31:21] as a base address.

GR1STEADR is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in GRSTCLR. During accesses to the lower 32-bit data, the address is stored in GR1STEADR0. During accesses to the 32 higher-order bits data, the address is stored in GR1STEADR1.

The setting of this register is used for accesses through the respective access port.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	EADR[20:16]

	EADR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.62 GR1STEADRn_VCI/PE1 Register Contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved These bits are always read as 0. The write value should also be 0.
20 to 0	EADR[20:0]	1st Error Address These bits monitor the address of the first error. The error address is set if an error occurs while all the error flags are 0 in GR1STERSTR. The address is updated if a 2-bit ECC error or an address parity error occurs while the 1-bit ECC error flag is set as the first error. Once a 2-bit ECC error or an address parity error occurs, the address is not updated.

29.2.6.4 Test Function

Through appropriate register setting, desired values can be written as RAM data and to the ECC and address parity bits. Also, data in the RAM and the ECC and address parity bits and the ECC decoder output data for RMW can all be read.

It is possible to input the desired data in the ECC decoder for RMW.

(1) Writing RAM Data

(a) Set the ECCTST bit in the global RAM test control register to 1 to set test mode.

(b) Set the corresponding DATSEL1 to 0 and DATSEL0 to 0 in the global RAM test control register to select RAM data for access when writing.

(c) When data is written to the global RAM, only the RAM data can be modified without updating the ECC bits.

How to exit this test mode:

(a) Set the ECCTST bit in the global RAM test control register to 0 to disable test mode (normal mode).

(2) Reading RAM Data

(a) Set the ECCDIS bit in the global RAM ECC control register to 1 to disable ECC error detection and correction.

(b) Read the global RAM. Since neither error detection nor correction proceeds when the global RAM is read, the RAM data is read unchanged.

How to exit this test mode:

(a) Set the ECCDIS bit in the global RAM ECC control register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC and Address Parity Bits

(a) Set the ECCTST bit in the global RAM test control register to 1 to set test mode.

(b) Set the corresponding DATSEL1 bit to 0 and DATSEL0 bit to 1 in the global RAM test control register to select the ECC bits and the address parity bit for access when writing.

(c) When data is written to the global RAM, only the ECC and address parity bits can be modified without updating the RAM data. At that time, bit[6:0] and bit[7] are respectively written to the ECC bits and to the address parity bit.

NOTE

Writing desired values to the RAM data and the address parity bit should be in order of 1) writing the RAM data and then 2) writing the address parity bit.
When writing desired values to the RAM data and ECC bits, you can start either by writing to the RAM data or ECC bits.

How to exit this test mode:

(a) Set the ECCTST bit in the local RAM test control register to 0 to disable test mode (normal mode).

(4) Reading the ECC and Address Parity Bits

(a) Set the ECCTST bit in the global RAM test control register to 1 to set test mode.

(b) Setting the DATSEL1 and DATSEL0 bits in the global RAM test control register to 0 and 1, respectively, to select the ECC and address parity bits for access when reading.

(c) When data in the global RAM is read, the ECC and address parity bits are stored in the corresponding register from among global RAM test data read buffers 0 to 3.

How to exit this test mode:

(a) Set the ECCTST bit in the global RAM test control register to 0 to disable test mode (normal mode).

(5) Self-Diagnosis of the ECC Check Function for the Access Ports

Desired values can be written to the RAM data and/or ECC bits by following the procedure described in (1) or (3) above. Therefore, a fault can be injected by, for example, inverting appropriate bits of the RAM data and/or ECC bits. After that, self-diagnosis of the ECC decoder is possible by reading the global RAM in normal mode and checking the result of error correction or detection.

(6) Self-Diagnosis of the Address Parity Check Function

(a) Self-diagnosis is enabled by following either of the two procedures below.

(b) Setting APTESTi (i = 0, 1, 2, 3) in the global RAM test control register to 1 inverts the result of address parity generation for the corresponding data area (the 32 higher-order bits or the 32 lower-order bits) of the corresponding bank (bank A or B). That is, a fault can be injected to the address parity generator. Writing to the corresponding data area of the corresponding bank in the global RAM in this state and checking the result of parity error detection allows self-diagnosis of the address parity check function in writing.

(c) Desired data can be written to the address parity bits through the procedure described in (4) above. This enables injection of a fault to the address parity bit by inverting the address parity bit. After that, self-diagnosis of the address parity bit checking function for reading is possible by reading the global RAM in normal mode and checking the result of parity error detection.

(7) Self-Diagnosis of the ECC Decoder for the Data Read Out in an RMW Operation

(a) Suitable erroneous values are injected as RAM data or to the ECC bits by following procedure (1) or (3) above.

(b) Setting the DATSEL1 and DATSEL0 bits in the test control registers for the global RAM to 1 and 0, respectively, makes the output data from the ECC decoder for the data read out in an RMW operation the target for reading.

(c) After RMW processing for the global RAM proceeds, the data read out in an RMW operation for global RAM are stored in the corresponding register from among global RAM test data read buffers 0 to 3. Checking the result allows self-diagnosis of the ECC decoder for the data read out in an RMW operation.

(8) Self-Diagnosis of the ECC Decoder for the Data being Updated at the Time of RMW Access

(a) Setting the DATSEL1 and DATSEL0 bits in the global RAM test control register to 1 makes the output data from the ECC decoder for the data being updated at the time of RMW access the target for reading.

(b) Through the above setting, the input data from the ECC decoder for the data being updated at the time of RMW access is switched to ECC decoder input buffer 0 or 1 (GRDECINBF0 or 1) from write data sent from the access ports. As a result, suitable erroneous values can be injected by setting an appropriate value in ECC decoder input buffer 0 or 1.

(c) After RMW processing for the global RAM proceeds, the data being updated at the time of RMW access for global RAM are stored in the corresponding register from among global RAM test data read buffers 0 to 3. Checking the result allows self-diagnosis of the ECC decoder when data are updated.

29.2.7 Instruction Cache ECC and EDC

29.2.7.1 Overview

The instruction cache ECC is summarized in the table below.

Table 29.63 Overview of Instruction Cache ECC

Item	Description
ECC error detection and correction	ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected. • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, neither error detection nor correction is carried out. In the state after reset, 1-bit error detection and correction and 2-bit error detection are carried out while the ECC function is enabled.
Address parity	None
Error notification	Upon occurrence of an ECC error, the ECM is notified of the error. **ECC Error:** • Error notification can be either enabled or disabled upon detection of a 2-bit ECC error. • Error notification can be either enabled or disabled upon detection of a 1-bit ECC error. In the state after reset, notification of the 2-bit ECC error is disabled, and notification of the 1-bit ECC error is disabled. The error notification signal is output, where a 2-bit ECC error is handled as one source, and a 1-bit ECC error is handled as one source.
Error status	A status register is provided, which indicates the statuses of 2-bit ECC error detection and 1-bit ECC error detection. If an error occurs while no error status flag is set, the corresponding status is set. The error status flag can be cleared using the clear register.
Address capture	If an ECC error occurs while no error status flag is set, the address at which the associated error has occurred is captured. The address is captured when a 2-bit ECC error or a 1-bit ECC error is detected. The error status flag serves as the enable bit of the capture address.
Self-diagnosis	A cache instruction is used to write the desired values as RAM data and to the ECC bits. Similarly, data in the RAM and the ECC bits can be read directly. Since instructions as described above go through the same encoding or decoding path as a normal cache fill or instruction fetch, only such instructions can be used in inserting and confirming errors.

29.2.7.2 List of Registers

Table 29.64 List of Registers

Address	Symbol	Register Name	R/W	Value after Reset	Access Size
FFC6 0400$_H$	IDECCCTL_PE1	Instruction cache data RAM ECC control register (PE1)	R/W	0000 0000$_H$	16/32
FFC6 0404$_H$	IDERRINT_PE1	Instruction cache data RAM error information control register (PE1)	R/W	0000 0000$_H$	8/16/32
FFC6 0408$_H$	IDSTCLR_PE1	Instruction cache data RAM error status clear register (PE1)	W	0000 0000$_H$	8/16/32
FFC6 040C$_H$	IDOVFSTR_PE1	Instruction cache data RAM error count overflow status register (PE1)	R	0000 0000$_H$	8/16/32
FFC6 0410$_H$	ID1STERSTR_PE1	Instruction cache data RAM 1st error status register (PE1)	R	0000 0000$_H$	8/16/32

FFC6 1410$_H$	IT1STERSTR_PE1	Instruction cache tag RAM 1st error status clear register (PE1)	R	0000 0000$_H$	8/16/32
FFC6 1450$_H$	IT1STEADR0_PE1	Instruction cache tag RAM (bank0) 1st error address register (PE1)	R	0000 0000$_H$	8/16/32

29.2.7.3 Details of Registers

(1) IDECCCTL_PE1 — Instruction Cache Data RAM ECC Control Register

IDECCCTL enables or disables ECC error detection and correction and 1-bit error correction for cache data RAM. Set PROT[1:0] bits to 01_B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	SECDIS	ECCDIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R\W	R\W

Table 29.65 IDECCCTL_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	SECDIS	1-Bit Error Correction Disable Enables or disables 1-bit error correction when ECC error detection and correction are enabled. 0: Enables correction of the 1-bit error detected. 1: Disables correction of the 1-bit error detected.
0	ECCDIS	ECC Disable Enables or disables ECC error detection and correction. 0: Enables ECC error detection and correction. 1: Disables ECC error detection and correction.

(2) IDERRINT_PE1 — Instruction Cache Data RAM Error Information Control Register

IDERRINT enables or disables generation of the error notification signal to the ECM upon detection of a 2-bit ECC error or a 1-bit ECC error in cache data RAM.

IDERRINT is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 29.66 IDERRINT_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	DEDIE	2-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 2-bit ECC error. 1: Enables notification of the 2-bit ECC error.
0	SEDIE	1-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 1-bit ECC error. 1: Enables notification of the 1-bit ECC error.

(3) IDSTCLR_PE1 — Instruction Cache Data RAM Error Status Clear Register

IDSTCLR clears the error flags in the error status register (ID1STERSTR), the overflow flag in the error count overflow status register (IDOVFSTR), and the error address register (ID1STEADR). IDSTCLR is a write-only register and is always read as 0.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 29.67 IDSTCLR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	STCLR1	Error Overflow Flag Clear (for bank 1) Writing 1 to this bit clears the DEDF1and SEDF1 flags in ID1STERSTR; ERROVF1 flag in IDOVFSTR; and ID1STEADR1.
0	STCLR0	Error Overflow Flag Clear (for bank 0) Writing 1 to this bit clears the DEDF0and SEDF0 flags in ID1STERSTR; ERROVF0 flag in IDOVFSTR; and ID1STEADR0.

(4) IDOVFSTR_PE1 — Instruction Cache Data RAM Error Count Overflow Status Register

IDOVFSTR monitors occurrence of error overflow in cache data RAM. If the second error occurs after the first error (= while any of the error flags in the error status register is set), the flag in this register is set. However, if the second error is identical to the first error (both the source and address are same), this flag is not set. ERROVF is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in IDSTCLR.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.68 IDOVFSTR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	ERROVF1	Error Overflow Flag (for bank 1) This flag is set if the second error occurs while any of the error flags (DEDF1 and SEDF1) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.
0	ERROVF0	Error Overflow Flag (for bank 0) This flag is set if the second error occurs while any of the error flags (DEDF0 and SEDF0) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.

(5) ID1STERSTR_PE1 — Instruction Cache Data RAM 1st Error Status Register

ID1STERSTR monitors occurrence of the first error in cache data RAM. The error status flag is set if an error occurs while all the error flags in the same bank are 0. The corresponding error flag is set if a 2-bit ECC error occurs while the 1-bit ECC error flag is set.

This register cannot be used to identify the way that had an error.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	DEDF1	SEDF1	—	—	—	—	—	—	DEDF0	SEDF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.69 ID1STERSTR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 10	—	Reserved These bits are always read as 0. The write value should also be 0.
9	DEDF1	2-Bit ECC Error Monitor Flag (for bank 1) Clearing condition: Cleared to 0 by a reset or by setting the STCLR1 bit to 1 in IDSTCLR. Setting condition: A 2-bit ECC error has occurred while the error flag DEDF1 is 0.
8	SEDF1	1-Bit ECC Error Monitor Flag (for bank 1) Clearing condition: Cleared to 0 by a reset or by setting the STCLR1 bit to 1 in IDSTCLR. Setting condition: A 1-bit ECC error has occurred while the error flags DEDF1 and SEDF1 are 0.
7 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	DEDF0	2-Bit ECC Error Monitor Flag (for bank 0) Clearing condition: Cleared to 0 by a reset or by setting the STCLR0 bit to 1 in IDSTCLR. Setting condition: A 2-bit ECC error has occurred while the error flag DEDF0 is 0.
0	SEDF0	1-Bit ECC Error Monitor Flag (for bank 0) Clearing condition: Cleared to 0 by a reset or by setting the STCLR0 bit to 1 in IDSTCLR. Setting condition: A 1-bit ECC error has occurred while the error flags DEDF0 and SEDF0 are 0.

(6) ID1STEADRn_PE1 — Instruction Cache Data RAM (Bank n) 1st Error Address Register (n = 0, 1)

ID1STEADR holds the address at which an error has occurred in cache data RAM.

The error address is set if an error occurs while all the error flags for the relevant banks are 0 in ID1STERSTR. The address is updated if a 2-bit ECC error is found while the 1-bit ECC error flag is set for a first error. Once a 2-bit ECC error occurs, the address is not updated.

EADRn[6:0] indicate the cache address [10:4]. EADRn[7] is always 0. EADRn[8] indicates the way group number.

ID1STEADR is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in IDSTCLR.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	EADRn[8:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.70 ID1STEADRn_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved These bits are always read as 0. The write value should also be 0.
8 to 0	EADRn[8:0]	1st Error Address (for bank n) These bits monitor the address of the first error. The error address is set if an error occurs while all the error flags for bank n are 0 in ID1STERSTR. The address is updated if a 2-bit ECC error is found while the 1-bit ECC error flag is set as the first error. Once a 2-bit ECC error occurs, the address is not updated.

(7) ITECCCTL_PE1 — Instruction Cache Tag RAM ECC Control Register

This register is used to enable or disable ECC error detection of the cache TAG RAM. Set PROT[1:0] bits to 01_B when writing to this register.

This register is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	PROT[1:0]	These bits enable to write to this register. The read value is 0.
13 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	ECCDIS	ECC Disable Enables or disables ECC error detection. 0: Enables ECC error detection. 1: Disables ECC error detection.

(8) ITERRINT_PE1 — Instruction Cache Tag RAM Error Information Control Register

ITERRINT enables or disables generation of the error notification signal to the ECM upon detection of a 2-bit ECC error or a 1-bit ECC error in cache tag RAM.

ITERRINT is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	DEDIE	2-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 2-bit ECC error. 1: Enables notification of the 2-bit ECC error.
0	SEDIE	1-Bit ECC Error Notification Enable Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the 1-bit ECC error. 1: Enables notification of the 1-bit ECC error.

(9) ITSTCLR_PE1 — Instruction Cache Tag RAM Error Status Clear Register

ITSTCLR clears the error flags in the error status register (IT1STERSTR), the overflow flag in the error count overflow status register (ITOVFSTR), and the error address register (IT1STEADR0). ITSTCLR is a write-only register and is always read as 0.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 29.73 ITSTCLR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	STCLR0	Error Overflow Flag Clear (for bank 0) Writing 1 to this bit clears the DEDF0 and SEDF0 flags in IT1STERSTR; ERROVF0 flag in ITOVFSTR; and IT1STEADR0.

(10) ITOVFSTR_PE1 — Instruction Cache Tag RAM Error Count Overflow Status Register

ITOVFSTR monitors occurrence of error overflow in cache tag RAM. If the second error occurs after the first error (= while any of the error flags in the error status register is set), the flag in this register is set. However, if the second error is identical to the first error (both the source and address are same), this flag is not set. ERROVF is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in ITSTCLR.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.74 ITOVFSTR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	ERROVF0	Error Overflow Flag (for bank 0) This flag is set if the second error occurs while any of the error flags (DEDF0 and SEDF0) in the error status register is set, except when both of the error address and source of the second error are the same as those of the first error.

(11) IT1STERSTR_PE1 — Instruction Cache Tag RAM 1st Error Status Register

IT1STERSTR monitors occurrence of the first error in cache tag RAM.

The error status flag is set if an error occurs while all the error flags are 0. The corresponding error flag is set if a 2-bit ECC error occurs while the 1-bit ECC error flag is set.

This register cannot be used to identify the way that had an error.

IT1STERSTR is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in ITSTCLR.

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.75 IT1STERSTR_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	DEDF0	2-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting the STCLR0 bit to 1 in ITSTCLR. Setting condition: A 2-bit ECC error has occurred while the error flag DEDF0 is 0.
0	SEDF0	1-Bit ECC Error Monitor Flag Clearing condition: Cleared to 0 by a reset or by setting the STCLR0 bit to 1 in ITSTCLR. Setting condition: A 1-bit ECC error has occurred while the error flags DEDF0 and SEDF0 are 0.

(12) IT1STEADR0_PE1 — Instruction Cache Tag RAM 1st Error Address Register

IT1STEADR0 holds the address at which an error has occurred in cache tag RAM.

The error address is set if an error occurs while all the error flags are 0 in IT1STERSTR. The address is updated if a 2-bit ECC error is found while the 1-bit ECC error flag is set as the first error. Once a 2-bit ECC error occurs, the address is not updated.

EADR[6:0] indicate the cache address [10:4]. EADR[7] is always 0. EADRn[8] indicates the way group number.

IT1STEADR0 is cleared by an internal reset, an external reset, or setting the STCLR bit to 1 in ITSTCLR.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	EADR[8:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.76 IT1STEADR0_PE1 Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved These bits are always read as 0. The write value should also be 0.
8 to 0	EADR[8:0]	1st Error Address Monitors the address of the first error. The error address is set if an error occurs while all the error flags are 0 in IT1STERSTR. The address is updated if a 2-bit ECC error is found while the 1-bit ECC error flag is set as the first error. Once a 2-bit ECC error or an address parity error occurs, the address is not updated.

29.2.7.4 Test Function

A cache instruction is used to write the desired values as RAM data and to the ECC bits, and read data in the RAM and the ECC bits directly.

Since instructions as described above go through the same encoding or decoding path as a normal cache fill or instruction fetch, only such instructions can be used in inserting and confirming errors.

For details, see RH850G3M User's Manual: Software.

29.2.8 DTS RAM ECC

See **Section 7, DMA**.

29.2.9 ECC for Peripheral RAM (32 Bits)

29.2.9.1 Overview

This is an ECC module for the RAM of the following peripheral modules.

RS-CAN, FlexRay, APA, and DFE

Error Detection and Correction

Seven-bit ECC data is appended to the 32-bit RAM data.

This ECC module provides 2-bit ECC error detection and 1-bit ECC error detection and correction.

CAUTION

This module is not capable of reliably detecting errors in three or more bits.

If errors occur in three or more bits, the module may detect the errors as 1- or 2-bit ECC errors or not detect any errors. Depending on the settings, this may lead to the correction of a bit that was not actually inverted.

Enabling or Disabling ECC Error Detection and Correction

- ECC error detection can be either enabled or disabled.
- One-bit ECC error correction can be either enabled or disabled.
- If all the bits of RAM output data are stuck to 0 or 1, it is detected as a 2-bit ECC error.

Error Notification

- The ECM is notified when 2-bit ECC errors are detected (this can be enabled or disabled).
- The ECM is notified when 1-bit ECC errors are detected (this can be enabled or disabled).

Once the ECM has been notified of an error, even if another ECC error is detected, the ECM is not notified until the error status bit corresponding to the initial error is cleared.

Error Status

- Detection of 2-bit and 1-bit ECC errors can be monitored.
- Special registers are provided to clear error status.

Address Capture

- Only one address at which an ECC error has occurred can be captured.
- When a 2-bit or 1-bit ECC error is detected, the error-causing address is captured. It is used to capture only when the first error is detected after the flag is cleared.

Testing Function (Error Insertion)

- By setting the test mode, register values can be used as the data to be output to the RAM. When a peripheral module writes to the RAM, the ECEDB[31:0] register value can be written to the RAM data section, and the ECERDB[6:0] register value can be written to the ECC redundant bit section.
- By setting the test mode, the ECC redundant bit section can be latched when RAM data is read, and the value can be confirmed.
- By setting the test mode, the ECC redundant bit (encoding circuit) and syndrome code (decoding circuit), which are generated from the input data, can be confirmed.

29.2.9.2 List of Registers

(1) List of ECC Modules

The RAMs of the multiple peripheral functions are provided with the ECC modules. The following table shows the peripheral functions provided with the ECC modules, the corresponding ECC module names, and base addresses of the ECC modules.

Table 29.77 Peripheral Functions, Corresponding ECC Module Names, and Base Addresses of ECC Modules

Peripheral Functions		ECC Module Names and Register Base Addresses			
		Master Side*1		Checker Side*1	
		Module Name	Base Address <base_addr>	Module Names	Base Address <base_addr>
RS-CAN		E7RC0M	FFC7 1000_H	E7RC0C	FFC7 1200_H
FlexRay	Message RAM (MRAM)	E7FR0M	FFC7 2000_H	E7FR0C	FFC7 2200_H
	Temporary buffer (TBF AA)	E7FR1M	FFC7 2400_H	E7FR1C	FFC7 2600_H
	Temporary buffer (TBF B)	E7FR2M	FFC7 2800_H	E7FR2C	FFC7 $2A00_H$
APA	Element RAM0 (ELRAM0)	E7AP0M	FFC7 6000_H	E7AP0C	FFC7 6200_H
	Element RAM1 (ELRAM1)	E7AP1M	FFC7 6400_H	E7AP1C	FFC7 6600_H
	Element RAM2 (ELRAM2)	E7AP2M	FFC7 6800_H	E7AP2C	FFC7 $6A00_H$
DFE	Coefficient memory (CMEM)	E7DF1M	FFC7 $D000_H$	E7DF1C	FFC7 $D200_H$

Note 1. Two ECC modules are provided to support BIST, one for the master and the other for the checker. For details, refer to **Section 29.7, BIST**.

(2) List of Registers

Each ECC module has the registers shown in the following table.

Table 29.78 List of ECC Module Registers

Register Name	Symbol	R/W	Value after Reset	Address	Access Size
ECC control register*1	E710CTL	R/W	$001X_H$	<base_addr> + 00_H	16/8
ECC test mode control register	E710TMC	R/W	0000_H	<base_addr> + 04_H	16/8
ECC redundant bit data control test register	E710TRC	R/W	0000 0000_H	<base_addr> + 08_H	32
ECC encoder and decoder data test register	E710TED	R/W	0000 0000_H	<base_addr> + $0C_H$	32
ECC error address register	E710EAD	R/W	0000 0000_H	<base_addr> + 10_H	32

Note 1. The reset value of the LSB in the ECC control register is undefined.

(3) Register Map

Table 29.79 List of Register Map

Symbol	31 24	23 16	15 8	7 0	Address
E710CTL	— (00_H)	— (00_H)	ECCTL[15:8]	ECCTL[7:0]	$nn00_H$
E710TMC	— (00_H)	— (00_H)	ECTMC[15:8]	ECTMC[7:0]	$nn04_H$
E710TRC	ECSYND[7:0]	ECHORD[7:0]	ECECRD[7:0]	ECERDB[7:0]	$nn08_H$
E710TED	ECEDB[31:24]	ECEDB[23:16]	ECEDB[15:8]	ECEDB[7:0]	$nn0C_H$
E710EAD	ECEAD[31:24]	ECEAD[23:16]	ECEAD[15:8]	ECEAD[7:0]	$nn10_H$

29.2.9.3 Details of Registers

(1) E710CTL — ECC Control Register

E710CTL controls the status and modes of the ECC module.

E710CTL can be read and written to using the 16-bit or 8-bit manipulation instruction.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EMCA[1:0]		—	—	—	ECER2C	ECER1C	—	ECTHM	—	EC1ECP	EC2EDIC	EC1EDIC	ECER2F	ECER1F	ECEMF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	Un-defined
R/W	R/W*1	R/W*1	R	R	R	R/W*1	R/W*1	R	R/W	R	R/W	R/W	R/W	R	R	R

Note 1. This bit is always read as 0.

Table 29.80 E710CTL Register Contents (1/2)

Bit Position	Bit Name	Function
15, 14	EMCA[1:0]	Access Control 1 and 0 to ECC Mode Select Bit These bits reserve the write trigger to bit 7. The read value is always 0.
10	ECER2C	2-Bit ECC Error Detection Flag Clear Clears the bit 2 (ECER2F) status flag. The read value is always 0, and writing 0 to ECER2C does not change the state. If writing 1 to ECER2C conflicts with the condition for setting bit 2, the former takes priority. Writing 1 to ECER2C while ECER2F is set clears ECER2F.
9	ECER1C	1-Bit ECC Error Detection Flag Clear Clears the bit 1 (ECER1F) status flag. The read value is always 0, and writing 0 to ECER1C does not change the state. If writing 1 to ECER1C conflicts with the condition for setting bit 1, the former takes priority. Writing 1 to ECER1C while ECER1F is set clears ECER1F.
7	ECTHM	ECC Function Disable Select Selects the ECC decoding operation. Write access to ECTHM is enabled when the value of bits 15 and 14 is 01_B. Therefore, only the 16-bit manipulation instruction is valid. Setting ECTHM to 1 disables error detection and bit correction. Here, if the data to be output to the peripheral module contains an error, the data is output without bit correction. Setting ECTHM to 1 has no effect on the encoder side. 0: Enables ECC detection and correction. 1: Disables ECC detection and correction.
5	EC1ECP	1-Bit ECC Error Correction Enable 0: Enables 1-bit error correction upon error detection. 1: Disables 1-bit error correction upon error detection.
4	EC2EDIC	2-Bit ECC Error Detection Notification Enable 0: When a 2-bit error is detected, the ECM is not notified of the error. 1: When a 2-bit error is detected, the ECM is notified of the error.
3	EC1EDIC	1-Bit ECC Error Detection Notification Enable 0: When a 1-bit error is detected, the ECM is not notified of the error. 1: When a 1-bit error is detected, the ECM is notified of the error.
2	ECER2F	2-Bit ECC Error Detection Flag Indicates that errors have been detected at two bits in bits 0 to 38 of the data read from the RAM during RAM read access while error detection is enabled. This bit is a read only flag. 0: 2-bit error is not generated 1: 2-bit error is generated Clearing conditions (1) Reset is applied. (2) 1 is written to ECER2C. (3) ECC detection and correction being disabled (ECTHM = 1).

Table 29.80 E710CTL Register Contents (2/2)

Bit Position	Bit Name	Function
1	ECER1F	1-Bit ECC Error Detection And Correction Flag Indicates that an error has been detected at one bit in bits 0 to 38 of the data read from the RAM during RAM read access while error detection is enabled. This bit is a read only flag. 0: 1-bit error is not generated 1: 1-bit error is generated Clearing conditions (1) Reset is applied. (2) 1 is written to ECER1C. (3) ECC detection and correction being disabled (ECTHM = 1).
0	ECEMF	ECC Error Message Flag Indicates that the current read data bus contains an error. ECEMF is updated every time RAM data is output. Since the RAM value after reset is undefined, the initial value of this module is determined to be an error, and thus ECEMF may be set. Therefore, the ECEMF value after reset is undefined. 0: The current read data bus contains no bit errors. 1: The current RAM output data contains bit errors. ECEMF remains set as long as RAM data containing a bit error is output with error detection being enabled. Clearing conditions (1) ECC detection and correction being disabled (ECTHM = 1). (2) Decoding circuit input data contains no 1-bit errors.

(2) E710TMC — ECC Test Mode Control Register

E710TMC is a 16-bit register to switch the mode to test mode and controls the mode.

E710TMC can be read and written to using the 16-bit or 8-bit manipulation instruction.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ETMA[1:0]		—	—	—	—	—	—	ECTMCE	—	—	ECTRRS	ECREOS	ECENS	ECDCS	ECREIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W*1	R/W*1	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Note 1. This bit is always read as 0.

Table 29.81 E710TMC Register Contents (1/2)

Bit Position	Bit Name	Function
15, 14	ETMA[1:0]	Access Control 1 and 0 to ECC Test Mode Control Enable Bit These bits reserve the write trigger to bit 7. The read value is always 0.
7	ECTMCE	ECC Test Mode Control Enable ECTMCE enables or disables access to the test registers and test control bits. Write access to ETCMCE is enabled when the value of bits 15 and 14 is 10_B. 0: Disables access to the test registers and test control bits. 1: Enables access to the test registers and test control bits.
4	ECTRRS	ECC RAM Read Test Mode Control Enable ECTRRS enables the read status of RAM to be generated by reading the E710TED register, and also allows the RAM output data to be read out when the E710TRC:ECERDB[7:0] bits and the E710TED register are read. Write access to ECTRRS is enabled only when ECTMCE is 1 (can be set simultaneously). ECTRRS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Disables generation of RAM read status for testing when E710TED is read. 1: Enables generation of RAM read status for testing when E710TED is read. When E710TRC:ECERDB[7:0] and E710TED are read, the values of the RAM output data pin are read out.
3	ECREOS	ECC Redundant Bit Output Data Select ECREOS selects either the ECC encoder output data or the ECERDB register value to be output as the ECC redundant bit output. Write access to ECREOS is enabled only when ECTMCE is 1 (can be set simultaneously). ECREOS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allows encoding result to be output as the ECC redundant bit output. 1: Allows the E710TRC:ECERDB[6:0] value to be output as the ECC redundant bit output.
2	ECENS	ECC Encoder Input Select ECENS selects either the data value from the peripheral module or the test register value (E710TED:ECEDB[31:0]) as the input signal to be encoded. Write access to ECENS is enabled only when ECTMCE is 1 (can be set simultaneously). ECENS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allows the RAM write data from the peripheral module to be input as the ECC encoder input data. 1: Allows the E710TED:ECEDB[31:0] value to be input as the ECC encoder input data.

Table 29.81 E710TMC Register Contents (2/2)

Bit Position	Bit Name	Function
1	ECDCS	ECC Decoder Input Select ECDCS selects either the lower 32-bit data value from the RAM or the test register value (E710TED:ECEDB[31:0]) as the lower 32-bit data of the input signal to be decoded. Write access to ECDCS is enabled only when ECTMCE is 1 (can be set simultaneously). ECDCS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allows the lower 32-bit RAM output data to be input to the data area (32 lower-order bits) to the decoder. 1: Allows the E710TED:ECEDB[31:0] value to be input to the data area to the decoder.
0	ECREIS	ECC Redundant Bit Input Data Select ECREIS selects either the upper 7-bit data value from the RAM (redundant bit area) or the test register value (E710TRC:ECERDB[6:0]) as the upper 7-bit data of the input signal to be decoded. Write access to ECREIS is enabled only when ECTMCE is 1 (can be set simultaneously). ECREIS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allows the upper 7-bit RAM output data to be input to the ECC redundant bit area to the decoder. 1: Allows the E710TRC:ECERDB[6:0] value to be input to the ECC redundant bit area to the decoder.

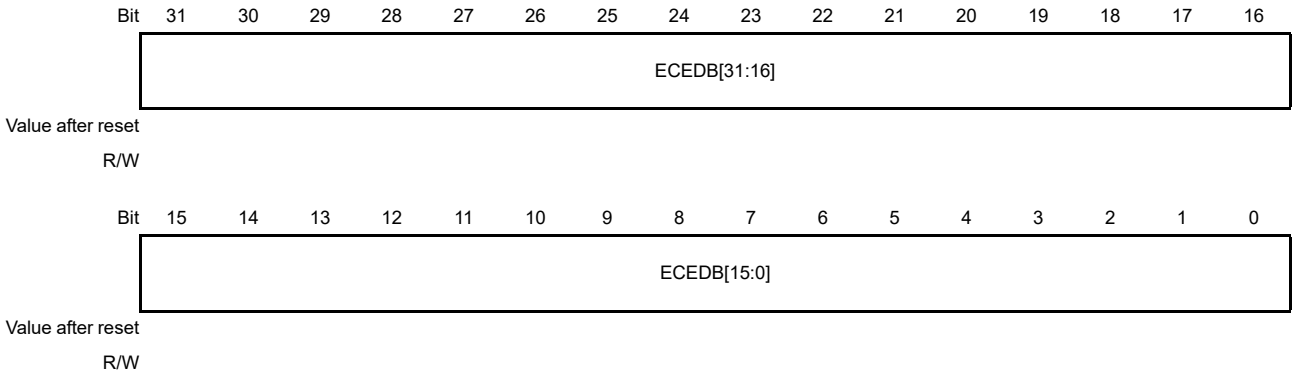
(3) E710TED — ECC Encoder and Decoder Data Test Register

E710TED is a 32-bit data test register for ECC encoding and decoding.

When ECTMCE = 1, E710TED can be read and written to using the 32-bit manipulation instruction.

When ECTMCE = 0, E710TED is always read as 0.

In test mode, the E710TED value can be used as the input data to the encoding circuit and decoding circuit.



NOTE

Changing ECTMCE from 1 to 0 resets E710TED synchronously.

When E710TMC:ECENS = 1, the ECEDB value is input to the encoding circuit and supplied to the RAM.

When E710TMC:ECDCS = 1, the ECEDB value is input as the 31th to 0th bits of the input data to the decoding circuit.

When E710TMC:ECTRRS = 1, reading ECEDB returns the RAM output data instead of the data written to ECEDB.

(4) E710TRC — ECC Redundant Bit Data Control Test Register

E710TRC is a 32-bit test register consisting of four fields (ECSYND, ECHORD, ECECRD, and ECRODM) corresponding to the ECC redundant bit area. Each field can be accessed as the 8-bit register with the same name. For details of each field, refer to the descriptions of these four registers.

When ECTMCE = 0, E710TRC is always read as 0.

When ECTMCE = 1, E710TRC can be read using the 32-bit manipulation instruction.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ECSYND								ECHORD							
Value after reset																
R/W																

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ECECRD								ECERDB							
Value after reset																
R/W																

NOTE

Changing ECTMCE from 1 to 0 resets E710TED synchronously.

(5) ECSYND — ECC Decoder Syndrome Data Register

ECSYND is a read-only register to confirm the syndrome code generated by the decoding circuit in test mode (ECTMCE = 1).

Write access to ECSYND is ignored.

Bit	7	6	5	4	3	2	1	0
	—	SYND[6:0]						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

When read, the ECSYND bits return the value of the syndrome code (synd[6:0]) generated based on the input data to the decoding circuit.

The ECSYND bits are not holding circuits; the register value changes as the input signal changes.

ECSYND is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

(6) ECHORD — ECC 7-Bit Redundant Data Holding Test Register

ECHORD holds the 7-bit ECC redundant area (upper 7-bit RAM data), which cannot be confirmed by the peripheral module, when the peripheral module accesses the RAM for reading in test mode (ECTMCE = 1).

Bit	7	6	5	4	3	2	1	0
	—	HORD[6:0]						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

The ECHORD bits are loaded with the upper 7-bit RAM output data at the next rising edge of the operating clock signal after the peripheral module accesses the RAM for reading data in test mode (ECTMCE = 1).

The ECHORD bits are also loaded with the data on the input pins EC7TERI38 to EC7TERI32 at the next operating clock pulse when the ECEDB[15:0] register is read while E710TMC:ECTRRS = 1.

ECHORD is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

(7) ECECRD — ECC Encoder Test Register

ECECRD is a read-only register to read the 7-bit redundant section generated by the encoding circuit in test mode (ECTMCE = 1).

Bit	7	6	5	4	3	2	1	0
	—	ECRD[6:0]						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

ECECRD is used to confirm the redundant bits generated by the input data from the peripheral module. Here, the read-out data is the result of encoding (ecc[6:0]), not the output value.

ECECRD is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

(8) ECERDB — ECC Redundant Bit Input and Output Substitution Buffer Register

ECERDB is a buffer register for the data that substitutes for the input and output data for the 7-bit ECC redundant data area in test mode (ECTMCE = 1).

ECERDB can be read and written to in ECC test mode (ECTMCE = 1).

Bit	7	6	5	4	3	2	1	0
	—	ERDB[6:0]						
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When ECREOSS = 1, the ECERDB value, instead of the seven redundant bits generated by the encoding circuit, is output to the pin to be supplied to the RAM.

When ECREIESS = 1, the ECERDB value, instead of the upper seven data bits to be input to the decoding circuit, is handled by the decoding circuit.

When ECTRRS = 1, reading ECERDB returns the signal value supplied to RAM instead of the data written to ECERDB.

(9) E710EAD — ECC Error Address Register

E710EAD is a read-only register to hold the address at which an ECC error has occurred.

If an ECC error is detected while ECC error detection is enabled, the RAM address is latched using the detection signal as a trigger, and the address is stored in E710EAD as the address at which the ECC error has occurred.

The address is stored upon detection of the first ECC error while no error status flag is set. However, if a 1-bit error is followed by a 2-bit error, the address of the latter is stored.

Only one address can be held in E710EAD.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ECEAD[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ECEAD[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

29.2.9.4 Notification to ECM

Detection of errors in two bits can be set for this module and the ECM is notified of detected errors.

- 1-bit Error Notification
  While EC1EDIC is set to 1_B, when an error is detected in one bit from among bits 0 to 38 of data read from RAM, the ECM is notified of the 1-bit error. When ECER1F or ECER2F is already set, however, the ECM will not be notified of the error.
- 2-bit Error Notification
  While EC2EDIC is set to 1_B, when an error is detected in two bits from among bits 0 to 38 of data read from RAM, the ECM is notified of the 2-bit error. When ECER2F is already set, however, the ECM will not be notified of the error.

29.2.9.5 Test Function

(1) Writing to RAM Data

Write data to the peripheral RAM. However, the ECC corresponding to the written data will be written to the ECC bits simultaneously. In order to write a specified value to the ECC bits, use the ECC test mode described in (3) below.

(2) Reading RAM Data

(a) Set the ECTHM bit in the ECC control register to 1 to disable ECC error detection and correction.

(b) Read the peripheral RAM. Since neither error detection nor correction proceeds when the peripheral RAM is read, the RAM data is read unchanged.

How to exit this test mode:

(a) Set the ECTHM bit in the ECC control register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC Bits

(a) Set the ECTMCE bit in the ECC test mode control register to 1 to set ECC test mode.

(b) Write the value for writing to the ECC bits to the E710TRC.ECERDB[6:0] bits.

(c) Set the ECREOS bit in the ECC test mode control register to 1 to select writing of the value of the E710TRC.ECERDB[6:0] bits to the ECC bits.

(d) When data are written to the peripheral RAM, the value in the E710TRC.ECERDB[6:0] bits will be written to the ECC bits.

How to exit this test mode:

(a) Set the ECTMCE bit in the ECC test mode control register to 0 to set normal mode.

(4) Reading the ECC Bits

(a) Set the ECTMCE bit in the ECC test mode control register to 1 to set ECC test mode.

(b) When data in the peripheral RAM is read, the ECC bits are stored in the E710TRC.ECHORD[6:0] bits.

How to exit this test mode:

(a) Set the ECTMCE bit in the ECC test mode control register to 0 to set normal mode.

29.2.10 ECC for Peripheral RAM (16 Bits)

29.2.10.1 Overview

This is an ECC module for the RAM of the following peripheral module.

DFE

Error Detection and Correction

Six-bit ECC data is appended to the 16-bit RAM data.

This ECC module provides 2-bit ECC error detection and 1-bit ECC error detection and correction.

CAUTION

If three or more bits of errors occur, they cannot be detected by this module. In this case, such errors may be detected as 1 or 2-bit errors; no errors may be detected; or a non-inverted bit may be corrected depending on the setting.

Enabling or Disabling ECC Error Detection and Correction

- ECC error detection can be either enabled or disabled.
- One-bit ECC error correction can be either enabled or disabled.
- If all the bits of RAM output data are stuck to 0 or 1, it is detected as a 2-bit ECC error.

Error Notification

- The ECM is notified when 2-bit ECC errors are detected (this can be enabled or disabled).
- The ECM is notified when 1-bit ECC errors are detected (this can be enabled or disabled).

Once the ECM has been notified of an error, even if another ECC error is detected, the ECM is not notified until the error status bit corresponding to the initial error is cleared.

Error Status

- Detection of 2- and 1-bit ECC errors can be monitored.
- Special registers are provided to clear error status.

Address Capture

- Only one address at which an ECC error has occurred can be captured.
- When a 2-bit or 1-bit ECC error is detected, the address where the error was found is captured (when the first (1-bit or 2-bit) error is detected after the flag is cleared).

Testing Function (Error Insertion)

- By setting the test mode, register values can be used as the data to be output to the RAM. When a peripheral module writes to the RAM, the ECEDB[15:0] register value can be written to the RAM data section, and the ECERDB[5:0] register value can be written to the ECC redundant bit section.
- By setting the test mode, the ECC redundant bit section can be latched when RAM data is read, and the value can be confirmed.
- By setting the test mode, the ECC redundant bit (encoding circuit) and syndrome code (decoding circuit), which are generated from the input data, can be confirmed.

29.2.10.2 List of Registers

(1) List of ECC Modules

The RAMs of the multiple peripheral functions are provided with the ECC modules. The following table shows the peripheral functions provided with the ECC modules, the corresponding ECC module names, and base addresses of the ECC modules.

Table 29.82 Peripheral Functions, Corresponding ECC Module Names, and Base Addresses of ECC Modules

Peripheral Functions		ECC Module Names and Register Base Addresses			
		Master Side*1		Checker Side*1	
		Module Name	Base Address <base_addr>	Module Names	Base Address <base_addr>
DFE	Data memory (DMEM0)	E6DF0M	FFC7 D400$_H$	E6DF0C	FFC7 D600$_H$
	Data memory (DMEM1)	E6DF1M	FFC7 D800$_H$	E6DF1C	FFC7 DA00$_H$

Note 1. Two ECC modules are provided to support BIST, one for the master and the other for the checker. For details, refer to **Section 29.7, BIST**.

(2) List of Registers

Each ECC module has the registers shown in the following table.

Table 29.83 List of ECC Module Registers

Register Name	Symbol	R/W	Value after Reset	Address	Access Size
ECC control register*1	E610CTL	R/W	001X$_H$	<base_addr> + 00$_H$	16/8
ECC test mode control register	E610TMC	R/W	0000$_H$	<base_addr> + 04$_H$	16/8
ECC redundant bit data control test register	E610TRC	R	0000 0000$_H$	<base_addr> + 08$_H$	32
ECC encoder and decoder data test register	E610TED	R/W	0000 0000$_H$	<base_addr> + 0C$_H$	32
ECC error address register	E610EAD	R	0000 0000$_H$	<base_addr> + 10$_H$	32

Note 1. The reset value of the LSB in the ECC control register is undefined.

(3) Register Map

Table 29.84 List of Register Map

Abbreviation	31 24	23 16	15 8	7 0	Address
E610CTL	— (00$_H$)	— (00$_H$)	ECCTL[15:8]	ECCTL[7:0]	nn00$_H$
E610TMC	— (00$_H$)	— (00$_H$)	ECTMC[15:8]	ECTMC[7:0]	nn04$_H$
E610TRC	ECSYND[7:0]	ECHORD[7:0]	ECECRD[7:0]	ECRODM[7:0]	nn08$_H$
E610TED	ECEDB[31:24]	ECEDB[23:16]	ECRIDM[15:8]	ECERDB[7:0]	nn0C$_H$
E610EAD	ECEAD[31:24]	ECEAD[23:16]	ECEAD[15:8]	ECEAD[7:0]	nn10$_H$

29.2.10.3 Register Details

(1) E610CTL — ECC Control Register

E610CTL controls the status and modes of the ECC module.

E610CTL can be read and written to using the 16-bit or 8-bit manipulation instruction.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EMCA[1:0]		—	—	—	ECER2C	ECER1C	—	ECTHM	—	EC1ECP	EC2EDIC	EC1EDIC	ECER2F	ECER1F	ECEMF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	Un-defined
R/W	R/W*1	R/W*1	R	R	R	R/W*1	R/W*1	R	R/W	R	R/W	R/W	R/W	R	R	R

Note 1. This bit is always read as 0.

Table 29.85 E610CTL Register Contents (1/2)

Bit Position	Bit Name	Function
15, 14	EMCA[1:0]	Access Control 1 and 0 to ECC Mode Select Bit These bits reserve the write trigger to bit 7. The read value is always 0.
10	ECER2C	2-Bit ECC Error Detection Flag Clear Clears the bit 2 (ECER2F) status flag. The read value is always 0, and writing 0 to ECER2C does not change the state. If writing 1 to ECER2C conflicts with the condition for setting bit 2, the former takes priority. Writing 1 to ECER2C while ECER2F is set clears ECER2F.
9	ECER1C	1-Bit ECC Error Detection And Correction Accumulated Flag Clear Clears the bit 1 (ECER1F) status flag. The read value is always 0, and writing 0 to ECER1C does not change the state. If writing 1 to ECER1C conflicts with the condition for setting bit 1, the former takes priority. Writing 1 to ECER1C while ECER1F is set clears ECER1F.
7	ECTHM	ECC Function Disable Selects the ECC decoding operation. Write access to ECTHM is enabled when the value of bits 15 and 14 is 01_B. Therefore, only the 16-bit manipulation instruction is valid. Setting ECTHM to 1 disables error detection and bit correction. Here, if the data to be output to the peripheral module contains an error, the data is output without bit correction. Setting ECTHM to 1 has no effect on the encoder side. 0: Enables ECC detection and correction 1: Disables ECC detection and correction. Has no effect on the encoder side.
5	EC1ECP	1-Bit ECC Error Correction Enable 0: Enables 1-bit error correction upon error detection. 1: Disables 1-bit error correction upon error detection.
4	EC2EDIC	2-Bit ECC Error Detection Notification Enable 0: When a 2-bit error is detected, the ECM is not notified of the error. 1: When a 2-bit error is detected, the ECM is notified of the error.
3	EC1EDIC	1-Bit ECC Error Detection Notification Enable 0: When a 1-bit error is detected, the ECM is not notified of the error. 1: When a 1-bit error is detected, the ECM is notified of the error.
2	ECER2F	2-Bit ECC Error Detection Flag Indicates that errors have been detected at two bits in bits 0 to 21 of the data read from the RAM during RAM read access while error detection is enabled. This bit is a read only flag. 0: 2-bit error is not generated. 1: 2-bit error is generated Clearing conditions (1) Reset is applied. (2) 1 is written to ECER2C. (3) ECC detection and correction being disabled (ECTHM = 1).

Table 29.85 E610CTL Register Contents (2/2)

Bit Position	Bit Name	Function
1	ECER1F	1-Bit ECC Error Detection And Correction Flag Indicates that an error has been detected at one bit in bits 0 to 21 of the data read from the RAM during RAM read access while error detection is enabled. This bit is a read only flag. 0: 1-bit error is not generated. 1: 1-bit error is generated Clearing conditions (1) Reset is applied. (2) 1 is written to ECER1C. (3) ECC detection and correction being disabled (ECTHM = 1).
0	ECEMF	ECC Error Message Flag Indicates that the current read data bus contains an error. Since the RAM value after reset is undefined, the initial value of this module is determined to be an error, and thus ECEMF may be set. Therefore, the ECEMF value after reset is undefined. 0: The current read data bus contains no bit errors. 1: The current RAM output data contains bit errors. ECEMF remains set as long as RAM data containing a bit error is output with error detection being enabled. Clearing conditions (1)ECC detection and correction being disabled (ECTHM = 1). (2) Decoding circuit input data contains no 1-bit errors.

(2) E610TMC — ECC Test Mode Control Register

E610TMC is a 16-bit register to switch the mode to test mode and controls the mode.

E610TMC can be read and written to using the 16-bit or 8-bit manipulation instruction.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ETMA[1:0]		—	—	—	—	—	—	ECTMCE	—	—	ECTRRS	ECREOS	ECENS	ECDCS	ECREIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W*1	R/W*1	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Note 1. This bit is always read as 0.

Table 29.86 E610TMC Register Contents (1/2)

Bit Position	Bit Name	Function
15, 14	ETMA[1:0]	Access Control 1 and 0 to ECC Test Mode Control Enable Bit These bits reserve the write trigger to bit 7. The read value is always 0.
7	ECTMCE	ECC Test Mode Control Enable ECTMCE enables or disables access to the test registers and test control bits. Write access to ETCMCE is enabled when the value of bits 15 and 14 is 10_B. 0: Disables access to the test registers and test control bits. 1: Enables access to the test registers and test control bits.
4	ECTRRS	ECC RAM Read Test Mode Control Enable ECTRRS enables the read status of RAM to be generated by reading the E610TED register, and also allows the RAM output data to be read out when the E610TED:ECEDB[15:0] and E610TED:ECRIDM[7:0] are read. Write access to ECTRRS is enabled only when ECTMCE is 1 (can be set simultaneously). ECTRRS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Disables generation of RAM read status for testing when E610TED is read. 1: Enables generation of RAM read status for testing when E610TED is read. When E610TED:ECEDB[15:0] and E610TED:ECRIDM[7:0] are read, the values of the RAM output data pin are read out.
3	ECREOS	ECC Redundant Bit Output Data Select ECREOS selects either the ECC encoder output data or the ECERDB register value to be output as the ECC redundant bit output. Write access to ECREOS is enabled only when ECTMCE is 1 (can be set simultaneously). ECREOS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allows encoding result to be output as the ECC redundant bit output. 1: Allows the E610TED:ECERDB[5:0] value to be output as the ECC redundant bit output.
2	ECENS	ECC Encoder Input Select ECENS selects either the data value from the peripheral module or the test register value (E610TED: ECEDB[15:0]) as the input signal to be encoded. Write access to ECENS is enabled only when ECTMCE is 1 (can be set simultaneously). ECENS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allows the RAM write data from the peripheral module to be input as the ECC encoder input data. 1: Allows the E610TED:ECEDB[15:0] value to be input as the ECC encoder input data.

Table 29.86 E610TMC Register Contents (2/2)

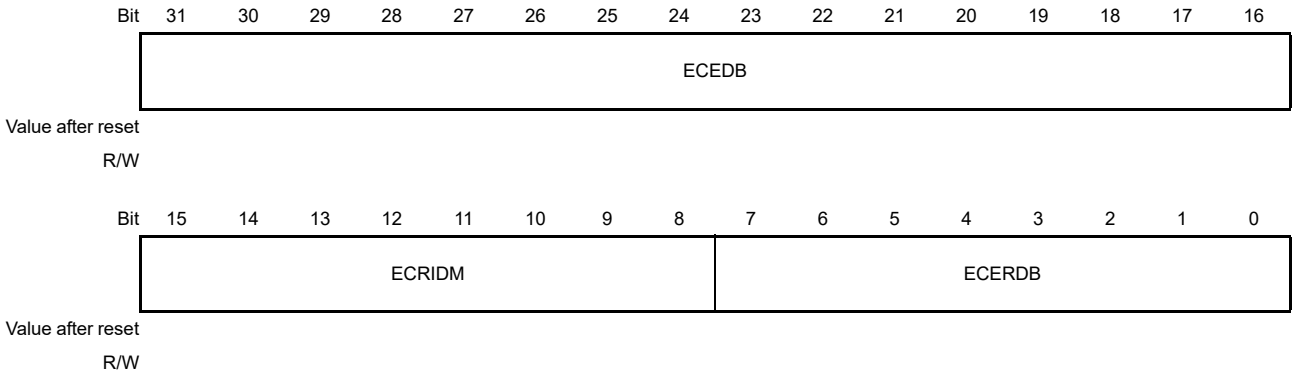
Bit Position	Bit Name	Function
1	ECDCS	ECC Decoder Input Select ECDCS selects either the lower 16-bit data value from the RAM or the test register value (E610TED:ECEDB[15:0]) as the lower 32-bit data of the input signal to be decoded. Write access to ECDCS is enabled only when ECTMCE is 1 (can be set simultaneously). ECDCS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allows the lower 16-bit RAM output data to be input to the data area (lower 16 bits) to the decoder. 1: Allows the E610TED:ECEDB[15:0] value to be input to the data area to the decoder.
0	ECREIS	ECC Redundant Bit Input Data Select ECREIS selects either the upper 6-bit data value from the RAM (redundant bit area) or the test register value (E610TED:ECERDB[5:0]) as the upper 6-bit data of the input signal to be decoded. Write access to ECREIS is enabled only when ECTMCE is 1 (can be set simultaneously). ECREIS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allows the upper 6-bit RAM output data to be input to the ECC redundant bit area to the decoder. 1: Allows the E610TED:ECERDB[5:0] value to be input to the ECC redundant bit area to the decoder.

(3) E610TED — ECC Encoder and Decoder Data Test Register

E610TED is a 32-bit test register consisting of three fields (ECEDB, ECRIDM, and ECERDB) corresponding to the ECC data area and redundant bit area. Each field can be accessed as the register with the same name. For details of each field, refer to the descriptions of these three registers.

When ECTMCE = 1, E610TED can be read and written to using the 32-bit manipulation instruction.

When ECTMCE = 0, E610TED is always read as 0.



NOTE

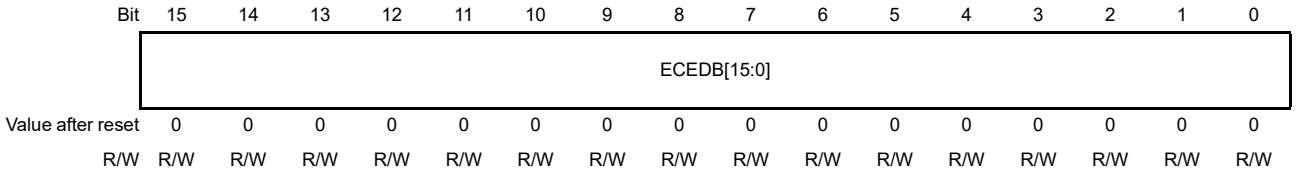
Changing ECTMCE from 1 to 0 resets E710TED synchronously.

(4) ECEDB — ECC Encoder and Decoder Data Input and Output Substitution Buffer Register

ECEDB is a 16-bit data buffer register for ECC encoding and decoding.

ECEDB can be read and written to in test mode (ECTMCE = 1).

When ECTMCE = 1, the ECEDB value can be used as the input data to the encoding circuit and decoding circuit.



When E610TMC:ECENS = 1, the ECEDB value is input to the encoding circuit and supplied to the RAM.

When E610TMC:ECDCS = 1, the ECEDB value is input as the 15th to 0th bits of the input data to the decoding circuit. When E610TMC:ECTRRS = 1, reading ECEDB returns the RAM output data instead of the data written to ECEDB.

(5) ECRIDM — ECC Redundant Bit Input Data Monitoring Register

ECRIDM is a read-only register to monitor the upper 6-bit data (redundant bit area) value from the RAM in test mode (ECTMCE = 1) when E610TMC:ECTRRS = 1. With ECRIDM, the RAM output data can be confirmed easily.

When ECTRRS = 0, ECRIDM is always read as 0.

Bit	7	6	5	4	3	2	1	0
	—	—	RIDM[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

(6) ECERDB — ECC Redundant Bit Input and Output Substitution Buffer Register

ECERDB is a buffer register for the data that substitutes for the input and output data for the 6-bit ECC redundant data area in test mode (ECTMCE = 1).

ECERDB can be read and written to in test mode (ECTMCE = 1).

Bit	7	6	5	4	3	2	1	0
	—	—	ERDB[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

When ECREOS = 1, the ECERDB value, instead of the six redundant bits generated by the encoding circuit, is output to the ECC redundant bit output pin to be supplied to the RAM.

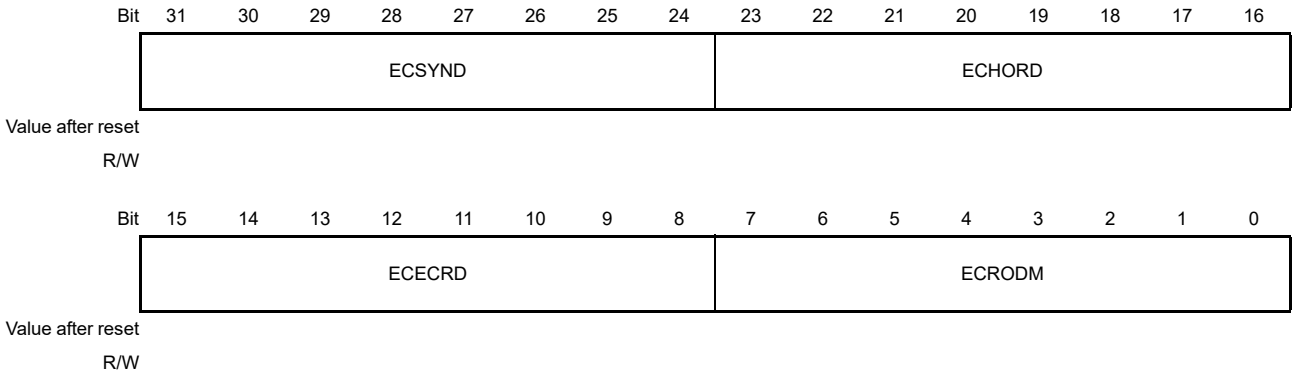
When ECREIS = 1, the ECERDB value, instead of the upper six data bits to be input to the decoding circuit, is handled by the decoding circuit.

(7) E610TRC — ECC Redundant Bit Data Control Test Register

E610TRC is a 32-bit test register consisting of four fields (ECSYND, ECHORD, ECECRD, and ECRODM) corresponding to the ECC redundant bit area. Each field can be accessed as the 8-bit register with the same name. For details of each field, refer to the descriptions of these four registers.

When ECTMCE = 0, E610TRC is always read as 0.

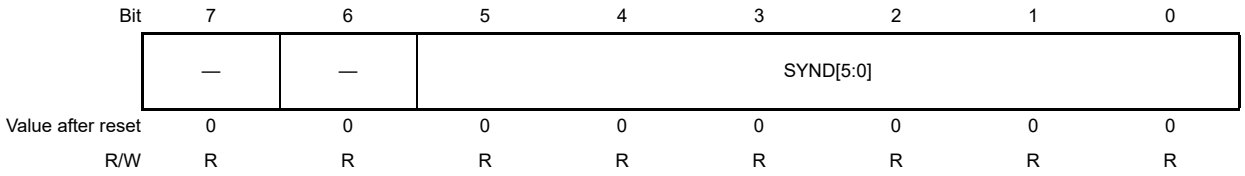
When ECTMCE = 1, E610TRC can be read using the 32-bit manipulation instruction.



(8) ECSYND — ECC Decoder Syndrome Data Register

ECSYND is a read-only register to confirm the syndrome code generated by the decoding circuit in test mode (ECTMCE = 1).

Write access to ECSYND is ignored.



When read, the ECSYND bits return the value of the syndrome code (synd[5:0]) generated based on the input data to the decoding circuit.

The ECSYND bits are not holding circuits; the register value changes as the input signal changes.

ECSYND is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

(9) ECHORD — ECC 6-Bit Redundant Data Holding Test Register

ECHORD holds the 6-bit ECC redundant area (upper 6-bit RAM data), which cannot be confirmed by the peripheral module, when the peripheral module accesses the RAM for reading in test mode (ECTMCE = 1).

Bit	7	6	5	4	3	2	1	0
	—	—	HORD[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

The ECHORD bits are loaded with the upper 6-bit RAM output data at the next rising edge of the operating clock signal after the peripheral module accesses the RAM for reading data in test mode (ECTMCE = 1).

The ECHORD bits are also loaded with the data on the input pins at the next operating clock pulse when the ECEDB[15:0] register is read while E610TMC:ECTRRS = 1.

ECHORD is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

(10) ECECRD — ECC Encoder Test Register

ECECRD is a read-only register to read the 6-bit redundant section generated by the encoding circuit in test mode (ECTMCE = 1).

Bit	7	6	5	4	3	2	1	0
	—	—	ECRD[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

ECECRD is used to confirm the redundant bits generated by the input data from the peripheral module. Here, the read-out data is the result of encoding (ecc[5:0]), not the value output from the ECC redundant bits.

ECECRD is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

(11) ECRODM — ECC Redundant Bit Output Data Monitoring Register

ECRODM is a read-only register to monitor the value of the ECC redundant bit output pin in test mode (ECTMCE = 1).

With ECRODM, the upper 6-bit output data to the RAM can be confirmed easily.

Bit	7	6	5	4	3	2	1	0
	—	—	RODM[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

ECRODM is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

(12) E610EAD — ECC Error Address Register

E610EAD is a read-only register to hold the address at which an ECC error has occurred.

If an ECC error is detected while ECC error detection is enabled, the RAM address is latched using the detection signal as a trigger, and the address is stored in E610EAD as the address at which the ECC error has occurred.

The address is stored upon detection of the first ECC error while no error status flag is set. However, if a 1-bit error is followed by a 2-bit error, the address of the latter is stored.

Only one address can be held in E610EAD.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ECEAD[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ECEAD[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

29.2.10.4 Notification to ECM

Detection of errors in two bits can be set for this module and the ECM is notified of detected errors.

- 1-bit Error Notification
  While EC1EDIC is set to 1_B, when an error is detected in one bit from among bits 0 to 21 of data read from RAM, the ECM is notified of the 1-bit error. When ECER1F or ECER2F is already set, however, the ECM will not be notified of the error.
- 2-bit Error Notification
  While EC2EDIC is set to 1_B, when an error is detected in two bits from among bits 0 to 21 of data read from RAM, the ECM is notified of the 2-bit error. When ECER2F is already set, however, the ECM will not be notified of the error.

29.2.10.5 Test Function

(1) Writing to RAM Data

Write data to the peripheral RAM. However, the ECC corresponding to the written data will be written to the ECC bits simultaneously. In order to write a specified value to the ECC bits, use the ECC test mode described in (3) below.

(2) Reading RAM Data

(a) Set the ECTHM bit in the ECC control register to 1 to disable ECC error detection and correction.

(b) Read the peripheral RAM. Since neither error detection nor correction proceeds when the peripheral RAM is read, the RAM data is read unchanged.

How to exit this test mode:

(a) Set the ECTHM bit in the ECC control register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC Bits

(a) Set the ECTMCE bit in the ECC test mode control register to 1 to set ECC test mode.

(b) Write the value for writing to the ECC bits to the E610TED.ECERDB[5:0] bits.

(c) Set the ECREOS bit in the ECC test mode control register to 1 to select writing of the value of the E610TED.ECERDB[5:0] bits to the ECC bits.

(d) When data are written to the peripheral RAM, the value in the E610TED.ECERDB[5:0] bits will be written to the ECC bits.

How to exit this test mode:

(a) Set the ECTMCE bit in the ECC test mode control register to 0 to set normal mode.

(4) Reading the ECC Bits

(a) Set the ECTMCE bit in the ECC test mode control register to 1 to set ECC test mode.

(b) When data in the peripheral RAM is read, the ECC bits are stored in the E610TRC.ECHORD[5:0] bits.

How to exit this test mode:

(a) Set the ECTMCE bit in the ECC test mode control register to 0 to set normal mode.

29.2.11 Data Parity for Data Transfer Paths

The following shows the transfer paths to which data parity is applied. Data parity errors can be detected during data transfer from the access sources to destinations shown below. If a parity error is detected in any of the paths, the ECM is notified of the error.

Table 29.87 Transfer Paths to which Data Parity is Applied

Access Source (Master)	Access Destination (Slave)
CPU1, PCU, DMAC, DTS	INTC2, DMA, DTS, APA, ATU-IV, CSIH, ΔΣAD, ADC port group 0, DNF, edge detection DNF
DMAC, DTS	CPU1 local RAM, global RAM

When a data parity error occurs during read operation, 0 is returned to CPU1 and error data is returned to other masters.

When a data parity error occurs during write operation, the write operation is cancelled if the slave is INTC 2, APA, ATU-IV, ΔΣAD, ADC (except IFC), DNF, or edge detection DNF.

Some of the parity-applied modules have the control registers in the parity controllers (encoder and decoder), which can enable or disable parity detection and hold status upon detection of an error. If a parity error is detected in these modules, it is possible to identify the access that caused the error.

On the other hand, parity controllers which do not have control registers always perform parity detection. Though the status upon detection of an error is not retained in these controllers, whether an error has been detected or not is retained in the ECM.

29.2.11.1 List of Registers

Table 29.88 List of Registers

Address	Symbol	Register Name	R/W	Value after Reset	Access Size
<Base_addr>+0_H	APDPERRST_xx	P-Bus data parity status register xx	R	0000 0000_H	8/16/32
<Base_addr>+4_H	APDPERRSTC_xx	P-Bus data parity status clear register xx	W	0000 0000_H	8/16/32
<Base_addr>+8_H	APDPTMC_xx	P-Bus data parity test mode control register xx	R/W	0000 0000_H	16/32
<Base_addr>+C_H	APDPERRADR_xx	P-Bus data parity error address register xx	R	0000 0000_H	32

The symbol xx in the above table indicates a parity-applied module for which the control register is provided. **Table 29.89** shows the parity-applied modules and base addresses<base_addr>.

Table 29.89 List of Data Parity Control Modules (1/2)

Module to Which Parity is Applied	xx	<base_addr>
INTC2	INTC2	FFC6 8800_H
DMA_DTS	PDMA	FFC6 8900_H
APA (other than APA input selector)	APAA	FFDC 2000_H

Note 1. The CSIHx registers are divided into the following two groups and controlled separately.
Group A: CSIHnCTL0 to CSIHnCTL2, CSIHnSTR0, and CSIHnSTCR0
Group B: Other than above.

Note 2. The port group registers are divided into the following two groups and controlled separately.
Group A: Registers other than PCRn_m registers (see **Section 2.1.4.1 Table 2.6**)
Group B: PCRn_m
Here, n represents the port group number (n = 0 to 17), and m represents the bit numbers (m = 0 to 15) in each port group.

29.2.11.2 Details of Registers

(1) APDPERRST_xx — P-Bus Data Parity Status Register

For the symbol xx, see **Table 29.89, List of Data Parity Control Modules**.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	APDPERR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.90 APDPERRST Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	APDPERR	Data Parity Error Monitor Flag Indicates occurrence of the parity error. APDPERR is cleared by setting the Data Parity error monitor flag clear bit (APDPERRC) to 1. 0: Indicates that a parity error has not occurred. 1: Indicates that a parity error has occurred.

(2) APDPERRSTC_xx — P-Bus Data Parity Status Clear Register

For the symbol xx, see **Table 29.89, List of Data Parity Control Modules**.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 29.91 APDPERRSTC Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should also be 0.
0	APDPERRC	Clears the Data Parity error monitor flag (APDPERR). Writing 1 to this bit with the APDPERR bit set clears APDPERR. This bit is always read as 0.

(3) APDPTMC_xx — P-Bus Data Parity Test Mode Control Register

For the symbol xx, see **Table 29.89, List of Data Parity Control Modules**.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	APDPTMC[1:0]		—	—	—	—	—	—	—	—	—	—	APDPEIC3	APDPEIC2	APDPEIC1	APDPEIC0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 29.92 APDPTMC Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15, 14	APDPTMC[1:0]	Data Parity Test Mode Control Setting APDPTMC[1:0] to 01_B enables write-accesses to the error insertion control bits 3 to 0 (APDPEIC3 to APDPEIC0). When APDPTMC[1:0] are not 01_B, APDPEIC3 to APDPEIC0 are not written to even though a write-access is attempted. These bits are always read as 0.
13 to 4	—	Reserved These bits are always read as 0. The write value should also be 0.
3	APDPEIC3	Byte-Lane 3 Error Insertion Control Changes the type of the parity bit generation and check for byte-lane 3 (bits 31 to 24) to odd parity. APDPEIC3 can be written to when APDPTMC[1:0] = 01_B. 0: Parity bit generation and check is performed with even parity. 1: Parity bit generation and check is performed with odd parity. (Error insertion)
2	APDPEIC2	Byte-Lane 2 Error Insertion Control Changes the type of the parity bit generation and check for byte-lane 2 (bits 23 to 16) to odd parity. APDPEIC2 can be written to when APDPTMC[1:0] = 01_B. 0: Parity bit generation and check is performed with even parity. 1: Parity bit generation and check is performed with odd parity. (Error insertion)
1	APDPEIC1	Byte-Lane 1 Error Insertion Control Changes the type of the parity bit generation and check for byte-lane 1 (bits 15 to 8) to odd parity. APDPEIC1 can be written to when APDPTMC[1:0] = 01_B. 0: Parity bit generation and check is performed with even parity. 1: Parity bit generation and check is performed with odd parity. (Error insertion)
0	APDPEIC0	Byte-Lane 0 Error Insertion Control Changes the type of the parity bit generation and check for byte-lane 0 (bits 7 to 0) to odd parity. APDPEIC0 can be written to when APDPTMC[1:0] = 01_B. 0: Parity bit generation and check is performed with even parity. 1: Parity bit generation and check is performed with odd parity. (Error insertion)

(4) APDPERRADR_xx — P-Bus Data Parity Error Address Register

For the symbol xx, see **Table 29.89, List of Data Parity Control Modules**.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	APDPERRADR[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	APDPERRADR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.93 APDPERRADR Register Contents

Bit Position	Bit Name	Function
31 to 0	APDPERRADR [31:0]	Data Parity Error Address Holds the address at which the first parity error has occurred while the Data Parity error monitor flag (APDPAERR) is not set. The retained information is not updated even though the next parity error occurs while DPAERR is set.

29.3 Lockstep

This product incorporates the CPU1 with the lockstep function to quickly detect CPU failures without special software. The CPU1 executes the program using two different cores, that is, master core and checker core, and constantly compares the execution results of the two cores. When the results do not agree, the CPU1 determines that an error has occurred in one of the cores, and notifies a lockstep compare error to the ECM.

Bus outputs to be compared are outputs to the local RAM for CPU1, global RAM, a CPU peripheral, interconnect, the P-bus, code flash memory, and the tag RAM and data RAM of the instruction cache.

The lockstep function of the CPU1 features failure insertion, with which errors can be intentionally caused and thus self-diagnosis of the lockstep operation is possible.

29.3.1 List of Registers

Table 29.94 List of Registers

Address	Symbol	Register Name	R/W	Value after Reset	Access Size
FFFE ED00$_H$	TESTCOMPREG0	Comparator test register 0	R/W	0000 0000$_H$	8/16/32
FFFE ED04$_H$	TESTCOMPREG1	Comparator test register 1	R/W	0000 0000$_H$	8/16/32

These registers are placed in the CPU Peripheral of the CPU1. These registers can only be accessed by the CPU1.

29.3.2 Details of Registers

29.3.2.1 TESTCOMPREG0 — Comparator Test Register 0

TESTCOMPREG0 is test register 0 used for the lockstep function of the CPU1.

Combining TESTCOMPREG0 with TESTCOMPREG1 enables self-diagnosis of the lockstep function. The following gives an example of self-diagnosis procedure.

(1) Write arbitrary value to TESTCOMPREG0.

(2) Write a different value to TESTCOMPREG1.

(3) Read TESTCOMPREG0. The different values are read and sent to the master core and checker core.

(4) Using the values read, run the comparator to be diagnosed.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TESTCOMPREG0[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TESTCOMPREG0[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.95 TESTCOMPREG0 Register Contents

Bit Position	Bit Name	Function
31 to 0	TESTCOMPREG0[31:0]	Write: Data is written to each byte. Read: PE1: TESTCOMPREG0[31:0] value is read. PE1C: TESTCOMPREG1[31:0] value is read.

29.3.2.2 TESTCOMPREG1 — Comparator Test Register 1

TESTCOMPREG1 is test register 0 used for the lockstep function of the CPU1.

Combining TESTCOMPREG1 with TESTCOMPREG0 enables self-diagnosis of the lockstep function.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TESTCOMPREG1[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TESTCOMPREG1[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.96 TESTCOMPREG1 Register Contents

Bit Position	Bit Name	Function
31 to 0	TESTCOMPREG1[31:0]	Write: Data is written to each byte. Read: PE1: TESTCOMPREG1[31:0] value is read. PE1C: TESTCOMPREG0[31:0] value is read.

29.4 Memory Protection

29.4.1 Overview

This product incorporates the memory protection function to prevent erroneous accesses to data in memories and control registers of the peripheral circuits.

- MPU
  The CPU1 and PCU protect memories against illegal accesses from the CPU1 and PCU themselves. Accesses to addresses that are prohibited by the MPU are never issued by the CPU1 or PCU. For details, refer to RH850G3M User's Manual: Software and RH850G3K User's Manual: Software.
- Slave Guard
  A specific memory is protected against illegal accesses from any bus master. Slave guard includes the following guard types. The details of each type are given in the following sections.

  – PEG
    The local RAM is protected against illegal accesses. However, accesses from the CPU incorporating the local RAM itself are excluded. For example, accesses from the CPU1 to local RAM in the CPU1 are not rejected by the PEG.
    For details, refer to **Section 3, CPU System**.
  – IPG
    The CPU Peripheral is protected against illegal accesses.
    For details, refer to **Section 3, CPU System**.
  – GRG
    The global RAM is protected against illegal accesses.
  – PBG
    The control registers in the peripheral circuits and memories are protected against illegal accesses. For details, refer to **Section 29.4.3**

29.4.1.1 Identifiers for Slave Guard

For the slave guard function, the type of illegal accesses to be rejected can be designated using the following identifiers.

Table 29.97 Identifiers for Slave Guard

Identifier	Function
UM	When the CPU makes an access, the operating mode of the CPU is indicated. 0: Supervisor mode 1: User mode When the DMAC or DTS makes an access, the value of this identifier is the value in the channel master setting register. When the other master makes an access, the value of this identifier is always 0.
SPID	When the CPU makes an access, the system protection identifier SPID that is assigned to the CPU is indicated. When the DMAC or DTS makes an access, the value of this identifier is the value in the channel master setting register. When the other master makes an access, the value of this identifier is always 00_B.
PEID	The access source bus master is indicated. 000_B: Reserved 001_B: CPU1 010_B: Reserved 011_B: PCU 100_B: Other bus master 101_B: Reserved 110_B: Reserved 111_B: Reserved When the DMAC or DTS makes an access, the value of this identifier is the value in the channel master setting register.

29.4.2 GRG (Global RAM Guard)

This product is provided with 4-channel GRG, which is described in detail in the following sections.

29.4.2.1 List of Registers

Table 29.98 List of Registers

Address	Symbol	Register Name	R/W	Value after Reset	Access Size
FFC4 9000_H	MGDGRPROT0	GRG protection setting register 0	R/W	07FF $FFF0_H$	8/16/32
FFC4 9004_H	MGDGRBAD0	GRG compare base address register 0	R/W	0000 0000_H	8/16/32
FFC4 9008_H	MGDGRADV0	GRG valid compare address register 0	R/W	0000 0000_H	8/16/32
FFC4 9010_H	MGDGRPROT1	GRG protection setting register 1	R/W	07FF $FFF0_H$	8/16/32
FFC4 9014_H	MGDGRBAD1	GRG compare base address register 1	R/W	0000 0000_H	8/16/32
FFC4 9018_H	MGDGRADV1	GRG valid compare address register 1	R/W	0000 0000_H	8/16/32
FFC4 9020_H	MGDGRPROT2	GRG protection setting register 2	R/W	07FF $FFF0_H$	8/16/32
FFC4 9024_H	MGDGRBAD2	GRG compare base address register 2	R/W	0000 0000_H	8/16/32
FFC4 9028_H	MGDGRADV2	GRG valid compare address register 2	R/W	0000 0000_H	8/16/32
FFC4 9030_H	MGDGRPROT3	GRG protection setting register 3	R/W	07FF $FFF0_H$	8/16/32
FFC4 9034_H	MGDGRBAD3	GRG compare base address register 3	R/W	0000 0000_H	8/16/32
FFC4 9038_H	MGDGRADV3	GRG valid compare address register 3	R/W	0000 0000_H	8/16/32
FFC4 9100_H	MGDGRSCTL_VCI	GRG control register (VCI)	R/W	0000 0000_H	8/16/32
FFC4 9104_H	MGDGRSSTAT_VCI	GRG error status register (VCI)	R	0000 0000_H	8/16/32
FFC4 9108_H	MGDGRSAD_VCI	GRG error address register (VCI)	R	0000 0000_H	8/16/32
FFC4 $910C_H$	MGDGRSTYPE_VCI	GRG error access type register (VCI)	R	0000 0000_H	8/16/32
FFC4 9200_H	MGDGRSCTL_PE1	GRG control register (PE1)	R/W	0000 0000_H	8/16/32
FFC4 9204_H	MGDGRSSTAT_PE1	GRG error status register (PE1)	R	0000 0000_H	8/16/32
FFC4 9208_H	MGDGRSAD_PE1	GRG error address register (PE1)	R	0000 0000_H	8/16/32
FFC4 $920C_H$	MGDGRSTYPE_PE1	GRG error access type register (PE1)	R	0000 0000_H	8/16/32

- MGDGRPROTn, MGDGRBADn, and MGDGRADVn set the protection specifications for each channel (n: 0 to 3).
- MGDGRSCTL_*, MGDGRSSTAT_*, MGDGRSAD_*, and MGDGRSTYPE_* indicate error information on each access port: "_VCI" represents access from the system interconnect 1 to the global RAM, and "_PE1" represents access from the CPU1 to the global RAM.

29.4.2.2 Details of Registers

(1) MGDGRPROTn — GRG Protection Setting Register n (n = 0 to 3)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	EN	—	—	—	—	UM	PEID[7:0]								—
Value after reset	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SPID[3:0]				DEB	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 29.99 MGDGRPROTn Register Contents

Bit Position	Bit Name	Function
31	—	Reserved This bit is always read as 0. The write value should also be 0.
30	EN	Protection Enable 0: Disables protection. 1: Enables protection. The access permitted by this register is enabled.
29 to 27	—	Reserved These bits are always read as 0. The write value should also be 0.
26	—	Reserved This bit is always read as 1. The write value should also be 1.
25	UM	User Mode Access 0: Enables access in supervisor mode. 1: Enables access in user mode and supervisor mode.
24 to 17	PEID[7:0]	PEID Access The PEID field is a bit list, in which one bit corresponds to one PEID value. Setting multiple bits enables the ID values of the multiple virtual processors simultaneously. For example, setting the PEID field to 0101_B enables access with PEID = 0 and PEID = 2. 0: Disables access with PEID = n. 1: Enables access with PEID = n.
16 to 9	—	Reserved These bits are always read as 1. The write value should also be 1.
8 to 5	SPID[3:0]	SPID Access The SPID field is a bit list, in which one bit corresponds to one SPID value. Setting multiple bits enables the multiple SPID values simultaneously. For example, setting the SPID field to 0101_B enables access with SPID = 0 and SPID = 2. 0: Disables access with SPID = n. 1: Enables access with SPID = n.
4	DEB	Debug Access 0: Disables access from the debug master. 1: Enables access from the debug master. Be sure to set this bit to 1. If the setting is 0, the debugger or RAM monitor tool may not operate correctly.
3 to 0	—	Reserved These bits are always read as 0. The write value should also be 0.

(2) MGDGRBADn — GRG Compare Base Address Register n (n = 0 to 3)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	AD[20:16]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AD[15:9]							—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R

Table 29.100 MGDGRBADn Register Contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved These bits are always read as 0. The write value should also be 0.
20 to 9	AD[20:9]	Compare base address
8 to 0	—	Reserved These bits are always read as 0. The write value should also be 0.

(3) MGDGRADVn — GRG Valid Compare Address Register n (n = 0 to 3)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	ADV[20:16]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADV[15:9]							—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R

Table 29.101 MGDGRADVn Register Contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved These bits are always read as 0. The write value should also be 0.
20 to 9	ADV[20:9]	Valid Compare Address Address comparison proceeds for addresses for which the corresponding bit in MGDGRADVn[20:9] is 1. When all MGDGRADVn[20:9] bits are set to 1, 512 bytes (the minimum unit) are targeted for protection based on the addresses specified by MGDGRBADn. When all MGDGRADVn[20:9] bits are set to 0, the scope of protection is the whole of the global RAM.
8 to 0	—	Reserved These bits are always read as 0. The write value should also be 0.

Setting example: When the setting of MGDGRBADn[20:9] is 800_H and that of MGDGRADVn[20:9] is $FF7_H$, for example, global RAM guard protection area n is FEF0 0000_H to FEF0 $01FF_H$ and FEF0 1000_H to FEF0 $11FF_H$.

Concept: When the setting of MGDGRBADn[20:9] is 800_H, the base address becomes FEF0 0000_H and the settable range of bits is enclosed in [ ] below.

1111 1110 111 [1 0000 0000 000] 0 0000 0000

F E F 0 0 0 0 0

When MGDGRADVn[20:9] is $FF7_H$, bits with 0 in that range and the 9 lower-order bits are ignored, so we have

1111 1110 111[1 0000 000X 000] X XXXX XXXX

which means that the 512-byte ranges (a total of 1 Kbyte) from

F E F 0 0 0 0 0 to

F E F 0 0 1 F F,

and

F E F 0 1 0 0 0 to

F E F 0 1 1 F F

will be protected.

(4) MGDGRSCTL_VCI/_PE1 — GRG Control Register n

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.106 MGDGRSTYPE_VCI/PE1 Register Contents

Bit Position	Bit Name	Function
31 to 18	—	Reserved These bits are always read as 0. The write value should also be 0.
17 and 16	PACKETID[1:0]	Packet ID upon Error Occurrence (Internal bus and interconnect signals. Reference information.)
15 to 13	PEID[2:0]	PEID upon Error Occurrence
12 to 10	—	Reserved These bits are always read as 0. The write value should also be 0.
9 and 8	SPID[1:0]	SPID upon Error Occurrence
7	—	Reserved This bit is always read as 0. The write value should also be 0.
6	UM	UM upon Error Occurrence
5	—	Reserved This bit is always read as 0. The write value should also be 0.
4 to 0	TYPE[4:0]	Transfer Type upon Error Occurrence (Internal bus and interconnect signals. Reference information.)

29.4.3 PBG

The PBG module is divided into several PBG groups, each of which is provided with a maximum of 16 protection channels. A single PBG channel can designate the access against which a single peripheral circuit should be protected. Each PBG group can hold the information of the access that has been rejected.

The following table lists the peripheral circuits to be protected, the corresponding PBG group names, and the PBG channel numbers.

Table 29.107 List of Peripheral Circuit Module To be Protected

PBG Group	PBG Channel Number	Module to be Protected
PBG0A	0	INTC2
	1	DMA_DTS
PBG0B	4	GRG (control register)
	5	GRG status (VCI2GRAM)
	6	GRG status (PE1)
PBG1A	0	APA (except input selector)
	1	APA (input selector)
PBG1B	0	ATU-IV
PBG2A	0	CSIH0 (group A)*1
	1	CSIH0 (group B)*1
	2	CSIH1 (group A)*1
	3	CSIH1 (group B)*1
	4	CSIH2 (group A)*1
	5	CSIH2 (group B)*1
	6	CSIH3 (group A)*1
	7	CSIH3 (group B)*1
PBG3A	0	ΔΣAD (shared register)
	1	ΔΣAD (CH0 register)
	2	ΔΣAD (CH1 register)
	3	ΔΣAD (CH2 register)
	4	ΔΣAD (CH3 register)
	5	ΔΣAD (CH4 register)
	6	ΔΣAD (CH5 register)
	7	ΔΣAD (CH6 register)
	8	ΔΣAD (CH7 register)
	9	ADC0
	10	ADC1
	11	ADC (IFC)
	12	ADC (ASF)
	13	ECM (M)
	14	ECM (C)
	15	ECM (Common)
PBG3B	0	Port group 0 (group A)*2
	1	Port group 0 (group B)*2

Note 1. The CSIHx registers are divided into the following two groups and controlled separately.
Group A: CSIHnCTL0 to CSIHnCTL2, CSIHnSTR0, and CSIHnSTCR0

Group B: Other than above.

Note 2. The port group registers are divided into the following two groups and controlled separately.
Group A: Registers other than PCR0_m registers (see **Section 2.1.4.1 Table 2.6**)
Group B: PCR0_m
Here, m represents the bit numbers (m = 0 to 14) in each port group.

29.4.3.1 List of Registers

The following table lists the register provided for each PBG channel.

Table 29.108 List of Registers (for PBG Channel)

Register Symbol	Register Name	R/W	Value after Reset	Address	Access Size
FSGDxxDPROTn	PBGxx protection register n	R/W	07FF FFFF$_H$	<base_addr0> + 4*n	8/16/32

The following table lists the registers provided for each PBG group.

Table 29.109 List of Registers (for PBG Group)

Register Symbol	Register Name	R/W	Value after Reset	Address	Access Size
ERRSLVxxCTL	PBGxx error control register	W	0000 0000$_H$	<base_addr1> + 0$_H$	8/16/32
ERRSLVxxSTAT	PBGxx error status register	R	0000 0000$_H$	<base_addr1> + 4$_H$	8/16/32
ERRSLVxxADDR	PBGxx error address register	R	0000 0000$_H$	<base_addr1> + 8$_H$	32
ERRSLVxxTYPE	PBGxx error type register	R	0000 0000$_H$	<base_addr1> + C$_H$	16/32

In the above tables, “xx” and “n” in the register names and symbols represents the PBG group numbers and PBG channel numbers, respectively. The table below shows the base address values <base_addr0> and <base_addr1>, which correspond to each of the PBG group numbers and PBG channel numbers.

Table 29.110 List of Base Address

PBG Group	PBG Group Number xx	PBG Channel Number n	<base_addr0>	<base_addr1>
PBG0A	0A	0, 1	FFC4 C000$_H$	FFC4 C800$_H$
PBG0B	0B	4 to 6	FFC4 C100$_H$	FFC4 C900$_H$
PBG1A	1A	0, 1	FFDC 0000$_H$	FFDC 0200$_H$
PBG1B	1B	0	FFDD D000$_H$	FFDD D200$_H$
PBG2A	2A	0 to 7	FFF9 4000$_H$	FFF9 4200$_H$
PBG3A	3A	0 to 15	FFC4 0000$_H$	FFC4 0200$_H$
PBG3B	3B	0, 1	FFC4 1000$_H$	FFC4 1200$_H$

29.4.3.2 Details of Registers

(1) FSGDxxDPROTn — PBGxx Protection Register n

FSGDxxDPROTn designates the access to be rejected against which the peripheral circuit control registers and RAM should be protected. Any access that is disabled using any of the identifiers is rejected as an illegal access.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	PROTUM	PROTPEID[7:0]								—
Value after reset	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	PROTSPID[3:0]				PROTDEB	PROTRDPDEF	PROTWRPDEF	PROTRD	PROTWR
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.111 FSGDxxDPROTn Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. The write value should also be 0.
26	—	Reserved This bit is always read as 1. The write value should also be 1.
25	PROTUM	User Mode Access 0: Enables access in supervisor mode. 1: Enables access in user mode and supervisor mode.
24 to 17	PROTPEID[7:0]	PEID Access The PROTnPEID field is a bit list, in which one bit corresponds to one PEID value. Setting multiple bits enables the ID values of the multiple virtual processors simultaneously. For example, setting the PROTnPEID field to 0101_B enables access with PEID = 0 and PEID = 2. 0: Disables access with PEID = n. 1: Enables access with PEID = n.
16 to 9	—	Reserved These bits are always read as 1. The write value should also be 1.
8 to 5	PROTSPID[3:0]	SPID Access The PROTnSPID field is a bit list, in which one bit corresponds to one SPID value. Setting multiple bits enables the multiple SPID values simultaneously. For example, setting the PROTnSPID field to 0101_B enables access with SPID = 0 and SPID = 2. 0: Disables access with SPID = n. 1: Enables access with SPID = n.
4	PROTDEB	Debug Access 0: Disables access from the debug master. 1: Enables access from the debug master. Be sure to set this bit to 1. If the setting of this bit is 0, the debugger or RAM monitor tool may not operate correctly.
3	PROTRDPDEF	Default Read Protection 0: Enables read access from any master. 1: Only enables read access from the master having permitted access.
2	PROTWRPDEF	Default Write Protection 0: Enables write access from any master. 1: Only enables write access from the master having permitted access

Table 29.111 FSGDxxDPROTn Register Contents (2/2)

Bit Position	Bit Name	Function
1	PROTRD	PROTnRD Read Permission 0: Disables read access from any master. 1: Only enables read access from the master having permitted access.
0	PROTWR	PROTnWR Write Permission 0: Disables write access from any master 1: Only enables write access from the master having permitted access.

(2) ERRSLVxxCTL — PBGxx Error Control Register

ERRSLVxxCTL clears the status in the error status register.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLRO	CLRE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 29.112 ERRSLVxxCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	CLRO	Clears the error entry overflow flag. 0: No operation. 1: Clears the overflow flag.
0	CLRE	Clears the error detection flag. 0: No operation. 1: Clears the error detection flag.

(3) ERRSLVxxSTAT — PBGxx Error Status Register

ERRSLVxxSTAT holds the status of the illegal access rejected with the PBGxx.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OVF	ERR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.113 ERRSLVxxSTAT Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should also be 0.
1	OVF	Error Entry Overflow Flag 0: No overflow. 1: Overflow occurred. Since the PBG only has 1 error entry stage, a further guard violation occurring after the error detection flag was set due to an earlier guard violation leads to an error entry overflow and this flag is set. The ECM is not notified of the overflow.
0	ERR	Error Detection Flag 0: No error. 1: Error occurred.

(4) ERRSLVxxADDR — PBGxx Error Address Register

ERRSLVxxADDR holds the address of the illegal access rejected with the PBGxx.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADDR[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADDR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.114 ERRSLVxxADDR Register Contents

Bit Position	Bit Name	Function
31 to 0	ADDR[31:0]	Address at which an error has occurred ADDR[1:0] are always fixed to 0.

(5) ERRSLVxxTYPE — PBGxx Error Type Register

ERRSLVxxTYPE holds the type of the illegal access rejected with the PBGxx.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PEID[2:0]			—	—	—	SPID[1:0]		—	UM	—	STRB[3:0]				WRITE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.115 ERRSLVxxTYPE Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should also be 0.
15 to 13	PEID[2:0]	PEID when an error has occurred
12 to 10	—	Reserved These bits are always read as 0. The write value should also be 0.
9, 8	SPID[1:0]	SPID when an error has occurred
7	—	Reserved This bit is always read as 0. The write value should also be 0.
6	UM	UM when an error has occurred
5	—	Reserved This bit is always read as 0. The write value should also be 0.
4 to 1	STRB[3:0]	Strobe signal when an error has occurred (this is an internal bus and interconnect signal and provides information for reference)
0	WRITE	Write signal when an error has occurred (this is an internal bus and interconnect signal and provides information for reference)

29.5 Multi-Input Signature Generator (MISG)

29.5.1 Overview

This LSI incorporates multi-input signature generators (MISG) for self-diagnosis by the CPUs.

The table below shows the overview of the MISG specifications.

Table 29.116 Specification Overview

Item	Description
Generating polynomials	Two polynomials are available for use in signature generation. • MISR1: $G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1$ • MISR2: $G(x) = x^{32} + x^{22} + x^{2} + x + 1$ *To support signature generation for 64-bit data, each CPU is connected with an MISG that has two MISRs (MISR1 and MISR2).
Signature generation	Signature generation can be enabled or disabled. • Signature generation in MISR1 is enabled or disabled. • Signature generation in MISR2 is enabled or disabled. The following two conditions can be selected as conditions for signature generation • Writing to the register A signature is generated by writing to the MISR calculation register (MISRCDRL) • Monitoring write access A signature is generated if writing to the address area specified for monitoring occurs when writing by the CPU is being monitored. The address area is specified by the monitoring area base address register and the monitoring area address mask register.
Automatic signature comparison	Two signature generation units are selected for comparison of signatures. Each signature generation unit has a data counter and comparison proceeds when the values of the data counters in the MISGs selected as the target for comparison match. The data counter counts the number of write accesses to the MISRCDRL register or the address area being monitored.
Error notification	When signatures are compared and do not match, the error control module is notified of an error. Enabling or disabling of error notification to the error control module can be selected. No interrupt request is not issued directly to the INTC.

29.5.2 Block Diagram

29.5.2.1 MISG

The figure below is a block diagram of the MISG. The MISG consists of two signature generation units and a signature comparison unit.

Write monitoring mode for signature generation conditions (**Section 29.5.3.1 (2), Write Monitoring Mode**) can only be executed between the corresponding signature generation unit and the CPU. Therefore, each signature generation unit is given a name corresponding to the CPU number(MISG_PE1, MISG_PCU). MISG_PE1 can monitor write access by CPU1. MISG_PCU cannot monitor write access by PCU.

When register write mode is the signature generation condition, there is no correspondence between a CPU and the signature generation unit. Any CPU can generate a signature in any signature generation unit.

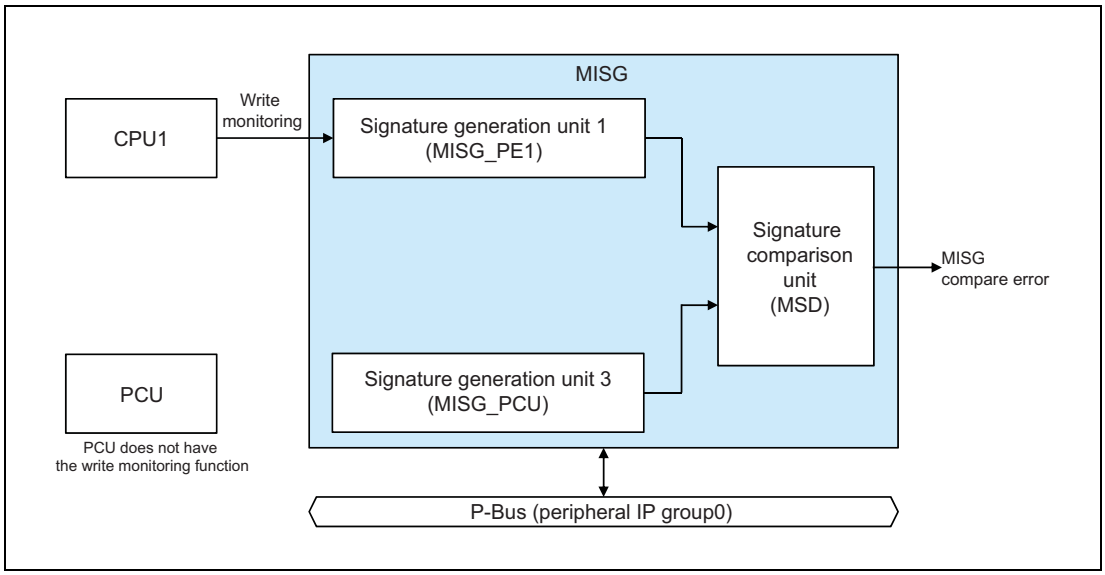

Figure 29.3 MISG Block Diagram (for a Single Core)

29.5.2.2 Signature Generation

The figure below shows the flow of data in signature generation. MISR1 and MISR2 consist of two 32-bit signature generation units (MISR1H and MISR1L, MISR2H and MISR2L).

MISR1H and MISR2H can generate a signature from the 32 higher-order bits of write data of the CPU to be monitored. MISR1L and MISR2L can generate signatures from the 32 lower-order bits of data written by the CPU to be monitored or data written to MISRCDRL.

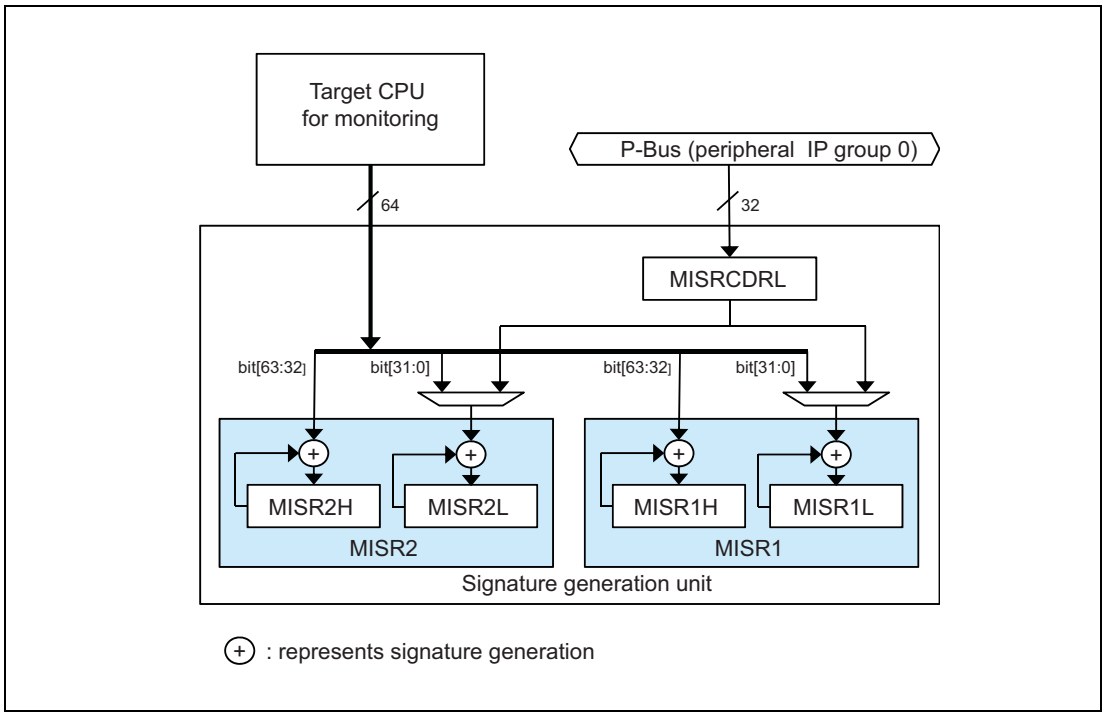

Figure 29.4 Signature Generation Units

Block diagrams of signature generation in MISR1H and MISR1L and the polynomials used for this are shown below.

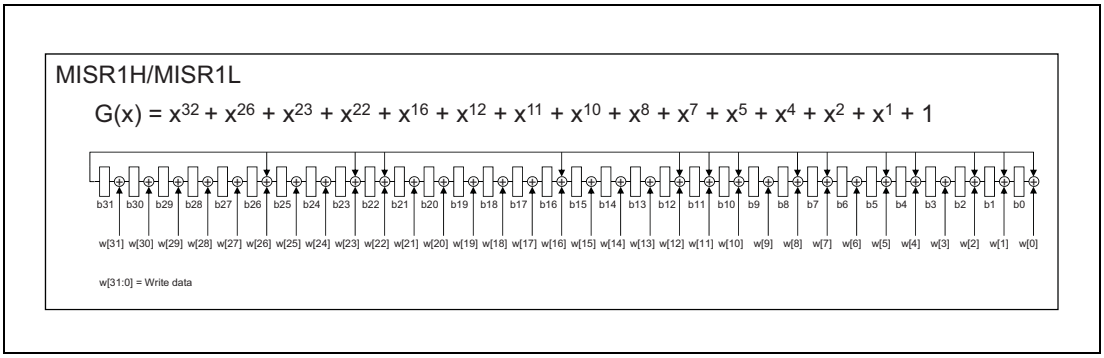

Figure 29.5 Block diagrams of signature generation in MISR1H and MISR1L and the polynomials

Block diagrams of signature generation in MISR2H and MISR2L and the polynomials used for this are shown below.

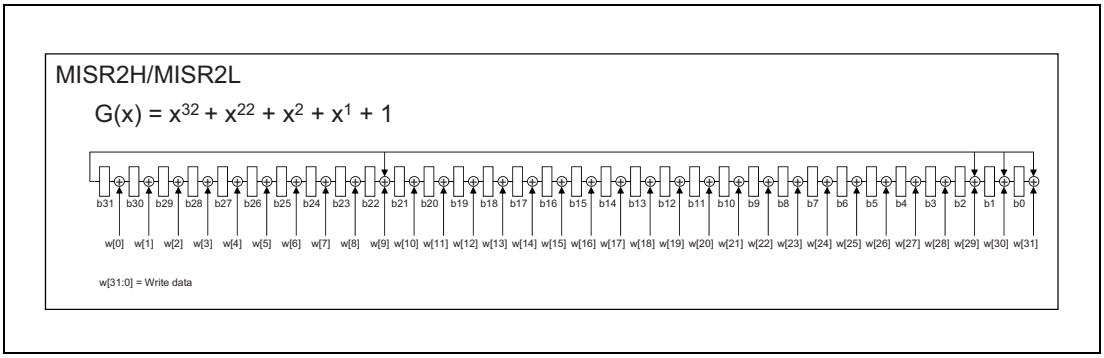

Figure 29.6 Block diagrams of signature generation in MISR2H and MISR2L and the polynomials

29.5.3 Functional Specification

29.5.3.1 Conditions for Signature Generation

The conditions for signature generation in MISR1 and MISR2 can be selected by the setting of the MISR control register (MISRCR).

Signature generation conditions in MISRi (i = 1, 2)

Table 29.117 Signature Generation Conditions of MISRi

MISRCR. MISRiEN	MISRCR. MISEiCND	Signature Generation Conditions
0	—	MISRi does not generate a signature.
1	0	Register write mode Writing to the MISRCDRL register leads to MISRi generating a signature.
1	1	Write monitoring mode MISRi generates a signature after the corresponding CPU writes to an address specified for monitoring.

(1) Register Write Mode

Writing to the MISR calculation register (MISRCDRL) while MISR1 is in register write mode leads to the generation of a 32-bit signature in MISR1 from the value held in the multi-input signature register 1L (MISR1L) and the data written to MISRCDRL, and the result is retained in MISR1L. Similarly, a 32-bit signature is generated in MISR2 from the value held in the multi-input signature register 2L (MISR2L) and the data written to MISRCDRL, and the result is retained in MISR2L. In register write mode, the values of MISR1H and MISR2H are not updated.

Writing to MISRCDRL can proceed in 8-, 16-, or 32-bit units, and bits to which a value is not written are treated as 0. For example, writing to the 16 lower-order bits of MISRCDRL leads to the generation of a signature with the 16 higher-order bits of write data treated as 0. Similarly, writing to the 16 higher-order bits of MISRCDRL leads to the generation of a signature with the 16 lower-order bits of write data treated as 0. However, these cases will not arise if access is by using the IO header file.

MISR1 and MISR2 do not identify the bus master which writes to the MISRCDRL. Writing by any bus master, whether a CPU, DMAC, or debugging master, produces a signature.

(2) Write Monitoring Mode

Writing to the address area specified for monitoring by the CPU while MISR1 is in write monitoring mode leads the generation of two 32-bit signatures in MISR1 from the value held in MISR1H and MISR1L and the data written to the CPU, and the result retained in MISR1H and MISR1L. At this time, MISR1H is for the 32 higher-order bits of write data, while MISR1L is for the 32 lower -order bits of write data. Similarly, writing to the address area specified for monitoring by the CPU while MISR2 is in write monitoring mode leads the generation of two 32-bit signatures in MISR2 from the value held in MISR2H and MISR2L and the data written to the CPU, and the result retained in MISR2H and MISR2L.

The address area specified for monitoring for signature generation is set by the MISR monitoring area base address register (MISRBASEADR) and the MISR monitoring area address mask register (MISRADRMSK). If the CPU write address is within the address area specified for monitoring, a signature is generated.

Write monitoring mode monitors write access by the corresponding CPU in 8-, -16, -32, or -64 units. When writing proceeds in 8-, -16, or -32 units, remaining bits to which a value is not written are treated as 0, and 64-bit data is always input to MISR1 or MISR2. Write data are allocated to the lower-order side regardless of the destination address. For example, when 32 bits are written to an address of the form 8N+4, the 32 bits are allocated to the lower-order side and a signature is generated with the 32 higher-order bits treated as 0.

The CPU write access destinations that can be monitored by MISR1 and MISR2 are as follows:

Local RAM, global RAM, CPU peripheral (local APB),

Peripheral circuit connected to the interconnect (GVCI) or to the P-Bus (global APB)

The following store operations are not subject to monitoring.

(1) Instructions that identify write data in slave responses: BitOp, CAXI, and STC.W

(2) Instructions for saving more than 64 bits on the stack: PREPARE and PUSHSP

Write monitoring mode can only be executed between the specified signature generation unit and the corresponding CPU.

In this product, the following monitoring operations are possible. Writing by the PCU cannot be monitored.

- Monitoring of CPU1 write access by signature generation unit 1

A signature is not generated if write monitoring mode is set for a signature generation unit that does not support write monitoring mode. At this time, reference to the values of MISRBASEADR and MISRADRMSK is not possible from anywhere.

29.5.3.2 Automatic Signature Comparison

Of the signature generation units, two signature generation units are selected for the comparison of signatures by the MISR1CMPEN2 bit or MISR2CMPEN2 bit. Each signature generation unit has a data counter, and the signatures are compared if the values of the data counters generated in two signature generation units selected as targets for comparison match.

If two signatures are to be compared, use MISR1CMPEN2 or MISR2CMPEN2 in the MISRCMPCTL register to enable signature comparison by two signature generation units.

29.5.3.3 Data Counter

The MISR data counter register (MISRDCNT) counts how many times writing to MISRCDRL or the address range specified by BASEADR and ADRMSK proceeds. When the CNTSTA bit = 1 and the CNTTRG bit = 0 in the data counter control register (MISRDCNTCTL), MISRDCNT counts the number of write accesses to MISRCDRL. When the CNTSTA bit = 1 and the CNTTRG bit = 1 in MISRDCNTCTL, MISRDCNT counts the number of write accesses by the corresponding CPU to the address range specified by MISRBASEADR and MISRADRMSK.

MISRDCNT can count the number of times either MISR1 or MISR2 or both MISR1 and MISR2 generate signatures by setting the trigger for counting up by MISRDCNT as the signature generation condition in MISR1 or MISR2. Note, however, that if the signature generation conditions for MISR1

and MISR2 and the trigger for counting up by the data counter are not consistent, the value of MISRDCNT and the signature generation count will not match.

CAUTIONS

1. **When the MISR1EN and MISR2EN bits in the MISRCR register are both 0, counting by MISRDCNT is not incremented even if writing to MISRCDRL and the address range specified by MISRBASEADR and MISRADRMSK proceeded.**
2. **In the signature generation unit that does not support write monitoring mode, counting by MISRDCNT is not incremented when the CPU write access to the monitoring address area is set as the trigger for counting up by the data counter.**

29.5.3.4 Error Notification

When the CMPERREN bit in the error notification control register (MISRERRCTL) is set to 1, the error control module is notified of an error when signatures are compared and do not match. At the same time, the error flag in the compare error status register is set.

An interrupt request for the INTC is not generated.

29.5.4 Register Specifications

29.5.4.1 Register Map

The table below lists the registers of the signature generation units.

The registers with symbols ending in "_PE1" are those of signature generation unit 1 (MISG_PE1).

The registers with symbols ending in "_PCU" are those of signature generation unit 3 (MISG_PCU).

Note that the endings of the register symbols ("_PE1", and "_PCU") are omitted if signature generation units 1 and 3 do not require identification.

MISG_PE1_base = FFC5 1000_H

MISG_PCU_base = FFC5 3000_H

The table below lists the registers of the signature comparison unit (MSD sub-block).

MSD_base = FFC5 0000_H

Table 29.119 List of Registers of the Signature Comparison Units

Register symbol	Register Name	R/W	Value after Reset	Address	Access Size		
					8	16	32
MISRCMPCTL	MISR comparator control register	R/W	0000_H	<MSD_base> + 00_H	√	√	
MISRCMPERSTR	MISR compare error status register	R	00_H	<MSD_base> + 04_H	√		
MISRCMPERRSTC	MISR compare error status clear register	W	00_H	<MSD_base> + 08_H	√		
MISRERRCTL	MISR error notification control register	R/W	00_H	<MSD_base> + $0C_H$	√		

Note 1. In case of access to a register in a unit smaller than 32 bits, the bits that are not specified are ignored when writing and read as 0.

The following describes the control registers of the signature comparison unit.

29.5.4.2 MISRCDRL_PE1/PCU — MISR Calculation Data Register

The MISR calculation data register is a 32-bit write-only register.

When signature generation in register write mode is selected, a signature is generated in MISR1 or MISR2 by writing to this register. Data written to this register is the data input to the multi-input signature register 1L (MISR1L) or the multi-input signature register 2L (MISR2L). For the conditions for signature generation, see **Section 29.5.3.1, Conditions for Signature Generation**.

This register can be written in 8-, 16-, or 32-bit units. When writing proceeds in 8- or 16-bit units, remaining bits to which a value is not written are treated as 0, and 32-bit data is always input to MISR1 or MISR2

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.120 MISRCDRL_PE1/PCU Register Contents

Bit Position	Bit Name	Functions
31 to 0	MISRCDRL31 to MISRCDRL0	Calculation Data Input data to MISR1 or MISR2. When the MISR1EN bit = 1 and the MISR1CND bit = 0 in the MISRCR register, or the MISR2EN bit = 1 and the MISR2CND bit = 0, a new signature is generated each time the MISRCDR register is written, and the result is retained in MISR1 or MISR2.

Note 1. If a signature is generated by writing to this register, the operation is only based on the 32 lower-order bits in MISR1 or MISR2 (MISR1L or MISR2L) and not on the 32 higher-order bits (MISR1H or MISR2H), the values of which remain the same.

29.5.4.3 MISR1L_PE1/PCU — Multi-Input Signature Register 1L

The multi-input signature register 1L is a 32-bit readable and writable register.

Once the signature generation condition is met, this register generates a new signature each time the condition is met and retains the generated value. For the conditions for signature generation, see **Section 29.5.3.1, Conditions for Signature Generation**.

Signatures are generated by using the following polynomial:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1$$

Bit Position	Bit Name	Functions
31 to 0	MISR1L31 to MISR1L0	Multi-Input Signature Register 1L When read, a new signature is always read.

29.5.4.4 MISR1H_PE1/PCU — Multi-Input Signature Register 1H

The multi-input signature register 1H is a 32-bit readable and writable register.

Once the signature generation condition is met, this register generates a new signature each time the condition is met and retains the generated value. For the conditions for signature generation, see **Section 29.5.3.1, Conditions for Signature Generation**.

Signatures are generated by using the following polynomial:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Note 1. In register write mode, this register is not updated even when the signature generation condition is met. This register is also provided in the signature generation unit that does not support write monitoring mode, but does not generate signatures.

29.5.4.5 MISR2L_PE1/PCU — Multi-Input Signature Register 2L

The multi-input signature register 2L is a 32-bit readable and writable register.

Once the signature generation condition is met, this register generates a new signature each time the condition is met and retains the generated value. For the conditions for signature generation, see **Section 29.5.3.1, Conditions for Signature Generation**.

Signatures are generated by using the following polynomial:

$$G(x) = x^{32} + x^{22} + x^2 + x + 1$$

29.5.4.6 MISR2H_PE1/PCU — Multi-Input Signature Register 2H

The multi-input signature register 2H is a 32-bit readable and writable register.

Once the signature generation condition is met, this register generates a new signature each time the condition is met and retains the generated value. For the conditions for signature generation, see **Section 29.5.3.1, Conditions for Signature Generation**.

Signatures are generated by using the following polynomial:

$$G(x) = x^{32} + x^{22} + x^2 + x + 1$$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 29.124 MISR2H_PE1/PCU Register Contents

Bit Position	Bit Name	Functions
31 to 0	MISR2H31 to MISR2H0	Multi-Input Signature Register 2H When read, a new signature is always read.

Note 1. In register write mode, this register is not updated even when the signature generation condition is met. This register is also provided in the signature generation unit that does not support write monitoring mode, but does not generate signatures.

29.5.4.7 MISRCR_PE1/PCU — MISR Control Register

MISR is an 8-bit readable and writable register.

The MISR1EN and MISR2EN bits are used to enable signature generation in MISR1 and MISR2. When the MISR1EN or MISR2EN bit is 1, MISR1 or MISR2 generates a signature and retains the generated value. When the MISR1EN or MISR2EN bit is 0, MISR1 or MISR2 does not generate signatures and the values of these registers are not updated.

When the MISR1EN or MISR2EN bit is 1, the MISR1CND or MISR2CND bit selects the signal generation condition in MISR1 orMISR2. Setting the MISR1CND or MISR2CND bit to 0 selects signature generation in register write mode by MISR1 or MISR2, so writing to MISRCDRL leads to signature generation. Setting the MISR1CND or MISR2CND bit to 1 selects signature generation in write monitoring mode by MISR1 or MISR2, writing by the CPU to the address range specified by the MISRBASEADR and MISRADRMSK registers leads to signature generation. For the conditions for signature generation, see **Section 29.5.3.1, Conditions for Signature Generation**.

Bit	7	6	5	4	3	2	1	0

Bit Position	Bit Name	Functions
7 to 4	—	Reserved
3	MISR2CND	MISR2 Signature Write Control This bit sets the signature generation condition in MISR2 when the MISR2EN bit = 1. 0: Register write mode 1: Write monitoring mode
2	MISR1CND	MISR1 Signature Write Control This bit sets the signature generation condition in MISR1 when the MISR1EN bit = 1. 0: Register write mode 1: Write monitoring mode
1	MISR2EN	MISR2 Enable 0: MISR2 does not generate a signature. 1: MISR2 generates a signature and the MISR2H and MISR2L values are updated.
0	MISR1EN	MISR1 Enable 0: MISR1 does not generate a signature. 1: MISR1 generates a signature and the MISR1H and MISR1L values are updated.

29.5.4.8 MISRBASEADR_PE1/PCU — MISR Monitoring Area Base Address Register

MISRBASEADR specifies the CPU write access area to be monitored by MISG when signature generation in write monitoring mode is selected. In combination with the setting of the monitoring area mask address register, this register specifies the address range of the monitoring area. For the conditions for signature generation, see **Section 29.5.3.1, Conditions for Signature Generation**.

29.5.4.9 MISRADRMSK_PE1/PCU — MISR Monitor Area Address Mask Register

MISRADRMSK specifies the CPU write access area to be monitored by MISG when signature generation in write monitoring mode is selected. In combination with the setting of the monitoring area base address register, this register specifies the address range of the monitoring area. For the conditions for signature generation, see **Section 29.5.3.1, Conditions for Signature Generation**.

31 to 0	ADRMSK31 to ADRMSK0	Monitoring Area Mask Address Register

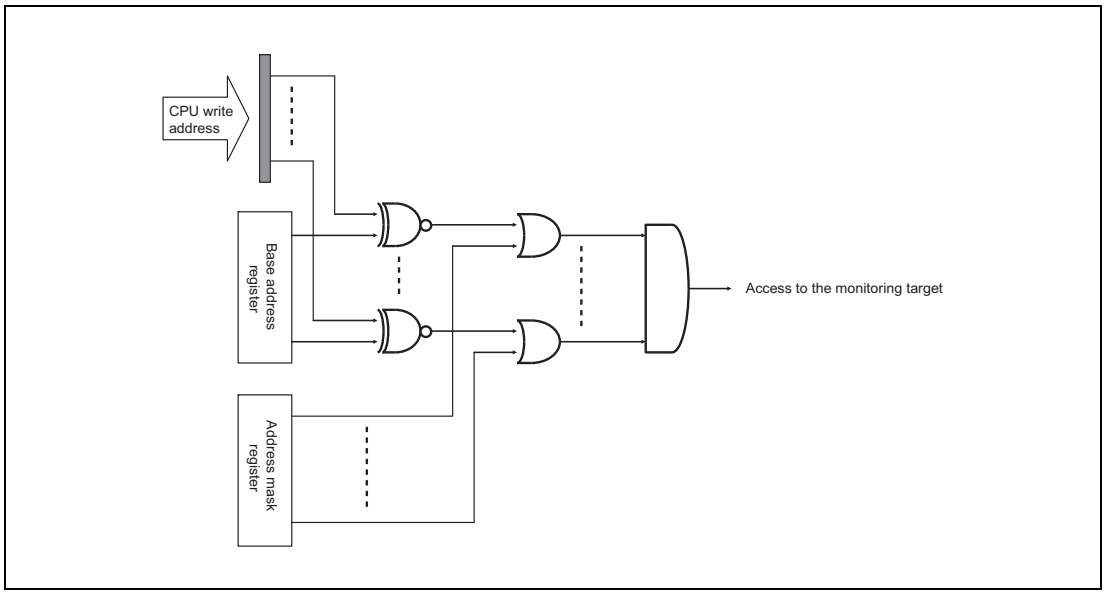

Figure 29.7 How to Detect Access to the Monitoring Area

29.5.4.10 MISRDCNTCTL_PE1/PCU — MISR Data Counter Control Register

This register controls operation of the MSIR data counter register. If the event selected by the CNTTRG bit occurs while the CNTSTA bit is 1, the data counter is incremented. For operation of the data counter, see **Section 29.5.3.3, Data Counter**.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CNTTRG	CNTSTA
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 29.128 MISRDCNTCTL_PE1/PCU Register Contents

Bit Position	Bit Name	Functions
7 to 2	—	Reserved
1	CNTTRG	Count-Up Trigger Select This bit selects the trigger for counting up by the data counter. 0: Write access to the MISRCDRL register 1: Write access to the address area specified by the MISRBASEADR and MISRADRMSK registers
0	CNTSTA	Data Counter Start This bit is an enable bit for the data counter. If the event selected by the CNTTRG bit occurs while CNTSTA = 1, the data counter is incremented. 0: The data counter is stopped. 1: The data counter is operating.

29.5.4.11 MISRDCNT_PE1/PCU — MISR Data Counter Register

The data counter is a 16-bit readable and writable register.

If the data counter values of two signature generation units selected for comparison match, automatic comparison of the signatures proceeds.

When the CNTTRG bit in the data counter control register is 0, the data counter is incremented by write access to the MISR calculation data register. When the CNTTRG bit in the data control register is 1, the data counter is incremented by write access by the corresponding CPU to the address area specified by the MISRBASEADR and MISRADRMSK registers. For operation of the data counter, see **Section 29.5.3.3, Data Counter**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DCNT[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.129 MISRDCNT_PE1/PCU Register Contents

Bit Position	Bit Name	Function
15 to 0	DCNT15 to DCNT0	Data Counter Register

The following describes the control registers of the MSD unit (signature comparison unit).

29.5.4.12 MISRCMPCTL — MISR Comparator Control Register

MISRCMPCTL is a 16-bit readable and writable register.

This register controls the comparator that compares signatures generated in the signature generation units. For automatic comparison of signatures, see **Section 29.5.3.2, Automatic Signature Comparison**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	MISR2CMPEN2	—	—	MISR1CMPEN2	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R/W	R	R

Table 29.130 MISRCMPCTL Register Contents

Bit Position	Bit Name	Functions
15 to 6	—	Reserved
5	MISR2CMPEN2	MISR2 Signature Compare Enable 2 This bit controls comparison of signatures retained in MISR2 of MISG_PCU and MISG_PE1. 0: Disables comparison 1: Enables comparison
4, 3	—	Reserved
2	MISR1CMPEN2	MISR1 Signature Compare Enable 2 This bit controls comparison of signatures retained in MISR1 of MISG_PCU and MISG_PE1. 0: Disables comparison 1: Enables comparison
1, 0	—	Reserved

29.5.4.13 MISRCMPERSTR — MISR Compare Error Status Register

The compare error status register is an 8-bit readable register.

If a mismatch occurs in signature comparison enabled by the comparator control register, the corresponding error flag is set.

The error flag is cleared by writing 1 to the corresponding clear bit in the compare error status clear register. The flag is also cleared by a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	MISR2ERR2	—	—	MISR1ERR2	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 29.131 MISRCMPERSTR Register Contents

Bit Position	Bit Name	Functions
7, 6	—	Reserved
5	MISR2ERR2	MISR2 Signature Compare Error Flag 2 This flag is set when signatures retained in MISR2 of MISG_PE1 and MISG_PCU are compared and do not match. 0: A mismatch has not occurred in signature comparison. 1: A mismatch has occurred in signature comparison.
4, 3	—	Reserved
2	MISR1ERR2	MISR1 Signature Compare Error Flag 2 This flag is set when signatures retained in MISR1 of MISG_PE1 and MISG_PCU are compared and do not match. 0: A mismatch has not occurred in signature comparison. 1: A mismatch has occurred in signature comparison.
1, 0	—	Reserved

29.5.4.14 MISRCMPERRSTC — MISR Compare Error Status Clear Register

The compare error status clear register is an 8-bit write-only register.

When an error flag in the compare error status register is 1, writing 1 to corresponding clear bit clears the error flag. Read the MISR compare error status register and write 1 to the clear bit for the flag being 1.

Bit	7	6	5	4	3	2	1	0
	—	—	MISR2CLR2	—	—	MISR1CLR2	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	W	R	R	W	R	R

Table 29.132 MISRCMPERRSTC Register Contents

Bit Position	Bit Name	Functions
7, 6	—	Reserved
5	MISR2CLR2	MISR2 Signature Compare Error Clear 2 Writing 1 to this bit clears the MISR2ERR2 bit in the CMPERRST register.
4, 3	—	Reserved
2	MISR1CLR2	MISR1 Signature Compare Error Clear 2 Writing 1 to this bit clears the MISR1ERR2 bit in the CMPERRST register.
1, 0	—	Reserved

29.5.4.15 MISRERRCTL — MISR Error Notification Control Register

The error notification control register is an 8-bit readable and writable register.

This register enables or disables error notification when signatures are compared by the automatic signature comparison and do not mach. For the automatic signature comparison and error notification, see **Section 29.5.3.2, Automatic Signature Comparison**, and **Section 29.5.3.4, Error Notification**

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CMPERREN
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 29.133 MISRERRCTL Register Contents

Bit Position	Bit Name	Functions
7 to 1	—	Reserved
0	CMPERREN	Compare Error Notification Enable This bit enables or disables error notification when signatures are compared and do not mach. 0: Error notification does not proceed even if a mismatch has occurred in signature comparison. 1: Error notification proceeds if a mismatch has occurred in signature comparison.

29.5.5 Usage

29.5.5.1 Usage Example 1

The self-diagnostic program eases diagnosis. By using the MISG to compress intermediate transitions, the self-diagnostic program makes the saving and comparison of all intermediate results unnecessary. Results of self diagnosis including intermediate transitions can be judged by comparing the results of compression by the MISG with the expected results when the program ends.

This has the effect of reducing requirements for memory capacity and times for processing comparisons (substitution by CRCs is also possible).

Example of settings (when PE1 is running the self-diagnostic program)

The descriptions of registers of an MISG below applies to the registers of signature generation unit 1 (MISG_PE1), which is for PE1.

(1) Initialize the multi-input signature register 1 (MISR1H/MISR1L), multi-input signature register 2 (MISR2H/MISR2L) and data counter register (MISRDCNT).

(2) Set the MISR1CND or MISR2CND bit in the MISR control register (MISRCR) to 1 to select signature generation by MISR1 or MISR2 in write monitoring mode.

(3) Use the MISR monitoring area base address register (MISRBASEADR) and MISR monitoring area address mask register (MISRADRMSK) to set the address area for monitoring.

(4) Set the MISR1EN or MISR2EN bit in the MISR control register to 1 to enable signature generation in MISR1 or MISR2.

(5) Run the self-diagnostic program on PE1.

(6) Upon completion of execution of the self-diagnostic program, MISR1H and MISR1L or MISR2H and MISR2L data is compared with the expected value in flash memory.

29.5.5.2 Usage Example 2

Use multiple processors to run the same processing (including the self-diagnostic program) to confirm the correctness of results. Comparing results from different hardware raises reliability.

Example of settings (when PE1 and PCU are running the same task)

The descriptions of registers of an MISG below applies to the MISG registers of PE1 and PCU.

(1) Initialize the multi-input signature register 1 (MISR1H or MISR1L), multi-input signature register 2 (MISR2H or MISR2L), and data counter register (MISRDCNT).

(2) Set the MISR1CND or MISR2CND bit in the MISR control register (MISRCR) to 0 to select signature generation by MISR1 or MISR2 in register write mode.

(3) Set MISR1CMPEN1 or MISR2CMPEN1 in the MISR comparator control register (MISRCMPCTL) to 1 to enable signature comparison by the comparator.

(4) Set the CMPERREN bit in the MISR error notification control register to 1 to enable error notification to the error control module.

(5) Set the CNTTRG bit in the MISR data counter control register (MISRDCNTCTL) to 0 to set writing to MISRCDRL as the trigger for counting up by the data counter. Set the CNTSTA bit to 1 to enable operation of the data counter.

(6) Set the MISR1EN or MISR2EN bit in the MISR control register to 1 to enable signature generation in MISR1 or MISR2.

(7) Run the self-diagnostic program on all CPUs.

(8) The self-diagnostic program stores intermediate results while the program is running in MISRCDRL of the signature generation units. The signatures in the MISR1 and MISR2 registers of MISG_PE1 and MISG_PCU are compared whenever the values of the data counter registers (MISRDCNT) of MISG_PE1 and MISG_PCU match.

(9) Check the comparison status register to see if there were errors in comparison.

29.6 Clock Monitors

29.6.1 Overview

This product incorporates the clock monitors to monitor the clock operation by detecting the abnormal frequency of the clock to be monitored. The clock monitors provide the following functions.

- Monitors to see if the frequency of the clock to be monitored is within the specified range based on the sampling clock.
- Issues an error notice to the ECM upon detection of the abnormal state of the clock.

Table 29.134 shows the clocks monitored by the clock monitors and the sampling clocks used.

Table 29.134 List of Clocks Monitored by Each Clock Monitor and Sampling Clocks Used

Clock Monitor Channel	Monitored Clock	Sampling Clock
CLMA0	Low-speed peripheral clock (40 MHz SSCG)	Non-modulated low-speed peripheral clock (40 MHz clean)
CLMA1	Non-modulated low-speed peripheral clock (40 MHz clean)	10 MHz (1/2 main OSC)
CLMA2	WDTA counter clock (1/80 main OSC)	Low-speed ROSC clock (ROSC)

29.6.2 List of Registers

29.6.2.1 Clock Monitor Channel Registers

Table 29.135 List of Registers

Address	Symbol	Register Name	R/W	Value after Reset	Access Size
<Base_adr + 00_H>	CLMAnCTL0	CLMAn control register 0	R/W	00_H	8
<Base_adr + 08_H>	CLMAnCMPL	CLMAn compare register L	R/W	0001_H	16
<Base_adr + $0C_H$>	CLMAnCMPH	CLMAn compare register H	R/W	$03FF_H$	16
<Base_adr + 10_H>	CLMAnPCMD	CLMAn protection command register	W	00_H	8
<Base_adr + 14_H>	CLMAnPS	CLMAn protection command status register	R	00_H	8

The base addresses of the registers are shown below.

Table 29.136 List of Base Address Registers

Clock Monitor Channel	<Base_addr>
CLMA0	$FFF8\ 8400_H$
CLMA1	$FFF8\ 8420_H$
CLMA2	$FFF8\ 8440_H$

29.6.2.2 Shared Registers

Table 29.137 List of Shared Registers

Register Symbol	Register Name	R/W	Value after Reset	Address	Access Size	Protection
CLMATEST	CLMA self-test register	R/W	0000 0000_H	FFF8 8204_H	32	PROT1PHCMD *1
CLMATESTS	CLMA self-test status register	R/W	0000 0000_H	FFF8 8208_H	32	

Note 1. For this register, refer to **Section 11, Clock Controller**.

29.6.3 Details of Registers

29.6.3.1 CLMAnCTL0 — CLMAn Control Register 0

CLMAnCTL0 controls the operation of the clock monitors. CLMAnCTL0 is protected by the CLMAnPCMD register.

CLMAnCTL0 can be initialized by either an internal reset or an external reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CLMAnCLME
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W*1

Note 1. CLMAnCTL0 can be cleared by a reset. Writing 0 is ignored.

Table 29.138 CLMAnCTL0 MISR1CMPEN2 Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	CLMAnCLME	Clock Monitor Operation 0: Disables operation. 1: Enables operation.

29.6.3.2 CLMAnCMPL — CLMAn Compare Register L

CLMAnCMPL sets the lower limit of the normal frequency range used for comparison.

CLMAnCMPL can be initialized by either an internal reset or an external reset.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CLMAnCMPL[11:0]											
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.139 CLMAnCMPL Register Contents

Bit Position	Bit Name	Function
15 to 12	—	Reserved These bits are always read as 0. The write value should also be 0.
11 to 0	CLMAnCMPL [11:0]	Lower Limit of Normal Frequency Range CLMAnCMPL can be written to when CLMAnCTL0.CLMAnCLME is 0. Once CLMAnCTL0.CLMAnCLME is set to 1, writing to CLMAnCMPL is invalid.

29.6.3.3 CLMAnCMPH — CLMAn Compare Register H

CLMAnCMPH sets the upper limit of the normal frequency range used for comparison.

CLMAnCMPH can be initialized by either an internal reset or an external reset.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CLMAnCMPH[11:0]											
Value after reset	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.140 CLMAnCMPH Register Contents

Bit Position	Bit Name	Function
15 to 12	—	Reserved These bits are always read as 0. The write value should also be 0.
11 to 0	CLMAnCMPH [11:0]	Upper Limit of Normal Frequency Range CLMAnCMPH can be written to when CLMAnCTL0.CLMAnCLME is 0. Once CLMAnCTL0.CLMAnCLME is set to 1, writing to CLMAnCMPH is invalid.

29.6.3.4 CLMAnPCMD — CLMAn Protection Command Register

CLMAnPCMD is a special sequential register for CLMAnCTL0.

CLMAnPCMD can be initialized by either an internal reset or an external reset.

Bit	7	6	5	4	3	2	1	0
	CLMAnPCMD[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

See **Section 29.6.6.1**, regarding this protection method on details.

29.6.3.5 CLMAnPS — CLMAn Protection Command Status Register

CLMAnPS is a special sequential register for CLMAnCTL0.

CLMAnPS can be initialized by either an internal reset or an external reset

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CLMAnPRERR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 29.141 CLMAnPS Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved These bits are always read as 0.
0	CLMAnPRERR	Protection Error Detection 0: A protection error has not been generated. 1: A protection error has been generated.

Operating conditions of the CLMAnPRERR bit:

Setting condition: Access to CLMAnCTL0, which is the target for protection specified by CLMAnPCMD, without following the protection cancelling sequence.

Clearing condition: Writing of A5H to the CLMAnPCMD register (step 1 in the protection cancelling sequence).

29.6.3.6 CLMATEST — CLMA Self-Test Register

CLMATEST is used for self-testing of CLMA2 to CLMA0.

CLMATEST can be protected by the PROT1PHCMD register.

CLMATEST is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	CLMA2TESTEN	CLMA1TESTEN	CLMA0TESTEN	ERRMSK	MONCLKMSK	RESCLM
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 29.142 CLMATEST Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved These bits are always read as 0. When writing, follow the procedure of the protection release sequence, write the value after reset, or the bit inverse value of the value after reset to these bits.
5 to 3	CLMA2TESTEN CLMA1TESTEN CLMA0TESTEN	These bits enable or disable self-testing of CLMA2 to CLMA0. 0: Disables self-testing of the corresponding CLMAn. 1: Enables self-testing of the corresponding CLMAn.
2	ERRMSK	Masks an error notification to the ECM when CLMAn detects an error. When the ERRMSK is set for a certain CLMAn, the associated CLMAn does not issue an error notification to the ECM even if it detects an error. ERRMSK setting is valid only for the CLMAn for which CLMAnTESTEN (n = 0 to 2) is set to 1. 0: Does not mask an error notification to the ECM. 1: Masks an error notification to the ECM.
1	MONCLKMSK	Fixes the level of the clock input to the CLMAn that should be monitored, to the low level. MONCLKMSK setting is valid only for the CLMAn for which CLMAnTESTEN (n = 0 to 2) is set to 1. 0: Does not fix the clock input to the CLMAn that should be monitored to the low level. 1: Fixes the clock input to the CLMAn that should be monitored to the low level.
0	RESCLM	Initializes CLMAn forcibly. RESCLM setting is valid only for the CLMAn for which CLMAnTESTEN (n = 0 to 2) is set to 1. 0: Does not initialize CLMAn. 1: Initializes CLMAn.

29.6.3.7 CLMATESTS — CLMA Self-Test Status Register

CLMATESTS indicates the self-testing result of CLMA2 to CLMA0.

CLMATESTS is initialized by an internal reset or an external reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	CLMA2 ERRS	CLMA1 ERRS	CLMA0 ERRS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 29.143 CLMATESTS Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved These bits are always read as 0.
2 to 0	CLMA2ERRS CLMA1ERRS CLAM0ERRS	These bits indicate whether or not CLMA2 to CLMA0 have detected an error. These bits are not affected by CLMATEST.ERRMSK. 0: The corresponding CLMAn has not yet detected an error. 1: The corresponding CLMAn has detected an error.

29.6.4 Detection of Abnormal Clock Frequency

1. CLMAn counts the number of rising edges of the monitored clock signal within 16 sampling clock cycles, and compares the count with the specified thresholds.
   - The lower threshold is specified using the CLMAnCMPL[11:0] bits in CLMAnCMPL register.
   - The upper threshold is specified using the CLMAnCMPH[11:0] bits in CLMAnCMPH register.
2. When the frequency of the monitored clock is low*1 and the counter value falls below the value set in CLMAnCMPL[11:0] in the CLMAnCMPL register, CLMAn notifies the ECM of the abnormal clock. CLMAn also notifies the ECM of the abnormal clock when the frequency of the monitored clock is high and the counter value exceeds the value set in CLMAnCMPH[11:0] in the CLMAnCMPH register.

Note 1. An abnormality may not be detected when a clock being monitored is completely stopped.

Note that even if the frequency of the monitored clock fluctuates during the sampling period, an error is not notified as long as the number of detected edges falls within the specified range.

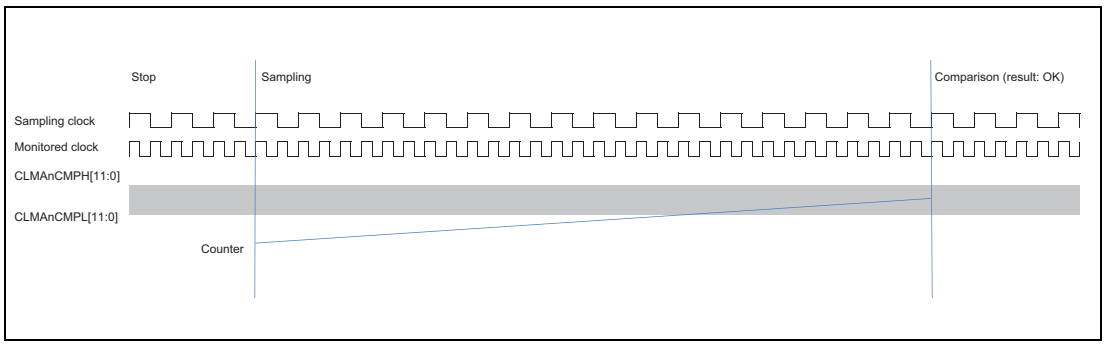

Figure 29.8 Operation When Clock Frequency is Within the Specified Range

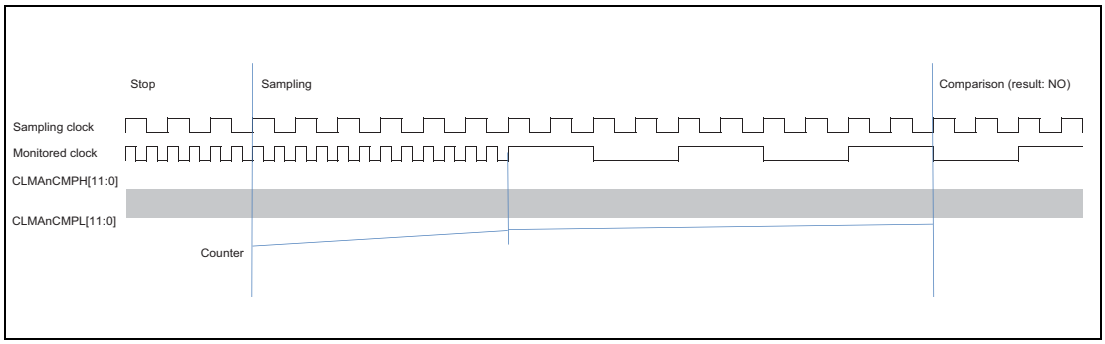

Figure 29.9 Operation When Clock Frequency is Lower than the Specified Range

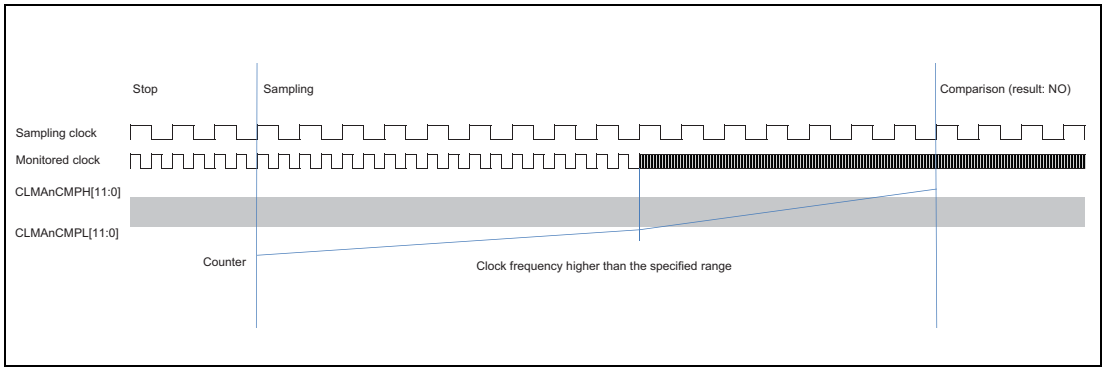

Figure 29.10 Operation When Clock Frequency is Higher than the Specified Range

(1) Calculating the thresholds set by CLMAnCMPL.CLMAnCMPL[11:0] and CLMAnCMPH.CLMAnCMPH[11:0]

The minimum and maximum values of the clock cycles of the monitored clock CLMATMON that are assumed to be valid within 16 cycles of the sampling clock CLMATSMP are set in the comparison registers CLMAnCMPL and CLMAnCMPH.

The expected clock cycle is indicated by “N”.

$$\frac{16}{f_{CLMATSMP}} = \frac{N}{f_{CLMATMON}}$$

$$N = \frac{f_{CLMATMON}}{f_{CLMATSMP}} \times 16$$

The thresholds are calculated considering allowable frequency deviation of CLMATMON and CLMATSMP.

$$\text{Lower threshold} = N_{min} = \frac{f_{CLMATMON(min)}}{f_{CLMATSMP(max)}} \times 16 - 1$$

$$\text{Upper threshold} = N_{max} = \frac{f_{CLMATMON(max)}}{f_{CLMATSMP(min)}} \times 16 + 1$$

NOTE

PLL jitter is covered by “+1” and “-1” as in the formulae.

Example

$f_{CLMATSMP}$ = 240 kHz (±8%) and $f_{CLMATMON}$ = 16 MHz (±5%), the recommendable thresholds will be as follows:

$$N_{min} = 15{,}200 / 259.2 \times 16 - 1$$
$$= 937.27$$
$$CLMAnCMPL = 937 = 03A9_H$$

$$N_{max} = 16{,}800 / 220.8 \times 16 + 1$$
$$= 1218.39$$
$$CLMAnCMPH = 1219 = 04C3_H$$

Minimum Threshold:

The following restrictions must be taken into consideration.

- CLMAnCMPL ≥ 0001_H
- CLMAnCMPH ≥ CLMAnCMPL + 0003_H

(2) Definition of initial values input to the threshold registers

The values of the threshold registers in the initial state and after a reset should permit the maximum frequency deviation of the monitor clock.

- CLMAnCMPL[11:0] = 0001_H
- CLMAnCMPH[11:0] = $03FF_H$

29.6.5 Self-Diagnosis

Self-diagnosis of the clock monitor is available as described below. In the description, the clock monitor to be self-diagnosed is operating.

(1) Set the thresholds for the clock monitor to be subject to self-diagnosis (set CLMAnCMPL and CLMAnCMPH).
At this time, the thresholds must be set such that an error will be produced.

(2) Specify the clock monitor to be self-diagnosed.
Setting the CLMATEST.CLMAnTESEN bit to 1 enables specifying the corresponding clock monitor to be self-diagnosed.

(3) To prevent conveyance of the error signal to the ECM based on self-diagnosis, set CLMATEST.ERRMSK simultaneously with step (2).

(4) Set the CLMAnCTL0.CLMAnCLME bit to 1 to enable operation of the clock monitor.

(5) Wait for the time long enough to allow error occurrence, read the CLMATESTS register to see if an error has been generated in the clock monitor to be self-diagnosed. The time from the start of self-diagnosis to the error occurrence depends on the sampling period. A maximum of two sampling cycles are required.

(6) Clear the error generated by self-diagnosis.
Setting CLMATEST.RESCLM to 1 enables initializing the clock monitor to be self-diagnosed.

(7) Terminate self-diagnosis.
Setting all the bits in CLMATEST to 0 enables terminating self-diagnosis.

Before restarting the clock monitor that has been self-diagnosed, set the registers again as required.

29.6.6 Notes on Register Setting

29.6.6.1 Writing to Protected Registers

Writing to the CLMAnCTL0 register (n = 0 to 2) of each clock monitor is only possible with the protection release sequence described below.

1) Write the fixed value ($A5_H$) to register CLMAnPCMD.

2) Write the new setting to register CLMAnCTL0. Write the value after a reset to the reserved bits.

3) Write the bitwise inverse of the setting value to register CLMAnCTL0. Write the inverse of the value after a reset to the reserved bits.

4) Write the new setting to register CLMAnCTL0. Write the value after a reset to the reserved bits.

A value can only be written to a write-protected register by following the procedure above.

Protection is not released if the procedure is not followed correctly, the setting is not written to the write-protected register, and the CLMAnPS.CLMAnPRERR bit is set to 1. (Although this is not a requirement, you can confirm if the values set in the targeted register was correctly written by checking that the setting of the CLMAnPS.CLMAnPRERR bit is 0 after step 4).)

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1) to 4) of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*1, writing to the protected register fails and the CLMAnPS.CLMAnPRERR bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

For writing to CLMATEST, see the description of the PROT1PHCMD register.

Note 1. “Another register in the same module” indicates a register under the same module name as that containing the write-protected register. For the module names of the registers, see **Appendix, List of Registers**.

29.6.6.2 Setting CLMAnCMPL/CLMAnCMPH Registers

The CLMAnCMPL/CLMAnCMPH registers should be set so that the following conditions are satisfied. If the clock monitor is otherwise used, operation cannot be guaranteed.

- $1 \leq$ CLMAnCMPL
- CLMAnCMPL + $3 \leq$ CLMAnCMPH (n = 0, 1, or 2)

29.7 BIST

This product incorporates the function to detect failures of the failure detection function itself, which is referred to as BIST. The functions shown in the table below have the dual hardware configuration, and a BIST error notice is issued to the ECM if a failure occurs in any function.

Table 29.144 List of Failure Detection Function

BIST-Applied Function	Remark
Lockstep comparator	Lockstep comparator for CPU1
ECC decoder	
Address parity decoder	

For the ECC decoder for the peripheral RAM and Data Flash, the hardware including the control registers has dual configuration. When using the BIST function, set the same values to the control registers of the master and checker.

The control register is not duplexed for other ECC decoder and address parity checker.

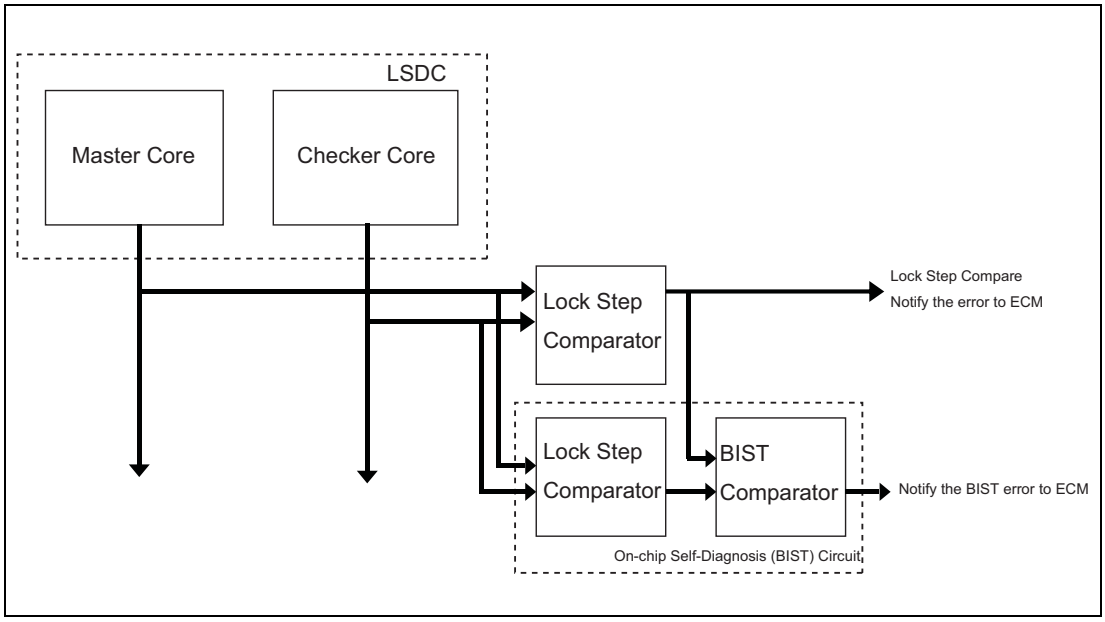

Figure 29.11 Lock Step Configuration

29.8 ECM

The ECM monitors various failure detection states in the LSI chip, and defines the operation to be carried out upon failure detection. For the details of the ECM, refer to **Section 30, Error Control Module (ECM)**.

Section 30 Error Control Module (ECM)

30.1 Overview

30.1.1 Specification Overview

The error control module (ECM) collects error signals coming from different error sources and monitoring circuits. It also outputs error signals (ERROROUT output) from the ERROROUT pin ($\overline{\text{ERROROUT\_M}}$ and $\overline{\text{ERROROUT\_C}}$) and generates interrupts and internal reset signals. **Table 30.1** shows the specification overview of the ECM.

Table 30.1 Specification Overview

Item	Description
Safety processing	The ECM can handle the following processing in response to error signal inputs from individual modules. • Error flag set • Maskable interrupt generation Maskable interrupt generation can be controlled (enabled/disabled) for individual errors. • FE level interrupt generation FE level interrupt generation can be controlled (enabled/disabled) for individual errors. • Internal reset generation Internal reset generation can be controlled (enabled/disabled) for individual errors. • ERROROUT output Pin output mask can be controlled (enabled/disabled) for individual errors. Output can be toggled in response to a timer input or made at a fixed level.
Error status	The ECM incorporates the ECM master/checker error source status register, which can be used to confirm the error status from the error flag. The error flags are only cleared by setting the bit corresponding to the ECM error source status clear trigger register to 1 or an external reset. In case of an internal reset, the error flags are kept and the reset generation source can be confirmed by reading the ECM master/checker error source status register after reset.
Debug, self-diagnosis	• Pseudo errors can be generated for debug and self-diagnosis. The operation during injection of pseudo errors is identical to that for the occurrence of real errors. All configurations for the mask to the ERROROUT output, interrupt, or internal reset apply in the same way. • The ECM incorporates a loop-back function of the ERROROUT output that is used to diagnose the path to the ERROROUT pin. The status of the ERROROUT pin is reflected to the ECM master/checker error source status register and can be confirmed by reading the register.
Timeout function	The ECM incorporates a function that generates an ERROROUT output or internal reset when the count value of the delay timer matches with the delay timer compare register because the delay timer was not stopped during the interrupt processing after being started simultaneously with the occurrence of an interrupt request. The value counted by the delay timer is in cycles of the low-speed peripheral clock.
Register protection	A write-protection with a special sequence is incorporated to protect registers from inadvertent write access.
Others	The ECM is duplexed. The ERROROUT pin is duplexed to the two pins of the mater pin and the checker pin. ERROROUT output of the ECM master and ECM checker are constantly compared. Upon a mismatch, the ECM compare error (error source 26) occurs.

30.1.2 Error Sources and Safety Processing

Table 30.2 shows the error sources and safety processing to the ECM of RH850/E1M-S.

Table 30.2 List of Error Sources and Safety Processing (1/2)

Error Source No.	Module	Error Sources	Error Flag Set	Maskable Interrupt	FE level Interrupt	Internal Reset	ERROR OUT Output	Delay Timer Start

Note 1. Refer to **Section 19 Window Watchdog Timer (WDTA)** for the details of the errors.
Note 2. The internal reset generation is enabled in the initial state.
Note 3. Refer to **Section 29 Safety** for the details of the errors.
Note 4. Refer to **Section 3 CPU System** for the details of the errors.
Note 5. Refer to **Table 30.1 Specification Overview** for the details of the errors.
Note 6. Refer to **Section 27 Delta-Sigma AD Converter (DS-ADC)** for the details of the errors.
Note 7. Refer to **Section 26 A/D Converter (ADCB)** for the details of the errors.
Note 8. Refer to ***RH850/E1x Flash Memory User's Manual: Hardware Interface*** for the details of the errors.
Note 9. Refer to **Section 7 DMA** for the details of the errors.
Note 10. Refer to **Section 20 OS Timer (OSTM)** for the details of the errors.
Note 11. Operation of the device is not guaranteed if an FACI reset transfer error has occurred. When clearing the error signal output by the ERROROUT pin after release from the reset state, confirm that an FACI reset transfer error has not occurred by checking that an error state is not being indicated again.

Error sources are merged as described in **Table 30.3**.

Table 30.3 Merging of Error Sources

Error Source No	Module	Error Sources	Note
0	WDTA	WDTA error (WDTA0, WDTA1)	Overflows of WDTA0 and WADT1 are merged. The internal reset generation is enabled in the initial state.
6	RAM	Local RAM (CPU1, PCU): 2-bit ECC error, Local RAM (CPU1): Address parity error	2-bit ECC errors (local RAM CPU1, PCU) and address parity errors (excluding PCU) are merged.
7		Local RAM (CPU1, PCU): 1-bit ECC error Local RAM (CPU1): Parity bit error	1-bit ECC errors (local RAM CPU1, PCU) and parity bit errors (excluding PCU) are merged.
8		Global RAM: 2-bit ECC error and address parity error	2-bit ECC errors and address parity errors when global RAM is accessed from each master are merged.
9		Global RAM: 1-bit ECC error	1-bit ECC errors when global RAM is accessed from each master are merged.
10		Peripheral RAM (FlexRay, CAN, DFE, DTS, APA): 2-bit ECC error	2-bit ECC errors for RAM of peripheral circuits are merged.
11		Peripheral RAM (FlexRay, CAN, DFE, DTS, APA): 1-bit ECCerror	1-bit ECC errors for RAM of peripheral circuits are merged.
12	Code flash	Code flash 2-bit ECC error Code flash address parity error	2-bit ECC errors and address parity errors when code flash is accessed from each master are merged.
13		Code flash 1-bit ECC error	1-bit ECC errors when code flash is accessed from each master are merged.
21	GRG (Global RAM Guard)	GRG error	GRG errors from each master in access to the global RAM are merged.
22	PBG	PBG error	Peripheral guard errors for each peripheral circuit are merged.
25	Data parity	Data parity error	Data parity errors for each access path are merged.
37	DSADC	AD parity error	AD parity errors for DSADC0-7 and ADC0-1 are merged.
	ADC	AD parity error	
41	DMA	DTS RAM Data ECC SEC-DED	2-bit ECC errors and 1-bit errors for DTS RAM are merged.
42	BIST	Error detection using on-chip self-diagnostic (BIST) circuit	Errors for each self-diagnostic circuit are merged.
43	DMA	DMAVIOL (DMA violation access notice)	DMA violation accesses for DMAC0, DMAC1, and DTS are merged.

Note: The error sources other than those listed in **Table 30.3** are not merged.

30.1.3 Operations for ERROROUT Output

The $\overline{\text{ERROROUT\_M}}$ pin outputs the error level in the reset state or after release from the reset state. Clear the error output by following the procedure described in **Section 30.3.3**, **CAUTIONS** before use. As the $\overline{\text{ERROROUT\_C}}$ pin is multiplexed with a general-purpose port and other functions, select the $\overline{\text{ERROROUT\_C}}$ function before use. For settings, see **Section 2, Pins**.

ERROROUT output can be set in two operating modes: non-dynamic mode and dynamic mode. ERROROUT output is in synchronization with the occurrence of error source conditions and the error level is output as the pin state regardless of the dynamic mode pulse cycle.

Table 30.4 Operations for ERROROUT Output

Error Status ECMmSSE031 to ECMmSSE000 ECMmSSE115 to ECMmSSE100	Operating Mode ECMSL0 Bit	ERROROUT Output Operating Mode	ERROROUT Output Level	Error Status
0	0	Non-dynamic	High level	Normal
	1	Dynamic	Toggles (along with timer input)*1	Normal
1	0	Non-dynamic	Low level	Error
	1	Dynamic	Low level	Error

Note 1. See **Section 20 OS Timer (OSTM)** for the details.

30.1.3.1 Dynamic Mode Enable

1. Initialize OSTM0.
2. Set the ERROROUT output to normal output by setting the ECMmECT bit (m = M/C) in the ECM master/checker error clear trigger register to 1.
3. Set the ECMSL0 bit in the ECM error pulse configuration register to 1 to specify dynamic mode.
4. Start up OSTM0.

30.1.3.2 Dynamic Mode Disable

1. Set the ERROROUT output to error output by setting the ECMmEST bit (m = M/C) in the ECM master/checker error set trigger register to 1.
2. Stop OSTM0.
3. Clear the ECMSL0 bit in the ECM error pulse configuration register to 0 to specify non-dynamic mode.

30.1.4 Loop-Back Function

The ECM incorporates a loop-back function that is used to check the path to the ERROROUT pin. The output level of the ERROROUT pin can be checked with the ECMmSSE131 bit (m = M/C) in the ECM master/checker error source status register 1.

30.1.5 Pseudo Error Generation

The ECM incorporates a function that can generate pseudo errors for test or debug purposes. The operation of the ECM during injection of pseudo errors is identical to that for the occurrence of real errors. All configurations for error masks, interrupt, internal reset, or delay timer apply in the same way.

30.1.6 Error Status

The error status is indicated by ECM master/checker error source status register 0 and ECM master/checker error source status register 1. The error status is only cleared by setting the bit corresponding to the ECM error source status clear trigger register to 1 or an external reset. In case of an internal reset, the error status is kept and the error of the reset source can be confirmed by reading the ECM master/checker error source status register 0 and ECM master/checker error source status register 1 after release from the reset state.

30.1.7 Write-Protected Registers

Write protected registers are protected from inadvertent write access due to erroneous program execution, etc.

30.1.7.1 Sequence of Writing to the Write-Protected Registers

Writing to the write-protected registers is only possible with the protection unlock sequence described below.

1. Write the fixed value (0000 $00A5_H$) to the ECM protection command register ECMPCMD1 and ECM master/checker protection command register ECMmPCMD0.
2. Write the new setting to the write-protected registers in the ECM and ECMm. Write the value after a reset to the reserved bits.
3. Write the bitwise inverse of the setting value to the same registers as in step 2. Write the inverse of the value after a reset to the reserved bits.
4. Write the new setting to the same registers as in step 2. Write the value after a reset to the reserved bits.

A value can only be written to a write-protected register by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting is not written to the write-protected register, and the ECMPRERR bit of the ECM protection status register ECMPS is set to 1. (Although this is not a requirement, you can confirm if the values set in the targeted register was correctly written by checking that the setting of the ECMPRERR bit of the ECM protection status register ECMPS is 0 after step 4.)

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1 to 4 of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*1, writing to the protected register fails and the protection status bit in the protection status register is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. As to ECM, all registers under the module name of ECM, ECMM, or ECMC in **Appendix, List of Registers** are treated as “another register in the same module”.

30.1.8 Timeout Function for Interrupt Processing

The ECM incorporates a function that generates an ERROROUT output or internal reset when the count value of the delay timer incorporated in the ECM matches with the value of the ECM delay timer compare register because the delay timer was not stopped during the interrupt processing after being started simultaneously with the occurrence of an interrupt request. The timer counting is not stopped when a break occurs.

The counting of the delay timer always starts from 0. Configure the duration until an internal reset or ERROROUT output is generated with the settings of the ECM delay timer compare register.

In response to the occurrence of a new error source condition with the setting to start the delay timer while the delay timer is operating, the counter value of the delay timer which is currently operating is not reset. Instead, counting by the timer continues.

30.2 Block Diagram

Figure 30.1 shows the outline of the ECM, and **Figure 30.2** shows connection of the ECM.

The ERROROUT output, internal reset, and ERROROUTZ signals are active low, while the maskable and FE level interrupt signals are active high. Note that the ERROROUTZ signal for PIC1 is not toggled even if the ECM is in dynamic mode.

$\overline{\text{ERROROUT\_M}}$ is ORed with the ERROROUT output of the voltage sensor.

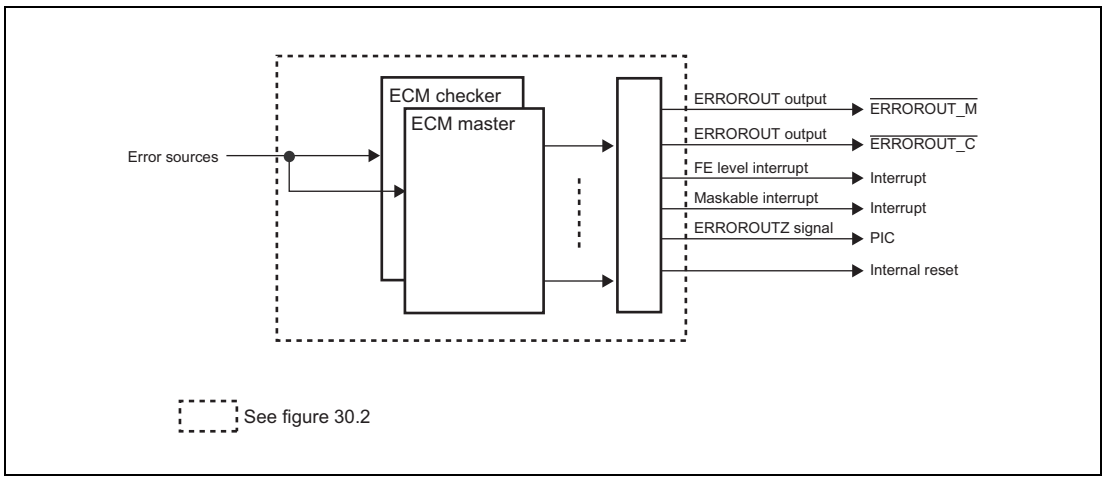

Figure 30.1 Outline of ECM

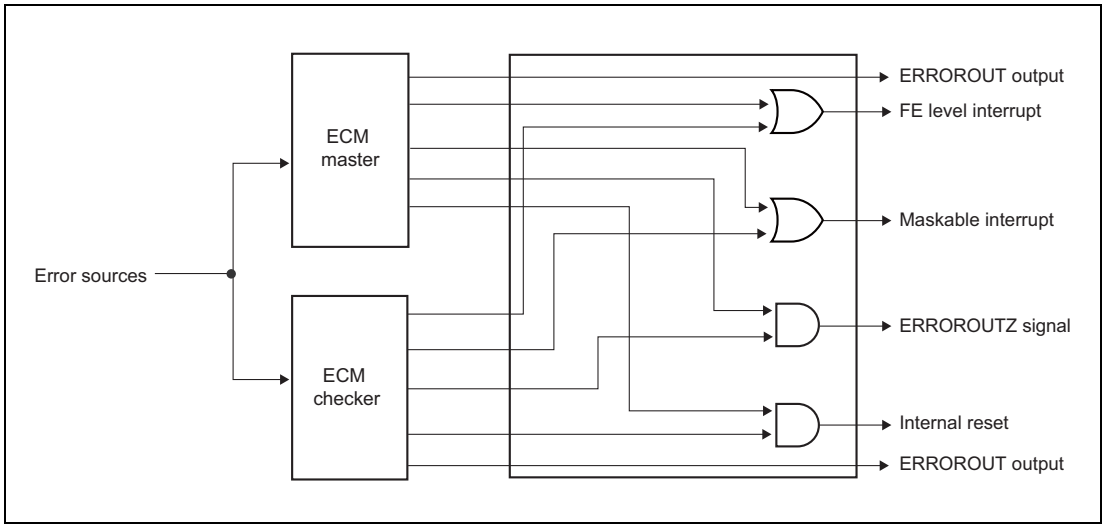

Figure 30.2 Connection of ECM

CAUTION

Pay attention to the difference in output voltage between the $\overline{\text{ERROROUT\_M}}$ and $\overline{\text{ERROROUT\_C}}$ pins because different power supply systems are used for those pins.

$\overline{\text{ERROROUT\_M}}$ pin: VCC (3.3 V)

$\overline{\text{ERROROUT\_C}}$ pin: **EVCC** (5 V) for P4_0 and P4_15; TTLVCC (5 V / 3.3 V) for P13_4

30.3 Register Specification

30.3.1 List of Registers

The ECM registers are divided into three address ranges. These are for the ECM master registers, the ECM checker registers, and the ECM registers common to both master and checker operation (ECM common registers). Writing to the common register area is effective simultaneously for both ECM master and checker. Reading from the common area returns the value for the ECM master. The ECM master registers and ECM checker registers allow separate writing.

The following shows the register map of the ECM master registers.

Table 30.5 List of Registers (ECM master)

<ECMM_base: FFCB 0000$_H$>

Register Symbol	Register Name	R/W	Value after Reset	Protection by Sequence	Address
ECMMESET	ECM master error set trigger register	W	00_H	Protected	<ECMM_base>
ECMMECLR	ECM master error clear trigger register	W	00_H	Protected	<ECMM_base> + 04_H
ECMMESSTR0	ECM master error source status register 0	R	0000 0000_H	Not protected	<ECMM_base> + 08_H
ECMMESSTR1	ECM master error source status register 1	R	0000 0000_H	Not protected	<ECMM_base> + $0C_H$
ECMMPCMD0	ECM master protection command register	W	Undefined	Not protected	<ECMM_base> + 10_H

The following shows the register map of the ECM checker registers.

Table 30.6 List of Registers (ECM checker)

<ECMC_base: FFCB 1000$_H$>

Register Symbol	Register Name	R/W	Value after Reset	Protection by Sequence	Address
ECMCESET	ECM checker error set trigger register	W	00_H	Protected	<ECMC_base>
ECMCECLR	ECM checker error clear trigger register	W	00_H	Protected	<ECMC_base> + 04_H
ECMCESSTR0	ECM checker error source status register 0	R	0000 0000_H	Not protected	<ECMC_base> + 08_H
ECMCESSTR1	ECM checker error source status register 1	R	0000 0000_H	Not protected	<ECMC_base> + $0C_H$
ECMCPCMD0	ECM checker protection command register	W	Undefined	Not protected	<ECMC_base> + 10_H

The following shows the register map of the ECM common registers.

Table 30.7 List of Registers (ECM common)

<ECM_base: FFCB 2000$_H$>

Register Symbol	Register Name	R/W	Value after reset	Protection by Sequence	Address
ECMEPCFG	ECM error pulse configuration register	R/W	00_H	Protected	<ECM_base>
ECMMICFG0	ECM maskable interrupt configuration register 0	R/W	$0000\ 0000_H$	Protected	<ECM_base> + 04_H
ECMMICFG1	ECM maskable interrupt configuration register 1	R/W	$0000\ 0000_H$	Protected	<ECM_base> + 08_H
ECMNMICFG0	ECM FE level interrupt configuration register 0	R/W	$0000\ 0000_H$	Protected	<ECM_base> + $0C_H$
ECMNMICFG1	ECM FE level interrupt configuration register 1	R/W	$0000\ 0000_H$	Protected	<ECM_base> + 10_H

ECMPE1	ECM pseudo error trigger register 1	W	$0000\ 0000_H$	Protected	<ECM_base> + 38_H
ECMDTMCTL	ECM delay timer control register	W	00_H	Protected	<ECM_base> + $3C_H$
ECMDTMR	ECM delay timer register	R	0000_H	Not protected	<ECM_base> + 40_H
ECMDTMCMP	ECM delay timer compare register	R/W	0000_H	Protected	<ECM_base> + 44_H
ECMDTMCFG0	ECM delay timer configuration register 0	R/W	$0000\ 0000_H$	Protected	<ECM_base> + 48_H
ECMDTMCFG1	ECM delay timer configuration register 1	R/W	$0000\ 0000_H$	Protected	<ECM_base> + $4C_H$
ECMDTMCFG2	ECM delay timer configuration register 2	R/W	$0000\ 0000_H$	Protected	<ECM_base> + 50_H
ECMDTMCFG3	ECM delay timer configuration register 3	R/W	$0000\ 0000_H$	Protected	<ECM_base> + 54_H

30.3.2 ECMmESET (m = M/C) — ECM Master/Checker Error Set Trigger Register

The ECM master/checker error set trigger register is for selecting output of the error signal from the ERROROUT pin. When an ECMmEST bit is set to 1, the ERROROUT pin immediately outputs the error signal. The output cannot be masked. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence. This register is always read as 00_H.

Access: This register can be written in 8-bit units.

Address: <ECMM_base>
<ECMC_base>

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ECMmESET
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 30.8 ECMmESET Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	ECMmESET	Error Set Trigger 0: Writing 0 is invalid 1: Set the output level from the ERROROUT pin to the error output.

CAUTIONS

Setting the ERROROUT output from the ERROROUT pin via the ECMmESET will set the ECMmSSE026 bit of the ECMmESSTR0 register (ECM compare error). Therefore, the ECMmESET or ECMmECLR register has to be set following the sequence below.

1. Set the ECMEMK026 bit of the ECMEMK0 register to “masked”.
2. Prevent the generation of interrupts by setting the ECMMIE026 bit of the ECMMICFG0 register to “prohibited” and the ECMNMIE026 bit of the ECMNMICFG0 register to “prohibited”.
3. Prevent generation of an internal reset by setting the ECMIRE026 bit of the ECMIRCFG0 register to “prohibited”.
4. Set the ERROROUT output bit by the ECMmESET register.
5. Clear error flags by setting the ECMCLSSE026 bit of the ECMESSTC0 register.
6. Make the following settings in accord with the condition of usage for the ECM compare error.
   If an ERROROUT is being output from the ERROROUT pin, set the ECMEMK026 bit of the ECMEMK0 register to “not masked”.
   If an interrupt is being enabled, set the ECMMIE026 bit of the ECMMICFG0 register to “enabled” or the ECMNMIE026 bit of the ECMNMICFG0 register to “enabled”.
   If an internal reset is being enabled, set the ECMIRE026 bit of the ECMIRCFG0 register to “enabled”.

30.3.3 ECMmECLR (m = M/C) — ECM Master/Checker Error Clear Trigger Register

The ECM master/checker error clear trigger register is for setting the error signal from the ERROROUT pin to the normal output. When an ECMmECT bit is set to 1, the ERROROUT pin outputs the normal signal level to indicate that an error has not been detected as long as there are no other sources that set the ERROROUT pin to the normal signal level, which indicates that an error has been detected. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence. This register is always read as 00_H.

Access: This register can be written in 8-bit units.

Address: <ECMM_base> + 04_H
<ECMC_base> + 04_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ECMmECT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 30.9 ECMmECLR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	ECMmECT	Error Clear Trigger 0: Writing 0 is invalid 1: Set the output level from the ERROROUT pin to the normal output.

CAUTIONS

Clearing of the ERROROUT pin is only possible if all errors, not masked by ECMEMK0/1, are cleared beforehand.

Clearing the ERROROUT output by the ECMmECLR register will set the ECMmSSE026 bit (ECM compare error) in the ECMmESSTR0 register. Therefore, the ECMmECLR register has to be set by following the sequence below.

1. Set the ECMEMK026 (ECM compare error) bit of the ECMEMK0 register to “masked”.
2. Disable interrupts by setting the ECMMIE026 bit of the ECMMICFG0 register to “disabled” and the ECMNMIE026 bit of the ECMNMICFG0 register to “disabled”.
3. Disable an internal reset by setting the ECMIRE026 bit of the ECMIRCFG0 register to “disabled”.
4. Clear error flags by setting the ECMmECLR (m = M/C) register.
5. Clear error flags by setting the ECMCLSSE026 bit of the ECMESSTC0 register.
6. Make the following settings in accordance with the condition of usage for the ECM compare error.
   - If ERROROUT will be output from the ERROROUT pin, set the ECMEMK026 bit in the ECMEMK0 register to "not masked".
   - If interrupts are to be enabled, set the ECMMIE026 bit in the ECMMICFG0 register to “enabled” or the ECMNMIE026 bit in the ECMNMICFG0 register to “enabled”.
   - If a reset exception is to be enabled, set the ECMIRE026 bit in the ECMIRCFG0 register to “enabled”.

30.3.4 ECMmESSTR0 (m = M/C) — ECM Master/Checker Error Source Status Register 0

The ECM master/checker error source status register represents the status of individual internal error sources, which is irrelevant to the setting of the error mask. The status can be cleared only by setting the bit corresponding to the ECM error source status clear trigger register 0 to 1 or by an external reset. When an internal reset will occur, the values of the flags of error source 0 (ECMmSSE000), error resource 4(ECMmSSE004), and error resource 12 (ECMmSSE012) will be retained.

Access: This register can be read in 32-bit units.

Address: <ECMM_base> + 08_H
<ECMC_base> + 08_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31, 30	ECMmSSE031, ECMmSSE030	Error Source Status ECMmSSE031 and ECMmSSE030 correspond to error sources 31 and 30. 0: Error not occurred 1: Error occurred
29, 28	—	Reserved When read, the value after reset is returned.
27 to 25	ECMmSSE027 to ECMmSSE025	Error Source Status ECMmSSE027 to ECMmSSE025 correspond to error sources 27 to 25. 0: Error not occurred 1: Error occurred
24, 23	—	Reserved When read, the value after reset is returned.
22 to 4	ECMmSSE022 to ECMmSSE004	Error Source Status ECMmSSE022 to ECMmSSE004 correspond to error sources 22 to 4. 0: Error not occurred 1: Error occurred
3 to 1	—	Reserved When read, the value after reset is returned.
0	ECMmSSE000	Error Source Status ECMmSSE000 corresponds to error source 0. 0: Error not occurred 1: Error occurred

30.3.5 ECMmESSTR1 (m = M/C) — ECM Master/Checker Error Source Status Register 1

The ECM master/checker error source status register 1 represents the status of individual internal error sources, which is irrelevant to the setting of the error mask. The status can be cleared only by setting the bit corresponding to the ECM error source status clear trigger register 1 to 1 or by an external reset. When an internal reset will occur, The value of flag of the delay timer overflow (ECMmSSE129) will be retained.

Access: This register can be read in 32-bit units.

Address: <ECMM_base> + $0C_H$
<ECMC_base> + $0C_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 30.11 ECMmESSTR1 Register Contents

Bit Position	Bit Name	Function
31	ECMmSSE131	Indicates the ERROROUT output loopback status. 0: The ERROROUT_m pin outputs the low level. 1: The ERROROUT_m pin outputs the high level. Note: m = M/C
30	ECMmSSE130	Indicates the ECMmESET write status. 0: No error 1: Error is set by the ECMmEST bit of the ECMmESET register
29	ECMmSSE129	Indicates whether delay timer overflow has occurred. 0: Delay timer overflow not occurred 1: Delay timer overflow occurred
28 to 13	—	Reserved When read, the value after reset is returned.
12 to 9	ECMmSSE112 to ECMmSSE109	Error Source Status ECMmSSE109 to ECMmSSE112 correspond to error sources 44 to 41. 0: Error not occurred 1: Error occurred
8	—	Reserved When read, the value after reset is returned.
7 to 5	ECMmSSE107 to ECMmSSE105	Error Source Status ECMmSSE107 to ECMmSSE105 correspond to error sources 39 to 37. 0: Error not occurred 1: Error occurred
4 to 0	—	Reserved When read, the value after reset is returned.

30.3.6 ECMmPCMD0 (m = M/C) — ECM Master/Checker Protection Command Register

This register is used to protect targeted registers against unauthorized write access such as incorrect programming.

Refer to **Section 30.3.1, List of Registers**, for the protected registers by the ECM master/checker protection command register.

Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be written in 32-bit units.

Address: <ECMM_base> + 10_H
<ECMC_base> + 10_H

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 to 0	ECMmREG0 [7:0]	Protection command that enables writing to write protected ECMm registers.

30.3.7 ECMEPCFG — ECM Error Pulse Configuration Register

The ECM error pulse configuration register is used to configure the ERROROUT output operation of ERROROUT pins. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be read/written in 8-bit units.

Address: <ECM_base>

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ECMSL0

Table 30.18 ECMIRCFG0 Register Contents

Bit Position	Bit Name	Function
31, 30	ECMIRE031, ECMIRE030	ECM Internal Reset Generation Control ECMIRE031 and ECMIRE030 correspond to error sources 31 and 30. 0: Internal reset generation disabled 1: Internal reset generation enabled
29, 28	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
27 to 25	ECMIRE027 to ECMIRE025	ECM Internal Reset Generation Control ECMIRE027 to ECMIRE025 correspond to error sources 27 to 25. 0: Internal reset generation disabled 1: Internal reset generation enabled
24, 23	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
22 to 4	ECMIRE022 to ECMIRE004	ECM Internal Reset Generation Control ECMIRE022 to ECMIRE004 correspond to error sources 22 to 4. 0: Internal reset generation disabled 1: Internal reset generation enabled
3 to 1	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	ECMIRE000	ECM Internal Reset Generation Control ECMIRE000 corresponds to error source 0. 0: Internal reset generation disabled 1: Internal reset generation enabled

30.3.13 ECMIRCFG1 — ECM Internal Reset Configuration Register 1

The ECM internal reset configuration register 1 is used to set the generation of internal resets in response to internal errors. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be read/written in 32-bit units.

Address: <ECM_base> + 18_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	ECMIRE129	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 30.19 ECMIRCFG1 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
29	ECMIRE129	ECM Internal Reset Occurrence Control Corresponds to delay timer overflow. 0: Internal reset generation disabled 1: Internal reset generation enabled
28 to 13	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
12 to 9	ECMIRE112 to ECMIRE109	ECM Internal Reset Control ECMIRE112 to ECMIRE109 correspond to error sources 44 to 41. 0: Internal reset generation disabled 1: Internal reset generation enabled
8, 7	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
6, 5	ECMIRE106, ECMIRE105	ECM Internal Reset Control ECMIRE106 and ECMIRE105 correspond to error sources 38 and 37. 0: Internal reset generation disabled 1: Internal reset generation enabled
4 to 0	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.

30.3.14 ECMEMK0 — ECM Error Mask Register 0

The ECM error mask register 0 is used to set masking of the individual error sources of the ERROROUT output. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be read/written in 32-bit units.

Address: <ECM_base> + $1C_H$

Value after reset: $0000\ 0000_H$

Table 30.20 ECMEMK0 Register Contents

Bit Position	Bit Name	Function
31, 30	ECMEMK031, ECMEMK030	ECM ERROROUT Output Mask Control ECMEMK031 and ECMEMK030 correspond to error sources 31 and 30. 0: ERROROUT output not masked 1: ERROROUT output masked
29, 28	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
27 to 25	ECMEMK027 to ECMEMK025	ECM ERROROUT Output Mask Control ECMEMK027 to ECMEMK025 correspond to error sources 27 to 25. 0: ERROROUT output not masked 1: ERROROUT output masked
24, 23	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
22 to 4	ECMEMK022 to ECMEMK004	ECM ERROROUT Output Mask Control ECMEMK022 to ECMEMK004 correspond to error sources 22 to 4. 0: ERROROUT output not masked 1: ERROROUT output masked
3 to 1	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	ECMEMK000	ECM ERROROUT Output Mask Control ECMEMK000 corresponds to error source 0. 0: ERROROUT output not masked 1: ERROROUT output masked

30.3.15 ECMEMK1 — ECM Error Mask Register 1

The ECM error mask register 1 is used to set masking of the individual error sources of the ERROROUT output. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be read/written in 32-bit units.

Address: <ECM_base> + 20_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 30.21 ECMEMK1 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
29	ECMEMK129	ECMEMK129 corresponds to an overflow of the delay timer. 0: ERROROUT output not masked 1: ERROROUT output masked
28 to 13	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
12 to 9	ECMEMK112 to ECMEMK109	ECM ERROROUT Output Mask Control ECMEMK112 to ECMEMK109 correspond to error sources 44 to 41. 0: ERROROUT output not masked 1: ERROROUT output masked
8	—	Reserved When read, the value after reset is returned. When writing to this bit, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
7 to 5	ECMEMK107 to ECMEMK105	ECM ERROROUT Output Mask Control ECMEMK107 to ECMEMK105 correspond to error sources 39 to 37. 0: ERROROUT output not masked 1: ERROROUT output masked
4 to 0	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.

30.3.16 ECMESSTC0 — ECM Error Source Status Clear Trigger Register 0

The ECM error source status clear trigger register 0 is used to clear the individual error source status of the ECM master/checker error source status register 0. Both the error status of the ECM master and the ECM checker are cleared simultaneously. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be written in 32-bit units.

Address: <ECM_base> + 24_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 30.22 ECMESSTC0 Register Contents

Bit Position	Bit Name	Function
31, 30	ECMCLSSE031, ECMCLSSE030	ECM Error Status Clear ECMCLSSE031 and ECMCLSSE030 correspond to error sources 31 and 30. 0: Corresponding error status unchanged 1: Corresponding error status cleared
29, 28	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
27 to 25	ECMCLSSE027 to ECMCLSSE025	ECM Error Status Clear ECMCLSSE027 to ECMCLSSE025 correspond to error sources 27 to 25. 0: Corresponding error status unchanged 1: Corresponding error status cleared
24, 23	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
22 to 4	ECMCLSSE022 to ECMCLSSE004	ECM Error Status Clear ECMCLSSE022 to ECMCLSSE004 correspond to error sources 22 to 4. 0: Corresponding error status unchanged 1: Corresponding error status cleared
3 to 1	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	ECMCLSSE000	ECM Error Status Clear ECMCLSSE000 corresponds to error source 0. 0: Corresponding error status unchanged 1: Corresponding error status cleared

30.3.17 ECMESSTC1 — ECM Error Source Status Clear Trigger Register 1

The ECM error source status clear trigger register 1 is used to clear the individual error source status of the ECM master/checker error source status register 1. Both the error status of the ECM master and the ECM checker are cleared simultaneously. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be written in 32-bit units.

Address: <ECM_base> + 28_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	ECMCLSSE130	ECMCLSSE129	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 30.23 ECMESSTC1 Register Contents

Bit Position	Bit Name	Function
31	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
30, 29	ECMCLSSE130, ECMCLSSE129	ECM Error Status Clear ECMCLSSE130 and ECMCLSSE129 correspond to writing status and delay timer overflow in the ECMmESET register. 0: Corresponding error status unchanged 1: Corresponding error status cleared
28 to 13	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
12 to 9	ECMCLSSE112 to ECMCLSSE109	ECM Error Status Clear ECMCLSSE112 to ECMCLSSE109 correspond to error source 44 to 41. 0: Corresponding error status unchanged 1: Corresponding error status cleared
8	—	Reserved When writing to this bit, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
7 to 5	ECMCLSSE107 to ECMCLSSE105	ECM Error Status Clear ECMCLSSE107 to ECMCLSSE105 correspond to error source 39 and 37. 0: Corresponding error status unchanged 1: Corresponding error status cleared
4 to 0	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.

30.3.18 ECMPCMD1 — ECM Protection Command Register

Refer to **Section 30.3.1, List of Registers**, for the protected registers by the ECM protection command register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be written in 32-bit units.

Address: <ECM_base> + $2C_H$

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 30.24 ECMPCMD1 Register Contents

Bit Position	Bit Name	Function
31 to 18	—	Reserved When writing to these bits, write the value after reset.
7 to 0	ECMREG1[7:0]	Protection command that enables writing to write protected ECM registers.

30.3.19 ECMPS — ECM Protection Status Register

The ECM protection status register is used to verify the write protected register has been written successfully or not. Refer to **Section 30.1.7, Write-Protected Registers**.

Access: This register can be read in 8-bit units.

Address: <ECM_base> + 30_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ECMPRERR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 30.25 ECMPS Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned.
0	ECMPRERR	ECM Protection Status Indicates whether writing to a write protected register is failed or not. 0: Writing was successfully completed. 1: Writing failed

30.3.20 ECMPE0 — ECM Pseudo Error Trigger Register 0

The ECM pseudo error trigger register is used to generate a pseudo error for test purposes. The ECM operation in response to the generation of a pseudo error is identical to that in response to a real error source. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be written in 32-bit units.

Address: <ECM_base> + 34_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	R	R	R	W

Table 30.26 ECMPE0 Register Contents

Bit Position	Bit Name	Function
31, 30	ECMPE031, ECMPE030	ECM Pseudo Error Trigger ECMPE031, ECMPE030 correspond to error sources 31 to 30. 0: Pseudo error not generated 1: Generates corresponding pseudo error
29, 28	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
27 to 25	ECMPE027 to ECMPE025	ECM Pseudo Error Trigger ECMPE027 to ECMPE025 correspond to error sources 27 to 25. 0: Pseudo error not generated 1: Generates corresponding pseudo error
24, 23	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
22 to 4	ECMPE022 to ECMPE004	ECM Pseudo Error Trigger ECMPE022 to ECMPE004 correspond to error sources 22 to 4. 0: Pseudo error not generated 1: Generates corresponding pseudo error
3 to 1	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	ECMPE000	ECM Pseudo Error Trigger ECMPE000 corresponds to error source 0. 0: Pseudo error not generated 1: Generates corresponding pseudo error

30.3.21 ECMPE1 — ECM Pseudo Error Trigger Register 1

The ECM pseudo error trigger register 1 is used to generate a pseudo error for test purposes. The ECM operation in response to the generation of a pseudo error is identical to that in response to a real error source. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be written in 32-bit units.

Address: <ECM_base> + 38_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	ECMPE129	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 30.27 ECMPE1 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
29	ECMPE129	ECM Pseudo Error Trigger Corresponds to delay timer overflow. 0: Pseudo error not generated 1: Generates corresponding pseudo error
28 to 13	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
12 to 9	ECMPE112 to ECMPE109	ECM Pseudo Error Trigger ECMPE112 to ECMPE109 correspond to error sources 44 to 41. 0: Pseudo error not generated 1: Generates corresponding pseudo error
8	—	Reserved When writing to this bit, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
7 to 5	ECMPE107 to ECMPE105	ECM Pseudo Error Trigger ECMPE107 to ECMPE105 correspond to error sources 39 to 37. 0: Pseudo error not generated 1: Generates corresponding pseudo error
4 to 0	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.

30.3.22 ECMDTMCTL — ECM Delay Timer Control Register

The ECM delay timer control register is used to control the delay timer. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be written in 8-bit units.

Address: <ECM_base> + $3C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	ECMSTP	ECMSTA
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	W	W

Table 30.28 ECMDTMCTL Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
1	ECMSTP	Delay Timer Stop Writing 1 to this bit initializes the delay timer counter, causing the delay timer to stop. Simultaneously, the ECMSTA bit is set to 0.
0	ECMSTA	Delay Timer Stop Writing 1 to this bit starts the delay timer when an interrupt is generated. (Writing 0 to this bit stops the delay timer.)

30.3.23 ECMDTMR — ECM Delay Timer Register

The ECM delay timer register represents the counter value of the delay timer.

The delay timer counter is initialized by writing 1 to the ECMSTP bit or writing 0 to the ECMSTA bit of the ECM delay timer control register (ECMDTMCTL).

Access: This register can be read in 16-bit units.

Address: <ECM_base> + 40_H

Value after reset: 0000_H

30.3.24 ECMDTMCMP — ECM Delay Timer Compare Register

A delay timer overflow signal is generated to set the ECMmSSE129n bit when this register matches with the value of the delay timer counter. Writing data to this register has to be conducted while the delay timer is stopped. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be read/written in 16-bit units.

Address: <ECM_base> + 44_H

Value after reset: 0000_H

30.3.25 ECMDTMCFG0 — ECM Delay Timer Configuration Register 0

The ECM delay timer configuration register 0 is used to set enable/disable of the delay timer start caused by maskable interrupts in response to errors. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be read/written in 32-bit units.

Address: <ECM_base> + 48_H

Value after reset: $0000\ 0000_H$

8, 7	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
6, 5	ECMTE106, ECMTE105	ECM Delay Timer Start Control ECMTE106 and ECMTE105 correspond to maskable interrupts generated by error sources 38 and 37. 0: Delay timer start disabled 1: Delay timer start enabled
4 to 0	—	Reserved When read, the value after reset is returned. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.

30.3.27 ECMDTMCFG2 — ECM Delay Timer Configuration Register 2

The ECM delay timer configuration register 2 is used to set enable/disable of the delay timer start caused by FE level interrupts in response to errors. You have to follow a predetermined protection unlock sequence for writing data to this register. Refer to **Section 30.1.7, Write-Protected Registers**, for the details of the protection unlock sequence.

Access: This register can be read/written in 32-bit units.

Section 31 Data CRC (DCRA)

This section explains the data CRC function A (DCRA).

Table 31.1 shows the register base address.

Table 31.1 Register Base Address

Base Address Name	Base Address
<DCRA0_base>	FFF7 0000_H

31.1 Overview

31.1.1 Functional Overview

The data CRC function A can verify or generate data streams protected by CRC with various lengths and different bit widths.

- Generating polynomial: Either 32-Ethernet (32-bit CRC code generation) or 16-CCITT (16-bit CRC code generation) can be selected with a register.
  The generating polynomials are as follows:
  - 32-Ethernet
    $(x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1)$
  - 16-CCITT $(x^{16} + x^{12} + x^5 + 1)$
- When 32-Ethernet is selected, a 32-bit CRC code is generated to a data block of an arbitrary length in units of 8/16/32 bits as specified with a register.
- When 16-CCITT is selected, a 16-bit CRC code is generated to a data block of an arbitrary length in units of 8/16/32 bits as specified with a register.
- After setting an initial value in the CRC data register (DCRA0COUT), the calculation is carried out by transferring an input data to the CRC input register (DCRA0CIN), and the result of the calculation is stored in the CRC data register (DCRA0COUT).

31.1.2 Block Diagram

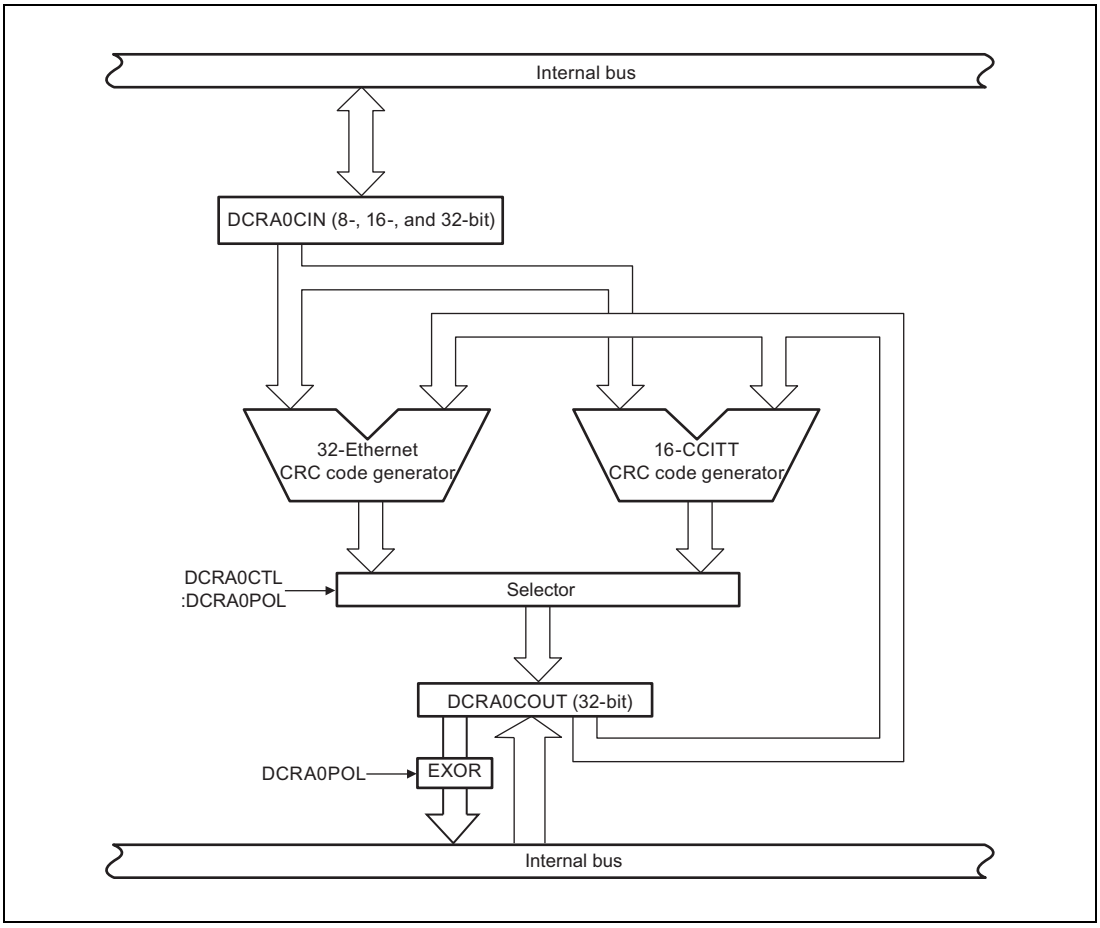

Figure 31.1 Data CRC Function A Block Diagram

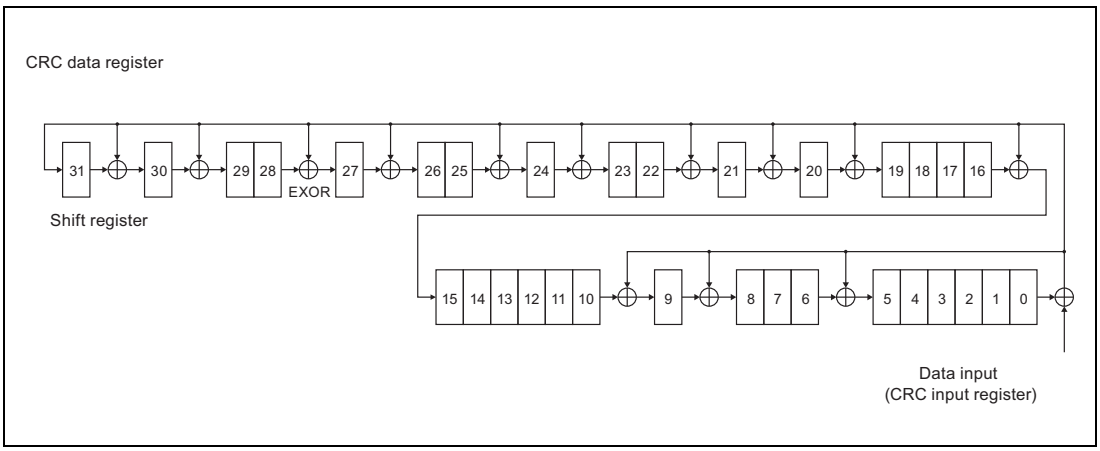
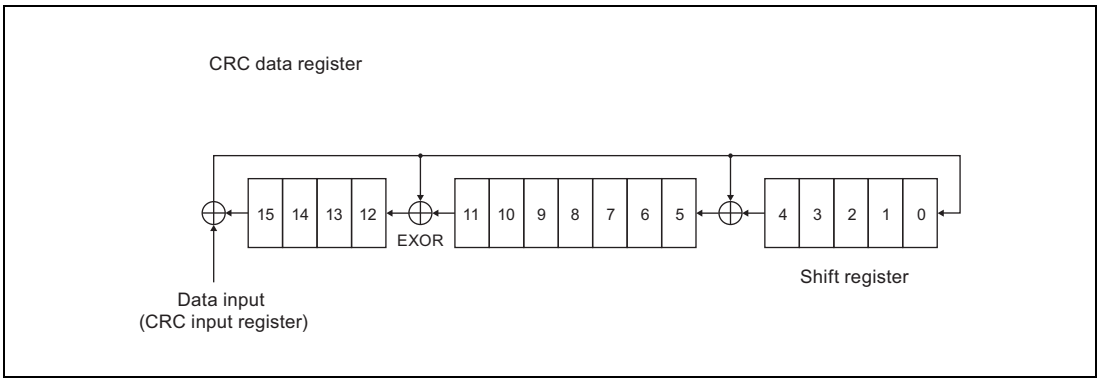
31.1.3 Calculation Circuit

- 32-Ethernet



- 16-CCITT



31.2 Register Specifications

31.2.1 List of Registers

Table 31.2 List of DCRA Registers

Register Name	Function	Address
DCRA0CIN	CRC input register	<DCRA0_base> + 00_H
DCRA0COUT	CRC data register	<DCRA0_base> + 04_H
DCRA0CTL	CRC control register	<DCRA0_base> + 20_H

31.2.2 DCRA0CIN — CRC Input Register

The CRC input register is a 32-bit register that stores input data.

When data is set in this register, the CRC code corresponding to the input is generated.

The DCRA0ISZ1 and DCRA0ISZ0 bits of the CRC control register specify the effective bit width used in the CRC calculation circuit.

Access: This register can be read/written in 32-bit units.

Address: FFF7 0000$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DCRA0CIN															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DCRA0CIN															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 31.3 DCRA0CIN Register Contents

Bit Position	Bit Name	Function
31 to 0	DCRA0CIN [31:0]	Input Data for CRC Calculation The effective bit widths are: • For 32 bits: DCRA0CIN[31:0] • For 16 bits: DCRA0CIN[15:0] • For 8 bits: DCRA0CIN[7:0]

31.2.3 DCRA0COUT — CRC Data Register

The CRC data register is a 32-bit register that stores the result of CRC (32-Ethernet/16-CCITT) calculation.

Access: This register can be read/written in 32-bit units.

Address: FFF7 0004$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DCRA0COUT															
Value after reset *1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DCRA0COUT															
Value after reset *1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. The read value after reset is 0000 0000$_H$ since the 32-bit Ethernet polynomial is selected as the CRC generating function after reset.

Table 31.4 DCRA0COUT Register Contents

Bit Position	Bit Name	Function
31 to 0	DCRA0COUT [31:0]	Result of the CRC Code Generation When the 16-bit CCITT polynomial is enabled, bits 15 to 0 show the CRC result. Bits 31 to 16 are undefined. The read value of this register is a value obtained by performing EXOR calculation for the following value: • For 32-bit Ethernet polynomial: FFFF FFFF$_H$ • For 16-bit CCITT polynomial: 0000$_H$ For example, when the 32-bit Ethernet polynomial is selected and DCRA0COUT is 5555 5555$_H$, AAAA AAAA$_H$ is read.

CAUTION

This register must be initialized (setting the initialized start value) before the first data of the data block is written to the DCRA0CIN register.

31.2.4 DCRA0CTL — CRC Control Register

The CRC control register is a bit register that controls CRC.

Access: This register can be read/written in 8-bit units.

Address: FFF7 0020_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	DCRA0ISZ[1:0]		DCRA0POL
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 31.5 DCRA0CTL Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Reserved
2,1	DCRA0ISZ[1:0]	Input Data Width Selection These bits specify the effective input data width of the CRC input register. bit2 bit1 0 0: Sets the effective input data width to 32 bits (DCRA0CIN31-0) 0 1: Sets the effective input data width to 16 bits (DCRA0CIN15-0) 1 0: Sets the effective input data width to 8 bits (DCRA0CIN7-0) 1 1: Setting prohibited
0	DCRA0POL	CRC Generating Polynomial Selection This bit specifies the CRC generating polynomial. 0: Selects 32-Ethernet (32-bit CRC code generation) 1: Selects 16-CCITT (16-bit CRC code generation)

CAUTIONS

1. **After changing the CRC generating function (DCRA0CTL.DCRA0POL), the DCRA0COUT register must be initialized.**
2. **The CRC bit width (DCRA0CTL.DCRA0ISZ[1:0]) must be set according to the data block bit width. Switching the CRC bit width is not allowed during processing of a data block. After the final CRC result is read from the DCRA0COUT register, the bit width can be changed. In this case, the DCRA0COUT register must be initialized (the initial start value must be set) afterwards.**

31.3 Functions

The data CRC function A generates a CRC (cyclic redundancy check) of an arbitrary data block length. The data is transferred to the data CRC function in 8-, 16- or 32-bit units. The CRC polynomial can either be selected for 32-bit Ethernet or 16-bit CCITT.

The initial start value must be set in the DCRA0COUT register before the first write access to the CRC input register (DCRA0CIN) is performed.

The flow chart below shows the CRC generating procedure.

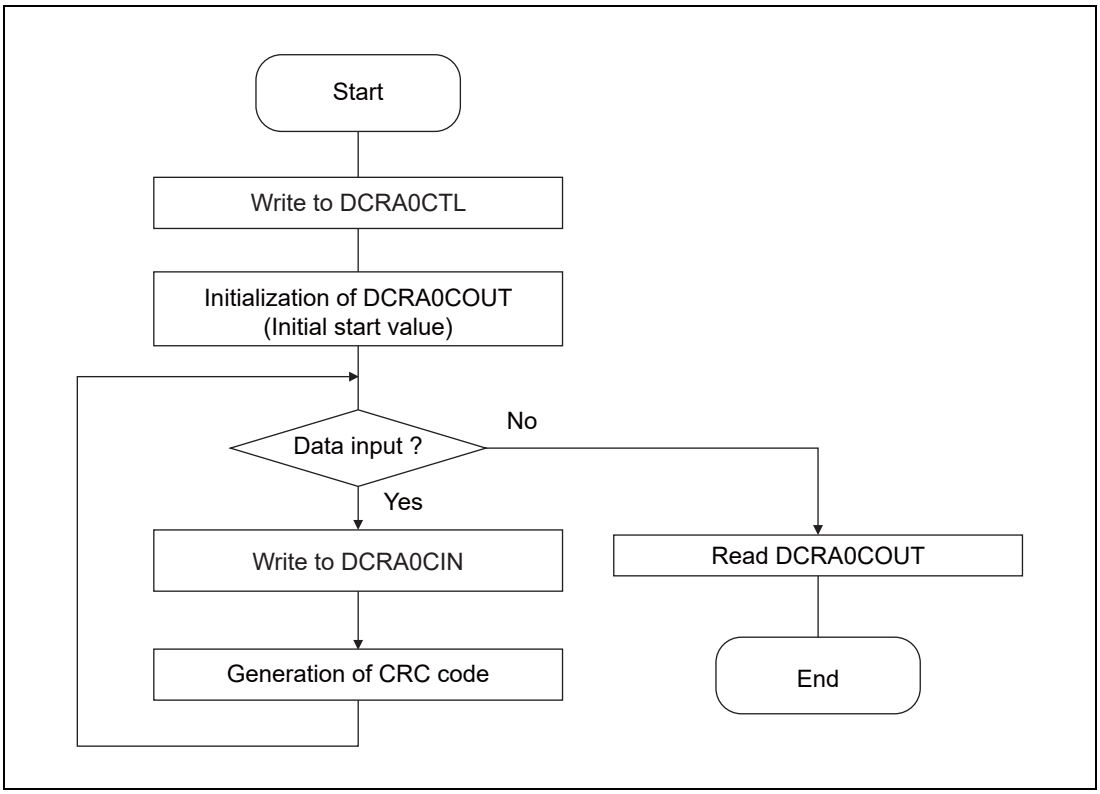


Figure 31.2 Flow of Data CRC Function A

NOTES

1. Before writing the first data to DCRA0CIN, the CRC output register DCRA0COUT must be initialized with the start value (initial start value).
2. Re-initialization of DCRA0COUT (initial start value) is also necessary when the polynomial is changed by changing DCRA0CTL.DCRA0POL.

Section 32 On-Chip Debugging Unit (OCD)

32.1 Debug Function

This microcontroller has an on-chip debug function. By using the on-chip debug emulator, programs can be debugged with the microcontroller mounted in the target system.

CAUTION

The debug functions described in this section are supported by the microcontroller but whether they are usable depends on the debugger. For details on debugging, see the user's manual of the debugger.

(1) Debug Interface

This microcontroller supports the NEXUS JTAG Interface, and low-pin debug interface (4-pin) (hereinafter referred to as LPD (4-pin)) as debug interfaces. Also it incorporates the AUD-RAM monitor and supports the AUD-RAM monitor interfaces to monitor and tune on-chip RAM data, peripheral registers, etc.

For the AUD-RAM monitor, see **Section 32.5, AUD-RAM Monitor (AUDR)**.

(2) Debug Monitoring

In debug mode, the monitoring program proceeds in the debugging-only area.

The basic debug functions below can be used by running a monitoring program.

- Downloading user programs
- Reading and writing user resources including the memory and registers while the user program is suspended
- Running the user program starting at any address

(3) On-chip Break Function

12 break points are included in the CPU1 and PCU each. Four of them can be designated for any access (access address and access data).

(4) Software Break Function

A software break point can be designated for any address.

(5) Forced Break Function

Execution of the user program can be forcibly suspended.

(6) Debug Interrupt Interface Function

Execution of the user program can be forcibly suspended by asserting an input signal on the $\overline{\text{EVTI}}$ pin from the outside.

(7) Forced Reset Function

The micro controller (this product) can be forcibly reset.

(8) Real-time RAM Monitoring (RRM)

The memory can be read during program execution. Because this read access uses debug-dedicated DMA, it has minimal effect on program execution.

(9) Dynamic Memory Modification (DMM)

The memory can be written during program execution. Because this write access uses debug-dedicated DMA, it has minimal effect on program execution.

(10) Timer Function

Using a 32-bit counter, the time for running the user program can be measured based on the clock for debug.

(11) Mask Function

A reset factor (external reset, software reset, and ECM reset) can be masked.

(12) Event Detection Function

Events can be detected by the following: execution address, access address, access data, range (comparison in size), and sequential execution.

(13) Trigger Input Interface

This microcontroller incorporates an event trigger input interface to accept external events. It can accept an external event in response to an input from the $\overline{\text{EVTI}}$ pin.

(14) Trigger Output Interface

An event trigger output interface is included in this microcontroller to notify the external debug device of event detection and the like. Output from the $\overline{\text{EVTO}}$ pin can output a trigger of event detection to the outside.

(15) Hot Plug-in Function

Debugging can be started in normal operating mode without an input of an external reset.

(16) Security Function

To prevent the contents of the flash memory from being read by an unauthorized person, a 128-bit ID code (OCD_ID) can be written to the microcontroller. If the code the user inputs when starting a debugger does not match the ID code written to the microcontroller, the flash memory cannot be accessed.

(17) Calibration Function

Emulating the flash memory and tuning ROM data can be executed by using the ERAM, the memory for emulation. For details, **Section 32.2, Calibration Function**.

(18) Tracing Function

Execution history, data changes, etc. of the user program can be obtained. For details, see **Section 32.3, Trace Control Function**.

(19) Multi Core Debug Function

The following functions are supported as the multi core debugger for the CPU1 and PCU: synchronization functions (including reset, execution, and break), synchronous setting.

32.2 Calibration Function

This microcontroller includes the emulation RAM as an emulation memory for the on-chip flash memory.

(1) Emulation RAM

An 8-Kbyte emulation RAM is provided.

(2) Flash Emulation Function

The emulation RAM can be mapped to any areas in the flash area .

- Bank 0: 8KB

(3) Tuning Function

The ROM data can be dynamically tuned during execution of the user program via the emulation RAM that has mapped to the flash area.

(4) Flash Cache Clear Function

The flash cache is cleared when the emulation RAM mapping is set. This preserves coherency of the contents between the on-chip flash memory or the emulation RAM and the flash cache memory.

32.3 Trace Control Function

This product can get the execution history of user program and changes of data by the software trace function.

The software information can be output through the debug interface (LPD (4-pin)).

32.4 Peripheral Break Control

The peripheral break function stops the peripheral modules if the user program is stopped, for instance upon a breakpoint hit.

The on-chip modules can be classified into two by its operation at the time of peripheral break as follows:

1. Modules that are unconditionally stopped: WDTA0, WDTA1
2. Modules that can select abeyance or continuation*1: OSTM0, OSTM1, OSTM2, TAPA2, TAPA3, TSG20, TSG21, ATU4

Note 1. When stopping the peripheral modules by peripheral break, TAPAn forcibly places TSG2n PWM output pins TSOn1 to TSOn6 in the Hi-Z state. Also, the value of the TAPAnHOF[10:8] bits in the TAPAnFLG register is set to 111_B.

32.5 AUD-RAM Monitor (AUDR)

32.5.1 Overview

This LSI includes the AUD (Advanced User Debugger) -RAM monitor (AUDR) to support debugging of a user program under conditions as if it were actually mounted in the system. The AUDR can read and write the resources mapped to memory spaces including an on-chip memory and a peripheral register during LSI operation.

Table 32.1 lists the outlines of the AUDR and **Figure 32.1** shows the block diagram of the AUDR.

Table 32.1 Outlines of the AUDR

Item	Outline
Transfer method	Clock-synchronous parallel interface (4 bits)
Transfer clock generation	Transfer clock is generated at the external host (RAM monitor tool) side.
Transfer clock frequency	Maximum 20 MHz
Access area	Physical address area on the system bus
Access data size	8, 16, 32, and 64 bits
Access address input bit width	8, 16, 24, and 32 bits The same values as those of the previous access address are used for the upper bits of access address, which are not input.
Data transfer method	• Single transfer: Single data is transferred to the access address that has been input. • Continuous transfer: Up to 16 data are continuously transferred from the access address that has been input. The access address is automatically incremented depending on data size.
I/O pin	7 pins ($\overline{\text{AUDRST}}$, AUDCK, $\overline{\text{AUDSYNC}}$, and AUDATA3 to AUDATA0)
Function	• RAM monitor function: Read and write are performed from a system bus to an accessible physical address area. This function enables reference to and modification of an on-chip memory, a peripheral register, and the like. • Configuration information retention (startup communication) function: The values of the AUDATA3 to AUDATA0 pins at the time of release from the internal reset state are retained. This function is used for communication with a RAM monitor tool. • Synchronization communication (message board) function: This flag register is used for communication of the firmware operated by the CPU with a RAM monitor tool.

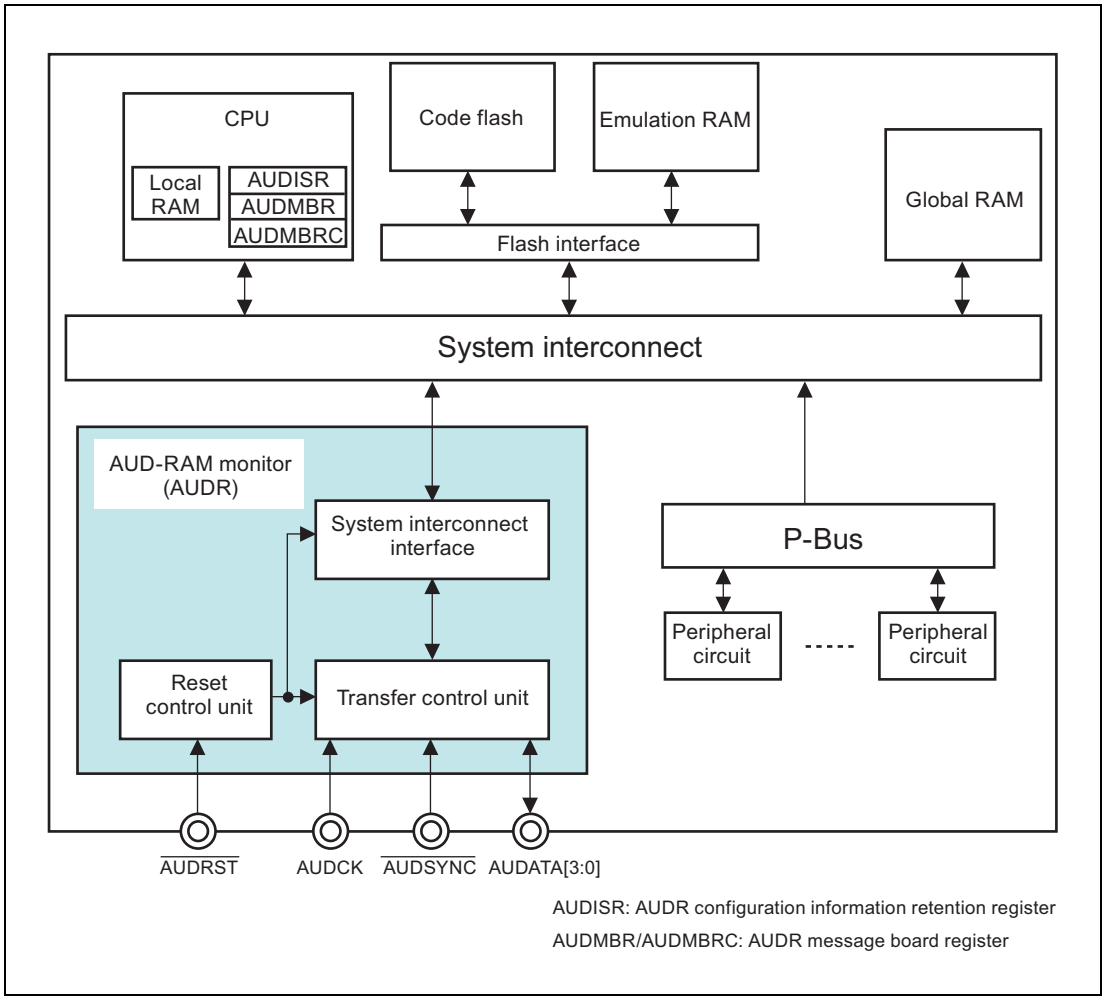

Figure 32.1 Blok Diagram of the AUDR

32.5.2 I/O Pins

Table 32.2 lists the I/O pins of the AUDR.

Table 32.2 I/O Pins of AUDR

Pin Name	I/O	Description
$\overline{\text{AUDRST}}$	Input	AUDR reset input pin. Inputting L to this pin resets the AUDR, but it does not initialize the AUDISR and AUDMBR/AUDMBRC (described below). When this pin is not connected, it is internally pulled-down.
AUDCK	Input	External clock input pin. The frequency of clock that can be input is less than 20 MHz. When this pin is not connected, it is internally pulled-up.
$\overline{\text{AUDSYNC}}$	Input	Timing control signal input pin. L: A command, an address, and write data are input and the status flag is output. H: The read-out data is output, and it causes the idle state. When this pin is not connected, it is internally pulled-up. **CAUTION** This pin should not be negated (to H) until the ready state is entered by inputting a command or the like from the outside to the AUDATA. For details, see the protocol mentioned below.
AUDATA3 to AUDATA0	Input/output	4-bit parallel data I/O pin. The following information is input and output by time division. • Command (input) • Address (input) • Write data (input)/Read data (output) • Status flag (output) When this pin is not connected, it is internally pulled-up.

32.5.3 Description of Registers

Table 32.3 lists the registers related to the AUDR.

These registers can be accessed only from CPU1.

Table 32.3 List of Registers

Register Name	Abbreviation	Value after Reset	R/W	Address	Access Size	Reference Section
AUDR configuration information retention register	AUDISR	$000X_H$*1	R	FA00 5000_H*4	16 *5	**32.5.3.1**
AUDR message board register	AUDMBR	0000_H	R/W *2	FA00 5004_H*4	16 *5	**32.5.3.2**
	AUDMBRC	0000_H	R/W *2,*3	FA00 5008_H*4	16 *5	

Note 1. The values of the AUDATA3 to AUDATA0 pins at the time of release from the internal reset state are retained in bit 3 to 0.

Note 2. Only 1 can be written to the bits that have been set to 0. 0 cannot be written to the bits that have been set to 1.

Note 3. All bits are cleared to 0 after read.

Note 4. The addresses of the AUDISR and AUDMBR/AUDMBRC bits differ when they are accessed from the program and the AUDR tool. Although these addresses are “Access prohibited” area, it is capable of accessing to this addresses for AUDR tool and communication.

Note 5. If an access in data sizes other than 16 bits (half-word) is performed, correct operation is not guaranteed.

32.5.3.1 AUDISR — AUDR Configuration Information Retention Register

AUDISR is a 16-bit readable register. It can be read out from the CPU and the AUDR.

Also it can be read out from the program and AUDR tool.

Use FA00 5000_H for an access from the program to the AUDISR.

Use F900 5000_H for an access from the AUDR tool to the AUDISR.

The AUDISR register is not initialized by AUDR reset. The AUDISR can be read out from the program during reset.

This register is used in the way described below.

- Retention of configuration information
  On release from an internal reset, the register retains the values corresponding to the levels on pins AUDATA3 to AUDATA0.

  Setting the levels on pins AUDATA3 to AUDATA0 in the emulator configuration allows programs to judge the connection configuration of the emulator.

  If nothing is connected to the AUD RAM monitoring-related pins, pins AUDATA3 to AUDATA0 are pulled up and the register is read as $000F_H$. If an AUD RAM monitoring tool is connected, the levels on pins AUDATA3 to AUDATA0 will correspond to a value other than $000F_H$. Reading of the AUDISR by the CPU can then be used to judge that a tool is connected.

  In addition, the values from pins AUDATA3 to AUDATA0 can be used to identify the vendor that is the source of the connected tool.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	DATA			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	Values of the AUDATA3 to AUDATA0 pins			
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 32.4 AUDISR Register Contents

Bit Position	Bit Name	Function
15 to 4	—	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	DATA	The values of the AUDATA3 to AUDATA0 pins at the time of release from the internal reset state are retained.

32.5.3.2 AUDMBR/AUDMBRC — AUDR Message Board Register

The AUDMBR/AUDMBRC register is a 16-bit readable/writable register. It can be read and written from the program and the AUDR tool.

Use FA00 5004_H or FA00 5008_H for an access from the program. Use F900 5004_H or F900 5008_H for an access from the AUDR tool.

When the program reads the AUDMBRC at FA00 5008_H, all bits of the AUDMBR/AUDMBRC are cleared to 0 after reading. When the program reads the AUDMBR at FA00 5004_H, the bits of the AUDMBR/AUDMBRC are not cleared.

When the AUDR tool reads the AUDMBRC at F900 5008_H, all bits of the AUDMBR/AUDMBRC are cleared to 0 after reading. When the AUDR tool reads the AUDMBR at F900 5004_H, the bits of the AUDMBR/AUDMBRC are not cleared.

The program and the AUDR tool can write to the AUDMBR/AUDMBRC from the above addresses. However, writing 0 to the bits that have been set to 1 will be ignored (they can only be set to 1).

Table 32.6 summarizes the recommended accesses to the AUDMBR/AUDMBRC.

The AUDMBR/AUDMBRC register is not initialized by AUDR reset. The AUDMBR/AUDMBRC can be read and written from the program during AUDR reset.

AUDMBR and AUDMBRC are used in the way described below.

- Synchronous communications (message board) function
  The firmware (program) run by the CPU uses AUDMBR as a flag register for use in communications with the emulator, which reads AUDMBR by using the RAM monitoring function. This allows the emulator to follow the state of firmware (program) operations.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AUDMBR															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 32.5 AUDMBR/AUDMBRC Register Contents

Bit Position	Bit Name	Function
15 to 0	AUDMBR	Communication flag between the AUDR and the CPU

Table 32.6 Recommended Access to the AUDMBR/AUDMBRC

Accessing Master	Address	R/W	Access	Remarks
Program	FA00 5004_H (AUDMBR)	Write	Only 1 can be written. Writing 0 is ignored.	—
		Read	Reading is enabled.	Not cleared after reading.
AUDR tool	F900 5008_H (AUDMBRC)	Write	Only 1 can be written. Writing 0 is ignored.	—
		Read	Reading is enabled.	All bits are cleared to 0 after reading.

32.5.4 RAM Monitoring

32.5.4.1 Communication Protocol

Input a command, counter value, address, and data to the AUDATA pin in the format shown in **Figure 32.2**. For details, see **Section 32.5.4.2, Operation**.

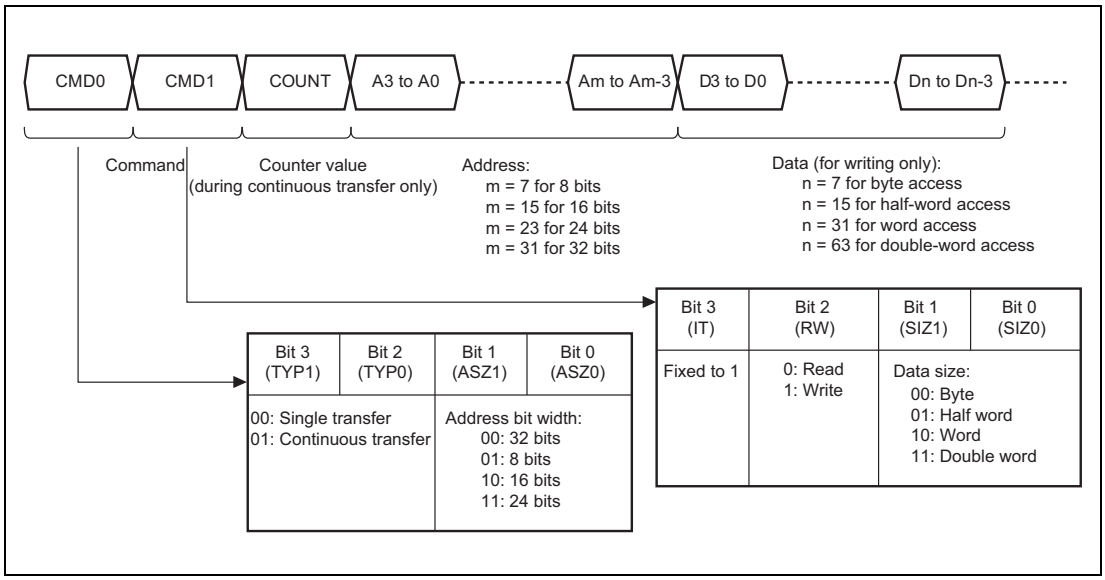

Figure 32.2 AUDATA Pin Input Format

32.5.4.2 Operation

(1) Single Transfer

Single transfer is a method of transmitting single data to an address that has been input for access. **Figure 32.3** shows an example of reading operation during single transfer and **Figure 32.4** shows an example of writing operation during single transfer.

When the $\overline{\text{AUDSYNC}}$ pin is asserted and a command, address and data (only for writing) are input to the AUDATA pin in the format shown in **Figure 32.2**, the AUDR starts reading or writing the specified address. The AUDR outputs the Not Ready flag (0000) to the AUDATA pin during this internal execution. After successful completion of the internal execution, the AUDR outputs the Ready flag (0001) to the AUDATA pin. (See **Figure 32.3** and **Figure 32.4**).

For reading, after the Ready flag is output and the $\overline{\text{AUDSYNC}}$ pin is negated, the read data is output from the AUDATA pin (see **Figure 32.3**).

After output of the read data and until input of the next command, at least one AUDCK cycle is required for switching of the input/output states of the pins.

In addition, after the $\overline{\text{AUDSYNC}}$ pin is negated following the completion of processing for write access, when the next command is input, at least one AUDCK cycle is required for switching of the input/output states of the pins. Therefore, the $\overline{\text{AUDSYNC}}$ pin is negated for two cycles of AUDCK.

If a command other than those shown in **Figure 32.2** is input to CMD0 and CMD1, the AUDR disables this processing as a command error and sets the CFLG bit in the Ready flag to 1. When a bus error occurs during the internal execution, the AUDR disables this processing and sets the BFLG bit in the Ready flag to 1 (see **Figure 32.5**). When an error is detected, the read data is not output.

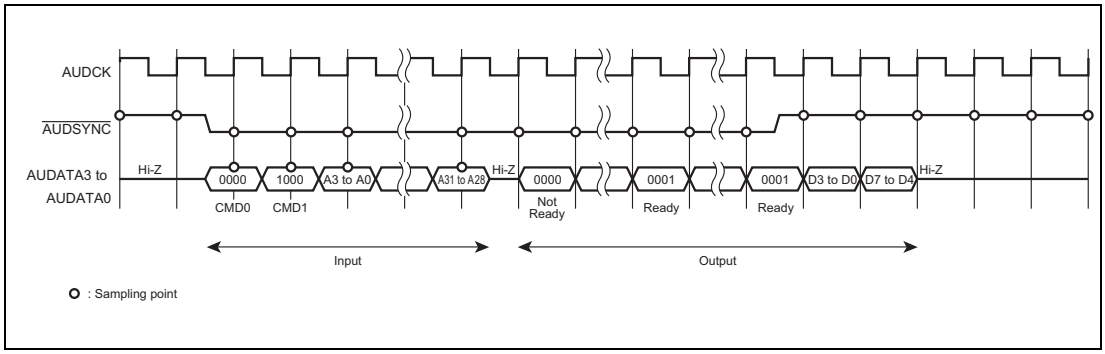

Figure 32.3 Example of Reading Operation in Single Transfer (Address 32 Bits; Byte Read)

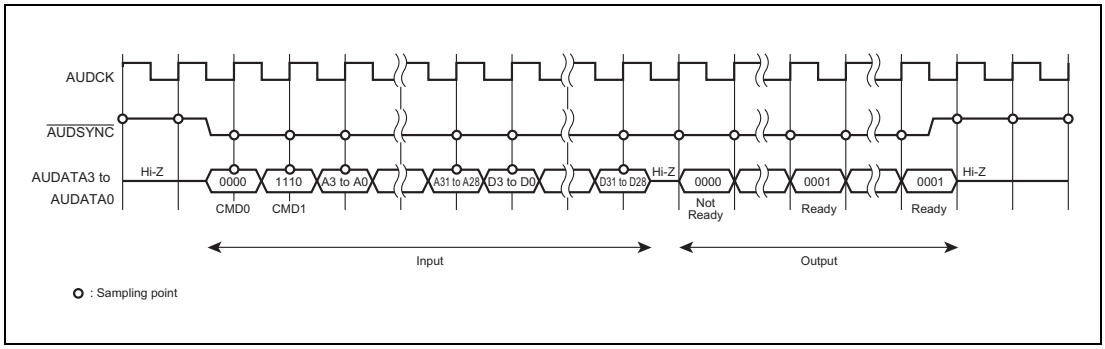

Figure 32.4 Example of Writing Operation in Single Transfer (Address 32 Bits; Word Write)

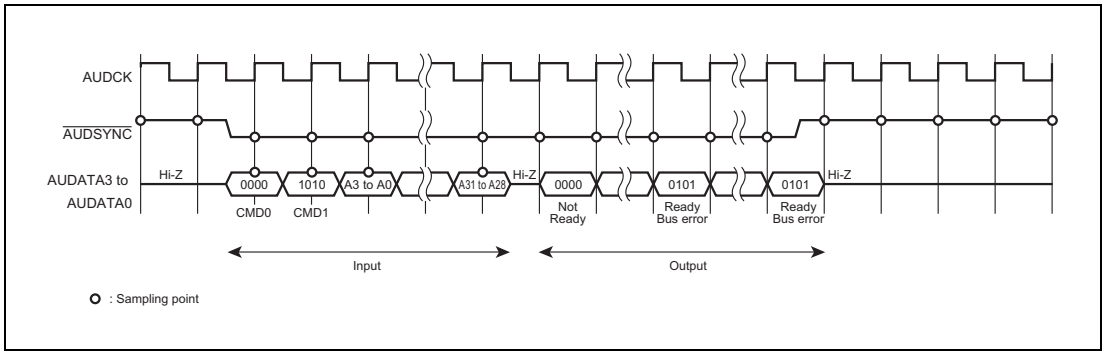

Figure 32.5 Example of Error Occurrence in Single Transfer (Address 32 Bits; Word Read)

(2) Continuous Transfer

Continuous transfer is a method of continuously transmitting up to 16 data to the address that has been input. The address to be accessed is automatically incremented depending on the data size after completion of each data transfer. **Figure 32.6** shows an example of reading operation during continuous transfer and **Figure 32.7** shows an example of writing operation during continuous transfer.

The first data transfer is equivalent to single transfer except that COUNT (counter value) shown in **Figure 32.2** should be input. The number of data to be transferred minus 1 is input to the COUNT.

In the second and subsequent data transfer, the input of CMD0, CMD1, COUNT, and addresses is skipped. The second and subsequent data transfer for reading and writing proceed as follows.

For reading, when the $\overline{\text{AUDSYNC}}$ pin is asserted after completion of the previous data transfer, the AUDR outputs the Not Ready flag (0000) to the AUDATA pin during this internal execution. After successful completion of the internal execution, the AUDR outputs the Ready flag (0001) to the AUDATA pin. Then after the $\overline{\text{AUDSYNC}}$ pin is negated, the read data is output from the AUDATA pin. This operation is repeated until the number of data specified in COUNT is read (see **Figure 32.6**).

For writing, when the $\overline{\text{AUDSYNC}}$ pin is asserted after completion of the previous data transfer, the AUDR inputs data to be written to the AUDATA pin. After that, the AUDR starts the internal execution. The AUDR outputs the Not Ready flag (0000) to the AUDATA pin during this operation. After successful completion of the internal execution, the AUDR outputs the Ready flag (0001) to the AUDATA pin. This operation is repeated until the number of data specified in the COUNT is written (see **Figure 32.7**).

When the $\overline{\text{AUDSYNC}}$ pin is re-asserted to input the next write data, at least two cycles of AUDCK are required for negating the $\overline{\text{AUDSYNC}}$ pin.

If a bus error occurs during the internal execution, the AUDR suspends data transfer and sets the BFLG bit in the Ready flag to 1 (see **Figure 32.8**).

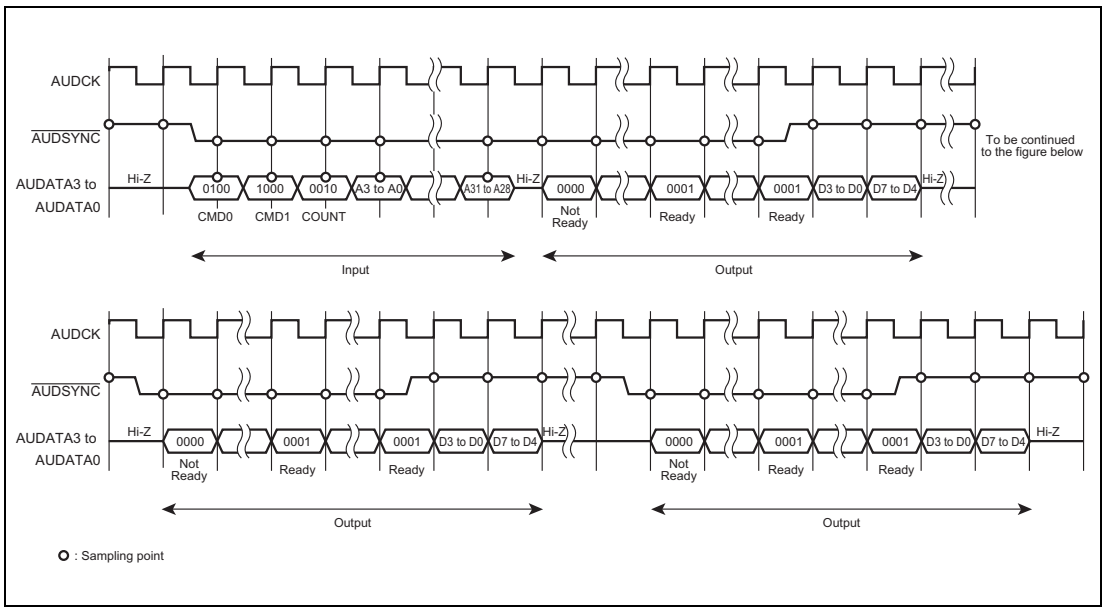

Figure 32.6 Example of Reading Operation in Continuous Transfer (Address 32 Bits; Byte Read × Three Units of Data)

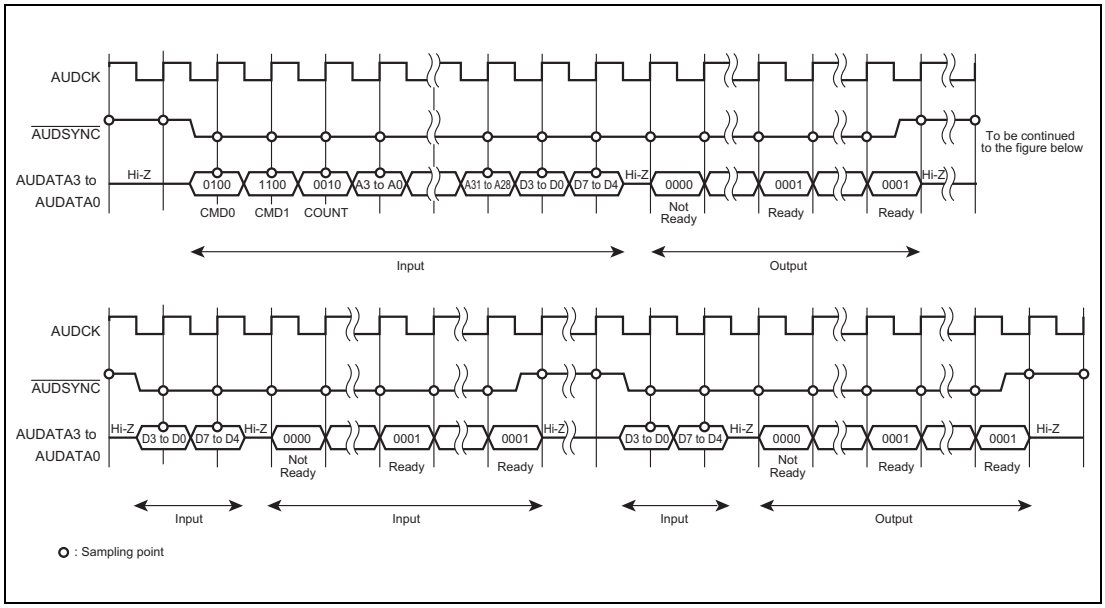

Figure 32.7 Example of Writing Operation in Continuous Transfer (Address 32 Bits; Byte Write × Three Units of Data)

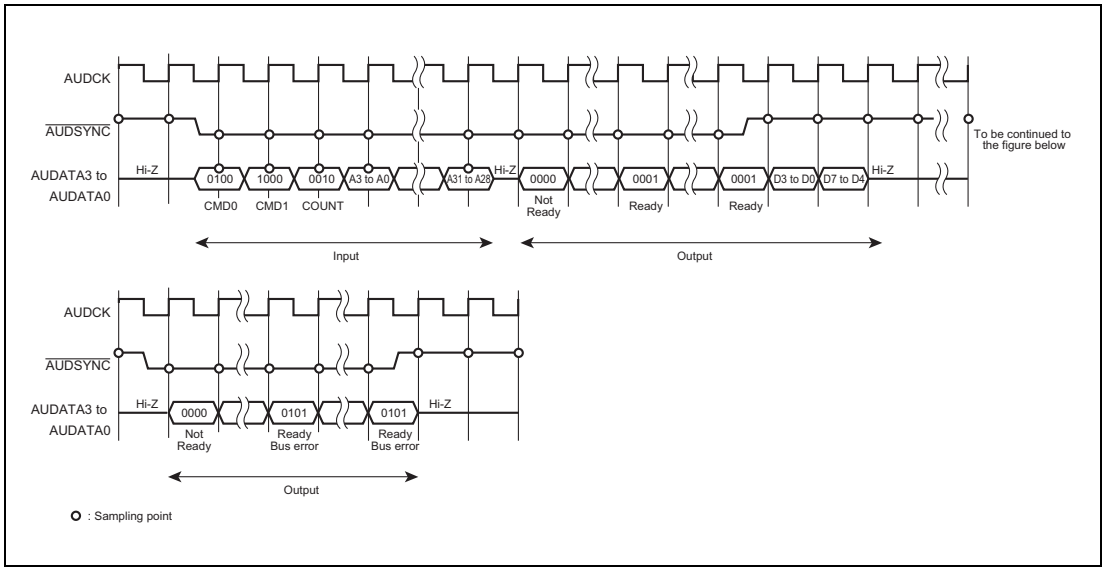

Figure 32.8 Example of Error Occurrence in Continuous Transfer (Address 32 Bits; Byte Read × Three Units of Data)

(3) Command Error Conditions

Table 32.7 Command (CMD0) Error Conditions

Bit 3 (TYP1)	Bit 2 (TYP0)	Bit 1 (ASZ1)	Bit 0 (ASZ0)	Description
0	0	0	0	Single transfer Address bit width: 32 bits
0	0	0	1	Single transfer Address bit width: 8 bits
0	0	1	0	Single transfer Address bit width: 16 bits
0	0	1	1	Single transfer Address bit width: 24 bits
0	1	0	0	Continued transfer Address bit width: 32 bits
0	1	0	1	Continued transfer Address bit width: 8 bits
0	1	1	0	Continued transfer Address bit width: 16 bits
0	1	1	1	Continued transfer Address bit width: 24 bits
1	×	×	×	Command error

Table 32.8 Command (CMD1) Error Conditions

Bit 3 (IT)	Bit 2 (RW)	Bit 1 (SIZ1)	Bit 0 (SIZ0)	Description
0	×	×	×	Command error
1	0	0	0	Read: Byte
1	0	0	1	Read: Half word
1	0	1	0	Read: Word
1	0	1	1	Read: Double word
1	1	0	0	Write: Byte
1	1	0	1	Write: Half word
1	1	1	0	Write: Word
1	1	1	1	Write: Double word

(4) Bus Error Conditions

- Half-word access is made to the address of 4n + 1 and 4n + 3.
- Word access is made to the address of 4n + 1, 4n + 2, and 4n + 3.
- Double-word access is made to the address of 8n + 1, 8n + 2, 8n + 3, 8n + 4, 8n + 5, 8n + 6, and 8n + 7.
- An error response is received from the system bus.

(5) AUDATA Pin Input Format

Table 32.9 Input Format Bit Position

Table 32.17 Read Data Format

Bit Name	Function	Description
D63 to D0	Output read data	The required number of bits depends on the setting of the SIZ[1:0] bits in CMD1 (for details, see **Table 32.16**).

32.5.4.3 Usage Notes on AUDR Function

- Do not negate the $\overline{\text{AUDSYNC}}$ pin until one cycle of AUDCK has elapsed after a command is input to the AUDATA pin and the Ready flag has been returned.
- When uninitialized memory is accessed through the AUDR, a bus error may occur due to ECC error detection.

32.5.4.4 Enabling and Disabling the RAM Monitor Function

Enabling or disabling of the AUDR can be specified using option bytes (stored in the flash memory and set by reset transfer).

AUDREN: AUDR Enable Bit

For setting of option bytes, see **Section 33, Flash Memory**.

NOTE

In serial programming mode, AUDR is disabled regardless of this setting.

32.6 Caution on Using On-Chip Debugger

(1) Treatment of Devices Used for Debugging
Do not install a device that was used for debugging on a mass-produced product, because the flash memory was rewritten during system debugging and thus the number of write/erase count of flash memory cannot be guaranteed.

(2) This product does not support hot plug out for power off (including removal of the connector) of the debug tool during debug mode. Do not turn off the power of the NEXUS tool (including removal of the connector) in debug mode.

(3) When ending on-chip debugging, set the $\overline{\text{TRST}}$ pin and external reset pin to the low level.

(4) When a debugger is used, the program written to the microcomputer before preparation for communications between the OCD emulator and microcomputer is complete is executed from the reset vector. For this reason, take care to ensure that this does not lead to any operations which you do not expect or intend.
This communications preparation period depends on the host PC environment of the OCD emulator and the operating frequency of the microcomputer.

Section 33 Flash Memory

This product incorporates code flash memory and data flash memory.

33.1 Features

- Code flash memory capacity: 4 Mbytes of user area and 32 Kbytes of user boot area
- Data flash memory capacity: 64 Kbytes of data area
- Methods of programming
  - Programming through transfer by a dedicated flash-memory programmer via a serial interface communication (serial programming)
  - Programming of flash memory by a user program (self-programming)
- Support for security functions to protect against illicit tampering and illicit reading with data in flash memory
- Support for protection functions to protect against erroneous overwriting of the flash memory
- Support for the detection and correction of errors in the flash memory
- Support for the BGO (Back Ground Operation) function
  - Code flash memory can be read while data flash memory is being programmed
- Interrupts acceptable during self-programming
- The initial settings of this product can be configured in the extended area (option bytes) of flash memory.

33.2 Structure of Memory

Figure 33.1 shows code flash memory map.

The user area in the code flash memory of this product is divided into 8- and 32-Kbyte blocks, which can be erased individually. The user area can be used to hold the user program. The user boot area can be used to hold a non-rewritable boot program during user program operation, such as a boot program for rewriting code flash memory through a selected user interface.

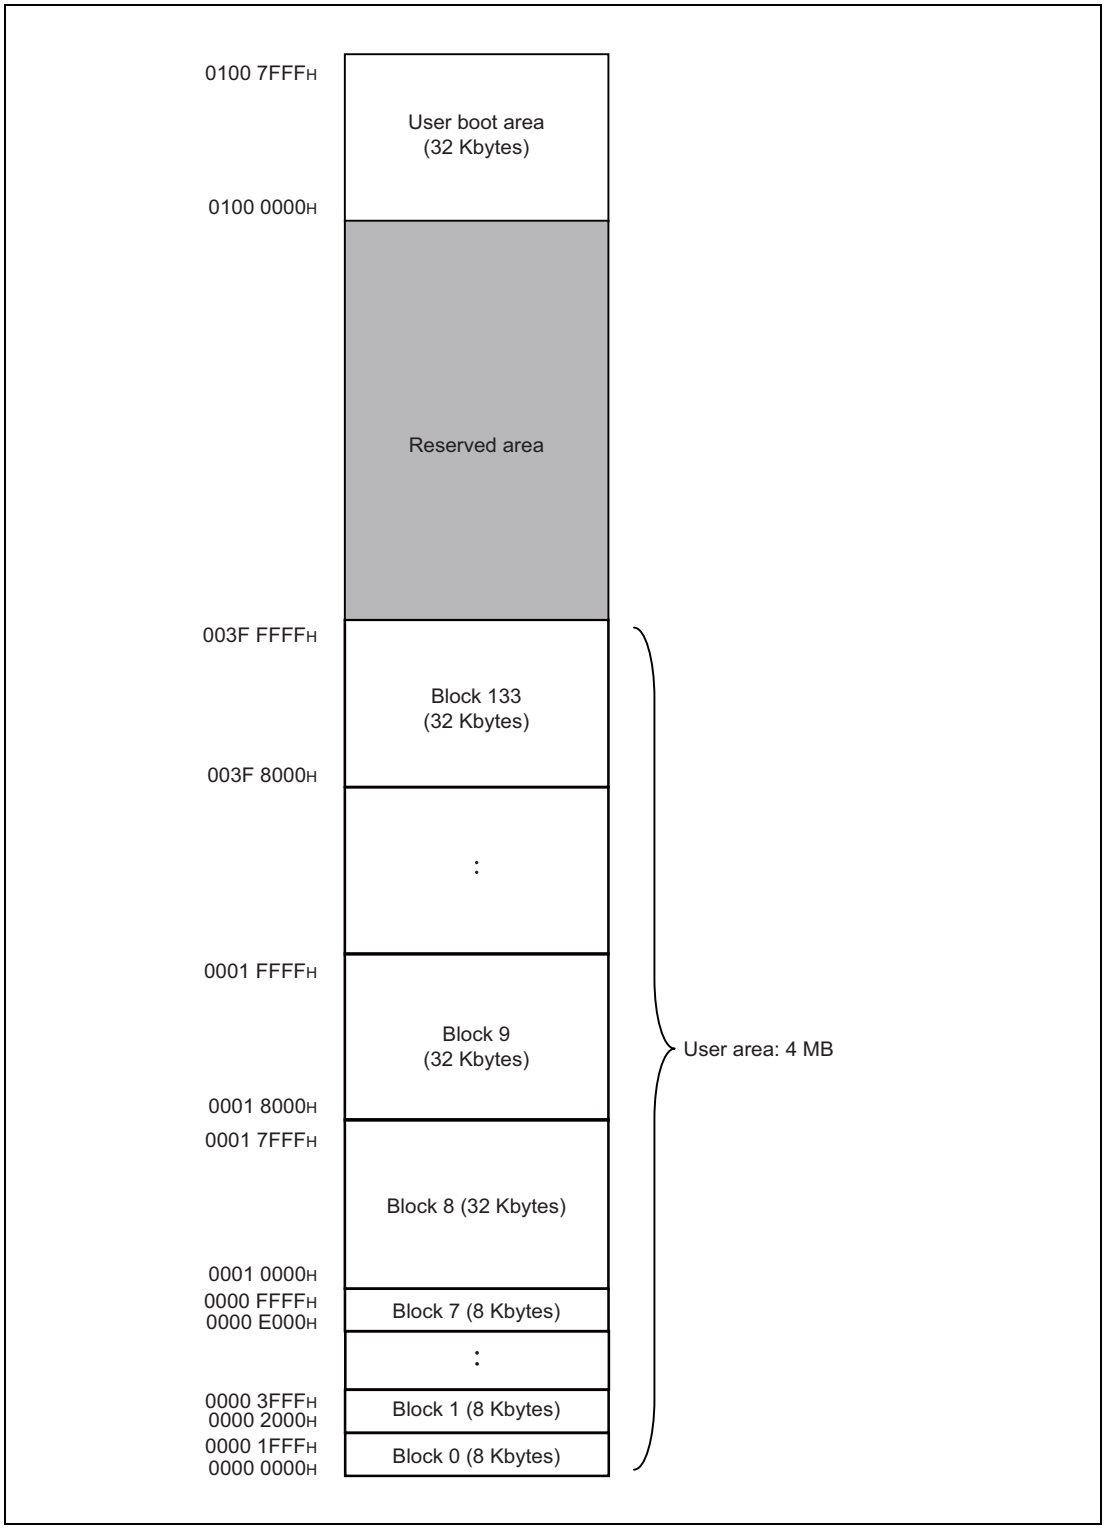

Figure 33.1 Code Flash Memory Map (1 bank, 8 Kbytes × 8 + 32 Kbytes × 126 configuration)

The data area of the data flash memory in this product is divided into 64-byte blocks, with each being a unit for erasure. **Figure 33.2** shows data flash memory map.

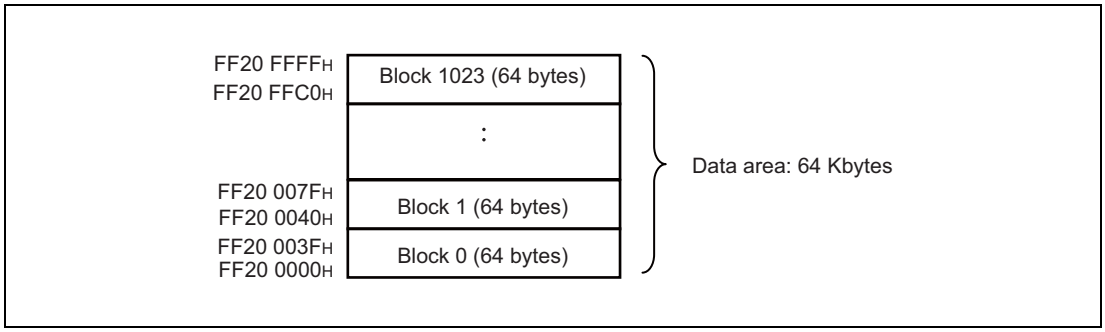

Figure 33.2 Data Flash Memory Map

33.3 Operating Modes Associated with Flash Memory

Figure 33.3 is a diagram of the mode transitions associated with the flash memory. For the procedures for setting the modes, refer to **Section 5, Operating Mode**.

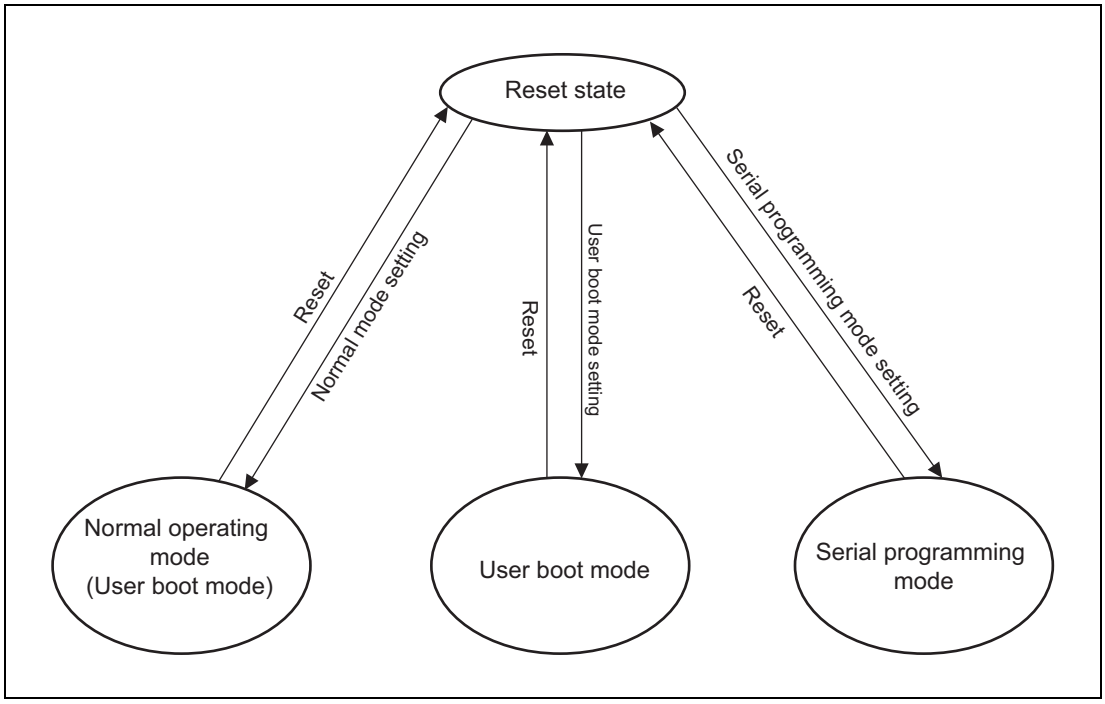

Figure 33.3 Mode Transition Associated with Flash Memory

The flash memory areas which are programmable and erasable and the boot program after a reset depend on the selected mode. The differences between modes are indicated in **Table 33.1**.

Table 33.1 Differences between Modes

Item	Normal Operating Mode (User boot mode)*1	User Boot Mode	Serial Programming Mode
Programmable and erasable area	• User area • Data area	• User area • Data area	• User area • User boot area • Data area
Boot program at a reset	Program in user area	Program in user boot area	Embedded program for serial programming

Note 1. See **Section 5 Operating Mode** for the details on each mode.

33.4 Functional Overview

By using a dedicated flash-memory programmer to program the flash memory of this device via a serial interface (serial programming), the device can be programmed regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit updating of the user program written in the on-chip flash memory are incorporated, and this can prevent tampering by third parties.

Programming by the user program (self-programming) is suited for applications where the target system program may require updating after the production or shipment. Protection features for the safe rewriting of the flash memory area are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as interrupt processing on an external communication control, etc., and this allows programming under various conditions.

Table 33.2 gives an overview of the methods of programming and the corresponding operating modes.

Table 33.2 Programming Methods

Programming Method	Functional Overview	Operating Mode
Serial programming	A dedicated flash-memory programmer is capable of on-board programming the flash memory after the device is mounted on the target system.	Serial programming mode
	A dedicated flash memory programmer and dedicated programming adapter board allow off-board programming of the flash memory, i.e. programming of the device before it is mounted on the target system.	
Self-programming	The user program that is written to code flash memory in advance by serial programming executing also allows updating the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data in code flash memory while the data flash memory is being programmed. For this reason, it is possible to update the data flash memory by executing a program written to the code flash memory. Instructions in the code flash memory cannot be fetched and data cannot be read while the code flash memory is being updated by self-programming. In such cases, a program for updating must be transferred to the local RAM or the global RAM in advance and executed.	Normal operating mode, user boot mode

When executing self-programming, see the *RH850/E1x Flash Memory User's Manual: Hardware Interface* which this product targets.

Table 33.3 lists the functions of the on-chip flash memory. Dedicated flash memory programmer commands realize serial programming, while reading of the on-chip flash memory by interface operation of flash memory or the user program realizes self-programming.

Table 33.3 Basic Functions at a Glance

Function	Description in Overview	Level of Support (√: Supported, △: Conditionally Supported, ×: Not Supported)	
		Serial programming	Self-programming
Blank checking	This is used to check a specified block to ensure that writing to it has not already proceeded. Results of reading from code flash memory and data flash memory to which nothing has been written after erasure are not guaranteed, so use blank checking to confirm that writing to memory has not proceeded after erasure.	√	√
Block erasure	This is for erasing the contents of a specified block of memory.	√	√
Programming	This is for writing to a specified address.	√	√
Verification and checksum	Data that are read out from flash memory are compared with data transferred from the flash memory programmer.	√	√
Reading	Data that have been written to the flash memory are read out.	√	√
Setting for OTP (one-time programming)	A specified block of code flash memory is set for OTP (OTP can only be set, that is, it is not possible to release a block's OTP setting).	√	√
Setting an ID	An ID setting is made for use in controlling the connection of a dedicated flash memory programmer for serial programming, and programming of the code flash memory by self-programming.	√	√
Security settings	Security settings are for use in serial programming.	√	△ (only when setting is prohibited after being permitted)
Protection settings	Lock bits for all blocks of code flash memory are provided.	√	√
Setting of option bytes	Option bytes are set to change them from the initial values for this product.	√	√
Clearing the configuration	ID setting, security settings, protection settings, and option byte settings are initialized.	√	×

For details on serial programming, refer to the *PG-FP5 Flash Memory Programmer User's Manual* and *Renesas Flash Programmer Flash Programming Software User's Manual.*

For details on self-programming, refer to the *RH850/E1x Flash Memory User's Manual: Hardware Interface* which this product targets.

The on-chip flash memory supports various security functions.

The OTP setting and authentication of the ID code are security functions for use with serial programming and self-programming.

In serial programming, authentication of the ID code, prohibiting connection of a dedicated flash memory programmer, and prohibition of commands (for block erasure, programming, and reading) are available for use as security functions.

Table 33.4, Summary of Security Functions lists security functions that are supported by the on-chip flash memory and **Table 33.5, Available Operations and Security Settings** lists security setting operations.

Table 33.4 Summary of Security Functions

Function	Description
OTP	OTP can be individually set for each block of the user area and the user boot area of code flash memory. When the OTP setting is made for an area, programming by serial programming and by self programming is prohibited. Once set, the OTP setting cannot be released. Furthermore, since execution of the configuration clearing command is prohibited for any area for which OTP has been set, changing a security setting from "prohibited" to "permitted" is not possible.
ID authentication	The result of ID authentication can be used to control the connection of a dedicated flash memory programmer for serial programming. The result of ID authentication can also be used to control enabling of code flash memory writing by self-programming.
Prohibition of connection of a dedicated flash memory programmer	The connection of a dedicated flash memory programmer for serial programming is prohibited. Since execution of the configuration clearing command is also prohibited when the connection of a dedicated Flash Memory programmer is prohibited, changing a security setting from "prohibited" to "permitted" is not possible.
Prohibition of block erasure commands	Block erasure commands at the time of serial programming are prohibited. Since execution of the configuration clearing command is also prohibited when block erasure commands are prohibited, changing a security setting from "prohibited" to "permitted" is not possible.
Prohibition of programming commands	Block erasure commands and programming commands at the time of serial programming are prohibited. Block erasure commands can only be executed by erasing all user areas in the following order starting from block 0: erasure of all areas → erasure of user boot area → erasure of data areas starting from block 0. The prohibition setting can only be initialized by issuing the configuration clearing command.
Prohibition of read commands	Read commands at the time of serial programming are prohibited. Only through execution of the configuration clearing command can the prohibition be lifted.

Table 33.5 Available Operations and Security Settings

Function	All Security Settings and Erasure, Programming, and Read Operations (√: Executable, ×: Not Executable, —: Not Supported)		Point for Caution Regarding the Security Setting	
	Serial programming	Self programming	Serial programming	Self programming
OTP	• Areas for which OTP is set – Block erasure commands: × – Programming commands: × – Read commands: √ • Areas for which OTP is not set – Block erasure commands: √ – Programming commands: √ – Read commands: √	• Areas for which OTP is set – Block erasure: × – Programming: × – Reading: √ • Areas for which OTP is not set – Block erasure: √ – Programming: √ – Reading: √	• The OTP setting cannot be released. • Execution of the configuration clearing command is not possible.	The OTP setting cannot be released.
ID authentication	• When the ID codes do not match – Block erasure commands: × – Programming commands: × – Read commands: × • When the ID codes match – Block erasure commands: √ – Programming commands: √ – Read commands: √	• When the ID codes do not match – Code flash memory - Block erasure: × - Programming: × - Reading: √ – Data flash memory - Block erasure: √ - Programming: √ - Reading: √ • When the ID codes match – Block erasure: √ – Programming: √ – Reading: √	• The configuration clearing command can initialize the setting for prohibition. • The setting for prohibition of block erasure commands is not available. • The setting for prohibition of programming commands is not available. • The setting for prohibition of read commands is not available.	ID authentication is always in effect.
Prohibition of the connection of a dedicated flash memory programmer	• Block erasure commands: × • Programming commands: × • Read commands: ×	• Block erasure: √ • Programming: √ • Reading: √	Since execution of the configuration clearing command is prohibited, initialization of the setting for prohibition is not possible.	Initialization of the settings prohibited is impossible because the configuration clearing command is not supported.
Prohibition of block erasure commands	• Block erasure commands: × • Programming commands: √ • Read commands: √	• Block erasure: √ • Programming: √ • Reading: √	• Since execution of the configuration clearing command is prohibited, initialization of the setting for prohibition is not possible. • The setting for ID authentication to be effective for serial programming is not available.	Initialization of the settings prohibited is impossible because the configuration clearing command is not supported.
Prohibition of programming commands	• Block erasure commands: ×*1 • Programming commands: × • Read commands: √	• Block erasure: √ • Programming: √ • Reading: √	• Executing the configuration clearing command only can initialize the settings prohibited. • The setting for ID authentication to be effective for serial programming is not available.	Initialization of the settings prohibited is impossible because the configuration clearing command is not supported.
Prohibition of read commands	• Block erasure commands: √ • Programming commands: √ • Read commands: ×	• Block erasure: √ • Programming: √ • Reading: √		

Note 1. Block erasure commands can only be executed by erasing all user areas in the following order starting from block 0: erasure of all areas → erasure of user boot area → erasure of data areas starting from block 0. The prohibition setting can only be initialized by issuing the configuration clearing command.

The on-chip flash memory supports various security functions. **Table 33.6, Summary of Protection Functions** lists protection functions that are supported by the on-chip flash memory.

Table 33.6 Summary of Protection Functions

Function	Description
Block protection	Lock bit settings can be individually made to enable or disable programming/erasure of each block of the user area of code flash memory. Programming and erasure by self programming of an area for which the lock bit is set and the lock bit function is enabled are prohibited. Programming or erasure can proceed again when the lock bit function is disabled after having been enabled. When a block of code flash memory is erased, the lock bit for that block is also erased.
User boot protection	Programming or erasure of the user boot area by self programming is prohibited. Programming or erasure of the user boot area by serial programming is available.

33.5 Serial Programming

A dedicated flash memory programmer can be used to program the flash memory in serial programming mode.

Serial Programming

The microcontroller is mounted on the system board at the time of serial programming. Providing a connector to the board enables programming of the target microcontroller by the flash memory programmer to proceed.

33.5.1 Environments for Programming

The recommended environments for programming the flash memory of the microcontroller with data are described below.

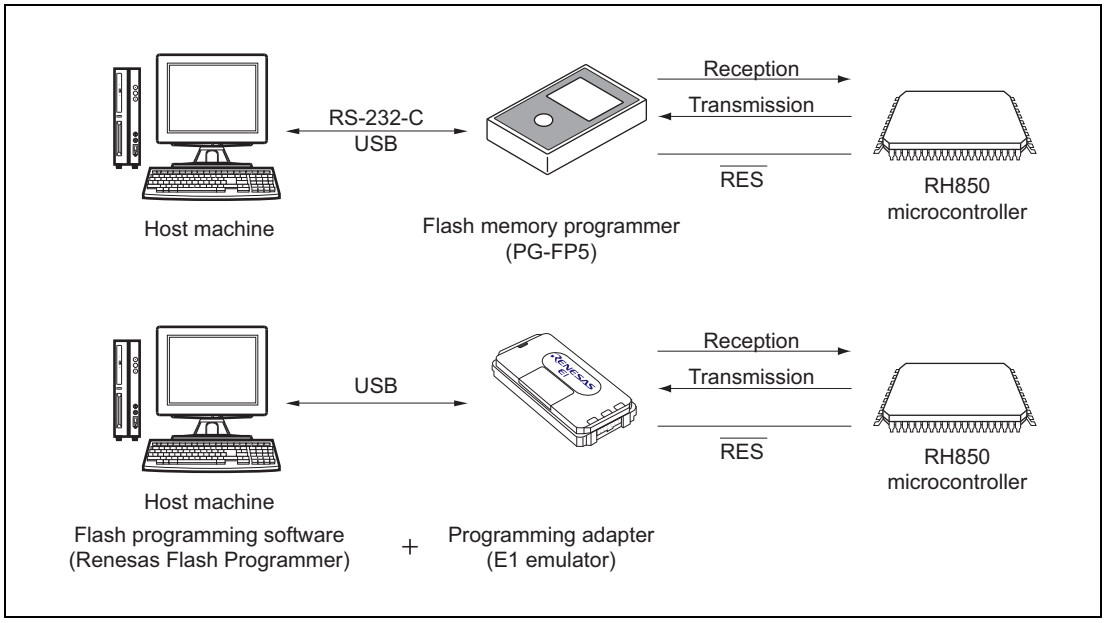

Figure 33.4 Environments for Programming Flash Memory

By using the PG-FP5 flash memory programmer or the combination of the Renesas Flash Programmer (software for writing to flash memory) running on the host machine and the E1 emulator as an programming adapter, the user is easily able to erase, program, and verify the contents of the on-chip memory of flash-memory-equipped microcontrollers from Renesas Electronics.

The PG-FP5 flash memory programmer handles programming from a host machine or programming in stand-alone mode while the Renesas Flash Programmer only handles programming from a host machine.

NOTE

For details on the PG-FP5, see the *PG-FP5 Flash Memory Programmer User's Manual*. For details on the Renesas Flash Programmer of flash programming software, see the *Renesas Flash Programmer Flash Programming Software User's Manual*.

33.6 Selection of the Communication Method

With this product, 2-wire UART connection or clock synchronous connection is selectable as a method of serial communications by the level on the FLMODE pin. For details of the FLMODE pin setting, see **Section 5, Operating Mode**. For setting of programming environment in line with each communication method, see the *PG-FP5 Flash Memory Programmer User's Manual* and *Renesas Flash Programmer Flash Programming Software User's Manual*.

33.7 Self-Programming

33.7.1 Overview

This product supports programming of the flash memory by user program itself. The code flash and data flash memory can be programmed by using the commands of flash memory application command interface (FACI) for flash memory programming in user's applications. Therefore, update of the user program and programming of constant data fields can be possible.

When the data flash memory is programmed, the background operation facility makes it possible to execute a programming program from the code flash memory to program the data flash memory. Furthermore, the programming program can be copied to the local RAM or the global RAM in advance and executed to program the data flash memory.

For comprehensive information on flash self-programming, see the *RH850/E1x Flash Memory User's Manual: Hardware Interface* which this product targets.

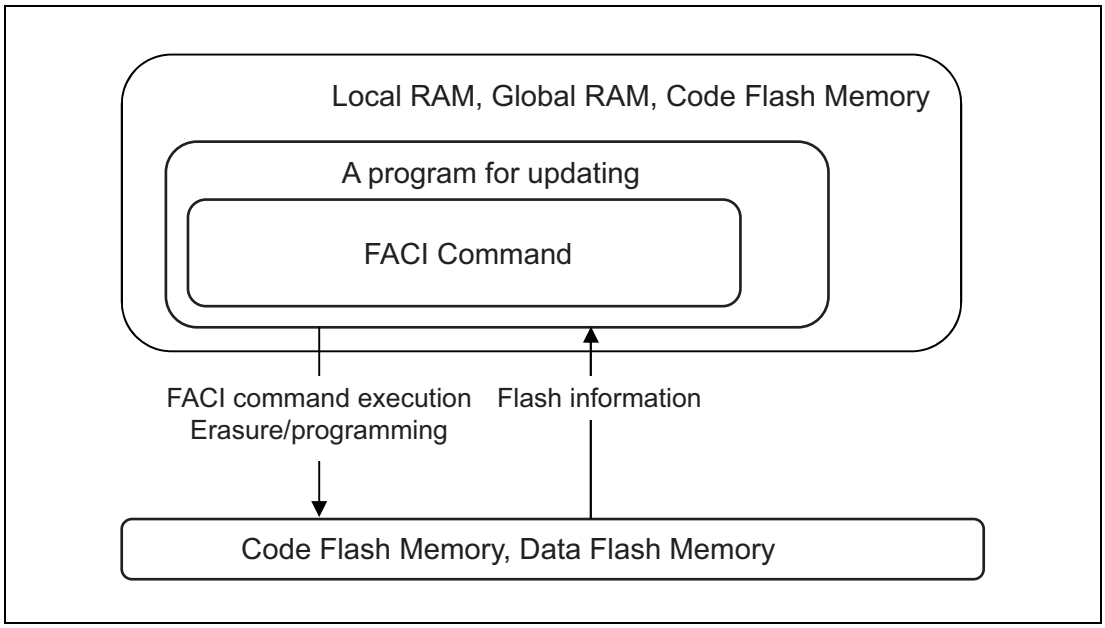

Figure 33.5 Concept of Self-Programming

33.7.2 Background Operation

Background operations can be used when the combination of the flash memory for writing and the flash memory for reading is any of those listed below.

Table 33.7 Conditions under which Background Operation is Usable

Range for Writing	Range for Reading
Data flash memory	Code flash memory

33.8 Reading Flash Memory

33.8.1 Reading Code Flash Memory

Special settings are not required to read code flash memory in normal mode and user boot mode. Data can simply be read out through access to addresses in the code flash memory.

Reading from an area of code flash memory that has been erased but not yet been programmed again (i.e. that is in the non-programmed state) can lead to the detection of an ECC error and generation of the corresponding exception. Furthermore, since the values of data cannot be guaranteed when an ECC error has been generated, use blank checking when you need to confirm that an area is in the non-programmed state. See **Section 29, Safety** for the details on ECC.

33.8.2 Reading Data Flash Memory

Configure the number of read cycles in the FRDCYCLD register prior to reading data from data flash memory in normal mode and user boot mode. Once this register is properly configured, data can be read by simply accessing addresses in the data flash memory. Once the setting for the number of cycles is made, data can simply be read out through access to addresses in the data flash memory.

Values read from data flash memory that has been erased but not yet been programming again are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

33.9 Description of Registers

33.9.1 Registers Related to Data Flash Memory

Table 33.8 shows the list of registers related to data flash memory.

Table 33.8 List of Registers Related to Data Flash Memory

Register Name	Abbreviation	R/W	Value after rest	Address	Access Size
Data flash memory read cycle setting register	FRDCYCLD	R/W	$0F_H$	FFC5 9810_H	8

33.9.1.1 FRDCYCLD — Data Flash Memory Read Cycle Setting Register

Access: This register can be read/written in 8-bit units.

Address: FFC5 9810_H

Value after reset: $0F_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	FRDCYCLD[3:0]			
Value after reset	0	0	0	0	1	1	1	1
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 33.9 FRDCYCLD Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Received
3 to 0	FRDCYCLD[3:0]	Number of Data Flash Memory Read Cycles Data flash memory is read in setting value + 1 cycles. 00_H to 02_H: Setting prohibited 03_H: Read cycle 4 04_H: Read cycle 5 05_H: Read cycle 6 06_H: Read cycle 7 07_H: Read cycle 8 08_H: Read cycle 9 09_H to $0F_H$: Read cycle 10

33.9.2 Registers Related to Write and Erase Protection of Flash Memory

Table 33.10 shows the list of registers related to write and erase protection of flash memory.

Table 33.10 Registers Related to Write and Erase Protection of Flash Memory

Register Name	Abbreviation	R/W	Value after Reset	Address	Access Size
FHVE15 control register	FHVE15	R/W	0000 0000_H	FFF8 $A430_H$	32
FHVE3 control register	FHVE3	R/W	0000 0000_H	FFF8 2410_H	32

33.9.2.1 FHVE15 — FHVE15 Control Register

FHVE15 is a readable/writable register for software protection of flash memory against programming and erasure. Set both the FHVE15 and FHVE3 registers in the programmable and erasable state ($0000\ 0001_H$) to program or erase flash memory.

Access: This register can be read/written in 32-bit units.

Address: FFF8 $A430_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 33.11 FHVE15 Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved
0	FHVE15CNT	0: Programming and erasure are disabled. 1: Programming and erasure are enabled.

33.9.2.2 FHVE3 — FHVE3 Control Register

FHVE3 is a readable/writable register for software protection of flash memory against programming and erasure. Set both the FHVE15 and FHVE3 registers in the programmable and erasable state ($0000\ 0001_H$) to program or erase flash memory.

Access: This register can be read/written in 32-bit units.

Address: $FFF8\ 2410_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Note 1. This is the value indicated in **Table 33.14, Relationship between Product Names and PRDNAME Initial Value (Value after Reset)**.

Table 33.15 List of Registers Related to Product Information

Bit Position	Bit Name	Function
31 to 0	PRDNAME[31:0]	Product name: Indicate product model names by using 16-byte ASCII code. PRDNAME1[31:0]: Fourth to first bytes of product model name PRDNAME2[31:0]: Eighth to fifth bytes of product model name PRDNAME3[31:0]: Twelfth to ninth bytes of the product model name PRDNAME4[31:0]: Sixteenth to thirteenth bytes of the product model name

33.10 Option Bytes

The flash memory has the extended area (option bytes) to store data specified by the user for various purposes. Changes in settings such as initial setting of peripheral functions using option bytes become effective after release from the reset state. **Table 33.16** shows option byte setting area. Reserved area is always read as 1. When writing, always write 1. For setting and reading option bytes, see the *PG-FP5 Flash Memory Programmer User's Manual* and *Renesas Flash Programmer Flash Programming Software User's Manual*, or the *RH850/E1x Flash Memory User's Manual: Hardware Interface*.

Table 33.16 Setting Area of Option Bytes

Option Byte Area (each 8 bits × 32 = Total 256 bits)	Setting Effective Area	Initial State of Shipped Product*1
Option bytes 4 to 1 (OPBT0)	Enable	7FFF FFFE$_H$
Option bytes 8 to 5 (OPBT1)	Reserved	FFFF FFFF$_H$
Option bytes 12 to 9 (OPBT2)	Enable	FFFF FFFF$_H$
Option bytes 16 to 13 (OPBT3)	Reserved	FFFF FFFF$_H$
Option bytes 20 to 17 (OPBT4)	Reserved	FFFF FFFF$_H$
Option bytes 24 to 21 (OPBT5)	Reserved	FFFF FFFF$_H$
Option bytes 28 to 25 (OPBT6)	Reserved	FFFF FFFF$_H$
Option bytes 32 to 29 (OPBT7)	Reserved	FFFF FFFF$_H$

Note 1. This is the initial value of the shipped product. The value can be modified by setting the option bytes.

33.10.1 OPBT0 — Option Byte 4 to 1 Bit Arrangement

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OPWD RUN	OPWD INT	OPWD WS1	OPWD WS0	OPWD OVF2	OPWD OVF1	OPWD OVF0	—	—	—	—	—	—	—	—	—

R/W	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2

Note 1. This is the initial value of the shipped product. The value can be modified by setting the option bytes.

Note 2. Only when an FACI command is used and when the PG-FP5 flash memory programmer and Renesas Flash Programmer flash programming software are used, reading and setting (R/W) are possible.

Table 33.17 OPBT0 Contents

Bit Position	Bit Name	Function
31	OPWDRUN	This bit selects the start mode of WDTA0. 0: WDTA0 software trigger start mode 1: WDTA0 default start mode
30	OPWDINT	This bit enables or disables a 75% interrupt request of WDTA0 (WDTA0TIT). 0: WDTA0TIT is disabled. 1: WDTA0TIT is enabled.
29, 28	OPWDWS1, OPWDWS0	These bits select the window-open period of WDTA0.

OPWDWS1	OPWDWS0	Window-Open Period
0	0	25%
0	1	50%
1	0	75%
1	1	100%

27 to 25	OPWDOVF2 to OPWDOVF0	These bits select the overflow interval time of WDTA0.

OPWDOVF2	OPWDOVF1	OPWDOVF0	Overflow Interval Time
0	0	0	2^9 / WDTATCKI
0	0	1	2^{10} / WDTATCKI
0	1	0	2^{11} / WDTATCKI
0	1	1	2^{12} / WDTATCKI
1	0	0	2^{13} / WDTATCKI
1	0	1	2^{14} / WDTATCKI
1	1	0	2^{15} / WDTATCKI
1	1	1	2^{16} / WDTATCKI

24 to 5	—	Reserved (The setting value should be 1.)
4	AUDREN	AUDRAM monitor enable 0: AUDRAM monitor is disabled. 1: AUDRAM monitor is enabled.
3, 2	—	Reserved (The setting value should be 1.)
1, 0	STMSEL1, STMSEL0	These bits select operating mode and startup area. When all of the MD0, MD1, and FLMODE pins are 0, the following operating mode and startup area are selected depending on the combination of the STMSEL1 and STMSEL0. For details, see **Section 5, Operating Mode**.

33.10.2 OPBT2 — Option Byte 12 to 9 Bits Arrangement

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	OPJTAG1	OPJTAG0	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial state*1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial state*1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2

Note 1. This is the initial value of the shipped product. The value can be modified by setting the option bytes.

Note 2. Only when an FACI command is used and when the PG-FP5 flash memory programmer and Renesas Flash Programmer flash programming software are used, reading and setting (R/W) are possible.

Table 33.18 OPBT2 Register Contents

Bit Position	Bit Name	Function
31	—	Reserved (The setting value should be 1.)
30, 29	OPJTAG1, OPJTAG0	Switch the debug interfaces. The following debug interface is selected depending on the combination of the values of OPJTAG1 and OPJTAG0.
28 to 0	—	Reserved (The setting value should be 1.)

OPJTAG1	OPJTAG0	Debug Interface
0	0	FLSCI3 (writer I/F)
0	1	LPD (4-pin)
1	0	Setting prohibited
1	1	Nexus (JTAG)

33.11 Usage Notes

(1) Reading areas where programming or erasure was interrupted

When programming or erasure of an area of flash memory is interrupted, the data stored in the area become undefined. To avoid undefined data that are read out becoming the source of faulty operation, take care not to fetch instructions or read data from areas where programming or erasure was interrupted.

(2) Reading the code flash memory that has been erased but not yet been programming again

Note that reading from an area of code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) can lead to the detection of an ECC error and generation of the corresponding exception. Use blank checking when you need to confirm that an area is in the non-programmed state.

(3) Prohibition of additional writing

Writing to a given area twice is not possible. If you want to overwrite data in an area of flash memory after writing to the area has been completed, erase the area first.

(4) Resets during programming and erasure

In the case of an internal or external reset during programming and erasure, wait for at least the minimum width of reset pulse once the operating voltage is within the range stipulated in the electrical characteristics before releasing the device from the reset state.

(5) Allocation of vectors for interrupts and other exceptions during programming and erasure

If an interrupt or other exception is generated during transfer of FCU firmware or during programming or erasure of code flash memory, mask the interrupt or other exception beforehand or allocate the interrupt handler address table* and exception handlers to a space from which instructions can be fetched other than code flash memory.

* This applies to cases where the table reference method is used as the method of selection for the addresses of interrupt handlers. For details, see the *RH850G3M User's Manual: Software*.

(6) Abnormal termination of programming and erasure

Even if programming/erasure ends abnormally due to the generation of an external reset or power cutoff, the programming or erasure state of the flash memory with undefined data cannot be verified or checked. For the area where programming or erasure ends abnormally, the blank check function cannot judge whether the area is erased successfully or not. Erase the area again to prove that the corresponding area is completely erased before using.

If programming and erasure of code flash memory are not completed normally, the lock bit for the target area may be enabled (locked). In such cases, erase the block to erase the lock bit while the lock bit is in the disabled state (the area is not locked).

(7) Items prohibited during programming, erasure, and blank checking

Do not perform the following operations during programming, erasure, and blank checking.

- Have the operating voltage from the power supply go beyond the allowed range.
- Update the values of FHVE15 and FHVE3.
- Change the operating frequency of peripheral clock.

(8) Flash memory commands prohibited before completion of clock gear-up sequence

Various commands during serial programming and self-programming must be executed after clock gear-up sequence is complete. For details of clock gear-up sequence, see **Section 11, Clock Controller**.

(9) Securing coherency of instruction cache and data buffer

After the code flash memory is programmed or erased, a reset or instruction cache and data buffer clearing are required to secure coherency of the instruction cache and data buffer. For details of instruction cache and data buffer, see **Section 3, CPU System**.

Section 34 Flash Security

To protect the code flash memory, data flash memory, and ID codes, this product has the functions described in **Section 33, Flash Memory**, and functions to restrict connection of the debug interface, which are described in this section.

For detailed descriptions of the security functions in serial programming mode and how to program the flash memory, see **Section 33, Flash Memory**.

In this section, the interfaces that may be used in on-chip debugging (the Nexus and 4-pin LPD) are referred to as “debug interfaces”. In addition, ID authentication to protect the code flash memory, data flash memory, and ID codes in user boot mode is referred to as “self ID authentication”, and ID authentication to protect against access through the on-chip debug functions is referred to as “OCD ID authentication”.

The data length of each ID code during self ID and OCD ID authentication as well as the ID code in the ID authentication stage of serial programming is 128 bits. In the initial state of the product at shipment, the ID codes are FFFF_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF$_H$.

34.1 Features

34.1.1 Protection of Code Flash Memory, Data Flash Memory, and ID Codes

This product includes the following security functions in user boot mode and serial programming mode to prevent any leaking of the user program programmed in the code flash memory.

34.1.1.1 Functions Unique to User Boot Mode

Self ID authentication protects against programming and erasure of code flash memory and reading of ID code.

(1) Security States

This mode has two security states, protection locked and protection unlocked. Transition between these two states can be made by changing self ID authentication and the ID codes.

1. Protection unlocked
   Security functions have been unlocked by self ID authentication so that protection against programming and erasure of code flash memory and reading of ID codes is not applied.
2. Protection locked
   Security functions have been enabled by self ID authentication and protection against programming and erasure of code flash memory and ID code reading is applied.

34.1.1.2 Functions Unique to Serial Programming Mode

Three functions are provided as security functions unique to serial programming mode: ID authentication, prohibition of programming, erasure, and read commands, and prohibition of serial programmer connection. Parallel use of these functions is not allowed.

(1) ID Authentication

ID codes are checked for authenticity to protect the code flash memory and data flash memory. Programming, erasure, and reading of the code flash and data flash memory can proceed upon successful ID authentication.

(2) Prohibition of Programming, Erasure, and Read Commands

Issuing of programming, erasure, and read commands can be enabled or disabled individually for the code flash memory and data flash memory. All commands are prohibited for both areas in the initial state of the product as shipped.

(3) Prohibition of Serial Programmer Connection

Issuing commands for programming, erasure, or reading to the code flash memory and data flash memory can be disabled in serial programming mode. Transitions to other functions are not possible once this state is set.

34.1.1.3 Common Function of User Boot Mode and Serial Programming Mode

(1) OTP (One Time Programming)

Setting an area of the code flash memory as OTP protects it against any further programming and erasure. For details of the setting, see **Section 33, Flash Memory**.

34.1.2 Connection Restriction Function of Debug Interface

This product is provided with unauthorized access protection via debug interfaces and two security levels are available.

- Security level 1:
  Debug interfaces can be used. At this level, the on-chip debugging function is protected by OCD ID authentication. For OCD to be used, it must be unlocked by using OCD ID authentication.
- Security level 2:
  At this level, the debug interfaces cannot be used.

As described above, restrictions on the connection of code flash and data flash memory, ID code protection, and availability of the debug interfaces differ according to the mode. **Table 34.1** summarizes security functions in each mode.

Table 34.1 Security Functions in Each Mode

Operation Mode	Code Flash, Data Flash, and ID Code Protection	Restriction on Debug Interface Connection
User boot mode	• SELF ID authentication • OTP (Parallel use of OTP with other security features is possible.)	• Security level 1 (OCD ID authentication) • Security level 2 (Debug interface connection is prohibited)
Serial programming mode	• ID authentication • Programming commands, block erasure commands, and read commands are prohibited. • Connection of serial programmers is prohibited. (The above three cannot be used in parallel.) • OTP (parallel use possible)	• No function (Debug interface connection is always prohibited.)

34.2 Security in User Boot Mode

34.2.1 SELF ID Authentication

To prevent leakage of the user program written to the code flash memory, this product has security functions to enable or disable the programming and erasure of code flash memory and the reading of ID codes. The setting of enabling or disabling of these functions can be switched through self ID authentication with the ID code the user has set as the expected value.

34.2.2 SELF ID Authentication and Security State

Table 34.2 and **Figure 34.1** show the security state by self ID authentication and conditions for transition.

Table 34.2 Security Setting State

State	Self ID Authentication	Protection against Programming and Erasure of Code Flash and Reading of ID Codes
Protection unlocked	Unlocked	Not protected
Protection locked	Locked	Protected

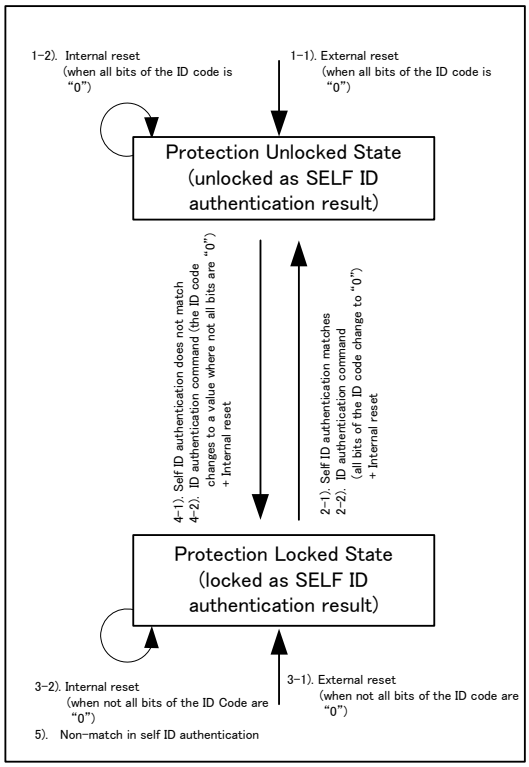

Figure 34.1 Security Setting State by SELF ID Authentication and Transition

The conditions for the transitions of security states shown in **Figure 34.1** are as follows.

- Conditions for Transitions to the Protection Unlocked State

1). Startup when protection is unlocked

1-1). When an external reset is applied while the ID code is all 0s, startup proceeds with protection unlocked.

1-2). When an internal reset is applied without modification of the ID code while all bits of the ID code are 0, startup proceeds with protection in place.

2). Transition from Protection Locked to Protection Unlocked

2-1). A transition to the protection unlocked state follows a match in self ID authentication matches.

2-2). When an internal reset is applied after changing the ID code has been changed from other than “all bits 0” to “all bits 0”, startup proceeds with protection unlocked.

- Conditions for Transitions to Protection Locked

3). Startup with protection in place

3-1). When an external reset is applied while the ID code is other than “all bits 0”, startup proceeds with protection in place.

3-2). When an internal reset is applied without modification of the ID code while not all bits of the ID code are 0, startup proceeds with protection in place.

4). Transition from protection unlocked to protection locked

4-1). A transition to the protection locked state follows a non-match in self ID authentication.

4-2). When an internal reset is applied after the ID code has been changed from other than “all bits 0” to “all bits 0”, startup proceeds with protection in place.

5). To retain protection locked

Protection remains in place in case of a non-match in self ID authentication.

34.3 Security Functions in Serial Programming Mode

For details of security functions in serial programming mode, see **Section 33, Flash Memory**.

34.4 Restricting Connection with Debug Interfaces

This product is capable of restricting connection of the debug interfaces to protect against unauthorized access via the debug interfaces. This feature has two security levels.

- Security level 1: Restrict access to OCD functions by using OCD ID authentication
- Security level 2: Prohibit all connection to the debug interfaces

These security levels can be changed by bits 30 and 29 (OPJTAG1 and OPJTAG0) in option byte 2 in the extended area of the flash memory.
In this section, OPJTAG0 and OPJTAG1 are referred to as the OPJTAG bits.

34.4.1 Security Levels and State of Restricting the Connection of Debug Interfaces

Table 34.3 show each security level and the corresponding security states and **Figure 34.2** shows the conditions for transitions.

Table 34.3 Security Levels and State of Restricting Connection to the Debug Interfaces

State	Result of OCD ID Authentication	OPJTAG Bit *1	Restriction on Debug Interface Connection
Security level 1	Unlocked	Other than 00_B	No restriction
	Locked	Other than 00_B	Restriction on access via the debug interfaces is in place.
Security level 2	—	00_B	Connection to the debug interfaces is prohibited.

Note 1. For a detailed description of the OPJTAG bits, see **Section 33, Flash Memory**.

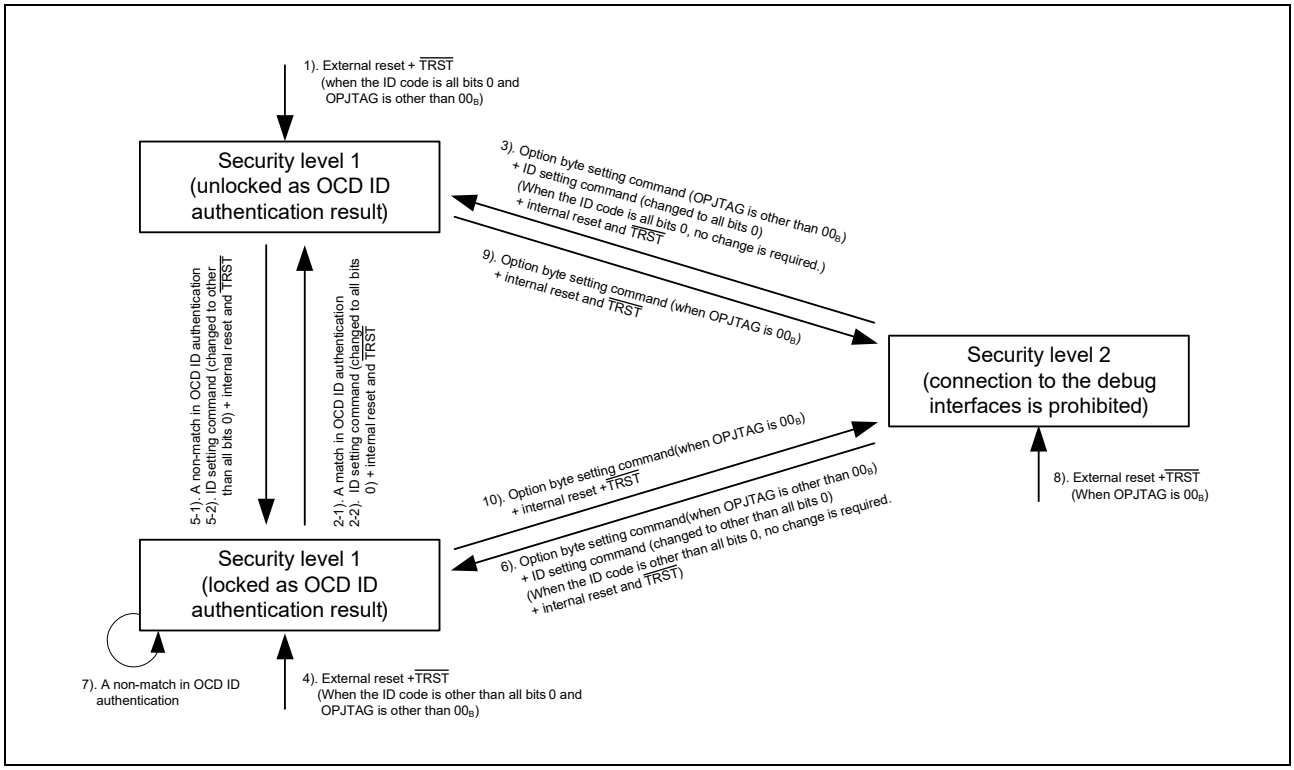

Figure 34.2 Transitions of Security Level

Conditions for transitions to each security level described in **Figure 34.2**.

- Conditions for transitions to security level 1 (locked as OCD ID authentication result)

  1). Startup in the state of security level 1 (unlocked as OCD ID authentication result)
  When an external reset and a reset by $\overline{\text{TRST}}$ are applied while the ID code is all 0s and while the value of the OPJTAG is other than 00_B, startup proceeds with security level 1 (unlocked as OCD ID authentication result).

  2). Transition from security level 1 (locked as OCD ID authentication result) to security level 1 (unlocked as OCD ID authentication result)

  2-1). Transition to security level 1 (unlocked as OCD ID authentication result) follows a match in OCD ID authentication.

2-2). When an internal reset or a reset by $\overline{\text{TRST}}$ is applied after changing the ID code to “all bits 0”, startup proceeds at security level 1 (unlocked as OCD ID authentication result).

3). Transition from security level 2 to security level 1 (unlocked as OCD ID authentication result)
When an internal reset or a reset by $\overline{\text{TRST}}$ is applied after changing the ID code to “all bits 0” and the value of the OPJTAG to other than 00_B, startup proceeds at security level 1 (unlocked as OCD ID authentication result).

- Conditions for Transitions to Security Level 1 (locked as OCD ID Authentication result)

4). Startup in the state of security level 1 (locked as OCD ID authentication result)
When an external reset or a reset by $\overline{\text{TRST}}$ is applied while the ID code is “other than all bits 0” and the value of the OPJTAG is other than 00_B, startup proceeds at security level 1 (locked OCD ID authentication result).

5). Transition from security level 1 (unlocked as OCD ID authentication result) to security level 1 (locked as OCD ID authentication result)

5-1). A transition to security level 1 (locked as OCD ID authentication result) follows a non-match in OCD ID authentication.

5-2). When an internal reset or a reset by $\overline{\text{TRST}}$ is applied after changing the ID code to “other than all bits 0”, startup proceeds at security level 1 (locked as OCD ID authentication result).

6). Transition from security level 2 to security level 1 (locked as OCD ID authentication result)
When an internal reset or a reset by $\overline{\text{TRST}}$ is applied after changing the ID code to “other than all bits 0” and the value of OPJTAG is other than 00_B, startup proceeds at security level 1 (locked as OCD ID authentication result).

7). Retaining security level 1 (locked as OCD ID authentication result)
In case of a non-match in OCD ID authentication, security level 1 (failure in OCD ID authentication) remains in place.

- Transition to security level 2

8). Startup at security level 2
When an external reset or a reset by $\overline{\text{TRST}}$ is applied while the value of OPJTAG is 00 B, startup proceeds at security level 2.

9). Transition from security level 1 (unlocked as OCD ID authentication result) to security level 2
When an internal reset or a reset by $\overline{\text{TRST}}$ is applied after changing the value of the OPJTAG to 00_B, startup proceeds at security level 2.

10). Transition from security level 1 (locked as OCD ID authentication result) to security level 2
When an internal reset or a reset by $\overline{\text{TRST}}$ is applied after changing the value of the OPJTAG to 00_B, startup proceeds at security level 2.

Section 35 RAM

35.1 List of On-Chip RAM

RH850/E1M-S includes the following RAMs.

- Local RAM (PE1): 64 Kbytes
- Local RAM (PCU): 32 Kbytes
- Global RAM: 256 Kbytes (32 Kbytes of data are retained in power-off standby mode)
- Emulation RAM: 8 Kbytes (RAM is not retained)

35.2 Features

Access:

The CPU, PCU, DMAC, and H-Bus can access the local RAM (PE1) and the global RAM.

The PCU also can access the local RAM (PCU).

The access latency from the CPU is the same as that of the local RAM (PE1) and local RAM (self).

For details of address map and access, see **Section 4, Address Space**.

Emulation RAM:

The specific area of the code flash can be replaced with this RAM per page. The access latency from the CPU after replacement is the same as that of the code flash.

The emulation RAM does not include the ECC. Use the emulation RAM only for debugging.

RAM Retention:

32 Kbytes of data in the global RAM are retained in power-off standby mode.

ECC:

The local RAM (PE1), local RAM (PCU), and global RAM include the ECC.

The local RAM (PE1) and global RAM also include the address parity. For details, see **Section 29, Safety**.

35.3 RAM Data Retention

Simultaneous occurrence of write and reset in the RAM space that retains data does not damage RAM data in power-off standby mode.

35.4 Emulation RAM

35.4.1 Emulation RAM

RH850/E1M-S includes the emulation RAM to emulate the code flash. The emulation RAM is placed for each bank of the code flash. RH850/E1M-S has the one-bank code flash and the 8-Kbyte emulation RAM (1 bank). The emulation RAM is available in the code flash emulation function described below, and also can be accessed from CPU1.

35.4.2 Code Flash Emulation Function Using the Emulation RAM

Mapping is enabled and disabled for each bank of the emulation RAM in any area of the code flash using an external debug device and calibration function unit (CFU). Mapping to a code flash area enables a code flash to move to the emulation RAM and it enables the emulation RAM to emulate the code flash. The ROM data can be dynamically modified during execution of a user program via the emulation RAM which has mapped to the code flash area.

Figure 35.1 shows the circuit configuration around the emulation RAM.

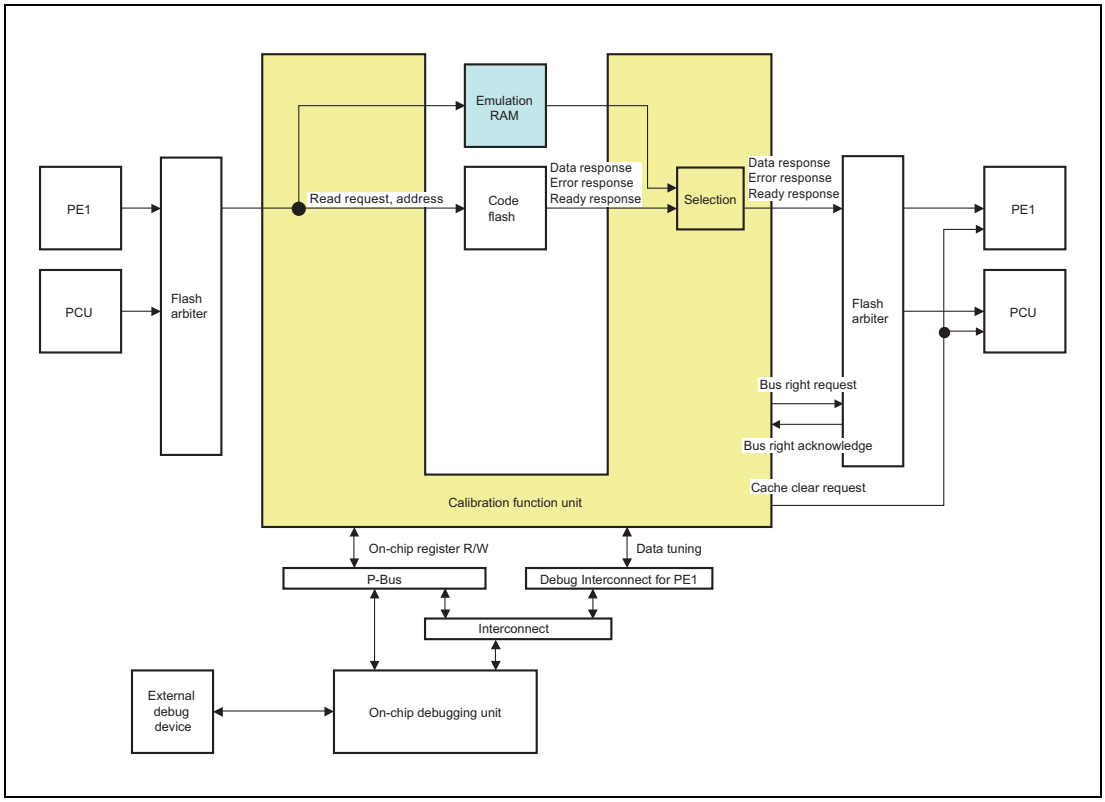

Figure 35.1 Circuit Configuration around the Emulation RAM

35.4.3 Memory Map of Emulation RAM

The memory map of the ERAM in this product is shown below.
The ERAM has 32 banks. Bank 0 only has 8 Kbytes. The ERAM area can be read and written only in 32-bit units.

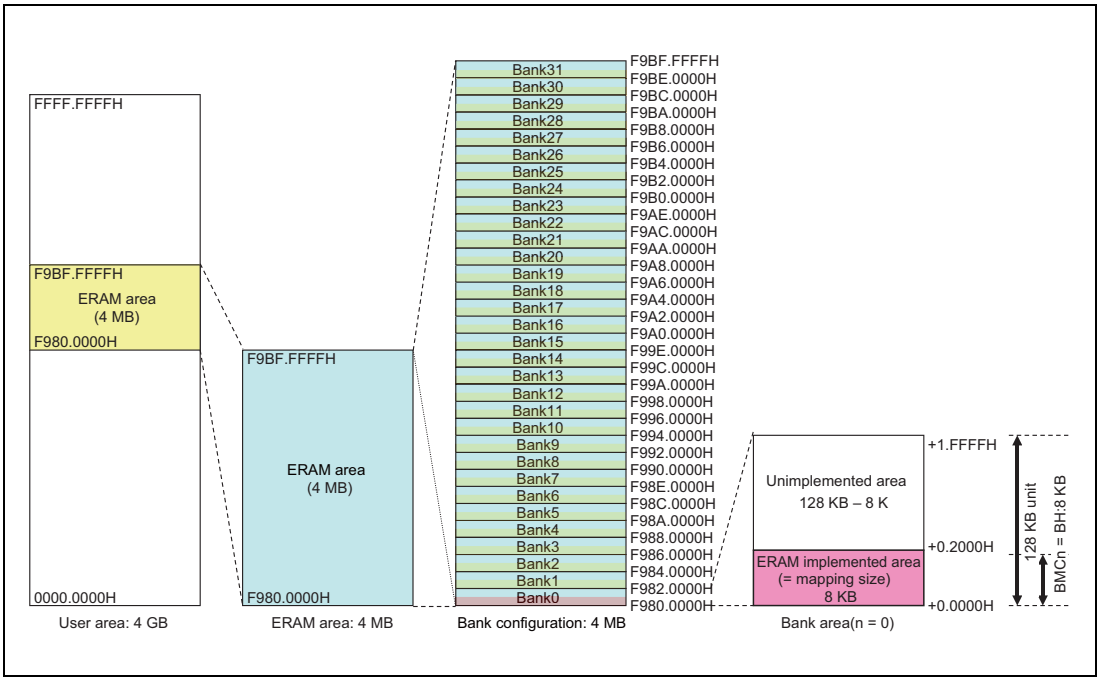

Figure 35.2 Memory Map of 8-KB Emulation RAM

35.4.4 List of CFU Registers

The list below shows function registers that control operations of the calibration function unit (CFU).

The base address of the CFU is FFFF $7800_{H.}$

Table 35.1 List of Function Registers

Address	Register Name	Function
<CFU_base>+08_H	TM_CC	Cache clear Operation register
<CFU_base>+10_H	TM_ME	ERAM bank 0 mapping enable register
<CFU_base>+14_H	TM_MS	ERAM bank 0 mapping status register
<CFU_base>+30_H	TM_BMC0	ERAM bank 0 mapping size setting register
<CFU_base>+40_H	TM_MA0	ERAM bank 0 mapping address register

35.4.5 TM_CC — Cache Clear Operation Register

The TM_CC register is used to issue requests for clearing of the unit (cache or buffer) that holds data from the flash ROM.

Access: This register can be read/written in 32-bit units.

Address: FFFF 7808$_H$

Value after reset 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CCLR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 35.2 TM_CC Register Contents

Bit Position	Bit name	Functions
31 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	CCLR	A cache clearing request is issued by writing 1 to this bit. Writing 0 has no effect. The value read is 1 if this bit is read before the response to a cache clearing request is completed and 0 after the response to a cache clearing request is completed. **CAUTION** • After 1 has been written to this bit, writing 1 to the bit is ignored if this is done before the response to the earlier cache clearing request is completed (the cache is not cleared in response to the latter request). • After 1 has been written to this bit, if 0 is written before the response to the cache clearing request is completed, this will not cancel the response to the earlier request 0: A cache clearing request is not being processed or the response to a cache clearing request has been completed (when read). 1: A cache clearing request is issued (when written), or a cache clearing request is being processed (when read).

35.4.6 TM_ME — Tuning Memory Mapping Enable Register

This register is used to control mapping of ERAM bank 0 to the flash memory area.

Access: This register can be read/written in 32-bit units.

Address: FFFF 7810$_H$

Value after reset 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TME0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 35.3 TM_ME Register Contents

Bit Position	Bit name	Functions
0	TME0	Tuning memory bank n mapping enable (n = 0) These bits control the mapping of ERAM banks n (n = 0) to the user area (flash area). 0: The bank is not mapped. 1: The bank is mapped.

Note 1. When the mapping enable bit TMEn is updated (including writing of its current value again), the cache is cleared.

Note 2. Before ERAM bank n and the tuning memory mapping address register n (TM_Man register) is updated, the corresponding mapping enable bit TMEn must be set to 0 (bank n is not mapped).

Note 3. After an update of the TM_ME register, wait and verify that the value in the TM_MS register has become the same as the setting of the TM_ME register.

35.4.7 TM_MS — Tuning Memory Mapping Status Register

This register is used to indicate the state of mapping to the flash area of ERAM bank 0.

Access: This register can be read in 32-bit units.

Address: FFFF 7814$_H$

Value after reset 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MES0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 35.4 TM_MS Register Contents

Bit Position	Bit name	Functions
0	MES0	Tuning memory bank n mapping enable status (n = 0) These bits indicate the state of mapping of ERAM banks n (n = 0) to the user area (flash area). 0: The bank is not being mapped. 1: The bank is being mapped.

35.4.8 TM_BMC0 — Tuning Memory Bank Mapping Size Configuration Register 0

These registers are used to set mapping size of bank 0 of the ERAM.

Access: This register can be read/written in 32-bit units.

Address: FFFF 7830$_H$

Value after reset 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	BMC0			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 35.5 TM_BMC0 Register Contents

Bit Position	Bit name	Functions
3 to 0	BMC0	Bank 0 mapping size setting

Mapping size each bank of the ERAM (banks 0) is set.

0$_H$	Reserved (setting prohibited)	8$_H$	Reserved (setting prohibited)
1$_H$	Reserved (setting prohibited)	9$_H$	8 KB/bank
2$_H$	Reserved (setting prohibited)	A$_H$	Reserved (setting prohibited)
3$_H$	Reserved (setting prohibited)	B$_H$	Reserved (setting prohibited)
4$_H$	Reserved (setting prohibited)	C$_H$	Reserved (setting prohibited)
5$_H$	Reserved (setting prohibited)	D$_H$	Reserved (setting prohibited)
6$_H$	Reserved (setting prohibited)	E$_H$	Reserved (setting prohibited)
7$_H$	Reserved (setting prohibited)	F$_H$	Reserved (setting prohibited)

Only the following combinations of settings for mapping size are available.

ERAM Capacity	Bank 0 Mapping Size Setting
8 Kbytes	9$_H$ (8 Kbytes/bank)
Any combination other than the above	

Note: The corresponding mapping enable bit TMEn must be set to 0 (bank n is not mapped) before updating the tuning memory bank mapping size configuration register (TM_BMC0 register) (n = 0).

35.4.9 TM_MA0 — Tuning Memory Mapping Address Register 0

These registers are used to set mapping addresses for bank 0 of the ERAM.

Access: This register can be read/written in 32-bit units.

Address: FFFF 7840$_H$

Value after reset 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TMAn[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TMAn[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 35.6 TM_MA0 Register Contents

Bit Position	Bit name	Functions
31 to 0	TMAn[31:0]	Tuning memory mapping address n (n = 0) Specify addresses for mapping ERAM banks n. **CAUTION** TMAn31 to 25 and TMAn12 to 0 are fixed to 0.

BMCn	Mapping Unit	Mapping Judge Bit	Bit to be Ignored
0_H to 8_H	Reserved (setting prohibited)	—	—
9_H	8 Kbytes/bank	TMAn24 to 13	TMAn31 to 25, 12 to 0
A_H to F_H	Reserved (setting prohibited)	—	—

CAUTION

1. **The corresponding mapping enable bit TMEn must be set to 0 (bank n is not mapped) before updating the tuning memory mapping address register n (TM_MAn registers).**
2. **Specify the address in the code flash area as the mapping address. Correct operation is not guaranteed if any other address is specified.**

35.4.10 Flow of Processing for Tuning

The flow of processing for tuning is shown below.

(1)	Mapping initial setting handling
(1-0)	Set the size and address of bank n to be tuned*1 Tuning memory bank mapping size configuration register 0 (TM_BMC0) Tuning memory mapping address register 0 (TM_MA0)
(2)	Handling tuning data
(2-1)	Write data to the ERAM area for use in tuning.
(3)	Mapping the banks
(3-1)	Set the mapping enable bit TME0 in bank 0 for which tuning is complete (n = 0) to 1 (mapping bank 0).
(3-2)	Read the mapping status bit MES0 to verify the completion of mapping settings.

Note 1. Set the corresponding mapping enable bit TME0 to 0 (de-mapping bank 0) to update the register.

When data are tuned (programming of data in the ERAM area) in a mapped bank, the cache must be cleared after tuning of the data.

35.4.11 Notes on Access to ERAM

When accessing from CPU1 to the ERAM area, an LSDC error (lockstep compare error) may occur. The following are the means to mask the error.

(1) Set the $\overline{\text{AUDRST}}$ to H (when the AUD RAM monitor is usable).

(2) Disable interrupts, resets, and error output due to the LSDC error by setting the ECM. Register access by the CFU does not cause the LSDC error.

35.5 Usage Notes

- When ECC error detection/correction is enabled for the local RAM and global RAM, initialize the RAM using a write instruction with the maximum bit length of its access size before using the RAM. For the maximum bit length of the RAM access size, see the applicable data width in **Table 29.1, ECC Overview**.
  If the RAM is accessed before its initialization, an ECC error may be detected. Also if initialization with the maximum bit length is not performed (e.g. if a 32-bit RAM is initialized by an 8-bit or 16-bit access), an ECC error may be detected.
- Buffers are included for high-speed access between the following RAMs and the CPU.
  - Local RAM (PE1), Local RAM (PCU)

  After a value has been written to an address, reading the value from the same address may lead to reading from the buffer instead of the RAM. Ways to make sure that values are being read from the RAM are as follows.
  - For Local RAM (PE1)
    1. Only read the first byte to have been written after having written more than 32 bytes of data.
    2. Issue a SYNCM instruction between a write instruction and an instruction to read from the same address.
  - For Local RAM (PCU)
    1. Only read the first byte to have been written after having written more than 4 bytes of data.
    2. Issue at least one instruction which is not accompanied by access to memory (an NOP instruction, SYNCM instruction, etc.) between a write instruction and an instruction to read from the same address.

Section 36 Boundary Scan

This LSI has the JTAG interface and provides the boundary scan function conforming to the IEEE1149.1 standard.

36.1 Features

- Five test signals (TCK, TDI, TDO, TMS, and $\overline{\text{TRST}}$)
- TAP controller
- Instruction register
- Bypass register
- Boundary scan register

The JTAG interface has six commands.

- BYPASS mode
  Test mode conforming to the IEEE 1149.1
- EXTEST mode
  Test mode conforming to the IEEE 1149.1
- SAMPLE/PRELOAD mode
  Test mode conforming to the IEEE 1149.1
- CLAMP mode
  Test mode conforming to the IEEE 1149.1
- HIGHZ mode
  Test mode conforming to the IEEE 1149.1
- IDCODE mode
  Test mode conforming to the IEEE 1149.1

Figure 36.1 shows a block diagram of the JTAG interface.

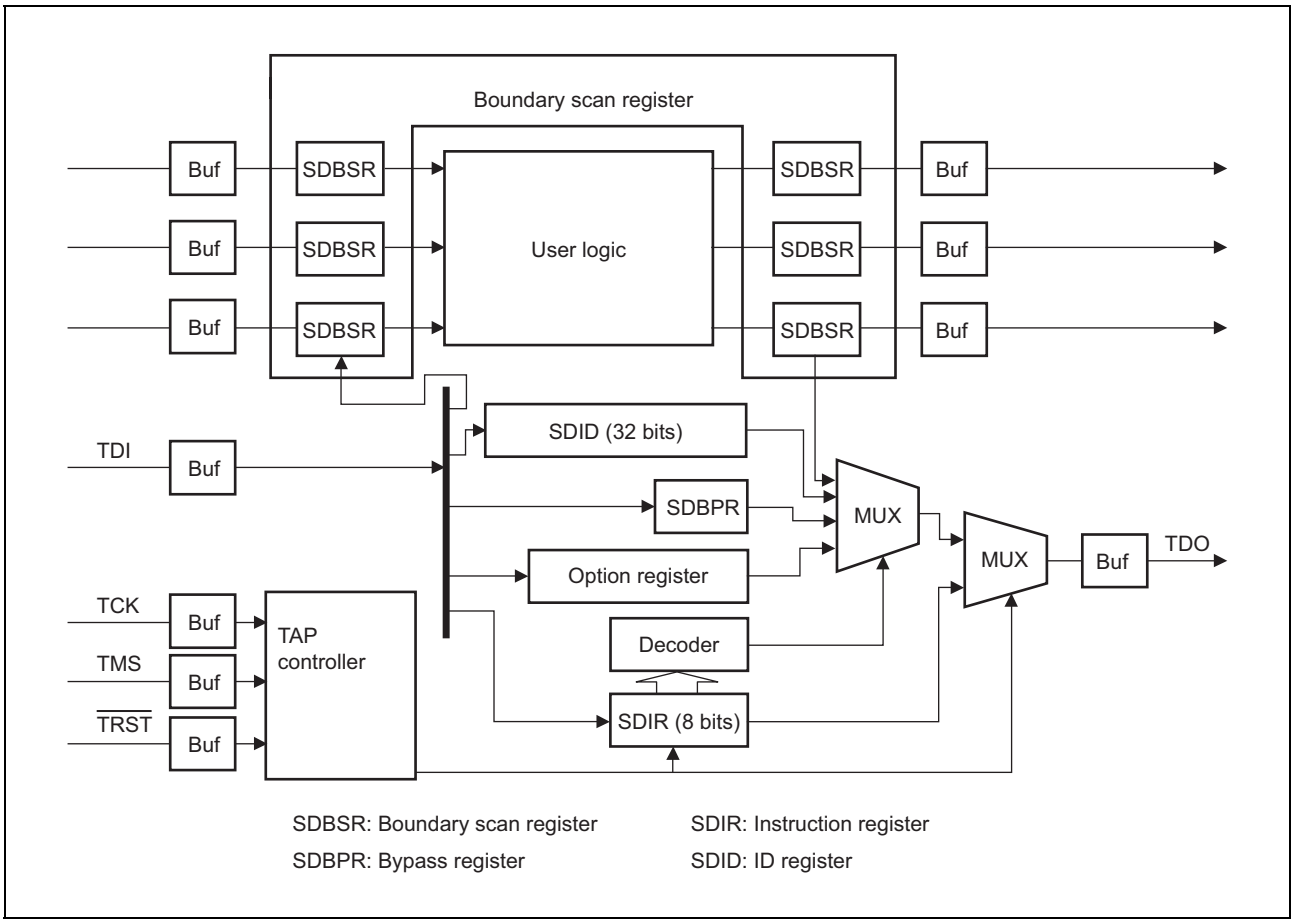

Figure 36.1 Block Diagram of JTAG Interface

36.2 Input/Output Pins

There are five JTAG control signals: TCK, TDI, TMS, TDO, and $\overline{\text{TRST}}$.

Table 36.1 shows the pin configuration.

Table 36.1 Pin Configuration

Pin Name	Description
TCK	Serial data input/output clock pin Data is supplied via the data input pin (TDI) and is output from the data output pin (TDO) in synchronization with this clock signal.
TMS	Mode select input pin Changing the level of this signal in synchronization with TCK changes the state of the TAP controller. For the protocol, refer to **Figure 36.2 TAP Controller State Transition Diagram**.
$\overline{\text{TRST}}$	Reset input pin A low-level input of this signal, which is accepted asynchronously with TCK, resets the JTAG interface. Even if the JTAG interface is not used, $\overline{\text{TRST}}$ must be held low for the specified time at a power on.
TDI	Serial data input pin Changing the state of this pin in synchronization with TCK allows data to be sent to the JTAG interface.
TDO	Serial data output pin Reading the state of this pin in synchronization with TCK allows data to be read from the JTAG interface.

36.3 Register Descriptions

The JTAG interface has the following registers. None of the registers can be accessed by the CPU.

- SDIR: Instruction register
- SDID: ID register
- SDBPR: Bypass register
- SDBSR: Boundary scan register

Table 36.2 Register Configuration

Register Name	Symbol	Access Size	Value after Reset*1
Instruction register	SDIR	8	55_H
ID register	SDID	32	*2
Bypass register	SDBPR	1	Undefined
Boundary scan register	SDBSR	—	Undefined

Note 1. Registers are initialized when the $\overline{\text{TRST}}$ pin is 0 or when TAP is in the test-logic-reset state.
Note 2. It is dependent on products. Contact our sales representative.

Commands can be serially transferred from the serial data input pin (TDI) and input to the instruction register (SDIR). The bypass register (SDBPR) is a 1-bit register, to which TDI and TDO are connected in BYPASS mode, CLAMP mode, and HIGHZ mode. The boundary scan register (SDBSR) is connected to TDI and TDO in SAMPLE/PRELOAD mode and EXTEST mode. The ID code register (SDID) is a 32-bit register, from which the ID code is output via TDO in IDCODE mode.

Table 36.3 shows the serial transfer types possible with the JTAG interface registers.

Table 36.3 Serial Transfer Types Possible with JTAG Interface Registers

Register	Serial Input	Serial Output
SDIR	Possible	Impossible*1
SDBPR	Possible	Possible
SDBSR	Possible	Possible
SDID	Impossible	Possible

Note 1. A fixed value is read out.

36.3.1 SDIR — Instruction Register

SDIR is an 8-bit register that holds a boundary scan command. SDIR is initialized when $\overline{\text{TRST}}$ is asserted or TAP is in the test-logic-reset state. Operation is not guaranteed when any reserved command is set in this register.

Table 36.4 Boundary Scan Commands

IR Code								Description
0	0	0	0	0	0	0	0	JTAG EXTEST
0	1	0	0	0	0	0	0	JTAG SAMPLE/PRELOAD
1	1	0	1	0	0	0	0	JTAG CLAMP
1	0	0	0	0	0	0	0	JTAG HIGHZ
0	1	0	1	0	1	0	1	JTAG IDCODE (value after reset)
1	1	1	1	1	1	1	1	JTAG BYPASS
Other than above								Reserved

36.3.2 SDID — ID Register

SDID is a 32-bit register that indicates an LSI-specific ID.

SDID can be read via the JTAG interface pin when the IDCODE command is set but cannot be written to.

For the read values, refer to **Table 36.2, Register Configuration**.

36.3.3 SDBPR — Bypass Register

SDBPR is a 1-bit register. When SDIR is set to BYPASS mode, SDBPR is connected between TDI and TDO. The value after reset is undefined. SDBPR is not initialized by a reset or asserted $\overline{\text{TRST}}$.

36.3.4 SDBSR — Boundary Scan Register

SDBSR is a shift register located on the PADs for controlling the external I/O pins. When SDIR is set to SAMPLE/PRELOAD or EXTEST mode, SDBSR is connected between TDI and TDO. The value after reset is undefined. SDBSR is not initialized by a reset or asserted $\overline{\text{TRST}}$.

36.4 Operation

36.4.1 TAP Controller

Figure 36.2 shows the TAP controller internal states.

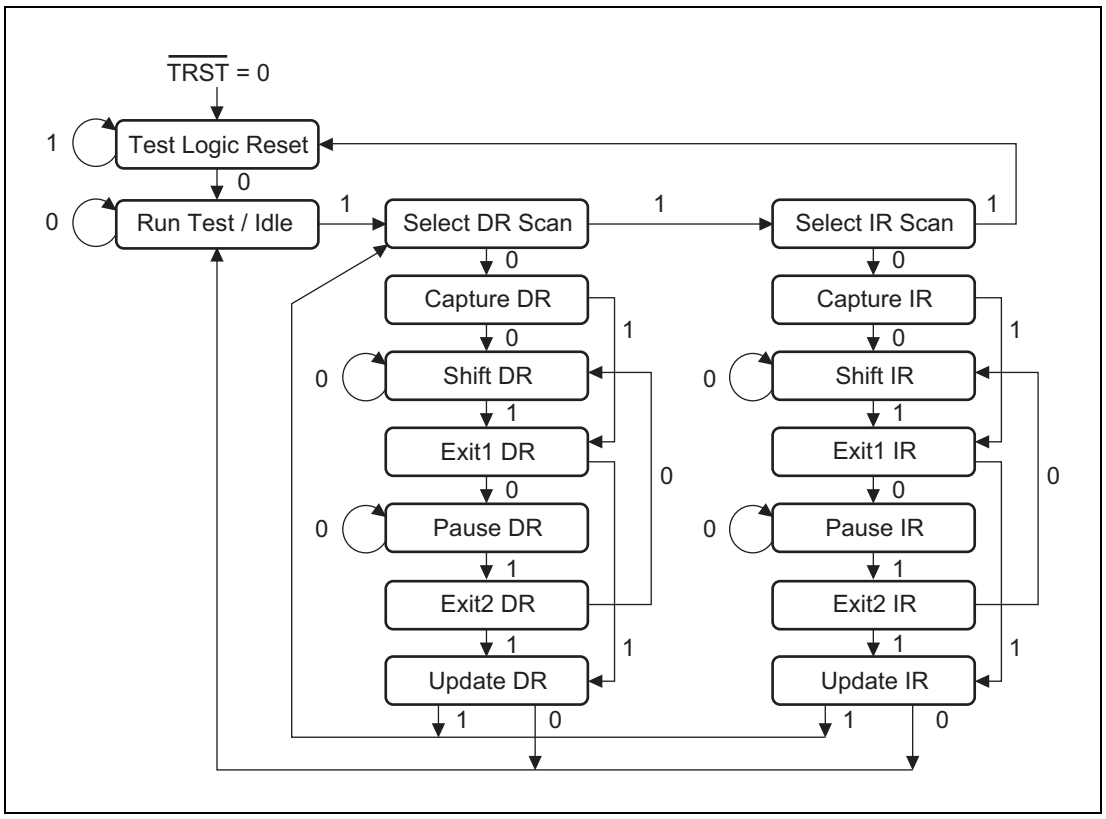

Figure 36.2 TAP Controller State Transition Diagram

Note 1. Transition is made according to the TMS value at the rising edge of TCK. The TDI value is sampled at the rising edge of TCK and is shifted at the falling edge. TDO is in the high-impedance state in the states other than Shift-DR and Shift-IR. Asserting $\overline{\text{TRST}}$ causes transition to the test-logic-reset state asynchronously with TCK.

36.4.2 Supported Commands

36.4.2.1 BYPASS

The BYPASS command is a standard command indispensable to bypass register operation. This command shortens the shift path to achieve high-speed serial data transfer of other LSIs on the printed-circuit board. During execution of this command, the test circuit has no effect on the system circuit.

36.4.2.2 SAMPLE/PRELOAD

The SAMPLE/PRELOAD command is used to input the value to the boundary scan register from the internal circuits of this LSI; to output the value from the scan path; and to load data onto the scan path. During execution of this command, the level of the input pin of this LSI is sent to the internal circuits as is, and the value of the internal circuits is output to the outside via the output pin as is. Executing this command has no effect on the system circuit of this LSI.

The SAMPLE operation allows taking in the snapshots of the value to be transferred to the internal circuits from the input pin or the value to be transferred to the output pin from the internal circuits to the boundary scan register and allows reading the snapshots from the scan path. Snapshots can be taken in without preventing the normal operation of this LSI.

The PRELOAD operation allows setting the initial value to the parallel output latch of the boundary scan register from the scan path prior to the EXTEST command. If the EXTEST command is executed without PRELOAD operation, the undefined value is output from the output pin until the first scan sequence is completed (transfer to the output latch) because the parallel output latch value is always output to the output pin with the EXTEST command.

36.4.2.3 EXTEST

The EXTEST command is used to test the external circuits when this LSI is mounted on the printed-circuit board. When this command is executed, the output pin is used to output the test data (previously set with the SAMPLE/PRELOAD command) from the boundary scan register to the printed-circuit board; whereas the input pin is used to take in the test result from the printed-circuit board to the boundary scan register. When the EXTEST command is executed N times for testing, the test data for the Nth execution is scanned in at the (N – 1)th scan-out.

If the data is loaded onto the boundary scan register of the output pin in the Capture-DR state of this command, it is not used for testing the external circuits (replaced through shift operation).

36.4.2.4 CLAMP

When the CLAMP command is selected, the output pin outputs the boundary scan register value that has been previously set with the SAMPLE/PRELOAD command. While the CLAMP command is selected, the boundary scan register retains the previous state regardless of the TAP controller state.

The bypass register is connected between TDI and TDO and operates in the same manner as when the BYPASS command is selected.

36.4.2.5 HIGHZ

When the HIGHZ command is selected, all the output pins go to the high-impedance state. While the HIGHZ command is selected, the boundary scan register retains the previous state regardless of the TAP controller state.

The bypass register is connected between TDI and TDO and operates in the same manner as when the BYPASS command is selected.

36.4.2.6 IDCODE

The IDCODE command sets the JTAG interface pins to IDCODE mode, which is defined by the JTAG standard. When the JTAG interface is initialized (by asserting $\overline{\text{TRST}}$ or placing TAP in the test-logic-reset state), IDCODE mode is set.

36.4.3 Notes

There are restrictions related to the JTAG interface as follows.

- The power supply/GND pins are not subjected to boundary scan.
- The reference voltage pins of the A/D converter (ADSVREFH, ADSVREFL, A0VREFH, and A1VREFH) are not subjected to boundary scan.
- The pins to be connected to a stabilizing capacitor (ADSVCL and RAMVCL) are not subjected to boundary scan.
- The EPT control pin (EPTVOUT) is not subjected to boundary scan.
- The NC pins are not subjected to boundary scan.

Table 36.5 lists the pins not subjected to boundary scan.

Table 36.5 Pins not Subjected to Boundary Scan

Type	Pins
Analog input	AN000/DSAN0P, AN001/DSAN0N, AN002/DSAN1P, AN003/DSAN1N, AN010/DSAN2P/P14_12, AN011/DSAN2N/P14_13, AN012/DSAN3P/P14_14, AN013/DSAN3N/P14_15, AN020/DSAN4P/P14_0, AN021/DSAN4N/P14_1, AN022/DSAN5P/P14_2, AN023/DSAN5N/P14_3, AN030/DSAN6P/P14_4, AN031/DSAN6N/P14_5, AN032/DSAN7P/P14_6, AN033/DSAN7N/P14_7, AN040/P14_8, AN041/P14_9, AN042/P14_10, AN043/P14_11, AN050/P15_0, AN051/P15_1, AN052/P15_2, AN053/P15_3, AN100, AN101, AN102, AN110, AN111, AN112, AN120, AN121, AN122, AN130, AN131, AN132, AN140, AN141, AN142, AN150/P16_0, AN151/P16_1, AN152/P16_6, AN160/P16_2, AN161/P16_3, AN162/P16_7, AN170/P16_4, AN171/P16_5, AN172/P16_8
Debug system	AUDCK, $\overline{\text{DRDY}}$/LPDCLKO, $\overline{\text{EVTI}}$, $\overline{\text{EVTO}}$, $\overline{\text{RES}}$, TCK/LPDCLKI, TDI/LPDI, TDO/LPDO, TMS/$\overline{\text{EVTO}}$, $\overline{\text{TRST}}$/LPDRST
LVDS	RHSB0FCLN, RHSB0FCLP, RHSB0SON, RHSB0SOP, RHSB1FCLN, RHSB1FCLP, RHSB1SON, RHSB1SOP
Mode setting	FLMODE, MD0, MD1
Clock	CK, EXTAL, XTAL

- The HIGHZ command is invalid for the pulled-down pins.

36.5 Usage Notes

1. Once a command is set, it is not modified until another command is issued again. To continuously issue the same commands, insert a command that has no effect on chip operation (such as BYPASS mode) between the desired commands.
2. To start the system in boundary scan mode, negate $\overline{\text{TRST}}$ while $\overline{\text{RES}}$ is high.
3. For the maximum clock frequency that can be input to TCK, refer to Section 37, Electrical Characteristics.
4. If the number of serially transferred bits exceeds the number of bits of the register connected between TDI and TDO, the data that is input from TDI is output from TDO after the serial data equal to the number of register bits are output.
5. If the serial transfer sequence is corrupted, be sure to reset $\overline{\text{TRST}}$. Here, start the transfer over again regardless of the point of transfer corruption.
6. Data is output via TDO in synchronization with the falling edge of TCK.
7. To facilitate debugging, route $\overline{\text{TRST}}$ on the board in such a way that patterns can be easily cut.
8. No commands can be accepted in power-off standby mode.

Section 37 Electrical Characteristics

37.1 Absolute Maximum Ratings

Table 37.1 lists absolute maximum ratings.

Table 37.1 Absolute Maximum Ratings

Item		Symbol	Rated Value	Unit	Note
Power voltage*1	PLLVCC, SYSVCC, VCC	VCC	–0.3 to +4.3	V	
	EVCC	EVCC	–0.3 to +6.5	V	
	VDD	VDD	–0.3 to +1.8	V	
	LVDVCC	VLVDVCC	–0.3 to +4.3	V	
	TTLVCC	VTTLVCC	–0.3 to +6.5	V	
Input voltage	SYSVCC power pin	Vin	–0.3 to SYSVCC +0.3	V	See **Table 37.3**
	VCC power pin	Vin	–0.3 to VCC +0.3	V	
	EVCC power pins	Vin	–0.3 to EVCC +0.3	V	
	5 V tolerant pin*2	Vin	–0.3 to +5.8	V	
RHSB power voltage		LVDVCC	–0.3 to +4.3	V	
		TTLVCC	–0.3 to +6.5	V	
RHSB input voltage		V_{LVDSIN}	–0.3 to LVDVCC +0.3	V	
		V_{TTLIN}	–0.3 to TTLVCC +0.3	V	
Analog power voltage		A0VCC, A1VCC	–0.3 to +6.5	V	
		ADSVCC	–0.3 to +6.5	V	
Analog reference voltage		A0VREFH	–0.3 to A0VCC +0.3	V	
		A1VREFH	–0.3 to A1VCC +0.3	V	
		ADSVREFH	–0.3 to ADSVCC +0.3	V	
		ADSVREFL	–0.3 to ADSVSS +0.3	V	
Analog input voltage		V_{AIN}	–0.3 to A0VCC +0.3 –0.3 to A1VCC +0.3	V	
		V_{ADSIN}	–0.3 to ADSVCC +0.3	V	
VSS differential voltage*3 (Condition: Between any two of VSS, A0VSS, A1VSS, ADSVSS, PLLVSS, and LVDVSS)			–0.1 to +0.1	V	
Maximum input current (per pin)	Digital input pin	Imax	–25 to +25	mA	Only 1 pin simultaneously
	Analog input pin	Imax	–25 to +25	mA	
Junction temperature*1		Tj	–40 to +150	°C	
Storage temperature		Tstg	–55 to +150	°C	After mounting

Note 1. Cumulative hours of operation of this LSI with Tj in the range from 125°C to 150°C must be kept within 3000 hours.

Note 2. Pins below described as “(5 V tol.)” in **Table 37.2, Relationship between Power Name and Pin**.
FLMODE, MD0, MD1, $\overline{RES}$, $\overline{TRST}$, NMI

Note 3. Of the digital power supplies on the board, short-circuit PLLVSS to VSS.

NOTE

Using this LSI without observing these absolute maximum ratings may result in permanent breakdown of the LSI. This product is used in combination of multiple power voltages simultaneously in some cases. Use this LSI conforming to power pin connections, conditions for combination of power voltages to be applied, voltages that can be applied to pins, and output voltage conditions, which are specified in the manual. Using this LSI with unspecified power connection or voltage may result in permanent breakdown of the LSI or damage to the system that contains this LSI.

37.2 DC Characteristics

Table 37.2 Relationship between Power Name and Pin (7/7)

Pin Name (Value after Reset)	Port Group	Circuit Power Name	I/O	Maximum Input Voltage (V)	Input Buffer Type	Output Driving Ability	Note
SYSVCC							
TTLVCC*1							
VDD							
VDD (N.C.)							
RAMVCL							
VSS							
VSS (N.C.)							

Note 1. The ground for TTLVCC is LVDVSS (the same as the ground for LVDVCC).

Note 2. Though the pins listed with the names of power supply pins (and as N.C.) do not affect operation of the microcontroller even if they are open-circuit, we recommend connecting the pins to the power supply of the same name as those that do not include N.C. to ensure that the power supply is stable. In addition, be sure to mount solder balls on the substrate. The pins listed with the names of power supply pins (and as N.C.) are internally connected with the power supply of the same name as those that do not include N.C.

37.2.2 Operating Conditions

Table 37.3 Operating Conditions

Symbol	Min.	Typ.	Max.	Unit
SYSVCC	3.0	3.3	3.6	V
VCC	3.0	3.3	3.6	V
PLLVCC	3.0	3.3	3.6	V
VDD	1.15	1.25	1.35	V
EVCC	4.5	5.0	5.5	V
LVDVCC	3.0	3.3	3.6	V
TTLVCC	3.0	3.3	3.6	V
	4.5	5.0	5.5	V
A0VCC*3, A1VCC	4.5	5.0	5.5	V
ADSVCC*3	4.5	5.0	5.5	V
A0VREFH, A1VREFH *1	4.5	5.0	5.5	V
ADSVREFH*2	4.5	5.0	5.5	V

Note 1. Set a value less than A0VCC and A1VCC.

Note 2. Set a value less than ADSVCC.

Note 3. Operated under the condition of A0VCC = ADSVCC.

Note: Supply the specified voltages to all power-supply voltage connections when starting operation. Turn off all power voltages when stopping operation. In power-off standby mode, turn off power voltages other than SYSVCC.

37.2.3 Input Voltage Characteristics

Table 37.4 DC Characteristics (Input Voltage)

Conditions: EVCC = 4.5 V to 5.5 V, TTLVCC = 4.5 V to 5.5 V or 3.0 V to 3.6 V, A0VCC, A1VCC = 4.5 V to 5.5 V,
A0VREFH = 4.5 V to A0VCC, A1VREFH = 4.5 V to A1VCC, ADSVCC = 4.5 V to 5.5 V,
ADSVREFH = 4.5 V to ADSVCC, PLLVCC = 3.0 V to 3.6 V, SYSVCC = 3.0 V to 3.6 V,
VCC = 3.0 V to 3.6 V, LVDVCC = 3.0 V to 3.6 V, VDD = 1.15 V to 1.35 V,
VSS = PLLVSS = A0VSS = A1VSS = ADSVSS = ADSVREFL = LVDVSS = 0 V
Tj = -40°C to 150°C

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement Condition
Schmitt trigger input voltage (Buffer type A)	V_T^+ (V_{IH})	SYSVCC × 0.75 VCC × 0.75	—	5.5 + 0.3*1 VCC + 0.3*2	V	See **Table 37.2** (Item of SchA input buffer type)

ADSVREFH = 4.5 V to ADSVCC, PLLVCC = 3.0 V to 3.6 V, SYSVCC = 3.0 V to 3.6 V,
VCC = 3.0 V to 3.6 V, LVDVCC = 3.0 V to 3.6 V, VDD = 1.15 V to 1.35 V,
VSS = PLLVSS = A0VSS = A1VSS = ADSVSS = ADSVREFL = LVDVSS = 0 V
Tj = -40°C to 150°C

Item		Symbol	Min.	Typ.	Max.	Unit
DC injection current (per pin)	Logic pin	I_{IC}	-2.0	—	2.0	mA
	Analog pin		-3.0	—	3.0	mA
DC injection current (total)		$\Sigma \mid I_{IC} \mid$	-50.0	—	50.0	mA

37.2.9 LVDS Driver

Table 37.10 DC Characteristics (LVDS Driver Characteristics)

Conditions: EVCC = 4.5 V to 5.5 V, TTLVCC = 4.5 V to 5.5 V or 3.0 V to 3.6 V, A0VCC, A1VCC = 4.5 V to 5.5 V,
A0VREFH = 4.5 V to A0VCC, A1VREFH = 4.5 V to A1VCC, ADSVCC = 4.5 V to 5.5 V,
ADSVREFH = 4.5 V to ADSVCC, PLLVCC = 3.0 V to 3.6 V, SYSVCC = 3.0 V to 3.6 V,
VCC = 3.0 V to 3.6 V, LVDVCC = 3.0 V to 3.6 V, VDD = 1.15 V to 1.35 V,
VSS = PLLVSS = A0VSS = A1VSS = ADSVSS = ADSVREFL = LVDVSS = 0 V
Tj = -40°C to 150°C

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement Condition
Output high-level voltage	V_{OH}	—	—	1525	mV	**Figure 37.1**, **Figure 37.2**
Output low-level voltage	V_{OL}	875	—	—	mV	
Output differential voltage	V_{OD}	150	—	400	mV	
Offset voltage	V_{OS}	1075	—	1325	mV	
Output impedance	R0	40	—	140	Ω	

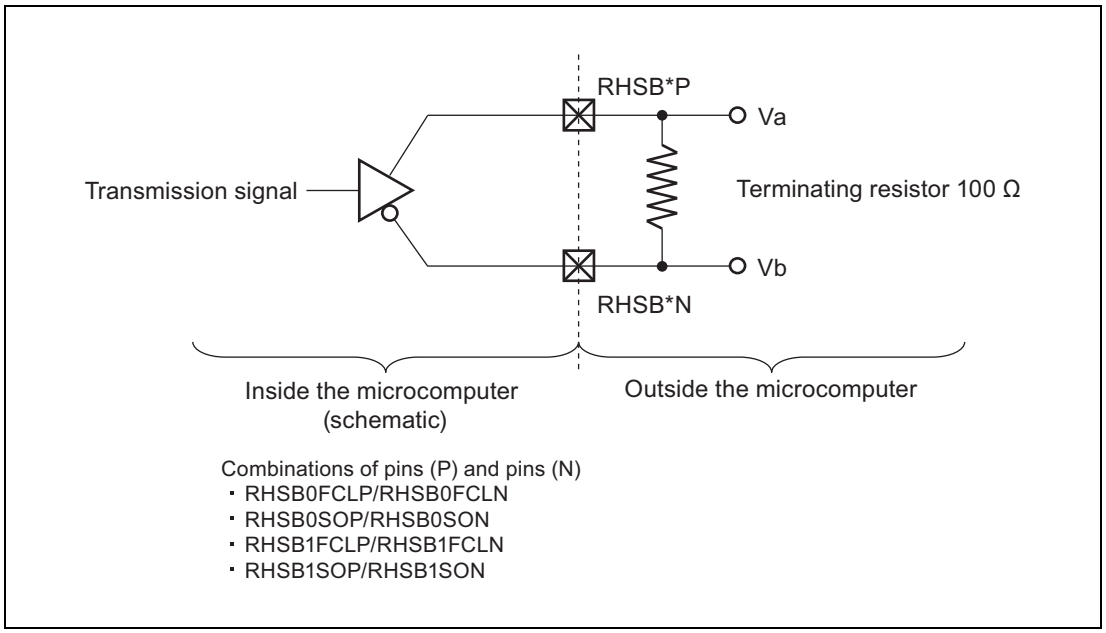

Figure 37.1 LVDS Driver Va/Vb Measurement Conditions

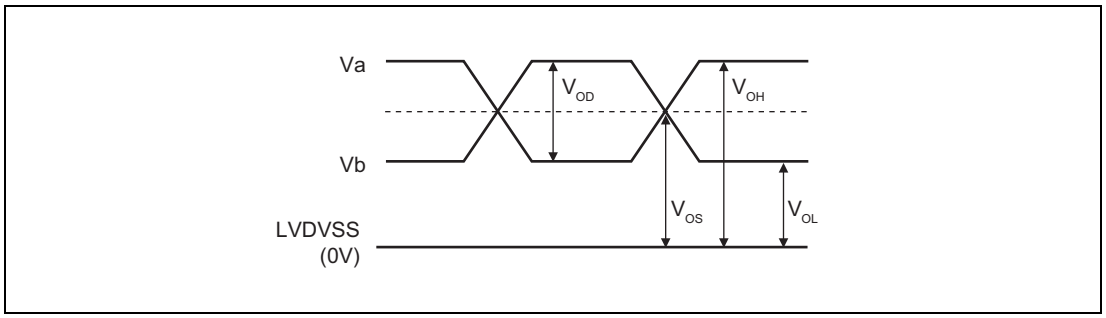

Figure 37.2 Meaning of LVDS Driver Symbols

37.2.10 Input Capacitance

Table 37.11 DC Characteristics (Input Capacitance)

Conditions: EVCC = 4.5 V to 5.5 V, TTLVCC = 4.5 V to 5.5 V or 3.0 V to 3.6 V, A0VCC, A1VCC = 4.5 V to 5.5 V, A0VREFH = 4.5 V to A0VCC, A1VREFH = 4.5 V to A1VCC, ADSVCC = 4.5 V to 5.5 V, ADSVREFH = 4.5 V to ADSVCC, PLLVCC = 3.0 V to 3.6 V, SYSVCC = 3.0 V to 3.6 V, VCC = 3.0 V to 3.6 V, LVDVCC = 3.0 V to 3.6 V, VDD = 1.15 V to 1.35 V, VSS = PLLVSS = A0VSS = A1VSS = ADSVSS = ADSVREFL = LVDVSS = 0 V

Item		Symbol	Min.	Typ.	Max.	Unit	Measurement Condition
Input capacitance	All pins	C_{in}	—	10	20	pF	Vin = 0 V, f = 1 MHz, Tj = 25°C

37.2.11 Supply Current Characteristics

Table 37.12 DC Characteristics (Supply Current)

Conditions: EVCC = 4.5 V to 5.5 V, TTLVCC = 4.5 V to 5.5 V or 3.0 V to 3.6 V, A0VCC, A1VCC = 4.5 V to 5.5 V,
A0VREFH = 4.5 V to A0VCC, A1VREFH = 4.5 V to A1VCC, ADSVCC = 4.5 V to 5.5 V,
ADSVREFH = 4.5 V to ADSVCC, PLLVCC = 3.0 V to 3.6 V, SYSVCC = 3.0 V to 3.6 V,
VCC = 3.0 V to 3.6 V, LVDVCC = 3.0 V to 3.6 V, VDD = 1.15 V to 1.35 V,
VSS = PLLVSS = A0VSS = A1VSS = ADSVSS = ADSVREFL = LVDVSS = 0 V
Tj = -40°C to 150°C

Item		Symbol	Min.	Typ.*1	Max.	Unit	Measurement Condition
Core supply current (VDD power)	Normal operation	Idd	—	230	420	mA	Operation at 320 MHz
			—	180	390	mA	Operation at 240 MHz
	Current during reset	Iddrst	10	70	200	mA	
VCC supply current (when EPT is not used)*2	Normal operation (excluding erasure of code flash)	I_{CC}	—	10	23	mA	
	Erasure of code flash	Icc_cferase	—	20	40	mA	
	Current during reset	Iccrst	3	7	15	mA	
System supply current (SYSVCC)	Normal operation	I_{SYS}	—	0.25	1	mA	
	Current during reset	I_{sysrst}	0.1	0.3	1	mA	
PLL supply current (PLLVCC)		I_{PLL}	2	3.5	5	mA	
RHSB supply current (LVDVCC)		I_{LVDS}	—	14	24	mA	
Analog power current (A0VCC, A1VCC)		I_{AVCC}	—	3.5	6	mA	
Analog power current (ADSVCC)		I_{ADSVCC}	—	12	15	mA	
ADC reference power current (A0VREFH, A1VREFH)		I_{AVREF}	—	220	500	µA	
ADC reference power current (ADSVREFH)		I_{AVREF_DS}	—	400	1000	µA	

Note 1. At Tj = 25°C

Note 2. When an EPT is to be used, calculate the current through the EPT from its current gain and the current from EPTVOUT, then add the result to the value for VCC.

CAUTIONS

1. **When the A/D converter is not used or it is in the standby state, do not open the A0VCC pin, A1VCC pin, A0VREFH pin, A1VREFH pin, ADSVREFH pin, ADSVREFL pin, A0VSS pin, and A1VSS pin.**
2. **Supply current values are with all output pins unloaded when V_{IH}min = VCC – 0.5 V/EVCC – 0.5 V and V_{IL} = 0.5 V.**

37.2.12 Standby Current

Table 37.13 DC Characteristics (Standby)

Conditions: EVCC = 0 V to EVCCstdby1, SYSVCC = SYSVCCLow to 3.6 V,
Other power supplies 0 V to operating voltage,
VSS = PLLVSS = A0VSS = A1VSS = ADSVSS = ADSVREFL = LVDVSS = 0 V
Tj = -40°C to 150°C

Item		Symbol	Min.	Typ.	Max.	Unit	Measurement Condition
Supply current (SYSVCC)	Power-off standby	I_{SB}	—	—	0.75	mA	-40°C <Tj ≤ 50°C
			—	—	1	mA	50°C < Tj ≤ 105°C
			—	—	1.5	mA	105°C < Tj ≤ 150°C

37.2.13 Power Voltage Monitoring Characteristics

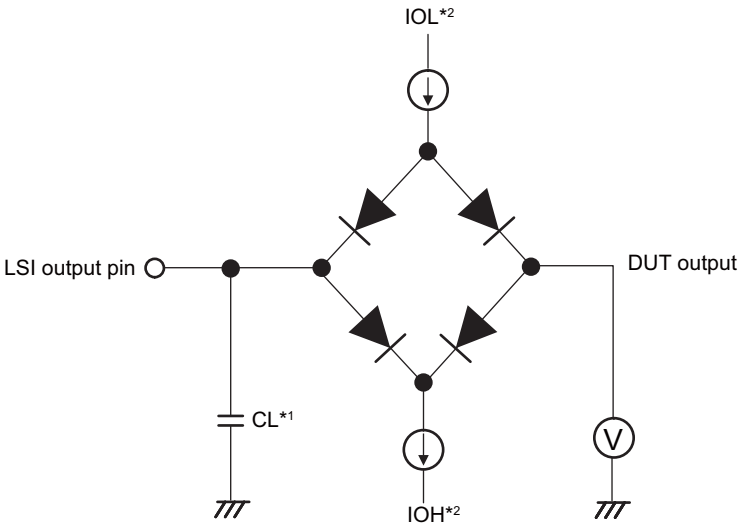
Table 37.14 DC Characteristics (Power Voltage Monitoring)

Conditions: EVCC = 4.5 V to 5.5 V, TTLVCC = 4.5 V to 5.5 V or 3.0 V to 3.6 V, A0VCC, A1VCC = 4.5 V to 5.5 V,
A0VREFH = 4.5 V to A0VCC, A1VREFH = 4.5 V to A1VCC, ADSVCC = 4.5 V to 5.5 V,
ADSVREFH = 4.5 V to ADSVCC, PLLVCC = 3.0 V to 3.6 V, SYSVCC = 3.0 V to 3.6 V,
VCC = 3.0 V to 3.6 V, LVDVCC = 3.0 V to 3.6 V,
VSS = PLLVSS = A0VSS = A1VSS = ADSVSS = ADSVREFL = LVDVSS = 0 V
Tj = -40°C to 150°C

Item			Symbol	Min.	Typ.	Max.	Unit	Measurement Condition
Power voltage monitoring upper-limit voltage	HDETCTL.VDDREFH 1/0 setting	00	—	1.40	1.50	1.60	V	
Power voltage monitoring lower-limit voltage	LDETCTL.VDDREFL 1/0 setting	00	—	0.85	0.95	1.05	V	

37.3 AC Characteristics

- Unless otherwise described, the following timing conditions are applied.
  SYSVCC = VCC = PLLVCC = LVDVCC = TTLVCC = 3.0 V to 3.6 V
  EVCC = 4.5 V to 5.5 V, A0VCC = A1VCC = 4.5 V to 5.5 V, A0VREFH = 4.5 V to A0VCC,
  A1VREFH = 4.5 V to A1VCC,
  ADSVCC = 4.5 V to 5.5 V, ADSVREFH = 4.5 V to ADSVCC, VDD = 1.15 to 1.35 V,
  VSS = PLLVSS = A0VSS = A1VSS = ADSVSS = ADSVREFL = LVDVSS = 0 V,
  Tj = -40°C to 150°C
- In the port control register, conditions where all output pins of the module used in the same channel are set to the same driving ability are applied to output pins whose driving ability is selectable. Unless otherwise specified, all driving ability settings are included.
- Unless otherwise described, AC measurement conditions described in **Figure 37.3** are applied.
  Input reference level High level: V_{IH} minimum value; Low level: V_{IL} maximum value
  Output reference level High level: 2.0 V; Low level: 0.8 V
  Input rising time, falling time: 1 ns



Notes: 1. CL is a total value including the capacitance of the measuring equipment.
Each pin is set as follows:
15 pF: FlexRay pin
30 pF: CK, NEXUS, JTAG, LDU, AUD RAM monitor pins
50 pF: Pins other than above
2. IOH = 200 uA, IOL = 1.6 mA

Figure 37.3 AC Measurement Conditions

37.3.1 Power On/Off Timings

(1) When EPT is not used

Table 37.15 Power On/Off Timings

Item	Symbol	Min.	Max.	Unit	Note	Reference
External reset L time at power-on	tRESW1	10	—	ms	*1	Figure 37.4
External reset L time at power-off	tRESW2	2	—	µs	*2	
PLL1 lock in time	tPLL1L0	—	1	ms	*3	

Note 1. tRESW1 is the reset time required for the supply of internal clock signals to become stable after all power supplies are turned on. No restriction applies to potential differences between each power supply during power up.

Note 2. tRESW2 is the time from assertion of the reset signal until all of the power voltages have dropped below the lower-limit voltages.

Note 3. tPLL1L0 is the time required for PLL1 to lock in after MOSC oscillation has become stable.

CAUTION

- **The states of I/O pins are not reset during the noise cancellation interval (max. 1.2 µs) of the reset signal following its assertion while power is being turned off. During that time, do not allow any input of mid-range potential to the pin or contention of output data.**
- **If power is disconnected during programming or erasure of flash memory, the flash memory may be destroyed.**

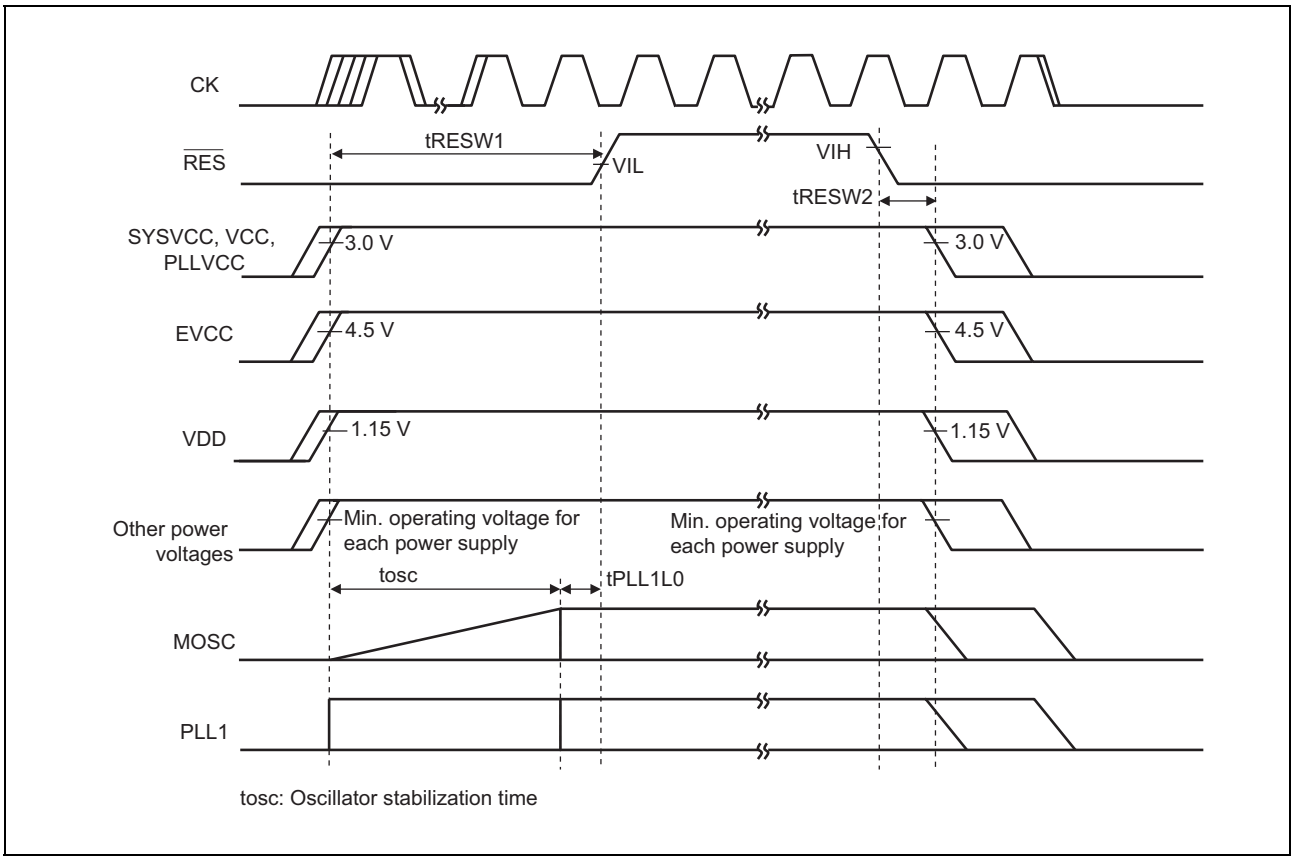


Figure 37.4 Power On/Off Timings When EPT is not Used

(2) When EPT is used

Table 37.16 Power On/Off Timings

Item	Symbol	Min.	Max.	Unit	Condition	Reference
External reset L time at power-on	tRESW4	10	—	ms	*1	**Figure 37.5**
External reset L time at power-off	tRESW5	2	—	µs	*2	
PPL1 lock-in time	tPLL1L0	—	1	ms	*3	

Note 1. tRESW4 is the reset time required for the supply of internal clock signals to become stable after all power supplies are turned on. No restriction applies to potential differences between each power supply during power up.

Note 2. tRESW5 is the time from assertion of the reset signal until all of the power voltages have dropped below the lower-limit voltages.

Note 3. tPLL1L0 is the time required for PLL1 to lock in after MOSC oscillation has become stable.

CAUTION

- **The states of I/O pins are not reset during the noise cancellation interval (max. 1.2 µs) of the reset signal following its assertion while power is being turned off. During that time, do not allow any input of mid-range potential to the pin or contention of output data.**
- **If power is disconnected during programming or erasure of flash memory, the flash memory may be destroyed.**

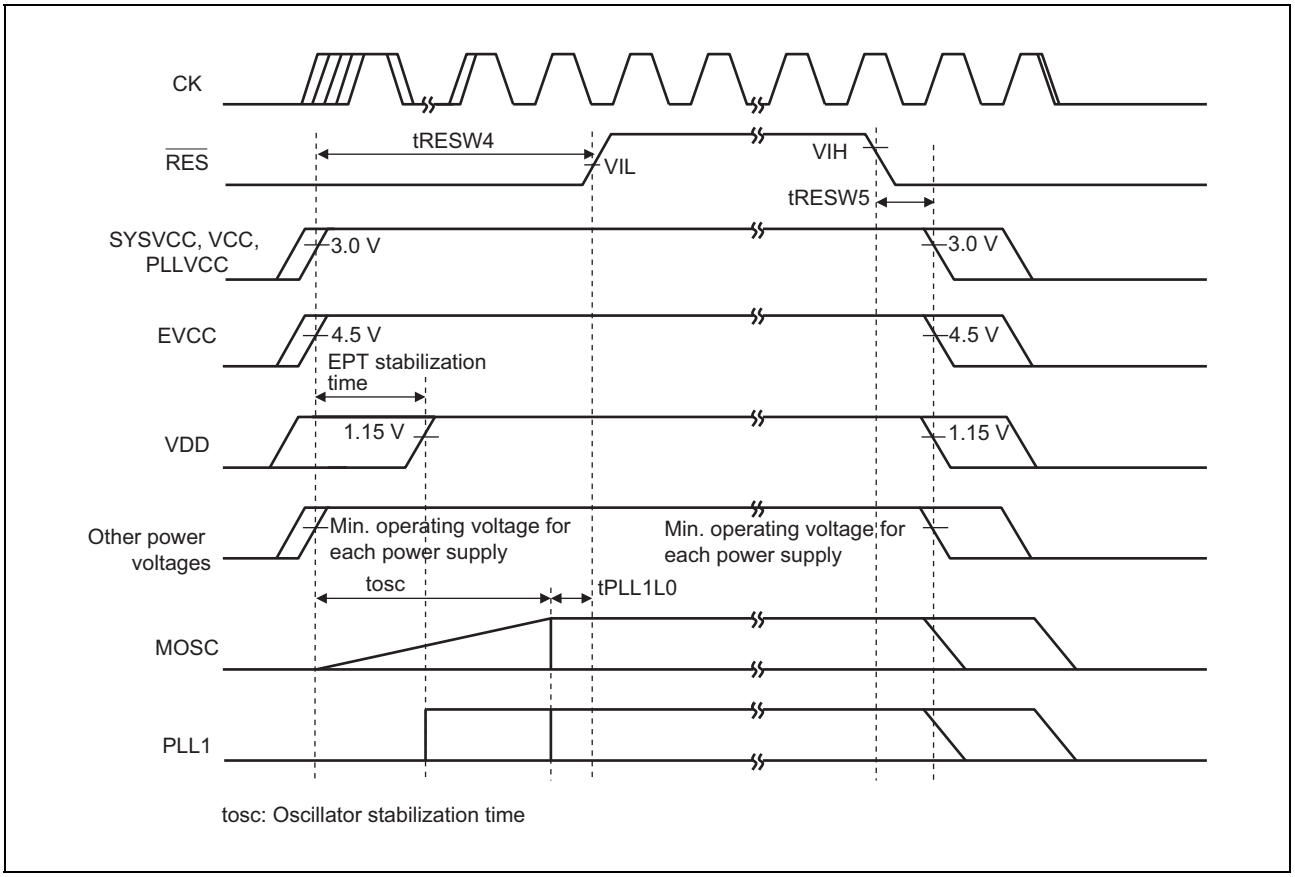

Figure 37.5 Power On/Off Timings when EPT is Used

37.3.2 Standby Transition/Return Timings

Table 37.17 Power-Off Standby Timing

Item	Symbol	Condition	Min.	Max.	Unit	Reference
Reset assertion time before VCC off	tVCC		2	—	µs	**Figure 37.6**
Reset assertion time before VDD off	tVDD		2	—	µs	
Reset assertion time before EVCC off	tEVCC		2	—	µs	
Reset assertion time before power off other than VCC, VDD, and EVCC	tVoltage		2	—	µs	
Reset hold time at return from power-off standby mode	tRESW3	*1	tRESW1	—	ms	
		*2	tRESW4		ms	
EVCC voltage at transition to power-off standby mode	EVCCstdby1	*3	2.1	—	V	
EVCC voltage at return from power-off standby mode	EVCCstdby2	*4	—	2.5	V	
SYSVCC voltage in power-off standby mode	SYSVCCLow		2.7	3.6	V	

Note 1. When EPT is not used.

Note 2. When EPT is used.

Note 3. This is the EVCC voltage for transition to power-off standby mode. This value must be equal to or less than the min. EVCCstdby1 value.

Note 4. This is the EVCC voltage for return from power-off standby mode. This value must be equal to or more than the max. EVCCstdby2 value.

CAUTION

For resetting while flash memory is being programmed or erased, follow the specifications in the *RH850/E1x Flash Memory User's Manual: Hardware Interface*.

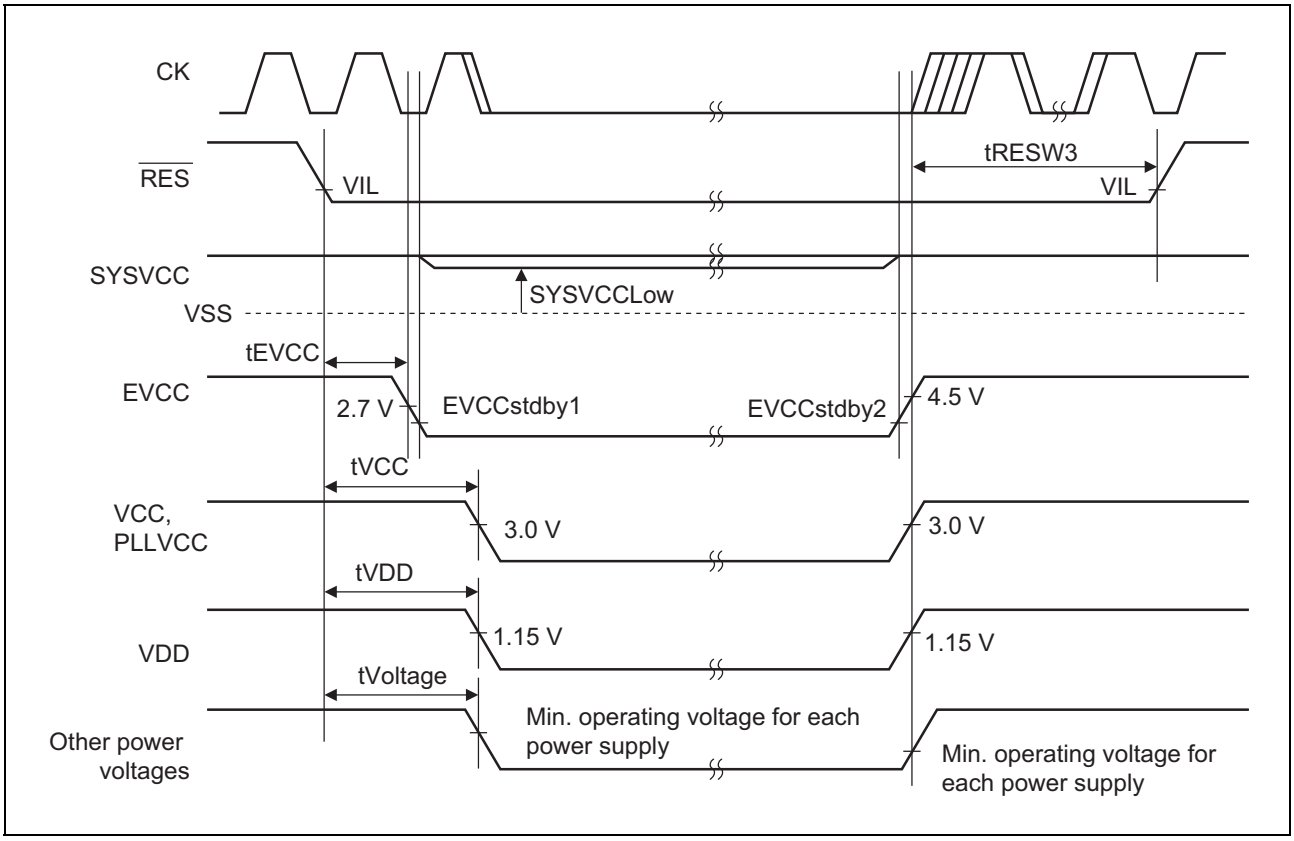

Figure 37.6 Power-Off Standby Timing

37.3.3 Clock Timing

37.3.3.1 External Clock and Output Clock

Table 37.18 Clock Timing

Item	Symbol	Min.	Typ.	Max.	Unit	Reference
EXTAL clock input frequency	f_{EX}	19.9	—	20	MHz	**Figure 37.7**
EXTAL clock input low-level pulse width	t_{EXL}	20	—	—	ns	
EXTAL clock input high-level pulse width	t_{EXH}	20	—	—	ns	
EXTAL clock input rising time	t_{EXR}	—	—	4	ns	
EXTAL clock input falling time	t_{EXF}	—	—	4	ns	
CK clock frequency*1	f_{op}	0.995	1	2	MHz	**Figure 37.8**
CK clock low-level pulse width	t_{CL}	230	—	—	ns	
CK clock high-level pulse width	t_{CH}	230	—	—	ns	
CK clock rising time*2	t_{CR}	—	—	15	ns	
CK clock falling time*2	t_{CF}	—	—	15	ns	

Note 1. The frequency of clock that is output from the CK pin is 1 MHz (when EXTAL input = 20 MHz), which is divided according to the setting by the baud rate generator (BRG). Clock jitter values depend on the board design.

Note 2. CL = 30pF

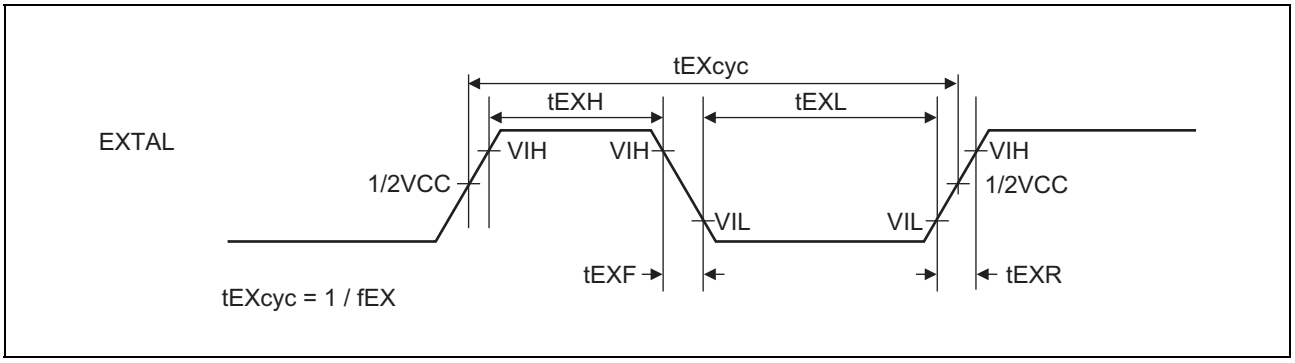

Figure 37.7 EXTAL Timing

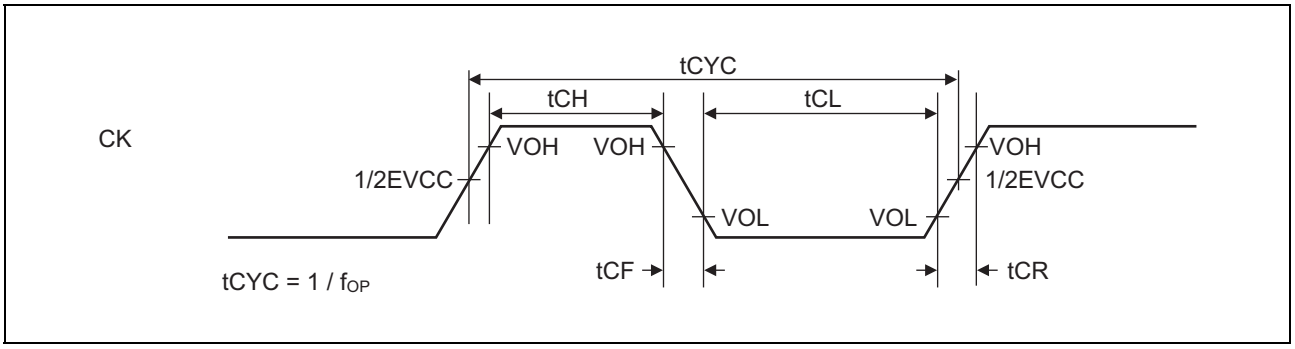

Figure 37.8 CK Timing

37.3.3.2 Spread Spectrum Clock Generator

Table 37.19 SSCG Timing

Item	Symbol	Min.	Typ.	Max.	Unit
Modulation frequency	fmod	20	—	100	kHz
Frequency dithering range[*1]	fdit	4.1	—	—	%
Frequency stabilization time (OFF → ON)		—	—	1.6	ms

Note 1. The modulation method is applied only to down spread.

37.3.3.3 Oscillation Frequency Accuracy of the On-Chip Oscillator

Table 37.20 Oscillation Frequency Accuracy of the On-Chip Oscillator

Item	Symbol	Min.	Typ.	Max.	Unit
ROSC oscillation frequency	fLOCO	160	240	360	kHz

37.3.4 Output Slew Rate

EVCC power supply pins

37.4 A/D Converter Characteristics

Table 37.37 ADC Converter Characteristics

Item		Symbol	Min.	Typ.	Max.	Unit	Reference
Digital resolution		—	—	12	—	bit	
Voltage resolution*1		—	1.10	1.22	1.34	mV	
A/D conversion time (f_{OP} = 20 MHz, 40 MHz)		—	—	1.0	—	µs	
Non-linearity error		—	—	—	±4.0	LSB	
Offset error		—	—	—	±7.5	LSB	
Full-scale error		—	—	—	±7.5	LSB	
Quantization error		—	—	—	±0.5	LSB	
Absolute error		—	—	—	±8.0	LSB	
Self-diagnosis absolute error	A/D conversion circuit self-diagnosis is in use	—	—	—	±8.0	LSB	
	Pin-level self-diagnosis is in use	—	—	—	±40	LSB	
Analog input capacitance	Waiting	—	—		10	pF	
	During sampling	—	—		20	pF	
Allowable analog signal source impedance		—	—	—	3	kΩ	
T&H hold time		—	—	—	10	µs	
Input Voltage Range	When T&H is not used	—	0		A0VREFH, A1VREFH	V	
	When T&H is used	—	0.2		A0VREFH, A1VREFH – 0.2	V	

Note 1. When AnVREFH (n = 0, 1) = 4.5 V, the resolution is 1.10 mV. When AnVREFH (n = 0, 1) = 5.5 V, the resolution is 1.34 mV.

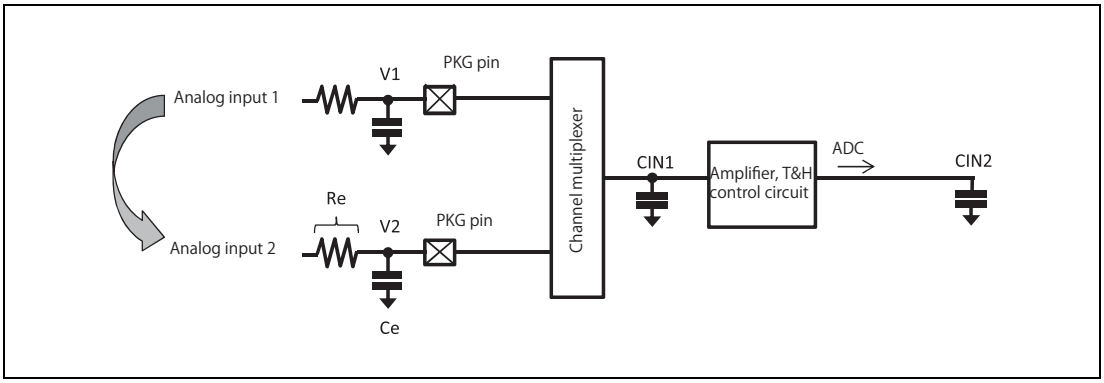
CAUTION

A current being injected to analog input pins while pin-level self-diagnosis is in use does not guarantee the conversion accuracy for the diagnostic voltage of the channels for these pins.

- Errors in the External Circuit of the A/D Convertor
  A formula for errors in sampled values due to the external circuit of the A/D converter is given below.
  These errors will depend on the input circuit and conversion cycle. The formula given below for the errors is simplified for the calculation of sampling errors based on internal stray capacitance, amplifier offset, resistance of the signal source, and conversion cycle. This formula can also be used to calculate the effects of the signal source resistance and conversion cycle on these errors. The formula gives the error of analog input 2 as shown in the figure below when A/D conversion is performed in the order analog input 1 then 2.

$$\text{Conversion error(LSB)} = \left[\left(\frac{|V2\text{-}V1| \times CIN1}{Ce + CIN1} + \frac{|Vvfaerr| \times CIN2}{Ce + CIN2} \right) \times \frac{1}{1\text{-}e^{-T1/(Re \times Ce)}} + \left(\frac{1}{T1} \times C1 \times V3 \times Re \right) \right] \times \frac{4096}{Vavrefh}$$

Item	Symbol	Reference	Unit
Common capacitance of the final stage of channel multiplexer	CIN1	1.4	pF
Common capacitance of the final state of the amplifier and T&H control circuit	CIN2	10	pF
External capacitor on analog input pin	Ce	Depends on user board	μF
Signal source impedance	Re		KΩ
Conversion cycle of conversion pins	T1		ms
AnVREFH voltage (n = 0, 1)	Vavrefh		V
Potential difference between V1 and V2	V2-V1	5	V
Offset voltage of amplifier and T&H control circuit	Vvfaerr	50	mV
Parasitic capacitance of the last stage of channel multiplexer	C1	2	pF
|AnVCC voltage /2.5 – measured pin voltage (V2)| (n = 0, 1)	V3	Depends on user board	V



- Values for conversion error calculated by using this formula do not include error (absolute error, etc.) specified in the A/D converter characteristics.
- This formula is a desktop formula and theoretical. When the signal source has an extremely high resistance or when the conversion cycle is too short, calculated and measured values may differ. Actual error depends on the capacitor, resistor, capacitance and resistance of board wiring, so please evaluate and verify the error on the user board is no greater than the value produced by this formula (Re < 1.5 MΩ and T1 ≥ 10μs, or 1.5 MΩ ≤ Re ≤ 2 MΩ and T1 ≥ 512 μs).

Table 37.38 ΔΣADC Conversion Characteristics (1/2)

37.5 Code Flash Characteristics

Table 37.40 Code Flash Basic Characteristics

Item	Symbol	Conditions	Min.	Typ.	Max.	Unit
Programming endurance*1	CWRT	Retained for 20 years *2	1000	—	—	Times
Temperature range of programming	TPRG	Tj	-40	—	+150	℃
Temperature range of reading	TREAD	Tj	-40	—	+150	℃

Note 1. Programming endurance is defined as the number of times each block is erased. Where programming endurance is n times (n = 1000 in this case), each block is erasable n times. For example, given a memory device that has 32-Kbyte erasure blocks, programming in the address range of each 256-byte programming block (128 programming operations, one for each block) in an erasure block and then erasing the block counts as one time in terms of programming endurance. However, programming of a given address range more than once after erasure is not possible (overwriting after programming is prohibited).

Note 2. The retained period when the average Ta is 85°C. This retained period is from when the erasure of the code flash memory has been normally completed.

Table 37.41 Code Flash Programming Characteristics

Conditions: EVCC = 4.5 V to 5.5 V, TTLVCC = 4.5 V to 5.5 V or 3.0 V to 3.6 V, A0VCC, A1VCC = 4.5 V to 5.5 V,
A0VREFH = 4.5 V to A0VCC, A1VREFH = 4.5 V to A1VCC, ADSVCC = 4.5 V to 5.5 V,
ADSVREFH = 4.5 V to ADSVCC, PLLVCC = 3.0 V to 3.6 V, SYSVCC = 3.0 V to 3.6 V,
VCC = 3.0 V to 3.6 V, LVDVCC = 3.0 V to 3.6 V, VDD = 1.15 V to 1.35 V,
VSS = PLLVSS = A0VSS = A1VSS = ADSVSS = ADSVREFL = LVDVSS = 0 V
Tj = -40°C to 150°C

Item	Condition	Block size	Min.	Typ.	Max.	Unit
Programming time	Programming endurance < 100 times	256 B	—	0.4*1	6*1	ms
		32KB	—	80	360	ms
	Programming endurance ≥ 100 times	256 B	—	0.5*1	7.2*1	ms
		32KB	—	96	432	ms
Erasing time	Programming endurance < 100 times	8 KB	—	39	120	ms
		32 KB	—	141	480	ms
	Programming endurance ≥ 100 times	8 KB	—	47	144	ms
		32 KB	—	169	576	ms

Note 1. Values are only for processing by hardware. Software overhead is not taken into account.

37.6 Data Flash Characteristics

Table 37.42 Data Flash Basic Characteristics

Item	Symbol	Condition	Min.	Typ.	Max.	Unit
Programming endurance*1	CWRT	Retained for 20 years*2	125000	—	—	Times
		Retained for 3 years*2	250000	—	—	Times
Temperature range of programming	TPRG	Tj	-40	—	+150	°C
Temperature range of reading	TREAD	Tj	-40	—	+150	°C

Note 1. Programming endurance is defined as the number of times each block is erased. Where programming endurance is n times (n = 125000 in this case), each block is erasable n times. For example, given a memory device that has 64-byte erasure blocks, programming in the address range of each 4-byte programming block (16 programming operations, one for each block) in an erasure block and then erasing the block counts as one time in terms of programming endurance. However, programming of a given address range more than once after erasure is not possible (overwriting after programming is prohibited).

Note 2. This is the case when the average Ta is 85°C. This retained period is from when the erasure of the data flash memory has been normally completed.

Table 37.43 Data Flash Programming Characteristics

Conditions: EVCC = 4.5 V to 5.5 V, TTLVCC = 4.5 V to 5.5 V or 3.0 V to 3.6 V, A0VCC,A1VCC = 4.5 V to 5.5 V,
A0VREFH = 4.5 V to A0VCC, A1VREFH = 4.5 V to A1VCC, ADSVCC = 4.5 V to 5.5 V,
ADSVREFH = 4.5 V to ADSVCC, PLLVCC = 3.0 V to 3.6 V, SYSVCC = 3.0 V to 3.6 V,
VCC = 3.0 V to 3.6 V, LVDVCC = 3.0 V to 3.6 V, VDD = 1.15 V to 1.35 V,
VSS = PLLVSS = A0VSS = A1VSS = ADSVSS = ADSVREFL = LVDVSS = 0 V
Tj = -40°C to 150°C

Item	Block size	Min.	Typ.	Max.	Unit
Programming time	4 B	—	0.16*1	1.7*1	ms
Erasing time	64 B	—	1.7*1	10*1	ms
Blank check time	4 B	—	—	30*1	µs
	64 B	—	—	100*1	µs

Note 1. Values are only for processing by hardware. Software overhead is not taken into account.

37.7 Thermal Characteristics

37.7.1 Parameters

Table 37.44 Thermal Resistance of RH850/E1M-S

Remaining copper rates		Thickness of conductors	
30-80-80-30%		35-35-35-35µm	

Appendix List of Registers

This section describes information of on-chip I/O registers of this LSI as follows.

- Registers are listed in ascending order of address (OS address).
- Do not access reserved addresses that are not listed below.

In the case of 16-bit or 32-bit addresses, LSB-side addresses are described on the assumption of little endian.

(1/201)

Module Name	Register Name	Register Symbol	Value After Reset	Number of Bits	Address	Peripheral Group	Access Size

REVISION HISTORY	RH850/E1M-S User's Manual: Hardware

Rev.	Date	Description	
		Page	Summary
1.00	Apr 21, 2015	—	First Edition issued
1.10	Apr 15, 2016	Section 1 Overview	
		71	Table 1.2 Pin Numbers and Pin Names (E1MS-BGA252) (6/6), "/" for W12 deleted
		72	Figure 1.3 Internal Block Diagram, description added
		Section 2 Pins	
		160	Table 2.74 Pin State (1/2), P7 and P8 pins modified, P9 and P12 deleted
		163	Table 2.75 Examples of the Handling of Unused Pins (2/4), description of "on-chip pull-down/pull-up resister" of "AUD RAM monitor" and "Debug" modified
		Section 3 CPU System	
		166	Figure 3.1 Block Configuration Diagram, modified (an arrow from "PCU (PE3") to "P-Bus" added)
		167	3.1.1 Block Configuration, description of P-Bus and H-Bus modified
		188	Table 3.32 FPIPR Register Contents, description of the FPIPR bit modified
		190	Table 3.34 PMR Register Contents, description of the PM15-0 bits modified
		251	Table 3.109 MCTL Register Contents, a note added to the functional description of the bit, description in Note 1 modified
		253	Table 3.112 PMR Register Contents, description of the PM7-0 bits modified
		267, 268	3.4.3.2 Operation of the LDL.W and STC.W Instructions, description modified, Note added
		269	3.5.1.1 When updated results in the control registers are reflected in the implementation of a subsequent instruction, description modified
		Section 6 Interrupt	
		279	6.2.1 Register Configuration, description modified
		290	6.2.10 PINT0 to PINT7, PINTCLR0 to PINTCLR7 — Peripheral Interrupt Status Registers and Peripheral Interrupt Status Clear Registers, description modified
		298	6.4 Interrupt Exception Handler and Priority Operations, CAUTION added
		322	Table 6.18 Interrupt Response Times, Note, Iϕ = CLK_CPU added, and modified "is" to "I$"
		Section 7 DMA	
		330	Figure 7.4 DTS Channel Arbitration, DMA transfer request cycles for channel 1 modified
		331	7.2.2.3 Interface Arbitration, description added
		341	7.3.1 Suspending and Resuming DMA Transfer by Software Control, description modified
		341	7.3.2 Suspending, Resuming, and Aborting Transfer by a DMAC Channel, description modified
		342, 343	7.3.3 Suspending, Resuming, and Aborting Transfer by the DTS, description modified
		344	Table 7.5 List of Suspend, Resume, and Transfer Abort Functions, description under "How to execute the function" modified
		348	Table 7.6 Master Information That Is Output from DMA, VCID deleted
		349	7.5.4.1 Restriction on the Next Channel in the Chain, description modified (description of VCID deleted)
		365	Table 7.11 DMACTL Register Contents, CAUTION added
		366	Table 7.12 DTSCTL1 Register Contents, CAUTION added
		373	Table 7.19 DM0CMV Register Contents, functional description of the MINF[6:1] bits modified
		374	Table 7.20 DM1CMV Register Contents, functional description of the MINF[6:1] bits modified
		375	Table 7.21 DTSCMV Register Contents, functional description of the MINF[6:1] bits modified
		385	Table 7.35 DTRTRDAT Register Contents, functional description of the TRDAT[6:0] bits modified
		387	7.9.2.20 DTSnnnCM — DTS Channel Master Setting Register (nnn = 000 to 127), the recommended procedure for setting the DTS channel master setting register, functional description of the bits modified
		393	Table 7.42 DTCTn Register Contents (1/3), functional description of bit 27 modified (DTSTn → DCSTn)
		Section 11 Clock Controller	
		453	Table 11.1 List of Clocks, ASIC clock added
		454	Figure 11.1 Block Diagram of Clock Controller, ASIC clock added

Rev.	Date	Description	
		Page	Summary
1.10	Apr 15, 2016	458, 459	Table 11.6 PLL0CLKC1 Register Contents, functional description of bits 7 to 3 and 2 to 0 modified
		466	11.4.10 PROT1PHCMD — Protect 1 Command Register, Note 1 modified
		475	Table 11.17 ACK0CKC Register Contents, Note 1 modified
		Section 12 Standby Controller	
		491	12.3.3 PROT0PHCMD — Protection Command Register, Note 1 modified
		Section 13 Clocked Serial Interface H (CSIH)	
		517	13.5.1 (2) Slave mode, NOTE modified
		556	13.6.3 CSIHnCTL2 — CSIH Control Register 2, description modified
		564	Table 13.23 CSIHnCFGx Register Contents (3/4), table in the functional description of bits 14 to 12 modified
		Section 14 Serial Communication Interface 3 (SCI3)	
		588	Table 14.11 Relationship between Setting N in SCI3nBRR and Bit Rate B, Note modified
		589	14.3.10 SCI3nBRR — Bit Rate Register, description modified
		591	Table 14.17 Relationship between SCI3nMDDR Setting and Bit Rate B when Bit Rate Modulation Function Is Used, Note modified
		595	14.4.3 Clock, description modified
		595	14.4.4 Double-Speed Operation, description modified
		596	Figure 14.5 Sample Flowchart for SCI3 Initialization, description in [5] modified
		599	Figure 14.8 Example Flowchart for Stopping the SCI3 after Serial Transmission, [6] and Note 1 modified
		602	Figure 14.10 Example of Serial Receive Flowchart (1), modified
		607	Figure 14.15 Example of Multi-Processor Serial Receive Flowchart (1), [1] modified
		608	Figure 14.16 Example of Multi-Processor Serial Receive Flowchart (2), Note 1 modified
		614	Figure 14.22 Example Flowchart for Stopping the SCI3 after Serial Transmission, Note 1 modified
		616	Figure 14.24 Example of Serial Receive Flowchart, description modified
		618	Figure 14.25 Example of Simultaneous Serial Transmission and Receive Flowchart, modified
		622	14.9.6 External Clock Input in Clock Synchronous Mode, description modified
		Section 16 CAN Interface (RS-CAN)	
		678	Table 16.8 External I/O Signals, title modified
		678	Table 16.8 External I/O Signals, description of Txm (m = 0 to 3) modified
		680	Table 16.9 RS-CAN Module Specifications (2/2), description of "interrupt source" modified (transmit mode → receive mode)
		862	16.6 Notes on the RS-CAN Module, modified
		Section 18 Renesas High-Speed Bus (RHSB)	
		1171	18.2.5.1 RHSBjUCR — Upstream Configuration Register, R/W of bits 12 to 8 modified to "R"
		Section 19 Window Watchdog Timer (WDTA)	
		1254	19.5.1.3 WDTA settings after reset release, setting of 75% interrupt mode in the table modified
		Section 20 OS Timer (OSTM)	
		1261	20.1 Functional Overview, description modified
		1272	Figure 20.4 Flow of Starting the OS Timer, description in Note 1 modified
		Section 21 Advanced Timer Unit IV (ATU-IV)	
		All	In the ATU-IV section, pin and signal names have been modified as follows: TOCxy → TIOCxy, TIA0 to 6 → TIA00 to 06
		1328	21.1.4 Clock Supply, added
		1347	Table 21.10 TCR2A Register Contents, entries modified (TIAx → TIA00 to 06)
		1358, 1359	Table 21.18 TIOR2A Register Contents, entries modified (TIAx → TIA00 to 06)
		1372	Table 21.26 NCRAx Register Contents, entries modified (TIAx → TIA0x)
		1377	Figure 21.11 Example of Free-Running Counter A (TCNTA) Operation: Overflow Timing, values of TCNTA modified
		1437	Figure 21.21 Compare-Match Operation of TCNTB6 and Output of CMFB6 Interrupt (IREGB6 = 00, 01), description modified

Rev.	Date	Description	
		Page	Summary
1.10	Apr 15, 2016	1437	Figure 21.22 CMFB6 Interrupt Output when IREGB6 = 10, Note modified
		1488	Figure 21.39 One-Shot Pulse Operation (Output Pin Initialization Timing Chart), pin names modified (toc, tocx[0] → TIOCxy)
		1490	Figure 21.42 One-Shot Pulse Output Cancellation Timing Chart, pin name modified (at_tioc00 → TIOC00)
		1495	21.7.1 Operation Overview, description modified (TOD0xA, TOD0xB → TOD0yA, TOD0yB)
		1502, 1503	21.7.2.3 TIOR1Dx — Timer I/O Control Registers 1Dx, description modified
		1504	21.7.2.4 TIOR2Dx — Timer I/O Control Register 2Dx, description modified (TODxA → TODxyA)
		1504	21.7.2.4 (1) IOBDxy[2:0] — I/O Control B, description modified (TODxA → TODxyA)
		1574, 1575	21.9.1 Operation Overview, description modified
		1575	Figure 21.59 Block Diagram of Subblocks of Timer F, signal name modified, Note 1 added
		1580	Table 21.112 NCMCR2F Register Contents, description modified
		1582	Table 21.114 NCCRF Register Contents, description modified
		1583	21.9.2.4 (1) NCEFx — Noise Canceller Enable Fx, description modified
		1585	Table 21.116 TCR1Fx Register Contents, functional description of bits 1 and 0 modified
		1586	21.9.2.6 (3) EGSELFx — Edge Select Fx, description modified
		1587	Table 21.117 TCR2Fx Register Contents, functional description of bits 7 to 5 modified
		1587	21.9.2.7 TCR2Fx — Timer Control Registers 2Fx, description modified
		1597	21.9.2.13 ECNTBFx — Event Counters Fx, description modified
		1597	Table 21.124 Event Counter Input Clocks and Count Edges for Each Operation Mode of Timer, input clock modified
		1602	21.9.2.18 GRCFx — General Registers CFx, description modified (TIFnA → TIFx)
		1608, 1609	21.9.2.23 NCNTFAx — Noise Canceler Counters FAx, description modified
		1612	Table 21.136 NCRFAx Register Contents, functional description modified
		1614	21.9.3.1 Edge Counting in a Given Time, description of ECNTBFx modified
		1616	21.9.3.2 Effective Edge Interval Counting, description modified
		1618	21.9.3.3 Measurement of Time during High/Low Input Levels, description modified
		1620	21.9.3.4 Measurement of PWM Input Waveform Timing, description modified
		1623	21.9.3.5 Rotation Speed/Pulse Measurement, description modified
		1624	Figure 21.67 Operation Example of Rotation Speed/Pulse Measurement, signal name modified
		1646	21.11.2.6 TCNT2H — Timer Counter 2H, description modified
		Section 22 Autonomous Pulse Adapter (APA)	
		1821	Table 22.65 Standard Setting and Operation Procedure, description of step 1 modified
		1822	Table 22.66 Setting Example for Avoiding Unintended Exception Processing, entries in the table and Note modified
		Section 23 Motor Control Timer (TSG2)	
		1839	Figure 23.1 Block Diagram of TSG2n, modified
		1840, 1841	Table 23.5 TSG2n (n = 0, 1) Registers, modified
		1848	Table 23.11 TSG2nCTL6 Register Contents (1/2), description of bits 7 and 4 modified (STADT0/1 → TSTADT0/1)
		1848	Table 23.11 TSG2nCTL6 Register Contents (1/2), description of bits 9 to 6 modified (TSTADT0 → TSTADT1)
		1893	Figure 23.8 Anytime Rewriting Timing (Example in PWM Mode), interrupt names modified
		1934	Figure 23.43 Example of Error Interrupt (INTTSG2nIER) Generation (PWM Mode), pin names modified (TSG2n01 and TSG2n02 pins → TSOn1 and TSOn2 pins)
		1934	Figure 23.44 Example of Error Interrupt (INTTSG2nIER) Generation for Each Active Level, pin names modified (TSG2n01 and TSG2n02 pins → TSOn1 and TSOn2 pins)
		1935	Figure 23.45 Example of Error Interrupt Operation, pin names modified
		1939	Table 23.47 Timer Output in PWM Mode, entry under "Pin" modified (TSG2nOm → TSOnm)
		1940	Table 23.50 Example of Setting Each Timer Output Condition in PWM Mode, entry under "Pin" modified (TSG2nOm → TSOnm)
		1944	23.11.1.3 Controlling Dead Time in PWM Mode, description modified (TSG2n02 → TSOn2)

Rev.	Date	Description

		2304	Table 29.40 LRFSTERSTR_PCU Register Contents, description of bits 1 and 0 modified
		2306	Table 29.42 LROVFSTR_PCU Register Contents, description of bit 0 modified
		2310	Table 29.46 LRTSTCTRL_PCU Register Contents, description of bits 1 and 0 modified
		2311	Table 29.47 LRTDATBF0_PCU Register Contents, bit names and description of bits 6 to 0 modified
		2316, 2317	Table 29.52 GRTSTCTL Register Contents, description of bits 7 to 4 and 2 to 0 modified
		2318	Table 29.53 GRTDATBFn Register Contents, Note added
		2325	29.2.6.3 (10) GR1STERSTR_VCI/PE1 — Global RAM 1st Error Status Register, description modified
		2325, 2326	Table 29.60 GR1STERSTR_VCI/PE1 Register Contents, entries under bit position and functional description modified
		2331	Table 29.62 Overview of Instruction Cache ECC, description of ECC error detection and correction modified
		2337	29.2.7.3 (5) ID1STERSTR_PE1 — Instruction Cache Data RAM 1st Error Status Register, description modified
		2337	Table 29.68 ID1STERSTR_PE1 Register Contents, description of bits 9, 8, 1, and 0 modified
		2338	29.2.7.3 (6) ID1STEADRn_PE1 — Instruction Cache Data RAM (Bank n) 1st Error Address Register (n = 0, 1), description modified
		2342	Table 29.73 ITOVFSTR_PE1 Register Contents, entries under bit position modified
		2343	29.2.7.3 (11) IT1STERSTR_PE1 — Instruction Cache Tag RAM 1st Error Status Register, description modified
		2343	Table 29.74 IT1STERSTR_PE1 Register Contents, description of bits 1 and 0 modified
		2344	29.2.7.3 (12) IT1STEADR0_PE1 — Instruction Cache Tag RAM 1st Error Address Register, description modified
		2379	29.3 Lockstep, description modified
		2389	Table 29.103 MGDGRSSTAT_VCI/PE1 Register Contents, description of bit 1 modified
		2394	Table 29.110 FSGDxxDPROTn Register Contents (1/2), description of bit 4 modified
		2396	Table 29.113 ERRSLVxxADDR Register Contents, functional description modified
		2397	Table 29.114 ERRSLVxxTYPE Register Contents, functional description modified
		2398	Table 29.115 Specification Overview, description of signature generation modified
		2404	29.5.3.3 Data Counter, CAUTIONS, description modified
		2405	Table 29.117 List of Registers of the Signature Generation Units, RFU, value after reset modified

REVISION HISTORY	RH850/E1M-S User's Manual: Hardware

Rev.	Date	Description	
		Page	Summary
1.10	Apr 15, 2016	2423	Table 29.133 List of Clocks Monitored by Each Clock Monitor and Sampling Clocks Used, description modified
		Section 30 Error Control Module (ECM)	
		2440	30.1.3 Operations for ERROROUT Output, description modified (after release from the reset state → in the reset state or after release from the reset state)
		Section 33 Flash Memory	
		2522	33.11 Usage Notes, (4) and (5) modified
		Section 35 RAM	
		2531	Figure 35.1 Circuit Configuration around the Emulation RAM, modified
		Section 36 Boundary Scan	
		2543	36.3 Register Descriptions, description modified
		2547	Table 36.5 Pins not Subjected to Boundary Scan, description of analog input modified
		2548	36.5 Usage Notes, 6., description modified
		Section 37 Electrical Characteristics	
		2549	Table 37.1 Absolute Maximum Ratings, Rated value of EVCC power pins modified
		2559	Table 37.4 DC Characteristics (Input Voltage), max. value of VT+ modified
		2559	Table 37.4 DC Characteristics (Input Voltage), notes added
		2562	Table 37.7 DC Characteristics (Output Voltage), min. value of EVCC power pin modified
		2567	Table 37.13 DC Characteristics (Standby), conditions modified
		2567	Table 37.14 DC Characteristics (Power Voltage Monitoring), conditions modified
		2569	Table 37.15 Power On/Off Timings, specification of PLL1 lock-in time modified
		2570	Table 37.16 Power On/Off Timings, specification of PLL1 lock-in time modified
		2577	Table 37.26 CSIH Timing in Master Mode, item added, entries modified
		2578	Figure 37.12 CSIH Timing (Master Mode), condition added
		2581	Table 37.27 CSIH Timing in Slave Mode, items added
		2582	Figure 37.16 CSIH Timing (Slave Mode), condition added
		2583	Figure 37.17 CSIH Timing (Slave Mode), item added
		2584	Figure 37.18 CSIH Timing (Slave Mode), pin names modified
		2585	Term unified (SCI → SCI3)
		2585	Table 37.28 SCI3 Timing (Master Mode), specification of transmit data delay time modified
		2585	Figure 37.20 SCI3 Input/Output Timing / Clock Synchronous Mode, modified
		2586	Table 37.29 SCI3 Timing (Slave Mode), specification of transmit data delay time and notes modified
		2591	Table 37.34 JTAG/NEXUS Timing, Max. value of tTDOD and tRDYD modified, name of the DRDY pin modified (RDY → DRDY)
		2591	Figure 37.25 JTAG/NEXUS Timing, name of the DRDY pin modified (RDY → DRDY)
		2594	Table 37.37 ADC Converter Characteristics, Self-diagnosis absolute error modified, CAUTION added
		2595	37.4 A/D Converter Characteristics, • Errors in the External Circuit of the A/D Convertor, items in the table modified
		2596	Table 37.38 ΔΣADC Conversion Characteristics (1/2), conditions in examples 1 to 4 modified
		2598	Table 37.40 Code Flash Basic Characteristics, Note 2, description modified
		2599	Table 37.43 Data Flash Programming Characteristics, unit of block size modified (4 B → 4 KB)
		Appendix List of Registers	
		2601 to 2801	Entries in the register table modified, "Peripheral Group" column added to the table
1.20	May 31, 2017	How to Use This Manual	
		6	3. Register Notation, figure modified and description added to "R:" in (4).
		Table of Contents	
		7	Table of Contents, spelling error corrected (Table of Contens → Table of Contents)
		Section 1 Overview	
		52	1.2 Features, description of interrupts/exception modified ((ECM) added to 1 FE level interrupt)

Rev.	Date	Description	
		Page	Summary
1.20	May 31, 2017	53	1.2 Features, description of advanced timer unit IV (ATU-IV) modified (Timer H: 32-bit compare match timer → Timer H: 32-bit interval timer)
		54	1.2 Features, description of FlexRay modified
		55	1.2 Features, description of boundary scan added
		72	Figure 1.3 Internal Block Diagram, modified
		Section 2 Pins	
		99	2.1.4.6 Pin-Unit Register, (1) PCRn_m — Port Control Register, CAUTIONS added
		Section 3 CPU System	
		169	Table 3.1 Features of the RH850G3M Core, description modified (Thirty-two 32-bit general registers→Thirty-two 32-bit general-purpose registers)
		199	(8) MCR — Memory protection setting check result register, description modified (Be sure to clear bit 31 to 9, 7, and 6 to 0.→Be sure to clear bit 31 to 9, 7, and 6.)
		222	3.2.4.2, (4) Register Set, (d) IPGPMTUM0 — Peripheral Device Protection Setting Register 0, description in a bit chart modified (Bit → R/W)
		225	Table 3.74 Register Contents of IPGPMTUM4, functional description of W0 and R0 bits modified
		227	Table 3.76 SEGCONT Register Contents (1/2), description of bit 15, 9, 6, and 5 modified
		227	Table 3.76 SEGCONT Register Contents (1/2), functional description of VCRE bit modified (note 2 added)
		228	Table 3.76 SEGCONT Register Contents (2/2) description of bit 4 modified
		228	Table 3.76 SEGCONT Register Contents (2/2), functional description of VCIE bit modified and Note 2 added
		231	3.2.4.3 System Error Notification Control Function (SEG), (c) SEGADDR — Error Factor Retention Register (Address), description added
		234	Table 3.80 Features of the RH850G3K Core, description modified (Thirty-two 32-bit general registers→Thirty-two 32-bit general-purpose registers)
		271	3.5.1 Synchronization of Store Instruction Completion and Subsequent Instruction Generation, body modified
		272	3.5.1.2 When the updated results in the control registers and memories are reflected in the instruction fetch of a subsequent instruction:, body modified
		272	3.5.1.3 When switching the code flash area, added
		272	3.5.1.4 When executing the SYNCM instruction to wait for the completion of update by the store instruction, added
		Section 6 Interrupt	
		285	Table 6.5 EIC Register Contents (2/2), functional description of EIMKn bit modified
		305	Table 6.14 Interrupt Exception Handler and Priority (4/13), functional module of TCNTC7 overflow interrupt (113) modified (ATU-IV timer D → ATU-IV timer C)
		325	Table 6.18 Interrupt Response Times (min.), title of the table modified, entries under "Operating Clock", "Synchronization", and "Total" modified, and Note 1 added
		325	6.6 Interrupt Response Times, table below table 6.18, entries under "In CPU1 (240MHz)" modified, header of the table modified (In PCU (320 MHz)), "In PCU (240 MHz)" column added
		Section 7 DMA	
		329	7.2.1.2 Executing a DMA Cycle, description added
		345	7.3.2 Suspending, Resuming, and Aborting Transfer by a DMAC Channel, description added
		349	Table 7.5 List of Functions for Suspending, Resuming, and Aborting Transfer, Note 3 added
		350	7.4.2 DMA Transfer Error, description added
		353	7.5.2.4 Illegal Access, description added
		393	7.9.2.20 DTSnnnCM — DTS Channel Master Setting Register (nnn = 000 to 127), description modified (Bits 31 to 26 of this register are reserved, →Bits 31 to 23 of this register are reserved,)
		399	Table 7.42 DTCTn Register Contents (2/3), functional description of SACM[1:0] bits modified (setting of SACM1 bit for "Setting prohibited" modified to 1)
		400	Table 7.42 DTCTn Register Contents (3/3), CAUTION 1 modified
		413	Figure 7.12 Structure of the TI, the position where the fields are separated in TI-H modified

Rev.	Date	Description	
		Page	Summary
1.20	May 31, 2017	415	7.11.1.4 Caution about accessing the TI, description modified (Bits 31 to 26 of the TI-H → Bits 31 to 23 of the TI-H)
		Section 8 Resets	
		432	8.3 Reset Sources, entries in the table modified
		437	8.4.6 SWRESA — Software Reset Request Register, Note 1 modified
		Section 9 Power Supply Circuit	
		439	9.1 Features, entry under "Uses of Power Supply" of TTLVCC in the table modified, and the reference added
		Section 10 Power Supply Voltage Monitor	
		455	10.5 Notes on Usage, body modified (DCU deleted)
		Section 11 Clock Controller	
		471	11.4.10 PROT1PHCMD — Protect 1 Command Register, Note 1 modified
		473	11.5.1 Operation When the Divide Function Is Used, 4., description modified (Write 001_B to the CLKD0DIV[2:0] bits→Write 010_B to the CLKD0DIV[2:0] bits)
		474	Figure 11.3 Example of Sequence for Shifting the Clock Gear Up, description of processing 6 modified (100010_B in CKSC1CTL.CKSC[5:0]→100100_B in CKSC1CTL.CKSC[5:0])
		Section 12 Standby Controller	
		491	12.2.1 Power Off Standby Mode, body modified
		495	12.3.3 PROT0PHCMD — Protection Command Register, Note 1 modified
		Section 13 Clocked Serial Interface H (CSIH)	
		526	Figure 13.7 Chip Select and RCB Example, description in the figure modified
		532	Table 13.7 Start of Data Transfer, description of Receive-only modified (Writing to the CSIHnTX0W register on→Writing to the CSIHnTX0W register or)
		534	13.5.7, (2), Example, description modified: 2 to 16 bits plus 8 bits → two 16 bits and 8 bits
		Section 14 Serial Communication Interface 3 (SCI3)	
		590	14.3.8 SCI3nSCMR — Serial Transfer Format Register, R/W of bits 7 to 4, 1, and 0 in a bit chart modified
		591	14.3.9 SCI3nSEMR — Serial Extended Mode Register, R/W of bits 5, 4, 1, and 0 in a bit chart modified
		598	14.4.2 Receive Data Sampling Timing and Receive Margin, description of "N" modified: SABCS → ABCS
		601	14.4.6 Serial Data Transmission (Asynchronous Mode), description added (Supplementary note on operation when data transmission in asynchronous mode is enabled)
		602	Figure 14.6 Example of Operation for Transmission in Asynchronous Mode (Example with 8-Bit Data, Parity, One Stop Bit), description in the figure modified (SCInTDR → SCI3nTDR)
		602	Figure 14.7 Example of Serial Transmission Flowchart, [1] SCI3 initialization, description added
		603	Figure 14.8 Example Flowchart for Stopping the SCI3 after Serial Transmission, description in the figure modified
		604	14.4.7 Serial Data Receive (Asynchronous Mode), description in 5 modified (RDRF flag → SCI3nRDR)
		611	Figure 14.15 Example of Multi-Processor Serial Receive Flowchart (1), description in the figure modified (ORER or RER → Is ORER or FER)
		624	14.8 Interrupt Sources, CAUTION modified
		Section 15 LIN Master Interface (RLIN2)	
		628	Table 15.5 Clock Supply, entries in the table modified
		630	Figure 15.1 LIN Master Interface Block Diagram, pin names modified
		645	Table 15.23 RLN21nmLiMST Register Contents, functional description of the reserved bits modified
		647	15.3.3.10 RLN21nmLiST — LIN Status Register, description of ERR flag (error detection flag) modified (TER → FTER)
		648	15.3.3.11 RLN21nmLiEST — LIN Error Status Register, description of "Access" modified (read → read/written)

Rev.	Date	Description	
		Page	Summary
1.20	May 31, 2017	649	15.3.3.11 RLN21nmLiEST — LIN Error Status Register, description of PBER flag (physical bus error flag) modified (physical error → physical bus error)
		653	15.3.3.14 RLN21nmLiCBR — LIN Checksum Buffer Register, body modified (frame transmission completion→ frame transmission/reception completion)
		669	Table 15.35 Types of Statuses, entry under "Status Set Condition" of "Header reception end" modified
		672	Figure 15.14 Connection in LIN Reset Mode, LIN Wake-Up Mode, and LIN Operation Mode, pin names modified
		673	Figure 15.15 Connection in LIN Self-Test Mode, pin names modified
		678	Figure 15.16 Block Diagram of Baud Rate Generation in LIN Master Mode, Note 3 modified (N → M)
		Section 16 CAN Interface (RS-CAN)	
		684	Table 16.9 RS-CAN Module Specifications (2/2), specification of "Interrupt source" modified (CANm transmit queue interrupt added)
		685	Figure 16.1 RS-CAN Module Block Diagram, incorrect names of interrupts modified
		719	16.3.2.4 RSCAN0CmERFL — Channel Error Flag Register (m = 0 to 3), description of BLE flag modified
		742	16.3.2.18 RSCAN0RMNDy — Receive Buffer New Data Register y (y = 0, 1), bit chart modified
		758	16.3.2.30 RSCAN0CFCCk — Transmit/Receive FIFO Buffer Configuration/Control Register (k = 0 to 11), description of CFITR and CFITSS bits added
		784	16.3.2.45 RSCAN0TMTRSTSy — Transmit Buffer Transmit Request Status Register y (y = 0, 1), bit chart modified
		786	16.3.2.46 RSCAN0TMTARSTSy — Transmit Buffer Transmit Abort Request Status Register (y = 0, 1), bit chart modified
		788	16.3.2.47 RSCAN0TMTCSTSy — Transmit Buffer Transmit Complete Status Register (y = 0, 1), bit chart modified
		790	16.3.2.48 RSCAN0TMTASTSy — Transmit Buffer Transmit Abort Status Register (y = 0, 1), bit chart modified
		792	16.3.2.49 RSCAN0TMIECy — Transmit Buffer Interrupt Enable Configuration Register (y = 0, 1), bit chart modified
		827	Figure 16.6 Entry of Receive Rules (in the case of setting channel 0,1) modified (Page11→Page15)
		843	16.5.1.2 Bit Timing Setting, description added
		845	Figure 16.19 Receive Rule Setting Procedure, description in the figure modified (RSCAN0GAFLCFGy → RSCAN0GAFLCFG0, "y = 0" deleted)
		Section 17 FlexRay	
		867	17.1 FlexRay Module, body modified
		868	17.1.1 Overview, specification of "Communication" modified
		869	17.1.2 Terms and Abbreviations, added
		872	17.1.3 Block Diagram, Timer (TIM), description modified (One absolute timer →Two absolute timers)
		913	Table 17.17 FLXA0FRT2C Register Contents, functional description of T2RC bit modified
		919	Table 17.20 FLXA0FRSUCC1 Register Contents (2/2), functional description of CMD[3:0] bits modified
		933	17.2.6.6 FLXA0FRPRTC2 — FlexRay PRT Configuration Register 2, value after reset of bit 8 modified
		985	17.2.8.4 FLXA0FRFCL — FlexRay FIFO Critical Level Register, value after reset of bit 7 modified
		1033	17.2.12.2 FLXA0FROTC — FlexRay Output Transfer Configuration Register, (6) FLXA0FROTC.OTCS, description modified (NDAT → ND, MBSC bits in the FLXA0FRMBSC register → MBC bits in the FLXA0FRMBSCi register)
		1061	Figure 17.6 Configuration of NIT Start and Offset Correction Start, register name modified
		1086	17.3.9.4 Frame Transmission, register name modified (FLXA0FRTRXQ1 → FLXA0FRTXRQ1)
		1119	17.3.16.1 Input Data Transfer, (3) Input pointer table, Equation 1 modified

Rev.	Date	Description	
		Page	Summary
1.20	May 31, 2017	1129	17.3.16.2 Output Data Transfer, (3) Output pointer table, body modified (NDAT bit → ND bit, MBSC bit → MBC bit)
		1130	17.3.16.2 Output Data Transfer, (5) Transfer function of dedicated message buffers, body modified (FLXA0FRNDAT register → FLXA0FRNDATi register, NDAT flag → ND flag, FLXA0FRMBSC register → FLXA0FRMBSCi register, MBSC flag → MBC flag)
		1140	17.3.16.5 Behaviors in Case of RAM Read Errors, (1) Read error during transfer from TBF to MBF, body modified (FLXA0FRNDAT flag →ND flag in the FLXA0FRNDATi register)
		1143	17.3.16.6 Data Transfer Timings, (2) System bus transfer time, formula of "Equation 8 System bus transfer time" modified
		1147	17.3.17 Byte Alignment, body modified
		Section 18 Renesas High-Speed Bus (RHSB)	
		1162	18.2.4.1 RHSBjDCR — Downstream Configuration Register, (7) Clock Line Phase (RHSBjDCR.RHSBjCLP), description modified (RHSBnFCLN (j = 0, 1)→RHSBjFCLN (j = 0, 1))
		1162	18.2.4.1 RHSBjDCR — Downstream Configuration Register, (8) Clock Active Control (RHSBjDCR.RHSBjCAC), body modified (RHSBjSOP → RHSBjFCLP, RHSBjSON → RHSBjFCLN)
		1205	Figure 18.9 Internal Transmission Processing of Command and Data Frames, description of processing D modified (Assemble command frame →Assemble data frame)
		Section 20 OS Timer (OSTM)	
		1269	20.2.2.2 OSTMnCNT — OSTM Counter Register, Value after reset, description added
		1272	Table 20.10 OSTMnTS Register Contents, functional description of OSTMnTS bit modified (This setting disables the counter.→This setting is invalid.)
		1272	Table 20.11 OSTMnTT Register Contents, functional description of OSTMnTT bit modified (This setting disables the counter.→This setting is invalid.)
		1277	Figure 20.4 Flow of Starting the OS Timer, description in the figure and Note 1 modified (OSTM0TOE → OSTMnTOE, OSTM0TO → OSTMnTO, OSTMTTOUT → OSTMnTTOUT, OSTMnTT.OSTMnTT → OSTMnTS.OSTMnTS, OSTM0 → OSTMn)
		Section 21 Advanced Timer Unit IV (ATU-IV)	
		All	In the ATU-IV section, noise cancellation mode names were modified as follows: subsequent edge → premature-transition, preceding edge → minimum time-at-level, level-accumulated → level accumulation
		All	In the ATU-IV section, the unit of filtering were modified as follows: individual subblocks/channels → each subblock/channel, individual channels → each channel, individual subblocks → each subblock
		All	In the ATU-IV section, the description was modified as follows: conflict → contention
		1342	Table 21.6 Settings That Determine Noise Cancellation Modes for Timer C, Note 1. modified (x = 0 to 15 → x = 0 to 7)
		1358	Table 21.15 NCMCR2A Register Contents functional description on bit5 to bit0 modified
		1365	21.4.2.8 TIOR2A — Timer I/O Control Register 2A , (3) NCEA0 to 6 — Noise Canceler Enable A0 to 6, body modified
		1376	21.4.2.15 NCNTAx — Noise Canceler Counters Ax (x = 0 to 6), body modified
		1379, 1380	21.4.3.1 Operation of Noise Canceler, body modified
		1379	Figure 21.7 Example of Noise Cancellation in Premature-Transition Cancellation Mode, title of the figure modified
		1380	Figure 21.8 Example of Noise Cancellation in Premature-Transition Cancellation Mode for Two Types of Input Waveforms, title of the figure modified
		1381	Figure 21.9 Example of Noise Cancellation in Minimum Time-at-Level Cancellation mode, title of the figure modified
		1382	21.4.3.2 Operation of Free-Running Counter, body modified
		1388	Figure 21.15 Timer B Block Diagram, description in the figure modified
		1389, 1390	21.5.2.1 TCRB — Timer Control Register B, body modified
		1392	21.5.2.2 TIORB — Timer I/O Control Register B , (6) IOB6 — I/O Control B6, body modified
		1393	Table 21.29 TSRB Register Contents, functional description of bits 9, 6, 4 to 2, and 0 modified
		1394 to 1396	21.5.2.3 TSRB — Timer Status Register B, body modified
		1407	21.5.2.12 TCNTB1 — Event Counter B1, body modified

Rev.	Date	Description	
		Page	Summary
1.20	May 31, 2017	1408	21.5.2.13 OCRB1 — Output Compare Register B1, body modified
		1409	21.5.2.14 OCRB10 — Output Compare Register B10, body modified
		1413	21.5.2.18 ICRB2 — Input Capture Register B2, body modified
		1416	21.5.2.21 TCNTB2 — Reload Counter B2, body modified
		1417	21.5.2.22 PIMR1 — Pulse Interval Multiplier Register 1, body modified
		1419	21.5.2.24 TCNTB6 — Multiplied Clock Counter B6, body modified
		1425	21.5.2.30 TCNTB3 — Correcting Event Counter B3, body modified
		1427	21.5.2.32 TCNTB4 — Multiplied-and-Corrected Clock Counter B4, body modified
		1447	Figure 21.27 Operation of TCNTB5 (with Correction at End of Cycle), erroneous values of TCNTB3 modified: 000040 00060 00000 00020 → 00060 00080 00000 00020
		1448	Figure 21.28 Operation of TCNTB5 (without Correction at End of Cycle), erroneous values of TCNTB3 modified: 000040 00060 00000 00020 → 00060 00080 00000 00020
		1452	Figure 21.31 Block Diagram of Timer C, Note added to "Sub Block:C5", "Sub Block:C6", and "Sub Block:C7", and Note modified
		1463	21.6.2.4 TSRCx — Timer Status Registers Cx (x = 0 to 7), (1) OCMFCxy — Output Compare Match Flag Cxy, title modified
		1464	21.6.2.4 TSRCx — Timer Status Registers Cx (x = 0 to 7), (3) IMFCxy — Input Capture/Compare Match Flag Cxy, body modified
		1470	21.6.2.7 TCNTCx — Timer Counters Cx (x = 0 to 7), body modified: TCNTCn → TCNTCx
		1471, 1472	21.6.2.8 GRCxy — General Registers Cxy, body modified, description added
		1476	21.6.2.11 OCRCxy — Output Compare Registers Cxy, description added
		1478	21.6.2.13 CUCRCx — Counter Upper-Limit Setting Compare Registers Cx, description added
		1488	21.6.3.2 Compare Match Mode — Compare Match Function, body modified
		1489	21.6.3.3 PWM Function, body modified: bit PWMx → bit PWMx0
		1492	Figure 21.37 Operation when the Compare Register Is Modified during One-Shot Pulse Output, omission of the vertical line modified
		1496	Figure 21.42 One-Shot Pulse Output Cancellation Timing Chart, omission of the vertical line modified
		1500	21.7.1 Operation Overview, description of DMAC modified
		1501	Figure 21.45 Block Diagram of Timer D modified ("x = 0 to 9 (number of subblocks), y = 0 to 3 (number of channels)" deleted)
		1505	21.7.2.2 TCRDx — Timer Control Registers Dx, (1) OBREDx — Timer Offset Base Register Enable, body modified
		1506	21.7.2.2 TCRDx — Timer Control Registers Dx, (4) CLR2Dx — TCNT2Dx Clear, title and body modified
		1506	21.7.2.2 TCRDx — Timer Control Registers Dx, (6) CLR1Dx — TCNT1Dx Clear, title and body modified
		1510, 1511	21.7.2.4 TIOR2Dx — Timer I/O Control Register 2Dx, body modified
		1516	Table 21.89 DSR2Dx Register Contents, functional description of bits 7 to 0 modified
		1519	21.7.2.11 DCRDx — Down Counter Control Registers Dx, (1) TRGSELDxy — Down Counter Start/Stop Trigger Select Bits Dxy, body modified
		1522	21.7.2.12, (4) CMFADxy — Compare Match A Flag Dxy, functional description modified (OCRDxy → ODR1Dxy)
		1523	21.7.2.12, (5) CMFBDxy — Compare Match B Flag Dxy, description modified: output compare B register (OCR2Dxy) → output compare register 2Dxy (OCR2Dxy)
		1528	21.7.2.16 TICTSELDx — Timer Input Capture Trigger Select Register Dx, Note 1 modified
		1533	21.7.2.21 OCR1Dxy — Output Compare Registers 1Dxy, description added
		1534	21.7.2.22 RCR1Dx — Range Comparison Value Setting Register 1Dx, body modified (OCR1Dxy + RCR1Dx -> (OCR1Dxy + the value of the range specified by RCR1Dx))
		1536	21.7.2.23 OCR2Dxy — Output Compare Registers 2Dxy, description added
		1537	21.7.2.24 RCR2Dx — Range Comparison Value Setting Register 2Dx, body modified (OCR2Dxy + RCR2Dx -> (OCR2Dxy + the value of the range specified by RCR2Dx))
		1543, 1547	21.7.3 Operation, body modified

Rev.	Date	Description	
		Page	Summary
1.20	May 31, 2017	1548	21.7.3.1 Range Comparison Function, body modified (OCR1Dxy + RCR1Dx -> (OCR1Dxy + the value of the range specified by RCR1Dx))
		1548	Figure 21.49 Operation of the Range Comparison Function, description in the figure modified ("OCR1Dxy + RCR1D" → "OCR1Dxy + the range value specified by RCR1Dx")
		1576	Figure 21.55 Operation of PWM (1) modified ("omice0" deleted)
		1582	21.9.2.1 TSTRF — Timer Start Register F, body modified: 0000 0000_H→ 0000_H
		1588	21.9.2.4 NCCRF — Noise Canceller Control Register F, body modified: 0000 0000_H→ 0000_H
		1598	21.9.2.10 TSRFx — Timer Status Registers Fx, body modified
		1610	21.9.2.20 GRDFx — General Registers DFx, Note 1 deleted, value after reset of bits 31 to 16 in a bit chart modified
		1639	Table 21.142 TSRGx Register Contents, functional description of OVFGx bit modified
		1639	21.10.2.3 TSRGx — Timer Status Registers Gx, body modified
		1647	21.11.2.2 TSRH — Timer Status Register H, body modified
		1660	21.12.2.4 TSRJx — Timer Status Register Jx, body modified
		1682	Figure 21.77 Data DMA Trigger Selection Circuit, the path of the DFE filter completion signal has been corrected to show that it passes through the synchronization circuit.
		1684	Figure 21.79 SAR-AD Trigger Selection Circuit, signal name modified (Timer G1 compare interrupt→Timer G2 compare interrupt)
		1686	21.14.1.2 Contention between Writing to Counter and Input Capture, bit name in the table modified (FDOVJx → FDOVFJx)
		1687	21.14.1.3 Contention between Setting and Clearing of Input Capture Status Flag, bit name in the table modified (FDOVJx → FDOVFJx)
		1689	21.14.2.2 Contention between Writing to CYLRExy and Cycle Match of TCNTExy, entry in the table modified (OCRB6 → OCRB6/OCRB7)
		1692	21.14.2.6 Contention between Writing to TCNTExy and Counter Clearing by Cycle Match, entry in the table modified (OCRB6 → OCRB6/OCRB7)
		1697	21.14.3.1 Contention between Data Transfer and Writing to Transfer Destination Register, "Transfer Data" modified (LDB + PIMR→LDB - PIMR)
		1698	21.14.3.2 Contention between Data Transfer and Writing to Transfer Source Register,"Transferred Value" modified (LDB + PIMR→LDB - PIMR)
		1702	Figure 21.98 Contention between TCNT1H Counter Overflow and Compare Match, erroneous values of TCNT1H modified
		1704	21.14.5.1 Contention between Writing to Noise Canceler Counter and Compare Match with Noise Canceler Register, body modified
		1705	21.14.5.2 Contention between Writing to Noise Canceler Register and Compare Match with Noise Canceler Counter, body modified
		1712	21.14.7.5 Contention between Clearing of the Counter to 0 by Timer B and Clearing of the Counter by the Counter Upper-Limit Setting Function, added
		1713, 1714	21.14.8 Different Specifications of Operation in Response to a Match in Comparison, added
		Section 22 Autonomous Pulse Adapter (APA)	
		1741	22.4.2.2 APAA0CHEN — APAA0 Channel Operation Enable Register, bit chart modified
		1743	22.4.2.3 APAA0CHST — APAA0 Channel Output Status Register, bit chart modified
		1753	22.4.4.2 APAA0EVSW — APAA0 Software Event Register, bit chart modified
		1756	22.4.4.4 APAA0ESTA — APAA0 Event Status Register A, bit chart modified
		Section 23 Motor Control Timer (TSG2)	
		All	Superfluous leading zeros in indices (m and k) have been deleted to alter the notation from two digits to a single digit (except those from 10 to 12).
		1850	Table 23.6 TSG2nCTL0 Register Contents, functional description of TSG2nDWD bit modified (reference modified)
		1853	23.4.2.4 TSG2nCTL4 — TSG2n Control Register 4, bit name of bits 4 to 0 in a bit chart modified (TSG2nRCC[0:0]4 → TSG2nRCC[04:00])
		1853	Table 23.9 TSG2nCTL4 Register Contents, bit name of bits 4 to 0 modified (TSG2nRCC[4:0] → TSG2nRCC[04:00])

Rev.	Date	Description	
		Page	Summary
1.20	May 31, 2017	1855, 1857, 1905, 1932, 1961	Bit name of bits 4 to 0 in TSG2nCTL4 register modified (TSG2nRCC4 to TSG2nRCC0 →TSG2nRCC04 to TSG2nRCC00)
		1864	Table 23.18 TSG2nSTR2 Register Contents (1/2), functional description of bits 9 to 5 modified
		1865	Table 23.18 TSG2nSTR2 Register Contents (2/2), functional description of bits 3 and 2 modified
		1875	23.4.2.22 TSG2nCMP1W — TSG2n Compare Registers 1 and 2, entry under "PWM Mode" of TSG2nCMP2 modified
		1876	23.4.2.23 TSG2nCMP5W — TSG2n Compare Registers 5 and 6, entry under "120-DC Mode" of TSG2nCMP6 modified
		1884	23.4.2.31 TSG2nPAT0W — TSG2n Pattern Register 0, body modified (bits 2 and 1 → bits 2 to 0)
		1885	23.4.2.32 TSG2nPAT1W — TSG2n Pattern Register 1, body modified (bits 2 and 1 → bits 2 to 0)
		1895	23.5.1 Basic Operation of 16-Bit Counter, description of INTTSG2nI[7] modified (TSG2nCMP6→TSG2nCMP7)
		1899	23.5.3 Compare Register Rewrite Operation, Anytime rewriting, body modified ("Caution" deleted)
		1900	Table 23.31 Active Width Setting in SP-PWM Mode, register name modified
		1901	Figure 23.8 Anytime Rewriting Timing (Example in PWM Mode), modified
		1903	23.5.3.2 Operation Example of Reloading (Simultaneous Rewriting), body modified (TSG2nCTL3 → TSG2nCTL4)
		1904	Figure 23.11 Simultaneous Rewriting Timing (2/2) (Example of PWM mode), interrupt modified (INTTSG2nIPEK → INTTSG2nI0)
		1906	23.5.4.1 Timer Output in Each Mode, body modified (timer outputs (TSOn1-TSOn6 and TSOn7)) → timer outputs (TSOn0 to TSOn7))
		1909	Table 23.39 List of Interrupts in Each Mode (3/5), entries under "INTTSG2nI[11]" modified
		1916	Figure 23.18 TSOn0 Pin Output depending onTSG2nIOC1.TSG2nTOS Setting, bit name modified (TSG2nCUF → TSG2nSUF)
		1917	Figure 23.19 Example of Positive /Negative Phase Simultaneous Activation Detection Flag Operation, bit name and description modified
		1919	Figure 23.22 Example of Noise Detection Flag Operation, bit name and description modified
		1920	Figure 23.23 Example of Pattern Order Detection Flag Operation (Normal Operation), bit name modified (TSG2nMDF → TSG2nTSF)
		1921	Figure 23.25 Example of Operation when Values Input to Two Pins of TAPTSn2-TAPTSn0 Change (Abnormal Operation), bit name modified (TSG2nTBF → TSG2nTSF)
		1922	Figure 23.26 Example of Pattern Error Detection Flag Operation (TAPTSn2-TAPTSn0 Pins = 111), bit name and description modified
		1932	Figure 23.35 When TSG2nRMC = 0 and TSG2nRIA = 0 in TSG2nCTL3 (without Reload Skipping), bit name modified
		1937	Figure 23.38 When TSG2nPIE = 1, TSG2nVIE = 1, and TSG2nRCC04 to TSG2nRCC00 = 00_B in TSG2nCTL4, and TSG2nACC01 and TSG2nACC00 = 00_B in TSG2nCTL5 (HT-PWM Mode), names of interrupts and values of bits modified
		1938	Figure 23.39 When TSG2nPIE = 0, TSG2nVIE = 1, and TSG2nRCC04 to TSG2nRCC00 = 02_B in TSG2nCTL4 and TSG2nACC01 and TSG2nACC00 = 00_B in TSG2nCTL5 (HT-PWM Mode), bit name modified (TSG2nICE → TSG2nPIE)
		1940	Figure 23.42 Example of Operation of A/D Conversion Trigger Skipping Function, description modified
		1943	Figure 23.45 Example of Error Interrupt Operation, bit name and description modified
		1971	23.11.2.8 Notes Concerning Dead Time Control in HT-PWM Mode, CAUTIONS 3 and 4 modified
		1974	Figure 23.64 Flow of Software Output Control in HT-PWM Mode, description in step (2) modified
		1980	Table 23.59 Compare Registers and Dead Time Setting Register Functions in SP-PWM Mode, a row for TSG2nDCMP0W and TSG2nDCMP2 registers added
		1995, 1996	23.11.4.3 Control Methods in 120-DC Mode, body modified
		2003, 2004	23.11.4.6 List of Output Patterns in 120-DC Mode, description added

Rev.	Date	Description	
		Page	Summary
1.20	May 31, 2017	2006	Figure 23.79 Control when Timer Output Starts in Reverse Rotation (when Normal Pattern is Input), pattern name modified
		2006	Figure 23.80 Control when Timer Output Starts in Normal Rotation (when Error Pattern is Input), modified
		2007	Figure 23.81 Control when Timer Output Starts in Reverse Rotation (when Error Pattern is Input), names of the pattern modified
		2018	Figure 23.91 Example of Switching from 120-DC Mode to Software Output Control Function, TSG2nSTCI0 signal deleted
		Section 24 Timer Option (TAPA)	
		2024	Table 24.3 TAPAnCTL0 Register Contents, functional description of TAPAnDCM bit modified (TAPAnOPHS0 deleted)
		2026	Table 24.6 TAPAnACTS Register Contents, functional description of TAPAnACTS bit modified (TAPAnACE → TAPAnACWE)
		2027	Table 24.7 TAPAnACTT Register Contents, functional description of TAPAnACTT bit modified (TAPAnACE=0 → TAPAnACWE=1)
		2031	24.3.2.3 Operating Procedure Example for Hi-Z Control in Response to Asynchronous Input, description in the table modified ((if TAPAnDCM = 0) and (if TAPAnDCM = 1) deleted, TAPAnASTT bit → TAPAnACTT bit)
		Section 25 Peripheral Interconnection (PIC)	
		All	Terms unified, channel group → scan group
		2034	Table 25.5 PIC1SSER2 Register Contents, functional description of bits 9 and 8 modified
		2035	Table 25.6 PIC1SSER3 Register Contents, functional description of bits 2 to 0 modified
		2041	Table 25.10 List of PIC2 Registers (1/3), register name modified (A/D converter trigger edge selection control register→A/D converter 1 trigger edge selection control register)
		2068	25.2.4.1 ADC Trigger Selection Function, body modified (ADCA hardware triggers→ADCB hardware triggers)
		Section 26 A/D Converter (ADCB)	
		2129	26.7.9.2 A/D Converter Self-Diagnosis, [Settings], description modified ((n = 0 to 47) deleted), and NOTE added
		2131	26.7.9.3 Wiring-Break Detection Self-Diagnosis, [Settings], description modified ((n = 0 to 39) deleted), and NOTE added
		2132	Figure 26.18 Timing Chart of Normal A/D Conversion Operation (Single Conversion), description in the figure modified (tCONV → tSAR, tSCAN → tSG)
		2137	Figure 26.22 Scan Conversion End Interrupt Occurrence Timing, peripheral clock modified
		2138	Figure 26.23 Example of an MPX Interrupt Occurrence, peripheral clock modified
		2139	Figure 26.24 Example of an Occurrence of A/D Error Interrupt and A/D Parity Error Notification, peripheral clock modified
		2144	26.9.3 Notes when Current is Being Injected, description in (2) modified (GCTRL bits → bits 4 and 3 (GCTRL))
		2155	26.11.5 Operation, [Setting Procedure], description in step 4 modified (from the first time → from the second time)
		Section 27 Delta-Sigma AD Converter (DS-ADC)	
		2177	27.5.5 DSADCmADCR — AD Control Register (m = 0 to 7), CAUTION 2 modified
		2178	27.5.6 DSADCmADSR — AD Status Register (m = 0 to 7), CAUTION modified
		2183	27.5.11 DSADCmFCR — Digital Filter FIR Control Register (m = 0 to 7), CAUTION modified (DSADCCOSMPRCRm → DSADCCOSMPRCR)
		2186	27.6.2 Setting Filter Type, body modified (DSADCCOSMPRCRm → DSADCCOSMPRCR)
		2186	Table 27.22 A/D Conversion Processing Time (Unit: Pϕ P-Bus Clock (40 MHz)), entries in the table modified and Note 1 added
		2187	Figure 27.4 A/D Conversion Start and End, Notes 1 and 2 added
		2188	27.6.4 Starting A/D Conversion by an External Trigger, description added
		2188	27.6.5 Terminating A/D Conversion by an External Trigger, description modified

Rev.	Date	Description	
		Page	Summary
1.20	May 31, 2017	Section 28 Digital Filter (DFE)	
		2197	Table 28.2 List of Terms (1/2), PH index register deleted
		2214	Table 28.11 TRGCHn Register Contents (1/2), functional description of PFE and AFE bits modified
		2223, 2224	Table 28.19 PITRG Register Contents, functional description modified
		2225, 2226	Table 28.20 MITRG Register Contents, functional description modified
		2227, 2228	Table 28.21 FITRG Register Contents, functional description modified
		2234	Figure 28.10 Usage of Memory, description in the figure modified
		2239	28.4.7.1 Timer Trigger Input, body modified
		2239	Figure 28.13 Timer Trigger Input, description in the figure modified
		2242	Table 28.28 Trigger Flag Functions and Processing, "Output data write" column of "PH performed" for "Accumulation/decimation disabled", modified (Not provided→Provided)
		2272	28.5.10 Restrictions on Trigger Setting Registers, body modified
		Section 29 Safety	
		2284	29.2.2.3 Details of Registers, (6) CF1STERSTR_VCI/_PE1/_PCU — Code Flash 1st Error Status Register, description added
		2288	29.2.2.4 Test Function, (4) Self-Diagnosis of the ECC and Address Parity for Code Flash Memory, added
		2303	Table 29.32 LRTDATBFn_PE1 Register Contents, functional description of LRTDATBF bits modified
		2308	29.2.4.3 Details of Registers, (8) LR1STERSTR_PE1 — Local RAM 1st Error Status Register, description added
		2310	29.2.4.4 Test Function, (6) Self-Diagnosis of the Address Parity Check Function, description in (b) modified
		2314	29.2.5.3 Details of Registers, (2) LRFSTERSTR_PCU — Local RAM 1st Error Status Register, description added
		2323	Figure 29.2 ECC of Global RAM and Address Parity, location of the figure modified
		2335	29.2.6.3 Details of Registers, (10) GR1STERSTR_VCI/PE1 — Global RAM 1st Error Status Register, description added
		2359	29.2.9.3, (1) E710CTL — ECC Control Register, R/W of bit 8 in a bit chart modified to R
		2372	29.2.10.3, (1) E610CTL — ECC Control Register, R/W of bit 8 in a bit chart modified to R
		2418	29.5.4.3 MISR1L_PE1/PCU — Multi-Input Signature Register 1L, body modified
		2419	29.5.4.4 MISR1H_PE1/PCU — Multi-Input Signature Register 1H, body modified
		2420	29.5.4.5 MISR2L_PE1/PCU — Multi-Input Signature Register 2L, body modified
		2421	29.5.4.6 MISR2H_PE1/PCU — Multi-Input Signature Register 2H, body modified
		2437	Table 29.142 CLMATEST Register Contents, functional description of MONCLKMSK bit modified
		2439	29.6.4 Detection of Abnormal Clock Frequency, description modified, and Note 1 added
		2442	29.6.5 Self-Diagnosis, (1) and (4) added, and description in (3) and (5) modified
		Section 30 Error Control Module (ECM)	
		2448	Table 30.2 List of Error Sources and Safety Processing (2/2), Note 11 added
		2453	Figure 30.1 Outline of ECM, description in the figure modified (ERRORUT output → ERROROUT output)
		2459	Table 30.11 ECMmESSTR1 Register Contents, functional description of bit 31 modified
		Section 31 Data CRC (DCRA)	
		2489	Table 31.4 DCRA0COUT Register Contents, functional description of DCRA0COUT[31:0] bits modified (DCRAnCOUT → DCRA0COUT)
		2489	31.2.3 DCRA0COUT — CRC Data Register, CAUTION modified (DCRAnCIN register → DCRA0CIN register)
		2490	31.2.4 DCRA0CTL — CRC Control Register, CAUTION 2 modified (DCRA0CTL.DCRA0ISZn[1:0] → DCRA0CTL.DCRA0ISZ[1:0], DCRAnCOUT register → DCRA0COUT register)

REVISION HISTORY	RH850/E1M-S User's Manual: Hardware

Rev.	Date	Description	
		Page	Summary
1.20	May 31, 2017	Section 33 Flash Memory	
		2533	33.11 Usage Notes, (7) Items prohibited during programming, erasure, and blank checking, description modified (programming and erasure → programming, erasure, and blank checking)
		Section 35 RAM	
		2543	Table 35.2 TM_CC Register Contents, description of bits 31 to 1 added
		2547	Table 35.6 TM_MA0 Register Contents, CAUTION in the functional description modified
		2547	35.4.9 TM_MA0 — Tuning Memory Mapping Address Register 0, CAUTION 3 deleted
		2548	35.4.11 Notes on Access to ERAM, description (lockstep compare error) added
		2549	35.5 Usage Notes, description added
		Section 37 Electrical Characteristics	
		2575	Table 37.11 DC Characteristics (Input Capacitance), typical value modified (1.0 → 10)
		2576	37.2.11 Supply Current Characteristics, CAUTION 1 modified (AVREFH pin → A1VREFH pin)
		2578	Figure 37.3 AC Measurement Conditions, IOL*2 added
		2604	Table 37.37 ADC Converter Characteristics, Note 1 modified (AVREFHn → AnVREFH)
		2610	Table 37.44 Thermal Resistance of RH850/E1M-S, a row for 4LΨjt added and Note modified
		2610	Table 37.45 JESD51-9 Compliant Board (4 layers), title of the table and entries in the table modified
