These bits represent a fixed-point number with the decimal point positioned between b27 and b26. The TIV[31:27] bits indicate nanoseconds, while the TIV[26:0] bits indicates sub-nanoseconds.

[Example]

- When the ESWCLK frequency is 50 MHz, 100 MHz, 200 MHz, 320 MHz, or 400 MHz, set this register to a value around A000 0000h (20.000 ns), 5000 0000h (10.000 ns), 2800 0000h (5.000 ns), 1900 0000h (3.125 ns), or 1400 0000h (2.500 ns), respectively.

39.2.2.4 Timer 0 Offset Value Configuration Register L (PTPTOVC0L)

Address(es): GPTP.PTPTOVC0L 874E 0030h, GPTP_NS.PTPTOVC0L 074E 0030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	TOVL[29:16]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TOVL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b29 to b0	TOVL[29:0]	Timer Offset Value Lower Part	Timer offset value in gPTP format.	R/W
b31, b30	—	Reserved	These bits are read as 0.	R

TOVL[29:0] Bits (Timer Offset Value Lower Part)

The PTPTOVC0L.TOVL[29:0] bits represent a part of Nanoseconds.

Writing in this register will load the new offset to timer 0.

{The PTPTOVC0U.TOVU[15:0] bits, the PTPTOVC0M.TOVM[31:0] bits, 00b, the PTPTOVC0L.TOVL[29:0] bits} is timer 0 offset.

[Restriction]

- SW: Only value from 0000 0000h to 3B9A C9FFh can be set to these bits.

39.2.2.5 Timer 0 Offset Value Configuration Register M (PTPTOVC0M)

Address(es): GPTP.PTPTOVC0M 874E 0034h, GPTP_NS.PTPTOVC0M 074E 0034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TOVM[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TOVM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TOVM[31:0]	Timer Offset Value Middle Part	Timer offset value in gPTP format.	R/W

TOVM[31:0] Bits (Timer Offset Value Middle Part)

The PTPTOVC0M.TOVM[31:0] bits represent lower 32 bits of Seconds.

{The PTPTOVC0U.TOVU[15:0] bits, the PTPTOVC0M.TOVM[31:0] bits, 00b, the PTPTOVC0L.TOVL[29:0] bits} is timer 0 offset.

[Update condition]

- SW: Writing the PTPTOVC0L register will update these bits to the latest value that has been written to it.

39.2.2.6 Timer 0 Offset Value Configuration Register U (PTPTOVC0U)

Address(es): GPTP.PTPTOVC0U 874E 0038h, GPTP_NS.PTPTOVC0U 074E 0038h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TOVU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TOVU[15:0]	Timer Offset Value Upper Part	Timer offset value in gPTP format.	R/W
b31 to b16	—	Reserved	These bits are read as 0.	R

TOVU[15:0] Bits (Timer Offset Value Upper Part)

The PTPTOVC0U.TOVU[15:0] bits represent upper 16 bits of Seconds.

{The PTPTOVC0U.TOVU[15:0] bits, the PTPTOVC0M.TOVM[31:0] bits, 00b, the PTPTOVC0L.TOVL[29:0] bits} is timer 0 offset.

[Update condition]

- SW: Writing the PTPTOVC0L register will update these bits to the latest value that has been written to it.

39.2.3 Timer Monitoring Registers

39.2.3.1 AVTP Timer 0 Monitoring Register L (PTPAVTPTM0L)

Address(es): GPTP.PTPAVTPTM0L 874E 0040h, GPTP_NS.PTPAVTPTM0L 074E 0040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	AVTPL[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	AVTPL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	AVTPL[31:0]	AVTP Timer Value Lower Part	AVTP time is in nanoseconds and derive from gPTP timer 0.	R

AVTPL[31:0] Bits (AVTP Timer Value Lower Part)

The PTPAVTPTM0L.AVTPL[31:0] bits represent either 32-bit AVTP timer or lower 32 bits of 64-bit AVTP timer. These bits are always equal to 32-bit AVTP timer or lower 32 bits of 64-bit AVTP timer.

39.2.3.2 AVTP Timer 0 Monitoring Register U (PTPAVTPTM0U)

Address(es): GPTP.PTPAVTPTM0U 874E 0044h, GPTP_NS.PTPAVTPTM0U 074E 0044h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	AVTPU[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	AVTPU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	AVTPU[31:0]	AVTP Timer Value Upper Part	AVTP time is in nanoseconds and derive from gPTP timer 0.	R

AVTPU[31:0] Bits (AVTP Timer Value Upper Part)

The PTPAVTPTM0U.AVTPU[31:0] bits represent upper 32 bits of 64-bit AVTP timer.
[Update condition]

- HW: Reading the PTPAVTPTM0L register update these bits to upper 32 bits of 64-bit AVTP timer.

39.2.3.3 gPTP Timer 0 Monitoring Register L (PTPGPTPTM0L)

Address(es): GPTP.PTPGPTPTM0L 874E 0050h, GPTP_NS.PTPGPTPTM0L 074E 0050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	GPTPL[29:16]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GPTPL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b29 to b0	GPTPL[29:0]	gPTP Timer Value Lower Part	These bits represent a part of Nanoseconds of gPTP timer.	R
b31, b30	—	Reserved	These bits are read as 0.	R

GPTPL[29:0] Bits (gPTP Timer Value Lower Part)

This register is always equal to a part of Nanoseconds of gPTP timer.

39.2.3.4 gPTP Timer 0 Monitoring Register M (PTPGPTPTM0M)

Address(es): GPTP.PTPGPTPTM0M 874E 0054h, GPTP_NS.PTPGPTPTM0M 074E 0054h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	GPTPM[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GPTPM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	GPTPM[31:0]	gPTP Timer Value Middle Part	These bits represent lower 32 bits of Seconds of gPTP timer.	R

GPTPM[31:0] Bits (gPTP Timer Value Middle Part)

[Update condition]

- HW: Reading the PTPGPTPTM0L register update these bits to lower 32 bits of Seconds of gPTP timer.

39.2.3.5 gPTP Timer 0 Monitoring Register U (PTPGPTPTM0U)

Address(es): GPTP.PTPGPTPTM0U 874E 0058h, GPTP_NS.PTPGPTPTM0U 074E 0058h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GPTPU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	GPTPU[15:0]	gPTP Timer Value Upper Part	These bits represent upper 16 bits of Seconds of gPTP timer.	R
b31 to b16	—	Reserved	These bits are read as 0.	R

GPTPU[15:0] Bits (gPTP Timer Value Upper Part)

[Update condition]

- HW: Reading the PTPGPTPTM0L register update these bits to upper 16 bits of Seconds of gPTP timer.

39.2.4 Media Clock Capture Registers

39.2.4.1 Media Clock m Capture Configuration Register (PTPMCCCm) (m = 0, 1)

Address(es): GPTP.PTPMCCC0 874E 0200h, GPTP.PTPMCCC1 874E 0210h, GPTP_NS.PTPMCCC0 074E 0200h, GPTP_NS.PTPMCCC1 074E 0210h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	MCTNS	MCTTS	MCNEE	MCPEE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MCPEE	Media Clock Capture Positive Edge Enable	0: Timer value will not be captured on positive edge of GPTP_CAPTUREm signal. 1: Timer value will be captured on positive edge of GPTP_CAPTUREm signal.	R/W
b1	MCNEE	Media Clock Capture Negative Edge Enable	0: Timer value will not be captured on negative edge of GPTP_CAPTUREm signal. 1: Timer value will be captured on negative edge of GPTP_CAPTUREm signal.	R/W
b2	MCTTS	Media Clock Capture Timer Type Select	0: Timer value will be captured on gPTP timer. 1: Timer values will be captures on AVTP timer.	R/W
b3	MCTNS	Media Clock Capture Timer Number Select	This register selects from which timer the timer values will be captured. Set this bit to 0 for this product.	R/W
b15 to b4	—	Reserved	These bits are read as 0.	R
b16	MCCR	Media Clock Capture Request	Writing 1 to this register will trig timer capture.	R/W
b31 to b17	—	Reserved	These bits are read as 0.	R

39.2.4.2 Media Clock m Capture Monitoring Register L (PTPMCCMmL) (m = 0, 1)

Address(es): GPTP.PTPMCCM0L 874E 0204h, GPTP.PTPMCCM1L 874E 0214h,
GPTP_NS.PTPMCCM0L 074E 0204h, GPTP_NS.PTPMCCM1L 074E 0214h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MCCTVL[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MCCTVL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	MCCTVL[31:0]	Media Clock Captured Timer Value Lower Part	• If a gPTP timer is captured, these bits represent a part of Nanoseconds of gPTP timer. • If an AVTP timer is captured, these bits represent either the 32bit-AVTP timer or lower 32 bits of the 64bit-AVTP timer.	R

MCCTVL[31:0] Bits (Media Clock Captured Timer Value Lower Part)

[Update conditions]

- Reading the PTPMCCMmL register will update the PTPMCCMmL register, the PTPMCCMmM register, and the PTPMCCMmU register to the next captures value.
- Capturing a timer while the capture buffer is empty will update the PTPMCCMmL register, the PTPMCCMmM register, and the PTPMCCMmU register to the captured value.

39.2.4.3 Media Clock m Capture Monitoring Register M (PTPMCCMmM) (m = 0, 1)

Address(es): GPTP.PTPMCCM0M 874E 0208h, GPTP.PTPMCCM1M 874E 0218h,
GPTP_NS.PTPMCCM0M 074E 0208h, GPTP_NS.PTPMCCM1M 074E 0218h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MCCTVM[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MCCTVM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	MCCTVM[31:0]	Media Clock Captured Timer Value Middle Part	• If a gPTP timer is captured, these bits represent lower 32 bits of Seconds of gPTP timer. • If an AVTP timer is captured, these bits represent upper 32 bits of 64bit-AVTP timer.	R

MCCTVM[31:0] Bits (Media Clock Captured Timer Value Middle Part)

[Update conditions]

- Reading the PTPMCCMmM register will update the PTPMCCMmL register, the PTPMCCMmM register, and PTPMCCMmU register to the next captures value.
- Capturing a timer while the capture buffer is empty will update the PTPMCCMmL register, the PTPMCCMmM register, and the PTPMCCMmU register to the captured value.

39.2.4.4 Media Clock m Capture Monitoring Register U (PTPMCCMmU) (m = 0, 1)

Address(es): GPTP.PTPMCCM0U 874E 020Ch, GPTP.PTPMCCM1U 874E 021Ch, GPTP_NS.PTPMCCM0U 074E 020Ch, GPTP_NS.PTPMCCM1U 074E 021Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	MCCN[1:0]		—	—	—	—	—	MCSWC	MCNEC	MCPEC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MCCTVU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	MCCTVU[15:0]	Media Clock Captured Timer Value Upper Part	• If a gPTP timer is captured, these bits represent upper 16 bits of Seconds of gPTP timer. • If an AVTP timer is captured, these bits are not used.	R
b16	MCPEC	Media Clock Positive Edge Captured		R
b17	MCNEC	Media Clock Negative Edge Captured		R
b18	MCSWC	Media Clock Software Captured		R
b23 to b19	—	Reserved	These bits are read as 0.	R
b25, b24	MCCN[1:0]	Media Clock Capture Number	These bits indicate the number of captures for the media clock.	R
b31 to b26	—	Reserved	These bits are read as 0.	R

MCCTVU[15:0] Bits (Media Clock Captured Timer Value Upper Part)

[Update conditions]

- Reading the PTPMCCMmU register will update the PTPMCCMmL register, the PTPMCCMmM register, and the PTPMCCMmU register to the next captures value.
- Capturing a timer while the capture buffer is empty will update the PTPMCCMmL register, the PTPMCCMmM register, and the PTPMCCMmU register to the captured value.

MCPEC Bit (Media Clock Positive Edge Captured)

[Update conditions]

- Reading the PTPMCCMmU register will update the PTPMCCMmL register, the PTPMCCMmM register, and the PTPMCCMmU register to the next captures value.
- Capturing a timer while the capture buffer is empty will update the PTPMCCMmL register, the PTPMCCMmM register, and the PTPMCCMmU register to the captured value.

MCNEC Bit (Media Clock Negative Edge Captured)

[Update conditions]

- Reading the PTPMCCMmU register will update the PTPMCCMmL register, the PTPMCCMmM register, and the PTPMCCMmU register to the next captures value.
- Capturing a timer while the capture buffer is empty will update the PTPMCCMmL register, the PTPMCCMmM register, and the PTPMCCMmU register to the captured value.

MCSWC Bit (Media Clock Software Captured)

[Update conditions]

- Reading the PTPMCCMmL register will update the PTPMCCMmL register, the PTPMCCMmM register, and the PTPMCCMmU register to the next captures value.
- Capturing a timer while the capture buffer is empty will update the PTPMCCMmL register, the PTPMCCMmM register, and the PTPMCCMmU register to the captured value.

MCCN[1:0] Bits (Media Clock Capture Number)

[Increment conditions]

- HW: Incremented by one when different than 10b and media capture unit m captures a timer.

[Decrement conditions]

- SW: Decremented by one when different than 0 and SW reads.

39.2.5 Media Clock Recovery Registers

39.2.5.1 Media Clock m Recovery Configuration Register (PTPMCRCm) (m = 0, 1)

Address(es): GPTP.PTPMCRC0 874E 0300h, GPTP.PTPMCRC1 874E 0310h, GPTP_NS.PTPMCRC0 074E 0300h, GPTP_NS.PTPMCRC1 074E 0310h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MRPL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	MRTNS	MRAMS	MRTTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MRTTS	Media Clock Recovery Timer Type Select	0: Timer value will be compared to gPTP timer. 1: Timer values will be compared to AVTP timer.	R/W
b1	MRAMS	Media Clock Recovery AVTP Mode Select	0: 64bit-AVTP will be used for comparison. 1: 32bit-AVTP will be used for comparison.	R/W
b2	MRTNS	Media Clock Recovery Timer Number Select	This bit selects from which timer the timer values will be taken. Set this bit to 0 for this product.	R/W
b15 to b3	—	Reserved	These bits are read as 0.	R
b31 to b16	MRPL[15:0]	Media Clock Recovery Pulse Length	Pulse length for clock recovery in ESWCLK clocks – 1	R/W

MRTTS Bit (Media Clock Recovery Timer Type Select)

[Restriction]

- HW: For gPTP timer, overflow is not supported. If a time less than current gPTP timer is set, the comparison will match instantaneously.

MRAMS Bit (Media Clock Recovery AVTP Mode Select)

[Restriction]

- HW: For 64-AVTP timer, overflow is not supported. If a time less than current AVTP timer is set, the comparison will match instantaneously.

39.2.5.2 Media Clock m Recovery Time Configuration Register L (PTPMCRTCmL) (m = 0, 1)

Address(es): GPTP.PTPMCRTC0L 874E 0304h, GPTP.PTPMCRTC1L 874E 0314h, GPTP_NS.PTPMCRTC0L 074E 0304h, GPTP_NS.PTPMCRTC1L 074E 0314h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	MRTVL[31:0]	Media Clock Recovery Timer Value Lower Part	• If the compared timer is a gPTP timer, these bits represent a part of Nanoseconds of gPTP timer. • If the compared timer is a 32-bit AVTP timer, these bits represent the 32bit-AVTP timer. • If the compared timer is a 64-bit AVTP timer, these bits represent lower 32 bits of 64-bit AVTP timer.	R/W

MRTVL[31:0] Bits (Media Clock Recovery Timer Value Lower Part)

Writing to this register will load the PTPMCCMmU.MCCTVU[15:0] bits, the PTPMCCMmM.MCCTVM[31:0] bits, and the PTPMCCMmL.MCCTVL[31:0] bits for comparison in the recovery buffer.

39.2.5.3 Media Clock m Recovery Time Configuration Register M (PTPMCRTCmM) (m = 0, 1)

Address(es): GPTP.PTPMCRTC0M 874E 0308h, GPTP.PTPMCRTC1M 874E 0318h, GPTP_NS.PTPMCRTC0M 074E 0308h, GPTP_NS.PTPMCRTC1M 074E 0318h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PE	Pin Enable	0: The GPTP_MATCHm pin is fixed to low 1: The GPTP_MATCHm pin outputs the comparison result of the PTPMCPCm.MRS bit recovery logic	R/W
b1	MRS	Media Clock Recovery Select	Select recovery logic for GPTP_MATCHm	R/W
b31 to b2	—	Reserved	These bits are read as 0.	R

PE Bit (Pin Enable)

[Restriction]

- Do not change this setting on any timer enabled (the PTPTMEC.TE0 bit = 1).

MRS Bit (Media Clock Recovery Select)

[Restriction]

- Do not change this setting on any timer enabled (the PTPTMEC.TE0 bit = 1).

39.2.6 Cyclic Compare Registers

39.2.6.1 Cyclic Compare c Configuration Register 0 (PTPCCCc0) (c = 0 to 7)

Address(es): GPTP.PTPCCC00 874E 0500h, GPTP.PTPCCC10 874E 0508h, GPTP.PTPCCC20 874E 0510h, GPTP.PTPCCC30 874E 0518h, GPTP.PTPCCC40 874E 0520h, GPTP.PTPCCC50 874E 0528h, GPTP.PTPCCC60 874E 0530h, GPTP.PTPCCC70 874E 0538h, GPTP_NS.PTPCCC00 074E 0500h, GPTP_NS.PTPCCC10 074E 0508h, GPTP_NS.PTPCCC20 074E 0510h, GPTP_NS.PTPCCC30 074E 0518h, GPTP_NS.PTPCCC40 074E 0520h, GPTP_NS.PTPCCC50 074E 0528h, GPTP_NS.PTPCCC60 074E 0530h, GPTP_NS.PTPCCC70 074E 0538h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	CCOPS	—	—	—	CCTNS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CCTNS	Cyclic Compare Timer Number Select	This bit selects from which timer the cyclic compare will be based on.	R/W
b3 to b1	—	Reserved	These bits are read as 0.	R
b4	CCOPS	Cyclic Compare Output Pin Select	CYCLIC_COMP[the PTPCCCc0.CCOPS bit][c] is selected as output for cyclic compare c.	R/W
b31 to b5	—	Reserved	These bits are read as 0.	R

39.2.6.2 Cyclic Compare c Configuration Register 1 (PTPCCCc1) (c = 0 to 7)

Address(es): GPTP.PTPCCC01 874E 0504h, GPTP.PTPCCC11 874E 050Ch, GPTP.PTPCCC21 874E 0514h, GPTP.PTPCCC31 874E 051Ch, GPTP.PTPCCC41 874E 0524h, GPTP.PTPCCC51 874E 052Ch, GPTP.PTPCCC61 874E 0534h, GPTP.PTPCCC71 874E 053Ch, GPTP_NS.PTPCCC01 074E 0504h, GPTP_NS.PTPCCC11 074E 050Ch, GPTP_NS.PTPCCC21 074E 0514h, GPTP_NS.PTPCCC31 074E 051Ch, GPTP_NS.PTPCCC41 074E 0524h, GPTP_NS.PTPCCC51 074E 052Ch, GPTP_NS.PTPCCC61 074E 0534h, GPTP_NS.PTPCCC71 074E 053Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CCV[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	CCV[31:0]	Cyclic Compare Value	Setting these bits to a value less than 32 will disable compare function. Setting these bits to a value greater or equal to 32 will enable compare function.	R/W

39.2.7 Interrupt Registers

39.2.7.1 Interrupt Status Register 0 (PTPIS0)

Address(es): GPTP.PTPIS0 874E 0700h, GPTP_NS.PTPIS0 074E 0700h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCOES1	MCCOES0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCS1	MCCS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MCCS0	Media Clock 0 Capture Status Flag	0: No Media Clock 0 Capture 1: Media Clock 0 Capture occurred.	R/W
b1	MCCS1	Media Clock 1 Capture Status Flag	0: No Media Clock 1 Capture 1: Media Clock 1 Capture occurred.	R/W
b15 to b2	—	Reserved	These bits are read as 0.	R
b16	MCCOES0	Media Clock 0 Capture Overflow Error Status Flag	0: No Media Clock 0 Capture Overflow Error 1: Media Clock 0 Capture Overflow Error occurred.	R/W
b17	MCCOES1	Media Clock 1 Capture Overflow Error Status Flag	0: No Media Clock 1 Capture Overflow Error 1: Media Clock 1 Capture Overflow Error occurred.	R/W
b31 to b18	—	Reserved	These bits are read as 0.	R

MCCSm Flag (Media Clock m Capture Status Flag) (m = 0, 1)

[Setting condition]

- HW: Media clock capture unit m captured a timer.

[Clearing condition]

- SW: Writing 1 to this flag will clear it.

MCCOESm Flag (Media Clock m Capture Overflow Error Status Flag) (m = 0, 1)

[Setting condition]

- HW: This flag is set to 1 when media clock capture unit m captured a timer but it could not be stored because the timer FIFO is full (the PTPMCCMmU.MCCN[1:0] bits equal to 10b).

[Clearing condition]

- SW: Writing 1 to this flag will clear it.

[Error recovery]

- HW: The captured timer is lost. Next capture will continue normally.
- SW: The timer reading is too slow, SW should be reviewed.

39.2.7.2 Interrupt Enable Register 0 (PTPIE0)

Address(es): GPTP.PTPIE0 874E 0704h, GPTP_NS.PTPIE0 074E 0704h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCOEE1	MCCOEE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCE1	MCCE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MCCE0	Media Clock 0 Capture Enable	0: Interrupt disabled 1: Interrupt enabled	R/(W) *1
b1	MCCE1	Media Clock 1 Capture Enable	0: Interrupt disabled 1: Interrupt enabled	R/(W) *1
b15 to b2	—	Reserved	These bits are read as 0.	R
b16	MCCOEE0	Media Clock 0 Capture Overflow Error Enable	0: Interrupt disabled 1: Interrupt enabled	R/(W) *1
b17	MCCOEE1	Media Clock 1 Capture Overflow Error Enable	0: Interrupt disabled 1: Interrupt enabled	R/(W) *1
b31 to b18	—	Reserved	These bits are read as 0.	R

Note 1. Only 1 can be written. To set this bit to 0, write 1 to the corresponding bit in the PTPID0 register.

MCCEm Bit (Media Clock m Capture Enable) (m = 0, 1)

[Setting condition]

- SW: Writing 1 to this bit will set it.

[Clearing condition]

- SW: Writing 1 to the PTPID0.MCCDm bit will clear this bit.

MCCOEEm Bit (Media Clock m Capture Overflow Error Enable) (m = 0, 1)

[Setting condition]

- SW: Writing 1 to this bit will set it.

[Clearing condition]

- SW: Writing 1 to the PTPID0.MCCOEDm bit will clear this bit.

39.2.7.3 Interrupt Disable Register 0 (PTPID0)

Address(es): GPTP.PTPID0 874E 0708h, GPTP_NS.PTPID0 074E 0708h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCOED1	MCCOED0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCCD1	MCCD0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MCCD0	Media Clock 0 Capture Disable	0: Has no effects. 1: Sets PTPIE0.MCCE0 bit to 0.	R/W
b1	MCCD1	Media Clock 1 Capture Disable	0: Has no effects. 1: Sets PTPIE0.MCCE1 bit to 0.	R/W
b15 to b2	—	Reserved	These bits are read as 0.	R
b16	MCCOED0	Media Clock 0 Capture Overflow Error Disable	0: Has no effects. 1: Sets PTPIE0.MCCOEE0 bit to 0.	R/W
b17	MCCOED1	Media Clock 1 Capture Overflow Error Disable	0: Has no effects. 1: Sets PTPIE0.MCCOEE1 bit to 0.	R/W
b31 to b18	—	Reserved	These bits are read as 0.	R

39.2.7.4 Interrupt Status Register 1 (PTPIS1)

Address(es): GPTP.PTPIS1 874E 0710h, GPTP_NS.PTPIS1 074E 0710h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCRMS1	MCRMS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MCRMS0	Media Clock 0 Recovery Match Status Flag	0: No Media Clock 0 Recovery Match 1: Media Clock 0 Recovery Match occurred.	R/W
b1	MCRMS1	Media Clock 1 Recovery Match Status Flag	0: No Media Clock 1 Recovery Match 1: Media Clock 1 Recovery Match occurred.	R/W
b31 to b2	—	Reserved	These bits are read as 0.	R

MCRMSn Flag (Media Clock n Recovery Match Status Flag) (n = 0, 1)

[Setting condition]

- HW: Media clock capture unit m oldest timer matched.

[Clearing condition]

- SW: Writing 1 to this flag will clear it.

39.2.7.5 Interrupt Enable Register 1 (PTPIE1)

Address(es): GPTP.PTPIE1 874E 0714h, GPTP_NS.PTPIE1 074E 0714h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCRME1	MCRME0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MCRME0	Media Clock 0 Recovery Match Enable	0: Interrupt disabled 1: Interrupt enabled	R/(W) *1
b1	MCRME1	Media Clock 1 Recovery Match Enable	0: Interrupt disabled 1: Interrupt enabled	R/(W) *1
b31 to b2	—	Reserved	These bits are read as 0.	R

Note 1. Only 1 can be written. To set this bit to 0, write 1 to the corresponding bit in the PTPID1 register.

MCRME0 Bit (Media Clock 0 Recovery Match Enable)

[Setting condition]

- SW: Writing 1 to this bit will set it.

[Clearing condition]

- SW: Writing 1 to the PTPID1.MCRMD0 bit will clear this bit.

MCRME1 Bit (Media Clock 1 Recovery Match Enable)

[Setting condition]

- SW: Writing 1 to this bit will set it.

[Clearing condition]

- SW: Writing 1 to the PTPID1.MCRMD1 bit will clear this bit.

39.2.7.6 Interrupt Disable Register 1 (PTPID1)

Address(es): GPTP.PTPID1 874E 0718h, GPTP_NS.PTPID1 074E 0718h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MCRMD1	MCRMD0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MCRMD0	Media Clock 0 Recovery Match Disable	0: Has no effects. 1: Sets PTPIE1.MCRME0 bit to 0.	R/W
b1	MCRMD1	Media Clock 1 Recovery Match Disable	0: Has no effects. 1: Sets PTPIE1.MCRME1 bit to 0.	R/W
b31 to b2	—	Reserved	These bits are read as 0.	R

39.2.8 Pulse Output Timer Configuration Registers

39.2.8.1 Pulse Output Timer Configuration Register (POTCFGR)

Address(es): GPTP.POTCFGR 874E 1000h, GPTP_NS.POTCFGR 074E 1000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	REFSEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	REFSEL	Reference Timer Select	0: Select and use the reference time of gPTP timer 0. 1: Setting prohibited	R/W
b31 to b1	—	Reserved	These bits are read as 0.	R

39.2.8.2 Pulse Output Timer Control Register n (POTCRn) (n = 0, 1)

Address(es): GPTP.POTCR0 874E 1004h, GPTP.POTCR1 874E 1034h,
GPTP_NS.POTCR0 074E 1004h, GPTP_NS.POTCR1 074E 1034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	START
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	START	Timer Start	0: Pulse output stop 1: Pulse output enable • Setting 1 enables pulse output generation and allows pulse output. • If set to 0, no pulse will be output. By writing 0 during pulse output, pulse output stops (0 output). • Pulse generation is performed by taking in the set values of the pulse generation registers when this bit is set to 1.	R/W
b31 to b1	—	Reserved	These bits are read as 0.	R

39.2.8.3 Pulse Output Start Time Setting Register nU (POTSTRnU) (n = 0, 1)

Address(es): GPTP.POTSTR0U 874E 1008h, GPTP.POTSTR1U 874E 1038h,

b29 to b0	—	—	These bits hold the nano seconds of the pulse output start time. • Can read the nano seconds of the time when the pulse output started.	R
b31, b30	—	Reserved	These bits are read as 0.	R

39.3 Operations

39.3.1 Timer 0

Each timer instantiation possesses three timers. A gPTP timer, a 64-bit AVTP timer, and a 32-bit AVTP timer.

39.3.1.1 gPTP Timer 0

The gPTP timer 0 GPTP[0] can be enabled by setting the PTPTMEC.TE0 bit to 1. When enabled, gPTP timer 0 will automatically calculate its value by using equation (1).

(1) *gptpTimer*[0] = *TimerOffset*[0] + *FreeRunningTimerValue*[0]

Where:

- *gptpTimer*[0] is the calculated timer value GPTP[0] and is divided in two parts. The second part *gptpSecond*[0] which is GPTP[0][77:30] and the nanosecond part *gptpNano*[0] which is GPTP[0][29:0].
- *TimerOffset*[0] is {the PTPTOVC0U.TOVU[15:0] bits, the PTPTOVC0M.TOVM[31:0] bits, the PTPTOVC0L.TOVL[29:0] bits}
- *FreeRunningTimerValue*[0] is the value of a free running timer starting from 0 (when timer is disabled) and being incremented by the PTPTIVC0.TIV[31:0] bits every cycle (The free running timer has a 27-bit sub-nanosecond part not described here so it should be set to *clk_period*[ns]*2^{27} where *clk_period* is the ESWCLK period).

Functions:

- When gPTP timer 0 is a master, the PTPTIVC0.TIV[31:0] bits and {the PTPTOVC0U.TOVU[15:0] bits, the PTPTOVC0M.TOVM[31:0] bits, the PTPTOVC0L.TOVL[29:0] bits} can be kept to fixed values.
- When gPTP timer 0 is a slave, the PTPTIVC0.TIV[31:0] bits can be used in priority for time re-synchronization. If gPTP timer 0 is too far from the corresponding master value, {the PTPTOVC0U.TOVU[15:0] bits, the PTPTOVC0M.TOVM[31:0] bits, the PTPTOVC0L.TOVL[29:0] bits} can be used for time re-synchronization.

39.3.1.2 64-bit AVTP Timer 0

64-bit AVTP timer 0 AVTP64[0] is used as a reference to synchronize any necessary media clocks and to determine when the payload of a stream is to be presented to the time-sensitive application. Media clocks vary with audio/video types therefore the exact usage of the AVTP presentation time is media format dependent [1722].
64-bit AVTP timer 0 is generated based on the gPTP timer 0 and can be calculated by using equation (2).

(2) *avtpTimer64*[0] = (*gptpSecond*[0] * 10^9 + *gptpNano*[0]) mod 2^{64}

Where:

- *avtpTimer64*[0] is the calculated timer value AVTP64[0].
- *gptpSecond*[0] is *gptpTimer*[0] second part GPTP[0][77:30].
- *gptpNano*[0] is *gptpTimer*[0] nanosecond part GPTP[0][29:0].

39.3.1.3 32-bit AVTP Timer 0

32-bit AVTP timer 0 AVTP32[0] is the 32-bit version of 64-bit AVTP timer 0 and can be calculated using equation (3).

(3) $avtpTimer32[0] = (gptpSecond[0] * 10^9 + gptpNano[0]) \bmod 2^{32}$

Where:

- *avtpTimer32*[0] is the calculated timer value AVTP32[0] (AVTP64[0][31:0]).
- *gptpSecond*[0] is *gptpTimer*[0] second part GPTP[0][77:30].
- *gptpNano*[0] is *gptpTimer*[0] nanosecond part GPTP[0][29:0].

39.3.1.4 PPS Signal

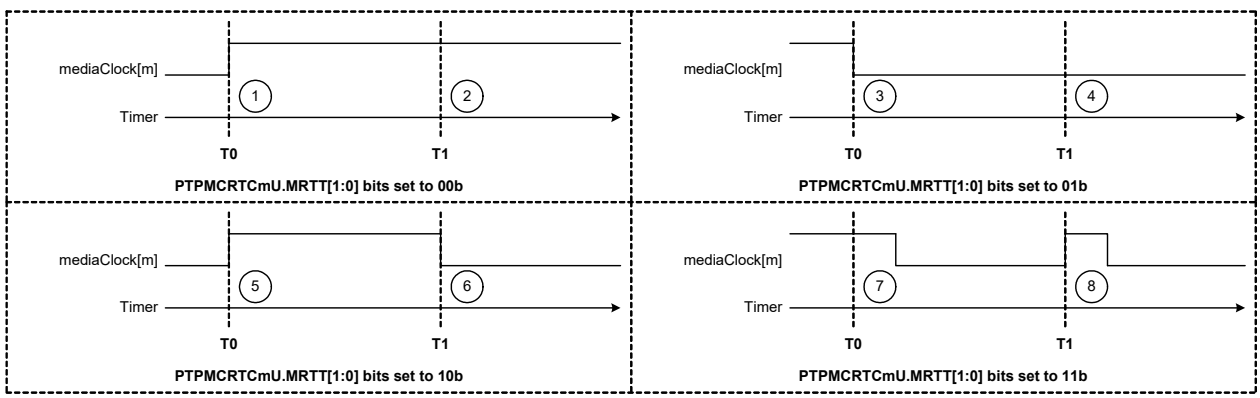
GPTP0_PPS signal is used to check if gPTP synchronization is success full. As per gPTP standard [GPTP], GPTP0_PPS signal should be output as pins at chip level to allow synchronization checking on oscilloscope. GPTP0_PPS is the PPS signal corresponding to timer number 0. For PPS signal details, refer to gPTP standard [GPTP].

39.3.2 Media Clock Capture m (m = 0, 1)

Media clock capture m aims at capturing timer values on the GPTP_CAPTUREm positive edge and/or negative edge.

Functions:

- The PTPMCCCm.MCPEE bit is used to enable timer value capture on the GPTP_CAPTUREm positive edge.
- The PTPMCCCm.MCNEE bit is used to enable timer value capture on the GPTP_CAPTUREm negative edge.
- The PTPMCCCm.MCTNS bit is used to select timer number for timer value capture.
- The PTPMCCCm.MCTTS bit is used to select between gPTP and AVTP timer for timer value capture.
- The PTPMCCMmL/PTPMCCMmM/PTPMCCMmU register are used to read the captured timer values.
- The PTPIS0.MCCSm flag is used to signal CPU that a timer value has been captured.
- The PTPIS0.MCCOESm flag is used to signal CPU that a captured timer value has been lost because the timer capture value FIFO were full.



39.3.3 Media Clock Recovery m (m = 0, 1)

Media clock recovery m aims at creating an internal clock mediaClock[m] which can be mapped to an output pin (section 39.3.4, mediaClock[m] Mapping to Output Pins).

Functions:

- The PTPMCRCm.MRTNS bit is used to select timer number for clock recovery.
- The PTPMCRCm.MRTTS bit is used to select between gPTP and AVTP timer for clock recovery.
- The PTPMCRCm.MRAMS bit is used to select between 32-bit AVTP timer and 64-bit AVTP timer for clock recovery when the PTPMCRCm.MRTTS bit is set to AVTP timer.
- The PTPMCRTCmL/PTPMCRTCmM/PTPMCRTCmU register are used to add a timer value and command to execute to mediaClock[m].
- The PTPIS1.MCRMS flag is used to signal CPU that the oldest timer value which did not match yet set in PTPMCRTCmL/PTPMCRTCmM/PTPMCRTCmU register matched the selected timer so mediaClock[m] value has been updated.

Figure 39.3 describes mediaClock[m] behavior when a timer value matches depending on the timer value type setting and the initial value of mediaClock[m].

1	Compare entry set with **PTPMCRTCmU.MRTT[1:0] bits** set to 00b matched at Timer T0 when mediaClock[m] is not set. mediaClock[m] gets set.
2	Compare entry set with **PTPMCRTCmU.MRTT[1:0] bits** set to 00b matched at Timer T1 when mediaClock[m] is set. mediaClock[m] stays set.
3	Compare entry set with **PTPMCRTCmU.MRTT[1:0] bits** set to 01b matched at Timer T0 when mediaClock[m] is set. mediaClock[m] gets cleared.
4	Compare entry set with **PTPMCRTCmU.MRTT[1:0] bits** set to 01b matched at Timer T1 when mediaClock[m] is not set. mediaClock[m] stays cleared.
5	Compare entry set with **PTPMCRTCmU.MRTT[1:0] bits** set to 10b matched at Timer T0 when mediaClock[m] is not set. mediaClock[m] gets inverted.
6	Compare entry set with **PTPMCRTCmU.MRTT[1:0] bits** set to 10b matched at Timer T1 when mediaClock[m] is set. mediaClock[m] gets inverted.
7	Compare entry set with **PTPMCRTCmU.MRTT[1:0] bits** set to 11b matched at Timer T0 when mediaClock[m] is set. mediaClock[m] stays set for **PTPMCRCm.MRPL[15:0]**+1 clock cycles.
8	Compare entry set with **PTPMCRTCmU.MRTT[1:0] bits** set to 11b matched at Timer T1 when mediaClock[m] is not set. mediaClock[m] gets set for **PTPMCRCm.MRPL[15:0]**+1 clock cycles.

Figure 39.3 mediaClock[m] Behavior

Note: When timer matched for an entry with PTPMCRTCmU.MRTT[1:0] set to 11b and the next matched happens before mediaClock[m] de-assertion, mediaClock[m] de-assertion command is overwritten and will not happen.

39.3.4 mediaClock[m] Mapping to Output Pins

The mediaClock[m] signal created by media clock recovery m (section 39.3.3, Media Clock Recovery m (m = 0, 1)) can be output to be used inside the chip or to be output as a chip pin.

Functions:

- By setting the PTPMCPCm.PE bit to 1 and the PTPMCPCm.MRS bit to m, mediaClock[m] signal will be assigned to the GPTP_MATCHm pin.

39.3.5 Cyclic Compare c (c = 0 to 7)

The cyclic compare c aims at creating a pulse cyclically on CYCLIC_COMP[i][c] for i = 0, 1 interface to trigger an event. It can be used, for example, to trigger a periodic data transmission for gPTP synchronization (network control frame transmission).

Functions:

- The PTPCCCc0.CCTNS bit is used to select timer number for cyclic compare. During cyclic compare, timer offset is ignored, and only incremental value is taken in account.
- The PTPCCCc1.CCV[31:0] bits are used to enable cyclic compare. When cyclic compare c is enabled, a pulse is sent every PTPCCCc1.CCV[31:0] bits to CYCLIC_COMP[the PTPCCCc0.CCOPS bit][c].
- When this feature is enabled (when the PTPCCCc1.CCV[31:0] bits configuration is updated to a value greater than 32), the first pulse from the comparator “c” is output immediately (after one system clock). (Regardless of the PTPCCCc1.CCV[31:0] bits configuration)

39.3.6 Pulse Output Timer n (n = 0, 1)

This module uses the reference time of the Ether Switch gPTP timer to generate a pulse output of any period and any pulse width.

39.3.6.1 gPTP Timer Selection

Select the gPTP timer of the reference time to be used by setting the POTCFGR.REFSEL bit.

The REFSEL bit Register Setting:
0: Generates a pulse output using the reference time of gPTP timer 0.

Functions:

- The reference time used for pulse generation can be selected by setting the POTCFGR.REFSEL bit.
- When the REFSEL bit = 0: Generates a pulse using the time input signal of gPTP timer 0.

Note: When changing the POTCFGR.REFSEL bit, stop the pulse output (the POTCRn.START bit = 0) before changing.

39.3.6.2 Pulse Output Generation Registers

By setting the following registers, it is possible to generate a high pulse with an arbitrary start time, an arbitrary period, and an arbitrary pulse width.

- Pulse output start time setting register: POTSTRnU, POTSTRnM, POTSTRnL
- Period setting register: POTPERnU, POTPERnM, POTPERnL
- Pulse width setting register: POTPWRn

If the value of the pulse width setting register is 0000h, no pulse is generated and the output is fixed at low.
If the period set in the period setting register is shorter than or equal to the pulse width, the output is fixed at high.

39.3.6.3 Pulse Output Start

By changing the POTCRn.START bit from 0 to 1, the values of the pulse output generation registers are captured and held. Pulses are generated according to the set value of the held pulse output generation registers.
The output pulse is as follows.

- Rise of the first pulse:
  Pulse width setting register ≠ 0000h: It goes high at the set start time.
  Pulse width setting register = 0000h: Low output (no pulse output)
- Fall of the pulse:
  Period > pulse width: It goes low when the number of ESWCLK is counted for the value of the pulse width setting register after the output goes high.
  Period ≤ pulse width: The output remains high until the POTCRn.START bit is set to 0.
- Rise after the second time:
  When pulse width ≠ 0000h and period > pulse width: It goes high at the time of the previous start time + period.

39.3.6.4 Pulse Output Stop

Pulse output can be stopped by setting the POTCRn.START bit to 0.
When stopped, the output is fixed at low.

When the POTCRn.START bit is set to 1 again, the register setting value is taken in and held, and a new pulse is generated and output.

Note: Even if the pulse output is stopped in the middle, it will not be restarted. A new pulse is generated and output.

39.3.6.5 Timing of Pulse Output Permission

If the POTCRn.START bit is changed from 0 to 1 after the set pulse output start time, no pulse output will be performed.
The pulse is output from the time when the reference time goes around once and the start time is reached again.

39.3.6.6 Interrupt Output

Detects the rising edge of the pulse output and outputs an interrupt signal synchronized with PCLKA.
There are 2 channels of interrupt output, and the interrupt signal corresponding to each pulse output channel is output.
The interrupt signal outputs high with a width of 1 Cycle of PCLKA.

39.3.7 Pulse Output Time Chart

An example of pulse output is shown below.

Case 1: When changing the POTCRn.START bit from 0 to 1 after setting the register and before the output start time
Case 2: When changing the POTCRn.START bit from 0 to 1 after setting the register and after the output start time
Case 3: When changing the POTCRn.START bit from 0 to 1 by setting the pulse width ≥ period
Case 4: When changing the POTCRn.START bit from 0 to 1 with pulse width = 0
Case 5: When stopping pulse output (when setting the POTCRn.START bit to 0)
Case 6: When the register setting is changed when the POTCRn.START bit is 1

(1) Case 1

When changing the POTCRn.START bit from 0 to 1 after setting the register and before the output start time

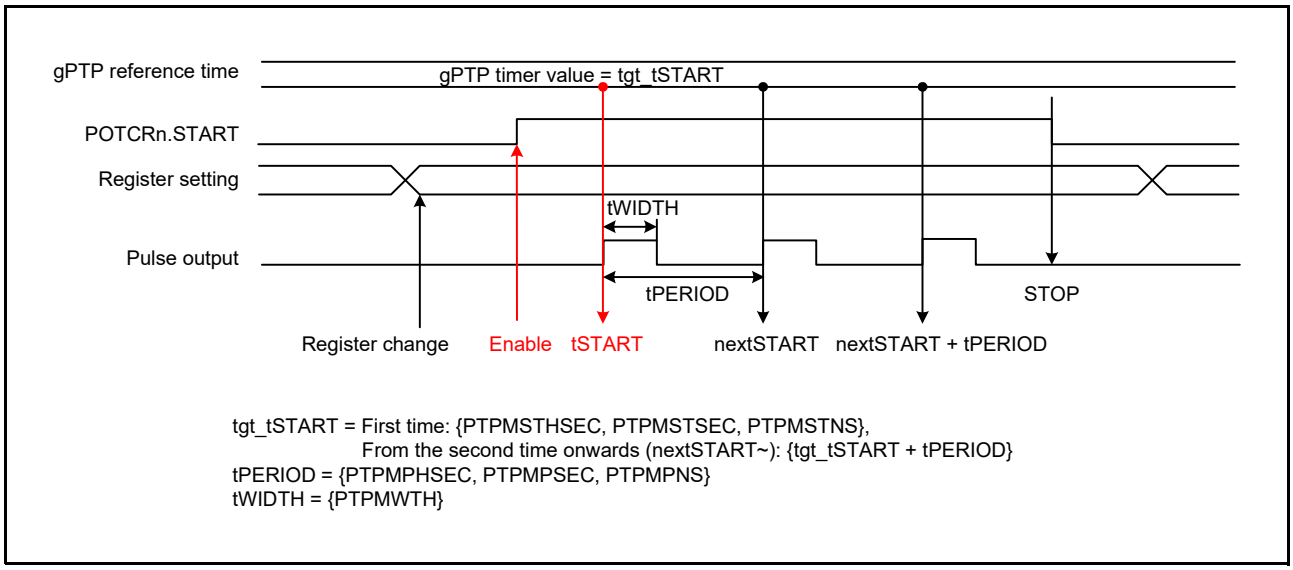


Figure 39.4 Example of Pulse Output Time (1)

(2) Case 2

When changing the POTCRn.START bit from 0 to 1 after setting the register and after the output start time

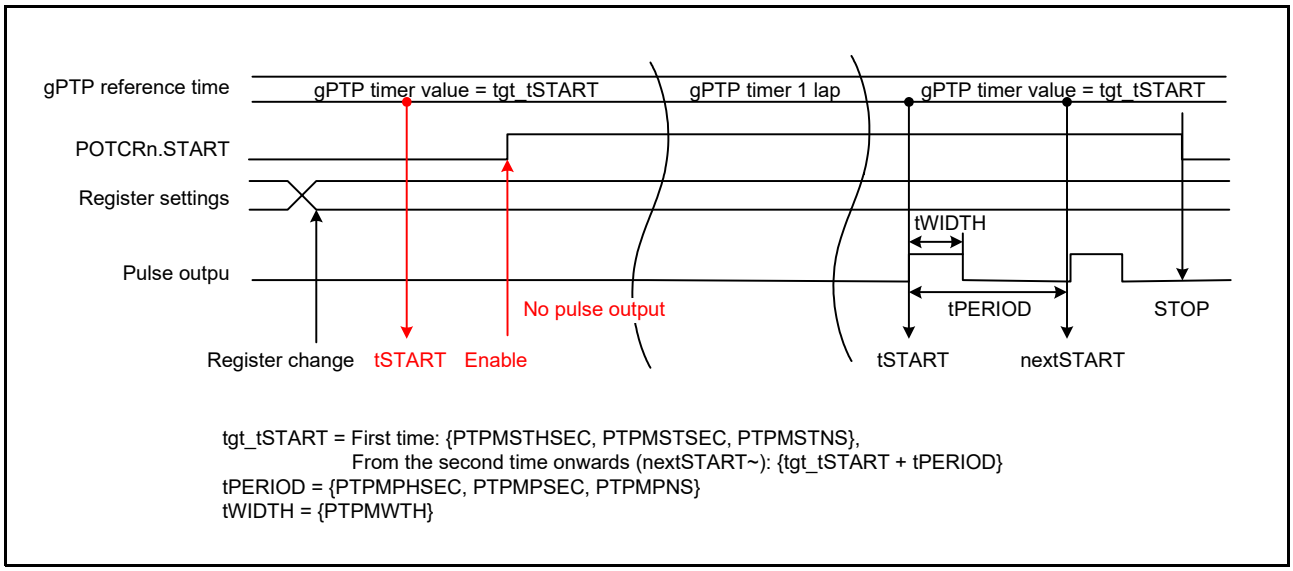

Figure 39.5 Example of Pulse Output Time (2)

(3) Case 3

When the POTCRn.START bit is changed from 0 to 1 by setting the pulse width ≥ the period

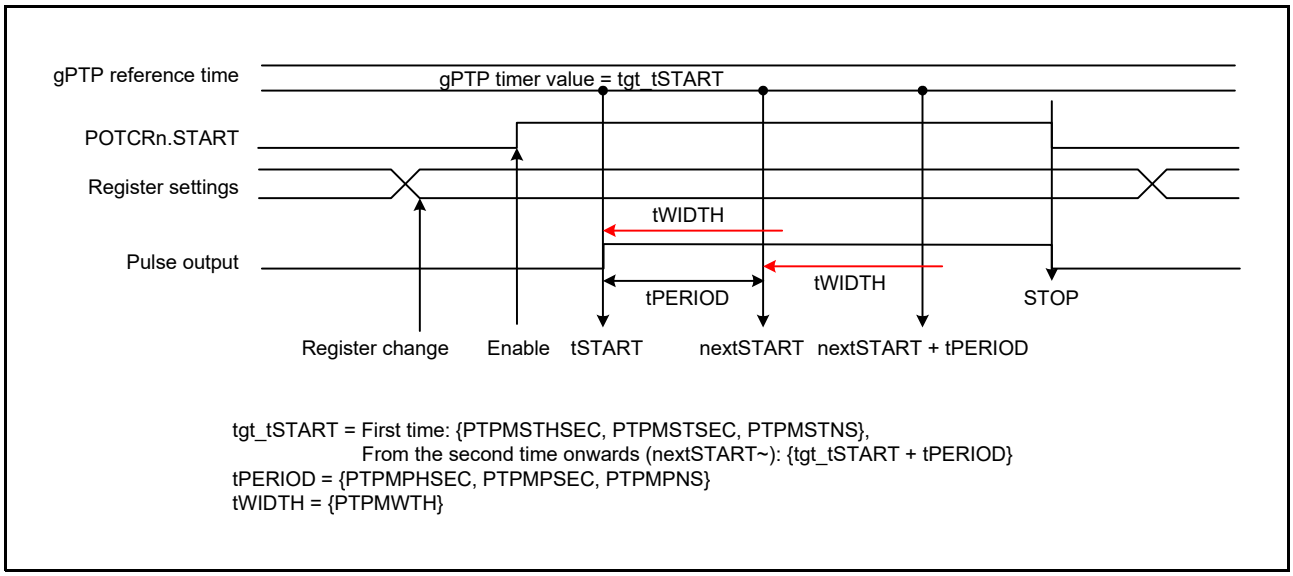

Figure 39.6 Example of Pulse Output Time (3)

(4) Case 4

When changing the POTCRn.START bit from 0 to 1 with pulse width = 0

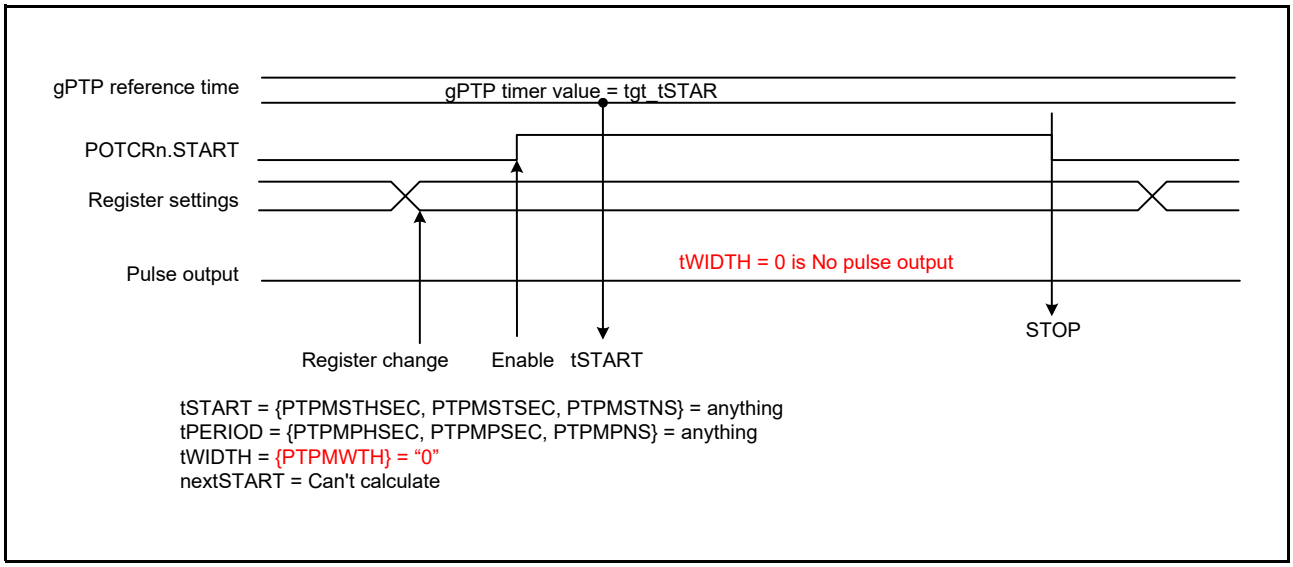

Figure 39.7 Example of Pulse Output Time (4)

(5) Case 5

When the pulse output is stopped (when the POTCRn.START bit is set to 0)

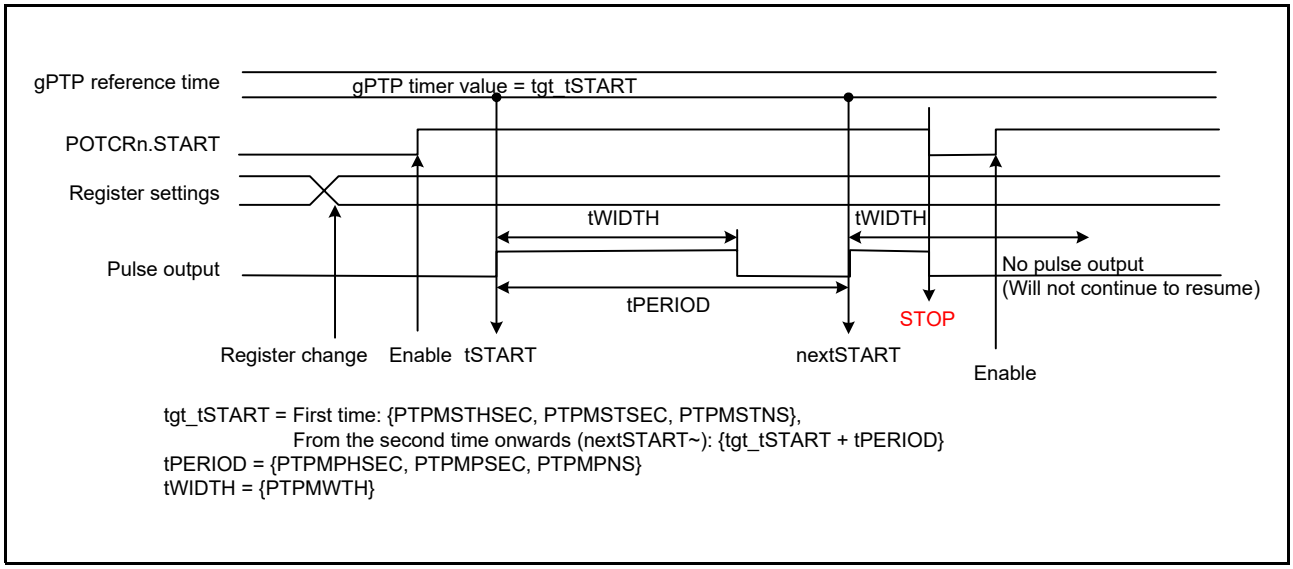

Figure 39.8 Example of Pulse Output Time (5)

(6) Case 6

When the register setting is changed when the POTCRn.START bit is 1

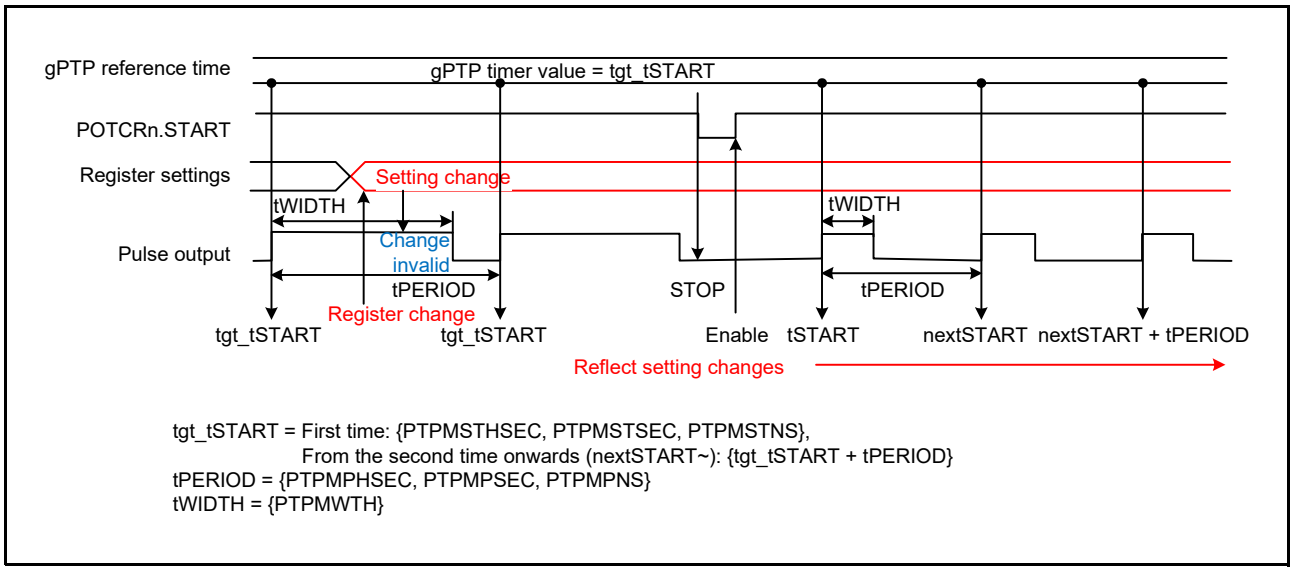

Figure 39.9 Example of Pulse Output Time (6)

39.3.8 Interrupt Output Time Chart

The time chart of interrupt output is shown below.
The interrupt output occurs only when the rising edge of the pulse output is detected.

(1) Interrupt Output

Detects the rising edge of the pulse output and outputs one pulse synchronized with PCLKA.

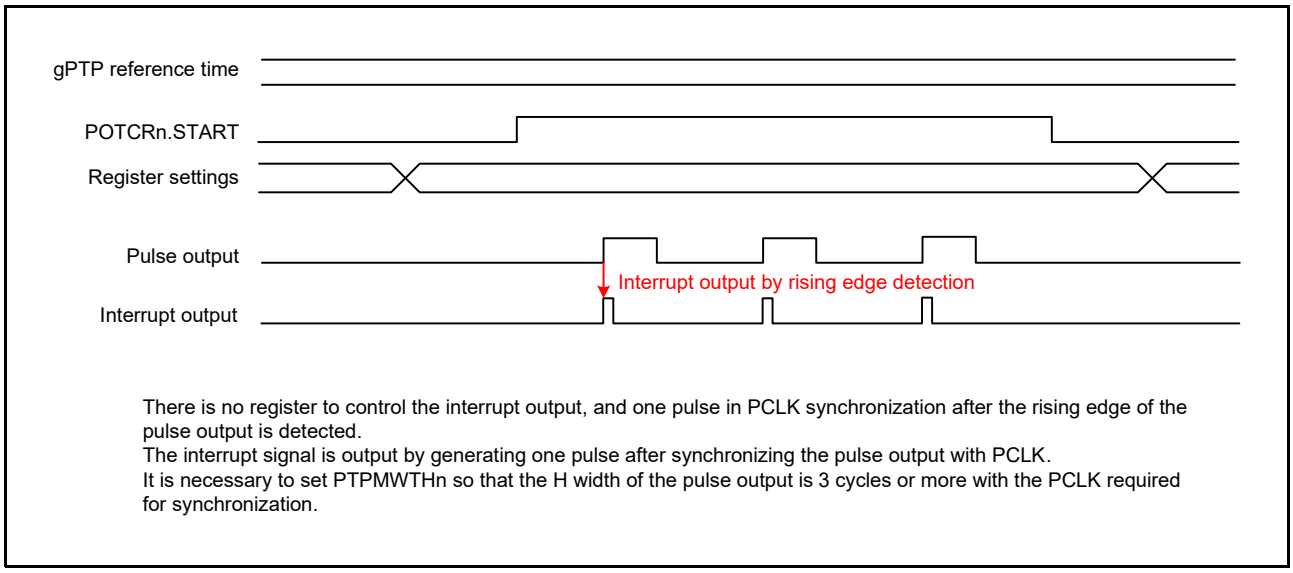

Figure 39.10 Example of Interrupt Output

39.3.9 Software Flows

39.3.9.1 Interrupt Handling Flow

The interrupt handling flow is described in Figure 39.11.

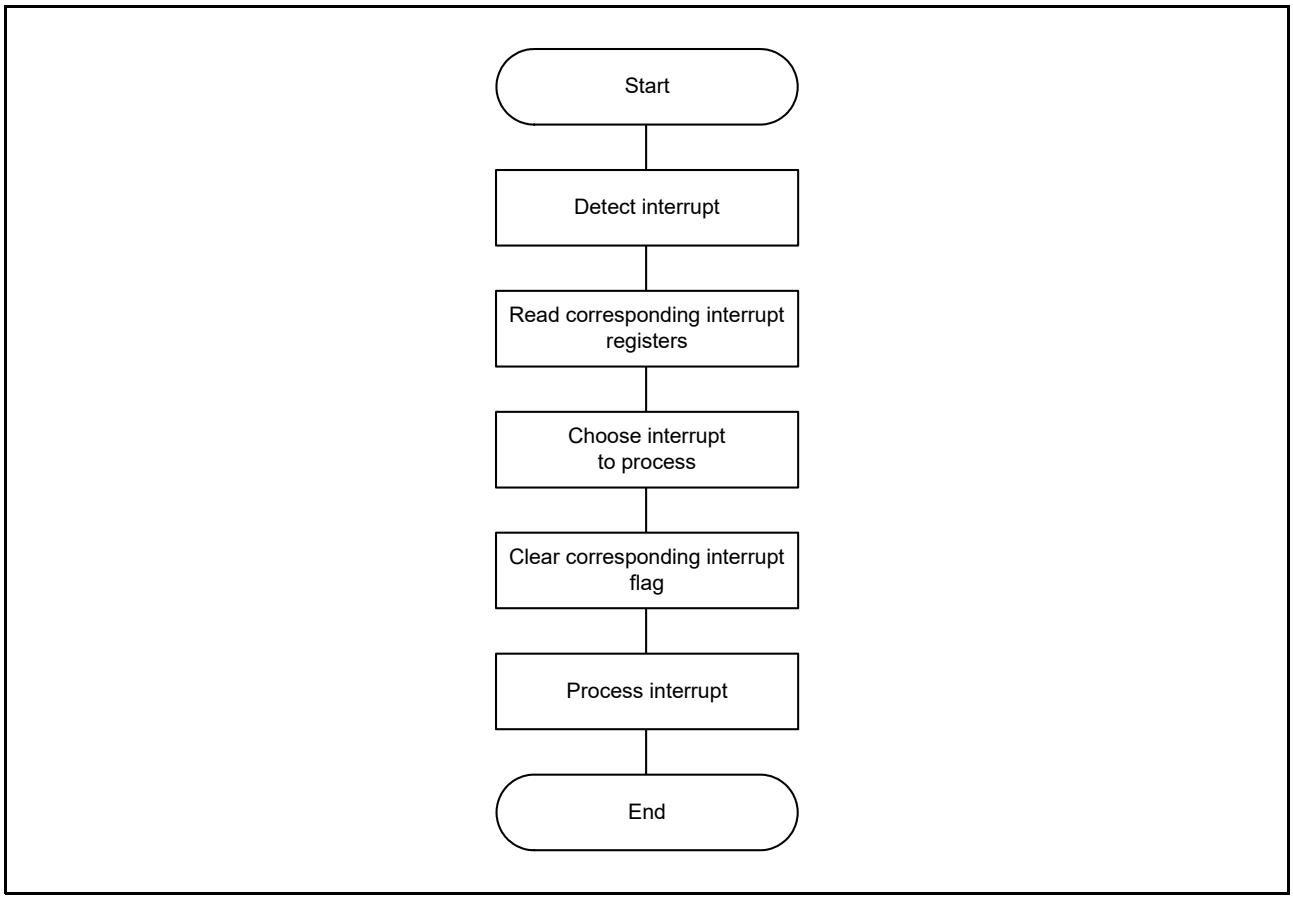

Figure 39.11 Interrupt Handling Flow

39.3.9.2 Timer 0 Flows

In this section are described the flows to set and monitor timer 0.

(1) Timer 0 Offset Setting Flow

The timer 0 offset setting flow is described in Figure 39.12.

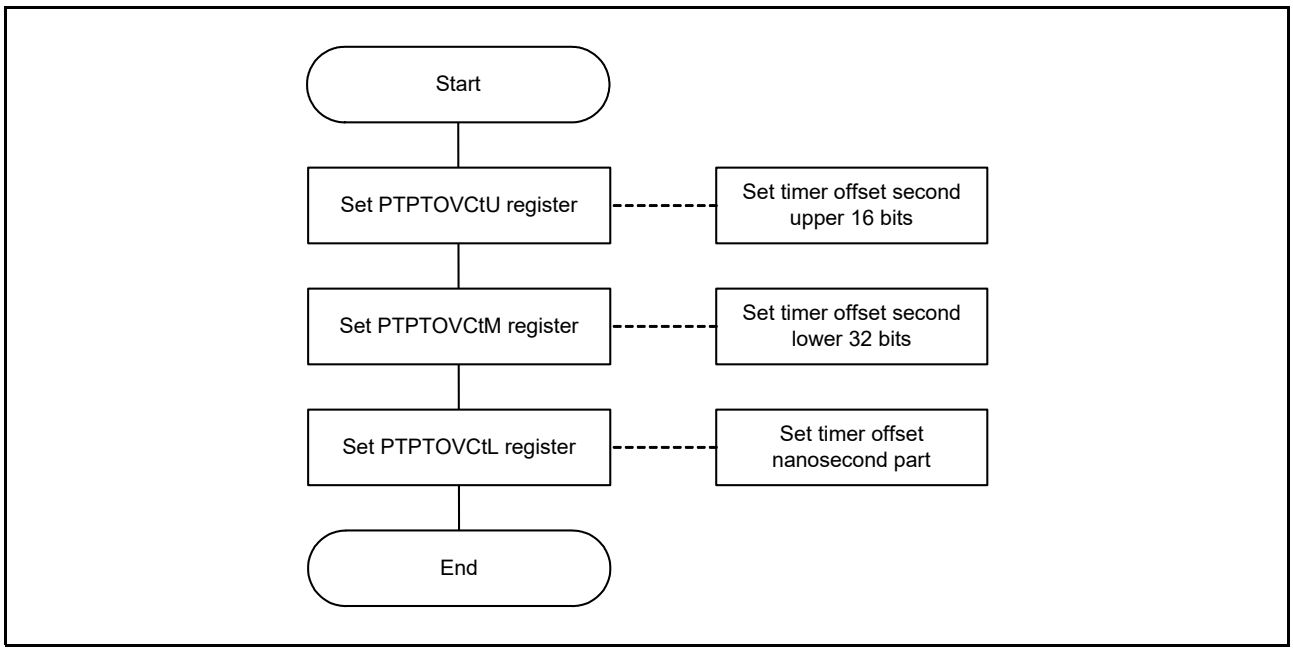

Figure 39.12 Timer 0 Offset Setting Flow

(2) 32-bit AVTP Timer 0 Reading Flow

The 32-bit AVTP timer 0 reading flow is described in Figure 39.13.

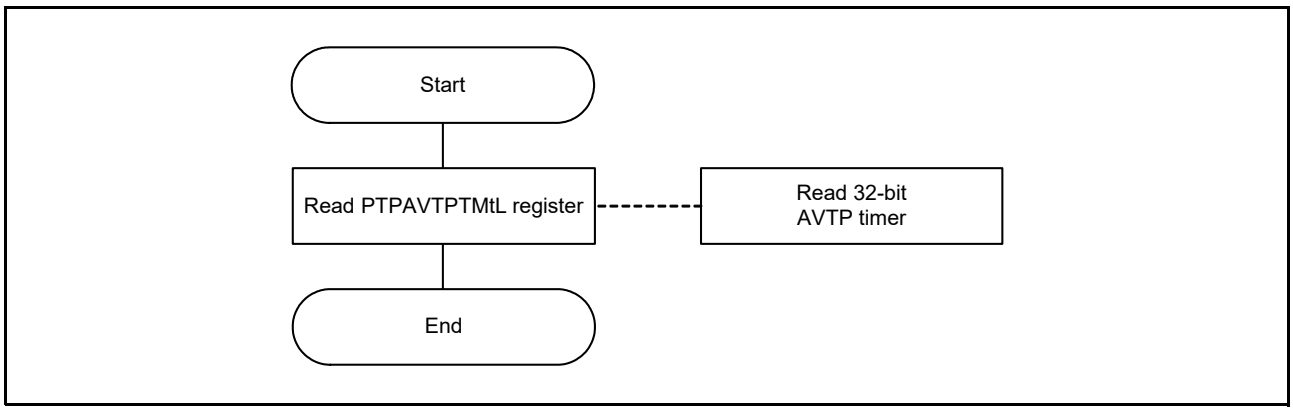

Figure 39.13 32-bit AVTP Timer 0 Reading Flow

(3) 64-bit AVTP Timer 0 Reading Flow

The 64-bit AVTP timer 0 reading flow is described in Figure 39.14.

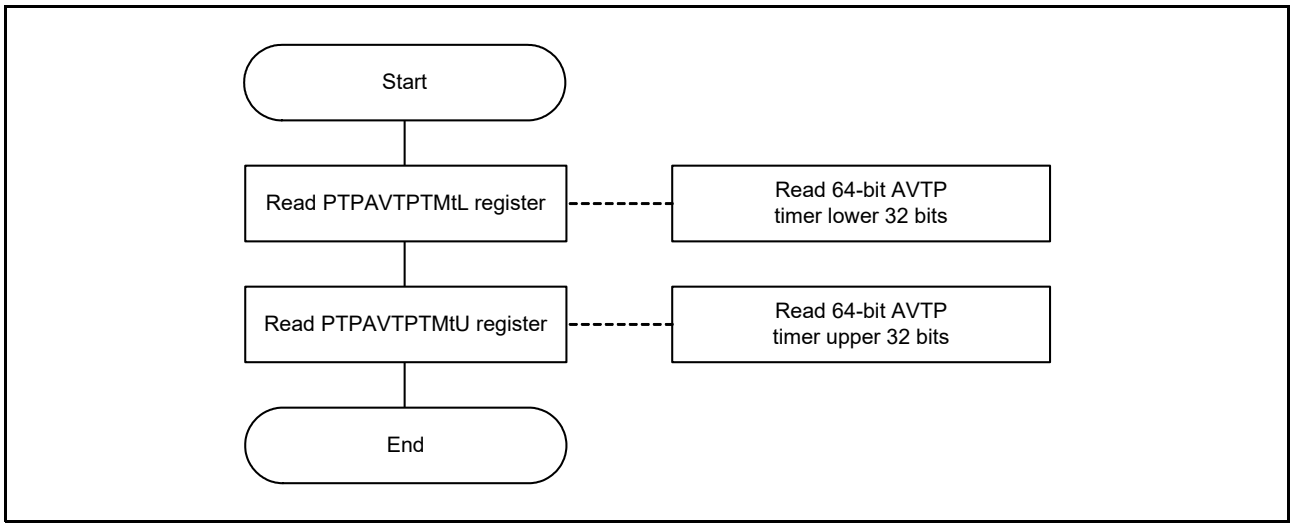

Figure 39.14 64-bit AVTP Timer 0 Reading Flow

(4) gPTP Timer 0 Reading Flow

The gPTP timer 0 reading flow is described in Figure 39.15.

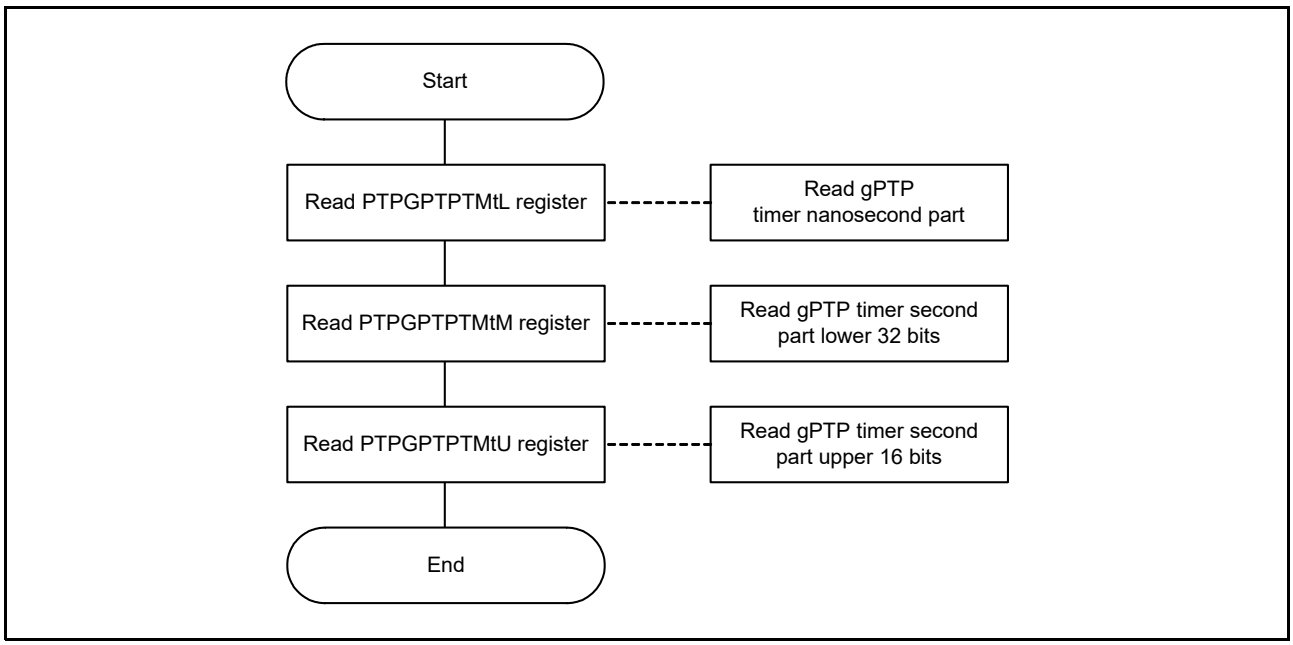

Figure 39.15 gPTP Timer 0 Reading Flow

(5) Register Writable Without Software Flow for Timer 0

Table 39.5 describes the registers writable without software flow and in which mode they can be written.

Table 39.5 Writable without Software Flow Registers

Register name	Writable anytime
PTPTMEC	Writable
PTPTMDC	Writable
PTPTIVC0	Writable

39.3.9.3 Media Clock m Capture Flows (m = 0, 1)

In this section are described the flows to set and monitor media clock m capture.

(1) 32-bit AVTP Timer Captured Value Reading Flow

The 32-bit AVTP timer captured value reading flow is described in Figure 39.16.

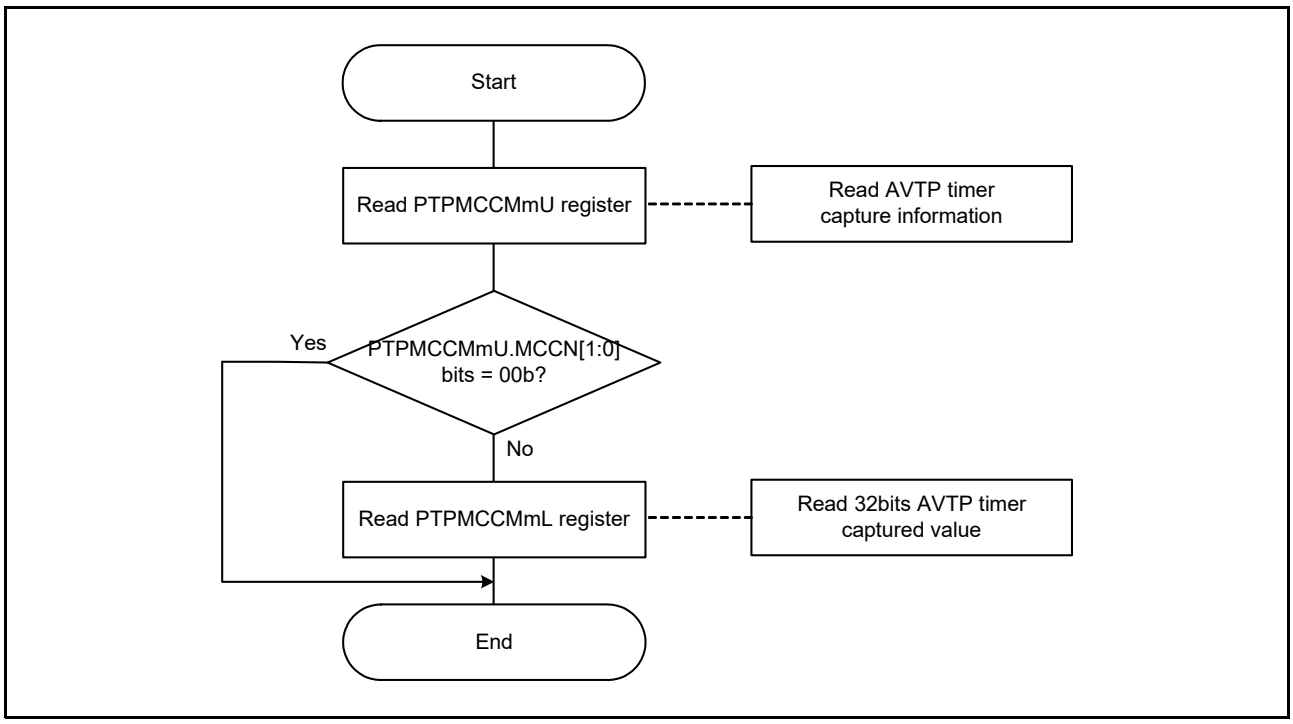

Figure 39.16 32-bit AVTP Timer Captured Value Reading Flow

(2) 64-bit AVTP Timer Captured Value Reading Flow

The 64-bit AVTP timer captured value reading flow is described in Figure 39.17.

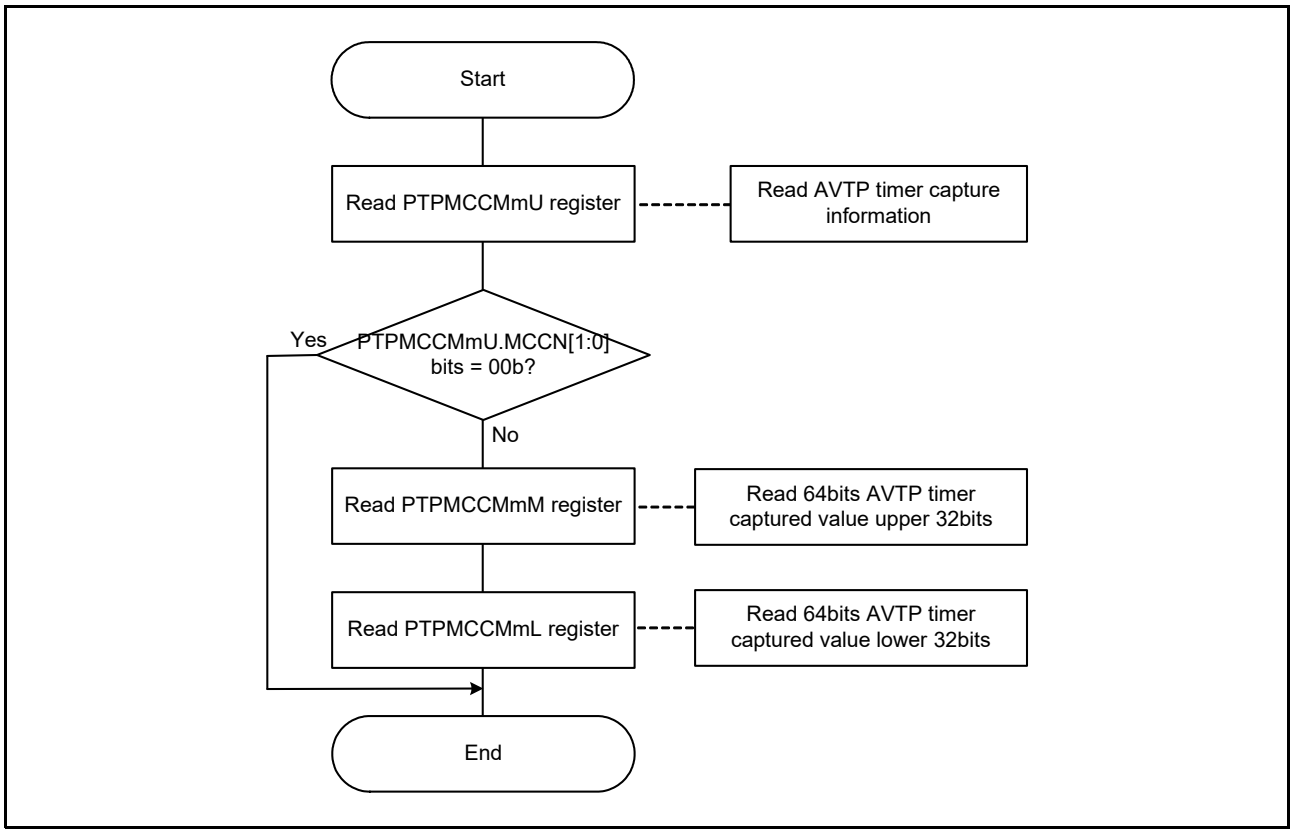

Figure 39.17 64-bit AVTP Timer Captured Value Reading Flow

(3) gPTP Timer Captured Value Reading Flow

The gPTP timer captured value reading flow is described in Figure 39.18.

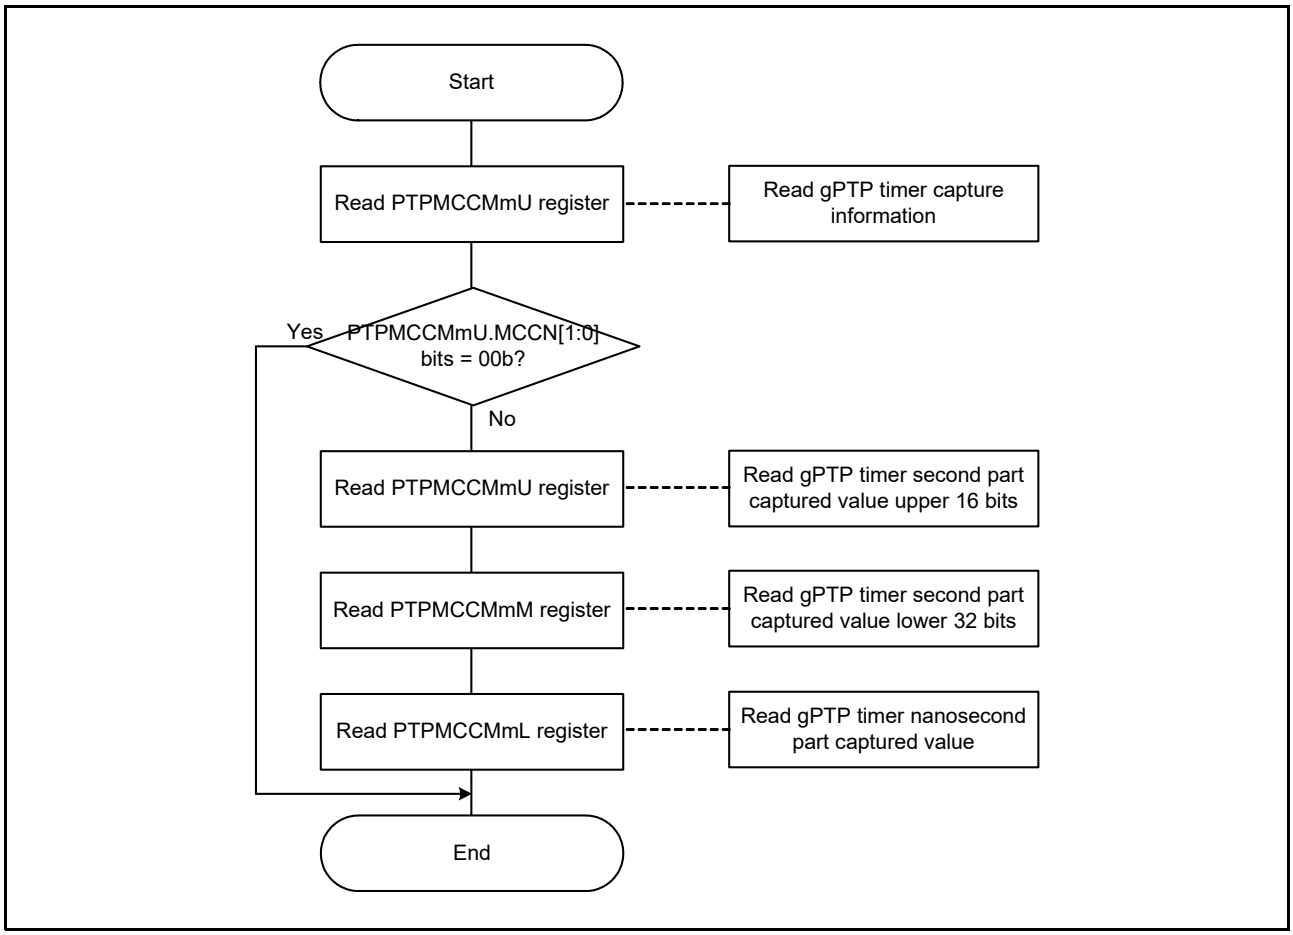

Figure 39.18 gPTP Timer Captured Value Reading Flow

(4) Register Writable Without Software Flow for Media Clock Capture m

Table 39.6 describes the registers writable without software flow and in which mode they can be written.

Table 39.6 Writable without Software Flow Registers

Register name	Writable anytime
PTPMCCCm	Writable

39.3.9.4 Media Clock Recovery m Flows (m = 0, 1)

In this section are described the flows to set and monitor media clock recovery m.

(1) Media Clock Recovery Time Value Setting Flow

The media clock recovery time value setting flow is described in Figure 39.19.

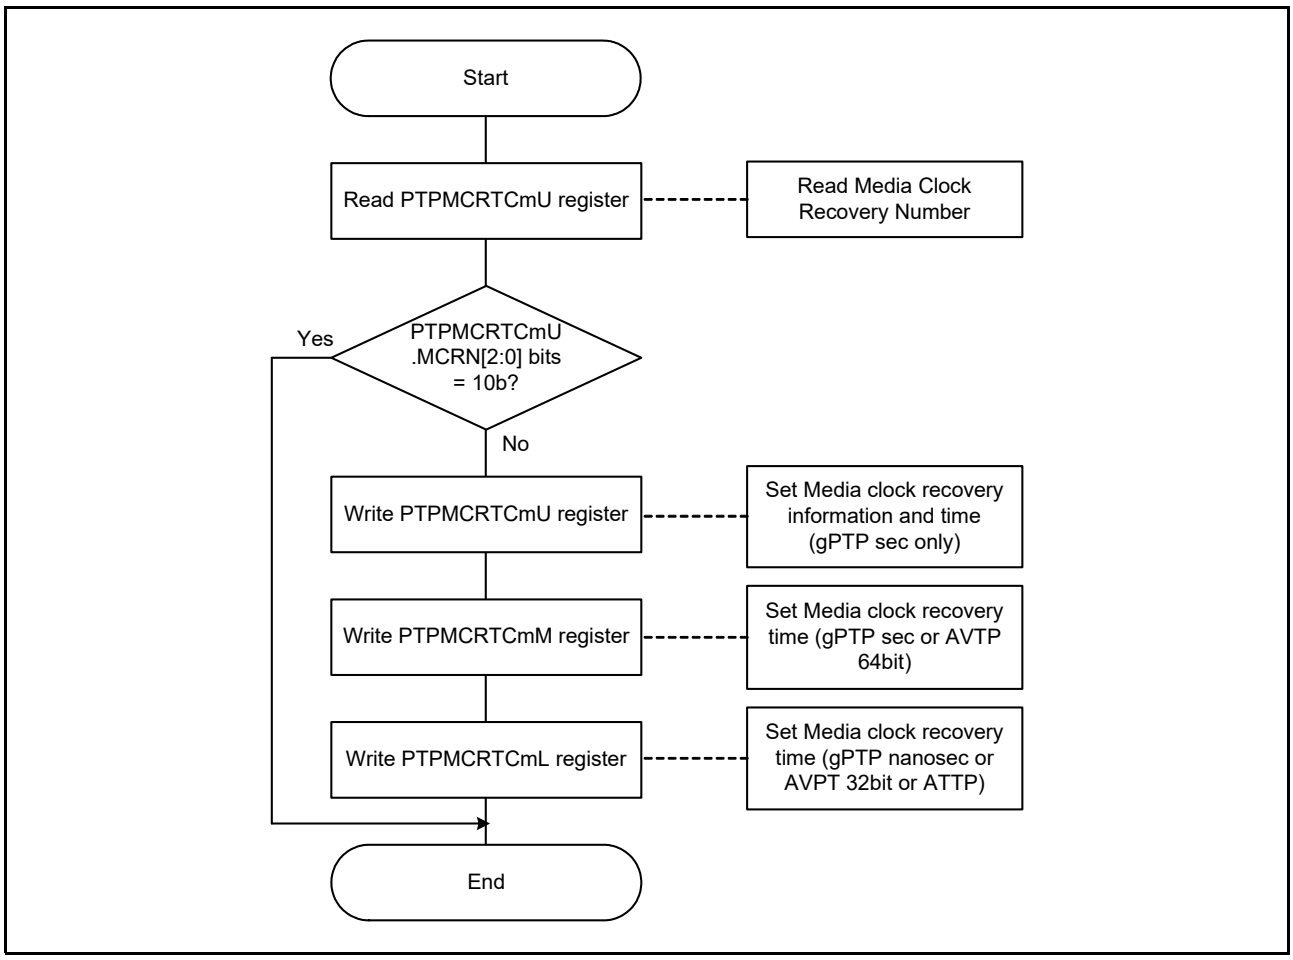

Figure 39.19 Media Clock Recovery Time Value Setting Flow

(2) Media Clock Recovery Buffer Clear Flow

The media clock recovery buffer clear flow is described in Figure 39.20.

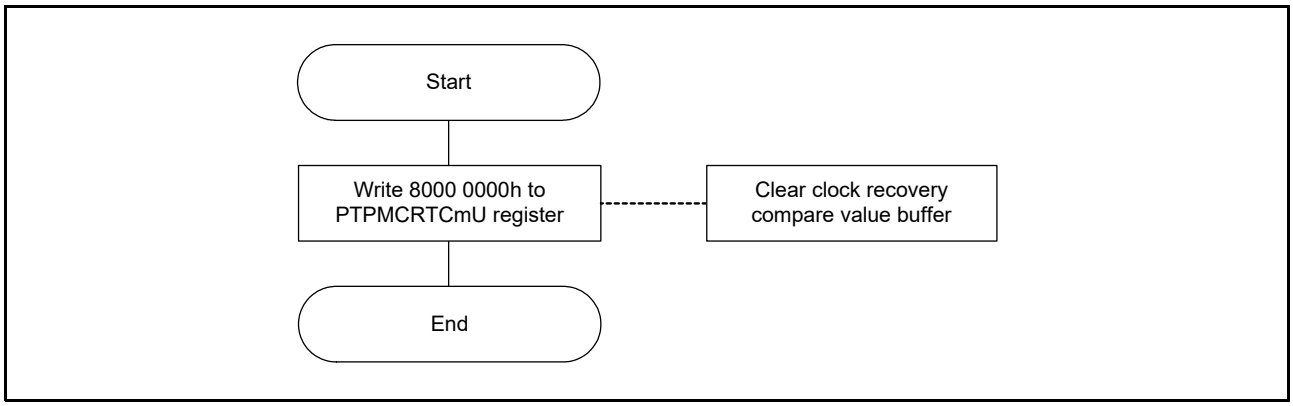

Figure 39.20 Media Clock Recovery Buffer Clear Flow

(3) Register Writable Without Software Flow for Media Clock Recovery m

Table 39.7 describes the registers writable without software flow and in which mode they can be written.

Table 39.7 Writable without Software Flow Registers

Register name	Writable anytime
PTPMCRCm	Writable

39.3.9.5 Cyclic Compare c Flows (c = 0 to 7)

In this section are described the flows to set and monitor cyclic compare c.

(1) Register Writable Without Software Flow for Cyclic Compare c

Table 39.8 describes the registers writable without software flow and in which mode they can be written.

Table 39.8 Writable without Software Flow Registers

Register name	Writable anytime
PTPCCCc0	Writable
PTPCCCc1	Writable

39.3.9.6 Pulse Output Timer n Operation Flow (n = 0, 1)

This section describes the flow of register setting required to operate the pulse output timer n.

(1) Operation Setting Flow

Operation setting flow of the pulse output timer is described in Figure 39.21.

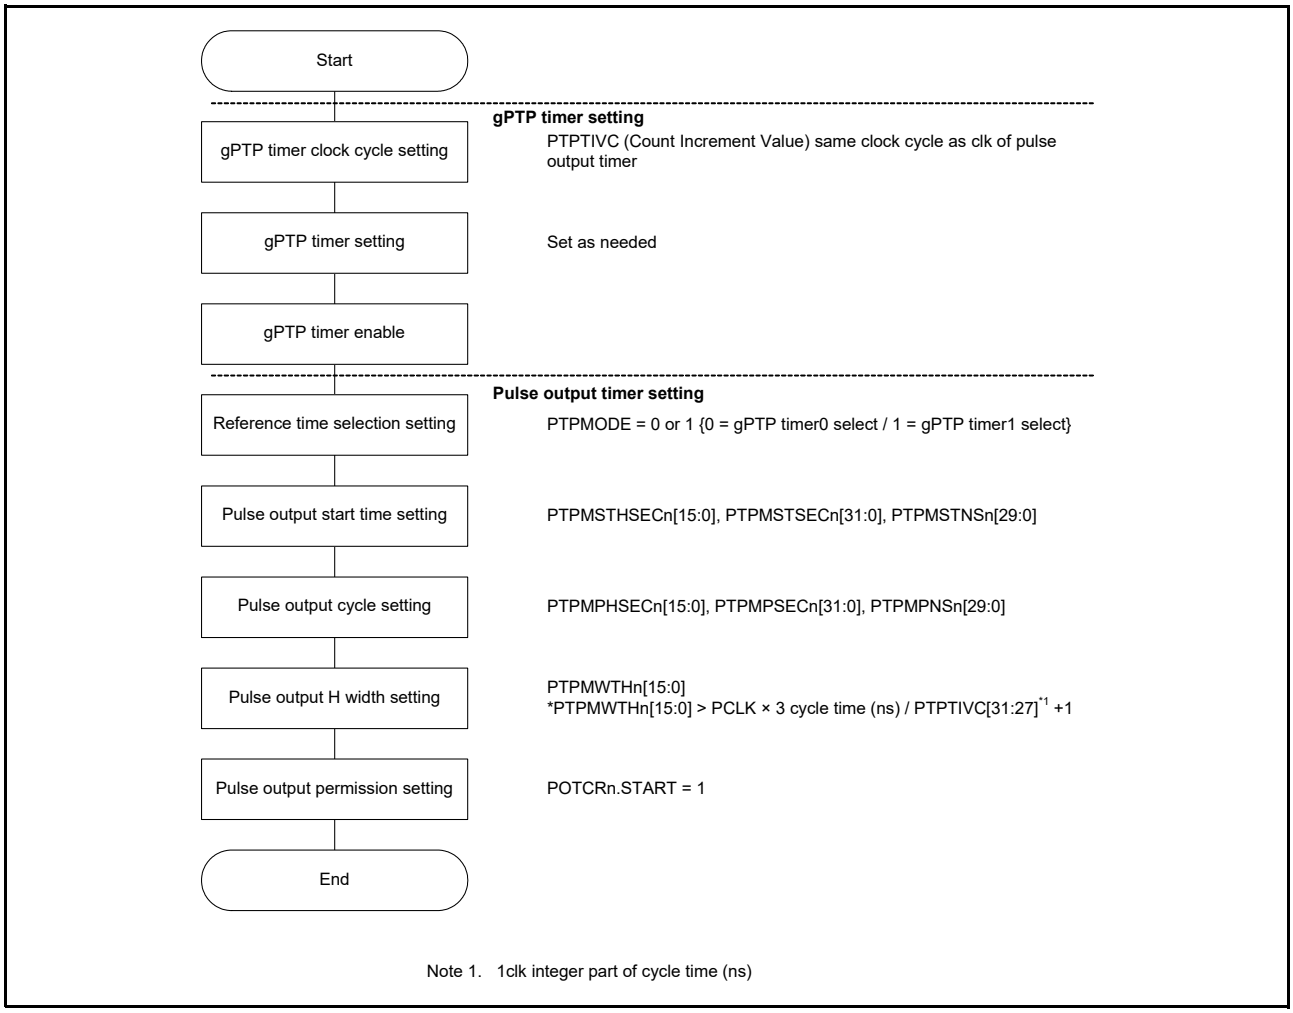

Figure 39.21 Operation Setting Flow

39.4 Usage Notes

39.4.1 Note on Register Setting

The POTCFGR.REFSEL bit switches the gPTP timer selection immediately when the setting is changed regardless of whether it is stopped or operating.
Be careful when changing during operation.

39.4.2 Restrictions on Register Setting

The following registers should be set within the limit range of the set value.

- POTSTRnL, POTPERnL: Set the value in the range of 0 to 3B9AC9FFh.

Note: 3B9ACA00h is 1 second, so if it is 1 second or longer, reflect it in the register in seconds and set it.

- POTPWRn: For settings other than 0, set for a time of 3 or more cycles of the PCLKA cycle.

Note: The time required to generate the interrupt output signal.

40. USB 2.0 Full-Speed Host/Function Module (USBf)

40.1 Overview

This MCU incorporates a USB 2.0 full-speed host/function module (USB0).
The USB module is a USB controller that is equipped to operate as a host controller or function controller. The module supports full-speed and low-speed (only for the host controller) transfer as defined in Universal Serial Bus (USB) Specification 2.0. The module has an internal USB transceiver and supports all of the transfer types defined in USB Specification 2.0.
The USB has buffer memory for data transfer, providing a maximum of 10 pipes. Pipes 1 to 9 can be assigned any endpoint number based on peripheral devices used for communication or based on the user system.
Table 40.1 shows the specifications of the USB.

Table 40.1 USB Specifications

Item	Specifications
Features	• USB Device Controller (UDC) and transceiver for USB 2.0 are incorporated. Host controller, function controller, and On-The-Go (OTG) are supported (one channel) • The host controller and the function controller can be switched by software. • Self-power mode or bus power mode can be selected.
	When the host controller is selected: • Full-speed transfer (12 Mbps) and low-speed transfer (1.5 Mbps) are supported • Automatic scheduling for SOF and packet transmissions • Programmable intervals for isochronous and interrupt transfers • Multiple peripheral devices can be connected for communication via a one-stage hub.
	When the function controller is selected: • Full-speed transfer (12 Mbps) is supported*1 • Control transfer stage control function • Device state control function • Auto response function for SET_ADDRESS request • SOF interpolation function
Communication data transfer type	• Control transfer • Bulk transfer • Interrupt transfer • Isochronous transfer
Pipe configuration	• Buffer memory for USB communication is provided. • Up to 10 pipes can be selected (including the default control pipe). • Pipes 1 to 9 can be assigned any endpoint number.
	Transfer conditions that can be set for each pipe: • Pipe 0: Control transfer, 64-byte single buffer • Pipes 1 and 2: 64-byte double buffer can be specified for bulk transfer and 256-byte double buffer for isochronous transfer • Pipes 3 to 5: Bulk transfer, 64-byte double buffer • Pipes 6 to 9: Interrupt transfer, 64-byte single buffer
Others	• Reception ending function using transaction count • Function that changes the BRDY interrupt event notification timing (BFRE) • Function that automatically clears the buffer memory after the data for the pipe specified at the DnFIFO (n = 0, 1) port has been read (DCLRM) • NAK setting function for response PID generated by end of transfer (SHTNAK) • On-chip pull-up and pull-down resistors of D+/D–
Low power consumption function	Module-stop state can be set.
Protect Zone filter	Security attribute can be set.*2

Note 1. When the function controller is selected, low-speed transfer (1.5 Mbps) is not supported.
Note 2. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Figure 40.1 shows a block diagram of the USB.

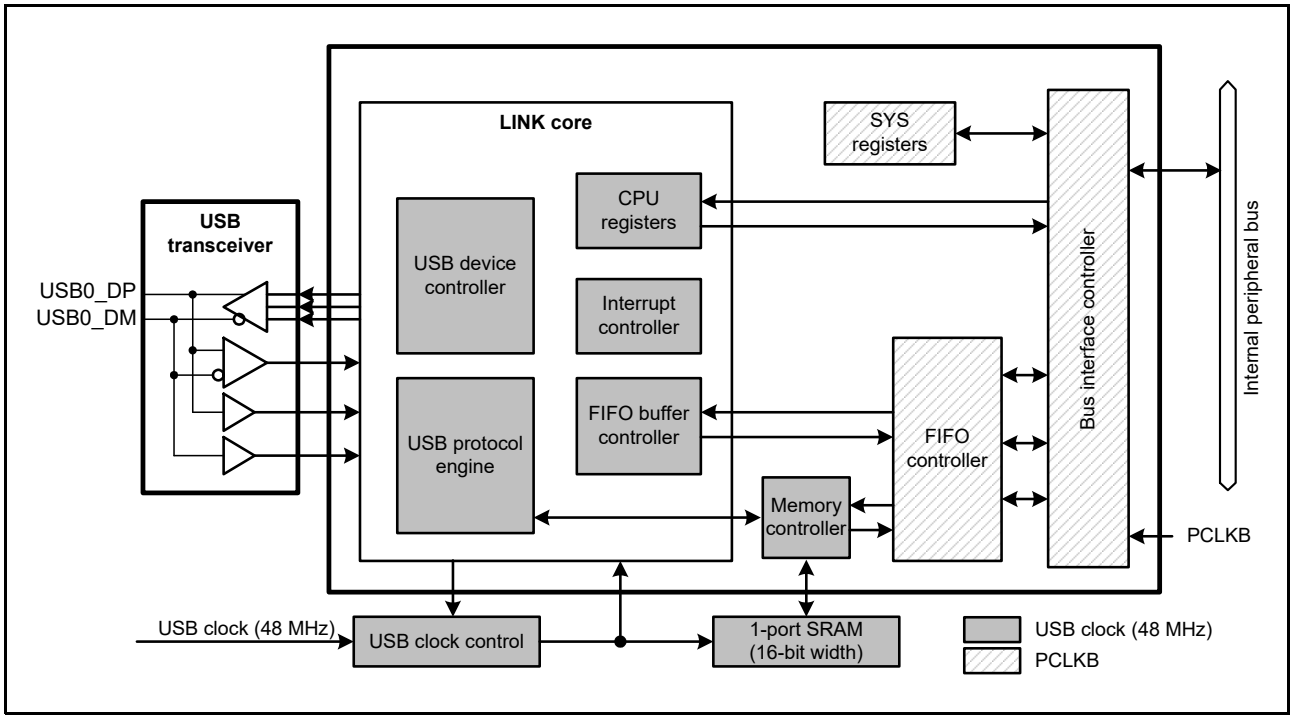

Figure 40.1 USB Block Diagram

Table 40.2 lists the I/O pins of the USB.

Table 40.2 USB Pin Configuration

Port	Pin Name	I/O	Function
USB0	USB0_DP	I/O	D+ I/O pin of the USB on-chip transceiver This pin should be connected to the D+ pin of the USB bus.
	USB0_DM	I/O	D– I/O pin of the USB on-chip transceiver This pin should be connected to the D– pin of the USB bus.
	USB0_VBUS	Input	USB cable connection monitor pin This pin should be connected to VBUS of the USB bus. The VBUS pin status (connected or disconnected) can be detected when the USB module is operating as a function controller.
	USB0_EXICEN	Output	Low-power control signal for external power supply (OTG) chip
	USB0_VBUSEN	Output	VBUS (5 V) supply enable signal for external power supply chip
	USB0_OVRCURA USB0_OVRCURB	Input	External overcurrent detection signals should be connected to these pins. VBUS comparator signals should be connected to these pins when the OTG power supply chip is connected.
	USB0_ID	Input	MicroAB connector ID input signal should be connected to this pin during operation in OTG mode.
Common	VCC_USB	Input	USB power supply pin
	VSS_USB	Input	USB ground pin

40.2 Register Descriptions

40.2.1 System Configuration Control Register (SYSCFG)

Address(es): USB0.SYSCFG 8785 0000h, USB0_NS.SYSCFG 0785 0000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SCKE	—	—	—	DCFM	DRPD	DPRPU	—	—	—	USBE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	USBE	USB Operation Enable	0: USB operation is disabled. 1: USB operation is enabled.	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	DPRPU	D+ Line Resistor Control	0: Pulling up the line is disabled. 1: Pulling up the line is enabled.	R/W
b5	DRPD	D+/D– Line Resistor Control	0: Pulling down the lines is disabled. 1: Pulling down the lines is enabled.	R/W
b6	DCFM	Controller Function Select	0: Function controller is selected. 1: Host controller is selected.	R/W
b9 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b10	SCKE	USB Clock Enable*1	0: Stops supplying the clock signal to the USB. 1: Enables supplying the clock signal to the USB.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. After writing 1 to the SCKE bit, read it and confirm it is set to 1.

USBE Bit (USB Operation Enable)

The USBE bit enables or disables operation of the USB.

Modifying the USBE bit from 1 to 0 initializes the register bits listed in Table 40.3.

This bit should be modified while the SCKE bit is 1.

When the host controller is selected, this bit should be set to 1 after setting the DRPD bit to 1, eliminating SYSSTS0.LNST[1:0] flag chattering, and confirming that the USB bus state is stabilized.

Table 40.3 Registers Initialized by Writing 0 to the SYSCFG.USBE Bit

Selected Function	Register	Bit	Remarks
Function controller	SYSSTS0	LNST[1:0]	The value is retained when the host controller is selected.
	DVSTCTR0	RHST[2:0]	
	INTSTS0	DVSQ[2:0]	The value is retained when the host controller is selected.
	USBADDR	USBADDR[6:0]	The value is retained when the host controller is selected.
	USBREQ	BREQUEST[7:0], BMREQUESTTYPE[7:0]	The value is retained when the host controller is selected.
	USBVAL	—	The value is retained when the host controller is selected.
	USBINDX	—	The value is retained when the host controller is selected.
	USBLENG	—	The value is retained when the host controller is selected.
Host controller	DVSTCTR0	RHST[2:0]	
	FRMNUM	FRNM[10:0]	The value is retained when the function controller is selected.

DPRPU Bit (D+ Line Resistor Control)

The DPRPU bit enables or disables pulling up the D+ line when the function controller is selected.
When the DPRPU bit is set to 1 while the function controller is selected, the bit forces a pull-up of the D+ line to notify the USB host of connection. Modifying the DPRPU bit from 1 to 0 allows the USB to release the D+ line, thus notifying the USB host of disconnection.
This bit should be set to 1 if the function controller is selected, and should be set to 0 if the host controller is selected.

DRPD Bit (D+/D– Line Resistor Control)

The DRPD bit enables or disables pulling down D+ and D– lines when the host controller is selected.
This bit should be set to 1 if the host controller is selected, and should be set to 0 if the function controller is selected.

DCFM Bit (Controller Function Select)

The DCFM bit selects the function of the USB.
This bit should be modified when the DPRPU and DRPD bits are all 0.

SCKE Bit (USB Clock Enable)

The SCKE bit stops or enables supplying 48-MHz clock signals to the USB.
When this bit is 0, only SYSCFG can be read from and written to; the other registers related to the USB cannot be read from or written to.

40.2.2 System Configuration Status Register 0 (SYSSTS0)

Address(es): USB0.SYSSTS0 8785 0004h, USB0_NS.SYSSTS0 0785 0004h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVCMON[1:0]		—	—	—	—	—	—	—	HTACT	SOFEA	—	—	IDMON	LNST[1:0]	
Value after reset:	0*1	0*1	0	0	0	0	0	0	0	0	0	0	0	0*1	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	LNST[1:0]	USB Data Line Status Monitor Flag	Refer to Table 40.4.	R
b2	IDMON	ID Input Pin Monitor Flag	0: USB0_ID pin is low 1: USB0_ID pin is high	R
b4, b3	—	Reserved	These bits are read as 0 and cannot be modified.	R
b5	SOFEA	SOF Active Monitor Flag When the Host Controller is Selected	Indicates the SOF output status. 0: SOF output is stopped. 1: SOF output is operating.	R
b6	HTACT	USB Host Sequencer Status Monitor Flag	0: Host sequencer of the USB is completely stopped. 1: Host sequencer of the USB is not completely stopped.	R
b13 to b7	—	Reserved	These bits are read as 0 and cannot be modified.	R
b15, b14	OVCMON[1:0]	OVRCURA/OVRCURB Input Pin Monitor Flag	The OVCMON[1] flag indicates the status of the USB0_OVRCURA pin. The OVCMON[0] flag indicates the status of the USB0_OVRCURB pin.	R

Note 1. Depends on the status of the USB0_OVRCURA/USB0_OVRCURB and USB0_ID pins.

LNST[1:0] Flags (USB Data Line Status Monitor Flag)

The LNST[1:0] flags indicate the state of the USB data lines (D+ and D– lines). Refer to Table 40.4.
The LNST[1:0] flags should be read after the connection processing (SYSCFG.DPRPU bit = 1) when the function controller is selected; whereas after enabling pull-down of the lines (SYSCFG.DRPD bit = 1) when the host controller is selected.

SOFEA Flag (SOF Active Monitor Flag When the Host Controller is Selected)

When the USB module is suspended while host mode is used, this bit can be used to confirm whether the last SOF has been output after DVSTCTR0.UACT is set to 0.
Confirm that both the HTACT and SOFEA flags are 0 before stopping the USB module while SYSCFG.USBE is 0 and setting the SYSCFG.SCKE bit to 0 to stop the clock during host mode communication.

HTACT Flag (USB Host Sequencer Status Monitor Flag)

The HTACT flag is 0 when the host sequencer of the USB is completely stopped.
Confirm that the HTACT flag is 0 before setting this controller to the USB suspended state while DVSTCTR0.UACT bit is 0 and setting the SCKE bit to 0 to stop the clock during host mode communication.

OVCMON[1:0] Flags (OVRCURA/OVRCURB Input Pin Monitor Flag)

The OVCMON[1:0] flags indicate the status of overcurrent from an external power supply chip.

Table 40.4 Status of USB Data Bus Lines (D+ Line, D– Line)

LNST[1:0] Flags	During Low-Speed Operation (Only in Host Controller Operation)	During Full-Speed Operation
00b	SE0	SE0
01b	K-State	J-State
10b	J-State	K-State
11b	SE1	SE1

40.2.3 Device State Control Register 0 (DVSTCTR0)

Address(es): USB0.DVSTCTR0 8785 0008h, USB0_NS.DVSTCTR0 0785 0008h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	HNPBTOA	EXICEN	VBUSEN	WKUP	RWUPE	USBRST	RESUME	UACT	—	RHST[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	RHST[2:0]	USB Bus Reset Status Flag	• When the host controller is selected b2 b0 0 0 0: Communication speed not determined (powered state or no connection) 1 x x: USB bus reset in progress 0 0 1: Low-speed connection 0 1 0: Full-speed connection • When the function controller is selected b2 b0 0 0 0: Communication speed not determined 0 0 1: USB bus reset in progress 0 1 0: USB bus reset in progress or full-speed connection	R
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	UACT	USB Bus Enable	0: Downstream port is disabled (SOF transmission is disabled). 1: Downstream port is enabled (SOF transmission is enabled).	R/W
b5	RESUME	Resume Output	0: Resume signal is not output. 1: Resume signal is output.	R/W
b6	USBRST	USB Bus Reset Output	0: USB bus reset signal is not output. 1: USB bus reset signal is output.	R/W
b7	RWUPE	Wakeup Detection Enable	0: Downstream port wakeup is disabled. 1: Downstream port wakeup is enabled.	R/W
b8	WKUP	Wakeup Output	0: Remote wakeup signal is not output. 1: Remote wakeup signal is output.	R/W
b9	VBUSEN	VBUSEN Output Pin Control	0: USB0_VBUSEN pin outputs low. 1: USB0_VBUSEN pin outputs high.	R/W
b10	EXICEN	EXICEN Output Pin Control	0: USB0_EXICEN pin outputs low. 1: USB0_EXICEN pin outputs high.	R/W
b11	HNPBTOA	Host Negotiation Protocol (HNP) Control	This bit is used when switching from device B to device A while in OTG mode. If the HNPBTOA bit is 1, the internal function control keeps the suspended state until the HNP processing ends even though SYSCFG.DPRPU = 0 or SYSCFG.DCFM = 1.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

x: Don’t care

RHST[2:0] Flags (USB Bus Reset Status Flag)

The RHST[2:0] flags indicate the status of the USB bus reset.
When the host controller is selected, the RHST[2:0] flags indicate 100b after the USBRST bit has been set to 1 by software.
The USB fixes the value of the RHST[2:0] flags when 0 is written to the USBRST bit by software and the USB completes SE0 driving.
When the function controller is selected, the RHST[2:0] flags indicate 010b (connection while DPRPU = 1) when the USB detects the USB bus reset, and a DVST interrupt is generated.

UACT Bit (USB Bus Enable)

The UACT bit enables operation of the USB bus (controls the SOF packet transmission to the USB bus) when the host controller is selected.
With this bit set to 1, the USB puts the USB port to the USB-bus enabled state and performs SOF output and data transmission and reception.
This module starts outputting SOF packets within one frame after 1 has been written to the UACT bit by software.
With this bit set to 0, the USB enters the idle state after outputting SOF packets.
The USB sets the UACT bit to 0 on any of the following conditions.

- A DTCH interrupt is detected during communication (while UACT = 1).
- An EOFERR interrupt is detected during communication (while UACT = 1).

Writing 1 to this bit should be done at the end of the USB reset processing (writing 0 to the USBRST bit) or at the end of the resume processing from the suspended state (writing 0 to the RESUME bit).
This bit should be set to 0 if the function controller is selected.

RESUME Bit (Resume Output)

The RESUME bit controls the resume signal output when the host controller is selected.
Setting the RESUME bit to 1 allows the USB to drive the port to the K-state and output the resume signal.
The USB sets the RESUME bit to 1 on detecting the remote wakeup signal while RWUPE is 1 in the USB suspended state.
The USB continues outputting K-state while the RESUME bit = 1 (until the RESUME bit is set to 0 by software). The RESUME bit should be 1 (= resume period) for the time defined by USB Specification 2.0.
This bit should be set to 1 in the suspended state.
Write 1 to the UACT bit simultaneously with the end of the resume processing (writing 0 to the RESUME bit).
This bit should be set to 0 if the function controller is selected.

USBRST Bit (USB Bus Reset Output)

The USBRST bit controls the USB bus reset signal output when the host controller is selected.
When the host controller is selected, setting this bit to 1 allows the USB to drive SE0 of the USB port to reset the USB bus.
The USB continues outputting SE0 while USBRST = 1 (until the USBRST bit is set to 1 by software). The USBRST bit should be 1 (= USB bus reset period) for the time defined by USB Specification 2.0.
Writing 1 to this bit during communication (the UACT bit = 1) or during the resume processing (the RESUME bit = 1) prevents the USB from starting the USB bus reset processing until both the UACT and RESUME bits become 0.
Write 1 to the UACT bit simultaneously with the end of the USB bus reset processing (writing 0 to the USBRST bit).
This bit should be set to 0 if the function controller is selected.

RWUPE Bit (Wakeup Detection Enable)

The RWUPE bit enables or disables the downstream port peripheral device to use the remote wakeup function (resume signal output) when the host controller is selected.
With this bit set to 1, on detecting the remote wakeup signal, the USB detects the resume signal (K-state for 2.5 µs) from the downstream port device and performs the resume processing (drives the port to the K-state).
With this bit set to 0, the USB ignores the detected remote wakeup signal (K-state) from the peripheral device connected to the USB port.
While the RWUPE bit is 1, the internal clock should not be stopped even in the suspended state (SYSCFG.SCKE bit should be set to 1).
This bit should be set to 0 if the function controller is selected.

WKUP Bit (Wakeup Output)

The WKUP bit enables or disables outputting the remote wakeup signal (resume signal) to the USB bus when the function controller is selected.
The USB controls the output time of a remote wakeup signal. When this bit is set to 1, the USB sets this bit to 0 after outputting the 10-ms K-state.
According to USB Specification 2.0, the USB bus idle state must be kept for 5 ms or longer before a remote wakeup signal is sent. If the USB writes 1 to this bit right after detection of the suspended state, the K-state will be output after 2 ms.
Do not write 1 to this bit, unless the device state is in the suspended state (INTSTS0.DVSQ[2:0] flags = 1xxb) and the USB host enables the remote wakeup signal. When this bit is set to 1, the internal clock must not be stopped even in the suspended state (write 1 to this bit while the SYSCFG.SCKE bit = 1).
This bit should be set to 0 if the host controller is selected.

HNPBTOA Bit (Host Negotiation Protocol (HNP) Control)

The HNPBTOA bit is used when switching from device B to device A while in OTG mode. If the HNPBTOA bit is 1, the internal function control keeps the suspended state until the HNP processing ends even though the SYSCFG.DPRPU bit = 0 or SYSCFG.DCFM = 1 is set. Even if the falling edge of the D+ signal is detected at this time, no resume (RESM) interrupt is generated.
After this bit is set to 1, write 0 to this bit by software to terminate the HNP processing when connection to the host (pull-up on the target side) or timeout of the HNP processing is detected.

40.2.4 CFIFO Port Register (CFIFO), D0FIFO Port Register (D0FIFO), D1FIFO Port Register (D1FIFO)

(1) When the MBW bit is 1

Address(es): USB0.CFIFO 8785 0014h, USB0.D0FIFO 8785 0018h, USB0.D1FIFO 8785 001Ch, USB0_NS.CFIFO 0785 0014h, USB0_NS.D0FIFO 0785 0018h, USB0_NS.D1FIFO 0785 001Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	FIFO Port	This port is used for reading receive data from the FIFO buffer and writing transmit data to the FIFO buffer.	R/W

(2) When the MBW bit is 0

Address(es): USB0.CFIFO.L 8785 0014h, USB0.D0FIFO.L 8785 0018h, USB0.D1FIFO.L 8785 001Ch, USB0_NS.CFIFO.L 0785 0014h, USB0_NS.D0FIFO.L 0785 0018h, USB0_NS.D1FIFO.L 0785 001Ch

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	FIFO Port	This port is used for reading receive data from the FIFO buffer and writing transmit data to the FIFO buffer.	R/W

There are three FIFO ports: CFIFO, D0FIFO, and D1FIFO. Each FIFO port is configured of a port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer memory and writing of data to the FIFO buffer memory, a port select register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that is used to select the pipe assigned to the FIFO port, and a port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR).
Each FIFO port has the following precautions.

- The FIFO buffer for DCP (control transfer) should be accessed through the CFIFO port.
- Accessing a FIFO buffer using DMA/DTC transfer should be performed through the D0FIFO or D1FIFO port.
- The D0FIFO and D1FIFO ports can also be accessed by the CPU.
- When using functions specific to a FIFO port, the pipe number (selected pipe) specified by the CURPIPE[3:0] bits in the port select register cannot be changed (when the DMA/DTC transfer function is used, etc.).
- The same pipe should not be assigned to two or more FIFO ports.
- There are two FIFO buffer states: the access right for a FIFO buffer can be on the CPU side or on the Serial Interface Engine (SIE) side. When the access right for a FIFO buffer is on the SIE side, the FIFO buffer cannot be accessed from the CPU.

FIFO Port Bit

Accessing the FIFO port bits allows reading the received data from the FIFO buffer or writing the transmit data to the FIFO buffer.

Each FIFO port register can be accessed only while the FRDY flag in each FIFO port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is 1.

The valid bits in a FIFO port register depend on the settings of the corresponding MBW bit of the FIFO port select register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL).

When the MBW bit is 1 (16-bit width), the data arrangement may differ from the data arrangement on the RAM depending on the value of the MDE.MDE[2:0] bits and the setting of the BIGEND bit (CFIFOSEL.BIGEND, D0FIFOSEL.BIGEND, or D1FIFOSEL.BIGEND). Table 40.5 lists the endian operation in 16-bit access. Note that if the total number of transmit data bytes is odd, access the lower byte in bytes when writing the last data.

When the MBW bit is 0 (8-bit width), access the lower byte in bytes.

Table 40.5 Endian Operation in 16-Bit Access

MDE.MDE[2:0] bits	CFIFOSEL.BIGEND Bit D0FIFOSEL.BIGEND Bit D1FIFOSEL.BIGEND Bit	Bits 15 to 8	Bits 7 to 0	Remarks
000b (big endian)	0 (little endian)	Data in address N + 1	Data in address N	Bytes reversed
	1 (big endian)	Data in address N	Data in address N + 1	
111b (little endian)	0 (little endian)	Data in address N + 1	Data in address N	
	1 (big endian)	Data in address N	Data in address N + 1	Bytes reversed

40.2.5 CFIFO Port Select Register (CFIFOSEL), D0FIFO Port Select Register (D0FIFOSEL), D1FIFO Port Select Register (D1FIFOSEL)

- CFIFOSEL

Address(es): USB0.CFIFOSEL 8785 0020h, USB0_NS.CFIFOSEL 0785 0020h

b9	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b10	MBW	CFIFO Port Access Bit Width	0: 8-bit width 1: 16-bit width	R/W
b13 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	REW	Buffer Pointer Rewind	0: The buffer pointer is not rewound. 1: The buffer pointer is rewound.	R/W*1
b15	RCNT	Read Count Mode	0: The CFIFOCTR.DTLN[8:0] flags are set to 000h when all of the receive data has been read from the CFIFO. (In double buffer mode, the DTLN[8:0] flag value is set to 000h when all the data has been read from only a single plane.) 1: The CFIFOCTR.DTLN[8:0] flags are decremented each time the receive data is read from the CFIFO.	R/W

Note 1. Only 0 can be read.

The same pipe should not be specified by the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

The pipe number should not be changed while the DMA/DTC transfer is enabled.

CURPIPE[3:0] Bits (CFIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number using which data is read or written through the CFIFO port.
After writing to these bits, read these bits to check that the written value agrees with the read value before proceeding to the next process.
Do not set the same pipe number to the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.
Even if an attempt is made to modify the setting of these bits during access to the FIFO buffer, the current access setting is retained until the access is completed. Then, the modification becomes effective, thus enabling continuous access.

ISEL Bit (CFIFO Port Access Direction When DCP is Selected)

After writing to the ISEL bit with the DCP being a selected pipe, read this bit to check that the written value agrees with the read value before proceeding to the next process.
Set this bit and the CURPIPE[3:0] bits simultaneously.

MBW Bit (CFIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the CFIFO port.
When the selected pipe is in the receiving direction, once reading data is started after setting this bit, this bit should not be modified until all the data has been read.
When the selected pipe is in the receiving direction, set the CURPIPE[3:0] bits to a different value once, and then set these bits and the MBW bit simultaneously. For the procedure for modifying the CURPIPE[3:0] bits, follow the description of these bits.
When the selected pipe is in the transmitting direction, the bit width cannot be changed from 8-bit width to 16-bit width while data is being written to the buffer memory.
An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

REW Bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.
When the selected pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data (in double buffer mode, re-reading the currently-read FIFO buffer plane from the first data is allowed).
Do not set the REW bit to 1 simultaneously with modifying the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY flag is 1.
To re-write to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

- D0FIFOSEL, D1FIFOSEL

Address(es): USB0.D0FIFOSEL 8785 0028h, USB0.D1FIFOSEL 8785 002Ch, USB0_NS.D0FIFOSEL 0785 0028h, USB0_NS.D1FIFOSEL 0785 002Ch

b11	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b12	DREQE	DMA/DTC Transfer Request Enable	0: DMA/DTC transfer request is disabled. 1: DMA/DTC transfer request is enabled.	R/W
b13	DCLRM	Automatic FIFO Buffer Memory Clear Mode after Selected Pipe is Read	0: Automatic buffer clear mode is disabled. 1: Automatic buffer clear mode is enabled.	R/W
b14	REW	Buffer Pointer Rewind	0: The buffer pointer is not rewound. 1: The buffer pointer is rewound.	R/W*1
b15	RCNT	Read Count Mode	0: The DnFIFOCTR.DTLN[8:0] flags are set to 000h when all of the receive data has been read from the DnFIFO. (In double buffer mode, the DTLN[8:0] flag value is set to 000h when all the data has been read from only a single plane.) 1: The DnFIFOCTR.DTLN[8:0] flags are decremented each time the receive data is read from the DnFIFO. (n = 0, 1)	R/W

Note 1. Only 0 can be read.

The same pipe should not be specified by the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

The pipe number should not be changed while the DMA/DTC transfer is enabled.

CURPIPE[3:0] Bits (FIFO Port Access Pipe Select)

The CURPIPE[3:0] bits specify the pipe number using which data is read or written through the D0FIFO port or D1FIFO port.
After writing to these bits, read these bits to check that the written value agrees with the read value before proceeding to the next process.
Do not set the same pipe number to the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.
Even if an attempt is made to modify the setting of these bits during access to the FIFO buffer, the current access setting is retained until the access is completed. Then, the modification becomes effective, thus enabling continuous access.

MBW Bit (FIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the D0FIFO port or D1FIFO port.
When the selected pipe is in the receiving direction, once reading data is started after setting this bit, this bit should not be modified until all the data has been read.
When the selected pipe is in the receiving direction, set the CURPIPE[3:0] bits to a different value once, and then set these bits and the MBW bit simultaneously. For the procedure for modifying the CURPIPE[3:0] bits, follow the description of these bits.
When the selected pipe is in the transmitting direction, the bit width cannot be changed from 8-bit width to 16-bit width while data is being written to the buffer memory.
An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

DREQE Bit (DMA/DTC Transfer Request Enable)

The DREQE bit enables or disables the DMA/DTC transfer request to be issued.
Before setting the DREQE bit to 1 to enable the DMA/DTC transfer request to be issued, set the CURPIPE[3:0] bits.
When modifying the setting of the CURPIPE[3:0] bits, set this bit to 0 first.

DCLRM Bit (Automatic FIFO Buffer Memory Clear Mode after Selected Pipe is Read)

The DCLRM bit enables or disables the buffer memory to be cleared automatically after data in the selected pipe has been read.
With this bit set to 1, the USB sets the BCLR bit to 1 for the FIFO buffer of the selected pipe on receiving a zero-length packet while the FIFO buffer assigned to the selected pipe is empty, or on receiving a short packet and reading the data while the PIPECFG.BFRE bit is 1.
When using the USB with the SOFCFG.BRDYM bit set to 1, set this bit to 0.

REW Bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.
When the selected pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data (in double buffer mode, re-reading the currently-read FIFO buffer plane from the first data is allowed).
Do not set the REW bit to 1 simultaneously with modifying the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY flag is 1.
To re-write to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

RCNT Bit (Read Count Mode)

The RCNT bit specifies the read mode for the value in the DnFIFOCTR.DTLN[8:0] flags.
When accessing DnFIFO with the PIPECFG.BFRE bit set to 1, set the RCNT bit to 0.

40.2.6 CFIFO Port Control Register (CFIFOCTR), D0FIFO Port Control Register (D0FIFOCTR), D1FIFO Port Control Register (D1FIFOCTR)

Address(es): USB0.CFIFOCTR 8785 0022h, USB0.D0FIFOCTR 8785 002Ah, USB0.D1FIFOCTR 8785 002Eh, USB0_NS.CFIFOCTR 0785 0022h, USB0_NS.D0FIFOCTR 0785 002Ah, USB0_NS.D1FIFOCTR 0785 002Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BVAL	BCLR	FRDY	—	—	—	—	DTLN[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	DTLN[8:0]	Receive Data Length Flag	Indicate the length of the receive data. These bits indicate different values depending on the setting of the RCNT bit in the port select register. For details, refer to the description on the DTLN[8:0] flags shown below.	R
b12 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13	FRDY	FIFO Port Ready Flag	0: FIFO port access is disabled. 1: FIFO port access is enabled.	R
b14	BCLR	CPU Buffer Clear	0: Does not operate. 1: Clears the buffer memory on the CPU side.	R/W*1
b15	BVAL	Buffer Memory Valid	0: Invalid 1: Writing ended	R/W

Note 1. Only 0 can be read.

Registers CFIFOCTR, D0FIFOCTR, and D1FIFOCTR correspond to CFIFO, D0FIFO, and D1FIFO, respectively.

DTLN[8:0] Flags (Receive Data Length Flag)

The DTLN[8:0] flags indicate the length of the receive data.
While the FIFO buffer is being read, the DTLN[8:0] flags indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1) value as described below.

- RCNT = 0
  The USB sets the DTLN[8:0] flags to indicate the length of the receive data until the CPU or DMAC/DTC has read all the received data from a single FIFO buffer plane.
  While the PIPECFG.BFRE bit = 1, these bits retain the length of the receive data until the BCLR bit is set to 1 even after all the data has been read.
- RCNT = 1
  The USB decrements the value indicated by the DTLN[8:0] flags each time data is read from the FIFO buffer. (The value is decremented by one when the MBW bit is 0, and by two when the MBW bit is 1.)
  The USB sets these bits to 0 when all the data has been read from one FIFO buffer plane. However, in double buffer mode, if data has been received in one FIFO buffer plane before all the data has been read from the other plane, the USB sets these bits to indicate the length of the receive data in the former plane when all the data has been read from the latter plane.

FRDY Flag (FIFO Port Ready Flag)

The FRDY flag indicates whether the FIFO port can be accessed by the CPU or DMAC/DTC.
In the following cases, the USB sets the FRDY flag to 1 but data cannot be read via the FIFO port because there is no data to be read. In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty.
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit = 1.

BCLR Bit (CPU Buffer Clear)

The BCLR bit should be set to 1 to clear the FIFO buffer on the CPU side for the selected pipe.
When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USB clears only the FIFO buffer on the CPU side even when both planes are read-enabled.
When the selected pipe is the DCP, setting the BCLR bit to 1 allows the USB to clear the FIFO buffer regardless of whether the FIFO buffer is on the CPU side or SIE side. To clear the buffer on the SIE side, set the DCPCTR.PID[1:0] bits for the DCP to 00b (NAK) before setting the BCLR bit to 1.
When the selected pipe is in the transmitting direction, if 1 is written to the BVAL bit and the BCLR bit simultaneously, the USB clears the data that has been written before it, enabling transmission of a zero-length packet.
When the selected pipe is not the DCP, writing 1 to the BCLR bit should be done while the FRDY flag in the FIFO port control register is 1 (set by the USB).

BVAL Bit (Buffer Memory Valid)

The BVAL bit should be set to 1 when data has been completely written to the FIFO buffer on the CPU side for the pipe selected using the CURPIPE[3:0] bits (selected pipe).
When the selected pipe is in the transmitting direction, set the BVAL bit to 1 in the following cases. Then, the USB switches the FIFO buffer from the CPU side to the SIE side, thus enabling transmission.

- To transmit a short packet, set the BVAL bit to 1 after data has been written.
- To transmit a zero-length packet, set the BVAL bit to 1 before data is written to the FIFO buffer.

When data of the maximum packet size has been written for the pipe in continuous transfer mode, the USB sets the BVAL bit to 1 and switches the FIFO buffer from the CPU side to the SIE side, thus enabling transmission.
Writing 1 to the BVAL bit should be done while the FRDY flag is 1 (set by the USB).
When the selected pipe is in the receiving direction, do not set the BVAL bit to 1.

40.2.7 Interrupt Enable Register 0 (INTENB0)

Address(es): USB0.INTENB0 8785 0030h, USB0_NS.INTENB0 0785 0030h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	BRDYE	Buffer Ready Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b9	NRDYE	Buffer Not Ready Response Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b10	BEMPE	Buffer Empty Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b11	CTRE	Control Transfer Stage Transition Interrupt Enable*1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b12	DVSE	Device State Transition Interrupt Enable *1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b13	SOFE	Frame Number Update Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b14	RSME	Resume Interrupt Enable*1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15	VBSE	VBUS Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W

Note 1. The RSME, DVSE, and CTRE bits can be set to 1 only when the function controller is selected. Set these bits to 0 when the host controller is selected.

On detecting the interrupt corresponding to the bit in the INTENB0 register to which 1 has been set by software, the USB generates the USB interrupt request.

The USB sets 1 to each status bit in the INTSTS0 register when a detection condition of the corresponding interrupt source has been satisfied regardless of the setting in the INTENB0 register (regardless of whether the interrupt output is enabled or disabled).

While the status bit in the INTSTS0 register corresponding to the interrupt source indicates 1, the USB generates the USB interrupt request when the corresponding interrupt enable bit in the INTENB0 register is modified from 0 to 1 by software.

40.2.8 Interrupt Enable Register 1 (INTENB1)

Address(es): USB0.INTENB1 8785 0032h, USB0_NS.INTENB1 0785 0032h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVRCRE	BCHGE	—	DTCHE	ATTCHE	—	—	—	—	EOFERRE	SIGNE	SACKE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	SACKE	Setup Transaction Normal Response Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b5	SIGNE	Setup Transaction Error Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b6	EOFERRE	EOF Error Detection Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b10 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11	ATTCHE	Connection Detection Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b12	DTCHE	Disconnection Detection Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b13	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b14	BCHGE	USB Bus Change Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15	OVRCRE	Overcurrent Input Change Interrupt Enable	0: Interrupt output disabled 1: Interrupt output enabled	R/W

Note: The bits in the INTENB1 register can be set to 1 only when the host controller is selected. Set these bits to 0 when the function controller is selected.

The INTENB1 register specifies the interrupt masks when the host controller is selected, and for the setup transaction. On detecting the interrupt corresponding to the bit in the INTENB1 register to which 1 has been set by software, the USB generates the USB interrupt request.

The USB sets 1 to each status bit in the INTSTS1 register when a detection condition of the corresponding interrupt source has been satisfied regardless of the setting in the INTENB1 register (regardless of whether the interrupt output is enabled or disabled).

While the status bit in the INTSTS1 register corresponding to the interrupt source indicates 1, the USB generates the USB interrupt request when the corresponding interrupt enable bit in the INTENB1 register is modified from 0 to 1 by software.

When the function controller is selected, the interrupts should not be enabled.

40.2.9 BRDY Interrupt Enable Register (BRDYENB)

Address(es): USB0.BRDYENB 8785 0036h, USB0_NS.BRDYENB 0785 0036h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPE9BRDYE	PIPE8BRDYE	PIPE7BRDYE	PIPE6BRDYE	PIPE5BRDYE	PIPE4BRDYE	PIPE3BRDYE	PIPE2BRDYE	PIPE1BRDYE	PIPE0BRDYE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0BRDYE	BRDY Interrupt Enable for Pipe 0	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b1	PIPE1BRDYE	BRDY Interrupt Enable for Pipe 1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b2	PIPE2BRDYE	BRDY Interrupt Enable for Pipe 2	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b3	PIPE3BRDYE	BRDY Interrupt Enable for Pipe 3	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b4	PIPE4BRDYE	BRDY Interrupt Enable for Pipe 4	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b5	PIPE5BRDYE	BRDY Interrupt Enable for Pipe 5	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b6	PIPE6BRDYE	BRDY Interrupt Enable for Pipe 6	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b7	PIPE7BRDYE	BRDY Interrupt Enable for Pipe 7	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b8	PIPE8BRDYE	BRDY Interrupt Enable for Pipe 8	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b9	PIPE9BRDYE	BRDY Interrupt Enable for Pipe 9	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The BRDYENB register enables or disables the INTSTS0.BRDY flag to be set to 1 when the BRDY interrupt is detected for each pipe.

On detecting the BRDY interrupt for the pipe corresponding to the bit in the BRDYENB register to which 1 has been set by software, the USB sets 1 to the corresponding BRDYSTS.PIPEnBRDY flag (n = 0 to 9) and the INTSTS0.BRDY flag. If INTENB0.BRDYE = 1 at this time, the USB generates the BRDY interrupt request.

While at least one PIPEnBRDY flag indicates 1, the USB generates the BRDY interrupt request when the corresponding interrupt enable bit in the BRDYENB register is modified from 0 to 1 by software.

40.2.10 NRDY Interrupt Enable Register (NRDYENB)

Address(es): USB0.NRDYENB 8785 0038h, USB0_NS.NRDYENB 0785 0038h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPE9NRDYE	PIPE8NRDYE	PIPE7NRDYE	PIPE6NRDYE	PIPE5NRDYE	PIPE4NRDYE	PIPE3NRDYE	PIPE2NRDYE	PIPE1NRDYE	PIPE0NRDYE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0NRDYE	NRDY Interrupt Enable for Pipe 0	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b1	PIPE1NRDYE	NRDY Interrupt Enable for Pipe 1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b2	PIPE2NRDYE	NRDY Interrupt Enable for Pipe 2	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b3	PIPE3NRDYE	NRDY Interrupt Enable for Pipe 3	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b4	PIPE4NRDYE	NRDY Interrupt Enable for Pipe 4	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b5	PIPE5NRDYE	NRDY Interrupt Enable for Pipe 5	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b6	PIPE6NRDYE	NRDY Interrupt Enable for Pipe 6	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b7	PIPE7NRDYE	NRDY Interrupt Enable for Pipe 7	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b8	PIPE8NRDYE	NRDY Interrupt Enable for Pipe 8	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b9	PIPE9NRDYE	NRDY Interrupt Enable for Pipe 9	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The NRDYENB register enables or disables the INTSTS0.NRDY flag to be set to 1 when the NRDY interrupt is detected for each pipe.

On detecting the NRDY interrupt for the pipe corresponding to the bit in the NRDYENB register to which 1 has been set by software, the USB sets 1 to the corresponding NRDYSTS.PIPEnNRDY flag (n = 0 to 9) and the INTSTS0.NRDY flag. If INTENB0.NRDYE = 1 at this time, the USB generates the NRDY interrupt request.

While at least one PIPEnNRDY flag indicates 1, the USB generates the NRDY interrupt request when the corresponding interrupt enable bit in the NRDYENB register is modified from 0 to 1 by software.

40.2.11 BEMP Interrupt Enable Register (BEMPENB)

Address(es): USB0.BEMPENB 8785 003Ah, USB0_NS.BEMPENB 0785 003Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPE9BEMPE	PIPE8BEMPE	PIPE7BEMPE	PIPE6BEMPE	PIPE5BEMPE	PIPE4BEMPE	PIPE3BEMPE	PIPE2BEMPE	PIPE1BEMPE	PIPE0BEMPE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0BEMPE	BEMP Interrupt Enable for Pipe 0	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b1	PIPE1BEMPE	BEMP Interrupt Enable for Pipe 1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b2	PIPE2BEMPE	BEMP Interrupt Enable for Pipe 2	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b3	PIPE3BEMPE	BEMP Interrupt Enable for Pipe 3	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b4	PIPE4BEMPE	BEMP Interrupt Enable for Pipe 4	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b5	PIPE5BEMPE	BEMP Interrupt Enable for Pipe 5	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b6	PIPE6BEMPE	BEMP Interrupt Enable for Pipe 6	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b7	PIPE7BEMPE	BEMP Interrupt Enable for Pipe 7	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b8	PIPE8BEMPE	BEMP Interrupt Enable for Pipe 8	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b9	PIPE9BEMPE	BEMP Interrupt Enable for Pipe 9	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The BEMPENB register enables or disables the INTSTS0.BEMP flag to be set to 1 when the BEMP interrupt is detected for each pipe.

On detecting the BEMP interrupt for the pipe corresponding to the bit in the BEMPENB register to which 1 has been set by software, the USB sets 1 to the corresponding BEMPSTS.PIPEnBEMP flag (n = 0 to 9) and the INTSTS0.BEMP flag. If INTENB0.BEMPE = 1 at this time, the USB generates the BEMP interrupt request.

While at least one PIPEnBEMP flag in the BEMPSTS register indicates 1, the USB generates the BEMP interrupt request when the corresponding interrupt enable bit in the BEMPENB register is modified from 0 to 1 by software.

40.2.12 SOF Output Configuration Register (SOFCFG)

Address(es): USB0.SOFCFG 8785 003Ch, USB0_NS.SOFCFG 0785 003Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TRNENSEL	—	BRDYM	—	EDGESTS	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	EDGESTS	Edge Interrupt Output Status Monitor Flag*1	Indicates 1 when the edge interrupt output signal is in the middle of the edge processing.	R
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	BRDYM	BRDY Interrupt Status Clear Timing	0: Software clears the status. 1: The USB clears the status when data has been read from the FIFO buffer or data has been written to the FIFO buffer.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b8	TRNENSEL	Transaction-Enabled Time Select*1	0: For non-low-speed communication 1: For low-speed communication	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Confirm that this bit is 0 before stopping the clock supply to the USB module.

EDGESTS Flag (Edge Interrupt Output Status Monitor Flag)

The EDGESTS flag indicates 1 when the edge interrupt output signal is in the middle of the edge processing.
Confirm that this flag is 0 before stopping the clock supply to the USB.

BRDYM Bit (BRDY Interrupt Status Clear Timing)

The BRDYM bit specifies the timing for clearing the BRDY interrupt status for each pipe.

TRNENSEL Bit (Transaction-Enabled Time Select)

The TRNENSEL bit selects, for full-speed or low-speed communication, the transaction-enabled time in which the USB issues tokens in a frame via the port.
Set the TRNENSEL bit to 1 when a low-speed device is connected.
The TRNENSEL bit is valid only when the host controller is selected.
This bit should be set to 0 if the function controller is selected.

40.2.13 Interrupt Status Register 0 (INTSTS0)

Address(es): USB0.INTSTS0 8785 0040h, USB0_NS.INTSTS0 0785 0040h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	VBINT	RESM	SOFR	DVST	CTRT	BEMP	NRDY	BRDY	VBSTS	DVSQ[2:0]			VALID	CTSQ[2:0]		
Value after reset:	0	0	0	0/1*1	0	0	0	0	0*2	0*3	0*3	0/1*3	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CTSQ[2:0]	Control Transfer Stage Flag	b2 b0 0 0 0: Idle or setup stage 0 0 1: Control read data stage 0 1 0: Control read status stage 0 1 1: Control write data stage 1 0 0: Control write status stage 1 0 1: Control write (no data) status stage 1 1 0: Control transfer sequence error	R
b3	VALID	USB Request Reception Flag	0: Setup packet is not received. 1: Setup packet is received.	R/W
b6 to b4	DVSQ[2:0]	Device State Flag	b6 b4 0 0 0: Powered state 0 0 1: Default state 0 1 0: Address state 0 1 1: Configured state 1 x x: Suspended state	R
b7	VBSTS	VBUS Input Status Flag	0: USB0_VBUS pin is low. 1: USB0_VBUS pin is high.	R
b8	BRDY	Buffer Ready Interrupt Status Flag	0: BRDY interrupts are not generated. 1: BRDY interrupts are generated.	R
b9	NRDY	Buffer Not Ready Interrupt Status Flag	0: NRDY interrupts are not generated. 1: NRDY interrupts are generated.	R
b10	BEMP	Buffer Empty Interrupt Status Flag	0: BEMP interrupts are not generated. 1: BEMP interrupts are generated.	R
b11	CTRT	Control Transfer Stage Transition Interrupt Status Flag*5	0: Control transfer stage transition interrupts are not generated. 1: Control transfer stage transition interrupts are generated.	R/W*4
b12	DVST	Device State Transition Interrupt Status Flag*5	0: Device state transition interrupts are not generated. 1: Device state transition interrupts are generated.	R/W*4
b13	SOFR	Frame Number Refresh Interrupt Status Flag	0: SOF interrupts are not generated. 1: SOF interrupts are generated.	R/W*4
b14	RESM	Resume Interrupt Status Flag *5,*6	0: Resume interrupts are not generated. 1: Resume interrupts are generated.	R/W*4
b15	VBINT	VBUS Interrupt Status Flag*6	0: VBUS interrupts are not generated. 1: VBUS interrupts are generated.	R/W*4

x: Don't care

Note 1. The value is 0 when the MCU is reset and 1 after a USB bus reset.
Note 2. The value is 1 when the USB0_VBUS pin is high and 0 when the USB0_VBUS pin is low.
Note 3. The value is 000b when the MCU is reset and 001b after a USB bus reset.
Note 4. To clear the VBINT, RESM, SOFR, DVST, CTRT, or VALID flag, write 0 only to the flags to be cleared; write 1 to the other flags. Do not write 0 to the status flags indicating 0.
Note 5. The status of the RESM, DVST, and CTRT flags are changed only when the function controller is selected. Set the corresponding interrupt enable bits to 0 (disabled) when the host controller is selected.
Note 6. A change in the status indicated by the VBINT and RESM flags can be detected even while the clock supply is stopped (the SCKE bit = 0), and the interrupts are output when the corresponding interrupt enable bits are enabled. Clearing the status through software should be done after enabling the clock supply.

CTSQ[2:0] Flags (Control Transfer Stage Flag)

When the host controller is selected, the read value is invalid.

VALID Flag (USB Request Reception Flag)

When the host controller is selected, the read value is invalid.

DVSQ[2:0] Flags (Device State Flag)

The DVSQ[2:0] flags are initialized by a USB bus reset.
When the host controller is selected, the read value is invalid.

BRDY Flag (Buffer Ready Interrupt Status Flag)

Indicates the BRDY interrupt status.
The USB sets the BRDY flag to 1 when at least one PIPEnBRDY flag (n = 0 to 9) is set to 1 among the PIPEnBRDY flags. These bits correspond to the BRDYENB.PIPEnBRDYE bits (n = 0 to 9) to which 1 has been set, when the USB detects the BRDY interrupt status in at least one pipe among the pipes for which the BRDY interrupt output is enabled by software.
For the conditions for PIPEnBRDY status assertion, refer to section 40.3.3.1, BRDY Interrupt.
The USB sets the BRDY flag to 0 when 0 is written by software to all the PIPEnBRDY flags corresponding to the PIPEnBRDYE bits that have been set to 1.
The BRDY flag cannot be set to 0 even if 0 is written to this bit by software.

NRDY Flag (Buffer Not Ready Interrupt Status Flag)

The USB sets the NRDY flag to 1 when at least one PIPEnNRDY flag (n = 0 to 9) is set to 1 among the PIPEnNRDY flags corresponding to the PIPEnNRDYE bits (n = 0 to 9) to which 1 has been set (when the USB detects the NRDY interrupt status in at least one pipe among the pipes for which software enables the NRDY interrupt output).
For the conditions for PIPEnNRDY status assertion, refer to section 40.3.3.2, NRDY Interrupt.
The USB sets the NRDY flag to 0 when 0 is written by software to all the PIPEnNRDY flags corresponding to the PIPEnNRDYE bits that have been set to 1.
The NRDY flag cannot be set to 0 even if 0 is written to this bit by software.

BEMP Flag (Buffer Empty Interrupt Status Flag)

The USB sets the BEMP flag to 1 when at least one PIPEnBEMP flag (n = 0 to 9) is set to 1 among the PIPEnBEMP flags corresponding to the PIPEnBEMPE bits (n = 0 to 9) to which 1 has been set (when the USB detects the BEMP interrupt status in at least one pipe among the pipes for which the BEMP interrupt output is enabled by software).
For the conditions for PIPEnBEMP status assertion, refer to section 40.3.3.3, BEMP Interrupt.
The USB sets the BEMP flag to 0 when 0 is written by software to all the PIPEnBEMP flags corresponding to the PIPEnBEMPE bits that have been set to 1.
The BEMP flag cannot be set to 0 even if 0 is written to this bit by software.

CTRT Flag (Control Transfer Stage Transition Interrupt Status Flag)

When the function controller is selected, the USB updates the value of the CTSQ[2:0] flags and sets the CTRT flag to 1 on detecting a change in the control transfer stage.
When a control transfer stage transition interrupt is generated, clear the status before the USB detects the next control transfer stage transition.
When the host controller is selected, the read value is invalid.

DVST Flag (Device State Transition Interrupt Status Flag)

When the function controller is selected, the USB updates the DVSQ[2:0] value and sets the DVST flag to 1 on detecting a change in the device state.
When a device state transition interrupt is generated, clear the status before the USB detects the next device state transition.
When the host controller is selected, the read value is invalid.

SOFR Flag (Frame Number Refresh Interrupt Status Flag)

(1) When the host controller is selected
The USB sets the SOFR flag to 1 on updating the frame number when the DVSTCTR0.UACT bit has been set to 1 by software. (A frame number refresh interrupt is detected every 1 ms.)
(2) When the function controller is selected
The USB sets the SOFR flag to 1 on updating the frame number. (A frame number refresh interrupt is detected every 1 ms.)
The USB can detect an SOFR interrupt through the internal interpolation function even when a damaged SOF packet is received from the USB host.

RESM Flag (Resume Interrupt Status Flag)

When the function controller is selected, the USB sets the RESM flag to 1 on detecting the falling edge of the signal on the USB0_DP pin in the suspended state (DVSQ[2:0] = 1xxb).
When the host controller is selected, the read value is invalid.

VBINT Flag (VBUS Interrupt Status Flag)

The USB sets the VBINT flag to 1 on detecting a level change (high to low or low to high) in the USB0_VBUS pin input value. The USB sets the VBSTS flag to indicate the USB0_VBUS pin input value. When the VBUS interrupt is generated, use software to repeat reading the VBSTS flag until the same value is read three or more times, and eliminate chattering.

40.2.14 Interrupt Status Register 1 (INTSTS1)

Address(es): USB0.INTSTS1 8785 0042h, USB0_NS.INTSTS1 0785 0042h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVRCR	BCHG	—	DTCH	ATTCH	—	—	—	—	EOFERR	SIGN	SACK	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	SACK	Setup Transaction Normal Response Interrupt Status Flag	0: SACK interrupts are not generated. 1: SACK interrupts are generated.	R/W *1
b5	SIGN	Setup Transaction Error Interrupt Status Flag	0: SIGN interrupts are not generated. 1: SIGN interrupts are generated.	R/W *1
b6	EOFERR	EOF Error Detection Interrupt Status Flag	0: EOFERR interrupts are not generated. 1: EOFERR interrupts are generated.	R/W *1
b10 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11	ATTCH	ATTCH Interrupt Status Flag	0: ATTCH interrupts are not generated. 1: ATTCH interrupts are generated.	R/W *1
b12	DTCH	USB Disconnection Detection Interrupt Status Flag	0: DTCH interrupts are not generated. 1: DTCH interrupts are generated.	R/W *1
b13	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b14	BCHG	USB Bus Change Interrupt Status Flag *2	0: BCHG interrupts are not generated. 1: BCHG interrupts are generated.	R/W *1
b15	OVRCR	Overcurrent Input Change Interrupt Status Flag*2	0: OVRCR interrupts are not generated. 1: OVRCR interrupts are generated.	R/W *1

Note 1. To clear the status indicated by the flags in the INTSTS1 register, write 0 only to the flags to be cleared; write 1 to the other flags.

Note 2. A change in the status indicated by the OVRCR or BCHG flag can be detected even while the clock supply is stopped (while the SYSCFG.SCKE bit = 0), and the interrupt is output when the corresponding interrupt enable bit is enabled. Clearing the status through software should be done after setting the SYSCFG.SCKE bit to 1.
No interrupts other than those indicated by the BCHG and OVRCR flags can be detected while the clock supply is stopped (while the SYSCFG.SCKE bit = 0).

The INTSTS1 register is used to confirm the status of each interrupt when the host controller is selected.
The various status change interrupts indicated by the flags in the INTSTS1 register should be enabled only when the host controller is selected.

SACK Flag (Setup Transaction Normal Response Interrupt Status Flag)

Indicates the status of the setup transaction normal response interrupt when the host controller is selected.
The USB detects the SACK interrupt when ACK response is returned from the peripheral device during the setup transactions issued by the USB, and sets the SACK flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the SACK interrupt.
When the function controller is selected, the read value is invalid.

SIGN Flag (Setup Transaction Error Interrupt Status Flag)

Indicates the status of the setup transaction error interrupt when the host controller is selected.
The USB detects the SIGN interrupt when ACK response is not returned from the peripheral device three consecutive times during the setup transactions issued by this module, and sets the SIGN flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the SIGN interrupt.
Specifically, the USB detects the SIGN interrupt when any of the following response conditions occur for three consecutive setup transactions.

- Timeout is detected by the USB when the peripheral device has returned no response.
- A damaged ACK packet is received.
- A handshake other than ACK (NAK, NYET, or STALL) is received.

When the function controller is selected, the read value is invalid.

EOFERR Flag (EOF Error Detection Interrupt Status Flag)

Indicates the status of the EOFERR interrupt when the host controller is selected.
The USB detects the EOFERR interrupt on detecting that communication is not completed at the EOF2 timing prescribed by USB Specification 2.0, and sets the EOFERR flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the EOFERR interrupt.
After detecting the EOFERR interrupt, the USB controls hardware as described below (irrespective of the setting of the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the USB port should be terminated by software and perform re-enumeration of the USB port.

- Modifies the DVSTCTR0.UACT bit for the port in which an EOFERR interrupt has been detected to 0.
- Puts the port in which an EOFERR interrupt has been generated into the idle state.

When the function controller is selected, the read value is invalid.

ATTCH Flag (ATTCH Interrupt Status Flag)

Indicates the status of the ATTCH interrupt when the host controller is selected.
The USB detects the ATTCH interrupt on detecting J-state or K-state of the full-speed or low-speed signal level for 2.5 µs, and sets the ATTCH flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.
Specifically, the USB detects the ATTCH interrupt on any of the following conditions.

- K-state, SE0, or SE1 changes to J-state, and J-state continues for 2.5 µs.
- J-state, SE0, or SE1 changes to K-state, and K-state continues for 2.5 µs.

When the function controller is selected, the read value is invalid.

DTCH Flag (USB Disconnection Detection Interrupt Status Flag)

Indicates the status of the USB disconnection detection interrupt when the host controller is selected.
The USB detects the DTCH interrupt on detecting USB bus disconnection, and sets the DTCH flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.
The USB detects bus disconnection based on USB Specification 2.0.
After detecting the DTCH interrupt, the USB controls hardware as described below (irrespective of the setting of the corresponding interrupt enable bit). All the pipes in which communications are currently carried out for the USB port should be terminated by software and make a transition to the wait state for bus connection to the USB port (wait state for ATTCH interrupt generation).

- Modifies the DVSTCTR0.UACT bit for the port in which a DTCH interrupt has been detected to 0.
- Puts the port in which a DTCH interrupt has been generated into the idle state.

When the function controller is selected, the read value is invalid.

BCHG Flag (USB Bus Change Interrupt Status Flag)

Indicates the status of the USB bus change interrupt.
The USB detects the BCHG interrupt when a change in the full-speed or low-speed signal level occurs on the USB port (a change from J-state, K-state, or SE0 to J-state, K-state, or SE0), and sets the BCHG flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.
The USB sets the LNST[1:0] flags to indicate the current input state of the USB port. When the BCHG interrupt is generated, use software to repeat reading the LNST[1:0] flags until the same value is read three or more times, and eliminate chattering.
A change in the USB bus state can be detected even while the internal clock supply is stopped.
When the function controller is selected, the read value is invalid.

OVRCR Flag (Overcurrent Input Change Interrupt Status Flag)

Indicates the status of the USB0_OVRCURA and USB0_OVRCURB input pin change interrupt.
The USB detects the OVRCR interrupt when a change (high to low or low to high) occurs in at least one of the input values to the USB0_OVRCURA and USB0_OVRCURB pins, and sets the OVRCR flag to 1. Here, if the corresponding interrupt enable bit has been set to 1 by software, the USB generates the interrupt.

40.2.15 BRDY Interrupt Status Register (BRDYSTS)

Address(es): USB0.BRDYSTS 8785 0046h, USB0_NS.BRDYSTS 0785 0046h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPE9BRDY	PIPE8BRDY	PIPE7BRDY	PIPE6BRDY	PIPE5BRDY	PIPE4BRDY	PIPE3BRDY	PIPE2BRDY	PIPE1BRDY	PIPE0BRDY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0BRDY	BRDY Interrupt Status Flag for Pipe 0*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b1	PIPE1BRDY	BRDY Interrupt Status Flag for Pipe 1*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b2	PIPE2BRDY	BRDY Interrupt Status Flag for Pipe 2*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b3	PIPE3BRDY	BRDY Interrupt Status Flag for Pipe 3*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b4	PIPE4BRDY	BRDY Interrupt Status Flag for Pipe 4*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b5	PIPE5BRDY	BRDY Interrupt Status Flag for Pipe 5*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b6	PIPE6BRDY	BRDY Interrupt Status Flag for Pipe 6*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b7	PIPE7BRDY	BRDY Interrupt Status Flag for Pipe 7*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b8	PIPE8BRDY	BRDY Interrupt Status Flag for Pipe 8*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b9	PIPE9BRDY	BRDY Interrupt Status Flag for Pipe 9*2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. When the SOFCFG.BRDYM bit is set to 0, to clear the status indicated by the flags in the BRDYSTS register, write 0 only to the flags to be cleared; write 1 to the other flags.

Note 2. When the SOFCFG.BRDYM bit is set to 0, clearing BRDY Interrupts should be done before accessing the FIFO.

40.2.16 NRDY Interrupt Status Register (NRDYSTS)

Address(es): USB0.NRDYSTS 8785 0048h, USB0_NS.NRDYSTS 0785 0048h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0NRDY	NRDY Interrupt Status Flag for Pipe 0	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b1	PIPE1NRDY	NRDY Interrupt Status Flag for Pipe 1	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b2	PIPE2NRDY	NRDY Interrupt Status Flag for Pipe 2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b3	PIPE3NRDY	NRDY Interrupt Status Flag for Pipe 3	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b4	PIPE4NRDY	NRDY Interrupt Status Flag for Pipe 4	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b5	PIPE5NRDY	NRDY Interrupt Status Flag for Pipe 5	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b6	PIPE6NRDY	NRDY Interrupt Status Flag for Pipe 6	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b7	PIPE7NRDY	NRDY Interrupt Status Flag for Pipe 7	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b8	PIPE8NRDY	NRDY Interrupt Status Flag for Pipe 8	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b9	PIPE9NRDY	NRDY Interrupt Status Flag for Pipe 9	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. To clear the status indicated by the flags in the NRDYSTS register, write 0 only to the flags to be cleared; write 1 to the other flags.

40.2.17 BEMP Interrupt Status Register (BEMPSTS)

Address(es): USB0.BEMPSTS 8785 004Ah, USB0_NS.BEMPSTS 0785 004Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPE9BEMP	PIPE8BEMP	PIPE7BEMP	PIPE6BEMP	PIPE5BEMP	PIPE4BEMP	PIPE3BEMP	PIPE2BEMP	PIPE1BEMP	PIPE0BEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIPE0BEMP	BEMP Interrupt Status Flag for Pipe 0	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b1	PIPE1BEMP	BEMP Interrupt Status Flag for Pipe 1	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b2	PIPE2BEMP	BEMP Interrupt Status Flag for Pipe 2	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b3	PIPE3BEMP	BEMP Interrupt Status Flag for Pipe 3	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b4	PIPE4BEMP	BEMP Interrupt Status Flag for Pipe 4	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b5	PIPE5BEMP	BEMP Interrupt Status Flag for Pipe 5	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b6	PIPE6BEMP	BEMP Interrupt Status Flag for Pipe 6	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b7	PIPE7BEMP	BEMP Interrupt Status Flag for Pipe 7	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b8	PIPE8BEMP	BEMP Interrupt Status Flag for Pipe 8	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b9	PIPE9BEMP	BEMP Interrupt Status Flag for Pipe 9	0: Interrupts are not generated. 1: Interrupts are generated.	R/W *1
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. To clear the status indicated by the flags in the BEMPSTS register, write 0 only to the flags to be cleared; write 1 to the other flags.

40.2.18 Frame Number Register (FRMNUM)

Address(es): USB0.FRMNUM 8785 004Ch, USB0_NS.FRMNUM 0785 004Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVRN	CRCE	—	—	—	FRNM[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	FRNM[10:0]	Frame Number Flag	Latest frame number	R
b13 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	CRCE	Receive Data Error Flag	0: No error 1: An error occurred	R/W*1
b15	OVRN	Overrun/Underrun Detection Status Flag	0: No error 1: An error occurred	R/W*1

Note 1. To clear the status, write 0 only to the bits to be cleared; write 1 to the other bits.

FRNM[10:0] Flags (Frame Number Flag)

These bits indicate the latest frame number for the USB after the issuing of an SOF packet every 1 ms or writing to the FRNM[10:0] flags at the SOF packet reception.

CRCE Flag (Receive Data Error Flag)

Indicates whether a CRC error or bit stuffing error has been detected in the pipe during isochronous transfer.
The CRCE flag can be set to 0 by writing 0 to the CRCE flag by software. Here, 1 should be written to the other bits in FRMNUM.
On detecting a CRC error, the USB generates the internal NRDY interrupt request.

OVRN Flag (Overrun/Underrun Detection Status Flag)

Indicates whether an overrun/underrun error has been detected in the pipe during isochronous transfer.
The OVRN flag can be set to 0 by writing 0 to the OVRN flag by software. Here, 1 should be written to the other bits in FRMNUM.

(1) When the host controller is selected

The USB sets the OVRN flag to 1 on any of the following conditions.

- For the isochronous transfer pipe in the transmitting direction, the time to issue an OUT token comes before all the transmit data has been written to the FIFO buffer.
- For the isochronous transfer pipe in the receiving direction, the time to issue an IN token comes when no FIFO buffer planes are empty.

(2) When the function controller is selected

The USB sets the OVRN flag to 1 on any of the following conditions.

- For the isochronous transfer pipe in the transmitting direction, the IN token is received before all the transmit data has been written to the FIFO buffer.
- For the isochronous transfer pipe in the receiving direction, the OUT token is received when no FIFO buffer planes are empty.

40.2.19 Device State Change Register (DVCHGR)

Address(es): USB0.DVCHGR 8785 004Eh, USB0_NS.DVCHGR 0785 004Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DVCHG	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b14 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	DVCHG	Device State Change	0: Disables the writing to the USBADDR.STSRECOV[3:0] bits and USBADDR.USBADDR[6:0] bits. 1: Enables the writing to the USBADDR.STSRECOV[3:0] bits and USBADDR.USBADDR[6:0] bits.	R/W

For details, refer to section 40.3.1.5, Release from Deep Software Standby Mode 1 Due to USB Suspend/ Resume Interrupts.

40.2.20 USB Address Register (USBADDR)

Address(es): USB0.USBADDR 8785 0050h, USB0_NS.USBADDR 0785 0050h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	STSRECOV[3:0]				—	USBADDR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	USBADDR[6:0]	USB Address	When the function controller is selected, these bits indicate the USB address assigned by the host when the SET_ADDRESS request is successfully processed.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b11 to b8	STSRECOV[3:0]	Status Recovery	• Recovery when the function controller is selected b11 b8 1 0 0 1: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b), bits INTSTS0.DVSQ[2:0] = 001b (Default state) 1 0 1 0: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b), bits INTSTS0.DVSQ[2:0] = 010b (Address state) 1 0 1 1: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b), bits INTSTS0.DVSQ[2:0] = 011b (Configured state) Settings other than above are prohibited. • Recovery when the host controller is selected b11 b8 1 0 0 0: Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b) Settings other than above are prohibited.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

USBADDR[6:0] Bits (USB Address)

On detecting the USB bus reset, the USB sets the USBADDR[6:0] bits to 00h.

The writing to these bits is enabled while the DVCHGR.DVCHG bits are set to 1. On returning from the USB power shut-off, the operation can resume to the USB address before the shut-off by the software.

When the host controller is selected, the USBADDR[6:0] bits are invalid.

The USBADDR[6:0] bits are initialized when a USB bus reset is detected.

STSRECOV[3:0] Bits (Status Recovery)

These bits are used to resume the state of the internal sequencer on returning from the USB power shut-off. For details, refer to section 40.3.1.5, Release from Deep Software Standby Mode 1 Due to USB Suspend/Resume Interrupts.

The writing to the STSRECOV[3:0] bits is enabled while the DVCHGR.DVCHG bit is set to 1.

40.2.21 USB Request Type Register (USBREQ)

Address(es): USB0.USBREQ 8785 0054h, USB0_NS.USBREQ 0785 0054h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BREQUEST[7:0]								BMREQUESTTYPE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	BMREQUESTTYPE[7:0]	Request Type	These bits store the USB request bmRequestType value.	R/W *1
b15 to b8	BREQUEST[7:0]	Request	These bits store the USB request bRequest value.	R/W *1

Note 1. When the function controller is selected, these bits can only be read from, and writing to these bits is invalid. When the host controller is selected, these bits can be read from and written to.

The USBREQ register stores setup requests for control transfers.
When the function controller is selected, the values of bRequest and bmRequestType that have been received are stored.
When the host controller is selected, the values of bRequest and bmRequestType to be transmitted are set.
The USBREQ register is initialized by a USB bus reset.

BMREQUESTTYPE[7:0] Bits (Request Type)

These bits hold the value of the bmRequestType field of a USB request.

- When the host controller is selected:
  Set these bits to the value of the USB request data in setup transactions for transmission. Do not modify the value of the BMREQUESTTYPE[7:0] bits while the DCPCTR.SUREQ bit is 1.
- When the function controller is selected:
  These bits indicate the value of the USB request data in setup transactions for reception. Writing to the bits has no effect.

BREQUEST[7:0] Bits (Request)

These bits store bRequest value of the USB request.

- When the host controller is selected:
  Set these bits to the value of the USB request data in setup transactions for transmission. Do not modify the value of the BREQUEST[7:0] bits while the DCPCTR.SUREQ bit is 1.
- When the function controller is selected:
  These bits indicate the value of the USB request data in setup transactions for reception. Writing to the bits has no effect.

40.2.22 USB Request Value Register (USBVAL)

Address(es): USB0.USBVAL 8785 0056h, USB0_NS.USBVAL 0785 0056h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

When the function controller is selected, the value of wValue that has been received is stored in the USBVAL register.
When the host controller is selected, the value of wValue to be transmitted is set.
The USBVAL register is initialized by a USB bus reset.

- When the host controller is selected:
  Set these bits to the value of the wValue field in USB requests of setup transactions for transmission. Do not modify the value of the USBVAL register while the DCPCTR.SUREQ bit is 1.
- When the function controller is selected:
  These bits indicate the value of the wValue field in USB requests received in setup transactions for reception. Writing to the USBVAL register has no effect.

40.2.23 USB Request Index Register (USBINDX)

Address(es): USB0.USBINDX 8785 0058h, USB0_NS.USBINDX 0785 0058h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The USBINDX register stores setup requests for control transfers.
When the function controller is selected, the value of wIndex that has been received is stored. When the host controller is selected, the value of wIndex to be transmitted is set.
The USBINDX register is initialized by a USB bus reset.

- When the host controller is selected:
  Set these bits to the value of the wIndex field in USB requests of setup transactions for transmission. Do not modify the value of the USBINDX register while the DCPCTR.SUREQ bit is 1.
- When the function controller is selected:
  These bits indicate the value of the wIndex field in USB requests received in setup transactions for reception. Writing to the USBINDX register has no effect.

40.2.24 USB Request Length Register (USBLENG)

Address(es): USB0.USBLENG 8785 005Ah, USB0_NS.USBLENG 0785 005Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The USBLENG register stores setup requests for control transfers.
When the function controller is selected, the value of wLength that has been received is stored. When the host controller is selected, the value of wLength to be transmitted is set.
The USBLENG register is initialized by a USB bus reset.

- When the host controller is selected:
  Set these bits to the value of the wLength field in USB requests of setup transactions for transmission. Do not modify the value of the USBLENG register while the DCPCTR.SUREQ bit is 1.
- When the function controller is selected:
  These bits indicate the value of the wLength field in USB requests received in setup transactions for reception. Writing to the USBLENG register has no effect.

40.2.25 DCP Configuration Register (DCPCFG)

Address(es): USB0.DCPCFG 8785 005Ch, USB0_NS.DCPCFG 0785 005Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	SHTNAK	—	—	DIR	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	DIR	Transfer Direction*1	0: Data receiving direction 1: Data transmitting direction	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	SHTNAK	Pipe Disabled at End of Transfer*1	0: Pipe continued at the end of transfer 1: Pipe disabled at the end of transfer	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Modify this bit while DCPCTR.PID[1:0] bits are 00b (NAK). Before modifying this bit after modifying the DCPCTR.PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the DCPCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

DIR Bit (Transfer Direction)

When the host controller is selected, the DIR bit sets the transfer direction of the data stage and status stage.
When the function controller is selected, the DIR bit should be set to 0.

SHTNAK Bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to modify PID[1:0] bits to 00b (NAK) upon the end of transfer when the selected pipe is in the receiving direction.
The SHTNAK bit is valid when the selected pipe in the receiving direction.
When the SHTNAK bit is set to 1, the USB modifies the DCPCTR.PID[1:0] bits for the DCP to 00b (NAK) on determining the end of the transfer. The USB determines that the transfer has ended on the following condition.

- A short packet (including a zero-length packet) is successfully received.

40.2.26 DCP Maximum Packet Size Register (DCPMAXP)

Address(es): USB0.DCPMAXP 8785 005Eh, USB0_NS.DCPMAXP 0785 005Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DEVSEL[3:0]				—	—	—	—	—	MXPS[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	MXPS[6:0]	Maximum Packet Size*1	These bits set the maximum amount of data (maximum packet size) in payloads for the DCP.	R/W
b11 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b12	DEVSEL[3:0]	Device Select*2	b15 b12 0 0 0 0: Address 0000 0 0 0 1: Address 0001 0 0 1 0: Address 0010 0 0 1 1: Address 0011 0 1 0 0: Address 0100 0 1 0 1: Address 0101 Settings other than above are prohibited.	R/W

Note 1. Modify the MXPS[6:0] bits while PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the DCPCTR.PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the DCPCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software. After modifying the MXPS[6:0] bits and the DCP has been set to the CURPIPE[3:0] bits in a port select register, clear the buffer by setting the BCLR bit the port control register to 1.

Note 2. Modify the DEVSEL[3:0] bits while PID[1:0] bits are 00b (NAK) and the DCPCTR.SUREQ bit is 0. To modify these bits after modifying the DCPCTR.PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the DCPCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

MXPS[6:0] Bits (Maximum Packet Size)

The MXPS[6:0] bits specify the maximum amount of data (maximum packet size) in payloads for the DCP. The initial value of the bits is 40h (64 bytes).

Ensure that the setting of the MXPS[6:0] bits is in compliance with USB Specification 2.0.

Do not write to the FIFO buffer or set PID[1:0] = 01b (BUF) while the setting of the MXPS[6:0] bits is 0.

DEVSEL[3:0] Bits (Device Select)

When the host controller is selected, these bits specify the address of the peripheral device which is the communication target during control transfer.

The DEVSEL[3:0] bits should be set after setting the address to the DEVADDn (n = 0 to 5) register corresponding to the value to be set in the DEVSEL[3:0] bits. For example, before setting the DEVSEL[3:0] bits to 0010b, the address should be set to DEVADD2.

When the function controller is selected, the DEVSEL[3:0] bits should be set to 0000b.

40.2.27 DCP Control Register (DCPCTR)

Address(es): USB0.DCPCTR 8785 0060h, USB0_NS.DCPCTR 0785 0060h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BSTS	SUREQ	—	—	SUREQ CLR	—	—	SQCLR	SQSET	SQMON	PBUSY	—	—	CCPL	PID[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PID[1:0]	Response PID	b1 b0 0 0: NAK response 0 1: BUF response (depending on the buffer state) 1 0: STALL response 1 1: STALL response	R/W
b2	CCPL	Control Transfer End Enable	0: Invalid 1: Completion of control transfer is enabled.	R/W
b4, b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	PBUSY	Pipe Busy Flag	0: DCP is not used for the transaction. 1: DCP is used for the transaction.	R
b6	SQMON	Sequence Toggle Bit Monitor Flag	0: DATA0 1: DATA1	R
b7	SQSET	Sequence Toggle Bit Set*2	0: Invalid 1: Specifies DATA1.	R/W*1
b8	SQCLR	Sequence Toggle Bit Clear*2	0: Invalid 1: Specifies DATA0.	R/W*1
b10, b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11	SUREQCLR	SUREQ Bit Clear	0: Invalid 1: Clears the SUREQ bit to 0.	R/W
b13, b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	SUREQ	Setup Token Transmission	0: Invalid 1: Transmits the setup packet.	R/W
b15	BSTS	Buffer Status Flag	0: Buffer access is disabled. 1: Buffer access is enabled.	R

Note 1. Only 0 can be read.
Note 2. Write 1 to the SQSET and SQCLR bits while PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PID[1:0] bits for the DCP from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

PID[1:0] Bits (Response PID)

The PID[1:0] bits control the response type of the USB during control transfer.

(1) When the host controller is selected

Modify the setting of the PID[1:0] bits from 00b (NAK) to 01b (BUF) using the following procedure.

- When the transmitting direction is set
  Write all the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and PID[1:0] bits are 00b (NAK), and then write 01b (BUF response). After PID[1:0] have been set to 01b (BUF), the USB executes the OUT transaction.
- When the receiving direction is set
  Check that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and PID[1:0] bits are 00b (NAK), and then set PID[1:0] bits to 01b (BUF). After PID[1:0] bits have been set to 01b (BUF), the USB executes the IN transaction.

The USB modifies the setting of the PID[1:0] bits as follows.

- The USB sets PID[1:0] bits to 11b (STALL) on receiving the data of a size exceeding the maximum packet size when the PID[1:0] bits has been set to 01b (BUF) by software.
- The USB sets PID[1:0] bits to 00b (NAK) on detecting a receive error, such as a CRC error, three consecutive times.
- The USB also sets PID[1:0] bits to 11b (STALL) on receiving the STALL handshake.

(2) When the function controller is selected

The USB modifies the setting of the PID[1:0] bits as follows.

- The USB modifies the PID[1:0] bits to 00b (NAK) on receiving the setup packet. Here, the USB sets the INTSTS0.VALID flag to 1. The setting of the PID[1:0] bits cannot be modified until the VALID flag is set to 0 by software.
- The USB sets PID[1:0] bits to 11b (STALL) on receiving the data of a size exceeding the maximum packet size when the PID[1:0] bits have been set to 01b (BUF) by software.
- The USB sets PID[1:0] bits to 1xb (STALL) on detecting the control transfer sequence error.
- The USB sets PID[1:0] bits to 00b (NAK) on detecting the USB bus reset.

The USB does not check the setting of the PID[1:0] bits while the SET_ADDRESS request is processed.
The PID[1:0] bits are initialized by a USB bus reset.

CCPL Bit (Control Transfer End Enable)

When the function controller is selected, setting the CCPL bit to 1 enables the status stage of the control transfer to be completed.
When the CCPL bit is set to 1 by software while the corresponding PID[1:0] bits are set to 01b (BUF), the USB completes the control transfer status stage.
During control read transfer, the USB transmits the ACK handshake in response to the OUT transaction from the USB host, and transmits the zero-length packet in response to the IN transaction from the USB host during control write or no-data control transfer. However, on detecting the SET_ADDRESS request, the USB operates in auto response mode from the setup stage up to the status stage completion irrespective of the setting of the CCPL bit.
The USB modifies the CCPL bit from 1 to 0 on receiving a new setup packet.
1 cannot be written to the CCPL bit by software while the INTSTS0.VALID flag is 1.
The CCPL bit is initialized by a USB bus reset.
When the host controller is selected, be sure to write 0 to the CCPL bit.

PBUSY Flag (Pipe Busy Flag)

The PBUSY flag indicates whether DCP is used or not for the transaction when USB changes the PID[1:0] bits from 01b (BUF) to 00b (NAK).
The USB modifies the PBUSY flag from 0 to 1 upon start of the USB transaction for the relevant pipe, and modifies the PBUSY flag from 1 to 0 upon completion of one transaction.
Reading the PBUSY flag after the PID[1:0] bits have been set to 00b (NAK) by software allows checking whether modification of the pipe settings is possible.
For details, refer to section 40.3.4.1, Pipe Control Register Switching Procedures.

SQMON Flag (Sequence Toggle Bit Monitor Flag)

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction during the DCP transfer.
The USB allows the SQMON flag to toggle upon normal completion of the transaction. However, the SQMON flag is not allowed to toggle when a data PID mismatch occurs during the transfer in the receiving direction.
When the function controller is selected, the USB sets the SQMON flag to 1 (specifies DATA1 as the expected value) upon successful reception of the setup packet.
When the function controller is selected, the USB does not reference the SQMON flag during the IN/OUT transaction of the status stage, and does not allow the SQMON flag to toggle upon normal completion.

SQSET Bit (Sequence Toggle Bit Set)

The SQSET bit specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during the DCP transfer.
Do not set the SQCLR and SQSET bits to 1 simultaneously.

SQCLR Bit (Sequence Toggle Bit Clear)

The SQCLR bit specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during the DCP transfer. The SQCLR bit indicates 0.
Do not set the SQCLR and SQSET bits to 1 simultaneously.

SUREQCLR Bit (SUREQ Bit Clear)

When the host controller is selected, setting the SUREQCLR bit to 1 clears the SUREQ bit to 0. The SUREQCLR bit indicates 0.
Set the SUREQCLR bit to 1 through software when communication has stopped with the SUREQ bit being 1 during the setup transaction. However, for normal setup transactions, the USB automatically clears the SUREQ bit to 0 upon completion of the transaction; therefore, clearing the SUREQ bit through software is not necessary.
Controlling the SUREQ bit through the SUREQCLR bit must be done while the DVSTCTR0.UACT bit is 0 and thus communication is halted or while no transfer is being performed with bus disconnection detected.
When the function controller is selected, be sure to write 0 to the SUREQCLR bit.

SUREQ Bit (Setup Token Transmission)

The USB transmits the setup packet by setting the SUREQ bit to 1 when the host controller is selected.
After completing the setup transaction process, the USB generates either the SACK or SIGN interrupt and sets the SUREQ bit to 0.
The USB also sets the SUREQ bit to 0 when software sets the SUREQCLR bit to 1.
Before setting the SUREQ bit to 1, set the DCPMAXP.DEVSEL[3:0] bits, registers USBREQ, USBVAL, USBINDX, and USBLENG appropriately to transmit the desired USB request in the setup transaction. Before setting this bit to 1, check that the PID[1:0] bits for the DCP are set to 00b (NAK). After setting the SUREQ bit to 1, do not modify the DCPMAXP.DEVSEL[3:0] bits, registers USBREQ, USBVAL, USBINDX, or USBLENG until the setup transaction is completed (the SUREQ bit = 1).
Write 1 to the SUREQ bit only when transmitting the setup token; for other purposes, write 0.
When the function controller is selected, be sure to write 0 to the SUREQ bit.

BSTS Flag (Buffer Status Flag)

Indicates whether DCP FIFO buffer access is enabled or disabled.
The meaning of the BSTS flag depends on the setting of ISEL bit in the port select register as shown below.

- When the ISEL bit = 0, the BSTS flag indicates whether the received data can be read from the buffer.
- When the ISEL bit = 1, the BSTS flag indicates whether the data to be transmitted can be written to the buffer.

40.2.28 Pipe Window Select Register (PIPESEL)

Address(es): USB0.PIPESEL 8785 0064h, USB0_NS.PIPESEL 0785 0064h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	PIPESEL[3:0]	Pipe Window Select	b3 b0 0 0 0 0: No pipe selected 0 0 0 1: Pipe 1 0 0 1 0: Pipe 2 0 0 1 1: Pipe 3 0 1 0 0: Pipe 4 0 1 0 1: Pipe 5 0 1 1 0: Pipe 6 0 1 1 1: Pipe 7 1 0 0 0: Pipe 8 1 0 0 1: Pipe 9 Settings other than above are prohibited.	R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Pipes 1 to 9 should be set using registers PIPESEL, PIPECFG, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN.

After selecting the pipe using the PIPESEL register, functions of the pipe should be set using registers PIPECFG, PIPEMAXP, and PIPEPERI. PIPEnCTR, PIPEnTRE, and PIPEnTRN can be set regardless of the pipe selection in the PIPESEL register.

PIPESEL[3:0] Bits (Pipe Window Select)

The PIPESEL[3:0] bits select the pipe number corresponding to registers PIPECFG, PIPEMAXP, and PIPEPERI which data are written to or read from.

Selecting a pipe number through the PIPESEL[3:0] bits allows writing to and reading from registers PIPECFG, PIPEMAXP, and PIPEPERI which correspond to the selected pipe number.

When PIPESEL[3:0] = 0000b, 0 is read from all of the bits in registers PIPECFG, PIPEMAXP, and PIPEPERI. Writing to these bits is invalid.

40.2.29 Pipe Configuration Register (PIPECFG)

Address(es): USB0.PIPECFG 8785 0068h, USB0_NS.PIPECFG 0785 0068h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TYPE[1:0]		—	—	—	BFRE	DBLB	—	SHTNAK	—	—	DIR	EPNUM[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	EPNUM[3:0]	Endpoint Number*1	These bits specify the endpoint number for the selected pipe. Setting 0000b means an unused pipe.	R/W
b4	DIR	Transfer Direction*2,*3	0: Receiving direction 1: Transmitting direction	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	SHTNAK	Pipe Disabled at End of Transfer*1	0: Pipe assignment continued at the end of transfer 1: Pipe assignment disabled at the end of transfer	R/W
b8	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b9	DBLB	Double Buffer Mode*2,*3	0: Single buffer 1: Double buffer	R/W
b10	BFRE	BRDY Interrupt Operation Specification*2,*3	0: BRDY interrupt upon transmitting or receiving data 1: BRDY interrupt upon completion of reading data	R/W
b13 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15, b14	TYPE[1:0]	Transfer Type*1	• Pipes 1 and 2 b15 b14 0 0: Pipe not used 0 1: Bulk transfer 1 0: Setting prohibited 1 1: Isochronous transfer • Pipes 3 to 5 b15 b14 0 0: Pipe not used 0 1: Bulk transfer 1 0: Setting prohibited 1 1: Setting prohibited • Pipes 6 to 9 b15 b14 0 0: Pipe not used 0 1: Setting prohibited 1 0: Interrupt transfer 1 1: Setting prohibited	R/W

Note 1. Modify the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

Note 2. Modify the BFRE, DBLB, and DIR bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), checking the PIPEnCTR.PBUSY flag through software is not necessary.

Note 3. To modify the BFRE, DBLB, and DIR bits after completing USB communication using the selected pipe, write 1 and then 0 to the PIPEnCTR.ACLRM bit continuously through software to clear the FIFO buffer assigned to the selected pipe while the PID[1:0] bits and CURPIPE[3:0] bits are in the state described in the above note 2.

The PIPECFG register specifies the transfer type, buffer memory access direction, and endpoint numbers for pipes 1 to 9. It also selects single or double buffer mode, and whether to continue or disable pipe operation at the end of transfer.

EPNUM[3:0] Bits (Endpoint Number)

The EPNUM[3:0] bits specify the endpoint number for the selected pipe.
Setting 0000b means an unused pipe.
Do not make the settings such that the combination of the settings of the DIR and EPNUM[3:0] bits should be the same for two or more pipes (EPNUM[3:0] bits = 0000b can be set for all of the pipes).

DIR Bit (Transfer Direction)

The DIR bit specifies the transfer direction for the selected pipe.
When the DIR bit has been set to 0 by software, the USB uses the selected pipe in the receiving direction, and when software has set the DIR bit to 1, the USB uses the selected pipe in the transmitting direction.

SHTNAK Bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to modify the PID[1:0] bits to 00b (NAK) upon the end of transfer when the selected pipe is in the receiving direction.
The SHTNAK bit is valid when the selected pipe is pipe 1 to 5 in the receiving direction.
When the SHTNAK bit has been set to 1 by software for the selected pipe in the receiving direction, the USB modifies the PIPEnCTR.PID[1:0] bits corresponding to the selected pipe to 00b (NAK) on determining the end of the transfer. The USB determines that the transfer has ended on any of the following conditions.

- A short packet (including a zero-length packet) is successfully received.
- The transaction counter is used and the number of packets specified by the counter are successfully received.

DBLB Bit (Double Buffer Mode)

The DBLB bit selects either single or double buffer mode for the FIFO buffer used by the selected pipe.
The DBLB bit is valid when the selected pipe is pipe 1 to 5.

BFRE Bit (BRDY Interrupt Operation Specification)

The BFRE bit specifies the BRDY interrupt generation timing from the USB to the CPU with respect to the selected pipe.
When the BFRE bit has been set to 1 by software and the selected pipe is in the receiving direction, the USB detects the transfer completion and generates the BRDY interrupt on having read the relevant packet.
When the BRDY interrupt is generated with the above conditions, 1 should be written to the BCLR bit in the port control register by software. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to the BCLR bit.
When the BFRE bit has been set to 1 by software and the selected pipe is in the transmitting direction, the USB does not generate the BRDY interrupt.
For details, refer to section 40.3.3.1, BRDY Interrupt.

TYPE[1:0] Bits (Transfer Type)

The TYPE[1:0] bits select the transfer type for the pipe selected by the PIPESEL.PIPESEL[3:0] bits (selected pipe).
Before setting the PID[1:0] bits to 01b (BUF) for the selected pipe (before starting USB communication using the selected pipe), set the TYPE[1:0] bits to a value other than 00b.

40.2.30 Pipe Maximum Packet Size Register (PIPEMAXP)

Address(es): USB0.PIPEMAXP 8785 006Ch, USB0_NS.PIPEMAXP 0785 006Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DEVSEL[3:0]				—	—	—	MXPS[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0/1 *1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	MXPS[8:0]	Maximum Packet Size*2	• Pipes 1 and 2: 1 byte (001h) to 256 bytes (100h) • Pipes 3 to 5: 8 bytes (008h), 16 bytes (010h), 32 bytes (020h), 64 bytes (040h) • Pipes 6 to 9: 1 byte (001h) to 64 bytes (040h)	R/W
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b12	DEVSEL[3:0]	Device Select*3	b3 b0 0 0 0 0: Address 0000 0 0 0 1: Address 0001 0 0 1 0: Address 0010 0 0 1 1: Address 0011 0 1 0 0: Address 0100 0 1 0 1: Address 0101 Settings other than above are prohibited.	R/W

Note 1. The value of these bits is 0000h when no pipe is selected with the PIPESEL.PIPESEL[3:0] bits and 0040h when a pipe is selected.

Note 2. Modify the MXPS[8:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

Note 3. Modify the DEVSEL[3:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK). To modify these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

The PIPEMAXP register specifies the maximum packet size for pipes 1 to 9.

MXPS[8:0] Bits (Maximum Packet Size)

The MXPS[8:0] bits specify the maximum data payload (maximum packet size) for the selected pipe.

These bits should be set to the appropriate value for each transfer type based on USB Specification 2.0. Note that the maximum value of pipes 1 and 2 is 256. While MXPS[8:0] = 000h, do not write to the FIFO buffer or do not set the PID[1:0] bits to 01b (BUF).

DEVSEL[3:0] Bits (Device Select)

When the host controller is selected, these bits specify the USB device address of the peripheral device which is the communication target.

The DEVSEL[3:0] bits should be set after setting the address to the DEVADDn (n = 0 to 5) register corresponding to the value to be set in the DEVSEL[3:0] bits. For example, before setting the DEVSEL[3:0] bits to 0010b, the address should be set to DEVADD2.

When the function controller is selected, the DEVSEL[3:0] bits should be set to 0000b.

40.2.31 Pipe Cycle Control Register (PIPEPERI)

Address(es): USB0.PIPEPERI 8785 006Eh, USB0_NS.PIPEPERI 0785 006Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	IITV[2:0]	Interval Error Detection Interval *1	Specify the interval error detection timing for the selected pipe in terms of frames, which is expressed as nth power of 2.	R/W
b11 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	IFIS	Isochronous IN Buffer Flush	0: The buffer is not flushed. 1: The buffer is flushed.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Modify the IITV[2:0] bits while the PIPEnCTR.PID[1:0] bits are 00b (NAK). To modify these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

The PIPEPERI register selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfer, and sets the interval error detection interval for pipes 1 to 9.

IITV[2:0] Bits (Interval Error Detection Interval)

Before modifying the IITV[2:0] bits after USB communication has been completed with the IITV[2:0] bits set to a certain value, set the PID[1:0] bits to 00b (NAK) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer.

The IITV[2:0] bits are invalid for pipes 3 to 5; set the IITV[2:0] bits to 000b for pipes 3 to 5.

IFIS Bit (Isochronous IN Buffer Flush)

Specifies whether to flush the buffer when the pipe selected by the PIPESEL.PIPESEL[3:0] bits (selected pipe) is used for isochronous IN transfers.

When the function controller is selected and the selected pipe is for isochronous IN transfers, the USB automatically clears the FIFO buffer when the USB fails to receive the IN token from the USB host within the interval set by the IITV[2:0] bits in terms of frames.

In double buffer mode (the PIPECFG.DBLB bit = 1), the USB only clears the data in the plane used earlier.

The USB clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USB has expected to receive the IN token. Even if the SOF packet is damaged, the USB also clears the FIFO buffer at the right timing to receive the SOF packet by using the internal interpolation function.

When the host controller is selected, set the IITV[2:0] bits to 000b.

When the selected pipe is not for isochronous transfer, set the IITV[2:0] bits to 000b.

40.2.32 Pipe n Control Registers (PIPEnCTR) (n = 1 to 9)

- PIPEnCTR (n = 1 to 5)

Address(es): USB0.PIPE1CTR 8785 0070h, USB0.PIPE2CTR 8785 0072h, USB0.PIPE3CTR 8785 0074h, USB0.PIPE4CTR 8785 0076h, USB0.PIPE5CTR 8785 0078h,
USB0_NS.PIPE1CTR 0785 0070h, USB0_NS.PIPE2CTR 0785 0072h, USB0_NS.PIPE3CTR 0785 0074h,
USB0_NS.PIPE4CTR 0785 0076h, USB0_NS.PIPE5CTR 0785 0078h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BSTS	INBUFM	—	—	—	ATREPM	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PID[1:0]	Response PID	b1 b0 0 0: NAK response 0 1: BUF response (depending on the buffer state) 1 0: STALL response 1 1: STALL response	R/W
b4 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	PBUSY	Pipe Busy Flag	0: The relevant pipe is not used for the transaction. 1: The relevant pipe is used for the transaction.	R
b6	SQMON	Sequence Toggle Bit Confirmation	0: DATA0 1: DATA1	R
b7	SQSET	Sequence Toggle Bit Set*2	0: Write disabled 1: Specifies DATA1.	R/W*1
b8	SQCLR	Sequence Toggle Bit Clear*2	0: Write disabled 1: Specifies DATA0.	R/W*1
b9	ACLRM	Auto Buffer Clear Mode*3	0: Disabled 1: Enabled (all buffers are initialized)	R/W
b10	ATREPM	Auto Response Mode*2	0: Auto response is disabled. 1: Auto response is enabled.	R/W
b13 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	INBUFM	Transmit Buffer Monitor Flag	0: There is no data to be transmitted in the buffer memory. 1: There is data to be transmitted in the buffer memory.	R
b15	BSTS	Buffer Status Flag	0: Buffer access by the CPU is disabled. 1: Buffer access by the CPU is enabled.	R

Note 1. Only 0 can be read.
Note 2. Modify the ATREPM bit or write 1 to the SQCLR or SQSET bit while the PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.
Note 3. Modify the ACLRM bit while PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying this bit after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

The PIPEnCTR register can be set regardless of the pipe selection in the PIPESEL register.

PID[1:0] Bits (Response PID)

The PID[1:0] bits specify the response type for the next transaction of the relevant pipe.
The default setting of the PID[1:0] bits are 00b (NAK). Modify the setting of the PID[1:0] bits to 01b (BUF) to use the relevant pipe for USB transfer. Table 40.6 and Table 40.7 show the basic operation (operation when there are no errors in the transmitted and received packets) of the USB depending on the PID[1:0] bit setting.
After modifying the setting of the PID[1:0] bits through software from 01b (BUF) to 00b (NAK) during USB communication using the relevant pipe, check that the PBUSY flag is 0 to see if USB transfer using the relevant pipe has actually entered the NAK state. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.
The USB modifies the setting of the PID[1:0] bits in the following cases.

- The USB sets the PID[1:0] bits to 00b (NAK) on recognizing the completion of the transfer when the relevant pipe is in the receiving direction and the PIPECFG.SHTNAK bit for the selected pipe has been set to 1 by software.
- The USB sets the PID[1:0] bits to 11b (STALL) on receiving a data packet with a payload exceeding the maximum packet size of the relevant pipe.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a USB bus reset when the function controller is selected.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a receive error, such as a CRC error, three consecutive times when the host controller is selected.
- The USB sets the PID[1:0] bits to 11b (STALL) on receiving the STALL handshake when the host controller is selected.

To specify each response type, set the PID[1:0] bits as follows.

- To make a transition from NAK (00b) to STALL, set 10b.
- To make a transition from BUF (01b) to STALL, set 11b.
- To make a transition from STALL (11b) to NAK, set 10b and then 00b.
- To make a transition from STALL (11b) to BUF, set 10b, 00b, and then 01b.
- To make a transition from STALL (10b) to BUF, set 00b and then 01b.

PBUSY Flag (Pipe Busy Flag)

The PBUSY flag indicates whether the relevant pipe is being currently used or not for the transaction.
The USB modifies the PBUSY flag from 0 to 1 upon start of the USB transaction for the relevant pipe, and modifies the PBUSY flag from 1 to 0 upon completion of one transaction.
Reading the PBUSY flag after the PID[1:0] bits have been set to 00b (NAK) by software allows checking whether modification of the pipe settings is possible.
For details, refer to section 40.3.4.1, Pipe Control Register Switching Procedures.

SQMON Bit (Sequence Toggle Bit Confirmation)

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction of the relevant pipe.
When the relevant pipe is not for the isochronous transfer, the USB allows the SQMON flag to toggle upon normal completion of the transaction. However, the SQMON flag is not allowed to toggle when a data PID mismatch occurs during the transfer in the receiving direction.

SQSET Bit (Sequence Toggle Bit Set)

The SQSET bit should be set to 1 to set DATA1 as the expected value of the sequence toggle bit for the next transaction of the relevant pipe.
Setting the SQSET bit to 1 through software allows the USB to set DATA1 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQSET bit to 0.

SQCLR Bit (Sequence Toggle Bit Clear)

The SQCLR bit should be set to 1 to clear the expected value (to set DATA0 as the expected value) of the sequence toggle bit for the next transaction of the relevant pipe.
Setting the SQCLR bit to 1 through software allows the USB to set DATA0 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQCLR bit to 0.

ACLRM Bit (Auto Buffer Clear Mode)

Enables or disables auto buffer clear mode for the relevant pipe.
To delete the information in the FIFO buffer assigned to the relevant pipe completely, write 1 and then 0 to the ACLRM bit continuously.
Table 40.8 shows the information cleared by writing 1 and 0 to the ACLRM bit continuously and the cases in which clearing the information is necessary.

ATREPM Bit (Auto Response Mode)

Enables or disables auto response mode for the relevant pipe.
When the function controller is selected and the relevant pipe is for bulk transfer, the ATREPM bit can be set to 1.
When the ATREPM bit is set to 1, the USB responds to the token from the USB host as described below.
(1) When the relevant pipe is for bulk IN transfer (the PIPECFG.TYPE[1:0] bits = 01b and the PIPECFG.DIR bit = 1)
When the ATREPM bit = 1 and PID[1:0] = 01b (BUF), the USB transmits a zero-length packet in response to the IN token.
The USB updates (allows toggling of) the sequence toggle bit (data PID) each time the USB receives ACK from the USB host (in a single transaction, IN token is received, zero-length packet is transmitted, and then ACK is received.).
In this case, the USB does not generate the BRDY or BEMP interrupt.
(2) When the relevant pipe is for bulk OUT transfer (the PIPECFG.TYPE[1:0] bits = 01b and the PIPECFG.DIR bit = 0)
When the ATREPM bit = 1 and PID[1:0] = 01b (BUF), the USB returns NAK in response to the OUT token and generates the NRDY interrupt.
For USB communication in auto response mode, set the ATREPM bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode.
When the relevant pipe is for isochronous transfer, be sure to set the ATREPM bit to 0.
When the host controller is selected, be sure to set the ATREPM bit to 0.

INBUFM Flag (Transmit Buffer Monitor Flag)

Indicates the relevant FIFO buffer status when the relevant pipe is in the transmitting direction.
When the relevant pipe is in the transmitting direction (the PIPECFG.DIR bit = 1), the USB sets the INBUFM flag to 1 when the CPU or DMAC/DTC completes writing data to at least one FIFO buffer plane.
The USB sets the INBUFM flag to 0 when the USB completes transmitting the data from the FIFO buffer plane to which all the data has been written. In double buffer mode (the PIPECFG.DBLB bit = 1), the USB sets the INBUFM flag to 0 when the USB completes transmitting the data from the two FIFO buffer planes before the CPU or DMAC/DTC completes writing data to one FIFO buffer plane.
The INBUFM flag indicates the same value as the BSTS flag when the relevant pipe is in the receiving direction (the PIPECFG.DIR bit = 0).

BSTS Flag (Buffer Status Flag)

Indicates the FIFO buffer status for the relevant pipe.

The meaning of the BSTS flag depends on the settings of the PIPECFG.DIR bit, PIPECFG.BFRE bit, and DnFIFOSEL.DCLRM bits as shown in Table 40.9.

Table 40.6 Operation of USB depending on PID[1:0] Bits Setting (When Host Controller is Selected)

PID[1:0] Bits	Transfer Type	Transfer Direction (DIR Bit)	Operation of USB
00b (NAK)	Operation does not depend on the setting.	Operation does not depend on the setting.	Does not issue tokens.
01b (BUF)	Bulk or interrupt	Operation does not depend on the setting.	Issues tokens while the DVSTCTR0.UACT bit is 1 and the FIFO buffer corresponding to the relevant pipe is ready for transmission and reception. Does not issue tokens while the DVSTCTR0.UACT bit is 0 or the FIFO buffer corresponding to the relevant pipe is not ready for transmission or reception.
	Isochronous	Operation does not depend on the setting.	Issues tokens irrespective of the status of the FIFO buffer corresponding to the relevant pipe.
10b (STALL) or 11b (STALL)	Operation does not depend on the setting.	Operation does not depend on the setting.	Does not issue tokens.

Table 40.7 Operation of USB depending on PID[1:0] Bits Setting (When Function Controller is Selected)

PID[1:0] Bits	Transfer Type	Transfer Direction (DIR Bit)	Operation of USB
00b (NAK)	Bulk or interrupt	Operation does not depend on the setting.	Returns NAK in response to the token from the USB host.
	Isochronous	Operation does not depend on the setting.	Returns nothing in response to the token from the USB host.
01b (BUF)	Bulk	Receiving direction (DIR bit = 0)	Receives data and returns ACK in response to the OUT token from the USB host if the FIFO buffer corresponding to the relevant pipe is ready for reception.
	Interrupt	Receiving direction (DIR bit = 0)	Receives data and returns ACK in response to the OUT token from the USB host if the FIFO buffer corresponding to the relevant pipe is ready for reception.
	Bulk or interrupt	Transmitting direction (DIR bit = 1)	Transmits data in response to the token from the USB host if the corresponding FIFO buffer is ready for transmission. Returns NAK if not ready.
	Isochronous	Receiving direction (DIR bit = 0)	Receives data in response to the OUT token from the USB host if the FIFO buffer corresponding to the relevant pipe is ready for reception. Discards data if not ready.
	Isochronous	Transmitting direction (DIR bit = 1)	Transmits data in response to the token from the USB host if the corresponding FIFO buffer is ready for transmission. Transmits the zero-length packet if not ready.
10b (STALL) or 11b (STALL)	Bulk or interrupt	Operation does not depend on the setting.	Returns STALL in response to the token from the USB host.
	Isochronous	Operation does not depend on the setting.	Returns nothing in response to the token from the USB host.

Table 40.8 Information Cleared by USB by Setting ACLRM = 1

No.	Information Cleared by ACLRM Bit Manipulation	Cases in which Clearing Information is Necessary
1	All the information in the FIFO buffer assigned to the relevant pipe (both FIFO buffer planes are cleared when double buffer mode is selected)	When the pipe is to be initialized
2	The interval count value when the relevant pipe is for isochronous transfer	When the interval count value is to be reset
3	Internal flags concerning the PIPECFG.BFRE bit	When the PIPECFG.BFRE setting is modified
4	FIFO buffer toggle control	When the PIPECFG.DBLB setting is modified
5	Internal flags concerning the transaction count	When the transaction count function is forcibly terminated

Table 40.9 Operation of BSTS Flag

DIR Bit	BFRE Bit	DCLRM Bit	BSTS Flag Function
0	0	0	The received data can be read from the FIFO buffer. The received data has been completely read from the FIFO buffer.
		1	Setting prohibited
	1	0	The received data can be read from the FIFO buffer. The BCLR bit in the port control register has been set to 1 by software after the received data has been completely read from the FIFO buffer.
		1	The received data can be read from the FIFO buffer. The received data has been completely read from the FIFO buffer.
1	0	0	The transmit data can be written to the FIFO buffer. The transmit data has been completely written to the FIFO buffer.
		1	Setting prohibited
	1	0	Setting prohibited
		1	Setting prohibited

	BSTS	—	—	—	—	—	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PID[1:0]	Response PID	b1 b0 0 0: NAK response 0 1: BUF response (depending on the buffer state) 1 0: STALL response 1 1: STALL response	R/W
b4 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	PBUSY	Pipe Busy Flag	0: The relevant pipe is not used at the USB bus. 1: The relevant pipe is used at the USB bus.	R
b6	SQMON	Sequence Toggle Bit Confirmation Flag	0: DATA0 1: DATA1	R
b7	SQSET	Sequence Toggle Bit Set*2	0: Invalid 1: Specifies DATA1.	R/W *1
b8	SQCLR	Sequence Toggle Bit Clear *2	0: Invalid 1: Specifies DATA0.	R/W *1
b9	ACLRM	Auto Buffer Clear Mode*2,*3	0: Auto buffer clear mode is disabled. 1: Auto buffer clear mode is enabled (all buffers are initialized)	R/W
b14 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	BSTS	Buffer Status Flag	0: Buffer access is disabled. 1: Buffer access is enabled.	R

Note 1. Only 0 can be read. Only 1 can be written.
Note 2. Write 1 to the SQCLR or SQSET bit while the PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.
Note 3. Modify the ACLRM bit while the PID[1:0] bits are 00b (NAK) and before the pipe is selected by the CURPIPE[3:0] bits in the port select register. Before modifying this bit after modifying the PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

PID[1:0] Bits (Response PID)

The PID[1:0] bits specify the response type for the next transaction of the relevant pipe.
The default setting of the PID[1:0] bits are 00b (NAK). Modify the setting of the PID[1:0] bits to 01b (BUF) to use the relevant pipe for USB transfer. Table 40.6 and Table 40.7 show the basic operation (operation when there are no errors in the transmitted and received packets) of the USB depending on the setting of the PID[1:0] bits.
After modifying the setting of the PID[1:0] bits through software from 01b (BUF) to 00b (NAK) during USB communication using the relevant pipe, check that the PBUSY flag is 0 to see if USB transfer using the relevant pipe has actually entered the NAK state. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.
The USB modifies the setting of the PID[1:0] bits in the following cases.

- The USB sets the PID[1:0] bits to 11b (STALL) on receiving a data packet with a payload exceeding the maximum packet size of the relevant pipe.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a USB bus reset when the function controller is selected.
- The USB sets the PID[1:0] bits to 00b (NAK) on detecting a receive error, such as a CRC error, three consecutive times when the host controller is selected.
- The USB sets the PID[1:0] bits to 11b (STALL) on receiving the STALL handshake when the host controller is selected.

To specify each response type, set the PID[1:0] bits as follows.

- To make a transition from NAK (00b) to STALL, set 10b.
- To make a transition from BUF (01b) to STALL, set 11b.
- To make a transition from STALL (11b) to NAK, set 10b and then 00b.
- To make a transition from STALL (11b) to BUF, set 10b, 00b, and then 01b.
- To make a transition from STALL (10b) to BUF, set 00b and then 01b.

PBUSY Flag (Pipe Busy Flag)

The PBUSY flag indicates whether the relevant pipe is being currently used or not for the transaction.
The USB modifies the PBUSY flag from 0 to 1 upon start of the USB transaction for the relevant pipe, and modifies the PBUSY flag from 1 to 0 upon completion of one transaction.
Reading the PBUSY flag after the PID[1:0] bits has been set to 00b (NAK) by software allows checking whether modification of the pipe settings is possible.

SQMON Flag (Sequence Toggle Bit Confirmation Flag)

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction of the relevant pipe.
The USB allows the SQMON flag to toggle upon normal completion of the transaction. However, the SQMON flag is not allowed to toggle when a data PID mismatch occurs during the transfer in the receiving direction.

SQSET Bit (Sequence Toggle Bit Set)

The SQSET bit should be set to 1 to set DATA1 as the expected value of the sequence toggle bit for the next transaction of the relevant pipe.
Setting the SQSET bit through software allows the USB to set DATA1 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQSET bit to 0.

SQCLR Bit (Sequence Toggle Bit Clear)

The SQCLR bit should be set to 1 to clear the expected value (to set DATA0 as the expected value) of the sequence toggle bit for the next transaction of the relevant pipe.
Setting the SQCLR bit to 1 through software allows the USB to set DATA0 as the expected value of the sequence toggle bit of the relevant pipe. The USB sets the SQCLR bit to 0.

ACLRM Bit (Auto Buffer Clear Mode)

Enables or disables auto buffer clear mode for the relevant pipe.

To delete the information in the FIFO buffer assigned to the relevant pipe completely, write 1 and then 0 to the ACLRM bit continuously.

Table 40.10 shows the information cleared by writing 1 and 0 to the ACLRM bit continuously and the cases in which clearing the information is necessary.

BSTS Flag (Buffer Status Flag)

Indicates the FIFO buffer status for the relevant pipe.

The meaning of the BSTS flag depends on the settings of the PIPECFG.DIR bit, PIPECFG.BFRE bit, and DnFIFOSEL.DCLRM bits as shown in Table 40.9.

Table 40.10 Information Cleared by USB by Setting the ACLRM Bit = 1

No.	Information Cleared by ACLRM Bit Manipulation	Cases in which Clearing Information is Necessary
1	All the information in the FIFO buffer assigned to the selected pipe	When the pipe is to be initialized
2	The interval count value when the selected pipe is for interrupt transfer and the host controller is selected	When the interval count value is to be reset
3	Internal flags concerning the PIPECFG.BFRE bit	When the PIPECFG.BFRE setting is modified
4	Internal flags concerning the transaction count	When the transaction count function is forcibly terminated

40.2.33 Pipe n Transaction Counter Enable Register (PIPEnTRE) (n = 1 to 5)

Address(es): USB0.PIPE1TRE 8785 0090h, USB0.PIPE2TRE 8785 0094h, USB0.PIPE3TRE 8785 0098h, USB0.PIPE4TRE 8785 009Ch, USB0.PIPE5TRE 8785 00A0h,
USB0_NS.PIPE1TRE 0785 0090h, USB0_NS.PIPE2TRE 0785 0094h, USB0_NS.PIPE3TRE 0785 0098h, USB0_NS.PIPE4TRE 0785 009Ch, USB0_NS.PIPE5TRE 0785 00A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	TRCLR	Transaction Counter Clear	0: Invalid 1: The current counter value is cleared.	R/W
b9	TRENB	Transaction Counter Enable	0: Transaction counter is disabled. 1: Transaction counter is enabled.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Modify each bit in the PIPEnTRE register while the PID[1:0] bits are 00b (NAK). Before modifying these bits after modifying the PIPEnCTR.PID[1:0] bits for the selected pipe from 01b (BUF) to 00b (NAK), check that the PIPEnCTR.PBUSY flag is 0. However, if the USB changes the PID[1:0] bits to 00b (NAK), the PBUSY flag does not need to be checked by software.

TRCLR Bit (Transaction Counter Clear)

Clears the current value of the transaction counter corresponding to the relevant pipe and then sets the TRCLR bit to 0.

TRENB Bit (Transaction Counter Enable)

Enables or disables the transaction counter.

For the pipe in the receiving direction, setting the TRENB bit to 1 after setting the total number of the packets to be received in the PIPEnTRN register through software allows the USB to control hardware as described below on having received the number of packets equal to the setting of the PIPEnTRN register.

- While the PIPECFG.SHTNAK bit is 1, the USB modifies the PID[1:0] bits to 00b (NAK) for the corresponding pipe on having received the number of packets equal to the setting of the PIPEnTRN register.
- While the PIPECFG.BFRE bit is 1, the USB asserts the BRDY interrupt on having received the number of packets equal to the setting of the PIPEnTRN register and then reading the last received data.

For the pipe in the transmitting direction, set the TRENB bit to 0.

When the transaction counter is not used, set the TRENB bit to 0.

When the transaction counter is used, set the PIPEnTRN register before setting the TRENB bit to 1. Set the TRENB bit to 1 before receiving the first packet to be counted by the transaction counter.

40.2.34 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5)

Address(es): USB0.PIPE1TRN 8785 0092h, USB0.PIPE2TRN 8785 0096h, USB0.PIPE3TRN 8785 009Ah, USB0.PIPE4TRN 8785 009Eh, USB0.PIPE5TRN 8785 00A2h,
USB0_NS.PIPE1TRN 0785 0092h, USB0_NS.PIPE2TRN 0785 0096h, USB0_NS.PIPE3TRN 0785 009Ah,
USB0_NS.PIPE4TRN 0785 009Eh, USB0_NS.PIPE5TRN 0785 00A2h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The PIPEnTRN register retains the setting by a USB bus reset.

- When written to:
  This register specifies the total of packets (number of transactions) to be received in corresponding pipe.
- When read from:
  This register indicates the specified number of transactions if the PIPEnTRE.TRENB bit is 0.
  This register indicates the number of currently counted transactions if the PIPEnTRE.TRENB bit is 1.

The USB increments the value of the PIPEnTRN register by one when all of the following conditions are satisfied on receiving the packet.

- The PIPEnTRE.TRENB bit = 1
- (PIPEnTRN set value ≠ current counter value + 1) on receiving the packet.
- The payload of the received packet agrees with the setting of the PIPEMAXP.MXPS[8:0] bits.

The USB sets the value of the PIPEnTRN register to 0000h when any of the following conditions are satisfied.

(1) All of the following conditions are satisfied.
- The PIPEnTRE.TRENB bit = 1
- (PIPEnTRN set value = current counter value + 1) on receiving the packet.
- The payload of the received packet agrees with the setting of the PIPEMAXP.MXPS[8:0] bits.

(2) All of the following conditions are satisfied.
- The PIPEnTRE.TRENB bit = 1
- The USB has received a short packet.

(3) All of the following conditions are satisfied.
- The PIPEnTRE.TRENB bit = 1
- The PIPEnTRE.TRCLR bit has been set to 1 by software.

For the pipe in the transmitting direction, set the PIPEnTRN register to 0000h.
When the transaction counter is not used, set the PIPEnTRN register to 0000h.
Setting the number of transactions to be transferred to the PIPEnTRN register is only enabled when the PIPEnTRE.TRENB bit is 0. To modify the number of transactions to be transferred, set the TRCLR bit to 1 (to clear the current counter value) before setting the PIPEnTRE.TRENB bit to 1.

40.2.35 Device Address n Configuration Register (DEVADDn) (n = 0 to 5)

Address(es): USB0.DEVADD0 8785 00D0h, USB0.DEVADD1 8785 00D2h, USB0.DEVADD2 8785 00D4h, USB0.DEVADD3 8785 00D6h, USB0.DEVADD4 8785 00D8h, USB0.DEVADD5 8785 00DAh, USB0_NS.DEVADD0 0785 00D0h, USB0_NS.DEVADD1 0785 00D2h, USB0_NS.DEVADD2 0785 00D4h, USB0_NS.DEVADD3 0785 00D6h, USB0_NS.DEVADD4 0785 00D8h, USB0_NS.DEVADD5 0785 00DAh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	USBSPD[1:0]		—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7, b6	USBSPD[1:0]	Transfer Speed of Communication Target Device	b7 b6 0 0: DEVADDn is not used 0 1: Low-speed 1 0: Full-speed 1 1: Setting prohibited	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The DEVADDn register specifies the transfer speed of the peripheral device which is the communication target for pipes 0 to 9.
When the host controller is selected, the bits in the DEVADDn register should be set before starting communication using each pipe.
The bits in the DEVADDn register should be modified while no valid pipes are using the settings of the bits. Valid pipes refer to the pipes satisfying both of the following conditions:

- The DEVADDn register is selected by the DEVSEL[3:0] bits.
- The PID[1:0] bits are set to 01b (BUF) for the selected pipe or the selected pipe is the DCP with the DCPCTR.SUREQ bit set to 1.

USBSPD[1:0] Bits (Transfer Speed of Communication Target Device)

The USBSPD[1:0] bits specify the USB transfer speed of the communication target peripheral device.
Set these bits to 10b when a full-speed device is connected via the HUB.
When the host controller is selected, the USB refers to the setting of the USBSPD[1:0] bits to generate packets.
When the function controller is selected, set these bits to 00b.

40.2.36 Deep Standby USB Transceiver Control/Pin Monitoring Register (DPUSR0R)

Address(es): USB0.DPUSR0R 8785 0400h, USB0_NS.DPUSR0R 0785 0400h

b22	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b23	DVBSTS0	VBUS Input Flag	Indicates the VBUS input signal.	R
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Use this bit during operation in deep software standby mode 1. For details, refer to section 40.3.1.5, Release from Deep Software Standby Mode 1 Due to USB Suspend/Resume Interrupts.

SRPC0 Bit (Single End Receiver Control)

The SRPC0 bit controls the D+ and D– inputs of the USB transceiver.

This bit is only valid when the FIXPHY0 bit is 1.

FIXPHY0 Bit (Transceiver Output Fix)

The FIXPHY0 bit keeps the outputs of the USB transceiver disabled.

40.2.37 Deep Standby USB Suspend/Resume Interrupt Register (DPUSR1R)

Address(es): USB0.DPUSR1R 8785 0404h, USB0_NS.DPUSR1R 0785 0404h

b23	DVBINT0	VBUS Interrupt Source Recovery Flag	0: The system has not returned from deep software standby mode 1. 1: The system has returned from deep software standby mode 1.	R
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

DPINTE0 Bit (D+ Interrupt Enable/Clear)

This bit enables or disables triggering of recovery from deep software standby mode 1 by the D+ input.
Writing 0 to the DPINTE0 bit while the DPINT0 flag is 1 sets the DPINT0 flag to 0.

DMINTE0 Bit (D– Interrupt Enable/Clear)

This bit enables or disables triggering of recovery from deep software standby mode 1 by the D– input. Writing 0 to the

DMINTE0 bit while the DMINT0 flag is 1 sets the DMINT0 flag to 0.

DOVRCRAE0 Bit (OVRCURA Interrupt Enable/Clear)

This bit enables or disables triggering of recovery from deep software standby mode 1 by the OVRCURA input. Writing 0 to the DOVRCRAE0 bit while the DOVRCRA0 flag is 1 sets the DOVRCRA0 flag to 0.

DOVRCRBE0 Bit (OVRCURB Interrupt Enable/Clear)

This bit enables or disables triggering of recovery from deep software standby mode 1 by the OVRCURB input. Writing 0 to the DOVRCRBE0 bit while the DOVRCRB0 flag is 1 sets the DOVRCRB0 flag to 0.

DVBSE0 Bit (VBUS Interrupt Enable/Clear)

This bit enables or disables triggering of recovery from deep software standby mode 1 by the VBUS input. Writing 0 to the DVBSE0 bit while the DVBINT0 flag is 1 sets the DVBINT0 flag to 0.

DPINT0 Flag (D+ Interrupt Source Recovery Flag)

This bit indicates that the system has returned from deep software standby mode 1 due to the D+ input. Recovery from deep software standby mode 1 due to D+ input is only enabled when the DPINTE0 bit is 1.
Writing 0 to the DPINTE0 bit while the DPINT0 flag is 1 sets the DPINT0 flag to 0.

DMINT0 Flag (D– Interrupt Source Recovery Flag)

This bit indicates that the system has returned from deep software standby mode 1 due to the D– input. Recovery from deep software standby mode 1 due to D– input is only enabled when the DMINTE0 bit is 1.
Writing 0 to the DPINTE0 bit while the DMINT0 flag is 1 sets the DMINT0 flag to 0.

DOVRCRA0 Flag (OVRCURA Interrupt Source Recovery Flag)

This bit indicates that the system has returned from deep software standby mode 1 due to the OVRCURA input. Recovery from deep software standby mode 1 due to OVRCURA input is only enabled when the DOVRCRAE0 bit is 1.
Writing 0 to the DOVRCRAE0 bit while the DOVRCRA0 flag is 1 sets the DOVRCRA0 flag to 0.

DOVRCRB0 Flag (OVRCURB Interrupt Source Recovery Flag)

This bit indicates that the system has returned from deep software standby mode 1 due to the OVRCURB input. Recovery from deep software standby mode 1 due to OVRCURB input is only enabled when the DOVRCRBE0 bit is 1.
Writing 0 to the DOVRCRBE0 bit while the DOVRCRB0 flag is 1 sets the DOVRCRB0 flag to 0.

DVBINT0 Flag (VBUS Interrupt Source Recovery Flag)

This indicates that the system has returned from deep software standby mode 1 due to the VBUS input. Recovery from deep software standby mode 1 due to VBUS input is only enabled when the DVBSE0 bit is 1.
Writing 0 to the DVBSE0 bit while the DVBINT0 flag is 1 sets the DVBINT0 flag to 0.

40.3 Operation

40.3.1 System Control

This section describes the register settings that are necessary for initialization of this module and power consumption control.

40.3.1.1 Setting Data to the USB Related Register

Setting the SYSCFG.USBE bit to 1 after starting the clock supply to the USB (SYSCFG.SCKE bit = 1) enables and starts USB operation.

40.3.1.2 Controller Function Selection

For the USB, the host or function controller can be selected using the SYSCFG.DCFM bit. Note that the DCFM bit should be modified in the initial settings immediately after a reset is released or when pull-up resistor of the D+line and pull-down resistors of the D+ and D– lines are disabled (the SYSCFG.DPRPU bit = 0 and DRPD bit = 0).

40.3.1.3 Controlling USB Data Bus Resistors

The USB has pull-up and pull-down resistors for the D+ and D– lines. Pull up or pull down these lines by setting the SYSCFG.DPRPU and DRPD bits.
When the function controller is selected, confirm that connection to the USB host is made, then set the DPRPU bit to 1 and pull up the D+ line (during full-speed).
When the DPRPU bit is set to 0 during communication with the PC, the USB module disables the pull-up resistor of the USB data line, thus notifying the USB host of disconnection.
When the host controller is selected, set the DRPD bit and pull down the D+ and D– lines.

Table 40.11 USB Data Bus Resistor Control

SYSCFG register				
DRPD bit	**DPRPU bit**	**D–**	**D+**	**Function**
0	0	Open	Open	Not in use
0	1	Open	Pull-up	When operating as the function controller (in full-speed)
1	0	Pull-down	Pull-down	When operating as the host controller
1	1	—	—	Setting prohibited

40.3.1.4 Example of USB External Connection Circuit

Figure 40.2 shows an example of connection between OTG device and USB connector in the self-powered state.
The USB controls the signals for enabling a pull-up resistor for the D+ signal and pull-down resistors for the D+ and D– signals. These signals can be pulled up or down using the SYSCFG.DPRPU and DRPD bits.
When the function controller is selected and the DPRPU bit is set to 0 during communication with the host controller, the pull-up resistor of the USB data line is disabled, making it possible to notify the USB host of the device disconnection.

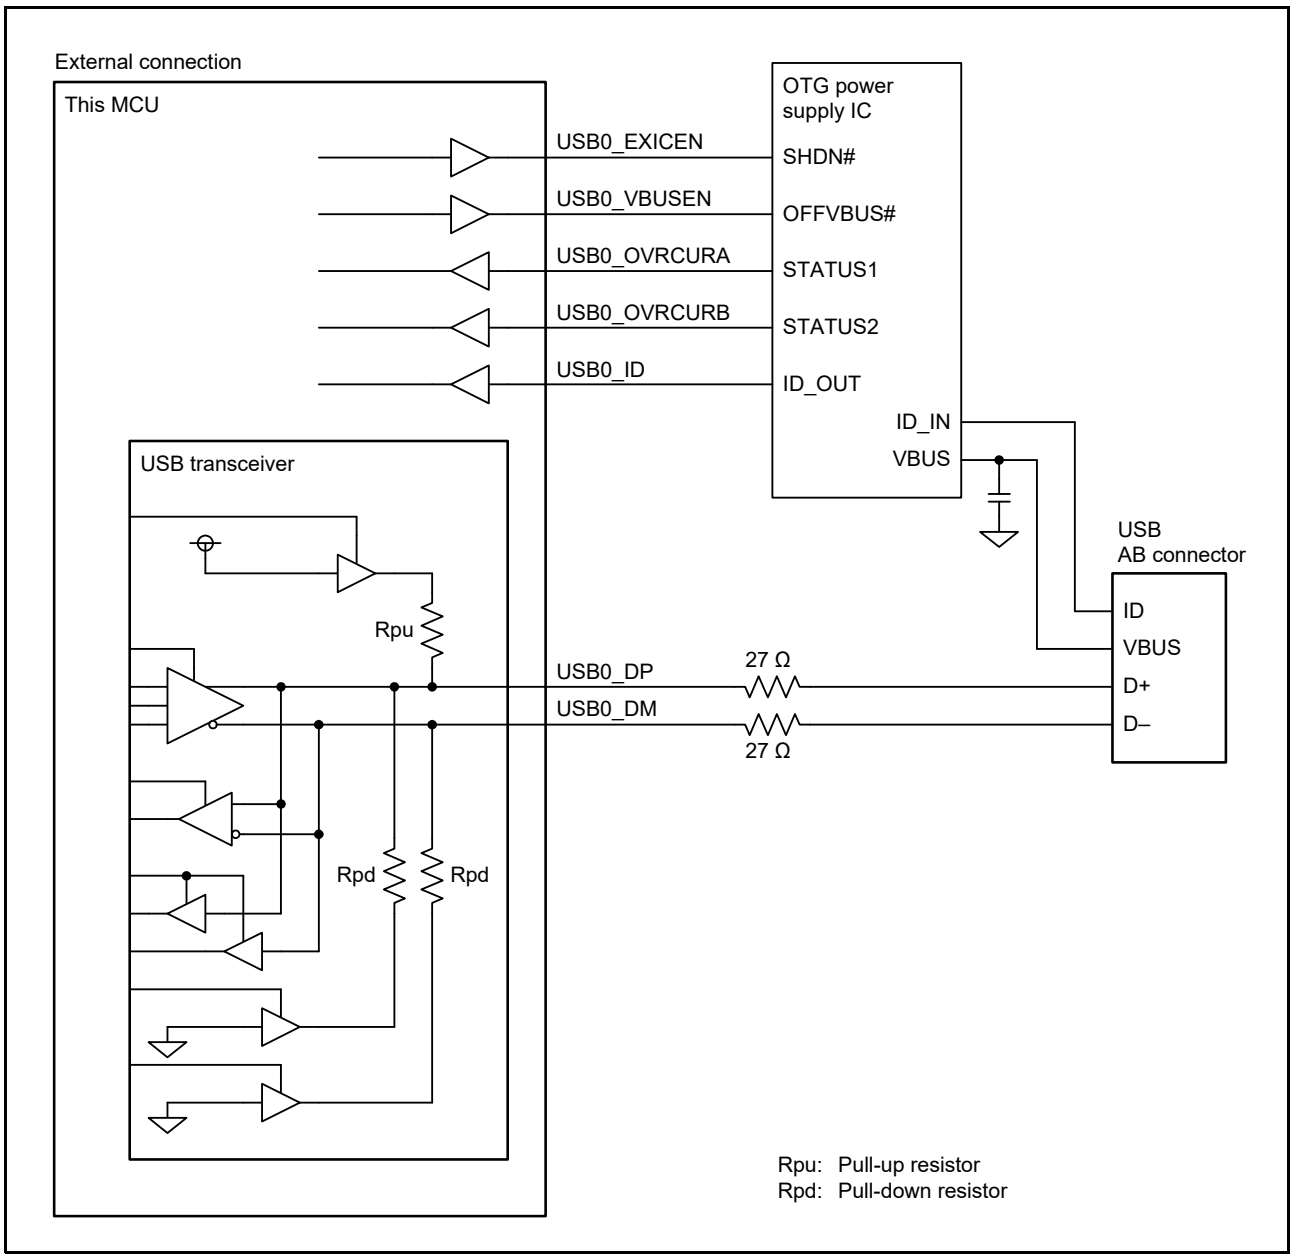

Figure 40.2 Example of Connection between Self-Powered OTG Device and USB Connector

Figure 40.3 shows an example of connection between function controller and USB connector in self-powered state.

Figure 40.4 shows an example of connection between host controller and USB connector.

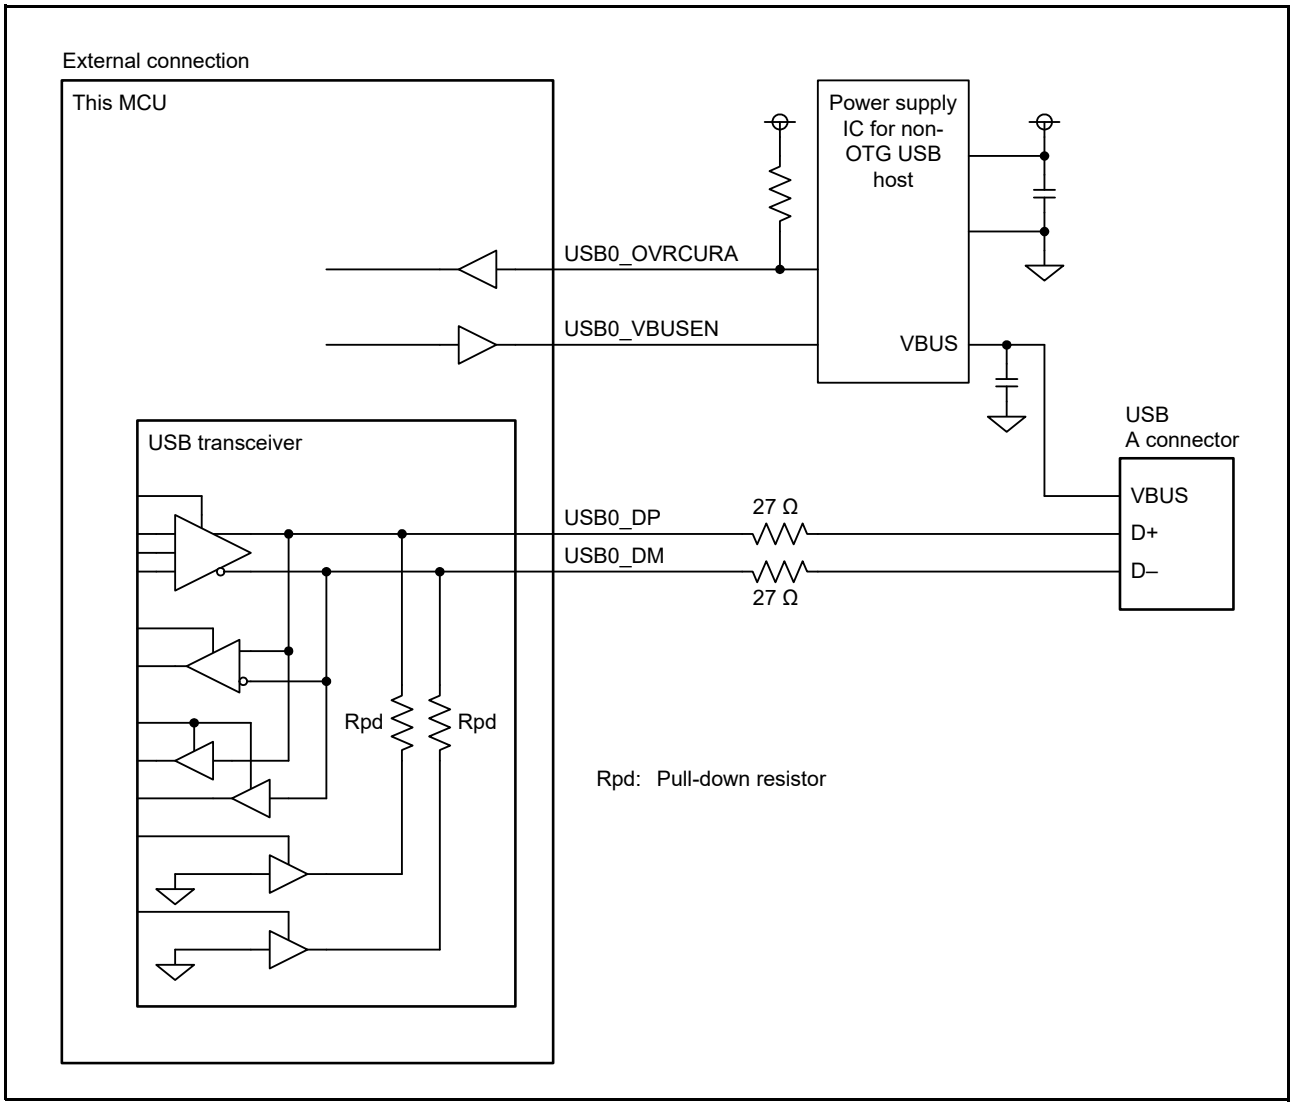

Figure 40.4 Example of Connection between Host and USB Connector

Figure 40.5 shows an example of connection between function controller and USB connector in bus powered state.

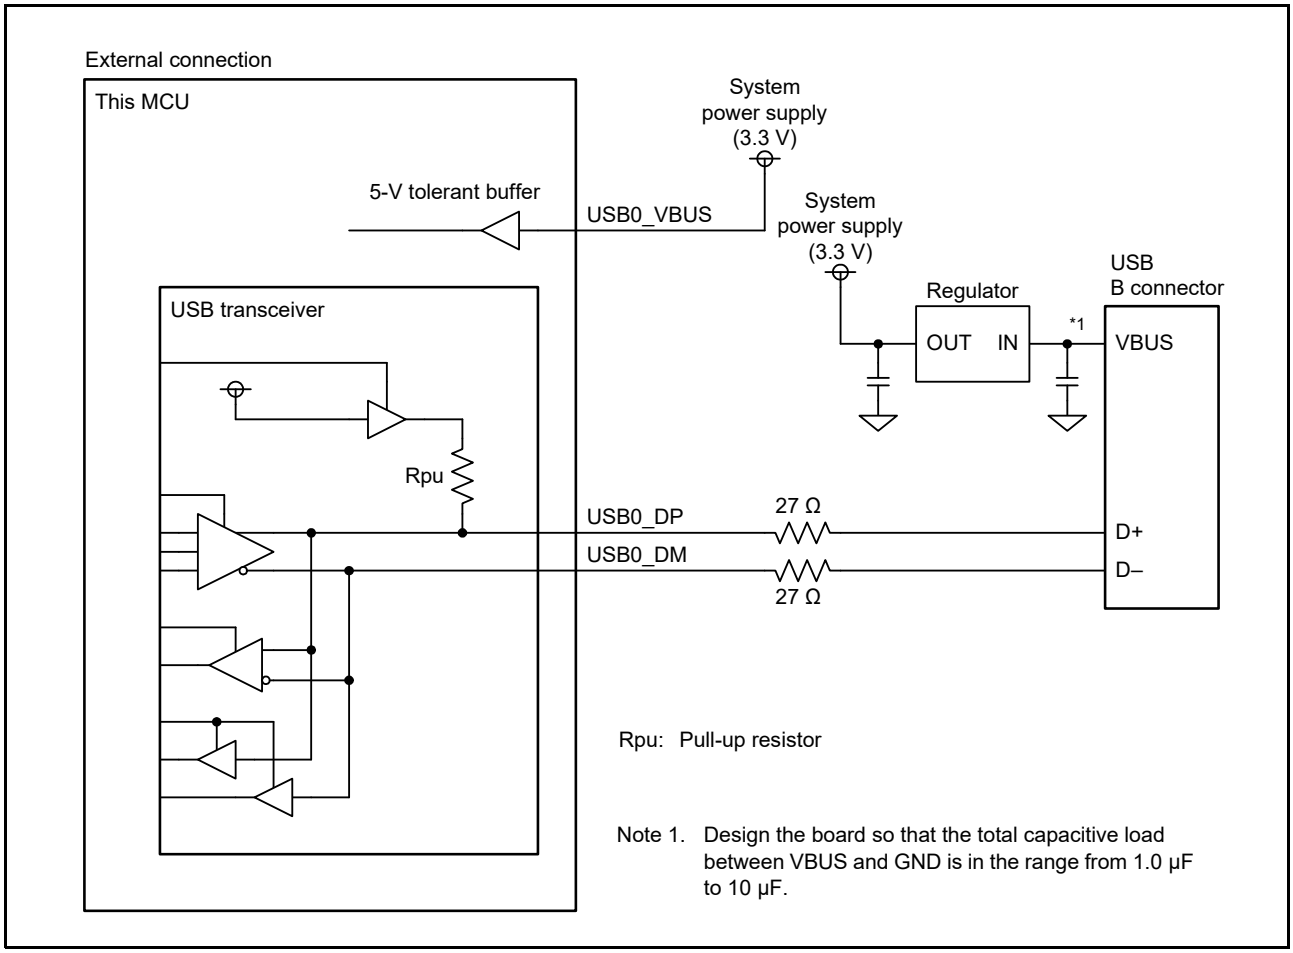

Figure 40.5 Example of Connection between Bus-Powered Function and USB Connector

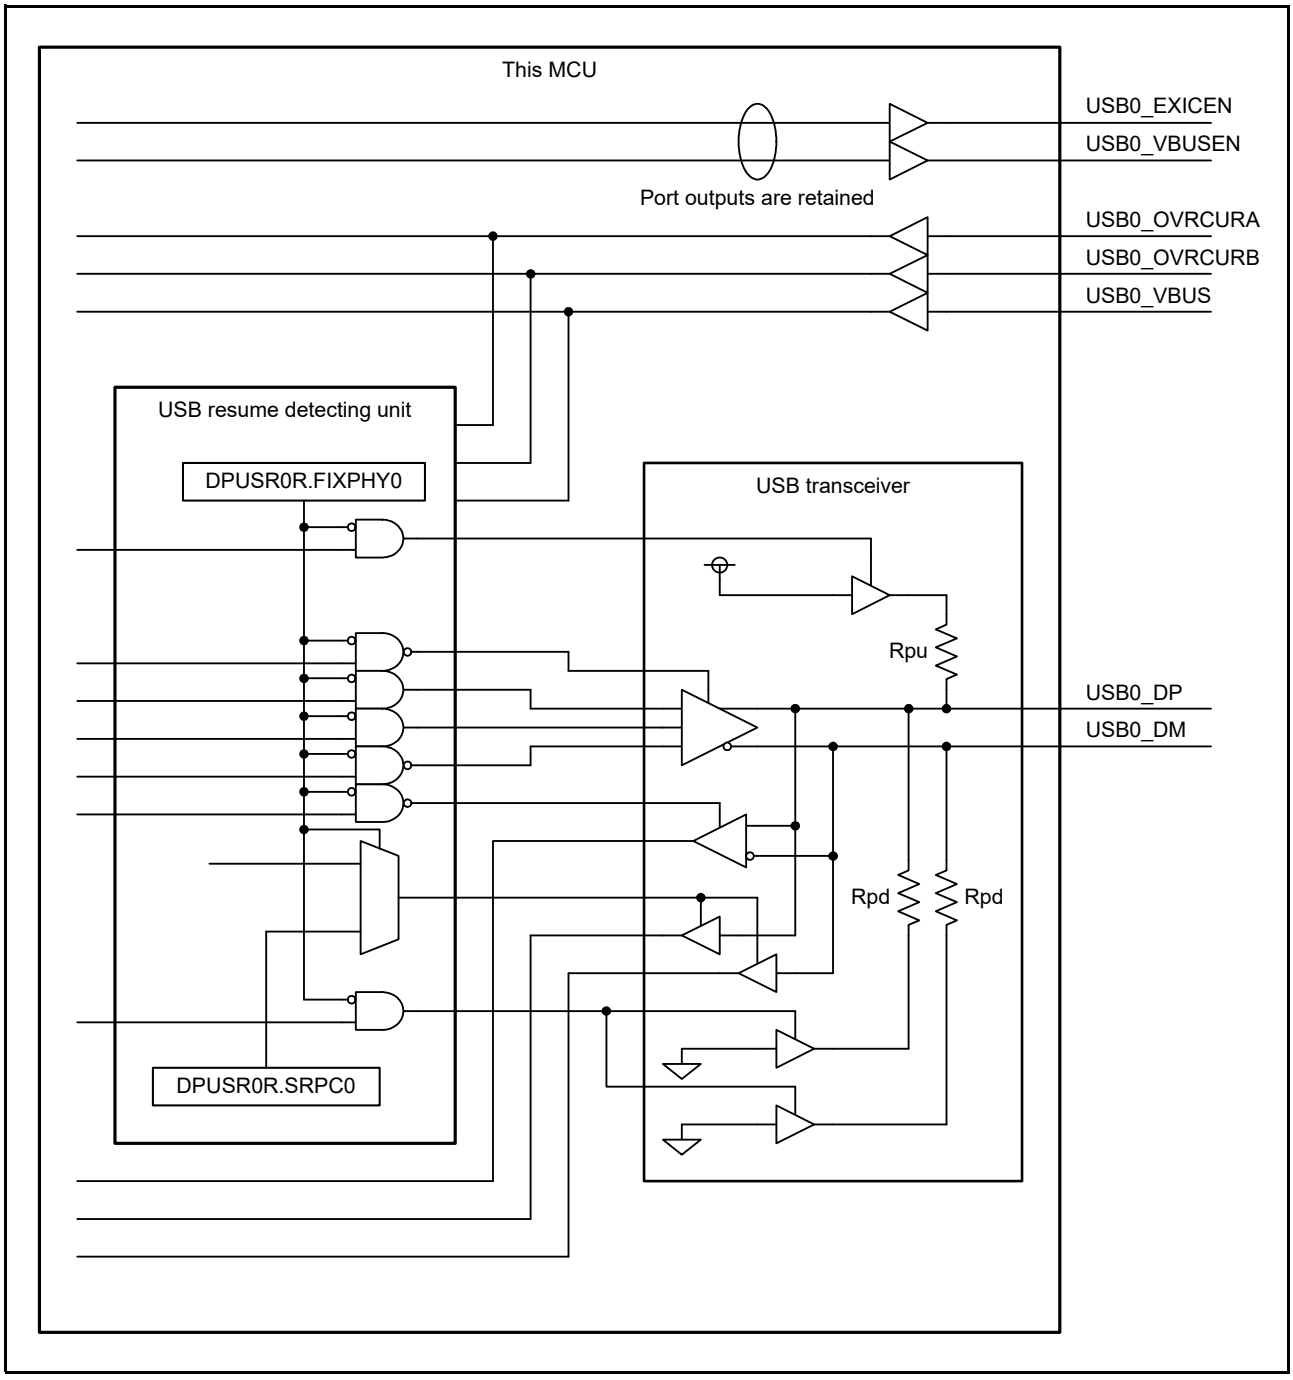
The examples of external circuits given in this section are simplified circuits, and their operation in every system is not guaranteed.

40.3.1.5 Release from Deep Software Standby Mode 1 Due to USB Suspend/Resume Interrupts

Deep software standby mode 1 can be canceled by a USB suspend/resume interrupt.
A USB suspend/resume interrupt is detected at the USB resume detecting unit. The USB resume detecting unit controls and monitors the I/O pins for USB to detect USB suspend/resume interrupts.
Figure 40.6 shows a schematic diagram of connection between the USB resume detecting unit and the I/O pins for USB0.



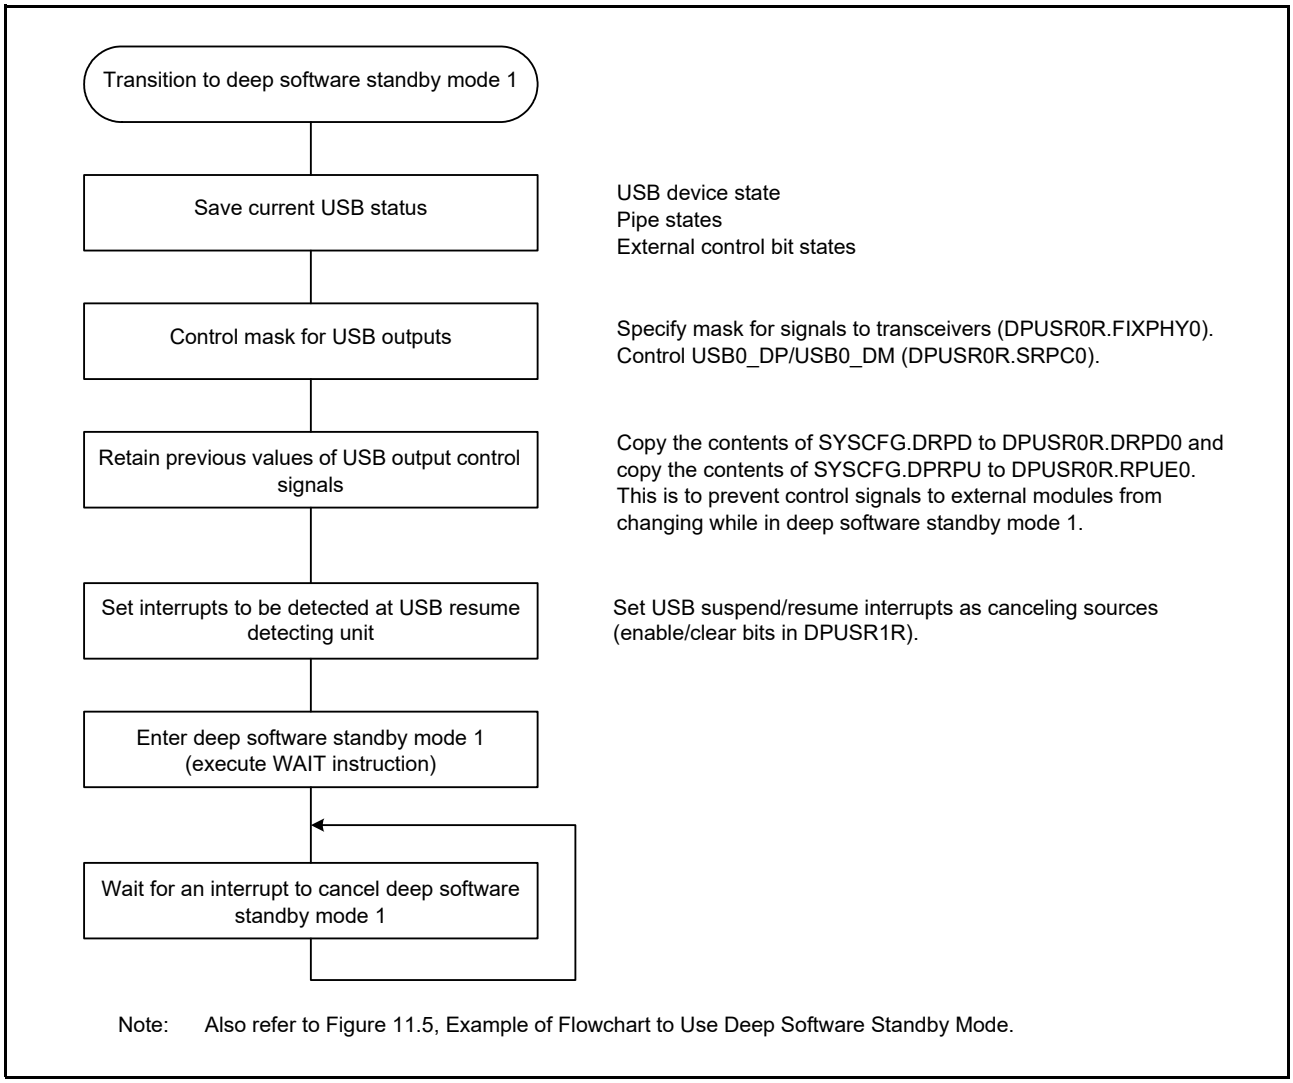


Figure 40.6 Overview of Connection between USB Resume Detecting Unit and USB I/O Pins

Table 40.12 shows the USB suspend/resume interrupt sources and their corresponding I/O pins.

Table 40.12 USB Suspend/Resume Interrupt Sources and Corresponding I/O Pins

USB Operating Mode	Source	Pin Name
Function/OTG	Resume	USB0_DP
Host/OTG	Connection/Disconnection	USB0_DP/USB0_DM
Function	Connection/Disconnection	USB0_VBUS
Host	Overcurrent detection	USB0_OVRCURA
OTG	Overcurrent detection	USB0_OVRCURA/USB0_OVRCURB

Figure 40.7 shows a flowchart for setting the USB when entering deep software standby mode 1 while the host controller or function controller is selected. Figure 40.8 shows a flowchart for setting the USB when canceling deep software standby mode 1 while the host controller is selected. Figure 40.9 shows a flowchart for setting the USB when canceling deep software standby mode 1 while the function controller is selected.

40.3.2 Interrupt Sources

Table 40.13 lists the interrupt sources in the USB.

When an interrupt generation condition is satisfied and the interrupt output is enabled using the corresponding interrupt enable register, a USB interrupt request is issued the Interrupt Controller (ICU) and an USB interrupt will be generated.

Table 40.13 Interrupt Sources

Bit to be Set	Name	Interrupt Source	Function That Generates the Interrupt	Status Flag
VBINT	VBUS interrupt	• When a change in the state of the USB0_VBUS input pin has been detected (low to high or high to low)	Host/function*1	INTSTS0. VBSTS
RESM	Resume interrupt	• When a change in the state of the USB bus has been detected in the suspended state (J-state to K-state or J-state to SE0)	Function	—
SOFR	Frame number update interrupt	[Host controller is selected] • When an SOF packet with a different frame number has been transmitted [Function controller is selected] • When an SOF packet with a different frame number has been received	Host/function	—
DVST	Device state transition interrupt	• When a device state transition has been detected (any of the following conditions) A USB bus reset detected Suspended state detected SET_ADDRESS request received SET_CONFIGURATION request received	Function	INTSTS0. DVSQ[2:0]
CTRT	Control transfer stage transition interrupt	• When a stage transition has been detected in control transfer (any of the following conditions) Setup stage completed Control write transfer status stage transition Control read transfer status stage transition Control transfer completed A control transfer sequence error occurred	Function	INTSTS0. CTSQ[2:0]
BEMP	Buffer empty interrupt	• When transmission of all data in the buffer memory has been completed and the buffer has become empty • When a packet larger than the maximum packet size has been received	Host/function	BEMPSTS. PIPEnBEMP
NRDY	Buffer not ready interrupt	[Host controller is selected] • When STALL has been received from the peripheral device for the issued token • When a response has not been received correctly from the peripheral device for the issued token (no response was returned three consecutive times or a packet reception error occurred three consecutive times) • When an overrun/underrun occurred during isochronous transfer [Function controller is selected] • When NAK has been returned for an IN or OUT token while the PID[1:0] bits are 01b (BUF) • When a CRC error or a bit stuffing error occurred during data reception in isochronous transfer • When an overrun/underrun occurred during data reception in isochronous transfer	Host/function	NRDYSTS. PIPEnNRDY
BRDY	Buffer ready interrupt	• When the buffer has become ready (reading or writing is enabled)	Host/function	BRDYSTS. PIPEnBRDY
OVRCR	Overcurrent input change interrupt	• When a change in the state of the USB0_OVRCURA or USB0_OVRCURB input pin has been detected (low to high or high to low)	Host	INTSTS1. OVRCR
BCHG	Bus change interrupt	• When a change of USB bus state has been detected	Host/function	SYSSTS0. LNST[1:0]
DTCH	Disconnection detection during full-speed operation	• When disconnection of a peripheral device has been detected in full-speed operation	Host	DVSTCTR0. RHST[2:0]
ATTCH	Device connection detection	• When J-state or K-state is detected on the USB port for 2.5 µs. Used for checking whether a peripheral device is connected.	Host	—
EOFERR	EOF error detection	• When an EOF error of a peripheral device has been detected	Host	—
SACK	Normal setup operation	• When the normal response (ACK) for the setup transaction has been received	Host	—
SIGN	Setup error	• When a setup transaction error (no response or ACK packet corruption) was detected three consecutive times	Host	—

Note 1. Though this interrupt can be generated while the host function is selected, it is not usually used with the host function.

Figure 40.10 shows the circuits related to the interrupts in the USB.

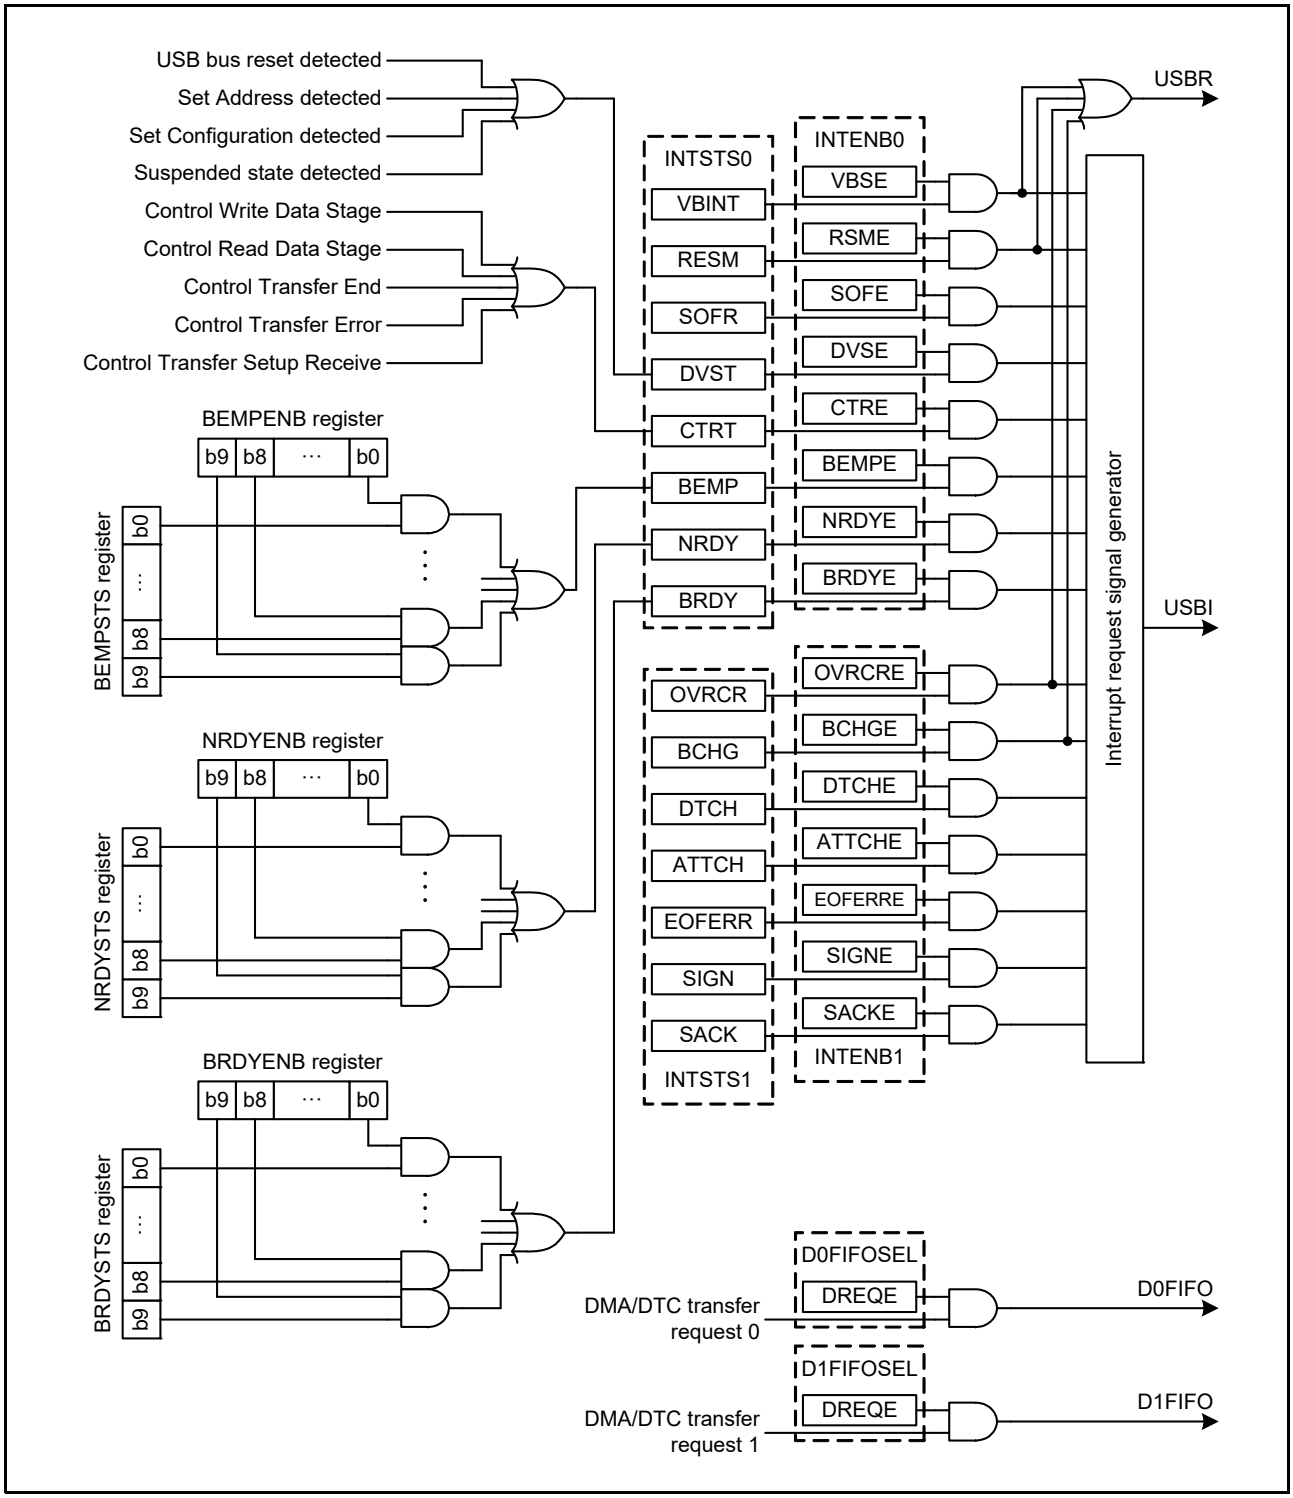

Figure 40.10 Circuits Related to Interrupts in USB

Table 40.14 shows the interrupts generated in the USB0.

Table 40.14 USB Interrupts

Interrupt Name	Interrupt Status Flag	DTC Activation	DMAC Activation
D0FIFO	DMA/DTC transfer request 0	Possible	Possible
D1FIFO	DMA/DTC transfer request 1	Possible	Possible
USBI	VBUS interrupt, resume interrupt, frame number update interrupt, device state transition interrupt, control transfer stage transition interrupt, buffer empty interrupt, buffer not ready interrupt, buffer ready interrupt, overcurrent input change interrupt, bus change interrupt, disconnection detection during full-speed operation, device connection detection, EOF error detection, normal setup operation, and setup error	Not possible	Not possible
USBR	VBUS interrupt, resume interrupt, overcurrent input change interrupt, and bus change interrupt	Not possible	Not possible

40.3.3 Interrupt Descriptions

40.3.3.1 BRDY Interrupt

The BRDY interrupt is generated when either of the host controller or function controller is selected. The following shows the conditions under which the USB sets 1 to a corresponding bit in the BRDYSTS register. Under this condition, the USB generates a BRDY interrupt if software has set 1 to the BRDYENB.PIPEnBRDYE bit that corresponds to the pipe and 1 to the INTENB0.BRDYE bit.
The conditions for generating and clearing the BRDY interrupt depend on the settings of the SOFCFG.BRDYM bit and PIPECFG.BFRE bit for each pipe as described below.

(1) When the SOFCFG.BRDYM Bit = 0 and the PIPECFG.BFRE Bit = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.
On any of the following conditions, the USB generates an internal BRDY interrupt request trigger and sets 1 to the BRDYSTS.PIPEnBRDY flag corresponding to the pertinent pipe.

(a) For the pipe in the transmitting direction:

- When the DIR bit is changed from 0 to 1 by software.
- When packet transmission is completed using the pertinent pipe while write-access from the CPU to the FIFO buffer for the pertinent pipe is disabled (when the BSTS flag is read as 0).
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode.
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is completed.
- When the hardware flushes the buffer of the pipe for isochronous transfers.
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to make transition from the write-disabled to write-enabled state.

No request trigger is generated for the DCP (that is, during data transmission for control transfers).

(b) For the pipe in the receiving direction:

- When packet reception is completed successfully thus enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the pertinent pipe is disabled (when the BSTS flag is read as 0).
  No request trigger is generated for the transaction in which data PID mismatch has occurred.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode.
  No request trigger is generated until completion of reading data from the currently-read FIFO buffer even if reception by the other FIFO buffer is completed.

When the function controller is selected, the BRDY interrupt is not generated in the status stage of control transfers.
The BRDY interrupt status of the pertinent pipe can be set to 0 by writing 0 to the corresponding PIPEnBRDY flag through software. In this case, 1s should be written to the PIPEnBRDY flags for the other pipes.
Clear the BRDY status before accessing the FIFO buffer.

(2) When the SOFCFG.BRDYM Bit = 0 and the PIPECFG.BFRE Bit = 1

With these settings, the USB generates a BRDY interrupt on completion of reading all data for a single transfer using the pipe in the receiving direction, and sets 1 to the bit in the BRDYSTS register corresponding to the pertinent pipe.
On any of the following conditions, the USB determines that the last data for a single transfer has been received.

- When a short packet including a zero-length packet is received.
- When the pipe n transaction counter register (PIPEnTRN) is used and the number of packets specified by the PIPEnTRN register are completely received.

When the pertinent data is completely read after any of the above conditions has been satisfied, the USB determines that all data for a single transfer has been completely read.
When a zero-length packet is received while the FIFO buffer is empty, the USB module determines that all data for a single transfer has been completely read when the FRDY flag in the FIFO port control register is 1 and the DTLN[8:0] flags are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the corresponding port control register through software.
With these settings, the USB does not detect a BRDY interrupt for the pipe in the transmitting direction.
The BRDY interrupt status of the pertinent pipe can be set to 0 by writing 0 to the corresponding BRDYSTS.PIPEnBRDY flag through software. In this case, 1s should be written to the PIPEnBRDY flags for the other pipes.
In this mode, the PIPECFG.BFRE bit setting should not be modified until all data for a single transfer has been processed. When it is necessary to modify the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pertinent pipe should be cleared using the PIPEnCTR.ACLRM bit.

(3) When the SOFCFG.BRDYM Bit = 1 and the PIPECFG.BFRE Bit = 0

With these settings, the BRDYSTS.PIPEnBRDY values are linked to the BSTS flag setting for each pipe. In other words, the BRDY interrupt status flags (PIPEnBRDY) are set to 1 or 0 by the USB depending on the FIFO buffer status.

(a) For the pipe in the transmitting direction:

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for write access, and are set to 0 when it is not ready.
However, the BRDY interrupt is not generated even if the DCP in the transmitting direction is ready for write access.

(b) For the pipe in the receiving direction:

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for read access, and are set to 0 when all data have been read (not ready for read access).
When a zero-length packet is received while the FIFO buffer is empty, the pertinent bit is set to 1 and the BRDY interrupt is continuously generated until BCLR = 1 is written through software.
With this setting, the PIPEnBRDY flag cannot be set to 0 through software.
When the SOFCFG.BRDYM bit is set to 1, all PIPECFG.BFRE bits (for all pipes) should be set to 0.

Figure 40.11 shows the timing of BRDY interrupt generation.

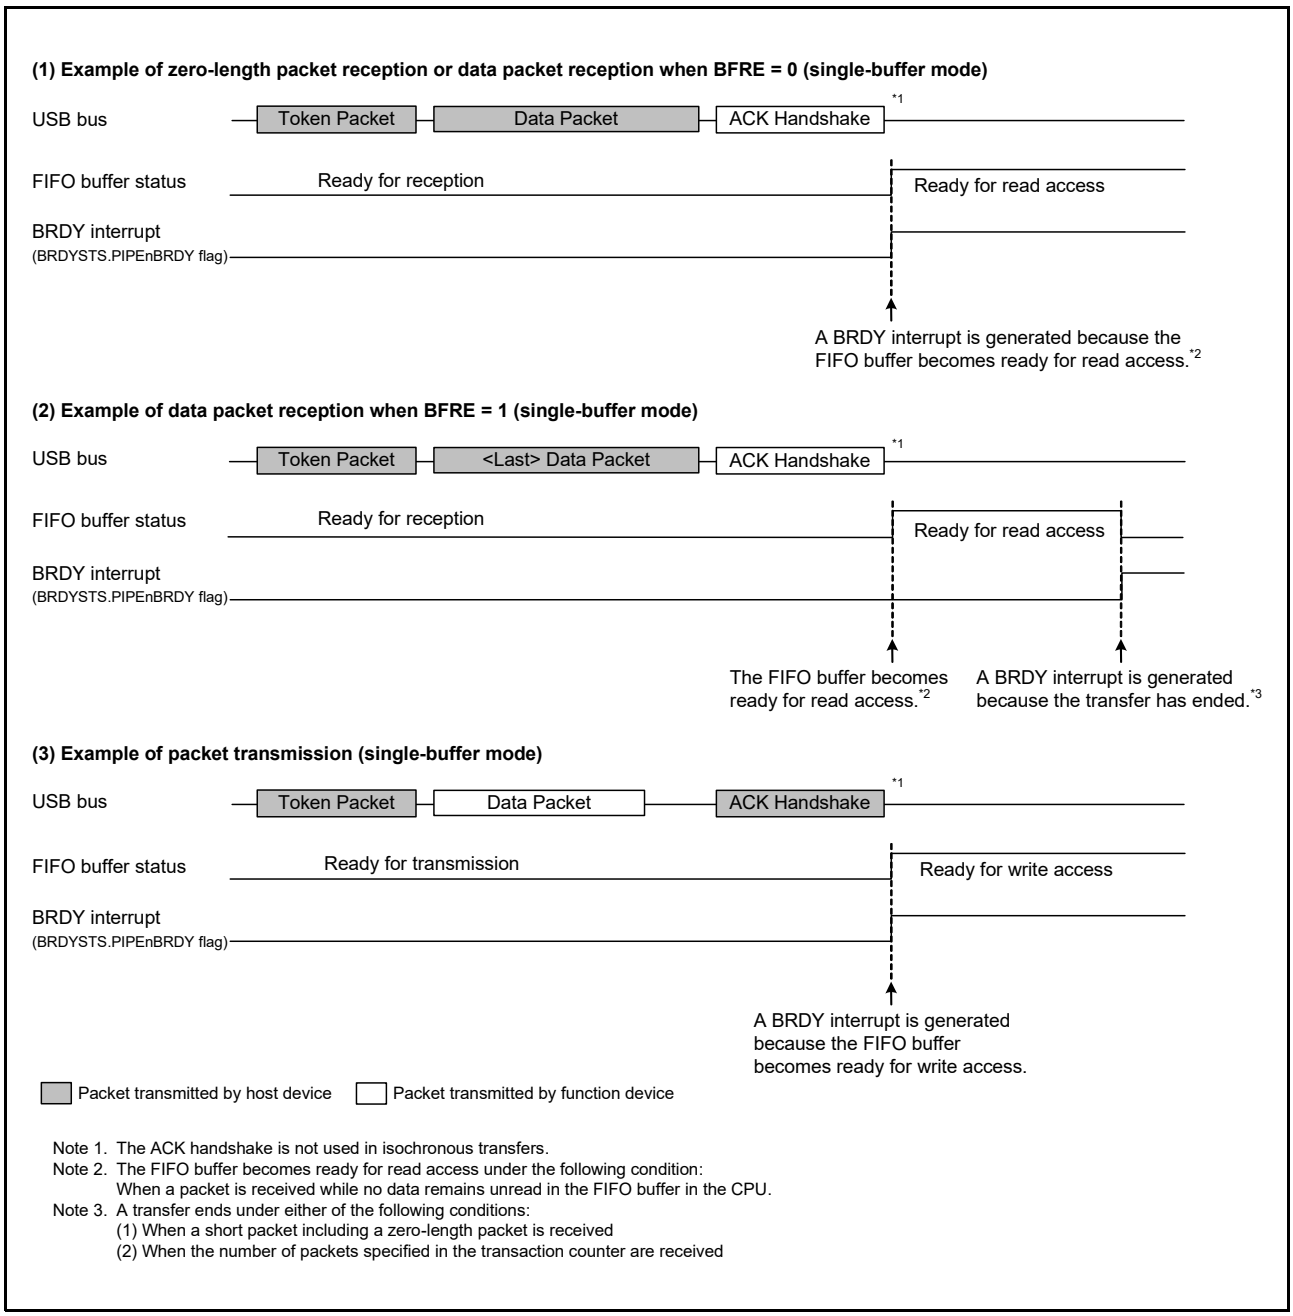

Figure 40.11 Timing of BRDY Interrupt Generation

The condition that USB clears the INTSTS0.BRDY flag depends on the SOFCFG.BRDYM bit setting. Table 40.15 shows the condition for clearing the BRDY flag.

Table 40.15 Condition for Clearing BRDY Flag

BRDYM Bit	Condition for Clearing BRDY Flag
0	The USB sets the BRDY flag to 0 when all bits in the BRDYSTS register have been set to 0 by software.
1	The USB sets the BRDY flag to 0 when the BSTS flags for all pipes have become 0.

40.3.3.2 NRDY Interrupt

On generating an internal NRDY interrupt request for the pipe whose PID[1:0] bits are set to 01b (BUF) by software, the USB sets the corresponding NRDYSTS.PIPEnNRDY flag to 1. If the corresponding bit in the NRDYENB register has been set to 1 by software, the USB sets the INTSTS0.NRDY flag to 1 and generates a USB interrupt.
The following describes the conditions on which the USB generates the internal NRDY interrupt request for a given pipe.
Note that the internal NRDY interrupt request is not generated during setup transaction execution when the host controller is selected. During setup transactions when the host controller is selected, the SACK or SIGN interrupt is detected.
The internal NRDY interrupt request is not generated during status stage execution of the control transfer when the function controller is selected.

(1) When Host Controller is Selected

(a) For the pipe in the transmitting direction:

On any of the following conditions, the USB detects an NRDY interrupt.

- For the pipe for isochronous transfers, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer.
  In this case, the USB transmits a zero-length packet following the OUT token and sets the bit corresponding to the NRDYSTS.PIPEnNRDY flag and the FRMNUM.OVRN flag to 1.
- During communications other than setup transactions using the pipe for the transfers other than isochronous transfers, when any combination of the following two cases occur three consecutive times: 1) no response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device) and 2) an error is detected in the packet from the peripheral device.
  In this case, the USB sets the bit corresponding to the PIPEnNRDY flag to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 00b (NAK).
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device.
  In this case, the USB sets the bit corresponding to the PIPEnNRDY flag to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL).

(b) For the pipe in the receiving direction:

- For the pipe for isochronous transfers, when the time to issue an IN token comes while there is no space available in the FIFO buffer.
  In this case, the USB discards the received data for the IN token and sets the PIPEnNRDY flag corresponding to the pipe and the OVRN flag to 1.
  When a packet error is detected in the received data for the IN token, the USB also sets the FRMNUM.CRCE flag to 1.
- For the pipe for the transfers other than isochronous transfers, when any combination of the following two cases occur three consecutive times: 1) no response is returned from the peripheral device for the IN token issued by the USB (when timeout is detected before detection of the DATA packet from the peripheral device) and 2) an error is detected in the packet from the peripheral device.
  In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 00b (NAK).
- For the pipe for isochronous transfers, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device.
  In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe to 1. (The setting of the PID[1:0] bits of the pipe is not modified.)

- For the pipe for isochronous transfers, when a CRC error or a bit stuffing error is detected in the received data packet.
  In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe and the CRCE flag to 1.
- When the STALL handshake is received.
  In this case, the USB sets the PIPEnNRDY flag corresponding to the pipe to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL).

(2) When Function Controller is Selected

(a) For the pipe in the transmitting direction:

- When an IN token is received while there is no data to be transmitted in the FIFO buffer.
  In this case, the USB generates a NRDY interrupt request at the reception of the IN token and sets the NRDYSTS.PIPEnNRDY flag to 1.
  For the pipe for the isochronous transfers in which an interrupt is generated, the USB transmits a zero-length packet and sets the FRMNUM.OVRN flag to 1.

(b) For the pipe in the receiving direction:

- When an OUT token is received while there is no space available in the FIFO buffer.
  For the pipe for the isochronous transfers in which an interrupt is generated, the USB generates a NRDY interrupt request at the reception of the OUT token and sets the PIPEnNRDY flag to 1 and OVRN flag to 1.
  For the pipe for the transfers other than isochronous transfers in which an interrupt is generated, the USB generates a NRDY interrupt request when a NAK handshake is transferred after the data following the OUT token is received, and sets the PIPEnNRDY flag to 1.
  However, during re-transmission (due to data PID mismatch), the NRDY interrupt request is not generated. In addition, if an error occurs in the DATA packet, the NRDY interrupt request is not generated.
- For the pipe for isochronous transfers, when a token is not received successfully within an interval frame.
  In this case, the USB generates a NRDY interrupt request when SOF is received, and sets the PIPEnNRDY flag to 1.

Figure 40.12 shows the timing of NRDY interrupt generation when the function controller is selected.

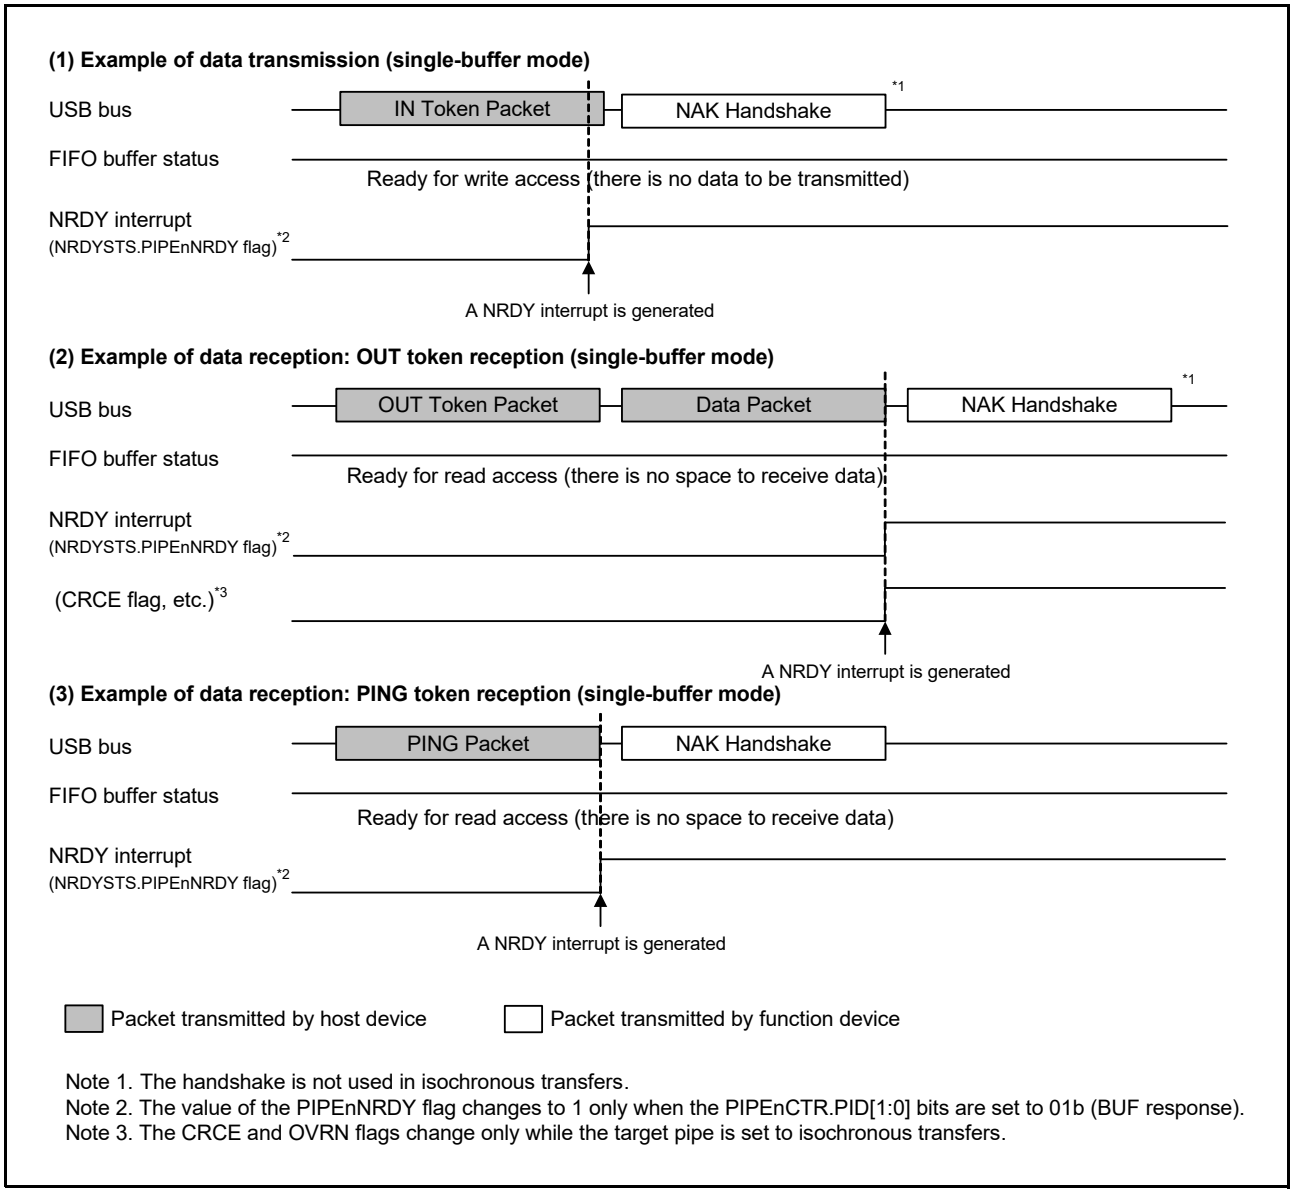

Figure 40.12 Timing of NRDY Interrupt Generation (When Function Controller is Selected)

40.3.3.3 BEMP Interrupt

On detecting a BEMP interrupt for the pipe whose PID[1:0] bits are set to 01b (BUF) by software, the USB sets the corresponding BEMPSTS.PIPEnBEMP flag to 1. If the corresponding bit in the BEMPENB register has been set to 1 by software, the USB sets the INTSTS0.BEMP flag to 1 and generates a USB interrupt.

The following describes the conditions on which the USB generates an internal BEMP interrupt request.

(1) For the pipe in the transmitting direction:

When the FIFO buffer of the corresponding pipe is empty on completion of transmission (including zero-length packet transmission).
In single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for the pipe other than DCP. However, the internal BEMP interrupt request is not generated on any of the following conditions.

- When the CPU or DMAC/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode.
- When the buffer is cleared (emptied) by setting the PIPEnCTR.ACLRM or the BCLR bit in the port control register to 1.
- When IN transfer (zero-length packet transmission) is performed during the control transfer status stage while the function controller is selected.

(2) For the pipe in the receiving direction:

When the successfully-received data packet size exceeds the specified maximum packet size.
In this case, the USB generates a BEMP interrupt request, sets the corresponding BEMPSTS.PIPEnBEMP flag to 1, discards the received data, and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL). Here, the USB returns no response when used as the host controller, and returns STALL response when used as the function controller.
However, the internal BEMP interrupt request is not generated on any of the following conditions.

- When a CRC error or a bit stuffing error is detected in the received data.
- When a setup transaction is being performed,
  Writing 0 to the BEMPSTS.PIPEnBEMP flag clears the status.
  Writing 1 to the BEMPSTS.PIPEnBEMP flag has no effect.

Figure 40.13 shows the timing of BEMP interrupt generation when the function controller is selected.

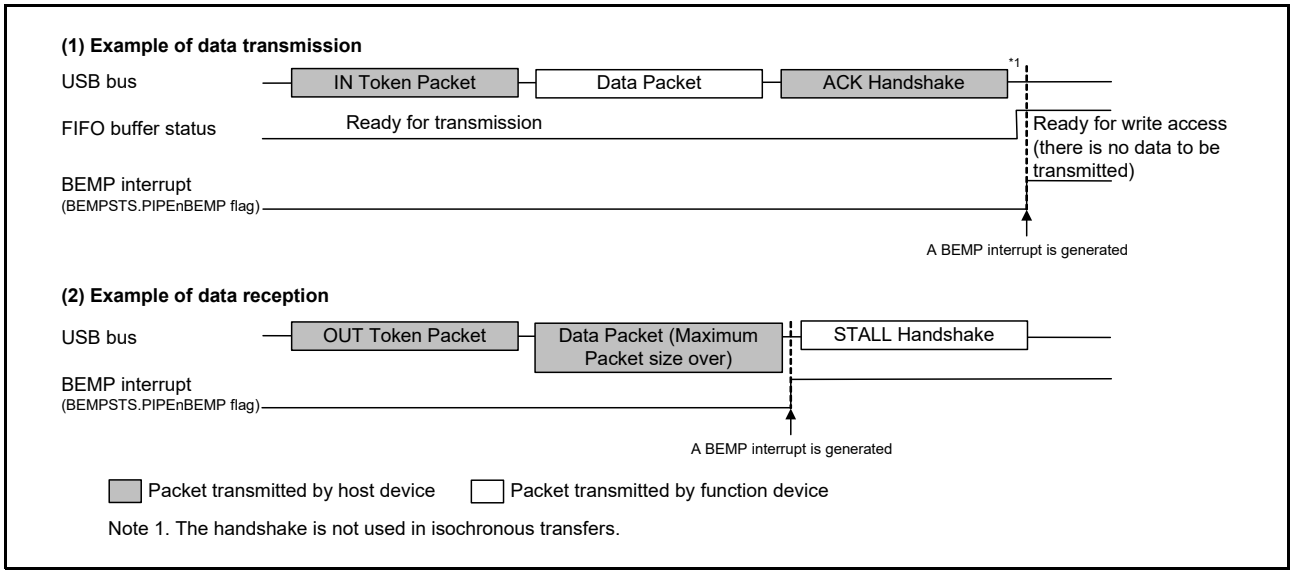

Figure 40.13 Timing of BEMP Interrupt Generation (When Function Controller is Selected)

40.3.3.4 Device State Transition Interrupt

Figure 40.14 is a diagram of device state transitions in the USB. The USB controls device state and generates device state transition interrupts. However, recovery from the suspended state (resume signal detection) is detected by means of the resume interrupt. The device state transition interrupts can be enabled or disabled individually using INTENB0. The device state to which a transition was made can be confirmed using the INTSTS0.DVSQ[2:0] flags.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is detected.

Device state can be controlled only when the function controller is selected. The device state transition interrupts can also be generated only when the function controller is selected.

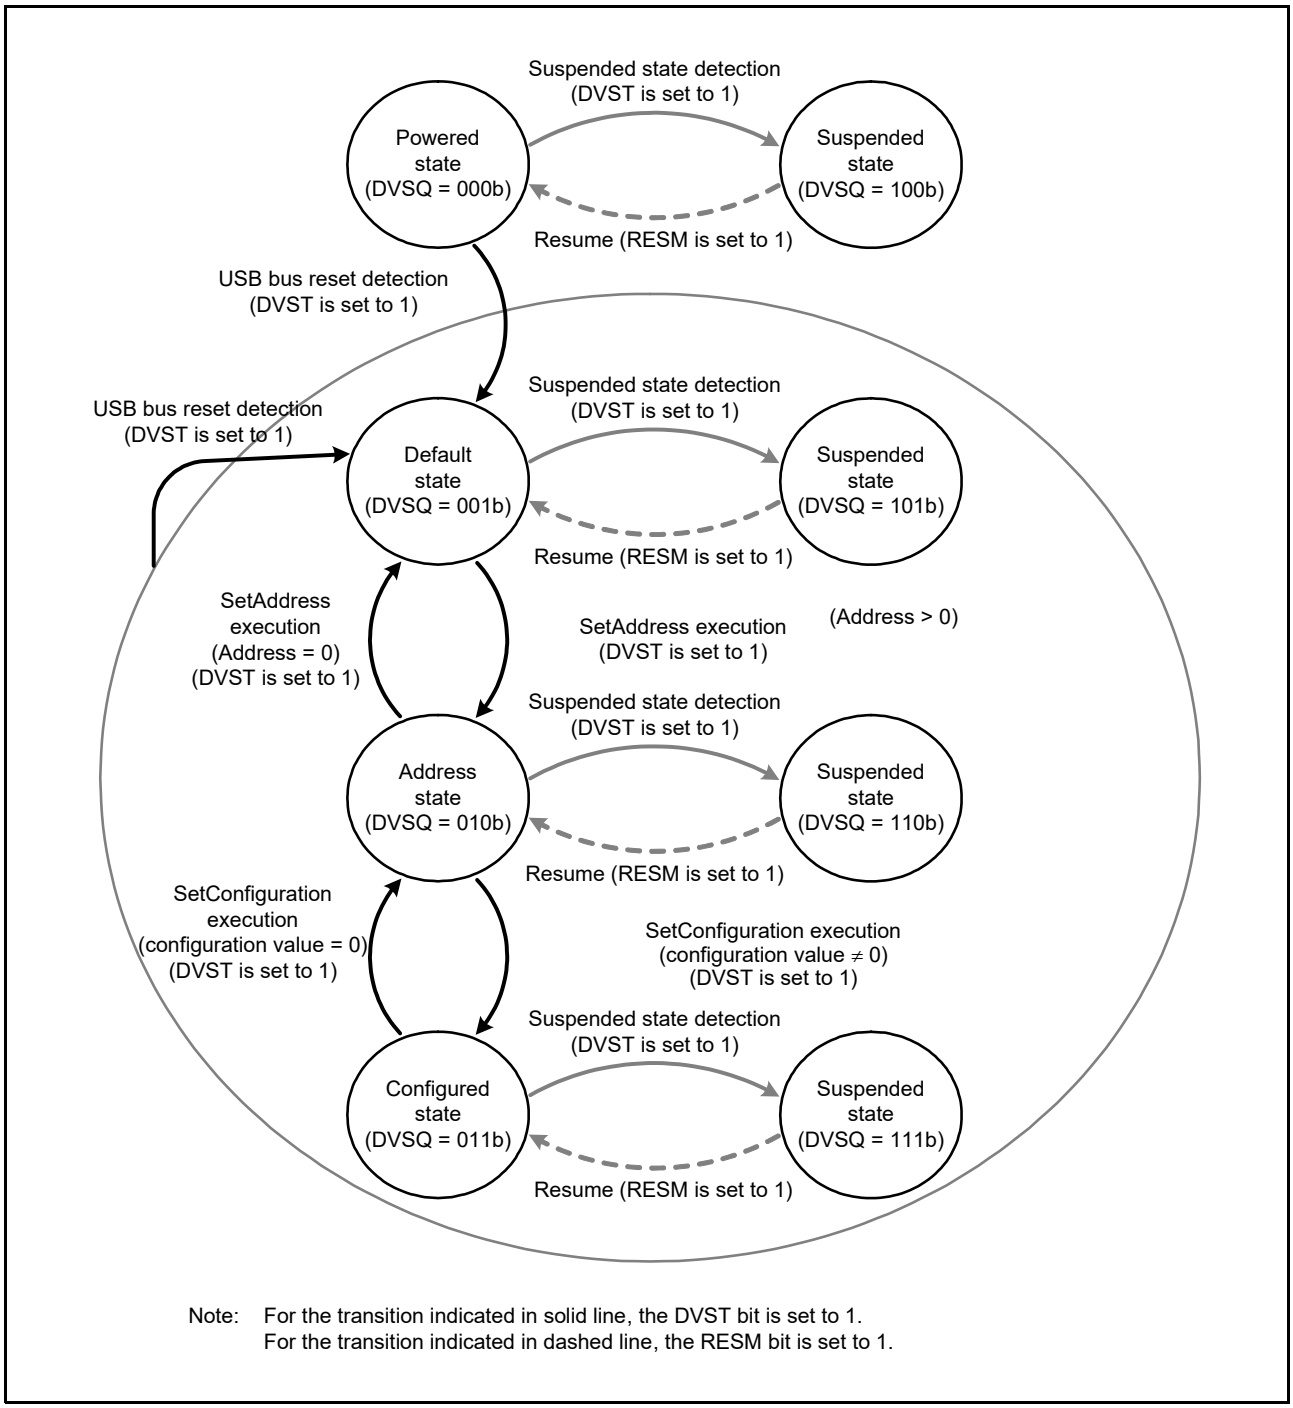

Figure 40.14 Device State Transitions

40.3.3.5 Control Transfer Stage Transition Interrupt

Figure 40.15 is a diagram of control transfer stage transitions in the USB. The USB controls the control transfer sequence and generates control transfer stage transition interrupts. The control transfer stage transition interrupts can be enabled or disabled individually using INTENB0. The transfer stage to which a transition was made can be confirmed using the INTSTS0.CTSQ[2:0] flags.

Control transfer stage transition interrupts are generated only when the function controller is selected.

The control transfer sequence errors are listed below. If an error occurs, the DCPCTR.PID[1:0] bits are set to 1xb (STALL response).

During control read transfer:

- An OUT token is received while no data has been transferred for the IN token at the data stage.
- An IN token is received at the status stage.
- A data packet with PID = DATA0 is received at the status stage.

During control write transfer:

- An IN token is received while no ACK response has been returned for the OUT token at the data stage.
- A data packet with PID = DATA0 is received for the first data packet at the data stage.
- An OUT token is received at the status stage

During no-data control transfers:

- An OUT token is received at the status stage.

At the control write transfer data stage, if the number of receive data exceeds the wLength value of the USB request, it cannot be recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT = 1), CTSQ[2:0] = 110b value is retained until the CTRT flag = 0 is written from the system (the interrupt status is cleared). Therefore, while CTSQ[2:0] = 110b is being held, the CTRT interrupt that ends the setup stage will not be generated even if a new USB request is received. (The USB retains the setup stage end, and after the interrupt status has been cleared by software, a setup stage end interrupt is generated.)

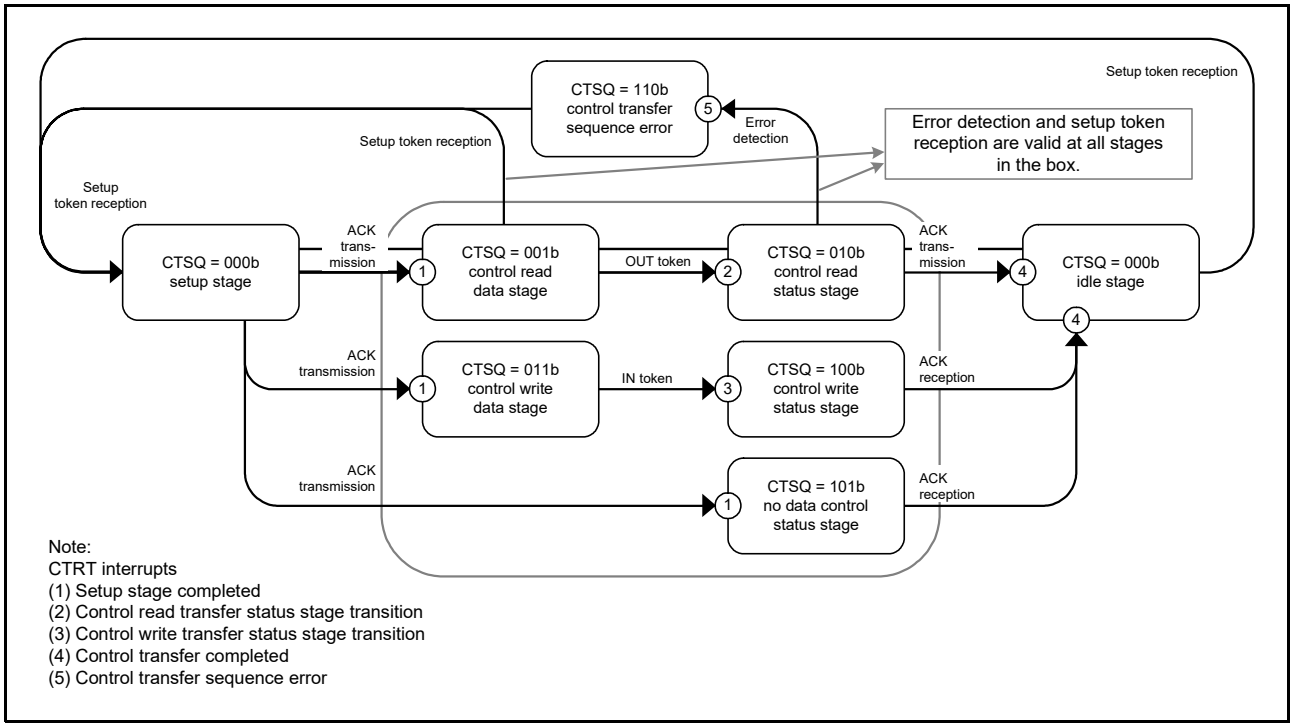

Figure 40.15 Control Transfer Stage Transitions

40.3.3.6 Frame Update Interrupt

With the host controller selected, an interrupt is generated at the timing when the frame number is updated. With the function controller selected, an SOFR interrupt is generated when the frame number is updated.
When the function controller is selected, the USB updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

40.3.3.7 VBUS Interrupt

When the USB0_VBUS pin level changes, a VBUS interrupt is generated. The level of the USB0_VBUS pin can be checked with the INTSTS0.VBSTS flag. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. However, if the system is activated with the host controller connected, the first VBUS interrupt is not generated because there is no change in the USB0_VBUS pin level.

40.3.3.8 Resume Interrupt

When the function controller is selected, a resume interrupt is generated when the device state is the suspended state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the suspended state is detected by means of the resume interrupt.
When the host controller is selected, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

40.3.3.9 OVRCR Interrupt

An OVRCR interrupt is generated when the USB0_OVRCURA or USB0_OVRCURB pin level has changed. The levels of the USB0_OVRCURA and USB0_OVRCURB pins can be checked with the SYSSTS0.OVCMON[1:0] bits. The external power supply IC can check whether overcurrent has been detected using the OVRCR interrupt.
For OTG connection, whether a change has been detected in the VBUS comparator can be checked using the OVRCR interrupt.

40.3.3.10 BCHG Interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether the peripheral device is connected and can also be used to detect a remote wakeup when the host controller is selected. The BCHG interrupt is generated regardless of whether the host controller or function controller is selected.

40.3.3.11 DTCH Interrupt

A DTCH interrupt is generated when disconnection of the USB bus is detected while the host controller is selected. The USB detects bus disconnection based on USB Specification 2.0.
After detecting a DTCH interrupt, the USB controls hardware as described below (irrespective of the value set in the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the pertinent port should be terminated by software and make a transition to the wait state for bus connection to the pertinent port (wait state for ATTCH interrupt generation).

- Modifies the DVSTCTR0.UACT bit for the port in which a DTCH interrupt has been detected to 0.
- Puts the port in which a DTCH interrupt has been generated into the idle state.

40.3.3.12 SACK Interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet has been received from the peripheral device with the host controller selected. The SACK interrupt can be used to confirm that the setup transaction has been completed successfully.

40.3.3.13 SIGN Interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet has not been correctly received from the peripheral device three consecutive times with the host controller selected. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

40.3.3.14 ATTCH Interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5 µs with the host controller selected. To be more specific, an ATTCH interrupt is detected on any of the following conditions.

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5 µs.
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5 µs.

40.3.3.15 EOFERR Interrupt

An EOFERR interrupt is generated when it is detected that communication is not completed at the EOF2 timing prescribed in USB Specification 2.0.
After detecting an EOFERR interrupt, the USB controls hardware as described below (irrespective of the value set in the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the pertinent port should be terminated by software and perform re-enumeration of the pertinent port.

- Modifies the DVSTCTR0.UACT bit for the port in which an EOFERR interrupt has been detected to 0.
- Puts the port in which an EOFERR interrupt has been generated into the idle state.

40.3.4 Pipe Control

Table 40.16 lists the pipe settings for the USB. With USB data transfer, data transfer is carried out using the pipe that the software has associated with the endpoint. The USB has ten pipes that are used for data transfer.
Appropriate settings should be made for each of the pipes according to the specifications of the system.

Table 40.16 Pipe Settings

Register Name	Bit Name	Setting	Remarks
DCPCFG PIPECFG	TYPE[1:0]	Specifies the transfer type	Pipes 1 to 9: Can be set
	BFRE	Selects the BRDY interrupt mode	Pipes 1 to 5: Can be set
	DBLB	Selects double buffer mode	Pipes 1 to 5: Can be set
	DIR	Selects transfer direction	IN or OUT can be set
	EPNUM[3:0]	Endpoint number	Pipes 1 to 9: Can be set A value other than 0000b should be set when the pipe is used.
	SHTNAK	Selects disabled state for pipe when transfer ends	Pipes 1 and 2: Can be set (only when bulk transfer has been selected) Pipes 3 to 5: Can be set
DCPMAXP PIPEMAXP	DEVSEL[3:0]	Selects a device	Referenced only when the host controller is selected.
	MXPS[8:0]	Maximum packet size	Compliant with USB Specification 2.0.
PIPEPERI	IFIS	Buffer flush	Pipes 1 and 2: Can be set (only when isochronous transfer has been selected) Pipes 3 to 9: Cannot be set
	IITV[2:0]	Interval counter	Pipes 1 and 2: Can be set (only when isochronous transfer has been selected) Pipes 3 to 5: Cannot be set Pipes 6 to 9: Can be set (only when the host controller has been selected)
DCPCTR PIPEnCTR	BSTS	Buffer status	For the DCP, receive buffer status and transmit buffer status are switched with the ISEL bit.
	INBUFM	IN buffer monitor	Available only for pipes 1 to 5.
	SUREQ	SETUP request	Can be set only for the DCP. Can be controlled only when the host controller has been selected.
	SUREQCLR	SUREQ clear	Can be set only for the DCP. Can be controlled only when the host controller has been selected.
	ATREPM	Auto response mode	Pipes 1 to 5: Can be set Can be set only when the function controller has been selected.
	ACLRM	Auto buffer clear	Pipes 1 to 9: Can be set
	SQCLR	Sequence clear	Clears the data toggle bit.
	SQSET	Sequence set	Sets the data toggle bit.
	SQMON	Sequence monitor	Monitors the data toggle bit.
	PBUSY	Pipe busy status	
	PID[1:0]	Response PID	Refer to section 40.3.4.6, Response PID.
PIPEnTRE	TRENB	Transaction counter enable	Pipes 1 to 5: Can be set
	TRCLR	Current transaction counter clear	Pipes 1 to 5: Can be set
PIPEnTRN	—	Transaction counter	Pipes 1 to 5: Can be set

40.3.4.1 Pipe Control Register Switching Procedures

The following bits in the pipe control registers can be modified only when USB communication is prohibited (PID[1:0] = 00b (NAK)).

The following shows the registers and bits that should not be modified when USB communication is enabled (PID[1:0] = 01b (BUF)).

- Bits in the DCPCFG and DCPMAXP registers
- The SQCLR and SQSET bits in the DCPCTR register
- Bits in registers PIPECFG, PIPEMAXP, and PIPEPERI
- The ATREPM, ACLRM, SQCLR, and SQSET bits in the PIPEnCTR register
- Bits in the PIPEnTRE and PIPEnTRN registers

In order to modify the above bits in the USB communication enabled (PID[1:0] = 01b (BUF)) state, follow the procedure shown below:

1. A request to modify bits in the pipe control register occurs.
2. Modify the PID[1:0] bits corresponding to the pipe to 00b (NAK).
3. Wait until the corresponding PBUSY flag is set to 0.
4. Modify the bits in the pipe control register.

The following bits in the pipe control registers can be modified only when the pertinent pipe information has not been set by the CURPIPE[3:0] bits in registers CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Registers that should not be set when the CURPIPE[3:0] bits are set:

- Bits in the DCPCFG and DCPMAXP register
- Bits in registers PIPECFG, PIPEMAXP and PIPEPERI

In order to modify pipe information, the CURPIPE[3:0] bits in the port select registers should be set to a pipe other than the pipe to be modified. For the DCP, the buffer should be cleared using the BCLR bit in the port control register after the pipe information is modified.

40.3.4.2 Transfer Types

The PIPECFG.TYPE[1:0] bits are used to specify the transfer type for each pipe. The transfer types that can be set for the pipes are as follows.

- DCP: No setting is necessary (fixed at control transfer).
- Pipes 1 and 2: These should be set to bulk transfer or isochronous transfer.
- Pipes 3 to 5: These should be set to bulk transfer.
- Pipes 6 to 9: These should be set to interrupt transfer.

40.3.4.3 Endpoint Number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to endpoint 15.

- DCP: No setting is necessary (fixed at endpoint 0).
- Pipes 1 to 9: The endpoint numbers from 1 to 15 should be selected and set.
  These should be set so that the combination of the PIPECFG.DIR bit and EPNUM[3:0] bits is unique.

40.3.4.4 Maximum Packet Size Setting

The DCPMAXP.MXPS[6:0] bits and the PIPEMAXP.MXPS[8:0] bits are used to specify the maximum packet size for each pipe. DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined by USB Specification 2.0. For pipes 6 to 9, 64 bytes are the upper limit of the maximum packet size. The maximum packet size should be set before beginning the transfer (PID[1:0] = 01b (BUF)).

- DCP: Set 8, 16, 32, or 64.
- Pipes 1 to 5: Set 8, 16, 32, or 64 when using bulk transfer.
- Pipes 1 and 2: Set a value between 1 and 256 when using isochronous transfer.
- Pipes 6 to 9: Set a value between 1 and 64.

40.3.4.5 Transaction Counter (For Pipes 1 to 5 in Reading Direction)

When the specified number of transactions has been completed in the data packet receiving direction, the USB recognizes that the transfer has ended. Two transaction counters are provided: one is the PIPEnTRN register that specifies the number of transactions to be executed and the other is the current counter that internally counts the number of executed transactions. With the PIPECFG.SHTNAK bit set to 1, when the current counter value matches the specified number of transactions, the corresponding PIPEnCTR.PID[1:0] bits are set to 00b (NAK) and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The information read from PIPEnTRN differs depending on the setting of the PIPEnTRE.TRENB bit.

- The TRENB bit = 0: The specified transaction counter value can be read.
- The TRENB bit = 1: The current counter value indicating the internally counted number of executed transactions can be read.

When operating the TRCLR bit, the following should be noted.

- If the transactions are being counted and PID[1:0] = 01b (BUF), the current counter cannot be cleared.
- If there is any data left in the buffer, the current counter cannot be cleared.

40.3.4.6 Response PID

The PID[1:0] bits in the DCPCTR and PIPEnCTR registers are used to set the response PID for each pipe.
The following shows the USB operation with various response PID settings:

(1) Response PID settings when the host controller is selected:

The response PID is used to specify the execution of transactions.

- NAK setting: Using pipes is disabled. No transaction is executed.
- BUF setting: Transactions are executed based on the status of the buffer memory.
  For OUT direction: If there are transmit data in the buffer memory, an OUT token is issued.
  For IN direction: If there is an area to receive data in the buffer memory, an IN token is issued.
- STALL setting: Using pipes is disabled. No transaction is executed.

Note: Setup transactions for the DCP are set with the DCPCTR.SUREQ bit.

(2) Response PID settings when the function controller is selected:

The response PID is used to specify the response to transactions from the host.

- NAK setting: The NAK response is returned in response to the generated transaction.
- BUF setting: Responses are made to transactions according to the status of the buffer memory.
- STALL setting: The STALL response is returned in response to the generated transaction.

Note: For setup transactions, an ACK response is returned regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

The USB may write to the PID[1:0] bits, depending on the results of the transaction as described below.

(3) When the host controller has been selected and the response PID is set by hardware:

- NAK setting: In the following cases, PID[1:0] = 00b (NAK) is set and issuing of tokens is automatically stopped:
  When a transfer other than isochronous transfer has been performed and an NRDY interrupt is generated.
  (For details, refer to section 40.3.3.2, NRDY Interrupt.)
  - If a short packet is received when the PIPECFG.SHTNAK bit has been set to 1 for bulk transfer.
  - If the transaction counting ends when the SHTNAK bit has been set to 1 for bulk transfer.
- BUF setting: There is no BUF writing by the USB.
- STALL setting: In the following cases, PID[1:0] = 1xb (STALL) is set and issuing of tokens is automatically stopped:
  When STALL is received in response to the transmitted token.
  When the size of the receive data packet exceeds the maximum packet size.

(4) When the function controller has been selected and the response PID is set by hardware:

- NAK setting: In the following cases, PID[1:0] = 00b (NAK) is set and NAK is returned in response to transactions:
  When the SETUP token is received normally (DCP only).
  If the transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit has been set to 1 for bulk transfer.
- BUF setting: There is no BUF writing by the USB.
- STALL setting: In the following cases, PID[1:0] = 1xb (STALL) is set and STALL is returned in response to transactions:
  When a maximum packet size exceeded error is detected in the received data packet.
  When a control transfer sequence error has been detected (DCP only).

40.3.4.7 Data PID Sequence Bit

The USB automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON flag in the DCPCTR and PIPEnCTR registers. When data is transmitted, the sequence bit switches at the timing of ACK handshake reception. When data is received, the sequence bit switches at the timing of ACK handshake transmission. The DCPCTR.SQCLR bit and the PIPEnCTR.SQSET bit can be used to change the data PID sequence bit.

When the function controller has been selected and control transfer is used, the USB automatically sets the sequence bit when a stage transition is made. DATA1 is returned when the setup stage is ended. The sequence bit is not referenced and PID = DATA1 is returned in a status stage. Therefore, software settings are not required. However, when the host controller has been selected and control transfer is used, the sequence bit should be set by software at a stage transition. For the ClearFeature request transmission or reception, the data PID sequence bit should be set by software regardless of whether the host controller or function controller is selected.

40.3.4.8 Response PID = NAK Function

The USB has a function that disables pipe operation (response PID = NAK) at the timing at which the final data packet of a transaction is received (the USB automatically distinguishes this based on reception of a short packet or the transaction counter) by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the buffer memory, using this function enables reception of data packets in transfer units. If pipe operation has been disabled, software should set the pipe to the enabled state again (response PID = BUF).

The response PID = NAK function can be used only when bulk transfers are used.

40.3.4.9 Auto Response Mode

With the pipes for bulk transfer (pipe 1 to pipe 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (the PIPECFG.DIR bit = 0), OUT-NAK mode is entered, and during an IN transfer (the DIR bit = 1), null auto response mode is entered.

40.3.4.10 OUT-NAK Mode

With the pipes for bulk OUT transfer, NAK is returned in response to an OUT token and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To make a transition from normal mode to OUT-NAK mode, OUT-NAK mode should be specified in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). After pipe operation has been enabled, OUT-NAK mode becomes valid. However, if an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To make a transition from OUT-NAK mode to normal mode, OUT-NAK mode should be canceled in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). In normal mode, reception of OUT data is enabled.

40.3.4.11 Null Auto Response Mode

With the pipes for bulk IN transfer, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To make a transition from normal mode to null auto response mode, null auto response mode should be set in the pipe operation disabled state (response PID = NAK) before enabling pipe operation (response PID = BUF). After pipe operation has been enabled, null auto response mode becomes valid. Before setting null auto response mode, the PIPEnCTR.INBUFM = 0 should be confirmed because the mode can be set only when the buffer is empty. If the INBUFM flag is 1, the buffer should be emptied with the PIPEnCTR.ACLRM bit. While a transition to null auto response mode is being made, data should not be written from the FIFO port.

To make a transition from null auto response mode to normal mode, pipe operation disabled state (response PID = NAK) should be retained for the period of zero-length packet transmission (about 10 µs) before canceling null auto response mode. In normal mode, data can be written from the FIFO port; therefore, packet transmission to the host is enabled by enabling pipe operation (response PID = BUF).

40.3.5 FIFO Buffer Memory

40.3.5.1 FIFO Buffer Memory

The USB has FIFO buffer memory for data transfer. The memory area used for each pipe is managed by the USB. The FIFO buffer memory has two states depending on whether the access right is assigned to the system (CPU side) or the USB (SIE side).

(1) Buffer Status

Table 40.17 and Table 40.18 show the buffer status in the USB. The buffer memory status can be confirmed using the DCPCTR.BSTS flag and the PIPEnCTR.INBUFM flag. The transfer direction for the buffer memory can be specified using either the PIPECFG.DIR bit or the CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM flag is valid for pipe 1 to pipe 5 in the transmitting direction.

When a transmitting pipe uses the double buffer configuration, software can read the BSTS flag to monitor the buffer memory status on the CPU side and the INBUFM flag to monitor the buffer memory status on the SIE side. When the BEMP interrupt may not show the buffer empty status because the write access to the FIFO port by the CPU or DMAC/DTC is slow, software can use the INBUFM flag to confirm the end of transmission.

Table 40.17 Buffer Status Indicated by the BSTS Flag

ISEL or DIR	BSTS	Buffer Memory Status
0 (receiving direction)	0	There is no received data, or data is being received. Reading from the FIFO port is disabled.
0 (receiving direction)	1	There is received data, or a zero-length packet has been received. Reading from the FIFO port is allowed. Note that when a zero-length packet is received, reading is not possible and the buffer must be cleared.
1 (transmitting direction)	0	The transmission has not been completed. Writing to the FIFO port is disabled.
1 (transmitting direction)	1	The transmission has been completed. CPU write is allowed.

Table 40.18 Buffer Status Indicated by the INBUFM Flag

DIR	INBUFM	Buffer Memory Status
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	The transmission has been completed. There is no waiting data to be transmitted.
1 (transmitting direction)	1	The FIFO port has written data to the buffer. There is data to be transmitted.

40.3.5.2 FIFO Buffer Clearing

Table 40.19 shows the clearing of the FIFO buffer memory by the USB. The buffer memory can be cleared using the BCLR, DnFIFOSEL.DCLRM, and PIPEnCTR.ACLRM bit in the port control register.
Either a single or double buffer configuration can be selected for pipes 1 to 5, using the PIPECFG.DBLB bit.

Table 40.19 List of Buffer Clearing Methods

FIFO Buffer Clearing Mode	Clearing Buffer Memory on CPU Side	Mode for Automatically Clearing Buffer Memory after Reading Specified Pipe Data	Auto Buffer Clear Mode for Discarding All Received Packets
Register used	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Bit used	BCLR	DCLRM	ACLRM
Clearing condition	Cleared by writing 1	1: Mode valid 0: Mode invalid	1: Mode valid 0: Mode invalid

(1) Auto Buffer Clear Mode Function

With the USB, all received data packets are discarded if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet has been received, the ACK response is returned to the host controller. The auto buffer clear mode function can be set only in the buffer memory reading direction.
If the ACLRM bit is set to 1 and then to 0, the buffer memory of the selected pipe can be cleared regardless of the access direction.
An access cycle of at least 100 ns is required for the internal hardware sequence processing time between ACLRM = 1 and ACLRM = 0.

40.3.5.3 FIFO Port Functions

Table 40.20 shows the settings for the FIFO port functions of the USB. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, the BVAL bit in the port control register should be set to end writing. To send a zero-length packet, the BCLR bit in the register should be used to clear the buffer and then the BVAL bit set in order to end writing.
In reading, reception of new packets is automatically enabled when all data has been read. Data cannot be read when a zero-length packet has been received (the DTLN[8:0] flags = 0), so the BCLR bit in the register should be used to clear the buffer. The length of the receive data can be confirmed using the DTLN[8:0] flags in the port control register.

Table 40.20 FIFO Port Function Settings

Register	Bit	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	Selects DTLN[8:0] read mode.
	REW	Buffer memory rewind (re-read, rewrite).
	DCLRM	Automatically clears receive data for a specified pipe after the data has been read (only for DnFIFO).
	DREQE	Enables DMA/DTC transfers (only for DnFIFO).
	MBW	FIFO port access bit width.
	BIGEND	Selects FIFO port endian.
	ISEL	FIFO port access direction (only for DCP).
	CURPIPE[3:0]	Selects the current pipe.
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	Ends writing to the buffer memory.
	BCLR	Clears the buffer memory on the CPU side.
	DTLN[8:0]	Checks the length of receive data.

(1) FIFO Port Selection

Table 40.21 shows the pipes that can be selected with the various FIFO ports. The pipe to be accessed should be selected using the CURPIPE[3:0] bits in the port select register. After the pipe is selected, whether the written value can be correctly read from the CURPIPE[3:0] bits should be checked. (If the previous pipe number is read, it indicates that the pipe modification is being executed by the USB controller.) Then, the FRDY flag in a port control register = 1 is checked.
In addition, the bus width to be accessed should be selected using the MBW bit in the port select register. The buffer memory access direction conforms to the PIPECFG.DIR bit. Only for the DCP, the ISEL bit in the port select register determines the direction.

Table 40.21 FIFO Port Access Categorized by Pipe

Pipe	Access Method	Port that can be Used
DCP	CPU access	CFIFO port register
Pipe 1 to pipe 9	CPU access	CFIFO port register D0FIFO/D1FIFO port register
	DMAC/DTC access	D0FIFO/D1FIFO port register

(2) REW Bit

It is possible to temporarily stop access to the pipe currently being accessed, access a different pipe, and then continue processing for the current pipe again. The REW bit in the port select register is used for this processing.
If a pipe is selected through the CURPIPE[3:0] bits in the port select register with the REW bit set to 1, the pointer used for reading from and writing to the buffer memory is reset, and reading or writing can be carried out from the first byte.
If a pipe is selected with 0 set for the REW bit, data can be read and written in continuation from the previous selection, without the pointer being reset.
To access the FIFO port, the FRDY flag in the port control register = 1 should be checked after selecting a pipe.

40.3.5.4 DMA Transfers (D0FIFO and D1FIFO Ports)

(1) Overview of DMA Transfers

For pipes 1 to 9, the FIFO port can be accessed using the DMAC. When accessing the buffer for the pipe targeted for DMA transfer is enabled, a DMA transfer request is issued.
The unit of transfer to the FIFO port should be selected using the DnFIFOSEL.MBW bit and the pipe targeted for the DMA transfer should be selected using the DnFIFOSEL.CURPIPE[3:0] bits. The selected pipe should not be changed during the DMA transfer.

(2) DnFIFO Auto Clear Mode (D0FIFO and D1FIFO Port Reading Direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USB automatically clears the buffer memory of the selected pipe when reading of data from the buffer memory has been completed.
Table 40.22 shows the packet reception and buffer memory clearing processing by software for each of the various settings. As shown in Table 40.22, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA transfers without involving software.
The DnFIFO auto clear mode can be set only in the buffer memory reading direction.

Table 40.22 Packet Reception and Buffer Memory Clearing Processing by Software

Buffer Status When Packet is Received	Register Setting			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	Clearing is not necessary	Clearing is not necessary	Clearing is not necessary	Clearing is not necessary
Zero-length packet reception	Clearing is necessary	Clearing is necessary	Clearing is not necessary	Clearing is not necessary
Normal short packet reception	Clearing is not necessary	Clearing is necessary	Clearing is not necessary	Clearing is not necessary
Transaction count end	Clearing is not necessary	Clearing is necessary	Clearing is not necessary	Clearing is not necessary

40.3.6 Control Transfers Using DCP

In the data stage of control transfers, data is transferred using the default control pipe (DCP).
The DCP buffer memory is a 64-byte single buffer and is a fixed area that is shared for both control reading and control writing. The buffer memory can be accessed only through the CFIFO port.

40.3.6.1 Control Transfers When the Host Controller is Selected

(1) Setup Stage

Registers USBREQ, USBVAL, USBINDX, and USBLENG are the registers that are used to transmit a USB request for setup transactions. Writing setup packet data to the registers and writing 1 to the DCPCTR.SUREQ bit transmits the specified data for setup transactions. Upon completion of the transaction, the SUREQ bit is set to 0. The above USB request registers should not be modified while SUREQ = 1.
After the attached state of the connected function device is detected, the first setup transaction for the device should be issued by using the sequence described above with the DCPMAXP.DEVSEL[3:0] bits set to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.
After the connected function device is shifted to the Address state, setup transactions should be issued by using the sequence described above with the assigned USB address set in the DEVSEL[3:0] bits and the bits in the DEVADDn register corresponding to the specified USB address set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in the DEVADD2 register; when PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in the DEVADD5 register.
When the setup transaction data has been sent, an interrupt request is generated according to the response received from the peripheral device (SIGN or SACK flag in the INTSTS1 register), by means of which the result of the setup transactions can be confirmed.
A data packet of DATA0 (USB request) is transmitted as the data packet for a setup transaction regardless of the setting of the DCPCTR.SQMON flag.

(2) Data Stage

Data is transferred using the DCP buffer memory.
The access direction of the DCP buffer memory should be specified using the CFIFOSEL.ISEL bit. The transfer direction should be specified using the DCPCFG.DIR bit.
For the first data packet of the data stage, the data PID should be transferred as DATA1. Set data PID = DATA1 in the DCPCTR.SQSET bit and the PID[1:0] bits = 01b (BUF). Completion of data transfer is detected using the BRDY or BEMP interrupt.
For control write transfers, when the number of data bytes to be sent is an integer multiple of the maximum packet size, software should control so as to send a zero-length packet at the end.

(3) Status Stage

Zero-length packet data is transferred in the direction opposite to that in the data stage. As in the data stage, data is transferred using the DCP buffer memory. Transactions are done in the same manner as the data stage.
For the data packets of the status stage, the data PID should be set to DATA1 using the DCPCTR.SQSET bit.
For reception of a zero-length packet, the received data length should be confirmed using the CFIFOCTR.DTLN[8:0] flags after a BRDY interrupt is generated, and the buffer memory should then be cleared using the CFIFOCTR.BCLR bit.

40.3.6.2 Control Transfers When the Function Controller is Selected

(1) Setup Stage

The USB sends an ACK response for a correct setup packet targeted to the USB. The operation of the USB in the setup stage is described below.
When receiving a new setup packet, the USB sets the following bits.

- Set the INTSTS0.VALID flag to 1.
- Set the DCPCTR.PID[1:0] bits to 00b (NAK).
- Set the DCPCTR.CCPL bit to 0.

When receiving a data packet right after the setup packet, the USB stores the USB request parameters in registers USBREQ, USBVAL, USBINDX, and USBLENG.

Response processing with respect to the control transfer should be carried out after setting the VALID flag = 0. In the VALID flag = 1 state, PID[1:0] = 01b (BUF) cannot be set, and the data stage cannot be terminated.
Using the function of the VALID flag, the USB can suspend the current request processing when receiving a new USB request during a control transfer, and can send a response to the newest request.
In addition, the USB automatically detects the direction bit (bit 8 of bmRequestType) and the request data length (wLength) of the received USB request, distinguishes between control read transfer, control write transfer, and no-data control transfer, and controls stage transitions. For a wrong sequence, the sequence error of the control transfer stage transition interrupt is generated, and the software is notified of occurrence of the error. For the stage control of the USB, refer to Figure 40.15.

(2) Data Stage

Data transfers corresponding to received USB requests should be done using the DCP. Before accessing the DCP buffer memory, the access direction should be specified using the CFIFOSEL.ISEL bit.
If the transfer data is larger than the size of the DCP buffer memory, the data transfer should be carried out using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

(3) Status Stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to 01b (BUF).
After the above settings have been made, the USB automatically executes the status stage in accordance with the data transfer direction determined at the setup stage. The specific procedure is as follows.

- For control read transfers
  A zero-length packet is received from the USB host and an ACK response is sent.
- For control write transfers and no-data control transfers
  A zero-length packet is transmitted and an ACK response is received from the USB host.

(4) Control Transfer Auto Response Function

The USB automatically responds to a correct SET_ADDRESS request. If any of the following errors occurs in the SET_ADDRESS request, a response from the software is necessary.

- bmRequestType is not 00h: Any transfer other than a control write transfer
- wIndex is not 00h: Request error
- wIndex is not 00h: Any transfer other than a no-data control transfer
- wValue is larger than 7Fh: Request error
- INTSTS0.DVSQ[2:0] are 011b (Configured state): Control transfer of a device state error

For all requests other than the SET_ADDRESS request, a response is required from the corresponding software.

40.3.7 Bulk Transfers (Pipes 1 to 5)

The buffer memory usage (single/double buffer setting) can be selected for bulk transfers. The USB provides the following functions for bulk transfers.

- BRDY interrupt function (PIPECFG.BFRE bit: refer to section 40.3.3.1, (2) When the SOFCFG.BRDYM Bit = 0 and the PIPECFG.BFRE Bit = 1)
- Transaction count function
  (PIPEnTRE.TRENB and TRCLR bits and PIPEnTRN register: refer to section 40.3.4.5, Transaction Counter (For Pipes 1 to 5 in Reading Direction))
- Response PID = NAK function (PIPECFG.SHTNAK bit: refer to section 40.3.4.8, Response PID = NAK Function)
- Auto response mode (PIPEnCTR.ATREPM bit: refer to section 40.3.4.9, Auto Response Mode)

40.3.8 Interrupt Transfers (Pipes 6 to 9)

When the function controller is selected, the USB carries out interrupt transfers in accordance with the timing controlled by the host controller.
When the host controller is selected, the timing of issuing a token can be specified using the interval counter.

40.3.8.1 Interval Counter during Interrupt Transfers When the Host Controller is Selected

For interrupt transfers, intervals between transactions are set in the PIPEPERI.IITV[2:0] bits. The USB controller issues interrupt transfer tokens based on the specified intervals.

(1) Counter Initialization

The interval counter is initialized when the MCU is reset or when the PIPEnCTR.ACLRM bit is set to 1. Note that the PIPEPERI.IITV[2:0] bits are not initialized when the ACLRM bit is used for initialization.

Note that the interval counter is not initialized in the following case.

- USB bus reset or USB suspended
  The IITV[2:0] bits are not initialized. Setting 1 to the DVSTCTR0.UACT bit starts counting from the value before entering the USB bus reset state or USB suspended state.

(2) Operation When Transmission/Reception is Impossible at Token Issuance Timing

The USB cannot issue tokens even at token issuance timing in the following cases. In such a case, the USB attempts transactions at the subsequent interval.

- When the PID[1:0] bits are set to 00b (NAK) or 1xb (STALL).
- When the buffer memory is full at the token sending timing in the receiving (IN) direction.
- When there is no data to be sent in the buffer memory at the token sending timing in the transmitting (OUT) direction.

40.3.9 Isochronous Transfers (Pipes 1 and 2)

The USB has the following functions for isochronous transfers.

- Notification of isochronous transfer error information
- Interval counter (specified by the PIPEPERI.IITV[2:0] bits)
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function (specified by the PIPEPERI.IFIS bit)

40.3.9.1 Error Detection in Isochronous Transfers

The USB has a function for detecting the error information described below, so that when errors occur in isochronous transfers, they can be controlled by software. Table 40.23 and Table 40.24 show the priority in which errors are confirmed and the interrupts generated corresponding to errors.

(a) PID errors

- If the PID of the received packet is illegal.

(b) CRC errors and bit stuffing errors

- If an error occurs in the CRC of the received packet or the bit stuffing is illegal.

(c) Maximum packet size exceeded

- The data of the received packet is larger than the specified maximum packet size.

(d) Overrun and underrun errors

- When the host controller is selected
  When the buffer memory is full at the token sending timing in the IN (receiving) direction.
  When there is no data to be sent in the buffer memory at the token sending timing in the OUT (transmitting) direction.
- When the function controller is selected
  When there is no data to be sent in the buffer memory at the token receiving timing in the IN (transmitting) direction.
  When the buffer memory is full at the token receiving timing in the OUT (receiving) direction.

(e) Interval errors

An interval error is generated on any of the following conditions when the function controller is selected.

- During an isochronous IN transfer, an IN token could not be received in the interval frame.
- During an isochronous OUT transfer, an OUT token could not be received in the interval frame.

Table 40.23 Error Detection When a Token is Received

Detection Priority	Error	Generated Interrupt and Status
1	PID errors	No interrupts are generated in both cases when the host controller is selected and the function controller is selected (ignored as a corrupted packet).
2	CRC errors and bit stuffing errors	No interrupts generated in both cases when the host controller is selected and the function controller is selected (ignored as a corrupted packet).
3	Overrun and underrun errors	An NRDY interrupt is generated to set the FRMNUM.OVRN flag to 1 in both cases when the host controller is selected and function controller is selected. When the function controller is selected, a zero-length packet is transmitted in response to IN token. However, no data packets are received in response to OUT token.
4	Interval errors	An NRDY interrupt is generated when the function controller is selected. It is not generated when the host controller is selected.

Table 40.24 Error Detection When a Data Packet is Received

Detection Priority	Error	Generated Interrupt and Status
1	PID errors	No interrupts are generated (ignored as a corrupted packet).
2	CRC errors and bit stuffing errors	An NRDY interrupt is generated to set the FRMNUM.CRCE to 1 bit in both cases when the host controller is selected and the function controller is selected.
3	Maximum packet size exceeded errors	A BEMP interrupt is generated to set the PID[1:0] bits to 1xb (STALL) in both cases when the host controller is selected and the function controller is selected.

40.3.9.2 Data PID

When the function controller is selected, the USB operates as follows in response to the received PID.
IN direction

- DATA0: Sent as data packet PID
- DATA1: Not sent
- DATA2: Not sent
- mDATA: Not sent

OUT direction

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets are ignored
- mDATA: Packets are ignored

40.3.9.3 Interval Counter

The isochronous transfer interval can be set using the PIPEPERI.IITV[2:0] bits. The interval counter enables the functions shown in Table 40.25 when the function controller is selected. When the host controller is selected, the USB generates the token issuance timing. When the host controller is selected, the interval counter operation is the same as that in the interrupt transfer.

Table 40.25 Interval Counter Function When the Function Controller is Selected

Transfer Direction	Function	Conditions for Detection
IN	Flushes transmit buffer	When an IN token cannot be successfully received in the interval frame during an isochronous IN transfer
OUT	Notifies that a token not being received	When an OUT token cannot be successfully received in the interval frame during an isochronous OUT transfer

The interval count is carried out when an SOF is received or for interpolated SOFs, so the isochronism can be maintained even if an SOF is damaged. The frame interval that can be set is the $2^{IITV[2:0]}$ frames.

(1) Counter Initialization When the Function Controller is Selected

The interval counter is initialized when the MCU is reset or when the PIPEnCTR.ACLRM bit is set to 1. Note that the PIPEPERI.IITV[2:0] bits are not initialized when the ACLRM bit is used for initialization.

After the interval counter has been initialized, counting is started under either of the following conditions 1 and 2 when a packet has been transferred successfully.

1. An SOF is received after transmission of data in response to an IN token while the PID[1:0] bits are 01b (BUF).
2. An SOF is received after reception of data of an OUT token while the PID[1:0] bits are 01b (BUF).

Note that the interval counter is not initialized under the following conditions.

- When the PID[1:0] bits are set to 00b (NAK) or 1xb (STALL)
  The interval timer does not stop. The USB attempts transactions at the subsequent interval.
- When the USB bus is reset or USB is suspended
  The IITV[2:0] bits are not initialized. When an SOF has been received, counting is restarted from the value prior to the reception of the SOF.

(2) Interval Counting and Transfer Control When the Host Controller is Selected

The USB controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bit settings. Specifically, the USB issues a token for a selected pipe once every $2^{IITV[2:0]}$ frames.
The USB starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits have been set to 01b (BUF) by software.

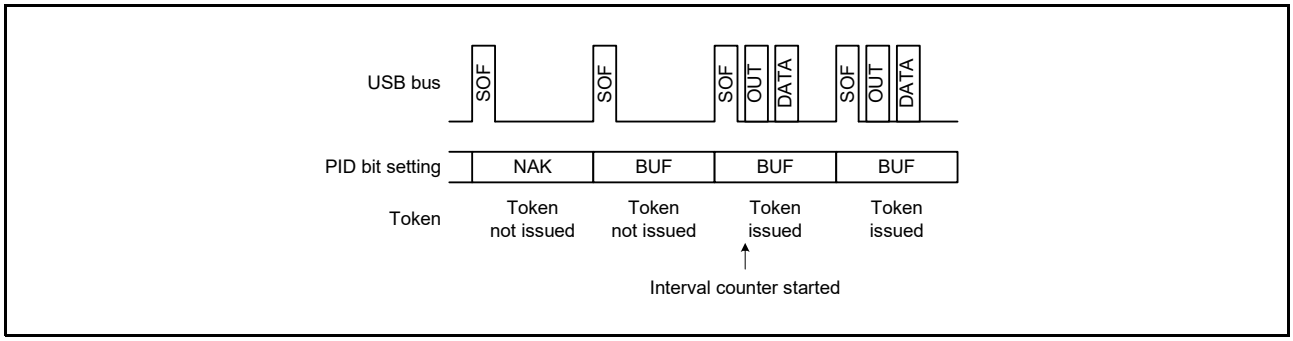

Figure 40.16 Token Issuance When IITV[2:0] = 000b

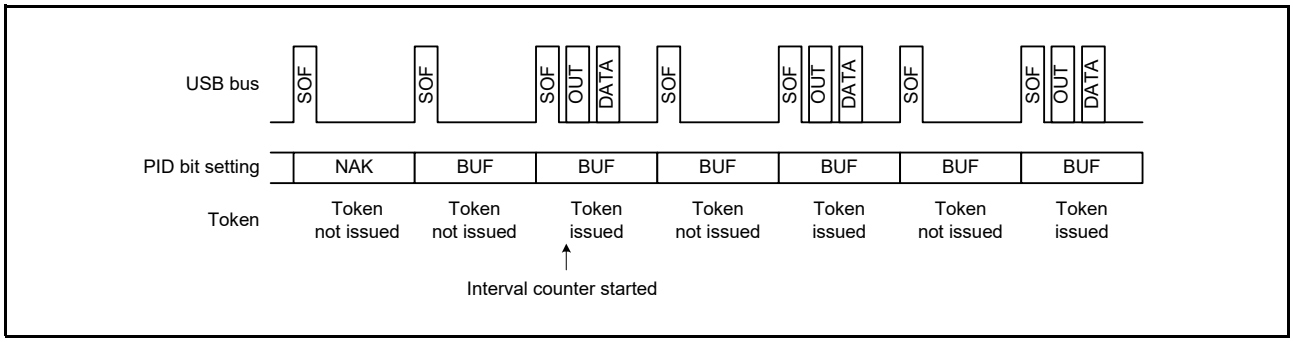

Figure 40.17 Token Issuance When IITV[2:0] = 001b

When the selected pipe is set for isochronous transfers, the USB carries out the following operation in addition to controlling the token issuance interval. The USB issues a token even when the NRDY interrupt generation condition is satisfied.

(a) When the selected pipe is for isochronous IN transfers

The USB generates an NRDY interrupt when the USB issues an IN token but does not receive a packet successfully from a peripheral device (no response or packet error).
The USB sets the FRMNUM.OVRN flag to 1 generating an NRDY interrupt when the time to issue an IN token comes while the USB cannot receive data because the FIFO buffer is full (due to the fact that the CPU or DMAC/DTC is too slow to read data from the FIFO buffer).

(b) When the selected pipe is for isochronous OUT transfers

The USB sets the OVRN flag to 1 generating an NRDY interrupt and transmitting a zero-length packet when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer (because the CPU or DMAC/DTC is too slow to write data to the FIFO buffer).
The token issuance interval is reset on any of the following conditions.

- When the USB is reset through a reset pin
  (The IITV[2:0] bits are also set to 0).
- When the PIPEnCTR.ACLRM bit has been set to 1 by software.

(3) Interval Counting and Transfer Control When the Function Controller is Selected

(a) When the selected pipe is for isochronous OUT transfers

The USB generates an NRDY interrupt when the USB fails to receive a data packet within the interval set by the PIPEPERI.IITV[2:0] bits.
The USB also generates an NRDY interrupt when the USB fails to receive data because of a CRC error or other errors contained in the data packet or because of the FIFO buffer being full.
The NRDY interrupt is generated at the timing of SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the interrupt to be generated at the timing to receive the SOF packet.
However, when the IITV[2:0] bits are set to a value other than 0, the USB generates an NRDY interrupt on receiving an SOF packet for every interval after starting interval counting operation.
When the PID[1:0] bits are set to 00b (NAK) by software after starting the interval timer, the USB does not generate an NRDY interrupt on receiving an SOF packet.
The timing to start interval counting depends on the setting of IITV[2:0] bits as shown below.

- When the IITV[2:0] = 000b: The interval counting starts when software has set the PID[1:0] bits for the selected pipe to 01b (BUF).

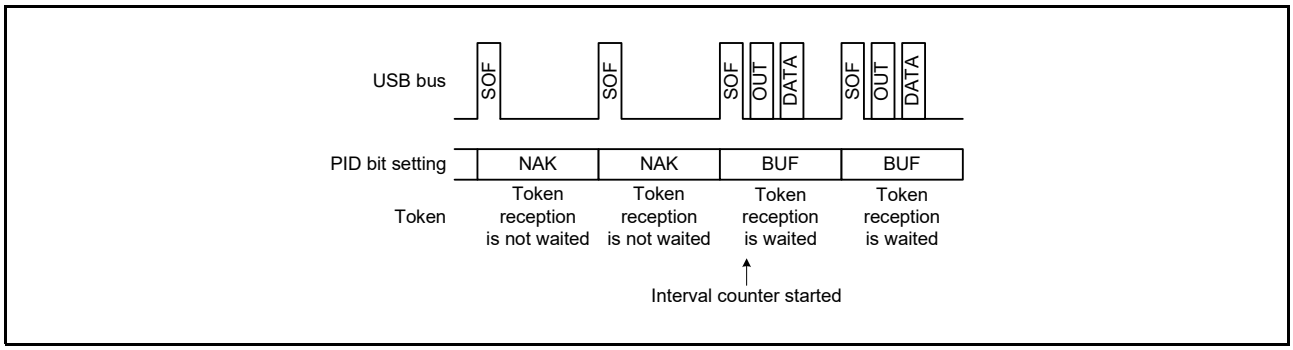

Figure 40.18 Relationship between Frames and Expected Token Reception When IITV[2:0] = 000b

- When the IITV[2:0] ≠ 000b: The interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe have been modified to 01b (BUF).

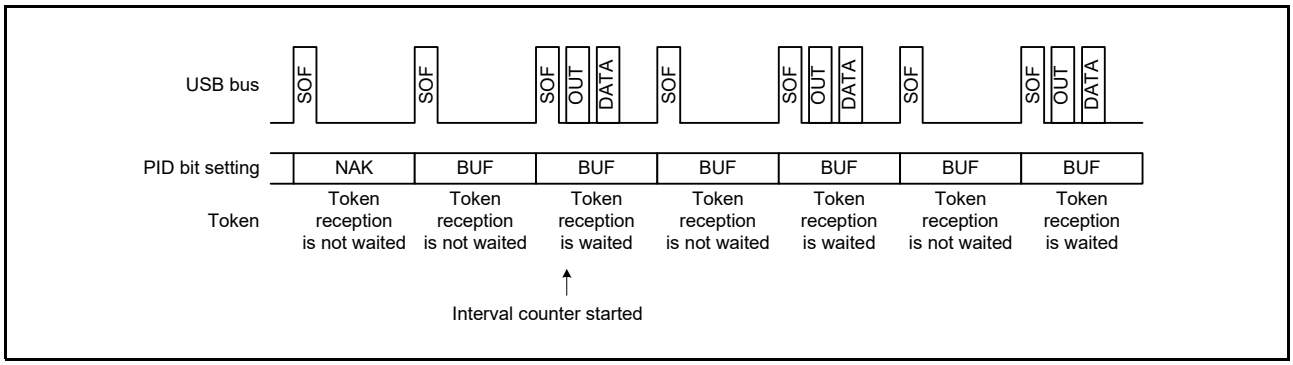

Figure 40.19 Relationship between Frames and Expected Token Reception When IITV[2:0] ≠ 000b

(b) When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit should be 1 for this use. When IFIS = 0, the USB transmits a data packet in response to the received IN token irrespective of the setting of the PIPEPERI.IITV[2:0] bits.
When IFIS = 1, the USB clears the FIFO buffer when the USB fails to receive an IN token in the frame at the interval set by the IITV[2:0] bits while there is data to be transmitted in the FIFO buffer.
The USB also clears the FIFO buffer when the USB fails to receive an IN token successfully because of a bus error such as a CRC error contained in the IN token.
The FIFO buffer is cleared at the timing of SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the FIFO buffer to be cleared at the timing to receive the SOF packet.

The timing to start interval counting depends on the setting of the IITV[2:0] bits (similar to the timing during OUT transfers).
The interval is counted on any of the following conditions in function controller mode.

- When a hardware-reset is applied to the USB (here, the IITV[2:0] bits are also set to 000b).
- When the PIPEnCTR.ACLRM bit is set to 1 by software.
- When the USB detects a USB bus reset.

(4) Setup of Data to be Transmitted Using Isochronous Transfer When the Function Controller is Selected

With isochronous data transmission using the USB in the function controller, after data has been written to the buffer memory, a data packet can be transmitted with the next frame after the frame in which an SOF packet is detected. This function is called the isochronous transfer transmission data setup function, and it makes it possible to designate the frame from which transmission began.

In a double buffer configuration, even after the writing of data to both buffers has been completed, transmission will be enabled for only one buffer to which data writing was completed first. Accordingly, even if multiple IN tokens are received, only one packet of data is transmitted from a single buffer.

When an IN token is received, if the buffer memory is in the transmission enabled state, the USB transmits data as a normal response. If the buffer memory is not in the transmission enabled state, however, a zero-length packet is sent and an underrun error occurs.

Figure 40.20 shows an example of transmission using the isochronous transfer transmission data setup function with the USB when IITV[2:0] = 000b (every frame) has been set.

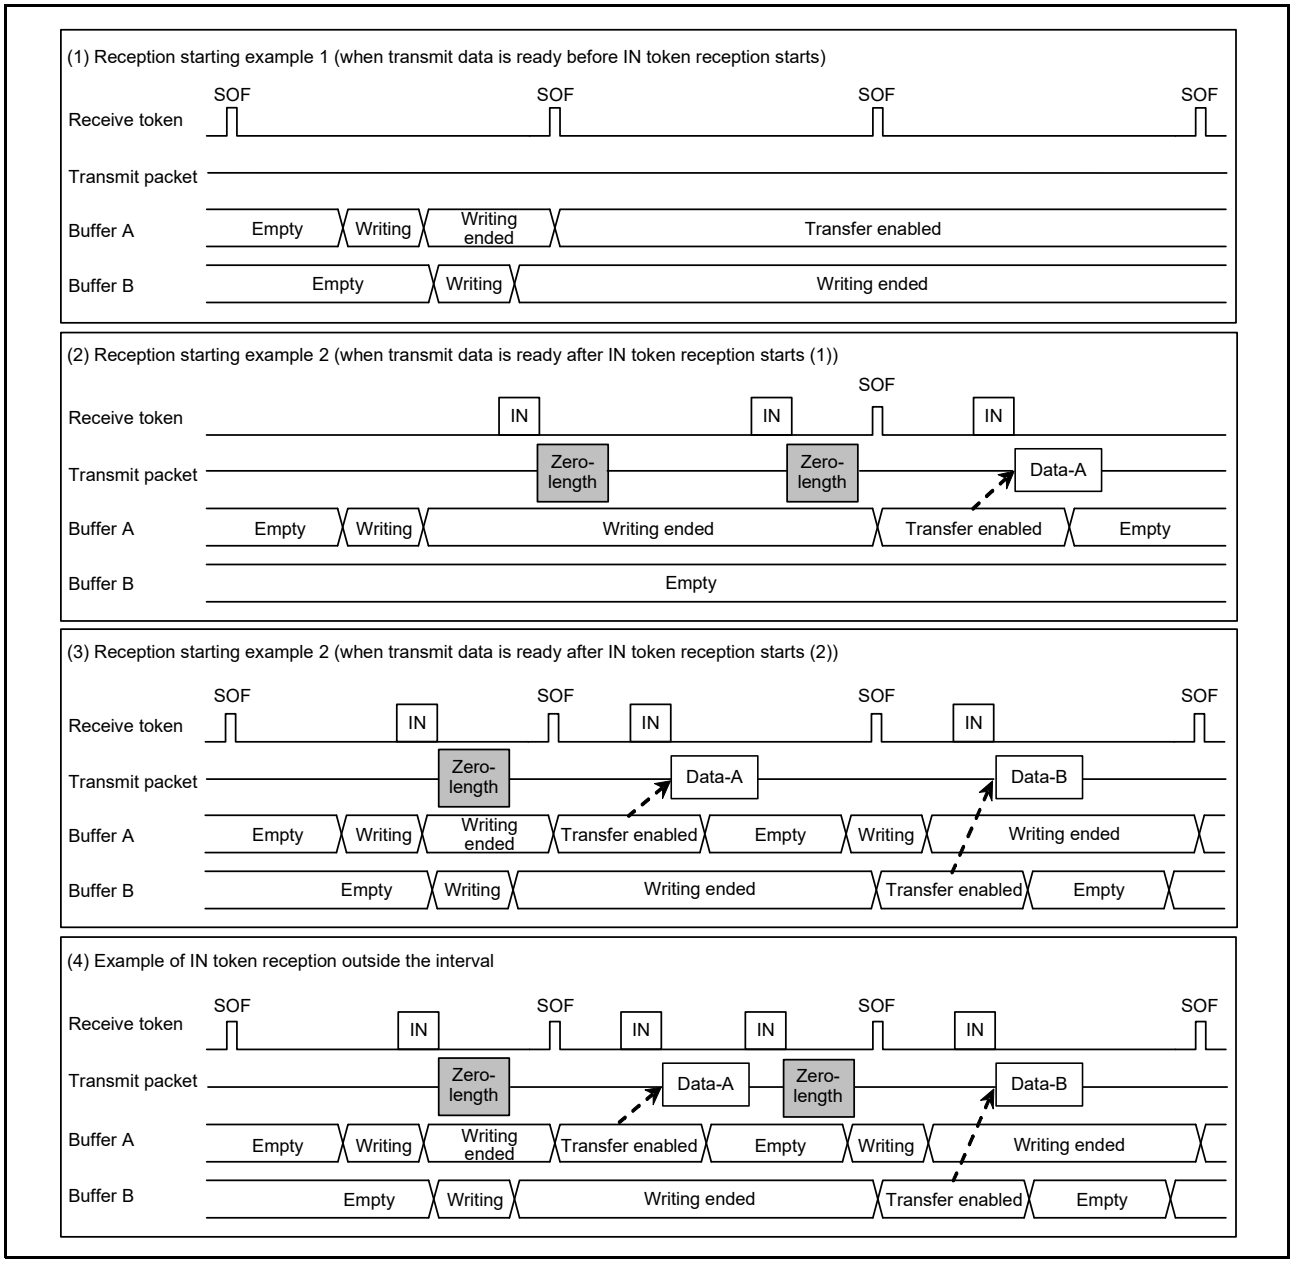

Figure 40.20 Example of Data Setup Function Operation

(5) Isochronous Transfer Transmission Buffer Flush When the Function Controller is Selected

If an SOF packet of the next frame is received without receiving an IN token in an interval frame during isochronous data transmission, the USB operates as if an IN token had been corrupted, and clears the buffer for which transmission is enabled, putting that buffer in the writing enabled state.
If a double buffer configuration is used and writing to both buffers has been completed, the buffer memory that was cleared is assumed as the data having been sent in the interval frame, and transmission is enabled for the buffer memory that is not cleared with SOF packet reception.
The timing of the buffer flush function depends on the setting of the PIPEPERI.IITV[2:0] bits.

- When the IITV[2:0] = 000b
  The buffer flush operation starts from the next frame after the pipe becomes valid.
- When the IITV[2:0] ≠ 000b
  The buffer flush operation is carried out after the first successful transaction.

Figure 40.21 shows an example of the buffer flush function in the USB. When an unanticipated token is received before the interval frame, the USB sends the write data or a zero-length packet as an underrun error according to the data setup state.

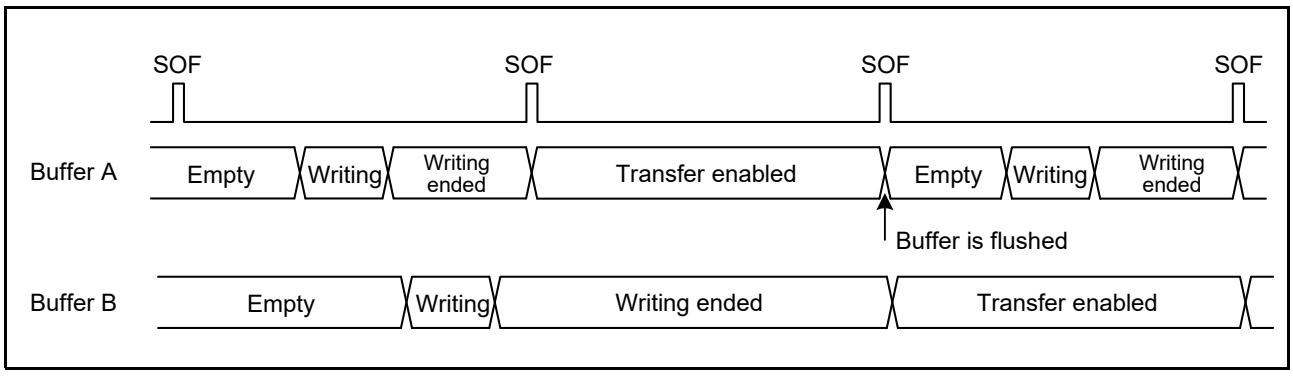

Figure 40.21 Example of Buffer Flush Operation

Figure 40.22 shows an example of interval error occurrence in the USB. There are five types of interval errors, as shown below. The interval error is generated at the timing indicated by ① in the figure, and the buffer flush function is activated.

If an interval error occurs during an IN transfers, the buffer flush function is activated; if it occurs during an OUT transfer, an NRDY interrupt is generated.

The FRMNUM.OVRN flag should be used to distinguish between NRDY interrupts such as received packet errors and overrun errors.

In response to tokens that are shaded in the figure, responses are sent according to the buffer memory status.

IN direction

- If the buffer is in the transmission enabled state, the data is transferred as a normal response.
- If the buffer is in the transmission disabled state, a zero-length packet is sent and an underrun error occurs.

OUT direction

- If the buffer is in the reception enabled state, the data is received as a normal response.
- If the buffer is in the reception disabled state, the data is discarded and an overrun error occurs.

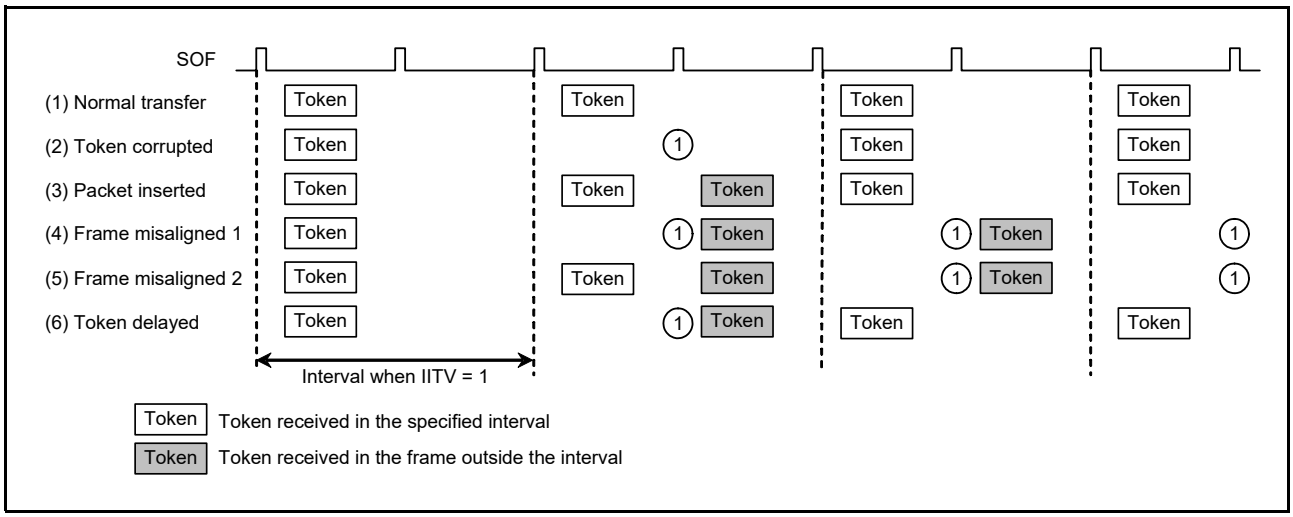

Figure 40.22 Example of Interval Error Occurrence When IITV[2:0] = 001b

40.3.10 SOF Interpolation Function

When the function controller is selected and if data could not be received at intervals of 1 ms because an SOF packet was corrupted or missing, the USB interpolates the SOF. The SOF interpolation operation begins when the USBE and SCKE bits in the SYSCFG register have been set to 1 and an SOF packet is received. The interpolation function is initialized under the following conditions.

- MCU reset
- USB bus reset
- Suspended state detected

The SOF interpolation operates as follows.

- The interpolation function is not activated until an SOF packet is received.
- After the first SOF packet is received, interpolation is carried out by counting 1 ms with an internal clock of 48 MHz.
- After the second and subsequent SOF packets are received, interpolation is carried out at the previous reception interval.
- Interpolation is not carried out in the suspended state or while a USB bus reset is being received.

The USB supports the following functions based on the SOF packet reception. These functions also operate normally with SOF interpolation, if the SOF packet was missing.

- Updating of the frame number
- SOFR interrupt timing
- Isochronous transfer interval count

If an SOF packet is missing during full-speed operation, the FRMNUM.FRNM[10:0] flags are not updated.

40.3.11 Pipe Schedule

40.3.11.1 Conditions for Generating a Transaction

When the host controller is selected and the DVSTCTR0.UACT bit has been set to 1, the USB generates a transaction under the conditions shown in Table 40.26.

Table 40.26 Conditions for Generating a Transaction

	Conditions for Generation				
Transaction	**DIR**	**PID[1:0]**	**IITV[0]**	**Buffer State**	**SUREQ**
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	Invalid	Receive area exists	—*1
	OUT	BUF	Invalid	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid	Receive area exists	—*1
	OUT	BUF	Valid	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. Symbols (—) in the table indicate that the condition is unrelated to the generating of tokens. "Valid" indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. "Invalid" indicates that a transaction is generated regardless of the interval counter.
Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.
Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

40.3.11.2 Transfer Schedule

This section describes the transfer scheduling within a frame of the USB. After the USB sends an SOF, the transfer is carried out in the sequence described below.

1. Execution of periodic transfers
   A pipe is searched in the order of Pipe 1 → Pipe 2 → Pipe 6 → Pipe 7 → Pipe 8 → Pipe 9, and then, if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.
2. Setup transactions for control transfers
   The DCP is checked, and if a setup transaction is possible, it is sent.
3. Execution of bulk transfers, control transfer data stages, and control transfer status stages
   A pipe is searched in the order of DCP → Pipe 1 → Pipe 2 → Pipe 3 → Pipe 4 → Pipe 5, and then, if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.
   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

40.3.11.3 Enabling USB Communication

Setting the DVSTCTR0.UACT bit to 1 initiates SOF transmission and transaction generation is enabled.
Setting the UACT bit to 0 stops SOF transmission and a suspend state is entered. If the setting of the UACT bit is changed from 1 to 0, processing stops after the next SOF is sent.

40.4 Usage Notes

40.4.1 Setting the Module-Stop Function

Operation of the USB module can be disabled or enabled by setting a bit in the module stop control register B (MSTPCRB). The USB is initially disabled after a reset. Registers in the USB only become accessible after it has been released from the module-stop state. For details, refer to section 11, Low Power Consumption.

41. USB 2.0 High-Speed Host/Function Module (USBHS)

41.1 Overview

This MCU incorporates a USB 2.0 high-speed host/function module (USBHS). The USBHS is a USB controller that is equipped to operate as a host controller or a function controller. As a host controller, the USBHS supports high-speed transfer, full-speed transfer, and low-speed transfer as defined in the Universal Serial Bus Specification Revision 2.0 (hereinafter referred to as USB 2.0). As a function controller, the USBHS supports high-speed transfer and full-speed transfer as defined in USB 2.0. The USBHS has an internal USB transceiver and supports all of the transfer types defined in USB 2.0. The USBHS has FIFO buffers for data transfer, providing a maximum of 10 pipes. Any endpoint numbers can be assigned to pipes 1 to 9, based on the peripheral devices or user system for communication.

Table 41.1 USBHS Specifications

Item	Specifications
Features	• Incorporates a USB device controller (UDC) and transceiver for USB 2.0 The host controller and function controller operations are provided and the On-The-Go (OTG) function is supported. • Host controller and function controller operations are switched by software.
	In host controller operation: • Supports high-speed transfer (480 Mbps), full-speed transfer (12 Mbps), and low-speed transfer (1.5 Mbps) • Automatic scheduling for Start-of-Frame (SOF) packets and other packet transmissions • Programmable intervals for isochronous and interrupt transfers • Communications with multiple peripheral devices connected via a single hub
	In function controller operation: • Supports high-speed transfer (480 Mbps) and full-speed transfer (12 Mbps) • Control transfer stage control function • Device state control function • Auto response function for SetAddress() request • SOF recovery function
Communication data transfer types	• Control transfer • Bulk transfer • Interrupt transfer • Isochronous transfer
Pipe configuration	• FIFO buffer of up to 8.5 Kbytes for USB communications is available. • Up to 10 pipes can be selected (including the default control pipe). • Programmable pipe configurations • Endpoint numbers can be assigned flexibly to pipes 1 to 9.
	• Transfer conditions that can be set for each pipe: Pipe 0 (default control pipe): Control transfer, 64-byte fixed single buffer Pipes 1 and 2: Bulk transfer/isochronous transfer in continuous transfer mode. Programmable buffer size up to 2 Kbytes. Selectable single buffer or double buffer mode. Pipes 3 to 5: Bulk transfer in continuous transfer mode. Programmable buffer size up to 2 Kbytes. Selectable single buffer or double buffer mode. Pipes 6 to 9: Interrupt transfer, 64-byte fixed single buffers
Other features	• Transfer ending function using transaction count • Function that changes the BRDY interrupt event notification timing • Function that automatically clears the FIFO buffer after the data for the pipe specified at the D0FIFO port or D1FIFO port has been read • NAK setting function for response packet ID (PID) generated by end of transfer • Internal pull-up and pull-down resistors for D+ and D– • Supports the USB 2.0 Engineering Change Notice for Link Power Management (LPM). A new sleep state (referred to as the L1 state) is available. • Supports Battery Charging Specification Revision 1.2 • To reduce power consumption, a classic-only mode where operation is only in accord with the USB 1.1 standard is selectable.
Protect Zone filter	Security attribute can be set.*1

Note 1. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Figure 41.1 shows a block diagram of the USBHS.

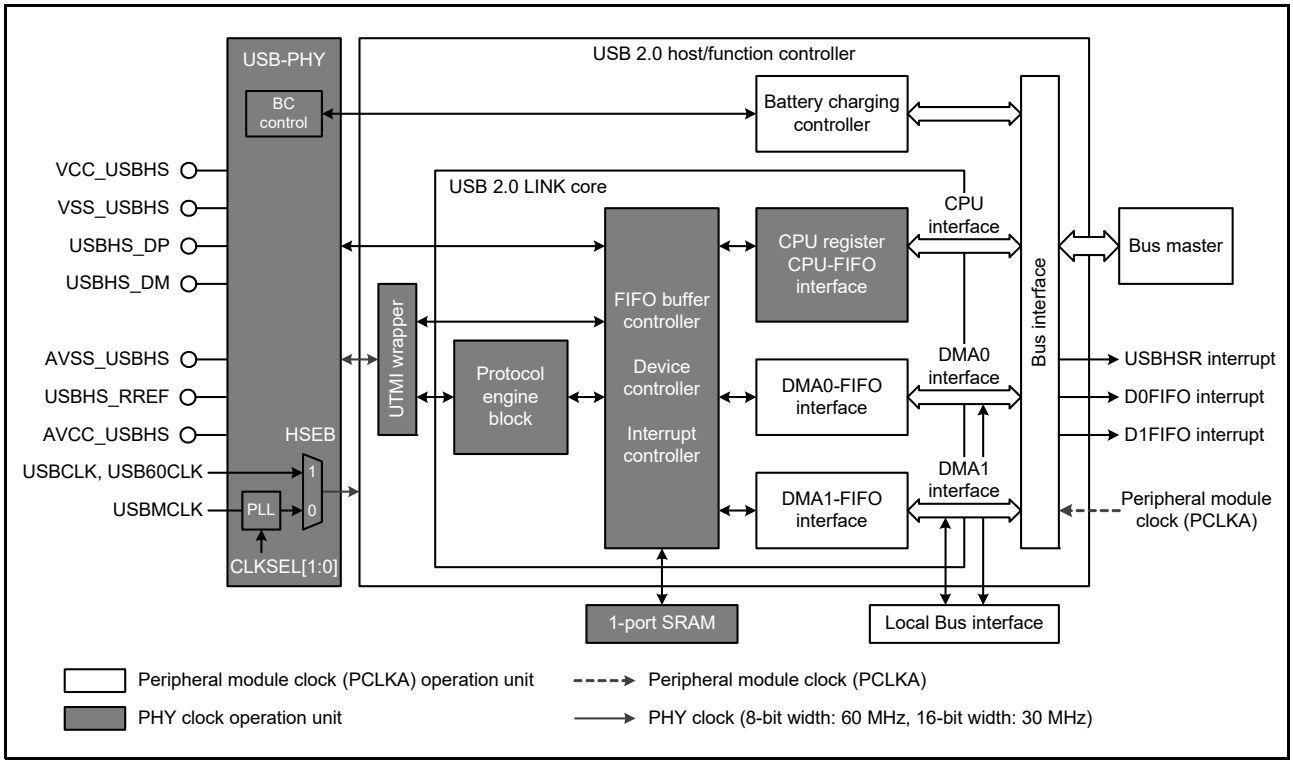

Figure 41.1 USBHS Block Diagram

Table 41.2 lists the I/O pins of the USBHS.

Table 41.2 Pin Configuration

Pin Symbol	I/O	Function
VCC_USBHS	Input	Power supply pin for the USBHS
VSS_USBHS	Input	Ground pin for the USBHS
AVCC_USBHS	Input	Analog power supply pin for the USBHS
AVSS_USBHS	Input	Analog ground pin for the USBHS.
USBHS_RREF	I/O	Reference current source pin for the USBHS. This pin should be connected to the AVSS_USBHS pin through a resistor of 2.2 kΩ (±1%).
USBHS_DP	I/O	I/O pin for the D+ data line of the USB bus
USBHS_DM	I/O	I/O pin for the D– data line of the USB bus
USBHS_EXICEN	Output	This pin should be connected to the OTG power supply IC.
USBHS_ID	Input	This pin should be connected to the OTG power supply IC.
USBHS_VBUSEN	Output	VBUS power enable pin for USB
USBHS_OVRCURA USBHS_OVRCURB	Input	Overcurrent pin for USB
USBHS_VBUS	Input	USB cable connection monitor input pin

41.2 Register Descriptions

41.2.1 System Configuration Control Register (SYSCFG)

Address(es): USBHS.SYSCFG 8745 1000h, USBHS_NS.SYSCFG 0745 1000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CNEN	HSE	DCFM	DRPD	DPRPU	—	—	—	USBE
Value after reset:	x	x	x	x	x	x	x	0	0	0	1	0	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	USBE	USB Operation Enable	0: USB operation is disabled. 1: USB operation is enabled.	R/W
b3 to b1	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b4	DPRPU	D+ Line Resistor Control	0: Pulling up the line is disabled. 1: Pulling up the line is enabled.	R/W
b5	DRPD	D+/D– Line Resistor Control	0: Pulling down the line is disabled. 1: Pulling down the line is enabled.	R/W
b6	DCFM	Controller Operation Select	0: Function controller operation is selected. 1: Host controller operation is selected.	R/W
b7	HSE	High-Speed Operation Enable	0: High-speed operation is disabled. (In function controller operation: Full-speed. In host controller operation: Full-/low-speed) 1: High-speed operation is enabled (the controller detects the communication speed).	R/W
b8	CNEN	Single End Receiver Enable	0: Single end receiver operation is disabled. 1: Single end receiver operation is enabled.	R/W
b15 to b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

The SYSCFG register can be write accessed even when the LPSTS.SUSPENDM bit is 0 (PHY clock is stopped). Note, however, that written values are only reflected in the SYSCFG register after the LPSTS.SUSPENDM bit is set to 1 (PHY clock is supplied to the LINK).

USBE Bit (USB Operation Enable)

The USBE bit enables and disables USBHS operation. Use the PHYSET.CLKSEL[1:0] bits to specify the input clock and verify that the PLLSTA.PLLLOCK flag is 1 before setting the USBE bit to 1. When operating in classic-only mode, set the PHYSET.HSEB bit to 1 before setting the USBE bit to 1. At that time, the USBCLK must be set to 48 MHz and USB60CLK must be set to 60 MHz. Refer to section 41.3.3 for details on setting clocks.

In host controller operation, set the DRPD bit to 1, eliminate chattering of the SYSSTS0.LNST[1:0] flags, and confirm that the USB bus state is stable before setting the USBE bit to 1.

When modifying the USBE bit from 1 to 0, some bits are initialized. Refer to Table 41.3 for a list of the bits initialized from setting the USBE bit to 0.

Table 41.3 Bits Initialized by Writing 0 to the SYSCFG.USBE Bit

Selected Function	Bits	Remarks
Function controller operation (when the DCFM bit is 0)	SYSSTS0.LNST[1:0]	The value is retained in host controller operation.
	DVSTCTR0.RHST[2:0]	
	INTSTS0.DVSQ[2:0]	The value is retained in host controller operation.
	USBADDR.USBADDR[6:0]	The value is retained in host controller operation.
	USBREQ.BREQUEST[7:0] and BMREQUESTTYPE[7:0]	The value is retained in host controller operation.
	USBVAL.WVALUE[15:0]	The value is retained in host controller operation.
	USBINDX.WINDEX[15:0]	The value is retained in host controller operation.
	USBLENG.WLENGTH[15:0]	The value is retained in host controller operation.
Host controller operation (When the DCFM bit is 1)	DVSTCTR0.RHST[2:0]	
	FRMNUM.FRNM[10:0]	The value is retained in function controller operation.
	UFRMNUM.UFRNM[2:0]	The value is retained in function controller operation.

DPRPU Bit (D+ Line Resistor Control)

In function controller operation, the DPRPU bit enables and disables pulling up the D+ line.

When the DPRPU bit is set to 1 in function controller operation, the USBHS pulls up the D+ line and notifies the USB host of the attached state. Modifying the DPRPU bit from 1 to 0 stops the USBHS from pulling up the D+ line, thus it appears that the USBHS is detached from the USB host.

Set the DPRPU bit to 1 in function controller operation, and set it to 0 in host controller operation.

DRPD Bit (D+/D– Line Resistor Control)

In host controller operation, the DRPD bit enables and disables pulling down the D+ and D– lines.

Set the DRPD bit to 1 in host controller operation. Set the DRPD bit to 0 when OTG is not used in function controller operation.

DCFM Bit (Controller Operation Select)

The DCFM bit selects the function of the USBHS. Modify this bit when both the DPRPU and DRPD bits are 0.

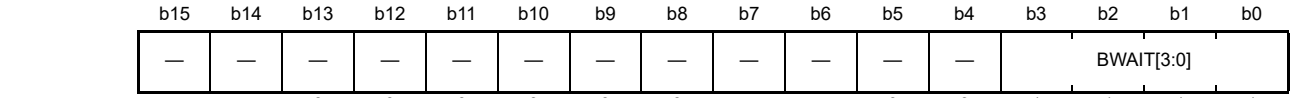
HSE Bit (High-Speed Operation Enable)

This bit enables or disables high-speed operation.

When the HSE bit is 1, the USBHS performs high-speed or full-speed operation based on the results of reset handshake.

1. In host controller operation
   Setting the HSE bit to 0 lets the USBHS perform low-speed operation or full-speed operation. If the DVSTCTR0.RHST[2:0] bits indicate the attach state of a peripheral device in low-speed operation, set the HSE bit to 0. Setting the HSE bit to 1 lets the USBHS perform high-speed or full-speed operation according to the results of the reset handshake protocol. Modify the HSE bit after detection of the attach state (detection of an ATTCH interrupt) and before USB bus reset (before setting the DVSTCTR0.USBRST bit to 1), or after detection of the detach state (DTCH interrupt detected).
2. In function controller operation
   When the HSE bit is set to 0, the USBHS performs full-speed operation. When the HSE bit is set to 1, the USBHS executes the reset handshake protocol, and then performs high-speed or full-speed operation according to the results. Modify the HSE bit when the DPRPU bit is 0.

CNEN Bit (Single End Receiver Enable)



Setting the CNEN bit to 1 enables single-ended receiver operation and enables the SYSSTS0.LNST[1:0] flags to monitor the states of the D+ and D– lines.

When the USBHS is detached, the CNEN bit is used to prevent through-current damage which may occur from a single-ended receiver floating.

In host controller operation, verify that the PHY clock is being supplied before setting this bit to 1. In function controller operation, set this bit to 1 when the VBUS is detected due to a VBUS interrupt, and set the bit to 0 when the VBUS is removed.

41.2.2 CPU Bus Wait Register (BUSWAIT)

Address(es): USBHS.BUSWAIT 8745 1002h, USBHS_NS.BUSWAIT 0745 1002h

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	BWAIT[3:0]	CPU Bus Access Wait Select	b3 b0 0 0 0 0: 0 waits (2 access cycles) 0 0 0 1: 1 wait (3 access cycles) 0 0 1 0: 2 waits (4 access cycles) 0 0 1 1: 3 waits (5 access cycles) 0 1 0 0: 4 waits (6 access cycles) 0 1 0 1: 5 waits (7 access cycles) 0 1 1 0: 6 waits (8 access cycles) 0 1 1 1: 7 waits (9 access cycles) 1 0 0 0: 8 waits (10 access cycles) 1 0 0 1: 9 waits (11 access cycles) 1 0 1 0: 10 waits (12 access cycles) 1 0 1 1: 11 waits (13 access cycles) 1 1 0 0: 12 waits (14 access cycles) 1 1 0 1: 13 waits (15 access cycles) 1 1 1 0: 14 waits (16 access cycles) 1 1 1 1: 15 waits (17 access cycles) (initial value)	R/W
b5, b4	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b7, b6	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b13 to b8	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b15, b14	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

BWAIT[3:0] Bits (CPU Bus Access Wait Select)

The BWAIT[3:0] bits specify the wait period to access registers associated with the USBHS.

Among the registers associated with the USBHS, when consecutively accessing registers other than the SYSCFG and BUSWAIT registers, the access cycle time must be at least 41 ns. Though the initial value of the BWAIT[3:0] bits is 1111b (17 access cycles), satisfy this condition by setting the best value for wait period in accordance with the frequency of the PCLKA. This setting is the same as the waits in accesses to the FIFO port register. The maximum speed for accessing the FIFO port registers is as follows:

MBW[1:0] bits are 00b (8-bit width): 15 Mbytes/s

MBW[1:0] bits are 01b (16-bit width): 30 Mbytes/s

MBW[1:0] bits are 10b (32-bit width): 60 Mbytes/s

41.2.3 System Configuration Status Register (SYSSTS0)

Address(es): USBHS.SYSSTS0 8745 1004h, USBHS_NS.SYSSTS0 0745 1004h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVCMON[1:0]		—	—	—	—	—	—	—	HTACT	SOFEA	—	—	IDMON	LNST[1:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	0	0	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	LNST[1:0]	USB Data Line Status Monitor Flags	These flags indicate the status of the USB data line. See Table 41.4 for details.	R
b2	IDMON	USBHS_ID Pin Monitor Flag	0: Low is input to the USBHS_ID pin. 1: High is input to the USBHS_ID pin.	R
b4, b3	—	Reserved	These bits are undefined when read.	R
b5	SOFEA	SOF Active Monitor Flag While in Host Controller Operation	0: (μ)SOF output is stopped. 1: (μ)SOF output is continued.	R
b6	HTACT	Host Sequencer Status Monitor Flag	0: Host sequencer is stopped. 1: Host sequencer is operating.	R
b13 to b7	—	Reserved	These bits are undefined when read.	R
b15, b14	OVCMON[1:0]	USBHS_OVRCURA/ USBHS_OVRCURB Pin Monitor Flags	The OVCMON[1] flag indicates the status of the USBHS_OVRCURA pin. The OVCMON[0] flag indicates the status of the USBHS_OVRCURB pin.	R

LNST[1:0] Flags (USB Data Line Status Monitor Flags)

These flags indicate the state of the USB data lines (D+ line and D– line). See Table 41.4 for details. In function controller operation, set the SYSCFG.CNEN and USBE bits to 1 before reading the LNST[1:0] flags. In host controller operation, set the SYSCFG.DRPD bit to 1 before reading the LNST[1:0] flags.

However, for hardware-based contact checking using the battery charging function in function controller operation, set the SYSCFG.DRPD, SYSCFG.CNEN, and BCCTRL.IDPSRCE bits to 1 before reading the LNST[1:0] flags. Refer to section 41.3.15, Battery Charging Detection Processing for details.

Table 41.4 Status of USB Data Bus Lines

LNST[1:0] Flags	During Low-Speed Operation (Only in Host Controller Operation)	During Full-Speed Operation	During High-Speed Operation	During Chirp Operation
00b	SE0	SE0	Squelch	Squelch
01b	K state	J state	Unsquelch	Chirp J
10b	J state	K state	Invalid	Chirp K
11b	SE1	SE1	Invalid	Invalid

Chirp: The reset handshake protocol is being executed when high-speed operation is enabled (HSE bit is set to 1).
Squelch: SE0 or Idle state
Unsquelch: High-speed J state or high-speed K state
Chirp J: Chirp J state
Chirp K: Chirp K state

SOFEA Flag (SOF Active Monitor Flag While in Host Controller Operation)

When the USB bus enters the Suspend state by setting the DVSTCTR0.UACT bit to 0 in host controller operation, the SOFEA flag is used to check whether the output of the last (μ)SOF is completed. If the SYSCFG.USBE bit is set to 0 to stop the USBHS module and the LPSTS.SUSPENDM bit is set to 0 to stop supply of the clock signal while

communications are in progress in host controller operation, make sure the HTACT and SOFEA flags are set to 0.

HTACT Flag (Host Sequencer Status Monitor Flag)

The HTACT flag is set to 0 when the host sequencer of the USBHS is completely stopped. In host controller operation, make sure the HTACT flag is set to 0 when setting the DVSTCTR0.UACT bit to 0 to place the USBHS interface in the USB bus Suspend state or setting the LPSTS.SUSPENDM bit to 0 to stop the clock. In addition, when communicating in host controller operation, make sure the HTACT flag and SOFEA flag are both 0 when setting the SYSCFG.USBE bit to 0 to stop the USBHS, or when setting the LPSTS.SUSPENDM bit to 0 to stop the clock.

OVCMON[1:0] Flags (USBHS_OVRCURA/USBHS_OVRCURB Pin Monitor Flags)

The OVCMON[1] flag indicates the status of the USBHS_OVRCURA pin, and the OVCMON[0] flag indicates the status of the USBHS_OVRCURB pin.

41.2.4 PLL Status Register (PLLSTA)

Address(es): USBHS.PLLSTA 8745 1006h, USBHS_NS.PLLSTA 0745 1006h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PLLLOCK
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	PLLLOCK	PLL Lock Flag	0: PLL is not locked. 1: PLL is locked.	R
b15 to b1	—	Reserved	These bits are undefined when read.	R

PLLLOCK Flag (PLL Lock Flag)

Indicates whether the USB-PHY internal PLL is locked or not. When classic-only mode is not used, make sure the PLL is locked before starting USB communication.

41.2.5 Device State Control Register 0 (DVSTCTR0)

Address(es): USBHS.DVSTCTR0 8745 1008h, USBHS_NS.DVSTCTR0 0745 1008h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b15 to b12	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

RHST[2:0] Bits (USB Reset Handshake Status)

These flags indicate that a reset handshake is in progress.

1. In host controller operation
   When the USBRST bit is set to 1, the RHST[2:0] bits become 100b. If the SYSCFG.HSE bit is 1, the RHST[2:0] bits become 111b as soon as the USBHS detects Chirp K from the function. When the USBRST bit is set to 0, the USBHS stops the USB bus reset signal, and the USBHS fixes the RHST[2:0] bit value. When setting the TESTMODE.UTST[3:0] bits to “1xxxb” (when the USB test signal is output in host controller operation), the RHST[2:0] bits become 011b.
2. In function controller operation
   If the SYSCFG.HSE bit is 1, when the USBHS detects a USB bus reset, the RHST[2:0] bits become 100b. Then, the USBHS outputs Chirp K, and when the USB host detects Chirp J and/or Chirp K three times, the RHST[2:0] bits become 011b. If high-speed is not confirmed within 2.5 ms of Chirp K being output, the RHST[2:0] bits become 010b. If the SYSCFG.HSE bit is 0, when the USBHS detects a USB bus reset, the RHST[2:0] bits become 010b.After the USBHS detects the USB bus reset, when the RHST[2:0] bits are confirmed to be 010b or 011b, the device state transition interrupt is generated.

UACT Bit (USB Bus Operation Enable for Host Controller Operation)

When the UACT bit is set to 1 in host controller operation, the USBHS enables the USB bus for the USB port.
The USBHS starts the output of an (µ)SOF packet within one (micro)frame period after the UACT bit is set to 1.
If the UACT bit is set to 0, the USBHS enters the Idle state after an (µ)SOF packet is output.
The USBHS sets the UACT bit to 0 on either of the following conditions.

- A DTCH interrupt is detected
- An EOFERR interrupt is detected

Set the UACT bit to 1 either when the USB bus reset processing is complete (USBRST bit is set to 0), or when the USBHS has exited the Suspend state (RESUME bit is set to 0).
When the HL1CTRL1.L1REQ bit is set to 1 to issue an LPM token and an ACK response is received, the USBHS sets the UACT bit to 0. In addition, after exiting the L1 state, the USBHS sets the UACT bit to 1.
In function controller operation, set the UACT bit to 0.

RESUME Bit (Resume Signal Output for Host Controller Operation)

This bit controls the output of the resume signal in host controller operation.
If the RESUME bit set to 1 while in the Suspend state, the USBHS outputs the resume signal to the USB port. In addition, if the RWUPE bit is 1 and a remote wakeup signal is detected while in the Suspend state, the USBHS sets the RESUME bit to 1, and USBHS outputs the resume signal to the USB port.
The USBHS continues outputting the resume signal until the RESUME bit is set to 0 by software. Ensure that the period the RESUME bit is 1 (resume period) complies with the time defined in USB 2.0. In addition, set the UACT bit to 1 at the same time the resume processing is complete (RESUME bit is set to 0).
If the RESUME bit to 1 during the L1 state, the USBHS outputs the resume signal to the USB port. The resume period is the period indicated by the HL1CTRL2.HIRD[3:0] bits. The USBHS sets the RESUME bit to 0 at the end of the resume period.
Only set the RESUME bit is 1 while in the Suspend state or L1 state. In addition, set the RESUME bit to 0 in function controller operation.

USBRST Bit (USB Bus Reset Output for Host Controller Operation)

In host controller operation, this bit controls the output of the USB bus reset signal.
In host controller operation, if the USBRST bit is set to 1, the USBHS performs a USB bus reset on the USB port. If the SYSCFG.HSE bit is 1, the reset handshake protocol is executed.
The USBHS continues outputting the bus reset signal until the USBRST bit is set to 0 by software. Ensure that the period the USBRST bit is 1 (USB bus reset period) complies with the time defined in USB 2.0.
When setting the USBRST bit to 1 either during communication (UACT bit is 1), or during the resume processing (RESUME bit is 1), the USBHS prevents the USB but reset processing from starting until both the UACT and RESUME bits become 0. Set the UACT bit to 1 at the same time the USB bus reset processing is complete (USBRST bit is set to 0).
In function controller operation, set the USBRST bit to 0.

RWUPE Bit (Remote Wakeup Detection Enable for Host Controller Operation)

In host controller operation, this bit enables and disables remote wakeup signals (resume signals) from peripheral devices connected to downstream ports.
While the RWUPE bit set to 1, the USBHS performs resume processing (resume signal is output) when a remote wakeup signal (K state for 2.5 µs) is detected from a peripheral device connected to a downstream port.
While the RWUPE bit is 0, even if the USBHS detects a remote wakeup signal from a peripheral device connected to the USB port, the remote wakeup signal is ignored.
When the RWUPE bit is set to 1, do not stop the PHY clock even in the Suspend state (keep the LPSTS.SUSPENDM bit to 1). Also, executing a USB bus reset (setting the USBRST bit to 1) while in the Suspend state is prohibited in USB 2.0.
In addition, the RWUPE bit is used to enable and disable detection of the remote wakeup signal while in the L1 state.
In function controller operation, set the RWUPE bit to 0.

WKUP Bit (Remote Wakeup Output for Function Controller Operation)

In function controller operation, this bit is used to output the remote wakeup signal (resume signal) to the USB port.
The USBHS controls the output time of the remote wakeup signal. When the WKUP bit is set to 1, the USBHS sets this bit to 0 after outputting a 10-ms remote wakeup signal.
According to USB 2.0, the USBHS must be in the USB bus Idle state for at least 5 ms before the remote wakeup signal is transmitted. For this reason, even if the WKUP bit is set to 1 immediately after the USB bus is detected as being in the suspended state, the USBHS waits 2 ms before outputting the remote wakeup signal.
Only set the WKUP bit to 1 when the device state is in the suspended state (INTSTS0.DVSQ[2:0] bits are 1xxb) and the remote wakeup signaling is enabled by the USB host.
Also, when the WKUP bit is set to 1, do not stop the PHY clock even if the USBHS is in the suspended state (keep the LPSTS.SUSPENDM bit to 1).
If the WKUP bit is set to 1 while the USBHS is in the L1 state, the USBHS outputs the remote wakeup signal for 50 µs and then sets the WKUP bit to 0.
In host controller operation, set the WKUP bit to 0.

HNPBTOA Bit (Host Negotiation Protocol (HNP) Control)

When the USBHS is used as an OTG device B, set this bit to switch from function controller operation to host controller operation.
If the HNPBTOA bit is 1, the USBHS remains in the suspended state until HNP processing is complete even if the SYSCFG.DPRPU bit is set to 0 or the SYSCFG.DCFM bit is set to 1. At this time, a resume interrupt is not generated even if a falling edge on the D+ line is detected.
After setting the HNPBTOA bit to 1, when attachment of a host is detected (due to pulling up by the other party) or if a timeout occurs during HNP processing, set the HNPBTOA bit to 0 to end HNP processing.

41.2.6 USB Test Mode Register (TESTMODE)

Address(es): USBHS.TESTMODE 8745 100Ch, USBHS_NS.TESTMODE 0745 100Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	UTST[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	UTST[3:0]	Test Mode	These bits output the USB test signals. See Table 41.5 for details on the output signals.	R/W
b15 to b4	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

UTST[3:0] Bits (Test Mode)

Writing values to these bits allows the USBHS to output a USB test signal in high-speed operation mode.
Table 41.5 lists the Test Mode Operation of the USBHS.

Table 41.5 Test Mode Operation

Test Mode	UTST[3:0] Bit Settings	
	In function controller operation	In host controller operation
Normal operation	0000b	0000b
Test_J	0001b	1001b
Test_K	0010b	1010b
Test_SE0_NAK	0011b	1011b
Test_Packet	0100b	1100b
Test_Force_Enable	—	1101b
Reserved	0101b to 0111b	1110b to 1111b

- In host controller operation:
  The UTST[3:0] bits can be set after setting the SYSCFG.DRPD bit to 1. After setting the UTST[3:0] bits, the USBHS outputs waveforms by setting the DVSTCTR0.UACT bit to 1. When the UTST[3:0] bits are set while in host controller operation, even if the USBHS is not connected to a peripheral device, the USBHS performs a test as if it were connected to a high-speed terminating resistor.
  Use the following procedure to set the UTST[3:0] bits.
  (1) Reset the MCU.
  (2) Start supplying the PHY clock and then set the LPSTS.SUSPENDM bit to 1.
  (3) Set the SYSCFG.DCFM and DRPD bits to 1 (the SYSCFG.HSE bit does not need to be set to 1).
  (4) Set the SYSCFG.USBE bit to 1.
  (5) Set the UTST[3:0] bits according to the test content.
  (6) Set the DVSTCTR0.UACT bit to 1.

  Use the following procedure to change the UTST[3:0] bits. Steps (1) to (6) described above are assumed to have been executed in advance.
  (1) Set the DVSTCTR0.UACT and SYSCFG.USBE bits to 0.
  (2) Set the SYSCFG.USBE bit to 1.
  (3) Set the UTST[3:0] bits according to the test content.
  (4) Set the DVSTCTR0.UACT bit to 1.

When the UTST[3:0] bits are set to 1011b (Test_SE0_NAK), the USBHS does not output (µ)SOF packets even if the DVSTCTR0.UACT bit is set to 1.
When the UTST[3:0] bits are set to 1101b (Test_Force_Enable), the USBHS outputs (µ)SOF packets by setting the DVSTCTR0.UACT bit is set to 1. Also, in this test mode, even if the USBHS detects a high-speed disconnection (DTCH interrupt detected), the USBHS does not control the hardware corresponding to the detection.
When setting the UTST[3:0] bits, set the PID[1:0] bits of all pipe control registers to 00b (NAK response).
When performing normal USB communication after setting test mode, reset the MCU.

- In function controller operation:
  Set the UTST[3:0] bits according to the SetFeature request from the USB host during high-speed communication.
  The USBHS does not enter the suspended state when the UTST[3:0] bits are set to a value from 0001b to 0100b.
  When performing normal USB communication after setting test mode, reset the MCU.

41.2.7 CFIFO Port Register (CFIFO), D0FIFO Port Register (D0FIFO), D1FIFO Port Register (D1FIFO)

(1) FIFO port register values when the MBW[1:0] bits are 10b (32-bit width)

Address(es): USBHS.CFIFO 8745 1014h, USBHS.D0FIFO 8745 1018h, USBHS.D1FIFO 8745 101Ch, USBHS_NS.CFIFO 0745 1014h, USBHS_NS.D0FIFO 0745 1018h, USBHS_NS.D1FIFO 0745 101Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	—	FIFO Port	From this port, receive data is read from the FIFO buffer and transmit data is written to the FIFO buffer.	R/W

(2) FIFO port register values when the MBW[1:0] bits are 01b (16-bit width) and the BIGEND bit is 0 (Little endian)

Address(es): USBHS.CFIFO.H 8745 1016h, USBHS.D0FIFO.H 8745 101Ah, USBHS.D1FIFO.H 8745 101Eh, USBHS_NS.CFIFO.H 0745 1016h, USBHS_NS.D0FIFO.H 0745 101Ah, USBHS_NS.D1FIFO.H 0745 101Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	FIFO Port	From this port, receive data is read from the FIFO buffer and transmit data is written to the FIFO buffer.	R/W

(3) FIFO port register values when the MBW[1:0] bits are 01b (16-bit width) and the BIGEND bit is 1 (Big endian)

Address(es): USBHS.CFIFO.L 8745 1014h, USBHS.D0FIFO.L 8745 1018h, USBHS.D1FIFO.L 8745 101Ch, USBHS_NS.CFIFO.L 0745 1014h, USBHS_NS.D0FIFO.L 0745 1018h, USBHS_NS.D1FIFO.L 0745 101Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	FIFO Port	From this port, receive data is read from the FIFO buffer and transmit data is written to the FIFO buffer.	R/W

There are three FIFO ports: CFIFO, D0FIFO, and D1FIFO. Each FIFO port is configured of a FIFO port register, FIFO port select register, and a FIFO port control register. The FIFO port registers (CFIFO, D0FIFO, and D1FIFO) read data from and write data to the FIFO buffers. The FIFO port select registers (CFIFOSEL, D0FIFOSEL, and D1FIFOSEL) are used to select the pipe assigned to the FIFO port. The FIFO port control registers are CFIFOCTR, D0FIFOCTR, and D1FIFOCTR.

The following are features and precautions pertaining to the FIFO ports:

- Access the FIFO buffer for the default control pipe (control transfer) through the CFIFO port.
- Accessing a FIFO buffer using DMA/DTC transfer should be performed through the D0FIFO or D1FIFO port.
- The D0FIFO and D1FIFO ports can also be accessed by the CPU.
- Registers configuring one FIFO port do not affect other FIFO ports.
- The same pipe should not be assigned to two or more FIFO ports.
- Access rights for a FIFO buffer can be on the CPU side or on the serial interface engine (SIE) side. When the access right for a FIFO buffer is on the SIE side, the FIFO buffer cannot be accessed from the CPU.

FIFO Port Bits

Using the FIFO port bits, the received data can be read from the FIFO buffer and the transmit data can be written to the FIFO buffer. The FIFO port registers can only be accessed when the FRDY flag in the corresponding FIFO port control register is 1. Valid bits in the FIFO port registers depend on the MBW[1:0] and BIGEND bit values in the corresponding FIFO port select register. When the MBW[1:0] bits are 01b or 10b, data allocation changes in relation to the MDE.MDE[2:0] bit value and the CFIFOSEL.BIGEND, D0FIFOSEL.BIGEND, and D1FIFOSEL.BIGEND bits. Table 41.6 and Table 41.7 show the various data allocation.

Table 41.6 Data Allocation in a 32-Bit Access (MBW[1:0] Bits are 10b)

MDE[2:0] Bits	BIGEND Bit	b31 to b24	b23 to b16	b15 to b8	b7 to b0	Remarks
000b (big endian)	0 (little endian)	Address N+3	Address N+2	Address N+1	Address N+0	Data is transmitted sequentially from address N+3. Data received is stored sequentially from address N+3.
	1 (big endian)	Address N+0	Address N+1	Address N+2	Address N+3	Data is transmitted sequentially from address N+0. Data received is stored sequentially from address N+0.
111b (little endian)	0 (little endian)	Address N+3	Address N+2	Address N+1	Address N+0	Data is transmitted sequentially from address N+0. Data received is stored sequentially from address N+0.
	1 (big endian)	Address N+0	Address N+1	Address N+2	Address N+3	Data is transmitted sequentially from address N+3. Data received is stored sequentially from address N+3.

Table 41.7 Data Allocation in a 16-Bit Access (MBW[1:0] Bits are 01b)

MDE[2:0] Bits	BIGEND Bit	b15 to b8	b7 to b0	Remarks
000b (big endian)	0 (little endian)	Address N+1	Address N+0	Access the upper word (.H). Data is transmitted sequentially from address N+1. Data received is stored sequentially from address N+1.
	1 (big endian)	Address N+0	Address N+1	Access the lower word (.L). Data is transmitted sequentially from address N+0. Data received is stored sequentially from address N+0.
111b (little endian)	0 (little endian)	Address N+1	Address N+0	Access the upper word (.H). Data is transmitted sequentially from address N+0. Data received is stored sequentially from address N+0.
	1 (big endian)	Address N+0	Address N+1	Access the lower word (.L). Data is transmitted sequentially from address N+1. Data received is stored sequentially from address N+1.

41.2.8 CFIFO Port Select Register (CFIFOSEL)

Address(es): USBHS.CFIFOSEL 8745 1020h, USBHS_NS.CFIFOSEL 0745 1020h

b13, b12	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b14	REW	Buffer Pointer Rewind	Set this bit to 1 to rewind the buffer pointer. Writing 0 has no effect.	R/W
b15	RCNT	Read Count Mode	0: The CFIFOCTR.DTLN[11:0] bits are set to 000h when all of the receive data has been read from the CFIFO register. 1: The CFIFOCTR.DTLN[11:0] bits are decremented each time the receive data is read from the CFIFO register.	R/W

The same pipe number should not be set to the CURPIPE[3:0] bits in registers CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

CURPIPE[3:0] Bits (FIFO Port Access Pipe Select)

The CURPIPE[3:0] bits specify the current pipe number for which data is read or written through the CFIFO port. When the CURPIPE[3:0] bits are modified, read the bits to confirm they have been successfully modified, and then proceed to the next processing.

Do not set the same pipe number in the CURPIPE[3:0] bits in registers CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

If the CURPIPE[3:0] bits are modified while accessing the FIFO buffer, access until that point is retained, and after the CURPIPE[3:0] bits are modified back to the original setting, access can be resumed.

ISEL Bit (FIFO Port Access Direction When Default Control Pipe is Selected)

If the ISEL bit is modified while the default control pipe is the current pipe, read the bit to confirm it has been successfully modified. Set the ISEL bit and the CURPIPE[3:0] bits simultaneously.

BIGEND Bit (FIFO Port Endian Control)

Set this bit to specify the byte endian of the CFIFO port.

MBW[1:0] Bits (CFIFO Port Access Bit Width)

Set this bit to specify the bit width for accessing the CFIFO port.
When the transfer direction of the current pipe is receiving, if the MBW[1:0] bits are set to start reading data from the FIFO buffer, do not modify the MBW[1:0] bits until all the data has been read. When modifying the MBW[1:0] bits, set the CURPIPE[3:0] bits to a different value first, and set the CURPIPE[3:0] bits and MBW[1:0] bits simultaneously.
When the transfer direction of the current pipe is transmitting, while data is being written to the FIFO buffer, the bit width cannot be changed from 8-bit width to 16- or 32-bit width, and 16-bit width cannot be changed to 32-bit width. Also, even when 16-bit or 32-bit width is selected, an odd number of bytes can be written by byte access.

REW Bit (Buffer Pointer Rewind)

When the transfer direction of the current pipe is receiving, if the REW bit is set to 1 while reading data from the FIFO buffer, the FIFO buffer can be reread from the first data. In double buffer mode, the buffer that was being read can be reread from the first data.
Do not modify the CURPIPE[3:0] bits when setting the REW bit to 1. Also, confirm that the FRDY flag is 1 before setting the REW bit to 1.
For pipes in the receiving transfer direction, to rewrite to the FIFO buffer from the first data, set the BCLR bit.

RCNT Bit (Read Count Mode)

When the RCNT bit is set to 0, when all data has been read from the FIFO buffer (in double buffer mode, when a single plane is done being read) for the pipe specified by the CURPIPE[3:0] bits, the USBHS sets the CFIFOCTR.DTLN[11:0] bits to 000h.
When the RCNT bit set to 1, each time data is read from the FIFO buffer for the pipe specified by the CURPIPE[3:0] bits, the USBHS decrements the value of the CFIFOCTR.DTLN[11:0] bits.

41.2.9 D0FIFO Port Select Register (D0FIFOSEL), D1FIFO Port Select Register (D1FIFOSEL)

Address(es): USBHS.D0FIFOSEL 8745 1028h, USBHS.D1FIFOSEL 8745 102Ch, USBHS_NS.D0FIFOSEL 0745 1028h, USBHS_NS.D1FIFOSEL 0745 102Ch

b13	DCLRM	Automatic FIFO Buffer Clear Mode after Current Pipe is Read	0: Automatic buffer clear mode is disabled. 1: Automatic buffer clear mode is enabled.	R/W
b14	REW	Buffer Pointer Rewind	Set this bit to 1 to rewind the buffer pointer. Writing 0 has no effect.	R/W
b15	RCNT	Read Count Mode	0: The DTLN[11:0] bits in the D0FIFOCTR/D1FIFOCTR register are set to 000h when all of the receive data has been read from D0FIFO/D1FIFO (after reading a single plane in double buffer mode). 1: The DTLN[11:0] bits in the D0FIFOCTR/D1FIFOCTR register are decremented each time the receive data is read from D0FIFO/D1FIFO.	R/W

The same pipe number should not be set to the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. In addition, a pipe is not assigned if the setting of the D0FIFOSEL/D1FIFOSEL.CURPIPE[3:0] bits is 0000b.

CURPIPE[3:0] Bits (FIFO Port Access Pipe Select)

The CURPIPE[3:0] bits specify the current pipe number for which data is read or written through the D0FIFO or D1FIFO port.

When the CURPIPE[3:0] bits are modified, read the bits to confirm they have been successfully modified, and then proceed to the next processing.

Do not set the same pipe number in the CURPIPE[3:0] bits in registers CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.
If the CURPIPE[3:0] bits are modified while accessing the FIFO buffer, access until that point is retained, and after the CURPIPE[3:0] bits are modified back to the original setting, access can be resumed.

BIGEND Bit (FIFO Port Endian Control)

Set this bit to specify the byte endian of the D0FIFO and D1FIFO port.

MBW[1:0] Bits (FIFO Port Access Bit Width)

This bit specifies the bit width for accessing the D0FIFO or D1FIFO port.
When the current pipe is in the receiving direction, once reading data from the FIFO buffer is started after setting the MBW[1:0] bits, these bits should not be modified until all the data has been read. When modifying the MBW[1:0] bits, set the CURPIPE[3:0] bits to 0000b first, and set the CURPIPE[3:0] bits and the MBW[1:0] bits simultaneously.
When the current pipe is in the transmitting direction, the bit width cannot be changed from 8-bit width to 16-bit/32-bit width or 16-bit width to 32-bit width while data is being written to the FIFO buffer. An odd number of bytes can also be written through byte-access control even when 16-bit or 32-bit width is selected.

DREQE Bit (DMA/DTC Transfer Request Enable)

This bit enables or disables the DMA/DTC transfer request.
Modify the bit when the CURPIPE[3:0] bits are 0000b.
To enable the DMA/DTC transfer request, set the CURPIPE[3:0] bits to the desired pipe number after setting the bit to 1.

DCLRM Bit (Automatic FIFO Buffer Clear Mode after Current Pipe is Read)

This bit enables or disables the automatic FIFO buffer clear after data in the current pipe is read. When the DCLRM bit is set to 1 on receiving a zero-length packet while the FIFO buffer assigned to the current pipe is empty, or when reading the received short packet is completed while the PIPECFG.BFRE bit is 1, the USBHS sets the BCLR bit in a FIFO port control register to 1. Set the DCLRM bit to 0 when the SOFCFG.BRDYM bit 1.

REW Bit (Buffer Pointer Rewind)

When the current pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data. When double-buffering is in use and reading is already in progress, reading either FIFO buffer from the first entry is possible. Do not set the REW bit to 1 simultaneously with modifying the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY flag is 1. To rewrite to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

RCNT Bit (Read Count Mode)

With the RCNT bit set to 0, the USBHS sets the DTLN[11:0] bits in the D0FIFOCTR/D1FIFOCTR register to 000h upon finishing reading all the received data in the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits (after reading a single plane in double buffer mode). With the RCNT bit set to 1, the USBHS decrements the value indicated by the DTLN[11:0] bits each time it reads data received from the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits. Set the RCNT bit to 0 when accessing D0FIFO/D1FIFO with the PIPECFG.BFRE bit set to 1.

41.2.10 CFIFO Port Control Register (CFIFOCTR), D0FIFO Port Control Register (D0FIFOCTR), D1FIFO Port Control Register (D1FIFOCTR)

Address(es): USBHS.CFIFOCTR 8745 1022h, USBHS.D0FIFOCTR 8745 102Ah, USBHS.D1FIFOCTR 8745 102Eh, USBHS_NS.CFIFOCTR 0745 1022h, USBHS_NS.D0FIFOCTR 0745 102Ah, USBHS_NS.D1FIFOCTR 0745 102Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BVAL	BCLR	FRDY	—	DTLN[11:0]											
Value after reset:	0	0	0	x	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	DTLN[11:0]	Receive Data Length	These bits indicate the length of the receive data. The meaning of the value of these bits differs with the setting of the RCNT bit in the FIFO port select register.	R
b12	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b13	FRDY	FIFO Port Ready Flag	0: FIFO port access is disabled 1: FIFO port access is enabled	R
b14	BCLR	CPU Buffer Clear	This bit should be set to 1 to clear the FIFO buffer on the CPU side for the pipe specified by the CURPIPE[3:0] bits. Writing 0 has no effect. This bit is 0 when read.	R/W
b15	BVAL	FIFO Buffer Valid	This bit should be set to 1 when data has been completely written to the FIFO buffer on the CPU side for the pipe specified by the CURPIPE[3:0] bits. Writing 0 has no effect.	R/W

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers respectively correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[11:0] Bits (Receive Data Length)

These bits indicate the length of the receive data. While data is being read from the FIFO buffer, the value of the DTLN[11:0] bits differs according to the setting of the RCNT bit in the FIFO port select registers as described below.

- When the RCNT bit is 0
  The USBHS sets the DTLN[11:0] bits to indicate the length of the receive data until the CPU or DMAC/DTC has read all the received data in the FIFO buffer (until a single plane has been read in double buffer mode).
  When the PIPECFG.BFRE bit for the current pipe is set to 1, the USBHS retains the length of the receive data until the BCLR bit is set to 1 even after all the data has been read.
- When the RCNT bit is 1
  The USBHS decrements the value indicated by the DTLN[11:0] bits each time the CPU or DMAC/DTC reads the receive data from the FIFO buffer. (The value is decremented by one when the MBW[1:0] bits are 00b, by two when the MBW[1:0] bits are 01b, and by four when the MBW[1:0] bits are 10b.)
  The DTLN[11:0] bits become 000h when all the data has been read from the FIFO buffer. However, in double buffer mode, if data reception is completed in one FIFO buffer plane before all the data has been read from the other plane, the DTLN[11:0] bits indicate the length of the receive data in the latter plane when all the data has been read from the former plane.
  In addition, updating the DTLN[11:0] bits can take up to 150 ns. After reading the FIFO buffer, wait at least 150 ns before reading the DTLN[11:0] bits.

FRDY Flag (FIFO Port Ready Flag)

This flag indicates whether the FIFO port can be accessed by the CPU or DMAC/DTC.
In the cases below, the FRDY flag also becomes 1, but data cannot be read via the FIFO port because there is no data to be read. In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

- A zero-length packet is received when the FIFO buffer assigned to the current pipe is empty.
- When the PIPECFG.BFRE bit for the current pipe is 1, a short packet is received and the data read operation is complete.

BCLR Bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU side of the current pipe.
When double buffer mode is set for the FIFO buffer assigned to the current pipe, the USBHS only clears the FIFO buffer on the CPU side even when both planes are readable.
When the current pipe is the default control pipe, setting the BCLR bit to 1 clears the FIFO buffer regardless of whether the FIFO buffer access rights are on the CPU side or the SIE side. To clear the FIFO buffer when the SIE has the access right, set the DCPCTR.PID[1:0] bits to 00b (NAK response) and then set the BCLR bit to 1.
When the current pipe is a pipe other than the default control pipe, set the BCLR bit to 1 when the FRDY flag in a FIFO port control register is 1.

BVAL Bit (FIFO Buffer Valid)

When the transfer direction of the pipe specified by the CURPIPE[3:0] bits is transmitting, set the BVAL bit to 1 in the cases listed below. When the BVAL bit is set to 1, the USBHS switches the FIFO buffer access right from the CPU side to the SIE side, enabling transmission.

- To transmit a short packet, set this bit to 1 after transmit data has been written.
- To transmit a zero-length packet, set this bit to 1 before transmit data is written.
- For pipes in continuous transfer mode, set this bit to 1 after writing data that is an integral multiple of the maximum packet size and less than the buffer size.

When the BVAL bit and BCLR bit are set to 1 simultaneously, the USBHS clears the data already written and enables the transmission of a zero-length packet. For pipes in discontinuous transfer mode, when the maximum packet size of data is written, the USBHS sets the BVAL bit to 1, and switches the FIFO buffer access right from the CPU side to the SIE side, enabling transmission.
Set the BVAL bit to 1 while the FRDY flag is 1.
When the transfer direction of the current pipe is receiving, do not set the BVAL bit to 1.

41.2.11 Interrupt Enable Register 0 (INTENB0)

Address(es): USBHS.INTENB0 8745 1030h, USBHS_NS.INTENB0 0745 1030h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b14	RSME	Resume Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b15	VBSE	VBUS Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled	R/W

Note 1. The CTRE bit, DVSE bit, and RSME bit can only be set to 1 in function controller operation. Set these bits to 0 in host controller operation.

When a status flag in the INTSTS0 register becomes 1, if the corresponding interrupt request enable bit in the INTENB0 register is 1, the USBHS requests the USBHSR interrupt.
Regardless of the INTENB0 register setting, if the conditions for each status are satisfied, the status flags corresponding to the INTSTS0 register become 1.
When the status flags in the INTSTS0 register are 1, if a corresponding interrupt request enable bit in the INTENB0 register is rewritten from 0 to 1, the USBHSR interrupt request is generated.

41.2.12 Interrupt Enable Register 1 (INTENB1)

b5	SIGNE	Setup Transaction Error Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b6	EOFERRE	End-of-Frame Error Detection Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b7	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b8	LPMENDE	LPM Transaction End Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b9	L1RSMENDE	L1 Resume End Interrupt Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b10	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b11	ATTCHE	Device Connection Detection Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b12	DTCHE	Device Disconnection Detection Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b13	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b14	BCHGE	Bus Change Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W
b15	OVRCRE	Overcurrent Change Interrupt Request Enable	0: Interrupt request output disabled 1: Interrupt request output enabled *1	R/W

Note 1. This bit can only be set to 1 in host controller operation. Set this bit to 0 in function controller operation.

When a status flag in the INTSTS1 register becomes 1, if the corresponding interrupt request enable bit in the INTENB1 register is 1, the USBHS requests the USBHSR interrupt.
Regardless of the INTENB1 register setting, if the conditions for each status are satisfied, the status flags corresponding to the INTSTS1 register become 1.
When the status flags in the INTSTS1 register are 1, if a corresponding interrupt request enable bit in the INTENB1 register is rewritten from 0 to 1, the USBHSR interrupt request is generated.

41.2.13 BRDY Interrupt Enable Register (BRDYENB)

Address(es): USBHS.BRDYENB 8745 1036h, USBHS_NS.BRDYENB 0745 1036h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBRDYE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPEBRDYE[9:0]	Pipe 9 to Pipe 0 BRDY Interrupt Request Enable *1	0: Interrupt request output disabled 1: Interrupt request output enabled	R/W
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. pipe 9 corresponds to the PIPEBRDYE[9] bit, pipe 8 corresponds to the PIPEBRDYE[8] bit, etc.).

When a flag in the BRDYSTS register becomes 1, if the corresponding BRDYENB.PIPEBRDYE[9:0] bit is 1, the INTSTS0.BRDY flag becomes 1.
In this case, if the INTENB0.BRDYE bit is 1, the USBHS requests the USBHSR interrupt.
When any of the BRDYSTS.PIPEBRDY[9:0] flags is 1, if the corresponding interrupt request enable bit in the BRDYENB register is rewritten from 0 to 1, the INTSTS0.BRDY flag becomes 1.

41.2.14 NRDY Interrupt Enable Register (NRDYENB)

Address(es): USBHS.NRDYENB 8745 1038h, USBHS_NS.NRDYENB 0745 1038h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPENRDYE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPENRDYE[9:0]	Pipe 9 to Pipe 0 NRDY Interrupt Enable *1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. pipe 9 corresponds to the PIPENRDYE[9] bit, pipe 8 corresponds to the PIPENRDYE[8] bit, etc.).

When a flag in the NRDYSTS register becomes 1, if the corresponding NRDYENB.PIPENRDYE[9:0] bit is 1, the INTSTS0.NRDY flag becomes 1.
In this case, if the INTENB0.NRDYE bit is 1, the USBHS requests the USBHSR interrupt.
When any of the NRDYSTS.PIPENRDY[9:0] flags is 1, if the corresponding interrupt request enable bit in the NRDYENB register is rewritten from 0 to 1, the INTSTS0.NRDY flag becomes 1.

41.2.15 BEMP Interrupt Enable Register (BEMPENB)

Address(es): USBHS.BEMPENB 8745 103Ah, USBHS_NS.BEMPENB 0745 103Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBEMPE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPEBEMPE[9:0]	Pipe 9 to Pipe 0 BEMP Interrupt Enable *1	0: Interrupt output disabled 1: Interrupt output enabled	R/W
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. pipe 9 corresponds to the PIPEBEMPE[9] bit, pipe 8 corresponds to the PIPEBEMPE[8] bit, etc.).

When a flag in the BEMPSTS register becomes 1, if the corresponding BEMPENB.PIPEBEMPE[9:0] bit is 1, the INTSTS0.BEMP flag becomes 1.
In this case, if the INTENB0.BEMPE bit is 1, the USBHS requests the USBHSR interrupt.
When any of the BEMPSTS.PIPEBEMP[9:0] flags is 1, if the corresponding interrupt request enable bit in the BEMPENB register is rewritten from 0 to 1, the INTSTS0.BEMP flag becomes 1.

41.2.16 SOF Output Configuration Register (SOFCFG)

Address(es): USBHS.SOFCFG 8745 103Ch, USBHS_NS.SOFCFG 0745 103Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TRNENSEL	—	BRDYM	INTL	EDGESTS	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	0	x	0	0	0	0	0	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b4	EDGESTS	Interrupt Edge Processing Status Flag*1	This flag is 1 when the USBHS outputs an edge interrupt request signal.	R
b5	INTL	Interrupt Signal Output Method Select *2	0: Do not set this value (edge output) 1: Level output	R/W
b6	BRDYM	PIPEBRDY Interrupt Status Clear Timing*3	0: The PIPEBRDY[9:0] flags are set to 0 by software. 1: The PIPEBRDY[9:0] flags are set to 0 by reading the FIFO buffer or writing to the FIFO buffer.	R/W
b7	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b8	TRNENSEL	Transaction-Enabled Time Select*4	0: Not low-speed compatible 1: Low-speed compatible	R/W
b15 to b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

Note 1. Confirm that the EDGESTS flag is 0 before stopping the clock supplied to the USBHS.
Note 2. Set this bit to 1 before operating the USBHS.
Note 3. When setting the BRDYM bit to 1, set the INTL bit to 1.
Note 4. The TRNENSEL bit setting is only valid in host controller operation. Even in host controller operation, the setting of this bit has no effect on the transaction-enabled time during high-speed communication.

EDGESTS Flag (Interrupt Edge Processing Status Flag)

This flag is enabled when the INTL bit is 0 (edge output).

When multiple interrupt requests are generated, if one of the interrupt requests is cleared, the USBHS temporarily negates the interrupt request signal, after waiting 666.6 µs, the interrupt request signal is reasserted. While the interrupt request signal is negated, the EDGESTS flag becomes 1.

Confirm the EDGESTS flag is 0 when stopping the PHY clock.

BRDYM Bit (PIPEBRDY Interrupt Status Clear Timing)

This bit specifies the timing to clear the BRDY interrupt status (BRDYSTS.PIPEBRDY[9:0] flags) for each pipe.

TRNENSEL Bit (Transaction-Enabled Time Select)

When the USB port is in use for full-speed or low-speed communications, this bit specifies the timing with which the USBHS issues tokens in a frame (transaction-enabled time).

Set the TRNENSEL bit to 1 when a low-speed device is connected.

The TRNENSEL bit is only valid in host controller operation.

Set this bit to 0 in function controller operation.

41.2.17 PHY Setting Register (PHYSET)

Address(es): USBHS.PHYSET 8745 103Eh, USBHS_NS.PHYSET 0745 103Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HSEB	—	—	—	—	—	REPSEL[1:0]		—	—	CLKSEL[1:0]		CDPEN	—	PLLRESET	DIRPD
Value after reset:	0	x	x	x	0	x	0	0	x	x	1	1	0	x	1	1

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	DIRPD	Power-Down Control	0: Normal operation 1: Power-down mode	R/W
b1	PLLRESET	PLL Reset Control*1	0: Disable PLL reset control for USB-PHY 1: Enable PLL reset control for USB-PHY	R/W
b2	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b3	CDPEN	Charging Downstream Port Enable	0: Disable the charging downstream port 1: Enable the charging downstream port	R/W
b5, b4	CLKSEL[1:0]	Input System Clock Frequency	b5 b4 0 0: 12 MHz 0 1: 48 MHz 1 0: 20 MHz 1 1: 24 MHz	R/W
b7, b6	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b9, b8	REPSEL[1:0]	Terminating Resistance Adjustment	b9 b8 0 0: Disable the terminating resistance adjustment 0 1: Enable the terminating resistance adjustment 1 0: Do not set this value. 1 1: Do not set this value.	R/W
b10	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b11	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b14 to b12	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b15	HSEB	Classic-Only Mode*2	0: Classic-only mode is disabled. 1: Classic-only mode is enabled.	R/W

Note 1. Since the PLLRESET bit is 1 after a reset, changing the setting after release from the reset state is not required because of PLL reset control. Setting the PLLRESET bit to 1 after setting it to 0 may cause the USBHS operate erroneously.
Note 2. Do not set the HSEB bit to 0 after setting it to 1. Doing so may cause the USBHS operate erroneously.

CLKSEL[1:0] Bits (Input System Clock Frequency)

These bits select the frequency of the PLL clock source (USBMCLK) necessary for generating the USBHS PHY clock. The USBHS PHY clock is generated by the PLL embedded in the USB-PHY. The CLKSEL[1:0] bits set the frequency of the clock source (USBMCLK) supplied to the PLL. The USBMCLK is input from the EXTAL pin, but the clock specification must follow the clock standard in the USB 2.0. In classic-only mode, the PLL in the USB-PHY is stopped, so writing to the CLKSEL[1:0] bits is invalid (refer to the HSEB bit description for details).
Refer to section 41.3.3, Supplying Clocks for details on setting clocks.

REPSEL[1:0] Bits (Terminating Resistance Adjustment)

These bits automatically adjust the terminating resistance. Before operating the USBHS, set the REPSEL[1:0] bits to 01b to enable the automatic adjustment function for the terminating resistance. Note that the automatic adjustment function for the terminating resistance is stopped when the HSEB bit is 1 (classic-only mode is enabled).

HSEB Bit (Classic-Only Mode)

This bit selects whether the USBHS module operates in classic-only mode.

High-speed transfer by the USBHS requires the use of internal high-speed analog circuits including the PLL and clock and data recovery (CDR) circuit in the USB-PHY block. Classic-only mode limits transfer to the USB 1.1 specification (full-speed and low-speed transfer), so power consumption can be reduced by stopping the PHY module's internal PLL and other high-speed analog circuits.

In classic-only mode, USBCLK (48 MHz) and USB60CLK (60 MHz) clocks generated in the clock generation circuit must be supplied to the USBHS.

Refer to section 9, Clock Generation Circuit for details on supplying the clock. Refer to section 41.3.3 for details on setting clocks.

41.2.18 Interrupt Status Register 0 (INTSTS0)

Address(es): USBHS.INTSTS0 8745 1040h, USBHS_NS.INTSTS0 0745 1040h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	VBINT	RESM	SOFR	DVST	CTRT	BEMP	NRDY	BRDY	VBSTS	DVSQ[2:0]			VALID	CTSQ[2:0]		
Value after reset:	0	0	0	0/1*1	0	0	0	0	x	0	0	0/1*1	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CTSQ[2:0]	Control Transfer Stage*2	b2 b0 0 0 0: Idle state or setup stage 0 0 1: Control read data stage 0 1 0: Control read status stage 0 1 1: Control write data stage 1 0 0: Control write status stage 1 0 1: Control write (no data) status stage 1 1 0: Control transfer sequence error 1 1 1: Reserved	R
b3	VALID	USB Request Reception Flag*2	0: Setup packet is not received 1: Setup packet is received	R/(W)
b6 to b4	DVSQ[2:0]	Device State*2	b6 b4 0 0 0: Powered state 0 0 1: Default state 0 1 0: Address state 0 1 1: Configured state 1 0 0: Suspended state 1 0 1: Suspended state 1 1 0: Suspended state 1 1 1: Suspended state	R
b7	VBSTS	VBUS Input Status Flag	0: The USBHS_VBUS pin is low 1: The USBHS_VBUS pin is high	R
b8	BRDY	BRDY Interrupt Status Flag	0: BRDY interrupt not requested 1: BRDY interrupt requested	R
b9	NRDY	NRDY Interrupt Status Flag	0: NRDY interrupt not requested 1: NRDY interrupt requested	R
b10	BEMP	BEMP Interrupt Status Flag	0: BEMP interrupt not requested 1: BEMP interrupt requested	R
b11	CTRT	Control Transfer Stage Transition Interrupt Status Flag*3	0: Control transfer stage transition interrupt not requested 1: Control transfer stage transition interrupt requested	R/(W) *4
b12	DVST	Device State Transition Interrupt Status Flag*3	0: Device state transition interrupt not requested 1: Device state transition interrupt requested	R/(W) *4
b13	SOFR	Frame Number Refresh Interrupt Status Flag	0: Frame number refresh interrupt not requested 1: Frame number refresh interrupt requested	R/(W) *4
b14	RESM	Resume Interrupt Status Flag*3	0: Resume interrupt not requested 1: Resume interrupt requested	R/(W) *4
b15	VBINT	VBUS Interrupt Status Flag*5	0: VBUS interrupt is not requested on detecting a change in the USBHS_VBUS pin. 1: VBUS interrupt is requested on detecting a change in the USBHS_VBUS pin.	R/(W) *4

Note 1. The value is 0 when the MCU is reset, and 1 when a USB bus reset occurs.
Note 2. The CTSQ[2:0] bits, VALID flag, and DVSQ[2:0] bits are only valid in function controller operation.
Note 3. The CTRT, DVST, and RESM flags are only changed in function controller operation. Set the corresponding interrupt enable bits to 0 (disabled) in host controller operation.
Note 4. To clear the CTRT, DVST, SOFR, RESM, or VBINT flags, write 0 only to the flags to be cleared, and write 1 to the other flags. Do not write 0 to the status flags indicating 0.
Note 5. The USBHS detects a change in the status indicated by the VBINT flag even while the clock supply is stopped (while the LPSTS.SUSPENDM bit is 0), and requests the USBHSR interrupt when the corresponding interrupt enable bit is 1. Clear these flags after supplying the PHY clock.

BRDY Flag (BRDY Interrupt Status Flag)

This flag indicates the state of the BRDY interrupt. Refer to section 41.2.13 for conditions of the BRDY flag becoming 1. The BRDY flag becomes 0 when 0 is written to the BRDYSTS.PIPEBRDY[9:0] flags for all pipes for which the BRDYENB.PIPEBRDYE[9:0] bits are 1 (interrupt request output enabled). The BRDY flag does not become 0 even when set to 0 by software.

NRDY Flag (NRDY Interrupt Status Flag)

This flag indicates the state of the NRDY interrupt. Refer to section 41.2.14 for conditions of the NRDY flag becoming 1. The NRDY flag becomes 0 when 0 is written to the NRDYSTS.PIPENRDY[9:0] flags for all pipes for which the NRDYENB.PIPENRDYE[9:0] bits are 1 (interrupt request output enabled). The NRDY flag does not become 0 even when set to 0 by software.

BEMP Flag (BEMP Interrupt Status Flag)

This flag indicates the state of the BEMP interrupt. Refer to section 41.2.15 for conditions of the BEMP flag becoming 1. The BEMP flag becomes 0 when 0 is written to the BEMPSTS.PIPEBEMP[9:0] flags for all pipes for which the BEMPENB.PIPEBEMPE[9:0] bits are 1 (interrupt request output enabled). The BEMP flag does not become 0 even when set to 0 by software.

CTRT Flag (Control Transfer Stage Transition Interrupt Status Flag)

In function controller operation, the USBHS updates the value of the CTSQ[2:0] bits and sets the CTRT flag to 1 on detecting a transition in the control transfer stage. When a control transfer stage transition interrupt is generated, set the CTRT flag to 0 before the USBHS detects the next control transfer stage transition. Values read from the CTRT flag are invalid in host controller operation.

DVST Flag (Device State Transition Interrupt Status Flag)

In function controller operation, the USBHS updates the value of the DVSQ[2:0] bits and sets the DVST flag to 1 when a change in the device state is detected. When a device state transition interrupt is generated, set the DVST flag to 0 before the USBHS detects the next device state transition. Values read from the DVST flag are invalid in host controller operation.

SOFR Flag (Frame Number Refresh Interrupt Status Flag)

(1) In host controller operation
When the DVSTCTR0.UACT bit is 1, the SOFR flag becomes 1 (a frame number refresh interrupt is detected every millisecond) when the frame number is updated.

(2) In function controller operation
The USBHS sets the SOFR flag to 1 (a frame number refresh interrupt is detected every millisecond) when the frame number is updated. The USBHS can detect a frame number refresh interrupt using the SOF recovery function even when a corrupted SOF packet is received from the USB host. Refer to section 41.3.13 for details on the SOF recovery function.

RESM Flag (Resume Interrupt Status Flag)

In function controller operation, the RESM flag becomes 1 when the USBHS detects the resume signal in the suspended state (DVSQ[2:0] bits are 1xxb). Values read from the RESM flag are invalid in host controller operation.

VBINT Flag (VBUS Interrupt Status Flag)

The VBINT flag becomes 1 when a level change (high to low or low to high) is detected in the USBHS_VBUS pin input signal. The USBHS sets the VBSTS flag to indicate the USBHS_VBUS pin input level. When the VBUS interrupt request is generated, eliminate chattering by reading the VBSTS flag several times by software and checking that the values read are the same.

41.2.19 Interrupt Status Register 1 (INTSTS1)

Address(es): USBHS.INTSTS1 8745 1042h, USBHS_NS.INTSTS1 0745 1042h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVRCR	BCHG	—	DTCH	ATTCH	—	L1RSMEND	LPMEND	—	EOFERR	SIGN	SACK	—	—	—	PDDETINT
Value after reset:	0	0	x	0	0	x	0	0	x	0	0	0	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	PDDETINT	Portable Device Detection Interrupt Status Flag*1	0: Portable Device detection interrupt not requested 1: Portable Device detection interrupt requested	R/(W) *2
b3 to b1	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b4	SACK	Setup Transaction Normal Response Interrupt Status Flag *3	0: SACK interrupt not requested 1: SACK interrupt requested	R/(W) *2
b5	SIGN	Setup Transaction Error Interrupt Status Flag*3	0: SIGN interrupt not requested 1: SIGN interrupt requested	R/(W) *2
b6	EOFERR	End-of-Frame Error Detection Interrupt Status Flag*3	0: EOFERR interrupt not requested 1: EOFERR interrupt requested	R/(W) *2
b7	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b8	LPMEND	LPM Transaction End Interrupt Status Flag*3	0: LPMEND interrupt not requested 1: LPMEND interrupt requested	R/(W) *2
b9	L1RSMEND	L1 Resume End Interrupt Status Flag*3	0: L1RSMEND interrupt not requested 1: L1RSMEND interrupt requested	R/(W) *2
b10	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b11	ATTCH	Device Attach Detection Interrupt Status Flag*3	0: ATTCH interrupt not requested 1: ATTCH interrupt requested	R/(W) *2
b12	DTCH	Device Detach Detection Interrupt Status Flag*3	0: DTCH interrupt not requested 1: DTCH interrupt requested	R/(W) *2
b13	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b14	BCHG	Bus Change Interrupt Status Flag*3	0: BCHG interrupt not requested 1: BCHG interrupt requested	R/(W) *2
b15	OVRCR	Overcurrent Change Interrupt Status Flag*1, *3	0: OVRCR interrupt not requested 1: OVRCR interrupt requested	R/(W) *2

Note 1. If a change in the status indicated by the PDDETINT or OVRCR flag is detected even while the clock is stopped (when the LPSTS.SUSPENDM bit is 0), and if the corresponding interrupt enable bit is 1, the USBHSR interrupt is requested. Supply the PHY clock before setting these flags to 0. Interrupts indicated by flags other than the PDDETINT and OVRCR flags are not detected while the PHY clock is stopped (when the LPSTS.SUSPENDM bit is 0).
Note 2. To clear the flags in the INTSTS1 register, write 0 only to the flags to be cleared; write 1 to the other flags.
Note 3. Only enable interrupts other than the Portable Device detection interrupt in host controller operation.

PDDETINT Flag (Portable Device Detection Interrupt Status Flag)

In host controller operation, this flag indicates the status of the Portable Device detection interrupt.
The PDDETINT flag becomes 1 when the USBHS detects a Portable Device. The USBHS indicates the D+ line status in the BCCTRL.PDDETSTS flag. When the Portable Device detection interrupt is generated, eliminate chattering by reading the BCCTRL.PDDETSTS flag several times by software and checking that the values read are the same.

SACK Flag (Setup Transaction Normal Response Interrupt Status Flag)

In host controller operation, this flag indicates the status of the setup transaction normal response interrupt (SACK interrupt). When the USBHS issues a setup transaction, if an ACK response is received from a peripheral device, the SACK flag becomes 1. At this time, if the INTENB1.SACKE bit is 1, the USBHS requests the SACK interrupt.
In function controller operation, the SACK flag read value is invalid.

SIGN Flag (Setup Transaction Error Interrupt Status Flag)

In host controller operation, this flag indicates the status of the setup transaction error interrupt (SIGN interrupt). When the USBHS issues a setup transaction, if an ACK response is not returned from a peripheral device three consecutive times, the SIGN flag becomes 1. At this time, if the INTENB1.SIGNE bit is 1, the USBHS requests the SIGN interrupt.
If any of the following conditions occurs three times consecutively, the USBHS detects the setup transaction error

- A timeout is detected by the USBHS when there is no response from a peripheral device
- An ACK packet is corrupted.
- A handshake other than ACK (i.e. NAK, NYET, or STALL) is received

In function controller operation, the SIGN flag read value is invalid.

EOFERR Flag (End-of-Frame Error Detection Interrupt Status Flag)

In host controller operation, this flag indicates the status of the EOF error detection interrupt (EOFERR interrupt). When communication is detected as not being complete at the EOF2 timing prescribed in USB 2.0, the EOFERR flag becomes 1. At this time, if the INTENB1.EOFERRE bit is 1, the USBHS requests the EOFERR interrupt. After detecting the EOF error, regardless of the INTENB1.EOFERRE bit setting, the USBHS sets the DVSTCTR0.UACT bit to 0 and enters the Idle state. controls hardware as described below. Use software to end all communication currently being performed on pipes, and repeat enumeration.
In function controller operation, the EOFERR flag read value is invalid.

LPMEND Flag (LPM Transaction End Interrupt Status Flag)

When the HL1CTRL1.L1REQ bit is set to 1, the USBHS transmits an LPM token. When the LPM transaction is ended because a response from the peripheral device or a timeout is detected, the LPMEND flag becomes 1.
In function controller operation, the LPMEND flag read value is invalid.

L1RSMEND Flag (L1 Resume End Interrupt Status Flag)

When performing processing to exit the L1 state, the L1RSMEND flag becomes 1 when the processing is completed.
In function controller operation, the L1RSMEND flag read value is invalid.

ATTCH Flag (Device Attach Detection Interrupt Status Flag)

In host controller operation, this flag indicates the status of the device attach detection interrupt (ATTCH interrupt). When the USBHS detects J state or K state of the full-speed or low-speed signal level for 2.5 µs on the port, the USBHS detects that a device has been attached, and sets the ATTCH flag to 1. At this time, if the INTENB1.ATTCHE bit is 1, the USBHS requests the USBHSR interrupt.
The conditions for the USBHS to detect a device being attached are as follows:

- The K state, SE0, or SE1 changes to the J state, and the J state continues for 2.5 µs
- The J state, SE0, or SE1 changes to the K state, and the K state continues for 2.5 µs

In function controller operation, the ATTCH flag read value is invalid.

DTCH Flag (Device Detach Detection Interrupt Status Flag)

In host controller operation, this flag indicates the status of the device detach detection interrupt (DTCH interrupt).
When a USB bus device disconnect is detected, the USBHS detects device disconnection, and the DTCH flag becomes 1. At this time, if the INTENB1.DTCHE bit is set to 1, the USBHS requests the USBHSR interrupt.
The USBHS detects bus disconnection based on USB 2.0.
After device disconnect is detected, regardless of the INTENB1.DTCHE bit setting, the USBHS sets the DVSTCTR0.UACT bit to 0 and enters the Idle state. Use software to end all communication currently being performed on pipes, and transition to the wait for attach (ATTCH interrupt generated) state.
In function controller operation, the DTCH flag read value is invalid.

BCHG Flag (Bus Change Interrupt Status Flag)

This flag indicates the status of the bus change interrupt (BCHG interrupt).
When a status change to full-speed or low-speed occurs on the USB port (when the J state, K state, or SE0 changes to the J state, K state, or SE0), the USBHS detects a change in the bus status, and the BCHG flag becomes 1. At this time, if the INTENB1.BCHGE bit is 1, the USBHS requests the USBHSR interrupt.
The SYSSTS0.LNST[1:0] flags indicate the current state of the USB port. When the BCHG interrupt is generated, in order to eliminate chattering, read the LNST[1:0] flags several times by software and confirm that the values read are the same.
In function controller operation, the BCHG flag read value is invalid.

OVRCR Flag (Overcurrent Change Interrupt Status Flag)

This flag indicates the status change interrupt (OVRCR interrupt) for the USBHS_OVRCURA pin or USBHS_OVRCURB pin.
If there is a change in the input of either the USBHS_OVRCURA pin or USBHS_OVRCURB pin (from high to low or low to high), the USBHS detects a change in the overcurrent pin, and the OVRCR flag becomes 1. At this time, if the INTENB1.OVRCRE bit is 1, the USBHS requests the USBHSR interrupt.
The SYSSTS0.OVCMON[1:0] flags to indicate the current status of the USBHS_OVRCURA and USBHS_OVRCURB pins.
In host controller operation, if an overcurrent notification signal (from the power supply IC which supplies VBUS to the peripheral devices) is connected to the USBHS_OVRCURA or USBHS_OVRCURB pin, software can detect an occurrence of overcurrent.

41.2.20 BRDY Interrupt Status Register (BRDYSTS)

Address(es): USBHS.BRDYSTS 8745 1046h, USBHS_NS.BRDYSTS 0745 1046h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBRDY[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPEBRDY[9:0]	Pipe 9 to Pipe 0 BRDY Interrupt Status Flags*1	0: Interrupt not generated 1: Interrupt generated	R/(W) *2
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. pipe 9 corresponds to the PIPEBRDY[9] bit, pipe 8 corresponds to the PIPEBRDY[8] bit, etc.).
Note 2. When the SOFCFG.BRDYM bit is 0, to clear the status indicated by the PIPEBRDY[9:0] flags, write 0 only to the flags to be cleared; write 1 to the other flags.
When the SOFCFG.BRDYM bit is set to 0, clear the BRDY interrupt before accessing the FIFO buffer.

PIPEBRDY[9:0] Flags (Pipe 9 to Pipe 0 BRDY Interrupt Status Flags)

When the BRDY interrupt is detected, the USBHS sets the bits corresponding to the PIPEBRDY[9:0] flags to 1. Refer to section 41.3.6.1 for details on the BRDY interrupt.

41.2.21 NRDY Interrupt Status Register (NRDYSTS)

Address(es): USBHS.NRDYSTS 8745 1048h, USBHS_NS.NRDYSTS 0745 1048h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPENRDY[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPENRDY[9:0]	Pipe 9 to Pipe 0 NRDY Interrupt Status Flags*1	0: Interrupt not generated 1: Interrupt generated	R/(W) *2
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. Pipe 9 corresponds to the PIPENRDY[9] bit, pipe 8 corresponds to the PIPENRDY[8] bit, etc.).
Note 2. To clear the status indicated by the PIPENRDY[9:0] flags, write 0 only to the flags to be cleared; write 1 to the other flags.

PIPENRDY[9:0] Flags (Pipe 9 to Pipe 0 NRDY Interrupt Status Flags)

If an NRDY interrupt source is detected while the PID[1:0] bits in a pipe control register are 01b (BUF response), the USBHS module sets the bits corresponding to the PIPENRDY[9:0] flags to 1. Refer to section 41.3.6.2 for details on the NRDY interrupt.

41.2.22 BEMP Interrupt Status Register (BEMPSTS)

Address(es): USBHS.BEMPSTS 8745 104Ah, USBHS_NS.BEMPSTS 0745 104Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBEMP[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PIPEBEMP[9:0]	Pipe 9 to Pipe 0 BEMP Interrupt Status Flags*1	0: Interrupt not generated 1: Interrupt generated (n = 0 to 9)	R/(W) *2
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note 1. Each bit corresponds to a pipe number (e.g. pipe 9 corresponds to the PIPEBEMP[9] bit, pipe 8 corresponds to the PIPEBEMP[8] bit, etc.).
Note 2. To clear the status indicated by the PIPEBEMP[9:0] flags, write 0 only to the flags to be cleared; write 1 to the other flags.

PIPEBEMP[9:0] Flags (Pipe 9 to Pipe 0 BEMP Interrupt Status Flags)

If a BEMP interrupt is detected while the PID[1:0] bits in a pipe control register are 01b (BUF response), the USBHS module sets the bits corresponding to the PIPEBEMP[9:0] flags to 1. Refer to section 41.3.6.3 for details on the BEMP interrupt.

41.2.23 Frame Number Register (FRMNUM)

Address(es): USBHS.FRMNUM 8745 104Ch, USBHS_NS.FRMNUM 0745 104Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVRN	CRCE	—	—	—	FRNM[10:0]										
Value after reset:	0	0	x	x	x	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	FRNM[10:0]	Frame Number	Latest frame number	R
b13 to b11	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b14	CRCE	CRC Error Detection Status Flag	0: No error occurred 1: Error occurred	R/(W) *2
b15	OVRN	Overrun/Underrun Detection Status Flag*1	0: No error occurred 1: Error occurred	R/(W) *2

Note 1. The OVRN flag is used for debugging. Design the timing so that no overrun or underrun occurs in the system.
Note 2. When setting this flag to 0, write 0 only to the flags to be cleared; write 1 to the other flags.

FRNM[10:0] Bits (Frame Number)

An SOF packet is issued or received every millisecond. Each time an SOF packet is issued or received, the USBHS rewrites these flags to indicate the latest frame number.

CRCE Flag (CRC Error Detection Status Flag)

This flag becomes 1 when a CRC error or bit stuffing error occurs during isochronous transfer. Write 0 to the CRCE flag to clear it. When writing 0 to the CRCE flag, write 1 to the other flags in the FRMNUM register. When a CRC error is detected, the USBHS generates an internal NRDY interrupt request.

OVRN Flag (Overrun/Underrun Detection Status Flag)

This flag becomes 1 when an overrun or underrun error occurs during isochronous transfer. Write 0 to the OVRN flag to clear it. When writing 0 to the OVRN flag, write 1 to the other flags in the FRMNUM register.

(1) In host controller operation
The USBHS sets the OVRN flag to 1 when either of the following conditions is satisfied.

- For pipes set to isochronous transfer for transmitting, the timing to issue an OUT token comes before all the transmit data has been written to the FIFO buffer.
- For pipes set to isochronous transfer for receiving, the timing to issue an IN token comes while no FIFO buffer plane is empty.

(2) In function controller operation
The USBHS sets the OVRN flag to 1 when any of the following conditions is satisfied.

- For pipes set to isochronous transfer for transmitting, the IN token is received before all the transmit data has been written to the FIFO buffer.
- For pipes set to isochronous transfer for receiving, the OUT token is received while no FIFO buffer plane is empty.

41.2.24 Microframe Number Register (UFRMNUM)

Address(es): USBHS.UFRMNUM 8745 104Eh, USBHS_NS.UFRMNUM 0745 104Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DVCHG	—	—	—	—	—	—	—	—	—	—	—	—	UFRNM[2:0]		
Value after reset:	0	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	UFRNM[2:0]	Microframe Number	Microframe number	R
b14 to b3	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b15	DVCHG	Device State Change	0: Writing to the USBADDR register is disabled. 1: Writing to the USBADDR register is enabled.	R/W

UFRNM[2:0] Bits (Microframe Number)

The USBHS sets these bits to indicate the microframe number during high-speed operation. During operation other than high-speed operation, the USBHS sets these bits to 000b. When reading these bits by software, confirm that the same value is read twice.

DVCHG Bit (Device State Change)

This bit enables or disables the writing to the USBADDR register. Set this bit to 1 when writing back the device state and device address after release from deep software standby mode 1. For details, refer to section 41.3.18, Release from Deep Software Standby Mode 1 in Response to the USBHS Resume Interrupt.

41.2.25 USB Address Register (USBADDR)

Address(es): USBHS.USBADDR 8745 1050h, USBHS_NS.USBADDR 0745 1050h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	STSRECOV0[2:0]			—	USBADDR[6:0]						
Value after reset:	x	x	x	x	x	0	0	0	x	0	0	0	0	0	0	0

x: Undefined

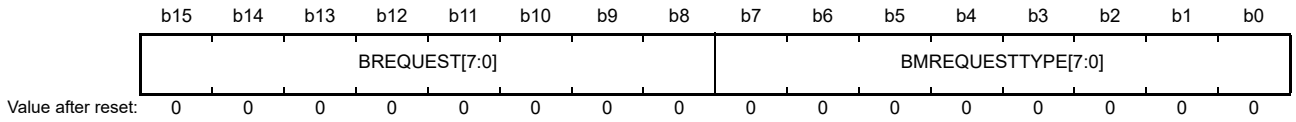
Bit	Symbol	Bit Name	Description	R/W
b6 to b0	USBADDR[6:0]	USB Address	In function controller operation, these flags indicate the USB address assigned by the host when the USBHS processed the SetAddress() request successfully.	R/(W) *1
b7	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b10 to b8	STSRECOV0[2:0]	Status Recovery	• In host controller operation These bits are used to rewrite the value of the DVSCTR0.RHST[2:0] bits. b10 b8 0 1 0: Set the RHST[2:0] bits to 001b (low-speed) 1 0 0: Set the RHST[2:0] bits to 010b (full-speed) 1 1 0: Set the RHST[2:0] bits to 011b (high-speed) Settings other than above are prohibited. • In function controller operation These bits are used to rewrite the value of the DVSCTR0.RHST[2:0] and INTSTS0.DVSQ[2:0] bits. b10 b8 0 0 0: Retained 0 0 1: Set the RHST[2:0] bits to 010b (full-speed) and the DVSQ[2:0] bits to 001b (Default state) 0 1 0: Set the RHST[2:0] bits to 010b (full-speed) and the DVSQ[2:0] bits to 010b (Address state) 0 1 1: Set the RHST[2:0] bits to 010b (full-speed) and the DVSQ[2:0] bits to 011b (Configured state) 1 0 0: Set the DVSQ[2:0] bits to 100b (Suspended state) 1 0 1: Set the RHST[2:0] bits to 011b (high-speed) and the DVSQ[2:0] bits to 001b (Default state) 1 1 0: Set the RHST[2:0] bits to 011b (high-speed) and the DVSQ[2:0] bits to 010b (Address state) 1 1 1: Set the RHST[2:0] bits to 011b (high-speed) and the DVSQ[2:0] bits to 011b (Configured state)	R/(W) *1
b15 to b11	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

Note 1. These bits can only be written when the UFRMNUM.DVCHG is 1.

USBADDR[6:0] Bits (USB Address)

In function controller operation, these bits indicate the USB address received in the USBADDR[6:0] bits when the USBHS processed the SetAddress() request successfully. The USBADDR[6:0] bits indicate 00h when a USB bus reset is detected.

After releasing from the deep software standby mode 1, set the UFRMNUM.DVCHG bit to 1 and write back the previously saved address.



In host controller operation, these bits are not used.

STSRECOV0[2:0] Bits (Status Recovery)

These bits are used to write back the device state after release from deep software standby mode 1. For details, refer to section 41.3.18, Release from Deep Software Standby Mode 1 in Response to the USBHS Resume Interrupt.

41.2.26 USB Request Type Register (USBREQ)

Address(es): USBHS.USBREQ 8745 1054h, USBHS_NS.USBREQ 0745 1054h

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	BMREQUESTTYPE[7:0]	Request Type	USB request *bmRequestType* value	R/W*1
b15 to b8	BREQUEST[7:0]	Request	USB request *bRequest* value	R/W*1

Note 1. In function controller operation, these bits are readable but writing to them is invalid. In host controller operation, these bits are both readable and writable.

BMREQUESTTYPE[7:0] Bits (Request Type)

These bits store the *bmRequestType* value of USB requests.

- In host controller operation
  Set these bits to the value of the USB request data in setup transactions to be transmitted. Do not modify these bits when the DCPCTR.SUREQ bit is 1.
- In function controller operation
  These bits indicate the value of the USB request data in setup transactions to be received. Writing to these bits is invalid.

BREQUEST[7:0] Bits (Request)

These bits store the *bRequest* value of USB requests.

- In host controller operation
  Set these bits to the value of the USB request data in setup transactions to be transmitted. Do not modify these bits when the DCPCTR.SUREQ bit is 1.
- In function controller operation
  These bits indicate the value of the USB request data in setup transactions to be received. Writing to these bits is invalid.

41.2.27 USB Request Value Register (USBVAL)

Address(es): USBHS.USBVAL 8745 1056h, USBHS_NS.USBVAL 0745 1056h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WVALUE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	WVALUE[15:0]	Value	Value of the USB request *wValue*	R/W*1

Note 1. In function controller operation, these bits are readable but writing to them is invalid. In host controller operation, these bits are both readable and writable.

WVALUE[15:0] Bits (Value)

These bits store the *wValue* value of USB requests.

- In host controller operation
  Set the *wValue* value of USB requests in setup transactions to be transmitted. Do not modify these bits when the DCPCTR.SUREQ bit is 1.
- In function controller operation
  These bits indicate the *wValue* value of USB requests in setup transactions to be received. Writing to these bits is invalid.

41.2.28 USB Request Index Register (USBINDX)

Address(es): USBHS.USBINDX 8745 1058h, USBHS_NS.USBINDX 0745 1058h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WINDEX[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	WINDEX[15:0]	Index	Value of the USB request *wIndex*	R/W*1

Note 1. In function controller operation, these bits are readable but writing to them is invalid. In host controller operation, these bits are both readable and writable.

WINDEX[15:0] Bits (Index)

These bits store the *wIndex* value of USB requests.

- In host controller operation
  Set the *wIndex* value of USB requests in setup transactions to be transmitted. Do not modify these bits when the DCPCTR.SUREQ bit is 1.
- In function controller operation
  These bits indicate the *wIndex* value of USB requests in setup transactions to be received. Writing to these bits is invalid.

41.2.29 USB Request Length Register (USBLENG)

Address(es): USBHS.USBLENG 8745 105Ah, USBHS_NS.USBLENG 0745 105Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WLENGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	WLENGTH[15:0]	Length	Value of the USB request *wLength*	R/W*1

Note 1. In function controller operation, these bits are readable but writing to them is invalid. In host controller operation, these bits are both readable and writable.

WLENGTH[15:0] Bits (Length)

These bits store the *wLength* value of USB requests.

- In host controller operation
  Set the *wLength* value of USB requests in setup transactions to be transmitted. Do not modify these bits when the DCPCTR.SUREQ bit is 1.
- In function controller operation
  These bits indicate the *wLength* value of USB requests in setup transactions to be received. Writing to these bits is invalid.

41.2.30 Default Control Pipe Configuration Register (DCPCFG)

Address(es): USBHS.DCPCFG 8745 105Ch, USBHS_NS.DCPCFG 0745 105Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CNTMD	SHTNAK	—	—	DIR	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	0	0	x	x	0	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b4	DIR	Transfer Direction*1	0: Receive data 1: Transmit data	R/W
b6, b5	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b7	SHTNAK	Pipe Disabled at End of Transfer*1	0: The pipe is continued at the end of transfer. 1: The pipe is disabled at the end of transfer.	R/W
b8	CNTMD	Continuous Transfer Mode*1	0: Discontinuous transfer mode 1: Continuous transfer mode	R/W
b15 to b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

Note 1. Only change the settings of bits in the DCPCFG register when the DCPCTR.PID[1:0] bits are 00b (NAK response). Only change the DCPCTR.PID[1:0] bits from 01b (BUF response) to 00b (NAK response) after confirming that the value of the DCPCTR.PBUSY flag is 0. However, the PBUSY flag does not need to be checked by software if the USBHS changes the PID[1:0] bits to 00b (NAK response).

DIR Bit (Transfer Direction)

In host controller operation, this bit sets the transfer direction of the data stage and status stage for control transfer.
In function controller operation, set this bit to 0.

SHTNAK Bit (Pipe Disabled at End of Transfer)

When the control transfer direction is receiving, this bit specifies whether the DCPCTR.PID[1:0] bits are changed from 00b (NAK response) when transfer is complete.
The SHTNAK bit is valid when the default control pipe transfer direction is receiving.
When the SHTNAK bit is 1, the DCPCTR.PID[1:0] bits become 00b (NAK response) when the USBHS transfer is complete. The USBHS determines that transfer is complete when short packet data (including the zero-length packet) is received successfully.

CNTMD Bit (Continuous Transfer Mode)

This bit specifies whether the default control pipe communicates in continuous transfer mode or not.

41.2.31 Default Control Pipe Maximum Packet Size Register (DCPMAXP)

Address(es): USBHS.DCPMAXP 8745 105Eh, USBHS_NS.DCPMAXP 0745 105Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DEVSEL[3:0]				—	—	—	—	—	MXPS[6:0]						
Value after reset:	0	0	0	0	x	x	x	x	x	1	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	MXPS[6:0]	Maximum Packet Size *1	These bits specify the maximum data payload (maximum packet size) for the default control pipe.	R/W
b11 to b7	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b15 to b12	DEVSEL[3:0]	Device Select*2	b15 b12 0 0 0 0: Address 0000b 0 0 0 1: Address 0001b 0 0 1 0: Address 0010b 0 0 1 1: Address 0011b 0 1 0 0: Address 0100b 0 1 0 1: Address 0101b 0 1 1 0: Address 0110b 0 1 1 1: Address 0111b 1 0 0 0: Address 1000b 1 0 0 1: Address 1001b 1 0 1 0: Address 1010b Only set the values listed above.	R/W

Note 1. Only change the MXPS[6:0] bit setting when the DCPCTR.CSSTS flag is 0, the DCPCTR.PID[1:0] bits are 00b (NAK response), and the CFIFOSEL.CURPIPE[3:0] bits are 0000b. When changing the setting after changing the DCPCTR.PID[1:0] bits from 01b (BUF response) to 00b (NAK response), confirm the DCPCTR.CSSTS flag and DCPCTR.PBUSY flag are 0 before modifying these bits. However, when the USBHS changes the DCPCTR.PID[1:0] bits from 01b (BUF response) to 00b (NAK response), the CSSTS flag and PBUSY flag do not need to be checked by software. In addition, after the MXPS[6:0] bit setting is changed, set the CFIFOCTR.BCLR bit to 1 to perform buffer clear processing.

Note 2. Only change the DEVSEL[3:0] bit setting when the DCPCTR.CSSTS flag is 0, the DCPCTR.PID[1:0] bits are 00b (NAK response), and the DCPCTR.SUREQ bit is 0. Only change the DCPCTR.PID[1:0] bits of the default control pipe from 01b (BUF response) to 00b (NAK response) after confirming the values of the DCPCTR.CSSTS flag and the DCPCTR.PBUSY flag are 0. However, the PBUSY flag does not need to be checked by software if the USBHS changes the DCPCTR.PID[1:0] bits to 00b (NAK response).

MXPS[6:0] Bits (Maximum Packet Size)

Set the default control pipe's maximum data payload (maximum packet size) to the MXPS[6:0] bits. The initial value is 40h (64 bytes).

The value set to the MXPS[6:0] bits must be compliant with USB 2.0.

When the MXPS[6:0] bits are set to 00h, do not write to the FIFO buffer and do not set the DCPCTR.PID[1:0] bits to 01b (BUF response).

DEVSEL[3:0] Bits (Device Select)

In host controller operation, these bits specify the peripheral device address of the communication target for control transfer.

Set the DEVADDm register corresponding to the value set in the DEVSEL[3:0] bits, and then set the DEVSEL[3:0] bits (m = 0 to A). For example, to set the DEVSEL[3:0] bits to 0010b, set the address in the DEVADD2 register.

In function controller operation, set the DEVSEL[3:0] bits to 0000b.

41.2.32 Default Control Pipe Control Register (DCPCTR)

Address(es): USBHS.DCPCTR 8745 1060h, USBHS_NS.DCPCTR 0745 1060h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BSTS	SUREQ	CSCLR	CSSTS	SUREQCLR	—	—	SQCLR	SQSET	SQMON	PBUSY	PINGE	—	CCPL	PID[1:0]	
Value after reset:	0	0	0	0	x	x	x	0	0	1	0	0	x	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PID[1:0]	Response PID	b1 b0 0 0: NAK response 0 1: BUF response (depending on the FIFO buffer state) 1 0: STALL response 1 1: STALL response	R/W
b2	CCPL	Control Transfer End Enable	0: Completion of control transfer is disabled. 1: Completion of control transfer is enabled.	R/W
b3	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b4	PINGE	PING Token Issue Enable	0: Issuing a PING token is disabled. 1: Normal PING operation	R/W
b5	PBUSY	Pipe Busy Flag	0: The default control pipe is not used for the USB bus. 1: The default control pipe is in use for the USB bus.	R
b6	SQMON	Sequence Toggle Bit Monitor Flag	0: DATA0 1: DATA1	R
b7	SQSET	Sequence Toggle Bit Set*1	This bit allows setting for the expected value of the sequence toggle bit of the next transaction for data 1 in default control pipe transfer. Writing 0 has no effect. This bit is read as 0.	R/W
b8	SQCLR	Sequence Toggle Bit Clear*1	This bit allows setting for the expected value of the sequence toggle bit of the next transaction for data 0 in default control pipe transfer. Writing 0 has no effect. This bit is read as 0.	R/W
b10, b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b11	SUREQCLR	SUREQ Bit Clear	In host controller operation, the SUREQ bit becomes 0 when this bit is set to 1. Writing 0 has no effect. This bit is read as 0.	R/W
b12	CSSTS	CSSTS Status Flag	0: Start-split (SSPLIT) transaction being processed, or split transaction unused device being processed 1: Complete-split (CSPLIT) transaction being processing	R
b13	CSCLR	CSSTS Status Flag Clear	In host controller operation, for transfers that use the SSPLIT transaction, the CSSTS flag becomes 0 by setting this bit to 1. Subsequently, the next default control pipe transfer restarts from the SSPLIT. Writing 0 has no effect. This bit is read as 1.	R/W
b14	SUREQ	SETUP Token Transmission	In host controller operation, setting this bit to 1 transmits the setup packet. Writing 0 has no effect.	R/W
b15	BSTS	Buffer Status Flag	0: Buffer access is disabled. 1: Buffer access is enabled.	R

Note 1. Only write 1 to bits SQSET, SQCLR, and PINGE while the DCPCTR.CSSTS flag is 0 and the DCPCTR.PID[1:0] bits are 00b (NAK response). Only change the DCPCTR.PID[1:0] bits from 01b (BUF response) to 00b (NAK response) after confirming that the value of the DCPCTR.CSSTS flag and DCPCTR.PBUSY flag are 0. However, the PBUSY flag does not need to be checked by software if the USBHS changes the DCPCTR.PID[1:0] bits to 00b (NAK response).

PID[1:0] Bits (Response PID)

The DCPCTR.PID[1:0] bits control the USB response for control transfer.

(1) In host controller operation

Perform the following to modify the DCPCTR.PID[1:0] bits from 00b (NAK response) to 01b (BUF response).

- When transmitting
  Write all the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and the DCPCTR.PID[1:0] bits are 00b (NAK response), and then set the DCPCTR.PID[1:0] bits to 01b (BUF response). After the DCPCTR.PID[1:0] bits have been set to 01b (BUF response), the USBHS executes the OUT transaction (or PING transaction).
- When receiving
  Confirm that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and the DCPCTR.PID[1:0] bits are 00b (NAK response), and then set the DCPCTR.PID[1:0] bits to 01b (BUF response). After the DCPCTR.PID[1:0] bits have been set to 01b (BUF response), the USBHS executes the IN transaction.

The USBHS modifies the value of the DCPCTR.PID[1:0] bits in the following cases.

- When the DCPCTR.PID[1:0] bits are set to 01b (BUF response) and the USBHS has received data exceeding the maximum packet size, the USBHS sets the DCPCTR.PID[1:0] bits to 11b (STALL response).
- When a reception error such as CRC error is detected three times in succession, the USBHS sets the DCPCTR.PID[1:0] bits to 00b (NAK response).
- When a STALL handshake is received, the USBHS sets the DCPCTR.PID[1:0] bits to 11b (STALL response).

(2) In function controller operation

The USBHS modifies the value of the DCPCTR.PID[1:0] bits in the following cases.

- When a setup packet is received, the USBHS modifies the DCPCTR.PID[1:0] bits to 00b (NAK response). At this time, the USBHS sets the INTSTS0.VALID flag to 1, and the DCPCTR.PID[1:0] bits cannot be modified by software until the VALID flag is set to 0 by software.
- When the DCPCTR.PID[1:0] bits are set to 01b (BUF response) and the USBHS receives data exceeding the maximum packet size, the USBHS sets the DCPCTR.PID[1:0] bits to 11b (STALL response).
- When the USBHS detects a control transfer sequence error, the DCPCTR.PID[1:0] bits are set to 10b or 11b (STALL response).
- When the USBHS detects a USB bus reset, the DCPCTR.PID[1:0] bits are set to 00b (NAK response).

The USBHS does not check the setting of the DCPCTR.PID[1:0] bits during the SetAddress() request processing (automatic processing).

CCPL Bit (Control Transfer End Enable)

In function controller operation, setting this bit to 1 enables completion of the status stage of the control transfer.
If the CCPL bit is set to 1 while the corresponding DCPCTR.PID[1:0] bits are 01b (BUF response), the USBHS completes the status stage of the control transfer.
During a control read transfer, the USBHS transmits an ACK handshake for the OUT transaction from the USB host.
During a control write or no-data control transfer, the USBHS transmits a zero-length packet for the IN transaction from the USB host. However, when the SetAddress() request is detected, the USBHS performs automatic responses from the SETUP stage until the status stage is completed regardless of the setting of the CCPL bit.
When a new setup packet is received, the USBHS modifies the CCPL bit from 1 to 0.
When the INTSTS0.VALID flag is 1, the CCPL bit cannot be set to 1.
The CCPL bit is initialized by the USB bus reset.
In host controller operation, set the CCPL bit to 0.

PINGE Bit (PING Token Issue Enable)

In host controller operation, when the PINGE bit is set to 1 by software, the USBHS issues the PING token based on transfer in the transmit direction. Transfer in the transmit direction starts from the PING transaction.
If an ACK handshake is detected in the PING transaction, the next transaction issued is an OUT transaction.
If a NAK handshake or NYET handshake is detected in the OUT transaction, the next transaction issued is a PING transaction.
In host controller operation, when the PINGE bit is set to 0 by software, the USBHS does not issue the PING token based on transfer in the transmit direction. All transfers in the transmit direction are issued by the OUT transaction.

PBUSY Flag (Pipe Busy Flag)

When the USBHS starts a USB transaction using the default control pipe, the USBHS changes the PBUSY flag from 0 to 1. The USBHS switches the PBUSY flag back to 0 at the end of the transaction.
After the DCPCTR.PID[1:0] bits are set to 00b (NAK response), the read value of the PBUSY flag indicates whether or not changes to pipe settings can proceed. Refer to section 41.3.7.1 for details.

SQMON Flag (Sequence Toggle Bit Monitor Flag)

This flag indicates the value of the sequence toggling bit for the next transaction in default control pipe transfer. When a transaction is processed successfully, the USBHS toggles the SQMON flag. However, the SQMON flag is not toggled when data PID mismatch occurs during data reception. In function controller operation, the USBHS sets the SQMON flag to 1 (setting the expected value for DATA1) when a setup packet is received successfully. In addition, in function controller operation, the USBHS does not check the SQMON flag during IN or OUT transactions in the status stage, and the flag is not toggled even at the end of a successful processing.

SQSET Bit (Sequence Toggle Bit Set)

This bit sets the value of the sequence toggling bit to DATA1 for the next transaction in default control pipe transfer. Do not set bits SQCLR and SQSET to 1 at the same time.

SQCLR Bit (Sequence Toggle Bit Clear)

This bit sets the value of the sequence toggling bit to DATA0 for the next transaction in default control pipe transfer. Do not set bits SQCLR and SQSET to 1 at the same time.

SUREQCLR Bit (SUREQ Bit Clear)

In host controller operation, the SUREQ bit can be cleared by setting the SUREQCLR bit to 1. If transfer stops while the SUREQ bit is set to 1 in a SETUP transaction, set the SUREQCLR bit to 1 by software. This is not necessary at the end of a successful setup transaction because the USBHS will automatically set the SUREQ bit to 0. Use the SUREQCLR bit to control the SUREQ bit when transfer stops while the DVSTCTR0.UACT bit is set to 0 or transfer is not proceeding because detaching of the port has been detected. Set the SUREQCLR bit to 0 in function controller operation.

CSSTS Flag (CSSTS Status Flag)

In host controller operation, the CSSTS flag indicates the transaction status of the complete-split transaction for non-isochronous transfers. When a CSPLIT transaction starts, the USBHS sets the CSSTS flag to 1, and when the CSPLIT transaction is detected as being complete, the CSSTS flag is set to 0.
In function controller operation, the value read from the CSSTS flag is not valid.

CSCLR Bit (CSSTS Status Flag Clear)

In host controller mode, when the CSCLR bit is set to 1, the CSSTS flag becomes 0. For transfers that use the split transaction, when the next transfer is forced to restart from the start-split, set the CSCLR bit to 1. In a normal split transaction, when the CSPLIT transaction is complete, the USBHS automatically sets the CSSTS flag to 0, so the flag does not need to be set to 0 by software. Use the CSCLR bit to set the CSSTS flag to 0, when the DVSTCTR0.UACT bit is 0, or when it is certain that transfer is not performed when a detach is detected. When the CSSTS flag is 0, it remains set to 0 even if the CSCLR bit is set to 1.
In function controller operation, set the CSCLR bit to 0.

SUREQ Bit (SETUP Token Transmission)

In host controller operation, a setup packet is transmitted when the SUREQ bit is set to 1. After the SETUP transaction processing is completed, the USBHS generates the SACK interrupt or SIGN interrupt and sets the SUREQ bit to 0. When the SUREQCLR bit is set to 1, the SUREQ bit becomes 0.
Set the SUREQ bit to 1 after a USB request to be transmitted in the setup transaction is set in the DCPMAXP.DEVSEL[3:0] bits and registers USBREQ, USBVAL, USBINDX, and USBLENG. Before setting the SUREQ bit to 1, confirm that the DCPCTR.PID[1:0] bits are set to 00b (NAK response). In addition, after the SUREQ bit is set to 1, until the setup transaction ends (SUREQ bit is 1), do not modify the DCPMAXP.DEVSEL[3:0] bits or values of registers USBREQ, USBVAL, USBINDX, and USBLENG. Set the SUREQ bit to 1 only when issuing a SETUP token. In other cases, be sure to write 0 to this bit. Set the SUREQ bit to 0 in function controller operation.

BSTS Flag (Buffer Status Flag)

This flag indicates whether the default control pipe’s FIFO buffer can be accessed.
The meaning of the BSTS flag varies depending on the setting of the CFIFOSEL.ISEL bit.

- When the ISEL bit is 0, the BSTS flag indicates whether receive data can be read.
- When the ISEL bit is 1, the BSTS flag indicates whether transmit data can be written.

41.2.33 Pipe Window Select Register (PIPESEL)

Address(es): USBHS.PIPESEL 8745 1064h, USBHS_NS.PIPESEL 0745 1064h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]			
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	PIPESEL[3:0]	Pipe Window Select	b3 b0 0 0 0 0: No pipe selected 0 0 0 1: Pipe 1 0 0 1 0: Pipe 2 0 0 1 1: Pipe 3 0 1 0 0: Pipe 4 0 1 0 1: Pipe 5 0 1 1 0: Pipe 6 0 1 1 1: Pipe 7 1 0 0 0: Pipe 8 1 0 0 1: Pipe 9 Only set the values listed above.	R/W
b15 to b4	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

Set pipes 1 to 9 using registers PIPESEL, PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI, PIPEnCTR (n = 1 to 9), PIPEnTRE (n = 1 to 5), and PIPEnTRN (n = 1 to 5). After selecting the pipe to be set by the PIPESEL register, each pipe setting is performed by the PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI registers. In addition, the PIPEnCTR, PIPEnTRE, and PIPEnTRN registers can be set regardless of the pipe selection by the PIPESEL register.

PIPESEL[3:0] Bits (Pipe Window Select)

When the pipe number is specified in the PIPESEL[3:0] bits, the pipe information is indicated in the PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI registers. Perform the pipe setting by modifying these registers.
When the PIPESEL[3:0] bits are set to 0000b, reading bits in the PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI registers returns 0. Writing has no effect.

41.2.34 Pipe Configuration Register (PIPECFG)

Address(es): USBHS.PIPECFG 8745 1068h, USBHS_NS.PIPECFG 0745 1068h

R/W

Note 1. Only change the settings of the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while the PIPEnCTR.CSSTS flag is 0, PIPEnCTR.PBUSY flag is 0, and the PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag and PIPEnCTR.CSSTS flag are 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBHS changes the PID[1:0] bits to 00b (NAK response).

Note 2. Only change the setting of the BFRE, DBLB, CNTMD, and DIR bits while the PIPEnCTR.CSSTS flag is 0, PIPEnCTR.PBUSY flag is 0, and the PIPEnCTR.PID[1:0] bits are 00b (NAK response) with the pipe not specified in the CURPIPE[3:0] bits of a FIFO port select register. Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.CSSTS flag and PIPEnCTR.PBUSY flag are 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBHS changes the PID[1:0] bits to 00b (NAK response).

Note 3. When the setting of the BFRE, DBLB, CNTMD, and DIR bits are modified after USB communications have been carried with the selected pipe, write 1 and 0 to the PIPEnCTR.ACLRM bit continuously by software and clear the FIFO buffer assigned to the selected pipe, in addition to the note described in Note 2.

EPNUM[3:0] Bits (Endpoint Number)

These bits specify the endpoint number for the selected pipe. Setting 0000b indicates the pipe not used. Set these bits so that the combination of the settings of the DIR and EPNUM[3:0] bits is different from the settings of other pipes. (The EPNUM[3:0] bits being set to 0000b can be set for all pipes.)

DIR Bit (Transfer Direction)

This bit specifies the transfer direction for the selected pipe. When the DIR bit is set to 0, the USBHS uses the selected pipe to receive data. When the DIR bit is set to 1, the USBHS uses the selected pipe to transmit data.

SHTNAK Bit (Pipe Disabled at End of Transfer)

This bit selects whether to modify the PIPEnCTR.PID[1:0] bits to 00b (NAK response) at the end of transfer when receiving direction is set for the selected pipe. This bit is valid when the selected pipe is pipe 1 to 5 in the receiving direction. When software processing sets this bit to 1 for a pipe in the receiving direction, the USBHS modifies the PIPEnCTR.PID[1:0] bits corresponding to the selected pipe to 00b (NAK response) on determining the end of the transfer. The USBHS determines that the transfer has ended from the following conditions.

- Short packet data (including a zero-length packet) is received successfully.
- The transaction counter is used and packets of the number specified by the transaction counter are received successfully.

CNTMD Bit (Continuous Transfer Mode)

This bit is valid when the selected pipe is pipe 1 to 5 of the bulk transfer type. According to the setting of this bit, the USBHS determines the completion of transmission or reception for the FIFO buffer allocated to the selected pipe as shown in Table 41.8.

Table 41.8 Relationship Between the CNTMD Bit Setting and Methods for Determining Completion of FIFO Buffer Transmission/Reception

CNTMD Bit Setting	Method for Determining Readability and Transmittability
0	Conditions for FIFO buffer readable state when receiving direction is set (DIR bit is 0): The USBHS has received one packet.
	Conditions for FIFO buffer transmittable state when transmitting direction is set (DIR bit is 1): When (1) or (2) is satisfied. (1) CPU (or DMAC/DTC) has written data of the maximum packet size to the FIFO buffer. (2) CPU (or DMAC/DTC) has written data of the short packet size (including 0 bytes) to the FIFO buffer and has set the BVAL bit in the FIFO port control register to 1.
1	Conditions for FIFO buffer readable state when receiving direction is set (DIR bit is 0): (1) The byte count of data received in the FIFO buffer allocated to the selected pipe is equal to the allocated byte count ((PIPEBUF.BUFSIZE[4:0] + 1) × 64). (2) While there is no data stored in the FIFO buffer allocated to the selected pipe, the USBHS has received a short packet except for a zero-length packet. (3) The USBHS has received a zero-length packet when data is already contained in the FIFO buffer allocated to the selected pipe. (4) The number of packets specified by the transaction counter set for the selected pipe have been received.
	Conditions for FIFO buffer transmittable state when transmitting direction is set (DIR bit is 1): When (1) or (2) is satisfied. (1) CPU (or DMAC/DTC) has written data that is equal to the size of the FIFO buffer allocated to the selected pipe. (2) CPU (or DMAC/DTC) has written data of size smaller than the size of the FIFO buffer allocated to the selected pipe (including 0 bytes) and has set the BVAL bit in the FIFO port control register to 1.

DBLB Bit (Double Buffer Mode)

This bit specifies single buffer or double buffer for the FIFO buffer used by the selected pipe. This bit is valid when the selected pipe is pipe 1 to 5. When this bit is set to 1, the USBHS allocates twice the FIFO buffer size specified by the PIPEBUF.BUFSIZE[4:0] bits for the selected pipe. The FIFO buffer size that the USBHS allocates to the selected pipe is (PIPEBUF.BUFSIZE[4:0] + 1) × 64 × (DBLB + 1) [bytes].

BFRE Bit (BRDY Interrupt Operation Specification)

This bit specifies the timing for transmitting the BRDY interrupt. When this bit is set to 1 and the selected pipe is used in the receiving direction, the USBHS detects the end of the transfer and issues a BRDY interrupt upon reading the packet. When a BRDY interrupt is generated with this setting, set the BCLR bit in a FIFO port control register to 1. Until the BCLR bit is set to 1, the FIFO buffer allocated to the selected pipe does not become the receivable state. When software processing sets this bit to 1 and the selected pipe is used in the transmitting direction, the USBHS generates no BRDY interrupt. Refer to section 41.3.6.1 for details.

TYPE[1:0] Bits (Transfer Type)

These bits specify the transfer type of the pipe specified by the PIPESEL.PIPESEL[3:0] bits. Before modifying the PIPEnCTR.PID[1:0] bits of the selected pipe to 01b (BUF response) (before starting the USB communication with the selected pipe), set the TYPE[1:0] bits to a value other than 00b.

41.2.35 Pipe Buffer Register (PIPEBUF)

Address(es): USBHS.PIPEBUF 8745 106Ah, USBHS_NS.PIPEBUF 0745 106Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	x	0	0	0	0	0	x	x	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description			R/W
b7 to b0	BUFNMB[7:0]	Buffer Number*1	These bits specify the start block of the FIFO buffer allocated to the selected pipe (04h to 87h).			R/W
b9, b8	—	Reserved	These bits are undefined when read. Set them to 0 when writing.			R/W
b14 to b10	BUFSIZE[4:0]	Buffer Size*1	00h: 64 bytes 01h: 128 bytes 02h: 192 bytes 03h: 256 bytes 04h: 320 bytes 05h: 384 bytes 06h: 448 bytes 07h: 512 bytes 08h: 576 bytes 09h: 640 bytes 0Ah: 704 bytes	0Bh: 768 bytes 0Ch: 832 bytes 0Dh: 896 bytes 0Eh: 960 bytes 0Fh: 1,024 bytes 10h: 1,088 bytes 11h: 1,152 bytes 12h: 1,216 bytes 13h: 1,280 bytes 14h: 1,344 bytes 15h: 1,408 bytes	16h: 1,472 bytes 17h: 1,536 bytes 18h: 1,600 bytes 19h: 1,664 bytes 1Ah: 1,728 bytes 1Bh: 1,792 bytes 1Ch: 1,856 bytes 1Dh: 1,920 bytes 1Eh: 1,984 bytes 1Fh: 2,048 bytes	R/W
b15	—	Reserved	This bit is undefined when read. Set it to 0 when writing.			R/W

Note 1. Only change the settings of bits in the PIPEBUF register while the PIPEnCTR.CSSTS flag is 0, PIPEnCTR.PID[1:0] bits are 00b (NAK response), and the CURPIPE[3:0] bits in the D0FIFOSEL/D1FIFOSEL register are 0000b. Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag and PIPEnCTR.CSSTS flag are 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBHS changes the PID[1:0] bits to 00b (NAK response).

BUFNMB[7:0] Bits (Buffer Number)

Specify the first block number of the FIFO buffer to be allocated to the selected pipe. Blocks of the FIFO buffer that the USBHS allocates to the selected pipe are shown below.
Block number: BUFNMB[7:0] to block number: BUFNMB[7:0] + (PIPEBUF.BUFSIZE[4:0] + 1) × (DBLB + 1) -1

Set the BUFNMB[7:0] bits to a value that observes the conditions below, and has a allocated block number between 04h and 87h (8.5 Kbytes of the on-chip memory).

- 00h is for default control pipe only.
- 04h is for pipe 6 only, but is available for other pipes when pipe 6 is not used. When pipe 6 is selected, writing a value to these bits is disabled. The USBHS automatically allocates 04h to the BUFNMB[7:0] bits for pipe 6.
- 05h is for pipe 7 only, but is available for other pipes when pipe 7 is not used. When pipe 7 is selected, writing a value to these bits is disabled. The USBHS automatically allocates 05h to the BUFNMB[7:0] bits for pipe 7.
- 06h is for pipe 8 only, but is available for other pipes when pipe 8 is not used. When pipe 8 is selected, writing a value to these bits is disabled. The USBHS automatically allocates 06h to the BUFNMB[7:0] bits for pipe 8.
- 07h is for pipe 9 only, but is available for other pipes when pipe 9 is not used. When pipe 9 is selected, writing a value to these bits is disabled. The USBHS automatically allocates 07h to the BUFNMB[7:0] bits for pipe 9.

BUFSIZE[4:0] Bits (Buffer Size)

Specify the FIFO buffer size (number of blocks) to be allocated to the selected pipe. One block is 64 bytes.
When the DBLB bit is set to 1, the USBHS allocates twice the FIFO buffer size specified by these bits for the selected pipe. Setting the DBLB bit to 1 is effective only when the selected pipe is pipe 1 to 5. The FIFO buffer size that the USBHS allocates to the selected pipe is shown below.

(BUFSIZE[4:0] + 1) × 64 × (DBLB + 1) [bytes]

Set a value within the following range for the BUFSIZE[4:0] bits.

(1) When the selected pipe is pipe 1 to 5, a value of 00h to 1Fh can be set (up to 2 Kbytes).
(2) When the selected pipe is pipe 6 to 9, only a value of 00h (64 bytes) can be set.

41.2.36 Pipe Maximum Packet Size Register (PIPEMAXP)

Address(es): USBHS.PIPEMAXP 8745 106Ch, USBHS_NS.PIPEMAXP 0745 106Ch

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	MXPS[10:0]	Maximum Packet Size *2	• For pipes 1 and 2 1 byte (001h) to 1,024 bytes (400h) • For pipes 3 to 5 8 bytes (008h), 16 bytes (010h), 32 bytes (020h), 64 bytes (040h), 512 bytes (200h) • For pipes 6 to 9 1 byte (001h) to 64 bytes (040h)	R/W
b11	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b15 to b12	DEVSEL[3:0]	Device Select *3	b15 b12 0 0 0 0: Address 0000b 0 0 0 1: Address 0001b 0 0 1 0: Address 0010b 0 0 1 1: Address 0011b 0 1 0 0: Address 0100b 0 1 1 0: Address 0110b 0 1 1 1: Address 0111b 1 0 0 0: Address 1000b 1 0 0 1: Address 1001b 1 0 1 0: Address 1010b 1011 to 1111: Reserved	R/W

Note 1. The initial value of the MXPS[10:0] bits for each pipe is 040h.

Note 2. Only change the settings of the MXPS[10:0] bits while the PIPEnCTR.CSSTS flag is 0, PIPEnCTR.PID[1:0] bits are 00b (NAK response), and the CURPIPE[3:0] bits in the D0FIFOSEL/D1FIFOSEL register are 0000b. Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming the value of the PIPEnCTR.PBUSY flag and PIPEnCTR.CSSTS flag are 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBHS changes the PID[1:0] bits to 00b (NAK response).

Note 3. Only change the settings of the DEVSEL[3:0] bits while the PIPEnCTR.CSSTS flag is 0 and PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag and PIPEnCTR.CSSTS flag are 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBHS changes the PID[1:0] bits to 00b (NAK response).

MXPS[10:0] Bits (Maximum Packet Size)

These bits set the maximum data payload (maximum packet size) for the selected pipe. Set the value of the MXPS[10:0] bits compliant with USB 2.0 for each transfer type. While the MXPS[10:0] bits are 000h, do not write data to the FIFO buffer or set the PIPEnCTR.PID[1:0] bits to 01b (BUF response). When the transfer type is an isochronous pipe, and when performing split transaction transfer, set the MXPS[10:0] bits to a value that is 188 bytes or less.

DEVSEL[3:0] Bits (Device Select)

In host controller operation, set the address of the communication target USB device for these bits. Set these bits after the settings for the DEVADDm register corresponding to the set value of the DEVSEL[3:0] bits has been made (m = 0 to A). When setting the DEVSEL[3:0] bits to 0010b, for example, set the DEVADD2 register. In function controller operation, set the DEVSEL[3:0] bits to 0000b.

41.2.37 Pipe Cycle Control Register (PIPEPERI)

Address(es): USBHS.PIPEPERI 8745 106Eh, USBHS_NS.PIPEPERI 0745 106Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Value after reset:	x	x	x	0	x	x	x	x	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	IITV[2:0]	Interval Error Detection Interval *1	These bits specify the interval error detection interval for the selected pipe as 2^n of the frame timing.	R/W
b11 to b3	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b12	IFIS	Isochronous IN Buffer Flush	0: The buffer is not flushed. 1: The buffer is flushed.	R/W
b15 to b13	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

Note 1. Only change the settings of the IITV[2:0] bits while the PIPEnCTR.CSSTS flag is 0 and PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag and PIPEnCTR.CSSTS flag are 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBHS changes the PID[1:0] bits to 00b (NAK response).

IITV[2:0] Bits (Interval Error Detection Interval)

To modify these bits to another value after these bits have been set and USB communication has been performed, set the PIPEnCTR.PID[1:0] bits to 00b (NAK response) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer. The IITV[2:0] bits are not provided for pipes 3 to 5. Write 000b to bit positions of the IITV[2:0] bits corresponding to pipes 3 to 5.

The IITV[2:0] bit function differs in host controller operation and function control operation. Refer to section 41.3.11 and section 41.3.12 for details.

IFIS Bit (Isochronous IN Buffer Flush)

This bit specifies whether to flush the buffer when the pipe specified by the PIPESEL.PIPESEL[3:0] bits is used for isochronous IN transfer.

In function controller operation, this bit provides a buffer flush function for the USBHS to automatically clear the FIFO buffer if the USBHS does not receive IN token from the USB host in (micro)frames at each interval set by the IITV[2:0] bits for the selected pipe of isochronous transfer type in the IN transfer direction.

When double buffer is specified (PIPECFG.DBLB bit is 1), the USBHS only clears the data in the plane used earlier.

The USBHS clears the FIFO buffer on receiving the (μ)SOF packet immediately after the (micro)frame in which the USBHS has expected to receive IN token. Even if the (μ)SOF packet is corrupted, the FIFO buffer is cleared by the recovery function at the timing when the (μ)SOF packet should be received.

In host controller operation, set the IITV[2:0] bits to 000b.

Set the IITV[2:0] bits to 000b when the selected pipe is not for isochronous transfer.

41.2.38 Pipe n Control Register (PIPEnCTR) (n = 1 to 9)

Address(es): USBHS.PIPE1CTR 8745 1070h, USBHS.PIPE2CTR 8745 1072h, USBHS.PIPE3CTR 8745 1074h, USBHS.PIPE4CTR 8745 1076h, USBHS.PIPE5CTR 8745 1078h, USBHS.PIPE6CTR 8745 107Ah, USBHS.PIPE7CTR 8745 107Ch, USBHS.PIPE8CTR 8745 107Eh, USBHS.PIPE9CTR 8745 1080h,
USBHS_NS.PIPE1CTR 0745 1070h, USBHS_NS.PIPE2CTR 0745 1072h, USBHS_NS.PIPE3CTR 0745 1074h, USBHS_NS.PIPE4CTR 0745 1076h, USBHS_NS.PIPE5CTR 0745 1078h, USBHS_NS.PIPE6CTR 0745 107Ah, USBHS_NS.PIPE7CTR 0745 107Ch, USBHS_NS.PIPE8CTR 0745 107Eh, USBHS_NS.PIPE9CTR 0745 1080h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	1	0	x	x	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PID[1:0]	Response PID	b1 b0 0 0: NAK response 0 1: BUF response (depending on buffer state) 1 0: STALL response 1 1: STALL response	R/W
b4 to b2	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b5	PBUSY	Pipe Busy Flag	0: Pipe n is not used for the USB bus. 1: Pipe n is in use for the USB bus.	R
b6	SQMON	Sequence Toggle Bit Monitor Flag	0: DATA0 1: DATA1	R
b7	SQSET	Sequence Toggle Bit Set*1	This bit is set to 1 when the expected value of the sequence toggle bit for the next transaction of pipe n is set for DATA1. Writing 0 has no effect. This bit is read as 0.	R/W
b8	SQCLR	Sequence Toggle Bit Clear*1	This bit is set to 1 when the expected value of the sequence toggle bit for the next transaction of pipe n is returned to DATA0. Writing 0 has no effect. This bit is read as 0.	R/W
b9	ACLRM	Auto Buffer Clear Mode*2	0: Disabled 1: Enabled (all buffers are initialized)	R/W
b10	ATREPM	Auto Response Mode*1, *3	0: Auto response mode is disabled. 1: Auto response mode is enabled	R/W
b11	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b12	CSSTS	CSSTS Status Flag	0: SSPLIT transaction being processing, or split transaction unused device being processed 1: CSPLIT transaction being processed	R
b13	CSCLR	CSPLIT Status Clear	Set this bit to 1 to set the CSSTS flag for pipe n to 0. Writing 0 has no effect.	R/W
b14	INBUFM	Transmit Buffer Monitor Flag*3	0: No transmittable data is present in the FIFO buffer. 1: Transmittable data is present in the FIFO buffer.	R
b15	BSTS	Buffer Status Flag	0: Buffer access is disabled. 1: Buffer access is enabled.	R

Note 1. Only change the settings of the ATREPM bit and write 1 to the SQCLR or SQSET bit while the PIPEnCTR.CSSTS flag is 0 and PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag and PIPEnCTR.CSSTS flag are 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBHS changes the PIPEnCTR.PID[1:0] bits to 00b (NAK response).

Note 2. Only change the settings of the ACLRM bit while the PIPEnCTR.CSSTS flag is 0, PIPEnCTR.PID[1:0] bits are 00b (NAK response), and the CURPIPE[3:0] bits in the D0FIFOSEL/D1FIFOSEL register are 0000b. Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag and PIPEnCTR.CSSTS flag are 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBHS changes the PID[1:0] bits to 00b (NAK response).

Note 3. The ATREPM bit and the INBUFM flag in registers PIPE6CTR to PIPE9CTR are reserved. This bit is undefined when read. Set it to 0 when writing.

PID[1:0] Bits (Response PID)

These bits specify the response type for the next transaction of pipe n.
The initial setting of the PIPEnCTR.PID[1:0] bits is 00b (NAK response). Modify these bits to 01b (BUF response) to use pipe n for USB transfer. The basic operation (with no error in communication packets) of the USBHS according to the setting of the PIPEnCTR.PID[1:0] bits is shown in Table 41.9 and Table 41.10.
After modifying the setting of the PIPEnCTR.PID[1:0] bits from 01b (BUF response) to 00b (NAK response) during communication using pipe n, check that the PBUSY flag is 0 to confirm that the USB transfer using pipe n has actually entered the NAK state.

The USBHS modifies the PIPEnCTR.PID[1:0] bits in the following cases.

- If pipe n is in the receiving direction, and the PIPECFG.SHTNAK bit for the selected pipe is set to 1, when the USBHS sets the PIPEnCTR.PID[1:0] bits to 00b (NAK response) on recognizing the completion of transfer.
- The USBHS sets the PIPEnCTR.PID[1:0] bits to 11b (STALL response) on receiving a data packet with a payload exceeding the maximum packet size of pipe n.
- The USBHS sets the PIPEnCTR.PID[1:0] bits to 00b (NAK response) on detecting a USB bus reset in function controller operation.
- The USBHS sets the PIPEnCTR.PID[1:0] bits to 00b (NAK response) on detecting a reception error, such as a CRC error, three consecutive times in host controller operation.
- The USBHS sets the PIPEnCTR.PID[1:0] bits to 11b (STALL response) on receiving the STALL handshake in host controller operation.

The PIPEnCTR.PID[1:0] bits should be set according to the procedure below.

- To make a transition from 00b (NAK response) to 10b (STALL response), write 10b.
- To make a transition from 01b (BUF response) to 11b (STALL response), write 11b.
- To make a transition from 11b (STALL response) to 00b (NAK response), write 10b and then 00b.
- To make a transition from 11b (STALL response) to 01b (BUF response), modify the bits to 00b (NAK response) and then to 01b (BUF response).

Table 41.9 USBHS Operation According to the PIPEnCTR.PID[1:0] Bit Setting (In Host Controller Operation)

PID[1:0] Bit Value	Transfer Type (TYPE[1:0] Bit Value)	Transfer Direction (DIR Bit Value)	USBHS Operation
00b (NAK response)	Does not depend on the setting.	Does not depend on the setting.	Does not issue tokens.
01b (BUF response)	Bulk or Interrupt	Does not depend on the setting.	Issues tokens when the DVSTCTR0.UACT bit is 1 and the FIFO buffer corresponding to the relevant pipe is ready for transmission and reception. Does not issue tokens when the DVSTCTR0.UACT bit is 0 or the FIFO buffer corresponding to the relevant pipe is not ready for transmission or reception.
	Isochronous	Does not depend on the setting.	Issues tokens when the DVSTCTR0.UACT bit is 1, regardless of the state of the FIFO buffer corresponding to pipe n. Does not issue tokens when the UACT bit is 0.
10b or 11b (STALL response)	Does not depend on the setting.	Does not depend on the setting.	Does not issue tokens.

Table 41.10 USBHS Operation According to the PIPEnCTR.PID[1:0] Bit Setting (In Function Controller Operation)

PID[1:0] Bit Value	Transfer Type (TYPE[1:0] Bit Value)	Transfer Direction (DIR Bit Value)	USBHS Operation
00b (NAK response)	Bulk or Interrupt	Does not depend on the setting.	Returns a NAK response to the token from the USB host.
	Isochronous	Receiving direction (DIR bit is 0)	Returns no response to the token from the USB host.
		Transmitting direction (DIR bit is 1)	Transmits a zero-length packet in response to the token from the USB host.
01b (BUF response)	Bulk	Receiving direction (DIR bit is 0)	Receives data and returns an ACK or NYET response in response to the OUT token from the USB host if the FIFO buffer corresponding to the relevant pipe is ready for reception. Otherwise, returns a NAK response. When there is a PING token from the USB host, if the FIFO buffer for the selected pipe is receive enabled, ACK is returned. If the FIFO buffer is not receive enabled, then NAK is returned.
	Interrupt	Receiving direction (DIR bit is 0)	Receives data and returns an ACK response in response to the OUT token from the USB host if the FIFO buffer corresponding to the relevant pipe is ready for reception. Otherwise, returns a NAK response.
	Bulk or Interrupt	Transmitting direction (DIR bit is 1)	Transmits data in response to the token from the USB host if the corresponding FIFO buffer is ready for transmission. Otherwise, returns a NAK response.
	Isochronous	Receiving direction (DIR bit is 0)	Receives data in response to the OUT token from the USB host if the corresponding FIFO buffer is ready for reception. Otherwise, discards data.
		Transmitting direction (DIR bit is 1)	Transmits data in response to the token from the USB host if the corresponding FIFO buffer is ready for transmission. Otherwise, transmits a zero-length packet.
10b or 11b (STALL response)	Bulk or Interrupt	Does not depend on the setting.	Returns a STALL response to the token from the USB host.
	Isochronous	Does not depend on the setting.	Returns no response to the token from the USB host.

PBUSY Flag (Pipe Busy Flag)

This flag indicates whether pipe n is being used for the current transaction. The USBHS modifies the PBUSY flag from 0 to 1 at the beginning of a USB transaction for pipe n, and modifies the PBUSY flag from 1 to 0 upon successful completion of one transaction. After setting the PIPEnCTR.PID[1:0] bits to 00b (NAK response), reading the PBUSY flag allows checking whether modification of the pipe setting is possible. Refer to section 41.3.7.1 for details.

SQMON Flag (Sequence Toggle Bit Monitor Flag)

This flag indicates the value of the sequence toggle bit for the next transaction of pipe n. When pipe n is not the isochronous transfer type, the USBHS toggles the SQMON flag upon successful completion of the transaction. However, the USBHS does not toggle the SQMON flag when a data PID inconsistency occurs during transfer in the receiving direction.

SQSET Bit (Sequence Toggle Bit Set)

This bit is set to 1 when the value of the sequence toggle bit for the next transaction of pipe n is set for DATA1. When the SQSET bit is set to 1, the USBHS sets the expected value of the sequence toggle bit of pipe n for DATA1.

SQCLR Bit (Sequence Toggle Bit Clear)

This bit is set to 1 when the value of the sequence toggle bit for the next transaction of pipe n is returned to DATA0. When the SQCLR bit is set to 1, the USBHS sets the expected value of the sequence toggle bit of pipe n for DATA0.

ACLRM Bit (Auto Buffer Clear Mode)

This bit enables or disables auto buffer clear mode for pipe n. To completely clear the information in the FIFO buffer allocated to pipe n, write 1 and then 0 to the ACLRM bit continuously. Also, allow 100 ns between modifying the ACLRM bit from 1 to 0 as sequence execution time for the internal hardware. The following lists the information cleared by the USBHS by writing 1 and 0 continuously to the ACLRM bit.

(a) All data in the FIFO buffer allocated to pipe n (both planes in double buffer mode).
(b) The interval counter value when the transfer type for pipe n is isochronous transfer or interrupt transfer.

Perform this processing when the following conditions are satisfied:

(a) When all data in the FIFO buffer allocated to pipe n needs to be cleared.
(b) When the interval counter value needs to be reset.
(c) When modifying the PIPECFG.DIR, DBLB, or BFRE bit.
(d) When the transaction count function is forcibly ended.

ATREPM Bit (Auto Response Mode)

This bit enables or disables the auto response of pipe n.
When the transfer type of pipe n is set to bulk IN function controller operation, this bit can be set to 1.
When this bit is set to 1, the USBHS responds as follows to the token from the USB host.

(1) When pipe n is bulk IN transfer type (PIPECFG.TYPE[1:0] bits are 01b and the PIPECFG.DIR bit is 1)
When the ATREPM bit is 1 and the PIPEnCTR.PID[1:0] bits are 01b (BUF response), the USBHS transmits a zero-length packet in response to IN token. The USBHS updates (toggles) the sequence toggle bit (data PID) each time the USBHS receives ACK from the USB host (in a single transaction, IN token is received, zero-length packet is transmitted, and then ACK is received). In this case, the USBHS generates no BRDY interrupt or BEMP interrupt.

(2) When pipe n is bulk OUT transfer type (PIPECFG.TYPE[1:0] bits are 01b and the PIPECFG.DIR bit is 0)
When the ATREPM bit is 1 and the PIPEnCTR.PID[1:0] bits are 01b (BUF response), the USBHS returns a NAK response to OUT token or PING token and generates an NRDY interrupt. When performing USB communication with this bit set to 1, set this bit while the FIFO buffer is empty. Do not write data to the FIFO buffer during USB communication with this bit set to 1. Be sure to set this bit to 0 when pipe n is used for isochronous transfer. In host controller operation, be sure to set this bit to 0.

CSSTS Flag (CSSTS Status Flag)

In host controller operation, the CSSTS flag indicates the transaction status of the complete-split transaction for non-isochronous transfers. When a CSPLIT transaction starts, the USBHS sets the CSSTS flag to 1, and when the CSPLIT transaction is detected as being complete, the CSSTS flag is set to 0. When a detach occurs during the CSPLIT transaction, the CSSTS flag may remain set to 1. In this case, set the CSCLR bit to 1 and set the CSSTS flag to 0.
In function controller operation, the value read from the CSSTS flag is invalid.

CSCLR Bit (CSPLIT Status Clear)

In host controller mode, when the CSCLR bit is set to 1, the CSSTS flag becomes 0. For transfers using a split transaction, when the next transfer is forced to restart from the start-split, set the CSCLR bit to 1. In a normal split transaction, when the CSPLIT transaction is complete, the USBHS automatically sets the CSSTS flag to 0, so the flag does not need to be set to 0 by software. Use the CSCLR bit to set the CSSTS flag to 0 when the DVSTCTR0.UACT bit is 0, or when it is certain that transfer is not performed when a detach is detected. When the CSSTS flag is 0, it remains set to 0 even if the CSCLR bit is set to 1. In function controller operation, set the CSCLR bit to 0.

INBUFM Flag (Transmit Buffer Monitor Flag)

This flag indicates the FIFO buffer status for pipe n in the transmitting direction. With pipe n set in the transmitting direction (PIPECFG.DIR bit is 1), the USBHS sets the INBUFM flag to 1 when the CPU or DMAC/DTC has completed writing data to at least one FIFO buffer plane. The USBHS sets the INBUFM flag to 0 when the USBHS has completely transmitted the data from the FIFO buffer plane to which all the data has been written. In double buffer mode (PIPECFG.DBLB bit is 1), the USBHS sets the INBUFM flag to 0 when the USBHS has completely transmitted data from the two FIFO buffer planes before the CPU or DMAC/DTC completes writing data to one FIFO buffer plane. The INBUFM flag indicates the same value as the BSTS flag when pipe n is in the receiving direction (PIPECFG.DIR bit is 0).

BSTS Flag (Buffer Status Flag)

This flag indicates the FIFO buffer status for pipe n. The meaning of the BSTS flag varies as shown in Table 41.11 depending on the settings of the PIPECFG.DIR bit, PIPECFG.BFRE bit, and DCLRM bit in the D0FIFOSEL/ D1FIFOSEL register.

Table 41.11 Operation of the BSTS Flag

DIR Bit Value	BFRE Bit Value	DCLRM Bit Value	Meaning of the BSTS Flag
0	0	0	Becomes 1 when receive data can be read from the FIFO buffer, and becomes 0 upon completion of data read.
		1	Do not set this combination.
	1	0	Becomes 1 when receive data can be read from the FIFO buffer, and becomes 0 when the BCLR bit is set in a FIFO port control register to 1 after the data read has been completed.
		1	Becomes 1 when receive data can be read from the FIFO buffer, and becomes 0 upon completion of data read.
1	0	0	Becomes 1 when transmit data can be written to the FIFO buffer, and becomes 0 upon completion of data write.
		1	Do not set this combination.
	1	0	Do not set this combination.
		1	Do not set this combination.

41.2.39 Pipe n Transaction Counter Enable Register (PIPEnTRE) (n = 1 to 5)

Address(es): USBHS.PIPE1TRE 8745 1090h, USBHS.PIPE2TRE 8745 1094h, USBHS.PIPE3TRE 8745 1098h, USBHS.PIPE4TRE 8745 109Ch, USBHS.PIPE5TRE 8745 10A0h,
USBHS_NS.PIPE1TRE 0745 1090h, USBHS_NS.PIPE2TRE 0745 1094h, USBHS_NS.PIPE3TRE 0745 1098h, USBHS_NS.PIPE4TRE 0745 109Ch, USBHS_NS.PIPE5TRE 0745 10A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	0	0	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b8	TRCLR	Transaction Counter Clear	This bit is set to 1 when the transaction counter is reset. Writing 0 has no effect. This bit is read as 0.	R/W
b9	TRENB	Transaction Counter Enable	0: The transaction count function is disabled. 1: The transaction count function is enabled.	R/W
b15 to b10	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

Note: Only change the settings of the PIPEnTRE register while the PIPEnCTR.CSSTS flag is 0 and PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag and PIPEnCTR.CSSTS flag are 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBHS changes the PID[1:0] bits to 00b (NAK response).

TRCLR Bit (Transaction Counter Clear)

The USBHS clears the current count value of the transaction counter corresponding to pipe n and then sets the TRCLR bit to 0.

TRENB Bit (Transaction Counter Enable)

This bit enables or disables the transaction counter.

When the total number of packets is set in the PIPEnTRN.TRNCNT[15:0] bits and then the TRENB bit is set to 1 for the pipe in the receiving direction, the USBHS performs the following control upon completion of receiving packets as many as the value of the TRNCNT[15:0] bits.

- In continuous transfer mode (CNTMD bit is 1), the USBHS toggles the TRENB bit to the CPU side even if the FIFO buffer is not full at the end of reception.
- When the PIPECFG.SHTNAK bit is 1, the USBHS modifies the PIPEnCTR.PID[1:0] bits of the corresponding pipe to 00b (NAK response) upon completion of receiving packets as many as the value of the TRNCNT[15:0] bits.
- When the PIPECFG.BFRE bit is 1, the USBHS asserts the BRDY interrupt upon completion of reading the final data after receiving packets as many as the value of the TRNCNT[15:0] bits.

For pipes in the transmitting direction, set the TRENB bit to 0.

When the transaction count function is not used, set the TRENB bit to 0.

When the transaction count function is used, set the TRNCNT[15:0] bits and then set the TRENB bit to 1. Furthermore, set the TRENB bit to 1 before receiving the first packet to be counted by the transaction counter.

41.2.40 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5)

Address(es): USBHS.PIPE1TRN 8745 1092h, USBHS.PIPE2TRN 8745 1096h, USBHS.PIPE3TRN 8745 109Ah, USBHS.PIPE4TRN 8745 109Eh, USBHS.PIPE5TRN 8745 10A2h,
USBHS_NS.PIPE1TRN 0745 1092h, USBHS_NS.PIPE2TRN 0745 1096h, USBHS_NS.PIPE3TRN 0745 109Ah, USBHS_NS.PIPE4TRN 0745 109Eh, USBHS_NS.PIPE5TRN 0745 10A2h

	TRNCNT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TRNCNT[15:0]	Transaction Counter*1	• When writing to the register These bits specify the number of total packets (number of transactions) to be received by the relevant pipe. • When reading the register When the PIPEnTRE.TRENB bit is 0, these bits indicate the specified number of transactions. When the PIPEnTRE.TRENB bit is 1, these bits indicate the number of transaction in the current count (current count value).	R/W

Note 1. Only change the settings of the TRNCNT[15:0] bits while the PIPEnCTR.CSSTS flag and PIPEnTRE.TRENB bit are 0 and the PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY flag and PIPEnCTR.CSSTS flag are 0. However, the PIPEnCTR.PBUSY flag does not need to be checked by software if the USBHS changes the PID[1:0] bits to 00b (NAK response).

The value set to the PIPEnTRN register is retained even if a USB bus reset occurs.

TRNCNT[15:0] Bits (Transaction Counter)

The USBHS increments the value of the TRNCNT[15:0] bits (current counter value) when all of the following conditions for reception state are satisfied.

- The PIPEnTRE.TRENB bit is 1.
- When receiving a packet, the value of the TRNCNT[15:0] bits is different from the current counter value + 1.
- The payload of the received packet matches the value set to the PIPEMAXP.MXPS[10:0] bits.

The USBHS sets the value of the TRNCNT[15:0] bits (current counter value) to 0 when any of the following conditions is satisfied.

(1) All of the following conditions are satisfied.
- The PIPEnTRE.TRENB bit is 1.
- When receiving a packet, the value of the TRNCNT[15:0] bits is the same as the current counted value + 1.
- The payload of the received packet matches the value set to the PIPEMAXP.MXPS[10:0] bits.

(2) Both of the following conditions are satisfied.
- The PIPEnTRE.TRENB bit is 1.
- The USBHS has received a short packet.

(3) The following condition is satisfied.
- The PIPEnTRE.TRCLR bit is set to 1.

For pipes in the transmitting direction, set the TRNCNT[15:0] bits to 0. When the transaction count function is not used, set the TRNCNT[15:0] bits to 0. The number of transactions can be set to the TRNCNT[15:0] bits only when the PIPEnTRE.TRENB bit is 0. If the specified number of transactions is modified, set the PIPEnTRE.TRCLR bit to 1 (the current counter is cleared) before setting the PIPEnTRE.TRENB bit to 1 (count starts).

41.2.41 Device Address m Configuration Register (DEVADDm) (m = 0 to A)

Address(es): USBHS.DEVADD0 8745 10D0h, USBHS.DEVADD1 8745 10D2h, USBHS.DEVADD2 8745 10D4h, USBHS.DEVADD3 8745 10D6h, USBHS.DEVADD4 8745 10D8h, USBHS.DEVADD5 8745 10DAh, USBHS.DEVADD6 8745 10DCh, USBHS.DEVADD7 8745 10DEh, USBHS.DEVADD8 8745 10E0h, USBHS.DEVADD9 8745 10E2h, USBHS.DEVADDA 8745 10E4h, USBHS_NS.DEVADD0 0745 10D0h, USBHS_NS.DEVADD1 0745 10D2h, USBHS_NS.DEVADD2 0745 10D4h, USBHS_NS.DEVADD3 0745 10D6h, USBHS_NS.DEVADD4 0745 10D8h, USBHS_NS.DEVADD5 0745 10DAh, USBHS_NS.DEVADD6 0745 10DCh, USBHS_NS.DEVADD7 0745 10DEh, USBHS_NS.DEVADD8 0745 10E0h, USBHS_NS.DEVADD9 0745 10E2h, USBHS_NS.DEVADDA 0745 10E4h

b15	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W

The DEVADDm register specifies the communication speed of the communication target peripheral device for pipes 0 to 9, and specifies the port number and address of the connected upstream facing hub. In host controller operation, set each bit in the DEVADDm register before communications start to pipes.

Modify each bit in the DEVADDm register while there is no valid pipe specified by such a bit. The valid pipe is defined as the pipe satisfying both the conditions listed below.

- The DEVSEL[3:0] bits specify the DEVADDm register.
- The PIPEnCTR.PID[1:0] bits of the selected pipe are 01b (BUF response), or the default control pipe is the selected pipe and the DCPCTR.SUREQ bit is set to 1.

In function controller operation, set each bit in this register to 0.

USBSPD[1:0] Bits (Transfer Speed of Communication Target Device)

In host controller operation, the USBHS generates a packet according to the value of these bits.

HUBPORT[2:0] Bits (HUB Port Connected for Communication)

In host controller operation, the USBHS generates a packet according to the value of these bits when a split transaction is executed.

UPPHUB[3:0] Bits (HUB Register Connected for Communication)

In host controller operation, the USBHS generates a packet according to the value of these bits when a split transaction is executed.

41.2.42 Low Power Control Register (LPCTRL)

Address(es): USBHS.LPCTRL 8745 1100h, USBHS_NS.LPCTRL 0745 1100h

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b7	HWUPM	Return Mode Setting	0: Hardware return is not made while the CPU clock is stopped. 1: Hardware return is made while the CPU clock is stopped.	R/W
b8	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b15 to b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

HWUPM Bit (Return Mode Setting)

This bit specifies whether to enable the hardware processing for return from a low power state of the LPM L1 state even while the CPU clock is stopped. In function controller operation, the processing for return from low power mode upon detecting resume signal is enabled even while the CPU clock is stopped. The HWUPM bit specifies whether to detect resume signal while the CPU clock is stopped. The PL1CTRL1.L1EXTMD bit controls whether to make hardware return. To make hardware return from a low power state of the LPM L1 state while the CPU clock is stopped, set the HWUPM bit and the PL1CTRL1.L1EXTMD bit to 1.

41.2.43 Low Power Status Register (LPSTS)

Address(es): USBHS.LPSTS 8745 1102h, USBHS_NS.LPSTS 0745 1102h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b8	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b11 to b9	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b12	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b13	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W
b14	SUSPENDM	SuspendM Control	0: Suspend mode 1: Normal mode	R/W
b15	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W

SUSPENDM Bit (SuspendM Control)

This bit controls the SuspendM signal output to the PHY. The initial value is 0 and the PHY is in suspend mode. To supply the PHY clock to operate the USB 2.0 host/function controller, set this bit to 1. Refer to section 41.3.3 for details on setting clocks.

When the SUSPENDM bit is 0, the registers in the USBHS are not writable, but are readable. However, registers listed in Table 41.12 below are write accessible even when the SUSPENDM bit is 0.

Table 41.12 Registers That Can be Written by Software when the SUSPENDM Bit is 0

Address	Register/Bit
8745 1000h or 0745 1000h	SYSCFG register
8745 1002h or 0745 1002h	BUSWAIT register
8745 1032h or 0745 1032h	INTENB1.PDDETINTE bit
8745 103Eh or 0745 103Eh	PHYSET register
8745 1100h or 0745 1100h	LPCTRL register
8745 1102h or 0745 1102h	LPSTS register
8745 1140h or 0745 1140h	BCCTRL register
8745 1164h or 0745 1164h	DPUSR1R register
8745 1168h or 0745 1168h	DPUSR2R register
8745 116Ah or 0745 116Ah	DPUSRCR register

However, the value written to the SYSCFG register while the PHY clock is stopped is updated after the PHY clock is oscillated. The PHY clock is oscillated in the following cases.

(1) The SUSPENDM bit is set to 1 and then the PLLSTA.PLLLOCK flag is set to 1 after the predetermined time has passed.
(2) USBCLK (48 MHz) and USB60CLK (60 MHz) are supplied to the USBHS from the main clock with the SUSPENDM bit set to 0
(Refer to section 41.2.17 for details on classic-only mode.)

While the PL1CTRL1.L1EXTMD bit is 0, the SUSPENDM bit must be controlled by software. When the PL1CTRL1.L1EXTMD bit is 1, when transitioning to the L1 or L2 state (suspended state), the SUSPENDM bit must be set to 0 by software, but when exiting the L1 or L2 state, the USBHS sets the SUSPENDM bit to 1.

41.2.44 Battery Charging Control Register (BCCTRL)

Address(es): USBHS.BCCTRL 8745 1140h, USBHS_NS.BCCTRL 0745 1140h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b9	PDDETSTS	D+ Line 0.6 V Input Detection Status Flag*2	0: Not detected 1: Detected	R
b15 to b10	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

Note 1. Valid when the IDMSINKE bit is 1.
Note 2. Valid when the IDPSINKE bit is 1.

IDPSRCE Bit (D+ Line IDPSRC Output Control)

In function controller operation, set this bit to 1 to perform Data Contact Detect. In the Battery Charging Specification Revision 1.2, there are two methods to handle Data Contact Detect; the method realized by software wait and the method to contact the data line by hardware. The IDPSRCE bit adopts the latter method. When the IDPSRCE bit is set to 1, the USBHS enables the IDP_SRC circuit and, at the same time, controls D– line pull-down.

IDMSINKE Bit (D– Line 0.6 V Input Detection (Comparator and Sink) Control)

In function controller operation, the following can be detected when the IDMSINKE bit is set to 1:

- During Primary Detection, VDMSRC (0.6 V) is input to the USBHS_DM pin from the host
- During Primary Detection, VDPSRC (0.6 V) output from the USBHS to the USBHS_DP pin is input to the USBHS_DM pin via the USB host

VDPSRCE Bit (D+ Line VDPSRC (0.6 V) Output Control)

In function controller operation, if Primary Detection is executed, this bit controls VDPSRC (0.6 V) output from the USBHS_DP pin.

IDPSINKE Bit (D+ Line 0.6 V Input Detection (Comparator and Sink) Control)

When the IDPSINKE bit is set to 1, the following states can be detected:

- In host controller operation
  During Primary Detection, VDPSRC (0.6 V) is input to the USBHS_DP pin from a peripheral device.
- In function controller operation
  During Secondary Detection, VDMSRC (0.6 V) output from the USBHS to the USBHS_DM pin is input to the USBHS_DP pin via the host.

VDMSRCE Bit (D– Line VDMSRC (0.6 V) Output Control)

- In host controller operation
  During Primary Detection, this bit controls VDMSRC (0.6 V) output from the USBHS_DM pin.
- In function controller operation
  During Secondary Detection, this bit controls VDMSRC (0.6 V) output from the USBHS_DM pin.

CHGDETSTS Flag (D– Line 0.6 V Input Detection Status Flag)

In function controller operation, this flag is enabled when the IDMSINKE bit is 1.
The CHGDETSTS flag becomes 1 under the following conditions:

- During Primary Detection, VDMSRC (0.6 V) is input to the USBHS_DM pin from the USB host.
- During Primary Detection, the VDPSRC (0.6 V) output from the USBHS to the USBHS_DP pin is input to the USBHS_DM pin via the USB host.

PDDETSTS Flag (D+ Line 0.6 V Input Detection Status Flag)

The PDDETSTS flag is enabled when the IDPSINKE bit is 1.
The PDDETSTS flag becomes 1 under the following conditions:

- In host controller operation
  During Primary Detection, VDPSRC (0.6 V) is input to the USBHS_DP pin from a peripheral device.
- In function controller operation
  During Secondary Detection, the VDMSRC (0.6 V) output from the USBHS to the USBHS_DM pin is input to the USBHS_DP pin via the host.

41.2.45 Function L1 Control Register 1 (PL1CTRL1)

Address(es): USBHS.PL1CTRL1 8745 1144h, USBHS_NS.PL1CTRL1 0745 1144h

When the received HIRD field is smaller than or equal to the value set to the HIRDTHR[3:0] bits, an NYET response is returned. 1: When the received HIRD field is smaller than the HIRDTHR[3:0] bit value, an ACK response is returned. When the received HIRD field is greater than or equal to the value set to the HIRDTHR[3:0] bits, an NYET response is returned.	R/W
b6 to b4	DVSQ[2:0]	Extension Device State	These flags indicate the same value with the INTSTS0.DVSQ[2:0] bits.	R
b7	DVSQ[3]		This flag indicates the L1 state together with the INTSTS0.DVSQ[2:0] bits. 0000: Powered state 0001: Default state 0010: Address state 0011: Configured state 0100: Suspended state 0101: Suspended state 0110: Suspended state 0111: Suspended state 1000 to 1011: L1 state	R
b11 to b8	HIRDTHR[3:0]	L1 Response Negotiation Threshold Value*1	HIRD threshold value used when the L1RESPMD[1:0] bits are 11b. The format is the same as the HIRD field in the HL1CTRL2 register.	R/W
b13, b12	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b14	L1EXTMD	PHY Control Mode at L1 Return	0: The LPSTS.SUSPENDM bit is not set by hardware when exiting the L1 state. 1: The LPSTS.SUSPENDM bit is set by hardware when exiting the L1 state.	R/W
b15	—	Reserved	This bit is undefined when read. Set it to 0 when writing.	R/W

Note 1. The L1NEGOMD bit is only valid when the L1RESPMD[1:0] bits are 11b.

L1RESPEN Bit (L1 Response Enable)

When the L1RESPEN bit is 0, even if the LPM token is received, the USBHS returns no response in regards to the LPM token. When the L1RESPEN bit is 1, if the LPM token is received, the USBHS returns a response in accordance with the L1RESPMD[1:0] bit setting.

L1RESPMD[1:0] Bits (L1 Response Mode)

When the L1RESPEN bit is set to 1, the USBHS returns a response to the LPM token in accordance with the L1RESPMD[1:0] bit setting.

L1NEGOMD Bit (L1 Response Negotiation Control)

The L1NEGOMD bit sets the response conditions for the HIRD[3:0] bit value. The L1NEGOMD bit is valid when the L1RESPMD[1:0] bits are 11b.

DVSQ[2:0] Bits (Extension Device State)

These flags mirror the INTSTS0.DVSQ[2:0] bits.

DVSQ[3] Bit (Extension Device State)

This flag is the fourth bit of the device state bits (DVSQ[2:0] bits).

HIRDTHR[3:0] Bits (L1 Response Negotiation Threshold Value)

The HIRDTHR[3:0] bits specify the HIRD threshold value used by the HIRD[3:0] bit value in the negotiation. The HIRDTHR[3:0] bits are valid when the L1RESPMD[1:0] bits are 11b.
The format of the set value is the same as the HL1CTRL2.HIRD[3:0] bits.

L1EXTMD Bit (PHY Control Mode at L1 Return)

In the L1 state, with the LPSTS.SUSPENDM bit set to 0 to stop the PHY clock, this bit specifies the LPSTS.SUSPENDM bit control method when receiving the resume signal.
When supporting the L1 state, set the L1EXTMD bit to 1 during the initialization process.
When entering the L1 state, the LPSTS.SUSPENDM bit must be set to 0 by software regardless of the L1EXTMD bit value.
When the L1EXTMD bit is set to 1, the USBHS also sets the LPSTS.SUSPENDM bit to 1 when exiting the L2 state (suspended state).

41.2.46 Function L1 Control Register 2 (PL1CTRL2)

Address(es): USBHS.PL1CTRL2 8745 1146h, USBHS_NS.PL1CTRL2 0745 1146h

b15 to b3	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W

L1REQ Bit (L1 Transition Request)

Set this bit to 1 to transition a peripheral device to the L1 state. When the L1REQ bit is set to 1, the USBHS starts the LPM transaction, and when the transaction is complete, the L1REQ bit is set to 0.

L1STATUS[1:0] Bits (L1 Request Completion Status)

These bits reflect the result of the LPM transaction executed by the L1REQ bit.

41.2.48 Host L1 Control Register 2 (HL1CTRL2)

b7 to b4	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b11 to b8	HIRD[3:0]	LPM Token HIRD	These bits specify the value to be set in the BESL field of the LPM token.	R/W
b12	L1RWE	LPM Token L1 Remote Wakeup Enable	These bits specify the value to be set in the bRemoteWake field of the LPM token.	R/W
b14, b13	—	Reserved	These bits are undefined when read. Set them to 0 when writing.	R/W
b15	BESL	BESL & Alternate HIRD	This bit selects the resume signal output period when exiting the L1 state.	R/W

L1ADDR[3:0] Bits (LPM Token Device Address)

When the HL1CTRL1.L1REQ bit is set to 1, these bits specify the value to be set in the ADDR field of the LPM token transmitted by the USBHS.

HIRD[3:0] Bits (LPM Token HIRD)

When the HL1CTRL1.L1REQ bit is set to 1, these bits specify the value to be set in the BESL field of the LPM token transmitted by the USBHS. Table 41.13 indicates the Relationship Between the Values Set to the HIRD[3:0] and BESL Bits With the HIRD and BESL Values.

Table 41.13 Relationship Between the Values Set to the HIRD[3:0] and BESL Bits With the HIRD and BESL Values

	When the BESL Bit is 0	When the BESL Bit is 1	
Value Set to the HIRD[3:0] Bits	HIRD value	HIRD value	BESL value
0000b	50 µs (do not set this value)	75 µs	125 µs
0001b	125 µs	100 µs	150 µs
0010b	200 µs	150 µs	200 µs
0011b	275 µs	250 µs	300 µs
0100b	350 µs	350 µs	400 µs
0101b	425 µs	450 µs	500 µs
0110b	500 µs	950 µs	1000 µs
0111b	575 µs	1,950 µs	2,000 µs
1000b	650 µs	2,950 µs	3,000 µs
1001b	725 µs	3,950 µs	4,000 µs
1010b	800 µs	4,950 µs	5,000 µs
1011b	875 µs	5,950 µs	6,000 µs
1100b	950 µs	6,950 µs	7,000 µs
1101b	1,025 µs (do not set this value)	7,950 µs	8,000 µs
1110b	1,100 µs (do not set this value)	8,950 µs	9,000 µs
1111b	1,175 µs (do not set this value)	9,950 µs	10,000 µs

Note: In host controller operation, the HIRD[3:0] bit setting value is used for the resume signal output period when exiting the L1 state.

L1RWE Bit (LPM Token L1 Remote Wakeup Enable)

When the HL1CTRL1.L1REQ bit is set to 1, this bit specifies the value to be set in the bRemoteWake field of the LPM token transmitted by the USBHS. Depending on the L1RWE bit setting, the USBHS does not control detection of the remote wakeup signal in the L1 state. The remote wakeup signal is controlled by the DVSTCTR0.RWUPE bit as is the case when the USBHS is in the L2 state (suspended state).

BESL Bit (BESL & Alternate HIRD)

In host controller operation, this bit selects the resume signal output period when exiting the L1 state. Refer to the description of the HIRD[3:0] bits for details.

41.2.49 Deep Standby USB Transceiver Pin Monitor Register (DPUSR0R)

Address(es): USBHS.DPUSR0R 8745 1160h, USBHS_NS.DPUSR0R 0745 1160h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b4	DOVCAHE	OVRCURA Interrupt Enable/Clear	0: Interrupt is disabled and the DOVCAH flag is cleared. 1: Interrupt is enabled.	R/W
b5	DOVCBHE	OVRCURB Interrupt Enable/Clear	0: Interrupt is disabled and the DOVCBH flag is cleared. 1: Interrupt is enabled.	R/W
b6	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b7	DVBSTSHE	VBUS Interrupt Enable/Clear	0: Interrupt is disabled and the DVBSTSH flag is cleared. 1: Interrupt is enabled.	R/W
b19 to b8	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b20	DOVCAH	OVRCURA Interrupt Source Resume Status Flag	0: OVRCURA interrupt is not detected. 1: OVRCURA interrupt is detected.	R
b21	DOVCBH	OVRCURB Interrupt Source Resume Status Flag	0: OVRCURB interrupt is not detected. 1: OVRCURB interrupt is detected.	R
b22	—	Reserved	This bit is read as 0. Set it to 0 when writing.	R/W
b23	DVBSTSH	VBUS Interrupt Source Resume Status Flag	0: VBUS interrupt is not detected. 1: VBUS interrupt is detected.	R
b31 to b24	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note: The value of this register is retained even in deep software standby mode 1. It is also not initialized by deep software standby reset 1.

This register is used to select the source to return from deep software standby mode 1.

DOVCAHE Bit (OVRCURA Interrupt Enable/Clear)

This bit is used to specify whether a change on the USBHS_OVRCURA pin is used as a source to return from deep software standby mode 1.

When this bit is set to 0 while the DOVCAH flag is 1, the DOVCAH is set to 0.

DOVCBHE Bit (OVRCURB Interrupt Enable/Clear)

This bit is used to specify whether a change on the USBHS_OVRCURB pin is used as a source to return from deep software standby mode 1.

When this bit is set to 0 while the DOVCBH flag is 1, the DOVCBH is set to 0.

DVBSTSHE Bit (VBUS Interrupt Enable/Clear)

This bit is used to specify whether a change on the USBHS_VBUS pin is used as a source to return from deep software standby mode 1.

When this bit is set to 0 while the DVBSTSH flag is 1, the DVBSTSH is set to 0.

DOVCAH Flag (OVRCURA Interrupt Source Resume Status Flag)

This flag indicates that the MCU has returned from deep software standby mode 1 due to a change on the USBHS_OVRCURA pin.

This flag is valid only when the DOVCAHE bit is set to 1. Writing 0 to the DOVCAHE bit sets this flag to 0.

DOVCBH Flag (OVRCURB Interrupt Source Resume Status Flag)

This flag indicates that the MCU has returned from deep software standby mode 1 due to a change on the USBHS_OVRCURB pin.

This flag is valid only when the DOVCBHE bit is set to 1. Writing 0 to the DOVCBHE bit sets this flag to 0.

DVBSTSH Flag (VBUS Interrupt Source Resume Status Flag)

This flag indicates that the MCU has returned from deep software standby mode 1 due to a change on the USBHS_VBUS pin.

This flag is valid only when the DVBSTSHE bit is set to 1. Writing 0 to the DVBSTSHE bit sets this flag to 0.

41.2.51 Deep Standby USB Resume Interrupt Register 2 (DPUSR2R)

Address(es): USBHS.DPUSR2R 8745 1168h, USBHS_NS.DPUSR2R 0745 1168h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	DPINTE	DMINTE	—	—	DMVAL	DPVAL	—	—	DPINT	DMINT
Value after reset:	0	0	0	0	0	0	0	0	0	0	x	x	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DMINT	D– Interrupt Source Resume Status Flag	0: D– interrupt is not detected. 1: D– interrupt is detected.	R
b1	DPINT	D+ Interrupt Source Resume Status Flag	0: D+ interrupt is not detected. 1: D+ interrupt is detected.	R
b3, b2	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b4	DPVAL	D+ Input Flag	This flag indicates the level of the input signal to the USBHS_DP pin.	R
b5	DMVAL	D– Input Flag	This flag indicates the level of the input signal to the USBHS_DM pin.	R
b7, b6	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b8	DMINTE	D– Interrupt Enable/Clear	0: Interrupt is disabled and the DMINT flag is cleared. 1: Interrupt is enabled.	R/W
b9	DPINTE	D+ Interrupt Enable/Clear	0: Interrupt is disabled and the DPINT flag is cleared. 1: Interrupt is enabled.	R/W
b15 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note: The value of this register is retained even in deep software standby mode 1. It is also not initialized by deep software standby reset 1.

This register is used to select the source to return from deep software standby mode 1.

DMINT Flag (D– Interrupt Source Resume Status Flag)

This flag indicates that the MCU has returned from deep software standby mode 1 in response to a change on the USBHS_DM pin. This flag is only valid when the setting of the DMINTE bit is 1. Writing 0 to the DMINTE bit sets this flag to 0.

DPINT Flag (D+ Interrupt Source Resume Status Flag)

This flag indicates that the MCU has returned from deep software standby mode 1 in response to a change on the USBHS_DP pin. This flag is only valid when the setting of the DPINTE bit is 1. Writing 0 to the DPINTE bit sets this flag to 0.

DMINTE Bit (D– Interrupt Enable/Clear)

This bit determines whether or not a signal transition on the USBHS_DM pin is used as a trigger for return from deep software standby mode 1. Setting this bit to 0 while the DMINT flag is 1 sets the DMINT flag to 0.

DPINTE Bit (D+ Interrupt Enable/Clear)

This bit determines whether or not a signal transition on the USBHS_DP pin is used as a trigger for return from deep software standby mode 1. Setting this bit to 0 while the DPINT flag is 1 sets the DPINT flag to 0.

41.2.52 Deep Standby USB Transceiver Control Register (DPUSRCR)

Address(es): USBHS.DPUSRCR 8745 116Ah, USBHS_NS.DPUSRCR 0745 116Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FIXPHYPD	FIXPHY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FIXPHY	USB-PHY Output Fix	0: Normal operation 1: USBHS_DP and USBHS_DM pin inputs are enabled during deep software standby mode 1.	R/W
b1	FIXPHYPD	USB-PHY Power-Down Signal Mask	0: Normal operation 1: USB-PHY power-down signal is masked.	R/W
b15 to b2	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W

Note: The value of this register is retained even in deep software standby mode 1. It is also not initialized by deep software standby reset 1.

FIXPHY Bit (USB-PHY Output Fix)

This bit is used to prevent the output of undefined values from the USBHS_DP and USBHS_DM pins during deep software standby mode 1. Set this bit to 1 when the resume interrupt or the BCHG interrupt is to be used as a trigger for return from deep software standby mode 1. Restore the setting of this bit to 0 after the MCU has returned from deep software standby mode 1.

FIXPHYPD Bit (USB-PHY Power-Down Signal Mask)

This bit is used to mask the USB-PHY power-down signal (PHYSET.DIRPD bit) to keep the USB-PHY block powered during deep software standby mode 1. Set this bit to 1 when the resume interrupt or the BCHG interrupt is to be used as a trigger for return from deep software standby mode 1. Restore the setting of this bit to 0 after the MCU has returned from deep software standby mode 1.

41.3 Operation

41.3.1 System Control

This section describes register settings necessary to initialize the USBHS and registers necessary for power consumption control.

41.3.1.1 Setting Registers Associated with the USBHS

After supplying the PHY clock, set the SYSCFG.USBE bit to 1 to enable USBHS operation.
Refer to section 41.3.3 for details on supplying the PHY clock.

41.3.1.2 Selecting the Controller Function

The USBHS can be used in host controller operation or function controller operation. Set the SYSCFG.DCFM bit to select a controller operation. However, modify the DCFM bit in the initial settings immediately after a reset, or when pulling up the D+ line is disabled, and pulling down the D+ and D– lines is disabled (both SYSCFG.DPRPU bit and SYSCFG.DRPD bit are 0).

41.3.2 Controlling the USB Data Bus Resistors

The USBHS incorporates pull-up and pull-down resistors for the D+ and D– lines. Set the SYSCFG.DPRPU bit and SYSCFG.DRPD bit to select pull up or pull down.
In function controller operation, confirm there is a connection to the USB host, then set the SYSCFG.DPRPU bit to 1 to pull up the D+ line. If the SYSCFG.DPRPU bit is set to 0 while communicating with the USB host, the pull-up resistor for the USB data line is disabled, and the USB host can be notified that the device has been disconnected.
In host controller operation, set the SYSCFG.DRPD bit to 1 to pull down the D+ and D– lines.
Table 41.14 lists the settings for the USB data bus resistors. Set the DRPD and DPRPU bits to select the USB data bus resistors.

Table 41.14 Controlling the USB Data Bus Resistors (Excluding OTG Operation)

Settings		USB Data Bus Resistor Control		
DRPD bit	DPRPU bit	D– line	D+ line	Remarks
0	0	Open	Open	When the resistor is not used
0	1	Open	Pull-up	When operating as the function controller
1	0	Pull-down	Pull-down	When operating as the host controller
1	1	—	—	Do not set this value except for OTG operation

41.3.3 Supplying Clocks

The two input clocks required for the USBHS are shown in Table 41.15.

Table 41.15 Input Clocks

Input Clock Name	Description
Peripheral module clock (PCLKA)	PCLKA is used to access USBHS registers from the CPU, DMAC, and DTC. The clock frequency has no restrictions on the USBHS side.
PHY clock	Generating the PHY clock • When the PHYSET.HSEB bit is 0 Supply a clock to the EXTAL pin from a crystal oscillator with an oscillation frequency of 12, 20, 24, or 48 MHz and a frequency accuracy of ±100 ppm or less, and use a PLL in the USB-PHY to generate the PHY clock. • When the PHYSET.HSEB bit is 1 (CL only mode) The PHY clock is supplied when USBCLK (48 MHz) and USB60CLK (60 MHz) are supplied to the USBHS from the clock generation circuit and the HSEB bit is set to 1. In this case, high-speed operation is not supported.

Figure 41.2 shows the PHY Clock Settings in Classic-Only Mode.

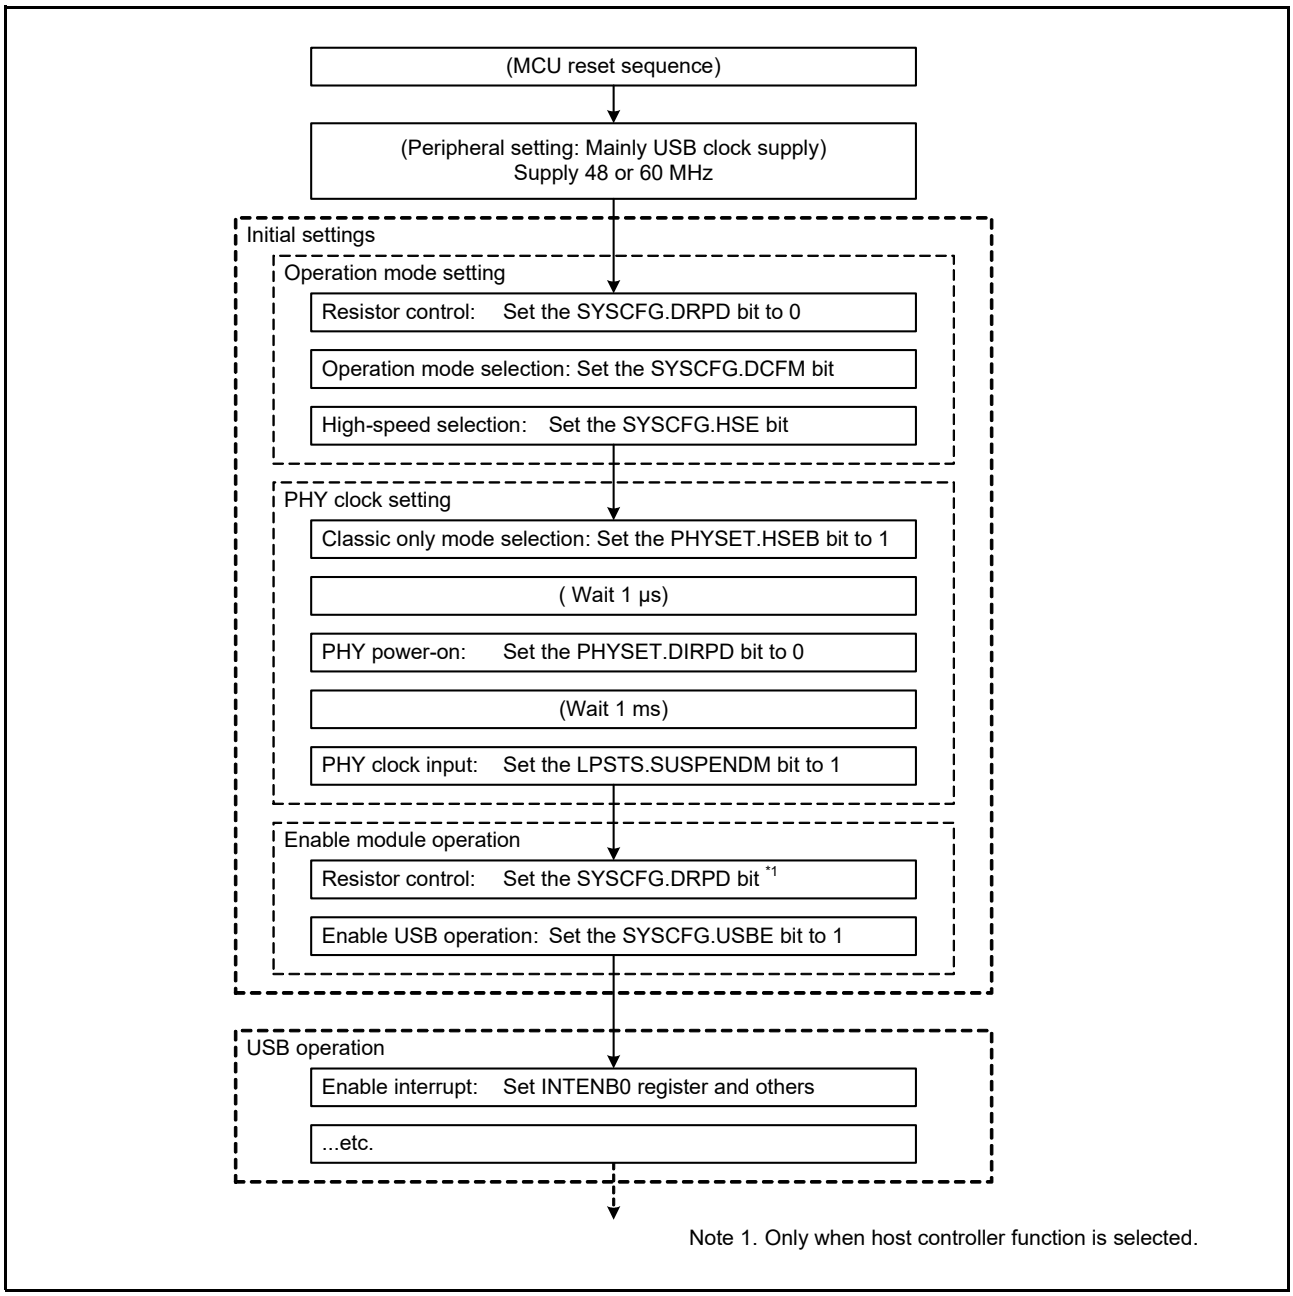

Figure 41.2 PHY Clock Settings in Classic-Only Mode

Figure 41.3 shows the PHY Clock Settings When Not Using Classic-Only Mode.

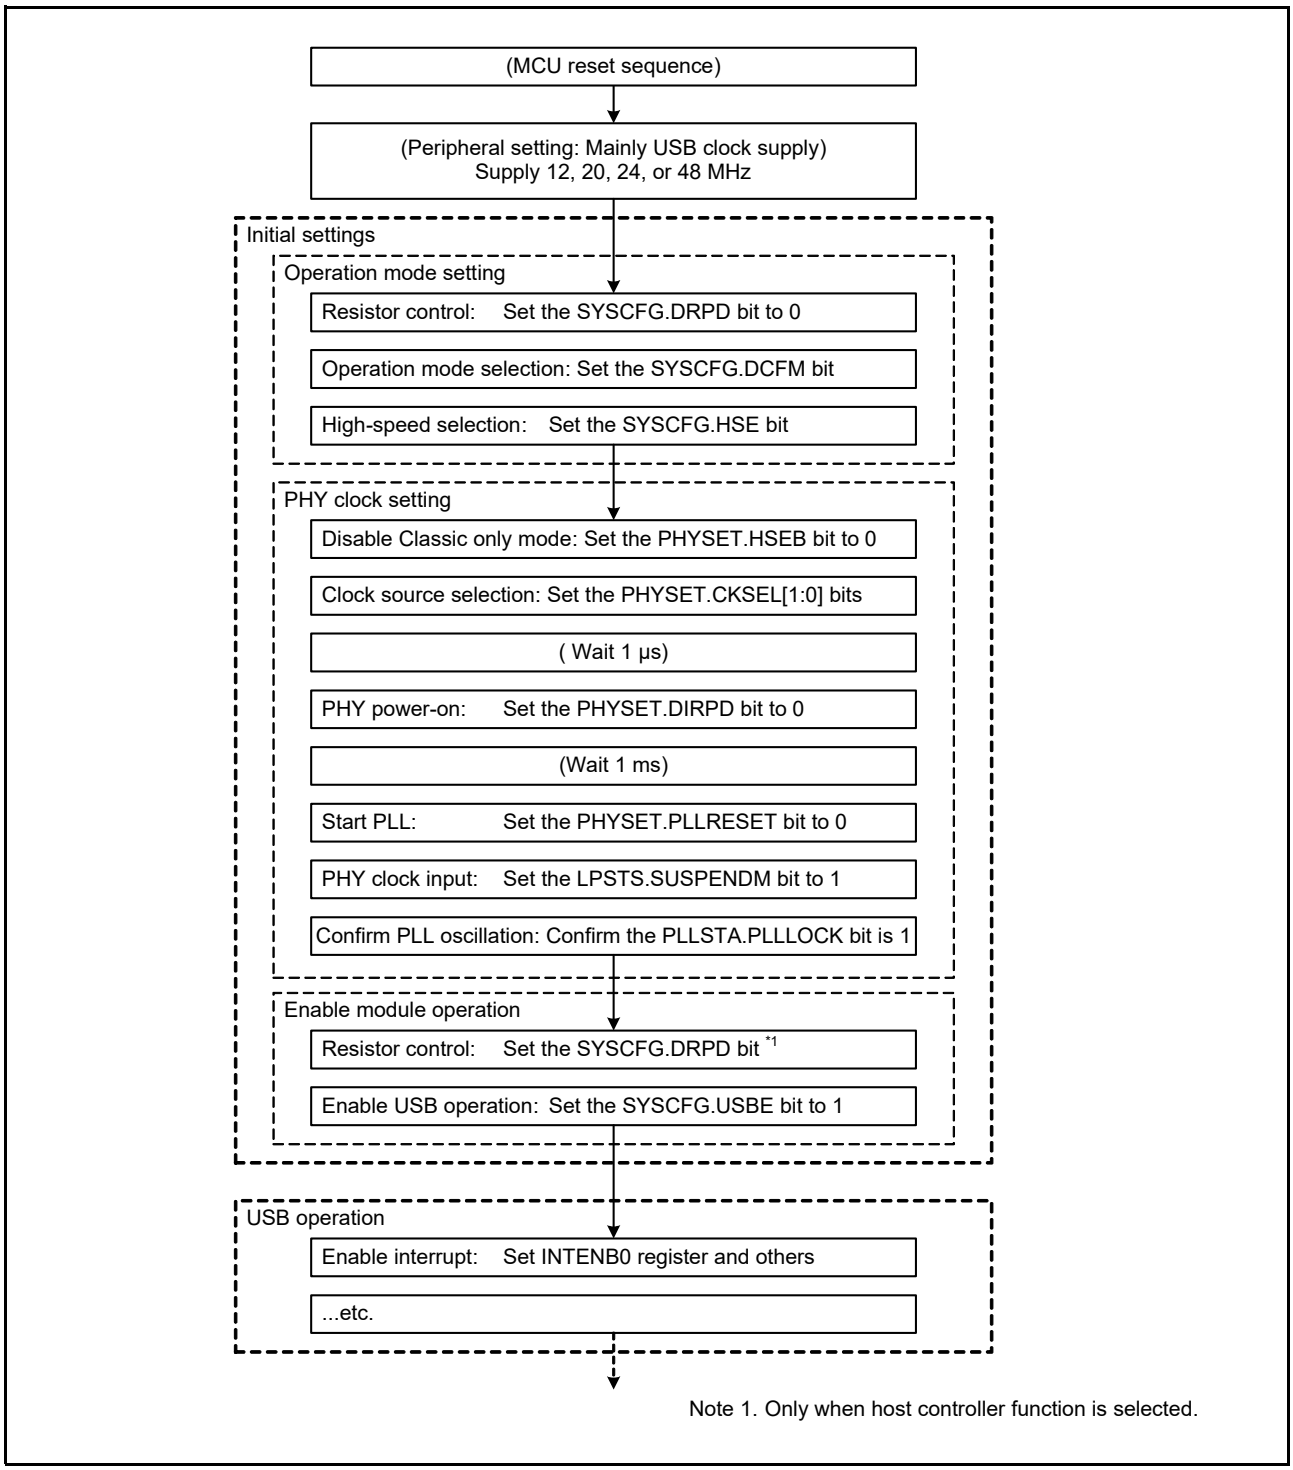

Figure 41.3 PHY Clock Settings When Not Using Classic-Only Mode

41.3.4 Notes on Stopping Clock

The CPU clock and PHY clock can be stopped when a device is disconnected or the USBHS is in the suspend state. However, in function controller operation, if either of these clocks are stopped while the USBHS is in the suspended state, they must be resupplied when exiting the suspended state. The PHY clock must be resupplied within 5.5 ms of generating the resume interrupt.

41.3.5 Interrupts

Table 41.16 lists the interrupt functions of the USBHS. When a condition to generate an interrupt is satisfied, and the interrupt output is enabled using the corresponding interrupt enable register, the USBHS issues a USBHSR interrupt request to the interrupt controller (ICU).

Table 41.16 List of Interrupt Functions (1/2)

Flag That Becomes 1	Interrupt	Interrupt Source	Function Generated	Status Flag
VBINT	VBUS interrupt	• USBHS_VBUS input pin state change was detected (from low to high and from high to low).	Host *1, function	INTSTS0. VBSTS
RESM	Resume interrupt	• USB bus state change was detected in the suspended state. (J state to K state or J state to SE0)	Function	—
SOFR	Frame number refresh interrupt	In host controller operation • An SOF packet with a different frame number was transmitted In function controller operation • An SOF packet with a different frame number was received. • Failed to receive an SOF packet when the microframe number is 0 due to packet corruption.	Host, function	—
DVST	Device state transition interrupt	• When device state transition was detected USB bus reset detection Suspension detection SetAddress() request received SetConfiguration request received	Function	INTSTS0. DVSQ[2:0]
CTRT	Control transfer stage transition interrupt	• When control transfer stage transition was detected Completed setup stage Transition to control write transfer status stage Transition to control read transfer status stage Completed control transfer A control transfer sequence error occurred	Function	INTSTS0. CTSQ[2:0]
BEMP	Buffer empty interrupt (BEMP interrupt)	• The buffer was empty after all FIFO buffer data was transmitted. • A packet exceeding the maximum packet size was received.	Host, function	BEMPSTS. PIPEBEMP[9:0]
NRDY	Buffer not ready interrupt (NRDY interrupt)	In host controller operation • The STALL response from the function was received in response to the token issued. • The response from the function in response to the issued token was not received successfully (no response three times in succession or packet receive error three times in succession). • An overrun or underrun error occurred during isochronous transfer. In function controller operation • When NAK has been returned for an IN or OUT token while the PID[1:0] bits are set to 01b (BUF response) • A CRC error or bit stuffing error occurred during data reception in isochronous transfer. • An interval error occurred during data reception in isochronous transfer.	Host, function	NRDYSTS. PIPENRDY[9:0]
BRDY	Buffer ready interrupt (BRDY interrupt)	• The buffer is ready (readable or writable state).	Host, function	BRDYSTS. PIPEBRDY[9:0]
OVRCR	Overcurrent change interrupt (OVRCR interrupt)	• USBHS_OVRCURA pin or USBHS_OVRCURB pin state change was detected (both low to high and high to low).	Host, function	SYSSTS0. OVCMON[1:0]
BCHG	Bus change interrupt (BCHG interrupt)	• USB bus state change was detected.	Host, function	SYSSTS0. LNST[1:0]
DTCH	Device disconnection detect interrupt (DTCH interrupt)	• Disconnection of peripheral device was detected.	Host	DVSTCTR0. RHST[2:0]

Table 41.16 List of Interrupt Functions (2/2)

Flag That Becomes 1	Interrupt	Interrupt Source	Function Generated	Status Flag
ATTCH	Device connection detect interrupt (ATTCH interrupt)	• The J state (continuous USB bus state for 2.5 µs) or K state (continuous USB bus state for 2.5 µs) was detected. This interrupt can be used for detecting connection of peripheral device.	Host	—
EOFERR	EOF error detect interrupt (EOFERR interrupt)	• EOF error of peripheral device was detected.	Host	—
SACK	SETUP transaction normal response interrupt (SACK interrupt)	• The SETUP transaction normal response (ACK) was received.	Host	—
SIGN	SETUP transaction error interrupt (SIGN interrupt)	• A SETUP transaction error (no response or corrupted ACK packet) was detected three times in succession.	Host	—
PDDETINT	Portable Device detection interrupt	• Portable Device connection was detected.	Host	BCCTRL. PDDETSTS
LPMEND	LPM transaction end interrupt (LPMEND interrupt)	• LPM transaction has been completed.	Host	HL1CTRL1. L1STATUS[1:0]
L1RSMEND	L1 resume end interrupt (L1RSMEND interrupt)	• Resume processing from L1 state has been completed.	Host	—

Note 1. Though this interrupt can be generated in host controller operation, it is not usually used in host controller operation.

41.3.5.1 Setting the USBHSR Interrupt Signal Output Method

The USBHSR interrupt signal output method can be selected by setting the SOFCFG.INTL bit. However, since the detection method for detecting USBHSR interrupts in this MCU is level sense, set the INTL bit to 1 (level output).

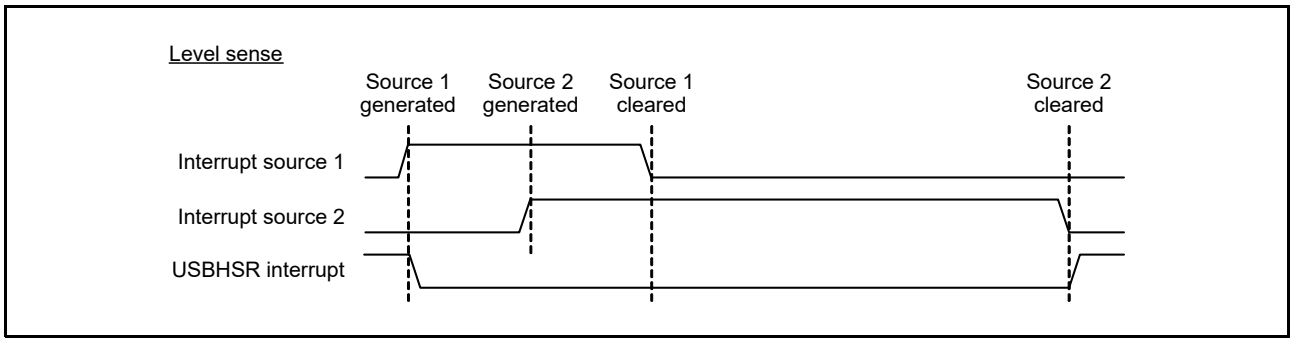

Figure 41.4 USBHSR Interrupt Operation

Figure 41.5 shows the Interrupt Association Diagram.

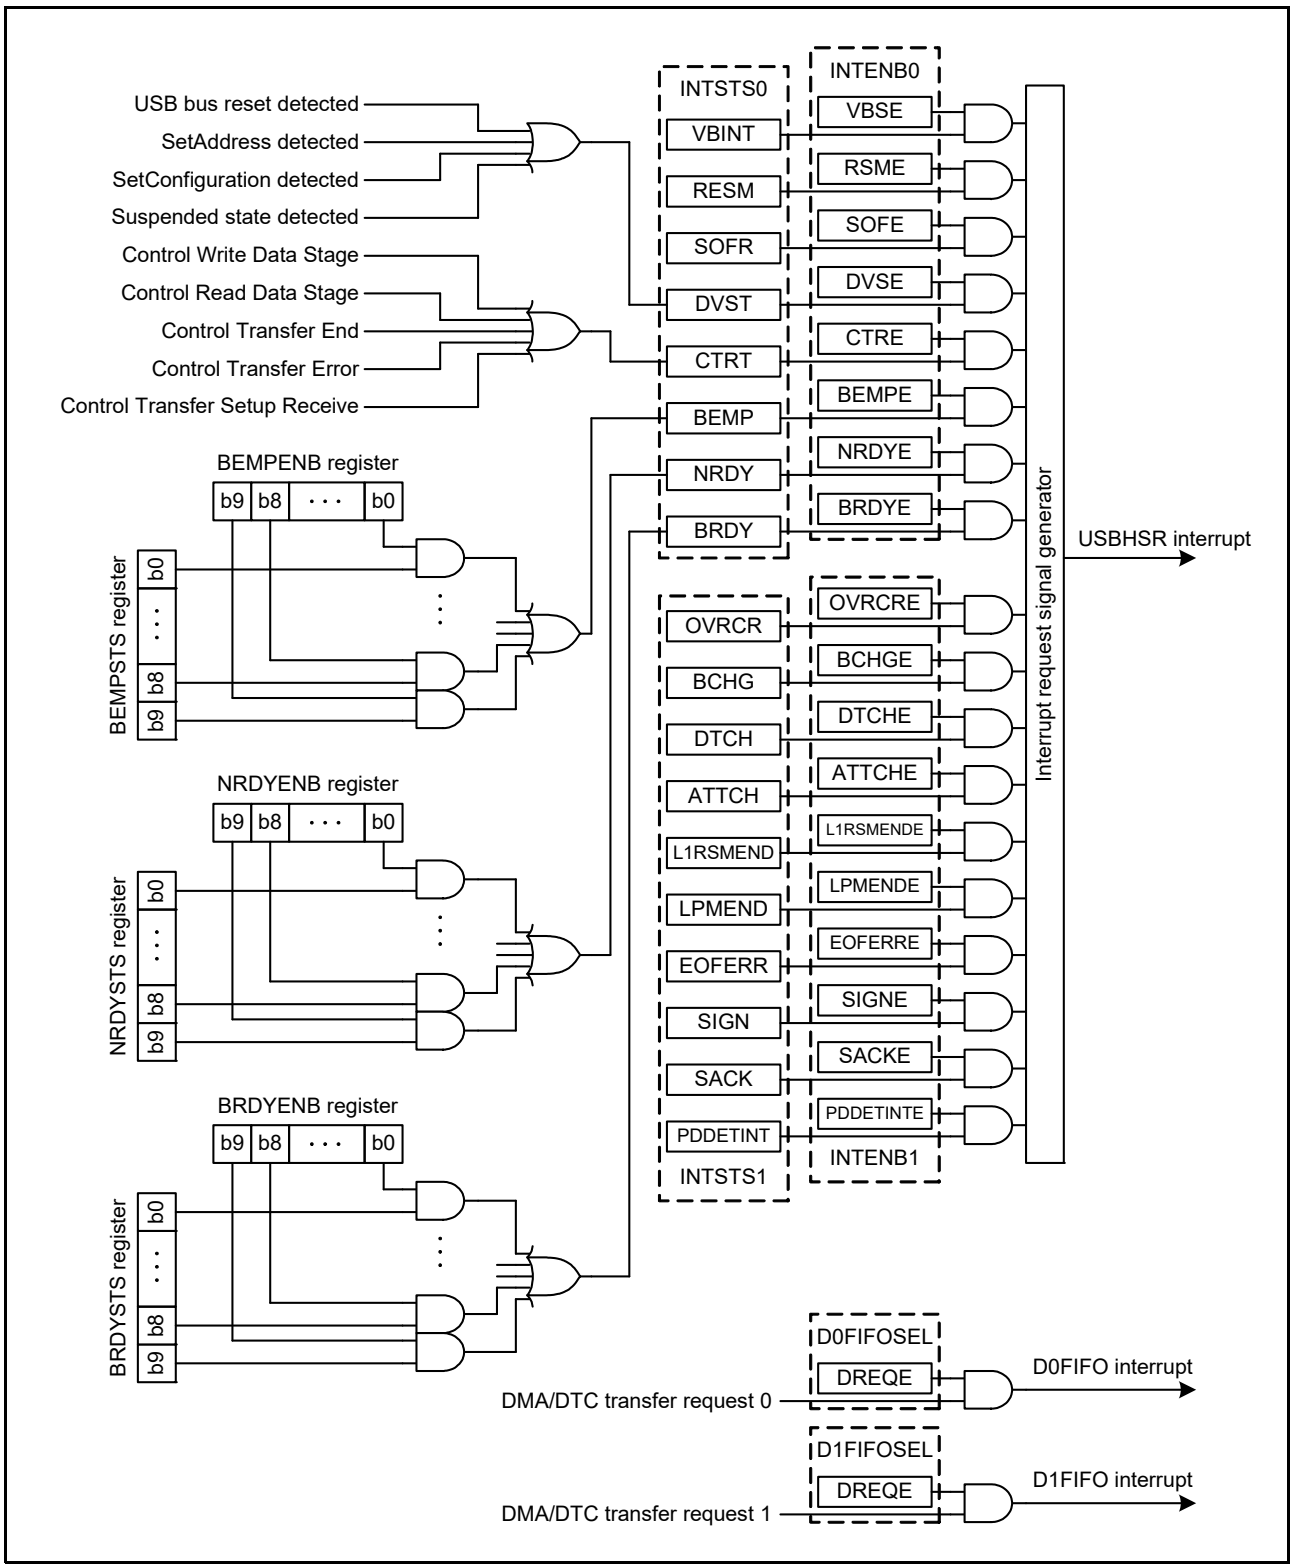

Figure 41.5 Interrupt Association Diagram

Table 41.17 lists the USBHS Interrupt Sources.

Table 41.17 USBHS Interrupt Sources

Interrupt	Interrupt Status Flag	DTC/DMAC Triggerable	Priority
D0FIFO	DMA/DTC transfer request 0	Yes	High
D1FIFO	DMA/DTC transfer request 1	Yes	↑
USBHSR	VBUS interrupt, resume interrupt, frame number refresh interrupt, device state transition interrupt, control transfer stage transition interrupt, buffer empty interrupt, buffer not ready interrupt, buffer ready interrupt, overcurrent change interrupt, bus change interrupt, device disconnection detect interrupt, device connection detect interrupt, EOF error detect interrupt, SETUP transaction normal response interrupt, SETUP transaction error interrupt, portable device detection interrupt, LPM transaction end interrupt, and L1 resume end interrupt	No	Low

41.3.6 Interrupt Descriptions

41.3.6.1 BRDY Interrupt

The BRDY interrupt is generated in both host controller operation and function controller operation. When each pipe satisfies the conditions listed below, the USBHS sets the corresponding bit in the BRDYSTS register to 1. Under these conditions, if a bit in the BRDYENB register that corresponds to a given pipe and the INTENB0.BRDYE bit are 1, the USBHS generates the BRDY interrupt request.
The conditions for generating and method for clearing the BRDY interrupt depend on the settings of the SOFCFG.BRDYM bit, and the PIPECFG.BFRE bit for each pipe as described below.

(1) When the SOFCFG.BRDYM Bit is 0 and the PIPECFG.BFRE Bit is 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible. On any of the following conditions, the USBHS generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEBRDY[9:0] flag corresponding to the pertinent pipe to 1.

(a) For pipes set to transmit:

- When the DIR bit is changed from 0 to 1.
- When writing by the CPU to the FIFO buffer for a given pipe is disabled (when the BSTS flag is read as 0) and the USBHS module has completed packet transmission.
  In continuous transfer mode, the BRDY interrupt is generated when data from one FIFO buffer is done being transmitted.
- If a FIFO buffer is specified as a double buffer, when data is done being written to one plane of the FIFO buffer, the other plane becomes empty.
  While data is being written to one plane of a FIFO buffer, even if the other plane is done transmitting, a request trigger is not generated until the data being written to the current plane is complete.
- When the hardware flushes the buffer of the pipe for isochronous transfers.
- Setting the PIPEnCTR.ACLRM bit to 1 changes the state of the FIFO buffer from write disabled to write enabled.

A request trigger is not generated for the default control pipe (during data transmission for control transfers).

(b) For pipes set to receive:

- When packet reception is completed successfully thus enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the pertinent pipe is disabled (when the BSTS flag is 0).
  However, no request trigger is generated for the transaction in which data PID mismatch has occurred.
  In continuous transfer mode, when the maximum packet size of data is received and there is still space in the FIFO buffer, the request trigger is not generated. When a short packet is received, the request trigger is generated even if the FIFO buffer has available space. When the transaction counter is used, the request trigger is generated on receiving the specified number of packets. In this case, the request trigger is generated even if the FIFO buffer has available space.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer even if reception by the other FIFO buffer is completed.

In function controller operation, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEBRDY interrupt status of the pertinent pipe can be set to 0 by writing 0 to the corresponding PIPEBRDY[9:0] flags. In this case, 1's should be written to the corresponding bits for the other pipes. Clear the BRDY status before accessing the FIFO buffer.

(2) When the SOFCFG.BRDYM Bit is 0 and the PIPECFG.BFRE Bit is 1

With these settings, the USBHS determines that a BRDY interrupt is generated on completion of reading all data for a single transfer using the pipe in the receiving direction, and sets 1 to the flag in the BRDYSTS register corresponding to the pertinent pipe.
On any of the following conditions, the USBHS determines that the last data for a single transfer has been received.

- When a short packet including a zero-length packet is received.
- When the PIPEnTRN register is used and the number of packets specified by the PIPEnTRN.TRNCNT[15:0] bits are completely received.

When the pertinent data is completely read after any of the above conditions has been satisfied, the USBHS determines that all data for a single transfer has been completely read. When a zero-length packet is received while the FIFO buffer is empty, the USBHS determines that all data for a single transfer has been completely read when the FRDY flag in a FIFO port control register is 1 and the DTLN[11:0] bits are 000h. In this case, to start the next transfer, write 1 to the BCLR bit in the corresponding FIFO port control register. With these settings, the USBHS does not detect a BRDY interrupt for the pipe in the transmitting direction. The PIPEBRDY interrupt status of the pertinent pipe can be set to 0 by writing 0 to the corresponding BRDYSTS.PIPEBRDY[9:0] flag. In this case, 1's should be written to the corresponding bits for the other pipes. In this mode, the PIPECFG.BFRE bit setting should not be modified until all data for a single transfer has been processed. When it is necessary to modify the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pertinent pipe should be cleared using the PIPEnCTR.ACLRM bit.

(3) When the SOFCFG.BRDYM Bit is 1 and the PIPECFG.BFRE Bit is 0

With these settings, the BRDYSTS.PIPEBRDY[9:0] flag values are linked to the BSTS flag setting for each pipe. The BRDY interrupt status bits are set to 1 or 0 by the USBHS depending on the FIFO buffer status.

(a) For the pipe in the transmitting direction:

The BRDY interrupt status bits are set to 1 when the FIFO port is ready for write access, and are set to 0 when it is not ready. However, the BRDY interrupt is not generated even if the default control pipe in the transmitting direction is ready for write access.

(b) For the pipe in the receiving direction:

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for read access, and are set to 0 when all data have been read (not ready for read access). When a zero-length packet is received while the FIFO buffer is empty, the pertinent bit is set to 1 and the BRDY interrupt is continuously generated until 1 is written to BCLR bit.

With this setting, the PIPEBRDY[9:0] flags cannot be set to 0 by software. When the SOFCFG.BRDYM bit is set to 1, the PIPECFG.BFRE bit (for all pipes) should be set to 0, and the SOFCFG.INTL bit should be set to 1 (level control).

Figure 41.6 shows the BRDY Interrupt Generation Timing.

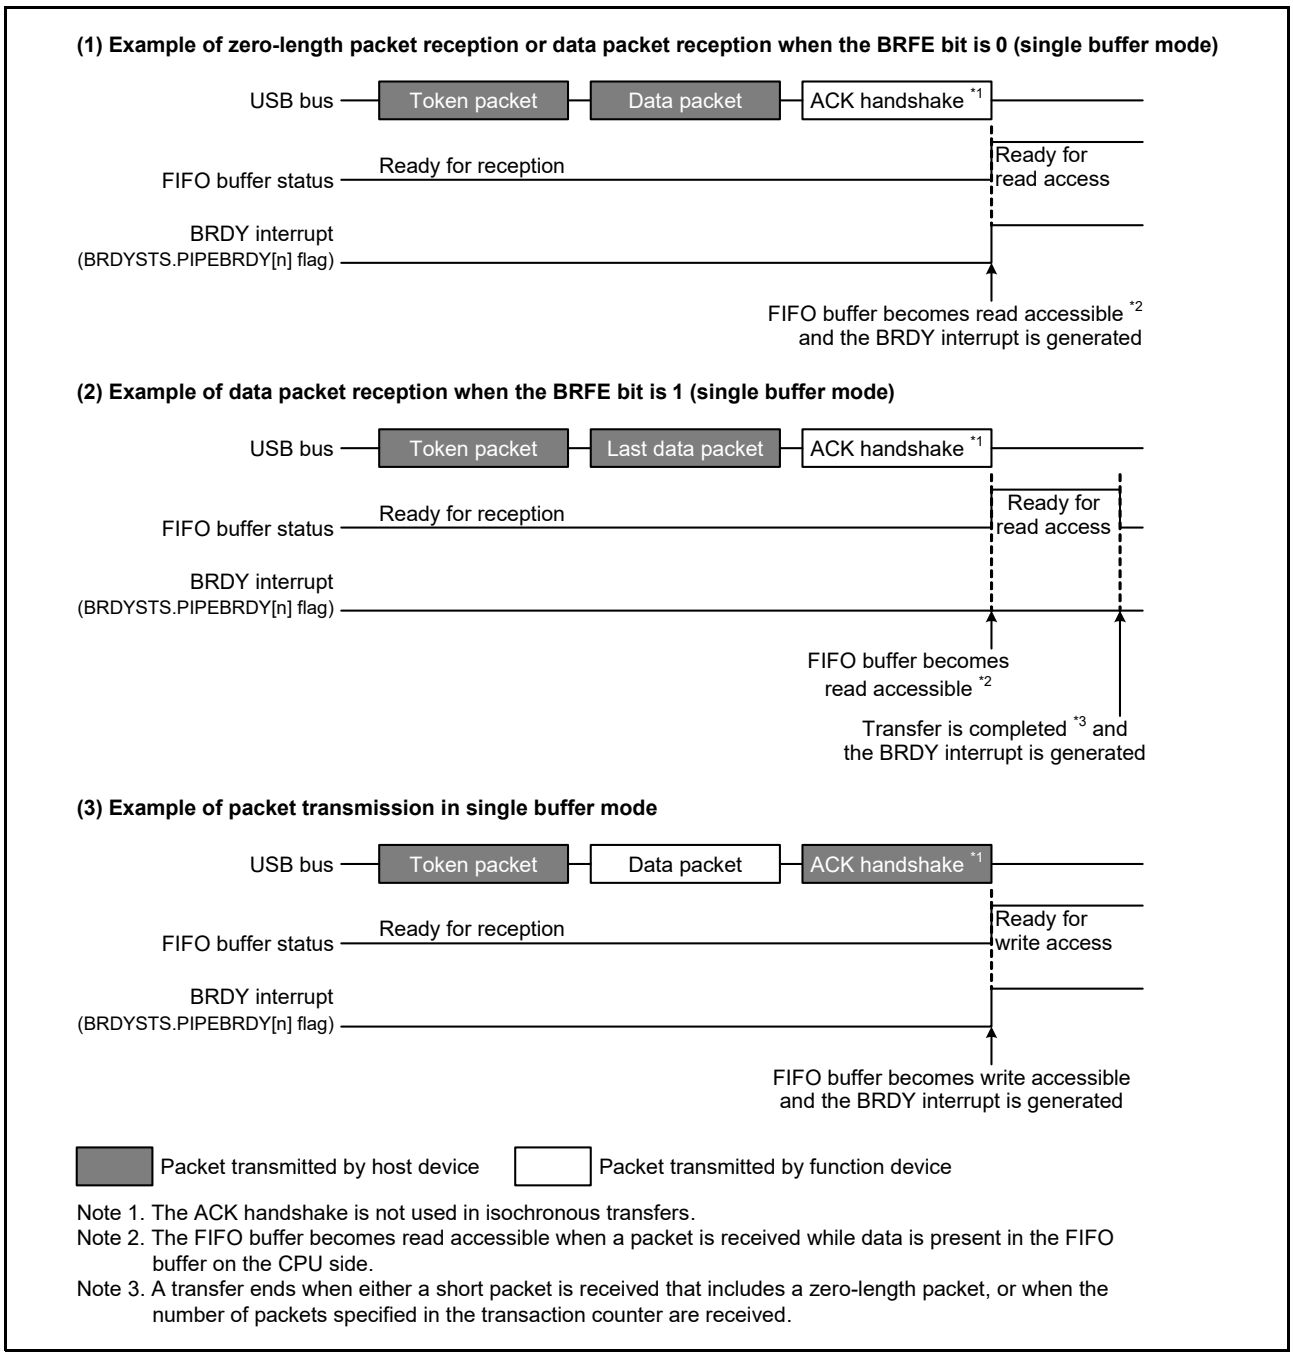

Figure 41.6 BRDY Interrupt Generation Timing

The condition that the USBHS clears the INTSTS0.BRDY flag depends on the SOFCFG.BRDYM bit setting value. Table 41.18 shows the condition for clearing the BRDY flag.

Table 41.18 Condition for Clearing BRDY Flag

BRDYM Bit	Condition for Clearing the BRDY Flag
0	The USBHS sets the BRDY flag to 0 when all flags in the BRDYSTS register have been set to 0 by software.
1	The USBHS sets the BRDY flag to 0 when the BSTS flags for all pipes have become 0.

41.3.6.2 NRDY Interrupt

On generating an internal NRDY interrupt request for the pipe whose PID[1:0] bits are set to 01b (BUF response), the USBHS sets the bit corresponding to the NRDYSTS.PIPENRDY[9:0] flag to 1. If the corresponding bit in the NRDYENB register has been set to 1, the USBHS sets the INTSTS0.NRDY flag to 1 and generates a USBHSR interrupt request.
The following describes the conditions in which the USBHS generates the internal NRDY interrupt request for a given pipe.
Note that the internal NRDY interrupt request is not generated during setup transaction execution in host controller operation. During setup transactions in host controller operation, the SACK or SIGN interrupt is detected.
The internal NRDY interrupt request is not generated during status stage execution of the control transfer in function controller operation.

(1) In Host Controller Operation, and Connecting When a SPLIT Transaction is Not Performed

(a) For the pipe in the transmitting direction:

On any of the following conditions, the USBHS detects an NRDY interrupt.

- For the pipe for isochronous transfers, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer.
  In this case, the USBHS transmits a zero-length packet following the OUT token and sets the bit corresponding to the NRDYSTS.PIPENRDY[9:0] flag and the FRMNUM.OVRN flag to 1.
- During communications other than setup transactions using the pipe for transfers other than isochronous transfers, when any combination of the following two cases occur three consecutive times: 1) no response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device) and 2) an error is detected in the packet from the peripheral device.
  In this case, the USBHS sets the bit corresponding to the PIPENRDY[9:0] flag to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 00b (NAK response).
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device (this corresponds not only to the STALL handshake for the OUT token, but also the STALL handshake for the PING token).
  In this case, the USBHS sets the bit corresponding to the PIPENRDY[9:0] flag to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL response).

(b) For the pipe in the receiving direction:

- For the pipe for isochronous transfers, when the time to issue an IN token comes while there is no space available in the FIFO buffer.
  In this case, the USBHS discards the received data for the IN token and sets the PIPENRDY[9:0] flag corresponding to the pipe and the OVRN flag to 1. When a packet error is detected in the received data for the IN token, the USBHS also sets the FRMNUM.CRCE flag to 1.
- For the pipe for transfers other than isochronous transfers, when any combination of the following two cases occur three consecutive times: 1) no response is returned from the peripheral device for the IN token issued by the USBHS (when timeout is detected before detection of the data packet from the peripheral device) and 2) an error is detected in the packet from the peripheral device.
  In this case, the USBHS sets the PIPENRDY[9:0] flag corresponding to each pipe to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to 00b (NAK response).
- For the pipe for isochronous transfers, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the data packet from the peripheral device) or an error is detected in the packet from the peripheral device.
  In this case, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to each pipe to 1. (The setting of the PID[1:0] bits of the pipe is not modified.)

- For the pipe for isochronous transfers, when a CRC error or a bit stuffing error is detected in the received data packet.
  In this case, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to each pipe and the CRCE flag to 1.
- When the STALL handshake is received.
  In this case, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to each pipe to 1 and modifies the setting of the PID[1:0] bits of the corresponding pipe to STALL.

(2) In Host Controller Operation, and Connecting When a SPLIT Transaction is Performed

On any of the following conditions, the USBHS detects an NRDY interrupt.

(a) For the pipe in the transmitting direction:

- For the isochronous transfers, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer
  In this case, when the start-split transaction is issued, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to the specified pipe to 1 and the FRMNUM.OVRN flag to 1. In addition, a zero-length packet is transmitted following the OUT token.
- If a start-split or complete-split transaction is used for a transfer other than the isochronous transfer, the NRDY interrupt is issued when any combination of the following conditions occur three times subsequently: 1) The hub returns no response (a timeout is detected without the handshake packet from the hub being detected); and 2) An error is detected in the packet from the hub.
  In this case, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to the specified pipe to 1 and modifies the PID[1:0] bits of the corresponding pipe to 00b (NAK response). When the complete-split is issued, if the NRDY interrupt is detected, the USBHS sets the CSSTS flag to 0.
- When the STALL handshake is received in response to the complete-split token.
  In this case, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to the specified pipe to 1, modifies the PID[1:0] bits of the corresponding pipe to 11b (STALL response), and sets the CSSTS flag to 0. However, the NRDY interrupt is not detected for the SETUP transaction.
- If a complete-split token is issued for an interrupt transfer, and the NYET handshake is received when the microframe is 4.
  In this case, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to the specified pipe to 1 and the CSSTS flag to 0 (the PID[1:0] bits of the corresponding pipe are not modified).

(b) For the pipe in the receiving direction:

- For isochronous transfers, when the time to issue an IN token comes while there is no space available in the FIFO buffer
  In this case, when the start-split token is issued, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to the specified pipe to 1 and the FRMNUM.OVRN flag to 1. In addition, the received data for the IN token is discarded.
- If a start-split token or complete-split token is issued for a bulk transfer or a transfer other than a SETUP transaction for the default control pipe, the NRDY interrupt is issued when any combination of the following conditions occur three times subsequently: 1) The hub returns no response (a timeout is detected without the data packet from the hub being detected) with respect to the IN token issued by the USBHS; and 2) An error is detected in the packet from the hub.
  In this case, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to the specified pipe to 1 and modifies the PID[1:0] bits of the corresponding pipe to 00b (NAK response). If these conditions are fulfilled when the complete-split is issued, the USBHS sets the CSSTS flag to 0.
- If a complete-split token is issued for an isochronous transfer or interrupt transfer, the NRDY interrupt is issued when any combination of the following conditions occur three times subsequently: 1) The hub returns no response

(a timeout is detected without the data packet from the hub being detected) with respect to the IN token issued by the USBHS; and 2) An error is detected in the packet from the hub.
When the transfer type is an interrupt pipe, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to the specified pipe to 1 and modifies the PID[1:0] bits of the corresponding pipe to 00b (NAK response). If these conditions are fulfilled when the complete-split is issued, the USBHS sets the CSSTS flag to 0.
When the transfer type is the isochronous type, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to the specified pipe to 1, the CRCE flag to 1, and the CSSTS flag to 0 (the PID[1:0] bits of the corresponding pipe are not modified).

- If a complete-split token is issued for a transfer other than an isochronous transfer, and a STALL handshake is received.
  In this case, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to the specified pipe to 1, modifies the PID[1:0] bits of the corresponding pipe to 11b (STALL response), and sets the CSSTS flag to 0.
- If a complete-split token is issued for an isochronous transfer or interrupt transfer, and the NYET handshake is received when the microframe is 4.
  In this case, the USBHS sets the NRDYSTS.PIPENRDY[9:0] flag corresponding to the specified pipe to 1, the CRCE flag to 1, and the CSSTS flag to 0 (the PID[1:0] bits of the corresponding pipe are not modified).

(3) In Function Controller Operation

(a) For the pipe in the transmitting direction:

- When an IN token is received while there is no data to be transmitted in the FIFO buffer.
  In this case, the USBHS generates an NRDY interrupt request at the reception of the IN token and sets the NRDYSTS.PIPENRDY[9:0] flag to 1. For the pipe for isochronous transfers in which an interrupt is generated, the USBHS transmits a zero-length packet and sets the FRMNUM.OVRN flag to 1.

(b) For the pipe in the receiving direction:

- When an OUT token is received while there is no space available in the FIFO buffer.
  For the pipe for isochronous transfers in which an interrupt is generated, the USBHS generates an NRDY interrupt request at the reception of the OUT token and sets the NRDYSTS.PIPENRDY[9:0] flag to 1 and FRMNUM.OVRN flag to 1. For the pipe for transfers other than isochronous transfers in which an interrupt is generated, the USBHS generates an NRDY interrupt request when a NAK handshake is transferred after the data following the OUT token is received, and sets the NRDYSTS.PIPENRDY[9:0] flag to 1. However, during re-transmission (due to data PID mismatch), the NRDY interrupt request is not generated. In addition, if an error occurs in the data packet, the NRDY interrupt request is not generated.
- A PING token is received when the FIFO buffer is not empty.
  When a PING token is received, the USBHS generates the NRDY interrupt request, and sets the NRDYSTS.PIPENRDY[9:0] flags to 1.
- For the pipe for isochronous transfers, when a token is not received successfully within an interval frame.
  In this case, the USBHS generates an NRDY interrupt request when (μ)SOF is received, and sets the NRDYSTS.PIPENRDY[9:0] flags to 1.

Figure 41.7 shows the NRDY Interrupt Generation Timing (In Function Controller Operation).

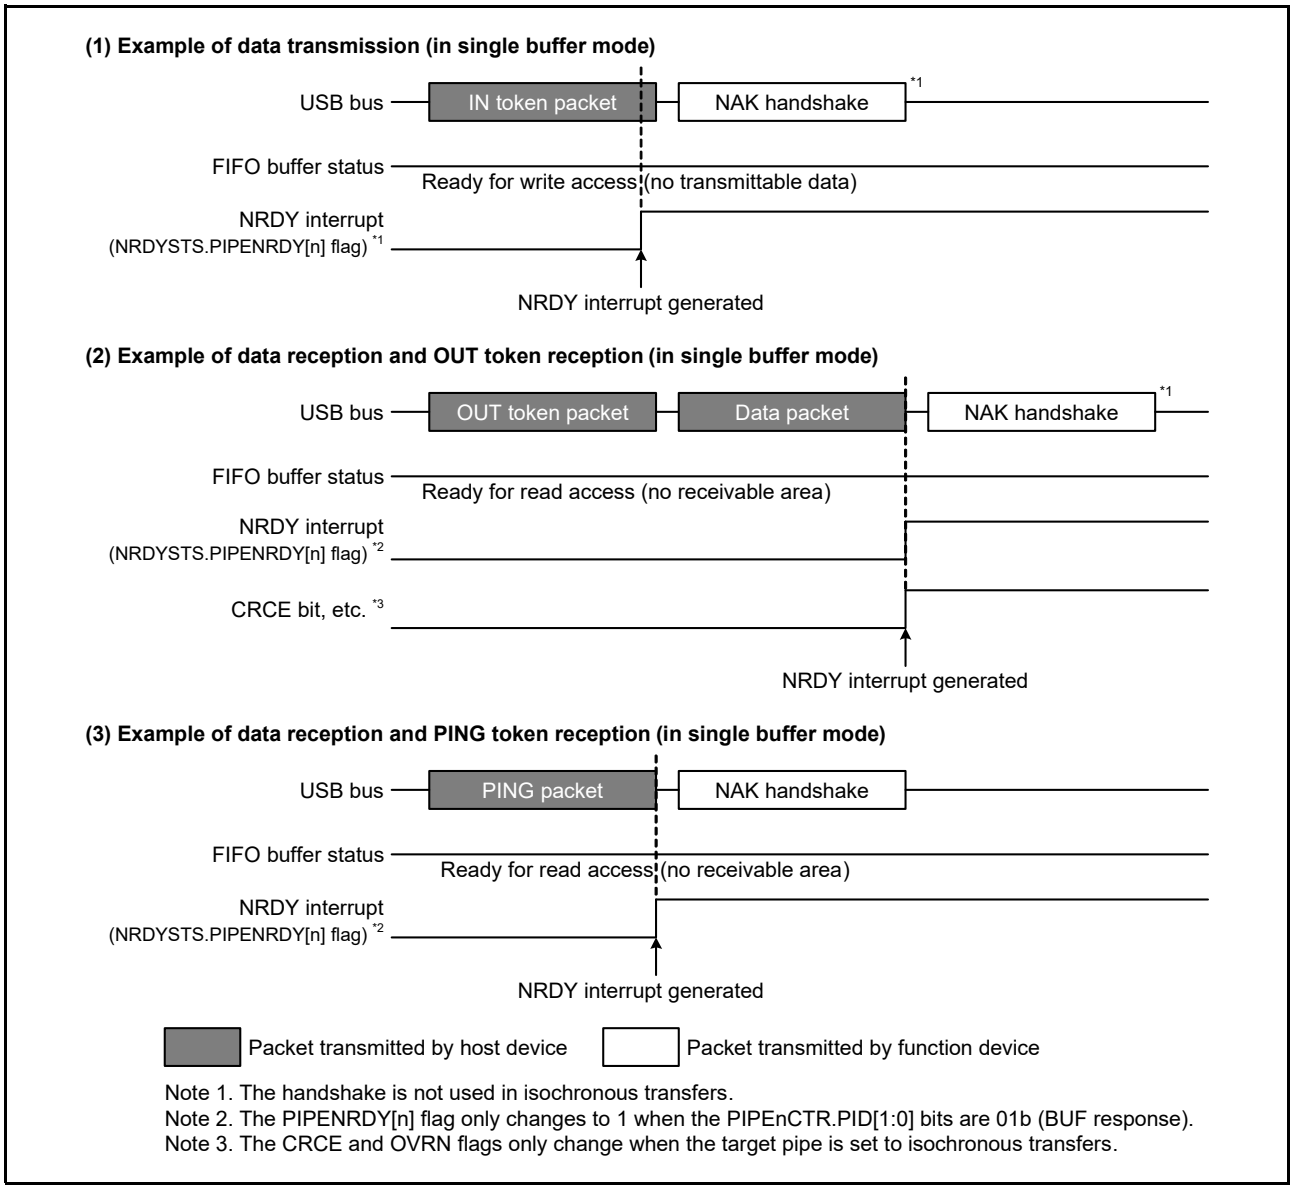

Figure 41.7 NRDY Interrupt Generation Timing (In Function Controller Operation)

41.3.6.3 BEMP Interrupt

On detecting a BEMP interrupt for the pipe whose PID[1:0] bits in the pipe control register are set to 01b (BUF response), the USBHS sets the bit corresponding to the BEMPSTS.PIPEBEMP[9:0] flag to 1. If the corresponding bit in the BEMPENB register is set to 1, the USBHS sets the INTSTS0.BEMP flag to 1 and generates a USBHSR interrupt request.
The following describes the conditions in which the USBHS generates an internal BEMP interrupt request.

(1) For the pipe in the transmitting direction:

When the FIFO buffer of the corresponding pipe is empty on completion of transmission (including zero-length packet transmission), and during single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for the pipe other than default control pipe. However, the internal BEMP interrupt request is not generated on any of the following conditions.

- In double buffer mode, data starts to be written to the FIFO buffer on the CPU side when data transfer from one plane is complete.
- When the buffer is cleared by setting the PIPEnCTR.ACLRM or the BCLR bit in a FIFO port control register to 1.
- When IN transfer (zero-length packet transmission) is performed during the control transfer status stage during function controller operation.

(2) For the pipe in the receiving direction:

When the successfully-received data packet size exceeds the specified maximum packet size. In this case, the USBHS generates a BEMP interrupt request, sets the corresponding BEMPSTS.PIPEBEMP[9:0] flag to 1, discards the received data, and modifies the setting of the PID[1:0] bits of the corresponding pipe to 11b (STALL response). Here, the USBHS returns no response in host controller operation, and returns a STALL response in function controller operation.
However, the internal BEMP interrupt request is not generated on any of the following conditions.

- When a CRC error or a bit stuffing error is detected in the received data.
- When a setup transaction is being performed

Figure 41.8 shows the BEMP Interrupt Generation Timing (In Function Controller Operation).

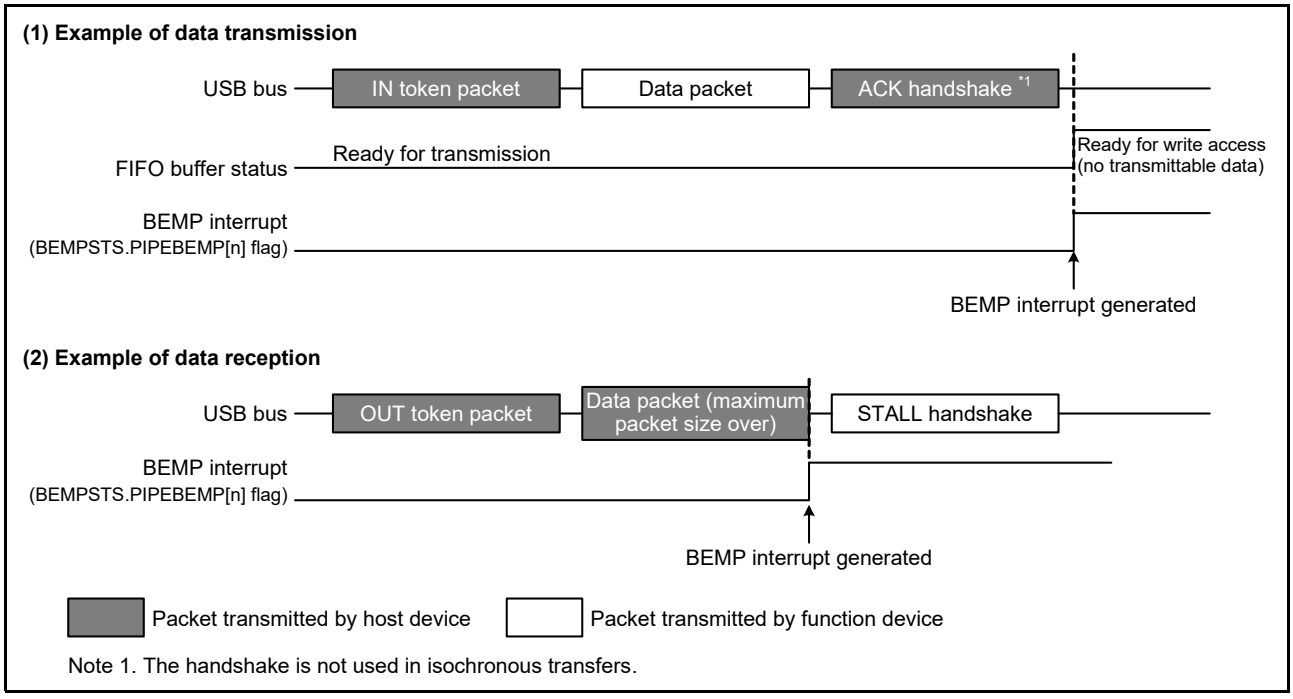

Figure 41.8 BEMP Interrupt Generation Timing (In Function Controller Operation)

41.3.6.4 Device State Transition Interrupt in Function Controller Operation

Figure 41.9 shows the Device State Transition Chart for the USBHS. The USBHS controls the device states and generates device state transition interrupts. However, the USBHS detects a return from the suspended state (by detecting the resume signal) by the resume interrupt. Device state transition interrupts can be enabled or disabled by the INTENB0 register. The transitioned device state can be checked by the INTSTS0.DVSQ[2:0] bits. To make a transition to the default state, a device state transition interrupt is generated after a USB bus reset is detected. The USBHS controls device states only in function controller operation. Device state transition interrupts are also generated only in function controller operation.

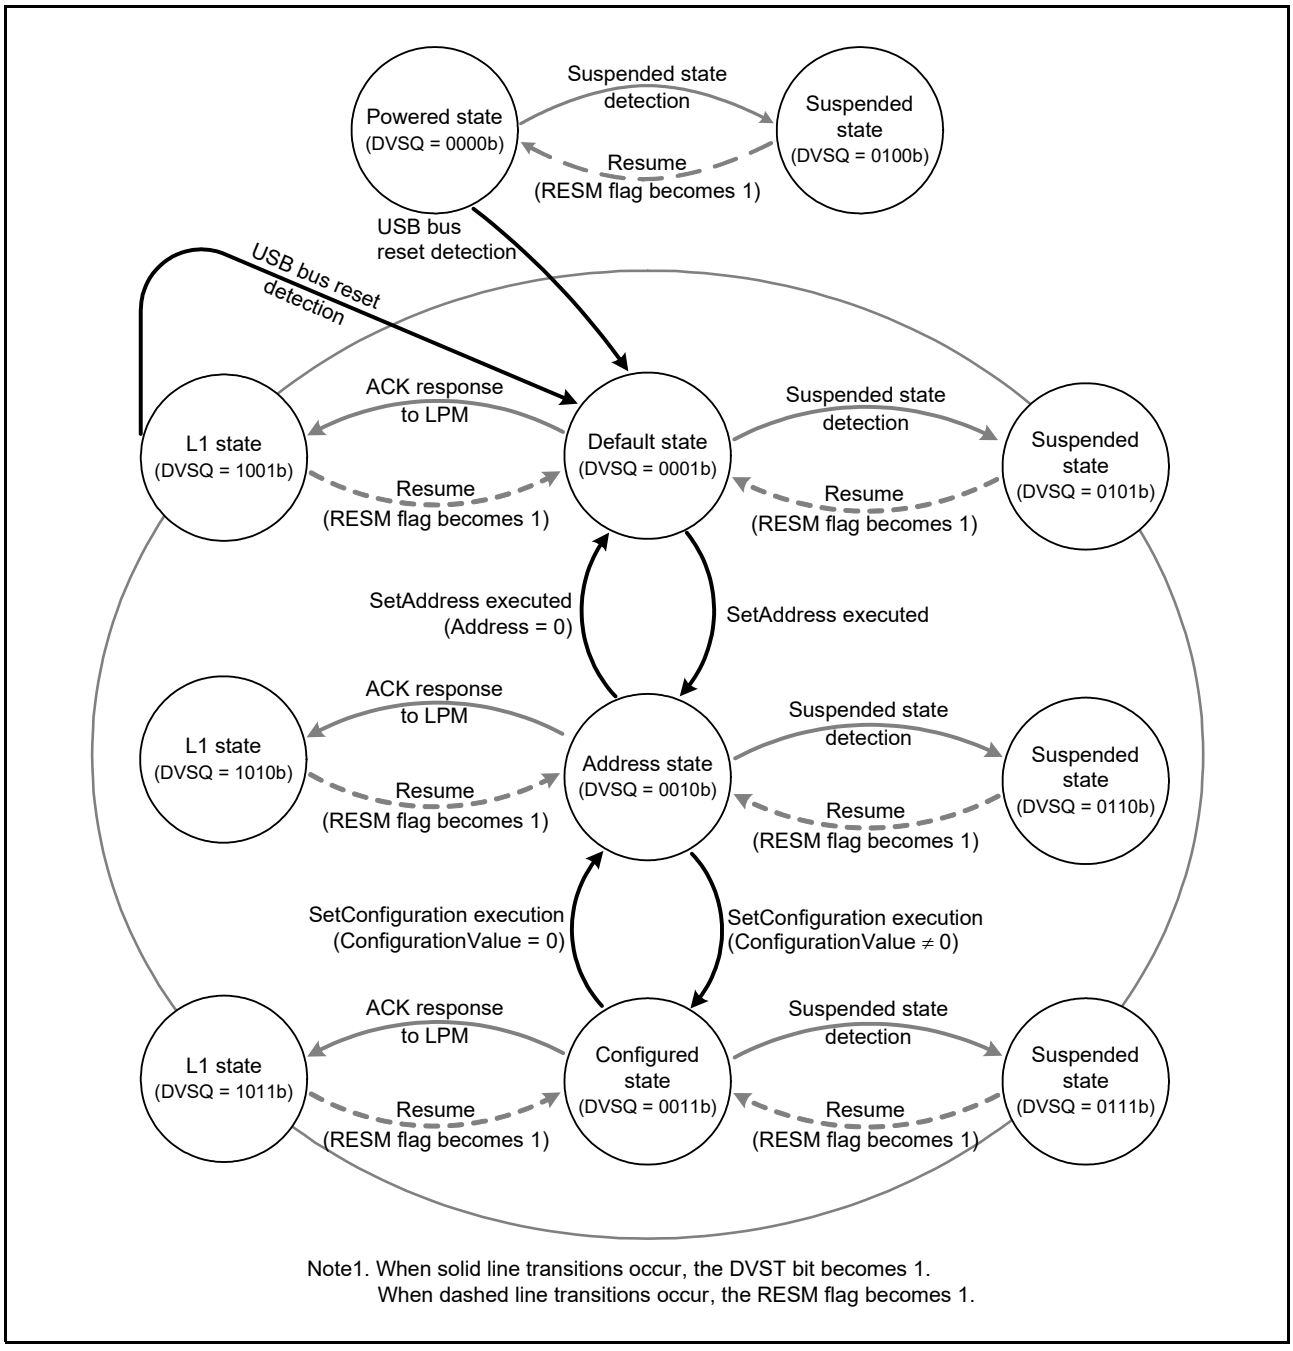

Figure 41.9 Device State Transition Chart

41.3.6.5 Control Transfer Stage Transition Interrupt in Function Controller Operation

Control transfer stage transitions of the USBHS are illustrated in Figure 41.10. The USBHS controls the control transfer sequence and generates control transfer stage transition interrupts. Control transfer stage transition interrupts can be enabled or disabled by the INTENB0 register. The transitioned transfer stage can be checked by the INTSTS0.CTSQ[2:0] bis. Control transfer stage transition interrupts are generated only in function controller operation. Control transfer sequence errors are shown below. When an error occurs, the DCPCTR.PID[1:0] bits are set to 10b or 11b (STALL response).

(1) Control read transfer
  (a) The OUT token is received with no data transferred in response to the IN or PING token in the data stage.
  (b) The IN token is received in the status stage.
  (c) A data packet of data PID = DATA0 is received in the status stage.
(2) Control write transfer
  (a) The IN token is received with no ACK response returned in response to the OUT token in the data stage.
  (b) The first data packet of data PID = DATA0 is received in the data stage.
  (c) The OUT or PING token is received in the status stage.
(3) Control write no data transfer
  (a) The OUT or PING token is received in the status stage.

If the number of pieces of receive data has exceeded the *wLength* value in the USB request in the control write transfer data stage, it is not recognized as a control transfer sequence error. When the USBHS receives a packet other than the zero-length packet in the control read transfer status stage, the USBHS returns an ACK response and completes the processing successfully.
When a control transfer stage transition interrupt is generated (INTSTS0.CTRT flag is 1) due to a sequence error, the value of CTSQ[2:0] bits are 110b is retained until the CTRT flag is set to 0 (interrupt status clear). Therefore, while CTSQ[2:0] bits are 110b is retained, the control transfer stage transition interrupt of setup stage completion is not generated even if a new USB request is received. (Completion of setup stage is retained by the USBHS, and a control transfer stage transition interrupt is generated after the interrupt status is cleared by software.)

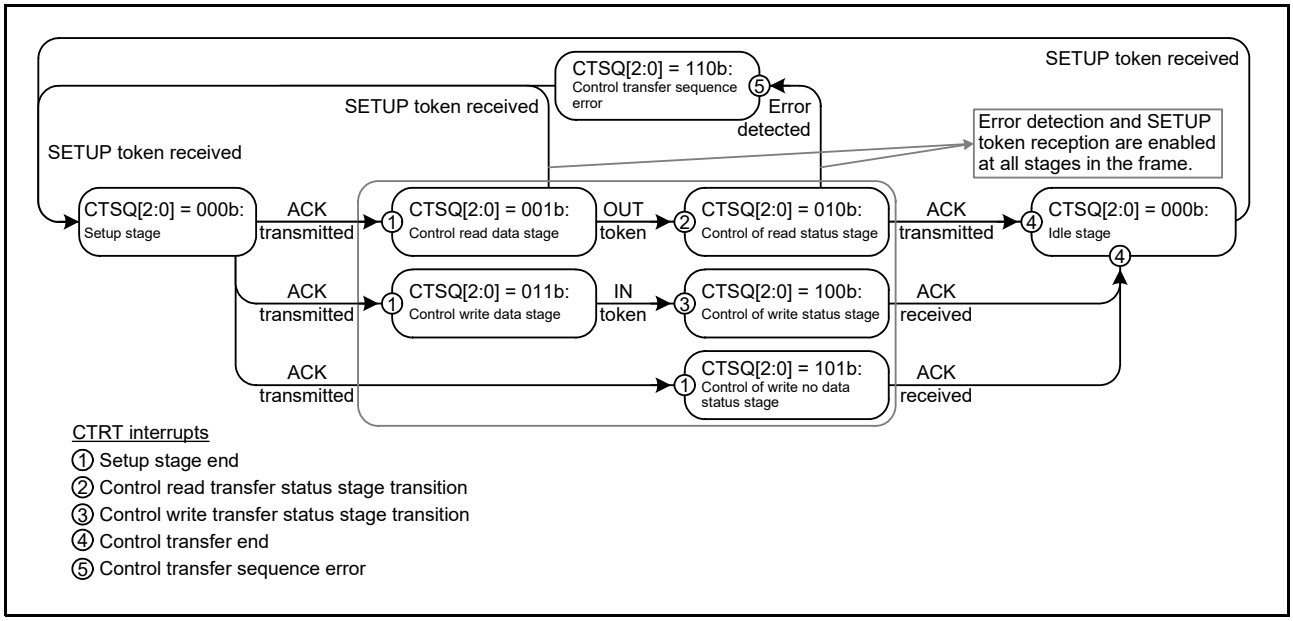

Figure 41.10 Control Transfer Stage Transition Chart

41.3.6.6 Frame Number Refresh Interrupt

In host controller operation, an interrupt is generated at the timing when the frame number is updated.
In function controller operation, a frame number refresh interrupt is generated when the frame number is updated. If the SOF cannot be received due to something like packet corruption, the frame number refresh interrupt is generated by the SOF recovery function. However, in this case the FRMNUM.FRNM[10:0] bits will not be updated.

41.3.6.7 VBUS Interrupt

When the USBHS_VBUS pin level changes, a VBUS interrupt is generated. The level of the USBHS_VBUS pin can be checked with the INTSTS0.VBSTS flag. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. However, if the system is activated with the host controller connected, the first VBUS interrupt is not generated because there is no change in the USBHS_VBUS pin level.

41.3.6.8 Resume Interrupt

In function controller operation, a resume interrupt is generated when the device state is the suspended state and the USB bus state has changed (from J state to K state, or from J state to SE0). Recovery from the suspended state is detected by means of the resume interrupt. When the host controller is selected, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

41.3.6.9 OVRCR Interrupt

An OVRCR interrupt is generated when the USBHS_OVRCURA or USBHS_OVRCURB pin level has changed. The levels of the USBHS_OVRCURA and USBHS_OVRCURB pins can be checked with the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent has been detected using the OVRCR interrupt.
For OTG connection, whether a change has been detected in the external power supply IC VBUS comparator can be checked using the OVRCR interrupt.

41.3.6.10 BCHG Interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether the peripheral device is connected and can also be used to detect a remote wakeup in host controller operation. The BCHG interrupt is generated regardless during host controller operation or function controller operation.

41.3.6.11 DTCH Interrupt

A DTCH interrupt is generated when disconnection of the USB bus is detected in host controller operation. The USBHS detects bus disconnection based on USB 2.0.
After detecting a DTCH interrupt, the USBHS controls hardware as described below (irrespective of the value set in the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the pertinent port should be terminated by software and make a transition to the wait state for bus connection to the pertinent port (wait state for ATTCH interrupt generation).

- Modifies and indicates the DVSTCTR0.UACT bit for the port in which a DTCH interrupt has been detected to 0.
- Puts the port in which a DTCH interrupt has been generated into the Idle state.

41.3.6.12 SACK Interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet has been received from the peripheral device in host controller operation. The SACK interrupt can be used to confirm that the setup transaction has been completed successfully.

41.3.6.13 SIGN Interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet has not been correctly received from the peripheral device three consecutive times in host controller operation. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

41.3.6.14 ATTCH Interrupt

An ATTCH interrupt is generated when J state or K state of the full-speed signal level is detected on the USB port for 2.5 µs in host controller operation. To be more specific, an ATTCH interrupt is detected on any of the following conditions.

- When K state, SE0, or SE1 changes to J state, and J state continues 2.5 µs.
- When J state, SE0, or SE1 changes to K state, and K state continues 2.5 µs.

41.3.6.15 EOFERR Interrupt

An EOFERR interrupt is generated when it is detected that communication is not completed at the EOF2 timing defined in USB 2.0.
After detecting an EOFERR interrupt, the USBHS controls hardware as described below (irrespective of the value set in the corresponding interrupt enable bit). All pipes in which communications are currently carried out for the pertinent port should be terminated by software and perform re-enumeration of the pertinent port.

- Modifies and indicates the DVSTCTR0.UACT bit for the port in which an EOFERR interrupt has been detected to 0.
- Puts the port in which an EOFERR interrupt has been generated into the Idle state.

41.3.6.16 Portable Device Detection Interrupt

The USBHS sets the INTSTS1.PDDETINT flag to 1 on detecting a portable device and generates the portable device detection interrupt. When the portable device detection interrupt is generated, use software to repeat reading the BCCTRL.PDDETSTS flag until the same value is read three or more times, and perform debounce processing.

41.3.6.17 LPMEND Interrupt

When the LPM transaction is ended because a response from the peripheral device or a timeout is detected, the INTSTS1.LPMEND flag is set to 1 and the LPMEND interrupt is generated.

41.3.6.18 L1RSMEND Interrupt

When performing processing to exit the L1 state, when the exit processing is complete, the INTSTS1.L1RSMEND flag becomes 1, and the L1RSMEND interrupt is generated.

41.3.7 Pipe Control

Pipe setting items of the USBHS are listed in Table 41.19. USB data transfer is performed through logical pipes called endpoints. The USBHS is provided with 10 pipes for data transfer. Set each pipe according to the user system specifications.

Table 41.19 Pipe Setting Items

Register	Bit	Setting	Note
DCPCFG PIPECFG	TYPE[1:0]	Transfer type	Pipes 1 to 9: Settable
	BFRE	BRDY interrupt mode	Pipes 1 to 5: Settable
	DBLB	Selection of double buffer	Pipes 1 to 5: Settable
	CNTMD	Select continuous transfer mode or discontinuous transfer mode	Pipes 1, 2: Settable only when bulk transfer is selected Pipes 3 to 5: Settable
	DIR	Selection of transfer direction	IN or OUT settable
	EPNUM[3:0]	Endpoint number	Pipes 1 to 9: Settable Set this number to a value other than 0000b when one or more pipes are used.
	SHTNAK	Selection of pipe disable at the end of transfer	Pipes 1, 2: Settable only when bulk transfer is selected Pipes 3 to 5: Settable
PIPEBUF	BUFSIZE[4:0]	FIFO buffer size	Default control pipe: Setting disabled (fixed to 64 bytes) Pipes 1 to 5: Settable (up to 2 Kbytes specifiable) Pipes 6 to 9: Setting disabled (fixed to 64 bytes)
	BUFNMB[7:0]	FIFO buffer number	default control pipe: Setting disabled (fixed to area 00h) Pipes 1 to 5: Setting disabled (area 08h to 87h specifiable) Pipes 6 to 9: Setting disabled (fixed to area 04h to 07h respectively)
DCPMAXP PIPEMAXP	DEVSEL[3:0]	Selection of device	Viewable only in host controller operation
	MXPS[6:0] MXPS[10:0]	Maximum packet size	Setting compliant with USB 2.0
PIPEPERI	IFIS	Buffer flush	Pipes 1, 2: Settable only when isochronous transfer is selected Pipes 3 to 5: Setting disabled Pipes 6 to 9: Setting disabled
	IITV[2:0]	Interval counter	Pipes 1, 2: Settable only when isochronous transfer is selected Pipes 3 to 5: Setting disabled Pipes 6 to 9: Settable only in host controller operation
DCPCTR PIPEnCTR	BSTS	Buffer status	States of receive/transmit buffers of default control pipe are switched by the ISEL bit
	INBUFM	IN buffer monitor	Provided only for pipes 1 to 5
	SUREQ	SETUP request	Settable only for the default control pipe Controllable only in host controller operation
	SUREQCLR	SUREQ bit clear	Settable only for the default control pipe Controllable only in host controller operation
	CSCLR	CSSTS clear	Controllable only in host controller operation
	CSSTS	Check SPLIT status	Controllable only in host controller operation
	ATREPM	Auto response mode	Pipes 1 to 5: Settable only in function controller operation
	ACLRM	Auto buffer clear	Pipes 1 to 9: Settable
	SQCLR	Sequence clear	Clearing the data toggle bit
	SQSET	Sequence set	Setting the data toggle bit
	SQMON	Sequence check	Checking the data toggle bit
	PBUSY	PIPE busy check	
	PID[1:0]	Response PID	
PIPEnTRE	TRENB	Transaction count enable	Pipes 1 to 5: Settable
	TRCLR	Current transaction counter clear	Pipes 1 to 5: Settable
PIPEnTRN	TRNCNT[15:0]	Transaction counter	Pipes 1 to 5: Settable

41.3.7.1 Pipe Control Register Switching Procedures

The following bits in the pipe control registers can be modified only when USB communication is prohibited (PID[1:0] bits are 00b (NAK response)). Figure 41.11 shows pipe control register switching procedures when USB communication is enabled (PID[1:0] bits are 01b (BUF response)).

The following shows the registers and bits that should not be modified when USB communication is enabled (PID[1:0] bits are 01b (BUF response)).

- Bits in registers DCPCFG and DCPMAXP
- DCPCTR.SQCLR and SQSET bits
- Bits in the PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI registers
- PIPEnCTR.ATREPM, ACLRM, SQCLR, and SQSET bits
- Bits in registers PIPEnTRE and PIPEnTRN
- Bits in the DEVADDm register (m = 0 to A)

For details on setting the CSCLR bit or setting the bits in the DEVADDm register, follow the procedures of each bit described in section 41.2, Register Descriptions.

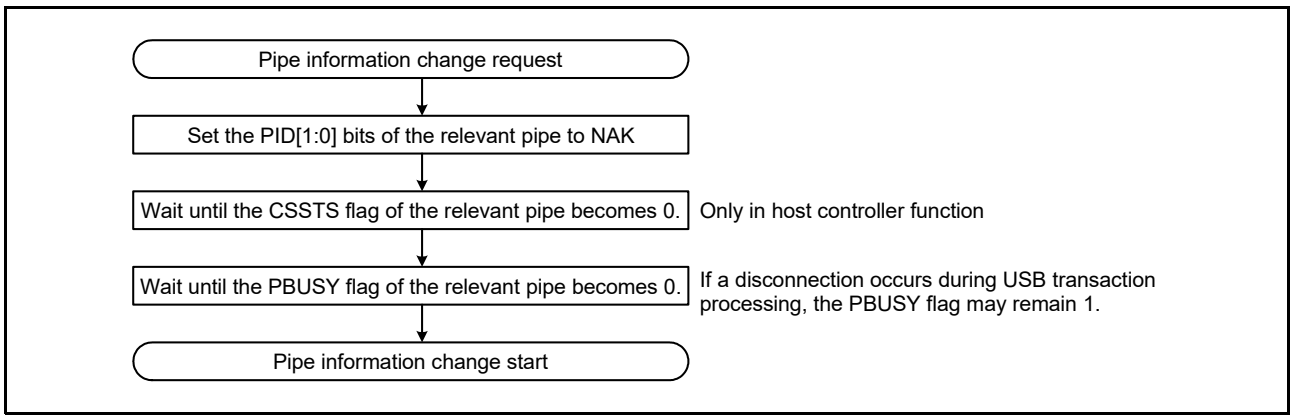

Figure 41.11 Procedure for Changing Pipe Information from the USB Communication Enabled State (PID[1:0] Bits are 01b (BUF Response))

The following bits in the pipe control registers can be modified only when the pertinent pipe information has not been set by the CURPIPE[3:0] bits in registers CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Registers that should not be set while the CURPIPE[3:0] bits are set:

- Bits in registers DCPCFG and DCPMAXP
- Bits in registers PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- PIPEnCTR.ACLRM bit

In order to modify pipe information, CURPIPE[3:0] bits should be set to a pipe other than the pipe to be modified. For the default control pipe, the buffer should be cleared using the BCLR bit after the pipe information is modified.

41.3.7.2 Transfer Types

The PIPECFG.TYPE[1:0] bits are used to specify the transfer type for each pipe. The transfer types that can be set for the pipes are as follows.

- Default control pipe: No setting is necessary (fixed at control transfer).
- Pipes 1 and 2: These should be set to bulk transfer or isochronous transfer.
- Pipes 3 to 5: These should be set to bulk transfer.
- Pipes 6 to 9: These should be set to interrupt transfer.

41.3.7.3 Endpoint Number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The default control pipe is fixed at endpoint 0. The other pipes can be set from endpoint 1 to endpoint 15.

- Default control pipe: No setting is necessary (fixed at endpoint 0).
- Pipes 1 to 9: The endpoint numbers from 1 to 15 should be selected and set.
  These should be set so that the combination of the PIPECFG.DIR bit and EPNUM[3:0] bits do not overlap.

41.3.7.4 Setting the Maximum Packet Size

Set the maximum packet size of each pipe with the DCPMAXP.MXPS[6:0] and PIPEMAXP.MXPS[10:0] bits. For the default control pipe and pipes 1 to 5, all maximum packet sizes defined in USB 2.0 can be set. For pipes 6 to 9, the maximum packet size is 64 bytes. Set the maximum packet size before starting a transfer (PID[1:0] bits are set to 01b (BUF response)).

- Default control pipe: Set 64 for high-speed operation.
  Select 8, 16, 32, or 64 for full-speed operation.
- Pipes 1 to 5: Set 512 for high-speed bulk transfer.
  Select 8, 16, 32, or 64 for full-speed bulk transfer.
- Pipes 1, 2: Set a value from 1 to 1024 for high-speed isochronous transfer.
  Set a value from 1 to 1023 for full-speed isochronous transfer.
- Pipes 6 to 9: Set a value of 1 to 64.

High bandwidth interrupt transfers and isochronous transfers are not supported.

41.3.7.5 Transaction Counter (For Pipes 1 to 5 in the Reading Direction)

When the specified number of transactions has been completed in the data packet receiving direction, the USBHS recognizes that the transfer has ended. Two transaction counters are provided: one is the PIPEnTRN register that specifies the number of transactions to be executed and the other is the current counter that internally counts the number of executed transactions. With the PIPECFG.SHTNAK bit set to 1, when the current counter value matches the specified number of transactions, the corresponding PIPEnCTR.PID[1:0] bits are set to 00b (NAK response) and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The information read from the PIPEnTRN register differs depending on the setting of the PIPEnTRE.TRENB bit.

- TRENB bit is 0: The specified transaction counter value can be read.
- TRENB bit is 1: The current counter value indicating the internally counted number of executed transactions can be read.

When operating the TRCLR bit, the following should be noted.

- If the transactions are being counted and the PIPEnCTR.PID[1:0] bits are set to 01b (BUF response), the current counter cannot be cleared.
- If there is any data left in the buffer, the current counter cannot be cleared.

41.3.7.6 Response PID

Set the response PID of each pipe by the PIPEnCTR.PID[1:0] bits DCPCTR.PID[1:0]. The following shows the USB operation with various response PID settings:

(1) Setting the response PID in host controller operation

Specify the execution of transaction for the response PID.

(a) NAK setting: Pipe prohibited state where no transaction is made.

(b) BUF setting: Transaction is made according to the FIFO buffer state.
OUT direction: The OUT token is issued when the FIFO buffer contains transmit data.
IN direction: The IN token is issued when the FIFO buffer is not full and can receive data.

(c) STALL setting: Pipe prohibited state where no transaction is made

Note: Make the default control pipe's setup transaction using the DCPCTR.SUREQ bit.

(2) Setting the response PID in function controller operation

For the response PID, specify the response to transactions from the host.

(a) NAK setting: A NAK response is always returned to generated transactions.

(b) BUF setting: A response is returned to transactions according to the FIFO buffer.

(c) STALL setting: A STALL response is always returned to generated transactions.

Note: An ACK response is always returned to the setup transaction regardless of the value of the PID[1:0] bits and the USB request is stored in the register.

The USBHS may write to the PID[1:0] bits, depending on the results of the transaction as described below.

(1) USBHS sets the response PID in host controller operation

(a) NAK setting: The PID[1:0] bits are set to 00b (NAK response) in the following cases, stopping issuance of tokens automatically.

- In the response to the transmitted token during a transfer other than the isochronous transfer, an NRDY interrupt occurs (refer to section 41.3.6.2 for details).
- A short packet was received during bulk transfer with the PIPECFG.SHTNAK bit set to 1.
- The transaction counter ended during bulk transfer with the PIPECFG.SHTNAK bit set to 1.

(b) BUF setting: BUF is not written by the USBHS.

(c) STALL setting: The PID[1:0] bits are set to STALL in the following cases, stopping issuance of tokens automatically.

- A STALL response was received in response to the transmitted token.
- A data packet exceeding the maximum packet size was received.

(2) USBHS sets the response PID in function controller operation

(a) NAK setting:

- The SETUP token was successfully received (only default control pipe).
- The PIPECFG.SHTNAK bit was set to 1 during the bulk transfer and the transaction counter ended, or a short packet was received.

(b) BUF setting: BUF is not written by the USBHS.

(c) STALL setting:

- A maximum packet size over error was detected in the receive data packet.
- A control transfer sequence error was detected.

41.3.7.7 Data PID Sequence Bit

When data is successfully transferred in the data stage, bulk transfer, or interrupt transfer of the control transfer, the sequence bit of the data PID is automatically toggled by the USBHS. The sequence bit of the data PID transmitted next can be checked by the SQMON flag in DCPCTR and PIPEnCTR. The sequence bit changes upon receiving the ACK handshake during data transmission, or upon transmitting the ACK handshake during data reception. Furthermore, the data PID sequence bit can be modified by the SQCLR and SQSET bits in DCPCTR and PIPEnCTR.
In the control transfer during function controller operation, the USBHS automatically sets the sequence bit at the stage transition. The data PID becomes DATA1 at the end of the setup stage. The sequence bit is not accessed in the status stage, and a response is returned with PID = DATA1. Therefore, sequence bit setting by software is not necessary. In the control transfer during host controller operation, the sequence bit must be set by software at the stage transition.
Note that the data PID sequence bit must be set by software when transmitting or receiving the ClearFeature() request regardless during the host or function controller operation.

41.3.7.8 Response PID = NAK Function

The USB has a function that disables pipe operation (PID[1:0] bits are set to 00b (NAK response)) at the timing at which the final data packet of a transaction is received (the USB automatically distinguishes this based on reception of a short packet or the transaction counter) by setting the PIPECFG.SHTNAK bit to 1. When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation has been disabled, the pipe should be set to the enabled state again (PID[1:0] bits are set to 01b (BUF response)) by software. The response PID = NAK function can be used only when bulk transfers are used.

41.3.7.9 Auto Response Mode

With the pipes for bulk transfer (pipe 1 to pipe 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (PIPECFG.DIR bit is 0), OUT-NAK mode is entered, and during an IN transfer (DIR bit is 1), null auto response mode is entered.

41.3.7.10 OUT-NAK Mode

With the pipes for bulk OUT transfer, NAK is returned in response to an OUT token and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To make a transition from normal mode to OUT-NAK mode, OUT-NAK mode should be specified in the pipe operation disabled state (PID[1:0] bits are set to 00b (NAK response)) before enabling pipe operation (PID[1:0] bits are set 01b (BUF response)). After pipe operation has been enabled, OUT-NAK mode becomes valid. However, if an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host. To transition from OUT-NAK mode to normal mode, OUT-NAK mode should be canceled in the pipe operation disabled state (PID[1:0] bits are set to 00b (NAK response)) before enabling pipe operation (PID[1:0] bits are set to 01b (BUF response)). In normal mode, reception of OUT data is enabled.

41.3.7.11 Null Auto Response Mode

With the pipes for bulk IN transfer, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1. To make a transition from normal mode to null auto response mode, null auto response mode should be set in the pipe operation disabled state (PID[1:0] bits are set to 00b (NAK response)) before enabling pipe operation (PID[1:0] bits are set to 01b (BUF response)). After pipe operation has been enabled, null auto response mode becomes valid. Before setting null auto response mode, confirm that the PIPEnCTR.INBUFM flag is 0 because the mode can be set only when the buffer is empty. If the INBUFM flag is 1, the buffer should be emptied with the PIPEnCTR.ACLRM bit. While a transition to null auto response mode is being made, data should not be written from the FIFO port. To make a transition from null auto response mode to normal mode, pipe operation disabled state (PID[1:0] bits are set to 00b (NAK response)) should be retained for the period of zero-length packet transmission (about 10 µs) before canceling null auto response mode. In normal mode, data can be written from the FIFO port; therefore, packet transmission to the host is enabled by enabling pipe operation (PID[1:0] bits are set to 01b (BUF response)).

41.3.8 FIFO Buffers

41.3.8.1 FIFO Buffers

The USBHS incorporates FIFO buffers for data transfer. The area used for each pipe is managed by the USBHS. Access rights to FIFO buffers can be assigned to the system (CPU side) or the USBHS (SIE side).

(1) Status of the FIFO Buffers

Table 41.20 and Table 41.21 list the states of the FIFO buffers in the USBHS. The state of the FIFO buffers can be confirmed by reading the DCPCTR.BSTS flag and PIPEnCTR.INBUFM flag. The transfer direction for the FIFO buffers can be specified using either the PIPECFG.DIR bit or the CFIFOSEL.ISEL bit (when default control pipe is selected). The INBUFM flag is valid for pipe 1 to pipe 5 when transmitting. When a transfer pipe on the transmitting side is set to double buffer mode, the BSTS flag is used to monitor the buffer status on the CPU side, and the INBUFM flag is used to monitor the buffer status on the SIE side. When the CPU or DMAC/DTC write access to the FIFO port is slow, and the buffer empty status cannot be determined by the BEMP interrupt, the end of transmission can be confirmed by the INBUFM flag.

Table 41.20 FIFO Buffer Status Indicated by the BSTS Flag

ISEL or DIR Bit	BSTS Flag	FIFO Buffer Status
0 (data reception)	0	There is no received data, or data is being received. Data cannot be read from the FIFO port.
0 (data reception)	1	There is received data, or a zero-length packet has been received. Data can be reading from the FIFO port. Note that when a zero-length packet is received, data cannot be read and the FIFO buffer must be cleared.
1 (data transmission)	0	Data transmission is not complete. Data cannot be written to the FIFO port.
1 (data transmission)	1	Data transmission has been completed. Data can be written to the FIFO buffer.

Table 41.21 Buffer Status Indicated by the INBUFM Flag

DIR Bit	INBUFM Flag	FIFO Buffer Status
0 (data reception)	Invalid	Invalid
1 (data transmission)	0	Data transmission has been completed. There is no data to be transmitted, or transmit data is being written to the FIFO port.
1 (data transmission)	1	Transmittable data is present.

41.3.8.2 Clearing the FIFO Buffers

Table 41.22 lists information pertaining to clearing FIFO buffers by the USBHS. FIFO buffers can be cleared using the BCLR bit in a FIFO port control register, DCLRM bit in the D0FIFOSEL/D1FIFOSEL register, and PIPEnCTR.ACLRM bit. Pipes 1 to 5 can be set to single buffer mode or double buffer mode using the PIPECFG.DBLB bit.

Table 41.22 Methods of Clearing the FIFO Buffers

Cleared	FIFO Buffers on the CPU Side	FIFO Buffer That Has Had All Transmit Data Read	All Data in the FIFO Buffer Allocated to Pipe n
Bit used	CFIFOCTR.BCLR bit D0FIFOCTR.BCLR bit D1FIFOCTR.BCLR bit	D0FIFOSEL.DCLRM bit D1FIFOSEL.DCLRM bit	PIPEnCTR.ACLRM bit
Operation	When the BCLR bit is set to 1, the FIFO buffers on the CPU side of the pipes specified by the CFIFOSEL.CURPIPE[3:0] bits and CURPIPE[3:0] bits in the D0FIFOSEL/D1FIFOSEL register are cleared.	If the DCLRM bit is set to 1, after reading the received data for the pipe specified by the CURPIPE[3:0] bits in the D0FIFOSEL/D1FIFOSEL register, the FIFO buffer is automatically cleared.	If the ACLRM bit is set to 1 and then set to 0, all data in the FIFO buffer (both planes in double buffer mode) allocated to pipe n is cleared. Also, If the PID[1:0] bits are set to 01b (BUF response) while the ACLRM bit is still set to 1, all packets received are discarded.

(1) Received Packet Read-and-Discard Function in Auto Buffer Clear Mode

If the PIPEnCTR.ACLRM bit is set to 1 and the PID[1:0] bits are set to 01b (BUF response), the USBHS discards all received data packets. However, if a normal data packet is received, the ACK response is returned to the host controller. The received packet read-and-discard function can only be set to FIFO buffers that are reading data. In addition, do not use pipes that are specified as isochronous transfer or interrupt transfer.

41.3.8.3 FIFO Port Functions

Table 41.23 shows the settings for the functions of the FIFO ports in the USBHS. When writing data to a FIFO buffer, data is written until the maximum packet size is reached, and the FIFO buffer automatically becomes enabled to transmit data. To enable transmission before the maximum packet size is reached, set the BVAL bit in a FIFO port control register to end the write access. To transmit a zero-length packet, after using the BCLR bit to clear the FIFO buffer, the BVAL bit must be set to end the write access.

When reading data from a FIFO buffer, after all data has been read from the FIFO buffer, it automatically becomes ready to receive new packets. However, when a zero-length packet is received (DTLN[11:0] bits are 000h), data cannot be read from the FIFO buffer, and the BCLR bit must be used to clear the buffer. The length of the receive data can be confirmed using the DTLN[11:0] bits in a FIFO port control register.

Table 41.23 FIFO Port Function Settings

Register Name	Bit Name	Description
CFIFOSEL, D0FIFOSEL, D1FIFOSEL	RCNT	Selects DTLN[11:0] read mode.
	REW	FIFO buffer rewind (reread, rewrite).
	DCLRM	Automatically clears receive data for a current pipe after the data has been read (only for D0FIFO and D1FIFO).
	DREQE	Enables DMA/DTC transfers (only for D0FIFO and D1FIFO).
	MBW[1:0]	FIFO port access bit width.
	BIGEND	Selects FIFO port endian.
	ISEL	FIFO port access direction (only for the default control pipe).
	CURPIPE[3:0]	Selects the current pipe.
CFIFOCTR, D0FIFOCTR, D1FIFOCTR	BVAL	Ends writing to the FIFO buffer.
	BCLR	Clears FIFO buffers on the CPU side.
	DTLN[11:0]	Checks the length of the receive data.

(1) FIFO Port Selection

Table 41.24 shows the pipes that can be selected with the various FIFO ports. Use the CURPIPE[3:0] bits in a FIFO port select register to select the pipe to be accessed. After the pipe is selected, check to see that the value written to the CURPIPE[3:0] bits can be read correctly, (if the previous pipe number is read, it indicates the USBHS is modifying the pipe). Then, check to see if the FRDY flag in a FIFO port control register is 1, and access the FIFO buffers. In addition, use the MBW[1:0] bits in a FIFO port select register to select the bus width to be accessed. The PIPECFG.DIR bit is used to select the FIFO buffer access direction, and the ISEL bit in a FIFO port select register determines the direction of the default control pipe.

Table 41.24 FIFO Port Access by Pipe

Pipe	Access Method	Port that can be Used
Default control pipe	CPU access	CFIFO port register
Pipe 1 to pipe 9	CPU access	CFIFO port register D0FIFO/D1FIFO port register
	DMAC/DTC access	D0FIFO/D1FIFO port register

(2) REW Bit

The pipe currently being accessed can be halted, another pipe can be accessed, and then it is possible to continue processing on the current pipe. Set the REW bit in a FIFO port select register to perform this. If a pipe is selected by setting the CURPIPE[3:0] bits in a FIFO port select register and the REW bit to 1 simultaneously, the pointer used to read from and write to the FIFO buffer is reset, and the read or write access can be carried out from the first byte. If a pipe is selected by setting the REW bit to 0, the pointer used to read from and write to the FIFO buffer is not reset, and the data access previously selected can be continued. To access a FIFO port, after selecting a pipe, check to see if an FRDY flag in a FIFO port control register is 1.

41.3.8.4 DMA/DTC Transfers (D0FIFO and D1FIFO Ports)

(1) Overview of DMA/DTC Transfers

The FIFO port can be accessed using the DMAC/DTC for pipes 1 to 9. When access to the buffer for the pipe targeted for DMA/DTC transfer is enabled, a DMA/DTC transfer request is issued.
Set the MBW[1:0] bits in the D0FIFOSEL/D1FIFOSEL register to select the transfer width to the FIFO port, set the CURPIPE[3:0] bits to select the pipe targeted for DMA/DTC transfer. Do not change the selected pipe during DMA/DTC transfer.

(2) D0FIFO/D1FIFO Auto Clear Mode (Reading Ports D0FIFO and D1FIFO)

When the DCLRM bit in the D0FIFOSEL/D1FIFOSEL register is set to 1, if the FIFO buffer read access is completed, the USBHS automatically clears the FIFO buffer of the selected pipe.
In Table 41.25, the relationship between packet reception and FIFO buffer clearing processing by software is shown for various bit settings. As shown in Table 41.25, the conditions for clearing a FIFO buffer depends on the PIPECFG.BFRE bit setting. Using the DCLRM bit eliminates the need for a FIFO buffer to be cleared by software in any situation that requires FIFO buffer clearing. This enables DMA/DTC transfers without involving software.
D0FIFO/D1FIFO auto clear mode can be used when reading a FIFO buffer.

Table 41.25 Relationship Between Packet Reception and FIFO Buffer Clearing Processing by Software

Buffer Status When a Packet is Received	Bit Setting			
	DCLRM bit is 0		DCLRM bit is 1	
	BFRE bit is 0	BFRE bit is 1	BFRE bit is 0	BFRE bit is 1
Buffer full	Clearing not necessary	Clearing not necessary	Clearing not necessary	Clearing not necessary
Zero-length packet reception	Clearing necessary	Clearing necessary	Clearing not necessary	Clearing not necessary
Normal short packet reception	Clearing not necessary	Clearing necessary	Clearing not necessary	Clearing not necessary
Transaction count end	Clearing not necessary	Clearing necessary	Clearing not necessary	Clearing not necessary

41.3.8.5 Allocating the FIFO Buffers

Figure 41.12 is an example of the memory map for a USBHS FIFO buffer. The FIFO buffer is an area shared by the CPU and the USBHS. Access rights to the FIFO buffers can be given to the CPU side or USBHS side (SIE side).

An independent area is set for the FIFO buffer of each pipe. A memory area is set by the first block number and the number of blocks (specified by the PIPEBUF.BUFSIZE[4:0] and BUFNMB[7:0] bits), regarding 64 bytes as one block. When the PIPECFG.CNTMD bit is 1 (continuous transfer mode), set the BUFSIZE[4:0] bits to an integral multiple of the maximum packet size. In addition, when the PIPECFG.DBLB bit is set to 1 (double buffer mode), twice the memory area specified by the PIPEBUF.BUFSIZE[4:0] bits is allocated to the same pipe.

Three FIFO ports are used to access (read data from and write data to) a FIFO buffer. Set the CFIFOSEL/D0FIFOSEL/D1FIFOSEL.CURPIPE[3:0] bits to specify the pipe the FIFO port is allocated to.

The BSTS flags in registers DCPCTR and PIPEnCTR, and the PIPEnCTR.INBUFM flag can be used to check the status of a FIFO buffer for each pipe. Use the CFIFOCTR/D0FIFOCTR/D1FIFOCTR.FRDY flag to check access rights for a FIFO port.

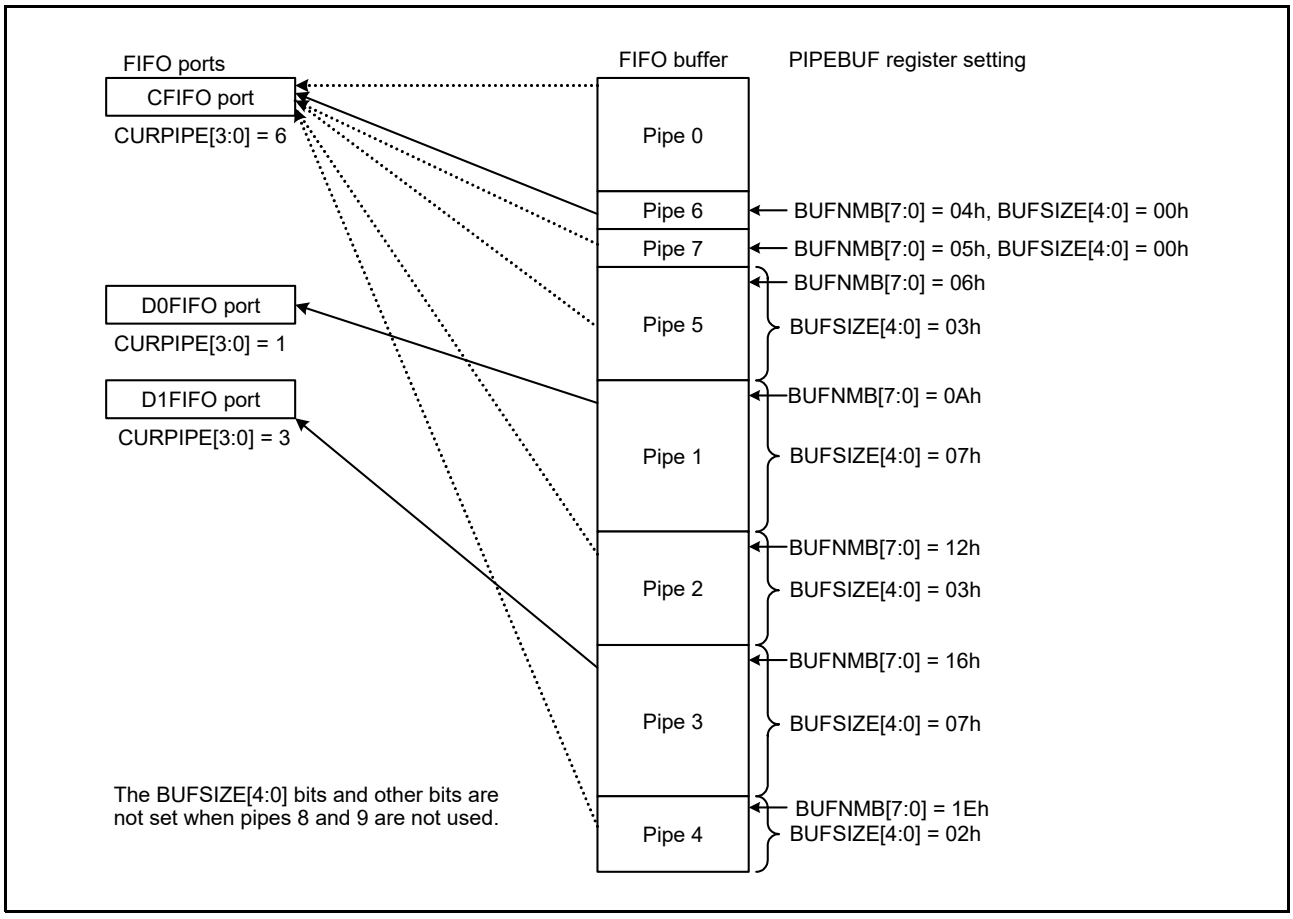

Figure 41.12 Example of a FIFO Buffer Memory Map

41.3.9 Control Transfer Using the Default Control Pipe

The default control pipe is used for data transfer in the control transfer data stage. The default control pipe's FIFO buffer is a 64-byte single buffer of the fixed area for both control read and control write. This FIFO buffer can only be accessed through the CFIFO port.

41.3.9.1 Control Transfer in Host Controller Operation

(1) Setup Stage

Registers USBREQ, USBVAL, USBINDX, and USBLENG are used to transmit the USB request of the SETUP transaction. Writing the setup packet data to the register and then setting the DCPCTR.SUREQ bit to 1 transmits the set data as the SETUP transaction. The SUREQ bit becomes 0 when the transaction is completed. Do not modify the above USB request registers while the SUREQ bit is 1. After the USBHS detects that the peripheral device is connected, issue the first SETUP transaction for the device using the sequence described above by setting the DCPMAXP.DEVSEL[3:0] bits to 0 and setting the DEVADD0.USBSPD[1:0] bits. After the connected peripheral device enters the Address state, issue SETUP transactions using the sequence described above with the assigned USBAddress set in the DEVSEL[3:0] bits and the bits in the DEVADDm register corresponding to the specified USBAddress set appropriately (m = 0 to A). For example, set the DEVADD2 register when the PIPEMAXP.DEVSEL[3:0] bits are 0010b, and set the DEVADD5 register when the PIPEMAXP.DEVSEL[3:0] bits are 0101b. When a transaction is transmitted, an interrupt request is generated by the response from the peripheral device (INTSTS1.SIGN and SACK flags). This interrupt request allows the USBHS to check the SETUP transaction result. The DATA0 data packet (USB request) of the SETUP transaction is transmitted regardless of the DCPCTR.SQMON flag setting.

(2) Data Stage

The data stage is used to transfer data using the default control pipe's FIFO buffer.
Before accessing the default control pipe's FIFO buffer, set the CFIFOSEL.ISEL bit to specify the access direction. In addition, set the DCPCFG.DIR bit to specify the transfer direction. The first data packet in the data stage must be transferred with the data PID set to DATA1. Transactions can be executed by setting the data PID to DATA1 using the DCPCTR.SQSET bit and setting the PID[1:0] bits to 01b (BUF response). Completion of data transfer is detected by the BRDY interrupt or the BEMP interrupt. Data transfer of multiple packets is enabled in continuous transfer mode. If the transmit data size is an integral multiple of the maximum packet size, control the control write transfer by software to transmit a zero-length packet last.

(3) Status Stage

The status stage is used for zero-length packet data transfer in the reverse direction of the data stage. As in the data stage, data transfer using the default control pipe's FIFO buffer is performed in the status stage. Transactions are executed using the same procedure as the data stage. Data packets in the status stage must be transmitted and received with the data PID set to DATA1. Set the data PID to DATA1 by the DCPCTR.SQSET bit. When a zero-length packet is received, check the receive-data length by the CFIFOCTR.DTLN[11:0] bits after the BRDY interrupt is generated, and then clear the FIFO buffer by using the BCLR bit.

41.3.9.2 Control Transfer in Function Controller Operation

(1) Setup Stage

The USBHS returns an ACK response in response to a normal setup packet for the USBHS. The following describes the USBHS operation in the setup stage.
The USBHS sets the following bits upon receiving a new setup packet.

- Sets the INTSTS0.VALID flag to 1.
- Sets the DCPCTR.PID[1:0] bits to 00b (NAK response).
- Sets the DCPCTR.CCPL bit to 0.

When the USBHS receives a data packet following a setup packet, the USBHS stores the USB request parameters in registers USBREQ, USBVAL, USBINDX, and USBLENG.

Before performing the response processing for the control transfer, be sure to set VALID flag to 0. While VALID flag is 1, the PID[1:0] bits cannot be set to 01b (BUF response) and the data stage cannot be finished. With the VALID flag function, the USBHS can suspend the ongoing request processing upon receiving a new USB request during the control transfer and return a response to the latest request.

Furthermore, the USBHS automatically checks the direction bit (bit 8 of *bmRequestType*), and the request data length (*wLength*) in the received USB request, and recognizes the control read transfer, control write transfer, and control write no data transfer to control stage transitions. In the case of an incorrect sequence, a sequence error of the control transfer stage transition interrupt occurs, and interrupt is reported to software. For details on stage control by the USBHS, see Figure 41.10, Control Transfer Stage Transition Chart.

(2) Data Stage

Perform data transfer by the default control pipe in response to the received USB request. Before accessing the default control pipe's FIFO buffer, set the CFIFOSEL.ISEL bit to specify the access direction. A transaction is executed when the DCPCTR.PID[1:0] bits are set to 10b (BUF response). Completion of data transfer is detected by the BRDY interrupt or BEMP interrupt. Use the BRDY interrupt for control write transfers, and use the BEMP interrupt for control read transfers. When performing a control write in high-speed operation, the response is the NYET handshake depending on the status of the FIFO buffer.

(3) Status Stage

While the DCPCTR.PID[1:0] bits are set to 01b (BUF response), control transfer can be finished by setting the DCPCTR.CCPL bit to 1.
After the DCPCTR.CCPL bit is set to 1, the USBHS automatically executes the status stage according to the data transfer direction determined in the setup stage. The status stage is executed specifically as follows.

- For control read transfer:

The USBHS receives a zero-length packet from the USB host and transmits an ACK response.

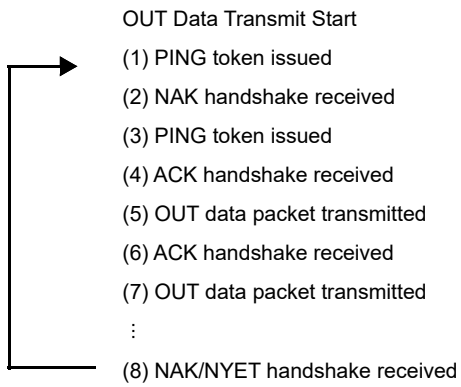
- For control write transfer and no data control transfer:

The USBHS transmits a zero-length packet and receives an ACK response from the USB host.

(4) Control Transfer Auto Response Function

The USBHS automatically responds to a normal SetAddress() request. If the SetAddress() request contains any of the following errors, a response must be returned by software.

- When *bmRequestType* is not 00h: Except control write transfer
- When the *wIndex* value is not 00h: Request error
- When the *wLength* value is not 00h: Except no data control transfer
- When the *wValue* value is larger than 7Fh: Request error
- When INTSTS0.DVSQ[2:0] bits are 011b (configured state): control transfer of device state error



To all requests other than SetAddress(), a response by the corresponding software is required.

41.3.10 Bulk Transfer for Pipes 1 to 5

The FIFO buffer usage (setting of single buffer/double buffer or continuous transfer mode/discontinuous transfer mode) is selectable for the bulk transfer. Up to 2 Kbytes of the FIFO buffer size can be set. The controller manages the FIFO buffer status, and the automatic response is a PING token or NYET handshake.

41.3.10.1 Controlling the PING Token in Host Controller Operation

The USBHS automatically issues the PING token in the OUT direction. As shown below, the USBHS communication in the transmit direction starts with the PING token. When an ACK handshake is received in response to the PING token, the OUT packet is transmitted. If NAK or NYET are received in response to the OUT transaction, the USBHS returns to the PING transmit state.

In addition, sources for the USBHS to return the PING token to the transmit state are a MCU reset, receiving a NYET/NAK handshake, clearing the SQCLR bit, and setting the ACLRM bit to clear the buffer.

41.3.10.2 Controlling the NYET Handshake in Function Controller Operation

Table 41.26 lists the tokens received in response to a bulk transfer and control transfer. When the USBHS receives an OUT token in response to a bulk transfer and control transfer, if there is only enough space in the FIFO buffer for 1 packet of data, the response is NYET. However, if a short packet is received, even if these conditions are met, there is no NYET response, but there is an ACK response.

Table 41.26 Responses for the Token Received

PID[1:0] Bit Setting Value	FIFO Buffer Status	Token Received	Response	Remarks
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY	OUT/PING	ACK	Data packet is received when an OUT token is received *1
	RCV-BRDY	OUT	NYET	Data packet is received *2
	RCV-BRDY	OUT (short)	ACK	Data packet is received *2
	RCV-BRDY	PING	ACK	See Note 2.
	RCV-NRDY	OUT/PING	NAK	
	TRN-BRDY	IN	DATA0/DATA1	Data packet is transmitted
	TRN-NRDY	IN	NAK	

The following are more specific.

Note 1. RCV-BRDY: When an OUT token or PING token is received, the FIFO buffer has at least 2 packets worth of empty space.

Note 2. RCV-BRDY: When an OUT token is received, the FIFO buffer only has 1 packet worth of empty space.
RCV-NRDY: When a PING token is received, there is no empty space in the FIFO buffer.
TRN-BRDY: When an IN token is received, there is transmit data in the FIFO buffer.
TRN-NRDY: When an IN token is received, there is no transmit data in the FIFO buffer.

41.3.11 Interrupt Transfer for Pipes 6 to 9

In function controller operation, the USBHS performs the interrupt transfer according to the cycle managed by the USB host. In the interrupt transfer, the USBHS ignores PING token (no response) and does not transmit the NYET handshake but returns an ACK, NAK, or STALL response.
In host controller operation, the token issuing timing can be set by the interval counter. The USBHS does not issue a PING token but issues an OUT token even for transfer in the OUT direction. The USBHS does not support high-bandwidth interrupt transfers.

41.3.11.1 Interval Counter for Interrupt Transfer in Host Controller Operation

To perform the interrupt transfer, specify the transaction interval for the PIPEPERI.IITV[2:0] bits. The USBHS issues interrupt transfer tokens according to the set interval.

(1) Initializing the Counter

When the MCU is reset, or when the PIPEnCTR.ACLRM bit is set to 1, the interval counter is initialized. Note that the PIPEPERI.IITV[2:0] bits are not initialized when the ACLRM bit is initialized.

Note that the interval counter is not initialized in the following case.

- USB bus reset, USB suspend
  The IITV[2:0] bits are not initialized. When the DVSTCTR0.UACT bit is set to 1, the count continues from the value before entering the USB bus reset state or the USB suspend state.

(2) Operation when Tokens Cannot Be Transmitted or Received at the Token Generation Timing

No token is generated in the following cases even at the token generation timing. In this case, try to execute a transaction in the next interval.

- The PID[1:0] bits are set to NAK response or STALL response.
- No available area is left in the FIFO buffer at the token transmit timing during transfer in the IN (receiving) direction.
- The FIFO buffer contains no transmit data at the token transmit timing during transfer in the OUT (transmitting) direction.

41.3.12 Isochronous Transfer for Pipes 1 and 2

The USBHS has the following functions for isochronous transfers.

- Notification of isochronous transfer error
- Interval counter (specified by the PIPEPERI.IITV[2:0] bits)
- Isochronous IN transfer data setup control (IDLE function)
- Isochronous IN transfer buffer flush function (specified by the PIPEPERI.IFIS bit)

The USBHS does not support high-bandwidth isochronous transfers.

41.3.12.1 Error Detection in Isochronous Transfers

The USBHS has a function for detecting the following error information for software to manage isochronous transfer errors. Table 41.27 and Table 41.28 show the priority in which errors are detected by the USBHS and the interrupts generated corresponding to errors.

(1) PID errors
- The PID value of the received packet is invalid.

(2) CRC errors and bit stuffing errors
- A CRC error was found in the received packet or the bit stuffing is incorrect.

(3) Maximum packet size over
- The data size of the received packet exceeded the maximum packet size.

(4) Overrun and underrun errors
- In host controller operation:
  No available area is left in the FIFO buffer at the token transmit timing during transfer in the IN (receiving) direction.
  The FIFO buffer contains no transmit data at the token transmit timing during transfer in the OUT (transmitting) direction.
- In function controller operation:
  The FIFO buffer contains no data when an IN token is received during transfer in the IN (transmitting) direction.
  No available area is left in the FIFO buffer when an OUT token is received during transfer in the OUT (receiving) direction.

(5) Interval error
In function controller operation, the following cases are treated as an interval error.
- Failed to receive an IN token in the interval frame during the isochronous IN transfer.
- Failed to receive an OUT token in the interval frame during the isochronous OUT transfer.

Table 41.27 Detecting an Error When a Token is Issued or Received

Detection Priority	Error Type	Interrupt Generated at Error Detection and Status
1	PID error	No interrupt is generated regardless of the selected controller function. (Ignored as a corrupted packet.)
2	CRC error, bit stuffing error	No interrupt is generated regardless of the selected controller function. (Ignored as a corrupted packet.)
3	Overrun error, underrun error	An NRDY interrupt is generated and the OVRN flag is set to 1 regardless of the selected controller function. In function controller operation, a zero-length packet is transmitted in response to the IN token. No data packet is received in response to the OUT token.
4	Interval error	An NRDY interrupt is generated in function controller operation, but no interrupt is generated in host controller operation.

Table 41.28 Detecting an Error When Receiving a Data Packet

Detection Priority	Error Type	Interrupt Generated at Error Detection and Status
1	PID error	No interrupt is generated (ignored as a corrupted packet.)
2	CRC error, bit stuffing error	An NRDY interrupt is generated and the CRCE flag is set to 1 regardless of the selected controller function.
3	Maximum packet size over error	A BEMP interrupt is generated and the PID[1:0] bits are set to STALL response regardless of the selected controller function.

41.3.12.2 Data PID

The USBHS does not support high-bandwidth transfers. The following describes actions to be taken for the received token in function controller operation.

(1) IN token:
- DATA0: Transmitted as PID of the data packet.
- DATA1: Not transmitted.
- DATA2: Not transmitted.
- mDATA: Not transmitted.

(2) OUT token (full-speed operation):
- DATA0: Successfully received as PID of the data packet.
- DATA1: Successfully received as PID of the data packet.
- DATA2: The packet is ignored.
- mDATA: The packet is ignored.

(3) OUT token (high-speed operation):
- DATA0: Successfully received as PID of the data packet.
- DATA1: Successfully received as PID of the data packet.
- DATA2: Successfully received as PID of the data packet.
- mDATA: Successfully received as PID of the data packet.

41.3.12.3 Interval Counter

The isochronous transfer interval can be set by the PIPEPERI.IITV[2:0] bits. In function controller operation, the interval counter enables functions shown in Table 41.29 below. In host controller operation, the token issuing timing is generated. In host controller operation, the interval counter operates in the same manner as in the interrupt transfer.

Table 41.29 Interval Counter Functions Provided in Function Controller Operation

Transfer Direction	Function	Detecting Condition
IN	Transmit buffer flush function	Failed to receive an IN token successfully in the interval frame during the isochronous IN transfer.
OUT	Notification of reception of no token	Failed to receive an OUT token successfully in the interval frame during the isochronous OUT transfer.

Since the interval counting is performed upon reception of (μ)SOF or by the recovered (μ)SOF, the isochronism can be maintained even if the (μ)SOF packet is corrupted. The settable frame interval is $2^{IITV[2:0]}$ (micro)frame.

(1) Initializing the Interval Counter in Function Controller Operation

When the MCU is reset, a USB bus reset is detected, or when the PIPEnCTR.ACLRM bit is set to 1, the interval counter is initialized. Note that the PIPEPERI.IITV[2:0] bits are initialized when the MCU is reset.

After the interval counter is initialized, the interval count starts under the following conditions after a packet is successfully transferred.

1. (μ)SOF is received after data is transmitted in response to the IN token with PID[1:0] bits set to 01b (BUF response).
2. (μ)SOF is received after data is received in response to the OUT token with PID[1:0] bits set to 01b (BUF response).

The interval counter is not initialized under the following conditions.

- When PID[1:0] bits are set to NAK response or STALL response
  The interval timer does not stop. Try to execute a transaction in the next interval.
- USB suspend
  The IITV[2:0] bits are not initialized. When (μ)SOF is received, the interval counter starts counting from the value before entering the suspended state.

(2) Interval Counting and Transfer Control in Host Controller Operation

The USBHS controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bit settings. Specifically, the USBHS issues a token for a selected pipe once every $2^{IITV[2:0]}$ frames.
The USBHS starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits have been set to 01b (BUF response).

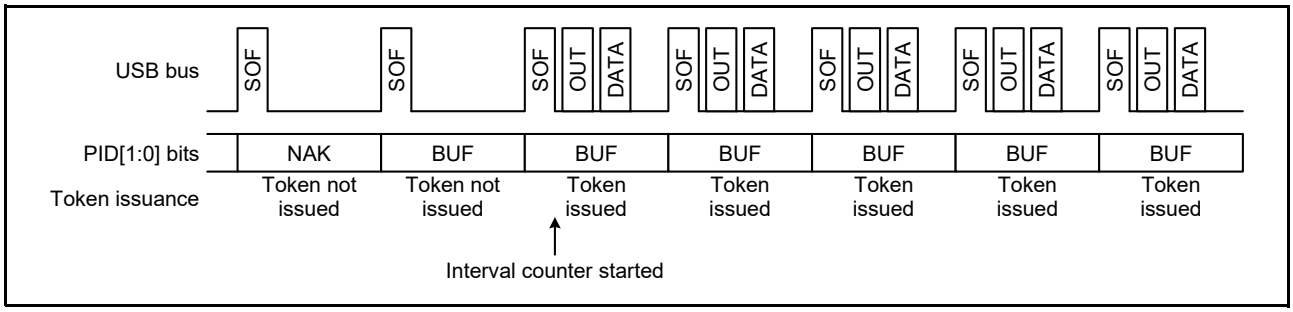


Figure 41.13 Token Issuance When IITV[2:0] Bits are 000b

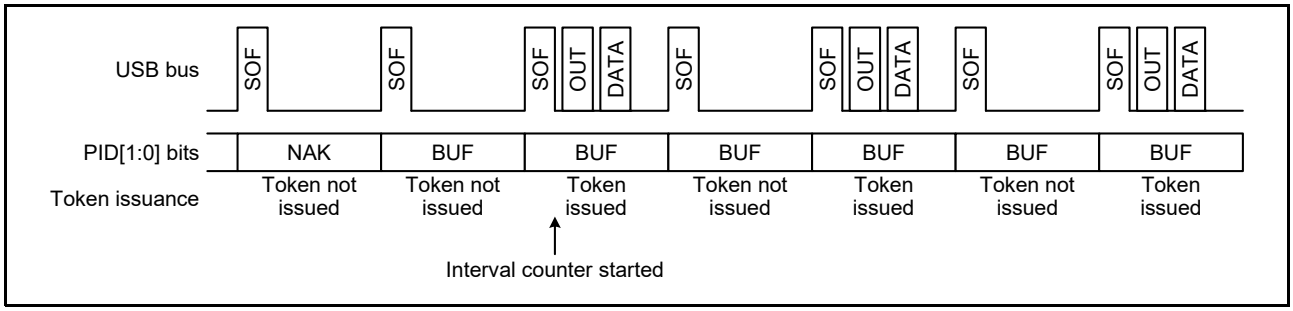

Figure 41.14 Token Issuance When IITV[2:0] Bits are 001b

When the selected pipe is set for isochronous transfers, the USBHS carries out the following operation in addition to controlling the token issuance interval. The USBHS issues a token even when the NRDY interrupt generation condition is satisfied.

(a) When the selected pipe is for isochronous IN transfers

The USBHS generates an NRDY interrupt when the USBHS issues an IN token but does not receive a packet successfully from a peripheral device (no response or packet error).
The USBHS sets the FRMNUM.OVRN flag to 1 generating an NRDY interrupt when the time to issue an IN token comes while the USBHS cannot receive data because the FIFO buffer is full (due to the fact that the CPU or DMAC/DTC is too slow to read data from the FIFO buffer).

(b) When the selected pipe is for isochronous OUT transfers

The USBHS sets the OVRN flag to 1 generating an NRDY interrupt and transmitting a zero-length packet when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer (because the CPU or DMAC/DTC is too slow to write data to the FIFO buffer).
The token issuance interval is reset on any of the following conditions.

- When the MCU is reset
  (The IITV[2:0] bits are also set to 000b).
- When the PIPEnCTR.ACLRM bit has been set to 1.

(3) Interval Counting and Transfer Control in Function Controller Operation

(a) When the selected pipe is for isochronous OUT transfers

The USBHS generates an NRDY interrupt when the USBHS fails to receive a data packet during the frame over the interval set by the PIPEPERI.IITV[2:0] bits.
The USBHS also generates an NRDY interrupt when the USBHS fails to receive data because of a CRC error or other errors contained in the data packet or because of the FIFO buffer being full.
The NRDY interrupt is generated at the timing of (µ)SOF packet reception. Even if the (µ)SOF packet is corrupted, the internal recovery function allows the interrupt to be generated at the timing to receive the (µ)SOF packet.
However, when the IITV[2:0] bits are set to a value other than 000b, the USBHS generates an NRDY interrupt on receiving an (µ)SOF packet for every interval after starting interval counting operation.
When the PID[1:0] bits are set to 00b (NAK response) after starting the interval timer, the USBHS does not generate an NRDY interrupt on receiving an (µ)SOF packet.
The condition to start interval counting depends on the setting of IITV[2:0] bits as shown below.

- When the IITV[2:0] bits are 000b:
  The interval counting starts when the PID[1:0] bits of the selected pipe are modified to BUF.

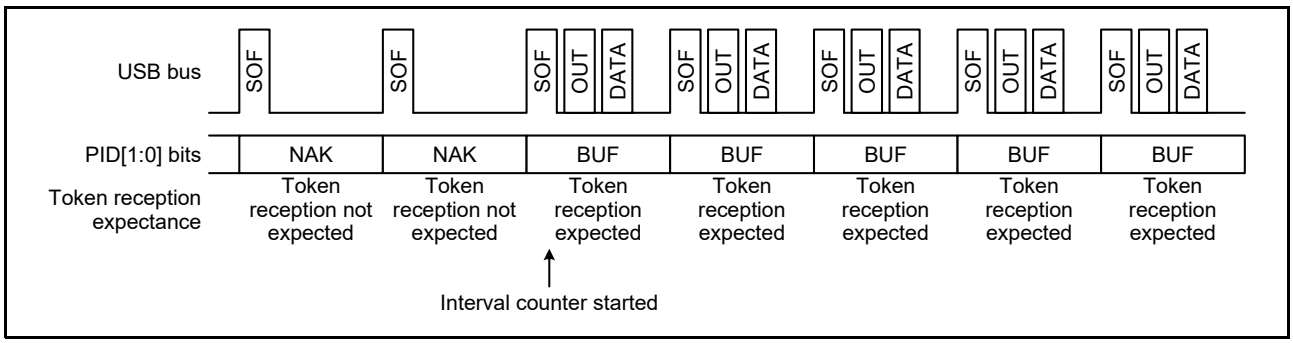

Figure 41.15 Relationship between Frames and Token Reception Expectance When the IITV[2:0] Bits are 000b

- When the IITV[2:0] bits are a value other than 000b:
  The interval counter starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe have been modified to 01b (BUF response).

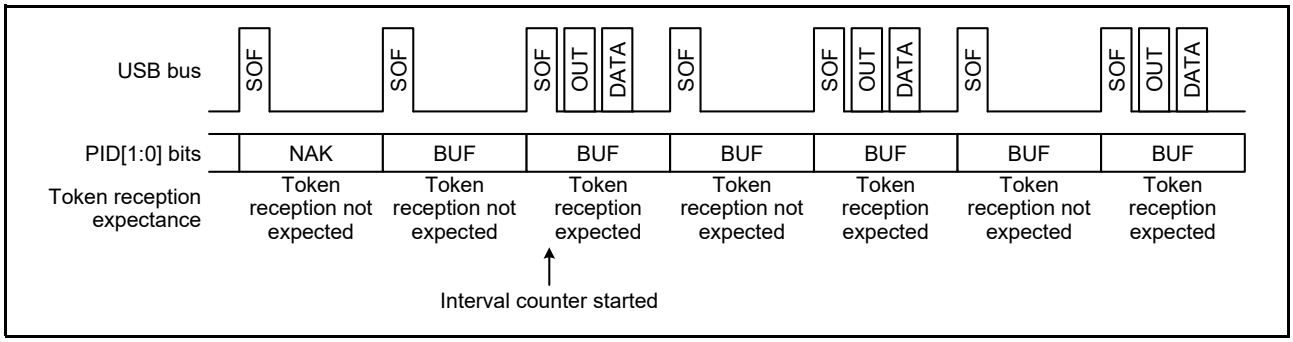

Figure 41.16 Relationship between Frames and Token Reception Expectance When the IITV[2:0] Bits are 001b

(b) When the selected pipe is for isochronous IN transfers

When the PIPEPERI.IFIS bit is cleared to 0, the USBHS transmits a data packet in response to a received IN token irrespective of the setting of the PIPEPERI.IITV[2:0] bits.
When the IFIS bit is set to 1, since the FIFO buffer contains data that can be transmitted, the USBHS clears the FIFO buffer if it fails to receive an IN token during the frame over the interval set by the IITV[2:0] bits.
The USBHS also clears the FIFO buffer when the USBHS fails to receive an IN token successfully because of a bus error such as a CRC error contained in the IN token.
The FIFO buffer is cleared at the timing of (µ)SOF packet reception. Even if the (µ)SOF packet is corrupted, the recovery function allows the FIFO buffer to be cleared at the timing to receive the (µ)SOF packet.

The timing to start interval counting depends on the setting of the IITV[2:0] bits (similar to the timing during OUT transfers).
The interval counter is cleared when any of the following conditions is fulfilled in function controller operation.

- When the MCU is reset (here, the IITV[2:0] bits are also set to 000b).
- When the PIPEnCTR.ACLRM bit is set to 1.
- When a USB bus reset is detected.

(4) Isochronous Transfer Transmit Data Setup in Function Controller Operation

In function controller operation, in the isochronous data transmission of the USBHS, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the (μ)SOF packet is detected. This function is called the isochronous transfer transmit data setup function. When double FIFO mode is used, only the one buffer that finished writing earlier can enter the transmittable state even when writing to both buffers has been completed. For this reason, even if two or more IN tokens are received in the same frame, only one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transmitted and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 41.17 shows an example of transmission using the isochronous transfer transmit data setup function when the IITV[2:0] bits are set to 000b (each frame) by the USBHS.

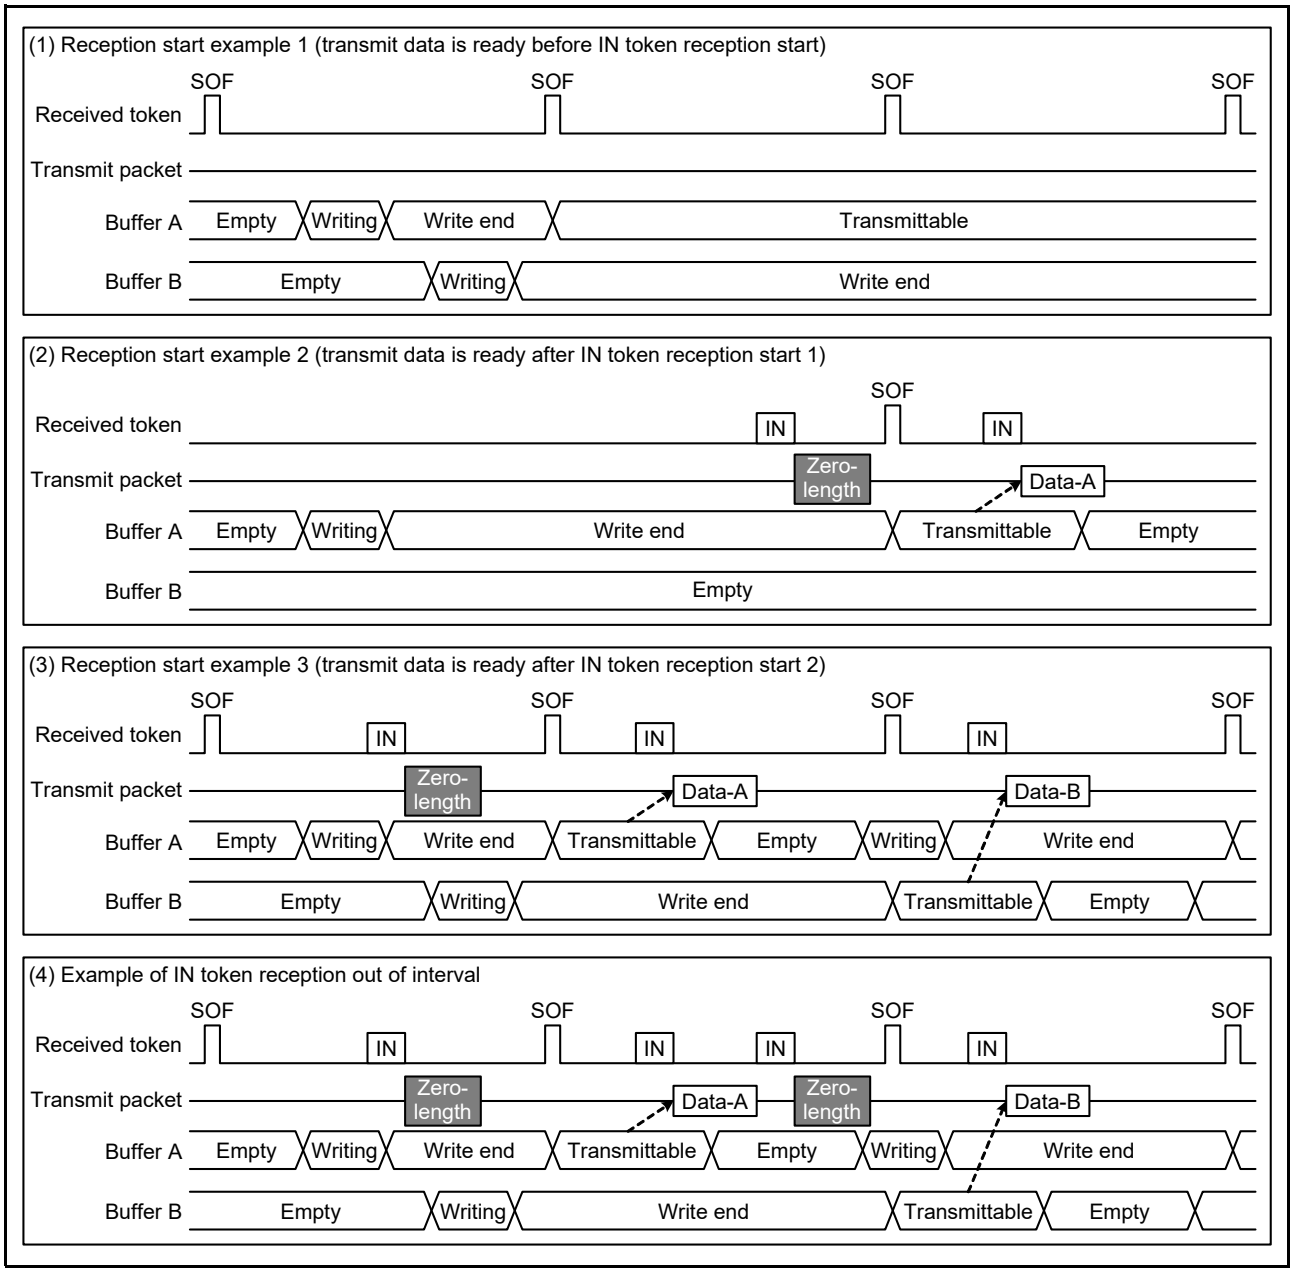

Figure 41.17 Example of Data Setup Function Operation

(5) Isochronous Transfer Transmit Buffer Flush in Function Controller Operation

In function controller operation, the USBHS does not receive an IN token in the interval frame during the isochronous data transmission. When the USBHS receives the (µ)SOF packet of the next frame, the USBHS treats it as a corrupted IN token and clears the buffer that is ready to transmit data to make it writable.

When the double-buffer is used and data has already been written to both of the buffers, the USBHS regards that the discarded FIFO buffer was transmitted in the same interval frame and makes the FIFO buffer (that is not discarded after the next (µ)SOF packet was received) transmittable.

The operation start timing of the buffer flush function varies depending on the value of the PIPEPERI.IITV[2:0] bits.

(1) When the PIPEPERI.IITV[2:0] bits are 000b, the buffer flush operation starts from the first frame after the pipe is enabled.

(2) When the PIPEPERI.IITV[2:0] bits are not 000b, the buffer flush operation starts after the first normal transaction.

Figure 41.18 shows an example of operation of the buffer flush function of the USBHS. However, for tokens prior to the interval frame (out of interval), the written data or a zero-length packet as an underrun error is transmitted according to the data setup status.

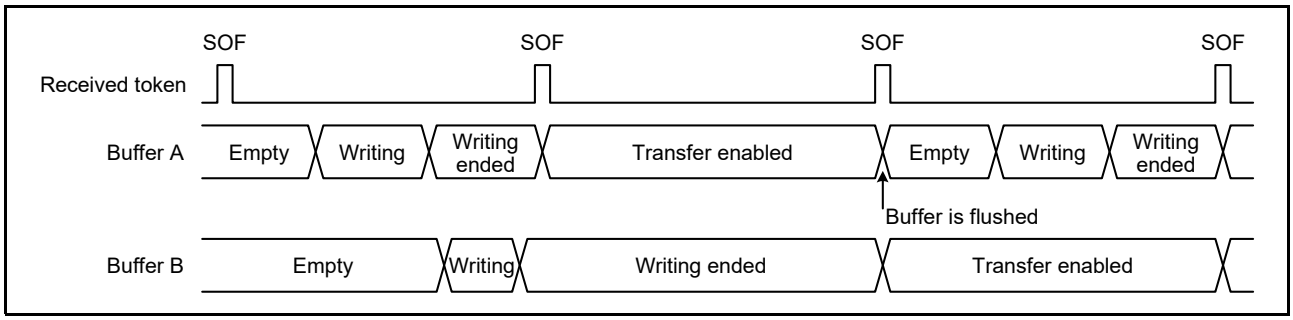

Figure 41.18 Example of Buffer Flush Operation

Figure 41.19 shows an example of occurrence of interval errors of the USBHS. There are five types of interval errors ((2) to (6)) shown in the figure below. An interval error occurs at timing ① and the buffer flush function works. Occurrence of an interval error during the IN transfer activates the buffer flush function, and occurrence of an interval error during the OUT transfer generates an NRDY interrupt.
Distinguish NRDY interrupt (such as receive packet error) from overrun error by the FRMNUM.OVRN flag.
A response according to the FIFO buffer status is returned to shaded tokens.

(1) IN token:

- When the FIFO buffer is ready to transmit data, the data is transmitted and a normal response is returned.
- When the FIFO buffer is not ready to transmit data, a zero-length packet is transmitted and an underrun error occurs.

(2) OUT token:

- When the FIFO buffer is ready to receive data, the data is received and a normal response is returned.
- When the FIFO buffer is not ready to receive data, the received data is discarded and an overrun error occurs.

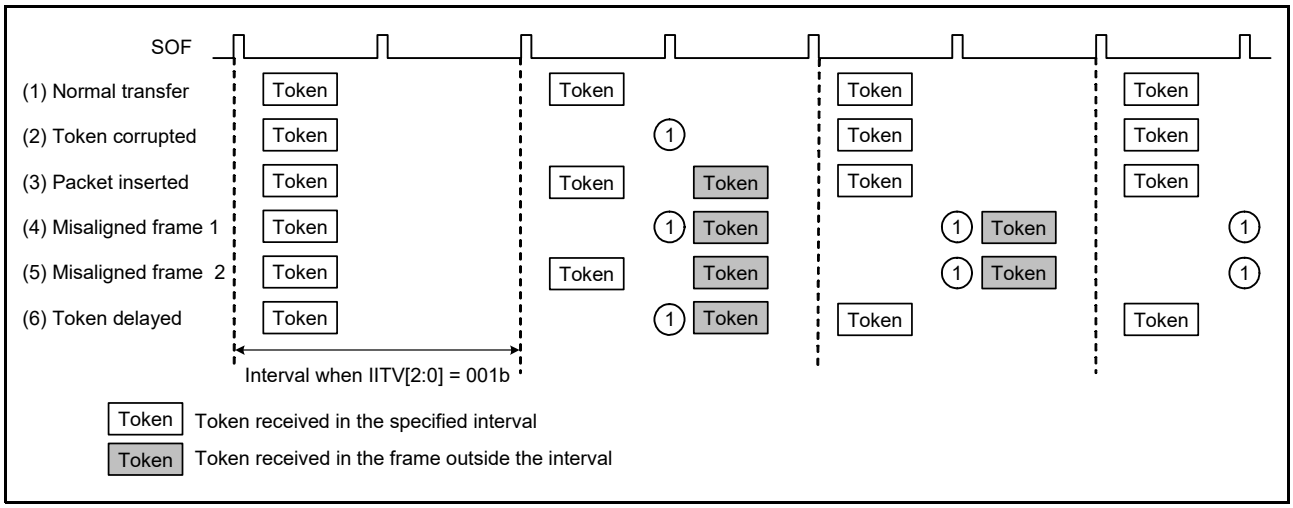

Figure 41.19 Example of Interval Error Occurrence When the PIPEPERI.IITV[2:0] Bits are 001b

41.3.13 SOF Recovery Function

In function controller operation, if an (µ)SOF packet is not received at intervals of 1 ms (full-speed operation) or 125 µs (high-speed operation) due to a corrupted or lost (µ)SOF packet, SOF recovery is made in the controller. The SOF recovery starts working when an (µ)SOF packet is received while the SYSCFG.USBE bit is set to 1 and the LPSTS.SUSPENDM bit is set to 1. The recovery function is initialized under the following conditions.

- MCU reset
- USB bus reset
- Detection of suspension

The SOF recovery function works with the following specifications.

(1) The frame interval (125 µs or 1 ms) follows the reset handshake protocol result.
(2) The recovery function does not work until an (µ)SOF packet is received.
(3) After the first (µ)SOF packet is received, 125 µs or 1 ms is counted by the internal 60-MHz clock to recover (µ)SOF packets.
(4) After the second (or subsequent) (µ)SOF packet is received, (µ)SOF packets are recovered using the previous reception interval.
(5) Recovery is not made during suspension or reception of a USB bus reset.
(In high-speed operation, when transitioning to suspend mode, recovery continues for 3 ms from the last packet.)

The USBHS carries out the following operations when receiving the (µ)SOF packet reception. These operations also operate normally with SOF recovery, if the (µ)SOF packet was missing.

(1) Updating frame number and microframe number
(2) Frame number refresh interrupt and µSOF lock
(3) Isochronous transfer interval count

If an SOF packet is lost during full-speed operation, the FRMNUM.FRNM[10:0] bits are not updated.
If a µSOF packet is lost during high-speed operation, the UFRMNUM.UFRNM[2:0] bits are updated. However, when the UFRNM[2:0] bits are set to 000b and a µSOF packet is lost, the FRNM[10:0] bits is not updated. In this case, even if the next µSOF packet for a UFRNM[2:0] bit value other than 000b is received successfully, the FRNM[10:0] bits are not updated.

41.3.14 Pipe Schedule

41.3.14.1 Conditions for Generating a Transaction

In host controller operation, after the DVSTCTR0.UACT bit has been set to 1, the USBHS generates a transaction under the conditions shown in Table 41.30.

Table 41.30 Conditions for Generating a Transaction

Transaction	Conditions for Generation				
	DIR	PID[1:0]	IITV[2:0]	Buffer State	SUREQ
Setup	— *1	— *1	— *1	— *1	Set 1
Control transfer data stage, status stage, bulk transfer	IN	BUF	— *1	Receive area exists	— *1
	OUT	BUF	— *1	Transmit data exists	— *1
Interrupt transfer	IN	BUF	Valid *2	Receive area exists	— *1
	OUT	BUF	Valid *2	Transmit data exists	— *1
Isochronous transfer	IN	BUF	Valid *2	See Note 3.	— *1
	OUT	BUF	Valid *2	See Note 4.	— *1

Note 1. The hyphen (—) in the table indicates that the condition is unrelated to the generating of tokens.
Note 2. “Valid” indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter.
Note 3. A transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.
Note 4. A transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

41.3.14.2 Transfer Schedule

This section describes the transfer scheduling within a frame of the USBHS. After the USBHS transmits an (µ)SOF packet, the transfer is carried out in the sequence described below.

1. Execution of interrupt transfers and isochronous transfers
   A pipe is searched in the order of Pipe 1 → Pipe 2 → Pipe 6 → Pipe 7 → Pipe 8 → Pipe 9, and then, if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.
2. Setup transactions for control transfers
   If a setup transaction is possible, it is transmitted.
3. Execution of bulk transfers, control transfer data stages, and control transfer status stages
   A pipe is searched in the order of default control pipe → Pipe 1 → Pipe 2 → Pipe 3 → Pipe 4 → Pipe 5, and then, if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.
   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

41.3.14.3 Enabling USB Communication

Setting the DVSTCTR0.UACT bit to 1 initiates (µ)SOF packet transmission and transaction generation is enabled. Setting the UACT bit to 0 stops (µ)SOF packet transmission and the USBHS enters the suspend state. If the setting of the UACT bit is changed from 1 to 0, processing stops after the next (µ)SOF packet is transmitted.

41.3.15 Battery Charging Detection Processing

Data Contact Detect processing (checking D+ line contact), Primary Detection processing (charger detection processing), and Secondary Detection processing (charger determination processing) defined by Battery Charging Specification Revision 1.2 can be controlled.
Section 41.3.15.1 and section 41.3.15.2 describe operations in host controller operation and function controller operation.

41.3.15.1 Processing in Function Controller Operation

To operate a USBHS as a battery charging Portable Device, the following processing is required. Figure 41.20 shows the processing flowchart.

(1) VBUS supply is detected by the VBUS interrupt and VBSTS flag.

(2) Start Primary Detection processing after detecting contact with the D+ and D– lines. Battery Charging Specification Revision 1.2 describes two processing methods for Data Contact Detect. The USBHS supports both methods in the ways described below.

- Software wait
  Perform a 300 to 900 ms software wait
- Detecting contact by hardware
  Apply 7 to 13 µA of current to the D+ line to hold the D+ line at the logical high level. This is done to detect the D+ and D– lines going to the logical low level due to pull-down resistors in the host when the D+ and D– lines come in contact with those of the host. The USBHS sets the BCCTRL.IDPSRCE bit to 1 and sets the D+ line high. When the D+ line is detected as becoming low by the SYSSTS0.LNST[1:0] bits, the BCCTRL.IDPSRCE bit is set to 0.

(3) Set the BCCTRL.VDPSRCE bit and BCCTRL.IDMSINKE bit to 1 simultaneously to start the Primary Detection processing. Then, perform a 40 ms software wait, and check the BCCTRL.CHGDETSTS flag. If the CHGDETSTS flag is 1, it is determined that a charger is detected, and the BCCTRL.VDPSRCE and BCCTRL.IDMSINKE bits are set to 0.

(4) Set the BCCTRL.VDMSRCE bit and BCCTRL.IDPSINKE bit to 1 simultaneously to start the Secondary Detection processing. Then, perform a 40 ms software wait, check the BCCTRL.PDDETSTS flag, and determine the result of the Secondary Detection processing.

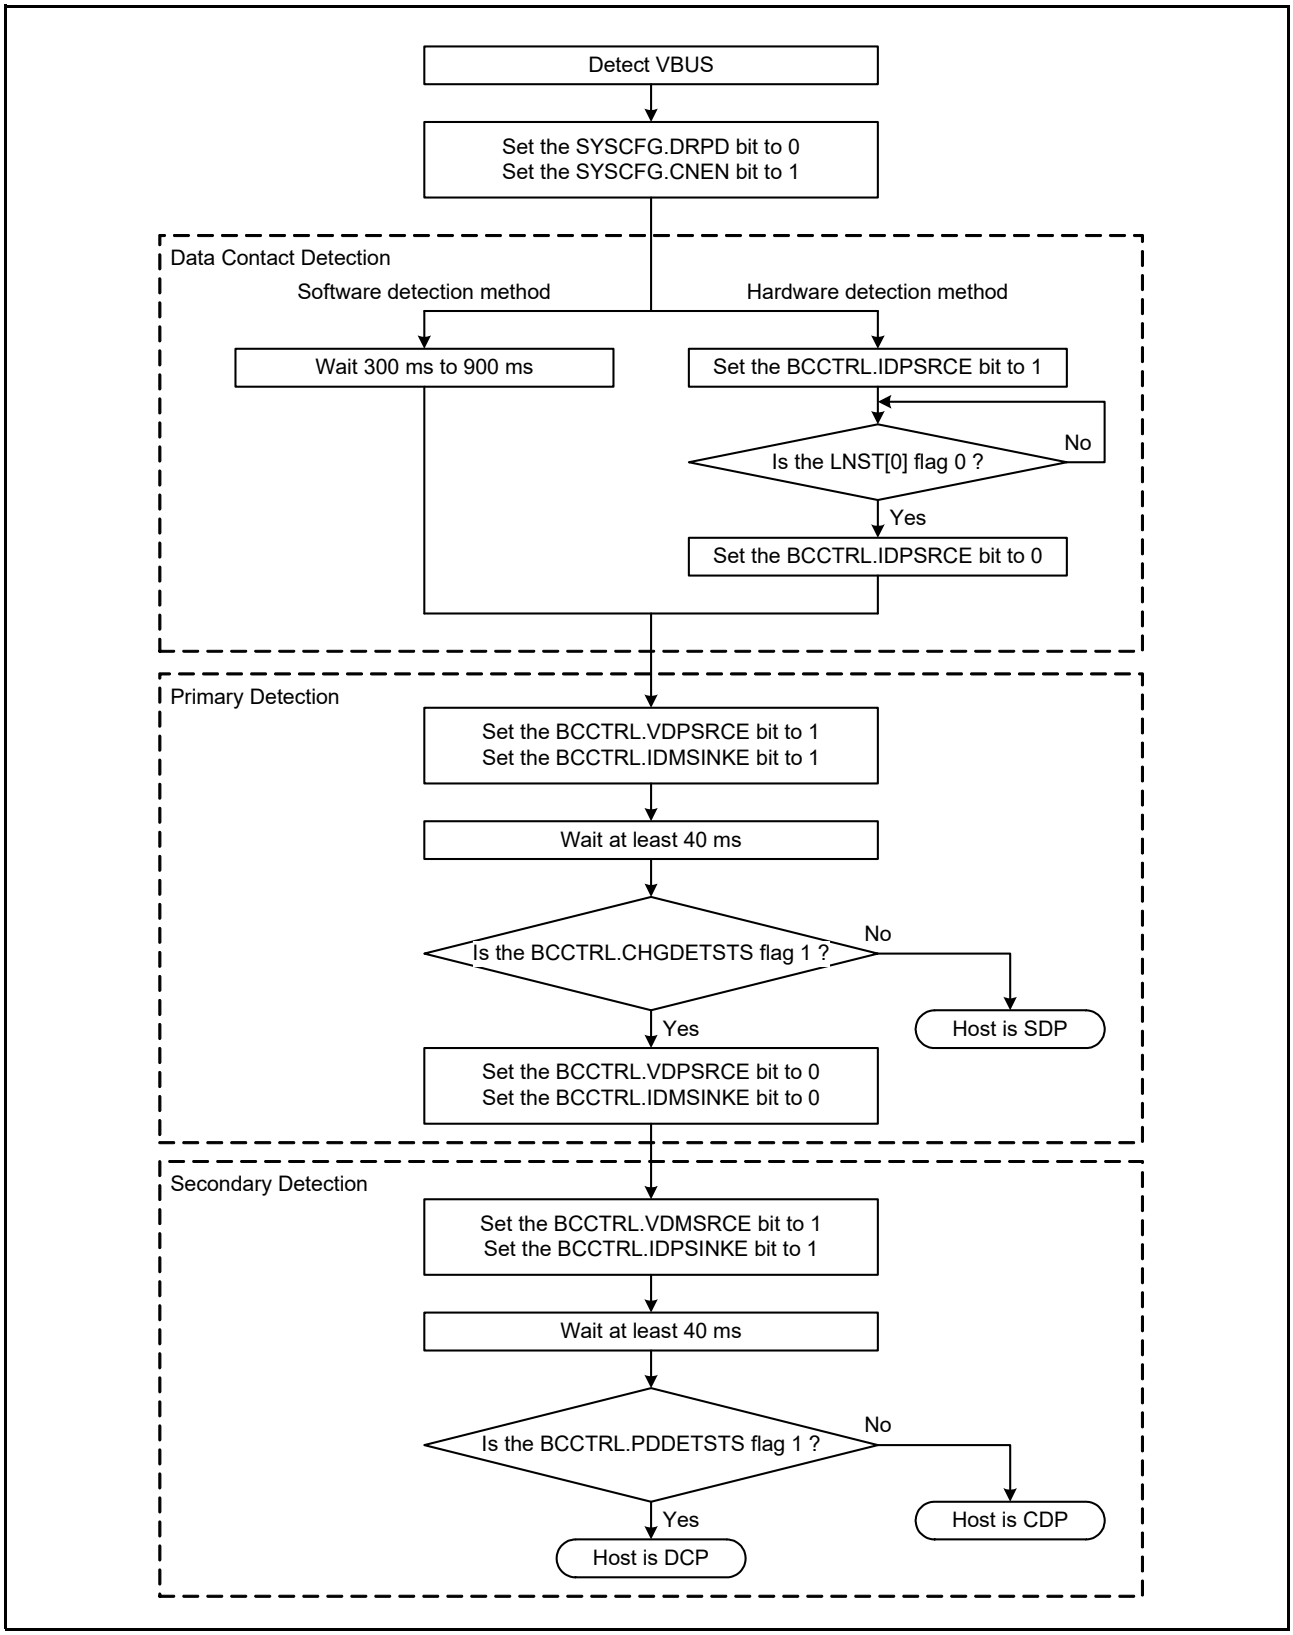

Figure 41.20 Processing as a Portable Device

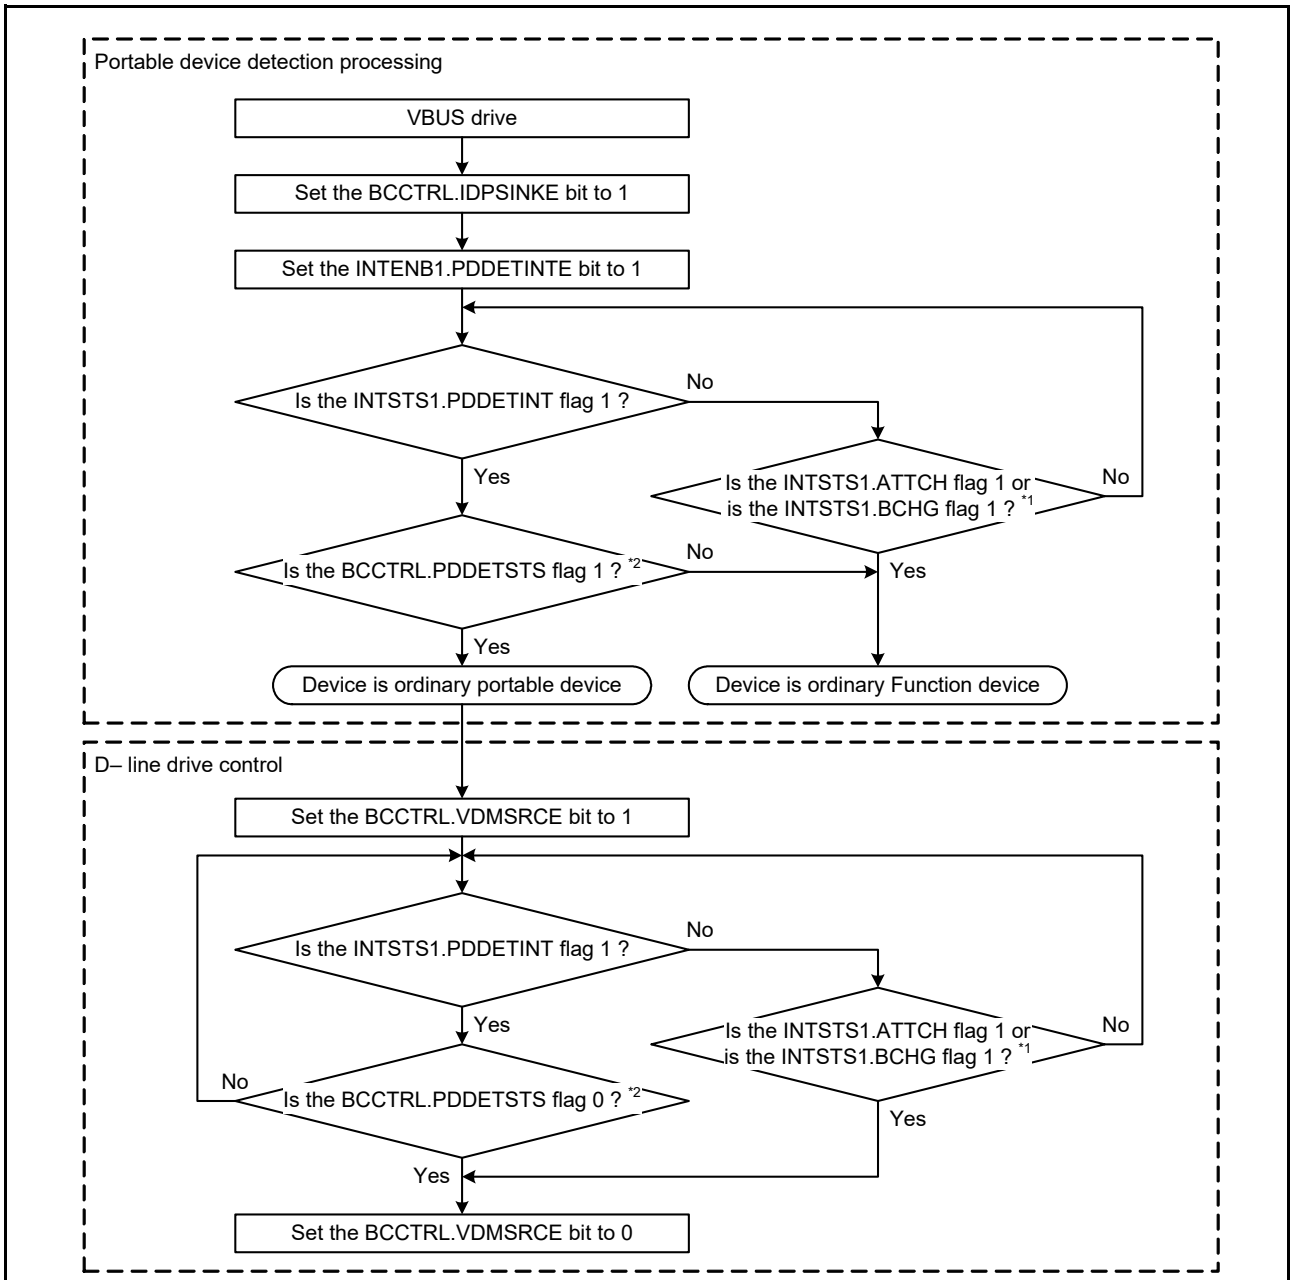
41.3.15.2 Processing in Host Controller Operation



In host controller operation, driving the D– line is required for a Portable Device to implement Primary Detection. Two Primary Detection methods are provided: one for when the hardware has a Portable Device detection function and the other for when the hardware does not have the function or the function is not used even though the hardware has it. Figure 41.21 and Figure 41.22 show processing for the respective methods.

- When using the Portable Device detection function
  The D– line is driven when a Portable Device is detected.

(1) Start driving the VBUS.
(2) Set the BCCTRL.IDMSINKE bit to 1 to enable the Portable Device detection circuit.
(3) Read the BCCTRL.PDDETSTS flag in the Portable Device detection interrupt processing. If the PDDETSTS flag is 1, set the BCCTRL.VDMSRCE bit to 1.
(4) When the BCCTRL.PDDETSTS flag is read in the Portable Device detection interrupt processing after driving the D– line, if the PDDETSTS flag is 0, set the BCCTRL.VDMSRCE bit to 0.

- When not using the Portable Device detection function
  Regardless of whether or not a Portable Device was detected, drive the D– line after device disconnection is detected, and leave the D– line open after connection is detected. Software handles the timing of (1) and (2).

(1) After device disconnection is detected, start driving the D– line within 200 ms.
(2) After device connection is detected, stop driving the D– line within 10 ms.

Note 1. If the PHY clock is being supplied (LPSTS.SUSPENDM bit is 1), the determination is made by the device connection detection interrupt; if the clock is stopped (SUSPENDM bit is 0), the determination is made by the bus change interrupt and the SYSSTS0.LNST[1:0] flags.
Note 2. Read the flag several times to eliminate chattering.

Figure 41.21 Processing Flow When Using the Portable Device Detection Function

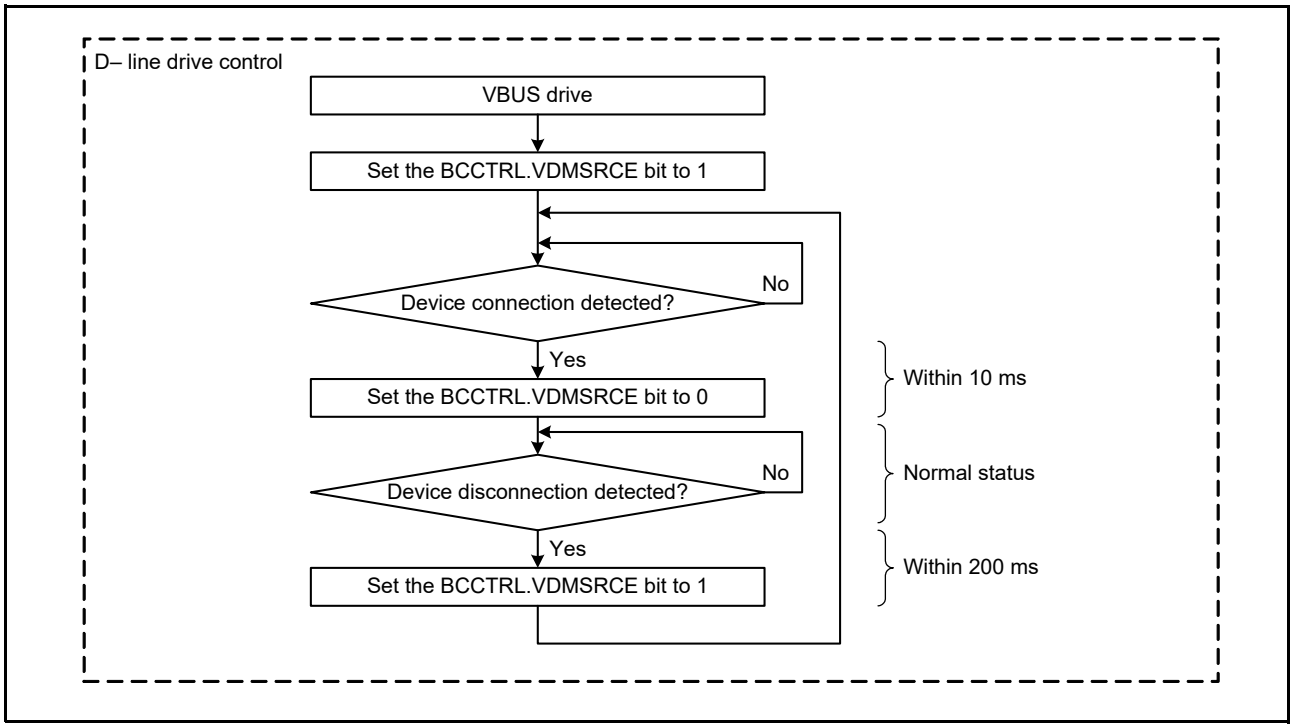


Figure 41.22 Processing Flow When Not Using Portable Device Detection Function

41.3.16 Link Power Management Processing

The Link Power Management standard defines the existing suspended state as the L2 state, and newly defines the L1 state as a state that can be entered into and exited from faster than the L2 state. Table 41.31 is a Comparison of the L1 State and L2 State.

Table 41.31 Comparison of the L1 State and L2 State

Item	L1 State	L2 State
Transition	LPM transaction	Idle for 3 ms
Exit caused by host	(1) Host Drive the K state for a period specified by the HIRD[3:0] bits. Drive period can be specified from 75 µs to 9.96 ms. (2) Function Exits within 10 µs	(1) Host Drive the K state for at least 20 ms (2) Function Exits within 10 ms
Exit caused by function	(1) Function Drive the K state for 50 µs (2) Host Drive the K state for 60 to 990 µs	(1) Function Drive the K state for 1 to 15 ms (2) Host Drive the K state for at least 20 ms
Signaling	Low- and full-speed idle	Low- and full-speed idle
Enabling remote wakeup	Specified by the LPM token	Specified by the SetFeature() request

41.3.16.1 Processing in Function Controller Operation

(1) Contents of the Descriptor

In function controller operation, the USBHS must return its Descriptor when a GetDescriptor() request is received. The content of the Descriptor to be returned must be modified depending on whether the USBHS accepts or denies transition to or exit from the L1 state according to the LPM transaction. Table 41.32 shows the Relationship Between LPM Support and the Descriptor.

Table 41.32 Relationship Between LPM Support and the Descriptor

LPM Support	*bcdUSB* Field	USB 2.0 Extension Descriptor		Response to Received LPM Request	Note
		Provided/ Not provided	LPM bit		
No	0200h	Not provided	—	No response	Normal operation when the LPM is not supported
	0201h	Provided	0	STALL	Setting when it is obvious that LPM is not supported. In this case, a STALL response must be returned.
Yes	0201h	Provided	1	ACK or NYET	Normal operation when the LPM is supported

The LPM bit in USB 2.0 Extension Descriptor declares whether the USBHS accepts or denies transition to or exit from the L1 state. To provide USB 2.0 Extension Descriptor, the *bcdUSB* field of the Standard Device Descriptor must be set to a value of 0201h or larger.

When the LPM is not supported, the USB 2.0 Extension Descriptor is not provided and the *bcdUSB* field value must be 0200h. Even if an LPM token is received in this case, it must be ignored.

When the LPM is not clearly supported, it is also possible to set *bcdUSB* field value to 0201h and the LPM bit in USB 2.0 Extension Descriptor to 0 (no support for the LPM token). In this case, however, the LPM token cannot be ignored and a STALL response must be returned.

When the LPM token is supported, set *bcdUSB* field value to 0201h and set the LPM bit in USB 2.0 Extension Descriptor to 1 (supports the LPM token). This allows acknowledgment of returning a NYET or ACK response to the LPM token.

(2) Processing When Receiving an LPM Token

The following describes the procedure to enter and exit the L1 state in function controller operation.

(1) When the USBHS receives an LPM token from the host, the settings of the PL1CTRL1.L1RESPEN, L1RESPMD[1:0], and L1NEGOMD bits determines whether to return an ACK, NYET, or STALL response, or ignore.

(2) When an LPM token is received and an ACK response is returned, if the LPM token is not retransmitted within 8 µs, the USBHS enters the L1 state. The USBHS processes retransmission of the LPM token and transition to the L1 state. The device state transition interrupt can be used to detect the transition to the L1 state.

(3) There are two types of processing for exiting the L1 state:

- When the host starts the resume:
  When the resume signal is detected, the resume interrupt is generated and the function starts processing to exit the L1 state.
- When the function outputs a remote wakeup signal:
  If the DVSTCTR0.WKUP bit is set to 1, a remote wakeup signal is output to the host. When exiting the L2 state, the DVSTCTR0.WKUP bit must be set to 0 by software, but the USBHS sets the DVSTCTR0.WKUP bit to 0 when exiting from the L1 state.

(3) BESL Field Value Negotiation Function

The BESL field value included in the LPM token is the period that the outputs the resume signal when returning from the L1 state. The BESL field value can be adjusted to accommodate the target system. For example, a low HIRD threshold value must be set for a system that focuses on improving transfer efficiency, while a high HIRD threshold value must be set for a system that focuses on low power consumption.

As per the PL1CTRL1.L1NEGOMD and HIRDTHR[3:0] bit settings, an ACK response or NYET response is returned when the received BESL field value is compared to the HIRD threshold value, and a request can be made to the host to modify the BESL field value.

41.3.16.2 Processing in Host Controller Operation

(1) Processing When Transmitting an LPM Token

The following describes the procedure to enter and exit the L1 state in host controller operation.

(1) When the HL1CTRL1.L1REQ bit is set to 1, an LPM token is transmitted from the host to the function.

(2) If an ACK response is received from the function, a transition to the L1 state starts within 10 µs and is completed within 50 µs. In this case, if a transaction error is detected, the LPM token starts retransmitting within 8 µs. Retransmission can be performed up to two times. The USBHS controls all of this processing.

(3) There are two types of processing for returning from the L1 state.

- When the host starts the resume:
  When the DVSTCTR0.RESUME bit is set to 1, the USBHS starts outputting the resume signal and starts the processing to exit the L1 state.
- When the function outputs a remote wakeup signal:
  When the USBHS detects a remote wakeup signal being output from the function, the USBHS sets the DVSTCTR0.RESUME bit *1 to 1 and starts outputting the resume signal.

Note 1. Unlike exiting from the L2 state, the USBHS sets the DVSTCTR0.RESUME bit to 0. When the RESUME bit becomes 0, the DVSTCTR0.UACT bit becomes 1, and the L1RSMEND interrupt request is generated.

41.3.17 USB External Connection Circuit

Figure 41.23 shows an example of the USB Connector's OTG Connection in Self Powered Mode.
The USBHS controls the pull-up resistor of the D+ line, and the pull-down resistor of the D+ and D– lines. Set the SYSCFG.DPRPU bit and DRPD bit to specify pull-up or pull-down for each line.
In addition, in function control operation, if the DPRPU bit is set to 0 while communicating with the USB host, the pull-up resistor for the USB data line becomes invalid, and the USB host can be notified of a device disconnection.

41.3.18 Release from Deep Software Standby Mode 1 in Response to the USBHS Resume Interrupt

The USBHS has blocks to which power is supplied in deep software standby mode 1. The USBHS resume interrupt generated by these blocks can be used as the trigger for release from deep software standby mode 1. Table 41.33 lists the sources for the USBHS resume interrupt.

Table 41.33 Sources of the USBHS Resume Interrupt

Operating Mode	Source	Interrupt to Be Used	Pins to Be Used
Host	Overcurrent detection	OVRCURA interrupt	USBHS_OVRCURA
OTG	Overcurrent detection	OVRCURA interrupt, OVRCURB interrupt	USBHS_OVRCURA, USBHS_OVRCURB
Function	Attach/Detach	VBUS interrupt	USBHS_VBUS
Host/OTG	Attach/Detach	D+ interrupt, D– interrupt	USBHS_DP, USBHS_DM
Function/OTG	Resume	D+ interrupt	USBHS_DP

Figure 41.27 shows a flow of settings for transition to deep software standby mode 1. Figure 41.28 shows a flow of settings after release from deep software standby mode 1 in host controller operation. Figure 41.29 shows a flow of settings after release from deep software standby mode 1 in function controller operation.

Note: A transition to deep software standby mode 1 while the USBHS module is attached to the USB bus should only proceed in the Suspended state.
Note: Do not allow a transition to deep software standby mode 1 when remote wakeup is enabled in host controller operation.

41.4 Notes on Using the USBHS

41.4.1 Setting the USBHS Module-Stop Function

The USBHS operation can be disabled or enabled by setting the module stop control register B (MSTPCRB). The USBHS is stopped after a reset. Registers in the USBHS can be accessed by releasing the module stop state. Refer to section 11, Low Power Consumption for details.
When operating the PHY circuit after releasing the module stop state, configure settings for items such as the frequency of the PLL clock source (USBMCLK), and then set the PHYSET.DIRPD bit to 0.

41.4.2 Setting to Transition to Deep Software Standby Mode

Before transitioning to deep software standby mode, set the DVSTCTR0.VBUSEN bit to 0.

42. Serial Communications Interface (RSCI)

In this section, “PCLK” is used to refer to PCLKA.

42.1 Overview

RSCI can handle both asynchronous and clock synchronous serial communications. RSCI has 16-stage FIFO buffers in transmission/reception blocks, and it can select the FIFO composition, and it can transmit/receive efficiently, and it can also communicate continuously.

Asynchronous serial data communications can be carried out with standard asynchronous communications chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communications Interface Adapter (ACIA). As an extended function in asynchronous communications mode, the RSCI also supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for identification cards).

The RSCI is also supports serial communication using Manchester code (Manchester mode), simple SPI interfaces, simple I2C-bus interfaces (single master), and extended serial communication.

In addition, asynchronous mode has a support function for generating AMI waveform of negative logic coding with 50% duty cycle used in home bus system (HBS) communications.

Table 42.1 lists the RSCI specifications.

Table 42.1 RSCI Specifications (1/3)

Item	Description
Serial communication modes	• Asynchronous • Manchester • Clock synchronous • Smart card interface • Simple I2C-bus • Simple SPI bus • Extended serial
Operating clock (TCLK)	Selectable from peripheral module clock (PCLKA) or SCI clock (SCICLK)
Transfer speed	Bit rate specifiable with the on-chip baud rate generator.
Full-duplex communications	Transmitter: Continuous transmission possible using double-buffer structure. Receiver: Continuous reception possible using double-buffer structure.
Half-duplex communications	Half-duplex communication is possible by using only TXDn pins
Data transfer	Selectable as LSB first or MSB first transfer
I/O signal level inverting function	Input signal and output signal can be inverted independently.
RXD input path selection	Encoded serial data can be input to RXD2 and RXD3 after having been decoded through GPTW10 and GPTW12, respectively.
TXD output path selection	Serial data output from TXD2 and TXD3 can be encoded through GPTW11 and GPTW13, respectively.
Interrupt sources	Transmit end, transmit data empty, receive data full, receive error, receive data ready, and receive data match Break Field detection/transmission, Bus collision detection, Active edge detection Completion of generation of a start condition, restart condition, or stop condition
RS-485 driver control function	Output DE signal to enable external transceiver transmit mode
Loopback function	Self-diagnosis of communication function is possible by connecting TXD and RXD inside the RSCI
Synchronizer bypass function	Synchronizer is bypassed when the peripheral module clock (PCLKA) is selected for the operating clock (TCLK).
Low power consumption function	Module stop state can be set for each channel.
Protect Zone filter	Security attribute can be set for each channel.*1

Table 42.1 RSCI Specifications (2/3)

Item		Description
Asynchronous mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Parity	Even parity, odd parity, or no parity
	Receive error detection	Parity, overrun, and framing errors
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
	Transmission/Reception	Selectable either 1 stage register or 16-stage FIFO
	Data match detection	The interrupt request can issue by detecting the match between receive data and comparison data.
	Start-bit detection	Low level or falling edge is selectable.
	Receive data sampling timing adjustment	Sampling point of receive data can be changed to front or rear of center of bit.
	Transmit signal transition timing adjustment	Falling or rising edge of the transmit data can be delayed.
	Break detection	When a framing error occurs, a break can be detected by reading the SSR register.
	Clock source	An internal, external, or TMR clock can be selected.
	Double-speed mode	Baud rate generator double-speed mode is selectable.
	Multi-processor communications function	Serial communication among multiple processors
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters.
	HBS support mode	Transmission/reception using inverted RZI (Return to Zero, Inverted) code is possible.
Manchester mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Receive error detection	Parity, overrun, framing, Manchester code errors, preface, start bit, and receive Sync
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission.
	Clock source	Only internal clock can be used. (The setting of external clock is prohibited because it is not the object of operation guarantee.)
	Double-speed mode	Baud rate generator double-speed mode is selectable.
	Multi-processor communications function	Serial communication among multiple processors
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters.
	Manchester encoding/ decoding function	Function to perform Manchester encoding/decoding of transmission/reception data and communicate using Manchester code
	Preface setting/detection function	Function to detect the beginning of a frame from the preface pattern. Preface pattern can be selected from 4 types. The length can also be changed from 0 to 15 bits.
	Start Bit setting/detection function	The Start Bit length can be set to 1 bit or 3 bits. In the case of 3-bit length, it is possible to judge the type of subsequent data with two types of patterns.
	Reception retiming function	Function to perform timing correction for each bit center edge by using Manchester code having edge at bit center
Smart card interface mode	Error processing	An error signal can be automatically transmitted when detecting a parity error during reception
		Data can be automatically retransmitted when receiving an error signal during transmission
	Data type	Both direct convention and inverse convention are supported.

Table 42.1 RSCI Specifications (3/3)

Item		Description
Extended serial mode	Start Frame Transmission	Break Field transmission possible, Break Field transmission complete interrupt output possible Bus collision detection possible, bus collision detection interrupt output possible
	Start Frame Reception	Break Field detectable, Break Field detected interrupt output possible Control Field 0/1 data comparison function Control Field 1 can set two types of comparison data of primary and secondary Priority interrupt bit can be set in Control Field 1 Bit rate measurement function
Simple I2C mode	Transfer format	I2C-bus format
	Operating mode	Master (single-master operation only)
	Transfer rate	Fast mode is supported (refer to section 42.2.7, Control Register 2 (SCR2) o the transfer rate).
	Noise cancellation	The signal paths from input on the SSCLn and SSDAn pins incorporate digital noise filters, and the interval for noise cancellation is adjustable.
Clock synchronous mode	Data length	8 bits
	Receive error detection	Overrun error
	Clock source	An internal clock (master mode) or external clock (slave mode) can be selected.
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Hardware flow control	CTSn# and RTSn# pins can be used in controlling transmission/reception.
	Transmission/Reception	Selectable either 1 stage register or 16-stage FIFO
Simple SPI bus (4-wire serial bus) mode	Data length	8 bits
	Detection of errors	Overrun error
	Clock source	An internal clock (master mode) or external clock (slave mode) can be selected.
	Double-speed mode	Baud rate generator double-speed mode is selectable
	SS input pin function	When the SSn# pin is high level, the output pin can be set to high impedance
	Clock settings	Four kinds of settings for clock phase and clock polarity are selectable.
	Transmission/Reception	Selectable either 1 stage register or 16-stage FIFO
Bit rate modulation function		Correction of outputs from the on-chip baud rate generator can reduce errors.
Event link function		Error (receive error or error signal detection) event output
		Receive data full event output
		Transmit data empty event output
		Transmit end event output
		Receive data match event output
		Receive data unmatch event output
		Active edge detection event output

Note 1. When each channel is set to the secure attribute, registers in the channel are accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When each channel is set to the non-secure attribute, registers in the channel are accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

42.2 Register Descriptions

This chapter describes the RSCI registers, their functional specifications, and their operating specifications.

42.2.1 Receive Shift Register (RSR)

RSR is a shift register which is used to receive serial data input from the RXDn pin and converts it into parallel data. When one frame of data has been received, it is automatically transferred to the RDR register.
The RSR register cannot be directly accessed by the CPU.

42.2.2 Receive Data Register (RDR)

Address(es): RSCI0.RDR 8745 8000h, RSCI1.RDR 8745 8100h, RSCI2.RDR 8745 8200h, RSCI3.RDR 8745 8300h, RSCI4.RDR 8745 8400h, RSCI5.RDR 8745 8500h, RSCI6.RDR 8745 8600h, RSCI7.RDR 8745 8700h, RSCI8.RDR 8745 8800h, RSCI9.RDR 8745 8900h, RSCI10.RDR 8745 8A00h, RSCI11.RDR 8745 8B00h, RSCI12.RDR 8745 8C00h,
RSCI0_NS.RDR 0745 8000h, RSCI1_NS.RDR 0745 8100h, RSCI2_NS.RDR 0745 8200h, RSCI3_NS.RDR 0745 8300h, RSCI4_NS.RDR 0745 8400h, RSCI5_NS.RDR 0745 8500h, RSCI6_NS.RDR 0745 8600h, RSCI7_NS.RDR 0745 8700h, RSCI8_NS.RDR 0745 8800h, RSCI9_NS.RDR 0745 8900h, RSCI10_NS.RDR 0745 8A00h, RSCI11_NS.RDR 0745 8B00h, RSCI12_NS.RDR 0745 8C00h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	RDAT[8:0]	Receive Data	RDAT[8:0] bits are a 9-bit field for storing received data. Received data is stored in [6:0] when 7-bit data is selected, in [7:0] when 8-bit data is selected, and in [8:0] when 9-bit data is selected. And 0 is stored in the unused bit.	R
b9	MPB	Multi-Processor Bit Monitor Flag	0: Data transmission cycles 1: ID transmission cycles	R
b10	DR	Receive Data Ready Flag	RFSR.DR flag can be read.	R
b11	PER	Parity Error Flag	(Valid only in asynchronous mode) 0: There is no parity error in the data read from the receive FIFO 1: There is parity error in the data read from the receive FIFO	R
b12	FER	Framing Error Flag	(Valid only in asynchronous mode) 0: There is no framing error in the data read from the receive FIFO 1: There is framing error in the data read from the receive FIFO	R
b23 to b13	—	Reserved	These bits are read as 0.	R
b24	ORER	Overrun Error Flag	SSR.ORER flag can be read.	R
b26, b25	—	Reserved	These bits are read as 0.	R
b27	APER	Aggregate Parity Error Flag	SSR.APER flag can be read.	R
b28	AFER	Aggregate Framing Error Flag	SSR.AFER flag can be read.	R
b31 to b29	—	Reserved	These bits are read as 0.	R

In FIFO mode (SCR3.FM bit = 1), this register is 16-stage FIFO buffer configuration.

RDAT[8:0] Bits (Receive Data)

After one frame of data is received, the received data is transferred from the RSR register to this registers, thus allowing the RSR register to receive the next data.
The RSR and RDR registers have a double-buffered construction to enable continuous reception.
In non-FIFO mode, read the RDR register only once when a receive data full interrupt (RXI) request is issued. Without reading received data from RDR register, if the next one frame is received, an overrun error occurs.
In FIFO mode, continuous reception is executed until 16 stages are stored. If data is read when there is no received data in the receive FIFO (RDR register), the value is undefined. When the receive FIFO (RDR register) are full of received data, subsequent serial receive data is lost.
The CPU cannot write to RDR register.
0 is stored in the bit position which isn't received (RDAT[8] or RDAT[7]) at the time of 7bit or 8bit communication of asynchronous and Manchester mode.

MPB Flag (Multi-Processor Bit Monitor Flag)

In asynchronous mode and Manchester mode, during multi-processor communication (SCR3.MP bit = 1), the value of the multi-processor bit corresponding to the received data (RDAT[8:0] bits) can be read.

PER Flag (Parity Error Flag)

Indicates whether the data read from the receive FIFO has a parity error.
The FER and PER flags store error information of received data only in FIFO mode. In non-FIFO mode, 0 is stored.

FER Flag (Framing Error Flag)

Indicates whether the data read from receive FIFO has a framing error.
The FER and PER flags store error information of received data only in FIFO mode. In non-FIFO mode, 0 is stored.

42.2.3 Transmit Data Register (TDR)

Address(es): RSCI0.TDR 8745 8004h, RSCI1.TDR 8745 8104h, RSCI2.TDR 8745 8204h, RSCI3.TDR 8745 8304h, RSCI4.TDR 8745 8404h, RSCI5.TDR 8745 8504h, RSCI6.TDR 8745 8604h, RSCI7.TDR 8745 8704h, RSCI8.TDR 8745 8804h, RSCI9.TDR 8745 8904h, RSCI10.TDR 8745 8A04h, RSCI11.TDR 8745 8B04h, RSCI12.TDR 8745 8C04h,

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SYNC	—	—	MPBT	TDAT[8:0]								
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	TDAT[8:0]	Transmit Data	TDAT[8:0] bits are a 9-bit field for setting transmit data. Transmit data is set in [6:0] when 7-bit data is selected, in [7:0] when 8-bit data is selected, and in [8:0] when 9-bit data is selected. When writing the TDR register in 8-bit units, write first to the TDR.LH and then TDR.LL.	R/W
b9	MPBT	Transmit Multi-Processor	Value of the multi-processor bit in the transmission frame. This bit is use in asynchronous and Manchester mode. When writing to this bit when not used, write the initial value. 0: Data transmission cycles 1: ID transmission cycles	R/W
b11, b10	—	Reserved	These bits are read as 1. The write value should be 1.	R
b12	SYNC	Sync Pulse Select	It is valid when MMCR.SBLEN bit = 1 and MMCR.SYNCE bit = 1 in Manchester mode. When writing to this bit when not used, write the initial value. 0: The Start Bit is transmitted as DATA Sync. 1: The Start Bit is transmitted as COMMAND Sync.	R/W
b31 to b13	—	Reserved	These bits are read as 1. The write value should be 1.	R

In FIFO mode (SCR3.FM bit = 1), this register is 16-stage FIFO buffer configuration.

TDAT[8:0] Bits (Transmit Data)

The TDAT[8:0] bits are a 9-bit field for storing transmit data.

When empty space is detected in the TSR register, the transmit data stored in the TDR register is transferred to TSR register, and transmitting is started.

The TSR and TDR registers have a double-buffered construction to realize continuous reception. When the next data to be transmitted is stored in TDR register after one frame of data has been transmitted, the transmitting operation is continued by transfer to the TSR register.

In non-FIFO mode, the TDR register is always readable and writable by the CPU. When a transmit data empty interrupt (TXI) request is issued and SCR0.TE bit is 1, write transmit data to the TDR register only once.

In FIFO mode, continuous serial transmission is executed until there is no transmit data left in the transmit FIFO (TDR register). When transmit FIFO is full of transmit data (16 frames), no more data can be written. If writing of new data is attempted, the data is ignored.

When writing the TDR register in 8-bit units, write first to the TDR.LH and then the TDR.LL.

MPBT Bit (Transmit Multi-Processor)

Selects the multi-processor bit of transmit frame.

SYNC Bit (Sync Pulse Select)

This bit is valid when the MMCR.SYNCE and MMCR.SBLEN bits are set to 1 in Manchester mode (SCR3.MOD[2:0] bits = 101b).

The Sync type of start bit area in the transmission frame can be set to Data Sync or Command Sync.

42.2.4 Transmit Shift Register (TSR)

TSR register is a shift register that transmits serial data. TSR register cannot be directly accessed by the CPU.

To perform serial data transmission, the SCI first automatically transfers transmit data from TDR register to TSR register, and then sends the data to the TXDn pin.

42.2.5 Control Register 0 (SCR0)

Address(es): RSCI0.SCR0 8745 8008h, RSCI1.SCR0 8745 8108h, RSCI2.SCR0 8745 8208h, RSCI3.SCR0 8745 8308h, RSCI4.SCR0 8745 8408h, RSCI5.SCR0 8745 8508h, RSCI6.SCR0 8745 8608h, RSCI7.SCR0 8745 8708h, RSCI8.SCR0 8745 8808h, RSCI9.SCR0 8745 8908h, RSCI10.SCR0 8745 8A08h, RSCI11.SCR0 8745 8B08h, RSCI12.SCR0 8745 8C08h,
RSCI0_NS.SCR0 0745 8008h, RSCI1_NS.SCR0 0745 8108h, RSCI2_NS.SCR0 0745 8208h, RSCI3_NS.SCR0 0745 8308h, RSCI4_NS.SCR0 0745 8408h, RSCI5_NS.SCR0 0745 8508h, RSCI6_NS.SCR0 0745 8608h, RSCI7_NS.SCR0 0745 8708h, RSCI8_NS.SCR0 0745 8808h, RSCI9_NS.SCR0 0745 8908h, RSCI10_NS.SCR0 0745 8A08h, RSCI11_NS.SCR0 0745 8B08h, RSCI12_NS.SCR0 0745 8C08h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RE	Receive Enable	0: Serial reception is disabled 1: Serial reception is enabled	R/W *1, *2
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	TE	Transmit Enable	0: Serial transmission is disabled 1: Serial transmission is enabled	R/W *1
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	MPIE	Multi-Processor Interrupt Enable	(Valid in asynchronous mode and Manchester mode when SCR3.MP is 1.) This bit should set 0 in smart card interface mode. 0: Non-multi-processor reception 1: Multi-processor reception When the data with the multi-processor bit set to 0 is received, the data is not read, and setting the status flags to 1 is disabled. When the data with the multiprocessor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and non-multi-processor reception is resumed. If you want to continue receiving operation using the multiprocessor function, set this bit to 1 sufficiently earlier than receiving the STOP bit of the next received frame.	R/W *3
b9	DCME	Data Compare Match Enable	(Valid only in asynchronous mode) 0: Data match detection function is disabled 1: Data match detection function is enabled	R/W *3
b10	IDSEL	ID Frame Select	(Valid only in asynchronous mode with multi-processor) 0: It's always compared data in spite of the value of the multi-processor bit. 1: It's compared data when the multi-processor bit is 1 (ID frame) only.	R/W *4
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	RIE	Receive Interrupt Enable	0: RXI and ERI interrupt requests are disabled 1: RXI and ERI interrupt requests are enabled	R/W
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	TIE	Transmit Interrupt Enable	0: TXI interrupt request is disabled 1: TXI interrupt request is enabled	R/W
b21	TEIE	Transmit End Interrupt Enable	This bit should set 0 in smart card interface mode. 0: TEI interrupt request is disabled 1: TEI interrupt request is enabled	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R

Bit	Symbol	Bit Name	Description	R/W
b24	SSE	SSn# Pin Function Enable	(Valid in simple SPI mode.) In slave mode (SCR3.CKE[1:0] bits = 1xb), set this bit to 1. 0: SSn# pin function is disabled. 1: SSn# pin function is enabled.	R/W *4
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. In clock synchronous mode (SCR3.MOD[2:0] bits = 010b), simple SPI mode (SCR3.MOD[2:0] bits = 011b), and simple I2C mode (SCR3.MOD[2:0] bits = 100b), 1 can be written only when TE bit = 0 and RE bit = 0. After setting TE bit or RE bit to 1, only 0 can be written in TE bit and RE bit. In other mode, writing is enabled under any condition.
Note 2. In clock synchronous mode and simple SPI mode, receive only setting with internal clock (master mode) is prohibited (TE bit = 0 and RE bit = 1 setting prohibited).
Note 3. This bit is a bit that is cleared by hardware. Note that writing to a bit other than this bit with a bit manipulation instruction may cause this bit to be unintentionally set to 1 by a read-modify-write operation.
Note 4. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

RE Bit (Receive Enable)

Enables or disables serial receive operation.

When this bit is set to 1, serial reception starts when RSCI detects the start bit in synchronous mode, the falling edge of the RXD input in Manchester mode, the synchronous clock input in clock synchronous mode, or the start bit in smart card interface mode.

Note that the SCR0 and SCR3 registers should be set prior to setting the RE bit to 1 in order to designate the reception format.

Except smart card interface mode, even if reception is halted by setting the RE bit to 0, the SSR.RDRF, AFER, APER, ORER, MMSR.MCER, SBER, SYER, and PFER flags in non-FIFO mode, and RFSR.DR flag in FIFO mode are not affected and the previous values is retained. In smart card interface mode, even if reception is halted by setting the RE bit to 0, the SSR.AFER, APER, and ORER flags are not affected and the previous value is retained.

TE Bit (Transmit Enable)

Enables or disables serial transmission.

When this bit is set to 1, serial transmission becomes possible. Transmission is started by writing transmit data to TDR register. Note that SCR3 should be set prior to setting the TE bit to 1 in order to designate the transmission format.

MPIE Bit (Multi-Processor Interrupt Enable)

When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags (SSR.RDRF, ORER, AFER, RFSR.DR, MMSR.MCER, SYER, PFER, SBER) are not set.

When the data with the multi-processor bit set to 1 is received, the MPIE is automatically cleared to 0, and normal reception is resumed. For details, refer to section 42.4, Multi-Processor Communication Function. If you want to continue receiving operation using the multiprocessor function, set this bit to 1 sufficiently earlier than receiving the STOP bit of the next received frame.

When the receive data includes the multi-processor bit set to 0, the receive data is not transferred from the RSR register to the RDR register, a receive error is not detected, and setting the flags ORER and AFER, MCER, SYER, PFER, and SBER to 1 is disabled.

When the receive data includes the multi-processor bit set to 1, the MPB flag is set to 1, the MPIE bit is automatically set to 0, the RXI and ERI interrupt requests are enabled (if SCR0.RIE bit is set to 1), and setting the flags ORER, AFER, MCER, SYER, PFER, and SBER to 1 is enabled.

MPIE should be set to 0 if multi-processor communications function is not to be used.

DCME Bit (Data Compare Match Enable)

It can select whether the data match detection function uses or not.

When DCME bit is 1, if RSCI detects the match to the comparison data (SCR4.CMPD[8:0] bits) with receive data, DCME bit is cleared automatically, and after that, RSCI operation mode will be receive mode without data match

detection function.
Refer to section 42.3.6, Data Match Detection.
The write value should be 0 other than asynchronous mode.

IDSEL Bit (ID Frame Select)

This bit specifies the condition of the received data to be compared. The bit is valid only when the DCME bit is 1.
When setting this bit to 1, only data in received frames (ID frames) in which the multi-processor bit has the value 1 are compared.
When this bit is set to 0, all received data is compared.

RIE Bit (Receive Interrupt Enable)

Enables or disables RXI and ERI interrupt requests.
RXI and ERI interrupt request is disabled by setting the RIE bit to 0.
An ERI interrupt request can be canceled by reading 1 from the SSR.ORER, AFER, or APER flag and then setting the flag to 0, or setting the RIE bit to 0.
In the case of Manchester mode, the MMSR.MCER, SYER, PFER, and SBER flags are also the cause of ERI interrupt request, so the same processing is necessary. For details of these flags, see section 42.2.12, Manchester Mode Control Register (MMCR) and section 42.2.21, Manchester Mode Status Register (MMSR).

TIE Bit (Transmit Interrupt Enable)

Enables or disables TXI interrupt request.
An TXI interrupt request is disabled by setting the TIE bit to 0. At the beginning of transmission, set 1 to SCR0.TE bit and SCR0.TIE bit simultaneously. Then the TXI interrupt request is generated.

TEIE Bit (Transmit End Interrupt Enable)

T Enables or disables a TEI interrupt request.
A TEI interrupt request is disabled by setting the TEIE bit to 0.
In simple I^2C mode, the TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STI). In this case, the TEIE bit can be used to enable or disable the STI.

SSE Bit (SSn# Pin Function Enable)

Set this bit to 1 if the SSn# pin is to be used in control of transmission and reception (in simple SPI mode). Set this bit to 0 in any other mode. Do not set both the SSE and CTSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).
In the slave mode (SCR3.CKE[1:0] bits = 10b or 11b), SSE should be set 1.
In the master mode (SCR3.CKE[1:0] bits = 00b or 01b) and single-master, the SSn# pin on the master side is not required to control reception and transmission, so SSE should be set 0.

42.2.6 Control Register 1 (SCR1)

Address(es): RSCI0.SCR1 8745 800Ch, RSCI1.SCR1 8745 810Ch, RSCI2.SCR1 8745 820Ch, RSCI3.SCR1 8745 830Ch, RSCI4.SCR1 8745 840Ch, RSCI5.SCR1 8745 850Ch, RSCI6.SCR1 8745 860Ch, RSCI7.SCR1 8745 870Ch, RSCI8.SCR1 8745 880Ch, RSCI9.SCR1 8745 890Ch, RSCI10.SCR1 8745 8A0Ch, RSCI11.SCR1 8745 8B0Ch, RSCI12.SCR1 8745 8C0Ch,

Bit	Symbol	Bit Name	Description	R/W
b16	LOOP	Loopback Mode Setting	It can be used when internal clock operation in asynchronous mode, internal mode operation in Manchester mode, internal clock operation in clock synchronous mode. 0: Normal mode 1: Loopback mode	R/W *1
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	HDSEL	Half-Duplex Communication Select	In the smart card interface mode, the simple I2C mode, or in the simple SPI mode, this bit should be set 0. 0: TXDn pin, RXDn pin independent 1: TXDn/RXDn pin combination use (Half-duplex communication using TXDn pin)	R/W *1
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R
b26 to b24	NFCS[2:0]	Noise Filter Clock Select	(Valid in asynchronous mode and Manchester mode, extended serial mode, and simple I2C mode.) Select for the noise filter's clock source. b26 b24 0 0 0: The base clock signal divided by 1. 0 0 1: The on-chip baud rate generator source clock*6 divided by 1. 0 1 0: The on-chip baud rate generator source clock*6 divided by 2. 0 1 1: The on-chip baud rate generator source clock*6 divided by 4. 1 0 0: The on-chip baud rate generator source clock*6 divided by 8. Settings other than above are prohibited. In simple I2C mode, 000b setting is prohibited. “The on-chip baud rate generator source clock” means the clock selected by SCR2.CKS[1:0] bits.	R/W *1
b27	—	Reserved	This bit is read as 0. The write value should be 0.	R
b28	NFEN	Digital Noise Filter Enable	(Valid in asynchronous mode, Manchester mode, extended serial mode and simple I2C) In asynchronous mode, Manchester mode and extended serial mode 0: Noise cancellation function for the RXDn input signal is disabled. 1: Noise cancellation function for the RXDn input signal is enabled. In simple I2C mode 0: Noise cancellation function for the SSCLn and SSDAn input signals is disabled. 1: Noise cancellation function for the SSCLn and SSDAn input signals is enabled.	R/W *1
b29	NFM	Digital Noise Filter Mode	(Valid in asynchronous mode with the SCR2.ABCSE2 bit set to 1) 0: Three times match mode 1: Majority mode	R/W *1
b31 to b30	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.
Note 2. This bit is available in asynchronous mode and Manchester mode. Set this bit to 0 in other mode.
Note 3. When the alternate output is enabled in HBS support mode.
Note 4. Use this bit in asynchronous mode and Manchester mode only. Movement by other mode isn’t guaranteed.
Note 5. The RINV and TINV bits should be set to 0 in smart card interface mode and simple I2C mode.
Note 6. The clock is selected by the SCR2.CKS[1:0] bits.

CTSE Bit (CTS Enable)

Set this bit to 1 if the SSn# pin is to be used for inputting of the CTS control signal to control of transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, simple I2C mode, and extended serial mode. Do not set both the CTSE and SSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

CRSEP Bit (CTS/RTS Separation)

This bit selects usage of the CTSn#, RTSn#, and CTSn#/RTSn# pins when the CTSE bit is 1.
When either CTS or RTS function is to be used, set this bit to 0.
When both CTS and RTS functions are to be used, set this bit to 1.
When the CTSE bit is set to 0, set this bit to 0.
Refer to Table 42.6 for the relationship between the CRSEP and CTSE bit settings and the pin functions.

Table 42.6 Relationship between the CRSEP and CTSE Bit Settings and Pin Functions

CTSE Bit	CRSEP Bit	CTSn#/RTSn# Multiplexed Pin	CTSn# Dedicated Pin	RTSn# Dedicated Pin
0	0	RTSn# signal output	Disabled	RTSn# signal output
1	0	CTSn# signal input	CTSn# signal input	Disabled
1	1	RTSn# signal output	CTSn# signal input	RTSn# signal output

SPB2DT Bit (Serial Port Break Data), SPB2IO Bit (Serial Port Break I/O)

The TXDn (TXDAn/TXDBn) pins status decided by combination of SCR0.TE bit, SCR1.SPB2IO bit and SCR1.SPB2DT bit is indicated in Table 42.7.

Table 42.7 Controlling the TXDn (TXDAn/TXDBn) Pins

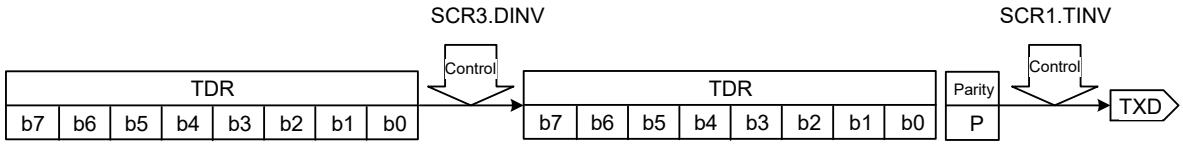
SCR0.TE Bit Setting	SCR1.SPB2IO Bit Setting	SCR1.SPB2DT Bit Setting	TINV Bit Setting	TXDn Pin Status
0 (Transmission disabled)	0 (Input)	0 or 1	0 or 1	Hi-Z
	1 (Output)	0	0	Low is output
			1	High is output
		1	0	High is output
			1	Low is output
1 (Transmission enabled)	0 or 1	0 or 1	0 or 1	Transmit data output pin

PE Bit (Parity Enable)

When PE bit to 1, the parity bit is added to transmit data before transmission, and the parity bit is checked in reception. In the multiprocessor format, the parity bit is not added or checked regardless of this bit setting.

PM Bit (Parity Mode)

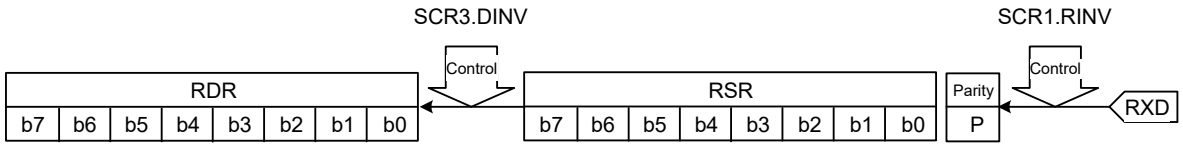
Selects the parity mode for transmission and reception (even or odd). In multi-processor mode, this bit is invalid.
For details on the usage of this bit in smart card interface mode, refer to section 42.7.2, Data Format (Except in Block Transfer Mode).



TINV Bit (Transmitter Output Invert), RINV Bit (Receiver Input Invert)

The data of RDR register is controlled by RINV bit and SCR3.DINV bit. And the data from TXDn pin is controlled by TINV bit and SCR3.DINV bit. The control by RINV/TINV bits are done to communication pins (RXDn/TXDn), so they can control not only data bits but also other bits (start bit, stop bit, parity bit). Please refer to Figure 42.2 in detail. When the TXDAn/TXDBn pins are used, the data is also inverted according to the TINV value.
During half-duplex communication and slave operation in simple SPI mode, use the TXDn pin for reception, so set the inversion control of the received data with the TINV bit.

Note: Sentences and a timing chart of the RSCI operation explanation are mentioned by TINV bit = 0 and RINV bit = 0 when TINV's value and RINV's value are not specified.



The receive/transmit data control (Data size = 8bits, Even parity, MSB first)

The transmit data is controlled by SCR1.TINV and SCR3.DINV.

SCR3. DINV	SCR1. TINV	TDR	TSR	Parity (even)	TXDn waveform
0	0	BEh	BEh	0	
0	1	BEh	BEh	0	
1	0	BEh	41h	0	
1	1	BEh	41h	0	

The received data is controlled by SCR1.RINV and SCR3.DINV.

SCR3. DINV	SCR1. RINV	RDR	RSR	Parity (even)	RXDn waveform
0	0	BEh	BEh	0	
1	0	41h	BEh	0	
0	1	BEh	BEh	0	
1	1	41h	BEh	0	

Figure 42.2 Example of the Receive/Transmit Data Control

LOOP Bit (Loopback Mode Setting)

When this bit is 1, RSCI blocks the input path from RXD and connects the output path to TXD to the reception data register.
Transmit data can be inverted and received by combining it with TINV bit.
Clock synchronous mode Set to 0 at slave operation and asynchronous mode use of external clock, and extended serial mode.

HDSEL Bit (Half-Duplex Communication Select)

Setting this bit to 1 enables half-duplex communication using the TXDn pin. However, it cannot be used in simple SPI mode, simple I^2C mode and smart card interface mode.
If this bit is set to 1 and SCR0.TE bit = 1, SCR0.RE bit = 0, the TXDn pin becomes communication output. If this bit is set to 1 and SCR0.TE bit = 0, SCR0.RE bit = 1, the TXDn pin becomes the communication input. For details, see section 42.16, Half-Duplex Communication Function.

NFCS[2:0] Bits (Noise Filter Clock Select)

These bits select the sampling clock for the digital noise filter.
To use the noise filter in asynchronous mode, Manchester mode and extended serial mode set these bits from 000b to 100b. In simple I^2C mode, set the bits to a value in the range from 001b to 100b.

NFEN Bit (Digital Noise Filter Enable)

This bit enables or disables the digital noise filter function. When the function is enabled, noise cancellation is applied to the RXDn input signal in asynchronous mode, Manchester mode, extended serial mode, and noise cancellation is applied to the SSDAn and SSCLn input signals in simple I^2C mode. In any mode other than above, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as is, as internal signals.

NFM Bit (Digital Noise Filter Mode)

This bit selects the operation mode of the digital noise filter function. Normally, set this bit to 0. When the SCR2.ABCSE2 bit is set to 1 in asynchronous mode, set this bit to 1.

42.2.7 Control Register 2 (SCR2)

Address(es): RSCI0.SCR2 8745 8010h, RSCI1.SCR2 8745 8110h, RSCI2.SCR2 8745 8210h, RSCI3.SCR2 8745 8310h, RSCI4.SCR2 8745 8410h, RSCI5.SCR2 8745 8510h, RSCI6.SCR2 8745 8610h, RSCI7.SCR2 8745 8710h, RSCI8.SCR2 8745 8810h, RSCI9.SCR2 8745 8910h, RSCI10.SCR2 8745 8A10h, RSCI11.SCR2 8745 8B10h, RSCI12.SCR2 8745 8C10h,

b21, b20	CKS[1:0]	Clock Select	b21 b20 0 0: TCLK (n = 0)*4 0 1: TCLK/4 (n = 1)*4 1 0: TCLK/16 (n = 2)*4 1 1: TCLK/64 (n = 3)*4	R/W *1
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31 to b24	MDDR[7:0]	Modulation Duty Setting	MDDR[7:0] bits corrects the bit rate adjusted by the BRR[7:0] bits.	R/W *1

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.
Note 2. S is the value of S in BRR[7:0] bits explanation.
Note 3. Do not set both the ABCSE and ABCSE2 bits to 1 at the same time.
Note 4. n is the decimal notation of the value of n in BRR[7:0] bits explanation.

BCP[2:0] Bits (Base Clock Pulse)

These bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode.
For details, refer to section 42.7.4, Receive Data Sampling Timing and Reception Margin.

BGDM Bit (Baud Rate Generator Double-Speed Mode Select)

This bit is valid when the on-chip baud rate generator is selected as the clock source (SCR3.CKE[1] bit = 0) in asynchronous mode, Manchester mode, clock synchronous mode, simple SPI mode. When external clock is selected (SCR3.CKE[1] bit = 1), set it to 0. For the clock output from the baud rate generator, either single or doubled frequency can be selected. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.
Set this bit to 0 in modes other than asynchronous mode or Manchester mode or clock synchronous mode or simple SPI.

ABCS Bit (Asynchronous Mode Base Clock Select)

Selects the clock cycles for 1-bit period.
Set it to 0 in modes other than asynchronous mode, Manchester mode and extended serial mode.

ABCSE Bit (Asynchronous Mode Base Clock Select Extended)

The pulse number for a base clock at 1-bit period is 6 and the clock of a double frequency is output from baud rate generator. Only when the bit rate is set to 6 dividing frequency of the bus clock, please use this bit and set SCR2.CKS[1:0] bits = 00b and BRR[7:0] bits = 0.
Set it to 0 in modes other than asynchronous mode. Even in asynchronous mode, set it to 0 when using external clock.

ABCSE2 Bit (Asynchronous Mode Base Clock Select Extended 2)

The pulse number for a base clock at 1-bit period is 4 and the clock of a double frequency is output from baud rate generator. Only when the bit rate is set to 4 dividing frequency of the bus clock, please use this bit and set SCR2.CKS[1:0] bits = 00b and BRR[7:0] bits = 0.
Set it to 0 in modes other than asynchronous mode. Even in asynchronous mode, set it to 0 when using external clock.

Table 42.8 Base Clock Cycle Number per 1-Bit Period

ABCSE2 Bit	ABCSE Bit	ABCS Bit	BGDM Bit	Number of Base Clocks Per 1-Bit Period	The Output Frequency of the Baud Rate Generator
0	0	0	0	16	×1
0	0	0	1	16	×2
0	0	1	0	8	×1
0	0	1	1	8	×2
0	1	0 or 1	0 or 1	6	×2
1	0	0 or 1	0 or 1	4	×2

BRR[7:0] Bits (Bit Rate Setting)

BRR[7:0] bits are an 8-bit field that adjusts the bit rate.

RSCI has independent baud rate generator control, different bit rates can be set for each. Table 42.9 shows the relationship between the setting (N) in the BRR[7:0] bits and the bit rate (B) for asynchronous mode, multiprocessor transfer, Manchester mode, clock synchronous mode, smart card interface mode, simple SPI mode, and simple I^2C mode.

Table 42.9 Relationship between N Setting in BRR[7:0] Bits and Bit Rate B

Mode	SCR2 Settings				BRR[7:0] Bit Setting	Error (%)
	BGDM bit	ABCS bit	ABCSE bit	ABCSE2 bit		
Asynchronous, multi-processor communication, Manchester*1, extended serial*2	0	0	0	0	$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{TCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	1	0	0	0	$N = \frac{TCLK \times 10^6}{32 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{TCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	0	1	0	0		
	1	1	0	0	$N = \frac{TCLK \times 10^6}{16 \times 2^{2n-1} \times B} - 1$	$Error = \left\{ \frac{TCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	0 or 1	0 or 1	1	0	N = 0*3	$Error = \left\{ \frac{TCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	0 or 1	0 or 1	0	1	N = 0*3	$Error = \left\{ \frac{TCLK \times 10^6}{B \times 8 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
Clock synchronous, simple SPI	0	0	0	0	$N = \frac{TCLK \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	
	1	0	0	0	$N = \frac{TCLK \times 10^6}{4 \times 2^{2n-1} \times B} - 1$	
Smart card interface					$N = \frac{TCLK \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$Error = \left\{ \frac{TCLK \times 10^6}{B \times S \times 2^{2n+1} \times (N+1)} - 1 \right\} \times 100$
Simple I^2C*4					$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	

B: Bit rate (bps)

N: BRR[7:0] bit setting ($0 \le N \le 255$)

TCLK: Operating frequency (MHz)

n and S: Determined by the settings of the SCR2 registers as listed in the table below.Please be careful about "$2^{(2n+1)}$" is used in the expression for smart card interface, "$2^{(2n-1)}$" is used in other mode.

Note 1. In Manchester mode, set the ABCSE and ABCSE2 bits to 0.
Note 2. In extended serial mode, set the BGDM, ABCSE, and ABCSE2 bits to 0.
Note 3. When the ABCSE or ABCSE2 bit is set to 1, set N = 0 and n = 0.
Note 4. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I2C mode satisfy the I2C standard.

Table 42.10 Calculating Widths at High and Low Level for SCL

Mode	SCL	Formula (Result in Seconds)
I2C	High period (minimum value)	$(N+1)\times 4\times 2^{2n-1}\times 7\times \frac{1}{TCLK\times 10^{6}}$
	Low period (minimum value)	$(N+1)\times 4\times 2^{2n-1}\times 8\times \frac{1}{TCLK\times 10^{6}}$

Table 42.11 Clock Source Settings

SCR2 Setting		
CKS[1:0] Bits	Clock Source	n
0 0	TCLK	0
0 1	TCLK/4	1
1 0	TCLK/16	2
1 1	TCLK/64	3

Table 42.12 Base Clock Settings in Smart Card Interface Mode

SCR2 Setting		
BCP[2:0] Bits	Base Clock Cycles for 1-bit Period	S
0 0 0	93 clock cycles	93
0 0 1	128 clock cycles	128
0 1 0	186 clock cycles	186
0 1 1	512 clock cycles	512
1 0 0	32 clock cycles	32
1 0 1	64 clock cycles	64
1 1 0	372 clock cycles	372
1 1 1	256 clock cycles	256

Table 42.13 and Table 42.14 list examples of N settings in BRR[7:0] in asynchronous mode and Manchester mode. Table 42.15 lists the maximum bit rate settable for each operating frequency. Examples of BRR[7:0] bits (N) settings in clock synchronous mode and simple SPI mode are listed in Table 42.18. Examples of BRR[7:0] bits (N) settings in smart card interface mode are listed in Table 42.20. Examples of BRR[7:0] bits (N) settings in simple I2C mode are listed in Table 42.22. In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, refer to section 42.7.4, Receive Data Sampling Timing and Reception Margin. Table 42.16 and Table 42.19 list the maximum bit rates with external clock input. Table 42.17 shows the maximum bit rate with TMR clock input.

When either the asynchronous mode base clock select bit (ABCS) or the baud rate generator double-speed mode select bit (BGDM) is set to 1 in asynchronous mode and Manchester mode, the bit rate becomes twice that listed in Table 42.13 and Table 42.14. When both of those registers are set to 1, the bit rate becomes four times the listed value.

Table 42.13 Examples of BRR[7:0] Bit Settings for Various Bit Rates (Asynchronous Mode and Manchester Mode) (1)

31250	0	13	0.00	0	15	0.00	0	16	1.20	0	17	0.00	0	19	–1.70
38400	—	—	—	0	12	0.16	0	13	0.00	0	14	–2.34	0	15	0.00

Note: This is an example when the SCR2.ABCS bit = 0, SCR2.BGDM bit = 0, SCR2.ABCSE bit = 0, and SCR2.ABCSE2 bit = 0.
When either ABCS bit or BGDM bit is set to 1, the bit rate doubles.
When both ABCS bit = 1 and BGDM bit = 1, the bit rate increases four times.

Note: This is an example when the SCR2.ABCS bit = 0, SCR2.BGDM bit = 0, SCR2.ABCSE bit = 0, and SCR2.ABCSE2 bit = 0.
When either ABCS bit or BGDM bit is set to 1, the bit rate doubles.
When both ABCS bit = 1 and BGDM bit = 1, the bit rate increases four times.

BRME Bit (Bit Rate Modulation Enable)

Enables and disables the bit rate modulation function. The bit rate generated by on-chip baud rate generator is evenly corrected when this function is enabled.

This bit can only be set to 1 in asynchronous mode and simple I²C mode. Set this bit to 0 in clock synchronous mode, simple SPI mode, smart card interface mode, Manchester mode, and extended serial mode. Also, Set this bit to 0 when the ABCSE2 bit is set to 1.

CKS[1:0] Bits (Clock Select)

These bits select the clock source for the on-chip baud rate generator.
For the relationship between the settings of these bits and the baud rate, refer to BRR[7:0] bits explanation.

MDDR[7:0] Bits (Modulation Duty Setting)

When the BRME bit is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected according to the settings of MDDR (M/256). The relationship between the MDDR[7:0] bit setting (M) and the bit rate (B) is given in Table 42.24.
The initial value of MDDR[7:0] bits is FFh. Bit 7 in this register is fixed to 1.

Table 42.24 Relationship between MDDR[7:0] Bit Setting (M) and Bit Rate (B) When Bit Rate Modulation Function is Used

Mode*1	SCR2 Settings			BRR[7:0] Bit Setting	Error (%)
	BGDM Bit	ABCS Bit	ABCSE Bit		
Asynchronous, multi-processor communication	0	0	0	$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{TCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
	1	0	0	$N = \frac{TCLK \times 10^6}{32 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{TCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{TCLK \times 10^6}{16 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	$Error = \left\{ \frac{TCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
	0 or 1	0 or 1	1	N = 0*2	$Error = \left\{ \frac{TCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times \frac{256}{M} \times (N+1)} - 1 \right\} \times 100$
Simple I2C*3				$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times \frac{256}{M} \times B} - 1$	

B: Bit rate (bps)
M: MDDR[7:0] bit setting (128 ≤ M ≤ 255)
N: BRR[7:0] bit setting (0 ≤ N ≤ 255)
TCLK: Operating frequency (MHz)
n: Determined by the settings of the SCR2.CKS[1:0] bits as listed in Table 42.11, Clock Source Settings.
Note 1. Do not use this function in clock synchronous mode, simple SPI mode, smart card Interface mode, Manchester mode and extended serial mode.
Note 2. When the ABCSE bit is set to 1, set N = 0 and n = 0.
Note 3. Adjust the bit rate so that the widths at high and low level of the SCL output in simple I2C mode satisfy the I2C standard.

Table 42.25 and Table 42.26 list examples of N settings in BRR[7:0] bits and M settings in MDDR[7:0] bits in asynchronous mode.

Table 42.25 Examples of BRR[7:0] Bits and MDDR[7:0] Bit Settings for Various Bit Rates (Asynchronous Mode) (1)

Bit	Symbol	Bit Name	Description	R/W
b0	CPHA	Clock Phase Select	(Valid in clock synchronous mode and simple SPI mode. Set this bit only when SCR0.TE bit = 0 and RE bit = 0.) 0: Data is sampled at an odd edge and changes at an even edge. (Clock is delayed.) 1: Data changes at an odd edge and is sampled at an even edge. (Clock is not delayed.)	R/W *1
b1	CPOL	Clock Polarity Select	(Valid in clock synchronous mode and simple SPI mode. Set this bit only when SCR0.TE bit = 0 and RE bit = 0.) 0: SCKn in idle state is 0. 1: SCKn in idle state is 1.	R/W *1
b6 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b7	SYNDIS	Synchronizer Disable	0: TCLK = SCICLK, synchronizer enabled 1: TCLK = PCLK, synchronizer disabled	R/W *1
b9, b8	CHR[1:0]	Character Length Select	(Valid in asynchronous mode and Manchester mode)*2 Select the data length for transmission and reception. b9 b8 0 0: Transmit/receive in 9-bit data length 0 1: Transmit/receive in 9-bit data length 1 0: Transmit/receive in 8-bit data length (initial value) 1 1: Transmit/receive in 7-bit data length*3	R/W *1
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	DDIR	Transfer Data Direction Select	0: MSB first 1: LSB first Set this bit to 0 in simple I^2C mode and set this bit to 1 in extended serial mode.	R/W *1
b13	DINV	Transfer Data Invert	0: TDR register contents are transmitted to TSR register as they are. RSR register contents are stored to RDR register as they are. 1: TDR register contents are inverted before being transmitted to TSR register. RSR register contents are inverted and stored to RDR register. Set this bit to 0 in simple I^2C mode. The level of communication pins (RXDn/TXDn) are controlled by combination of this bit and SCR1.TINV/RINV. Please refer to Figure 42.2 for details.	R/W *1
b14	STOP	Stop Bit Length Select	(Valid in asynchronous mode, Manchester mode, extended serial mode) 0: 1 stop bit/break delimiter length is 1bit 1: 2 stop bits/break delimiter length is 2bits	R/W *1

Bit	Symbol	Bit Name	Description	R/W
b15	RXDESEL	Asynchronous Start Bit Edge Detection Select	(Valid only in asynchronous mode) Set this bit to 1 in extended serial mode. 0: The low level on the RXDn pin is detected as the start bit. 1: A falling edge on the RXDn pin is detected as the start bit.	R/W *1
b18 to b16	MOD[2:0]	Communication Mode Select	Select the RSCI communication mode. b18 b16 0 0 0: Asynchronous mode 0 0 1: Smart card interface mode 0 1 0: Clock synchronous mode 0 1 1: Simple SPI mode 1 0 0: Simple I^2C mode 1 0 1: Manchester mode 1 1 0: Extended serial mode 1 1 1: Setting prohibited	R/W *1
b19	MP	Multi-Processor Mode	(Valid in asynchronous mode, Manchester mode) 0: Multi-processor communications function is disabled 1: Multi-processor communications function is enabled	R/W *1
b20	FM	FIFO Mode Select	(Valid in asynchronous mode (including multi-processor mode), clock synchronous mode, simple SPI mode) 0: TDR register, RDR register is non-FIFO buffer configuration 1: TDR register, RDR register is FIFO buffer configuration	R/W *1
b21	DEEN	Driver Control Function Enable	(Valid only in asynchronous mode) 0: RS-485 driver control function disable. 1: RS-485 driver control function enable.	R/W *1
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b25, b24	CKE[1:0]	Clock Enable	In the case of asynchronous mode b25 b24 0 0: On-chip baud rate generator The SCKn pin is available for use as an I/O port in accord with the I/O port settings. 0 1: On-chip baud rate generator The clock with the same frequency as the bit rate is output from the SCKn pin. 1 x: External clock or TMR clock A clock with a frequency of 16 times (when the SCR2.ABCS bit is 0) or 8 times (when the SCR2.ABCS bit is 1) the bit rate should be input from the SCKn pin or TMR. When the TMR clock is used, the SCKn pin can be used as an I/O port by setting the I/O port. In the case of Manchester mode and extended serial mode b25 b24 0 0: On-chip baud rate generator The SCKn pin functions as I/O port. Settings other than above are prohibited. In the case of clock synchronous mode and simple SPI mode b25 b24 0 x: Internal clock (master operation) The SCKn pin functions as the clock output pin. 1 x: External clock (slave operation) The SCKn pin functions as the clock input pin. In the case of smart card interface mode When SCR3.GM bit = 0 b25 b24 0 0: Output disabled (The SCKn pin is available for use as an I/O port in accord with the I/O port settings.) 0 1: Clock output 1 x: Prohibited When SCR3.GM bit = 1 b25 b24 0 0: Output fixed low 0 1: Clock output 1 0: Output fixed high 1 1: Clock output	R/W *1

Bit	Symbol	Bit Name	Description	R/W
b26	ACS0	Asynchronous Mode Clock Source Select	(Valid only in asynchronous mode) 0: External clock 1: TMR clock (logical AND of two compare-match outputs from the TMR)*4	R/W *1
b27	—	Reserved	This bit is read as 0. The write value should be 0.	R
b28	GM	GSM Mode	(Valid only in smart card interface mode) 0: Non-GSM mode operation 1: GSM mode operation	R/W *1
b29	BLK	Block Transfer Mode	(Valid only in smart card interface mode) 0: Non-block transfer mode operation 1: Block transfer mode operation	R/W *1
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.
Note 2. In other than asynchronous mode and Manchester mode, this bit setting is invalid and a fixed data length of 8 bits is used. Set these bits to 10b in extended serial mode.
Note 3. LSB first is fixed and the MSB (bit 7) in TDR register is not transmitted in transmission.
Note 4. When the ACS0 bit is set to 1, the SYNDIS bit should also be set to 1.

CPHA Bit (Clock Phase Select)

This bit selects the phase of the clock signal output through the SCKn pin. Refer to Figure 42.108 for details.
Set the bit to 1 in other than simple SPI mode and clock synchronous mode.

CPOL Bit (Clock Polarity Select)

This bit selects the polarity of the clock signal output through the SCKn pin. Refer to Figure 42.108 for details.
Set the bit to 1 in other than simple SPI mode and clock synchronous mode.

SYNDIS Bit (Synchronizer Disable)

This bit is used to bypass the synchronizers for clock domain crossing. When this bit is set to 1, the peripheral module clock (PCLK) is selected as the operating clock (TCLK) and the synchronizers are bypassed. For details, refer to section 42.17, Synchronizer Bypass Function.

CHR[1:0] Bits (Character Length Select)

Selects the data length for transmission and reception.
Except of asynchronous mode and Manchester mode, a fixed data length of 8 bits is used.

DDIR Bit (Transfer Data Direction Select)

Select whether to transmit/receive data in MSB first or LSB first.

DINV Bit (Transfer Data Invert)

DINV bit can invert the transmit data bit from TDR register to TSR register, and also can invert the received data from RSR register to RDR register. This bit does not affect the logic level of the parity bit. To invert the parity bit, invert the SCR1.PM bit.

STOP Bit (Stop Bit Length Select)

Selects the stop bit length in transmission.
In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.
In addition, it is used as break delimiter length setting when sending Start Frame in extended serial mode.

RXDESEL Bit (Asynchronous Start Bit Edge Detection Select)

Selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data receiving operation depends on the settings of this bit. Set this bit to 1 when reception should be stopped while a break occurs or when reception should be started without retaining the RXDn pin input at high level for the period of one data frame or longer after completion of the break.

Set this bit to 1 in extended serial mode. Set this bit to 0 in modes except of asynchronous mode and extended serial mode.

MOD[2:0] Bits (Communication Mode Select)

Selects the RSCI communication mode.

Table 42.27 Relationship between Communication Mode Selection Bits (MOD[2:0]), Other Operation Mode Setting Bits

Communication mode	Asynchronous								Smart Card I/F	Clock Synchronous		Simple SPI				Simple I²C	Manchester		Extended Serial
SCR3.MOD[2:0]	000b								001b	010b		011b				100b	101b		110b
SCR3.MP	0				1				—	—		—				—	0	1	—
SCR3.FM	0		1		0		1		—	0	1	0		1		—	—		—
SCR3.DEEN	0	1	0	1	0	1	0	1	—	—		—				—	—		—
SCR3.SSE	—								—	—		0	1	0	1	—	—		—

—: Prohibited setting

MP Bit (Multi-Processor Mode)

Disables/enables the multi-processor communications function. The settings of the PE bit and PM bit are invalid in multi-processor mode.

FM Bit (FIFO Mode Select)

When the FM bit is set to 1, the TDR register/RDR register switches to FIFO configuration, and transmit FIFO (TDR register)/receive FIFO (RDR register) can be used for serial transmission/reception.

DEEN Bit (Driver Control Function Enable)

Select RS-485 Driver control function disable or enable.

CKE[1:0] Bits (Clock Enable)

These bits select the clock source and SCKn pin function.

The combination of the settings of these bits and of the SCR3.ACS0 bit sets the TMR clock.

In smart card interface mode, these bits control the clock output from the SCKn pin.

In GSM mode, clock output can be dynamically switched. For details, refer to section 42.7.8, Clock Output Control.

ACS0 Bit (Asynchronous Mode Clock Source Select)

This bit is used to select the clock source in the asynchronous mode. Set this bit to 0 in other than asynchronous mode. The ACS0 bit is valid when an external clock is selected (SCR3.CKE[1] bit = 1) in asynchronous mode (SCR3.MOD[2:0] bits = 000b). The external clock or the TMR clock can be selected. When the TMR clock is selected, set the SYNDIS bit to 1 to select PCLK as the operating clock (TCLK).

The TMR clock is the logical AND of two compare-match outputs from the TMR. The even channels of the RSCI use the outputs of TMR unit 0 (TMO0, TMO1), and the odd channels use the outputs of TMR unit 1 (TMO2, TMO3). A setting example is shown in Figure 42.3.

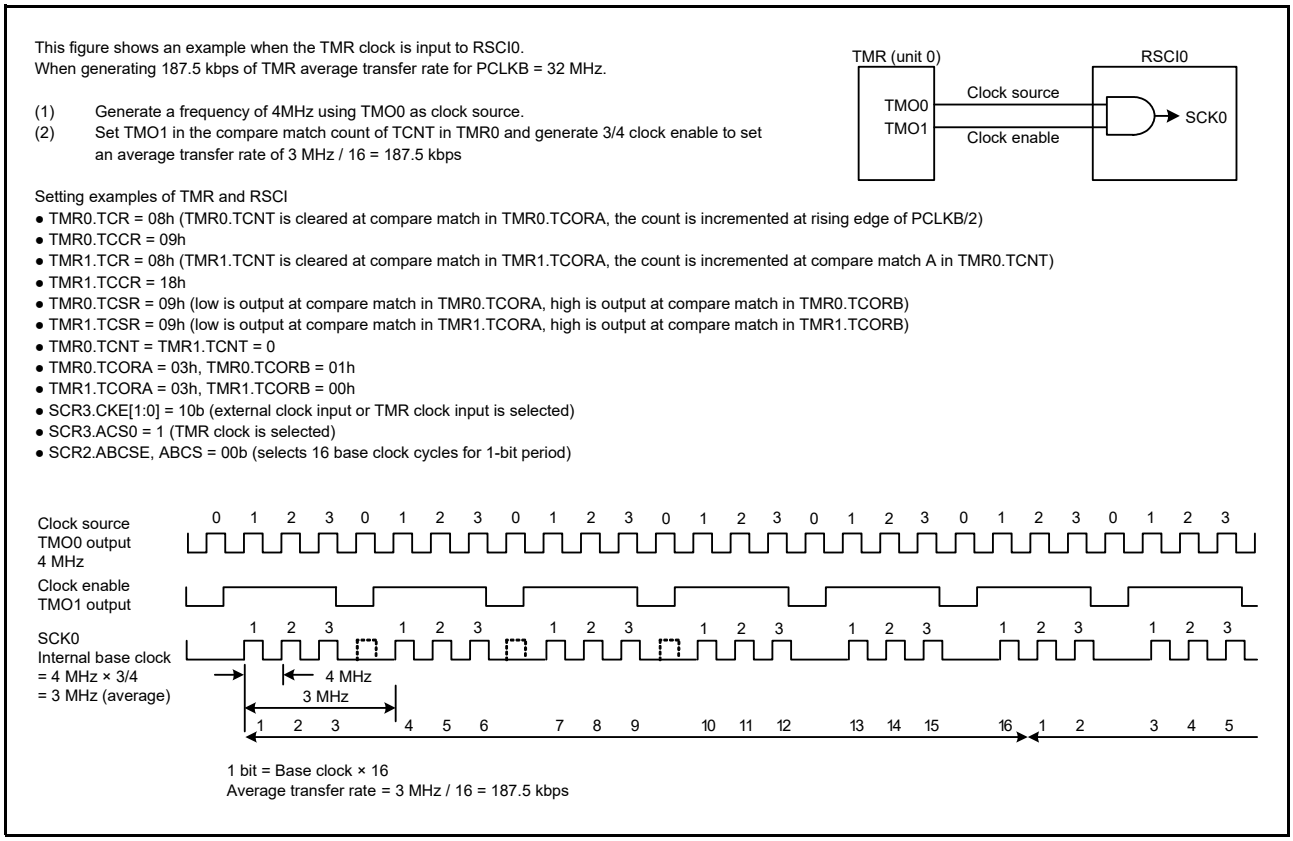

Figure 42.3 Example of Average Transfer Rate Setting When TMR Clock is Input.

GM Bit (GSM Mode)

Setting this bit to 1 allows GSM mode operation.

In GSM mode, the SSR.TEND flag set timing is put forward to 11.0 etu (elementary time unit = 1-bit transfer time) from the start and the clock output control function is appended. For details, refer to section 42.7.6, Serial Data Transmission (Except in Block Transfer Mode) and section 42.7.8, Clock Output Control.

BLK Bit (Block Transfer Mode)

Setting this bit to 1 allows block transfer mode operation.

For details, refer to section 42.7.3, Block Transfer Mode.

42.2.9 Control Register 4 (SCR4)

Address(es): RSCI0.SCR4 8745 8018h, RSCI1.SCR4 8745 8118h, RSCI2.SCR4 8745 8218h, RSCI3.SCR4 8745 8318h, RSCI4.SCR4 8745 8418h, RSCI5.SCR4 8745 8518h, RSCI6.SCR4 8745 8618h, RSCI7.SCR4 8745 8718h, RSCI8.SCR4 8745 8818h, RSCI9.SCR4 8745 8918h, RSCI10.SCR4 8745 8A18h, RSCI11.SCR4 8745 8B18h, RSCI12.SCR4 8745 8C18h,

b31 to b28	TTMG[3:0]	Transmit Signal Transition Timing Select	b31 b28 1 1 1 1: Delays the 1 to 0 transitions for 7 clocks. 1 1 1 0: Delays the 1 to 0 transitions for 6 clocks. 1 1 0 1: Delays the 1 to 0 transitions for 5 clocks. 1 1 0 0: Delays the 1 to 0 transitions for 4 clocks. 1 0 1 1: Delays the 1 to 0 transitions for 3 clocks. 1 0 1 0: Delays the 1 to 0 transitions for 2 clocks. 1 0 0 1: Delays the 1 to 0 transitions for 1 clocks. x 0 0 0: Does not change the waveform. 0 0 0 1: Delays the 0 to 1 transitions for 1 clock. 0 0 1 0: Delays the 0 to 1 transitions for 2 clock. 0 0 1 1: Delays the 0 to 1 transitions for 3 clock. 0 1 0 0: Delays the 0 to 1 transitions for 4 clock. 0 1 0 1: Delays the 0 to 1 transitions for 5 clock. 0 1 1 0: Delays the 0 to 1 transitions for 6 clock. 0 1 1 1: Delays the 0 to 1 transitions for 7 clock.	R/W *1

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

CMPD[8:0] Bits (Compare Match Data)

Set the comparison data for receive data, when data match detection function is enabled (SCR0.DCME bit = 1). SCR4.CMPD[8:0] bits should be written while SCR0.DCME bit is 0.

For the comparison data, it can select length from 3 types, they are CMPD[6:0] with 7bit length enable, CMPD[7:0] with 8bit, and CMPD[8:0] with 9bit length.

RTADJ Bit (Receive Data Sampling Timing Adjustment)

When this bit is 1, the receive sampling timing adjustment function is enabled.

In asynchronous mode using internal clock, refer to section 42.3.10, Receive Data Sampling Timing Adjustment for details. The operation when the extended serial mode internal clock is selected is the same as when the asynchronous clock internal clock is selected.

TTADJ Bit (Transmit Signal Transition Timing Adjustment)

When this bit is 1, the transmit signal transition timing adjustment function is enabled. The transmit signal transition timing adjustment function can adjust the edge timing of the waveform output from the TXDn pin. Refer to section 42.3.11, Transmit Data Transition Timing Adjustment for details.

RTMG[3:0] Bits (Receive Data Sampling Timing Select)

When the RTADJ bit is 1, the receive sampling timing can be adjusted according to this bit setting value. The adjustment value is the base clock × RTMG[2:0] setting value.

TTMG[3:0] Bits (Transmit Signal Transition Timing Select)

The edge timing of the TXDn pin specified by the TTMG[3:0] bits is adjusted by the base clock × TTMG[2:0] setting value. Make sure that the TTMG[2:0] bit setting is less than the number of base clock cycles for 1-bit period.

42.2.10 I²C Mode Register (SIMR)

Address(es): RSCI0.SIMR 8745 8020h, RSCI1.SIMR 8745 8120h, RSCI2.SIMR 8745 8220h, RSCI3.SIMR 8745 8320h, RSCI4.SIMR 8745 8420h, RSCI5.SIMR 8745 8520h, RSCI6.SIMR 8745 8620h, RSCI7.SIMR 8745 8720h, RSCI8.SIMR 8745 8820h, RSCI9.SIMR 8745 8920h, RSCI10.SIMR 8745 8A20h, RSCI11.SIMR 8745 8B20h, RSCI12.SIMR 8745 8C20h, RSCI0_NS.SIMR 0745 8020h, RSCI1_NS.SIMR 0745 8120h, RSCI2_NS.SIMR 0745 8220h, RSCI3_NS.SIMR 0745 8320h, RSCI4_NS.SIMR 0745 8420h, RSCI5_NS.SIMR 0745 8520h, RSCI6_NS.SIMR 0745 8620h, RSCI7_NS.SIMR 0745 8720h, RSCI8_NS.SIMR 0745 8820h, RSCI9_NS.SIMR 0745 8920h, RSCI10_NS.SIMR 0745 8A20h, RSCI11_NS.SIMR 0745 8B20h, RSCI12_NS.SIMR 0745 8C20h

b19	—	Reserved	This bit is read as 0. The write value should be 0.	R
b21, b20	IICSDAS[1:0]	SDA Output Select	b21 b20 0 0: Serial data output 0 1: Generate a start, restart, or stop condition. 1 0: Output the low level on the SSDAn pin. 1 1: Place the SSDAn pin in the high-impedance state.	R/W
b23, b22	IICSCLS[1:0]	SCL Output Select	b23 b22 0 0: Serial clock output 0 1: Generate a start, restart, or stop condition. 1 0: Output the low level on the SSCLn pin. 1 1: Place the SSCLn pin in the high-impedance state.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

Note 2. In the bus free state, perform the start condition generation.
Note 3. In the bus busy state, perform restart or stop condition generation when the SSCLn pin after acknowledgment described in Figure 42.79 and Figure 42.80 is low level.
Note 4. Do not set more than one from among the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.
Note 5. Execute the generation of a condition after the value of the IICSTIF flag is 0.
Note 6. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

IICDL[4:0] Bits (SDA Output Delay Select)

These bits are used to set a delay for output on the SSDAn pin relative to the falling edge of the output on the SSCLn pin. The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generators the base. The signal obtained by frequency-dividing TCLK by the divisor set in SCR2.CKS[1:0] bits is supplied as the clock signal from the on-chip baud rate generator.
Set these bits to 00000b unless operation is in simple I^2C mode. In simple I^2C mode, set the bits to a value in the range from 00001b to 11111b.

IICINTM Bit (I^2C Interrupt Mode Select)

This bit selects the sources of interrupt requests in simple I^2C mode.

IICCSC Bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SCL signal is to be synchronized when the SSCLn pin has been placed at the low level in the case of a wait inserted by the other device, etc.
The internal SCL signal is not synchronized if the IICCSC bit is 0. The internal SCL signal is generated in accordance with the rate selected in the BRR[7:0] bits regardless of the level being input on the SSCLn pin.
Set the IICCSC bit to 1 except during debugging.

IICACKT Bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set this bit to 1 when ACK and NACK bits are received.

IICSTAREQ Bit (Start Condition Generation)

When a start condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTAREQ bit to 1.
If you want to generate the start condition after generating the stop condition, start the generation of the start condition with a half cycle period of the bit rate from the stop condition generation interrupt request output.
[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the start condition

IICRSTAREQ Bit (Restart Condition Generation)

When a restart condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICRSTAREQ bit to 1.
[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the restart condition

IICSTPREQ Bit (Stop Condition Generation)

When a stop condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTPREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the stop condition

IICSDAS[1:0] Bits (SDA Output Select)

These bits control output from the SSDAn pin.

IICSCLS[1:0] Bits (SCL Output Select)

These bits control output from the SSCLn pin.

42.2.11 FIFO Control Register (FCR)

Address(es): RSCI0.FCR 8745 8024h, RSCI1.FCR 8745 8124h, RSCI2.FCR 8745 8224h, RSCI3.FCR 8745 8324h, RSCI4.FCR 8745 8424h, RSCI5.FCR 8745 8524h, RSCI6.FCR 8745 8624h, RSCI7.FCR 8745 8724h, RSCI8.FCR 8745 8824h, RSCI9.FCR 8745 8924h, RSCI10.FCR 8745 8A24h, RSCI11.FCR 8745 8B24h, RSCI12.FCR 8745 8C24h,

Bit	Symbol	Bit Name	Description	R/W
b0	DRES	Receive Data Ready Interrupt Select	(Valid in asynchronous mode) This bit select the interrupt request for a reception data ready detection. 0: Reception data full interrupt (RXI) 1: Receive error interrupt (ERI)	R/W *1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12 to b8	TTRG[4:0]	Transmit FIFO Threshold Setting	(Valid in asynchronous mode (including multi-processor mode), clock synchronous mode, simple SPI mode) b12 b8 0 0 0 0 0: Trigger number 0 : : 0 1 1 1 1: Trigger number 15 Settings other than above are prohibited.	R/W *1
b14, b13	—	Reserved	These bits are read as 0. The write value should be 0.	R
b15	TFRST	Transmit FIFO Reset	This bit enables only when SCR3.FM bit is 1. The read value is always 0. 0: It is invalid. It does not affect the operation. 1: The number of data stored in transmit FIFO (TDR register) are made 0 The read value is always 0.	W*1
b20 to b16	RTRG[4:0]	Receive FIFO Threshold Setting	(Valid in asynchronous mode (including multi-processor mode), clock synchronous mode, simple SPI mode) b20 b16 0 0 0 0 0: Trigger number 0 : : 0 1 1 1 1: Trigger number 15 Settings other than above are prohibited.	R/W *1
b22, b21	—	Reserved	These bits are read as 0. The write value should be 0.	R
b23	RFRST	Receive FIFO Reset	This bit enables only when SCR3.FM bit is 1. The read value is always 0. 0: It is invalid. It does not affect the operation. 1: The number of data stored in receive FIFO (RDR register) are made 0 The read value is always 0.	W*1
b28 to b24	RSTRG[4:0]	RTS# Output Threshold Setting	(Valid in asynchronous mode (including multi-processor mode), clock synchronous mode) This bit enables only when SCR3.FM bit = 1, SCR1.CTSE bit = 0, and SCR0.SSE bit = 0. b28 b24 0 0 0 0 0: Trigger number 0 : : 0 1 1 1 1: Trigger number 15 Settings other than above are prohibited.	R/W *1

Bit	Symbol	Bit Name	Description	R/W
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

DRES Bit (Receive Data Ready Interrupt Select)

Select whether the detection of receive data ready (RFSR.DR flag = 1) is the cause of RXI interrupt request or the cause of ERI interrupt request.

TTRG[4:0] Bits (Transmit FIFO Threshold Setting)

The TDRE flag is set to 1 when the quantity of transmit data in the transmit FIFO (TDR register) is equal to or less than the specified transmit triggering number. If SCR0.TIE bit = 1, TXI interrupt request is occurred.

TFRST Bit (Transmit FIFO Reset)

When the TFRST bit is set to 1, the number of the transmission data stored in transmit FIFO (TDR register) is made 0.

RTRG[4:0] Bits (Receive FIFO Threshold Setting)

The SSR.RDRF flag is set to 1 when the quantity of receive data in the receive FIFO (RDR register) is equal to or greater than the specified receive triggering number. If SCR0.RIE bit = 1, RXI interrupt request is occurred. When FCR.RTRG[4:0] bits are set to 0, RDRF flag is set if the quantity of data in receive FIFO is greater than or equal to 1.

RFRST Bit (Receive FIFO Reset)

When the RFRST bit is set to 1, the number of the reception data stored in receive FIFO (RDR register) is made 0.

RSTRG[4:0] Bits (RTS# Output Threshold Setting)

When the quantity of receive data stored in the receive FIFO (RDR register) is equal to or greater than this number, the RTSn# signal is in the High state. When FCR.RSTRG[4:0] bits are set to 0, RTSn# is in the high state if the quantity of data in receive FIFO is greater than or equal to 1.

42.2.12 Manchester Mode Control Register (MMCR)

Address(es): RSCI0.MMCR 8745 802Ch, RSCI1.MMCR 8745 812Ch, RSCI2.MMCR 8745 822Ch, RSCI3.MMCR 8745 832Ch, RSCI4.MMCR 8745 842Ch, RSCI5.MMCR 8745 852Ch, RSCI6.MMCR 8745 862Ch, RSCI7.MMCR 8745 872Ch, RSCI8.MMCR 8745 882Ch, RSCI9.MMCR 8745 892Ch, RSCI10.MMCR 8745 8A2Ch, RSCI11.MMCR 8745 8B2Ch, RSCI12.MMCR 8745 8C2Ch,
RSCI0_NS.MMCR 0745 802Ch, RSCI1_NS.MMCR 0745 812Ch, RSCI2_NS.MMCR 0745 822Ch, RSCI3_NS.MMCR 0745 832Ch, RSCI4_NS.MMCR 0745 842Ch, RSCI5_NS.MMCR 0745 852Ch, RSCI6_NS.MMCR 0745 862Ch, RSCI7_NS.MMCR 0745 872Ch, RSCI8_NS.MMCR 0745 882Ch, RSCI9_NS.MMCR 0745 892Ch, RSCI10_NS.MMCR 0745 8A2Ch, RSCI11_NS.MMCR 0745 8B2Ch, RSCI12_NS.MMCR 0745 8C2Ch

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DECS	Decoding Convention Select	Sets the polarity of the received Manchester code 0: Low to high transition is decoded to a logic 0 and high to low transition is decoded to a logic 1. 1: high to low transition is decoded to a logic 0 and low to high transition is decoded to a logic 1.	R/W *1
b1	ENCS	Encoding Convention Select	Sets the polarity of the transmit Manchester code 0: Logic 0 is encoded to a low to high transition and logic 1 is encoded to a high to low transition. 1: Logic 0 is encoded to a high to low transition and logic 1 is encoded to a low to high transition.	R/W *1
b2	SADJE	Receive Timing Self Adjustment Enable	Sets the receive retiming function 0: Disables the receive retiming function 1: Enables the receive retiming function	R/W *1
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	SBPTN	Start Bit Pattern Select	Sets the Sync type of the start bit(s) in the Manchester code When the start bit area consists of one bit. (SBLEN bit = 0) • When transmitting 0: The start bit is added as a low to high transition. 1: The start bit is added as a high to low transition. • When receiving 0: Only when the start bit is a low to high transition, the data is received. The other cases are judged as an error. 1: Only when the start bit is a high to low transition, the data is received. The other cases are judged as an error. When the start bit area consists of three bits. (SBLEN bit = 1) • When transmitting 0: The start bits are added as a low to high transition. (DATA Sync) 1: The start bits are coded as a high to low transition. (COMMAND Sync) • When receiving When the start bit area consists of three bits, data is received regardless of the value of this bit.	R/W *1
b5	SYNCE	Sync Enable	0: The start bit pattern is set with the SBPTN bit. 1: The start bit pattern is set with the SYNC bit.	R/W *1
b6	SBLEN	Start Bit Length Select	0: The start bit area consists of one bit. 1: The start bit area consists of three bits. (COMMAND Sync or DATA Sync)	R/W *1
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R

Bit	Symbol	Bit Name	Description	R/W
b11 to b8	TPLEN[3:0]	Transmit Preface Length Setting	Set the preface length of the transmit data in Manchester mode 0: Disables the transmit preface generation 1 to 15: Transmit preface length (bit length)	R/W *1
b13, b12	TPPAT[1:0]	Transmit Preface Pattern Select	Set the preface pattern of the transmit data b13 b12 0 0: ALL ZERO 0 1: ZERO ONE 1 0: ONE ZERO 1 1: ALL ONE	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R
b19 to b16	RPLEN[3:0]	Receive Preface Length Setting	Set the preface length in received frames when Manchester mode is enabled 0: Disables the receive preface generation 1 to 15: Receive preface length (bit length)	R/W *1
b21, b20	RPPAT[1:0]	Receive Preface Pattern Select	Set the preface pattern of received frames b21 b20 0 0: ALL ZERO 0 1: ZERO ONE 1 0: ONE ZERO 1 1: ALL ONE	R/W *1
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	PFERIE	Preface Error Interrupt Enable	Specifies whether to handle a preface error as an interrupt source 0: Does not handle a preface error as an interrupt source 1: Handles a preface error as an interrupt source	R/W *1
b25	SYERIE	Sync Error Interrupt Enable	Specifies whether to handle a receive Sync error as an interrupt source 0: Does not handle a receive Sync error as an interrupt source 1: Handles a receive Sync error as an interrupt source	R/W *1
b26	SBERIE	Start Bit Error Interrupt Enable	Specifies whether to handle a start bit error as an interrupt source 0: Does not handle a start bit error as an interrupt source 1: Handles a start bit error as an interrupt source	R/W *1
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

DECS Bit (Decoding Convention Select)

This bit sets the polarity of the received Manchester code. For details on the data reception, see section 42.5.7, Serial Data Reception in Manchester Mode.

ENCS Bit (Encoding Convention Select)

This bit sets the polarity of the transmit Manchester code. For details on the data transmission, see section 42.5.6, Serial Data Transmission in Manchester Mode.

SADJE Bit (Receive Timing Self Adjustment Enable)

This bit sets the receive retiming function in Manchester mode.

For information on the receive retiming function, see section 42.5.9, Receive Retiming.

SBPTN Bit (Start Bit Pattern Select)

This bit is valid when the SYNCE bit is set to 0.

The Sync type can be set by combining this bit and the SBLEN bit.

For the start bit area determined by the combination of this bit and the SBLEN bit, see Figure 42.37 and Figure 42.38.

SYNCE Bit (Sync Enable)

This bit is valid when the SBLEN bit is set to 1. This bit determines the destination to be referred to for setting the Sync type of the start bit area added to Manchester frames.
When this bit is set to 0, the SBPTN bit is referred to.
When this bit is set to 1, the TDR.SYNC bit is referred to.

SBLEN Bit (Start Bit Length Select)

This bit sets the start bit area in Manchester frames.
When this bit is set to 1, the start bit area added to each frame consists of three bits, and the SYNCE and SBPTN bits are valid.
When this bit is set to 0, the start bit area added to each frame consists of one bit.

TPLEN[3:0] Bits (Transmit Preface Length Setting)

These bits set the preface bit length of the transmit data in Manchester mode.
The settable range is 0h to Fh (0 to 15). 0h disables the transmit preface, which is not added.

TPPAT[1:0] Bits (Transmit Preface Pattern Select)

These bits set one of the four preface patterns in Manchester mode. For the transmit data when the TPPAT[1:0] bits are set, see Figure 42.36.
When these bits are set to 00b, the preface area is set to all zeros.
When these bits are set to 01b, the preface area is set to the zero-one-zero-one pattern.
When these bits are set to 10b, the preface area is set to the one-zero-one-zero pattern.
When these bits are set to 11b, the preface area is set to all ones.

RPLEN[3:0] Bits (Receive Preface Length Setting)

These bits set the preface bit length of the received frames in Manchester mode.
The settable range is 0h to Fh (0 to 15). 0h disables the receive preface, which is not added. When 1h to Fh is set, the set value is handled as the receive preface bit length.

RPPAT[1:0] Bits (Receive Preface Pattern Select)

These bits set one of the four preface patterns in Manchester mode. For the transmit and receive data when the TPPAT[1:0] bits are set, see Figure 42.36.
When these bits are set to 00b, the preface area is handled as all zeros.
When these bits are set to 01b, the preface area is handled as the zero-one-zero-one pattern.
When these bits are set to 10b, the preface area is handled as the one-zero-one-zero pattern.
When these bits are set to 11b, the preface area is handled as all ones.

PFERIE Bit (Preface Error Interrupt Enable)

This bit specifies whether to handle a preface error as an interrupt source.
When it is set to 0, a preface error is not handled as an interrupt source. When it is set to 1, a preface error is handled as an interrupt source.

SYERIE Bit (Sync Error Interrupt Enable)

This bit specifies whether to handle a receive Sync error as an interrupt source.
When it is set to 0, a receive Sync error is not handled as an interrupt source. When it is set to 1, a receive Sync error is handled as an interrupt source.

SBERIE Bit (Start Bit Error Interrupt Enable)

This bit specifies whether to handle a start bit error as an interrupt source.

When it is set to 0, a start bit error is not handled as an interrupt source. When it is set to 1, a start bit error is handled as an interrupt source.

42.2.13 DE Signal Control Register (DECR)

Address(es): RSCI0.DECR 8745 8030h, RSCI1.DECR 8745 8130h, RSCI2.DECR 8745 8230h, RSCI3.DECR 8745 8330h, RSCI4.DECR 8745 8430h, RSCI5.DECR 8745 8530h, RSCI6.DECR 8745 8630h, RSCI7.DECR 8745 8730h, RSCI8.DECR 8745 8830h, RSCI9.DECR 8745 8930h, RSCI10.DECR 8745 8A30h, RSCI11.DECR 8745 8B30h, RSCI12.DECR 8745 8C30h,
RSCI0_NS.DECR 0745 8030h, RSCI1_NS.DECR 0745 8130h, RSCI2_NS.DECR 0745 8230h, RSCI3_NS.DECR 0745 8330h, RSCI4_NS.DECR 0745 8430h, RSCI5_NS.DECR 0745 8530h, RSCI6_NS.DECR 0745 8630h, RSCI7_NS.DECR 0745 8730h, RSCI8_NS.DECR 0745 8830h, RSCI9_NS.DECR 0745 8930h, RSCI10_NS.DECR 0745 8A30h, RSCI11_NS.DECR 0745 8B30h, RSCI12_NS.DECR 0745 8C30h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	DEHLD[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	DESU[4:0]					—	—	—	—	—	—	—	DELVL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DELVL	DE Signal Active Level Select	(Valid only in asynchronous mode) 0: The DE signal is active high. 1: The DE signal is active low.	R/W *1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12 to b8	DESU[4:0]	DE Signal Setup Time Setting	(Valid only in asynchronous mode) Set the DE signal setup time in the number of the base clock cycles. The bit setting is enabled when the SCR3.DEEN bit is 1. Do not set 00000b.	R/W *1
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20 to b16	DEHLD[4:0]	DE Signal Hold Time Setting	(Valid only in asynchronous mode) Set the DE signal hold time in the number of the base clock cycles. The bit setting is enabled when the SCR3.DEEN bit is 1. Do not set 00000b.	R/W *1
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

DELVL Bit (DE Signal Active Level Select)

Select the active level of the DE (driver enable) signal.

DESU[4:0] Bits (DE Signal Setup Time Setting)

Set the DE signal setup time (time from the assertion of the DE signal to the start of transmission of the start bit). It is expressed in the number of the base clock cycles (1/4, 1/6, 1/8, or 1/16 bit period). The actual transmission of the start bit starts after the setup time and transmission wait time have elapsed.

DEHLD[4:0] Bits (DE Signal Hold Time Setting)

Set the DE signal hold time (time from the completion of transmission of the stop bit of the last transmission message to negation of the DE signal). It is expressed in the number of the base clock cycles (1/4, 1/6, 1/8, or 1/16 bit period).
If the transmission data is written during the hold time, transmit starting operation is different depends on the writing timing (following two cases: the transmission of the start bit starts after the transmission wait time has elapsed without negating the DE signal, or it starts after the DE signal is negated and asserted again and then the setup time and transmission wait time have elapsed.).

42.2.14 Extended Serial Mode Control Register 0 (XCR0)

Address(es): RSCI0.XCR0 8745 8034h, RSCI1.XCR0 8745 8134h, RSCI2.XCR0 8745 8234h, RSCI3.XCR0 8745 8334h, RSCI4.XCR0 8745 8434h, RSCI5.XCR0 8745 8534h, RSCI6.XCR0 8745 8634h, RSCI7.XCR0 8745 8734h, RSCI8.XCR0 8745 8834h, RSCI9.XCR0 8745 8934h, RSCI10.XCR0 8745 8A34h, RSCI11.XCR0 8745 8B34h, RSCI12.XCR0 8745 8C34h,

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	TCSS[1:0]	Timer Count Clock Source Select	(Valid in extended serial mode) Select the clock source of the timer in the extended serial module. b1 b0 0 0: TCLK 0 1: TCLK/4 1 0: TCLK/16 1 1: TCLK/64	R/W *1, *2
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	BFE	Break Field Detection Enable	Set the presence or absence of Break Field of Start Frame. 0: No Break Field 1: With Break Field	R/W *1, *3
b9	CF0RE	Control Field 0 Reception Enable	Set the presence or absence of Control Field 0 of Start Frame. 0: No Control Field 0 1: With Control Field 0	R/W *1, *3
b11, b10	CF1DS[1:0]	Control Field 1 Compare Data Select	Select the compare data for Control Field 1 b11 b10 0 0: Select XCR1.PCF1D[7:0] bits as the compare data 0 1: Select XCR1.SCF1D[7:0] bits as the compare data 1 0: Select both XCR1.PCF1D[7:0] bits and XCR1.SCF1D[7:0] bits as the compare data 1 1: Prohibition	R/W *1, *3
b12	PIBE	Priority Interrupt Bit Enable	0: Priority interrupt bit disable 1: Priority interrupt bit enable	R/W *1, *3
b15 to b13	PIBS[2:0]	Priority Interrupt Bit Select	Specify one of bits 0 to 7 of Control Field 1 as the priority interrupt bit. b15 b13 0 0 0: Bit 0 of Control Field 1 0 0 1: Bit 1 of Control Field 1 0 1 0: Bit 2 of Control Field 1 0 1 1: Bit 3 of Control Field 1 1 0 0: Bit 4 of Control Field 1 1 0 1: Bit 5 of Control Field 1 1 1 0: Bit 6 of Control Field 1 1 1 1: Bit 7 of Control Field 1	R/W *1, *3
b16	BFOIE	Break Field Low Width Output Complete Interrupt Enable	Select whether to include Break Field transmission completion as a TXI interrupt factor. 0: Break Field transmission completion is not included in TXI interrupt factor 1: Break Field transmission completion is included in TXI interrupt factor	R/W *1

Bit	Symbol	Bit Name	Description	R/W
b17	BCDIE	Bus Collision Detected Interrupt Enable	Select whether to output an ERI interrupt when a bus collision is detected. 0: Bus conflict detection is not included in ERI interrupt factor 1: Bus conflict detection is included in ERI interrupt factor	R/W *1
b19, b18	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	BFDIE	Break Field Low Width Detected Interrupt Enable	Select whether to output a BFD interrupt when a Break Field is detected. 0: Break Field detection interrupt disable 1: Break Field detection interrupt enable	R/W *1
b21	COFIE	Count Overflow Interrupt Enable	Select whether to include counter overflow as an ERI interrupt factor. 0: Counter overflow is not included in ERI interrupt factor 1: Counter overflow is included in ERI interrupt factor	R/W *1
b22	AEDIE	Effective Edge Detected Interrupt Enable	Select whether to output an AED interrupt when a valid edge is detected. 0: Active edge detection interrupt disable 1: Active edge detection interrupt enable	R/W *1
b23	—	Reserved	This bit is read as 0. The write value should be 0.	R
b25, b24	BCCS[1:0]	Bus Collision Detection Clock Select	Select the sampling clock for the bus conflict detection circuit. When SCR2.ABCS bit = 1, setting BCCS[1:0] bits = 1xb is prohibited. b25 b24 0 0: Base clock*4 0 1: Base clock/2 1 0: Base clock/4 1 1: Prohibition	R/W *1
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.
Note 2. Rewrite the TCSS[1:0] bits only when the timer is stopped (XCR1.TCST bit = 0, XCR1.SDST bit = 0, and XCR1.BRME bit = 0).
Note 3. This bit is a setting bit required for Start Frame reception operation. Rewrite this bit when Start Frame reception or transmission is not in progress (XCR1.SDST bit = 0 and XCR1.TCST bit = 0).
Note 4. Base clock: 1/16 period of 1 bit period when SCR2.ABCS bit = 0, 1/8 period of 1 bit period when SCR2.ABCS bit = 1.

TCSS[1:0] Bits (Timer Count Clock Source Select)

Select clock source of timer in extended serial module.

BFE Bit (Break Field Detection Enable)

Set the presence or absence of Break Field of Start Frame.

CF0RE Bit (Control Field 0 Reception Enable)

Set the presence or absence of Control Field 0 of Start Frame.

CF1DS[1:0] Bits (Control Field 1 Compare Data Select)

Select the compare data for Control Field 1.

PIBE Bit (Priority Interrupt Bit Enable)

Select whether to enable priority interrupt bit comparison of Control Field 1. When this bit is 1, regardless of the XCR1.CF1CE[7:0] bit setting value, the bit specified in the PIBS[2:0] bits is compared with the primary comparison data for Control Field 1 (XCR1.PCF1D[7:0] bits).

PIBS[2:0] Bits (Priority Interrupt Bit Select)

Specify bit N (N = 0 to 7) of Control Field 1 as the priority interrupt bit.

BFOIE Bit (Break Field Low Width Output Complete Interrupt Enable)

Select whether to include Break Field transmission completion as a TXI interrupt factor. Set SCR0.TIE bit = 1 and SCR3.MOD[2:0] bits = 110b, to output TXI upon completion of Break Field transmission.

BCDIE Bit (Bus Collision Detected Interrupt Enable)

Select whether to output an ERI interrupt when a bus collision is detected. In extended serial mode (SCR3.MOD[2:0] bits = 110b), ERI output control is performed with this bit. When SCR3.MOD[2:0] bits = 110b and BCDIE bit = 1, an ERI interrupt is issued when a bus collision is detected even if SCR0.RIE bit = 0.

COFIE Bit (Count Overflow Interrupt Enable)

Select whether to include counter overflow as an ERI interrupt factor. Set SCR0.RIE bit = 1 and SCR3.MOD[2:0] bits = 110b are required to output ERI upon counter overflow.

AEDIE Bit (Effective Edge Detected Interrupt Enable)

Select whether to output an AED interrupt when a valid edge is detected. To output AED with valid edge detection, XCR1.BRME bit = 1 and SCR3.MOD[2:0] bits = 110b must be set.

BCCS[1:0] Bits (Bus Collision Detection Clock Select)

Select the sampling clock for the bus conflict detection circuit.

42.2.15 Extended Serial Mode Control Register 1 (XCR1)

Address(es): RSCI0.XCR1 8745 8038h, RSCI1.XCR1 8745 8138h, RSCI2.XCR1 8745 8238h, RSCI3.XCR1 8745 8338h, RSCI4.XCR1 8745 8438h, RSCI5.XCR1 8745 8538h, RSCI6.XCR1 8745 8638h, RSCI7.XCR1 8745 8738h, RSCI8.XCR1 8745 8838h, RSCI9.XCR1 8745 8938h, RSCI10.XCR1 8745 8A38h, RSCI11.XCR1 8745 8B38h, RSCI12.XCR1 8745 8C38h,

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TCST	Break Field Low Width Output Timer Count Start	0: Break Field transmission timer count stopped 1: Break Field transmission timer count start Do not set this bit and SDST bit to 1 at the same time.	R/W *1
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	SDST	Start Frame Detection Start	0: Start Frame/Break Field detection disabled 1: Start Frame/Break Field detection enabled Do not set this bit and TCST bit to 1 at the same time.	R/W *1
b5	BRME	Bit Rate Measurement Enable	0: Bit rate measurement disabled 1: Bit rate measurement enabled Set this bit to 1 simultaneously with the SDST bit. When this bit is set to 0, it can be set to 0 at any timing.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b15 to b8	PCF1D[7:0]	Primary Control Field 1 Compare Data	The priority compare data for Control Field 1	R/W *1
b23 to b16	SCF1D[7:0]	Secondary Control Field 1 Compare Data	The secondary compare data for Control Field 1	R/W *1
b31 to b24	CF1CE[7:0]	Control Field 1 Compare Enable	Select whether to compare bit N of Control Field 1. (N = 0 to 7) 0: Control Field 1 bit N compare disabled 1: Control Field 1 bit N compare enabled	R/W *1

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

TCST Bit (Break Field Low Width Output Timer Count Start)

[Clearing condition]

- When 0 is written to TCST bit. Break Field transmission timer count is stopped and TXDn pin output becomes idle level.
- When Break Field transmission for the period set in XCR2.BFLW[15:0] bits is completed.

[Setting condition]

- When 1 is written to TCST bit. Start Break Field transmission from TXDn pin. Holds 1 during Break Field transmission.

SDST Bit (Start Frame Detection Start)

When 1 is written to this bit, Start Frame detection starts. When XCR0.BFE bit = 1 is set, Break Field can be detected during Start Frame is detected and after Start frame is detected. When XCR0.BFE bit = 0 is set, Break Field is not

detected.
When 0 is written to this bit, Start Frame detection and Break Field detection are stopped. However, if XSR0.RXDSF flag = 0 at the time of stop, it is not possible to stop data reception with this bit. Write 0 to SCR0.RE bit to stop the reception operation or perform reception completion processing (clearing the SSR.RDRF flag or reading the RDR register) after reception is completed.

BRME Bit (Bit Rate Measurement Enable)

Set this bit to 1 simultaneously with the SDST bit. When this bit is set to 1, the valid edge interval of Control Field 0 and Control Field 1 data is measured.

PCF1D[7:0] Bits (Primary Control Field 1 Compare Data)

Set the priority compare data for Control Field 1.

SCF1D[7:0] Bits (Secondary Control Field 1 Compare Data)

Set the secondary compare data for Control Field 1.

CF1CE[7:0] Bits (Control Field 1 Compare Enable)

Select whether to compare bit N of Control Field 1. (N = 0 to 7)
When all of these bits are set to 0 (CF1CE[7:0] bits = 00h), it is always judged that Control Field 1 matches when reception is completed, and XSR0.CF1MF flag is set. This bit is a comparison enable with PCF1D[7:0] bits or SCF1D[7:0] bits, and it is not a priority interrupt bit comparison enable.

42.2.16 Extended Serial Mode Control Register 2 (XCR2)

Address(es): RSCI0.XCR2 8745 803Ch, RSCI1.XCR2 8745 813Ch, RSCI2.XCR2 8745 823Ch, RSCI3.XCR2 8745 833Ch, RSCI4.XCR2 8745 843Ch, RSCI5.XCR2 8745 853Ch, RSCI6.XCR2 8745 863Ch, RSCI7.XCR2 8745 873Ch, RSCI8.XCR2 8745 883Ch, RSCI9.XCR2 8745 893Ch, RSCI10.XCR2 8745 8A3Ch, RSCI11.XCR2 8745 8B3Ch, RSCI12.XCR2 8745 8C3Ch,

	CF0CE[7:0]								CF0D[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CF0D[7:0]	Control Field Compare Data	The compare data for Control Field 0	R/W *1
b15 to b8	CF0CE[7:0]	Control Field Compare Enable	Select whether to compare bit N of Control Field 0. (N = 0 to 7) 0: Control Field 0 bit N compare disabled 1: Control Field 0 bit N compare enabled	R/W *1
b31 to b16	BFLW[15:0]	Break Field Low Width Setting	This bit sets the Break Field length. The break field length is (BFLW[15:0] setting value + 1) × clock of the timer. The upper limit for setting this register is FFFEh. (Setting prohibited for FFFFh)	R/W *1

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

CF0D[7:0] Bits (Control Field Compare Data)

The compare data for Control Field 0.

CF0CE[7:0] Bits (Control Field Compare Enable)

Select whether to compare bit N of Control Field 0. (N = 0 to 7)

When all of these bits are set to 0 (CF0CE[7:0] bits = 00h), it is always judged that Control Field 0 matches when reception is completed, and the XSR0.CF0MF flag is set.

BFLW[15:0] Bits (Break Field Low Width Setting)

The BFLW[15:0] bits are 16-bit Break Field length setting bits and the initial value is FFFEh.

Set the break field length to 1 frame or more. The LIN standard stipulates that the Break Field length is 13 bits or more.

When sending the Break Field, writing 1 to the TCST bit leads RSCI to output the Break Field on the TXDn pin. At the same time, the timer starts counting with the timer count clock source selected by the XCR0.TCSS[1:0] bits. When the count value matches the value set in this register, up-counting is stopped and Break Field transmission from the TXDn pin is also stopped.

When detecting the Break Field, writing 1 to the SDST bit leads Start Frame detection to be enabled. RSCI starts counting from the negative edge of the RXDn signal. The timer count clock source is selected by the XCR0.TCSS[1:0] bits. When the count value matches the value set in this register, it is determined that a break field has been detected. Up-counting continues until the next valid edge or counter overflow.

42.2.17 Status Register (SSR)

Address(es): RSCI0.SSR 8745 8048h, RSCI1.SSR 8745 8148h, RSCI2.SSR 8745 8248h, RSCI3.SSR 8745 8348h, RSCI4.SSR 8745 8448h, RSCI5.SSR 8745 8548h, RSCI6.SSR 8745 8648h, RSCI7.SSR 8745 8748h, RSCI8.SSR 8745 8848h, RSCI9.SSR 8745 8948h, RSCI10.SSR 8745 8A48h, RSCI11.SSR 8745 8B48h, RSCI12.SSR 8745 8C48h,

R
b30	TEND	Transmit End Flag	0: A character is being transmitted or standing by for transmission. 1: Character transfer has been completed, or sending Break Field.	R
b31	RDRF	Receive Data Full Flag	[Non-FIFO selected (SCR3.FM bit = 0)] 0: No received data is in RDR register 1: Received data is in RDR register [FIFO selected (SCR3.FM bit = 1)] 0: The quantity of receive data written in receive FIFO falls below the specified receive triggering number. 1: The quantity of receive data written in receive FIFO is equal to or greater than the specified receive triggering number.	R

ERS Flag (Error Signal Status Flag)

[Setting condition]

- When an error signal Low is sampled.

[Clearing condition]

- When write 1 to SSCR.ERSC bit.

DCMF Flag (Data Match Flag)

Indicates that RSCI detects the match to the comparison data (SCR4.CMPD[8:0] bits) with receive data.

Clearing the SCR0.RE bit to 0 does not affect the DCMF flag, which retains its previous state.

[Setting condition]

- Matched to the comparison data (SCR4.CMPD[8:0] bits) with receive data, while SCR0.DCME bit = 1.

[Clearing condition]

- When write 1 to SSCR.DCMFC bit.

DPER Flag (Matched Data Parity Error Flag)

It indicates that a parity error occurred at data match detection.

Clearing the SCR0.RE bit to 0 does not affect the DPER flag, which retains its previous state.

[Setting condition]

- When a parity error was detected by the frame in which an data match was detected.

[Clearing condition]

- When write 1 to SSCR.DPERC bit.

Refer to section 15.5.2, Level Detection to exit from the interrupt handling routine after setting the DPER flag to 0.

DFER Flag (Matched Data Framing Error Flag)

It indicates that a framing error occurred at data match detection.
Clearing the SCR0.RE bit to 0 does not affect the DFER flag, which retains its previous state.
[Setting condition]

- When a stop bit of the frame in which an data match was detected is 0.
  When it is a 2-stop mode, the 1st bit of stop bit judges only whether it's 1 and doesn't check the 2nd bit of stop bit.

[Clearing condition]

- When write 1 to SSCR.DFERC bit.

Refer to section 15.5.2, Level Detection to exit from the interrupt handling routine after setting the DFER flag to 0.

ORER Flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.
Clearing the SCR0.RE bit to 0 does not affect the ORER flag, which retains its previous state. In simple I^2C mode, this bit is not use.
[Setting condition with non-FIFO mode (SCR3.FM bit = 0)]

- When the next data is received before reading out RDR register with no error reception data stored in RDR register.

In RDR register, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, reception data isn't forwarded to RDR register. Note that, in clock synchronous mode and simple SPI mode, serial reception will be stop.
[Setting condition with FIFO mode (SCR3.FM bit = 1)]

- When the next serial reception is completed while the receive FIFO is full of 16 receive data.

[Clearing condition]

- When write 1 to SSCR.ORERC bit.

Refer to section 15.5.2, Level Detection to exit from the interrupt handling routine after setting the ORER flag to 0.

MFF Flag (Mode Fault Flag)

This bit indicates mode faults. In a multi-master configuration, determine the mode fault occurrence by reading the MFF flag.
[Setting condition]

- Input on the SSn# pin being at the low level during master operation (SCR3.CKE[1:0] bits = 00b or 01b) in simple SPI mode.

[Clearing condition]

- When write 1 to SSCR.MFFC bit.

APER Flag (Aggregate Parity Error Flag)

Indicates that a parity error has occurred during reception and the reception ends abnormally.
Clearing the SCR0.RE bit to 0 does not affect the APER flag, which retains its previous state.
In clock synchronous mode, simple SPI mode and simple I^2C mode, this bit not used.
[Setting condition]

- In non-FIFO mode, when a parity error is detected during reception.
- In FIFO mode, when one or more parity error is detected for data in receive FIFO.

In non-FIFO mode, the received data when the parity error occurs is transferred to RDR register, but no RXI interrupt request occurs. Note that when the APER flag is being set to 1, the subsequent receive data is not transferred to RDR register.
[Clearing condition]

- When write 1 to SSCR.APERC bit.

Refer to section 15.5.2, Level Detection to exit from the interrupt handling routine after setting the APER flag to 0.

AFER Flag (Aggregate Framing Error Flag)

Indicates that a framing error has occurred during reception and the reception ends abnormally. Clearing the SCR0.RE bit to 0 does not affect the AFER flag, which retains its previous state.
In clock synchronous mode, simple SPI mode and simple I^2C mode, this bit not used.
[Setting condition]

- In non-FIFO mode, when 0 is sampled as the stop bit during reception.
- In FIFO mode, when one or more framing error is detected for data in receive FIFO.
- In Manchester mode, when both sampling results (1/4 and 3/4 sampling points) are not 1 for 1 stop bit.

In 2 stop bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked.
In non-FIFO mode, the received data when the framing error occurs is transferred to RDR register, but no RXI interrupt request occurs. In addition, when the AFER flag is being set to 1, the subsequent receive data is not transferred to RDR register.
In extended serial mode, even if a condition that changes to 1 occurs when XCR1.SDST bit = 1, the AFER flag set timing is delayed up to the Break Field judgment timing at the longest, since it may be a Break Field. If an edge is detected on the RXD signal before the Break Field judgment timing, AFER is detected. If no edge is detected in the RXD signal before the Break Field judgment timing, Break Field is detected.
[Clearing condition]

- When write 1 to SSCR.AFERC bit.

Refer to section 15.5.2, Level Detection to exit from the interrupt handling routine after setting the AFER flag to 0.

TDRE Flag (Transmit Data Empty Flag)

(1) Non-FIFO selected (SCR3.FM bit = 0)
Indicates the presence of transmit data in the TDR register.
The condition of SCR0.TE bit = 0 has priority over the condition of 0.
If other conditions that become 1 and conditions that become 0 are satisfied at the same time, the TDRE flag is set to 0.
[Setting condition]

- When SCR0.TE bit is 0.
- When data is transmitted from the TDR register to the TSR register.

[Clearing condition]

- When write 1 to SSCR.TDREC bit.
- When the transmission data is written to the TDR register during SCR0.TE bit = 1.

(2) FIFO selected (SCR3.FM bit = 1)
Indicates that data has been transferred from the transmit FIFO (TDR register) into the transmit shift register (TSR), the quantity of data in transmit FIFO has fallen below the specified transmit triggering number.
When the condition which becomes 1 and the condition which becomes 0 were formed at the same time, TDRE flag will be 0. After that, when the number of data stored in transmit FIFO is judged, and if that is equal to or less than TTRG[4:0] value, TDRE flag is set to 1 after 1 PCLK cycle.
[Setting condition]

- When the quantity of transmit data written in transmit FIFO is equal to or less than the specified transmit triggering number*1.

[Clearing condition]

- When write 1 to SSCR.TDREC bit.
- When the transmission data is written to transmit FIFO by the DTC or DMAC (the last block transfer when block transfer).

Note 1. Because the transmit FIFO is a 16-stage FIFO register, the maximum number of data that can be written to the TDR register when the TDRE flag is 1 is “16 – TFSR.T[5:0]”. All other data written to the TDR register above that value is ignored.

TEND Flag (Transmit End Flag)

(1) Non-FIFO selected (SCR3.FM bit = 0), and not smart card interface mode (SCR3.MOD[2:0] bits ≠ 001b)

Indicates completion of transmission.

[Setting condition]

- When SCR0.TE bit is 0.
- When the SCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted.
- When the TDR register is not updated at the end of DE signal hold time with DE control function enable (SCR3.DEEN bit = 1).
- When Break Field is sending.

[Clearing condition]

- When the transmission data was written to the TDR register during SCR0.TE bit = 1.
- When write 1 to SSCR.TDREC bit during SCR0.TE bit = 1.

Refer to section 15.5.2, Level Detection to exit from the interrupt handling routine after setting the TEND flag to 0.

(2) Non-FIFO selected (SCR3.FM bit = 0), and smart card interface mode (SCR3.MOD[2:0] bits = 001b)

With no error signal from the receiving side, this bit is set to 1 when further data for transfer is ready to be transferred to the TDR register.

[Setting condition]

- When SCR0.TE bit is 0.
- When the SCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period has elapsed after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated.
  The set timing is determined by register settings as listed below.
  When GM bit = 0 and BLK bit = 0, 12.5 etu after the start of transmission
  When GM bit = 0 and BLK bit = 1, 11.5 etu after the start of transmission
  When GM bit = 1 and BLK bit = 0, 11.0 etu after the start of transmission
  When GM bit = 1 and BLK bit = 1, 11.0 etu after the start of transmission

[Clearing condition]

- When the transmission data was written to the TDR register during SCR0.TE bit = 1.
- When write 1 to SSCR.TDREC bit during SCR0.TE bit = 1.

(3) FIFO selected (SCR3.FM bit = 1)

Indicates that the transmit FIFO does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- TEND is set to 1 when transmit FIFO does not contain transmit data when the last bit of a one-byte serial character is transmitted.
- When the TDR register is not updated at the end of DE signal hold time with DE control function enable (SCR3.DEEN bit = 1).

[Clearing condition]

- When the transmission data was written to the TDR.TDAT[7:0] bits during SCR0.TE bit = 1.

RDRF Flag (Receive Data Full Flag)

(1) Non-FIFO selected (SCR3.FM bit = 0)

Indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing condition]

- When write 1 to SSCR.RDRFC bit.
- When the read data is read from the RDR register.

(2) FIFO selected (SCR3.FM bit = 1)

Indicates that receive data has been transferred to the receive FIFO (RDR register), and the quantity of data in receive FIFO is equal to or greater than the specified receive triggering number. When FCR.RTRG[4:0] bits are set to 0, RDRF flag is set if the quantity of data in receive FIFO is greater than or equal to 1.

[Setting condition]

RDRF is set to 1 when the quantity of receive data in receive FIFO is equal to or greater than the specified receive triggering number*2.

[Clearing condition]

- When write 1 to SSCR.RDRFC bit.
- When the reception data is read form receive FIFO by the DTC or DMAC (the last block transfer when block transfer).

When the condition which becomes 1 and the condition which becomes 0 were formed at the same time, RDRF flag will be 0. After that, when the number of stored data in receive FIFO is judged, and if that is equal to or greater than RTRG[4:0] value, RDRF flag is set to 1 after 1 PCLK cycle.

Note 2. Since the receive FIFO is a 16-stage FIFO register, the maximum number of data that can be read when RDRF is 1 is indicated by the RFSR.R[5:0] bits. After reading all the data in the RDR register, continuing a read access results in an undefined value.

Note: In non-FIFO mode, do not clear the RDRF and TDRE flags by the SSCR register except when the communication is to be aborted.

42.2.18 I²C Status Register (SISR)

Address(es): RSCI0.SISR 8745 804Ch, RSCI1.SISR 8745 814Ch, RSCI2.SISR 8745 824Ch, RSCI3.SISR 8745 834Ch, RSCI4.SISR 8745 844Ch, RSCI5.SISR 8745 854Ch, RSCI6.SISR 8745 864Ch, RSCI7.SISR 8745 874Ch, RSCI8.SISR 8745 884Ch, RSCI9.SISR 8745 894Ch, RSCI10.SISR 8745 8A4Ch, RSCI11.SISR 8745 8B4Ch, RSCI12.SISR 8745 8C4Ch, RSCI0_NS.SISR 0745 804Ch, RSCI1_NS.SISR 0745 814Ch, RSCI2_NS.SISR 0745 824Ch, RSCI3_NS.SISR 0745 834Ch, RSCI4_NS.SISR 0745 844Ch, RSCI5_NS.SISR 0745 854Ch, RSCI6_NS.SISR 0745 864Ch, RSCI7_NS.SISR 0745 874Ch, RSCI8_NS.SISR 0745 884Ch, RSCI9_NS.SISR 0745 894Ch, RSCI10_NS.SISR 0745 8A4Ch, RSCI11_NS.SISR 0745 8B4Ch, RSCI12_NS.SISR 0745 8C4Ch

b1	—	Reserved	This bit is read as 0.	R
b2	—	Reserved	The read value is undefined.	R
b3	IICSTIF	Condition Generation Completed Flag	0: There are no requests for generating conditions or a condition is being generated. 1: A start, restart, or stop condition is completely generated.	R
b5, b4	—	Reserved	The read value is undefined.	R
b31 to b6	—	Reserved	These bits are read as 0.	R

IICACKR Flag (ACK Reception Data Flag)

Received ACK and NACK bits can be read from this flag.

The IICACKR flag is updated at the rising of SSCLn signal for the ACK/NACK receiving bit.

IICSTIF Flag (Condition Generation Completed Flag)

After generating a condition, this flag indicates that the generation is completed. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR0.TEIE bit, an STI request is output.

[Setting condition]

- Completion of the generation of a start, restart, or stop condition (however, in cases where this conflicts with any of the conditions for the flag becoming 0 listed below, the clearing condition takes precedence)

[Clearing condition]

- Writing 1 to SISCR.IICSTIFC bit
- When operation is not in simple I²C
- Writing 0 to SCR0.TE bit

42.2.19 Receive FIFO Status Register (RFSR)

Address(es): RSCI0.RFSR 8745 8050h, RSCI1.RFSR 8745 8150h, RSCI2.RFSR 8745 8250h, RSCI3.RFSR 8745 8350h, RSCI4.RFSR 8745 8450h, RSCI5.RFSR 8745 8550h, RSCI6.RFSR 8745 8650h, RSCI7.RFSR 8745 8750h, RSCI8.RFSR 8745 8850h, RSCI9.RFSR 8745 8950h, RSCI10.RFSR 8745 8A50h, RSCI11.RFSR 8745 8B50h, RSCI12.RFSR 8745 8C50h,
RSCI0_NS.RFSR 0745 8050h, RSCI1_NS.RFSR 0745 8150h, RSCI2_NS.RFSR 0745 8250h, RSCI3_NS.RFSR 0745 8350h, RSCI4_NS.RFSR 0745 8450h, RSCI5_NS.RFSR 0745 8550h, RSCI6_NS.RFSR 0745 8650h, RSCI7_NS.RFSR 0745 8750h, RSCI8_NS.RFSR 0745 8850h, RSCI9_NS.RFSR 0745 8950h, RSCI10_NS.RFSR 0745 8A50h, RSCI11_NS.RFSR 0745 8B50h, RSCI12_NS.RFSR 0745 8C50h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	FEC[5:0]						—	—	PEC[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	R[5:0]						—	—	—	—	—	—	—	DR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DR	Receive Data Ready Flag	0: Receiving is in progress, or no received data has remained in receive FIFO after normally completed receiving. (receive FIFO is empty) 1: The following receive data does not come for a fixed period after storing data below the threshold in the receive FIFO	R
b1	—	Reserved	This bit is undefined when read.	R
b7 to b2	—	Reserved	These bits are read as 0.	R
b13 to b8	R[5:0]	Receive FIFO Data Count	(Valid in asynchronous mode (including multi-processor), clock synchronous mode, simple SPI mode, when SCR3.FM bit is 1.) Indicate the quantity of receive data stored in receive FIFO	R
b15, b14	—	Reserved	These bits are read as 0.	R
b21 to b16	PEC[5:0]	Parity Error Count	(Valid only in asynchronous mode) Indicates the quantity of data with a parity error among the receive data stored in the receive FIFO data register.	R
b23, b22	—	Reserved	These bits are read as 0.	R
b29 to b24	FEC[5:0]	Framing Error Count	(Valid only in asynchronous mode) Indicates the quantity of data with a framing error among the receive data stored in the receive FIFO data register.	R
b31, b30	—	Reserved	These bits are read as 0.	R

DR Flag (Receive Data Ready Flag)

Indicates that the quantity of data stored in the receive FIFO (RDR register) falls below the specified receive triggering number, and that no next data has been received yet after the elapse of 15 etu from the last stop bit in asynchronous mode. This flag becomes 1 only when the FIFO buffer is enabled in synchronous mode (including multiprocessor mode), and does not become 1 in other modes.

[Setting conditions]

DR is set to 1 when the following conditions are met.

- After receive FIFO (RDR register) receives less data than the specified receive triggering number, no next data has been received yet after the elapse of 15 etu*1 from the last stop bit
- SSR.AFER and APER flags are 0.

[Clearing conditions]

- When all receive data in the receive FIFO (RDR register) is read and 1 is written to RFSCR.DRC bit.

- When SCR3.FM bit is 0.

Refer to section 15.5.2, Level Detection to exit from the interrupt handling routine after setting the DR flag to 0 when the DR flag is set to the source of the receive error interrupt by setting the FCR.DRES bit to 1.

Note 1. This is equivalent to one and a half (1.5) frames in the 8-bit format with one stop bit (etu: elementary time unit).

R[5:0] Bits (Receive FIFO Data Count)

Indicate the quantity of receive data stored in receive FIFO.
00h means no receive data. 10h means receive FIFO is full.

PEC[5:0] Bits (Parity Error Count)

The value indicates the quantity of data stored in the receive FIFO registers with a parity error.

FEC[5:0] Bits (Framing Error Count)

The value indicates the quantity of data stored in the receive FIFO registers with a framing error.

42.2.20 Transmit FIFO Status Register (TFSR)

Address(es): RSCI0.TFSR 8745 8054h, RSCI1.TFSR 8745 8154h, RSCI2.TFSR 8745 8254h, RSCI3.TFSR 8745 8354h, RSCI4.TFSR 8745 8454h, RSCI5.TFSR 8745 8554h, RSCI6.TFSR 8745 8654h, RSCI7.TFSR 8745 8754h, RSCI8.TFSR 8745 8854h, RSCI9.TFSR 8745 8954h, RSCI10.TFSR 8745 8A54h, RSCI11.TFSR 8745 8B54h, RSCI12.TFSR 8745 8C54h,
RSCI0_NS.TFSR 0745 8054h, RSCI1_NS.TFSR 0745 8154h, RSCI2_NS.TFSR 0745 8254h, RSCI3_NS.TFSR 0745 8354h, RSCI4_NS.TFSR 0745 8454h, RSCI5_NS.TFSR 0745 8554h, RSCI6_NS.TFSR 0745 8654h, RSCI7_NS.TFSR 0745 8754h, RSCI8_NS.TFSR 0745 8854h, RSCI9_NS.TFSR 0745 8954h, RSCI10_NS.TFSR 0745 8A54h, RSCI11_NS.TFSR 0745 8B54h, RSCI12_NS.TFSR 0745 8C54h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	T[5:0]	Transmit FIFO Data Count	(Valid in asynchronous mode (including multi-processor), clock synchronous mode, simple SPI mode, when SCR3.FM bit is 1.) Indicate the quantity of non-transmit data stored in transmit FIFO	R
b31 to b6	—	Reserved	These bits are read as 0.	R

T[5:0] Bits (Transmit FIFO Data Count)

Indicate the quantity of non-transmitted data stored in transmit FIFO.

00h means no untransmitted data. 10h means transmit FIFO is full.

42.2.21 Manchester Mode Status Register (MMSR)

Address(es): RSCI0.MMSR 8745 8058h, RSCI1.MMSR 8745 8158h, RSCI2.MMSR 8745 8258h, RSCI3.MMSR 8745 8358h, RSCI4.MMSR 8745 8458h, RSCI5.MMSR 8745 8558h, RSCI6.MMSR 8745 8658h, RSCI7.MMSR 8745 8758h, RSCI8.MMSR 8745 8858h, RSCI9.MMSR 8745 8958h, RSCI10.MMSR 8745 8A58h, RSCI11.MMSR 8745 8B58h, RSCI12.MMSR 8745 8C58h,
RSCI0_NS.MMSR 0745 8058h, RSCI1_NS.MMSR 0745 8158h, RSCI2_NS.MMSR 0745 8258h, RSCI3_NS.MMSR 0745 8358h, RSCI4_NS.MMSR 0745 8458h, RSCI5_NS.MMSR 0745 8558h, RSCI6_NS.MMSR 0745 8658h, RSCI7_NS.MMSR 0745 8758h, RSCI8_NS.MMSR 0745 8858h, RSCI9_NS.MMSR 0745 8958h, RSCI10_NS.MMSR 0745 8A58h, RSCI11_NS.MMSR 0745 8B58h, RSCI12_NS.MMSR 0745 8C58h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	RSYNC	—	MCER	—	SBER	SYER	PFER
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PFER	Preface Error Flag	This bit is set when a preface error (pattern mismatch) is detected 0: No preface error detected 1: Preface error detected	R
b1	SYER	Sync Error Flag	This bit is set when no edge is detected in the adjustable range during receive retiming 0: No receive Sync error detected 1: Receive Sync error detected	R
b2	SBER	Start Bit Error Flag	This bit is set when a pattern mismatch in the start bit area is detected 0: No start bit error detected 1: Start bit error detected	R
b3	—	Reserved	This bit is read as 0.	R
b4	MCER	Manchester Code Error Flag	Valid for Manchester mode only 0: No Manchester code error occurred 1: Manchester code error has occurred	R
b5	—	Reserved	This bit is read as 0.	R
b6	RSYNC	Received Sync Data	It is valid when MMCR.SBLEN bit = 1 in Manchester mode, 0 is read otherwise. 0: The received the Start Bit is DATA Sync 1: The received the Start Bit is COMMAND Sync	R
b31 to b7	—	Reserved	These bits are read as 0.	R

PFER Flag (Preface Error Flag)

This bit indicates that a preface error was detected when receiving frames in Manchester mode.

Even when the SCR0.RE bit is set to 0 (serial reception is disabled), the PFER flag is not affected and retains its previous value.

[Setting condition]

When detecting a preface error when receiving frames in Manchester mode

The following operations are performed when a preface error occurs.

<When MMCR.PFERIE = 1>

The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the PFER flag is being set to 1, the subsequently received data is not transferred to the RDR register.

<When MMCR.PFERIE = 0>

The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the PFER flag being set to 1.
[Clearing condition]
Write 1 to MMSCR.PFERC bit.
Refer to section 15.5.2, Level Detection to exit from the interrupt handling routine after setting the PFER flag to 0.

SYER Flag (Sync Error Flag)

This bit indicates that a receive Sync error was detected when receiving frames in Manchester mode with MMCR.SADJE bit = 1 (Manchester edge retiming enabled).
Even when the SCR0.RE bit is set to 0 (serial reception is disabled), the SYER flag is not affected and retains its previous value.
[Setting condition]
When detecting a receive Sync error when receiving frames in Manchester mode
The following operations are performed when a receive Sync error occurs.
<When MMCR.SYERIE = 1>
Although the received data is transferred to the RDR register, no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the SYER flag is being set to 1, the subsequently received data is not transferred to the RDR register.
<When MMCR.SYERIE = 0>
The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SYER flag being set to 1.
[Clearing condition]
Write 1 to MMSCR.SYERC bit.
Refer to section 15.5.2, Level Detection to exit from the interrupt handling routine after setting the SYER flag to 0.

SBER Flag (Start Bit Error Flag)

This bit indicates that a start bit error was detected when receiving frames in Manchester mode.
Even when the SCR0.RE bit is set to 0 (serial reception is disabled), the SBER flag is not affected and retains its previous value.
[Setting condition]
When detecting a start bit error when receiving frames in Manchester mode
The following operations are performed when a start bit error occurs.
<When MMCR.SBERIE bit = 1>
The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the SBER flag is being set to 1, the subsequently received data is not transferred to the RDR register.
<When MMCR.SBERIE bit = 0>
The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SBER flag being set to 1.
[Clearing condition]
Write 1 to MMSCR.SBERC bit.
Refer to section 15.5.2, Level Detection to exit from the interrupt handling routine after setting the SBER flag to 0.

MCER Flag (Manchester Code Error Flag)

When data is received in Manchester mode, Manchester code error is detected, and it is displayed. Even when the SCR0.RE bit is set to 0 (serial reception is disabled), the MCER flag is not affected and retains its previous value.
[Setting conditions]
When receiving in Manchester mode and detecting Manchester code error in data area of received frame.
Received data when an error occurs is transferred to the RDR register, but the RXI interrupt request is not generated.
When the Manchester code error flag is set to 1, subsequent receive data is not transferred to the RDR register.
For details on Manchester code error, see section 42.5.11, Errors in Manchester Mode.
[Clearing condition]
Write 1 to MMSCR.MCERC bit.
Refer to section 15.5.2, Level Detection to exit from the interrupt handling routine after setting the MCER flag to 0.

RSYNC Flag (Received Sync Data)

When Manchester mode (SCR3.MOD[2:0] = 101b) and MMCR.SBLEN = 1, this bit indicates the type of Sync of the received the start bit. For other settings, it is fixed to 0.

42.2.22 Extended Serial Mode Status Register 0 (XSR0)

Address(es): RSCI0.XSR0 8745 805Ch, RSCI1.XSR0 8745 815Ch, RSCI2.XSR0 8745 825Ch, RSCI3.XSR0 8745 835Ch, RSCI4.XSR0 8745 845Ch, RSCI5.XSR0 8745 855Ch, RSCI6.XSR0 8745 865Ch, RSCI7.XSR0 8745 875Ch, RSCI8.XSR0 8745 885Ch, RSCI9.XSR0 8745 895Ch, RSCI10.XSR0 8745 8A5Ch, RSCI11.XSR0 8745 8B5Ch, RSCI12.XSR0 8745 8C5Ch, RSCI0_NS.XSR0 0745 805Ch, RSCI1_NS.XSR0 0745 815Ch, RSCI2_NS.XSR0 0745 825Ch, RSCI3_NS.XSR0 0745 835Ch, RSCI4_NS.XSR0 0745 845Ch, RSCI5_NS.XSR0 0745 855Ch, RSCI6_NS.XSR0 0745 865Ch, RSCI7_NS.XSR0 0745 875Ch, RSCI8_NS.XSR0 0745 885Ch, RSCI9_NS.XSR0 0745 895Ch, RSCI10_NS.XSR0 0745 8A5Ch, RSCI11_NS.XSR0 0745 8B5Ch, RSCI12_NS.XSR0 0745 8C5Ch

b23 to b16	CF0RD[7:0]	Control Field 0 Received Data	Control Field 0 received data.	R
b31 to b24	CF1RD[7:0]	Control Field 1 Received Data	Control Field 1 received data.	R

Note 1. Wait at least 1 TCLK cycle after the receive data full interrupt (RXI) before reading this register.

SFSF Flag (Start Frame Status Flag)

Indicates whether detect Start Frame is being detected.
[Setting condition]

- When 1 is written to XCR1.SDST bit.
- When a Break Field is detected in the Control Field 0/Control Field 1/Information Field phase and the transition to the Control Field 0 or Control Field 1 reception state occurs.

[Clearing condition]

- When XCR1.SDST bit is 0.
- When Start Frame detection is completed.

RXDSF Flag (RXD Input Status Flag)

Indicates the RXD input status to the RSCI core. When this bit is 1, RXD input is received only by the extended serial module and the Break Field is detected and is not input to the RSCI core.

42.2.23 Extended Serial Mode Status Register 1 (XSR1)

Address(es): RSCI0.XSR1 8745 8060h, RSCI1.XSR1 8745 8160h, RSCI2.XSR1 8745 8260h, RSCI3.XSR1 8745 8360h, RSCI4.XSR1 8745 8460h, RSCI5.XSR1 8745 8560h, RSCI6.XSR1 8745 8660h, RSCI7.XSR1 8745 8760h, RSCI8.XSR1 8745 8860h, RSCI9.XSR1 8745 8960h, RSCI10.XSR1 8745 8A60h, RSCI11.XSR1 8745 8B60h, RSCI12.XSR1 8745 8C60h,

	CCV[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CCV[15:0]	Captured Count Value	Stores the 16-bit counter capture value.	R
b31 to b16	—	Reserved	These bits are read as 0.	R

CCV[15:0] Bits (Captured Count Value)

Stores the capture value of the 16-bit counter of the extended serial module.

When sending Start Frame

This register holds the previous value.

When receiving Start Frame with bit rate measurement disabled

If a Break Field is detected in the Break Field detection state (refer to Figure 42.74), the Break Field length is captured and held (counter value is captured at the rising edge of RXD).

If a Break Field is detected in a state other than the Break Field detection state, the previous value is retained.

If the counter overflows, it will not be captured.

When receiving Start Frame with bit rate measurement enabled

The count value is captured and held at the valid edge (both RXD edges). However, in the Break Field detection state, the count value is not captured even if a valid edge occurs. Counter capture value retention is canceled by this register read. Even if a valid edge occurs before reading, the counter value is not captured.

42.2.24 Status Clear Register (SSCR)

Address(es): RSCI0.SSCR 8745 8068h, RSCI1.SSCR 8745 8168h, RSCI2.SSCR 8745 8268h, RSCI3.SSCR 8745 8368h, RSCI4.SSCR 8745 8468h, RSCI5.SSCR 8745 8568h, RSCI6.SSCR 8745 8668h, RSCI7.SSCR 8745 8768h, RSCI8.SSCR 8745 8868h, RSCI9.SSCR 8745 8968h, RSCI10.SSCR 8745 8A68h, RSCI11.SSCR 8745 8B68h, RSCI12.SSCR 8745 8C68h,

b15	AEDCL	AEDF Clear	Setting this bit to 1 clears the XSR0.AEDF flag. The read value is always 0.	W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

42.2.29 Internal Signal Status Register (SISSR)

Address(es): RSCI0.SISSR 8745 801Ch, RSCI1.SISSR 8745 811Ch, RSCI2.SISSR 8745 821Ch, RSCI3.SISSR 8745 831Ch, RSCI4.SISSR 8745 841Ch, RSCI5.SISSR 8745 851Ch, RSCI6.SISSR 8745 861Ch, RSCI7.SISSR 8745 871Ch, RSCI8.SISSR 8745 881Ch, RSCI9.SISSR 8745 891Ch, RSCI10.SISSR 8745 8A1Ch, RSCI11.SISSR 8745 8B1Ch, RSCI12.SISSR 8745 8C1Ch,
RSCI0_NS.SISSR 0745 801Ch, RSCI1_NS.SISSR 0745 811Ch, RSCI2_NS.SISSR 0745 821Ch, RSCI3_NS.SISSR 0745 831Ch, RSCI4_NS.SISSR 0745 841Ch, RSCI5_NS.SISSR 0745 851Ch, RSCI6_NS.SISSR 0745 861Ch, RSCI7_NS.SISSR 0745 871Ch, RSCI8_NS.SISSR 0745 881Ch, RSCI9_NS.SISSR 0745 891Ch, RSCI10_NS.SISSR 0745 8A1Ch, RSCI11_NS.SISSR 0745 8B1Ch, RSCI12_NS.SISSR 0745 8C1Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	ITEF	—	—	—	IREF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IREF	Internal RE Signal Monitor Flag	0: Internal RE signal state is 0. 1: Internal RE signal state is 1.	R
b3 to b1	—	Reserved	These bits are read as 0.	R
b4	ITEF	Internal TE Signal Monitor Flag	0: Internal TE signal state is 0. 1: Internal TE signal state is 1.	R
b7 to b5	—	Reserved	These bits are read as 0.	R

A different clock than the operating clock of the control registers (PCLK) can be selected for the operating clock of the transmitter and receiver (TCLK). Synchronizers are inserted between the control registers and the transmitter/receiver to ensure correct operation even when a different clock is selected. For this reason, after rewriting the control register, it takes time for the value to propagate internally.

This register is used to monitor the status of the SCR0.TE bit and SCR0.RE bit, which are used to permit transmission and reception, after they have passed through the synchronizer. When changing the SCR0.TE and SCR0.RE bits from 1 to 0 to rewrite control registers for the next communication, be sure to rewrite them after the ITEF and IREF flags have both become 0.

42.2.30 HBS Support Mode Control Register (HBSCR)

Address(es): RSCI0.HBSCR 8745 801Eh, RSCI1.HBSCR 8745 811Eh, RSCI2.HBSCR 8745 821Eh, RSCI3.HBSCR 8745 831Eh, RSCI4.HBSCR 8745 841Eh, RSCI5.HBSCR 8745 851Eh, RSCI6.HBSCR 8745 861Eh, RSCI7.HBSCR 8745 871Eh, RSCI8.HBSCR 8745 881Eh, RSCI9.HBSCR 8745 891Eh, RSCI10.HBSCR 8745 8A1Eh, RSCI11.HBSCR 8745 8B1Eh, RSCI12.HBSCR 8745 8C1Eh,
RSCI0_NS.HBSCR 0745 801Eh, RSCI1_NS.HBSCR 0745 811Eh, RSCI2_NS.HBSCR 0745 821Eh, RSCI3_NS.HBSCR 0745 831Eh, RSCI4_NS.HBSCR 0745 841Eh, RSCI5_NS.HBSCR 0745 851Eh, RSCI6_NS.HBSCR 0745 861Eh, RSCI7_NS.HBSCR 0745 871Eh, RSCI8_NS.HBSCR 0745 881Eh, RSCI9_NS.HBSCR 0745 891Eh, RSCI10_NS.HBSCR 0745 8A1Eh, RSCI11_NS.HBSCR 0745 8B1Eh, RSCI12_NS.HBSCR 0745 8C1Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	LPS	AOE	—	HBSE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	HBSE	HBS Support Mode Enable	0: Pulse width for data 0 is specified as 100% of a bit period (NRZ coding). 1: Pulse width for data 0 is specified as 50% of a bit period (RZI coding and inversion).	R/W *1
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R
b2	AOE	Alternate Output Enable	0: Data is output from the TXDn pin. 1: Data 0 is alternately output from the TXDAn and TXDBn pins.	R/W *1
b3	LPS	Leading Output Pin Select	0: When HBSE bit = 1 and AOE bit = 1, transmission starts from TXDAn pin 1: When HBSE bit = 1 and AOE bit = 1, transmission starts from TXDBn pin	R/W *1
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writable only when SCR0.TE bit = 0 and SCR0.RE bit = 0.

HBSE Bit (HBS Support Mode Enable)

When this bit is 1, the transmitter encodes the transmit data to the negative logic RZI code and the receiver decodes the receive data to the NRZ code. Also, transmit data can be output from the TXDAn/TXDBn pin. This function should be used only in asynchronous mode.

AOE Bit (Alternate Output Enable)

This bit is used to select whether the data is output from the TXDn pin or data 0 is alternately output from the TXDAn and TXDBn pins in HBS support mode.

LPS Bit (Leading Output Pin Select)

This bit is used when the AOE bit is 1 in HBS support mode.
When it is set to 0, the start bit is transmitted from TXDAn pin and the data 0 is output alternately from the TXDBn and TXDAn pins.
When it is set to 1, the start bit is transmitted from TXDBn pin and the data 0 is output alternately from the TXDAn and TXDBn pins.
For details, refer to the operation description in section 42.6, HBS Support Mode.

42.2.31 RXD Input Path Select Register (RXDSEL)

Address(es): RSCI2.RXDSEL 8780 7000h, RSCI3.RXDSEL 8780 7020h, RSCI2_NS.RXDSEL 0780 7000h, RSCI3_NS.RXDSEL 0780 7020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ISEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ISEL	Input Path Select*1	This bit selects the signals for input to the GTIOCnA and GTIOCnB pins of GPTW (n = 11, 13). For GPTW11: 0: Input signals from the GTIOC11A and GTIOC11B pins 1: The TXD2 signal output by RSCI2 For GPTW13: 0: Input signals from the GTIOC13A and GTIOC13B pins 1: The TXD3 signal output by RSCI3	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. When the ISEL bit is set to 1, the RSCI and GPTW should have the same security attribute.

42.3 Operation in Asynchronous Mode

Figure 42.4 shows the general format for asynchronous serial communications.
One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level).
In asynchronous serial communications, the communications line is held in the mark state (high level) when not communicating.
The RSCI monitors the communications line. When the RSCI detects a start bit, it starts serial communication. The detection condition of the start bit changes according to the SCR3.RXDESEL bit setting. RSCI regards space (low level) as a start bit when SCR3.RXDESEL bit is 0. RSCI regards a fall edge as a start bit when RXDESEL bit is 1.
Inside the RSCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and the receiver also have a double-buffered structure (it has also FIFO mode), so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

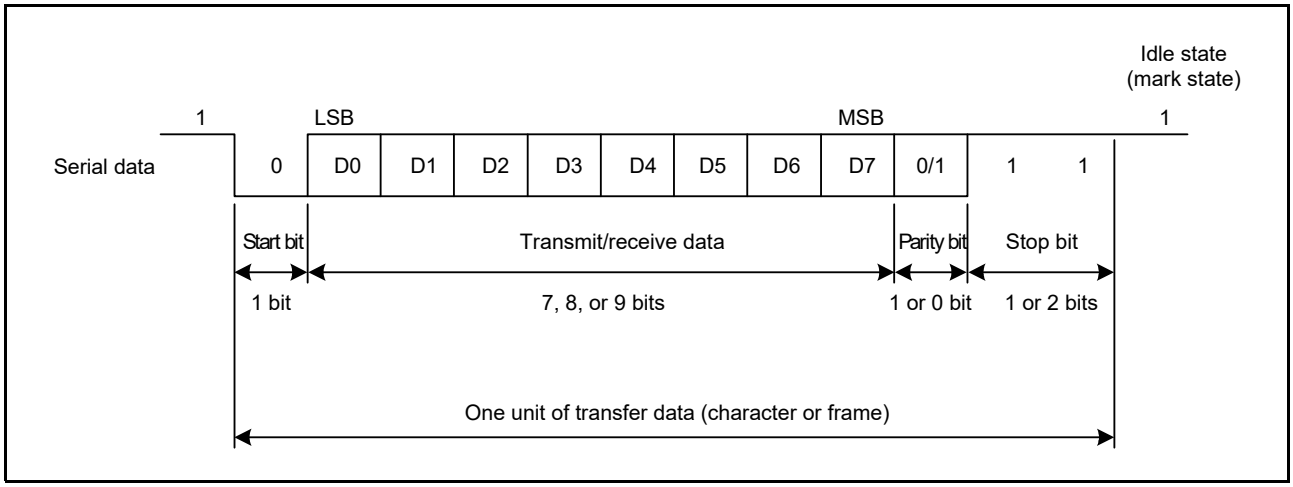

Figure 42.4 Data Format in Asynchronous Serial Communications (Example with 8-Bit Data, Parity, 2 Stop Bits)

42.3.1 Serial Data Transfer Format

Table 42.28 lists the serial data transfer formats that can be used in asynchronous mode.
Any of 18 transfer formats can be selected according to the SCR1 and SCR3 setting. For details of multi-processor function, refer to section 42.4, Multi-Processor Communication Function.

Table 42.28 Serial Transfer Formats (Asynchronous Mode)

SCR3		SCR1	SCR3		Serial Transfer Format and Frame Length
CHR[1]	CHR[0]	PE	MP	STOP	1 2 3 4 5 6 7 8 9 10 11 12 13
0	0	0	0	0	S 9-bit data STOP
0	0	0	0	1	S 9-bit data STOP STOP
0	0	1	0	0	S 9-bit data P STOP
0	0	1	0	1	S 9-bit data P STOP STOP
1	0	0	0	0	S 8-bit data STOP
1	0	0	0	1	S 8-bit data STOP STOP
1	0	1	0	0	S 8-bit data P STOP
1	0	1	0	1	S 8-bit data P STOP STOP
1	1	0	0	0	S 7-bit data STOP
1	1	0	0	1	S 7-bit data STOP STOP
1	1	1	0	0	S 7-bit data P STOP
1	1	1	0	1	S 7-bit data P STOP STOP
0	0	—	1	0	S 9-bit data MPB STOP
0	0	—	1	1	S 9-bit data MPB STOP STOP
1	0	—	1	0	S 8-bit data MPB STOP
1	0	—	1	1	S 8-bit data MPB STOP STOP
1	1	—	1	0	S 7-bit data MPB STOP
1	1	—	1	1	S 7-bit data MPB STOP STOP

S: Start bit
STOP: Stop bit
P: Parity bit
MPB: Multi-processor bit

42.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the RSCI operates on a base clock with a frequency of 16 times*1 the bit rate.
In reception, the RSCI samples the falling edge of the start bit using the base clock, and performs internal synchronization*2. When sampling timing does not adjust (SCR4.RTADJ bit = 0 or SCR4.RTADJ bit = 1 and SCR4.RTMG[2:0] bits = 000b), receive data is sampled at the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle of each bit, as shown in Figure 42.5. Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\ (\%) \quad \cdots \text{Formula (1)}$$

M: Reception margin
N: Ratio of bit rate to clock
(N = 16 when SCR2.ABCSE2 = 0, SCR2.ABCSE = 0, and SCR2.ABCS = 0, N = 8 when SCR2.ABCSE2 = 0, SCR2.ABCSE = 0, and SCR2.ABCS = 1, N = 6 when SCR2.ABCSE2 = 0 and SCR2.ABCSE = 1, N = 4 when SCR2.ABCSE2 = 1 and SCR2.ABCSE = 0)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 13)
F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined by the formula below.

$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ (\%)$

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

Note 1. This is an example when the ABCSE2, ABCSE, and ABCS bits in the SCR2 register is 0. When the ABCSE2 and ABCSE bits are 0 and the ABCS bit is 1, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock. When the ABCSE2 bit is 0 and the ABCSE bit is 1, a frequency of 6 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 3rd pulse of the base clock. When the ABCSE2 bit is 1 and the ABCSE bit is 0, a frequency of 4 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 2nd pulse of the base clock.

Note 2. The determination condition of the start bit is as follows.
In the case of the function of adjust sampling timing is OFF (RTADJ bit = 0):
The determination condition of a start bit is that Low beyond half bit length continues. It is same as the sampling timing.
In Figure 42.5, the low period should be kept over 8-cycles to detect a start bit. If Low period does not keep over 8-cycles, the RSCI judges this as a noise. So, the RSCI does not start reception and wait start bit.
In the case of the function of adjust sampling timing is ON (RTADJ bit = 1):
The determination condition of a start bit is that Low keeps up until the sampling timing.
Adjusting the sampling timing forward (RTMG[3] bit = 1) increases the possibility of erroneously determining a noise as the start bit.

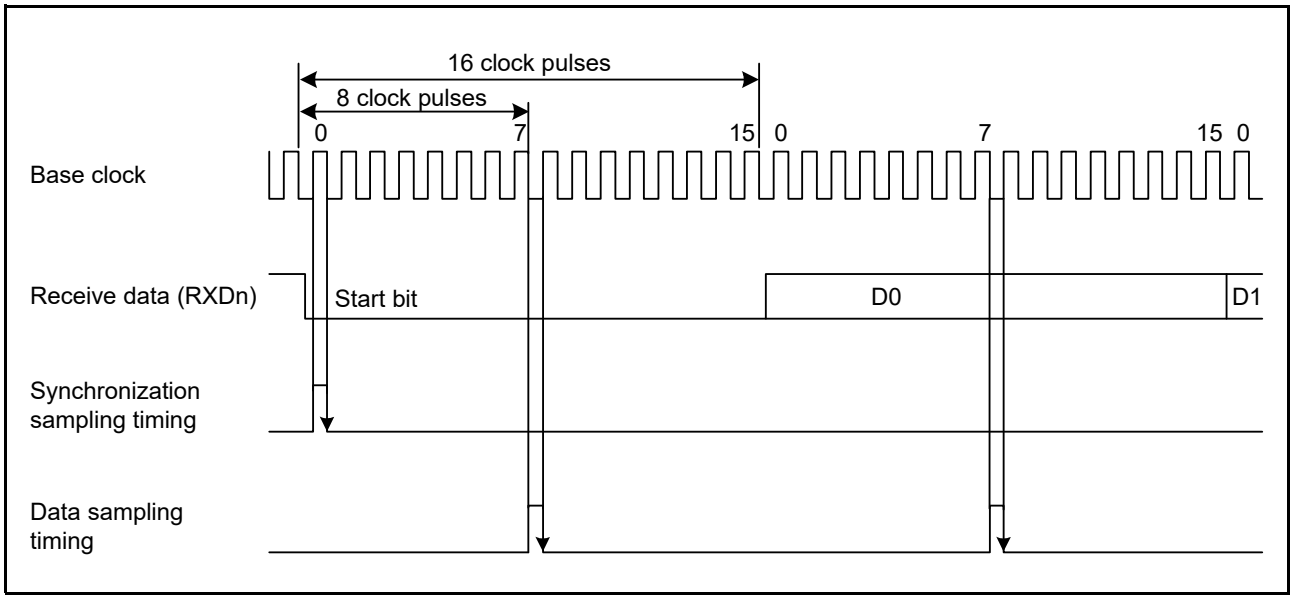

Figure 42.5 Receive Data Sampling Timing in Asynchronous Mode

42.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the RSCI's transfer clock, according to the setting of the SCR3.CKE[1:0] bits.

When an external clock is input to the SCKn pin, the clock frequency should be 16 times the bit rate (when SCR2.ABCS bit = 0) and 8 times the bit rate (when SCR2.ABCS bit = 1). In addition, when an external clock is selected, the base clock generated by TMR0 and TMR1 or TMR2 and TMR3 can be selected by the SCR3.ACS0 bit.

When the RSCI is operated on an internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 42.6.

If you selected an internal clock, the SCKn pin is outputted after SCR0.TE bit is set to 1 or SCR0.RE bit is set to 1.

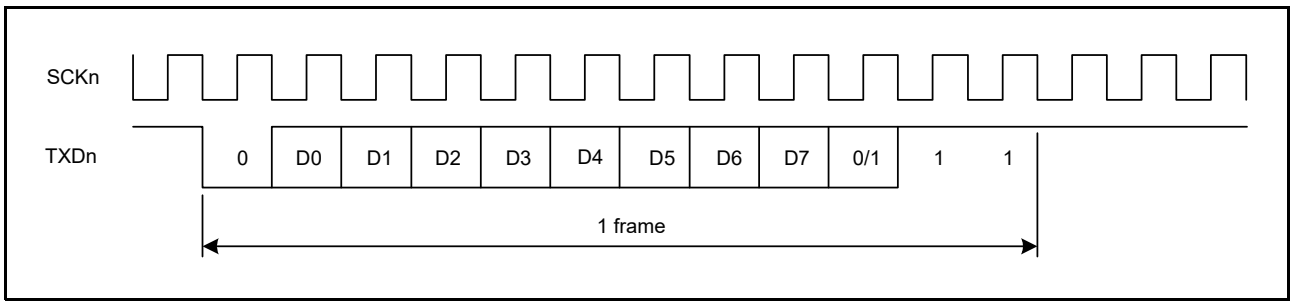

Figure 42.6 Phase Relationship between Output Clock and Transmit Data (Asynchronous Mode: SCR1.PE Bit = 1, SCR3.CHR[1:0] Bits = 10b, MP Bit = 0, STOP Bit = 1)

42.3.4 Double-Speed Mode, Divide-by-6 Mode, and Divided-by-4 Mode

When SCR2.ABCS bit is set to 1, the RSCI operates on the bit rate twice that in the case where ABCS bit is set to 0. And when SCR2.BGDM bit is set to 1, the cycle of the base clock is halved and the bit rate is doubled from that in the case where BGDM bit is set to 0. When SCR3.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the RSCI to operate on a bit rate four times that in the case ABCS bit = 0 and BGDM bit = 0.

When SCR2.ABCSE2 bit is set to 0 and SCR2.ABCSE bit is set to 1, the number of base clock pulses are 6 during a period of 1 bit, and the base clock frequency is half. And RSCI works 16/3 times of bit rate compared with a case of ABCS bit = 0, BGDM bit = 0, ABCSE bit = 0, and ABCSE2 bit = 0.

When SCR2.ABCSE2 bit is set to 1 and SCR2.ABCSE bit is set to 0, the number of base clock pulses are 4 during a period of 1 bit, and the base clock frequency is half. And RSCI works 8 times of bit rate compared with a case of ABCS bit = 0, BGDM bit = 0, ABCSE bit = 0, and ABCSE2 bit = 0.

As shown by Formula (1) in section 42.3.2, Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, the reception margin decreases when ABCS bit is set to 1, ABCSE bit is set to 1, or ABCSE2 bit is set to 1. Therefore, if the desired bit rate can be obtained with ABCS bit set to 0, ABCSE bit set to 0, and ABCSE2 bit set to 0, it is recommended to use the RSCI with ABCS bit set to 0, ABCSE bit set to 0, and ABCSE2 bit set to 0.

42.3.5 CTS and RTS Functions

The CTS function is the transmission control function by the CTSn# pin. Setting the SCR1.CTSE bit to 1 enables the CTS function. For the functions of CTS and RTS, you can select the alternate setting that uses either function with one pin or the dedicated setting that uses each function independently with two pins. This setting is done with the SCR1.CRSEP bit.

When the CTS function is enabled, placing the low level on the CTSn# pin causes transmission to start.

Even if the CTSn# pin goes high after transmission starts, the frame being transmitted is not affected and transmission will continue.

The RTS function is the transmission request function by the RTSn# pin. In the RTS function, the RTSn# pin output low level when reception becomes possible. Conditions for output of the low and high level are shown below.

(a) When the SCR3.FM Bit is 0 (Non-FIFO Mode)

[Conditions for low-level output]

When the following conditions are all satisfied

- The SCR0.RE bit is 1
- There are no received data yet to be read and reception is not in progress
- The ORER, AFER, and APER flags in the SSR are all 0

[Condition for high-level output]

When the conditions for low-level output are not satisfied

(b) When the SCR3.FM Bit is 1 (FIFO Mode)

[Conditions for low-level output]

When the following conditions are all satisfied

- The SCR0.RE bit is 1
- The number of data stored in the receive FIFO is less than the threshold (FCR.RSTRG[4:0] bits)
- The SSR.ORER (RDR.ORER) flag is 0

[Condition for high-level output]

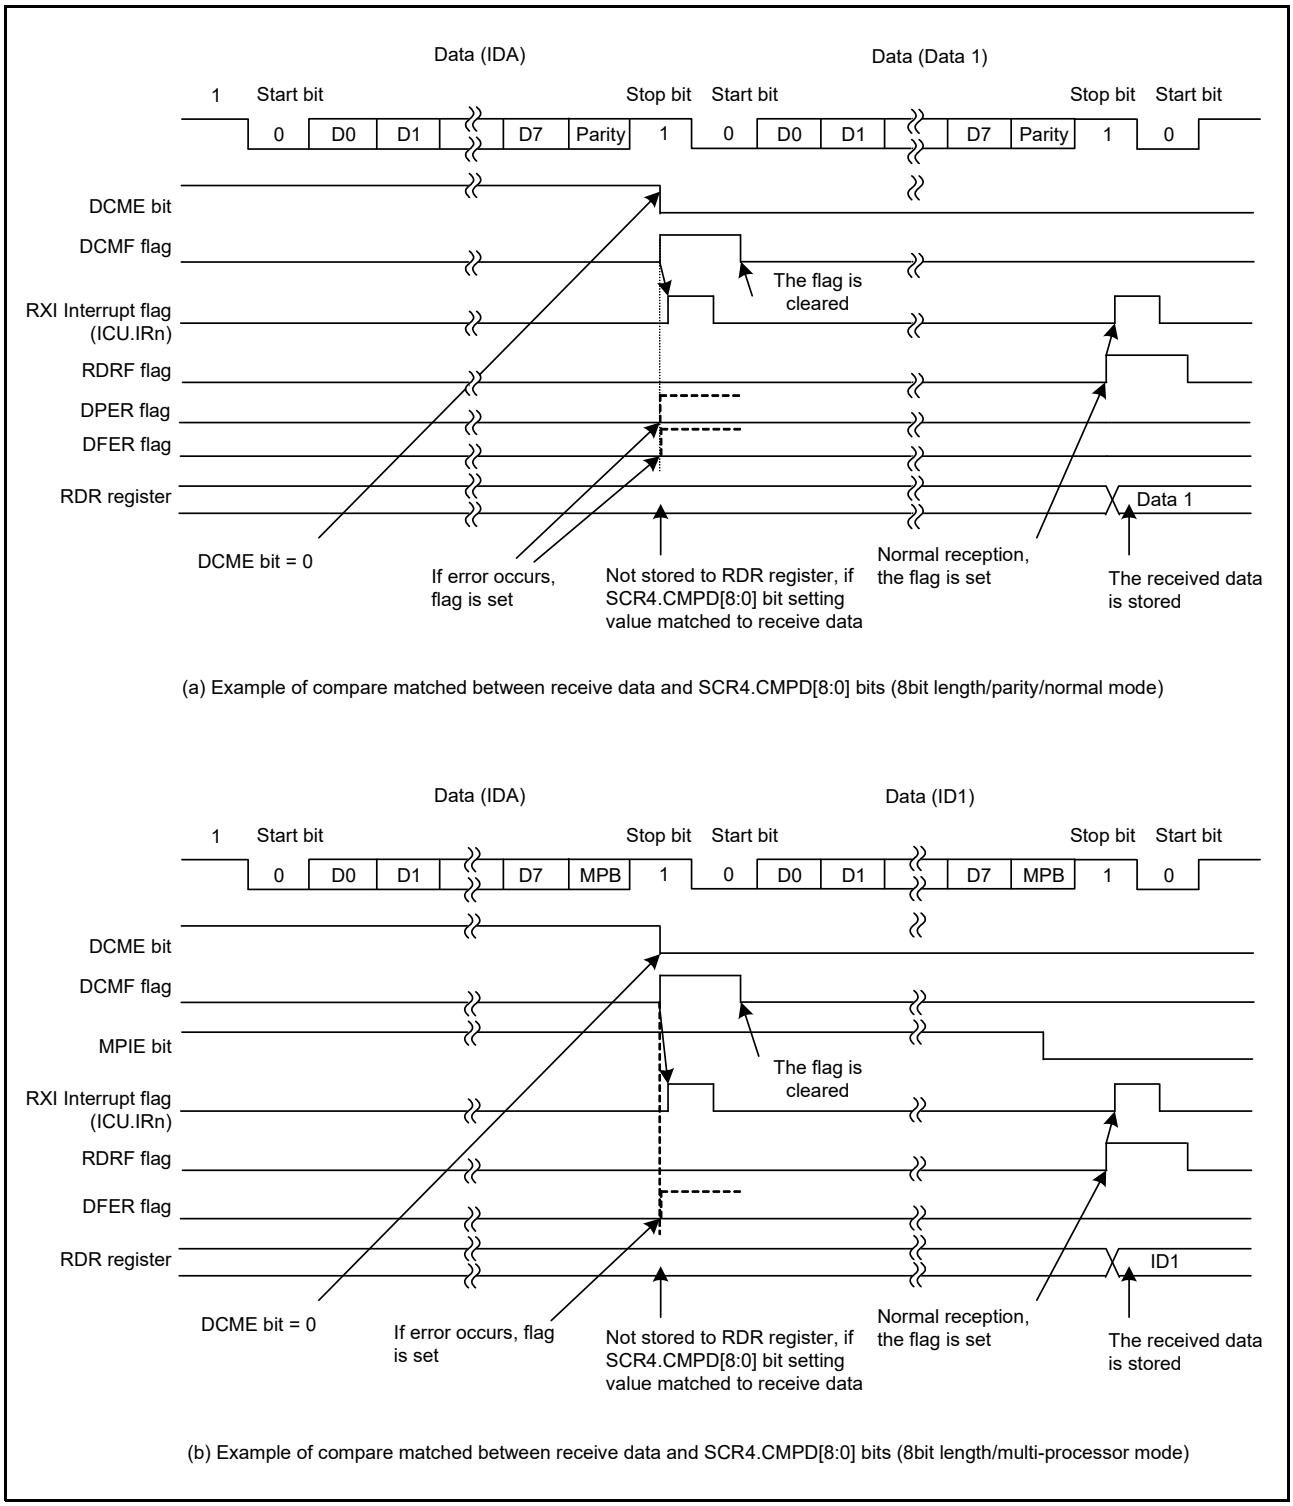
When the conditions for low-level output are not satisfied

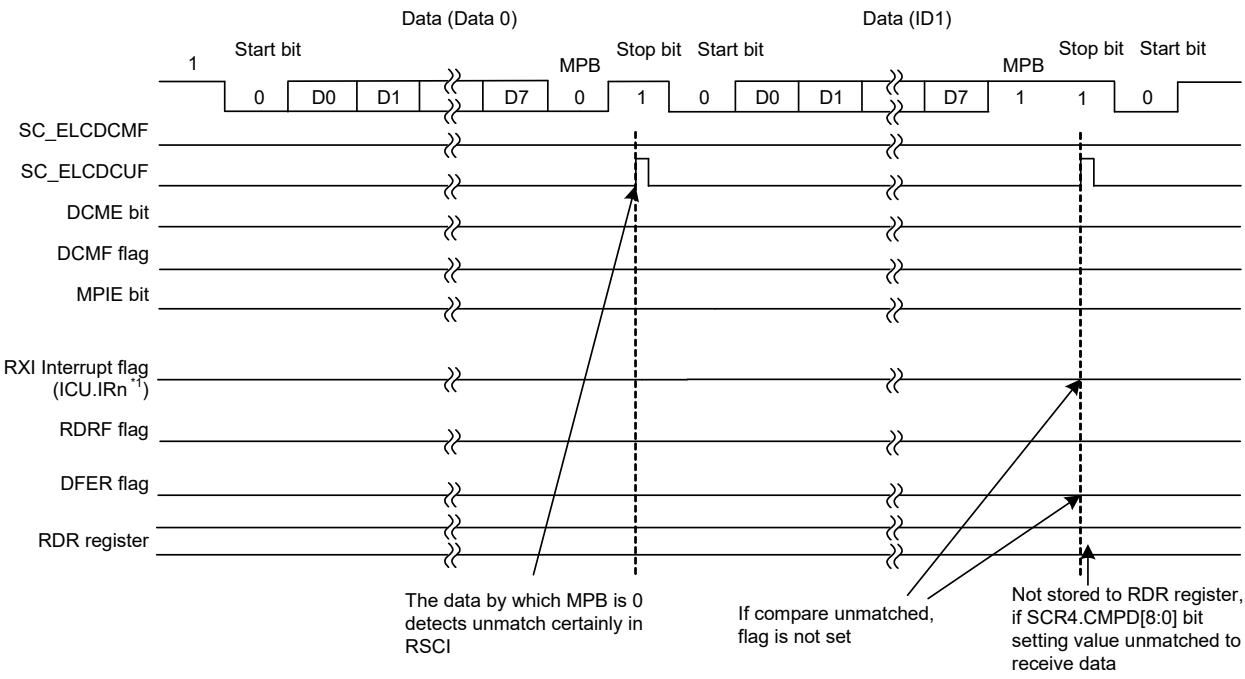
42.3.6 Data Match Detection

The data match detection function can use only the asynchronous mode.
If SCR0.DCME bit is set to 1*2, when one frame of data has been received, RSCI compares that receive data with the data which is set to SCR4.CMPD[8:0] bits. If RSCI detects the match to the comparison data (SCR4.CMPD[8:0] bits*1) with receive data, RSCI can issue RXI interrupt request.
If SCR3.MP bit is set to 0, this comparative target in communication data is valid only data field in receive format. In multi-processor mode (SCR3.MP bit = 1), if SCR0.IDSEL bit is set to 1, the reception data at which MPB is 1 detects data match or unmatch, and the reception data at which MPB is 0 detects always unmatch. If SCR0.IDSEL bit is set to 0, RSCI detects data match or unmatch despite the value of the MPB of the reception data at every reception complete.
Until RSCI detects the match to the comparison data (SCR4.CMPD[8:0] bits) with receive data, the communication data is skipped (discarded), and RSCI can not detect parity error, framing error. When RSCI detects the match, the SCR0.DCME bit is automatically cleared, and SSR.DCMF flag is set to 1. If SCR0.IDSEL bit is set to 1 at this time, SCR0.MPIE bit is automatically cleared. And if SCR0.IDSEL bit is set to 0 at this time, SCR0.MPIE bit is kept. At the same time, if SCR0.RIE bit is set to 1, RSCI issues RXI interrupt request. If RSCI detects framing error in comparative receive data which is detected the match, SSR.DFER flag is set to 1, and if RSCI detects parity error in that frame, SSR.DPER flag is set to 1. That comparative receive data and MPB are not stored to RDR register, and SSR.RDRF flag is retained to 0.
After RSCI detects the match, and the SCR0.DCME bit is automatically cleared, it receives next data continuously in current register setting.
When SSR.DFER flag or SSR.DPER flag is set, the data match isn't detected. Before making the data match detection function effective, please be sure to set SSR.DFER and SSR.DPER flags as 0.
Figure 42.7 and Figure 42.8 show the data match detection example.

Note 1. This comparative target can select one length of 3 types, they are CMPD[6:0] bits with 7bit length enable, CMPD[7:0] bits with 8bit, and CMPD[8:0] bits with 9bit length.

Note 2. Set the SCR0.DCME bit to 1 before receiving the start bit of the received frame that performs data matching.





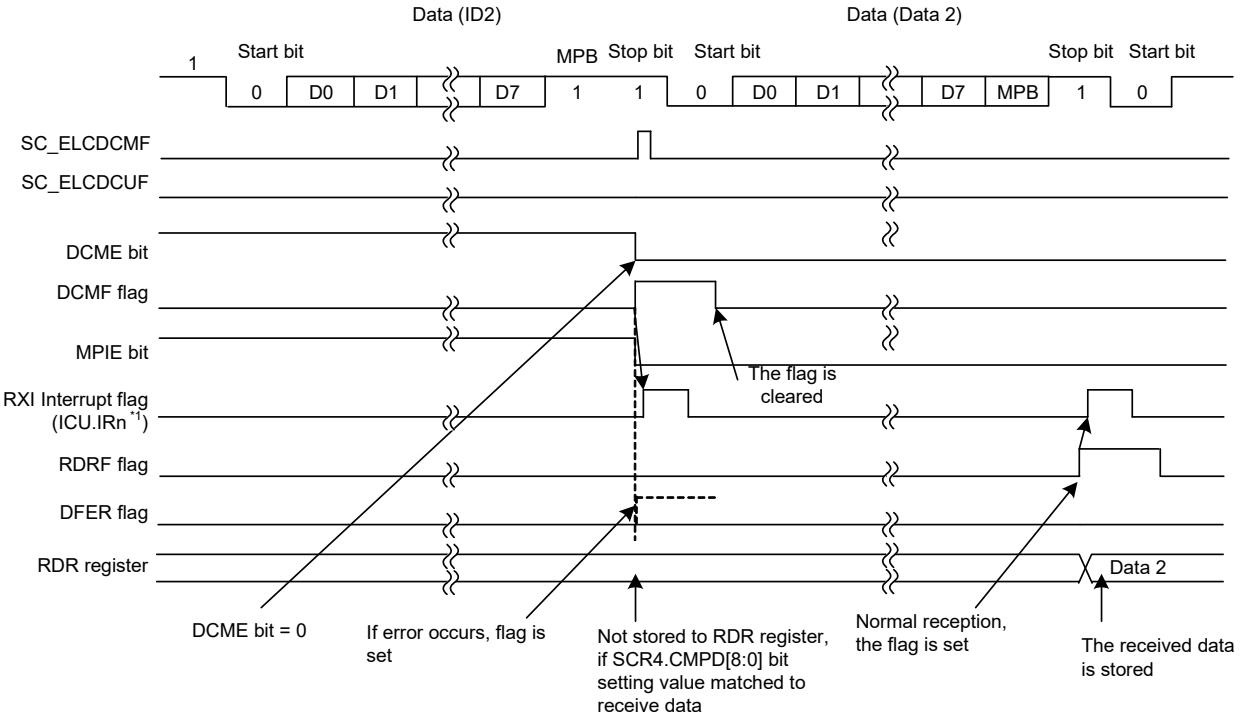


Figure 42.7 Example of Data Match Detection (1) 8bit-Data

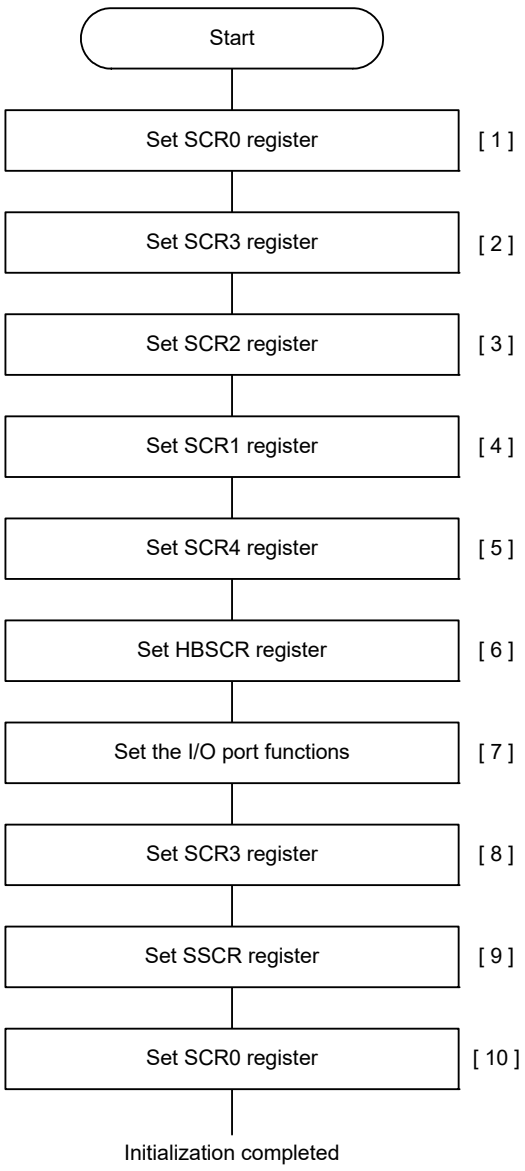
(a) Example of compare unmatched between receive data and SCR4.CMPD[8:0] bits (8bit length/IDSEL = 1)

(b) Example of compare matched between receive data and SCR4.CMPD[8:0] bits (8bit length/IDSEL = 1)

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.8 Example of Data Match Detection (2) Multi-Processor Mode/8bit-Data

42.3.7 RSCI Initialization (Asynchronous Mode)



Before transmitting and receiving data, start by writing 0 to SCR0.TE and SCR0.RE bits (or writing the initial value to SCR0 register) and then continue through the procedure (select to non-FIFO or FIFO) for RSCI given in Figure 42.9 or Figure 42.10. Whenever the operating mode or transfer format is changed, SCR0.TE and SCR0.RE bits must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied even during initialization.

Note that setting the SCR0.RE bit to 0 initializes neither the ORER, AFER, APER, RDRF, DR flags, and RDR register.

In FIFO mode, even if the TE bit is set as 0, the TEND flag isn't initialized, so please be careful. Please be also careful at the time of change in the operation mode.

Moreover, note that switching the value of the SCR0.TE bit from 0 to 1 while the SCR0.TIE bit is 1 leads to the generation of a TXI interrupt request.

[1] Set the following bits of SCR0 register to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set up following function and communication mode.
Driver control function for RS-485
FIFO no-use
Multi-Processor mode
Communication mode (MOD[2:0] bits = 000b)
Transmission/reception format
Clock enable (Leave the CKE[1:0] bits at their initial values when outputting the clock)
Leave unused bits at their initial values.

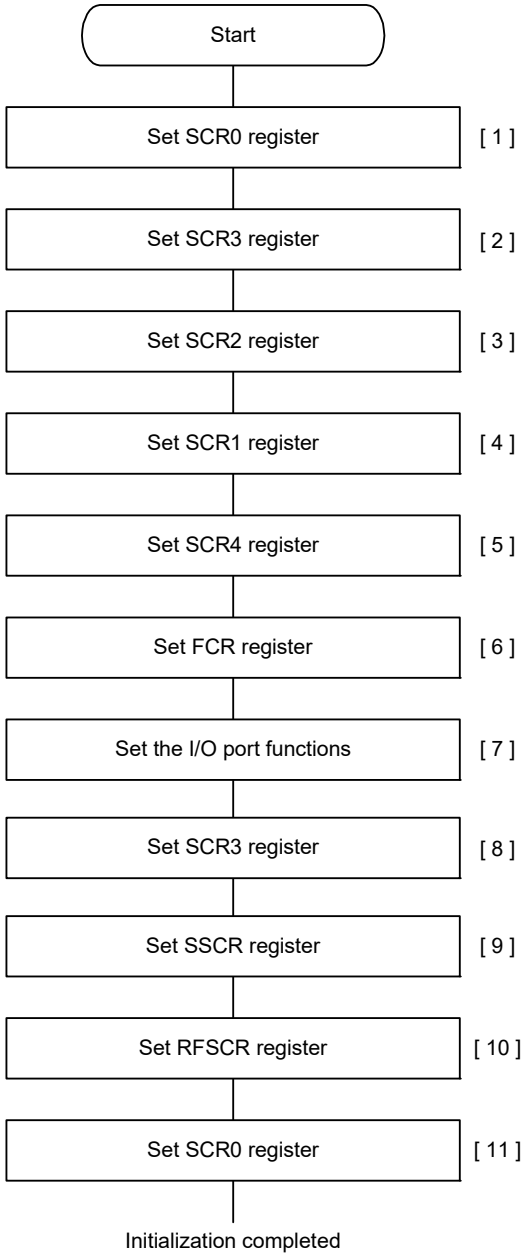
[3] Set up the bit-rate-modulation function*1, *2, select clock, set bit rate*2.

[4] Set up the Noise-filter function, the loop-back function, communication terminal status, the parity check function, and the CTS/RTS function.

[5] Set up the adjust sampling timing function and the adjust transmit timing function.

[6] When using the HBS support mode, enable or set the function. If this function is not used, leave the default value.

[7] Make I/O port settings to enable input and output functions as required for TXDn (TXDAn/TXDBn), RXDn, and SCKn pins.



[8] Set clock enable bit (CKE[1:0] bits) at this step when outputting the clock. After setting the bits, the SCKn pin becomes output mode (the clock is output after setting the TE or RE bit to 1).

[9] Write 1 to the following bits and clear the corresponding flag.
SSCR.RDRFC, AFERC, APERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
If it's initialization flow after a reset, you can skip this step.

[10] Set the TE or RE bit to 1.
To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Also, set the data match detection function and multiprocessor function. Setting the TE and RE bits allows TXDn (TXDAn/TXDBn) and RXDn to be used.

Note 1. If you do not use the bit rate modulation function, you do not need to set it.
Note 2. If you use an external clock, you do not need to set it.

Figure 42.9 Sample RSCI Initialization Flowchart (Asynchronous Mode/Non-FIFO Mode)

[1] Set the following bits of SCR0 register to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set up following function and communication mode.
Driver control function for RS-485
FIFO use
Multi-Processor mode
Communication mode (MOD[2:0] bits = 000b)
Transmission/reception format
Clock enable (Leave the CKE[1:0] bits at their initial values when outputting the clock)
Leave unused bits at their initial values.

[3] Set up the bit-rate-modulation function*1, 2,select clock, set bit rate*2.

[4] Set up the Noise-filter function, the loop-back function, communication terminal status, the parity check function, and the CTS/RTS function.

[5] Set up the adjust sampling timing function and the adjust transmit timing function.

[6] Set the TFRST and RFRST to 1 to empty FIFO.
Set the DRES, TTRG[4:0], RTRG[4:0], and RSTRG[4:0] bits

[7] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.

[8] Set clock enable bit (CKE[1:0] bits) at this step when outputting the clock. After setting the bits, the SCKn pin becomes output mode (the clock is output after setting the TE or RE bit to 1).

[9] Write 1 to the following bits and clear the corresponding flag.
SSCR.RDRFC, AFERC, APERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
If it is initialization flow after a reset, you can skip this step.

[10] Write 1 to The RFSCR.DRC bit and clear the corresponding flag.
If it is initialization flow after a reset, you can skip this step.

[11] Set the TE or RE bit to 1.
To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Also, set the data match detection function and multiprocessor function.
Setting the TE and RE bits allows TXDn and RXDn to be used.

Note 1. If you do not use the bit rate modulation function, you do not need to set it.
Note 2. If you use an external clock, you do not need to set it.

Figure 42.10 Sample RSCI Initialization Flowchart (Asynchronous Mode, FIFO Mode)

Figure 42.11 shows an example of the timing when data is transmitted after reset is released, and RSCI is set to asynchronous mode according to Figure 42.9 or Figure 42.10. As shown in the figure, when the pin function is set to the TXDn pin, the SCR0.TE bit is 0, so the pin is high impedance. When transmit data is written after setting the SCR0.TE bit to 1, data transmission starts. There is a transmission wait time from writing TDR register to data transmission starts. In asynchronous mode, TXDn is high during this period.

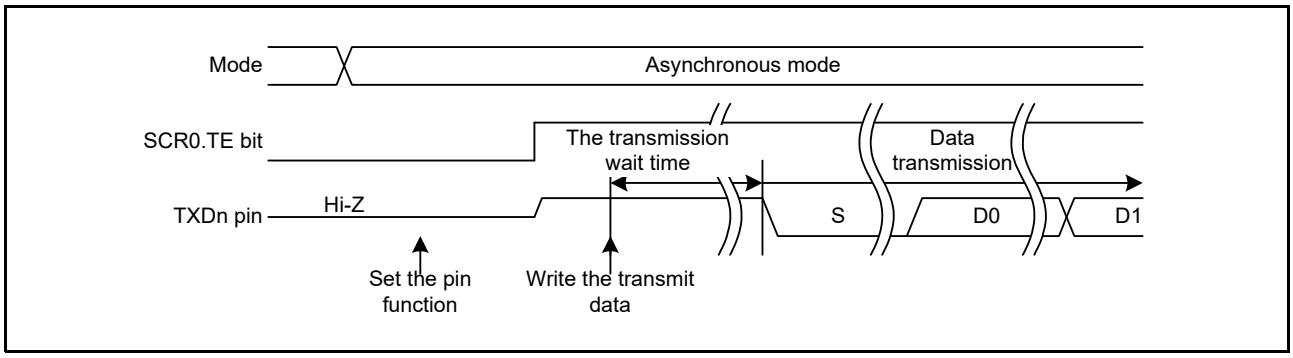


Figure 42.11 Example of Data Transmission Timing in Asynchronous Mode

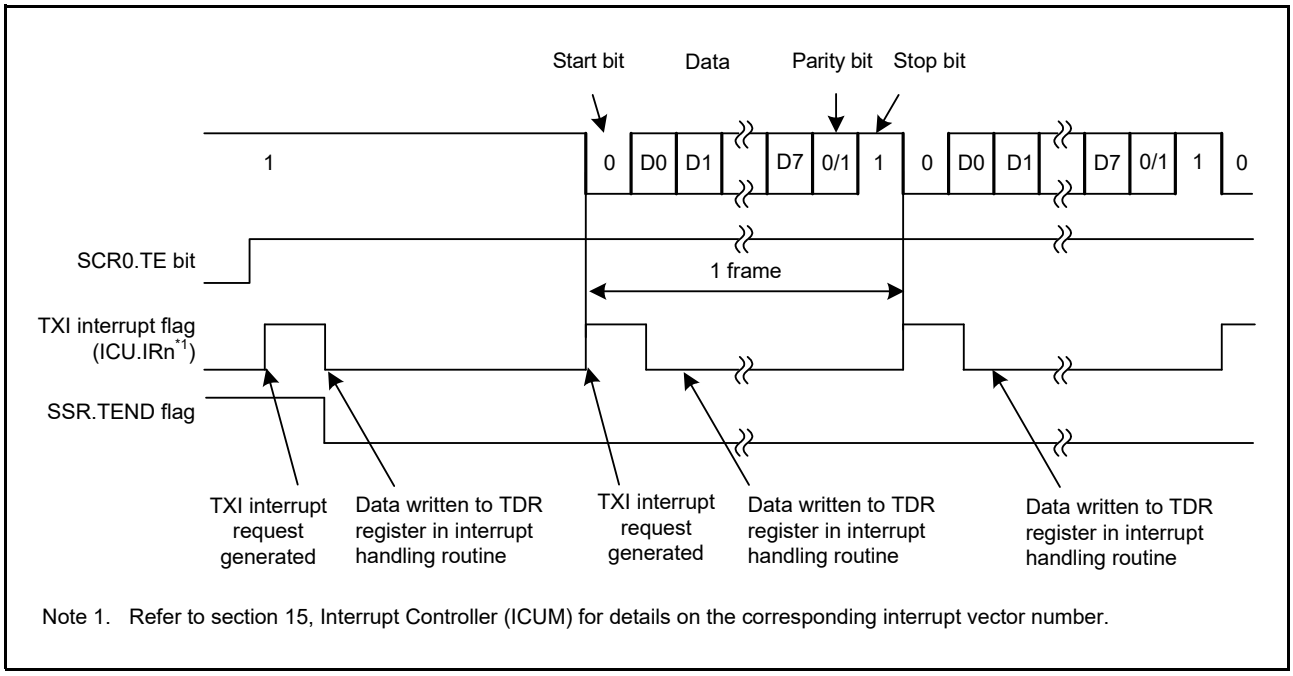
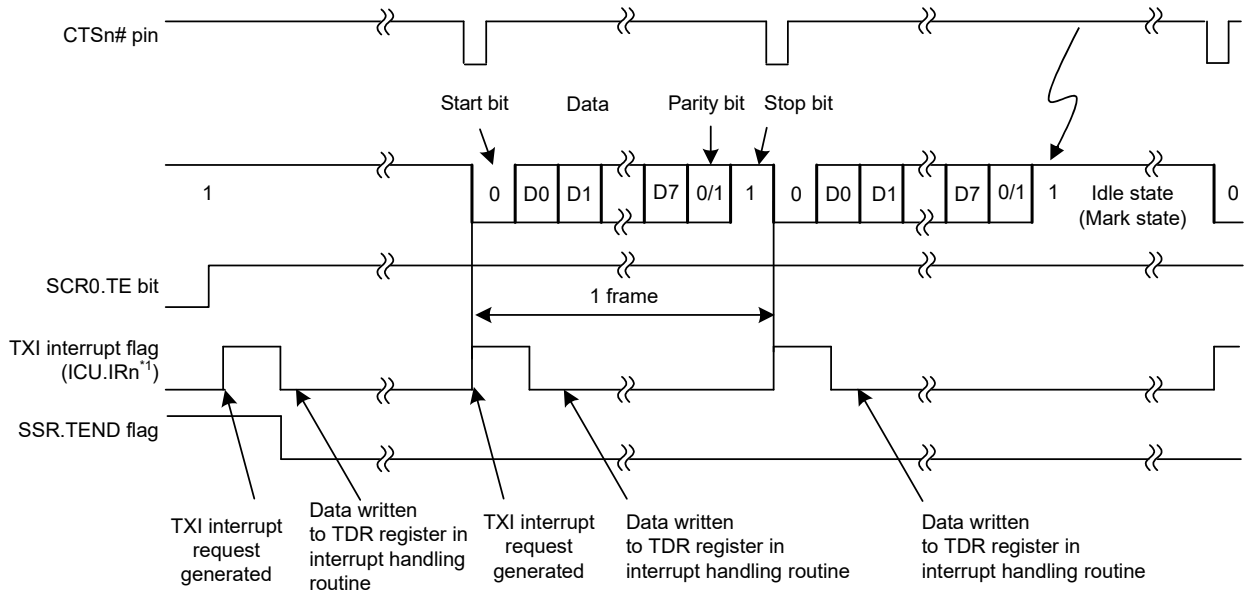


42.3.8 Serial Data Transmission (Asynchronous Mode)

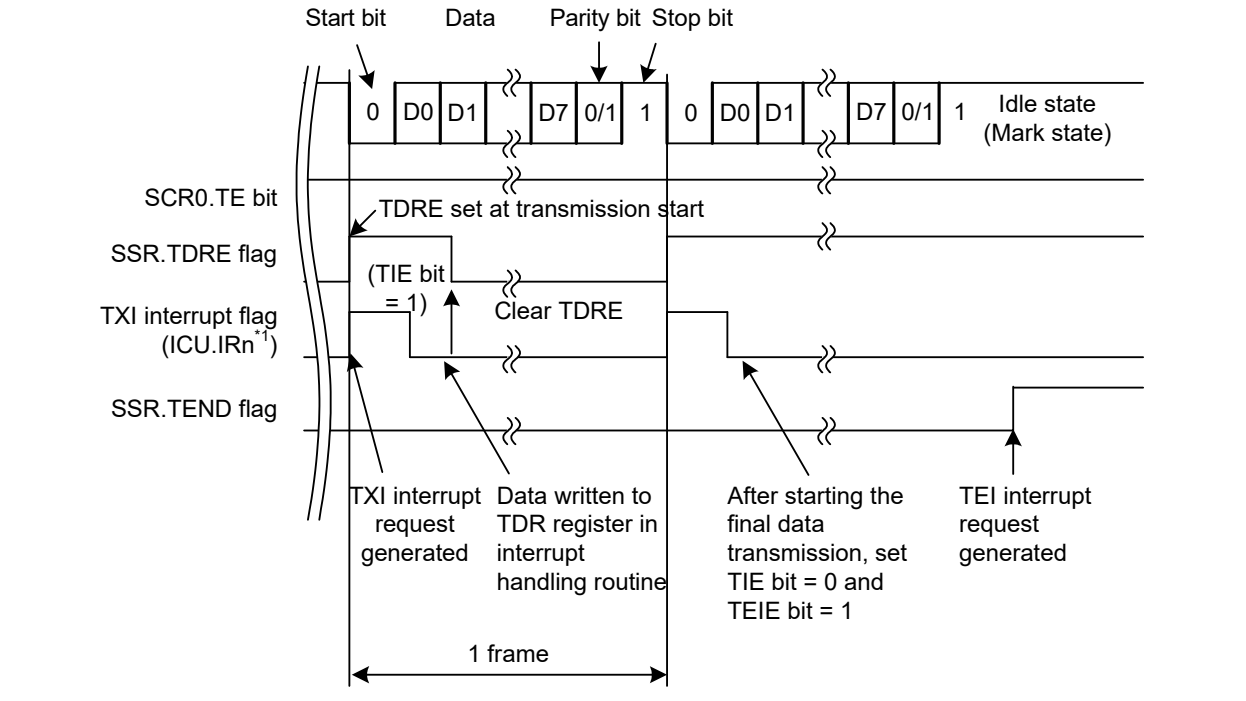
(1) Non-FIFO Mode

Figure 42.12 to Figure 42.14 show an example of the operation for serial transmission in asynchronous mode.
In serial transmission, the RSCI operates as described below.



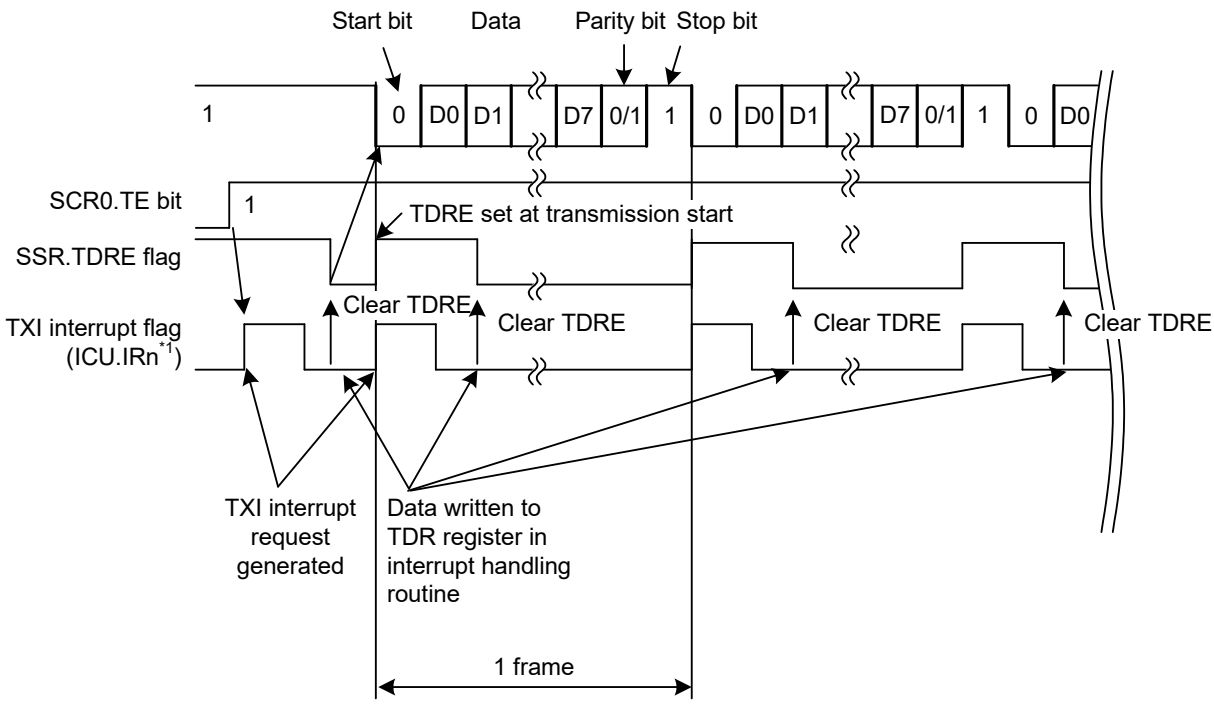
1. The RSCI transfers data from the TDR register to the TSR register when data is written to the TDR register in the TXI interrupt handling routine. At the beginning of transmission, set 1 to the SCR0.TE bit and the SCR0.TIE bit simultaneously. Then the TXI interrupt request is generated.
2. Transmission starts at data transfer from the TDR register to the TSR register when the SCR1.CTSE bit = 0 (CTS function is disabled) or when the CTS# pin level is low. If the SCR0.TIE bit is 1 at this time, a TXI interrupt request is generated. Continuous transmission is obtainable by writing the next transmit data to the TDR register in the TXI interrupt handling routine before transmission of the current transmit data is completed. Write the last transmission data, then the last data transmit start, and TXI is generated. When TEI interrupt requests are in use, before the last data transmit end, set the SCR0.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR0.TEIE bit to 1 (a TEI interrupt request is enabled) using the TXI interrupt handling routine.
3. Data is sent from the TXDn pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The RSCI checks for updating of (writing to) the TDR register at the time of stop bit output.
5. When the TDR register is updated, setting of the SCR1.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn# pin cause the next transfer of the next transmit data from the TDR register to the TSR register and sending of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register is not updated, the SSR.TEND flag is set to 1, the stop bit is sent, and then the mark state is entered in which 1 is output. If the SCR0.TEIE bit is 1 at this time, a TEI interrupt request is generated.

Figure 42.16 shows the example of Serial Transmission Flowchart.



Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

**Figure 42.12 Example of Operation for Serial Transmission in Asynchronous Mode (1)
(with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, at the Beginning of Transmission)**



Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.13 Example of Operation for Serial Transmission in Asynchronous Mode (2) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Used, at the Beginning of Transmission)

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.14 Example of Operation for Serial Transmission in Asynchronous Mode (3) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, from the Middle of Transmission until Transmission Completion)

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.15 Example of Operation for Serial Transmission in Asynchronous Mode (4) (with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, during Transmission)

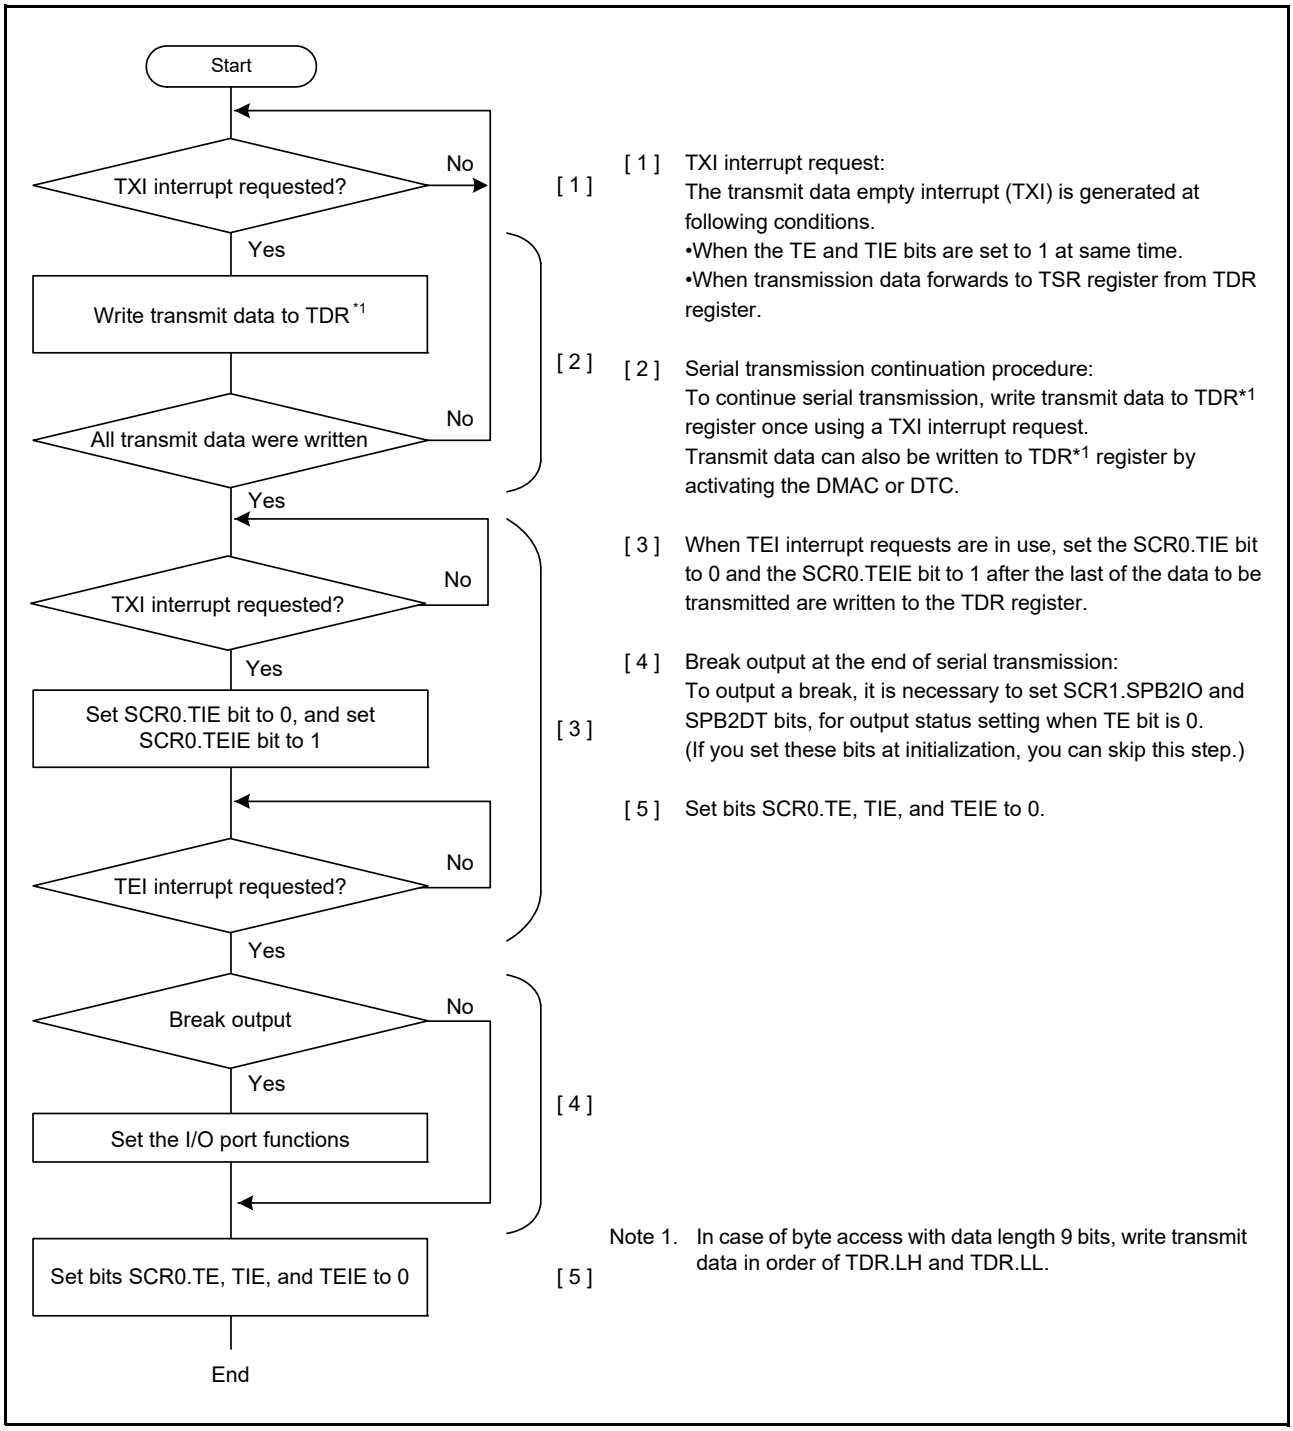


Figure 42.16 Example of Serial Transmission Flowchart in Asynchronous Mode (Non-FIFO Mode)

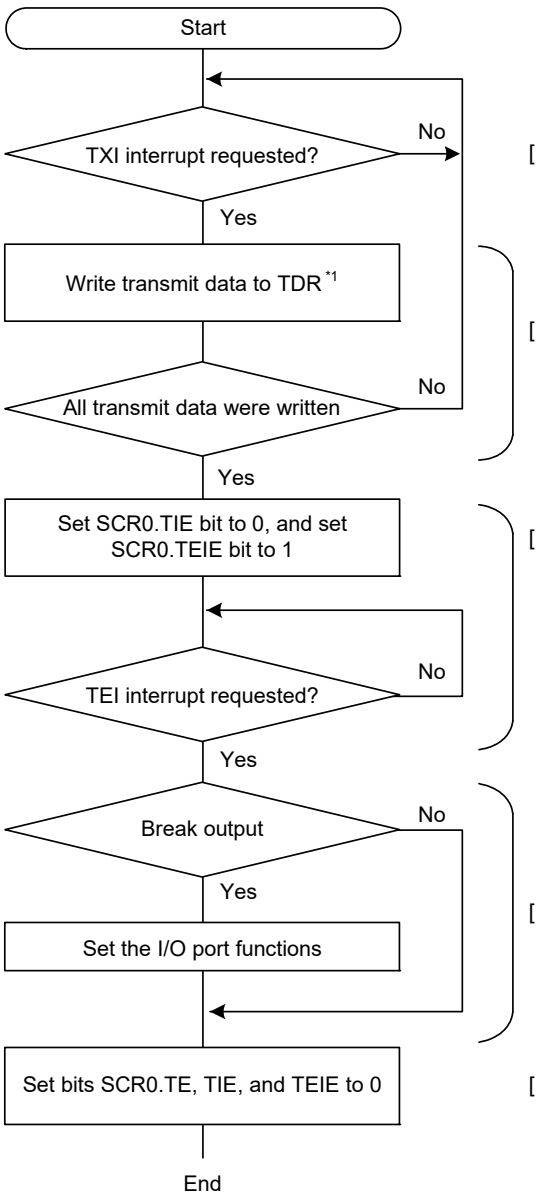
(2) FIFO Mode

Table 42.29 shows an example of data format that is written to transmit FIFO (TDR register) in asynchronous mode with FIFO selected.

Write the MPBT bit to bit 9 of the transmit FIFO (TDR register). When 7-bit data length is selected, write data to the TDR.TDAT[6:0] bits; when 8-bit data length is selected, write data to the TDR.TDAT[7:0] bits; when 9-bit data length is selected, write data to the TDR.TDAT[8:0] bits. Write 0 to unused bits. When accessing in byte units, write data in the order of the TDR.LH to the TDR.LL.

Table 42.29 Data Format That is Written to Transmit FIFO (TDR) (FIFO Mode)



Data Length	Register setting		Transmit Data in TDR.L															
	SCR3	CHR[1:0]	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	—	—	—	—	—	—	MPBT	—	—	TDAT[6:0]						
8 bits	1	0	—	—	—	—	—	—	MPBT	—	TDAT[7:0]							
9 bits	0	0 or 1	—	—	—	—	—	—	MPBT	TDAT[8:0]								

—: Do not used. It should write to 0.

In serial transmission, the RSCI operates as described below.

1. The RSCI transfers data from transmit FIFO (TDR register) to TSR register when data is written to transmit FIFO (TDR register) in the TXI interrupt handling routine. The writable transmit data number is until (16 – transmit FIFO (TDR register)) bytes. At the beginning of transmission, set 1 to SCR0.TE and SCR0.TIE bits simultaneously. Then the TXI interrupt request is generated.
2. Transmission starts at data transfer from transmit FIFO (TDR register) to TSR register when SCR1.CTSE bit = 0 (CTS function is disabled) or when the CTS# pin level is low. When the quantity of transmit data written in transmit FIFO (TDR register) is equal to or less than the specified transmit triggering number, SSR.TDRE flag is set to 1. If SCR0.TIE bit is 1 at this time, a TXI interrupt request is generated. Continuous transmission is obtainable by writing the next transmit data to transmit FIFO (TDR register) in the TXI interrupt handling routine before transmission of the current transmit data is completed. Write the last transmission data, then the last data transmit start, and TXI is generated. When TEI interrupt requests are in use, before the last data transmit end, set the SCR0.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR0.TEIE bit to 1 (a TEI interrupt request is enabled) using the TXI interrupt handling routine.
3. Data is sent from the TXDn pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The RSCI checks whether non-transmitted data in transmit FIFO (TDR register) or not at the time of stop bit output.
5. When data is set to transmit FIFO (TDR register), setting of SCR1.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn# pin cause the next transfer of the next transmit data from transmit FIFO (TDR register) to TSR register and sending of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set to transmit FIFO (TDR register), SSR.TEND flag is set to 1, the stop bit is sent, and then the mark state is entered in which 1 is output. If SCR0.TEIE bit is 1 at this time, a TEI interrupt request is generated.

Figure 42.17 shows a sample flowchart for serial transmission in asynchronous mode at FIFO selected.

[1] TXI interrupt request:
The transmit data empty interrupt (TXI) is generated at following conditions.
•When the TE and TIE bits are set to 1 at same time.
•When transmission data forwards to TSR from the transmit FIFO (TDR register) and the number of transmit data written in the transmit FIFO is equal to or less than the transmit FIFO threshold.

[2] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to the transmit FIFO (TDR register)*1 by using a TXI interrupt and clear the SSR.TDRE flag to 0. (Transmit data can also be written to the transmit FIFO (TDR register)*1 by activating the DMAC or DTC. In this case, the TDRE flag is cleared automatically, so please don't operate the TDRE flag.)
The number of transmission data it's possible to write in is 16 (the number of stored transmit FIFO data).

[3] If you use TEI, set TIE bit = 0 and TEIE bit = 1 after writing the last transmit data to TDR*1 register.

[4] Break output at the end of serial transmission:
To output a break, it is necessary to set SCR1.SPB2IO and SPB2DT bits, for output status setting when TE bit is 0.
(If you set these bits at initialization, you can skip this step.)

[5] Set bits SCR0.TE, TIE, and TEIE to 0.

Note 1. In case of byte access with data length 9 bits, write transmit data in order of TDR.LH and TDR.LL.

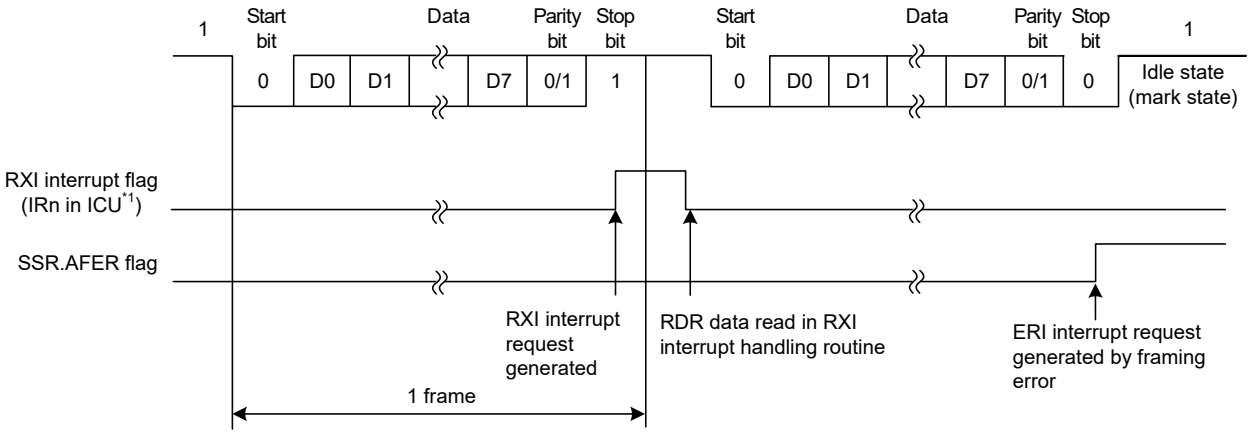


Figure 42.17 Example of Serial Transmission Flowchart in Asynchronous Mode (FIFO Mode)

42.3.9 Serial Data Reception (Asynchronous Mode)

(1) Non-FIFO Mode

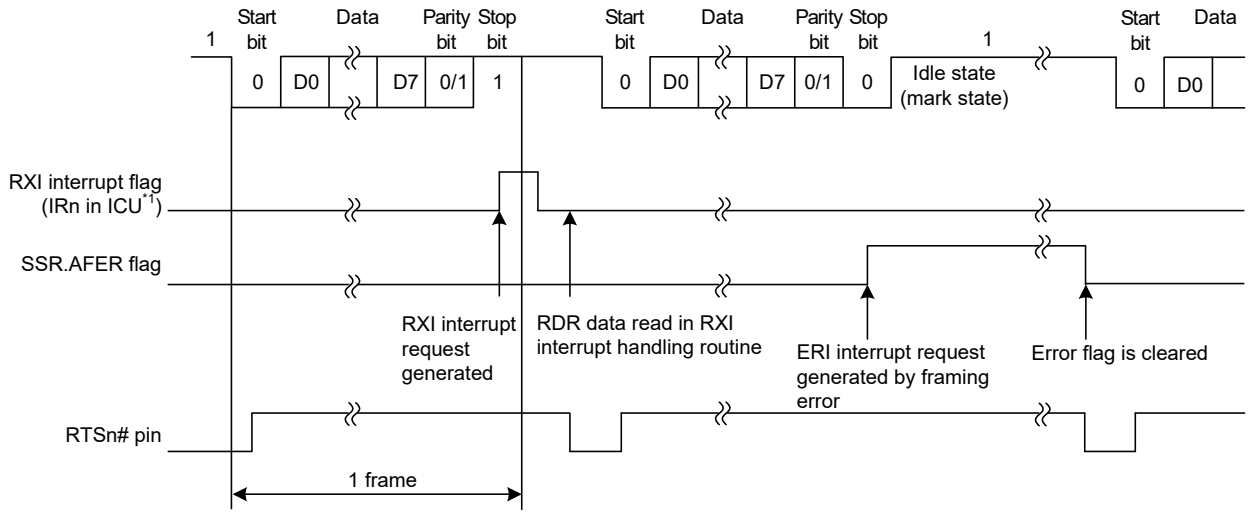

Figure 42.18 and Figure 42.19 show an example of the operation for serial data reception in asynchronous mode. In serial data reception, the RSCI operates as described below.

1. When the value of SCR0.RE bit becomes 1, the output signal on the RTSn# pin goes to the low level in the case of RTS function use.
2. When the RSCI monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in RSR register, and checks the parity bit and stop bit.
3. If an overrun error occurs, SSR.ORER flag is set to 1. If SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR register.
4. If a parity error is detected, SSR.APER flag is set to 1 and receive data is transferred to RDR register. If the SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated.
5. If a framing error (when the stop bit is 0) is detected, SSR.AFER flag is set to 1 and receive data is transferred to RDR register. If SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to RDR register. If SCR0.RIE bit is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to RDR register in this RXI interrupt handling routine before reception of the next receive data is completed. Reading the received data that have been transferred to RDR register causes the RTSn# pin to output the low level in the case of RTS function use. If you do not want to turn the RTSn# pin output low after receiving the last data, set SCR0.RE bit to 0, before reading the RDR register.

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.18 Example of RSCI Operation for Serial Reception in Asynchronous Mode (1) (8-Bit Data, Parity, 1 Stop Bit, RTS Function is Not Used)

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.19 Example of RSCI Operation for Serial Reception in Asynchronous Mode (2) (8-Bit Data, Parity, 1 Stop Bit, RTS Function is Used)

Table 42.30 lists the states of the flags in SSR status register and receive data handling when a receive error is detected. If a receive error is detected, an ERI interrupt request is generated but an RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, AFER, and APER flags to 0 before resuming reception. Moreover, be sure to read the RDR register during overrun error processing. When a reception is forcibly terminated by setting SCR0.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in RDR register.
Figure 42.20 and Figure 42.21 show samples of flowcharts for serial data reception.

Table 42.30 Flags in the SSR Status Register and Receive Data Handling

Flags in the SSR Status Register				
ORER	**AFER**	**APER**	**Receive Data**	**Receive Error Type**
1	0	0	Lost	Overrun error
0	1	0	Transferred to RDR	Framing error
0	0	1	Transferred to RDR	Parity error
1	1	0	Lost	Overrun error + framing error
1	0	1	Lost	Overrun error + parity error
0	1	1	Transferred to RDR	Framing error + parity error
1	1	1	Lost	Overrun error + framing error + parity error

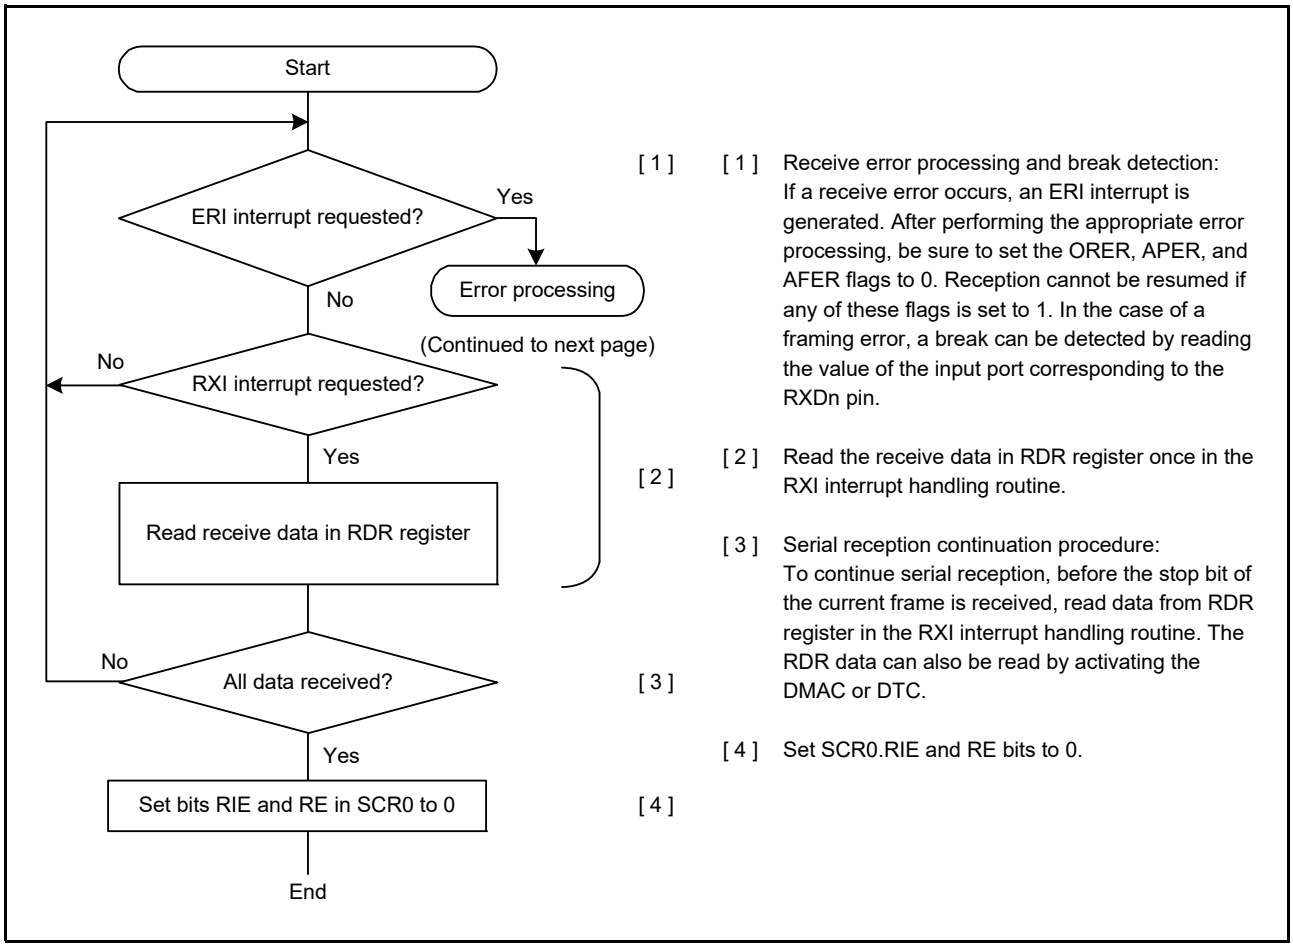

Figure 42.20 Example Flowchart of Serial Reception in Asynchronous Mode (Non-FIFO Mode) (1)

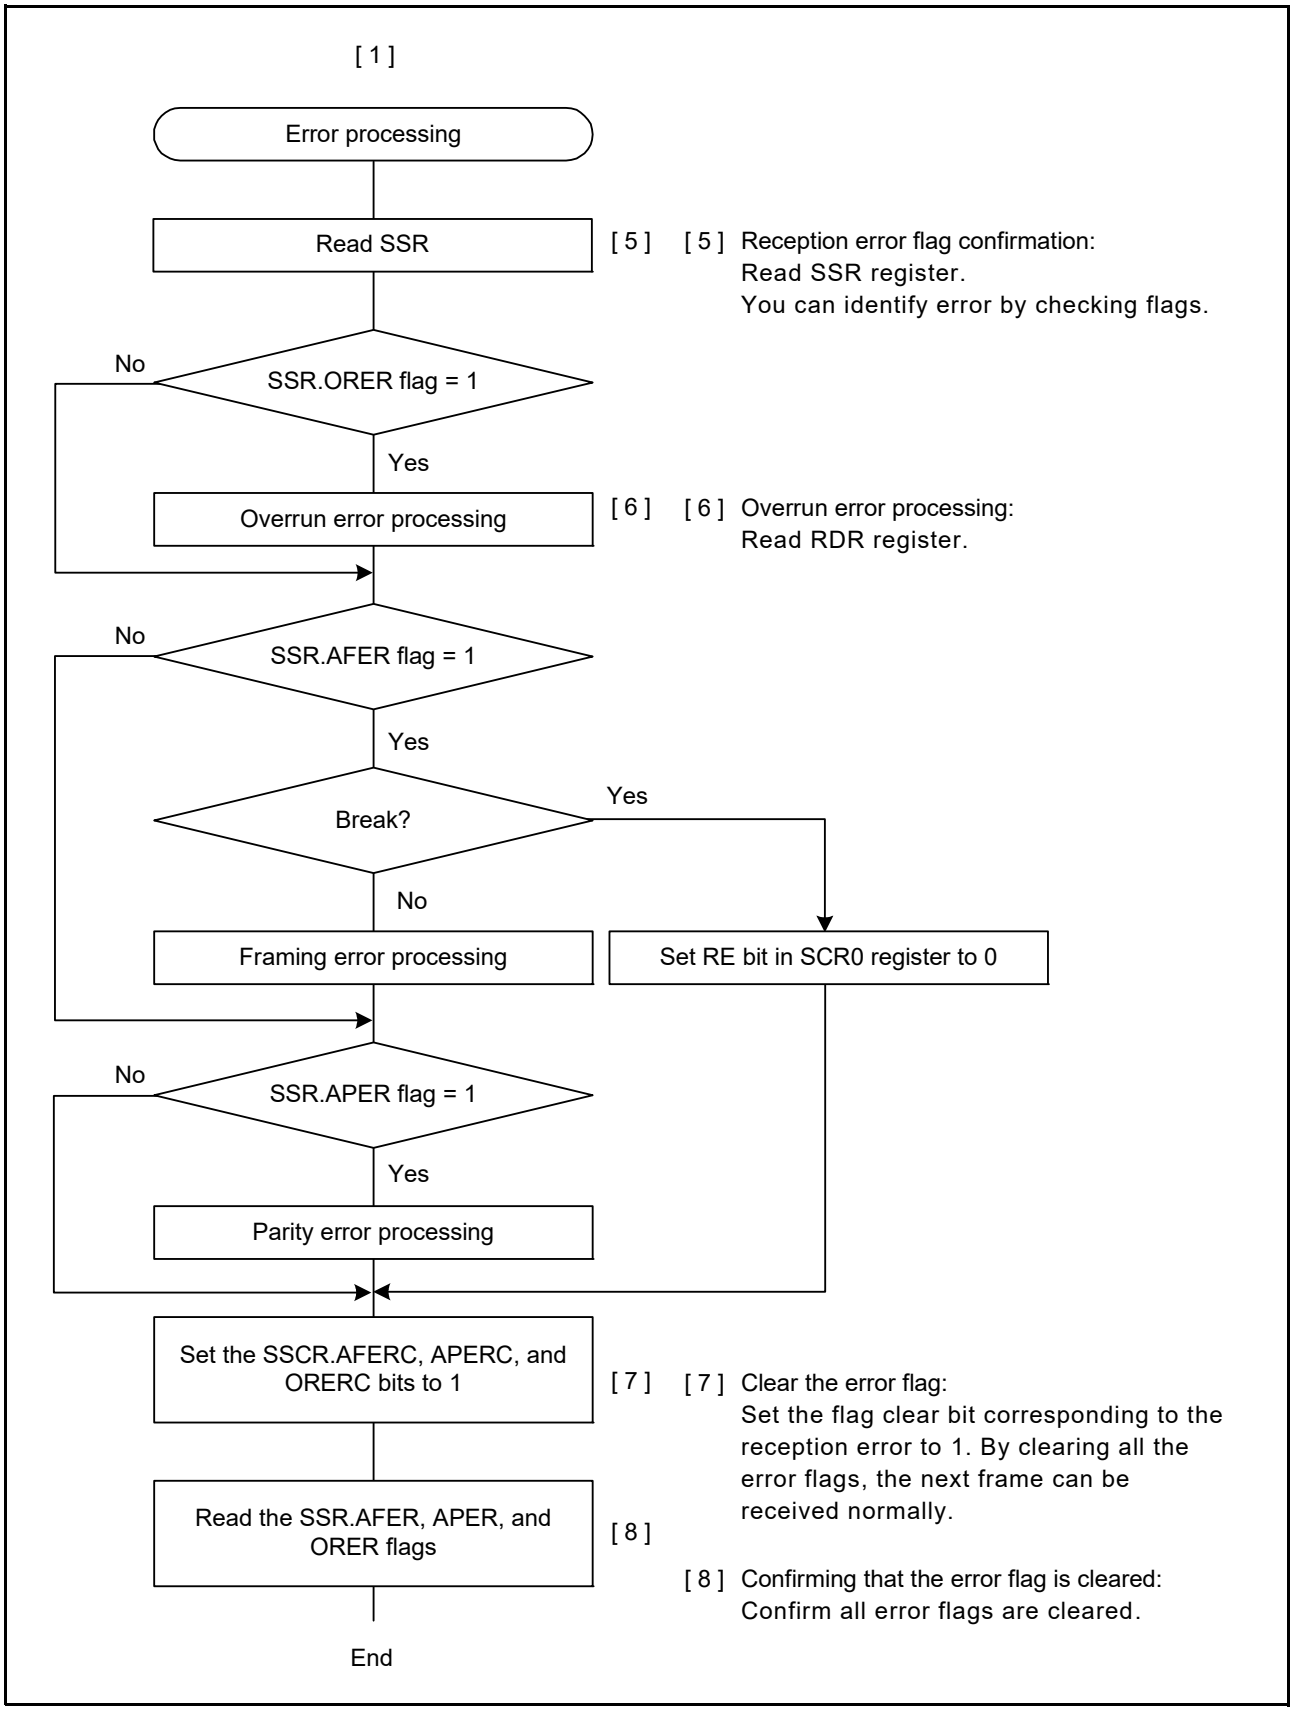

Figure 42.21 Example Flowchart of Serial Reception in Asynchronous Mode (Non-FIFO Mode) (2)

(2) FIFO Mode

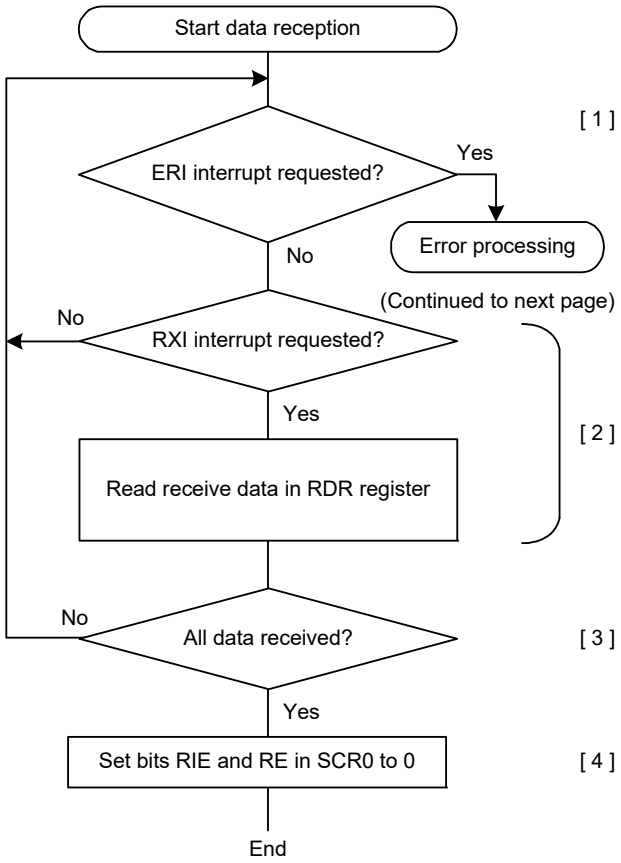
Table 42.31 shows an example of data format stored to receive FIFO (RDR register) in asynchronous mode.
MPB flag (Receive FIFO (RDR register) bit9) is stored 0. Data is stored to receive FIFO (RDR register) corresponded to data length. It is stored to 0 for unused bits. If receive FIFO (RDR register) is read, RSCI updates to next data which are FER flag, PER flag, and receive data (RDAT[8:0] bits) in receive FIFO. The flags which are AFER, APER, ORER, and DR flag in receive FIFO, are always indicated to the flags corresponded to SSR register and RFSR register.

Table 42.31 Data Format Stored in the Receive FIFO (RDR) (FIFO Mode)

Data Length	Register setting		Arrangement of Receive Flag, MPB Flag and Received Data in RDR Register															
	SCR3	CHR[1:0]	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	—	—	—	FER	PER	DR	MPB	0	0	RDAT[6:0]						
8 bits	1	0	—	—	—	FER	PER	DR	MPB	0	RDAT[7:0]							
9 bits	0	0 or 1	—	—	—	FER	PER	DR	MPB	RDAT[8:0]								
Data Length	**SCR3**	**CHR[1:0]**	**b31**	**b30**	**b29**	**b28**	**b27**	**b26**	**b25**	**b24**	**b23**	**b22**	**b21**	**b20**	**b19**	**b18**	**b17**	**b16**
7 bits	1	1	—	—	—	AFER	APER	—	—	ORER	—	—	—	—	—	—	—	—
8 bits	1	0	—	—	—	AFER	APER	—	—	ORER	—	—	—	—	—	—	—	—
9 bits	0	0 or 1	—	—	—	AFER	APER	—	—	ORER	—	—	—	—	—	—	—	—

Note: 0 is always read from the MPB flag (RDR register bit9).
When a 7-bit data length is selected, 0 is read from the RDAT[8:7] bits.
When a 8-bit data length is selected, 0 is read from the RDAT[8] bit.

Table 42.32 lists the states of the flags in SSR register status register and receive data handling when a receive error is detected in FIFO mode. Figure 42.22 and Figure 42.23 show samples of flowcharts for serial data reception in FIFO mode.
In serial data reception, the RSCI operates as described below.



1. When the value of SCR0.RE bit becomes 1, the output signal on the RTSn# pin goes to the low level in the case of RTS function use.
2. When the RSCI monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
3. If there is no space in receive FIFO (RDR register), an overrun error occurs and the SSR.ORER flag is set to 1. If SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to receive FIFO (RDR register).
4. If a parity error is detected, SSR.APER flag is set to 1 and receive data is transferred to receive FIFO (RDR register). If the SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated.
5. If a framing error (when the stop bit is 0) is detected, SSR.AFER flag is set to 1 and receive data is transferred to RDR register. If SCR0.RIE bit is 1 at this time, an ERI interrupt request is generated.
6. After framing error is detected, when RSCI detects that continuous receive data is 0 for 1 frame, the reception stops.
7. When quantity of data stored in the receive FIFO data register (RDR register) falls the specified receive triggering number, and that no next data has been received yet after the elapse of 15 etu from the last stop bit in asynchronous mode, RFSR.DR flag is set to 1. If RIE bit is set to 1, RSCI occurs RXI interrupt request when FCR.DRES bit is 0 and RSCI occurs ERI interrupt request when FCR.DRES bit is 1.
8. When reception finishes successfully, receive data is transferred to receive FIFO (RDR register). The SSR.RDRF flag is set to 1 when the quantity of receive data which is equal to or greater than the specified receive triggering number are stored in receive FIFO (RDR register). If SCR0.RIE bit is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to receive FIFO (RDR register)

in this RXI interrupt handling routine, before overrun error is occurred. Reading the received data that have been transferred to receive FIFO (RDR register), and if it is less than RTS trigger number, causes the RTSn# pin to output the low level. in the case of RTS function use.

Table 42.32 Flags in the SSR Status Register and Receive Data Handling (FIFO Mode)

SSR Register				
ORER	**AFER*1**	**APER*1**	**Receive Data**	**Receive Error Type**
1	0	0	Lost	Overrun error
0	1	0	Transferred to RDR	Framing error
0	0	1	Transferred to RDR	Parity error
1	1	0	Lost	Overrun error + framing error
1	0	1	Lost	Overrun error + parity error
0	1	1	Transferred to RDR	Framing error + parity error
1	0	0	Lost	Overrun error + framing error + parity error

Note 1. This flag indicates whether there is an error in received data when reception is completed.

[1] Receive error processing and break detection:
If a receive error occurs, an ERI interrupt is generated. After performing the appropriate error processing, be sure to set the ORER flag to 0. Reception cannot be resumed if ORER flag is set to 1. Reception can continue even if APER, AFER, and DR flags are 1.

[2] Read the receive data in the receive FIFO (RDR register) in the RXI interrupt handling routine. The reception data stored in the receive FIFO (RDR register) is read until the number of stored data will be below the FCR.RTRG[4:0] value at least. You can confirm the number of the reception data in the FIFO by RFSR.R[5:0] bits.

[3] Serial reception continuation procedure:
To continue serial reception, before an overrun error occurs, please read data from the receive FIFO (RDR register) in the RXI interrupt handling routine and clear SSR.RDRF flag and RFSR.DR flag to 0. The receive FIFO data can also be read by activating the DMA or DTC. The RDRF flag is cleared automatically in this case, so please don't operate the RDRF flag.

[4] Set SCR0.RIE and RE bits to 0.

Figure 42.22 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO Mode) (1)

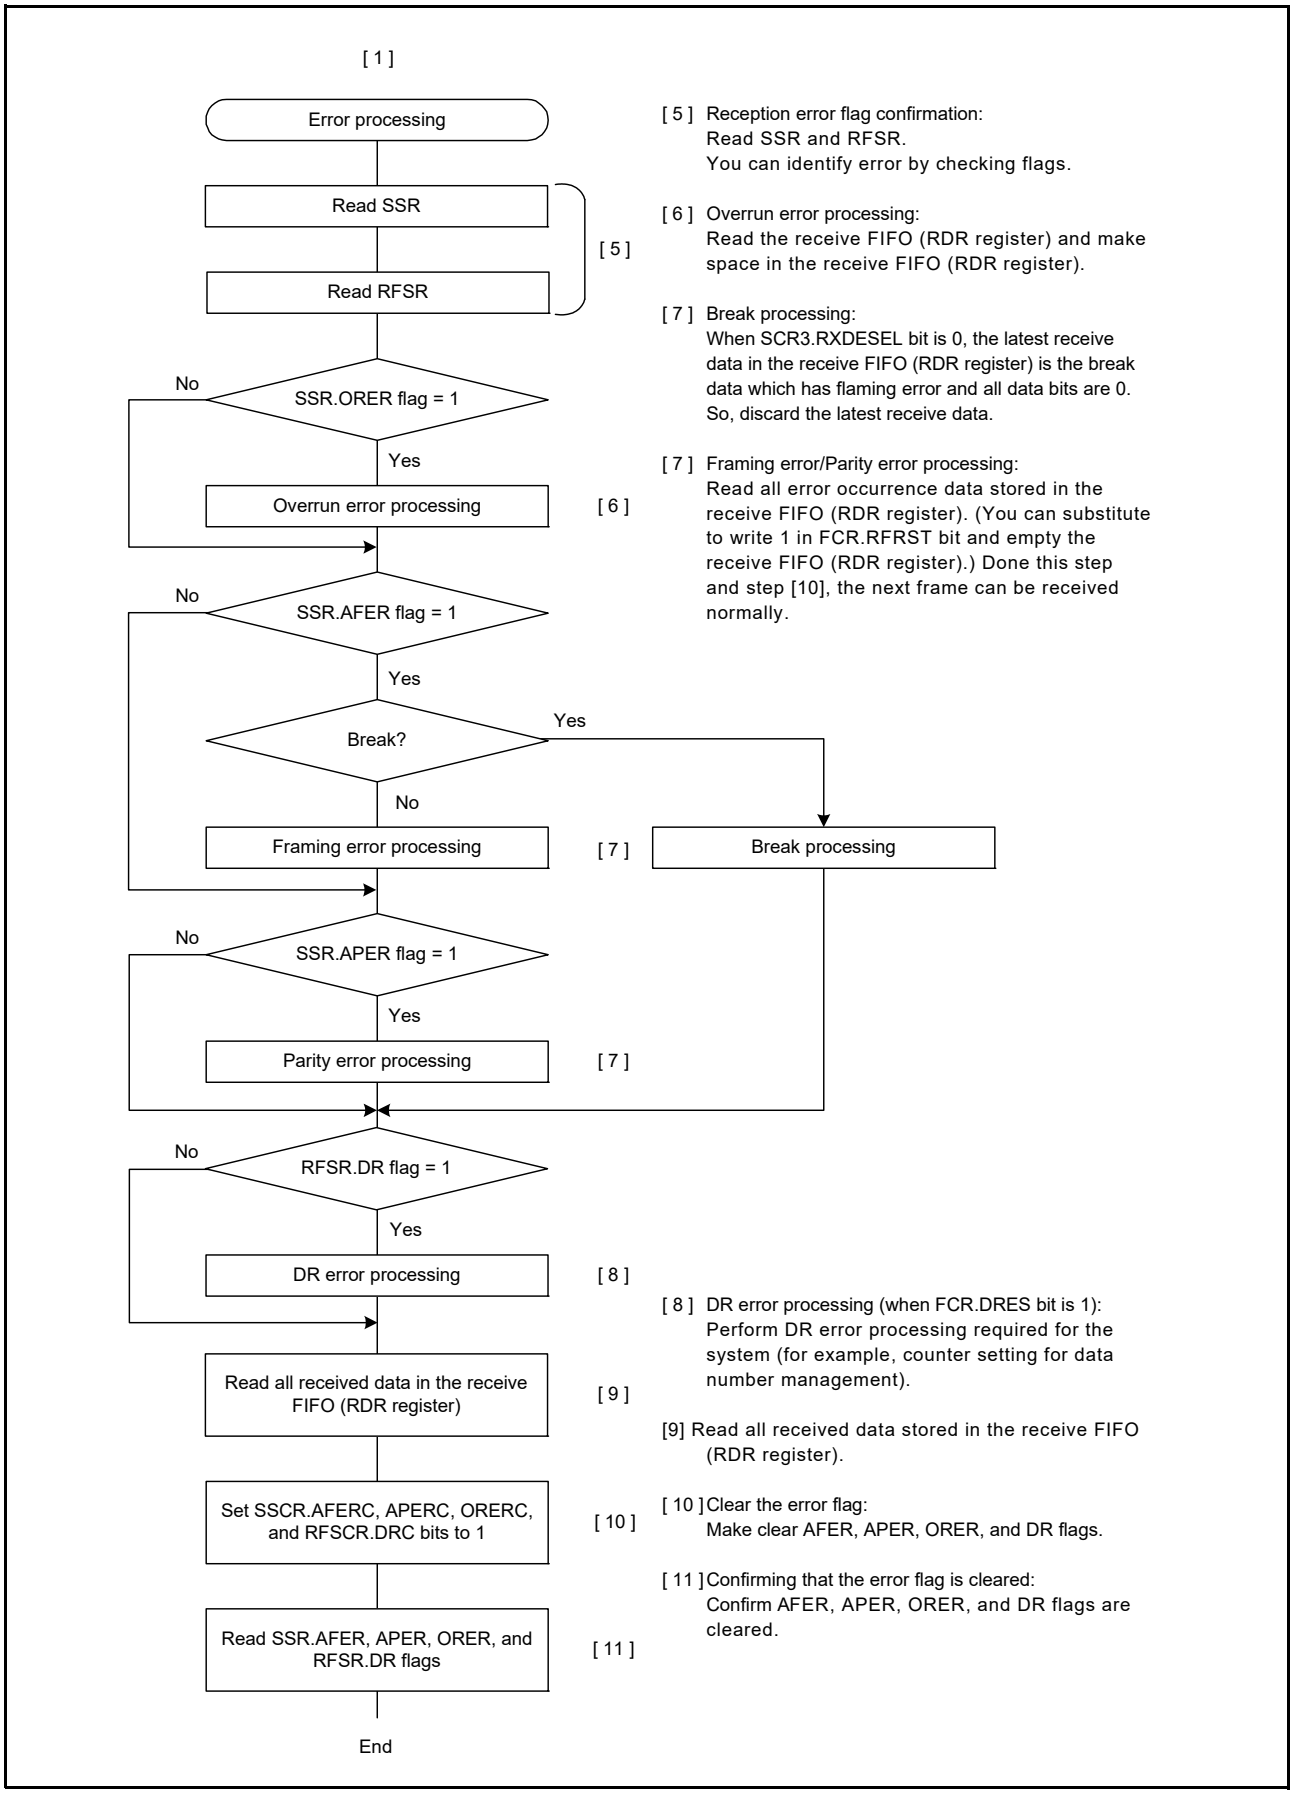


Figure 42.23 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO Mode) (2)

42.3.10 Receive Data Sampling Timing Adjustment

When a waveform such that high width is different from low width because the difference between rising time and falling time is large is received, adjust the timing for data to be sampled at the center of the narrower pulse. When low width is narrower than high width, move the sampling timing forward, and when high width is narrower than low width, move the sampling timing backward.

When the SCR4.RTMG[3:0] bits are set to an offset to the default sampling point and then the SCR4.RTADJ bit is set to 1, received data is sampled at the specified position.

Figure 42.24 shows an example of the sampling timing adjustment.

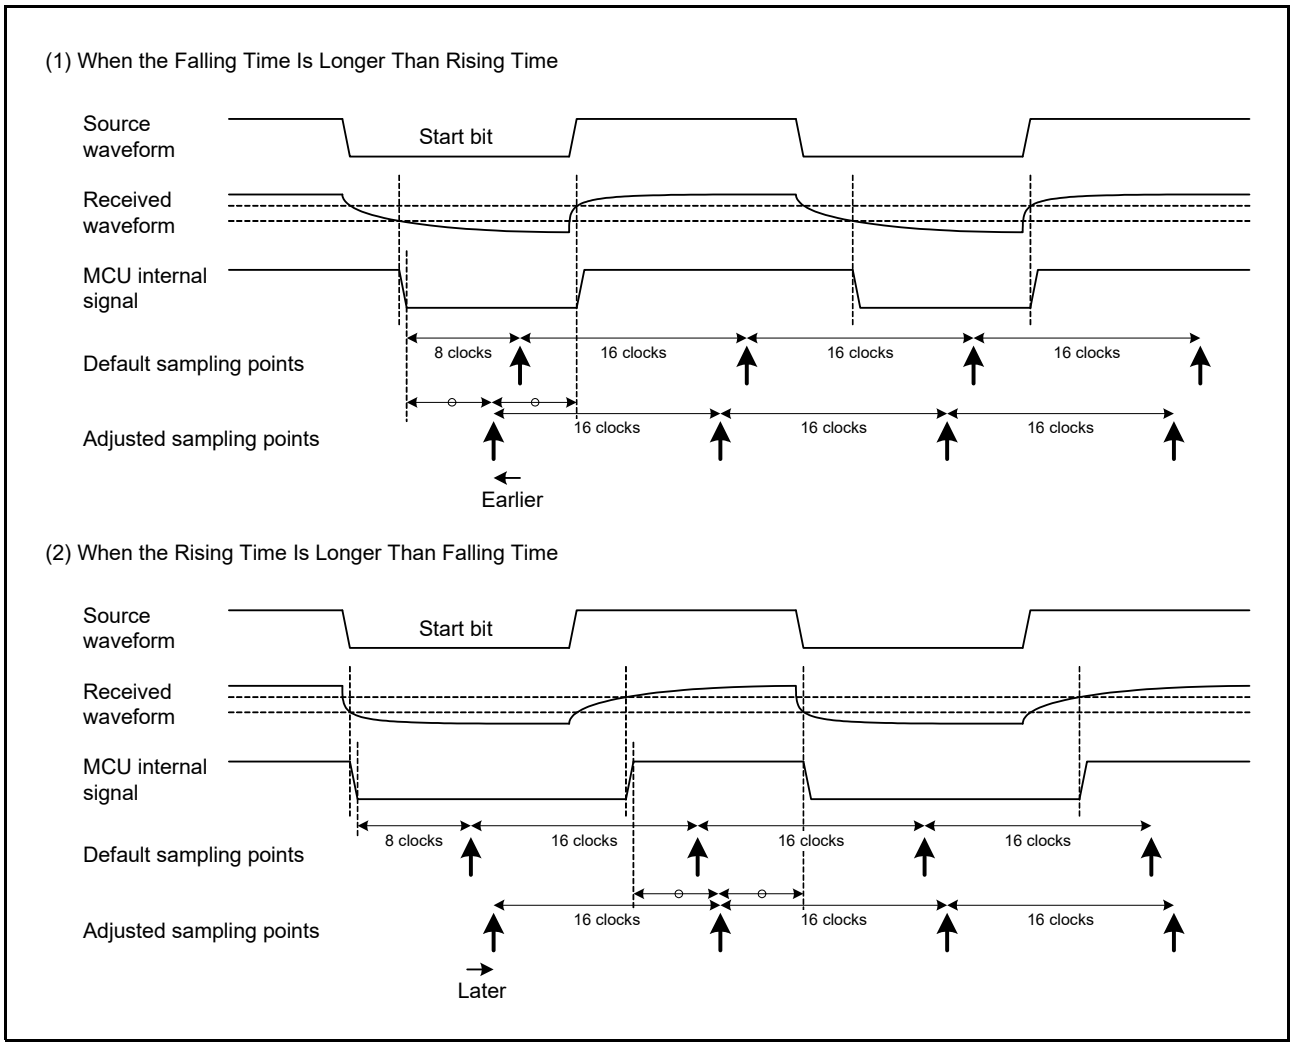

Figure 42.24 Example of Sampling Timing Adjustment (SCR2.ABCSE2 Bit = 0, SCR2.ABCSE Bit = 0, and SCR2.ABCS Bit = 0)

42.3.11 Transmit Data Transition Timing Adjustment

When a difference between high width and low width for a waveform transmitted by this MCU arises at the receiver, it is also possible to make a difference between the high width and the low width beforehand at transmission to adjust so that the difference disappears at the receiver. When high width becomes narrower at the receiver, expand the high width of the transmit signal by delaying the falling edges, and when low width becomes narrower at the receiver, expand the low width of the transmit signal by delaying the rising edges.

When the SCR4.TTMG[3:0] bits are set to the transition direction and the delay amount and the SCR4.TTADJ bit is set to 1, transmit data changes at the specified point.

Figure 42.25 shows an example of the transition timing adjustment.

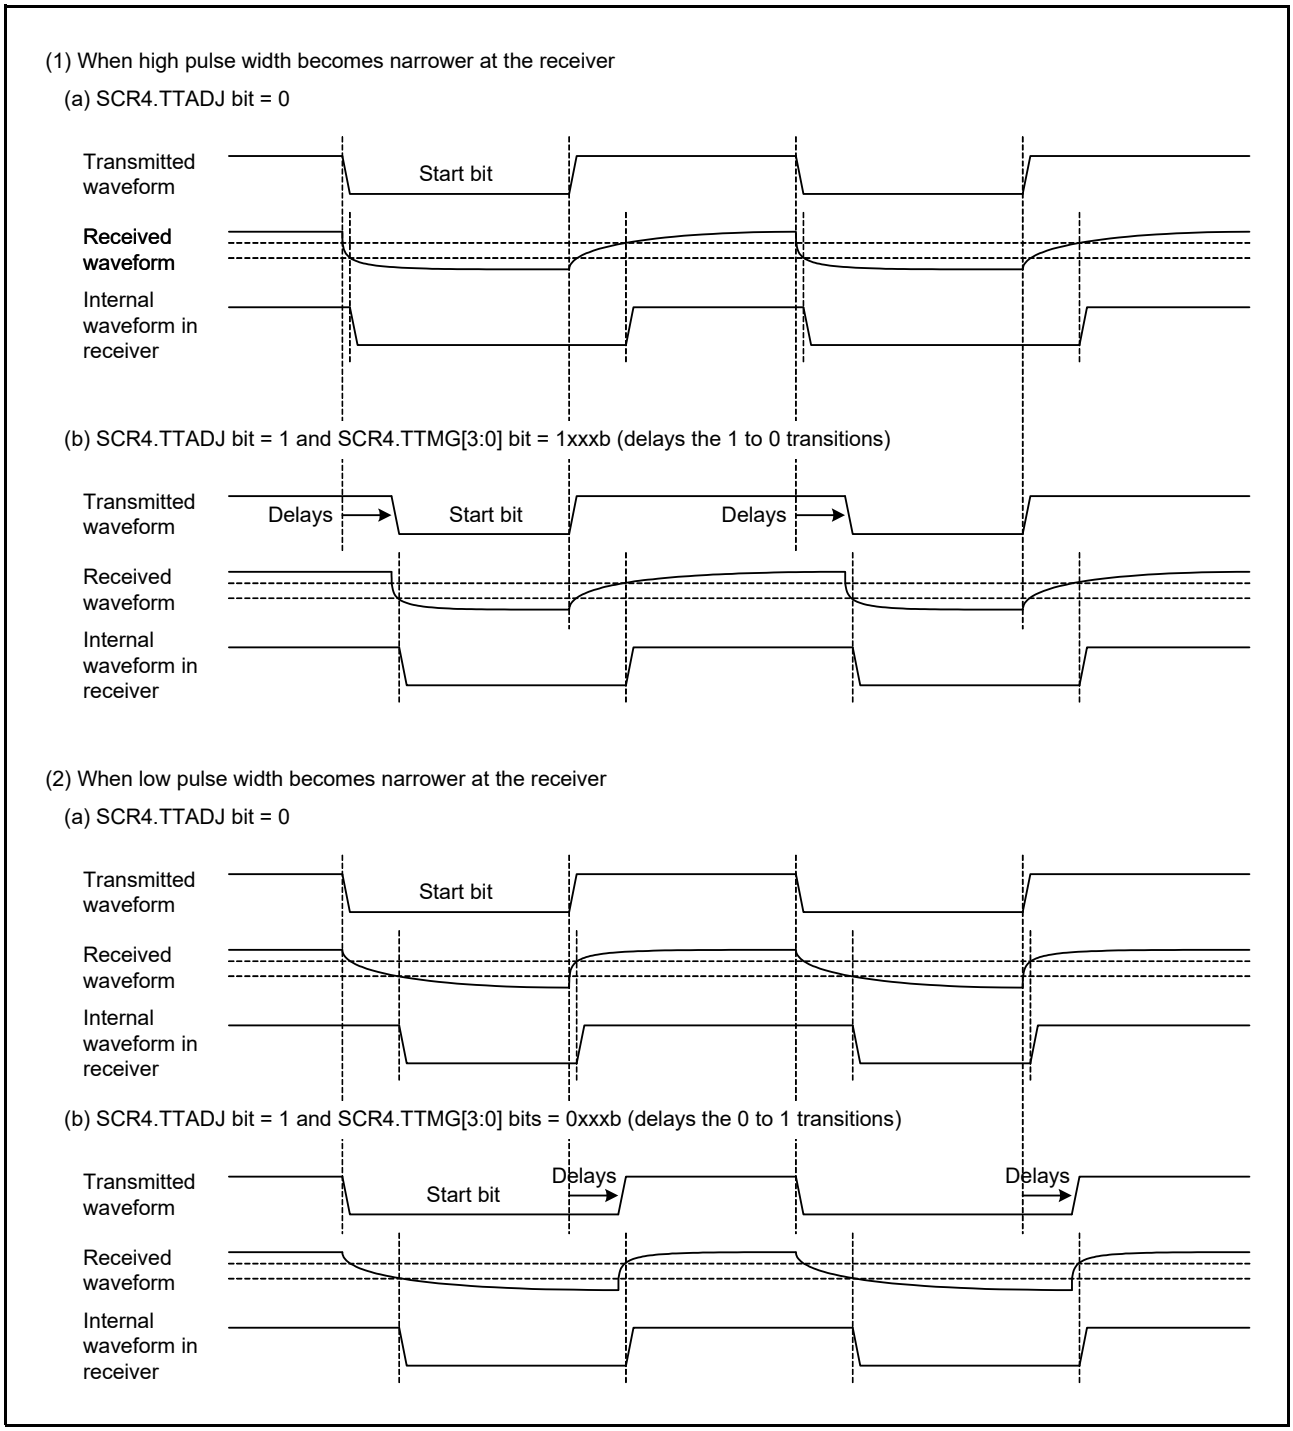

Figure 42.25 Example of Transition Timing Adjustment

42.4 Multi-Processor Communication Function

Using the multi-processor communication functions enables to transmit and receive data by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle and when the multiprocessor bit is set to 0, it indicates the data transmission cycle. Figure 42.26 shows an example of communication between processors by using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits the communication data in which the multi-processor bit set to 0 is added to the transmit data. Upon receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself and if the two matches, receives the communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until again receiving the communication data in which the multi-processor bit is set to 1.
RTS control cannot be used at the time of multi-processor communication function use, because this is a function corresponding to one-to-many communications.

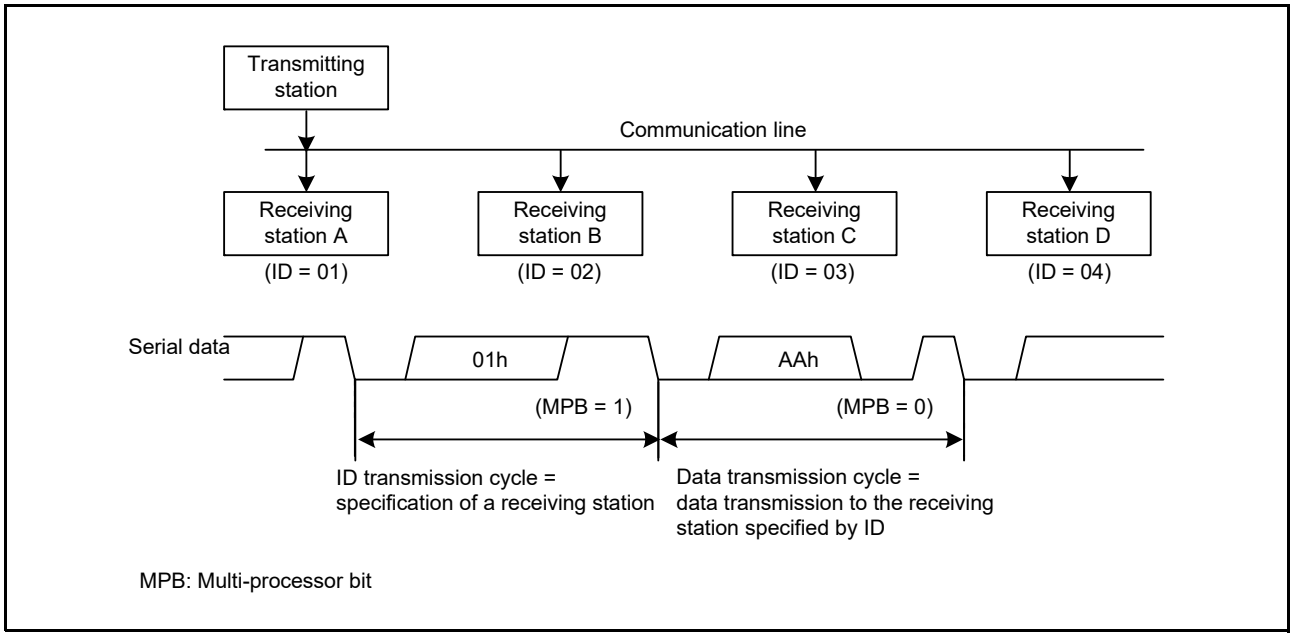

Figure 42.26 An Example of Communication using the Multi-Processor Format (Example of Transmission of Data AAh to Receiving Station A)

(1) Non-FIFO Mode

For supporting this function, the RSCI provides the MPIE bit in SCR0 register. When the MPIE bit is set to 1, transfer of receive data from the RSR register to the RDR register, detection of a receive error, and setting the respective status flags RDRF, ORER and AFER in SSR are disabled until reception of data in which the multi-processor bit is set to 1.
Upon receiving a reception character in which the multi-processor bit is set to 1, the MPB flag in RDR register is set to 1 and the MPIE bit in SCR0 register is automatically cleared, thus returning to a non-multi-processor reception operation. At this time, an RXI interrupt is generated if the RIE bit in SCR0 register is set.
When the multi-processor format is specified, specification of the parity bit is disabled.
Apart from this, there is no difference from the operation in the non-multi-processor asynchronous mode. A clock which is used for the multi-processor communication is also the same as the clock used in the non-multi-processor asynchronous mode.

(2) FIFO Mode

For transmission, SW should write to TDR.MPBT (Multi-Processor Bit Transfer) which corresponds to transmit data in TDR.TDAT[8:0] bits. For reception, multi-processor bit that is a part of receive data, is stored to RDR.MPB flag, and receive data is stored to RDR.RDAT[8:0] bits. When the MPIE bit is set to 1, transfer of receive data from the RSR to the RDR.RDAT[8:0] bits, detection of a receive error, and detection of DR flag, and setting the respective status flags RDRF, ORER, and AFER in SSR are disabled until reception of data in which the multi-processor bit is set to 1.

Upon receiving a reception character in which the multi-processor bit is set to 1, the MPB flag in RDR register is set to 1,and receive data is stored to receive FIFO (RDR.RDAT[8:0] bits), and the MPIE bit in SCR0 register is automatically cleared, thus returning to a non-multi-processor reception operation. At this time, an RXI interrupt is generated if the RIE bit in SCR0 register is set.

When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the non-multi-processor asynchronous mode and FIFO mode.

42.4.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO Mode

Figure 42.27 shows a sample flowchart of multi-processor data transmission. In the ID transmission cycle, the ID should be transmitted with the MPBT bit in TDR register set to 1. In the data transmission cycle, the data should be transmitted with the MPBT bit set to 0. The other operations are the same as the operations in asynchronous mode.

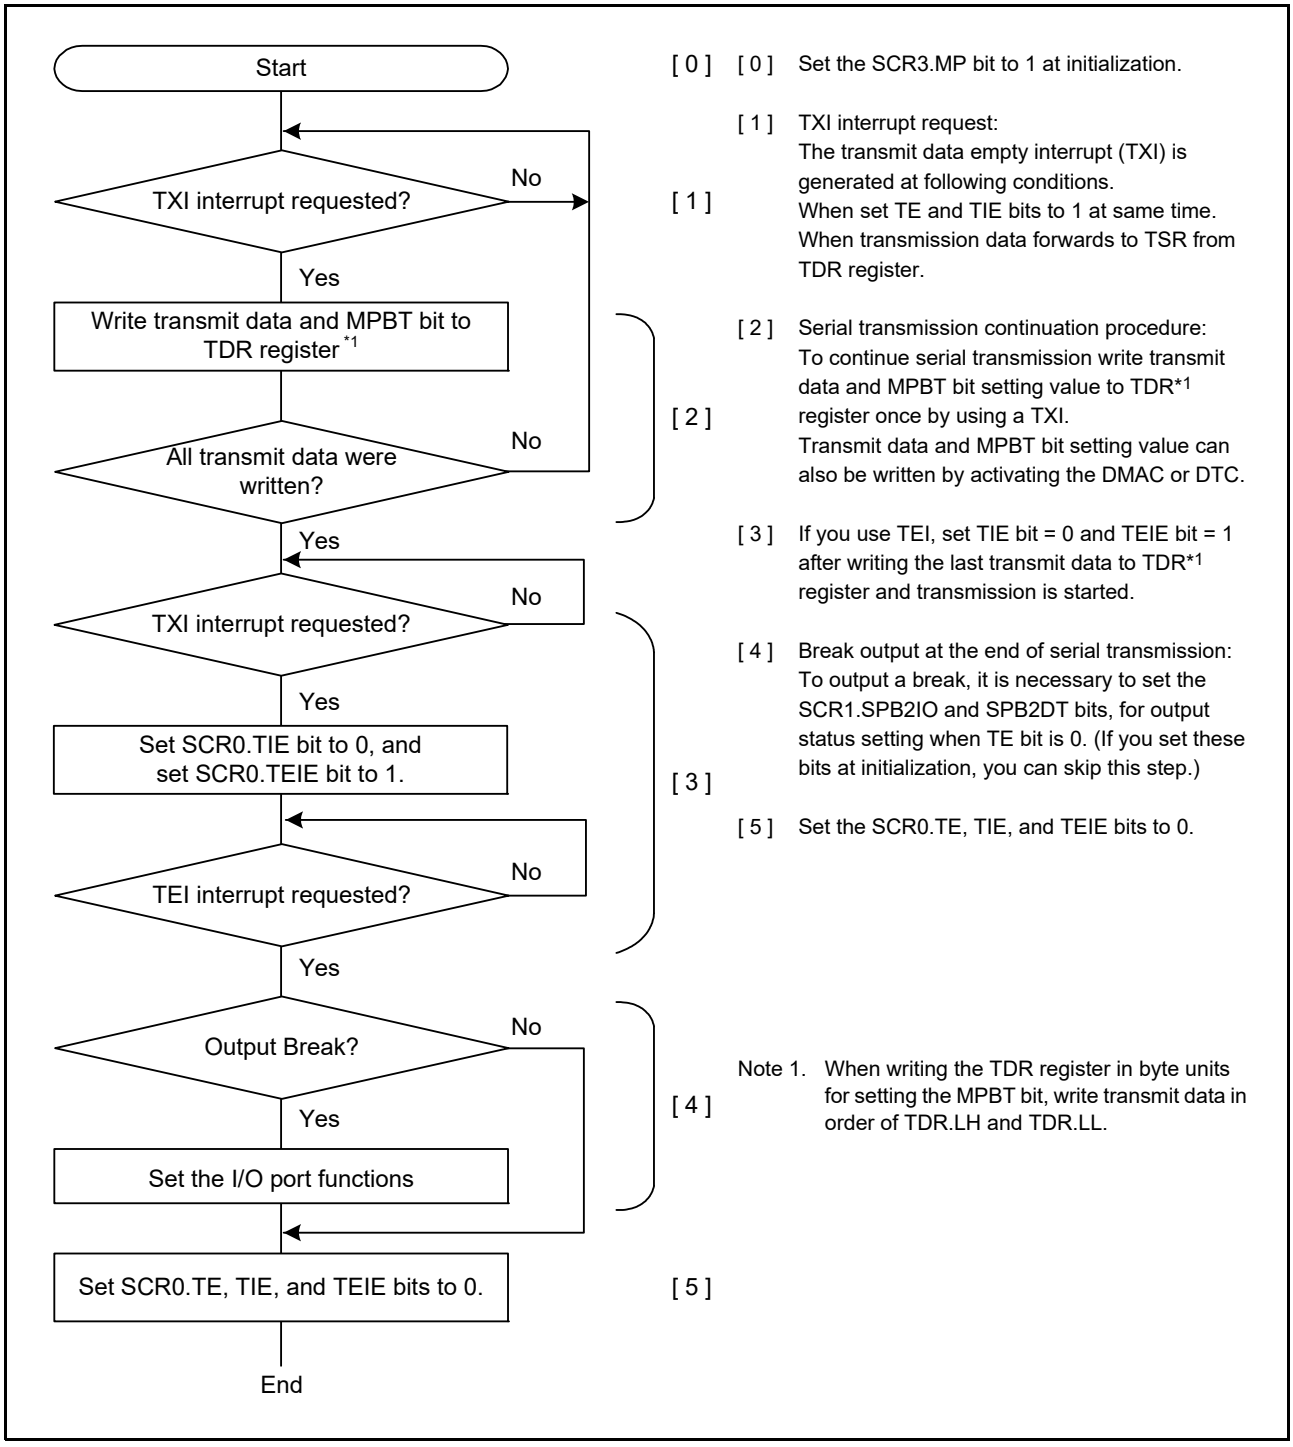

Figure 42.27 Example of Multi-Processor Serial Transmission Flowchart (Non-FIFO Mode)

(2) FIFO Mode

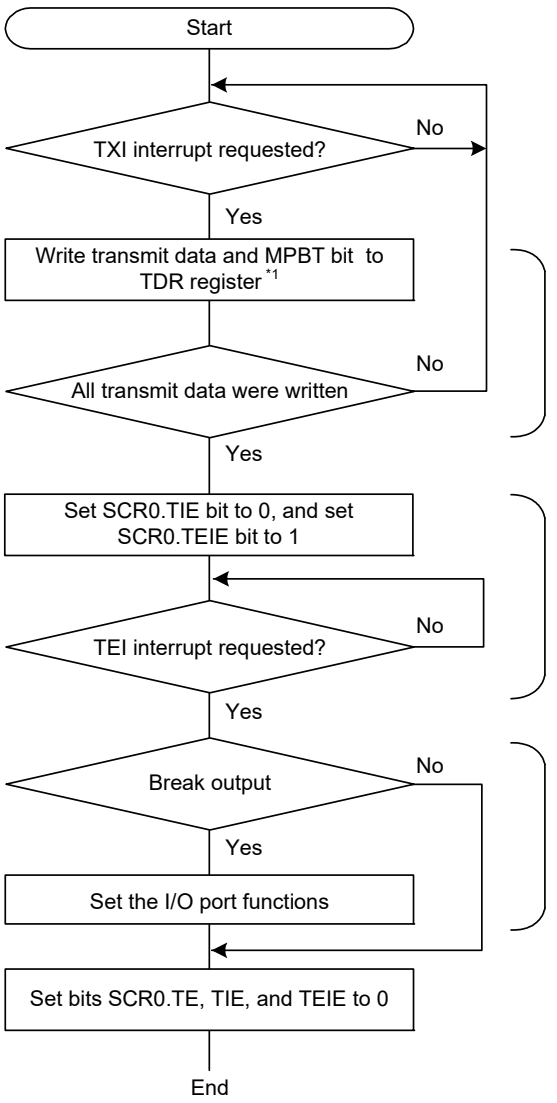

Table 42.33 shows an example of data format that is written to transmit FIFO (TDR register) in multi-processor mode. Write MPBT in bit9 of TDR. And write data to transmit FIFO (TDR register) corresponded to data length. It should write to 0 for unused bits.

Table 42.33 Data Format in Multi-processor Mode that is Written to Transmit FIFO (TDR Register)

Data Length	Register setting		Transmit Data in TDR.L															
	SCR3	CHR[1:0]	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	—	—	—	—	—	—	MPBT	—	—	TDAT[6:0]						
8 bits	1	0	—	—	—	—	—	—	MPBT	—	TDAT[7:0]							
9 bits	0	0 or 1	—	—	—	—	—	—	MPBT	TDAT[8:0]								

—: Do not used. It should write to 0.

Figure 42.28 shows a sample flowchart for multi-processor data transmission in FIFO mode. In the ID transmission cycle, the ID should be transmitted with the MPBT bit in TDR register set to 1. In the data transmission cycle, the data should be transmitted with the MPBT bit set to 0. The other operations are the same as the operations in asynchronous mode with FIFO enabled.

[0] Set the SCR3.FM and MP bits to 1 at initialization.

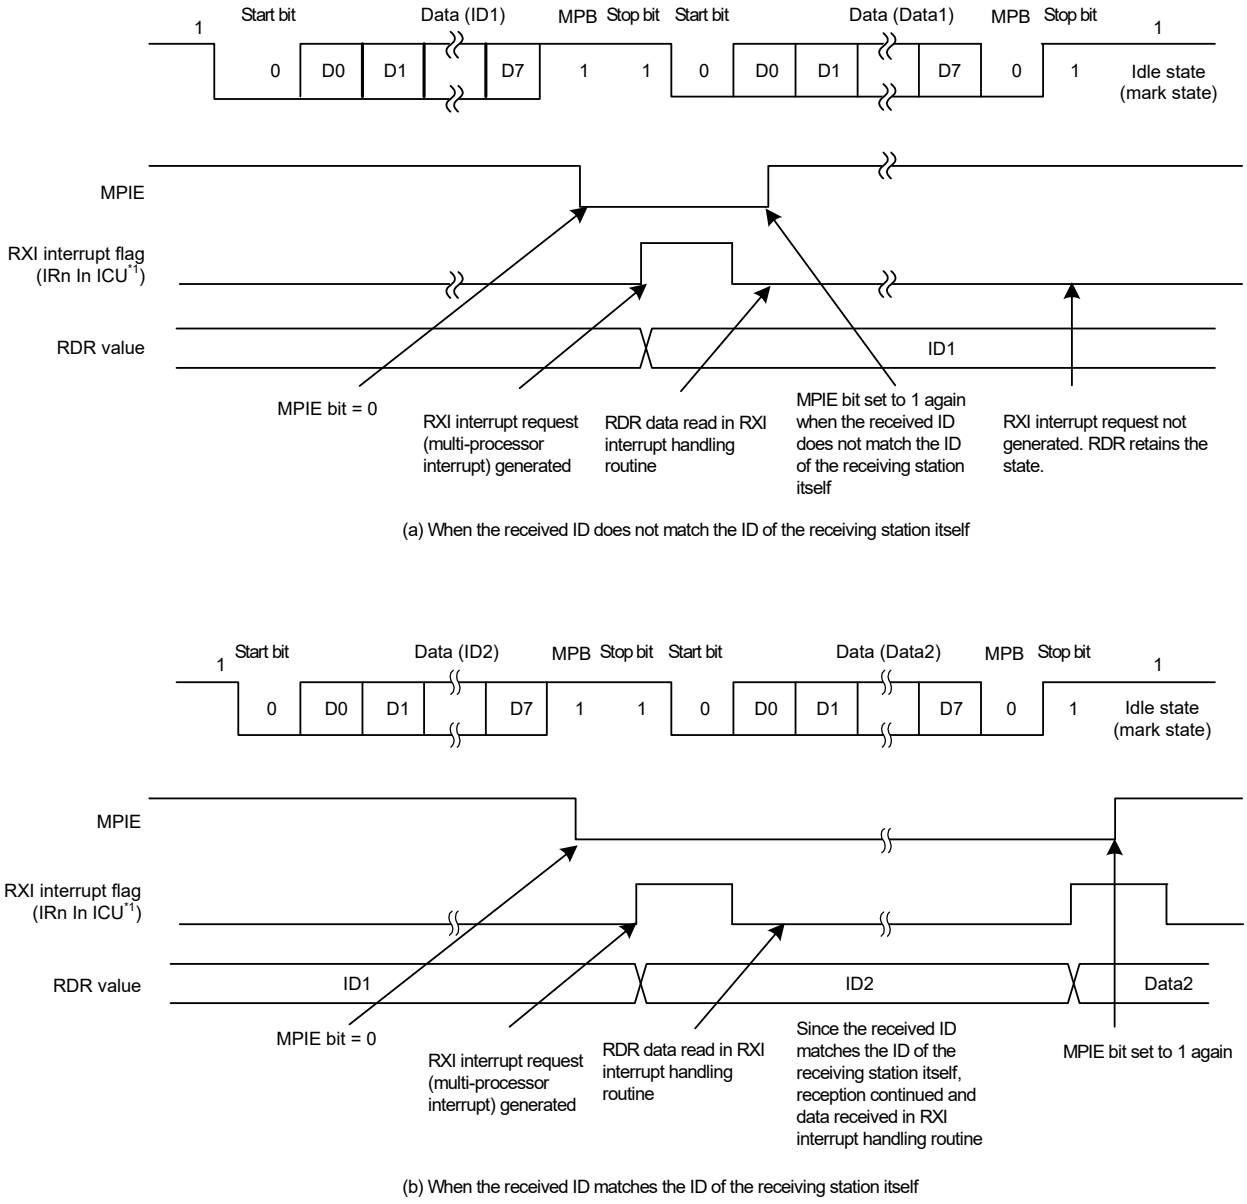
[1] TXI interrupt request:
The transmit data empty interrupt (TXI) is generated when transmission data forwards to TSR from the transmit FIFO (TDR register) and the number of transmit data written in the transmit FIFO is equal to or less than the transmit FIFO threshold.

[2] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data and MPBT bit setting value to the transmit FIFO (TDR register) by using a TXI interrupt. Transmit data and MPBT bit setting value can also be written to the transmit FIFO (TDR register) by activating the DMAC or DTC.

[4] If you use TEI, set TIE bit = 0 and TEIE bit = 1 after writing the last transmit data to TDR*1 register.

[5] Break output at the end of serial transmission:
To output a break, it is necessary to set the SCR1.SPB2IO and SPB2DT bits, for output status setting when TE bit is 0.
(If you set these bits at initialization, you can skip this step.)

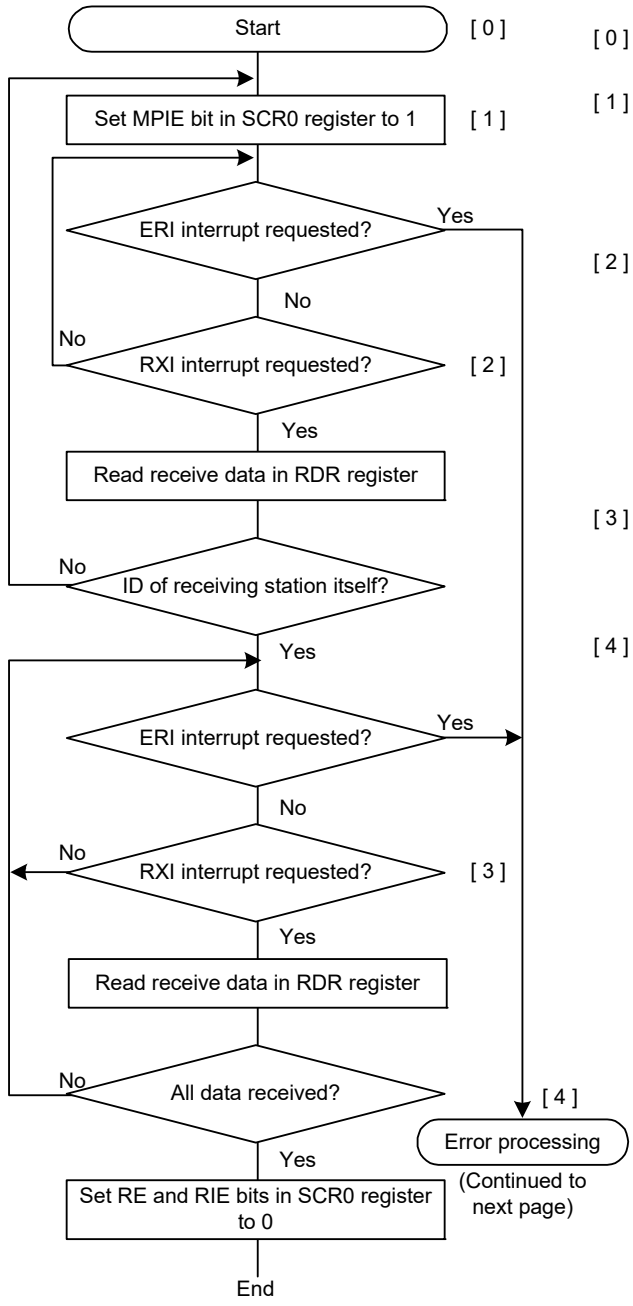
[6] Set bits SCR0.TE, TIE, and TEIE to 0.



Note 1. When writing the TDR register in byte units for setting the MPBT bit, write transmit data in order of TDR.LH and TDR.LL.

Figure 42.28 Example of Multi-Processor Serial Transmission Flowchart (FIFO Mode)

42.4.2 Multi-Processor Serial Data Reception



(1) Non-FIFO Mode

Figure 42.30 and Figure 42.31 are sample flowcharts of multi-processor data reception. When the MPIE bit in SCR0 register is set to 1, reading the communication data is skipped until reception of the communication data in which the multi-processor bit is set to 1. When the communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to RDR register. At this time, the RXI interrupt request is generated. The other operations are the same as the operations in asynchronous mode.
Figure 42.29 is the example of operation for reception.

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.29 Example of RSCI Reception (8-Bit Data/Multi-Processor Bit/1 Stop Bit)

[0] Set the SCR3.MP bit to 1 at initialization.

[1] ID reception cycle:
Set SCR0.MPIE bit to 1 and wait for ID reception.
If you set this bits at initialization, you can skip this Step.

[2] RSCI status confirmation and reception and comparison of ID:
Read data in RDR register at the first RXI interrupt and compare it with the ID of the receiving station itself. If the ID does not match the ID of the receiving station itself, set the MPIE bit to 1 again, and wait for another RXI interrupt request.

[3] Data reception at an RXI interrupt:
Read data in RDR register once in the RXI interrupt routine.

[4] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and AFER flags in SSR. After performing the appropriate error processing be sure to clear the ORER and AFER flags. Reception cannot be resumed if any of these flags is set to 1.
In the case of a framing error, a break can be detected by reading SSR.RXDMON flag.

Figure 42.30 Example of Multi-Processor Serial Reception Flowchart (1) (Non-FIFO Mode)

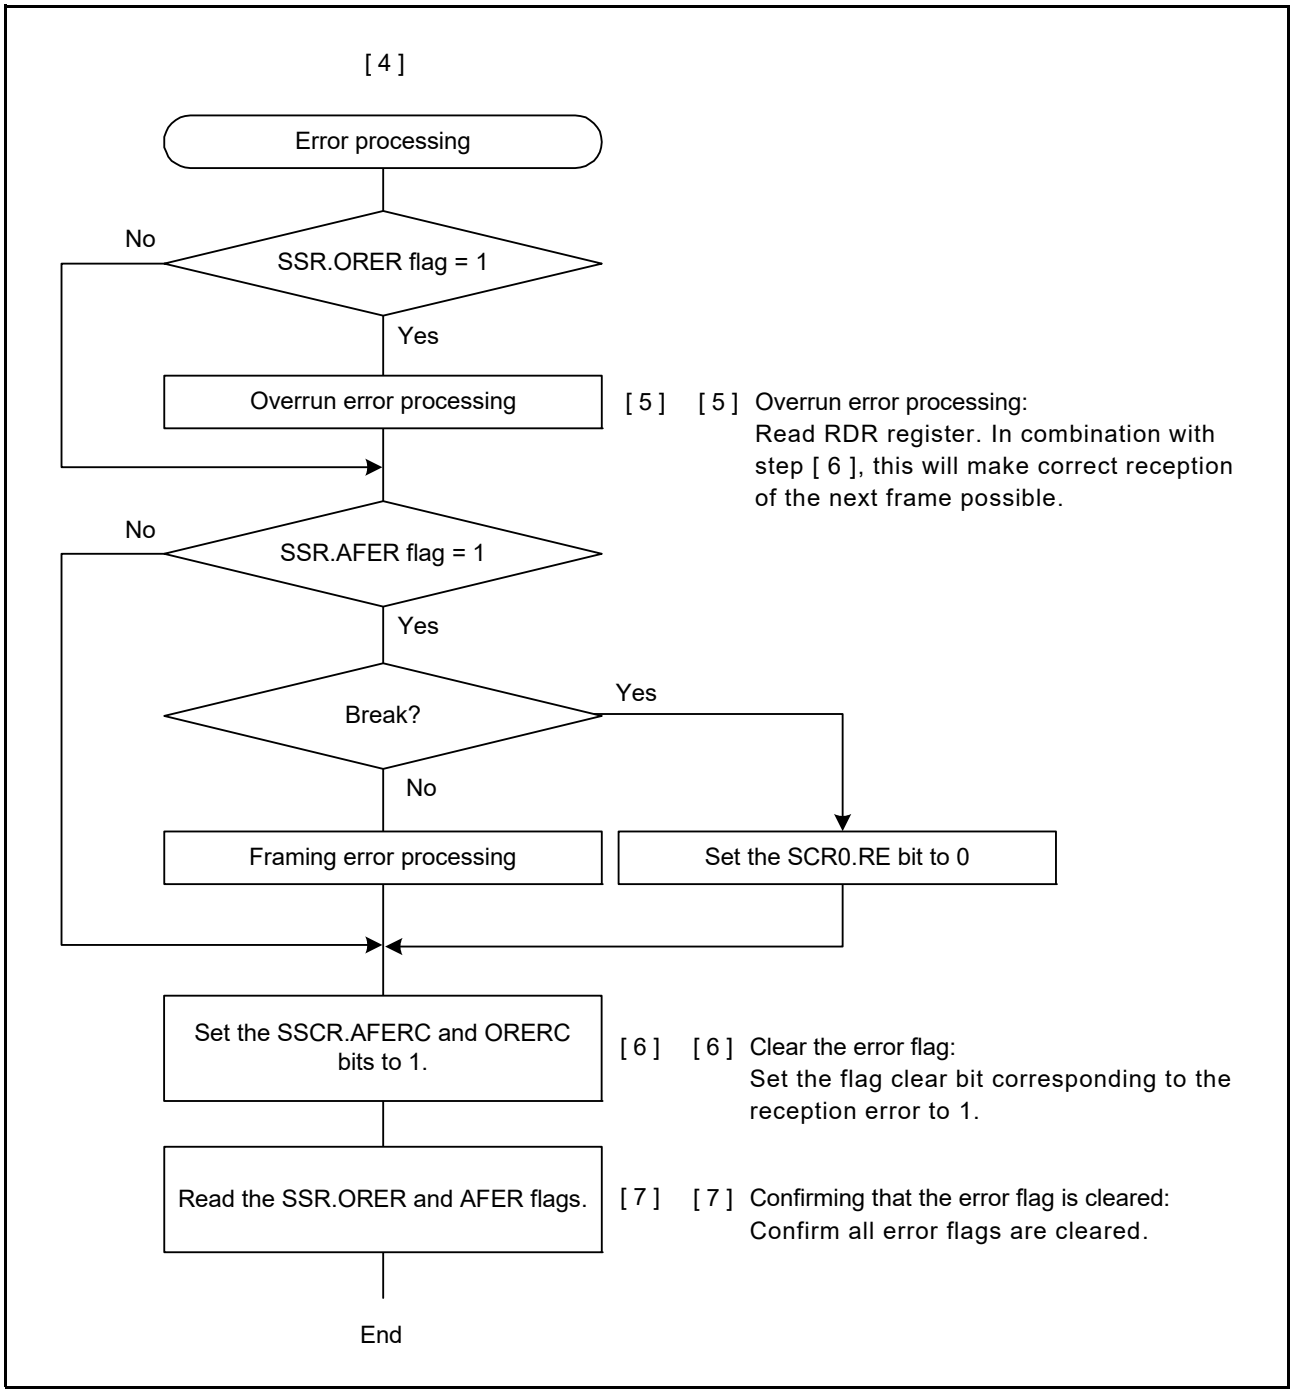


Figure 42.31 Example of Multi-Processor Serial Reception Flowchart (2) (Non-FIFO Mode)

(2) FIFO Mode

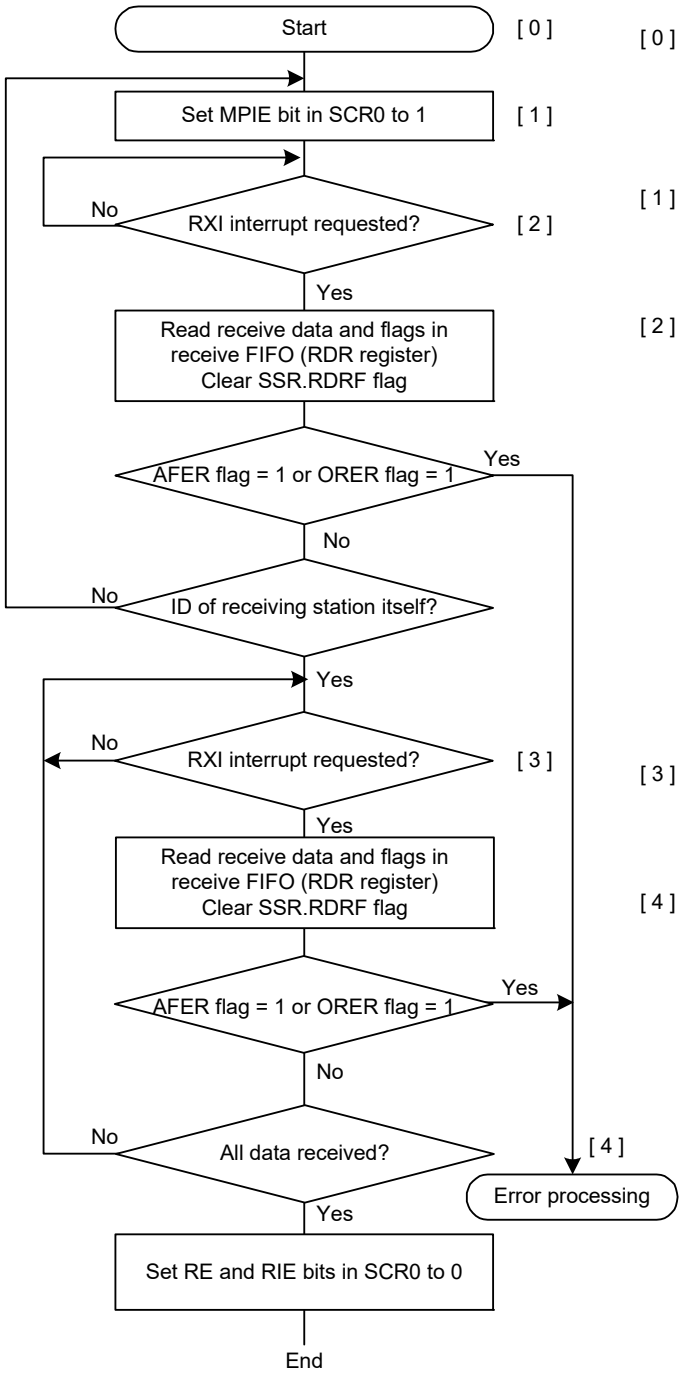

Table 42.34 shows an example of data format that is stored to receive FIFO (RDR register) in multi-processor mode. MPB flag is stored in bit9 of RDR register. 0 is stored to APER and PER flags. Data is stored to receive FIFO RDAT[8:0] bits corresponded to data length. It is stored to 0 for unused bits. Reading the receive FIFO (RDR register) updates the FER, PER, MPB flags and receive data (RDAT[8:0] bits) in the receive FIFO (RDR register) with the next received data. The AFER, APER, and ORER flags in the receive FIFO (RDR register) always reflect the status of the corresponding flags in the SSR and RFSR registers.

Table 42.34 Data Format in Multi-Processor Mode that is Stored to Receive FIFO (FIFO Mode)

Data Length	Register setting		Received Data in RDR Register															
	SCR3 CHR[1:0]		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	1	0	0	0	FER	PER	DR	MPB	0	0	RDAT[6:0]						
8 bits	1	0	0	0	0	FER	PER	DR	MPB	0	RDAT[7:0]							
9 bits	0	0 or 1	0	0	0	FER	PER	DR	MPB	RDAT[8:0]								
Data Length	**SCR3 CHR[1:0]**		**b31**	**b30**	**b29**	**b28**	**b27**	**b26**	**b25**	**b24**	**b23**	**b22**	**b21**	**b20**	**b19**	**b18**	**b17**	**b16**
7 bits	1	1	0	0	0	AFER	APER	0	0	ORER	0	0	0	0	0	0	0	0
8 bits	1	0	0	0	0	AFER	APER	0	0	ORER	0	0	0	0	0	0	0	0
9 bits	0	0 or 1	0	0	0	AFER	APER	0	0	ORER	0	0	0	0	0	0	0	0

Note: When data length is 7bit, it can read always 0 in RDAT[8:7] bits.
When data length is 8bit, it can read always 0 in RDAT[8] bit.

Figure 42.32 shows a sample flowchart for multi-processor data reception in FIFO mode. When the MPIE bit in SCR0 register is set to 1, reading the communication data is skipped until reception of the communication data in which the multiprocessor bit is set to 1. When the communication data in which the multi-processor bit is set to 1 is received, the received data, MPB flag and each errors are transferred to receive FIFO (RDR register), and the MPIE bit in SCR0 register is automatically cleared, thus returning to a normal reception operation. After a framing error occurred and SSR.AFER flag is set to 1, but RSCI continues data reception.
The other operations are the same as the operations in asynchronous mode with FIFO enabled.

[0] Set the SCR3.FM and MP bits to 1.
Also, set the FCR.RTRG[4:0] bits to 00001b and DRES bit to 0 to generate an RXI interrupt request when data with the MPB flag set to 1 is received.

[1] ID reception cycle:
Set SCR0.MPIE bit to 1. And wait for ID reception. If you set this bits at initialization, you can skip this Step.

[2] RSCI status confirmation and reception and comparison of ID:
RSCI skips the received data until it receives the data with the MPB flag set to 1. When receiving data with the MPB flag set to 1, RSCI generates an RXI interrupt request.
In the RXI interrupt routine, read the data from the receive FIFO (RDR register) and compare it with the ID of the receiving station itself. If the ID does not match the ID of the receiving station itself, set the MPIE bit to 1 again and wait for another RXI interrupt request. If it matches the ID of the receiving station itself, set the receive FIFO threshold to the desired value.

[3] Data reception at an RXI interrupt:
Read data in the receive FIFO (RDR register) once in the RXI interrupt routine.

[4] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and AFER flags in SSR register (There is no problem reading the SSR.ORER and AFER flags again.). After performing the appropriate error processing be sure to clear the ORER and AFER flags. In the case of a framing error, a break can be detected by reading the SSR.RXDMON flag.

Figure 42.32 Example Flowchart of Serial Reception in Multi-Processor Mode (1) (FIFO Mode)

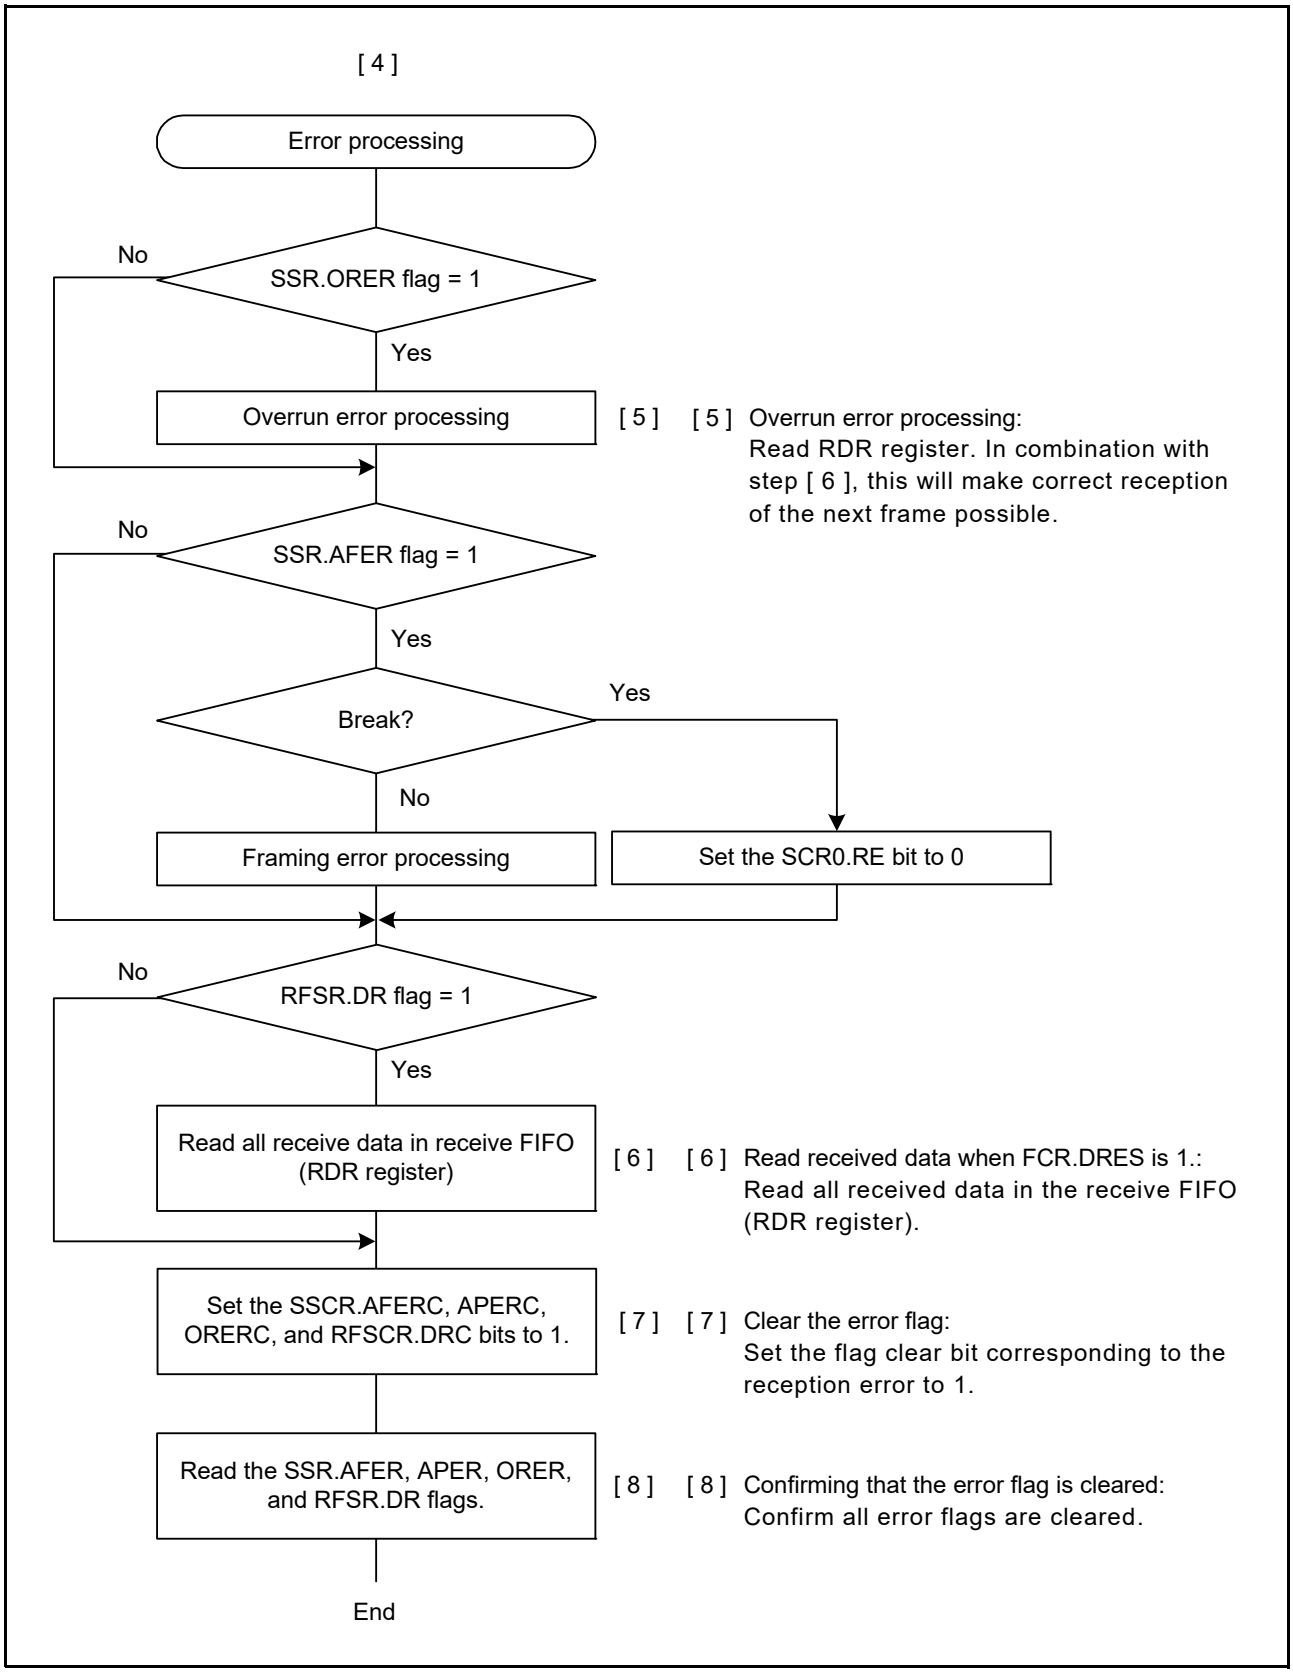

Figure 42.33 Example Flowchart of Serial Reception in Multi-Processor Mode (2) (FIFO Mode)

42.5 Manchester Mode

In Manchester mode, the transmit or receive serial data is coded in Manchester encoding.
Figure 42.34 shows the conceptual image of Manchester encoding.

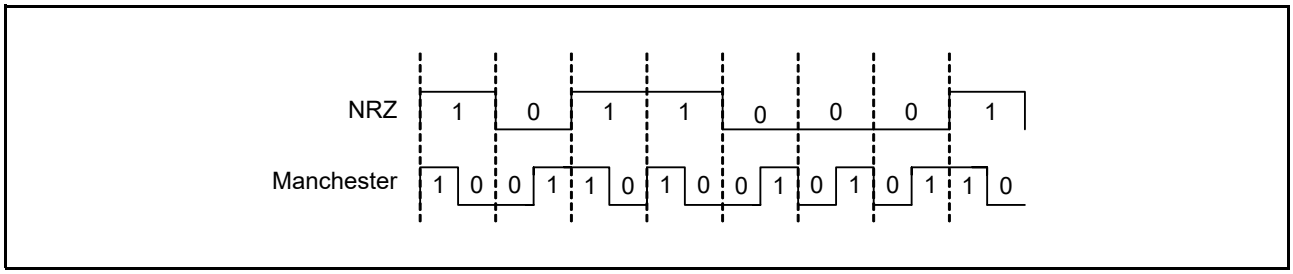

Figure 42.34 Example of Manchester Encoding

In Manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.
For details on the frame format, see section 42.5.1, Frame Format.

42.5.1 Frame Format

Figure 42.35 shows the frame format in Manchester mode.
In the upper half of the figure, relevant setting registers are shown.
The preface area and the data area are encoded in Manchester encoding.

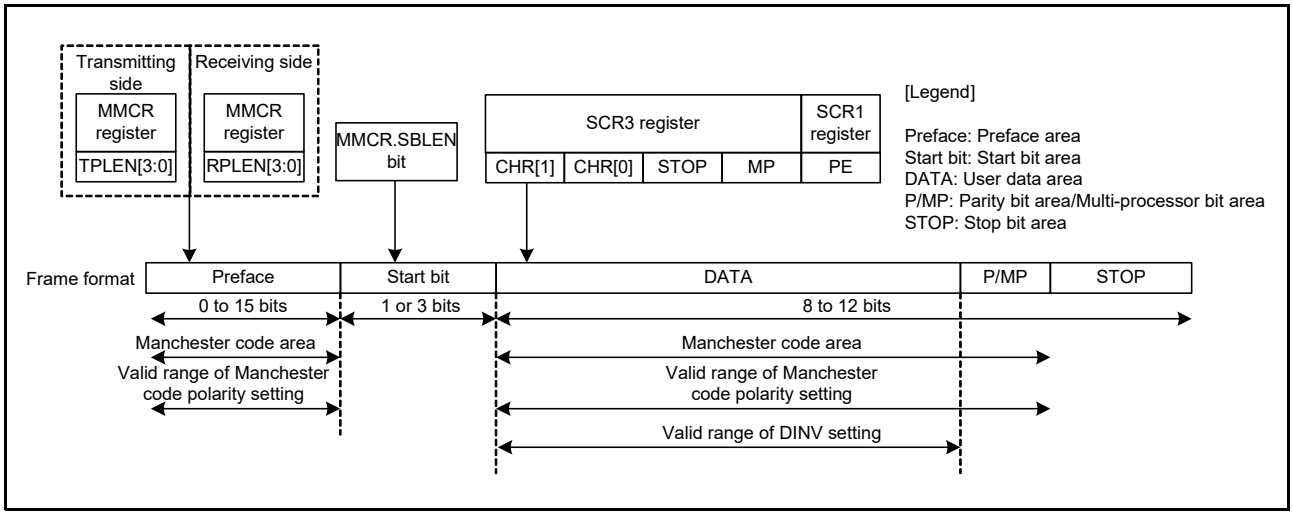

Figure 42.35 Frame Format in Manchester Mode

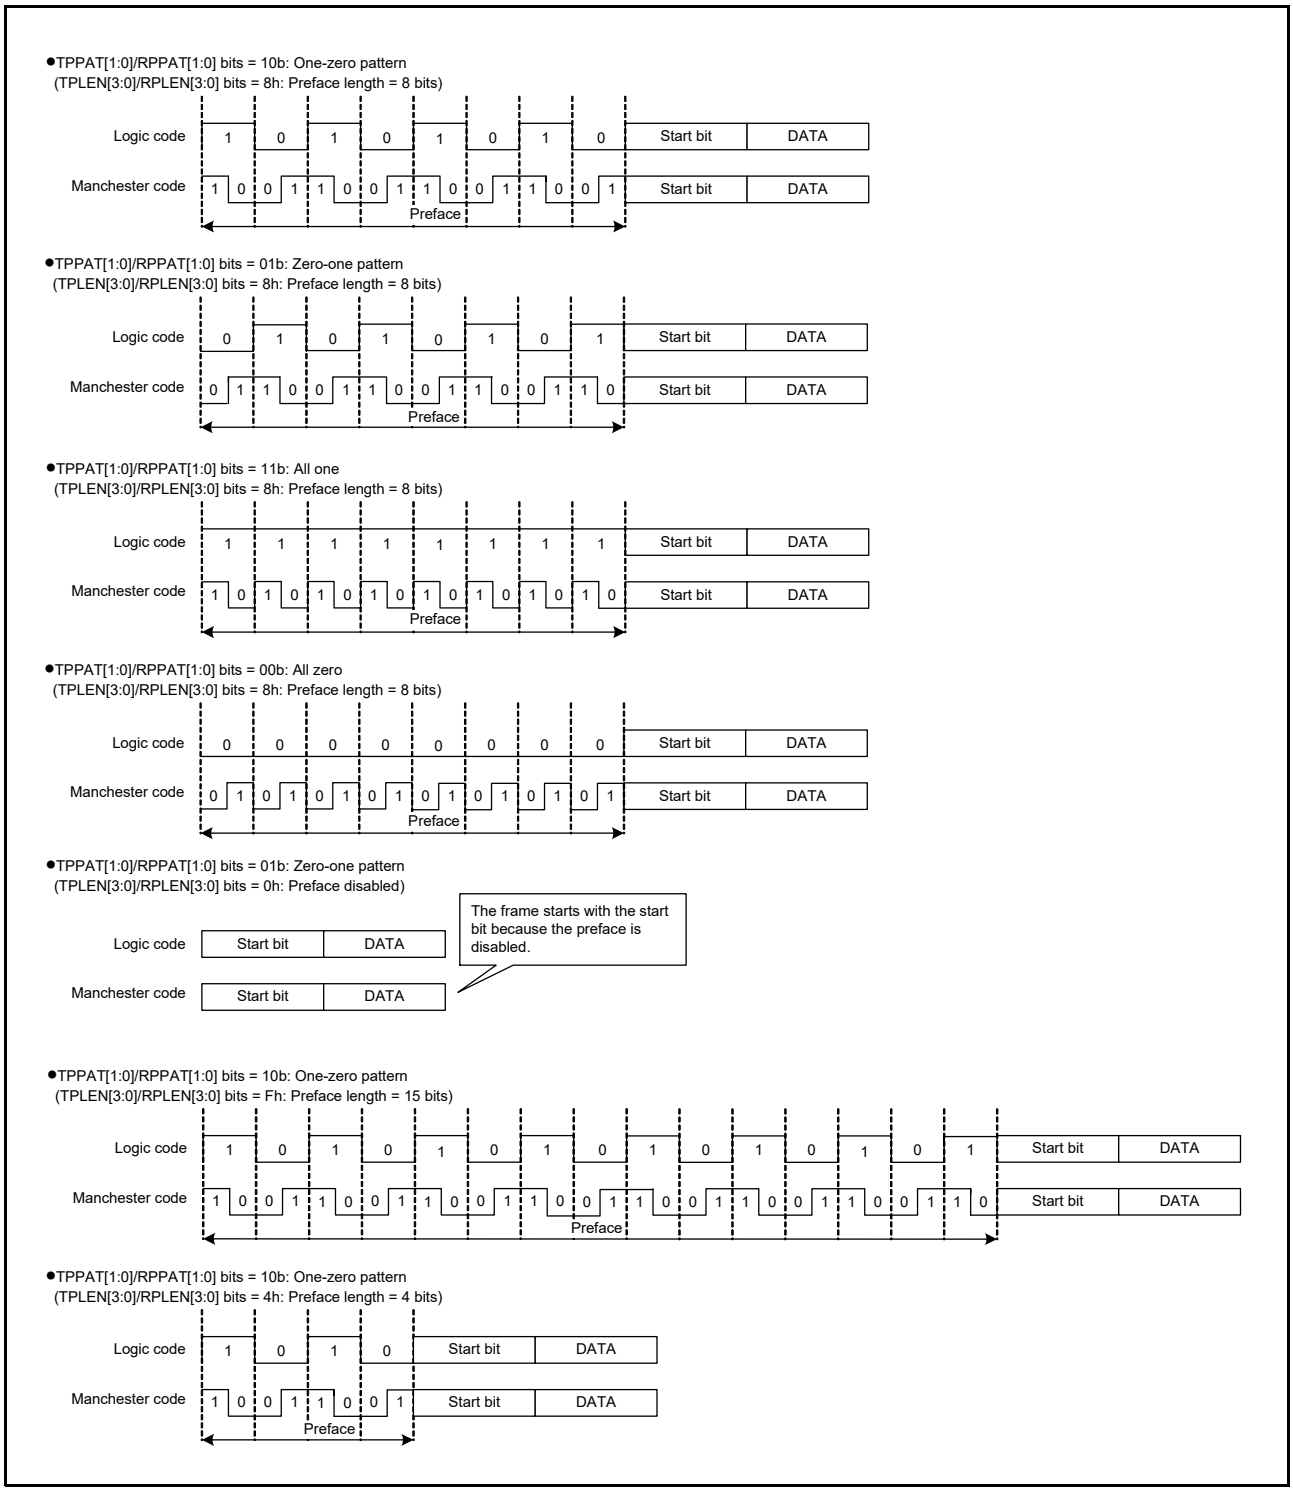
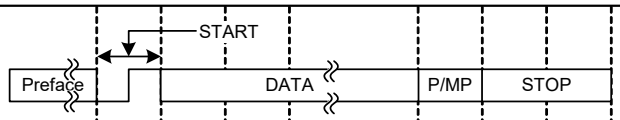
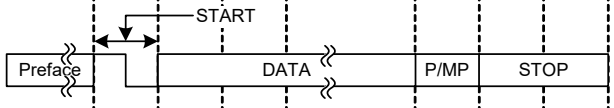
(1) Preface Area

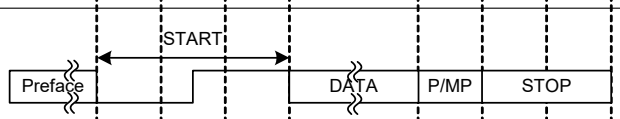
This is a fixed pattern area located at the beginning of each frame.
Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting MMCR.TPLEN[3:0] bits for transmission. It is determined by setting MMCR.RPLEN[3:0] bits for reception.
If it is set to 0, the transmit preface is disabled and is not added.
If it is set to 1d to 15d, a preface whose length is determined by this setting is added.
(For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)
In addition, the preface pattern can be changed by setting, and it can be selected from four types of patterns by setting

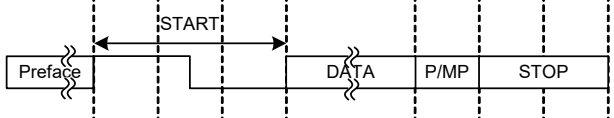
MMCR.TPPAT[1:0] bits for transmission and MMCR.RPPAT[1:0] bits for reception.
Figure 42.36 shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

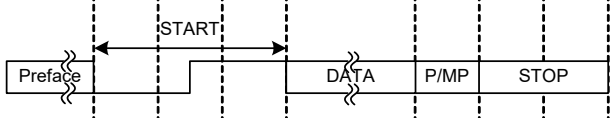












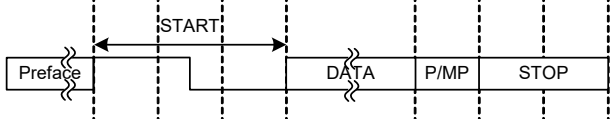


Figure 42.36 Preface Pattern Setting Example

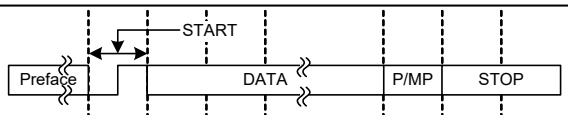

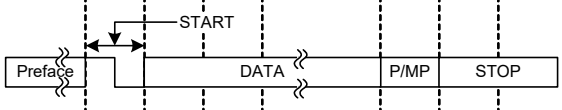

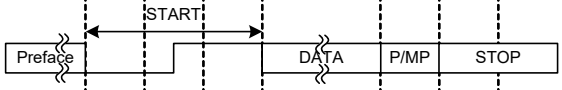

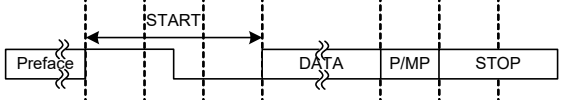

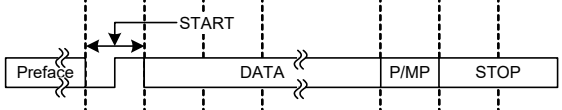

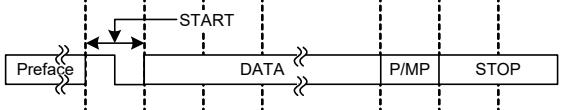

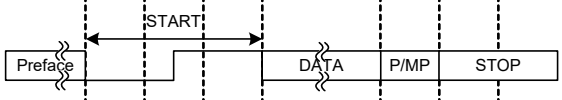

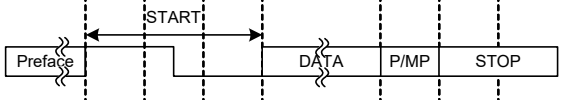

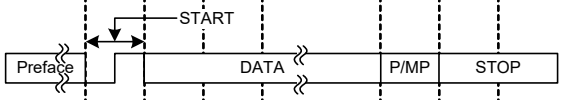

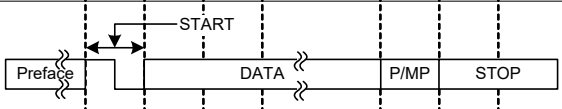

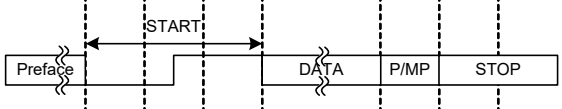

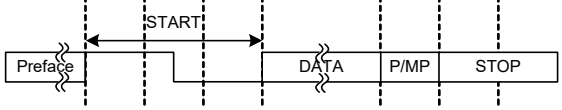

(2) Start Bit Area

This is an area indicating the start of valid data in a frame. It is added after the preface area.
The start bit length is determined by MMCR.SBLEN bit setting. When MMCR.SBLEN bit = 0, the start bit length is 1 bit. When MMCR.SBLEN bit = 1, the start bit length is 3 bits.
When MMCR.SBLEN bit = 1, the Sync type can be selected from command Sync and data Sync.
Command Sync means the three start bits are added as a one-to-zero transition.
Data Sync means the three start bits are added as a zero-to-one transition.
The Sync type is determined by the MMCR.SYNCE, MMCR.SBPTN and TDR.SYNC bit settings. (When receiving, the received result is applied to MMSR.RSYNC bit.)
When MMCR.SBLEN bit = 0, the start bit is added as a zero-to-one or one-to-zero transition. The selection is determined by the MMCR.SBPTN setting.
The MMCR.SYNCE bit specifies the destination to be referred to when setting for transmission. When the MMCR.SYNCE bit is set to 1, the MMCR.SBPTN setting is referred to. When the MMCR.SYNCE bit is set to 0, the TDR.SYNC bit setting is referred to.
Figure 42.37 shows the state of the start bit area according to the settings in the MMCR.SYNCE, MMCR.SBPTN and TDR.SYNC bits in the case of transmission. Figure 42.38 shows that in the case of reception.
The start bit(s) is not affected by the MMCR.ENCS bit or MMCR.DECS bit setting.

Register Setting				Output Signal	Output Start Bit
MMCR			TDR	Output TXD Waveform	
SBLEN	SYNCE	SBPTN	SYNC		
0	d.c.	0	d.c.		1bit 0 to 1 transition
0	d.c.	1	d.c.		1bit 1 to 0 transition
1	0	0	d.c.		3bit 0 to 1 transition
1	0	1	d.c.		3bit 1 to 0 transition

Preface: Preface area
START: Start bit area
DATA: User data area
P: Parity bit area
MP: Multi-processor bit area
STOP: Stop bit area

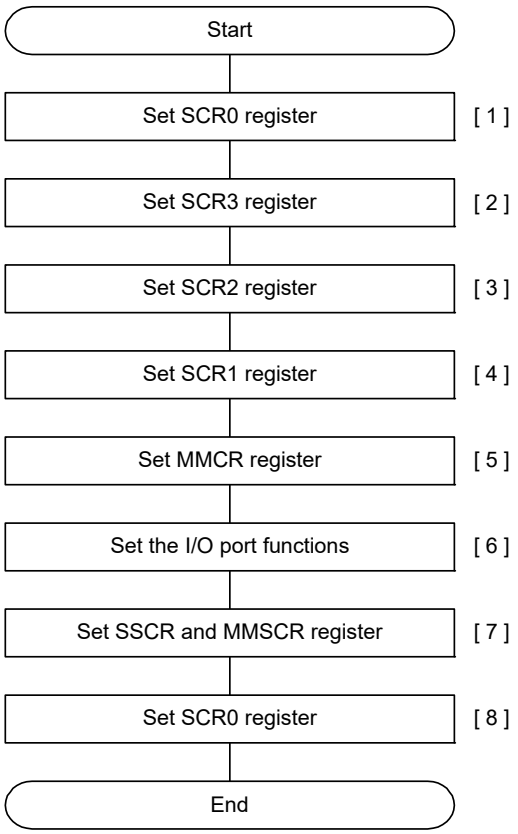
Note 1. Data other than the start bit is assumed to be normal.

Figure 42.38 Settings Related to and Judgment of the Start Bit Area at Reception

(3) Data



Since the format of the data area is the same as that of the asynchronous mode, see section 42.3.1, Serial Data Transfer Format.
As shown in Figure 42.35, Frame Format in Manchester Mode, the stop bit is not included in the Manchester encoding range.

42.5.2 Clock

As the transfer clock in Manchester mode, the clock generated by the on-chip baud rate generator is used by setting the SCR2.CKS[1:0] bits.
Also it is possible to set the oversampling (transfer rate of one bit period) by SCR2.ABCS bit. When the SCR2.ABCS bit is set to 0, oversampling ×16 is selected with the one-bit period being 16 cycles of the base clock. When the SCR2.ABCS bit is set to 1, oversampling ×8 is selected with the one-bit period being 8 cycles of the base clock.

42.5.3 RSCI Initialization of Manchester Mode

Before transferring data, write 0 to SCR0.TE and SCR0.RE bits (or write the initial value to SCR0 register), and initialize the RSCI following the example of flowchart shown in Figure 42.39.
Be sure to write 0 to SCR0.TE and SCR0.RE bits before changing the operation mode or communication format.
Note that setting the SCR0.RE bit to 0 initializes none of the SSR.ORER, AFER, APER, RDRF, MMSR.MCER, SYER, PFER and SBER flags, and the RDR registers.
Note also that switching the value of SCR0.TE bit from 0 to 1 when SCR0.TIE bit is 1 generates a TXI interrupt request.

[1] Set the following bits of SCR0 register to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set the driver control, multi-processor communication, the communication mode, transmission/reception format, and clock enable.
Leave unused bits such as CPOL and CPHA bits at their initial values.

[3] Set the clock selection, bit rate setting.
Leave unused function bits at their initial values.

[4] Set the noise filter, loopback control, communication terminal status, parity check, and CTS/RTS function.

[5] Set Manchester transmission/reception setting.
Start bit setting, retiming setting, Manchester polarity setting, transmission preface setting, reception preface setting.

[6] Set the I/O port so that the required pin function is valid among the TXDn, RXDn, and SCKn pins.

[7] Set 1 to the following clear bits in the SSCR and MMSCR registers to clear the target flag.
SSCR.RDRFC, AFERC, APERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
MMSCR.MCERC, SBERC, SYERC, PFERC
This procedure can be omitted for the initial setting after reset.

[8] Set the SCR0.TE or RE bit to 1. To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Set the multiprocessor function. The TXDn and RXDn pins can be used by setting the TE and RE bits.

Figure 42.39 RSCI Initialization Flow in Manchester Mode

42.5.4 Double Speed Operation

When the ABCS bit in SCR2 register is set to 1 and eight pulses of the base clock for a 1 bit period is selected, the RSCI operates on the bit rate twice that of when ABCS is set to 0.
When the BGDM bit in SCR2 register is set to 1, the cycle of the base clock is reduced to half and the RSCI operates on the bit rate twice that of when BGDM is set to 0.
When the ABCS bit in SCR2 register and the BGDM bit in SCR2 register are set to 1, the RSCI operates on the bit rate four times that of when the ABCS bit in SCR2 register and the BGDM bit in SCR2 register are set to 0.

42.5.5 CTS, RTS Functions

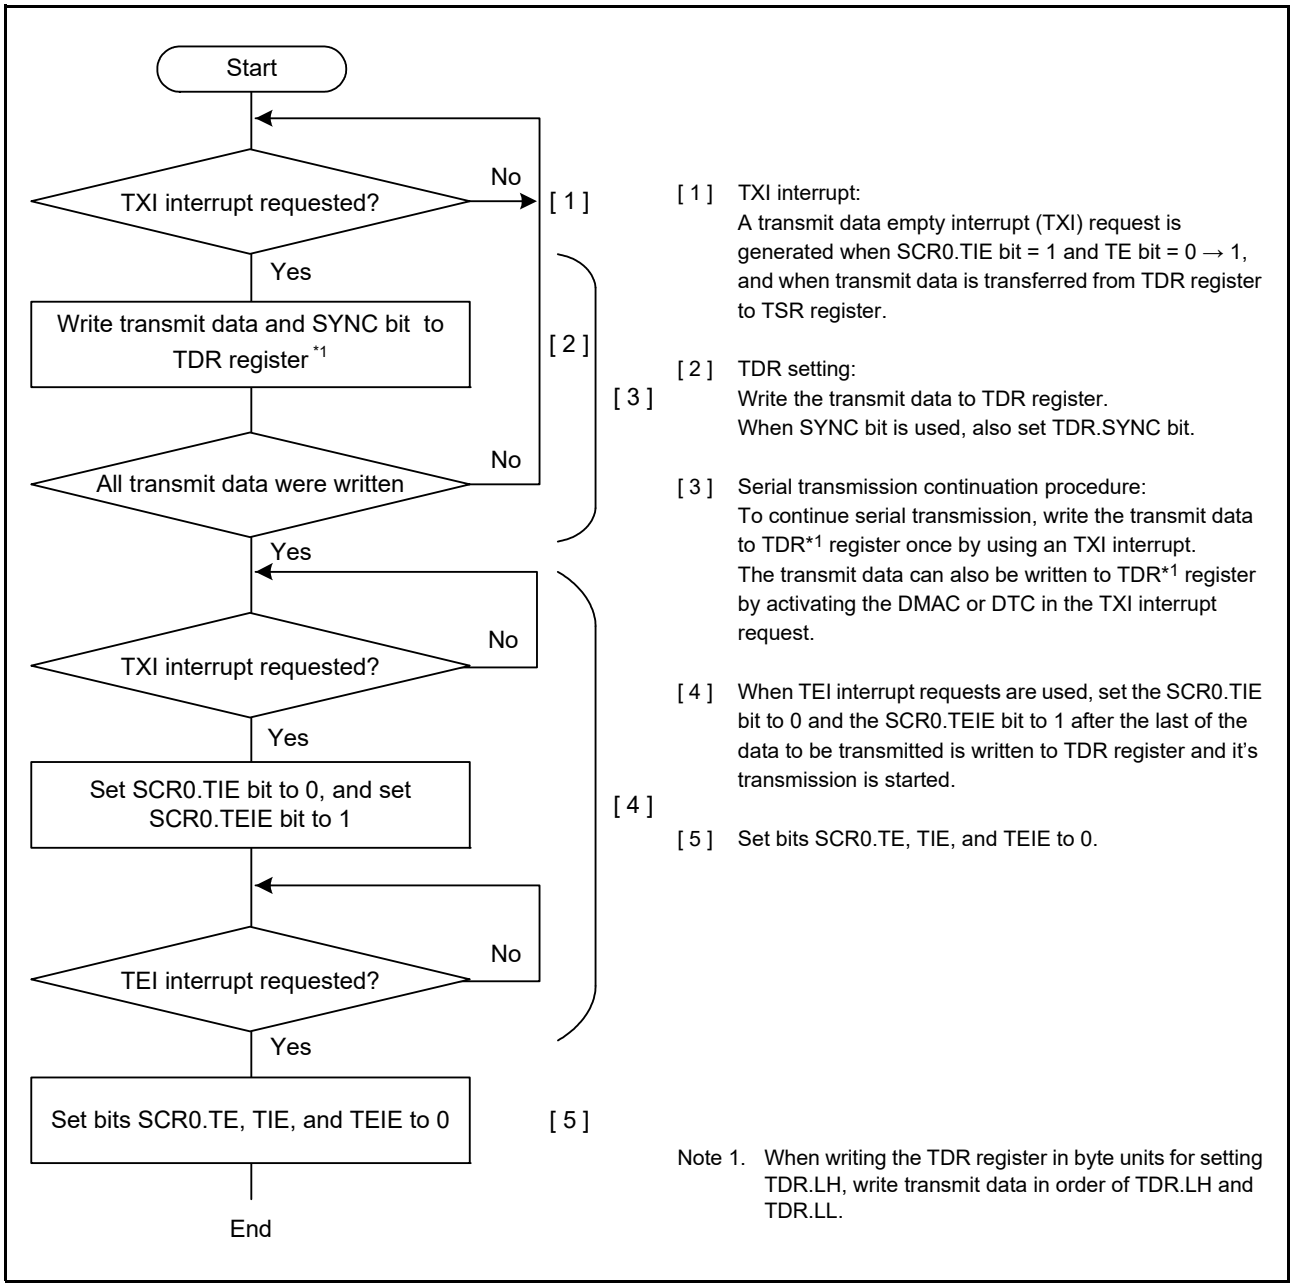
The CTS function controls transmission using the CTSn# pin input. Setting the CTSE bit in SCR1 register to 1 enables the CTS function. The CTSn#/RTSn# pin can be set as a multiplexed pin which allows one pin to be used for either function, or as dedicated pins with each pin for a single function. Use the CRSEP bit in SCR1 register for this setting.
When the CTS function is enabled, transmission starts only when the CTSn# pin is at the low level.
Even if the level of CTSn# pin goes High after transmission starts, does not affect transmission of the current frame, which continues.
The RTS function uses output on the RTSn# pin to request transmission. When the RSCI is ready to receive, it outputs a low level to the RTSn# pin, Conditions for output of the low level and high level are as follows:
[Conditions for low-level output]
When all conditions listed below are satisfied:

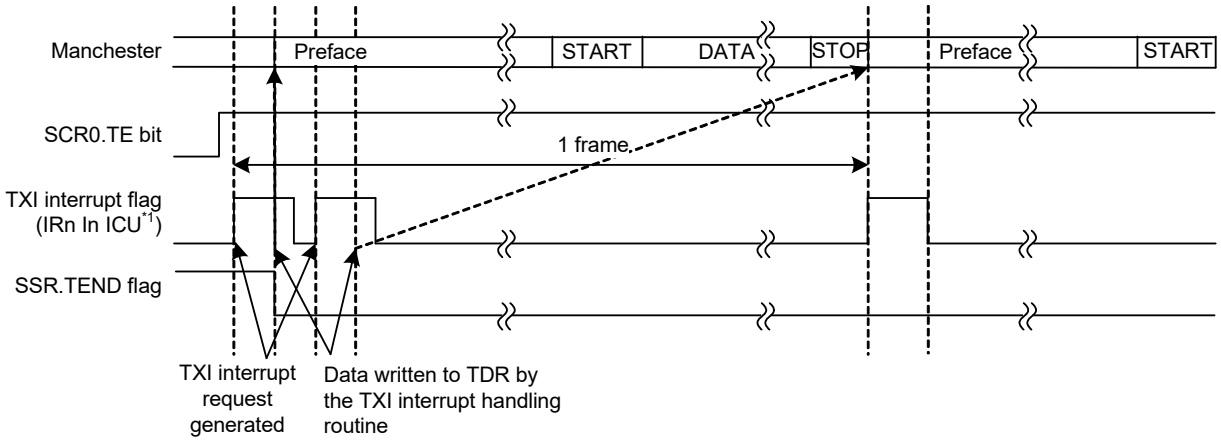
- The value of the SCR0.RE bit is 1.
- There are no received data yet to be read and reception is not in progress.
- All of the following flags are set to 0:
  SSR.ORER, AFER, APER and MMSR.MCER, SBER (when SBERIE bit = 1), SYER (when SYERIE bit = 1), PFER (when PFERIE bit = 1)

[Conditions for high-level output]
When the conditions for low output are not satisfied.

42.5.6 Serial Data Transmission in Manchester Mode

The RSCI encodes data in Manchester encoding and sends the resultant data in Manchester mode.
When the polarity setting (MMCR.ENCS bit) set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.
When the polarity setting (MMCR.ENCS bit) set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.
For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See Figure 42.34)
The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.
For details on the frame format, see section 42.5.1, Frame Format.
Figure 42.40 shows the flowchart in transmission. At transmission starts, set the SCR0.TIE and SCR0.TE bits to 1 simultaneously with one instruction. Then, a TXI interrupt request is generated.
Figure 42.41 to Figure 42.43 show examples of the operation for serial transmission in Manchester mode.





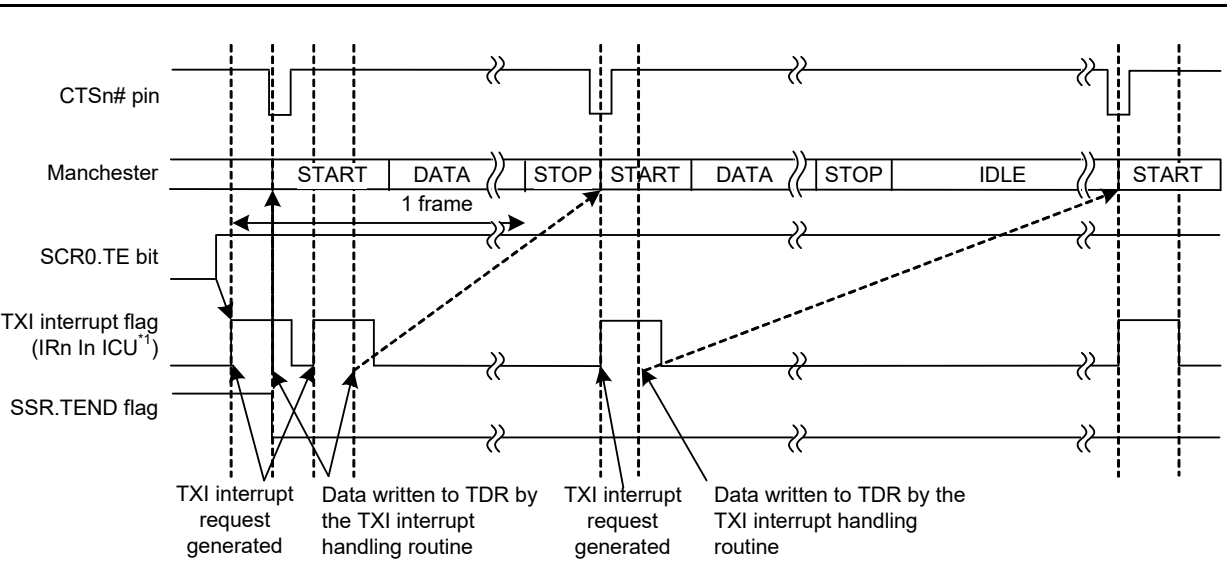


Figure 42.40 Serial Transmission Flowchart in Manchester Mode

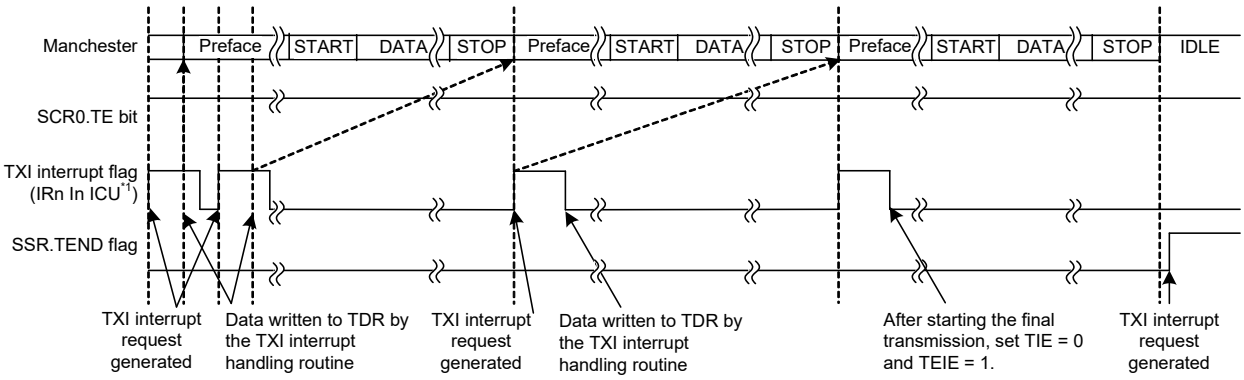

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.42 Example of Start-of-Transmission Operation for Serial Transmission in Manchester Mode (without Preface but with the CTS Function)

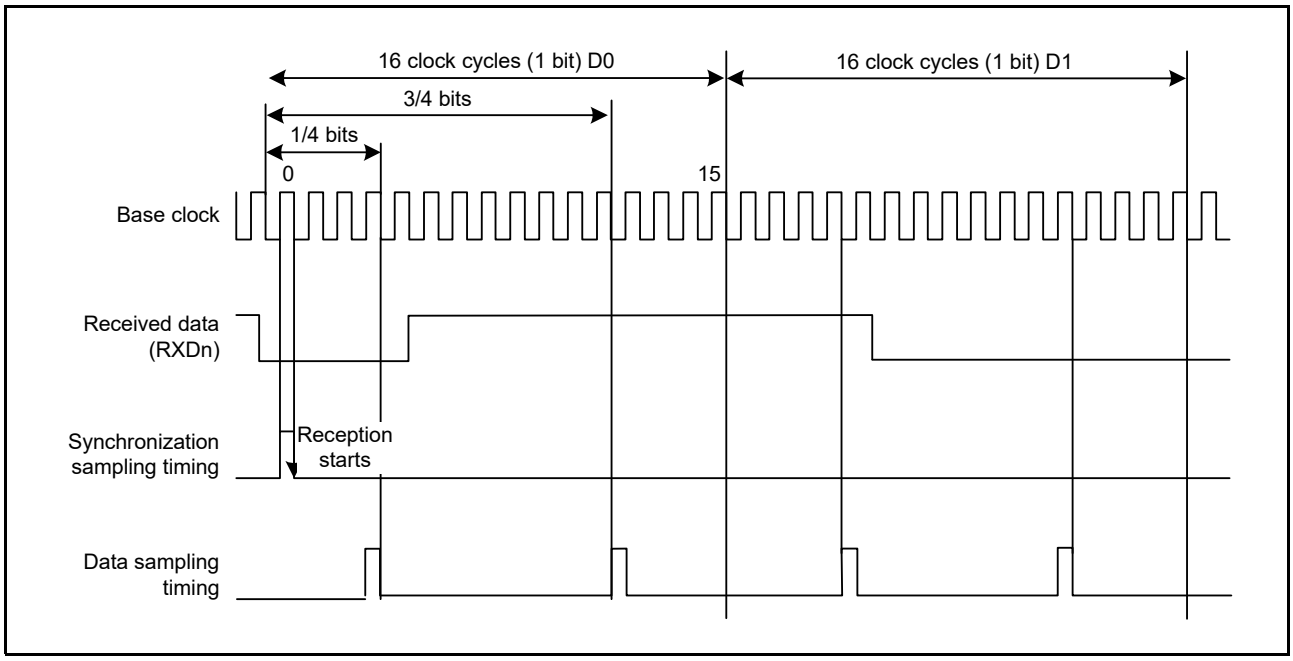
Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.43 Example of End-of-Transmission Operation for Serial Transmission in Manchester Mode (with Preface but without the CTS Function)

42.5.7 Serial Data Reception in Manchester Mode

In Manchester mode, the RSCI operates on a base clock with a frequency of 16 times*1 the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in Figure 42.44, reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the RSCI judges it as an error and waits for a falling edge again.
If a high level is expected in the first half of a bit in the received data, the RSCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when SCR2.ABCS bit = 0. When SCR2.ABCS bit = 1, the RSCI operates on a base clock with a frequency of 8 times the bit rate.



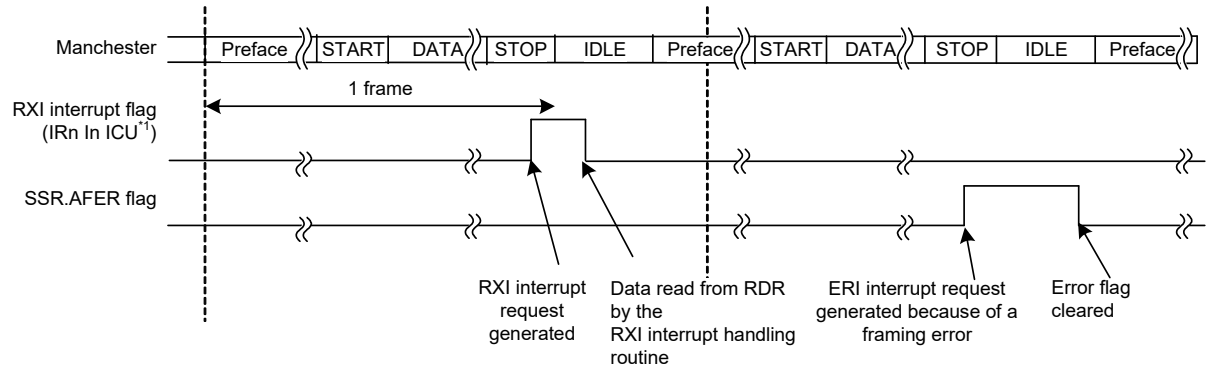


Figure 42.44 Data Reception Sampling Timing in Manchester Mode

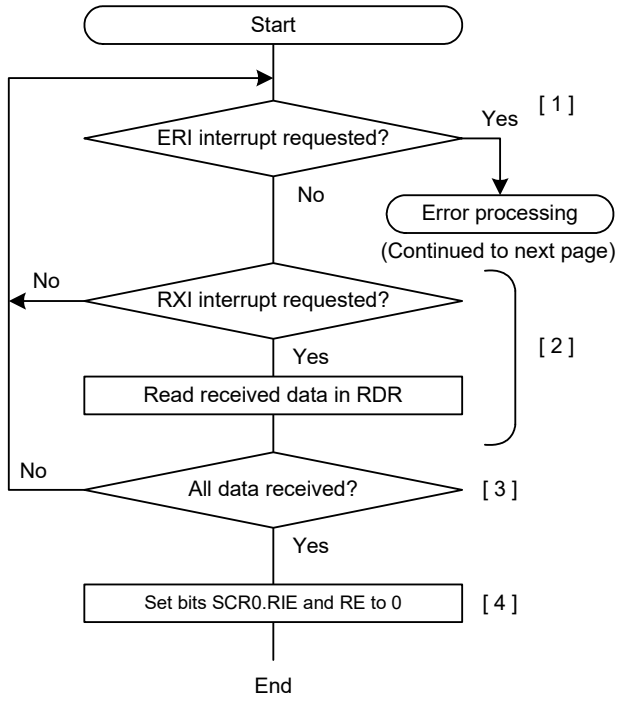
In Manchester mode, data reception starts with detection of a preface and start bit area.
The RSCI checks the input from the RXDn pin to see whether a preface is added based on the value of MMCR.RPLEN[3:0] bits.
If the preface is disabled (MMCR.RPLEN[3:0] bits = 0), it moves on to the detection of a start bit area without detecting a preface.
When a preface is enabled, it identifies a preface pattern setting according to the set value in MMCR.RPPAT[1:0] bits, and compares it with the RXD input for a pattern match to detect a preface pattern.
Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.
If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).
For start bit detection, the RSCI selects an expected value based on the register settings (MMCR.SBLEN and SBPTN bits), compares it with the RXD input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.
Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.
Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).
In data processing, the RSCI shifts the data by the expected received data length based on the register settings (SCR3.CHR[1:0] bits) through the RSR register. If two sampling points in a bit of the received data are identical, the RSCI judges this as a Manchester code error. For details, see section 42.5.11, Errors in Manchester Mode (4).

When the parity function is disabled (SCR1.PE bit = 0), the RSCI moves on to the next phase of stop bit detection. When the parity function is enabled (SCR1.PE bit = 1), the RSCI performs parity checking. If detecting a parity error, it asserts a parity error flag (APER), and then moves on to stop-bit detection.
In stop bit detection, the RSCI checks the following in the stop bit area of the received frame:
It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (AFER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.
Figure 42.45 shows an example of the operation for serial data reception in Manchester mode.



Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.45 Example of Operation for Serial Data Reception in Manchester Mode (with a Preface)

For the state of each status flag in the SSR and MMSR registers and RXD input processing when a receive error is detected, see section 42.5.11, Errors in Manchester Mode.
If a receive error is detected, an ERI interrupt request is generated but an RXI interrupt request is not generated.
Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, AFER, APER, MCER, SYER*2, PFER*2, SBER*2 flags to 0 before resuming reception. Also, be sure to read the RDR register during overrun error processing. When a reception is forcibly terminated by setting the SCR0.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in the RDR register.
Figure 42.46 and Figure 42.47 show examples of serial data reception flowchart in Manchester mode.

Note 2. Effective when the corresponding bit is enabled.

[1] Receive error processing:
When a receive error occurs, RSCI generates an ERI interrupt. An error is identified by reading the ORER, APER, AFER in SSR register and MCER, SBER, SYER, PFER in MMSR register. After performing the appropriate error processing, always set the ORER, APER, AFER, MCER, SBER, SYER, PFER flags to 0. Reception cannot be resumed if any of these flags is set to 1.

Note: Each of the PFER, SYER, SBER bits in MMSR register has an enable bit (PFERIE, SYERIE, and SBERIE bits in MMCR). If the corresponding enable bit is set to 0 (disable), the flag value does not affect the communication. Perform error processing as required.

[2] Read the received data in RDR register once in the RXI interrupt handling routine.

[3] Serial reception continuation procedure:
To continue serial reception, before the stop bit of a frame is received, read data from RDR register in the RXI interrupt handling routine. The RDR data can also be read by activating the DMAC or DTC.

[4] Write 0 to SCR0.RIE and RE bits.

Figure 42.46 Example of Serial Data Reception in Manchester Mode (Normal)

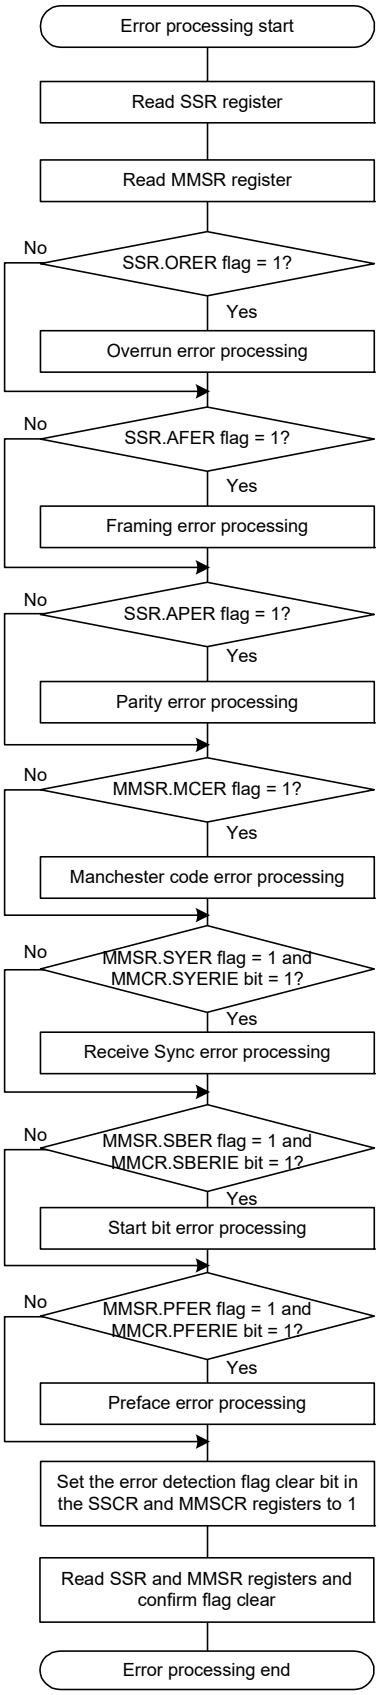


Figure 42.47 Example of Serial Reception Flowchart in Manchester Mode (Error Processing)

42.5.8 Operation When Multi-Processor Bit is Used

See section 42.4, Multi-Processor Communication Function (1) for the operation in Manchester mode when using multi-processor mode because the operation is the same.
A preface and a start bit area are added to the frame format in Manchester mode.
See Figure 42.47 for error processing in Manchester mode for the reception flowchart (Figure 42.30). Refer to Table 42.37 for the operation status when detecting various errors.

42.5.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.
The receive retiming function can be turned on or off by setting the SADJE bit in the MMCR register.
When the receive retiming function is turned off (MMCR.SADJE bit = 0), retiming is not performed, causing misalignment between the internal clock and the RXD input to be accumulated and the receive margin to be reduced.
When the receive retiming function is turned on (MMCR.SADJE bit = 1), retiming is performed for the preface area, the start bit area*1, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling ×16 is selected is shown below.
When detecting an RXD input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.
When detecting a RXD input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.
(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)
Figure 42.48 shows the conceptual image of receive retiming range.
When detecting an edge in the tolerance area in the figure, data is received as is without making correction.
When detecting an edge in the SyncJump area in the figure, data is corrected for reception.
When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.
For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the RSCI reports a code error.

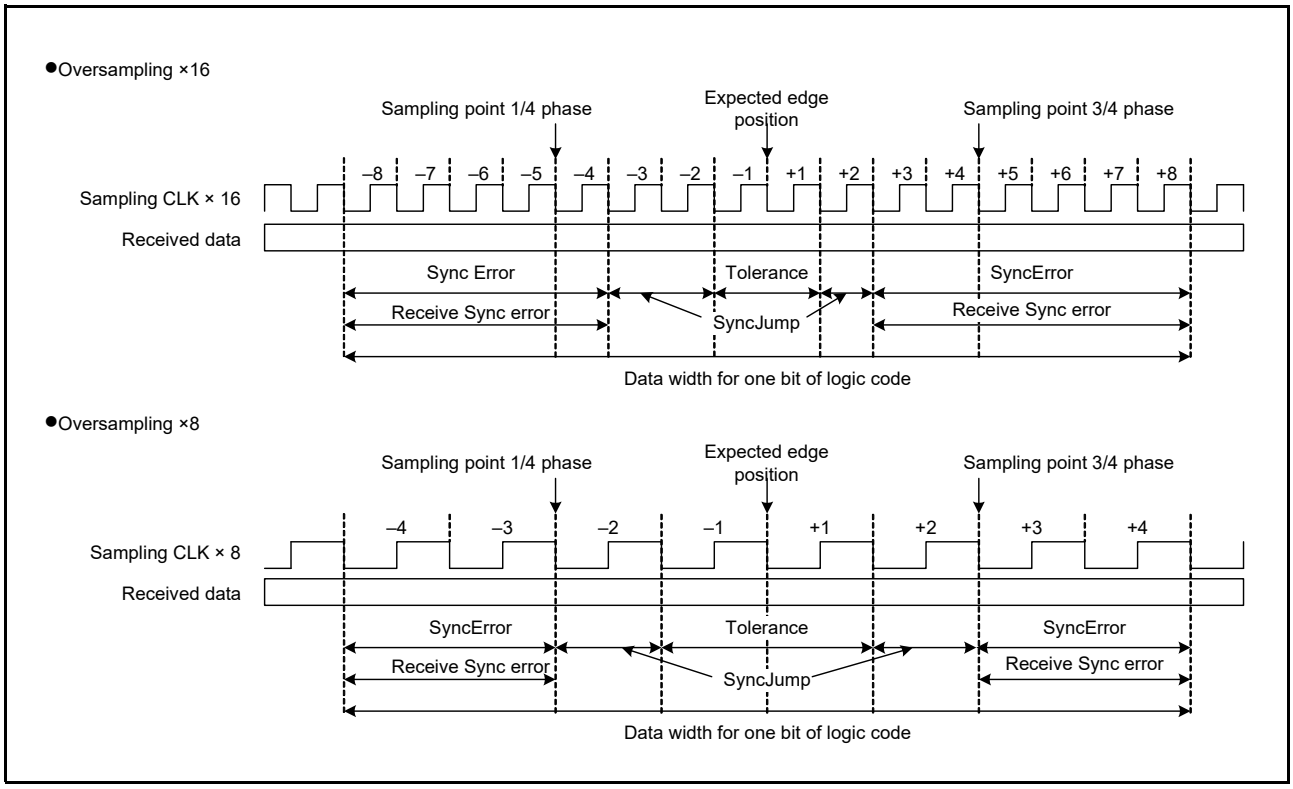

Figure 42.48 Conceptual Image of Reception Retiming Range

42.5.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Control Register (MMCR).
It can be set separately for transmission and reception. Use the MMCR.ENCS bit to set the polarity for transmission and the MMCR.DECS bit to set the polarity for reception.
The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.
When the initial settings (ENCS/DECS bit = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code.
If the settings are changed to ENCS/DECS bit = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 42.49 shows the conceptual image of the settings and operation.
Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (SCR3.DINV bit). Since the polarity of Manchester code (MMCR.ENCS/DECS bit) can be set separately from the transmitted/received data invert function (SCR3.DINV bit), if both are set to inversion (MMCR.ENCS/DECS bit = 1 and SCR3.DINV bit = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).
The polarity of the start bit area can be set by a register different from the ones mentioned above.
Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.
For details on the setting for the start bit area, see section 42.5.1, Frame Format (2).

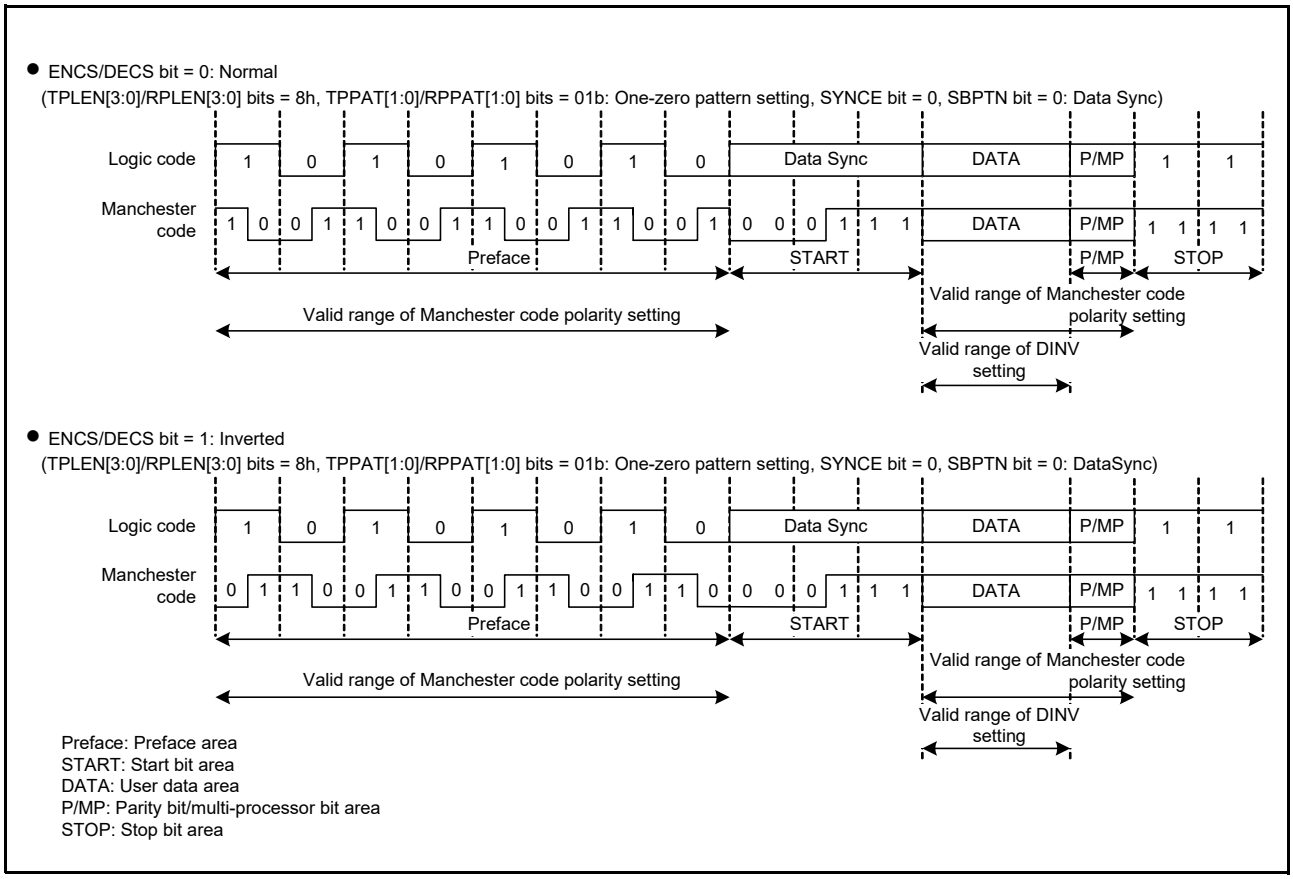

Figure 42.49 Valid Range of the Manchester Code Polarity Setting

42.5.11 Errors in Manchester Mode

There are the following errors in Manchester mode:

(1) Parity error
(2) Over run error
(3) Framing error
(4) Manchester code error
(5) Preface error
(6) Start bit error
(7) Receive Sync error

For errors (1) to (3), see section 42.3.9, Serial Data Reception (Asynchronous Mode) (1) because they are the same as in asynchronous mode.
Each error is judged in each area, but they are reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.
Table 42.35 lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR register.
Table 42.36 lists the errors that can be detected in each area of a Manchester frame. If a Preface error or Start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous frame, data will not be received, but errors in the preface area and start bit area will update that flag. Table 42.37 shows the flags and actions in this case.

(4) Manchester Code Error

A Manchester code error is generated when a Manchester code error is detected.
In Manchester code, there must be an edge (transition) in the center of the bit.
In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values matches.
If a Manchester code error is detected, the Manchester code error flag (MMSR.MCER flag) is asserted.
If a Manchester code error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

(5) Preface Error

A preface error is generated when the preface pattern does not match or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (MMSR.PFER flag) is asserted.
It is possible to set whether to use this error flag as an interrupt source with the setting of the MMCR register.
When MMCR.PFERIE bit = 1, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.
When MMCR.PFERIE bit = 0, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MMSR.PFER flag.

(6) Star Bit Error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MMSR.SBER) is asserted.
It is possible to set whether to use the start bit error as an interrupt source with the setting of the MMCR register.
When MMCR.SBERIE bit = 1, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MMCR.SBERIE bit = 0, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MMSR.SBER flag.

(7) Receive Sync Error (SyncError)

When the receive retiming function described in section 42.5.9, Receive Retiming is enabled, the receive retiming operation is performed.
If no edges are detected within the receive retiming range (SyncError area in Figure 42.48) when receive timing operation is being performed, a receive Sync error is generated. Upon detection of a receive Sync error, a receive Sync error flag (MMSR.SYER) is asserted. In areas not subject to receive retiming, receive Sync errors are not detected.
The preface area *1, the start bit area*1, *2, and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.
It is possible to set whether to use the receive Sync error as an interrupt source with the setting of the MMCR register.
When MMCR.SYERIE bit = 1, a receive Sync error is handled as an interrupt source or event source. If a receive Sync error is detected, the next reception is not performed until the corresponding error flag is cleared.
When MMCR.SYERIE bit = 0, a receive Sync error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive Sync error is notified to MMSR.SYER flag.

Note 1. In the case of a frame that starts with a pattern that expects the first half of the bit to be High, it is excluded from retiming.

Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming. Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

Table 42.35 Flags in the Status Register and Receive Data Handling in Manchester

Flags in the SSR Register			Flags in the MMSR Register					
ORER	AFER	APER	MCER	SBER *1	PFER *1	SYER	Received Data	Received Error Status (ERI Interrupt/Event Generation)
0	0	0	0	0	0	0	Transfer to RDR	No error
0	1	0	0	0	0	0	Transfer to RDR	Framing error
0	0	1	0	0	0	0	Transfer to RDR	Parity error
0	1	1	0	0	0	0	Transfer to RDR	Framing error + Parity error
0	0	0	1	0	0	0	Transfer to RDR	Manchester code error
0	1	0	1	0	0	0	Transfer to RDR	Framing error + Manchester code error
0	0	1	1	0	0	0	Transfer to RDR	Parity error + Manchester code error
0	1	1	1	0	0	0	Transfer to RDR	Framing error + Parity error + Manchester code error
1	0	0	0	0	0	0	Lost	Overrun error
1	1	0	0	0	0	0	Lost	Overrun + Framing error
1	0	1	0	0	0	0	Lost	Overrun + Parity error
1	1	1	0	0	0	0	Lost	Overrun + Framing error + Parity error
1	0	0	1	0	0	0	Lost	Overrun + Manchester code error
1	1	0	1	0	0	0	Lost	Overrun + Framing error + Manchester code error
1	0	1	1	0	0	0	Lost	Overrun + Parity error + Manchester code error
1	1	1	1	0	0	0	Lost	Overrun + Framing error + Parity error + Manchester code error
0	Combination of the above errors			0	0	1	Transfer to RDR	Error above + Receive Sync error*2
1				0	0	1	Lost	Error above + Receive Sync error*2
hold	hold	hold	hold	0	1	0	Lost	Preface error*3
hold	hold	hold	hold	1	0	0	Lost	Start bit error*3
hold	hold	hold	hold	0	1	1	Lost	Preface error*3 + Receive Sync error*2
hold	hold	hold	hold	1	0	1	Lost	Start bit error*3 + Receive Sync error*2

Note 1. Start bit error and preface error never become 1 at the same time.
Note 2. When MMCR.SYERIE bit = 1, ERI interrupt/event is generated by SYER factor.
Note 3. If MMCR.PFERIE bit = 1 or MMCR.SBERIE bit = 1, an ERI interrupt/event is generated when the corresponding flag is set.

Table 42.36 Errors Detectable in Each Area

	Preface Error (PFER)	Start Bit Error (SBER)	Manchester Code Error (MCER)	Receive Sync Error (SYER)	Parity Error (APER)	Framing Error (AFER)
Preface area	✓	—	—*1	✓*2	—	—
Start bit area	—	✓	—	✓*2	—	—
Data area	—	—	✓	✓	—	—
Parity area	—	—	✓	✓	✓	—
Multi-processor area	—	—	✓	✓	—	—
Stop bit area	—	—	—	—	—	✓

✓: Detected, —: Not detected
Note 1. When an Manchester code error occurs in the preface area, it is defined as a preface error.
Note 2. It may not be subject to receive Sync error detection. For details see section 42.5.11, Errors in Manchester Mode (7)

Table 42.37 Operation Status due to Presence/Absence of Error in Previous Frame and Operation Status List in Multiprocessor Mode (SCR0.MPIE Bit = 0)

Previous Frame	Each Area of the Frame					PFE RIE	SBE RIE	SYE RIE	Received Data	Error Flag	Interrupt Request	Event Signal
	Preface	Start Bit	Data	Parity Bit	Stop Bit							
No error	PFER, No SYER*1	No error	—	—	—	0	—	—	Lost	Set PFER*1	Not output	Not output
						1					Output	Output
	No error	SBER, No SYER*1	—	—	—	—	0	—	Lost	Set SBER*1	Not output	Not output
							1				Output	Output
	SYER, No PFER	No error	—	—	—	—	—	0	Transfer to RDR	Set SYER	Not output	Not output
								1	Lost		Output	Output
	No error	SYER, No SBER	—	—	—	—	—	0	Transfer to RDR	Set SYER	Not output	Not output
								1	Lost		Output	Output
	No error	No error	SYER		No error	—	—	0	Transfer to RDR	Set SYER	Not output	Not output
								1			Output	Output
	No error	No error	MCER		No error	—	—	—	Transfer to RDR	Set MCER	Output	Output
	No error	No error	—	APER	No error	—	—	—	Transfer to RDR	Set APER	Output	Output
	No error	No error	—	—	AFER	—	—	—	Transfer to RDR	Set AFER	Output	Output
	There is some error ORER					—	—	—	Lost	Set some flags*2	Output	Output
	No error	No error	No error	No error	No error, ORER	—	—	—	Lost	Set ORER	Output	Output
Some error*3, *6	PFER, No SYER*1	No error	—	—	—	0	—	—	Lost	Set PFER*1	Output*4	Not output*5
						1						
	No error	SBER, No SYER*1	—	—	—	—	0	—		Set SBER*1		
							1					
	SYER, No PFER	No error	—	—	—	—	—	0		Set SYER		
								1				
	No error	SYER, No SBER	—	—	—	—	—	0		Set SYER		
								1				
	No error	No error	SYER		No error	—	—	0		don't set any flags		
								1				
	No error	No error	MCER		No error	—	—	—				
	No error	No error	—	APER	No error	—	—	—				
	No error	No error	—	—	AFER	—	—	—				
	There is some error ORER					—	—	—				
	No error	No error	No error	No error	No error, ORER	—	—	—				

Note 1. If SYER is detected, the SYER flag is also set. Other operations are as shown in this table.
Note 2. Other detected error flags including ORER are also set.

Note 3. If all the error flags are cleared before the STOP bit is judged, the operation will be the same as the case where there is no error in the previous frame of this table.
Note 4. Since the ERI interrupt request is level output, it remains active due to errors in the previous frame regardless of the presence or absence of errors in the relevant frame.
Note 5. Since the error cause is continuously detected, the ERI event is not newly output regardless of the presence of errors in the relevant frame.
Note 6. For MMSR.PFER, SBER, and SYER, when each enable bit is set to disable, it is treated as no error.

Table 42.38 Operation Status List in Multiprocessor Mode (SCR0.MPIE Bit = 1)

MPB*1	Each Area of the Frame					PFERIE	SBERIE	SYERIE	Received Data	Error Flag	Interrupt Request	Event Signal
	Preface	Start Bit	Data	Parity Bit	Stop Bit							
1	No error	No error	—	—	—	—	—	—	Transfer to RDR	Set some flags	Output	Output
	No PFER, SYER	No SBER, SYER	—	—	—	—	—	0				
								1	Lost	don't set any flags	Not output	Not output
	PFER	No error	—	—	—	—	—	—				
	No error	SBER	—	—	—	—	—					

Note 1. If the received MPB flag is 0, it is not received the frame, and the operation is the same as lost of the reception data of this table.
Note 2. If no error is detected, RXI interrupt request or event is output, and if it is detected, ERI interrupt request or event is output.
Note 3. When SYER is detected in the preface area or the start bit area, the behavior of handling as an error depending on the MMCR.SYERIE bit changes.

42.6 HBS Support Mode

Setting the HBSCR.HBSE bit to 1 supports the negative logic RZI coding to generate waveforms (AMI, 50% duty cycle, negative logic) required by the home bus system. Since this function operates only in the asynchronous mode, refer to the asynchronous mode for the setting, transmission flow, and reception flow.

42.6.1 Reception in HBS Support Mode

When receiving in HBS support mode, the falling edge of the input from the RXDn pin is detected and the signal after the start bit is recognized is received. One frame is sampled according to the set bit rate, and if the stop bit is correctly received without error, the data value is stored in the receive data register RDR.

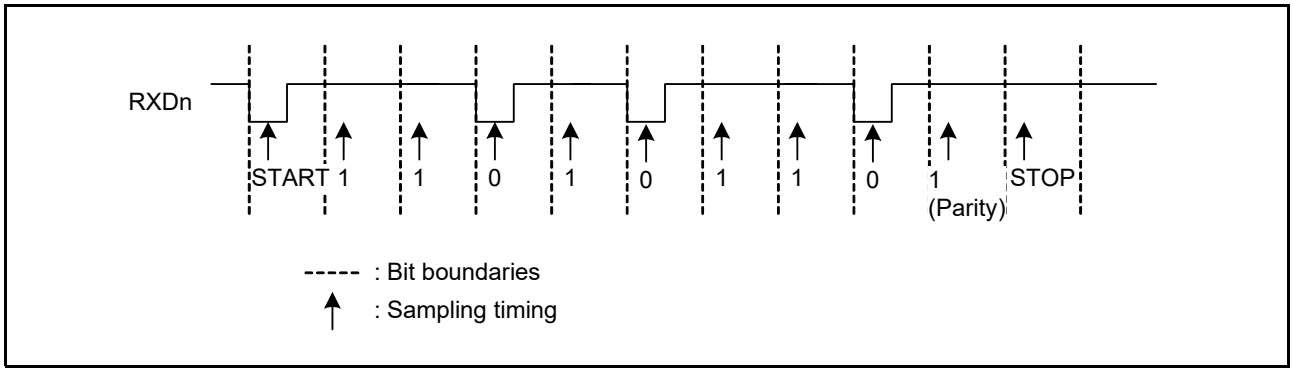

Figure 42.50 HBS Support Mode Reception Timing Chart

To receive in the HBS support mode, it is necessary to sample at the timing of 1/4 of 1 bit in order to capture the pulse in the first half of the 1 bit period. Sampling operates with a frequency 16 times the bit rate*1 as the base clock, similar to the asynchronous mode. The start bit is detected by detecting the Low level from the falling edge of RXD four times continuously with the base clock. When High is detected on the way, it is regarded as noise and waits for the next fall edge.

To set the sampling timing to 1/4 of the 1-bit period, enable the reception sampling timing adjustment function with the SCR4.RTADJ bit, set the SCR4.RTMG[3:0] bits to 1100b, and adjust Adjust from the center of the bit, which is the previous sampling timing, four clocks ahead of the base clock.

Since the sampling timing can be adjusted backward and forward using the reception sampling timing adjustment function, this timing can be adjusted according to the reception status. Increasing the SCR4.RTMG[3:0] bits value from 1100b will move the sampling timing forward, and decreasing it will move it backward. Refer to section 42.3.2, Receive Data Sampling Timing and Reception Margin in Asynchronous Mode for the details of adjustment.

After recognizing the start bit, sampling is performed at the timing according to the set bit rate, but the low width and high width of the waveform are not checked. Therefore, it is possible to receive even a normal asynchronous waveform.

Note 1. HBS support mode supports only following setting: SCR2.ABCS bit = 0, SCR2.ABCSE bit = 0, and SCR2.ABCSE2 bit = 0.

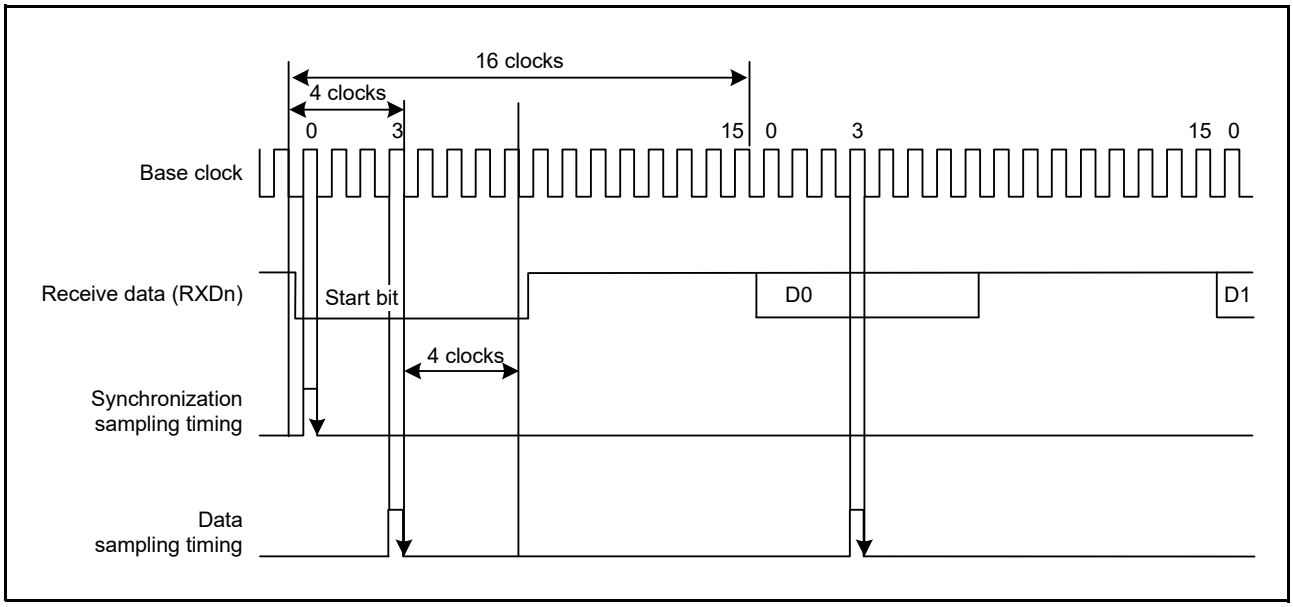

Figure 42.51 Details of Reception Sampling Timing in HBS Support Mode

42.6.2 Transmission in HBS Support Mode

Transmission in HBS support mode, data 0 is output as a low pulse for the first half of the 1-bit period.

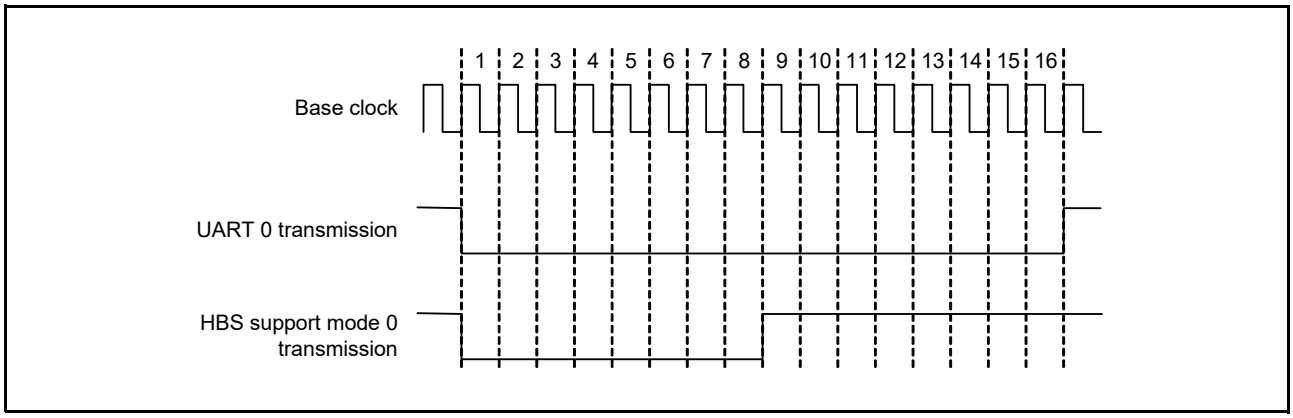

Figure 42.52 Transmission Waveform of HBS Support Mode

When HBSCR.AOE bit = 0, the all bits are output from TXDn pins, and when HBSCR.AOE bit = 1, data 0 is output alternately from TXDAn and TXDBn pins. Use the HBSCR.LPS bit to select which transmission pin starts output of the start bit.

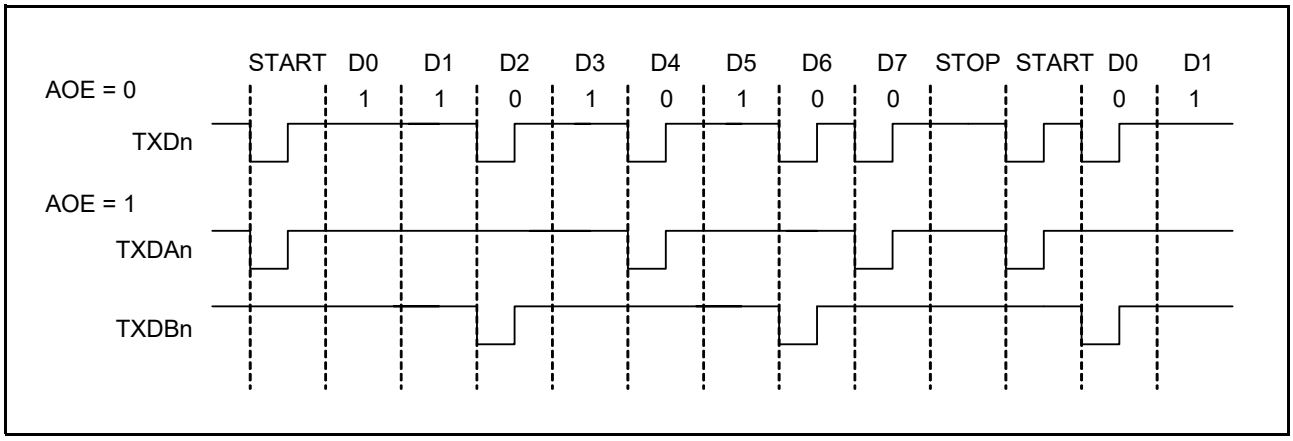

Figure 42.53 Difference in Transmission Waveform Depending on AOE Bit (When LPS Bit = 0)

Figure 42.53 shows an example of the transmission waveform for each HBSCR.AOE bit value. When the AOE bit is set to 0, the waveform is output from the TXDn pin, but when the AOE bit is set to 1, data 0 including start bit is output alternately from the TXDAn pin and the TXDBn pin.

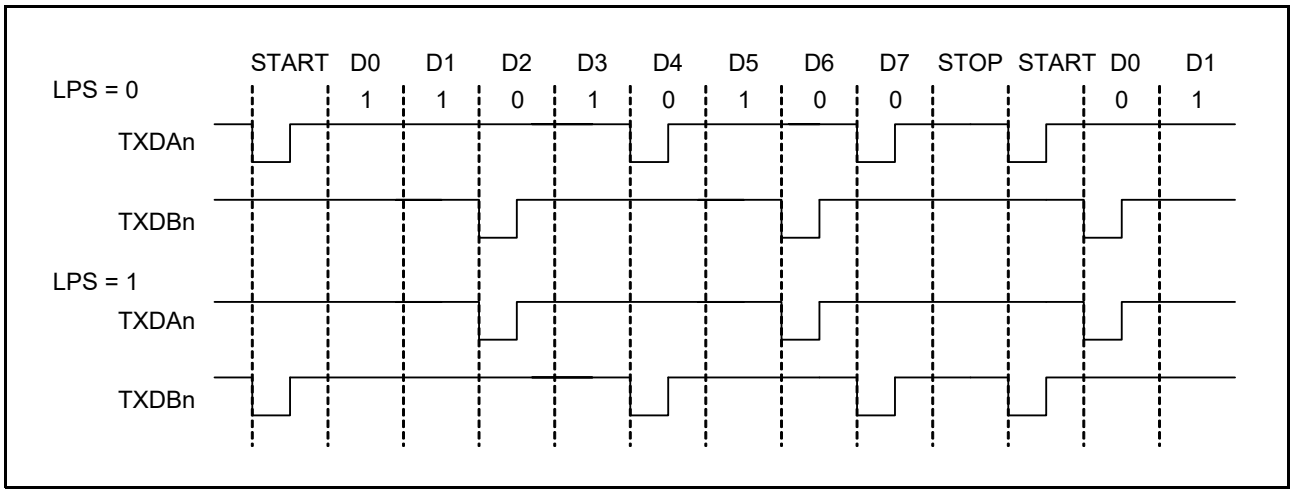

Figure 42.54 Difference in Transmission Waveform Depending on LPS Bit (When AOE Bit = 1)

Figure 42.54 shows an example of the transmission waveform for each HBSCR.LPS bit.
When the HBSCR.LPS bit = 0, the start bit is output from the TXDAn pin, and when the HBSCR.LPS bit is 1, the start bit is output from the TXDBn pin, and data 0 is output to each pin alternately. The start bit of the next frame starts output again from the pin specified by the HBSCR.LPS bit.
If the HBSCR.HBSE bit = 0, the TXDBn pin becomes High regardless of the settings of other bits.
When SCR0.TE bit = 0, both TXDn/TXDAn/TXDBn pins become high impedance, but can be controlled by SCR1.SPB2IO bit and SCR1.SPB2DT bit. At this time, the same output is applied to the TXDn/TXDAn/TXDBn pins.

42.6.3 Register Setting for HBS Support Mode

The HBS support mode is a part of asynchronous mode function, but there are some settings that are not supported when using this function. Set each bit of the control register as shown in Table 42.39 before use. Register bits not described can be set in the same way as the asynchronous mode.

Table 42.39 Control Register Setting Value for HBS Support Mode

Register Bit Name	Value	Remarks
SCR0.DCME	0	Use it when the data match detection function is disabled.
SCR1.NFCS[2:0]	000b	Use this setting when using the noise filter.
SCR1.HDSEL	0	Half-duplex communication with the TXDn pin cannot be used.
SCR1.CTSE	0	Please use it without the CTS function.
SCR2.BRME	0	Bit rate modulation function cannot be used.
SCR2.ABCSE2	0	The setting that 4 cycles of the base clock becomes 1 bit cannot be used.
SCR2.ABCSE	0	The setting that 6 cycles of the base clock becomes 1 bit cannot be used.
SCR2.ABCS	0	Only the setting that 16 cycles of the base clock becomes 1 bit can be used.
SCR3.CKE[1:0]	00b	Use with internal clock and without clock output.
SCR3.DEEN	0	Use without the RS-485 driver function.
SCR3.FM	0	Use without FIFO function.
SCR3.MOD[2:0]	000b	Set to asynchronous mode.
SCR3.RXDESEL	1	Detect the start bit at the falling edge of the RXDn pin input.
SCR3.STOP	0	Use with stop bit 1.
SCR3.DINV	0	Use without data inversion.
SCR3.DDIR	1	Use with LSB first.
SCR3.CHR[1:0]	10b	Use with 8 bit length.
SCR4.RTMG[3:0]	1100b	Use this setting when receiving in HBS support mode.*1
SCR4.TTADJ	0	Use without adjust transmit timing function.
SCR4.RTADJ	1	Use this setting when receiving in HBS support mode.

Note 1. This is the timing to sample at the center of the effective pulse. It can be adjusted if needed.

42.7 Smart Card Interface Mode

The RSCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function.
Smart card interface mode can be selected using the appropriate register.

42.7.1 Sample Connection

Figure 42.55 shows a sample connection between a smart card (IC card) and this MCU.
As in the figure, since this MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.
Setting the TE and RE bits in the SCR0 register to 1 with an IC card disconnected enables closed transmission/reception allowing self-diagnosis.
To supply an IC card with the clock pulses generated by the RSCI, input the SCKn pin output to the CLK pin of an IC card.
The output port can be used to output the reset signal.

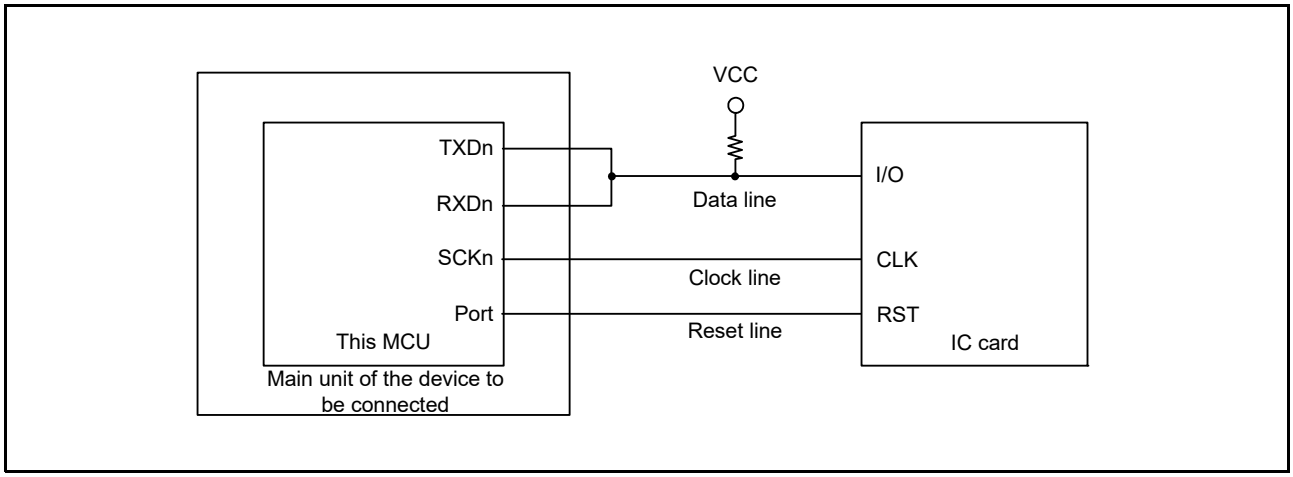

Figure 42.55 Sample Connection with a Smart Card (IC Card)

42.7.2 Data Format (Except in Block Transfer Mode)

Figure 42.56 shows the data transfer formats in smart card interface mode.

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etu (elementary time unit: time required for transferring 1 bit) is secured as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low-level error signal is output for 1 etu after 10.5 etu has passed from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etu.

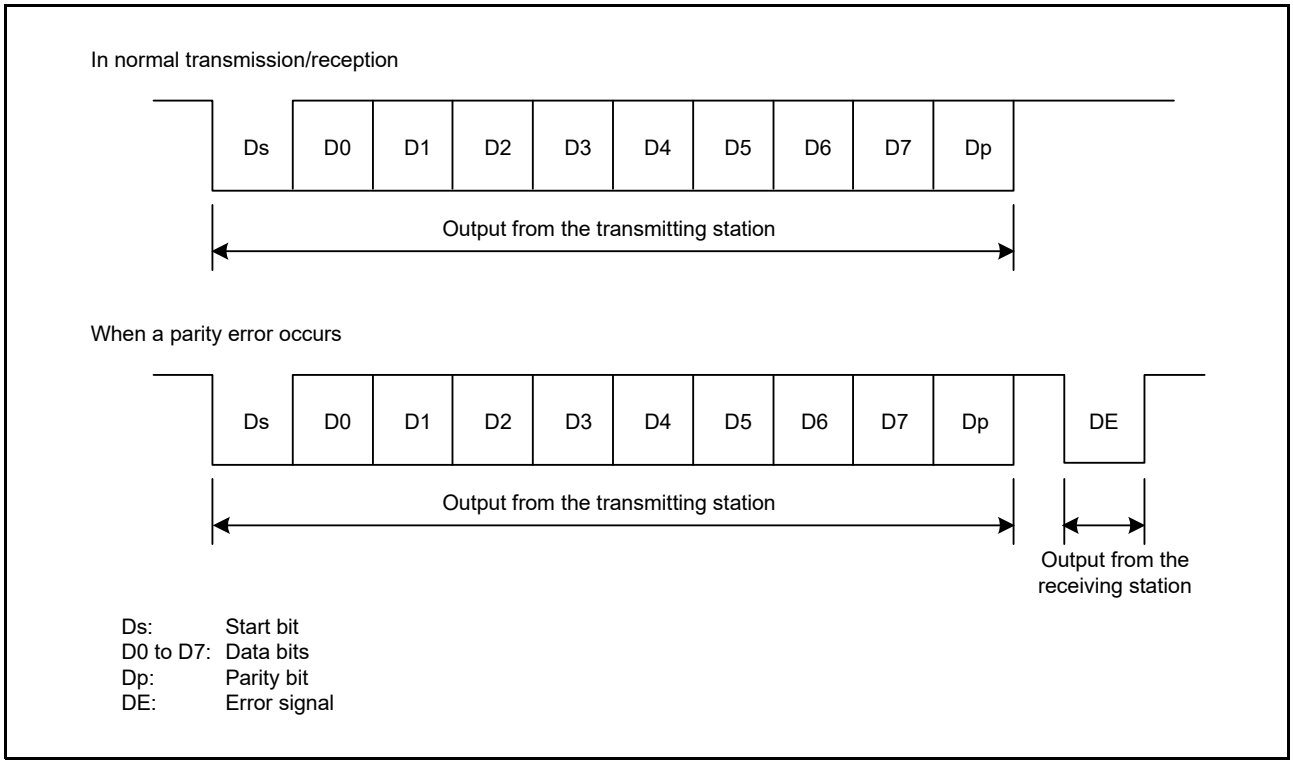

Figure 42.56 Data Formats in Smart Card Interface Mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedure below.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 correspond to states Z and A, respectively, and data is transferred with LSB first as the start character, as shown in Figure 42.57. Therefore, data in the start character in the figure is 3Bh. When using the direct convention type, write 1 to the SCR3.DDIR bit and 0 to the SCR3.DINV bit. Write 0 to the PM bit in the SCR1 register in order to use even parity, which is prescribed by the smart card standard.

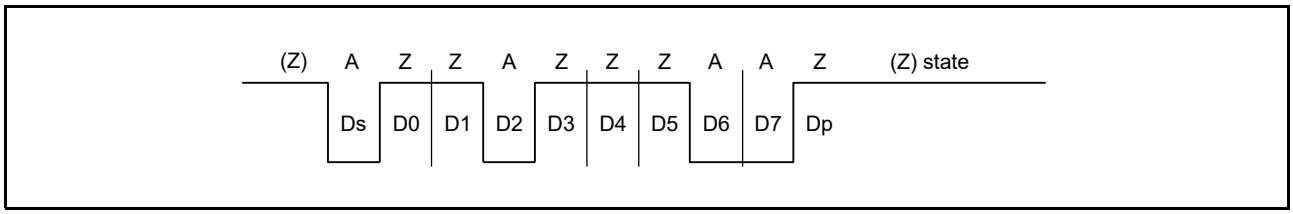

Figure 42.57 Direct Convention (SCR3.DDIR Bit = 1, SCR3.DINV Bit = 0, SCR1.PM Bit = 0)

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 correspond to states A and Z, respectively and data is transferred with MSB first as the start character, as shown in Figure 42.58. Therefore, data in the start character in the figure is 3Fh. When using the inverse convention type, write 0 to the SCR3.DDIR bit and 1 to the SCR3.DINV bit. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to state Z. Since the DINV bit of the this MCU only inverts data bits D7 to D0, write 1 to the PM bit in the SCR1 register to invert the parity bit for both transmission and reception.

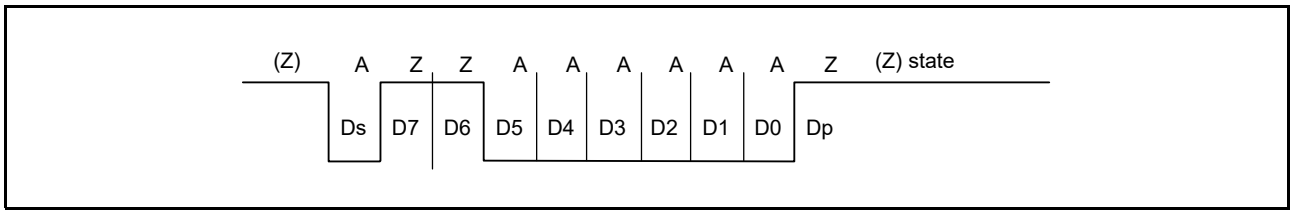

Figure 42.58 Inverse Convention (SCR3.DDIR Bit = 0, SCR3.DINV Bit = 1, SCR1.PM Bit = 1)

42.7.3 Block Transfer Mode

Block transfer mode is different from non-block transfer mode in the following respects.

- Even if a parity error is detected during reception, no error signal is output. Since the APER flag in the SSR register is set by error detection, clear the APER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is secured as a guard time from the end of the parity bit until the start of the next frame.
- Since the same data is not retransmitted during transmission, the TEND flag in the SSR register is set 11.5 etu after transmission start.
- In block transfer mode, the ERS flag in the SSR register indicates the error signal status as in non-block transfer mode, but the flag is read as 0 because no error signal is transferred.

42.7.4 Receive Data Sampling Timing and Reception Margin

Only the base clock generated by the on-chip baud rate generator can be used as a transmit/receive clock in smart card interface mode.

In this mode, the RSCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate according to the settings of the SCR2.BCP[2:0] bits.

For data reception, the falling edge of the start bit is sampled with the base clock to perform synchronization. Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 42.59. The reception margin here is determined by the following formula.

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\ (\%)$$

M: Reception margin (%)
N: Ratio of bit rate to clock (N = 32, 64, 372, 256)
D: Duty cycle of clock (D = 0 to 1.0)
L: Frame length (L = 10)
F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the above formula, the reception margin is determined by the formula below.

M = {0.5 – 1/(2 × 372)} × 100 (%) = 49.866 (%)

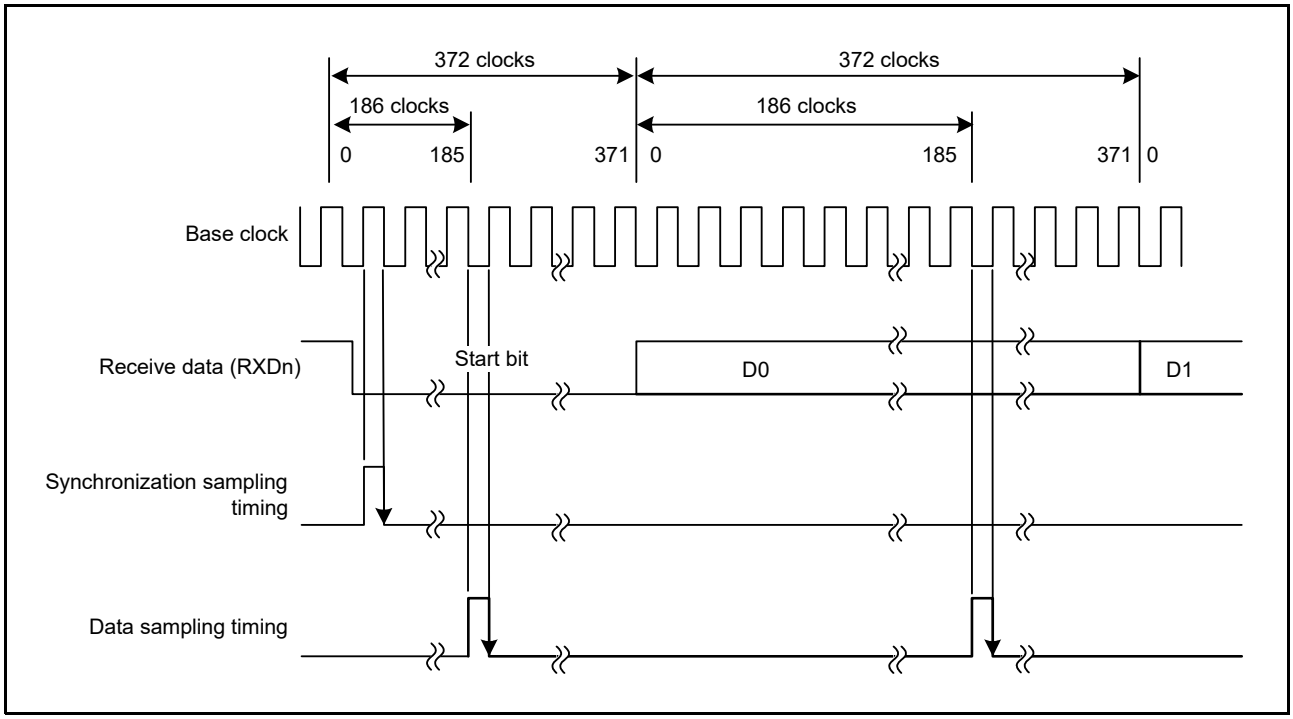

Figure 42.59 Receive Data Sampling Timing in Smart Card Interface Mode (When Clock Frequency is 372 Times the Bit Rate)

42.7.5 RSCI Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, write 0 to SCR0.TE bit and SCR0.RE bit (or write the initial value to SCR0 register). And initialize RSCI following example flowchart in Figure 42.60.
Be sure to set the initial value in the TIE, RIE, TE, RE, and TEIE bits in SCR0 register before switching from transmission mode to reception mode and vice versa. Even if the RE bit is set to 0, the RDR register is not initialized. In transmission mode, set 1 to the TE bit and TIE bit simultaneously, then the TXI interrupt request is generated. To change reception mode to transmission mode, first check that reception has completed, and then initialize RSCI. At the end of initialization, set TE bit = 1 and RE bit = 0. Reception completion can be verified by RXI interrupt request, SSR.ORER, or SSR.APER flag. To change transmission mode to reception mode, first check that transmission has completed, and then initialize RSCI. At the end of initialization, set TE bit = 0 and RE bit = 1. Transmission completion can be verified by reading SSR.TEND flag.

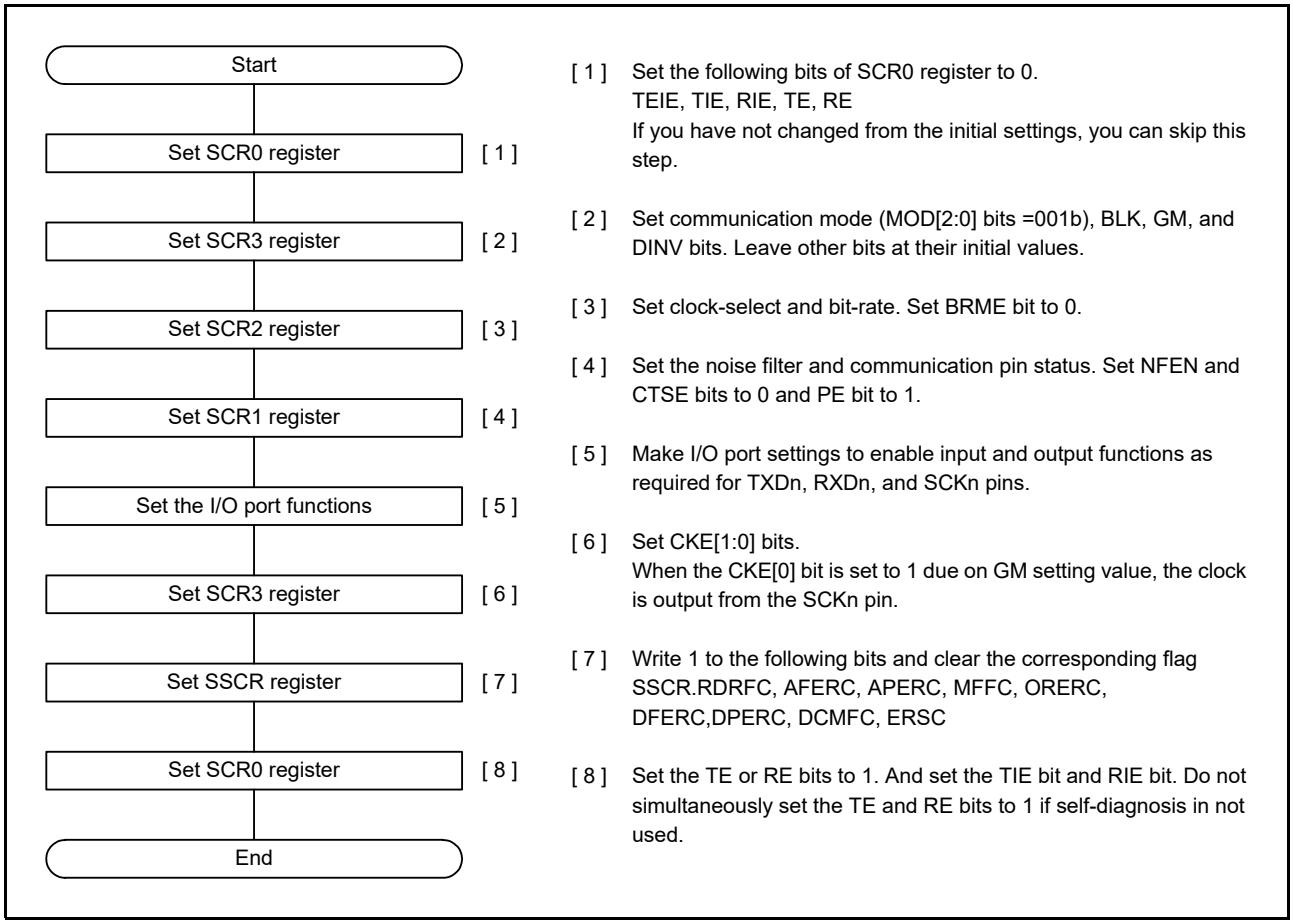

Figure 42.60 Example of RSCI Initialization Flowchart (Smart Card Interface Mode)

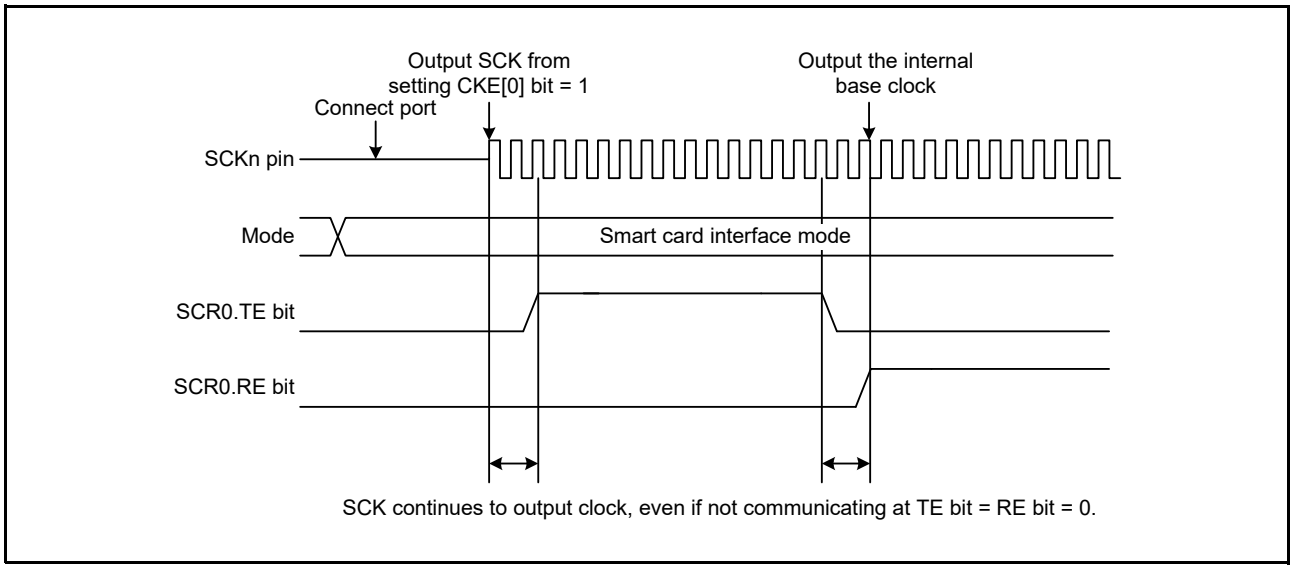
Figure 42.61 is a timing chart when data transmission is performed by making transition to the Smart Card Interface mode according to the above flow chart. The figure shows the case when SCR3.GM bit is 0. As shown in the figure, when the pin function is set to the SCKn pin, the SCKn pin is high impedance because the SCR3.CKE[0] bit is 0. When the TXDn pin is set, the TXDn pin is high impedance because the SCR0.TE bit is 0. Start clock output to the SCKn pin with the clock output setting SCR3.CKE[0] bit to 1, start data transmission by writing transmit data after setting SCR0.TE bit to 1.
In the smart card interface mode, even if not communicating at SCR0.TE bit = 0 and SCR0.RE bit = 0, the clock is continuously output if the clock output setting is used.



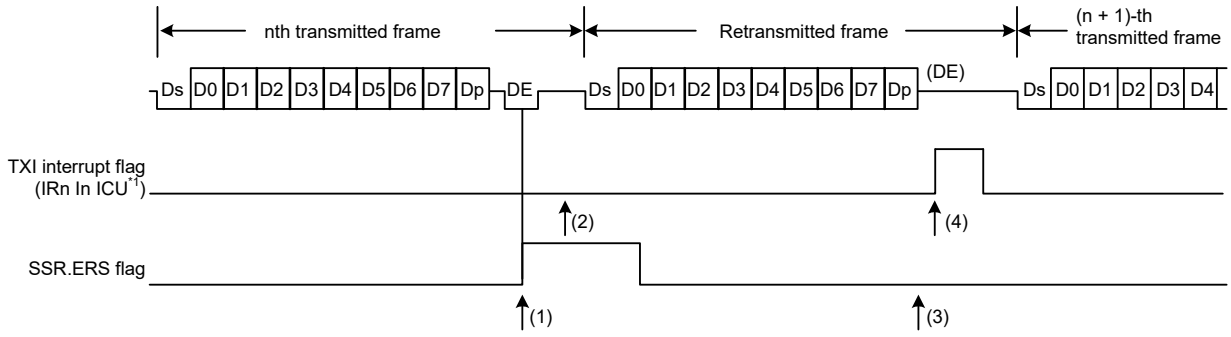


Figure 42.61 Example of Data Transmission Timing in Smart Card Interface Mode

42.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode), in that an error signal is sampled and data can be retransmitted, is different from that in non-smart card interface mode. Figure 42.62 shows the data retransmit operation during transmission.

(1) When an error signal from the receiver end is sampled after one-frame data has been transmitted, the ERS flag in the SSR register is set to 1. If the RIE bit in the SCR0 register is 1 at this time, an ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
(2) For a frame in which an error signal is received, the TEND flag in the SSR register is not set. Data is retransferred from the TDR register to the TSR register allowing automatic data retransmission.
(3) If no error signal is returned from the receiver, the ERS flag is not set to 1.
(4) In this case, the RSCI judges that transmission of one-frame data (including retransmission) has been completed, and the TEND flag is set. If the TIE bit in the SCR0 register is 1 at this time, a TXI interrupt request is generated. Writing transmit data to the TDR register starts transmission of the next data.

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.62 Data Retransmit Operation in RSCI Transmit Mode

Figure 42.64 shows a sample flowchart of serial transmission. All the processing steps are automatically performed by using a TXI interrupt request to activate the DTC or DMAC. When SSR.TEND flag is set to 1 in transmission, if the SCR0.TIE bit is 1, a TXI interrupt request is generated. The DTC or DMAC is activated by a TXI interrupt request if the TXI interrupt request is specified as a source of DTC or DMAC activation beforehand, allowing transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data. If an error occurs, the RSCI automatically retransmits the same data. During this retransmission, the TEND flag is kept to 0 and the DTC or DMAC is not activated. Therefore, the RSCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, since the ERS flag is not automatically cleared, set the RIE bit to 1 beforehand to enable an ERI interrupt request to be generated at error occurrence, and clear the ERS flag to 0.
When transmitting/receiving data using the DTC or DMAC, be sure to make settings to enable the DTC or DMAC before making RSCI settings. For DTC or DMAC settings, refer to section 18, DMA Controller (DMACAa) and section 20, Data Transfer Controller (DTCA).
Note that SSR.TEND flag is set in different timings depending on the SCR3.GM bit setting. Figure 42.63 shows the timing for setting the TEND flag.

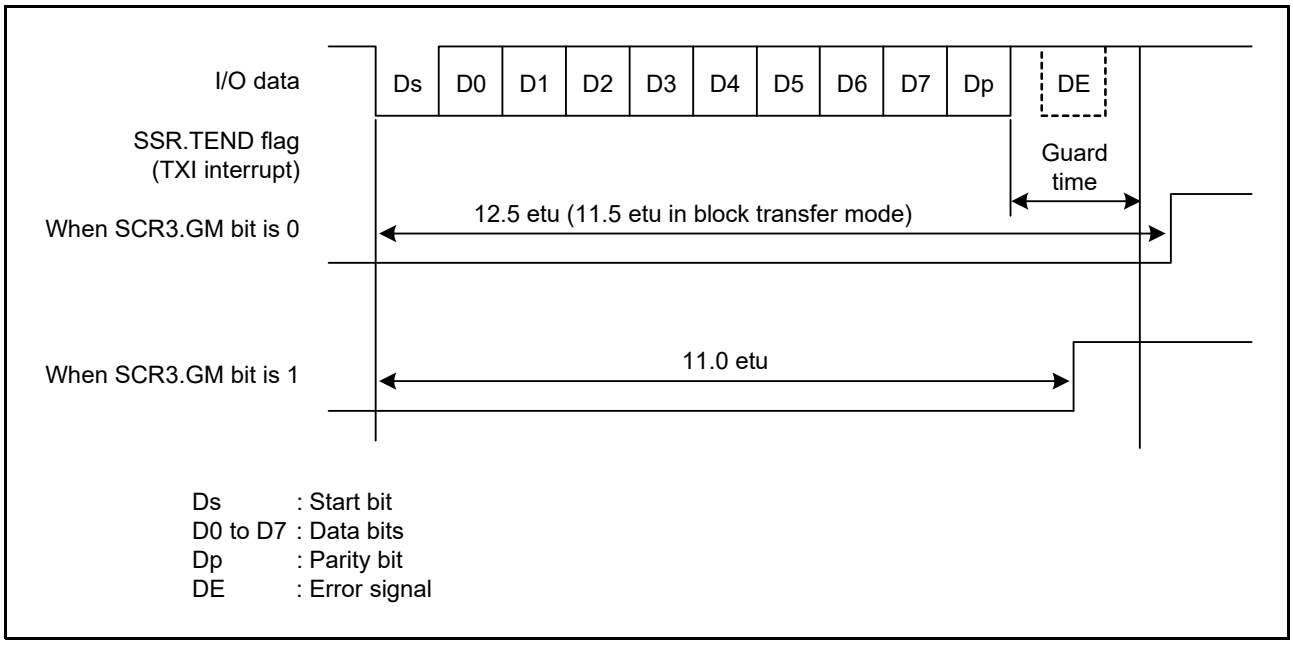

Figure 42.63 Timing for Setting the SSR.TEND Flag during Transmission

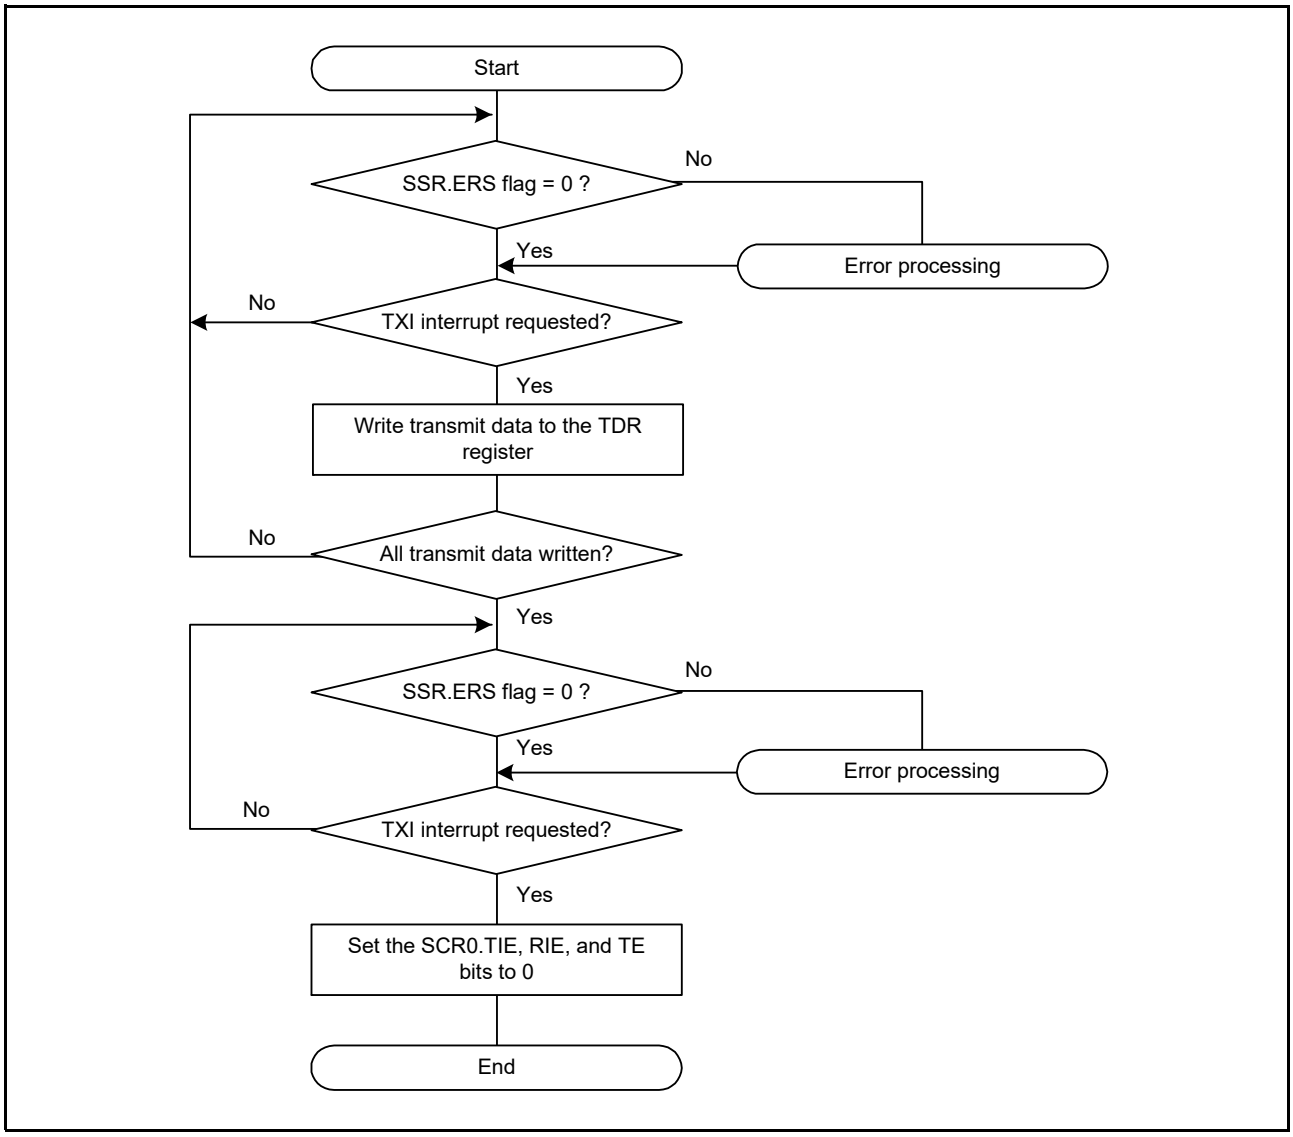

Figure 42.64 Sample Smart Card Interface Transmission Flowchart

42.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 42.65 shows the data retransmit operation in receive mode.

(1) If a parity error is detected in receive data, the APER flag in the SSR register is set to 1. When the RIE bit in the SCR0 register is 1 at this time, an ERI interrupt request is generated. Clear the APER flag to 0 before the next parity bit is sampled.
(2) For a frame in which a parity error is detected, no RXI interrupt is generated.
(3) When no parity error is detected, the APER flag in the SSR register is not set to 1.
(4) In this case, data is determined to have been received successfully. When the RIE bit in the SCR0 register is 1, an RXI interrupt request is generated.

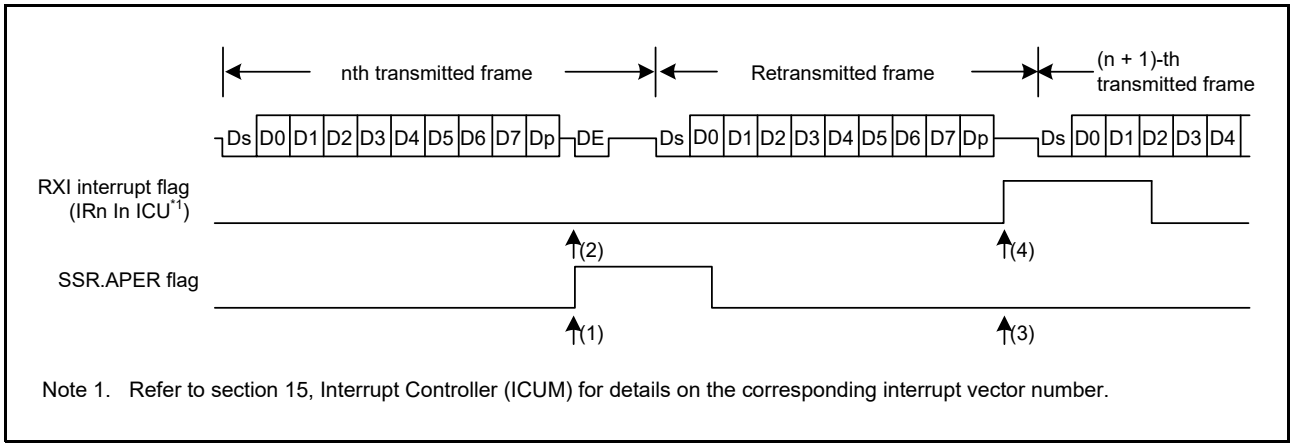

Figure 42.65 Data Retransmit Operation in RSCI Receive Mode (Data Retransmit Operation during Reception)

Figure 42.66 shows a sample flowchart for serial data reception. All the processing steps are automatically performed using an RXI interrupt request to activate the DTC or DMAC. In reception, setting the RIE bit to 1 allows an RXI interrupt request to be generated. The DTC or DMAC is activated by an RXI interrupt request if the RXI interrupt request is specified as a source of DTC or DMAC activation beforehand, allowing transfer of receive data. If an error occurs during reception and either the SSR.ORER or APER flag is set to 1, a receive error interrupt (ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred. Even if a parity error occurs and the APER flag is set to 1 during reception, receive data is transferred to RDR register, thus allowing the data to be read. When a reception is forcibly terminated by setting the SCR0.RE bit to 0 during operation, read the RDR register because the received data which has not yet been read may be left in RDR register.

Note: For operations in block transfer mode, refer to section 42.3, Operation in Asynchronous Mode.

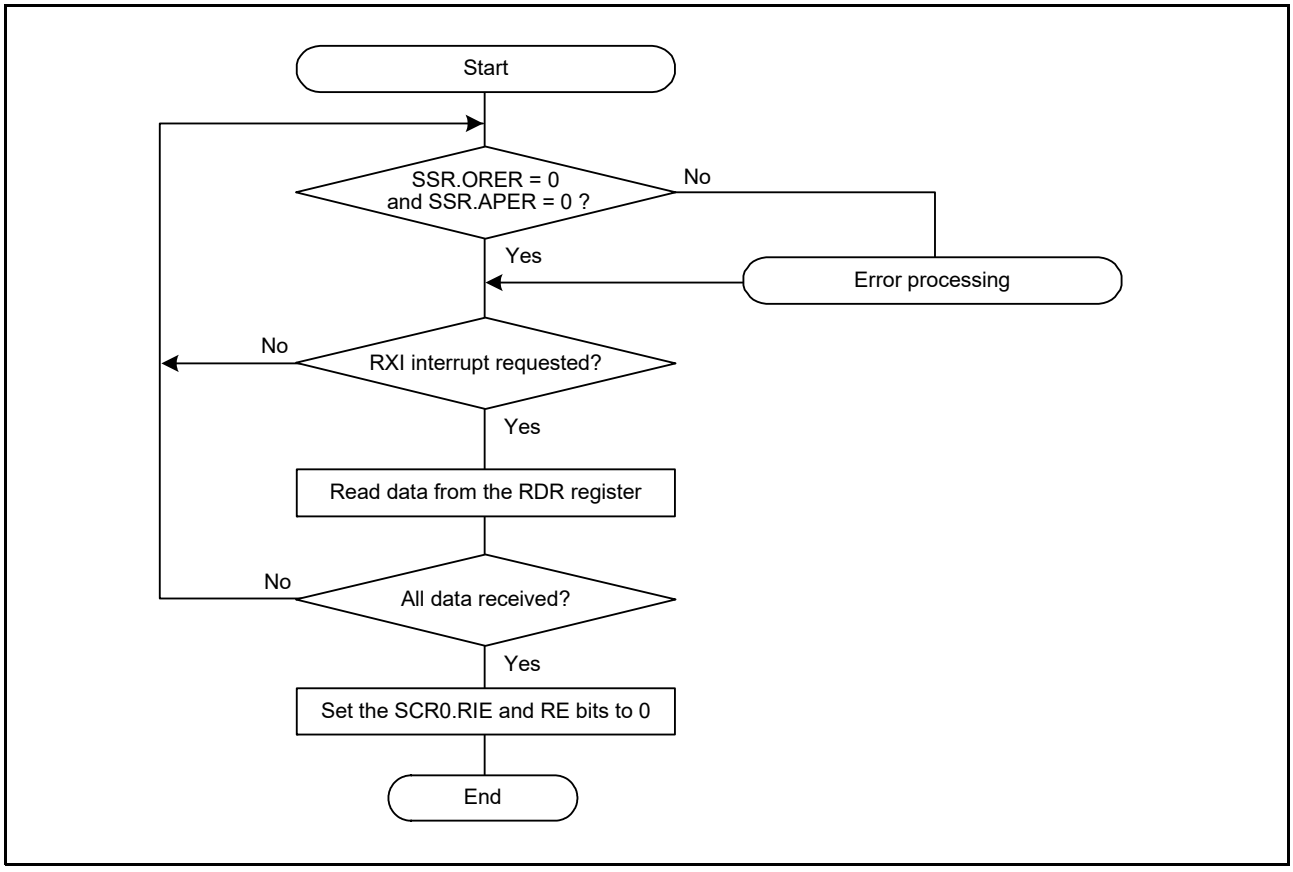

Figure 42.66 Sample Smart Card Interface Reception Flowchart

42.7.8 Clock Output Control

When the SCR3.GM bit is set to 1, the clock output can be controlled by the SCR3.CKE[1:0] bits. Refer to the description of the SCR3.CKE[1:0] bits in section 42.2.8, Control Register 3 (SCR3). When setting the clock output, the base clock described in section 42.7.4, Receive Data Sampling Timing and Reception Margin is output, so the width of the clock pulse can be kept to the width specified by setting the bit rate. It is described in section 42.2.7, Control Register 2 (SCR2), the bit rate is set by SCR2.CKS[1:0] bits, SCR2.BCP[2:0] bits and BRR[7:0] bits.
Figure 42.67 shows the timing chart for explaining clock output control. This is an example when the SCR3.CKE[1] bit is set to 0 and the SCR3.CKE[0] bit is controlled.
When the SCR3.GM bit is 0, output control by the SCR3.CKE[0] bit is immediately reflected on the SCKn pin, so there is a possibility that pulses with an unintended width may be output from the SCKn pin.
When the SCR3.GM bit is 1, the output pulse control by the SCR3.CKE[0] bit controls the pulse width set to be based on the state of the base clock.

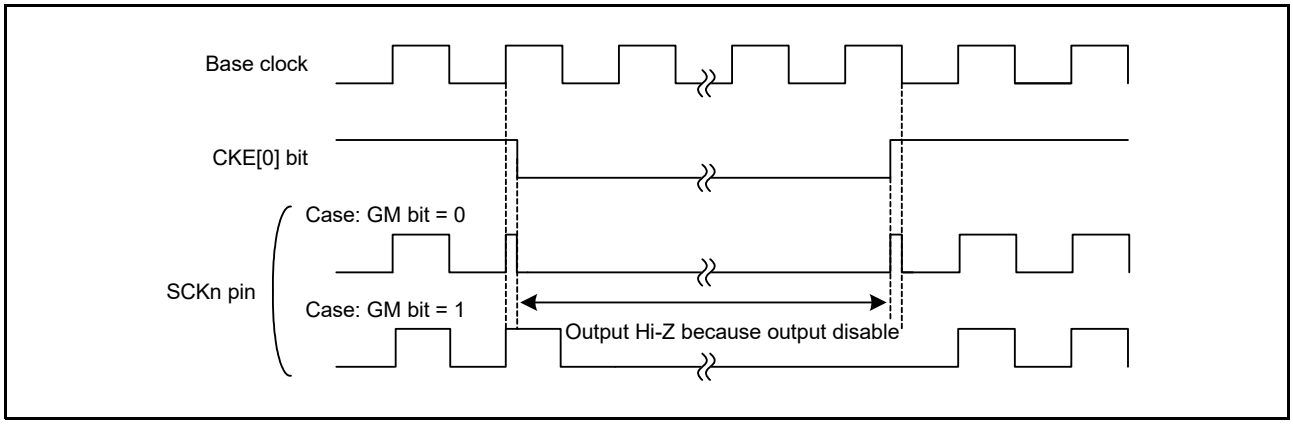

Figure 42.67 Clock Control Timing Chart by SCR3.GM Bit

42.8 Extended Serial Mode

42.8.1 Serial Transfer Protocol

As an extended function of the RSCI, the RSCI supports the serial communication protocol (Figure 42.68) consisting of a Start Frame and an Information Frame. Extended serial mode is enabled by the SCR3.MOD[2:0] bits = 110b. Since the extended serial mode uses the same circuit as the asynchronous mode for transmission/reception control other than Break Field, the basic communication settings required for the asynchronous mode are also required for the extended serial mode (however, set the SCR3.RXDESEL bit to 1).
The Start Frame consists of a Break Field, Control Field 0, and Control Field 1. The Information Frame can be configured with some Data Fields, a CRC16 Upper Field, and a CRC16 Lower Field.

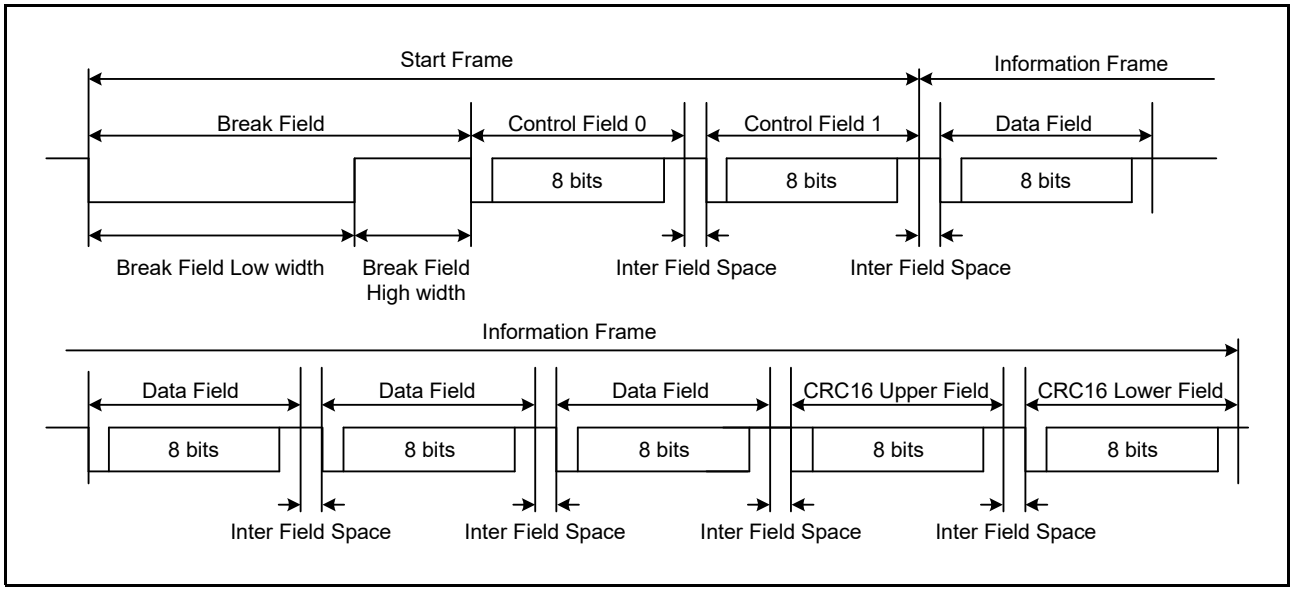

Figure 42.68 Protocol for Serial Transfer by the Extended Serial Mode

The following describes operations in extended serial mode. In this section, operations are described with the following conditions:
Communication pin (RXDn/TXDn) level inversion function: OFF (RINV bit = TINV bit = 0)
When using the communication pin (RXDn/TXDn) level inversion function enabled, replace the RXD and TXD signal levels with their inverted levels.

42.8.2 Transmitting a Start Frame

Figure 42.69 shows an example of transmission of the Start Frame consisting of a Break Field, Control Field 0, and Control Field 1. (Omit Break Field and Control Field 0 according to the Start Frame configuration.)
Figure 42.70 shows a flowchart for Start Frame transmission.
The RSCI operates as follows during Start Frame transmission.

(1) Make the initial settings for the RSCI according to the RSCI initialization flow (Figure 42.9) in asynchronous mode. In extended serial mode, do not set SCR0.TE and TIE bits to 1 at the same time to avoid TXI output before the Break Field. Therefore, perform the following two steps sequentially to set the RSCI initialization flow (asynchronous mode) procedure [10].

- Set the bits except SCR0.TIE bit. (SCR0.TIE bit = 0, SCR0.TE bit = 1, and SCR0.RE bit = 0)
- Set SCR0.TIE bit to 1.

(2) When 1 is written to TCST, the timer in the extended serial module starts counting and outputs a low level (Break Field) from the TXDn pin for the period set in XCR2.BFLW[15:0] bits. A timer count clock source can be selected by XCR0.TCSS[1:0] bits.
Writing 0 to XCR1.TCST bit suspends output of the Break Field. After the suspension, set SCR0.TE bit = 0 and turn off the transmission.

(3) When the extended serial module timer count value matches the set XCR2.BFLW[15:0] bits value, the timer stops counting and inverts the TXDn pin output level, and the XSR0.BFOF flag is set to 1*1. Furthermore, if XCR0.BFOIE bit has been set to 1 at this time, a TXI interrupt is generated.

(4) After confirming the BFOF flag is set to 1, send the Control Field 0 data.*2

(5) After the Control Field 0 data has been transmitted, write the Control Field 1 data to TDR. And it is transmitted.

(6) After the Control Field 1 data has been transmitted, the Information Frame data is transmitted.

Note 1. After XSR0.BFOF flag is set to 1, if 1 is written to XCR1.TCST bit without clearing it, no TXI interrupt is output at the end of Break Field transmission. Clear XSR0.BFOF flag before writing 1 to XCR1.TCST bit.

Note 2. LIN communication requires a Break delimiter (IDLE period) of 1 bit or more from the end of Break Field transmission until the next data transmission starts. For this reason, the Break delimiter length is counted upon completion of Break Field transmission. If transmit data is written while the Break delimiter length is being counted, transmission does not start until the Break delimiter length counting is completed. When transmit data is written after the Break delimiter length has been counted, transmission starts at the same timing as normal data transmission.
Break delimiter length count time after Break Field transmission: 1-bit to 2-bit length (SCR3.STOP bit = 0) 2-bit to 3-bit length (SCR3.STOP bit = 1)

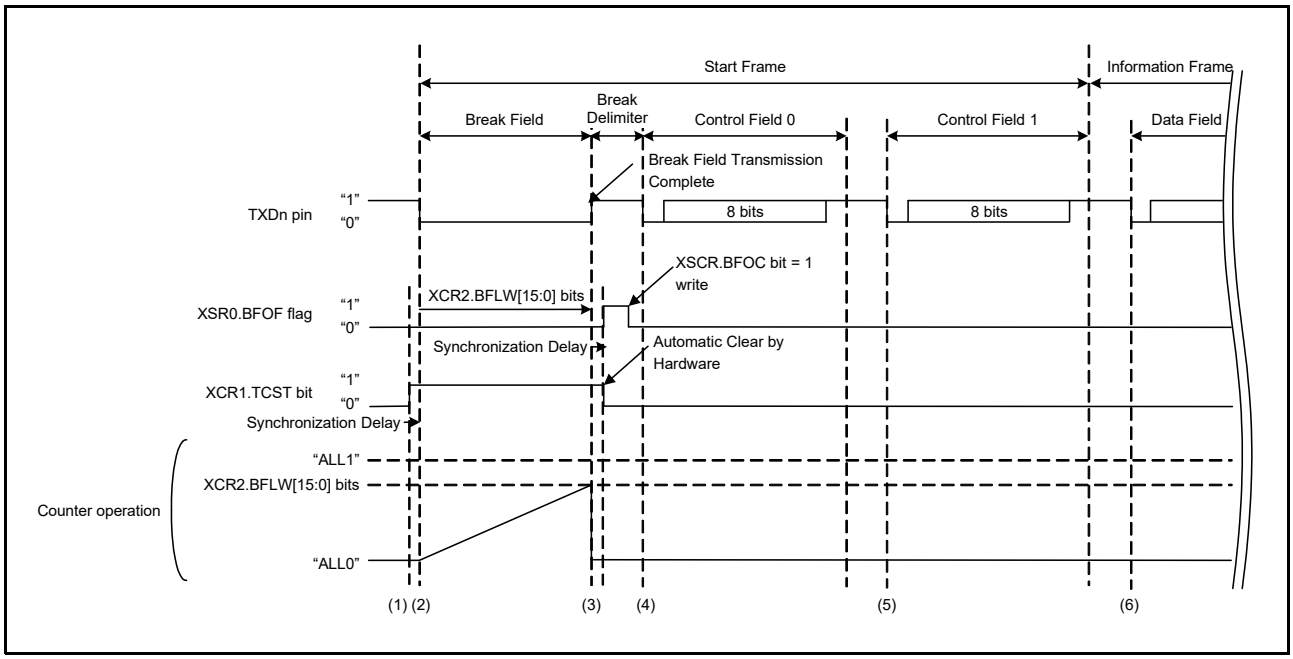

Figure 42.69 Example of Operations When Transmitting a Start Frame

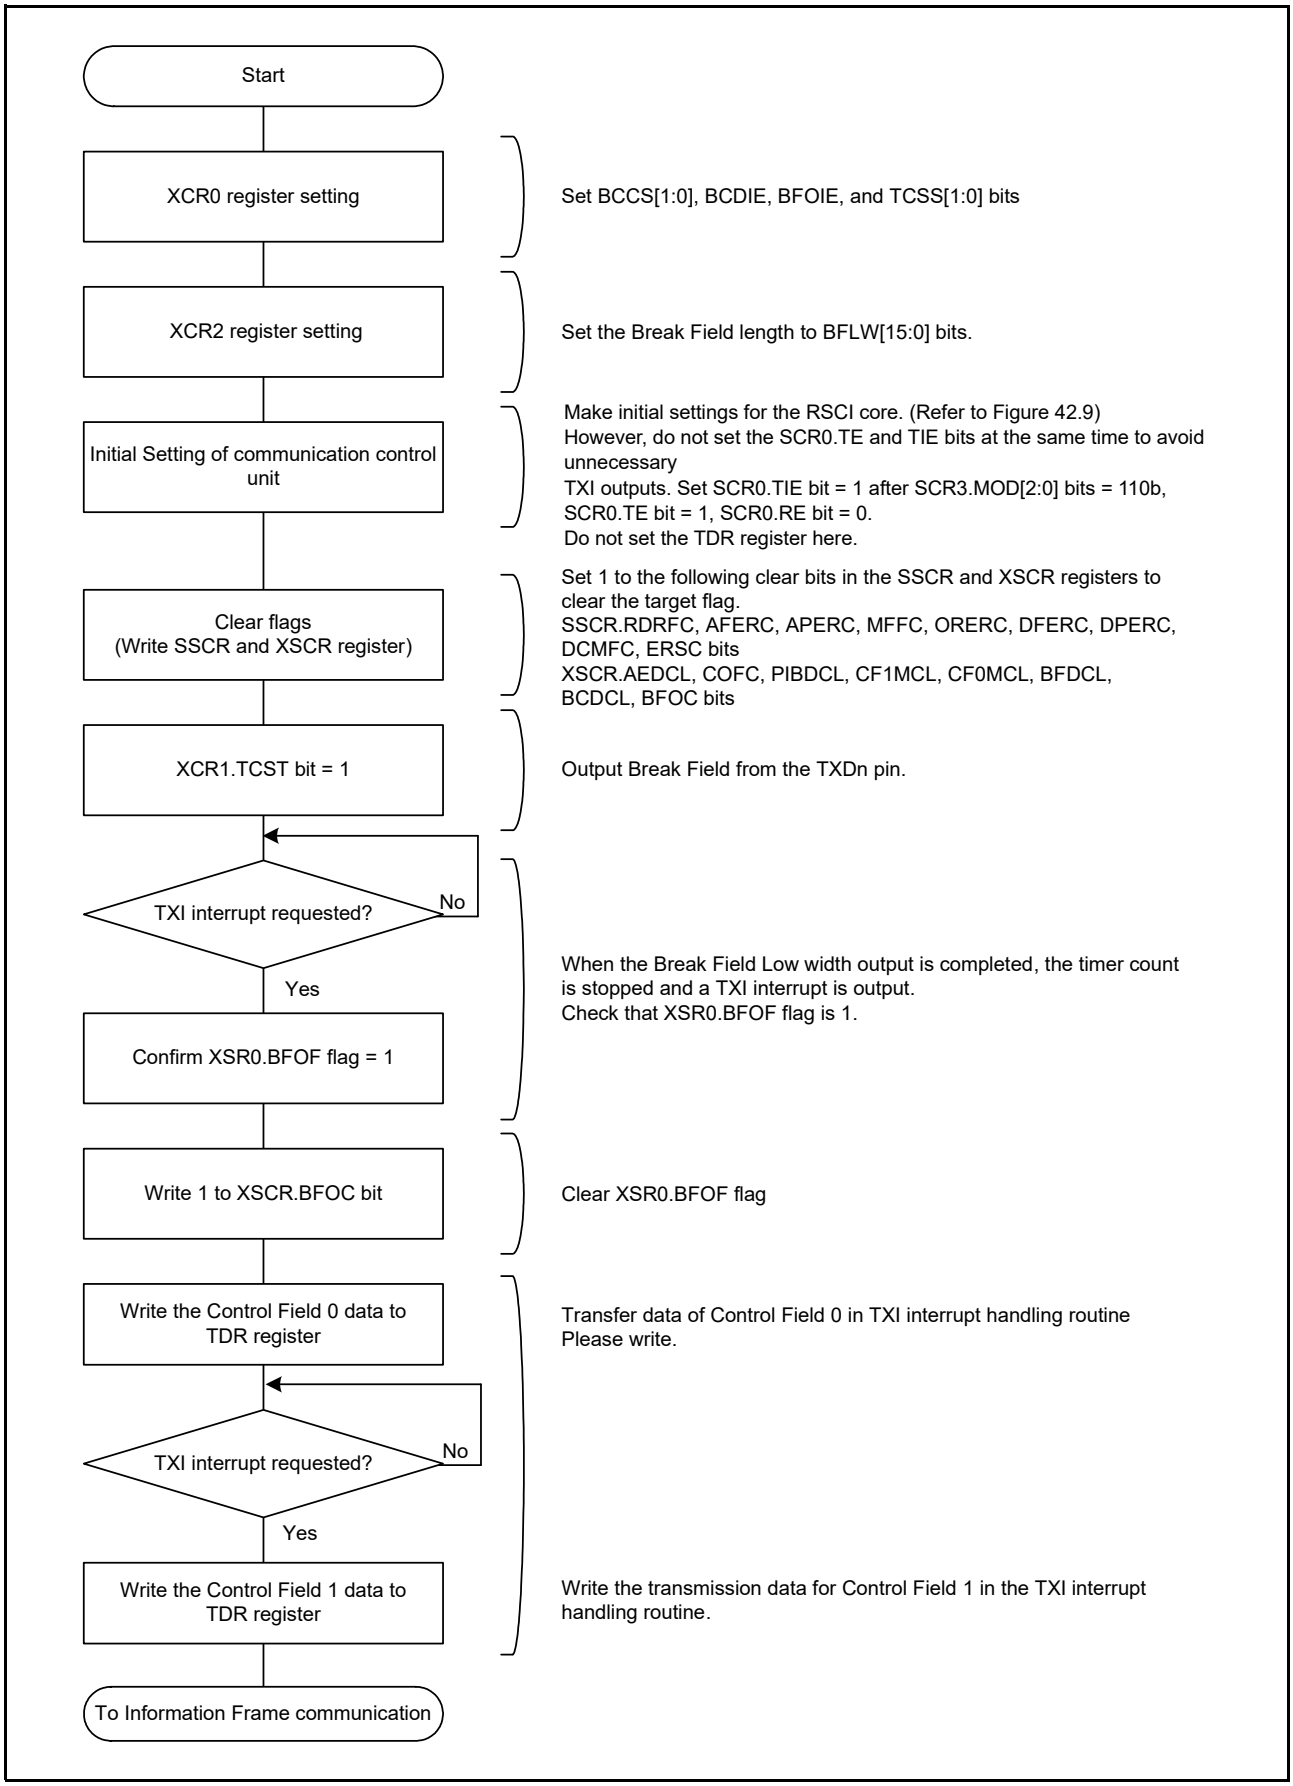

Figure 42.70 Example of Start Frame Transmission

42.8.3 Receiving a Start Frame

The extended serial mode control section is capable of receiving Start Frames with the structures listed in Table 42.40.

Table 42.40 Structures of Start Frames

XCR0		Start Frame Configuration
BFE	CF0RE	
0	0	Control Field1 (8 bits) → Information Frame
0	1	Control Field0 (8 bits) → Control Field1 (8 bits) → Information Frame
1	0	Break Field (Low width) → Control Field1 (8 bits) → Information Frame
1	1	Break Field (Low width) → Control Field0 (8 bits) → Control Field1 (8 bits) → Information Frame

42.8.3.1 Extended Serial Normal Reception of Start Frame (PIB not Used)

Figure 42.71 shows an example of normal reception of the Start Frame consisting of a Break Field, Control Field0, and Control Field1. Figure 42.72 shows an example of reception to detect the Break Field during Control Field 1. Figure 42.73 shows a flowchart to receive the Start Frame, and Figure 42.74 shows a state transition diagram.
When receiving the Start Frame, the RSCI operates as follows. Omit the processing of Break Field and Control Field0 according to the Start Frame configuration.

(1) Writing 1 to XCR1.SDST bit makes it possible to detect the Start Frame. When XCR0.BFE bit = 1, RXD input to the RSCI core is disabled until the Break Field is detected (because XSR0.RXDSF flag is set to 1). Once the Break Field is detected, RXD input can be received to the RSCI core (XSR0.RXDSF flag = 0).
(2) When a low level is input from the RXDn pin, the Break Field detection count starts. A timer count clock source can be selected by XCR0.TCSS[1:0] bits.
(3) When a low level that is equal to or longer than the period set in XCR2.BFLW[15:0] bits is input from the RXDn pin, it is determined as Break Field. At this time, XSR0.BFDF flag is set to 1. If XCR0.BFDIE bit has been set to 1 at this time, a BFD interrupt is generated.
The timer continues counting until the RXD rising edge or counter overflow.
(4) After the Break Field is detected, when the input level from the RXDn pin becomes high, the count value is captured to XSR1.CCV[15:0] bits when XCR1.BRME bit = 0. At this time, XSR0.RXDSF flag is cleared to 0 and the RSCI core starts receiving the RXD input.
(5) The RSCI core starts receiving Control Field 0. Because the extended serial continuously counts the edge interval, it determines a low level that is equal to or longer than the period set in XCR2.BFLW[15:0] bits as detection of the Break Field. When the Break Field is detected in the Control Field 0 phase, the RSCI core waits for reception of Control Field 0 again (Figure 42.72).
(6) When Control Field 0 has been received, an RXI interrupt is generated and the Control Field 0 data is stored in XSR0.CF0RD[7:0] bits. When the received data matches the set XCR2.CF0D[7:0] bits value, XSR0.CF0MF flag is set to 1. If the received data differs from the set XCR2.CF0D[7:0] bits value, the RSCI transitions to the state before the Break Field is detected.
(7) The RSCI core starts receiving Control Field 1. When BFE bit = 1, the Break Field detection function is continuously enabled while SDST bit = 1 as in the case of Control Field 0. When the Break Field is detected in the Control Field 1 phase, the RSCI core waits for reception of Control Field 0 again.
(8) When Control Field 1 has been received, an RXI interrupt is generated and the Control Field 1 data is stored in XSR0.CF1RD[7:0] bits. When the received data matches the set XCR1.PCF1D[7:0] bits value or the set

XCR1.SCF1D[7:0] bits value, XSR0.CF1MF flag is set to 1. If the received Control Field 1 data matches neither the set XCR1.PCF1D[7:0] bits value nor the set XCR1.SCF1D[7:0] bits value, the RSCI transitions to the state before the Break Field is detected.

(9) The RSCI core performs Information Frame communication.

(10) When communication is completed, write 0 to XCR1.SDST bit and 0 to SCR0.RE bit to stop reception.

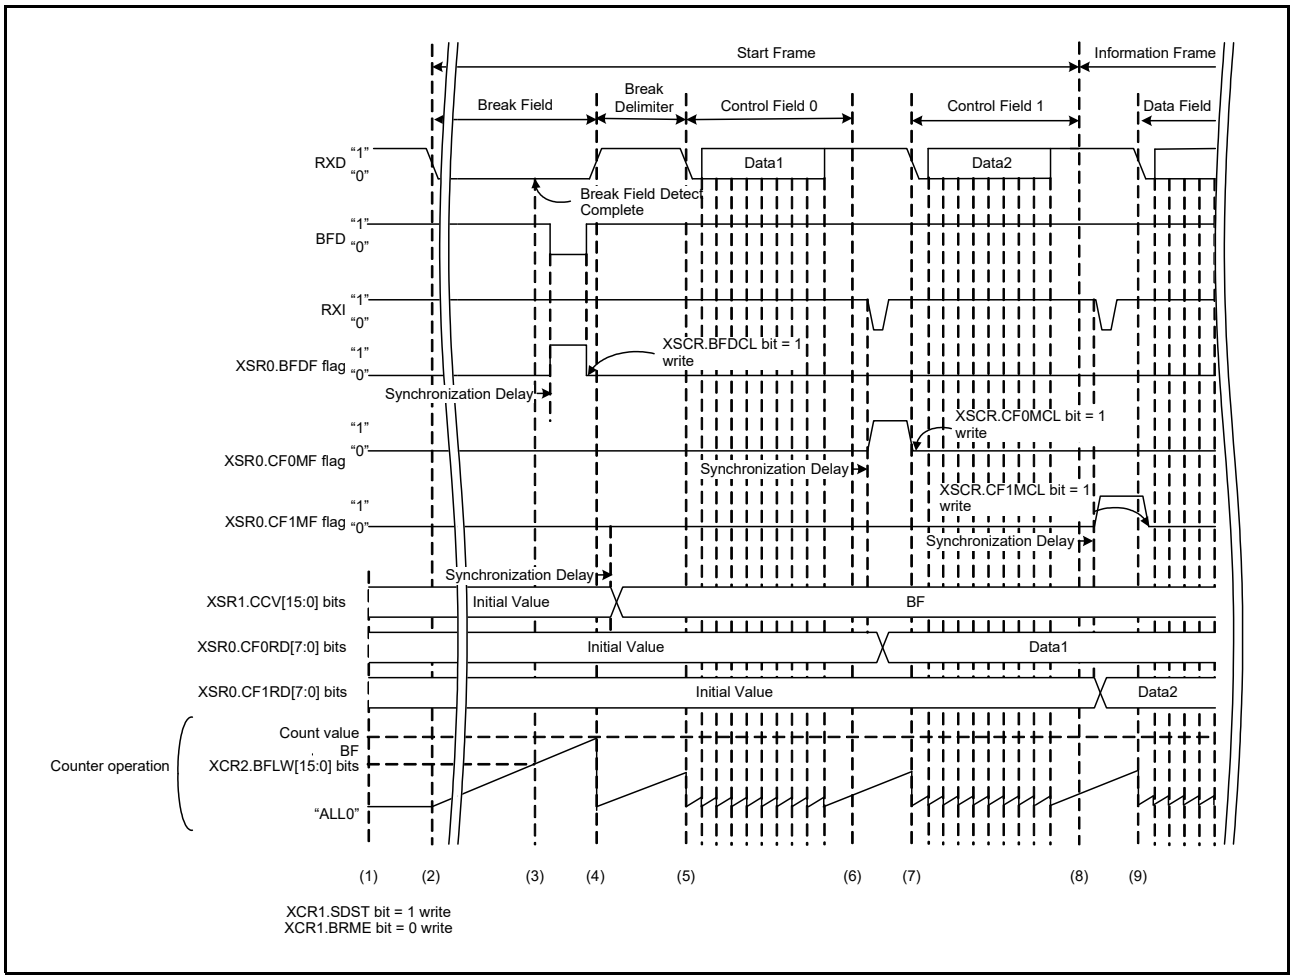

Figure 42.71 Normal Reception Example of Start Frame (PIB Not Used)

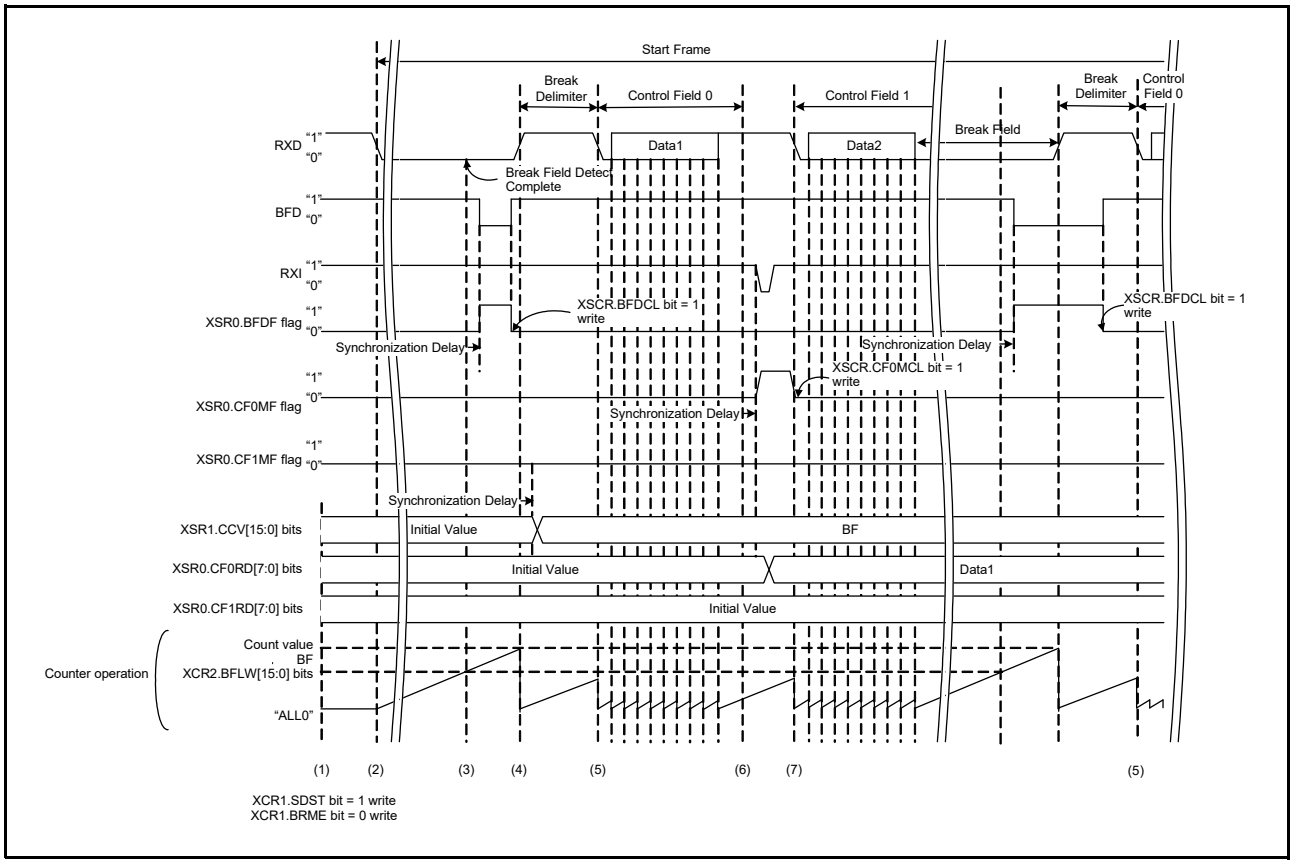

Figure 42.72 Start Frame Reception Example (PIB Not Used) Break Field Detected during Control Field 1

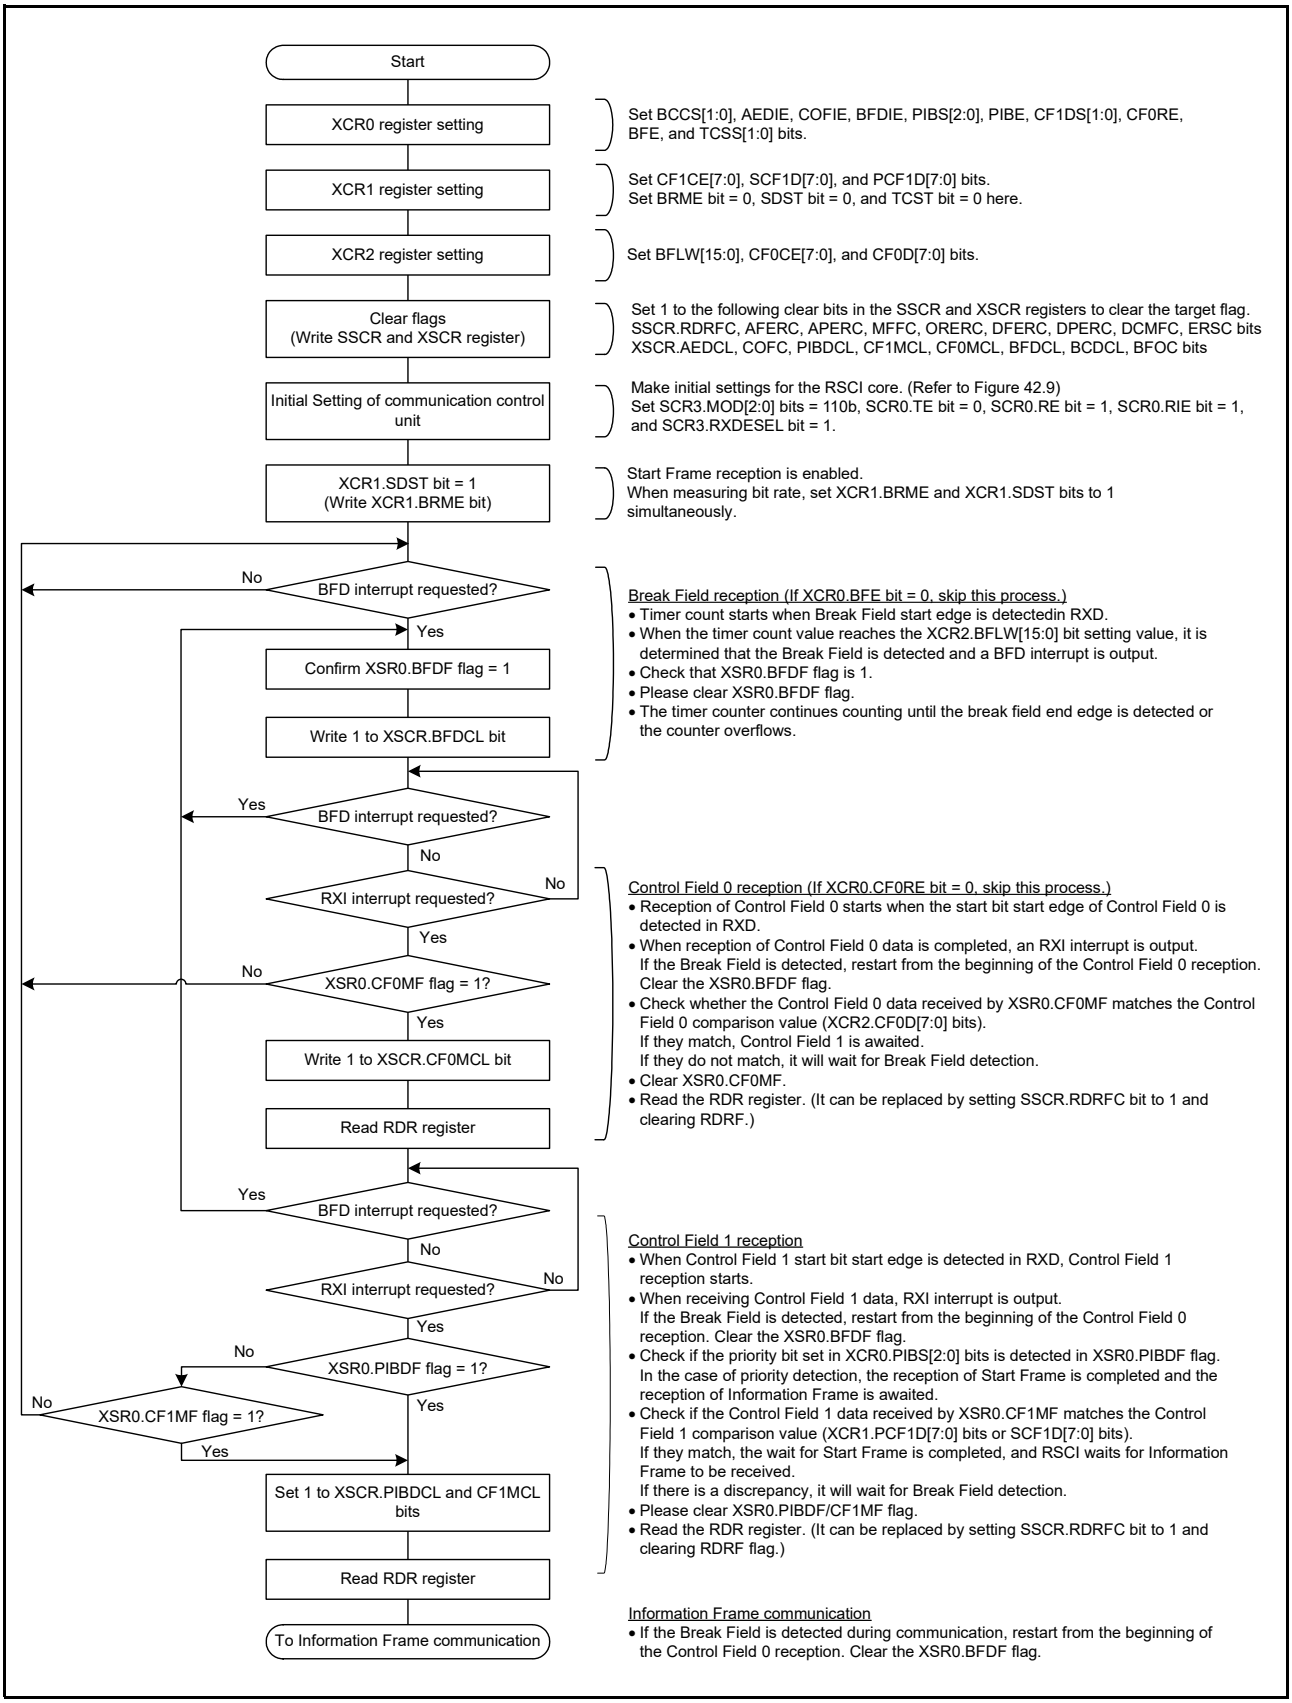

Figure 42.73 Sample Flowchart for Reception of a Start Frame

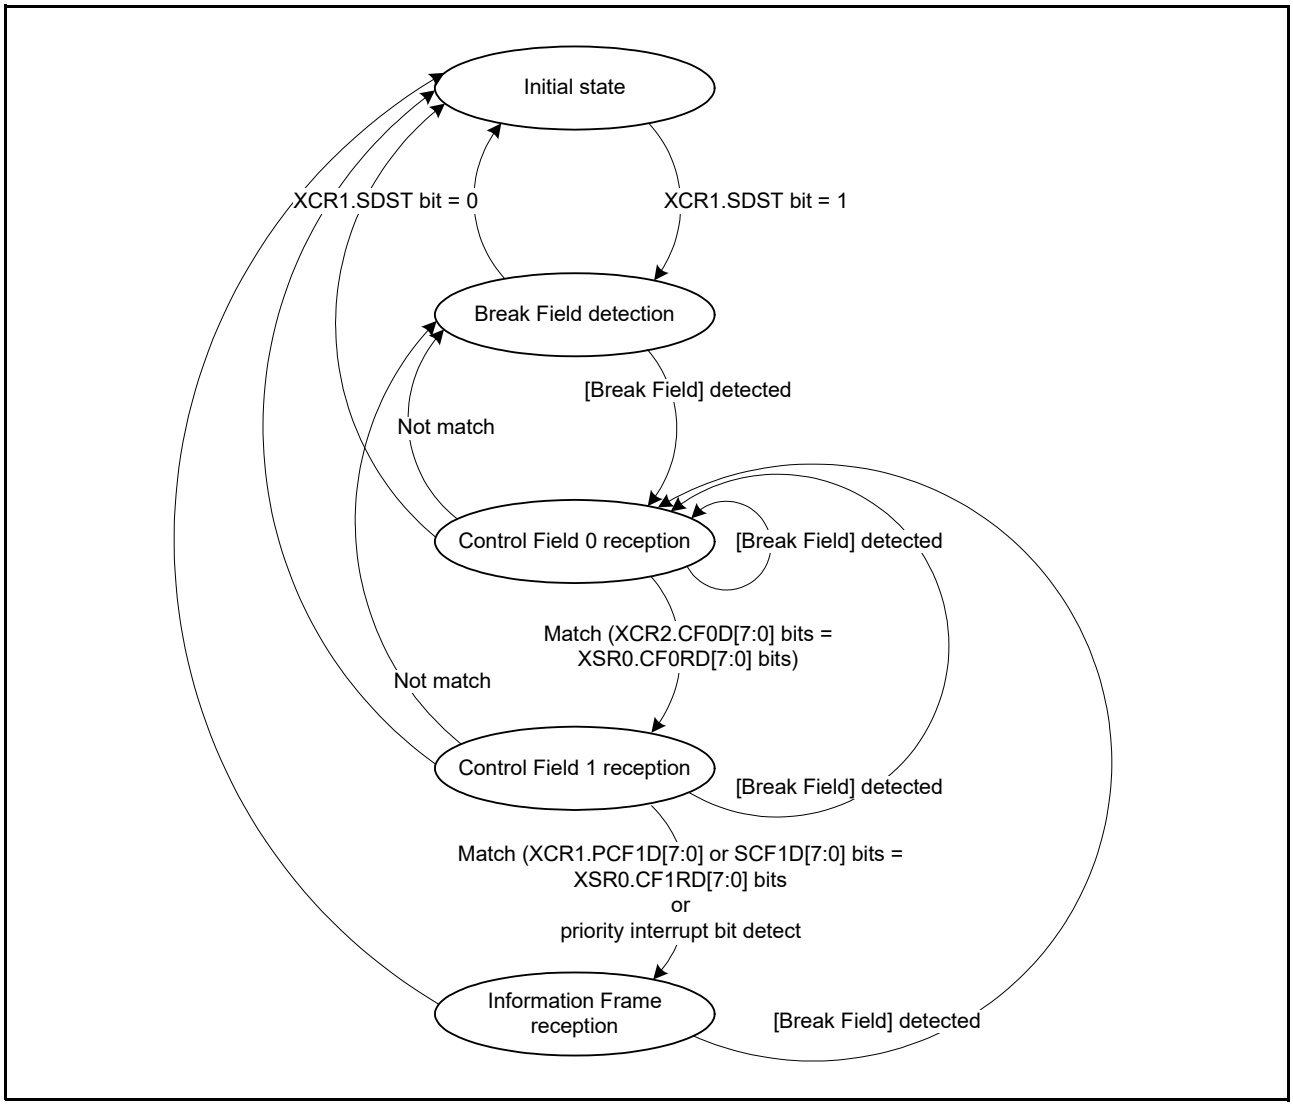

Figure 42.74 State Transition Diagram of Start Frame Reception

42.8.3.2 Priority Interrupt Bit

Figure 42.75 shows an example of Start Frame reception using the priority interrupt bit. The priority interrupt bit is enabled by setting XCR0.PIBE bit to 1.

The RSCI operates as follows during Start Frame reception using the priority interrupt bit.

Steps (1) to (7) are the same as in Figure 42.71, for Start Frame reception.

(8) When the value specified in the XCR0.PIBS[2:0] bits matches the set XCR1.PCF1D[7:0] bits value, XSR0.PIBDF flag is set to 1and the RSCI core performs communication of the Information Frame. If the data received in Control Field 1 matches neither the set XCR1.PCF1D[7:0] bits value nor the set XCR1.SCF1D[7:0] bits value and the priority interrupt bit is not detected, the RSCI transitions to the state before the Break Field is detected.

(9) The RSCI core performs Information Frame communication.

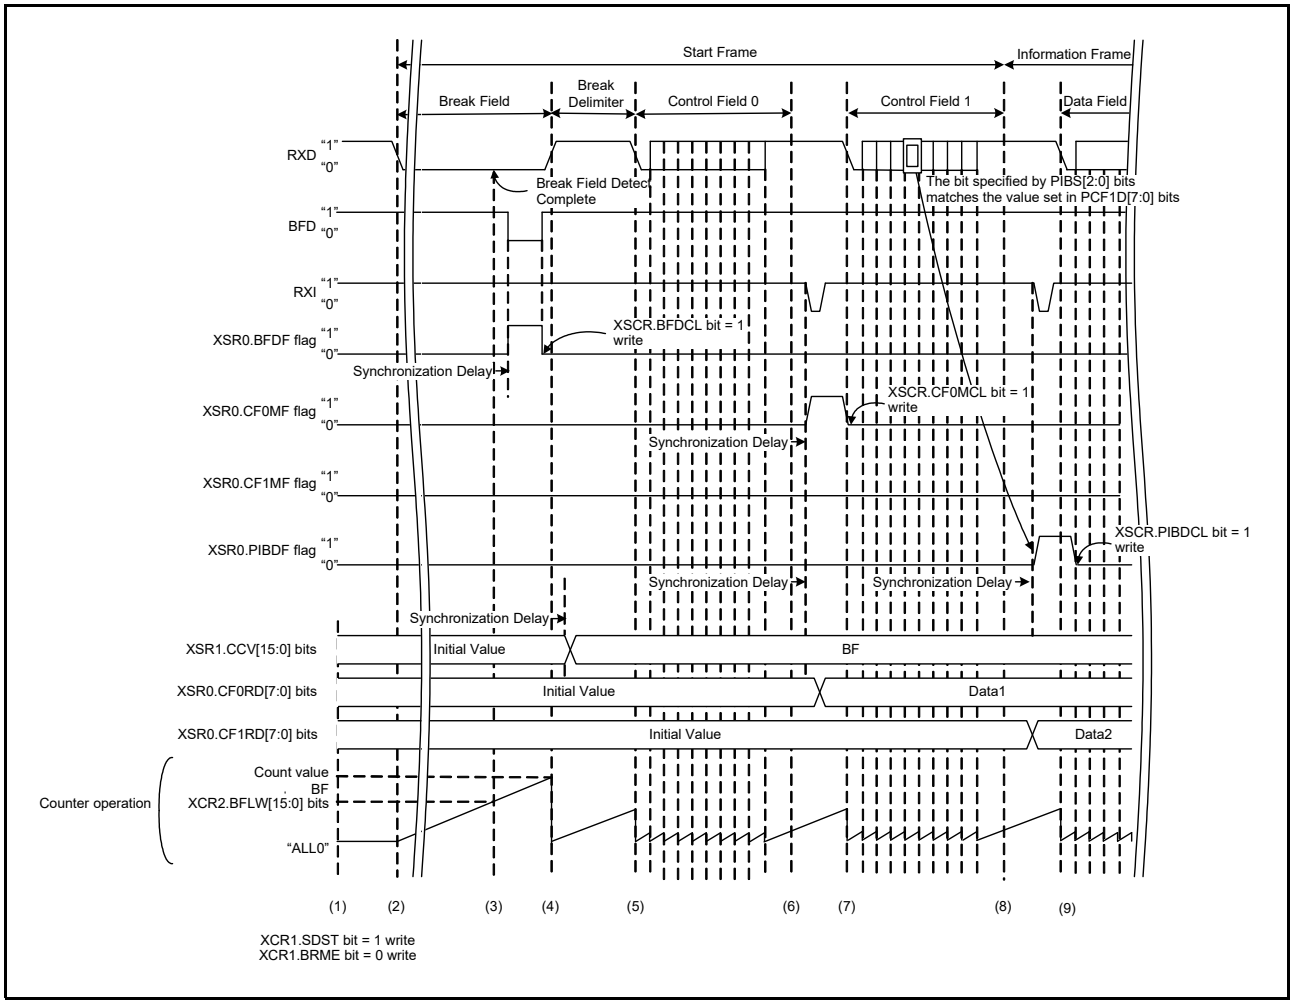

Figure 42.75 Start Frame Reception Example (Priority Interrupt Bit Used)

42.8.4 Detection of Bus Collisions

In extended serial mode (SCR3.MOD[2:0] bits = 110b) when TE bit = 1, the bus conflict detection function works during Break Field transmission and during data transmission.

Figure 42.76 shows an operation example of the bus conflict detection function. The TXDn pin output and the RXDn pin input are sampled by the bus conflict detection clock set in XCR0.BCCS[1:0] bits. When a mismatch occurs three times in a row, XSR0.BCDF flag is set to 1, and if XCR0.BCDIE bit has been set to 1 at this time, an ERI interrupt is generated.

When an ERI interrupt is generated, stop transmission according to Figure 42.77. Check the bus state to decide whether to resume transmission.

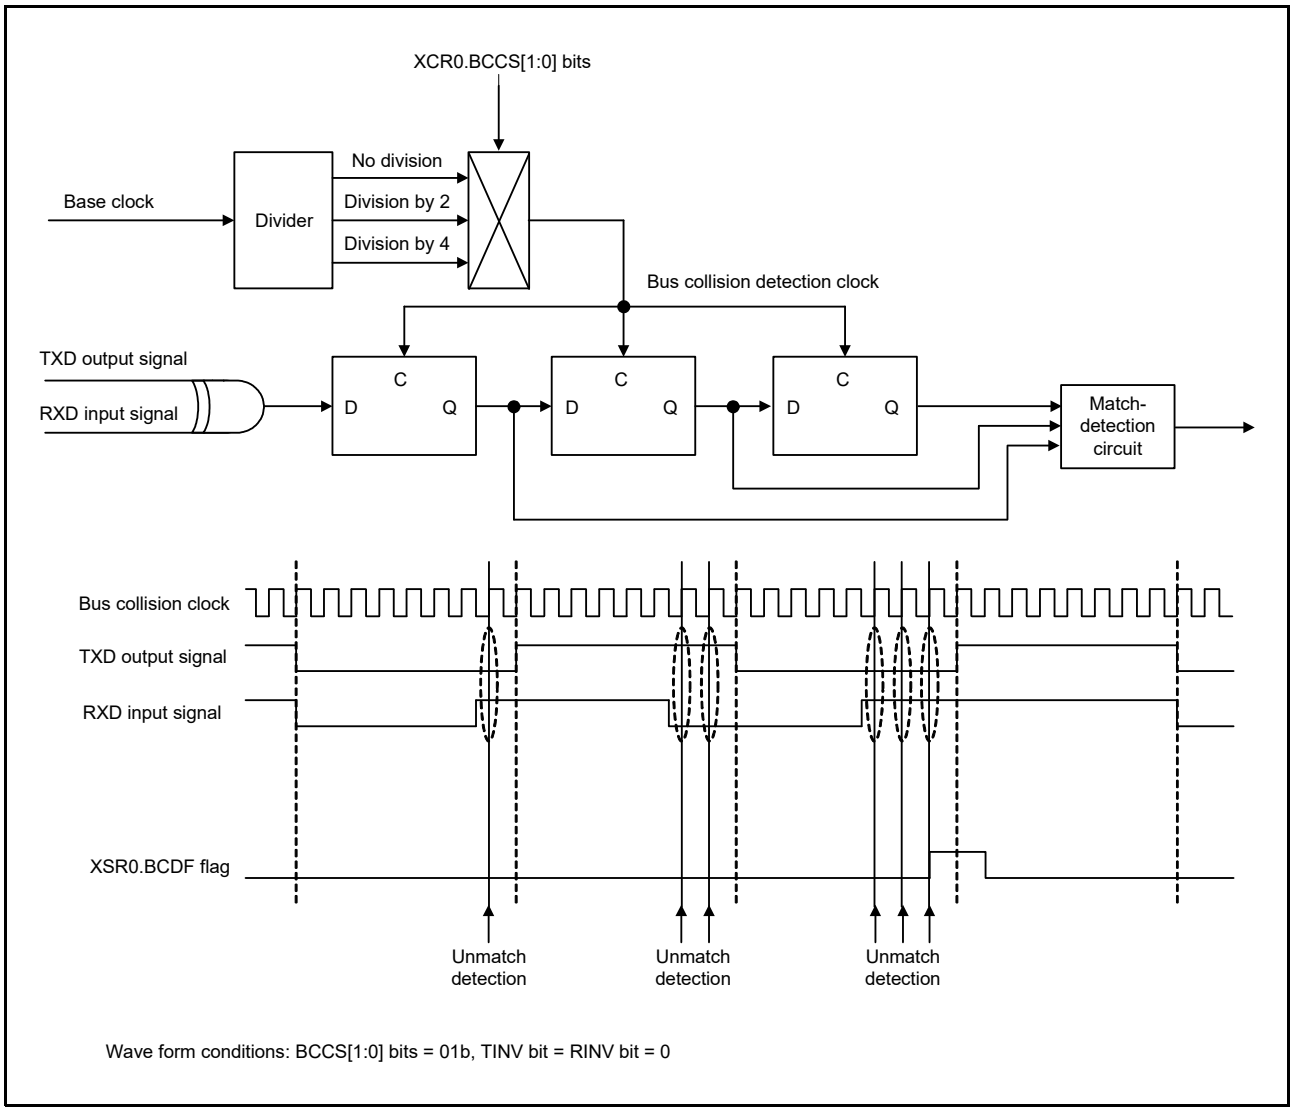

Figure 42.76 Example of Operations with Bus Collision Detection

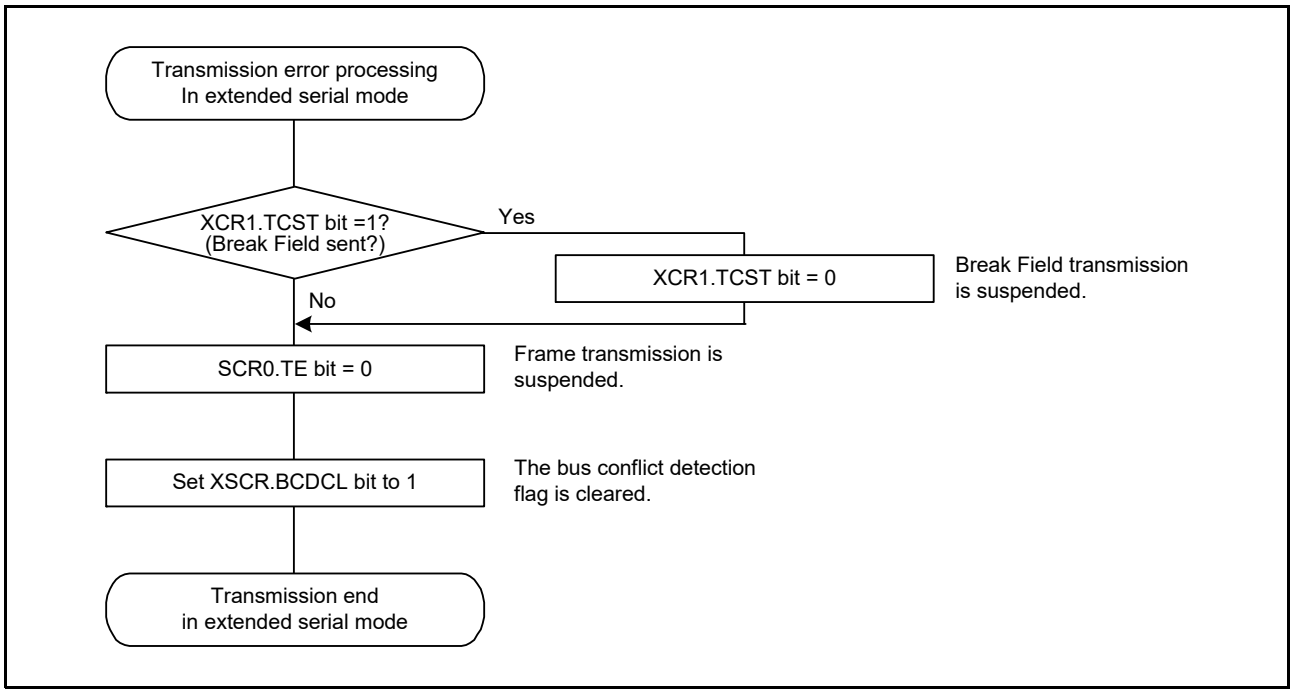

Figure 42.77 ERI Interrupt Handling Flow at Transmission in Extended Serial Mode

42.8.5 Bit Rate Measurement

This function measures a bit rate between the effective edges of the input signal from the RXDn pin. Figure 42.78 shows an operation example of the bit rate measurement function.

(1) Writing 1 to XCR1.SDST and XCR1.BRME bits enables bit rate measurement. When this bit is set to 1, the valid edge interval of Control Field 0 and Control Field 1 data is measured. However, bit rate is not measured between the Break Field and the Break Delimiter. Set XCR1.BRME and XCR1.SDST bits to 1 simultaneously, only when measuring bit rate.
(2) Because bit rate is not measured in the Break Field, the effective edge detection flag is not set to 1 at the rising edge at the end of the Break Field, and the counter capture value is not stored in XSR1.CCV[15:0] bits.
(3) The counter starts counting from the falling edge of the start bit in Control Field 0. The Break Delimiter count value is not captured in XSR1.CCV[15:0] bits.
(4) The rising edge of the start bit is detected as an effective edge, and then the XSR0.AEDF flag is set to 1. If XCR0.AEDIE bit has been set to 1 at this time, an AED interrupt is output. The start bit count value is stored in XSR1.CCV[15:0] bits. The XSR1.CCV[15:0] value is retained until the effective capture value is read.
(5) Even if an effective edge is input from the RXD input pin, the count value of this effective edge timing is not captured because the XSR1.CCV[15:0] bits value has not been read and retention has not been released. In this case, an AED interrupt is not output.
(6) The XSR1.CCV[15:0] value is read. Then the retention of XSR1.CCV[15:0] bits is released and the XSR0.AEDF flag is cleared by hardware.
(7) Because the retention of XSR1.CCV[15:0] bits has been released, the count value is captured at the effective edge and is retained. At the same time, the XSR0.AEDF flag is set to 1, and if XCR0.AEDIE bit has been set to 1, an AED interrupt is output. The bit rate can be adjusted by calculating it from the count value between effective edges by software and by changing the RSCI settings.
(8) To disable bit rate measurement, write 0 to XCR1.BRME bit.
(9) The XSR0.AEDF value and the XSR1.CCV[15:0] value remain unchanged at the effective edge timing because the bit rate measurement function is disabled.

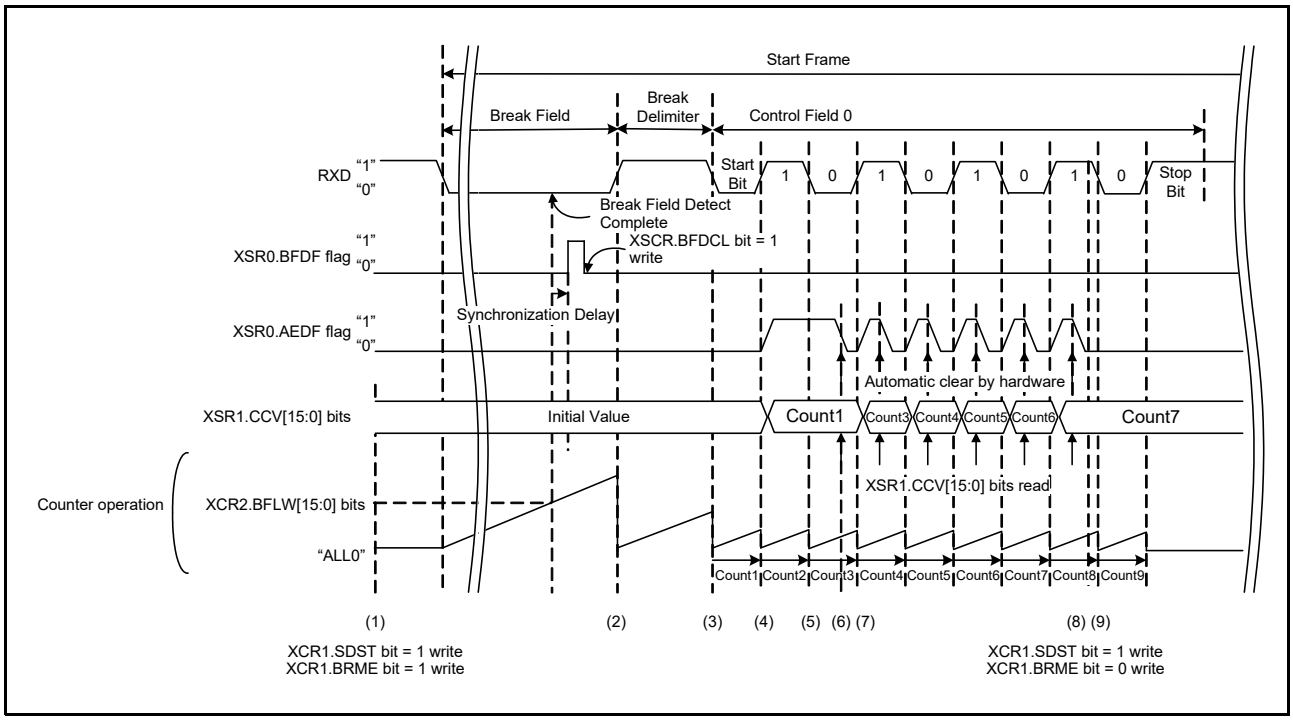

Figure 42.78 Operation Example of the Bit Rate Measurement Function

42.9 Operation in Simple I2C Mode

Simple I2C-bus format is composed of 8 data bits and an acknowledge bit. The frame following the start condition or restart condition is the slave-address frame, which is used by the master device to specify a slave device with which it is communicating. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8-bit data of each frame is transmitted from MSB.
Figure 42.79 shows I2C bus format, and Figure 42.80 shows the timing of I2C.

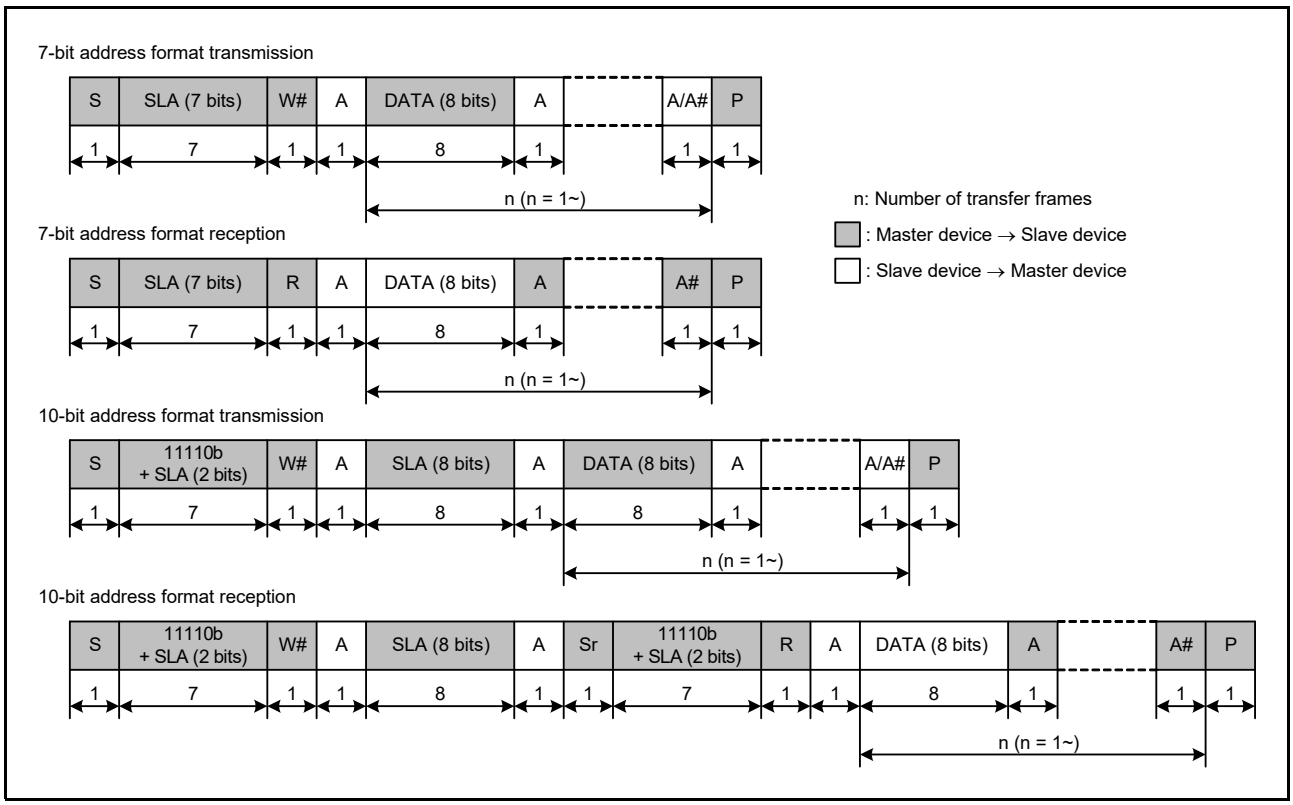

Figure 42.79 I2C-Bus Format

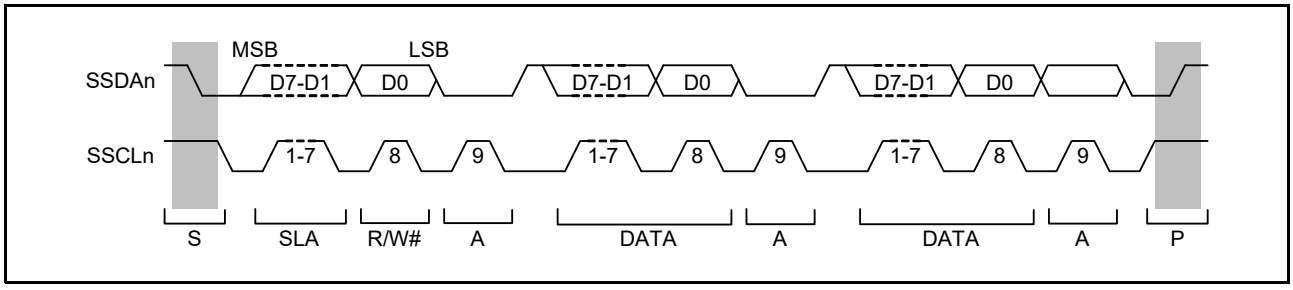

Figure 42.80 I2C-Bus Timing (When SLA is 7 Bits)

S: Indicates a start condition. The master device changing the level on the SSDAn line from the high to the low level when the SSCLn line is at the high level.
SLA: Indicates a slave address. The master device selects a slave device.
R/W#: Indicates the direction of transfer (reception or transmission). When R/W# is high, the transfer direction is from the slave device to the master device. When R/W# is low, the transfer direction is from the master device to the slave device.
A/A#: Indicates an acknowledge. This is returned by the slave device for master transmission and by the master device for master reception. The low level indicates ACK and the high level indicates NACK.
Sr: Indicates a restart condition. The master device changing the level on the SSDAn line from the high to the low level when the SSCLn line is at the high level.
DATA: Indicates the received or transmitted data.
P: Indicates a stop condition. The master device changing the level on the SSDAn line from the low to the high level when the SSCLn line is at the high level.

42.9.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to SIMR.IICSTAREQ bit causes the generation of a start condition. The following operations are done at the generation of a start condition.

- The level on the SSDAn line falls (from the high level to the low level) and the SSCLn line is kept in the released state.
- The hold time for the start condition is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The level on the SSCLn line falls (from the high level to the low level), the SIMR.IICSTAREQ bit is set (to 0), and a start-condition generated interrupt is output.

Writing 1 to SIMR.IICRSTAREQ bit causes the generation of a restart condition. The following operations are done at the generation of a restart condition.

- The SSDAn line is released and the SSCLn line is kept at the low level.
- The period at low level for the SSCLn line is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The SSCLn line is released (transition from the low to the high level).
- Once the high level on the SSCLn line is detected, the setup time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The level on the SSDAn line falls (from the high level to the low level).
- The hold time for the restart condition is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The level on the SSCLn line falls (from the high level to the low level), the SIMR.IICRSTAREQ bit is set (to 0), and a restart-condition generated interrupt is output.

Writing 1 to SIMR.IICSTPREQ bit causes the generation of a stop condition. The following operations are done at the generation of a stop condition.

- The level on the SSDAn line falls (from the high level to the low level) and the SSCLn line is kept at the low level.
- The period at low level for the SSCLn line is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The SSCLn line is released (transition from the low to the high level).
- Once the high level on the SSCLn line is detected, the setup time for the stop condition is secured as half of a bit period at the bit rate determined by the setting of the SCR2.BRR[7:0] bits.
- The SSDAn is released (transition from the low to the high level), the SIMR.IICSTPREQ bit is set (to 0), and a stop condition generated interrupt is output.

Figure 42.81 shows the timing of operations in the generation of start, restart and stop conditions.

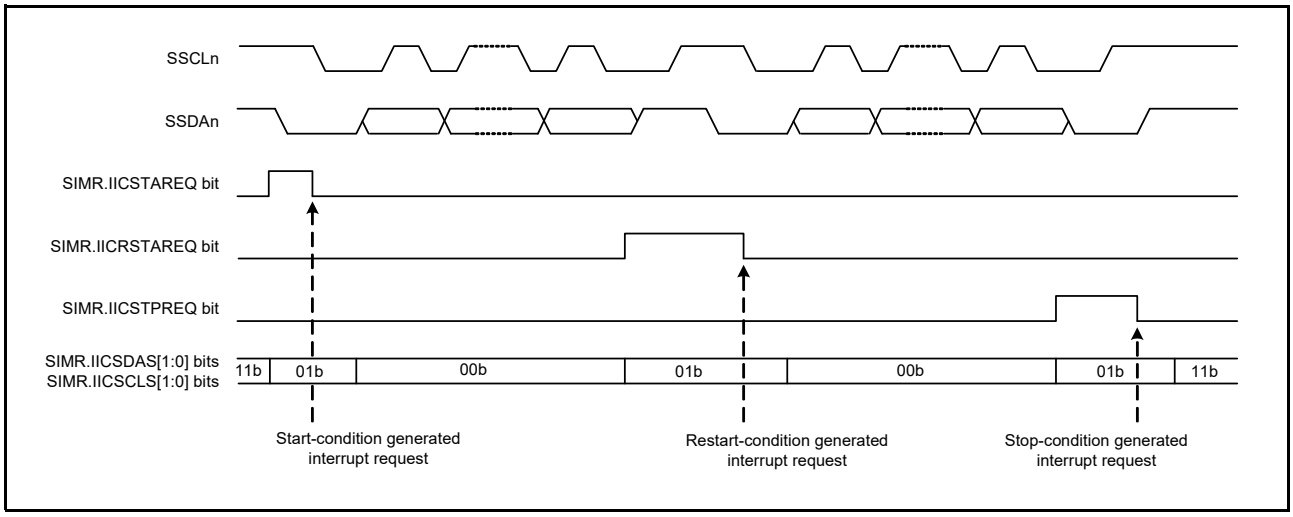

Figure 42.81 Timing of Operations in the Generation of Start, Restart, and Stop Conditions

42.9.2 Clock Synchronization

The slave device of the communication partner may make SSCLn line Low-level with a view to insert a wait. Setting the SIMR.IICCSC bit to 1, applies control to obtain synchronization when the levels of the internal SCL signal and the level being input on the SSCLn pin differ.

When the SIMR.IICCSC bit is set to 1, the level of the internal SCL signal changes from low to high, counting to determine the period at high level is stopped while the low level is being input on the SSCLn pin, and counting to determine the period at high level starts after the transition of the input on the SSCLn pin to the high level. The interval until counting to determine the period at high level starts on the transition of the SSCLn pin to the high level is the total time which contains the SSCLn input delay, the noise filtering delay of the SSCLn pin (2 or 3 cycles of the filtering clock), and the internal processing delay (1 or 2 cycles of TCLK). The period at high level of the internal SCL signal is extended even if other devices are not placing the low level on the SSCLn line.

If the SIMR.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SSCLn pin and the internal SCL signal. If the SIMR.IICCSC bit is 0, synchronization with the internal SCL signal is obtained for the transmission and reception of data.

If a slave device inserts a period of waiting into the interval until the transition of the internal SCL signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a period of waiting after the transition of the internal SCL signal from the low to the high level, although the generation-completed interrupt is issued without stopping the period of waiting, generation of the condition itself is not guaranteed.

Figure 42.82 shows an example of operations to synchronize the clocks.

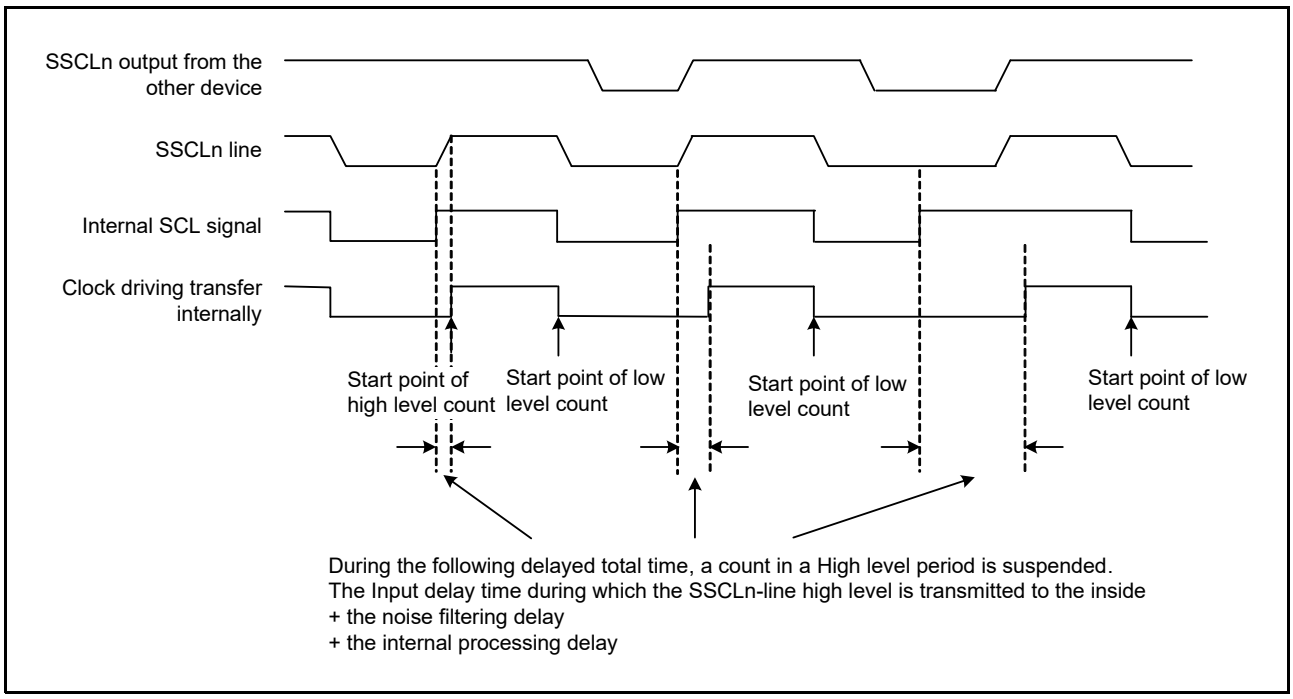

Figure 42.82 Example of Operations for Clock Synchronization

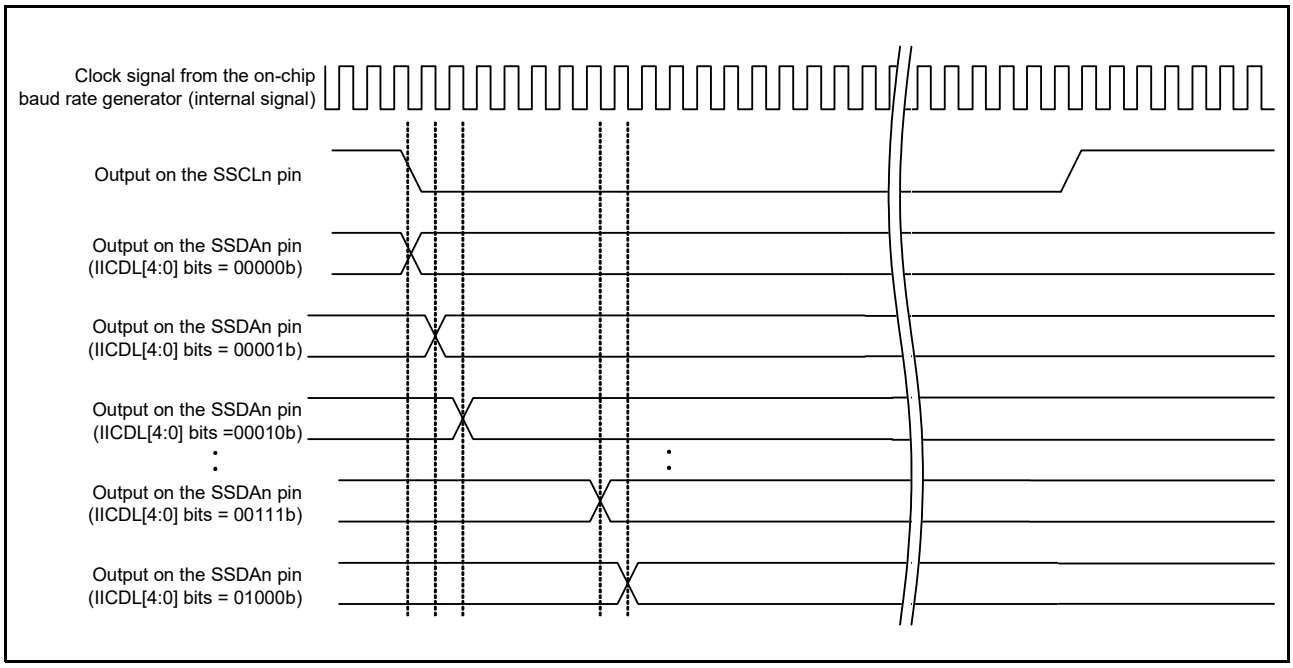
42.9.3 SDA Output Delay

The SIMR.IICDL[4:0] bits can be used to set a delay for output on the SSDAn pin relative to falling edges of output on the SSCLn pin. The delay-time settings are selectable from 0 to 31 cycles of the clock signal from the on-chip baud rate generator (The base is TCLK and selected the divided clock by the SCR2.CKS[1:0] bits). About Start/Restart/Stop conditions, 8bit-transmission data and acknowledge, the SSDAn pin output can be delayed.

If the SDA output delay is shorter than the falling time of the SSCLn output pin, the change of the SSDAn output pin will start while the SSCLn output pin level is falling, then there is a possibility of erroneous operation for slave devices. Ensure setting the SDA output delay greater than the SSCLn maximum falling time. (300 ns for I^2C normal/fast mode.)

Figure 42.83 shows the timing of delays in SDA output.



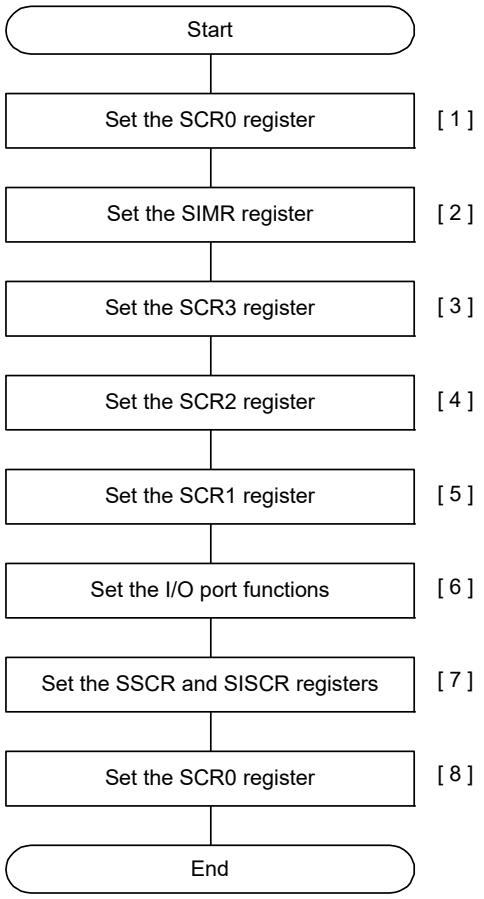


Figure 42.83 Timing of Delays in SDA Output

42.9.4 RSCI Initialization (Simple I2C Mode)

Write initial value (0000 0000h) to SCR0, then initialize RSCI according to Figure 42.84.
When changing the operating mode, transfer format, and so on, be sure to set 0 to SCR0.TE bit and SCR0.RE bit before proceeding with the changes. (Or write initial value to SCR0 again.) In simple I2C mode, the open-drain setting for the communication ports should be made on the port side.

[1] Set the following bits of SCR0 register to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set the IICSDAS[1:0] and IICSCLS[1:0] bits to 11b.
Set the IICDL[4:0] and IICINTM bits as required.
Set the IICACKT and IICCSC bits to 1.

[3] Set the transmission/reception format as the communication mode (MOD[2:0] bits = 100b) and CKE[1:0] bits = 00b.

[4] Set the bit rate modulation function*1, the clock selection, and the bit rate.

[5] Set noise filter, communication pin status, parity check, CTS/RTS function.

[6] Set I/O port settings that allow use (on NMOS opendrain output pins and Hi-Z) of the SSCLn and SSDAn pin functions.

[7] Write 1 to the following bits and clear the corresponding flag.
SSCR.RDRFC, AFERC, APERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
SISCR.IICSTIFC

[8] Set the TE and RE bits to 1.
To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time.
(for transmission and when the SIMR.IICINTM bit is 1, clear the RIE bit.) Setting the TE and RE bits to 1 makes the SSCLn and SSDAn pin functions available.

Note 1. If you do not use the bit rate modulation unction, you do not need to set it.

Note: Set the SCR0.TE and RE bits to 0 or 1 at the same time.

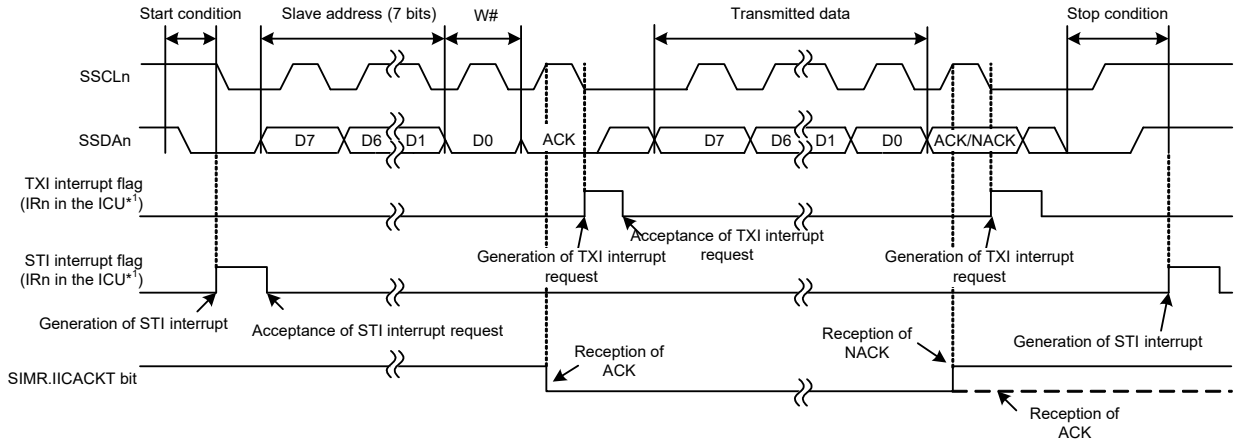

Figure 42.84 Example of the Flowchart of RSCI Initialization (for Simple I2C Mode)

42.9.5 Operation in Master Transmission (Simple I2C Mode)

Figure 42.85 and Figure 42.86 show examples of operations in master transmission, Figure 42.87 to Figure 42.89 show the example flowcharts. See Table 42.47 about the STI interrupt.

Figure 42.85 shows the operation example when SIMR.IICINTM bit is 1 (Reception/Transmission interrupt are in use). In this case, you can start DMAC or DTC by TXI interrupt. However, if you use DMAC or DTC, ACK/NACK can not be confirmed. So, if you want to confirm ACK/NACK, prepare transmit data by CPU. In simple I2C mode, TXI interrupt is generated when communication of one frame is completed. And it isn't used reception interrupt in master transmission, so the SCR0.RIE bit set to 0.

Figure 42.87 shows a flow chart in the case of SIMR.IICINTM bit is 1 and address transmission by CPU and data transmission by DTC or DMAC. Figure 42.88 shows a flow chart of address and data transmission by CPU. When 10-bit slave addresses are in use, steps [3] and [4] are repeated twice.

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

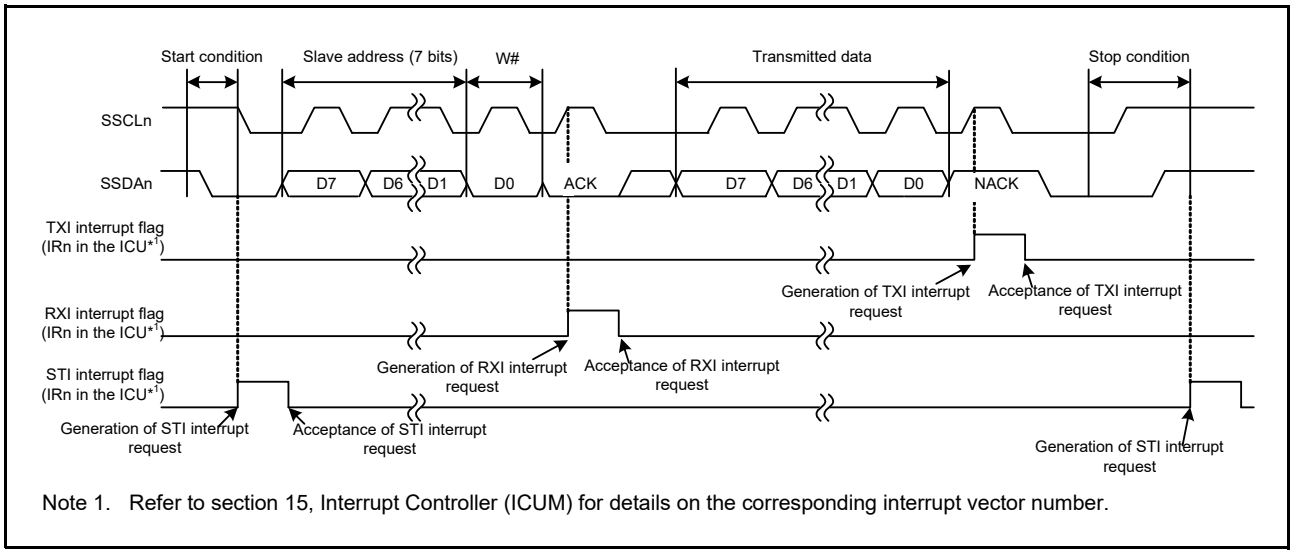

Figure 42.85 Example 1 of Operations for Master Transmission in Simple I2C Mode (with 7-Bit Slave Addresses, Transmission Interrupts, and Reception Interrupts in Use (SIMR.IICINTM Bit = 1))

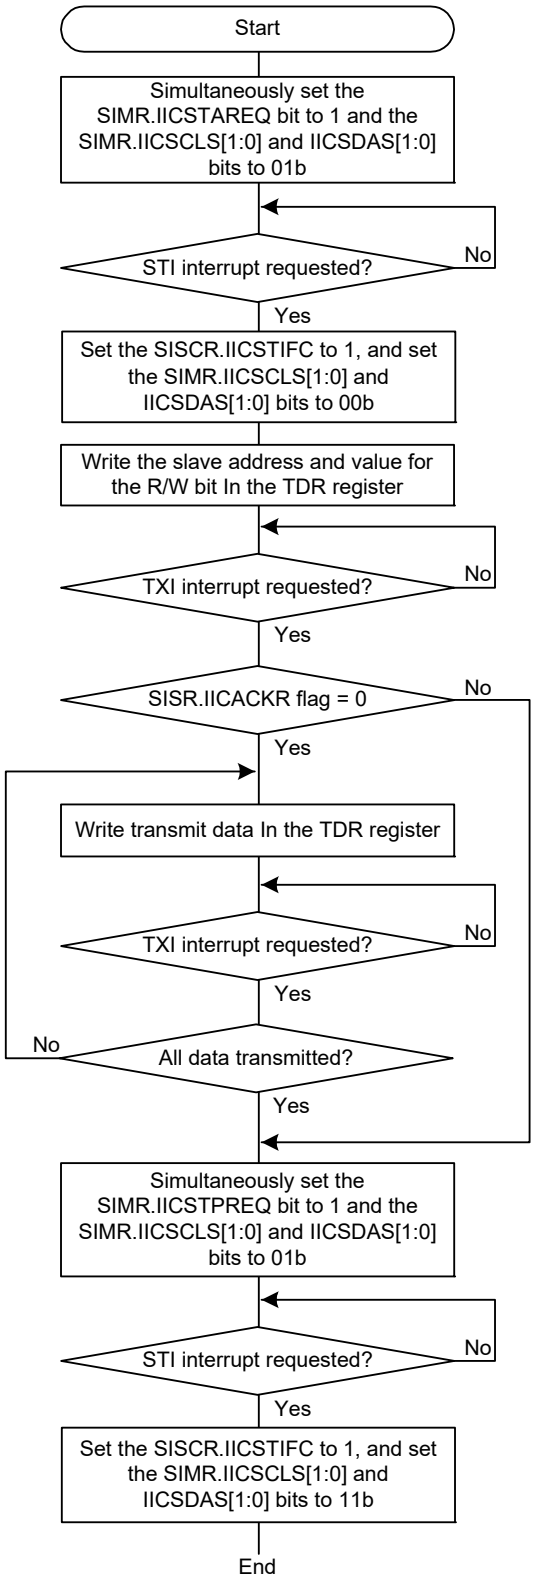
Figure 42.86 shows an example of operations when SIMR.IICINTM bit is 0 (ACK and NACK interrupt in use). In this case, DTC or DMAC is activated by the ACK interrupt, and necessary number of data bytes are transmitted. When the NACK is received, error processing, such as transmission stop and retransmission, is performed by the NACK interrupt as the trigger.

Figure 42.89 shows a flow chart of SIMR.IICINTM bit is 0



To resume communication after interrupting communication for some reason after writing transmit data to TDR, follow the procedure below.

1. Set the SCR0.TE and SCR0.RE bits to 0 to stop communication.
2. Set SIMR.IICSCLS[1:0] and SIMR.IICSDAS[1:0] bits to 11b, release the I2C bus, and clear various condition generation requests.
3. When the SSR.RDRF flag is 1, the RDR register is read by dummy and the RDRF bit is set to 0.
4. Set the SCR0.TE and SCR0.RE bits to 1 and restart communication.

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

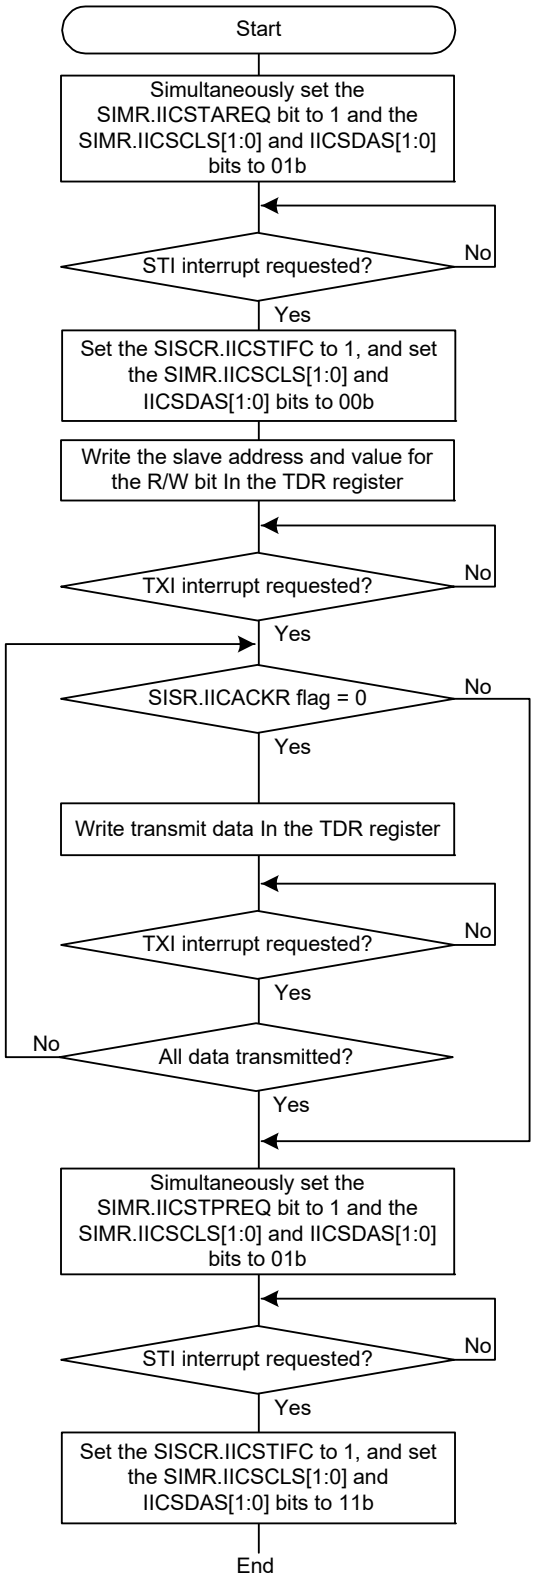
Figure 42.86 Example 2 of Operations for Master Transmission in Simple I²C Mode (with 7-Bit Slave Addresses, ACK Interrupts, and NACK Interrupts in Use (SIMR.IICINTM Bit = 0))

[0] [0] For transmission, set the SCR0.RIE bit to 0 at initialization. (RXI and ERI interrupts requests are disabled)

[1] [1] Generate a start condition.

[2] [2] Writing to TDR register:
Writing the slave address and value for the R/W bit to TDR register.

[3] [3] Confirming ACK response from the slave address:
Check the SISR.IICACKR bit. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device so the next transition is to generation of the stop condition.



If 10-bit slave addresses are in use, processing of [2] and [3] is repeated twice.

[4] [4] Steps for continuing with serial transmission:
When transmission is to continue, write further transmit data to TDR register. Except for the first data to be transmitted, a TXI request can activate the DMAC or DTC to handle writing of data to TDR register.
But it cannot be confirmed status of ACK or NACK in this case.

[5] [5] Generation of a stop condition.

Note: In simple I^2C mode, the TXI interrupt request is generated when communication is completed, unlike the timing during clock synchronous transmission.

Figure 42.87 Example of the Procedure for Master Transmission Operations in Simple I^2C Mode (when SIMR.IICINTM Bit is 1, and when Confirming ACK/NACK by Address Transmission Only)

[0] [0] For transmission, set the SCR0.RIE bit to 0 at initialization. (RXI and ERI interrupts requests are disabled)

[1] [1] Generate a start condition.

[2] [2] Writing to TDR register:
Writing the slave address and value for the R/W bit to TDR register.

[3] Confirming ACK response from the slave address:
Check the SISR.IICACKR bit. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device so the next transition is to generation of the stop condition.

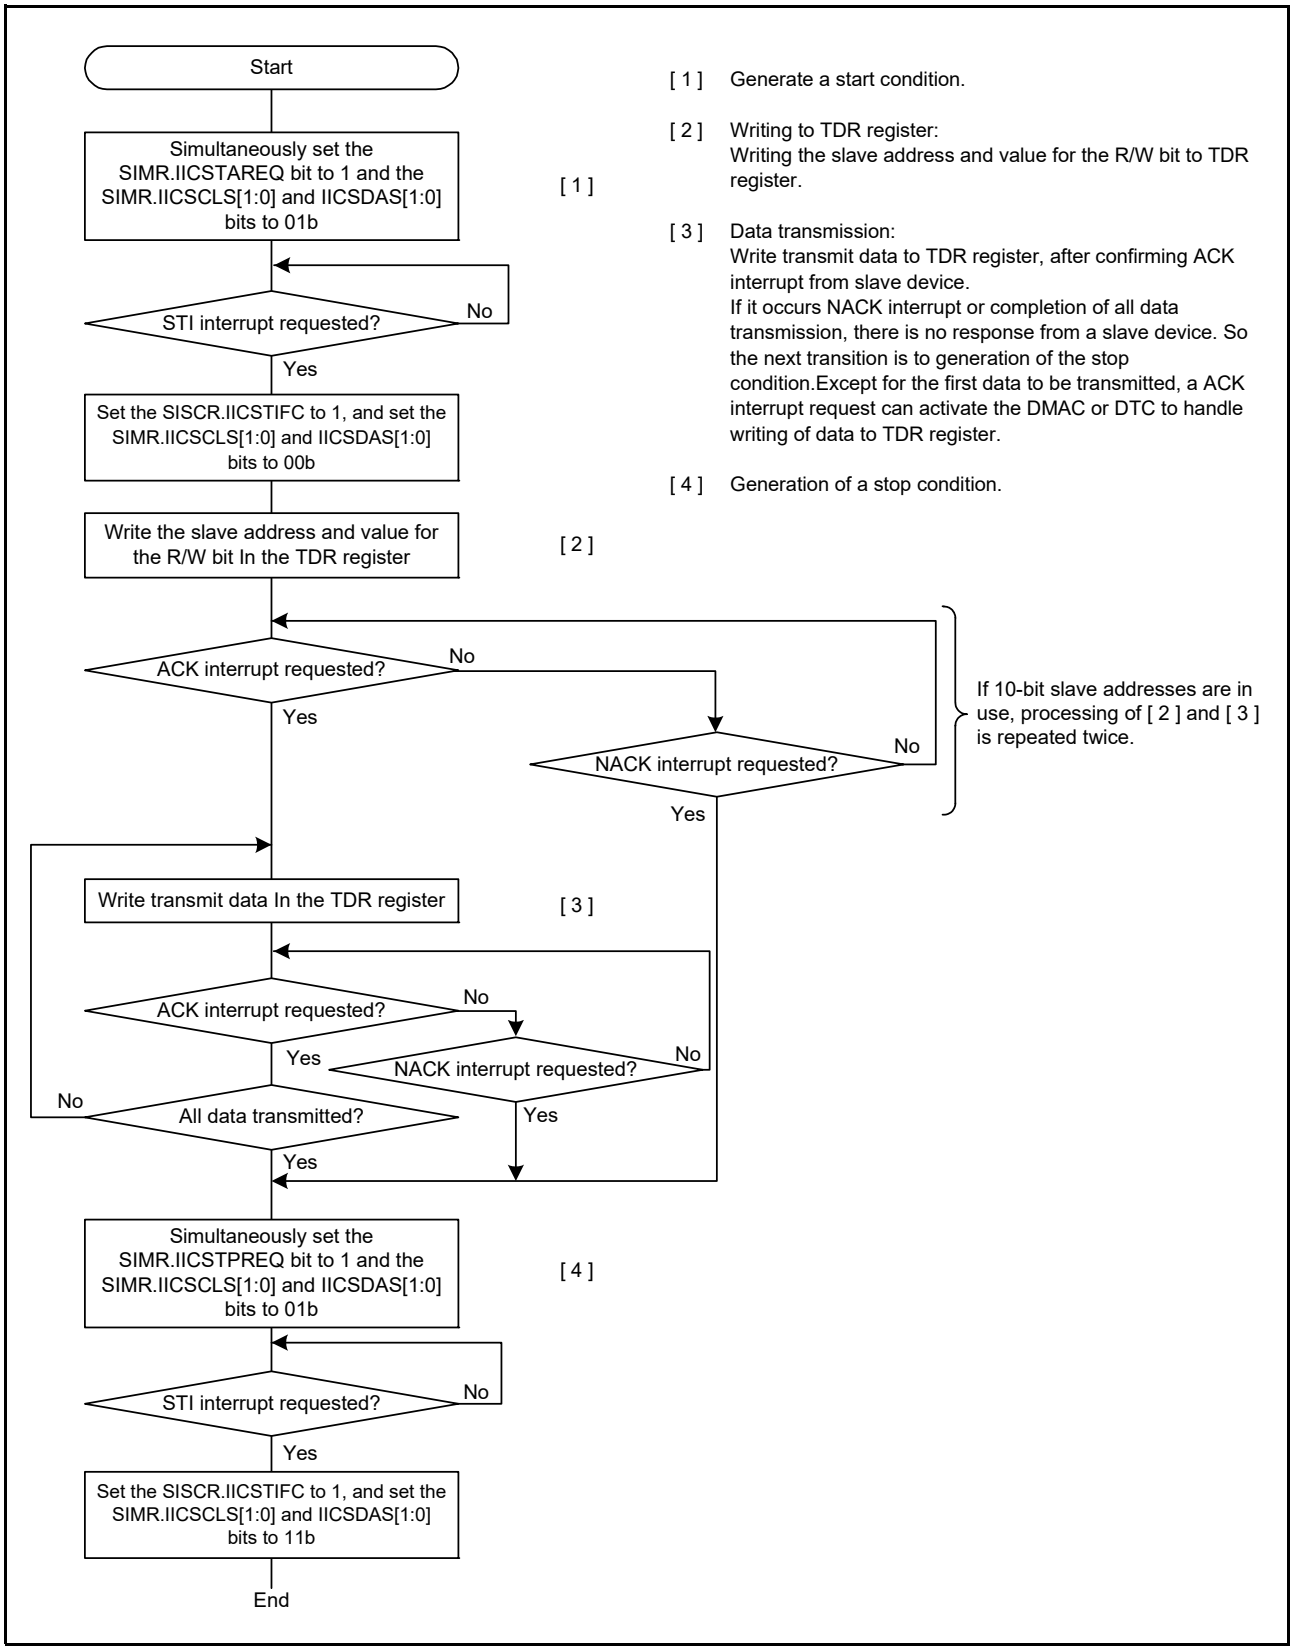
If 10-bit slave addresses are in use, processing of [2] and [3] is repeated twice.

[4] Steps for continuing with serial transmission:
When transmission is to continue, write further transmit data to TDR. To checking whether ACK or NACK in every transmission, you cannot use DMA or DTC.

[5] Generation of a stop condition.

Note: In simple I^2C mode, the TXI interrupt request is generated when communication is completed, unlike the timing during clock synchronous transmission.

Figure 42.88 Example of the Procedure for Master Transmission Operations in Simple I^2C Mode (when SIMR.IICINTM Bit is 1, and when Confirming ACK/NACK in All Transmissions)



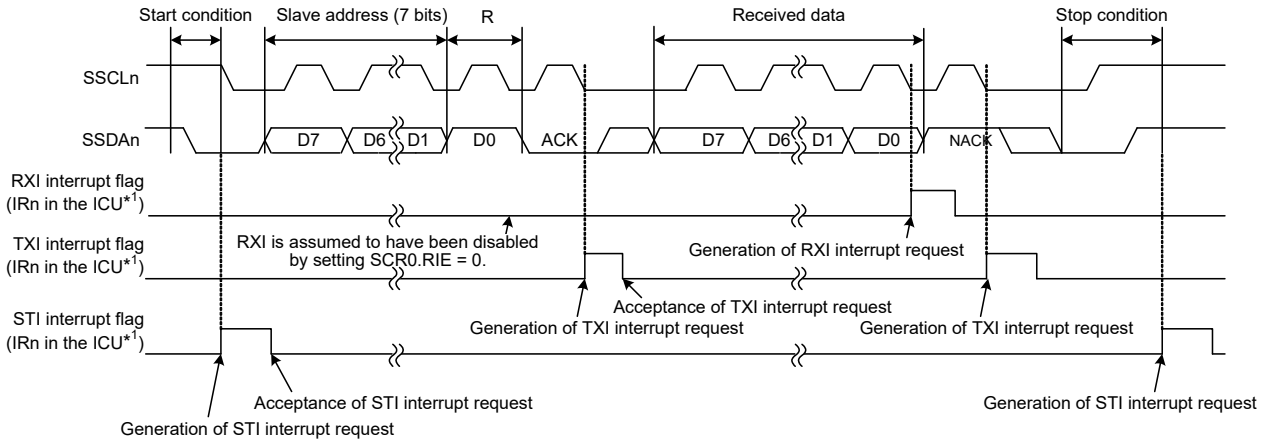


Figure 42.89 Example of the Procedure for Master Transmission Operations in Simple I²C Mode (when SIMR.IICINTM Bit is 0)

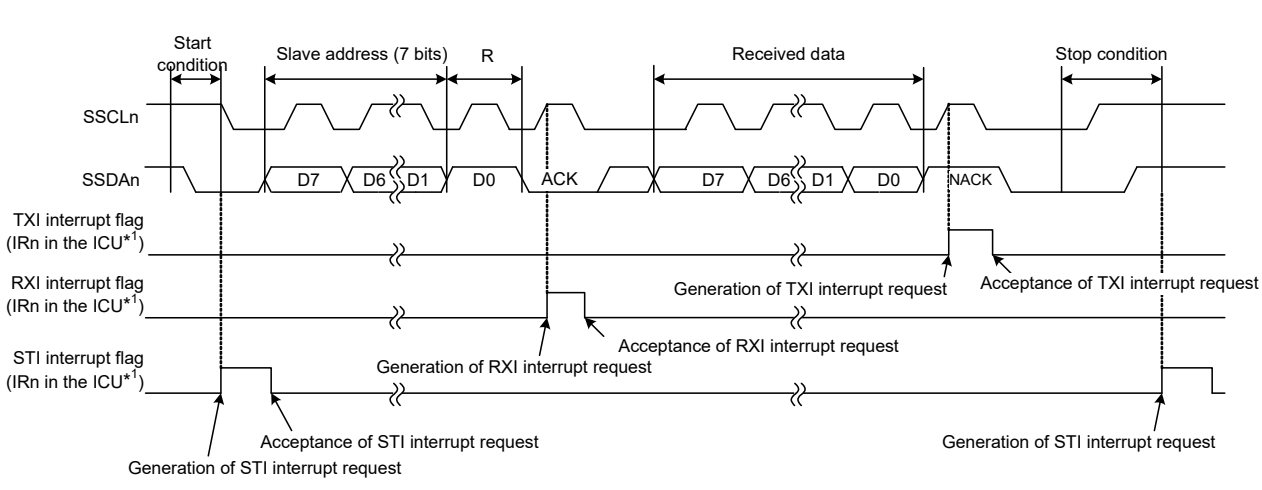

42.9.6 Master Reception (Simple I2C Mode)

Figure 42.90 and Figure 42.91 show example of operations in simple I2C mode master reception. Figure 42.92 and Figure 42.93 show flowchart of the master reception. The value of the SIMR.IICINTM bit is assumed to be 1 (use reception and transmission interrupts) and 0 (use ACK and NACK interrupts).
In simple I2C mode, the transmit end interrupt (TXI) is generated when communication of one frame is completed.

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.90 Example of Operations for Master Reception in Simple I2C Mode (with 7-Bit Slave Addresses, Transmission Interrupts, and Reception Interrupts in Use (SIMR.IICINTM Bit = 1))

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.91 Example of Operations for Master Reception in Simple I2C Mode (with 7-Bit Slave Addresses, ACK and NACK Interrupt in Use (SIMR.IICINTM Bit = 0))

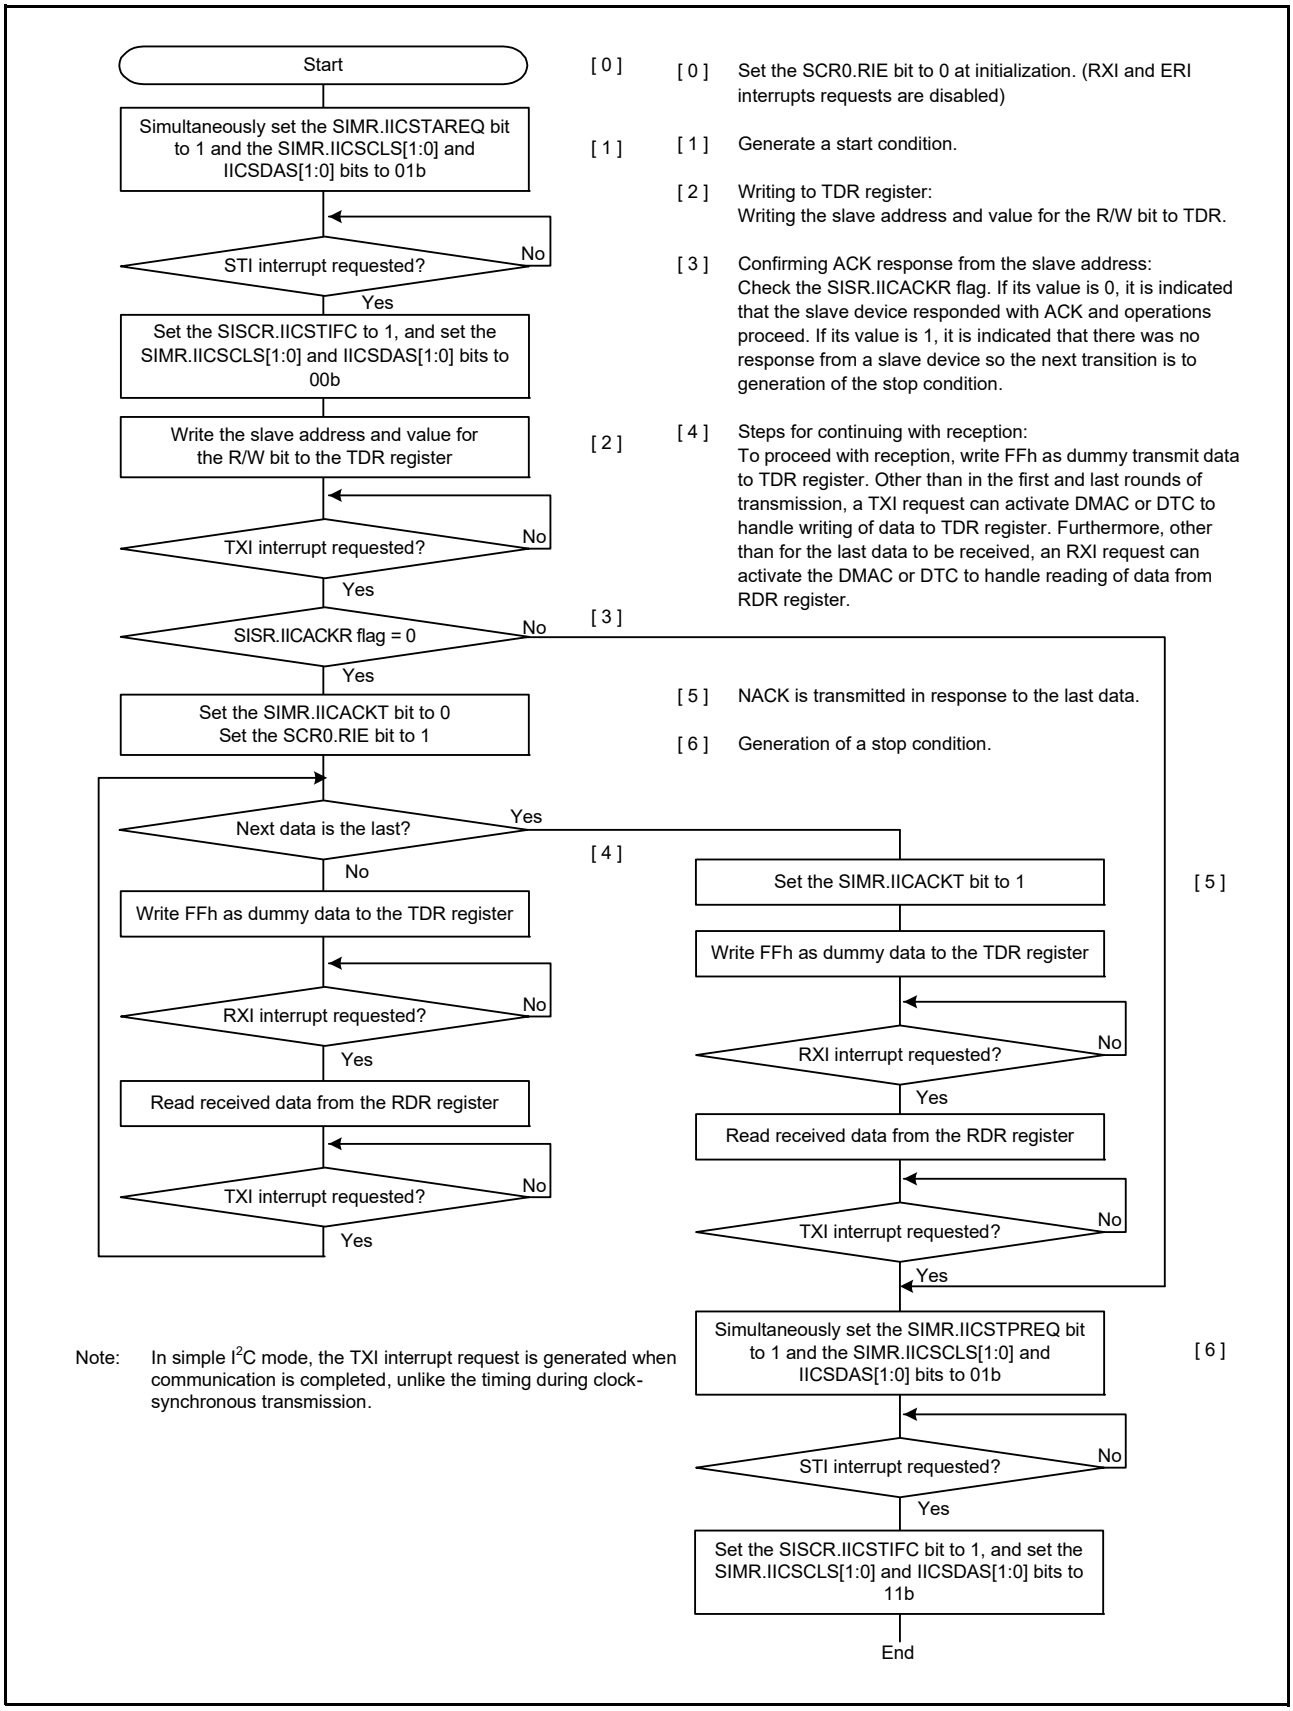

Figure 42.92 Example of the Procedure for Master Reception Operations in Simple I²C Mode (When SIMR.IICINTM Bit is 1, and Transmission Interrupts and Reception Interrupts in Use)

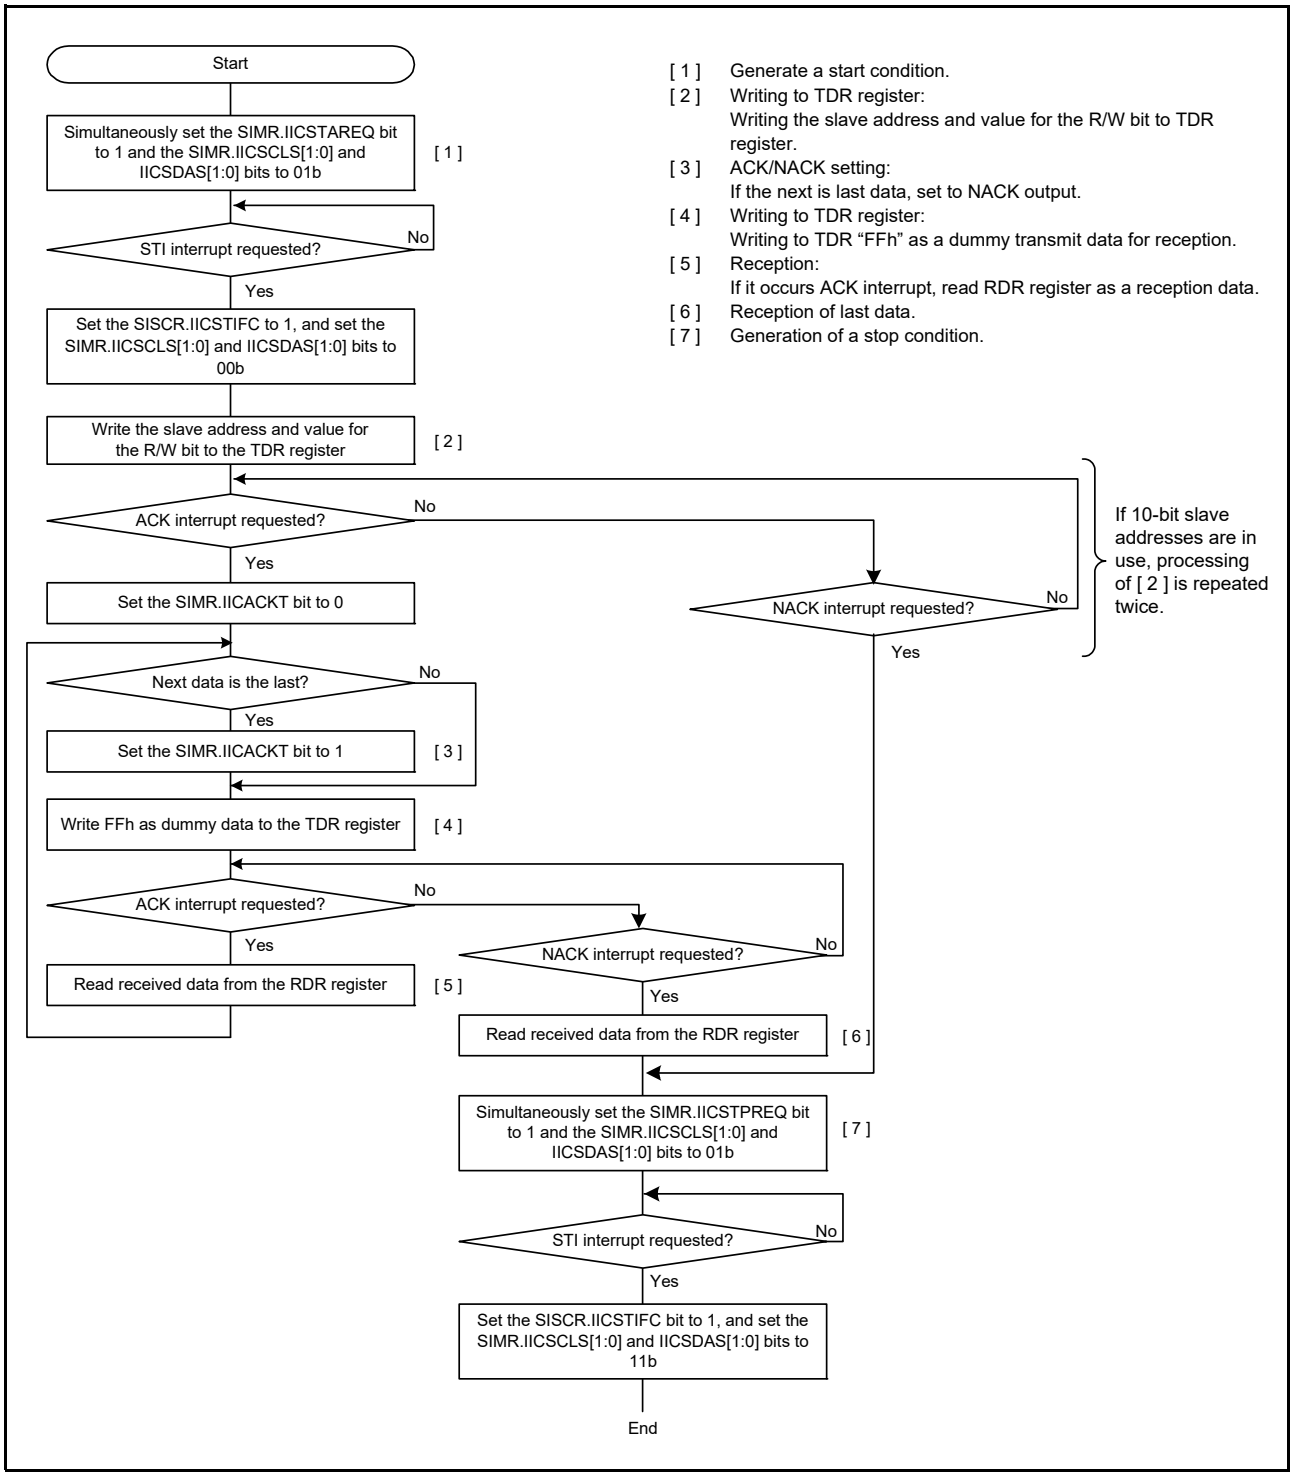

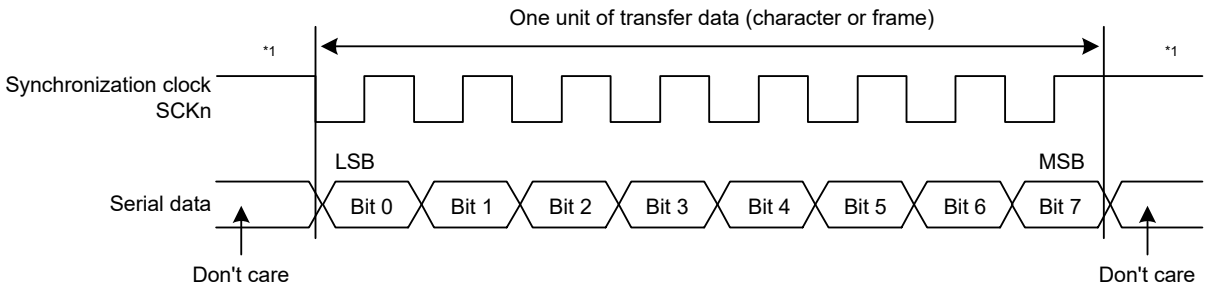

Figure 42.93 Example of the Procedure for Master Reception Operations in Simple I²C Mode (When SIMR.IICINTM Bit is 0, and ACK Interrupts and NACK Interrupts are in Use)

42.10 Operation in Clock Synchronous Mode

Figure 42.94 shows the communication data format of clock synchronous serial communication.
In clock synchronous mode, data is transmitted and received in synchronization with clock pulses. A communication data character consists of 8-bit data. In clock synchronous mode, no parity bit can be added.
In data transmission when CPHA bit = 1 and CPOL bit = 1, the RSCI outputs data from the falling edge of the sync clock until the next falling edge. In data reception, data is read at the rising edges of the sync clock. After 8-bit data is output, the communication line holds the final-bit output state. In slave communication when CPHA bit = 0, however, the communication line holds the first-bit output state.
Because the RSCI has an internal transmitter and a receiver independently, RSCI enable full-duplex communication by sharing a communication clock of the transmitter and the receiver. Furthermore, because both the transmitter and the receiver have a double- buffer structure, continuous transmission and reception are possible by writing the next transmit data during transmission and reading the previous receive data during reception.

Note 1. Holds a high level except during continuous transfer or reception.

Figure 42.94 Data Format in Clock Synchronous Serial Communications (LSB First, CPHA Bit = 1, CPOL Bit = 1)

42.10.1 Clock

When using the SCKn at its highest frequency (= 1/2 TCLK), the PCLK frequency should be at least 1/2 the TCLK frequency.

(1) When the Internal Clock is Selected

When the SCR3.CKE[1:0] bits are set to 00b or 01b (master mode), the internal clock generated by the on-chip baud rate generator can be selected and the sync clock is output from the SCKn pin. Eight pulses of the sync clock are output during single-character transmission/reception. The sync clock remains at a high level*1 while no transmission or reception is performed. In transmission-only or transmission/reception, the sync clock is not output unless transmit data is prepared.
When the internal clock is selected, the clock with a delay from the SCKn signal is used for the master reception sampling clock. This ensures the data setup time and hold time for high-speed communication.

Note 1. When SCR3.CPHA bit = 0 and SCR3.CPOL bit = 1 or when SCR3.CPHA bit = 1 and SCR3.CPOL bit = 1, the sync clock stops at a high level. When SCR3.CPHA bit = 0 and SCR3.CPOL bit = 0 or when SCR3.CPHA bit = 1 and SCR3.CPOL bit = 0, the sync clock stops at a low level.

(2) When the External Clock is Selected

When the SCR3.CKE[1:0] bits are set to 10b or 11b (slave mode), data is transmitted and received using the external clock that is input from the SCKn pin.

42.10.2 CTS and RTS Functions

The CTS function performs transmission/reception and controls transmission start using the CTSn# pin input when the internal clock is selected. Setting the SCR1.CTSE bit to 1 enables the CTS function. In clock synchronous communication, the CTS function can be used for the internal clock and the RTS function can be used for the external clock, so the CTS function and RTS function cannot be used at the same time.
When the CTS function is enabled, transmission/reception and transmission start only when the CTSn# pin input level is low.
When using the FIFO, if the CTSn# signal remains high before transmission, transmission will not start, but the number of data stored will be “number written to the TDR register – 1” (unlike using FIFO in asynchronous mode). This is because data is transferred to the TSR register after writing to the TDR register, but if the CTSn# signal is set to low level, transmission starts from the TSR register, so there is no problem.
Even if the CTSn# pin input becomes high level during transmission/reception or transmission operation, frames that are being transmitted/received or being transmitted are not affected and transmission/reception or transmission operation continues.
The RTS function makes a serial communication start request using the RTSn# pin output when the external sync clock is selected. When serial communication is enabled, the RTSn# pin outputs a low level. A low level and a high level are output under the following conditions.

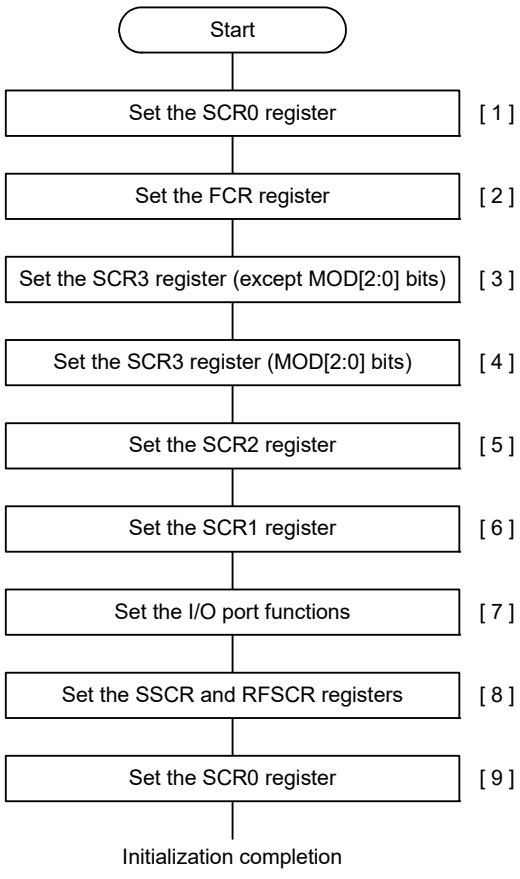
(a) When the SCR3.FM Bit is 0 (Non-FIFO Mode)

[Conditions for low-level output]
When the following conditions are all satisfied

- The SCR0.RE or SCR0.TE bit is 1
- No receive data are present before reading and reception is not in progress. (when SCR0.RE bit = 1)
- Data written in the TDR register is ready for transmission (when SCR0.TE bit = 1)
- The SSR.ORER flag is 0

[Condition for high-level output]
The conditions for low-level output have not been satisfied.
When SCR0.RE bit is set to 0 without reading the RDR register to terminate reception after reception is complete, the RTSn# pin output level remains high. At this time, write 0 to SCR0.RE bit.

(b) When the SCR3.FM Bit is 1 (FIFO Mode)



[Conditions for low-level output]
When the following conditions are all satisfied

- The SCR0.RE or SCR0.TE bit is 1
- The number of receive data stored in the receive FIFO (RDR register) is less than the value set in FCR.RSTRG[4:0] (when SCR0.RE bit = 1)
- Data written in the transmit FIFO (TDR register) is ready for transmission (when SCR0.TE bit = 1)
- The SSR.ORER flag is 0

[Condition for high-level output]
When the conditions for low-level output are not satisfied

42.10.3 RSCI Initialization (Clock Synchronous Mode)

Before starting data transmission/reception, write 0 to SCR0.TE bit and SCR0.RE bit (or write initial values to the SCR0 register) and initialize the RSCI according to the flowchart example in Figure 42.95.
Before changing operating mode or communication format, also be sure to write 0 to TE bit and RE bit.
Note that writing 0 to the RE bit does not initialize the ORER, AFER, APER, and RDRF flags in SSR register and the RDR register. Also note that writing 0 to the TE bit does not initialize the SSR.TEND flag in FIFO mode. Attention is also needed for changing operating mode.
When the SCR0.TIE bit = 1, note that setting the TE bit to 1 from 0 generates a TXI interrupt.

[1] Set the following bits of SCR0 register to 0[*1].
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set the TFRST and RFRST bits to 1 to empty FIFO.
Set the TTRG[4:0], RTRG[4:0], and RSTRG[4:0] bits.

[3] Set SCR3 except of communication mode.
FIFO use/no-use
Transmission/reception format
Clock setting
Leave unused bits (CHR[1:0], STOP, RXDESEL, MP, DEEN, GM, BLK) at their initial values.[*2]

[4] Set communication mode (MOD[2:0] bits = 010b)[*2].

[5] Select clock, set bit rate[*3]. Leave unused bits (SCR2.BCP[2:0], ABCS, ABCSE, ABCSE2, BRME, and MDDR[7:0]) at their initial values.

[6] Set up the half-duplex communication, the loop-back function, communication pin status, and the CTS/RTS function.

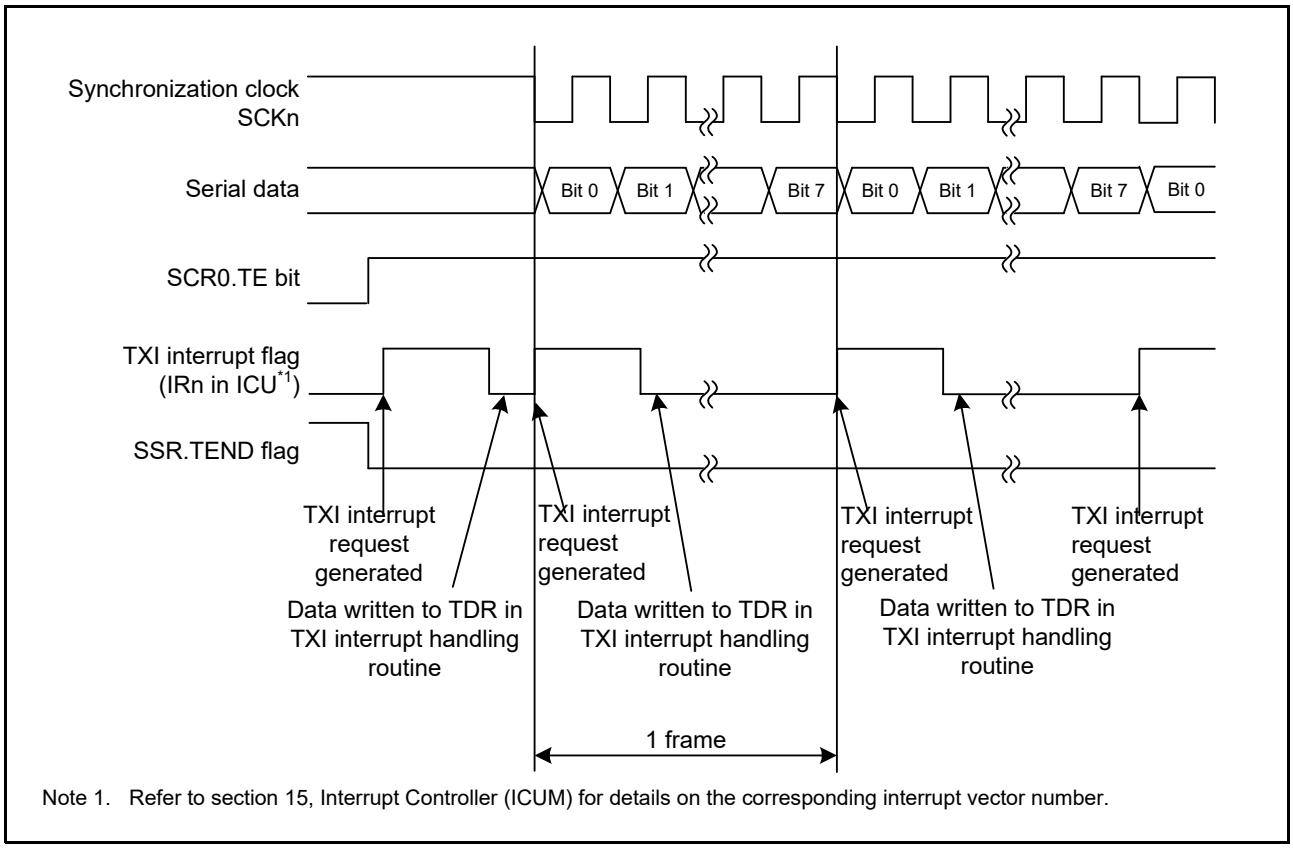
[7] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.

[8] Write 1 to the following bits to clear the corresponding flag.
SSCR.RDRFC, AFERC, APERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
RFSCR.DRC

[9] Set the TE or RE bit to 1.[*1, *4] To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time.
Setting the TE and RE bits allows TXDn and RXDn to be used.

Note 1. In simultaneous transmit and receive operations, the TE and RE bits in SCR0 should both be to 0 or set to 1 simultaneously.
Note 2. Set the clock (CPOL and CPHA bits) before setting the communication mode.
Note 3. If you use an external clock, you do not need to set it.
Note 4. When using the internal clock (master), the setting of reception only is prohibited.

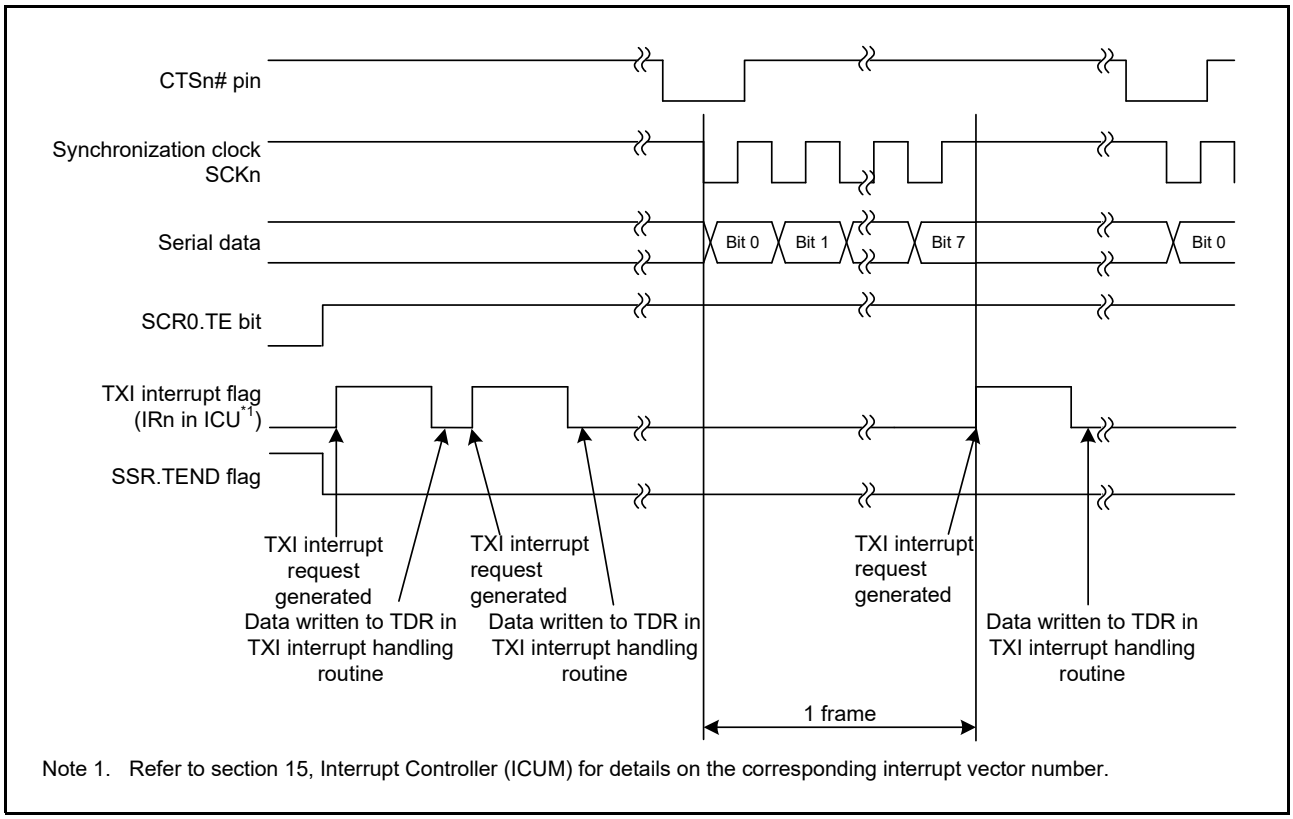
Figure 42.95 Example of RSCI Initialization Flowchart (Clock Synchronous Mode)



42.10.4 Serial Data Transmission (Clock Synchronous Mode)

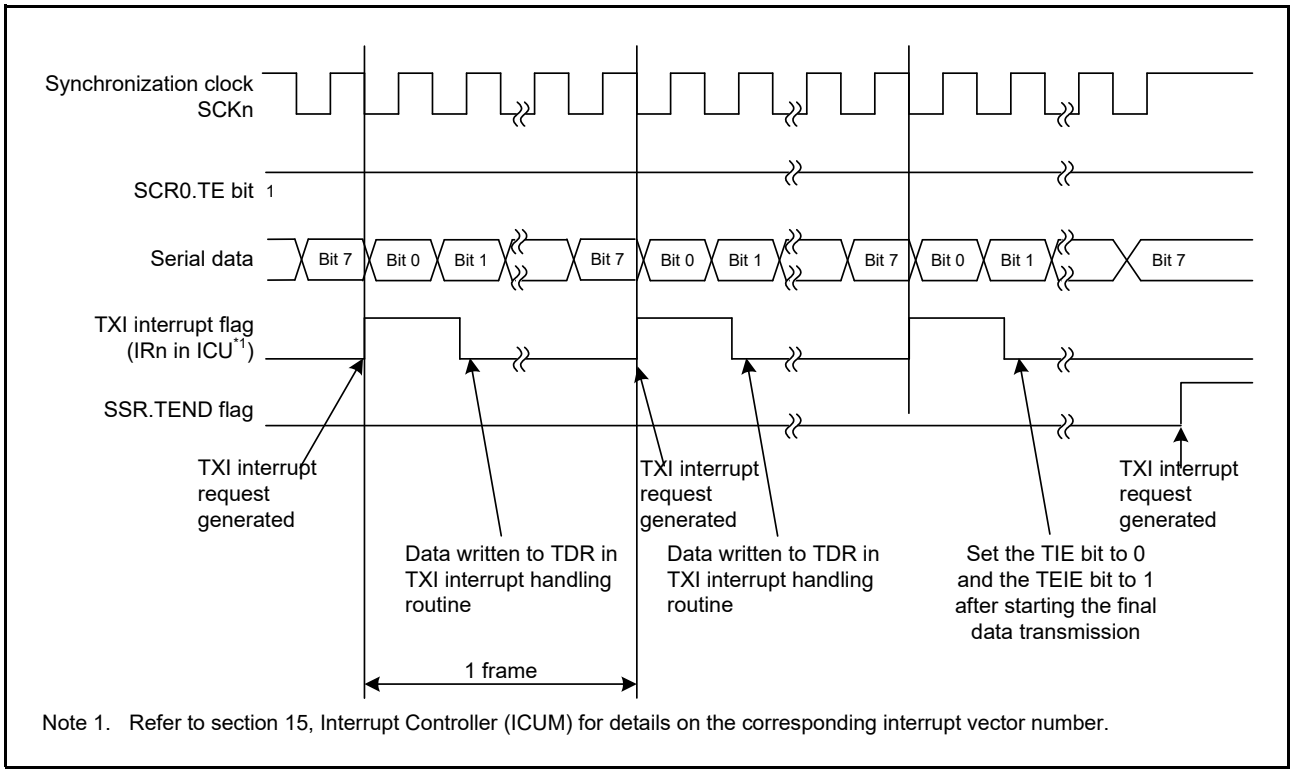
(1) Non-FIFO Mode

Figure 42.96 to Figure 42.98 show an example of the operation for serial transmission in clock synchronous mode. In serial data transmission, the RSCI operates as described below.



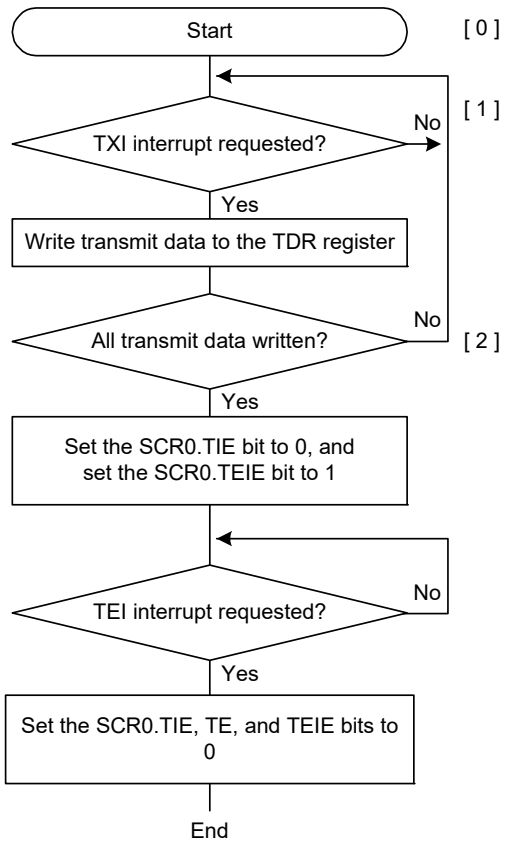
1. When data is written to the TDR register in the TXI interrupt routine, the RSCI transfers the data from the TDR register to the TSR register. When starting data transmission, set the SCR0.TIE bit and the SCR0.TE bit to 1 simultaneously by a single instruction. Then a TXI interrupt request is generated.
2. The written data is transferred from the TDR register to the TSR register, which starts transmission. When the SCR0.TIE bit is set to 1 at this time, a TXI interrupt request is generated. Writing the next transmit data to the TDR register before transmission of data transferred previously in the TXI interrupt routine is complete enables continuous transmission. When a TEI interrupt request is used, after the final transmit data is written to the TDR register in the TXI interrupt request processing routine and the final data's transmission is started, set 0 to the SCR0.TIE bit and set 1 to the TEIE bit.
3. The TXDn pin outputs 8-bit data in synchronization with the output clock (in clock output mode) or with the input clock (when external clock is selected). When the SCR1.CTSE bit = 1 (CTS function enabled), the output clock starts after the CTS signal input becomes low level.
4. Update (data write) of the TDR register is checked at the final-bit transmission timing.
5. When the TDR register has been updated, data is transferred from the TDR register to the TSR register to start sending the next frame.
6. If the TDR register has not been updated, the SSR.TEND flag is set to 1 and the final-bit output state is retained. When the SCR0.TEIE bit is set to 1 at this time, a TEI interrupt request is generated. The SCKn pin is held high.

Figure 42.99 shows a sample flowchart of serial data transmission.



Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.96 Serial Transmission Example in Clock Synchronous Mode (1) (CTS Function Not Used/ Transmission Start/CPHA Bit = 1, CPOL Bit = 1)



Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.97 Serial Transmission Example in Clock Synchronous Mode (2) (CTS Function Used/Transmission Start/CPHA Bit = 1, CPOL Bit = 1)

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.98 Serial Transmission Example in Clock Synchronous Mode (3) (During Transmission to Transmission End/CPHA Bit = 1, CPOL Bit = 1)

[0] Set the SCR0.TE and TIE bits to 1 at initialization.

[1] Writing transmit data to TDR register by a TXI interrupt request:
The transmit data empty interrupt (TXI) is generated when transmission data forwards to TSR from TDR register. Write transmit data to TDR register once in the TXI interrupt handling routine.

[2] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR register in the TXI interrupt handling routine. Transmit data can also be written by activating the DMAC or DTC.
If you use TEI interrupt request, set SCR0.TIE bit to 0 and TEIE bit to 1 after writing the last transmit data to TDR register.

Note: When the external clock is in use (the value of the SCR3.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR.TEND flag to 1. Setting SCR0.TE bit to 0 immediately after this, then it may lead to insufficient received data hold time on the receiver side.

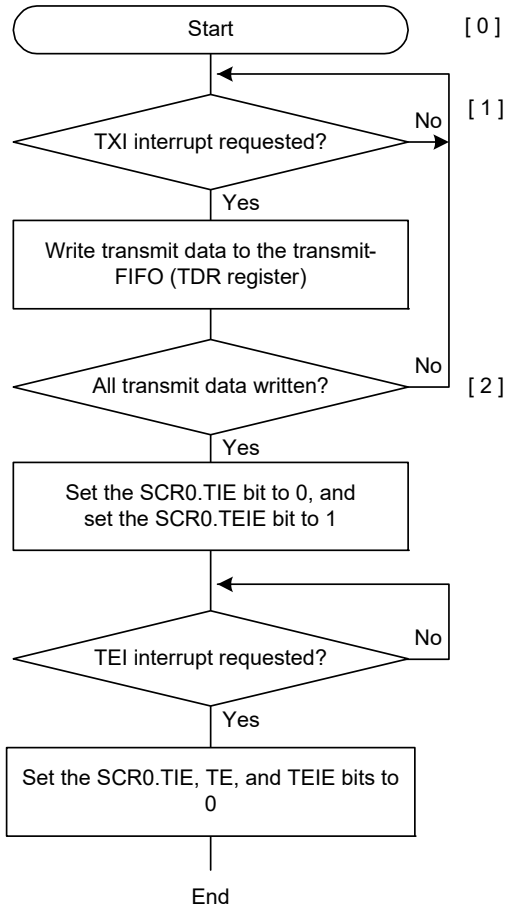


Figure 42.99 Example Flowchart of Serial Transmission in Clock Synchronous Mode (Non-FIFO Mode)

(2) FIFO Mode

Figure 42.100 shows an example of flowchart of serial transmission (a FIFO buffer selected) in clock synchronous mode with FIFO enabled.
The RSCI operates as follows when serial data transmission.

1. When data is written to the transmit FIFO (TDR register) in the TXI interrupt routine, the RSCI transfers the data from the transmit FIFO (TDR register) to the TSR register. The number of writable transmit data is [16 – number of unsent transmit data stored in the transmit FIFO (TDR register)]. If the SCR0.TIE and SCR0.TE bits are simultaneously set to 1 at the start of data transmission, a TXI interrupt request is generated.
2. Data is transferred from the transmit FIFO (TDR register) to the TSR register and transmission starts. When the number of data stored in the transmit FIFO (TDR register) is equal to or less than the threshold value of the transmit FIFO, the SSR.TDRE flag is set to 1. When the SCR0.TIE bit is set to 1 at this time, a TXI interrupt request is generated. Writing the next transmit data to the transmit FIFO (TDR register) in the TXI interrupt routine before transmission of data written to the transmit FIFO (TDR register) is complete enables continuous transmission. When a TEI interrupt request is used, after the final transmit data is written to the transmit FIFO (TDR register) in the TXI interrupt request processing routine, set 0 to the SCR0.TIE bit and set 1 to the TEIE bit.
3. The TXDn pin outputs 8-bit data in synchronization with the output clock (in clock output mode) or with the input clock (when external clock is selected). When the SCR1.CTSE bit = 1 (CTS function enabled), the output clock starts after the CTSn# pin input becomes low level.
4. The RSCI checks whether unsent transmit data is remaining in the transmit FIFO (TDR register)*1 at the final-bit transmission timing.
5. When data is remaining in the transmit FIFO (TDR register), the data is transferred from the transmit FIFO (TDR register) to the TSR register to start sending the next frame.
6. If no data is remaining in the transmit FIFO (TDR register), the SSR.TEND flag is set to 1 and the final-bit output state is retained. When the SCR0.TEIE bit is set to 1 at this time, a TEI interrupt request is generated. The SCKn pin is held high.

Note 1. The number of unsent transmit data stored in the TDR register (transmit FIFO) can be monitored by reading the TFSR.T[5:0] bits.

[0] Set the SCR0.TE and TIE bits to 1 at initialization.

[1] Writing transmit data to transmit FIFO (TDR) by a TXI interrupt request:
The transmit data empty interrupt (TXI) is generated when transmission data forwards to TSR from the transmit FIFO (TDR register) and the number of transmit-data written in the transmit FIFO is equal to or less than the transmit FIFO threshold.

[2] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to the transmit FIFO (TDR register) by using a TXI interrupt and clear the SSR.TDRE flag to 0.
The number of transmission data it's possible to write in is 16 minus (the number of stored data in transmit FIFO).
Transmit data can also be written to the transmit FIFO (TDR register) by activating the DMAC or DTC by TXI interrupt request. In this case, the TDRE flag is cleared automatically, so please don't operate the TDRE flag.
If you use TEI, set TIE bit to 0 and TEIE bit to 1 after writing the last transmit data to TDR register.

Note: When the external clock is in use (the value of the CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR.TEND flag to 1. Setting SCR0.TE bit to 0 immediately after this, then it may lead to insufficient received data hold time on the receiver side.

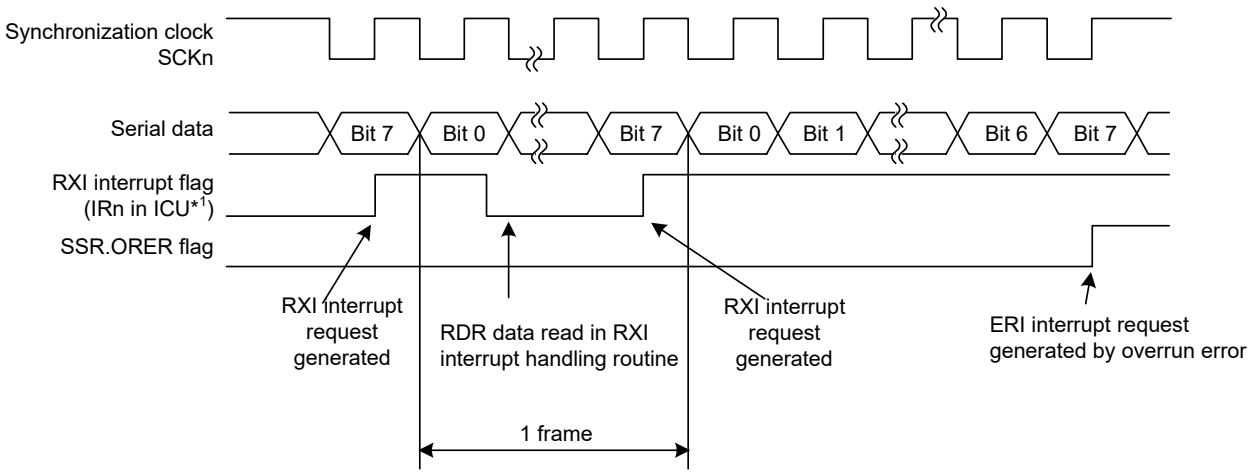

Figure 42.100 Example Flowchart of Serial Transmission in Clock Synchronous Mode (FIFO Mode)

42.10.5 Serial Data Reception (Clock Synchronous Mode)

(1) Non-FIFO Mode

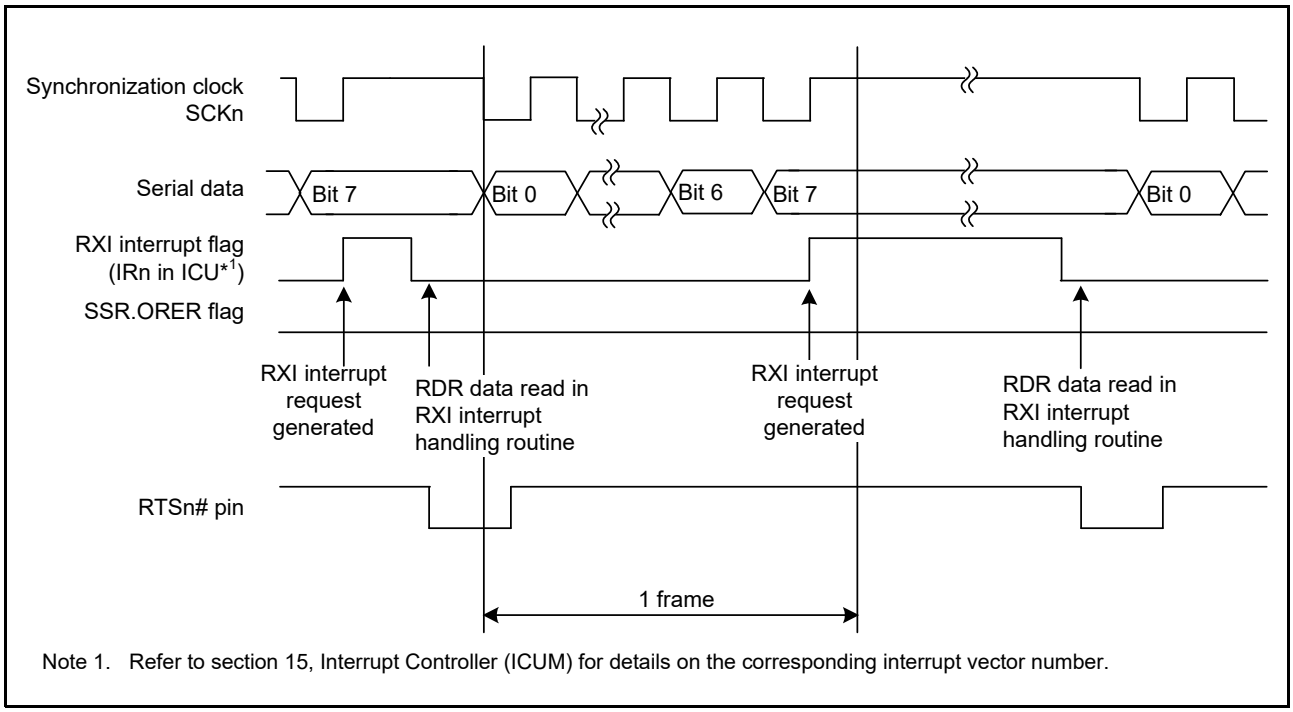

Figure 42.101 and Figure 42.102 show operation examples of serial data reception in clock synchronous mode.
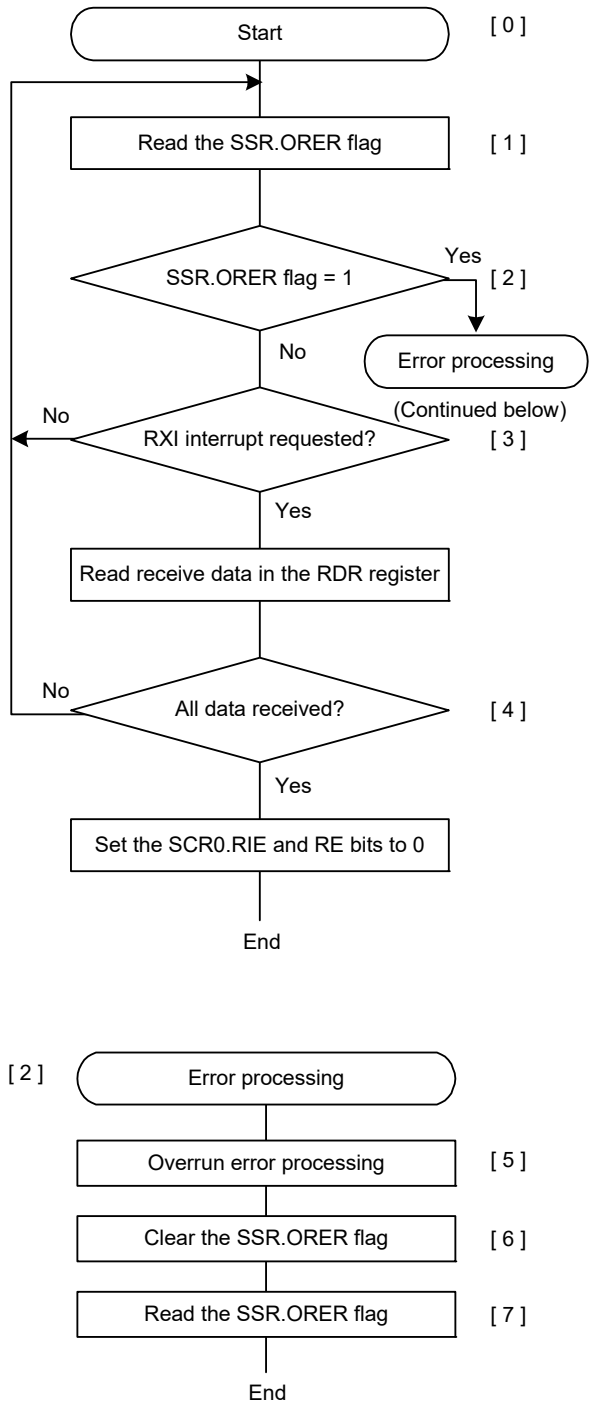
The RSCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

1. When the SCR0.RE bit is set to 1, the RTSn# pin output becomes low (when the RTS function is used).
2. The RSCI starts data reception in synchronization with input or output of the sync clock, and transfers receive data to the RSR register.
3. When an overrun error occurs, the SSR.ORER flag is set to 1. When the SCR0.RIE bit = 1 at this time, an ERI interrupt request is generated and the received data is not transferred to the RDR register.
4. When data is normally received, the received data is transferred to the RDR register. When the RIE bit = 1 at this time, an RXI interrupt request is generated. Reading the received data transferred to the RDR register in the RXI interrupt handling routine before the next data is completely received enables continuous reception. When the received data transferred to the RDR register is read, the RTSn# pin output becomes low (when the RTS function is used).
   If you want to prevent the RTSn# pin output from turning low after the final data is received, clear the SCR0.RE bit to 0 and then read the RDR register.

Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.101 Example of Operation for Serial Reception in Clock Synchronous Mode (1)
(When RTS Function is Not Used/CPHA Bit = 1, CPOL Bit = 1)



Note 1. Refer to section 15, Interrupt Controller (ICUM) for details on the corresponding interrupt vector number.

Figure 42.102 Example of Operation for Serial Reception in Clock Synchronous Mode (2) (When RTS Function is Used/CPHA Bit = 1, CPOL Bit = 1)

While the reception error flag is set to 1, subsequent reception are disabled. Therefore, before continuing reception, be sure to clear the ORER, AFER, and APER flag in SSR to 0. Also be sure to read the RDR register in the overrun error processing. If the SCR0.RE bit is set to 0 during reception to forcibly terminate the reception operation, unread receive data may be remaining in the RDR register. In this case, read the RDR register.

Figure 42.103 shows a sample flowchart for serial data reception.

[0] Set the SCR0.RE and RIE bits to 1 at initialization.

[1][2]Receive error processing:
If a receive error occurs, after performing the appropriate error processing, be sure to ORER flag is 0. Reception cannot be resumed if ORER flag is 1.

[3] Read the receive data in the RDR register once in the receive data full interrupt (RXI) request handling routine.

[4] Serial reception continuation procedure:
To continue serial reception, before the MSB (bit 7) of the current frame is received, read data from RDR register in the RXI interrupt handling routine. The RDR data can also be read by activating the DMAC or DTC by the receive data full interrupt (RXI) request.

[5] Overrun error processing:
Read the RDR register.

[6] Clearing the error flag:
Set the flag clear bit corresponding to the reception error to 1. Done this step and step [5], the next frame can be received normally.

[7] Confirming that the error flag is cleared:
Confirm all error flags are cleared.

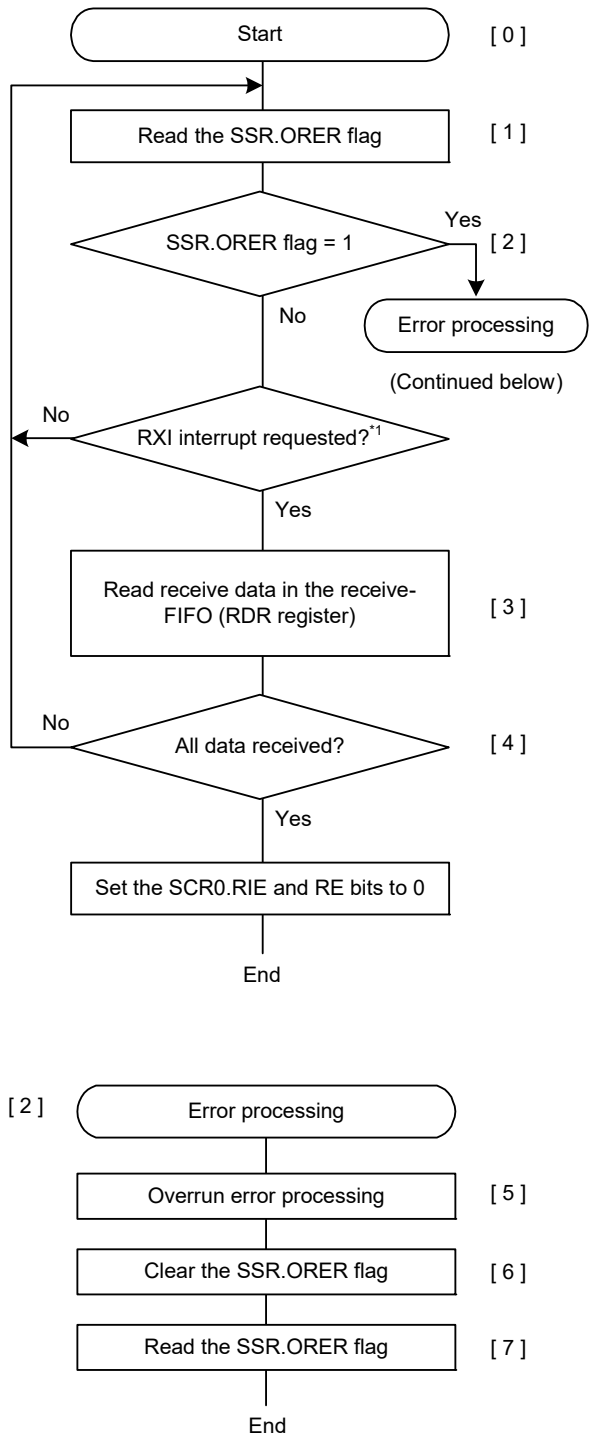


Figure 42.103 Example Flowchart of Serial Reception in Clock Synchronous Mode (Non-FIFO Mode)

(2) FIFO Mode

Figure 42.104 shows an example of serial data reception flowchart in clock synchronous mode with FIFO enabled. The RSCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

1. When the SCR0.RE bit is set to 1, the RTSn# pin output turns low (when the RTS function is used).
2. The RSCI starts receiving data in synchronization with input or output of the sync clock, and transfers the received data to the receive FIFO (RDR register).
3. When an overrun error occurs, the SSR.ORER flag is set to 1. When the SCR0.RIE bit = 1 at this time, an ERI interrupt request is generated and the received data is not transferred to the receive FIFO (RDR register)*1.
4. When data is normally received, the received data is transferred to the receive FIFO (RDR register)*1. When the number of receive data stored in the receive FIFO (RDR register) is equal to or more than the threshold value of the receive FIFO, the SSR.RDRF flag is set to 1. When the RIE bit = 1 at this time, an RXI interrupt request is generated. Reading the received data transferred to the receive FIFO (RDR register) in the RXI interrupt handling routine before an overrun error occurs enables continuous reception. When the received data transferred to the receive FIFO (RDR register) is read and the number of data becomes lower than the RTS# output threshold value, the RTSn# pin output becomes low (when the RTS function is used).

Note 1. The RDR.RDAT[8] bit is not used.

[0] Set the SCR0.RE and RIE bits to 1 at initialization.

[1][2]Receive error processing:
If a receive error occurs, after performing the appropriate error processing, be sure to ORER flag is 0. Reception cannot be resumed if ORER flag is 1.

[3] Read the receive data in the receive FIFO (RDR register) in the RXI interrupt handling routine. The reception data stored in the receive FIFO (RDR register) is read until the number of stored data will be below the FCR.RTRG[4:0] value at least. When the RDR register is read, the SSR.RDRF flag is cleared. You can confirm the number of the reception data in the FIFO by RFSR.R[5:0] bits.

[4] Serial reception continuation procedure:
To continue serial reception, before the overrun error occurs, read data from RDR register. The RDR data can also be read by activating the DMAC or DTC by the receive data full interrupt (RXI) request.

Note 1. Set all received data to an integer multiple of the receive FIFO threshold. If it is not an integral multiple, an RXI interrupt is not generated and it will become an infinite loop, so set a timeout time separately using a timer etc.

[5] Overrun error processing:
Read the RDR register.

[6] Clearing the error flag:
Set the flag clear bit corresponding to the reception error to 1. Done this step and step [5], the next frame can be received normally.

[7] Confirming that the error flag is cleared:
Confirm all error flags are cleared.

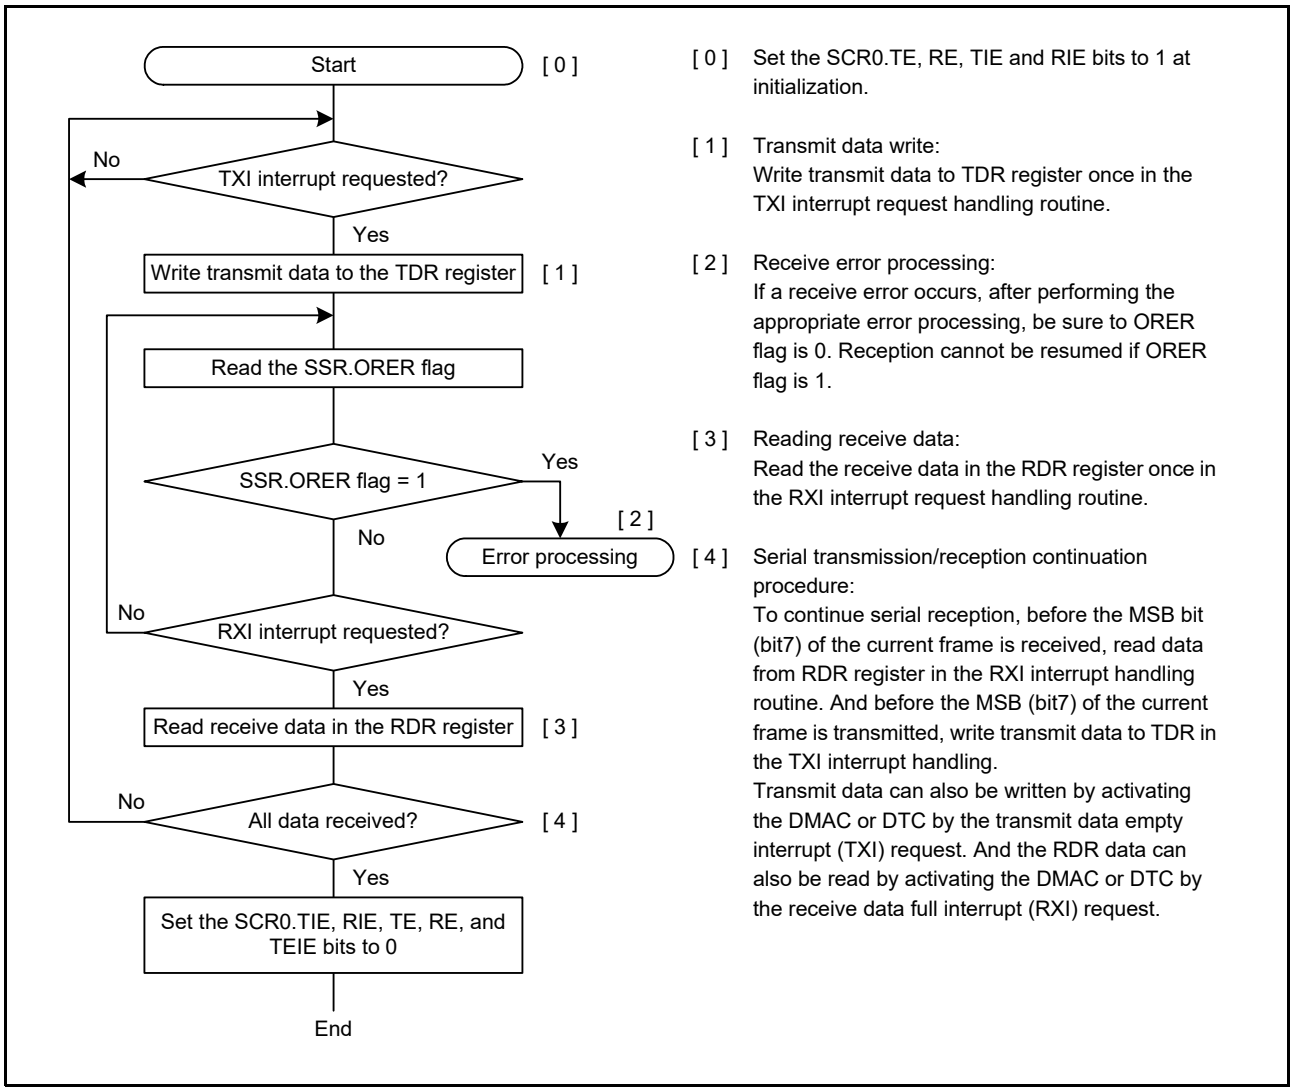
Figure 42.104 Example Flowchart of Serial Reception in Clock Synchronous Mode (FIFO Mode)

42.10.6 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

In clock synchronous mode, transmission and reception are simultaneously performed, so the number of transmitted data and the number of received data are the same.

(1) Non-FIFO Mode

Figure 42.105 shows an example of serial data concurrent transmission/reception flowchart in clock synchronous mode.
After the RSCI is initialized, perform the following procedure for serial data concurrent transmission/reception.
When switching mode from transmission to concurrent transmission/reception, check that the SSR.TEND flag is set to 1 to ensure that the RSCI is in the transmission complete state. Then set SCR0.TE bit = 0 and RE bit = 0 and then set the TE, RE, TIE, and RIE bits in SCR0 register to 1 simultaneously by a single instruction.
When switching mode from reception to concurrent transmission/reception, check that the RSCI is in the reception complete state, and then set SCR0.TE bit = 0 and RE bit = 0. After that, check that the error flags (ORER, AFER, and APER flags) in SSR are cleared to 0, and then set the TE, RE, TIE, and RIE bits in SCR0 register to 1 simultaneously by a single instruction.
When the RTS function is used in the concurrent transmission/reception operation, if you want to prevent the RTSn# pin output from turning to low after the final data is received as in the reception operation, clear the RE and TE bits in SCR0 register to 0 simultaneously, and then read the RDR register.



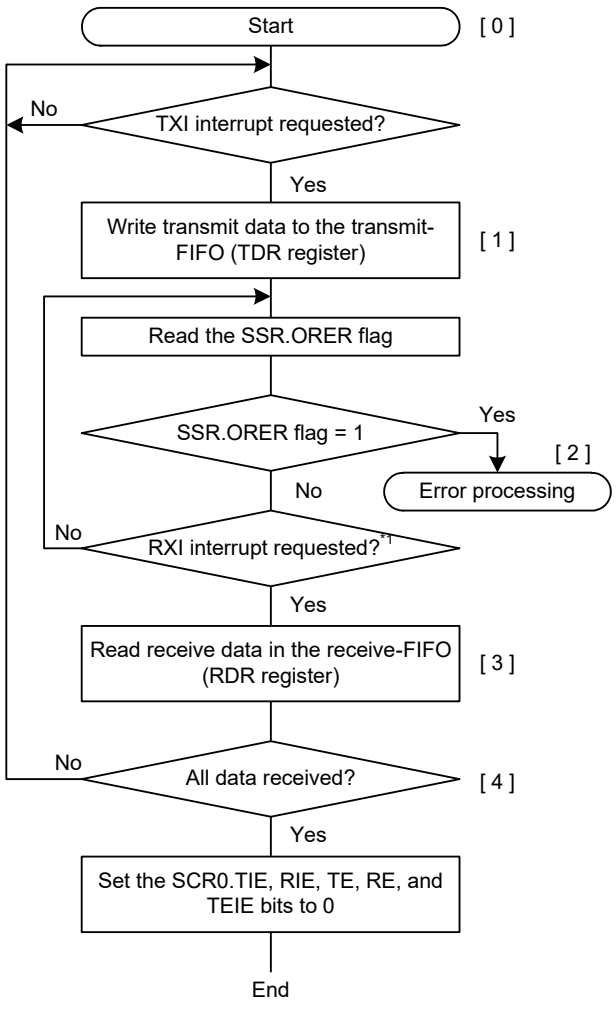


Figure 42.105 Example Flowchart of Simultaneous Serial Transmission and Reception in Clock Synchronous Mode (Non-FIFO Mode)

(2) FIFO Mode

Figure 42.106 shows an example of serial data concurrent transmission/reception flowchart in clock synchronous mode with FIFO enabled.

After the RSCI is initialized, perform the following procedure for serial data concurrent transmission/reception.When switching mode from transmission to concurrent transmission/reception, check that the SSR.TEND flag is set to 1 to ensure that the RSCI is in the transmission complete state. Then set SCR0.TE bit = 0 and RE bit = 0 and then set the TE, RE, TIE, and RIE bits in SCR0 register to 1 simultaneously by a single instruction.

When switching mode from reception to concurrent transmission/reception, check that the RSCI is in the reception complete state, and then set SCR0.TE bit = 0 and RE bit = 0. After that, check that the error flags (ORER, AFER, and APER flags) in SSR are cleared to 0, and then set the TE, RE, TIE, and RIE bits in SCR0 to 1 simultaneously by a single instruction.

Note 1. Set the number of all received data to an integer multiple of the receive FIFO threshold. If it is not an integral multiple, an RXI interrupt is not generated and it will become an infinite loop, so set a timeout time separately using a timer etc.

[0] Set the SCR0.TE, RE, TIE and RIE bits to 1 at initialization.

[1] Transmit data write:
Write transmit data to transmit FIFO (TDR register) in the TXI Interrupt request handling routine. The number of data to be written should match the number specified in the receive FIFO threshold.

[2] Receive error processing:
If a receive error occurs, read the SSR.ORER flag, perform the appropriate error processing such as stopping communication and reading all received data to clear the SSR.RDRF flag, and then set the ORER flag to 0. Reception cannot be resumed if ORER flag is 1.

[3] Reading receive data:
Read the same number of received data stored in the receive FIFO (RDR register) as the number specified in the receive FIFO threshold.

[4] Serial transmission/reception continuation procedure:
To continue serial reception, before the overrun error occurs, read data from the receive FIFO (RDR register) and clear SSR.RDRF flag. To continue serial transmission, write transmit data to the transmit FIFO (TDR) by using a TXI interrupt and clear TDRE flag to 0. Transmit data can also be written to the transmit FIFO (TDR register) by activating the DMAC or DTC by the transmit data empty interrupt (TXI) request. And The RDR data can also be read by activating the DMAC or DTC by the receive data full interrupt (RXI) request. In this case, the TDRE and RDRF flags are cleared automatically, so please don't operate the TDRE and RDRF flags.

Figure 42.106 Example Flowchart of Simultaneous Serial Transmission and Reception in Clock Synchronous Mode (FIFO Mode)

42.11 Operation in Simple SPI Mode

As an extended function, the RSCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Making the settings for simple SPI mode (SCR3.MOD[2:0] bits = 011b) plus setting the SSE bit in the SCR0 register to 1 places the RSCI in simple SPI mode. However, the SS pin function on the master side is unnecessary for connection of the device used as the master in simple SPI mode when the configuration only has a single master, so set the SSE bit in the SCR0 to 0 in such cases.

Figure 42.107 shows an example of connections for simple SPI mode.

In simple SPI mode, data are transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended to this.

Since the receiver and transmitter are independent of each other within the RSCI module, full-duplex communications are possible, with a common clock signal. Furthermore, since both the transmitter and receiver have a double-buffered structure, writing of further transmit data while transmission is in progress and reading of previously received data while reception is in progress are both possible. Continuous transfer is thus possible.

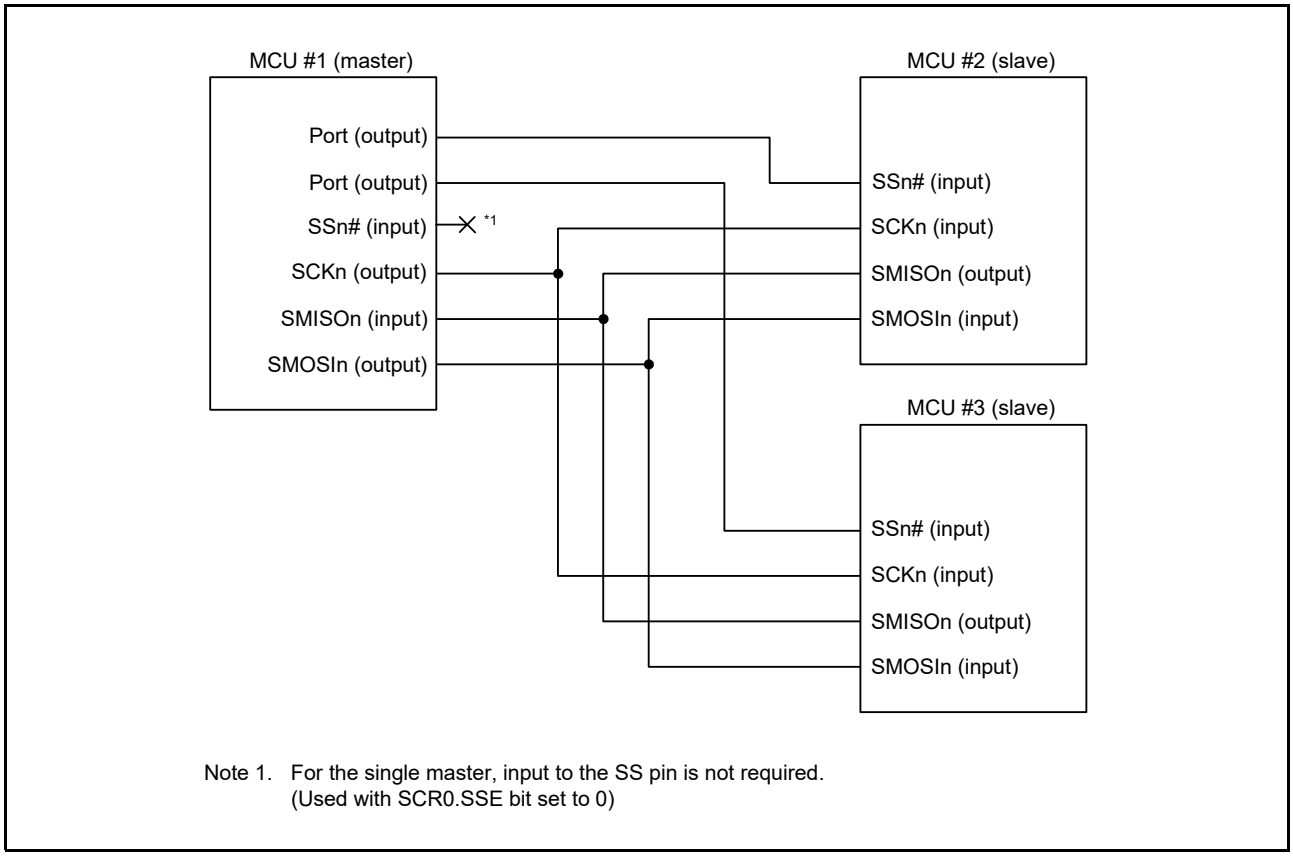

Figure 42.107 Example of Connections via a Simple SPI Mode

42.11.1 Clock

When using the SCKn at its highest frequency (= 1/2 TCLK), the PCLK frequency should be at least 1/2 the TCLK frequency.

42.11.2 States of Pins in Master and Slave Modes

In simple SPI mode, input and output directions of each pin vary depending on master mode (SCR3.CKE[1:0] bits = 00b or 01b) and slave mode (SCR3.CKE[1:0] bits = 10b or 11b).
Table 42.41 lists the states of pins according to the mode and the level on the SSn# pin.

Table 42.41 States of Pins by Mode and Input Level on the SSn# Pin

Mode	Input on SSn# Pin	State of SMOSIn Pin	State of SMISOn Pin	State of SCKn Pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission*2	Clock input

Note 1. When there is only a single master (SCR0.SSE bit = 0), transfer is possible regardless of the input level on the SSn# pin (this is equivalent to input of a high level on the SSn# pin). Since the SSn# pin function is not required, the pin is available for other purposes.
Note 2. The SMISOn pin is in the high-impedance state when serial transmission is disabled (SCR0.TE bit = 0).
Note 3. The SCKn pin is in the high-impedance state when serial transmission is disabled (SCR0.TE bit = 0 and RE bit = 0) in a multi-master configuration (SCR0.SSE bit = 1).

42.11.3 SS Function in Master Mode

Setting the SCR3.CKE[1:0] bits to 00b or 01b enables master mode.
In single master mode (SSE bit = 0), the SSn# pin is not used and data transmission and reception are enabled regardless of the SSn# pin input level. The SSn# pin is available for other purposes.
When in multi-master mode (SSE bit = 1) and the SSn# pin input is high, the master outputs a clock from the SCKn pin and performs transmission and reception operations. And outputting clock indicates “There are no other masters” or “Another master is not performing reception or transmission”. When the SSn# pin input level is low in multi-master mode (SSE bit = 1), this means that another master exists and it is performing data transmission/reception. At this time, the RSCI makes the TXDn pin output and the SCKn pin output high impedance and does not start data transmission/reception. In addition, the SSR.MFF flag is set to 1 as a mode fault. In multi-master mode, read this flag bit to perform the error processing. If a mode fault occurs during the transmission/reception operation, the SCKn pin and the TXDn pin output are made high impedance while the SSn# pin input level is low. In this case, any of TXI, RXI, and TEI interrupts occurs.
Control the SS signal output in master mode with a general-purpose port.

42.11.4 SS Function in Slave Mode

Setting the SCR3.CKE[1:0] bits to 10b or 11b enables slave mode.
When the SSn# pin input level is high, the RXDn pin output becomes high impedance and the clock input from the SCKn pin is ignored. When the SSn# pin input level is low, the clock input from the SCKn pin becomes effective, enabling data transmission and reception.
When the SSn# pin input changes from low to high level during the transmission/reception operation, the RXDn pin output is made high impedance and the transmission/reception operation is immediately suspended. If the transmission is in progress, the SSR.TEND flag will not be set, a transmit end interrupt will not be output, and an abnormal stop status will occur. So, do not negate the SSn# pin during slave transmission/reception. If an abnormal stop occurs, set the SCR0.RE and SCR0.TE bits to 0 to stop transmission/reception. To resume transmission/reception, set the SCR0.RE and SCR0.TE bits to 1 after at least 3 TCLK cycles plus 3 PCLK cycles.

42.11.5 Relationship between Clock and Transmit/Receive Data

The clock to be used for data transmission/reception is selectable from four types using the SCR3.CPOL and CPHA bits. Figure 42.108 shows the relationship between clock and transmit data/receive data. The same relationship applies to master mode and slave mode.

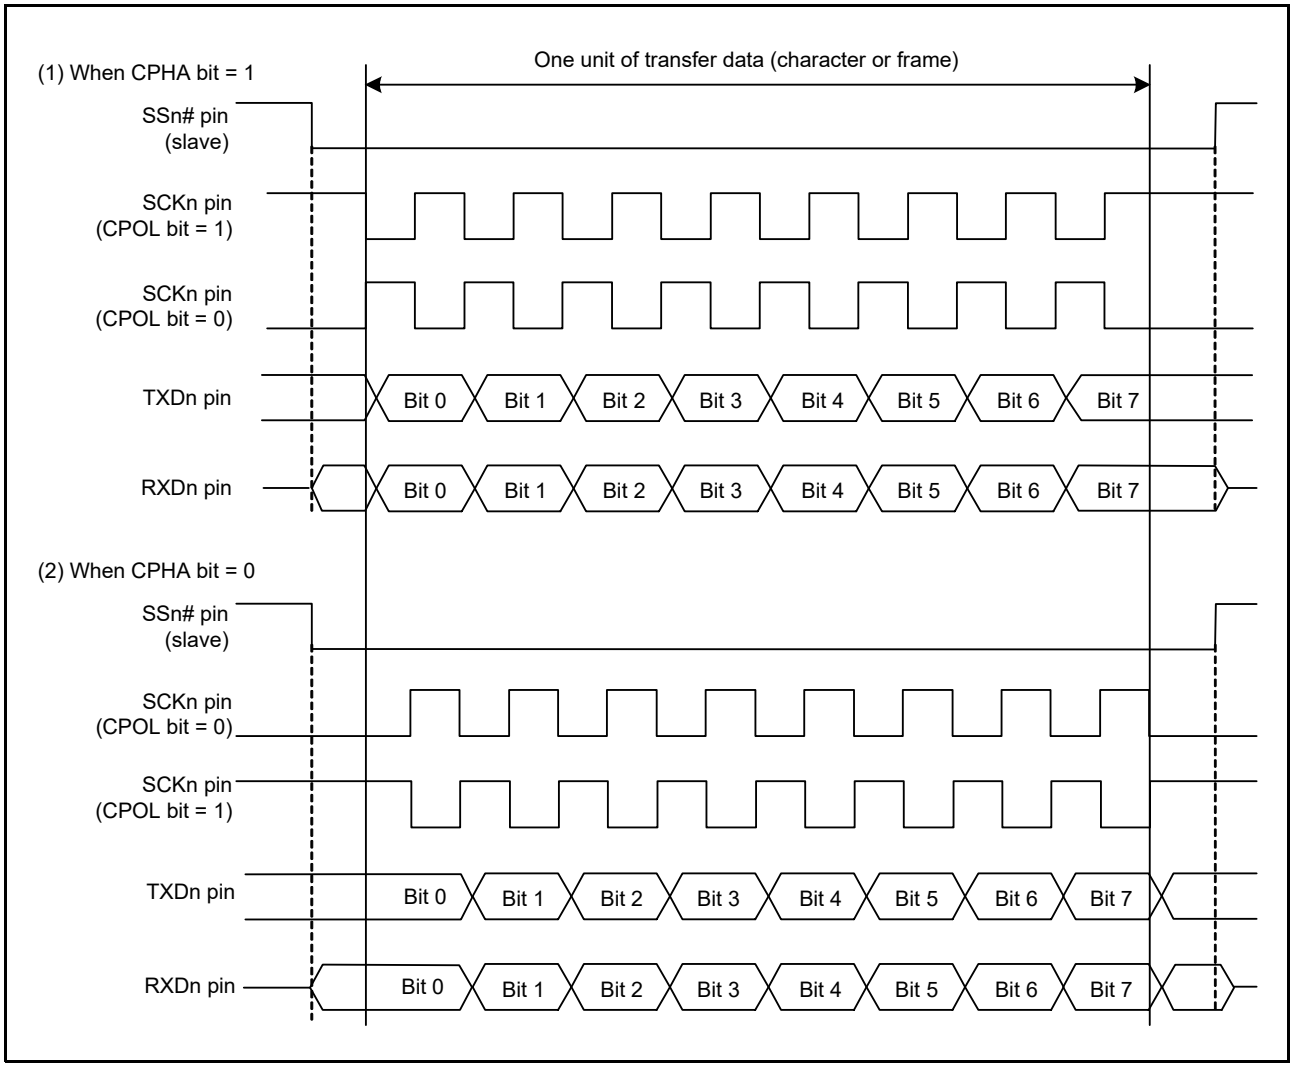

Figure 42.108 Relation between Clock Signal and Transmit/Receive Data in Simple SPI Mode

42.11.6 RSCI Initialization (Simple SPI Mode)

The RSCI can be initialized using the same initialization procedure as for clock synchronous mode (Figure 42.95, Example of RSCI Initialization Flowchart (Clock Synchronous Mode)). The master devices and slave devices use the same clock type selected by the SCR3.CPOL and CPHA bits.
Before performing initialization or changing operating mode or communication format, be sure to stop communication (SCR0.RE bit = 0 and SCR0.TE bit = 0).
Note that setting the RE bit to 0 does not initialize the ORER, AFER, and APER flags in SSR register and the RDR register.
Note that, when SCR0.TIE bit = 1, setting the TE bit to 1 from 0 generates a TXI interrupt.

42.11.7 Transmission and Reception of Serial Data (Simple SPI Mode)

In master mode, set the SSn# pin of the destination slave device to low level before starting data transmission/reception and set to high level after the end of data transmission/reception. In multiple master operation with SCR0.SSE bit = 1 even in master mode, a mode fault will occur if the SSn# pin goes low. Therefore, make sure that no mode fault has occurred before starting communication, and start communication, and make sure that no mode fault has occurred even after communication ends. If a mode fault has occurred, communication may be incomplete, so measures such as retransmission are required. The other procedures are the same as in clock synchronous mode.
In slave mode, it operates according to the SSn# pin input level. Other steps are the same as those of clock synchronous mode.

42.12 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be corrected by evenly enabling the clocks of the number specified in the SCR2.MDDR[7:0] bits among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in SCR2 register.

Figure 42.109 shows an example where the TCLK is selected by the CKS[1:0] bits in SCR2 register and the BRR[7:0] bits and MDDR[7:0] bits are set to 0 and 160 respectively in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256). Note that there is an imbalance in enabling the internal clock, and expansion and contraction occur in the pulse width of the base clock.

Note: Do not use this function in clock synchronous mode, simple-SPI mode, smart card Interface mode, Manchester mode and extended serial mode.

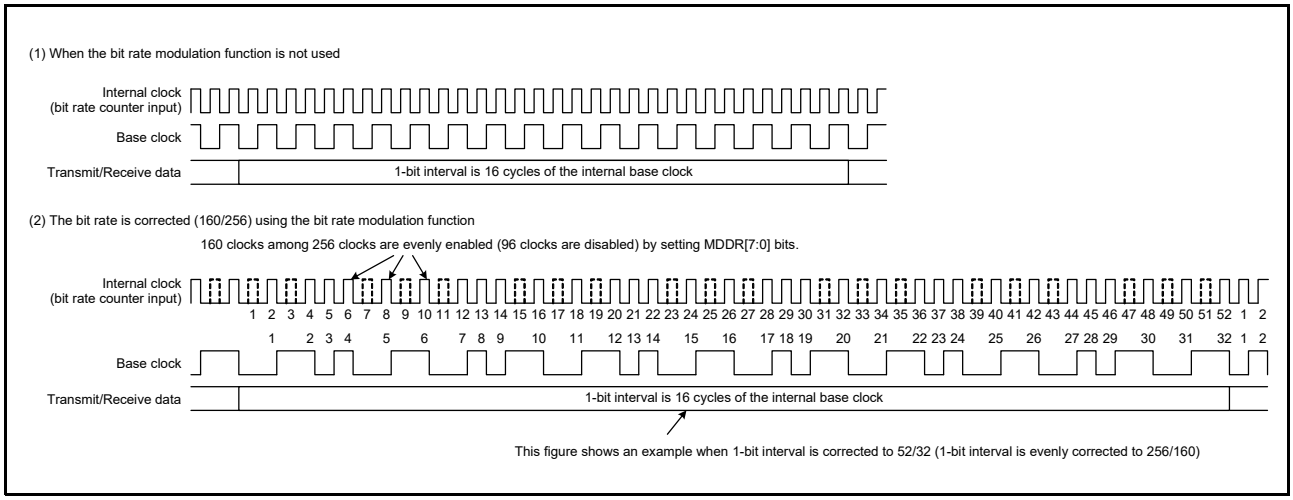

Figure 42.109 Example of Base Clock when Using the Bit Rate Modulation Function

42.13 Noise Cancellation Function

Figure 42.110 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a two-stage flip-flop circuits, a match detection circuit, and a majority voting circuit. When the SCR1.NFM bit is set to 0, when the input signals of the noise filter and the output signals of the two-stage flip-flop circuits completely match, the matched level is propagated as an internal signal. Unless otherwise matched, the previous value is retained. (When the same level is retained for three cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for three cycles or shorter is considered as a noise, not as a receive signal). When the SCR2.ABCSE2 bit is set to 1 in asynchronous mode, the above method cannot be used because there are only four base clock cycles in one bit period. In this case, set the NFM bit to 1 to select majority mode.

In asynchronous mode, Manchester mode and extended serial mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The sampling period of the noise filter can be selected from the base clock period (1/16 of one bit period when SCR2.ABCS bit = 0, SCR2.ABCSE bit = 0, and SCR2.ABCSE2 bit = 0. 1/8 of one bit period when ABCS bit = 1, ABCSE bit = 0, and ABCSE2 bit = 0. 1/6 of one bit period when ABCSE2 bit = 0 and ABCSE bit = 1. 1/4 of one bit period when ABCSE2 bit = 1 and ABCSE bit = 0.) or the baud rate generator source clock divided by 1, 2, 4, or 8 by setting the SCR1.NFCS[2:0] bits. When setting the ABCSE2 or ABCSE bit to 1, set the NFCS[2:0] bits to 000b or 001b.

In simple I2C mode, the noise elimination function can be used for the input pins of TXDn/SSDAn and RXDn/SSCLn. The sampling period of the noise filter can be selected from the divided clock of the baud rate generator clock source by SCR1.NFCS[2:0] bits.

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR0.TE and SCR0.RE bits are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, it is determined that a level match is detected and is propagated as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles (NFM bit = 0) or two or more sampling cycles (NFM bit = 1).

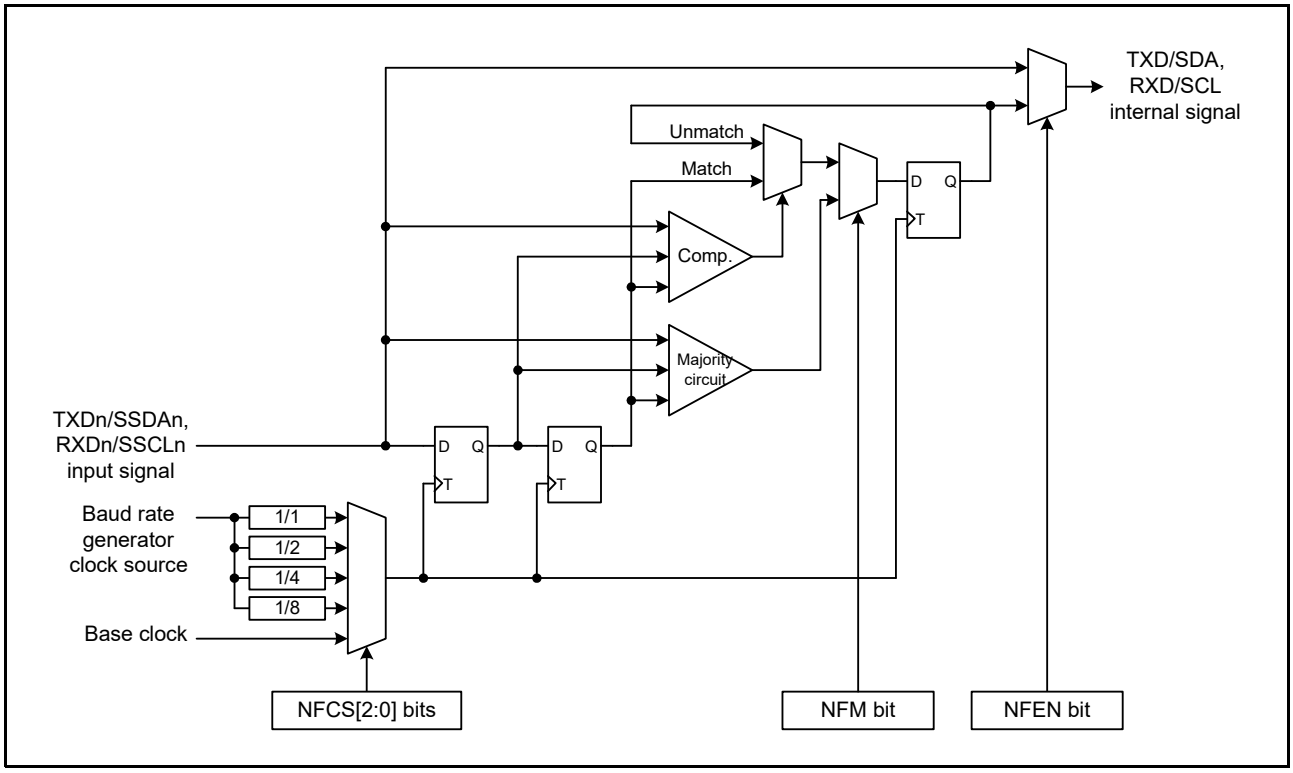

Figure 42.110 Block Diagram of Digital Noise Filter

42.14 RS-485 Driver Control Function

Setting the DEEN bit in the RSCI control register 3 (SCR3) to 1 enables the RS-485 driver control function and generates a DE (Driver Enable) signal that enables the external transceiver transmission mode. The DE signal outputs a valid level for the period with setup time and hold time added before and after data transmission. The DE signal valid level is set by the DELVL bit in the DE signal control register (DECR).

The setup time is the time from when the DE signal is valid until the start bit starts. Set by DESU[4:0] bits of DE signal control register (DECR).

The hold time is the time from the end of the last stop bit of the transmitted message to the invalidation of the DE signal. Set with DEHLD[4:0] bits of the DE signal control register (DECR).

DESU[4:0] and DEHLD[4:0] bits are expressed in base clock units (1/4, 1/6, 1/8, or 1/16 bit time). For details, refer to section 42.2.13, DE Signal Control Register (DECR).

When this function is used (DEEN bit = 1), the TEND set timing and TEI interrupt output timing are at the end of the DE signal hold time.

When transmission is completed and the next transmission data is not written before the DE signal is negated, the DE signal is negated once. If the timing for writing the next transmit data is not in time, the DE signal is negated and asserted again, the setup time is inserted, and the next data is transmitted. If you want to perform the next transmission with the DE signal asserted, write the next transmission data to the TDR quickly enough.

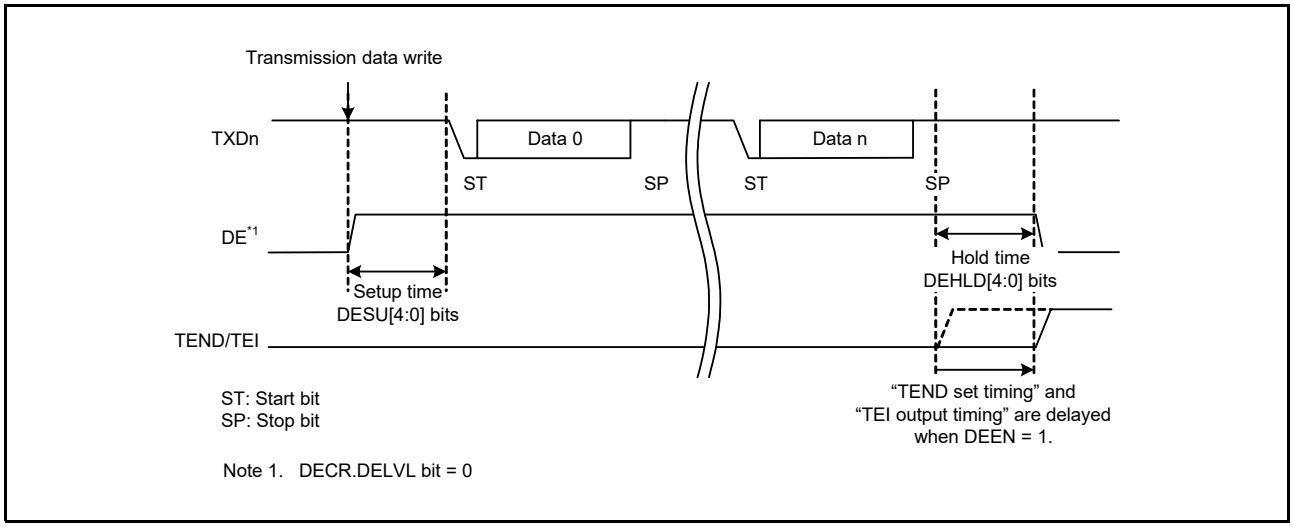

Figure 42.111 Image Waveform for RS-485 Driver Control DE Signal Output

42.15 Loopback Function

The loopback function can be used in Asynchronous mode with the internal clock, and Manchester mode with the internal clock, and Clock synchronous mode with the internal clock.
When 1 is written to the LOOP bit in the SCR1 register, RSCI blocks the external input (RXD) path and connects the output path of the transmit data register and the input path of the receive data register.
When this function is used with TINV bit = 1, inversion of transmission data becomes reception data. However, this function can be used with TINV bit = 1 only when operating in clock synchronous mode internal clock.
Table 42.42 shows the relationship between the TINV and LOOP bit settings and the received data.

Table 42.42 TINV and LOOP Bit Settings and Received Data

			Communication Mode		
TINV	**LOOP**	**Receive Data**	**Async Internal Clock**	**Manchester Internal Clock**	**Clock Sync Internal Clock**
0 or 1	0	Receive data from RXDn pin	Possible	Possible	Possible
0	1	Transmit data	Possible	Possible	Possible
1	1	Inverted transmit data	Impossible	Impossible	Possible

Figure 42.112 shows the configuration of the shift register input/output path in loopback mode.

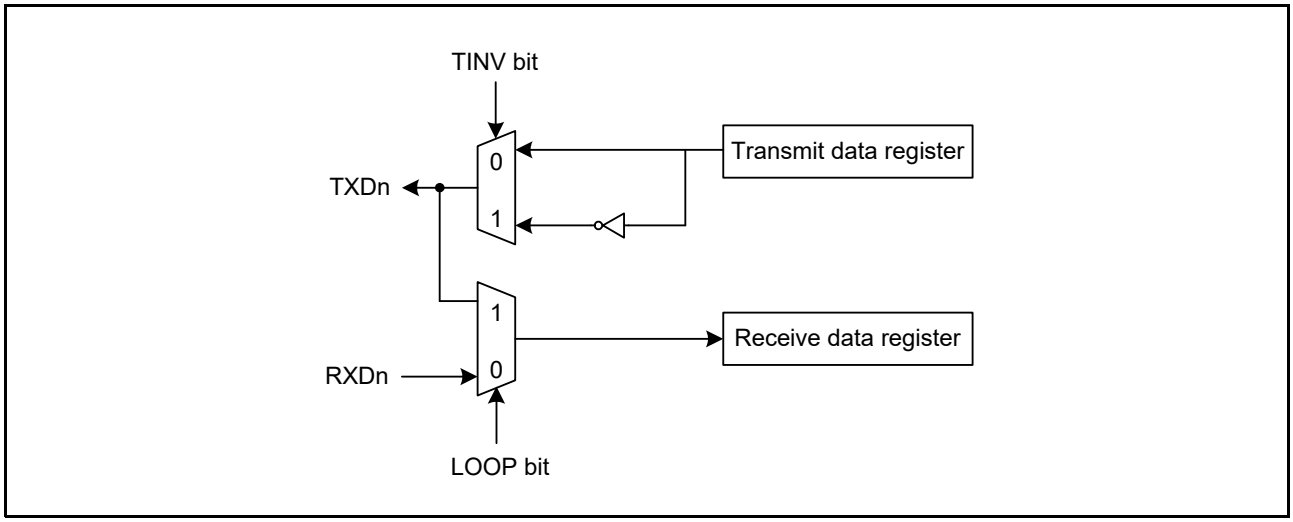

Figure 42.112 Shift Register Input/Output Configuration Image in Loopback Mode

42.16 Half-Duplex Communication Function

Do not use the half-duplex communication function in simple I^2C mode, simple-SPI mode, and smart card interface mode.

In other communication modes, if the SCR1.HDSEL bit is set to 1, half-duplex communication using the TXDn pin is possible. When half-duplex communication is used, transmission and reception must be performed exclusively. Transmission and reception settings (SCR0.TE bit = 1 and SCR0.RE bit = 1) is prohibited.

However, if half-duplex communication is performed as the master reception in clock synchronous mode, perform transmission/reception settings (SCR0.TE bit = 1 and SCR0.RE bit = 1) and perform dummy transmission. By dummy transmission (arbitrary transmission data is written to TDR), SCKn is output and reception is enabled. The dummy transmission data is discarded inside the RSCI and is not actually transmitted.

During half-duplex communication, the only communication port terminal used is the TXDn pin. Output when SCR0.TE bit = 1, input when SCR0.TE bit = 0.

42.17 Synchronizer Bypass Function

Each RSCI has a circuit that operates in synchronization with the peripheral module clock (PCLK) and a circuit that operates in synchronization with the operating clock (TCLK). From the entry of signals for transfer between these two types of circuit to the given synchronizer, the signals take two to three cycles of PCLK or TCLK to pass through the synchronizer, producing a corresponding delay. However, setting the SCR3.SYNDIS bit to 1 selects the peripheral module clock as the operating clock, and the synchronizer is bypassed. In this case, the above delay is reduced to zero, which improves the responsiveness. Furthermore, for the RSCI, although there is also a synchronizer between the circuit that operates in synchronization with the transfer clock and the circuit that operates in synchronization with the operating clock, bypassing that synchronizer is not possible.

42.18 Interrupt Signal

Table 42.43 lists RSCI interrupt signals.

The interrupt explanation corresponding to each operation mode is described in sections 42.18.2 to 42.18.5. Also, TXI and RXI have an interrupt buffer function. Refer to section 42.18.1, Buffer Operations for TXI and RXI Interrupts. When performing transmission and reception using DTC or DMAC, be sure to set DTC or DMAC first, and then enable RSCI before setting. Refer to section 20, Data Transfer Controller (DTCA) and section 18, DMA Controller (DMACAa) for how to set DTC or DMAC.

Table 42.43 RSCI Interrupt List

Interrupt Symbol	Interrupt Function	Pulse/ Level	Pulse Width	Active Level	SYNC Clock	Note
ERI	Error interrupt Bus collision detection interrupt	Level	—	Low	PCLK	
RXI	Simple I²C: Reception end interrupt Other mode: Receive data full interrupt	Pulse	1 cycle	Low	PCLK	
TXI	Simple I²C and smart card interface: Transmit end interrupt Other mode: Transmit data empty interrupt, Break Field transmission completion	Pulse	1 cycle	Low	PCLK	
TEI	Simple I²C: Completion of generation of a start, restart, or stop condition (STI) Other mode: Transmit end interrupt	Level	—	Low	PCLK	
AED	Active edge detection interrupt	Pulse	1 cycle	Low	PCLK	
BFD	Break Field detection interrupt	Level	—	Low	PCLK	Only when extended serial mode

42.18.1 Buffer Operations for TXI and RXI Interrupts

The TXI and RXI interrupts have an interrupt buffer function. When the first interrupt request is generated during interrupt handling and the next interrupt request is generated (when the status flag of the interrupt controller (ICU) is 1), the RSCI does not output the interrupt request, and holds it internally. The interrupt that can be held is up to one.

42.18.2 Interrupt in Asynchronous Mode, Manchester Mode, Clock Synchronous Mode, and Simple SPI Mode

A different interrupt vector is assigned to each interrupt source, and individual interrupt sources can be enabled or disabled with the enable bits in SCR0 register.

(1) Non-FIFO Mode

Table 42.44 lists interrupt sources in asynchronous mode, Manchester mode, clock synchronous mode, and simple SPI mode.

If the SCR0.TIE bit is 1, a TXI interrupt request is generated when transmit data is transferred from the TDR register to the TSR register. At the start of transmission, a TXI interrupt request can also be generated by using a single instruction to set the SCR0.TE and SCR0.TIE bit to 1 at the same time. A TXI interrupt request can activate the DTC or DMAC to handle data transfer.

A TXI interrupt request is not generated by setting the SCR0.TIE bit to 1 while the setting of the SCR0.TE bit is 1.*1

When the SCR0.TEIE bit is 1, the SSR.TEND flag becomes 1 and the TEI interrupt request is generated if the next data is not written to the TDR register by the timing to transmit the last bit of transmission data. In addition, the TEND flag holds 1 during the period from setting the SCR0.TE bit to 1 until writing transmit data to the TDR register, and if the TEIE bit is set to 1, a TEI interrupt request is generated.

Writing data to the TDR register clears the TEND flag and cancels the TEI interrupt request, but it takes time to cancel it.

If the SCR0.RIE bit is 1, an RXI interrupt request is generated when received data is stored in the RDR register. An RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting of any from among the ORER, AFER, and APER flags in the SSR register or the MCER, SYER (if SYERIE = 1)*2, PFER (if PFERIE = 1)*2, and SBER (if SBERIE = 1)*2 flags in MMSR register to 1 while the SCR0.RIE bit is 1 leads to the generation of an ERI interrupt request.

An RXI interrupt request is not generated at this time. Clearing all flags (ORER, AFER, APER, MCER, SYER (if SYERIE = 1)*2, PFER (if PFERIE = 1)*2, and SBER (if SBERIE = 1)*2) leads to discarding of the ERI interrupt request.

Note 1. To temporarily prohibit TXI interrupts at the time of transmission of the last of the data and so on when you wish a new round of transmission to start after handling of the transmit end interrupt, control prohibiting and permitting of the interrupt by using the interrupt request enable bit in the interrupt controller rather than using the TIE bit. This can prevent the suppression of TXI interrupt requests in the transfer of new data.

Note 2. In Manchester mode only, MMSR.SYER (if SYERIE bit = 1), PFER (if PFERIE bit = 1), SBER (if SBERIE bit = 1) flags are added to the ERI interrupt sources.

(2) FIFO Mode

Table 42.45 lists interrupt sources in asynchronous mode, Manchester mode, clock synchronous mode, and simple SPI mode with FIFO enabled.

If the SCR0.TIE bit is 1, a TXI interrupt request is generated when the stored number of data in transmit FIFO becomes equal to or less than the transmit FIFO threshold. A TXI interrupt request can also be generated by using a single instruction to set the SCR0.TE and SCR0.TIE bit to 1 at the same time. A TXI interrupt request is not generated by setting the SCR0.TE bit to 1 while the setting of the SCR0.TIE bit is 0 or by setting the SCR0.TIE bit to 1 while the setting of the SCR0.TE bit is 1.

If SCR0.TEIE bit is 1, when the next data isn't being written in transmit FIFO by the timing to which the last bit of the transmission data is sent, SSR.TEND flag will be 1 and TEI interrupt request is generated.

If the SCR0.RIE bit is 1, RXI interrupt request is generated when the stored number of data in receive FIFO exceeds the threshold. When the threshold value is set to 0, RXI interrupt request is occurred if the quantity of data in receive FIFO is greater than or equal to 1.

If the SCR0.RIE bit is 1, when SSR.ORER flag is set to 1 or the data a framing error or a parity error generated is stored in receive FIFO, ERI interrupt request is generated.

When the number of data stored in a receive FIFO at this time is a threshold value or above, RXI interrupt request is also generated. The ERI interrupt request can be canceled by clearing all flags (SSR.ORER, AFER, APER).

Table 42.44 RSCI Interrupt Sources (in Non-FIFO Mode)

Name	Interrupt Source	Interrupt Flag	Interrupt Enable	DTC/DMAC Activation
ERI	Receive error	ORER, AFER, APER, DFER, DPER, MCER, SYER (SYERIE = 1), PFER (PFERIE = 1), SBER (SBERIE = 1)	RIE	Not possible
RXI	Receive data full	RDRF	RIE	Possible
	Receive data match	DCMF		
TXI	Transmit data empty	TDRE	TIE	Possible
	TE = 0 → 1 detection			
TEI	Transmit end	TEND	TEIE	Not possible

Table 42.45 RSCI Interrupt Sources (in FIFO Mode)

Name	Interrupt Source	Interrupt Flag	Interrupt Enable	DTC/DMAC Activation
ERI	Receive error	ORER, AFER, APER, DFER, DPER, DR (FCR.DRES bit = 1)	RIE	Not possible
RXI	Receive FIFO data full	RDRF	RIE	Possible
	Receive data ready	DR (FCR.DRES bit = 0)		
	Receive data match	DCMF		
TXI	Transmit FIFO data empty	TDRE	TIE	Possible
	TE = 0 → 1 detection			
TEI	Transmit end	TEND	TEIE	Not possible

42.18.3 Interrupt in Smart Card Interface Mode

Table 42.46 lists interrupt sources in smart card interface mode. A transmit end interrupt (TEI) request cannot be used in this mode.

Table 42.46 RSCI Interrupt Sources in Smart Card Interface Mode

Name	Interrupt Source	Interrupt Flag	Interrupt Enable	DTC/DMAC Activation
ERI	Receive error or error signal detection	ORER, APER, ERS	RIE	Not possible
RXI	Receive data full	RDRF	RIE	Possible
TXI	Transmit end	TEND	TIE	Possible
	TE = 0 → 1 detection			

Data transmission/reception using the DTC or DMAC is also possible in smart card interface mode. In transmission operation, when the SSR.TEND flag is set to 1, a TXI interrupt request is generated. This TXI interrupt request activates the DTC or DMAC allowing transfer of transmit data if the TXI request is specified beforehand as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.
If an error occurs, the RSCI automatically retransmits the same data. During the retransmission, the TEND flag is kept to 0 and the DTC or DMAC is not activated. Therefore, the RSCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, the SSR.ERS flag is not automatically cleared to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR0.RIE bit to 1 to enable an ERI interrupt request to be generated at error occurrence.
In reception operation, an RXI interrupt request is generated when receive data is set to RDR register. This RXI interrupt request activates the DTC or DMAC allowing transfer of receive data if the RXI request is specified beforehand as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an ERI interrupt request is issued to the CPU instead; the error flag must be cleared.
When transmitting/receiving data using the DTC or DMAC, be sure to make settings to enable the DTC or DMAC before making RSCI settings. For DTC or DMAC settings, refer to section 20, Data Transfer Controller (DTCA) and section 18, DMA Controller (DMACAa).

42.18.4 Interrupts in Simple I2C Mode

Table 42.47 lists RSCI interrupts in Simple I2C mode.

The STI interrupt is allocated to the transmit end interrupt (TEI) request. The receive error interrupt (ERI) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple I2C mode.

When the value of the SIMR.IICINTM bit is 1, a RXI request will be generated on the falling edge of the SSCLn signal for the eighth bit. If the RXI has been set up as an activating request for the DTC or DMAC beforehand, the RXI request will activate the DTC or DMAC to handle transfer of the received data. Furthermore, a TXI request is generated on the falling edge of the SSCLn signal for the ninth bit (acknowledge bit). If the TXI has been set up as an activating request for the DTC or DMAC beforehand, the TXI request will activate the DTC or DMAC to handle transfer of the transmit data. (In this case, ACK/NACK judging are impossible.)

When the value of the SIMR.IICINTM bit is 0, RSCI moves as follows. RXI request (ACK detection) is generated if the input on the SSDAn pin is at the low level on the rising edge of the SSCLn signal for the ninth bit (acknowledge bit). TXI request (NACK detection) is generated if the input on the SSDAn pin is at the high level on the rising edge of the SSCLn signal for the ninth bit (acknowledge bit). If the RXI has been set up as an activating request for the DTC or DMAC beforehand, the RXI request will activate the DTC or DMAC to handle transfer of the received data. Also, if the DTC or DMAC is used for data transfer in reception or transmission, be sure to set up and enable the DTC or DMAC before setting up the RSCI.

When the SIMR.IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 42.47 RSCI Interrupt Sources in Simple I2C Mode

Name	Interrupt Source		Interrupt Flag	Interrupt Enable	DTC/DMAC Activation
	IICINTM bit = 1	IICINTM bit = 0			
RXI	Reception end	—	—	RIE	Possible*1
	—	ACK detection	—		Possible
TXI	Transmit end	—	—	TIE	Possible*1
	—	NACK detection	—		Possible
STI	Completion of generation of a start, restart, or stop condition		IICSTIF	TEIE	Not possible

Note 1. If the DMAC or DTC are being used, you can not confirm whether ACK or NACK.

42.18.5 Interrupts in Extended Serial Mode

Table 42.48 lists interrupt sources in extended serial mode.

Table 42.48 RSCI Interrupt Sources in Extended Serial Mode

Name	Interrupt Source	Interrupt Flag	Flag the needs to be confirmed	Interrupt Enable	DTC/DMAC Activation
ERI	Error	ORER, AFER, APER	—	RIE	Not possible
		BCDF		BCDIE	
		COF		RIE, COFIE	
RXI	Reception data full	RDRF	CF0MF, CF1MF, PIBDF	RIE	XSR0.SFSF flag = 0: Possible XSR0.SFSF flag = 1: Not possible
AED	Active edge detection	AEDF	—	AEDIE	Possible
TXI	Transmit data empty	TDRE	—	TIE	Possible
	TE = 0 → 1 detection				
	Break Field transmission completion	BFOF	—	TIE, BFOIE	
TEI	Transmit end	TEND	—	TEIE	Not possible
BFD	Break Field detection	BFDF	—	BFDIE	Not Possible (Unnecessary)

In extended serial mode, in addition to reception errors (overrun, framing, and parity errors), an ERI interrupt request is output when a bus conflict is detected during transmission, or when a counter overflow of the extended serial module occurs. At this time, a RXI interrupt request is not output. The ERI interrupt request can be canceled by clearing all the flags.

When transmitting Start Frame, if SCR0.TIE bit = 1 and XCR0.BFOIE bit = 1, a TXI interrupt request is output when Break Field transmission is completed. When Control Field 0 data is written to the TDR register, data transmission starts. Therefore, transmission using DTC or DMAC is possible.

Set SCR0.TEIE bit = 1 after writing the last transmit data to the TDR register and transmission starts.

During Start Frame reception (XSR0.SFSF flag = 1), reception using DTC or DMAC by RXI interrupt is not possible. Check the SSR register and XSR0 register, check the reception status (See Figure 42.73), and then clear the flag.When data is received, read the RDR register so that an overrun error does not occur (if you do not need to check the received data value, clear the RDRF flag without reading the RDR register). When reception of Control Field 1 is completed (XSR0.CF1MF flag = 1), Start Frame detection is disabled (XSR0.SFSF flag = 0) and reception using DTC or DMAC is possible. Be sure to read the RDR register.

When Start Frame/Break Field detection is enabled (XCR1.SDST bit = 1), if a Break Field longer than the period set in XCR2.BFLW[15:0] bits is received, the BFDF flag is set and a BFD interrupt request is output. Then RSCI becomes the Start Frame reception state. Clear the BFDF flag.

When Start Frame/Break Field detection is enabled (XCR1.SDST bit = 1) and the bit rate measurement function is enabled (XCR1.BRME bit = 1), an AED interrupt factor is output when an active edge is detected. Read the timer count capture value (XSR1.CCV[15:0] bits).

42.19 Event Linking

By employing interrupt request signals as event signals, RSCI can provide linked operation through the event link controller (ELC) for modules selected in advance.
Event signals can be output regardless of the values of the corresponding interrupt request enable bits. And even when the next interrupt source occurs while the corresponding interrupt status flag is 1, the event signal can be output.
All event output is a pulsed output and becomes negated behind 1 PCLK of asserting.
Table 42.49 lists RSCI event link signals.

Table 42.49 RSCI Event Link Signal List

Function	Pulse/Level	Pulse Width	Active Level	Synchronize Clock
Error event	Pulse	1 cycle	High	PCLK
Receive data full event	Pulse	1 cycle	High	PCLK
Transmit data empty event	Pulse	1 cycle	High	PCLK
Transmit end event	Pulse	1 cycle	High	PCLK
Receive data match event	Pulse	1 cycle	High	PCLK
Receive data unmatch event	Pulse	1 cycle	High	PCLK
Active edge detect event	Pulse	1 cycle	High	PCLK

(1) Error Event Output (Receive Error, Error Signal Detection)

- This output indicates abnormal termination due to a parity error during reception.
- This output indicates abnormal termination due to a framing error during reception.
- This output indicates abnormal termination due to an overrun error during reception.
- This output indicates abnormal termination due to a Manchester code error during reception (only in Manchester mode).
- This output indicates that a preface error occurred upon reception and abnormal termination occurred (only in Manchester mode and MMCR.PFERIE bit = 1).
- This output indicates that a start bit error occurred during reception and abnormal termination occurred (only in Manchester mode and MMCR.SBERIE bit = 1).
- This output indicates that a reception sync error occurred during reception and abnormal termination occurred (only in Manchester mode and only when MMCR.SYERIE bit = 1).
- This output indicates detection of the error signal during transmission in smart card interface mode.
- SSR.AFER and APER flags are 0, and reception data less than receive FIFO data trigger number is set in a receive FIFO buffer, and this output indicates that time of 15 etu has passed when FIFO enabled and FCR.DRES bit is 1.
- In extended serial mode, this output indicates that the 16-bit counter in the extended serial module has overflowed.
- In extended serial mode, a bus collision is detected during transmission (SCR0.TE bit = 1).

(2) Receive Data Full Event Output

- In non-FIFO mode, this output indicates that received data have been set in the receive data register (RDR).
- This output indicates that ACK has been detected if the SIMR.IICINTM bit is 0 in simple I^2C mode.
- This output indicates that the 8th-bit SSCLn falling edge has been detected if the SIMR.IICINTM bit is 1 in simple I^2C mode.
- When the SIMR.IICINTM bit is 1 during master transmission in simple I^2C mode, set the event link controller (ELC) so that receive data full events are not used.

Note: Do not use this event in FIFO mode.

(3) Transmit Data Empty Event Output

- This output indicates that the SCR0.TE bit has been changed from 0 to 1.
- In non-FIFO mode, this output indicates that transmit data have been transferred from the transmit data register (TDR) to the transmit shift register (TSR).
- This output indicates that transmission has been completed in smart card interface mode.
- This output indicates that NACK has been detected if the SIMR.IICINTM bit is 0 in simple I^2C mode.
- This output indicates that the ninth-bit SSCLn falling edge has been detected if the SIMR.IICINTM bit is 1 in simple I^2C mode.
- In extended serial mode, this output indicates that Break Field transmission is complete.

Note: Do not use this event in FIFO mode.

(4) Transmit End Event Output

- This output indicates the completion of transmission.
- This output indicates that the starting condition, resumption condition, or termination condition has been generated in simple I^2C mode.
- In smart card interface mode, the transmit end event is not output.

Note: Do not use this event in FIFO mode.

(5) Receive Data Match Event Output

- This output indicates that the received data matched the value of the SCR4.CMPD[8:0] bits in asynchronous mode (including multi-processor mode).

(6) Receive Data Unmatch Event Output

- This output indicates that the received data did not match the value of the SCR4.CMPD[8:0] bits in asynchronous mode (including multi-processor mode).

(7) Active Edge Detection Event Output

- In extended serial mode, when XCR1.BRME bit is 1, this output indicates that a valid edge has been detected in the RXD input signal.

42.20 Usage Notes

42.20.1 Setting the Module Stop Function

Module stop control register B (MSTPCRB) is used to stop and start RSCI operations. With the value after a reset, RSCI operations are stopped. The registers of the modules only become accessible after release from the module stop state. For details, refer to section 11, Low Power Consumption.

42.20.2 RSCI Operations during Low Power Consumption State

(1) Transmission

Before using the power consumption reduction function to reduce RSCI's power consumption, please do the following to confirming transmission end (SSR.TEND flag = 1):

- Set the output terminal state after transmission operation is stopped by SCR1.SPB2DT and SPB2IO bits.
- Stop the transmission (SCR0.TIE bit = 0, TE bit = 0, TEIE bit = 0)

When transitions to these states are made during transmission, the data being transmitted become indeterminate.
To transmit data in the same operating mode after cancellation of the low power consumption state, set the TE bit to 1, read SSR register, and write data to TDR sequentially to start data transmission. To transmit data with a different operating mode, initialize the RSCI first.
To start transmission using the DMAC/DTC after cancellation from software standby mode, set the TE and TIE bit to 1 simultaneously. The TXI interrupt is generated and transmission starts using the DMAC/DTC.
Figure 42.113 shows a sample flowchart for transition to software standby mode during transmission. Figure 42.114 and Figure 42.115 show the port pin states during transition to software standby mode.

(2) Reception

Before specifying the module stop state or making a transition to software standby mode, stop the receive operations (SCR0.RE bit = 0). If transition is made during data reception, the data being received will be invalid.
Figure 42.116 shows a sample flowchart for reception to software standby mode during reception.

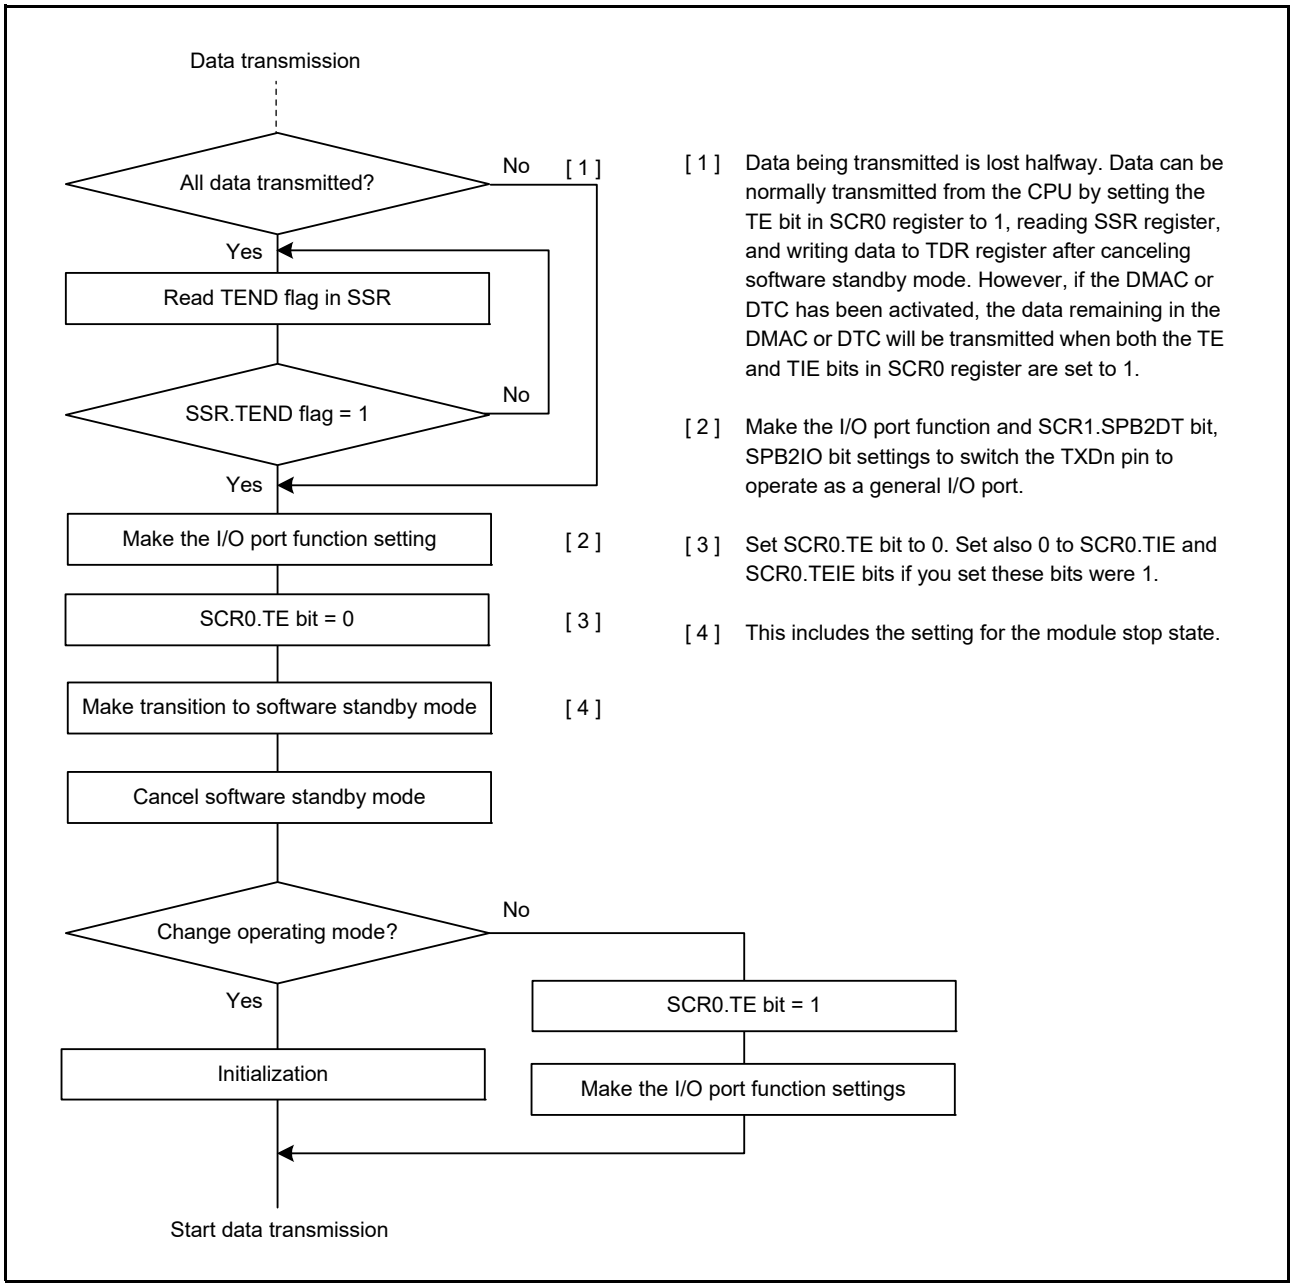

Figure 42.113 Example of Flowchart for Transition to Software Standby Mode during Transmission

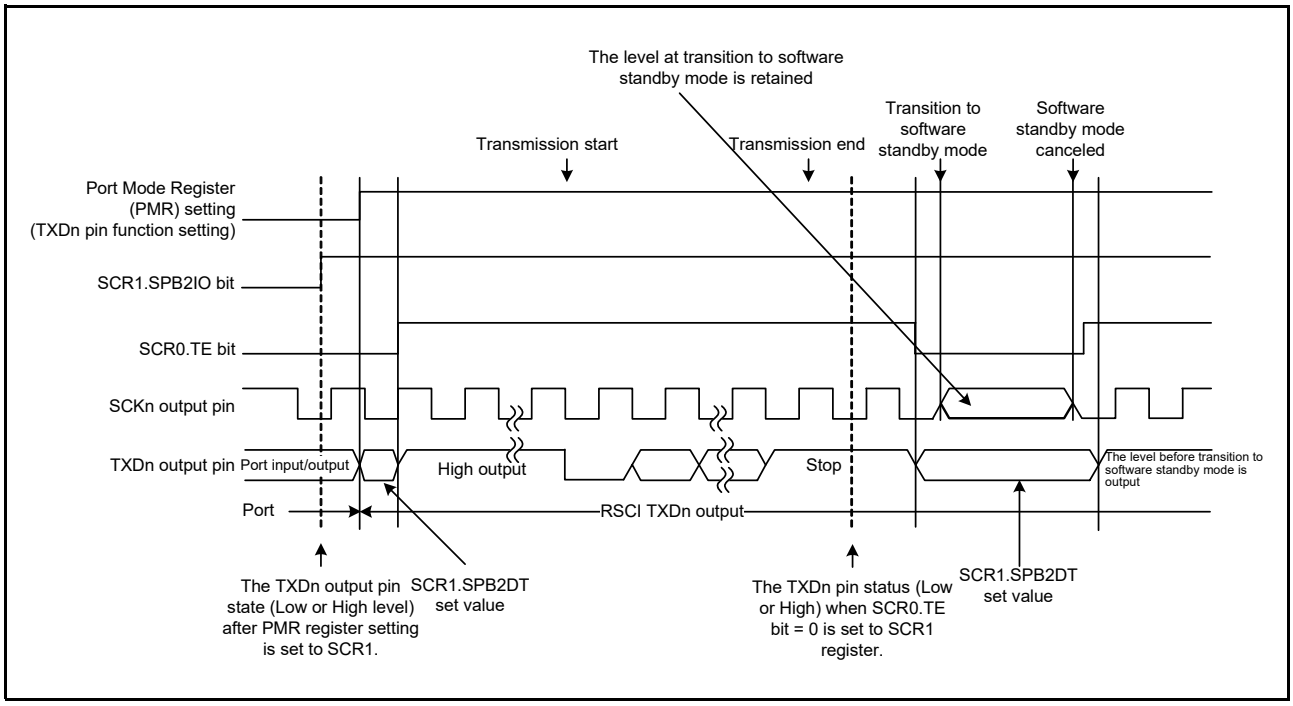

Figure 42.114 Port Pin States during Transition to Software Standby Mode (Internal Clock, Asynchronous Transmission)

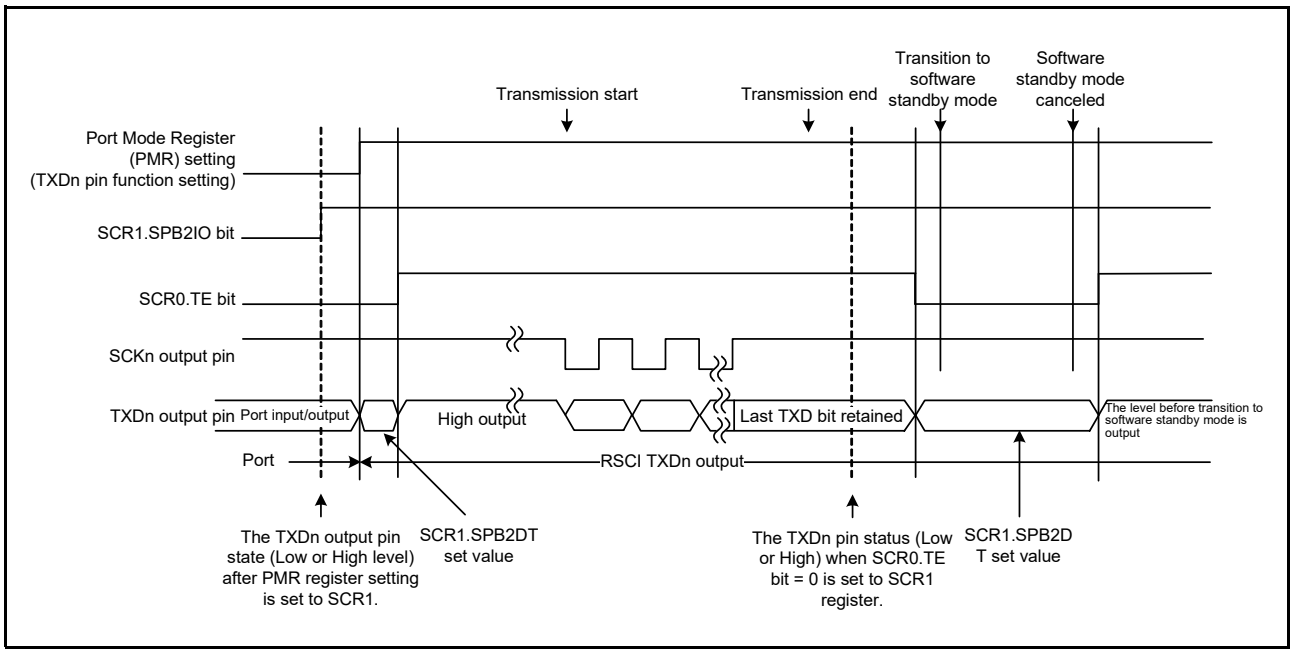

Figure 42.115 Port Pin States during Transition to Software Standby Mode (Internal Clock, Clock Synchronous Transmission)

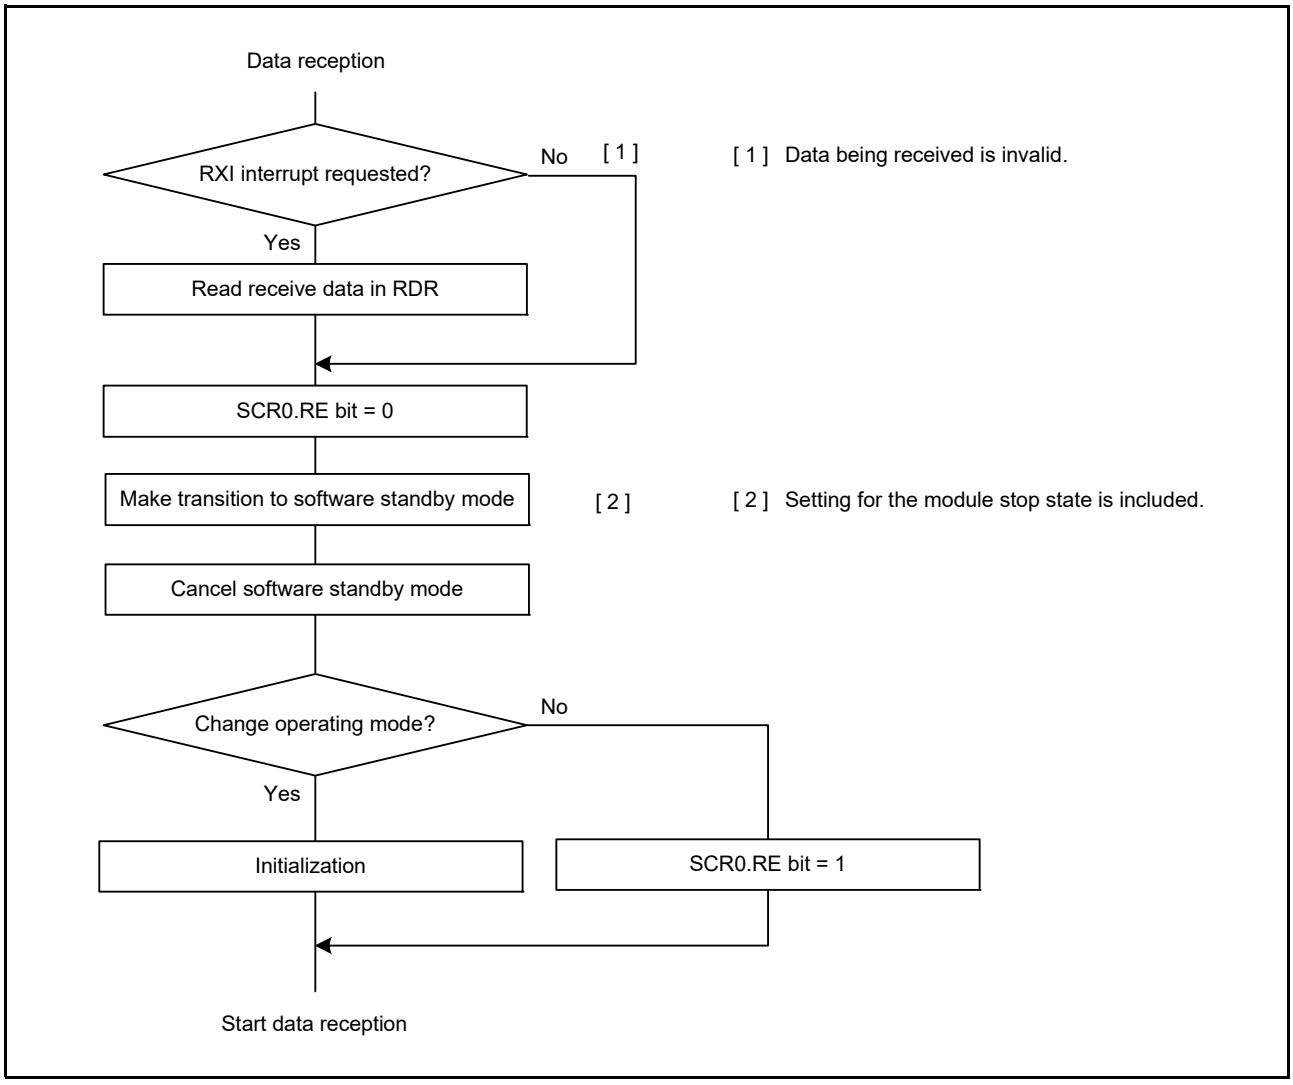

Figure 42.116 Example of Flowchart for Transition to Software Standby Mode during Reception

42.20.3 Break Detection and Processing

(1) Non-FIFO Mode

When a framing error is detected, a break can be detected by reading SSR.RXDMON flag value. In a break, the input from the RXDn pin becomes all low, and so the SSR.AFER flag is set to 1 (framing error has occurred), and the SSR.APER flag may also be set to 1 (parity error has occurred). When the SCR3.RXDESEL bit is 0, the RSCI continues the receive operation even after a break is received. Therefore, note that even if the AFER flag is set to 0 (no framing error occurred), it will be set to 1 again. When the SCR3.RXDESEL bit is 1, the RSCI sets the SSR.AFER flag to 1 and stops receiving operation until a start bit of the next data frame is detected. If the SSR.AFER flag is set to 0 at this time, the SSR.AFER flag retains 0 during the break. When the RXDn pin becomes high and the break ends, detecting the start bit at the first falling edge of the RXDn pin allows the RSCI to start the receiving operation.

(2) FIFO Mode

After a framing error is detected, when RSCI detects that continuous receive data is low for 1 frame, the data stored into the receive FIFO (RDR register) and reception stops. When a framing error is detected, a break can be detected by reading SSR.RXDMON flag value. After the RXD signal is in the mark state and it has finished the break, a stock of reception data to the receive FIFO (RDR register) resumes.

42.20.4 Mark State and Sending Breaks

When the SCR0.TE bit is 0 (serial transmission is disabled), the state of the TXDn pin can be set by SCR1.SPB2IO bit and SCR1.SPB2DT bit. Using this, it's possible to do a TXDn pin in the mark state and send a break out. When you want to make a communication-line is in the mark state (the state of 1) until the SCR0.TE bit is set to 1 (serial transmission is enabled). First, set it as High-level output by setting SPB2IO bit and SPB2DT. Next, it's changed to a TXDn pin by I/O port function. On the other hand, if you want to send a break when sending data, set the SCR0.TE bit to 0 after setting the SPB2IO and SPB2DT bits in the SCR1 register to low level output. Setting the TE bit to 0 initializes the transmitter regardless of the current transmission status.

42.20.5 Receive Error Flags and Transmit Operations (Clock Synchronous Mode and Simple SPI Mode)

Transmission can be start by writing transmit-data to TDR register even if SSR.ORER flag is 1. However, reception can not be started. Note also that the receive error flags cannot be set to 0 even if the SCR0.RE bit is set to 0 (serial reception is disabled).

42.20.6 Writing Data to the TDR Register

(1) Non-FIFO Mode

Data can be written to TDR register anytime when TE bit is 1. However, if new data is written to TDR register when transmit data is remaining in TDR register, the previous data in TDR register is lost because it has not been transferred to TSR register yet. If you use DTC or DMAC, be sure to write transmit data to TDR register in the TXI interrupt request handling routine.

(2) FIFO Mode

Data can be written to transmit FIFO (TDR register) when TE bit is 1. Check the number of writable data with the TFSR.T[5:0] bits.

42.20.7 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode and Simple SPI Mode)

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of Transmission

Update TDR register by the CPU, DMAC, or DTC and wait at least the following time until the start of the external clock input: (See Figure 42.117)
Time considering the output AC characteristics of the SMISO pin of this product and the input AC characteristics of the master reception + 1 PCLK cycle + 2 to 3 TCLK cycles (delay time of the synchronizer).

(2) Continuous Transmission

The next transmit data must be transferred to the TSR register before the falling edge*1 of the transmit clock for bit 7. Write the transmit data to TDR register taking into account the delay time of the synchronizer. If the transmit data can not be written in time, the previous frame data is resent. (See Figure 42.117)

Note 1. When SCR3.CPOL bit = 1 and SCR3.CPHA bit = 0, or SCR3.CPOL bit = 0 and SCR3.CPHA bit = 1. In the case of SCR3.CPOL bit = 0 and SCR3.CPHA bit = 0, or SCR3.CPOL bit = 1 and SCR3.CPHA bit = 1, it's the rising edge.

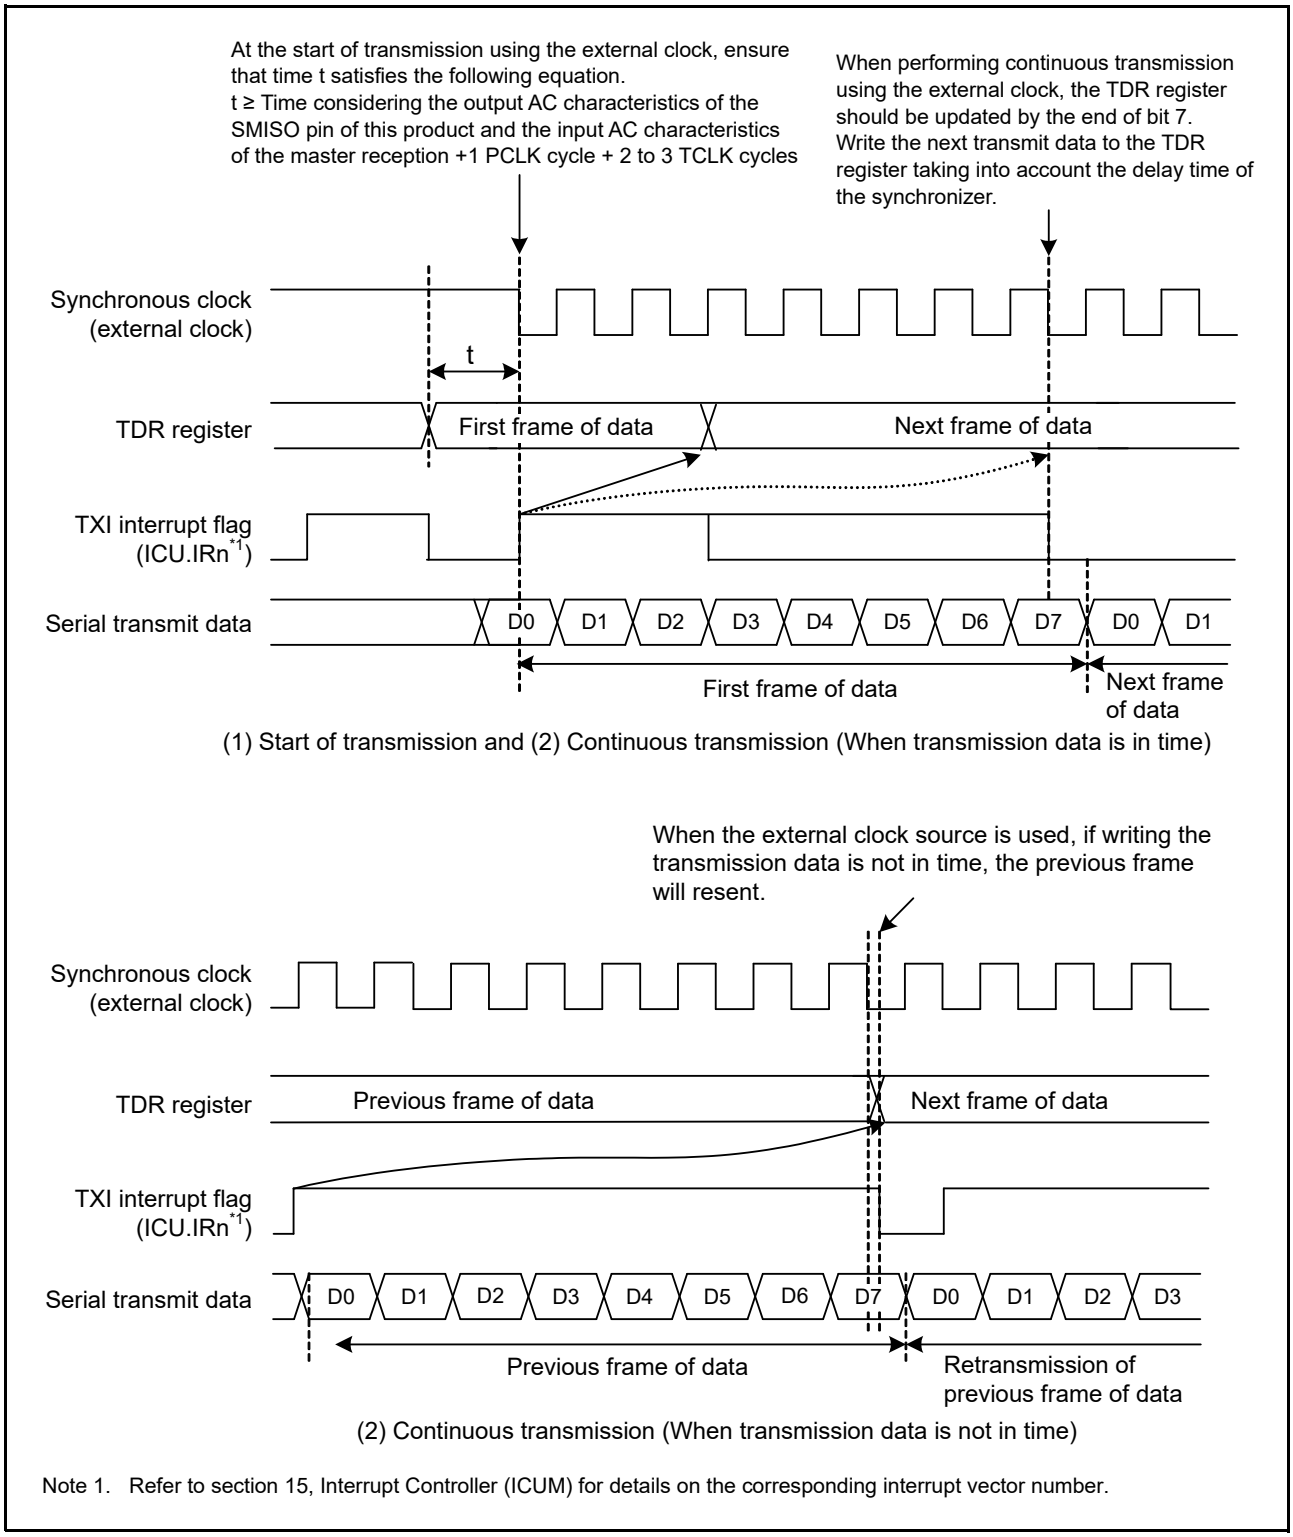

Figure 42.117 Restrictions on Use of External Clock in Clock Synchronous Transmission

42.20.8 Restrictions on Using DMAC or DTC

When using the DMAC or DTC to read RDR register, be sure to set the receive data full interrupt (RXI) as the activation source of the relevant RSCI.
During the operation in transmission/reception using the DMAC or DTC, it should not set transfer information of DMAC/DTC.

42.20.9 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IRn.IR flag) in the interrupt controller is 1, follow the procedure below to clear interrupt requests before permitting operations (by setting the SCR0.TE or SCR0.RE bit to 1). For details on the interrupt status flag, refer to section 15, Interrupt Controller (ICUM).

- Confirm that transfer has stopped (the setting of the SCR0.TE or SCR0.RE bits is 0).
- Set the corresponding interrupt enable bit (SCR0.TIE or SCR0.RIE) to 0.
- Read the corresponding interrupt enable bit (SCR0.TIE or SCR0.RIE bit) to check that it has become 0.
- Set the interrupt status flag (IRn.IR flag) in the interrupt controller to 0.

42.20.10 Limitations on Simple SPI Mode

(1) Master Mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set by the SCR3.CPHA and CPOL bits when the SCR0.SSE bit is 1. This prevents the clock line from being placed in the high-impedance state when the SCR0.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR0.TE bit is changed from 0 to 1.
  In a single-master configuration, pull up or pull down the clock line is not necessary because the clock line does not become high-impedance state when SCR0.SSE bit = 0 and SCR0.TE bit = 0.
- In the case of the setting for clock delay (SCR3.CPHA bit is 0), the receive data full interrupt (RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 42.118. If the TE and RE bits become 0 at this time before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Furthermore, an RXI interrupt may lead to the input signal on the SSn# pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, take care because the SCKn pin output becomes high-impedance while the input on the SSn# pin is at the low level if a mode fault occurs as the current character is being transferred. And stopping supply of the clock signal to the connected slave. Remake the settings for the connected slave to avoid misaligned bits when transfer is restarted.

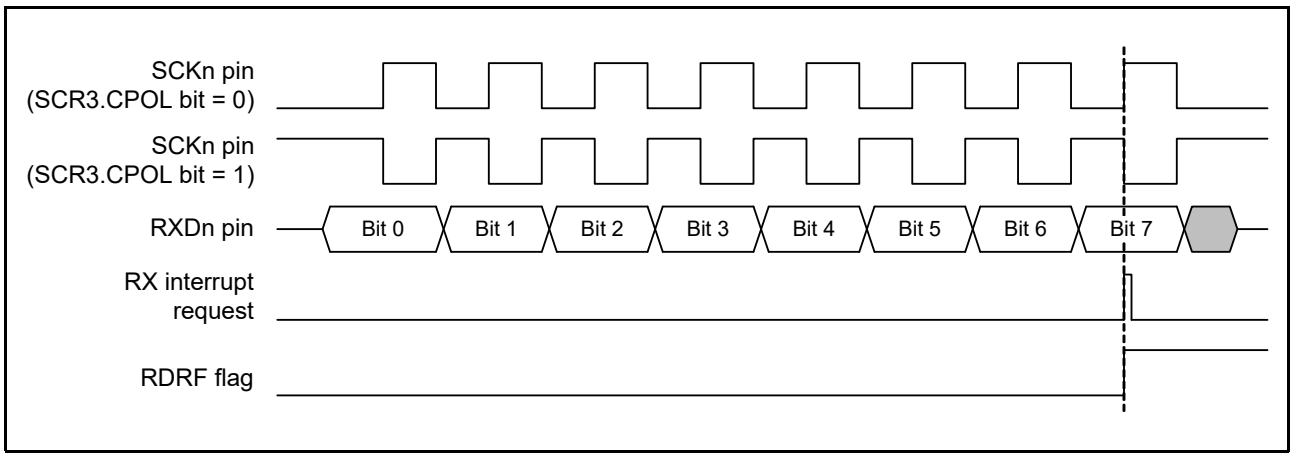

Figure 42.118 Timing of the RXI Interrupt in Simple SPI Mode (with Clock Delay)

(2) Slave Mode

- It takes “1 PCLK + 2 to 3 TCLK cycles (delay time of the synchronizer) + data output delay time (AC characteristics)” from writing the transmit data to the TDR register until the data is output to the RXDn pin. Take these into account when starting external clock input.
- Provide an external clock signal to the master the same as the data length for transfer.
- Secure the SS input setup time (AC characteristics) from the SSn# low-level input to the start of external clock input.
- Control the input on the SSn# pin before the start and after the end of data transfer.
- When the level being input on the SSn# pin is to be changed from low to high while the current character is being transferred, the transmission and reception is stopped immediately. Set the TE and RE bits in the SCR0 register to 0 and, after remaking the settings, restart transfer of the first byte.

42.20.11 Note on Transmit Enable Bit (TE Bit)

In the initial register value, when setting the SCR0.TE bit to 0 (serial transmission is disabled) while the pin function is "TXDn", output of the TXDn pin becomes high-impedance.
Prevent the TXDn line from becoming high-impedance by any of the following ways:

(a) Connect a pull-up or pull-down resistor to the TXDn line.
(b) Set the SCR1 register to determine the level of the TXDn pin when the TE bit is 0.

42.20.12 Note on Extended Serial Mode

In extended serial mode (SCR3.MOD[2:0] bits = 110b), the following functions cannot be used.

- CTS and RTS functions
- Multi-processor communication function
- Bit Rate Modulation function
- Loopback function
- FIFO buffer

42.20.13 Notes on RS-485 Driver Control Function

- RS-485 Driver control function is valid only in Asynchronous mode.
- When RS-485 Driver control function is active (SCR3.DEEN bit = 1), the TEND set timing/TEI output timing changes as follows. Wait for the TEI interrupt and set the TE bit to 0.
  When RS-485 Driver control function is inactive: When STOP bit output is completed.
  When RS-485 Driver control function is active: At the end of DE signal hold time.

42.20.14 Notes on Loopback Function

The Loopback function is valid in Asynchronous mode with internal clock, in Manchester mode with internal clock and Clock synchronous mode with internal clock.
It can also operate in the asynchronous HBS support mode, and when the HBSCR.AOE bit = 1, it loops back the signal with the logical AND of the TXDAn and TXDBn pin outputs (Use with TINV bit = RINV bit = 0).

42.20.15 Note on Register Access When the Frequency of the Operating Clock (TCLK) is Lower Than the Frequency of the Peripheral Module Clock (PCLK)

If the TCLK frequency is lower than the PCLK frequency, when a new value is written to the SCR0.TE or RE bit, the time until the value is propagated to the transmitter or receiver is longer than the register access time. Before rewriting registers and bits that can only be rewritten while the TE and RE bits are set to 0, be sure to set the TE and RE bits to 0 and to confirm that the values of the SISSR.ITEF and IREF flags have become 0.

42.20.16 Note on Aborting Operation

If 0 is written to SCR0.RE bit during data reception and the receive operation is aborted, the status may become invalid depending on the timing. Therefore, do not use the received data (value stored in the RDR register) or the flag value of each status register. To abort the receive operation, disable the interrupt and event link related to reception, and then write 0 to the SCR0.RE bit.

43. I3C Bus Interface (RI3C)

This MCU has a single-channel I3C bus interface (RI3C0).
The RI3C module conforms with the MIPI Alliance I3C bus interface and the NXP I2C-bus (Inter-IC bus) interface, and provides a subset of their functions.

43.1 Overview

Table 43.1 and Table 43.2 list the specifications of the RI3C and Figure 43.1 and Figure 43.2 show block diagrams of the RI3C. Table 43.3 lists the I/O pins of the RI3C.

Table 43.1 RI3C Specifications (I2C Protocol Mode) (1/2)

Item	Specification
Operation mode	Four • Master transmit mode, master receive mode, slave transmit mode, and slave receive mode
Communication format/ Transfer rate	• I2C-bus format - Standard-mode (Sm): 0 to 100 kbps - Fast-mode (Fm): 0 to 400 kbps - Fast-mode Plus (Fm+): 0 to 1 Mbps - High-speed mode (Hs-mode): 0 to 3.4 Mbps • SMBus format: 10 to 100 kbps • Master mode or slave mode selectable • Automatic securing of the various setup times, hold times, and bus-free times for the transfer rate
Serial clock (SCL)	• For master operation, the duty cycle of the SCL is selectable in the range from 4 to 96%.
Generating and detecting conditions	START, repeated START, and STOP conditions are automatically generated. START conditions (including repeated START conditions) and STOP conditions are detectable.
Address detection	• Slave address (static address) (max 3 address) • 7-bit and 10-bit address formats are supported. • General call address • Hs-mode master code • Device ID • Host address
Acknowledgment	• For transmission, the acknowledgment bit is automatically loaded. Transfer of the next data for transmission can be automatically suspended on detection of a not-acknowledge signal. • For reception, the acknowledgment bit is automatically transmitted. If a wait between the eighth and ninth clock pulses has been selected, software control of the acknowledgment in response to the received data is possible.
Wait function (clock stretch)	• During reception, cycles of waiting by holding the SCL line low can be inserted at the following two types of timing: Waiting between the eighth and ninth clock pulses Waiting between the ninth clock pulse and the first clock pulse of the next byte
SDA output delay function	It is possible to delay the change timing of the output of the transmission data bits and the acknowledgment bit relative to the falling edge of SCL.
Arbitration	• For multi-master operation Clock synchronization for the SCL line in cases of conflict with the SCL signal from another master is possible. When generating the START condition would create conflict on the bus, loss in arbitration is detected by testing for non-matching between the internal data level and the actual level on the SDA line. During master operation, loss in arbitration is detected by testing for non-matching between the actual level on the SDA line and the internal data level. • Loss in arbitration due to detection of the START condition while the bus is busy is detectable (to prevent the generating of double START conditions). • Loss in arbitration in transfer of a not-acknowledge signal due to the internal signal (NACK) and the actual level on the SDA line not matching is detectable. • Loss in arbitration due to non-matching of internal data level and the actual level on the SDA line is detectable in slave transmission.
Timeout function	The internal timeout function is capable of detecting long-interval stop of the SCL.
Noise filter	• Analog noise filter • Digital noise filter

Table 43.1 RI3C Specifications (I^2C Protocol Mode) (2/2)

Item	Specification
Interrupt source	Five sources: • Transmit data empty (TXI) • Receive data full (RXI) • Transmission end (TEI) • Communication error or communication event (EEI) - START condition detection (including repeated START condition) - STOP condition detection - NACK detection - Arbitration lost - Timeout detection • Wake-up (WUI) - Slave address match detection
Event link function (output)	• Transmit data empty • Receive data full • Transmission end • Communication error or communication event
Low power consumption function	Module stop state can be set.
Protect Zone filter	Security attributes can be set.*1

Note 1. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Table 43.2 RI3C Specifications (I3C Protocol Mode) (1/2)

Item	Specification
Operation mode	Controller (Primarily Controller/Secondary Controller) mode and Target mode selectable
Data handler	• Controller: - High-priority FIFO buffer transfer - FIFO buffer transfer • Target: - FIFO buffer transfer
Communication protocol	• SDR (I3C single data rate) mode - Private message - Broadcast message (common command code (CCC)) - Direct message (common command code (CCC)) • Legacy I^2C message - Fast-mode (Fm): 0 to 400 kbps - Fast-mode Plus (Fm+): 0 to 1 Mbps
IBI	• Target Interrupt Request (TIR) • Controller Role Request (CRR) (Secondary Controller only)
Address format	7-bit address
Address detection	• Target address (Static Address or Dynamic Address) • Broadcast Address (7Eh)
Clock stalling	The I3C Controller can stall the I3C bus while the SCL line is low.
Timing control	• Synchronous time control - Sync Mode • Asynchronous time control - Async Mode 0: Asynchronous Basic Mode - Async Mode 1: Asynchronous Advanced Mode

Table 43.2 RI3C Specifications (I3C Protocol Mode) (2/2)

Item	Specification
Interrupt source	12 sources: • Transmit data empty (TXI) • Receive data full (RXI) • Command queue empty (CMDI) • Response queue full (RESPI) • IBI queue empty/full (IBII) • Receive status queue full (RCVI) • High-priority transmit data empty (HTXI) • High-priority receive data full (HRXI) • High-priority command queue empty (HCMDI) • High-priority response queue full (HRESPI) • Communication error or communication event (EEI) - START condition detection (including repeated START condition) - STOP condition detection - HDR exit pattern detection - Timeout detection - Buffer access error detection - Data transfer abort - Data transfer error - High-priority data transfer abort - High-priority data transfer error • Wake-up (WUI) - Low detection on the SDA line (START condition detection) - Target address match detection
Error detection	• Buffer access error • Address header error • Address NACKed or Dynamic Address Assignment NACKed • Receive overflow or transmit underflow error • Transfer abort • NACK is received during an I^2C write data transfer • Timeout
Event link output	• Transmit data empty event • Receive data full event • Command queue empty • Response queue full • IBI queue empty/full • Receive status queue full • High-priority transmit data empty • High-priority receive data full • High-priority command queue empty • High-priority response queue full • Communication error or communication event • Synchronous timing event • C_REF counter overflow event • C_REF capture event • Additional bus event
Event link input	• T_C1 capture event
Low power consumption function	Module stop state can be set.
Protect Zone filter	Security attributes can be set.*1

Note 1. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

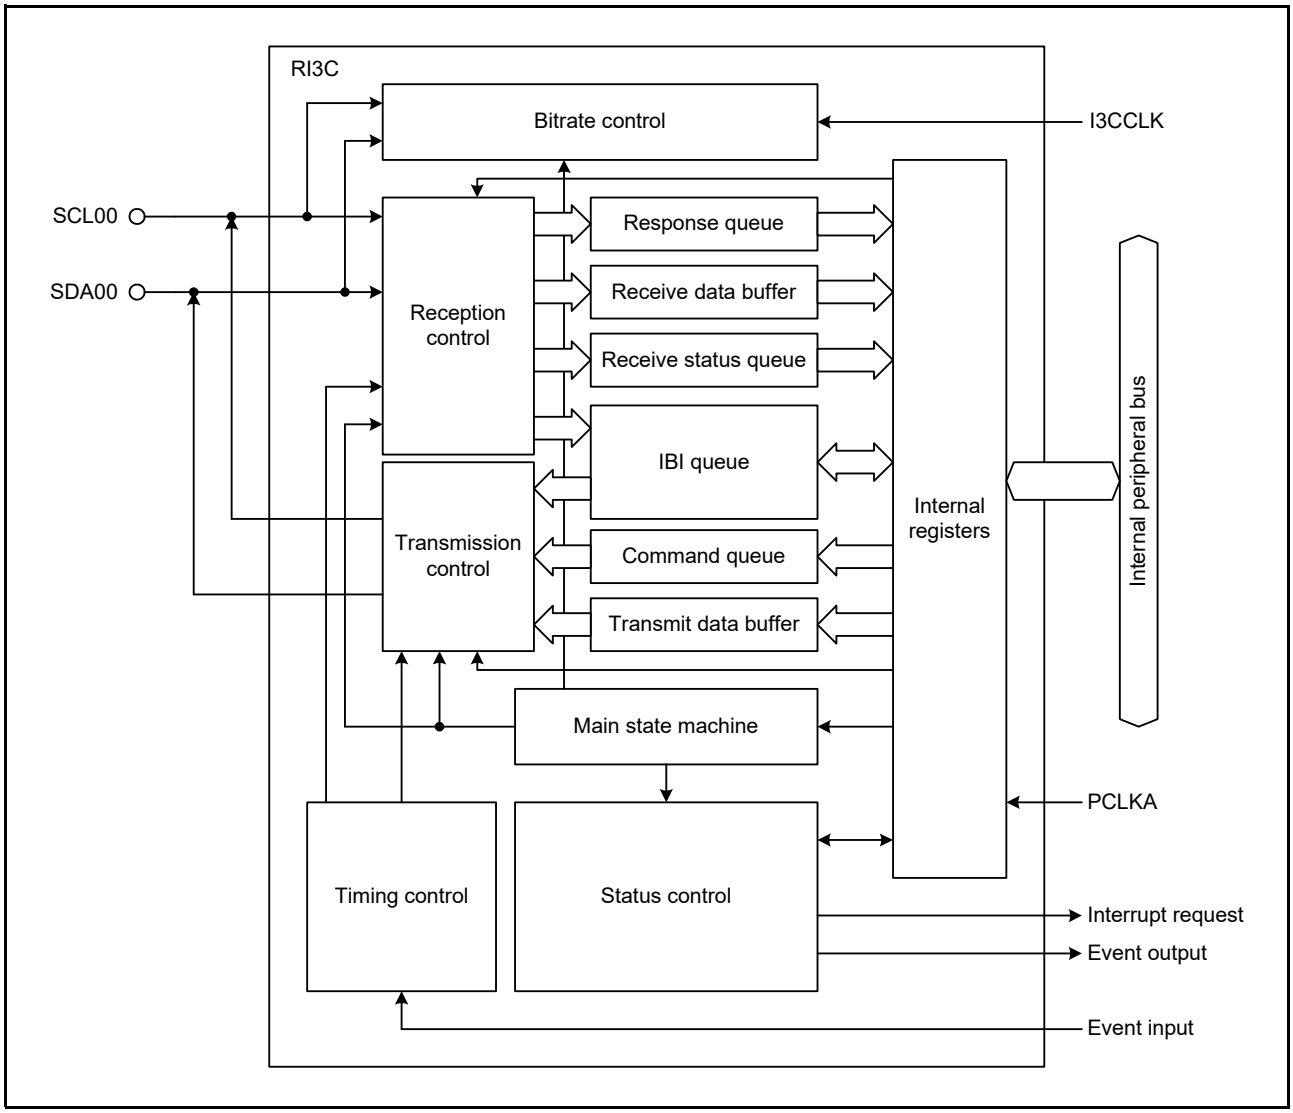

Figure 43.2 RI3C Block Diagram (I3C Protocol Mode)

Table 43.3 RI3C Pin Configuration

Channel	Pin Name	I/O	Function
RI3C0	SCL00	I/O	Serial clock I/O pin
	SDA00	I/O	Serial data I/O pin

43.2 Register Descriptions

43.2.1 Mode Register (ICMR)

Address(es): RI3C0.ICMR 8745 F000h, RI3C0_NS.ICMR 0745 F000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OMS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	OMS	Operating Mode Select*1	0: I3C protocol mode 1: I2C protocol mode	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Rewrite this bit while the ICRCR.ISRST bit is set to 1.

43.2.2 Control Register (ICCR)

Address(es): RI3C0.ICCR 8745 F014h, RI3C0_NS.ICCR 0745 F014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ICE	RESUME	ABORT	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BAEXITMD	IBAINC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IBAINC	I3C Broadcast Address Include *1	0: Do not include I3C Broadcast Address for private transfers 1: Include I3C Broadcast Address for private transfers	R/W
b1	BAEXITMD	Broadcast Address Exit Mode*1	0: Does not add an HDR Exit Pattern 1: Add an HDR Exit Pattern	R/W
b28 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b29	ABORT	Host Controller Abort*1	Writing 1 to this bit aborts the currently issued transfer. Write 0 to this bit to clear the Aborted state. Values when read: 0: Aborted state is cleared. 1: RI3C remains in Aborted state.	R/W
b30	RESUME	Host Controller Resume*1	Writing 1 to this bit while RI3C is in the Halt state can resume the operation. Values when read: 0: RI3C is running. 1: RI3C is suspended.	R/W
b31	ICE	Bus Interface Enable	0: The I3C bus operation is disabled. (SCL00 and SDA00 pins in inactive state) 1: The I3C bus operation is enabled. (SCL00 and SDA00 pins in active state)	R/W

Note 1. This bit is used in I3C Primarily Controller and I3C Secondary Controller modes.
Note 2. This bit is used in I3C protocol mode.

IBAINC Bit (I3C Broadcast Address Include)

This bit controls whether the I3C Broadcast Address (7Eh) is included for private transfers.
If the I3C Broadcast Address is not included for private transfers, then IBIs driven from Target devices might not win the arbitration, potentially delaying acceptance of the IBIs.

BAEXITMD Bit (Broadcast Address Exit Mode)

This bit is used to generate the HDR Exit Pattern on the I3C bus for error recovery.
When this bit is set to 1, the HDR Exit Pattern is sent following the I3C Broadcast Address (7Eh).

ABORT Bit (Host Controller Abort)

When 1 is written to this bit, RI3C starts the abort operation which terminates the currently issued transfer.
In response to an Abort request, RI3C issues the STOP condition to terminate the current transaction on the I3C bus after the complete data byte is transferred or received. At this time, this bit becomes 1.
To resume operation, write 0 to this bit.
If this bit is set to 1 to abort the transaction, ignore the ERR_STATUS field in the Response Descriptor.

RESUME Bit (Host Controller Resume)

This bit is used to resume I3C operation following the Halt state.
RI3C enters the Halt state as a result of any type of error occurring in a transfer. The error type is indicated by the ERR_STATUS field in Response Descriptor.
After RI3C has entered the Halt state, the application must write 1 to this bit to resume operation. This bit is automatically set to 0 when RI3C restarts the transfer (starting the next command).

ICE Bit (Bus Interface Enable)

Enables or disables the operation on the I3C bus.
When using RI3C, set this bit to 1. When this bit is 1, the SCL00 and SDA00 pins are active.
Set this bit to 0 when RI3C is not used. When the ICE bit is 0, the SCL00 and SDA00 pins are inactive.
When this bit is read as 0, it indicates that I3C bus operation is prohibited.

43.2.3 Controller Device Address Register (ICCAR)

Address(es): RI3C0.ICCAR 8745 F018h, RI3C0_NS.ICCAR 0745 F018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DAV	—	—	—	—	—	—	—	—	DADR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b22 to b16	DADR[6:0]	Dynamic Address	Set the Dynamic Address of RI3C.	R/W
b30 to b23	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31	DAV	Dynamic Address Valid	0: The DADR[6:0] bits are not valid. 1: The DADR[6:0] bits are valid.	R/W

Note: This register is used in I3C Primarily Controller mode.

This register is used to store the Dynamic Address of RI3C.
When the ICCR.ICE bit is set to 1 after setting this register, the device will act as Primary Controller.
If the ICCR.ICE bit is set to 1 after setting the ICDCTR.ROLE[1:0] bits to 00b (I3C Target) or the ICTDCTRm.ROLE[1:0] bits to 01b (I3C Controller capable) without setting this register, the device will act as Target.

DADR[6:0] Bits (Dynamic Address)

These bits are used to program RI3C Controller Dynamic Address. RI3C uses this address to respond to Controller transactions in I3C interface mode (Target or Secondary Controller mode).
In I3C Active Controller mode, the software shall program the Dynamic Address as it self-assigns its Dynamic Address.

DAV Bit (Dynamic Address Valid)

This bit indicates whether or not the value in the DADR[6:0] bits is valid.
In I3C Active Controller mode, set this bit to 1 as it self-assigns its Dynamic Address.

43.2.4 Reset Control Register (ICRCR)

Address(es): RI3C0.ICRCR 8745 F020h, RI3C0_NS.ICRCR 0745 F020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ISRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	HRBRST	HTBRST	HRQRST	HCQRST	—	—	SQRST	IQRST	RBRST	TBRST	RQRST	CQRST	MRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MRST	Module Reset*1	Writing 1 to this bit resets all registers and internal circuits. This bit automatically returns to 0 when the reset is complete.	R/W
b1	CQRST	Command Queue Reset*2	Writing 1 to this bit flushes the command queue. This bit automatically returns to 0 when the command queue has been flushed.	R/W
b2	RQRST	Response Queue Reset*2	Writing 1 to this bit flushes the response queue. This bit automatically returns to 0 when the response queue has been flushed.	R/W
b3	TBRST	Transmit Data Buffer Reset*2	Writing 1 to this bit flushes the transmit data buffer. This bit automatically returns to 0 when the transmit data buffer has been flushed.	R/W
b4	RBRST	Receive Data Buffer Reset*2	Writing 1 to this bit flushes the receive data buffer. This bit automatically returns to 0 when the receive data buffer has been flushed.	R/W
b5	IQRST	IBI Queue Reset*2	Writing 1 to this bit flushes the IBI queue. This bit automatically returns to 0 when the IBI queue has been flushed.	R/W
b6	SQRST	Receive Status Queue Reset*3	Writing 1 to this bit flushes the receive status queue. This bit automatically returns to 0 when the receive status queue has been flushed.	R/W
b8, b7	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9	HCQRST	High-Priority Command Queue Reset*4	Writing 1 to this bit flushes the high-priority command queue. This bit automatically returns to 0 when the high-priority command queue has been flushed.	R/W
b10	HRQRST	High-Priority Response Queue Reset*4	Writing 1 to this bit flushes the high-priority response queue. This bit automatically returns to 0 when the high-priority response queue has been flushed.	R/W
b11	HTBRST	High-Priority Transmit Data Buffer Reset*4	Writing 1 to this bit flushes the high-priority transmit data buffer. This bit automatically returns to 0 when the high-priority transmit data buffer has been flushed.	R/W
b12	HRBRST	High-Priority Receive Data Buffer Reset*4	Writing 1 to this bit flushes the high-priority receive data buffer. This bit automatically returns to 0 when the high-priority receive data buffer has been flushed.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	ISRST	Internal Status Reset	0: Some registers and internal circuits are released from reset. 1: Some registers and internal circuits are reset.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Do not write any value to this register when this bit is 1.
Note 2. This bit is used in I3C protocol mode.
Note 3. This bit is used in I3C Secondary Controller and I3C Target modes.
Note 4. This bit is used in I3C Primarily Controller and I3C Secondary Controller modes.

ISRST Bit (Internal Status Reset)

When this bit is set to 1, some registers and internal circuits are reset. Refer to section 43.8, Reset Description for detail on the registers.

Set this bit to 0 to release from the reset.

43.2.5 Operating Mode Monitor Register (ICMMR)

Address(es): RI3C0.ICMMR 8745 F024h, RI3C0_NS.ICMMR 0745 F024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	WP	—	—	TRS	—	ACF	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b2	ACF	Active Controller Flag*1, *2	• In I3C protocol mode 0: RI3C is not the Active Controller. 1: RI3C is the Active Controller. • In I2C protocol mode 0: Slave mode 1: Master mode	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	TRS	Transmit/Receive Mode Flag*3	0: Receive mode 1: Transmit mode	R
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b7	WP	Write Protect*1	0: Writing to the ACF flag is disabled. 1: Writing to the ACF flag is enabled (when writing simultaneously with the value of the target bit).	W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. This bit is used in I3C Primarily Controller, I3C Secondary Controller, and I2C protocol modes.
Note 2. When setting a value to the ACF flag, set the WP bit to 1 at the same time.
Note 3. This bit is used in I2C protocol mode.

ACF Flag (Active Controller Flag)

In I3C protocol mode:
This flag indicates whether the RI3C is presently the Active Controller.
[Setting conditions]

- When 1 is written to the WP bit and the ACF flag at the same time.
- When 1 is written to the ICCAR.DAV bit. (in I3C Primarily Controller mode)
- When GETACCCR reception is successfully completed by issuing STOP condition, after the ACK is responded to the Controller Role Request transmitted to the Secondary Controller. (in I3C Primarily Controller mode)
- When GETACCCR reception is successfully completed by issuing STOP condition, after the ACK is responded to the Controller Role Request transmitted to the Active Controller. (in I3C Secondary Controller mode)

[Clearing conditions]

- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When 1 is written to the WP bit and 0 is written to the ACF flag at the same time.
- When 0 written to the ICCAR.DAV bit. (in I3C Primarily Controller mode)
- When GETACCCR transmission is successfully completed by issuing STOP condition, after responding ACK to the Controller Role Request received from the Secondary Controller. (in I3C Primarily Controller mode)
- When GETACCCR transmission is successfully completed by issuing STOP condition, after responding ACK to

the Controller Role Request received from another Controller-capable device. (in I3C Secondary Controller mode)

In I^2C protocol mode:

This flag indicates master or slave mode.

The RI3C is in slave mode when the ACF flag is set to 0 and is in master mode when the flag is set to 1. Combination of this flag and the TRS flag indicates the operating mode of the RI3C.

The value of the ACF flag is automatically changed to 1 for master mode or 0 for slave mode by generating of a START condition and generating or detection of a STOP condition, etc. Although writing to the ACF flag is possible when the WP bit is set to 1, writing to this flag is not necessary during normal usage.

[Setting conditions]

- When 1 is written to the WP bit and the ACF flag at the same time.
- When a START condition is generated normally according to the START condition generation request (when a START condition is detected with the ICCGR.ST bit set to 1).

[Clearing conditions]

- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.
- When 1 is written to the WP bit and 0 is written to the ACF flag at the same time.
- When a STOP condition is detected.
- When the ICSR2.AL flag becomes 1 (arbitration is lost).

TRS Flag (Transmit/Receive Mode Flag)

This flag indicates transmit or receive mode. It is used in I^2C protocol mode.

The RI3C is in receive mode when the TRS flag is set to 0 and is in transmit mode when the bit is set to 1. Combination of this flag and the ACF flag indicates the operating mode of the RI3C.

The value of TRS flag is automatically changed to 1 for transmit mode or 0 for receive mode by generating or detection of a START condition and setting of the R/W# bit.

[Setting conditions]

- When a START condition is generated normally according to the START condition generation request (when a START condition is detected with the ICCGR.ST bit set to 1).
- When a repeated START condition is generated normally according to the repeated START condition generation request (when a repeated START condition is detected with the ICCGR.RS bit set to 1).
- When the R/W# bit added to the slave address is set to 0 in master mode.
- When the address received in slave mode matches the address enabled in the ICSCR register, with the R/W# bit set to 1.

[Clearing conditions]

- When a STOP condition is detected.
- When the ICSR2.AL flag becomes 1 (arbitration is lost).
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended.
- In slave mode, a match between the received address and the address enabled in the ICSCR register when the value of the received R/W# bit is 0 (including cases where the received address is the general call address).
- In slave mode, a repeated START condition is detected (a START condition is detected with ICBSR.BFREE flag = 0 and ACF flag = 0).
- When 1 is written to ICRCR.MRST bit or ICRCR.ISRST bit to reset the RI3C or the internal status.

WP Bit (Write Protect)

This bit is used to rewrite the ACF flag.

When setting a value to the ACF flag, set this bit to 1 at the same time.

This bit is automatically set to 0. The read value is 0.

43.2.6 Internal Status Register (ICISR)

Address(es): RI3C0.ICISR 8745 F030h, RI3C0_NS.ICISR 0745 F030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b10	BERF	Buffer Access Error Flag	0: Buffer access error has not been detected. 1: Buffer access error was detected.	R/W*1
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C protocol mode.
Note 1. To clear this flag, confirm that the flag is 1 and then set it to 0.

BERF Flag (Buffer Access Error Flag)

This flag indicates that an access error to data buffers or queue buffers has been detected.

[Setting conditions]

When any of the following conditions is satisfied while the ICISER.BERDE bit is 1.

- When a transmit data is written while the transmit data buffer is completely full.
- When a received data is read while the receive data buffer is completely empty.
- When a Command Descriptor is written while the command queue is completely full.
- When a Response Descriptor is read while the response queue is completely empty.
- When a Receive Status Descriptor is read while the receive status queue is completely empty.
- When an IBI Status Descriptor is read while the ICMMR.ACF flag is 1 (Active Controller) and the IBI queue is completely empty.
- When an IBI data is written while the ICMMR.ACF flag is 0 (not Active Controller) and the IBI queue is completely full.
- When the response queue, IBI queue, or receive status queue overflows.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.

43.2.7 Internal Status Detection Enable Register (ICISER)

Address(es): RI3C0.ICISER 8745 F034h, RI3C0_NS.ICISER 0745 F034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	BERIE	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b10	BERIE	Buffer Access Error Detection Interrupt Enable	0: Buffer access error detection interrupt is disabled. 1: Buffer access error detection interrupt is enabled.	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C protocol mode.

BERIE Bit (Buffer Access Error Detection Interrupt Enable)

When the BERF flag becomes 1 while this bit is 1, an interrupt is generated.

43.2.9 Device Characteristics Table Index Register (ICDCTIR)

Address(es): RI3C0.ICDCTIR 8745 F044h, RI3C0_NS.ICDCTIR 0745 F044h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	INDEX[4:0]					—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b18 to b0	—	Reserved	These bits are read as 0.	R
b23 to b19	INDEX[4:0]	DCT Table Index	Current index of the DCT, which is used as the starting index for the I3C ENTDAA CCC.	R
b31 to b24	—	Reserved	These bits are read as 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

INDEX[4:0] Bits (DCT Table Index)

Once the complete characteristics of device that won the arbitration are written to the Device Characteristics Table (DCT) during ENTDAA using address assignment command, this index is incremented by 1.

43.2.10 IBI Notify Control Register (ICINCR)

Address(es): RI3C0.ICINCR 8745 F058h, RI3C0_NS.ICINCR 0745 F058h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	RTIRN	—	RCRRN	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R
b1	RCRRN	Rejected Controller Role Request Notify	0: Do not pass the rejected IBI status to the IBI queue, if a Controller Role Request is rejected. 1: Pass the rejected IBI status to the IBI queue, if a Controller Role Request is rejected.	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R
b3	RTIRN	Rejected Target Interrupt Request Notify	0: Do not pass the rejected IBI status to the IBI queue, if a Target Interrupt Request is rejected. 1: Pass the rejected IBI status to the IBI queue, if a Target Interrupt Request is rejected.	R/W
b31 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

RCRRN Bit (Rejected Controller Role Request Notify)

This bit enables or disables reporting rejection of individual Controller Role Requests (CRR), if the incoming CRR is NACKed and is auto-disabled based on the setting of the relevant ICTDATRm.CRRRJ bit (m = 0 to 7).

RTIRN Bit (Rejected Target Interrupt Request Notify)

This bit enables or disables reporting rejection of individual Target Interrupt Requests (TIR), if the incoming TIR is NACKed and is auto-disabled based on the setting of the relevant ICTDATRm.TIRRJ bit.

43.2.11 Function Enable Register (ICFER)

Address(es): RI3C0.ICFER 8745 F060h, RI3C0_NS.ICFER 0745 F060h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HSME	FMPE	—	SMBS	—	—	—	SCLE	—	—	—	—	—	SALE	NALE	MALE
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	MALE	Master Arbitration-Lost Detection Enable	0: Master arbitration-lost detection is disabled. (Disables the arbitration-lost detection function and does not clear the ICMMR.ACF and ICMMR.TRS flags automatically when arbitration is lost.) 1: Master arbitration-lost detection is enabled. (Enables the arbitration-lost detection function and clears the ICMMR.ACF and ICMMR.TRS flags automatically when arbitration is lost.)	R/W
b1	NALE	NACK Transmission Arbitration-Lost Detection Enable	0: NACK transmission arbitration-lost detection is disabled. 1: NACK transmission arbitration-lost detection is enabled.	R/W
b2	SALE	Slave Arbitration-Lost Detection Enable	0: Slave arbitration-lost detection is disabled. 1: Slave arbitration-lost detection is enabled.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	SCLE	SCL Synchronization Enable	0: SCL synchronization is disabled. 1: SCL synchronization is enabled.	R/W
b11 to b9	—	Reserved	These bits are read as 0 and cannot be modified.	R
b12	SMBS	SMBus/I2C-bus Selection	0: The I2C-bus select 1: The SMBus select	R/W
b13	—	Reserved	This bit is read as 0. The write value should be 0.	R
b14	FMPE	Fast-mode Plus Enable	0: No Fm+ slope control circuit is used for the SCL00 pin and SDA00 pin. 1: An Fm+ slope control circuit is used for the SCL00 pin and SDA00 pin.	R/W
b15	HSME	Hs-mode Enable	0: High speed mode is disabled. 1: High speed mode is enabled.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I2C protocol mode.

MALE Bit (Master Arbitration-Lost Detection Enable)

This bit uses to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE Bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit uses to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

SALE Bit (Slave Arbitration-Lost Detection Enable)

This bit uses to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

SCLE Bit (SCL Synchronization Enable)

This bit uses to specify whether to synchronize the SCL output with the SCL input. Normally, set this bit to 1.
When the SCLE bit set to 0 (SCL synchronization is disabled), the RI3C does not synchronize the SCL output with the SCL input. In this setting, the RI3C outputs the clock with the transfer rate set in the ICBRH and ICBRL registers regardless of the SCL00 line state. For this reason, if the load of the I^2C bus line is much larger than the specification value or if the SCL output overlaps in multiple masters, the short-cycle SCL that does not meet the specification may be output. When the SCL synchronization is not, it also affects the generation of a START condition, repeated START condition, and STOP condition, and the continuous output of additional SCL.
This bit must not be set to 0 except for checking the output of the set transfer rate.

FMPE Bit (Fast-mode Plus Enable)

This bit uses to specify whether to use a slope control circuit for Fast-mode Plus (Fm+).
When this bit set to 1, a slope control circuit conforming to the Fast-mode Plus (Fm+) slope control standard (tof) of the I^2C-bus is selected. When this bit set to 0, a slope control circuit conforming to the Standard-mode (Sm) and Fast-mode (Fm) slope control standard (tof) of the I^2C-bus is selected.
Set this bit to 1 when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus (Fm+)) of the I^2C-bus standard. Set this bit to 0 when using the transmission rate at other rates (up to 100 kbps (Sm), up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps). When performing Hs-mode communication, set this bit according to the mode when sending the Hs-mode master code.

HSME Bit (Hs-mode Enable)

This bit is used for communicating in Hs-mode.
When this bit is set to 1, the Hs-mode master code is recognized and Hs-mode communication is possible.
After the START condition is detected, if Hs-mode master code (0000 1XXXb) transmission is recognized, Hs-mode communication starts from repeated START condition after receiving the NACK response.
It communicates at the bit rate set in the ICFBR register until the NACK response, and automatically switches from repeated START condition issuance after receiving the NACK response to the bit rate set in the ICHBR register.
Hs-mode continues until a STOP condition is detected.
When the STOP condition is detected, the bit rate is automatically switched to the bit rate set in the ICFBR register.

Note: When this bit is set to 1, the ICSR2.NACKF flag will not be set even if a NACK response is received after sending the Hs-mode master code.

43.2.12 Target Mode Control Register (ICTCR)

Address(es): RI3C0.ICTCR 8745 F064h, RI3C0_NS.ICTCR 0745 F064h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	TA0DE	Target Address 0 Detection Enable	0: The value of the ICDAMR0.TADR[9:0] bits is disabled. 1: The value of the ICDAMR0.TADR[9:0] bits is enabled.	R/W
b17	TA1DE	Target Address 1 Detection Enable	0: The value of the ICDAMR1.TADR[9:0] bits is disabled. 1: The value of the ICDAMR1.TADR[9:0] bits is enabled.	R/W
b18	TA2DE	Target Address 2 Detection Enable	0: The value of the ICDAMR2.TADR[9:0] bits is disabled. 1: The value of the ICDAMR2.TADR[9:0] bits is enabled.	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

TAyDE Bit (Target Address y Detection Enable) (y = 0 to 2)

This bit is used to enable or disable the Target address set in ICDAMRy.TADR[9:0] bits.

When this bit is set to 1, the Target address set in ICDAMRy.TADR[9:0] bits is enabled and is compared with the received Target address.

When this bit is set to 0, the Target address set in ICDAMRy.TADR[9:0] bits is disabled and is ignored even if it matches the received Target address.

43.2.13 Slave Mode Control Register (ICSCR)

Address(es): RI3C0.ICSCR 8745 F064h, RI3C0_NS.ICSCR 0745 F064h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	GCAE	General Call Address Detection Enable	0: General call address detection is disabled. 1: General call address detection is enabled.	R/W
b4 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b5	HSMCE	Hs-mode Master Code Detection Enable	0: Hs-mode master code detection is disabled. 1: Hs-mode master code detection is enabled.	R/W
b6	DIDE	Device-ID Address Detection Enable	0: Device-ID address detection is disabled. 1: Device-ID address detection is enabled.	R/W
b14 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R
b15	HOAE	Host Address Detection Enable	0: Host address detection is disabled. 1: Host address detection is enabled.	R/W
b16	SAR0E	Slave Address 0 Detection Enable	0: The value of the SAMR0.SVA[9:0] bits is disabled. 1: The value of the SAMR0.SVA[9:0] bits is enabled.	R/W
b17	SAR1E	Slave Address 1 Detection Enable	0: The value of the SAMR1.SVA[9:0] bits is disabled. 1: The value of the SAMR1.SVA[9:0] bits is enabled.	R/W
b18	SAR2E	Slave Address 2 Detection Enable	0: The value of the SAMR2.SVA[9:0] bits is disabled. 1: The value of the SAMR2.SVA[9:0] bits is enabled.	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I²C protocol mode.

GCAE Bit (General Call Address Detection Enable)

This bit is used to specify whether to ignore the general call address (0000 000b + 0 (write): All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the RI3C recognizes the received slave address as the general call address independently of the slave addresses set in SAMRy.SVA[9:0] bits and performs data receive operation.

When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

HSMCE Bit (Hs-mode Master Code Detection Enable)

This bit is used to specify whether to recognize and execute the Hs-mode master code (0000 1XXXb) is received in the first byte after a START condition is detected.

When this bit is set to 1, if the received first byte matches the Hs-mode master code, RI3C recognizes that the Hs-mode master code has been received.

The first byte after repeated START condition after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set in the SAMRy.SVA[9:0] bits (y = 0 to 2).

If the addresses match, the transmission/reception operation continues according to the R/W# bit value.

Hs-mode continues until a STOP condition is detected.

When this bit is set to 0, RI3C will ignore the pattern until a STOP condition is detected, even if it matches the Hs-mode

master code.
When this bit is set to 1, set the ICCSCR.WAITAE bit to 0 and ICCSCR.WAITRE bit to 1.

DIDE Bit (Device-ID Address Detection Enable)

This bit is used to specify whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first frame after a START condition or repeated START condition is detected.
When this bit is set to 1, if the received first frame matches the device ID, the RI3C recognizes that the device-ID address has been received. When the following R/W# bit is 0 (write), the RI3C recognizes the second and the following frames as slave addresses and continues the receive operation.
When this bit is set to 0, the RI3C ignores the received first frame even if it matches the device ID address and recognizes the first frame as a normal slave address.
For details on the device-ID address detection, refer to section 43.5.4.3, Device-ID Address Detection.

HOAE Bit (Host Address Detection Enable)

This bit uses to specify whether to ignore received host address (0001 000b) when the ICFER.SMBS bit is 1.
When this bit set to 1 while the ICFER.SMBS bit is 1, if the received slave address matches the host address, the RI3C recognizes the received slave address as the host address independently of the slave addresses set in SAMRy.SVA[9:0] bits and performs the receive operation.
When the ICFER.SMBS bit or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

SARyE Bit (Slave Address y Detection Enable) (y = 0 to 2)

This bit is used to enable or disable the slave address set in SAMRy.SVA[9:0] bits.
When this bit is set to 1, the slave address set in SAMRy.SVA[9:0] bits is enabled and is compared with the received slave address.
When this bit is set to 0, the slave address set in SAMRy.SVA[9:0] bits is disabled and is ignored even if it matches the received slave address.

43.2.14 Reference Clock Control Register (ICRCCR)

Address(es): RI3C0.ICRCCR 8745 F070h, RI3C0_NS.ICRCCR 0745 F070h

b15 to b8	ODHW[7:0]	Open-Drain High Width Setting	Count value for the high period of SCL in Open-Drain mode.	R/W
b21 to b16	PPLW[5:0]	Push-Pull Low Width Setting	Count value for the low period of SCL in Push-Pull mode.	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b29 to b24	PPHW[5:0]	Push-Pull High Width Setting	Count value for the high period of SCL in Push-Pull mode.	R/W
b30	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31	ODDBL	Open-Drain High/Low Width Doubling	0: Set the high and low widths to the set value in Open-Drain mode. 1: Double the high and low widths of the set values in Open-Drain mode.	R/W

Note 1. This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

This register is used to set the bit rate when the I3C SDR0 mode is specified in the MODE field of the Command Descriptor. When the I3C SDR2 mode is specified, a bit rate of 1/2 the bit rate set in this register is used.

ODLW[7:0] Bits (Open-Drain Low Width Setting)

The ODLW[7:0] bits are used to set the low period of SCL in Open-Drain mode.
The RI3C counts the low period with I3CCLK.

ODHW[7:0] Bits (Open-Drain High Width Setting)

The ODHW[7:0] bits are used to set the high period of SCL in Open-Drain mode.
These bits are valid in master/Controller mode.
The RI3C counts the high period with I3CCLK.

PPLW[5:0] Bits (Push-Pull Low Width Setting)

The PPLW[5:0] bits are used to set the low period of SCL in Push-Pull mode.
RI3C counts the low period with I3CCLK.

PPHW[5:0] Bits (Push-Pull High Width Setting)

The PPHW[5:0] bits are used to set the high period of SCL in Push-Pull mode.
These bits are valid in Controller mode.
RI3C counts the high period with I3CCLK.

The transfer rate and the duty cycle are calculated using the following expression.

t_{LOW} = ODLW[7:0] / I3CCLK
t_{HIGH} = ODHW[7:0] / I3CCLK
Transfer rate = 1 / (t_{LOW} + t_{HIGH} + t_r + t_f)
Duty cycle = (t_r + t_{HIGH}) / (t_{LOW} + t_{HIGH} + t_r + t_f)

t_{LOW}: Low period of the SCL
t_{HIGH}: high period of the SCL
t_r: Rise time of the SCL signal*1
t_f: Fall time of the SCL signal*1

Note 1. The SCL line rise time [t_r] and SCL line fall time [t_f] depend on the total bus line capacitance [C_b] and the pull-up resistor [R_p]. For details, refer to the I3C bus standard from MIPI Alliance.

43.2.16 F/S-Mode Bitrate Register (ICFBR)

Address(es): RI3C0.ICFBR 8745 F074h, RI3C0_NS.ICFBR 0745 F074h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DBL	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	1	1	1	1	1	1	0	0	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HIGH[7:0]								LOW[7:0]							
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	LOW[7:0]	Low Width Setting	Count value for the low period of SCL.	R/W
b15 to b8	HIGH[7:0]	High Width Setting	Count value for the high period of SCL.	R/W
b21 to b16	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b29 to b24	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b30	—	Reserved	This bit is read as 0. The write value should be 0.	R
b31	DBL	High/Low Width Doubling	0: Set the high and low widths to the set value. 1: Double the high and low widths of the set values.	R/W

Note: This register is used in I^2C protocol mode.

This register is used to specify the bit rate other than Hs-mode.

LOW[7:0] Bits (Low Width Setting)

The LOW[7:0] bits are used to set the low period of SCL.

The RI3C counts the low period with the internal reference clock source (IICφ) specified by the ICRCCR.CKS[2:0] bits. These bits also work to generate the data setup time for automatic SCL low-hold operation (refer to section 43.5.5, Automatic Low-Hold Function for SCL (I^2C Protocol Mode)); when the RI3C is used in slave mode, these bits need to be set to a value longer than the data setup time*1.

If the digital noise filter is enabled (the ICICR.NFE bit is 1), set the LOW[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICICR.NF[3:0] bits.

Note 1. Data setup time ($t_{SU;DAT}$)
250 ns (up to 100 kbps: Standard-mode (Sm))
100 ns (up to 400 kbps: Fast-mode (Fm))
50 ns (up to 1 Mbps: Fast-mode Plus (Fm+))

HIGH[7:0] Bits (High Width Setting)

The HIGH[7:0] bits are used to set the high period of SCL.

These bits are valid in master/Controller mode. If the RI3C is used only in I^2C slave mode, these bits need not to set the high period.

The RI3C counts the high period with the internal reference clock source (IICφ) specified by the ICRCCR.CKS[2:0] bits.

If the digital noise filter is enabled (the ICICR.NFE bit is 1), set the HIGH[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICICR.NF[3:0] bits.

The transfer rate and the duty cycle are calculated using the following expression.

t_{LOW} = (LOW[7:0] + NF[3:0] +1) / IICφ
t_{HIGH} = (HIGH[7:0] + NF[3:0] +1) / IICφ
Transfer rate = 1 / (t_{LOW} + t_{HIGH} + t_r + t_f)
Duty cycle = (t_r + t_{HIGH}) / (t_{LOW} + t_{HIGH} + t_r + t_f)

t_{LOW}: Low period of the SCL
t_{HIGH}: high period of the SCL
t_r: Rise time of the SCL signal*1
t_f: Fall time of the SCL signal*1

Note 1. The SCL line rise time [t_r] and SCL line fall time [t_f] depend on the total bus line capacitance [C_b] and the pull-up resistor [R_p]. For details, refer to the I²C-bus standard from NXP Semiconductors.

Table 43.4 Example of the ICFBR Register Settings for Transfer Rate (I3CCLK = 120 MHz)

Transfer Rate (kbps)	CKS[2:0] Bits	HIGH[7:0] Bits	LOW[7:0] Bits	NFE Bit	NF[3:0] Bits
10	101b	122 (7Ah)	247 (F7h)	0	—
	101b	121 (79h)	246 (F6h)	1	0001b
50	011b	91 (5Bh)	188 (BCh)	0	—
	011b	90 (5Ah)	187 (BBh)	1	0001b
100	010b	108 (6Ch)	151 (97h)	0	—
	010b	107 (6Bh)	150 (96h)	1	0001b
400	000b	68 (44h)	158 (9Eh)	0	—
	000b	67 (43h)	157 (9Dh)	1	0001b
	001b	34 (22h)	78 (4Eh)	0	—
	001b	33 (21h)	77 (4Dh)	1	0001b
1000	000b	27 (1Bh)	63 (3Fh)	0	—
	000b	26 (1Ah)	62 (3Eh)	1	0001b
	001b	13 (0Dh)	31 (1Fh)	0	—
	001b	12 (0Ch)	30 (1Eh)	1	0001b

Rise time of SCL signal (t_r)
- 100 kbps or less (Sm): 1000 ns
- 400 kbps (Fm): 300 ns
- 1 Mbps (Fm+): 120 ns

Fall time of SCL signal (t_f)
- 400 kbps (Sm/Fm): 300 ns
- 1 Mbps (Fm+): 120 ns

43.2.17 Extended Bitrate Register (ICEBR)

Address(es): RI3C0.ICEBR 8745 F078h, RI3C0_NS.ICEBR 0745 F078h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	PPHW[5:0]						—	—	PPLW[5:0]					
Value after reset:	0	0	1	1	1	1	1	1	0	0	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ODHW[7:0]								ODLW[7:0]							
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	ODLW[7:0]	Open-Drain Low Width Setting	Count value for the low period of SCL in Open-Drain mode.	R/W
b15 to b8	ODHW[7:0]	Open-Drain High Width Setting	Count value for the high period of SCL in Open-Drain mode.	R/W
b21 to b16	PPLW[5:0]	Push-Pull Low Width Setting	Count value for the low period of SCL in Push-Pull mode.	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b29 to b24	PPHW[5:0]	Push-Pull High Width Setting	Count value for the high period of SCL in Push-Pull mode.	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

This register is used to set the bit rate when the I3C SDR1 mode is specified in the MODE field of the Command Descriptor. When the I3C SDR3 mode is specified, a bit rate of 1/2 the bit rate set in this register is used. When the I3C SDR4 mode is specified, a bit rate of 1/4 the bit rate set in this register is used.

ODLW[7:0] Bits (Open-Drain Low Width Setting)

The ODLW[7:0] bits are used to set the low period of SCL in Open-Drain mode.
The RI3C counts the low period with I3CCLK.

ODHW[7:0] Bits (Open-Drain High Width Setting)

The ODHW[7:0] bits are used to set the high period of SCL in Open-Drain mode.
These bits are valid in master/Controller mode.
The RI3C counts the high period with I3CCLK.

PPLW[5:0] Bits (Push-Pull Low Width Setting)

The PPLW[5:0] bits are used to set the low period of SCL in Push-Pull mode.
The RI3C counts the low period with the I3CCLK.

PPHW[5:0] Bits (Push-Pull High Width Setting)

The PPHW[5:0] bits are used to set the high period of SCL in Push-Pull mode.
These bits are valid in Controller mode.
The RI3C counts the high period with the I3CCLK.

The transfer rate and the duty cycle are calculated using the following expression.

t_{LOW} = ODLW[7:0] / I3CCLK
t_{HIGH} = ODHW[7:0] / I3CCLK
Transfer rate = 1 / (t_{LOW} + t_{HIGH} + t_r + t_f)
Duty cycle = (t_r + t_{HIGH}) / (t_{LOW} + t_{HIGH} + t_r + t_f)

t_{LOW}: Low period of the SCL
t_{HIGH}: high period of the SCL
t_r: Rise time of the SCL signal*1
t_f: Fall time of the SCL signal*1

Note 1. The SCL line rise time [t_r] and SCL line fall time [t_f] depend on the total bus line capacitance [C_b] and the pull-up resistor [R_p]. For details, refer to the I3C bus standard from MIPI Alliance.

43.2.18 Hs-Mode Bitrate Register (ICHBR)

Address(es): RI3C0.ICHBR 8745 F078h, RI3C0_NS.ICHBR 0745 F078h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	1	1	1	1	1	1	0	0	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HIGH[7:0]								LOW[7:0]							
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	LOW[7:0]	Low Width Setting	Count value for the low period of SCL.	R/W
b15 to b8	HIGH[7:0]	High Width Setting	Count value for the high period of SCL.	R/W
b21 to b16	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b29 to b24	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I2C protocol mode.

This register is used to specify the bit rate in Hs-mode.

LOW[7:0] Bits (Low Width Setting)

The LOW[7:0] bits are used to set the low period of SCL.
The RI3C counts the low period with the internal reference clock source (IICφ) specified by the ICRCCR.CKS[2:0] bits. These bits also work to generate the data setup time for automatic SCL low-hold operation (refer to section 43.5.5, Automatic Low-Hold Function for SCL (I2C Protocol Mode)); when the RI3C is used in slave mode, these bits need to be set to a value longer than the data setup time*1.
If the digital noise filter is enabled (the ICICR.NFE bit is 1), set the LOW[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICICR.NF[3:0] bits.

Note 1. Data setup time ($t_{SU;DAT}$)
10 ns (up to 3.4 Mbps: Hs-mode (Hs))

HIGH[7:0] Bits (High Width Setting)

The HIGH[7:0] bits are used to set the high period of SCL.
These bits are valid in master/Controller mode. If the RI3C is used only in I2C slave mode, these bits need not to set the high period.
The RI3C counts the high period with the internal reference clock source (IICφ) specified by the ICRCCR.CKS[2:0] bits.
If the digital noise filter is enabled (the ICICR.NFE bit is 1), set the HIGH[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICICR.NF[3:0] bits.

The transfer rate and the duty cycle are calculated using the following expression.

t_{LOW} = (LOW[7:0] + NF[3:2] +1) / IICφ
t_{HIGH} = (HIGH[7:0] + NF[3:2] +1) / IICφ
Transfer rate = 1 / (t_{LOW} + t_{HIGH} + t_r + t_f)
Duty cycle = (t_r + t_{HIGH}) / (t_{LOW} + t_{HIGH} + t_r + t_f)

t_{LOW}: Low period of the SCL
t_{HIGH}: high period of the SCL
t_r: Rise time of the SCL signal*1
t_f: Fall time of the SCL signal*1

Note 1. The SCL line rise time [t_r] and SCL line fall time [t_f] depend on the total bus line capacitance [C_b] and the pull-up resistor [R_p]. For details, refer to the I2C-bus standard from NXP Semiconductors.

43.2.19 Bus Free Time Setting Register (ICBFTR)

Address(es): RI3C0.ICBFTR 8745 F07Ch, RI3C0_NS.ICBFTR 0745 F07Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to specify the time from when the STOP condition is detected until the ICBSR.BFREE flag is set to 1. The upper 23 bits are reserved. These bits are read as 0 and the write value should be 0.
The number set in this register is counted using IICφ (in I2C protocol mode) or I3CCLK (in I3C protocol mode) as the count source.
Set a value that satisfies the t_{BUF} (bus free time between a STOP and START condition) specified in the I2C-bus specification.

43.2.20 Bus Available Time Setting Register (ICBATR)

Address(es): RI3C0.ICBATR 8745 F080h, RI3C0_NS.ICBATR 0745 F080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C protocol mode.

This register is used to specify the time from when the STOP condition is detected until the ICBSR.BAVL flag is set to 1.
The upper 23 bits are reserved. These bits are read as 0 and the write value should be 0.
The number set in this register is counted using I3CCLK as the count source.

43.2.21 Bus Idle Time Setting Register (ICBITR)

Address(es): RI3C0.ICBITR 8745 F084h, RI3C0_NS.ICBITR 0745 F084h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C protocol mode.

This register is used to specify the time from when the STOP condition is detected until the ICBSR.BIDL flag is set to 1.
The upper 14 bits are reserved. These bits are read as 0 and the write value should be 0.
The number set in this register is counted using I3CCLK as the count source.

43.2.22 Output Signal Control Register (ICOCR)

Address(es): RI3C0.ICOCR 8745 F088h, RI3C0_NS.ICOCR 0745 F088h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DLCS	—	—	—	—	SDDL[2:0]			—	—	—	CLO	—	SOWP	SCLO	SDAO
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SDAO	SDA Output Control*1	0: The RI3C drives the SDA00 pin low. 1: The RI3C releases the SDA00 pin.	R/W
b1	SCLO	SCL Output Control*1	0: The RI3C drives the SCL00 pin low. 1: The RI3C releases the SCL00 pin.	R/W
b2	SOWP	SCLO/SDAO Write Protect*1	0: Writing to the SCLO and SDAO bits is disabled. 1: Writing to the SCLO and SDAO bits is enabled (when writing simultaneously with the value of the target bit). This bit is read as 0.	W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	CLO	Additional SCL Output*2	0: Does not output an additional SCL (default). 1: Outputs an additional SCL. (This bit automatically becomes 0 after output of one clock pulse.)	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b10 to b8	SDDL[2:0]	SDA Output Delay Setting*2	• When ICOCR.DLCS bit is 0 (IICφ) b10 b8 0 0 0: No output delay 0 0 1: 1 IICφ cycle 0 1 0: 2 IICφ cycles 0 1 1: 3 IICφ cycles 1 0 0: 4 IICφ cycles 1 0 1: 5 IICφ cycles 1 1 0: 6 IICφ cycles 1 1 1: 7 IICφ cycles • When ICOCR.DLCS bit is 1 (IICφ/2) b10 b8 0 0 0: No output delay 0 0 1: 1 or 2 IICφ cycles 0 1 0: 3 or 4 IICφ cycles 0 1 1: 5 or 6 IICφ cycles 1 0 0: 7 or 8 IICφ cycles 1 0 1: 9 or 10 IICφ cycles 1 1 0: 11 or 12 IICφ cycles 1 1 1: 13 or 14 IICφ cycles	R/W
b14 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R
b15	DLCS	SDA Output Delay Clock Source Select*2	0: The internal reference clock (IICφ) is selected as the clock source of the SDA output delay counter. 1: The internal reference clock divided by 2 (IICφ/2) is selected as the clock source of the SDA output delay counter.*3	R/W
b16	—	Reserved	This bit is read as 1. The write value should be 1.	R
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. This bit is used in I3C Primarily Controller, I3C Secondary Controller, and I²C protocol modes.
Note 2. This bit is used in I²C protocol mode.
Note 3. This setting (IICφ/2) is valid only when the SCL pin is low. When the SCL pin is high, this setting is invalid and the clock source becomes the internal reference clock (IICφ).

SDAO Bit (SDA Output Control) and SCLO Bit (SCL Output Control)

These bits are used to directly control the SDA00 and SCL00 signals output from the RI3C.
When writing to these bits, also write 1 to the SOWP bit at the same time.
The result of setting these bits is input to the RI3C via the input buffer. When slave/Target mode is selected, a START condition may be detected and the bus may be released depending on the bit settings.
Do not rewrite these bits during a START condition, STOP condition, repeated START condition, transmission, or reception. Operation after rewriting under the above conditions is not guaranteed.

CLO Bit (Additional SCL Output)

This bit is used to output an additional SCL for debugging or error processing.
Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.
For details on this function, refer to section 43.5.8.2, Additional SCL Output Function.

43.2.23 Input Signal Control Register (ICICR)

Address(es): RI3C0.ICICR 8745 F08Ch, RI3C0_NS.ICICR 0745 F08Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	NF[3:0]	Noise Filter Stage Select	• Except in Hs-mode b3 b0 0 0 0 0: Noise of up to 1 IICφ cycle is filtered out (single-stage filter). 0 0 0 1: Noise of up to 2 IICφ cycles is filtered out (2-stage filter). 0 0 1 0: Noise of up to 3 IICφ cycles is filtered out (3-stage filter). : : 1 1 1 1: Noise of up to 16 IICφ cycles is filtered out (16-stage filter). • In Hs-mode b3 b2 0 0: Noise of up to 1 IICφ cycle is filtered out (single-stage filter). 0 1: Noise of up to 2 IICφ cycles is filtered out (2-stage filter). 1 0: Noise of up to 3 IICφ cycles is filtered out (3-stage filter). 1 1: Noise of up to 4 IICφ cycles is filtered out (4-stage filter). The lower 2 bits (b1 and b0) are ignored.	R/W
b4	NFE	Digital Noise Filter Enable	0: Digital noise filters are not used. 1: Digital noise filters are used.	R/W
b5	ANFE	Analog Noise Filter Enable	0: Analog noise filters are not used. 1: Analog noise filters are used.	R/W
b7, b6	—	Reserved	These bits are read as 1. The write value should be 1.	R
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I²C protocol mode.

NF[3:0] Bits (Noise Filter Stage Select)

These bits are used to select the number of stages in the digital noise filter.
For details on the digital noise filter function, refer to section 43.5.3, Digital Noise Filters (I²C Protocol Mode).

Note: Set the noise range to be filtered out by the noise filter within a range less than the SCL00 line high period or low period. If the noise filter width is set to a value of [the shorter one of either SCL high width or SCL low width] – {1.5 × t_{IICcyc} (cycle time of internal reference clock (IICφ)) + 120 ns (pulse width suppressed by the analog noise filter, reference values)} or a greater value, the serial clock is regarded as noise by the noise filter function of the RI3C, which may prevent the RI3C from operating normally.

43.2.24 Timeout Control Register (ICTOR)

Address(es): RI3C0.ICTOR 8745 F090h, RI3C0_NS.ICTOR 0745 F090h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	TMOS[1:0]	Timeout Detection Time Select	b1 b0 0 0: Timeout counter is 16 bits (up to 65536 counts) 0 1: Timeout counter is 14 bits (up to 16384 counts) 1 0: Timeout counter is 8 bits (up to 256 counts) 1 1: Timeout counter is 6 bits (up to 64 counts)	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	TMOL	Timeout L Count Control	0: Count is disabled while the SCL00 line is low. 1: Count is enabled while the SCL00 line is low.	R/W
b5	TMOH	Timeout H Count Control	0: Count is disabled while the SCL00 line is high. 1: Count is enabled while the SCL00 line is high.	R/W
b7, b6	TMOM[1:0]	Timeout Detection Mode Select	b7 b6 0 0: Timeout function is enabled in any of the following conditions. • When the ICBSR.BFREE flag is 0 (bus busy) in master/Controller mode • When the ICBSR.BFREE flag is 0 (bus busy) when the received slave/Target address matches its own slave/Target address in slave/Target mode • When the ICBSR.BFREE flag is 1 (bus free) while the ICCGR.ST is 1 (request to generate a START condition) 0 1: Timeout function is enabled during ICBSR.BFREE flag is 0 (bus busy). 1 0: Timeout function is enabled during ICBSR.BFREE flag is 1 (bus free). 1 1: Setting prohibited	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

TMOS[1:0] Bits (Timeout Detection Time Select)

These bits are used to select for the timeout detection time when the timeout function is enabled (ICSER.TMOE bit = 1). While the SCL00 line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with the internal reference clock (IICφ) or I3CCLK as a count source.

For details on the timeout function, refer to section 43.5.8.1, Timeout Function or 43.5.16.3 Timeout Detection in section 43.5.16, Error Detection (I3C Protocol Mode).

TMOL Bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL00 line is held low when the timeout function is enabled (ICSER.TMOE bit = 1).

TMOH Bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL00 line is held high when the timeout function is enabled (ICSER.TMOE bit = 1).

TMOM[1:0] Bits (Timeout Detection Mode Select)

These bits are used to set the timeout detection condition when the timeout function is enabled (ICSER.TMOE bit = 1).
When these bits are set to 00b, timeout detection is enabled during one of the following periods.

- When the bus is busy in master/Controller mode
- When RI3C is the target of the communication in slave/Target mode and the bus is busy
- When the bus is free while a START condition is requested

When these bits are set to 01b, timeout detection is enabled when the bus is busy.
When these bits are set to 10b, timeout detection is enabled when the bus is free.

43.2.25 Wake-Up Unit Control Register (ICWUCR)

Address(es): RI3C0.ICWUCR 8745 F098h, RI3C0_NS.ICWUCR 0745 F098h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	WUFE	WUFSYNE	—	WUANFE	—	—	—	WUACKS
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	WUACKS	Wake-Up Acknowledge Select*1	The response mode can be selected in combination with the ICRCR.ISRST bit. Refer to Table 43.5 for details.	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	WUANFE	Analog Noise Filter Enable*1	0: Analog noise filter for wake-up is disabled. 1: Analog noise filter for wake-up is enabled.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R
b6	WUFSYNE	Synchronous Operation Select	0: Asynchronous operation 1: Internal clock synchronous operation	R/W
b7	WUFE	Wake-Up Function Enable	0: Wake-Up function is disabled. 1: Wake-Up function is enabled.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. This bit is used in I2C protocol mode.

WUACKS Bit (Wake-Up Acknowledge Select)

This bit selects the ACK response when a wake-up condition is detected. This bit is used in I2C protocol mode.

Table 43.5 Response Mode

ICRCR.ISRST Bit	WUACKS Bit	Response Mode	Description
0	0	Normal wake-up mode 1	Responds with an ACK and holds the SCL line low.
0	1	Normal wake-up mode 2*1	Holds the SCL line low after eighth clock pulse, and when the low power consumption mode is released, release the SCL line and responds with an ACK.
1	0	Command recovery mode	Responds with an ACK but does not hold the SCL line low.
1	1	EEP response mode	Responds with a NACK but does not hold the SCL line low.

Note 1. This mode cannot be used in Hs mode.

WUANFE Bit (Analog Noise Filter Enable)

This bit enables/disables the analog noise filter for the SCL and SDA input signals. This bit is used in I2C protocol mode.

WUFSYNE Bit (Synchronous Operation Select)

This bit selects whether to synchronize the SCL and SDA lines with the internal clock or to use them as asynchronous. Asynchronous operation can be selected only when the WUFE bit is 1.

When this bit is set to 0, the ICWUSR.WUASYNF flag becomes 1 when bus-free is detected and the wake-up detection circuit is enabled. At this time, data reception is performed asynchronously with the internal clock.

When this bit is set to 1 after the wake-up condition is detected, the wake-up detection circuit is disabled and the normal reception circuit operates. If this bit is set to 1 when the wake-up condition is not detected, the wake-up detection circuit

is disabled when a STOP condition is detected.

43.2.26 Acknowledgment Bit Control Register (ICACKR)

Address(es): RI3C0.ICACKR 8745 F0A0h, RI3C0_NS.ICACKR 0745 F0A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	ACKWP	ACKBT	ACKBR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ACKBR	Received Acknowledge	0: 0 is received as the acknowledgment bit (ACK reception). 1: 1 is received as the acknowledgment bit (NACK reception).	R
b1	ACKBT	Transmit Acknowledge	0: 0 is to be sent as the acknowledgment bit (ACK transmission). 1: 1 is to be sent as the acknowledgment bit (NACK transmission).	R/W*1
b2	ACKWP	ACKBT Write Protect	0: Writing to the ACKBT bit is disabled. 1: Writing to the ACKBT bit is enabled (when writing simultaneously with the value of the target bit).	W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I²C protocol mode.
Note 1. When setting a value to the ACKBT bit, set the ACKWP bit to 1 at the same time

ACKBR Bit (Received Acknowledge)

This bit is used to store the acknowledgment bit received from the receiver in transmit mode.
[Setting condition]

- When 1 is received as the acknowledgment bit with the ICMMR.TRS flag set to 1.

[Clearing conditions]

- When 0 is received as the acknowledgment bit with the ICMMR.TRS flag set to 1.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

ACKBT Bit (Transmit Acknowledge)

[Setting condition]

- When 1 is written to the ACKWP and ACKBT bits at the same time.

[Clearing conditions]

- When 1 is written to the ACKWP bit and 0 is written to the ACKBT bit at the same time.
- When a STOP condition generation is detected. (When a STOP condition is detected with the ICCGR.SP bit set to 1.)

ACKWP Bit (ACKBT Write Protect)

This bit is used to control the modification of the ACKBT bit.
When setting a value to the ACKBT bit, set this bit to 1 at the same time.
This bit is automatically set to 0. The read value is 0.

43.2.27 Clock Stretch Control Register (ICCSCR)

Address(es): RI3C0.ICCSCR 8745 F0A4h, RI3C0_NS.ICCSCR 0745 F0A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WAITRE	WAITAE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	WAITAE	Acknowledgment Generation Wait Enable	0: The ICCSR.RDRF flag becomes 1 at the rising edge of the ninth SCL. (The SCL00 line is not held low at the falling edge of the eighth clock pulse.) 1: The ICCSR.RDRF flag becomes 1 at the rising edge of the eighth SCL. (The SCL00 line is held low at the falling edge of the eighth clock pulse.) Low-hold is released by writing a value to the ICACKR.ACKBT bit.	R/W
b1	WAITRE	Receive Data Read Wait Enable	0: No WAIT (The period between ninth clock pulse and first clock pulse is not held low.) 1: WAIT (The period between ninth clock pulse and first clock pulse is held low.) Low-hold is released by reading ICDR register.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I²C protocol mode.

WAITAE Bit (Acknowledgment Generation Wait Enable)

This bit is used to select the ICCSR.RDRF flag set timing in receive mode and also to select whether to hold the SCL00 line low at the falling edge of the eighth SCL.

When the WAITAE bit is 0, the SCL00 line is not held low at the falling edge of the eighth SCL, and the ICCSR.RDRF flag is set to 1 at the rising edge of the ninth SCL.

When the WAITAE bit is 1, the ICCSR.RDRF flag is set to 1 at the rising edge of the eighth SCL and the SCL00 line is held low at the falling edge of the eighth SCL. The low-hold of the SCL00 line is released by writing a value to the ICACKR.ACKBT bit. After data is received with this setting, the SCL00 line is automatically held low before the acknowledgment bit is sent. This enables processing to send ACK (ICACKR.ACKBT bit = 0) or NACK (ICACKR.ACKBT bit = 1) according to receive data.

WAITRE Bit (Receive Data Read Wait Enable)

This bit is used to control whether to hold the period between the ninth SCL and the first SCL low until the receive data buffer (ICDR register) is completely read each time single-byte data is received in receive mode.

When the WAITRE bit is 0, the receive operation is continued without holding the period between the ninth and the first SCL low. When both the WAITAE and WAITRE bits are 0, continuous receive operation is enabled with the double buffer.

When the WAITRE bit is 1, the SCL00 line is held low from the falling edge of the ninth SCL until the ICDR register value is read each time single-byte data is received. This enables receive operation in byte units.

Note: Read the ICDR register before setting the WAITRE bit to 0.

43.2.28 Clock Stall Control Register (ICSTCR)

Address(es): RI3C0.ICSTCR 8745 F0B0h, RI3C0_NS.ICSTCR 0745 F0B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	APSE	PBSE	—	AASE	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	STT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	STT[15:0]	Stall Time Setting	Set the clock stall time for each phase.	R/W
b27 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R
b28	AASE	Assigned Address Phase Stall Enable	0: Do not stall SCL before the Assigned Address phase. 1: Stall SCL before the Assigned Address phase.	R/W
b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b30	PBSE	Parity Bit Stall Enable	0: Does not stall the SCL during the parity bit period. 1: Stall the SCL during the parity bit period.	R/W
b31	APSE	ACK/NACK Phase Stall Enable	0: Does not stall the SCL during the ACK/NACK phase. 1: Stall the SCL during the ACK/NACK phase.	R/W

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

When setting this register, follow section 6.10, Controller Clock Stalling of MIPI I3C Specification Version 1.2, and use it only when necessary because of its negative impacts on bus performance.

STT[15:0] Bits (Stall Time Setting)

These bits is used to set the SCL stall time. The SCL stall time is counted by I3CCLK. This is a counter common to the enable bits of each phase.

AASE Bit (Assigned Address Phase Stall Enable)

This bit is used to select whether the Controller stalls SCL during the low period of the first bit of the Assigned Address phase of the ENTDAA CCC command. It can gain time in assigning Dynamic Address to the Device based on the BCR and DCR of the Target. However, because the Dynamic Address Assignment procedure sends the Dynamic Address set in the ICTDATRm register in sequence, it is not necessary to set this bit and it is prohibited.

PBSE Bit (Parity Bit Stall Enable)

This bit is used to select whether the Controller stalls SCL at the parity bit of the transmit data of I3C write transfer to avoid underrun of the transmit FIFO. However, when the transmit FIFO of the I3C Controller becomes empty, SCL stalling is performed regardless of the setting of this bit, it is not necessary to set this bit and it is prohibited.

APSE Bit (ACK/NACK Phase Stall Enable)

Determine the need to perform SCL stalling during the ACK/NACK phase based on the following criteria:

- It is necessary to set this bit when the I3C and I^2C Targets connected to the bus require preparation time to receive or transmit data.
- In legacy I^2C communication, if there is a possibility that the FIFO of the I3C Controller might underrun or overrun. It is not necessary to set this bit because SCL stalling is performed by FIFO Empty or Full regardless of the setting

of this bit.

- Other than legacy I2C communication, the FIFO of I3C Controller might underrun or overrun, and if SCL stalling is required in ACK phase, this bit can be set. However, it is necessary to build the software so that the FIFO does not underrun or overrun due to the interrupt generated according to the FIFO threshold setting (ICQBTCR, ICDBTCR, ICSQTCR).
- When I3C Controller responds ACK/NACK to IBI, it is not necessary to set this bit because ACK/NACK response can be set in advance by ICTDATRm.CRRRJ and ICTDATRm.TIRRJ.
- It is necessary to set this bit when the I3C Target connected to the bus requires preparation time to transmit data for Direct GET CCC.

43.2.29 Target Transmit/Receive Data Length Register (ICTDLR)

Address(es): RI3C0.ICTDLR 8745 F0C0h, RI3C0_NS.ICTDLR 0745 F0C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DLGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ATSTRG	Software Trigger	Writing 1 to this bit generates a software trigger signal.	W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

43.2.33 Asynchronous Timing Counter Control Register (ICASTCCR)

Address(es): RI3C0.ICASTCCR 8745 F12Ch, RI3C0_NS.ICASTCCR 0745 F12Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ATCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ATCE	Asynchronous Timing Counter Operation Enable	0: Asynchronous timing counters are disabled. 1: Asynchronous timing counters are enabled.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C protocol mode.

43.2.34 Condition Generation Request Register (ICCGR)

Address(es): RI3C0.ICCGR 8745 F140h, RI3C0_NS.ICCGR 0745 F140h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	SP	RS	ST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ST	START Condition Generation Request	0: Do not request to generate a START condition. 1: Requests to generate a START condition.	R/W
b1	RS	Repeated START Condition Generation Request	0: Do not request to generate a repeated START condition. 1: Requests to generate a repeated START condition.	R/W
b2	SP	STOP Condition Generation Request	0: Do not request to generate a STOP condition. 1: Requests to generate a STOP condition.	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I2C protocol mode.

ST Bit (START Condition Generation Request)

This bit is used to request transition to master mode and generation of a START condition.

For details on the START condition generation, refer to section 43.5.7, START Condition/Repeated START Condition/STOP Condition Generating Function (I2C Protocol Mode).

[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit.
- When a START condition has been generated (a START condition is detected).
- When the ICSR2.AL flag becomes 1 (arbitration is lost).
- When 1 is written to ICRCR.MRST bit or ICRCR.ISRST bit to apply a RI3C reset or an internal reset.

Note: Set the ST bit to 1 (requests to generate a START condition) when the ICBSR.BFREE flag is set to 1 (bus free state).
Note that arbitration may be lost if the ST bit is set to 1 (requests to generate a START condition) when the ICBSR.BFREE flag is set to 0 (bus busy state).

RS Bit (Repeated START Condition Generation Request)

This bit is used to request that a repeated START condition be generated in master mode.

When this bit is set to 1 to request to generate a repeated START condition, a repeated START condition is generated when the BFREE flag is set to 0 (bus busy state) and the ICMMR.ACF flag is set to 1 (master mode).

For details on the repeated START condition generation, refer to section 43.5.7, START Condition/Repeated START Condition/STOP Condition Generating Function (I2C Protocol Mode).

[Setting condition]

- When 1 is written to the RS bit with the ICBSR.BFREE flag set to 0.

[Clearing conditions]

- When 0 is written to the RS bit.
- When a repeated START condition has been generated. (a repeated START condition is detected.)
- When the ICSR2.AL flag becomes 1 (arbitration is lost).
- When 1 is written to ICRCR.MRST bit or ICRCR.ISRST bit to apply a RI3C reset or an internal reset.

Note: Do not set the RS bit to 1 while generating a STOP condition.
Note: If 1 (requests to generate a repeated START condition) is written to the RS bit in slave mode, the repeated START condition is not generated but the RS bit remains set to 1.
If the operating mode changes to master mode with the bit not being cleared, note that the repeated START condition may be generated.

SP Bit (STOP Condition Generation Request)

This bit is used to request that a STOP condition be generated in master mode.
When this bit is set to 1 to request to generate a STOP condition, a STOP condition is generated when the ICBSR.BFREE flag is set to 0 (bus busy state) and the ICMMR.ACF flag is set to 1 (master mode).
For details on the STOP condition generation, refer to section 43.5.7, START Condition/Repeated START Condition/STOP Condition Generating Function (I^2C Protocol Mode).
[Setting condition]

- When 1 is written to the SP bit with the ICBSR.BFREE flag set to 0 and the ICMMR.ACF flag set to 1.

[Clearing conditions]

- When 0 is written to the SP bit.
- When a STOP condition has been generated. (a STOP condition is detected.)
- When the ICSR2.AL flag becomes 1 (arbitration is lost).
- When a START condition and a repeated START condition are detected.
- When 1 is written to ICRCR.MRST bit or ICRCR.ISRST bit to apply an RI3C reset or an internal reset.

Note: When the ICBSR.BFREE flag is 1 (bus free state), writing 1 to the SP bit is ignored.
Note: Do not set the SP bit to 1 while a repeated START condition is being generated.

43.2.35 Command Queue Register (ICCQR)

Address(es): RI3C0.ICCQR 8745 F150h, RI3C0_NS.ICCQR 0745 F150h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C protocol mode.

The ICCQR register is a 32-bit write-only register used to enqueue Command Descriptors into the command queue. Command Descriptors should be written in order from lower (b31-b0) to higher (b63-b32).
Refer to section 43.3.1, Command Descriptor for details on Command Descriptors.

43.2.36 Response Queue Register (ICRQR)

Address(es): RI3C0.ICRQR 8745 F154h, RI3C0_NS.ICRQR 0745 F154h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C protocol mode.

The ICRQR register is a 32-bit read-only register used to read the Response Descriptors generated in the response queue after a command has been processed.
Refer to section 43.3.2, Response Descriptor for details on Response Descriptors.

43.2.37 Transmit/Receive Data Register (ICDR)

(1) I3C Protocol Mode

Address(es): RI3C0.ICDR 8745 F158h, RI3C0_NS.ICDR 0745 F158h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ICDR register is a 32-bit read/write register used to read data from the receive data buffer and write data to the transmit data buffer.

For Read Operation:

Receive data is stored in the receive data buffer every 4 bytes. If the number of data received is not an integer multiple of 4 bytes, the last 32 bits of the stored data will contain invalid bytes. Check the number of valid data bytes in the DATA_LENGTH field of the Response Descriptor.

For Write Operation:

Transmit data must be written to the ICDR register in 4-byte units. If the number of data to be transmitted is not an integer multiple of 4 bytes, add dummy data after the final data to make it 4 bytes before writing to the ICDR register. RI3C sends the number of bytes of data specified in the DATA_LENGTH field of the Command Descriptor.

(2) I²C Protocol Mode

Address(es): RI3C0.ICDR 8745 F158h, RI3C0_NS.ICDR 0745 F158h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ICDR register is a 32-bit read/write register used to read data from the receive data buffer and write data to the transmit data buffer. This register can be accessed in 32-bit or 8-bit units. The upper 24 bits are reserved and should be written as 0 when data is written in 32-bit units.

For Read Operation:

When 1 byte of data has been received, the received data is transferred from the internal shift register to the ICDR register to enable the next data to be received.

The double-buffer structure of the shift register and the ICDR register allows continuous receive operation if the received data has been read from the ICDR register while the shift register is receiving data.

Read data from the ICDR register once when a receive data full interrupt (RXI) request is generated.

If the ICDR register receives the next receive data before the current data is read from the ICDR register (while the ICCSR.RDRF flag is 1), the RI3C automatically holds the SCL00 line low one cycle before the RDRF flag is set to 1 next.

For Write Operation:

When the ICDR register detects a space in the internal shift register, it transfers the transmit data that has been written to the ICDR register to the shift register and starts transmitting data in transmit mode.

The double-buffer structure of the ICDR register and the shift register allows continuous transmit operation if the next transmit data has been written to the ICDR register while the shift register data is being transmitted.

Write transmit data to the ICDR register once when a transmit data empty interrupt (TXI) request is generated.

43.2.38 IBI Queue Register (ICIQR)

Address(es): RI3C0.ICIQR 8745 F17Ch, RI3C0_NS.ICIQR 0745 F17Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C protocol mode.

The ICIQR register is a 32-bit read-only register used to read an IBI Status Descriptor and IBI data from the IBI queue after an IBI has been received.
Refer to section 43.3.3, IBI Status Descriptor for details on IBI Status Descriptors.

43.2.39 Receive Status Queue Register (ICSQR)

Address(es): RI3C0.ICSQR 8745 F180h, RI3C0_NS.ICSQR 0745 F180h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Secondary Controller and I3C Target modes.

The ICSQR register is a 32-bit read-only register used to read an Receive Status Descriptor from the receive status queue.
Refer to section 43.3.4, Receive Status Descriptor for details on Receive Status Descriptors.

43.2.40 High-Priority Command Queue Register (ICHCQR)

Address(es): RI3C0.ICHCQR 8745 F184h, RI3C0_NS.ICHCQR 0745 F184h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

The ICHCQR register is a 32-bit write-only register used to enqueue Command Descriptors into the high-priority command queue. Command Descriptors should be written in order from lower (b31-b0) to higher (b63-b32).
Refer to section 43.3.1, Command Descriptor for details on Command Descriptors.

43.2.41 High-Priority Response Queue Register (ICHRQR)

Address(es): RI3C0.ICHRQR 8745 F188h, RI3C0_NS.ICHRQR 0745 F188h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

The ICHRQR register is a 32-bit read-only register used to read the Response Descriptors generated in the high-priority response queue after a high-priority command has been processed.
Refer to section 43.3.2, Response Descriptor for details on Response Descriptors.

43.2.42 High-Priority Transmit/Receive Data Register (ICHDR)

Address(es): RI3C0.ICHDR 8745 F18Ch, RI3C0_NS.ICHDR 0745 F18Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

The ICHDR register is a 32-bit read/write register used to read data from the high-priority receive data buffer and write data to the high-priority transmit data buffer.

For Read Operation:

Receive data is stored in the high-priority receive data buffer every 4 bytes. If the number of data received is not an integer multiple of 4 bytes, the last 32 bits of the stored data will contain invalid bytes. Check the number of valid data bytes in the DATA_LENGTH field of the Response Descriptor.

For Write Operation:

High-priority transmit data must be written to the ICHDR register in 4-byte units. If the number of data to be transmitted is not an integer multiple of 4 bytes, add dummy data after the final data to make it 4 bytes before writing to the ICHDR register. RI3C sends the number of bytes of data specified in the DATA_LENGTH field of the Command Descriptor.

43.2.43 Queue Buffer Threshold Control Register (ICQBTCR)

Address(es): RI3C0.ICQBTCR 8745 F190h, RI3C0_NS.ICQBTCR 0745 F190h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IQTH[7:0]								IDSS[7:0]							
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RQTH[7:0]								CQTH[7:0]							
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CQTH[7:0]	Command Queue Empty Interrupt Threshold Setting	00h: Interrupt is generated when command queue is completely empty. 01h: Interrupt is generated when command queue has one free entry. 02h: Interrupt is generated when command queue has two free entry. 03h: Interrupt is generated when command queue has three free entry. Settings other than above are prohibited.	R/W
b15 to b8	RQTH[7:0]	Response Queue Full Interrupt Threshold Setting	00h: Interrupt is generated when response queue contains one entry (4 bytes). 01h: Interrupt is generated when response queue contains two entries (8 bytes). 02h: Interrupt is generated when response queue contains three entries (12 bytes). 03h: Interrupt is generated when response queue contains four entries (16 bytes). Settings other than above are prohibited.	R/W
b23 to b16	IDSS[7:0]	IBI Data Segment Size Setting*1	Set the maximum size of IBI data segments in 4-byte units. Setting range: 1 (4 bytes) to 7 (28 bytes)	R/W
b31 to b24	IQTH[7:0]	IBI Queue Empty/Full Interrupt Threshold Setting	• I3C Controller mode: 00h: Interrupt is generated when there is at least one outstanding IBI status. 01h: Interrupt is generated when there are two outstanding IBI status. Settings other than above are prohibited. • I3C Target mode: 00h: Interrupt is generated when IBI queue is completely empty. 01h: Interrupt is generated when IBI queue has one free entry. : 07h: Interrupt is generated when IBI queue has seven free entries. Settings other than above are prohibited.	R/W

Note: This register is used in I3C protocol mode.
Note 1. These bits are used in I3C Primarily Controller and I3C Secondary Controller modes.

This register controls the interrupt generation thresholds for the command queue, response queue, and IBI queue.

CQTH[7:0] Bits (Command Queue Empty Interrupt Threshold Setting)

These bits control the minimum number of free command queue entries needed to generate the command queue empty interrupt (CMDI).

RQTH[7:0] Bits (Response Queue Full Interrupt Threshold Setting)

These bits control the minimum number of response queue entries needed to generate the response queue full interrupt (RESPI).

IDSS[7:0] Bits (IBI Data Segment Size Setting)

These bits specify the maximum size of IBI data segments in 4-byte units.
These bits allow the incoming IBI data to be sliced into multiple segments generating status individually, to support cut-through readout of a long IBI payload data.

IQTH[7:0] Bits (IBI Queue Empty/Full Interrupt Threshold Setting)

(1) For I3C Controller mode (ICMMR.ACF flag = 1):
These bits control generation of the IBI queue empty/full interrupt (IBII), based on the value of the number of outstanding IBI status in the IBI queue.
Each IBI status entry can represent either the complete IBI payload (if the IBI payload size is 4 × IDSS[7:0] bytes or less), or a segment of the IBI payload (if the IBI payload size is more than 4 × IDSS[7:0] bytes).
(2) For I3C Target mode (ICMMR.ACF flag = 0):
These bits control the minimum number of free IBI data buffer entries needed to generate the IBI queue empty/full interrupt (IBII).

43.2.44 Data Buffer Threshold Control Register (ICDBTCR)

Address(es): RI3C0.ICDBTCR 8745 F194h, RI3C0_NS.ICDBTCR 0745 F194h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Settings other than above are prohibited.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C protocol mode.
Note 1. These bits are used in I3C Primarily Controller and I3C Secondary Controller modes.

The ICDBTCR register controls the interrupt trigger thresholds for the receive data buffer and the transmit data buffer.

TETH[2:0] Bits (Transmit Data Empty Interrupt Threshold Setting)

These bits specify the minimum number of free transmit data buffer stages needed to generate the transmit data empty interrupt (TXI).

RFTH[2:0] Bits (Receive Data Full Interrupt Threshold Setting)

These bits specify the minimum number of filled receive data buffer stages needed to generate the receive data full interrupt (RXI).

TSTH[2:0] Bits (Transmit Start Threshold Setting)

When preparing to initiate a Write Transfer on the I3C bus, RI3C waits until the indicated number of stages of data have been written to the transmit buffer.

RSTH[2:0] Bits (Receive Start Threshold Setting)

When preparing to initiate a Read Transfer on the I3C bus, RI3C waits until the receive buffer has the indicated number of free stages to receive the data bytes.

43.2.45 Receive Status Queue Threshold Control Register (ICSQTCR)

Address(es): RI3C0.ICSQTCR 8745 F1C0h, RI3C0_NS.ICSQTCR 0745 F1C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	SQTH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	SQTH[7:0]	Receive Status Queue Full Interrupt Threshold Setting	00h: Interrupt is generated when receive status queue contains one entry (4 bytes). 01h: Interrupt is generated when receive status queue contains two entries (8 bytes). Settings other than above are prohibited.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

SQTH[7:0] Bits (Receive Status Queue Full Interrupt Threshold Setting)

These bits control the minimum number of receive status queue entries needed to generate the receive status queue full interrupt (RCVI).

43.2.46 High-Priority Queue Buffer Threshold Control Register (ICHQBTCR)

Address(es): RI3C0.ICHQBTCR 8745 F1C4h, RI3C0_NS.ICHQBTCR 0745 F1C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HRQTH[7:0]								HCQTH[7:0]							
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	HCQTH[7:0]	High-Priority Command Queue Empty Interrupt Threshold Setting	00h: Interrupt is generated when high-priority command queue is completely empty. 01h: Interrupt is generated when high-priority command queue has one free entry. Settings other than above are prohibited.	R/W
b15 to b8	HRQTH[7:0]	High-Priority Response Queue Full Interrupt Threshold Setting	00h: Interrupt is generated when high-priority response queue contains one entry (4 bytes). 01h: Interrupt is generated when high-priority response queue contains two entries (8 bytes). Settings other than above are prohibited.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

This register controls the interrupt generation thresholds for the high-priority command queue and high-priority response queue.

HCQTH[7:0] Bits (High-Priority Command Queue Empty Interrupt Threshold Setting)

These bits control the minimum number of free high-priority command queue entries needed to generate the high-priority command queue empty interrupt (HCMDI).

HRQTH[7:0] Bits (High-Priority Response Queue Full Interrupt Threshold Setting)

These bits control the minimum number of high-priority response queue entries needed to generate the high-priority response queue full interrupt (HRESPI).

43.2.47 High-Priority Data Buffer Threshold Control Register (ICHDBTCR)

Address(es): RI3C0.ICHDBTCR 8745 F1C8h, RI3C0_NS.ICHDBTCR 0745 F1C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	HRSTH[2:0]			—	—	—	—	—	HTSTH[2:0]		
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	HRFTH[2:0]			—	—	—	—	—	HTETH[2:0]		
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	HTETH[2:0]	High-Priority Transmit Data Empty Interrupt Threshold Setting	b2 b0 0 0 0: Interrupt is generated when the free level of the high-priority transmit data buffer reaches 2 stages (8 bytes). 0 0 1: Reserved Settings other than above are prohibited.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R
b10 to b8	HRFTH[2:0]	High-Priority Receive Data Full Interrupt Threshold Setting	b10 b8 0 0 0: Interrupt is generated when the fill level of the high-priority receive data buffer reaches 2 stages (5 to 8 bytes). 0 0 1: Reserved Settings other than above are prohibited.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R
b18 to b16	HTSTH[2:0]	High-Priority Transmit Start Threshold Setting	b18 b16 0 0 0: Transmission starts when the fill level of the high-priority transmit data buffer reaches 2 stages (5 to 8 bytes). 0 0 1: Reserved Settings other than above are prohibited.	R/W
b23 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R
b26 to b24	HRSTH[2:0]	High-Priority Receive Start Threshold Setting	b26 b24 0 0 0: Reception starts when the free level of the high-priority receive data buffer reaches 2 stages (8 bytes). 0 0 1: Reserved Settings other than above are prohibited.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

The ICHDBTCR register controls the interrupt trigger thresholds for the high-priority receive data buffer and the high-priority transmit data buffer.

HTETH[2:0] Bits (High-Priority Transmit Data Empty Interrupt Threshold Setting)

These bits specify the minimum number of free high-priority transmit data buffer stages needed to generate the high-priority transmit data empty interrupt (HTXI).

HRFTH[2:0] Bits (High-Priority Receive Data Full Interrupt Threshold Setting)

These bits specify the minimum number of filled high-priority receive data buffer stages needed to generate the high-priority receive data full interrupt (HRXI).

HTSTH[2:0] Bits (High-Priority Transmit Start Threshold Setting)

When preparing to initiate a Write Transfer on the I3C bus, RI3C waits until the indicated number of stages of data have been written to the high-priority transmit buffer.

HRSTH[2:0] Bits (High-Priority Receive Start Threshold Setting)

When preparing to initiate a Read Transfer on the I3C bus, RI3C waits until the high-priority receive buffer has the indicated number of free stages to receive the data bytes.

43.2.48 Status Register 2 (ICSR2)

Address(es): RI3C0.ICSR2 8745 F1D0h, RI3C0_NS.ICSR2 0745 F1D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	WUDF	—	—	—	TMOF	—	—	—	AL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TEND	—	—	—	NACKF	—	HDRXDF	STOP	START
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	START	START Condition Detection Flag	0: START condition is not detected. 1: START condition is detected.	R/(W) *1
b1	STOP	STOP Condition Detection Flag	0: STOP condition is not detected. 1: STOP condition is detected.	R/(W) *1
b2	HDRXDF	HDR Exit Pattern Detection Flag *2	0: HDR Exit Pattern is not detected. 1: HDR Exit Pattern is detected.	R/(W) *1
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	NACKF	NACK Detection Flag*3	0: NACK is not detected 1: NACK is detected.	R/(W) *1
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	TEND	Transmission End Flag*3	0: Data is being transmitted. 1: Data has been transmitted.	R/(W) *1
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	AL	Arbitration Lost Flag*3	0: Arbitration is not lost. 1: Arbitration is lost.	R/(W) *1
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	TMOF	Timeout Detection Flag	0: Timeout is not detected. 1: Timeout is detected.	R/(W) *1
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	WUDF	Wake-Up Condition Detection Flag	0: Wake-up condition is not detected. 1: Wake-up condition is detected.	R/(W) *1
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Only 0 can be written to this bit.
Note 2. This bit is used in I3C protocol mode.
Note 3. This bit is used in I^2C protocol mode.

START Flag (START Condition Detection Flag)

[Setting condition]

- When a START condition (or a repeated START condition) is detected while the ICSER.STDE bit is 1.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

STOP Flag (STOP Condition Detection Flag)

[Setting condition]

- When a STOP condition is detected while the ICSER.SPDE bit is 1.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

HDRXDF Flag (HDR Exit Pattern Detection Flag)

[Setting condition]

- When a HDR Exit Pattern is detected while the ICSER.HDRXDE bit is 1.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.

NACKF Flag (NACK Detection Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICSER.NAKDE bit is 1 (NACK detection is enabled).
  2. When ACK is not received (NACK is received) from the receiver in transmit mode.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

TEND Flag (Transmission End Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICSER.TEDE bit is 1 (transmission end detection is enabled).
  2. At the rising edge of the ninth SCL while the ICCSR.TDRE flag is 1. Excluding when sending an address.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When data is written to the ICDR register.
- When a STOP condition is detected.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

AL Flag (Arbitration Lost Flag)

[Setting condition]

When master arbitration-lost detection is enabled (ICSER.ALE bit = 1, ICFER.MALE bit = 1):

- When the internal SDA output state does not match the SDA00 line level at the rising edge of SCL except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDA00 line is driven low while the internal SDA output is high (the SDA00 pin is in the high-impedance state)).
- The following 1 and 2 are satisfied.
  1. When the START condition is detected while the ICCGR.ST bit is 1.
  2. When the internal SDA output state does not match the SDA00 line level.
- When the ICCGR.ST bit is set to 1 (requests to generate a START condition) while the ICBSR.BFREE flag is 0.

When NACK transmission arbitration-lost detection is enabled (ICSER.ALE bit = 1, ICFER.NALE bit = 1):

- When the internal SDA output state does not match the SDA00 line level at the rising edge of SCL in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICSER.ALE bit = 1, ICFER.SALE bit = 1):

- When the internal SDA output state does not match the SDA00 line level at the rising edge of SCL except for the ACK period during data transmission in slave transmit mode.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

TMOF Flag (Timeout Detection Flag)

[Setting condition]

- All of the following 1 to 3 are satisfied.
  1. The ICSER.TMOE bit is 1 (timeout detection is enabled).
  2. When the master/Controller mode or the received slave/Target address matches the slave/Target address n in slave/Target mode.
  3. When the SCL00 line state remains unchanged for the period specified by ICTOR register.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

WUDF Flag (Wake-Up Condition Detection Flag)

This flag indicates that the condition for generating a wake-up interrupt has been met.

[Setting condition]

- When any of the following conditions is satisfied while the ICWUCR.WUFE bit is 1 (wake-up function is enabled), the ICSER.WUDE bit is 1 (wake-up condition detection is enabled), and ICWUSR.WUASYNF flag is 1 (PCLKA and I3CCLK are stopped).
  1. When the SDA line goes low (in I3C Controller mode)
  2. When the address received after the Broadcast Address (7Eh) matches its own Dynamic Address (in I3C Target mode)
  3. When the received slave address matches any of the addresses permitted for detection by the ICSCR.SAR0E to SAR2E bits, the ICSCR.HOAE bit, and the ICSCR.GCAE bit (in I^2C slave mode)

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1 while the ICWUSR.WUASYNF flag is 0 (PCLKA and I3CCLK are operating).

43.2.49 Status Detection Enable Register (ICSER)

Address(es): RI3C0.ICSER 8745 F1D4h, RI3C0_NS.ICSER 0745 F1D4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b0	STDE	START Condition Detection Enable	0: START condition detection is disabled. 1: START condition detection is enabled.	R/W
b1	SPDE	STOP Condition Detection Enable	0: STOP condition detection is disabled. 1: STOP condition detection is enabled.	R/W
b2	HDRXDE	HDR Exit Pattern Detection Enable*1	0: HDR Exit Pattern detection is disabled. 1: HDR Exit Pattern detection is enabled.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	NAKDE	NACK Detection Enable*2	0: NACK detection is disabled. 1: NACK detection is enabled.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	TEDE	Transmission End Detection Enable*2	0: Transmission end detection is disabled. 1: Transmission end detection is enabled.	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	ALE	Arbitration Lost Detection Enable *2	0: Arbitration lost detection is disabled. 1: Arbitration lost detection is enabled.	R/W
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	TMOE	Timeout Detection Enable	0: Timeout detection is disabled. 1: Timeout detection is enabled.	R/W
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	WUDE	Wake-Up Condition Detection Enable	0: Wake-up condition detection is disabled. 1: Wake-up condition detection is enabled.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. This bit is used in I3C protocol mode.
Note 2. This bit is used in I2C protocol mode.

This register is used to enable or disable detection of each status. When the status enabled by this register is detected, the corresponding flag in the ICSR2 register is set to 1.

43.2.50 Status Interrupt Enable Register (ICSIER)

Address(es): RI3C0.ICSIER 8745 F1D8h, RI3C0_NS.ICSIER 0745 F1D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STIE	START Condition Detection Interrupt Enable	0: START condition detection interrupt is disabled. 1: START condition detection interrupt is enabled.	R/W
b1	SPIE	STOP Condition Detection Interrupt Enable	0: STOP condition detection interrupt is disabled. 1: STOP condition detection interrupt is enabled.	R/W
b2	HDRXIE	HDR Exit Pattern Detection Interrupt Enable*1	0: HDR Exit Pattern detection interrupt is disabled. 1: HDR Exit Pattern detection interrupt is enabled.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	NAKIE	NACK Detection Interrupt Enable*2	0: NACK detection interrupt is disabled. 1: NACK detection interrupt is enabled.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	TEIE	Transmission End Interrupt Enable*2	0: Transmission end interrupt is disabled. 1: Transmission end interrupt is enabled.	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	ALIE	Arbitration Lost Detection Interrupt Enable*2	0: Arbitration lost interrupt is disabled. 1: Arbitration lost interrupt is enabled.	R/W
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20	TMOIE	Timeout Detection Interrupt Enable	0: Timeout detection interrupt is disabled. 1: Timeout detection interrupt is enabled.	R/W
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	WUDIE	Wake-Up Interrupt Enable	0: Wake-up interrupt is disabled. 1: Wake-up interrupt is enabled.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. This bit is used in I3C protocol mode.
Note 2. This bit is used in I2C protocol mode.

This register is used to enable or disable interrupts for each status. When a flag in the ICSR2 register becomes 1 and the corresponding interrupt enable bit is 1, an interrupt request is output.

43.2.51 Communication Status Register (ICCSR)

Address(es): RI3C0.ICCSR 8745 F1E0h, RI3C0_NS.ICCSR 0745 F1E0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	SQFF	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TDRE	Transmit Data Empty Flag	• In I3C protocol mode 0: The free level of the transmit data buffer is less than the threshold specified by the ICDBTCR.TETH[2:0] bits. 1: The free level of the transmit data buffer is equal to or more than the threshold specified by the TETH[2:0] bits. • In I2C protocol mode 0: Transmit data buffer contains transmit data. 1: Transmit data buffer contains no transmit data.	R/(W) *1
b1	RDRF	Receive Data Full Flag	• In I3C protocol mode 0: The fill level of the receive data buffer is less than the threshold specified by the ICDBTCR.RFTH[2:0] bits 1: The fill level of the receive data buffer is equal to or more than the threshold specified by the RFTH[2:0] bits. • In I2C protocol mode 0: Receive data buffer contains no receive data. 1: Receive data buffer contains receive data.	R/(W) *1
b2	IQEFF	IBI Queue Empty/Full Flag*2	• In I3C Controller mode 0: The number of IBI statuses in IBI queue is less than the threshold specified by the ICQBTCR.IQTH[7:0] bits. 1: The number of IBI statuses in IBI queue is equal to or more than the threshold specified by the IQTH[7:0] bits. • In I3C Target mode and if the IQTH[7:0] bits are 00h: 0: IBI queue contains entry. 1: IBI queue contains no entries. • In I3C Target mode and if the IQTH[7:0] bits are not 00h: 0: The number of free IBI queue entries is less than the threshold specified by the IQTH[7:0] bits. 1: The number of free IBI queue entries is equal to or more than the threshold specified by the IQTH[7:0] bits.	R/(W) *1
b3	CQEF	Command Queue Empty Flag*2	• If the ICQBTCR.CQTH[7:0] bits are 00h: 0: Command queue contains data. 1: Command queue contains no data. • If the CQTH[7:0] bits are not 00h: 0: The number of free command queue entries is less than the threshold specified by the CQTH[7:0] bits. 1: The number of free command queue entries is equal to or more than the threshold specified by the CQTH[7:0] bits.	R/(W) *1
b4	RQFF	Response Queue Full Flag*2	0: The number of response queue entries is less than the threshold specified by the ICQBTCR.RQTH[7:0] bits. 1: The number of response queue entries is equal to or more than the threshold specified by the RQTH[7:0] bits.	R/(W) *1
b5	DTAF	Data Transfer Abort Flag*2	0: Data transfer abort does not occur. 1: Data transfer abort occurs.	R/(W) *1
b8 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9	DTEF	Data Transfer Error Flag*2	0: Data transfer error does not occur. 1: Data transfer error occurs.*3	R/(W) *1

Bit	Symbol	Bit Name	Description	R/W
b19 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	SQFF	Receive Status Queue Full Flag *4	0: The number of receive status queue entries is less than the threshold specified by the ICSQTCR.SQTH[7:0] bits. 1: The number of receive status queue entries is equal to or more than the threshold specified by the SQTH[7:0] bits.	R/(W) *1
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. To clear this flag, confirm that the flag is 1 and then set it to 0.
Note 2. This bit is used in I3C protocol mode.
Note 3. The Error type for this error is available in the Response or Receive Status Descriptor structure corresponding to the transfer or command.
Note 4. This bit is used in I3C Secondary Controller and I3C Target modes.

TDRE Flag (Transmit Data Empty Flag)

[Setting condition]

In I3C protocol mode:

- When the free level of the transmit data buffer is equal to or more than the threshold specified by the ICDBTCR.TETH[2:0] bits while the ICCSER.TDE bit is 1 (detection of transmit data empty is enabled).

In I^{2}C protocol mode:

- When any of the following conditions is satisfied while the ICCSER.TDE bit is 1 (detection of transmit data empty is enabled).
  1. When data is transferred from transmit data buffer to shift register and transmit data buffer becomes empty.
  2. When the ICMMR.TRS flag is set to 1.
  3. When the received slave address matches while the TRS flag is 1.

[Clearing condition]

In I3C protocol mode:

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last write access to the transmit data buffer by DMAC/DTC.
- When the free level of the transmit data buffer is less than the threshold specified by the TETH[2:0] bits.

In I^{2}C protocol mode:

- When data is written to ICDR register.
- When the ICMMR.TRS flag is set to 0.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

Note: When the ICSR2.NACKF flag is set to 1 while the ICSER.NAKDE bit is 1, RI3C aborts data transmission/reception. Here, if the TDRE flag is 0 (next transmit data has been written), data is transferred to the shift register and the transmit data buffer becomes empty at the rising edge of the ninth clock cycle, but the TDRE flag is not set to 1.

RDRF Flag (Receive Data Full Flag)

[Setting condition]

In I3C protocol mode:

- When the fill level of the receive data buffer is equal to or more than the threshold specified by the ICDBTCR.RFTH[2:0] bits while the ICCSER.RDE bit is 1 (detection of receive data full is enabled).

In I^{2}C protocol mode:

- When any of the following conditions is satisfied while the ICCSER.RDE bit is 1 (detection of receive data full is enabled).
  1. When receive data is transferred from shift register to receive data buffer.

The RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL (selected in the ICCSCR.WAITAE bit).

2. When the received slave address matches after a START (or repeated START) condition is detected with the ICMMR.TRS flag set to 0.

[Clearing condition]

In I3C protocol mode:

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last read access to the receive data buffer by DMAC/DTC.
- When the fill level of the receive data buffer is less than the threshold specified by the RFTH[2:0] bits.

In I^2C protocol mode:

- When data is read from ICDR register.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

IQEFF Flag (IBI Queue Empty/Full Flag)

[Setting condition]

When any of the following conditions is satisfied while the ICCSER.IQEFDE bit is 1 (detection of IBI queue empty/full is enabled).

In I3C Controller mode:

- When the number of the IBI queue entries is equal to or more than the threshold specified by the ICQBTCR.IQTH[7:0] bits.

In I3C Target mode:

- When the IBI queue is completely empty (when the IQTH[7:0] bits are 00h).
- When the number of the free IBI queue entries is equal to or more than the threshold specified by the IQTH[7:0] bits (when the IQTH[7:0] bits are other than 00h).

[Clearing condition]

In I3C Controller mode:

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last read access to the IBI queue by DMAC/DTC.
- When the number of the IBI queue entries is less than the threshold specified by the IQTH[7:0] bits.

In I3C Target mode:

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last write access to the IBI queue by DMAC/DTC.
- When the IBI queue is not completely empty (when the IQTH[7:0] bits are 00h).
- When the number of the free IBI queue entries is less than the threshold specified by the IQTH[7:0] bits (when the IQTH[7:0] bits are other than 00h).

CQEF Flag (Command Queue Empty Flag)

[Setting condition]

When any of the following conditions is satisfied while the ICCSER.CQEDE bit is 1 (detection of command queue empty is enabled).

- When the command queue is completely empty (when the ICQBTCR.CQTH[7:0] bits are 00h).
- When the number of the free command queue entries is equal to or more than the threshold specified by the CQTH[7:0] bits (when the CQTH[7:0] bits are other than 00h).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last write access to the command queue by DMAC/DTC.

- When the command queue is not completely empty (when the CQTH[7:0] bits are 00h).
- When the number of the free command queue entries is less than the threshold specified by the CQTH[7:0] bits (when the CQTH[7:0] bits are other than 00h).

RQFF Flag (Response Queue Full Flag)

[Setting condition]

- When the number of the response queue entries is equal to or more than the threshold specified by the ICQBTCR.RQTH[7:0] bits while the ICCSER.RQFDE bit is 1 (detection of response queue full is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last read access to the response queue by DMAC/DTC.
- When the number of the response queue entries is less than the threshold specified by the RQTH[7:0] bits.

DTAF Flag (Data Transfer Abort Flag)

[Setting condition]

- When any data transfer is aborted while the ICCSER.DTADE bit is 1 (detection of data transfer abort is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.

DTEF Flag (Data Transfer Error Flag)

[Setting condition]

- When any data transfer error occurs on the I3C bus while the ICCSER.DTEDE bit is 1 (detection of data transfer error is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.

SQFF Flag (Receive Status Queue Full Flag)

[Setting condition]

- When the number of the receive status queue entries is equal to or more than the threshold specified by the ICSQTCR.SQTH[7:0] bits while the ICCSER.SQFDE bit is 1 (detection of receive status queue full is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last read access to the receive status queue by DMAC/DTC.
- When the number of the receive status queue entries is less than the threshold specified by the SQTH[7:0] bits.

43.2.52 Communication Status Detection Enable Register (ICCSER)

Address(es): RI3C0.ICCSER 8745 F1E4h, RI3C0_NS.ICCSER 0745 F1E4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TDE	Transmit Data Empty Detection Enable	0: Detection of transmit data empty is disabled. 1: Detection of transmit data empty is enabled.	R/W
b1	RDE	Receive Data Full Detection Enable	0: Detection of receive data full is disabled. 1: Detection of receive data full is enabled.	R/W
b2	IQEFDE	IBI Queue Empty/Full Detection Enable*1	0: Detection of IBI queue empty/full is disabled. 1: Detection of IBI queue empty/full is enabled.	R/W
b3	CQEDE	Command Queue Empty Detection Enable*1	0: Detection of command queue empty is disabled. 1: Detection of command queue empty is enabled.	R/W
b4	RQFDE	Response Queue Full Detection Enable*1	0: Detection of response queue full is disabled. 1: Detection of response queue full is enabled.	R/W
b5	DTADE	Data Transfer Abort Detection Enable*1	0: Detection of data transfer abort is disabled. 1: Detection of data transfer abort is enabled.	R/W
b8 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9	DTEDE	Data Transfer Error Detection Enable*1	0: Detection of data transfer error is disabled. 1: Detection of data transfer error is enabled.	R/W
b19 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	SQFDE	Receive Status Queue Full Detection Enable*2	0: Detection of receive status queue full is disabled. 1: Detection of receive status queue full is enabled.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. This bit is used in I3C protocol mode.
Note 2. This bit is used in I3C Secondary Controller and I3C Target modes.

This register is used to enable or disable detection of each status. When the status enabled by this register is detected, the corresponding flag in the ICCSR register is set to 1.

43.2.53 Communication Status Interrupt Enable Register (ICCSIER)

Address(es): RI3C0.ICCSIER 8745 F1E8h, RI3C0_NS.ICCSIER 0745 F1E8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	SQFIE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	DTEIE	—	—	—	DTAIE	RQFIE	CQEIE	IQEFIE	RIE	TIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TIE	Transmit Data Empty Interrupt Enable	0: Transmit data empty interrupt is disabled. 1: Transmit data empty interrupt is enabled.	R/W
b1	RIE	Receive Data Full Interrupt Enable	0: Receive data full interrupt is disabled. 1: Receive data full interrupt is enabled.	R/W
b2	IQEFIE	IBI Queue Empty/Full Interrupt Enable*1	0: IBI queue empty/full interrupt is disabled. 1: IBI queue empty/full interrupt is enabled.	R/W
b3	CQEIE	Command Queue Empty Interrupt Enable*1	0: Command queue empty interrupt is disabled. 1: Command queue empty interrupt is enabled.	R/W
b4	RQFIE	Response Queue Full Interrupt Enable*1	0: Response queue full interrupt is disabled. 1: Response queue full interrupt is enabled.	R/W
b5	DTAIE	Data Transfer Abort Interrupt Enable*1	0: Data transfer abort interrupt is disabled. 1: Data transfer abort interrupt is enabled.	R/W
b8 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9	DTEIE	Data Transfer Error Interrupt Enable*1	0: Data transfer error interrupt is disabled. 1: Data transfer error interrupt is enabled.	R/W
b19 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	SQFIE	Receive Status Queue Full Interrupt Enable*2	0: Receive status queue full interrupt is disabled. 1: Receive status queue full interrupt is enabled.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. This bit is used in I3C protocol mode.
Note 2. This bit is used in I3C Secondary Controller and I3C Target modes.

This register is used to enable or disable interrupts for each status. When a flag in the ICCSR register becomes 1 and the corresponding interrupt enable bit is 1, an interrupt request is generated.

43.2.54 High-Priority Communication Status Register (ICHCSR)

Address(es): RI3C0.ICHCSR 8745 F200h, RI3C0_NS.ICHCSR 0745 F200h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	HDTEF	—	—	—	HDTAF	HRQFF	HCQEF	—	HRDRF	HTDRE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	HTDRE	High-Priority Transmit Data Empty Flag	0: The free level of the high-priority transmit data buffer is less than the threshold specified by the ICHDBTCR.HTETH[2:0] bits. 1: The free level of the high-priority transmit data buffer is equal to or more than the threshold specified by the HTETH[2:0] bits.	R/(W) *1
b1	HRDRF	High-Priority Receive Data Full Flag	0: The fill level of the high-priority receive data buffer is less than the threshold specified by the ICHDBTCR.HRFTH[2:0] bits 1: The fill level of the high-priority receive data buffer is equal to or more than the threshold specified by the HRFTH[2:0] bits.	R/(W) *1
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R
b3	HCQEF	High-Priority Command Queue Empty Flag	• If the ICHQBTCR.HCQTH[7:0] bits are 00h: 0: High-priority command queue contains data. 1: High-priority command queue contains no data. • If the HCQTH[7:0] bits are not 00h: 0: The number of free high-priority command queue entries is less than the threshold specified by the HCQTH[7:0] bits. 1: The number of free high-priority command queue entries is equal to or more than the threshold specified by the HCQTH[7:0] bits.	R/(W) *1
b4	HRQFF	High-Priority Response Queue Full Flag	0: The number of high-priority response queue entries is less than the threshold specified by the ICHQBTCR.HRQTH[7:0] bits. 1: The number of high-priority response queue entries is equal to or more than the threshold specified by the HRQTH[7:0] bits.	R/(W) *1
b5	HDTAF	High-Priority Data Transfer Abort Flag	0: High-priority data transfer abort does not occur. 1: High-priority data transfer abort occurs.	R/(W) *1
b8 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9	HDTEF	High-Priority Data Transfer Error Flag	0: High-priority data transfer error does not occur. 1: High-priority data transfer error occurs.*2	R/(W) *1
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.
Note 1. To clear this flag, confirm that the flag is 1 and then set it to 0.
Note 2. The Error type for this error is available in the Response Descriptor structure corresponding to the transfer or command.

HTDRE Flag (High-Priority Transmit Data Empty Flag)

[Setting condition]

- When the free level of the high-priority transmit data buffer is equal to or more than the threshold specified by the ICHDBTCR.HTETH[2:0] bits while the ICHCSER.HTDE bit is 1 (detection of high-priority transmit data empty is

enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last write access to the high-priority transmit data buffer by DMAC/DTC.
- When the free level of the high-priority transmit data buffer is less than the threshold specified by the HTETH[2:0] bits.

HRDRF Flag (High-Priority Receive Data Full Flag)

[Setting condition]

- When the fill level of the high-priority receive data buffer is equal to or more than the threshold specified by the ICHDBTCR.HRFTH[2:0] bits while the ICHCSER.HRDE bit is 1 (detection of high-priority receive data full is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last read access to the high-priority receive data buffer by DMAC/DTC.
- When the fill level of the high-priority receive data buffer is less than the threshold specified by the HRFTH[2:0] bits.

HCQEF Flag (High-Priority Command Queue Empty Flag)

[Setting condition]

When any of the following conditions is satisfied while the ICHCSER.HCQEDE bit is 1 (detection of high-priority command queue empty is enabled).

- When the high-priority command queue is completely empty (when the ICHQBTCR.HCQTH[7:0] bits are 00h).
- When the number of the free high-priority command queue entries is equal to or more than the threshold specified by the HCQTH[7:0] bits (when the HCQTH[7:0] bits are other than 00h).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last write access to the high-priority command queue by DMAC/DTC.
- When the high-priority command queue is not completely empty (when the HCQTH[7:0] bits are 00h).
- When the number of the free high-priority command queue entries is less than the threshold specified by the HCQTH[7:0] bits (when the HCQTH[7:0] bits are other than 00h).

HRQFF Flag (High-Priority Response Queue Full Flag)

[Setting condition]

- When the number of the high-priority response queue entries is equal to or more than the threshold specified by the ICHQBTCR.HRQTH[7:0] bits while the ICHCSER.HRQFDE bit is 1 (detection of high-priority response queue full is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- On completion of the last read access to the high-priority response queue by DMAC/DTC.
- When the number of the high-priority response queue entries is less than the threshold specified by the HRQTH[7:0] bits.

HDTAF Flag (High-Priority Data Transfer Abort Flag)

[Setting condition]

- When any high-priority data transfer is aborted while the ICHCSER.HDTADE bit is 1 (detection of high-priority

data transfer abort is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.

HDTEF Flag (High-Priority Data Transfer Error Flag)

[Setting condition]

- When any high-priority data transfer error occurs on the I3C bus while the ICHCSER.HDTEDE bit is 1 (detection of high-priority data transfer error is enabled).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.

43.2.55 High-Priority Communication Status Detection Enable Register (ICHCSER)

Address(es): RI3C0.ICHCSER 8745 F204h, RI3C0_NS.ICHCSER 0745 F204h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	HTDE	High-Priority Transmit Data Empty Detection Enable	0: Detection of high-priority transmit data empty is disabled. 1: Detection of high-priority transmit data empty is enabled.	R/W
b1	HRDE	High-Priority Receive Data Full Detection Enable	0: Detection of high-priority receive data full is disabled. 1: Detection of high-priority receive data full is enabled.	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R
b3	HCQEDE	High-Priority Command Queue Empty Detection Enable	0: Detection of high-priority command queue empty is disabled. 1: Detection of high-priority command queue empty is enabled.	R/W
b4	HRQFDE	High-Priority Response Queue Full Detection Enable	0: Detection of high-priority response queue full is disabled. 1: Detection of high-priority response queue full is enabled.	R/W
b5	HDTADE	High-Priority Data Transfer Abort Detection Enable	0: Detection of high-priority data transfer abort is disabled. 1: Detection of high-priority data transfer abort is enabled.	R/W
b8 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9	HDTEDE	High-Priority Data Transfer Error Detection Enable	0: Detection of high-priority data transfer error is disabled. 1: Detection of high-priority data transfer error is enabled.	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

This register is used to enable or disable detection of each status. When the status enabled by this register is detected, the corresponding flag in the ICHCSR register is set to 1.

43.2.56 High-Priority Communication Status Interrupt Enable Register (ICHCSIER)

Address(es): RI3C0.ICHCSIER 8745 F208h, RI3C0_NS.ICHCSIER 0745 F208h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	HDTEIE	—	—	—	HDTAIE	HRQFIE	HCQEIE	—	HRIE	HTIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	HTIE	High-Priority Transmit Data Empty Interrupt Enable	0: High-priority transmit data empty interrupt is disabled. 1: High-priority transmit data empty interrupt is enabled.	R/W
b1	HRIE	High-Priority Receive Data Full Interrupt Enable	0: High-priority receive data full interrupt is disabled. 1: High-priority receive data full interrupt is enabled.	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R
b3	HCQEIE	High-Priority Command Queue Empty Interrupt Enable	0: High-priority command queue empty interrupt is disabled. 1: High-priority command queue empty interrupt is enabled.	R/W
b4	HRQFIE	High-Priority Response Queue Full Interrupt Enable	0: High-priority response queue full interrupt is disabled. 1: High-priority response queue full interrupt is enabled.	R/W
b5	HDTAIE	High-Priority Data Transfer Abort Interrupt Enable	0: High-priority data transfer abort interrupt is disabled. 1: High-priority data transfer abort interrupt is enabled.	R/W
b8 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9	HDTEIE	High-Priority Data Transfer Error Interrupt Enable	0: High-priority data transfer error interrupt is disabled. 1: High-priority data transfer error interrupt is enabled.	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

This register is used to enable or disable interrupts for each status. When a flag in the ICHCSR register becomes 1 and the corresponding interrupt enable bit is 1, an interrupt request is generated.

43.2.57 Bus Status Register (ICBSR)

Address(es): RI3C0.ICBSR 8745 F210h, RI3C0_NS.ICBSR 0745 F210h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	BIDL	BAVL	BFREE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BFREE	Bus Free Flag	0: Have not detected bus free. 1: Have detected bus free.	R
b1	BAVL	Bus Available Detection Flag*1	0: Have not detected bus available. 1: Have detected bus available.	R
b2	BIDL	Bus Idle Detection Flag*1	0: Have not detected bus idle. 1: Have detected bus idle.	R
b31 to b3	—	Reserved	These bits are read as 0.	R

Note 1. This bit is used in I3C protocol mode.

BFREE Flag (Bus Free Flag)

This flag indicates whether the I3C bus is occupied (bus busy) or released (bus free).

[Setting condition]

- When the number of cycles set in the ICBFTR register has elapsed when the SCL00 and SDA00 lines are high after a STOP condition is detected.
- When the number of cycles set in the ICBFTR register has elapsed when the SCL00 and SDA00 lines are high after setting the ICCR.ICE bit to 1.

[Clearing condition]

- When SCL00 line and SDA00 line are other than high (in I3C protocol mode).
- When a START condition is detected (in I^2C protocol mode).
- When the ICCR.ICE bit is set to 0.
- When the RI3C is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

BAVL Flag (Bus Available Detection Flag)

The Bus Available condition is a period during which the Bus Free condition is sustained continuously for a duration of at least tAVAL (refer to section 67.5.7.10, RI3C). A Target can only issue a START Request (for an IBI or for a CRR) after a Bus Available condition.

[Setting condition]

- When the number of cycles set in the ICBATR register has elapsed when the SCL00 and SDA00 lines are high after a STOP condition is detected.
- When the number of cycles set in the ICBATR register has elapsed when the SCL00 and SDA00 lines are high after setting the ICCR.ICE bit to 1.

[Clearing condition]

- When SCL00 line and SDA00 line are other than high.

- When the ICCR.ICE bit is set to 0.

BIDL Flag (Bus Idle Detection Flag)

The Bus Idle condition is a period during which the Bus Available condition is sustained continuously for a duration of at least tIDLE (refer to section 67.5.7.10, RI3C).

[Setting condition]

- When the number of cycles set in the ICBITR register has elapsed when the SCL00 and SDA00 lines are high after a STOP condition is detected.
- When the number of cycles set in the ICBITR register has elapsed when the SCL00 and SDA00 lines are high after setting the ICCR.ICE bit to 1.

[Clearing condition]

- When SCL00 line and SDA00 line are other than High.
- When the ICCR.ICE bit is set to 0.

43.2.58 Slave Mode Status Register (ICSSR)

Address(es): RI3C0.ICSSR 8745 F214h, RI3C0_NS.ICSSR 0745 F214h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	AAS2	AAS1	AAS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HOA	—	—	—	—	—	—	—	—	DID	HSMC	—	—	—	—	GCA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	GCA	General Call Address Detection Flag	0: General call address is not detected. 1: General call address is detected.	R/(W) *1
b4 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b5	HSMC	Hs-mode Master Code Detection Flag	0: Hs-mode master code is not detected. 1: Hs-mode master code is detected.	R/(W) *1
b6	DID	Device-ID Address Detection Flag	0: Device-ID address is not detected. 1: Device-ID address is detected. • This bit is set to 1 when the first frame received immediately after a START condition is detected matches a value of (device ID (1111 100b) + 0 (write)).	R/(W) *1
b14 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R
b15	HOA	Host Address Detection Flag	0: Host address is not detected. 1: Host address is detected. • This bit is set to 1 when the received slave address matches the host address (0001 000b).	R/(W) *1
b16	AAS0	Slave Address 0 Detection Flag	0: Slave address 0 is not detected. 1: Slave address 0 is detected.	R/(W) *1
b17	AAS1	Slave Address 1 Detection Flag	0: Slave address 1 is not detected. 1: Slave address 1 is detected.	R/(W) *1
b18	AAS2	Slave Address 2 Detection Flag	0: Slave address 2 is not detected. 1: Slave address 2 is detected.	R/(W) *1
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I²C protocol mode.
Note 1. Only 0 can be written to this bit.

GCA Flag (General Call Address Detection Flag)

[Setting condition]

- This flag is set to 1 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.GCAE bit is 1 (general call address detection is enabled).
  2. When the received slave address matches the general call address (0000 000b + 0 (write)).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.
- When a repeated START condition is detected.

HSMC Flag (Hs-mode Master Code Detection Flag)

[Setting condition]

- This flag is set to 1 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.HSMCE bit is 1 (Hs-mode master code detection is enabled).
  2. When the first byte received immediately after a START condition is detected matches a value of Hs-mode master code (0000 1XXXb) + 1 (NACK).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.

DID Flag (Device-ID Address Detection Flag)

[Setting condition]

- This flag is set to 1 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.DIDE bit is 1 (device-ID address detection is enabled).
  2. When the first byte received immediately after a START condition or repeated START condition is detected matches a value of device ID (1111 100b) + 0 (write).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.
- This flag is set to 0 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 or 1 and 3 are satisfied.
  1. The ICSCR.DIDE bit is 1 (device-ID address detection is enabled).
  2. When the first byte received immediately after a START condition or repeated START condition is detected does not match a value of device ID (1111 100b).
  3. When the first byte received immediately after a START condition or repeated START condition is detected matches a value of (device ID (1111 100b) + 0 (write)) and the second byte does not match any of slave addresses 0 to 2.

HOA Flag (Host Address Detection Flag)

[Setting condition]

- This flag is set to 1 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.HOAE bit is 1 (host address detection is enabled).
  2. When the received slave address matches the host address (0001 000b).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.
- When a repeated START condition is detected.

AASy Flag (Slave Address y Detection Flag) (y = 0 to 2)

[Setting condition]

For 7-bit address format (SAMRy.FS flag = 0):

- This flag is set to 1 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.SARyE bit is 1 (slave y is enabled).
  2. When the received slave address matches the SAMRy.SVA[6:0] bits value.

For 10-bit address format (SAMRy.FS flag = 1):

- This flag is set to 1 at the rising edge of the ninth SCL in the second byte when the following 1 and 2 are satisfied.
  1. The ICSCR.SARyE bit is 1 (slave y is enabled).
  2. When the received slave address matches a value of 1111 0b + SAMRy.SVA[9:8] bits and the following address matches the SAMRy.SVA[7:0] bits value.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.

For 7-bit address format (SAMRy.FS flag = 0):

- This flag is set to 0 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.SARyE bit is 1 (slave y is enabled).
  2. When the received slave address does not match SAMRy.SVA[6:0] bits value.

For 10-bit address format (SAMRy.FS flag = 1):

- This flag is set to 0 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.SARyE bit is 1 (slave y is enabled).
  2. When the received slave address does not match a value of 1111 0b + SAMRy.SVA[9:8] bits.
- This flag is set to 0 at the rising edge of the ninth SCL in the second byte when the following 1 and 2 are satisfied.
  1. The ICSCR.SARyE bit is 1 (slave y is enabled).
  2. When the received slave address matches a value of 1111 0b + SAMRy.SVA[9:8] bits and the following address does not match the SAMRy.SVA[7:0] bits value.

43.2.59 Wake-Up Unit Status Register (ICWUSR)

Address(es): RI3C0.ICWUSR 8745 F218h, RI3C0_NS.ICWUSR 0745 F218h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WUASYNF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	WUASYNF	Wake-Up Detection Circuit Status Flag	0: Wake-up detection circuit is disabled (PCLKA and I3CCLK are operating). 1: Wake-up detection circuit is enabled (PCLKA and I3CCLK are stopped).	R
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

WUASYNF Flag (Wake-Up Detection Circuit Status Flag)

This bit indicates whether the wake-up detection circuit is enabled or disabled.

[Setting condition]

- When the ICBSR.BFREE flag is set to 1 (bus free) while the ICWUCR.WUFE bit is 1 (wake-up function is enabled) and the WUFSYNE bit is 0 (asynchronous operation).

[Clearing condition]

- When the ICWUCR.WUFE bit is set to 0 (wake-up function is disabled).
- When a wake-up event is detected while the WUFE bit is 1, and then the ICWUCR.WUFSYNE bit is set to 1 (internal clock synchronous operation) while this flag is set to 1 (in I^2C slave mode).
- When a STOP condition is detected after a wake-up event is detected while the WUFE bit is 1 and the WUFSYNE bit is set to 1 while this flag is set to 1 (in I3C Target mode).
- When a STOP condition is detected while the WUFE bit is 1, this flag is 1, and the WUFSYNE bit is 1 (in I^2C slave mode or in I3C Target mode).
- When a wake-up event is detected while the WUFE bit is 1 and the WUFSYNE bit is set to 1 while this flag is set to 1 (in I3C Controller mode).

43.2.60 C_SyncCNT Capture Register (ICCSCCR)

Address(es): RI3C0.ICCSCCR 8745 F21Ch, RI3C0_NS.ICCSCCR 0745 F21Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

The ICCSCCR register is a 32-bit read-only register used to read the value of C_SyncCNT captured by aBE. This register is used only in Async Mode 1.

43.2.61 Target Device Address Table Register m (ICTDATRm) (m = 0 to 7)

Address(es): RI3C0.ICTDATR0 8745 F224h, RI3C0.ICTDATR1 8745 F22Ch, RI3C0.ICTDATR2 8745 F234h, RI3C0.ICTDATR3 8745 F23Ch, RI3C0.ICTDATR4 8745 F244h, RI3C0.ICTDATR5 8745 F24Ch, RI3C0.ICTDATR6 8745 F254h, RI3C0.ICTDATR7 8745 F25Ch, RI3C0_NS.ICTDATR0 0745 F224h, RI3C0_NS.ICTDATR1 0745 F22Ch, RI3C0_NS.ICTDATR2 0745 F234h, RI3C0_NS.ICTDATR3 0745 F23Ch, RI3C0_NS.ICTDATR4 0745 F244h, RI3C0_NS.ICTDATR5 0745 F24Ch, RI3C0_NS.ICTDATR6 0745 F254h, RI3C0_NS.ICTDATR7 0745 F25Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TYPE	NACKRC[1:0]		—	—	—	—	—	DADR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	IBITSE	CRRRJ	TIRRJ	IBIPL	—	—	—	—	—	SADR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	SADR[6:0]	Static Address	I3C/I2C static address	R/W
b11 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	IBIPL	IBI Payload	0: IBIs from this device do not carry data payload. 1: IBIs from this device carry data payload.	R/W
b13	TIRRJ	Target Interrupt Request Reject	0: RI3C ACKs Target Interrupt Requests from this device. 1: RI3C NACKs Target Interrupt Requests from this device and automatically sends DISEC CCC.	R/W
b14	CRRRJ	Controller Role Request Reject	0: RI3C ACKs Controller Role Requests from this device. 1: RI3C NACKs Controller Role Requests from this device and automatically sends DISEC CCC.	R/W
b15	IBITSE	IBI Timestamp Enable	0: RI3C does not timestamp IBIs from this device with Controller timestamps. 1: RI3C timestamps IBIs from this device with Controller timestamps.	R/W
b23 to b16	DADR[7:0]	Dynamic Address	DADR[6:0] bits: Dynamic Address for this device DADR[7] bit: Parity bit	R/W
b28 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R
b30, b29	NACKRC[1:0]	NACK Retry Count Setting	0h: No retries on NACK 1h to 3h: Up to 1 to 3 retries on NACK	R/W
b31	TYPE	Device Type	0: I3C device 1: I2C device	R/W

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

The Device Address Table (DAT) stores the device addresses and control information of Target devices attached to the I3C bus and is implemented in RI3C as the ICTDATRm registers. The Command Descriptor of a command that requires this register information has a DEV_INDEX field, and the register is selected by the field.

IBIPL Bit (IBI Payload)

This bit indicates whether IBIs from the corresponding device have a data payload. This bit reflects the ICTDCTRm.IBIPL bit (BCR[2]: IBI Payload bit in the Bus Characteristics Register).
During IBI handling for this device, the Controller shall use this bit to determine whether or not to drive reception of the IBI data payload. Data continuation is indicated by the T-Bit.

TIRRJ Bit (Target Interrupt Request Reject)

This bit controls whether RI3C, when operating in the Active Controller role, will accept or reject Target Interrupt Requests (TIR) from the Target device indicated by this register.

CRRRJ Bit (Controller Role Request Reject)

This bit controls whether RI3C, when operating in the Active Controller role, will accept or reject Controller Role Requests (CRR) from the Secondary Controller indicated by this register.

IBITSE Bit (IBI Timestamp Enable)

This bit enables or disables IBI timestamping for a specific device.

Note: The IBI Status Descriptor for each IBI event indicates whether or not the individual IBI event was actually timestamped. Set to 0 except for Async Mode 0 and Async Mode 1 of Timing Control Mode.

NACKRC[1:0] Bits (NACK Retry Count Setting)

These bits set the number of retries when a NACK response is received from the Target for the transaction set in the Command Descriptor.

Note: When ENTDAA CCC is executed by address assignment command (refer to section 43.3.1.1, Address Assignment Command), the setting of this bit is ignored and the transaction ends when NACK is received once.
Note: When a NACK is received for a Broadcast Address, RI3C does not retry regardless of the setting of the NACKRC[1:0] bits.
Note: When the NACKRC[1:0] bits are set to 00b, the RI3C does not retry even for Direct CCCs.

43.2.62 Extended Target Device Address Table Register (ICEDATR)

Address(es): RI3C0.ICEDATR 8745 F2A0h, RI3C0_NS.ICEDATR 0745 F2A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TYPE	NACKRC[1:0]		—	—	—	—	—	DADR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	SADR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	SADR[6:0]	Static Address	I3C/I²C static address	R/W
b15 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R
b23 to b16	DADR[7:0]	Dynamic Address	DADR[6:0] bits: Dynamic Address for this device DADR[7] bit: Parity bit	R/W
b28 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R
b30, b29	NACKRC[1:0]	NACK Retry Count Setting	0h: No retries on NACK 1h to 3h: Up to 1 to 3 retries on NACK	R/W
b31	TYPE	Device Type	0: I3C device 1: I²C device	R/W

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

43.2.63 Device Address Register y (ICDARy) (y = 0 to 2)

Address(es): RI3C0.ICDAR0 8745 F2B0h, RI3C0.ICDAR1 8745 F2B4h, RI3C0.ICDAR2 8745 F2B8h,
RI3C0_NS.ICDAR0 0745 F2B0h, RI3C0_NS.ICDAR1 0745 F2B4h, RI3C0_NS.ICDAR2 0745 F2B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	DADR[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	IBIPL	—	—	SADR[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	SADR[9:0]	Static Address	Set a static address.	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	IBIPL	IBI Payload	This bit is the mirror bit of the ICDCTR.IBIPL. 0: IBIs from this device do not carry a data payload. 1: IBIs from this device carry a data payload.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R
b22 to b16	DADR[6:0]	Dynamic Address	Dynamic Address is set.	R/W
b31 to b23	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.
Note: Do not write to this register when RI3C is Primary Controller.

The Device Characteristics Table (DCT) is a register set that stores the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.
The ICDARy register is used to store the values of the assigned Dynamic Address.

SADR[9:0] Bits (Static Address)

Set the static address in Target mode to the lower 7 bits.
The upper 3 bits are reserved. Set them to 0.

IBIPL Bit (IBI Payload)

Indicates whether IBIs from this Device have a Data Payload. This bit reflects the IBI Payload bit in the Device's Bus Characteristics Register (BCR).
During IBI handling for this Device, the Controller shall use this bit to determine whether or not to drive reception of the IBI Data Payload. Data continuation is indicated by the T-Bit.

DADR[6:0] Bits (Dynamic Address)

These bits store the Dynamic Address assigned in Target mode.
These bits are updated when one any of the following events occurs.

- When writing Dynamic Address value.
- When Target Address is equal to its own Static Address in receiving SETDASA CCC (Direct), these bits are updated to the value of the subsequent Dynamic Address.
- When Dynamic Address Assignment procedure that starts by receiving ENTDAA CCC (Broadcast) is established.
- When receiving RSTDAA CCC (Broadcast), all bits are set to 0.
- When Target Address is equal to its own Dynamic Address in receiving RSTDAA CCC (Direct), all bits are set to 0.

- When Target Address is equal to its own Dynamic Address in receiving SETNEWDA CCC (Direct), these bits are updated to the value of the subsequent new Dynamic Address.
- When receiving SETAASA CCC (Broadcast), these bits are updated to the value of the SADR[6:0] bits.

43.2.64 Slave Address Register y (SARy) (y = 0 to 2)

Address(es): RI3C0.SAR0 8745 F2B0h, RI3C0.SAR1 8745 F2B4h, RI3C0.SAR2 8745 F2B8h,
RI3C0_NS.SAR0 0745 F2B0h, RI3C0_NS.SAR1 0745 F2B4h, RI3C0_NS.SAR2 0745 F2B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	FS	SVA[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	SVA[9:0]	Slave Address	Set a slave address.	R/W
b10	FS	Address Format Select	0: 7-bit address format 1: 10-bit address format	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I^2C protocol mode.

FS Bit (Address Format Select)

This bit is used to select 7-bit address or 10-bit address for slave address (SVA[9:0] bits).
When this bit is 0, the 7-bit address format is selected for slave address, the SVA[6:0] bit setting is valid, and the SVA[9:7] bit setting is ignored.
When this bit is 1, the 10-bit address format is selected for slave address and the SVA[9:0] bit setting is valid.
When the ICSCR.SARyE bit is 0, the setting of this bit is ignored.

43.2.65 Target Device Characteristics Table Register m (ICTDCTRm) (m = 0 to 7)

Address(es): RI3C0.ICTDCTR0 8745 F2D0h, RI3C0.ICTDCTR1 8745 F2D4h, RI3C0.ICTDCTR2 8745 F2D8h, RI3C0.ICTDCTR3 8745 F2DCh, RI3C0.ICTDCTR4 8745 F2E0h, RI3C0.ICTDCTR5 8745 F2E4h, RI3C0.ICTDCTR6 8745 F2E8h, RI3C0.ICTDCTR7 8745 F2ECh, RI3C0_NS.ICTDCTR0 0745 F2D0h, RI3C0_NS.ICTDCTR1 0745 F2D4h, RI3C0_NS.ICTDCTR2 0745 F2D8h, RI3C0_NS.ICTDCTR3 0745 F2DCh, RI3C0_NS.ICTDCTR4 0745 F2E0h, RI3C0_NS.ICTDCTR5 0745 F2E4h, RI3C0_NS.ICTDCTR6 0745 F2E8h, RI3C0_NS.ICTDCTR7 0745 F2ECh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ROLE[1:0]		ADVCAP	VTSUP	OFLC	IBIPL	IBIRQC	LIMIT	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	LIMIT	Max Data Speed Limitation	0: No limitation 1: Limitation	R/W
b9	IBIRQC	IBI Request Capable	0: Not capable 1: Capable	R/W
b10	IBIPL	IBI Payload	0: No data byte follows the accepted IBI. 1: One or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit.	R/W
b11	OFLC	Offline Capable	0: Device will always respond to I3C bus commands. 1: Device will not always respond to I3C bus commands.	R/W
b12	VTSUP	Virtual Target Support	0: Device is not a Virtual Target and does not expose other downstream Device(s). 1: Device is a Virtual Target or expose other downstream Device(s).	R/W
b13	ADVCAP	Advanced Capabilities	0: Device does not support optional advanced capabilities. 1: Device supports optional advanced capabilities. Use GETCAPS CCC to determine which ones.	R/W
b15, b14	ROLE[1:0]	Device Role Setting	b15 b14 0 0: I3C Target 0 1: I3C Controller capable*1 Other than above are reserved.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.
Note 1. For an I3C Device acting as I3C Primary Controller, the ROLE[1:0] bits will contain the value 01b.

The Device Characteristics Table (DCT) is a register set that stores the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.
The ICTDCTRm register contains the value of the Bus Characteristic Register (BCR) of the Target device captured by the RI3C during Controller operation.
This register is updated when the Bus Characteristics Register (BCR) is received from the device in the Dynamic Address Allocation procedure starting by receiving the ENTDAA CCC (Broadcast).

LIMIT Bit (Max Data Speed Limitation)

This bit corresponds to bit 0 in the BCR (BCR[0]).
Controller shall use the GETMXDS CCC to interrogate the Target for specific limitation.

IBIRQC Bit (IBI Request Capable)

This bit corresponds to bit 1 in the BCR (BCR[1]).

IBIPL Bit (IBI Payload)

This bit corresponds to bit 2 in the BCR (BCR[2]).

OFLC Bit (Offline Capable)

This bit corresponds to bit 3 in the BCR (BCR[3]).
Offline capable devices retain the Dynamic Address.

VTSUP Bit (Virtual Target Support)

This bit corresponds to bit 4 in the BCR (BCR[4]).

ADVCAP Bit (Advanced Capabilities)

This bit corresponds to bit 5 in the BCR (BCR[5]).

ROLE[1:0] Bits (Device Role Setting)

This bit corresponds to bits 7 and 6 in the BCR (BCR[7:6]).

43.2.66 Device Characteristics Table Register (ICDCTR)

Address(es): RI3C0.ICDCTR 8745 F320h, RI3C0_NS.ICDCTR 0745 F320h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	DCR[7:0]	Device Characteristics	255 available codes for describing the type of sensor, or device. Examples: Accelerometer, gyroscope, composite devices Default value is 00h: Generic device	R/W
b8	LIMIT	Max Data Speed Limitation*1	0: No limitation 1: Limitation	R/W
b9	IBIRQC	IBI Request Capable	0: Not capable 1: Capable	R/W
b10	IBIPL	IBI Payload	0: No data byte follows the accepted IBI. 1: One or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit.	R/W
b11	OFLC	Offline Capable*2	0: Device will always respond to I3C bus commands. 1: Device will not always respond to I3C bus commands.	R/W
b12	VTSUP	Virtual Target Support	0: Device is not a Virtual Target and does not expose other downstream Device(s). 1: Device is a Virtual Target or expose other downstream Device(s).	R/W
b13	ADVCAP	Advanced Capabilities	0: Device does not support optional advanced capabilities. 1: Device supports optional advanced capabilities.	R/W
b15, b14	ROLE[1:0]	Device Role Setting	b15 b14 0 0: I3C Target 0 1: I3C Controller capable*3 Settings other than above are prohibited.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.
Note 1. Controller shall use the GETMXDS CCC to interrogate the Target for specific limitation.
Note 2. Offline Capable Devices retain the Dynamic Address.
Note 3. For an I3C Device acting as I3C Primarily Controller, the ROLE[1:0] bits will contain the value 01b.

The Device Characteristics Table (DCT) is a register set that stores the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.
The ICDCTR register is used to store the values of the RI3C Bus Characteristics Register (BCR) and Device Characteristics Register (DCR). The BCR consists of the ROLE[1:0], OFLC, IBIPL, IBIRQC, and LIMIT bits.

DCR[7:0] Bits (Device Characteristics)

Each I3C device that is connected to the I3C bus has an associated Device Characteristics Register (DCR). This register describes the I3C compliant device type such as accelerometer and gyroscope, for use in Dynamic Address assignment and Common Command Codes.

LIMIT Bit (Max Data Speed Limitation)

This bit corresponds to bit 0 in the BCR (BCR[0]).

IBIRQC Bit (IBI Request Capable)

This bit corresponds to bit 1 in the BCR (BCR[1]).

IBIPL Bit (IBI Payload)

This bit corresponds to bit 2 in the BCR (BCR[2]).

OFLC Bit (Offline Capable)

This bit corresponds to bit 3 in the BCR (BCR[3]).

VTSUP Bit (Virtual Target Support)

This bit corresponds to bit 4 in the BCR (BCR[4]).

ADVCAP Bit (Advanced Capabilities)

This bit corresponds to bit 5 in the BCR (BCR[5]).

ROLE[1:0] Bits (Device Role Setting)

This bit corresponds to bits 7 and 6 in the BCR (BCR[7:6]).

When RI3C is in Target mode and issues IBI by Command Descriptor, set the BCR as follows:

(1) Target Interrupt Request: No IBI Payload follow the accepted IBI:

- IBIRQC = 1
- IBIPL = 0

Note: Set DATA_LENGTH field of Command Descriptor to 0000h.

(2) Target Interrupt Request: IBI Payload follow the accepted IBI:

- IBIRQC = 1
- IBIPL = 1

Note: Set DATA_LENGTH field of Command Descriptor to any value.

(3) Controller Role Request:

- IBIRQC = 1
- ROLE[1:0] = 01b

When RI3C is in Target mode and receives CCC from I3C Controller, it performs the following operations according to the setting of the BCR:

- When the IBIPL bit is 1, RI3C sends the value set in the ICMRLR.IBIPL[7:0] bits as the 3rd byte data to GETMRL CCC from I3C Controller.
- When the LIMIT bit is 0, RI3C NACKs GETMXDS CCC from I3C Controller.
- When the LIMIT bit is 1, RI3C ACKs GETMXDS CCC from I3C Controller and sends data set in the ICMWSR, ICMRSR, and ICMTTR registers.

43.2.67 Provisioned ID Low Register (ICPIDLR)

Address(es): RI3C0.ICPIDLR 8745 F324h, RI3C0_NS.ICPIDLR 0745 F324h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Secondary Controller and I3C Target modes.

The Device Characteristics Table (DCT) is a register set that stores the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.
This register stores the lower 16 bits of the provisioned ID (b15 to b0 of the PID).
The upper 16 bits are reserved. These bits are read as 0 and the write value should be 0.

43.2.68 Provisioned ID High Register (ICPIDHR)

Address(es): RI3C0.ICPIDHR 8745 F328h, RI3C0_NS.ICPIDHR 0745 F328h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Secondary Controller and I3C Target modes.

The Device Characteristics Table (DCT) is a register set that stores the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.
This register stores the upper 32 bits of the provisioned ID (b47 to b16 of the PID).

43.2.69 Device Address Monitor Register y (ICDAMRy) (y = 0 to 2)

Address(es): RI3C0.ICDAMR0 8745 F330h, RI3C0.ICDAMR1 8745 F334h, RI3C0.ICDAMR2 8745 F338h, RI3C0_NS.ICDAMR0 0745 F330h, RI3C0_NS.ICDAMR1 0745 F334h, RI3C0_NS.ICDAMR2 0745 F338h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DAV	SAV	—	—	—	—	TADR[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0.	R
b25 to b16	TADR[9:0]	Target Address	Target address is set.	R
b29 to b26	—	Reserved	These bits are read as 0.	R
b30	SAV	Static Address Valid Flag	0: Static address is disabled. 1: Static address is enabled.	R
b31	DAV	Dynamic Address Valid Flag	0: Dynamic Address is disabled. 1: Dynamic Address is enabled.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

TADR[9:0] Bits (Target Address)

The TADR[9:0] bits indicate a valid Target address.

- When the DAV flag is 1:
  The TADR[9:7] bits are 000b.
  The TADR[6:0] bits are the ICDARy.DADR[6:0] bits.
- When the SAV flag is 1:
  The TADR[9:7] bits are 000b.
  The TADR[6:0] bits are the ICDARy.SADR[6:0] bits.

SAV Flag (Static Address Valid Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICTCR.TAyDE bit is 1 (detection of Target address y is enabled).
  2. The DAV flag is 0 (Dynamic Address is disabled).
  3. The ICDARy.SADR[6:0] bits are not 0000000b.

[Clearing condition]

- [Setting condition] is not satisfied.

DAV Flag (Dynamic Address Valid Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICTCR.TAyDE bit is 1 (detection of Target address y is enabled).
  2. The ICDARy.DADR[6:0] bits are not 0000000b.

[Clearing condition]

- [Setting condition] is not satisfied.

43.2.70 Slave Address Monitor Register y (SAMRy) (y = 0 to 2)

Address(es): RI3C0.SAMR0 8745 F330h, RI3C0.SAMR1 8745 F334h, RI3C0.SAMR2 8745 F338h, RI3C0_NS.SAMR0 0745 F330h, RI3C0_NS.SAMR1 0745 F334h, RI3C0_NS.SAMR2 0745 F338h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	SAV	—	—	FS	—	SVA[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0.	R
b25 to b16	SVA[9:0]	Slave Address	Slave address is set.	R
b26	—	Reserved	This bit is read as 0.	R
b27	FS	Address Format Flag	0: The 7-bit address format is selected. 1: The 10-bit address format is selected.	R
b29, b28	—	Reserved	These bits are read as 0.	R
b30	SAV	Slave Address Valid Flag	0: Slave address is disabled. 1: Slave address is enabled.	R
b31	—	Reserved	This bit is read as 0.	R

Note: This register is used in I²C protocol mode.

SVA[9:0] Bits (Slave Address)

The SVA[9:0] bits indicate a valid slave address.

- When the SAV flag is 1 and the FS flag is 0:
  The SVA[9:7] bits are 000b.
  The SVA[6:0] bits are the SARy.SVA[6:0] bits.
- When the SAV flag is 1 and the FS flag is 1:
  The SVA[9:0] bits are the SARy.SVA[9:0] bits.

FS Flag (Address Format Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICSCR.SARyE bit is 1 (detection of slave y is enabled).
  2. The SARy.FS bit is 1 (the address length is 10 bits).

[Clearing condition]

- [Setting condition] is not satisfied.

SAV Flag (Slave Address Valid Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICSCR.SARyE bit is 1 (detection of slave address y is enabled).
  2. The SARy.SVA[6:0] bits are not 0000000b when the FS flag is 0.
     The SARy.SVA[9:0] bits are not 0000000000b when the FS flag is 1.

[Clearing condition]

- [Setting condition] is not satisfied.

43.2.71 Target Event Register (ICTEVR)

Address(es): RI3C0.ICTEVR 8745 F350h, RI3C0_NS.ICTEVR 0745 F350h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ENCR	ENINT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ENINT	Target Interrupt Request Enable Flag	0: Target-initiated interrupts is disabled by the Controller. 1: Target-initiated interrupts is enabled by the Controller.	R/W
b1	ENCR	Controller Role Request Enable Flag	0: Controller Role Requests from Secondary Controllers is disabled by the Active Controller. 1: Controller Role Requests from Secondary Controllers is enabled by the Active Controller.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

ENINT Flag (Target Interrupt Request Enable Flag)

This flag allows the Controller to control when Target-initiated interrupts are allowed on the I3C bus.

[Setting conditions]

- When writing 1.
- When receiving ENEC CCC (Broadcast) with the ENINT field set to 1.
- When receiving ENEC CCC (Direct) with the ENINT field set to 1 and with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with the DISINT field set to 1.
- When receiving DISEC CCC (Direct) with the DISINT field set to 1 and with its own Target address.

ENCR Flag (Controller Role Request Enable Flag)

This flag allows the Active Controller to control when Controller Role Requests from Secondary Controller are allowed on the I3C bus.

[Setting conditions]

- When writing 1.
- When receiving ENEC CCC (Broadcast) with the ENCR field set to 1.
- When receiving ENEC CCC (Direct) with the ENCR field set to 1 and with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with the DISCR field set to 1.
- When receiving DISEC CCC (Direct) with the DISCR field set to 1 and with its own Target address.

43.2.72 Activity State Register (ICASR)

Address(es): RI3C0.ICASR 8745 F354h, RI3C0_NS.ICASR 0745 F354h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	ENTAS3	ENTAS2	ENTAS1	ENTAS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ENTAS0	Activity State 0 Flag*1	0: Other than activity state 0 1: Activity state 0	R/W
b1	ENTAS1	Activity State 1 Flag*1	0: Other than activity state 1 1: Activity state 1	R/W
b2	ENTAS2	Activity State 2 Flag*1	0: Other than activity state 2 1: Activity state 2	R/W
b3	ENTAS3	Activity State 3 Flag*1	0: Other than activity state 3 1: Activity state 3	R/W
b31 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.
Note 1. Do not set multiple bits to 1 at the same time.

ENTAS0 Flag (Activity State 0 Flag)

[Setting conditions]

- When writing 1.
- When receiving ENTAS0 CCC (Broadcast).
- When receiving ENTAS0 CCC (Direct) with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving ENTAS1 CCC (Broadcast), ENTAS2 CCC (Broadcast), or ENTAS3 CCC (Broadcast).
- When receiving ENTAS1 CCC (Direct), ENTAS2 CCC (Direct), or ENTAS3 CCC (Direct) with its own Target address.

ENTAS1 Flag (Activity State 1 Flag)

[Setting conditions]

- When writing 1.
- When receiving ENTAS1 CCC (Broadcast).
- When receiving ENTAS1 CCC (Direct) with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving ENTAS0 CCC (Broadcast), ENTAS2 CCC (Broadcast), or ENTAS3 CCC (Broadcast).
- When receiving ENTAS0 CCC (Direct), ENTAS2 CCC (Direct), or ENTAS3 CCC (Direct) with its own Target address.

ENTAS2 Flag (Activity State 2 Flag)

[Setting conditions]

- When writing 1.
- When receiving ENTAS2 CCC (Broadcast).
- When receiving ENTAS2 CCC (Direct) with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving ENTAS0 CCC (Broadcast), ENTAS1 CCC (Broadcast), or ENTAS3 CCC (Broadcast).
- When receiving ENTAS0 CCC (Direct), ENTAS1 CCC (Direct), or ENTAS3 CCC (Direct) with its own Target address.

ENTAS3 Flag (Activity State 3 Flag)

[Setting conditions]

- When writing 1.
- When receiving ENTAS3 CCC (Broadcast).
- When receiving ENTAS3 CCC (Direct) with its own Target address.

[Clearing conditions]

- When writing 0.
- When receiving ENTAS0 CCC (Broadcast), ENTAS1 CCC (Broadcast), or ENTAS2 CCC (Broadcast).
- When receiving ENTAS0 CCC (Direct), ENTAS1 CCC (Direct), or ENTAS2 CCC (Direct) with its own Target address.

43.2.73 Max Write Length Register (ICMWLR)

Address(es): RI3C0.ICMWLR 8745 F358h, RI3C0_NS.ICMWLR 0745 F358h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MWL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	MWL[15:0]	Max Write Length	Set the maximum data write length in bytes to respond to GETMWL CCC. Set a value of 8 or more. These bits are automatically updated when SETMWL CCC is received.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

MWL[15:0] Bits (Max Write Length)

These bits are used when the I3C Controller sets the maximum data write length in RI3C or gets the maximum data write length from RI3C.

The value of these bits is automatically transmitted in response to GETMRL CCC.

When receiving SETMWL CCC (Broadcast) or SETMWL CCC (Direct) with its own Target address, these bits are automatically updated to the received MWL value.

43.2.74 Max Read Length Register (ICMRLR)

Address(es): RI3C0.ICMRLR 8745 F35Ch, RI3C0_NS.ICMRLR 0745 F35Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	IBIPL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MRL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	MRL[15:0]	Max Read Length	Set the maximum data read length in bytes to respond to GETMRL CCC. Set a value of 16 or more. These bits are automatically updated when SETMRL CCC is received.	R/W
b23 to b16	IBIPL[7:0]	IBI Payload Size	Set the maximum IBI payload size in bytes to respond to GETMRL CCC. These bits are automatically updated when SETMRL CCC is received.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

MRL[15:0] Bits (Max Read Length)

These bits are used when the I3C Controller sets the maximum data read length in RI3C or gets the maximum data read length from RI3C.

The value of these bits is automatically transmitted as the first two bytes of the response to GETMRL CCC.

When receiving SETMRL CCC (Broadcast) or SETMRL CCC (Direct) with its own Target address, these bits are automatically updated to the received MRL value.

IBIPL[7:0] Bits (IBI Payload Size)

These bits are used when the I3C Controller sets the maximum IBI payload size in RI3C or gets the maximum IBI payload size from RI3C.

When the ICDCTR.IBIPL bit is 1, the value of these bits is transmitted as the third byte of the response to GETMRL CCC. When the IBIPL bit is 0, these bits are not transmitted.

When receiving SETMRL CCC (Broadcast) or SETMRL CCC (Direct) with its own Target address, these bits are automatically updated to the received IBI Payload Size value.

43.2.75 Test Mode Register (ICTMR)

Address(es): RI3C0.ICTMR 8745 F360h, RI3C0_NS.ICTMR 0745 F360h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TM[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TM[7:0]	Test Mode	00h: Exit test mode This value removes all I3C devices from test mode. 01h: Vendor test mode This value indicates that I3C devices shall return a random 32-bit value in the provisioned ID during the Dynamic Address Assignment procedure. Settings other than above are prohibited.	R
b31 to b8	—	Reserved	These bits are read as 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

TM[7:0] Bits (Test Mode)

These bits are used when the I3C Controller puts RI3C into test mode.

When receiving ENTTM CCC (Broadcast), these bits are automatically updated to the received Test Mode Byte value.

43.2.76 Device Status Register (ICDSR)

Address(es): RI3C0.ICDSR 8745 F364h, RI3C0_NS.ICDSR 0745 F364h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	VRSV[7:0]								CAS[1:0]		PERR	—	PNDINT[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	PNDINT[3:0]	Pending Interrupt Number	Contains the interrupt number of any pending interrupt, or 0000b if no interrupts are pending.	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R
b5	PERR	Protocol Error Flag	0: The Target has not detected a protocol error since the last status read. 1: The Target has detected a protocol error since the last status read.	R
b7, b6	CAS[1:0]	Current Activity State	b7 b6 0 0: Activity state 0 0 1: Activity state 1 1 0: Activity state 2 1 1: Activity state 3	R/W
b15 to b8	VRSV[7:0]	Vendor Reserved Area	Reserved for vendor-specific meaning	R/W
b31 to b16	—	Reserved	This bit is read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to store the status to be returned when current status is requested from I3C Controller.
The value of bits b15 to b0 in this register is automatically transmitted when a GETSTATUS CCC (Direct) is received.

PNDINT[3:0] Bits (Pending Interrupt Number)

These bits are used to indicate whether any interrupts are pending. If no interrupts are pending, set these bits to 0000b.
If multiple interrupts are pending, set the interrupt number of the highest priority interrupt.

PERR Flag (Protocol Error Flag)

This bit indicates whether the Target has detected a protocol error since the last status read.
This flag is automatically cleared each time the Controller successfully reads the Target status.
[Setting condition]

- When the Target detected a protocol error.

[Clearing condition]

- When a transmission of status (value set in this register) is successfully completed in response to GETSTATUS CCC (Direct) with its own Target address.

CAS[1:0] Bits (Current Activity State)

These bits are used to indicate the current Activity state of RI3C.

43.2.77 Max Write Speed Register (ICMWSR)

Address(es): RI3C0.ICMWSR 8745 F368h, RI3C0_NS.ICMWSR 0745 F368h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	MSWDR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	MSWDR[2:0]	Maximum Sustained Write Data Rate	b2 b0 0 0 0: Maximum value of f_{SCL} 0 0 1: 8 MHz 0 1 0: 6 MHz 0 1 1: 4 MHz 1 0 0: 2 MHz Settings other than above are prohibited.	R/W
b31 to b3	—	Reserved	This bit is read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to store the maximum write speed to be returned when the maximum data speed is requested from I3C Controller.

The value of bits b7 to b0 in this register is automatically transmitted as MaxWr when a GETMXDS CCC (Direct) is received.

43.2.78 Max Read Speed Register (ICMRSR)

Address(es): RI3C0.ICMRSR 8745 F36Ch, RI3C0_NS.ICMRSR 0745 F36Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	TSCO[2:0]			MSRDR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	MSRDR[2:0]	Maximum Sustained Read Data Rate	b2 b1 b0 0 0 0: Maximum value of f_{SCL} 0 0 1: 8 MHz 0 1 0: 6 MHz 0 1 1: 4 MHz 1 0 0: 2 MHz Settings other than above are prohibited.	R/W
b5 to b3	TSCO[2:0]	Clock-to-Data Turnaround Time	b5 b4 b3 0 0 0: 8 ns or less 0 0 1: 9 ns or less 0 1 0: 10 ns or less 0 1 1: 11 ns or less 1 0 0: 12 ns or less 1 1 1: t_{SCO} is more than 12 ns, and is reported by private agreement. Settings other than above are prohibited.	R/W
b31 to b6	—	Reserved	This bit is read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to store the maximum read speed to be returned when the maximum data speed is requested from I3C Controller.

The value of bits b7 to b0 in this register is automatically transmitted as MaxRd when a GETMXDS CCC (Direct) is received.

43.2.79 Maximum Read Turnaround Time Register (ICMTTR)

Address(es): RI3C0.ICMTTR 8745 F370h, RI3C0_NS.ICMTTR 0745 F370h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MRTTE	—	—	—	—	—	—	—	MRTT[23:16]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MRTT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	MRTT[23:0]	Maximum Read Turnaround Time	Set the read turnaround time in 1 µs units in the range of 0 to 16 seconds. 000000h: 0 µs (minimum value) 000001h: 1 µs : : F42400h: 16 seconds (maximum value) Settings other than above are prohibited.	R/W
b30 to b24	—	Reserved	This bit is read as 0. The write value should be 0.	R
b31	MRTTE	Maximum Read Turnaround Time Transmit Enable	0: Disables transmission of the maximum read turnaround time. (GETMXDS format 1: without turnaround) 1: Enables transmission of the maximum read turnaround time. (GETMXDS format 2: with turnaround)	R/W

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to store the three-byte maximum read turnaround time to be returned when the maximum data speed is requested from I3C Controller.

The value of bits b23 to b0 in this register is automatically transmitted as MaxRdTurn when a GETMXDS CCC (Direct) is received.

43.2.80 Timing Support Information Register (ICTSIR)

Address(es): RI3C0.ICTSIR 8745 F374h, RI3C0_NS.ICTSIR 0745 F374h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	INAC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FREQ[7:0]								—	—	—	—	—	SAM1	SAM0	SSM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SSM	Supports Sync Mode	0: Sync Mode is not supported. 1: Sync Mode is supported.	R/W
b1	SAM0	Supports Async Mode 0	0: Async Mode 0 is not supported. 1: Async Mode 0 is supported.	R/W
b2	SAM1	Supports Async Mode 1	0: Async Mode 1 is not supported. 1: Async Mode 1 is supported.	R/W
b7 to b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b15 to b8	FREQ[7:0]	Frequency Setting	These bits specify the Target's internal oscillation frequency in increments of 0.5 MHz. b15 b8 00000000: Approximately 32.0 kHz 00000001: 0.5 MHz 00000010: 1.0 MHz : : 11111101: 126.5 MHz 11111110: 127.0 MHz 11111111: 127.5 MHz	R/W
b23 to b16	INAC[7:0]	Frequency Inaccuracy Setting	These bits specify the inaccuracy of the oscillation frequency from 0.0% to 25.5% in increments of 0.1%. b23 b16 00000000: 0.0% 00000001: 0.1% : : 11111110: 25.4% 11111111: 25.5%	R/W
b31 to b24	—	Reserved	This bit is read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to store the value to be returned when the timing information is requested from I3C Controller. When a GETXTIME CCC (Direct) is received, the values of bits b7 to b0, b15 to b8, and b23 to b16 in this register are automatically transmitted as Supported Mode Byte, Frequency Byte, and Inaccuracy Byte, respectively.

43.2.81 Timing Support Information Register 2 (ICTSIR2)

Address(es): RI3C0.ICTSIR2 8745 F378h, RI3C0_NS.ICTSIR2 0745 F378h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	OVF	—	—	—	—	AM1E	AM0E	SME
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SME	Sync Mode Enabled	0: Sync Mode is disabled. 1: Sync Mode is enabled.	R/W
b1	AM0E	Async Mode 0 Enabled	0: Async Mode 0 is disabled. 1: Async Mode 0 is enabled.	R/W
b2	AM1E	Async Mode 1 Enabled	0: Async Mode 1 is disabled. 1: Async Mode 1 is enabled.	R/W
b6 to b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b7	OVF	Overflow Flag	0: No counter overflow has occurred since the last check. 1: Counter overflow has occurred since the last check.	R/W
b31 to b8	—	Reserved	This bit is read as 0. The write value should be 0.	R

Note: This register is used in I3C Secondary Controller and I3C Target modes.

This register is used to store the value to be returned when the timing information is requested from I3C Controller. When a GETXTIME CCC (Direct) is received, the value of bits b7 to b0 in this register is automatically transmitted as State Byte.

When receiving SETXTIME CCC (Broadcast) or SETXTIME CCC (Direct) with its own Target address, the AM0E and AM1E bits are automatically updated according to the received Sub-Command Byte value (DFh: Enter Async Mode 0, EFh: Enter Async Mode 1).

43.2.82 Bit Count Register (ICBCR)

Address(es): RI3C0.ICBCR 8745 F380h, RI3C0_NS.ICBCR 0745 F380h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	BC[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	BC[4:0]	Bit Counter	These bits indicate the number of bits remaining to be transferred. Refer to Table 43.6 and Table 43.7 for details.	R
b31 to b5	—	Reserved	These bits are read as 0.	R

BC[4:0] Bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a rising edge on the SCL00 line.

Table 43.6 Counter Value and Number of Remaining Bits (I^2C/Legacy I^2C Transfer)

	Master/Controller		Slave/Target	
BC[4:0]	Address Phase	Data Phase	Address Phase	Data Phase
00h	2 or 1 bits	2 or 1 bits	3 to 1 bits	2 or 1 bits
01h	3 bits	3 bits	4 bits	3 bits
02h	4 bits	4 bits	5 bits	4 bits
03h	5 bits	5 bits	6 bits	5 bits
04h	6 bits	6 bits	7 bits	6 bits
05h	7 bits	7 bits	8 bits	7 bits
06h	8 bits	8 bits	9 bits	8 bits
07h	9 bits	9 bits	—	9 bits

Table 43.7 Counter Value and Number of Remaining Bits (I3C Transfer)

	SDR*1	
BC[4:0]	Transmission	Reception
00h	1 bit	2 or 1 bits
01h	2 bits	3 bits
02h	3 bits	4 bits
03h	4 bits	5 bits
04h	5 bits	6 bits
05h	6 bits	7 bits
06h	7 bits	8 bits
07h	8 bits	9 bits
08h	9 bits	—

Note 1. The address phase is the same as in Table 43.6.

43.2.83 Queue Buffer Status Register (ICQBSR)

Address(es): RI3C0.ICQBSR 8745 F394h, RI3C0_NS.ICQBSR 0745 F394h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	HRQFL[7:0]								HCQFL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	HCQFL[7:0]	High-Priority Command Queue Free Level	Number of free entries currently in the high-priority command queue.	R
b15 to b8	HRQFL[7:0]	High-Priority Response Queue Fill Level	Number of entries currently in the high-priority response queue.	R
b31 to b16	—	Reserved	These bits are read as 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

43.2.87 High-Priority Data Buffer Status Register (ICHDBSR)

Address(es): RI3C0.ICHDBSR 8745 F3C8h, RI3C0_NS.ICHDBSR 0745 F3C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HRBFL[7:0]								HTBFL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	HTBFL[7:0]	High-Priority Transmit Data Buffer Free Level	Indicates the free level of the high-priority transmit data buffer.	R
b15 to b8	HRBFL[7:0]	High-Priority Receive Data Buffer Fill Level	Indicates the fill level of the high-priority receive data buffer.	R
b31 to b16	—	Reserved	These bits are read as 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

43.2.88 Internal Status Monitor Register (ICIMR)

Address(es): RI3C0.ICIMR 8745 F3CCh, RI3C0_NS.ICIMR 0745 F3CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	SDAO	SCLO	SDAI	SCLI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SCLI	SCL Line Monitor Flag	0: SCL00 line is low. 1: SCL00 line is high.	R
b1	SDAI	SDA Line Monitor Flag	0: SDA00 line is low. 1: SDA00 line is high.	R
b2	SCLO	SCL Output Monitor Flag	0: The RI3C drives the SCL00 pin low. 1: The RI3C releases the SCL00 pin.	R
b3	SDAO	SDA Output Monitor Flag	0: The RI3C drives the SDA00 pin low. 1: The RI3C releases the SDA00 pin.	R
b31 to b4	—	Reserved	These bits are read as 0.	R

SCLO Flag (SCL Output Monitor Flag) and SDAO Flag (SDA Output Monitor Flag)

When reading these bits, the state of signals output from the RI3C can be read.

43.2.89 Controller Error Count Register (ICCECR)

Address(es): RI3C0.ICCECR 8745 F3D0h, RI3C0_NS.ICCECR 0745 F3D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	CE2C[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CE2C[7:0]	CE2 Error Counter	These bits counts I3C Type CE2 errors on the I3C bus. These bits are cleared when read.	R
b31 to b8	—	Reserved	These bits are read as 0.	R

Note: This register is used in I3C Primarily Controller and I3C Secondary Controller modes.

43.2.90 T_C1 Capture Register (ICTC1CR)

Address(es): RI3C0.ICTC1CR 8745 F3E0h, RI3C0_NS.ICTC1CR 0745 F3E0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Secondary Controller and I3C Target modes.

The ICTC1CR register is a 32-bit read-only register used to read the captured T_C1 counter value. This register is used in Async Mode 0 and Async Mode 1.
The upper 16 bits are reserved and the read value is 0.

43.2.91 T_C2 Capture Register (ICTC2CR)

Address(es): RI3C0.ICTC2CR 8745 F3E4h, RI3C0_NS.ICTC2CR 0745 F3E4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register is used in I3C Secondary Controller and I3C Target modes.

The ICTC2CR register is a 32-bit read-only register used to read the captured T_C2 counter value. This register is used in Async Mode 0 and Async Mode 1.
The upper 16 bits are reserved and the read value is 0.

43.2.92 Communication Clock Control Register (ICCCR)

Address(es): RI3C0.ICCCR 8745 F010h, RI3C0_NS.ICCCR 0745 F010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CCE	Communication Clock Enable	0: Clock disable 1: Clock enable	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

CCE Bit (Communication Clock Enable)

This bit enables or disables the clock supply to the transmit/receive circuits.
Set this bit to 1 before setting the ICCR.ICE bit to 1 (the I3C bus operation is enabled), and set this bit to 0 after setting the ICE bit to 0 (the I3C bus operation is disabled).

43.3 Data Structures

43.3.1 Command Descriptor

The Command Descriptor is 64 bits in length. The Command Descriptor is added to the command queue via writes to the command queue register (ICCQR).

Write to the ICCQR register in the following order:

1. First write: The lower 32 bits of Command Descriptor
2. Second write: The upper 32 bits of Command Descriptor.

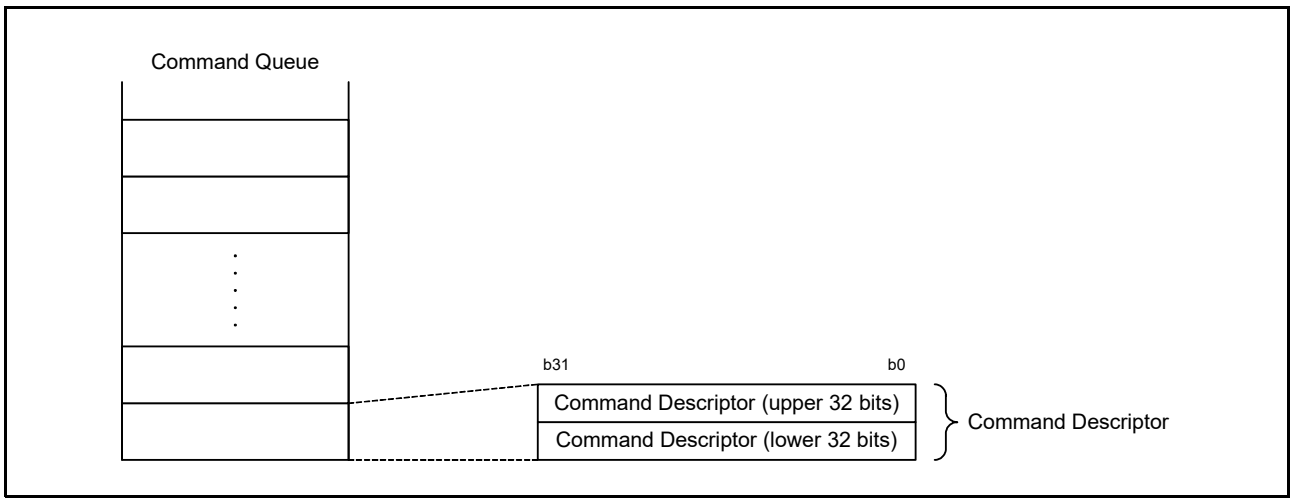

Figure 43.3 Command Descriptor Data Structure

RI3C provides a Command Descriptor structure for each command type as follows:

- Address Assignment Command
- Immediate Data Transfer Command
- Regular Data Transfer Command
- Combo Transfer Command
- Internal Control Command

43.3.1.1 Address Assignment Command

This command is used for Address Assignment (ENTDAA, SETDASA)*1.
Details of the address assignment command structure are as follows.

Note 1. When issuing SETAASA CCC, use the immediate data transfer command.

	b63	b62	b61	b60	b59	b58	b57	b56	b55	b54	b53	b52	b51	b50	b49	b48
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b47	b46	b45	b44	b43	b42	b41	b40	b39	b38	b37	b36	b35	b34	b33	b32
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TOC	ROC	DEV_COUNT				—	—	—	—	EXT_DEVICE	DEV_INDEX				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	CMD								TID				CMD_ATTR		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attributes	Set this field to 010b (address assignment command).	W
b6 to b3	TID	Transaction ID	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b14 to b7	CMD	Transfer Command CCC Value	Specify the command code of the command to be used. ENTDAA (Broadcast): 07h SETDASA (Direct): 87h	W
b15	—	Reserved	Set this field to 0.	W
b20 to b16	DEV_INDEX	Device Index	Specify the DAT table index (m of the ICTDATRm register) for the Target device being assigned an address via Dynamic Address Assignment.	W
b21	EXT_DEVICE	Extended Device Index	0: Use the ICTDATRm register indicated by the DEV_INDEX field. 1: Use the ICEDATR register.	W
b25 to b22	—	Reserved	The write value should be 0.	W
b29 to b26	DEV_COUNT	Device Count	Specify the number of devices that a Dynamic Address shall be assigned to.	W
b30	ROC	Response on Completion	0: NOT_REQUIRED: Response status is not required. 1: REQUIRED: Response status is required.	W
b31	TOC	Terminate on Completion	0: RESTART: Issue repeated START condition (Sr) at end of transfer 1: STOP: Issue STOP condition (P) at end of transfer	W
b63 to b32	—	Reserved	The write value should be 0.	W

TID Field (Transaction ID)

The value specified in this field is reflected in the TID field of the Response Descriptor.

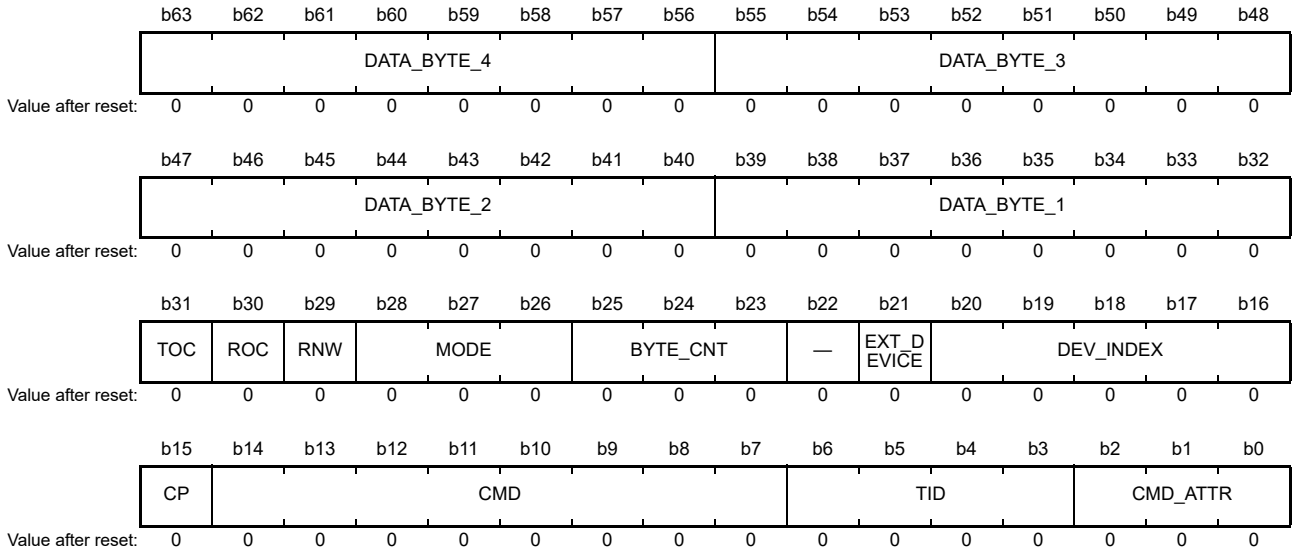
DEV_INDEX Field (Device Index)

Indicates the DAT table index for the Target device being assigned an address via Dynamic Address Assignment.
Write a Dynamic Address into each DAT entry (the ICTDATRm registers) that will be used with this command type, as well as a Static Address (when used with the SETDASA CCC).

DEV_COUNT Field (Device Count)

Indicates the number of devices that a Dynamic Address is assigned to. The DAT entries are processed starting at index DEV_INDEX for up to DEV_COUNT times.

ROC Field (Response on Completion)



Controls whether Response status is sent after successful completion of the transfer command. The successful completion shall be read from the ICRQR register. Upon unsuccessful transfer the Response status shall always be sent.

TOC Field (Terminate on Completion)

Controls what bus condition to issue after the transfer command completes.
For ENTDAA, a STOP condition is issued regardless of the value set in this field.
When sending SETDASA CCC with the TOC field set to 0 (RESTART), the next command must also be set to an address assignment command specifying SETDASA CCC. When the next command is not SETDASA CCC, the TOC field must be set to 1 (STOP).

43.3.1.2 Immediate Data Transfer Command

This Command Descriptor directly contains data bytes (up to 4 bytes) to be transferred, and as a result is only useful for shorter write-type transfers or CCCs that write data. This command shall not be used for read-type transfers.
Details of the immediate data transfer command structure are as follows.

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attribute	Set this field to 001b (immediate data transfer command).	W
b6 to b3	TID	Transaction ID	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b14 to b7	CMD	Transfer Command CCC Value	Specify the command code of the command to be used.	W
b15	CP	Command Present	0: TRANSFER: This structure describes an SDR transfer, so the CMD field is not valid. 1: CCC: This structure describes a CCC transfer, so the CMD field is valid.	W
b20 to b16	DEV_INDEX	Device Index	Specify the DAT table index (m of the ICTDATRm register) for the Target device being addressed with the transfer.	W
b21	EXT_DEVICE	Extended Device Index	0: Use the ICTDATRm table indicated by DEV_INDEX. 1: Use the ICEDATR table.	W
b22	—	Reserved	The write value should be 0.	W
b25 to b23	BYTE_CNT	Byte Count	Number of valid data bytes to use in this descriptor. Specify in the range of 0h (no payload) to 4h (4 bytes).	W
b28 to b26	MODE	Mode and Speed	• I3C transfer b28 b26 0 0 0: I3C SDR0, ICSBR register setting (up to 12.5 MHz) 0 0 1: I3C SDR1, ICEBR register setting (up to 8 MHz) 0 1 0: I3C SDR2, ICSBR register setting × 2 (up to 6 MHz) 0 1 1: I3C SDR3, ICEBR register setting × 2 (up to 4 MHz) 1 0 0: I3C SDR4, ICEBR register setting × 4 (up to 2 MHz) Settings other than above are prohibited. • I^2C transfer b28 b26 0 0 0: I^2C FM, ICSBR register setting (up to 400 kHz) 0 0 1: I^2C FM+, ICEBR register setting (up to 1 MHz) Settings other than above are prohibited.	W
b29	RNW	Transfer Direction (RnW)	Set this field to 0 (write transfer)	W
b30	ROC	Response on Completion	0: NOT_REQUIRED: Response status is not required. 1: REQUIRED: Response status is required.	W

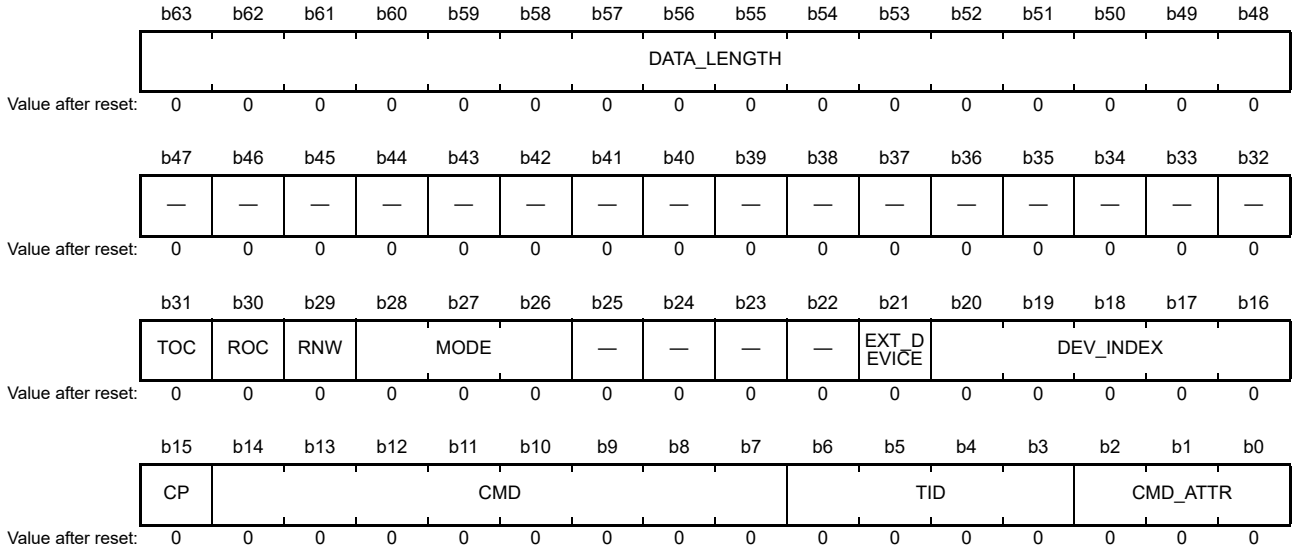
Bit	Symbol	Bit Name	Description	R/W
b31	TOC	Terminate on Completion	0: RESTART: Issue repeated START condition (Sr) at end of transfer 1: STOP: Issue STOP condition (P) at end of transfer	W
b39 to b32	DATA_BYTE_1	Data Byte 1	First byte of data to be transmitted	W
b47 to b40	DATA_BYTE_2	Data Byte 2	Second byte of data to be transmitted	W
b55 to b48	DATA_BYTE_3	Data Byte 3	Third byte of data to be transmitted	W
b63 to b56	DATA_BYTE_4	Data Byte 4	Fourth byte of data to be transmitted	W

DEV_INDEX Field (Device Index)

Indicates the DAT table (the ICTDATRm register) index for the Target device being addressed with the transfer. The ICTDATRm register indicated by this field must contain a valid Dynamic Address. This field is ignored for Broadcast CCCs.

BYTE_CNT Field (Byte Count)

Number of valid data bytes to use in this descriptor. This field should be set to non-zero value, except for CCCs that do not have any payload defined.



MODE Field (Mode and Speed)

Sets the mode and speed for the I3C or I^2C transfer.
Interpretation of this field depends on the TYPE bit in the ICTDATRm register indexed by the DEV_INDEX field.

43.3.1.3 Regular Data Transfer Command

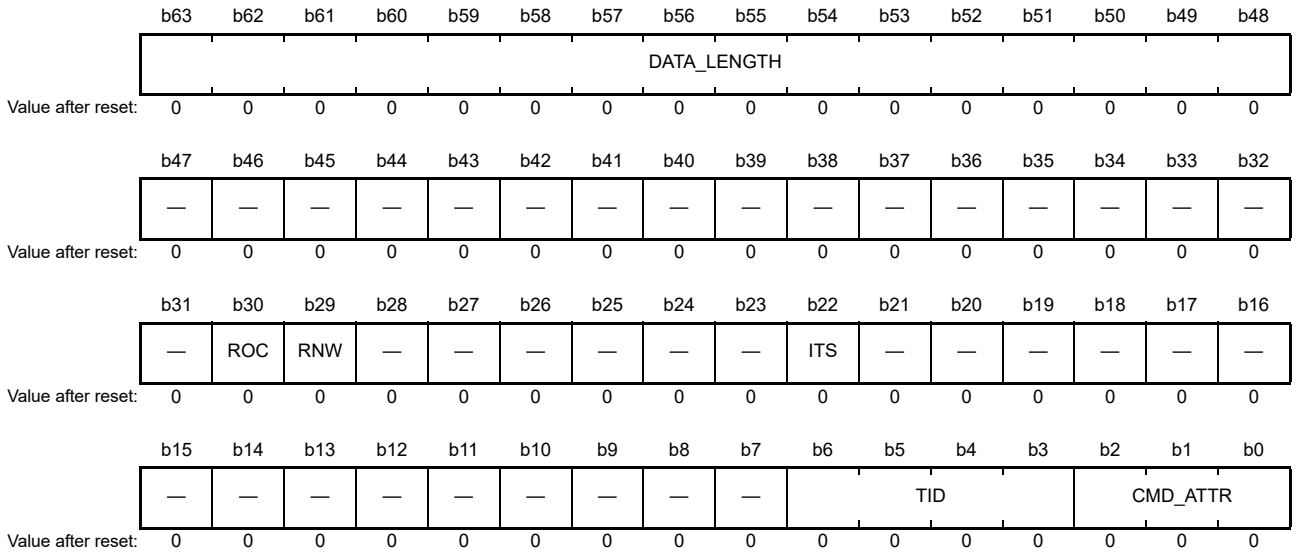
This Command Descriptor does not contain data to be transferred. For I3C Controller mode, data is transferred via the transmit/receive data register (ICDR), and for I3C Target mode, data is transferred via the IBI queue register (ICIQR). Details of the regular data transfer command structure of each mode are as follows.

(1) I3C Controller Mode

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attribute	Set this field to 000b (regular data transfer command).	W
b6 to b3	TID	Transaction ID	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b14 to b7	CMD	Transfer Command CCC Value	Specify the command code of the command to be used.	W
b15	CP	Command Present	0: TRANSFER: This structure describes an SDR transfer, so the CMD field is not valid. 1: CCC: This structure describes a CCC transfer, so the CMD field is valid.	W
b20 to b16	DEV_INDEX	Device Index	Specify the DAT table index (m of the ICTDATRm register) for the Target device being addressed with the transfer.	W
b21	EXT_DEVICE	Extended Device Index	0: Use the ICTDATRm table indicated by DEV_INDEX. 1: Use the ICEDATR table.	W
b25 to b22	—	Reserved	The write value should be 0.	W
b28 to b26	MODE	Mode and Speed	• I3C transfer b28 b26 0 0 0: I3C SDR0, ICSBR register setting (up to 12.5 MHz) 0 0 1: I3C SDR1, ICEBR register setting (up to 8 MHz) 0 1 0: I3C SDR2, ICSBR register setting × 2 (up to 6 MHz) 0 1 1: I3C SDR3, ICEBR register setting × 2 (up to 4 MHz) 1 0 0: I3C SDR4, ICEBR register setting × 4 (up to 2 MHz) Settings other than above are prohibited. • I^2C transfer b28 b26 0 0 0: I^2C FM, ICSBR register setting (up to 400 kHz) 0 0 1: I^2C FM+, ICEBR register setting (up to 1 MHz) Settings other than above are prohibited.	W
b29	RNW	Transfer Direction (RnW)	0: WRITE: Write transfer 1: READ: Read transfer	W

Bit	Symbol	Bit Name	Description	R/W
b30	ROC	Response on Completion	0: NOT_REQUIRED: Response status is not required. 1: REQUIRED: Response status is required.	W
b31	TOC	Terminate on Completion	0: RESTART: Issue repeated START condition (Sr) at end of transfer 1: STOP: Issue STOP condition (P) at end of transfer	W
b47 to b32	—	Reserved	The write value should be 0.	W
b63 to b48	DATA_LENGTH	Data Length	Indicates the number of bytes to be transferred.	W

RNW Field (Transfer Direction (RnW))



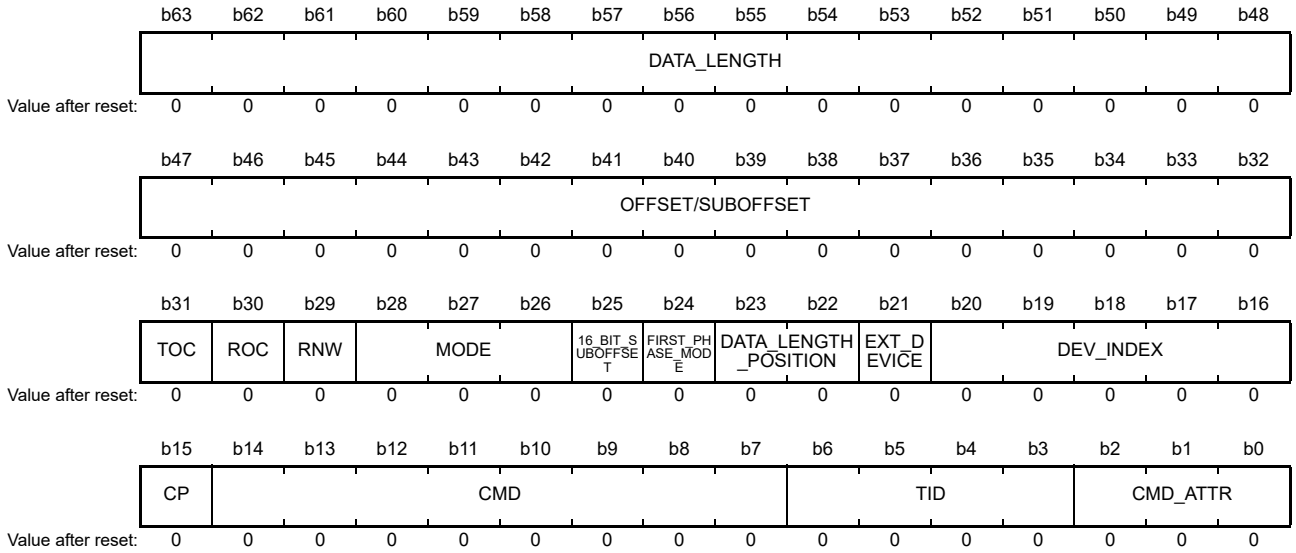
Identifies the direction of this transfer.

DATA_LENGTH Field (Data Length)

Number of bytes to be transferred.

This field should be set to a non-zero value, except for CCCs that do not have payload defined. Length setting of GETMXDS command should be fixed to “0005h”.

(2) I3C Target Mode



Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attribute	Set this field to 000b (regular data transfer command).	W
b6 to b3	TID	Transaction ID	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b21 to b7	—	Reserved	The write value should be 0.	W
b22	ITS	Include Timestamp	0: Do not include timestamp. 1: Include timestamp.	W
b28 to b23	—	Reserved	The write value should be 0.	W
b29	RNW	Transfer Direction (RnW)	0: WRITE: Write transfer (Controller Role Request) 1: READ: Read transfer (Target Interrupt Request)	W
b30	ROC	Response on Completion	0: NOT_REQUIRED: Response status is not required. 1: REQUIRED: Response status is required.	W
b47 to b31	—	Reserved	The write value should be 0.	W
b63 to b48	DATA_LENGTH	Data Length	Indicates the number of bytes to be transferred.	W

RNW Field (Transfer Direction (RnW))

Identifies the direction of this transfer.

43.3.1.4 Combo Transfer Command

This Command Descriptor describes a combined Write + Read or Write + Write operation.
Data is transferred via the transmit/receive data register (ICDR).
Details of the combo transfer command structure are as follows.

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attribute	Set this field to 011b (combo transfer command).	W
b6 to b3	TID	Transaction ID	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b14 to b7	CMD	Transfer Command CCC Value	This field is reserved for this command. Set it to 00h.	W
b15	CP	Command Present	Set this field to 0 for this command.	W
b20 to b16	DEV_INDEX	Device Index	Specify the DAT table index (m of the ICTDATRm register) for the Target device being addressed with the transfer.	W
b21	EXT_DEVICE	Extended Device Index	0: Use the ICTDATRm table indicated by DEV_INDEX. 1: Use the ICEDATR table.	W
b23, b22	DATA_LENGTH_POSITION	Data Length Field Position	Set this field to 00b.	W
b24	FIRST_PHASE_MODE	First Phase Mode	0: SDR: First phase is executed in SDR mode. 1: MODE: First phase is executed in the mode indicated by the MODE field.	W
b25	16_BIT_SUBOFFSET	Sub Offset Size	0: 8_BIT_SUBOFFSET: Sub-offset is 8 bits long. Value is encoded in lower byte of OFFSET/SUBOFFSET field. 1: 16_BIT_SUBOFFSET: Sub-offset is 16 bits long.	W
b28 to b26	MODE	Mode and Speed	• I3C transfer b28 b26 0 0 0: I3C SDR0, ICSBR register setting (up to 12.5 MHz) 0 0 1: I3C SDR1, ICEBR register setting (up to 8 MHz) 0 1 0: I3C SDR2, ICSBR register setting × 2 (up to 6 MHz) 0 1 1: I3C SDR3, ICEBR register setting × 2 (up to 4 MHz) 1 0 0: I3C SDR4, ICEBR register setting × 4 (up to 2 MHz) Settings other than above are prohibited. • I²C transfer b28 b26 0 0 0: I²C FM, ICSBR register setting (up to 400 kHz) 0 0 1: I²C FM+, ICEBR register setting (up to 1 MHz) Settings other than above are prohibited.	W

Bit	Symbol	Bit Name	Description	R/W
b29	RNW	Transfer Direction (RnW)	0: WRITE: Write transfer 1: READ: Read transfer	W
b30	ROC	Response on Completion	0: NOT_REQUIRED: Response status is not required. 1: REQUIRED: Response status is required.	W
b31	TOC	Terminate on Completion	0: RESTART: Issue repeated START condition (Sr) at end of transfer 1: STOP: Issue STOP condition (P) at end of transfer	W
b47 to b32	OFFSET/ SUBOFFSET	Offset/Sub-Offset	Set the value of the Offset field to be transferred in the first phase.	W
b63 to b48	DATA_LENGTH	Data Length	Specify the number of bytes to be transferred in the second phase. This field must be set to non-zero value.	W

DATA_LENGTH_POSITION Field (Data Length Field Position)

Indicates whether and where to put Data Length (DATA_LENGTH) in the first phase of the transfer.

FIRST_PHASE_MODE Field (First Phase Mode)

Indicates whether the first phase of the combo transfer is executed in SDR mode, vs. the mode indicated by the MODE field.

16_BIT_SUBOFFSET Field (Sub Offset Size)

Indicates whether the length of the Offset and Length fields in the first phase of the transfer is 8 bits or 16 bits. For 8-bit, data should be written in lower bytes of the OFFSET/SUBOFFSET and DATA_LENGTH fields.

RNW Field (Transfer Direction (RnW))

Identifies the direction of the second phase of the transfer.

43.3.1.5 Internal Control Command

This Command Descriptor is used for controlling RI3C itself (not for I3C transfer commands).
Details of the internal control command structure are as follows.

	b63	b62	b61	b60	b59	b58	b57	b56	b55	b54	b53	b52	b51	b50	b49	b48
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b47	b46	b45	b44	b43	b42	b41	b40	b39	b38	b37	b36	b35	b34	b33	b32
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

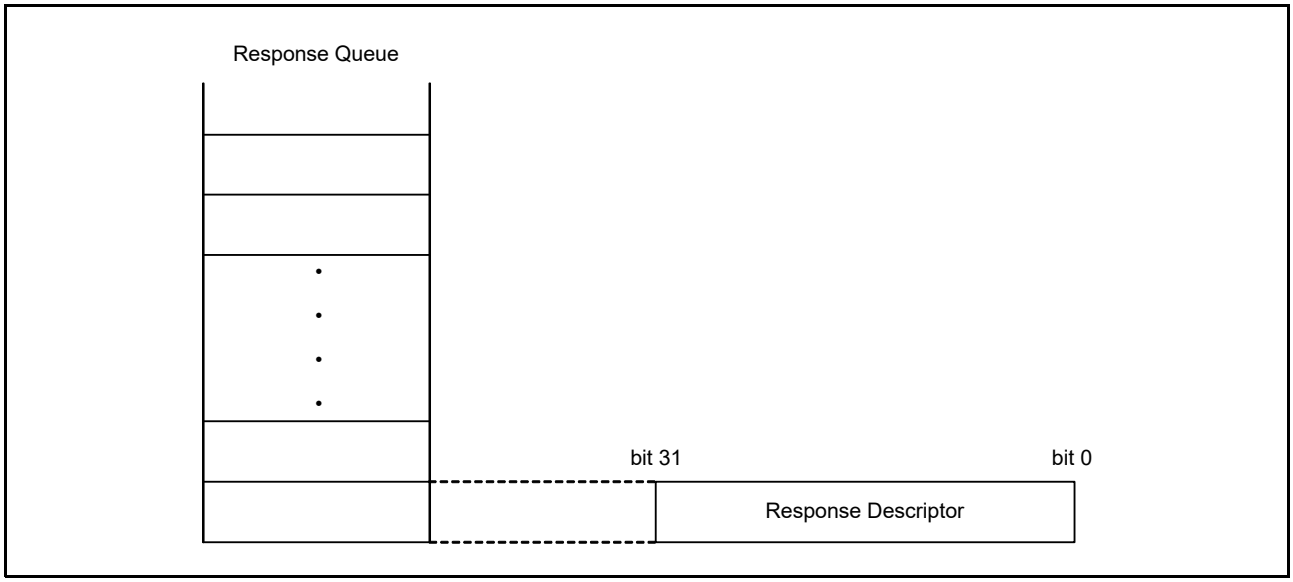
	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	ON_OFF	MIPI_CMD				—	TID				CMD_ATTR		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CMD_ATTR	Command Attribute	Set this field to 111b (internal control command).	W
b6 to b3	TID	Transaction ID*1	Used as a tag for this command. Specify in the range of 0h to 7h.	W
b7	—	Reserved	The write value should be 0.	W
b11 to b8	MIPI_CMD	MIPI Alliance Command	b11 b8 0 0 0 0: NoOp (performs no transfer) 0 0 1 0: Broadcast Address automatic transmission Settings other than above are prohibited.	W
b12	ON_OFF	On/Off	0: disables automatic transmission of Broadcast Address 1: enables automatic transmission of Broadcast Address*2	W
b63 to b13	—	Reserved	The write value should be 0.	W

Note 1. The Response Descriptor is not stored when the internal control command is executed.
Note 2. Automatic transmission of Broadcast Address enabled by this command is disabled when the ICRCR.ISRST is set to 1.

43.3.2 Response Descriptor

The Response Descriptor is a 32-bit read-only structure describing the success or failure of a command, and the amount of data transferred.
The Response Descriptor is read from the response queue via the response queue register (ICRQR).



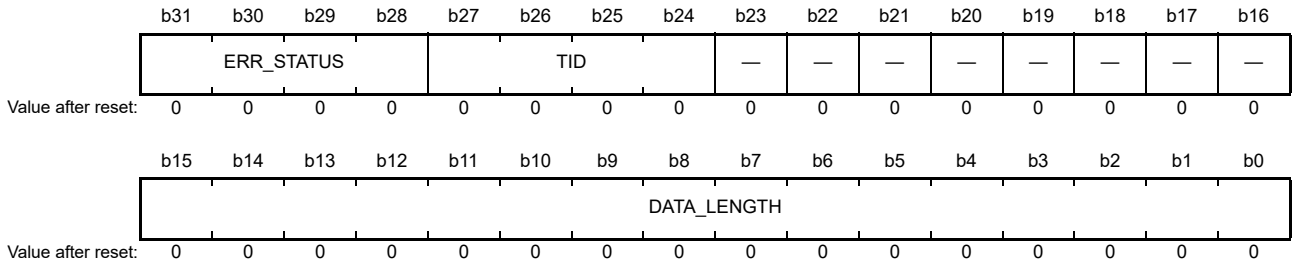


Figure 43.4 Response Descriptor Data Structure

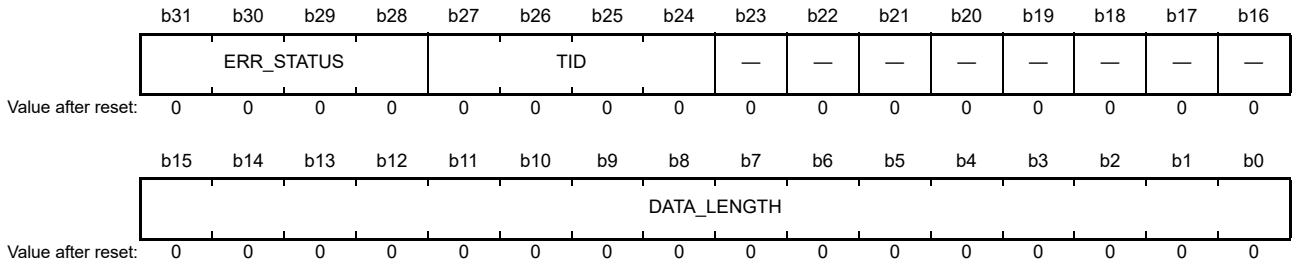
The Response Descriptor structure differs between I3C Controller mode and I3C Target mode.
Details of the Response Descriptor structure of each mode are as follows.

(1) I3C Controller Mode

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DATA_LENGTH	Data Length/Device Count	For write transfer: Remaining data length (in bytes) For read transfer: Received data length (in bytes) For address assignment: Remaining device count	R
b23 to b16	—	Reserved	These bits are read as 0.	R
b27 to b24	TID	Transaction ID	This value shall match the value of the TID field, for a previously enqueued Command Descriptor that was sent on the bus.	R
b31 to b28	ERR_STATUS	Error Status	b31 b28 0 0 0 0: SUCCESS: Transfer successful, no error 0 1 0 0: ADDR_HEADER: Address header error 0 1 0 1: NACK: Address NACKed or Dynamic Address Assignment NACKed 0 1 1 0: OVL: Receive overflow or transmit underflow error 1 0 0 0: ABORTED: Transfer aborted 1 0 0 1: I2C_WR_DATA_NACK: NACK is received during an I^2C write data transfer 1 0 1 0: NOT_SUPPORTED: Command is not supported	R

TID Field (Transaction ID)



This field reflects the value specified in the TID field of the Command Descriptor. Software can determine which command the response is for by checking this field.

ERR_STATUS Field (Error Status)

This field indicates the transfer status of the command indicated by the TID field.
The details of each error are as follows.

- ADDR_HEADER: No Target devices acknowledge the Broadcast Address.
- NACK: Any Target device that responds to the ENTDAA procedure does not accept the Dynamic Address or an addressed Target device does not acknowledge its Dynamic Address.
- OVL: Transmit data buffer underflowed or receive data buffer overflowed.
- ABORTED: A transaction was aborted.
- I2C_WR_DATA_NACK: The I^2C Target device does not acknowledge the I^2C write data transfer.
- NOT_SUPPORTED: A Command Descriptor structure with an illegal or invalid combination of field values was stored.

(2) I3C Target Mode

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DATA_LENGTH	Data Length	For Target Interrupt Request: Remaining data length (in bytes)	R
b23 to b16	—	Reserved	These bits are read as 0.	R
b27 to b24	TID	Transaction ID	This value shall match the value of the TID field, for a previously enqueued Command Descriptor that was sent on the bus.	R
b31 to b28	ERR_STATUS	Error Status	b31 b28 0 0 0 0: SUCCESS: Transfer successful, no error 0 1 0 0: ADDR_HEADER: Address header error 0 1 0 1: NACK: Address NACKed or Dynamic Address Assignment NACKed 0 1 1 0: OVL: Receive overflow or transmit underflow error 1 0 0 0: ABORTED: Transfer aborted 1 0 1 0: NOT_SUPPORTED: Command is not supported	R

ERR_STATUS Field (Error Status)

This field indicates the transfer status of the command indicated by the TID field.
The details of each error are as follows.

- ADDR_HEADER: No Target devices acknowledge the Broadcast Address.
- NACK: Any Target device that responds to the ENTDAA procedure does not accept the Dynamic Address or an addressed Target device does not acknowledge its Dynamic Address.
- OVL: Transmit data buffer underflowed or receive data buffer overflowed.
- ABORTED: A transaction was aborted.
- NOT_SUPPORTED: A Command Descriptor structure with an illegal or invalid combination of field values was stored, an IBI disabled by the ICTEVR register is requested, or an IBI is disabled by DISEC CCC after a Command Descriptor structure for the IBI was enqueued in the command queue.

43.3.3 IBI Status Descriptor

The IBI Status Descriptor is a 32-bit read-only structure describing an IBI event received from a Target device on the I3C bus. This Descriptor is used in I3C Controller mode.
The IBI Status Descriptor is read from the IBI queue via the IBI queue register (ICIQR).

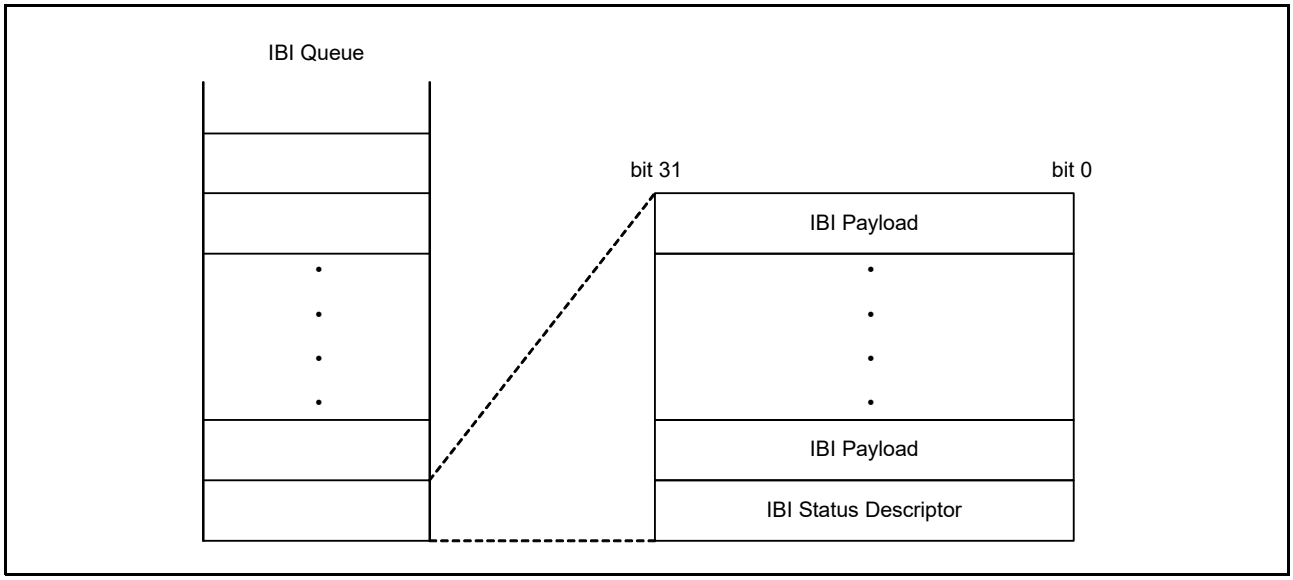


Figure 43.5 IBI Status Descriptor Data Structure

Details of the IBI Status Descriptor Structure are as follows.

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IBI_STS	—	—	ERR_STATUS			TS	LAST_STATUS	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	IBI_ID								DATA_LENGTH							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	DATA_LENGTH	IBI Data Length	Number of data bytes in IBI data.	R
b15 to b8	IBI_ID	IBI Received ID	• Target Interrupt Request or Controller Role Request: b15 to b9: Target's Device Address b8: Value of RnW bit	R
b23 to b16	—	Reserved	These bits are read as 0.	R
b24	LAST_STATUS	Last IBI Status	0: This is not the last IBI Status Descriptor. 1: This is the last IBI Status Descriptor.	R
b25	TS	IBI Timestamp Present	Indicates whether a timestamp is available for the IBI. 0: OFF: IBI is not timestamped. 1: ON: IBI is timestamped.	R
b28 to b26	ERR_STATUS	IBI Error Status	b28 b26 0 0 0: SUCCESS 0 1 1: FRAME: Frame error 1 0 0: ADDR_HEADER: Address header error 1 0 1: NACK: Address NACKed 1 1 1: ABORT: Aborted to Controller	R

Bit	Symbol	Bit Name	Description	R/W
b30, b29	—	Reserved	These bits are read as 0.	R
b31	IBI_STS	IBI Received Status	0: The IBI was handled with ACK. 1: The IBI was handled with NACK, and then Auto-Disabled.	R

LAST_STATUS Field (Last IBI Status)

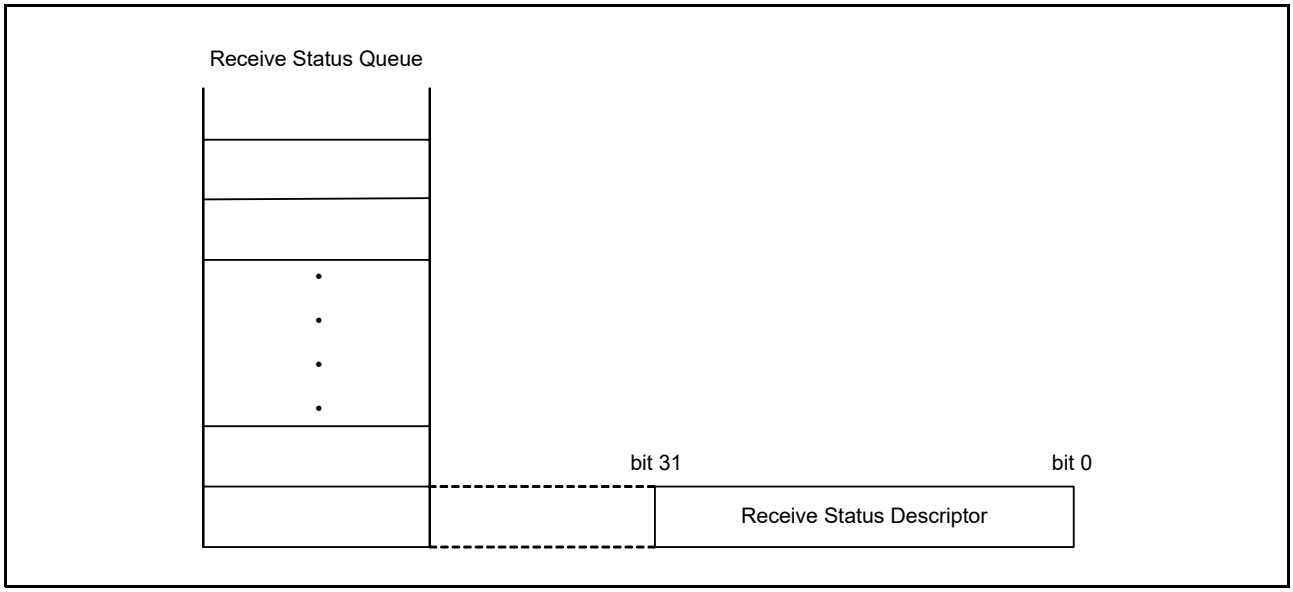
For some IBIs, multiple IBI Status Descriptors might be needed to describe a single IBI event. A 0 in this field indicates that there is a subsequent IBI Status Descriptor.
Even if this field is set to 0, examine the DATA_LENGTH field to evaluate the data payload length.

IBI_STS Field (IBI Received Status)

Indicates how the received IBI was handled by Active Controller.

43.3.4 Receive Status Descriptor

The Receive Status Descriptor is a 32-bit read-only structure describing the success or failure of read/write transfer issued by the Controller, and the amount of data transferred. This Descriptor is used in I3C Target mode.
The Receive Status Descriptor is read from the receive status queue via the receive status queue register (ICSQR).



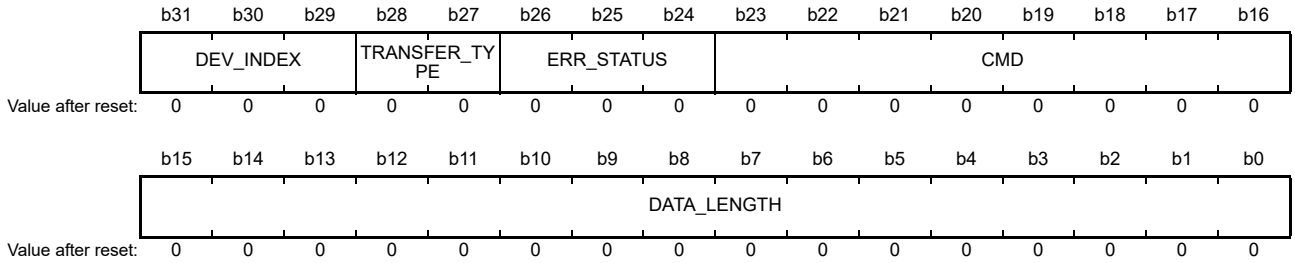


Figure 43.6 Receive Status Descriptor Data Structure

Details of the Receive Status Descriptor structure are as follows.

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DATA_LENGTH	Data Length	For Write Transfer: Received data length (in bytes) For Read Transfer: Transmitted data length (in bytes)	R
b23 to b16	CMD	Command Code	• I3C SDR private transfer or Legacy I^2C transfer: b23: Transfer type (0: Write/1: Read) b22 to b20: Reserved b19: Transfer mode (0: I3C SDR/1: Legacy I^2C) b18 to b16: Reserved • SDR CCC transfer: Indicates the CCC command code specified in the Command Descriptor of the transfer.	R
b26 to b24	ERR_STATUS	Error Status	b26 b24 0 0 0: SUCCESS: Transfer successful, no error 1 0 0: ADDR_HEADER: Address header error 1 0 1: NACK: Target NACKed 1 1 0: OVL: FIFO overflow/underflow 1 1 1: ABORTED: Aborted to Controller	R

Bit	Symbol	Bit Name	Description	R/W
b28, b27	TRANSFER_TYPE	Transfer Type	b28 b27 0 0: I3C SDR private transfer or Legacy I^2C transfer 0 1: I3C CCC	R
b31 to b29	DEV_INDEX	Device Index	Indicates the DAT table index (m of the ICTDATRm register) for the responded device with the transfer.	R

43.4 Operation

43.4.1 Transfer Methods

The relationship between the transfer method and the queue buffer/data buffer is shown in Table 43.8.

Table 43.8 Transfer Method and Size of Queue/Buffer

Protocol Mode	Transfer Method	Queue/Buffer	Size	Controller	Target	Secondary Controller
I3C	FIFO buffer transfer	Command Queue	64 bits × 4 stages	✓	✓	✓
		Response Queue	32 bits × 4 stages	✓	✓	✓
		Transmit Data Buffer	32 bits × 16 stages	✓	✓	✓
		Receive Data Buffer	32 bits × 16 stages	✓	✓	✓
		Receive Status Queue	32 bits × 2 stages	—	✓	✓
		IBI Status Queue	32 bits × 2 stages	✓	—	✓
		IBI Data Buffer	32 bits × 8 stages	✓	✓	✓
	High-priority FIFO buffer transfer	High-priority Command Queue	32 bits × 2 stages	✓	—	✓
		High-priority Response Queue	32 bits × 2 stages	✓	—	✓
		High-priority Transmit Data Buffer	32 bits × 2 stages	✓	—	✓
		High-priority Receive Data Buffer	32 bits × 2 stages	✓	—	✓
I^2C	Single buffer transfer	Transmit Data Buffer	1 byte	✓	✓	—
		Receive Data Buffer	1 byte	✓	✓	—

(1) FIFO Buffer Transfer

RI3C autonomously starts transfer when data and command are written.

Figure 43.7 shows transactions using FIFO buffer transfer. In the I3C bus protocol, transactions are initiated by the Controller. The Target transmits and receives data according to the command sent by the Controller.

- Controller transmission
  When data and a command descriptor is written to the ICDR and ICCQR registers, respectively, a write transaction is issued on the I3C bus.
- Controller reception
  Writing a command descriptor to the ICCQR register issues a read transaction on the I3C bus. The data sent by the Target is stored in the receive data buffer. Use the ICDR register to read the received data.
- Target transmission
  When the data requested by the read transaction issued by the Controller is written to the ICDR register, the data is transmitted.
- Target reception
  The data is stored in the receive data buffer by a write transaction issued by the Controller. Use the ICDR register to read the received data.

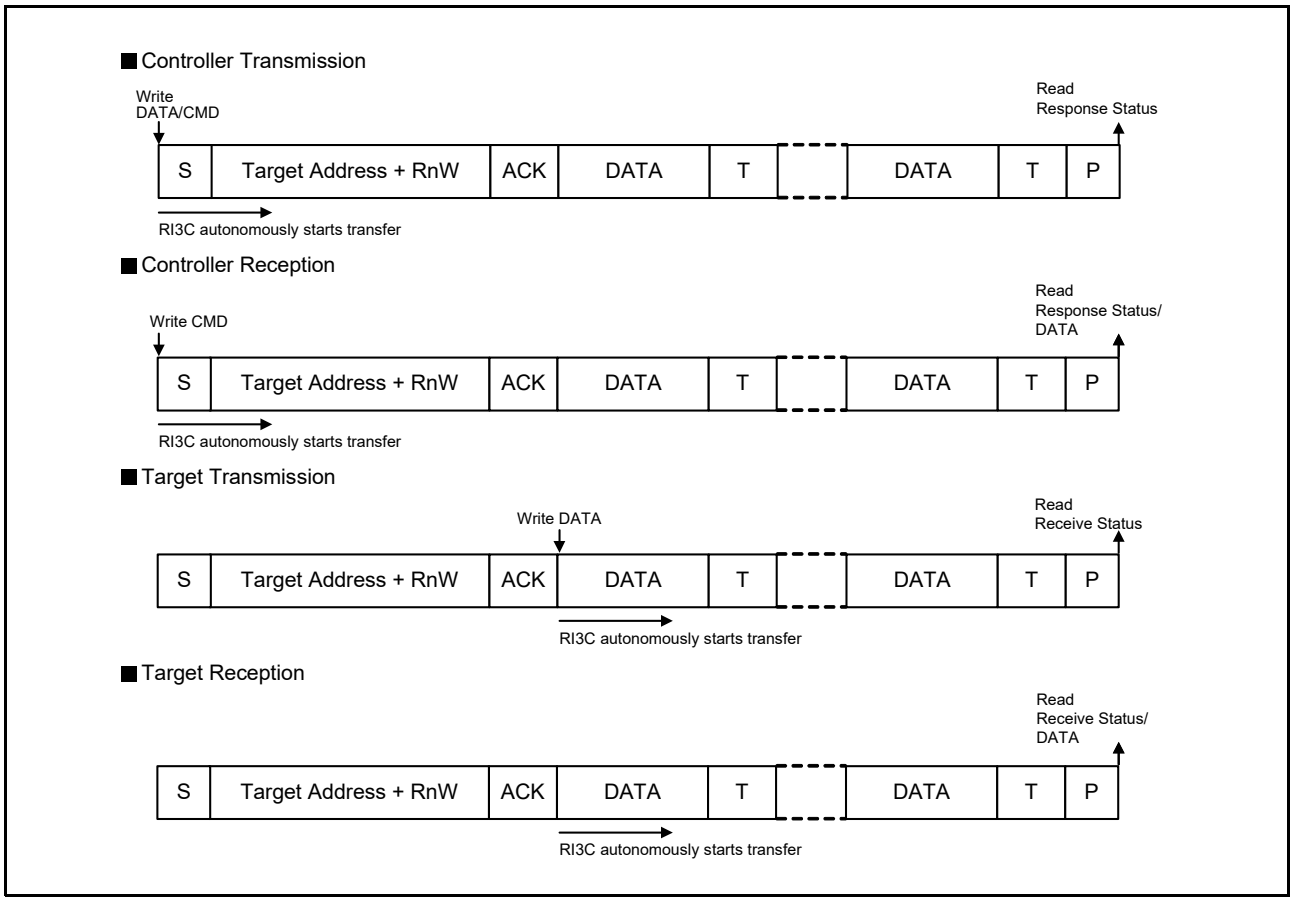

Figure 43.7 Data Handling with FIFO Buffer Transfer

(2) High-Priority FIFO Buffer Transfer

High-priority FIFO buffer transfers are only available in Controller mode, and take priority over normal FIFO buffer transfers. If a normal FIFO buffer transfer is already being executed, the high-priority FIFO buffer transfer is performed after waiting for the STOP condition for the currently executed transfer. The interrupted FIFO buffer transfer is resumed after the high-priority FIFO buffer transfer is completed.

The transactions using high-priority FIFO buffer transfer are the same as the Controller transmission and Controller reception in Figure 43.7.

(3) Single Buffer Transfer

In single buffer transfer, all operation such as issuing conditions, transferring data, and ACK/NACK responses are controlled by software. Figure 43.8 shows transactions using single buffer transfer.

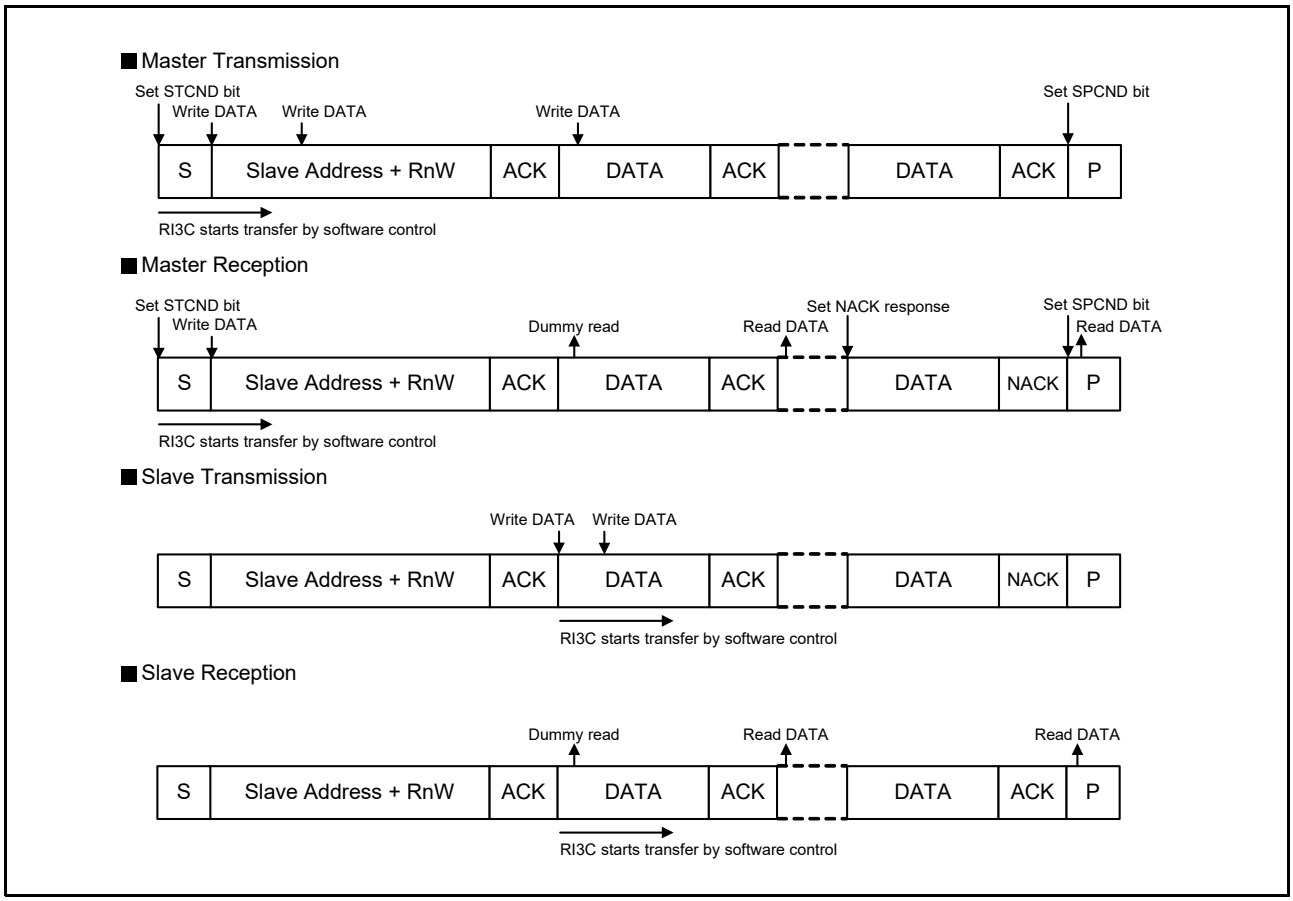

Figure 43.8 Data Handling with Single Buffer Transfer

43.4.2 I3C Protocol

43.4.2.1 Communication Protocol

(1) I3C Communication Data Format

Figure 43.9 through Figure 43.12 illustrate a typical communication for each of the supported I3C Protocols. While these diagrams do not exhaustively illustrate all possible RI3C communications, they do serve as useful introductions to the signaling and transmission formatting used in each supported I3C Protocol.

Figure 43.9 illustrates example communication using I3C Single Data Rate (SDR) mode with Broadcast Address (7Eh). It shows the Controller reading a byte of data from the Target at Address 2Bh in SDR Mode.
From the Bus Free condition, the Controller issues a START condition by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (7Eh) followed by RnW (0 for Write). Then the Controller turns on a pull-up resistor and goes to Open Drain. All Targets ACK by pulling the SDA line Low (in the Figure, pink fill means the Target is in control of the SDA line at this time). The Controller then issues a repeated START condition, then the Address of the Target (2Bh) it wants to read followed by RnW (1 for Read). The Controller then turns on a pull-up resistor and goes to Open Drain, allowing the Target to acknowledge by pulling the SDA line Low. At this point, the Controller continues to toggle the SCL line and release the SDA line, allowing the Target to drive SDA to send one byte of data (4Ah) followed by T. T = 1 informs the Controller that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Target drives SDA High until SCL goes High, at which time it releases SDA. The Controller has the option of holding SDA High with a weak pull-up, which signals to the Target that the Controller allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a repeated START condition), which would signal to the Target that the Controller has terminated the Read and is taking over.

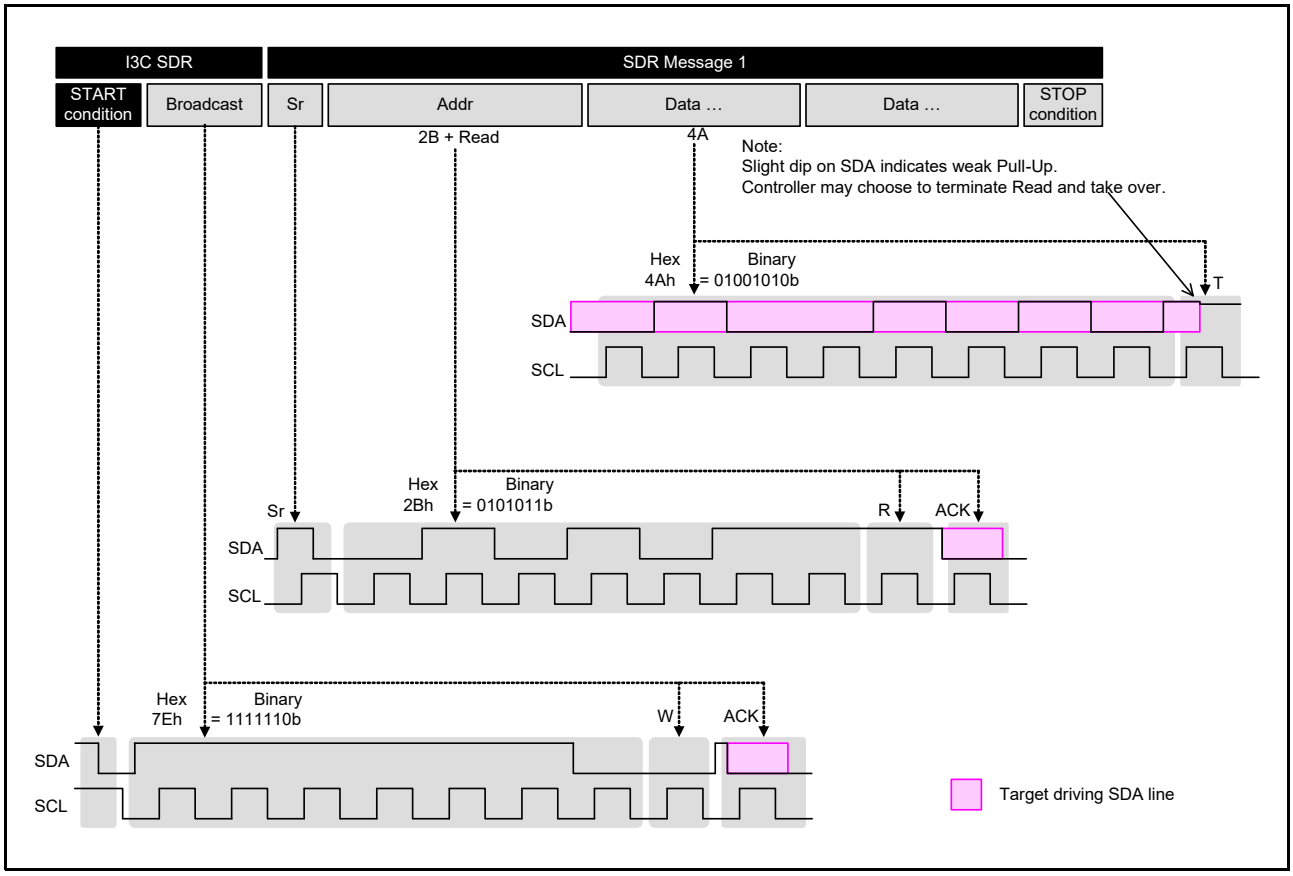

Figure 43.9 Example Communication Using I3C SDR Mode with Broadcast Address (7Eh)

Figure 43.10 illustrates example communication using I3C Single Data Rate (SDR) mode without Broadcast Address (7Eh). It shows the Controller reading a byte of data from the Target at Address 2Bh in SDR Mode.
From the Bus Free condition, the Controller issues a START condition, then the Address of the Target (2Bh) it wants to read followed by RnW (1 for Read). The Controller then turns on a pull-up resistor and goes to Open Drain, allowing the Target to acknowledge by pulling the SDA line Low. At this point, the Controller continues to toggle the SCL line and release the SDA line, allowing the Target to drive SDA to send one byte of data (4Ah) followed by T. T = 1 informs the Controller that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Target drives SDA High until SCL goes High, at which time it releases SDA. The Controller has the option of holding SDA High with a weak pull-up, which signals to the Target that the Controller allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a repeated START condition), which would signal to the Target that the Controller has terminated the Read and is taking over.

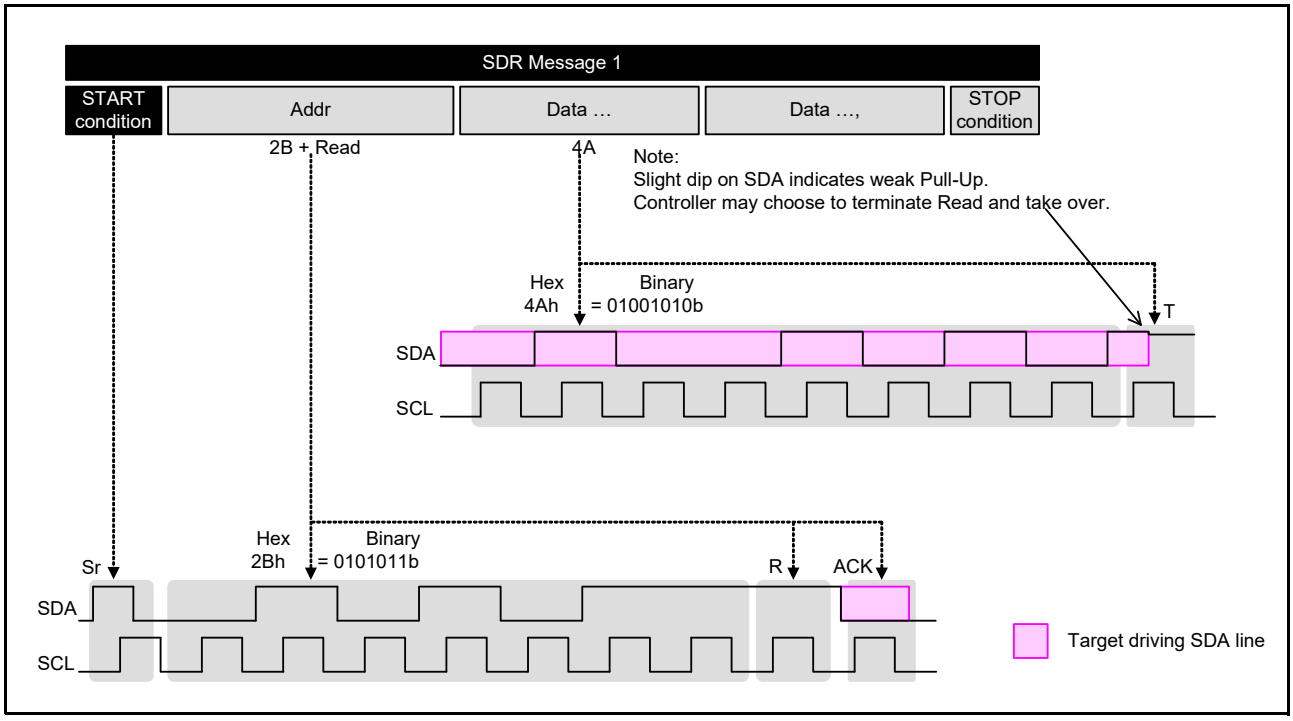

Figure 43.10 Example Communication Using I3C SDR Mode without Broadcast Address (7Eh)

Figure 43.11 shows the Controller issuing a Direct CCC to a single Target. This particular command (GETPID) reads the Provisioned ID of a Target.
From the Bus Free condition, the Controller issues a START condition by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (7Eh) followed by RnW (0 for Write). Then the Controller turns on a pull-up resistor and goes to Open Drain. All Targets ACK by pulling SDA Low (in the Figure, pink fill means the Targets are in control of SDA at this time). The Controller then issues the Direct Common Command Code for GETPID (8Dh) followed by parity bit T (odd parity = 1 for 8Dh) then the 7-bit Dynamic Address of the Target (chosen arbitrarily here to be 2Bh) followed by a RnW bit (1 for Read). Then the Controller turns on a pull-up resistor and goes to Open Drain, allowing the Target at Address 2Bh to ACK by pulling SDA Low, which tells the Controller that the Target acknowledges the command and will comply. (Alternatively, the Target may NACK by not pulling SDA Low, which would inform the Controller that the Target will not comply – in this case, that an error occurred.) Following the ACK the Target outputs its 48-bit PID one byte at a time, and then the Controller issues a repeated START condition (this part of the waveform sequence is not shown in the Figure).

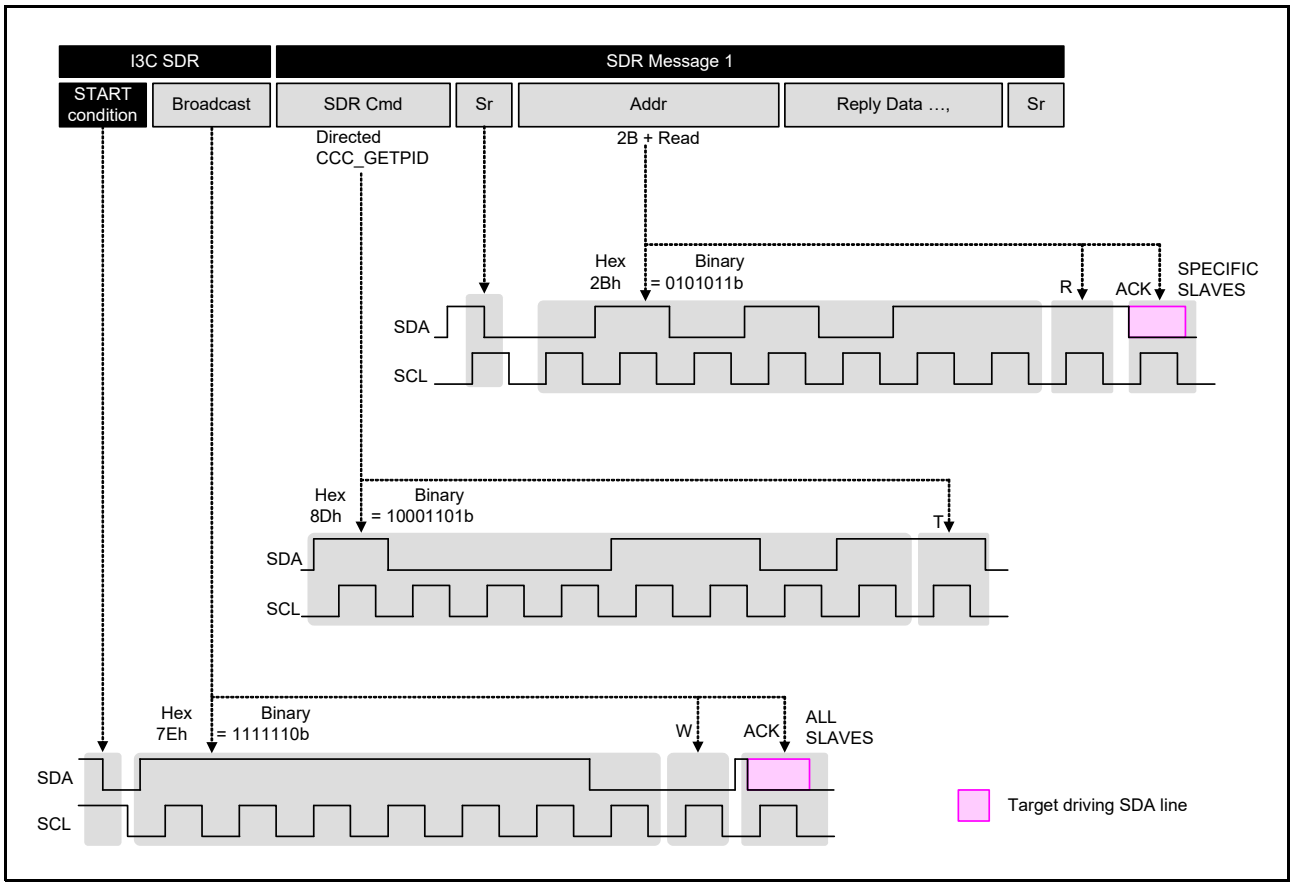

Figure 43.11 Example Communication Using I3C SDR Mode with Direct CCC

Figure 43.12 illustrates example SDR communication with a Broadcast CCC. The command used in this example sets the Maximum Read Length of all Targets to 43 bytes (002Bh).
From the Bus Free condition, the Controller issues a START condition by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (7Eh) followed by RnW (0 for Write). Then the Controller turns on a pull-up resistor and goes to Open Drain. All Targets ACK by pulling SDA Low (in the Figure, pink fill means the Targets are in control of SDA at this time). The Controller then issues the Broadcast Common Command Code for SETMRL (0Ah) followed by parity bit T (odd parity = 1 for 0Ah), and then 2 data bytes (MSB first) to define the maximum number of bytes that can be read from a Target in a single read operation. Each data byte is followed by a T bit (parity bit – odd parity). After this the Controller issues a repeated START condition.

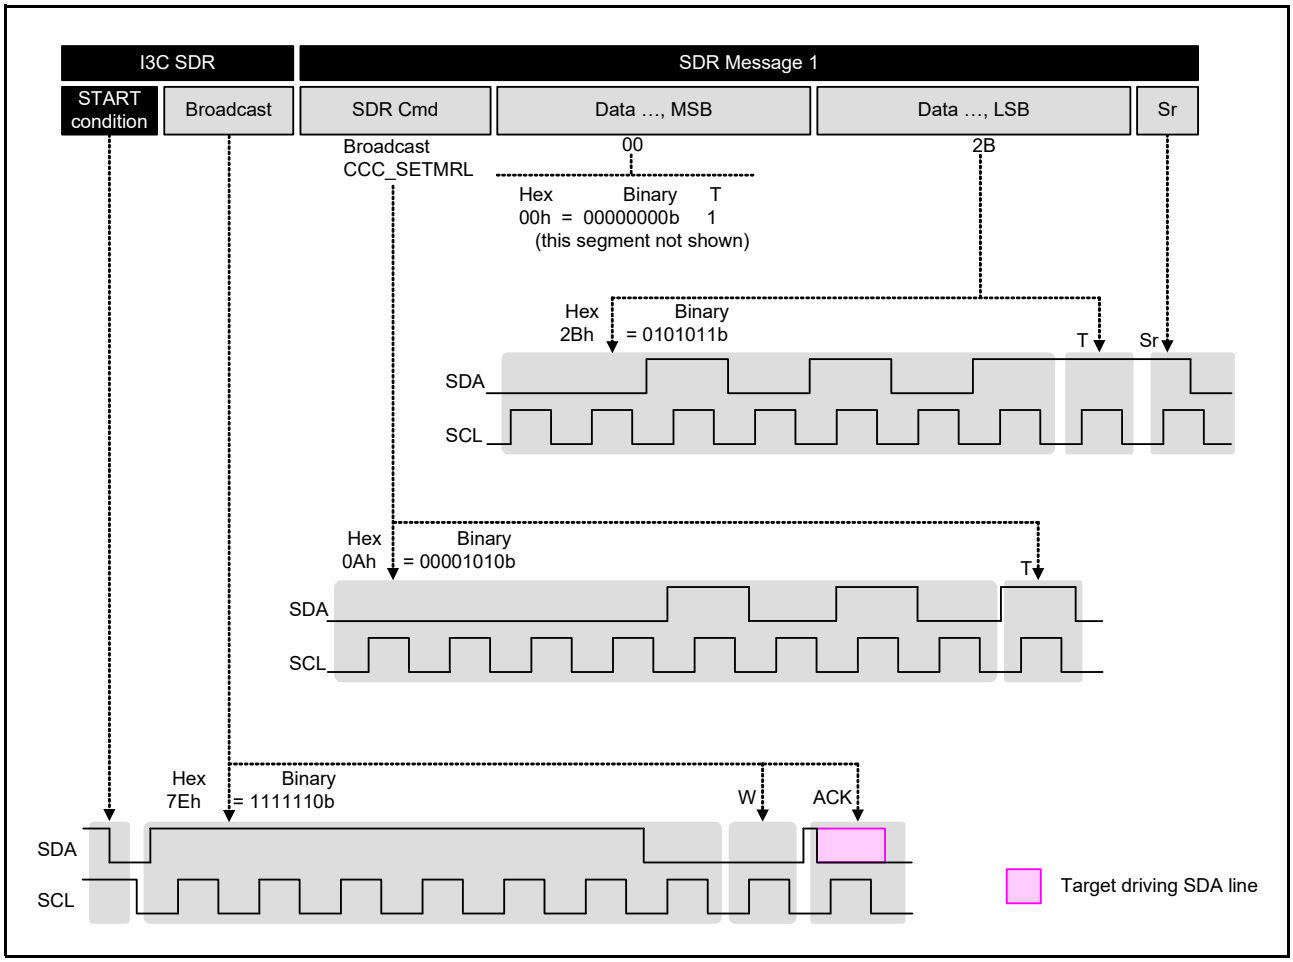

Figure 43.12 Example Communication Using I3C SDR Mode with Broadcast CCC

43.4.2.2 Bus Conditions

RI3C defines three distinct conditions in which the I3C bus shall be considered inactive: Bus Free, Bus Available, and Bus Idle (see Figure 43.13).

(1) Bus Free Condition

State on the I3C bus where both the SCL line and the SDA line are High for at least the period set by ICBFTR register.

(2) Bus Available Condition (I3C protocol mode)

State on the I3C bus where both the SCL line and the SDA line are High for at least the period set by ICBATR register.

A Target may only issue a START Request (For example, for an IBI, or for a CRR) after a Bus Available condition.

(3) Bus Idle Condition (I3C protocol mode)

State on the I3C bus where both the SCL line and the SDA line are High for at least the period set by ICBITR register.

A Target may only issue a START Request after a Bus Idle condition.

Specifications are as follows. Bus Idle period needs to be the largest.

ICBFTR < ICBATR < ICBITR

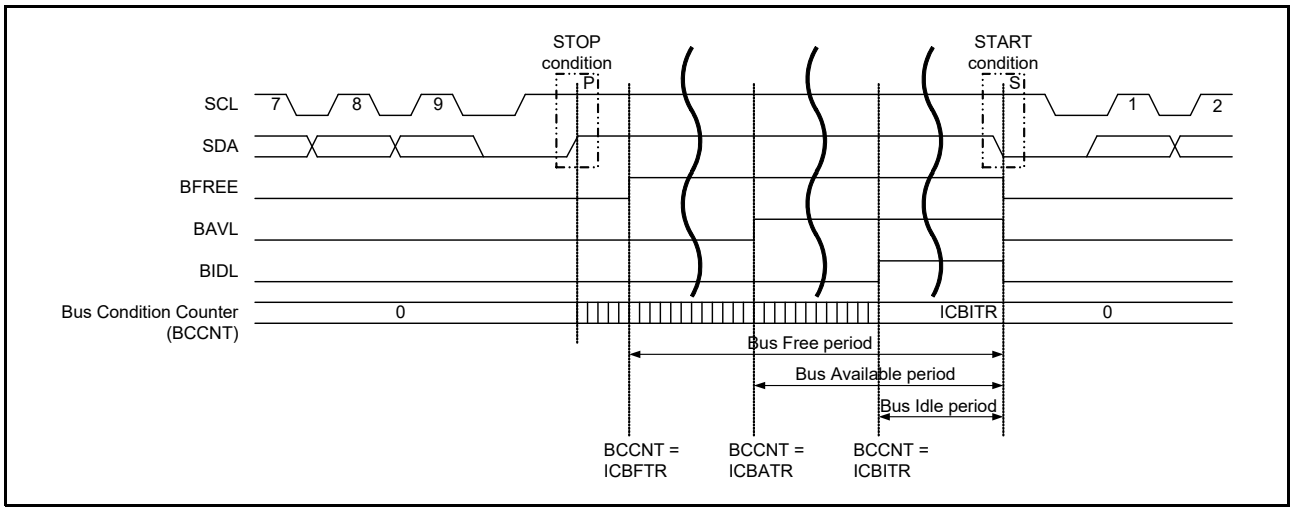

Figure 43.13 Bus Conditions

43.4.3 I²C Protocol

(1) I²C Communication Data Format

The I²C-bus format consists of 8-bit data and 1-bit acknowledgment. The frame following a START condition or repeated START condition is an address frame used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a STOP condition is generated. Figure 43.14 shows the I²C-bus format, and Figure 43.15 shows the I²C-bus timing.

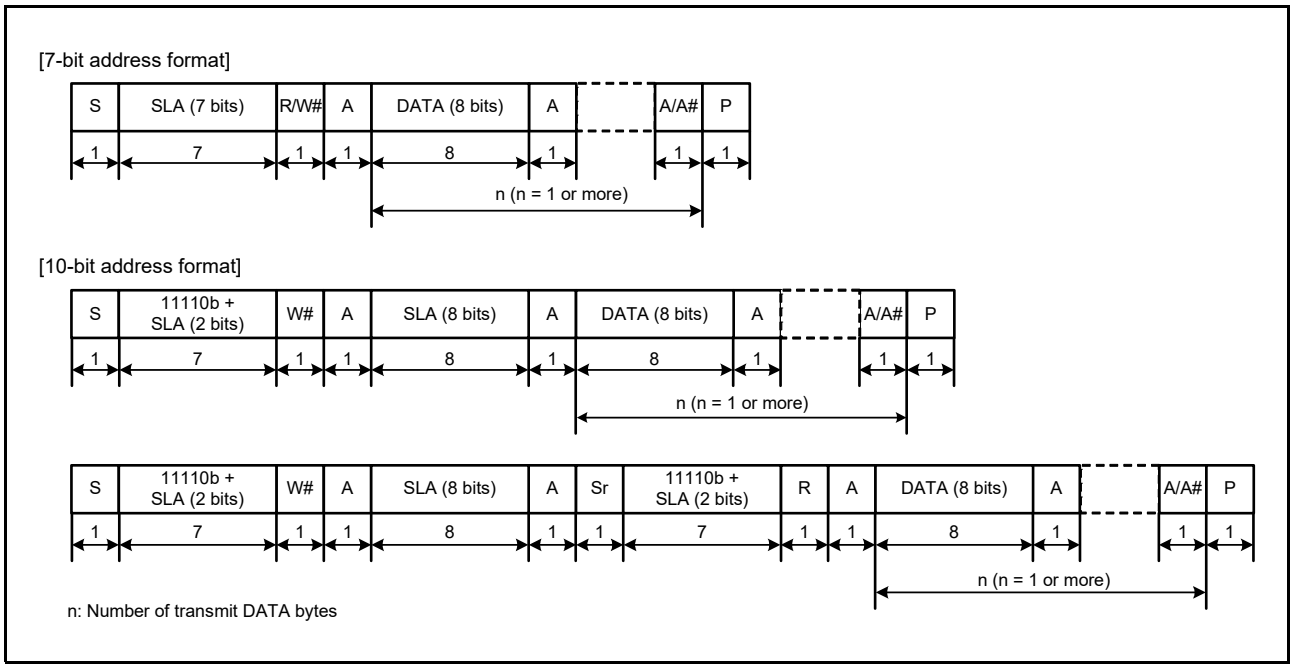

Figure 43.14 I²C-bus Format

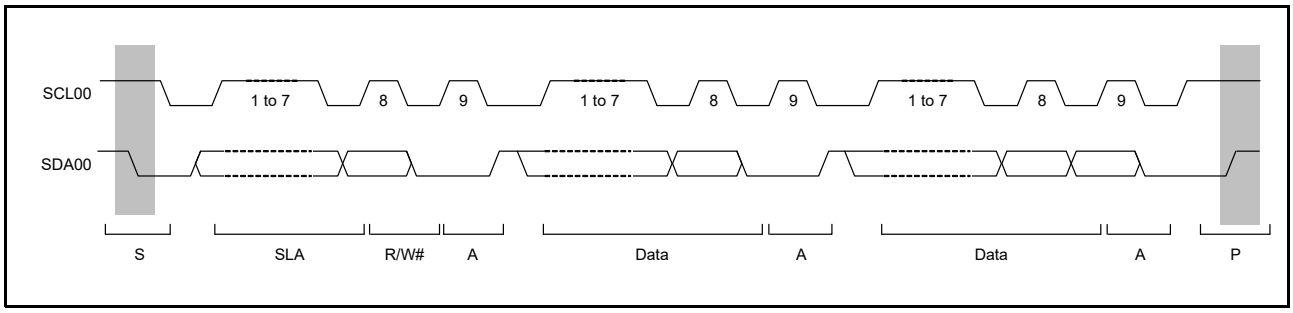

Figure 43.15 I²C-bus Timing (SLA = 7 Bits)

S: START condition. The master device drives the SDA00 line low from high while the SCL00 line is high.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W# is 1, or from the master device to the slave device when R/W# is 0.

A: Acknowledge. The receiver drives the SDA00 line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)

A#: Not Acknowledge. The receiver drives the SDA00 line high.

Sr: Repeated START condition. The master device drives the SDA00 line low from high after the setup time has elapsed with the SCL00 line high.

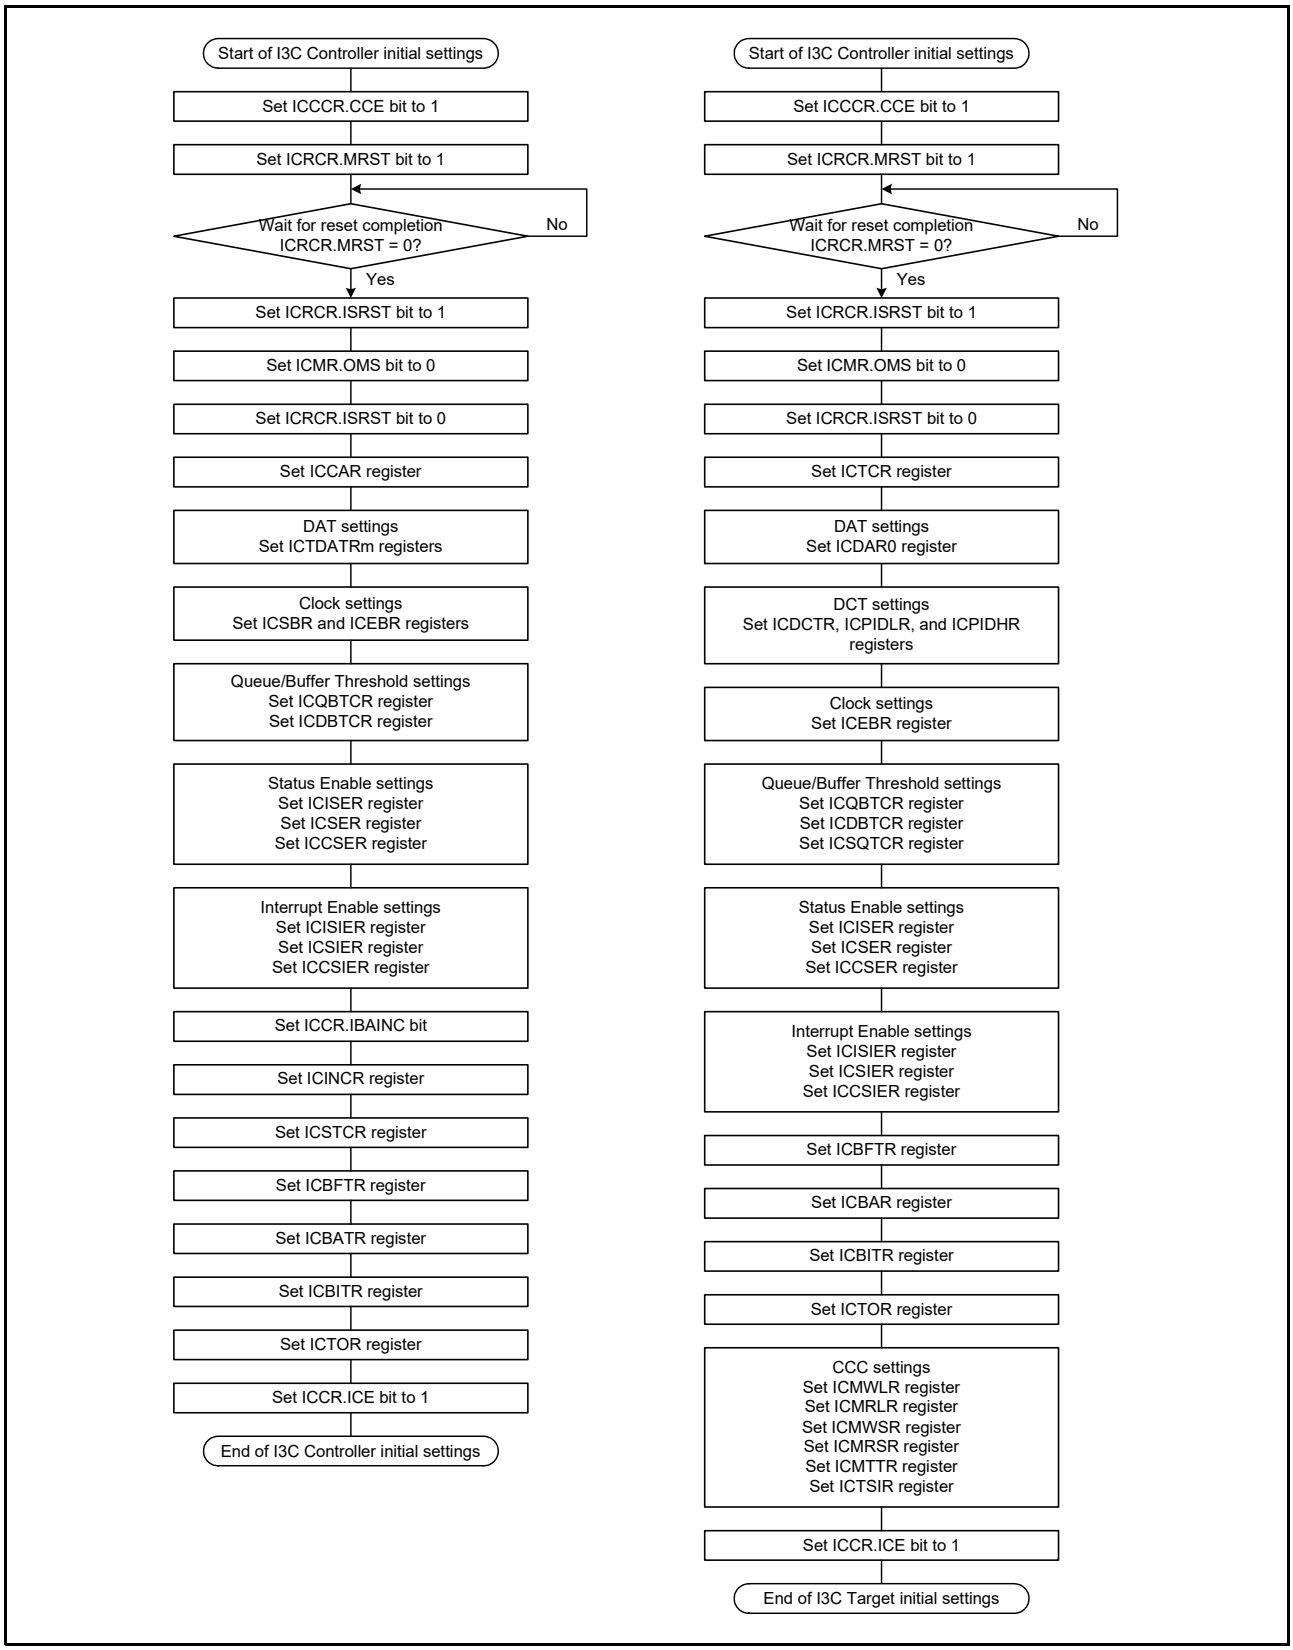
DATA: Transmitted or received data

P: STOP condition. The master device drives the SDA00 line high from low while the SCL00 line is high.

43.4.4 Initial Settings

(1) I3C Protocol Mode

Before starting data transmission and reception, initialize the RI3C according to the procedure in Figure 43.16.



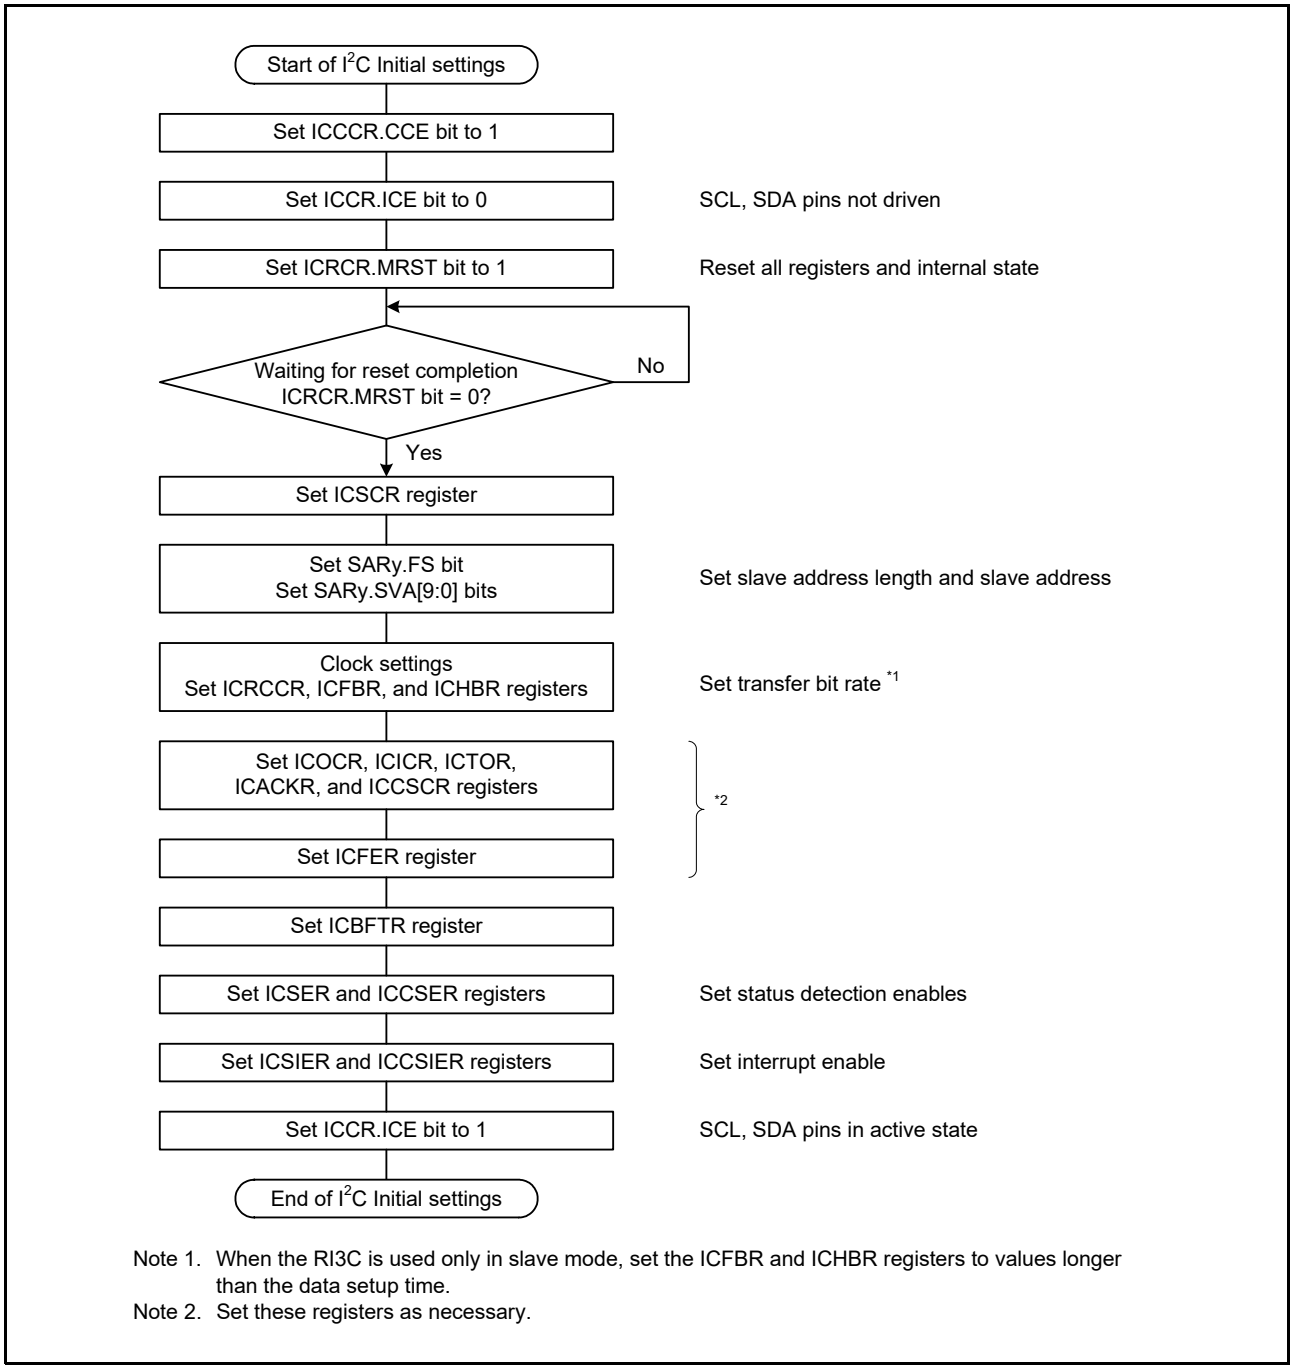


Figure 43.16 Example of RI3C Initialization Flowchart

(2) I2C Protocol Mode

Before starting data transmission and reception, initialize the RI3C according to the procedure in Figure 43.17.
First, Set the ICCR.ICE bit to 0 (SCL00, SDA00 pins not driven).
Next, Set the ICRCR.MRST bit to 1 (RI3C reset). This initialize the all registers and internal state. Refer to Table 43.16, Reset Control of Registers. Then, it waits for MRST to become 0.
After that, set SARy.FS bit, SARy.SVA[9:0] bits, ICFBR register, ICICR register, ICOCR register, ICTOR register, ICCSCR register, ICACKR register, ICFER register, and set the other registers as necessary (y = 0 to 2).

Note 1. When the RI3C is used only in slave mode, set the ICFBR and ICHBR registers to values longer than the data setup time.
Note 2. Set these registers as necessary.

Figure 43.17 Example of RI3C Initialization Flowchart (y = 0 to 2)

43.4.5 I3C Communication Flow

Figure 43.18 illustrates how I3C communication is initiated:

- All I3C communication occurs within a frame. The frame begins with a START condition, followed by one or more transfers, and a STOP condition.

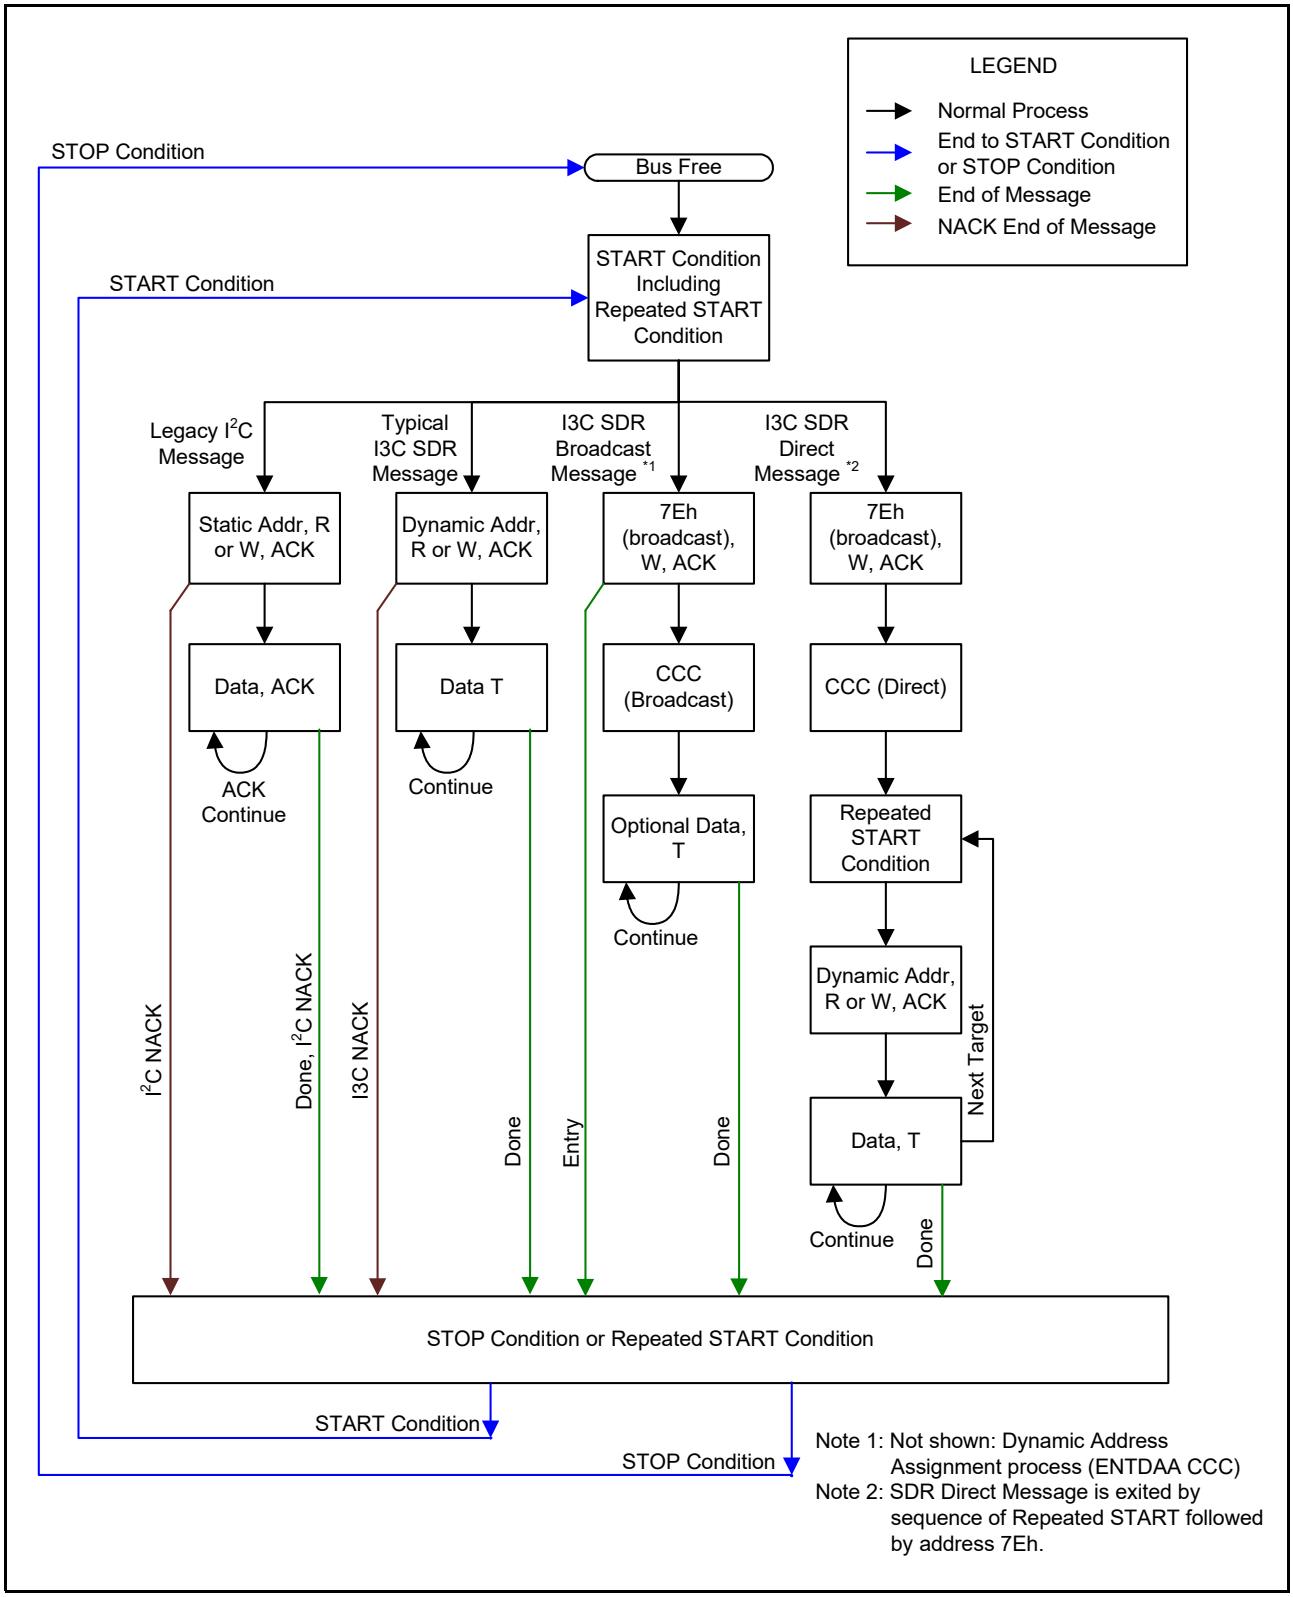

Figure 43.18 I3C Communication Flow

I3C is based on a frame encapsulation approach. A frame includes a data payload. The transfer protocol for the data payload is SDR. Frames are bordered by I^2C-like bus management.
The I3C frame always includes at least the START condition, the Header, the Data, and the STOP condition. The Header following a START condition allows for bus arbitration. The Controller uses the Header to address Target device(s). Target device(s) may use the Header Arbitration for multiple purposes: for IBI and for Secondary Controller functionality.
I3C allows only one Controller to have control of the I3C bus at a time. Mechanisms for handoff of the Controller role from one device to another device are provided.

43.4.6 I3C Controller Operation

43.4.6.1 Dynamic Address Assignment Procedure

After initializing RI3C, first execute Dynamic Address Assignment Procedure for I3C Target connected on the I3C bus. The following describes the procedure.

(1) Initial setting (refer to section 43.4.4, Initial Settings for details)

(2) Execute Dynamic Address Assignment with ENTDAA or SETDASA Common Command Code (CCC) for I3C Target set in DAT (ICTDATRm register).
Write Command Descriptor (address assignment command) to command queue via the ICCQR register.

(3) When Command Descriptor is written to command queue, Transaction is issued on I3C bus.

(4) When ENTDAA is specified for the CMD field of address assignment command:
Executes Dynamic Address Assignment for I3C Targets corresponding to the number of the ICTDATRm registers specified by the DEV_COUNT field starting with the ICTDATRm register indexed by the DEV_INDEX field of address assignment command.
When SETDASA is specified for the CMD field of address assignment command:
Execute Dynamic Address Assignment for I3C Target indicated by the ICTDATRm register indexed by the DEV_INDEX field of address assignment command.

(5) In case of ENTDAA, the Provisioned ID, BCR, DCR transmitted from I3C Target is stored in Receive Data Buffer (BCR is also automatically stored in the ICTDCTRm register).
Read the Provisioned ID, BCR, and DCR from the receive data buffer via the ICDR register with a receive data full interrupt.

(6) When execution of Dynamic Address Assignment is completed, issue STOP condition and store the Response Descriptor into the response queue.

(7) Read the Response Descriptor via the ICRQR register and check the status.

(8) Check whether the value of the DATA_LENGTH field of the Response Descriptor matches the value of the DEV_COUNT field of the address assignment command.

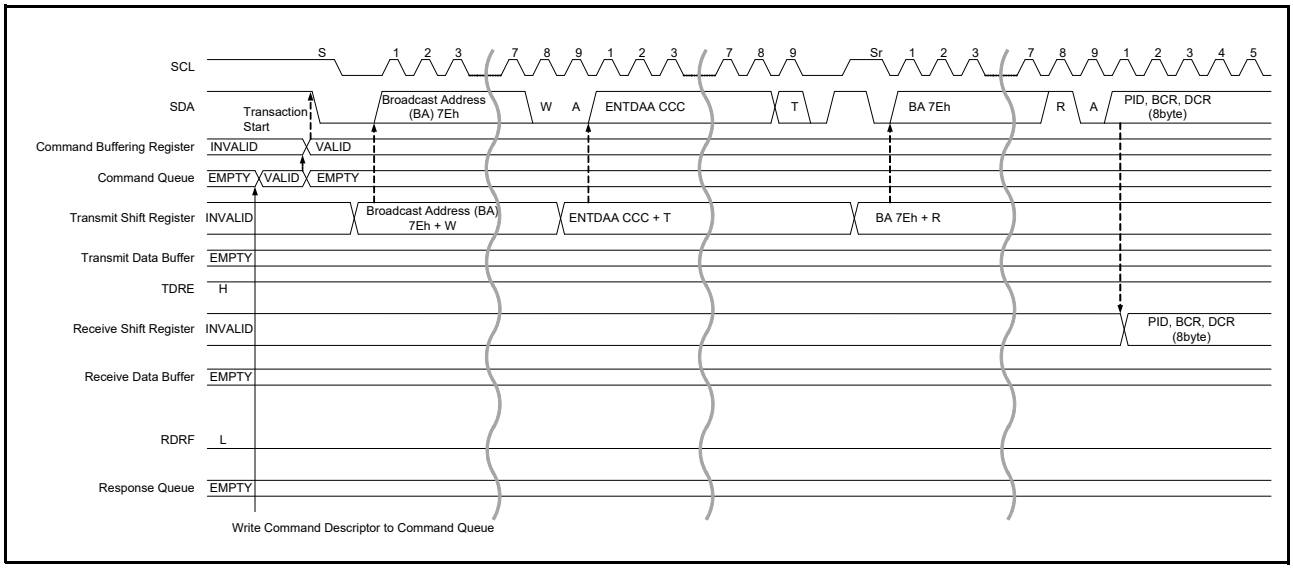

Figure 43.19 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (1/3)

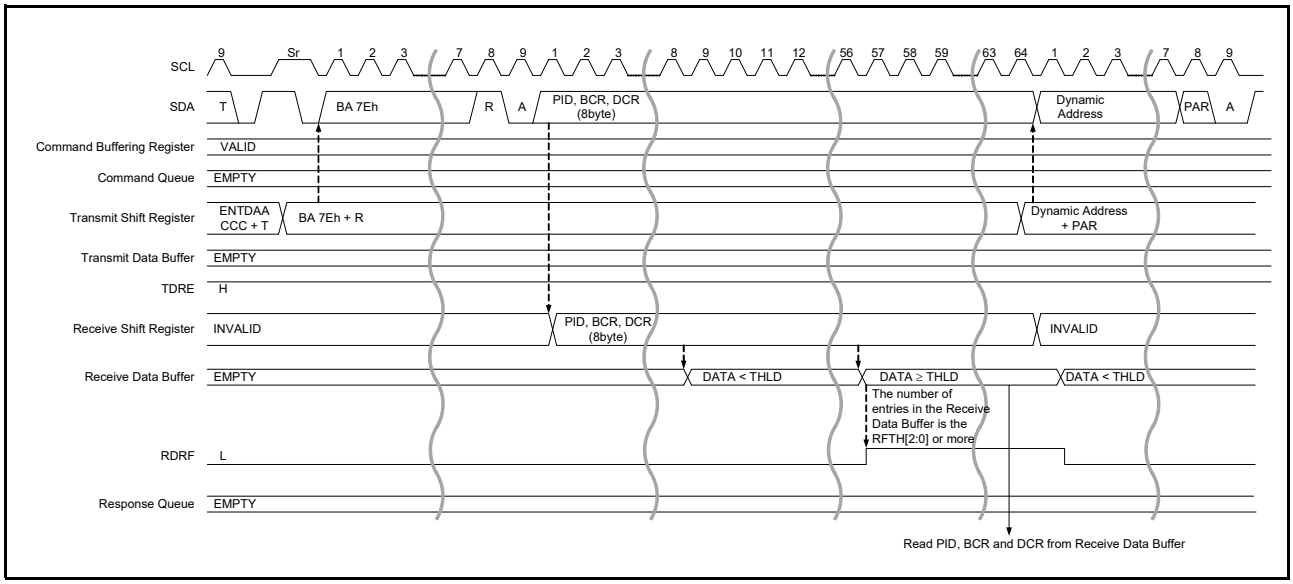

Figure 43.20 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (2/3)

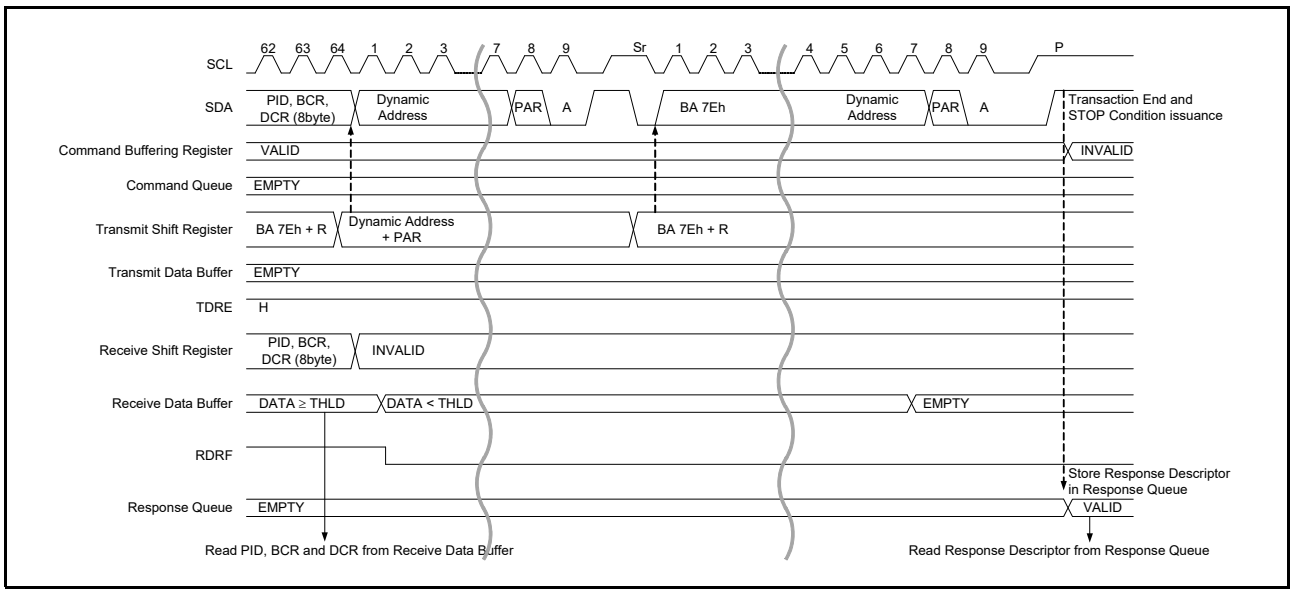

Figure 43.21 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (3/3)

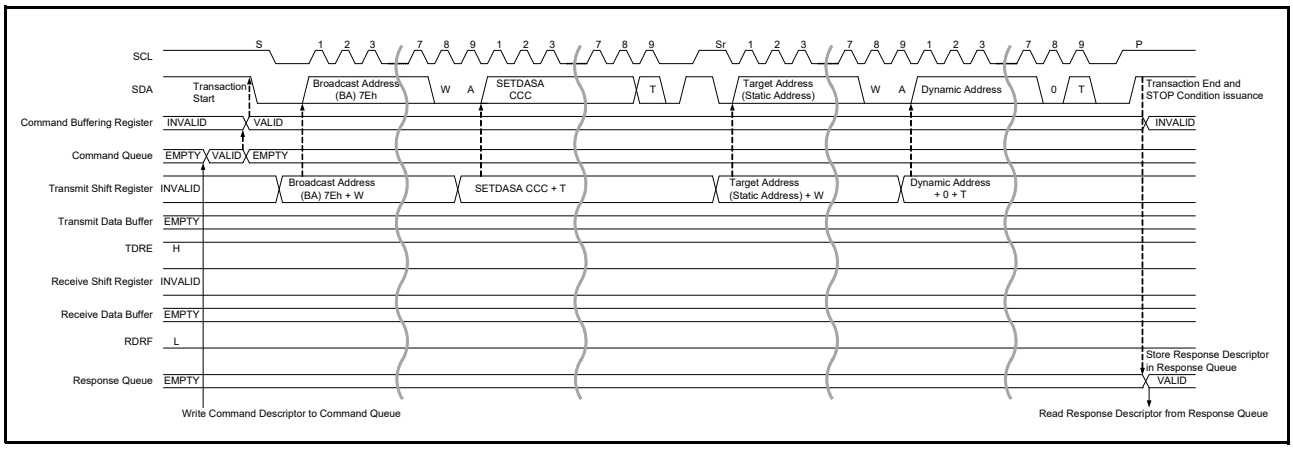

Figure 43.22 Dynamic Address Assignment Procedure (SETDASA CCC) Timing

43.4.6.2 SDR Write Transfer

(1) Write data for transmission to the Transmit Data Buffer via the ICDR register.
(2) Write a Command Descriptor (immediate data transfer command or regular data transfer command or combo transfer command) for Data Transfer to the command queue via the ICCQR register.
(3) When Command Descriptor is written to command queue, transaction is issued on I3C bus.
When NACK is received with the Address header, transaction of the same command is automatically issued according to the NACK Retry Count value (ICTDATRm.NACKRC[1:0]) of DAT.
(4) If data for transmission still remain, write data for transmission by a transmit data empty interrupt to the Transmit Data Buffer via the ICDR register.
(5) When data transmission for the number of bytes specified in the DATA_LENGTH field of the Command Descriptor is completed, the repeated START condition or STOP condition is issued and the Response Descriptor is stored in the response queue.
(6) Read the Response Descriptor via the ICRQR register and check the status.
(7) Check that the value of the DATA_LENGTH field of the Response Descriptor is 0.

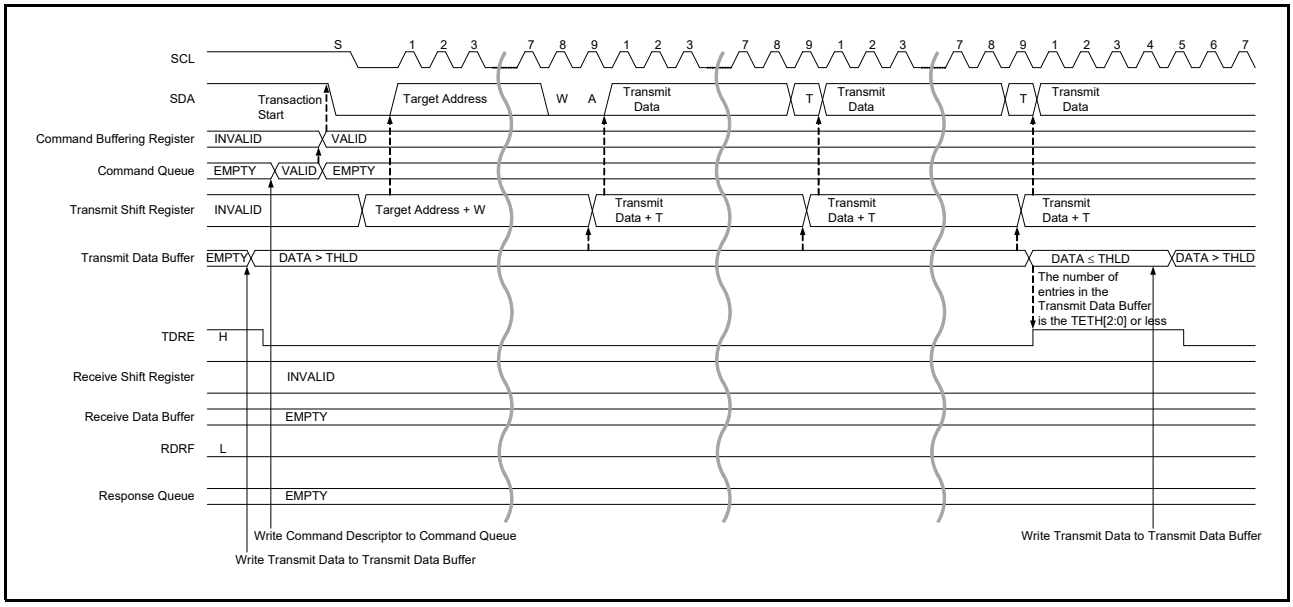

Figure 43.23 SDR Write Transfer Timing (1/2)

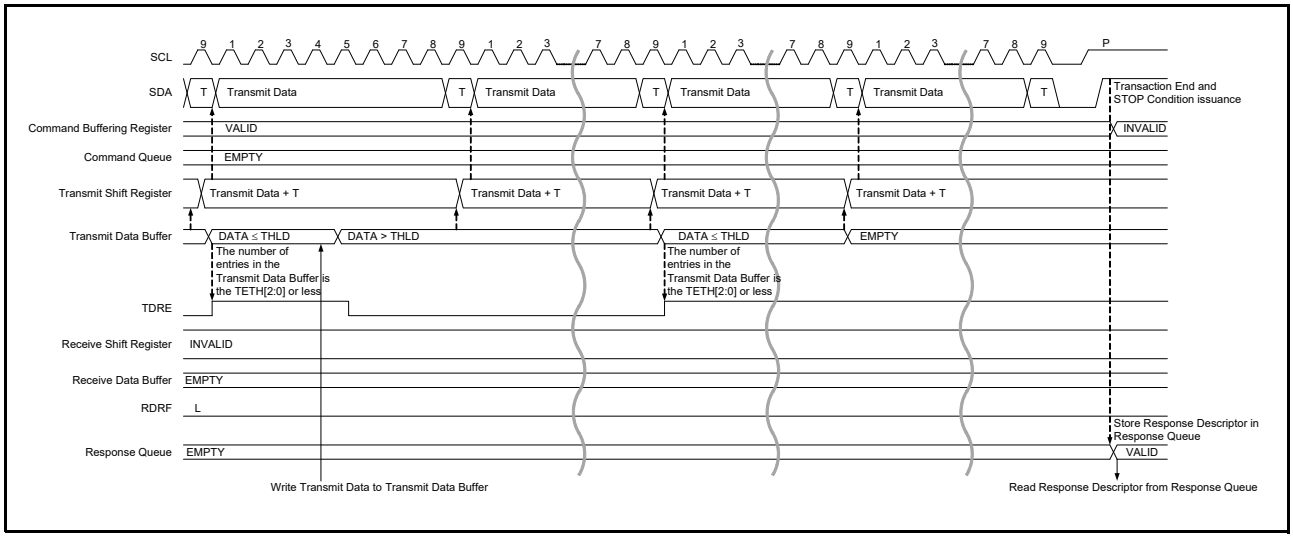

Figure 43.24 SDR Write Transfer Timing (2/2)

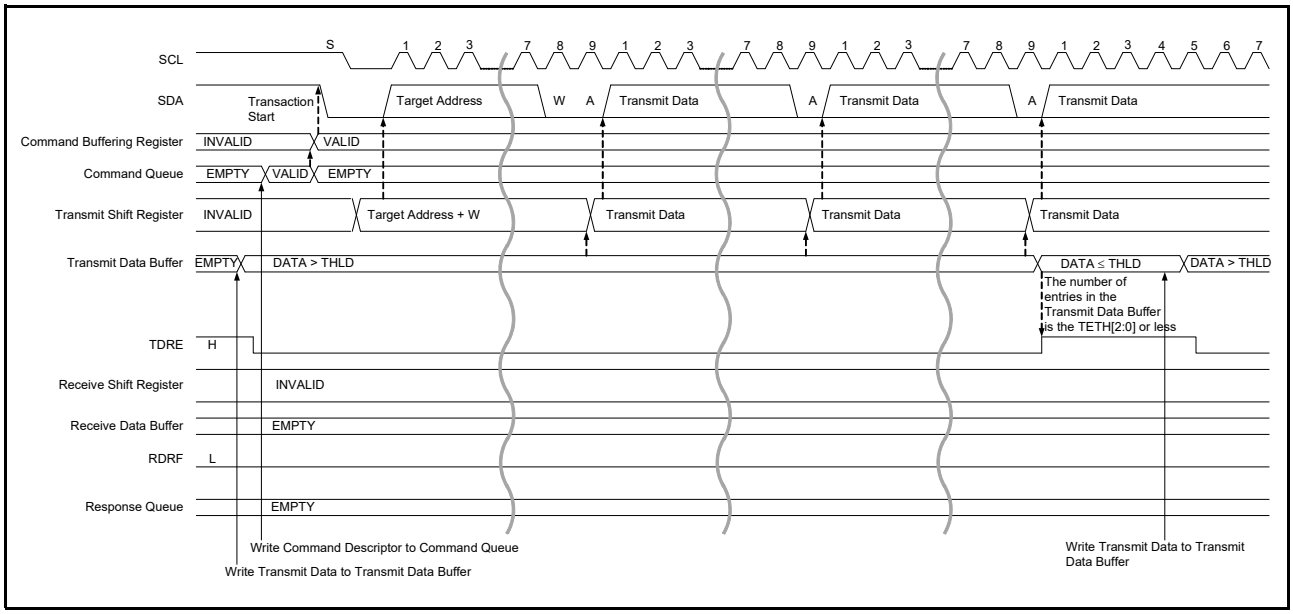

Figure 43.25 Legacy I²C Write Transfer Timing (1/2)

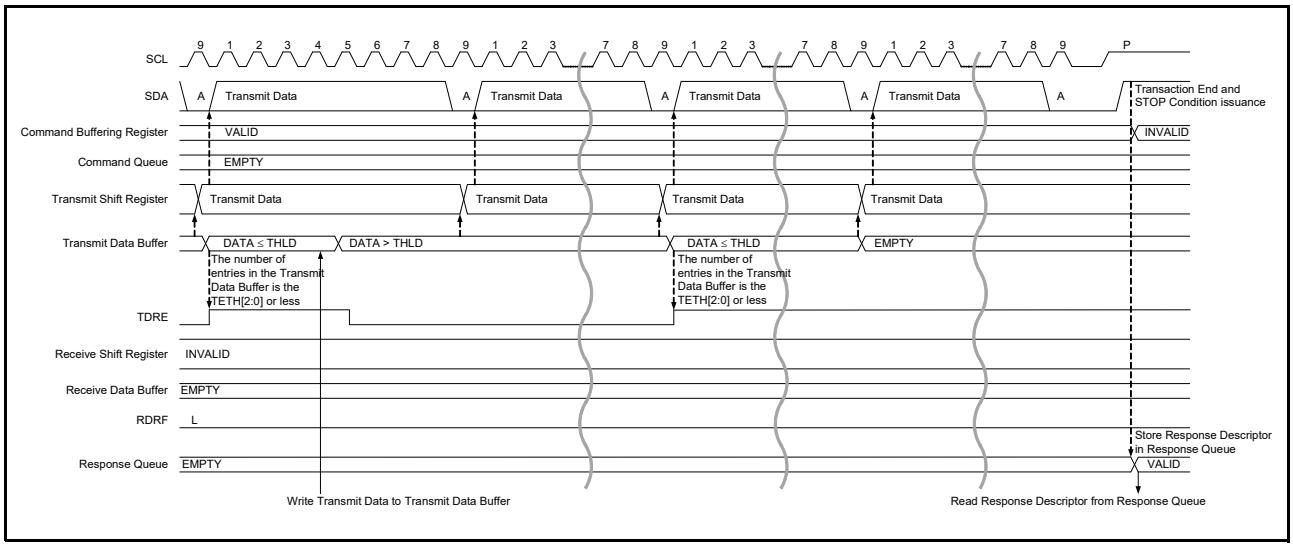

Figure 43.26 Legacy I²C Write Transfer Timing (2/2)

43.4.6.3 SDR Read Transfer

(1) Write a Command Descriptor (immediate data transfer command or regular data transfer command or combo transfer command) for Data Transfer to the command queue via the ICCQR register.

(2) When Command Descriptor is written to command queue, transaction is issued on I3C bus.
When NACK is received with the Address header, transaction of the same command is automatically issued according to the NACK Retry Count value (ICTDATRm.NACKRC[1:0]) of DAT.

(3) Data received from the I3C Target is stored in the Receive Data Buffer.

(4) In the receive data full interrupt, read the received data from the Receive Data Buffer via the ICDR register.

(5) SDR:
Detecting Low in T-bit or receiving Data for the number of bytes specified in the DATA_LENGTH field of Command Descriptor is completed, issue repeated START condition or STOP condition and store the Response Descriptor into the response queue.
Legacy I^2C Message:
When data reception for the number of bytes specified in the DATA_LENGTH field of Command Descriptor is completed, NACK is issued. After that, issue a repeated START condition or STOP condition and store the Response Descriptor into the response queue.

(6) Read the Response Descriptor via the ICRQR register and check the status.

(7) Check whether the value of the DATA_LENGTH field of the Response Descriptor matches the data length setting value of the Command Descriptor.

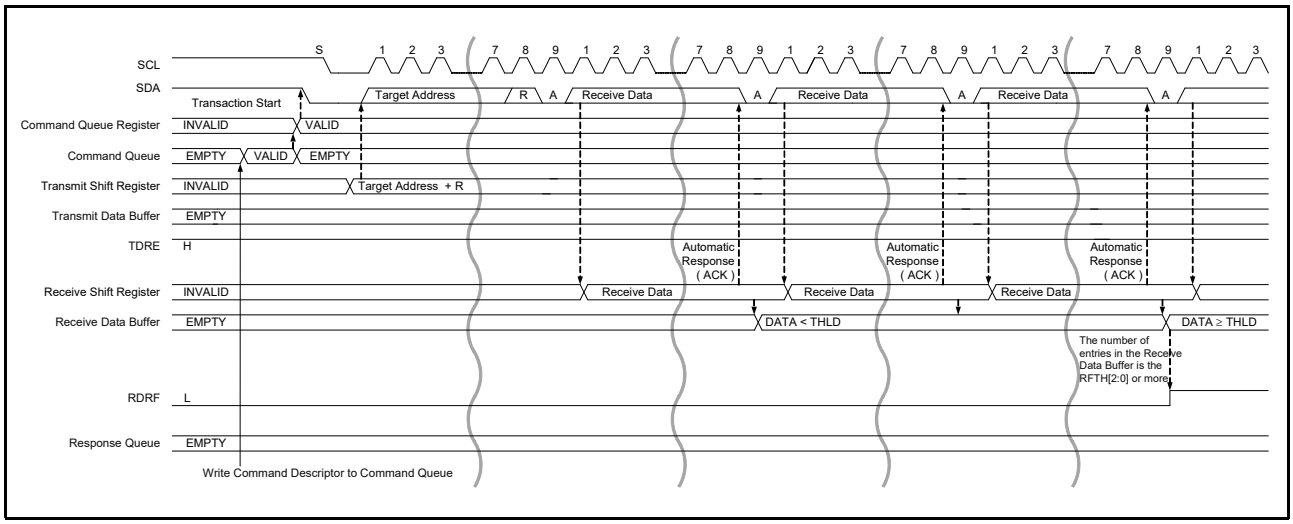

Figure 43.27 SDR Read Transfer Timing (1/2)

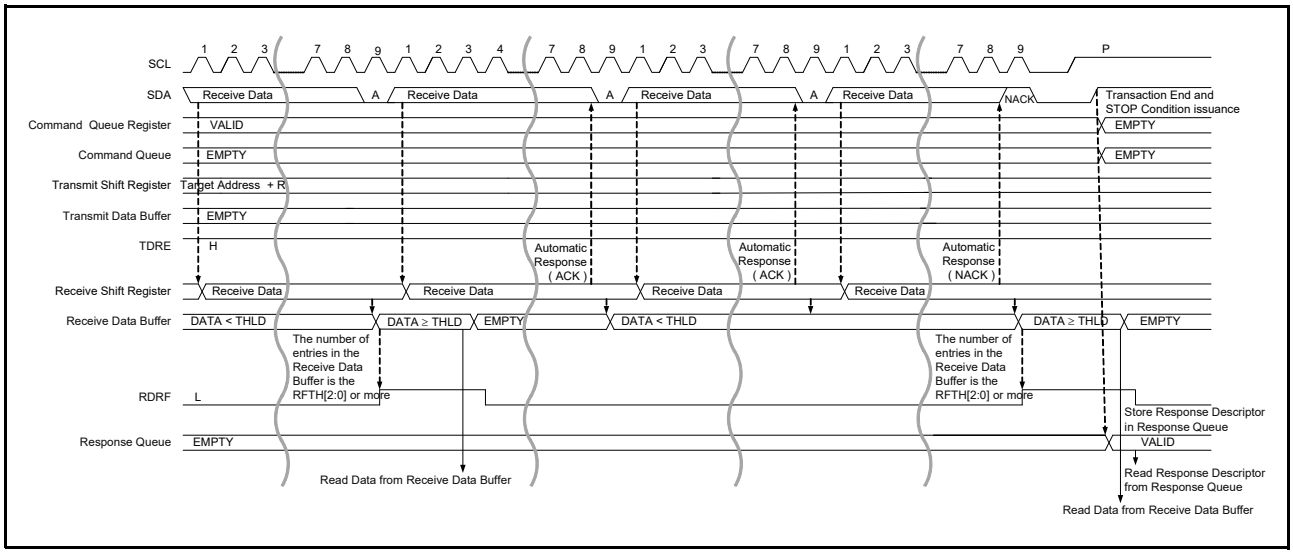

Figure 43.28 SDR Read Transfer Timing (2/2)

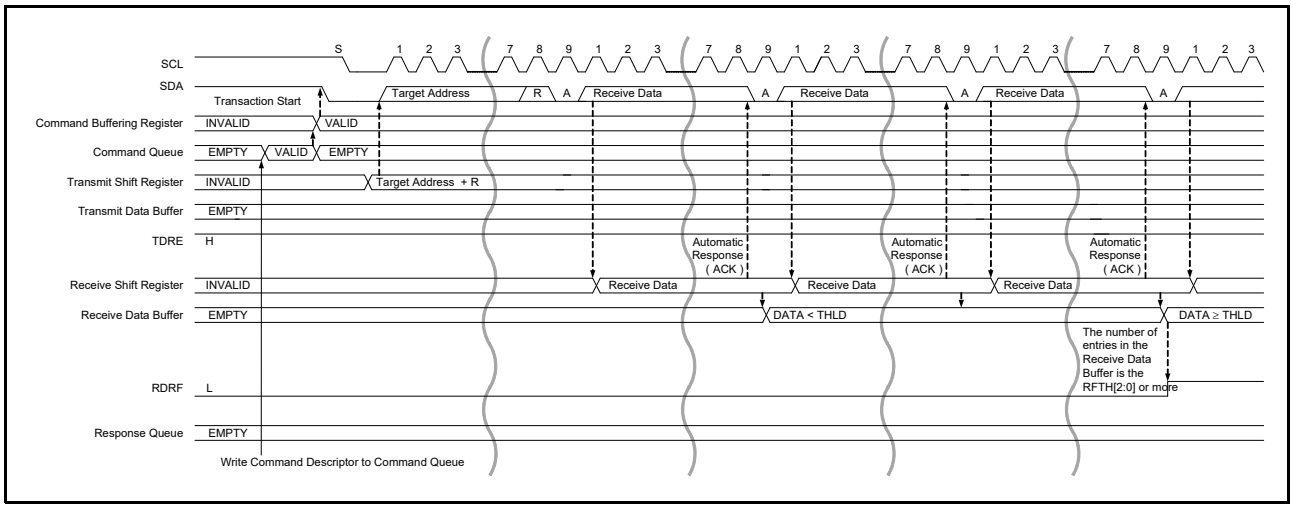

Figure 43.29 Legacy I²C Read Transfer Timing (1/2)

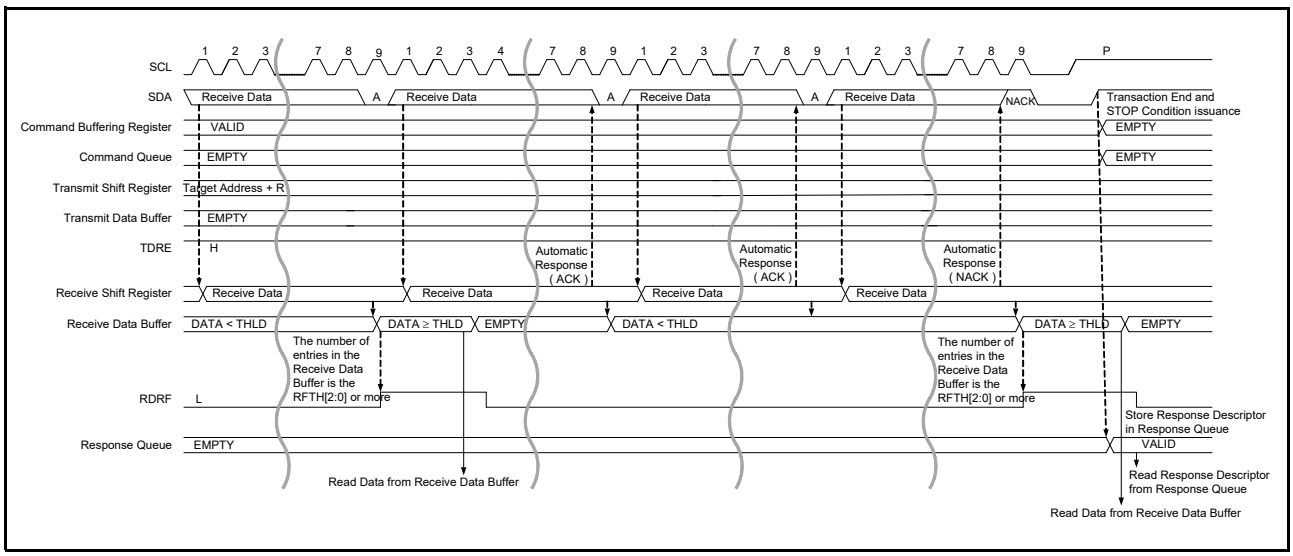

Figure 43.30 Legacy I²C Read Transfer Timing (2/2)

43.4.6.4 IBI Transfer

(1) Write Command Descriptor to the command queue and issue Transaction on I3C bus.
If START Request (SDA Low Drive) is issued from the Target device, RI3C drives SCL to Low and completes START condition.
Thereafter, the SCL is supplied and IBI Request is received.
(2) In Target Address and RnW field in the Address header, if losing Arbitration by issuing IBI from I3C Target, stop issuing Transaction.
(3) According to section 43.5.13, IBI (I3C Protocol Mode), detect IBI and process.
(4) In the IBI queue empty/full interrupt routine, read the IBI Status Descriptor from the IBI queue via the ICIQR register and check the status.
When detected a Target Interrupt Request and responded with ACK, Read the IBI Data for the Data Length indicated by the DATA_LENGTH field of the IBI Status Descriptor from the IBI queue via the ICIQR register.
(5) Restart issuing Transaction of Command of Step1.

An example of the processing procedure after detection of IBI is shown below.

Processing procedure for detecting Controller Role Request and transferring Controller role to Secondary Controller

(1) If the I3C Secondary Controller wins the Arbitration, issue a DEFTGTS CCC and notify Target information to Secondary Controller.
(2) Issue a GETACCCR CCC and complete CCC by a STOP condition.

Note: • After transferring Controller role to Secondary Controller, to get Controller role again, issue a Controller Role Request according to section 43.4.6.4, IBI Transfer.
• After Controller Role Request is accepted by the Active Controller, to get Controller role again at receiving the GETACCCR CCC and complete CCC by a STOP condition.

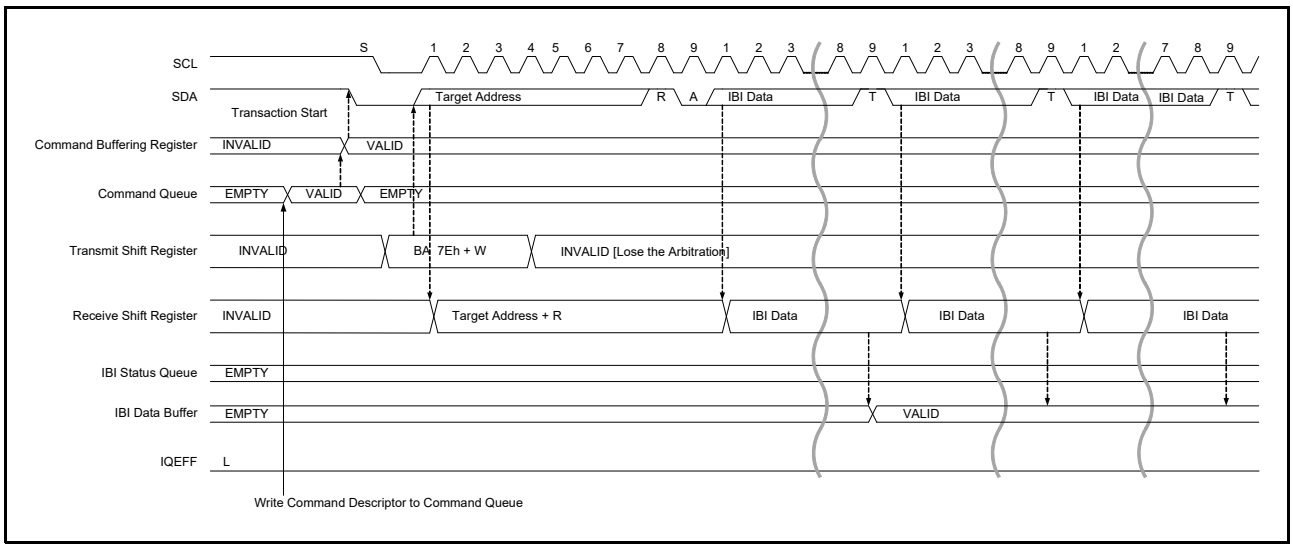

Figure 43.31 I3C Controller IBI Transfer Timing (1/2)

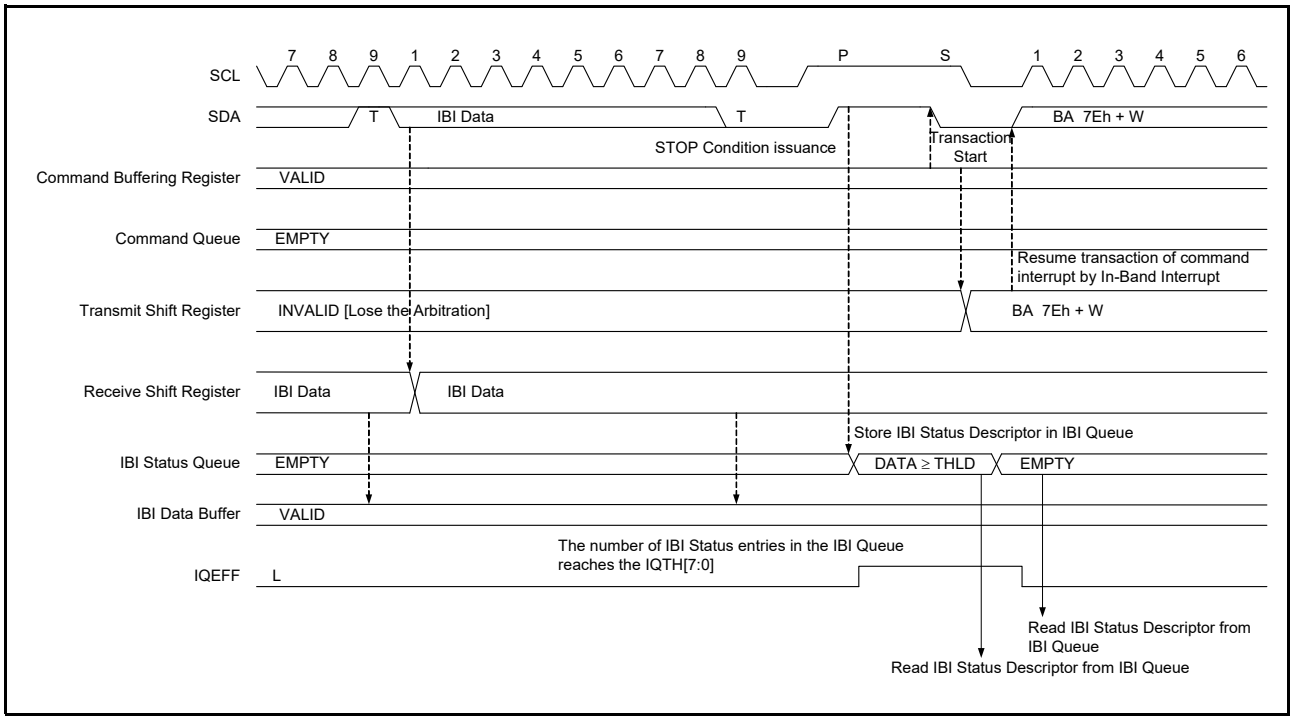

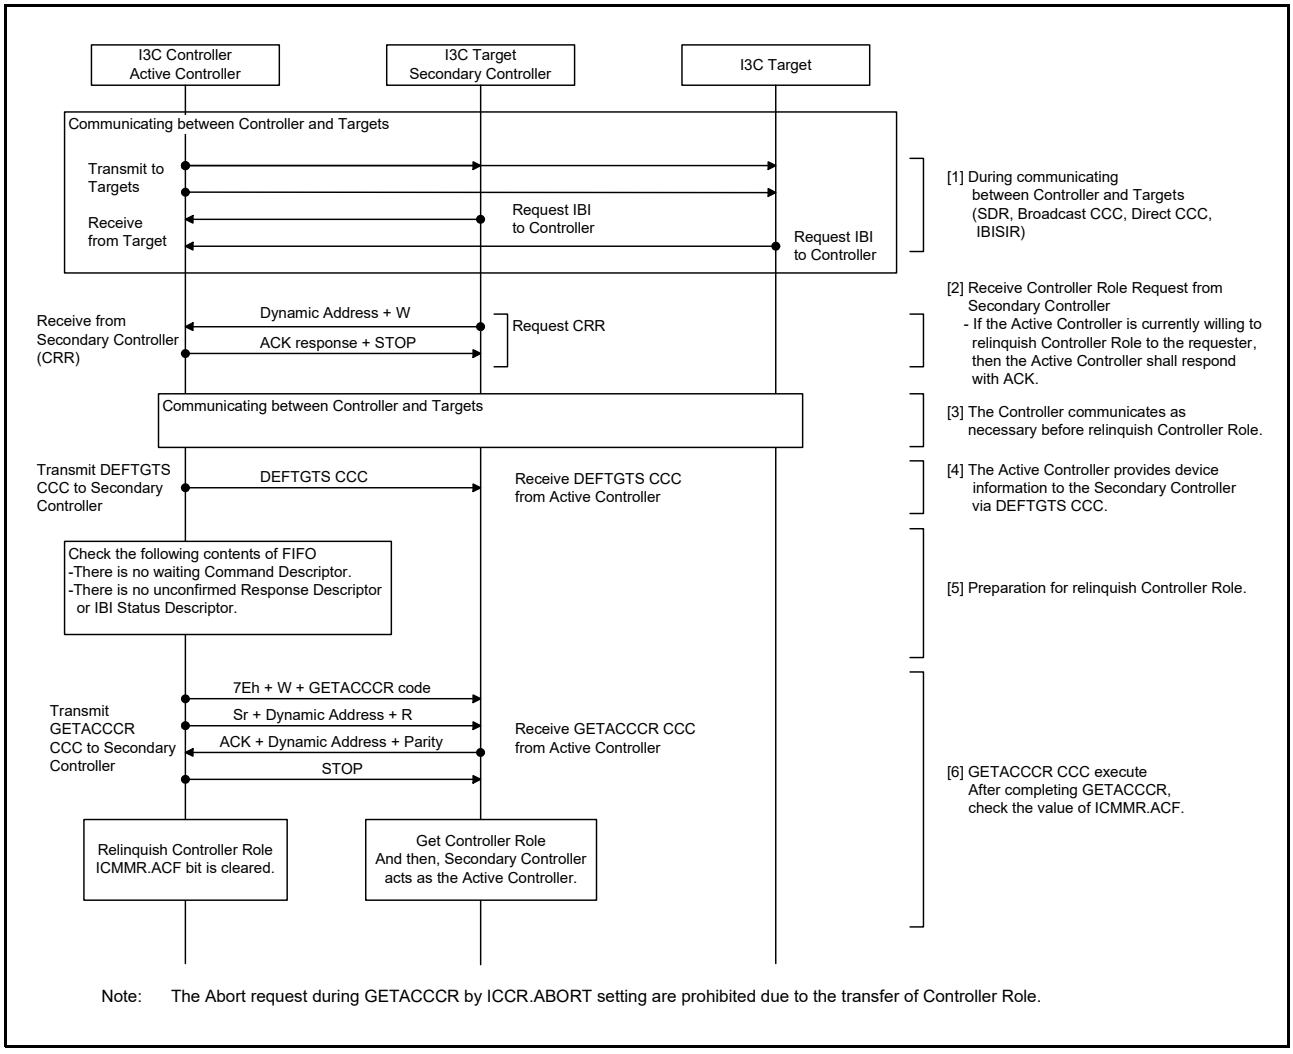

Figure 43.32 I3C Controller IBI Transfer Timing (2/2)

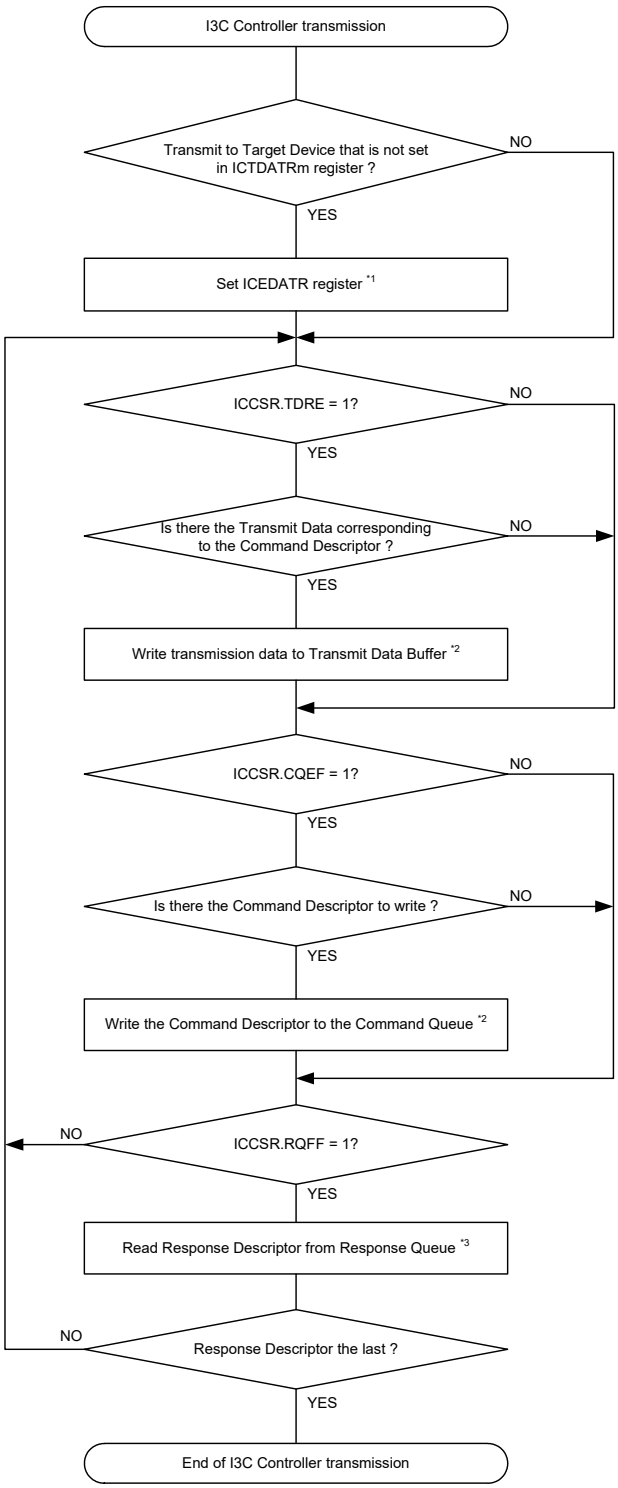
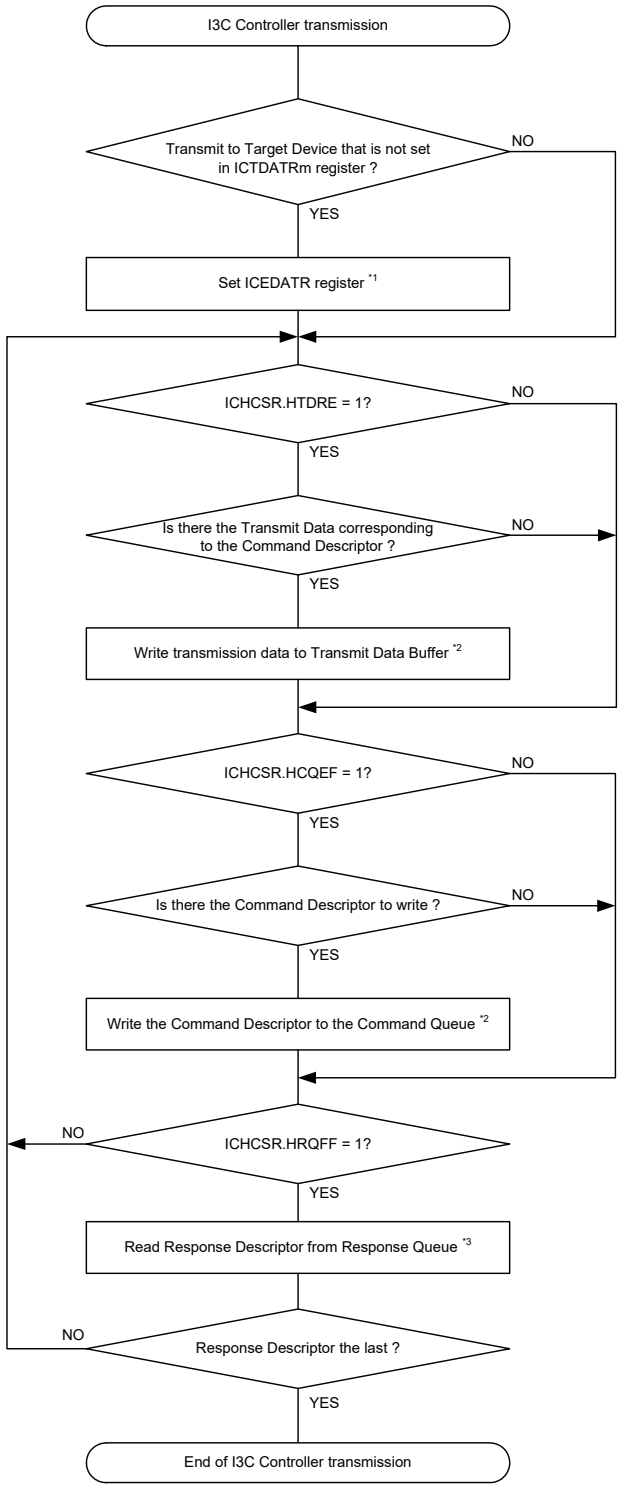


Note: The Abort request during GETACCCR by ICCR.ABORT setting are prohibited due to the transfer of Controller Role.

Figure 43.33 I3C Controller CRR Processing Flow

43.4.6.5 I3C Controller Transmission Flow (FIFO Buffer Transfer)

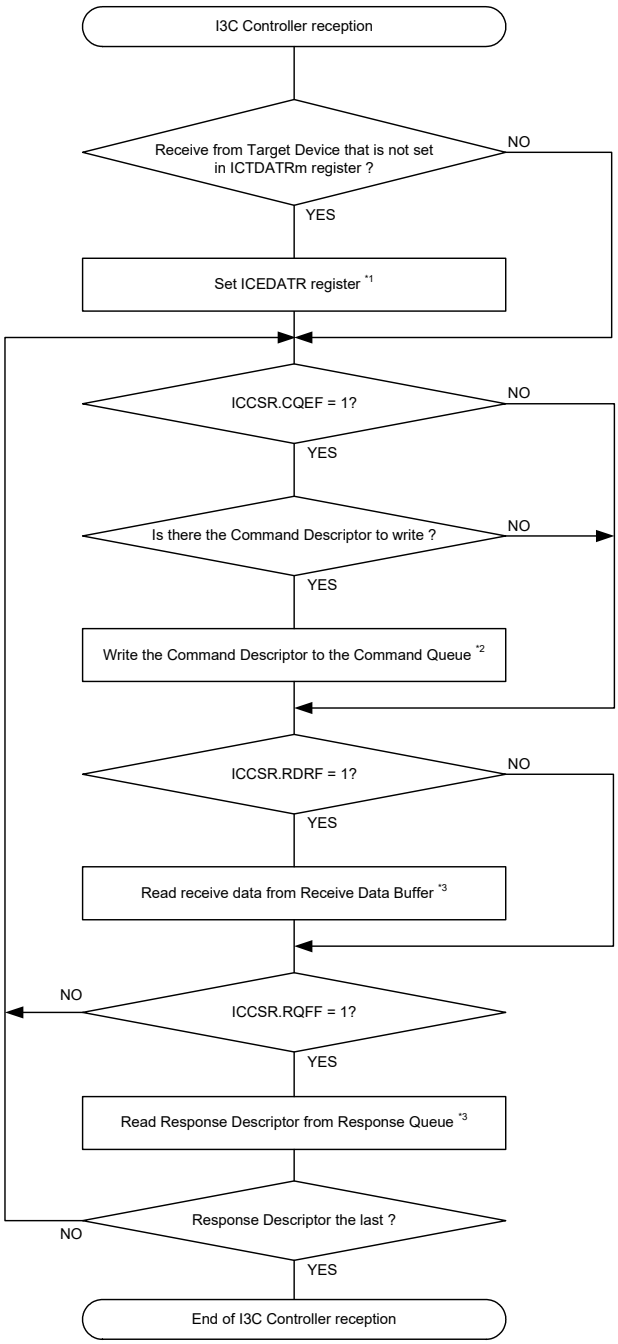


Controller transmission flow in FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).

Note 1. Changing the ICEDATR register is prohibited until all Response Descriptors of command for the Target device set in the ICEDATR register are stored.
Note 2. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 3. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 43.34 Example of I3C Controller Transmission Flowchart (FIFO Buffer Transfer)

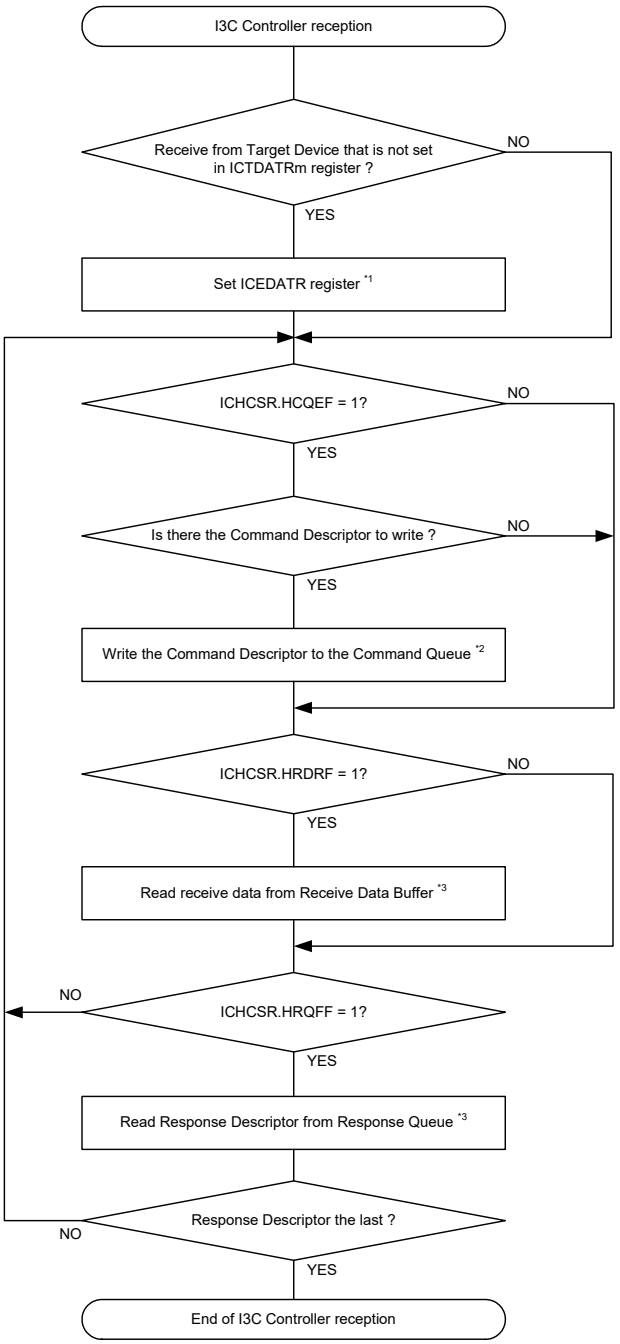
43.4.6.6 I3C Controller Transmission Flow (High-Priority FIFO Buffer Transfer)



Note 1. Changing the ICEDATR register is prohibited until all Response Descriptors of command for the Target device set in the ICEDATR register are stored.
Note 2. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 3. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 43.35 Example of I3C Controller Transmission Flowchart (High-Priority FIFO Buffer Transfer)

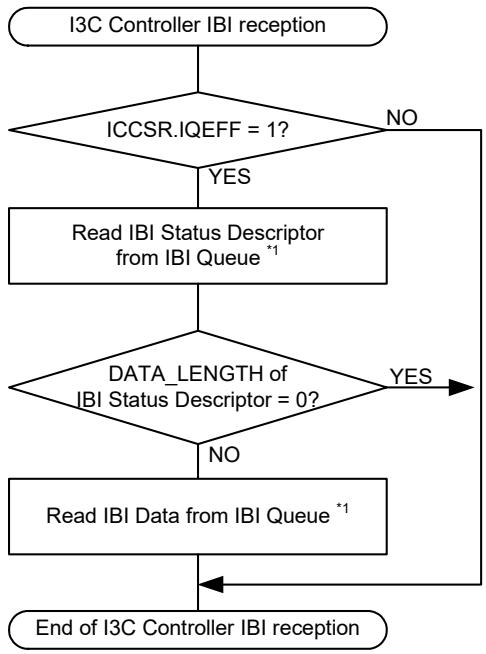
43.4.6.7 I3C Controller Reception Flow (FIFO Buffer Transfer)



Controller reception flow in FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).

Note 1. Changing the ICEDATR register is prohibited until all Response Descriptors of command for the Target device set in the ICEDATR register are stored.
Note 2. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 3. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 43.36 Example of I3C Controller Reception Flowchart (FIFO Buffer Transfer)



43.4.6.8 I3C Controller Reception Flow (High-Priority FIFO Buffer Transfer)

Note 1. Changing the ICEDATR register is prohibited until all Response Descriptors of command for the Target device set in the ICEDATR register are stored.
Note 2. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 3. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

43.4.6.9 I3C Controller IBI Reception Flow

Note 1. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 43.38 Example of I3C Controller IBI Reception Flowchart

43.4.7 I3C Target Operation

43.4.7.1 Dynamic Address Assignment Procedure

After initializing RI3C, the I3C Controller first performs Dynamic Address Assignment Procedure.
The operation of RI3C during the Dynamic Address Assignment Procedure by ENTDAA CCC is described below.

(1) Initial setting (For details, refer to section 43.4.4, Initial Settings)
(2) When ENTDAA CCC is received, RI3C transmits Provisioned ID (the ICPIDHR register and bits b15 to b0 of the ICPIDLR register), BCR (bits b15 to b8 of the ICDCTR register), DCR (bits b7 to b0 of the ICDCTR register) until a Dynamic Address is assigned. (For details, refer to In case of Broadcast CCC (ENTDAA) of 43.5.11 CCC detection function (I3C protocol mode).)
(3) When ENTDAA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in the receive status queue.
(4) Read Receive Status Descriptor via the ICSQR register and check the status.
(5) Read the data for the data length indicated by the DATA_LENGTH field of the Receive Status Descriptor from the Receive Data Buffer via the ICDR register.

Note: When multiple RI3C (I3C Target) are connected on the I3C bus assign Dynamic Addresses in the following order.
1. Set the ICPIDHR and ICPIDLR registers (6 bytes in total) of the RI3C (I3C Target) to a value (all 1 etc.) that has a lower priority than other Target devices by Dynamic Address Arbitration.
2. After setting the Static Address in the RI3C (I3C Target), assign the Dynamic Address using the SETDASA/ SETAASA command.
3. Assign a Dynamic Address to an I3C Target Device other than the RI3C (I3C Target) using the ENTDAA command.

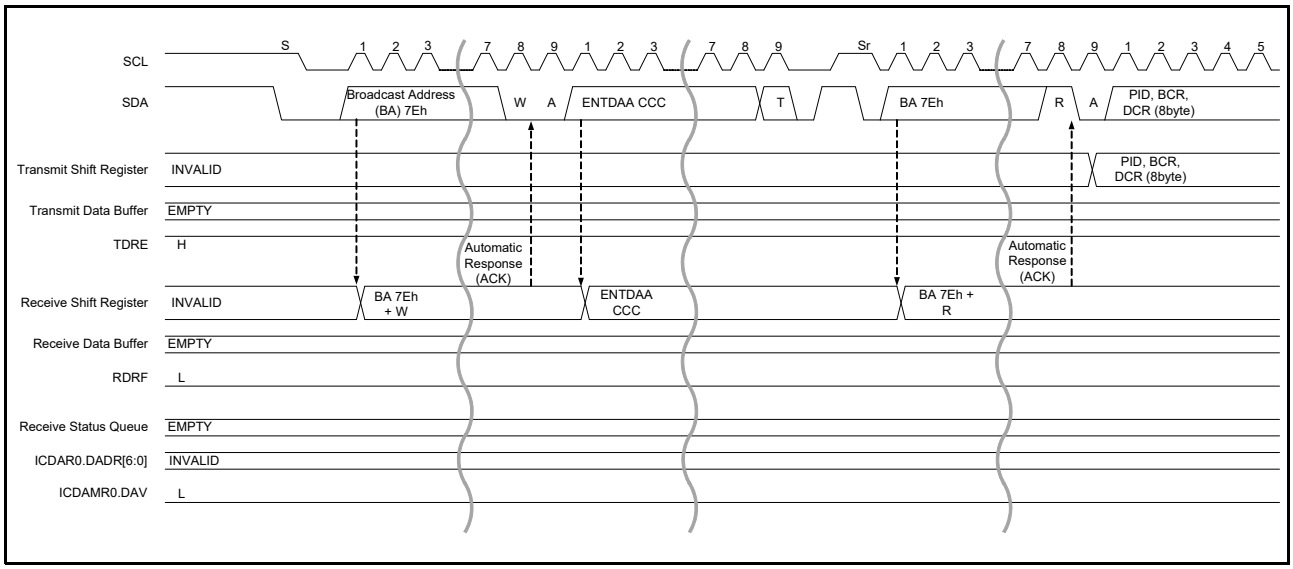

Figure 43.39 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (1/3)

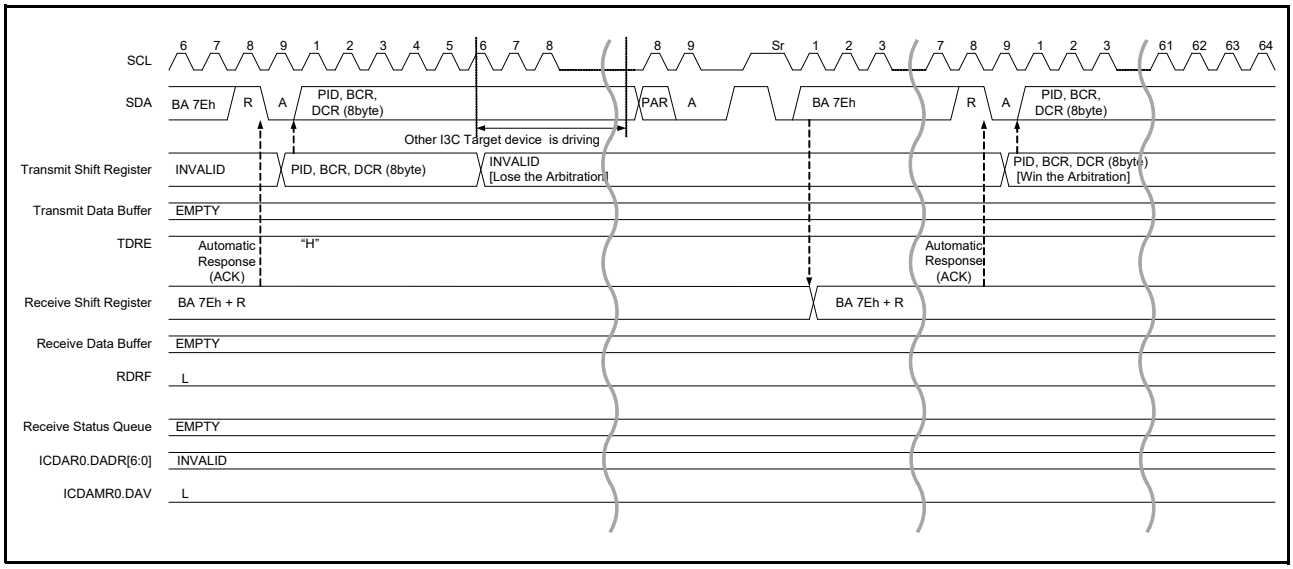

Figure 43.40 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (2/3)

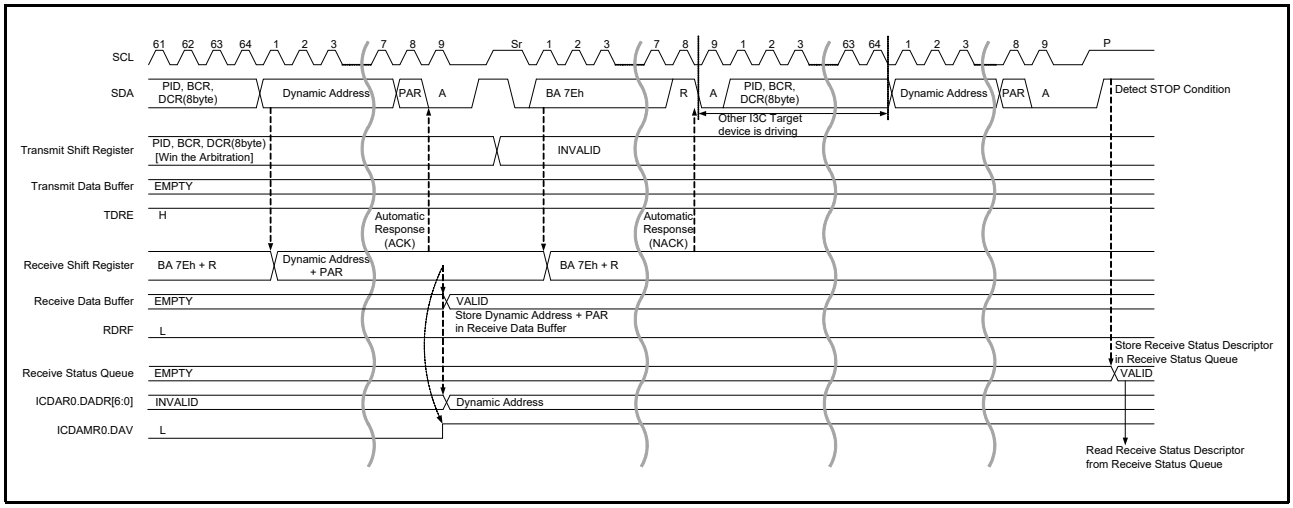

Figure 43.41 Dynamic Address Assignment Procedure (ENTDAA CCC) Timing (3/3)

When communicating with a Static Address until the Dynamic Address is assigned from the I3C Controller, by setting to the ICDARy.SADR[6:0] bits, the ICDAMRy.SAV flag is set to 1 and the Static Address Will be effective.

If the I3C Target has a Static Address and the I3C Controller executes the Dynamic Address Assignment Procedure, it is possible to assign a Dynamic Address with SETDASA CCC.

The operation of RI3C during SETDASA CCC Dynamic Address Assignment Procedure is described below.

(1) Initial setting (For details, refer to section 43.4.4, Initial Settings)

(2) When SETDASA CCC which agrees with its own Static Address is received, the ICDARy.DADR[6:0] bits are renewed and the ICDAMRy.DAV flag is set to 1. (For details, refer to In case of Direct Write CCC of 43.5.11 CCC detection function (I3C protocol mode).)

(3) When SETDASA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in receive status queue.

(4) Read Receive Status Descriptor via ICSQR register and check the status.

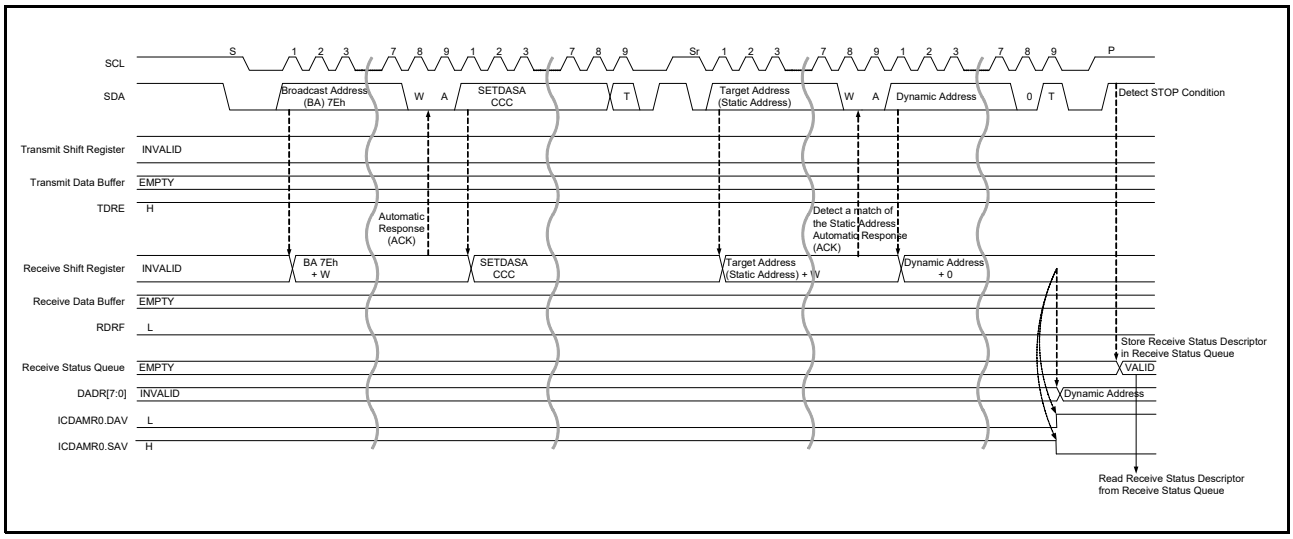

Figure 43.42 Dynamic Address Assignment Procedure (SETDASA CCC) Timing

43.4.7.2 SDR Write Transfer

(1) When Transaction is issued from the I3C Controller, it compares the Target Address in Address header with its own Target Address, and if it matches, RI3C responds with ACK.
When a Transaction is received, if the Receive Data Buffer is full, the I3C Target will respond with NACK in the Address header.
In preparation for retrying the I3C Controller, read the data from the Receive Data Buffer via the ICDR register, and empty the Receive Data Buffer.

(2) Data received from I3C Controller is stored in the Receive Data Buffer.

(3) In the receive data full interrupt, read the received data from the Receive Data Buffer via the ICDR register.

(4) When repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the receive status queue.

(5) Read Receive Status Descriptor via ICSQR register and check the status.

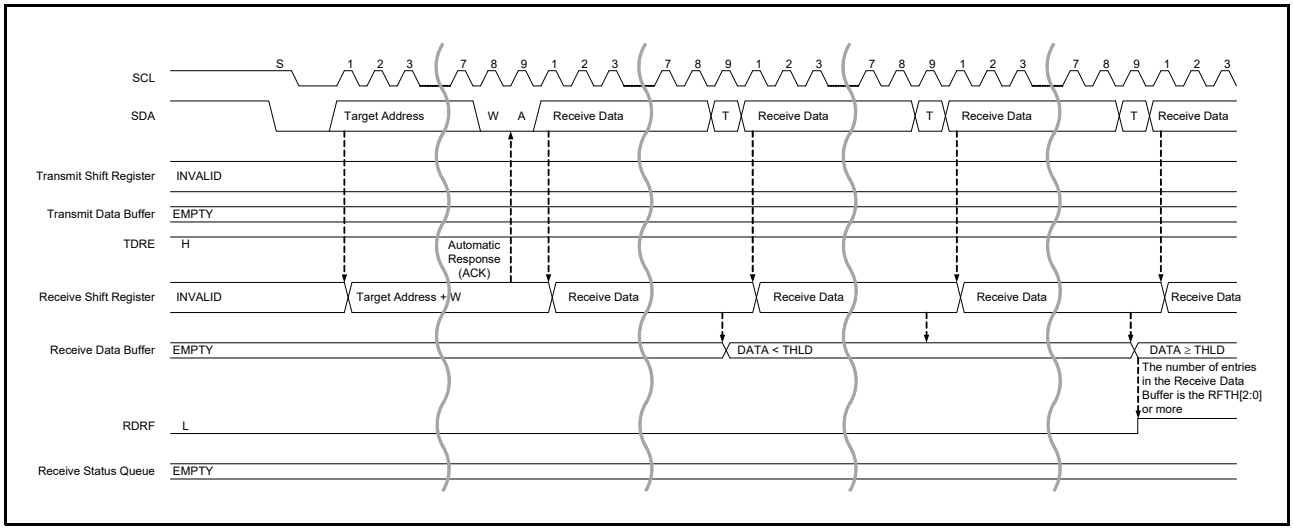

Figure 43.43 SDR Write Transfer Timing (1/2)

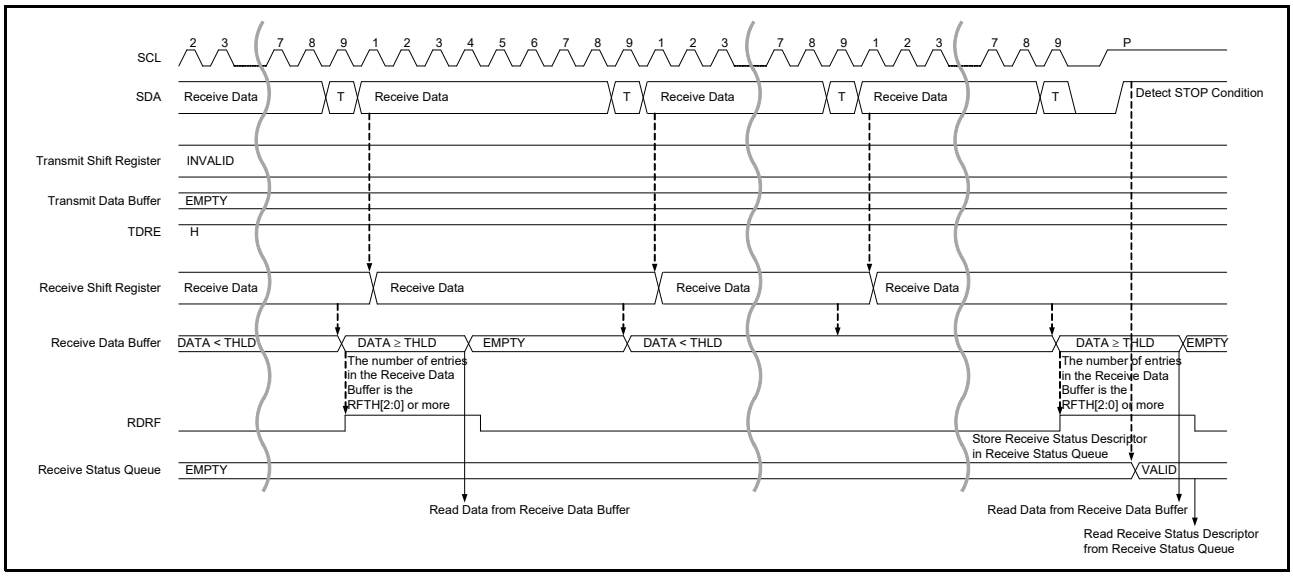

Figure 43.44 SDR Write Transfer Timing (2/2)

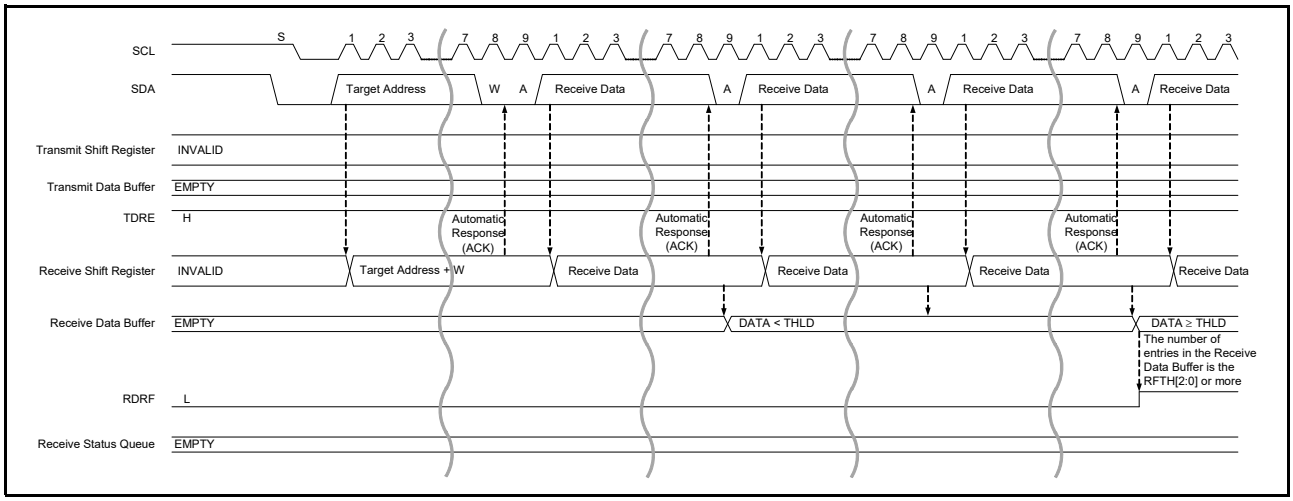

Figure 43.45 Legacy I²C Write Transfer Timing (1/2)

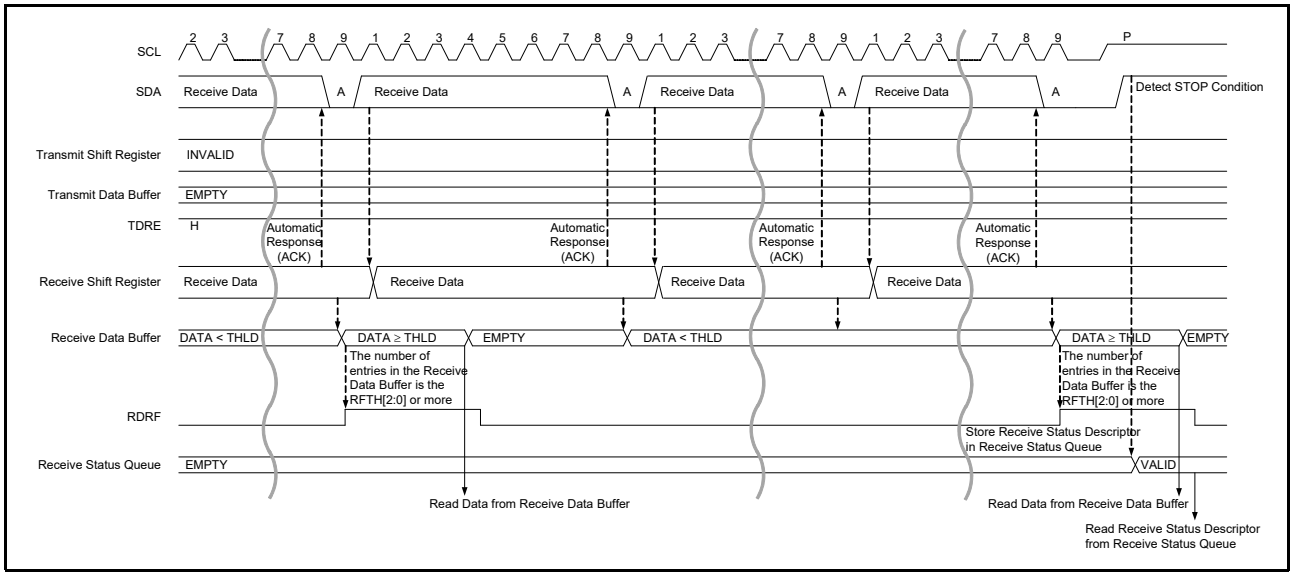

Figure 43.46 Legacy I²C Write Transfer Timing (2/2)

43.4.7.3 SDR Read Transfer

(1) Write the data requested from the I3C Controller to the Transmit Data Buffer via the ICDR register.

(2) When Transaction is issued from the I3C Controller, it compares the Target Address in Address header with its own Target Address, and if it matches, RI3C responds with ACK.
When a Transaction is received, if the Transmit Data Buffer is EMPTY, I3C Target responds with NACK with the Address header.
In preparation for retrying the I3C Controller, write data to the Transmit Data Buffer via the ICDR register.

(3) Transmit the data stored in the Transmit Data Buffer.

(4) If data to be transmitted still remains, write the data to be transmitted with a transmit data empty interrupt to the Transmit Data Buffer via the ICDR register.

(5) SDR:
When the transmission of the data stored in the Transmit Data Buffer is completed, Low is output to the T-bit following Data, and it is notified to the I3C Controller that it is the final data.
Legacy I^2C Message:
When NACK is detected, data transmission is terminated.

(6) When a repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the receive status queue.

(7) Read the Receive Status Descriptor via ICSQR and check the status.
If the data length does not match, set the ICRCR.ISRST bit to 1 and then reset the internal states of this module.
For details, refer to 43.5.16.6 Error Recovery Operation.

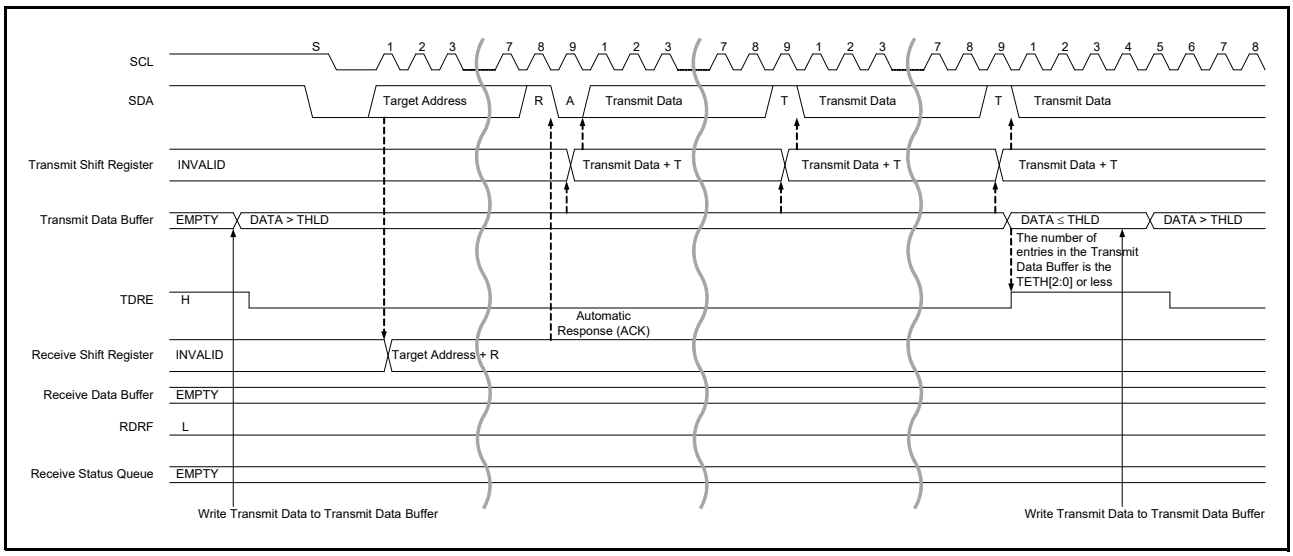

Figure 43.47 SDR Read Transfer Timing (1/2)

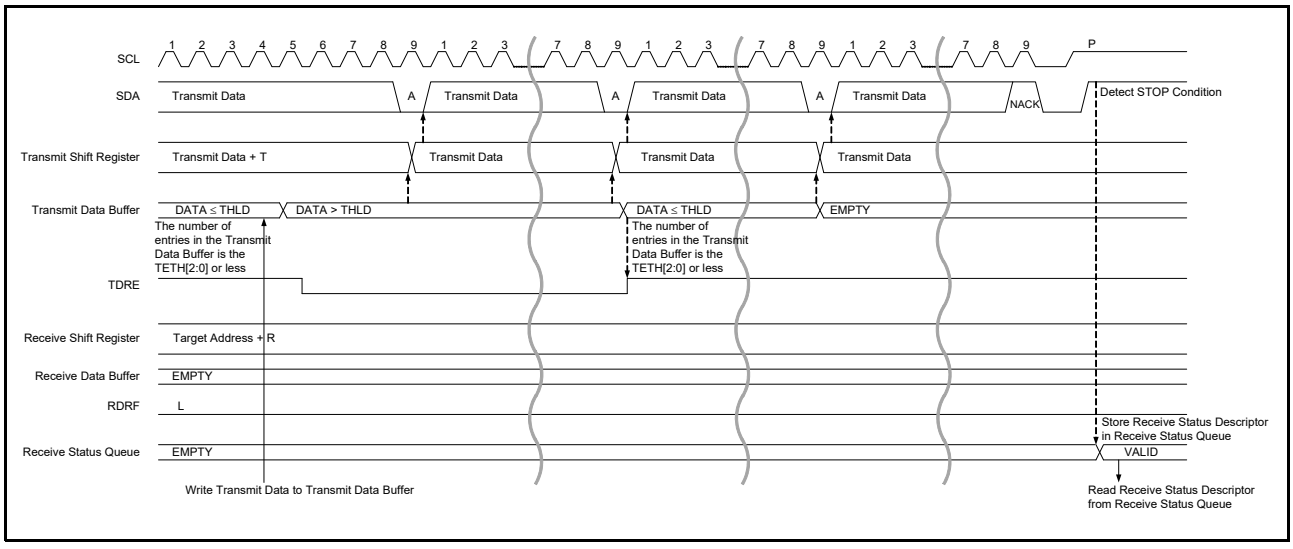

Figure 43.50 Legacy I²C Read Transfer Timing (2/2)

43.4.7.4 IBI Transfer

(1) When sending Target Interrupt Request.
When transmitting IBI Data, write IBI Data to the IBI Data Buffer via the ICIQR register.

(2) Write Command Descriptor (immediate data transfer command or regular data transfer command) to the command queue for IBI Transfer via the ICCQR register.

(3) When Command Descriptor is written to command queue, IBI Transaction is issued under the following conditions.

- Detect a START condition. (Does not apply a repeated START condition)
- If no START condition is forthcoming within the following bus condition, then this module issue a START Request by pulling the SDA line Low.
- (a) Target Interrupt Request, Controller Role Request: Bus Available

(4) In Target Address and RnW field in the Address header, if losing Arbitration by issuing a Transaction from I3C Controller, stop issuing Transaction.
When detecting repeated START condition or STOP condition, store the Response Descriptor into the response queue.

(5) When sending Target Interrupt Request:

- When IBI data for transmission still remain, write IBI data with an IBI queue empty/full interrupt to the IBI queue via the ICIQR register.
- When the transmission of IBI Data for the number of data length specified by the DATA_LENGTH field of the Command Descriptor is completed, output Low to the T-bit following IBI Data and notify the I3C Controller that it is the final IBI Data.

(6) When detecting repeated START condition or STOP condition, store the Response Descriptor into the response queue.

(7) Read the Response Descriptor from the response queue with the ICRQR register and check the status. If NACK is responded, repeat steps (1) to (7).

(8) When sending Target Interrupt Request:
Check that the value of the DATA_LENGTH field of the Response Descriptor is 0.

The CRR processing flow is shown in Figure 43.53.

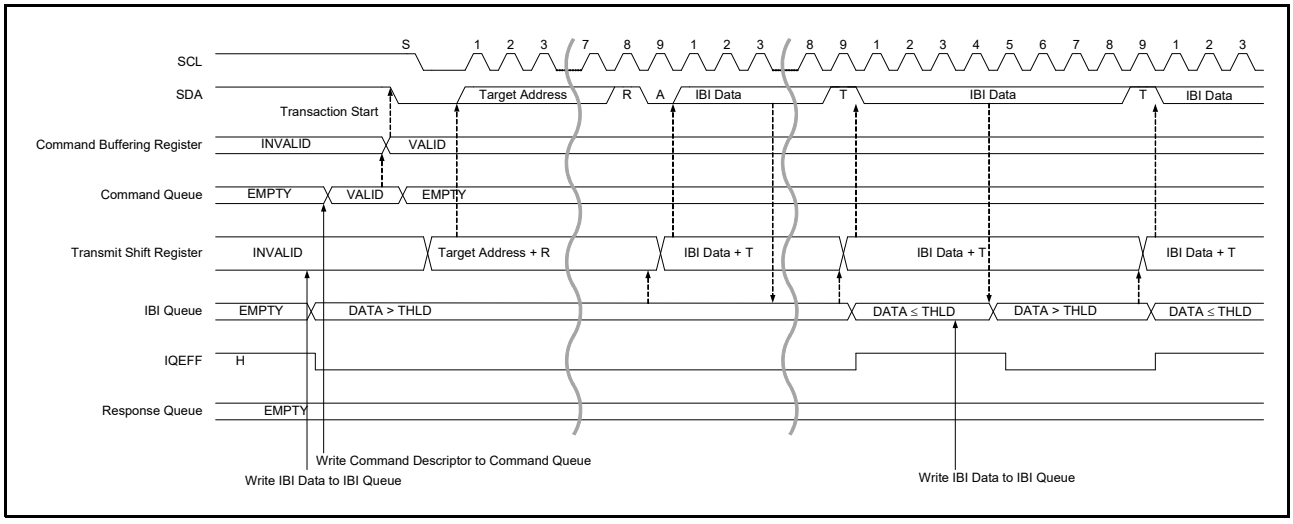

Figure 43.51 I3C Target IBI Transfer Timing (1/2)

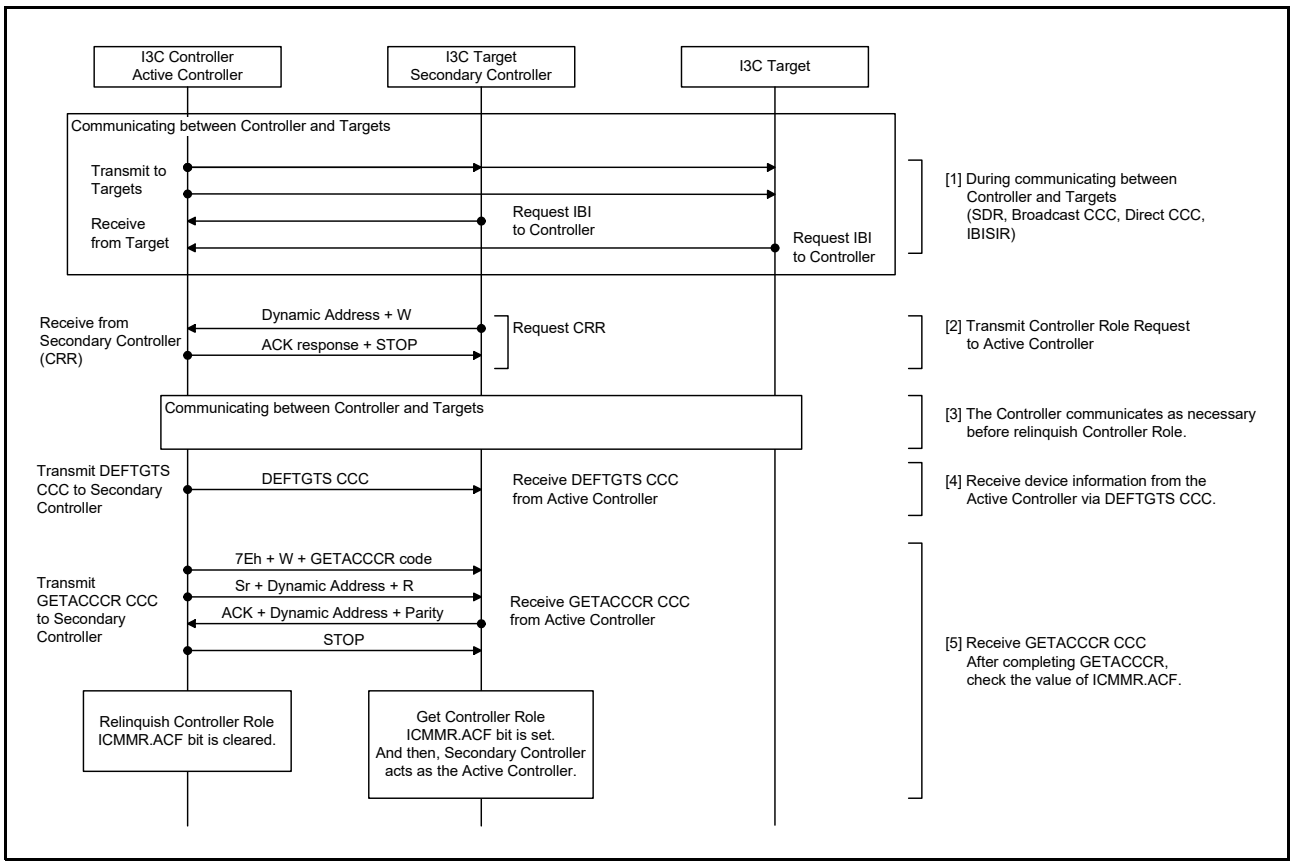

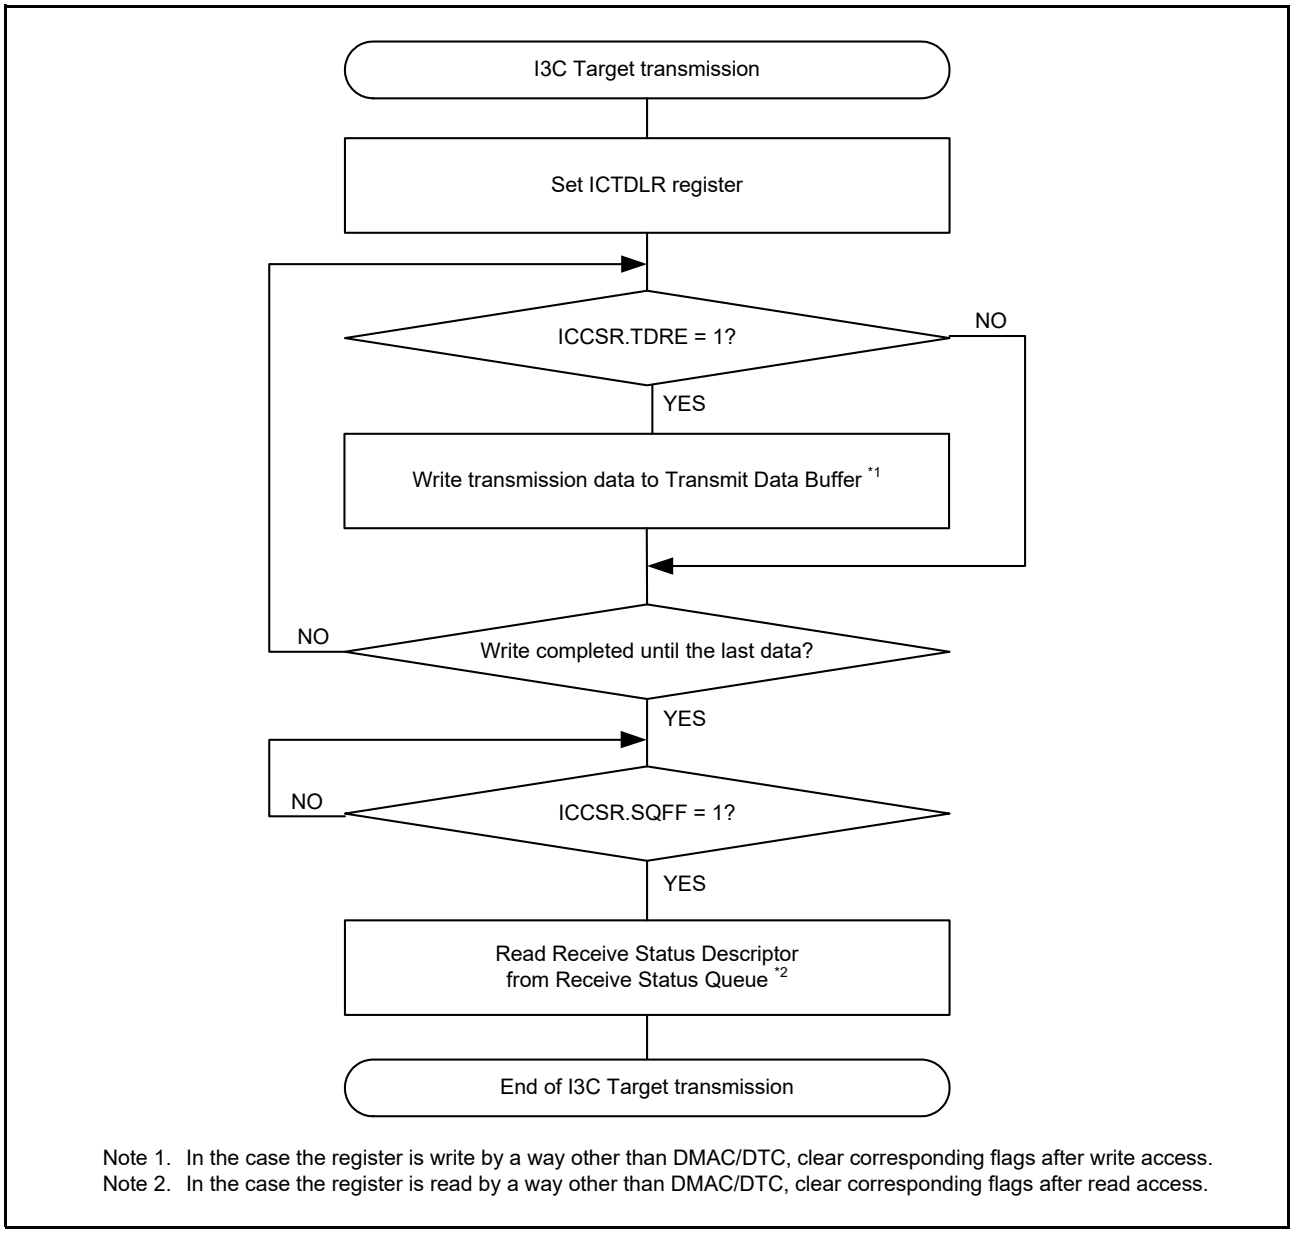

Figure 43.53 I3C Target CRR Processing Flow

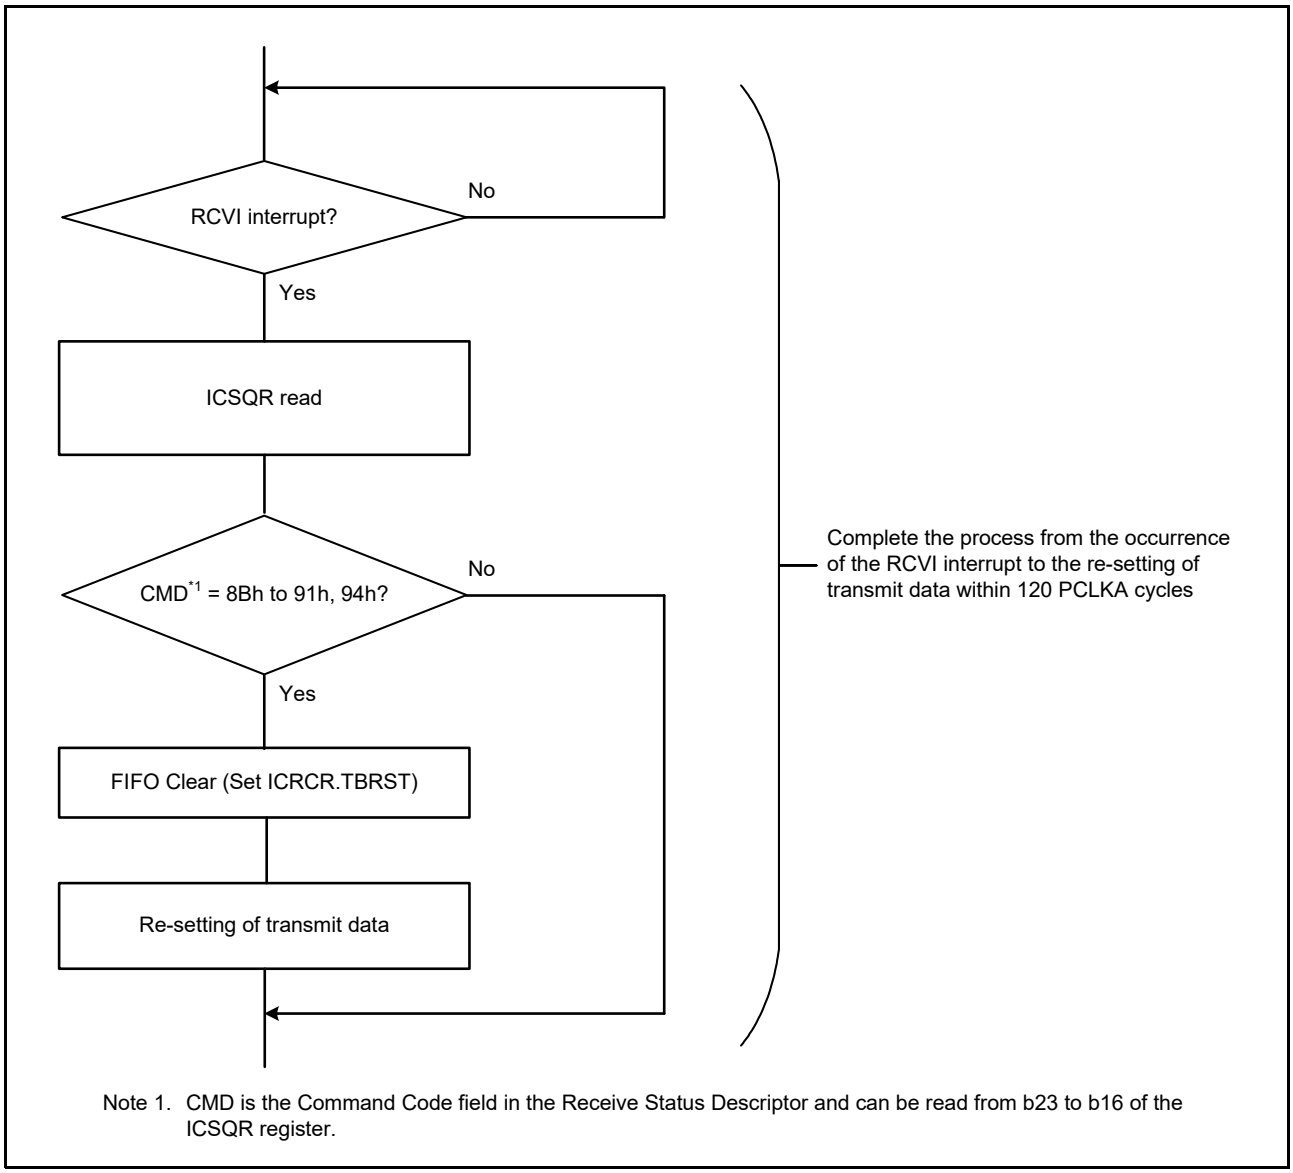
43.4.7.5 I3C Target Transmission Flow (FIFO Buffer Transfer)

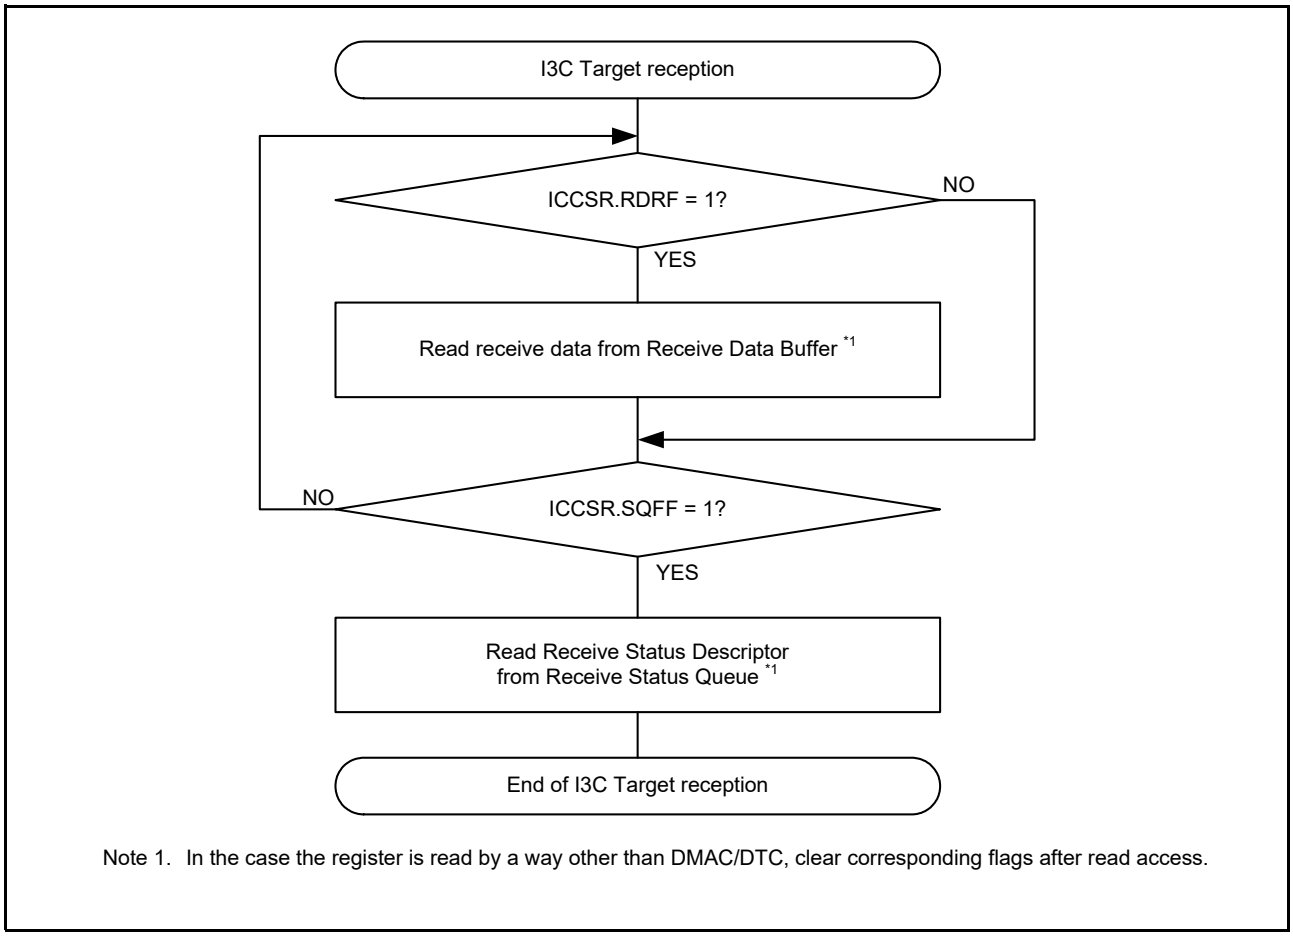


Target Transmission Flow in FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).

Note 1. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 2. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 43.54 Example of I3C Target Transmission Flowchart (FIFO Buffer Transfer)

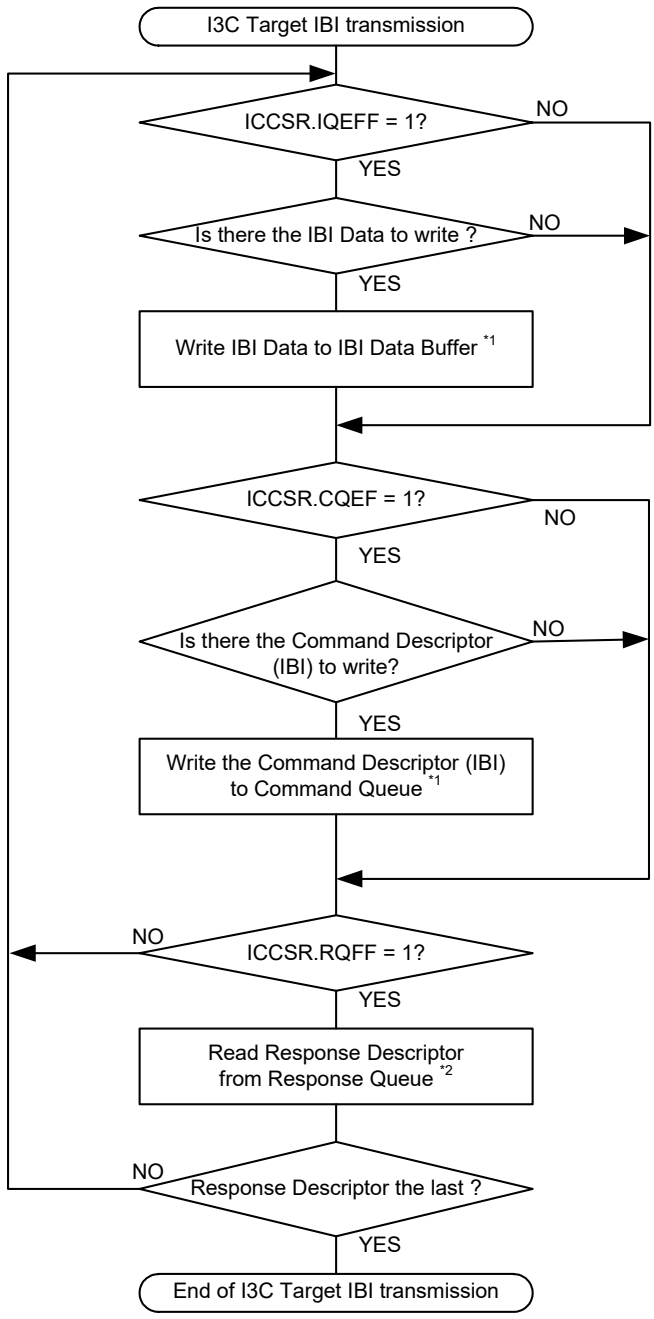
When using the RI3C as an I3C Target, if I3C Target receives GET CCC while data exists by writing from the ICDR register to the transmit buffer, follow the flow below.



Note 1. CMD is the Command Code field in the Receive Status Descriptor and can be read from b23 to b16 of the ICSQR register.

Figure 43.55 I3C Target Receives GET CCC Command while Data Exists by Writing from the ICDR Register to the Transmit Buffer

43.4.7.6 I3C Target Reception Flow (FIFO Buffer Transfer)



Target Reception Flow in FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).

Note 1. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 43.56 Example of I3C Target Reception Flowchart (FIFO Buffer Transfer)

43.4.7.7 I3C Target IBI Transmission Flow

Note 1. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 2. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 43.57 Example of I3C Target IBI Transmission Flowchart

43.4.8 I2C Master Operation

43.4.8.1 Master Transmit Operation

In master transmit operation, the RI3C outputs the SCL and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 43.58 shows an example of usage of master transmission and Figure 43.59 to Figure 43.61 show the timing of operations in master transmission.
The following describes the procedure and operations for master transmission.

(1) Initial settings. For details, refer to section 43.4.4, Initial Settings.
(2) Read the ICBSR.BFREE flag to check that the bus is open, and then set the ICCGR.ST bit to 1 (requests to generate a START condition). Upon receiving the request, the RI3C generates a START condition. At the same time, the BFREE flag is automatically set to 0, the ICSR2.START flag is automatically set to 1 and the ICCGR.ST bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the SDA00 line have matched while the ICCGR.ST bit is 1, the RI3C recognizes that generating of the START condition as requested by the ICCGR.ST bit has been successfully completed, and the ICMMR.ACF and ICMMR.TRS flags are automatically set to 1, placing the RI3C in master transmit mode. The ICCSR.TDRE flag is also automatically set to 1 in response to setting of the TRS flag to 1.
(3) Check that the ICCSR.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDR register. Once the data for transmission are written to ICDR register, the ICCSR.TDRE flag is automatically set to 0, and the ICCSR.TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS flag is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RI3C continues in master transmit mode. Since the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCGR.SP bit to generate a STOP condition.
For data transmission with an address in the 10-bit format, start by writing 1111 0b, the 2 higher-order bits of the slave address, and W to ICDR register as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to ICDR register.
(4) After confirming that the ICCSR.TDRE flag is 1, write the data for transmission to the ICDR register. The RI3C automatically holds the SCL00 line low until the data for transmission are ready or a STOP condition is generated
(5) After all bytes of data for transmission have been written to the ICDR register, wait until the value of the ICSR2.TEND flag returns to 1, and then set the ICCGR.SP bit to 1 (requests to generate a STOP condition). Upon receiving a STOP condition generation request, the RI3C generates the STOP condition.
(6) Upon detecting the STOP condition, the RI3C automatically sets the ICMMR.ACF and ICMMR.TRS flags to 00b and enters slave receive mode. Furthermore, it automatically sets the ICCSR.TDRE flag to 0, ICSR2.TEND flag to 0 and sets the ICSR2.STOP flag to 1.
(7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

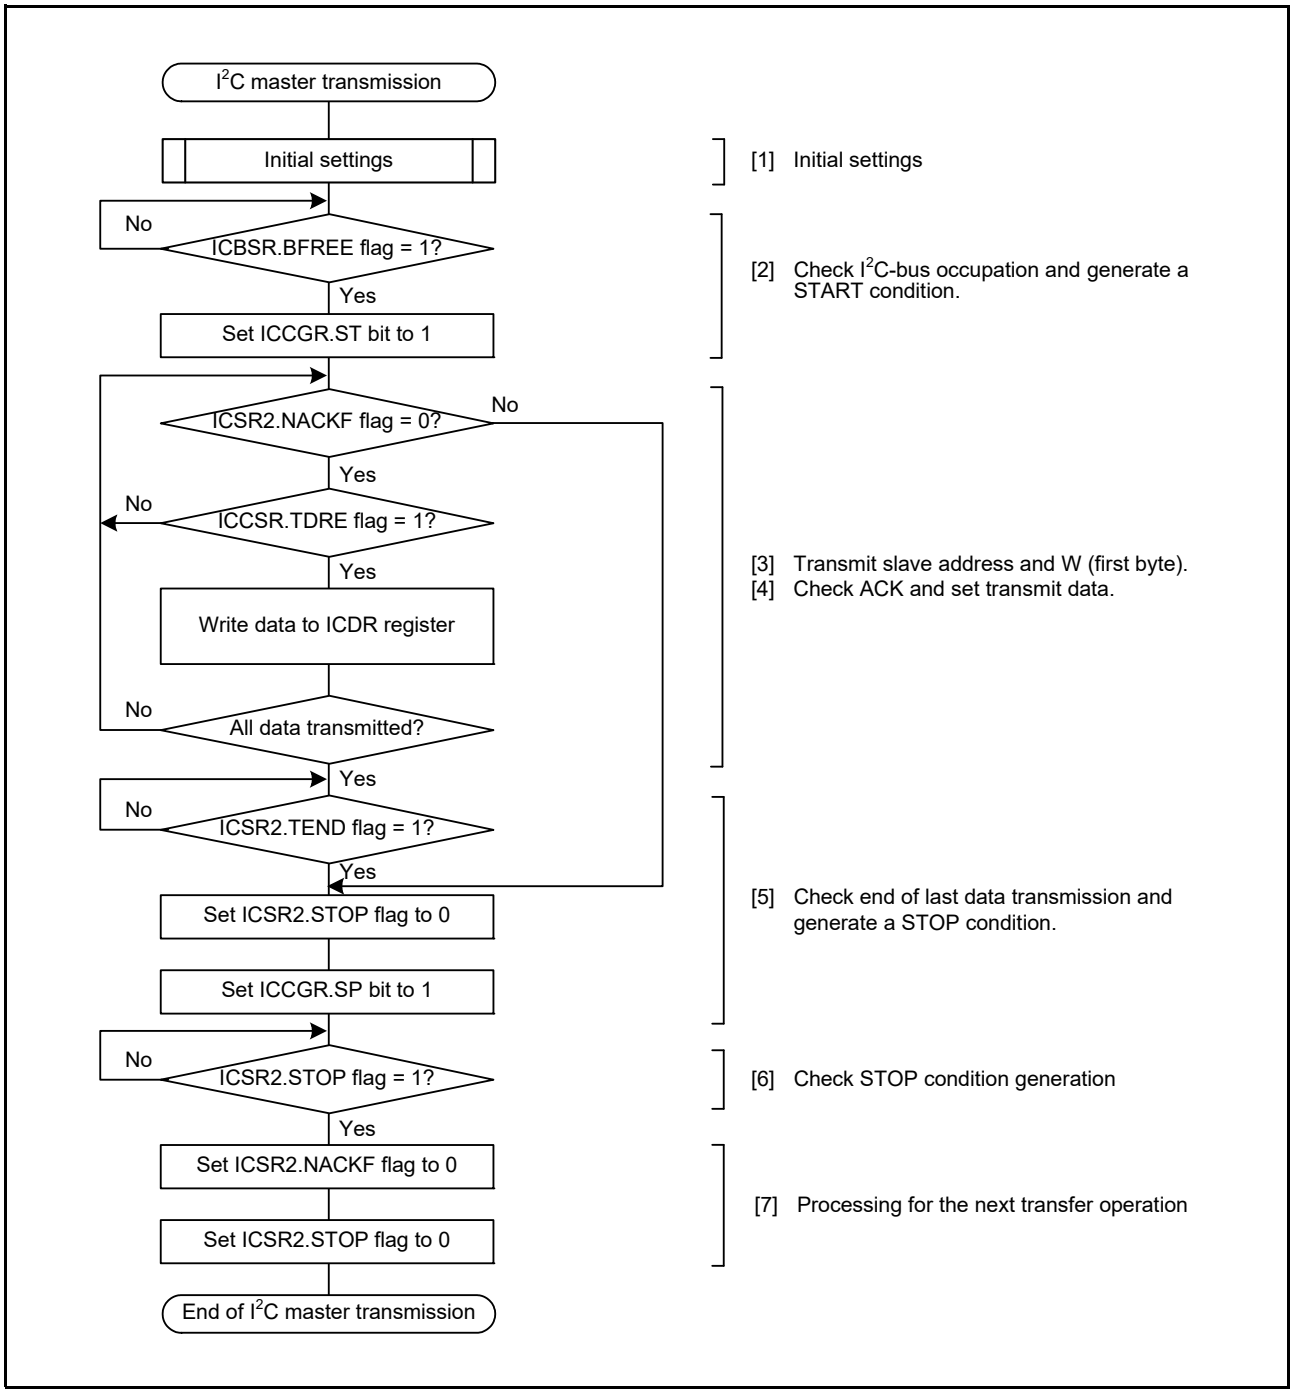


Figure 43.58 Example of I2C Master Transmission Flowchart

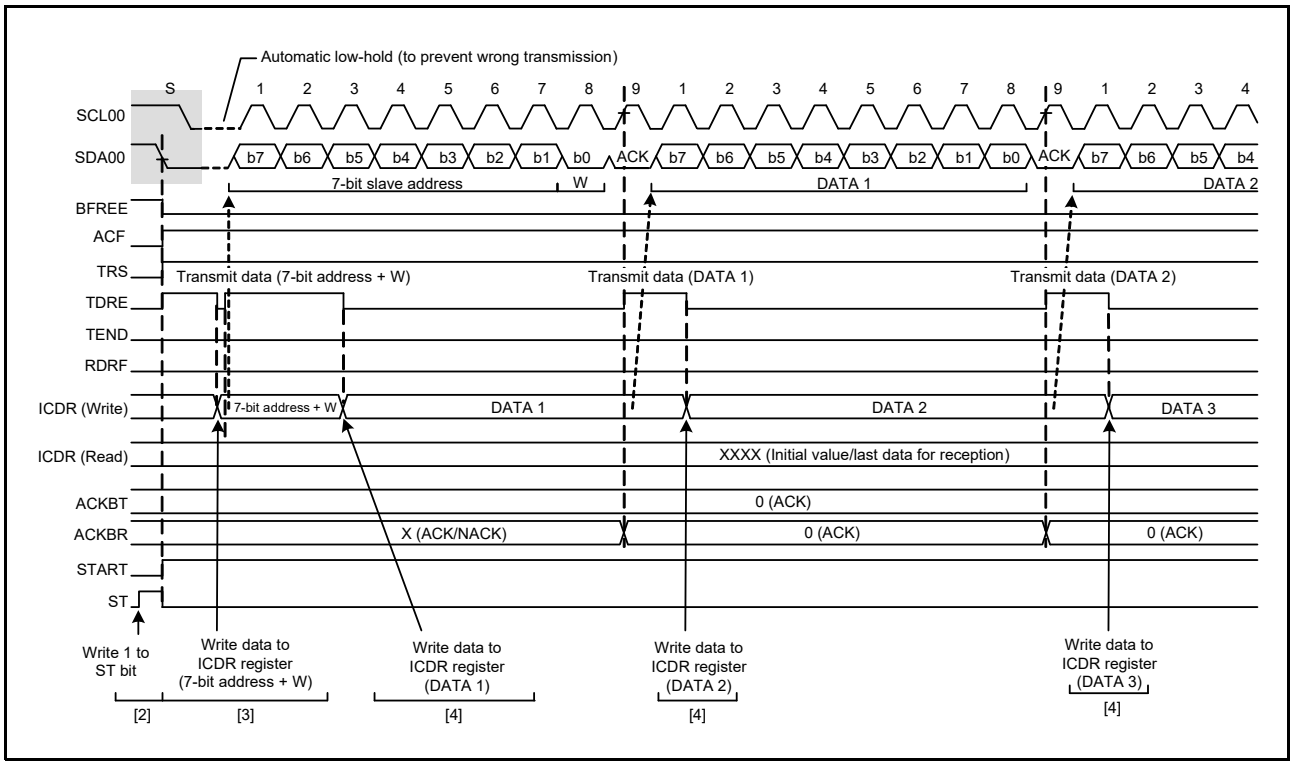

Figure 43.59 Master Transmit Operation Timing (1) (7-Bit Address Format)

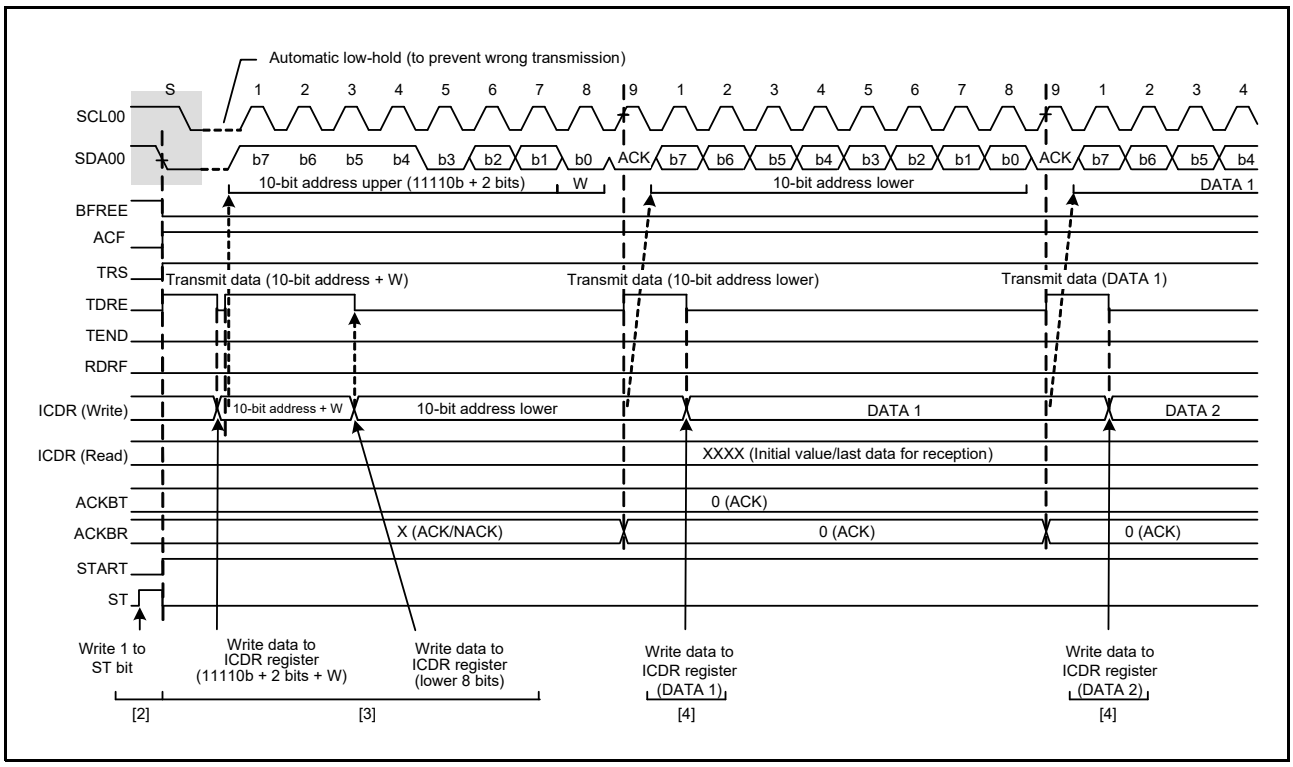

Figure 43.60 Master Transmit Operation Timing (2) (10-Bit Address Format)

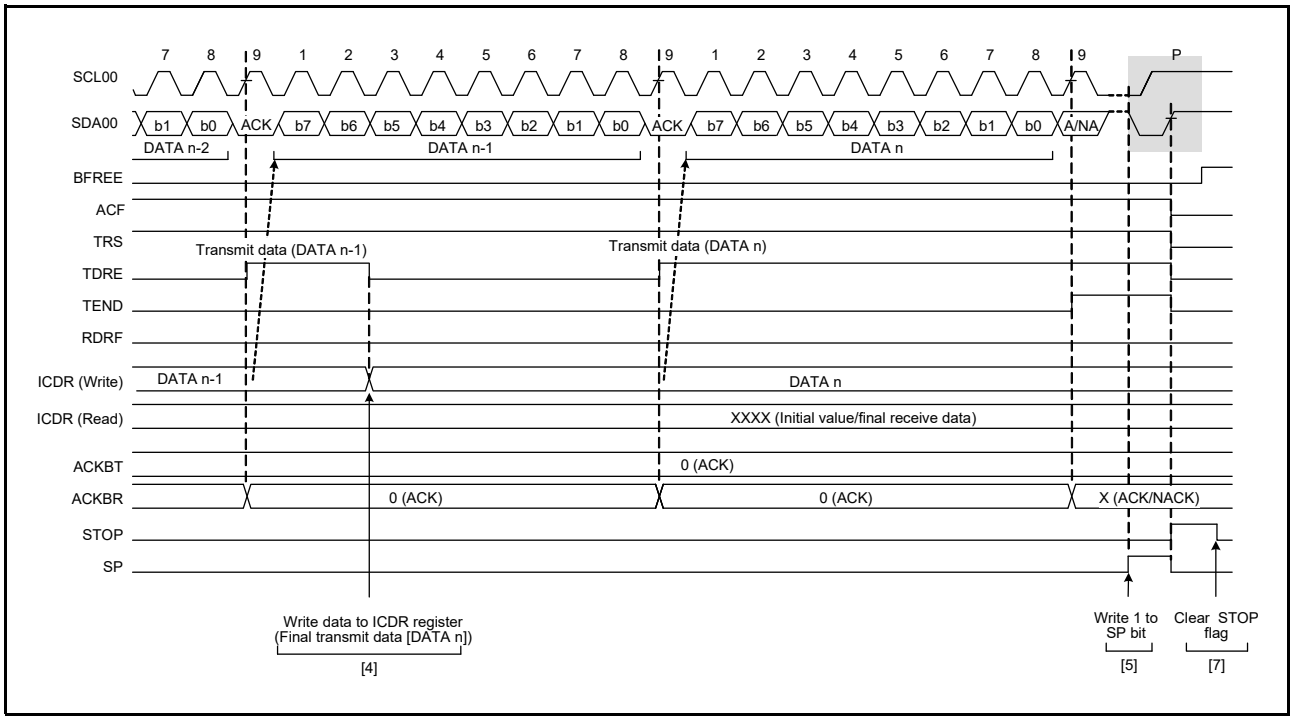

Figure 43.61 Master Transmit Operation Timing (3)

43.4.8.2 Master Receive Operation

In master receive operation, the RI3C as a master device outputs the SCL, receives data from the slave device, and returns acknowledgments. Since the RI3C must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.
Figure 43.62 and Figure 43.63 show examples of usage of master reception and Figure 43.64 to Figure 43.66 show the timing of operations in master reception.
The following describes the procedure and operations for master reception.

(1) Initial settings. For details, refer to section 43.4.4, Initial Settings.
(2) Read the ICBSR.BFREE flag to check that the bus is open, and then set the ICCGR.ST bit to 1 (requests to generate a START condition). Upon receiving the request, the RI3C generates a START condition. When the RI3C detects the START condition, the ICBSR.BFREE flag is automatically set to 0 and the ICSR2.START flag is automatically set to 1 and the ICCGR.ST bit is automatically set to 0. At this time, if the START condition is detected and the levels for the SDA output and the levels on the SDA00 line have matched while the ICCGR.ST bit is 1, the RI3C recognizes that generating of the START condition as requested by the ICCGR.ST bit has been successfully completed, and the ICMMR.ACF and ICMMR.TRS flags are automatically set to 1, placing the RI3C in master transmit mode. The ICCSR.TDRE flag is also automatically set to 1 in response to setting of the TRS flag to 1.
(3) Check that the ICCSR.TDRE flag is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDR register. Once the data for transmission are written to ICDR register, the ICCSR.TDRE flag is automatically set to 0, and the ICCSR.TDRE flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the ICMMR.TRS flag is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRS flag is set to 0 on the rising edge of the ninth SCL, placing the RI3C in master receive mode. At this time, the ICCSR.TDRE flag is set to 0 and if the slave device acknowledges the ICCSR.RDRF flag is automatically set to 1.
If no slave device recognized the address or there was an error in communications, the ICSR2.NACKF flag becomes 1. In this case, write 1 to the ICCGR.SP bit to generate a STOP condition. For master reception from a device with a 10-bit address, start by using master transmission to send the 10-bit address, and then generate a repeated START condition. After that, transmitting 1111 0b, the two higher-order bits of the slave address, and the R bit places the RI3C in master receive mode.
(4) Dummy read ICDR register after confirming that the ICCSR.RDRF flag is 1; this makes the RI3C start output of the SCL and start data reception.
(5) After 1 byte of data has been received, the ICCSR.RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL (the clock signal) as selected by the ICCSCR.WAITAE bit. Reading out ICDR register at this time will produce the received data, and the RDRF flag is automatically set to 0 at the same time. Furthermore, the value of the acknowledgment bit received during the ninth SCL is returned as the value set in the ICACKR.ACKBT bit. Furthermore, if the next byte to be received is the next to last byte, set the ICCSCR.WAITRE bit to 1 (for wait insertion) before reading the ICDR register (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ICACKR.ACKBT bit to 1 (NACK) in step (6), due to other interrupts, etc., this fixes the SCL00 line to low on the falling edge of the ninth clock pulse in reception of the last byte, so the state is such that generating a STOP condition is possible.
(6) When the ICCSCR.WAITAE bit is 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ICACKR.ACKBT bit to 1 (NACK).
(7) After reading out the byte before last from the ICDR register, if the value of the ICCSR.RDRF flag is confirmed to be 1, write 1 to the ICCGR.SP bit (requests to generate a STOP condition) and then read the last byte from ICDR register. When the ICCGR.SP bit is set to 1, the RI3C is released from the wait state and generates the STOP condition after low-level output in the ninth clock pulse is completed or the SCL00 line is released from the low-hold state.

(8) Upon detecting the STOP condition, the RI3C automatically sets the ICMMR.ACF and ICMMR.TRS flags to 00b and enters slave receive mode. Furthermore, detection of the STOP condition leads to setting of the ICSR2.STOP flag to 1.

(9) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

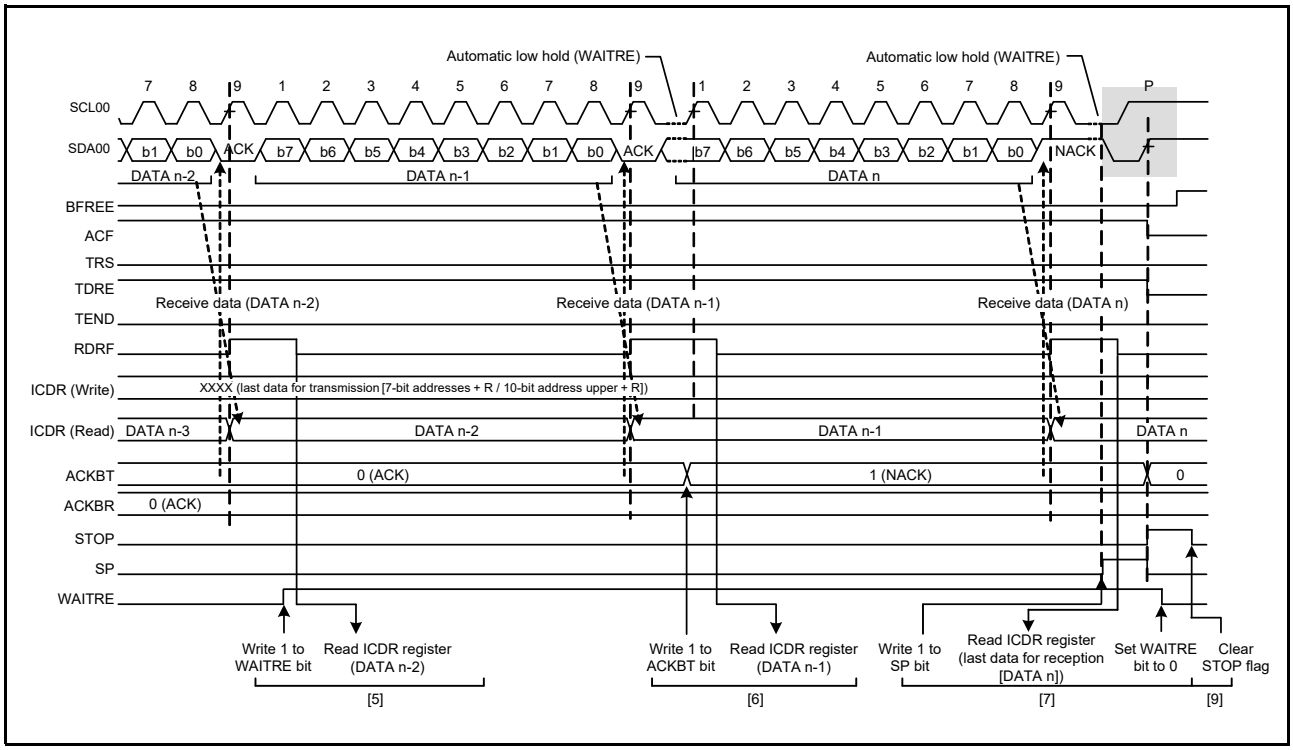

Figure 43.66 Master Receive Operation Timing (3) (When WAITAE = 0)

43.4.9 I2C Slave Operation

43.4.9.1 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL, the RI3C transmits data as a slave device, and the master device returns acknowledgments.
Figure 43.67 shows an example of usage of slave transmission and Figure 43.68 and Figure 43.69 show the timing of operations in slave transmission.
The following describes the procedure and operations for slave transmission.

(1) Initial settings. For details, refer to section 43.4.4, Initial Settings.
After initial settings, the RI3C will stay in the standby state until it receives a slave address that it matches.
(2) After receiving a matching slave address, the RI3C sets one of the corresponding flags ICSSR.HOA, ICSSR.GCA, and ICSSR.AASy (y = 0 to 2) to 1 on the rising edge of the ninth SCL (the clock signal) and outputs the value set in the ICACKR.ACKBT bit to the acknowledgment bit on the ninth SCL. Set the ACKBT bit to 0 in advance. If the value of the R/W# bit that was also received at this time is 1, the RI3C automatically places itself in slave transmit mode by setting both the ICMMR.TRS flag and the ICCSR.TDRE flag to 1.
(3) After the ICCSR.TDRE flag is confirmed to be 1, write the data for transmission to the ICDR register. At this time, if the RI3C receives no acknowledgment from the master device (receives an NACK signal) while the ICSER.NAKDE bit is 1, the RI3C suspends transfer of the next data.
(4) Wait until the ICSR2.TEND flag is set to 1 while the ICCSR.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDR register. When the ICSR2.NACKF flag or the TEND flag is 1, the RI3C drives the SCL00 line low on the falling edge of ninth SCL.
(5) When the ICSR2.NACKF flag or the ICSR2.TEND flag is 1, dummy read ICDR register to complete the processing. This releases the SCL00 line.
(6) Upon detecting the STOP condition, the RI3C automatically sets flags ICSSR.HOA, ICSSR.GCA, and ICSSR.AASy (y = 0 to 2), flags ICCSR.TDRE and ICSR2.TEND, and the ICMMR.TRS flag to 0, and enters slave receive mode.
(7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and ICSR2.STOP flags to 0 for the next transfer operation.

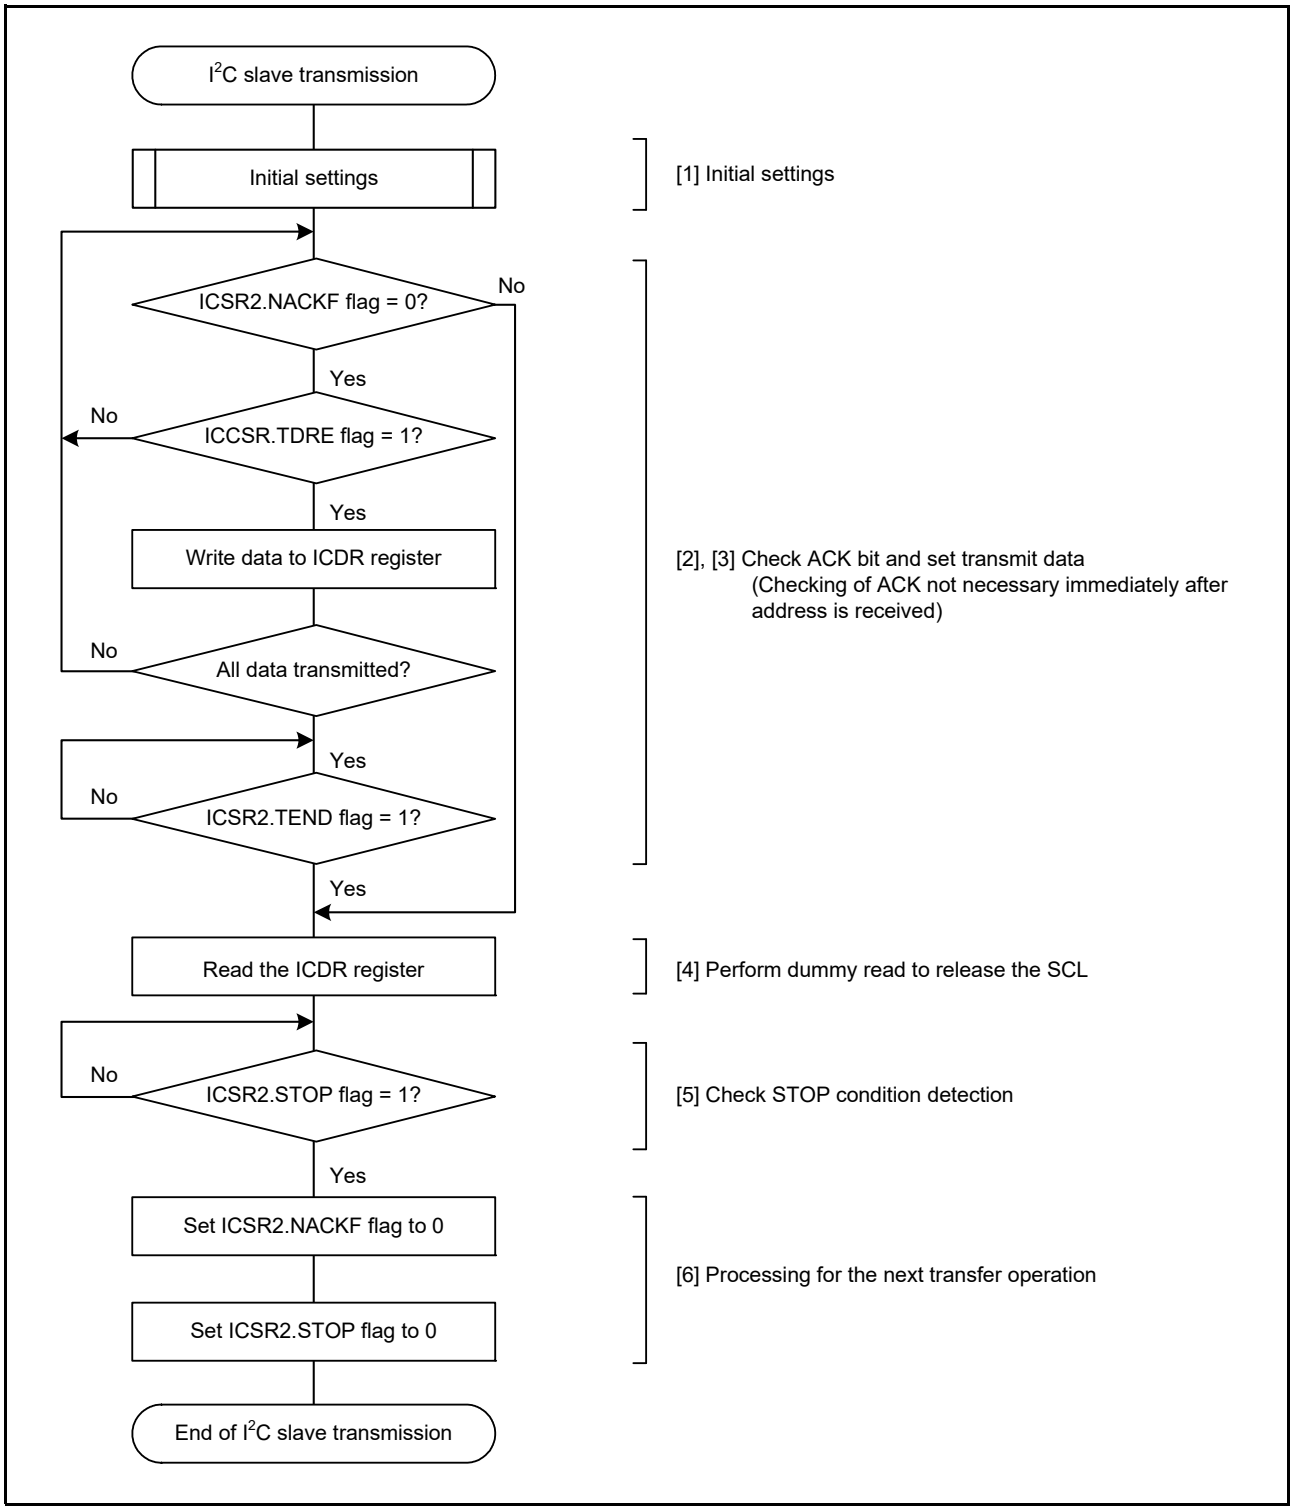

Figure 43.67 Example of I²C Slave Transmission Flowchart

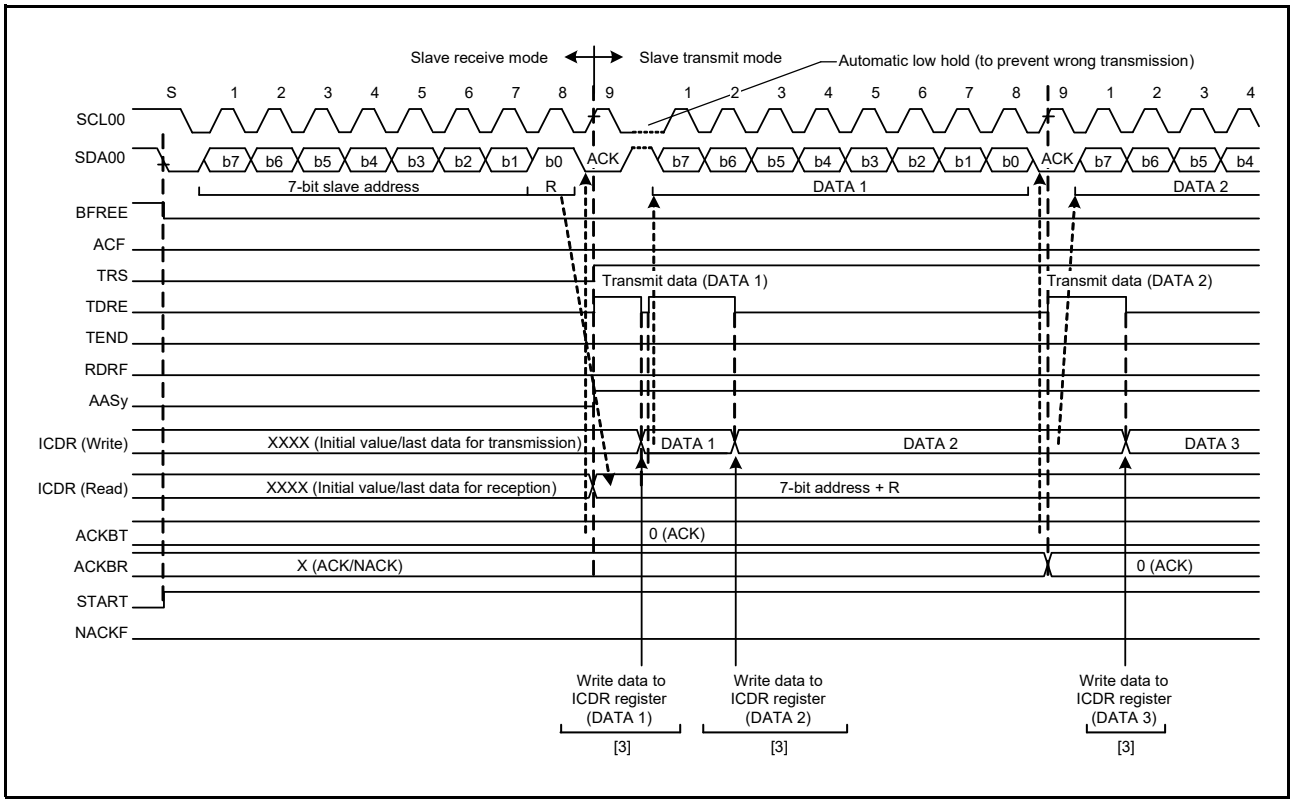

Figure 43.68 Slave Transmit Operation Timing (1) (7-Bit Address Format)

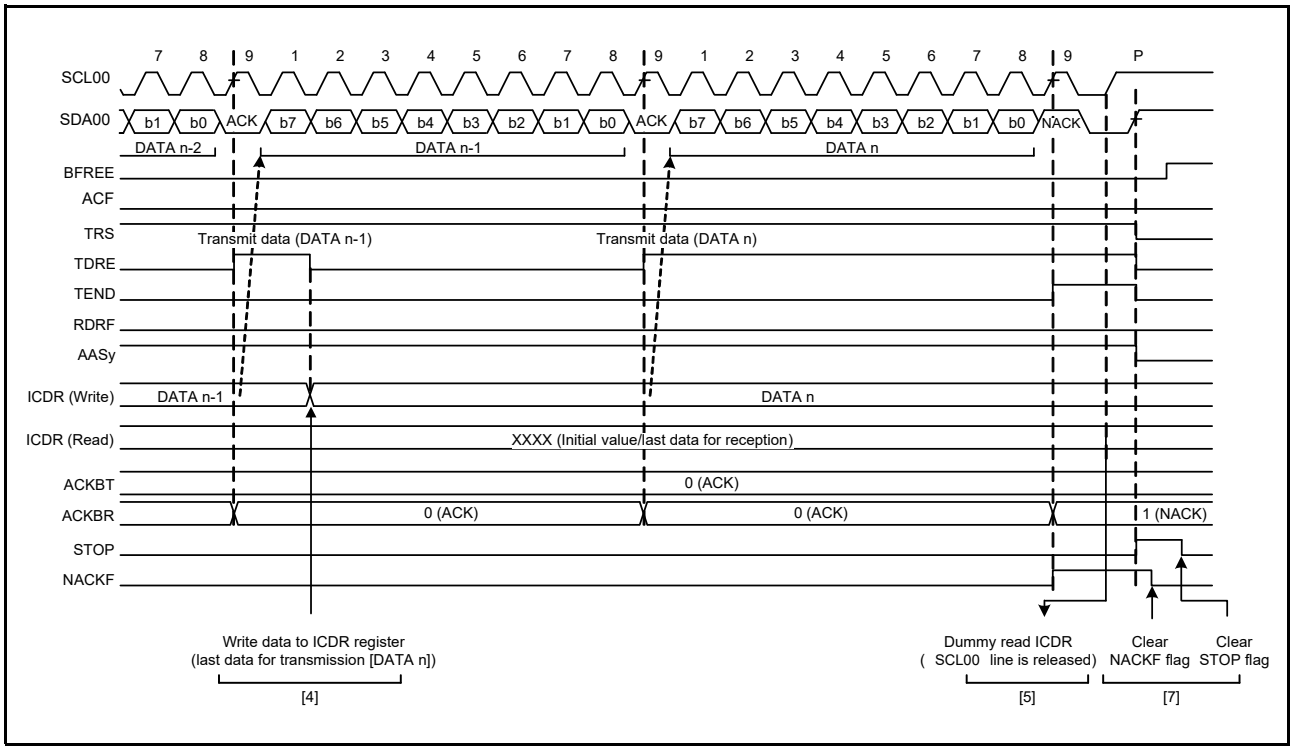

Figure 43.69 Slave Transmit Operation Timing (2)

43.4.9.2 Slave Receive Operation

In slave receive operation, the master device outputs the SCL and transmit data, and the RI3C returns acknowledgments as a slave device.

Figure 43.70 shows an example of usage of slave reception and Figure 43.71 and Figure 43.72 show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

(1) Initial settings. For details, refer to section 43.4.4, Initial Settings. After initial settings, the RI3C will stay in the standby state until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RI3C sets one of the corresponding flags ICSSR.HOA, ICSSR.GCA, and ICSSR.AASy (y = 0 to 2) to 1 on the rising edge of the ninth SCL (the clock signal) and outputs the value set in the ICACKR.ACKBT bit to the acknowledgment bit on the ninth SCL. Set the ACKBT bit to 0 in advance. If the value of the R/W# bit that was also received at this time is 0, the RI3C continues to place itself in slave receive mode and sets the ICCSR.RDRF flag to 1.

(3) After the ICSR2.STOP flag is confirmed to be 0 and the ICCSR.RDRF flag to be 1, dummy read ICDR register (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8-bits when the 10-bit address format is selected).

(4) When ICDR register is read, the RI3C automatically sets the ICCSR.RDRF flag to 0. If reading of ICDR register is delayed and a next byte is received while the RDRF flag is still set to 1, the RI3C holds the SCL00 line low from one SCL cycle before the timing with which RDRF should be set. In this case, reading ICDR register releases the SCL00 line from being held low.
When the ICSR2.STOP flag is 1 and the ICCSR.RDRF flag is also 1 or when all the data is completely received, read the ICDR register.

(5) Upon detecting the STOP condition, the RI3C automatically sets flags ICSSR.HOA, ICSSR.GCA, and ICSSR.AASy (y = 0 to 2) to 0.

(6) After checking that the ICSR2.STOP flag is 1, set the ICSR2.STOP flag to 0 for the next transfer operation.

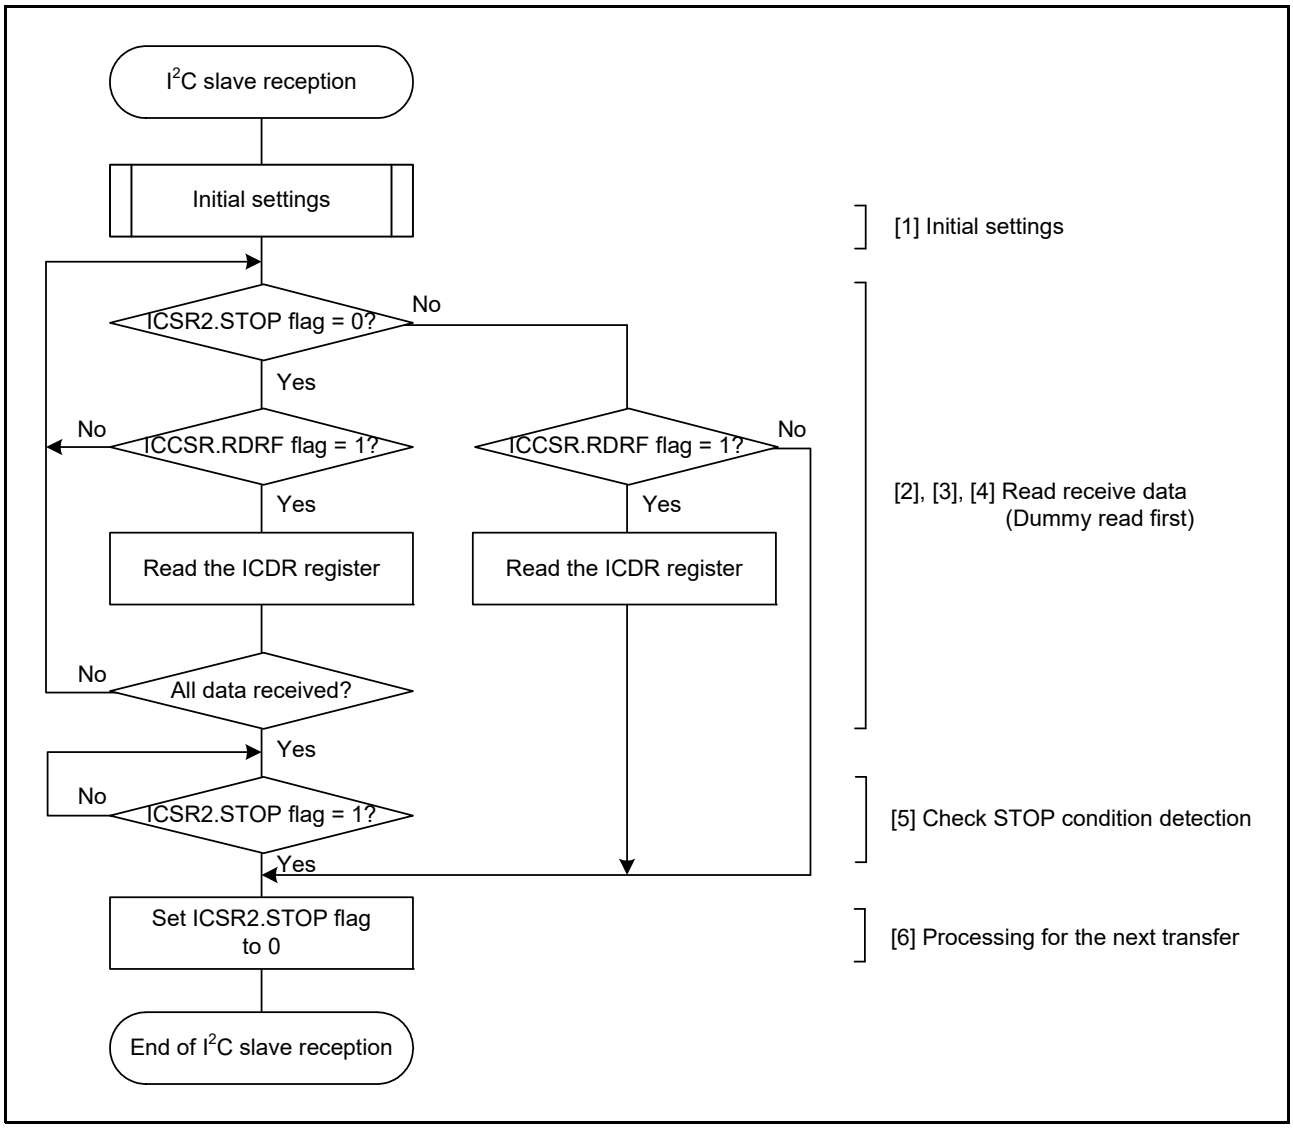

Figure 43.70 Example of I2C Slave Reception Flowchart

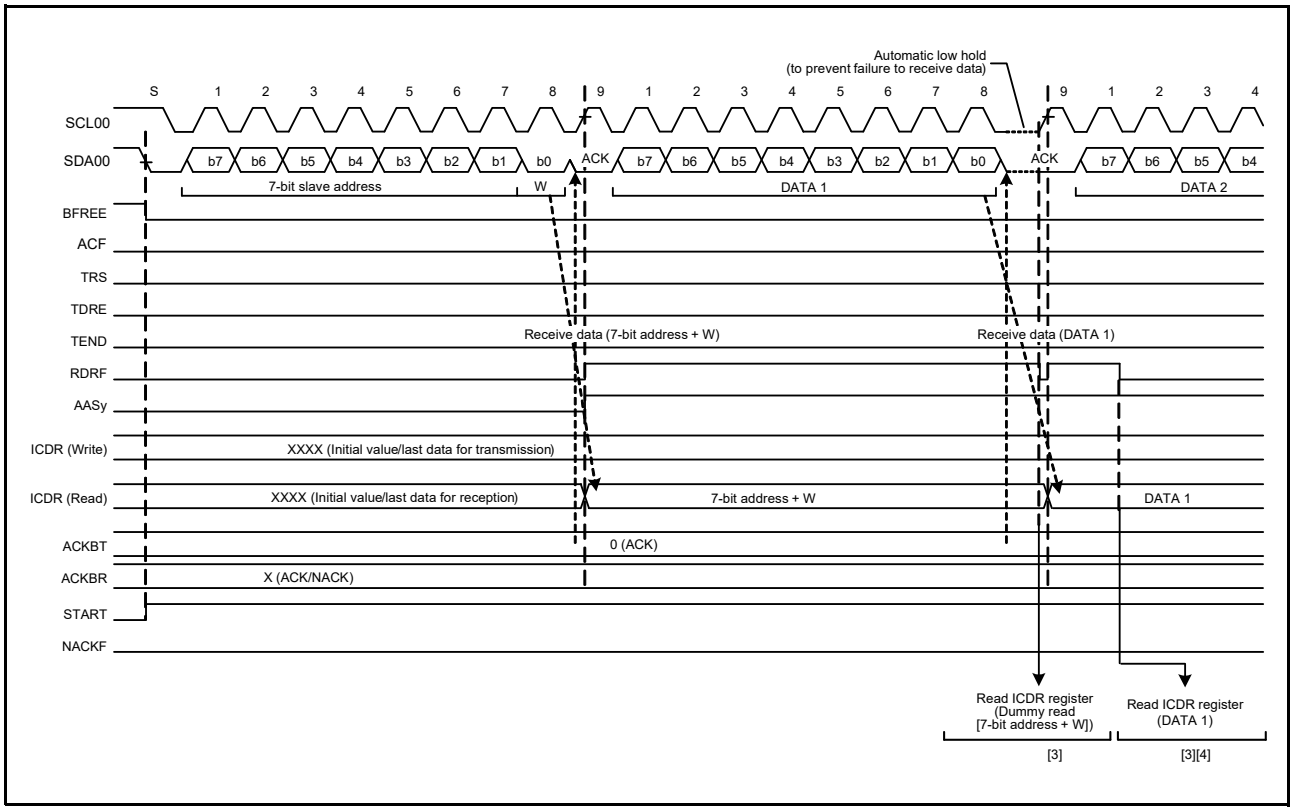

Figure 43.71 Slave Receive Operation Timing (1) (7-Bit Address Format, when WAITAE = 0)

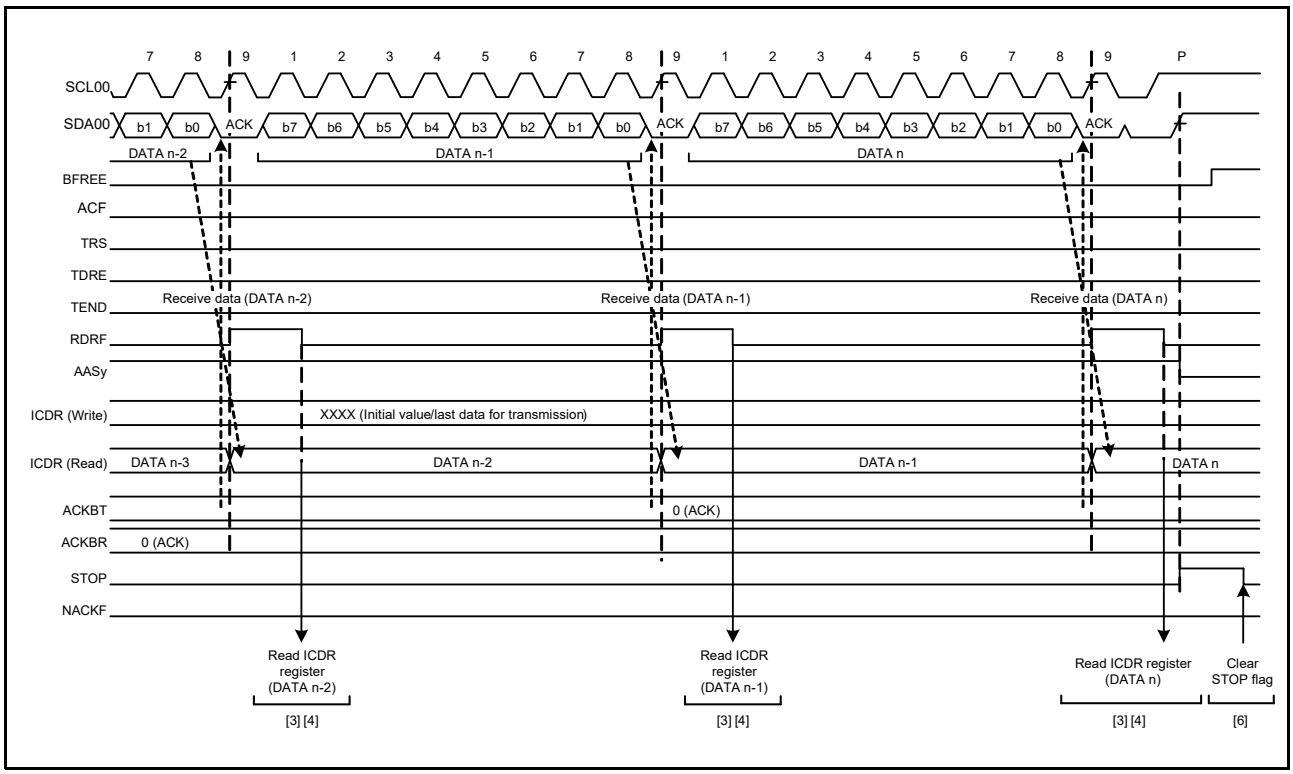

Figure 43.72 Slave Receive Operation Timing (2) (when WAITAE = 0)

43.5 Details of Function

43.5.1 SCL Synchronization Circuit (I2C Protocol Mode)

In generation of the SCL, the RI3C starts counting out the value for width at high level specified in the ICFBR.HIGH[7:0] bits when it detects a rising edge on the SCL00 line and drives the SCL00 line low once counting of the width at high level is complete. When the RI3C detects the falling edge of the SCL00 line, it starts counting out the width at low period specified in the ICFBR.LOW[7:0] bits, and then stops driving the SCL00 line (releases the line) once counting of the width at low level is complete. The SCL is thus generated.

If multiple master devices are connected to the I2C-bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, the RI3C is equipped with a function (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL signals by monitoring the SCL00 line while in master mode.

When the RI3C has detected a rising edge on the SCL00 line and thus started counting out the width at high level specified in the ICFBR.HIGH[7:0] bits, and the level on the SCL00 line falls because an SCL signal is being generated by another master device, the RI3C stops counting when it detects the falling edge, drives the level on the SCL00 line low, and starts counting out the width at low level specified in the ICFBR.LOW[7:0] bits. When the RI3C finishes counting out the width at low level, it stops driving the SCL00 line to low (i.e. releases the line). At this time, if the width at low level of the SCL signal from the other master device is longer than the width at low level set in the RI3C, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCL00 line has been released. When the RI3C finishes outputting the low period of the SCL, the SCL00 line is released and the SCL rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the ICFER.SCLE bit is set to 1.

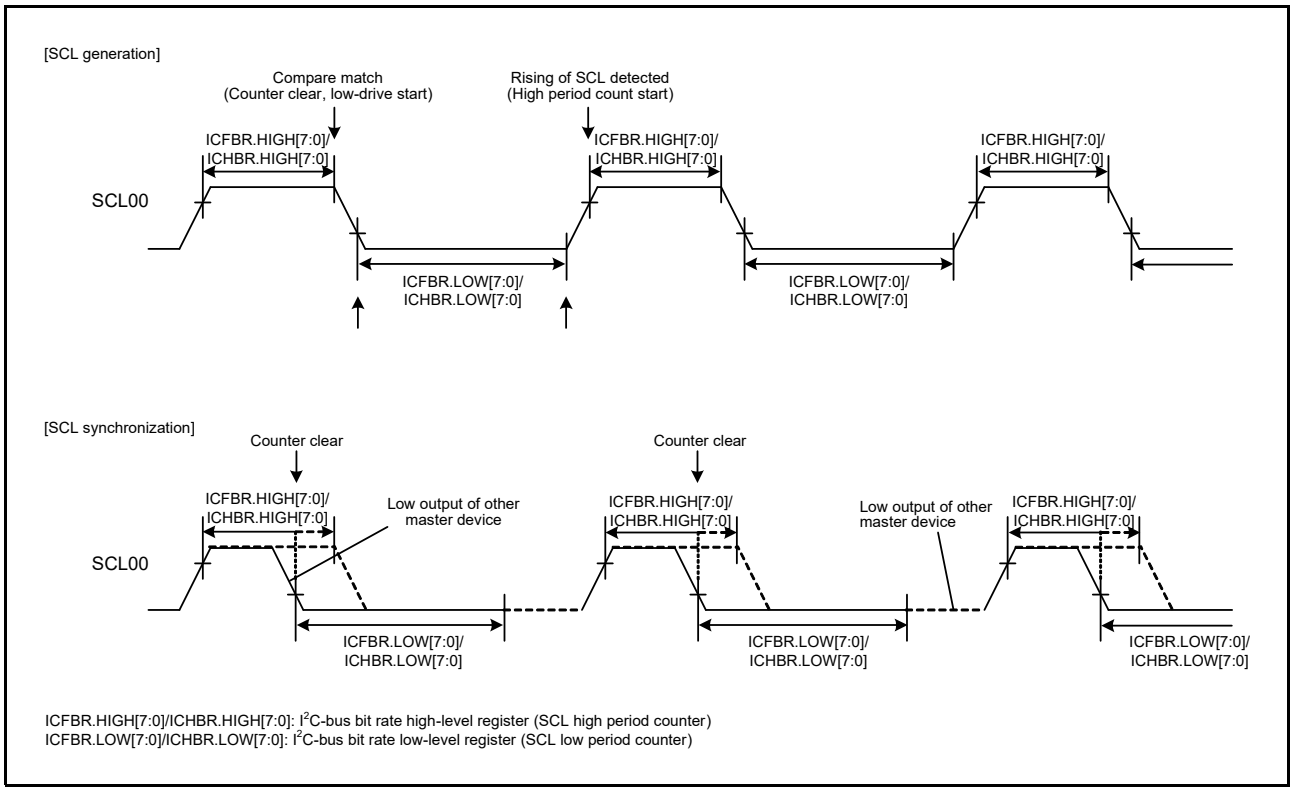

Figure 43.73 Generation and Synchronization of the SCL Signal

43.5.2 SDA Output Delay Function (I²C Protocol Mode)

The RI3C module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (generating of the START, repeated START, and STOP conditions, data, and the ACK and NACK signals) on the SDA line.

The SDA output delay function is used to delay the SDA output timing from a falling edge of SCL to ensure that the SDA signal changes while the SCL is low and can be used to prevent erroneous operation of communications devices. This function is also used to satisfy the 300 ns (min.) of data hold time specified by the SMBus specification.

The output delay facility is enabled by setting the ICOCR.SDDL[2:0] bits to any value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled (the SDDL[2:0] bits are not 000b), the SDA output delay counter counts the number of cycles set in the SDDL[2:0] bits with the count source selected by the ICOCR.DLCS bit (internal reference clock (IICφ) or internal reference clock divided by 2 (IICφ/2)). When the counting of the delay cycles is completed, the RI3C output the SDA signal (generating of the START, repeated START, or STOP condition, data, or an ACK or NACK signal).

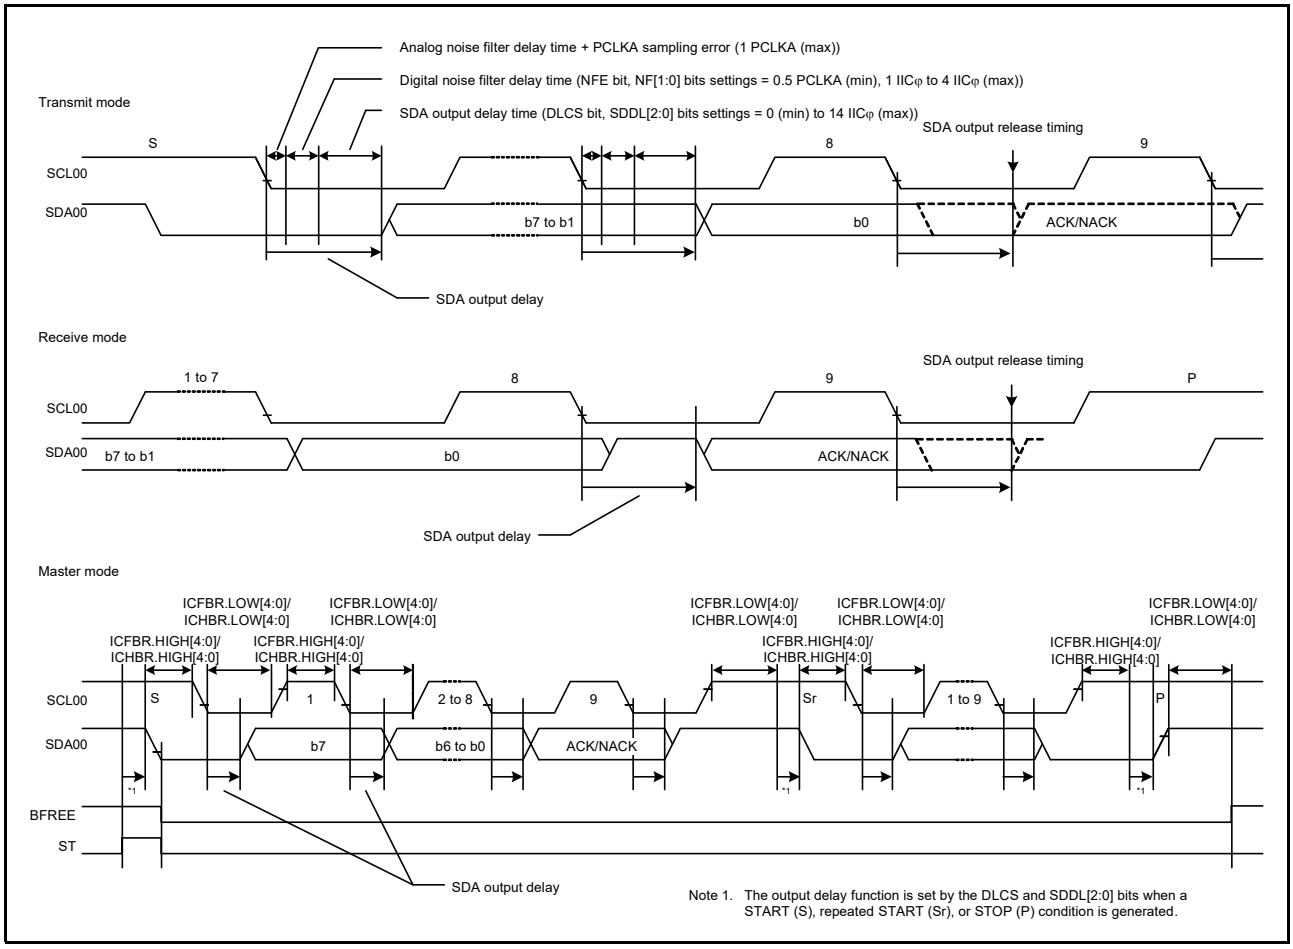

Figure 43.74 SDA Output Delay Function

43.5.3 Digital Noise Filters (I2C Protocol Mode)

The states of the SCL00 and SDA00 pins are conveyed to the internal circuitry through analog noise filter and digital noise filter. Figure 43.75 is a block diagram of the digital noise filter.

The on-chip digital noise filter of the RI3C consists of 16 flip-flop circuit stages connected in series and a match-detection circuit. When Hs-mode is selected, only the first four flip-flops are enabled.

The number of effective stages in the digital noise filter is selected by the ICICR.NF[3:0] bits (ICICR.NF[3:2] bits in Hs-mode). The selected number of effective stages determines the noise-filtering capability as a period from 1 to 16 IICφ cycles (one to four IICφ cycles in Hs-mode).

The input signal from the SCL00 pin (also the SDA00 pin) is sampled on rising edges of the IICφ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the ICICR.NF[3:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (I3CCLK) and the transfer rate is small (e.g. data transfer at 400 kbps with I3CCLK = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise. In such cases, disable the digital noise filter (by setting the ICICR.NFE bit to 0) and use only the analog noise filter.

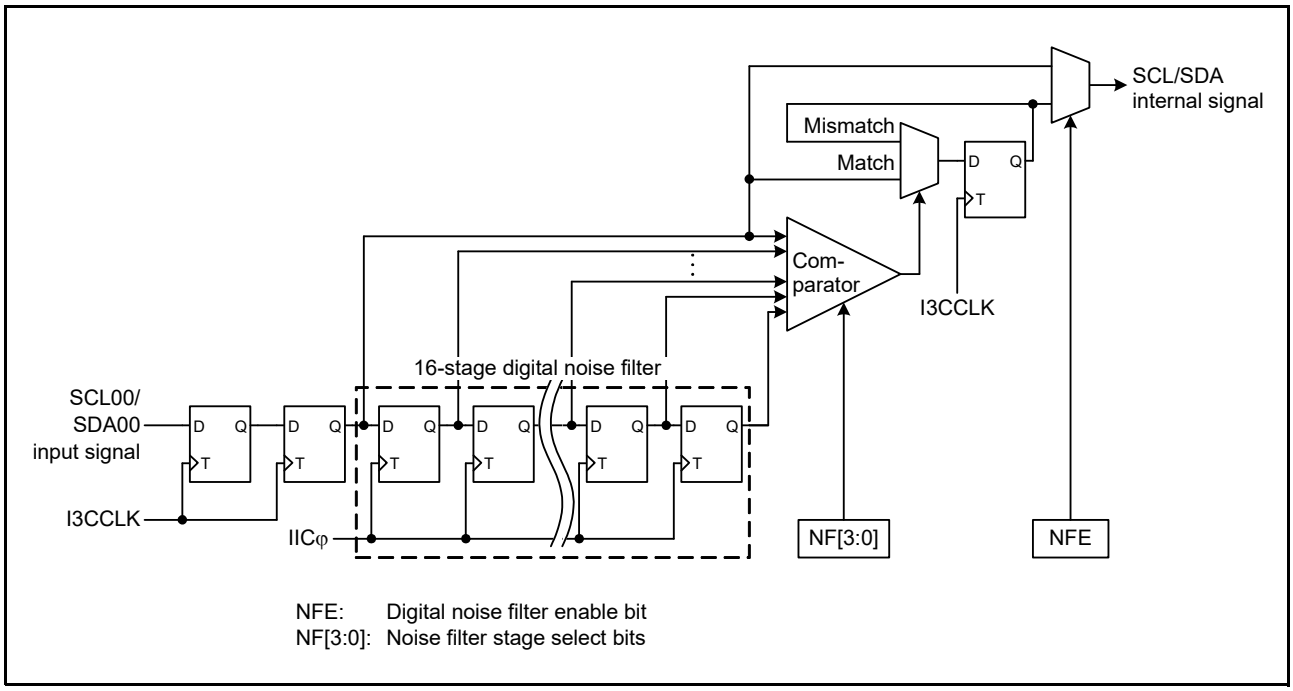

Figure 43.75 Block Diagram of Digital Noise Filter

43.5.4 Address Match Detection (I2C Protocol Mode)

The RI3C can set three unique slave addresses in addition to the general call address and host address, and also can set 7-bit or 10-bit slave addresses.

43.5.4.1 Slave-Address Match Detection

The RI3C can set three unique slave addresses, and has a slave address detection function for each unique slave address. When the ICSCR.SARyE bit (y = 0 to 2) is set to 1, the slave addresses set in SAMRy register (y = 0 to 2) can be detected.

When the RI3C detects a match of the set slave address, the corresponding ICSSR.AASy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL, and the ICCSR.RDRF flag or the ICCSR.TDRE flag is set to 1 according to the R/W# bit. This causes a receive data full interrupt (RXI) or transmit data empty interrupt (TXI) to be generated. The AASy flag is used to identify which slave address has been specified.

Figure 43.76 to Figure 43.78 show the AASy flag set timing in three cases.

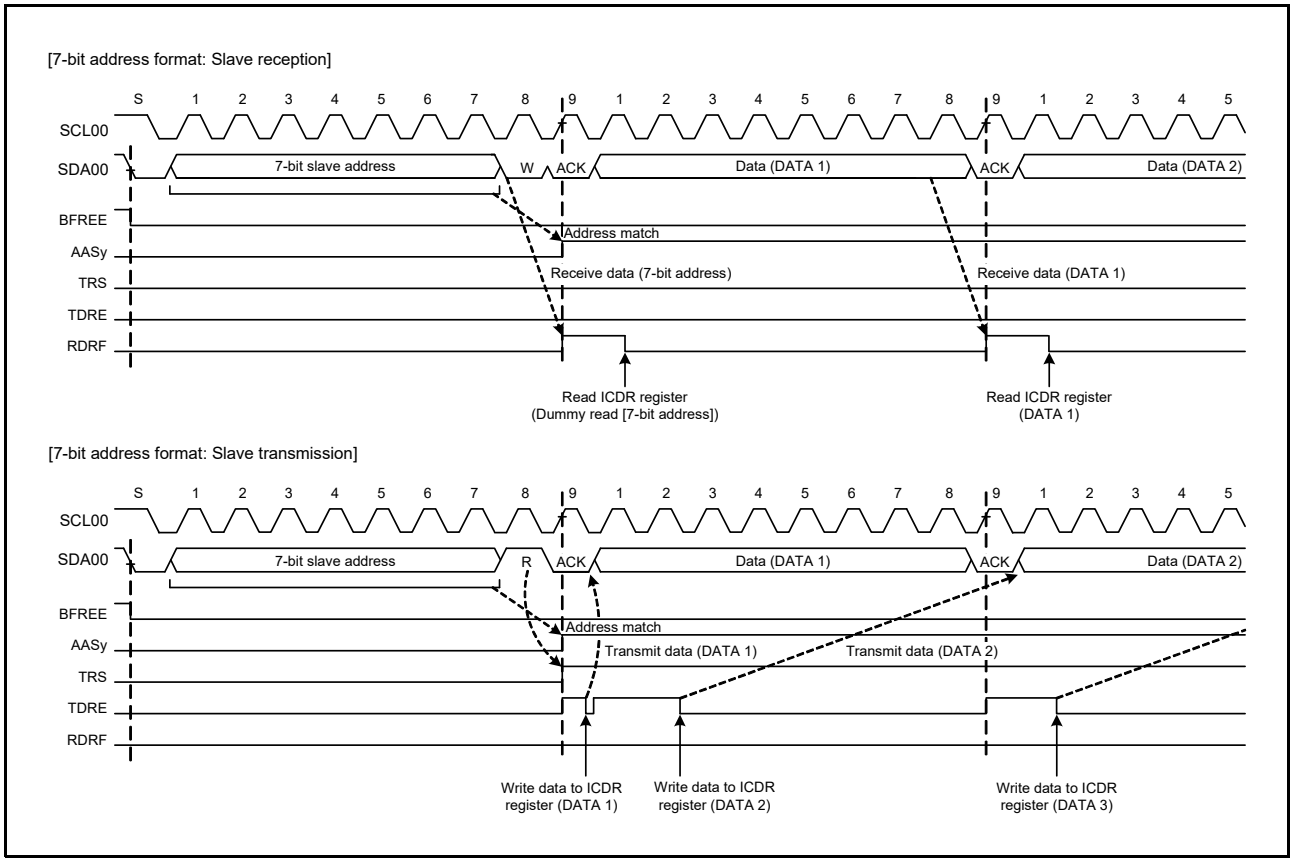

Figure 43.76 AASy Flag Set Timing with 7-Bit Address Format Selected

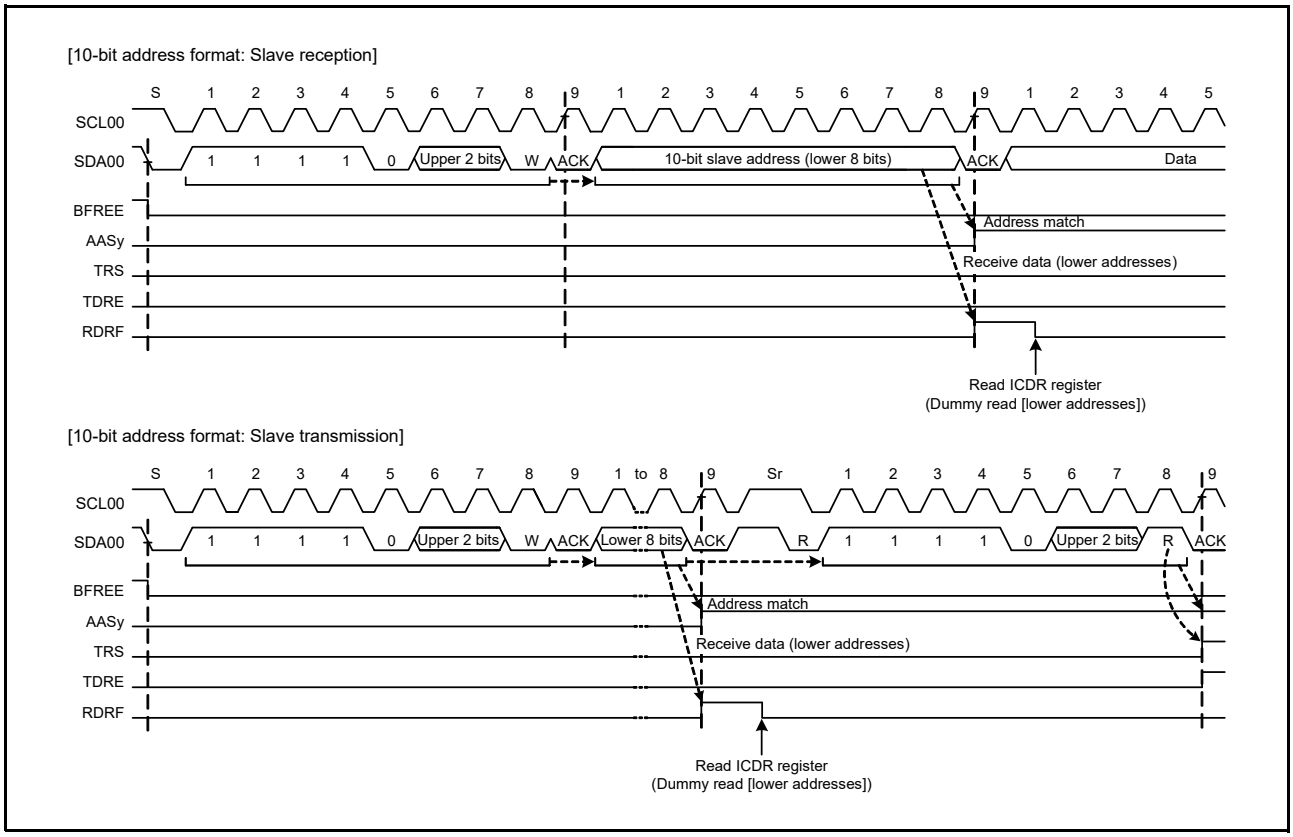

Figure 43.77 AASy Flag Set Timing with 10-Bit Address Format Selected

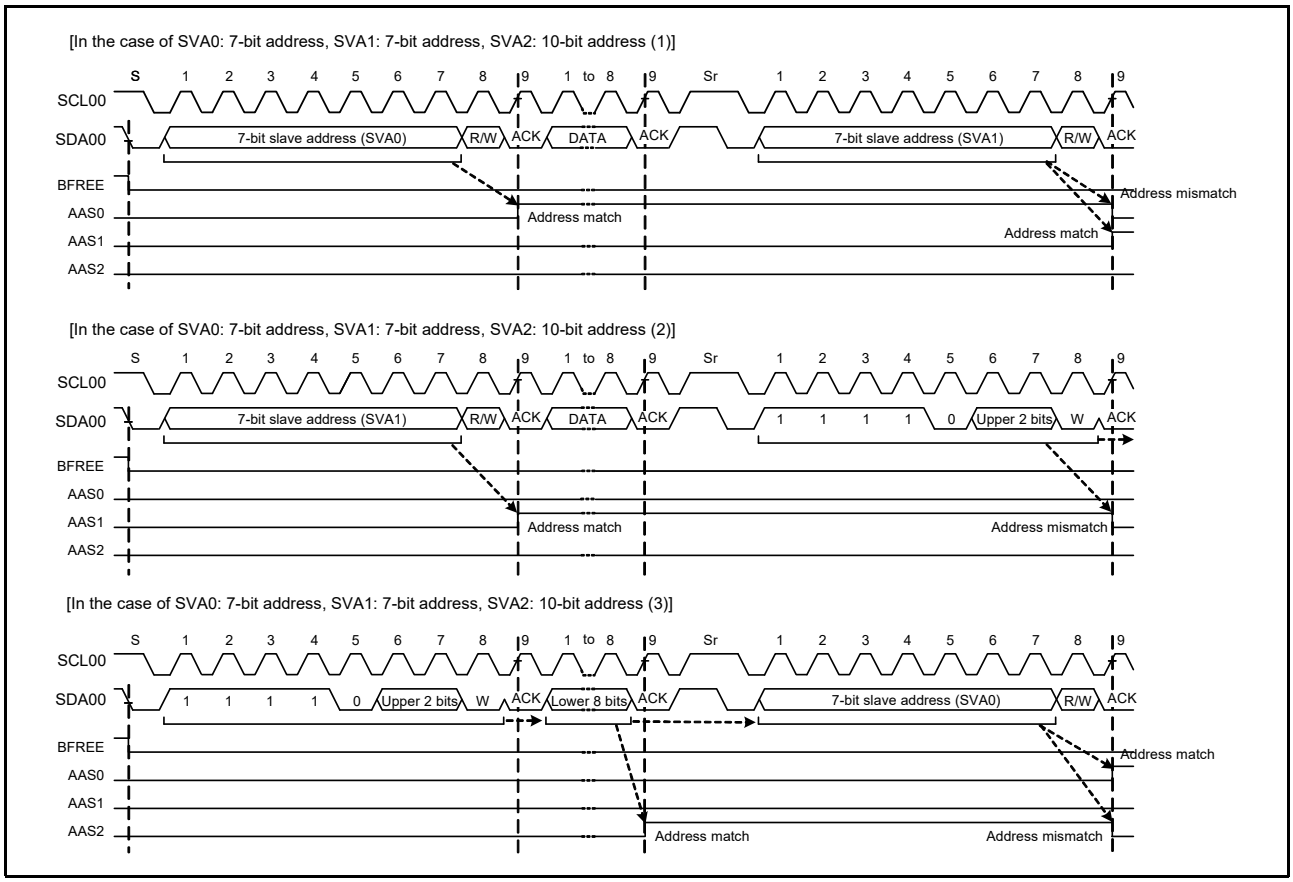

Figure 43.78 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed

43.5.4.2 General Call Address Detection

The RI3C has a function for detecting the general call address (0000 000b + 0 (write)). This is enabled by setting the ICSCR.GCAE bit to 1.

If the address following a START or repeated START condition is 0000 000b + 1 (read) (start byte), the RI3C recognizes this as the address of a slave device with an “all-zero” address but not as the general call address.

When the RI3C detects the general call address, both the ICSSR.GCA flag and the ICCSR.RDRF flag are set to 1 on the rising edge of the ninth SCL. This leads to the generation of a receive data full interrupt (RXI). The value of the GCA flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

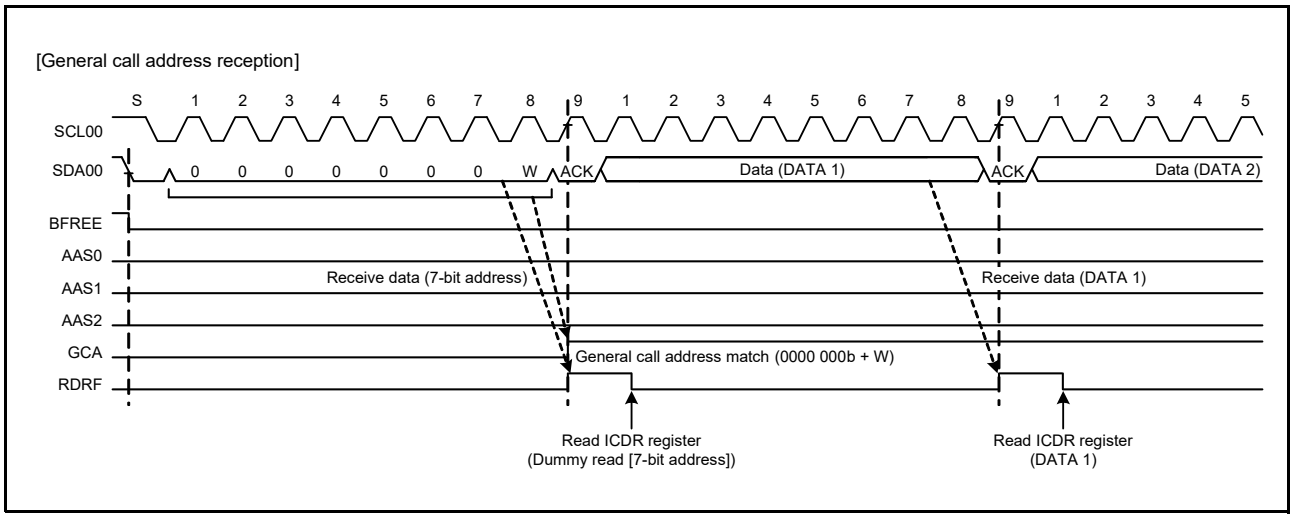

Figure 43.79 Timing of GCA Flag Setting during Reception of General Call Address

43.5.4.3 Device-ID Address Detection

The RI3C module has a function for detecting device-ID addresses conformant with the I^2C-bus specification.
When the RI3C receives 1111 100b as the first seven bits of the first byte following a START condition or repeated START condition while the ICSCR.DIDE bit is 1, the RI3C recognizes the address as a device ID address, sets the ICSSR.DID flag to 1 on the rising edge of the ninth SCL when the following R/W# bit is 0, and then compares the second and following bytes with its own slave address. If the received address matches the value in the slave address register, the RI3C sets the corresponding ICSSR.AASy flag (y = 0 to 2) to 1.
After that, when the first byte received after a START or repeated START condition is generated matches the device ID address (1111 100b) again and the following R/W# bit is 1, the RI3C does not compare the second and subsequent bytes and sets the ICCSR.TDRE flag to 1.
In the device-ID address detection function, the RI3C sets the DID flag to 0 if a match with the RI3C's own slave address is not obtained or a match with the device ID address is not obtained after a match with the RI3C's own slave address and the detection of a repeated START condition. If the first byte after detection of a START or repeated START condition matches the device ID address (1111 100b) and the R/W# bit is 0, the RI3C sets the DID flag to 1 and compares the second and subsequent bytes with the RI3C's slave address. If the R/W# bit is 1, the DID flag holds the previous value and the RI3C does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DID flag after confirming that ICCSR.TDRE flag is 1.
Furthermore, prepare the device-ID fields (three bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

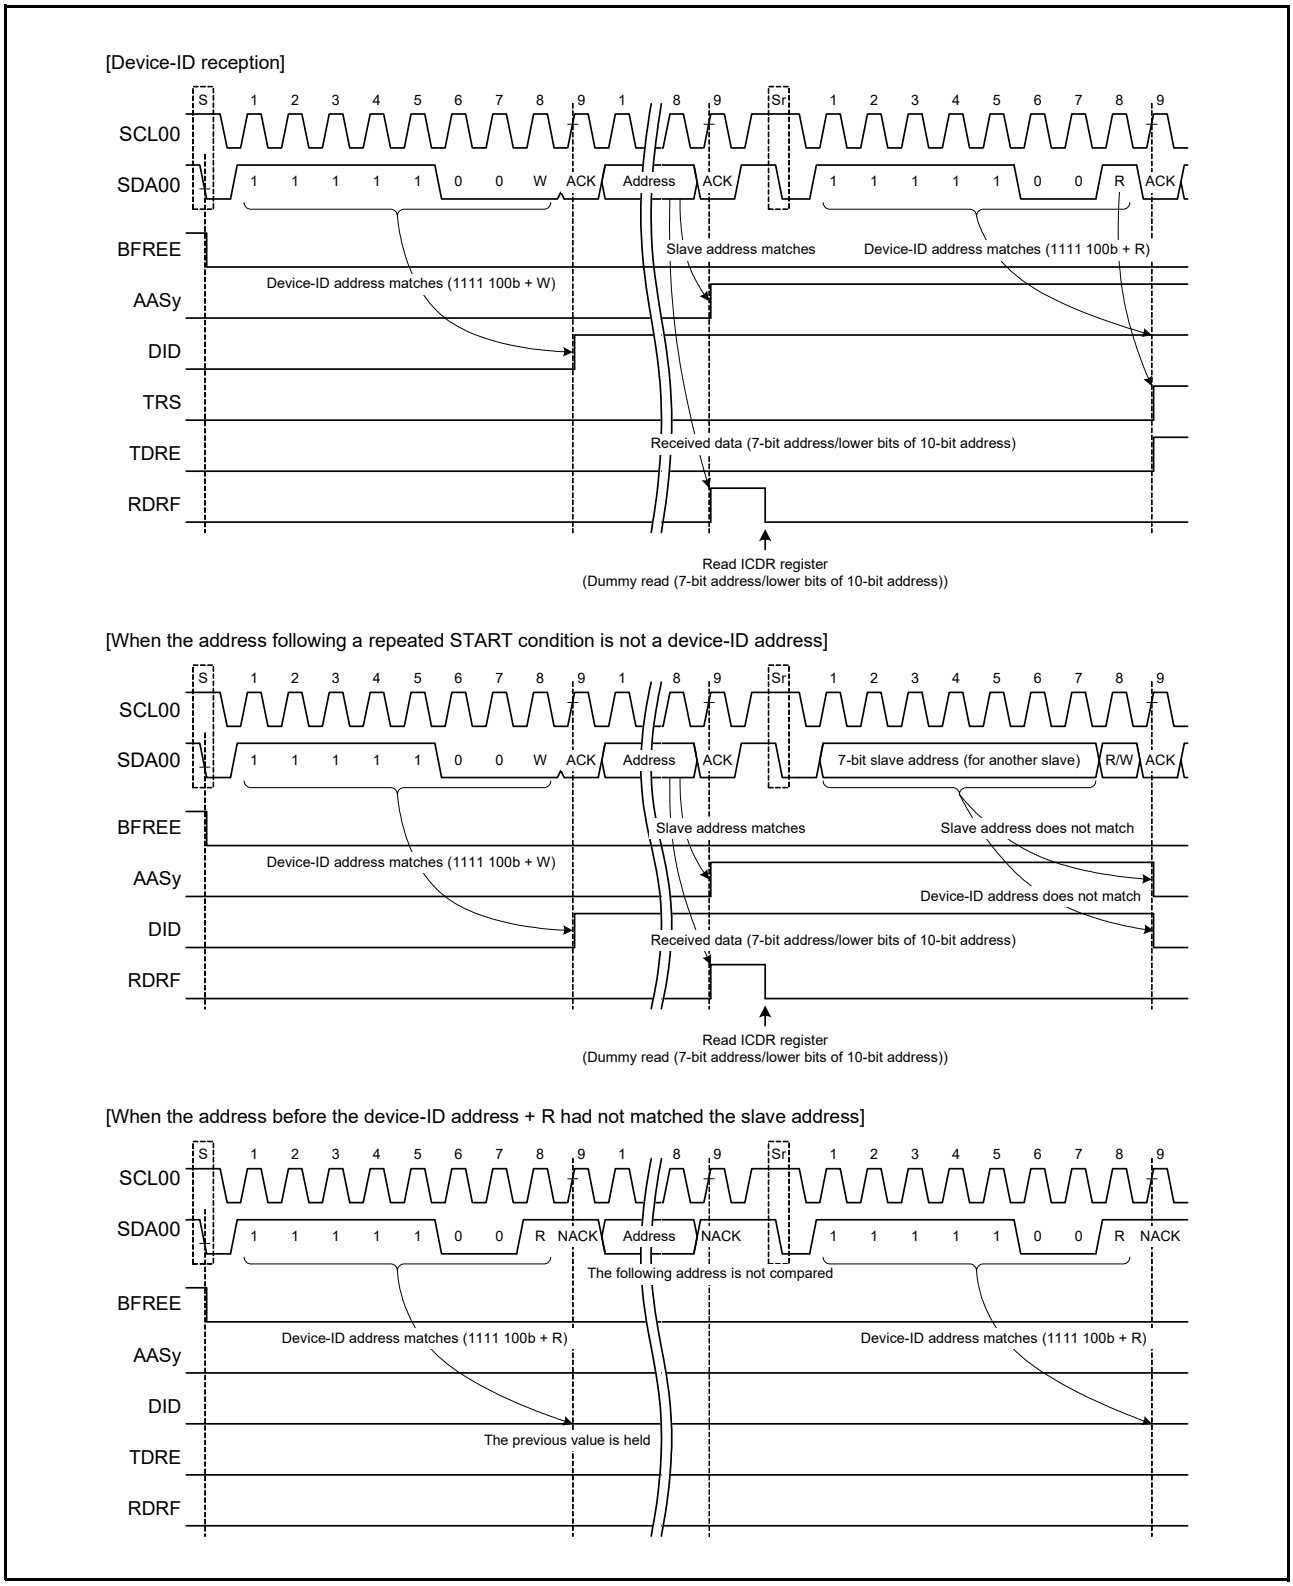

Figure 43.80 Set/Clear Timing of the AASy and DID Flags during Reception of Device-ID Address

43.5.4.4 Hs-Mode Master Code Detection

The RI3C has a function to detect the Hs-mode master code (0000 1XXXb).
When the RI3C receives 0000 1XXXb as the first byte following a START condition while the ICSCR.HSMCE bit is 1, the RI3C recognizes it as Hs-mode master code and set the ICSSR.HSMC flag to 1 at the rising edge of the ninth SCL. The RI3C does not acknowledge the master code regardless of the value of the ICACKR.ACKBT bit (the SDA00 pin remains high).
The first byte following a repeated START condition after the NACK bit is recognized as the slave address and compared with the SAMRy.SVA[9:0] bits (y = 0 to 2). When they match, the corresponding ICSSR.AASy flag is set to 1 at the rising edge of the ninth SCL. Also, the ICCSR.RDRF or TDRE flag is set to 1 depending on the value of the R/W# bit. When a STOP condition is detected, the ICSSR.HSMC flag is set to 0.

Note: If the RI3C receives Hs-mode master code while the ICSCR.HSMCE bit is 0, it ignores all data patterns until a STOP condition is detected.

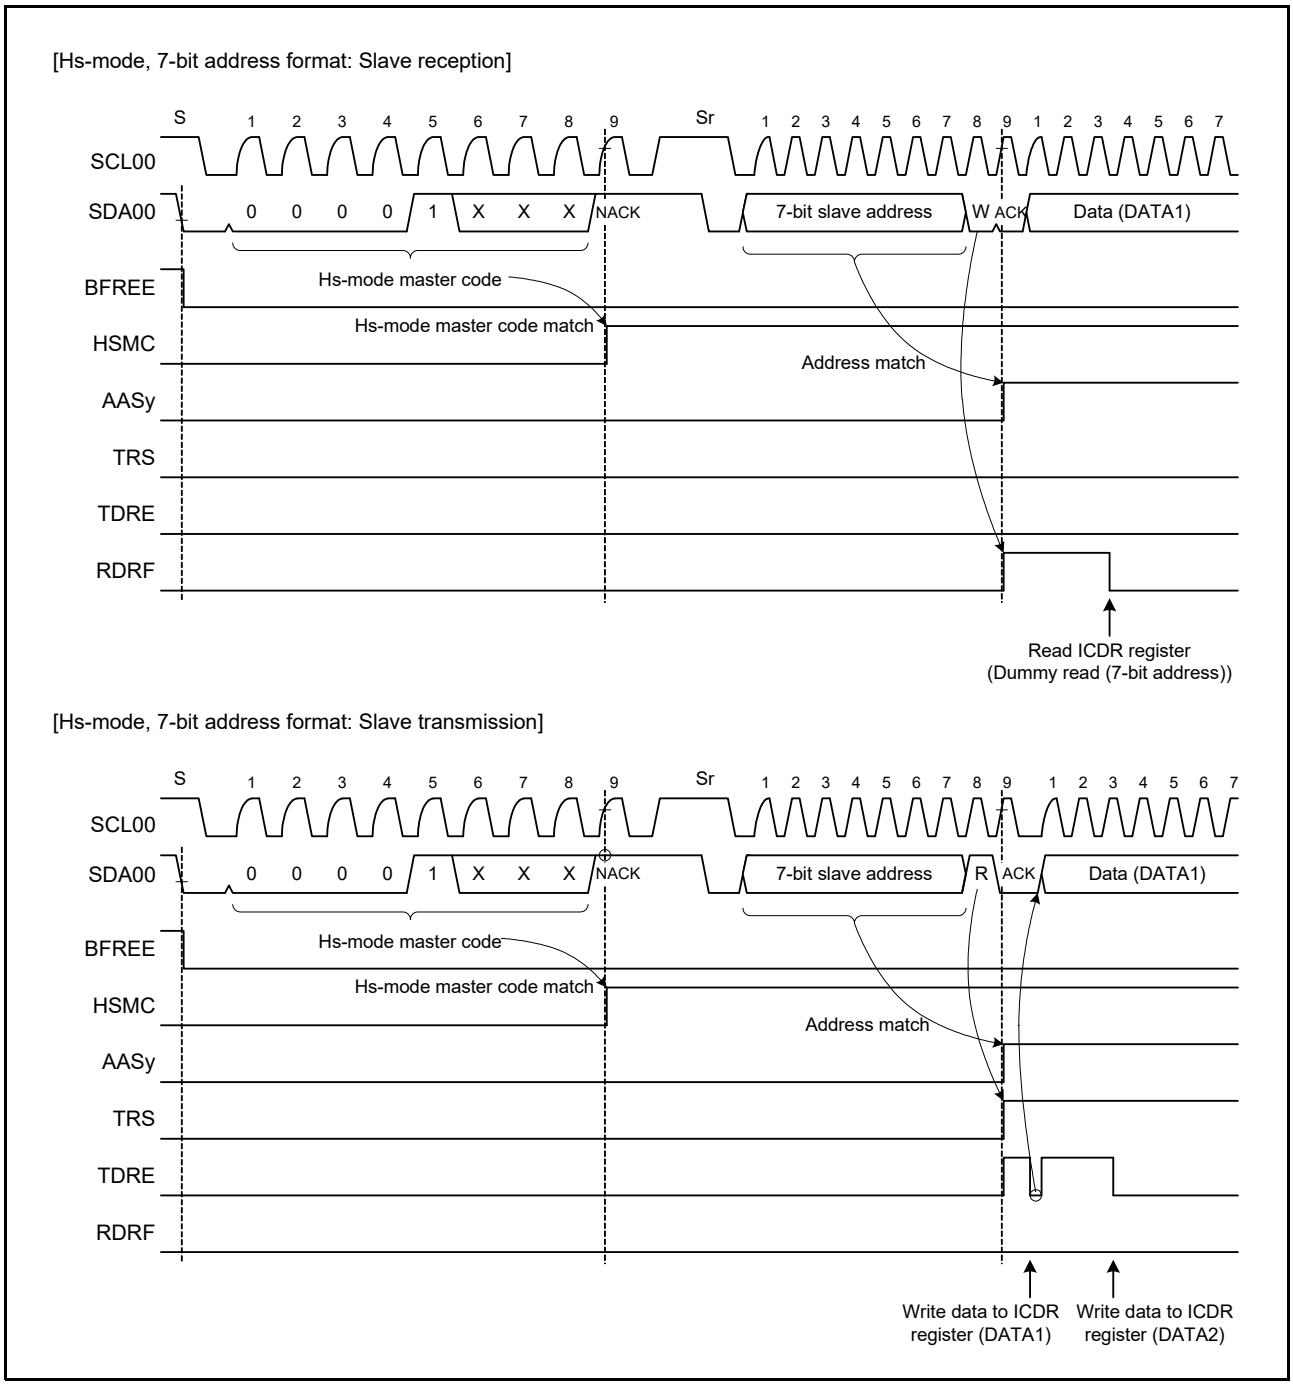

Figure 43.81 Set Timing of the HSMC and AASy Flags during Reception of Hs-Mode Master Code

43.5.4.5 Host Address Detection

The RI3C has a function to detect the host address while the SMBus is operating. When the ICSCR.HOAE bit is set to 1 while the ICFER.SMBS bit is 1, the RI3C can detect the host address (0001 000b) in slave receive mode (ICMMR.ACF and ICMMR.TRS flags = 00b).

When the RI3C detects the host address, the ICSSR.HOA flag is set to 1 at the rising edge of the ninth SCL, and at the same time, the ICCSR.RDRF flag is set to 1 when the R/W# bit is 0 (write). This causes a receive data full interrupt (RXI) to be generated. The HOA flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address (0001 000b) is an R bit (R/W# bit = 1), the RI3C can also detect the host address. After the host address is detected, the RI3C operates in the same manner as normal slave operation.

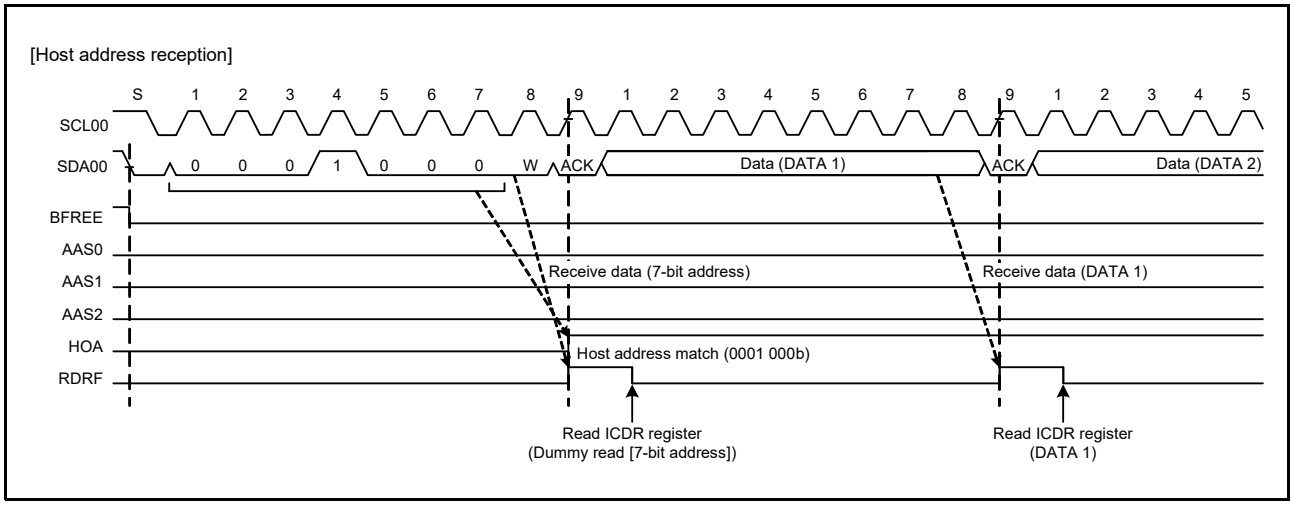

Figure 43.82 HOA Flag Set Timing during Reception of Host Address

43.5.5 Automatic Low-Hold Function for SCL (I^2C Protocol Mode)

43.5.5.1 Function to Prevent Wrong Transmission of Transmit Data

When data have not been written to the transmit data register (ICDR register) with the RI3C in transmission mode (ICMMR.TRS flag = 1), the SCL00 line is automatically held low over the periods shown below. This low period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low period after a START condition or repeated START condition is generated
- Low period between the ninth clock pulse of one transfer and the first clock pulse of the next

Slave transmit mode

- Low period between the ninth clock pulse of one transfer and the first clock pulse of the next

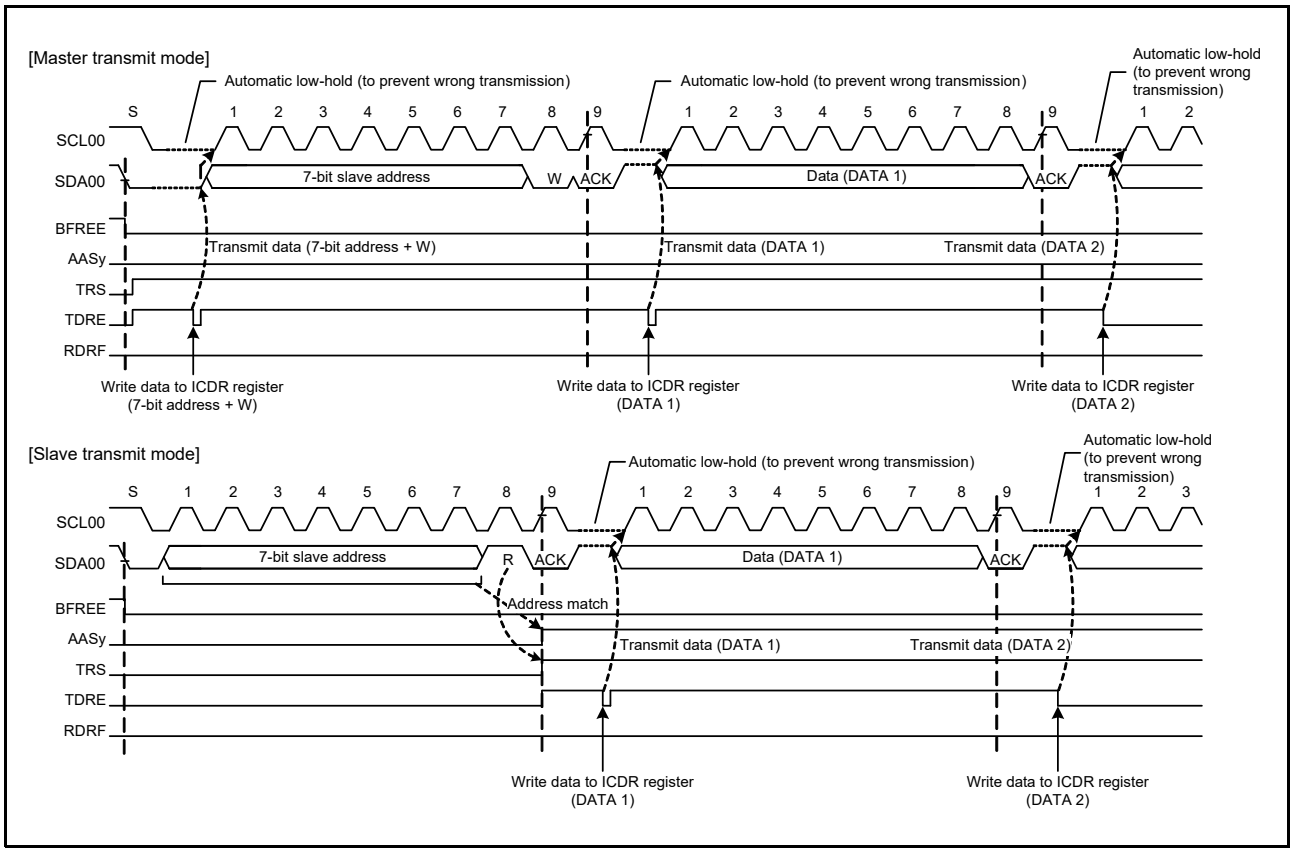

Figure 43.83 Automatic Low-Hold Operation in Transmit Mode

43.5.5.2 NACK Reception Transfer Suspension Function

The RI3C has a function to suspend transfer operation when NACK is received in transmit mode (ICMMR.TRS flag = 1).

This function is enabled when the ICSER.NAKDE bit is set to 1 (transfer suspension enabled). If the next transmit data has already been written (ICCSR.TDRE flag = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL is automatically suspended. This prevents the SDA00 line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (ICSR2.NACKF flag = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to set the NACKF flag to 0. In master transmit mode, issue a repeated START or STOP condition, set the NACKF flag to 0, and then issue a START condition again.

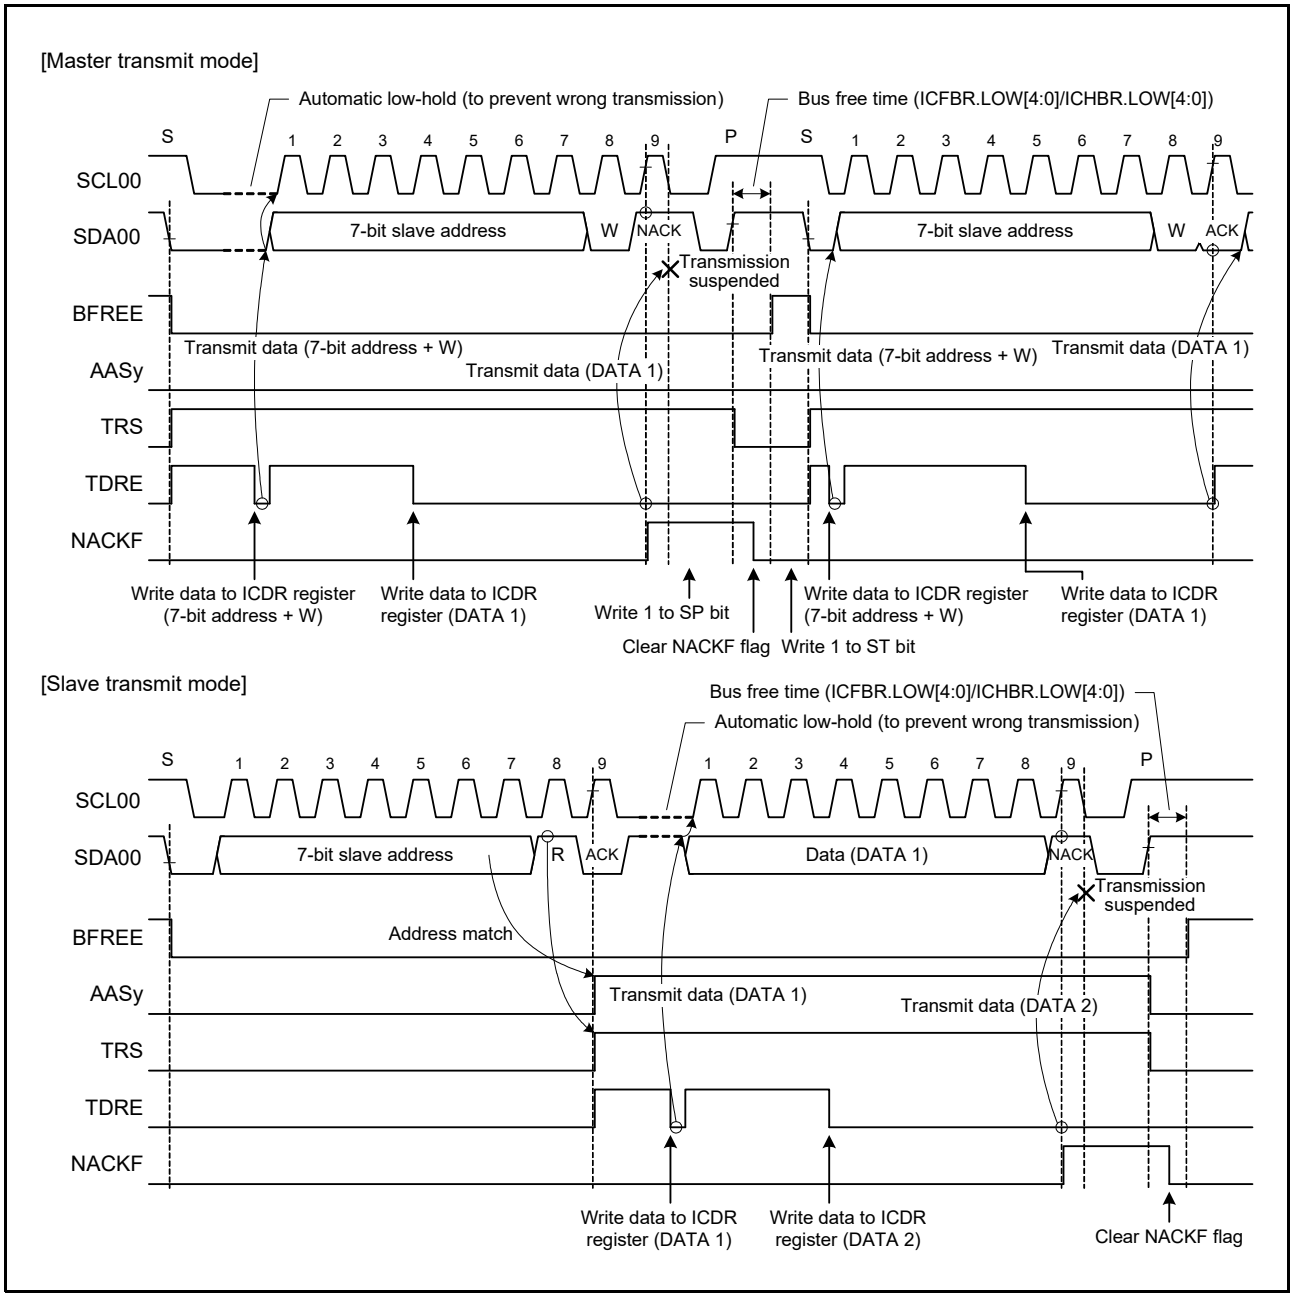

Figure 43.84 Suspension of Data Transmission When NACK is Received (NAKDE = 1)

43.5.5.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDR register) read is delayed for a period of one transfer frame or more with receive data full (ICCSR.RDRF flag = 1) in receive mode (ICMMR.TRS flag = 0), the RI3C holds the SCL00 line low automatically immediately before the next data is received to prevent failure to receive data.
This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RI3C's own slave address or a slave address for the other device is designated after a STOP condition is generated.
Sections in which the SCL00 line is held low can be selected with a combination of the ICCSCR.WAITRE and ICCSCR.WAITAE bits.

(1) 1-Byte Receive Operation and Automatic Low-Hold Function Using the WAITRE Bit

When the ICCSCR.WAITRE bit is set to 1, the RI3C performs 1-byte receive operation using the WAITRE bit function. Furthermore, when the ICCSCR.WAITAE bit is 0, the RI3C automatically sends the ICACKR.ACKBT bit value for the acknowledgment bit in the period from the falling edge of the eighth SCL to the falling edge of the ninth SCL, and automatically holds the SCL00 line low at the falling edge of the ninth SCL using the WAITRE bit function. This low-hold is released by reading data from ICDR register, which enables bytewise receive operation.
The WAITRE bit function is enabled for receive frames after a match with the RI3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(2) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the WAITAE Bit

When the ICCSCR.WAITAE bit is set to 1, the RI3C performs 1-byte receive operation using the WAITAE bit function. When the WAITAE bit is set to 1, the ICCSR.RDRF flag (receive data full) is set to 1 at the rising edge of the eighth SCL, and the SCL00 line is automatically held low at the falling edge of the eighth SCL. This low-hold is released by writing a value to the ICACKR.ACKBT bit, but cannot be released by reading data from ICDR register, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.
The WAITAE bit function is enabled for receive frames after a match with the RI3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

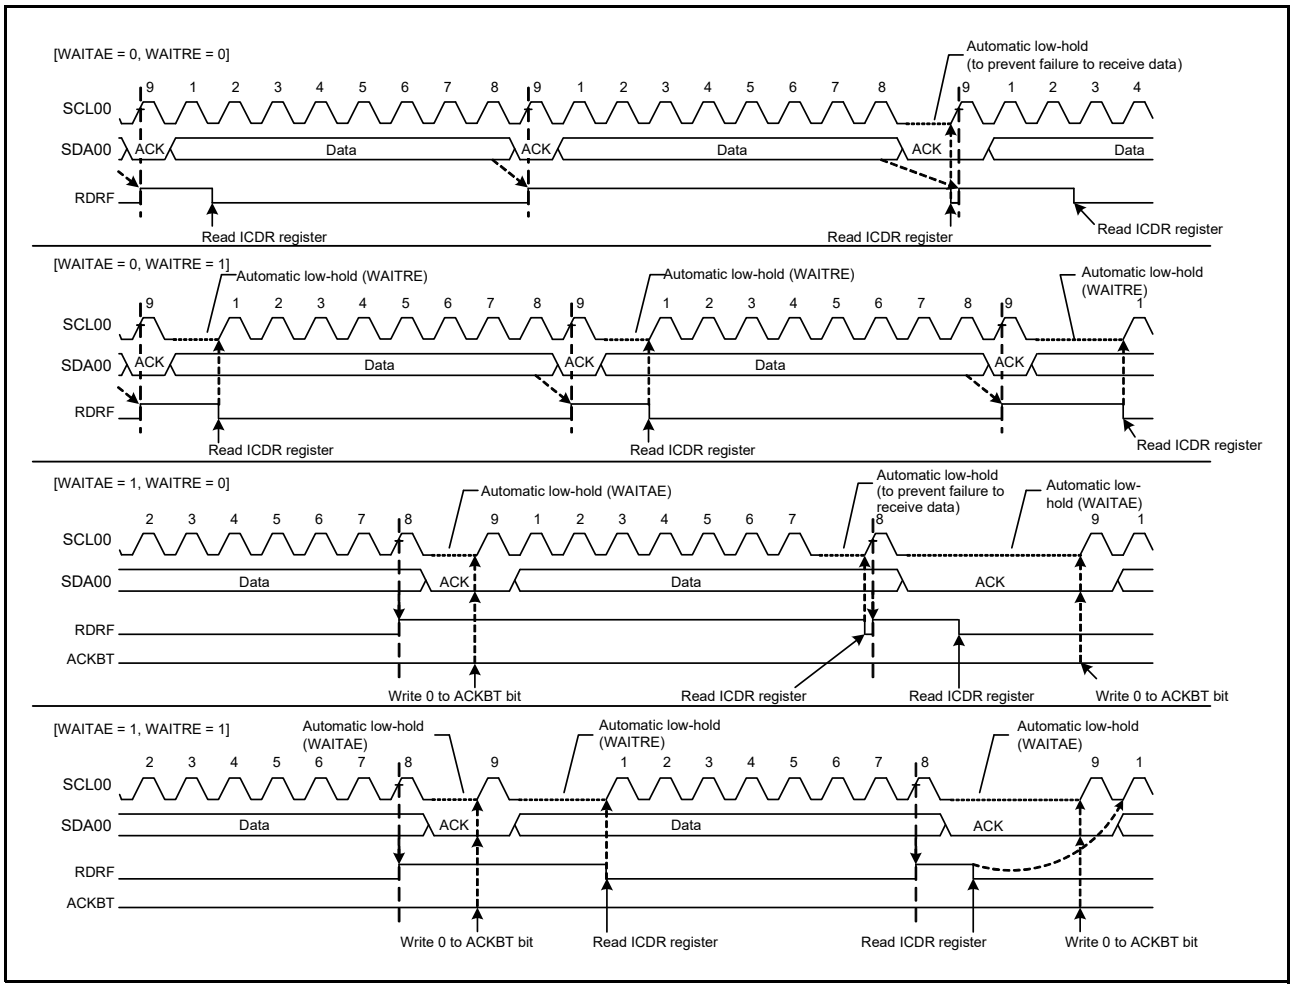

Figure 43.85 Automatic Low-Hold Operation in Receive Mode (Using WAITAE and WAITRE Bits)

43.5.6 Arbitration-Lost Detection Functions (I^2C Protocol Mode)

In addition to the normal arbitration-lost detection function specified in the I^2C-bus specification, the RI3C also has functions to prevent double generation of START conditions, to detect arbitration-lost during NACK transmission, and to detect arbitration-lost during slave transmission.

43.5.6.1 Master Arbitration-Lost Detection Function (MALE Bit)

The RI3C drives the SDA00 line low to generate a START condition. However, if the SDA00 line is already driven low by another master device that generates a START condition, the RI3C generates an arbitration-lost and gives a priority to the transfer by the other master device. Similarly, if the ICCGR.ST bit is set to 1 while the ICBSR.BFREE flag is 0 (bus busy), the RI3C generates an arbitration-lost and gives a priority to the transfer by the other master device. No START condition is generated in this case.
After a START condition is generated successfully, if the level of the transmit data including the address bits (i.e. the internal SDA output level) and the level on the SDA00 line do not match (the internal SDA output is high (the SDA00 pin is high-impedance) but low is detected on the SDA00 line), the RI3C generates an arbitration-lost.
If a master arbitration-lost is generated, the RI3C immediately transitions to slave receive mode. If a slave address including the general call address matches its own address at this time, the RI3C continues the slave operation.
The RI3C detects master arbitration-lost when one of the following conditions is met while the ICSER.ALE and ICFER.MALE bits are 1 (master arbitration-lost detection enabled).

Conditions for detecting master arbitration-lost

- When the internal SDA output level and the level on the SDA00 line do not match (START condition generation error) when a START condition is generated by setting the ICCGR.ST bit to 1 while the ICBSR.BFREE flag is 1.
- When the ICCGR.ST bit is set to 1 while the BFREE flag is 0 (START condition double generation error).
- When the transmit data excluding acknowledgment bit (internal SDA signal output level) and the level on the SDA00 line do not match in master transmit mode (the ICMMR.ACF and ICMMR.TRS flags are 1).

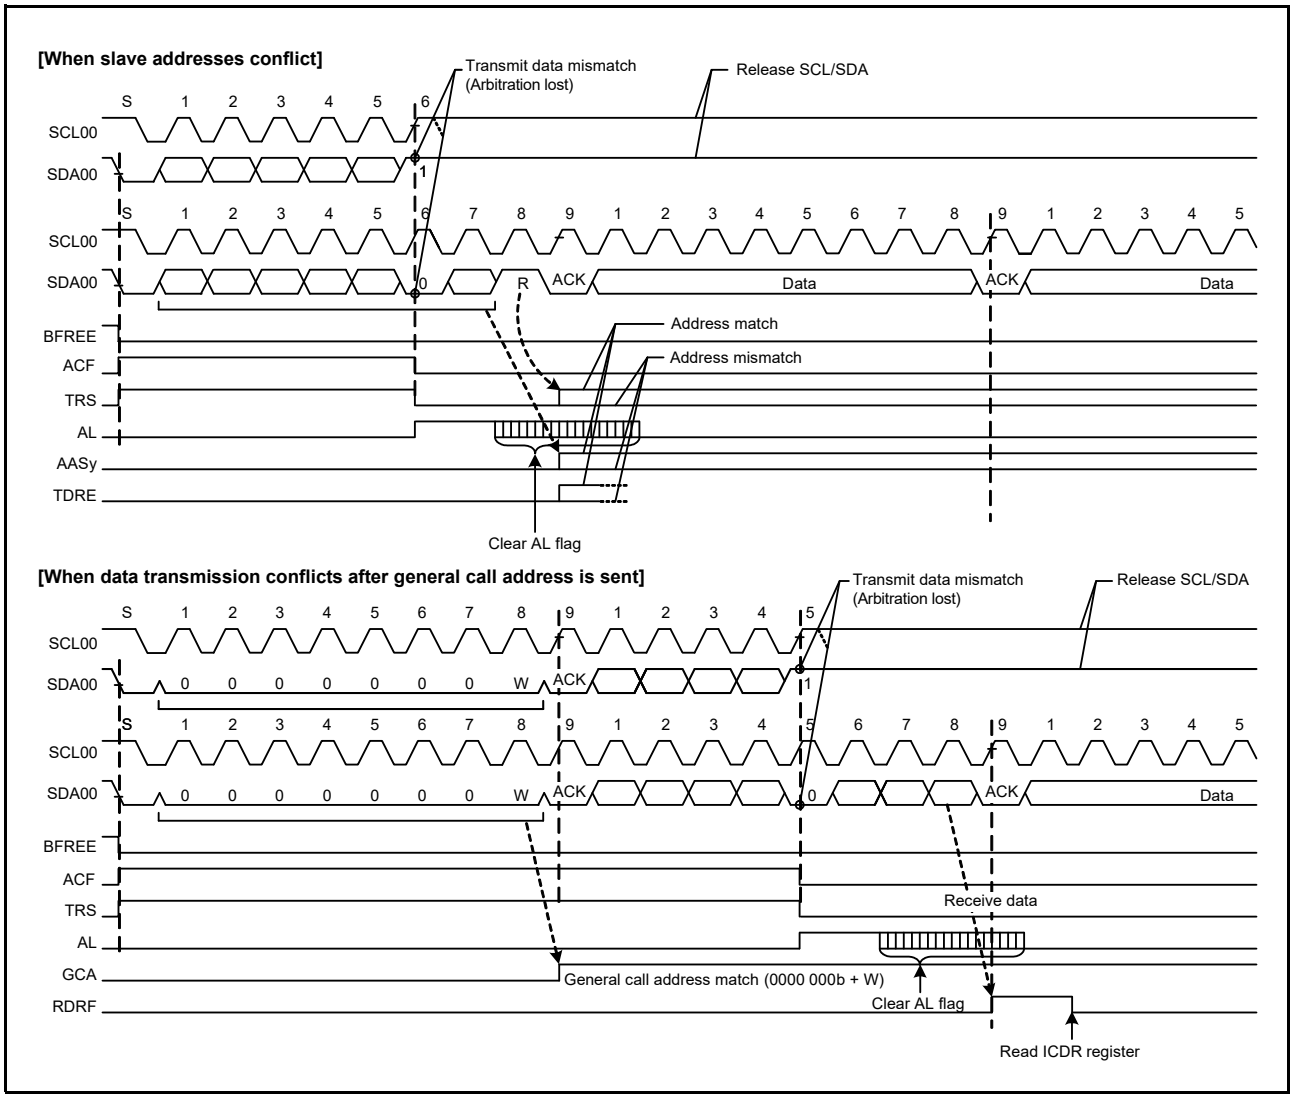

Figure 43.86 Examples of Master Arbitration-Lost Detection (MALE = 1)

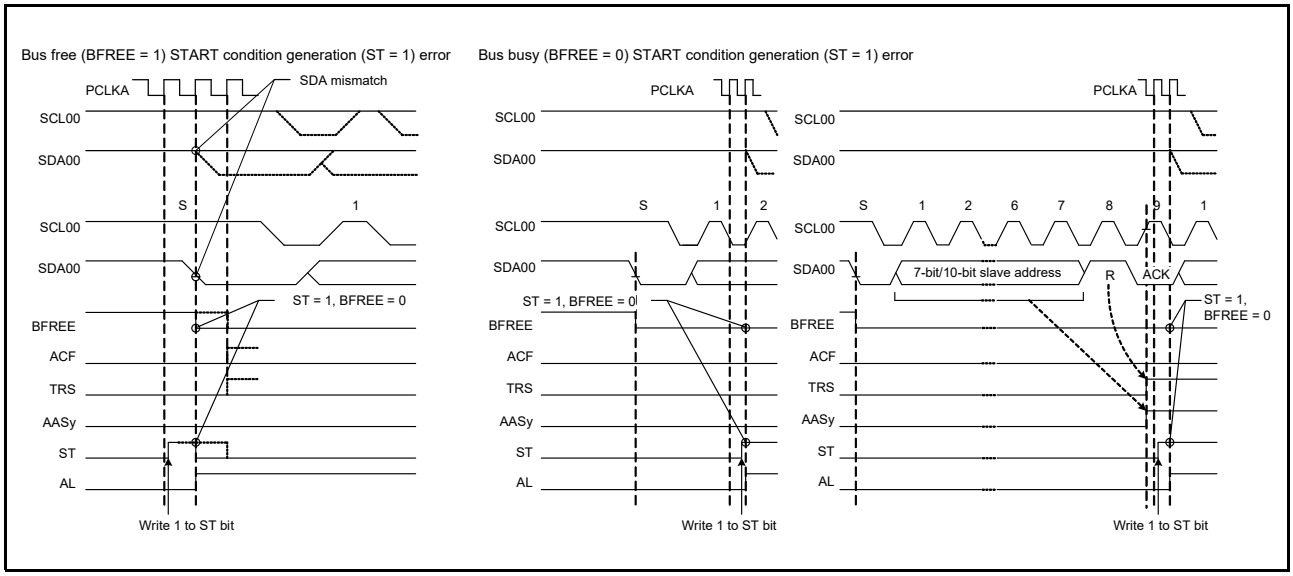

Figure 43.87 Arbitration-Lost Detection When a START Condition is Generated (MALE = 1)

43.5.6.2 NACK Transmission Arbitration-Lost Detection Function (NALE Bit)

The RI3C has a function to generate an arbitration-lost if the internal SDA output level and the level on the SDA00 line do not match (the internal SDA output is high (the SDA00 pin is high-impedance) but low is detected on the SDA00 line) during NACK transmission in receive mode. NACK transmission arbitration-lost is generated by a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflicts can occur when multiple master devices exchange common information through a single slave device.

Figure 43.88 shows an example of NACK transmission arbitration-lost detection when two master devices (master A and master B) and one slave device are connected to the bus.

In this example, master A receives two bytes of data from the slave device, and master B receives four bytes of data from the slave device. If master A and master B access the slave device at the same time, arbitration-lost does not occur on either master A or master B when accessing the slave device because the slave addresses are the same. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Here, master A sends a NACK when it has received second byte, the last byte of data, from the slave device. On the other hand, master B sends an ACK because it has not yet received four bytes of data from the slave device. At this time, a conflict occurs between the NACK of master A and the ACK of master B.

If master A cannot detect the ACK sent by master B when such a conflict occurs, master A generates a STOP condition. This conflicts with the SCL output of master B and interferes with communication.

The RI3C can generate an arbitration-lost if it receives an ACK while sending an NACK. This prevents the generation of a STOP condition and prevents bus communication interference. Also, in the ARP command processing of SMBus, it is possible to omit surplus processing (FFh transmission processing) after the NACK transmission when the UDID (unique device identification) of the “Assign Address” does not match and after the NACK transmission of the “Get UDID (General)” after the “Assign Address” is confirmed.

The RI3C detects NACK transmission arbitration-lost when the following condition is met while the ICSER.ALE and ICFER.NALE bits are 1 (NACK transmission arbitration-lost detection is enabled).

If the NACK transmission arbitration-lost occurs, the RI3C cancels the slave address matched state and enters slave receive mode.

Condition for detecting NACK transmission arbitration-lost

- When the internal SDA output level does not match the SDA00 line (ACK is received) during transmission of NACK (the ICACKR.ACKBT bit is 1)

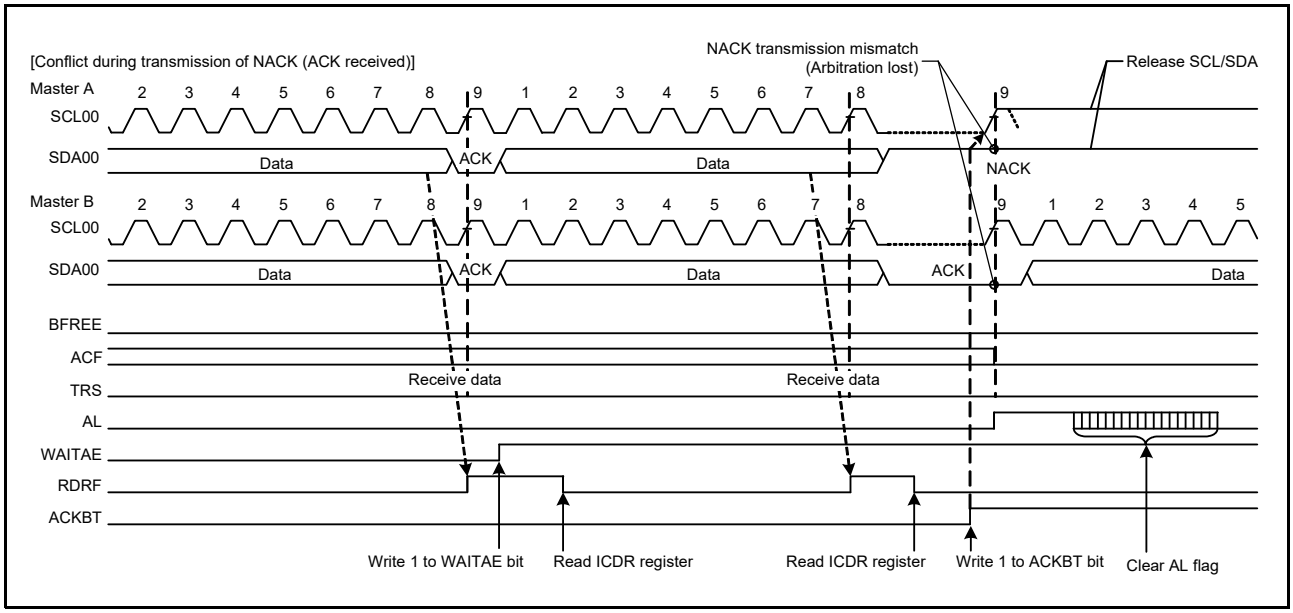

Figure 43.88 Example of NACK Transmission Arbitration-Lost Detection (NALE = 1)

43.5.6.3 Slave Arbitration-Lost Detection Function (SALE Bit)

The RI3C has a function to generate an arbitration-lost if the transmit data (i.e. the internal SDA output level) and the level on the SDA00 line do not match (the internal SDA output is high (the SDA00 pin is high-impedance) but low is detected on the SDA00 line) in slave transmit mode.
The slave arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identification) of SMBus. This function can detect a data conflict during UDID transmission of SMBus and omit surplus processing (FFh transmission processing) after the data conflict.
The RI3C detects slave arbitration-lost when the following condition is met while the ICSER.ALE and ICFER.SALE bits are 1 (slave arbitration-lost detection enabled).
If the slave arbitration-lost occurs, the RI3C cancels the slave address matched state and enters slave receive mode.

Condition for detecting slave arbitration-lost

- When the transmit data excluding acknowledgment bit (internal SDA output level) does not match the level on the SDA00 line in slave transmit mode (the ICMMR.ACF flag is 0 and the ICMMR.TRS flag is 1)

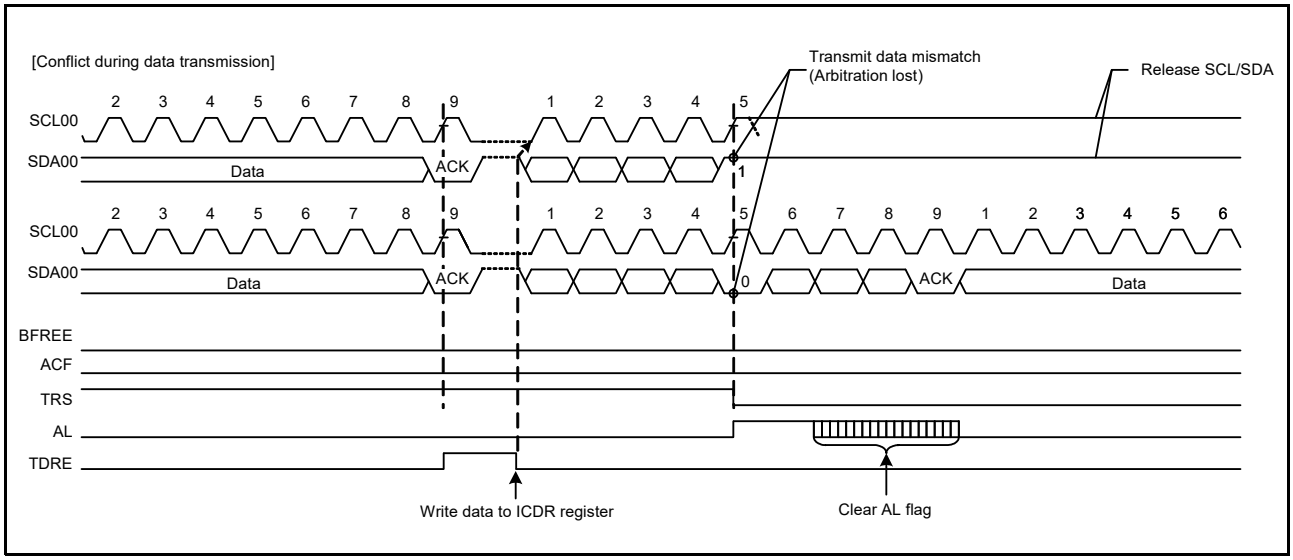

Figure 43.89 Example of Slave Arbitration-Lost Detection (SALE = 1)

43.5.7 START Condition/Repeated START Condition/STOP Condition Generating Function (I^2C Protocol Mode)

43.5.7.1 Generating a START Condition

The RI3C generates a START condition when the ICCGR.ST bit is set to 1.
When the ST bit is set to 1 (requests to generate a START condition) while the ICBSR.BFREE flag is set to 1 (bus free state), the RI3C generates a START condition.
When a START condition is generated normally, the RI3C automatically shifts to the master transmit mode.
A START condition is generated in the following sequence.

START condition generation

(1) Drive the SDA00 line low (high to low).
(2) Secure the START condition hold time with the time set in the ICFBR.HIGH[7:0] bits.
(3) Drive the SCL00 line low (high to low).
(4) Detect a low of the SCL00 line and secure the low period of SCL00 line with the time set in the ICFBR.LOW[7:0] bits.

43.5.7.2 Generating a Repeated START Condition

The RI3C generates a repeated START condition when the ICCGR.RS bit is set to 1.
When the RS bit is set to 1, generation of a repeated START condition is requested. When the ICBSR.BFREE flag is 0 (bus busy state) and the ICMMR.ACF flag is 1 (master mode), the RI3C generates a repeated START condition.
A repeated START condition is generated in the following sequence.

Repeated START condition generation

(1) Release the SDA00 line.
(2) Secure the low period of SCL00 line with the time set in the ICFBR.LOW[7:0] bits.
(3) Release the SCL00 line (low to high).
(4) Detect a high of the SCL00 line and secure the repeated START condition setup time with the time set in the ICFBR.LOW[7:0] bits.
(5) Drive the SDA00 line low (high to low).
(6) Secure the repeated START condition hold time with the time set in the ICFBR.HIGH[7:0] bits.
(7) Drive the SCL00 line low (high to low).
(8) Detect a low of the SCL00 line and secure the low period of SCL00 line with the time set in the ICFBR.LOW[7:0] bits.

Note: When requesting generation of a repeated START condition, write the slave address to the ICDR register after confirming that the ICCGR.RS bit is 0. Data written while the ICCGR.RS bit is 1 is not transferred because it is considered to be before the repeated START condition is generated.

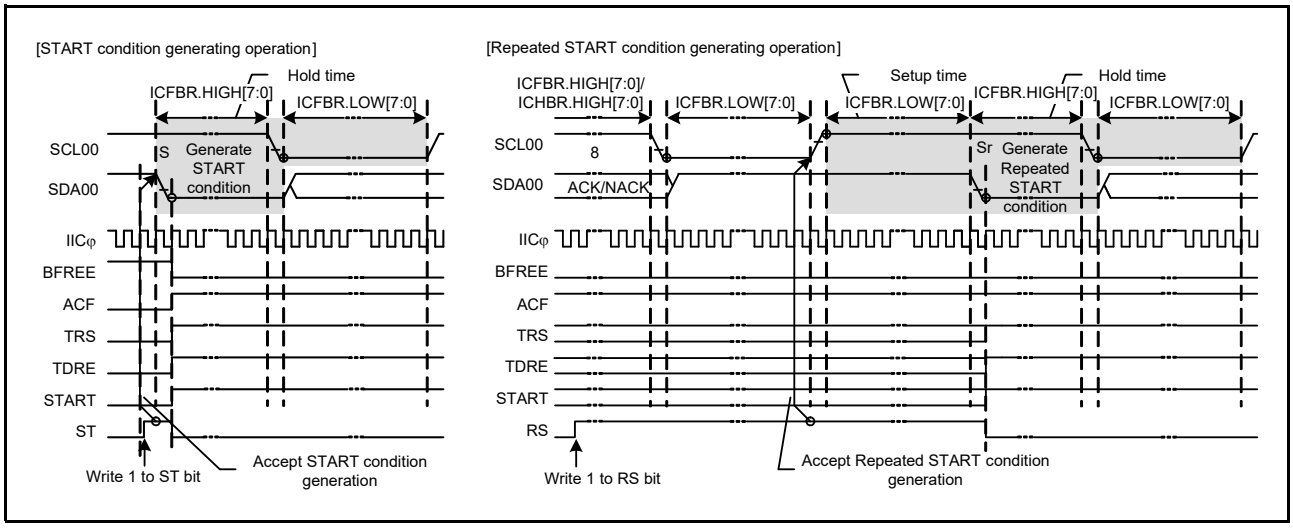

Figure 43.90 START Condition/Repeated START Condition Generating Timing (ST and RS Bits)

Figure 43.91 shows the operation timing when generating a repeated START condition after the master transmission.

Repeated START condition generation after the master transmission

(1) Initial setting. For details, refer to section 43.4.4, Initial Settings.

(2) Read the ICBSR.BFREE flag to check that the bus is open, and then set the ICCGR.ST bit to 1 (requests to generate a START condition). Upon receiving the request, the RI3C generates a START condition. At the same time, the BFREE flag is automatically set to 0, the ICSR2.START flag is automatically set to 1, and the ST bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the SDA00 line have matched while the ST bit is 1, the RI3C recognizes that generating of the START condition as requested by the ST bit has been successfully completed, and ICMMR.ACF and ICMMR.TRS flags are automatically set to 1, placing the RI3C in master transmit mode. The ICCSR.TDRE flag is also automatically set to 1 in response to setting of the TRS flag to 1.

(3) Check that the ICCSR.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to the ICDR register. Once the data for transmission are written to the ICDR register, the TDRE flag is automatically set to 0, the data are transferred from the ICDR register, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS flag is automatically updated to select master transmit or master receive mode in accordance with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RI3C continues in master transmit mode. Since the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to ICCGR.SP bit to generate a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0b, the 2 higher-order bits of the slave address, and W to the ICDR register as the first address transmission. Then, as the second address transmission, write the lower 8 bits of the slave address to ICDR register.

(4) After confirming that the ICCSR.TDRE flag is 1, write the data for transmission to the ICDR register. The RI3C automatically holds the SCL00 line low until the data for transmission are ready, a repeated START condition is generated, or a STOP condition is generated.

(5) After all bytes of data for transmission have been written to the ICDR register, wait until the value of the ICSR2.TEND flag returns to 1, and then, after check that the ICSR2.START flag is 1, set the ICSR2.START flag to 0.

(6) Set the ICCGR.RS bit to 1 (requests to generate a repeated START condition). Upon receiving the request, the RI3C generates a repeated START condition.

(7) After check that the ICSR2.START flag is 1, write the value for transmission (the slave address and the R/W# bit) to the ICDR register.

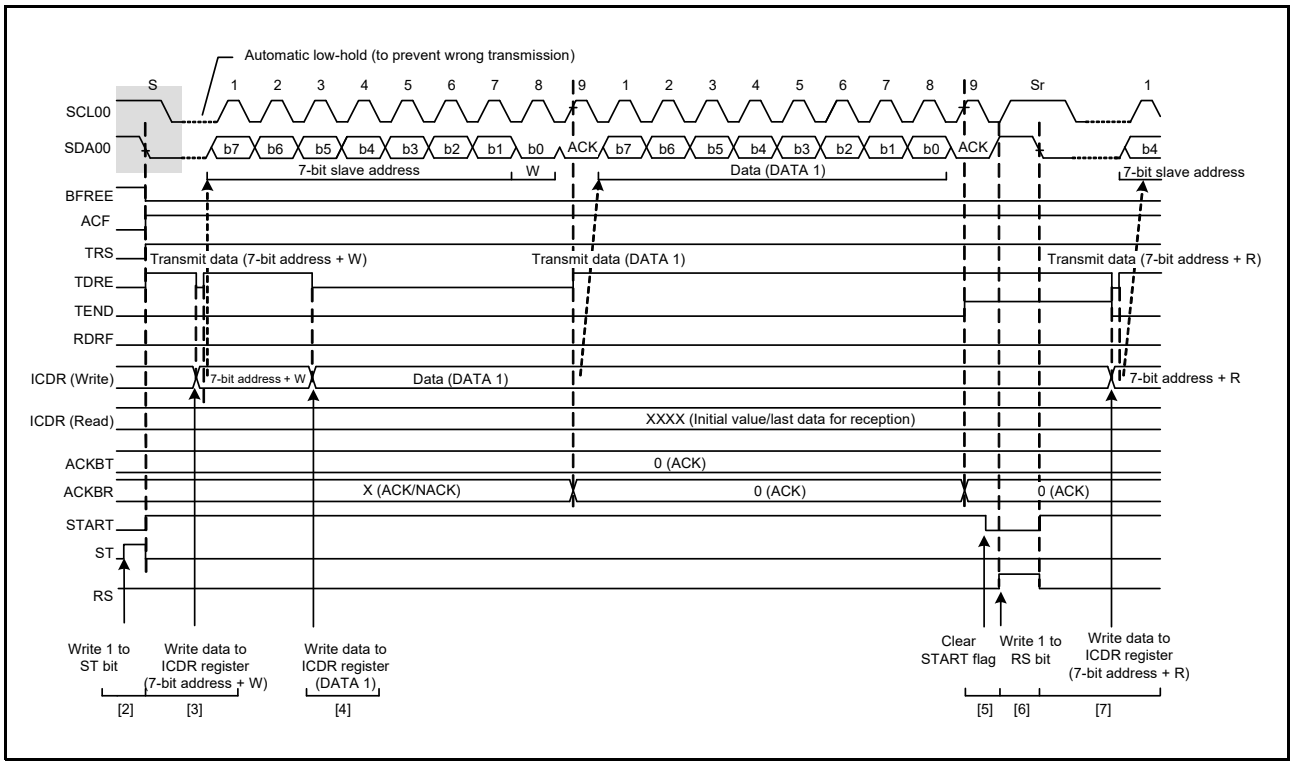

Figure 43.91 Repeated START Condition Generation Timing after the Master Transmission

43.5.7.3 Generating a STOP Condition

The RI3C generates a STOP condition when the ICCGR.SP bit is set to 1.
When the SP bit is set to 1, generation of a STOP condition is requested. When the ICBSR.BFREE flag is 0 (bus busy state) and the ICMMR.ACF flag is 1 (master mode), the RI3C generates a STOP condition.
A STOP condition is generated in the following sequence.

STOP condition generation

(1) Drive the SDA00 line low (high to low).
(2) Secure the low period of SCL00 line with the time set in the ICFBR.LOW[7:0] bits.
(3) Release the SCL00 line (low to high).
(4) Detect a high of the SCL00 line and secure the STOP condition setup time with the time set in the ICFBR.HIGH[7:0] bits.
(5) Release the SDA00 line (low to high).
(6) Secure the bus free time with the time set in the ICFBR.LOW[7:0] bits.
(7) Set the BFREE flag to 1 (to release the bus).

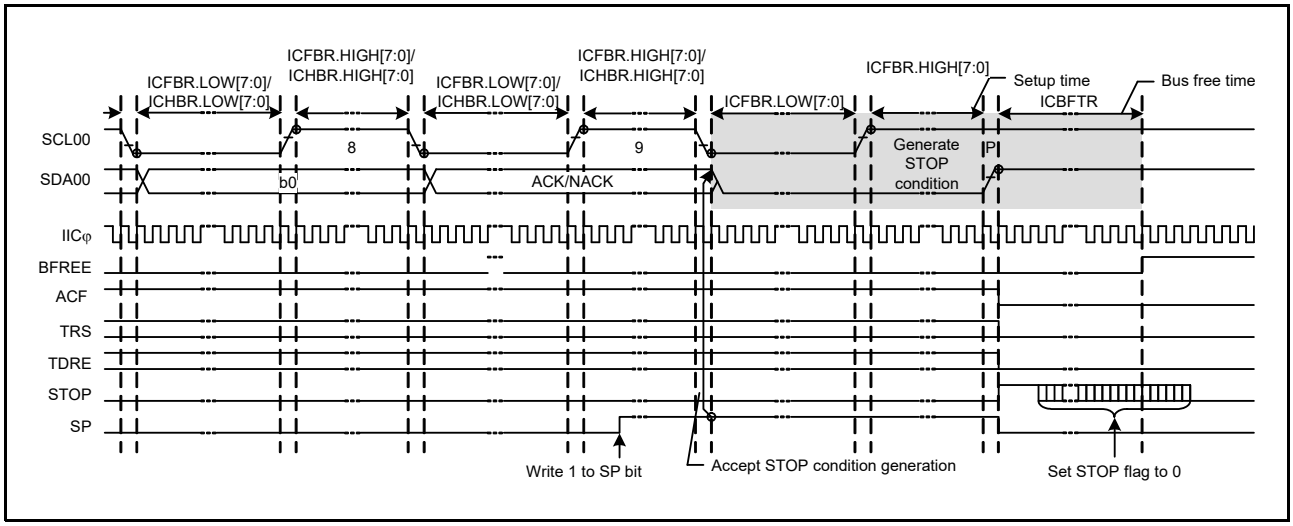

Figure 43.92 STOP Condition Generating Timing (SP Bit)

43.5.8 Bus Hanging (I2C Protocol Mode)

43.5.8.1 Timeout Function

The RI3C includes a timeout function for detecting when the SCL00 line has been stuck longer than the predetermined time. The RI3C can detect an abnormal bus state by monitoring that the SCL00 line is stuck low or high for a predetermined time.

The timeout function monitors the SCL00 line state and counts the low period or high period using the internal counter. The timeout function resets the internal counter each time the SCL00 line changes (rising or falling), but continues to count unless the SCL00 line changes. If the internal counter overflows due to no SCL00 line change, the RI3C can detect the timeout and report the bus hung state.

This timeout function is enabled when the ICSER.TMOE bit is 1. It detects a hung state that the SCL00 line is stuck low or high during the following conditions: (when ICTOR.TMOM[1:0] bits = 00b)

- The bus is busy (ICBSR.BFREE flag is 0) in master mode (ICMMR.ACF flag is 1).
- The RI3C's own slave address is detected (ICSSR register is not 0000 0000h) and the bus is busy (ICBSR.BFREE flag is 0) in slave mode (ICMMR.ACF flag is 0).
- The bus is free (ICBSR.BFREE flag is 1) while generation of a START condition is requested (ICCGR.ST bit is 1).

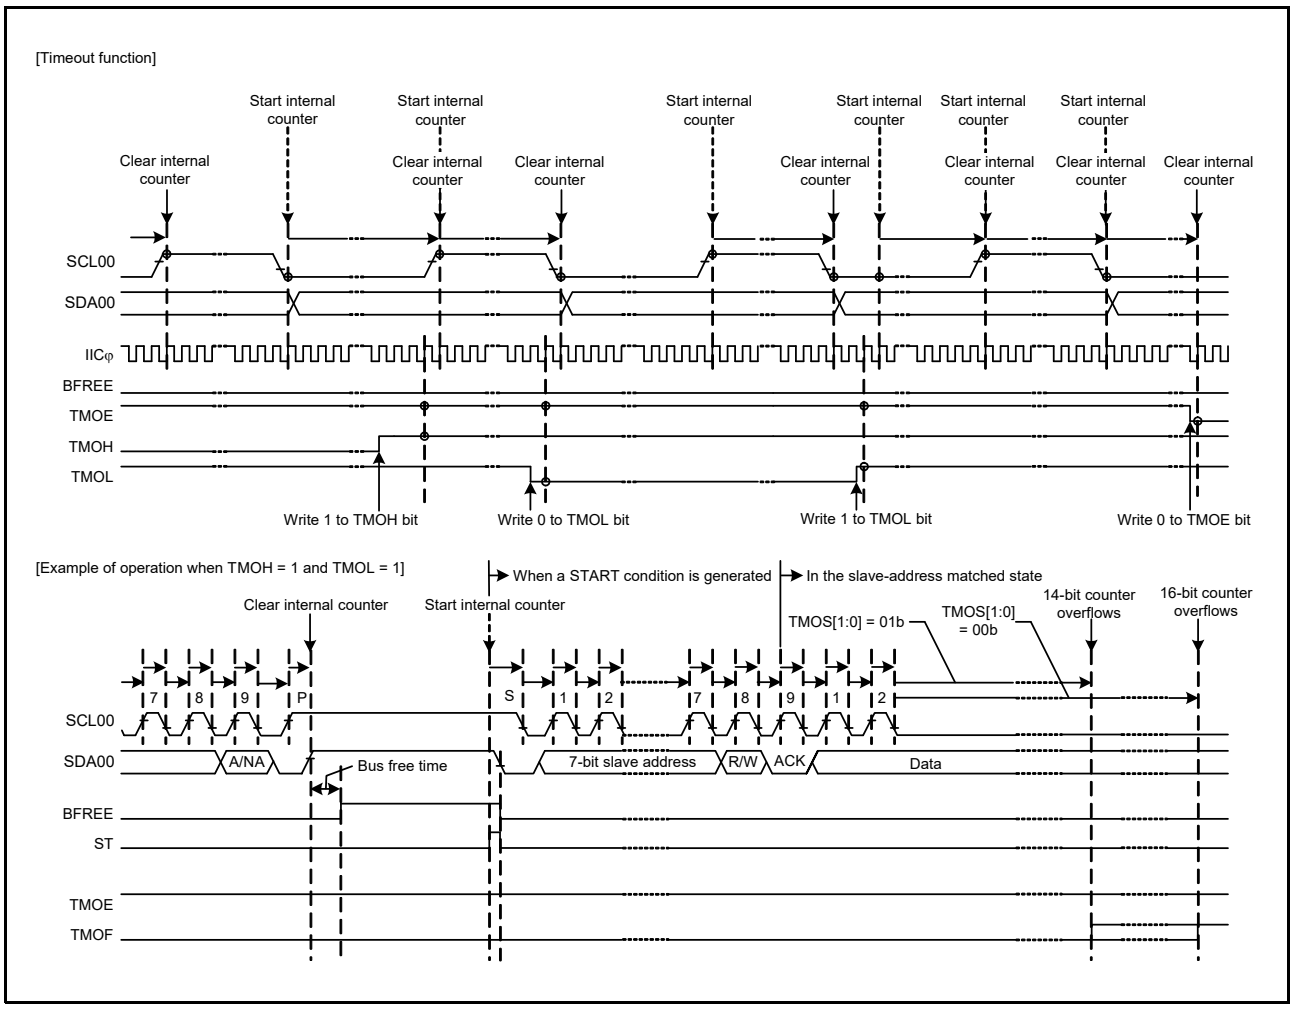

Figure 43.93 Timeout Function (TMOE, TMOS[1:0], TMOH, and TMOL Bits)

43.5.8.2 Additional SCL Output Function

In master mode, the RI3C module has a function for the output of additional SCL to release the SDA00 line from being held low by the slave device due to the master being out of synchronization with the slave device.
This function is mainly used in master mode to release the SDA00 line from the state of being stuck low by including additional SCL output from the RI3C with single cycles of the SCL as the unit in the case of a bus error where the RI3C cannot generate a STOP condition because the slave device is holding the SDA00 line low. Do not use this function in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.
When the ICOCR.CLO bit is set to 1, an additional clock pulse at the frequency set by the ICRCCR.CKS[2:0] bits and the HIGH[7:0] and LOW[7:0] bits in the ICFBR register (ICHBR register in Hs-mode) is output from the SCL00 pin. After output of this clock pulse, the CLO bit automatically becomes 0. The SCL00 pin is held low when the ICBSR.BFREE flag is 0 and held high when the BFREE flag is 1. Consecutive additional clock pulses can be output by the software program writing 1 to the CLO bit after having read CLO = 0.
When the RI3C module is in master mode and the slave device is holding the SDA00 line low because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a STOP condition is not possible. The additional SCL output function can be used to output additional clock pulses one by one to make the slave device release the SDA00 line from being held low, thus recovering the bus from an unusable state. Release of the SDA00 line by the slave device can be monitored by reading the ICIMR.SDAI flag After confirming release of the SDA00 line by the slave device, complete communications by regenerating the STOP condition.
Use this function with the ICFER.MALE bit set to 0 (master arbitration-lost detection disabled). If using this function with the ICFER.MALE bit set to 1, arbitration may be lost due to a mismatch between the value of the ICOCR.SDAO bit and the level of the SDA00 line.

Conditions for using the ICOCR.CLO bit

- When the bus is free (ICBSR.BFREE flag = 1) or in master mode (ICMMR.ACF flag = 1 and ICBSR.BFREE flag = 0)
- When the communication device does not hold the SCL00 line low

Figure 43.94 shows the operation timing of the additional SCL output function (CLO bit).

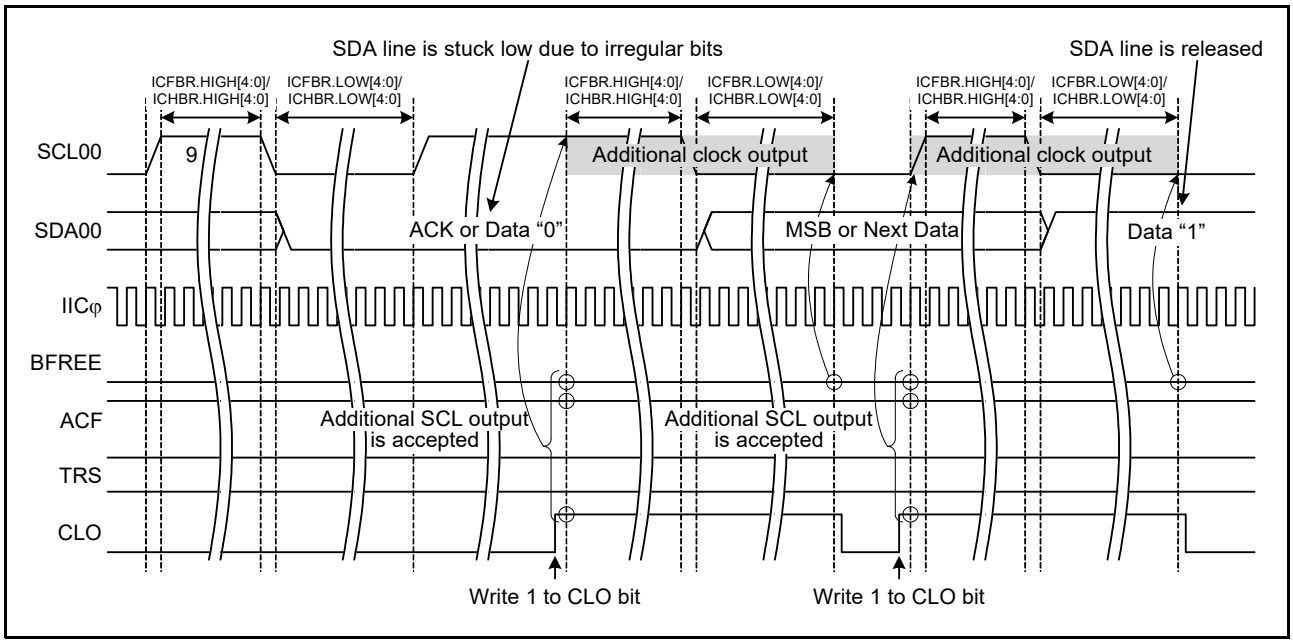

Figure 43.94 Additional SCL Output Function (CLO Bit)

43.5.9 Wake-Up Function (I2C Protocol Mode)

The RI3C includes a wake-up function to return the MCU from low power consumption states. The wake-up function enables data reception even when the operating clock (I3CCLK) is stopped, and is used to generate a wake-up interrupt when the received address matches its own slave address.
To receive data even when the operating clock is stopped, the wake-up unit must be set to asynchronous operation. After a wake-up interrupt occurs, return to synchronous operation so that communication can continue.
There are four wake-up response modes, as shown in Table 43.9.

Table 43.9 Wake-Up Response Modes

Response Mode	Response Timing	Response	SCL Status
Normal wake-up mode 1	Before returning to synchronous operation	ACK	Hold low after ACK response (at the ninth SCL falling edge), release after returning to synchronous operation.
Normal wake-up mode 2	After returning to synchronous operation	ACK	Hold low at the eighth SCL falling edge, release after returning to synchronous operation with ACK response.
Command recovery mode	Before returning to synchronous operation	ACK	Open.
EEP response mode	Before returning to synchronous operation	NACK	Open.

There are five wake-up interrupt sources.

- Host address detection (ICFER.SMBS bit = 1, ICSCR.HOAE bit = 1)
- General call address detection (ICSCR.GCAE bit = 1)
- Slave address 0 detection (ICSCR.SAR0E bit = 1, SAR0.FS bit = 0)
- Slave address 1 detection (ICSCR.SAR1E bit = 1, SAR1.FS bit = 0)
- Slave address 2 detection (ICSCR.SAR2E bit = 1, SAR2.FS bit = 0)

43.5.9.1 Normal Wake-Up Mode 1

In normal wake-up mode 1, the RI3C operates as follows after a wake-up interrupt occurs.

(1) Generates an ACK for the data byte that contains its own slave address.
(2) Holds the SCL line low at the ninth SCL falling edge.
(3) When 1 is written to the ICWUCR.WUFSYNE bit, it returns to synchronous operation and sets the ICWUSR.WUASYNF flag to 0.
(4) Releases the SCL line and returns to normal operation.

Note: When returning from low power consumption states due to wake-up interrupt, the setting of the ICCSCR.WAITRE bit is ignored.

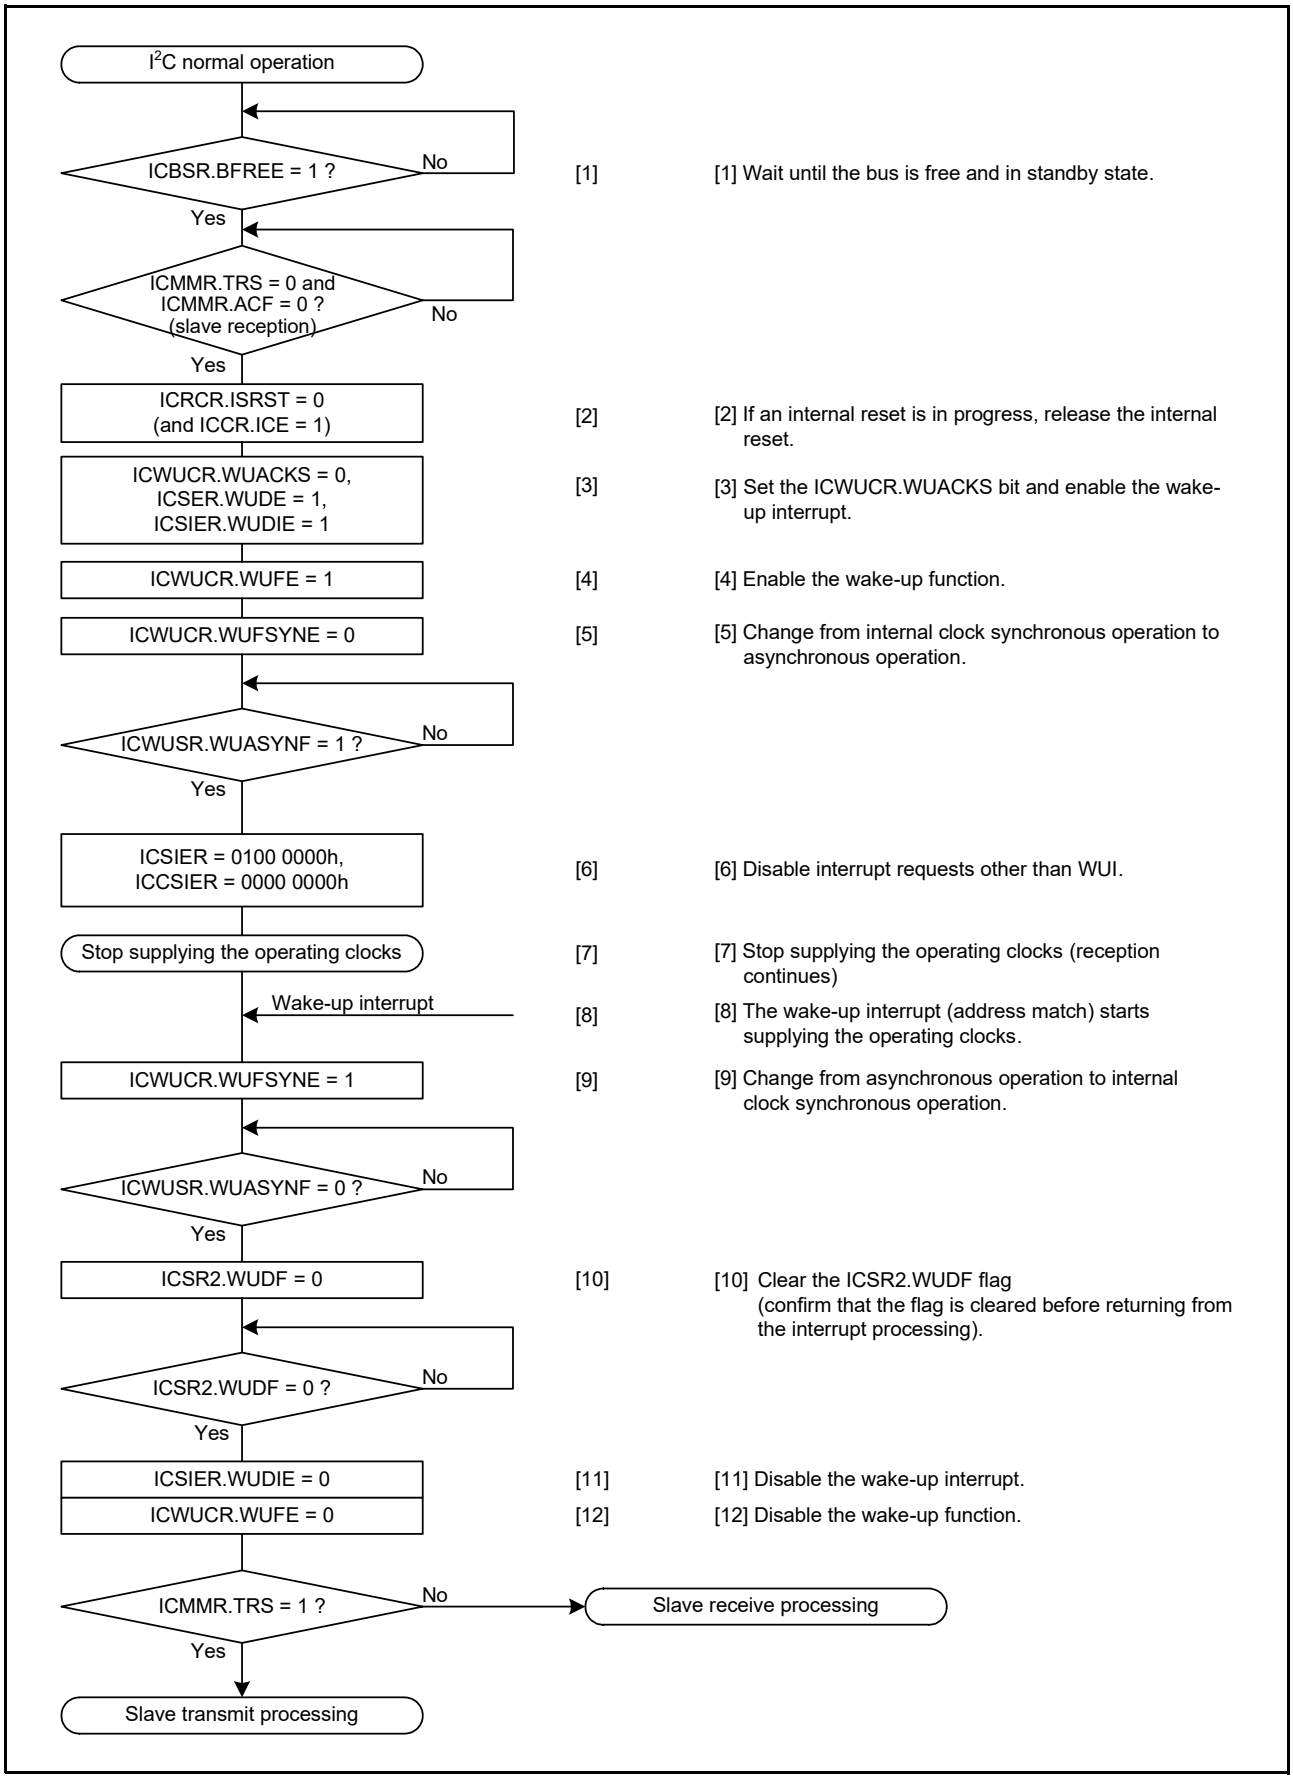

Figure 43.95 Example of Using Normal Wake-Up Mode 1

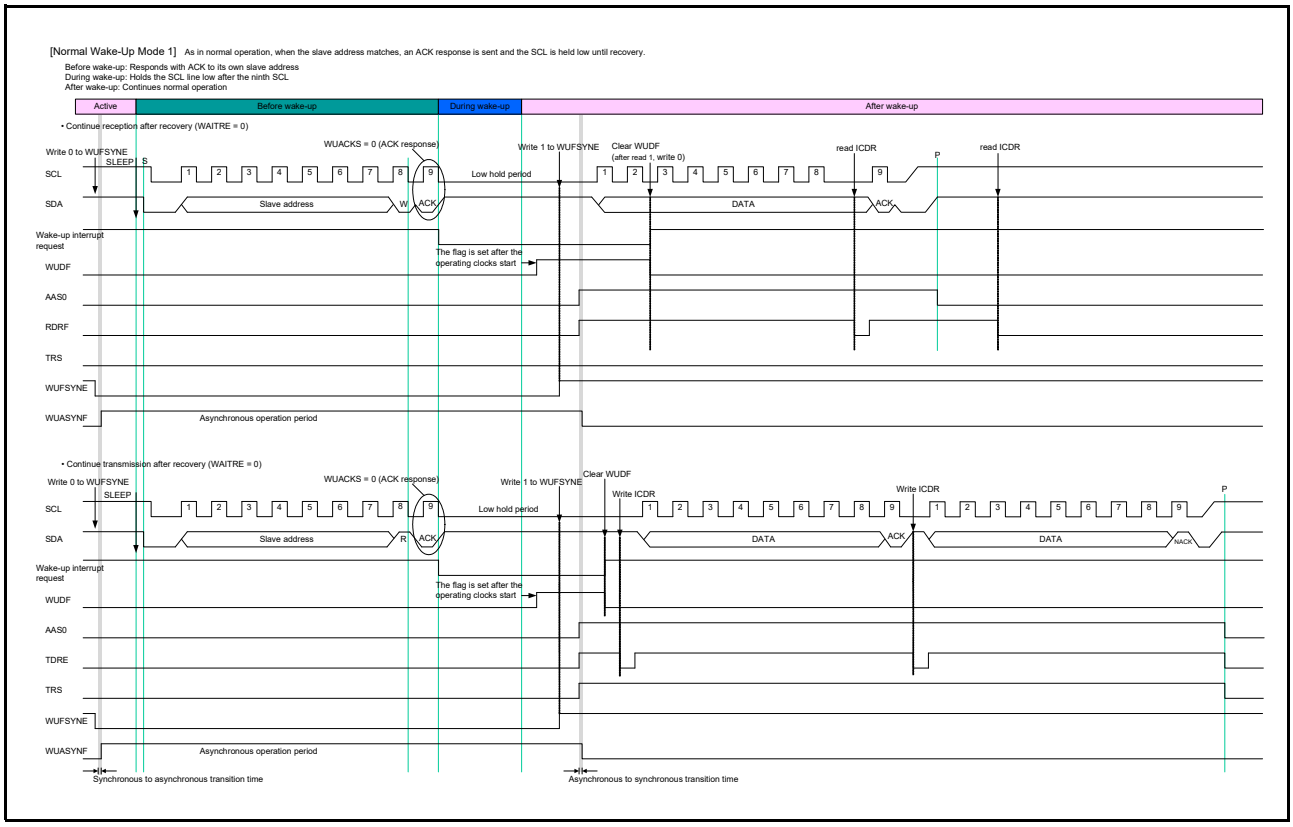

Figure 43.96 Operation Timing of Normal Wake-Up Mode 1

43.5.9.2 Normal Wake-Up Mode 2

In normal wake-up mode 2, the RI3C operates as follows after a wake-up interrupt occurs.

(1) Holds the SCL line low at the eighth SCL falling edge for the data byte that contains its own slave address.
(2) When 1 is written to the ICWUCR.WUFSYNE bit, it returns to synchronous operation and sets the ICWUSR.WUASYNF flag to 0.
(3) Generates an ACK and release the SCL line.
(4) Returns to normal operation.

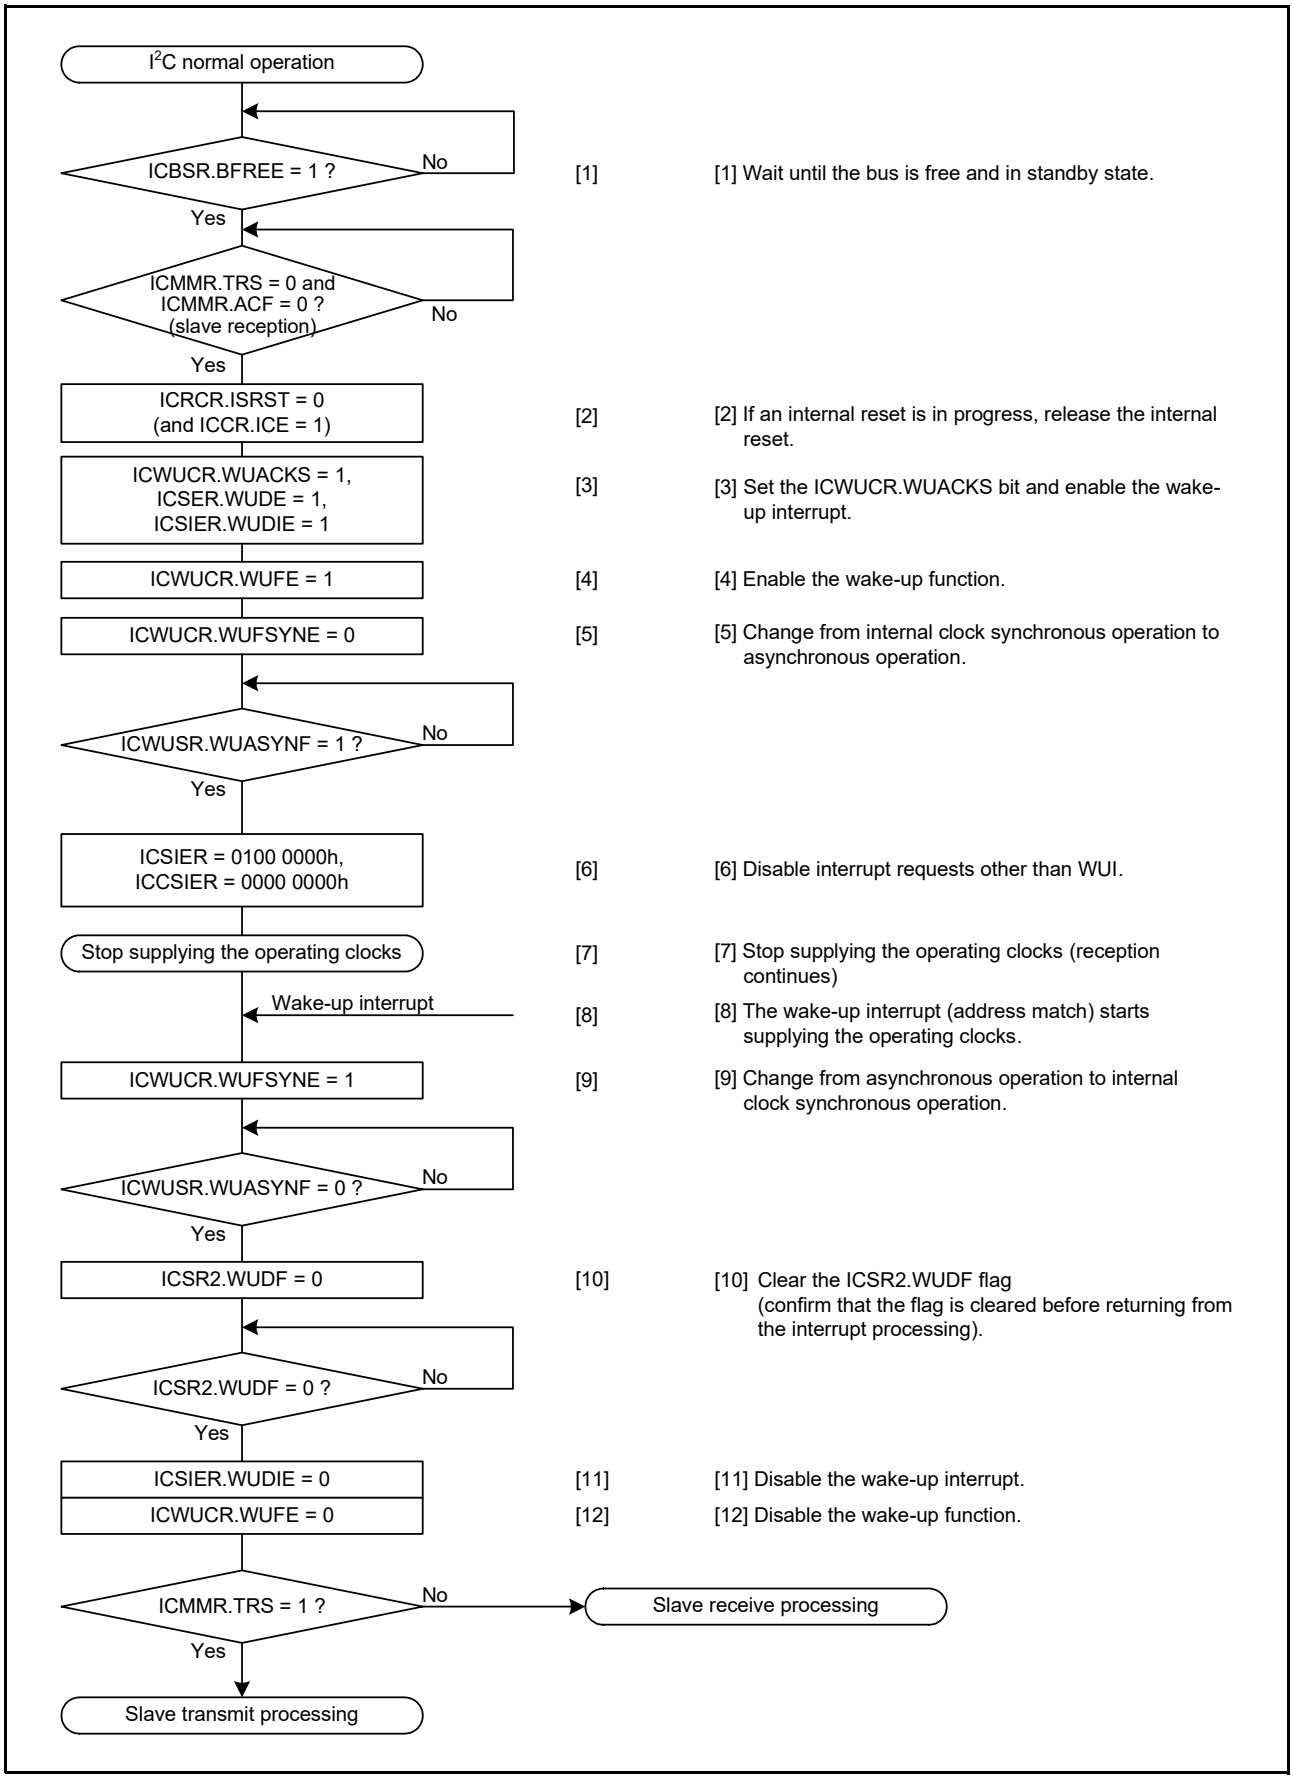

Figure 43.97 Example of Using Normal Wake-Up Mode 2

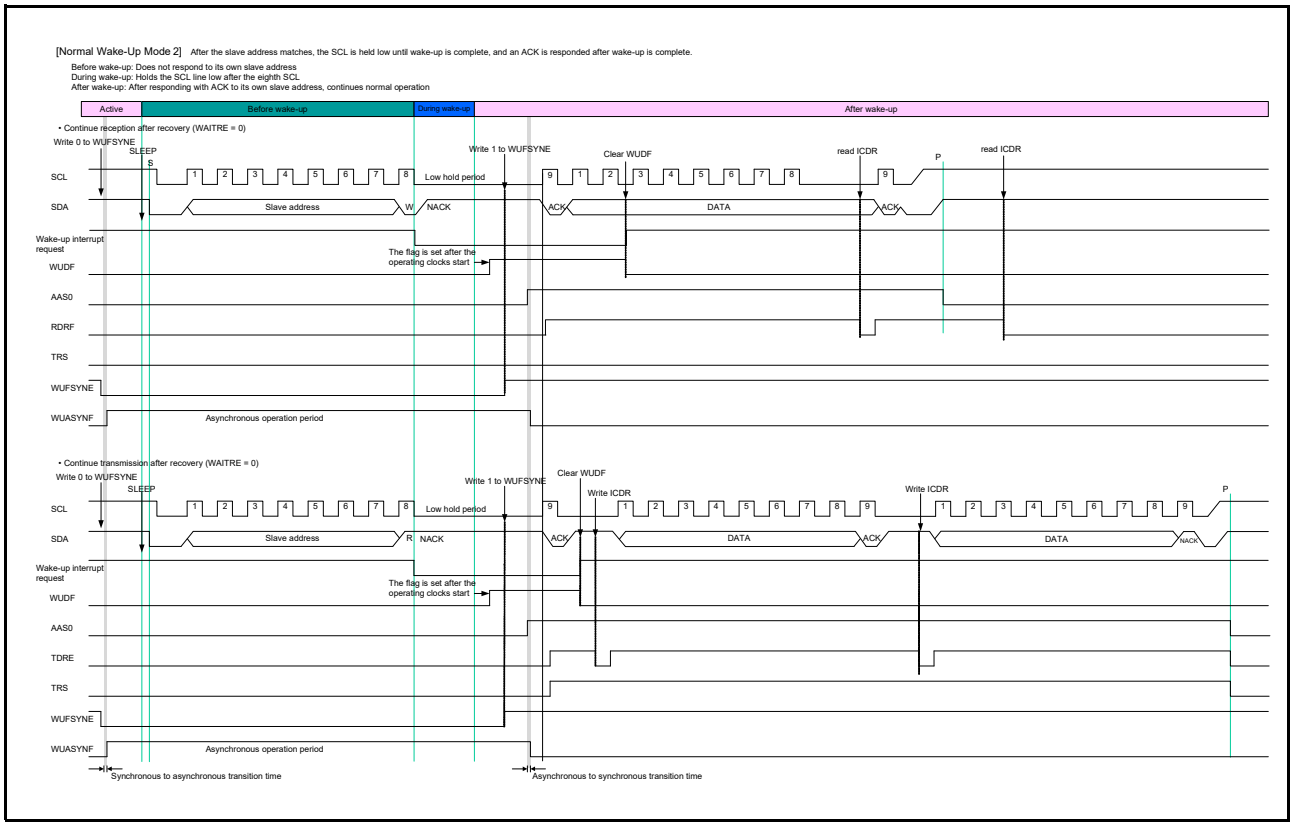

Figure 43.98 Operation Timing of Normal Wake-Up Mode 2

43.5.9.3 Command Recovery Mode and EEP Response Mode

In command recovery mode and EEP response mode, the SCL line is not held low during wake-up operations. As a result, other devices can use the bus during this period, but the RI3C cannot perform subsequent data transmission and reception.

In these modes, the ICRCR.ISRST bit is set to 1, so after returning from low power consumption states, set the ICRCR.MRST bit to 1 (module reset) and then perform the initial settings.

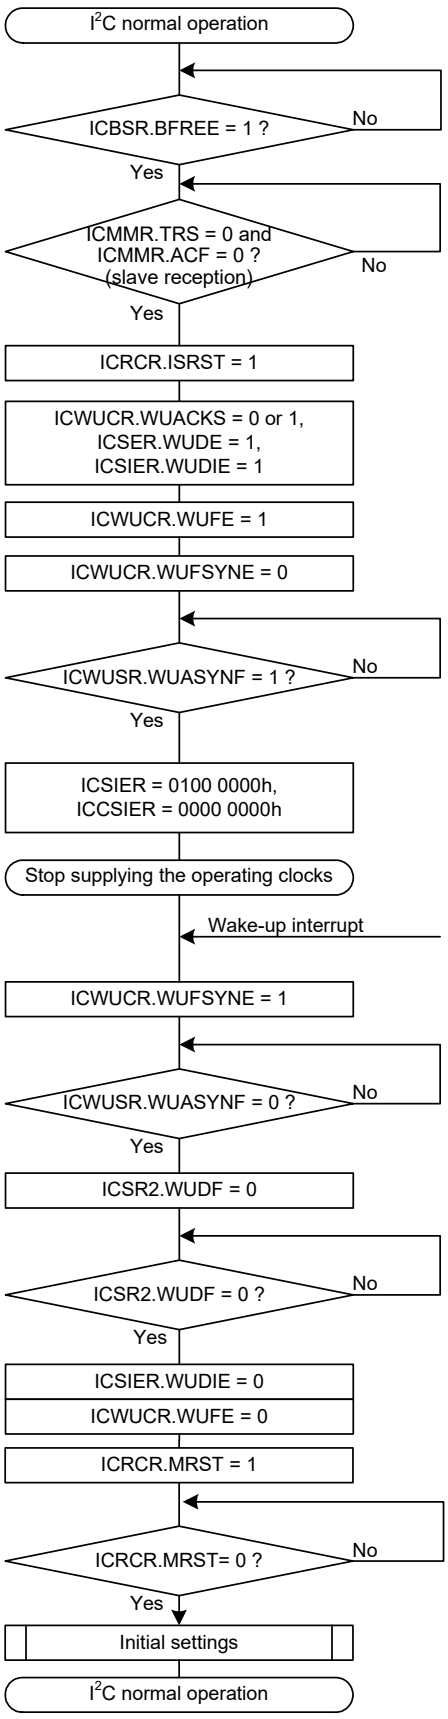

Figure 43.99 Example of Using Command Recovery Mode and EEP Response Mode

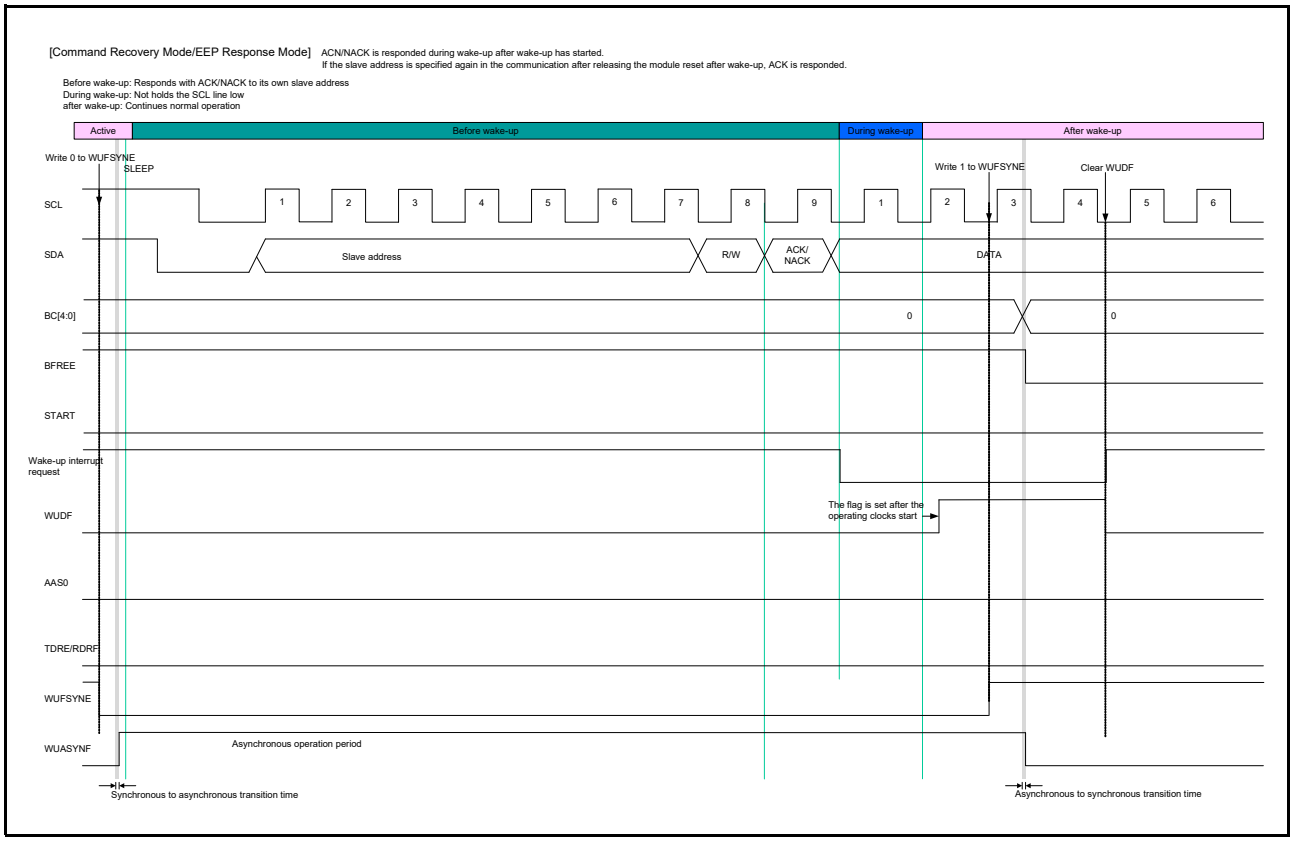

Figure 43.100 Operation Timing of Command Recovery Mode and EEP Response Mode

43.5.9.4 Notes on Using Wake-Up Function

Note the following points when using the wake-up function.

(1) Before setting the ICWUCR.WUFSYNE bit to 0 (asynchronous operation), set the following registers/bits.
   (a) Set the ICWUCR.WUFE, ICSER.WUDE, and ICSIER.WUDIE bits to 1, and the ICMMR.ACF and TRS flags to 0.
   (b) The wake-up function does not support device ID addresses and 10-bit address formats. Set the ICSCR.DIDE bit and SARy.FS bit (y = 0 to 2) to 0.
   (c) The timeout function cannot be used. Set the ICSER.TMOE bit to 0.

(2) When the wake-up detection circuit is disabled, the next reception may start if a START condition is detected at the timing when the ICWUCR.WUFSYNE bit is written to 0. In this case, the ICWUSR.WUASYNF flag becomes 1 after the communication is completed and a STOP condition is detected.

(3) After setting the ICWUCR.WUFSYNE bit to 0, do not rewrite the ICFER, ICCSCR, ICACKR, ICICR, ICTCR, and SARy registers until the ICWUSR.WUASYNF flag is set to 1. If rewritten, RI3C may malfunction.

(4) Do not access the RI3C registers except for the ICSIER register, ICCSIER register, and ICWUCR.WUFSYNE bit while the ICWUSR.WUASYNF flag is 1 (wake-up detection circuit enabled).

(5) When using normal wake-up mode 2, do not set the ICACKR.ACKBT bit to 1.

(6) If the ICWUCR.WUFSYNE bit is set to 1 (synchronous operation) when no wake-up condition is detected or when the bus is free, the wake-up detection circuit is disabled only after a STOP condition is detected.

43.5.10 SMBus Operation (I^2C Protocol Mode)

The RI3C is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the ICFER.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus standard, set the ICRCCR.CKS[2:0] bits, the ICFBR.HIGH[7:0] bits, and the ICFBR.LOW[7:0] bits. In addition, determine the values of the ICOCR.DLCS bit and the ICOCR.SDDL[2:0] bits to meet the data hold time (300 ns (min.)). When the RI3C is used only as a slave device, the transfer rate setting is not necessary, whereas the ICFBR.LOW[7:0] bits need to be set to a value longer than the data setup time (250 ns).
For the SMBus device default address (1100 001b), use one of the slave address registers 0 to 2 (SAR0, SAR1, and SAR2), and set the corresponding FS bit (7-bit/10-bit address format select) in SARy (y = 0 to 2) to 0 (7-bit address format).
When transmitting the UDID (Unique Device Identifier), set the ICFER.SALE bit to 1 to enable the slave arbitration lost detection function.

43.5.10.1 SMBus Timeout Measurement

(1) Measuring timeout of slave device

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication.

- From START condition to STOP condition

To measure timeout for slave devices, measure the period from START condition detection to STOP condition detection with a timer such as TMR using a START condition detection interrupt (STI) and STOP condition detection interrupt (SPI) of the RI3C. The measured timeout period must be within cumulative clock low extend time (slave device) ($T_{LOW:SEXT}$: 25 ms (max.)) of the SMBus standard.
If the time measured with the timer exceeds the detect clock low timeout ($T_{TIMEOUT}$: 25 ms (min.)) of the SMBus standard, the slave device must release the bus by writing 1 to the ICRCR.ISRST bit to perform an internal reset of the RI3C. When an internal reset is performed, the RI3C stops driving the bus for the SCL00 pin and SDA00 pin and make the SCL00/SDA00 pin outputs high-impedance, which releases the bus.

(2) Measuring timeout of master device

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication.

- From START condition to acknowledgment bit
- Between acknowledgment bits
- From acknowledgment bit to STOP condition

To measure timeout for master devices, measure these periods with a timer such as TMR using a START condition detection interrupt (STI), STOP condition detection interrupt (SPI), and transmission end interrupt (TEI) or receive data full interrupt (RXI) of the RI3C. The measured timeout period must be within the cumulative clock low extend time (master device) ($T_{LOW:MEXT}$: 10 ms (max.)) of the SMBus standard, and the total of all $T_{LOW:MEXT}$ from START condition to STOP condition must be within $T_{LOW:SEXT}$: 25 ms (max.).
For the ACK receive timing (rising edge of the ninth SCL), monitor the ICSR2.TEND flag in master transmit mode (master transmitter) and the ICCSR.RDRF flag in master receive mode (master receiver). For this reason, perform bytewise transmit operation in master transmit mode, and hold the ICCSCR.WAITAE bit 0 until the byte just before reception of the final byte in master receive mode. While the WAITAE bit is 0, the RDRF flag is set to 1 at the rising edge of the ninth SCL.
If the period measured with the timer exceeds the cumulative clock low extend time (master device) ($T_{LOW:MEXT}$: 10 ms (max.)) of the SMBus standard or the total of measured periods exceeds the detect clock low timeout ($T_{TIMEOUT}$: 25 ms (min.)) of the SMBus standard, the master device must stop the transaction by generating a STOP condition. In master transmit mode, immediately stop the transmit operation (writing data to ICDR register).

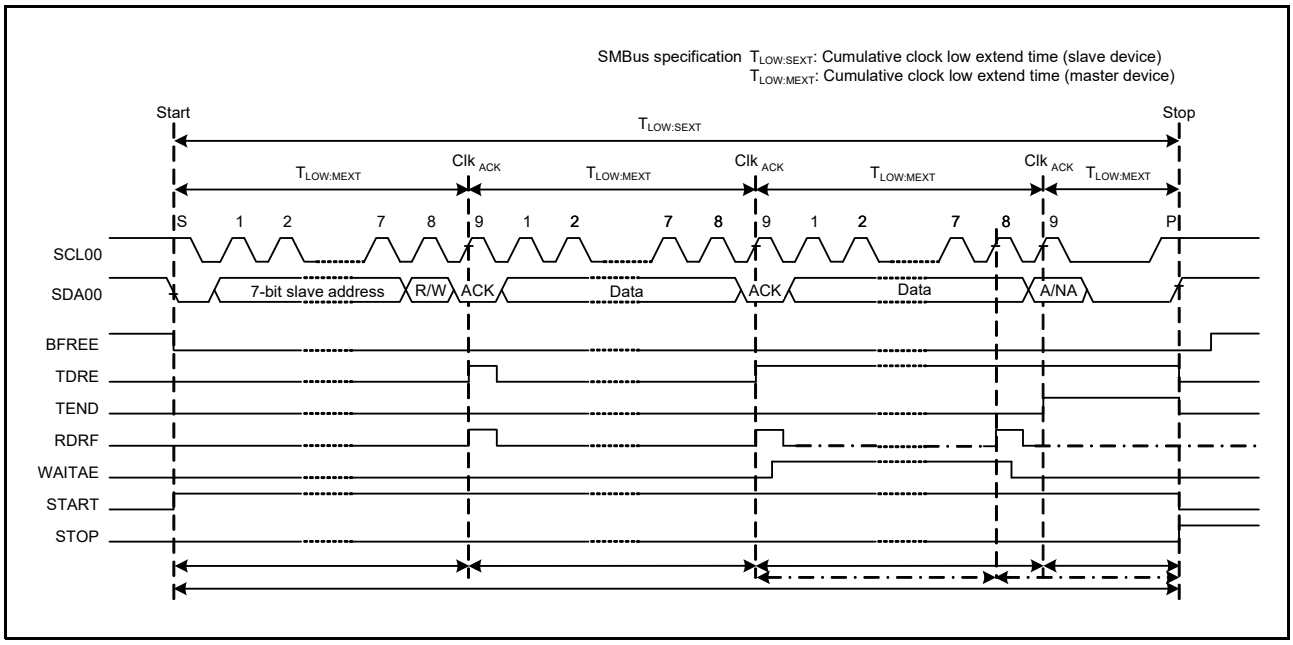

Figure 43.101 SMBus Timeout Measurement

43.5.10.2 Packet Error Code (PEC)

This MCU incorporates a CRC calculator. The CRC calculator enables transmission of a packet error code (PEC) or checking the received data of the SMBus in data communication of the RI3C. For the CRC generating polynomials of the CRC calculator, refer to section 50, CRC Calculator (CRCA).

The PEC data in master transmit mode can be generated by writing all transmit data to the CRC data input register (CRCDIR) in the CRC calculator.

The PEC data in master receive mode can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC data output register (CRCDOR) with the received PEC data.

To send ACK or NACK according to the match or mismatch result when the final byte is received as a result of the PEC code check, set the ICCSCR.WAITAE bit to 1 before the rising edge of the eighth SCL during reception of the final byte, and hold the SCL00 line low at the falling edge of the eighth clock pulse.

43.5.10.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of (or request the SMBus host for) its own slave address or to request its own slave address from the SMBus host.

For a product of the this MCU to operate as an SMBus host (or ARP master), the host address (0001 000b) sent from the slave device must be detected as a slave address, so the RI3C has a function for detecting the host address. To detect the host address as a slave address, set the ICFER.SMBS bit and the ICSCR.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

43.5.11 CCC detection function (I3C protocol mode)

In case of Broadcast CCC

(1) Receive Broadcast Address (7Eh) and RnW = 0 after START condition or repeated START condition.
(2) Respond with ACK.
(3) Receive Common Command Code (CCC).
(4) In accordance with the CCC, the following data is stored. (Storage destination: refer to Table 43.10)
(5) Store the Receive Status Descriptor into the receive status queue.

In case of Broadcast CCC (ENTDAA)

(1) Receive Broadcast Address (7Eh) and RnW = 0 after START condition.
(2) Respond with ACK.
(3) Receive ENTDAA.
(4) If receives Broadcast Address (7Eh) and RnW = 1 after repeated START condition.
(5) When the Dynamic Address is not assigned, ACK response is done.
(6) This Provisioned ID (the ICPIDHR register and bits b15 to b0 of the ICPIDLR register), BCR (bits b15 to b8 of the ICDCTR register), DCR (bits b7 to b0 of the ICDCTR register) are transmitted.
(7) When winning the arbitration in a transmission of the above Step 6, the Dynamic Address following that is received.
When losing arbitration in a transmission of the above Step 6, processing of Step 6 is repeated from Step 4.
(8) When parity of the Dynamic Address is valid, ACK response is done.
(9) When parity of the Dynamic Address is invalid, NACK replies, and repeat the process from Steps 4 to 7.
(10) ICDARy.DADR[6:0] bits are renewed and the ICDAMRy.DAV flag is set to 1.
(11) Upon detecting the STOP condition, Store the Receive Status Descriptor into the receive status queue.

In case of Direct Write CCC

(1) Receive Broadcast Address (7Eh) and RnW = 0 after START condition or repeated START condition.
(2) Respond with ACK.
(3) Receive Common Command Code (CCC).
(4) Receive Dynamic Address and RnW = 0 after repeated START condition.
(5) Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, RI3C responds with ACK.
If they do not match, it responds with NACK and waits for repeated START condition or STOP condition.
(6) In accordance with the CCC, the following data is stored. (Storage destination: refer to Table 43.10)
(7) Store the Receive Status Descriptor into the receive status queue.

In case of Direct Read CCC

(1) It receives Broadcast Address (7Eh) and RnW = 1 after START condition or repeated START condition.
(2) Respond with ACK.
(3) Receive Common Command Code (CCC).
(4) Receive Dynamic Address and RnW = 1 after repeated START condition.
(5) Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, RI3C responds with ACK.
If they do not match, it responds with NACK and waits for repeated START condition or STOP condition.
(6) Respond from register according to CCC. (Responding CCC: refer to Table 43.10)
(7) Store the Receive Status Descriptor into the receive status queue.

Table 43.10 Common Command Code Operation

Command Code	CCC Type	Command Name	With Data	Auto Response	Storage
00h	Broadcast	ENEC	Yes	—	Register
01h	Broadcast	DISEC	Yes	—	Register
02h	Broadcast	ENTAS0	No	—	Register

94h	Direct Read	GETMXDS	—	Yes	Register

43.5.12 Clock Stalling (I3C Protocol Mode)

RI3C has the function of stalling the SCL during the SCL Low period.
The SCL stall control is described in the table below.

Table 43.11 I3C Clock Stalling

Clock Stalling Condition	Clock Stalling Control	Clock Stalling Period
I3C Transfer, ACK/NACK Phase	ICSTCR.APSE bit setting	During the count period of ICSTCR.STT[15:0] value
	Transmit FIFO Empty	Until data is written to the transmit FIFO
	Receive FIFO Full	Until data is read from the receive FIFO
I3C Write Data Transfer, Parity Bit	ICSTCR.PBSE bit setting	During the count period of ICSTCR.STT[15:0] value
	Transmit FIFO Empty	Until data is written to the transmit FIFO
I3C Read Transfer, Transition Bit	Receive FIFO Full	Until data is read from the receive FIFO
Assigned Address Phase	ICSTCR.AASE bit setting	During the count period of ICSTCR.STT[15:0] value

The following figure shows the stalling timing of each condition.

(1) I3C Transfer, ACK/NACK Phase

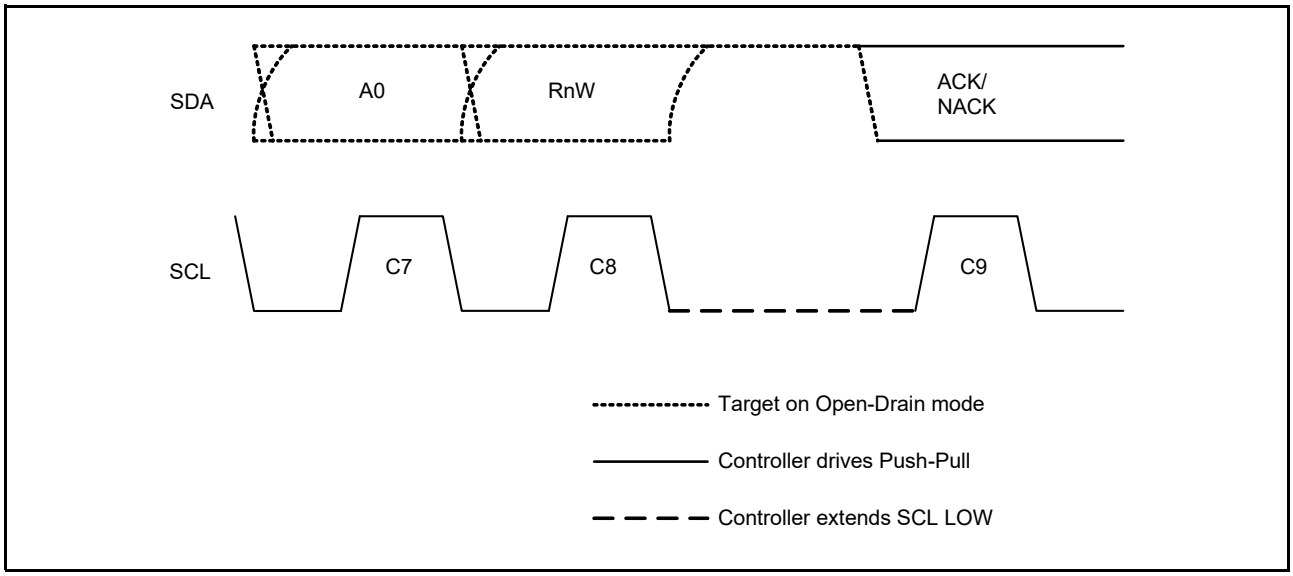

Figure 43.102 Controller Clock Stalling in ACK Phase

(2) I3C Write Data Transfer, Parity Bit

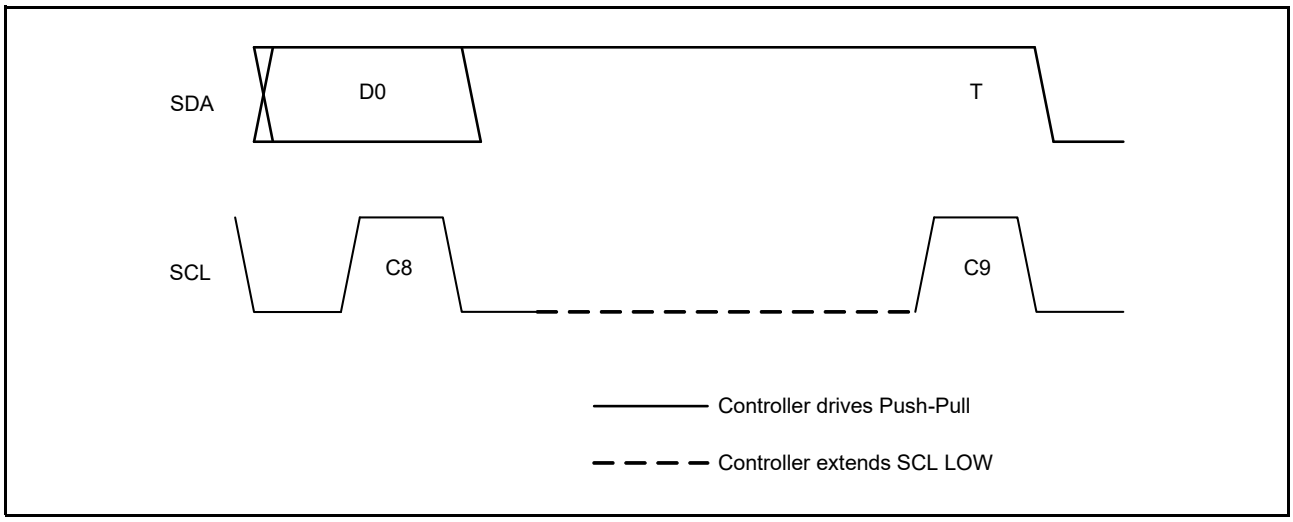

Figure 43.103 Controller Clock Stalling in Write Parity Bit

(3) I3C Read Transfer, Transition Bit

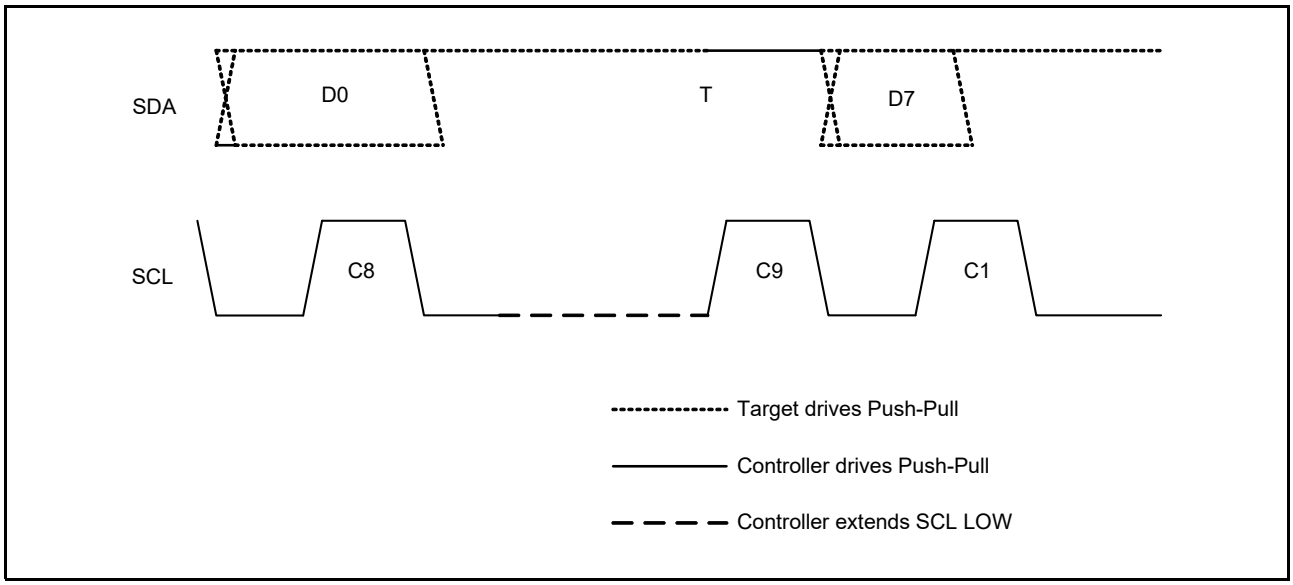

Figure 43.104 Controller Clock Stalling in T-bit Before Next Read Data

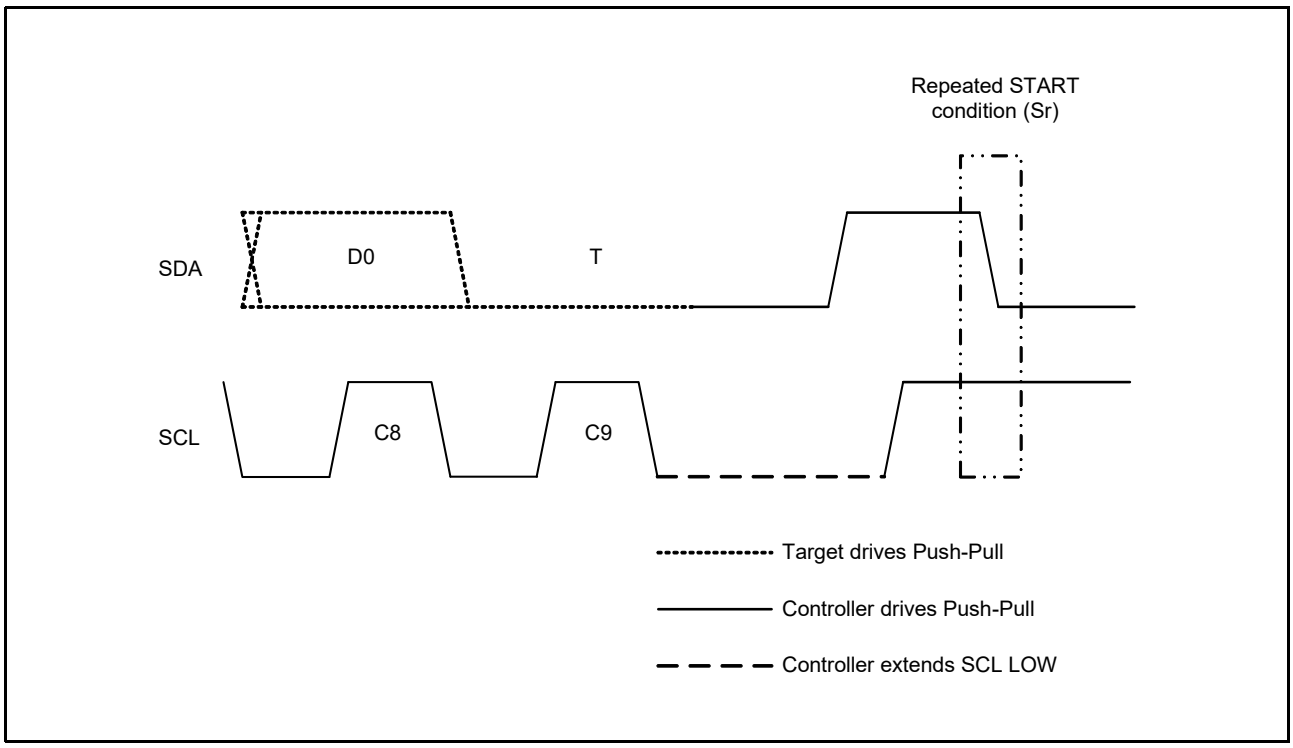

Figure 43.106 Controller Clock Stalling in Low T-bit before Repeated START Condition

(4) Dynamic Address Assignment, First Bit of Assigned Address

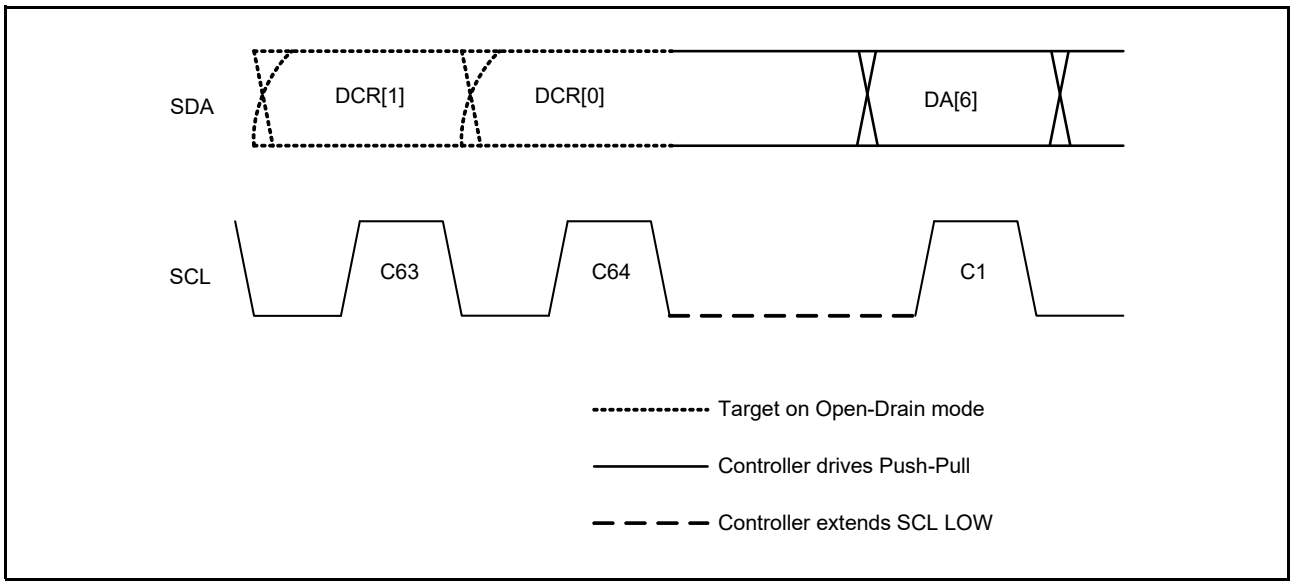

Figure 43.107 Controller Clock Stalling in Dynamic Address First Bit

43.5.13 IBI (I3C Protocol Mode)

RI3C detects IBI in the arbitrated Address header following a START condition (but not following a repeated START condition). If START Request (SDA Low Drive) is issued from Target Device, RI3C drives SCL low and completes START condition. After that, it supplies SCL and receives IBI Request.
The IBI to be detected is classified into the following three types.

- Target Interrupt Request
- Controller Role Request

The operation when detecting each IBI is described below.

43.5.13.1 Target Interrupt Request

(1) Detect Target Address with RnW bit High in Address header.
(2) Compare the detected Target Address with the DADR[7:0] bits in each DAT (the ICTDATRm register).
(3) When it does not match the ICTDATRm.DADR[7:0] bits:
• Responds with NACK, then issues a STOP condition.
When it matches the ICTDATRm.DADR[7:0] bits and the ICTDATRm.TIRRJ bit = 1:
• RI3C operates in the following order:
1. Responds with NACK.
2. Issues a repeated START condition, then automatically issues Direct DISEC CCC to the detected Target.
3. Issues a STOP condition.
When it matches the ICTDATRm.DADR[7:0] bits and the ICTDATRm.TIRRJ bit = 0:
• Responds with ACK.
(4) When the ICTDATRm.IBIPL bit is 0:
• Issues a STOP condition.
When the ICTDATRm.IBIPL bit is 1:
• RI3C operates in the following order:
1. Drives the SCL to receive the IBI Data from the Target following the ACK response and receives IBI Data.
2. It stores the received IBI Data into the IBI queue.
3. Each time IBI Data of the size set by the ICQBTCR.IDSS[7:0] bits is received, the IBI Status Descriptor is stored in the IBI queue.
(5) After detection of Low of T-bit following IBI Data, issues a STOP condition.
(6) After issuing the STOP condition,
NACK response:
• If the ICINCR.RTIRN bit is 0, the IBI Status Descriptor is not stored into the IBI queue.
• If the ICINCR.RTIRN bit is 1, the IBI Status Descriptor is stored into the IBI queue.
ACK response:
• Stores the IBI Status Descriptor into the IBI queue.

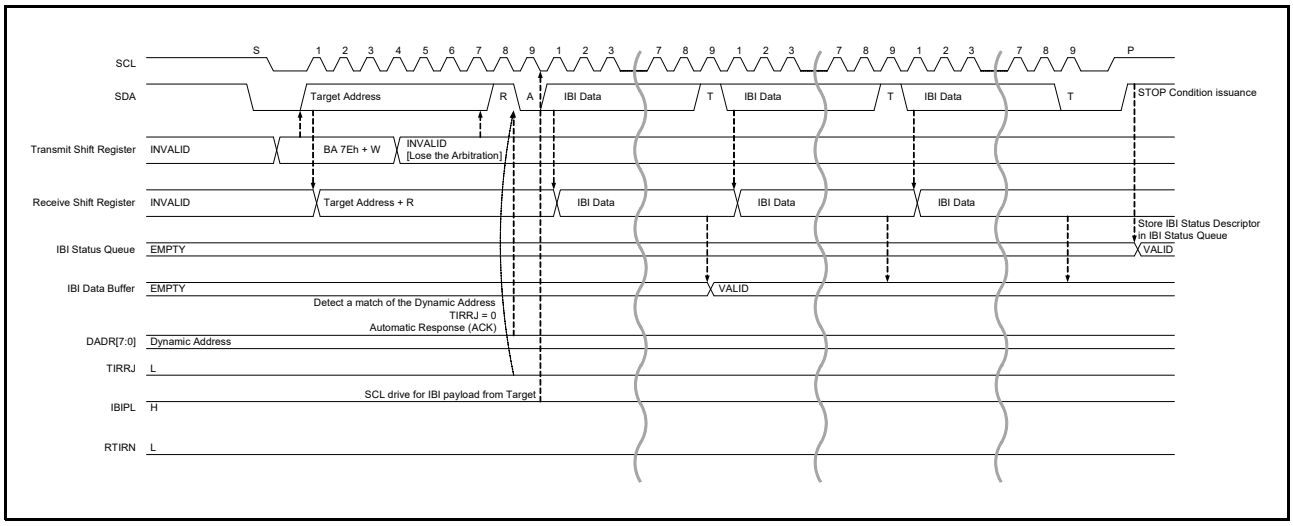

Figure 43.108 Target Interrupt Request: ACK and IBIPL = 1

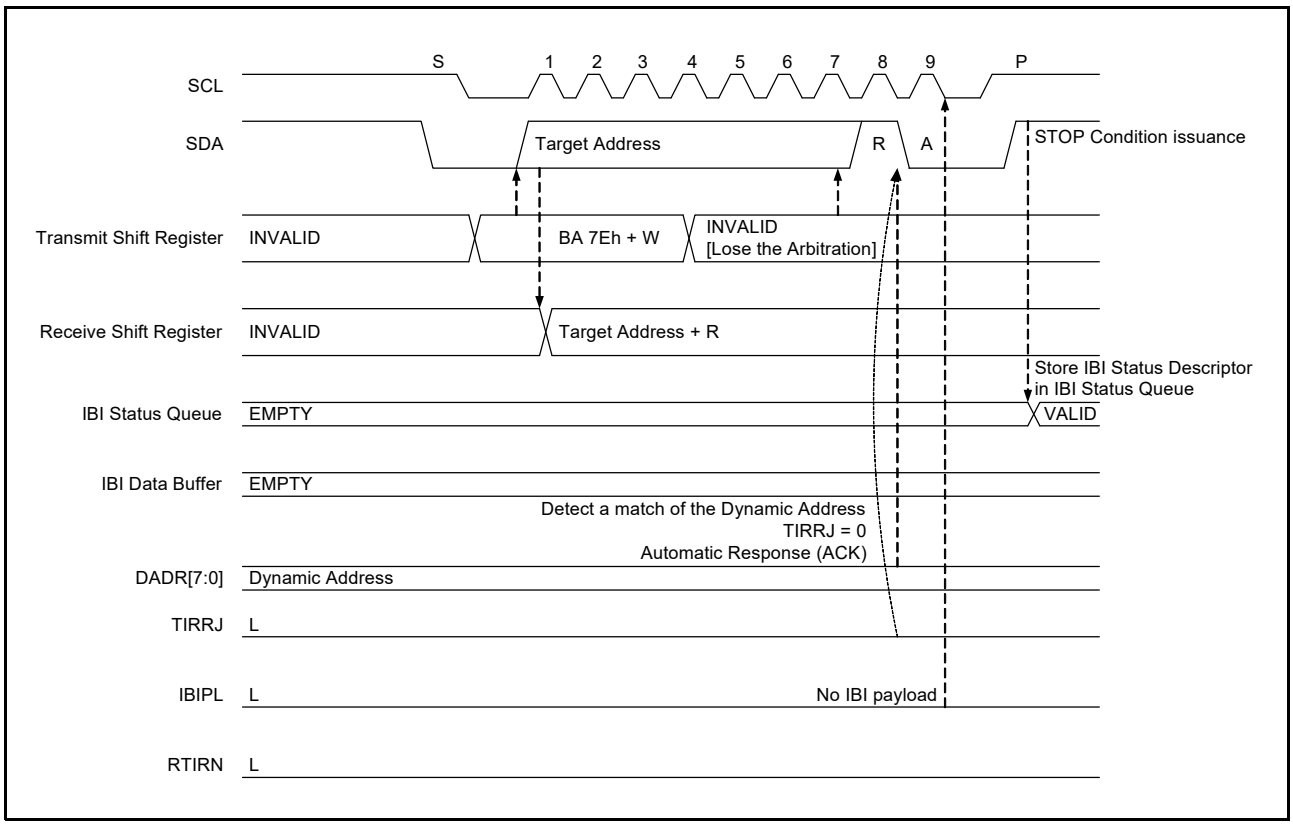

Figure 43.109 Target Interrupt Request: ACK and IBIPL = 0

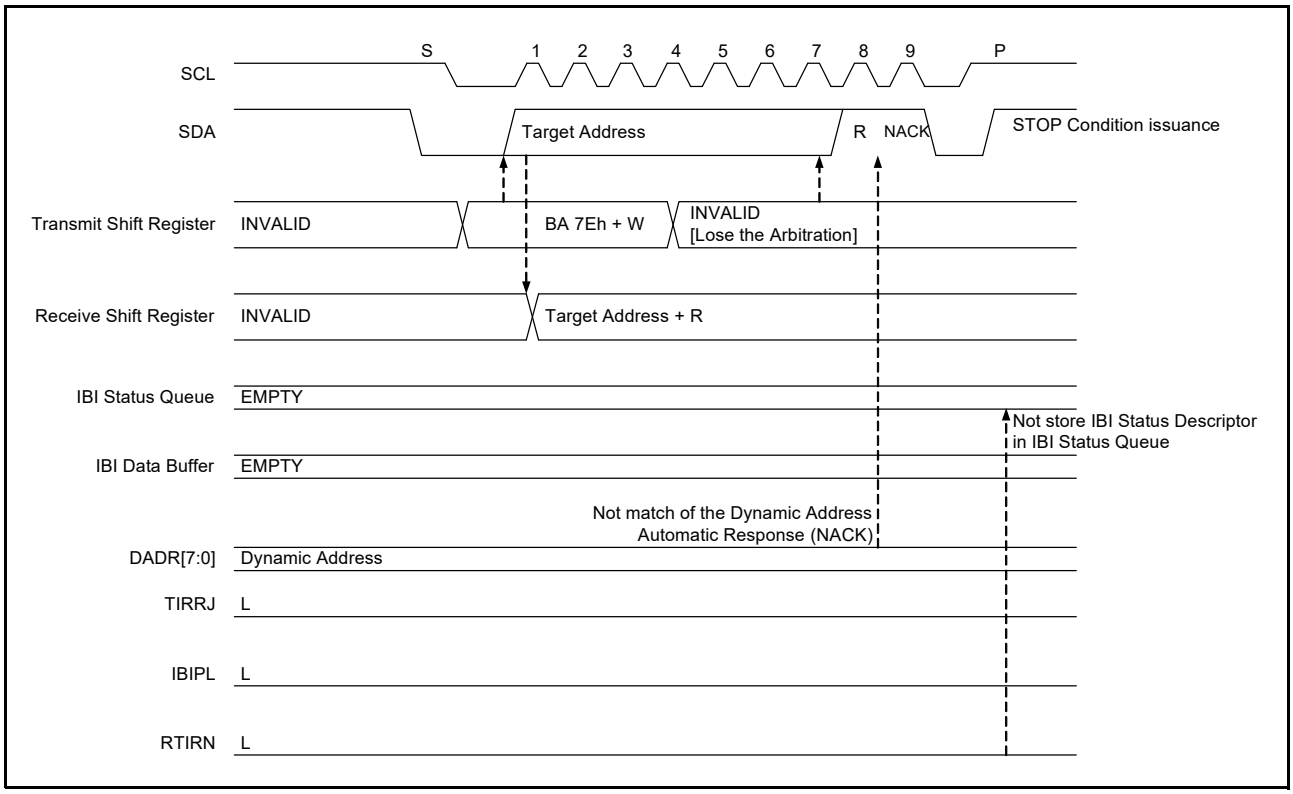

Figure 43.110 Target Interrupt Request: NACK (Not Match the DADR[7:0] Bits) and RTIRN = 0

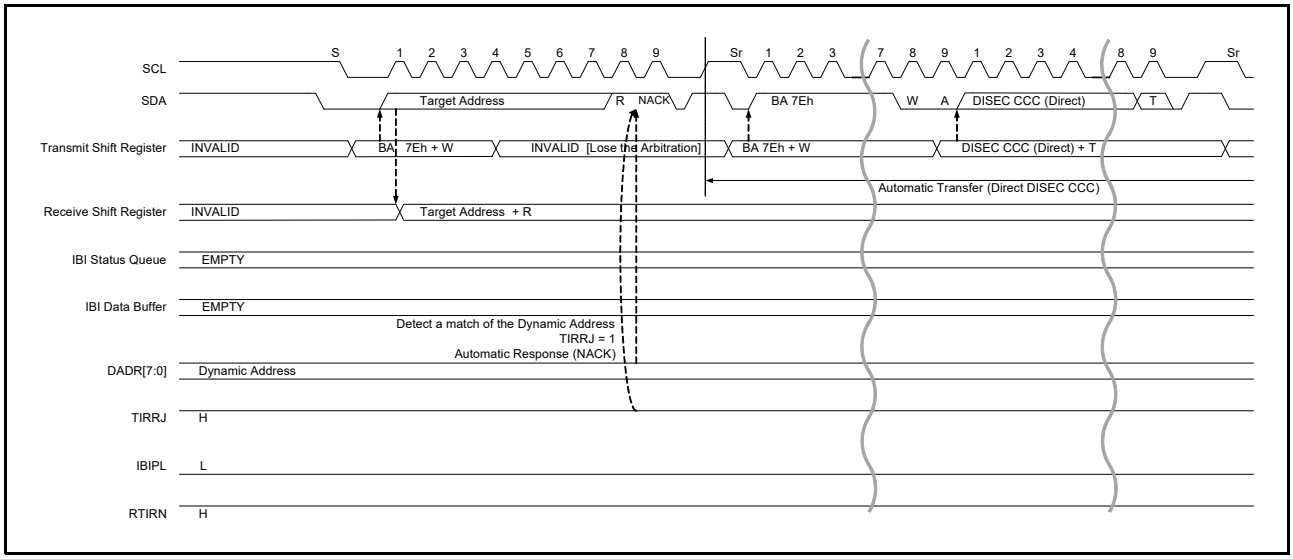

Figure 43.111 Target Interrupt Request: NACK (TIRRJ = 1) and RTIRN = 1 (1/2)

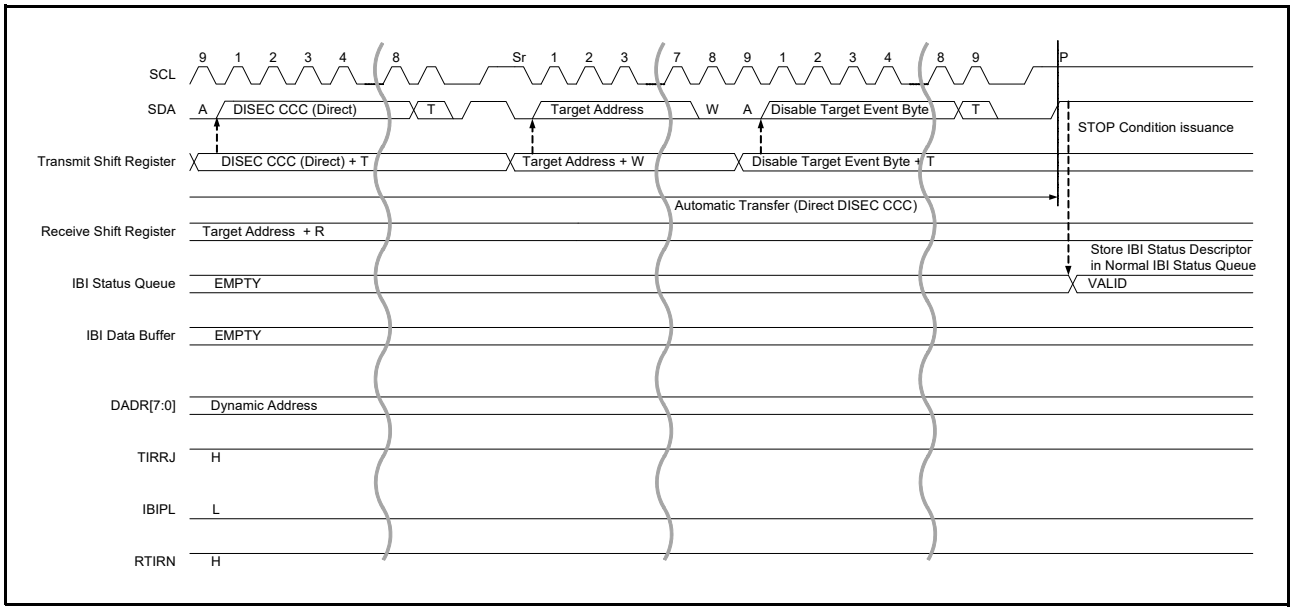

Figure 43.112 Target Interrupt Request: NACK (TIRRJ = 1) and RTIRN = 1 (2/2)

43.5.13.2 Controller Role Request

(1) Detect Target Address with RnW bit Low in Address header.

(2) Compare the detected Target Address with the DADR[7:0] bits in each DAT (the ICTDATRm register).

(3) When it does not match the ICTDATRm.DADR[7:0] bits:

• Responds with NACK, then issues a STOP condition.

When it matches the ICTDATRm.DADR[7:0] bits and the ICTDCTRm.ROLE[1:0] bits (BCR[7:6]) are “00b” (I3C Target):

• Responds with NACK, then issues a STOP condition.

When it matches the ICTDATRm.DADR[7:0] bits and the ICTDCTRm.ROLE[1:0] bits (BCR[7:6]) are “01b” (I3C Controller capable):

(a) When the ICTDATRm.CRRRJ bit is 1:

• RI3C operates in the following order.

1. Responds with NACK.
2. Issues a repeated START condition and automatically issues Direct DISEC CCC to the detected Target.
3. Issues a STOP condition.

(b) When the ICTDATRm.CRRRJ bit is 0:

• Responds with ACK, then issues a STOP condition.

(4) After issuing the STOP condition,

NACK response:

• If the ICINCR.RCRRN bit is 0, the IBI Status Descriptor is not stored into the IBI queue.

• If the ICINCR.RCRRN bit is 1, the IBI Status Descriptor is stored into the IBI queue.

ACK response:

• Stores the IBI Status Descriptor into the IBI queue.

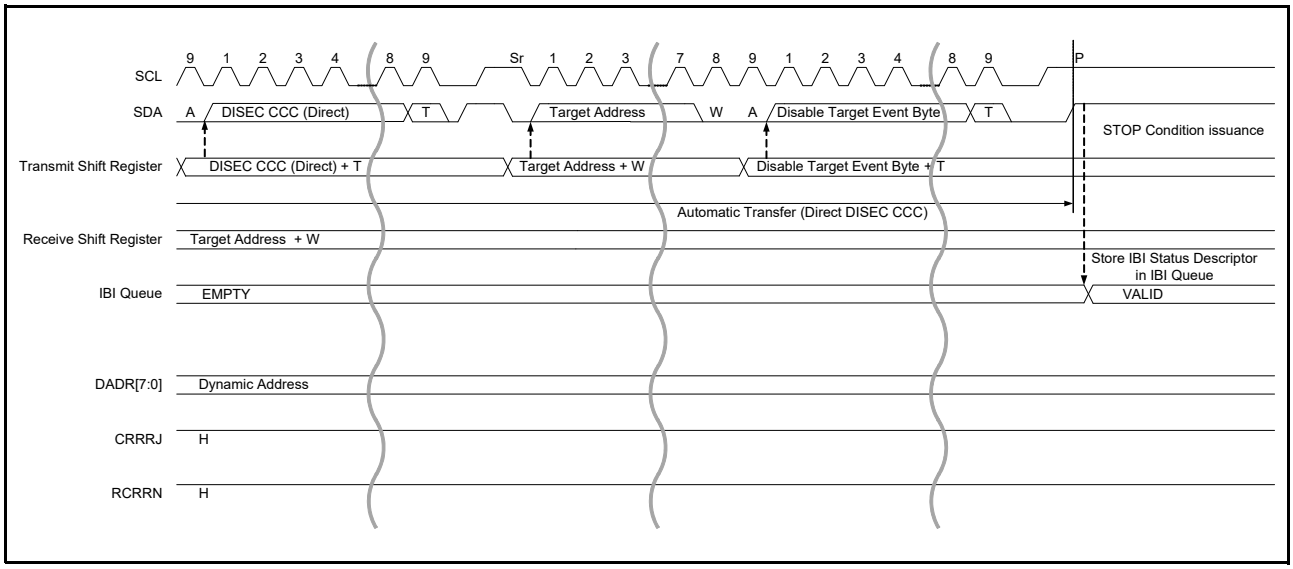

Figure 43.117 Controller Role Request: NACK (CRRRJ = 1) and RCRRN = 1 (2/2)

43.5.14 Timing Control (I3C Protocol Mode)

Timing Control is a function that allows the Controller to efficiently read data from the Target by controlling and understanding the timing at which the Target device samples sensor values. For details, refer to Section 6.6, Timing Control in the MIPI I3C Specification Version 1.2.

RI3C supports the following three modes.

- Sync Mode
- Async Mode 0 (Asynchronous Basic Mode)
- Async Mode 1 (Asynchronous Advanced Mode)

43.5.14.1 Sync Mode

Whether the RI3C is the Controller or the Target, operate a counter with a period of T_Ph (T_Ph counter) using a timer such as GPTW, and configure the ELC so that the counter value can be captured with a synchronous timing event.

(1) I3C Controller

When the ICSYTCR.STOE bit is set to 1, a synchronous timing event is output when the Controller sends a SETXTIME CCC with the Sync Tick (ST) Sub-Command (ST Message).

Calculate the delay time from the start of counting of the T_Ph counter to the start of sending the ST message using the value of the T_Ph counter captured by the synchronous timing event, and send it in a SETXTIME CCC with the Delay Time (DT) Sub-Command (DT Message).

Send an ST Message and a DT Message each time the T_Ph counter overflows.

(2) I3C Target

When the ICSYTCR.STOE bit is set to 1, a synchronous timing event is output each time the Target detects a START condition. When an ST Message is received, the STOE bit is set to 0.

After confirming receipt of the ST Message in the Receive Status Descriptor, correct the T_Ph counter start timing based on the value of the T_Ph counter captured by the synchronous timing event and the delay time obtained from the subsequent DT Message.

43.5.14.2 Async Mode 0 (Asynchronous Basic Mode)

When performing timing control in Async Mode 0, set the ICASTCR register as necessary.

(1) I3C Controller

Async Mode 0 uses a 32-bit C_REF counter and a 16-bit C_C2 counter.

- C_REF counter*1
  When the ICASTCCR.ATCE bit is set to 1, the C_REF counter starts counting. The count value of the C_REF counter is captured on the first rising edge of SCL after the ACK response to IBI.
- C_C2 counter
  When the ICASTCCR.ATCE bit is 1, the C_C2 counter starts counting on the first rising edge of SCL after the ACK response to IBI. The count value of the C_C2 counter is captured on the first rising edge of SCL after the T bit of the Mandatory Byte.

When an IBI is received from a Target whose corresponding ICTDATRm.IBITSE bit (m = 0 to 7) is 1, the captured values of the C_REF counter and C_C2 counter are each stored as 64-bit data after the IBI Status Descriptor. The Mandatory Byte and subsequent data are stored after that. The value of the DATA_LENGTH field in the IBI Status Descriptor is increased by 16.

Note 1. If the length of the C_REF counter is insufficient at 32 bits, use the C_REF counter overflow event to count up a timer such as GPTW. The C_REF capture event can be used to capture the count value. To use these event outputs, set the ICASTCR.CREFOE bit to 1.

(2) I3C Target

Async Mode 0 uses a 16-bit T_C1 counter and an 8-bit T_C2 counter.

- T_C1 counter
  When the trigger specified by the ICASTCR.ATTRGS bit is input while the ICASTCCR.ATCE bit is set to 1, the T_C1 counter starts counting. The count value of the T_C1 counter is captured on the first rising edge of SCL after the ACK response to IBI.
- T_C2 counter
  When the ICASTCCR.ATCE bit is 1, the T_C2 counter starts counting on the first rising edge of SCL after the ACK response to IBI. The count value of the T_C2 counter is captured on the first rising edge of SCL after the T bit of the Mandatory Byte.

When the ICTSIR2.AM0E bit is 1 and the ITS bit in the Command Descriptor used to issue an IBI is 1, the captured values of the T_C1 and T_C2 counters are transmitted in the following order: T_C1 lower byte, T_C1 higher byte, and T_C2, following the Mandatory Byte. In this case, set the DATA_LENGTH field in the Command Descriptor to a value that is 3 bytes longer than the number of data to be transmitted.
When the T_C1 counter or T_C2 counter overflows, the captured values become FFFFh and FFh, respectively, and the ICTSIR2.OVF flag becomes 1.

43.5.14.3 Async Mode 1 (Asynchronous Advanced Mode)

When performing timing control in Async Mode 1, set the ICASTCR register as necessary.

(1) I3C Controller

Async Mode 1 uses a 32-bit C_REF counter, a 32-bit C_SyncCNT counter, and a 16-bit C_C2 counter.

- C_REF counter
  When the ICASTCCR.ATCE bit is set to 1, the C_REF counter starts counting. The count value of the C_REF

counter is captured on the first rising edge of SCL after the ACK response to IBI.

- C_SyncCNT counter
  When the ICASTCCR.ATCE bit is set to 1, the C_SyncCNT counter starts counting. The count value of the C_SyncCNT counter is captured each time an aBE (additional Bus Event: the falling edge of SCL after a START condition) is detected.
- C_C2 counter
  When the ICASTCCR.ATCE bit is 1, the C_C2 counter starts counting on the first rising edge of SCL after the ACK response to IBI. The count value of the C_C2 counter is captured on the first rising edge of SCL after the T bit of the Mandatory Byte.

When an IBI is received from a Target whose corresponding ICTDATRm.IBITSE bit (m = 0 to 7) is 1, the captured values of the C_REF counter and C_C2 counter are each stored as 64-bit data after the IBI Status Descriptor. The Mandatory Byte and subsequent data are stored after that. The value of the DATA_LENGTH field in the IBI Status Descriptor is increased by 16.
The captured value of the C_SyncCNT counter is stored in the ICCSCCR register. When the ICASTCR.ABEOE bit is 1, an additional bus event is output each time an aBE is detected. Use this event signal as a trigger to read the captured value of the C_SyncCNT counter from the ICCSCCR register and store it in memory.

(2) I3C Target

Async Mode 1 uses a 16-bit T_C1 counter, an 8-bit aBE_TICK counter, and an 8-bit T_C2 counter.

- T_C1 counter
  When the trigger specified by the ICASTCR.ATTRGS bit is input while the ICASTCCR.ATCE bit is set to 1, the T_C1 counter starts counting. The count value of the T_C1 counter is captured at the first aBE.
- aBE_TICK counter
  When the ICASTCCR.ATCE bit is 1, the aBE_TICK counter is incremented each time aBE is detected. The count value of the aBE_TICK counter is captured on the first rising edge of SCL after the ACK response to IBI.
  The counter value is cleared at the first aBE after the T_C1 counter trigger is input.
- T_C2 counter
  When the ICASTCCR.ATCE bit is 1, the T_C2 counter starts counting on the first rising edge of SCL after the ACK response to IBI. The count value of the T_C2 counter is captured on the first rising edge of SCL after the T bit of the Mandatory Byte.

When the ICTSIR2.AM1E bit is 1 and the ITS bit in the Command Descriptor used to issue an IBI is 1, the captured values of the T_C1, T_C2, and aBE_TICK counters are transmitted in the following order: T_C1 lower byte, T_C1 higher byte, T_C2, and aBE_TICK, following the Mandatory Byte. In this case, set the DATA_LENGTH field in the Command Descriptor to a value that is 4 bytes longer than the number of data to be transmitted.
When the T_C1 counter or T_C2 counter overflows, the captured values become FFFFh and FFh, respectively, and the ICTSIR2.OVF flag becomes 1.

43.5.15 Common Command Codes (CCC) (I3C Protocol Mode)

Command Code E0h to FEh Vendor Extension-Direct CCCs defined are not supported.
The MIPI reserved area and Vendor Extension area of Command Code are not supported.
Do not use an unsupported CCC when using this module with I3C Target.
If the I3C Controller must use an unsupported CCC, use the added CCC after using ENTASx CCC to put this module to Sleep mode.

43.5.16 Error Detection (I3C Protocol Mode)

43.5.16.1 SDR Error Detection and Recovery Methods for I3C Target Devices

The seven error types summarized in Table 43.12 are supported for all I3C Target devices. Each error type is further explained below the table.

Table 43.12 SDR Target Error Types

Error Type	Description	Error Detection Method	Error Recovery Method
TE0	Broadcast Address/W (= 7Eh/W) or Dynamic Address/RW	Detect any of the following: 3Eh/W 5Eh/W 6Eh/W 76h/W 7Ah/W 7Ch/W 7Fh/W 7Eh/R	Enable HDR Exit Detector and ignore all other patterns
TE1	CCC code	Parity check, using T-Bit	Enable HDR Exit Detector and neglect other patterns
TE2	Write data	Parity check, using T-Bit	Enable STOP condition detector and neglect other patterns
TE3	Assigned address during Dynamic Address arbitration	Parity check, using PAR Bit	Generate NACK (after PAR), then wait for another repeated START condition and 7Eh/R to re-transmit the Provisioned ID
TE4	7Eh/R after Sr during Dynamic Address arbitration	Detect any value other than 7Eh/R after Sr during Dynamic Address Arbitration	Generate NACK (after 7Eh/R), then enable STOP condition detector and ignore all other patterns
TE5	Transaction after detecting CCC	Detect illegally formatted CCC	Generate NACK (after Target Address), then enable STOP condition detector and ignore all other patterns
TE6 (optional)	Monitoring error	Target detects (through monitoring) that transmitted Data differs from what it intended to transmit (Does not apply during Dynamic Address arbitration)	Stop the transmission, then enable STOP condition detector and ignore all other patterns

43.5.16.2 SDR Error Detection and Recovery Methods for I3C Controller Devices

The two error types summarized in Table 43.13 are supported for all I3C Controller devices. Each error type is further explained below the table.

Table 43.13 SDR Controller Error Types

Error Type	Description	Error Detection Method	Error Recovery Method
CE0	Transaction after sending CCC	Detect illegally formatted CCC	Stop the transmission, then send STOP condition and retry the transmission.
CE1 (optional)	Monitoring error	Controller detects (through monitoring) transmitted data different from what it intended to transmit (does not apply during Dynamic Address arbitration)	Stop the transmission, then send STOP condition and retry the transmission.
CE2	No response to Broadcast Address (7Eh)	Controller detects NACK after Broadcast Address (7Eh) transmission	Upon detection of NACK, Controller transmits HDR Exit Pattern followed by STOP condition

43.5.16.3 Timeout Detection

RI3C includes a timeout function for detecting when the SCL line has been stuck longer than the predetermined time. RI3C can detect an abnormal bus state by monitoring that the SCL line is stuck low or high for a predetermined time. The timeout function monitors the SCL line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCL line changes (rising or falling), but continues to count unless the SCL line changes. If the internal counter overflows due to no SCL line change, RI3C can detect the timeout and report the bus hung state.

This timeout function is enabled when ICSER.TMOE = 1. It detects a hung state that the SCL line is stuck low or high during the following conditions: (When ICTOR.TMOM[1:0] = 00b)

- The bus is busy (ICBSR.BFREE = 0) in Controller mode (ICMMR.ACF = 1).
- The bus is busy (ICBSR.BFREE = 0) in Target mode (ICMMR.ACF = 0).

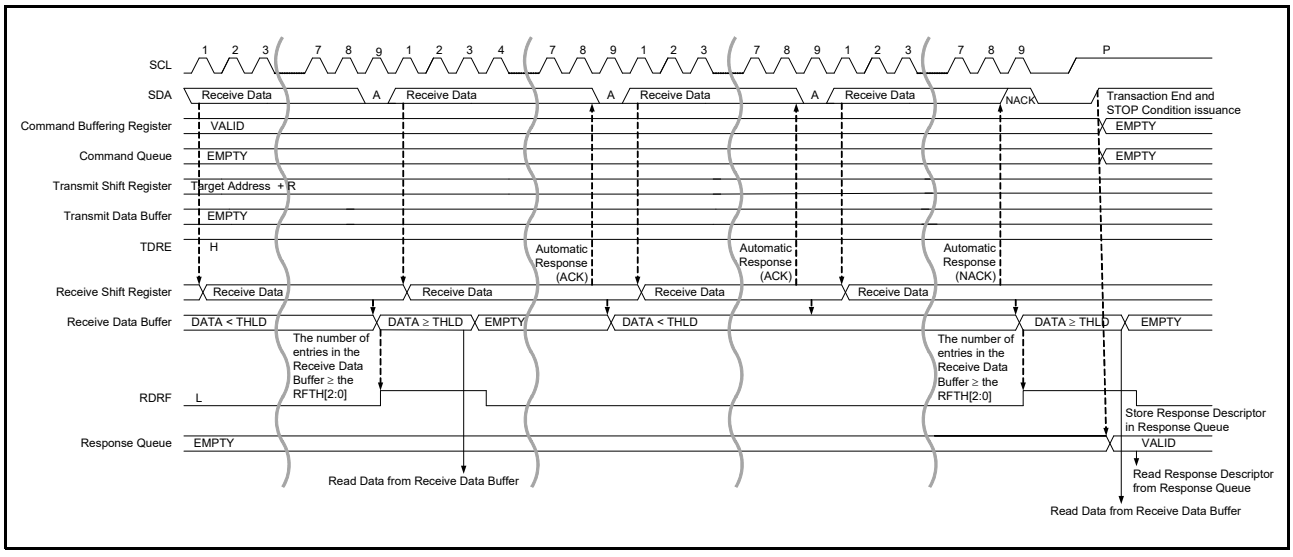

Figure 43.118 Timeout Detection (TMOE, TMOS[1:0], TMOH, and TMOL bits)

43.5.16.4 Resume Operation

RI3C enters the Halt state as a result of any type of error occurring in a transfer.
The error type is indicated by the field ERR_STATUS in Response Descriptor or Receive Status Descriptor. After RI3C has entered the Halt state, the user must write the value 1 to the RESUME bit to resume operation. RI3C shall auto-clear the RESUME bit once it has initiated the next Command transfer or detected the START condition.

43.5.16.5 Abort Operation

When the ICCR.ABORT bit is set to 1, RI3C relinquish control of the bus before completing the currently issued transfer. In response to an Abort request, RI3C issues the STOP condition on the bus after the complete data byte is transmitted or received. After RI3C has aborted, the user shall clear the ICCR.ABORT bit to allow operation on the bus.

Note: For Read transaction, received data are stored in the receive data buffer even if the ICCR.ABORT bit is set to 1.

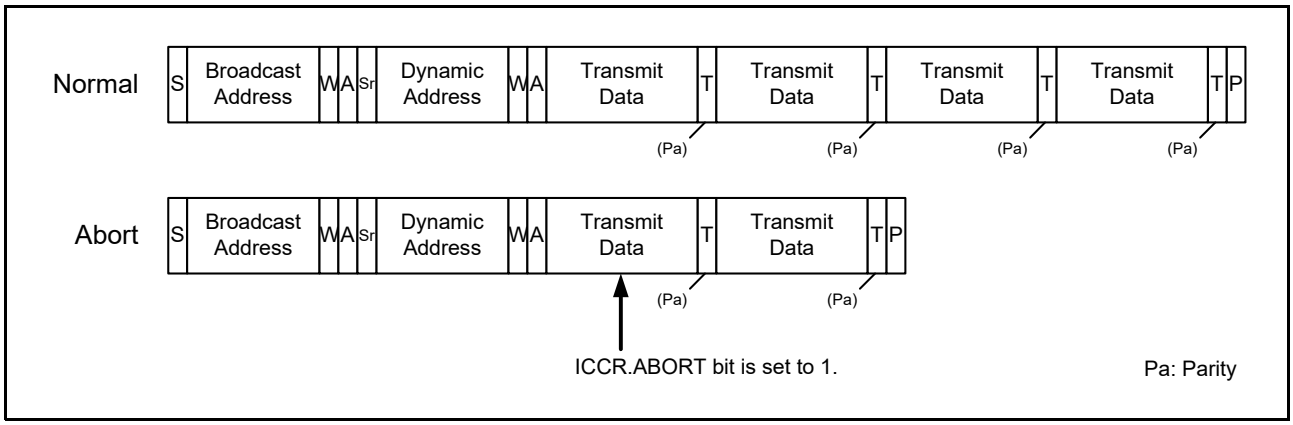

Figure 43.119 Abort Operation of SDR Write Transfer

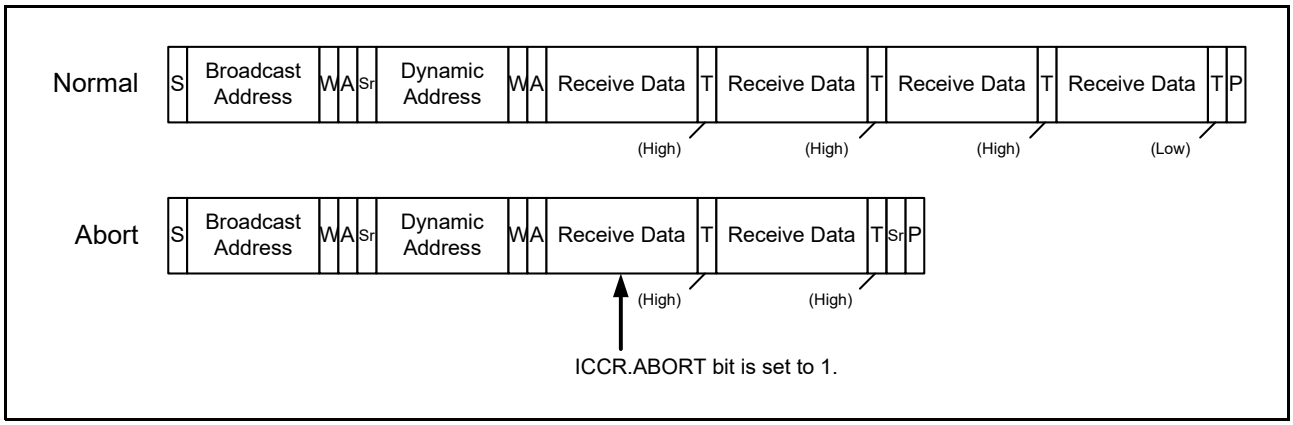

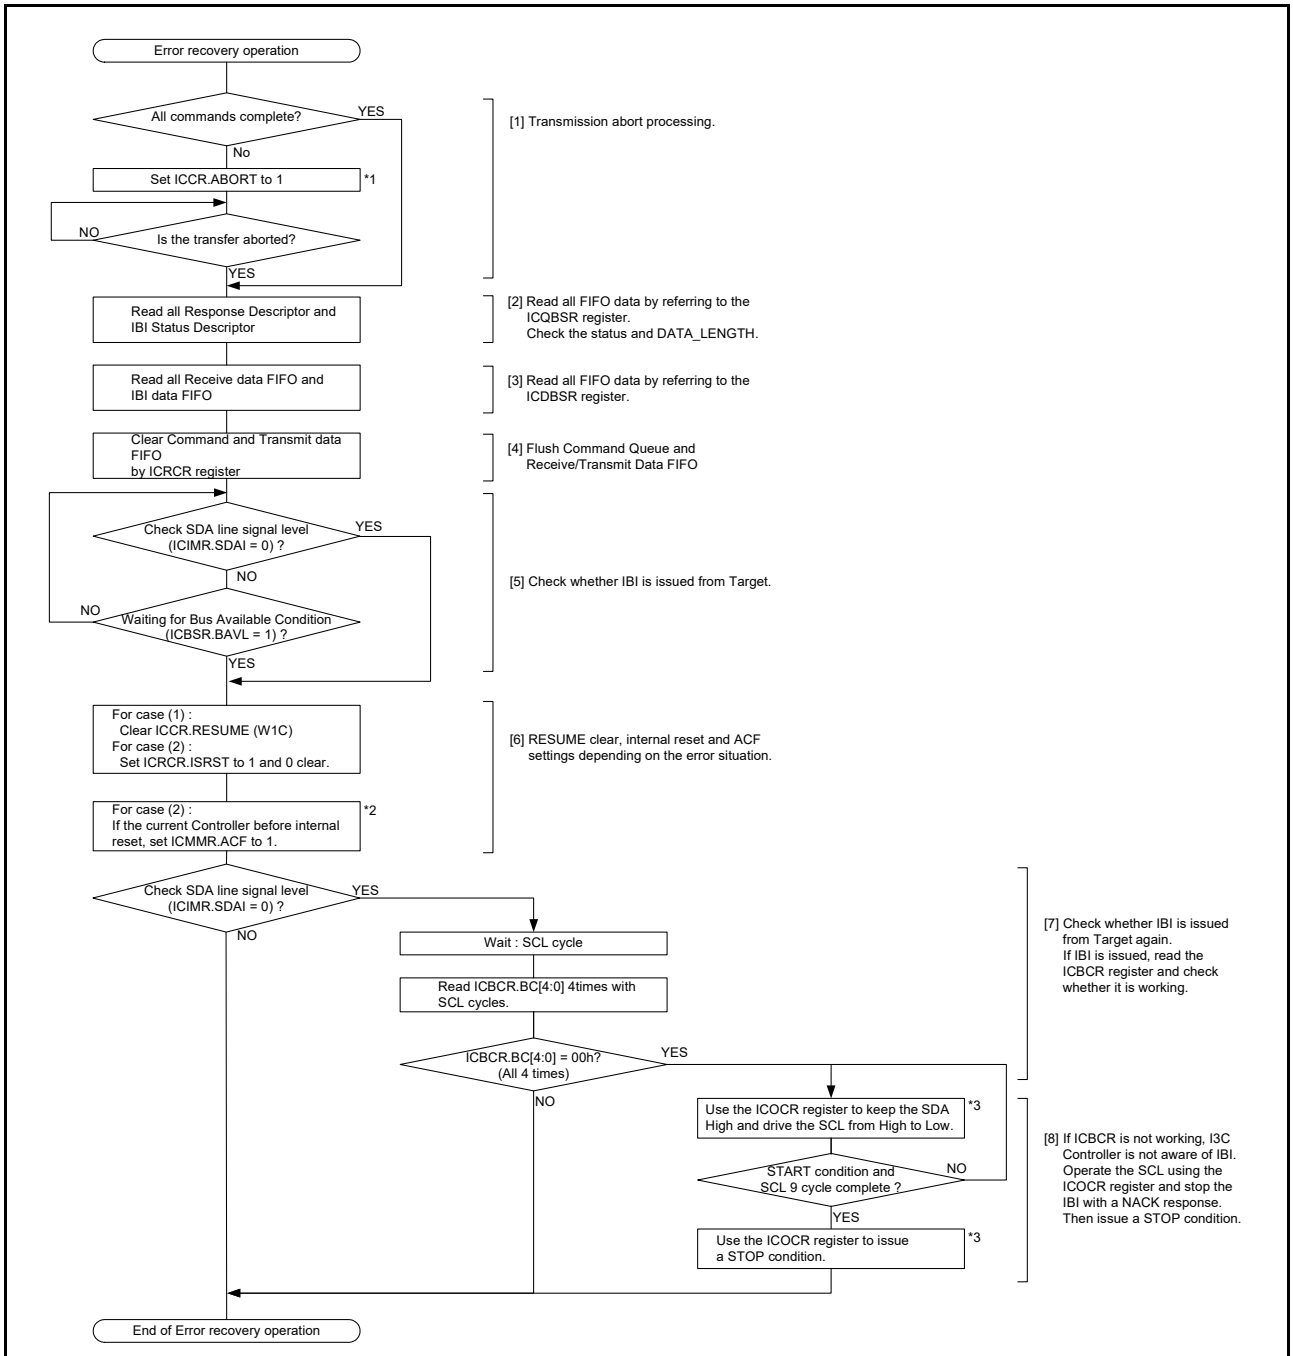

Figure 43.120 Abort Operation of SDR Read Transfer

43.5.16.6 Error Recovery Operation

When an error occurs, the ICISR.BERF, ICCSR.DTEF, and ICCSR.DTAF flags are set to 1 according to the cause of the error, or the interrupts associated with each flag are asserted (when detection and interrupts are enabled).
There is a possibility of communication error or internal module error.
The I3C Controller must perform an error recovery flow according to the following case:

- When DTEF is detected.

Figure 43.121 and Figure 43.122 show the error recovery flow.

Note 1. If the transfer is not aborted due to an error, set the ICCR.ABORT bit to 1 and then abort the transfer.
Note 2. When writing to the ACF flag, set ICMMR.WP bit to 1 at the same time.
Note 3. When writing to the SDAO and SCLO bit, set ICOCR.SOWP bit to 1 at the same time.

Figure 43.121 Example of Error Recovery Operation Flowchart for I3C Controller

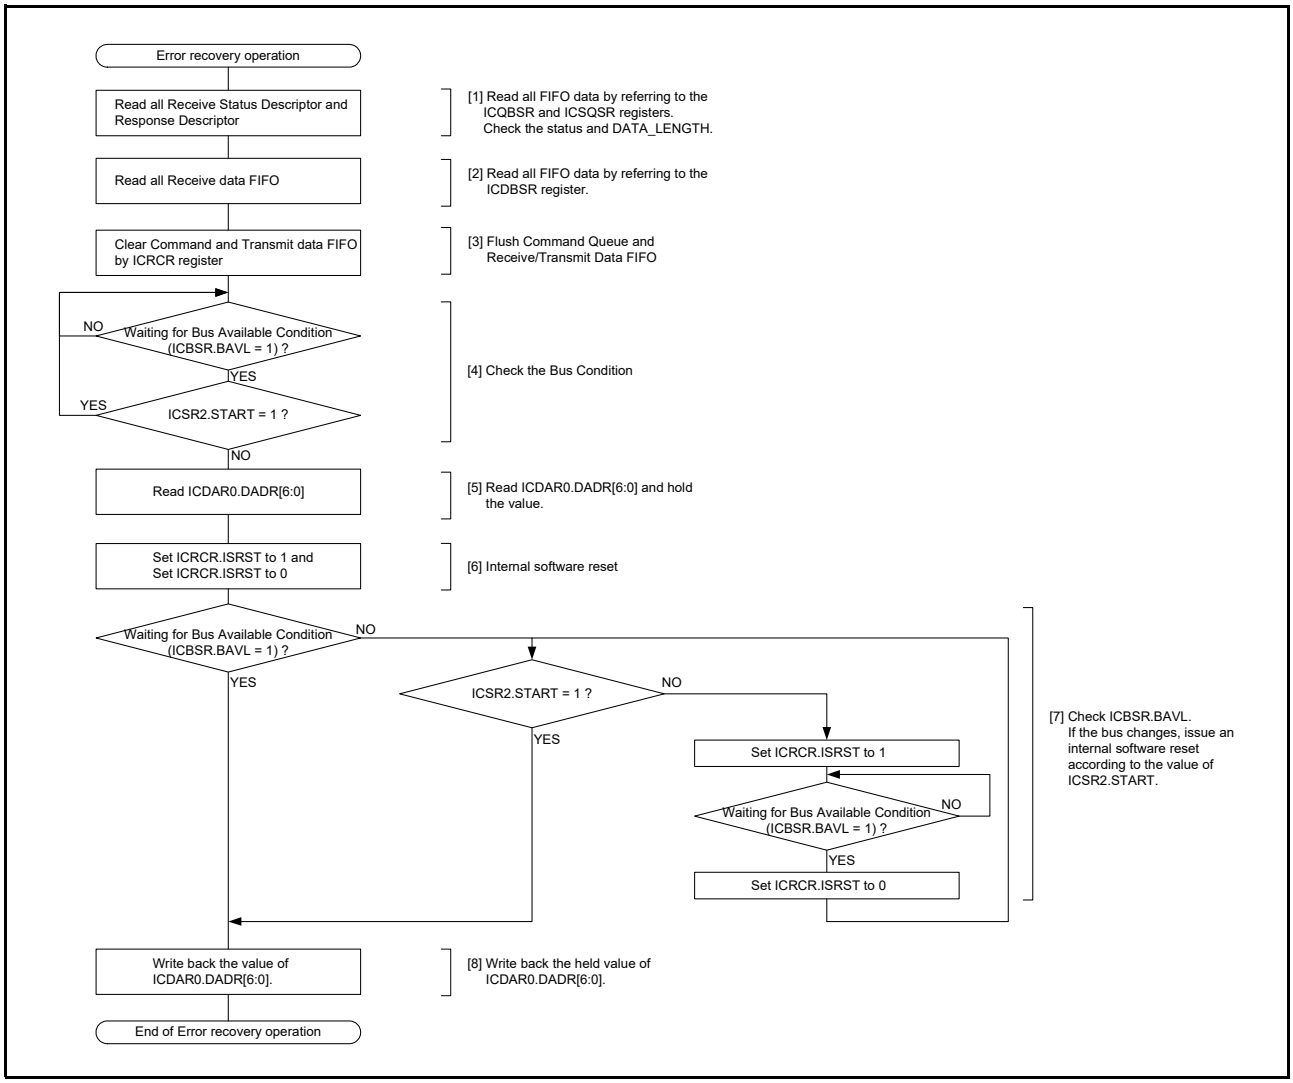

Figure 43.122 Example of Error Recovery Operation Flowchart for I3C Target

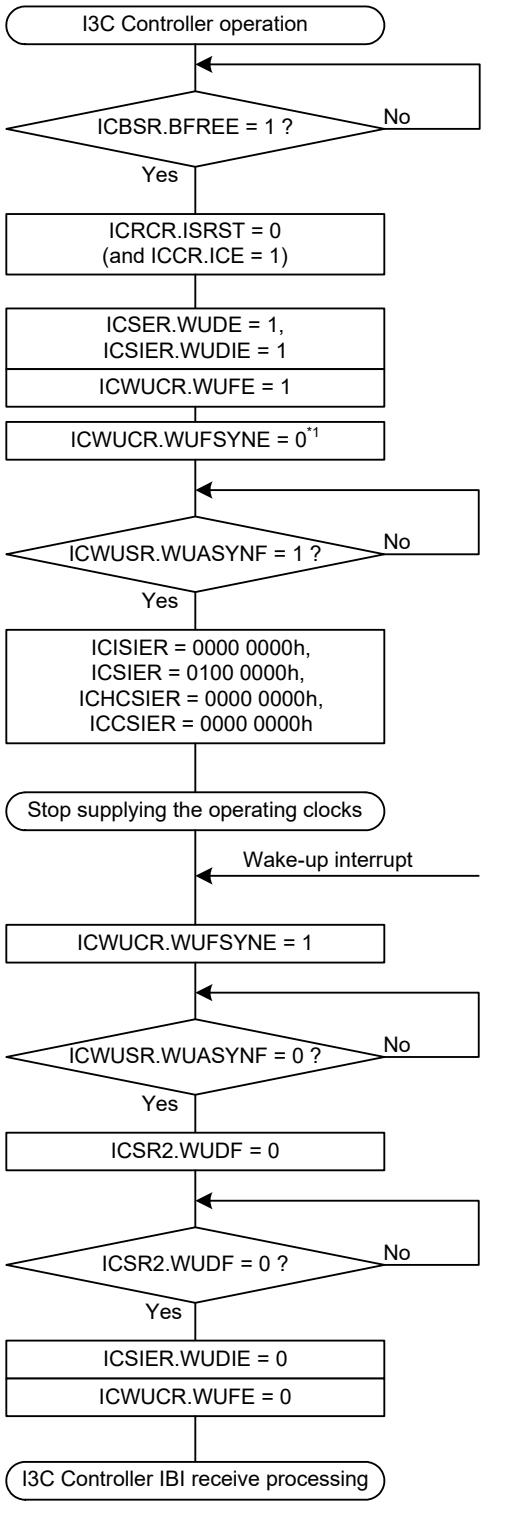
43.5.17 Wake-Up Function (I3C Protocol Mode)

The RI3C includes a wake-up function to return the MCU from low power consumption states. The wake-up interrupt source differs between controller mode and target mode.



- I3C Controller mode: Low detection on the SDA line (IBI request from Target device)
- I3C Target mode: Detection of matches between the Target Address following Broadcast Address and its own Dynamic Address

43.5.17.1 I3C Controller Wake-Up Function

The wake-up detection circuit in I3C Controller mode operates as follows.

(1) Generates a wake-up interrupt when the SDA line is detected to be low.
(2) Holds the SCL line high until the wake-up function is disabled.
(3) When 1 is written to the ICWUCR.WUFSYNE bit, it sets the ICWUSR.WUASYNF flag to 0.
(4) Drives the SCL line low to complete the START condition.
(5) Supplies SCL and receives IBI from the Target device.

Set the ICWUCR.WUFE bit to 0 when the ICIMR.SDAI flag is 1 (SDA line is high).
If the low power consumption state is released by an interrupt other than a wake-up interrupt, disable the wake-up function as necessary.

[1] [1] Wait until the bus is free and in standby state.

[2] [2] If an internal reset is in progress, release the internal reset.

[3] [3] Enable the wake-up interrupt.

[4] [4] Enable the wake-up function.

[5] [5] Change from internal clock synchronous operation to asynchronous operation.*1

[6] [6] Disable interrupt requests other than WUI.

[7] [7] Stop supplying the operating clocks (reception continues)

[8] [8] The wake-up interrupt starts supplying the operating clocks.

[9] [9] Change from asynchronous operation to internal clock synchronous operation.

[10] [10] Clear the ICSR2.WUDF flag (confirm that the flag is cleared before returning from the interrupt processing).

[11] [11] Disable the wake-up interrupt.

[12] [12] Disable the wake-up function.

Note 1. When switching from internal clock synchronous operation to asynchronous operation, temporarily set the SDA pin to a general-purpose input port.

Figure 43.123 Example of Using I3C Controller Wake-Up

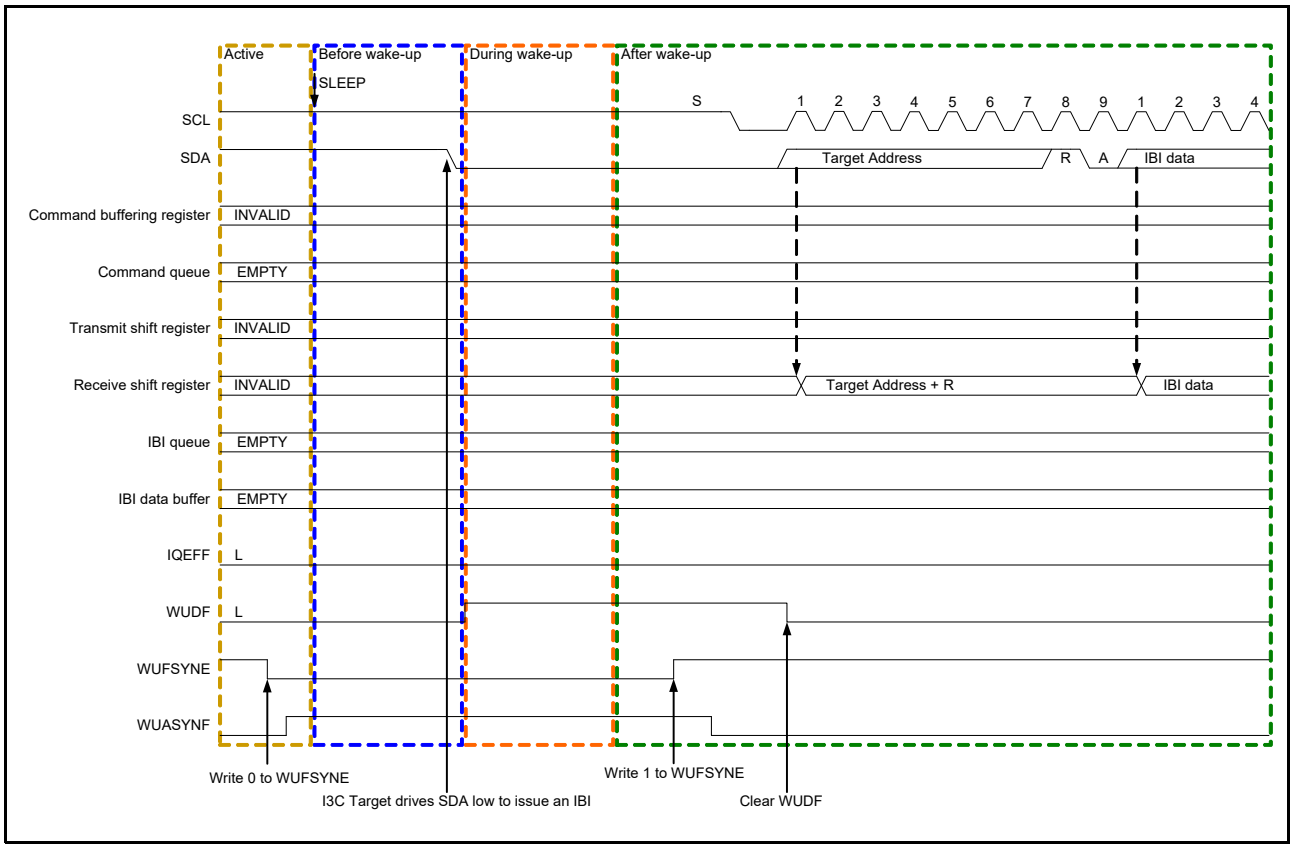


Figure 43.124 I3C Controller Wake-Up Timing

43.5.17.2 I3C Target Wake-Up Function

The wake-up detection circuit in I3C Target mode operates as follows.

(1) Generates an ACK when a Broadcast Address (7Eh) following a START or repeated START condition is detected.
(2) If the Target Address following the repeated START condition matches its own Dynamic Address, it responds with NACK and generates a wake-up interrupt.
(3) Responds with NACK to all data bytes until the wake-up function is disabled.
(4) When 1 is written to the ICWUCR.WUFSYNE bit, it sets the ICWUSR.WUASYNF flag to 0 at the next STOP condition.
(5) Returns to normal operation.

If the low power consumption state is released by an interrupt other than a wake-up interrupt, disable the wake-up function as necessary.

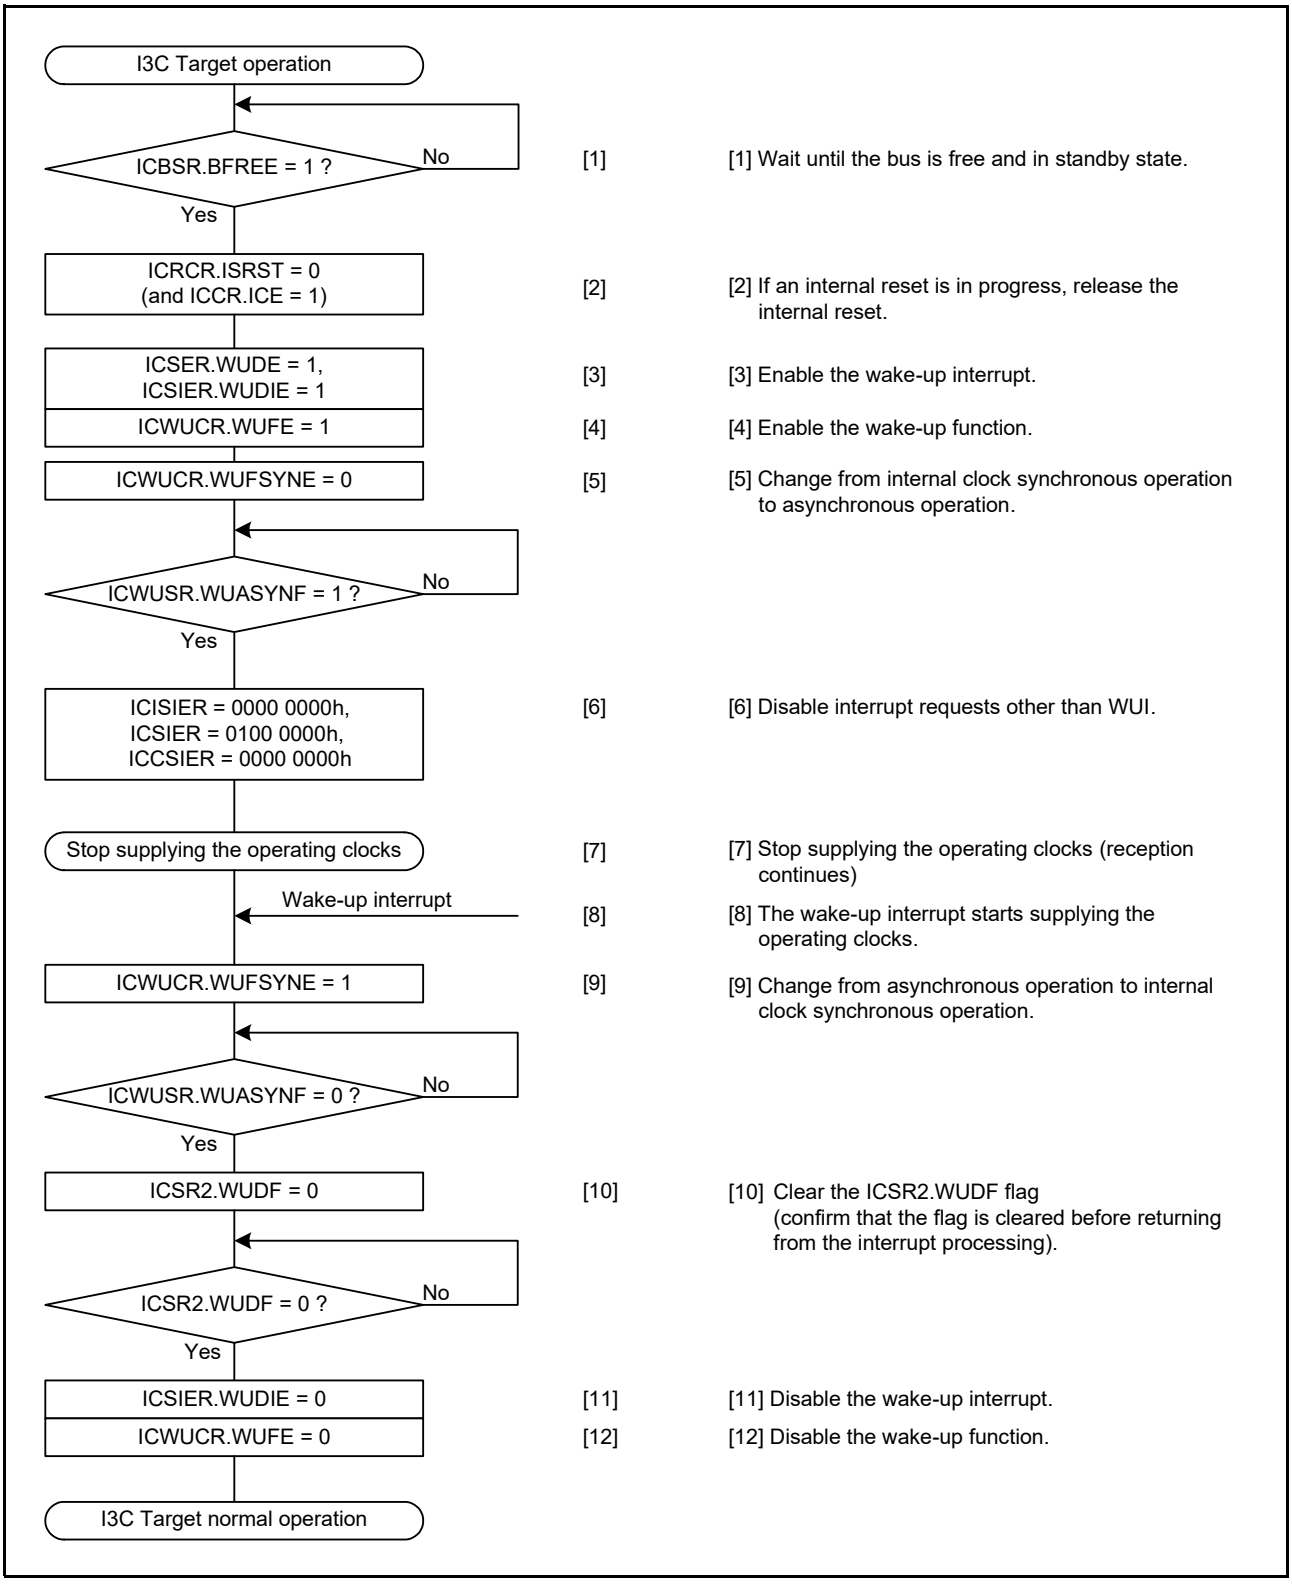

Figure 43.125 Example of Using I3C Target Wake-Up

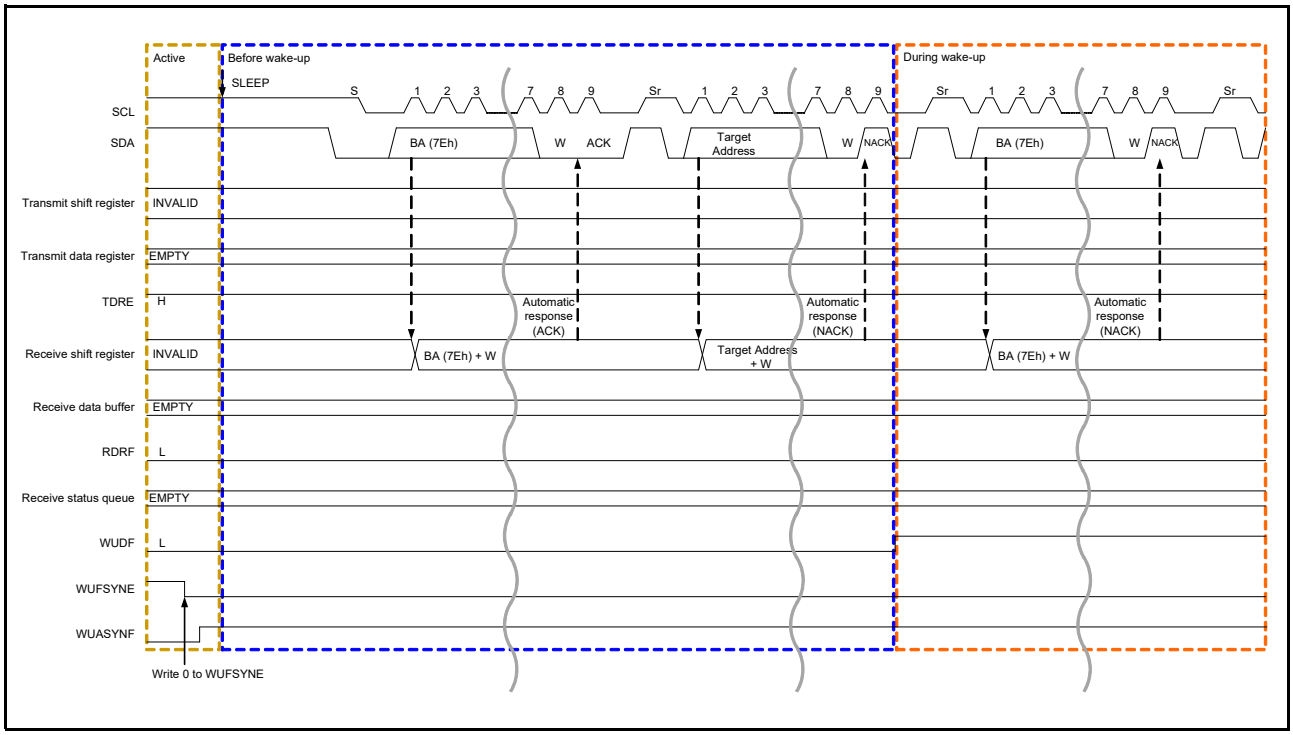

Figure 43.126 I3C Target Wake-Up Timing (1/2)

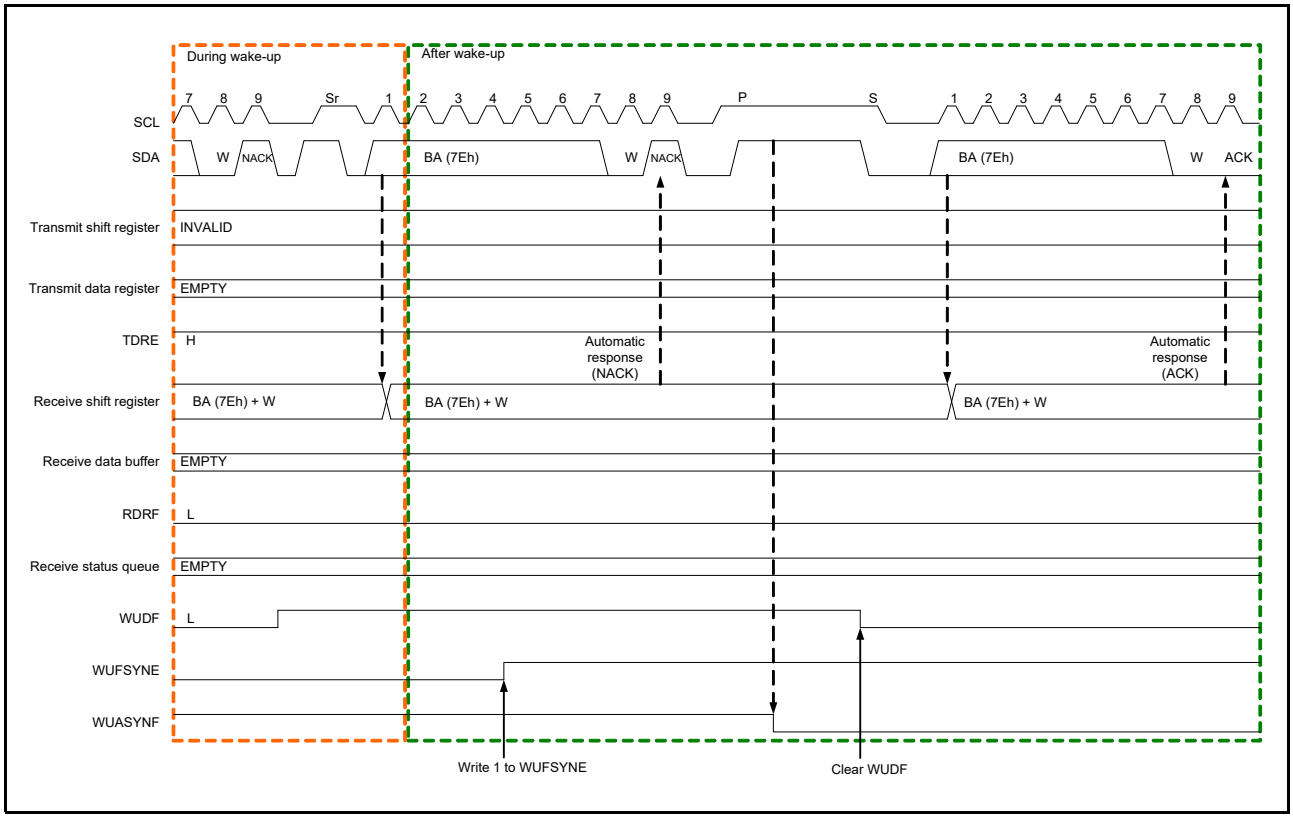

Figure 43.127 I3C Target Wake-Up Timing (2/2)

43.5.17.3 Notes on Using Wake-Up Function

When the wake-up function is enabled (ICWUCR.WUFE bit = 1), the timeout function cannot be used. Set the ICSER.TMOE bit to 0.

43.6 Interrupt Sources

(1) Interrupts in I3C Protocol Mode

The RI3C generates 12 types of interrupt requests, as shown in Table 43.14. The transmit data empty, receive data full, command queue empty, response queue full, IBI queue empty/full, and receive status queue full, high-priority transmit data empty, high-priority receive data full, high-priority command queue empty, and high-priority response queue full interrupt requests allow the DTC or DMAC to start data transfer.

Table 43.14 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	Interrupt Enable Bit	Start DTC/DMA Transfer	Interrupt Generation Condition
TXI*1	Transmit data empty	ICCSR.TDRE	ICCSIER.TIE	Possible	TDRE = 1 and TIE = 1
RXI*2	Receive data full	ICCSR.RDRF	ICCSIER.RIE	Possible	RDRF = 1 and RIE = 1
CMDI*3	Command queue empty	ICCSR.CQEF	ICCSIER.CQEIE	Possible	CQEF = 1 and CQEIE = 1
RESPI*3	Response queue full	ICCSR.RQFF	ICCSIER.RQFIE	Possible	RQFF = 1 and RQFIE = 1
IBII*3	IBI queue empty/full	ICCSR.IQEFF	ICCSIER.IQEFIE	Possible	IQEFF = 1 and IQEFIE = 1
RCVI*3	Receive status queue full	ICCSR.SQFF	ICCSIER.SQFIE	Possible	SQFF = 1 and SQFIE = 1
HTXI*1	High-priority transmit data empty	ICHCSR.HTDRE	ICHCSIER.HTIE	Possible	HTDRE = 1 and HTIE = 1
HRXI*2	High-priority receive data full	ICHCSR.HRDRF	ICHCSIER.HRIE	Possible	HRDRF = 1 and HRIE = 1
HCMDI*3	High-priority command queue empty	ICHCSR.HCQEF	ICHCSIER.HCQEIE	Possible	HCQEF = 1 and HCQEIE = 1
HRESPI*3	High-priority response queue full	ICHCSR.HRQFF	ICHCSIER.HRQFIE	Possible	HRQFF = 1 and HRQFIE = 1
EEI	Communication error/ communication event	ICSR2.START	ICSIER.STIE	Not possible	START = 1 and STIE = 1
		ICSR2.STOP	ICSIER.SPIE		STOP = 1 and SPIE = 1
		ICSR2.HDRXDF	ICSIER.HDRXIE		HDRXDF = 1 and HDRXIE = 1
		ICSR2.TMOF	ICSIER.TMOIE		TMOF = 1 and TMOIE = 1
		ICISR.BERF	ICISIER.BERIE		BERF = 1 and BERIE = 1
		ICCSR.DTAF	ICCSIER.DTAIE		DTAF = 1 and DTAIE = 1
		ICCSR.DTEF	ICCSIER.DTEIE		DTEF = 1 and DTEIE = 1
		ICHCSR.HDTAF	ICHCSIER.HDTAIE		HDTAF = 1 and HDTAIE = 1
		ICHCSR.HDTEF	ICHCSIER.HDTEIE		HDTEF = 1 and HDTEIE = 1
WUI	Wake-up	ICSR2.WUDF	ICSIER.WUDIE	Not possible	WUDF = 1 and WUDIE = 1

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or an interrupt request has been masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt handling. Returning from interrupt handling without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

Note 1. Because TXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICCSR.TDRE flag (a condition for TXI) is automatically set to 0 when transmit data is written to the ICDR register or when a STOP condition is detected (ICSR2.STOP flag is 1).

Note 2. Because RXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICCSR.RDRF flag (a condition for RXI) is automatically set to 0 when data is read from the ICDR register.

Note 3. Because these interrupts are edge-detected interrupted, they do not require clearing. Furthermore, the each flag (a condition for interrupt) is automatically set to 0 when the corresponding queue is read or written to.

Clear each flag or mask the interrupt request during interrupt handling.

(2) Interrupts in I2C Protocol Mode

The RI3C generates five types of interrupt requests, as shown in Table 43.15. The transmit data empty and receive data full interrupt requests allow the DTC or DMAC to start data transfer.

Table 43.15 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	Interrupt Enable Bit	Start DTC/DMA Transfer	Interrupt Generation Condition
TXI*1	Transmit data empty	ICCSR.TDRE	ICCSIER.TIE	Possible	TDRE = 1 and TIE = 1
RXI*2	Receive data full	ICCSR.RDRF	ICCSIER.RIE	Possible	RDRF = 1 and RIE = 1
TEI*3	Transmission end	ICSR2.TEND	ICSIER.TEIE	Not possible	TEND = 1 and TEIE = 1
EEI	Communication error/ communication event	ICSR2.START	ICSIER.STIE	Not possible	START = 1 and STIE = 1
		ICSR2.STOP	ICSIER.SPIE		STOP = 1 and SPIE = 1
		ICSR2.NACKF	ICSIER.NAKIE		NACKF = 1 and NAKIE = 1
		ICSR2.AL	ICSIER.ALIE		AL = 1 and ALIE = 1
		ICSR2.TMOF	ICSIER.TMOIE		TMOF = 1 and TMOIE = 1
WUI	Wake-up	ICSR2.WUDF	ICSIER.WUDIE	Not possible	WUDF = 1 and WUDIE = 1

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or an interrupt request has been masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt handling. Returning from interrupt handling without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

Note 1. Because TXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICCSR.TDRE flag (a condition for TXI) is automatically set to 0 when transmit data is written to the ICDR register or when a STOP condition is detected (ICSR2.STOP flag is 1).

Note 2. Because RXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICCSR.RDRF flag (a condition for RXI) is automatically set to 0 when data is read from the ICDR register.

Note 3. When using the TEI interrupt, clear the ICSR2.TEND flag in the TEI interrupt handling.
Note that the ICSR2.TEND flag is automatically set to 0 when transmit data is written to the ICDR register or when a STOP condition is detected (ICSR2.STOP flag is 1).

Clear each flag or mask the interrupt request during interrupt handling.

43.6.1 Buffer Operation for TXI and RXI Interrupts

If the conditions for generating a TXI or RXI interrupt is satisfied while the corresponding ICU.IRn.IR flag is 1, the interrupt request is not output to the ICU but retained internally (up to one request can be retained internally for each source).

When the IR flag becomes 0, the retained interrupt request is output to the ICU. The retained interrupt request is automatically cleared under normal conditions of usage.

The retained interrupt request can also be cleared by writing 0 to the corresponding interrupt enable bit in the ICCSIER register.

43.7 Event Link Function

The RI3C outputs the corresponding event signal to the event link controller (ELC) when any of the following events occur.

(1) I3C Protocol Mode

- Transmit data empty
- Receive data full
- Command queue empty
- Response queue full
- IBI queue empty/full
- Receive status queue full
- High-priority transmit data empty
- High-priority receive data full
- High-priority command queue empty
- High-priority response queue full
- Communication error or communication event
- Synchronous timing event
- C_REF counter overflow event
- C_REF capture event
- Additional bus event

(2) I²C Protocol Mode

- Transmit data empty
- Receive data full
- Transmission end
- Communication error/communication event

43.7.1 Interrupt Handling and Event Linking

Each of the RI3C interrupts has an enable bit that controls whether the interrupt is enabled or disabled. When an interrupt request source occurs, an interrupt request signal is output to the ICU if the corresponding interrupt enable bit is 1.
On the other hand, the event signal is transmitted via the ELC to other modules when the corresponding interrupt request source occurs, regardless of the interrupt enable bit.
For details on interrupt sources, refer to Table 43.14 and Table 43.15.

43.9 Usage Notes

43.9.1 Settings of the Module Stop Function

RI3C operation can be disabled or enabled by module stop control register B (MSTPCRB).
After a reset, the RI3C is stopped. The registers become accessible when it is released from the module stop state. For details, refer to section 11, Low Power Consumption.

44. High-Speed I2C-bus Interface (RIICHS)

This MCU has two-channel I2C-bus interfaces (RIICHS1, RIICHS2).
The RIICHS module conforms with the NXP I2C-bus (Inter-IC bus) interface and provides a subset of its functions.

44.1 Overview

Table 44.1 lists the specifications of the RIICHS and Figure 44.1 shows a block diagram of the RIICHS. Table 44.2 lists the I/O pins of the RIICHS.

Table 44.1 RIICHS Specifications (1/2)

Item	Specification
Operation mode	Four • Master transmit mode, master receive mode, slave transmit mode, and slave receive mode
Communication format/ Transfer rate	• I2C-bus format - Standard-mode (Sm): 0 to 100 kbps - Fast-mode (Fm): 0 to 400 kbps - Fast-mode Plus (Fm+): 0 to 1 Mbps - High-speed mode (Hs-mode): 0 to 3.4 Mbps • SMBus format: 10 to 100 kbps • Master mode or slave mode selectable • Automatic securing of the various setup times, hold times, and bus-free times for the transfer rate
Serial clock (SCL)	• For master operation, the duty cycle of the SCL is selectable in the range from 4 to 96%.
Generating and detecting conditions	START, repeated START, and STOP conditions are automatically generated. START conditions (including repeated START conditions) and STOP conditions are detectable.
Address detection	• Slave address (static address) (max 3 address) • 7-bit and 10-bit address formats are supported. • General call address • Hs-mode master code • Device ID • Host address
Acknowledgment	• For transmission, the acknowledgment bit is automatically loaded. Transfer of the next data for transmission can be automatically suspended on detection of a not-acknowledge signal. • For reception, the acknowledgment bit is automatically transmitted. If a wait between the eighth and ninth clock pulses has been selected, software control of the acknowledgment in response to the received data is possible.
Wait function (clock stretch)	• During reception, cycles of waiting by holding the SCL line low can be inserted at the following two types of timing: Waiting between the eighth and ninth clock pulses Waiting between the ninth clock pulse and the first clock pulse of the next byte
SDA output delay function	It is possible to delay the change timing of the output of the transmission data bits and the acknowledgment bit relative to the falling edge of SCL.
Arbitration	• For multi-master operation Clock synchronization for the SCL line in cases of conflict with the SCL signal from another master is possible. When generating the START condition would create conflict on the bus, loss in arbitration is detected by testing for non-matching between the internal data level and the actual level on the SDA line. During master operation, loss in arbitration is detected by testing for non-matching between the actual level on the SDA line and the internal data level. • Loss in arbitration due to detection of the START condition while the bus is busy is detectable (to prevent the generating of double START conditions). • Loss in arbitration in transfer of a not-acknowledge signal due to the internal signal (NACK) and the actual level on the SDA line not matching is detectable. • Loss in arbitration due to non-matching of internal data level and the actual level on the SDA line is detectable in slave transmission.
Timeout function	The internal timeout function is capable of detecting long-interval stop of the SCL.
Noise filter	• Analog noise filter • Digital noise filter

Table 44.1 RIICHS Specifications (2/2)

Item	Specification
Interrupt source	Five sources: • Transmit data empty (TXI) • Receive data full (RXI) • Transmission end (TEI) • Communication error or communication event (EEI) - START condition detection (including repeated START condition) - STOP condition detection - NACK detection - Arbitration lost - Timeout detection • Wake-up (WUI) - Slave address match detection
Event link function (output)	• Transmit data empty • Receive data full • Transmission end • Communication error or communication event
Low power consumption function	Module stop state can be set.
Protect Zone filter	Security attributes can be set for each channel.*1

Note 1. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Table 44.2 RIICHS Pin Configuration

Channel	Pin Name	I/O	Function
RIICHS1	SCLHS1	I/O	Serial clock I/O pin
	SDAHS1	I/O	Serial data I/O pin
RIICHS2	SCLHS2	I/O	Serial clock I/O pin
	SDAHS2	I/O	Serial data I/O pin

44.2 Register Descriptions

44.2.1 Control Register (ICCR)

Address(es): RIICHS1.ICCR 8745 F414h, RIICHS2.ICCR 8745 F814h,
RIICHS1_NS.ICCR 0745 F414h, RIICHS2_NS.ICCR 0745 F814h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ICE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b30 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31	ICE	Bus Interface Enable	0: The I2C-bus operation is disabled. (SCLHSn and SDAHSn pins in inactive state) 1: The I2C-bus operation is enabled. (SCLHSn and SDAHSn pins in active state)	R/W

ICE Bit (Bus Interface Enable)

Enables or disables the operation on the I2C-bus.

When using RIICHS, set this bit to 1. When this bit is 1, the SCLHSn and SDAHSn pins are active.

Set this bit to 0 when RIICHS is not used. When the ICE bit is 0, the SCLHSn and SDAHSn pins are inactive.

When this bit is read as 0, it indicates that I2C-bus operation is prohibited.

44.2.2 Reset Control Register (ICRCR)

Address(es): RIICHS1.ICRCR 8745 F420h, RIICHS2.ICRCR 8745 F820h, RIICHS1_NS.ICRCR 0745 F420h, RIICHS2_NS.ICRCR 0745 F820h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ISRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MRST	Module Reset*1	Writing 1 to this bit resets all registers and internal circuits. This bit automatically returns to 0 when the reset is complete.	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	ISRST	Internal Status Reset	0: Some registers and internal circuits are released from reset. 1: Some registers and internal circuits are reset.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Do not write any value to this register when this bit is 1.

ISRST Bit (Internal Status Reset)

When this bit is set to 1, some registers and internal circuits are reset. Refer to section 44.7, Reset Description for detail on the registers.

Set this bit to 0 to release from the reset.

44.2.3 Operating Mode Monitor Register (ICMMR)

Address(es): RIICHS1.ICMMR 8745 F424h, RIICHS2.ICMMR 8745 F824h,
RIICHS1_NS.ICMMR 0745 F424h, RIICHS2_NS.ICMMR 0745 F824h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	MSWP	—	—	TRS	—	MST	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b2	MST	Master/Slave Mode Flag*1	0: Slave mode 1: Master mode	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	TRS	Transmit/Receive Mode Flag	0: Receive mode 1: Transmit mode	R
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b7	MSWP	MST Write Protect	0: Writing to the MST flag is disabled. 1: Writing to the MST flag is enabled (when writing simultaneously with the value of the target bit).	W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. When setting a value to the MST flag, set the MSWP bit to 1 at the same time.

MST Flag (Master/Slave Mode Flag)

This flag indicates master or slave mode.

The RIICHS is in slave mode when the MST flag is set to 0 and is in master mode when the flag is set to 1. Combination of this flag and the TRS flag indicates the operating mode of the RIICHS.

The value of the MST flag is automatically changed to 1 for master mode or 0 for slave mode by generating of a START condition and generating or detection of a STOP condition, etc. Although writing to the MST flag is possible when the MSWP bit is set to 1, writing to this flag is not necessary during normal usage.

[Setting conditions]

- When 1 is written to the MSWP bit and the MST flag at the same time.
- When a START condition is generated normally according to the START condition generation request (when a START condition is detected with the ICCGR.ST bit set to 1).

[Clearing conditions]

- When the RIICHS is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.
- When 1 is written to the MSWP bit and 0 is written to the MST flag at the same time.
- When a STOP condition is detected.
- When the ICSR2.AL flag becomes 1 (arbitration is lost).

TRS Flag (Transmit/Receive Mode Flag)

This flag indicates transmit or receive mode.

The RIICHS is in receive mode when the TRS flag is set to 0 and is in transmit mode when the bit is set to 1.

Combination of this flag and the MST flag indicates the operating mode of the RIICHS.
The value of TRS flag is automatically changed to 1 for transmit mode or 0 for receive mode by generating or detection of a START condition and setting of the R/W# bit.
[Setting conditions]

- When a START condition is generated normally according to the START condition generation request (when a START condition is detected with the ICCGR.ST bit set to 1).
- When a repeated START condition is generated normally according to the repeated START condition generation request (when a repeated START condition is detected with the ICCGR.RS bit set to 1).
- When the R/W# bit added to the slave address is set to 0 in master mode.
- When the address received in slave mode matches the address enabled in the ICSCR register, with the R/W# bit set to 1.

[Clearing conditions]

- When a STOP condition is detected.
- When the ICSR2.AL flag becomes 1 (arbitration is lost).
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended.
- In slave mode, a match between the received address and the address enabled in the ICSCR register when the value of the received R/W# bit is 0 (including cases where the received address is the general call address).
- In slave mode, a repeated START condition is detected (a START condition is detected with ICBSR.BFREE flag = 0 and MST flag = 0).
- When 1 is written to ICRCR.MRST bit or ICRCR.ISRST bit to reset the RIICHS or the internal status.

MSWP Bit (MST Write Protect)

This bit is used to rewrite the MST flag.
When setting a value to the MST flag, set this bit to 1 at the same time.
This bit is automatically set to 0. The read value is 0.

44.2.4 Function Enable Register (ICFER)

Address(es): RIICHS1.ICFER 8745 F460h, RIICHS2.ICFER 8745 F860h, RIICHS1_NS.ICFER 0745 F460h, RIICHS2_NS.ICFER 0745 F860h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HSME	FMPE	—	SMBS	—	—	—	SCLE	—	—	—	—	—	SALE	NALE	MALE
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	MALE	Master Arbitration-Lost Detection Enable	0: Master arbitration-lost detection is disabled. (Disables the arbitration-lost detection function and does not clear the ICMMR.MST and ICMMR.TRS flags automatically when arbitration is lost.) 1: Master arbitration-lost detection is enabled. (Enables the arbitration-lost detection function and clears the ICMMR.MST and ICMMR.TRS flags automatically when arbitration is lost.)	R/W
b1	NALE	NACK Transmission Arbitration-Lost Detection Enable	0: NACK transmission arbitration-lost detection is disabled. 1: NACK transmission arbitration-lost detection is enabled.	R/W
b2	SALE	Slave Arbitration-Lost Detection Enable	0: Slave arbitration-lost detection is disabled. 1: Slave arbitration-lost detection is enabled.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	SCLE	SCL Synchronization Enable	0: SCL synchronization is disabled. 1: SCL synchronization is enabled.	R/W
b11 to b9	—	Reserved	These bits are read as 0 and cannot be modified.	R
b12	SMBS	SMBus/I2C-bus Selection	0: The I2C-bus select 1: The SMBus select	R/W
b13	—	Reserved	This bit is read as 0. The write value should be 0.	R
b14	FMPE	Fast-mode Plus Enable	0: No Fm+ slope control circuit is used for the SCLHSn pin and SDAHSn pin. 1: An Fm+ slope control circuit is used for the SCLHSn pin and SDAHSn pin.	R/W
b15	HSME	Hs-mode Enable	0: High speed mode is disabled. 1: High speed mode is enabled.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

MALE Bit (Master Arbitration-Lost Detection Enable)

This bit uses to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE Bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit uses to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

SALE Bit (Slave Arbitration-Lost Detection Enable)

This bit uses to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

SCLE Bit (SCL Synchronization Enable)

This bit uses to specify whether to synchronize the SCL output with the SCL input. Normally, set this bit to 1.
When the SCLE bit set to 0 (SCL synchronization is disabled), the RIICHS does not synchronize the SCL output with the SCL input. In this setting, the RIICHS outputs the clock with the transfer rate set in the ICBRH and ICBRL registers regardless of the SCLHSn line state. For this reason, if the load of the I2C bus line is much larger than the specification value or if the SCL output overlaps in multiple masters, the short-cycle SCL that does not meet the specification may be output. When the SCL synchronization is not, it also affects the generation of a START condition, repeated START condition, and STOP condition, and the continuous output of additional SCL.
This bit must not be set to 0 except for checking the output of the set transfer rate.

FMPE Bit (Fast-mode Plus Enable)

This bit uses to specify whether to use a slope control circuit for Fast-mode Plus (Fm+).
When this bit set to 1, a slope control circuit conforming to the Fast-mode Plus (Fm+) slope control standard (tof) of the I2C-bus is selected. When this bit set to 0, a slope control circuit conforming to the Standard-mode (Sm) and Fast-mode (Fm) slope control standard (tof) of the I2C-bus is selected.
Set this bit to 1 when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus (Fm+)) of the I2C-bus standard. Set this bit to 0 when using the transmission rate at other rates (up to 100 kbps (Sm), up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps). When performing Hs-mode communication, set this bit according to the mode when sending the Hs-mode master code.

HSME Bit (Hs-mode Enable)

This bit is used for communicating in Hs-mode.
When this bit is set to 1, the Hs-mode master code is recognized and Hs-mode communication is possible.
After the START condition is detected, if Hs-mode master code (0000 1XXXb) transmission is recognized, Hs-mode communication starts from repeated START condition after receiving the NACK response.
It communicates at the bit rate set in the ICFBR register until the NACK response, and automatically switches from repeated START condition issuance after receiving the NACK response to the bit rate set in the ICHBR register.
Hs-mode continues until a STOP condition is detected.
When the STOP condition is detected, the bit rate is automatically switched to the bit rate set in the ICFBR register.

Note: When this bit is set to 1, the ICSR2.NACKF flag will not be set even if a NACK response is received after sending the Hs-mode master code.

44.2.5 Slave Mode Control Register (ICSCR)

Address(es): RIICHS1.ICSCR 8745 F464h, RIICHS2.ICSCR 8745 F864h, RIICHS1_NS.ICSCR 0745 F464h, RIICHS2_NS.ICSCR 0745 F864h

b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R

GCAE Bit (General Call Address Detection Enable)

This bit is used to specify whether to ignore the general call address (0000 000b + 0 (write): All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the RIICHS recognizes the received slave address as the general call address independently of the slave addresses set in SAMRy.SVA[9:0] bits and performs data receive operation.

When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

HSMCE Bit (Hs-mode Master Code Detection Enable)

This bit is used to specify whether to recognize and execute the Hs-mode master code (0000 1XXXb) is received in the first byte after a START condition is detected.

When this bit is set to 1, if the received first byte matches the Hs-mode master code, RIICHS recognizes that the Hs-mode master code has been received.

The first byte after repeated START condition after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set in the SAMRy.SVA[9:0] bits (y = 0 to 2).

If the addresses match, the transmission/reception operation continues according to the R/W# bit value.

Hs-mode continues until a STOP condition is detected.

When this bit is set to 0, RIICHS will ignore the pattern until a STOP condition is detected, even if it matches the Hs-mode master code.

When this bit is set to 1, set the ICCSCR.WAITAE bit to 0 and ICCSCR.WAITRE bit to 1.

DIDE Bit (Device-ID Address Detection Enable)

This bit is used to specify whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first frame after a START condition or repeated START condition is detected.
When this bit is set to 1, if the received first frame matches the device ID, the RIICHS recognizes that the device-ID address has been received. When the following R/W# bit is 0 (write), the RIICHS recognizes the second and the following frames as slave addresses and continues the receive operation.
When this bit is set to 0, the RIICHS ignores the received first frame even if it matches the device ID address and recognizes the first frame as a normal slave address.
For details on the device-ID address detection, refer to section 44.4.4.3, Device-ID Address Detection.

HOAE Bit (Host Address Detection Enable)

This bit uses to specify whether to ignore received host address (0001 000b) when the ICFER.SMBS bit is 1.
When this bit set to 1 while the ICFER.SMBS bit is 1, if the received slave address matches the host address, the RIICHS recognizes the received slave address as the host address independently of the slave addresses set in SAMRy.SVA[9:0] bits and performs the receive operation.
When the ICFER.SMBS bit or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

SARyE Bit (Slave Address y Detection Enable) (y = 0 to 2)

This bit is used to enable or disable the slave address set in SAMRy.SVA[9:0] bits.
When this bit is set to 1, the slave address set in SAMRy.SVA[9:0] bits is enabled and is compared with the received slave address.
When this bit is set to 0, the slave address set in SAMRy.SVA[9:0] bits is disabled and is ignored even if it matches the received slave address.

44.2.6 Reference Clock Control Register (ICRCCR)

Address(es): RIICHS1.ICRCCR 8745 F470h, RIICHS2.ICRCCR 8745 F870h,
RIICHS1_NS.ICRCCR 0745 F470h, RIICHS2_NS.ICRCCR 0745 F870h

	HIGH[7:0]								LOW[7:0]							
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	LOW[7:0]	Low Width Setting	Count value for the low period of SCL.	R/W
b15 to b8	HIGH[7:0]	High Width Setting	Count value for the high period of SCL.	R/W
b30 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31	DBL	High/Low Width Doubling	0: Set the high and low widths to the set value. 1: Double the high and low widths of the set values.	R/W

This register is used to specify the bit rate other than Hs-mode.

LOW[7:0] Bits (Low Width Setting)

The LOW[7:0] bits are used to set the low period of SCL.
The RIICHS counts the low period with the internal reference clock source (IICφ) specified by the ICRCCR.CKS[2:0] bits.
These bits also work to generate the data setup time for automatic SCL low-hold operation (refer to section 44.4.5, Automatic Low-Hold Function for SCL); when the RIICHS is used in slave mode, these bits need to be set to a value longer than the data setup time*1.
If the digital noise filter is enabled (the ICICR.NFE bit is 1), set the LOW[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICICR.NF[3:0] bits.

Note 1. Data setup time ($t_{SU;DAT}$)
250 ns (up to 100 kbps: Standard-mode (Sm))
100 ns (up to 400 kbps: Fast-mode (Fm))
50 ns (up to 1 Mbps: Fast-mode Plus (Fm+))

HIGH[7:0] Bits (High Width Setting)

The HIGH[7:0] bits are used to set the high period of SCL.
These bits are valid in master mode. If the RIICHS is used only in I2C slave mode, these bits need not to set the high period.
The RIICHS counts the high period with the internal reference clock source (IICφ) specified by the ICRCCR.CKS[2:0] bits.
If the digital noise filter is enabled (the ICICR.NFE bit is 1), set the HIGH[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICICR.NF[3:0] bits.

The transfer rate and the duty cycle are calculated using the following expression.

t_{LOW} = (LOW[7:0] + NF[3:0] +1) / IICφ
t_{HIGH} = (HIGH[7:0] + NF[3:0] +1) / IICφ
Transfer rate = 1 / (t_{LOW} + t_{HIGH} + t_r + t_f)
Duty cycle = (t_r + t_{HIGH}) / (t_{LOW} + t_{HIGH} + t_r + t_f)

t_{LOW}: Low period of the SCL
t_{HIGH}: high period of the SCL
t_r: Rise time of the SCL signal*1
t_f: Fall time of the SCL signal*1

Note 1. The SCL line rise time [t_r] and SCL line fall time [t_f] depend on the total bus line capacitance [C_b] and the pull-up resistor [R_p]. For details, refer to the I2C-bus standard from NXP Semiconductors.

Table 44.3 Example of the ICFBR Register Settings for Transfer Rate (I3CCLK = 120 MHz)

Transfer Rate (kbps)	CKS[2:0] Bits	HIGH[7:0] Bits	LOW[7:0] Bits	NFE Bit	NF[3:0] Bits
10	101b	122 (7Ah)	247 (F7h)	0	—
	101b	121 (79h)	246 (F6h)	1	0001b
50	011b	91 (5Bh)	188 (BCh)	0	—

100	010b	108 (6Ch)	151 (97h)	0	—
	010b	107 (6Bh)	150 (96h)	1	0001b
400	000b	68 (44h)	158 (9Eh)	0	—
	000b	67 (43h)	157 (9Dh)	1	0001b
	001b	34 (22h)	78 (4Eh)	0	—
	001b	33 (21h)	77 (4Dh)	1	0001b
1000	000b	27 (1Bh)	63 (3Fh)	0	—
	000b	26 (1Ah)	62 (3Eh)	1	0001b
	001b	13 (0Dh)	31 (1Fh)	0	—
	001b	12 (0Ch)	30 (1Eh)	1	0001b

Rise time of SCL signal (t_r)
- 100 kbps or less (Sm): 1000 ns
- 400 kbps (Fm): 300 ns
- 1 Mbps (Fm+): 120 ns

Fall time of SCL signal (t_f)
- 400 kbps (Sm/Fm): 300 ns
- 1 Mbps (Fm+): 120 ns

44.2.8 Hs-Mode Bitrate Register (ICHBR)

Address(es): RIICHS1.ICHBR 8745 F478h, RIICHS2.ICHBR 8745 F878h,
RIICHS1_NS.ICHBR 0745 F478h, RIICHS2_NS.ICHBR 0745 F878h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HIGH[7:0]								LOW[7:0]							
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	LOW[7:0]	Low Width Setting	Count value for the low period of SCL.	R/W
b15 to b8	HIGH[7:0]	High Width Setting	Count value for the high period of SCL.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

This register is used to specify the bit rate in Hs-mode.

LOW[7:0] Bits (Low Width Setting)

The LOW[7:0] bits are used to set the low period of SCL.
The RIICHS counts the low period with the internal reference clock source (IICφ) specified by the ICRCCR.CKS[2:0] bits.
These bits also work to generate the data setup time for automatic SCL low-hold operation (refer to section 44.4.5, Automatic Low-Hold Function for SCL); when the RIICHS is used in slave mode, these bits need to be set to a value longer than the data setup time*1.
If the digital noise filter is enabled (the ICICR.NFE bit is 1), set the LOW[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICICR.NF[3:0] bits.

Note 1. Data setup time ($t_{SU;DAT}$)
10 ns (up to 3.4 Mbps: Hs-mode (Hs))

HIGH[7:0] Bits (High Width Setting)

The HIGH[7:0] bits are used to set the high period of SCL.
These bits are valid in master mode. If the RIICHS is used only in I2C slave mode, these bits need not to set the high period.
The RIICHS counts the high period with the internal reference clock source (IICφ) specified by the ICRCCR.CKS[2:0] bits.
If the digital noise filter is enabled (the ICICR.NFE bit is 1), set the HIGH[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICICR.NF[3:0] bits.

The transfer rate and the duty cycle are calculated using the following expression.

t_{LOW} = (LOW[7:0] + NF[3:2] +1) / IICφ
t_{HIGH} = (HIGH[7:0] + NF[3:2] +1) / IICφ
Transfer rate = 1 / (t_{LOW} + t_{HIGH} + t_r + t_f)
Duty cycle = (t_r + t_{HIGH}) / (t_{LOW} + t_{HIGH} + t_r + t_f)

t_{LOW}: Low period of the SCL
t_{HIGH}: high period of the SCL
t_r: Rise time of the SCL signal*1
t_f: Fall time of the SCL signal*1

Note 1. The SCL line rise time [t_r] and SCL line fall time [t_f] depend on the total bus line capacitance [C_b] and the pull-up resistor [R_p]. For details, refer to the I2C-bus standard from NXP Semiconductors.

44.2.9 Bus Free Time Setting Register (ICBFTR)

Address(es): RIICHS1.ICBFTR 8745 F47Ch, RIICHS2.ICBFTR 8745 F87Ch, RIICHS1_NS.ICBFTR 0745 F47Ch, RIICHS2_NS.ICBFTR 0745 F87Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to specify the time from when the STOP condition is detected until the ICBSR.BFREE flag is set to 1. The upper 23 bits are reserved. These bits are read as 0 and the write value should be 0.
The number set in this register is counted using IICφ as the count source.
Set a value that satisfies the t_{BUF} (bus free time between a STOP and START condition) specified in the I2C-bus specification.

44.2.10 Output Signal Control Register (ICOCR)

Address(es): RIICHS1.ICOCR 8745 F488h, RIICHS2.ICOCR 8745 F888h,
RIICHS1_NS.ICOCR 0745 F488h, RIICHS2_NS.ICOCR 0745 F888h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DLCS	—	—	—	—	SDDL[2:0]			—	—	—	CLO	—	SOWP	SCLO	SDAO
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SDAO	SDA Output Control	0: The RIICHS drives the SDAHSn pin low. 1: The RIICHS releases the SDAHSn pin. (SDAHSn line is pulled high by an external pull-up resistor.)	R/W
b1	SCLO	SCL Output Control	0: The RIICHS drives the SCLHSn pin low. 1: The RIICHS releases the SCLHSn pin. (SCLHSn line is pulled high by an external pull-up resistor.)	R/W
b2	SOWP	SCLO/SDAO Write Protect	0: Writing to the SCLO and SDAO bits is disabled. 1: Writing to the SCLO and SDAO bits is enabled (when writing simultaneously with the value of the target bit). This bit is read as 0.	W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R
b4	CLO	Additional SCL Output	0: Does not output an additional SCL (default). 1: Outputs an additional SCL. (This bit automatically becomes 0 after output of one clock pulse.)	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b10 to b8	SDDL[2:0]	SDA Output Delay Setting	• When ICOCR.DLCS bit is 0 (IICφ) b10 b8 0 0 0: No output delay 0 0 1: 1 IICφ cycle 0 1 0: 2 IICφ cycles 0 1 1: 3 IICφ cycles 1 0 0: 4 IICφ cycles 1 0 1: 5 IICφ cycles 1 1 0: 6 IICφ cycles 1 1 1: 7 IICφ cycles • When ICOCR.DLCS bit is 1 (IICφ/2) b10 b8 0 0 0: No output delay 0 0 1: 1 or 2 IICφ cycles 0 1 0: 3 or 4 IICφ cycles 0 1 1: 5 or 6 IICφ cycles 1 0 0: 7 or 8 IICφ cycles 1 0 1: 9 or 10 IICφ cycles 1 1 0: 11 or 12 IICφ cycles 1 1 1: 13 or 14 IICφ cycles	R/W
b14 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R
b15	DLCS	SDA Output Delay Clock Source Select	0: The internal reference clock (IICφ) is selected as the clock source of the SDA output delay counter. 1: The internal reference clock divided by 2 (IICφ/2) is selected as the clock source of the SDA output delay counter.*1	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. This setting (IICφ/2) is valid only when the SCL pin is low. When the SCL pin is high, this setting is invalid and the clock source becomes the internal reference clock (IICφ).

SDAO Bit (SDA Output Control) and SCLO Bit (SCL Output Control)

These bits are used to directly control the SDAHSn and SCLHSn signals output from the RIICHS.
When writing to these bits, also write 1 to the SOWP bit at the same time.
The result of setting these bits is input to the RIICHS via the input buffer. When slave mode is selected, a START condition may be detected and the bus may be released depending on the bit settings.
Do not rewrite these bits during a START condition, STOP condition, repeated START condition, transmission, or reception. Operation after rewriting under the above conditions is not guaranteed.

CLO Bit (Additional SCL Output)

This bit is used to output an additional SCL for debugging or error processing.
Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.
For details on this function, refer to section 44.4.8.2, Additional SCL Output Function.

44.2.11 Input Signal Control Register (ICICR)

Address(es): RIICHS1.ICICR 8745 F48Ch, RIICHS2.ICICR 8745 F88Ch, RIICHS1_NS.ICICR 0745 F48Ch, RIICHS2_NS.ICICR 0745 F88Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	ANFE	NFE	NF[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	NF[3:0]	Noise Filter Stage Select	• Except in Hs-mode b3 b0 0 0 0 0: Noise of up to 1 IICφ cycle is filtered out (single-stage filter). 0 0 0 1: Noise of up to 2 IICφ cycles is filtered out (2-stage filter). 0 0 1 0: Noise of up to 3 IICφ cycles is filtered out (3-stage filter). : : 1 1 1 1: Noise of up to 16 IICφ cycles is filtered out (16-stage filter). • In Hs-mode b3 b2 0 0: Noise of up to 1 IICφ cycle is filtered out (single-stage filter). 0 1: Noise of up to 2 IICφ cycles is filtered out (2-stage filter). 1 0: Noise of up to 3 IICφ cycles is filtered out (3-stage filter). 1 1: Noise of up to 4 IICφ cycles is filtered out (4-stage filter). The lower 2 bits (b1 and b0) are ignored.	R/W
b4	NFE	Digital Noise Filter Enable	0: Digital noise filters are not used. 1: Digital noise filters are used.	R/W
b5	ANFE	Analog Noise Filter Enable	0: Analog noise filters are not used. 1: Analog noise filters are used.	R/W
b7, b6	—	Reserved	These bits are read as 1. The write value should be 1.	R
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

NF[3:0] Bits (Noise Filter Stage Select)

These bits are used to select the number of stages in the digital noise filter.
For details on the digital noise filter function, refer to section 44.4.3, Digital Noise Filters.

Note: Set the noise range to be filtered out by the noise filter within a range less than the SCLHSn line high period or low period. If the noise filter width is set to a value of [the shorter one of either SCL high width or SCL low width] – {1.5 × t_{IICcyc} (cycle time of internal reference clock (IICφ)) + 120 ns (pulse width suppressed by the analog noise filter, reference values)} or a greater value, the serial clock is regarded as noise by the noise filter function of the RIICHS, which may prevent the RIICHS from operating normally.

44.2.12 Timeout Control Register (ICTOR)

Address(es): RIICHS1.ICTOR 8745 F490h, RIICHS2.ICTOR 8745 F890h, RIICHS1_NS.ICTOR 0745 F490h, RIICHS2_NS.ICTOR 0745 F890h

Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	TMOS[1:0]	Timeout Detection Time Select	b1 b0 0 0: Timeout counter is 16 bits (up to 65536 counts) 0 1: Timeout counter is 14 bits (up to 16384 counts) 1 0: Timeout counter is 8 bits (up to 256 counts) 1 1: Timeout counter is 6 bits (up to 64 counts)	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	TMOL	Timeout L Count Control	0: Count is disabled while the SCLHSn line is low. 1: Count is enabled while the SCLHSn line is low.	R/W
b5	TMOH	Timeout H Count Control	0: Count is disabled while the SCLHSn line is high. 1: Count is enabled while the SCLHSn line is high.	R/W
b7, b6	TMOM[1:0]	Timeout Detection Mode Select	b7 b6 0 0: Timeout function is enabled in any of the following conditions. • When the ICBSR.BFREE flag is 0 (bus busy) in master mode • When the ICBSR.BFREE flag is 0 (bus busy) when the received slave address matches its own slave address in slave mode • When the ICBSR.BFREE flag is 1 (bus free) while the ICCGR.ST is 1 (request to generate a START condition) 0 1: Timeout function is enabled during ICBSR.BFREE flag is 0 (bus busy). 1 0: Timeout function is enabled during ICBSR.BFREE flag is 1 (bus free). 1 1: Setting prohibited	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

TMOS[1:0] Bits (Timeout Detection Time Select)

These bits are used to select for the timeout detection time when the timeout function is enabled (ICSER.TMOE bit = 1). While the SCLHSn line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with the internal reference clock (IICφ) as a count source.
For details on the timeout function, refer to section 44.4.8.1, Timeout Function.

TMOL Bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCLHSn line is held low when the timeout function is enabled (ICSER.TMOE bit = 1).

TMOH Bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCLHSn line is held high when the timeout function is enabled (ICSER.TMOE bit = 1).

TMOM[1:0] Bits (Timeout Detection Mode Select)

These bits are used to set the timeout detection condition when the timeout function is enabled (ICSER.TMOE bit = 1).
When these bits are set to 00b, timeout detection is enabled during one of the following periods.

- When the bus is busy in master mode
- When RIICHS is the target of the communication in slave mode and the bus is busy
- When the bus is free while a START condition is requested

When these bits are set to 01b, timeout detection is enabled when the bus is busy.
When these bits are set to 10b, timeout detection is enabled when the bus is free.

44.2.13 Wake-Up Unit Control Register (ICWUCR)

Address(es): RIICHS1.ICWUCR 8745 F498h, RIICHS2.ICWUCR 8745 F898h, RIICHS1_NS.ICWUCR 0745 F498h, RIICHS2_NS.ICWUCR 0745 F898h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	WUFE	WUFSYNE	—	WUANFE	—	—	—	WUACKS
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	WUACKS	Wake-Up Acknowledge Select	The response mode can be selected in combination with the ICRCR.ISRST bit. Refer to Table 44.4 for details.	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	WUANFE	Analog Noise Filter Enable	0: Analog noise filter for wake-up is disabled. 1: Analog noise filter for wake-up is enabled.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R
b6	WUFSYNE	Synchronous Operation Select	0: Asynchronous operation 1: Internal clock synchronous operation	R/W
b7	WUFE	Wake-Up Function Enable	0: Wake-Up function is disabled. 1: Wake-Up function is enabled.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R

WUACKS Bit (Wake-Up Acknowledge Select)

This bit selects the ACK response when a wake-up condition is detected.

Table 44.4 Response Mode

ICRCR.ISRST Bit	WUACKS Bit	Response Mode	Description
0	0	Normal wake-up mode 1	Responds with an ACK and holds the SCL line low.
0	1	Normal wake-up mode 2*1	Holds the SCL line low after eighth clock pulse, and when the low power consumption mode is released, release the SCL line and responds with an ACK.
1	0	Command recovery mode	Responds with an ACK but does not hold the SCL line low.
1	1	EEP response mode	Responds with a NACK but does not hold the SCL line low.

Note 1. This mode cannot be used in Hs mode.

WUANFE Bit (Analog Noise Filter Enable)

This bit enables/disables the analog noise filter for the SCL and SDA input signals.

WUFSYNE Bit (Synchronous Operation Select)

This bit selects whether to synchronize the SCL and SDA lines with the internal clock or to use them as asynchronous. Asynchronous operation can be selected only when the WUFE bit is 1.

When this bit is set to 0, the ICWUSR.WUASYNF flag becomes 1 when bus-free is detected and the wake-up detection circuit is enabled. At this time, data reception is performed asynchronously with the internal clock.

When this bit is set to 1 after the wake-up condition is detected, the wake-up detection circuit is disabled and the normal reception circuit operates. If this bit is set to 1 when the wake-up condition is not detected, the wake-up detection circuit

is disabled when a STOP condition is detected.

44.2.14 Acknowledgment Bit Control Register (ICACKR)

Address(es): RIICHS1.ICACKR 8745 F4A0h, RIICHS2.ICACKR 8745 F8A0h,
RIICHS1_NS.ICACKR 0745 F4A0h, RIICHS2_NS.ICACKR 0745 F8A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	ACKWP	ACKBT	ACKBR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ACKBR	Received Acknowledge	0: 0 is received as the acknowledgment bit (ACK reception). 1: 1 is received as the acknowledgment bit (NACK reception).	R
b1	ACKBT	Transmit Acknowledge	0: 0 is to be sent as the acknowledgment bit (ACK transmission). 1: 1 is to be sent as the acknowledgment bit (NACK transmission).	R/W*1
b2	ACKWP	ACKBT Write Protect	0: Writing to the ACKBT bit is disabled. 1: Writing to the ACKBT bit is enabled (when writing simultaneously with the value of the target bit).	W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. When setting a value to the ACKBT bit, set the ACKWP bit to 1 at the same time

ACKBR Bit (Received Acknowledge)

This bit is used to store the acknowledgment bit received from the receiver in transmit mode.

[Setting condition]

- When 1 is received as the acknowledgment bit with the ICMMR.TRS flag set to 1.

[Clearing conditions]

- When 0 is received as the acknowledgment bit with the ICMMR.TRS flag set to 1.
- When the RIICHS is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

ACKBT Bit (Transmit Acknowledge)

[Setting condition]

- When 1 is written to the ACKWP and ACKBT bits at the same time.

[Clearing conditions]

- When 1 is written to the ACKWP bit and 0 is written to the ACKBT bit at the same time.
- When a STOP condition generation is detected. (When a STOP condition is detected with the ICCGR.SP bit set to 1.)

ACKWP Bit (ACKBT Write Protect)

This bit is used to control the modification of the ACKBT bit.

When setting a value to the ACKBT bit, set this bit to 1 at the same time.

This bit is automatically set to 0. The read value is 0.

44.2.15 Clock Stretch Control Register (ICCSCR)

Address(es): RIICHS1.ICCSCR 8745 F4A4h, RIICHS2.ICCSCR 8745 F8A4h,
RIICHS1_NS.ICCSCR 0745 F4A4h, RIICHS2_NS.ICCSCR 0745 F8A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WAITRE	WAITAE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	WAITAE	Acknowledgment Generation Wait Enable	0: The ICCSR.RDRF flag becomes 1 at the rising edge of the ninth SCL. (The SCLHSn line is not held low at the falling edge of the eighth clock pulse.) 1: The ICCSR.RDRF flag becomes 1 at the rising edge of the eighth SCL. (The SCLHSn line is held low at the falling edge of the eighth clock pulse.) Low-hold is released by writing a value to the ICACKR.ACKBT bit.	R/W
b1	WAITRE	Receive Data Read Wait Enable	0: No WAIT (The period between ninth clock pulse and first clock pulse is not held low.) 1: WAIT (The period between ninth clock pulse and first clock pulse is held low.) Low-hold is released by reading ICDR register.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

WAITAE Bit (Acknowledgment Generation Wait Enable)

This bit is used to select the ICCSR.RDRF flag set timing in receive mode and also to select whether to hold the SCLHSn line low at the falling edge of the eighth SCL.

When the WAITAE bit is 0, the SCLHSn line is not held low at the falling edge of the eighth SCL, and the ICCSR.RDRF flag is set to 1 at the rising edge of the ninth SCL.

When the WAITAE bit is 1, the ICCSR.RDRF flag is set to 1 at the rising edge of the eighth SCL and the SCLHSn line is held low at the falling edge of the eighth SCL. The low-hold of the SCLHSn line is released by writing a value to the ICACKR.ACKBT bit. After data is received with this setting, the SCLHSn line is automatically held low before the acknowledgment bit is sent. This enables processing to send ACK (ICACKR.ACKBT bit = 0) or NACK (ICACKR.ACKBT bit = 1) according to receive data.

WAITRE Bit (Receive Data Read Wait Enable)

This bit is used to control whether to hold the period between the ninth SCL and the first SCL low until the receive data buffer (ICDR register) is completely read each time single-byte data is received in receive mode.

When the WAITRE bit is 0, the receive operation is continued without holding the period between the ninth and the first SCL low. When both the WAITAE and WAITRE bits are 0, continuous receive operation is enabled with the double buffer.

When the WAITRE bit is 1, the SCLHSn line is held low from the falling edge of the ninth SCL until the ICDR register value is read each time single-byte data is received. This enables receive operation in byte units.

Note: Read the ICDR register before setting the WAITRE bit to 0.

44.2.16 Condition Generation Request Register (ICCGR)

Address(es): RIICHS1.ICCGR 8745 F540h, RIICHS2.ICCGR 8745 F940h,
RIICHS1_NS.ICCGR 0745 F540h, RIICHS2_NS.ICCGR 0745 F940h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	SP	RS	ST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ST	START Condition Generation Request	0: Do not request to generate a START condition. 1: Requests to generate a START condition.	R/W
b1	RS	Repeated START Condition Generation Request	0: Do not request to generate a repeated START condition. 1: Requests to generate a repeated START condition.	R/W
b2	SP	STOP Condition Generation Request	0: Do not request to generate a STOP condition. 1: Requests to generate a STOP condition.	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

ST Bit (START Condition Generation Request)

This bit is used to request transition to master mode and generation of a START condition.
For details on the START condition generation, refer to section 44.4.7, START Condition/Repeated START Condition/STOP Condition Generating Function.
[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit.
- When a START condition has been generated (a START condition is detected).
- When the ICSR2.AL flag becomes 1 (arbitration is lost).
- When 1 is written to ICRCR.MRST bit or ICRCR.ISRST bit to apply a RIICHS reset or an internal reset.

Note: Set the ST bit to 1 (requests to generate a START condition) when the ICBSR.BFREE flag is set to 1 (bus free state).
Note that arbitration may be lost if the ST bit is set to 1 (requests to generate a START condition) when the ICBSR.BFREE flag is set to 0 (bus busy state).

RS Bit (Repeated START Condition Generation Request)

This bit is used to request that a repeated START condition be generated in master mode.
When this bit is set to 1 to request to generate a repeated START condition, a repeated START condition is generated when the BFREE flag is set to 0 (bus busy state) and the ICMMR.MST flag is set to 1 (master mode).
For details on the repeated START condition generation, refer to section 44.4.7, START Condition/Repeated START Condition/STOP Condition Generating Function.
[Setting condition]

- When 1 is written to the RS bit with the ICBSR.BFREE flag set to 0.

[Clearing conditions]

- When 0 is written to the RS bit.
- When a repeated START condition has been generated. (a repeated START condition is detected.)
- When the ICSR2.AL flag becomes 1 (arbitration is lost).
- When 1 is written to ICRCR.MRST bit or ICRCR.ISRST bit to apply a RIICHS reset or an internal reset.

Note: Do not set the RS bit to 1 while generating a STOP condition.
Note: If 1 (requests to generate a repeated START condition) is written to the RS bit in slave mode, the repeated START condition is not generated but the RS bit remains set to 1.
If the operating mode changes to master mode with the bit not being cleared, note that the repeated START condition may be generated.

SP Bit (STOP Condition Generation Request)

This bit is used to request that a STOP condition be generated in master mode.
When this bit is set to 1 to request to generate a STOP condition, a STOP condition is generated when the ICBSR.BFREE flag is set to 0 (bus busy state) and the ICMMR.MST flag is set to 1 (master mode).
For details on the STOP condition generation, refer to section 44.4.7, START Condition/Repeated START Condition/STOP Condition Generating Function.
[Setting condition]

- When 1 is written to the SP bit with the ICBSR.BFREE flag set to 0 and the ICMMR.MST flag set to 1.

[Clearing conditions]

- When 0 is written to the SP bit.
- When a STOP condition has been generated. (a STOP condition is detected.)
- When the ICSR2.AL flag becomes 1 (arbitration is lost).
- When a START condition and a repeated START condition are detected.
- When 1 is written to ICRCR.MRST bit or ICRCR.ISRST bit to apply an RIICHS reset or an internal reset.

Note: When the ICBSR.BFREE flag is 1 (bus free state), writing 1 to the SP bit is ignored.
Note: Do not set the SP bit to 1 while a repeated START condition is being generated.

44.2.17 Transmit/Receive Data Register (ICDR)

Address(es): RIICHS1.ICDR 8745 F558h, RIICHS2.ICDR 8745 F958h,
RIICHS1_NS.ICDR 0745 F558h, RIICHS2_NS.ICDR 0745 F958h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ICDR register is a 32-bit read/write register used to read data from the receive data buffer and write data to the transmit data buffer. This register can be accessed in 32-bit or 8-bit units. The upper 24 bits are reserved and should be written as 0 when data is written in 32-bit units.

For Read Operation:

When 1 byte of data has been received, the received data is transferred from the internal shift register to the ICDR register to enable the next data to be received.

The double-buffer structure of the shift register and the ICDR register allows continuous receive operation if the received data has been read from the ICDR register while the shift register is receiving data.

Read data from the ICDR register once when a receive data full interrupt (RXI) request is generated.

If the ICDR register receives the next receive data before the current data is read from the ICDR register (while the ICCSR.RDRF flag is 1), the RIICHS automatically holds the SCLHSn line low one cycle before the RDRF flag is set to 1 next.

For Write Operation:

When the ICDR register detects a space in the internal shift register, it transfers the transmit data that has been written to the ICDR register to the shift register and starts transmitting data in transmit mode.

The double-buffer structure of the ICDR register and the shift register allows continuous transmit operation if the next transmit data has been written to the ICDR register while the shift register data is being transmitted.

Write transmit data to the ICDR register once when a transmit data empty interrupt (TXI) request is generated.

44.2.18 Status Register 2 (ICSR2)

Address(es): RIICHS1.ICSR2 8745 F5D0h, RIICHS2.ICSR2 8745 F9D0h,
RIICHS1_NS.ICSR2 0745 F5D0h, RIICHS2_NS.ICSR2 0745 F9D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	WUDF	—	—	—	TMOF	—	—	—	AL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	START	START Condition Detection Flag	0: START condition is not detected. 1: START condition is detected.	R/(W) *1
b1	STOP	STOP Condition Detection Flag	0: STOP condition is not detected. 1: STOP condition is detected.	R/(W) *1
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	NACKF	NACK Detection Flag	0: NACK is not detected 1: NACK is detected.	R/(W) *1
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	TEND	Transmission End Flag	0: Data is being transmitted. 1: Data has been transmitted.	R/(W) *1
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	AL	Arbitration Lost Flag	0: Arbitration is not lost. 1: Arbitration is lost.	R/(W) *1
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	TMOF	Timeout Detection Flag	0: Timeout is not detected. 1: Timeout is detected.	R/(W) *1
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	WUDF	Wake-Up Condition Detection Flag	0: Wake-up condition is not detected. 1: Wake-up condition is detected.	R/(W) *1
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Only 0 can be written to this bit.

START Flag (START Condition Detection Flag)

[Setting condition]

- When a START condition (or a repeated START condition) is detected while the ICSER.STDE bit is 1.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.
- When the RIICHS is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

STOP Flag (STOP Condition Detection Flag)

[Setting condition]

- When a STOP condition is detected while the ICSER.SPDE bit is 1.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When the RIICHS is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

NACKF Flag (NACK Detection Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICSER.NAKDE bit is 1 (NACK detection is enabled).
  2. When ACK is not received (NACK is received) from the receiver in transmit mode.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When the RIICHS is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

TEND Flag (Transmission End Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICSER.TEDE bit is 1 (transmission end detection is enabled).
  2. At the rising edge of the ninth SCL while the ICCSR.TDRE flag is 1. Excluding when sending an address.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When data is written to the ICDR register.
- When a STOP condition is detected.
- When the RIICHS is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

AL Flag (Arbitration Lost Flag)

[Setting condition]

When master arbitration-lost detection is enabled (ICSER.ALE bit = 1, ICFER.MALE bit = 1):

- When the internal SDA output state does not match the SDAHSn line level at the rising edge of SCL except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDAHSn line is driven low while the internal SDA output is high (the SDAHSn pin is in the high-impedance state)).
- The following 1 and 2 are satisfied.
  1. When the START condition is detected while the ICCGR.ST bit is 1.
  2. When the internal SDA output state does not match the SDAHSn line level.
- When the ICCGR.ST bit is set to 1 (requests to generate a START condition) while the ICBSR.BFREE flag is 0.

When NACK transmission arbitration-lost detection is enabled (ICSER.ALE bit = 1, ICFER.NALE bit = 1):

- When the internal SDA output state does not match the SDAHSn line level at the rising edge of SCL in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICSER.ALE bit = 1, ICFER.SALE bit = 1):

- When the internal SDA output state does not match the SDAHSn line level at the rising edge of SCL except for the ACK period during data transmission in slave transmit mode.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When the RIICHS is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

TMOF Flag (Timeout Detection Flag)

[Setting condition]

- All of the following 1 to 3 are satisfied.
  1. The ICSER.TMOE bit is 1 (timeout detection is enabled).
  2. When the master mode or the received slave address matches the slave address n in slave mode.
  3. When the SCLHSn line state remains unchanged for the period specified by ICTOR register.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When the RIICHS is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

WUDF Flag (Wake-Up Condition Detection Flag)

This flag indicates that the condition for generating a wake-up interrupt has been met.

[Setting condition]

- When the received slave address matches any of the addresses permitted for detection by the ICSCR.SAR0E to SAR2E bits, the ICSCR.HOAE bit, and the ICSCR.GCAE bit while the ICWUCR.WUFE bit is 1 (wake-up function is enabled), the ICSER.WUDE bit is 1 (wake-up condition detection is enabled), and ICWUSR.WUASYNF flag is 1 (PCLKA and I3CCLK are stopped) (in slave mode).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1 while the ICWUSR.WUASYNF flag is 0 (PCLKA and I3CCLK are operating).

44.2.19 Status Detection Enable Register (ICSER)

Address(es): RIICHS1.ICSER 8745 F5D4h, RIICHS2.ICSER 8745 F9D4h,

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STDE	START Condition Detection Enable	0: START condition detection is disabled. 1: START condition detection is enabled.	R/W
b1	SPDE	STOP Condition Detection Enable	0: STOP condition detection is disabled. 1: STOP condition detection is enabled.	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	NAKDE	NACK Detection Enable	0: NACK detection is disabled. 1: NACK detection is enabled.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	TEDE	Transmission End Detection Enable	0: Transmission end detection is disabled. 1: Transmission end detection is enabled.	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	ALE	Arbitration Lost Detection Enable	0: Arbitration lost detection is disabled. 1: Arbitration lost detection is enabled.	R/W
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	TMOE	Timeout Detection Enable	0: Timeout detection is disabled. 1: Timeout detection is enabled.	R/W
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	WUDE	Wake-Up Condition Detection Enable	0: Wake-up condition detection is disabled. 1: Wake-up condition detection is enabled.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R

This register is used to enable or disable detection of each status. When the status enabled by this register is detected, the corresponding flag in the ICSR2 register is set to 1.

44.2.20 Status Interrupt Enable Register (ICSIER)

Address(es): RIICHS1.ICSIER 8745 F5D8h, RIICHS2.ICSIER 8745 F9D8h,
RIICHS1_NS.ICSIER 0745 F5D8h, RIICHS2_NS.ICSIER 0745 F9D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	WUDIE	—	—	—	TMOIE	—	—	—	ALIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TEIE	—	—	—	NAKIE	—	—	SPIE	STIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STIE	START Condition Detection Interrupt Enable	0: START condition detection interrupt is disabled. 1: START condition detection interrupt is enabled.	R/W
b1	SPIE	STOP Condition Detection Interrupt Enable	0: STOP condition detection interrupt is disabled. 1: STOP condition detection interrupt is enabled.	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	NAKIE	NACK Detection Interrupt Enable	0: NACK detection interrupt is disabled. 1: NACK detection interrupt is enabled.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	TEIE	Transmission End Interrupt Enable	0: Transmission end interrupt is disabled. 1: Transmission end interrupt is enabled.	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	ALIE	Arbitration Lost Detection Interrupt Enable	0: Arbitration lost interrupt is disabled. 1: Arbitration lost interrupt is enabled.	R/W
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R
b20	TMOIE	Timeout Detection Interrupt Enable	0: Timeout detection interrupt is disabled. 1: Timeout detection interrupt is enabled.	R/W
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	WUDIE	Wake-Up Interrupt Enable	0: Wake-up interrupt is disabled. 1: Wake-up interrupt is enabled.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R

This register is used to enable or disable interrupts for each status. When a flag in the ICSR2 register becomes 1 and the corresponding interrupt enable bit is 1, an interrupt request is output.

44.2.21 Communication Status Register (ICCSR)

Address(es): RIICHS1.ICCSR 8745 F5E0h, RIICHS2.ICCSR 8745 F9E0h,
RIICHS1_NS.ICCSR 0745 F5E0h, RIICHS2_NS.ICCSR 0745 F9E0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RDRF	TDRE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TDRE	Transmit Data Empty Flag	0: Transmit data buffer contains transmit data. 1: Transmit data buffer contains no transmit data.	R
b1	RDRF	Receive Data Full Flag	0: Receive data buffer contains no receive data. 1: Receive data buffer contains receive data.	R
b31 to b2	—	Reserved	These bits are read as 0.	R

TDRE Flag (Transmit Data Empty Flag)

[Setting condition]

- When any of the following conditions is satisfied while the ICCSER.TDE bit is 1 (detection of transmit data empty is enabled).
  1. When data is transferred from transmit data buffer to shift register and transmit data buffer becomes empty.
  2. When the ICMMR.TRS flag is set to 1.
  3. When the received slave address matches while the TRS flag is 1.

[Clearing condition]

- When data is written to ICDR register.
- When the ICMMR.TRS flag is set to 0.
- When the RIICHS is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

Note: When the ICSR2.NACKF flag is set to 1 while the ICSER.NAKDE bit is 1, RIICHS aborts data transmission/reception. Here, if the TDRE flag is 0 (next transmit data has been written), data is transferred to the shift register and the transmit data buffer becomes empty at the rising edge of the ninth clock cycle, but the TDRE flag is not set to 1.

RDRF Flag (Receive Data Full Flag)

[Setting condition]

- When any of the following conditions is satisfied while the ICCSER.RDE bit is 1 (detection of receive data full is enabled).
  1. When receive data is transferred from shift register to receive data buffer.
     The RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL (selected in the ICCSCR.WAITAE bit).
  2. When the received slave address matches after a START (or repeated START) condition is detected with the ICMMR.TRS flag set to 0.

[Clearing condition]

- When data is read from ICDR register.

- When the RIICHS is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

44.2.22 Communication Status Detection Enable Register (ICCSER)

Address(es): RIICHS1.ICCSER 8745 F5E4h, RIICHS2.ICCSER 8745 F9E4h,
RIICHS1_NS.ICCSER 0745 F5E4h, RIICHS2_NS.ICCSER 0745 F9E4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RDE	TDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TDE	Transmit Data Empty Detection Enable	0: Detection of transmit data empty is disabled. 1: Detection of transmit data empty is enabled.	R/W
b1	RDE	Receive Data Full Detection Enable	0: Detection of receive data full is disabled. 1: Detection of receive data full is enabled.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

This register is used to enable or disable detection of each status. When the status enabled by this register is detected, the corresponding flag in the ICCSR register is set to 1.

44.2.23 Communication Status Interrupt Enable Register (ICCSIER)

Address(es): RIICHS1.ICCSIER 8745 F5E8h, RIICHS2.ICCSIER 8745 F9E8h,
RIICHS1_NS.ICCSIER 0745 F5E8h, RIICHS2_NS.ICCSIER 0745 F9E8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RIE	TIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TIE	Transmit Data Empty Interrupt Enable	0: Transmit data empty interrupt is disabled. 1: Transmit data empty interrupt is enabled.	R/W
b1	RIE	Receive Data Full Interrupt Enable	0: Receive data full interrupt is disabled. 1: Receive data full interrupt is enabled.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

This register is used to enable or disable interrupts for each status. When a flag in the ICCSR register becomes 1 and the corresponding interrupt enable bit is 1, an interrupt request is generated.

44.2.24 Bus Status Register (ICBSR)

Address(es): RIICHS1.ICBSR 8745 F610h, RIICHS2.ICBSR 8745 FA10h,
RIICHS1_NS.ICBSR 0745 F610h, RIICHS2_NS.ICBSR 0745 FA10h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BFREE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BFREE	Bus Free Flag	0: Have not detected bus free. 1: Have detected bus free.	R
b31 to b1	—	Reserved	These bits are read as 0.	R

BFREE Flag (Bus Free Flag)

This flag indicates whether the I2C-bus is occupied (bus busy) or released (bus free).

[Setting condition]

- When the number of cycles set in the ICBFTR register has elapsed when the SCLHSn and SDAHSn lines are high after a STOP condition is detected.
- When the number of cycles set in the ICBFTR register has elapsed when the SCLHSn and SDAHSn lines are high after setting the ICCR.ICE bit to 1.

[Clearing condition]

- When a START condition is detected.
- When the ICCR.ICE bit is set to 0.
- When the RIICHS is reset by setting the ICRCR.MRST bit to 1.
- When the internal status is reset by setting the ICRCR.ISRST bit to 1.

44.2.25 Slave Mode Status Register (ICSSR)

Address(es): RIICHS1.ICSSR 8745 F614h, RIICHS2.ICSSR 8745 FA14h, RIICHS1_NS.ICSSR 0745 F614h, RIICHS2_NS.ICSSR 0745 FA14h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	AAS2	AAS1	AAS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HOA	—	—	—	—	—	—	—	—	DID	HSMC	—	—	—	—	GCA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	GCA	General Call Address Detection Flag	0: General call address is not detected. 1: General call address is detected.	R/(W) *1
b4 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b5	HSMC	Hs-mode Master Code Detection Flag	0: Hs-mode master code is not detected. 1: Hs-mode master code is detected.	R/(W) *1
b6	DID	Device-ID Address Detection Flag	0: Device-ID address is not detected. 1: Device-ID address is detected. • This bit is set to 1 when the first frame received immediately after a START condition is detected matches a value of (device ID (1111 100b) + 0 (write)).	R/(W) *1
b14 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R
b15	HOA	Host Address Detection Flag	0: Host address is not detected. 1: Host address is detected. • This bit is set to 1 when the received slave address matches the host address (0001 000b).	R/(W) *1
b16	AAS0	Slave Address 0 Detection Flag	0: Slave address 0 is not detected. 1: Slave address 0 is detected.	R/(W) *1
b17	AAS1	Slave Address 1 Detection Flag	0: Slave address 1 is not detected. 1: Slave address 1 is detected.	R/(W) *1
b18	AAS2	Slave Address 2 Detection Flag	0: Slave address 2 is not detected. 1: Slave address 2 is detected.	R/(W) *1
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Only 0 can be written to this bit.

GCA Flag (General Call Address Detection Flag)

[Setting condition]

- This flag is set to 1 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.GCAE bit is 1 (general call address detection is enabled).
  2. When the received slave address matches the general call address (0000 000b + 0 (write)).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.
- When a repeated START condition is detected.

HSMC Flag (Hs-mode Master Code Detection Flag)

[Setting condition]

- This flag is set to 1 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.HSMCE bit is 1 (Hs-mode master code detection is enabled).
  2. When the first byte received immediately after a START condition is detected matches a value of Hs-mode master code (0000 1XXXb) + 1 (NACK).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.

DID Flag (Device-ID Address Detection Flag)

[Setting condition]

- This flag is set to 1 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.DIDE bit is 1 (device-ID address detection is enabled).
  2. When the first byte received immediately after a START condition or repeated START condition is detected matches a value of device ID (1111 100b) + 0 (write).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.
- This flag is set to 0 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 or 1 and 3 are satisfied.
  1. The ICSCR.DIDE bit is 1 (device-ID address detection is enabled).
  2. When the first byte received immediately after a START condition or repeated START condition is detected does not match a value of device ID (1111 100b).
  3. When the first byte received immediately after a START condition or repeated START condition is detected matches a value of (device ID (1111 100b) + 0 (write)) and the second byte does not match any of slave addresses 0 to 2.

HOA Flag (Host Address Detection Flag)

[Setting condition]

- This flag is set to 1 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.HOAE bit is 1 (host address detection is enabled).
  2. When the received slave address matches the host address (0001 000b).

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.
- When a repeated START condition is detected.

AASy Flag (Slave Address y Detection Flag) (y = 0 to 2)

[Setting condition]

For 7-bit address format (SAMRy.FS flag = 0):

- This flag is set to 1 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.SARyE bit is 1 (slave y is enabled).
  2. When the received slave address matches the SAMRy.SVA[6:0] bits value.

For 10-bit address format (SAMRy.FS flag = 1):

- This flag is set to 1 at the rising edge of the ninth SCL in the second byte when the following 1 and 2 are satisfied.
  1. The ICSCR.SARyE bit is 1 (slave y is enabled).
  2. When the received slave address matches a value of 1111 0b + SAMRy.SVA[9:8] bits and the following address matches the SAMRy.SVA[7:0] bits value.

[Clearing condition]

- When 0 is written to this flag after confirming that it is 1.
- When a STOP condition is detected.

For 7-bit address format (SAMRy.FS flag = 0):

- This flag is set to 0 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.SARyE bit is 1 (slave y is enabled).
  2. When the received slave address does not match SAMRy.SVA[6:0] bits value.

For 10-bit address format (SAMRy.FS flag = 1):

- This flag is set to 0 at the rising edge of the ninth SCL in the first byte when the following 1 and 2 are satisfied.
  1. The ICSCR.SARyE bit is 1 (slave y is enabled).
  2. When the received slave address does not match a value of 1111 0b + SAMRy.SVA[9:8] bits.
- This flag is set to 0 at the rising edge of the ninth SCL in the second byte when the following 1 and 2 are satisfied.
  1. The ICSCR.SARyE bit is 1 (slave y is enabled).
  2. When the received slave address matches a value of 1111 0b + SAMRy.SVA[9:8] bits and the following address does not match the SAMRy.SVA[7:0] bits value.

44.2.26 Wake-Up Unit Status Register (ICWUSR)

Address(es): RIICHS1.ICWUSR 8745 F618h, RIICHS2.ICWUSR 8745 FA18h, RIICHS1_NS.ICWUSR 0745 F618h, RIICHS2_NS.ICWUSR 0745 FA18h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WUASYNF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	WUASYNF	Wake-Up Detection Circuit Status Flag	0: Wake-up detection circuit is disabled (PCLKA and I3CCLK are operating). 1: Wake-up detection circuit is enabled (PCLKA and I3CCLK are stopped).	R
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

WUASYNF Flag (Wake-Up Detection Circuit Status Flag)

This bit indicates whether the wake-up detection circuit is enabled or disabled.

[Setting condition]

- When the ICBSR.BFREE flag is set to 1 (bus free) while the ICWUCR.WUFE bit is 1 (wake-up function is enabled) and the WUFSYNE bit is 0 (asynchronous operation).

[Clearing condition]

- When the ICWUCR.WUFE bit is set to 0 (wake-up function is disabled).
- When a wake-up event is detected while the WUFE bit is 1, and then the ICWUCR.WUFSYNE bit is set to 1 (internal clock synchronous operation) while this flag is set to 1 (in slave mode).
- When a STOP condition is detected while the WUFE bit is 1, this flag is 1, and the WUFSYNE bit is 1 (in slave mode).

44.2.27 Slave Address Register y (SARy) (y = 0 to 2)

Address(es): RIICHS1.SAR0 8745 F6B0h, RIICHS1.SAR1 8745 F6B4h, RIICHS1.SAR2 8745 F6B8h, RIICHS2.SAR0 8745 FAB0h, RIICHS2.SAR1 8745 FAB4h, RIICHS2.SAR2 8745 FAB8h, RIICHS1_NS.SAR0 0745 F6B0h, RIICHS1_NS.SAR1 0745 F6B4h, RIICHS1_NS.SAR2 0745 F6B8h, RIICHS2_NS.SAR0 0745 FAB0h, RIICHS2_NS.SAR1 0745 FAB4h, RIICHS2_NS.SAR2 0745 FAB8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	FS	SVA[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	SVA[9:0]	Slave Address	Set a slave address.	R/W
b10	FS	Address Format Select	0: 7-bit address format 1: 10-bit address format	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R

FS Bit (Address Format Select)

This bit is used to select 7-bit address or 10-bit address for slave address (SVA[9:0] bits).

When this bit is 0, the 7-bit address format is selected for slave address, the SVA[6:0] bit setting is valid, and the SVA[9:7] bit setting is ignored.

When this bit is 1, the 10-bit address format is selected for slave address and the SVA[9:0] bit setting is valid.

When the ICSCR.SARyE bit is 0, the setting of this bit is ignored.

44.2.28 Slave Address Monitor Register y (SAMRy) (y = 0 to 2)

Address(es): RIICHS1.SAMR0 8745 F730h, RIICHS1.SAMR1 8745 F734h, RIICHS1.SAMR2 8745 F738h, RIICHS2.SAMR0 8745 FB30h, RIICHS2.SAMR1 8745 FB34h, RIICHS2.SAMR2 8745 FB38h, RIICHS1_NS.SAMR0 0745 F730h, RIICHS1_NS.SAMR1 0745 F734h, RIICHS1_NS.SAMR2 0745 F738h, RIICHS2_NS.SAMR0 0745 FB30h, RIICHS2_NS.SAMR1 0745 FB34h, RIICHS2_NS.SAMR2 0745 FB38h

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0.	R
b25 to b16	SVA[9:0]	Slave Address	Slave address is set.	R
b26	—	Reserved	This bit is read as 0.	R
b27	FS	Address Format Flag	0: The 7-bit address format is selected. 1: The 10-bit address format is selected.	R
b29, b28	—	Reserved	These bits are read as 0.	R
b30	SAV	Slave Address Valid Flag	0: Slave address is disabled. 1: Slave address is enabled.	R
b31	—	Reserved	This bit is read as 0.	R

SVA[9:0] Bits (Slave Address)

The SVA[9:0] bits indicate a valid slave address.

- When the SAV flag is 1 and the FS flag is 0:
  The SVA[9:7] bits are 000b.
  The SVA[6:0] bits are the SARy.SVA[6:0] bits.
- When the SAV flag is 1 and the FS flag is 1:
  The SVA[9:0] bits are the SARy.SVA[9:0] bits.

FS Flag (Address Format Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICSCR.SARyE bit is 1 (detection of slave y is enabled).
  2. The SARy.FS bit is 1 (the address length is 10 bits).

[Clearing condition]

- [Setting condition] is not satisfied.

SAV Flag (Slave Address Valid Flag)

[Setting condition]

- All of the following are satisfied.
  1. The ICSCR.SARyE bit is 1 (detection of slave address y is enabled).
  2. The SARy.SVA[6:0] bits are not 0000000b when the FS flag is 0.
     The SARy.SVA[9:0] bits are not 0000000000b when the FS flag is 1.

[Clearing condition]

- [Setting condition] is not satisfied.

44.2.29 Bit Count Register (ICBCR)

Address(es): RIICHS1.ICBCR 8745 F780h, RIICHS2.ICBCR 8745 FB80h,
RIICHS1_NS.ICBCR 0745 F780h, RIICHS2_NS.ICBCR 0745 FB80h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SCLI	SCL Line Monitor Flag	0: SCLHSn line is low. 1: SCLHSn line is high.	R
b1	SDAI	SDA Line Monitor Flag	0: SDAHSn line is low. 1: SDAHSn line is high.	R
b2	SCLO	SCL Output Monitor Flag	0: The RIICHS drives the SCLHSn pin low. 1: The RIICHS releases the SCLHSn pin.	R
b3	SDAO	SDA Output Monitor Flag	0: The RIICHS drives the SDAHSn pin low. 1: The RIICHS releases the SDAHSn pin.	R
b31 to b4	—	Reserved	These bits are read as 0.	R

SCLO Flag (SCL Output Monitor Flag) and SDAO Flag (SDA Output Monitor Flag)

When reading these bits, the state of signals output from the RIICHS can be read.

44.3 Operation

44.3.1 Communication Data Format

The I2C-bus format consists of 8-bit data and 1-bit acknowledgment. The frame following a START condition or repeated START condition is an address frame used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a STOP condition is generated. Figure 44.2 shows the I2C-bus format, and Figure 44.3 shows the I2C-bus timing.

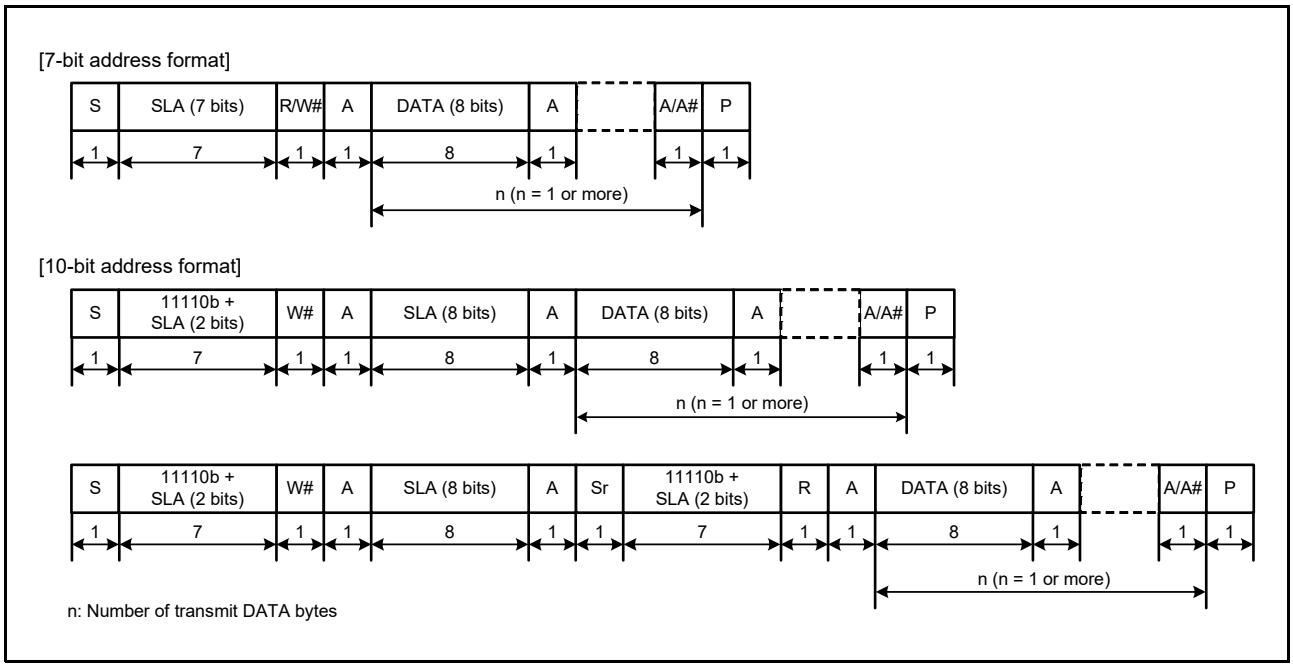

Figure 44.2 I2C-bus Format

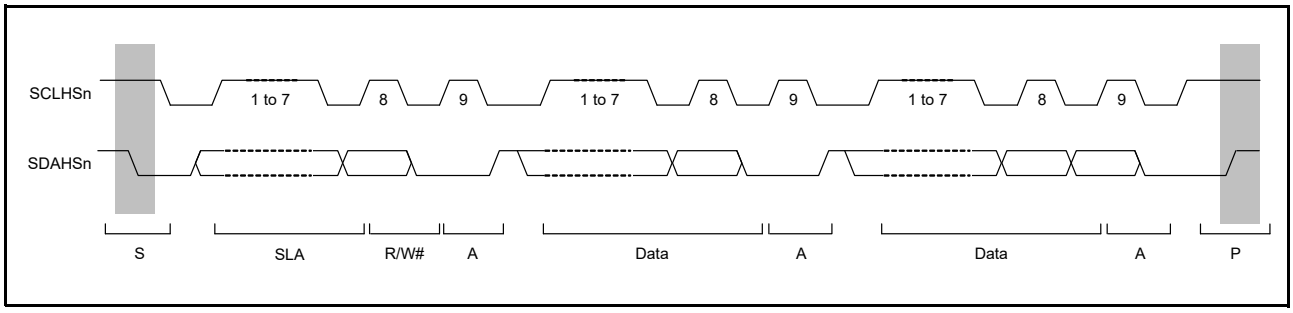

Figure 44.3 I2C-bus Timing (SLA = 7 Bits)

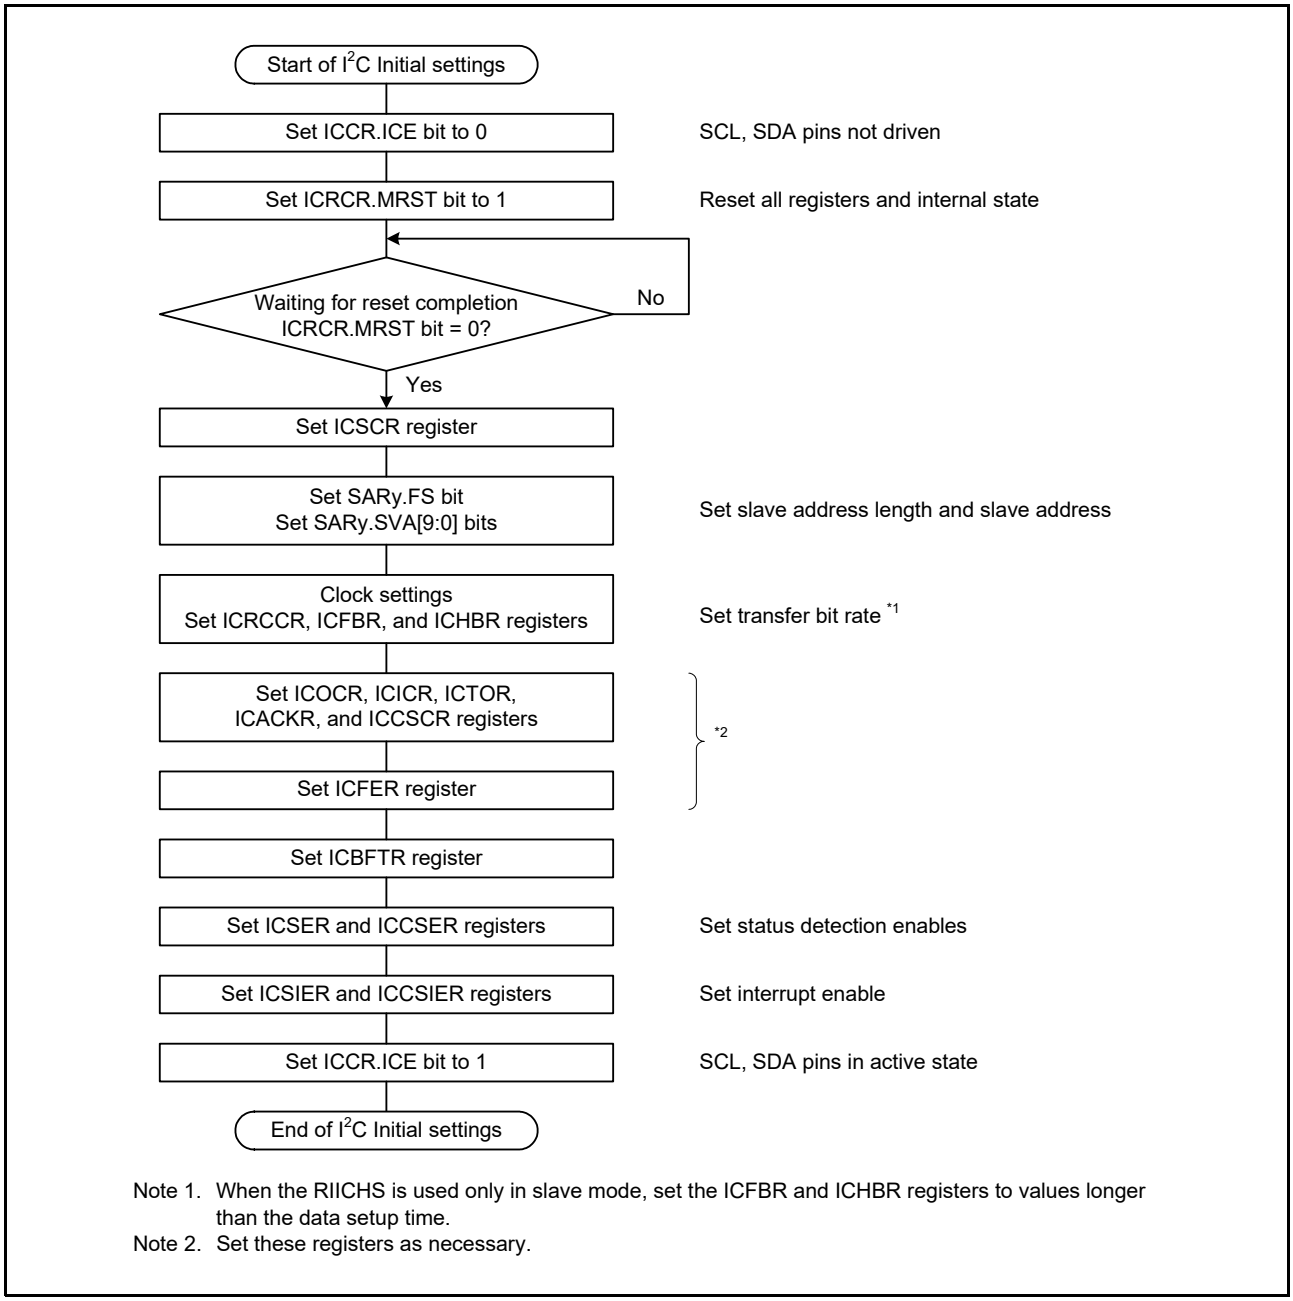
S: START condition. The master device drives the SDAHSn line low from high while the SCLHSn line is high.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W# is 1, or from the master device to the slave device when R/W# is 0.

A: Acknowledge. The receiver drives the SDAHSn line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)

A#: Not Acknowledge. The receiver drives the SDAHSn line high.



Sr: Repeated START condition. The master device drives the SDAHSn line low from high after the setup time has elapsed with the SCLHSn line high.

DATA: Transmitted or received data

P: STOP condition. The master device drives the SDAHSn line high from low while the SCLHSn line is high.

44.3.2 Initial Settings

Before starting data transmission and reception, initialize the RIICHS according to the procedure in Figure 44.4.
First, Set the ICCR.ICE bit to 0 (SCLHSn, SDAHSn pins not driven).
Next, Set the ICRCR.MRST bit to 1 (RIICHS reset). This initialize the all registers and internal state. Refer to Table 44.8, Reset Control of Registers. Then, it waits for MRST to become 0.
After that, set SARy.FS bit, SARy.SVA[9:0] bits, ICFBR register, ICICR register, ICOCR register, ICTOR register, ICCSCR register, ICACKR register, ICFER register, and set the other registers as necessary (y = 0 to 2).

Note 1. When the RIICHS is used only in slave mode, set the ICFBR and ICHBR registers to values longer than the data setup time.
Note 2. Set these registers as necessary.

Figure 44.4 Example of RIICHS Initialization Flowchart (y = 0 to 2)

44.3.3 I2C Master Operation

44.3.3.1 Master Transmit Operation

In master transmit operation, the RIICHS outputs the SCL and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 44.5 shows an example of usage of master transmission and Figure 44.6 to Figure 44.8 show the timing of operations in master transmission.
The following describes the procedure and operations for master transmission.

(1) Initial settings. For details, refer to section 44.3.2, Initial Settings.
(2) Read the ICBSR.BFREE flag to check that the bus is open, and then set the ICCGR.ST bit to 1 (requests to generate a START condition). Upon receiving the request, the RIICHS generates a START condition. At the same time, the BFREE flag is automatically set to 0, the ICSR2.START flag is automatically set to 1 and the ICCGR.ST bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the SDAHSn line have matched while the ICCGR.ST bit is 1, the RIICHS recognizes that generating of the START condition as requested by the ICCGR.ST bit has been successfully completed, and the ICMMR.MST and ICMMR.TRS flags are automatically set to 1, placing the RIICHS in master transmit mode. The ICCSR.TDRE flag is also automatically set to 1 in response to setting of the TRS flag to 1.
(3) Check that the ICCSR.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDR register. Once the data for transmission are written to ICDR register, the ICCSR.TDRE flag is automatically set to 0, and the ICCSR.TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS flag is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RIICHS continues in master transmit mode. Since the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCGR.SP bit to generate a STOP condition.
For data transmission with an address in the 10-bit format, start by writing 1111 0b, the 2 higher-order bits of the slave address, and W to ICDR register as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to ICDR register.
(4) After confirming that the ICCSR.TDRE flag is 1, write the data for transmission to the ICDR register. The RIICHS automatically holds the SCLHSn line low until the data for transmission are ready or a STOP condition is generated
(5) After all bytes of data for transmission have been written to the ICDR register, wait until the value of the ICSR2.TEND flag returns to 1, and then set the ICCGR.SP bit to 1 (requests to generate a STOP condition). Upon receiving a STOP condition generation request, the RIICHS generates the STOP condition.
(6) Upon detecting the STOP condition, the RIICHS automatically sets the ICMMR.MST and ICMMR.TRS flags to 00b and enters slave receive mode. Furthermore, it automatically sets the ICCSR.TDRE flag to 0, ICSR2.TEND flag to 0 and sets the ICSR2.STOP flag to 1.
(7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

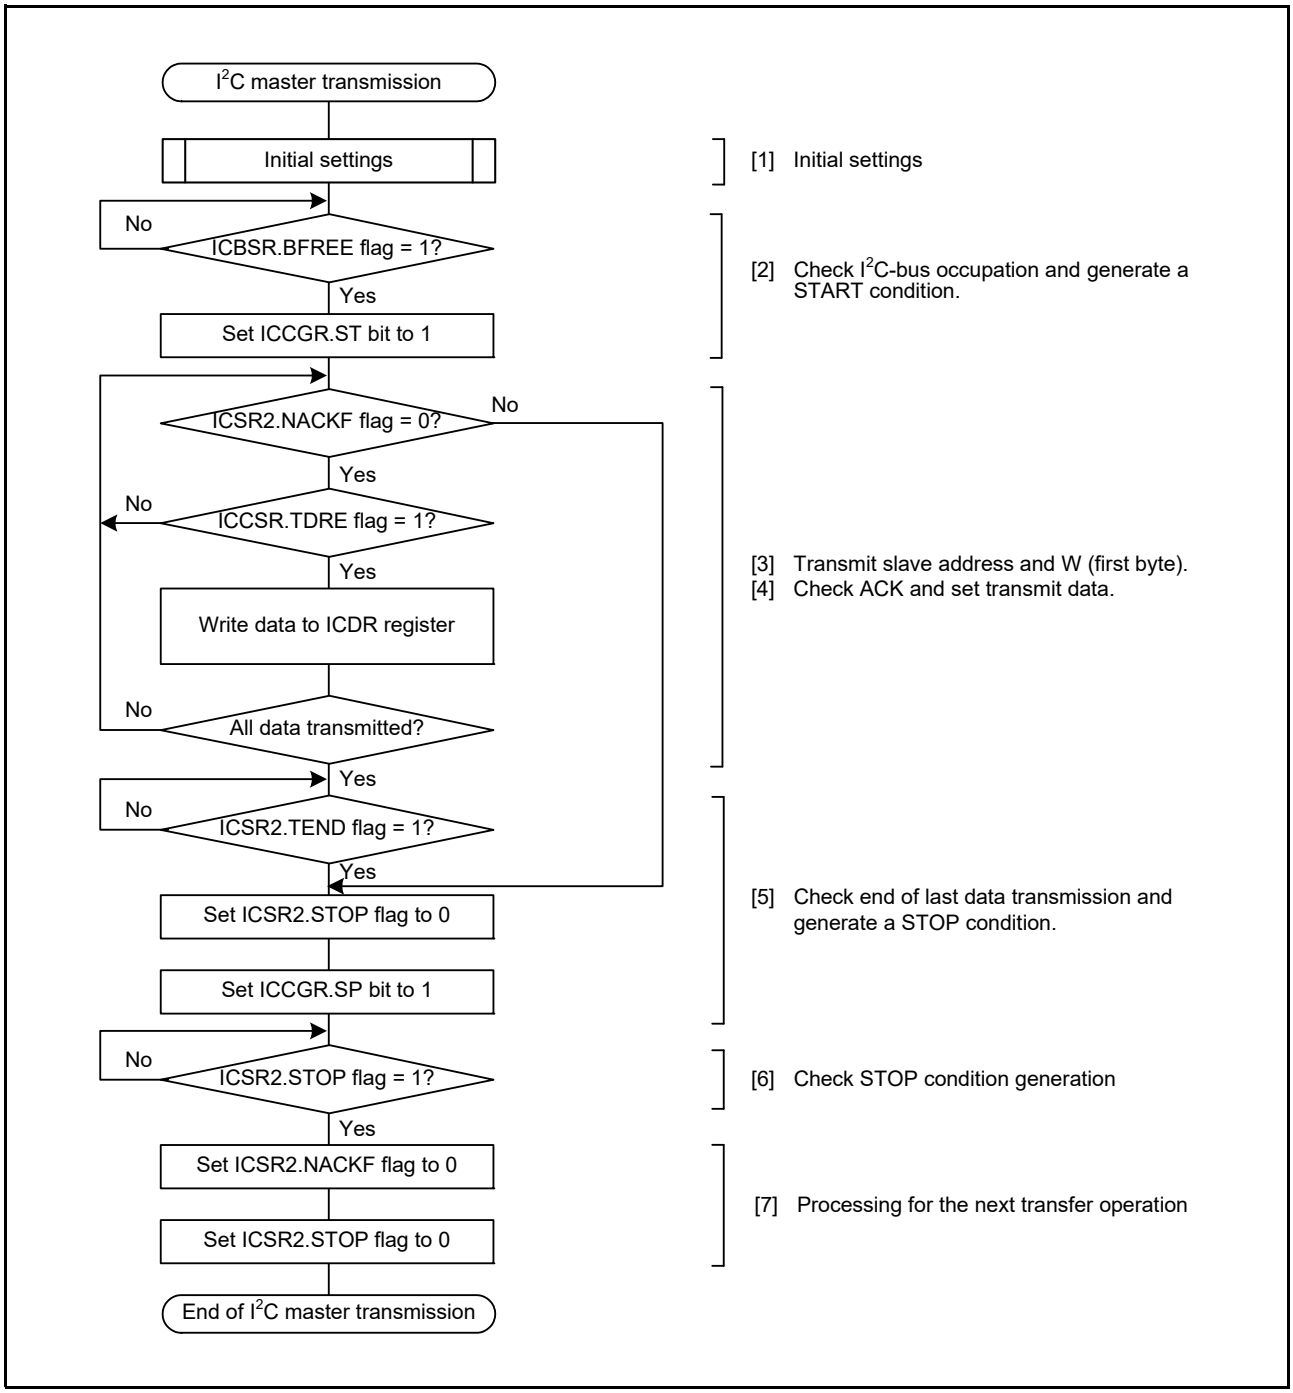


Figure 44.5 Example of I2C Master Transmission Flowchart

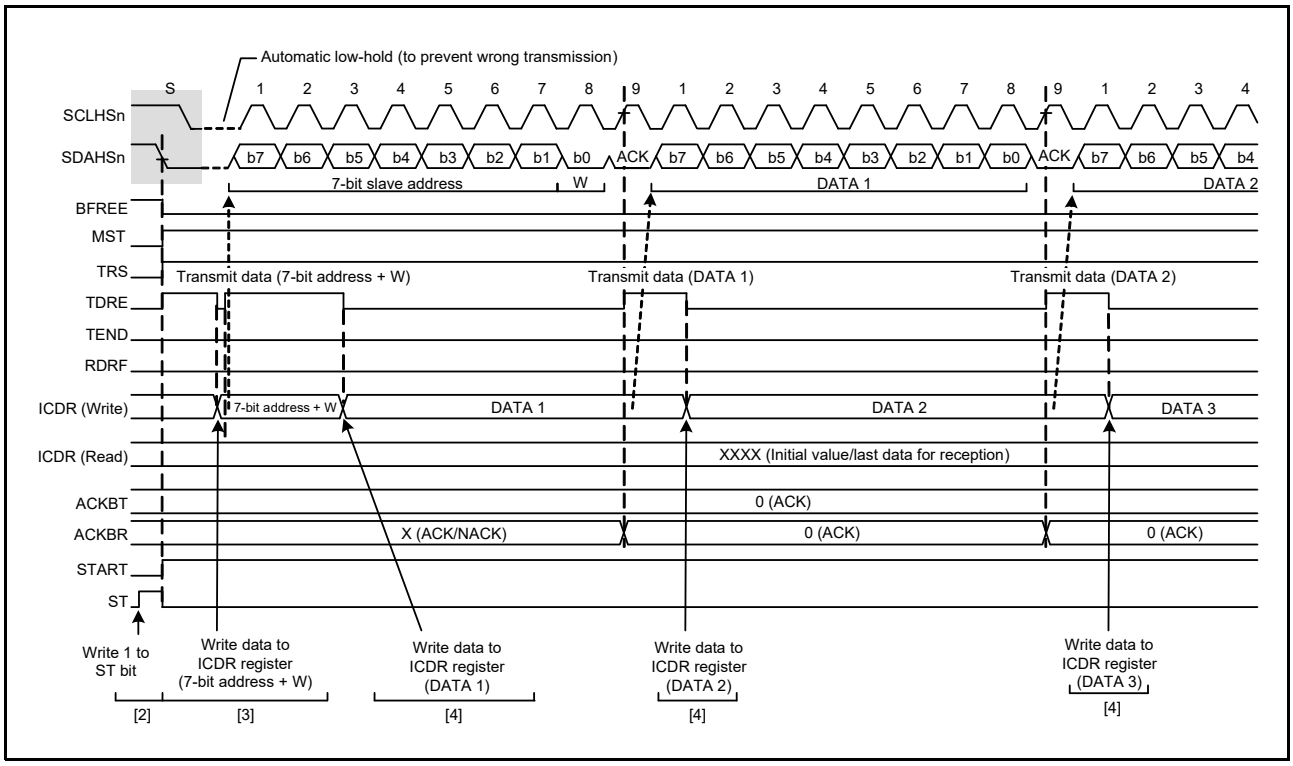

Figure 44.6 Master Transmit Operation Timing (1) (7-Bit Address Format)

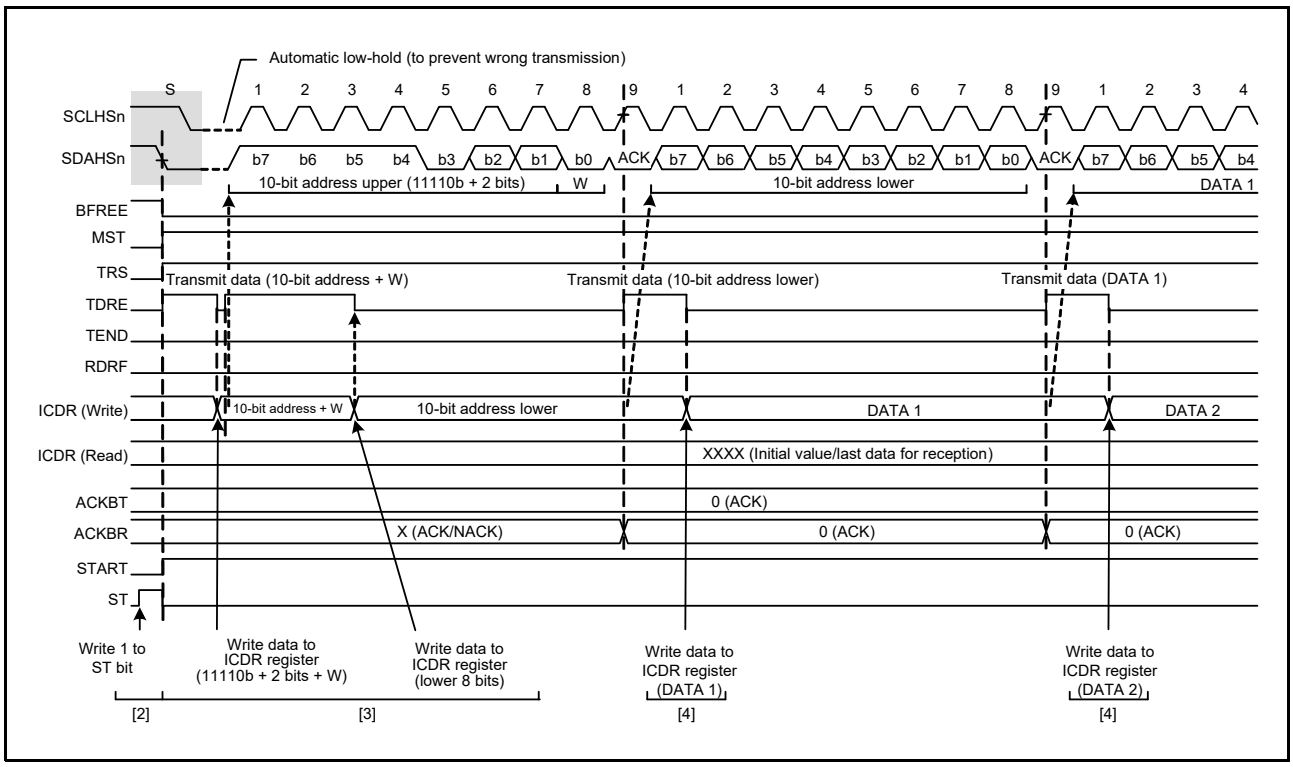

Figure 44.7 Master Transmit Operation Timing (2) (10-Bit Address Format)

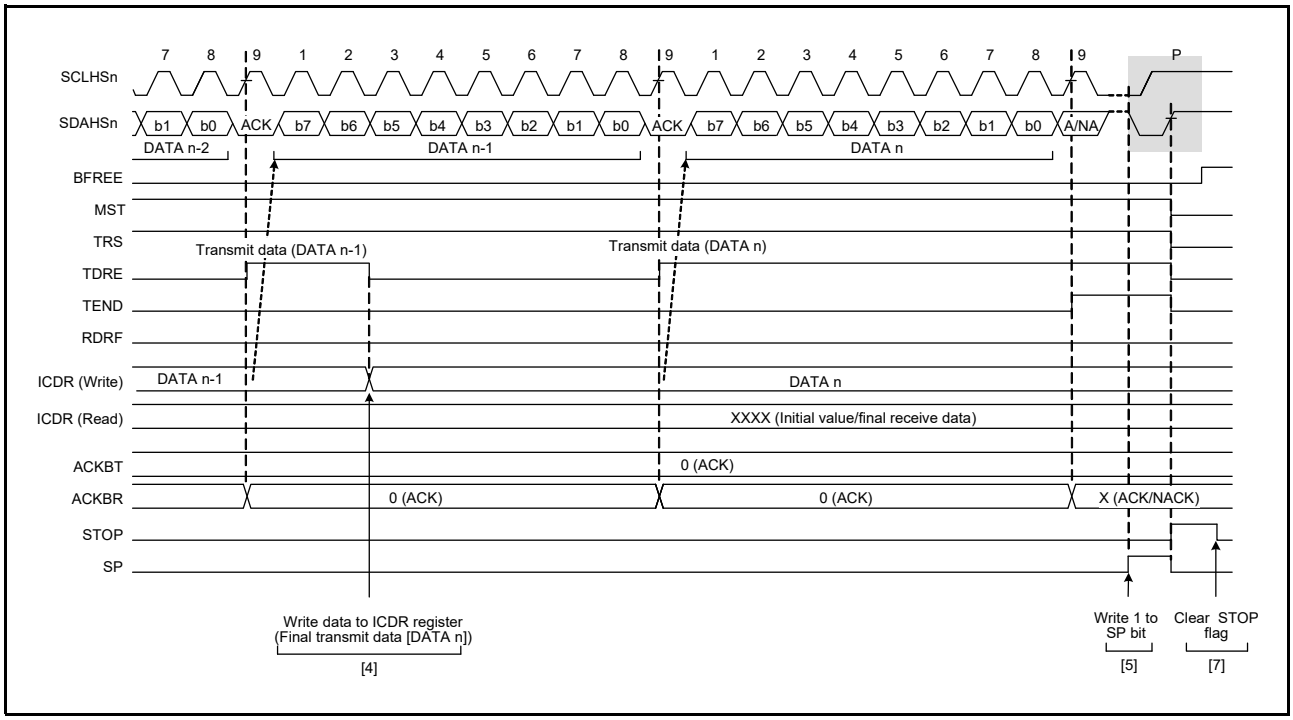

Figure 44.8 Master Transmit Operation Timing (3)

44.3.3.2 Master Receive Operation

In master receive operation, the RIICHS as a master device outputs the SCL, receives data from the slave device, and returns acknowledgments. Since the RIICHS must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.
Figure 44.9 and Figure 44.10 show examples of usage of master reception and Figure 44.11 to Figure 44.13 show the timing of operations in master reception.
The following describes the procedure and operations for master reception.

(1) Initial settings. For details, refer to section 44.3.2, Initial Settings.
(2) Read the ICBSR.BFREE flag to check that the bus is open, and then set the ICCGR.ST bit to 1 (requests to generate a START condition). Upon receiving the request, the RIICHS generates a START condition. When the RIICHS detects the START condition, the ICBSR.BFREE flag is automatically set to 0 and the ICSR2.START flag is automatically set to 1 and the ICCGR.ST bit is automatically set to 0. At this time, if the START condition is detected and the levels for the SDA output and the levels on the SDAHSn line have matched while the ICCGR.ST bit is 1, the RIICHS recognizes that generating of the START condition as requested by the ICCGR.ST bit has been successfully completed, and the ICMMR.MST and ICMMR.TRS flags are automatically set to 1, placing the RIICHS in master transmit mode. The ICCSR.TDRE flag is also automatically set to 1 in response to setting of the TRS flag to 1.
(3) Check that the ICCSR.TDRE flag is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDR register. Once the data for transmission are written to ICDR register, the ICCSR.TDRE flag is automatically set to 0, and the ICCSR.TDRE flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the ICMMR.TRS flag is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRS flag is set to 0 on the rising edge of the ninth SCL, placing the RIICHS in master receive mode. At this time, the ICCSR.TDRE flag is set to 0 and if the slave device acknowledges the ICCSR.RDRF flag is automatically set to 1.
If no slave device recognized the address or there was an error in communications, the ICSR2.NACKF flag becomes 1. In this case, write 1 to the ICCGR.SP bit to generate a STOP condition. For master reception from a device with a 10-bit address, start by using master transmission to send the 10-bit address, and then generate a repeated START condition. After that, transmitting 1111 0b, the two higher-order bits of the slave address, and the R bit places the RIICHS in master receive mode.
(4) Dummy read ICDR register after confirming that the ICCSR.RDRF flag is 1; this makes the RIICHS start output of the SCL and start data reception.
(5) After 1 byte of data has been received, the ICCSR.RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL (the clock signal) as selected by the ICCSCR.WAITAE bit. Reading out ICDR register at this time will produce the received data, and the RDRF flag is automatically set to 0 at the same time. Furthermore, the value of the acknowledgment bit received during the ninth SCL is returned as the value set in the ICACKR.ACKBT bit. Furthermore, if the next byte to be received is the next to last byte, set the ICCSCR.WAITRE bit to 1 (for wait insertion) before reading the ICDR register (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ICACKR.ACKBT bit to 1 (NACK) in step (6), due to other interrupts, etc., this fixes the SCLHSn line to low on the falling edge of the ninth clock pulse in reception of the last byte, so the state is such that generating a STOP condition is possible.
(6) When the ICCSCR.WAITAE bit is 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ICACKR.ACKBT bit to 1 (NACK).
(7) After reading out the byte before last from the ICDR register, if the value of the ICCSR.RDRF flag is confirmed to be 1, write 1 to the ICCGR.SP bit (requests to generate a STOP condition) and then read the last byte from ICDR register. When the ICCGR.SP bit is set to 1, the RIICHS is released from the wait state and generates the STOP condition after low-level output in the ninth clock pulse is completed or the SCLHSn line is released from the low-hold state.

(8) Upon detecting the STOP condition, the RIICHS automatically sets the ICMMR.MST and ICMMR.TRS flags to 00b and enters slave receive mode. Furthermore, detection of the STOP condition leads to setting of the ICSR2.STOP flag to 1.

(9) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

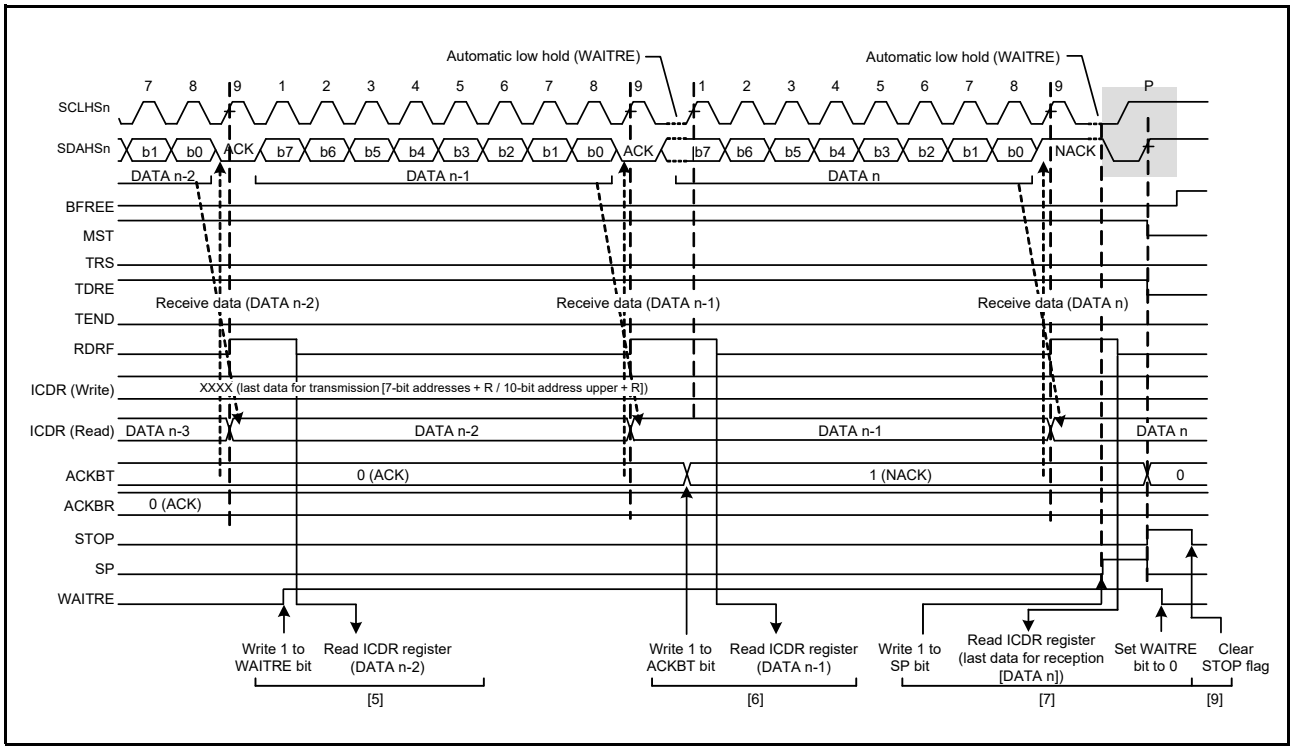

Figure 44.13 Master Receive Operation Timing (3) (When WAITAE = 0)

44.3.4 I2C Slave Operation

44.3.4.1 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL, the RIICHS transmits data as a slave device, and the master device returns acknowledgments.
Figure 44.14 shows an example of usage of slave transmission and Figure 44.15 and Figure 44.16 show the timing of operations in slave transmission.
The following describes the procedure and operations for slave transmission.

(1) Initial settings. For details, refer to section 44.3.2, Initial Settings.
After initial settings, the RIICHS will stay in the standby state until it receives a slave address that it matches.
(2) After receiving a matching slave address, the RIICHS sets one of the corresponding flags ICSSR.HOA, ICSSR.GCA, and ICSSR.AASy (y = 0 to 2) to 1 on the rising edge of the ninth SCL (the clock signal) and outputs the value set in the ICACKR.ACKBT bit to the acknowledgment bit on the ninth SCL. Set the ACKBT bit to 0 in advance. If the value of the R/W# bit that was also received at this time is 1, the RIICHS automatically places itself in slave transmit mode by setting both the ICMMR.TRS flag and the ICCSR.TDRE flag to 1.
(3) After the ICCSR.TDRE flag is confirmed to be 1, write the data for transmission to the ICDR register. At this time, if the RIICHS receives no acknowledgment from the master device (receives an NACK signal) while the ICSER.NAKDE bit is 1, the RIICHS suspends transfer of the next data.
(4) Wait until the ICSR2.TEND flag is set to 1 while the ICCSR.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDR register. When the ICSR2.NACKF flag or the TEND flag is 1, the RIICHS drives the SCLHSn line low on the falling edge of ninth SCL.
(5) When the ICSR2.NACKF flag or the ICSR2.TEND flag is 1, dummy read ICDR register to complete the processing. This releases the SCLHSn line.
(6) Upon detecting the STOP condition, the RIICHS automatically sets flags ICSSR.HOA, ICSSR.GCA, and ICSSR.AASy (y = 0 to 2), flags ICCSR.TDRE and ICSR2.TEND, and the ICMMR.TRS flag to 0, and enters slave receive mode.
(7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and ICSR2.STOP flags to 0 for the next transfer operation.

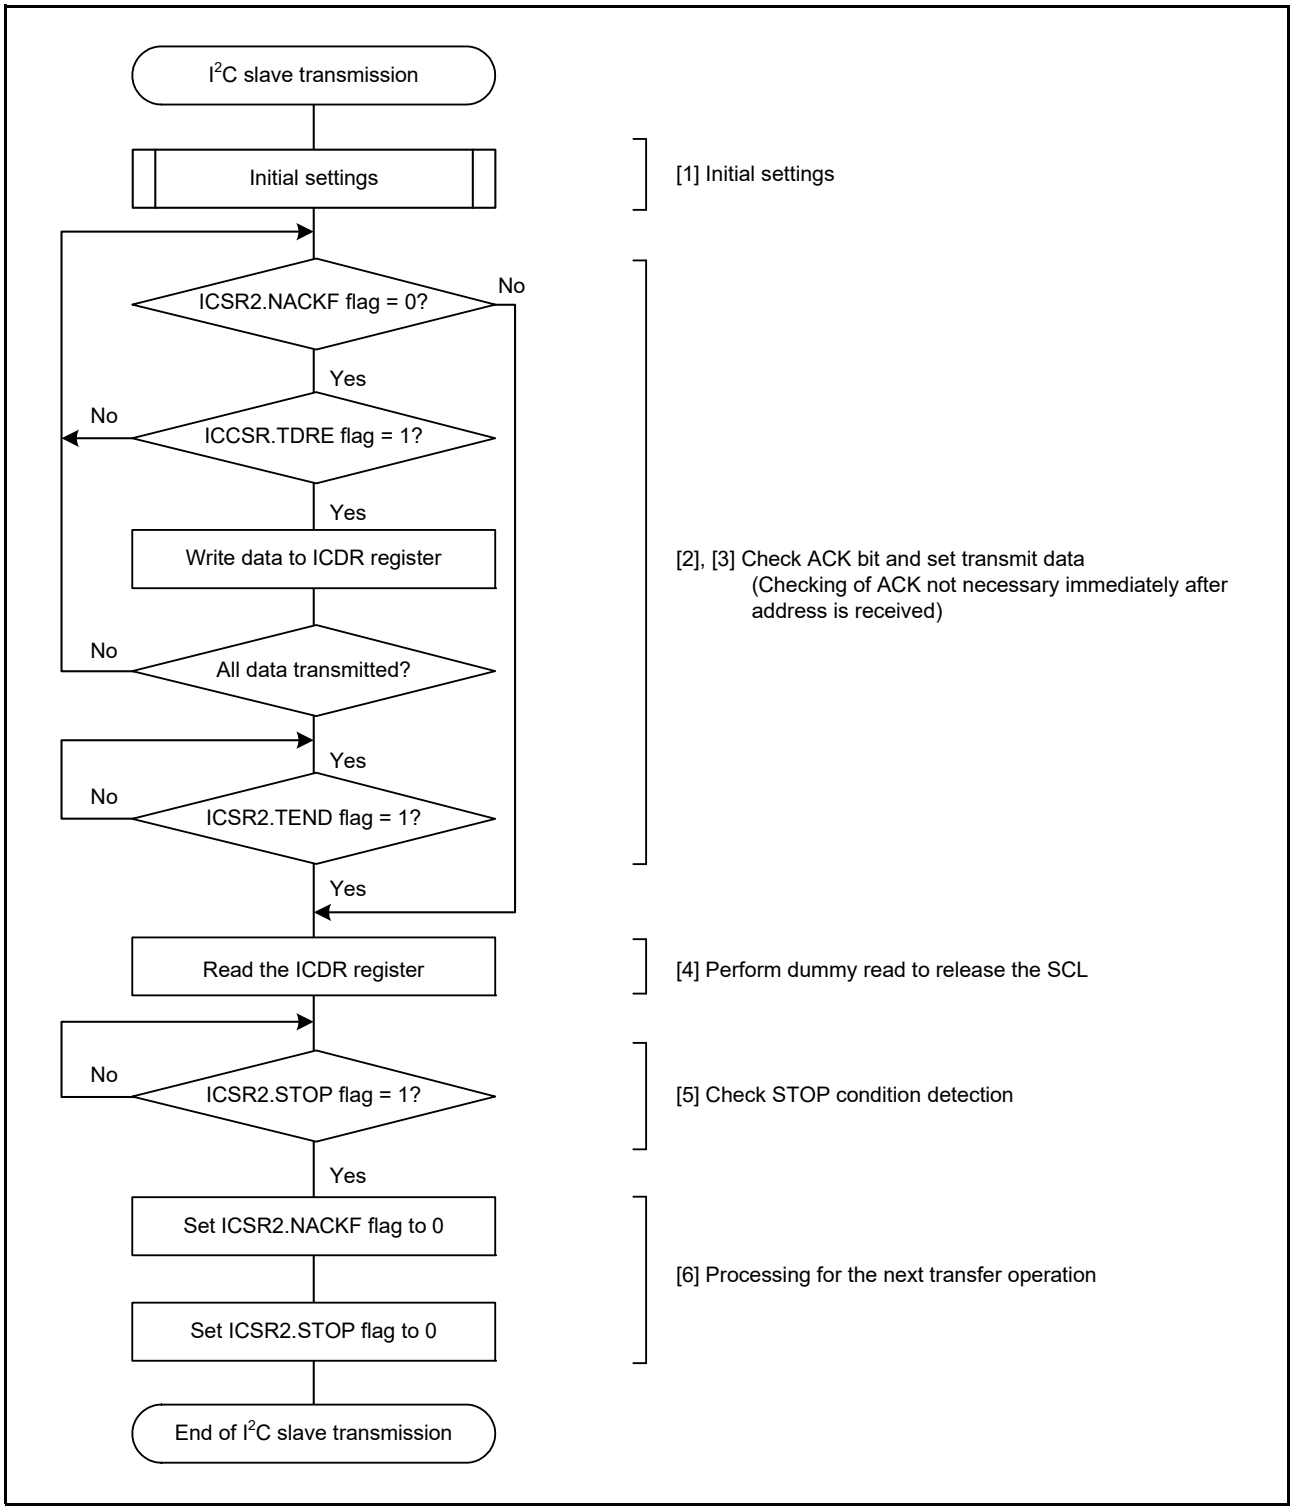

Figure 44.14 Example of I2C Slave Transmission Flowchart

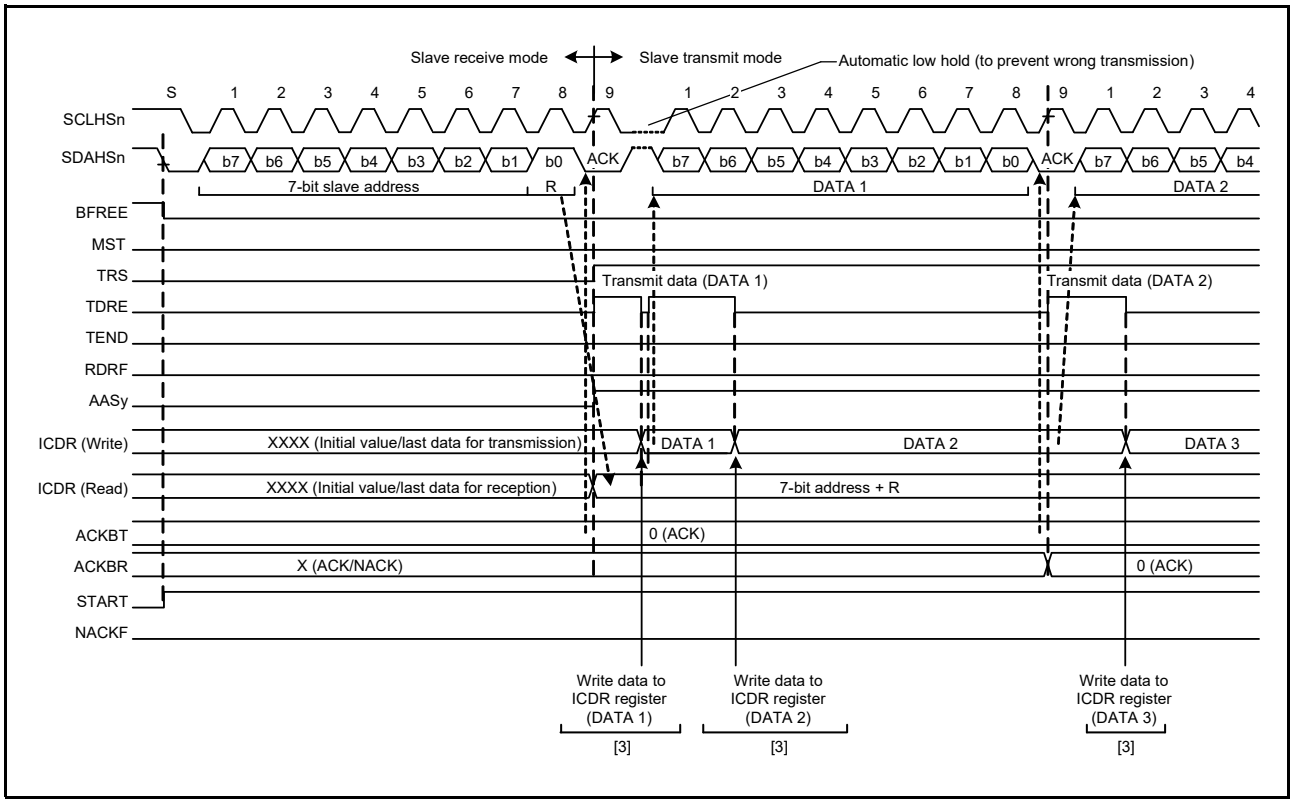

Figure 44.15 Slave Transmit Operation Timing (1) (7-Bit Address Format)

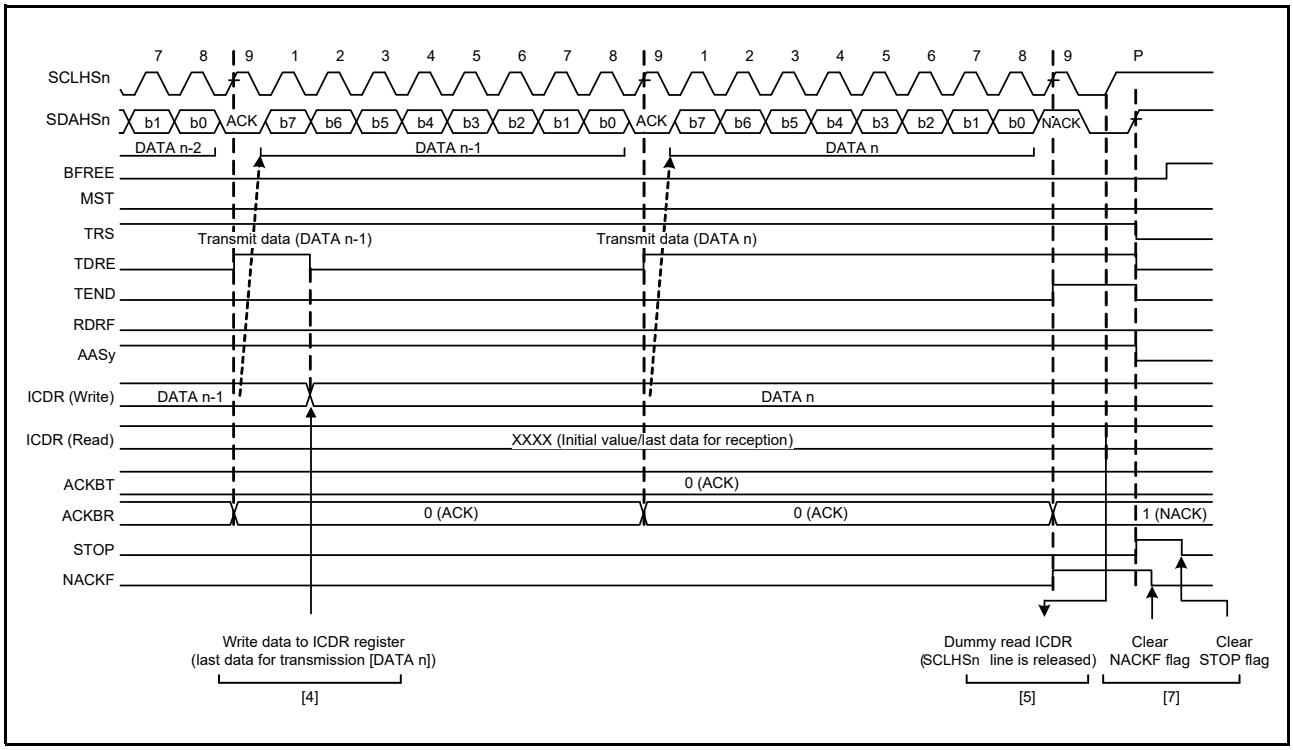

Figure 44.16 Slave Transmit Operation Timing (2)

44.3.4.2 Slave Receive Operation

In slave receive operation, the master device outputs the SCL and transmit data, and the RIICHS returns acknowledgments as a slave device.

Figure 44.17 shows an example of usage of slave reception and Figure 44.18 and Figure 44.19 show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

(1) Initial settings. For details, refer to section 44.3.2, Initial Settings. After initial settings, the RIICHS will stay in the standby state until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RIICHS sets one of the corresponding flags ICSSR.HOA, ICSSR.GCA, and ICSSR.AASy (y = 0 to 2) to 1 on the rising edge of the ninth SCL (the clock signal) and outputs the value set in the ICACKR.ACKBT bit to the acknowledgment bit on the ninth SCL. Set the ACKBT bit to 0 in advance. If the value of the R/W# bit that was also received at this time is 0, the RIICHS continues to place itself in slave receive mode and sets the ICCSR.RDRF flag to 1.

(3) After the ICSR2.STOP flag is confirmed to be 0 and the ICCSR.RDRF flag to be 1, dummy read ICDR register (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8-bits when the 10-bit address format is selected).

(4) When ICDR register is read, the RIICHS automatically sets the ICCSR.RDRF flag to 0. If reading of ICDR register is delayed and a next byte is received while the RDRF flag is still set to 1, the RIICHS holds the SCLHSn line low from one SCL cycle before the timing with which RDRF should be set. In this case, reading ICDR register releases the SCLHSn line from being held low.
When the ICSR2.STOP flag is 1 and the ICCSR.RDRF flag is also 1 or when all the data is completely received, read the ICDR register.

(5) Upon detecting the STOP condition, the RIICHS automatically sets flags ICSSR.HOA, ICSSR.GCA, and ICSSR.AASy (y = 0 to 2) to 0.

(6) After checking that the ICSR2.STOP flag is 1, set the ICSR2.STOP flag to 0 for the next transfer operation.

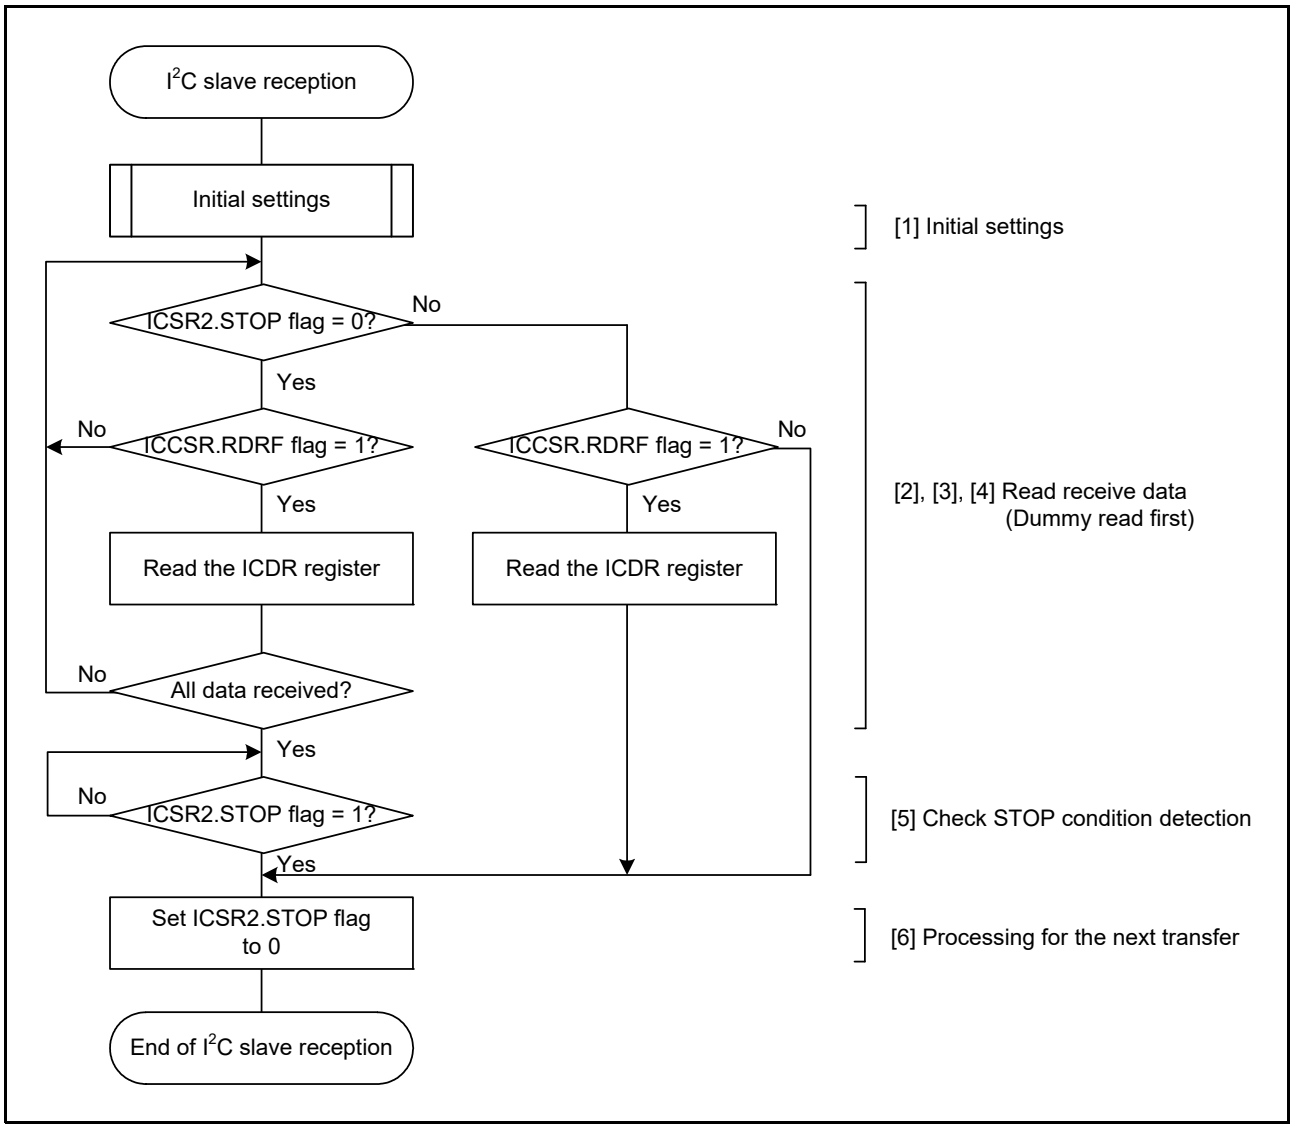

Figure 44.17 Example of I2C Slave Reception Flowchart

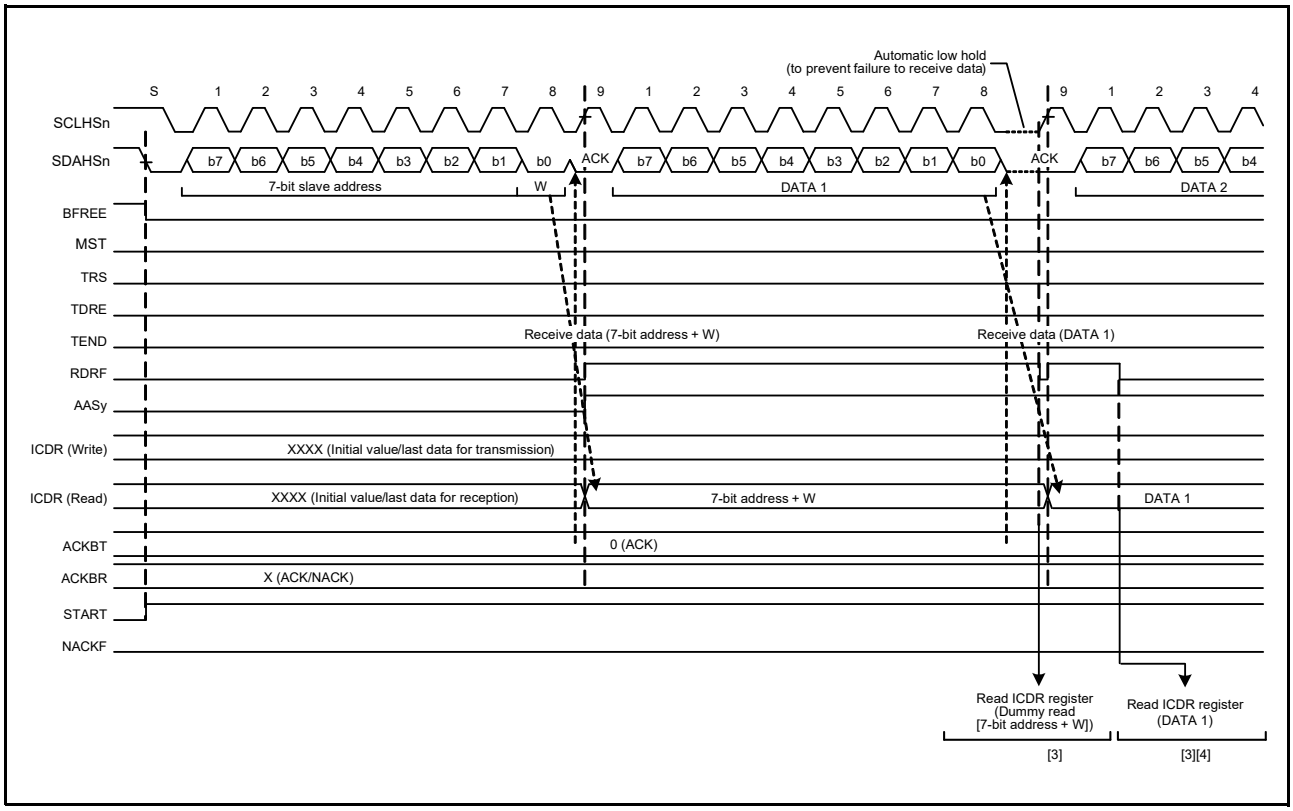

Figure 44.18 Slave Receive Operation Timing (1) (7-Bit Address Format, when WAITAE = 0)

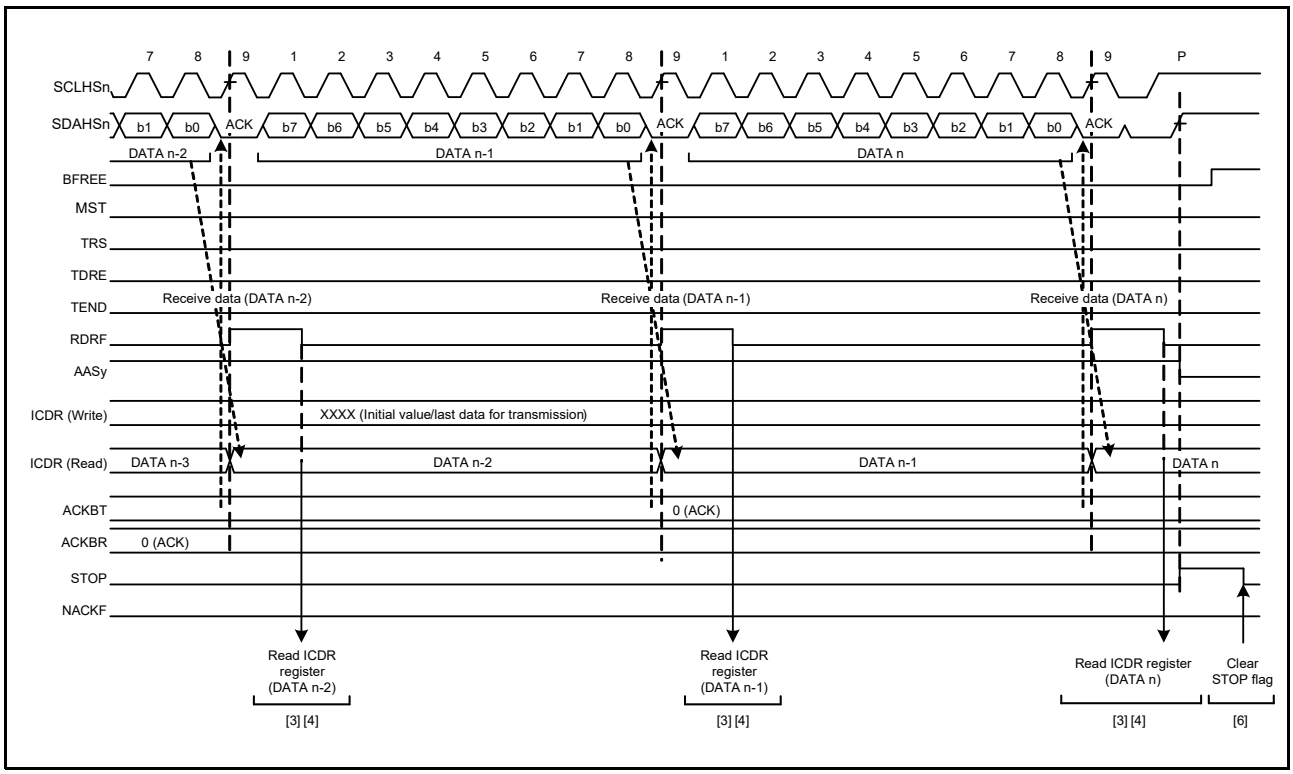

Figure 44.19 Slave Receive Operation Timing (2) (when WAITAE = 0)

44.4 Details of Function

44.4.1 SCL Synchronization Circuit

In generation of the SCL, the RIICHS starts counting out the value for width at high level specified in the ICFBR.HIGH[7:0] bits when it detects a rising edge on the SCLHSn line and drives the SCLHSn line low once counting of the width at high level is complete. When the RIICHS detects the falling edge of the SCLHSn line, it starts counting out the width at low period specified in the ICFBR.LOW[7:0] bits, and then stops driving the SCLHSn line (releases the line) once counting of the width at low level is complete. The SCL is thus generated.

If multiple master devices are connected to the I2C-bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, the RIICHS is equipped with a function (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL signals by monitoring the SCLHSn line while in master mode.

When the RIICHS has detected a rising edge on the SCLHSn line and thus started counting out the width at high level specified in the ICFBR.HIGH[7:0] bits, and the level on the SCLHSn line falls because an SCL signal is being generated by another master device, the RIICHS stops counting when it detects the falling edge, drives the level on the SCLHSn line low, and starts counting out the width at low level specified in the ICFBR.LOW[7:0] bits. When the RIICHS finishes counting out the width at low level, it stops driving the SCLHSn line to low (i.e. releases the line). At this time, if the width at low level of the SCL signal from the other master device is longer than the width at low level set in the RIICHS, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCLHSn line has been released. When the RIICHS finishes outputting the low period of the SCL, the SCLHSn line is released and the SCL rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the ICFER.SCLE bit is set to 1.

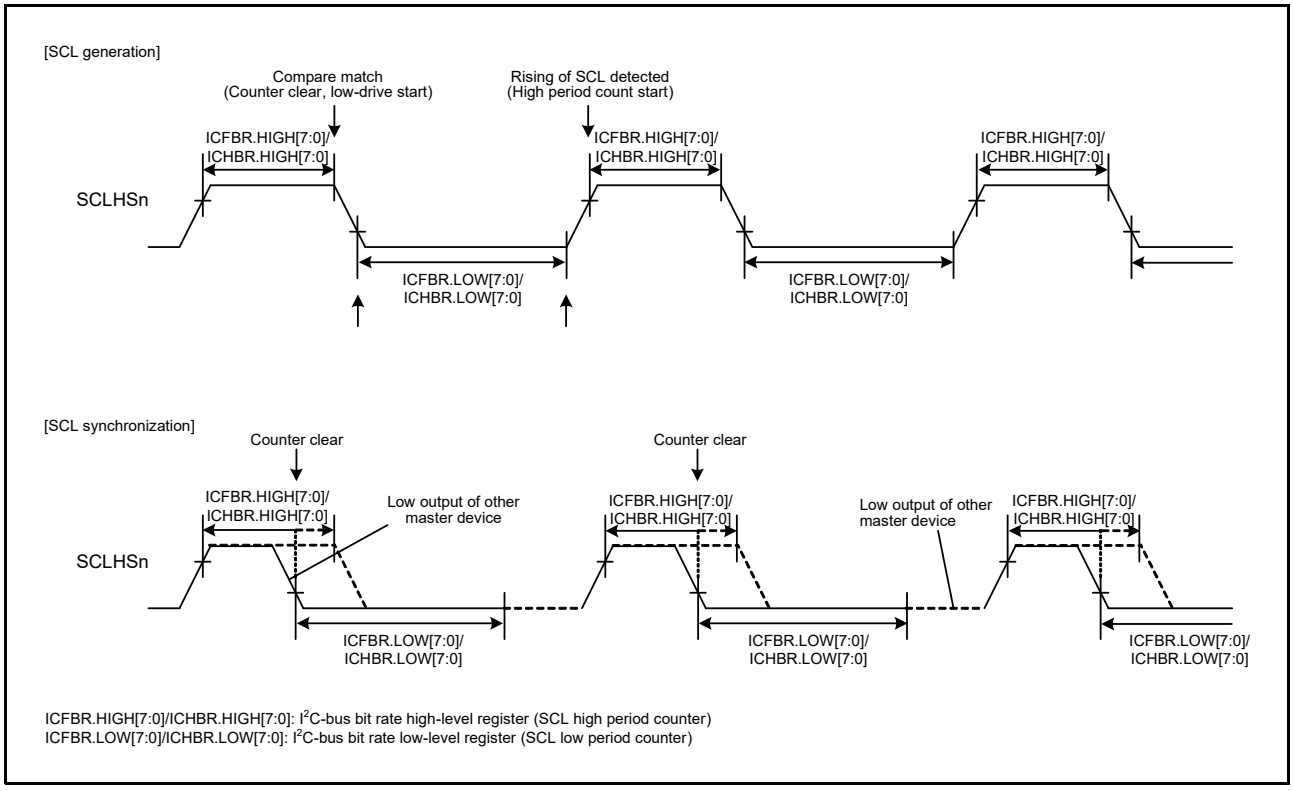

Figure 44.20 Generation and Synchronization of the SCL Signal

44.4.2 SDA Output Delay Function

The RIICHS module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (generating of the START, repeated START, and STOP conditions, data, and the ACK and NACK signals) on the SDA line.

The SDA output delay function is used to delay the SDA output timing from a falling edge of SCL to ensure that the SDA signal changes while the SCL is low and can be used to prevent erroneous operation of communications devices. This function is also used to satisfy the 300 ns (min.) of data hold time specified by the SMBus specification.

The output delay facility is enabled by setting the ICOCR.SDDL[2:0] bits to any value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled (the SDDL[2:0] bits are not 000b), the SDA output delay counter counts the number of cycles set in the SDDL[2:0] bits with the count source selected by the ICOCR.DLCS bit (internal reference clock (IICφ) or internal reference clock divided by 2 (IICφ/2)). When the counting of the delay cycles is completed, the RIICHS output the SDA signal (generating of the START, repeated START, or STOP condition, data, or an ACK or NACK signal).

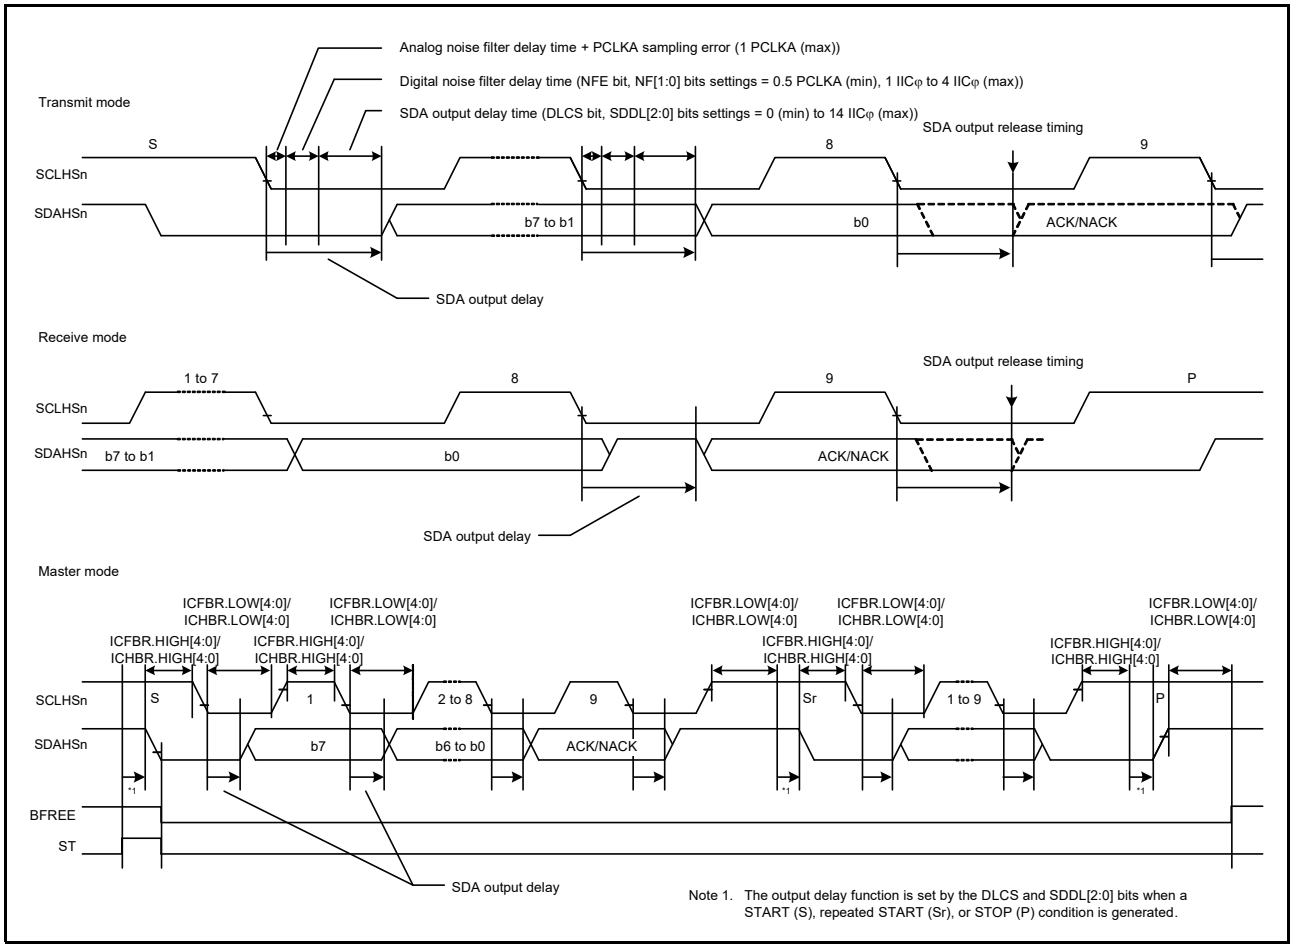

Figure 44.21 SDA Output Delay Function

44.4.3 Digital Noise Filters

The states of the SCLHSn and SDAHSn pins are conveyed to the internal circuitry through analog noise filter and digital noise filter. Figure 44.22 is a block diagram of the digital noise filter.

The on-chip digital noise filter of the RIICHS consists of 16 flip-flop circuit stages connected in series and a match-detection circuit. When Hs-mode is selected, only the first four flip-flops are enabled.

The number of effective stages in the digital noise filter is selected by the ICICR.NF[3:0] bits (ICICR.NF[3:2] bits in Hs-mode). The selected number of effective stages determines the noise-filtering capability as a period from 1 to 16 IICφ cycles (one to four IICφ cycles in Hs-mode).

The input signal from the SCLHSn pin (also the SDAHSn pin) is sampled on rising edges of the IICφ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the ICICR.NF[3:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (I3CCLK) and the transfer rate is small (e.g. data transfer at 400 kbps with I3CCLK = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise. In such cases, disable the digital noise filter (by setting the ICICR.NFE bit to 0) and use only the analog noise filter.

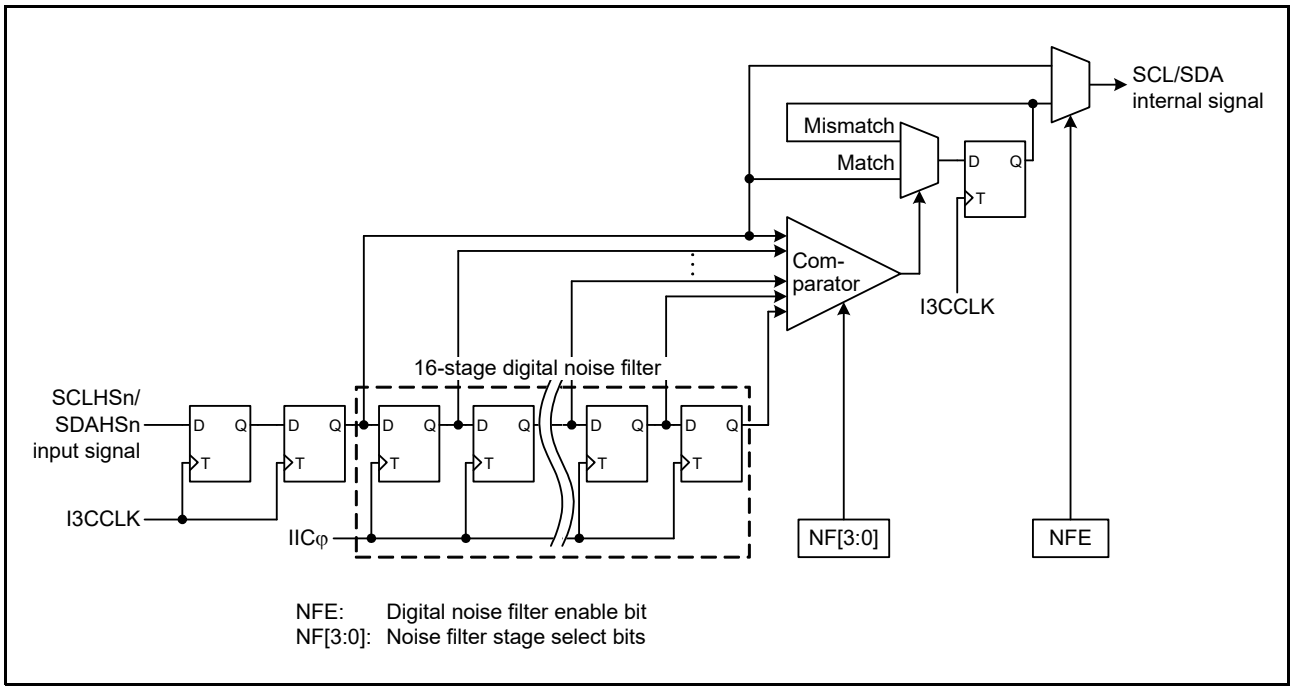

Figure 44.22 Block Diagram of Digital Noise Filter

44.4.4 Address Match Detection

The RIICHS can set three unique slave addresses in addition to the general call address and host address, and also can set 7-bit or 10-bit slave addresses.

44.4.4.1 Slave-Address Match Detection

The RIICHS can set three unique slave addresses, and has a slave address detection function for each unique slave address.

When the ICSCR.SARyE bit (y = 0 to 2) is set to 1, the slave addresses set in SAMRy register (y = 0 to 2) can be detected.

When the RIICHS detects a match of the set slave address, the corresponding ICSSR.AASy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL, and the ICCSR.RDRF flag or the ICCSR.TDRE flag is set to 1 according to the R/W# bit. This causes a receive data full interrupt (RXI) or transmit data empty interrupt (TXI) to be generated. The AASy flag is used to identify which slave address has been specified.

Figure 44.23 to Figure 44.25 show the AASy flag set timing in three cases.

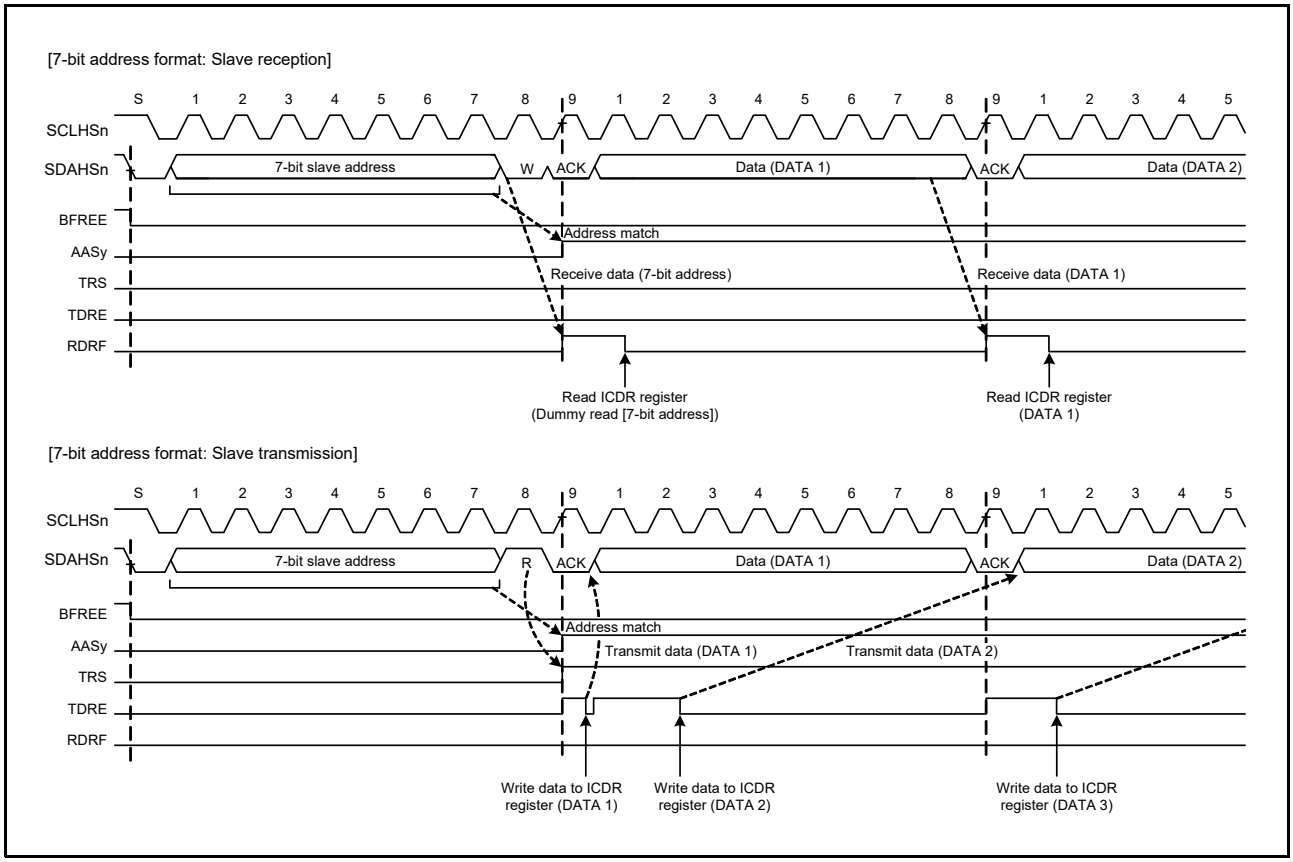

Figure 44.23 AASy Flag Set Timing with 7-Bit Address Format Selected

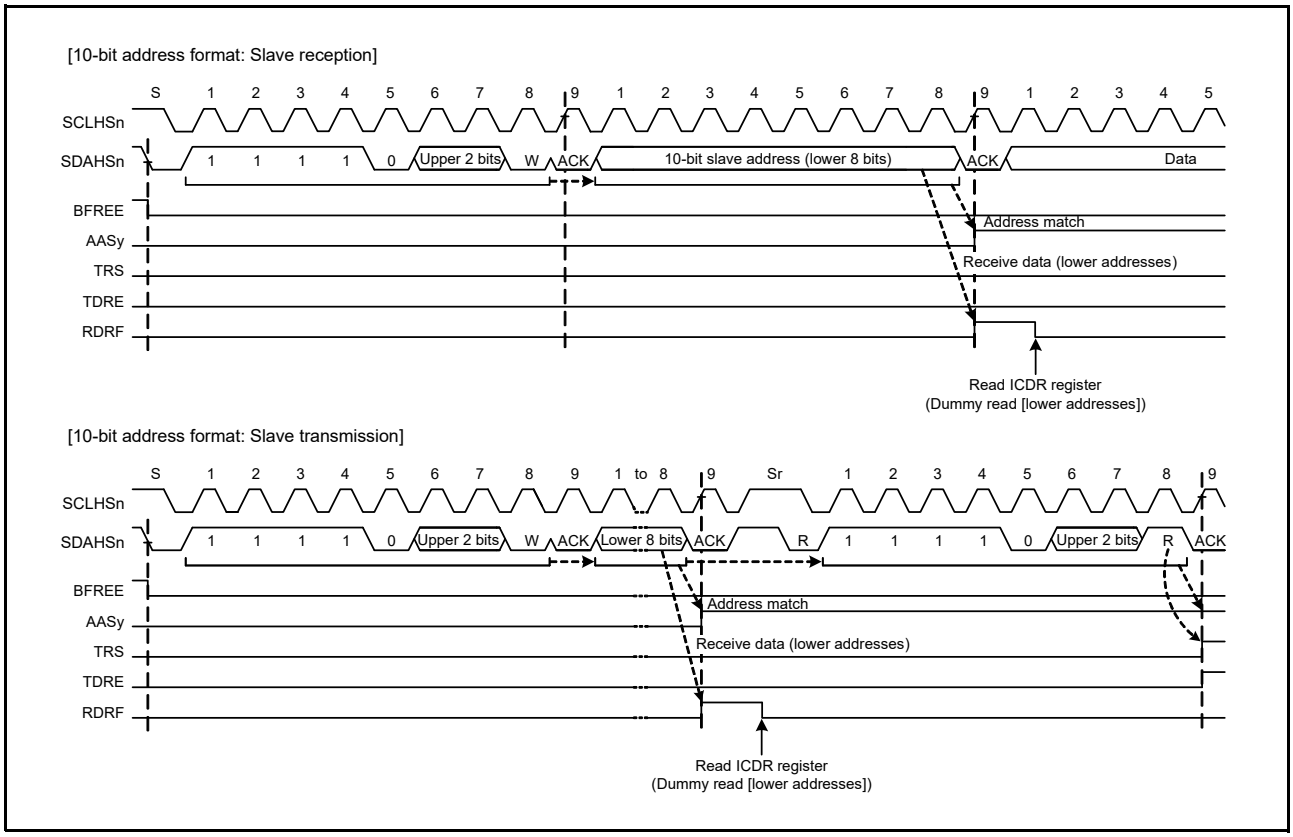

Figure 44.24 AASy Flag Set Timing with 10-Bit Address Format Selected

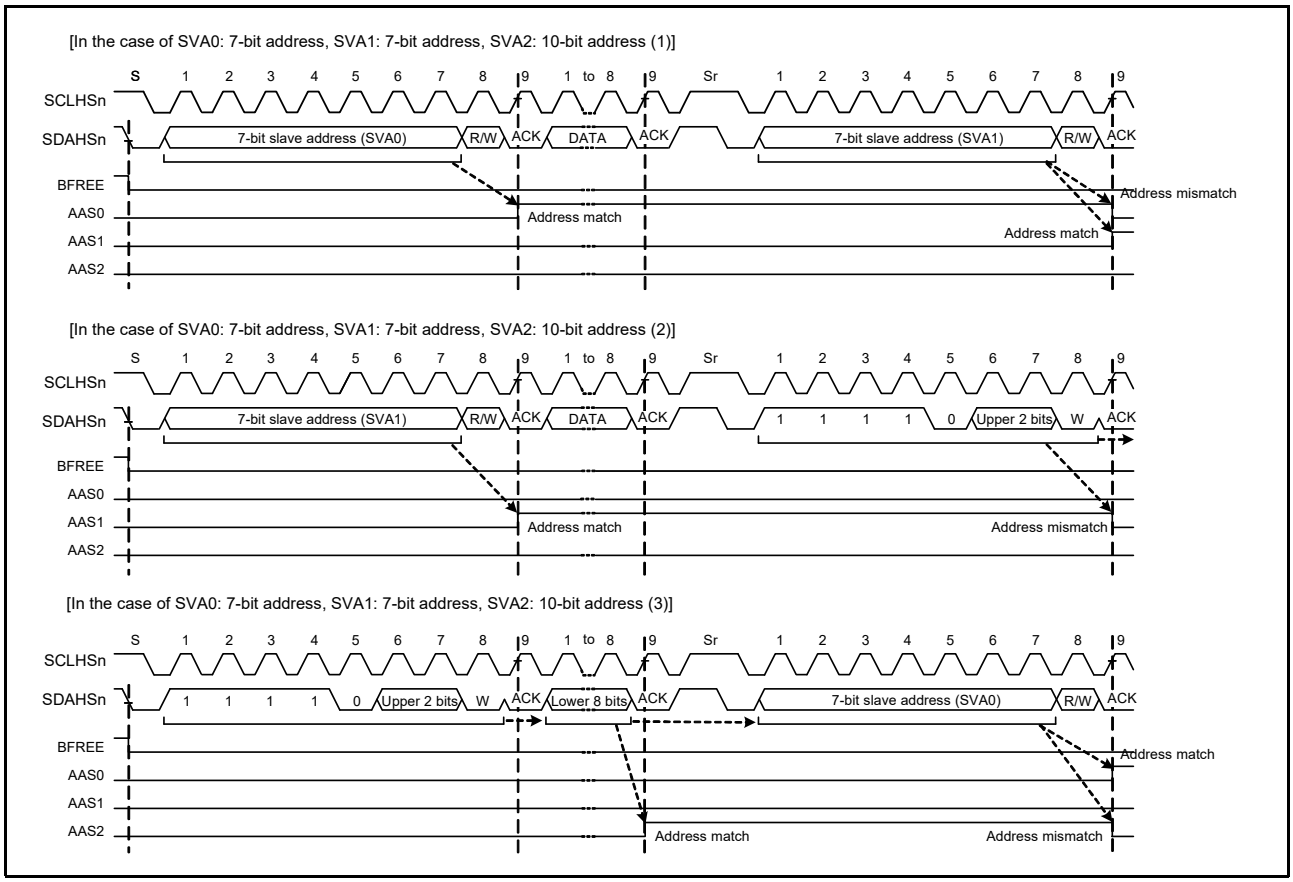

Figure 44.25 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed

44.4.4.2 General Call Address Detection

The RIICHS has a function for detecting the general call address (0000 000b + 0 (write)). This is enabled by setting the ICSCR.GCAE bit to 1.

If the address following a START or repeated START condition is 0000 000b + 1 (read) (start byte), the RIICHS recognizes this as the address of a slave device with an “all-zero” address but not as the general call address.

When the RIICHS detects the general call address, both the ICSSR.GCA flag and the ICCSR.RDRF flag are set to 1 on the rising edge of the ninth SCL. This leads to the generation of a receive data full interrupt (RXI). The value of the GCA flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

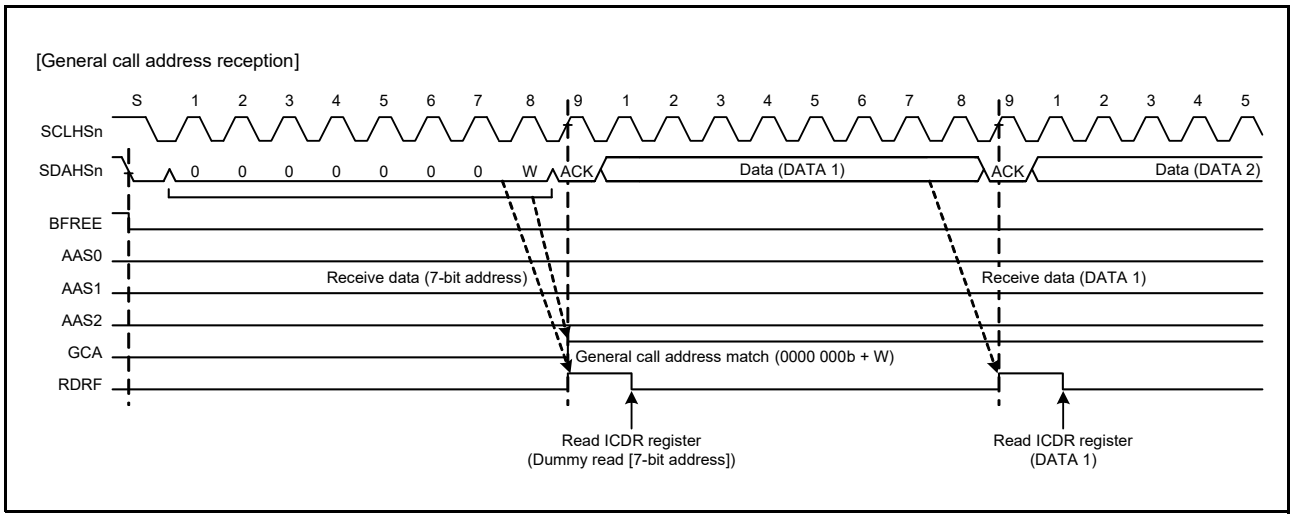

Figure 44.26 Timing of GCA Flag Setting during Reception of General Call Address

44.4.4.3 Device-ID Address Detection

The RIICHS module has a function for detecting device-ID addresses conformant with the I2C-bus specification.
When the RIICHS receives 1111 100b as the first seven bits of the first byte following a START condition or repeated START condition while the ICSCR.DIDE bit is 1, the RIICHS recognizes the address as a device ID address, sets the ICSSR.DID flag to 1 on the rising edge of the ninth SCL when the following R/W# bit is 0, and then compares the second and following bytes with its own slave address. If the received address matches the value in the slave address register, the RIICHS sets the corresponding ICSSR.AASy flag (y = 0 to 2) to 1.
After that, when the first byte received after a START or repeated START condition is generated matches the device ID address (1111 100b) again and the following R/W# bit is 1, the RIICHS does not compare the second and subsequent bytes and sets the ICCSR.TDRE flag to 1.
In the device-ID address detection function, the RIICHS sets the DID flag to 0 if a match with the RIICHS's own slave address is not obtained or a match with the device ID address is not obtained after a match with the RIICHS's own slave address and the detection of a repeated START condition. If the first byte after detection of a START or repeated START condition matches the device ID address (1111 100b) and the R/W# bit is 0, the RIICHS sets the DID flag to 1 and compares the second and subsequent bytes with the RIICHS's slave address. If the R/W# bit is 1, the DID flag holds the previous value and the RIICHS does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DID flag after confirming that ICCSR.TDRE flag is 1.
Furthermore, prepare the device-ID fields (three bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

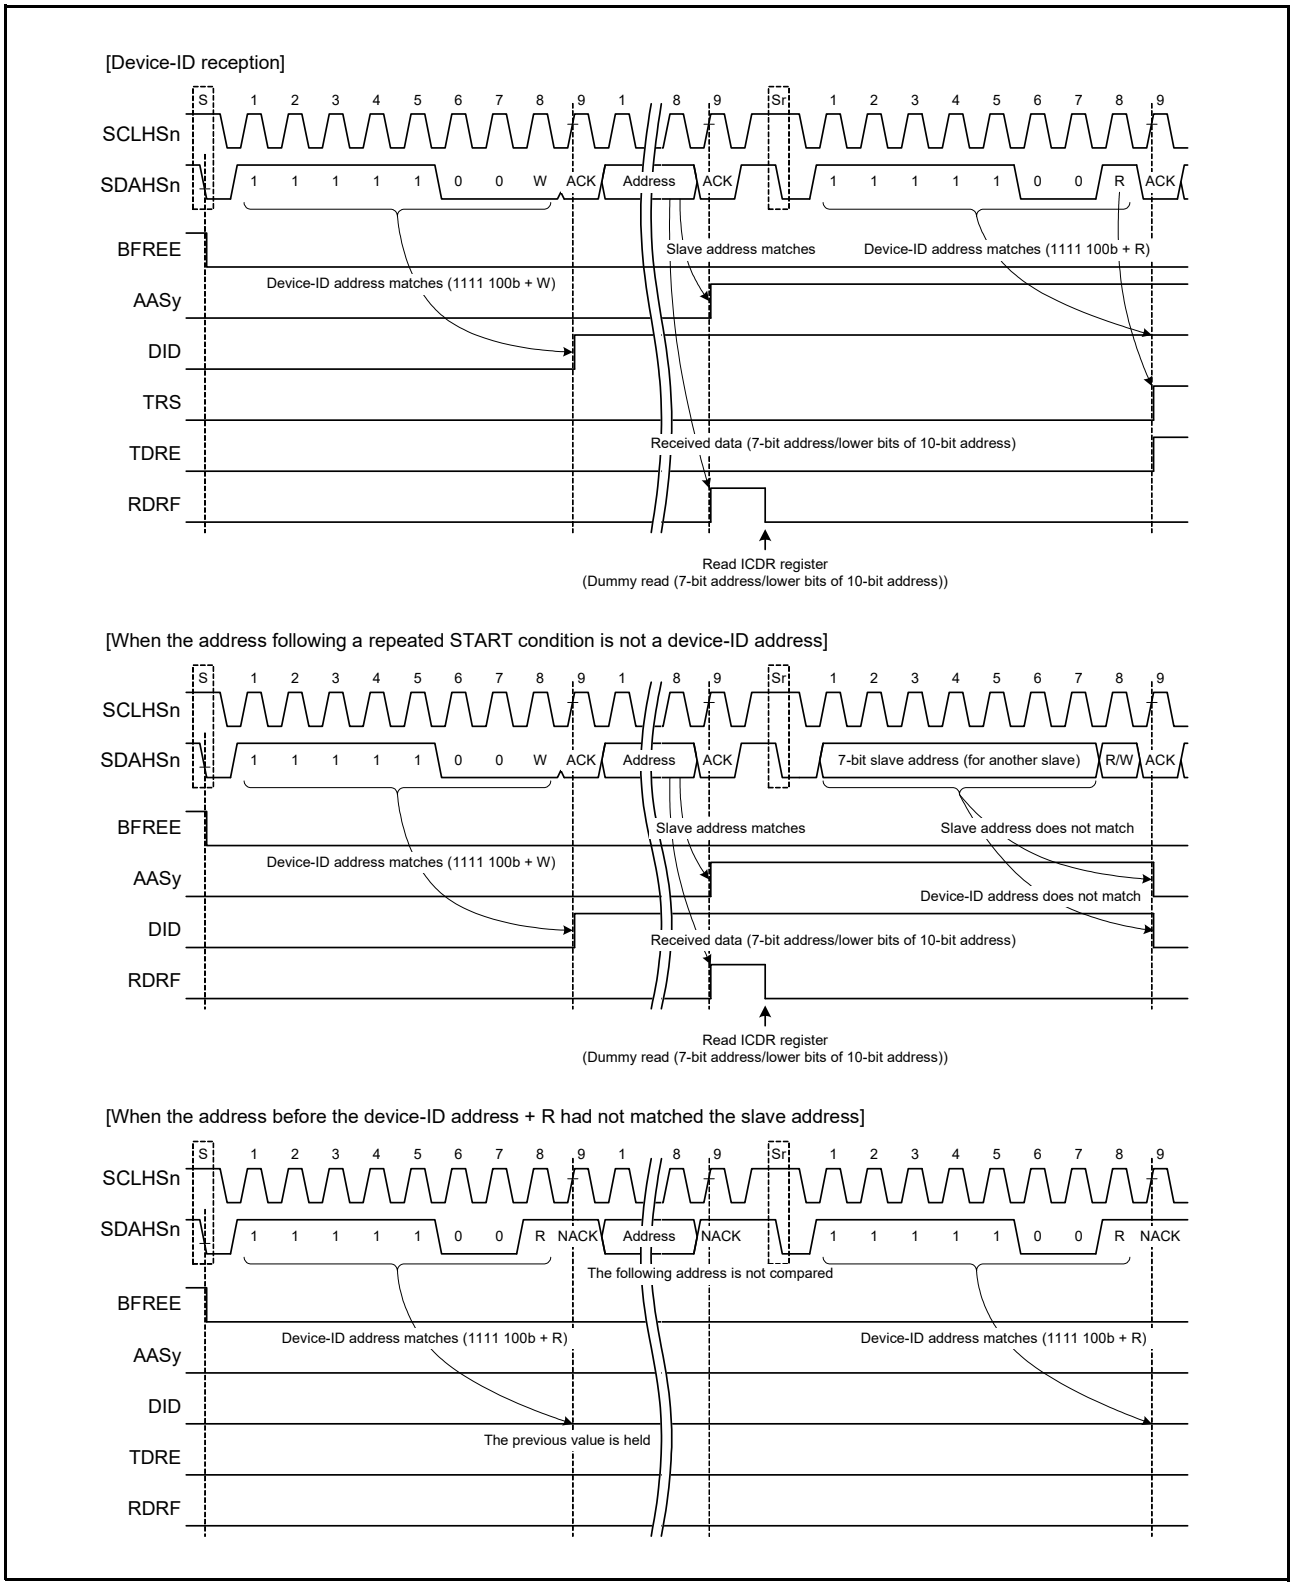

Figure 44.27 Set/Clear Timing of the AASy and DID Flags during Reception of Device-ID Address

44.4.4.4 Hs-Mode Master Code Detection

The RIICHS has a function to detect the Hs-mode master code (0000 1XXXb).
When the RIICHS receives 0000 1XXXb as the first byte following a START condition while the ICSCR.HSMCE bit is 1, the RIICHS recognizes it as Hs-mode master code and set the ICSSR.HSMC flag to 1 at the rising edge of the ninth SCL. The RIICHS does not acknowledge the master code regardless of the value of the ICACKR.ACKBT bit (the SDAHSn pin remains high).
The first byte following a repeated START condition after the NACK bit is recognized as the slave address and compared with the SAMRy.SVA[9:0] bits (y = 0 to 2). When they match, the corresponding ICSSR.AASy flag is set to 1 at the rising edge of the ninth SCL. Also, the ICCSR.RDRF or TDRE flag is set to 1 depending on the value of the R/W# bit.
When a STOP condition is detected, the ICSSR.HSMC flag is set to 0.

Note: If the RIICHS receives Hs-mode master code while the ICSCR.HSMCE bit is 0, it ignores all data patterns until a STOP condition is detected.

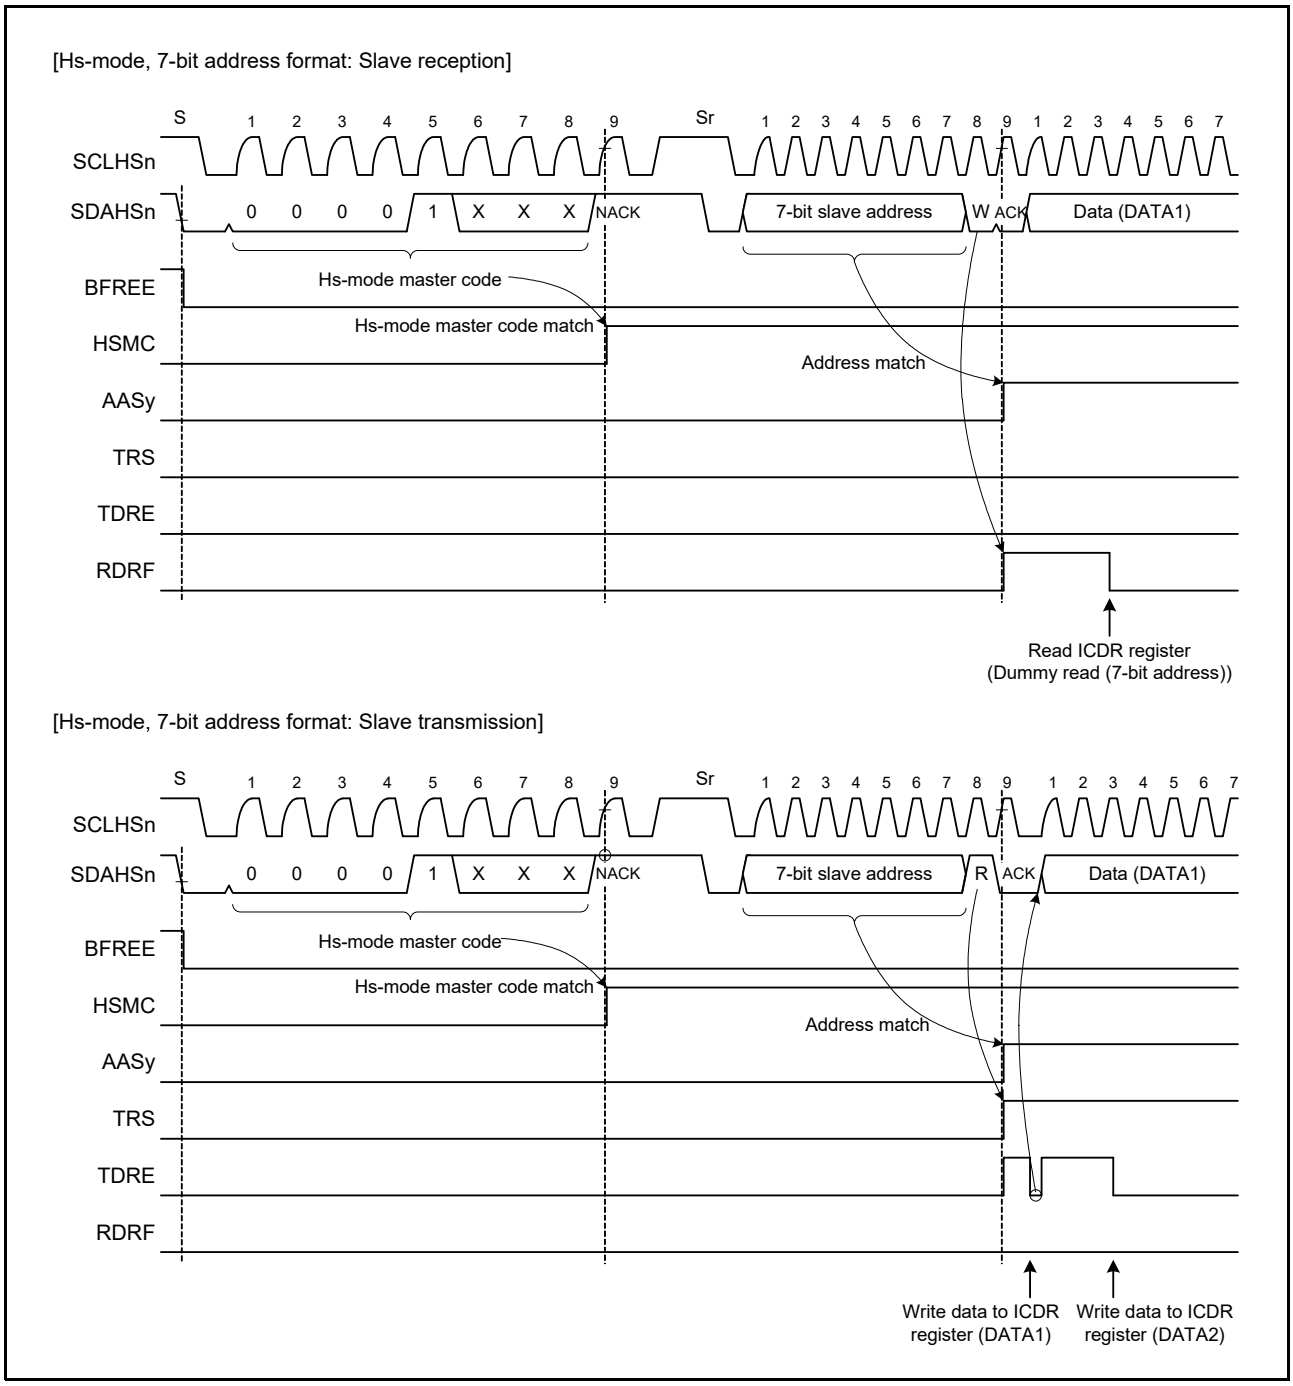

Figure 44.28 Set Timing of the HSMC and AASy Flags during Reception of Hs-Mode Master Code

44.4.4.5 Host Address Detection

The RIICHS has a function to detect the host address while the SMBus is operating. When the ICSCR.HOAE bit is set to 1 while the ICFER.SMBS bit is 1, the RIICHS can detect the host address (0001 000b) in slave receive mode (ICMMR.MST and ICMMR.TRS flags = 00b).

When the RIICHS detects the host address, the ICSSR.HOA flag is set to 1 at the rising edge of the ninth SCL, and at the same time, the ICCSR.RDRF flag is set to 1 when the R/W# bit is 0 (write). This causes a receive data full interrupt (RXI) to be generated. The HOA flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address (0001 000b) is an R bit (R/W# bit = 1), the RIICHS can also detect the host address. After the host address is detected, the RIICHS operates in the same manner as normal slave operation.

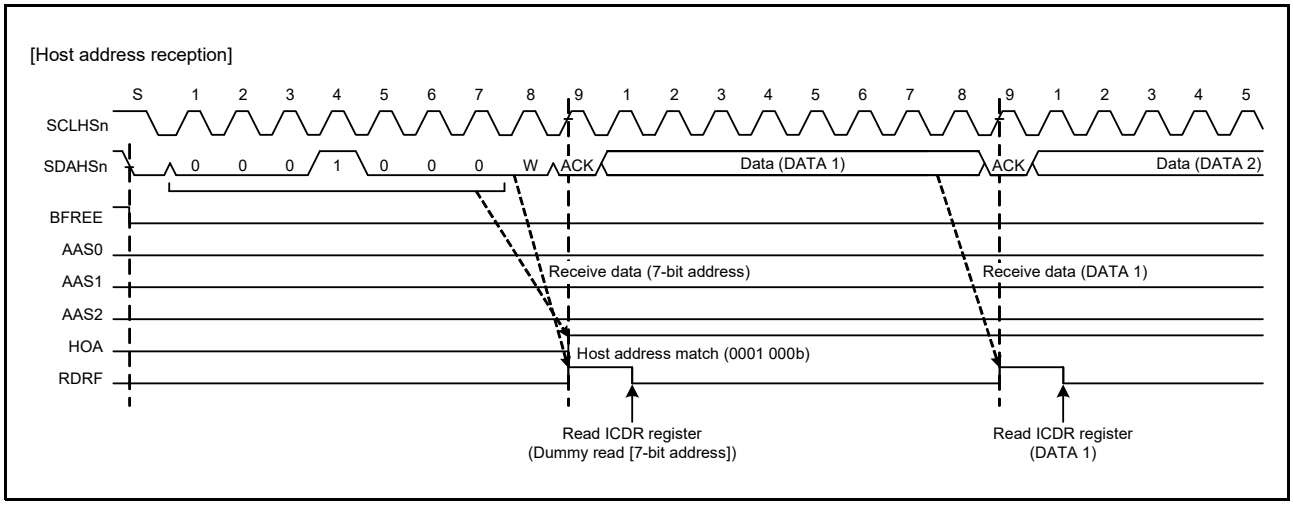

Figure 44.29 HOA Flag Set Timing during Reception of Host Address

44.4.5 Automatic Low-Hold Function for SCL

44.4.5.1 Function to Prevent Wrong Transmission of Transmit Data

When data have not been written to the transmit data register (ICDR register) with the RIICHS in transmission mode (ICMMR.TRS flag = 1), the SCLHSn line is automatically held low over the periods shown below. This low period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low period after a START condition or repeated START condition is generated
- Low period between the ninth clock pulse of one transfer and the first clock pulse of the next

Slave transmit mode

- Low period between the ninth clock pulse of one transfer and the first clock pulse of the next

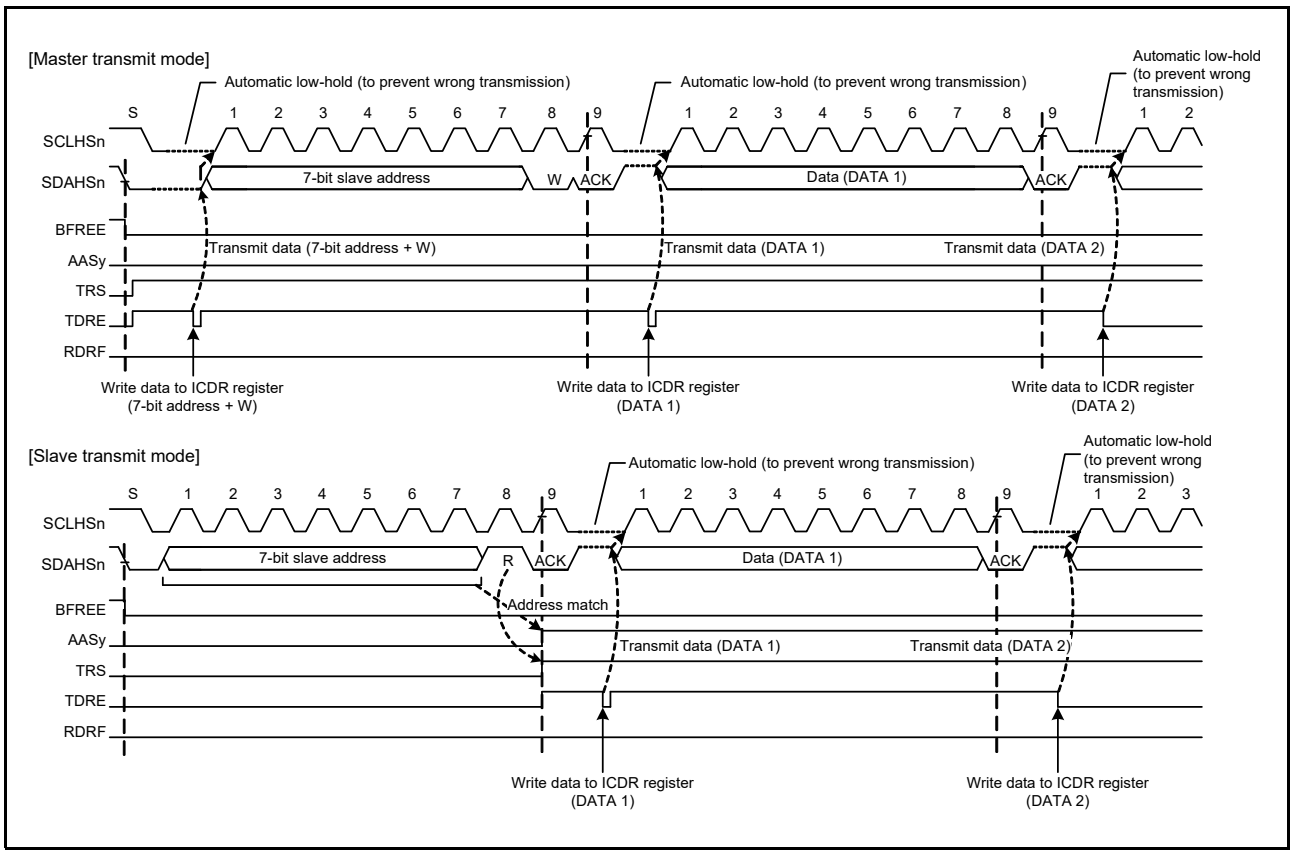

Figure 44.30 Automatic Low-Hold Operation in Transmit Mode

44.4.5.2 NACK Reception Transfer Suspension Function

The RIICHS has a function to suspend transfer operation when NACK is received in transmit mode (ICMMR.TRS flag = 1).

This function is enabled when the ICSER.NAKDE bit is set to 1 (transfer suspension enabled). If the next transmit data has already been written (ICCSR.TDRE flag = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL is automatically suspended. This prevents the SDAHSn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (ICSR2.NACKF flag = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to set the NACKF flag to 0. In master transmit mode, issue a repeated START or STOP condition, set the NACKF flag to 0, and then issue a START condition again.

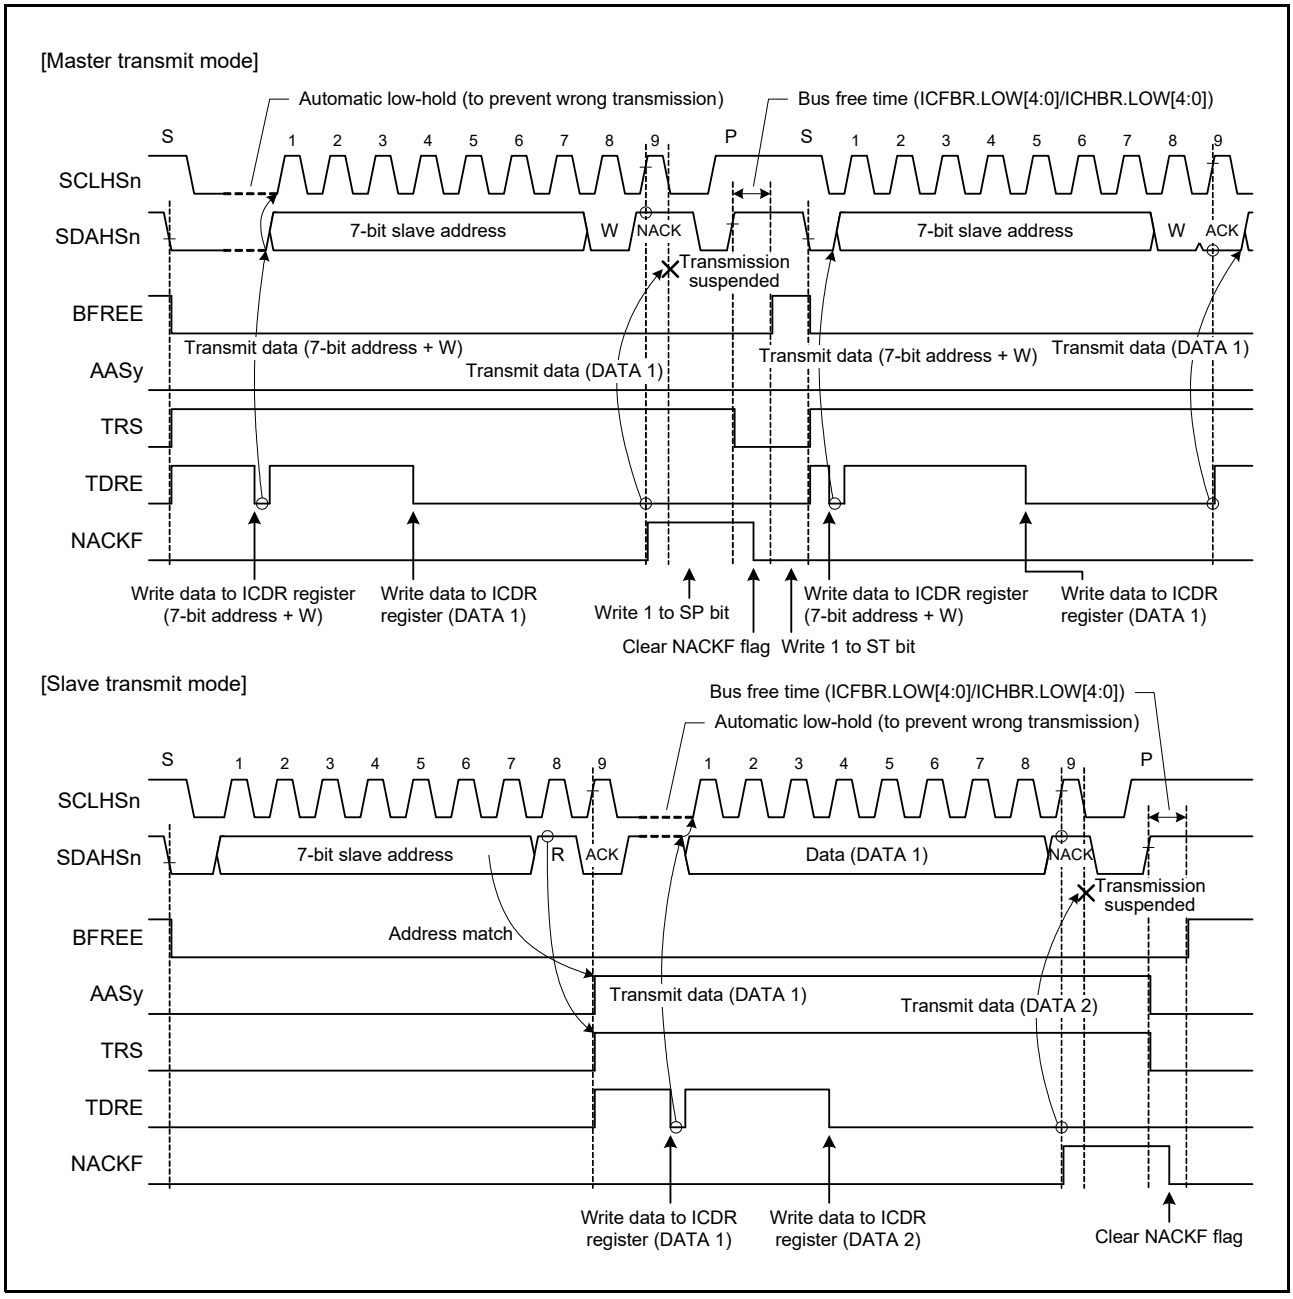

Figure 44.31 Suspension of Data Transmission When NACK is Received (NAKDE = 1)

44.4.5.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDR register) read is delayed for a period of one transfer frame or more with receive data full (ICCSR.RDRF flag = 1) in receive mode (ICMMR.TRS flag = 0), the RIICHS holds the SCLHSn line low automatically immediately before the next data is received to prevent failure to receive data.
This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RIICHS's own slave address or a slave address for the other device is designated after a STOP condition is generated.
Sections in which the SCLHSn line is held low can be selected with a combination of the ICCSCR.WAITRE and ICCSCR.WAITAE bits.

(1) 1-Byte Receive Operation and Automatic Low-Hold Function Using the WAITRE Bit

When the ICCSCR.WAITRE bit is set to 1, the RIICHS performs 1-byte receive operation using the WAITRE bit function.
Furthermore, when the ICCSCR.WAITAE bit is 0, the RIICHS automatically sends the ICACKR.ACKBT bit value for the acknowledgment bit in the period from the falling edge of the eighth SCL to the falling edge of the ninth SCL, and automatically holds the SCLHSn line low at the falling edge of the ninth SCL using the WAITRE bit function. This low-hold is released by reading data from ICDR register, which enables bytewise receive operation.
The WAITRE bit function is enabled for receive frames after a match with the RIICHS's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(2) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the WAITAE Bit

When the ICCSCR.WAITAE bit is set to 1, the RIICHS performs 1-byte receive operation using the WAITAE bit function.
When the WAITAE bit is set to 1, the ICCSR.RDRF flag (receive data full) is set to 1 at the rising edge of the eighth SCL, and the SCLHSn line is automatically held low at the falling edge of the eighth SCL. This low-hold is released by writing a value to the ICACKR.ACKBT bit, but cannot be released by reading data from ICDR register, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.
The WAITAE bit function is enabled for receive frames after a match with the RIICHS's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

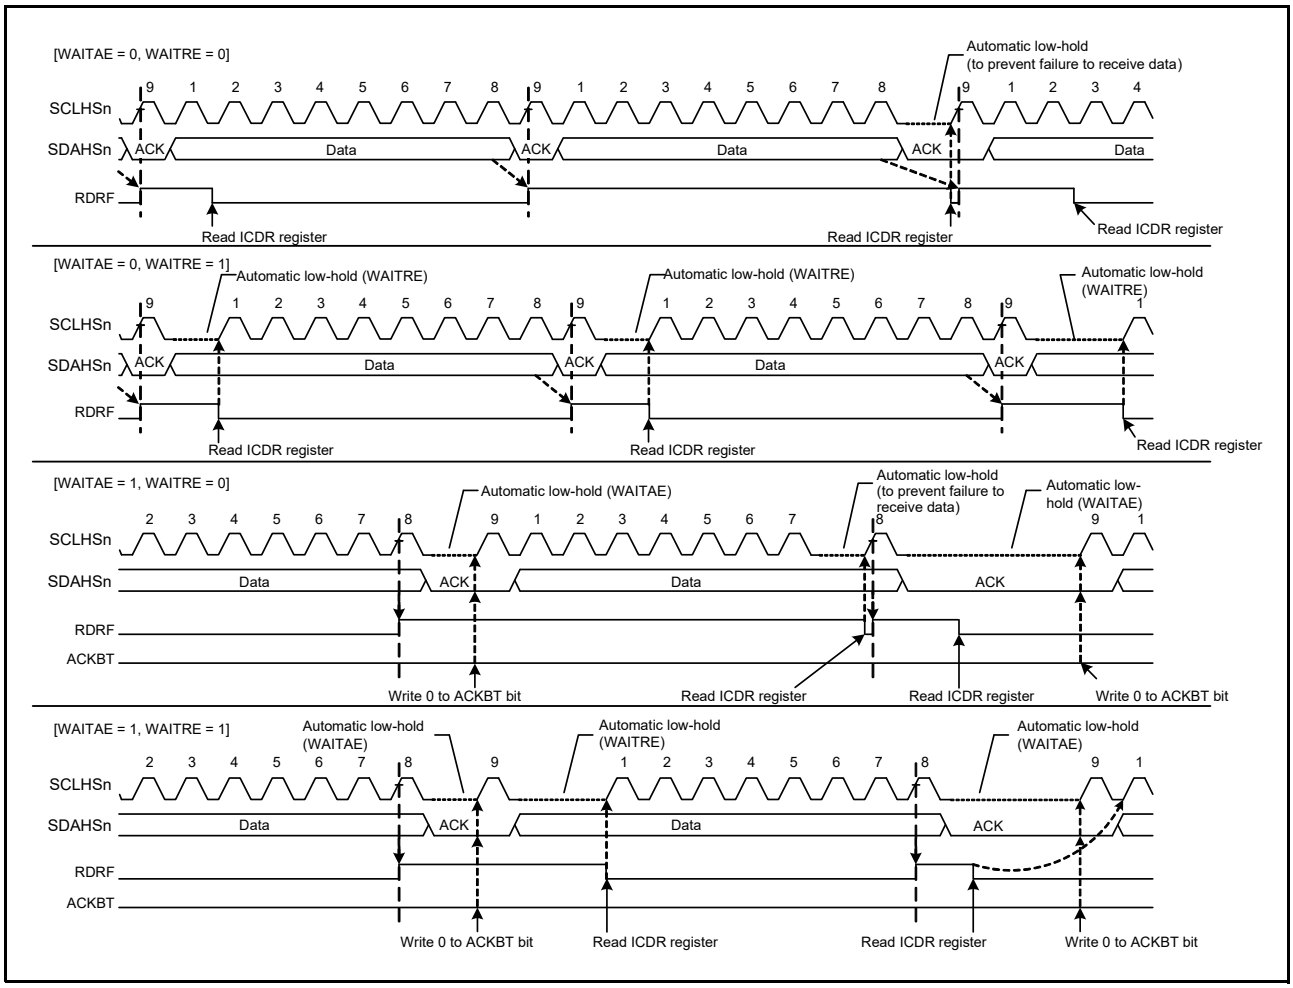

Figure 44.32 Automatic Low-Hold Operation in Receive Mode (Using WAITAE and WAITRE Bits)

44.4.6 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function specified in the I2C-bus specification, the RIICHS also has functions to prevent double generation of START conditions, to detect arbitration-lost during NACK transmission, and to detect arbitration-lost during slave transmission.

44.4.6.1 Master Arbitration-Lost Detection Function (MALE Bit)

The RIICHS drives the SDAHSn line low to generate a START condition. However, if the SDAHSn line is already driven low by another master device that generates a START condition, the RIICHS generates an arbitration-lost and gives a priority to the transfer by the other master device. Similarly, if the ICCGR.ST bit is set to 1 while the ICBSR.BFREE flag is 0 (bus busy), the RIICHS generates an arbitration-lost and gives a priority to the transfer by the other master device. No START condition is generated in this case.
After a START condition is generated successfully, if the level of the transmit data including the address bits (i.e. the internal SDA output level) and the level on the SDAHSn line do not match (the internal SDA output is high (the SDAHSn pin is high-impedance) but low is detected on the SDAHSn line), the RIICHS generates an arbitration-lost.
If a master arbitration-lost is generated, the RIICHS immediately transitions to slave receive mode. If a slave address including the general call address matches its own address at this time, the RIICHS continues the slave operation.
The RIICHS detects master arbitration-lost when one of the following conditions is met while the ICSER.ALE and ICFER.MALE bits are 1 (master arbitration-lost detection enabled).

Conditions for detecting master arbitration-lost

- When the internal SDA output level and the level on the SDAHSn line do not match (START condition generation error) when a START condition is generated by setting the ICCGR.ST bit to 1 while the ICBSR.BFREE flag is 1.
- When the ICCGR.ST bit is set to 1 while the BFREE flag is 0 (START condition double generation error).
- When the transmit data excluding acknowledgment bit (internal SDA signal output level) and the level on the SDAHSn line do not match in master transmit mode (the ICMMR.MST and ICMMR.TRS flags are 1).

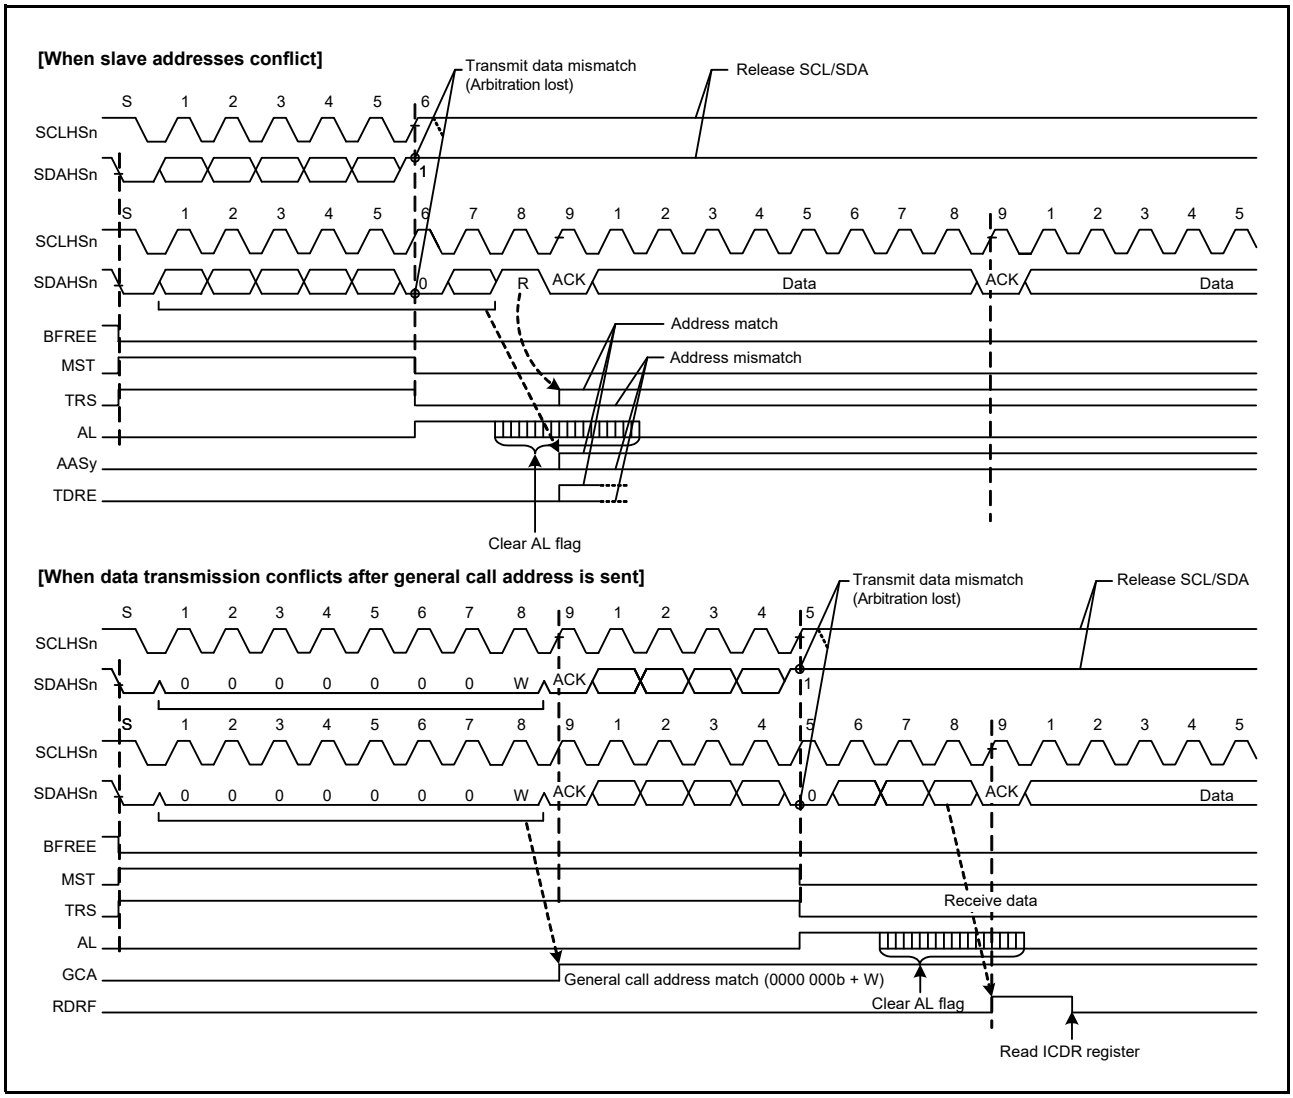

Figure 44.33 Examples of Master Arbitration-Lost Detection (MALE = 1)

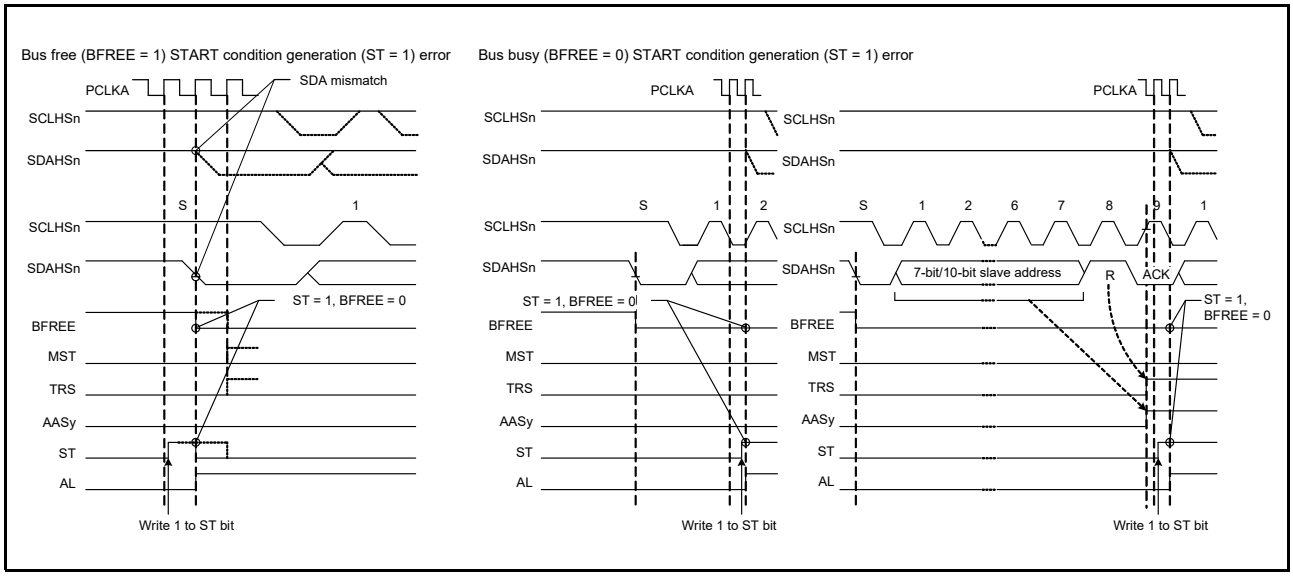

Figure 44.34 Arbitration-Lost Detection When a START Condition is Generated (MALE = 1)

44.4.6.2 NACK Transmission Arbitration-Lost Detection Function (NALE Bit)

The RIICHS has a function to generate an arbitration-lost if the internal SDA output level and the level on the SDAHSn line do not match (the internal SDA output is high (the SDAHSn pin is high-impedance) but low is detected on the SDAHSn line) during NACK transmission in receive mode. NACK transmission arbitration-lost is generated by a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflicts can occur when multiple master devices exchange common information through a single slave device.

Figure 44.35 shows an example of NACK transmission arbitration-lost detection when two master devices (master A and master B) and one slave device are connected to the bus.

In this example, master A receives two bytes of data from the slave device, and master B receives four bytes of data from the slave device. If master A and master B access the slave device at the same time, arbitration-lost does not occur on either master A or master B when accessing the slave device because the slave addresses are the same. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Here, master A sends a NACK when it has received second byte, the last byte of data, from the slave device. On the other hand, master B sends an ACK because it has not yet received four bytes of data from the slave device. At this time, a conflict occurs between the NACK of master A and the ACK of master B.

If master A cannot detect the ACK sent by master B when such a conflict occurs, master A generates a STOP condition. This conflicts with the SCL output of master B and interferes with communication.

The RIICHS can generate an arbitration-lost if it receives an ACK while sending an NACK. This prevents the generation of a STOP condition and prevents bus communication interference. Also, in the ARP command processing of SMBus, it is possible to omit surplus processing (FFh transmission processing) after the NACK transmission when the UDID (unique device identification) of the “Assign Address” does not match and after the NACK transmission of the “Get UDID (General)” after the “Assign Address” is confirmed.

The RIICHS detects NACK transmission arbitration-lost when the following condition is met while the ICSER.ALE and ICFER.NALE bits are 1 (NACK transmission arbitration-lost detection is enabled).

If the NACK transmission arbitration-lost occurs, the RIICHS cancels the slave address matched state and enters slave receive mode.

Condition for detecting NACK transmission arbitration-lost

- When the internal SDA output level does not match the SDAHSn line (ACK is received) during transmission of NACK (the ICACKR.ACKBT bit is 1)

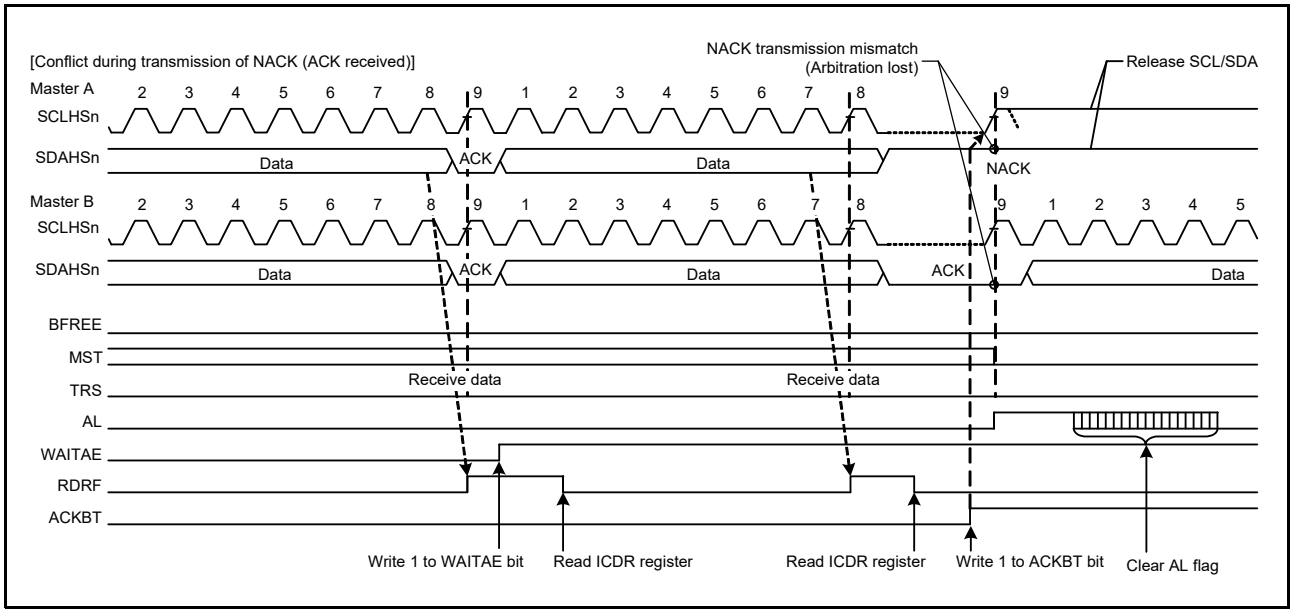

Figure 44.35 Example of NACK Transmission Arbitration-Lost Detection (NALE = 1)

44.4.6.3 Slave Arbitration-Lost Detection Function (SALE Bit)

The RIICHS has a function to generate an arbitration-lost if the transmit data (i.e. the internal SDA output level) and the level on the SDAHSn line do not match (the internal SDA output is high (the SDAHSn pin is high-impedance) but low is detected on the SDAHSn line) in slave transmit mode.

The slave arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identification) of SMBus. This function can detect a data conflict during UDID transmission of SMBus and omit surplus processing (FFh transmission processing) after the data conflict.

The RIICHS detects slave arbitration-lost when the following condition is met while the ICSER.ALE and ICFER.SALE bits are 1 (slave arbitration-lost detection enabled).

If the slave arbitration-lost occurs, the RIICHS cancels the slave address matched state and enters slave receive mode.

Condition for detecting slave arbitration-lost

- When the transmit data excluding acknowledgment bit (internal SDA output level) does not match the level on the SDAHSn line in slave transmit mode (the ICMMR.MST flag is 0 and the ICMMR.TRS flag is 1)

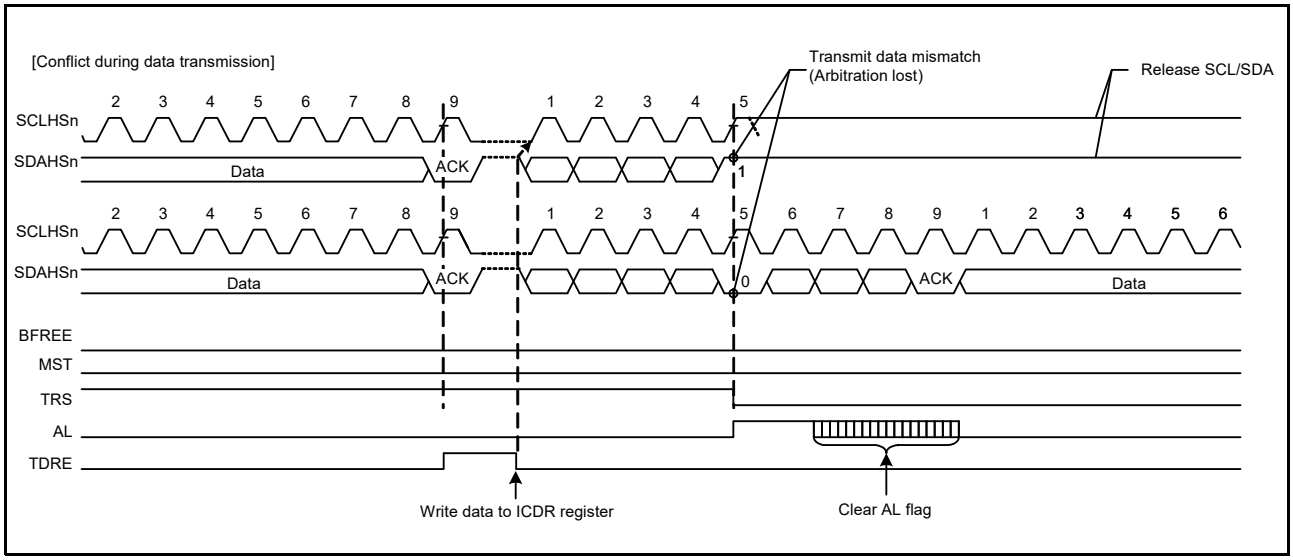

Figure 44.36 Example of Slave Arbitration-Lost Detection (SALE = 1)

44.4.7 START Condition/Repeated START Condition/STOP Condition Generating Function

44.4.7.1 Generating a START Condition

The RIICHS generates a START condition when the ICCGR.ST bit is set to 1.
When the ST bit is set to 1 (requests to generate a START condition) while the ICBSR.BFREE flag is set to 1 (bus free state), the RIICHS generates a START condition.
When a START condition is generated normally, the RIICHS automatically shifts to the master transmit mode.
A START condition is generated in the following sequence.

START condition generation

(1) Drive the SDAHSn line low (high to low).
(2) Secure the START condition hold time with the time set in the ICFBR.HIGH[7:0] bits.
(3) Drive the SCLHSn line low (high to low).
(4) Detect a low of the SCLHSn line and secure the low period of SCLHSn line with the time set in the ICFBR.LOW[7:0] bits.

44.4.7.2 Generating a Repeated START Condition

The RIICHS generates a repeated START condition when the ICCGR.RS bit is set to 1.
When the RS bit is set to 1, generation of a repeated START condition is requested. When the ICBSR.BFREE flag is 0 (bus busy state) and the ICMMR.MST flag is 1 (master mode), the RIICHS generates a repeated START condition.
A repeated START condition is generated in the following sequence.

Repeated START condition generation

(1) Release the SDAHSn line.
(2) Secure the low period of SCLHSn line with the time set in the ICFBR.LOW[7:0] bits.
(3) Release the SCLHSn line (low to high).
(4) Detect a high of the SCLHSn line and secure the repeated START condition setup time with the time set in the ICFBR.LOW[7:0] bits.
(5) Drive the SDAHSn line low (high to low).
(6) Secure the repeated START condition hold time with the time set in the ICFBR.HIGH[7:0] bits.
(7) Drive the SCLHSn line low (high to low).
(8) Detect a low of the SCLHSn line and secure the low period of SCLHSn line with the time set in the ICFBR.LOW[7:0] bits.

Note: When requesting generation of a repeated START condition, write the slave address to the ICDR register after confirming that the ICCGR.RS bit is 0. Data written while the ICCGR.RS bit is 1 is not transferred because it is considered to be before the repeated START condition is generated.

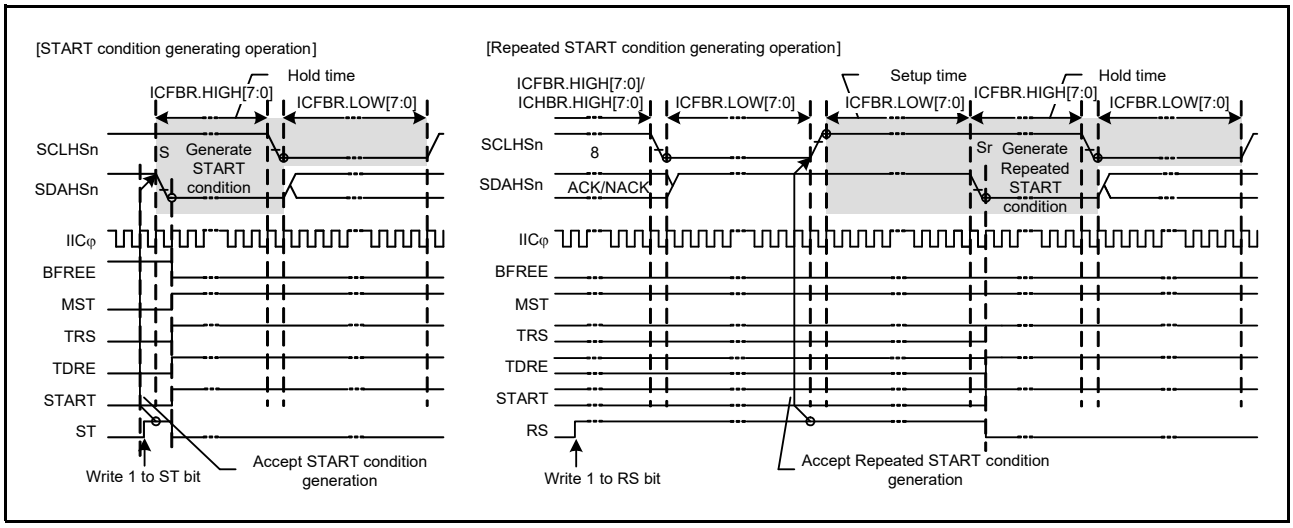

Figure 44.37 START Condition/Repeated START Condition Generating Timing (ST and RS Bits)

Figure 44.38 shows the operation timing when generating a repeated START condition after the master transmission.

Repeated START condition generation after the master transmission

(1) Initial setting. For details, refer to section 44.3.2, Initial Settings.

(2) Read the ICBSR.BFREE flag to check that the bus is open, and then set the ICCGR.ST bit to 1 (requests to generate a START condition). Upon receiving the request, the RIICHS generates a START condition. At the same time, the BFREE flag is automatically set to 0, the ICSR2.START flag is automatically set to 1, and the ST bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the SDAHSn line have matched while the ST bit is 1, the RIICHS recognizes that generating of the START condition as requested by the ST bit has been successfully completed, and ICMMR.MST and ICMMR.TRS flags are automatically set to 1, placing the RIICHS in master transmit mode. The ICCSR.TDRE flag is also automatically set to 1 in response to setting of the TRS flag to 1.

(3) Check that the ICCSR.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to the ICDR register. Once the data for transmission are written to the ICDR register, the TDRE flag is automatically set to 0, the data are transferred from the ICDR register, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS flag is automatically updated to select master transmit or master receive mode in accordance with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RIICHS continues in master transmit mode. Since the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to ICCGR.SP bit to generate a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0b, the 2 higher-order bits of the slave address, and W to the ICDR register as the first address transmission. Then, as the second address transmission, write the lower 8 bits of the slave address to ICDR register.

(4) After confirming that the ICCSR.TDRE flag is 1, write the data for transmission to the ICDR register. The RIICHS automatically holds the SCLHSn line low until the data for transmission are ready, a repeated START condition is generated, or a STOP condition is generated.

(5) After all bytes of data for transmission have been written to the ICDR register, wait until the value of the ICSR2.TEND flag returns to 1, and then, after check that the ICSR2.START flag is 1, set the ICSR2.START flag to 0.

(6) Set the ICCGR.RS bit to 1 (requests to generate a repeated START condition). Upon receiving the request, the RIICHS generates a repeated START condition.

(7) After check that the ICSR2.START flag is 1, write the value for transmission (the slave address and the R/W# bit) to the ICDR register.

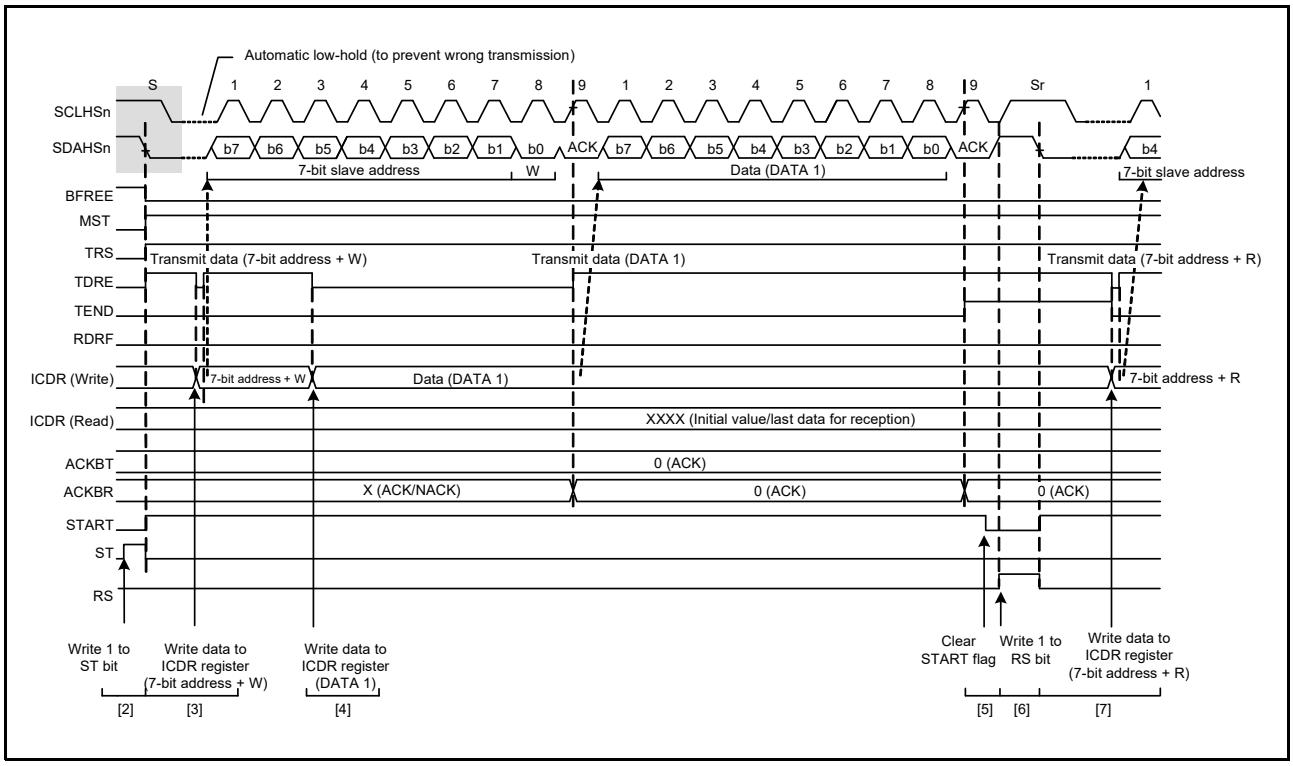

Figure 44.38 Repeated START Condition Generation Timing after the Master Transmission

44.4.7.3 Generating a STOP Condition

The RIICHS generates a STOP condition when the ICCGR.SP bit is set to 1.
When the SP bit is set to 1, generation of a STOP condition is requested. When the ICBSR.BFREE flag is 0 (bus busy state) and the ICMMR.MST flag is 1 (master mode), the RIICHS generates a STOP condition.
A STOP condition is generated in the following sequence.

STOP condition generation

(1) Drive the SDAHSn line low (high to low).
(2) Secure the low period of SCLHSn line with the time set in the ICFBR.LOW[7:0] bits.
(3) Release the SCLHSn line (low to high).
(4) Detect a high of the SCLHSn line and secure the STOP condition setup time with the time set in the ICFBR.HIGH[7:0] bits.
(5) Release the SDAHSn line (low to high).
(6) Secure the bus free time with the time set in the ICFBR.LOW[7:0] bits.
(7) Set the BFREE flag to 1 (to release the bus).

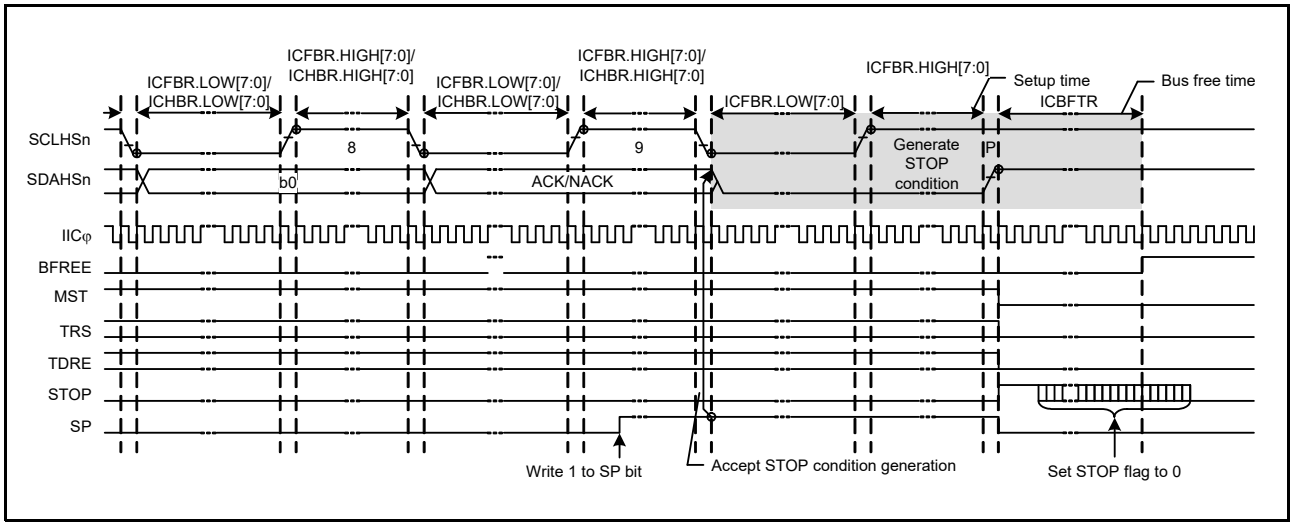

Figure 44.39 STOP Condition Generating Timing (SP Bit)

44.4.8 Bus Hanging

44.4.8.1 Timeout Function

The RIICHS includes a timeout function for detecting when the SCLHSn line has been stuck longer than the predetermined time. The RIICHS can detect an abnormal bus state by monitoring that the SCLHSn line is stuck low or high for a predetermined time.

The timeout function monitors the SCLHSn line state and counts the low period or high period using the internal counter. The timeout function resets the internal counter each time the SCLHSn line changes (rising or falling), but continues to count unless the SCLHSn line changes. If the internal counter overflows due to no SCLHSn line change, the RIICHS can detect the timeout and report the bus hung state.

This timeout function is enabled when the ICSER.TMOE bit is 1. It detects a hung state that the SCLHSn line is stuck low or high during the following conditions: (when ICTOR.TMOM[1:0] bits = 00b)

- The bus is busy (ICBSR.BFREE flag is 0) in master mode (ICMMR.MST flag is 1).
- The RIICHS's own slave address is detected (ICSSR register is not 0000 0000h) and the bus is busy (ICBSR.BFREE flag is 0) in slave mode (ICMMR.MST flag is 0).
- The bus is free (ICBSR.BFREE flag is 1) while generation of a START condition is requested (ICCGR.ST bit is 1).

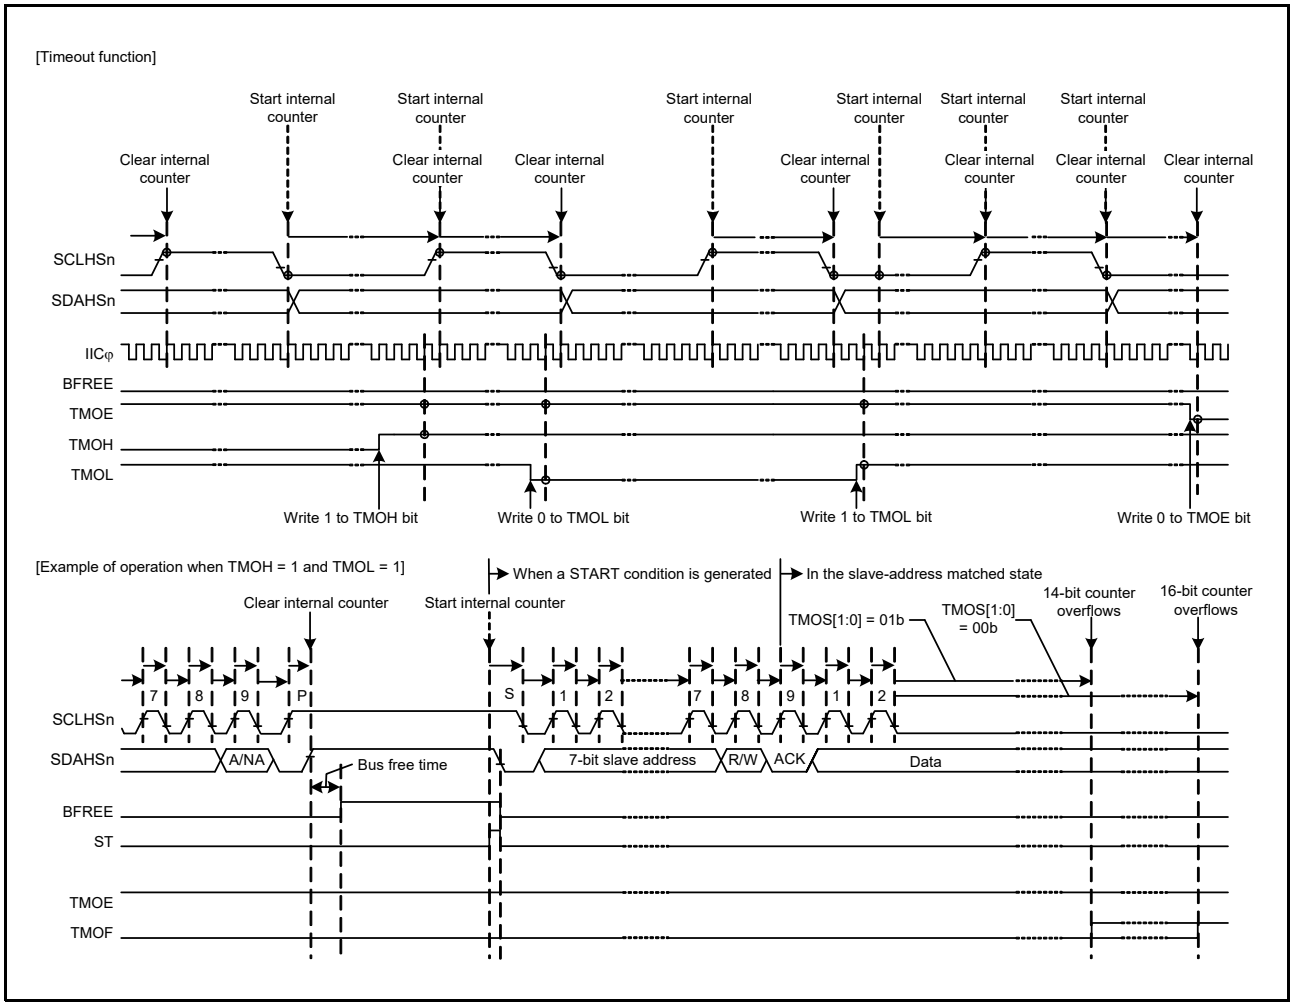

Figure 44.40 Timeout Function (TMOE, TMOS[1:0], TMOH, and TMOL Bits)

44.4.8.2 Additional SCL Output Function

In master mode, the RIICHS module has a function for the output of additional SCL to release the SDAHSn line from being held low by the slave device due to the master being out of synchronization with the slave device.
This function is mainly used in master mode to release the SDAHSn line from the state of being stuck low by including additional SCL output from the RIICHS with single cycles of the SCL as the unit in the case of a bus error where the RIICHS cannot generate a STOP condition because the slave device is holding the SDAHSn line low. Do not use this function in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.
When the ICOCR.CLO bit is set to 1, an additional clock pulse at the frequency set by the ICRCCR.CKS[2:0] bits and the HIGH[7:0] and LOW[7:0] bits in the ICFBR register (ICHBR register in Hs-mode) is output from the SCLHSn pin. After output of this clock pulse, the CLO bit automatically becomes 0. The SCLHSn pin is held low when the ICBSR.BFREE flag is 0 and held high when the BFREE flag is 1. Consecutive additional clock pulses can be output by the software program writing 1 to the CLO bit after having read CLO = 0.
When the RIICHS module is in master mode and the slave device is holding the SDAHSn line low because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a STOP condition is not possible. The additional SCL output function can be used to output additional clock pulses one by one to make the slave device release the SDAHSn line from being held low, thus recovering the bus from an unusable state. Release of the SDAHSn line by the slave device can be monitored by reading the ICIMR.SDAI flag After confirming release of the SDAHSn line by the slave device, complete communications by regenerating the STOP condition.
Use this function with the ICFER.MALE bit set to 0 (master arbitration-lost detection disabled). If using this function with the ICFER.MALE bit set to 1, arbitration may be lost due to a mismatch between the value of the ICOCR.SDAO bit and the level of the SDAHSn line.

Conditions for using the ICOCR.CLO bit

- When the bus is free (ICBSR.BFREE flag = 1) or in master mode (ICMMR.MST flag = 1 and ICBSR.BFREE flag = 0)
- When the communication device does not hold the SCLHSn line low

Figure 44.41 shows the operation timing of the additional SCL output function (CLO bit).

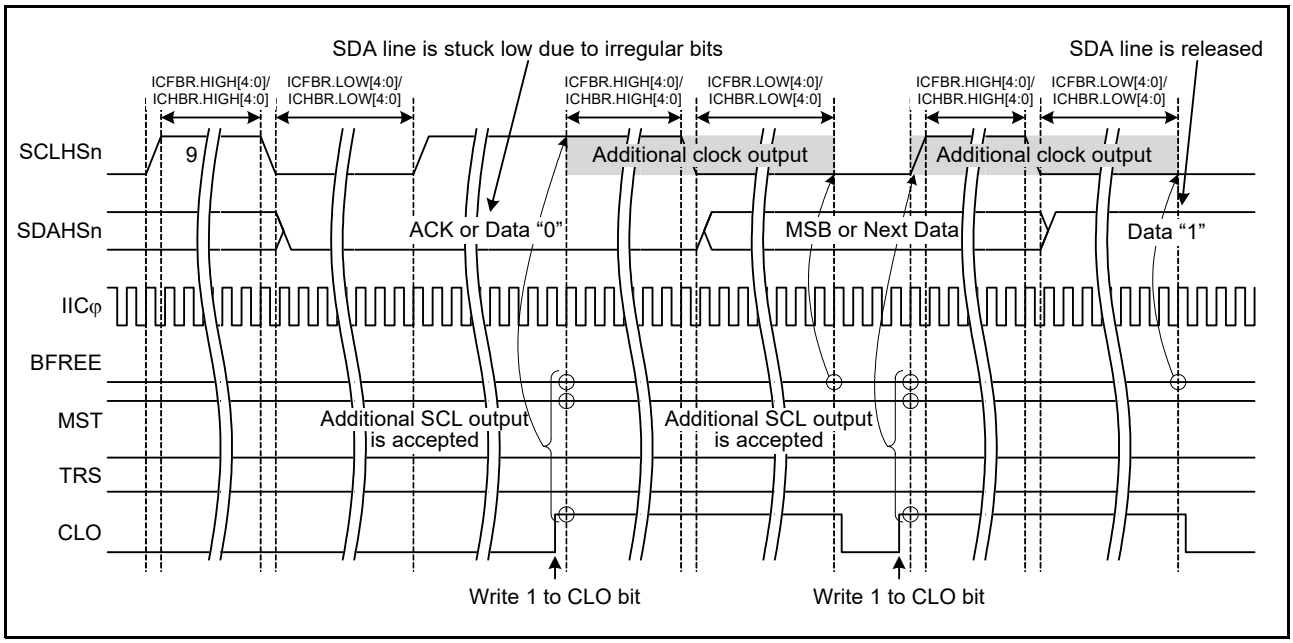

Figure 44.41 Additional SCL Output Function (CLO Bit)

44.4.9 Wake-Up Function

The RIICHS includes a wake-up function to return the MCU from low power consumption states. The wake-up function enables data reception even when the operating clock (I3CCLK) is stopped, and is used to generate a wake-up interrupt when the received address matches its own slave address.
To receive data even when the operating clock is stopped, the wake-up unit must be set to asynchronous operation. After a wake-up interrupt occurs, return to synchronous operation so that communication can continue.
There are four wake-up response modes, as shown in Table 44.6.

Table 44.6 Wake-Up Response Modes

Response Mode	Response Timing	Response	SCL Status
Normal wake-up mode 1	Before returning to synchronous operation	ACK	Hold low after ACK response (at the ninth SCL falling edge), release after returning to synchronous operation.
Normal wake-up mode 2	After returning to synchronous operation	ACK	Hold low at the eighth SCL falling edge, release after returning to synchronous operation with ACK response.
Command recovery mode	Before returning to synchronous operation	ACK	Open.
EEP response mode	Before returning to synchronous operation	NACK	Open.

There are five wake-up interrupt sources.

- Host address detection (ICFER.SMBS bit = 1, ICSCR.HOAE bit = 1)
- General call address detection (ICSCR.GCAE bit = 1)
- Slave address 0 detection (ICSCR.SAR0E bit = 1, SAR0.FS bit = 0)
- Slave address 1 detection (ICSCR.SAR1E bit = 1, SAR1.FS bit = 0)
- Slave address 2 detection (ICSCR.SAR2E bit = 1, SAR2.FS bit = 0)

44.4.9.1 Normal Wake-Up Mode 1

In normal wake-up mode 1, the RIICHS operates as follows after a wake-up interrupt occurs.

(1) Generates an ACK for the data byte that contains its own slave address.
(2) Holds the SCL line low at the ninth SCL falling edge.
(3) When 1 is written to the ICWUCR.WUFSYNE bit, it returns to synchronous operation and sets the ICWUSR.WUASYNF flag to 0.
(4) Releases the SCL line and returns to normal operation.

Note: When returning from low power consumption states due to wake-up interrupt, the setting of the ICCSCR.WAITRE bit is ignored.

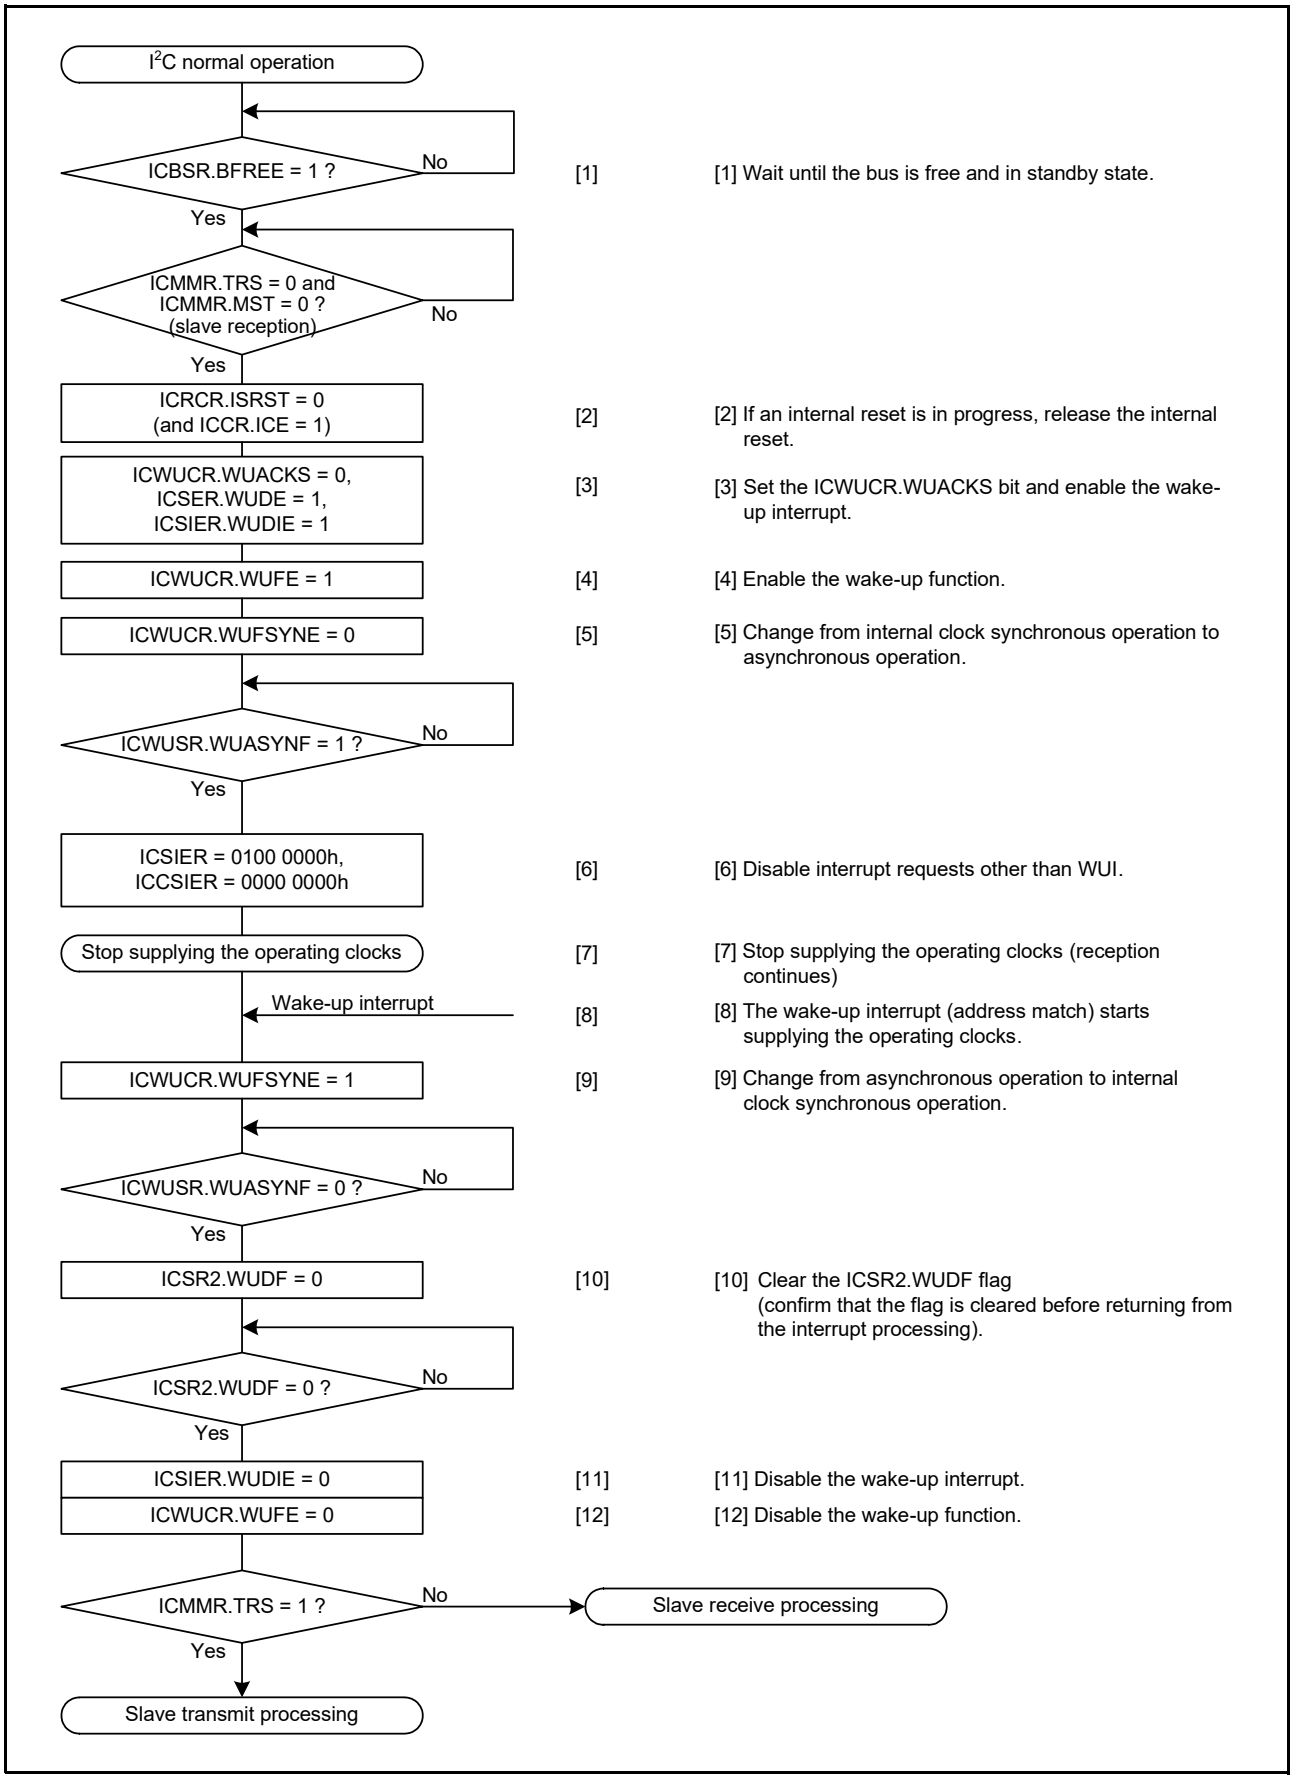

Figure 44.42 Example of Using Normal Wake-Up Mode 1

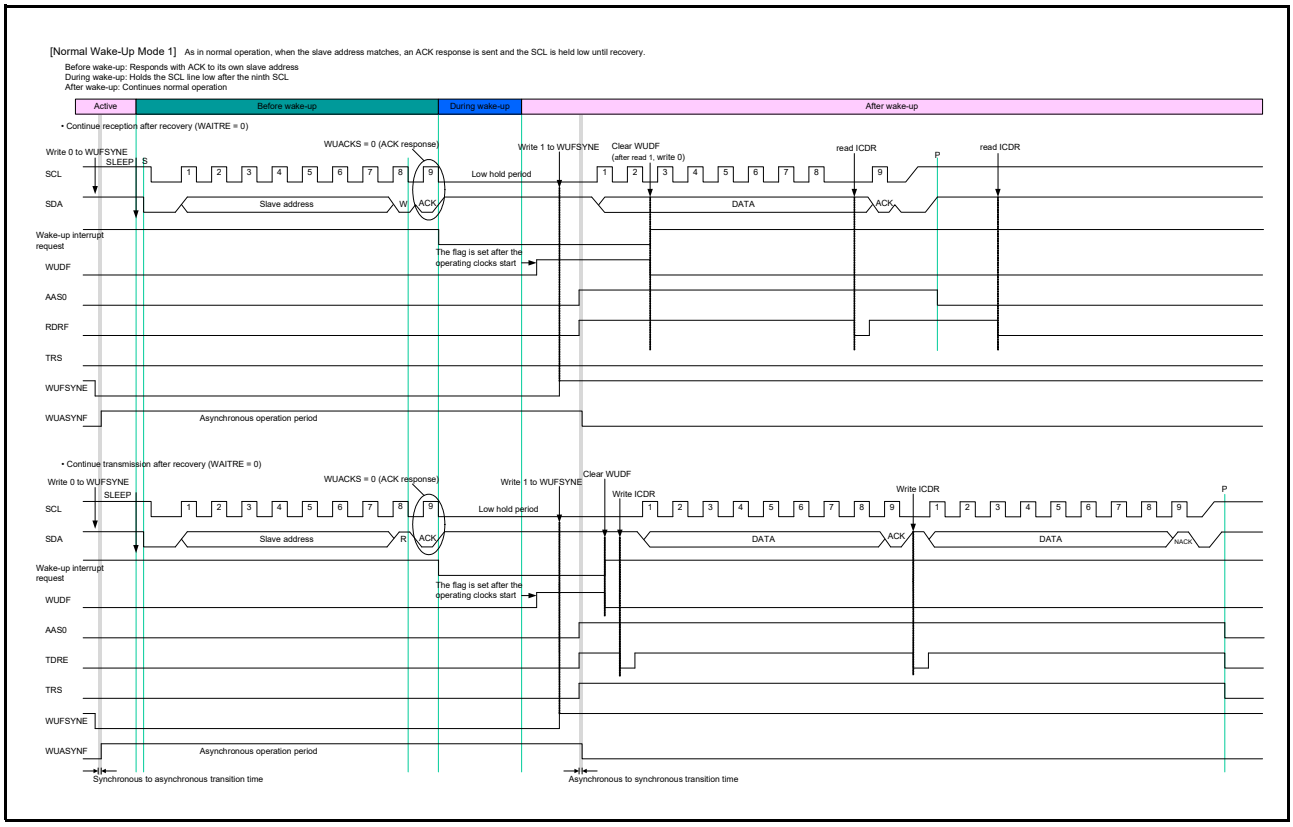

Figure 44.43 Operation Timing of Normal Wake-Up Mode 1

44.4.9.2 Normal Wake-Up Mode 2

In normal wake-up mode 2, the RIICHS operates as follows after a wake-up interrupt occurs.

(1) Holds the SCL line low at the eighth SCL falling edge for the data byte that contains its own slave address.
(2) When 1 is written to the ICWUCR.WUFSYNE bit, it returns to synchronous operation and sets the ICWUSR.WUASYNF flag to 0.
(3) Generates an ACK and release the SCL line.
(4) Returns to normal operation.

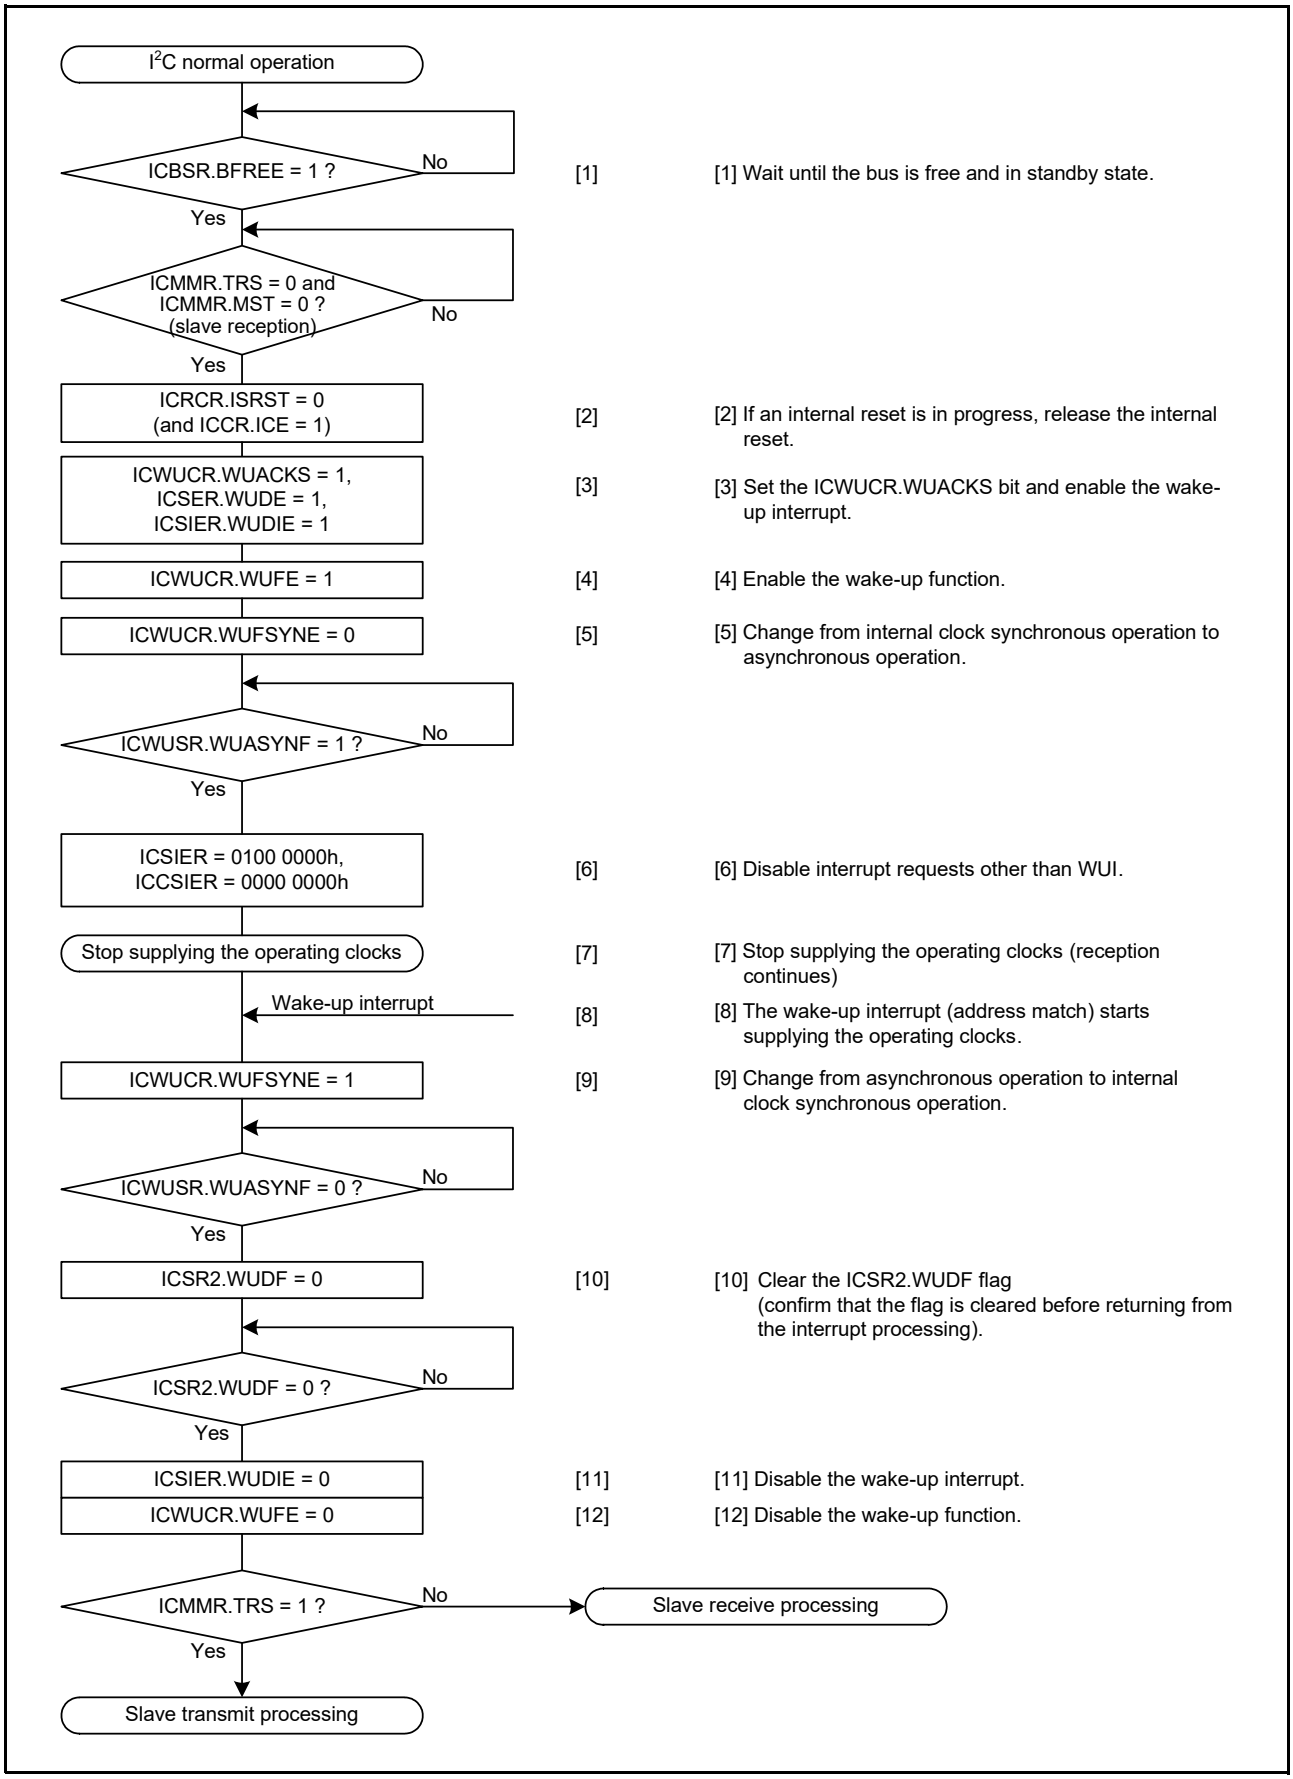

Figure 44.44 Example of Using Normal Wake-Up Mode 2

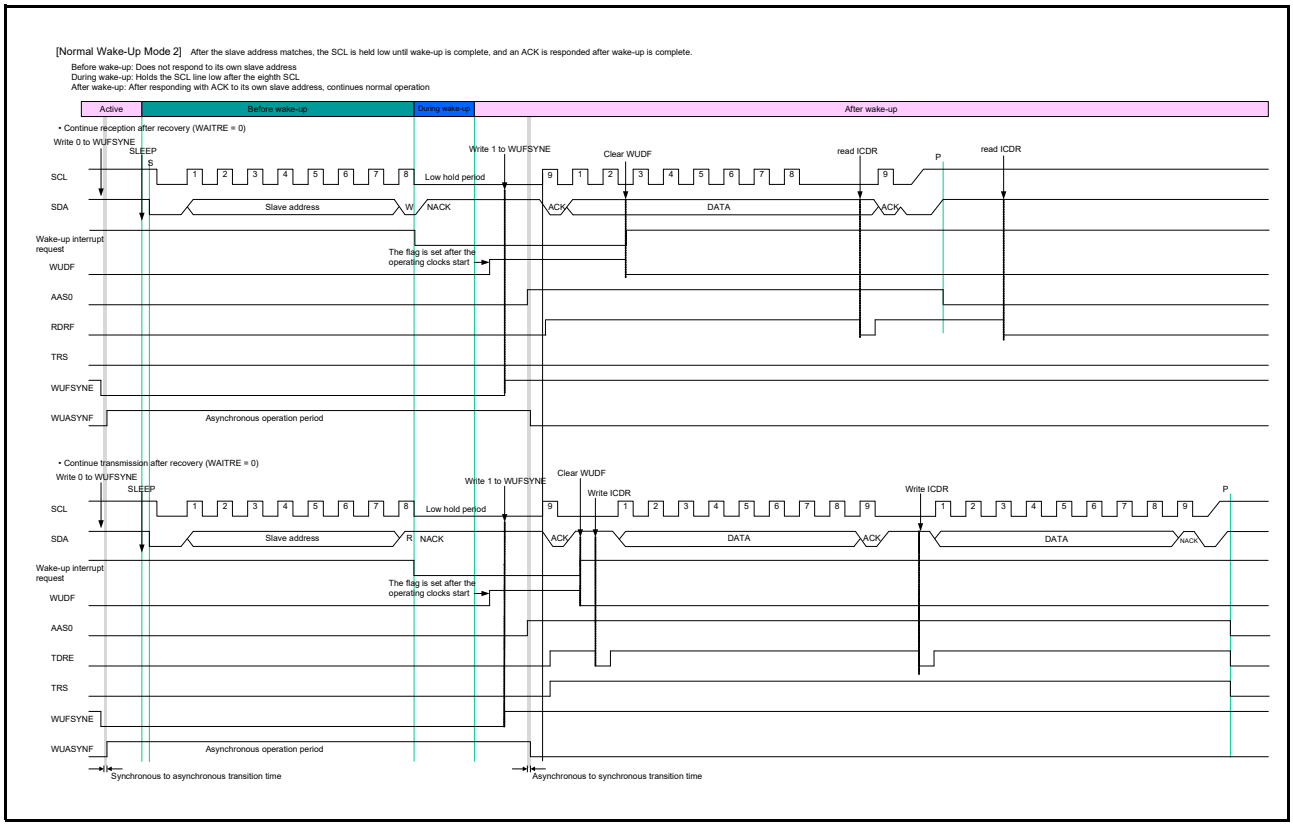

Figure 44.45 Operation Timing of Normal Wake-Up Mode 2

44.4.9.3 Command Recovery Mode and EEP Response Mode

In command recovery mode and EEP response mode, the SCL line is not held low during wake-up operations. As a result, other devices can use the bus during this period, but the RIICHS cannot perform subsequent data transmission and reception.

In these modes, the ICRCR.ISRST bit is set to 1, so after returning from low power consumption states, set the ICRCR.MRST bit to 1 (module reset) and then perform the initial settings.

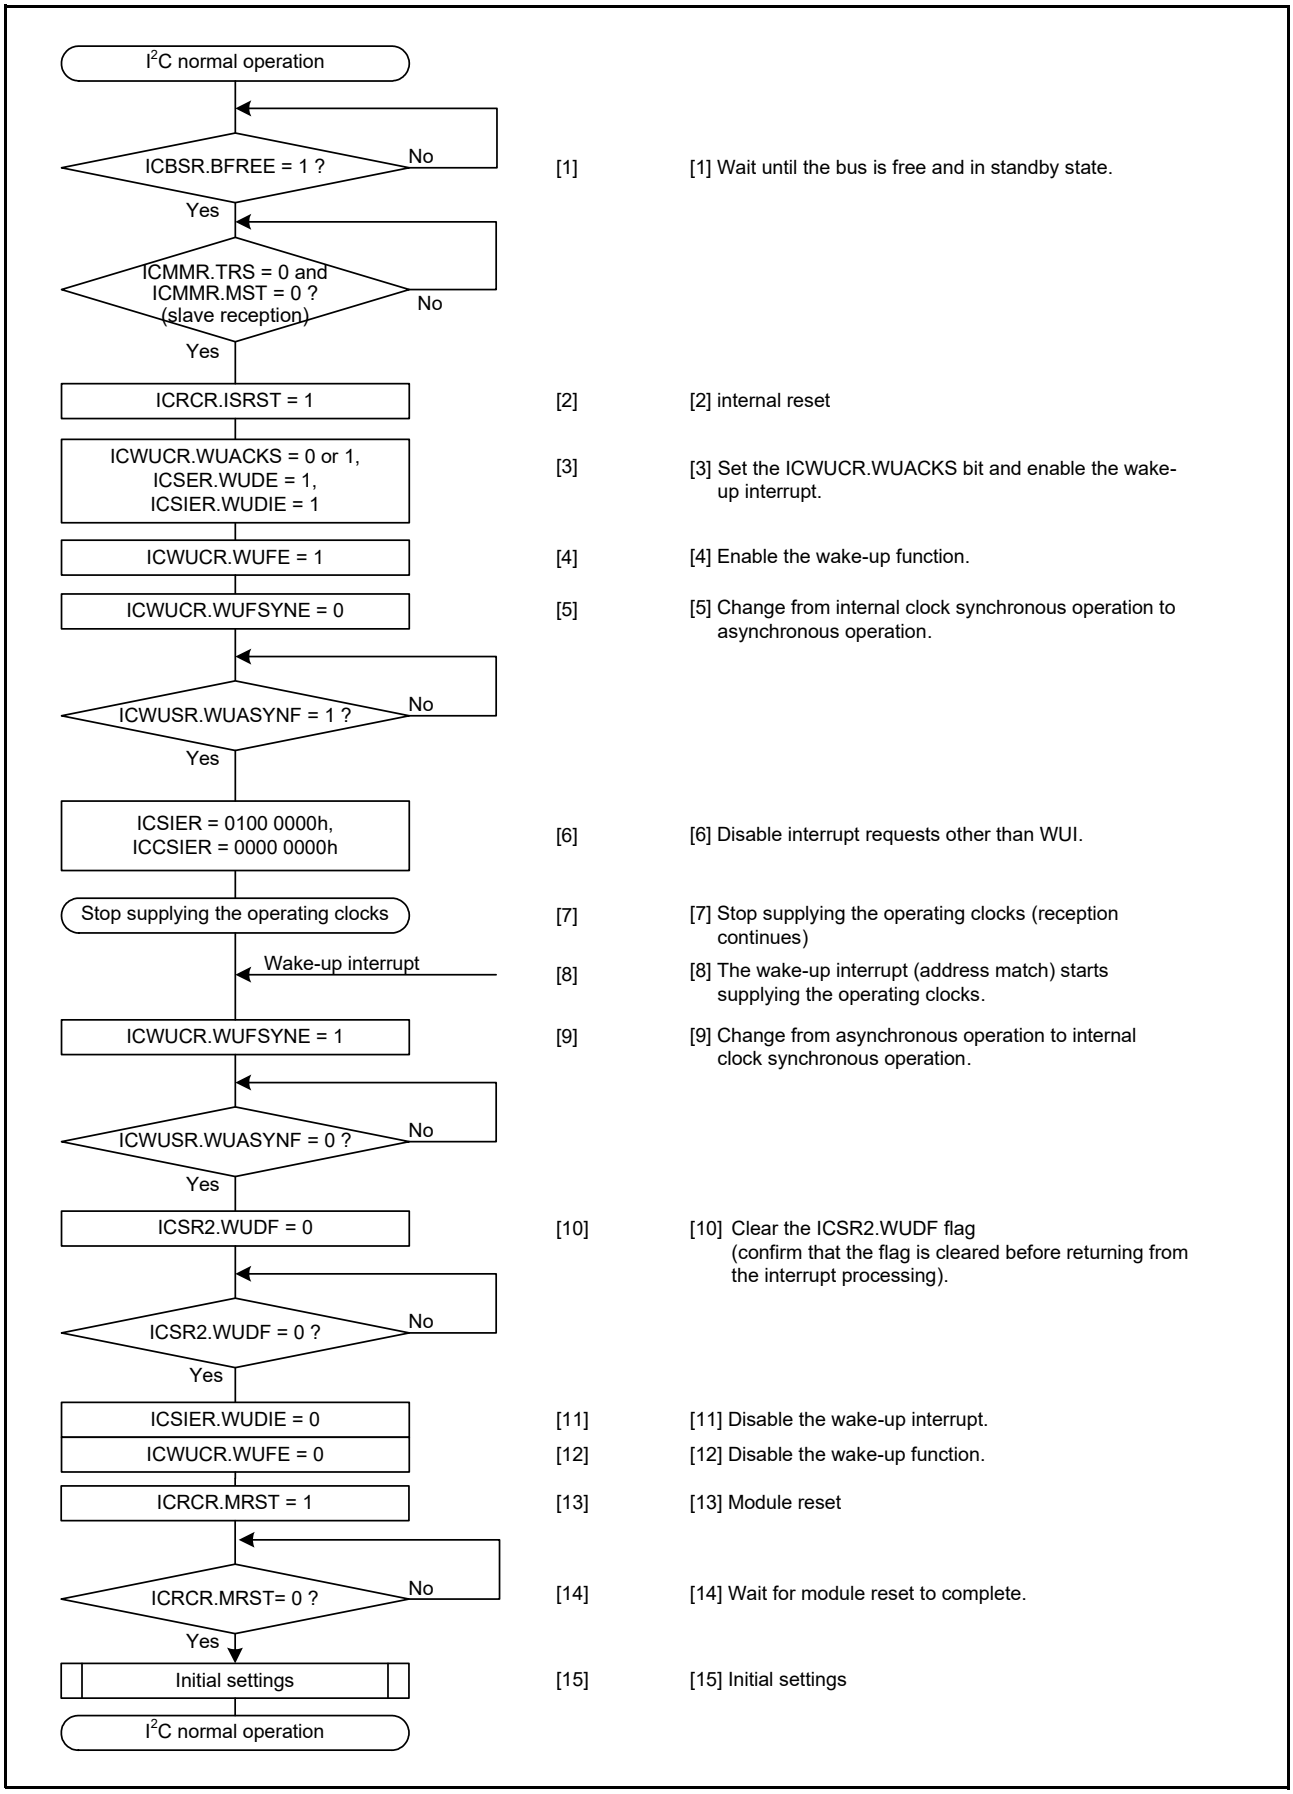

Figure 44.46 Example of Using Command Recovery Mode and EEP Response Mode

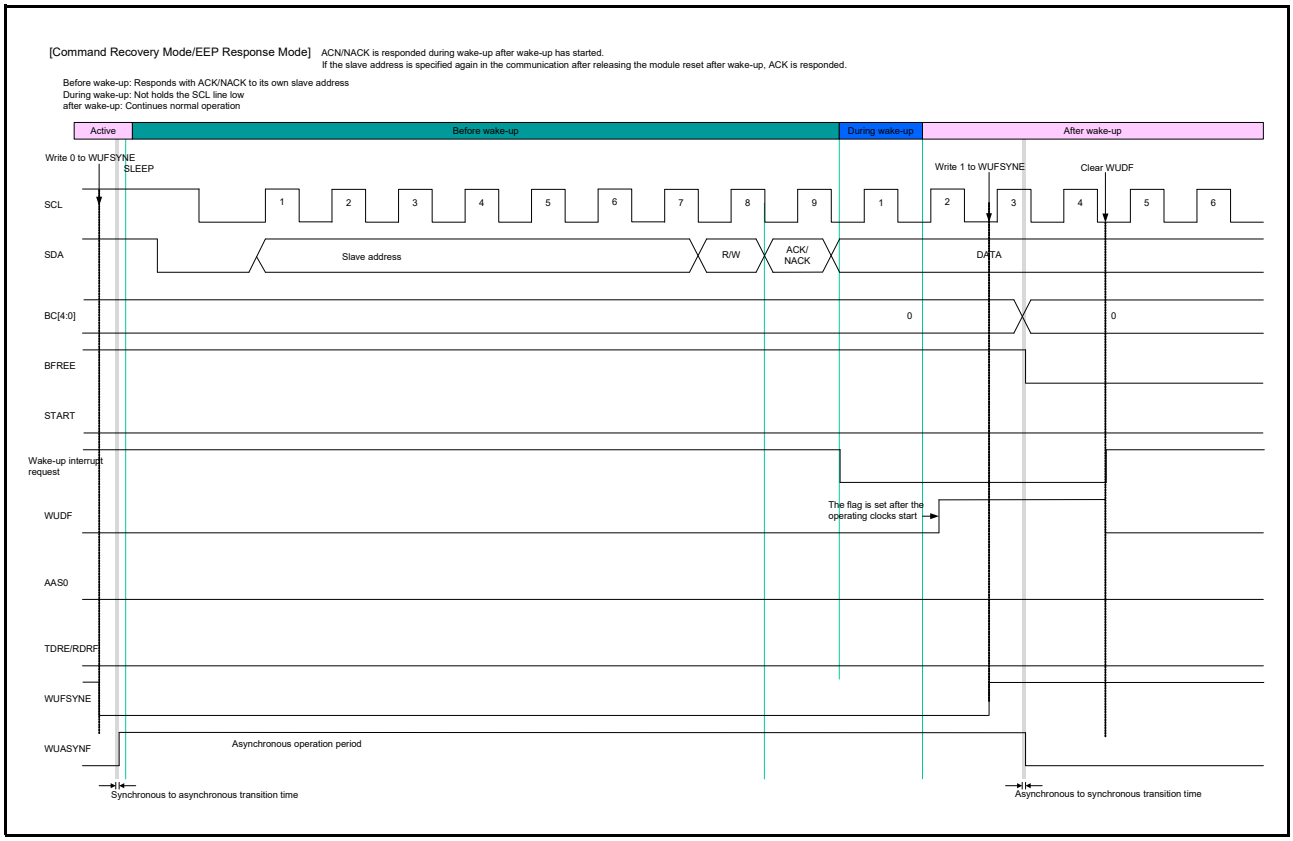

Figure 44.47 Operation Timing of Command Recovery Mode and EEP Response Mode

44.4.9.4 Notes on Using Wake-Up Function

Note the following points when using the wake-up function.

(1) Before setting the ICWUCR.WUFSYNE bit to 0 (asynchronous operation), set the following registers/bits.
   (a) Set the ICWUCR.WUFE, ICSER.WUDE, and ICSIER.WUDIE bits to 1, and the ICMMR.MST and TRS flags to 0.
   (b) The wake-up function does not support device ID addresses and 10-bit address formats. Set the ICSCR.DIDE bit and SARy.FS bit (y = 0 to 2) to 0.
   (c) The timeout function cannot be used. Set the ICSER.TMOE bit to 0.

(2) When the wake-up detection circuit is disabled, the next reception may start if a START condition is detected at the timing when the ICWUCR.WUFSYNE bit is written to 0. In this case, the ICWUSR.WUASYNF flag becomes 1 after the communication is completed and a STOP condition is detected.

(3) After setting the ICWUCR.WUFSYNE bit to 0, do not rewrite the ICFER, ICCSCR, ICACKR, ICICR, ICTCR, and SARy registers until the ICWUSR.WUASYNF flag is set to 1. If rewritten, RIICHS may malfunction.

(4) Do not access the RIICHS registers except for the ICSIER register, ICCSIER register, and ICWUCR.WUFSYNE bit while the ICWUSR.WUASYNF flag is 1 (wake-up detection circuit enabled).

(5) When using normal wake-up mode 2, do not set the ICACKR.ACKBT bit to 1.

(6) If the ICWUCR.WUFSYNE bit is set to 1 (synchronous operation) when no wake-up condition is detected or when the bus is free, the wake-up detection circuit is disabled only after a STOP condition is detected.

44.4.10 SMBus Operation

The RIICHS is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the ICFER.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus standard, set the ICRCCR.CKS[2:0] bits, the ICFBR.HIGH[7:0] bits, and the ICFBR.LOW[7:0] bits. In addition, determine the values of the ICOCR.DLCS bit and the ICOCR.SDDL[2:0] bits to meet the data hold time (300 ns (min.)). When the RIICHS is used only as a slave device, the transfer rate setting is not necessary, whereas the ICFBR.LOW[7:0] bits need to be set to a value longer than the data setup time (250 ns).
For the SMBus device default address (1100 001b), use one of the slave address registers 0 to 2 (SAR0, SAR1, and SAR2), and set the corresponding FS bit (7-bit/10-bit address format select) in SARy (y = 0 to 2) to 0 (7-bit address format).
When transmitting the UDID (Unique Device Identifier), set the ICFER.SALE bit to 1 to enable the slave arbitration lost detection function.

44.4.10.1 SMBus Timeout Measurement

(1) Measuring timeout of slave device

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication.

- From START condition to STOP condition

To measure timeout for slave devices, measure the period from START condition detection to STOP condition detection with a timer such as TMR using a START condition detection interrupt (STI) and STOP condition detection interrupt (SPI) of the RIICHS. The measured timeout period must be within cumulative clock low extend time (slave device) ($T_{LOW:SEXT}$: 25 ms (max.)) of the SMBus standard.
If the time measured with the timer exceeds the detect clock low timeout ($T_{TIMEOUT}$: 25 ms (min.)) of the SMBus standard, the slave device must release the bus by writing 1 to the ICRCR.ISRST bit to perform an internal reset of the RIICHS. When an internal reset is performed, the RIICHS stops driving the bus for the SCLHSn pin and SDAHSn pin and make the SCLHSn/SDAHSn pin outputs high-impedance, which releases the bus.

(2) Measuring timeout of master device

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication.

- From START condition to acknowledgment bit
- Between acknowledgment bits
- From acknowledgment bit to STOP condition

To measure timeout for master devices, measure these periods with a timer such as TMR using a START condition detection interrupt (STI), STOP condition detection interrupt (SPI), and transmission end interrupt (TEI) or receive data full interrupt (RXI) of the RIICHS. The measured timeout period must be within the cumulative clock low extend time (master device) ($T_{LOW:MEXT}$: 10 ms (max.)) of the SMBus standard, and the total of all $T_{LOW:MEXT}$ from START condition to STOP condition must be within $T_{LOW:SEXT}$: 25 ms (max.).
For the ACK receive timing (rising edge of the ninth SCL), monitor the ICSR2.TEND flag in master transmit mode (master transmitter) and the ICCSR.RDRF flag in master receive mode (master receiver). For this reason, perform bytewise transmit operation in master transmit mode, and hold the ICCSCR.WAITAE bit 0 until the byte just before reception of the final byte in master receive mode. While the WAITAE bit is 0, the RDRF flag is set to 1 at the rising edge of the ninth SCL.
If the period measured with the timer exceeds the cumulative clock low extend time (master device) ($T_{LOW:MEXT}$: 10 ms (max.)) of the SMBus standard or the total of measured periods exceeds the detect clock low timeout ($T_{TIMEOUT}$: 25 ms (min.)) of the SMBus standard, the master device must stop the transaction by generating a STOP condition. In master transmit mode, immediately stop the transmit operation (writing data to ICDR register).

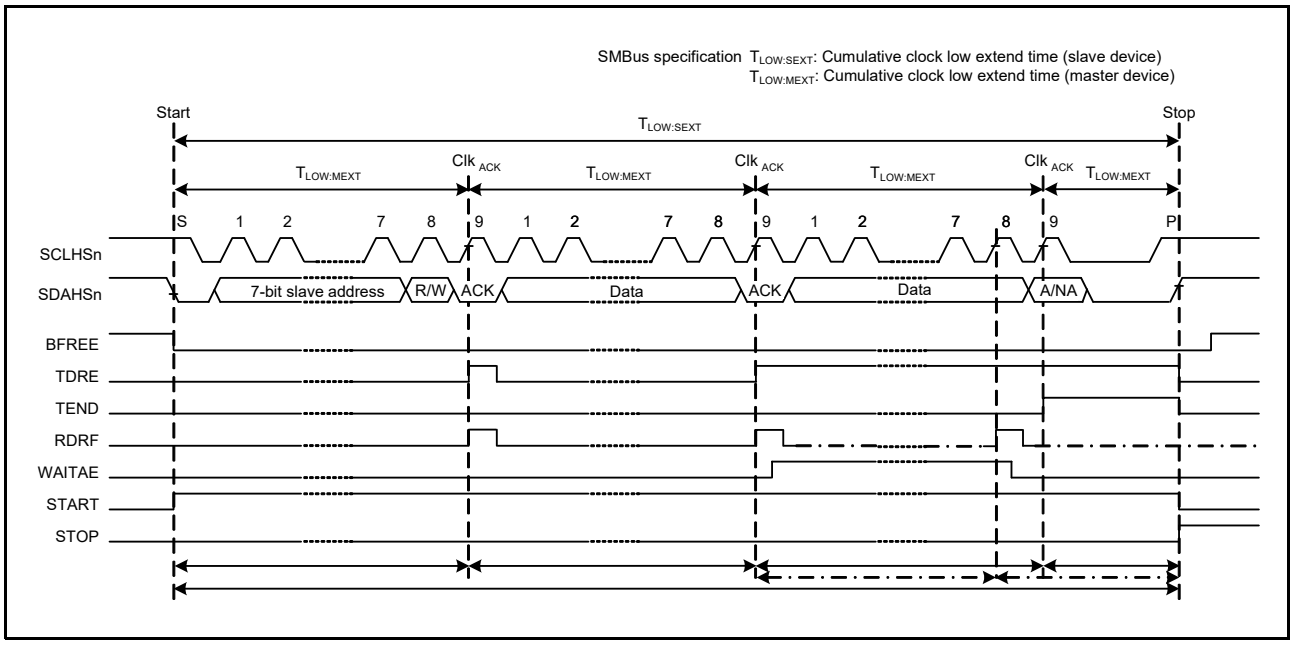

Figure 44.48 SMBus Timeout Measurement

44.4.10.2 Packet Error Code (PEC)

This MCU incorporates a CRC calculator. The CRC calculator enables transmission of a packet error code (PEC) or checking the received data of the SMBus in data communication of the RIICHS. For the CRC generating polynomials of the CRC calculator, refer to section 50, CRC Calculator (CRCA).

The PEC data in master transmit mode can be generated by writing all transmit data to the CRC data input register (CRCDIR) in the CRC calculator.

The PEC data in master receive mode can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC data output register (CRCDOR) with the received PEC data.

To send ACK or NACK according to the match or mismatch result when the final byte is received as a result of the PEC code check, set the ICCSCR.WAITAE bit to 1 before the rising edge of the eighth SCL during reception of the final byte, and hold the SCLHSn line low at the falling edge of the eighth clock pulse.

44.4.10.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of (or request the SMBus host for) its own slave address or to request its own slave address from the SMBus host.

For a product of the this MCU to operate as an SMBus host (or ARP master), the host address (0001 000b) sent from the slave device must be detected as a slave address, so the RIICHS has a function for detecting the host address. To detect the host address as a slave address, set the ICFER.SMBS bit and the ICSCR.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

44.5 Interrupt Sources

The RIICHS generates five types of interrupt requests, as shown in Table 44.7. The transmit data empty and receive data full interrupt requests allow the DTC or DMAC to start data transfer.

Table 44.7 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	Interrupt Enable Bit	Start DTC/DMA Transfer	Interrupt Generation Condition
TXI*1	Transmit data empty	ICCSR.TDRE	ICCSIER.TIE	Possible	TDRE = 1 and TIE = 1
RXI*2	Receive data full	ICCSR.RDRF	ICCSIER.RIE	Possible	RDRF = 1 and RIE = 1
TEI*3	Transmission end	ICSR2.TEND	ICSIER.TEIE	Not possible	TEND = 1 and TEIE = 1
EEI	Communication error/ communication event	ICSR2.START	ICSIER.STIE	Not possible	START = 1 and STIE = 1
		ICSR2.STOP	ICSIER.SPIE		STOP = 1 and SPIE = 1
		ICSR2.NACKF	ICSIER.NAKIE		NACKF = 1 and NAKIE = 1
		ICSR2.AL	ICSIER.ALIE		AL = 1 and ALIE = 1
		ICSR2.TMOF	ICSIER.TMOIE		TMOF = 1 and TMOIE = 1
WUI	Wake-up	ICSR2.WUDF	ICSIER.WUDIE	Not possible	WUDF = 1 and WUDIE = 1

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or an interrupt request has been masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt handling. Returning from interrupt handling without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

Note 1. Because TXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICCSR.TDRE flag (a condition for TXI) is automatically set to 0 when transmit data is written to the ICDR register or when a STOP condition is detected (ICSR2.STOP flag is 1).

Note 2. Because RXI is an edge-detected interrupted, it does not require clearing. Furthermore, the ICCSR.RDRF flag (a condition for RXI) is automatically set to 0 when data is read from the ICDR register.

Note 3. When using the TEI interrupt, clear the ICSR2.TEND flag in the TEI interrupt handling.
Note that the ICSR2.TEND flag is automatically set to 0 when transmit data is written to the ICDR register or when a STOP condition is detected (ICSR2.STOP flag is 1).

Clear each flag or mask the interrupt request during interrupt handling.

44.5.1 Buffer Operation for TXI and RXI Interrupts

If the conditions for generating a TXI or RXI interrupt is satisfied while the corresponding ICU.IRn.IR flag is 1, the interrupt request is not output to the ICU but retained internally (up to one request can be retained internally for each source).

When the IR flag becomes 0, the retained interrupt request is output to the ICU. The retained interrupt request is automatically cleared under normal conditions of usage.

The retained interrupt request can also be cleared by writing 0 to the corresponding interrupt enable bit in the ICCSIER register.

44.6 Event Link Function

The RIICHS outputs the corresponding event signal to the event link controller (ELC) when any of the following events occur.

- Transmit data empty
- Receive data full
- Transmission end
- Communication error/communication event

44.6.1 Interrupt Handling and Event Linking

Each of the RIICHS interrupts has an enable bit that controls whether the interrupt is enabled or disabled. When an interrupt request source occurs, an interrupt request signal is output to the ICU if the corresponding interrupt enable bit is 1.
On the other hand, the event signal is transmitted via the ELC to other modules when the corresponding interrupt request source occurs, regardless of the interrupt enable bit.
For details on interrupt sources, refer to Table 44.7.

44.8 Usage Notes

44.8.1 Settings of the Module Stop Function

RIICHS operation can be disabled or enabled by module stop control register B (MSTPCRB).
After a reset, the RIICHS is stopped. The registers become accessible when it is released from the module stop state. For details, refer to section 11, Low Power Consumption.

45. CAN FD Module with Gateway Functionality (CANFDG)

45.1 Overview

This MCU incorporates a single CAN FD module with gateway functionality (CANFDG0: CANFD0, CANFD1), each featuring two built-in CAN FD (Controller Area Network with Flexible Data Rate) controllers compliant with the ISO 11898-1:2015 standard.

Table 45.1 lists the specifications of the CANFDG module, and Figure 45.1 shows a block diagram of the CANFDG module.

Table 45.1 CANFDG Module Specifications

Item	Description
Protocol	ISO 11898-1:2015 compliant
Number of channels	Two channels
Gateway functionality	CAN 2.0 ↔ CAN 2.0 CAN 2.0 ↔ CAN FD (only when the payload size is 8 bytes)*1 CAN FD ↔ CAN FD*1
Data transfer rate	Arbitration phase: up to 1 Mbps Data phase: up to 8 Mbps individually for each CAN channel*1, *2
Operating frequency*3	Register block: up to 150 MHz (PCLKA) Message buffer RAM: up to 300 MHz (PCLKE)
Operating clock for data link layer (DLL clock)	Up to 80 MHz (either CANFDMCLK or CANFDCLK can be selected)
Frame types	Classic CAN (CAN 2.0) • Data frame in base format (11-bit ID) • Data frame in extended format (29-bit ID) • Remote frame in base format (11-bit ID) • Remote frame in extended format (29-bit ID) CAN FD*1 • Data frame in base format (11-bit ID) • Data frame in extended format (29-bit ID)
Data length	Classic CAN: 0 to 8 bytes CAN FD*1: 0 to 8, 12, 16, 20, 24, 32, 48, or 64 bytes
Message buffers	• 32 receive message buffers, shared among all CAN channels • 16 transmit message buffers per channel • Four transmit queue per channel Messages can be automatically transferred to the transmit queue.
FIFOs	Variable size FIFO buffers • Eight receive FIFOs • Six common FIFOs, each of which can be configured as a receive FIFO, transmit FIFO, or gateway FIFO
Automatic transmission interval adjustment	Available when the common FIFO is configured as a transmit FIFO or a gateway FIFO The interval between messages sent from the FIFO can be adjusted.
Acceptance filter	Filterable in the following fields: • IDE bit (base format, extended format, or both) • ID field • RTR bit (data frame or remote frame) (only for Classic CAN) • DLC field (data length) Protection function when the payload size is exceeded Acceptance filter list (AFL) entries can be updated during communication.
Software support	Label information is automatically added to received messages
Timer	Transmission and reception timestamp function
Power down function	Module start/stop function for CAN node (CH_SLEEP and GL_SLEEP mode) Transition to module stop state is possible.
RAM	RAM with ECC protection
Bus traffic measurement	CAN bus traffic measurement of each channel is possible
Protect Zone filter	Security attribute can be set for each module.*4

Note 1. This is only available for products that support the CAN FD protocol.
Note 2. The bit rate for communications depends on the board design and external environment. Determine it following sufficient evaluation.
Note 3. The frequency ratio of PCLKE and PCLKA should be 2 : 1. Also, the frequency of PCLKA should be equal to or higher than that of the DLL clock.
Note 4. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

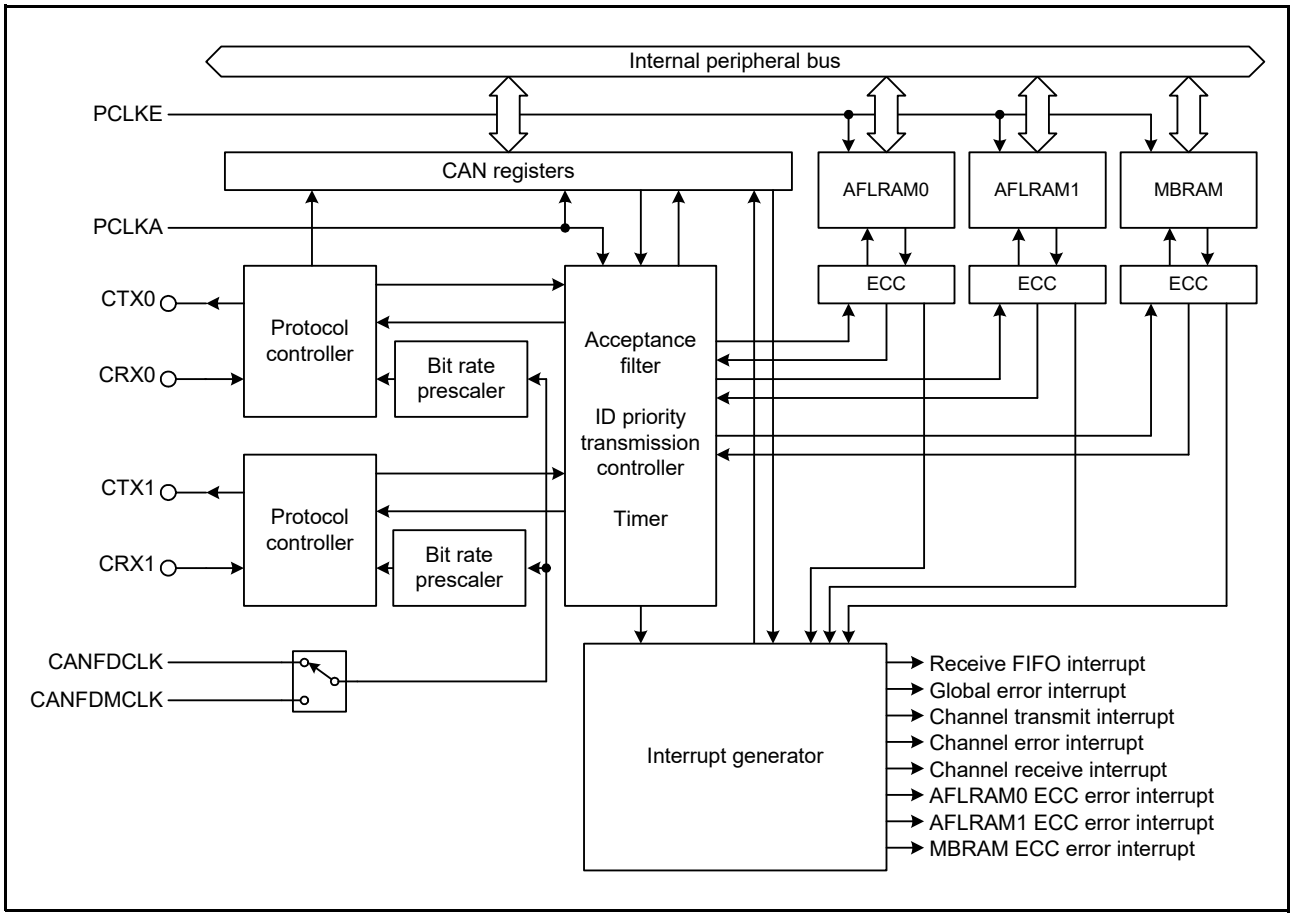

Figure 45.1 CANFDG Module Block Diagram

- CRXi, CTXi (i = 0, 1)
  I/O pins of the CAN FD controller
- Protocol controller
  Handles CAN FD protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, error handling, etc.
- Acceptance filter list RAM (AFLRAM0, AFLRAM1)
  Dedicated RAMs to storing the acceptance filter list entries. Each entry contains comparison information for filtering received messages and a destination for messages that match the filter. To accelerate the acceptance filter processing, two acceptance filter list RAMs are provided.
- Message buffer RAM (MBRAM)
  Used for message buffers or FIFOs for transmitting and receiving messages. Each entry has an individual identifier, data length code, a data field, a message pointer for upper layer application, and a timestamp.
- Acceptance filter
  Performs filtering of received messages. The entries configured in the acceptance filter list are used for the filtering process.

- Timers
  Two timers: one used for the receive timestamp function and the other for adjusting the message transmission interval from the transmit FIFO.

Table 45.2 lists the pin configuration of the CANFDG module.

Table 45.2 CANFDG Module Pin Configuration

Pin Name	I/O	Function
CRX0	Input	Receive data input
CTX0	Output	Transmit data output
CRX1	Input	Receive data input
CTX1	Output	Transmit data output

45.2 Register Descriptions

45.2.1 Nominal Bit Rate Configuration Register (NBCR)

Address(es): CANFD0.NBCR 8748 0000h, CANFD1.NBCR 8748 0010h,
CANFD0_NS.NBCR 0748 0000h, CANFD1_NS.NBCR 0748 0010h

	TSEG2[6:0]							TSEG1[7:0]								SJW[6]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SJW[5:0]						BRP[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	BRP[9:0]	Bit Rate Prescaler Setting	000h: No division 001h: Divided by 2 : : 3FEh: Divided by 1023 3FFh: Divided by 1024	R/W
b16 to b10	SJW[6:0]	Resynchronization Jump Width Control	00h: 1 Tq 01h: 2 Tq : : 7Eh: 127 Tq 7Fh: 128 Tq	R/W
b24 to b17	TSEG1[7:0]	Time Segment 1 Control	00h: Setting prohibited 01h: 2 Tq 02h: 3 Tq 03h: 4 Tq : : FEh: 255 Tq FFh: 256 Tq	R/W
b31 to b25	TSEG2[6:0]	Time Segment 2 Control	00h: Setting prohibited 01h: 2 Tq 02h: 3 Tq : : 7Eh: 127 Tq 7Fh: 128 Tq	R/W

This register is used to set the nominal bit rate during transmission and reception of the corresponding channel.
The value cannot be changed in CH_OPERATION or CH_SLEEP mode. Rewrite this register in CH_RESET or CH_HALT mode.
For details on the setting values, refer to section 45.4.1.2, Bit Timing.

BRP[9:0] Bits (Bit Rate Prescaler Setting)

These bits are used to define a period of 1 Tq (Time Quantum) that is the basis for CAN communication. Set the division ratio for the operating clock of the data link layer (DLL clock) selected by the GCFG.DLLCS bit. If the set value is n, the bit rate prescaler divides the DLL clock by n + 1.

SJW[6:0] Bits (Resynchronization Jump Width Control)

These bits are used to specify the resynchronization jump width with a Tq value. A value from 1 to 128 Tq can be set. Set a value less than or equal to that of the TSEG2[6:0] bits.

TSEG1[7:0] Bits (Time Segment 1 Control)

These bits are used to specify the total value (TSEG1) of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1) with a Tq value. A value from 2 to 256 Tq can be set.

TSEG2[6:0] Bits (Time Segment 2 Control)

These bits are used to specify the value (TSEG2) of the phase buffer segment 2 (PHASE_SEG2) with a Tq value. A value from 2 to 128 Tq can be set. Set a value less than that of the TSEG1[7:0] bits.

45.2.2 Channel Control Register (CHCR)

Address(es): CANFD0.CHCR 8748 0004h, CANFD1.CHCR 8748 0014h,

Note 1. Set this bit in CH_OPERATION mode.
Note 2. Rewrite these bits in CH_RESET mode.
Note 3. Do not set this bit to 1 in Classic Only mode.
Note 4. Set this bit in CH_RESET or CH_HALT mode.
Note 5. Set these bits in CH_HALT mode.

This register controls the modes of the corresponding channel. It is also used to enable interrupt generation when an error is detected on the CAN bus and to set the test mode.
In CH_SLEEP mode, values other than the SLPRQ bit cannot be changed.

MDC[1:0] Bits (Channel Mode Control)

The MDC[1:0] bits are used to specify the mode of the CAN channel. For the CAN mode transition, refer to section 45.3.2, Channel Modes.
When the CANFDG module is in GL_HALT mode, these bits can only be set to 10b (CH_HALT mode) or 01b (CH_RESET mode).
These bits automatically become 10b when the mode is changed to CH_HALT mode by the setting of the CHCR.BOM[1:0] bits.
When writing to these bits and transition to CH_HALT mode (at the entry to bus-off state when the CHCR.BOM[1:0] bits are 01b, and at the end of bus-off state when the CHCR.BOM[1:0] bits are 10b) occur at the same time, priority is given to writing from the CPU. The value of these bits are automatically updated only if the above event occurs when these bits are 00b (CH_OPERATION mode).

SLPRQ Bit (CH_SLEEP Mode Request)

This bit is used to control the transition to CH_SLEEP mode and the return from CH_SLEEP mode.
Setting this bit to 1 in CH_RESET mode requests the channel to transition to CH_SLEEP mode. Setting this bit to 0 in CH_SLEEP mode requests the channel to transition to CH_RESET mode. These bits cannot be changed in other modes.

RTBO Bit (Forced Recovery from Bus-Off)

This bit is used to forcibly recover from the bus-off state. Use this bit only when the CHCR.BOM[1:0] bits are 00b.
This bit is automatically set to 0 after being set to 1. The read value is always 0.
When this bit is set to 1 during bus-off state, the channel transitions from bus-off state to integrating state within 1 bit time. Also the CHSR.REC[7:0] and TEC[7:0] bits are set to 00h and the CHSR.BOST flag is set to 0. Other registers and

bits do not change. In this case, even if the bus-off recovery interrupt is enabled, the bus-off recovery interrupt does not generated.
If this bit is set to 1 except in the bus-off state, nothing occurs.

BEIE Bit (Bus Error Interrupt Enable)

When the CHESR.BEDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

EWIE Bit (Error Warning Interrupt Enable)

When the CHESR.EWDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

EPIE Bit (Error Passive Interrupt Enable)

When the CHESR.EPDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

BOEIE Bit (Bus-Off Entry Interrupt Enable)

When the CHESR.BOEDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

BORIE Bit (Bus-Off Recovery Interrupt Enable)

When the CHESR.BORDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

OLIE Bit (Overload Interrupt Enable)

When the CHESR.OLDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

BLIE Bit (Bus Lock Interrupt Enable)

When the CHESR.BLDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

ALIE Bit (Arbitration Lost Interrupt Enable)

When the CHESR.ALDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

TAIE Bit (Transmission Abort Interrupt Enable)

When the transmission from the transmit message buffer is successfully aborted while this bit is 1, a channel transmit interrupt request is generated.

ECOVIE Bit (Error Occurrence Counter Overflow Interrupt Enable)

When the FDSTS.ECOV flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

SCOVIE Bit (Success Occurrence Counter Overflow Interrupt Enable)

When the FDSTS.SCOV flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

TDCVIE Bit (Transceiver Delay Compensation Violation Interrupt Enable)

When the FDSTS.TDCV flag is set to 1 while this bit is 1, a channel error interrupt request is generated. Do not set this bit to 1 in Classic only mode.

BOM[1:0] Bits (Bus-Off Recovery Mode Select)

These bits control the recovery timing from the bus-off state.

EDM Bit (Error Display Mode Select)

This bit controls the indication mode of the error flags (b14 to b8) in the CHESR register.
When this bit is 0, only the flag corresponding to the first error detected becomes 1. If multiple errors are detected at the

same time, all corresponding flags become 1. The other flags do not become 1 until all the flags in b14 to b8 have been cleared.
When this bit is 1, the error flags are updated each time an error is detected.

CTME Bit (Channel Test Mode Enable)

This bit is used to enable the channel test mode.
When the channel transitions to CH_RESET mode, this bit becomes 0.

CTMS[1:0] Bits (Channel Test Mode Select)

These bits are used to select the test mode.
When the channel transitions to CH_RESET mode, these bits become 00b.

BFT Bit (Bit Flip Test)

This bit is used to check the CRC generator in the protocol controller.
Setting this bit to 1 inverts the first bit of the message data stream (ID bit) so that the result of the internally generated CRC does not match the received CRC value.
Note that as a result of bit inversion, a stuff error may be detected instead of a CRC error. Refer to the bit stuffing rule when using this function.
The CRC value generated internally can be checked in the following bits.

- The CHESR.CRC15[14:0] bits (for Classical CAN frames)
- The FDCRC.CRC21[20:0] bits (for CAN FD frames)

When using the BFT bit, it is necessary to have another CAN nodes transmit a reference message.

Note: Since the transmit and receive modes share the same CRC generator, there is no need to test for CRC errors in transmit mode separately.

Bit flip test mode is enabled when both the BFT and CTME bits are 1 and the CTMS[1:0] bits are 00b (basic test mode).
Using this function on the transmitter node causes a bit error or arbitration lost.
When the channel transitions to CH_RESET mode, this bit becomes 0.

ROME Bit (Restricted Operation Mode Enable)

When both this bit and the CTME bit are 1, the limited operation mode is enabled. Use this mode only in basic test mode (CTMS[1:0] bits = 00b). Also, do not set this bit to 1 in Classic only mode.
When the channel transitions to CH_RESET mode, this bit becomes 0.

45.2.3 Channel Status Register (CHSR)

Address(es): CANFD0.CHSR 8748 0008h, CANFD1.CHSR 8748 0018h,
CANFD0_NS.CHSR 0748 0008h, CANFD1_NS.CHSR 0748 0018h

b7	CRDY	Communication Ready Flag	0: Channel is not ready for communication 1: Channel is ready for communication	R
b8	RESI	Receive ESI Flag*1	0: No message with ESI flag set to 1 was received. 1: At least 1 message with ESI flag set to 1 was received.	R/(W) *2
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	REC[7:0]	Reception Error Count	These bits increment or decrement the counter value according to error status of the CAN channel during reception.	R
b31 to b24	TEC[7:0]	Transmission Error Count	These bits increment or decrement the counter value according to error status of the CAN channel during transmission.	R

Note 1. This flag can be set to 0 only in CH_OPERATION or CH_HALT mode.
Note 2. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the mode, error and transmission or reception status of the related CAN channel together with its reception and transmission error count values.

RSTST Flag (CH_RESET Status Flag)

The RSTST flag indicates whether the related CAN channel is in CH_RESET mode.
This flag is automatically set to 1 when the related CAN channel enters CH_RESET mode, and is automatically set to 0 when the related CAN channel exits CH_RESET mode. When the mode is changed from CH_RESET mode to CH_SLEEP mode, the RSTST flag remains 1.

HLTST Flag (CH_HALT Status Flag)

The HLTST flag indicates whether the related CAN channel is in CH_HALT mode.
This flag is automatically set to 1 when the related CAN channel enters CH_HALT mode, and is automatically set to 0 when the related CAN channel exits CH_HALT mode.

SLPST Flag (CH_SLEEP Status Flag)

The SLPST flag indicates whether the related CAN channel is in CH_SLEEP mode.
This flag is automatically set to 1 when the related CAN channel enters CH_SLEEP mode, and is automatically set to 0 when the related CAN channel exits CH_SLEEP mode.

EPST Flag (Error Passive Status Flag)

The EPST flag indicates whether the related CAN channel has entered the error passive state.
This flag is automatically set to 1 when the value of the REC[7:0] or TEC[7:0] bits exceeds 127.
This flag is automatically set to 0 when the related CAN channel exits the error passive state or enters CH_RESET mode.

BOST Flag (Bus-Off Status Flag)

The BOST flag indicates whether the related CAN channel has entered the bus-off state.
This flag is automatically set to 1 when the value of the TEC[7:0] bits exceeds 255 and the related CAN channel is in the bus-off state.
This flag is automatically set to 0 when the related CAN channel exits bus-off state.

TRMST Flag (Transmit Status Flag)

The TRMST flag indicates whether the related CAN channel is transmitting a message.
This flag is automatically set to 1 when the related CAN channel is operating as a transmitter node or is in the bus-off state, and is automatically set to 0 when the related CAN channel is in the idle state or starts operating as a receiver node.

RECST Flag (Receive Status Flag)

The RECST flag indicates whether the related CAN channel is receiving a message.
This flag is automatically set to 1 when the related CAN channel is operating as a receiver node, and is automatically set to 0 when the related CAN channel is in the idle state or starts operating as a transmitter node.

CRDY Flag (Communication Ready Flag)

The CRDY flag indicates whether the related CAN channel is ready for communication.
This flag is automatically set to 1 when the related CAN channel is ready to perform communication following the detection of 11 consecutive recessive bits after exiting CH_RESET or CH_HALT mode.
This flag is automatically set to 0 when the related CAN channel enters CH_RESET or CH_HALT mode.

Note: This flag is 1 in the bus-off state.

RESI Flag (Receive ESI Flag)

The RESI flag is set to 1 when the ESI bit is sampled recessively for a received message without any error. When in loop-back or mirror mode, the self-transmitted messages are considered reception messages.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is cleared by writing 0 to it. This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode.
Do not use the bit clear instruction to clear this flag. Set only this flag to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

REC[7:0] Bits (Reception Error Count)

The REC[7:0] bits indicate the value of the reception error counter.
The value in bus-off state is indeterminate.
These bits are automatically set to 00h when the CANFDG module enters GL_RESET or the CAN channel enters CH_RESET mode.

TEC[7:0] Bits (Transmission Error Count)

The TEC[7:0] bits indicate the value of the transmission error counter.
These bits are automatically set to 00h when CANFDG module enters GL_RESET or CAN channel enters CH_RESET mode.

45.2.4 Channel Error Status Register (CHESR)

Address(es): CANFD0.CHESR 8748 000Ch, CANFD1.CHESR 8748 001Ch,
CANFD0_NS.CHESR 0748 000Ch, CANFD1_NS.CHESR 0748 001Ch

b14	ADEDF	ACK Delimiter Error Detect Flag*1	0: Acknowledge delimiter error is not detected 1: Acknowledge delimiter error is detected	R/(W) *2
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b30-b16	CRC15[14:0]	CRC_15 Test	These bits show the CRC_15 value calculated for the CAN2.0 CAN frame.	R
b31	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. This flag can be set to 0 only in CH_OPERATION or CH_HALT mode.
Note 2. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the status of various error conditions detectable regardless of the interrupt enable/disable setting of the Channel Control Register (CHCR). It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) for the conditions under which each error occurs.

Only a single bit can be cleared at a time. Do not use the bit clear instruction to clear the flag. Set only the flag to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

BEDF Flag (Bus Error Detect Flag)

The BEDF flag indicates a detection of an error state, flagged by b14 to b8 in this register.
This flag is automatically set to 1 when a bus error is detected, and is automatically set to 0 when the related CAN channel enters CH_RESET mode.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

EWDF Flag (Error Warning Detect Flag)

The EWDF flag indicates whether an error warning condition has been detected for the CAN channel.
This flag is automatically set to 1 when the value of either the CHSR.TEC[7:0] or REC[7:0] bits exceeds 95.
The setting of this flag only occurs when the value of the TEC[7:0] or REC[7:0] bits initially exceeds 95. Therefore, if the TEC[7:0] or REC[7:0] bits remains > 95 and the EWDF flag is cleared by software, it is not set to 1 again until the value of both the TEC[7:0] and REC[7:0] bits go below 96 and either TEC[7:0] or REC[7:0] bits crosses over again from a value ≤ 95 to a value > 95.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. It is automatically set to 0 when the related CAN channel enters CH_RESET mode.

EPDF Flag (Error Passive Detect Flag)

The EPDF flag indicates a detection of a CAN channel error passive state.
This flag is automatically set to 1 when the CAN error state becomes error passive state.
The setting of this flag only occurs when the value of either the CHSR.TEC[7:0] or REC[7:0] bits initially exceeds 127. Therefore, if the value of either the TEC[7:0] or REC[7:0] bits remains > 127 and the flag is cleared by software, it is not set to 1 again until the value of both the TEC[7:0] and REC[7:0] bits go below 128 and either TEC[7:0] or REC[7:0] bits crosses over again from a value ≤ 127 to a value > 127.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. It is automatically set to 0 when the related CAN channel enters CH_RESET mode.

BOEDF Flag (Bus-Off Entry Detect Flag)

The BOEDF flag indicates a detection of a CAN channel bus-off entry state.
This flag is automatically set to 1 when the CAN error state enters the bus-off state.
This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode. If a set condition occurs simultaneously with a clear condition, then the flag is set to 1.

BORDF Flag (Bus-Off Recovery Detect Flag)

The BORDF flag indicates a detection of a CAN channel bus-off recovery state.
This flag is automatically set to 1 if CAN channel recovers from bus-off state in the following conditions:

- When the CHCR.BOM[1:0] bits are 00b and normal recovery (128 occurrence of 11 consecutive recessive bits are detected) occurs
- When the CHCR.BOM[1:0] bits are 10b and normal recovery (128 occurrence of 11 consecutive recessive bits are detected) occurs
- When the CHCR.BOM[1:0] bits are 11b and normal recovery (128 occurrence of 11 consecutive recessive bits are detected) occurs.

The flag is not set to 1 if CAN channel recovers from bus-off state in the following conditions:

- When the CH_RESET mode is requested
- When setting the CHCR.RTBO bit to 1 (the CAN channel returns to error active)
- When the CHCR.BOM[1:0] bits are 01b

- When the CHCR.BOM[1:0] bits are 11b and a halt request is asserted before the CAN channel reaches the end of the bus-off state.

This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode. If a set condition occurs simultaneously with a clear condition, the flag is set to 1.

OLDF Flag (Overload Detect Flag)

The OLDF flag indicates a detection of a CAN channel overload state.
This flag is automatically set to 1 when an overload condition is detected. If a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode.

BLDF Flag (Bus Lock Detect Flag)

The BLDF flag indicates a detection of a CAN channel bus lock condition.
This flag is automatically set to 1 when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in CH_OPERATION mode.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode.

ALDF Flag (Arbitration Lost Detect Flag)

The ALDF flag indicates a detection of a CAN channel bus arbitration lost condition.
The flag is automatically set to 1 when an arbitration lost condition is detected on the CAN bus while the CAN channel is in CH_OPERATION mode.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode.

SEDF Flag (Stuff Error Detect Flag)

The SEDF flag indicates a detection of a CAN stuff error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a stuff error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

FEDF Flag (Form Error Detect Flag)

The FEDF flag indicates a detection of a CAN form error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a form error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

AEDF Flag (Acknowledge Error Detect Flag)

The AEDF flag indicates a detection of a CAN acknowledge error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.

This flag is automatically set to 1 when an acknowledge error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

CEDF Flag (CRC Error Detect Flag)

The CEDF flag indicates a detection of a CAN CRC error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a CRC error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

B1EDF Flag (Bit 1 Error Detect Flag)

The B1EDF flag indicates a detection of a recessive bit error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a recessive bit error (expected recessive bit, sampled as dominant bit) is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

B0EDF Flag (Bit 0 Error Detect Flag)

The B0EDF flag indicates a detection of a dominant bit error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a dominant bit error (expected dominant bit, sampled as recessive bit) is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

ADEDF Flag (ACK Delimiter Error Detect Flag)

The ADEDF flag indicates a detection of an acknowledge delimiter bit error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a form error is detected during the acknowledge delimiter state of frame transmission. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the related CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

CRC15[14:0] Bits (CRC_15 Test)

The CRC15[14:0] bits indicate the calculated CRC_15 value when the CHCR.CTME bit is 1 (channel test mode enabled). If the CHCR.CTME bit is 0, then these bits are always read as 0000h.
The CRC_15 value which is read from these bits show the CAN2.0 CRC value calculated by the CAN channel logic.
The value of the CRC15[14:0] bits is updated in the first bit of the CRC field of the Classical CAN frame.
These bits are automatically set to 0000h when the related CAN channel enters CH_RESET mode.

45.2.5 Data Bit Rate Configuration Register (DBCR)

Address(es): CANFD0.DBCR 8748 1400h, CANFD1.DBCR 8748 1420h,
CANFD0_NS.DBCR 0748 1400h, CANFD1_NS.DBCR 0748 1420h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	SJW[3:0]				—	—	—	—	TSEG2[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	TSEG1[4:0]					BRP[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	BRP[7:0]	Bit Rate Prescaler Setting	00h: No division 01h: Divided by 2 : : FEh: Divided by 255 FFh: Divided by 256	R/W
b12 to b8	TSEG1[4:0]	Time Segment 1 Control	00h: Setting prohibited 01h: 2 Tq 02h: 3 Tq 03h: 4 Tq : : 1Eh: 31 Tq 1Fh: 32 Tq	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b19 to b16	TSEG2[3:0]	Time Segment 2 Control	0h: Setting prohibited 1h: 2 Tq : : Eh: 15 Tq Fh: 16 Tq	R/W
b23 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b24	SJW[3:0]	Resynchronization Jump Width Control	0h: 1 Tq 1h: 2 Tq : : Fh: 16 Tq	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Set this register in CH_RESET or CH_HALT mode.

This register configures the transmission/reception data bit rate parameters of the corresponding channel.
In Classic only mode, there is no need to configure this register.

BRP[7:0] Bits (Bit Rate Prescaler Setting)

The BRP[7:0] bits define the number of the DLL clock contained in 1 Tq (Time Quantum).

TSEG1[4:0] Bits (Time Segment 1 Control)

The TSEG1[4:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. A value from 2 to 32 Tq can be set.
The TSEG1[4:0] bits are also used to set the propagation time segment.
Do not write any other value to these bits. Refer to section 45.4.1.2, Bit Timing for more details.

TSEG2[3:0] Bits (Time Segment 2 Control)

The TSEG2[3:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. A

value from 2 to 16 Tq can be set.
Do not write any other value to these bits.

SJW[3:0] Bits (Resynchronization Jump Width Control)

The SJW[3:0] bits set the resynchronization jump width. A value from 1 to 16 Tq can be set.

45.2.6 CAN FD Configuration Register (FDCFG)

Address(es): CANFD0.FDCFG 8748 1404h, CANFD1.FDCFG 8748 1424h,
CANFD0_NS.FDCFG 0748 1404h, CANFD1_NS.FDCFG 0748 1424h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	CLOE	REFE	FDOE	—	GWBRS	GWFDF	GWEN	TDCO[7:0]							
Value after reset:	0	0/1*1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	TESI	TDCE	SSPC	—	—	—	—	—	ECC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	ECC[2:0]	Error Occurrence Counter Configuration*2	b2 b0 0 0 0: All CAN transmitter or receiver frames 0 0 1: All CAN transmitter frames 0 1 0: All CAN receiver frames 0 1 1: Setting prohibited 1 0 0: Only transmitter or receiver CAN FD data-phase (high-speed bits) 1 0 1: Only transmitter CAN FD data-phase (high-speed bits) 1 1 0: Only receiver CAN FD data-phase (high-speed bits) 1 1 1: Setting prohibited	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	SSPC	Secondary Sample Point Configuration*2	0: Measured + offset 1: Offset-only	R/W
b9	TDCE	Transceiver Delay Compensation Enable*2	0: Transceiver delay compensation is disabled 1: Transceiver delay compensation is enabled	R/W
b10	TESI	Transmit ESI Configuration*2	0: The ESI flag in the transmission frame reflects the error status of the node itself. 1: The ESI flag in the transmission frame reflects the ESI bit in the message buffer if the node is not error passive, and the error status of the node itself If the node is error passive.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	TDCO[7:0]	Transceiver Delay Compensation Offset*2	Sets the offset value for the transceiver delay compensation	R/W
b24	GWEN	Gateway Function Enable*3	0: Gateway function is disabled 1: Gateway function is enabled	R/W
b25	GWFDF	Gateway FDF Configuration*3	0: Forwarded messages are translated into Classical CAN frames. 1: Forwarded messages are translated into CAN FD frame.	R/W
b26	GWBRS	Gateway BRS Configuration*3	0: Messages are forwarded with the BRS bit set to 0. 1: Messages are forwarded with the BRS bit set to 1.	R/W
b27	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b28	FDOE	FD Only Mode Enable*3	0: FD only mode is disabled 1: FD only mode is enabled	R/W
b29	REFE	Receive Edge Filter Enable*3	0: Reception edge filter is disabled 1: Reception edge filter is enabled	R/W
b30	CLOE	Classic Only Mode Enable*3, *4	0: Classic only mode is disabled 1: Classic only mode is enabled	R/W
b31	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. The value after reset is 0 for products that support the CAN FD protocol, and 1 for products that support only CAN 2.0 protocol.

Note 2. Set these bits in CH_RESET or CH_HALT mode.
Note 3. Set these bits in CH_RESET mode.
Note 4. This bit can only be written for products that support the CAN FD protocol. For products that support only CAN 2.0 protocol, this bit is reserved and fixed to 1.

This register configures which communication direction (transmitter/receiver) errors are counted.

ECC[2:0] Bits (Error Occurrence Counter Configuration)

The ECC[2:0] bits select which type of CAN frame the protocol errors should be counted for.

SSPC Bit (Secondary Sample Point Configuration)

The SSPC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CAN channel. If the bit is 0, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1, the position of the SSP is defined only by the offset.
Do not set this bit to 1 in Classic only mode.

TDCE Bit (Transceiver Delay Compensation Enable)

The TDCE bit enables the transceiver delay compensation for the CAN channel.
Do not set this bit to 1 in Classic only mode.

TESI Bit (Transmit ESI Configuration)

The TESI bit selects whether to reflect the error status of the node itself or the value of the ESI bit in the message buffer (CFBn.HF2.ESI bit or TMBn.HF2.ESI bit) in the ESI flag of the transmit message.
When the gateway function is used, the ESI flag in the CAN FD message to be forwarded must be sent with the same value as the original message, regardless of the status of the gateway, bridge, or router.
Do not set this bit to 1 in Classic only mode.

TDCO[7:0] Bits (Transceiver Delay Compensation Offset)

The TDCO[7:0] bits set the offset of the secondary sample point. How this value is used, depends on the SSPC setting. If the SSPC bit is 0, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in the TDCO[7:0] bits, rounded down to the nearest integer number of Tq. Otherwise, the result is equal to the value in the TDCO[7:0] bits. Refer to section 45.4.1.5, Transceiver Delay Compensation for details.
The actual offset value is interpreted as TDCO[7:0] + 1. For example, if 4 is set in TDCO[7:0], the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.
Do not set to these bits in Classic only mode.

GWEN Bit (Gateway Function Enable)

When the GWEN bit is set to 1, the gateway function is enabled.
Configure the common FIFO as gateway FIFO mode (CFCRn.MODE[1:0] bits = 10b) or configure the transmit queue as gateway mode.
The FDF and BRS bits of the message to be forwarded can be specified by the GWFDF and GWBRS bits.

Example:

When the GWEN bit is 1 and the GWFDF bit is 1 on channel 1:
If a Classical CAN frame is received on channel 0 and forwarded to channel 1, this CAN frame is sent as a CAN FD frame by the GWFDF bit.

Table 45.3 shows the received message and converted message corresponding to each bit setting.

Table 45.3 Bit Settings and Message Conversion

Received Message			Value of the GWFDF bit	Forwarded Message		
Frame type	DLC	BRS		DLC	BRS	Frame type
CAN2.0	0 to 8	N/A	1	No changes	Value of the GWBRS bit	CAN FD
CAN2.0	9 to 15	N/A	1	8	Value of the GWBRS bit	CAN FD
CAN FD	0 to 8	Any value	1	No changes	Value of the GWBRS bit	CAN FD
CAN FD	9 to 15	Any value	1	No changes	Value of the GWBRS bit	CAN FD
CAN2.0	0 to 8	N/A	0	No changes	N/A	CAN2.0
CAN2.0	9 to 15	N/A	0	No changes	N/A	CAN2.0
CAN FD	0 to 8	Any value	0	No changes	N/A	CAN2.0
CAN FD	9 to 15	Any value	0	8	N/A	CAN2.0

Note that for different frame types, the payload size is limited to 8 bytes. If the frame type of the received message and the forwarded message are the same, the DLC value remains unchanged.
If a CAN FD frame with a payload size greater than 8 bytes is routed to a Classical CAN node, only the first 8 bytes of data are forwarded and the remaining data is discarded.
When routing a Classical CAN frame with the DLC value greater than 8, the DLC value is changed to 8 at the destination CAN FD node.
Do not route remote frames when the GWEN bit is set to 1.
When the FDOE bit for the destination node is set to 1 (FD only mode is enabled), set both the GWEN and GWFDF bits to 1.
When the CLOE bit for the destination node is set to 1 (Classic only mode is enabled), set the GWEN bit to 1 and the GWFDF bit to 0.

GWFDF Bit (Gateway FDF Configuration)

When the GWEN bit is set to 1, the FDF bit of the transmitted frame is replaced by the value of the GWFDF bit.
Do not set this bit to 1 in Classic only mode.

GWBRS Bit (Gateway BRS Configuration)

When the GWEN bit is set to 1, the BRS bit of the transmitted frame is replaced by the value of the GWBRS bit.
In Classical CAN frames, the BRS bit is not used.
Do not set this bit to 1 in Classic only mode.

FDOE Bit (FD Only Mode Enable)

The FDOE bit enables the transmission and reception of CAN FD frames only. If enabled, communication in Classical CAN frame format is disabled. The value of the FDF bit in the message buffer (CFBn.HF2.FDF bit or TMBn.HF2.FDF bit) is arbitrary because transmission of Classical CAN frames is not possible.
If messages with Classical CAN frame format are received, the protocol controller treats them as invalid frames and responds with error frames. If a Classical CAN frame is configured for transmission, the FDF bit is transmitted recessive, therefore a CAN FD frame is transmitted. If the data length code (DLC) is configured to be 9 bytes or more, the remaining data bytes are padded with CCh.
Do not set the FDOE and CLOE bits to 1 simultaneously.

REFE Bit (Receive Edge Filter Enable)

The REFE bit enables the reception edge filter during the integrating state. When this bit is 1, two or more consecutive dominant Tq are required to detect an edge for hard synchronization.
Do not set this bit to 1 in Classic only mode.

CLOE Bit (Classic Only Mode Enable)

The CLOE bit enables the Classic only mode. If this bit is set to 1, the protocol controller can only transmit Classical CAN frames and responds to CAN FD frames with a form error or CRC error.
Do not set the CLOE and FDOE bits to 1 simultaneously.

Table 45.4 Operation Mode Configuration

CLOE bit	FDOE bit	Operation mode
0	0	CAN FD mode
0	1	FD only mode
1	0	Classic only mode
1	1	Setting prohibited

45.2.7 CAN FD Control Register (FDCTR)

Address(es): CANFD0.FDCTR 8748 1408h, CANFD1.FDCTR 8748 1428h,
CANFD0_NS.FDCTR 0748 1408h, CANFD1_NS.FDCTR 0748 1428h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SCCL	ECCL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECCL	Error Occurrence Counter Clear	When 1 is written to this bit, the error occurrence counter is cleared. This bit is read as 0.	R/W
b1	SCCL	Success Occurrence Counter Clear	When 1 is written to this bit, the success occurrence counter is cleared. This bit is read as 0.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the error and success occurrence counters.

ECCL Bit (Error Occurrence Counter Clear)

The ECCL bit is used to clear the error occurrence counter.
This bit cannot be written in CH_SLEEP or CH_RESET mode.
This bit is automatically set to 0 and is also set to 0 when the CAN channel enters CH_RESET mode.

SCCL Bit (Success Occurrence Counter Clear)

The SCCL bit is used to clear the success occurrence counter.
This bit cannot be written in CH_SLEEP or CH_RESET mode.
This bit is automatically set to 0 and is also set to 0 when the CAN channel enters CH_RESET mode.

45.2.8 CAN FD Status Register (FDSTS)

Address(es): CANFD0.FDSTS 8748 140Ch, CANFD1.FDSTS 8748 142Ch,
CANFD0_NS.FDSTS 0748 140Ch, CANFD1_NS.FDSTS 0748 142Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SC[7:0]								EC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TDCV	—	—	—	—	—	SCOV	ECOV	TDCR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TDCR[7:0]	Transceiver Delay Compensation Result	Indicates the transceiver delay compensation result when the transceiver delay has been measured	R
b8	ECOV	Error Occurrence Counter Overflow Flag*1	0: Error occurrence counter has not overflowed 1: Error occurrence counter has overflowed	R/(W) *2
b9	SCOV	Success Occurrence Counter Overflow Flag*1	0: Success occurrence counter has not overflowed 1: Success occurrence counter has overflowed	R/(W) *2
b14 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	TDCV	Transceiver Delay Compensation Violation Flag*1	0: Transceiver delay compensation violation has not occurred 1: Transceiver delay compensation violation has occurred	R/(W) *2
b23 to b16	EC[7:0]	Error Occurrence Counter	These bits show the error occurrence counter value.	R
b31 to b24	SC[7:0]	Success Occurrence Counter	These bits show the success occurrence counter value.	R

Note 1. Set this flag to 0 only in CH_OPERATION or CH_HALT mode.
Note 2. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register indicates the transceiver compensation delay result and its related FIFO message lost status.

TDCR[7:0] Bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.
The measured delay is in cycles of the DLL clock. The result depends on the configuration of the FDCFG.SSPC bit and the offset value in the FDCFG.TDCO[7:0] bits. Refer to section 45.4.1.5, Transceiver Delay Compensation for details.
The TDCR[7:0] bits are updated at the falling edge between the FDF bit and res bit when the FDCFG.SSPC bit is 0 and the FDCFG.TDCE bit is 1 (transceiver delay compensation is enabled).
These bits are automatically set to 00h when the CAN channel enters CH_RESET mode.

ECOV Flag (Error Occurrence Counter Overflow Flag)

The ECOV flag indicates whether the CAN channel error occurrence counter has overflowed.
This flag is set to 1 if a CAN bus error specified in the FDCFG.ECC[2:0] bits is detected when the EC[7:0] bits are FFh.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

SCOV Flag (Success Occurrence Counter Overflow Flag)

The SCOV flag indicates whether the CAN channel success occurrence counter has overflowed.
This flag is set to 1 if a successful message reception or successful message transmission occurs when the SC[7:0] bits are FFh.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.
Do not use the bit clear instruction to clear this flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

TDCV Flag (Transceiver Delay Compensation Violation Flag)

The CANFDG module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.
The transceiver delay has some variations depending on the physical parameters such as temperature. The TDCR[7:0] bits are updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCV flag captures this violation.
This flag is set to 1 when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times – 2 DLL clocks) and the internal bit overruns.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.
Do not use the bit clear instruction to clear this flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

EC[7:0] Bits (Error Occurrence Counter)

The EC[7:0] bits are used together with the SC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.
This higher error rate can be detected depending on the configuration of the FDCFG.ECC[2:0] bits.
The EC[7:0] bits are set only by CANFDG module logic. These bits are cleared by writing 1 to the FDCTR.ECCL bit.
These bits are updated when an error occurs, according to the configuration of the FDCFG.ECC[2:0] bits. When the counter reaches the value of FFh, the update stops.
These bits are automatically set to 00h when the CAN channel enters CH_RESET mode.

SC[7:0] Bits (Success Occurrence Counter)

The SC[7:0] bits are used together with the EC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.
The SC[7:0] bits are set only by CANFDG module logic. These bits are cleared by writing 1 to the FDCTR.SCCL bit.
These bits are updated when the occurrence of any error-free messages on the bus is detected through reception or transmission. When the counter reaches the value of FFh, the update stops.
These bits are automatically set to 00h when the CAN channel enters CH_RESET mode.

Note: In loop-back mode, the counter is incremented twice.

45.2.9 CAN FD CRC Register (FDCRC)

Address(es): CANFD0.FDCRC 8748 1410h, CANFD1.FDCRC 8748 1430h,
CANFD0_NS.FDCRC 0748 1410h, CANFD1_NS.FDCRC 0748 1430h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	SBC[3:0]				—	—	—	CRC21[20:16]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CRC21[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b20 to b0	CRC21[20:0]	CRC_21 Test	These bits show the CRC_17 value or CRC_21 value calculated for the CAN FD frame.	R
b23 to b21	—	Reserved	These bits are read as 0.	R
b27 to b24	SBC[3:0]	Stuff Bit Counter	These bits shows the stuff bit count (Mod 8) for the CAN FD frame.	R
b31 to b28	—	Reserved	These bits are read as 0.	R

This register holds the CRC value calculated for the CAN FD frame.

CRC21[20:0] Bits (CRC_21 Test)

The calculated CRC_17 value or CRC_21 value can be read from these bits when the CHCR.CTME bit is 1 (channel test mode).
When the CHCR.CTME bit is 0, the CRC21[20:0] bits are read as 000000h.
The CRC21[20:0] bits is updated in the first bit of the CRC field of the CAN FD frame.
When the CRC_17 field is used, the CRC21[20:17] bits are read as 0.
These bits are automatically set to 000000h when the CAN channel enters CH_RESET mode.

SBC[3:0] Bits (Stuff Bit Counter)

The SBC[3:0] bits contain the stuff count value of the CAN FD frame. These bits indicate the number of inserted stuff bits (modulo 8, Gray-coded) for a CAN FD frame when the CHCR.CTME bit is enabled in SBC[3:1]. SBC[0] is the parity bit.
When the CHCR.CTME bit is 0, the SBC[3:0] bits are always read as 0000b.
The value of the SBC[3:0] bits is updated in the first bit of CRC field of the CAN FD frame. These bits are automatically set to 0000b when the CAN channel enters CH_RESET mode.

45.2.10 Global Configuration Register (GCFG)

Address(es): CANFDG0.GCFG 8748 0084h, CANFDG0_NS.GCFG 0748 0084h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ITP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

b3	MME	Mirror Mode Enable	0: Mirror mode is disabled 1: Mirror mode is enabled	R/W
b4	DLLCS	DLL Clock Select	0: CANFDCLK 1: CANFDMCLK	R/W
b5	OMRC	Payload-Overflowed Message Reception Configuration	0: The message is discarded. 1: The message payload is cut to fit the specified message size	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11 to b8	TSP[3:0]	Timestamp Counter Prescaler Setting	b11 b8 0 0 0 0: No division 0 0 0 1: Divide-by-2 (= 2^1) 0 0 1 0: Divide-by-4 (= 2^2) 0 0 1 1: Divide-by-8 (= 2^3) : : 1 1 0 1: Divide-by-8192 (= 2^{13}) 1 1 1 0: Divide-by-16384 (= 2^{14}) 1 1 1 1: Divide-by-32768 (= 2^{15})	R/W
b12	TSCS	Timestamp Counter Source Select	0: Clock source for timestamp counter is peripheral module clock (PCLKA) 1: Clock source for timestamp counter is bit time clock	R/W
b15 to b13	TSBTCS[2:0]	Bit Time Clock Select	b15 b13 0 0 0: Select the bit time clock of channel 0 0 0 1: Select the bit time clock of channel 1 Settings other than above are prohibited.	R/W
b31 to b16	ITP[15:0]	Interval Timer Prescaler Setting	FIFO interval timer prescaler value. Set the divided value for the peripheral module clock (PCLKA)	R/W

This register is used to select the transmission priority to be used for all the transmit message buffers and the clock source for the CAN protocol engine. The GCFG register is also used to select the source for the timestamp clock and to configure the frequency for the timestamp clock and interval timer reference clock.

TPRI Bit (Transmission Priority Setting)

The TPRI bit selects the transmission priority for the CAN channel.

This bit cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode. Do not select message buffer number priority when using the transmit queue.

DCE Bit (DLC Check Enable)

The DCE bit enables data length code (DLC) check for the CAN channel.
This bit cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode.

DRE Bit (DLC Replacement Enable)

When the DRE bit is 1 and the DCE bit is 1, the CANFDG module stores the configured value (AFLn.PTR0.DLC[3:0]) of the DLC in the destination receive message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination receive message buffer or FIFO buffer is unchanged.
This bit cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode.

MME Bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for the CAN channel.
This bit cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode.

DLLCS Bit (DLL Clock Select)

The DLLCS bit selects the clock source for CAN communication.
This bit cannot be written in GL_SLEEP or GL_OPERATION mode. Write to this bit only in GL_RESET mode.

OMRC Bit (Payload-Overflowed Message Reception Configuration)

The OMRC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size (RMCR.PLS[2:0], RFCRn.PLS[2:0], and CFCRn.PLS[2:0]). The received message payload is always compared with the available message payload size in the message buffer.
This bit cannot be written in GL_SLEEP or GL_OPERATION mode. Write to this bit only in GL_RESET mode.
When this bit is set to 1 and payload overflow occurs, the DLC value is stored in the receive message buffer or FIFO buffer unchanged.

TSP[3:0] Bits (Timestamp Counter Prescaler Setting)

The value configured in the TSP[3:0] bits defines the period of the clock source used for the timestamp counter.
These bits cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode.

TSCS Bit (Timestamp Counter Source Select)

The TSCS bit allows the selection of the clock source for the timestamp counter.
This bit cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode. Additionally, do not set this bit to 1 when CAN FD communication is used.

Note: The bit time clock varies depending on the nominal bit rate and data bit rate configuration.

TSBTCS[2:0] Bits (Bit Time Clock Select)

The TSBTCS[2:0] bits select which channel's bit time clock to use when the bit time clock is selected as the clock source for the timestamp counter (TSCS bit = 1).
These bits cannot be written in GL_SLEEP mode. Write to these bits only in GL_RESET mode.

ITP[15:0] Bits (Interval Timer Prescaler Setting)

The ITP[15:0] bits allow the definition of a reference clock for the FIFO interval timer clock source. When these bits are 0000h, the timer is disabled.
These bits cannot be written in GL_SLEEP mode. Write to these bits only in GL_RESET mode.

45.2.11 Global Control Register (GCR)

Address(es): CANFDG0.GCR 8748 0088h, CANFDG0_NS.GCR 0748 0088h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b1, b0	MDC[1:0]	Global Mode Control	b1 b0 0 0: Request transition to GL_OPERATION mode 0 1: Request transition to GL_RESET mode 1 0: Request transition to GL_HALT mode 1 1: Keep current value	R/W
b2	SLPRQ	GL_SLEEP Mode Request	0: Request to release GL_SLEEP 1: Request transition to GL_SLEEP	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	DEIE	DLC Error Interrupt Enable	0: DLC error interrupt is disabled 1: DLC error interrupt is enabled	R/W
b9	MLIE	Message Lost Interrupt Enable	0: Message lost interrupt is disabled 1: Message lost interrupt is enabled	R/W
b10	THLIE	Transmission History Entry Lost Interrupt Enable	0: Transmission history entry lost interrupt is disabled 1: Transmission history entry lost interrupt is enabled	R/W
b11	POIE	Payload Overflow Interrupt Enable	0: Payload overflow interrupt is disabled 1: Payload overflow interrupt is enabled	R/W
b13, b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	TQMLIE	Transmit Queue Message Lost Interrupt Enable	0: Transmit queue message lost interrupt is disabled 1: Transmit queue message lost interrupt is enabled	R/W
b15	CFOWIE	Common FIFO Message Overwrite Interrupt Enable	0: Common FIFO message overwrite interrupt is disabled 1: Common FIFO message overwrite interrupt is enabled	R/W
b16	TSCR	Timestamp Counter Reset	When 1 is written to this bit, the timestamp counter is reset. This bit is read as 0.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the Global mode of the CANFDG module and the timestamp function. The register also enables and disables the global error interrupts.

MDC[1:0] Bits (Global Mode Control)

The MDC[1:0] bits are used to specify the modes of the CANFDG module. For the mode transition of the CANFDG module, refer to section 45.3.1, Global Modes.

These bits cannot be written in GL_SLEEP mode.

To request the CANFDG module to transition to GL_SLEEP mode, first set these bits to 01b to enter GL_RESET mode, then set the GCR.SLPRQ bit to 1.

SLPRQ Bit (GL_SLEEP Mode Request)

The SLPRQ bit is used to control the transition to GL_SLEEP mode and the return from GL_SLEEP mode.

When this bit is set to 1, the transition to CH_SLEEP mode is also requested for all CAN channels.
This bit can only be written in GL_RESET or GL_SLEEP mode.

DEIE Bit (DLC Error Interrupt Enable)

When the DEIE bit is 1, an interrupt is generated if a DLC error is detected in the received frames.
This bit cannot be written in GL_SLEEP mode.

MLIE Bit (Message Lost Interrupt Enable)

When the MLIE bit is 1, an interrupt is generated if a message lost condition occurs.
This bit cannot be written in GL_SLEEP mode.

THLIE Bit (Transmission History Entry Lost Interrupt Enable)

When the THLIE bit is 1, an interrupt is generated if a transmission history entry lost condition occurs.
This bit cannot be written in GL_SLEEP mode.

POIE Bit (Payload Overflow Interrupt Enable)

When the POIE bit is 1, an interrupt is generated when a message payload overflow condition occurs.
This bit cannot be written in GL_SLEEP mode.

TQMLIE Bit (Transmit Queue Message Lost Interrupt Enable)

When the TQMLIE bit is 1, an interrupt is generated when a transmit queue message lost condition occurs.
This bit cannot be written in GL_SLEEP mode.

CFOWIE Bit (Common FIFO Message Overwrite Interrupt Enable)

When the CFOWIE bit is 1 and the common FIFO is configured for gateway FIFO mode, an interrupt is generated when a message in the common FIFO is overwritten.
This bit cannot be written in GL_SLEEP mode.

TSCR Bit (Timestamp Counter Reset)

When the TSCR bit is 1, the Timestamp Counter Register (TSCR) is reset to 00000000h.
This bit cannot be written in GL_SLEEP mode. Do not write to this bit in GL_RESET mode.
This bit is automatically set to 0.

45.2.12 Global Status Register (GSR)

Address(es): CANFDG0.GSR 8748 008Ch, CANFDG0_NS.GSR 0748 008Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	RAMST	SLPST	HLTST	RSTST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	RSTST	GL_RESET Status Flag	0: Not in GL_RESET mode 1: In GL_RESET mode	R
b1	HLTST	GL_HALT Status Flag	0: Not in GL_HALT mode 1: In GL_HALT mode	R
b2	SLPST	GL_SLEEP Status Flag	0: Not in GL_SLEEP mode 1: In GL_SLEEP mode	R
b3	RAMST	RAM Initialization Status Flag	0: RAM initialization is completed 1: RAM initialization is in progress	R
b31 to b4	—	Reserved	These bits are read as 0.	R

This register indicates the global status of the CANFDG module.

RSTST Flag (GL_RESET Status Flag)

The RSTST flag indicates the status of the CANFDG module in GL_RESET mode.
This flag is automatically set to 1 when the CANFDG module enters GL_RESET mode. When the mode changes from GL_RESET mode to GL_SLEEP mode, this bit remains 1. This flag is automatically set to 0 when the CANFDG module enters GL_HALT or GL_OPERATION mode.

HLTST Flag (GL_HALT Status Flag)

The HLTST flag indicates the status of the CANFDG module in GL_HALT mode.
This flag is automatically set to 1 when the CANFDG module enters GL_HALT mode. This flag is automatically set to 0 when the CANFDG module exits the GL_HALT mode.

SLPST Flag (GL_SLEEP Status Flag)

The SLPST flag indicates the status of the CANFDG module in GL_SLEEP mode.
This flag is automatically set to 1 when the CANFDG module enters GL_SLEEP mode. This flag is automatically set to 0 when the CANFDG module exits the GL_SLEEP mode.

RAMST Flag (RAM Initialization Status Flag)

The RAMST flag indicates the status of the CANFDG module's RAM initialization.
This flag is automatically set to 1 when the CANFDG module enters GL_SLEEP mode by resetting the MCU. This flag is automatically set to 0 when the CANFDG module completed RAM initialization.

45.2.13 Global Error Status Register (GESR)

Address(es): CANFDG0.GESR 8748 0090h, CANFDG0_NS.GESR 0748 0090h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EEDF1	EEDF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DEDF	DLC Error Detect Flag	0: DLC error is not detected 1: DLC error is detected	R/(W) *1
b1	MLDF	Message Lost Detect Flag	0: Message lost error is not detected 1: Message lost error is detected	R
b2	THLDF	Transmission History Entry Lost Detect Flag	0: Transmission history entry lost is not detected 1: Transmission history entry lost is detected	R
b3	PODF	Payload Overflow Detect Flag	0: Payload overflow is not detected 1: Payload overflow is detected	R/(W) *1
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R
b6	TQMLDF	Transmit Queue Message Lost Detect Flag	0: Transmit queue message lost is not detected 1: Transmit queue message lost is detected	R
b7	CFOWDF	Common FIFO Message Overwrite Detect Flag	0: Message overwrite is not detected 1: Message overwrite is detected	R
b9, b8	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	EEDF0	Channel 0 ECC Error Detect Flag	0: ECC error is not detected during transmission scan for channel 0 1: ECC error is detected during transmission scan for channel 0	R/(W) *1
b17	EEDF1	Channel 1 ECC Error Detect Flag	0: ECC error is not detected during transmission scan for channel 1 1: ECC error is detected during transmission scan for channel 1	R/(W) *1
b31 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register indicates the detection of global errors.

DEDF Flag (DLC Error Detect Flag)

The DEDF flag indicates the error status of the DLC.

This flag cannot be written in GL_SLEEP or GL_RESET mode.

Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

This flag is automatically set to 1 when a DLC error is detected in a received frame.

This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

The flag is cleared by writing 0 to it. This flag is automatically set to 0 when the CANFDG module enters GL_RESET mode.

MLDF Flag (Message Lost Detect Flag)

The MLDF flag indicates the status of the message lost error.
This flag is automatically set to 1 when a FIFO message lost error is detected.
This flag is automatically set to 0 when:

- All FIFO message lost flags (RFSRn.LOST, CFSRn.LOST) are cleared
- The CANFDG module enters GL_RESET mode.

THLDF Flag (Transmission History Entry Lost Detect Flag)

The THLDF flag indicates the status of the transmission history entry lost error.
This flag is automatically set to 1 when a transmission history entry lost error is detected.
This flag is automatically set to 0 when:

- The transmission history lost flag (THSR.LOST) is cleared
- The CANFDG module enters GL_RESET mode.

PODF Flag (Payload Overflow Detect Flag)

The PODF flag is automatically set to 1 when a message payload overflow is detected on any channel.
This flag cannot be written in GL_SLEEP or GL_RESET mode.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is automatically set to 0 when the CANFDG module enters GL_RESET mode.

TQMLDF Flag (Transmit Queue Message Lost Detect Flag)

The TQMLDF flag is automatically set to 1 when a message lost is detected in any transmit queue.
This flag is automatically set to 0 when:

- All transmit queue message lost flags (TQSR0.LOST, TQSR1.LOST, TQSR2.LOST, TQSR3.LOST) are cleared
- The CANFDG module enters GL_RESET mode.

CFOWDF Flag (Common FIFO Message Overwrite Detect Flag)

The CFOWDF flag is automatically set to 1 when a message overwrite is detected in any of the common FIFOs while the common FIFO is in gateway FIFO mode.
This flag is automatically set to 0 when:

- All the common FIFO message overwrite flags (CFOWSR.CFOWFn) are cleared
- The CANFDG module enters GL_RESET mode.

EEDFi Flag (Channel i ECC Error Detect Flag) (i = 0, 1)

The EEDFi flag indicates whether an ECC error has occurred on channel i.
This flag cannot be written in GL_SLEEP or GL_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This bit is automatically set to 0 when the CANFDG module enters GL_RESET mode.

45.2.14 Transmit Interrupt Status Register (TISR)

Address(es): CANFDG0.TISR 8748 1300h, CANFDG0_NS.TISR 0748 1300h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b14	CFOTIF1	Channel 1 Common FIFO One Frame Transmission Interrupt Monitor Flag	0: Channel 1 common FIFO one frame transmission interrupt is not generated. 1: Channel 1 common FIFO one frame transmission interrupt is generated.	R

Bit	Symbol	Bit Name	Description	R/W
b31 to b15	—	Reserved	These bits are read as 0.	R

This register indicates the detection of transmit specific interrupts.

TSIF0 Flag (Channel 0 Transmission Successful Interrupt Monitor Flag)

The TSIF0 flag becomes 1 if transmission from the transmit message buffer n of channel 0 is successful when the transmit message buffer n interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (TMIER0.TMIEn bits = 0)
- When the transmission result flags (TMSRn.TXRF[1:0]) are cleared
- When in GL_RESET or CH_RESET mode.

TAIF0 Flag (Channel 0 Transmission Abort Interrupt Monitor Flag)

The TAIF0 flag becomes 1 if transmission from the transmit message buffer n of channel 0 is aborted when the transmission abort interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (CHCR.TAIE bit = 0)
- When the transmission result flags (TMSRn.TXRF[1:0]) are cleared
- When in GL_RESET or CH_RESET mode.

TQIF0 Flag (Channel 0 Transmit Queue Interrupt Monitor Flag)

The TQIF0 flag becomes 1 if the transmit queue interrupt flag of channel 0 is set to 1 when the transmit queue interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (TQCR0.TQIE, TQCR1.TQIE, TQCR2.TQIE, or TQCR3.TQIE bit = 0)
- When the transmit queue interrupt flag (TQSR0.TQIF, TQSR1.TQIF, TQSR2.TQIF, or TQSR3.TQIF) is cleared
- When in GL_RESET or CH_RESET mode.

CFTIF0 Flag (Channel 0 Common FIFO Transmission Interrupt Monitor Flag)

The CFTIF0 flag becomes 1 if the common FIFO transmit interrupt flag (CFSRn.CFTIF (n = 0 to 5)) of channel 0 is set to 1 when the common FIFO transmit interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (CFCRn.CFTIE bit = 0)
- When the common transmit FIFO interrupt flag (CFSRn.CFTIF) is cleared
- When in GL_RESET or CH_RESET mode.

THIF0 Flag (Channel 0 Transmission History Interrupt Monitor Flag)

The THIF0 flag becomes 1 if the transmission history interrupt flag (THSR.THIF) of channel 0 is set to 1 when the transmission history interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (THCR.THIE bit = 0)
- When the transmission history interrupt flag (THSR.THIF) is cleared
- When in GL_RESET or CH_RESET mode.

TQOTIF0 Flag (Channel 0 Transmit Queue One Frame Transmission Interrupt Monitor Flag)

The TQOTIF0 flag becomes 1 if the transmit queue one frame transmission interrupt flag of channel 0 is set to 1 when the transmit queue one frame transmission interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (TQCR0.TQOTIE, TQCR1.TQOTIE, TQCR2.TQOTIE, or TQCR3.TQOTIE bit = 0)
- When the transmit queue one frame transmission interrupt flag (TQSR0.TQOTIF, TQSR1.TQOTIF, TQSR2.TQOTIF, or TQSR3.TQOTIF) is cleared
- When in GL_RESET or CH_RESET mode.

CFOTIF0 Flag (Channel 0 Common FIFO One Frame Transmission Interrupt Monitor Flag)

The CFOTIF0 flag becomes 1 if the common FIFO one frame transmission interrupt flag of channel 0 is set to 1 when the common FIFO one frame transmission interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (CFECRn.CFOTIE bit = 0)
- When the common FIFO one frame transmission interrupt flag (CFSRn.CFOTIF) is cleared
- When in GL_RESET or CH_RESET mode.

TSIF1 Flag (Channel 1 Transmission Successful Interrupt Monitor Flag)

The TSIF1 flag becomes 1 if transmission from the transmit message buffer n of channel 1 is successful when the transmit message buffer n interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (TMIER0.TMIEn bits = 0)
- When the transmission result flags (TMSRn.TXRF[1:0]) of transmit message buffer n are cleared
- When in GL_RESET or CH_RESET mode.

TAIF1 Flag (Channel 1 Transmission Abort Interrupt Monitor Flag)

The TAIF1 flag becomes 1 if transmission from the transmit message buffer n of channel 1 is aborted when the transmission abort interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (CHCR.TAIE bit = 0)
- When the transmission result flags (TMSRn.TXRF[1:0]) of transmit message buffer n are cleared
- When in GL_RESET or CH_RESET mode.

TQIF1 Flag (Channel 1 Transmit Queue Interrupt Monitor Flag)

The TQIF1 flag becomes 1 if the transmit queue interrupt flag of channel 1 is set to 1 when the transmit queue interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (TQCR0.TQIE, TQCR1.TQIE, TQCR2.TQIE, or TQCR3.TQIE bit = 0)
- When the transmit queue interrupt flag (TQSR0.TQIF, TQSR1.TQIF, TQSR2.TQIF, or TQSR3.TQIF) is cleared
- When in GL_RESET or CH_RESET mode.

CFTIF1 Flag (Channel 1 Common FIFO Transmission Interrupt Monitor Flag)

The CFTIF1 flag becomes 1 if the common FIFO transmit interrupt flag (CFSRn.CFTIF (n = 0 to 5)) of channel 1 is set to 1 when the common FIFO transmit interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (CFCRn.CFTIE bit = 0)

- When the common transmit FIFO interrupt flag (CFSRn.CFTIF) is cleared
- When in GL_RESET or CH_RESET mode.

THIF1 Flag (Channel 1 Transmission History Interrupt Monitor Flag)

The THIF1 flag becomes 1 if the transmission history interrupt flag (THSR.THIF) of channel 1 is set to 1 when the transmission history interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (THCR.THIE bit = 0)
- When the transmission history interrupt flag (THSR.THIF) is cleared
- When in GL_RESET or CH_RESET mode.

TQOTIF1 Flag (Channel 1 Transmit Queue One Frame Transmission Interrupt Monitor Flag)

The TQOTIF1 flag becomes 1 if the transmit queue one frame transmission interrupt flag of channel 1 is set to 1 when the transmit queue one frame transmission interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (TQCR0.TQOTIE, TQCR1.TQOTIE, TQCR2.TQOTIE, or TQCR3.TQOTIE bit = 0)
- When the transmit queue one frame transmission interrupt flag (TQSR0.TQOTIF, TQSR1.TQOTIF, TQSR2.TQOTIF, or TQSR3.TQOTIF) is cleared
- When in GL_RESET or CH_RESET mode.

CFOTIF1 Flag (Channel 1 Common FIFO One Frame Transmission Interrupt Monitor Flag)

The CFOTIF1 flag becomes 1 if the common FIFO one frame transmission interrupt flag of channel 1 is set to 1 when the common FIFO one frame transmission interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (CFECRn.CFOTIE bit = 0)
- When the common FIFO one frame transmission interrupt flag (CFSRn.CFOTIF) is cleared
- When in GL_RESET or CH_RESET mode.

45.2.15 Timestamp Counter Register (TSCR)

Address(es): CANFDG0.TSCR 8748 0094h, CANFDG0_NS.TSCR 0748 0094h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is a read-only register that stores a timestamp based on the selected configuration.
The timestamp value is stored in the TSCR register based on the configuration of the GCFG.TSCS bit, TSBTCS[2:0] bits, and TSP[3:0] bits. The accuracy of the timestamp counter cannot be guaranteed when transitioning to GL_HALT state.
This register is automatically set to 00000000h in GL_RESET mode.

45.2.16 Acceptance Filter List Control Register (AFCR)

Address(es): CANFDG0.AFCR 8748 0098h, CANFDG0_NS.AFCR 0748 0098h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	AFLWE	—	—	—	—	PAGE[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	PAGE[3:0]	Access Page Setting	Set the page number of the Acceptance Filter List, a value between 0 and 7.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	AFLWE	AFL Write Enable	0: Writing data to the Acceptance Filter List is disabled 1: Writing data to the Acceptance Filter List is enabled	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to select the Acceptance Filter List page for reading or writing entries into the Acceptance Filter List.

PAGE[3:0] Bits (Access Page Setting)

The PAGE[3:0] bits are used to select the page number to access the desired RAM area of the Acceptance Filter List.
One Acceptance Filter List page consists of 16 Acceptance Filter List entries.
Read/write accesses to the Acceptance Filter List can only be performed through a fixed window.
These bits cannot be written in GL_SLEEP mode.

AFLWE Bit (AFL Write Enable)

Setting the AFLWE bit to 0 after configuration of the Acceptance Filter List prevents writing to the Acceptance Filter List.
Data can be read from the Acceptance Filter List independent of the status of this bit.
This bit cannot be written in GL_SLEEP mode.
Setting this bit to 1 enables write access for the Acceptance Filter List.

45.2.17 Acceptance Filter List Configuration Register (AFCFG)

Address(es): CANFDG0.AFCFG 8748 009Ch, CANFDG0_NS.AFCFG 0748 009Ch

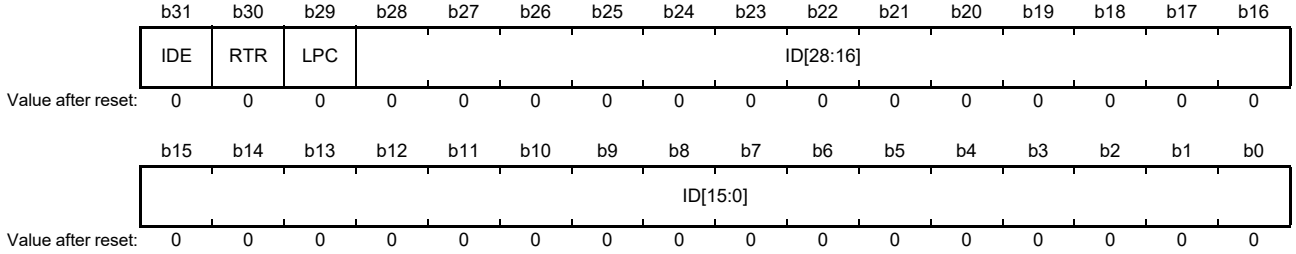
	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	RN0[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RN1[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	RN1[8:0]	Number of Rules Setting for Channel 1	Number of rules in the Acceptance Filter List for Channel 1	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24 to b16	RN0[8:0]	Number of Rules Setting for Channel 0	Number of rules in the Acceptance Filter List for Channel 0	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to define the number of rules for entry in the Acceptance Filter List.
The maximum number of available entries in the Acceptance Filter List is 64 per channel.

RN1[8:0] Bits (Number of Rules Setting for Channel 1)



The RN1[8:0] bits define the number of rules in the Acceptance Filter List for channel 1. These bits can be set to a value of 64 rules or less.
These bits can only be written in GL_RESET mode.

RN0[8:0] Bits (Number of Rules Setting for Channel 0)

The RN0[8:0] bits define the number of rules in the Acceptance Filter List for channel 0. These bits can be set to a value of 64 rules or less.
These bits can only be written in GL_RESET mode.

45.2.18 Acceptance Filter List n ID Register (AFLn.IDR) (n = 0 to 15)

Address(es): CANFDG0.AFL0.IDR 8748 1800h, CANFDG0.AFL1.IDR 8748 1810h, CANFDG0.AFL2.IDR 8748 1820h, CANFDG0.AFL3.IDR 8748 1830h, CANFDG0.AFL4.IDR 8748 1840h, CANFDG0.AFL5.IDR 8748 1850h, CANFDG0.AFL6.IDR 8748 1860h, CANFDG0.AFL7.IDR 8748 1870h, CANFDG0.AFL8.IDR 8748 1880h, CANFDG0.AFL9.IDR 8748 1890h, CANFDG0.AFL10.IDR 8748 18A0h, CANFDG0.AFL11.IDR 8748 18B0h, CANFDG0.AFL12.IDR 8748 18C0h, CANFDG0.AFL13.IDR 8748 18D0h, CANFDG0.AFL14.IDR 8748 18E0h, CANFDG0.AFL15.IDR 8748 18F0h,
CANFDG0_NS.AFL0.IDR 0748 1800h, CANFDG0_NS.AFL1.IDR 0748 1810h, CANFDG0_NS.AFL2.IDR 0748 1820h, CANFDG0_NS.AFL3.IDR 0748 1830h, CANFDG0_NS.AFL4.IDR 0748 1840h, CANFDG0_NS.AFL5.IDR 0748 1850h, CANFDG0_NS.AFL6.IDR 0748 1860h, CANFDG0_NS.AFL7.IDR 0748 1870h, CANFDG0_NS.AFL8.IDR 0748 1880h, CANFDG0_NS.AFL9.IDR 0748 1890h, CANFDG0_NS.AFL10.IDR 0748 18A0h, CANFDG0_NS.AFL11.IDR 0748 18B0h, CANFDG0_NS.AFL12.IDR 0748 18C0h, CANFDG0_NS.AFL13.IDR 0748 18D0h, CANFDG0_NS.AFL14.IDR 0748 18E0h, CANFDG0_NS.AFL15.IDR 0748 18F0h

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	ID Field	ID part of the Acceptance Filter List entry	R/W
b29	LPC	Loop-Back Configuration	0: Perform normal processing of received messages 1: Only accept its own transmitted messages	R/W
b30	RTR	RTR	0: Data frame 1: Remote frame	R/W
b31	IDE	IDE	0: Standard ID 1: Extended ID	R/W

Note: Set this register in CH_RESET or CH_HALT mode.

This register is used to configure the ID field in the rule entry of the Acceptance Filter List.
When rewriting this register, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.

ID[28:0] Bits (ID Field)

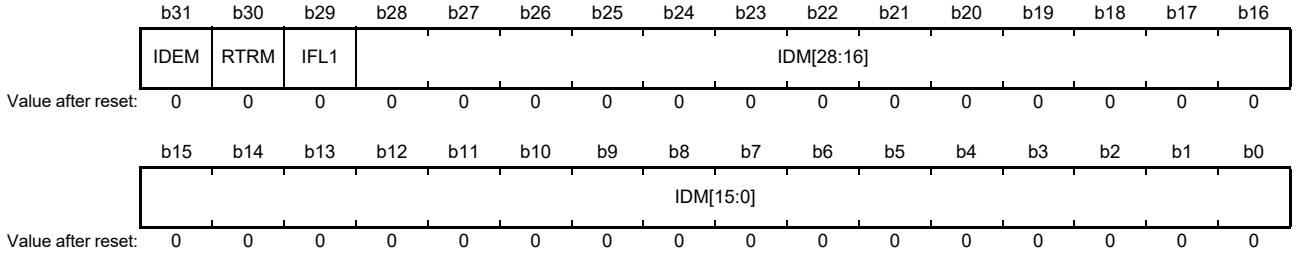
The ID[28:0] bits indicate the CAN identifier (ID) field of each entry in the Acceptance Filter List.
The acceptance filter process compares this field against the ID of a received message. For alignment of these bits in base and extended formats, refer to section 45.2.78, Identifier Bits Alignment.

LPC Bit (Loop-Back Configuration)

The LPC bit specifies the processing of received messages in loop-back mode and mirror mode for each entry in the Acceptance Filter List. For normal received messages, set this bit to 0.
Entries with this bit set to 1 only match its own transmitted messages in loop-back mode or mirror mode. Entries with this bit set to 0 match all messages transmitted by other nodes, and its own transmitted messages in loop-back mode.
For details, refer to section 45.5.8, Loop-Back Configuration.

RTR Bit (RTR)

The RTR bit allows the configuration of the specified frame format (data frame or remote frame) for each entry of the Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the RTR bit of the received message.



IDE Bit (IDE)

The IDE bit allows the configuration of the ID format (standard ID or extended ID) for each entry in the Acceptance

Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the IDE bit of the received message.

45.2.19 Acceptance Filter List n Mask Register (AFLn.MASK) (n = 0 to 15)

Address(es): CANFDG0.AFL0.MASK 8748 1804h, CANFDG0.AFL1.MASK 8748 1814h, CANFDG0.AFL2.MASK 8748 1824h, CANFDG0.AFL3.MASK 8748 1834h, CANFDG0.AFL4.MASK 8748 1844h, CANFDG0.AFL5.MASK 8748 1854h, CANFDG0.AFL6.MASK 8748 1864h, CANFDG0.AFL7.MASK 8748 1874h, CANFDG0.AFL8.MASK 8748 1884h, CANFDG0.AFL9.MASK 8748 1894h, CANFDG0.AFL10.MASK 8748 18A4h, CANFDG0.AFL11.MASK 8748 18B4h, CANFDG0.AFL12.MASK 8748 18C4h, CANFDG0.AFL13.MASK 8748 18D4h, CANFDG0.AFL14.MASK 8748 18E4h, CANFDG0.AFL15.MASK 8748 18F4h,
CANFDG0_NS.AFL0.MASK 0748 1804h, CANFDG0_NS.AFL1.MASK 0748 1814h, CANFDG0_NS.AFL2.MASK 0748 1824h, CANFDG0_NS.AFL3.MASK 0748 1834h, CANFDG0_NS.AFL4.MASK 0748 1844h, CANFDG0_NS.AFL5.MASK 0748 1854h, CANFDG0_NS.AFL6.MASK 0748 1864h, CANFDG0_NS.AFL7.MASK 0748 1874h, CANFDG0_NS.AFL8.MASK 0748 1884h, CANFDG0_NS.AFL9.MASK 0748 1894h, CANFDG0_NS.AFL10.MASK 0748 18A4h, CANFDG0_NS.AFL11.MASK 0748 18B4h, CANFDG0_NS.AFL12.MASK 0748 18C4h, CANFDG0_NS.AFL13.MASK 0748 18D4h, CANFDG0_NS.AFL14.MASK 0748 18E4h, CANFDG0_NS.AFL15.MASK 0748 18F4h

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	IDM[28:0]	ID Mask Field	0: Corresponding ID bit is not used for ID matching 1: Corresponding ID bit is used for ID matching	R/W
b29	IFL1	Information Label 1	Set an information label 1 to be attached to a received message	R/W
b30	RTRM	RTR Mask	0: RTR bit is not used for ID matching 1: RTR bit is used for ID matching	R/W
b31	IDEM	IDE Mask	0: IDE bit is not used for ID matching 1: IDE bit is used for ID matching	R/W

Note: Set this register in CH_RESET or CH_HALT mode.

This register is used to configure the mask field of each rule for entries in the Acceptance Filter List.
When rewriting this register, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.

IDM[28:0] Bits (ID Mask Field)

The IDM[28:0] bits are the filter mask bits for the related bits in the CAN Identifier field of each Acceptance Filter List entry.

IFL1 Bit (Information Label 1)

The IFL1 bit is the upper bit of a 2-bit information label to be attached to a received message accepted by the associated entry in the Acceptance Filter List.
This bit is stored in the upper bit of the Information Label Field (RMBn.HF2.IFL[1], RFBn.HF2.IFL[1], CFBn.HF2.IFL[1]) of the storage location of a received message. This bit is also stored in THACR1n.IFL[1] if the Gateway function is enabled and the THCRn.THRGC bit is set to 1.

RTRM Bit (RTR Mask)

The RTRM bit is the RTR mask bit for each entry in the Acceptance Filter List.

IDEM Bit (IDE Mask)

The IDEM bit is the IDE mask bit for each entry in the Acceptance Filter List.

When the IDE mask bit is 0, the ID comparison depends on the IDE bit of the received message.

- If the IDE bit of the received message is 0, the standard ID comparison takes place.
- If the IDE bit of the received message is 1, the extended ID comparison takes place.

45.2.20 Acceptance Filter List n Pointer Register 0 (AFLn.PTR0) (n = 0 to 15)

Address(es): CANFDG0.AFL0.PTR0 8748 1808h, CANFDG0.AFL1.PTR0 8748 1818h, CANFDG0.AFL2.PTR0 8748 1828h, CANFDG0.AFL3.PTR0 8748 1838h, CANFDG0.AFL4.PTR0 8748 1848h, CANFDG0.AFL5.PTR0 8748 1858h, CANFDG0.AFL6.PTR0 8748 1868h, CANFDG0.AFL7.PTR0 8748 1878h, CANFDG0.AFL8.PTR0 8748 1888h, CANFDG0.AFL9.PTR0 8748 1898h, CANFDG0.AFL10.PTR0 8748 18A8h, CANFDG0.AFL11.PTR0 8748 18B8h, CANFDG0.AFL12.PTR0 8748 18C8h, CANFDG0.AFL13.PTR0 8748 18D8h, CANFDG0.AFL14.PTR0 8748 18E8h, CANFDG0.AFL15.PTR0 8748 18F8h,
CANFDG0_NS.AFL0.PTR0 0748 1808h, CANFDG0_NS.AFL1.PTR0 0748 1818h, CANFDG0_NS.AFL2.PTR0 0748 1828h, CANFDG0_NS.AFL3.PTR0 0748 1838h, CANFDG0_NS.AFL4.PTR0 0748 1848h, CANFDG0_NS.AFL5.PTR0 0748 1858h, CANFDG0_NS.AFL6.PTR0 0748 1868h, CANFDG0_NS.AFL7.PTR0 0748 1878h, CANFDG0_NS.AFL8.PTR0 0748 1888h, CANFDG0_NS.AFL9.PTR0 0748 1898h, CANFDG0_NS.AFL10.PTR0 0748 18A8h, CANFDG0_NS.AFL11.PTR0 0748 18B8h, CANFDG0_NS.AFL12.PTR0 0748 18C8h, CANFDG0_NS.AFL13.PTR0 0748 18D8h, CANFDG0_NS.AFL14.PTR0 0748 18E8h, CANFDG0_NS.AFL15.PTR0 0748 18F8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	DLC[3:0]	DLC Field	Set a minimum number of data bytes to be accepted.	R/W
b4	RDS0	Routing Destination Select 0	0: The routing destination is the common FIFO 0. 1: The routing destination is the transmit queue 0.	R/W
b5	RDS1	Routing Destination Select 1	0: The routing destination is the common FIFO 1. 1: The routing destination is the transmit queue 1.	R/W
b6	RDS2	Routing Destination Select 2	0: The routing destination is the common FIFO 2. 1: The routing destination is the transmit queue 2.	R/W
b7	IFL0	Information Label 0	Set an information label 0 to be attached to a received message.	R/W
b14 to b8	DMB[6:0]	Destination Message Buffer Setting	Set the receive message buffer number for storing received messages.	R/W
b15	DMBE	Destination Message Buffer Setting Enable	0: The setting of the DMB[6:0] bits is disabled. 1: The setting of the DMB[6:0] bits is enabled.	R/W
b31 to b16	PTR[15:0]	Pointer	Set a 16-bit pointer to be attached to a received message	R/W

Note: Set this register in CH_RESET or CH_HALT mode.

This register is used to configure the data length code (DLC), software pointer, and destination message buffer for each rule entry in the Acceptance Filter List.

When rewriting this register, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.

DLC[3:0] Bits (DLC Field)

The DLC[3:0] bits allow the configuration of a minimum data length code (DLC) value for a message to be accepted by the associated entry in the Acceptance Filter List (automatic DLC filter function).

DLC filter process is only passed if the DLC value of the message accepted by an entry in the Acceptance Filter List is equal to or higher than the DLC value configured for this associated Acceptance Filter List entry. Automatic DLC filter function is disabled for the corresponding rule entry when this field is set to 0000b.

RDSj Bit (Routing Destination Select j) (j = 0 to 2)

The RDSj bit is used to select whether the destination for routing is the common FIFO or the transmit queue.
When the RDSj bit is set to 1, setting the corresponding AFLn.PTR1.CFmE bit (m = 0 to 5) to 1 selects the transmit queue. When the RDSj bit is set to 0, setting the corresponding AFLn.PTR1.CFmE bit to 1 selects the common FIFO.

IFL0 Bit (Information Label 0)

The IFL0 bit is the lower bit of a 2-bit information label that can be attached to a received message accepted by the Acceptance Filter List entry.
This bit is stored in the lower bit of the Information Label Field (RMBn.HF2.IFL[0], RFBn.HF2.IFL[0], CFBn.HF2.IFL[0]) of the storage location of a received message. If the gateway function is enabled and the THCRn.THRGC bit is 1, it is also stored in THACR1n.IFL[0].

DMB[6:0] Bits (Destination Message Buffer Setting)

The DMB[6:0] bits allow the configuration of a message buffer as the destination for a received message that passes the acceptance check of the Acceptance Filter List entry. Configure the destination message buffer number.
Write the RMCR.NMB[7:0] bits to configure the number of receive message buffers. The value to be entered in the DMB[6:0] bits should only be between 0000000b and ‘NMB[7:0] – 1’.
If the RMCR.NMB[7:0] bits are 00000000b, set the DMBE bit to 0.

DMBE Bit (Destination Message Buffer Setting Enable)

The DMBE bit allows the enabling or disabling of the receive message buffer as the destination message buffer for a received message that passes the acceptance check of the Acceptance Filter List entry.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits allow the configuration of a 16-bit pointer to be attached to a received message accepted by the Acceptance Filter List entry. The pointer is added during message storage in the message buffer area and can be used by the application as a support function. The pointer information can be used for example, to support PDU Identifier allocation for the received message in AUTOSAR systems.

45.2.21 Acceptance Filter List n Pointer Register 1 (AFLn.PTR1) (n = 0 to 15)

Address(es): CANFDG0.AFL0.PTR1 8748 180Ch, CANFDG0.AFL1.PTR1 8748 181Ch, CANFDG0.AFL2.PTR1 8748 182Ch, CANFDG0.AFL3.PTR1 8748 183Ch, CANFDG0.AFL4.PTR1 8748 184Ch, CANFDG0.AFL5.PTR1 8748 185Ch, CANFDG0.AFL6.PTR1 8748 186Ch, CANFDG0.AFL7.PTR1 8748 187Ch, CANFDG0.AFL8.PTR1 8748 188Ch, CANFDG0.AFL9.PTR1 8748 189Ch, CANFDG0.AFL10.PTR1 8748 18ACh, CANFDG0.AFL11.PTR1 8748 18BCh, CANFDG0.AFL12.PTR1 8748 18CCh, CANFDG0.AFL13.PTR1 8748 18DCh, CANFDG0.AFL14.PTR1 8748 18ECh, CANFDG0.AFL15.PTR1 8748 18FCh,

b0	RF0E	Receive FIFO 0 Destination Enable	0: Do not select receive FIFO 0 as the message storage destination 1: Selects receive FIFO 0 as the message storage destination	R/W
b1	RF1E	Receive FIFO 1 Destination Enable	0: Do not select receive FIFO 1 as the message storage destination 1: Selects receive FIFO 1 as the message storage destination	R/W
b2	RF2E	Receive FIFO 2 Destination Enable	0: Do not select receive FIFO 2 as the message storage destination 1: Selects receive FIFO 2 as the message storage destination	R/W
b3	RF3E	Receive FIFO 3 Destination Enable	0: Do not select receive FIFO 3 as the message storage destination 1: Selects receive FIFO 3 as the message storage destination	R/W
b4	RF4E	Receive FIFO 4 Destination Enable	0: Do not select receive FIFO 4 as the message storage destination 1: Selects receive FIFO 4 as the message storage destination	R/W
b5	RF5E	Receive FIFO 5 Destination Enable	0: Do not select receive FIFO 5 as the message storage destination 1: Selects receive FIFO 5 as the message storage destination	R/W
b6	RF6E	Receive FIFO 6 Destination Enable	0: Do not select receive FIFO 6 as the message storage destination 1: Selects receive FIFO 6 as the message storage destination	R/W
b7	RF7E	Receive FIFO 7 Destination Enable	0: Do not select receive FIFO 7 as the message storage destination 1: Selects receive FIFO 7 as the message storage destination	R/W
b8	CF0E	Common FIFO 0/Channel 0 Transmit Queue 0 Destination Enable	0: Do not select common FIFO 0 and channel 0 transmit queue 0 as the message storage destination 1: Selects common FIFO 0 or channel 0 transmit queue 0 as the message storage destination	R/W
b9	CF1E	Common FIFO 1/Channel 0 Transmit Queue 1 Destination Enable	0: Do not select common FIFO 1 and channel 0 transmit queue 1 as the message storage destination 1: Selects common FIFO 1 or channel 0 transmit queue 1 as the message storage destination	R/W
b10	CF2E	Common FIFO 2/Channel 0 Transmit Queue 2 Destination Enable	0: Do not select common FIFO 2 and channel 0 transmit queue 2 as the message storage destination 1: Selects common FIFO 2 or channel 0 transmit queue 2 as the message storage destination	R/W

Bit	Symbol	Bit Name	Description	R/W
b11	CF3E	Common FIFO 3/Channel 1 Transmit Queue 0 Destination Enable	0: Do not select common FIFO 3 and channel 1 transmit queue 0 as the message storage destination 1: Selects common FIFO 3 or channel 1 transmit queue 0 as the message storage destination	R/W
b12	CF4E	Common FIFO 4/Channel 1 Transmit Queue 1 Destination Enable	0: Do not select common FIFO 4 and channel 1 transmit queue 1 as the message storage destination 1: Selects common FIFO 4 or channel 1 transmit queue 1 as the message storage destination	R/W
b13	CF5E	Common FIFO 5/Channel 1 Transmit Queue 2 Destination Enable	0: Do not select common FIFO 5 and channel 1 transmit queue 2 as the message storage destination 1: Selects common FIFO 5 or channel 1 transmit queue 2 as the message storage destination	R/W
b31 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Set this register in CH_RESET or CH_HALT mode.

This register is used to configure the destination FIFO buffer for each rule entry in the Acceptance Filter List.
Up to eight storage destinations can be specified for received messages using any of the following combinations:

- Eight FIFO buffers
- Seven FIFO buffers and one receive message buffer
- Eight transmit queues
- Seven transmit queues and one receive message buffer
- Total of eight FIFO buffers and transmit queues

When rewriting this register, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.

RFmE Bit (Receive FIFO m Destination Enable) (m = 0 to 7)

The RFmE bit allows the configuration of the receive FIFO m as a storage destination of a received message that passes the acceptance check of the Acceptance Filter List entry.

CFmE Bit (Common FIFO m/Channel i Transmit Queue j Destination Enable) (m = i × 3 + j; i = 0, 1; j = 0 to 2)

The CFmE bit allows the configuration of the common FIFO m or transmit queue j of channel i as a storage destination of a received message that passes the acceptance check of the Acceptance Filter List entry.
When specifying a common FIFO as the storage destination, the specified common FIFO must be configured as a receive FIFO or gateway FIFO.
When specifying a transmit queue as the storage destination, the specified transmission queue buffer must be in gateway mode.

45.2.22 Receive Message Buffer Configuration Register (RMCR)

Address(es): CANFDG0.RMCR 8748 00ACh, CANFDG0_NS.RMCR 0748 00ACh

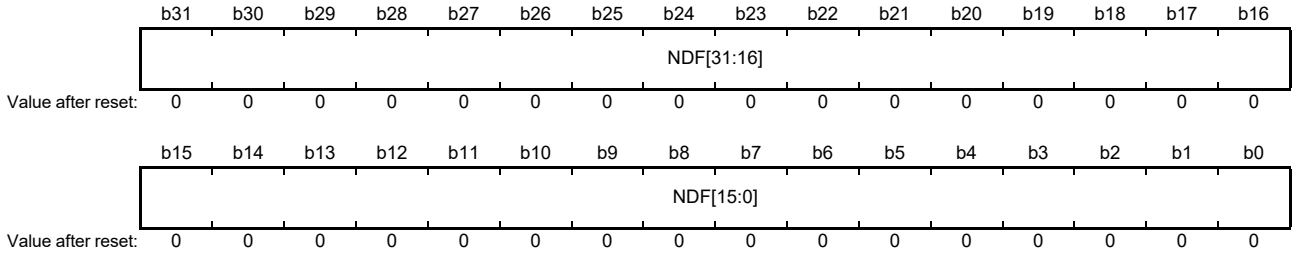
	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	PLS[2:0]			NMB[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	NMB[7:0]	Number of Message Buffer Setting	Configure the number of receive message buffers	R/W
b10 to b8	PLS[2:0]	Payload Size Setting	b10 b8 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to configure the total number of receive message buffers allocated to a channel.

NMB[7:0] Bits (Number of Message Buffer Setting)



The NMB[7:0] bits are used to configure the number of receive message buffers.
These bits can only be written in GL_RESET mode.
Set a value between 0 and 32. A value of 0 indicates that no receive message buffer is allocated.

PLS[2:0] Bits (Payload Size Setting)

The PLS[2:0] bits are used to configure the message buffer payload size.
These bits can only be written in GL_RESET mode.

45.2.23 Receive Message Buffer New Data Register 0 (RMNDR0)

Address(es): CANFDG0.RMNDR0 8748 00B0h, CANFDG0_NS.RMNDR0 0748 00B0h

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	NDF[31:0]	New Data Flag	0: New data is not stored in corresponding receive message buffer 1: New data is stored in corresponding receive message buffer	R/(W) *1

Note 1. Writing 1 has no effect. These flags are cleared by writing 0 to them.

This register specifies the new data storage status of the receive message buffers.
The bit number of this register corresponds to the buffer number of the receive message buffer.

NDF[31:0] Flags (New Data Flag)

The NDF[31:0] flags indicate that the new data is stored in the corresponding receive message buffer. The NDF[0] flag corresponds to receive message buffer 0.
These flags are automatically set to 1 when storage of new messages are in the corresponding receive message buffer. When RMCR.PLS[2:0] = 000b (payload size is 8 bytes), the time required to store a message is 6 PCLKA cycles. When RMCR.PLS[2:0] > 000b, the time increases by 1 PCLKA cycle for every 4 bytes of payload size (20 PCLKA cycles for 64 bytes).
Do not write to these flags in GL_RESET or GL_SLEEP mode.
These flags are automatically set to 0 when the CANFDG module enters GL_RESET mode.
These flags cannot be cleared when message storage in the corresponding receive message buffer is in progress.
Do not use the bit clear instruction to clear the flags. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

45.2.24 Receive FIFO n Configuration Register (RFCRn) (n = 0 to 7)

Address(es): CANFDG0.RFCR0 8748 00C0h, CANFDG0.RFCR1 8748 00C4h, CANFDG0.RFCR2 8748 00C8h, CANFDG0.RFCR3 8748 00CCh, CANFDG0.RFCR4 8748 00D0h, CANFDG0.RFCR5 8748 00D4h, CANFDG0.RFCR6 8748 00D8h, CANFDG0.RFCR7 8748 00DCh, CANFDG0_NS.RFCR0 0748 00C0h, CANFDG0_NS.RFCR1 0748 00C4h, CANFDG0_NS.RFCR2 0748 00C8h, CANFDG0_NS.RFCR3 0748 00CCh, CANFDG0_NS.RFCR4 0748 00D0h, CANFDG0_NS.RFCR5 0748 00D4h, CANFDG0_NS.RFCR6 0748 00D8h, CANFDG0_NS.RFCR7 0748 00DCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFFIE

b11	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b12	RFIM	Receive FIFO Interrupt Mode Setting	0: Interrupt is generated when the number of messages stored in the receive FIFO reaches the value of the RFITH[2:0] bits from a value smaller than the RFITH[2:0] bits 1: Interrupt is generated at the end of every received message storage	R/W
b15 to b13	RFITH[2:0]	Receive FIFO Interrupt Threshold Setting	b15 b13 0 0 0: Interrupt generated when FIFO is 1/8 full 0 0 1: Interrupt generated when FIFO is 1/4 full 0 1 0: Interrupt generated when FIFO is 3/8 full 0 1 1: Interrupt generated when FIFO is 1/2 full 1 0 0: Interrupt generated when FIFO is 5/8 full 1 0 1: Interrupt generated when FIFO is 3/4 full 1 1 0: Interrupt generated when FIFO is 7/8 full 1 1 1: Interrupt generated when FIFO is full	R/W
b16	RFFIE	Receive FIFO Full Interrupt Enable	0: FIFO full interrupt generation is disabled 1: FIFO full interrupt generation is enabled	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

These registers are used to configure and control the eight receive FIFOs.

RFE Bit (Receive FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0, the receive FIFO is cleared to empty.
This bit can only be written in GL_HALT or GL_OPERATION mode.
This bit can be set to 1 only when the FIFO depth is 4 or greater (FDS[2:0] ≥ 001b).
Set the RFE bit to 1 with a separate write access to the RFCRn register, after all the other flags in the RFCRn register are set.
This bit is automatically set to 0 when the CANFDG module enters GL_RESET mode.

RFIE Bit (Receive FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.
This bit cannot be written in GL_SLEEP mode.

PLS[2:0] Bits (Payload Size Setting)

The PLS[2:0] bits define the message data payload size in the RAM.
This is the maximum number of bytes which can be received by this FIFO.
These bits can only be written in GL_RESET mode.

FDS[2:0] Bits (FIFO Depth Setting)

The FDS[2:0] bits select the depth of the FIFO in units of the number of messages. If the FIFO depth is set to 0, the FIFO cannot be used.
These bits can only be written in GL_RESET mode.

RFIM Bit (Receive FIFO Interrupt Mode Setting)

The RFIM bit selects the interrupt generation condition for the FIFO.
This bit cannot be written in GL_SLEEP mode.
Write to this bit only in GL_RESET mode.

RFITH[2:0] Bits (Receive FIFO Interrupt Threshold Setting)

The RFITH[2:0] bits select the counter value of the FIFO for generation of receive FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.
These bits cannot be written in GL_SLEEP mode.
The setting of the RFITH[2:0] bits is restricted by the value of the FDS[2:0] bits. For details, refer to section 45.6.2.1, FIFO Buffers Configuration.
Write to these bits only in GL_RESET mode.

RFFIE Bit (Receive FIFO Full Interrupt Enable)

When the RFFIE bit is set to 1, an interrupt is generated when the receive FIFO becomes full.
This bit cannot be written in GL_SLEEP mode.
This bit can be used as follows:

- Generate an interrupt at any stage (setting of the RFITH[2:0] bits)
- Generate an interrupt when FIFO is full

These interrupt notifications allow you to manage the received data in the FIFO.

45.2.25 Receive FIFO n Status Register (RFSRn) (n = 0 to 7)

Address(es): CANFDG0.RFSR0 8748 00E0h, CANFDG0.RFSR1 8748 00E4h, CANFDG0.RFSR2 8748 00E8h, CANFDG0.RFSR3 8748 00ECh, CANFDG0.RFSR4 8748 00F0h, CANFDG0.RFSR5 8748 00F4h, CANFDG0.RFSR6 8748 00F8h, CANFDG0.RFSR7 8748 00FCh, CANFDG0_NS.RFSR0 0748 00E0h, CANFDG0_NS.RFSR1 0748 00E4h, CANFDG0_NS.RFSR2 0748 00E8h, CANFDG0_NS.RFSR3 0748 00ECh, CANFDG0_NS.RFSR4 0748 00F0h, CANFDG0_NS.RFSR5 0748 00F4h, CANFDG0_NS.RFSR6 0748 00F8h, CANFDG0_NS.RFSR7 0748 00FCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFFIF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FLVL[7:0]								—	—	—	—	RFIF	LOST	FULL	EMPTY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Receive FIFO Empty Flag	0: Message in receive FIFO 1: No message in receive FIFO (empty)	R
b1	FULL	Receive FIFO Full Flag	0: Receive FIFO not full 1: Receive FIFO full	R
b2	LOST	Message Lost Flag	0: Receive FIFO message lost has not occurred 1: Receive FIFO message lost has occurred	R/(W) *1
b3	RFIF	Receive FIFO Interrupt Flag	0: Receive FIFO interrupt condition is not satisfied 1: Receive FIFO interrupt condition is satisfied	R/(W) *1
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	FLVL[7:0]	Receive FIFO Fill Level	Indicate the number of messages stored in receive FIFO	R
b16	RFFIF	Receive FIFO Full Interrupt Flag	0: FIFO full interrupt condition is not satisfied 1: FIFO full interrupt condition is satisfied	R/(W) *1
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

These registers show the status of messages stored in the corresponding FIFO buffers.

EMPTY Flag (Receive FIFO Empty Flag)

The EMPTY flag is automatically set to 1 when:

- The FLVL[7:0] flags are 00000000b
- The RFCRn.RFE bit is set to 0 (receive FIFO is disabled)
- The CANFDG module enters GL_RESET mode.

The EMPTY flag is automatically set to 0 when the first message is stored in the receive FIFO.

FULL Flag (Receive FIFO Full Flag)

The FULL flag is automatically set to 1 when the number of messages stored in the FIFO buffer matches the configured FIFO depth.

The FULL flag is automatically set to 0 when:

- The number of messages stored in the FIFO buffer is less than the configured FIFO depth
- The RFCRn.RFE bit is set to 0 (receive FIFO is disabled)
- The CANFDG module enters GL_RESET mode.

LOST Flag (Message Lost Flag)

The LOST flag is automatically set to 1 whenever a message is lost due to attempted storage when the FIFO buffer is already full. This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The flag is set to 0:

- By writing 0 to it
- When the CANFDG module enters GL_RESET mode.

This flag can only be written in GL_HALT or GL_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

RFIF Flag (Receive FIFO Interrupt Flag)

The RFIF flag is automatically set to 1 when the configured interrupt condition is satisfied. This flag is not automatically cleared when the receive FIFO is disabled.
The flag is set to 0:

- By writing 0 to it
- When the CANFDG module enters GL_RESET mode.

This flag can only be written in GL_HALT or GL_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

FLVL[7:0] Bits (Receive FIFO Fill Level)

The FLVL[7:0] bits indicate the number of messages stored in the receive FIFO that can be read by the CPU. These bits are automatically set to 00000000b when the FIFO is disabled or when the CANFDG module enters GL_RESET mode.

RFFIF Flag (Receive FIFO Full Interrupt Flag)

The RFFIF flag is automatically set to 1 when the FIFO full interrupt condition is satisfied. This flag is not automatically cleared when the receive FIFO is disabled.
The flag is set to 0:

- By writing 0 to it
- When the CANFDG module enters GL_RESET mode.

This flag can only be written in GL_HALT or GL_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

45.2.26 Receive FIFO n Pointer Control Register (RFPCRn) (n = 0 to 7)

Address(es): CANFDG0.RFPCR0 8748 0100h, CANFDG0.RFPCR1 8748 0104h, CANFDG0.RFPCR2 8748 0108h, CANFDG0.RFPCR3 8748 010Ch, CANFDG0.RFPCR4 8748 0110h, CANFDG0.RFPCR5 8748 0114h, CANFDG0.RFPCR6 8748 0118h, CANFDG0.RFPCR7 8748 011Ch, CANFDG0_NS.RFPCR0 0748 0100h, CANFDG0_NS.RFPCR1 0748 0104h, CANFDG0_NS.RFPCR2 0748 0108h, CANFDG0_NS.RFPCR3 0748 010Ch, CANFDG0_NS.RFPCR4 0748 0110h, CANFDG0_NS.RFPCR5 0748 0114h, CANFDG0_NS.RFPCR6 0748 0118h, CANFDG0_NS.RFPCR7 0748 011Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register can be used to increment the read pointer of the corresponding receive FIFOs.

When the value 000000FFh is written to this register, the pointer of the corresponding receive FIFO is moved to the next FIFO entry. Write to this register only when the corresponding receive FIFO is enabled and not empty.

The read value from this register is always 00000000h.

This register can only be written in GL_HALT or GL_OPERATION mode.

Do not write to this register when DTC/DMA transfer is enabled (DTCR.RFDTEn bit = 1).

45.2.27 Common FIFO n Configuration Register (CFCRn) (n = 0 to 5)

Address(es): CANFDG0.CFCR0 8748 0120h, CANFDG0.CFCR1 8748 0124h, CANFDG0.CFCR2 8748 0128h, CANFDG0.CFCR3 8748 012Ch, CANFDG0.CFCR4 8748 0130h, CANFDG0.CFCR5 8748 0134h,
CANFDG0_NS.CFCR0 0748 0120h, CANFDG0_NS.CFCR1 0748 0124h, CANFDG0_NS.CFCR2 0748 0128h, CANFDG0_NS.CFCR3 0748 012Ch, CANFDG0_NS.CFCR4 0748 0130h, CANFDG0_NS.CFCR5 0748 0134h

b23 to b21	FDS[2:0]	FIFO Depth Setting	b23 b21 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages 1 1 0: 64 messages 1 1 1: 128 messages	R/W
b31 to b24	TINT[7:0]	Transmission Interval Setting	Delay the start of transmission from the FIFO if configured in transmit mode, delay is a multiple of basic interval timer clock source unit	R/W

CFE Bit (Common FIFO Enable)

Setting the CFE bit to 1 enables the FIFO. The FIFO is disabled when this bit is set to 0.
This bit can also be used, by clearing it, to abort transmission from common FIFO when configured in transmit FIFO mode or gateway FIFO mode, or to stop reception into the common FIFO in receive FIFO mode.
This bit can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode or gateway FIFO mode, this bit can only be written when the corresponding CAN channel is not in CH_RESET mode.
This bit can only be set to 1 when the FIFO depth is 4 or greater (FDS[2:0] ≥ 001b).
Set the CFE bit to 1 with a separate write access to the CFCRn register, after setting all the other bits in this register.
This bit is automatically set to 0 when the CANFDG module enters GL_RESET mode. Also, if the common FIFO is configured as transmit FIFO mode or gateway FIFO mode, this bit is automatically set to 0 when the corresponding CAN channel enters CH_RESET mode.

CFRIE Bit (Common FIFO Receive Interrupt Enable)

The CFRIE bit enables or disables generation of common FIFO receive interrupt. If this flag is 1, common FIFO receive interrupt is generated when the common FIFO receive interrupt flag is set to 1 after reception of a frame in the corresponding FIFO buffer.
Do not write to this bit in GL_SLEEP mode.

CFTIE Bit (Common FIFO Transmit Interrupt Enable)

The CFTIE bit enables or disables generation of common FIFO transmit interrupt. If this flag is 1, common FIFO transmit interrupt is generated when the common FIFO transmit interrupt flag is set to 1 after transmission of a frame from the corresponding FIFO buffer.
Do not write to this bit in GL_SLEEP mode.

PLS[2:0] Bits (Payload Size Setting)

The PLS[2:0] bits define the message data payload size in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.

For details, refer to section 45.6, FIFO Buffers and Message Buffer Configuration.
These bits can only be written in GL_RESET mode.

MODE[1:0] Bits (Operation Mode Setting)

The MODE[1:0] bits are used to select the operation mode of the common FIFO. When the MCU reset is applied, all the common FIFO are configured in receive FIFO mode.
These bits cannot be written in GL_OPERATION or GL_SLEEP mode.
Write to these bits only in GL_RESET mode.

ITCS Bit (Interval Timer Clock Source Select)

The ITCS bit is used to select the clock source for the transmission interval timer.
Do not write to this bit in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1.
Do not write 1 to this bit when CAN FD communication is used.

Note: The bit time clock can vary depending on the nominal bit rate and data bit rate configuration.

ITR Bit (Interval Timer Resolution Select)

The ITR bit is used to select the resolution of the reference clock for the transmission interval timer.
This bit cannot be written in GL_SLEEP mode. Do not write to this bit when the CFE bit is set to 1.

CFIM Bit (Common FIFO Interrupt Mode Setting)

The CFIM bit is used to select the condition for the generation of common FIFO interrupts.
This bit cannot be written in GL_SLEEP mode.
Write to this bit only in GL_RESET mode.

CFITH[2:0] Bits (Common FIFO Receive Interrupt Threshold Setting)

The CFITH[2:0] bits are used to select the message counter value for the generation of common FIFO interrupts. These values represent fractions of the FIFO depth at which the interrupt is to be generated.
These bits cannot be written in GL_SLEEP mode.
The setting of the CFITH[2:0] bits is restricted by the value of the FDS[2:0] bits. For details, refer to section 45.6.2.1, FIFO Buffers Configuration.
Write to these bits only in GL_RESET mode.

LTM[4:0] Bits (Linked Transmit Message Buffer Select)

The LTM[4:0] bits are used to select the number of the transmit message buffer that links common FIFO configured in transmit FIFO mode or gateway FIFO mode, for transmission scanning. Set these bits to a value between 0 and 7. Setting these bits to 0 selects transmit message buffer 32, and setting them to 7 selects transmit message buffer 39.
These bits cannot be written in GL_OPERATION or GL_SLEEP mode.
Write to these bits only in GL_RESET mode.

FDS[2:0] Bits (FIFO Depth Setting)

The FDS[2:0] bits are used to select the FIFO depth in units of the number of messages. If the FIFO depth is configured to 0, the FIFO cannot be used.
These bits can only be written in GL_RESET mode.

TINT[7:0] Bits (Transmission Interval Setting)

The TINT[7:0] bits are used to select the delay in the start of transmission for all messages transmitted from the common FIFO configured in transmit FIFO mode or gateway FIFO mode. The delay is an integral multiple of the clock source cycle of the interval timer (reference clock period × 1, reference clock period × 10, or bit-time clock period).

These bits cannot be written in GL_SLEEP mode.
Do not write to these bits when the CFE bit is set to 1.
When the GCFG.ITP[15:0] bits are set to 0000h, set the TINT[7:0] bits to 00h.

45.2.28 Common FIFO n Extended Configuration Register (CFECRn) (n = 0 to 5)

Address(es): CANFDG0.CFECR0 8748 0180h, CANFDG0.CFECR1 8748 0184h, CANFDG0.CFECR2 8748 0188h, CANFDG0.CFECR3 8748 018Ch, CANFDG0.CFECR4 8748 0190h, CANFDG0.CFECR5 8748 0194h,
CANFDG0_NS.CFECR0 0748 0180h, CANFDG0_NS.CFECR1 0748 0184h, CANFDG0_NS.CFECR2 0748 0188h,
CANFDG0_NS.CFECR3 0748 018Ch, CANFDG0_NS.CFECR4 0748 0190h, CANFDG0_NS.CFECR5 0748 0194h

Bit	Symbol	Bit Name	Description	R/W
b0	CFFIE	Common FIFO Full Interrupt Enable	0: FIFO full interrupt generation is disabled 1: FIFO full interrupt generation is enabled	R/W
b1	CFORIE	Common FIFO One Frame Reception Interrupt Enable	0: One frame reception interrupt generation is disabled 1: One frame reception interrupt generation is enabled	R/W
b2	CFOTIE	Common FIFO One Frame Transmit Interrupt Enable	0: One frame transmit interrupt generation is disabled 1: One frame transmit interrupt generation is enabled	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	CFOWM	Common FIFO Message Overwrite Mode Select	0: When FIFO is full, the received messages are discarded 1: When FIFO is full, the received messages are overwritten	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	CFBME	Common FIFO Buffering Mode Enable	0: Transmission from common FIFO is disabled 1: Transmission from common FIFO is enabled	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to configure the operation of the common FIFO.

CFFIE Bit (Common FIFO Full Interrupt Enable)

When the CFFIE bit is 1, an interrupt occurs if the common FIFO full interrupt flag becomes 1 after a frame is received.
This bit cannot be written in GL_SLEEP mode.

CFORIE Bit (Common FIFO One Frame Reception Interrupt Enable)

The CFORIE bit enables or disables the common FIFO one frame reception interrupt.
When this bit is set to 1, an interrupt occurs if the common FIFO one frame reception interrupt flag becomes 1 after a frame is received in the corresponding FIFO buffer.
This bit cannot be written in GL_SLEEP mode.

CFOTIE Bit (Common FIFO One Frame Transmit Interrupt Enable)

The CFOTIE bit enables or disables the common FIFO one frame transmit interrupt.

When this bit is set to 1, an interrupt occurs if the common FIFO one frame transmit interrupt flag becomes 1 after a frame in the corresponding FIFO buffer is transmitted.
This bit cannot be written in GL_SLEEP mode.

CFOWM Bit (Common FIFO Message Overwrite Mode Select)

The CFOWM bit is used to select whether to overwrite received messages when there is no space available in the FIFO. When this bit is 0, the received message is discarded when there is no space available in the FIFO. When this bit is 1, the message already stored in the FIFO is overwritten with the new received message.
This bit cannot be written in GL_SLEEP mode.
The CFOWM bit should be set to 1 only when the common FIFO is in gateway mode.
When the CFCRn.CFE bit is 1, do not change the CFOWM bit.

CFBME Bit (Common FIFO Buffering Mode Enable)

When the CFBME bit is 0, messages are sent from the FIFO. When the bit is 1, messages are not sent from the FIFO.
This bit cannot be written in GL_SLEEP mode.
When the CFCRn.CFE bit is 1, do not change the CFBME bit from 0 to 1.

45.2.29 Common FIFO n Status Register (CFSRn) (n = 0 to 5)

Address(es): CANFDG0.CFSR0 8748 01E0h, CANFDG0.CFSR1 8748 01E4h, CANFDG0.CFSR2 8748 01E8h, CANFDG0.CFSR3 8748 01ECh, CANFDG0.CFSR4 8748 01F0h, CANFDG0.CFSR5 8748 01F4h,
CANFDG0_NS.CFSR0 0748 01E0h, CANFDG0_NS.CFSR1 0748 01E4h, CANFDG0_NS.CFSR2 0748 01E8h, CANFDG0_NS.CFSR3 0748 01ECh, CANFDG0_NS.CFSR4 0748 01F0h, CANFDG0_NS.CFSR5 0748 01F4h

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Common FIFO Empty Flag	0: Message in common FIFO 1: No message in common FIFO (empty)	R
b1	FULL	Common FIFO Full Flag	0: Common FIFO is not full 1: Common FIFO is full	R
b2	LOST	Message Lost Flag	0: No message lost in common FIFO 1: Common FIFO message lost	R/(W) *1
b3	CFRIF	Common FIFO Receive Interrupt Flag	0: Common FIFO receive interrupt condition is not satisfied 1: Common FIFO receive interrupt condition is satisfied	R/(W) *1
b4	CFTIF	Common FIFO Transmit Interrupt Flag	0: Common FIFO transmit interrupt condition is not satisfied 1: Common FIFO transmit interrupt condition is satisfied	R/(W) *1
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	FLVL[7:0]	Common FIFO Fill Level	Indicate the number of messages stored in common FIFO	R
b16	CFFIF	Common FIFO Full Interrupt Flag	0: Common FIFO full interrupt condition is not satisfied 1: Common FIFO full interrupt condition is satisfied	R/(W) *1
b17	CFORIF	Common FIFO One Frame Reception Interrupt Flag	0: Common FIFO one frame reception interrupt condition is not satisfied 1: Common FIFO one frame reception interrupt condition is satisfied	R/(W) *1
b18	CFOTIF	Common FIFO One Frame Transmit Interrupt Flag	0: Common FIFO one frame transmit interrupt condition is not satisfied 1: Common FIFO one frame transmit interrupt condition is satisfied	R/(W) *1
b23 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24	CFOWF	Common FIFO Message Overwrite Flag	0: No message overwrite occurred in common FIFO 1: Message overwrite occurred in common FIFO	R/(W) *1
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the status of messages stored in the corresponding FIFO buffers.

EMPTY Flag (Common FIFO Empty Flag)

The EMPTY flag is automatically set to 1 when:

- The CPU has read all messages from the FIFO buffer in receive FIFO mode

- All messages have been transmitted from the FIFO buffer in transmit FIFO mode or gateway FIFO mode
- The common FIFO is disabled by setting the CFCRn.CFE bit to 0
- The CANFDG module enters GL_RESET mode
- The CAN channel enters CH_RESET mode in transmit FIFO mode or gateway FIFO mode.

The EMPTY flag is automatically set to 0 when:

- The first reception message is stored in the FIFO buffer in receive FIFO mode
- The first message to be transmitted is stored in the FIFO buffer in transmit FIFO mode or gateway FIFO mode.

FULL Flag (Common FIFO Full Flag)

The FULL flag is automatically set to 1 when the number of messages stored in the FIFO matches the configured FIFO depth.
The FULL flag is automatically set to 0 when:

- The number of messages stored in the FIFO buffer becomes less than the configured FIFO depth
- The common FIFO is disabled by setting the CFCRn.CFE bit to 0
- The CANFDG module enters GL_RESET mode
- The CAN channel enters CH_RESET mode in transmit FIFO mode or gateway FIFO mode.

LOST Flag (Message Lost Flag)

The LOST flag is automatically set to 1 whenever a message is lost due to attempted storage of a new message when FIFO buffer is already full in receive FIFO mode or gateway FIFO mode.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode or gateway FIFO mode, this bit can only be written when the corresponding CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
The LOST flag is set to 0:

- By writing 0 to it
- When the CANFDG module enters GL_RESET mode
- When the CAN channel enters CH_RESET mode in transmit FIFO mode or gateway FIFO mode.

CFRIF Flag (Common FIFO Receive Interrupt Flag)

The CFRIF flag is set to 1 when the configured interrupt condition is satisfied in receive FIFO mode or gateway FIFO mode.
The CFRIF flag is not cleared automatically if the common FIFO is disabled.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode or gateway FIFO mode, this bit can only be written when the corresponding CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The CFRIF flag is set to 0:

- By writing 0 to it
- When the CANFDG module enters GL_RESET mode.
- The CAN channel enters CH_RESET mode in gateway FIFO mode.

CFTIF Flag (Common FIFO Transmit Interrupt Flag)

The CFTIF flag is set to 1 when the configured interrupt condition is satisfied in transmit FIFO mode or gateway FIFO mode.
The CFTIF flag is not cleared automatically if the common FIFO is disabled.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode or gateway FIFO mode, this bit can only be written when the corresponding CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The CFTIF flag is set to 0:

- By writing 0 to it
- When the CANFDG module enters GL_RESET mode
- When the CAN channel enters CH_RESET mode in transmit FIFO mode or gateway FIFO mode.

FLVL[7:0] Bits (Common FIFO Fill Level)

The FLVL[7:0] bits indicate the following:

- The number of messages stored by the CPU and waiting to be transmitted in transmit FIFO mode
- The number of messages stored by the CANFDG module and available for the CPU to read in receive FIFO mode.
- The number of messages stored by the CANFDG module in gateway FIFO mode

The FLVL[7:0] bits are automatically set to 00000000b when:

- The common FIFO is disabled by setting the CFCRn.CFE bit to 0
- The CANFDG module enters GL_RESET mode
- The CAN channel enters CH_RESET mode in transmit FIFO mode or gateway FIFO mode.

CFFIF Flag (Common FIFO Full Interrupt Flag)

The CFFIF flag is set to 1 when the configured common FIFO full interrupt condition is satisfied in receive FIFO mode or gateway FIFO mode.
This flag is not cleared automatically if the common FIFO is disabled.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode or gateway FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The CFFIF flag is set to 0:

- By writing 0 to it
- When the CANFDG module enters GL_RESET mode
- When the CAN channel enters CH_RESET mode in transmit FIFO mode or gateway FIFO mode.

CFORIF Flag (Common FIFO One Frame Reception Interrupt Flag)

The CFORIF flag is set to 1 when the configured common FIFO one frame reception interrupt condition is satisfied in receive FIFO mode or gateway FIFO mode.
This flag is not cleared automatically if the common FIFO is disabled.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode or gateway FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET

mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The CFORIF flag is set to 0:

- By writing 0 to it
- When the CANFDG module enters GL_RESET mode
- When the CAN channel enters CH_RESET mode in gateway FIFO mode.

CFOTIF Flag (Common FIFO One Frame Transmit Interrupt Flag)

The CFOTIF flag is set to 1 when the configured common FIFO one frame transmit interrupt condition is satisfied in transmit FIFO mode or gateway FIFO mode.
This flag is not cleared automatically if the common FIFO is disabled.
This flag is not affected by the value of the CFCRn.CFIM bit.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode or gateway FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The CFOTIF flag is set to 0:

- By writing 0 to it
- When the CANFDG module enters GL_RESET mode
- When the CAN channel enters CH_RESET mode in transmit FIFO mode or gateway FIFO mode.

CFOWF Flag (Common FIFO Message Overwrite Flag)

In gateway FIFO mode, when the FIFO is full and the CFECRn.CFOWM bit = 1, the CFOWF flag is set to 1 each time a stored message is overwritten with a new message.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode or gateway FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The CFOWF flag is set to 0:

- By writing 0 to it
- When the CANFDG module enters GL_RESET mode
- When the CAN channel enters CH_RESET mode in transmit FIFO mode or gateway FIFO mode.

45.2.30 Common FIFO n Pointer Control Register (CFPCRn) (n = 0 to 5)

Address(es): CANFDG0.CFPCR0 8748 0240h, CANFDG0.CFPCR1 8748 0244h, CANFDG0.CFPCR2 8748 0248h, CANFDG0.CFPCR3 8748 024Ch, CANFDG0.CFPCR4 8748 0250h, CANFDG0.CFPCR5 8748 0254h, CANFDG0_NS.CFPCR0 0748 0240h, CANFDG0_NS.CFPCR1 0748 0244h, CANFDG0_NS.CFPCR2 0748 0248h, CANFDG0_NS.CFPCR3 0748 024Ch, CANFDG0_NS.CFPCR4 0748 0250h, CANFDG0_NS.CFPCR5 0748 0254h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register can be used to increment the read or write pointer of the corresponding common FIFO.
When the value 000000FFh is written into this register, the read pointer of the corresponding common FIFO in receive FIFO mode, or the write pointer of the corresponding common FIFO in transmit FIFO mode moves to the next FIFO entry.
The read value from this register is always 00000000h.
This register can only be written in GL_HALT or GL_OPERATION mode.
In gateway FIFO mode, writing is prohibited.
Write to this register only when:

- The common FIFO is enabled and is not empty in receive FIFO mode
- The common FIFO is enabled and is not full in transmit FIFO mode.

Do not write to the CFPCRn register when DTC/DMA transfer is enabled (DTCR.CFDTEn bit = 1).

45.2.31 FIFO Empty Status Register (FESR)

Address(es): CANFDG0.FESR 8748 02A0h, CANFDG0_NS.FESR 0748 02A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	RFEMP0	Receive FIFO 0 Empty Flag	0: Message in corresponding receive FIFO 0 1: No message in corresponding receive FIFO 0 (empty)	R
b1	RFEMP1	Receive FIFO 1 Empty Flag	0: Message in corresponding receive FIFO 1 1: No message in corresponding receive FIFO 1 (empty)	R
b2	RFEMP2	Receive FIFO 2 Empty Flag	0: Message in corresponding receive FIFO 2 1: No message in corresponding receive FIFO 2 (empty)	R
b3	RFEMP3	Receive FIFO 3 Empty Flag	0: Message in corresponding receive FIFO 3 1: No message in corresponding receive FIFO 3 (empty)	R
b4	RFEMP4	Receive FIFO 4 Empty Flag	0: Message in corresponding receive FIFO 4 1: No message in corresponding receive FIFO 4 (empty)	R
b5	RFEMP5	Receive FIFO 5 Empty Flag	0: Message in corresponding receive FIFO 5 1: No message in corresponding receive FIFO 5 (empty)	R
b6	RFEMP6	Receive FIFO 6 Empty Flag	0: Message in corresponding receive FIFO 6 1: No message in corresponding receive FIFO 6 (empty)	R
b7	RFEMP7	Receive FIFO 7 Empty Flag	0: Message in corresponding receive FIFO 7 1: No message in corresponding receive FIFO 7 (empty)	R
b8	CFEMP0	Common FIFO 0 Empty Flag	0: Message in corresponding common FIFO 0 1: No message in corresponding common FIFO 0 (empty)	R
b9	CFEMP1	Common FIFO 1 Empty Flag	0: Message in corresponding common FIFO 1 1: No message in corresponding common FIFO 1 (empty)	R
b10	CFEMP2	Common FIFO 2 Empty Flag	0: Message in corresponding common FIFO 2 1: No message in corresponding common FIFO 2 (empty)	R
b11	CFEMP3	Common FIFO 3 Empty Flag	0: Message in corresponding common FIFO 3 1: No message in corresponding common FIFO 3 (empty)	R
b12	CFEMP4	Common FIFO 4 Empty Flag	0: Message in corresponding common FIFO 4 1: No message in corresponding common FIFO 4 (empty)	R
b13	CFEMP5	Common FIFO 5 Empty Flag	0: Message in corresponding common FIFO 5 1: No message in corresponding common FIFO 5 (empty)	R
b31 to b14	—	Reserved	These bits are read as 0.	R

This register shows the status of the empty flags of the FIFO buffers.

RFEMPn Flag (Receive FIFO n Empty Flag) (n = 0 to 7)

The RFEMPn flag is set to 1 when the RFSRn.EMPTY flag is set to 1, and is set to 0 when the RFSRn.EMPTY flag is set to 0.

The RFEMPn flag is set to 1 when the CANFDG module enters GL_RESET mode.

CFEMPn Flag (Common FIFO n Empty Flag) (n = 0 to 5)

The CFEMPn flag is set to 1 when the CFSRn.EMPTY flag is set to 1, and is set to 0 when the CFSRn.EMPTY flag is set to 0.

The CFEMPn flag is set to 1 when the CANFDG module enters GL_RESET mode.

45.2.32 FIFO Full Status Register (FFSR)

Address(es): CANFDG0.FFSR 8748 02A4h, CANFDG0_NS.FFSR 0748 02A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFFUL0	Receive FIFO 0 Full Flag	0: Corresponding receive FIFO 0 is not full 1: Corresponding receive FIFO 0 is full	R
b1	RFFUL1	Receive FIFO 1 Full Flag	0: Corresponding receive FIFO 1 is not full 1: Corresponding receive FIFO 1 is full	R
b2	RFFUL2	Receive FIFO 2 Full Flag	0: Corresponding receive FIFO 2 is not full 1: Corresponding receive FIFO 2 is full	R
b3	RFFUL3	Receive FIFO 3 Full Flag	0: Corresponding receive FIFO 3 is not full 1: Corresponding receive FIFO 3 is full	R
b4	RFFUL4	Receive FIFO 4 Full Flag	0: Corresponding receive FIFO 4 is not full 1: Corresponding receive FIFO 4 is full	R
b5	RFFUL5	Receive FIFO 5 Full Flag	0: Corresponding receive FIFO 5 is not full 1: Corresponding receive FIFO 5 is full	R
b6	RFFUL6	Receive FIFO 6 Full Flag	0: Corresponding receive FIFO 6 is not full 1: Corresponding receive FIFO 6 is full	R
b7	RFFUL7	Receive FIFO 7 Full Flag	0: Corresponding receive FIFO 7 is not full 1: Corresponding receive FIFO 7 is full	R
b8	CFFUL0	Common FIFO 0 Full Flag	0: Common FIFO 0 is not full 1: Common FIFO 0 is full	R
b9	CFFUL1	Common FIFO 1 Full Flag	0: Common FIFO 1 is not full 1: Common FIFO 1 is full	R
b10	CFFUL2	Common FIFO 2 Full Flag	0: Common FIFO 2 is not full 1: Common FIFO 2 is full	R
b11	CFFUL3	Common FIFO 3 Full Flag	0: Common FIFO 3 is not full 1: Common FIFO 3 is full	R
b12	CFFUL4	Common FIFO 4 Full Flag	0: Common FIFO 4 is not full 1: Common FIFO 4 is full	R
b13	CFFUL5	Common FIFO 5 Full Flag	0: Common FIFO 5 is not full 1: Common FIFO 5 is full	R
b31 to b14	—	Reserved	These bits are read as 0.	R

This register shows the status of the full flags of the FIFO buffers.

RFFULn Flag (Receive FIFO n Full Flag) (n = 0 to 7)

The RFFULn flag is set to 1 when the RFSRn.FULL flag is set to 1, and is set to 0 when the RFSRn.FULL flag is set to 0.

The RFFULn flag is set to 0 when the CANFDG module enters GL_RESET mode.

CFFULn Flag (Common FIFO n Full Flag) (n = 0 to 5)

The CFFULn flag is set to 1 when the CFSRn.FULL flag is set to 1 is set to 0 when the CFSRn.FULL flag is set to 0.
The CFFULn flag is set to 0 when the CANFDG module enters GL_RESET mode.

45.2.33 FIFO Message Lost Status Register (FMLSR)

Address(es): CANFDG0.FMLSR 8748 02A8h, CANFDG0_NS.FMLSR 0748 02A8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	CFML5	CFML4	CFML3	CFML2	CFML1	CFML0	RFML7	RFML6	RFML5	RFML4	RFML3	RFML2	RFML1	RFML0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFML0	Receive FIFO 0 Message Lost Flag	0: No message lost has occurred in receive FIFO 0 1: Message lost has occurred in receive FIFO 0	R
b1	RFML1	Receive FIFO 1 Message Lost Flag	0: No message lost has occurred in receive FIFO 1 1: Message lost has occurred in receive FIFO 1	R
b2	RFML2	Receive FIFO 2 Message Lost Flag	0: No message lost has occurred in receive FIFO 2 1: Message lost has occurred in receive FIFO 2	R
b3	RFML3	Receive FIFO 3 Message Lost Flag	0: No message lost has occurred in receive FIFO 3 1: Message lost has occurred in receive FIFO 3	R
b4	RFML4	Receive FIFO 4 Message Lost Flag	0: No message lost has occurred in receive FIFO 4 1: Message lost has occurred in receive FIFO 4	R
b5	RFML5	Receive FIFO 5 Message Lost Flag	0: No message lost has occurred in receive FIFO 5 1: Message lost has occurred in receive FIFO 5	R
b6	RFML6	Receive FIFO 6 Message Lost Flag	0: No message lost has occurred in receive FIFO 6 1: Message lost has occurred in receive FIFO 6	R
b7	RFML7	Receive FIFO 7 Message Lost Flag	0: No message lost has occurred in receive FIFO 7 1: Message lost has occurred in receive FIFO 7	R
b8	CFML0	Common FIFO 0 Message Lost Flag	0: No message lost has occurred in common FIFO 0 1: Message lost has occurred in common FIFO 0	R
b9	CFML1	Common FIFO 1 Message Lost Flag	0: No message lost has occurred in common FIFO 1 1: Message lost has occurred in common FIFO 1	R
b10	CFML2	Common FIFO 2 Message Lost Flag	0: No message lost has occurred in common FIFO 2 1: Message lost has occurred in common FIFO 2	R
b11	CFML3	Common FIFO 3 Message Lost Flag	0: No message lost has occurred in common FIFO 3 1: Message lost has occurred in common FIFO 3	R
b12	CFML4	Common FIFO 4 Message Lost Flag	0: No message lost has occurred in common FIFO 4 1: Message lost has occurred in common FIFO 4	R
b13	CFML5	Common FIFO 5 Message Lost Flag	0: No message lost has occurred in common FIFO 5 1: Message lost has occurred in common FIFO 5	R
b31 to b14	—	Reserved	These bits are read as 0.	R

This register shows the status of the message lost flags of the FIFO buffers.

RFMLn Flag (Receive FIFO n Message Lost Flag) (n = 0 to 7)

The RFMLn flag is set to 1 when the RFSRn.LOST flag is set to 1, and is set to 0 when the RFSRn.LOST flag is set to 0. The RFMLn flag is cleared when the CANFDG module enters GL_RESET mode.

CFMLn Flag (Common FIFO n Message Lost Flag) (n = 0 to 5)

The CFMLn flag is set to 1 when the CFSRn.LOST flag is set to 1, and is set to 0 when the CFSRn.LOST flag is set to 0. The CFMLn flag is cleared when the CANFDG module enters GL_RESET mode.

45.2.34 Receive FIFO Interrupt Status Register (RFISR)

Address(es): CANFDG0.RFISR 8748 02ACh, CANFDG0_NS.RFISR 0748 02ACh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	RFFIF7	RFFIF6	RFFIF5	RFFIF4	RFFIF3	RFFIF2	RFFIF1	RFFIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	RFIF7	RFIF6	RFIF5	RFIF4	RFIF3	RFIF2	RFIF1	RFIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFIF0	Receive FIFO 0 Interrupt Flag	0: Receive FIFO 0 interrupt condition is not satisfied 1: Receive FIFO 0 interrupt condition is satisfied	R
b1	RFIF1	Receive FIFO 1 Interrupt Flag	0: Receive FIFO 1 interrupt condition is not satisfied 1: Receive FIFO 1 interrupt condition is satisfied	R
b2	RFIF2	Receive FIFO 2 Interrupt Flag	0: Receive FIFO 2 interrupt condition is not satisfied 1: Receive FIFO 2 interrupt condition is satisfied	R
b3	RFIF3	Receive FIFO 3 Interrupt Flag	0: Receive FIFO 3 interrupt condition is not satisfied 1: Receive FIFO 3 interrupt condition is satisfied	R
b4	RFIF4	Receive FIFO 4 Interrupt Flag	0: Receive FIFO 4 interrupt condition is not satisfied 1: Receive FIFO 4 interrupt condition is satisfied	R
b5	RFIF5	Receive FIFO 5 Interrupt Flag	0: Receive FIFO 5 interrupt condition is not satisfied 1: Receive FIFO 5 interrupt condition is satisfied	R
b6	RFIF6	Receive FIFO 6 Interrupt Flag	0: Receive FIFO 6 interrupt condition is not satisfied 1: Receive FIFO 6 interrupt condition is satisfied	R
b7	RFIF7	Receive FIFO 7 Interrupt Flag	0: Receive FIFO 7 interrupt condition is not satisfied 1: Receive FIFO 7 interrupt condition is satisfied	R
b15 to b8	—	Reserved	These bits are read as 0.	R
b16	RFFIF0	Receive FIFO 0 Full Interrupt Flag	0: Receive FIFO 0 full interrupt condition is not satisfied 1: Receive FIFO 0 full interrupt condition is satisfied	R
b17	RFFIF1	Receive FIFO 1 Full Interrupt Flag	0: Receive FIFO 1 full interrupt condition is not satisfied 1: Receive FIFO 1 full interrupt condition is satisfied	R
b18	RFFIF2	Receive FIFO 2 Full Interrupt Flag	0: Receive FIFO 2 full interrupt condition is not satisfied 1: Receive FIFO 2 full interrupt condition is satisfied	R
b19	RFFIF3	Receive FIFO 3 Full Interrupt Flag	0: Receive FIFO 3 full interrupt condition is not satisfied 1: Receive FIFO 3 full interrupt condition is satisfied	R
b20	RFFIF4	Receive FIFO 4 Full Interrupt Flag	0: Receive FIFO 4 full interrupt condition is not satisfied 1: Receive FIFO 4 full interrupt condition is satisfied	R
b21	RFFIF5	Receive FIFO 5 Full Interrupt Flag	0: Receive FIFO 5 full interrupt condition is not satisfied 1: Receive FIFO 5 full interrupt condition is satisfied	R
b22	RFFIF6	Receive FIFO 6 Full Interrupt Flag	0: Receive FIFO 6 full interrupt condition is not satisfied 1: Receive FIFO 6 full interrupt condition is satisfied	R
b23	RFFIF7	Receive FIFO 7 Full Interrupt Flag	0: Receive FIFO 7 full interrupt condition is not satisfied 1: Receive FIFO 7 full interrupt condition is satisfied	R
b31 to b24	—	Reserved	These bits are read as 0.	R

This register shows the status of the interrupt flags of the receive FIFOs.

RFIFn Flag (Receive FIFO n Interrupt Flag) (n = 0 to 7)

The RFIFn flag is set to 1 when the RFSRn.RFIF flag is set to 1, and is set to 0 when the RFSRn.RFIF flag is set to 0.

The RFIFn flag is cleared when the CANFDG module enters GL_RESET mode.

RFFIFn Flag (Receive FIFO n Full Interrupt Flag) (n = 0 to 7)

The RFFIFn flag is set to 1 when the RFSRn.RFFIF flag is set to 1, and is set to 0 when the RFSRn.RFFIF flag is set to 0. The RFFIFn flag is cleared when the CANFDG module enters GL_RESET mode.

45.2.35 Common FIFO Receive Interrupt Status Register (CFRISR)

Address(es): CANFDG0.CFRISR 8748 02B0h, CANFDG0_NS.CFRISR 0748 02B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	CFRIF5	CFRIF4	CFRIF3	CFRIF2	CFRIF1	CFRIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CFRIF0	Common FIFO 0 Receive Interrupt Flag	0: Common FIFO 0 receive interrupt condition is not satisfied 1: Common FIFO 0 receive interrupt condition is satisfied	R
b1	CFRIF1	Common FIFO 1 Receive Interrupt Flag	0: Common FIFO 1 receive interrupt condition is not satisfied 1: Common FIFO 1 receive interrupt condition is satisfied	R
b2	CFRIF2	Common FIFO 2 Receive Interrupt Flag	0: Common FIFO 2 receive interrupt condition is not satisfied 1: Common FIFO 2 receive interrupt condition is satisfied	R
b3	CFRIF3	Common FIFO 3 Receive Interrupt Flag	0: Common FIFO 3 receive interrupt condition is not satisfied 1: Common FIFO 3 receive interrupt condition is satisfied	R
b4	CFRIF4	Common FIFO 4 Receive Interrupt Flag	0: Common FIFO 4 receive interrupt condition is not satisfied 1: Common FIFO 4 receive interrupt condition is satisfied	R
b5	CFRIF5	Common FIFO 5 Receive Interrupt Flag	0: Common FIFO 5 receive interrupt condition is not satisfied 1: Common FIFO 5 receive interrupt condition is satisfied	R
b31 to b6	—	Reserved	These bits are read as 0.	R

This register shows the status of the receive interrupt flags of the common FIFOs.

CFRIFn Flag (Common FIFO n Receive Interrupt Flag) (n = 0 to 5)

The CFRIFn flag is set to 1 when the CFSRn.CFRIF flag is set to 1, and is set to 0 when the CFSRn.CFRIF flag is set to 0.

The CFRIFn flag is cleared when the CANFDG module enters GL_RESET mode.

45.2.36 Common FIFO Transmit Interrupt Status Register (CFTISR)

Address(es): CANFDG0.CFTISR 8748 02B4h, CANFDG0_NS.CFTISR 0748 02B4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	CFTIF5	CFTIF4	CFTIF3	CFTIF2	CFTIF1	CFTIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CFTIF0	Common FIFO 0 Transmit Interrupt Flag	0: Common FIFO 0 transmit interrupt condition is not satisfied 1: Common FIFO 0 transmit interrupt condition is satisfied	R
b1	CFTIF1	Common FIFO 1 Transmit Interrupt Flag	0: Common FIFO 1 transmit interrupt condition is not satisfied 1: Common FIFO 1 transmit interrupt condition is satisfied	R
b2	CFTIF2	Common FIFO 2 Transmit Interrupt Flag	0: Common FIFO 2 transmit interrupt condition is not satisfied 1: Common FIFO 2 transmit interrupt condition is satisfied	R
b3	CFTIF3	Common FIFO 3 Transmit Interrupt Flag	0: Common FIFO 3 transmit interrupt condition is not satisfied 1: Common FIFO 3 transmit interrupt condition is satisfied	R
b4	CFTIF4	Common FIFO 4 Transmit Interrupt Flag	0: Common FIFO 4 transmit interrupt condition is not satisfied 1: Common FIFO 4 transmit interrupt condition is satisfied	R
b5	CFTIF5	Common FIFO 5 Transmit Interrupt Flag	0: Common FIFO 5 transmit interrupt condition is not satisfied 1: Common FIFO 5 transmit interrupt condition is satisfied	R
b31 to b6	—	Reserved	These bits are read as 0.	R

This register shows the status of the transmit interrupt flags of the common FIFOs.

CFTIFn Flag (Common FIFO n Transmit Interrupt Flag) (n = 0 to 5)

The CFTIFn flag is set to 1 when the CFSRn.CFTIF flag is set to 1, and is set to 0 when the CFSRn.CFTIF flag is set to 0.

The CFTIFn flag is cleared when the CANFDG module enters GL_RESET mode.

45.2.37 FIFO Full Interrupt Status Register (FFISR)

Address(es): CANFDG0.FFISR 8748 02C4h, CANFDG0_NS.FFISR 0748 02C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	CFFIF5	CFFIF4	CFFIF3	CFFIF2	CFFIF1	CFFIF0	RFFIF7	RFFIF6	RFFIF5	RFFIF4	RFFIF3	RFFIF2	RFFIF1	RFFIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFFIF0	Receive FIFO 0 Full Interrupt Flag	0: Receive FIFO 0 full interrupt condition is not satisfied 1: Receive FIFO 0 full interrupt condition is satisfied	R
b1	RFFIF1	Receive FIFO 1 Full Interrupt Flag	0: Receive FIFO 1 full interrupt condition is not satisfied 1: Receive FIFO 1 full interrupt condition is satisfied	R
b2	RFFIF2	Receive FIFO 2 Full Interrupt Flag	0: Receive FIFO 2 full interrupt condition is not satisfied 1: Receive FIFO 2 full interrupt condition is satisfied	R
b3	RFFIF3	Receive FIFO 3 Full Interrupt Flag	0: Receive FIFO 3 full interrupt condition is not satisfied 1: Receive FIFO 3 full interrupt condition is satisfied	R
b4	RFFIF4	Receive FIFO 4 Full Interrupt Flag	0: Receive FIFO 4 full interrupt condition is not satisfied 1: Receive FIFO 4 full interrupt condition is satisfied	R
b5	RFFIF5	Receive FIFO 5 Full Interrupt Flag	0: Receive FIFO 5 full interrupt condition is not satisfied 1: Receive FIFO 5 full interrupt condition is satisfied	R
b6	RFFIF6	Receive FIFO 6 Full Interrupt Flag	0: Receive FIFO 6 full interrupt condition is not satisfied 1: Receive FIFO 6 full interrupt condition is satisfied	R
b7	RFFIF7	Receive FIFO 7 Full Interrupt Flag	0: Receive FIFO 7 full interrupt condition is not satisfied 1: Receive FIFO 7 full interrupt condition is satisfied	R
b8	CFFIF0	Common FIFO 0 Full Interrupt Flag	0: Common FIFO 0 full interrupt condition is not satisfied 1: Common FIFO 0 full interrupt condition is satisfied	R
b9	CFFIF1	Common FIFO 1 Full Interrupt Flag	0: Common FIFO 1 full interrupt condition is not satisfied 1: Common FIFO 1 full interrupt condition is satisfied	R
b10	CFFIF2	Common FIFO 2 Full Interrupt Flag	0: Common FIFO 2 full interrupt condition is not satisfied 1: Common FIFO 2 full interrupt condition is satisfied	R
b11	CFFIF3	Common FIFO 3 Full Interrupt Flag	0: Common FIFO 3 full interrupt condition is not satisfied 1: Common FIFO 3 full interrupt condition is satisfied	R
b12	CFFIF4	Common FIFO 4 Full Interrupt Flag	0: Common FIFO 4 full interrupt condition is not satisfied 1: Common FIFO 4 full interrupt condition is satisfied	R
b13	CFFIF5	Common FIFO 5 Full Interrupt Flag	0: Common FIFO 5 full interrupt condition is not satisfied 1: Common FIFO 5 full interrupt condition is satisfied	R
b31 to b14	—	Reserved	These bits are read as 0.	R

This register shows the status of the FIFO full interrupt flags of the common FIFOs.

RFFIFn Flag (Receive FIFO n Full Interrupt Flag) (n = 0 to 7)

The RFFIFn flag is set to 1 when the RFSRn.RFFIF flag is set to 1, and is set to 0 when the RFSRn.RFFIF flag is set to 0. The RFFIFn flag is cleared when the CANFDG module enters GL_RESET mode.

CFFIFn Flag (Common FIFO n Full Interrupt Flag) (n = 0 to 5)

The CFFIFn flag is set to 1 when the CFSRn.CFFIF flag is set to 1, and is set to 0 when the CFSRn.CFFIF flag is set to 0. The CFFIFn flag is cleared when the CANFDG module enters GL_RESET mode.

45.2.38 Common FIFO Message Overwrite Status Register (CFOWSR)

Address(es): CANFDG0.CFOWSR 8748 02C0h, CANFDG0_NS.CFOWSR 0748 02C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	CFOWF5	CFOWF4	CFOWF3	CFOWF2	CFOWF1	CFOWF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CFOWF0	Common FIFO 0 Message Overwrite Flag	0: Common FIFO 0 message overwrite condition is not satisfied 1: Common FIFO 0 message overwrite condition is satisfied	R
b1	CFOWF1	Common FIFO 1 Message Overwrite Flag	0: Common FIFO 1 message overwrite condition is not satisfied 1: Common FIFO 1 message overwrite condition is satisfied	R
b2	CFOWF2	Common FIFO 2 Message Overwrite Flag	0: Common FIFO 2 message overwrite condition is not satisfied 1: Common FIFO 2 message overwrite condition is satisfied	R
b3	CFOWF3	Common FIFO 3 Message Overwrite Flag	0: Common FIFO 3 message overwrite condition is not satisfied 1: Common FIFO 3 message overwrite condition is satisfied	R
b4	CFOWF4	Common FIFO 4 Message Overwrite Flag	0: Common FIFO 4 message overwrite condition is not satisfied 1: Common FIFO 4 message overwrite condition is satisfied	R
b5	CFOWF5	Common FIFO 5 Message Overwrite Flag	0: Common FIFO 5 message overwrite condition is not satisfied 1: Common FIFO 5 message overwrite condition is satisfied	R
b31 to b6	—	Reserved	These bits are read as 0.	R

This register shows the status of the message overwrite flags of the common FIFOs. This register is valid only in gateway FIFO mode.

CFOWFn Flag (Common FIFO n Message Overwrite Flag) (n = 0 to 5)

The CFOWFn flag is set to 1 when the CFSRn.CFOWF flag is set to 1, and is set to 0 when the CFSRn.CFOWF flag is set to 0.

The CFOWFn flag is cleared when the CANFDG module enters GL_RESET mode.

45.2.39 Common FIFO One Frame Receive Interrupt Status Register (CFORISR)

Address(es): CANFDG0.CFORISR 8748 02B8h, CANFDG0_NS.CFORISR 0748 02B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	CFORIF5	CFORIF4	CFORIF3	CFORIF2	CFORIF1	CFORIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CFORIF0	Common FIFO 0 One Frame Receive Interrupt Flag	0: Common FIFO 0 one frame receive interrupt condition is not satisfied 1: Common FIFO 0 one frame receive interrupt condition is satisfied	R
b1	CFORIF1	Common FIFO 1 One Frame Receive Interrupt Flag	0: Common FIFO 1 one frame receive interrupt condition is not satisfied 1: Common FIFO 1 one frame receive interrupt condition is satisfied	R
b2	CFORIF2	Common FIFO 2 One Frame Receive Interrupt Flag	0: Common FIFO 2 one frame receive interrupt condition is not satisfied 1: Common FIFO 2 one frame receive interrupt condition is satisfied	R
b3	CFORIF3	Common FIFO 3 One Frame Receive Interrupt Flag	0: Common FIFO 3 one frame receive interrupt condition is not satisfied 1: Common FIFO 3 one frame receive interrupt condition is satisfied	R
b4	CFORIF4	Common FIFO 4 One Frame Receive Interrupt Flag	0: Common FIFO 4 one frame receive interrupt condition is not satisfied 1: Common FIFO 4 one frame receive interrupt condition is satisfied	R
b5	CFORIF5	Common FIFO 5 One Frame Receive Interrupt Flag	0: Common FIFO 5 one frame receive interrupt condition is not satisfied 1: Common FIFO 5 one frame receive interrupt condition is satisfied	R
b31 to b6	—	Reserved	These bits are read as 0.	R

This register shows the status of the one frame receive interrupt flags of the common FIFOs.

CFORIFn Flag (Common FIFO n One Frame Receive Interrupt Flag) (n = 0 to 5)

The CFORIFn flag is set to 1 when the CFSRn.CFORIF flag is set to 1, and is set to 0 when the CFSRn.CFORIF flag is set to 0.

The CFORIFn flag is cleared when the CANFDG module enters GL_RESET mode.

45.2.40 Common FIFO One Frame Transmit Interrupt Status Register (CFOTISR)

Address(es): CANFDG0.CFOTISR 8748 02BCh, CANFDG0_NS.CFOTISR 0748 02BCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	CFOTIF5	CFOTIF4	CFOTIF3	CFOTIF2	CFOTIF1	CFOTIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CFOTIF0	Common FIFO 0 One Frame Transmit Interrupt Flag	0: Common FIFO 0 one frame transmit interrupt condition is not satisfied 1: Common FIFO 0 one frame transmit interrupt condition is satisfied	R
b1	CFOTIF1	Common FIFO 1 One Frame Transmit Interrupt Flag	0: Common FIFO 1 one frame transmit interrupt condition is not satisfied 1: Common FIFO 1 one frame transmit interrupt condition is satisfied	R
b2	CFOTIF2	Common FIFO 2 One Frame Transmit Interrupt Flag	0: Common FIFO 2 one frame transmit interrupt condition is not satisfied 1: Common FIFO 2 one frame transmit interrupt condition is satisfied	R
b3	CFOTIF3	Common FIFO 3 One Frame Transmit Interrupt Flag	0: Common FIFO 3 one frame transmit interrupt condition is not satisfied 1: Common FIFO 3 one frame transmit interrupt condition is satisfied	R
b4	CFOTIF4	Common FIFO 4 One Frame Transmit Interrupt Flag	0: Common FIFO 4 one frame transmit interrupt condition is not satisfied 1: Common FIFO 4 one frame transmit interrupt condition is satisfied	R
b5	CFOTIF5	Common FIFO 5 One Frame Transmit Interrupt Flag	0: Common FIFO 5 one frame transmit interrupt condition is not satisfied 1: Common FIFO 5 one frame transmit interrupt condition is satisfied	R
b31 to b6	—	Reserved	These bits are read as 0.	R

This register shows the status of the one frame transmit interrupt flags of the common FIFOs.

CFOTIFn Flag (Common FIFO n One Frame Transmit Interrupt Flag) (n = 0 to 5)

The CFOTIFn flag is set to 1 when the CFSRn.CFOTIF flag is set to 1, and is set to 0 when the CFSRn.CFOTIF flag is set to 0.

The CFOTIFn flag is cleared when the CANFDG module enters GL_RESET mode.

45.2.41 DMA Transfer Control Register (DTCR)

Address(es): CANFDG0.DTCR 8748 1330h, CANFDG0_NS.DTCR 0748 1330h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CFDTE1	CFDTE0	RFDTE7	RFDTE6	RFDTE5	RFDTE4	RFDTE3	RFDTE2	RFDTE1	RFDTE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFDTE0	Receive FIFO 0 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b1	RFDTE1	Receive FIFO 1 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b2	RFDTE2	Receive FIFO 2 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b3	RFDTE3	Receive FIFO 3 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b4	RFDTE4	Receive FIFO 4 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b5	RFDTE5	Receive FIFO 5 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b6	RFDTE6	Receive FIFO 6 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b7	RFDTE7	Receive FIFO 7 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b8	CFDTE0	Channel 0 Common FIFO DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b9	CFDTE1	Channel 1 Common FIFO DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the start and stop of DTC/DMA transfer operation.

RFDTEn Bit (Receive FIFO n DMA Transfer Enable) (n = 0 to 7)

The RFDTEn bit enables or disables DTC/DMA transfer request for receive FIFO n.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
This bit is set to 0 when the CANFDG module enters GL_RESET mode.

CFDTE0 Bit (Channel 0 Common FIFO DMA Transfer Enable)

The CFDTE0 bit enables or disables DTC/DMA transfer request for common FIFO 0 of channel 0.
Receive DTC/DMA transfers using common FIFOs can only be performed on common FIFO 0 of each channel.
Do not enable DTC/DMA transfer for the common FIFO 0 that is configured as transmit FIFO or gateway FIFO.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
This bit is set to 0 when the CANFDG module enters GL_RESET mode.

CFDTE1 Bit (Channel 1 Common FIFO DMA Transfer Enable)

The CFDTE1 bit enables or disables DTC/DMA transfer request for common FIFO 0 of channel 1.

Receive DTC/DMA transfers using common FIFOs can only be performed on common FIFO 0 of each channel (common FIFO 3 for channel 1).
Do not enable DTC/DMA transfer for the common FIFO 3 that is configured as transmit FIFO or gateway FIFO.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
This bit is set to 0 when the CANFDG module enters GL_RESET mode.

45.2.42 DMA Transfer Status Register (DTSR)

Address(es): CANFDG0.DTSR 8748 1334h, CANFDG0_NS.DTSR 0748 1334h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CFDTS1	CFDTS0	RFDTS7	RFDTS6	RFDTS5	RFDTS4	RFDTS3	RFDTS2	RFDTS1	RFDTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFDTS0	Receive FIFO 0 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b1	RFDTS1	Receive FIFO 1 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b2	RFDTS2	Receive FIFO 2 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b3	RFDTS3	Receive FIFO 3 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b4	RFDTS4	Receive FIFO 4 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b5	RFDTS5	Receive FIFO 5 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b6	RFDTS6	Receive FIFO 6 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b7	RFDTS7	Receive FIFO 7 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b8	CFDTS0	Channel 0 Common FIFO DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b9	CFDTS1	Channel 1 Common FIFO DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b31 to b10	—	Reserved	These bits are read as 0.	R

This register shows the status of the DTC/DMA transfer.

RFDTSn Flag (Receive FIFO n DMA Transfer Status Flag) (n = 0 to 7)

The RFDTSn flag is automatically set to 1 when the DTCR.RFDTEn bit is set to 1 and the receive FIFO 0 is not empty.
This flag is automatically set to 0 when the DTC/DMA transfer stops either because the DTCR.RFDTEn bit is set to 0 or the receive FIFO n is empty.
When the DTCR.RFDTEn bit is set to 0 while DTC/DMA transfer for the receive FIFO n is in progress, the RFDTSn flag becomes 0 when the DTC/DMA transfer is completed.
This flag is set to 0 when the CANFDG module enters GL_RESET mode.

CFDTS0 Flag (Channel 0 Common FIFO DMA Transfer Status Flag)

The CFDTS0 flag is automatically set to 1 when the DTCR.CFDTE0 bit is set to 1 and the common FIFO 0 of channel 0 is not empty.
This flag is automatically set to 0 when the DTC/DMA transfer stops either because the DTCR.CFDTE0 bit is set to 0 or the common FIFO 0 of channel 0 is empty.
When the DTCR.CFDTE0 bit is set to 0 while DTC/DMA transfer for the common FIFO 0 of channel 0 is in progress,

the CFDTS0 flag becomes 0 when the DTC/DMA transfer is complete.
This flag is set to 0 when the CANFDG module enters GL_RESET mode.

CFDTS1 Flag (Channel 1 Common FIFO DMA Transfer Status Flag)

The CFDTS1 flag is automatically set to 1 when the DTCR.CFDTE1 bit is set to 1 and the common FIFO 0 of channel 1 (common FIFO 3) is not empty.
This flag is automatically set to 0 when the DTC/DMA transfer stops either because the DTCR.CFDTE1 bit is set to 0 or the common FIFO 3 is empty.
When the DTCR.CFDTE1 bit is set to 0 while DTC/DMA transfer for the common FIFO 3 is in progress, the CFDTS1 flag becomes 0 when the DTC/DMA transfer is complete.
This flag is set to 0 when the CANFDG module enters GL_RESET mode.

45.2.43 Transmit DMA Transfer Control Register (TDTCR)

Address(es): CANFDG0.TDTCR 8748 1340h, CANFDG0_NS.TDTCR 0748 1340h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFDTE1	CFDTE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	TQDTE13	TQDTE03	—	—	—	—	—	—	TQDTE10	TQDTE00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TQDTE00	Channel 0 Transmit Queue 0 DMA Transfer Enable	0: DTC/DMA transmit transfer request is disabled 1: DTC/DMA transmit transfer request is enabled	R/W
b1	TQDTE10	Channel 1 Transmit Queue 0 DMA Transfer Enable	0: DTC/DMA transmit transfer request is disabled 1: DTC/DMA transmit transfer request is enabled	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	TQDTE03	Channel 0 Transmit Queue 3 DMA Transfer Enable	0: DTC/DMA transmit transfer request is disabled 1: DTC/DMA transmit transfer request is enabled	R/W
b9	TQDTE13	Channel 1 Transmit Queue 3 DMA Transfer Enable	0: DTC/DMA transmit transfer request is disabled 1: DTC/DMA transmit transfer request is enabled	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	CFDTE0	Channel 0 Common FIFO DMA Transfer Enable	0: DTC/DMA transmit transfer request is disabled 1: DTC/DMA transmit transfer request is enabled	R/W
b17	CFDTE1	Channel 1 Common FIFO DMA Transfer Enable	0: DTC/DMA transmit transfer request is disabled 1: DTC/DMA transmit transfer request is enabled	R/W
b31 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the start and stop of DTC/DMA transmit transfer operations.

TQDTEi0 Bit (Channel i Transmit Queue 0 DMA Transfer Enable) (i = 0, 1)

The TQDTEi0 bit enables or disables a DTC/DMA transmit transfer request for transmit queue 0.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
This bit is set to 0 when the CANFDG module enters GL_RESET mode.

TQDTEi3 Bit (Channel i Transmit Queue 3 DMA Transfer Enable) (i = 0, 1)

The TQDTEi3 bit enables or disables a DTC/DMA transmit transfer request for transmit queue 3.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
This bit is set to 0 when the CANFDG module enters GL_RESET mode.

CFDTE0 Bit (Channel 0 Common FIFO DMA Transfer Enable)

The CFDTE0 bit enables or disables a DTC/DMA transmit transfer request for common FIFO 2 of channel 0.
DTC/DMA transmit transfers using common FIFO can only be performed using common FIFO 2 of each channel.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
This bit is set to 0 when the CANFDG module enters GL_RESET mode.
When common FIFO 2 is configured as receive FIFO mode or gateway FIFO mode, do not set this bit to 1.

CFDTE1 Bit (Channel 1 Common FIFO DMA Transfer Enable)

The CFDTE1 bit enables or disables a DTC/DMA transmit transfer request for common FIFO 2 of channel 1.
DTC/DMA transmit transfers using common FIFO can only be performed using common FIFO 2 of each channel (common FIFO 5 for channel 1).
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
This bit is set to 0 when the CANFDG module enters GL_RESET mode.
When common FIFO 5 is configured as receive FIFO mode or gateway FIFO mode, do not set this bit to 1.

45.2.44 Transmit DMA Transfer Status Register (TDTSR)

Address(es): CANFDG0.TDTSR 8748 1344h, CANFDG0_NS.TDTSR 0748 1344h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFDTS1	CFDTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TQDTS00	Channel 0 Transmit Queue 0 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped 1: DTC/DMA transfer is enabled	R
b1	TQDTS10	Channel 1 Transmit Queue 0 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped 1: DTC/DMA transfer is enabled	R
b7 to b2	—	Reserved	These bits are read as 0.	R
b8	TQDTS03	Channel 0 Transmit Queue 3 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped 1: DTC/DMA transfer is enabled	R
b9	TQDTS13	Channel 1 Transmit Queue 3 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped 1: DTC/DMA transfer is enabled	R
b15 to b10	—	Reserved	These bits are read as 0.	R
b16	CFDTS0	Channel 0 Common FIFO DMA Transfer Status Flag	0: DTC/DMA transfer is stopped 1: DTC/DMA transfer is enabled	R
b17	CFDTS1	Channel 1 Common FIFO DMA Transfer Status Flag	0: DTC/DMA transfer is stopped 1: DTC/DMA transfer is enabled	R
b31 to b18	—	Reserved	These bits are read as 0.	R

This register shows the status of the DTC/DMA transfer. The same value as the TDTCR register can be read.

TQDTSi0 Flag (Channel i Transmit Queue 0 DMA Transfer Status Flag) (i = 0, 1)

The TQDTSi0 flag is set to 1 when the TDTCR.TQDTEi0 bit is set to 1, and is set to 0 when the TDTCR.TQDTEi0 bit is set to 0.

The TQDTSi0 flag is cleared when the CANFDG module enters GL_RESET mode.

TQDTSi3 Flag (Channel i Transmit Queue 3 DMA Transfer Status Flag) (i = 0, 1)

The TQDTSi3 flag is set to 1 when the TDTCR.TQDTEi3 bit is set to 1, and is set to 0 when the TDTCR.TQDTEi3 bit is set to 0.

The TQDTSi3 flag is cleared when the CANFDG module enters GL_RESET mode.

CFDTSi Flag (Channel i Common FIFO DMA Transfer Status Flag) (i = 0, 1)

The CFDTSi flag is set to 1 when the TDTCR.CFDTEi bit is set to 1, and is set to 0 when the TDTCR.CFDTEi bit is set to 0.

The CFDTSi flag is cleared when the CANFDG module enters GL_RESET mode.

45.2.45 Receive Interrupt Status Register (RISR)

Address(es): CANFD0.RISR 8748 1350h, CANFD1.RISR 8748 1354h,

b31	—	Reserved	This bit is read as 0.	R

TQFIFm Flag (Transmit Queue m Full Interrupt Monitor Flag) (m = 0 to 2)

The TQFIFm flag is automatically set to 1 when the transmit queue full interrupt flag of the corresponding channel becomes 1 while interrupts are enabled.
The TQFIFm flag is set to 0:

- When interrupts are disabled
- When the transmit queue result status flag is cleared
- When the CANFDG module enters GL_RESET mode or the CAN channel enters CH_RESET mode

TQORIFm Flag (Transmit Queue m One Frame Receive Interrupt Monitor Flag) (m = 0 to 2)

The TQORIFm flag is automatically set to 1 when the transmit queue one frame receive interrupt flag of the corresponding channel becomes 1 while interrupts are enabled.
The TQORIFm flag is set to 0:

- When interrupts are disabled
- When the transmit queue result status flag is cleared
- When the CANFDG module enters GL_RESET mode or the CAN channel enters CH_RESET mode

CFRIFm Flag (Common FIFO m Receive Interrupt Monitor Flag) (m = 0 to 2)

The CFRIFm flag is automatically set to 1 when the common FIFO receive interrupt flag of the corresponding channel becomes 1 while interrupts are enabled.
The CFRIFm flag is set to 0:

- When interrupts are disabled
- When the common FIFO reception result status flag is cleared
- When the CANFDG module enters GL_RESET mode or the CAN channel enters CH_RESET mode

CFFIFm Flag (Common FIFO m Full Interrupt Monitor Flag) (m = 0 to 2)

The CFFIFm flag is automatically set to 1 when the common FIFO full interrupt flag of the corresponding channel becomes 1 while interrupts are enabled.
The CFFIFm flag is set to 0:

- When interrupts are disabled
- When the common FIFO reception result status flag is cleared
- When the CANFDG module enters GL_RESET mode or the CAN channel enters CH_RESET mode

CFORIFm Flag (Common FIFO m One Frame Receive Interrupt Monitor Flag) (m = 0 to 2)

The CFORIFm flag is automatically set to 1 when the common FIFO one frame receive interrupt flag of the corresponding channel becomes 1 while interrupts are enabled.
The CFORIFm flag is set to 0:

- When interrupts are disabled
- When the common FIFO reception result status flag is cleared
- When the CANFDG module enters GL_RESET mode or the CAN channel enters CH_RESET mode

45.2.46 Transmit Message Buffer n Control Register (TMCRn) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103)

Address(es): CANFDG0.TMCR0 8748 02D0h to CANFDG0.TMCR7 8748 02D7h,
CANFDG0.TMCR32 8748 02F0h to CANFDG0.TMCR39 8748 02F7h,
CANFDG0.TMCR64 8748 0310h to CANFDG0.TMCR71 8748 0317h,
CANFDG0.TMCR96 8748 0330h to CANFDG0.TMCR103 8748 0337h,

CANFDG0_NS.TMCR96 0748 0330h to CANFDG0_NS.TMCR103 0748 0337h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	ONESHOT	TARQ	TXRQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXRQ	Transmission Request	0: Message transmission is not requested 1: Message transmission is requested	R/W
b1	TARQ	Transmission Abort Request	0: Message transmission abort is not requested 1: Message transmission abort is requested	R/W
b2	ONESHOT	One-shot Transmission Enable	0: One-shot transmission is disabled 1: One-shot transmission is enabled	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register configures the transmit message buffer functions.

TXRQ Bit (Transmission Request)

When the TXRQ bit is set to 1, the CANFDG module attempts to transmit the message stored in the corresponding message buffer.
This bit can only be written in CH_HALT or CH_OPERATION mode.
This bit cannot be set to 1 if the corresponding transmit message buffer is linked to the common FIFO configured in transmit FIFO or gateway FIFO mode, or is a part of the transmit queue.
This bit can be set to 1 only when the TMSRn.TXRF[1:0] flags are set to 00b.
This bit cannot be directly cleared by a CPU write access. The TXRQ bit is automatically set to 0:

- At the end of a successful transmission
- At the end of a transmission abort, requested by the TARQ bit
- When a CAN bus error or arbitration lost is detected while the ONESHOT bit is set to 1
- When the CANFDG module enters GL_RESET or the CAN channel enters CH_RESET mode.

TARQ Bit (Transmission Abort Request)

When the TARQ bit is set to 1, the CANFDG module attempts to abort transmission of the frame stored in the corresponding message buffer.
In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame will be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.

However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (pin for reception) before it starts transmission from the selected message buffer.
This bit can only be written in CH_HALT or CH_OPERATION mode. This bit can be set to 1 only when the TXRQ bit is set to 1.
This bit cannot be set to 0 by a CPU write access. This bit is set to 0 if writing 1 by CPU and clearing by the CAN channel occur at the same time.
The TARQ bit is automatically set to 0:

- At the end of a successful transmission
- At the end of a transmission abort
- When a CAN bus error or arbitration lost is detected
- When the CANFDG module enters GL_RESET or the CAN channel enters CH_RESET mode.

ONESHOT Bit (One-shot Transmission Enable)

When the ONESHOT bit is set to 1, the CANFDG module attempts to transmit the message only once.
If the transmission is successful, the TMSRn.TXRF[1:0] flags are set to 10b or 11b. If a transmission fails due to a bus error or an arbitration lost detection, the transmission is automatically aborted and TMSRn.TXRF[1:0] flags are set to 01b.
The ONESHOT bit remains 1 if the transmission has completed successfully or aborted due to a CAN bus error or an arbitration lost detection.
This bit can only be written in CH_HALT or CH_OPERATION mode.
Set this bit to 1 at the same time as the TXRQ bit. To set this bit to 0, write 0.
If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.
The ONESHOT bit is automatically set to 0 when the CANFDG module enters GL_RESET or the CAN channel enters CH_RESET mode.

45.2.47 Transmit Message Buffer n Status Register (TMSRn) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103)

Address(es): CANFDG0.TMSR0 8748 07D0h to CANFDG0.TMSR7 8748 07D7h,
CANFDG0.TMSR32 8748 07F0h to CANFDG0.TMSR39 8748 07F7h,
CANFDG0.TMSR64 8748 0810h to CANFDG0.TMSR71 8748 0817h,
CANFDG0.TMSR96 8748 0830h to CANFDG0.TMSR103 8748 0837h,
CANFDG0_NS.TMSR0 0748 07D0h to CANFDG0_NS.TMSR7 0748 07D7h,
CANFDG0_NS.TMSR32 0748 07F0h to CANFDG0_NS.TMSR39 0748 07F7h,
CANFDG0_NS.TMSR64 0748 0810h to CANFDG0_NS.TMSR71 0748 0817h,
CANFDG0_NS.TMSR96 0748 0830h to CANFDG0_NS.TMSR103 0748 0837h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	TARQS	TXRQS	TXRF[1:0]		TXSF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXSF	Transmission Status Flag	0: No transmission is in progress 1: Transmission is in progress	R
b2, b1	TXRF[1:0]	Transmission Result Flag	b2 b1 0 0: No result (transmission is not requested or in progress) 0 1: Transmission was aborted. 1 0: Transmission was successful and transmission abort is not requested. 1 1: Transmission was successful and transmission abort is requested.	R/W
b3	TXRQS	Transmission Request Status Flag	0: Transmission is not requested 1: Transmission is requested	R
b4	TARQS	Transmission Abort Request Status Flag	0: Transmission abort is not requested 1: Transmission abort is requested	R
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register shows the status of the transmission and transmission abort for the transmit message buffers.

TXSF Flag (Transmission Status Flag)

The TXSF flag is automatically set to 1 at the start of the transmission from the corresponding transmit message buffer. This flag is automatically set to 0 when:

- Transmission stops
- The CANFDG module enters GL_RESET mode
- The CAN channel enters CH_RESET mode.

TXRF[1:0] Flags (Transmission Result Flag)

The TXRF[1:0] flags show the transmission result for the transmit message buffer.
These flags can only be written in CH_HALT or CH_OPERATION mode.
Each bit of these flags is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The TXRF[1:0] flags are automatically set to 00b when the CANFDG module enters GL_RESET or the CAN channel enters CH_RESET mode.

TXRQS Flag (Transmission Request Status Flag)

The TXRQS flag reflects the value of the TMCRn.TXRQ bit.
The TXRQS flag is set to 1 when the TMCRn.TXRQ bit is set to 1. This flag is set to 0 when the TMCRn.TXRQ bit is set to 0.

TARQS Flag (Transmission Abort Request Status Flag)

The TARQS flag reflects the value of the TMCRn.TARQ bit.

The TARQS flag is set to 1 when the TMCRn.TARQ bit is set to 1. This flag is set to 0 when the TMCRn.TARQ bit is set to 0.

45.2.48 Transmit Message Buffer Transmission Request Status Register m (TMTRSRm) (m = 0 to 3)

Address(es): CANFDG0.TMTRSR0 8748 0CD0h, CANFDG0.TMTRSR1 8748 0CD4h, CANFDG0.TMTRSR2 8748 0CD8h, CANFDG0.TMTRSR3 8748 0CDCh,
CANFDG0_NS.TMTRSR0 0748 0CD0h, CANFDG0_NS.TMTRSR1 0748 0CD4h, CANFDG0_NS.TMTRSR2 0748 0CD8h, CANFDG0_NS.TMTRSR3 0748 0CDCh

b5	TXRQS5			R
b6	TXRQS6			R
b7	TXRQS7			R
b31 to b8	—	Reserved	These bits are read as 0.	R

Note: For the transmit message buffer numbers corresponding to each flag, refer to Table 45.5.

This register shows the status of the transmission request in each transmit message buffer.

TXRQSj Flag (Transmit Message Buffer n Transmission Request Status Flag) (j = 0 to 7; n = m × 32 + j)

The TXRQSj flag indicates status of the TMCRn.TXRQ bit.

Each flag is set to 1 only when the TMCRn.TXRQ bit is set to 1 and the message buffer does not belong to a transmit queue.

Each flag is automatically set to 0 when:

- The TMCRn.TXRQ bit is set to 0
- The CANFDG module enters GL_RESET mode
- The CAN channel enters CH_RESET mode.

Table 45.5 TXRQSj Flag and the Transmit Message Buffer Number

Channel	Register Number (m)	Bit Number (j)	Transmit Message Buffer Number (n)
Channel 0	0	0	0
		1	1
		:	:
		7	7
	1	0	32

b4	TARQS4			R
b5	TARQS5			R
b6	TARQS6			R
b7	TARQS7			R
b31 to b8	—	Reserved	These bits are read as 0.	R

Note: For the transmit message buffer numbers corresponding to each flag, refer to Table 45.5.

This register shows the status of the transmission abort request in each transmit message buffer.

TARQSj Flag (Transmit Message Buffer n Transmission Abort Request Status Flag)
(j = 0 to 7; n = m × 32 + j)

The TARQSj flag indicates status of the TMCRn.TARQ bit.
Each flag is set to 1 when the TMCRn.TARQ bit is set to 1 or the message buffer belongs to a transmit queue.
Each flag is automatically set to 0 when:

- The TMCRn.TARQ bit is set to 0
- The CANFDG module enters GL_RESET mode
- The CAN channel enters CH_RESET mode.

45.2.50 Transmit Message Buffer Transmission Completion Status Register m (TMTCSRm) (m = 0 to 3)

Address(es): CANFDG0.TMTCSR0 8748 0E10h, CANFDG0.TMTCSR1 8748 0E14h, CANFDG0.TMTCSR2 8748 0E18h, CANFDG0.TMTCSR3 8748 0E1Ch,
CANFDG0_NS.TMTCSR0 0748 0E10h, CANFDG0_NS.TMTCSR1 0748 0E14h, CANFDG0_NS.TMTCSR2 0748 0E18h, CANFDG0_NS.TMTCSR3 0748 0E1Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXCF0	Transmit Message Buffer n Transmission Complete Flag	0: Transmission is not completed for the transmit message buffer n, 1: Transmission is completed for the transmit message buffer n,	R
b1	TXCF1			R
b2	TXCF2			R
b3	TXCF3			R
b4	TXCF4			R
b5	TXCF5			R
b6	TXCF6			R
b7	TXCF7			R
b31 to b8	—	Reserved	These bits are read as 0.	R

Note: For the transmit message buffer numbers corresponding to each flag, refer to Table 45.5.

This register shows the transmission completion status for each transmit message buffer.

TXCFj Flag (Transmit Message Buffer n Transmission Completion Status) (j = 0 to 7; n = m × 32 + j)

The TXCFj flag indicates the transmission completion status for the transmit message buffer n.
Each flag is automatically set to 1 when the TMSRn.TXRF[1] bit is set to 1.
Each flag is automatically set to 0 when:

- The TMSRn.TXRF[1] bit is set to 0
- The CANFDG module enters GL_RESET mode
- The CAN channel enters CH_RESET mode.

45.2.51 Transmit Message Buffer Transmission Abort Status Register m (TMTASRm) (m = 0 to 3)

Address(es): CANFDG0.TMTASR0 8748 0EB0h, CANFDG0.TMTASR1 8748 0EB4h, CANFDG0.TMTASR2 8748 0EB8h, CANFDG0.TMTASR3 8748 0EBCh,
CANFDG0_NS.TMTASR0 0748 0EB0h, CANFDG0_NS.TMTASR1 0748 0EB4h, CANFDG0_NS.TMTASR2 0748 0EB8h, CANFDG0_NS.TMTASR3 0748 0EBCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TAF7	TAF6	TAF5	TAF4	TAF3	TAF2	TAF1	TAF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TAF0	Transmit Message Buffer n Transmission Abort Status Flag	0: Transmission is not aborted for the transmit message buffer n. 1: Transmission is aborted for the transmit message buffer n.	R
b1	TAF1			R
b2	TAF2			R
b3	TAF3			R
b4	TAF4			R
b5	TAF5			R
b6	TAF6			R
b7	TAF7			R
b31 to b8	—	Reserved	These bits are read as 0.	R

Note: For the transmit message buffer numbers corresponding to each flag, refer to Table 45.5.

This register shows the transmission abort status for each transmit message buffer.

TAFj Flag (Transmit Message Buffer n Transmission Abort Status Flag) (j = 0 to 7; n = m × 32 + j)

The TAFj flag indicates the transmission abort status for the transmit message buffer n.
Each flag is automatically set to 1 when the TMSRn.TXRF[1:0] flags are set to 01b.
Each flag is automatically set to 0 when:

- The TMSRn.TXRF[1:0] flags are set to 00b
- The CANFDG module enters GL_RESET mode
- The CAN channel enters CH_RESET mode.

45.2.52 Transmit Message Buffer Interrupt Enable Register m (TMIERm) (m = 0 to 3)

Address(es): CANFDG0.TMIER0 8748 0F50h, CANFDG0.TMIER1 8748 0F54h, CANFDG0.TMIER2 8748 0F58h, CANFDG0.TMIER3 8748 0F5Ch, CANFDG0_NS.TMIER0 0748 0F50h, CANFDG0_NS.TMIER1 0748 0F54h, CANFDG0_NS.TMIER2 0748 0F58h, CANFDG0_NS.TMIER3 0748 0F5Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TMIE7	TMIE6	TMIE5	TMIE4	TMIE3	TMIE2	TMIE1	TMIE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMIE0	Transmit Message Buffer n Interrupt Enable	0: Interrupt for transmit message buffer n is disabled. 1: Interrupt for transmit message buffer n is enabled.	R/W
b1	TMIE1			R/W
b2	TMIE2			R/W
b3	TMIE3			R/W
b4	TMIE4			R/W
b5	TMIE5			R/W
b6	TMIE6			R/W
b7	TMIE7			R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: For the transmit message buffer numbers corresponding to each flag, refer to Table 45.5.

This register enables or disables the interrupt for each transmit message buffer.

TMIEj Bit (Transmit Message Buffer n Interrupt Enable) (j = 0 to 7; n = m × 32 + j)

If the TMIEj bit is set to 1, an interrupt is generated when transmission from the transmit message buffer n is completed successfully.

Refer to section 45.11, Interrupts and DTC/DMA Requests for the specification of the interrupt for transmit message buffer.

This bit cannot be written in GL_SLEEP mode.

Do not write to the TMIEj bit when:

- The CAN channel is in CH_SLEEP mode
- The transmit message buffer n is part of a transmit queue
- The transmit message buffer n is linked to a common FIFO by the CFCRn.LTM[4:0] bits.

45.2.53 Transmit Queue n Configuration Register (TQCRn) (n = 0 to 3)

Address(es): CANFD0.TQCR0 8748 1000h, CANFD1.TQCR0 8748 1004h, CANFD0.TQCR1 8748 1060h, CANFD1.TQCR1 8748 1064h, CANFD0.TQCR2 8748 10C0h, CANFD1.TQCR2 8748 10C4h, CANFD0.TQCR3 8748 1120h, CANFD1.TQCR3 8748 1124h, CANFD0_NS.TQCR0 0748 1000h, CANFD1_NS.TQCR0 0748 1004h, CANFD0_NS.TQCR1 0748 1060h, CANFD1_NS.TQCR1 0748 1064h, CANFD0_NS.TQCR2 0748 10C0h, CANFD1_NS.TQCR2 0748 10C4h, CANFD0_NS.TQCR3 0748 1120h, CANFD1_NS.TQCR3 0748 1124h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TQE	Transmit Queue Enable	0: Transmit queue is disabled. 1: Transmit queue is enabled.	R/W
b1	TQGWE	Transmit Queue Gateway Mode Enable*1	0: Transmit queue gateway mode is disabled. 1: Transmit queue gateway mode is enabled.	R/W
b4 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	TQIE	Transmit Queue Interrupt Enable	0: Transmit queue transmission interrupt is disabled. 1: Transmit queue transmission interrupt is enabled.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	TQIM	Transmit Queue Interrupt Mode Setting	0: When the last message is successfully transmitted 1: At every successful transmission	R/W
b12 to b8	QDS[4:0]	Queue Depth Setting	b12 b8 0 0 0 0 0: 0 messages (disabled) 0 0 0 0 1: Setting prohibited 0 0 0 1 0: 3 messages 0 0 0 1 1: 4 messages : 0 0 1 1 1: 8 messages	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	TQFIE	Transmit Queue Full Interrupt Enable*1	0: Transmit queue full interrupt is disabled. 1: Transmit queue full interrupt is enabled.	R/W
b17	TQORIE	Transmit Queue One Frame Receive Interrupt Enable*1	0: One frame receive interrupt is disabled. 1: One frame receive interrupt is enabled.	R/W
b18	TQOTIE	Transmit Queue One Frame Transmit Interrupt Enable	0: One frame transmit interrupt is disabled. 1: One frame transmit interrupt is enabled.	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. This bit is reserved in the TQCR3 register. This bit is read as 0. The write value should be 0.

This register is used to configure the transmit queue n.

A transmit queue is configured using transmit message buffers. A transmit message buffer used for a transmit queue cannot be used as a normal transmit message buffer.

Table 45.6 shows the transmit message buffers that can be used for each transmit queue and the configuration for each queue depth setting.

Table 45.6 Transmit Message Buffers Available for Each Transmit Queue and the Configuration for Each Queue Depth Setting

Transmit Queue	Configuration of Message Buffers	Queue Depth Setting and Transmit Message Buffer to be used
Transmit queue 0	Transmit message buffer 0 to transmit message buffer 7	3 messages (transmit message buffer 0 to 2) 4 messages (transmit message buffer 0 to 3) : 8 messages (transmit message buffer 0 to 7)
Transmit queue 1	Transmit message buffer 7 to transmit message buffer 0	3 messages (transmit message buffer 7 to 5) 4 messages (transmit message buffer 7 to 4) : 8 messages (transmit message buffer 7 to 0)
Transmit queue 2	Transmit message buffer 32 to transmit message buffer 39	3 messages (transmit message buffer 32 to 35) 4 messages (transmit message buffer 32 to 36) : 8 messages (transmit message buffer 32 to 39)
Transmit queue 3	Transmit message buffer 39 to transmit message buffer 32	3 messages (transmit message buffer 39 to 37) 4 messages (transmit message buffer 39 to 36) : 8 messages (transmit message buffer 39 to 32)

Note: When using transmit queue 0 and transmit queue 1 at the same time, and when using transmit queue 2 and transmit queue 3 at the same time, be sure not to overlap the transmit message buffers to be used.

TQE Bit (Transmit Queue Enable)

The TQE bit enables the transmit queue. When the TQE bit is set to 1, transmit message buffers are used to configure the transmit queue.

The TQE bit cannot be set to 1 if the configured transmit queue depth is 0 (TQCRn.QDS[4:0] = 00000b).

This bit cannot be written in GL_SLEEP mode.

Also, this bit cannot be written in CH_RESET or CH_SLEEP mode.

The TQE bit is automatically set to 0 when the CAN channel enters CH_RESET mode.

TQGWE Bit (Transmit Queue Gateway Mode Enable)

When the TQGWE bit is set to 1, the transmit queue is used as transmit queue in the gateway mode.

When the TQGWE bit is set to 1, do not access the transmit queue from the CPU.

This bit cannot be written in GL_SLEEP mode. Also, this bit cannot be written in CH_HALT or CH_OPERATION mode.

Do not write to this bit when the CAN channel is in CH_SLEEP mode.

TQIE Bit (Transmit Queue Interrupt Enable)

When the TQIE bit is set to 1, an interrupt is generated based on the setting of the TQIM bit.

This bit cannot be written in GL_SLEEP mode.

Do not write to this bit when the CAN channel is in CH_SLEEP mode.

TQIM Bit (Transmit Queue Interrupt Mode Setting)

The TQIM bit selects the interrupt generation condition for the transmit queue.

This bit cannot be written in GL_SLEEP mode.

Do not write to this bit when the CAN channel is in CH_SLEEP, CH_HALT, or CH_OPERATION mode.

QDS[4:0] Bits (Queue Depth Setting)

The QDS[4:0] bits select the depth of the transmit queue.

For the relationship between the queue depth setting and the transmit message buffers to be used, refer to Table 45.6.

These bits cannot be written in GL_SLEEP mode.

Also, these bits cannot be written in CH_HALT or CH_OPERATION mode.
Do not write to these bits when the CAN channel is in CH_SLEEP mode.

TQFIE Bit (Transmit Queue Full Interrupt Enable)

When the TQFIE bit is set to 1, an interrupt occurs according to the setting of the TQSRn.TQFIF flag.
Set this bit to 1 only when the transmit queue is in gateway mode (TQCRn.TQGWE bit = 1).
This bit cannot be written in GL_SLEEP mode.
Do not write to this bit when the CAN channel is in CH_SLEEP mode.

TQORIE Bit (Transmit Queue One Frame Receive Interrupt Enable)

When the TQORIE bit is set to 1, an interrupt occurs according to the setting of the TQSRn.TQORIF flag.
Set this bit to 1 only when the transmit queue is in gateway mode (TQCRn.TQGWE bit = 1).
This bit cannot be written in GL_SLEEP mode.
Do not write to this bit when the CAN channel is in CH_SLEEP mode.

TQOTIE Bit (Transmit Queue One Frame Transmit Interrupt Enable)

When the TQOTIE bit is set to 1, an interrupt occurs according to the setting of the TQSRn.TQOTIF flag.
This bit cannot be written in GL_SLEEP mode.
Do not write to this bit when the CAN channel is in CH_SLEEP mode.

45.2.54 Transmit Queue n Status Register (TQSRn) (n = 0 to 3)

Address(es): CANFD0.TQSR0 8748 1020h, CANFD1.TQSR0 8748 1024h, CANFD0.TQSR1 8748 1080h, CANFD1.TQSR1 8748 1084h, CANFD0.TQSR2 8748 10E0h, CANFD1.TQSR2 8748 10E4h, CANFD0.TQSR3 8748 1140h, CANFD1.TQSR3 8748 1144h, CANFD0_NS.TQSR0 0748 1020h, CANFD1_NS.TQSR0 0748 1024h, CANFD0_NS.TQSR1 0748 1080h, CANFD1_NS.TQSR1 0748 1084h, CANFD0_NS.TQSR2 0748 10E0h, CANFD1_NS.TQSR2 0748 10E4h, CANFD0_NS.TQSR3 0748 1140h, CANFD1_NS.TQSR3 0748 1144h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	LOST	TQOTIF	TQORIF	TQFIF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	FLVL[5:0]						—	—	—	—	—	TQIF	FULL	EMPTY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Transmit Queue Empty Flag	0: There is at least one message in transmit queue 1: No message in transmit queue (empty)	R
b1	FULL	Transmit Queue Full Flag	0: Transmit queue is not full 1: Transmit queue is full	R
b2	TQIF	Transmit Queue Interrupt Flag	0: Transmit queue interrupt condition is not satisfied 1: Transmit queue interrupt condition is satisfied	R/(W) *1
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	FLVL[5:0]	Transmit Queue Fill Level	Indicates the number of messages in the transmit queue	R
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	TQFIF	Transmit Queue Full Interrupt Flag *2	0: Transmit queue full interrupt condition is not satisfied 1: Transmit queue full interrupt condition is satisfied	R/(W) *1
b17	TQORIF	Transmit Queue One Frame Receive Interrupt Flag*2	0: Transmit queue one frame receive interrupt condition is not satisfied 1: Transmit queue one frame receive interrupt condition is satisfied	R/(W) *1
b18	TQOTIF	Transmit Queue One Frame Transmit Interrupt Flag	0: Transmit queue one frame transmit interrupt condition is not satisfied 1: Transmit queue one frame transmit interrupt condition is satisfied	R/(W) *1
b19	LOST	Transmit Queue Message Lost Flag *2	0: Message lost has not occurred in the transmit queue 1: Message lost has occurred in the transmit queue	R/(W) *1
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.
Note 2. This bit is reserved in the TQSR3 register. This bit is read as 0. The write value should be 0.

This register shows the status of the transmit queue n.

EMPTY Flag (Transmit Queue Empty Flag)

This flag is automatically set to 1 when:

- The TQCRn.TQE bit is set to 0 (transmit queue is disabled)
- No messages are stored in the transmit queue
- The last message is transmitted from the transmit queue
- The CAN channel enters CH_RESET mode.

This flag is automatically set to 0 when the first message to be transmitted is stored in the transmit queue.

FULL Flag (Transmit Queue Full Flag)

The FULL flag is automatically set to 1 when the number of messages stored in the transmit queue matches the configured transmit queue depth.
This flag is automatically set to 0 when:

- The number of messages stored in the transmit queue is less than the configured transmit queue depth
- The CAN channel enters CH_RESET mode.

TQIF Flag (Transmit Queue Interrupt Flag)

The TQIF flag is not cleared automatically if the transmit queue is disabled.
When stopping the transmit queue, this flag should be cleared, after setting the TQCRn.TQE bit to 0 and checking an empty state of transmit queue.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is automatically set to 1 when the configured interrupt condition is satisfied for the transmit queue.
This flag is set to 0:

- By writing 0 to it
- When the CAN channel enters CH_RESET mode.

This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag cannot be written in CH_SLEEP or CH_RESET mode.

FLVL[5:0] Bits (Transmit Queue Fill Level)

The FLVL[5:0] bits indicates the number of messages in the transmit queue.
These bits are automatically set to 000000b when the CAN channel enters CH_RESET mode.

TQFIF Flag (Transmit Queue Full Interrupt Flag)

The TQFIF flag is automatically set to 1 when the transmit queue is set to gateway mode (TQCRn.TQGWE bit = 1) and the transmit queue is full.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.
This flag is not automatically cleared if the transmit queue is disabled (TQCRn.TQE bit = 0).
When stopping the transmit queue, this flag should be cleared, after setting the TQE bit to 0 and checking an empty state of transmit queue.
This flag cannot be written in CH_SLEEP or CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

TQORIF Flag (Transmit Queue One Frame Receive Interrupt Flag)

The TQORIF flag is automatically set to 1 when the transmit queue is set to gateway mode (TQCRn.TQGWE bit = 1) and received data is transferred to the transmit queue.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.
This flag is not automatically cleared if the transmit queue is disabled (TQCRn.TQE bit = 0).
When stopping the transmit queue, this flag should be cleared, after setting the TQE bit to 0 and checking an empty state of transmit queue.
This flag cannot be written in CH_SLEEP or CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

TQOTIF Flag (Transmit Queue One Frame Transmit Interrupt Flag)

The TQOTIF flag is automatically set to 1 when message is successfully transmitted from the transmit queue.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.
This flag is not cleared automatically if the transmit queue is disabled (TQCRn.TQE bit = 0).
When stopping the transmit queue, this flag should be cleared, after setting the TQE bit to 0 and checking an empty state of transmit queue.
This flag cannot be written in CH_SLEEP or CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

LOST Flag (Transmit Queue Message Lost Flag)

The LOST flag is automatically set to 1 when the transmit queue is set to gateway mode (TQCRn.TQGWE bit = 1) and message lost has occurred in the transmit queue.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.
This flag is not automatically cleared if the transmit queue is disabled (TQCRn.TQE bit = 0).
When stopping the transmit queue, this flag should be cleared, after setting the TQE bit to 0 and checking an empty state of transmit queue.
This flag cannot be written in CH_SLEEP or CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

45.2.55 Transmit Queue n Pointer Control Register (TQPCRn) (n = 0 to 3)

Address(es): CANFD0.TQPCR0 8748 1040h, CANFD1.TQPCR0 8748 1044h, CANFD0.TQPCR1 8748 10A0h, CANFD1.TQPCR1 8748 10A4h, CANFD0.TQPCR2 8748 1100h, CANFD1.TQPCR2 8748 1104h, CANFD0.TQPCR3 8748 1160h, CANFD1.TQPCR3 8748 1164h, CANFD0_NS.TQPCR0 0748 1040h, CANFD1_NS.TQPCR0 0748 1044h, CANFD0_NS.TQPCR1 0748 10A0h, CANFD1_NS.TQPCR1 0748 10A4h, CANFD0_NS.TQPCR2 0748 1100h, CANFD1_NS.TQPCR2 0748 1104h, CANFD0_NS.TQPCR3 0748 1160h, CANFD1_NS.TQPCR3 0748 1164h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to increment the write pointer to the transmit queue.
When the value 000000FFh is written to this register, the write pointer to the transmit queue is updated and transmission of the existing message is requested.
The read value from this register is always 00000000h.
This register cannot be written in CH_SLEEP or CH_RESET mode.
Write to this register only when:

- The transmit queue is enabled and not full.
- When DTC/DMA transfer is not used to write to the transmit queue
- When the transmit queue is not in gateway mode

45.2.56 Transmit Queue Empty Status Register (TQESR)

Address(es): CANFDG0.TQESR 8748 1180h, CANFDG0_NS.TQESR 0748 1180h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TQEMP13	TQEMP12	TQEMP11	TQEMP10	TQEMP03	TQEMP02	TQEMP01	TQEMP00
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	TQEMP00	Channel 0 Transmit Queue 0 Empty Flag	0: There is at least one message in transmit queue 1: No message in transmit queue (empty)	R
b1	TQEMP01	Channel 0 Transmit Queue 1 Empty Flag		R
b2	TQEMP02	Channel 0 Transmit Queue 2 Empty Flag		R
b3	TQEMP03	Channel 0 Transmit Queue 3 Empty Flag		R
b4	TQEMP10	Channel 1 Transmit Queue 0 Empty Flag		R
b5	TQEMP11	Channel 1 Transmit Queue 1 Empty Flag		R
b6	TQEMP12	Channel 1 Transmit Queue 2 Empty Flag		R
b7	TQEMP13	Channel 1 Transmit Queue 3 Empty Flag		R
b31 to b8	—	Reserved	These bits are read as 0.	R

This register shows the empty status of each transmit queue.

TQEMPin Flag (Channel i Transmit Queue n Empty Flag) (i = 0, 1; n = 0 to 3)

The TQEMPin flag shows the state of the EMPTY flag for the corresponding transmit queue.

This flag is automatically set to 1 when the corresponding flag becomes 1, and automatically set to 0 when the corresponding flag becomes 0.

This flag is set to 1 when the CANFDG module enters GL_RESET mode

45.2.57 Transmit Queue Full Interrupt Status Register (TQFISR)

Address(es): CANFDG0.TQFISR 8748 1184h, CANFDG0_NS.TQFISR 0748 1184h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	TQFIF12	TQFIF11	TQFIF10	—	TQFIF02	TQFIF01	TQFIF00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TQFIF00	Channel 0 Transmit Queue 0 Full Interrupt Flag	0: Transmit queue full interrupt condition is not satisfied 1: Transmit queue full interrupt condition is satisfied	R
b1	TQFIF01	Channel 0 Transmit Queue 1 Full Interrupt Flag		R
b2	TQFIF02	Channel 0 Transmit Queue 2 Full Interrupt Flag		R
b3	—	Reserved	These bits are read as 0.	R
b4	TQFIF10	Channel 1 Transmit Queue 0 Full Interrupt Flag	0: Transmit queue full interrupt condition is not satisfied 1: Transmit queue full interrupt condition is satisfied	R
b5	TQFIF11	Channel 1 Transmit Queue 1 Full Interrupt Flag		R
b6	TQFIF12	Channel 1 Transmit Queue 2 Full Interrupt Flag		R
b31 to b7	—	Reserved	These bits are read as 0.	R

This register shows the state of the transmit queue full interrupt flag for each transmit queue.

TQFIFin Flag (Channel i Transmit Queue n Full Interrupt Flag) (i = 0, 1; n = 0 to 2)

The TQFIFin flag shows the state of the TQFIF flag of the corresponding transmit queue.

This flag is automatically set to 1 when the corresponding flag becomes 1, and automatically set to 0 when the corresponding flag becomes 0.

This flag is set to 0 when the CANFDG module enters GL_RESET mode

45.2.58 Transmit Queue Message Lost Status Register (TQMLSR)

Address(es): CANFDG0.TQMLSR 8748 1188h, CANFDG0_NS.TQMLSR 0748 1188h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	TQML12	TQML11	TQML10	—	TQML02	TQML01	TQML00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TQML00	Channel 0 Transmit Queue 0 Message Lost Interrupt Flag	0: Message lost has not occurred in the transmit queue 1: Message lost has occurred in the transmit queue	R
b1	TQML01	Channel 0 Transmit Queue 1 Message Lost Interrupt Flag		R
b2	TQML02	Channel 0 Transmit Queue 2 Message Lost Interrupt Flag		R
b3	—	Reserved	These bits are read as 0.	R
b4	TQML10	Channel 1 Transmit Queue 0 Message Lost Interrupt Flag	0: Message lost has not occurred in the transmit queue 1: Message lost has occurred in the transmit queue	R
b5	TQML11	Channel 1 Transmit Queue 1 Message Lost Interrupt Flag		R
b6	TQML12	Channel 1 Transmit Queue 2 Message Lost Interrupt Flag		R
b31 to b7	—	Reserved	These bits are read as 0.	R

This register shows the state of the transmit queue message lost flag for each transmit queue.

TQMLin Flag (Channel i Transmit Queue n Message Lost Flag) (i = 0, 1; n = 0 to 2)

The TQMLin flag shows the state of the LOST flag of the corresponding transmit queue.

This flag is automatically set to 1 when the corresponding flag becomes 1, and automatically set to 0 when the corresponding flag becomes 0.

This flag is set to 0 when the CANFDG module enters GL_RESET mode

45.2.59 Transmit Queue Interrupt Status Register (TQISR)

Address(es): CANFDG0.TQISR 8748 1190h, CANFDG0_NS.TQISR 0748 1190h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TQIF13	TQIF12	TQIF11	TQIF10	TQIF03	TQIF02	TQIF01	TQIF00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TQIF00	Channel 0 Transmit Queue 0 Interrupt Flag	0: Transmit queue interrupt condition is not satisfied 1: Transmit queue interrupt condition is satisfied	R
b1	TQIF01	Channel 0 Transmit Queue 1 Interrupt Flag		R
b2	TQIF02	Channel 0 Transmit Queue 2 Interrupt Flag		R
b3	TQIF03	Channel 0 Transmit Queue 3 Interrupt Flag		R
b4	TQIF10	Channel 1 Transmit Queue 0 Interrupt Flag		R
b5	TQIF11	Channel 1 Transmit Queue 1 Interrupt Flag		R
b6	TQIF12	Channel 1 Transmit Queue 2 Interrupt Flag		R
b7	TQIF13	Channel 1 Transmit Queue 3 Interrupt Flag		R
b31 to b8	—	Reserved	These bits are read as 0.	R

This register shows the interrupt status of each transmit queue.

TQIFin Flag (Channel i Transmit Queue n Interrupt Flag) (i = 0, 1; n = 0 to 3)

The TQIFin flag shows the state of the TQIF flag for the corresponding transmit queue.

This flag is automatically set to 1 when the corresponding flag becomes 1, and automatically set to 0 when the corresponding flag becomes 0.

This flag is set to 0 when the CANFDG module enters GL_RESET mode

45.2.60 Transmit Queue One Frame Transmit Interrupt Status Register (TQOTISR)

Address(es): CANFDG0.TQOTISR 8748 1194h, CANFDG0_NS.TQOTISR 0748 1194h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TQOTIF13	TQOTIF12	TQOTIF11	TQOTIF10	TQOTIF03	TQOTIF02	TQOTIF01	TQOTIF00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TQOTIF00	Channel 0 Transmit Queue 0 One Frame Transmit Interrupt Flag	0: Transmit queue one frame transmit interrupt condition is not satisfied 1: Transmit queue one frame transmit interrupt condition is satisfied	R
b1	TQOTIF01	Channel 0 Transmit Queue 1 One Frame Transmit Interrupt Flag		R
b2	TQOTIF02	Channel 0 Transmit Queue 2 One Frame Transmit Interrupt Flag		R
b3	TQOTIF03	Channel 0 Transmit Queue 3 One Frame Transmit Interrupt Flag		R
b4	TQOTIF10	Channel 1 Transmit Queue 0 One Frame Transmit Interrupt Flag		R
b5	TQOTIF11	Channel 1 Transmit Queue 1 One Frame Transmit Interrupt Flag		R
b6	TQOTIF12	Channel 1 Transmit Queue 2 One Frame Transmit Interrupt Flag		R
b7	TQOTIF13	Channel 1 Transmit Queue 3 One Frame Transmit Interrupt Flag		R
b31 to b8	—	Reserved	These bits are read as 0.	R

This register shows the one frame transmit interrupt status of each transmit queue.

TQOTIFin Flag (Channel i Transmit Queue n One Frame Transmit Interrupt Flag) (i = 0, 1; n = 0 to 3)

The TQOTIFin flag shows the state of the TQOTIF flag for the corresponding transmit queue.

This flag is automatically set to 1 when the corresponding flag becomes 1, and automatically set to 0 when the corresponding flag becomes 0.

This flag is set to 0 when the CANFDG module enters GL_RESET mode

45.2.61 Transmit Queue One Frame Receive Interrupt Status Register (TQORISR)

Address(es): CANFDG0.TQORISR 8748 1198h, CANFDG0_NS.TQORISR 0748 1198h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	TQORIF12	TQORIF11	TQORIF10	—	TQORIF02	TQORIF01	TQORIF00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TQORIF00	Channel 0 Transmit Queue 0 One Frame Receive Interrupt Flag	0: Transmit queue one frame receive interrupt condition is not satisfied 1: Transmit queue one frame receive interrupt condition is satisfied	R
b1	TQORIF01	Channel 0 Transmit Queue 1 One Frame Receive Interrupt Flag		R
b2	TQORIF02	Channel 0 Transmit Queue 2 One Frame Receive Interrupt Flag		R
b3	—	Reserved	These bits are read as 0.	R
b4	TQORIF10	Channel 1 Transmit Queue 0 One Frame Receive Interrupt Flag	0: Transmit queue one frame receive interrupt condition is not satisfied 1: Transmit queue one frame receive interrupt condition is satisfied	R
b5	TQORIF11	Channel 1 Transmit Queue 1 One Frame Receive Interrupt Flag		R
b6	TQORIF12	Channel 1 Transmit Queue 2 One Frame Receive Interrupt Flag		R
b31 to b7	—	Reserved	These bits are read as 0.	R

This register shows the one frame receive interrupt status of each transmit queue.

TQORIFin Flag (Channel i Transmit Queue n Full Interrupt Flag) (i = 0, 1; n = 0 to 2)

The TQORIFin flag shows the state of the TQORIF flag of the corresponding transmit queue.
This flag is automatically set to 1 when the corresponding flag becomes 1, and automatically set to 0 when the corresponding flag becomes 0.
This flag is set to 0 when the CANFDG module enters GL_RESET mode

45.2.62 Transmit Queue Full Status Register (TQFSR)

Address(es): CANFDG0.TQFSR 8748 119Ch, CANFDG0_NS.TQFSR 0748 119Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TQFUL13	TQFUL12	TQFUL11	TQFUL10	TQFUL03	TQFUL02	TQFUL01	TQFUL00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TQFUL00	Channel 0 Transmit Queue 0 Full Flag	0: Transmit queue is not full 1: Transmit queue is full	R
b1	TQFUL01	Channel 0 Transmit Queue 1 Full Flag		R
b2	TQFUL02	Channel 0 Transmit Queue 2 Full Flag		R
b3	TQFUL03	Channel 0 Transmit Queue 3 Full Flag		R
b4	TQFUL10	Channel 1 Transmit Queue 0 Full Flag		R
b5	TQFUL11	Channel 1 Transmit Queue 1 Full Flag		R
b6	TQFUL12	Channel 1 Transmit Queue 2 Full Flag		R
b7	TQFUL13	Channel 1 Transmit Queue 3 Full Flag		R
b31 to b8	—	Reserved	These bits are read as 0.	R

This register shows the state of the full flag for each transmit queue.

TQFULin Flag (Channel i Transmit Queue n Full Flag) (i = 0, 1; n = 0 to 3)

The TQFULin flag shows the state of the FULL flag for the corresponding transmit queue.
This flag is automatically set to 1 when the corresponding flag becomes 1, and automatically set to 0 when the corresponding flag becomes 0.
This flag is set to 0 when the CANFDG module enters GL_RESET mode

45.2.63 Transmission History Configuration Register (THCR)

Address(es): CANFD0.THCR 8748 1200h, CANFD1.THCR 8748 1204h,
CANFD0_NS.THCR 0748 1200h, CANFD1_NS.THCR 0748 1204h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	THRGC	THRC	THIM	THIE	—	—	—	—	—	—	—	THE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	THE	Transmission History Enable	0: Transmission history buffer is disabled 1: Transmission history buffer is enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	THIE	Transmission History Interrupt Enable	0: Transmission history interrupt is disabled 1: Transmission history interrupt is enabled	R/W
b9	THIM	Transmission History Interrupt Mode Setting	0: Interrupt is generated if transmission history level reaches 3/4 of the transmission history depth 1: Interrupt is generated for every successfully stored entry	R/W
b10	THRC	Transmission History Recording Condition Setting	0: Transmit FIFO + Transmit queue 1: Transmit message buffer + Transmit FIFO + Transmit queue	R/W
b11	THRGC	Transmission History of Gateway FIFO Recording Condition Setting	0: Recording the transmission history of gateway FIFO is disabled 1: Recording the transmission history of gateway FIFO is enabled	R/W
b31 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register configures the transmission history functions.

THE Bit (Transmission History Enable)

The THE bit enables the transmission history buffer when it is set to 1.
This bit cannot be written in CH_RESET or CH_SLEEP mode.
This bit is automatically set to 0 when the CAN channel enters CH_RESET mode.

THIE Bit (Transmission History Interrupt Enable)

The THIE bit enables the generation of the transmission history interrupt when it is set to 1.
This bit cannot be written in GL_SLEEP mode.

THIM Bit (Transmission History Interrupt Mode Setting)

The THIM bit selects the transmission history interrupt generation condition.
This bit cannot be written in GL_SLEEP mode.
Do not write to this bit in GL_HALT or GL_OPERATION mode.

THRC Bit (Transmission History Recording Condition Setting)

The THRC bit selects the condition for storing an entry in the transmission history buffer after successful transmission.
This bit cannot be written in GL_SLEEP mode.

Do not write to this bit in GL_HALT or GL_OPERATION mode.

THRGC Bit (Transmission History of Gateway FIFO Recording Condition Setting)

The THRGC bit selects whether to store in the transmission history buffer after successful transmission in the gateway FIFO.
This bit cannot be written in GL_SLEEP mode.
Do not write to this bit in GL_HALT or GL_OPERATION mode.

45.2.64 Transmission History Status Register (THSR)

Address(es): CANFD0.THSR 8748 1220h, CANFD1.THSR 8748 1224h,
CANFD0_NS.THSR 0748 1220h, CANFD1_NS.THSR 0748 1224h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	FLVL[5:0]						—	—	—	—	THIF	LOST	FULL	EMPTY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Transmission History Empty Flag	0: There is a transmission history in the transmission history buffer 1: There is no transmission history in the transmission history buffer (empty)	R
b1	FULL	Transmission History Full Flag	0: Transmission history buffer is not full 1: Transmission history buffer is full	R
b2	LOST	Transmission History Lost Flag	0: Transmission history has not been lost 1: Transmission history has been lost	R/(W) *1
b3	THIF	Transmission History Interrupt Flag	0: Transmission history interrupt condition is not satisfied 1: Transmission history interrupt condition is satisfied	R/(W) *1
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	FLVL[5:0]	Transmission History Fill Level	Number of transmission histories stored in transmission history buffer	R
b31 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the status of data stored in the transmission history buffer.

EMPTY Flag (Transmission History Empty Flag)

This flag is automatically set to 0 when the first transmission history is stored to the transmission history buffer.
This flag is automatically set to 1 when:

- The CPU has read all the transmission histories from the transmission history buffer
- The THCR.THE bit is set to 0 (transmission history buffer is disabled)
- The CAN channel enters CH_RESET mode.

FULL Flag (Transmission History Full Flag)

Up to 32 transmission histories can be stored in the transmission history buffer for each channel. The FULL flag is automatically set to 1 when the number of transmission histories in the transmission history buffer is 32.
This flag is automatically set to 0 when:

- The number of transmission histories in the transmission history buffer is less than 32
- The THCR.THE bit is set to 0 (transmission history buffer is disabled)
- The CAN channel enters CH_RESET mode.

LOST Flag (Transmission History Lost Flag)

The LOST flag is set to 1 when a new transmission history cannot be stored because the related transmission history

buffer is already full.
This flag can only be written in CH_HALT or CH_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is set to 0:

- By writing 0 to it
- When the CAN channel enters CH_RESET mode.

THIF Flag (Transmission History Interrupt Flag)

The THIF flag is set to 1 when the configured interrupt condition is satisfied.
This flag can only be written in CH_HALT or CH_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is set to 0:

- By writing 0 to it
- When the CAN channel enters CH_RESET mode.

FLVL[5:0] Bits (Transmission History Fill Level)

The FLVL[5:0] bits show the number of transmission histories stored in the transmission history buffer.
These bits are automatically set to 000000b when the CAN channel enters CH_RESET mode.

45.2.65 Transmission History Access Register 0 (THACR0)

Address(es): CANFD0.THACR0 8748 8000h, CANFD1.THACR0 8748 8008h,
CANFD0_NS.THACR0 0748 8000h, CANFD1_NS.THACR0 0748 8008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GWMF	—	—	—	—	—	BN[6:0]							BT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	BT[2:0]	Transmitted Buffer Type	b2 b0 0 0 1: Transmit message buffer 0 1 0: Common FIFO 1 0 0: Transmit Queue	R
b9 to b3	BN[6:0]	Transmitted Buffer Number	Number of the message buffer	R
b14 to b10	—	Reserved	These bits are read as 0.	R
b15	GWMF	Gateway Mode Transfer Flag	0: Transmit from other than gateway 1: Transmit through a gateway	R
b31 to b16	TS[15:0]	Transmitted Timestamp	Transmit timestamp value	R

This register is used to access to the histories in the transmission history buffer based on the read pointer value.

BT[2:0] Bits (Transmitted Buffer Type)

The BT[2:0] bits indicate which type of buffer the message was transmitted from.

BN[6:0] Bits (Transmitted Buffer Number)

The BN[6:0] bits indicate which buffer number the message was transmitted from.
For a common FIFO, these bits indicate the number of the linked transmit message buffer.

GWMF Flag (Gateway Mode Transfer Flag)

The GWMF flag indicates whether the message was transferred through a gateway.

TS[15:0] Bits (Transmitted Timestamp)

The TS[15:0] bits indicate the timestamp used by the software driver.

45.2.66 Transmission History Access Register 1 (THACR1)

Address(es): CANFD0.THACR1 8748 8004h, CANFD1.THACR1 8748 800Ch,
CANFD0_NS.THACR1 0748 8004h, CANFD1_NS.THACR1 0748 800Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IFL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	PTR[15:0]	Transmitted Pointer	Stores the value of the PTR[15:0] field attached to the transmit message	R
b17, b16	IFL[1:0]	Transmitted Information Label	Stores the value of the IFL[1:0] field attached to the transmit message	R
b31 to b18	—	Reserved	These bits are read as 0.	R

This register is used to access to the histories in the transmission history buffer based on the read pointer value.

PTR[15:0] Bits (Transmitted Pointer)

The PTR[15:0] bits store the value of the pointer field (TMBn.HF2.PTR[15:0] bits or CFBn.HF2.PTR[15:0] bits) attached to the transmit message.
When transmitting in gateway mode, the value of the AFL pointer field (AFLn.PTR0.PTR[15:0] bits) is stored instead of the TMBn.HF2.PTR[15:0] bits.

IFL[1:0] Bits (Transmitted Information Label)

The IFL[1:0] bits store the value of the information label field (TMBn.HF2.IFL[1:0] bits or CFBn.HF2.IFL[1:0] bits) attached to the transmit message.
When transmitting in gateway mode, the value of the AFL information label field (AFLn.MASK.IFL1 bit and AFLn.PTR0.IFL0 bit) is stored instead of the TMBn.HF2.IFL[1:0] bits.

45.2.67 Transmission History Pointer Control Register (THPCR)

Address(es): CANFD0.THPCR 8748 1240h, CANFD1.THPCR 8748 1244h,
CANFD0_NS.THPCR 0748 1240h, CANFD1_NS.THPCR 0748 1244h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to increment the read pointer of the transmission history buffer.
When 000000FFh is written to this register, the read pointer of the transmission history buffer is moved to the next history.
The read value from this register is 00000000h.
This register can only be written in CH_HALT or CH_OPERATION mode.
Write 000000FFh to this register only when the transmission history buffer is enabled and not empty.

45.2.68 Global Reset Control Register (GRCR)

Address(es): CANFDG0.GRCR 8748 1380h, CANFDG0_NS.GRCR 0748 1380h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	SRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SRST	Software Reset	0: Releases the software reset 1: Initiates the software reset	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits control rewriting of the SRST bit. These bits are read as 00h.	W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SRST Bit (Software Reset)

When the SRST bit is set to 1, the CANFDG module is in the same state as the MCU reset. When a reset is required, write 1 to this bit and then 0.

When the software reset is released, the CANFDG module is in GL_SLEEP mode.

After a software reset, the RAM initialization sequence is not performed. Initialize the RAM with software.

Similarly, if a software reset is performed during RAM initialization, the RAM is not initialized. Initialize the RAM with software.

KEY[7:0] Bits (Key Code)

When rewriting the value of the SRST bit, set these bits to C4h at the same time (write this register in 32 bits).

45.2.69 Global Test Mode Configuration Register (GTMCR)

Address(es): CANFDG0.GTMCR 8748 1308h, CANFDG0_NS.GTMCR 0748 1308h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	RTPS[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ICBTMC1	ICBTMC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ICBTMC0	Internal CAN Bus Communication Test Mode Channel 0	0: Channel 0 is not tested in the internal CAN bus communication test 1: Channel 0 is tested in the internal CAN bus communication test	R/W
b1	ICBTMC1	Internal CAN Bus Communication Test Mode Channel 1	0: Channel 1 is not tested in the internal CAN bus communication test 1: Channel 1 is tested in the internal CAN bus communication test	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25 to b16	RTPS[9:0]	RAM Test Page Select	Select the page of RAM to be tested	R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to specify the page number of the RAM to be tested in RAM test mode. This register is also used to configure the CAN channel to be tested in the internal CAN bus communication test mode.

ICBTMCi Bit (Channel i Internal CAN Bus Communication Test Mode Enable) (i = 0, 1)

When the ICBTMCi bit is 1 and the CANFDG module is set to the internal CAN bus communication test mode, CAN channel i is tested in the internal CAN bus communication test mode.
This bit cannot be written in GL_RESET or GL_SLEEP mode. Write to this bit only in GL_HALT mode.
This bit is automatically set to 0 when the CAN channel enters GL_RESET mode.

RTPS[9:0] Bits (RAM Test Page Select)

The RTPS[9:0] bits select the RAM page number that the CPU reads and writes when the CANFDG module is in RAM test mode. Specify the page number in the range of 0 to 39.
Refer to section 45.9.2.1, RAM Test Mode for the specifications of the RAM test mode.
These bits cannot be written in GL_RESET or GL_SLEEP mode. Write to these bits only in GL_HALT mode.
These bits are automatically set to 00h when the CAN channel enters GL_RESET mode.

45.2.70 Global Test Mode Enable Register (GTMER)

Address(es): CANFDG0.GTMER 8748 130Ch, CANFDG0_NS.GTMER 0748 130Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	RTME	—	ICBTME
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ICBTME	Internal CAN Bus Communication Test Mode Enable	0: Internal CAN bus communication test mode is disabled. 1: Internal CAN bus communication test mode is enabled.	R/W
b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b2	RTME	RAM Test Mode Enable	0: RAM Test mode is disabled. 1: RAM Test mode is enabled.	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to control the global test modes of the CANFDG module.

ICBTME Bit (Internal CAN Bus Communication Test Mode Enable)

Setting the ICBTME bit to 1 enables internal CAN bus communication for CAN channels that have the GTMCR.ICBTMCi bit set to 1.

Refer to section 45.9.2.2, Internal CAN Bus Communication Test Mode for the specifications of the internal CAN bus communication test mode.

This bit can only be set to 1 in GL_HALT mode. To exit the internal CAN bus communication test mode, set this bit to 0 in GL_HALT mode.

This bit is automatically set to 0 when the CANFDG module enters GL_RESET mode.

RTME Bit (RAM Test Mode Enable)

When the RTME bit is set to 1, the CANFDG module is in RAM test mode. Refer to section 45.9.2.1, RAM Test Mode for the specifications of the RAM test mode.

This bit can only be set to 1 in GL_HALT mode. To exit the RAM test mode, set this bit to 0 in GL_HALT mode.

This bit is automatically set to 0 when the CANFDG module enters GL_RESET mode.

45.2.71 Global CAN FD Configuration Register (GFDCFG)

Address(es): CANFDG0.GFDCFG 8748 1314h, CANFDG0_NS.GFDCFG 0748 1314h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TSCPS[1:0]		—	—	—	—	—	—	—	PXEDIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PXEDIS	Protocol Exception Event Detection Disable	0: Protocol exception event detection is enabled. 1: Protocol exception event detection is disabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	TSCPS[1:0]	Timestamp Capturing Point Select	b9 b8 0 0: Sample point of SOF (start of frame) 0 1: EOF (end of frame) when frame is taken valid 1 0: Sample point of SOF (Classical CAN frame), or sample point of res bit following the FDF bit (CAN FD frame) 1 1: Setting prohibited	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

PXEDIS Bit (Protocol Exception Event Detection Disable)

The PXEDIS bit configures the protocol exception event handling according to ISO 11898-1.

When this bit is set to 1, protocol exception event detection is disabled, and an error frame is transmitted if a protocol exception (a recessive reserved bit following the FDF bit) is detected.

This bit can only be written in GL_RESET mode.

TSCPS[1:0] Bits (Timestamp Capturing Point Select)

The TSCPS[1:0] bits selects the capture point of the timestamps for transmitted and received messages.

When the TSCPS[1:0] bits are 10b, the timestamp is captured at the reserved bit following the FDF bit in CAN FD frames and at the SOF in Classical CAN frames.

These bits can only be written in GL_RESET mode.

45.2.72 Global Test Mode Lock Key Register (GTMLKR)

Address(es): CANFDG0.GTMLKR 8748 131Ch, CANFDG0_NS.GTMLKR 0748 131Ch

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to unlock the protection for RAM test mode. Refer to section 45.9.2, Global Test Modes for the specification of the lock key.
To put the CANFDG module into RAM test mode, two unlock keys must be written to this register in consecutive bus cycles.
The read value from this register is always 00000000h.
This register cannot be written in GL_SLEEP or GL_RESET mode.
Do not write to this register in GL_OPERATION mode.

45.2.73 RAM Test Page Access Register k (RTPARk) (k = 0 to 63)

Address(es): CANFDG0.RTPAR0 8748 8400h to CANFDG0.RTPAR63 8748 84FCh,
CANFDG0_NS.RTPAR0 0748 8400h to CANFDG0_NS.RTPAR63 0748 84FCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register can be read or written in RAM test mode.
This register can only be written in GL_HALT mode when RAM test mode is enabled.

45.2.74 Bus Load Control Register (BLCCR)

Address(es): CANFD0.BLCCR 8748 1418h, CANFD1.BLCCR 8748 1438h,
CANFD0_NS.BLCCR 0748 1418h, CANFD1_NS.BLCCR 0748 1438h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	BLCLD	—	—	—	—	—	—	—	BLCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BLCE	Bus Load Counter Enable	0: Bus load counter is disabled 1: Bus load counter is enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	BLCLD	Bus Load Counter Load	When this bit is set to 1, the bus load counter value is loaded and the counter is reset.	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

BLCE Bit (Bus Load Counter Enable)

The BLCE bit enables the operation of the bus load counter. When the BLCE bit is set to 0, the bus load counter stops, but the counter value is not cleared.

This bit is automatically set to 0 when the CAN channel enters CH_RESET mode.

This bit cannot be written in CH_SLEEP mode.

Write to this register after setting the NBCR register.

BLCLD Bit (Bus Load Counter Load)

When the BLCLD bit is set to 1, the bus load counter value is loaded into the BLCR register and then the bus load counter is reset.

The read value is always 0.

45.2.75 Bus Load Counter Register (BLCR)

Address(es): CANFD0.BLCR 8748 141Ch, CANFD1.BLCR 8748 143Ch,
CANFD0_NS.BLCR 0748 141Ch, CANFD1_NS.BLCR 0748 143Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is a read-only register that indicates the value of the bus load counter.
The bus load counter is incremented synchronously with CANFDCLK when the CAN bus is idle.
When the BLCCR.BLCLD bit is set to 1, the bus load counter value is loaded to this register and then the bus load counter is reset.
The lower 3 bits of the BLCR register are 000b.

45.2.76 Acceptance Filter List Ignore Entry Setting Register (AFIGSR)

Address(es): CANFDG0.AFIGSR 8748 1324h, CANFDG0_NS.AFIGSR 0748 1324h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	IGCS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	IGES[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	IGES[8:0]	Ignore Entry Select	Set the rule number to be ignored during acceptance filtering.	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b18 to b16	IGCS[2:0]	Ignore Channel Select	Set the channel number for which entries are to be ignored during acceptance filtering.	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

IGES[8:0] Bits (Ignore Entry Select)

The IGES[8:0] bits are used to specify the rule number to update when updating the acceptance filter.

Write to these bits only when the AFIGER.IGEE bit is 0.

These bits cannot be written in GL_SLEEP mode.

IGCS[2:0] Bits (Ignore Channel Select)

The IGCS[2:0] bits are used to specify the channel number for which the AFL entry is updated when the acceptance filter is updated.

Write to these bits only when the AFIGER.IGEE bit is 0.

These bits cannot be written in GL_SLEEP mode.

45.2.77 Acceptance Filter List Ignore Entry Enable Register (AFIGER)

Address(es): CANFDG0.AFIGER 8748 1328h, CANFDG0_NS.AFIGER 0748 1328h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	IGEE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IGEE	Ignore Entry Enable	0: The value of the AFIGSR.IGES[8:0] bits is invalid. 1: The value of the AFIGSR.IGES[8:0] bits is valid.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits control rewriting of the IGEE bit. These bits are read as 00h.	W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

IGEE Bit (Ignore Entry Enable)

When the IGEE bit is set to 1, the entry selected by the AFIGSR.IGES[8:0] bits is ignored during acceptance filtering. This bit is automatically set to 0 when the CANFDG module enters GL_RESET mode.

KEY[7:0] Bits (Key Code)

When rewriting the value of the IGEE bit, set these bits to C4h at the same time (write this register in 32 bits).

45.2.78 Identifier Bits Alignment

Base format (11-bit length identifier): ID-28 to ID-18 are located in b10 to b0, and b28 to b11 are 0.
Extended format (29-bit length identifier): ID-28 to ID-0 are located in b28 to b0

Table 45.7 Standard Identifier (11-bit format)

45.2.79 Message Buffer Structure

The message buffer configuration consists of four types of message buffers:

- Receive message buffer (RMBn)
- Receive FIFO (RFBn)
- Common FIFO (CFBn)
- Transmit message buffer (TMBn)

"n" is a message buffer number whose range changes depending on the type of message buffer.
Refer to Figure 45.33 for an overview of this configuration. For more information on the number and types of message buffers, refer to section 45.6, FIFO Buffers and Message Buffer Configuration.

45.2.79.1 Start Addresses

The start address of each message buffer is calculated using the number of related message buffer components.
The start addresses for each register in the message buffer are listed in Table 45.9.

Table 45.9 Start Address for Each Register of the Message Buffer Component

Message Buffer	Symbol	n	Register	p	Start Address (Only Secure Addresses Are Listed)
Receive Message Buffer	RMBn	0 to 31	HF0	—	8748 2000h + n × 80h
			HF1	—	8748 2004h + n × 80h
			HF2	—	8748 2008h + n × 80h
			DFp	0 to 15	8748 200Ch + n × 80h + p × 4
Receive FIFO	RFBn	0 to 7	HF0	—	8748 6000h + n × 80h
			HF1	—	8748 6004h + n × 80h
			HF2	—	8748 6008h + n × 80h
			DFp	0 to 15	8748 600Ch + n × 80h + p × 4
Common FIFO	CFBn	0 to 5	HF0	—	8748 6400h + n × 80h
			HF1	—	8748 6404h + n × 80h
			HF2	—	8748 6408h + n × 80h
			DFp	0 to 15	8748 640Ch + n × 80h + p × 4
Transmit Message Buffer	TMBn	0 to 7, 32 to 39, 64 to 71, 96 to 103	HF0	—	8749 0000h + n × 80h
			HF1	—	8749 0004h + n × 80h
			HF2	—	8749 0008h + n × 80h
			DFp	0 to 15	8749 000Ch + n × 80h + p × 4

45.2.79.2 Receive Message Buffer n (RMBn) (n = 0 to 31)

The total number of the receive message buffers (RMB) is 32, as shown in Figure 45.33.
The receive message buffer consists of the following registers:

- RMBn.HF0
- RMBn.HF1
- RMBn.HF2
- RMBn.DF0 to RMBn.DF15

Table 45.10 shows the structure of this buffer.

Table 45.10 Structure of Receive Message Buffer

Address Offset	Symbol	Register Name	Contents
+00h	RMBn.HF0	Receive Message Buffer n Header Field 0	IDE, RTR, ID
+04h	RMBn.HF1	Receive Message Buffer n Header Field 1	DLC, timestamp
+08h	RMBn.HF2	Receive Message Buffer n Header Field 2	Pointer, information label, FDF, BRS, ESI
+0Ch	RMBn.DF0	Receive Message Buffer n Data Field 0	DATA0 to DATA3
+10h	RMBn.DF1	Receive Message Buffer n Data Field 1	DATA4 to DATA7
+14h	RMBn.DF2	Receive Message Buffer n Data Field 2	DATA8 to DATA11
+18h	RMBn.DF3	Receive Message Buffer n Data Field 3	DATA12 to DATA15
+1Ch	RMBn.DF4	Receive Message Buffer n Data Field 4	DATA16 to DATA19
+20h	RMBn.DF5	Receive Message Buffer n Data Field 5	DATA20 to DATA23
+24h	RMBn.DF6	Receive Message Buffer n Data Field 6	DATA24 to DATA27
+28h	RMBn.DF7	Receive Message Buffer n Data Field 7	DATA28 to DATA31
+2Ch	RMBn.DF8	Receive Message Buffer n Data Field 8	DATA32 to DATA35
+30h	RMBn.DF9	Receive Message Buffer n Data Field 9	DATA36 to DATA39
+34h	RMBn.DF10	Receive Message Buffer n Data Field 10	DATA40 to DATA43
+38h	RMBn.DF11	Receive Message Buffer n Data Field 11	DATA44 to DATA47
+3Ch	RMBn.DF12	Receive Message Buffer n Data Field 12	DATA48 to DATA51
+40h	RMBn.DF13	Receive Message Buffer n Data Field 13	DATA52 to DATA55
+44h	RMBn.DF14	Receive Message Buffer n Data Field 14	DATA56 to DATA59
+48h	RMBn.DF15	Receive Message Buffer n Data Field 15	DATA60 to DATA63

45.2.79.3 Receive Message Buffer n Header Field 0 (RMBn.HF0) (n = 0 to 31)

Address(es): CANFDG0.RMB0.HF0 8748 2000h, CANFDG0.RMB1.HF0 8748 2080h, CANFDG0.RMB2.HF0 8748 2100h, CANFDG0.RMB3.HF0 8748 2180h, CANFDG0.RMB4.HF0 8748 2200h, CANFDG0.RMB5.HF0 8748 2280h, CANFDG0.RMB6.HF0 8748 2300h, CANFDG0.RMB7.HF0 8748 2380h, CANFDG0.RMB8.HF0 8748 2400h, CANFDG0.RMB9.HF0 8748 2480h, CANFDG0.RMB10.HF0 8748 2500h, CANFDG0.RMB11.HF0 8748 2580h, CANFDG0.RMB12.HF0 8748 2600h, CANFDG0.RMB13.HF0 8748 2680h, CANFDG0.RMB14.HF0 8748 2700h, CANFDG0.RMB15.HF0 8748 2780h, CANFDG0.RMB16.HF0 8748 2800h, CANFDG0.RMB17.HF0 8748 2880h, CANFDG0.RMB18.HF0 8748 2900h, CANFDG0.RMB19.HF0 8748 2980h, CANFDG0.RMB20.HF0 8748 2A00h, CANFDG0.RMB21.HF0 8748 2A80h, CANFDG0.RMB22.HF0 8748 2B00h, CANFDG0.RMB23.HF0 8748 2B80h, CANFDG0.RMB24.HF0 8748 2C00h, CANFDG0.RMB25.HF0 8748 2C80h, CANFDG0.RMB26.HF0 8748 2D00h, CANFDG0.RMB27.HF0 8748 2D80h, CANFDG0.RMB28.HF0 8748 2E00h, CANFDG0.RMB29.HF0 8748 2E80h, CANFDG0.RMB30.HF0 8748 2F00h, CANFDG0.RMB31.HF0 8748 2F80h,

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	Identifier	Standard ID/extended ID field	R
b29	—	Reserved	This bit is read as 0.	R
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R

This register stores the ID field, IDE bit, and RTR bit of the received message.

ID[28:0] Bits (Identifier)

The ID[28:0] bits store the standard or extended identifier field of message stored in the receive message buffer.
For alignment of these bits in base and extended format, refer to section 45.2.78, Identifier Bits Alignment.

RTR Bit (Remote Transmission Request)

The RTR bit stores the value of the RTR bit of the received message.
The RTR bit indicates whether the receive message buffer stores a data frame or a remote frame.

Note: There are no remote frames in CAN FD format. When a CAN FD frame is received, this bit reflects the value of the RRS bit.

IDE Bit (Identifier Extension)

The IDE bit stores the value of the IDE bit of the received message.
The IDE bit indicates whether the message stored in the receive message buffer has a standard identifier or extended identifier.

45.2.79.4 Receive Message Buffer n Header Field 1 (RMBn.HF1) (n = 0 to 31)

Address(es): CANFDG0.RMB0.HF1 8748 2004h, CANFDG0.RMB1.HF1 8748 2084h, CANFDG0.RMB2.HF1 8748 2104h, CANFDG0.RMB3.HF1 8748 2184h, CANFDG0.RMB4.HF1 8748 2204h, CANFDG0.RMB5.HF1 8748 2284h, CANFDG0.RMB6.HF1 8748 2304h, CANFDG0.RMB7.HF1 8748 2384h, CANFDG0.RMB8.HF1 8748 2404h, CANFDG0.RMB9.HF1 8748 2484h, CANFDG0.RMB10.HF1 8748 2504h, CANFDG0.RMB11.HF1 8748 2584h, CANFDG0.RMB12.HF1 8748 2604h, CANFDG0.RMB13.HF1 8748 2684h, CANFDG0.RMB14.HF1 8748 2704h, CANFDG0.RMB15.HF1 8748 2784h, CANFDG0.RMB16.HF1 8748 2804h, CANFDG0.RMB17.HF1 8748 2884h, CANFDG0.RMB18.HF1 8748 2904h, CANFDG0.RMB19.HF1 8748 2984h, CANFDG0.RMB20.HF1 8748 2A04h, CANFDG0.RMB21.HF1 8748 2A84h, CANFDG0.RMB22.HF1 8748 2B04h, CANFDG0.RMB23.HF1 8748 2B84h, CANFDG0.RMB24.HF1 8748 2C04h, CANFDG0.RMB25.HF1 8748 2C84h, CANFDG0.RMB26.HF1 8748 2D04h, CANFDG0.RMB27.HF1 8748 2D84h, CANFDG0.RMB28.HF1 8748 2E04h, CANFDG0.RMB29.HF1 8748 2E84h, CANFDG0.RMB30.HF1 8748 2F04h, CANFDG0.RMB31.HF1 8748 2F84h,

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TS[15:0]	Timestamp	Timestamp value stored for the message in the receive message buffer	R
b27 to b16	—	Reserved	These bits are read as 0.	R
b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes received in a CAN frame.	R

This register stores the data length code (DLC) and timestamp of the received message.

TS[15:0] Bits (Timestamp)

The TS[15:0] bits store the timestamp of the received message captured at the point specified by the GFDCFG.TSCPS[1:0] bits.

DLC[3:0] Bits (Data Length Code)

The DLC[3:0] bits store the number of data bytes of the received message.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

Note: The maximum number of data bytes in the buffer is specified by the RMCR.PLS[2:0] bits.

Bit	Symbol	Bit Name	Description	R/W
b0	ESI	Error State Indicator Flag	0: CAN FD frame received from error active node 1: CAN FD frame received from error passive node	R
b1	BRS	Bit Rate Switch Flag	0: CAN FD frame received with no bit rate switch 1: CAN FD frame received with bit rate switch	R
b2	FDF	FD Format Indicator Flag	0: Non CAN FD frame received 1: CAN FD frame received	R
b7 to b3	—	Reserved	These bits are read as 0.	R
b9, b8	IFL[1:0]	Information Label	This field stores the information label attached by the Acceptance Filter	R
b15 to b10	—	Reserved	These bits are read as 0.	R
b31 to b16	PTR[15:0]	Pointer	This field stores the pointer attached by the Acceptance Filter	R

This register stores the FDF bit, BRS bit, and ESI flag of the received message, and pointer for the received message.

ESI Flag (Error State Indicator Flag)

The ESI flag stores the value of the ESI flag of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

BRS Flag (Bit Rate Switch Flag)

The BRS flag stores the value of the BRS bit of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

FDF Flag (FD Format Indicator Flag)

The FDF flag stores the value of the FDF bit of the received CAN FD frame.

IFL[1:0] Bits (Information Label)

The IFL[1:0] bits store the information label value set in the corresponding entry in the acceptance filter list.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits store the pointer value set in the corresponding entry in the acceptance filter list.

These registers are read-only registers that store the data byte (p × 4 + 3) to data byte (p × 4) of the received message. Unused data bytes are filled with 00h.

These registers are read-only registers that store the data bytes of the received message. Unused data bytes are filled with 00h.

45.2.79.8 Receive FIFO n (RFBn) (n = 0 to 7)

The total number of the receive FIFOs (RFB) is eight, as shown in Figure 45.33.
The receive FIFO consists of the following registers:

- RFBn.HF0
- RFBn.HF1
- RFBn.HF2
- RFBn.DF0 to RFBn.DF15

Table 45.11 shows the structure of this buffer.

Table 45.11 Structure of Receive FIFO

Address Offset	Symbol	Register Name	Contents
+00h	RFBn.HF0	Receive FIFO n Header Field 0	IDE, RTR, ID
+04h	RFBn.HF1	Receive FIFO n Header Field 1	DLC, timestamp
+08h	RFBn.HF2	Receive FIFO n Header Field 2	Pointer, information label, FDF, BRS, ESI
+0Ch	RFBn.DF0	Receive FIFO n Data Field 0	DATA0 to DATA3
+10h	RFBn.DF1	Receive FIFO n Data Field 1	DATA4 to DATA7
+14h	RFBn.DF2	Receive FIFO n Data Field 2	DATA8 to DATA11
+18h	RFBn.DF3	Receive FIFO n Data Field 3	DATA12 to DATA15
+1Ch	RFBn.DF4	Receive FIFO n Data Field 4	DATA16 to DATA19
+20h	RFBn.DF5	Receive FIFO n Data Field 5	DATA20 to DATA23
+24h	RFBn.DF6	Receive FIFO n Data Field 6	DATA24 to DATA27
+28h	RFBn.DF7	Receive FIFO n Data Field 7	DATA28 to DATA31
+2Ch	RFBn.DF8	Receive FIFO n Data Field 8	DATA32 to DATA35
+30h	RFBn.DF9	Receive FIFO n Data Field 9	DATA36 to DATA39
+34h	RFBn.DF10	Receive FIFO n Data Field 10	DATA40 to DATA43
+38h	RFBn.DF11	Receive FIFO n Data Field 11	DATA44 to DATA47
+3Ch	RFBn.DF12	Receive FIFO n Data Field 12	DATA48 to DATA51
+40h	RFBn.DF13	Receive FIFO n Data Field 13	DATA52 to DATA55
+44h	RFBn.DF14	Receive FIFO n Data Field 14	DATA56 to DATA59
+48h	RFBn.DF15	Receive FIFO n Data Field 15	DATA60 to DATA63

45.2.79.9 Receive FIFO n Header Field 0 (RFBn.HF0) (n = 0 to 7)

Address(es): CANFDG0.RFB0.HF0 8748 6000h, CANFDG0.RFB1.HF0 8748 6080h, CANFDG0.RFB2.HF0 8748 6100h, CANFDG0.RFB3.HF0 8748 6180h, CANFDG0.RFB4.HF0 8748 6200h, CANFDG0.RFB5.HF0 8748 6280h, CANFDG0.RFB6.HF0 8748 6300h, CANFDG0.RFB7.HF0 8748 6380h, CANFDG0_NS.RFB0.HF0 0748 6000h, CANFDG0_NS.RFB1.HF0 0748 6080h, CANFDG0_NS.RFB2.HF0 0748 6100h, CANFDG0_NS.RFB3.HF0 0748 6180h, CANFDG0_NS.RFB4.HF0 0748 6200h, CANFDG0_NS.RFB5.HF0 0748 6280h, CANFDG0_NS.RFB6.HF0 0748 6300h, CANFDG0_NS.RFB7.HF0 0748 6380h

Bit	Symbol	Bit Name	Description	R/W
b28-b0	ID[28:0]	Identifier	Standard ID/extended ID field	R
b29	—	Reserved	This bit is read as 0.	R
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R

This register stores the ID field, IDE bit, and RTR bit of the received message.

ID[28:0] Bits (Identifier)

The ID[28:0] bits store the standard or extended identifier field of message stored in the receive FIFO.
For alignment of these bits in base and extended format, refer to section 45.2.78, Identifier Bits Alignment.

RTR Bit (Remote Transmission Request)

The RTR bit stores the value of the RTR bit of the received message.
The RTR bit indicates whether the receive message buffer stores a data frame or a remote frame.

Note: There are no remote frames in CAN FD format. When a CAN FD frame is received, this bit reflects the value of the RRS bit.

IDE Bit (Identifier Extension)

The IDE bit stores the value of the IDE bit of the received message.
The IDE bit indicates whether the message stored in the receive FIFO buffer has a standard identifier or extended identifier.

45.2.79.10 Receive FIFO n Header Field 1 (RFBn.HF1) (n = 0 to 7)

Address(es): CANFDG0.RFB0.HF1 8748 6004h, CANFDG0.RFB1.HF1 8748 6084h, CANFDG0.RFB2.HF1 8748 6104h, CANFDG0.RFB3.HF1 8748 6184h, CANFDG0.RFB4.HF1 8748 6204h, CANFDG0.RFB5.HF1 8748 6284h, CANFDG0.RFB6.HF1 8748 6304h, CANFDG0.RFB7.HF1 8748 6384h, CANFDG0_NS.RFB0.HF1 0748 6004h, CANFDG0_NS.RFB1.HF1 0748 6084h, CANFDG0_NS.RFB2.HF1 0748 6104h, CANFDG0_NS.RFB3.HF1 0748 6184h, CANFDG0_NS.RFB4.HF1 0748 6204h, CANFDG0_NS.RFB5.HF1 0748 6284h, CANFDG0_NS.RFB6.HF1 0748 6304h, CANFDG0_NS.RFB7.HF1 0748 6384h

	TS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TS[15:0]	Timestamp	Timestamp value of the received CAN frame	R
b27 to b16	—	Reserved	These bits are read as 0.	R
b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes received in a CAN frame	R

This register stores the data length code (DLC) and timestamp of the received message.

TS[15:0] Bits (Timestamp)

The TS[15:0] bits store the timestamp of the received message captured at the point specified by the GFDCFG.TSCPS[1:0] bits.

DLC[3:0] Bits (Data Length Code)

The DLC[3:0] bits store the number of data bytes of the received message.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

Note: The maximum number of data bytes in the buffer is specified by the RFCRn.PLS[2:0] bits.

45.2.79.11 Receive FIFO n Header Field 2 (RFBn.HF2) (n = 0 to 7)

Address(es): CANFDG0.RFB0.HF2 8748 6008h, CANFDG0.RFB1.HF2 8748 6088h, CANFDG0.RFB2.HF2 8748 6108h, CANFDG0.RFB3.HF2 8748 6188h, CANFDG0.RFB4.HF2 8748 6208h, CANFDG0.RFB5.HF2 8748 6288h, CANFDG0.RFB6.HF2 8748 6308h, CANFDG0.RFB7.HF2 8748 6388h, CANFDG0_NS.RFB0.HF2 0748 6008h, CANFDG0_NS.RFB1.HF2 0748 6088h, CANFDG0_NS.RFB2.HF2 0748 6108h, CANFDG0_NS.RFB3.HF2 0748 6188h, CANFDG0_NS.RFB4.HF2 0748 6208h, CANFDG0_NS.RFB5.HF2 0748 6288h, CANFDG0_NS.RFB6.HF2 0748 6308h, CANFDG0_NS.RFB7.HF2 0748 6388h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESI	Error State Indicator Flag	0: CAN FD frame received from error active node 1: CAN FD frame received from error passive node	R
b1	BRS	Bit Rate Switch Flag	0: CAN FD frame received with no bit rate switch 1: CAN FD frame received with bit rate switch	R
b2	FDF	FD Format Indicator Flag	0: Non CAN FD frame received 1: CAN FD frame received	R
b7 to b3	—	Reserved	These bits are read as 0.	R
b9, b8	IFL[1:0]	Information Label	This field stores the information label attached by the Acceptance Filter	R
b15 to b10	—	Reserved	These bits are read as 0.	R
b31 to b16	PTR[15:0]	Pointer	This field stores the pointer attached by the Acceptance Filter	R

This register stores the FDF bit, BRS bit, and ESI flag of the received message, and pointer for the received message.

ESI Flag (Error State Indicator Flag)

The ESI flag stores the value of the ESI flag of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

BRS Flag (Bit Rate Switch Flag)

The BRS flag stores the value of the BRS bit of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

FDF Flag (FD Format Indicator Flag)

The FDF flag stores the value of the FDF bit of the received CAN FD frame.

IFL[1:0] Bits (Information Label)

The IFL[1:0] bits store the information label value set in the corresponding entry in the acceptance filter list.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits store the pointer value set in the corresponding entry in the acceptance filter list.

45.2.79.12 Receive FIFO n Data Field p (RFBn.DFp) (n = 0 to 7; p = 0 to 15)

Address(es): CANFDG0.RFB0.DF0 8748 600Ch to CANFDG0.RFB0.DF15 8748 6048h,

These registers are read-only registers that store the data bytes of the received message. Unused data bytes are filled with 00h.

45.2.79.14 Common FIFO n (CFBn) (n = 0 to 5)

The total number of the common FIFOs (CFB) is six, as shown in Figure 45.33.
The common FIFO consists of the following registers:

- CFBn.HF0
- CFBn.HF1
- CFBn.HF2
- CFBn.DF0 to CFBn.DF15

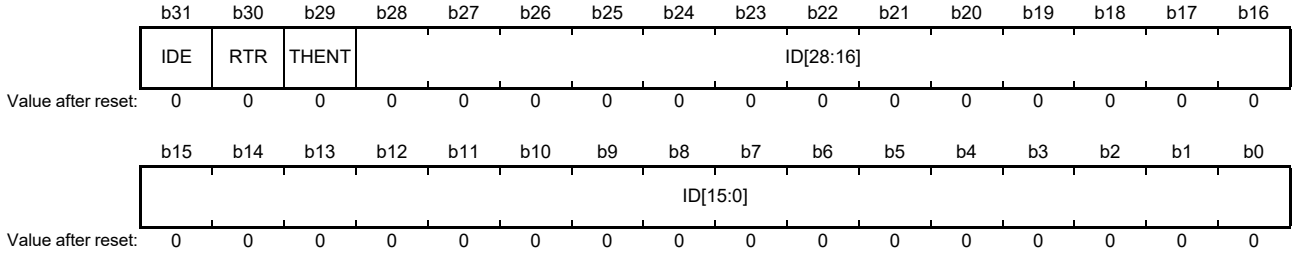

Table 45.12 shows the structure of this buffer.

Table 45.12 Structure of Common FIFO

Address Offset	Symbol	Register Name	Contents
+00h	CFBn.HF0	Common FIFO n Header Field 0	IDE, RTR, ID
+04h	CFBn.HF1	Common FIFO n Header Field 1	DLC, timestamp
+08h	CFBn.HF2	Common FIFO n Header Field 2	Pointer, information label, FDF, BRS, ESI

45.2.79.15 Common FIFO n Header Field 0 (CFBn.HF0) (n = 0 to 5)

Address(es): CANFDG0.CFB0.HF0 8748 6400h, CANFDG0.CFB1.HF0 8748 6480h, CANFDG0.CFB2.HF0 8748 6500h, CANFDG0.CFB3.HF0 8748 6580h, CANFDG0.CFB4.HF0 8748 6600h, CANFDG0.CFB5.HF0 8748 6680h, CANFDG0_NS.CFB0.HF0 0748 6400h, CANFDG0_NS.CFB1.HF0 0748 6480h, CANFDG0_NS.CFB2.HF0 0748 6500h, CANFDG0_NS.CFB3.HF0 0748 6580h, CANFDG0_NS.CFB4.HF0 0748 6600h, CANFDG0_NS.CFB5.HF0 0748 6680h

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	Identifier	Standard ID/extended ID field	R/W
b29	THENT	Transmission History Entry	Receive FIFO mode or gateway FIFO mode: Reserved. This bit is read as 0. Transmit FIFO mode: 0: Entry is not stored to the Transmission History after successful transmission. 1: Entry is stored to the Transmission History after successful transmission.	R/W
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R/W
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R/W

In receive FIFO mode or gateway FIFO mode, this register is a read-only register for reading the ID field, IDE bit, and RTR bit of the received message from the beginning of the FIFO buffer.
In transmit FIFO mode, this register is a read/write register for writing the ID field, IDE bit, and RTR bit of the message to be transmitted at the end of the FIFO buffer.

ID[28:0] Bits (Identifier)

In receive FIFO mode, the ID[28:0] bits store the standard or extended identifier field of the received message.
In transmit FIFO mode, the ID[28:0] bits are used to set the value of the standard or extended identifier field of the message to be transmitted.
For alignment of these bits in base and extended format, refer to section 45.2.78, Identifier Bits Alignment.

THENT Bit (Transmission History Entry)

This bit is valid only in transmit FIFO mode.
The THENT bit controls whether the corresponding entry is stored in the transmission history after a successful transmission of the message.

RTR Bit (Remote Transmission Request)

In receive FIFO mode, the RTR bit stores the value of the RTR bit of the received message.
In transmit FIFO mode, the RTR bit is used to specify the value of the RTR bit of the message to be transmitted.

Note: There are no remote frames in CAN FD format. When a CAN FD frame was received (receive mode), this bit reflects the value of the RRS bit. When transmitting a CAN FD frame (CFBn.HF2.FDF = 1), this bit is transmitted dominant regardless of the value of this bit.

IDE Bit (Identifier Extension)

In receive FIFO mode, the IDE bit stores the value of the IDE bit of the received message.
In transmit FIFO mode, the IDE bit is used to specify the value of the IDE bit of the message to be transmitted.

45.2.79.16 Common FIFO n Header Field 1 (CFBn.HF1) (n = 0 to 5)

Address(es): CANFDG0.CFB0.HF1 8748 6404h, CANFDG0.CFB1.HF1 8748 6484h, CANFDG0.CFB2.HF1 8748 6504h, CANFDG0.CFB3.HF1 8748 6584h, CANFDG0.CFB4.HF1 8748 6604h, CANFDG0.CFB5.HF1 8748 6684h, CANFDG0_NS.CFB0.HF1 0748 6404h, CANFDG0_NS.CFB1.HF1 0748 6484h, CANFDG0_NS.CFB2.HF1 0748 6504h, CANFDG0_NS.CFB3.HF1 0748 6584h, CANFDG0_NS.CFB4.HF1 0748 6604h, CANFDG0_NS.CFB5.HF1 0748 6684h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	TS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TS[15:0]	Timestamp	Timestamp value of the received CAN frame (in receive FIFO mode)	R/W
b27 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes received in a CAN frame, or to be transmitted in a CAN frame	R/W

In receive FIFO mode or gateway FIFO mode, this register is a read-only register for reading the data length code (DLC) and timestamp of the received message from the beginning of the FIFO buffer.
In transmit FIFO mode, this register is a read/write register for writing the data length code (DLC) of the message to be transmitted at the end of the FIFO buffer.

TS[15:0] Bits (Timestamp)

These bits are valid only in receive FIFO mode.
The TS[15:0] bits store the timestamp of the received message captured at the point specified by the GFDCFG.TSCPS[1:0] bits.

DLC[3:0] Bits (Data Length Code)

In receive FIFO mode, the DLC[3:0] bits store the number of data bytes of the received message.
In transmit FIFO mode, The DLC[3:0] bits are used to specify the number of data bytes of the message to be transmitted.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

Note: The maximum number of data bytes in the buffer is specified by the CFCRn.PLS[2:0] bits.

45.2.79.17 Common FIFO n Header Field 2 (CFBn.HF2) (n = 0 to 5)

Address(es): CANFDG0.CFB0.HF2 8748 6408h, CANFDG0.CFB1.HF2 8748 6488h, CANFDG0.CFB2.HF2 8748 6508h, CANFDG0.CFB3.HF2 8748 6588h, CANFDG0.CFB4.HF2 8748 6608h, CANFDG0.CFB5.HF2 8748 6688h, CANFDG0_NS.CFB0.HF2 0748 6408h, CANFDG0_NS.CFB1.HF2 0748 6488h, CANFDG0_NS.CFB2.HF2 0748 6508h, CANFDG0_NS.CFB3.HF2 0748 6588h, CANFDG0_NS.CFB4.HF2 0748 6608h, CANFDG0_NS.CFB5.HF2 0748 6688h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	IFL[1:0]		—	—	—	—	—	FDF	BRS	ESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESI	Error State Indicator	0: CAN FD frame received or to transmit by error active node 1: CAN FD frame received or to transmit by error passive node	R/W
b1	BRS	Bit Rate Switch	0: CAN FD frame received or to transmit with no bit rate switch 1: CAN FD frame received or to transmit with bit rate switch	R/W
b2	FDF	FD Format Indicator	0: Non CAN FD frame received or to transmit 1: CAN FD frame received or to transmit	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	IFL[1:0]	Information Label	This field stores the information label attached by the Acceptance Filter or is used to set the information label to be stored in the Transmission History	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b16	PTR[15:0]	Pointer	This field stores the pointer attached by the Acceptance Filter or is used to set the pointer to be stored in the Transmission History	R/W

In receive FIFO mode or gateway FIFO mode, this register is a read-only register for reading the FDF bit, BRS bit, and ESI flag of the received message, and information label and pointer for the received message from the beginning of the FIFO buffer.
In transmit FIFO mode, this register is a read/write register for writing the FDF bit, BRS bit, and ESI flag of the message to be transmitted, and the information label and pointer to be stored in the transmission history at the end of the FIFO buffer.

ESI Bit (Error State Indicator)

In receive FIFO mode or gateway FIFO mode, the ESI bit stores the value of the ESI flag of the received CAN FD frame. When the received FDF bit is 0 (Classical CAN frame), 0 is stored to this bit.
In transmit FIFO mode, the ESI bit is used to specify the value of the ESI flag of the CAN FD frame to be transmitted. If the channel is not in error passive, the ESI flag of the transmitted message equals the value of this bit. If the channel is in error passive, this bit is transmitted recessive regardless of the value of this bit.

BRS Bit (Bit Rate Switch)

In receive FIFO mode or gateway FIFO mode, the BRS bit stores the value of the BRS bit of the received CAN FD frame. When the received FDF bit is 0 (Classical CAN frame), 0 is stored to this bit.
In transmit FIFO mode, the BRS bit is used to specify the value of the BRS bit of the CAN FD frame to be transmitted.

FDF Bit (FD Format Indicator)

In receive FIFO mode or gateway FIFO mode, the FDF bit stores the value of the FDF bit of the received CAN FD frame.
In transmit FIFO mode, the FDF bit is used to specify the value of the FDF bit of the CAN FD frame to be transmitted.

IFL[1:0] Bits (Information Label)

In receive FIFO mode or gateway FIFO mode, the IFL[1:0] bits store the information label value set in the corresponding entry in the acceptance filter list.
In transmit FIFO mode, the IFL[1:0] bits are used to specify the information label value to be stored in the transmission history after a successful transmission of the message.

PTR[15:0] Bits (Pointer)

In receive FIFO mode or gateway FIFO mode, the PTR[15:0] bits store the pointer value set in the corresponding entry in the acceptance filter list.
In transmit FIFO mode, the PTR[15:0] bits are used to specify the pointer value to be stored in the transmission history after a successful transmission of the message.

45.2.79.18 Common FIFO n Data Field p (CFBn.DFp) (n = 0 to 5; p = 0 to 15)

Address(es): CANFDG0.CFB0.DF0 8748 640Ch to CANFDG0.CFB0.DF15 8748 6448h,

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

In receive FIFO mode or gateway FIFO mode, these registers are read-only registers for reading the data byte (p × 4 + 3) to data byte (p × 4) of the received message from the beginning of the FIFO buffer. Unused data bytes are filled with 00h.
In transmit FIFO mode, these registers are read/write registers for storing data byte (p × 4 + 3) to data byte (p × 4) of the message to be transmitted.

45.2.79.19 Common FIFO n Data k (CFBn.DATAk) (n = 0 to 5; k = 0 to 63)

Address(es): CANFDG0.CFB0.DATA0 8748 640Ch to CANFDG0.CFB0.DATA63 8748 644Bh,
CANFDG0.CFB1.DATA0 8748 648Ch to CANFDG0.CFB1.DATA63 8748 64CBh,
CANFDG0.CFB2.DATA0 8748 650Ch to CANFDG0.CFB2.DATA63 8748 654Bh,
CANFDG0.CFB3.DATA0 8748 658Ch to CANFDG0.CFB3.DATA63 8748 65CBh,
CANFDG0.CFB4.DATA0 8748 660Ch to CANFDG0.CFB4.DATA63 8748 664Bh,
CANFDG0.CFB5.DATA0 8748 668Ch to CANFDG0.CFB5.DATA63 8748 66CBh,
CANFDG0_NS.CFB0.DATA0 0748 640Ch to CANFDG0_NS.CFB0.DATA63 0748 644Bh,
CANFDG0_NS.CFB1.DATA0 0748 648Ch to CANFDG0_NS.CFB1.DATA63 0748 64CBh,
CANFDG0_NS.CFB2.DATA0 0748 650Ch to CANFDG0_NS.CFB2.DATA63 0748 654Bh,
CANFDG0_NS.CFB3.DATA0 0748 658Ch to CANFDG0_NS.CFB3.DATA63 0748 65CBh,
CANFDG0_NS.CFB4.DATA0 0748 660Ch to CANFDG0_NS.CFB4.DATA63 0748 664Bh,
CANFDG0_NS.CFB5.DATA0 0748 668Ch to CANFDG0_NS.CFB5.DATA63 0748 66CBh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

In receive FIFO mode, these registers are read-only registers for reading the data bytes of the received message from the beginning of the FIFO buffer. Unused data bytes are filled with 00h.
In transmit FIFO mode, these registers are read/write registers for storing the data bytes of the message to be transmitted.

45.2.79.20 Transmit Message Buffer n (TMBn) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103)

The total number of transmit message buffers (TMB) is 32, as shown in Figure 45.33.
The transmit message buffer consists of the following registers:

- TMBn.HF0
- TMBn.HF1
- TMBn.HF2
- TMBn.DF0 to TMBn.DF15

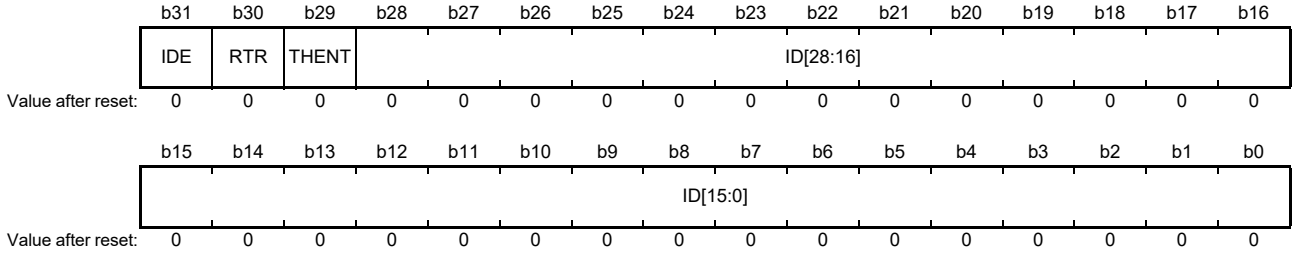

Table 45.13 shows the structure of this buffer.

Table 45.13 Structure of Transmit Message Buffer

Address Offset	Symbol	Register Name	Contents
+00h	TMBn.HF0	Transmit Message Buffer n Header Field 0	IDE, RTR, ID

45.2.79.21 Transmit Message Buffer n Header Field 0 (TMBn.HF0) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103)

Address(es): CANFDG0.TMB0.HF0 8749 0000h, CANFDG0.TMB1.HF0 8749 0080h, CANFDG0.TMB2.HF0 8749 0100h, CANFDG0.TMB3.HF0 8749 0180h, CANFDG0.TMB4.HF0 8749 0200h, CANFDG0.TMB5.HF0 8749 0280h, CANFDG0.TMB6.HF0 8749 0300h, CANFDG0.TMB7.HF0 8749 0380h, CANFDG0.TMB32.HF0 8749 1000h, CANFDG0.TMB33.HF0 8749 1080h, CANFDG0.TMB34.HF0 8749 1100h, CANFDG0.TMB35.HF0 8749 1180h, CANFDG0.TMB36.HF0 8749 1200h, CANFDG0.TMB37.HF0 8749 1280h, CANFDG0.TMB38.HF0 8749 1300h, CANFDG0.TMB39.HF0 8749 1380h, CANFDG0.TMB64.HF0 8749 2000h, CANFDG0.TMB65.HF0 8749 2080h, CANFDG0.TMB66.HF0 8749 2100h, CANFDG0.TMB67.HF0 8749 2180h, CANFDG0.TMB68.HF0 8749 2200h, CANFDG0.TMB69.HF0 8749 2280h, CANFDG0.TMB70.HF0 8749 2300h, CANFDG0.TMB71.HF0 8749 2380h, CANFDG0.TMB96.HF0 8749 3000h, CANFDG0.TMB97.HF0 8749 3080h, CANFDG0.TMB98.HF0 8749 3100h, CANFDG0.TMB99.HF0 8749 3180h, CANFDG0.TMB100.HF0 8749 3200h, CANFDG0.TMB101.HF0 8749 3280h, CANFDG0.TMB102.HF0 8749 3300h, CANFDG0.TMB103.HF0 8749 3380h, CANFDG0_NS.TMB0.HF0 0749 0000h, CANFDG0_NS.TMB1.HF0 0749 0080h, CANFDG0_NS.TMB2.HF0 0749 0100h, CANFDG0_NS.TMB3.HF0 0749 0180h, CANFDG0_NS.TMB4.HF0 0749 0200h, CANFDG0_NS.TMB5.HF0 0749 0280h, CANFDG0_NS.TMB6.HF0 0749 0300h, CANFDG0_NS.TMB7.HF0 0749 0380h, CANFDG0_NS.TMB32.HF0 0749 1000h, CANFDG0_NS.TMB33.HF0 0749 1080h, CANFDG0_NS.TMB34.HF0 0749 1100h, CANFDG0_NS.TMB35.HF0 0749 1180h, CANFDG0_NS.TMB36.HF0 0749 1200h, CANFDG0_NS.TMB37.HF0 0749 1280h, CANFDG0_NS.TMB38.HF0 0749 1300h, CANFDG0_NS.TMB39.HF0 0749 1380h, CANFDG0_NS.TMB64.HF0 0749 2000h, CANFDG0_NS.TMB65.HF0 0749 2080h, CANFDG0_NS.TMB66.HF0 0749 2100h, CANFDG0_NS.TMB67.HF0 0749 2180h, CANFDG0_NS.TMB68.HF0 0749 2200h, CANFDG0_NS.TMB69.HF0 0749 2280h, CANFDG0_NS.TMB70.HF0 0749 2300h, CANFDG0_NS.TMB71.HF0 0749 2380h, CANFDG0_NS.TMB96.HF0 0749 3000h, CANFDG0_NS.TMB97.HF0 0749 3080h, CANFDG0_NS.TMB98.HF0 0749 3100h, CANFDG0_NS.TMB99.HF0 0749 3180h, CANFDG0_NS.TMB100.HF0 0749 3200h, CANFDG0_NS.TMB101.HF0 0749 3280h, CANFDG0_NS.TMB102.HF0 0749 3300h, CANFDG0_NS.TMB103.HF0 0749 3380h

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	Identifier	Standard ID/extended ID field	R/W
b29	THENT	Transmission History Entry	0: Entry is not stored in transmission history after successful transmission. 1: Entry is stored in transmission history after successful transmission.	R/W
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R/W
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R/W

This register is used to store the ID field, IDE bit, and RTR bit of the message to be transmitted, and to specify whether to store it in the transmission history.
Do not write to this register in CH_SLEEP mode.

ID[28:0] Bits (Identifier)

The ID[28:0] bits are used to set the value of the standard or extended identifier field of the message stored in the transmit message buffer.
For alignment of these bits in base and extended format, refer to section 45.2.78, Identifier Bits Alignment.

THENT Bit (Transmission History Entry)

The THENT bit controls whether the corresponding entry is stored in the transmission history after a successful transmission of the message stored in the transmit message buffer.

RTR Bit (Remote Transmission Request)

The RTR bit is used to specify the value of the RTR bit of the message to be transmitted.

Note: There are no remote frames in CAN FD format. When transmitting a CAN FD frame (TMBn.HF2.FDF = 1), this bit is transmitted dominant regardless of the value of this bit.

IDE Bit (Identifier Extension)

The IDE bit is used to specify the value of the IDE bit of the message to be transmitted.

45.2.79.22 Transmit Message Buffer n Header Field 1 (TMBn.HF1) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103)

Address(es): CANFDG0.TMB0.HF1 8749 0004h, CANFDG0.TMB1.HF1 8749 0084h, CANFDG0.TMB2.HF1 8749 0104h, CANFDG0.TMB3.HF1 8749 0184h, CANFDG0.TMB4.HF1 8749 0204h, CANFDG0.TMB5.HF1 8749 0284h, CANFDG0.TMB6.HF1 8749 0304h, CANFDG0.TMB7.HF1 8749 0384h, CANFDG0.TMB32.HF1 8749 1004h, CANFDG0.TMB33.HF1 8749 1084h, CANFDG0.TMB34.HF1 8749 1104h, CANFDG0.TMB35.HF1 8749 1184h, CANFDG0.TMB36.HF1 8749 1204h, CANFDG0.TMB37.HF1 8749 1284h, CANFDG0.TMB38.HF1 8749 1304h, CANFDG0.TMB39.HF1 8749 1384h, CANFDG0.TMB64.HF1 8749 2004h, CANFDG0.TMB65.HF1 8749 2084h, CANFDG0.TMB66.HF1 8749 2104h, CANFDG0.TMB67.HF1 8749 2184h, CANFDG0.TMB68.HF1 8749 2204h, CANFDG0.TMB69.HF1 8749 2284h, CANFDG0.TMB70.HF1 8749 2304h, CANFDG0.TMB71.HF1 8749 2384h, CANFDG0.TMB96.HF1 8749 3004h, CANFDG0.TMB97.HF1 8749 3084h, CANFDG0.TMB98.HF1 8749 3104h, CANFDG0.TMB99.HF1 8749 3184h, CANFDG0.TMB100.HF1 8749 3204h, CANFDG0.TMB101.HF1 8749 3284h, CANFDG0.TMB102.HF1 8749 3304h, CANFDG0.TMB103.HF1 8749 3384h, CANFDG0_NS.TMB0.HF1 0749 0004h, CANFDG0_NS.TMB1.HF1 0749 0084h, CANFDG0_NS.TMB2.HF1 0749 0104h, CANFDG0_NS.TMB3.HF1 0749 0184h, CANFDG0_NS.TMB4.HF1 0749 0204h, CANFDG0_NS.TMB5.HF1 0749 0284h, CANFDG0_NS.TMB6.HF1 0749 0304h, CANFDG0_NS.TMB7.HF1 0749 0384h, CANFDG0_NS.TMB32.HF1 0749 1004h, CANFDG0_NS.TMB33.HF1 0749 1084h, CANFDG0_NS.TMB34.HF1 0749 1104h, CANFDG0_NS.TMB35.HF1 0749 1184h, CANFDG0_NS.TMB36.HF1 0749 1204h, CANFDG0_NS.TMB37.HF1 0749 1284h, CANFDG0_NS.TMB38.HF1 0749 1304h, CANFDG0_NS.TMB39.HF1 0749 1384h, CANFDG0_NS.TMB64.HF1 0749 2004h, CANFDG0_NS.TMB65.HF1 0749 2084h, CANFDG0_NS.TMB66.HF1 0749 2104h, CANFDG0_NS.TMB67.HF1 0749 2184h, CANFDG0_NS.TMB68.HF1 0749 2204h, CANFDG0_NS.TMB69.HF1 0749 2284h, CANFDG0_NS.TMB70.HF1 0749 2304h, CANFDG0_NS.TMB71.HF1 0749 2384h, CANFDG0_NS.TMB96.HF1 0749 3004h, CANFDG0_NS.TMB97.HF1 0749 3084h, CANFDG0_NS.TMB98.HF1 0749 3104h, CANFDG0_NS.TMB99.HF1 0749 3184h, CANFDG0_NS.TMB100.HF1 0749 3204h, CANFDG0_NS.TMB101.HF1 0749 3284h, CANFDG0_NS.TMB102.HF1 0749 3304h, CANFDG0_NS.TMB103.HF1 0749 3384h

b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes to be transmitted in a CAN frame.	R/W

This register is used to store the data length code (DLC) fields of the message to be transmitted.
Do not write to this register in CH_SLEEP mode.

DLC[3:0] Bits (Data Length Code)

The DLC[3:0] bits are used to specify the number of data bytes of the message to be transmitted when the corresponding TMBn.HF0.RTR bit is set to 0.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

Bit	Symbol	Bit Name	Description	R/W
b0	ESI	Error State Indicator	0: CAN FD frame to transmit by error active node 1: CAN FD frame to transmit by error passive node	R/W
b1	BRS	Bit Rate Switch	0: CAN FD frame to transmit with no bit rate switch 1: CAN FD frame to transmit with bit rate switch	R/W
b2	FDF	FD Format Indicator	0: Non CAN FD frame to transmit 1: CAN FD frame to transmit	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	IFL[1:0]	Information Label	This field is used to set the information label to be stored in the Transmission History	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b16	PTR[15:0]	Pointer	This field is used to set the pointer to be stored in the Transmission History	R/W

This register is used to store the FDF bit, BRS bit, and ESI flag of the message to be transmitted, and the information label and pointer to be stored in the transmission history.
Do not write to this register in CH_SLEEP mode.

ESI Bit (Error State Indicator)

The ESI bit is used to specify the value of the ESI flag of the CAN FD frame to be transmitted.
If the channel is not in error passive, the ESI flag of the transmitted message equals the value of this bit. If the channel is in error passive, this bit is transmitted recessive regardless of the value of this bit.

BRS Bit (Bit Rate Switch)

The BRS bit is used to specify the value of the BRS bit of the CAN FD frame to be transmitted.

FDF Bit (FD Format Indicator)

The FDF bit is used to specify the value of the FDF bit of the CAN FD frame to be transmitted.

IFL[1:0] Bits (Information Label)

The IFL[1:0] bits are used to specify the information label value to be stored in the transmission history after a successful transmission of the message.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits are used to specify the pointer value to be stored in the transmission history after a successful transmission of the message.

45.2.79.24 Transmit Message Buffer n Data Field p (TMBn.DFp) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103; p = 0 to 15)

Bit	Symbol	Bit Name	Description	R/W
b0	ECEF	ECC Error Flag	0: There is no ECC error in the last RAM data read. 1: There is an ECC error in the last RAM data read.	R
b1	EC1EF	1-Bit ECC Error Detection Flag	0: 1-bit ECC error is not detected. 1: 1-bit ECC error is detected.	R
b2	EC2EF	2-Bit ECC Error Detection Flag	0: 2-bit ECC error is not detected. 1: 2-bit ECC error is detected.	R
b3	EC1EIE	1-Bit ECC Error Detection Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b4	EC2EIE	2-Bit ECC Error Detection Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b5	EC1ECD	1-Bit ECC Error Correction Disable	0: Perform error correction when 1-bit ECC error is detected. 1: Does not perform error correction when 1-bit ECC error is detected.	R/W
b6	ECEDE	ECC Error Detection Enable	0: ECC error detection is disabled. 1: ECC error detection is enabled.	R/W
b8, b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9	EC1EC	EC1EF Flag Clear	Writing 1 to this bit clears the EC1EF flag. Writing 0 to this bit is ignored. This bit is read as 0.	R/W
b10	EC2EC	EC2EF Flag Clear	Writing 1 to this bit clears the EC2EF flag. Writing 0 to this bit is ignored. This bit is read as 0.	R/W
b11	ECOVF	ECC Overflow Detection Flag	0: The ECEAR register overflow has not occurred. 1: The ECEAR register overflow has occurred.	R
b13, b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15, b14	ECEDWC[1:0]	ECEDE Bit Write Control	Enables or disables write access to the ECEDE bit.	R/W
b16	EC1EAS	1-Bit ECC Error Detected Address Stored Flag	0: No valid address is stored in the ECEAR register. 1: The address where 1-bit ECC error occurred is stored in the ECEAR register.	R
b17	EC2EAS	2-Bit ECC Error Detected Address Stored Flag	0: No valid address is stored in the ECEAR register. 1: The address where 2-bit ECC error occurred is stored in the ECEAR register.	R
b31 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ECEF Flag (ECC Error Flag)

The ECEF flag indicates whether there is an ECC error in the last RAM data read. This flag is updated every time the

RAM is read.
If the ECEDE bit is set to 1 without initializing the RAM, the value of this flag has no meaning.

[Setting condition]

- When there is an ECC error in read RAM data while the ECEDE bit is set to 1 (ECC error detection is enabled)

[Clearing condition]

- When there are no ECC error in read RAM data
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

EC1EF Flag (1-Bit ECC Error Detection Flag)

The EC1EF flag indicates that a 1-bit ECC error is detected in the data read from RAM.
When this flag is set to 1 while the interrupt is enabled, an ECC error interrupt (AFLRAM0EI, AFLRAM1EI, MBRAMEI) is generated.
If a 1-bit ECC error is detected again while this flag is 1, no further interrupt is generated.

[Setting condition]

- When a 1-bit ECC error is detected in the data read from RAM while the ECEDE bit is set to 1 (ECC error detection is enabled)

[Clearing condition]

- Writing 1 to the EC1EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If a 1-bit ECC error is detected at the same time that the EC1EC bit is set to 1, the EC1EF flag becomes 0.

EC2EF Flag (2-Bit ECC Error Detection Flag)

The EC2EF flag indicates that a 2-bit ECC error is detected in the data read from RAM.
When this flag is set to 1 while the interrupt is enabled, an ECC error interrupt (AFLRAM0EI, AFLRAM1EI, MBRAMEI) is generated.
If a 2-bit ECC error is detected again while this flag is 1, no further interrupt is generated.

[Setting condition]

- When a 2-bit ECC error is detected in the data read from RAM while the ECEDE bit is set to 1 (ECC error detection is enabled)

[Clearing condition]

- Writing 1 to the EC2EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If a 2-bit ECC error is detected at the same time that the EC2EC bit is set to 1, the EC2EF flag becomes 0.

EC1EIE Bit (1-Bit ECC Error Detection Interrupt Enable)

The EC1EIE bit enables or disables the interrupt generated by 1-bit ECC error detection.
When the EC1EF flag is set to 1 while this bit is 1, an ECC error interrupt (AFLRAM0EI, AFLRAM1EI, MBRAMEI) is generated.

EC2EIE Bit (2-Bit ECC Error Detection Interrupt Enable)

The EC2EIE bit enables or disables the interrupt generated by 2-bit ECC error detection.
When the EC2EF flag is set to 1 while this bit is 1, an ECC error interrupt (AFLRAM0EI, AFLRAM1EI, MBRAMEI) is generated.

EC1ECD Bit (1-Bit ECC Error Correction Disable)

The EC1ECD bit sets whether 1-bit ECC error correction is performed when the ECEDE bit is set to 1 (ECC error detection is enabled). When this bit is set to 1, the RAM output data is not corrected even if a 1-bit ECC error is detected.

ECEDE Bit (ECC Error Detection Enable)

Setting this bit to 1 enables the ECC error detection.
Writing to this bit is valid only when the ECEDWC[1:0] bits are set to 01b.

EC1EC Bit (EC1EF Flag Clear)

The EC1EC bit is used to clear the EC1EF flag.
The EC1EF flag is cleared by writing 1 to this bit while the EC1EF flag is set to 1. Additionally, the ECOVF flag, EC1EAS flag, and EC2EAS flag are also cleared.
If a 1-bit ECC error is detected at the same time that the EC1EC bit is set to 1, the EC1EF flag becomes 0.

EC2EC Bit (EC2EF Flag Clear)

The EC2EC bit is used to clear the EC2EF flag.
The EC2EF flag is cleared by writing 1 to this bit while the EC2EF flag is set to 1. Additionally, the ECOVF flag, EC1EAS flag, and EC2EAS flag are also cleared.
If a 2-bit ECC error is detected at the same time that the EC2EC bit is set to 1, the EC2EF flag becomes 0.

ECOVF Flag (ECC Overflow Detection Flag)

If a new ECC error is detected and the address is overwritten when an address is already stored in the ECEAR register, the ECOVF flag is set to 1 and an ECC error interrupt (AFLRAM0EI, AFLRAM1EI, MBRAMEI) is generated.
If a new ECC error is detected while this flag is 1, an ECC error interrupt is generated again.

[Setting condition]

- When new error address is captured under the condition that error address is already captured in the ECEAR register.

[Clearing condition]

- When the EC1EC bit is set to 1
- When the EC2EC bit is set to 1
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

When clearing the ECOVF flag by the EC1EC or EC2EC bit and setting the ECOVF flag occur at the same time, the ECOVF flag becomes 0.

ECEDWC[1:0] Bits (ECEDE Bit Write Control)

The ECEDWC[1:0] bits are used to enable or disable write access to the ECEDE bit. The read value is always 00b.
A value can be written to the ECEDE bit only when the value of these bits is 01b. If these bits are set to a value other than 01b, writing to the ECEDE bit is ignored and the value does not change.

EC1EAS Flag (1-Bit ECC Error Detected Address Stored Flag)

The EC1EAS flag indicates that the ECEAR register stores the address where the 1-bit ECC error occurred while the ECEDE bit is set to 1 (ECC error detection is enabled).
If a 1-bit ECC error is detected while an address where the 2-bit ECC error has occurred is already stored in the ECEAR register, the ECEAR register is not updated and this flag is not updated.

[Setting condition]

- When a 1-bit ECC error is detected while the ECEDE bit is set to 1 (ECC error detection is enabled), and the address is stored in the ECEAR register

[Clearing condition]

- When writing 1 to the EC1EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

When clearing the EC1EAS flag by the EC1EC bit and setting the EC1EAS flag occur at the same time, the EC1EAS

flag becomes 0.

EC2EAS Flag (2-Bit ECC Error Detected Address Stored Flag)

The EC2EAS flag indicates that the ECEAR register stores the address where the 2-bit ECC error occurred while the ECEDE bit is set to 1 (ECC error detection is enabled).
If a 2-bit ECC error is detected while an address where the 1-bit ECC error has occurred is already stored in the ECEAR register, the ECEAR register is updated and this flag becomes 1.

[Setting condition]

- When a 2-bit ECC error is detected while the ECEDE bit is set to 1 (ECC error detection is enabled), and the address is stored in the ECEAR register

[Clearing condition]

- When writing 1 to the EC2EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

When clearing the EC2EAS flag by the EC2EC bit and setting the EC2EAS flag occur at the same time, the EC2EAS flag becomes 0.

45.2.81 ECC Test Mode Register (AFLRAM0.ECTMR, AFLRAM1.ECTMR, MBRAM.ECTMR)

Address(es): CANFDG0.AFLRAM0.ECTMR 8746 E004h,
CANFDG0.AFLRAM1.ECTMR 8746 E104h,
CANFDG0.MBRAM.ECTMR 8746 E204h,
CANFDG0_NS.AFLRAM0.ECTMR 0746 E004h,
CANFDG0_NS.AFLRAM1.ECTMR 0746 E104h,
CANFDG0_NS.MBRAM.ECTMR 0746 E204h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ECTMWC[1:0]		—	—	—	—	—	—	ECTME	—	—	—	—	—	ECDIS	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	ECDIS	ECC Decoder Input Select	0: RAM output data is input to data input of decoder 1: Value of the ECTDR register is input to data input of decoder	R/W
b6 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	ECTME	ECC Test Mode Enable	0: Access to the ECDIS bit and the ECTDR register is disabled 1: Access to the ECDIS bit and the ECTDR register is enabled	R/W
b13 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15, b14	ECTMWC[1:0]	ECTME Bit Write Control	Enable or disable write access to the ECTME bit.	R/W

ECDIS Bit (ECC Decoder Input Select)

The ECDIS bit selects whether the data value read from RAM or the value of the ECTDR register is to be used as input data to the ECC decoder.

Writing to this bit is valid only when the ECTME bit is set to 1. It is acceptable to write to this bit at the same time as setting the ECTME bit to 1.

Setting the ECTME bit to 0 also sets this bit to 0.

ECTME Bit (ECC Test Mode Enable)

The ECTME bit is used to enable or disable access to the ECDIS bit and the ECTDR register.

This bit can be written only when the ECTMWC[1:0] bits is set to 10b.

ECTMWC[1:0] Bits (ECTME Bit Write Control)

The ECTMWC[1:0] bits are used to enable or disable write access to the ECTME bit. The read value is always 00b.

A value can be written to the ECTME bit only when the value of these bits is set to 10b. If these bits are set to a value other than 10b, write access to the ECTME bit is ignored and the value does not change.

45.2.82 ECC Decoder Test Data Register (AFLRAM0.ECTDR, AFLRAM1.ECTDR, MBRAM.ECTDR)

Address(es): CANFDG0.AFLRAM0.ECTDR 8746 E00Ch,
CANFDG0.AFLRAM1.ECTDR 8746 E10Ch,
CANFDG0.MBRAM.ECTDR 8746 E20Ch,
CANFDG0_NS.AFLRAM0.ECTDR 0746 E00Ch,
CANFDG0_NS.AFLRAM1.ECTDR 0746 E10Ch,
CANFDG0_NS.MBRAM.ECTDR 0746 E20Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to set the data for testing the ECC decoder.
When the ECTMR.ECTME bit is set to 1, this register can be read and written.
When the ECTMR.ECTME bit is set to 0, the value of this register becomes 00000000h.
When the ECTMR.ECDIS bit is set to 1, the value set in this register is used as the input data of the ECC decoder instead of the data read from RAM.

45.2.83 ECC Error Address Register (AFLRAM0.ECEAR, AFLRAM1.ECEAR, MBRAM.ECEAR)

Address(es): CANFDG0.AFLRAM0.ECEAR 8746 E010h,
CANFDG0.AFLRAM1.ECEAR 8746 E110h,
CANFDG0.MBRAM.ECEAR 8746 E210h,
CANFDG0_NS.AFLRAM0.ECEAR 0746 E010h,
CANFDG0_NS.AFLRAM1.ECEAR 0746 E110h,
CANFDG0_NS.MBRAM.ECEAR 0746 E210h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register holds the address where the ECC error occurred.
If an ECC error is detected when the ECCSR.ECEDE bit is 1 (ECC error detection is enabled), b12 to b2 of the RAM address are stored in b10 to b0 of this register.
If the same error occurred again, this register is not updated.
If a 2-bit ECC error is detected while the address where the 1-bit ECC error occurred is already stored, the ECEAR register is overwritten with the new address and the ECCSR.EC2EAS flag is set to 1.
If a 1-bit ECC error is detected while the address where the 2-bit ECC error occurred is already stored, the ECEAR register is not updated and the ECCSR.EC1EAS flag is not updated.

45.3 Operating Mode

The operating modes of the CANFDG module can be classified into two groups:

- Global modes
- Channel modes

45.3.1 Global Modes

These modes are applicable for the complete CANFDG module and therefore are called Global modes.
The Global modes of the CANFDG module are:

- GL_SLEEP
- GL_RESET
- GL_HALT
- GL_OPERATION

Figure 45.2 shows the possible transitions between the Global modes.

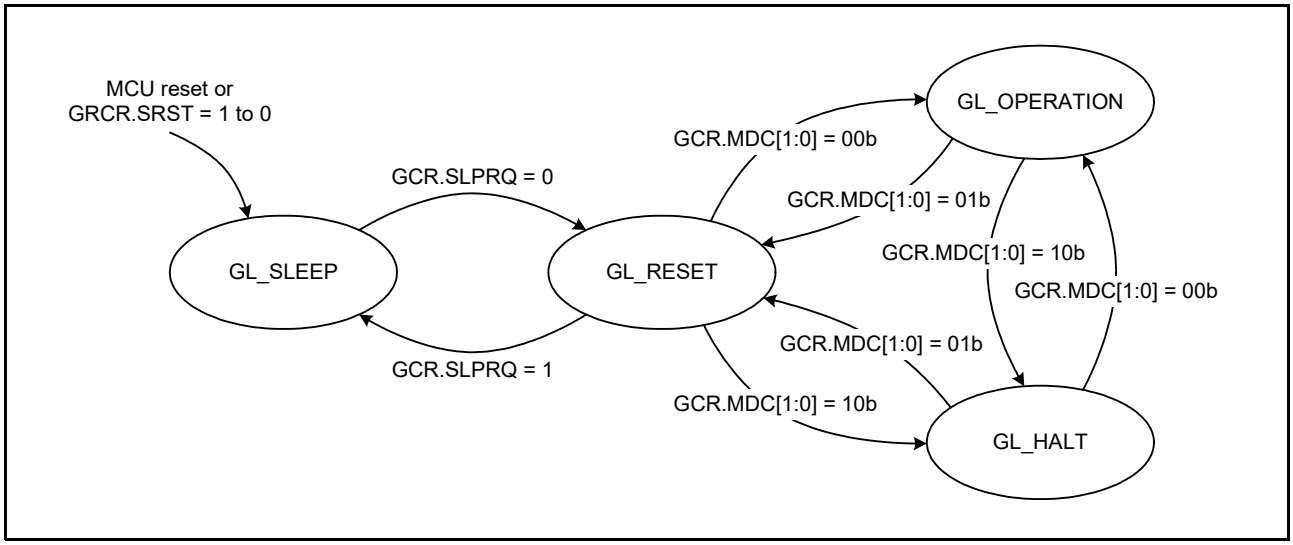

Figure 45.2 Transition between CANFDG Global Modes

Change in the Global mode can affect the Channel mode. For details, refer to section 45.3.3, Global Mode and Channel Mode Transition Interactions.

45.3.1.1 GL_SLEEP Mode

The CANFDG module automatically enters GL_SLEEP mode when the MCU reset is released or the software reset bit (GRCR.SRST) is changed from 1 to 0.
The CANFDG module also enters the GL_SLEEP mode when the GCR.SLPRQ bit is set to 1 while it is in GL_RESET mode. The SLPRQ bit cannot be set to 1 in GL_HALT or GL_OPERATION mode.
Setting the GCR.SLPRQ bit to 1 sets all the CHCR.SLPRQ bits to 1 and forces all CAN channels into the CH_SLEEP mode.
GL_SLEEP mode is used for power saving purpose. When CANFDG module is in GL_SLEEP mode, only the clock for writing to the SLPRQ bit is active. All other clocks are stopped and all other functions of the CANFDG module are suspended.
Read access from all registers is still possible and all register values are preserved.
After setting the GCR.SLPRQ bit to 1, it is necessary to confirm the GSR.SLPST flag that the GL_SLEEP status has been updated, indicating successful transition to GL_SLEEP mode before the GCR.SLPRQ bit can be cleared again.

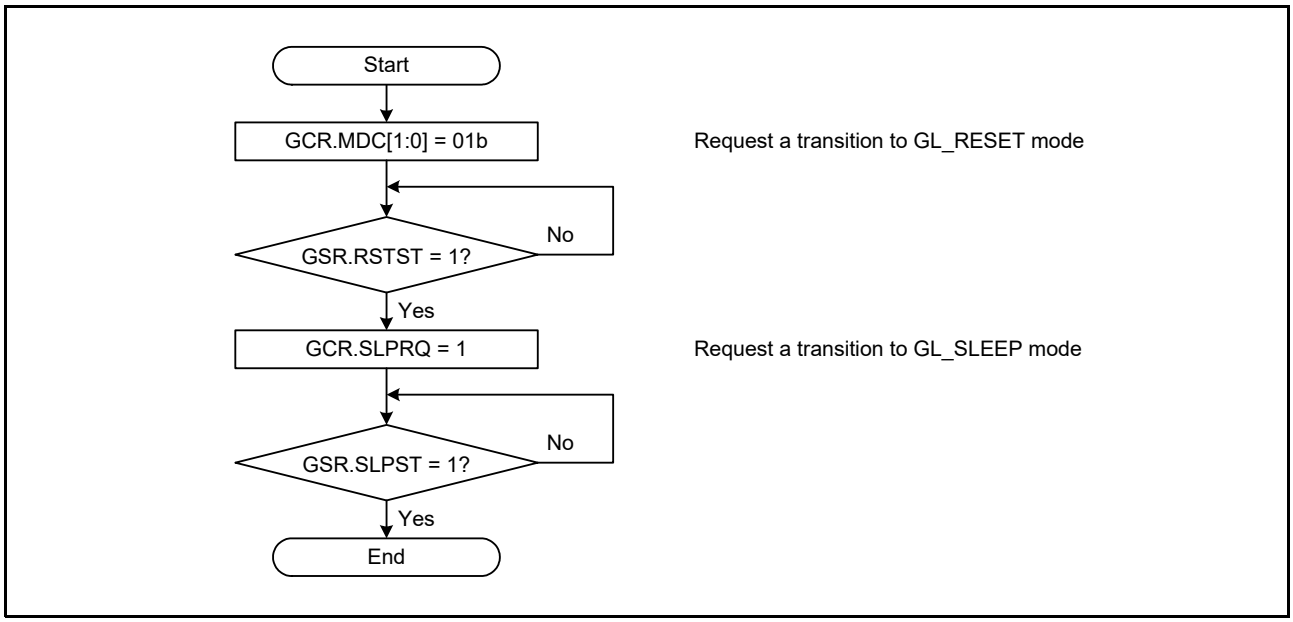

Figure 45.3 Procedure for Entering GL_SLEEP Mode

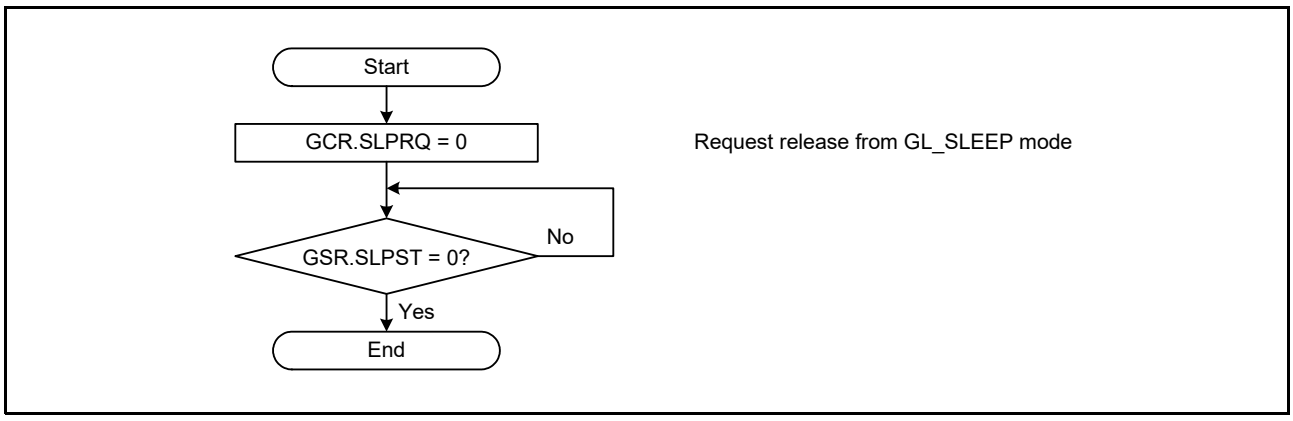

Figure 45.4 Procedure for Exiting GL_SLEEP Mode

45.3.1.2 GL_RESET Mode

The CANFDG module enters GL_RESET mode in the following ways:

- The GCR.MDC[1:0] bits are set to 01b while the CANFDG module is in GL_HALT or GL_OPERATION mode.
- The GCR.SLPRQ bit is set to 0 while the CANFDG module is in GL_SLEEP mode.

In GL_RESET mode, all CANFDG module functions are suspended and all status and flag registers are initialized. Additionally all FIFOs and all transmit queues are disabled and transmission control bits are cleared.
In this mode, configuration registers other than the GTMCR register and interrupt enable registers are not initialized, so the CANFDG module can be configured.
Setting the Global mode to GL_RESET by setting the GCR.MDC[1:0] bits to 01b sets the CHCR.MDC[1:0] bits to 01b and forces the channel into the CH_RESET mode.
For channels that are already in CH_RESET mode or CH_SLEEP mode, the channel mode remains unchanged.
After setting the GCR.MDC[1:0] bits to 01b (GL_RESET mode), it is necessary to confirm that the GSR.RSTST flag has been updated, indicating successful transition to GL_RESET mode before the GCR.MDC[1:0] bits can be changed again.

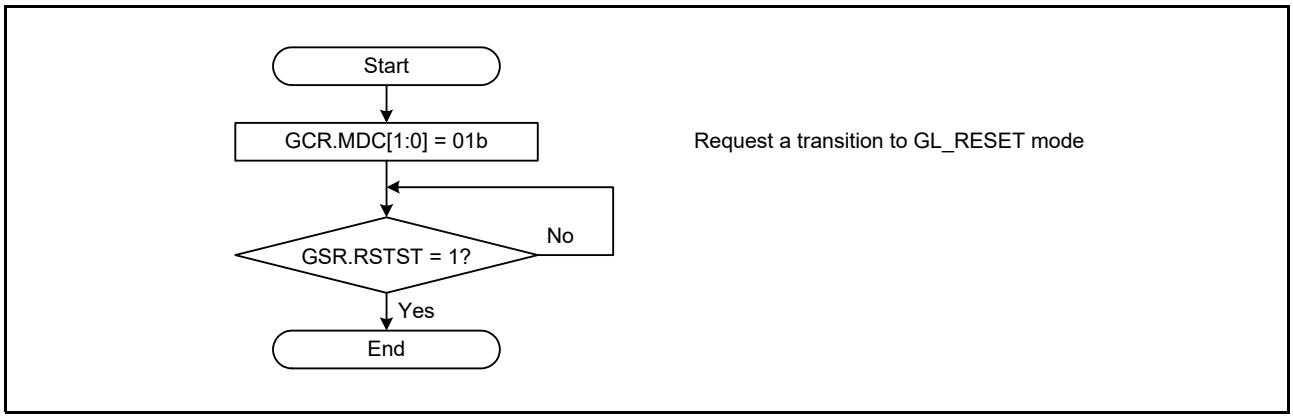

Figure 45.5 Procedure for Entering GL_RESET Mode

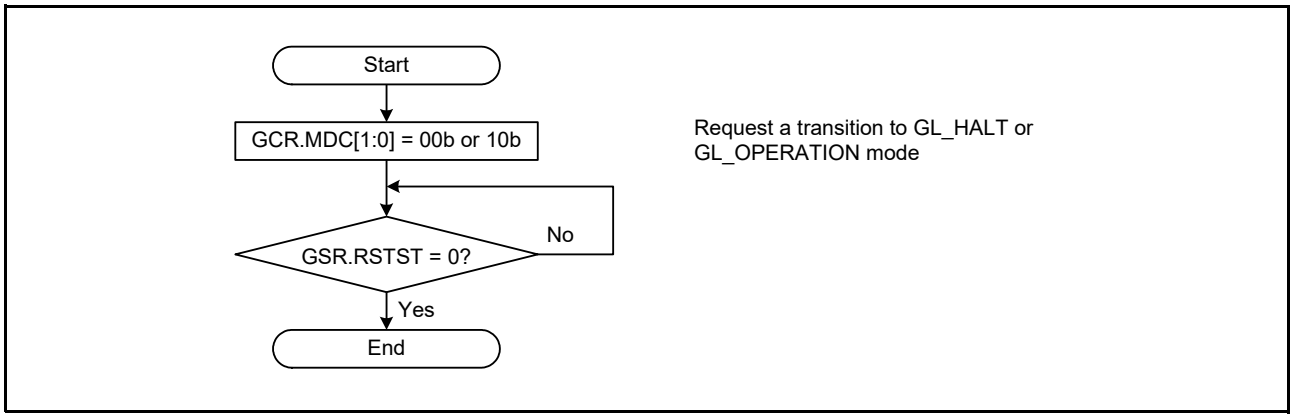

Figure 45.6 Procedure for Exiting GL_RESET Mode

45.3.1.3 GL_HALT Mode

The CANFDG module enters GL_HALT mode in the following ways:

- Set the GCR.MDC[1:0] bits to 10b while the CANFDG module is in GL_RESET mode:
  - The channels are in either CH_RESET or CH_SLEEP mode and remain in this mode.
- Set the GCR.MDC[1:0] bits to 10b while the CANFDG module is in GL_OPERATION mode:
  - All CAN channels in CH_RESET, CH_HALT, or CH_SLEEP mode remain in that mode.
  - All CAN channels in CH_OPERATION mode transit to CH_HALT mode.
  - The GSR.HLTST flag is set to 1 when all CAN channels exit CH_OPERATION mode.

If a transmission or reception is in progress for a CAN channel, the channel enters CH_HALT mode after waiting for completion of the communication.
Similarly, if a CAN channel is in the bus-off state, the channel may not enter CH_HALT mode until the bus-off recovery sequence is completed, depending on the channel configuration.
In GL_HALT mode, all communications are suspended and the status and flag registers do not change (only when a channel is in the bus-off state, its CHSR.REC[7:0] and TEC[7:0] bits are set to 00h).
Additionally, the GTMCR register and GTMER register are not initialized in this mode. The GL_HALT mode is used to configure Global Test Modes.
Setting the Global mode to GL_HALT by setting the GCR.MDC[1:0] bits to 10b sets the CHCR.MDC[1:0] bits to 10b for the channels that are in CH_OPERATION mode and forces these channels into the CH_HALT mode.
For channels that are already in CH_RESET, CH_HALT, or CH_SLEEP mode, the channel mode remains unchanged.
Therefore, the GL_HALT mode request can be used to shut down all CAN channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channels).
After setting the GCR.MDC[1:0] bits to 10b (GL_HALT mode), it is necessary to confirm that the GSR.HLTST flag has been updated to indicate a successful transition to GL_HALT mode. Do not set any other registers until confirming the GSR.HLTST flag is set.

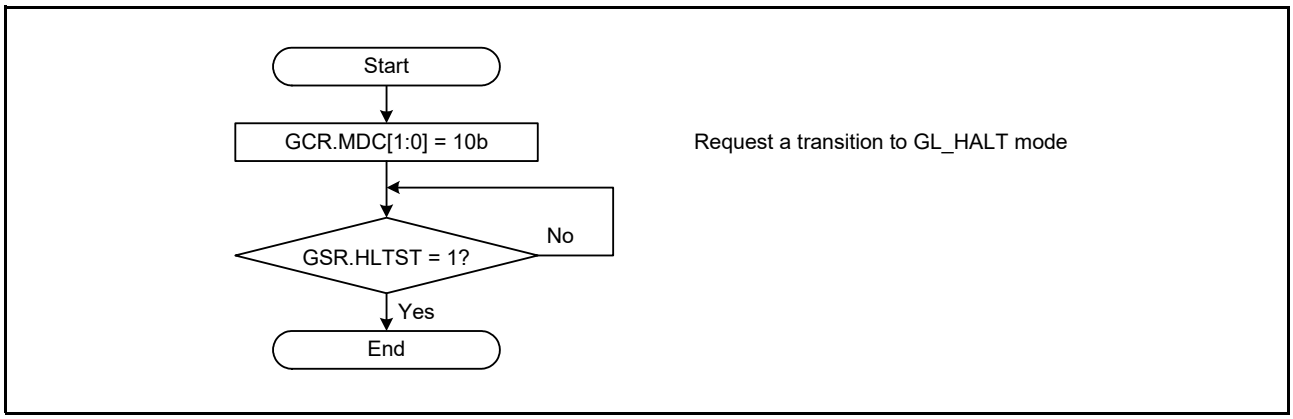

Figure 45.7 Procedure for Entering GL_HALT Mode

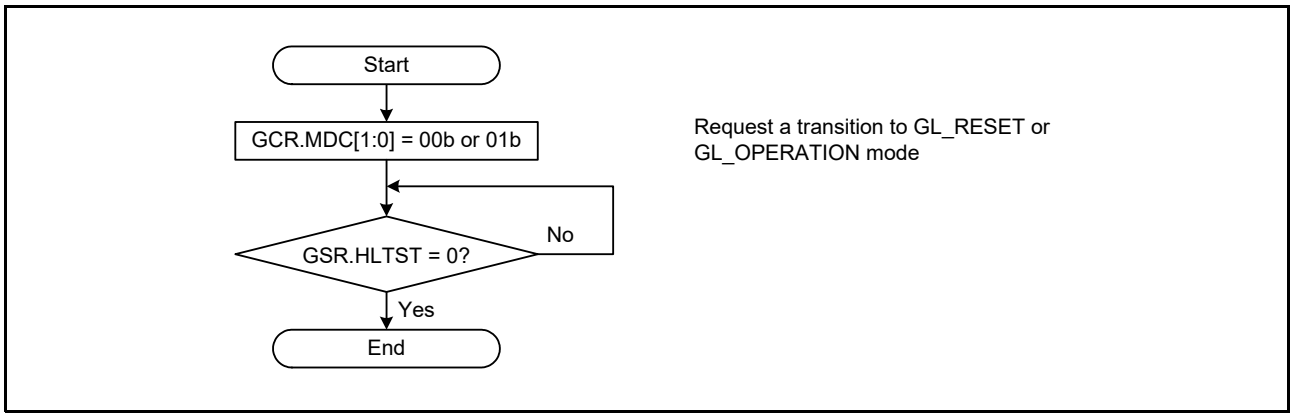

Figure 45.8 Procedure for Exiting GL_HALT Mode

45.3.1.4 GL_OPERATION Mode

The CANFDG module enters this mode when the GCR.MDC[1:0] bits are set to 00b.
The CAN channel can be set to CH_OPERATION mode and start CAN communication only when the CANFDG module is in GL_OPERATION mode.
After setting the GCR.MDC[1:0] bits to 00b (GL_OPERATION mode), it is necessary to confirm that the GSR.RSTST flag and the GSR.HLTST flag have been set to 0 to indicate a successful transition to GL_OPERATION mode before the GCR.MDC[1:0] bits can be modified again.

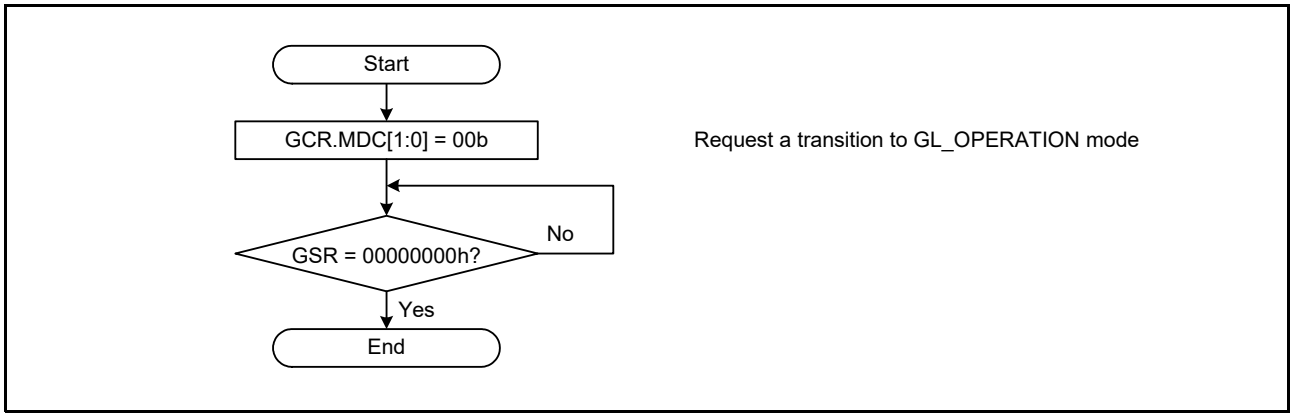

Figure 45.9 Procedure for Entering GL_OPERATION Mode

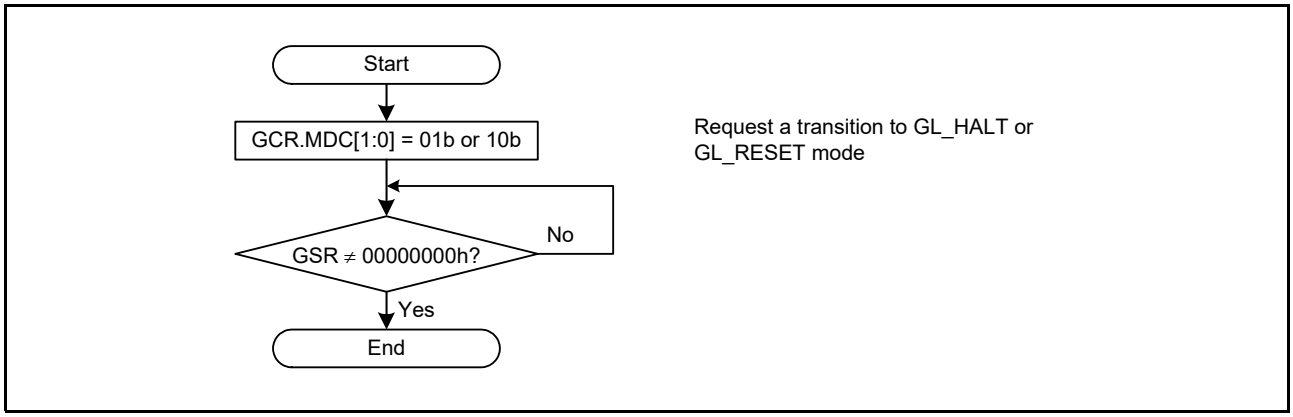

Figure 45.10 Procedure for Exiting GL_OPERATION Mode

45.3.2 Channel Modes

The Channel modes of the CANFDG module are:

- CH_SLEEP
- CH_RESET
- CH_HALT
- CH_OPERATION

Figure 45.11 shows the possible transitions between the channel modes.

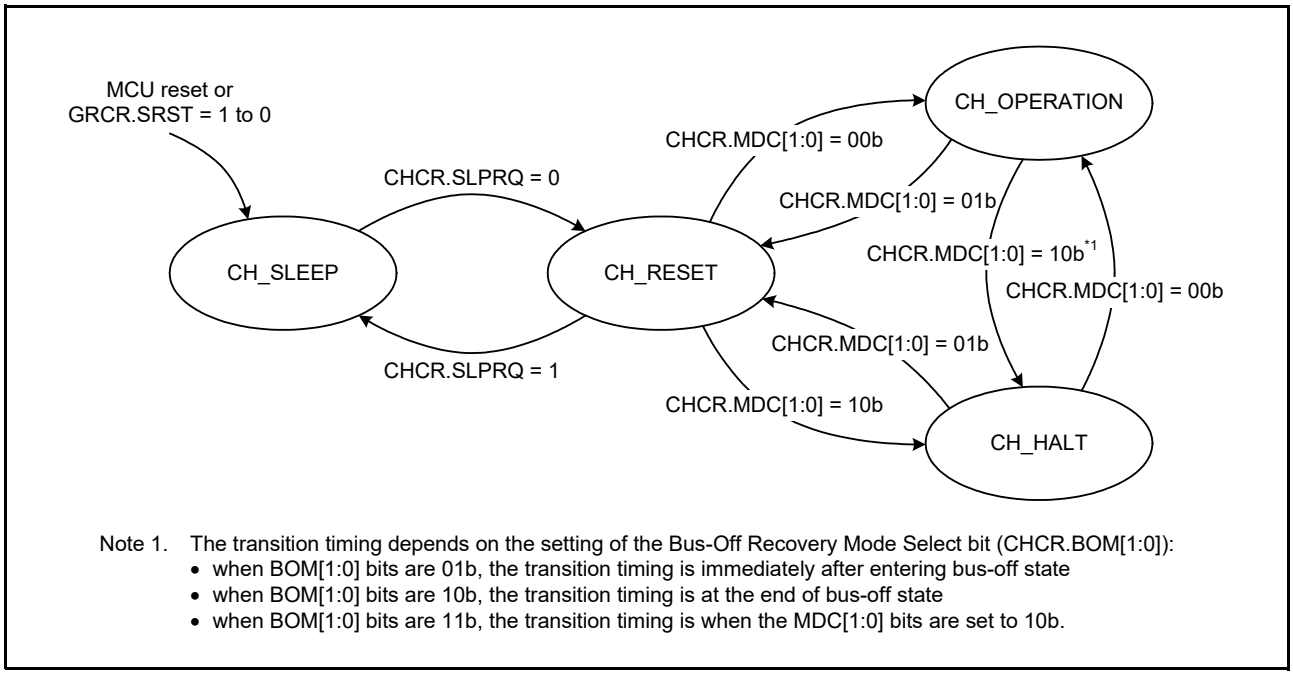

Figure 45.11 Transition between CAN Channel Modes

45.3.2.1 CH_SLEEP Mode

The CAN channel of the CANFDG module automatically enters CH_SLEEP mode when the MCU reset is released or the software reset bit (GRCR.SRST) is changed from 1 to 0.

The CAN channel also enters CH_SLEEP mode when the CHCR.SLPRQ bit is set to 1 while the CAN channel is in CH_RESET mode. The CHCR.SLPRQ bit cannot be set to 1 in CH_HALT or CH_OPERATION mode.

Entering CH_SLEEP mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.

After setting the CHCR.SLPRQ bit to 1 and before setting it to 0 again, it is necessary to use the CHSR.SLPST flag to confirm that transition to CH_SLEEP mode was successful.

During CH_SLEEP mode, do not write to channel related registers. Read operation is still possible.

45.3.2.2 CH_RESET Mode

The CAN channel of CANFDG module enters this mode in the following ways:

- The CHCR.MDC[1:0] bits are set to 01b while the CAN channel is in CH_HALT or CH_OPERATION mode
- The CHCR.SLPRQ bit is set to 0 while the CAN channel is in CH_SLEEP mode
- The GCR.MDC[1:0] bits are set to 01b while the CAN channel is not in CH_SLEEP or CH_RESET mode.

In CH_RESET mode, all CAN channel status and flags are initialized.
In addition, all transmission-related control bits of the channel are cleared, and the transmit queue of the channel is also disabled.
In this mode, the configuration registers except for the bits related to the channel test mode are not initialized, so the CAN channel can be configured for communication.
After setting the CHCR.MDC[1:0] bits to 01b (CH_RESET mode) and before modifying these bits again, it is necessary to use the CHSR.RSTST flag to confirm that transition to CH_RESET mode was successful.
Refer to Table 45.14 for the behavior of transitioning to CH_RESET mode while CAN communication is in progress.

45.3.2.3 CH_HALT Mode

The CAN channel of CANFDG module enters this mode in the following ways:

- The CHCR.MDC[1:0] bits are set to 10b while the CAN channel is in CH_RESET or CH_OPERATION mode
- The GCR.MDC[1:0] bits are set to 10b while the CAN channel is in CH_OPERATION mode.

In CH_HALT mode, all CAN communication of the channel is suspended, but all statuses and flags remain unchanged during CH_HALT mode (except for the bus-off state where the CHSR.REC[7:0] and TEC[7:0] bits for the channel are set to 00h).
In addition, in this mode, the bits related to the channel test mode are not initialized. Use CH_HALT mode to configure the channel test mode.
After setting the CHCR.MDC[1:0] bits to 10b (CH_HALT mode) and before modifying these bits again, it is necessary to use the CHSR.HLTST flag to confirm that transition to CH_HALT mode was successful.
Refer to Table 45.14 for the transition behavior to CH_HALT mode while CAN communication is in progress.

Table 45.14 Transition Behavior in CH_RESET Mode and CH_HALT Mode

Mode	State		
	Receiver	**Transmitter**	**Bus-Off**
CH_RESET mode (CHCR.MDC[1:0] = 01b)	The CAN channel transits to CH_RESET mode without waiting for the completion of the ongoing reception.*1	The CAN channel transits to CH_RESET mode without waiting for the completion of the ongoing transmission.*1	The CAN channel transits to CH_RESET mode without waiting for the completion of the bus-off recovery.
CH_HALT mode (CHCR.MDC[1:0] = 10b)	CAN channel transits to CH_HALT mode at the end of the ongoing reception or when an error occurs.*2	CAN channel transits to CH_HALT mode after completion of the ongoing transmission.	When the CHCR.BOM[1:0] bits are 00b, a CH_HALT mode request is accepted only after the completion of the full bus-off recovery sequence. When the CHCR.BOM[1:0] bits are 10b, the CAN channel transits automatically to CH_HALT mode after waiting for the completion of the bus-off recovery. When the CHCR.BOM[1:0] bits are 01b, the CAN channel transits automatically to CH_HALT mode without waiting for the completion of the bus-off recovery. When the CHCR.BOM[1:0] bits are 11b, the CAN channel transits to CH_HALT mode as soon as CH_HALT mode is requested (without waiting for the completion of the bus-off recovery).

Note 1. If the entry to CH_RESET mode is required only at the end of an ongoing communication, then CH_HALT mode can be requested first to prevent interruption of CAN communication by direct transition to CH_RESET mode. After the CAN channel enters CH_HALT mode, the CH_RESET mode can be requested.

Note 2. If CAN communication is locked at dominant level after an error flag, software can detect this situation by monitoring the channel related BusLock flag and resolve lock condition by setting the CAN channel to CH_RESET mode.

45.3.2.4 CH_OPERATION Mode (in Other than Bus-Off State)

The CH_OPERATION mode is activated by setting the CHCR.MDC[1:0] bits to 00b. If 11 consecutive recessive bits are detected after entering the CH_OPERATION mode, the CHSR.CRDY flag is set to 1 and the CAN channel:

- Enables the functions of the communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters.

At this point, the CAN channel can start transmission and reception of messages.
Within the CH_OPERATION mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (refer to Figure 45.12):

- Idle mode: The CAN channel is neither receiving nor transmitting
- Receive mode: The channel is receiving a message transmitted by another CAN node
- Transmit mode: The channel is transmitting a message
  (The channel may receive its own message simultaneously when Self Test mode is enabled.)
- Bus-off mode: The CAN channel is cut-off from CAN bus communication.

After setting the CHCR.MDC[1:0] bits to 00b (CH_OPERATION mode) and before modifying these bits again, it is necessary to use the CHSR.RSTST flag and the CHSR.HLTST flag to confirm that transition to CH_OPERATION mode was successful.

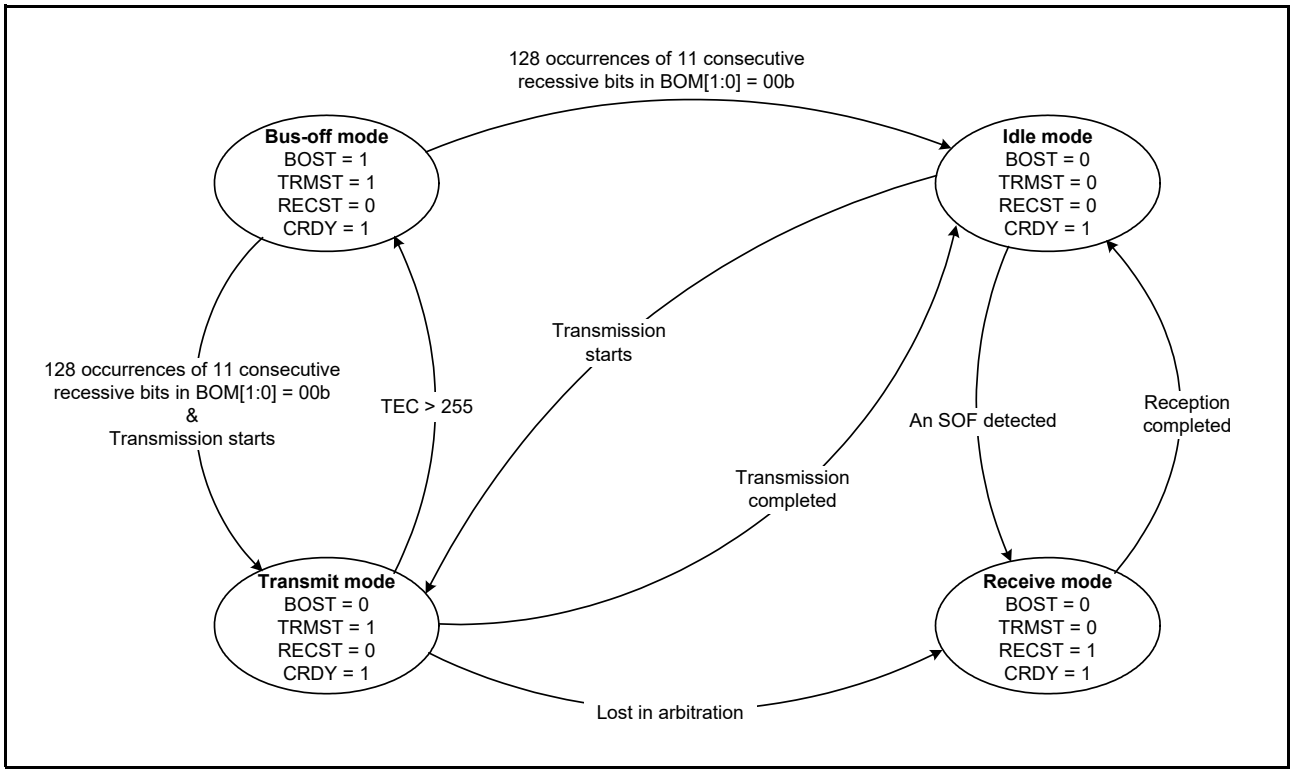

Figure 45.12 Sub-modes of CH_OPERATION Mode (only when CHCR.BOM[1:0] = 00b)

45.3.2.5 CH_OPERATION Mode (in Bus-Off State)

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CH_OPERATION mode from the bus-off state:

- CHCR.BOM[1:0] = 00b:
  Bus-off recovery is compliant to ISO 11898-1. The CAN channel re-enters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h, and the CHESR.BORDF flag is set to 1 in this case.
- CHCR.BOM[1:0] = 01b:
  When entering bus-off state, the CAN channel changes the value of the CHCR.MDC[1:0] bits to 10b and enters CH_HALT mode automatically. The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h and the CHESR.BORDF flag is not set to 1 in this case.
- CHCR.BOM[1:0] = 10b:
  When entering bus-off state, the CAN channel changes the value of the CHCR.MDC[1:0] bits to 10b and enters CH_HALT mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h and the CHESR.BORDF flag is set to 1 in this case.
- CHCR.BOM[1:0] = 11b:
  Bus-off recovery is initiated but CAN channel can immediately enter CH_HALT mode when still in bus-off state if a request is made to enter CH_HALT mode. The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h and the CHESR.BORDF flag is not set to 1.
  Without setting CHCR.MDC[1:0] = 10b and when 11 consecutive recessive bits are detected 128 times, transition conditions become the same as CHCR.BOM[1:0] = 00b.

If the recovery from bus-off occurs normally in this mode (after waiting for 128 occurrences of 11 consecutive recessive bits), and no CH_HALT request has been generated during this period, then the CHESR.BORDF flag is set to 1.
When software writes to the CHCR.MDC[1:0] bits at the same time as the CAN channel enters CH_HALT mode (at the start of bus-off when CHCR.BOM[1:0] = 01b, or at the end of bus-off when CHCR.BOM[1:0] = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CHCR.MDC[1:0] bits to CH_HALT mode request is performed when the CHCR.MDC[1:0] bits value is previously 00b (CH_OPERATION mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting the CHCR.RTBO bit to 1. The error state changes from bus-off state to integrating state with a maximum delay of 1 bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The CHESR.BORDF flag is not set to 1 in this case, and the CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h.
Before setting the CHCR.RTBO bit to 1, all pending transmissions from the transmit message buffers, transmit queues and/or common FIFO in transmit mode or gateway mode should be disabled.
The disable of the pending transmit message buffer, transmit queue or common FIFO must be confirmed by the corresponding acknowledge flags (TMSRn.TXRF[1:0] flags, TQSRn.EMPTY flag, and CFSRn.EMPTY flag).
The CHCR.RTBO bit should be used for bus-off recovery only when the CHCR.BOM[1:0] bits are set to 00b.
Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.
Table 45.15 lists the behavior of the bus-off entry detect flag (CHESR.BOEDF) and the bus-off recovery detect flag (CHESR.BORDF) according to the CHCR.BOM[1:0] bit settings.

Table 45.15 Behavior of Bus-off Entry and Recovery Flags

CHCR.BOM[1:0] Bits	CHESR.BOEDF Flag	CHESR.BORDF Flag
00b	Becomes 1 on entry to bus-off state.	Becomes 1 on exit from bus-off state.
00b Set the CHCR.RTBO bit to 1		Becomes 1 only if normal bus-off recovery occurs before setting the CHCR.RTBO bit to 1.
01b		Does not become 1.
10b		Becomes 1 on exit from bus-off state.
11b		Becomes 1 only if normal bus-off recovery occurs before requesting a transition to CH_HALT mode.

To make efficient software, it is not necessary to wait for the bus-off recovery sequence to end.
It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in Figure 45.13.

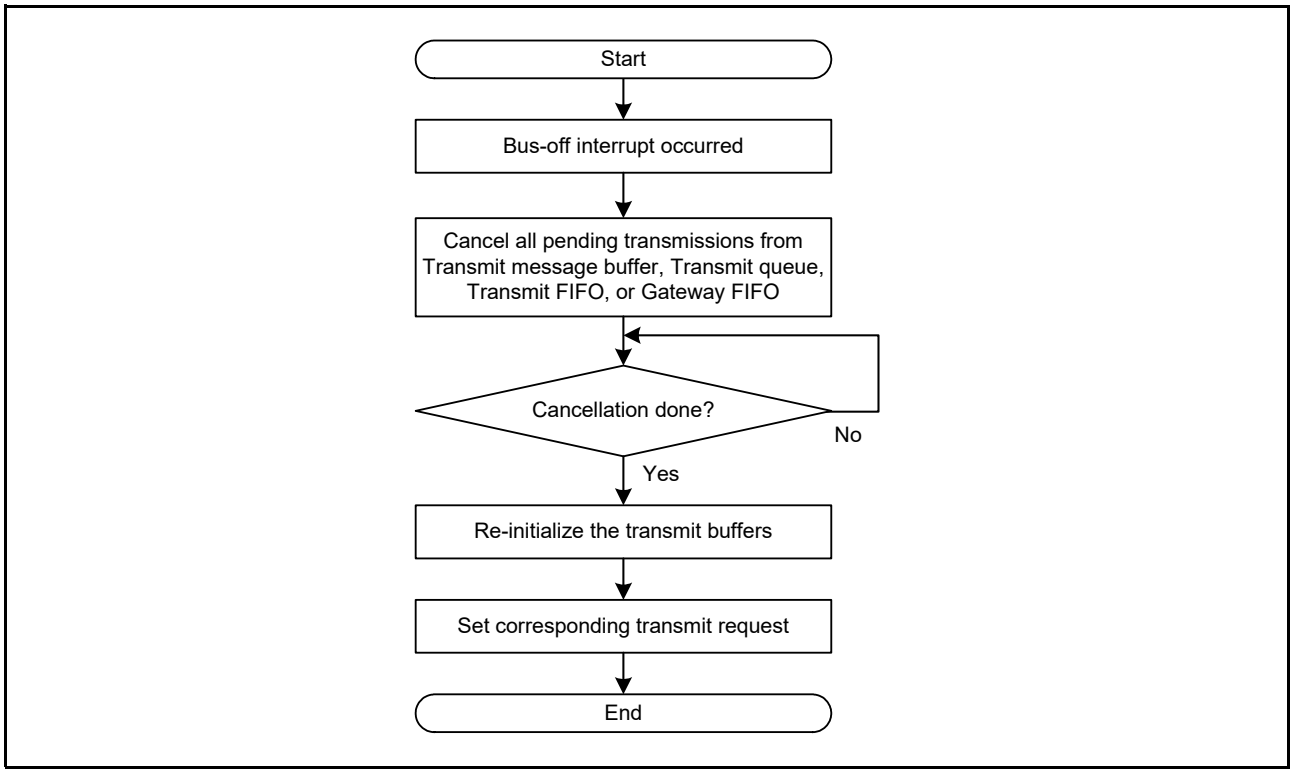

Figure 45.13 Transmission Re-Initialization During Bus-Off

45.3.3 Global Mode and Channel Mode Transition Interactions

The interaction between Global mode setting and Channel mode setting is as follows:

- Changing the CHCR.MDC[1:0] bits does not affect the GCR.MDC[1:0] bits.
- Changing the GCR.MDC[1:0] bits affects the channel mode control as described in Table 45.16.

Table 45.16 Interaction between Global Mode and Channel Mode Transition

Global Mode Change	Channel Mode before Changing Global Mode	Channel Mode after Changing Global Mode
GL_SLEEP → GL_RESET	CH_SLEEP	CH_SLEEP (no changes)
GL_RESET → GL_SLEEP	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_SLEEP
GL_RESET → GL_HALT	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
GL_RESET → GL_OPERATION	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
GL_HALT → GL_RESET	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
	CH_HALT	CH_RESET
GL_HALT → GL_OPERATION	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
	CH_HALT	CH_HALT (no changes)
GL_OPERATION → GL_RESET	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
	CH_HALT	CH_RESET
	CH_OPERATION	CH_RESET
GL_OPERATION → GL_HALT	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
	CH_HALT	CH_HALT (no changes)
	CH_OPERATION	After communication ends, CH_HALT

45.3.3.1 Transition Time for Global Mode Change

Table 45.17 shows the transition times when changing the global mode.

Table 45.17 Maximum Transition Times for Global Mode Changes

From	To	Maximum Transition Time
GL_SLEEP	GL_RESET	3 × PCLKA*1
GL_RESET	GL_SLEEP	3 × PCLKA
GL_RESET	GL_HALT	10 × PCLKA
GL_RESET	GL_OPERATION	10 × PCLKA
GL_HALT	GL_RESET	2 bit times (1 Tq + 16 × PCLKA + 2 DLL clock cycles)
GL_HALT	GL_OPERATION	3 × PCLKA
GL_OPERATION	GL_RESET	2 bit times (1 Tq + 16 × PCLKA + 2 DLL clock cycles)
GL_OPERATION	GL_HALT	3 CAN frames (1 CAN frame + 3424 × PCLKA)*2, *3

Note 1. Exit GL_SLEEP mode only when the GSR.RAMST flag is cleared.
Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked receive lines or continued error conditions.
Note 3. Tq, CAN frame and bit times vary for each channel. The maximum transition time must be calculated on the channel with the lowest bit rate.

45.3.3.2 Transition Time for Channel Mode Change

Table 45.18 shows the transition times when changing the channel mode.

Table 45.18 Maximum Transition Times for Channel Mode Changes

From	To	Maximum Transition Time
CH_SLEEP	CH_RESET	3 × PCLKA
CH_RESET	CH_SLEEP	3 × PCLKA
CH_RESET	CH_HALT	3 bit times (1 CAN bit + 2 Tq + 8 × PCLKA + 2 DLL clock cycles)
CH_RESET	CH_OPERATION	4 bit times (2 CAN bits + 1 TSEG1 + 12 × PCLKA + 2 DLL clock cycles)
CH_HALT	CH_RESET	2 bit times (1 Tq + 10 × PCLKA + 2 DLL clock cycles)
CH_HALT	CH_OPERATION	4 bit times (< 4 CAN bits)*1
CH_OPERATION	CH_RESET	2 bit times (1 Tq + 10 × PCLKA + 2 DLL clock cycles)
CH_OPERATION	CH_HALT	2 CAN frames (1 CAN frame + 13 CAN bits)*2, *3

Note 1. In general, if the bit rate prescaler value (NBCR.BRP[9:0]) is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the Tq clock, and new BRP value is captured when the counter reaches the value 0.

Note 2. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CHCR.BOM[1:0] bits.

Note 3. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked receive lines or continued error conditions.

45.4 Initialization of CANFDG Module

Before starting CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data bit rate)
- Bit Rate setting (nominal and data bit rate)
- CANFDG setting
- Acceptance Filter setting (configuration of Acceptance Filter List)
- Receive FIFO, Transmit FIFO, and Gateway FIFO setting
- CAN operating mode setting.

45.4.1 Initialization of CAN Clock, Bit Timing, and Bit Rate

45.4.1.1 Bit Timing Conditions

The following lines describe the settings for each segment and the limitations that apply to those settings.

1. Each segment setting

- SS = Fixed to 1 Tq
  TSEG1 = 2 Tq to 256 Tq (NBCR), 2 Tq to 32 Tq (DBCR)
  TSEG2 = 2 Tq to 128 Tq (NBCR), 2 Tq to 16 Tq (DBCR)
  SJW = 1 Tq to 128 Tq (NBCR), 1 Tq to 16 Tq (DBCR)
  SS + TSEG1 + TSEG2 = 8 Tq to 385 Tq (NBCR), 5 Tq to 49 Tq (DBCR)

2. Limitations on TSEG1, TSEG2 and SJW
   NBCR register: TSEG1 > TSEG2 ≥ SJW
   DBCR register: TSEG1 ≥ TSEG2 ≥ SJW

Table 45.19 shows an example of how to set the bit timing to achieve the required sample point settings.

Table 45.19 Bit Timing Examples

1 Bit	Set Value (Tq)				Sample Point (%)
	SS	TSEG1	TSEG2	SJW	
5 Tq	1	2	2	1	60.00
8 Tq	1	4	3	1	62.50
	1	5	2	1	75.00
10 Tq	1	6	3	1	70.00
	1	7	2	1	80.00
12 Tq	1	8	3	1	75.00
	1	9	2	1	83.33
15 Tq	1	10	4	1	73.33
	1	11	3	1	80.00
16 Tq	1	10	5	1	68.75
	1	11	4	1	75.00
20 Tq	1	12	7	1	65.00
	1	13	6	1	70.00
24 Tq	1	15	8	1	66.66
	1	16	7	1	70.83
50 Tq	1	39	10	4	80.00

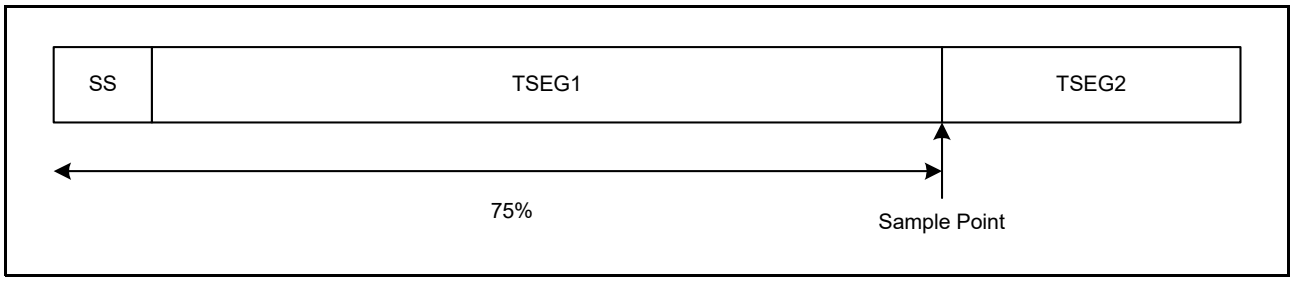

Figure 45.14 The Sample Point (in Case of 75%)

45.4.1.2 Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured individually for each channel using the NBCR and DBCR registers.

Figure 45.15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (Tq), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the bit rate prescaler (nominal and data bit rate).

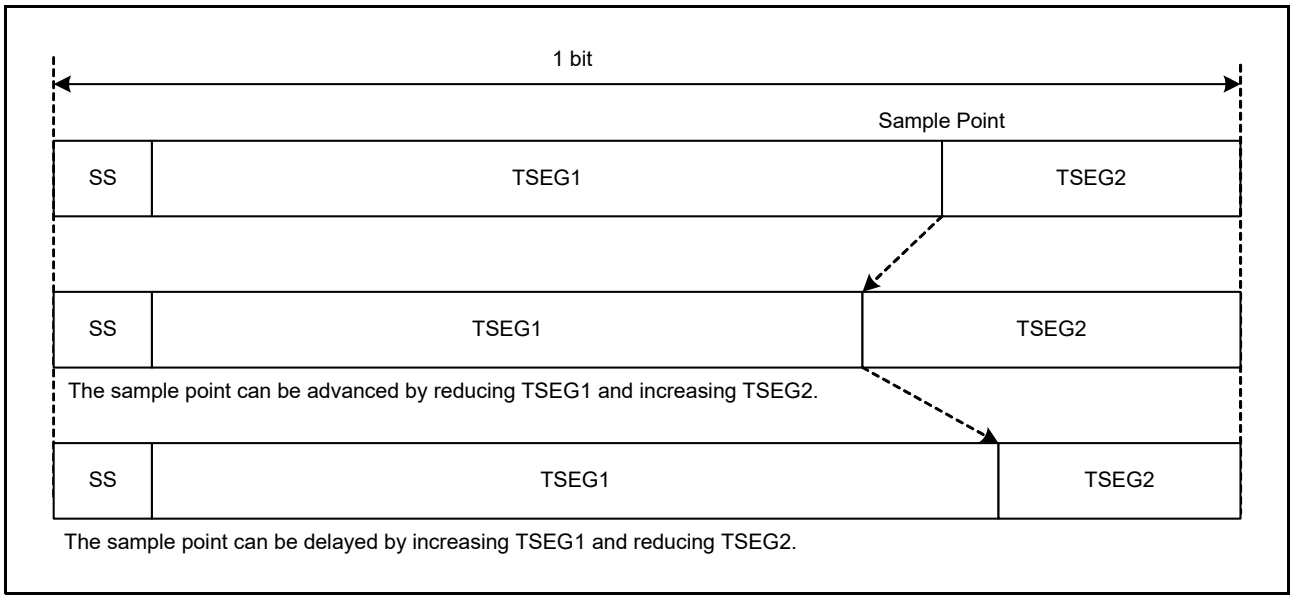

Figure 45.15 Segment Composition of A Bit and The Sample Point

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. The interframe space consists of the intermission, suspend transmission, and bus idle fields; during the bus idle field, all nodes may begin transmission.
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.

3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While transmitting or receiving a message, communication frames between some nodes may get out of sync due to a drift in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.
4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 45.15 shows an example of a typical sample point.

45.4.1.3 Bit Rate

The CAN communication clocks are generated by dividing the operating clock for data link layer (DLL clock). The DLL clock can be selected from either the internal clock (CANFDCLK) or the external clock (CANFDMCLK).
Figure 45.16 shows a block diagram of the circuit that generates the CAN communication clock.

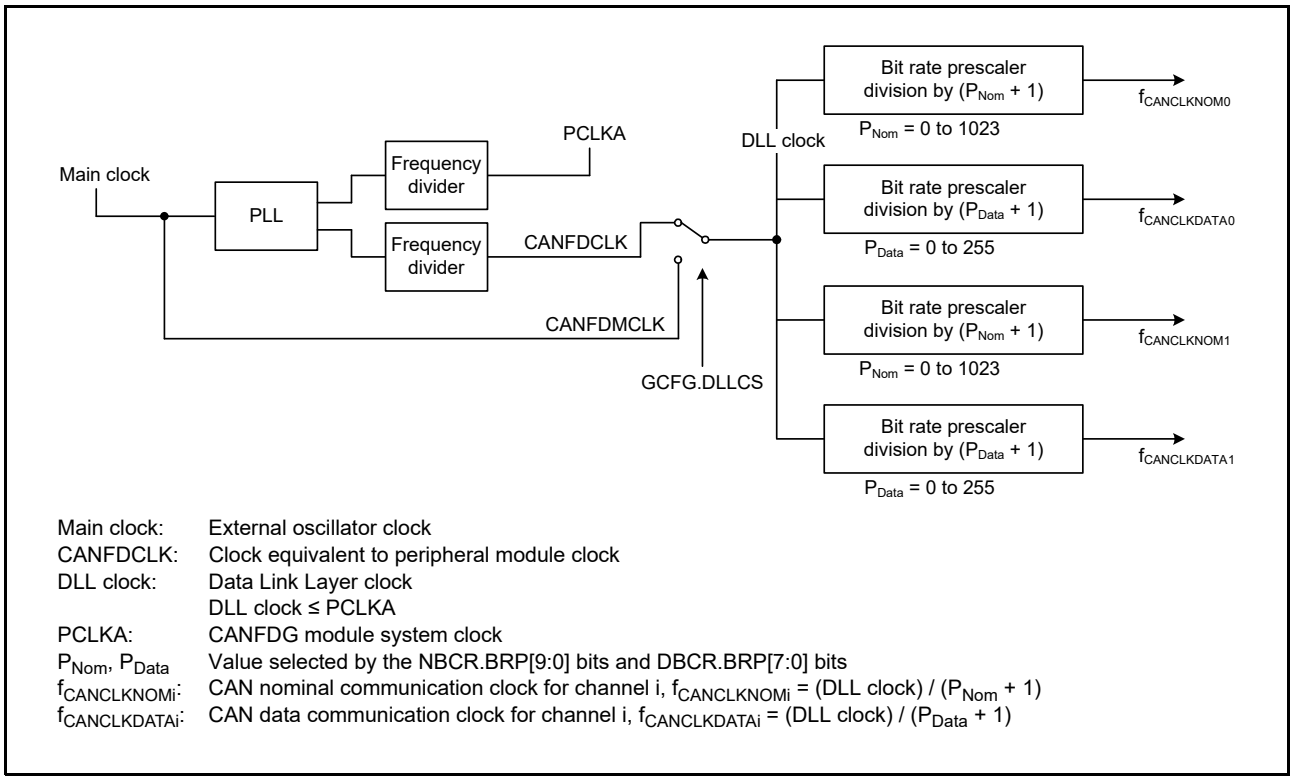

Figure 45.16 Block Diagram of the Circuit that Generates the CAN Communication Clock

The bit rate is determined by the DLL clock frequency, the division value of the bit rate prescaler (P + 1), and the number of Tq per bit.

$$\text{Bit rate} = \frac{\text{DLL clock frequency}}{\text{Number of Tq per bit} \times (\text{P} + 1)} = \frac{\text{CAN communication clock frequency}}{\text{Number of Tq per bit}}$$

Table 45.20 lists examples of setting the nominal bit rate for Classical CAN frame.

Table 45.20 Nominal Bit Rate Setting Examples for Classical CAN Frame

Bit Rate	DLL Clock Frequency																	
	80 MHz		40 MHz		32 MHz		30 MHz		24 MHz		20 MHz		16 MHz		10 MHz		8 MHz*1

Note 1. Minimum frequency to achieve a nominal bit rate of 1 Mbps.

For optimum clock tolerance in networks using the CAN FD frame, the length of the time quantum should be the same in nominal bit time and in data bit time. This means NBCR.BRP[9:0] = DBCR.BRP[7:0].
In addition, do not set the DBCR.BRP[7:0] bits greater than 1 when using transceiver delay compensation.
Table 45.21 lists examples of setting the nominal and data bit rate for CAN FD frame.

Table 45.21 Nominal and Data Bit Rate Setting Examples for CAN FD Frame

Bit Rate		DLL Clock Frequency								
		80 MHz			40 MHz			20 MHz		
		No. of Tq			No. of Tq			No. of Tq		
Nominal	Data	Nom.	Data	P+1	Nom.	Data	P+1	Nom.	Data	P+1
1 Mbps	8 Mbps	80 Tq	10 Tq	1	40 Tq	5 Tq	1	20 Tq	—	1
1 Mbps	5 Mbps	80 Tq	16 Tq	1	40 Tq	8 Tq	1	20 Tq	—	1
500 kbps	2 Mbps	160 Tq	40 Tq	1	80 Tq	20 Tq	1	40 Tq	10 Tq	1

45.4.1.4 Setting of CAN Clock, Bit Timing and Bit Rate

Figure 45.17 shows the procedure for setting the bit timing and the bit rate.
These settings should be configured when the CAN channel is in CH_RESET mode.
The bit rate must be configured before moving to the channel communication state. Otherwise the mode does not switch correctly.

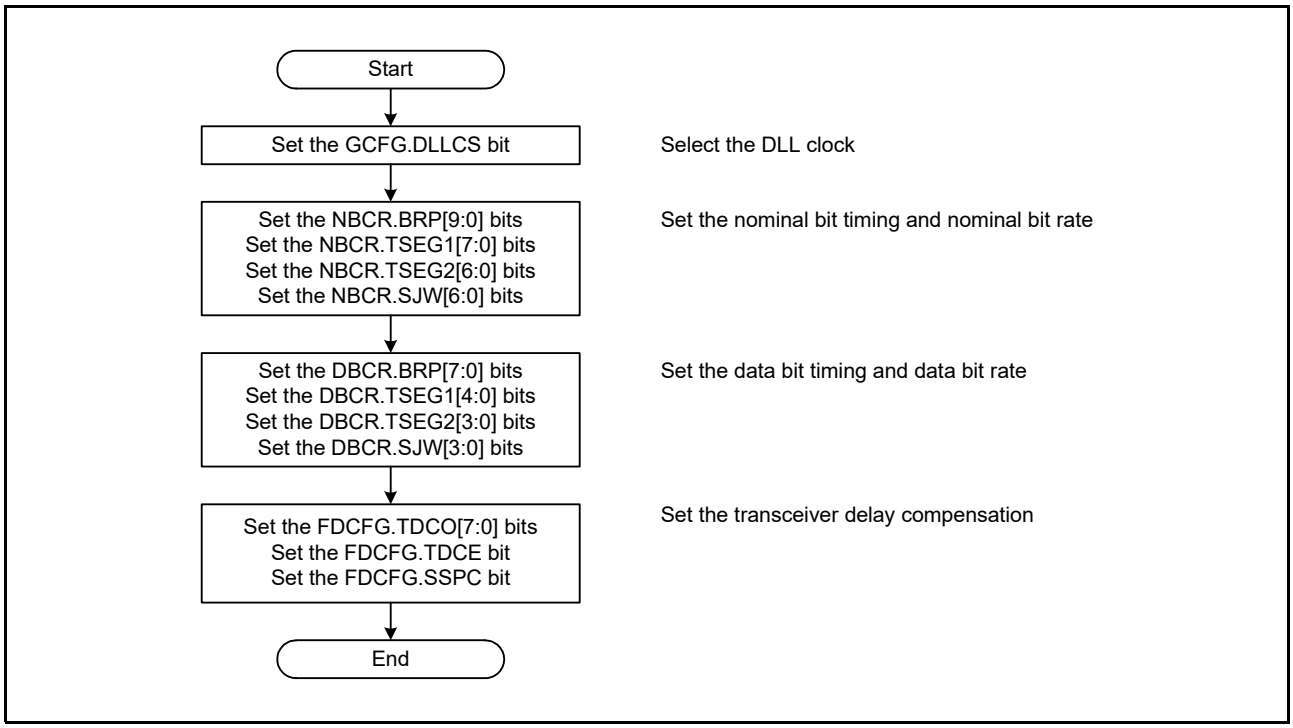

Figure 45.17 Procedure for Setting the Bit Timing and Bit Rate

45.4.1.5 Transceiver Delay Compensation

When a high bit rate is used such as 5 to 8 Mbps for the data phase, the transceiver delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CAN FD frame. The transceiver delay compensation function compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.

There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CAN FD frames. This is derived from the Transceiver Delay Compensation Result bit (FDSTS.TDCR[7:0]) as shown in Figure 45.18.

The resolution of the configuration, measured and offset values is based on the CAN channel DLL clock.

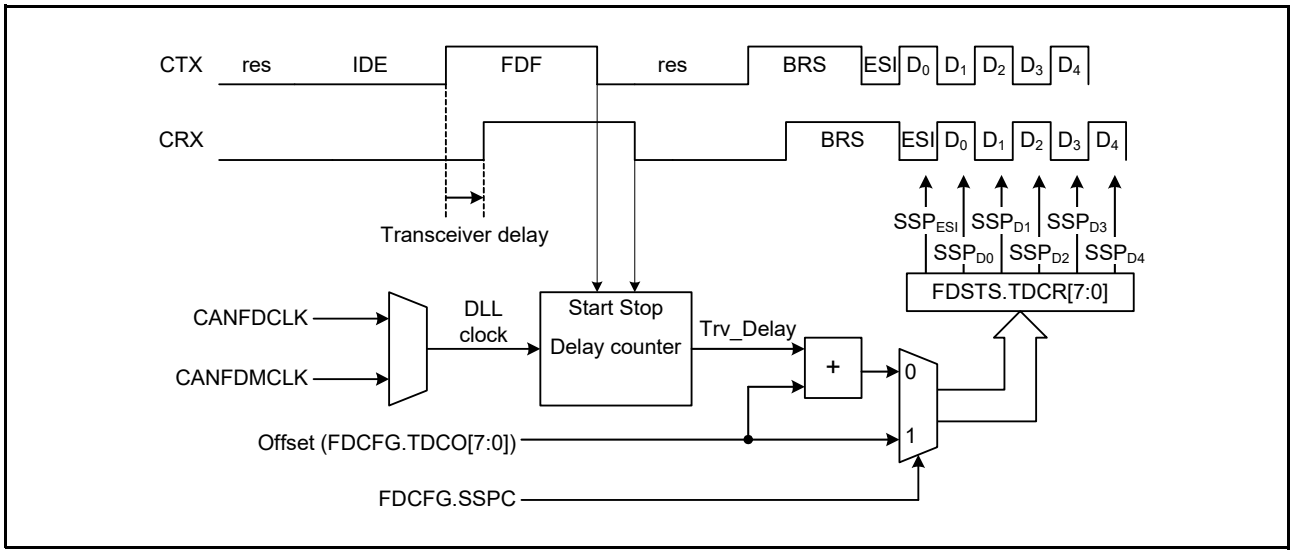

Figure 45.18 Transceiver Delay Compensation

The measured Trv_Delay is based on the number of DLL clock cycles. It counts up by one for each start clock until the dominant value can be observed at the CRX pin. Figure 45.19 shows the measurement example. Trv_Delay is counted up to 127 on each DLL clock.

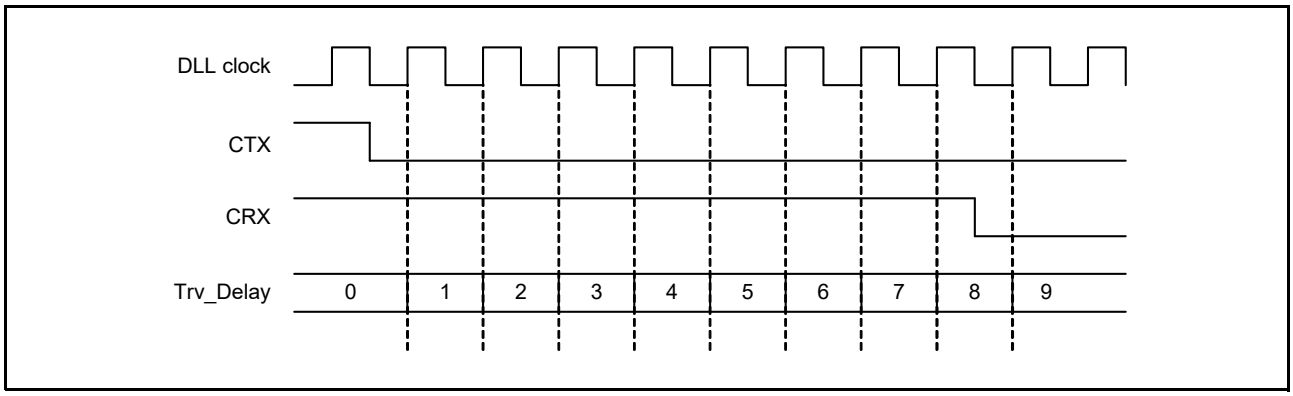

Figure 45.19 Trv_Delay Measurement Example

The SSP is calculated by taking the result from the FDSTS.TDCR[7:0] bits and rounding the value down to the nearest integer number of data Tq.

Figure 45.20 shows the positioning of the secondary sample point (SSP). When the FDCFG.SSPC bit is set to 0, the SSP is equal to the Trv_Delay (measured delay) + FDCFG.TDCO[7:0], rounded down to the nearest integer number of Tq. Normally, the TDCO[7:0] value has the magnitude of SS + TSEG1 in the data phase to position the SSP to a theoretical location of the sample point.

If the FDCFG.SSPC bit is set to 1, the SSP is defined by the FDCFG.TDCO[7:0] bits. If the DBCR.BRP[7:0] bits are greater than 00h, the value is also rounded down to the nearest integer number of Tq.

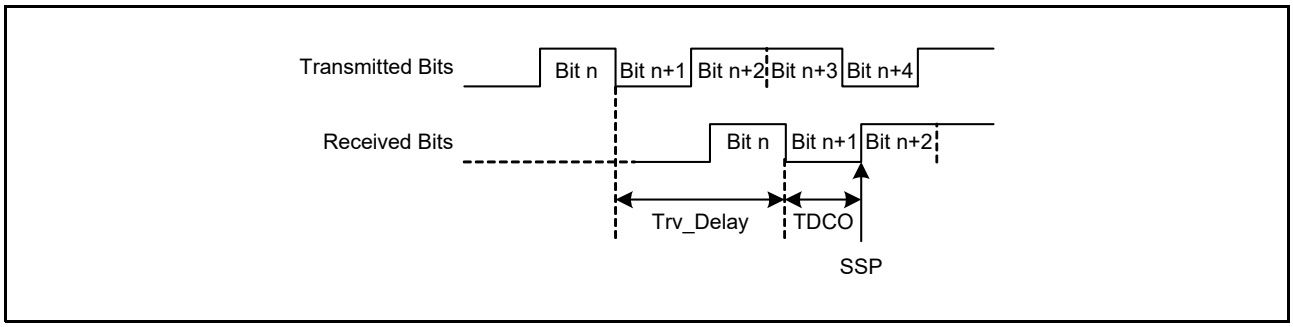

Figure 45.20 Positioning of the Secondary Sample Point (SSP)

The maximum delay time (Trv_Delay + TDCO[7:0]) which can be compensated by the CANFDG module is (6 data bit times – 2 DLL clocks). The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom.
If different values are used for the NBCR.BRP[9:0] bits and DBCR.BRP[7:0] bits, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in Figure 45.21.
The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means NBCR.BRP[9:0] = DBCR.BRP[7:0].
The bit rate can be changed by selecting different settings for the time segments. The nominal bit rate can be set from 8 to 385 Tqs and the data bit rate from 5 to 49 Tqs.

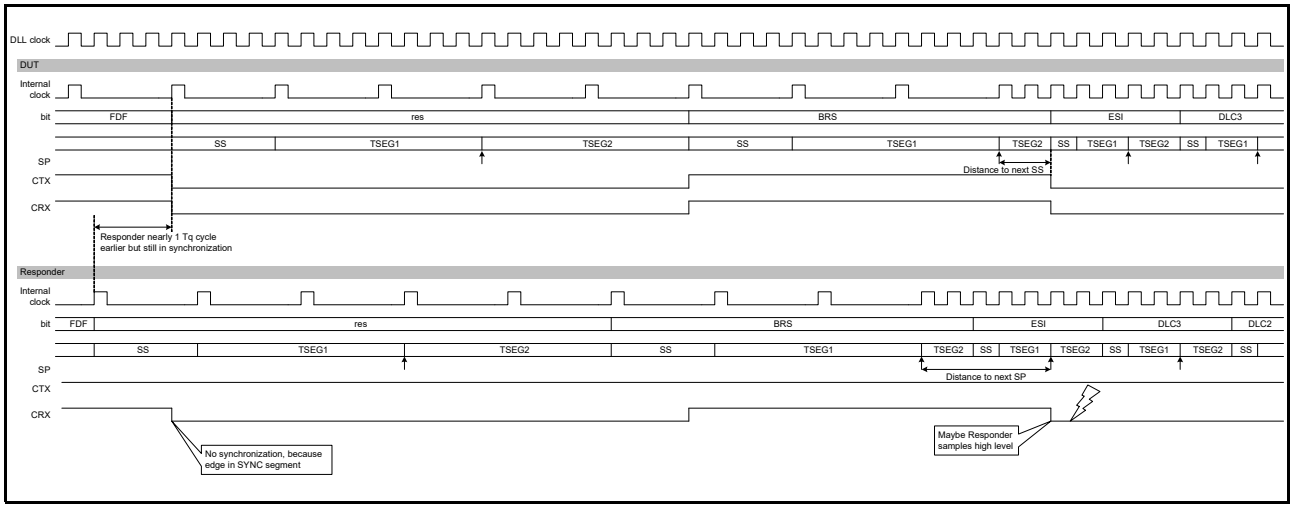

Figure 45.21 Loss of Synchronization Between Two CAN Nodes

The transceiver delay compensation measurement result is updated at the falling edge from FDF bit to res bit when configured accordingly (FDCFG.TDCE = 1, FDCFG.SSPC = 0).
Figure 45.22 shows the read flow to get the measured transceiver delay compensation result.

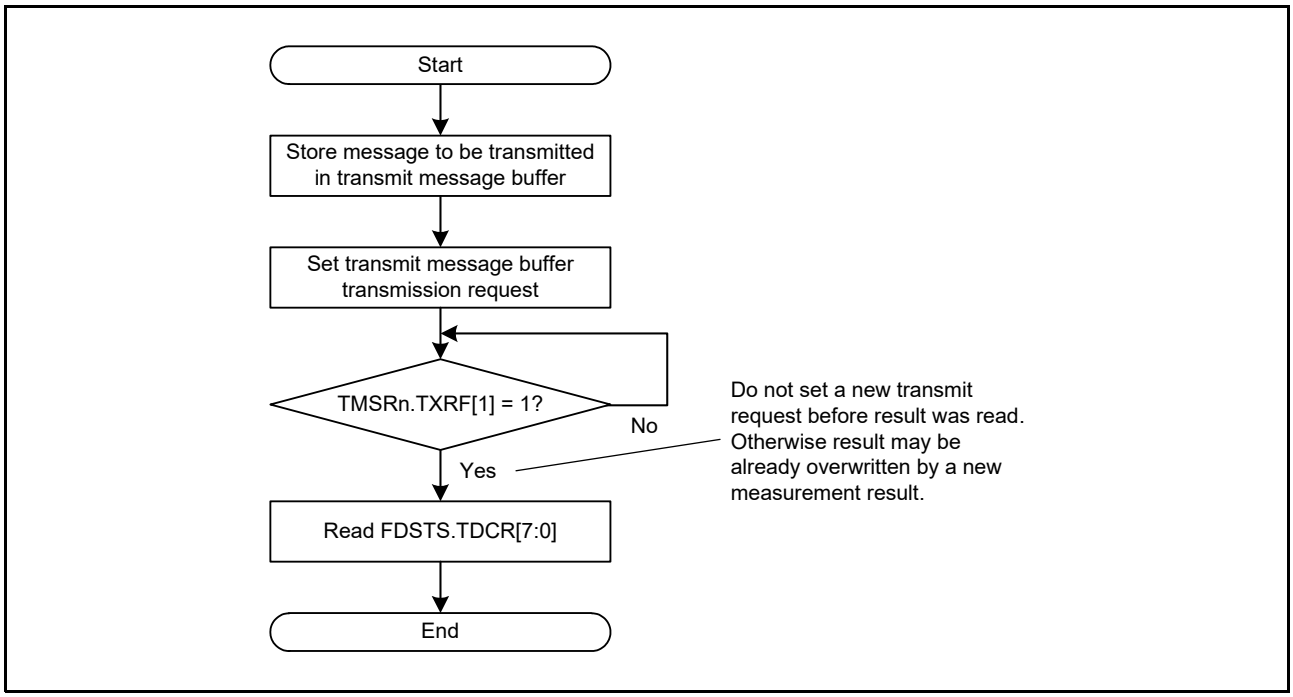

Figure 45.22 Transceiver Delay Compensation Result Read Flow

45.4.2 CANFDG Module Configuration after a Reset

After resetting the MCU or applying a software reset using the GRCR.SRST bit, the CANFDG module automatically enters GL_SLEEP mode.
To configure the CANFDG module, set the GCR.SLPRQ bit to 0 to exit GL_SLEEP mode.
After resetting the MCU, the CANFDG module starts RAM initialization when the module-stop state is released and clocks are supplied. At this time, the GSR.RAMST flag is automatically set to 1, indicating that the CANFDG module is initializing the RAM.
After RAM initialization is complete, this flag is automatically set to 0.
RAM initialization is necessary to prevent false detection of ECC errors due to undefined data in RAM after MCU reset. Do not access (read or write) any other CANFDG registers until the RAM initialization is complete and the RAMST flag is set to 0.
Before entering communication mode, the Acceptance Filter List and message FIFO buffers must be configured. In addition, the CAN channel settings such as CAN bit timing must be configured. To make this configuration, the CAN channel must be released from CH_SLEEP mode and configured for communication in CH_RESET mode (configuration mode).
Figure 45.23 shows the configuration procedure. For details about each step, refer to section 45.5, Filtering Using Acceptance Filter List (AFL), section 45.6, FIFO Buffers and Message Buffer Configuration, section 45.11, Interrupts and DTC/DMA Requests, and section 45.4.1.3, Bit Rate.
The CANFDG module does not perform the RAM initialization sequence after executing a software reset by setting the GRCR.SRST bit to 1.

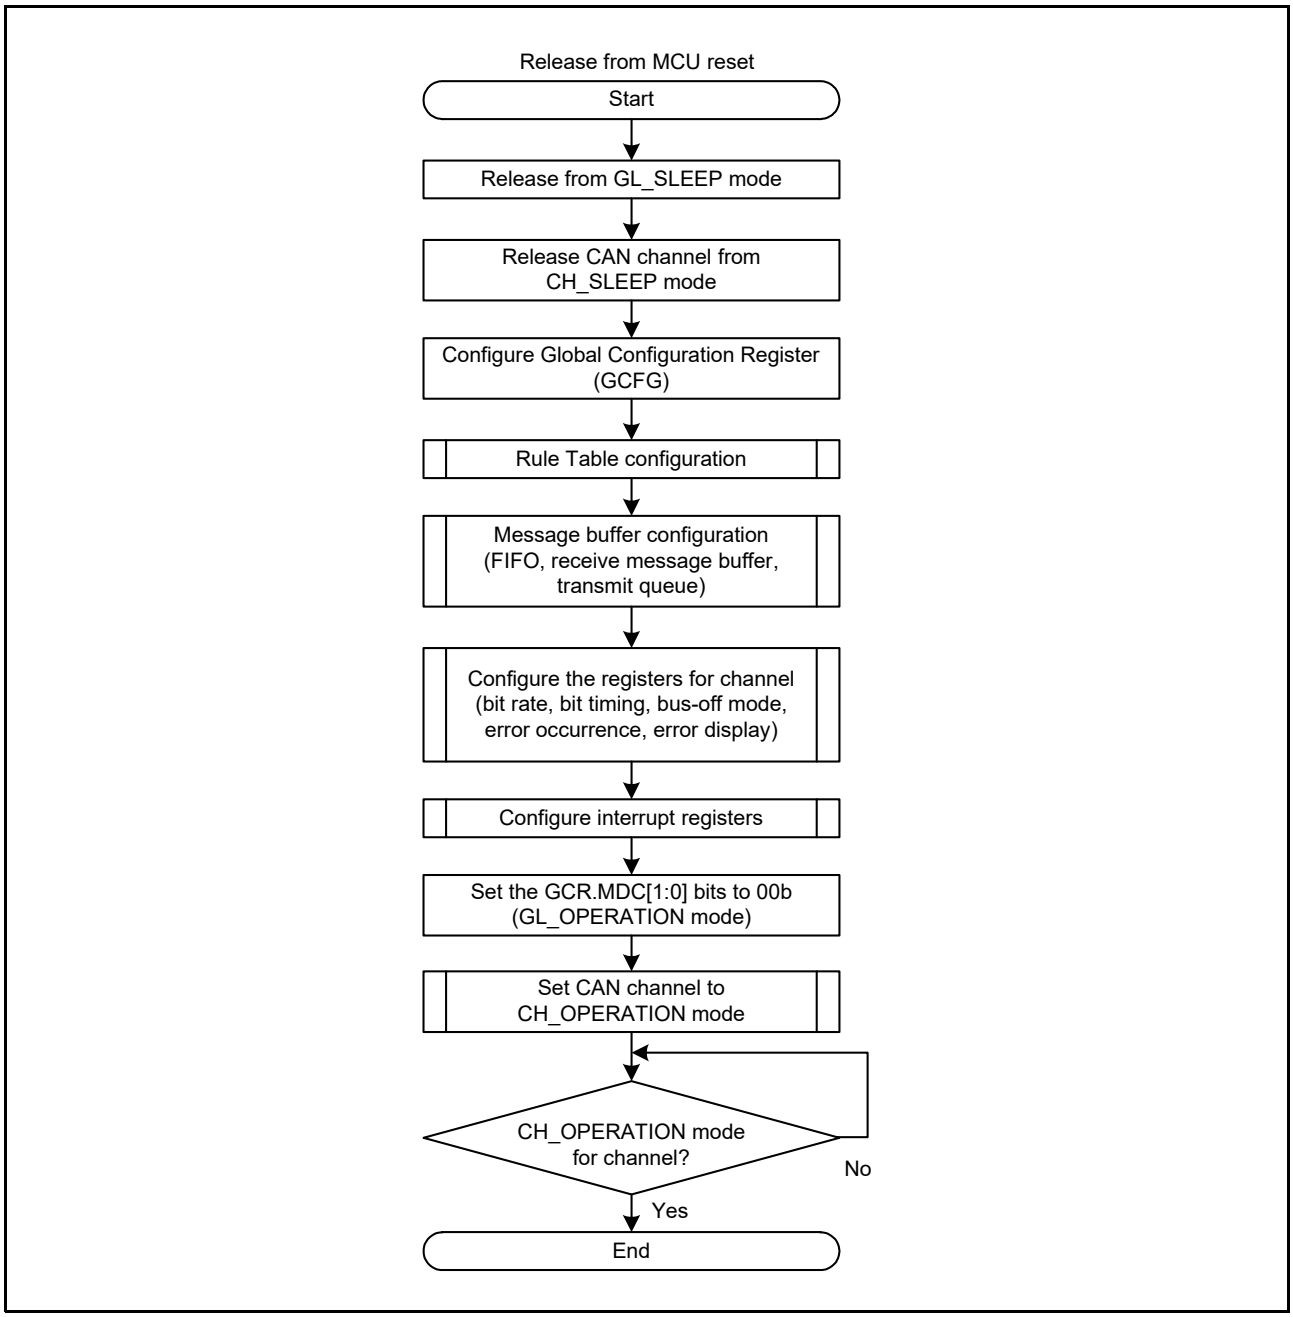

Figure 45.23 Configuration Procedure After An MCU Reset

45.5 Filtering Using Acceptance Filter List (AFL)

The CANFDG module allows you to use the Acceptance Filter List (AFL) to filter message acceptance for channels. Each entry of the AFL defines a filter rule for received messages.
The followings are performed based on the AFL entries:

- Acceptance filtering based on the RTR value, IDE value, and ID value of received message
- DLC filtering based on DLC value of received message
- Payload overflow based on the GCFG.OMRC bit
- Storage of accepted messages in the specified message buffer/FIFO buffer
- Attaching a 16-bit pointer to the stored messages, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages.

The CANFDG module allows up to 128 AFL entries. Up to 64 AFL entries can be used per channel.

45.5.1 Acceptance Filtering Process

Acceptance filtering matches each AFL entry in a channel with the received message. Matching starts with the lowest AFL entry number in the channel.
The AFL search stops when the received message ID matches the specified ID/mask combination, or when the received message ID has been matched against all defined AFL entries. If no match occurs, then the received message is discarded. No notification is given to the application in this case.

45.5.2 DLC Filtering Process

DLC filtering is performed for each accepted message if DLC check is enabled (GCFG.DCE bit = 1). If the DLC value of the received message is equal to or higher than the DLC value specified for the AFL entry whose ID matches in the Acceptance Filtering process (the matching AFL entry), the DLC check is passed.
If DLC replacement is enabled (GCFG.DRE bit = 1), DLC value configured in the matching AFL entry is greater than 0000b and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination receive message buffer (RMBn) or FIFO buffer. If DLC value of the received message is greater than the DLC value specified in the matching AFL entry, the excess data bytes are not stored in the RMBn/FIFO buffer. These excess data bytes are stored as 00h in the RMBn/FIFO buffer.
If DLC replacement is enabled and the DLC value specified in the matching AFL entry is 0000b (DLC filter function is disabled), the DLC value of the received message is stored in the RMBn/FIFO buffer.
If DLC replacement is disabled (GCFG.DRE bit = 0) and DLC check passes, the DLC value of the received message is stored in the RMBn/FIFO buffer. If the DLC value of the received message is greater than the DLC value specified in the matching AFL entry, the excess data bytes are also stored in the RMBn/FIFO buffer.
If DLC value of the received message is less than the DLC value specified in the matching AFL entry, DLC check fails. In this case, the received message is discarded and is not stored anywhere.
Additionally, when the DLC check fails, the GESR.DEDF flag is set to 1. If interrupts are enabled, an error interrupt is also generated. If the DLC check fails, the DLC replacement setting has no effect.

45.5.3 Message Storage

If a received message has passed both acceptance filtering and DLC filtering, the message is stored in receive message buffers 0 to 31, receive FIFO 0 to 7, or common FIFO 0 to 5 configured in receive FIFO mode or gateway FIFO mode. This message storage target information is also defined in the AFL entry. Do not set a target at the AFL entry which is not configured.
Up to eight message storage destinations can be specified. Do not specify more than eight destinations.

45.5.4 Payload Overflow Process

There is a protection mechanism in case the received message contains data with a payload size that is longer than the size that can be stored in the storage (RMCR.PLS[2:0], RFCRn.PLS[2:0] (n = 0 to 7), or CFCRn.PLS[2:0] (n = 0 to 5)).
If GCFG.OMRC = 0 (message is discarded), the message with data bytes that exceed the specified payload size are discarded and not stored. In this case, even if the FIFO is full, the corresponding FMLSR.RFMLn (n = 0 to 7) or CFMLn (n = 0 to 5) flag is not set to 1.
If GCFG.OMRC = 1 (cut to specified size), only data bytes that exceed the specified payload size are discarded. In this case, if the FIFO is full, the corresponding FMLSR.RFMLn (n = 0 to 7) or CFMLn (n = 0 to 5) flag is set to 1 (message lost has occurred).
Depending on the GCFG.DRE bit setting, either the DLC value of the received message or the DLC value specified in the AFL entry is stored.
Regardless of the GCFG.OMRC bit setting, the GESR.PODF flag is set to 1 if a payload overflow condition is detected. The DLC filtering is performed before the payload overflow processing. Therefore, for each received frame, only one of the GESR.DEDF and GESR.PODF flags is set to 1.

45.5.5 Allocation of AFL Entries to Each CAN Channel

The number of AFL entries (number of rules) per channel can be configured using the AFCFG register (refer to Figure 45.24).

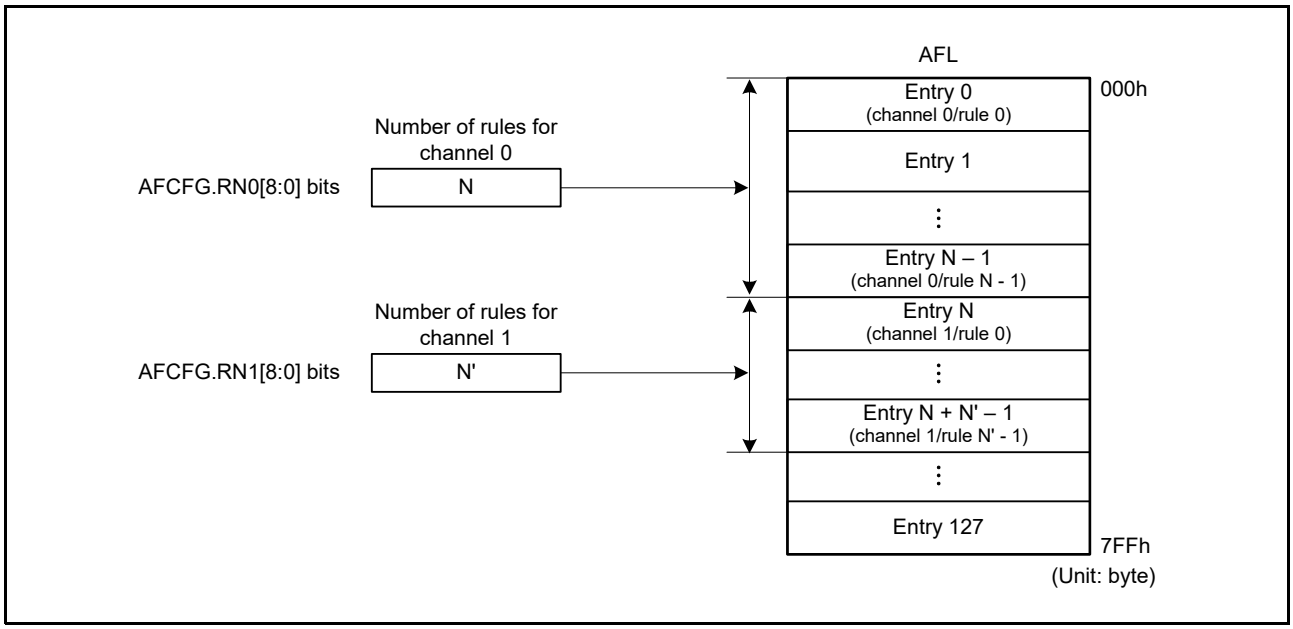

Figure 45.24 Configuration of AFL

The minimum number of entries for one channel is 0 (no entries defined for the channel) and the maximum number of entries for one channel is 64. The total number of entries is up to 128.
All entries are unique for a channel and overlapping or sharing of entries is not supported. Correct configuration of the AFL is the responsibility of the application.
The CANFDG module does not flag errors related to the configuration of the AFL.

45.5.6 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.
Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier field (11 bits for Standard Frame format, 29 bits for Extended Frame format):
  Acceptance filter unit matches this field with the identifier field of the received message (29 bits of identifier field can be masked individually, refer to the description of Mask for Identifier field below).
- IDE bit:
  Acceptance filter unit matches this bit with the IDE bit of the received message and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, refer to the description of Mask for IDE bit below).
- RTR bit:
  Acceptance filter unit only accepts data frames (RTR = 0) or remote frames (RTR = 1) according to the setting of this bit (masking of RTR bit is possible, refer to the description of Mask for RTR bit below).
- Loop-Back Configuration bit:
  This bit can enable or disable the AFL entry depending on the loop-back configuration or mirror mode condition.
- Mask for Identifier field (29 bits):
  Each bit in the identifier mask field can mask the corresponding identifier bit in the AFL entry (refer to Figure 45.25).
- Mask for IDE bit:
  If this Mask bit masks the IDE bit of an AFL entry, the AFL entry can accept messages in both Standard Identifier format and Extended Identifier format. For messages in Standard Identifier format, the Standard Identifier part of the AFL entry is compared, and for messages in Extended Identifier format, the Extended Identifier part of the AFL entry is compared.
- Mask for RTR bit:
  If this Mask bit masks the RTR bit of an AFL entry, the AFL entry can accept frame formats in both data frame and remote frame.
- Pointer (16 bits):
  This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added when storing a message in the message buffer area and can be used as a support function in the application.
  For example, the pointer information can be used to support the assignment of PDU IDs to the received message in AUTOSAR systems.
- Information label (2 bits):
  This 2-bit label is attached to a message accepted by the related AFL entry. This label is added when storing a message in the message buffer area and can be used as support function in the application.
- DLC field:
  If the DLC value of the received message is equal to or higher than the value set in this field, the DLC check is passed.
  If the DLC value of an AFL entry is set to 0000b, the DLC filtering for this entry is effectively disabled (all accepted messages pass DLC filtering).

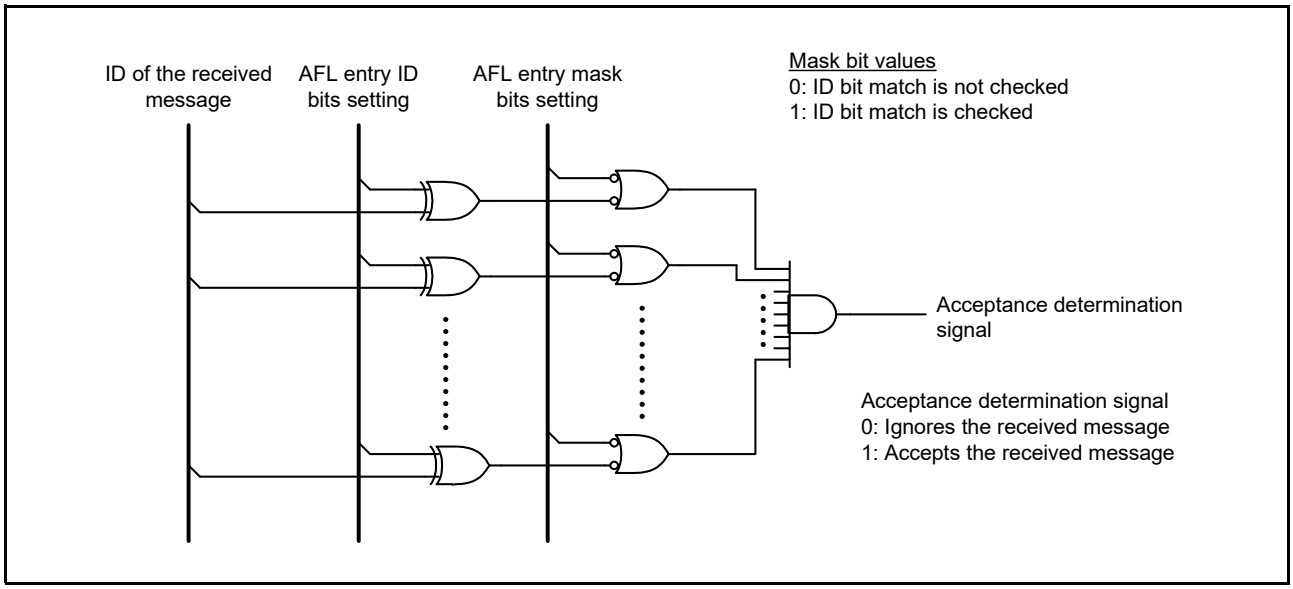

Figure 45.25 Acceptance Filter Function

Each AFL entry contains the following information for processing the received messages:

- Message buffer number of the receive message buffer used as the storage destination for received messages
- The Destination Message Buffer Setting Enable bit to specify the receive message buffer as the storage destination for received messages
- The FIFO Destination Enable bit to specify the FIFO as the storage destination for received messages.

Note: Received messages can be stored in a common FIFO for another channel. If the common FIFO is configured in gateway FIFO mode, the messages stored in the common FIFO is transmitted from that channel.

There is no protection function for storing messages. Therefore, the FIFO Destination Enable bit must be set carefully.

45.5.7 Entering Entries in the AFL

One complete entry can be entered into AFL via the following registers:

- AFLn.IDR register: First part of the AFL entry
- AFLn.MASK register: Second part of the AFL entry
- AFLn.PTR0 register: Third part of the AFL entry
- AFLn.PTR1 register: Fourth part of the AFL entry

A set of 16 of these registers configures one page of AFL entries. The CANFDG module has 128 entries, and all of these entries can be accessed by specifying the page with the AFCR.PAGE[3:0] bits. Set the AFL in CH_RESET or CH_HALT mode. Table 45.22 shows pages and their corresponding AFL entries.

Table 45.22 Pages Linked to the AFL Entries

Page	Linked AFL Entries
Page 0	Entry 0 to 15
Page 1	Entry 16 to 31
Page 2	Entry 32 to 47
Page 3	Entry 48 to 63
Page 4	Entry 64 to 79
Page 5	Entry 80 to 95
Page 6	Entry 96 to 111
Page 7	Entry 112 to 127

AFL access control is performed using the AFCR register (Figure 45.26). This register has the following bits:

- The PAGE[3:0] bits for selecting the AFL page number
- The AFLWE bit that enables or disables the writing of data to prevent unnecessary write access to the AFL.

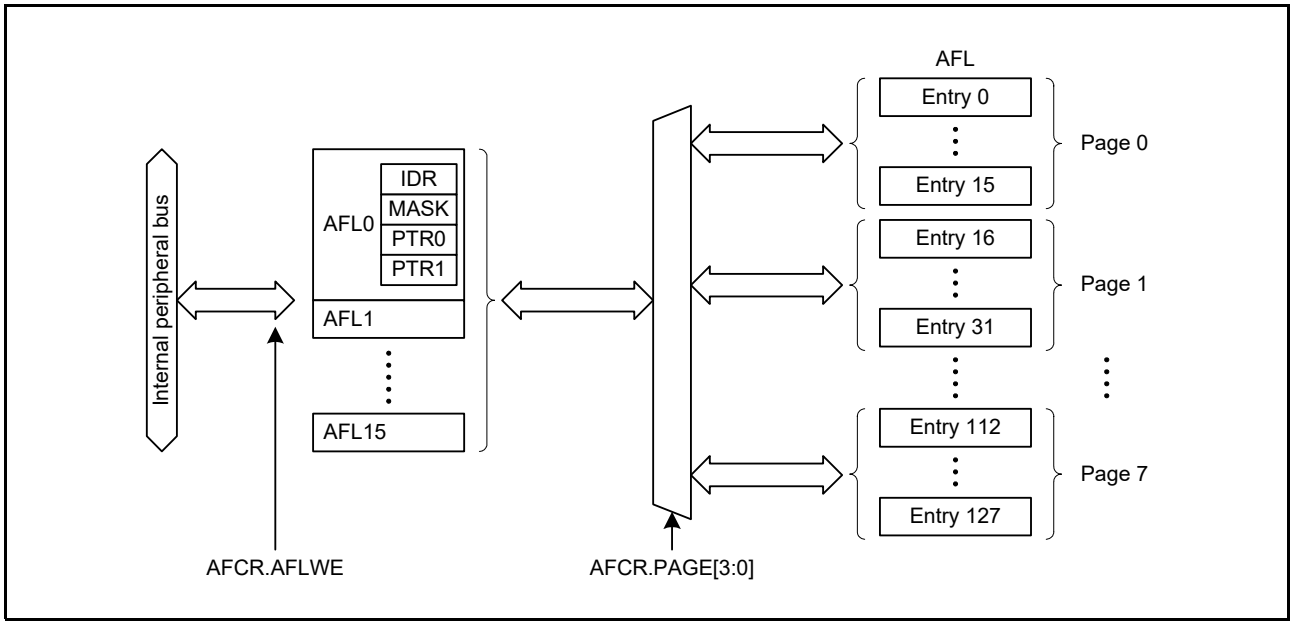

Figure 45.26 AFL Page Access

Follow the flow shown in Figure 45.27 to configure the AFL.
After entering all the entries, writing to the AFL must be disabled to prevent unnecessary write access to the AFL.
If the AFCR.AFLWE bit is set to 0, write protection is enabled during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION).
Even if the AFCR.AFLWE bit is set to 0, reading from AFL is possible during all Global modes (the consistency of AFL contents can be checked during execution).

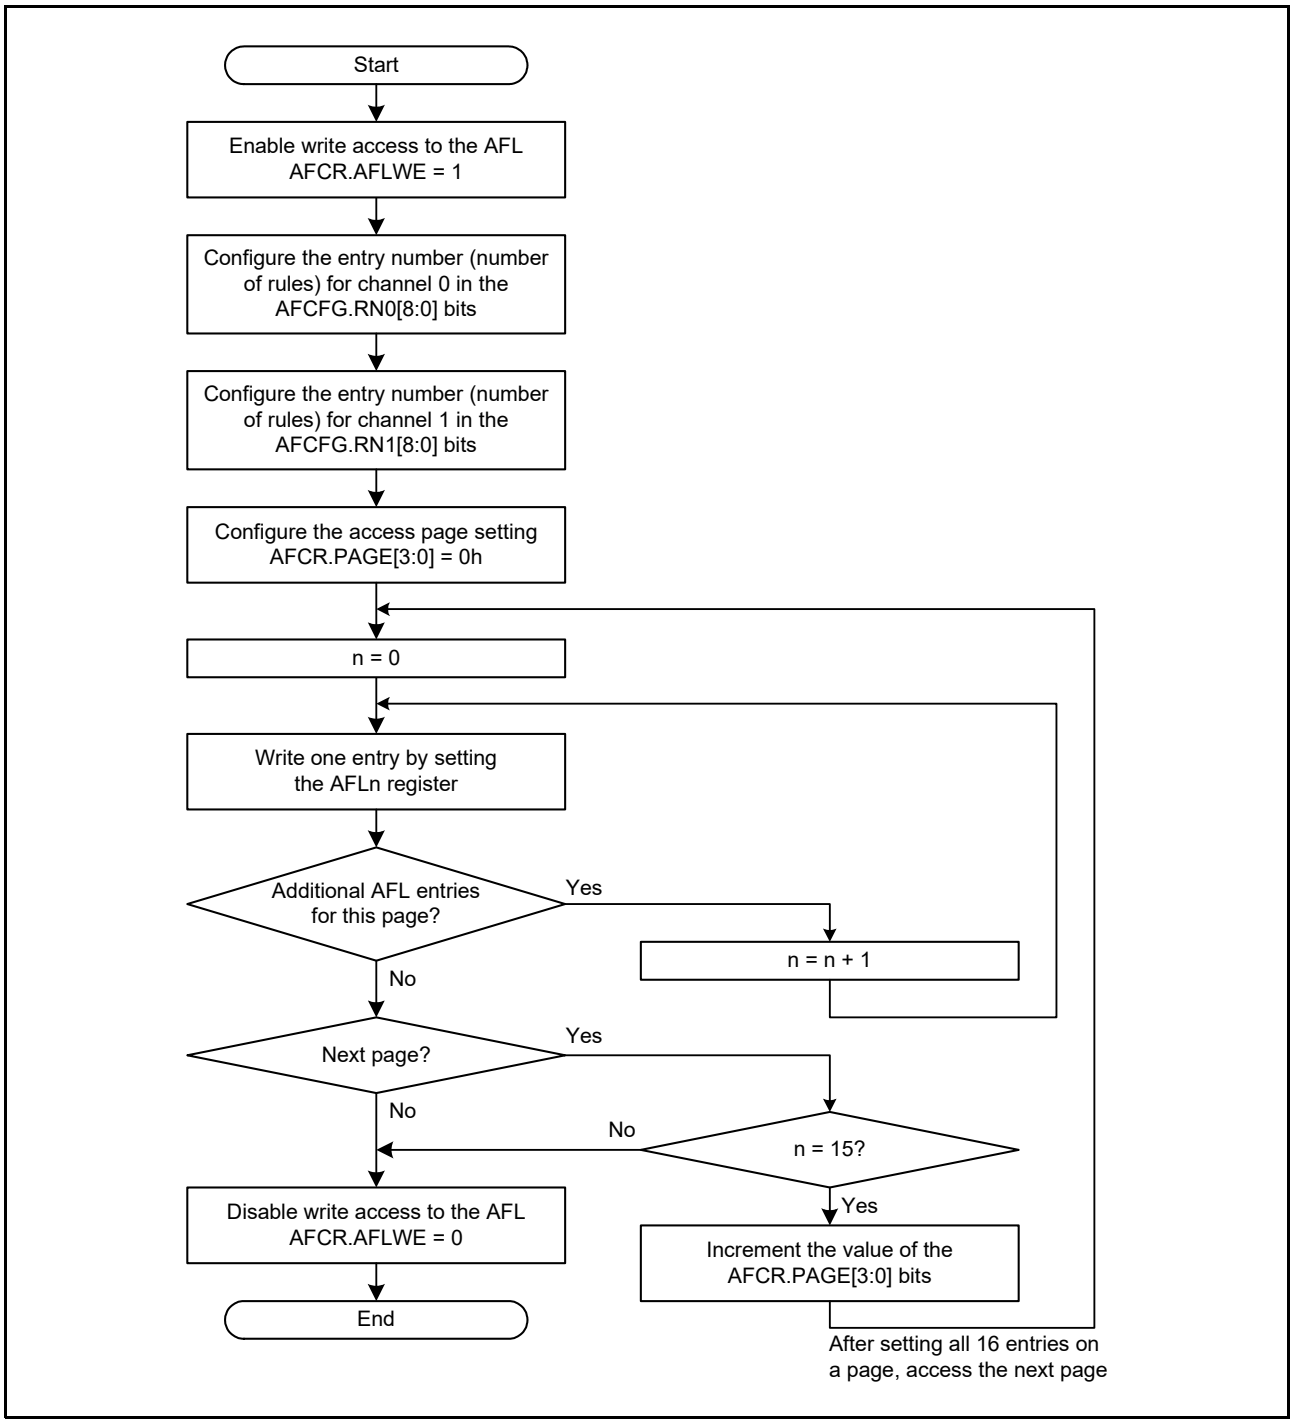

Figure 45.27 AFL Configuration Flow

45.5.8 Loop-Back Configuration

AFL entries with the AFLn.IDR.LPC bit set to 1 are used only when it receives a message transmitted by the CAN channel itself in loop-back mode (self-test mode 0 or self-test mode 1) or mirror mode. If a message transmitted by another node on the CAN bus is received while in loop-back mode, the AFL entry will not be used.

AFL entries with the LPC bit set to 0 are used only when the following messages are received.

- Messages transmitted by other nodes
- Messages transmitted by the CAN channel itself in loop-back mode

The mirror mode can be enabled with the GCFG.MME bit. If the message is successfully transmitted when the GCFG.MME bit is 1, the message is stored in the receive message buffer or FIFO buffer if there is a matching entry in the AFL for that channel. The AFLn.IDR.LPC bit in the matching AFL entry must be set to 1 to store this message. If mirror mode and loop-back mode are set at the same time, the loop-back mode behavior is applied. Table 45.23 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 45.23 Behavior of Acceptance Filter Based on the Loop-Back Setting in AFL Entry

Mirror Mode (MME Bit)	Loop-Back Mode (Self-Test Mode 0 or Self-Test Mode 1)	Channel Mode	LPC Bit	AFL Entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

45.5.9 IDE Masking

The IDE bit set in the AFL entry with the AFLn.MASK.IDEM bit set to 0 is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is selected based on the received IDE bit.
The following lines show the examples.

- The ID and mask fields of an AFL entry x is configured as follows:
  - AFLx.IDR = C0553A20h → IDE = 1, RTR = 1, LPC = 0, ID[10:0] = 220h/ID[28:0] = 00553A20h
  - AFLx.MASK = 0000FFFFh → IDEM = 0, RTRM = 0, IDM[10:0] = 7FFh/IDM[28:0] = 0000FFFFh
- The comparison result for the four different received IDs with AFL entry x is described as follows:
  - If a frame with IDE = 0 and ID = 220h is received, this is considered as a match
  - If a frame with IDE = 0 and ID = 320h is received, this is not a match
  - If a frame with IDE = 1 and ID = 1FFF3A20h is received, this is considered as a match
  - If a frame with IDE = 1 and ID = 08803220h is received, this is not a match.

45.5.10 Updating AFL Entry during Communication

The AFL entry can be updated without disabling CAN communications.
Set the AFL entry number to update to the ignore entry select bits and set the ignore entry enable bit to 1.
The entry number specified here is ignored by AFL matching while the entry is being updated.
Figure 45.28 shows the update flow for an AFL entry.

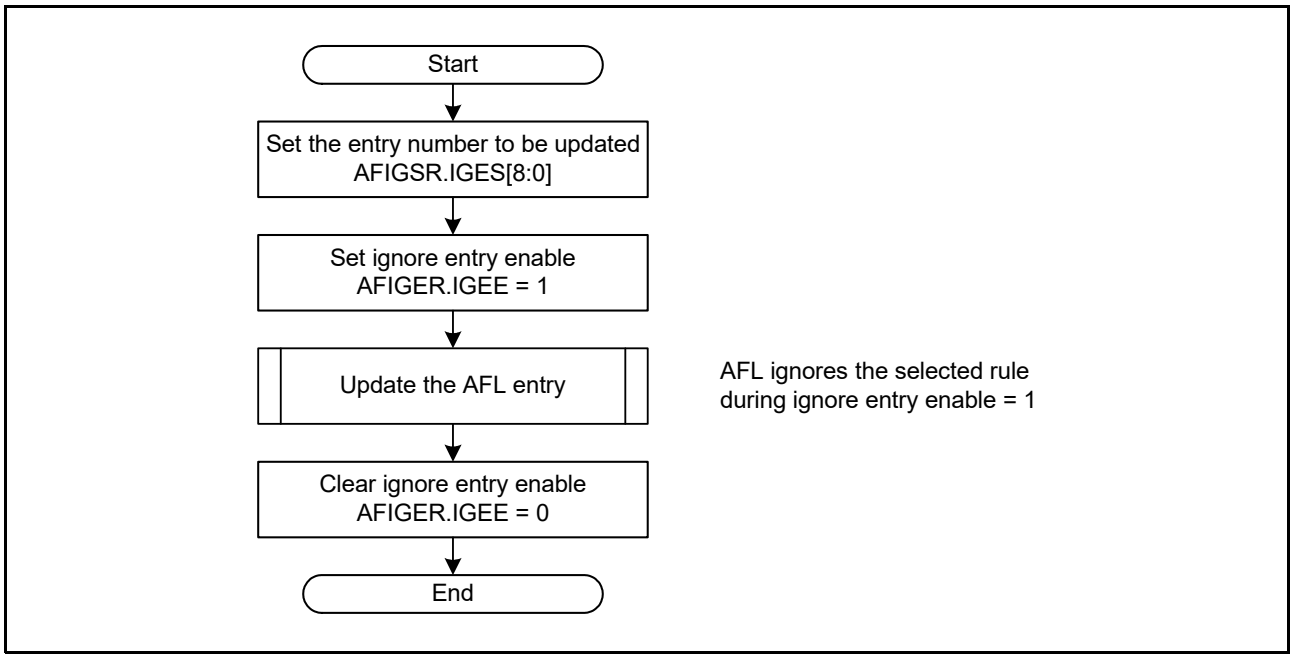

Figure 45.28 Update Flow for An AFL Entry

The method to update an AFL entry is as follows:

1. Set the channel number and entry number*1 to be updated to the AFIGSR.IGCS[2:0] and IGES[8:0] bits.
2. Set the value 0000C401h (key code and ignore entry enabled) to the AFIGER register.
3. Set the page number which includes the entry to be updated to the AFCR.PAGE[3:0] bits. Set the AFCR.AFLWE bit to 1.
4. Set the new rule to the AFLn.IDR, AFLn.MASK, AFLn.PTR0, AFLn.PTR1 registers.
5. The AFCR.AFLWE bit is set to 0.
6. Set the value 0000C400h (key code and ignore entry disabled) to the AFIGER register.

Note 1. This entry number is not used for acceptance filtering between (2) and (5).

(1) Example 1: Deleting an Entry

The following describes how to delete entry 3 in channel 1 when the total number of entries per channel is 6.

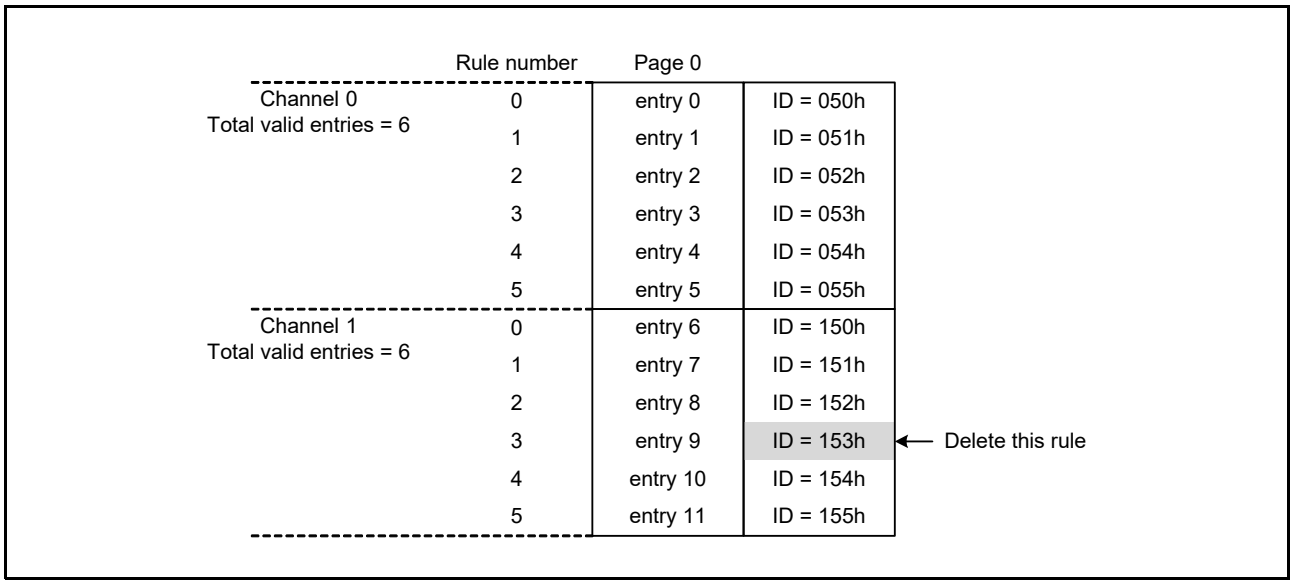

Figure 45.29 Example of Deleting an Entry (Before Deleting Entry 9)

[How to delete an entry]

(1) Set 00010003h to the AFIGSR register.
(2) Set 0000C401h to the AFIGER register.
(3) Set 00000100h to the AFCR register.
(4) Set the same rule as the previous entry by accessing the AFL9.IDR, AFL9.MASK, AFL9.PTR0, AFL9.PTR1 registers.
(5) Set 00000000h to the AFCR register.
(6) Set 0000C400h to the AFIGER register.

Entry 9 is now deleted.

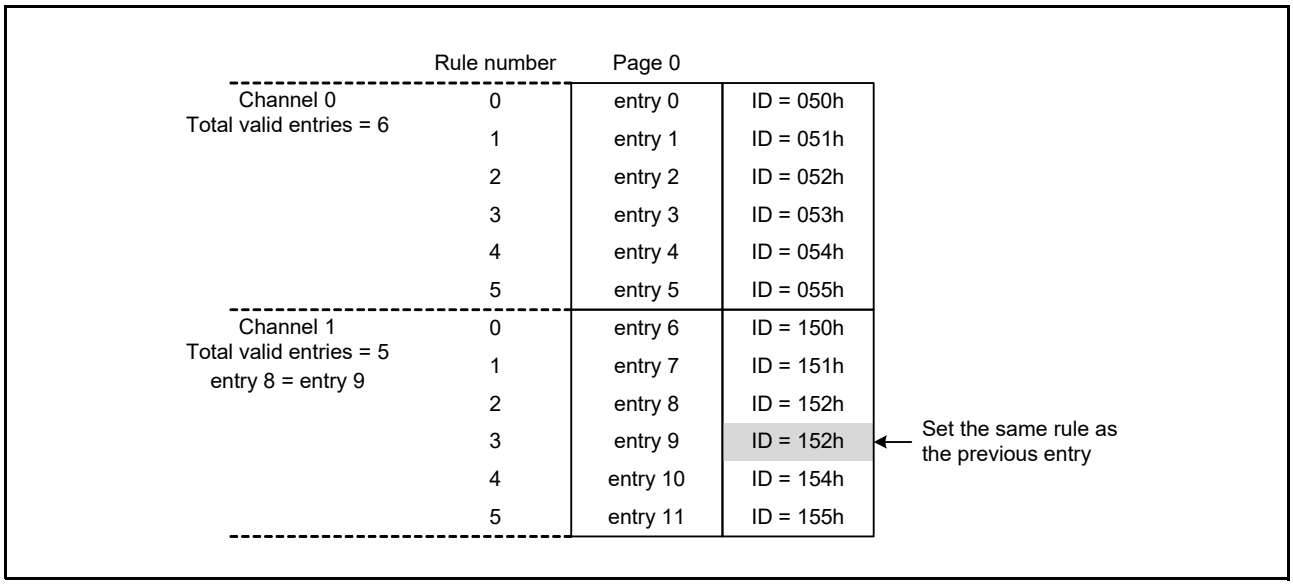

Figure 45.30 Example of Deleting an Entry (After Deleting Entry 9)

(2) Example 2: Adding an Entry (Update Unused Entry)

The following describes how to add a new rule to entry 3 in channel 1 when the total number of entries per channel is 6.

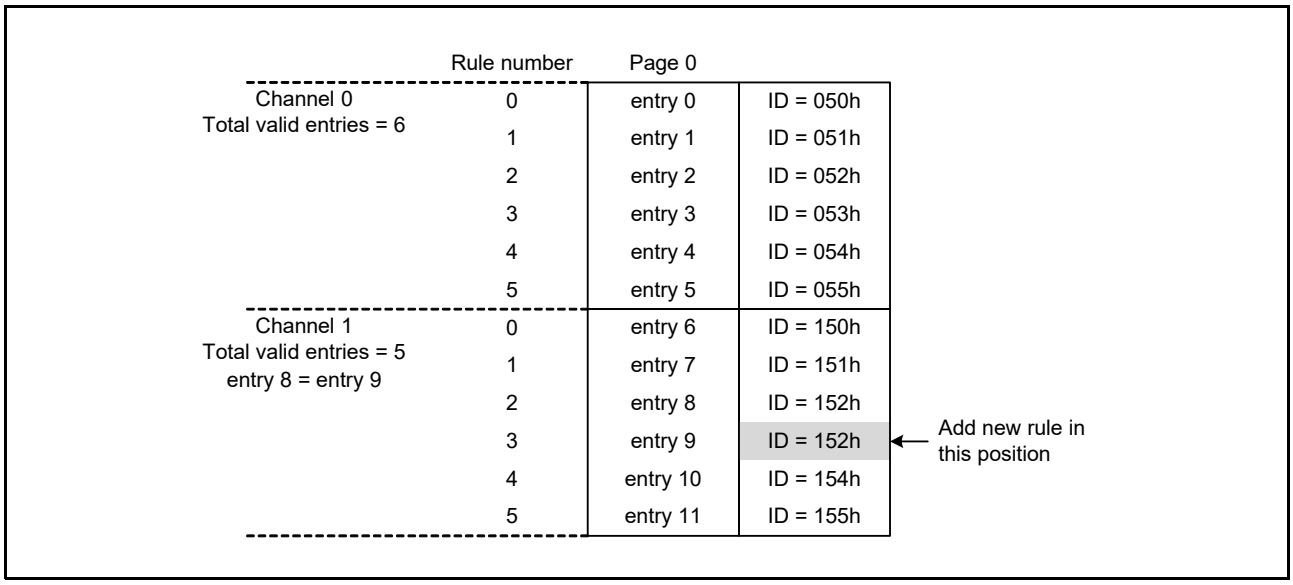

Figure 45.31 Example of Adding an Entry (Before Updating Entry 9)

[How to add an entry]

(1) Set 00010003h to the AFIGSR register.
(2) Set 0000C401h to the AFIGER register.
(3) Set 00000100h to the AFCR register.
(4) Set the new rule by accessing the AFL9.IDR, AFL9.MASK, AFL9.PTR0, AFL9.PTR1 registers.
(5) Set 00000000h to the AFCR register.
(6) Set 0000C400h to the AFIGER register.

The new entry is now added.

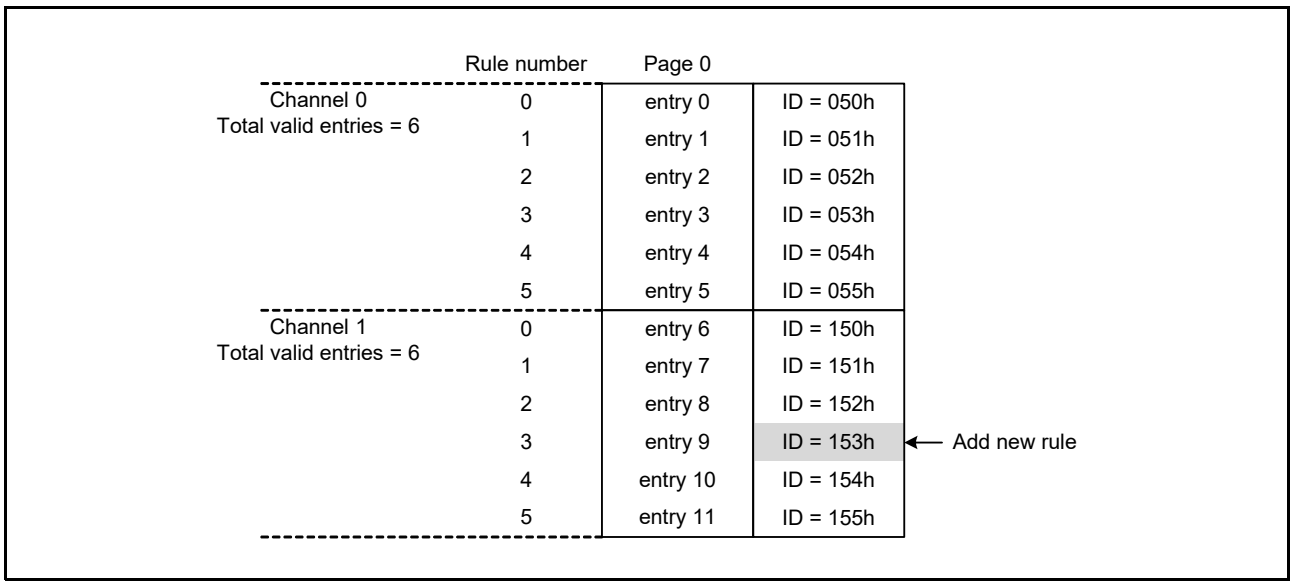

Figure 45.32 Example of Adding an Entry (After Updating Entry 9)

The acceptance filter can use entries in the range of value set in the AFCFG register and entries can be added/deleted within that range. Therefore, the AFCFG register should be set to the maximum number of entries to use.

45.6 FIFO Buffers and Message Buffer Configuration

This section describes the process for configuring the number of receive message buffers, the FIFO buffers, and the transmit message buffers in the CANFDG module. The message buffers are mapped as shown in Figure 45.33.
The receive message buffers can be accessed with the RMBn register (n = 0 to 31).
The receive FIFOs can be accessed with the RFBn register (n = 0 to 7).
The common FIFO can be accessed with the CFBn (n = 0 to 5) register.
If the common FIFO is configured in transmit FIFO mode, data can only be written to the FIFO buffer by the CFBn register.
If the common FIFO is configured in receive FIFO mode or gateway FIFO mode, data can only be read by the CFBn register.
The transmit message buffers can be accessed with the TMBn register (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103).
If unused message buffer is read, it is read as undefined.

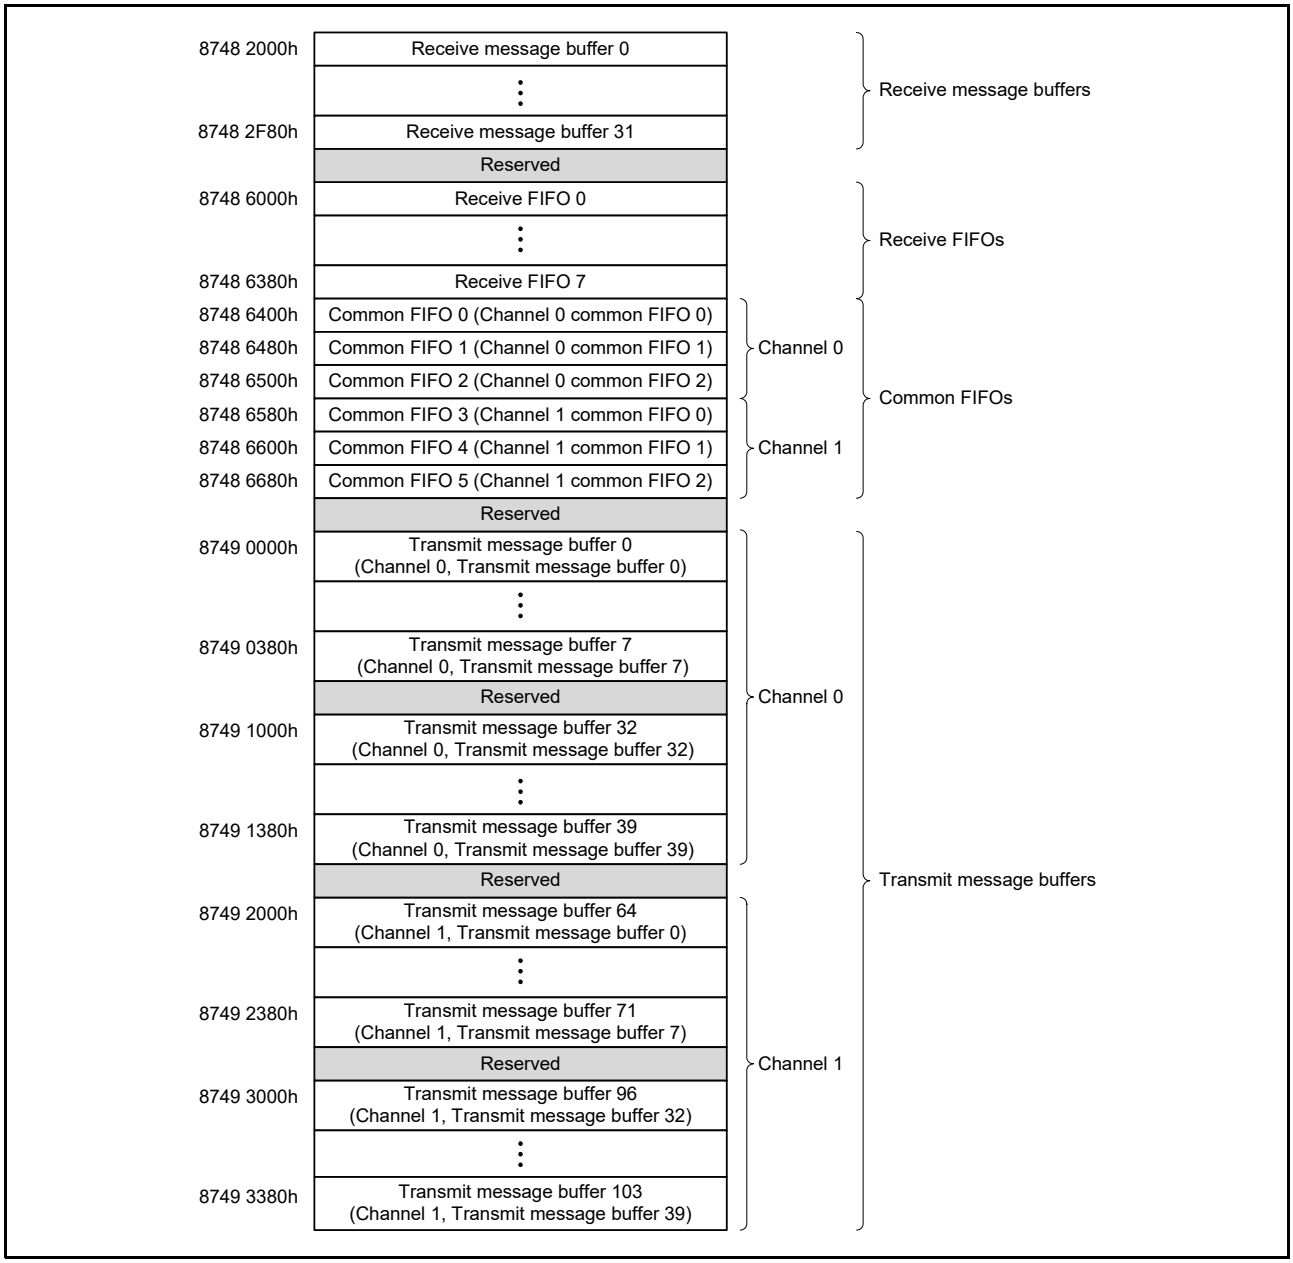

Figure 45.33 Message Buffer Configuration

45.6.1 Receive Message Buffers

In CANFDG module, the received frames can be stored in receive message buffers based on the configuration of the AFL entries.
Additionally, the number of receive message buffers required by the system can be selected from 0 to 32.

45.6.1.1 Receive Message Buffer Configuration

The number of receive message buffers in CANFDG module can be configured by writing to the RMCR.NMB[7:0] bits. Set the number of message buffers in the range 0 (no receive message buffers) to 32. Do not set a value larger than this.
The AFL entries for routing the received messages to receive message buffers must be configured to match the requirements of the system.
The AFL entries must also be configured properly, and an AFL entry for receive message buffers should not exceed the number of message buffers configured in the RMCR.NMB[7:0] bits.

Note: There is no internal check procedure provided in CANFDG module against wrong configuration of the AFL.

The payload size of the receive message buffer can be configured with the RMCR.PLS[2:0] bits. The default size is 8 bytes and the maximum size is 64 bytes.
If the payload size of the received frame exceeds the specified payload size, the message is discarded or the payload is cut according to the setting of the GCFG.OMRC bit.

45.6.2 FIFO Buffers

The CANFDG module provides FIFO buffers for storing received frames and frames to be transmitted, respectively. There are eight receive-only FIFO buffers, but common FIFOs can be configured to store messages for transmission, reception, or gateway use. There are three common FIFOs per channel.
These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- FIFO depth
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the transmit FIFO or gateway FIFO

If the payload size of the received frame exceeds the specified payload size, the message is discarded or the payload is cut according to the setting of the GCFG.OMRC bit.

45.6.2.1 FIFO Buffers Configuration

In CANFDG module, the FIFO buffers can be configured to match the system requirements.
The total number of FIFO buffers is 14 (8 receive FIFOs + 6 common FIFOs).

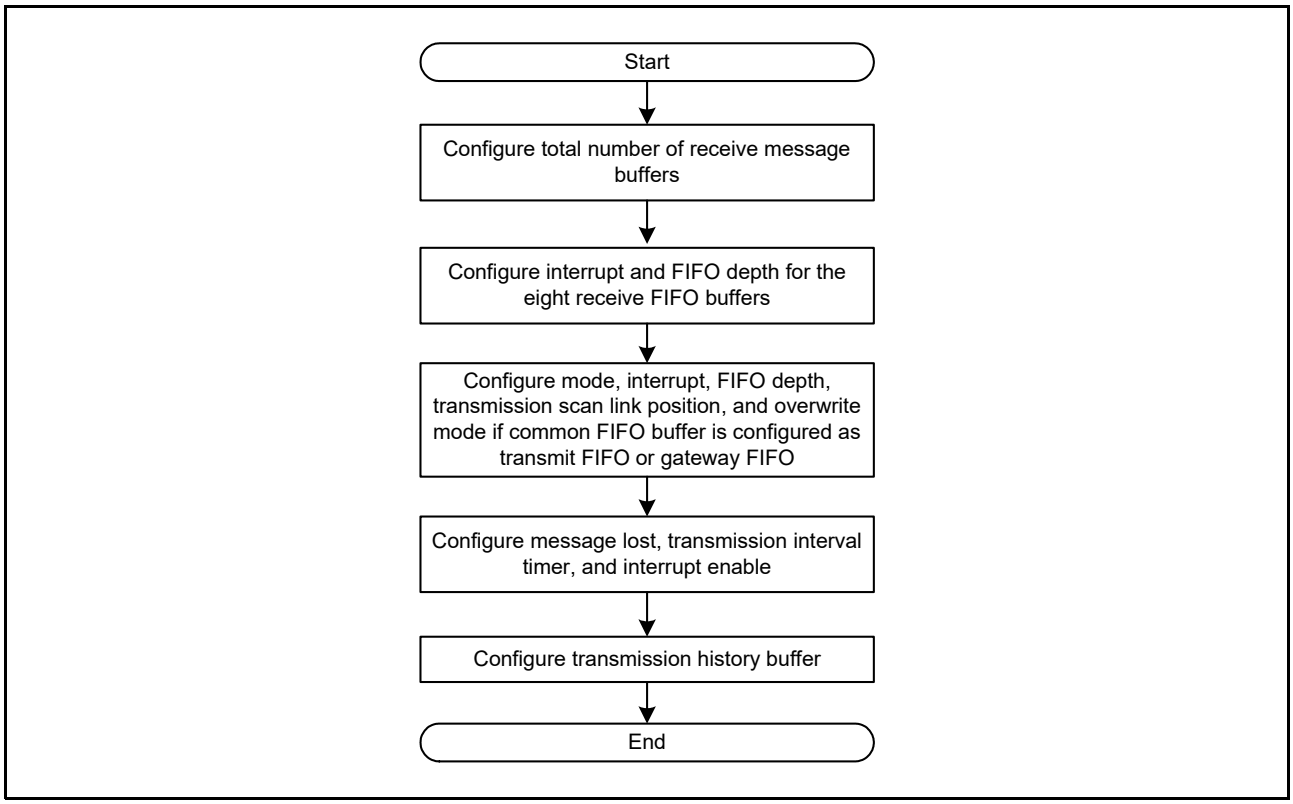

Figure 45.34 FIFO Buffer Configuration Flow in CANFDG module

As shown in Figure 45.34, the various FIFO buffers can be configured by writing to the Receive FIFO n Configuration Register and the Common FIFO n Configuration Register.

For the receive FIFOs, the following parameters can be configured:

- Interrupts
- FIFO depth
- Payload size

For the common FIFO, the following parameters can be configured:

- Mode
- Interrupts
- FIFO depth
- Payload size
- Transmission scan link position

(1) FIFO mode configuration of common FIFO

The mode of the common FIFO can be configured by writing to the CFCRn.MODE[1:0] bits. The modes that can be configured in the common FIFO are as follows:

- 00b: Receive FIFO mode (default mode after an MCU reset)
- 01b: Transmit FIFO mode
- 10b: Gateway FIFO mode
- 11b: Setting prohibited

Messages can only be read from the receive FIFOs and the common FIFO configured in receive FIFO mode. Messages are stored by the CANFDG module in these FIFO buffers based on the AFL entries.
Messages can be read and written into the common FIFO configured in transmit FIFO mode. These messages are transmitted on the corresponding CAN channel.
In the common FIFO configured as gateway FIFO mode, messages can only be read.
The pointers can be incremented only when a new message is stored in the FIFO buffer and decremented only when a message is transmitted on the corresponding CAN channel by the CANFDG module.
After an MCU reset, all the common FIFO is configured in receive FIFO mode by default. Only enable the FIFO buffers after configuring the common FIFO in the required modes.
In gateway FIFO mode, if a new message is received and stored in a FIFO buffer that is already full, the existing message is overwritten or the received message is discarded, depending on the setting of the CFECRn.CFOWM bit, as follows:

- When the CFECRn.CFOWM bit is 0:
  The received message is discarded and the CFSRn.LOST flag is set to 1.
- When the CFECRn.CFOWM bit is 1:
  The oldest message in the buffer is overwritten with the received message, and the read pointer moves to the second oldest message. The CFSRn.CFOWF flag becomes 1, indicating that the message has been overwritten.

In addition, when a CAN bus error or arbitration-lost for the transmit message occurs in the FIFO buffer with full state, the message is discarded and retransmission for the message is not performed. The read pointer automatically moves to the next message.
When the CFCRn.CFE bit is 1, do not change the CFECRn.CFOWM bit.

(2) FIFO transmit message buffer link configuration

When the common FIFO is configured as transmit FIFO or gateway FIFO, the FIFO buffer must be linked to a normal transmit message buffer to participate in the transmission scan of a CAN channel.
Two or more common FIFOs cannot be linked to the same transmit message buffer.
Do not write data into a transmit message buffer that is linked to a common FIFO. Also, the transmit message buffer linked to a common FIFO should not be a part of the transmit queue.
The link to the transmit message buffer of each common FIFO can be configured by writing to the CFCRn.LTM[4:0] bits. The options available for linking the transmit message buffer are:

- 00000b: Transmit message buffer 32
- 00001b: Transmit message buffer 33
- 00010b: Transmit message buffer 34
- 00011b: Transmit message buffer 35
- 00100b: Transmit message buffer 36
- 00101b: Transmit message buffer 37
- 00110b: Transmit message buffer 38
- 00111b: Transmit message buffer 39

(3) FIFO depth configuration

The depth of each FIFO buffer can be configured by writing to the RFCRn.FDS[2:0] bits and CFCRn.FDS[2:0] bits. The eight available options for depth configuration are:

- 000b: 0 messages (FIFO buffer cannot be used)
- 001b: 4 messages
- 010b: 8 messages
- 011b: 16 messages
- 100b: 32 messages
- 101b: 48 messages
- 110b: 64 messages
- 111b: 128 messages

The RAM allocated to the receive message buffers and FIFO buffers is limited to 64 messages (4864 bytes) when the payload size is set to 64 bytes. Do not configure the receive message buffers and FIFO buffers that exceed this maximum limit. CANFDG module does not have the function to check the validity of the configuration.

Note: If the FIFO depth of the common FIFO is 4 messages or more (CFCRn.FDS[2:0] > 000b), the link between the common FIFO and the transmit message buffer is valid regardless of whether the FIFO is disabled or enabled. If the FIFO depth is 0 messages, the link between the common FIFO and transmit message buffer is invalid regardless of whether the FIFO is disabled or enabled.

(4) FIFO payload size configuration

The payload size of each FIFO buffer can be configured by writing to the RFCRn.PLS[2:0] bits and CFCRn.PLS[2:0] bits. The eight available options for payload size configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes.

The RAM allocated to the receive message buffers and FIFO buffers is limited to 64 messages (4864 bytes) when the payload size is set to 64 bytes. Do not configure the receive message buffers and FIFO buffers that exceed this maximum limit. CANFDG module does not have the function to check the validity of the configuration.

(5) FIFO interrupt configuration

The interrupt generation conditions for the FIFO buffers can be configured by writing to the RFCRn.RFIM bit and CFCRn.CFIM bit. The two available options are:

- RFIM/CFIM = 0:
  - Receive FIFO mode: An interrupt is generated when the FIFO fill level reaches RFCRn.RFITH[2:0] or CFCRn.CFITH[2:0] value
  - Transmit FIFO mode: An interrupt is generated when the FIFO transmits the last message successfully
  - Gateway FIFO mode:
    When receiving, an interrupt is generated when the FIFO fill level reaches CFCRn.CFITH[2:0] value
    When transmitting, an interrupt is generated when the FIFO transmits the last message successfully.
- RFIM/CFIM = 1:
  - Receive FIFO mode: An interrupt is generated each time the received message is stored
  - Transmit FIFO mode: An interrupt is generated each time a message is successfully transmitted.
  - Gateway FIFO mode:
    When receiving, an interrupt is generated each time the received message is stored
    When transmitting, an interrupt is generated each time a message is successfully transmitted.

If the RFCRn.RFIM bit for the receive FIFO is 0, an interrupt is generated based on the setting of the RFCRn.RFITH[2:0] bits.
Similarly, if the CFCRn.CFIM bit for a common FIFO set to receive FIFO mode is 0, an interrupt is generated based on the setting of the CFCRn.CFITH[2:0] bits.
The eight options available to set the FIFO fill level for generating interrupts are:

- 000b: Interrupt generated when FIFO is 1/8 Full
- 001b: Interrupt generated when FIFO is 1/4 Full
- 010b: Interrupt generated when FIFO is 3/8 Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8 Full
- 101b: Interrupt generated when FIFO is 3/4 Full
- 110b: Interrupt generated when FIFO is 7/8 Full
- 111b: Interrupt generated when FIFO is Full.

In this case, an interrupt is generated when the message fill level matches the set value.
However, as shown in Table 45.24, there are some restrictions on the RFITH[2:0] and CFITH[2:0] bit settings, depending on the FDS[2:0] bits (FIFO depth setting) of each register.
