Rev.1.10 Jul 2026

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.
3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You shall be responsible for determining what licenses are required from any third parties, and obtaining such licenses for the lawful import, export, manufacture, sales, utilization, distribution or other disposal of any products incorporating Renesas Electronics products, if required.
5. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.
6. Renesas Electronics products are classified according to the following two quality grades: “Standard” and “High Quality”. The intended applications for each Renesas Electronics product depends on the product’s quality grade, as indicated below.
   "Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.
   "High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.

   Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user’s manual or other Renesas Electronics document.
7. No semiconductor product is absolutely secure. Notwithstanding any security measures or features that may be implemented in Renesas Electronics hardware or software products, Renesas Electronics shall have absolutely no liability arising out of any vulnerability or security breach, including but not limited to any unauthorized access to or use of a Renesas Electronics product or a system that uses a Renesas Electronics product. RENESAS ELECTRONICS DOES NOT WARRANT OR GUARANTEE THAT RENESAS ELECTRONICS PRODUCTS, OR ANY SYSTEMS CREATED USING RENESAS ELECTRONICS PRODUCTS WILL BE INVULNERABLE OR FREE FROM CORRUPTION, ATTACK, VIRUSES, INTERFERENCE, HACKING, DATA LOSS OR THEFT, OR OTHER SECURITY INTRUSION (“Vulnerability Issues”). RENESAS ELECTRONICS DISCLAIMS ANY AND ALL RESPONSIBILITY OR LIABILITY ARISING FROM OR RELATED TO ANY VULNERABILITY ISSUES. FURTHERMORE, TO THE EXTENT PERMITTED BY APPLICABLE LAW, RENESAS ELECTRONICS DISCLAIMS ANY AND ALL WARRANTIES, EXPRESS OR IMPLIED, WITH RESPECT TO THIS DOCUMENT AND ANY RELATED OR ACCOMPANYING SOFTWARE OR HARDWARE, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY, OR FITNESS FOR A PARTICULAR PURPOSE.
8. When using Renesas Electronics products, refer to the latest product information (data sheets, user’s manuals, application notes, “General Notes for Handling and Using Semiconductor Devices” in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.
9. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.
10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
11. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.
12. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.
13. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
14. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note1) “Renesas Electronics” as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.

(Note2) “Renesas Electronics product(s)” means any product developed or manufactured by or for Renesas Electronics.

General Precautions in the Handling of Microprocessing Unit and Microcontroller Unit Products

The following usage notes are applicable to all Microprocessing unit and Microcontroller unit products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

1. Precaution against Electrostatic Discharge (ESD)
   A strong electrical field, when exposed to a CMOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop the generation of static electricity as much as possible, and quickly dissipate it when it occurs. Environmental control must be adequate. When it is dry, a humidifier should be used. This is recommended to avoid using insulators that can easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors must be grounded. The operator must also be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions must be taken for printed circuit boards with mounted semiconductor devices.
2. Processing at power-on
   The state of the product is undefined at the time when power is supplied. The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the time when power is supplied. In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the time when power is supplied until the reset process is completed. In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the time when power is supplied until the power reaches the level at which resetting is specified.
3. Input of signal during power-off state
   Do not input signals or an I/O pull-up power supply while the device is powered off. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Follow the guideline for input signal during power-off state as described in your product documentation.
4. Handling of unused pins
   Handle unused pins in accordance with the directions given under handling of unused pins in the manual. The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of the LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible.
5. Clock signals
   After applying a reset, only release the reset line after the operating clock signal becomes stable. When switching the clock signal during program execution, wait until the target clock signal is stabilized. When the clock signal is generated with an external resonator or from an external oscillator during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Additionally, when switching to a clock signal produced with an external resonator or by an external oscillator while program execution is in progress, wait until the target clock signal is stable.
6. Voltage application waveform at input pin
   Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between V_{IL} (Max.) and V_{IH} (Min.) due to noise, for example, the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between V_{IL} (Max.) and V_{IH} (Min.).
7. Prohibition of access to reserved addresses
   Access to reserved addresses is prohibited. The reserved addresses are provided for possible future expansion of functions. Do not access these addresses as the correct operation of the LSI is not guaranteed.
8. Differences between products
   Before changing from one product to another, for example to a product with a different part number, confirm that the change will not lead to problems. The characteristics of a microprocessing unit or microcontroller unit products in the same group but having a different part number might differ in terms of internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.

How to Use This Manual

1. Purpose and Target Readers

This manual is designed to provide the user with an understanding of the hardware functions and electrical characteristics of the MCU. It is intended for users designing application systems incorporating the MCU. A basic knowledge of electric circuits, logical circuits, and MCUs is necessary in order to use this manual.
The manual comprises an overview of the product, descriptions of the CPU, system control functions, peripheral functions, electrical characteristics, and usage notes.

Particular attention should be paid to the precautionary notes when using the manual. These notes can be found within the body of the text, at the end of each section, and in the Usage Notes section.

The revision history summarizes the locations of revisions and additions. It does not list all revisions. Refer to the text of the manual for details.

The following documents apply to the RX74N Group. Make sure to refer to the latest versions of these documents. The latest versions of the listed documents are available from the Renesas Electronics website.

Document Type	Description	Document Title	Document No.
Datasheet	Hardware overview and electrical characteristics	RX74N Group Datasheet	R01DS0434EJ
User's Manual: Hardware	Hardware specifications (pin assignments, memory maps, peripheral specifications, electrical characteristics, and timing charts) and operation description Note: Refer to the application notes for details on using peripheral functions.	RX74N Group User's Manual: Hardware	This User's manual
User's Manual: Software	Description of CPU instruction set	RX Family RXv3e Instruction Set Architecture User's Manual: Software	R01US0745EJ
Application Note	Notes on Printed Circuit Board Patterns	RX Family Hardware Design Guide	R01AN1411EJ
	Information on using peripheral functions and application examples Sample programs	Available from Renesas Electronics website.	
Renesas Technical Update	Product specifications, updates on documents, etc.		

2. Notation of Numbers and Symbols

Each register description includes a bit chart, illustrating the arrangement of bits, and a table of bits, describing the meanings of the bit settings. The standard format and notation for bit charts and tables are described below.

X.X.X ... Register

Address(es): xxxx xxxxh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	...[1:0]		...4	—	—	—	...0
Value after reset:	x	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	...0	.....	0: ..... 1: Setting prohibited (3)	R/W (1)
b3 to b1	—	Reserved (2)	These bits are read as 0. The write value should be 0.	R/W
b4	...4	.....	0: 1:	R
b6, b5	...[1:0]	.....	0 0: ..... 0 1: ..... Settings other than above are prohibited. (3)	R/(W)*1
b7	—	Reserved	The read value is undefined. Writing to this bit has no effect.	R

(1) R/W: The bit or field is readable and writable.
R/(W): The bit or field is readable and writable. However, writing to this bit or field has some limitations. For details on the limitations, see the description or notes of respective registers.
R: The bit or field is readable. Writing to this bit or field has no effect.

(2) Reserved.
Use the specified value when writing to this bit or field; otherwise, the correct operation is not guaranteed.

(3) Setting prohibited. The correct operation is not guaranteed if such a setting is performed.

3. List of Abbreviations and Acronyms

Abbreviation	Full Form
ACIA	Asynchronous Communications Interface Adapter
bps	bits per second
CRC	Cyclic Redundancy Check
DMA	Direct Memory Access
DMAC	Direct Memory Access Controller
GSM	Global System for Mobile Communications
Hi-Z	High Impedance
IEBus	Inter Equipment Bus
I/O	Input / Output
IrDA	Infrared Data Association
LSB	Least Significant Bit
MSB	Most Significant Bit
NC	Non-Connect
PLL	Phase Locked Loop
PWM	Pulse Width Modulation
SFR	Special Function Registers
SIM	Subscriber Identity Module
UART	Universal Asynchronous Receiver / Transmitter
VCO	Voltage Controlled Oscillator

Block Select Register for Non-Secure Application (BLSEL_NS) ... 391
7.2.9 BLSEL Attribute Select Register (BLSEL_SEL) ... 392
7.2.10 Block Swap Setting Register n for Secure Application (BLKSWPn_S) (n = 0 to 3),
Block Swap Setting Register n for Non-Secure Application (BLKSWPn_NS) (n = 0 to 3) ... 393
7.2.11 Start-Up Area Setting Register (SAS) ... 395
7.2.12 Start-Up Area Setting Register 2 (SAS2) ... 396
7.2.13 Option Function Select Register 1 for Secure Application (OFS1_S),
Option Function Select Register 1 for Non-Secure Application (OFS1_NS) ... 397
7.2.14 OFS1 Attribute Select Register (OFS1_SEL) ... 399
7.2.15 MRAM Security Attribute Boundary Register (MRAMSABR) ... 400
7.2.16 Block Protect Register n for Secure Application (BPSn_S) (n = 0 to 15, 64 to 71),
Block Protect Register n for Non-Secure Application (BPSn_NS) (n = 0 to 15, 64 to 71) ... 402
7.2.17 Data MRAM Block Protect Register 0 for Secure Application (BPSD0_S),
Data MRAM Block Protect Register 0 for Non-Secure Application (BPSD0_NS) ... 404
7.2.18 Permanent Block Protect Register m for Secure Application (PBPSm_S)
(m = 0 to 3, 16, 17),
Permanent Block Protect Register m for Non-Secure Application (PBPSm_NS)
(m = 0 to 3, 16, 17) ... 406
7.2.19 Data MRAM Permanent Block Protect Register 0 for Secure Application (PBPSD0_S),
Data MRAM Permanent Block Protect Register 0 for Non-Secure Application
(PBPSD0_NS) ... 407
7.2.20 Secure MRAM Option Setting Memory Protect Register n (MOFSPSn_S) (n = 0 to 3) ... 408
7.2.21 Non-secure MRAM Option Setting Memory Protect Register 0 (MOFSPS0_NS) ... 408
7.2.22 Secure Switchable OTP Option Setting Memory Protect Register n (SOFSPSn_S)
(n = 0 to 3) ... 409
7.2.23 Non-secure Switchable OTP Option Setting Memory Protect Register 0 (SOFSPS0_NS) ... 409
7.2.24 FSBL Control Register 0 (FSBLCTRL0) ... 410
7.2.25 FSBL Control Register 1 (FSBLCTRL1) ... 411
7.2.26 FSBL Control Register 2 (FSBLCTRL2) ... 412
7.2.27 Code Certificate 0 Start Address Register n (SACC0n) (n = 0 to 3) ... 413
7.2.28 Code Certificate 1 Start Address Register n (SACC1n) (n = 0 to 3) ... 413
7.2.29 Measurement Report Start Address Register (SAMR) ... 414
7.2.30 OEM_ROOT_PK Revoke Register (REVOKE) ... 415
7.2.31 OEM_ROOT_PKn Hash Register [i] (HOEMRTPKn[i]) (n = 0 to 3; i = 0 to 11) ... 416
7.2.32 HUK Zeroization Register (ZHUK) ... 417
7.2.33 Anti-Rollback Counter Setting Register (ARCCS) ... 418
7.2.34 Anti-Rollback Counter for Secure Application [i] (ARCS[i]) (i = 0 to 31) ... 419

7.2.35 Anti-Rollback Counter n for Non-Secure Application [i] (ARCNSn[i]) (n = 0 to 3, i = 0 to 7) ... 419
7.2.36 Anti-Rollback Counter for Non-Secure Application [i] (ARCNS[i]) (i = 0 to 31) ... 420
7.2.37 Anti-Rollback Counter for OEM Boot Loader [i] (ARCOEMBL[i]) (i = 0, 1) ... 420
7.2.38 User Extra MRAM Configuration Register (UMRECR) ... 421
7.3 Setting the Option-Setting Memory ... 422
7.3.1 Allocation of Data in the Option-Setting Memory ... 422
7.3.2 Programming to Option-Setting Memory ... 422
7.3.3 Security Attributes of Option-Setting Memory ... 422
7.3.4 Registers with Selectable Security Attributes for Each Bit ... 423
7.3.5 Reflection Timing of the Setting Value ... 423
7.4 Usage Note ... 424
7.4.1 Set Value for Reserved Area ... 424
7.4.2 Notes on the First-Stage Boot Loader (FSBL) ... 424
8. Programmable Voltage Detection Circuit (PVD) ... 425
8.1 Overview ... 425
8.2 Register Descriptions ... 428
8.2.1 Programmable Voltage Detection Security Attribute Setting Register (PVDSAR) ... 428
8.2.2 Voltage Monitoring m Comparator Control Register (PVDmCMPCR) (m = 1, 2) ... 429
8.2.3 Voltage Monitoring n Comparator Control Register (PVDnCMPCR) (n = 4, 5) ... 430
8.2.4 Voltage Monitoring m Circuit Control Register 0 (PVDmCR0) (m = 1, 2) ... 431
8.2.5 Voltage Monitoring n Circuit Control Register 0 (PVDnCR0) (n = 4, 5) ... 433
8.2.6 Voltage Monitoring m Circuit Control Register 1 (PVDmCR1) (m = 1, 2) ... 434
8.2.7 Voltage Monitoring m Circuit Status Register (PVDmSR) (m = 1, 2) ... 435
8.2.8 Voltage Monitoring m Function Control Register (PVDmFCR) (m = 1, 2) ... 436
8.2.9 Voltage Monitoring n Function Control Register (PVDnFCR) (n = 4, 5) ... 437
8.2.10 Voltage Monitoring Lock Register (PVDLR) ... 438
8.3 VCC Input Voltage Monitoring ... 439
8.3.1 Monitoring Vdet0 ... 439
8.3.2 Monitoring Vdetm ... 439
8.4 Voltage Monitoring 0 Reset ... 440
8.5 Voltage Monitoring m Interrupt and Voltage Monitoring m Reset (m = 1, 2) ... 441
8.6 Voltage Monitoring n Reset (n = 4, 5) ... 445
8.7 Event Link Output ... 447
8.7.1 Interrupt Handling and Event Linking ... 447
9. Clock Generation Circuit ... 448
9.1 Overview ... 448
9.2 Register Descriptions ... 454
9.2.1 Clock Generation Function Security Attribute Register (CGFSAR) ... 454
9.2.2 System Clock Frequency Division Control Register (SCKDIVCR) ... 456
9.2.3 System Clock Frequency Division Control Register 2 (SCKDIVCR2) ... 459
9.2.4 System Register Access Status Register (SYRACCR) ... 460

9.2.5 System Clock Source Control Register (SCKSCR) 461
9.2.6 PLL Clock Control Register (PLLCCR) 462
9.2.7 PLL Clock Control Register 2 (PLLCCR2) 463
9.2.8 PLL Control Register (PLLCR) 464
9.2.9 PLL2 Clock Control Register (PLL2CCR) 465
9.2.10 PLL2 Clock Control Register 2 (PLL2CCR2) 466
9.2.11 PLL2 Control Register (PLL2CR) 467
9.2.12 External Bus Clock Control Register (BCKCR) 468
9.2.13 Main Clock Oscillator Control Register (MOSCCR) 469
9.2.14 Sub-Clock Oscillator Control Register (SOSCCR) 470
9.2.15 Low-Speed On-Chip Oscillator Control Register (LOCOCR) 471
9.2.16 High-Speed On-Chip Oscillator Control Register (HOCOCR) 472
9.2.17 High-Speed On-Chip Oscillator Control Register 2 (HOCOCR2) 473
9.2.18 Middle-Speed On-Chip Oscillator Control Register (MOCOCR) 474
9.2.19 FLL Control Register 1 (FLLCR1) 475
9.2.20 FLL Control Register 2 (FLLCR2) 477
9.2.21 Oscillation Stabilization Flag Register (OSCSF) 478
9.2.22 Oscillator Monitor Register (OSCMONR) 480
9.2.23 Oscillation Stop Detection Control Register (OSTDCR) 481
9.2.24 Oscillation Stop Detection Status Register (OSTDSR) 482
9.2.25 Sub-Clock Oscillation Stop Detection Control Register (SOSTDCR) 483
9.2.26 Sub-Clock Oscillation Stop Detection Status Register (SOSTDSR) 484
9.2.27 Main Clock Oscillator Wait Control Register (MOSCWTCR) 485
9.2.28 Main Clock Oscillator Mode Oscillation Control Register (MOMCR) 486
9.2.29 Sub-Clock Oscillator Mode Control Register (SOMCR) 487
9.2.30 Clock Output Control Register (CKOCR) 488
9.2.31 External Bus Clock Output Control Register (EBCKOCR) 489
9.2.32 SDRAM Clock Output Control Register (SDCKOCR) 489
9.2.33 LOCO User Trimming Control Register (LOCOUTCR) 490
9.2.34 MOCO User Trimming Control Register (MOCOUTCR) 491
9.2.35 HOCO User Trimming Control Register (HOCOUTCR) 492
9.2.36 Main Clock Oscillator Standby Control Register (MOSCSCR) 493
9.2.37 High-Speed On-Chip Oscillator Standby Control Register (HOCOSCR) 494
9.2.38 Middle-Speed On-Chip Oscillator Standby Control Register (MOCOSCR) 495
9.2.39 USB Clock Frequency Division Control Register (USBCKDIVCR) 496
9.2.40 XSPI Clock Frequency Division Control Register (XSPICKDIVCR) 497
9.2.41 CANFD Core Clock Frequency Division Control Register (CANFDCKDIVCR) 498
9.2.42 USBHS-PHY Clock Frequency Division Control Register (USB60CKDIVCR) 499
9.2.43 I3C Clock Frequency Division Control Register (I3CCKDIVCR) 500
9.2.44 USB Clock Control Register (USBCKCR) 501
9.2.45 XSPI Clock Control Register (XSPICKCR) 503

9.2.46 CANFD Core Clock Control Register (CANFDCKCR) 505
9.2.47 USBHS-PHY Clock Control Register (USB60CKCR) 507
9.2.48 I3C Clock Control Register (I3CCKCR) 509
9.2.49 SCI Clock Frequency Division Control Register (SCICKDIVCR) 510
9.2.50 SPI Clock Frequency Division Control Register (SPICKDIVCR) 511
9.2.51 ADC Clock Frequency Division Control Register (ADCCKDIVCR) 512
9.2.52 GPT Clock Frequency Division Control Register (GPTCKDIVCR) 513
9.2.53 SCI Clock Control Register (SCICKCR) 514
9.2.54 SPI Clock Control Register (SPICKCR) 516
9.2.55 ADC Clock Control Register (ADCCKCR) 518
9.2.56 GPT Clock Control Register (GPTCKCR) 520
9.2.57 Asynchronous External Bus Clock Frequency Division Control Register (BCKADIVCR) 521
9.2.58 ESWM Clock Frequency Division Control Register (ESWCKDIVCR) 522
9.2.59 ESWM-PHY Clock Frequency Division Control Register (ESWPCKDIVCR) 523
9.2.60 Ethernet-PHY Clock Frequency Division Control Register (ETHPCKDIVCR) 524
9.2.61 Asynchronous External Bus Clock Control Register (BCKACR) 525
9.2.62 ESWM Clock Control Register (ESWCKCR) 527
9.2.63 ESWM-PHY Clock Control Register (ESWPCKCR) 529
9.2.64 Ethernet-PHY Clock Control Register (ETHPCKCR) 531
9.3 Main Clock Oscillator 533
9.3.1 Connecting a Resonator 533
9.3.2 Inputting an External Clock 534
9.3.3 Note on the External Clock Input 534
9.3.4 Notes on Oscillation Keeping in Software Standby Mode 534
9.4 Sub-Clock Oscillator 535
9.4.1 Connecting a 32.768-kHz Crystal Resonator 535
9.4.2 Handling of Pins when the Sub-Clock Oscillator is Not in Use 535
9.4.3 Input of an External Clock 535
9.5 Low-Speed On-Chip Oscillator (LOCO) 536
9.5.1 LOCO Operating Conditions 536
9.5.2 LOCO Stop Conditions 536
9.5.3 Restrictions on LOCO Operation and Stopping 537
9.6 Middle-Speed On-Chip Oscillator (MOCO) 538
9.6.1 MOCO Operating Conditions 538
9.6.2 MOCO Stop Conditions 538
9.6.3 Restrictions on MOCO Operation and Stopping 539
9.7 High-Speed On-Chip Oscillator (HOCO) 540
9.7.1 Frequency Locked Loop Function 540
9.7.2 Notes on Oscillation Keeping in Software Standby Mode 540
9.8 PLL Circuits 541
9.9 Oscillation Stop Detection Function 543

9.9.1 Main Clock Oscillation Stop Detection and Operation after Detection 543
9.9.2 Main Clock Oscillation Stop Detection Interrupts 545
9.9.3 Sub-Clock Oscillation Stop Detection and Operation after Detection 545
9.9.4 Sub-Clock Oscillation Stop Detection Interrupts 548
9.10 Internal Clocks 549
9.10.1 CPU Clock (CPUCLK0) 550
9.10.2 MRAM Code Bus Clock (MRICLK) 550
9.10.3 MRAM Peripheral Bus Clock (MRPCLK) 550
9.10.4 System Clock (ICLK) 551
9.10.5 Peripheral Module Clock (PCLKA, PCLKB, PCLKC, PCLKD, PCLKE) 552
9.10.6 External Bus Clock (BCLK, EBCLK) 552
9.10.7 SDRAM Clock (SDCLK) 552
9.10.8 SCI Clock (SCICLK) 553
9.10.9 SPI Clock (SPICLK) 553
9.10.10 XSPI Clock (XSPICLK, XSPIDIVCLK) 553
9.10.11 CANFD Core Clock (CANFDCLK) 554
9.10.12 USB Clock (USBCLK) 554
9.10.13 USBHS-PHY Clock (USB60CLK) 554
9.10.14 MOSC Clock for USBHS (USBMCLK) 555
9.10.15 ADC Clock (ADCCLK) 555
9.10.16 GPT Clock (GPTCLK) 555
9.10.17 I3C Clock (I3CCLK) 556
9.10.18 Asynchronous External Bus Clock (BCLKA, EBCLK) 556
9.10.19 ESWM Clock (ESWCLK) 556
9.10.20 ESWM-PHY Clock (ESWPHYCLK) 557
9.10.21 Ethernet-PHY Clock (ETHPHYCLK) 557
9.10.22 CANFD Main Clock (CANFDMCLK) 557
9.10.23 CAC Clock (CACCLK) 557
9.10.24 RTC Clock (RTCSCLK, RTCLCLK) 558
9.10.25 IWDT Clock (IWDTCLK) 558
9.10.26 PDMIF Clock (PDMIFCLK) 558
9.10.27 External Pin Output Clock (CLKOUT) 558
9.10.28 JTAG Clock 558
9.11 Clock Setting 559
9.11.1 Setting the System Clock 559
9.11.1.1 Initial Settings of the System Clock 559
9.11.1.2 Setting the System Clock to Increase the Frequency 560
9.11.1.3 Setting the System Clock to Decrease the Frequency 561
9.11.2 Setting Peripheral Module-Dedicated Clocks 562
9.11.2.1 Initial Settings of a Peripheral Module-Dedicated Clock 562
9.11.2.2 Changing the Clock Source of a Peripheral Module-Dedicated Clock 563

9.11.2.3 Changing the Division Ratio of a Peripheral Module-Dedicated Clock 564
9.11.3 Setting the Main Clock Oscillator 565
9.11.4 Setting the Sub-Clock Oscillator 565
9.11.5 Setting the High-Speed On-Chip Oscillator 566
9.11.5.1 Initial Settings of the HOCO Clock 566
9.11.5.2 Setting the HOCO by the FLL Function 567
9.11.6 Setting PLL Circuits 568
9.11.6.1 Initial Settings of a PLL Clock 568
9.11.6.2 Changing the PLL Settings 569
9.12 Usage Notes 570
9.12.1 Notes on the Clock Generation Circuit 570
9.12.2 Restrictions on a Resonator 570
9.12.3 Notes on Board Design 571
9.12.4 Notes on Resonator Connection Pins 571
9.12.5 Notes on Using the Sub-Clock Oscillator 571
9.12.6 Notes on the Reset Conditions of the SOSC and LOCO 572
10. Clock Frequency Accuracy Measurement Circuit (CAC) 573
10.1 Overview 573
10.2 Register Descriptions 575
10.2.1 CAC Control Register 0 (CACR0) 575
10.2.2 CAC Control Register 1 (CACR1) 576
10.2.3 CAC Control Register 2 (CACR2) 578
10.2.4 CAC Interrupt Request Enable Register (CAICR) 580
10.2.5 CAC Status Register (CASTR) 581
10.2.6 CAC Upper-Limit Value Setting Register (CAULVR) 582
10.2.7 CAC Lower-Limit Value Setting Register (CALLVR) 582
10.2.8 CAC Counter Buffer Register (CACNTBR) 582
10.3 Operation 583
10.3.1 Measuring Clock Frequency 583
10.3.2 Digital Filtering of Signals on the CACREF Pin 584
10.4 Interrupt Requests 584
10.5 Usage Notes 585
10.5.1 Module Stop Function Setting 585
11. Low Power Consumption 586
11.1 Overview 586
11.2 Register Descriptions 593
11.2.1 Low Power Consumption Mode Security Attribution Register (LPMSAR) 593
11.2.2 Power Gating Security Attribution Register (PGCSAR) 595
11.2.3 Deep Software Standby Interrupt Source Security Attribution Register (DPFSAR) 596
11.2.4 Deep Software Standby Interrupt Source Security Attribution Register 1 (DPFSAR1) 600
11.2.5 RAM Standby Control Security Attribution Register (RSCSAR) 602

11.2.6 Module Stop Control Register A (MSTPCRA) 604
11.2.7 Module Stop Control Register B (MSTPCRB) 605
11.2.8 Module Stop Control Register C (MSTPCRC) 607
11.2.9 Module Stop Control Register D (MSTPCRD) 609
11.2.10 Module Stop Control Register E (MSTPCRE) 610
11.2.11 Module Stop Control Register F (MSTPCRF) 611
11.2.12 Power Gating Shift Control Register (PGSCR) 612
11.2.13 Power Switch Control Start Time Control Register n (PSSTCRn) (n = 2, 4, 5) 612
11.2.14 ESWM Power Domain Control Register (PDCTRESWM) 613
11.2.15 SRAM Power Domain Standby Control Register 0 (PDRAMSCR0) 614
11.2.16 SRAM Power Domain Standby Control Register 2 (PDRAMSCR2) 616
11.2.17 Standby Control Register (SBYCR) 617
11.2.18 Software Standby Control Register 1 (SSCR1) 618
11.2.19 Low Power Consumption State Control Register (LPSCR) 619
11.2.20 Deep Software Standby Control Register (DPSBYCR) 621
11.2.21 Deep Software Standby Interrupt Enable Register 0 (DPSIER0) 622
11.2.22 Deep Software Standby Interrupt Enable Register 1 (DPSIER1) 623
11.2.23 Deep Software Standby Interrupt Enable Register 2 (DPSIER2) 624
11.2.24 Deep Software Standby Interrupt Enable Register 3 (DPSIER3) 625
11.2.25 Deep Software Standby Interrupt Enable Register 4 (DPSIER4) 626
11.2.26 Deep Software Standby Interrupt Enable Register 5 (DPSIER5) 627
11.2.27 Deep Software Standby Interrupt Flag Register 0 (DPSIFR0) 628
11.2.28 Deep Software Standby Interrupt Flag Register 1 (DPSIFR1) 629
11.2.29 Deep Software Standby Interrupt Flag Register 2 (DPSIFR2) 630
11.2.30 Deep Software Standby Interrupt Flag Register 3 (DPSIFR3) 632
11.2.31 Deep Software Standby Interrupt Flag Register 4 (DPSIFR4) 634
11.2.32 Deep Software Standby Interrupt Flag Register 5 (DPSIFR5) 635
11.2.33 Deep Software Standby Interrupt Edge Register 0 (DPSIEGR0) 636
11.2.34 Deep Software Standby Interrupt Edge Register 1 (DPSIEGR1) 637
11.2.35 Deep Software Standby Interrupt Edge Register 2 (DPSIEGR2) 638
11.2.36 Deep Software Standby Interrupt Edge Register 3 (DPSIEGR3) 639
11.2.37 Deep Software Standby Interrupt Edge Register 4 (DPSIEGR4) 640
11.2.38 PLL1-LDO Control Register (PLL1LDOCR) 641
11.2.39 PLL2-LDO Control Register (PLL2LDOCR) 642
11.2.40 HOCO/LDO Control Register (HOCOLDOCR) 643
11.2.41 Voltage Scaling Control Register (VSCR) 644
11.2.42 SSTBY Voltage Scaling Control Register (SVSCR) 645
11.2.43 LDO Efficiency Control Register (LDOECR) 646
11.2.44 DSTBY Condition Control Register (DCCR) 647
11.2.45 CPU Low Power Control Register (CLPCR) 648
11.3 Reducing Power Consumption by Switching Clock Signals 649

11.4 Module-Stop Function 649
11.5 Power Gating Control 650
11.5.1 Power Gating Control Using the Power Domain Control Register 650
11.6 Low Power Consumption Modes 651
11.6.1 CPU Sleep Mode/CPU Deep Sleep Mode 651
11.6.1.1 Transition to CPU Sleep Mode or CPU Deep Sleep Mode 651
11.6.1.2 Release from CPU Sleep Mode/CPU Deep Sleep Mode 652
11.6.2 Software Standby Mode 654
11.6.2.1 Transitioning to Software Standby Mode 654
11.6.2.2 Release from Software Standby Mode 656
11.6.2.3 Example of Software Standby Mode Application 657
11.6.3 Deep Software Standby Mode 658
11.6.3.1 Transition to Deep Software Standby Mode 658
11.6.3.2 Release from Deep Software Standby Mode 659
11.6.3.3 Pin States at the Time of Release from Deep Software Standby Mode 660
11.6.3.4 Example of Deep Software Standby Mode Application 660
11.6.3.5 Flowchart to Use Deep Software Standby Mode 662
11.7 Voltage Scaling Control 663
11.8 Usage Notes 665
11.8.1 Register Access 665
11.8.2 I/O Port States 665
11.8.3 Module-Stop State of DMAC and DTC 665
11.8.4 On-Chip Peripheral Module Interrupts 665
11.8.5 Input Buffer Control by the DIRQnE Bit (n = 0 to 31) 665
11.8.6 Timing of the WAIT Instruction 666
11.8.7 Writing to the WDT/IWDT Registers by the DMAC or DTC 666
11.8.8 Timing of Writing to the Module Stop Bits 666
11.8.9 Notes on Transition to and Return from Low Power Modes 666
12. Battery Backup Function (VBATTBa) 669
12.1 Overview 669
12.2 Register Descriptions 672
12.2.1 VBATT Security Attribution Register (VBSAR) 672
12.2.2 Backup Register Security Attribute Boundary Register (BKRSABR) 673
12.2.3 Battery Voltage Measurement Function Control Register (VBATTMCR) 674
12.2.4 Battery Backup Function Control Register 1 (VBATTCR1) 675
12.2.5 Battery Backup Function Control Register 2 (VBATTCR2) 676
12.2.6 Backup Domain Power Status Register (BKPSR) 677
12.2.7 Tamper Status Register (TAMPSR) 678
12.2.8 Tamper Control Register (TAMPCR) 679
12.2.9 Tamper Control Register 2 (TAMPCR2) 680
12.2.10 Time Capture Event Control Register (TCECR) 681

12.2.11 Tamper/RTCIC Input Control Register 1 (TAMPICR1) 682
12.2.12 Tamper/RTCIC Input Control Register 2 (TAMPICR2) 683
12.2.13 Tamper/RTCIC Input Control Register 3 (TAMPICR3) 684
12.2.14 Tamper/RTCIC Input Monitoring Register (TAMPIMR) 685
12.2.15 Backup Register Control Register (BKRCR) 686
12.2.16 Backup Register n (BKRn) (n = 0 to 127) 686
12.3 Operation 687
12.3.1 Battery Backup Function 687
12.3.2 Power-Down Detector 689
12.3.3 Backup Registers 689
12.3.4 Tamper Detector 690
12.4 Interrupt 692
12.5 Usage Notes 692
12.5.1 Voltage Monitor 0 Reset 692
12.5.2 When the Battery Backup Function is Not to be Used 692
12.5.3 Current Injection Flowing into the VBATT Pin 693
13. Register Write Protection Function 694
13.1 Register Descriptions 695
13.1.1 Protect Register (PRCR_S) 695
13.1.2 Protect Register (PRCR_NS) 696
14. Exception Handling 697
14.1 Exception Events 697
14.1.1 Undefined Instruction Exception 698
14.1.2 Privileged Instruction Exception 698
14.1.3 Access Exception 698
14.1.4 Secure Exception 698
14.1.5 Address Exception 698
14.1.6 Single-Precision Floating-Point Exception 698
14.1.7 Reset 698
14.1.8 Non-Maskable Interrupt 699
14.1.9 Interrupt 699
14.1.10 Unconditional Trap 700
14.2 Exception Handling Procedure 701
14.2.1 Exception Handling Procedure without World Transitions 702
14.2.2 Exception Handling Procedure with World Transitions 704
14.3 Acceptance of Exception Events 706
14.3.1 Timing of Acceptance and Saved PC Value 706
14.3.2 Vector and Location for Saving the PC and PSW 707
14.4 Hardware Processing for Accepting and Returning from Exceptions 708
14.4.1 Hardware Processing for Accepting and Returning from Exceptions Not Involving World Transitions 708

14.4.2 Hardware Processing for Accepting and Returning from Exceptions Involving World Transitions ... 709
14.5 Hardware Pre-Processing ... 710
14.5.1 Undefined Instruction Exception ... 710
14.5.2 Privileged Instruction Exception ... 710
14.5.3 Access Exception ... 710
14.5.4 Secure Exception ... 710
14.5.5 Address Exceptions ... 711
14.5.6 Single-Precision Floating-Point Exceptions ... 711
14.5.7 Reset ... 711
14.5.8 Non-Maskable Interrupts (with Normal Acceptance) ... 711
14.5.9 Non-Maskable Interrupts (with World-Transition Acceptance) ... 711
14.5.10 Interrupts (with Normal Acceptance) ... 712
14.5.11 Interrupts (with World-Transition Acceptance) ... 712
14.5.12 Unconditional Trap (with Normal Acceptance) ... 712
14.5.13 Unconditional Trap (with World-Transition Acceptance) ... 713
14.6 Return from Exception Handling Routine ... 714
14.7 Priority of Exception Events ... 714
14.8 Exception Generated in Coprocessor ... 715
14.8.1 Double-Precision Floating-Point Exceptions ... 715
15. Interrupt Controller (ICUM) ... 716
15.1 Overview ... 716
15.2 Register Descriptions ... 718
15.2.1 Interrupt Request Register n (IRn) (n = 16 to 255) ... 718
15.2.2 Interrupt Request Enable Register m (IERm) (m = 2 to 31) ... 720
15.2.3 Interrupt Source Priority Register r (IPRr) (r = 0 to 255) ... 721
15.2.4 Fast Interrupt Set Register (FIR) ... 722
15.2.5 Software Interrupt Generation Register (SWINTR) ... 723
15.2.6 Software Interrupt 2 Generation Register (SWINT2R) ... 723
15.2.7 DTC Transfer Request Enable Register n (DTCERn) (n = 26 to 255) ... 724
15.2.8 DMAC Trigger Select Register m (DMRSRm) (m = 0 to 7) ... 725
15.2.9 IRQi Pin Interrupt Control Register (IRQCRi) (i = 0 to 31) ... 726
15.2.10 Non-Maskable Interrupt Status Register (NMISR) ... 727
15.2.11 Non-Maskable Interrupt Enable Register (NMIER) ... 731
15.2.12 Non-Maskable Interrupt Status Clear Register (NMICLR) ... 733
15.2.13 NMI Pin Interrupt Control Register (NMICR) ... 734
15.2.14 Group ILi Non-Secure Interrupt Request Register (GRPILi_NS) (i = 0, 1), Group BLi Non-Secure Interrupt Request Register (GRPBLi_NS) (i = 0, 1), Group ALi Non-Secure Interrupt Request Register (GRPALi_NS) (i = 0 to 6) ... 735
15.2.15 Group ILi Secure Interrupt Request Register (GRPILi_S) (i = 0, 1), Group BLi Secure Interrupt Request Register (GRPBLi_S) (i = 0, 1), Group ALi Secure Interrupt Request Register (GRPALi_S) (i = 0 to 6) ... 737

15.2.16 Group ILi Non-Secure Interrupt Request Enable Register (GENILi_NS) (i = 0, 1), Group BLi Non-Secure Interrupt Request Enable Register (GENBLi_NS) (i = 0, 1), Group ALi Non-Secure Interrupt Request Enable Register (GENALi_NS) (i = 0 to 6) 739
15.2.17 Group ILi Secure Interrupt Request Enable Register (GENILi_S) (i = 0, 1), Group BLi Secure Interrupt Request Enable Register (GENBLi_S) (i = 0, 1), Group ALi Secure Interrupt Request Enable Register (GENALi_S) (i = 0 to 6) 741
15.2.18 Software Configurable Interrupt Request Register Xk (PIXRk) (k = 0, 1) 743
15.2.19 Software Configurable Interrupt Request Register k (PIRk) (k = 0 to 127) 744
15.2.20 Software Configurable Interrupt Source Select Register Xn (SLIXRn) (n = 128 to 143) 745
15.2.21 Software Configurable Interrupt Source Select Register n (SLIRn) (n = 144 to 255) 746
15.2.22 EXDMAC Trigger Select Register n (SELEXDRn) (n = 0, 1) 757
15.2.23 Non-Secure Software Configurable Interrupt Source Select Register Write Protect Register (SLIPRCR_NS) 758
15.2.24 Secure Software Configurable Interrupt Source Select Register Write Protect Register (SLIPRCR_S) 759
15.2.25 ICU Security Attribution Register A (ICUSARA) 760
15.2.26 ICU Security Attribution Register B (ICUSARB) 761
15.2.27 ICU Security Attribution Register C (ICUSARC) 762
15.2.28 ICU Security Attribution Register D (ICUSARD) 763
15.2.29 ICU Security Attribution Register 0 (ICU0SAR0) 764
15.2.30 ICU Security Attribution Register 1 (ICU0SAR1) 766
15.2.31 ICU Security Attribution Register 2 (ICU0SAR2) 768
15.2.32 ICU Security Attribution Register 3 (ICU0SAR3) 770
15.2.33 ICU Security Attribution Register 4 (ICU0SAR4) 772
15.2.34 ICU Security Attribution Register 5 (ICU0SAR5) 774
15.2.35 ICU Security Attribution Register 6 (ICU0SAR6) 776
15.2.36 ICU Security Attribution Register 7 (ICU0SAR7) 778
15.2.37 Trusted Event Route Control Register (TEVTRCR) 779
15.2.38 ICU Non-Secure Access Control Register (ICUNSACR) 780
15.2.39 Protect Zone Interrupt Control Register (PRTZCR) 781
15.3 Vector Table 782
15.3.1 Interrupt Vector Table 782
15.3.2 Fast Interrupt Vector Area 790
15.3.3 Non-maskable Interrupt Vector Area 790
15.4 Types of Interrupts 791
15.4.1 Peripheral Interrupts 791
15.4.2 Software Interrupts 791
15.4.3 External Pin Interrupt 791
15.4.4 Group Interrupts 792
15.4.5 Software Configurable Interrupts 799
15.4.6 Non-Maskable Interrupts 800
15.5 Interrupt Detection 801
15.5.1 Edge Detection 801

15.5.2 Level Detection ... 803
15.5.3 Interrupt Detection for Group Interrupts ... 804
15.5.4 Interrupt Detection for Software Configurable Interrupts ... 806
15.6 Determining Priority of Interrupt Requests ... 806
15.7 Interrupt Setting Procedure ... 807
15.7.1 Enabling Interrupt Requests ... 807
15.7.2 Disabling Interrupt Requests ... 807
15.7.3 Selecting Interrupt Request Destination ... 807
15.7.3.1 Interrupt Request Destination Setting Procedure ... 807
15.7.3.2 Operations When the DTC/DMAC Selected ... 809
15.7.3.3 Changing the Interrupt Request Destination ... 809
15.7.4 Setting the External Pin Interrupt ... 810
15.7.5 Setting Non-Maskable Interrupts ... 810
15.7.6 Digital Noise Filter ... 811
15.7.7 Setting Software Configurable Interrupts ... 811
15.7.7.1 Polling for Software Configurable Interrupts ... 812
15.8 Multiple Interrupt ... 812
15.9 Fast interrupt ... 812
15.10 Exiting Low Power Consumption State ... 813
15.10.1 Exiting Sleep Mode or Deep Sleep Mode ... 813
15.10.2 Exiting Software Standby Mode ... 813
15.11 Usage Notes ... 814
15.11.1 Notes on the WAIT instruction When Using the Non-Maskable Interrupt ... 814
15.11.2 Interrupt Requests in Software Standby Mode ... 814
15.11.3 Notes on Bus Error during DTC/DMA Transfer ... 814
16. Buses ... 815
16.1 Overview ... 815
16.2 Description of Buses ... 819
16.2.1 Arbitration ... 819
16.2.2 External Bus ... 819
16.2.3 Parallel Operation ... 823
16.2.4 Bus Settings ... 823
16.2.5 Restrictions ... 824
16.2.5.1 Restriction on Endian ... 824
16.2.5.2 Bufferable Write ... 824
16.2.5.3 Notes on the Timing of Writing Completion ... 824
16.3 Register Descriptions ... 825
16.3.1 Bus Security Attribution Register A (BUSSARA) ... 825
16.3.2 Bus Security Attribution Register B (BUSSARB) ... 826
16.3.3 Bus Security Attribution Register C (BUSSARC) ... 827
16.3.4 CSn Control Register (CSnCR) (n = 0 to 7) ... 828

16.3.5 CSn Recovery Cycle Register (CSnREC) (n = 0 to 7) 830
16.3.6 CS Recovery Cycle Insertion Enable Register (CSRECEN) 832
16.3.7 CSn Mode Register (CSnMOD) (n = 0 to 7) 834
16.3.8 CSn Wait Control Register 1 (CSnWCR1) (n = 0 to 7) 836
16.3.9 CSn Wait Control Register 2 (CSnWCR2) (n = 0 to 7) 838
16.3.10 SDC Control Register (SDCCR) 841
16.3.11 SDC Mode Register (SDCMOD) 842
16.3.12 SDRAM Access Mode Register (SDAMOD) 843
16.3.13 SDRAM Self-Refresh Control Register (SDSELF) 844
16.3.14 SDRAM Refresh Control Register (SDRFCR) 845
16.3.14.1 Auto-Refresh Request Interval and RFC Set Value 846
16.3.15 SDRAM Auto-Refresh Control Register (SDRFEN) 846
16.3.16 SDRAM Initialization Sequence Control Register (SDICR) 847
16.3.17 SDRAM Initialization Register (SDIR) 848
16.3.18 SDRAM Address Register (SDADR) 849
16.3.19 SDRAM Timing Register (SDTR) 850
16.3.20 SDRAM Mode Register (SDMOD) 852
16.3.21 SDRAM Status Register (SDSR) 853
16.3.22 EXBUS Error Status Register (EXBERR) 854
16.3.23 EXBUS Error Enable Register (EXBEREN) 855
16.3.24 EXBUS Error Status Clear Register (EXBECLR) 856
16.3.25 EXBUS Error Address Register (EXBEAD) 857
16.3.26 EXBUS Hold Enable Register (EXHLDEN) 857
16.3.27 Bus Slave Arbitration Control Register 0 (BUSSABT0MRE0BI, BUSSABT0S0BI, BUSSABT0S1BI, BUSSABT0ECBI, BUSSABT0XSPI0BI, BUSSABT0XSPI1BI, BUSSABT0PBBI, BUSSABT0PABI, BUSSABT0PIBI, BUSSABT0PSBI, BUSSABT0PS0BI) 858
16.3.28 Bus Slave Arbitration Control Register 1 (BUSSABT1MRC0BI, BUSSABT1MRC1BI) 860
16.3.29 Bus Error Status Register (BUSERRSTATCPU0IF, BUSERRSTATCPU0OA, BUSERRSTATDMAC0, BUSERRSTATEXDMAC, BUSERRSTATEDMAC, BUSERRSTATXSPI0, BUSERRSTATXSPI1) 861
16.3.30 Bus Error Clear Register (BUSERRCLRCPU0IF, BUSERRCLRCPU0OA, BUSERRCLRDMAC0, BUSERRCLREXDMAC, BUSERRCLREDMAC, BUSERRCLRXSPI0, BUSERRCLRXSPI1) 863
16.3.31 Bus Operation after Detection Register (BUSOAD) 864
16.3.32 Bus Operation after Detection Protect Register (BUSOADPT) 865
16.3.33 Master Bufferable Write Error Status Register (MBWERRSTAT) 866
16.3.34 Master Bufferable Write Error Clear Register (MBWERRCLR) 867
16.3.35 Bus Error Interrupt Enable Register (BUSINTENCPU0IF, BUSINTENCPU0OA, BUSINTENDMAC0, BUSINTENEXDMAC, BUSINTENEDMAC, BUSINTENXSPI0, BUSINTENXSPI1) 868
16.4 Endian and Data Alignment 869
16.4.1 Data Alignment Control for CS Area 869

16.4.2 Data Alignment Control for SDRAM Area 875
16.5 Operation of CS Area Controller 882
16.5.1 Separate Bus 882
16.5.2 Address/Data Multiplexed Bus 899
16.5.3 External Wait Function 901
16.5.4 Insertion of Recovery Cycles 905
16.5.5 No Access State 909
16.5.6 Limitations 909
16.6 SDRAM Area Controller Operation 911
16.6.1 Enabling/Disabling SDRAM Access and Setting SDRAM Bus Width 911
16.6.2 No Access State 911
16.6.3 Insertion of Recovery Cycles 911
16.6.4 SDRAM Commands 912
16.6.5 Conditions for Setting SDRAMC Registers 912
16.6.6 Self-Refresh 913
16.6.7 Auto-Refresh 916
16.6.8 Initialization Sequencer 918
16.6.9 Setting Mode Register 919
16.6.10 Read/Write Access 920
16.6.11 SDRAMC Setting Examples 922
16.6.11.1 SDRAMC Access Procedure 922
16.6.11.2 Procedure for Transition to and Recovery from Self-Refresh Mode 923
16.6.11.3 Timing Register Settings and Access Timing 925
16.6.12 Address Multiplexing 934
16.6.13 Examples for Connecting with SDRAMs 935
16.6.13.1 32-Bit Bus Space 935
16.6.13.2 16-Bit Bus Space 938
16.6.14 Restrictions 941
16.7 External Bus Hold 941
16.8 Bus Error Monitoring Section 942
16.8.1 Types of Bus Error 942
16.8.2 Operations When a Bus Error Occurs 942
16.8.3 Conditions Leading to Illegal Address Access Errors 946
16.8.4 Timeout 951
16.8.4.1 Peripheral Bus 951
16.8.4.2 External Bus Access Wait with WAIT# Signal 951
16.8.4.3 External Bus Hold with BREQ# and BACK# Signals 951
17. Memory-Protection Unit (MPU) 952
17.1 Overview 952
17.2 CPU MPU 953
17.2.1 Overview of CPU MPU 953

17.2.1.1 Types of Access Control 954
17.2.1.2 Access Control Regions 954
17.2.1.3 Cache Attribute 954
17.2.1.4 Background Region 955
17.2.1.5 Overlap between Regions 955
17.2.1.6 Instructions and Data that Span Regions 955
17.2.2 Register Descriptions of CPU MPU 956
17.2.2.1 Region-n Start Page Number Register (RSPAGEn) (n = 0 to 7) 956
17.2.2.2 Region-n End Page Number Register (REPAGEn) (n = 0 to 7) 957
17.2.2.3 Memory-Protection Enable Register (MPEN) 958
17.2.2.4 Background Access Control Register (MPBAC) 959
17.2.2.5 Memory-Protection Error Status Clear Register (MPECLR) 960
17.2.2.6 Memory-Protection Error Status Register (MPESTS) 961
17.2.2.7 Data Memory-Protection Error Address Register (MPDEA) 962
17.2.2.8 Region Search Address Register (MPSA) 962
17.2.2.9 Region Search Operation Register (MPOPS) 963
17.2.2.10 Region Invalidation Operation Register (MPOPI) 964
17.2.2.11 Instruction-Hit Region Register (MHITI) 965
17.2.2.12 Data-Hit Region Register (MHITD) 967
17.2.3 Functions of CPU MPU 969
17.2.3.1 Memory Protection Function 969
17.2.3.2 Cache Attribute Setting Function 969
17.2.3.3 Region Search 969
17.2.3.4 Protection of Registers Related to the Memory-Protection Unit 969
17.2.3.5 Flow for Determining Access by the Memory Protection Function 970
17.2.3.6 Flow for Determining the Cache Attributes 972
17.2.4 Procedures for Using the Memory Protection Function 973
17.2.4.1 Setting the Access Control Information and Cache Attributes 973
17.2.4.2 Enabling the Memory Protection and Cache Attribute Setting Functions 973
17.2.4.3 Transition to User Mode 973
17.2.4.4 Modifying the Cache Attributes 974
17.2.4.5 Processing in Response to a Memory-Protection Error 975
17.3 Bus Master MPU 976
17.3.1 Overview of Bus Master MPU 976
17.3.2 Register Descriptions of Bus Master MPU 977
17.3.2.1 Master Memory-Protection Unit Security Attribute Register B (MMPUSARB) 977
17.3.2.2 MMPU Start Address Register for xSPI (MMPUSXSPImn) (m = 0, 1; n = 0 to 3) 978
17.3.2.3 MMPU End Address Register for xSPI (MMPUEXSPImn) (m = 0, 1; n = 0 to 3) 979
17.3.2.4 MMPU Access Control Register for xSPI (MMPUACXSPImn) (m = 0, 1, n = 0 to 3) 980

17.3.2.5 MMPU Enable Register for xSPI (MMPUENXSPIm) (m = 0, 1) 981
17.3.2.6 MMPU Enable Protect Register for xSPI (MMPUENPTXSPIm) (m = 0, 1) 982
17.3.2.7 MMPU Region Protect Register for xSPI (MMPURPTXSPIm) (m = 0, 1) 983
17.3.2.8 MMPU Post-Detection Operation Register (MMPUOAD) 984
17.3.2.9 MMPU Post-Detection Operation Protect Register (MMPUOADPT) 985
17.3.3 Functions of Bus Master MPU 986
17.3.3.1 Bus Master Memory Protection 986
17.3.3.2 Register Protection 988
17.3.3.3 Memory-Protection Error 988
18. DMA Controller (DMACAa) 989
18.1 Overview 989
18.2 Register Descriptions 991
18.2.1 DMAC Channel Security Attribution Register (DMACCHSAR) 991
18.2.2 DMA Controller Security Attribution Register (DMACSAR) 992
18.2.3 DMA Source Address Register (DMSAR) 993
18.2.4 DMA Source Reload Address Register (DMSRR) 994
18.2.5 DMA Destination Address Register (DMDAR) 995
18.2.6 DMA Destination Reload Address Register (DMDRR) 996
18.2.7 DMA Transfer Count Register (DMCRA) 997
18.2.8 DMA Block Transfer Count Register (DMCRB) 998
18.2.9 DMA Transfer Mode Register (DMTMD) 999
18.2.10 DMA Interrupt Setting Register (DMINT) 1000
18.2.11 DMA Address Mode Register (DMAMD) 1002
18.2.12 DMA Offset Register (DMOFR) 1005
18.2.13 DMA Transfer Enable Register (DMCNT) 1006
18.2.14 DMA Software Start Register (DMREQ) 1007
18.2.15 DMA Status Register (DMSTS) 1008
18.2.16 DMAC Trigger Source Flag Control Register (DMCSL) 1009
18.2.17 DMA Source Buffer Size Register (DMSBS) 1010
18.2.18 DMA Destination Buffer Size Register (DMDBS) 1011
18.2.19 DMA Bufferable Write Enable Register (DMBWR) 1012
18.2.20 DMAC Module Start Register (DMAST) 1013
18.2.21 DMAC Error Channel Register (DMECHR) 1014
18.2.22 DMAC74 Interrupt Status Monitor Register (DMIST) 1016
18.2.23 DMAC Control Register (DMCTL) 1017
18.3 Operation 1018
18.3.1 Transfer Mode 1018
18.3.2 Extended Repeat Area Function 1028
18.3.3 Free-Running Function 1030
18.3.4 Address Update Function using Offset 1032
18.3.5 Address-Update Function in Repeat-Block Transfer Mode 1036

18.3.6 Example of Using Repeat-Block Transfer Mode 1040
18.3.7 Trigger Sources 1042
18.3.8 Operation Timing 1043
18.3.9 Activating the DMAC 1044
18.3.10 Starting DMA Transfer 1046
18.3.11 Registers during DMA Transfer 1046
18.3.12 Channel Priority 1047
18.3.13 Channel Security 1047
18.4 Ending DMA Transfer 1048
18.4.1 Transfer End by Completion of Specified Total Number of Transfer Operations 1048
18.4.2 Transfer End by Repeat Size End Interrupt 1048
18.4.3 Transfer End by Interrupt on Extended Repeat Area Overflow 1049
18.5 Processing on DMA Transfer Error 1050
18.6 Interrupts 1051
18.6.1 Transfer End Interrupt 1051
18.6.2 Transfer Error Interrupt 1053

20.1 Overview 1119
20.2 Register Descriptions 1121
20.2.1 DTC Mode Register A (MRA) 1121
20.2.2 DTC Mode Register B (MRB) 1123
20.2.3 DTC Mode Register C (MRC) 1125
20.2.4 DTC Transfer Source Register (SAR) 1126
20.2.5 DTC Transfer Destination Register (DAR) 1126
20.2.6 DTC Transfer Count Register A (CRA) 1127

20.2.7 DTC Transfer Count Register B (CRB) 1128
20.2.8 DTC Control Register for Secure Application (DTCCR_S), DTC Control Register for Non-secure Application (DTCCR_NS) 1128
20.2.9 DTC Vector Base Register for Secure Application (DTCVBR_S), DTC Vector Base Register for Non-secure Application (DTCVBR_NS) 1129
20.2.10 DTC Module Start Register (DTCST) 1130
20.2.11 DTC Status Register (DTCSTS) 1131
20.2.12 DTC Index Table Base Register (DTCIBR) 1132
20.2.13 DTC Operation Register (DTCOR) 1133
20.2.14 DTC Sequence Transfer Enable Register (DTCSQE) 1134
20.2.15 DTC Address Displacement Register (DTCDISP) 1134
20.2.16 DTC Error Vector Register (DTCEVR) 1135
20.2.17 DTC Security Attribution Register (DTCSAR) 1136
20.3 Request Sources 1137
20.3.1 Allocating Transfer Information and DTC Vector Table 1137
20.4 Operation 1139
20.4.1 Transfer Information Read Skip Function 1141
20.4.2 Transfer Information Write-Back Skip Function 1142
20.4.2.1 Write-Back Skip by Fixing Addresses 1142
20.4.2.2 Write-Back Skip by the MRA.WBDIS Bit 1142
20.4.3 Normal Transfer Mode 1143
20.4.4 Repeat Transfer Mode 1144
20.4.5 Block Transfer Mode 1145
20.4.6 Chain Transfer 1146
20.4.7 Operation Timing 1147
20.4.8 Sequence Transfer 1149
20.4.9 DTC Index Table 1151
20.4.10 Example of Sequence Transfer 1153
20.5 DTC Setting Procedure 1159
20.6 Examples of DTC Usage 1160
20.6.1 Normal Transfer 1160
20.6.2 Chain Transfer 1160
20.6.3 Chain Transfer When the Counter is 0 1162
20.6.4 Sequence Transfer 1163
20.7 Interrupt Source 1164
20.8 Event Link 1164
20.9 Low Power Consumption Function 1165
20.10 Usage Notes 1166
20.10.1 Start Address of Transfer Information 1166
20.10.2 Allocating Transfer Information 1166
20.10.3 Setting the DTC Transfer Request Enable Register in the Interrupt Controller (ICU.DTCERn) 1166

20.10.4 Notes on Using the Sequence Transfer 1166
21. Event Link Controller (ELC) 1167
21.1 Overview 1167
21.2 Register Descriptions 1168
21.2.1 ELC Security Attribution Register A (ELCSARA) 1168
21.2.2 ELC Security Attribution Register B (ELCSARB) 1169
21.2.3 ELC Security Attribution Register C (ELCSARC) 1170
21.2.4 ELC Security Attribution Register D (ELCSARD) 1171
21.2.5 Event Link Control Register (ELCR) 1172
21.2.6 Software Event Generation Register m (ELSEGRm) (m = 0 to 3) 1173
21.2.7 Event Link Setting Register n (ELSRn) (n = 0 to 26, 46, 47, 50 to 52, 73 to 78, 88 to 91) 1174
21.2.8 Event Link Option Setting Register A (ELOPA) 1185
21.2.9 Event Link Option Setting Register B (ELOPB) 1185
21.2.10 Event Link Option Setting Register C (ELOPC) 1186
21.2.11 Event Link Option Setting Register D (ELOPD) 1187
21.3 Operation 1188
21.3.1 Relation between Interrupt Handling and Event Linking 1188
21.3.2 Event Linkage 1189
21.3.3 Operation of Peripheral Timer Modules When Event Signal is Input 1190
21.3.4 Operation of GPTW When Event Signal is Input 1190
21.3.5 Operation of A/D and D/A Converters When Event Signal is Input 1190
21.3.6 Example of Procedure for Linking Events 1191
21.4 Usage Notes 1192
21.4.1 Setting ELSR88, ELSR89, ELSR90, and ELSR91 Registers 1192
21.4.2 Linking DMA/DTC Transfer End Signal as Event 1192
21.4.3 Clock Settings 1192
21.4.4 Module Stop Function Setting 1192
21.4.5 Internal Propagation Delay Times in the ELC 1193
22. I/O Ports 1194
22.1 Overview 1194
22.2 Configuration of I/O Ports 1197
22.3 Register Descriptions 1198
22.3.1 Port Control Register 1 (PCNTR1) 1198
22.3.2 Port Direction Register (PDR) 1200
22.3.3 Port Output Data Register (PODR) 1201
22.3.4 Port Control Register 2 (PCNTR2) 1202
22.3.5 Port Input Data Register (PIDR) 1203
22.3.6 Port Event Input Data Register (EIDR) 1204
22.3.7 Port Control Register 3 (PCNTR3) 1205
22.3.8 Port Output Set Register (POSR) 1207
22.3.9 Port Output Reset Register (PORR) 1208

22.3.10 Port Control Register 4 (PCNTR4) ... 1209
22.3.11 Event Output Set Register (EOSR) ... 1210
22.3.12 Event Output Reset Register (EORR) ... 1211
22.3.13 Pmn Pin Function Selection Register (PmnPFS) (m = 0 to 9, A to G; n = 00 to 15) ... 1212
22.3.14 Non-secure World Write Protection Register (PWPR_NS) ... 1241
22.3.15 Secure World Write Protection Register (PWPR_S) ... 1242
22.3.16 Port m Security Attribute Setting Register (PmSAR) (m = 0 to 9, A to G) ... 1243
22.3.17 Low-Voltage Operating Characteristics Control Register (LVOCR) ... 1244
22.4 Operation ... 1245
22.4.1 General-Purpose I/O Port ... 1245
22.4.2 Selecting Pin Functions ... 1245
22.4.3 Port Group Function of the ELC ... 1245
22.4.3.1 Operation when the ELC_PORTn (n = B to E) Signal is Input from the ELC ... 1245
22.4.3.2 Operation when an Event Pulse is Applied to the ELC ... 1247
22.5 Handling of Unused Pins ... 1248
22.6 Notes ... 1250
22.6.1 Procedure for Setting Pin Functions ... 1250
22.6.2 Procedure for Using the Event Output Function to ELC ... 1250
22.6.3 Method of Setting the Port Output Data Register (PODR) ... 1250
22.6.4 Note on Using Analog Functions ... 1251
22.6.5 Notes on Using the RTC Time-Capture Event Inputs and Tampering Detection ... 1251
22.6.6 Selecting the USB0_DP and USB0_DM Pins ... 1251
22.6.7 Pulling the PF00 and PF01 Pins Used for USB or General I/O Signals Up or Down ... 1252
22.6.8 Note on Using the NMI Pin ... 1252
22.6.9 Note on Using the Main Clock Oscillator ... 1252
22.6.10 Note on Using the Sub-Clock Oscillator ... 1252
22.6.11 Initialization of the Port Direction Register (PDR) ... 1253
23. Software Configurable 32-Bit Programmable I/O Port (PIO) ... 1256
23.1 Overview ... 1256
23.2 Register Descriptions ... 1257
23.2.1 PIO Operation Enable Register (PIOENR) ... 1257
23.2.2 PIO Port Input Enable Register (PIOIER) ... 1259
23.2.3 PIO Port Output Enable Register (PIOOER) ... 1260
23.2.4 PIO Port Input Data Register (PIOIDR) ... 1261
23.2.5 PIO Port Output Data Register (PIOODR) ... 1262
23.2.6 PIO Port Output Setting Register (PIOOSR) ... 1263
23.2.7 PIO Port Output Resetting Register (PIOORR) ... 1265
23.2.8 PIO Port Selection Register 0 (PIOSEL0) ... 1267
23.2.9 PIO Port Selection Register 1 (PIOSEL1) ... 1267
23.2.10 PIO Port Selection Register 2 (PIOSEL2) ... 1268

23.2.11 PIO Port Selection Register 3 (PIOSEL3) 1268
23.2.12 PIO Port Selection Register 4 (PIOSEL4) 1269
23.2.13 PIO Port Selection Register 5 (PIOSEL5) 1269
23.2.14 PIO Port Selection Register 6 (PIOSEL6) 1270
23.2.15 PIO Port Selection Register 7 (PIOSEL7) 1270
23.3 Operation 1271
23.3.1 Input 1271
23.3.2 Output 1271
23.4 Initial Settings 1272
24. General PWM Timer (GPTW) 1273
24.1 Overview 1273
24.2 Register Descriptions 1281
24.2.1 General PWM Timer Write-Protection Register (GTWP) 1281
24.2.2 General PWM Timer Software Start Register (GTSTR) 1284
24.2.3 General PWM Timer Software Stop Register (GTSTP) 1285
24.2.4 General PWM Timer Software Clear Register (GTCLR) 1287
24.2.5 General PWM Timer Start Source Select Register (GTSSR) 1288
24.2.6 General PWM Timer Stop Source Select Register (GTPSR) 1290
24.2.7 General PWM Timer Clear Source Select Register (GTCSR) 1292
24.2.8 General PWM Timer Count-Up Source Select Register (GTUPSR) 1296
24.2.9 General PWM Timer Count-Down Source Select Register (GTDNSR) 1299
24.2.10 General PWM Timer Input Capture Source Select Register A (GTICASR) 1302
24.2.11 General PWM Timer Input Capture Source Select Register B (GTICBSR) 1305
24.2.12 General PWM Timer Switch Source Select Register (GTSWSR) 1308
24.2.13 General PWM Timer Switch Offset Setting Register (GTSWOS) 1310
24.2.14 General PWM Timer Control Register (GTCR) 1311
24.2.15 General PWM Timer Count Direction and Duty Setting Register (GTUDDTYC) 1318
24.2.16 General PWM Timer I/O Control Register (GTIOR) 1321
24.2.17 General PWM Timer Interrupt Output Setting Register (GTINTAD) 1326
24.2.18 General PWM Timer Status Register (GTST) 1330
24.2.19 General PWM Timer Buffer Enable Register (GTBER) 1336
24.2.20 General PWM Timer Buffer Enable Register 2 (GTBER2) 1340
24.2.21 General PWM Timer Interrupt and A/D Conversion Start Request Skipping Setting Register (GTITC) 1345
24.2.22 General PWM Timer Counter (GTCNT) 1347
24.2.23 General PWM Timer Compare Capture Register m (GTCCRm) (m = A to F) 1348
24.2.24 General PWM Timer Period Setting Register (GTPR) 1349
24.2.25 General PWM Timer Period Setting Buffer Register (GTPBR) 1349
24.2.26 General PWM Timer Period Setting Double-Buffer Register (GTPDBR) 1350
24.2.27 A/D Conversion Start Request Timing Register m (GTADTRm) (m = A, B) 1351
24.2.28 A/D Conversion Start Request Timing Buffer Register m (GTADTBRm) (m = A, B) 1352

24.2.29 A/D Conversion Start Request Timing Double-Buffer Register m (GTADTDBRm) (m = A, B) ... 1353
24.2.30 General PWM Timer Dead Time Control Register (GTDTCR) ... 1354
24.2.31 General PWM Timer Dead Time Value Register m (GTDVm) (m = U, D) ... 1356
24.2.32 General PWM Timer Dead Time Value Buffer Register m (GTDBm) (m = U, D) ... 1357
24.2.33 General PWM Timer Output Protection Function Status Register (GTSOS) ... 1358
24.2.34 General PWM Timer Output Protection Function Temporary Release Register (GTSOTR) ... 1359
24.2.35 General PWM Timer A/D Conversion Start Request Signal Monitoring Register (GTADSMR) ... 1360
24.2.36 General PWM Timer Extended Interrupt Skipping Counter Control Register (GTEITC) ... 1362
24.2.37 General PWM Timer Extended Interrupt Skipping Setting Register 1 (GTEITLI1) ... 1365
24.2.38 General PWM Timer Extended Interrupt Skipping Setting Register 2 (GTEITLI2) ... 1367
24.2.39 General PWM Timer Extended Buffer Transfer Skipping Setting Register (GTEITLB) ... 1369
24.2.40 General PWM Timer Inter Channel Logical Operation Function Setting Register (GTICLF) ... 1372
24.2.41 General PWM Timer Cycle Count Register (GTPC) ... 1374
24.2.42 General PWM Timer A/D Conversion Start Request Compare Match Skipping Control Register (GTADCMSC) ... 1376
24.2.43 General PWM Timer A/D Conversion Start Request Compare Match Skipping Setting Register (GTADCMSS) ... 1378
24.2.44 General PWM Timer Operation Enable Bit Simultaneous Control Channel Select Register (GTSECSR) ... 1381
24.2.45 General PWM Timer Operation Enable Bit Simultaneous Control Register (GTSECR) ... 1383
24.2.46 General PWM Timer Output Level Buffer Register (GTOLBR) ... 1386
24.2.47 General PWM Timer Inter Channel Cooperation Input Capture Control Register (GTICCR) ... 1387
24.2.48 General PWM Timer-linked Synchronization Control Register (GTSYNCFCR) ... 1391
24.2.49 General PWM Timer-linked Synchronization Signal Output Control Register (GTSYNCSCR) ... 1392
24.2.50 Output Phase Switching Control Register (OPSCR) ... 1393
24.2.51 General PWM Timer Clock Control Register (GTCLKCR) ... 1396
24.3 Operation ... 1397
24.3.1 Basic Operation ... 1397
24.3.1.1 Counter Operation ... 1397
24.3.1.2 Waveform Output by Compare Match ... 1406
24.3.1.3 Input Capture Function ... 1410
24.3.2 Buffer Operation ... 1415
24.3.2.1 GTPR Register Buffer Operation ... 1415
24.3.2.2 Buffer Operation for the GTCCRA and GTCCRB Registers ... 1421
24.3.2.3 Buffer Operation for the GTADTRA and GTADTRB Registers ... 1427
24.3.2.4 Buffer Operation for the GTIOA[4:0] and GTIOB[4:0] Bits ... 1431
24.3.3 PWM Output Operating Mode ... 1434
24.3.3.1 Sawtooth-Wave PWM Mode 1 ... 1434

24.3.3.2 Sawtooth-Wave PWM Mode 2 ... 1437
24.3.3.3 Sawtooth-Wave One-Shot Pulse Mode ... 1441
24.3.3.4 Triangle-Wave PWM Mode 1 (32-Bit Transfer at Trough) ... 1444
24.3.3.5 Triangle-Wave PWM Mode 2 (32-Bit Transfer at Crest and Trough) ... 1446
24.3.3.6 Triangle-Wave PWM Mode 3 (64-Bit Transfer at Trough) ... 1448
24.3.3.7 Complementary PWM mode 1, 2, 3 ... 1451
24.3.3.8 Complementary PWM Mode 4 ... 1475
24.3.4 Automatic Dead Time Setting Function ... 1490
24.3.5 Count Direction Changing Function ... 1495
24.3.6 Duty Cycle 0%/100% Output Function ... 1496
24.3.7 Hardware Count Start/Count Stop and Clear Operation ... 1500
24.3.7.1 Hardware Start Operation ... 1500
24.3.7.2 Hardware Stop Operation ... 1504
24.3.7.3 Hardware Clear Operation ... 1509
24.3.8 Hardware Count Switch Operation ... 1515
24.3.9 Inter-Channel Synchronous Operation ... 1525
24.3.9.1 Software Control of Inter-Channel Synchronous Operation ... 1525
24.3.9.2 Hardware Source Control of Inter-Channel Synchronous Operation ... 1529
24.3.9.3 Synchronous Clear Operation by Inter Channel Cooperation ... 1533
24.3.9.4 Input Capture Operation by Inter Channel Cooperation ... 1537
24.3.10 PWM Output Operation Examples ... 1539
24.3.11 Cycle Count Function ... 1545
24.3.12 Phase Counting Mode ... 1546
24.3.13 External Pulse Width Measuring Function ... 1554
24.3.14 Output Phase Switching Control Function (OPS) ... 1556
24.3.14.1 Input Selection and Sampling ... 1558
24.3.14.2 Rotation Direction Control ... 1559
24.3.14.3 Input Phase Decode ... 1559
24.3.14.4 Output Selection Control ... 1560
24.3.14.5 Output Selection Control (Group Output Disable Function) ... 1561
24.3.14.6 Event Link Controller (ELC) Output ... 1561
24.3.14.7 OPS Start Operation Setting Flow ... 1561
24.3.15 Inter Channel Logical Operation Function ... 1562
24.3.16 GTIOCnA/GTIOCnB Input/Output Pin Polarity Reversal Function ... 1564
24.3.17 Timer-Linked Synchronization Signal Output Function ... 1565
24.4 Interrupt Sources ... 1570
24.4.1 Interrupt Sources and Priorities ... 1570
24.4.2 DMAC/DTC Activation ... 1574
24.4.3 Interrupt and A/D Conversion Start Request Skipping Function ... 1574
24.4.3.1 Interrupt Skipping Function by GTITC Register ... 1574
24.4.3.2 Extended Interrupt Skipping Function ... 1578

24.4.3.3 A/D conversion Start Request Compare Match Skipping Function 1590
24.5 A/D Conversion Start Request 1595
24.6 Operations Linked by the ELC 1599
24.6.1 Event Signal Output to the ELC 1599
24.6.2 GPTW Operations in Response to Receiving Event Signals from the ELC 1599
24.7 Noise Filter Function 1600
24.8 Protection Function 1601
24.8.1 Write-Protection for Registers 1601
24.8.2 Disabling of Buffer Operation 1601
24.8.2.1 Simultaneous Control of Buffer Operations of Multiple Channels 1603
24.8.2.2 Repeated Double-Buffered Operation When Disabling GTCCR Buffer Transfer 1606
24.8.3 GTIOCnm Pin Output Negate Control (n = 0 to 15; m = A, B) 1612
24.8.4 Output Protection Function for GTIOCnm Pin Output (n = 0 to 15; m = A, B) 1613
24.9 Initialization Method of Output Pins 1619
24.9.1 Pin Settings after Reset 1619
24.9.2 Pin Initialization Due to Error during Operation 1619
24.10 Usage Notes 1620
24.10.1 Module Stop Function Setting 1620
24.10.2 Settings of the GTCCRm Register during Compare Match Operation (m = A to F) 1620
24.10.3 Range of Settings for the GTPBR and GTPDBR Registers in the Complementary PWM Mode 1621
24.10.4 Setting Range of the GTCNT Counter 1621
24.10.5 The GTCNT Counter Start/Stop 1622
24.10.6 Order of Priority in Events 1622
24.10.7 Note on Counter Clearing in the Complementary PWM Mode 1623
24.10.8 Note on Disabling PWM Initial Output After Synchronous Clearing in the Complementary PWM Mode 1623
24.10.9 Correspondence to Count Switch Operation of Each Function 1623
24.10.10 Note on Transitions to Software Standby Mode 1625
24.10.11 Interval between Interrupt Requests 1625
25. High Resolution PWM Waveform Generation Circuit (HRPWMb) 1626
25.1 Overview 1626
25.2 Register Descriptions 1628
25.2.1 HRPWM Operation Control Register (HROCR) 1628
25.2.2 HRPWM Operation Control Register 2 (HROCR2) 1629
25.2.3 GTIOCnA Pin Rising Edge Adjustment Register (HRREARnA) (n = 0 to 3) 1630
25.2.4 GTIOCnA Pin Falling Edge Adjustment Register (HRFEARnA) (n = 0 to 3) 1631
25.2.5 GTIOCnB Pin Rising Edge Adjustment Register (HRREARnB) (n = 0 to 3) 1632
25.2.6 GTIOCnB Pin Falling Edge Adjustment Register (HRFEARnB) (n = 0 to 3) 1633
25.3 Operation 1634
25.3.1 Adjustment to the Timing of Rising and Falling Edges in PWM Waveforms 1634

25.3.2 Transfer Timing of HRREARnA, HRREARnB, HRFEARnA, and HRFEARnB Register Settings (n = 0 to 3) ... 1636
25.4 Usage Notes ... 1638
25.4.1 Settings for the Module-Stop Function ... 1638
25.4.2 Note on Selecting Timer Prescaler in the GTCNT Counter While Using the HRPWM ... 1638
25.4.3 Notes on Delay Settings for HRPWM ... 1638
26. GPTW Port Output Enable (POEGd) ... 1639
26.1 Overview ... 1639
26.2 Register Descriptions ... 1642
26.2.1 POEG Group x Setting Register (POEGGx) (x = A to D) ... 1642
26.2.2 POEGx Pin Input Control Register (POEGPICRx) (x = A to D) ... 1644
26.3 Operation ... 1646
26.3.1 Output Disabling Request by Detection of Input Level on the GTETRGx Pin (x = A to D) ... 1646
26.3.1.1 Digital Noise Filter ... 1646
26.3.2 Output Disabling Request by Detection of Input Level or Input Edge on the POEGx Pin (x = A to D) ... 1647
26.3.2.1 Digital Noise Filter ... 1647
26.3.3 Output Disabling Request by Output Disabling Condition Detection Signal from GPTW ... 1647
26.3.4 Output Disabling Request by Oscillation Stop Detection Signal ... 1648
26.3.5 Output Disabling Request by a Register ... 1648
26.3.6 Canceling Output Disabling Request ... 1649
26.3.6.1 Cancellation of Output Disabling Request by Reset ... 1649
26.3.6.2 Cancellation of Output Disabling Request by Clearing Flags in the POEGGx or POEGPICRx Register ... 1649
26.4 Interrupt Sources ... 1650
26.5 External Trigger Output to GPTW ... 1651
26.6 Usage Notes ... 1651
26.6.1 Transitions to Low-Power Consumption Mode ... 1651
26.6.2 Setting the Function for Stopping the Module ... 1651
26.6.3 Duplication of Output Disabling Request ... 1651
27. 8-Bit Timer (TMRa) ... 1652
27.1 Overview ... 1652
27.2 Register Descriptions ... 1657
27.2.1 Timer Counter (TCNT) ... 1657
27.2.2 Time Constant Register A (TCORA) ... 1658
27.2.3 Time Constant Register B (TCORB) ... 1658
27.2.4 Timer Control Register (TCR) ... 1659
27.2.5 Timer Counter Control Register (TCCR) ... 1660
27.2.6 Timer Control/Status Register (TCSR) ... 1662
27.2.7 Timer Counter Start Register (TCSTR) ... 1664
27.3 Operation ... 1665

27.3.1 Pulse Output 1665
27.3.2 External Counter Reset Input 1666
27.4 Operation Timing 1667
27.4.1 TCNT Count Timing 1667
27.4.2 Timing of Interrupt Signal Output on a Compare Match 1668
27.4.3 Timing of Timer Output Signal at Compare Match 1668
27.4.4 Timing of Counter Clear by Compare Match 1669
27.4.5 Timing of the External Reset for TCNT 1669
27.4.6 Timing of Interrupt Signal Output on an Overflow 1670
27.5 Operation with Cascaded Connection 1671
27.5.1 16-Bit Count Mode 1671
27.5.2 Compare Match Count Mode 1671
27.6 Interrupt Sources 1672
27.6.1 Interrupt Sources and DTC Activation 1672
27.7 Link Operation by ELC 1673
27.7.1 Event Signal Output to ELC 1673
27.7.2 TMR Operation when Receiving an Event Signal from ELC 1673
27.7.3 Notes on Operating TMR According to an Event Signal from ELC 1674
27.8 Usage Notes 1675
27.8.1 Module Stop State Setting 1675
27.8.2 Notes on Setting Cycle 1675
27.8.3 Conflict between TCNT Write and Counter Clear 1675
27.8.4 Conflict between TCNT Write and Increment 1676
27.8.5 Conflict between TCORA or TCORB Write and Compare Match 1676
27.8.6 Conflict between Compare Matches A and B 1677
27.8.7 Switching of Internal Clocks and TCNT Operation 1677
27.8.8 Clock Source Setting with Cascaded Connection 1679
27.8.9 Continuous Output of Compare Match Interrupt Signal 1679
27.8.10 Transition to Software Standby Mode 1679
28. Compare Match Timer (CMT) 1680
28.1 Overview 1680
28.2 Register Descriptions 1682
28.2.1 Compare Match Timer Start Register 0 (CMSTR0) 1682
28.2.2 Compare Match Timer Start Register 1 (CMSTR1) 1682
28.2.3 Compare Match Timer Control Register (CMCR) 1683
28.2.4 Compare Match Counter (CMCNT) 1684
28.2.5 Compare Match Constant Register (CMCOR) 1684
28.3 Operation 1685
28.3.1 Cyclic Count Operation 1685
28.3.2 CMCNT Count Timing 1685
28.4 Interrupts 1686

28.4.1 Interrupt Sources ... 1686
28.4.2 Timing of Compare Match Interrupt Generation ... 1686
28.5 Link Operations by ELC ... 1687
28.5.1 Event Signal Output to ELC ... 1687
28.5.2 CMT Operation When Receiving an Event Signal from ELC ... 1687
28.5.3 Notes on Operating CMT According to an Event Signal from ELC ... 1687
28.6 Usage Notes ... 1688
28.6.1 Setting the Module Stop Function ... 1688
28.6.2 Conflict between CMCNT Counter Writing and Compare Match ... 1688
28.6.3 Conflict between CMCNT Counter Writing and Incrementing ... 1688
28.6.4 Transition to Software Standby Mode ... 1689
29. Compare Match Timer W (CMTW) ... 1690
29.1 Overview ... 1690
29.2 Register Descriptions ... 1693
29.2.1 Timer Start Register (CMWSTR) ... 1693
29.2.2 Timer Control Register (CMWCR) ... 1694
29.2.3 Timer I/O Control Register (CMWIOR) ... 1696
29.2.4 Timer Counter (CMWCNT) ... 1697
29.2.5 Compare Match Constant Register (CMWCOR) ... 1697
29.2.6 Input Capture Register n (CMWICRn) (n = 0, 1) ... 1698
29.2.7 Output Compare Register n (CMWOCRn) (n = 0, 1) ... 1698
29.3 Operation ... 1699
29.3.1 Cyclic Count Operation ... 1699
29.3.2 Compare Match Function ... 1699
29.3.3 Output Compare Function ... 1701
29.3.4 Input Capture Function ... 1702
29.3.5 Counter Size ... 1703
29.3.6 Count Timing of CMWCNT Counter ... 1703
29.3.7 Output Compare Output Timing ... 1703
29.3.8 Input Capture Timing ... 1704
29.4 Interrupts ... 1705
29.4.1 CMTW Interrupt Sources and DTC/DMAC Transfer Requests ... 1705
29.4.2 Timing of Compare Match Interrupt Generation ... 1706
29.5 Link Operations by ELC ... 1708
29.5.1 Event Signal Output to ELC ... 1708
29.5.2 CMTW Operation When Receiving an Event Signal from ELC ... 1709
29.5.3 Conflict between Event Link Operation and Register Access ... 1711
29.6 Usage Notes ... 1713
29.6.1 Setting the Module Stop Function ... 1713
29.6.2 Conflict between CMWCNT Counter Writing and Compare Match ... 1713
29.6.3 Conflict between CMWCNT Counter Writing and Incrementing or Clearing ... 1714

29.6.4 Conflict between CMWCOR Register Writing and Compare Match 1714
29.6.5 Conflict between CMWOCRn Register Writing and Compare Match (n = 0, 1) 1715
29.6.6 Conflict between CMWCNT Counter Reading and Incrementing or Clearing 1715
29.6.7 Conflict between CMWICRn Register Reading and Input Capture (n = 0, 1) 1716
29.6.8 Transition to Software Standby Mode 1716
30. Realtime Clock (RTCBb) 1717
30.1 Overview 1717
30.2 Register Descriptions 1719
30.2.1 64-Hz Counter (R64CNT) 1719
30.2.2 Second Counter (RSECCNT)/Binary Counter 0 (BCNT0) 1720
30.2.3 Minute Counter (RMINCNT)/Binary Counter 1 (BCNT1) 1721
30.2.4 Hour Counter (RHRCNT)/Binary Counter 2 (BCNT2) 1722
30.2.5 Day-of-Week Counter (RWKCNT)/Binary Counter 3 (BCNT3) 1723
30.2.6 Date Counter (RDAYCNT) 1724
30.2.7 Month Counter (RMONCNT) 1725
30.2.8 Year Counter (RYRCNT) 1726
30.2.9 Second Alarm Register (RSECAR)/ Binary Counter 0 Alarm Register (BCNT0AR) 1727
30.2.10 Minute Alarm Register (RMINAR)/ Binary Counter 1 Alarm Register (BCNT1AR) 1728
30.2.11 Hour Alarm Register (RHRAR)/ Binary Counter 2 Alarm Register (BCNT2AR) 1729
30.2.12 Day-of-Week Alarm Register (RWKAR)/ Binary Counter 3 Alarm Register (BCNT3AR) 1730
30.2.13 Date Alarm Register (RDAYAR)/ Binary Counter 0 Alarm Enable Register (BCNT0AER) 1731
30.2.14 Month Alarm Register (RMONAR)/ Binary Counter 1 Alarm Enable Register (BCNT1AER) 1732
30.2.15 Year Alarm Register (RYRAR)/ Binary Counter 2 Alarm Enable Register (BCNT2AER) 1733
30.2.16 Year Alarm Enable Register (RYRAREN)/ Binary Counter 3 Alarm Enable Register (BCNT3AER) 1734
30.2.17 RTC Control Register 1 (RCR1) 1735
30.2.18 RTC Control Register 2 (RCR2) 1737
30.2.19 RTC Control Register 4 (RCR4) 1739
30.2.20 Frequency Register H/L (RFRH/RFRL) 1739
30.2.21 Time Error Adjustment Register (RADJ) 1741
30.2.22 Time Capture Control Register n (RTCCRn) (n = 0 to 2) 1742
30.2.23 Second Capture Register n (RSECCPn) (n = 0 to 2)/ BCNT0 Capture Register n (BCNT0CPn) (n = 0 to 2) 1744
30.2.24 Minute Capture Register n (RMINCPn) (n = 0 to 2)/ BCNT1 Capture Register n (BCNT1CPn) (n = 0 to 2) 1745
30.2.25 Hour Capture Register n (RHRCPn) (n = 0 to 2)/ BCNT2 Capture Register n (BCNT2CPn) (n = 0 to 2) 1746

30.2.26 Date Capture Register n (RDAYCPn) (n = 0 to 2)/ BCNT3 Capture Register n (BCNT3CPn) (n = 0 to 2) ... 1747
30.2.27 Month Capture Register n (RMONCPn) (n = 0 to 2) ... 1748
30.3 Operation ... 1749
30.3.1 Outline of Initial Settings of Registers after Power On ... 1749
30.3.2 Clock and Count Mode Setting Procedure ... 1750
30.3.3 Setting the Time ... 1753
30.3.4 30-Second Adjustment ... 1755
30.3.5 Reading 64-Hz Counter and Time ... 1756
30.3.6 Alarm Function ... 1757
30.3.7 Procedure for Disabling Alarm Interrupt ... 1758
30.3.8 Time Error Adjustment Function ... 1758
30.3.8.1 Automatic Adjustment ... 1758
30.3.8.2 Adjustment by Software ... 1759
30.3.8.3 Procedure for Changing the Mode of Adjustment ... 1760
30.3.8.4 Procedure for Stopping Adjustment ... 1760
30.3.9 Time Capture Function ... 1761
30.4 Interrupt Sources ... 1762
30.5 Event Link Output ... 1764
30.5.1 Interrupt Handling and Event Linking ... 1764
30.6 Usage Notes ... 1765
30.6.1 Register Writing during Counting ... 1765
30.6.2 Use of Periodic Interrupts ... 1765
30.6.3 RTCOUT (1-Hz/64-Hz) Clock Output ... 1765
30.6.4 Transitions to Low Power Consumption Modes after Setting Registers ... 1766
30.6.5 Notes on Writing to and Reading from Registers ... 1766
30.6.6 Changing the Count Mode ... 1766
30.6.7 Notes on Using the Time Capture Function ... 1766
30.6.8 Initialization Procedure When the Realtime Clock is Not to be Used ... 1767
31. Watchdog Timer (WDTA) ... 1769
31.1 Overview ... 1769
31.2 Register Descriptions ... 1771
31.2.1 WDT Refresh Register (WDTRR) ... 1771
31.2.2 WDT Control Register (WDTCR) ... 1772
31.2.3 WDT Status Register (WDTSR) ... 1775
31.2.4 WDT Reset Control Register (WDTRCR) ... 1776
31.2.5 WDT Count Stop Control Register (WDTCSTPR) ... 1777
31.2.6 Option Function Select Register 0 (OFS0) ... 1777
31.3 Operation ... 1778
31.3.1 Count Operation in Each Start Mode ... 1778
31.3.1.1 Register Start Mode ... 1778

31.3.1.2 Auto-Start Mode ... 1780
31.3.2 Refresh Operation ... 1781
31.3.3 Reset Output ... 1782
31.3.4 Interrupt Source ... 1782
31.3.5 Reading the Counter Value ... 1782
31.3.6 Correspondence between Option Function Select Register 0 (OFS0) and WDT Registers ... 1783
31.4 Link Operation by ELC ... 1783
32. Independent Watchdog Timer (IWDTa) ... 1784
32.1 Overview ... 1784
32.2 Register Descriptions ... 1786
32.2.1 IWDT Refresh Register (IWDTRR) ... 1786
32.2.2 IWDT Control Register (IWDTCR) ... 1787
32.2.3 IWDT Status Register (IWDTSR) ... 1790
32.2.4 IWDT Reset Control Register (IWDTRCR) ... 1791
32.2.5 IWDT Count Stop Control Register (IWDTCSTPR) ... 1792
32.2.6 Option Function Select Register 0 (OFS0) ... 1792
32.3 Operation ... 1793
32.3.1 Count Operation in Each Start Mode ... 1793
32.3.1.1 Register Start Mode ... 1793
32.3.1.2 Auto-Start Mode ... 1795
32.3.2 Refresh Operation ... 1796
32.3.3 Status Flags ... 1798
32.3.4 Reset Output ... 1798
32.3.5 Interrupt Sources ... 1798
32.3.6 Reading the Counter Value ... 1799
32.3.7 Correspondence between Option Function Select Register 0 (OFS0) and IWDT Registers ... 1800
32.4 Link Operation by ELC ... 1800
32.5 Usage Notes ... 1801
32.5.1 Refresh Operations ... 1801
32.5.2 Count Clock Frequency Setting ... 1801
32.5.3 Reading Counter after Returning from Deep Software Standby Mode 1 ... 1801
32.5.4 Transitions to Low Power Consumption Mode ... 1801
33. Ethernet Module ... 1802
33.1 Overview ... 1802
33.2 Register Description ... 1806
33.2.1 ESWM Interface Control Registers ... 1806
33.2.1.1 Media Interface Reset Register (MIIRR) ... 1806
33.2.1.2 Media Interface Control Register 0 (MIICR0) ... 1807
33.2.1.3 Media Clock Capture Event Select Register (MCCESR) ... 1808
33.2.1.4 TAS Status Monitor Signal Select Register (TASSTSR) ... 1809

33.2.1.5 Ether Bus Control Register (ETHBUSCR) ... 1810
33.2.2 Interrupt Mapping Function Registers ... 1811
33.2.2.1 Error and Status Interrupt Mapping Register 1 (TPEMIMC1) ... 1811
33.2.2.2 Error and Status Interrupt Mapping Register 2 (TPEMIMC2) ... 1813
33.2.2.3 Error and Status Interrupt Mapping Register 3 (TPEMIMC3) ... 1814
33.2.2.4 Error and Status Interrupt Mapping Register 6n (TPEMIMC6n) (n = 0, 1) ... 1815
33.2.2.5 Error and Status Interrupt Mapping Register 7n (TPEMIMC7n) (n = 0 to 63) ... 1816
33.2.3 Interrupt Mirroring Registers ... 1817
33.2.3.1 ESWM Interrupt Mirroring Register (TSIM) ... 1817
33.2.3.2 MFWD Interrupt Mirroring Register (TFIM) ... 1818
33.2.3.3 COMA Interrupt Mirroring Register (TCIM) ... 1819
33.2.3.4 GWCA0 Interrupt Mirroring Register (TGIM0) ... 1820
33.2.3.5 ETHA0 Interrupt Mirroring Register (TEIM0) ... 1821
33.3 Operation ... 1822
33.3.1 Operating Clocks ... 1822
33.3.2 Interface Modes ... 1822
33.3.2.1 MII/GMII Interface ... 1822
33.3.2.2 RGMII Interface ... 1823
33.3.2.3 RMII Interface ... 1823
33.3.2.4 MAC-to-MAC Connection ... 1823
33.3.3 Software Flows ... 1824
33.3.3.1 Initialization Flow ... 1824
33.3.3.2 Disable Flow ... 1824
33.3.3.3 Reset Flow ... 1825
33.3.3.4 Emergency Reset Flow ... 1825
33.4 Interrupts and Events ... 1826
33.5 Usage Notes ... 1827
33.5.1 Module-Stop Function Setting ... 1827
33.5.2 Transition to Software Standby Mode ... 1827
33.5.3 Return from Software Standby Mode ... 1827
33.5.4 Notes on Cutting Off the Power Supply to ESWM ... 1827
33.5.5 Note on Resuming Power Supply to ESWM ... 1827
33.5.6 Notes on Using Half-Duplex Mode ... 1827
34. Ethernet Message Forwarding Engine (MFWD) ... 1828
34.1 Overview ... 1828
34.2 Register Descriptions ... 1831
34.2.1 General Function Registers ... 1831
34.2.1.1 General Configuration Register (FWGC) ... 1831
34.2.1.2 TAG TPID Configuration Register 0 (FWTTC0) ... 1832
34.2.1.3 TAG TPID Configuration Register 1 (FWTTC1) ... 1833
34.2.1.4 CPU Exceptional Path Target Configuration Register (FWCEPTC) ... 1834

34.2.1.5 CPU Exceptional Path Reason Configuration Register 0 (FWCEPRC0) 1835
34.2.1.6 CPU Exceptional Path Reason Configuration Register 2 (FWCEPRC2) 1837
34.2.1.7 CPU Mirroring Path Target Configuration Register (FWCMPTC) 1837
34.2.1.8 Ethernet Mirroring Path Target Configuration Register (FWEMPTC) 1839
34.2.1.9 Source-Destination Mirroring Path Target Configuration Register (FWSDMPTC) 1840
34.2.1.10 Source-Destination Mirroring Path Vector Configuration Register (FWSDMPVC) 1841
34.2.1.11 Port i Level Based Watermark Configuration Register (FWLBWMCi) (i = 0, 2) 1842
34.2.1.12 Port i Configuration Register 1 (FWPCi1) (i = 0, 2) 1846
34.2.2 Port Based Forwarding Function Registers 1847
34.2.2.1 Port Based Forwarding Configuration Register i (FWPBFCi) (i = 0, 2) 1847
34.2.2.2 Port i Port Based Forwarding CSD Configuration Register 0 (FWPBFCSDCi0) (i = 0, 2) 1848
34.2.3 MFWD Counter Registers 1849
34.2.3.1 Port 2 Direct Descriptor Forwarded Descriptor Counter Register (FWDDFDCN2) 1849
34.2.3.2 Port i Port Based Forwarded Descriptor Counter Register (FWPBFDCNi) (i = 0, 2) 1850
34.2.3.3 Port i Watermark Rejected Descriptor Counter Register (FWWMRDCNi) (i = 0 to 2) 1851
34.2.3.4 Port 2 Direct Descriptor Rejected Descriptor Counter Register (FWDDRDCN2) 1852
34.2.3.5 Port i Port Based Rejected Descriptor Counter Register (FWPBRDCNi) (i = 0, 2) 1853
34.2.4 MFWD Interrupt Registers 1854
34.2.4.1 Port i Error Interrupt Status Register 0 (FWEIS0i) (i = 0, 2) 1854
34.2.4.2 Port i Error Interrupt Enable Register 0 (FWEIE0i) (i = 0, 2) 1857
34.2.4.3 Port i Error Interrupt Disable Register 0 (FWEID0i) (i = 0, 2) 1859
34.3 Operations 1860
34.3.1 General Functionalities 1860
34.3.1.1 Descriptors 1860
34.3.1.2 ESWM Modes 1861
34.3.1.3 ESWM TPIDs 1861
34.3.1.4 ESWM Frame Input Priority 1862
34.3.1.5 ESWM Debug Functions 1863
34.3.1.6 Watermark 1866
34.3.2 Forwarding/Routing 1868
34.3.2.1 Direct Descriptor Forwarding 1869
34.3.2.2 Port Based Forwarding 1872
34.3.3 Data Representation in RAMs 1875
34.3.3.1 RAM Address Dependencies 1875
34.3.3.2 RAM Access by Agents 1876
34.3.4 Fabric Time Arbiter 1878
34.3.4.1 Agents Done Signal Distribution 1878
34.3.4.2 Done Signal Patterns 1879

34.3.4.3 Fabric Jitter 1880
34.3.4.4 Fabric Minimum Latency 1880
34.3.5 Source Port Generation 1881
34.3.6 Software Flows 1882
34.3.6.1 Interrupt Handling Flow 1882
34.3.6.2 Port i Setting Flow 1882
34.3.6.3 Port Based Forwarding Flows 1883
34.3.6.4 Called Software Flows 1884
34.3.6.5 Register Writable Without Software Flow After Initialization 1887
35. Ethernet Common Agent (COMA) 1888
35.1 Overview 1888
35.1.1 Features 1888
35.1.2 COMA Block Diagram 1889
35.2 Register Description 1890
35.2.1 Global Registers 1890
35.2.1.1 IP Version Register (RIPV) 1890
35.2.1.2 Reset Configuration Register (RRC) 1891
35.2.1.3 Clock Enable Configuration Register (RCEC) 1892
35.2.1.4 Clock Disable Configuration Register (RCDC) 1893
35.2.2 Buffer Pool Function Registers 1894
35.2.2.1 Buffer Pool IPV Based Watermark Configuration Register i (CABPIBWMCi) (i = 0 to 7) 1894
35.2.2.2 Buffer Pool Watermark Level Configuration Register (CABPWMLC) 1895
35.2.2.3 Buffer Pointer Pause Frame Level i Configuration Register (CABPPFLCi) (i = 0, 1) 1896
35.2.2.4 Port i Buffer Pool Watermark Level Configuration Register (CABPPWMLCi) (i = 0 to 2) 1897
35.2.2.5 Port i Buffer Pointer Pause Frame Level j Configuration Register (CABPPPFLCij) (i = 0 to 2; j = 0, 1) 1898
35.2.2.6 Port i Buffer Pointer Utilization Level Configuration Register (CABPULCi) (i = 0 to 2) 1899
35.2.2.7 Buffer Pool Initialization Register Monitoring Register (CABPIRM) 1900
35.2.2.8 Buffer Pool Pointer Count Monitoring Register (CABPPCM) 1901
35.2.2.9 Buffer Pool Pointer Least Count Monitoring Register (CABPLCM) 1902
35.2.2.10 Port i Buffer Pointer Count Monitoring Register (CABPCPMi) (i = 0 to 2) 1903
35.2.2.11 Port i Buffer Pointer Maximum Count Monitoring Register (CABPMCPMi) (i = 0 to 2) 1904
35.2.3 Reject RAM Function Registers 1905
35.2.3.1 Rejected Descriptor Number Monitoring Register (CARDNM) 1905
35.2.3.2 Rejected Descriptor Maximum Number Monitoring Register (CARDMNM) 1906
35.2.4 Reject RAM Counter Registers 1907
35.2.4.1 Rejected Descriptor Counter Register (CARDCN) 1907
35.2.5 Error Interrupt Registers 1908

35.2.5.1 Error Interrupt Status Register 0 (CAEIS0) 1908
35.2.5.2 Error Interrupt Enable Register 0 (CAEIE0) 1910
35.2.5.3 Error Interrupt Disable Register 0 (CAEID0) 1911
35.2.5.4 Error Interrupt Status Register 1 (CAEIS1) 1912
35.2.5.5 Error Interrupt Enable Register 1 (CAEIE1) 1913
35.2.5.6 Error Interrupt Disable Register 1 (CAEID1) 1914
35.2.6 Monitoring Interrupt Registers 1915
35.2.6.1 Monitoring Interrupt Status Register 0 (CAMIS0) 1915
35.2.6.2 Monitoring Interrupt Enable Register 0 (CAMIE0) 1916
35.2.6.3 Monitoring Interrupt Disable Register 0 (CAMID0) 1916
35.2.6.4 Monitoring Interrupt Status Register 1 (CAMIS1) 1917
35.2.6.5 Monitoring Interrupt Enable Register 1 (CAMIE1) 1918
35.2.6.6 Monitoring Interrupt Disable Register 1 (CAMID1) 1919
35.3 Operations 1920
35.3.1 Watermark Function 1920
35.3.1.1 IPV Based Watermark 1920
35.3.1.2 Global Level-Based Watermark 1921
35.3.1.3 Per-Port Level-Based Watermark 1922
35.3.2 Pause Function 1923
35.3.2.1 Global Pause Function 1923
35.3.2.2 Per-Port Pause Function 1924
35.3.3 Per Port Memory Allocation Function 1925
35.3.3.1 Shared Memory Setting 1925
35.3.3.2 Reduced Memory Setting 1 1926
35.3.3.3 Reduced Memory Setting 2 1927
35.3.3.4 Hybrid Memory Setting 1928
35.3.4 Software Flows 1929
35.3.4.1 Interrupt Handling Flow 1929
35.3.4.2 Called Software Flows 1930
36. Ethernet Agent (ETHA) 1934
36.1 Overview 1934
36.1.1 Features 1934
36.1.2 Ethernet Agent Block Diagram 1935
36.2 Register Description 1936
36.2.1 ETHA Mode Function Registers 1936
36.2.1.1 Mode Configuration Register (EAMC) 1936
36.2.1.2 Mode Status Register (EAMS) 1937
36.2.2 Transmission Function Registers 1938
36.2.2.1 IPV Remapping Configuration Register [802.1Q] (EAIRC) 1938
36.2.2.2 TX Descriptor Queue Security Configuration Register (EATDQSC) 1939
36.2.2.3 TX Descriptor Queue Configuration Register (EATDQC) 1940

36.2.2.4 TX Descriptor Queue Arbitration Configuration Register (EATDQAC) 1942
36.2.2.5 Transmission Maximum Frame Size Configuration Register q (EATMFSCq) (q = 0 to 7) 1943
36.2.2.6 Transmission Descriptor Queue Depth Configuration Register q (EATDQDCq) (q = 0 to 7) 1944
36.2.2.7 Transmission Descriptor Queue q Monitoring Register (EATDQMq) (q = 0 to 7) 1945
36.2.2.8 Transmission Descriptor Queue q Max Level Monitoring Register (EATDQMLMq) (q = 0 to 7) 1946
36.2.3 TAG Function Registers 1947
36.2.3.1 VLAN Control Configuration Register (EAVCC) 1947
36.2.3.2 VLAN TAG Configuration Register (EAVTC) 1947
36.2.3.3 Reception TAG Filtering Configuration Register (EARTFC) 1948
36.2.4 ETHA Counter Registers 1949
36.2.4.1 Under Minimum Frame Size Error Counter Register (EAUSMFSECN) 1949
36.2.4.2 TAG Filtering Error Counter Register (EATFECN) 1950
36.2.4.3 Frame Size Error Counter Register (EAFSECN) 1951
36.2.4.4 Descriptor Queue Overflow Error Counter Register (EADQOECN) 1952

37.2.1.3 PHY Interfaces Monitoring Register (MPIM) 1991
37.2.1.4 I/O Configuration Register (MIOC) 1992
37.2.1.5 Transmission Frame Format Configuration Register (MTFFC) 1993
37.2.1.6 Transmission Pause or PFC Frame Configuration Register (MTPFC) 1994
37.2.1.7 Transmission Pause or PFC Frame Configuration Register 2 (MTPFC2) 1996
37.2.1.8 Transmission Pause or PFC Frame Configuration Register 3t (MTPFC3t) (t = 0, 1) ... 1998
37.2.1.9 Transmission Flow Control JAM Configuration Register (MTFCJC) 1999
37.2.1.10 Reception General Configuration Register (MRGC) 2000
37.2.1.11 Reception MAC Address Configuration Register 0 (MRMAC0) 2002
37.2.1.12 Reception MAC Address Configuration Register 1 (MRMAC1) 2002
37.2.1.13 Reception Address Filter Configuration Register (MRAFC) 2003
37.2.1.14 Reception Storm Configuration for E-Frames Register (MRSCE) 2005
37.2.1.15 Reception Storm Counter Configuration Register (MRSCC) 2006
37.2.1.16 Reception Frame Size Configuration for E-Frames Register (MRFSCE) 2007
37.2.1.17 Timestamp Reception Configuration Register (MTRC) 2008
37.2.1.18 Reception Pause or PFC Frame Monitoring Register (MRPFM) 2009
37.2.1.19 PTP Filtering Register Configuration Register t (MPFCt) (t = 0 to 15) 2010
37.2.1.20 Energy Efficient Ethernet Configuration Register (MEEEC) 2011
37.2.1.21 Loopback Configuration Register (MLBC) 2012
37.2.2 Counter Registers 2013
37.2.2.1 Manual Pause Frame Transmit Counter Register (MMPFTCT) 2013
37.2.2.2 Automatic Pause Frame Transmit Counter Register (MAPFTCT) 2014
37.2.2.3 Pause Frame Receive Counter Register (MPFRCT) 2015
37.2.2.4 False Carrier Indication Counter Register (MFCICT) 2016
37.2.2.5 Energy Efficient Ethernet Counter Register (MEEECT) 2017
37.2.2.6 Manual PFC Frame Transmit Counter Register t (MMPCFTCTt) (t = 0, 1) 2018
37.2.2.7 Automatic PFC Frame Transmit Counter Register t (MAPCFTCTt) (t = 0, 1) 2019
37.2.2.8 PFC Frame Receive Counter Register t (MPCFRCTt) (t = 0 to 7) 2020
37.2.2.9 Receive Overflow Counter Register (MROVFC) 2021
37.2.2.10 Received Byte Counter E-Frames Upper Side Register (MRXBCEU) 2022

37.2.2.11 Received Byte Counter E-Frames Lower Side Register (MRXBCEL) 2023
37.2.2.12 Received Good Frame Counter E-Frames Register (MRGFCE) 2024
37.2.2.13 Received Good Broadcast Frame Counter Register (MRBFC) 2025
37.2.2.14 Received Good Multicast Frame Counter Register (MRMFC) 2026
37.2.2.15 Received Good Unicast Frame Counter Register (MRUFC) 2027
37.2.2.16 Received PHY Error Frame Count Register (MRPEFC) 2028
37.2.2.17 Received Nibble Error Frame Count Register (MRNEFC) 2029
37.2.2.18 Received FCS/mCRC Error Frame Count Register (MRFMEFC) 2030
37.2.2.19 Received Final Fragment Missing Error Frame Count Register (MRFFMEFC) 2031
37.2.2.20 Received C-Fragment Count Error Frame Count Register (MRCFCEFC) 2032
37.2.2.21 Received Fragment Count Error Frame Count Register (MRFCEFC) 2033
37.2.2.22 Received MAC Filter Error Frame Count Register (MRRCFEFC) 2034
37.2.2.23 Received Frame Count Register (MRFC) 2034
37.2.2.24 Received Good Undersize Error Frame Count Register (MRGUEFC) 2035
37.2.2.25 Received Bad Undersize Error Frame Count Register (MRBUEFC) 2035
37.2.2.26 Received Good Oversize Error Frame Count Register (MRGOEFC) 2036
37.2.2.27 Received Bad Oversize Error Frame Count Register (MRBOEFC) 2036
37.2.2.28 Transmitted Byte Counter E-Frames Upper Side Register (MTXBCEU) 2037
37.2.2.29 Transmitted Byte Counter E-Frames Lower Side Register (MTXBCEL) 2038
37.2.2.30 Transmitted Good Frame Counter E-Frames Register (MTGFCE) 2039
37.2.2.31 Transmitted Broadcast Frame Counter Register (MTBFC) 2040
37.2.2.32 Transmitted Multicast Frame Counter Register (MTMFC) 2040
37.2.2.33 Transmitted Unicast Frame Counter Register (MTUFC) 2041
37.2.2.34 Transmitted Error Frame Counter Register (MTEFC) 2041
37.2.2.35 Transmitted Half Duplex Good Frame Counter Register (MTHDGFC) 2042
37.2.3 Interrupt Registers 2043
37.2.3.1 Error Interrupt Status Register (MEIS) 2043
37.2.3.2 Error Interrupt Enable Register (MEIE) 2050
37.2.3.3 Error Interrupt Disable Register (MEID) 2055
37.2.3.4 Monitoring Interrupt Status Register 0 (MMIS0) 2057
37.2.3.5 Monitoring Interrupt Enable Register 0 (MMIE0) 2059
37.2.3.6 Monitoring Interrupt Disable Register 0 (MMID0) 2060
37.2.3.7 Monitoring Interrupt Status Register 1 (MMIS1) 2061
37.2.3.8 Monitoring Interrupt Enable Register 1 (MMIE1) 2063
37.2.3.9 Monitoring Interrupt Disable Register 1 (MMID1) 2065
37.2.3.10 Monitoring Interrupt Status Register 2 (MMIS2) 2066
37.2.3.11 Monitoring Interrupt Enable Register 2 (MMIE2) 2068
37.2.3.12 Monitoring Interrupt Disable Register 2 (MMID2) 2069
37.3 Operation 2070
37.3.1 Flow Control 2070
37.3.1.1 Flow Control by PAUSE Frame 2070

37.3.1.2 Flow Control by PFC Frame 2072
37.3.1.3 Flow Control by JAM 2076
37.3.2 Timestamping 2077
37.3.2.1 Timestamp Capture 2077
37.3.3 Station Management 2079
37.3.3.1 Management Register Access 2079
37.3.3.2 Management Data Clock (MDC) Setting 2082
37.3.3.3 Management Data Timing Adjustment 2082
37.3.4 Energy Efficient Ethernet 2083
37.3.4.1 LPI Control 2083
37.3.5 MAC Address Filtering on Reception 2084
37.3.6 Operation Modes 2086
37.3.6.1 Frame Handling 2086
37.3.7 Software Flows 2087
37.3.7.1 Initialization Flow 2087
37.3.7.2 Interrupt Handling Flow 2088
37.3.7.3 PHY MDIO and eMDIO Access Flows 2089
37.3.7.4 LPI Transition for Transmit Port 2091
37.3.7.5 LINK Verification 2092
38. Ethernet CPU Agent (GWCA) 2093
38.1 Overview 2093
38.1.1 Features 2093
38.1.2 GWCA Block Diagram 2094
38.2 Register Descriptions 2095
38.2.1 GWCA Mode Function Registers 2095
38.2.1.1 Mode Configuration Register (GWMC) 2095
38.2.1.2 Mode Status Register (GWMS) 2096
38.2.2 Reception Function Registers 2097
38.2.2.1 IPV Remapping Configuration Register [802.1Q] (GWIRC) 2097
38.2.2.2 RX Descriptor Queue Security Configuration Register (GWRDQSC) 2098
38.2.2.3 RX Descriptor Queue Control Register (GWRDQC) 2099
38.2.2.4 RX Descriptor Queue Arbitration Control Register (GWRDQAC) 2100
38.2.2.5 RX General Configuration Register (GWRGC) 2101
38.2.2.6 Reception Maximum Frame Size Configuration Register q (GWRMFSCq) (q = 0 to 7) 2102
38.2.2.7 Reception Descriptor Queue q Depth Configuration Register (GWRDQDCq) (q = 0 to 7) 2103
38.2.2.8 RX Descriptor Queue q Monitoring Register (GWRDQMq) (q = 0 to 7) 2104
38.2.2.9 RX Descriptor Queue q Max Level Monitoring Register (GWRDQMLMq) (q = 0 to 7) 2105
38.2.3 Reception Multicast Function Registers 2106
38.2.3.1 Multicast Table Initialization Register Monitoring Register (GWMTIRM) 2106

38.2.3.2 Multicast Table Learning Setting Register (GWMSTLS) 2107
38.2.3.3 Multicast Table Learning Result Register (GWMSTLR) 2108
38.2.3.4 Multicast Table Searching Setting Register (GWMSTSS) 2109
38.2.3.5 Multicast Table Searching Result Register (GWMSTSR) 2110
38.2.4 MAC Function Registers 2111
38.2.4.1 MAC Address Configuration Register 0 (GWMAC0) 2111
38.2.4.2 MAC Address Configuration Register 1 (GWMAC1) 2111
38.2.5 TAG Function Registers 2112
38.2.5.1 VLAN Control Configuration Register (GWVCC) 2112
38.2.5.2 VLAN TAG Configuration Register (GWVTC) 2113
38.2.5.3 Transmission TAG Filtering Configuration Register (GWTTFC) 2114
38.2.6 Timestamp Function Registers 2115
38.2.6.1 Timestamp Descriptor Chain s Address Configuration Register 0 (GWTDCACs0) (s = 0, 1) 2115
38.2.6.2 Timestamp Descriptor Chain s Address Configuration Register 1 (GWTDCACs1) (s = 0, 1) 2116
38.2.6.3 Timestamp Descriptor Chain s Configuration Register (GWTSDCCs) (s = 0, 1) 2117
38.2.6.4 Timestamp Number Monitoring Register (GWTSNM) 2118
38.2.6.5 Timestamp Maximum Number Monitoring Register (GWTSMNM) 2118
38.2.7 AXI Master Registers 2119
38.2.7.1 AXI Control Register (GWAC) 2119
38.2.7.2 Descriptor Chain Base Address Configuration Register 0 (GWDCBAC0) 2120
38.2.7.3 Descriptor Chain Base Address Configuration Register 1 (GWDCBAC1) 2120
38.2.7.4 Maximum Descriptor Number Configuration Register (GWMDNC) 2121
38.2.7.5 Transmission Request Configuration Register i (GWTRCi) (i = 0, 1) 2122
38.2.7.6 Transmission Pause Configuration Register p (GWTPCp) (p = 0, 1) 2125
38.2.7.7 AXI RAM Initialization Register Monitoring Register (GWARIRM) 2126
38.2.7.8 Descriptor Chain i Configuration Register (GWDCCi) (i = 0 to 63) 2127
38.2.7.9 AXI Address RAM Searching Setting Register (GWAARSS) 2129
38.2.7.10 AXI Address RAM Searching Result Register 0 (GWAARSR0) 2130
38.2.7.11 AXI Address RAM Searching Result Register 1 (GWAARSR1) 2131
38.2.7.12 Incremental Data Area i Used Area Size Register (GWIDAUASi) (i = 0 to 3) 2132
38.2.7.13 Incremental Data Area i Size Monitoring Register (GWIDASMi) (i = 0 to 3) 2133
38.2.7.14 Incremental Data Area i Start Address Monitoring Register 0 (GWIDASAMi0) (i = 0 to 3) 2134
38.2.7.15 Incremental Data Area i Start Address Monitoring Register 1 (GWIDASAMi1) (i = 0 to 3) 2135
38.2.7.16 Incremental Data Area i Current Address Monitoring Register 0 (GWIDACAMi0) (i = 0 to 3) 2136
38.2.7.17 Incremental Data Area i Current Address Monitoring Register 1 (GWIDACAMi1) (i = 0 to 3) 2137

38.2.8 Rate Limiter Function Registers 2138
38.2.8.1 Global Rate Limiter Configuration Register (GWGRLC) 2138
38.2.8.2 Global Rate Limiter Upper Limit Configuration Register (GWGRLULC) 2139
38.2.8.3 Rate Limiter i Configuration Register (GWRLCi) (i = 0 to 7) 2140
38.2.8.4 Rate Limiter i Upper Limit Configuration Register (GWRLULCi) (i = 0 to 7) 2141
38.2.9 Interrupt Function Registers 2142
38.2.9.1 Interrupt Delay Prescaler Configuration Register (GWIDPC) 2142
38.2.9.2 Interrupt Delay Configuration Register (GWIDCi) (i = 0 to 63) 2143
38.2.10 Counter Registers 2144
38.2.10.1 Received Data Counter Register (GWRDCN) 2144
38.2.10.2 Transmitted Data Counter Register (GWTDCN) 2145
38.2.10.3 Timestamp Counter Register (GWTSCN) 2146
38.2.10.4 Timestamp Overflow Error Counter Register (GWTSOVFECN) 2147
38.2.10.5 Under Minimum Frame Size Error Counter Register (GWUSMFSECN) 2148
38.2.10.6 TAG Filtering Error Counter Register (GWTFECN) 2149
38.2.10.7 Sequence Error Counter Register (GWSEQECN) 2150

39.2.7 Interrupt Registers 2330
39.2.7.1 Interrupt Status Register 0 (PTPIS0) 2330
39.2.7.2 Interrupt Enable Register 0 (PTPIE0) 2331
39.2.7.3 Interrupt Disable Register 0 (PTPID0) 2332
39.2.7.4 Interrupt Status Register 1 (PTPIS1) 2333
39.2.7.5 Interrupt Enable Register 1 (PTPIE1) 2334
39.2.7.6 Interrupt Disable Register 1 (PTPID1) 2335
39.2.8 Pulse Output Timer Configuration Registers 2336
39.2.8.1 Pulse Output Timer Configuration Register (POTCFGR) 2336
39.2.8.2 Pulse Output Timer Control Register n (POTCRn) (n = 0, 1) 2337
39.2.8.3 Pulse Output Start Time Setting Register nU (POTSTRnU) (n = 0, 1) 2338
39.2.8.4 Pulse Output Start Time Setting Register nM (POTSTRnM) (n = 0, 1) 2339
39.2.8.5 Pulse Output Start Time Setting Register nL (POTSTRnL) (n = 0, 1) 2340
39.2.8.6 Period Setting Register nU (POTPERnU) (n = 0, 1) 2341
39.2.8.7 Period Setting Register nM (POTPERnM) (n = 0, 1) 2342
39.2.8.8 Period Setting Register nL (POTPERnL) (n = 0, 1) 2343
39.2.8.9 Pulse Width Setting Register n (POTPWRn) (n = 0, 1) 2344
39.2.9 Pulse Output Timer Monitoring Registers 2345
39.2.9.1 Time Capture Register nU (POTCPRnU) (n = 0, 1) 2345
39.2.9.2 Time Capture Register nM (POTCPRnM) (n = 0, 1) 2346
39.2.9.3 Time Capture Register nL (POTCPRnL) (n = 0, 1) 2347
39.3 Operations 2348
39.3.1 Timer 0 2348
39.3.1.1 gPTP Timer 0 2348
39.3.1.2 64-bit AVTP Timer 0 2348
39.3.1.3 32-bit AVTP Timer 0 2349
39.3.1.4 PPS Signal 2349
39.3.2 Media Clock Capture m (m = 0, 1) 2350
39.3.3 Media Clock Recovery m (m = 0, 1) 2351
39.3.4 mediaClock[m] Mapping to Output Pins 2352

39.3.5 Cyclic Compare c (c = 0 to 7) 2352
39.3.6 Pulse Output Timer n (n = 0, 1) 2353
39.3.6.1 gPTP Timer Selection 2353
39.3.6.2 Pulse Output Generation Registers 2353
39.3.6.3 Pulse Output Start 2353
39.3.6.4 Pulse Output Stop 2354
39.3.6.5 Timing of Pulse Output Permission 2354
39.3.6.6 Interrupt Output 2354
39.3.7 Pulse Output Time Chart 2355
39.3.8 Interrupt Output Time Chart 2359
39.3.9 Software Flows 2360
39.3.9.1 Interrupt Handling Flow 2360
39.3.9.2 Timer 0 Flows 2361
39.3.9.3 Media Clock m Capture Flows (m = 0, 1) 2364
39.3.9.4 Media Clock Recovery m Flows (m = 0, 1) 2367
39.3.9.5 Cyclic Compare c Flows (c = 0 to 7) 2369
39.3.9.6 Pulse Output Timer n Operation Flow (n = 0, 1) 2369
39.4 Usage Notes 2370
39.4.1 Note on Register Setting 2370
39.4.2 Restrictions on Register Setting 2370
40. USB 2.0 Full-Speed Host/Function Module (USBf) 2371
40.1 Overview 2371
40.2 Register Descriptions 2373
40.2.1 System Configuration Control Register (SYSCFG) 2373
40.2.2 System Configuration Status Register 0 (SYSSTS0) 2375
40.2.3 Device State Control Register 0 (DVSTCTR0) 2377
40.2.4 CFIFO Port Register (CFIFO),
D0FIFO Port Register (D0FIFO),
D1FIFO Port Register (D1FIFO) 2380
40.2.5 CFIFO Port Select Register (CFIFOSEL),
D0FIFO Port Select Register (D0FIFOSEL),
D1FIFO Port Select Register (D1FIFOSEL) 2382
40.2.6 CFIFO Port Control Register (CFIFOCTR),
D0FIFO Port Control Register (D0FIFOCTR),
D1FIFO Port Control Register (D1FIFOCTR) 2386
40.2.7 Interrupt Enable Register 0 (INTENB0) 2388
40.2.8 Interrupt Enable Register 1 (INTENB1) 2389
40.2.9 BRDY Interrupt Enable Register (BRDYENB) 2390
40.2.10 NRDY Interrupt Enable Register (NRDYENB) 2391
40.2.11 BEMP Interrupt Enable Register (BEMPENB) 2392
40.2.12 SOF Output Configuration Register (SOFCFG) 2393
40.2.13 Interrupt Status Register 0 (INTSTS0) 2394
40.2.14 Interrupt Status Register 1 (INTSTS1) 2397

40.2.15 BRDY Interrupt Status Register (BRDYSTS) 2400
40.2.16 NRDY Interrupt Status Register (NRDYSTS) 2401
40.2.17 BEMP Interrupt Status Register (BEMPSTS) 2402
40.2.18 Frame Number Register (FRMNUM) 2403
40.2.19 Device State Change Register (DVCHGR) 2404
40.2.20 USB Address Register (USBADDR) 2405
40.2.21 USB Request Type Register (USBREQ) 2406
40.2.22 USB Request Value Register (USBVAL) 2407
40.2.23 USB Request Index Register (USBINDX) 2407
40.2.24 USB Request Length Register (USBLENG) 2408
40.2.25 DCP Configuration Register (DCPCFG) 2409
40.2.26 DCP Maximum Packet Size Register (DCPMAXP) 2410
40.2.27 DCP Control Register (DCPCTR) 2411
40.2.28 Pipe Window Select Register (PIPESEL) 2414
40.2.29 Pipe Configuration Register (PIPECFG) 2415
40.2.30 Pipe Maximum Packet Size Register (PIPEMAXP) 2417
40.2.31 Pipe Cycle Control Register (PIPEPERI) 2418
40.2.32 Pipe n Control Registers (PIPEnCTR) (n = 1 to 9) 2419
40.2.33 Pipe n Transaction Counter Enable Register (PIPEnTRE) (n = 1 to 5) 2427
40.2.34 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5) 2428
40.2.35 Device Address n Configuration Register (DEVADDn) (n = 0 to 5) 2429
40.2.36 Deep Standby USB Transceiver Control/Pin Monitoring Register (DPUSR0R) 2430
40.2.37 Deep Standby USB Suspend/Resume Interrupt Register (DPUSR1R) 2431
40.3 Operation 2433
40.3.1 System Control 2433
40.3.1.1 Setting Data to the USB Related Register 2433
40.3.1.2 Controller Function Selection 2433
40.3.1.3 Controlling USB Data Bus Resistors 2433
40.3.1.4 Example of USB External Connection Circuit 2434
40.3.1.5 Release from Deep Software Standby Mode 1 Due to USB Suspend/Resume Interrupts 2438
40.3.2 Interrupt Sources 2442
40.3.3 Interrupt Descriptions 2444
40.3.3.1 BRDY Interrupt 2444
40.3.3.2 NRDY Interrupt 2448
40.3.3.3 BEMP Interrupt 2451
40.3.3.4 Device State Transition Interrupt 2452
40.3.3.5 Control Transfer Stage Transition Interrupt 2453
40.3.3.6 Frame Update Interrupt 2454
40.3.3.7 VBUS Interrupt 2454
40.3.3.8 Resume Interrupt 2454

40.3.3.9 OVRCR Interrupt 2454
40.3.3.10 BCHG Interrupt 2454
40.3.3.11 DTCH Interrupt 2454
40.3.3.12 SACK Interrupt 2455
40.3.3.13 SIGN Interrupt 2455
40.3.3.14 ATTCH Interrupt 2455
40.3.3.15 EOFERR Interrupt 2455
40.3.4 Pipe Control 2456
40.3.4.1 Pipe Control Register Switching Procedures 2457
40.3.4.2 Transfer Types 2457
40.3.4.3 Endpoint Number 2457
40.3.4.4 Maximum Packet Size Setting 2458
40.3.4.5 Transaction Counter (For Pipes 1 to 5 in Reading Direction) 2458
40.3.4.6 Response PID 2459
40.3.4.7 Data PID Sequence Bit 2460
40.3.4.8 Response PID = NAK Function 2460
40.3.4.9 Auto Response Mode 2460
40.3.4.10 OUT-NAK Mode 2460
40.3.4.11 Null Auto Response Mode 2461
40.3.5 FIFO Buffer Memory 2461
40.3.5.1 FIFO Buffer Memory 2461
40.3.5.2 FIFO Buffer Clearing 2462
40.3.5.3 FIFO Port Functions 2463
40.3.5.4 DMA Transfers (D0FIFO and D1FIFO Ports) 2464
40.3.6 Control Transfers Using DCP 2465
40.3.6.1 Control Transfers When the Host Controller is Selected 2465
40.3.6.2 Control Transfers When the Function Controller is Selected 2466
40.3.7 Bulk Transfers (Pipes 1 to 5) 2467
40.3.8 Interrupt Transfers (Pipes 6 to 9) 2467
40.3.8.1 Interval Counter during Interrupt Transfers When the Host Controller is Selected 2467
40.3.9 Isochronous Transfers (Pipes 1 and 2) 2468
40.3.9.1 Error Detection in Isochronous Transfers 2468
40.3.9.2 Data PID 2469
40.3.9.3 Interval Counter 2469
40.3.10 SOF Interpolation Function 2476
40.3.11 Pipe Schedule 2477
40.3.11.1 Conditions for Generating a Transaction 2477
40.3.11.2 Transfer Schedule 2477
40.3.11.3 Enabling USB Communication 2477
40.4 Usage Notes 2478
40.4.1 Setting the Module-Stop Function 2478

41. USB 2.0 High-Speed Host/Function Module (USBHS) 2479
41.1 Overview 2479
41.2 Register Descriptions 2481
41.2.1 System Configuration Control Register (SYSCFG) 2481
41.2.2 CPU Bus Wait Register (BUSWAIT) 2483
41.2.3 System Configuration Status Register (SYSSTS0) 2484
41.2.4 PLL Status Register (PLLSTA) 2485
41.2.5 Device State Control Register 0 (DVSTCTR0) 2486
41.2.6 USB Test Mode Register (TESTMODE) 2489
41.2.7 CFIFO Port Register (CFIFO), D0FIFO Port Register (D0FIFO), D1FIFO Port Register (D1FIFO) 2491
41.2.8 CFIFO Port Select Register (CFIFOSEL) 2494
41.2.9 D0FIFO Port Select Register (D0FIFOSEL), D1FIFO Port Select Register (D1FIFOSEL) 2496
41.2.10 CFIFO Port Control Register (CFIFOCTR), D0FIFO Port Control Register (D0FIFOCTR), D1FIFO Port Control Register (D1FIFOCTR) 2498
41.2.11 Interrupt Enable Register 0 (INTENB0) 2500
41.2.12 Interrupt Enable Register 1 (INTENB1) 2501
41.2.13 BRDY Interrupt Enable Register (BRDYENB) 2502
41.2.14 NRDY Interrupt Enable Register (NRDYENB) 2502
41.2.15 BEMP Interrupt Enable Register (BEMPENB) 2503
41.2.16 SOF Output Configuration Register (SOFCFG) 2504
41.2.17 PHY Setting Register (PHYSET) 2505
41.2.18 Interrupt Status Register 0 (INTSTS0) 2507
41.2.19 Interrupt Status Register 1 (INTSTS1) 2509
41.2.20 BRDY Interrupt Status Register (BRDYSTS) 2512
41.2.21 NRDY Interrupt Status Register (NRDYSTS) 2512
41.2.22 BEMP Interrupt Status Register (BEMPSTS) 2513
41.2.23 Frame Number Register (FRMNUM) 2514
41.2.24 Microframe Number Register (UFRMNUM) 2515
41.2.25 USB Address Register (USBADDR) 2516
41.2.26 USB Request Type Register (USBREQ) 2517
41.2.27 USB Request Value Register (USBVAL) 2518
41.2.28 USB Request Index Register (USBINDX) 2518
41.2.29 USB Request Length Register (USBLENG) 2519
41.2.30 Default Control Pipe Configuration Register (DCPCFG) 2520
41.2.31 Default Control Pipe Maximum Packet Size Register (DCPMAXP) 2521
41.2.32 Default Control Pipe Control Register (DCPCTR) 2522
41.2.33 Pipe Window Select Register (PIPESEL) 2526
41.2.34 Pipe Configuration Register (PIPECFG) 2527
41.2.35 Pipe Buffer Register (PIPEBUF) 2530

41.2.36 Pipe Maximum Packet Size Register (PIPEMAXP) 2532
41.2.37 Pipe Cycle Control Register (PIPEPERI) 2533
41.2.38 Pipe n Control Register (PIPEnCTR) (n = 1 to 9) 2534
41.2.39 Pipe n Transaction Counter Enable Register (PIPEnTRE) (n = 1 to 5) 2539
41.2.40 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5) 2540
41.2.41 Device Address m Configuration Register (DEVADDm) (m = 0 to A) 2541
41.2.42 Low Power Control Register (LPCTRL) 2542
41.2.43 Low Power Status Register (LPSTS) 2543
41.2.44 Battery Charging Control Register (BCCTRL) 2544
41.2.45 Function L1 Control Register 1 (PL1CTRL1) 2546
41.2.46 Function L1 Control Register 2 (PL1CTRL2) 2548
41.2.47 Host L1 Control Register 1 (HL1CTRL1) 2549
41.2.48 Host L1 Control Register 2 (HL1CTRL2) 2550
41.2.49 Deep Standby USB Transceiver Pin Monitor Register (DPUSR0R) 2551
41.2.50 Deep Standby USB Resume Interrupt Register (DPUSR1R) 2552
41.2.51 Deep Standby USB Resume Interrupt Register 2 (DPUSR2R) 2554
41.2.52 Deep Standby USB Transceiver Control Register (DPUSRCR) 2555
41.3 Operation 2556
41.3.1 System Control 2556
41.3.1.1 Setting Registers Associated with the USBHS 2556
41.3.1.2 Selecting the Controller Function 2556
41.3.2 Controlling the USB Data Bus Resistors 2556
41.3.3 Supplying Clocks 2556
41.3.4 Notes on Stopping Clock 2558
41.3.5 Interrupts 2559
41.3.5.1 Setting the USBHSR Interrupt Signal Output Method 2560
41.3.6 Interrupt Descriptions 2563
41.3.6.1 BRDY Interrupt 2563
41.3.6.2 NRDY Interrupt 2566
41.3.6.3 BEMP Interrupt 2570
41.3.6.4 Device State Transition Interrupt in Function Controller Operation 2571
41.3.6.5 Control Transfer Stage Transition Interrupt in Function Controller Operation 2572
41.3.6.6 Frame Number Refresh Interrupt 2573
41.3.6.7 VBUS Interrupt 2573
41.3.6.8 Resume Interrupt 2573
41.3.6.9 OVRCR Interrupt 2573
41.3.6.10 BCHG Interrupt 2573
41.3.6.11 DTCH Interrupt 2573
41.3.6.12 SACK Interrupt 2574
41.3.6.13 SIGN Interrupt 2574
41.3.6.14 ATTCH Interrupt 2574

41.3.6.15 EOFERR Interrupt 2574
41.3.6.16 Portable Device Detection Interrupt 2574
41.3.6.17 LPMEND Interrupt 2574
41.3.6.18 L1RSMEND Interrupt 2574
41.3.7 Pipe Control 2575
41.3.7.1 Pipe Control Register Switching Procedures 2576
41.3.7.2 Transfer Types 2577
41.3.7.3 Endpoint Number 2577
41.3.7.4 Setting the Maximum Packet Size 2577
41.3.7.5 Transaction Counter (For Pipes 1 to 5 in the Reading Direction) 2577
41.3.7.6 Response PID 2578
41.3.7.7 Data PID Sequence Bit 2579
41.3.7.8 Response PID = NAK Function 2579
41.3.7.9 Auto Response Mode 2579
41.3.7.10 OUT-NAK Mode 2579
41.3.7.11 Null Auto Response Mode 2580
41.3.8 FIFO Buffers 2581
41.3.8.1 FIFO Buffers 2581
41.3.8.2 Clearing the FIFO Buffers 2582
41.3.8.3 FIFO Port Functions 2582
41.3.8.4 DMA/DTC Transfers (D0FIFO and D1FIFO Ports) 2584
41.3.8.5 Allocating the FIFO Buffers 2585
41.3.9 Control Transfer Using the Default Control Pipe 2586
41.3.9.1 Control Transfer in Host Controller Operation 2586
41.3.9.2 Control Transfer in Function Controller Operation 2587
41.3.10 Bulk Transfer for Pipes 1 to 5 2588
41.3.10.1 Controlling the PING Token in Host Controller Operation 2588
41.3.10.2 Controlling the NYET Handshake in Function Controller Operation 2589
41.3.11 Interrupt Transfer for Pipes 6 to 9 2590
41.3.11.1 Interval Counter for Interrupt Transfer in Host Controller Operation 2590
41.3.12 Isochronous Transfer for Pipes 1 and 2 2591
41.3.12.1 Error Detection in Isochronous Transfers 2591
41.3.12.2 Data PID 2592
41.3.12.3 Interval Counter 2592
41.3.13 SOF Recovery Function 2599
41.3.14 Pipe Schedule 2600
41.3.14.1 Conditions for Generating a Transaction 2600
41.3.14.2 Transfer Schedule 2600
41.3.14.3 Enabling USB Communication 2600
41.3.15 Battery Charging Detection Processing 2601
41.3.15.1 Processing in Function Controller Operation 2601

41.3.15.2 Processing in Host Controller Operation 2603
41.3.16 Link Power Management Processing 2606
41.3.16.1 Processing in Function Controller Operation 2606
41.3.16.2 Processing in Host Controller Operation 2607
41.3.17 USB External Connection Circuit 2608
41.3.18 Release from Deep Software Standby Mode 1 in Response to the USBHS Resume Interrupt 2612
41.4 Notes on Using the USBHS 2615
41.4.1 Setting the USBHS Module-Stop Function 2615
41.4.2 Setting to Transition to Deep Software Standby Mode 2615
42. Serial Communications Interface (RSCI) 2616
42.1 Overview 2616
42.2 Register Descriptions 2625
42.2.1 Receive Shift Register (RSR) 2625
42.2.2 Receive Data Register (RDR) 2625
42.2.3 Transmit Data Register (TDR) 2627
42.2.4 Transmit Shift Register (TSR) 2628
42.2.5 Control Register 0 (SCR0) 2629
42.2.6 Control Register 1 (SCR1) 2632
42.2.7 Control Register 2 (SCR2) 2637
42.2.8 Control Register 3 (SCR3) 2653
42.2.9 Control Register 4 (SCR4) 2658
42.2.10 I^2C Mode Register (SIMR) 2660
42.2.11 FIFO Control Register (FCR) 2663
42.2.12 Manchester Mode Control Register (MMCR) 2665
42.2.13 DE Signal Control Register (DECR) 2669
42.2.14 Extended Serial Mode Control Register 0 (XCR0) 2670
42.2.15 Extended Serial Mode Control Register 1 (XCR1) 2673
42.2.16 Extended Serial Mode Control Register 2 (XCR2) 2675
42.2.17 Status Register (SSR) 2676
42.2.18 I^2C Status Register (SISR) 2682
42.2.19 Receive FIFO Status Register (RFSR) 2683
42.2.20 Transmit FIFO Status Register (TFSR) 2685
42.2.21 Manchester Mode Status Register (MMSR) 2686
42.2.22 Extended Serial Mode Status Register 0 (XSR0) 2689
42.2.23 Extended Serial Mode Status Register 1 (XSR1) 2691
42.2.24 Status Clear Register (SSCR) 2692
42.2.25 I^2C Status Clear Register (SISCR) 2693
42.2.26 Receive FIFO Status Clear Register (RFSCR) 2693
42.2.27 Manchester Mode Status Clear Register (MMSCR) 2694
42.2.28 Extended Serial Mode Status Clear Register (XSCR) 2695

42.2.29 Internal Signal Status Register (SISSR) 2696
42.2.30 HBS Support Mode Control Register (HBSCR) 2697
42.2.31 RXD Input Path Select Register (RXDSEL) 2698
42.2.32 GTIOC Input Path Select Register (GTIOCSEL) 2698
42.3 Operation in Asynchronous Mode 2699
42.3.1 Serial Data Transfer Format 2699
42.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode 2701
42.3.3 Clock 2703
42.3.4 Double-Speed Mode, Divide-by-6 Mode, and Divided-by-4 Mode 2703
42.3.5 CTS and RTS Functions 2704
42.3.6 Data Match Detection 2705
42.3.7 RSCI Initialization (Asynchronous Mode) 2708
42.3.8 Serial Data Transmission (Asynchronous Mode) 2712
42.3.9 Serial Data Reception (Asynchronous Mode) 2718
42.3.10 Receive Data Sampling Timing Adjustment 2726
42.3.11 Transmit Data Transition Timing Adjustment 2727
42.4 Multi-Processor Communication Function 2728
42.4.1 Multi-Processor Serial Data Transmission 2730
42.4.2 Multi-Processor Serial Data Reception 2733
42.5 Manchester Mode 2739
42.5.1 Frame Format 2739
42.5.2 Clock 2743
42.5.3 RSCI Initialization of Manchester Mode 2743
42.5.4 Double Speed Operation 2744
42.5.5 CTS, RTS Functions 2745
42.5.6 Serial Data Transmission in Manchester Mode 2745
42.5.7 Serial Data Reception in Manchester Mode 2749
42.5.8 Operation When Multi-Processor Bit is Used 2753
42.5.9 Receive Retiming 2753
42.5.10 Polarity Setting for Manchester Code 2754
42.5.11 Errors in Manchester Mode 2756
42.6 HBS Support Mode 2761
42.6.1 Reception in HBS Support Mode 2761
42.6.2 Transmission in HBS Support Mode 2762
42.6.3 Register Setting for HBS Support Mode 2764
42.7 Smart Card Interface Mode 2765
42.7.1 Sample Connection 2765
42.7.2 Data Format (Except in Block Transfer Mode) 2766
42.7.3 Block Transfer Mode 2767
42.7.4 Receive Data Sampling Timing and Reception Margin 2768
42.7.5 RSCI Initialization (Smart Card Interface Mode) 2769

42.7.6 Serial Data Transmission (Except in Block Transfer Mode) 2771
42.7.7 Serial Data Reception (Except in Block Transfer Mode) 2774
42.7.8 Clock Output Control 2776
42.8 Extended Serial Mode 2777
42.8.1 Serial Transfer Protocol 2777
42.8.2 Transmitting a Start Frame 2778
42.8.3 Receiving a Start Frame 2781
42.8.3.1 Extended Serial Normal Reception of Start Frame (PIB not Used) 2781
42.8.3.2 Priority Interrupt Bit 2786
42.8.4 Detection of Bus Collisions 2787
42.8.5 Bit Rate Measurement 2789
42.9 Operation in Simple I2C Mode 2790
42.9.1 Generation of Start, Restart, and Stop Conditions 2791
42.9.2 Clock Synchronization 2793
42.9.3 SDA Output Delay 2794
42.9.4 RSCI Initialization (Simple I2C Mode) 2795
42.9.5 Operation in Master Transmission (Simple I2C Mode) 2796
42.9.6 Master Reception (Simple I2C Mode) 2801
42.10 Operation in Clock Synchronous Mode 2804
42.10.1 Clock 2804
42.10.2 CTS and RTS Functions 2805
42.10.3 RSCI Initialization (Clock Synchronous Mode) 2806
42.10.4 Serial Data Transmission (Clock Synchronous Mode) 2807
42.10.5 Serial Data Reception (Clock Synchronous Mode) 2813
42.10.6 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode) 2818
42.11 Operation in Simple SPI Mode 2820
42.11.1 Clock 2820
42.11.2 States of Pins in Master and Slave Modes 2821
42.11.3 SS Function in Master Mode 2821
42.11.4 SS Function in Slave Mode 2821
42.11.5 Relationship between Clock and Transmit/Receive Data 2822
42.11.6 RSCI Initialization (Simple SPI Mode) 2823
42.11.7 Transmission and Reception of Serial Data (Simple SPI Mode) 2823
42.12 Bit Rate Modulation Function 2824
42.13 Noise Cancellation Function 2825
42.14 RS-485 Driver Control Function 2826
42.15 Loopback Function 2827
42.16 Half-Duplex Communication Function 2828
42.17 Synchronizer Bypass Function 2828
42.18 Interrupt Signal 2829
42.18.1 Buffer Operations for TXI and RXI Interrupts 2829

42.18.2 Interrupt in Asynchronous Mode, Manchester Mode, Clock Synchronous Mode, and Simple SPI Mode ... 2830
42.18.3 Interrupt in Smart Card Interface Mode ... 2832
42.18.4 Interrupts in Simple I2C Mode ... 2833
42.18.5 Interrupts in Extended Serial Mode ... 2834
42.19 Event Linking ... 2835
42.20 Usage Notes ... 2837
42.20.1 Setting the Module Stop Function ... 2837
42.20.2 RSCI Operations during Low Power Consumption State ... 2837
42.20.3 Break Detection and Processing ... 2841
42.20.4 Mark State and Sending Breaks ... 2841
42.20.5 Receive Error Flags and Transmit Operations (Clock Synchronous Mode and Simple SPI Mode) ... 2841
42.20.6 Writing Data to the TDR Register ... 2841
42.20.7 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode and Simple SPI Mode) ... 2842
42.20.8 Restrictions on Using DMAC or DTC ... 2844
42.20.9 Notes on Starting Transfer ... 2844
42.20.10 Limitations on Simple SPI Mode ... 2845
42.20.11 Note on Transmit Enable Bit (TE Bit) ... 2846
42.20.12 Note on Extended Serial Mode ... 2846
42.20.13 Notes on RS-485 Driver Control Function ... 2846
42.20.14 Notes on Loopback Function ... 2846
42.20.15 Note on Register Access When the Frequency of the Operating Clock (TCLK) is Lower Than the Frequency of the Peripheral Module Clock (PCLK) ... 2846
42.20.16 Note on Aborting Operation ... 2846
43. I3C Bus Interface (RI3C) ... 2847
43.1 Overview ... 2847
43.2 Register Descriptions ... 2852
43.2.1 Mode Register (ICMR) ... 2852
43.2.2 Control Register (ICCR) ... 2853
43.2.3 Controller Device Address Register (ICCAR) ... 2855
43.2.4 Reset Control Register (ICRCR) ... 2856
43.2.5 Operating Mode Monitor Register (ICMMR) ... 2858
43.2.6 Internal Status Register (ICISR) ... 2860
43.2.7 Internal Status Detection Enable Register (ICISER) ... 2861
43.2.8 Internal Status Interrupt Enable Register (ICISIER) ... 2861
43.2.9 Device Characteristics Table Index Register (ICDCTIR) ... 2862
43.2.10 IBI Notify Control Register (ICINCR) ... 2863
43.2.11 Function Enable Register (ICFER) ... 2864
43.2.12 Target Mode Control Register (ICTCR) ... 2866
43.2.13 Slave Mode Control Register (ICSCR) ... 2867

43.2.14 Reference Clock Control Register (ICRCCR) 2869
43.2.15 Standard Bitrate Register (ICSBR) 2870
43.2.16 F/S-Mode Bitrate Register (ICFBR) 2872
43.2.17 Extended Bitrate Register (ICEBR) 2874
43.2.18 Hs-Mode Bitrate Register (ICHBR) 2876
43.2.19 Bus Free Time Setting Register (ICBFTR) 2877
43.2.20 Bus Available Time Setting Register (ICBATR) 2878
43.2.21 Bus Idle Time Setting Register (ICBITR) 2878
43.2.22 Output Signal Control Register (ICOCR) 2879
43.2.23 Input Signal Control Register (ICICR) 2881
43.2.24 Timeout Control Register (ICTOR) 2882
43.2.25 Wake-Up Unit Control Register (ICWUCR) 2884
43.2.26 Acknowledgment Bit Control Register (ICACKR) 2886
43.2.27 Clock Stretch Control Register (ICCSCR) 2887
43.2.28 Clock Stall Control Register (ICSTCR) 2888
43.2.29 Target Transmit/Receive Data Length Register (ICTDLR) 2889
43.2.30 Synchronous Timing Control Register (ICSYTCR) 2890
43.2.31 Asynchronous Timing Control Register (ICASTCR) 2890
43.2.32 Asynchronous Timing Trigger Register (ICASTTR) 2891
43.2.33 Asynchronous Timing Counter Control Register (ICASTCCR) 2891
43.2.34 Condition Generation Request Register (ICCGR) 2892
43.2.35 Command Queue Register (ICCQR) 2894
43.2.36 Response Queue Register (ICRQR) 2894
43.2.37 Transmit/Receive Data Register (ICDR) 2895
43.2.38 IBI Queue Register (ICIQR) 2897
43.2.39 Receive Status Queue Register (ICSQR) 2897
43.2.40 High-Priority Command Queue Register (ICHCQR) 2898
43.2.41 High-Priority Response Queue Register (ICHRQR) 2898
43.2.42 High-Priority Transmit/Receive Data Register (ICHDR) 2899
43.2.43 Queue Buffer Threshold Control Register (ICQBTCR) 2900
43.2.44 Data Buffer Threshold Control Register (ICDBTCR) 2902
43.2.45 Receive Status Queue Threshold Control Register (ICSQTCR) 2903
43.2.46 High-Priority Queue Buffer Threshold Control Register (ICHQBTCR) 2904
43.2.47 High-Priority Data Buffer Threshold Control Register (ICHDBTCR) 2905
43.2.48 Status Register 2 (ICSR2) 2907
43.2.49 Status Detection Enable Register (ICSER) 2910
43.2.50 Status Interrupt Enable Register (ICSIER) 2911
43.2.51 Communication Status Register (ICCSR) 2912
43.2.52 Communication Status Detection Enable Register (ICCSER) 2916
43.2.53 Communication Status Interrupt Enable Register (ICCSIER) 2917
43.2.54 High-Priority Communication Status Register (ICHCSR) 2918

43.2.55 High-Priority Communication Status Detection Enable Register (ICHCSER) 2920
43.2.56 High-Priority Communication Status Interrupt Enable Register (ICHCSIER) 2921
43.2.57 Bus Status Register (ICBSR) 2922
43.2.58 Slave Mode Status Register (ICSSR) 2924
43.2.59 Wake-Up Unit Status Register (ICWUSR) 2927
43.2.60 C_SyncCNT Capture Register (ICCSCCR) 2928
43.2.61 Target Device Address Table Register m (ICTDATRm) (m = 0 to 7) 2929
43.2.62 Extended Target Device Address Table Register (ICEDATR) 2930
43.2.63 Device Address Register y (ICDARy) (y = 0 to 2) 2931
43.2.64 Slave Address Register y (SARy) (y = 0 to 2) 2932
43.2.65 Target Device Characteristics Table Register m (ICTDCTRm) (m = 0 to 7) 2933
43.2.66 Device Characteristics Table Register (ICDCTR) 2935
43.2.67 Provisioned ID Low Register (ICPIDLR) 2937
43.2.68 Provisioned ID High Register (ICPIDHR) 2937
43.2.69 Device Address Monitor Register y (ICDAMRy) (y = 0 to 2) 2938
43.2.70 Slave Address Monitor Register y (SAMRy) (y = 0 to 2) 2940
43.2.71 Target Event Register (ICTEVR) 2942
43.2.72 Activity State Register (ICASR) 2943
43.2.73 Max Write Length Register (ICMWLR) 2945
43.2.74 Max Read Length Register (ICMRLR) 2946
43.2.75 Test Mode Register (ICTMR) 2947
43.2.76 Device Status Register (ICDSR) 2948
43.2.77 Max Write Speed Register (ICMWSR) 2949
43.2.78 Max Read Speed Register (ICMRSR) 2950
43.2.79 Maximum Read Turnaround Time Register (ICMTTR) 2951
43.2.80 Timing Support Information Register (ICTSIR) 2952
43.2.81 Timing Support Information Register 2 (ICTSIR2) 2953
43.2.82 Bit Count Register (ICBCR) 2954
43.2.83 Queue Buffer Status Register (ICQBSR) 2955
43.2.84 Data Buffer Status Register (ICDBSR) 2955
43.2.85 Receive Status Queue Status Register (ICSQSR) 2956
43.2.86 High-Priority Queue Buffer Status Register (ICHQBSR) 2956
43.2.87 High-Priority Data Buffer Status Register (ICHDBSR) 2957
43.2.88 Internal Status Monitor Register (ICIMR) 2957
43.2.89 Controller Error Count Register (ICCECR) 2958
43.2.90 T_C1 Capture Register (ICTC1CR) 2958
43.2.91 T_C2 Capture Register (ICTC2CR) 2959
43.2.92 Communication Clock Control Register (ICCCR) 2959
43.3 Data Structures 2960
43.3.1 Command Descriptor 2960
43.3.1.1 Address Assignment Command 2961

43.3.1.2 Immediate Data Transfer Command 2963
43.3.1.3 Regular Data Transfer Command 2965
43.3.1.4 Combo Transfer Command 2968
43.3.1.5 Internal Control Command 2970
43.3.2 Response Descriptor 2971
43.3.3 IBI Status Descriptor 2974
43.3.4 Receive Status Descriptor 2976
43.4 Operation 2978
43.4.1 Transfer Methods 2978
43.4.2 I3C Protocol 2981
43.4.2.1 Communication Protocol 2981
43.4.2.2 Bus Conditions 2985
43.4.3 I2C Protocol 2986
43.4.4 Initial Settings 2987
43.4.5 I3C Communication Flow 2989
43.4.6 I3C Controller Operation 2991
43.4.6.1 Dynamic Address Assignment Procedure 2991
43.4.6.2 SDR Write Transfer 2993
43.4.6.3 SDR Read Transfer 2995
43.4.6.4 IBI Transfer 2997
43.4.6.5 I3C Controller Transmission Flow (FIFO Buffer Transfer) 3000
43.4.6.6 I3C Controller Transmission Flow (High-Priority FIFO Buffer Transfer) 3001
43.4.6.7 I3C Controller Reception Flow (FIFO Buffer Transfer) 3002
43.4.6.8 I3C Controller Reception Flow (High-Priority FIFO Buffer Transfer) 3003
43.4.6.9 I3C Controller IBI Reception Flow 3004
43.4.7 I3C Target Operation 3005
43.4.7.1 Dynamic Address Assignment Procedure 3005
43.4.7.2 SDR Write Transfer 3007
43.4.7.3 SDR Read Transfer 3009
43.4.7.4 IBI Transfer 3011
43.4.7.5 I3C Target Transmission Flow (FIFO Buffer Transfer) 3013
43.4.7.6 I3C Target Reception Flow (FIFO Buffer Transfer) 3015
43.4.7.7 I3C Target IBI Transmission Flow 3016
43.4.8 I2C Master Operation 3017
43.4.8.1 Master Transmit Operation 3017
43.4.8.2 Master Receive Operation 3021
43.4.9 I2C Slave Operation 3026
43.4.9.1 Slave Transmit Operation 3026
43.4.9.2 Slave Receive Operation 3029
43.5 Details of Function 3032
43.5.1 SCL Synchronization Circuit (I2C Protocol Mode) 3032

43.5.2 SDA Output Delay Function (I^2C Protocol Mode) 3033
43.5.3 Digital Noise Filters (I^2C Protocol Mode) 3034
43.5.4 Address Match Detection (I^2C Protocol Mode) 3035
43.5.4.1 Slave-Address Match Detection 3035
43.5.4.2 General Call Address Detection 3037
43.5.4.3 Device-ID Address Detection 3038
43.5.4.4 Hs-Mode Master Code Detection 3040
43.5.4.5 Host Address Detection 3042
43.5.5 Automatic Low-Hold Function for SCL (I^2C Protocol Mode) 3043
43.5.5.1 Function to Prevent Wrong Transmission of Transmit Data 3043
43.5.5.2 NACK Reception Transfer Suspension Function 3044
43.5.5.3 Function to Prevent Failure to Receive Data 3045
43.5.6 Arbitration-Lost Detection Functions (I^2C Protocol Mode) 3047
43.5.6.1 Master Arbitration-Lost Detection Function (MALE Bit) 3047
43.5.6.2 NACK Transmission Arbitration-Lost Detection Function (NALE Bit) 3049
43.5.6.3 Slave Arbitration-Lost Detection Function (SALE Bit) 3050
43.5.7 START Condition/Repeated START Condition/STOP Condition Generating Function (I^2C Protocol Mode) 3051
43.5.7.1 Generating a START Condition 3051
43.5.7.2 Generating a Repeated START Condition 3051
43.5.7.3 Generating a STOP Condition 3054
43.5.8 Bus Hanging (I^2C Protocol Mode) 3055
43.5.8.1 Timeout Function 3055
43.5.8.2 Additional SCL Output Function 3056
43.5.9 Wake-Up Function (I^2C Protocol Mode) 3057
43.5.9.1 Normal Wake-Up Mode 1 3057
43.5.9.2 Normal Wake-Up Mode 2 3059
43.5.9.3 Command Recovery Mode and EEP Response Mode 3061

45.2.17 Acceptance Filter List Configuration Register (AFCFG) ... 3245

45.2.18 Acceptance Filter List n ID Register (AFLn.IDR) (n = 0 to 15) 3246
45.2.19 Acceptance Filter List n Mask Register (AFLn.MASK) (n = 0 to 15) 3247
45.2.20 Acceptance Filter List n Pointer Register 0 (AFLn.PTR0) (n = 0 to 15) 3248
45.2.21 Acceptance Filter List n Pointer Register 1 (AFLn.PTR1) (n = 0 to 15) 3250
45.2.22 Receive Message Buffer Configuration Register (RMCR) 3252
45.2.23 Receive Message Buffer New Data Register 0 (RMNDR0) 3253
45.2.24 Receive FIFO n Configuration Register (RFCRn) (n = 0 to 7) 3254
45.2.25 Receive FIFO n Status Register (RFSRn) (n = 0 to 7) 3256
45.2.26 Receive FIFO n Pointer Control Register (RFPCRn) (n = 0 to 7) 3258
45.2.27 Common FIFO n Configuration Register (CFCRn) (n = 0 to 5) 3259
45.2.28 Common FIFO n Extended Configuration Register (CFECRn) (n = 0 to 5) 3262
45.2.29 Common FIFO n Status Register (CFSRn) (n = 0 to 5) 3264
45.2.30 Common FIFO n Pointer Control Register (CFPCRn) (n = 0 to 5) 3268
45.2.31 FIFO Empty Status Register (FESR) 3269
45.2.32 FIFO Full Status Register (FFSR) 3271
45.2.33 FIFO Message Lost Status Register (FMLSR) 3273
45.2.34 Receive FIFO Interrupt Status Register (RFISR) 3274
45.2.35 Common FIFO Receive Interrupt Status Register (CFRISR) 3276
45.2.36 Common FIFO Transmit Interrupt Status Register (CFTISR) 3277
45.2.37 FIFO Full Interrupt Status Register (FFISR) 3278
45.2.38 Common FIFO Message Overwrite Status Register (CFOWSR) 3279
45.2.39 Common FIFO One Frame Receive Interrupt Status Register (CFORISR) 3280
45.2.40 Common FIFO One Frame Transmit Interrupt Status Register (CFOTISR) 3281
45.2.41 DMA Transfer Control Register (DTCR) 3282
45.2.42 DMA Transfer Status Register (DTSR) 3284
45.2.43 Transmit DMA Transfer Control Register (TDTCR) 3286
45.2.44 Transmit DMA Transfer Status Register (TDTSR) 3288
45.2.45 Receive Interrupt Status Register (RISR) 3289
45.2.46 Transmit Message Buffer n Control Register (TMCRn) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103) 3291
45.2.47 Transmit Message Buffer n Status Register (TMSRn) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103) 3293
45.2.48 Transmit Message Buffer Transmission Request Status Register m (TMTRSRm) (m = 0 to 3) 3294
45.2.49 Transmit Message Buffer Transmission Abort Request Status Register m (TMARSRm) (m = 0 to 3) 3296
45.2.50 Transmit Message Buffer Transmission Completion Status Register m (TMTCSRm) (m = 0 to 3) 3297
45.2.51 Transmit Message Buffer Transmission Abort Status Register m (TMTASRm) (m = 0 to 3) 3298
45.2.52 Transmit Message Buffer Interrupt Enable Register m (TMIERm) (m = 0 to 3) 3299
45.2.53 Transmit Queue n Configuration Register (TQCRn) (n = 0 to 3) 3300
45.2.54 Transmit Queue n Status Register (TQSRn) (n = 0 to 3) 3303

45.2.55 Transmit Queue n Pointer Control Register (TQPCRn) (n = 0 to 3) 3306
45.2.56 Transmit Queue Empty Status Register (TQESR) 3307
45.2.57 Transmit Queue Full Interrupt Status Register (TQFISR) 3308
45.2.58 Transmit Queue Message Lost Status Register (TQMLSR) 3309
45.2.59 Transmit Queue Interrupt Status Register (TQISR) 3310
45.2.60 Transmit Queue One Frame Transmit Interrupt Status Register (TQOTISR) 3311
45.2.61 Transmit Queue One Frame Receive Interrupt Status Register (TQORISR) 3312
45.2.62 Transmit Queue Full Status Register (TQFSR) 3313
45.2.63 Transmission History Configuration Register (THCR) 3314
45.2.64 Transmission History Status Register (THSR) 3316
45.2.65 Transmission History Access Register 0 (THACR0) 3318
45.2.66 Transmission History Access Register 1 (THACR1) 3319
45.2.67 Transmission History Pointer Control Register (THPCR) 3320
45.2.68 Global Reset Control Register (GRCR) 3321
45.2.69 Global Test Mode Configuration Register (GTMCR) 3322
45.2.70 Global Test Mode Enable Register (GTMER) 3323
45.2.71 Global CAN FD Configuration Register (GFDCFG) 3324
45.2.72 Global Test Mode Lock Key Register (GTMLKR) 3325
45.2.73 RAM Test Page Access Register k (RTPARk) (k = 0 to 63) 3325
45.2.74 Bus Load Control Register (BLCCR) 3326
45.2.75 Bus Load Counter Register (BLCR) 3327
45.2.76 Acceptance Filter List Ignore Entry Setting Register (AFIGSR) 3328
45.2.77 Acceptance Filter List Ignore Entry Enable Register (AFIGER) 3329
45.2.78 Identifier Bits Alignment 3330
45.2.79 Message Buffer Structure 3331
45.2.79.1 Start Addresses 3331
45.2.79.2 Receive Message Buffer n (RMBn) (n = 0 to 31) 3332
45.2.79.3 Receive Message Buffer n Header Field 0 (RMBn.HF0) (n = 0 to 31) 3333
45.2.79.4 Receive Message Buffer n Header Field 1 (RMBn.HF1) (n = 0 to 31) 3334
45.2.79.5 Receive Message Buffer n Header Field 2 (RMBn.HF2) (n = 0 to 31) 3335
45.2.79.6 Receive Message Buffer n Data Field p (RMBn.DFp) (n = 0 to 31; p = 0 to 15) 3337
45.2.79.7 Receive Message Buffer n Data k (RMBn.DATAk) (n = 0 to 31; k = 0 to 63) 3338
45.2.79.8 Receive FIFO n (RFBn) (n = 0 to 7) 3339
45.2.79.9 Receive FIFO n Header Field 0 (RFBn.HF0) (n = 0 to 7) 3340
45.2.79.10 Receive FIFO n Header Field 1 (RFBn.HF1) (n = 0 to 7) 3341
45.2.79.11 Receive FIFO n Header Field 2 (RFBn.HF2) (n = 0 to 7) 3342
45.2.79.12 Receive FIFO n Data Field p (RFBn.DFp) (n = 0 to 7; p = 0 to 15) 3343
45.2.79.13 Receive FIFO n Data k (RFBn.DATAk) (n = 0 to 7; k = 0 to 63) 3343
45.2.79.14 Common FIFO n (CFBn) (n = 0 to 5) 3344
45.2.79.15 Common FIFO n Header Field 0 (CFBn.HF0) (n = 0 to 5) 3345

45.2.79.16 Common FIFO n Header Field 1 (CFBn.HF1) (n = 0 to 5) 3346
45.2.79.17 Common FIFO n Header Field 2 (CFBn.HF2) (n = 0 to 5) 3347
45.2.79.18 Common FIFO n Data Field p (CFBn.DFp) (n = 0 to 5; p = 0 to 15) 3349
45.2.79.19 Common FIFO n Data k (CFBn.DATAk) (n = 0 to 5; k = 0 to 63) 3349
45.2.79.20 Transmit Message Buffer n (TMBn) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103) 3350
45.2.79.21 Transmit Message Buffer n Header Field 0 (TMBn.HF0) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103) 3351
45.2.79.22 Transmit Message Buffer n Header Field 1 (TMBn.HF1) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103) 3352
45.2.79.23 Transmit Message Buffer n Header Field 2 (TMBn.HF2) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103) 3353
45.2.79.24 Transmit Message Buffer n Data Field p (TMBn.DFp) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103; p = 0 to 15) 3355
45.2.79.25 Transmit Message Buffer n Data k (TMBn.DATAk) (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103; k = 0 to 63) 3356
45.2.80 ECC Control/Status Register (AFLRAM0.ECCSR, AFLRAM1.ECCSR, MBRAM.ECCSR) 3357
45.2.81 ECC Test Mode Register (AFLRAM0.ECTMR, AFLRAM1.ECTMR, MBRAM.ECTMR) 3361
45.2.82 ECC Decoder Test Data Register (AFLRAM0.ECTDR, AFLRAM1.ECTDR, MBRAM.ECTDR) 3362
45.2.83 ECC Error Address Register (AFLRAM0.ECEAR, AFLRAM1.ECEAR, MBRAM.ECEAR) 3362
45.3 Operating Mode 3363
45.3.1 Global Modes 3363
45.3.1.1 GL_SLEEP Mode 3364
45.3.1.2 GL_RESET Mode 3365
45.3.1.3 GL_HALT Mode 3366
45.3.1.4 GL_OPERATION Mode 3368
45.3.2 Channel Modes 3369
45.3.2.1 CH_SLEEP Mode 3369
45.3.2.2 CH_RESET Mode 3370
45.3.2.3 CH_HALT Mode 3370
45.3.2.4 CH_OPERATION Mode (in Other than Bus-Off State) 3371
45.3.2.5 CH_OPERATION Mode (in Bus-Off State) 3372
45.3.3 Global Mode and Channel Mode Transition Interactions 3375
45.3.3.1 Transition Time for Global Mode Change 3375
45.3.3.2 Transition Time for Channel Mode Change 3376
45.4 Initialization of CANFDG Module 3377
45.4.1 Initialization of CAN Clock, Bit Timing, and Bit Rate 3377
45.4.1.1 Bit Timing Conditions 3377
45.4.1.2 Bit Timing 3378
45.4.1.3 Bit Rate 3379
45.4.1.4 Setting of CAN Clock, Bit Timing and Bit Rate 3381

45.4.1.5 Transceiver Delay Compensation 3382
45.4.2 CANFDG Module Configuration after a Reset 3384
45.5 Filtering Using Acceptance Filter List (AFL) 3386
45.5.1 Acceptance Filtering Process 3386
45.5.2 DLC Filtering Process 3386
45.5.3 Message Storage 3387
45.5.4 Payload Overflow Process 3387
45.5.5 Allocation of AFL Entries to Each CAN Channel 3388
45.5.6 AFL Entry Description 3389
45.5.7 Entering Entries in the AFL 3391
45.5.8 Loop-Back Configuration 3393
45.5.9 IDE Masking 3394
45.5.10 Updating AFL Entry during Communication 3394
45.6 FIFO Buffers and Message Buffer Configuration 3397
45.6.1 Receive Message Buffers 3398
45.6.1.1 Receive Message Buffer Configuration 3398
45.6.2 FIFO Buffers 3399
45.6.2.1 FIFO Buffers Configuration 3399
45.6.2.2 FIFO Buffers Control 3403
45.7 Reception and Transmission 3404
45.7.1 Reception 3404
45.7.1.1 Message Storage in Receive Message Buffers 3404
45.7.1.2 Message Storage in FIFO Buffers 3406
45.7.1.3 Timestamp 3408
45.7.2 Transmission 3409
45.7.2.1 Transmission Priority 3410
45.7.2.2 Message Transmission from Transmit Message Buffer 3411
45.7.2.3 Message Transmission from FIFO Buffer 3414
45.7.2.4 Transmit Queue 3419
45.7.2.5 Transmission History 3422
45.7.2.6 Transmit Data Padding 3424
45.8 ECC Check 3425
45.8.1 ECC Function Setting 3425
45.8.2 ECC Decoder Testing 3426
45.9 Test Mode 3427
45.9.1 Channel Specific Test Modes 3427
45.9.1.1 Basic Test Mode 3427
45.9.1.2 Listen-Only Mode 3427
45.9.1.3 Self Test Mode 0 (External Loop-Back Mode) 3428
45.9.1.4 Self Test Mode 1 (Internal Loop-Back Mode) 3429
45.9.1.5 Restricted Operation Mode 3429

47.2.17 RSPI Transmit FIFO Status Register (SPTFSR) ... 3671
47.2.18 RSPI Receive FIFO Status Register (SPRFSR) ... 3671
47.2.19 RSPI Polling Status Register (SPPSR) ... 3672

47.2.20 RSPI Status Clear Register (SPSCLR) 3673
47.2.21 RSPI FIFO Clear Register (SPFCLR) 3674
47.3 Operation 3675
47.3.1 Overview of RSPI Operations 3675
47.3.2 Controlling RSPI Pins 3677
47.3.3 RSPI System Configuration Examples 3677
47.3.3.1 Single Master/Single Slave (with This MCU Acting as Master) 3677
47.3.3.2 Single Master/Single Slave (with This MCU Acting as Slave) 3678
47.3.3.3 Single Master/Multi-Slave (with This MCU Acting as Master) 3679
47.3.3.4 Single Master/Multi-Slave (with This MCU Acting as Slave) 3680
47.3.3.5 Multi-Master/Multi-Slave (with This MCU Acting as Master) 3681
47.3.3.6 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Master) 3682
47.3.3.7 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Slave) 3682
47.3.4 Data Format 3683
47.3.4.1 Data Format of One Frame 3683
47.3.4.2 When Parity is Disabled (SPCR.SPPE = 0) 3684
47.3.4.3 When Parity is Enabled (SPCR.SPPE = 1) 3688
47.3.4.4 Byte Swap Transmission 3692
47.3.4.5 Byte Swap Reception 3694
47.3.5 Transfer Format (Frame Format) 3698
47.3.5.1 When CPHA = 0 3698
47.3.5.2 When CPHA = 1 3699
47.3.6 Communication Mode 3701
47.3.6.1 Transmit-Receive Mode (SPCR.CMMD[1:0] = 00b) 3701
47.3.6.2 Transmit-Only Mode (SPCR.CMMD[1:0] = 01b) 3702
47.3.6.3 Receive-Only Mode (SPCR.CMMD[1:0] = 10b) 3703
47.3.7 Transmit Buffer Empty/Receive Buffer Full Interrupts 3704
47.3.8 Idle Interrupts 3706
47.3.9 Communication End Interrupts 3708
47.3.9.1 Transmit-Receive Master Mode or Transmit-Only Master Mode 3708
47.3.9.2 Receive-Only Master Mode 3710
47.3.9.3 Transmit-Receive Slave Mode or Transmit-Only Slave Mode on SPI Operation 3712
47.3.9.4 Receive-Only Slave Mode on SPI Operation 3714
47.3.9.5 Transmit-Receive Slave Mode or Transmit-Only Slave Mode on Clock Synchronous Operation 3716
47.3.9.6 Receive-Only Slave Mode on Clock Synchronous Operation 3717
47.3.10 Error Detection 3718
47.3.10.1 Overrun Error 3719
47.3.10.2 Parity Error 3724

47.3.10.3 Mode Fault Error ... 3725
47.3.10.4 Underrun Error ... 3725

47.3.12.1 Initialization by Clearing the SPE Bit ... 3727
47.3.12.2 System Reset ... 3727
47.3.13 SPI Operation ... 3728
47.3.13.1 Master Mode Operation ... 3728
47.3.13.2 Slave Mode Operation ... 3741
47.3.14 Clock Synchronous Operation ... 3747
47.3.14.1 Master Mode Operation ... 3747
47.3.14.2 Slave Mode Operation ... 3751
47.3.15 Loopback Mode ... 3753
47.3.16 Self-Diagnosis of Parity Bit Function ... 3754
47.3.17 Interrupt Sources ... 3755
47.3.18 Link Operation by Event Linking ... 3756
47.3.18.1 Receive Buffer Full Event Output ... 3756
47.3.18.2 Transmit Buffer Empty Event Output ... 3756
47.3.18.3 Error Event Output ... 3757
47.3.18.4 Idle Event Output ... 3758
47.3.18.5 Communication End Event Output ... 3759
47.3.19 Synchronizer Bypass Function ... 3761
47.4 Usage Notes ... 3762
47.4.1 Settings of the Module Stop Function ... 3762
47.4.2 Notes on Starting Transfer ... 3762
47.4.3 Note on Error Events Output ... 3762
47.4.4 Note on Low Power Consumption Functions ... 3762
47.4.5 Note on the SPRF and SPTEF flags ... 3762
47.4.6 Notes on Burst Transfer in Master Mode ... 3762
47.4.7 Notes on Operating in TI SSP Slave Mode ... 3762
47.4.8 Notes on Data Length and Frequency Ratio ... 3763
47.4.9 Notes on Rewriting Registers ... 3763
48. Expanded Serial Peripheral Interface (XSPI) ... 3765
48.1 Overview ... 3765
48.2 Register Descriptions ... 3769
48.2.1 Operating Mode Setting Register (DIPCFG) ... 3769
48.2.2 Controller Mode Registers ... 3770
48.2.2.1 Timing Configuration Register (WRAPCFG) ... 3770
48.2.2.2 Common Configuration Register (COMCFG) ... 3771
48.2.2.3 Memory-Mapped Mode Configuration Register (BMCFGCH0) ... 3772

48.2.2.4 CSi Area Memory-Mapped Mode Configuration Register 0 (CMCFG0CSi) (i = 0, 1) ... 3774
48.2.2.5 CSi Area Memory-Mapped Mode Configuration Register 1 (CMCFG1CSi) (i = 0, 1) ... 3776
48.2.2.6 CSi Area Memory-Mapped Mode Configuration Register 2 (CMCFG2CSi) (i = 0, 1) ... 3777
48.2.2.7 CSi Area I/O Signal Configuration Register (LIOCFGCSi) (i = 0, 1) ... 3778
48.2.2.8 Memory Access Extension Configuration Register (MEMEXTCFG) ... 3781
48.2.2.9 Memory-Mapped Mode Control Register 0 (BMCTL0) ... 3782
48.2.2.10 Memory-Mapped Mode Control Register 1 (BMCTL1) ... 3783
48.2.2.11 Memory-Mapped Mode Command Control Register (CMCTLCH0) ... 3784
48.2.2.12 Indirect Access Mode Control Register 0 (CDCTL0) ... 3785
48.2.2.13 Indirect Access Mode Control Register 1 (CDCTL1) ... 3786
48.2.2.14 Indirect Access Mode Control register 2 (CDCTL2) ... 3787
48.2.2.15 Command Buffer m Transaction Type Register (CDTBUFm) (m = 0 to 3) ... 3788
48.2.2.16 Command Buffer m Address Register (CDABUFm) (m = 0 to 3) ... 3790
48.2.2.17 Command Buffer m Data Register 0 (CDD0BUFm) (m = 0 to 3) ... 3791
48.2.2.18 Command Buffer m Data Register 1 (CDD1BUFm) (m = 0 to 3) ... 3791
48.2.2.19 Signal Pattern Control Register 0 (LPCTL0) ... 3792
48.2.2.20 Signal Pattern Control Register 1 (LPCTL1) ... 3794
48.2.2.21 I/O Signal Control Register (LIOCTL) ... 3796
48.2.2.22 CSi Area Calibration Control Register 0 (CCCTL0CSi) (i = 0, 1) ... 3797
48.2.2.23 CSi Area Calibration Control Register 1 (CCCTL1CSi) (i = 0, 1) ... 3799
48.2.2.24 CSi Area Calibration Control Register 2 (CCCTL2CSi) (i = 0, 1) ... 3800
48.2.2.25 CSi Area Calibration Control Register 3 (CCCTL3CSi) (i = 0, 1) ... 3801
48.2.2.26 CSi Area Calibration Control Register 4 (CCCTL4CSi) (i = 0, 1) ... 3801
48.2.2.27 CSi Area Calibration Control Register 5 (CCCTL5CSi) (i = 0, 1) ... 3802
48.2.2.28 CSi Area Calibration Control Register 6 (CCCTL6CSi) (i = 0, 1) ... 3802
48.2.2.29 CSi Area Calibration Control Register 7 (CCCTL7CSi) (i = 0, 1) ... 3803
48.2.2.30 Common Status Register (COMSTT) ... 3804
48.2.2.31 CSi Area Calibration Status Register (CASTTCSi) (i = 0, 1) ... 3806
48.2.2.32 Interrupt Status Register (INTS) ... 3808
48.2.2.33 Interrupt Clear Register (INTC) ... 3810
48.2.2.34 Interrupt Enable Register (INTE) ... 3811
48.2.3 Target Mode Registers ... 3812
48.2.3.1 L1.5 Configuration Register 0 (L15CFG0) ... 3812
48.2.3.2 L1.5 Configuration Register 1 (L15CFG1) ... 3813
48.2.3.3 L1.5 Configuration Register 2 (L15CFG2) ... 3814
48.2.3.4 L2 Configuration Register 0 (L2CFG0) ... 3815
48.2.3.5 L2 Configuration Register 1 (L2CFG1) ... 3816
48.2.3.6 Target Write Address Register (TWADR) ... 3817
48.2.3.7 Target Write Length Register (TWLEN) ... 3817

48.2.3.8 Target Write Control Register (TWCNT) ... 3818
48.2.3.9 Target Read Address Register (TRADR) ... 3818
48.2.3.10 Target Read Length Register (TRLEN) ... 3819
48.2.3.11 Target Read Control Register (TRCNT) ... 3819
48.2.3.12 Transfer Control Register (TRNSC) ... 3820
48.2.3.13 Target Write Buffer Status Register (TWBS) ... 3821
48.2.3.14 Target Write Transfer Status Register (TWTS) ... 3821
48.2.3.15 Target Read Buffer Status Register (TRBS) ... 3822
48.2.3.16 Target Read Transfer Status Register (TRTS) ... 3822

52.2.6 SD Status Register 1 (SDSTS1) ... 3932
52.2.7 SD Status Register 2 (SDSTS2) ... 3935
52.2.8 SD Interrupt Mask Register 1 (SDIMSK1) ... 3939
52.2.9 SD Interrupt Mask Register 2 (SDIMSK2) ... 3940
52.2.10 SDHI Clock Control Register (SDCLKCR) ... 3941
52.2.11 Transfer Data Size Register (SDSIZE) ... 3942
52.2.12 Card Access Option Register (SDOPT) ... 3943
52.2.13 SD Error Status Register 1 (SDERSTS1) ... 3945

52.2.14 SD Error Status Register 2 (SDERSTS2) 3946
52.2.15 SD Buffer Register (SDBUFR) 3947
52.2.16 SDIO Mode Control Register (SDIOMD) 3948
52.2.17 SDIO Status Register (SDIOSTS) 3950
52.2.18 SDIO Interrupt Mask Register (SDIOIMSK) 3951
52.2.19 DMA Transfer Enable Register (SDDMAEN) 3952
52.2.20 SDHI Software Reset Register (SDRST) 3953
52.2.21 SD/MMC Interface Mode Register (SDIFMD) 3954
52.2.22 Swap Control Register (SDSWAP) 3955
52.3 SDHI Operation 3956
52.3.1 Data Block Format of the SD Card/MMC 3956
52.3.2 SD Buffer and the SDBUFR Register 3957
52.3.3 SD Card/MMC Detection 3958
52.3.3.1 Using the SD0_CD Pin to Detect an SD Card/MMC 3958
52.3.3.2 Using the SD0_DAT3 Pin to Detect an SD Card 3959
52.3.4 SD Card/MMC Write Protection 3959
52.3.4.1 Using the SD0_WP Pin to Enable Write Protection 3959
52.3.4.2 Using a Command to Enable Write Protection 3959
52.3.5 Communication Errors and Timeouts 3960
52.3.6 Examples of Issuing a Command 3961
52.3.6.1 Command Absent of Response Reception and Data Transfer 3961
52.3.6.2 Command Absent of Data Transfer 3962
52.3.6.3 Single Block Read Command (CMD17) 3963
52.3.6.4 Single Block Write Command (CMD24) 3965
52.3.6.5 Multi-Block Read Command (CMD18) 3967
52.3.6.6 Multi-Block Write Command (CMD25) 3969
52.3.6.7 Multi-Block Write Command (CMD54) 3971
52.3.6.8 IO_RW_DIRECT Command (CMD52) 3973
52.3.6.9 IO_RW_EXTENDED Command (CMD53 (Multi-Block Read)) 3974
52.3.6.10 IO_RW_EXTENDED (CMD53 Multi-Block Write) 3976
52.3.6.11 DMA Transfer 3978
52.4 Interrupts 3980
52.4.1 DMA Transfer Triggered by Interrupt Requests 3981
52.5 Notes on Using the SDHI 3982
52.5.1 Illegal Read Access During a Multi-Block Read and How To Avoid It 3982
52.5.2 SDBUFR Register Illegal Write Error 3982
52.5.3 Automatic Control of the SDHI Clock Output 3983
52.5.4 Restrictions on Setting the C52PUB Bit During a Multi-Block Write Sequence 3983
52.5.5 Note on Setting the SDCLKCR Register 3983
52.5.6 Writing to the SDSTOP Register During a Multi-Block Read Sequence 3983
52.5.7 Controlling Module Operation 3983

53. Parallel Data Capture Unit (PDC) 3984
53.1 Overview 3984
53.2 Register Descriptions 3986

53.2.2 PDC Control Register 1 (PCCR1) 3988
53.2.3 PDC Status Register (PCSR) 3989
53.2.4 PDC Pin Monitor Register (PCMONR) 3991
53.2.5 PDC Receive Data Register (PCDR) 3991
53.2.6 Vertical Capture Register (VCR) 3993
53.2.7 Horizontal Capture Register (HCR) 3994
53.3 Operation 3995
53.3.1 Transfer Formats 3995
53.3.2 Transfer Timing 3996
53.3.3 Settings of the VCR and HCR Registers and the Captured Range 3997
53.3.4 Operations for Reception 3999
53.3.5 Operation during the Horizontal Blanking Period 4000
53.3.6 Operations for Continued Reception at the Time of Frame End 4000
53.3.7 Error Detection 4001
53.3.8 Initial Settings 4004
53.3.9 Flows of Operations 4005
53.3.10 Interrupt Source 4007
53.3.11 Reset State 4008
53.4 Usage Notes 4009
53.4.1 Setting of the Module Stop Function 4009
53.4.2 Notes on the Power Consumption Reduction Function 4009
53.4.3 Notes on Error Interrupts 4009
53.4.4 Notes on Use of the DTC 4009
53.4.5 Notes on Use of the DMAC 4009
53.4.6 Notes on Start of Transfer 4010
54. Boundary Scan 4011
54.1 Overview 4011
54.2 Register Descriptions 4012
54.2.1 Instruction Register (JTIR) 4013
54.2.2 ID Code Register (JTIDR) 4013
54.2.3 Bypass Register (JTBPR) 4014
54.2.4 Boundary Scan Register (JTBSR) 4014
54.3 Operations 4043
54.3.1 TAP Controller 4043
54.3.2 List of Commands 4044
54.4 Usage Notes 4045

55. Arithmetic Unit for Trigonometric Functions (TFUv2) 4046
55.1 Overview 4046
55.2 Register Descriptions 4048
55.2.1 Fixed-Point Sincos Input and Output Setting Register (FXSCIOC) 4048
55.2.2 Fixed-Point Atanhypot_k Input and Output Setting Register (FXATIOC) 4049
55.2.3 Trigonometric Status Register (TRGSTS) 4050
55.2.4 Floating-Point Sincos Data Register 0 (FPSCDT0) 4051
55.2.5 Floating-Point Sincos Data Register 1 (FPSCDT1) 4051
55.2.6 Floating-Point Atanhypot_k Data Register 0 (FPATDT0) 4052
55.2.7 Floating-Point Atanhypot_k Data Register 1 (FPATDT1) 4052
55.2.8 Fixed-Point Sincos Data Register 0 (FXSCDT0) 4053
55.2.9 Fixed-Point Sincos Data Register 1 (FXSCDT1) 4053
55.2.10 Fixed-Point Atanhypot_k Data Register 0 (FXATDT0) 4055
55.2.11 Fixed-Point Atanhypot_k Data Register 1 (FXATDT1) 4055
55.2.12 Data Saving and Restoring Register 0 (DTSR0) 4057
55.2.13 Data Saving and Restoring Register 1 (DTSR1) 4057
55.2.14 TFU Security Attribution Register (TFUSAR) 4058
55.3 Operation 4059
55.3.1 Arithmetic Processing 4059
55.3.2 Input and Output Value Formats 4059
55.3.2.1 Single-Precision Floating-Point Numbers 4059
55.3.2.2 Fixed-Point Numbers 4060
55.3.3 Units of Angles 4061
55.3.4 Relationship Between Input and Output Values for Sincos Operation 4061
55.3.5 Relationship Between Input and Output Values for Atan Operation 4062
55.3.6 Relationship Between Input and Output Values for hypot_k Operation 4062
55.4 Usage Procedures 4063
55.4.1 Procedures for Using the TFU 4063
55.4.2 How to Use Interrupts 4065
56. Security Features 4066
56.1 Features 4066
56.2 Detection of Tampering 4067
56.3 Protect Zone Feature 4068
56.3.1 Protect Zone Technology 4068
56.3.2 Flat-Project and Non-Flat-Project 4068
56.3.3 Relationship Between Interrupts and Worlds 4069
56.3.3.1 When Set for Operation for Non-Flat-Project 4070
56.3.3.2 When Set for Operation for Flat-Project 4070
56.3.4 Protect Zone Initial State 4070
56.4 Bus Access and Address Space 4071
56.5 Security Attribution Unit (SAU) 4074

56.5.1 Types of CPU Access 4074
56.5.2 Address-Space Security Attribute 4074
56.5.3 Transaction Types Issued 4074
56.5.4 Access Across Different Security Attribute Spaces 4074
56.5.5 Functions 4075
56.5.5.1 Secure Memory Protection Function 4075
56.5.5.2 Protection of Security Attribution Management Registers 4075
56.5.5.3 Access Determination Flow for the Secure Memory Protection Function 4075
56.5.6 Instructions for Use 4077
56.5.6.1 Handling Secure Exceptions 4077
56.6 Memory Security Attributes 4077
56.7 Security Attribution of Peripherals 4080
56.8 Protect Zone Access Error 4080
56.9 Register Descriptions 4081
56.9.1 Secure Address-Space Attribute Setting Register (AAS) 4081
56.9.2 Secure Exception Status Register (SESTS) 4082
56.9.3 Secure Exception Status Clear Register (SECLR) 4083
56.9.4 Secure Exception Address Register (SEA) 4084
56.9.5 Peripheral Security Attribution Register B (PSARB) 4085
56.9.6 Peripheral Security Attribution Register C (PSARC) 4087
56.9.7 Peripheral Security Attribution Register D (PSARD) 4089
56.9.8 Peripheral Security Attribution Register E (PSARE) 4090
56.9.9 Peripheral Security Attribution Register F (PSARF) 4091
56.9.10 Module Stop Security Attribution Register (MSSAR) 4092
56.9.11 Code MRAM Security Attribution Monitor Register (CMSAMON) 4093
56.9.12 Data MRAM Security Attribution Monitor Register (DMSAMON) 4094
56.9.13 Device Lifecycle Management State Monitor Register (DLMMON) 4095
56.9.14 Master Security Attribution Operation-After-Detection Register (MSAOAD) 4096
56.9.15 Master Security Attribution Protect Register (MSAPT) 4097
56.10 Secure Key Injection 4098
56.11 Secure Factory Programming 4100
56.12 Secure Boot 4102
56.13 Field Updating in Dual Mode 4109
56.14 Device Lifecycle Management 4110
56.14.1 Changing Lifecycle States 4111
56.14.2 Protection and Authentication Levels 4111
56.14.3 Serial Programming 4113
56.14.4 Device Lifecycle States and PL Change Examples 4113
56.14.5 Failure Analysis 4113
56.15 Usage Notes 4114
56.15.1 Notes on Settings of the Security Attribution Bits 4114

56.15.2 Security Attribution Bit Write Timing 4114
56.15.3 Executing the WAIT Instruction in Non-Flat-Project Operation 4114
57. Renesas Secure IP (RSIP-E50D) 4115
57.1 Overview 4115
57.2 Operation 4117
57.2.1 Encryption Engine 4117
57.2.2 Encryption and Decryption 4118
57.3 Usage Notes 4118
57.3.1 Standby Mode 4118
57.3.2 Setting the Module Stop Function 4118
57.3.3 Protection against SPA/DPA 4118
57.3.4 RSIP Library 4118
58. Pulse-Density Modulation Interface (PDM-IF) 4119
58.1 Overview 4119
58.2 Register Descriptions 4121
58.2.1 Register Map 4121
58.2.2 Channel Software Start Trigger Register (PDCSTRTR) 4125
58.2.3 Channel Software Stop Trigger Register (PDCSTPTR) 4125
58.2.4 Channel Software Change Trigger Register (PDCCHGTR) 4126
58.2.5 Channel Interrupt Control Register (PDCICR) 4126
58.2.6 Channel Status Register (PDCSR) 4127
58.2.7 Channel Status Clear Register (PDCSCR) 4129
58.2.8 Channel Audio Detection Control Register (PDCSDCR) 4129
58.2.9 Channel Data Read Control Register (PDCDRCR) 4130
58.2.10 Channel Data Clear Register (PDCDCR) 4130
58.2.11 Version Register (PDVR) 4131
58.2.12 Software Start Trigger Register Channel 0 (PDSTRTRCH0) 4131
58.2.13 Software Stop Trigger Register Channel 0 (PDSTPTRCH0) 4132
58.2.14 Software Change Trigger Register Channel 0 (PDCHGTRCH0) 4132
58.2.15 Interrupt Control Register Channel 0 (PDICRCH0) 4133
58.2.16 Status Detection Control Register Channel 0 (PDSDCRCH0) 4134
58.2.17 Status Register Channel 0 (PDSRCH0) 4135
58.2.18 Status Clear Register Channel 0 (PDSCRCH0) 4137
58.2.19 Mode Setting Register Channel 0 (PDMDSRCH0) 4138
58.2.20 Sinc Filter Control Register Channel 0 (PDSFCRCH0) 4139
58.2.21 High-Pass Filter Coefficient s (0) Register Channel 0 (PDHFCS0RCH0) 4141
58.2.22 High-Pass Filter Coefficient k (1) Register Channel 0 (PDHFCK1RCH0) 4141
58.2.23 High-Pass Filter Coefficient h (0) Register Channel 0 (PDHFCH0RCH0) 4142
58.2.24 High-Pass Filter Coefficient h (1) Register Channel 0 (PDHFCH1RCH0) 4142
58.2.25 Compensation Filter Coefficient h (0) Register Channel 0 (PDCFCH00RCH0) 4143
58.2.26 Compensation Filter Coefficient h (1) Register Channel 0 (PDCFCH01RCH0) 4143

58.2.27 Compensation Filter Coefficient h (2) Register Channel 0 (PDCFCH02RCH0) 4144
58.2.28 Compensation Filter Coefficient h (3) Register Channel 0 (PDCFCH03RCH0) 4144
58.2.29 Compensation Filter Coefficient h (4) Register Channel 0 (PDCFCH04RCH0) 4145
58.2.30 Compensation Filter Coefficient h (5) Register Channel 0 (PDCFCH05RCH0) 4145
58.2.31 Compensation Filter Coefficient h (6) Register Channel 0 (PDCFCH06RCH0) 4146
58.2.32 Compensation Filter Coefficient h (7) Register Channel 0 (PDCFCH07RCH0) 4146
58.2.33 Compensation Filter Coefficient h (8) Register Channel 0 (PDCFCH08RCH0) 4147
58.2.34 Compensation Filter Coefficient h (9) Register Channel 0 (PDCFCH09RCH0) 4147
58.2.35 Compensation Filter Coefficient h (10) Register Channel 0 (PDCFCH10RCH0) 4148
58.2.36 Low-Pass Filter Coefficient h0 (10) Register Channel 0 (PDLFCH010RCH0) 4148
58.2.37 Low-Pass Filter Coefficient h1 (0) Register Channel 0 (PDLFCH100RCH0) 4149
58.2.38 Low-Pass Filter Coefficient h1 (1) Register Channel 0 (PDLFCH101RCH0) 4149
58.2.39 Low-Pass Filter Coefficient h1 (2) Register Channel 0 (PDLFCH102RCH0) 4150
58.2.40 Low-Pass Filter Coefficient h1 (3) Register Channel 0 (PDLFCH103RCH0) 4150
58.2.41 Low-Pass Filter Coefficient h1 (4) Register Channel 0 (PDLFCH104RCH0) 4151
58.2.42 Low-Pass Filter Coefficient h1 (5) Register Channel 0 (PDLFCH105RCH0) 4151
58.2.43 Low-Pass Filter Coefficient h1 (6) Register Channel 0 (PDLFCH106RCH0) 4152
58.2.44 Low-Pass Filter Coefficient h1 (7) Register Channel 0 (PDLFCH107RCH0) 4152
58.2.45 Low-Pass Filter Coefficient h1 (8) Register Channel 0 (PDLFCH108RCH0) 4153
58.2.46 Low-Pass Filter Coefficient h1 (9) Register Channel 0 (PDLFCH109RCH0) 4153
58.2.47 Low-Pass Filter Coefficient h1 (10) Register Channel 0 (PDLFCH110RCH0) 4154
58.2.48 Low-Pass Filter Coefficient h1 (11) Register Channel 0 (PDLFCH111RCH0) 4154
58.2.49 Low-Pass Filter Coefficient h1 (12) Register Channel 0 (PDLFCH112RCH0) 4155
58.2.50 Low-Pass Filter Coefficient h1 (13) Register Channel 0 (PDLFCH113RCH0) 4155
58.2.51 Low-Pass Filter Coefficient h1 (14) Register Channel 0 (PDLFCH114RCH0) 4156
58.2.52 Low-Pass Filter Coefficient h1 (15) Register Channel 0 (PDLFCH115RCH0) 4156
58.2.53 Low-Pass Filter Coefficient h1 (16) Register Channel 0 (PDLFCH116RCH0) 4157
58.2.54 Low-Pass Filter Coefficient h1 (17) Register Channel 0 (PDLFCH117RCH0) 4157
58.2.55 Low-Pass Filter Coefficient h1 (18) Register Channel 0 (PDLFCH118RCH0) 4158
58.2.56 Low-Pass Filter Coefficient h1 (19) Register Channel 0 (PDLFCH119RCH0) 4158
58.2.57 Audio Detection Lower Threshold Register Channel 0 (PDSDLTRCH0) 4159
58.2.58 Audio Detection Upper Threshold Register Channel 0 (PDSDUTRCH0) 4159
58.2.59 Data Buffer Control Register Channel 0 (PDDBCRCH0) 4160
58.2.60 Short-Circuit Threshold Setting Register Channel 0 (PDSCTSRCH0) 4160
58.2.61 Overvoltage Lower Threshold Register Channel 0 (PDOVLTRCH0) 4161
58.2.62 Overvoltage Upper Threshold Register Channel 0 (PDOVUTRCH0) 4161
58.2.63 Data Read Control Register Channel 0 (PDDRCRCH0) 4162
58.2.64 Data Clear Register Channel 0 (PDDCRCH0) 4162
58.2.65 Data Read Register Channel 0 (PDDRRCH0) 4163
58.2.66 Data Status Register Channel 0 (PDDSRCH0) 4163
58.2.67 Mirroring Registers 4164

58.3 Operation 4165
58.3.1 Clock Specifications 4165
58.3.1.1 Output Sampling Frequency 4165
58.3.2 Channel Start and Channel Stop 4166
58.3.3 Changing the PDMCLK0 Frequency 4166
58.3.4 Filters 4167
58.3.4.1 Data Clipping and Shifting Among Filters 4167
58.3.4.2 Sinc Filter 4172
58.3.4.3 High-Pass Filter 4174
58.3.4.4 Compensation Filter 4175
58.3.4.5 Low-Pass (Half-Band Decimation) Filter 4176
58.3.4.6 Moving Average Filter 4177
58.3.4.7 Settling Times of Channel Start and Setting Change 4178
58.3.5 Audio Detection 4179
58.3.6 Data Buffer 4180
58.3.7 Short-Circuit Detection 4181
58.3.8 Overvoltage Detection 4182
58.3.9 Errors 4183
58.3.10 Interrupt Functions 4183
58.4 Setting Flows 4184
58.4.1 Start Flow 4187
58.4.2 Stop Flow 4188
58.4.3 Normal Processing Flow 4189
58.4.4 Low Power Consumption Mode Transition Flow 4190
58.4.5 Normal Mode Transition Flow 4191
58.5 Usage Notes 4192
58.5.1 Setting the Data Receive Interrupt Threshold 4192
58.5.2 Default Filter Frequency Characteristics 4192
59. Phase-Counting Interface (PCIF) 4194
59.1 Overview 4194
59.2 Register Descriptions 4198
59.2.1 PCIF Clock Enable Register (CLKER) 4198
59.2.2 PCIF Clock Status Register (CLKSR) 4199
59.2.3 PCIF Clock Control Register (CLKCR) 4200
59.2.4 PCIF Control Register (CTLR) 4201
59.2.5 PCIF Maximum Position Setting Register (POSMAXR) 4202
59.2.6 PCIF Start/Stop Trigger Register (TRGR) 4203
59.2.7 PCIF Status Register (SR) 4204
59.2.8 PCIF Phase Counting Mode Control Register (PHCCTLR) 4205
59.2.9 Carrier Period Event Difference Threshold Select Register for PCIF Phase Counting Mode (PHCCEDTHR) 4207

59.2.10 PCIF Phase Counting Mode Carrier Period Setting Register (PHCPERIODR) 4208
59.2.11 PCIF Phase Counting Mode Edge Count Setting Register (PHCECR) 4209
59.2.12 PCIF Phase Counting Mode Position Count Monitor Register (PHCPCMR) 4210
59.2.13 PCIF Phase Counting Mode Position Counter Write Register (PHCPCWDR) 4211
59.2.14 PCIF Phase Counting Mode Status Register (PHCSR) 4212
59.2.15 PCIF Phase Counting Mode Status Clear Register (PHCSCR) 4213
59.2.16 PCIF Phase Counting Mode Status Enable Register (PHCSER) 4214
59.2.17 PCIF Incremental Mode Control Register (INCCTLR) 4215
59.2.18 PCIF Incremental Mode Z-Phase Generation Control Register (INCZGCTLR) 4217
59.2.19 PCIF Incremental Mode Position Counter Clear Enable Register (INCPCCER) 4219
59.2.20 PCIF Incremental Mode Software Trigger Register (INCSWTRGR) 4220
59.2.21 PCIF Incremental Mode Position Counter Monitor Register (INCPCMR) 4221
59.2.22 PCIF Software Reset Register (SWRSTR) 4222
59.3 Operation 4223
59.3.1 Phase Counting Mode 4223
59.3.1.1 Startup Control 4224
59.3.1.2 Stop Control 4225
59.3.1.3 Carrier Period Control 4227
59.3.1.4 Position Counter Control 4230
59.3.1.5 Generating A-, B-, and Z-Phase Signals 4232
59.3.1.6 States 4233
59.3.2 Incremental Mode 4238
59.3.2.1 Startup/Stop Control 4239
59.3.2.2 Generating A- and B-Phase Signals 4241
59.3.2.3 Generating Z-Phase Signals 4250
59.3.3 Output Controller 4257
59.3.3.1 ABZ-Phase Output Inversion Function 4257
59.3.4 Operating Flows 4258
59.3.4.1 Overall Operation 4258
59.3.4.2 PCIF Startup Processing 4259
59.3.4.3 Flows of Phase Counting Mode 4260
59.3.4.4 Flows of Incremental Mode 4264
59.3.4.5 PCIF Stop Processing 4267
59.4 Event Link Function 4268
59.4.1 Carrier Period Event Input (ELC_IN) 4268
59.4.2 Clearing the Internal Counters by Crest/Trough Event Trigger Input (PEK_IN, VLY_IN) 4268
59.4.3 Generating Z-Phase Output by Crest/Trough Event Trigger Input (PEK_IN, VLY_IN) 4268
59.5 Usage Notes 4269
59.5.1 Restrictions on Input Pins 4269
59.5.2 Restriction on Register Settings 4269

59.5.3 Restrictions on Operation 4270
59.5.4 Transition to Software Standby Mode 4270
59.5.5 Return from Software Standby Mode 4270
60. 16-Bit A/D Converter (ADC16H) 4271
60.1 Overview 4271
60.2 Register Descriptions 4282
60.2.1 A/D Conversion Clock Enable Register (ADCLKENR) 4282
60.2.2 A/D Conversion Clock Status Register (ADCLKSR) 4283
60.2.3 A/D Conversion Clock Control Register (ADCLKCR) 4284
60.2.4 A/D Converter Synchronous Operation Control Register (ADSYCR) 4285
60.2.5 A/D Converter Unit Sleep Control Register 0 (ADUSLPCR0) 4287
60.2.6 A/D Converter Unit Sleep Control Register 1 (ADUSLPCR1) 4287
60.2.7 A/D Converter Unit Sleep Control Register 2 (ADUSLPCR2) 4288
60.2.8 A/D Conversion Error Interrupt Enable Register (ADERINTCR) 4288
60.2.9 A/D Conversion Overflow Interrupt Enable Register (ADOVFINTCR) 4289
60.2.10 Calibration interrupt Enable Register (ADCALINTCR) 4289
60.2.11 A/D Converter Mode Selection Register (ADMDR) 4290
60.2.12 A/D Group scan Priority Control Register (ADGSPCR) 4291
60.2.13 Scan Group Enable Register (ADSGER) 4292
60.2.14 Scan Group Control Register 0 (ADSGCR0) 4293
60.2.15 Scan Group Control Register 1 (ADSGCR1) 4294
60.2.16 Scan Group Control Register 2 (ADSGCR2) 4295
60.2.17 Scan End Interrupt Enable Register (ADINTCR) 4296
60.2.18 External Trigger Enable Register n (ADTRGEXTn) (n = 0 to 11) 4296
60.2.19 ELC Trigger Enable Register n (ADTRGELCn) (n = 0 to 11) 4297
60.2.20 GPT Trigger Enable Register n (ADTRGGPTn) (n = 0 to 11) 4298
60.2.21 A/D Conversion Start Trigger Enable Register (ADTRGENR) 4299
60.2.22 A/D Conversion Start Trigger Delay Register 0 (ADTRGDLR0) 4300
60.2.23 A/D Conversion Start Trigger Delay Register 1 (ADTRGDLR1) 4301
60.2.24 A/D Conversion Start Trigger Delay Register 2 (ADTRGDLR2) 4302
60.2.25 A/D Conversion Start Trigger Delay Register 3 (ADTRGDLR3) 4303
60.2.26 A/D Conversion Start Trigger Delay Register 4 (ADTRGDLR4) 4304
60.2.27 A/D Conversion Start Trigger Delay Register 5 (ADTRGDLR5) 4305
60.2.28 Hybrid Mode (Fixed Channel Continuous Scan Mode) Conversion Count per Scan Register 0 (ADSWNR0) 4306
60.2.29 Hybrid Mode (Fixed Channel Continuous Scan Mode) Conversion Count per Scan Register 1 (ADSWNR1) 4308
60.2.30 Hybrid Mode (Fixed Channel Continuous Scan Mode) Conversion Count per Scan Register 2 (ADSWNR2) 4310
60.2.31 Oversampling Mode (Same Channel Continuous Scan Mode) Decimation Control Register (ADDECCR) 4312
60.2.32 A/D Converter Accuracy Mode Register (ADACMDR) 4313

60.2.33 A/D Conversion Channel Configuration Register n (ADCHCRn) (n = 0 to 49) 4314
60.2.34 A/D Conversion Data Operation Control A Register n (ADDOPCRAn) (n = 0 to 49) 4317
60.2.35 A/D Conversion Data Operation Control B Register n (ADDOPCRBn) (n = 0 to 49) 4319
60.2.36 A/D Conversion Data Operation Control C Register n (ADDOPCRCn) (n = 0 to 49) 4321
60.2.37 Scan Group Diagnosis Function Control Register n (ADSGDCRn) (n = 0 to 11) 4323
60.2.38 Sampling State Table Register 0 (ADSSTR0) 4325
60.2.39 Sampling State Table Register 1 (ADSSTR1) 4325
60.2.40 Sampling State Table Register 2 (ADSSTR2) 4326
60.2.41 Sampling State Table Register 3 (ADSSTR3) 4326
60.2.42 Sampling State Table Register 4 (ADSSTR4) 4327
60.2.43 Sampling State Table Register 5 (ADSSTR5) 4327
60.2.44 Sampling State Table Register 6 (ADSSTR6) 4328
60.2.45 Sampling State Table Register 7 (ADSSTR7) 4328
60.2.46 A/D Conversion State Register (ADCNVSTR) 4329
60.2.47 Channel-Dedicated Sample-and-Hold Circuit Control Register 0 (ADSHCR0) 4330
60.2.48 Channel-Dedicated Sample-and-Hold Circuit Diagnosis Control Register 0 (ADSHDCR0) 4331
60.2.49 Channel-Dedicated Sample-and-Hold Circuit State Register 0 (ADSHSTR0) 4332
60.2.50 Channel-Dedicated Sample-and-Hold Circuit Single-Ended Input Mode Bypass Control Register (ADSHSBPCR) 4333
60.2.51 Channel-Dedicated Sample-and-Hold Circuit Differential Input Mode Bypass Control Register (ADSHDBPCR) 4335
60.2.52 Channel-Dedicated Sample-and-Hold Circuit Self-Diagnosis Control Register 0 (ADSHSDCR0) 4337
60.2.53 Channel-Dedicated Sample-and-Hold Circuit Self-Diagnosis Control Register 1 (ADSHSDCR1) 4339
60.2.54 Channel-Dedicated Sample-and-Hold Circuit Constant Sampling Control Register (ADSHCSCR) 4340
60.2.55 Internal Reference Voltage Monitor Enable Register (ADREFCR) 4341
60.2.56 A/D Converter Digital Filter Selection Register n (ADDFSRn) (n = 0 to 2) 4342
60.2.57 A/D Converter Self-Calibration State Register (ADCALSTCR) 4343
60.2.58 Channel-Dedicated Sample-and-Hold Circuit Self-Calibration State Register (ADCALSHCR) 4344
60.2.59 User Offset Table Register n (ADUOFTRn) (n = 0 to 7) 4345
60.2.60 User Gain Table Register n (ADUGTRn) (n = 0 to 7) 4346
60.2.61 Limiter Clip Interrupt Enable Register (ADLIMINTCR) 4346
60.2.62 Limiter Clip Table Register n (ADLIMTRn) (n = 0 to 7) 4347
60.2.63 Limiter Clip Scan Group Status Register (ADLIMGRSR) 4347
60.2.64 Limiter Clip Channel Status Register 0 (ADLIMCHSR0) 4348
60.2.65 Limiter Clip Channel Status Register 1 (ADLIMCHSR1) 4348
60.2.66 Extended Analog Limiter Clip Status Register (ADLIMEXSR) 4349

60.2.67 Limiter Clip Scan Group Status Clear Register (ADLIMGRSCR) 4350
60.2.68 Limiter Clip Channel Status Clear Register 0 (ADLIMCHSCR0) 4351
60.2.69 Limiter Clip Channel Status Clear Register 1 (ADLIMCHSCR1) 4351
60.2.70 Extended Analog Limiter Clip Status Clear Register (ADLIMEXSCR) 4352
60.2.71 Compare Match Enable Register (ADCMPENR) 4353
60.2.72 Compare Match Interrupt Enable Register (ADCMPINTCR) 4353
60.2.73 Composite Compare Match Configuration Register n (ADCCMPCRn) (n = 0 to 7) 4354
60.2.74 Compare Match Mode Selection Register 0 (ADCMPMDR0) 4355
60.2.75 Compare Match Mode Selection Register 1 (ADCMPMDR1) 4356
60.2.76 Compare Match Table Register n (ADCMPTBRn) (n = 0 to 7) 4357
60.2.77 Compare Match Table Status Register (ADCMPTBSR) 4357
60.2.78 Compare Match Table Status Clear Register (ADCMPTBSCR) 4358
60.2.79 Compare Match Channel Status Register 0 (ADCMPCHSR0) 4359
60.2.80 Compare Match Channel Status Register 1 (ADCMPCHSR1) 4359
60.2.81 Extended Analog Compare Match Status Register (ADCMPEXSR) 4360
60.2.82 Compare Match Channel Status Clear Register 0 (ADCMPCHSCR0) 4361
60.2.83 Compare Match Channel Status Clear Register 1 (ADCMPCHSCR1) 4361
60.2.84 Extended Analog Compare Match Status Clear Register (ADCMPEXSCR) 4362
60.2.85 A/D Converter Self-Calibration Start Register (ADCALSTR) 4363
60.2.86 A/D Conversion Synchronous Software Start Register (ADSYSTR) 4365
60.2.87 A/D Conversion Software Start Register n (ADSTRn) (n = 0 to 11) 4366
60.2.88 A/D Conversion Stop Register (ADSTOPR) 4367
60.2.89 A/D Conversion Status Register (ADSR) 4368
60.2.90 Scan Group Status Register (ADGRSR) 4369
60.2.91 Scan End Status Register (ADSCANENDSR) 4369
60.2.92 Scan End Status Clear Register (ADSCANENDSCR) 4370
60.2.93 A/D Conversion Error Status Register (ADERSR) 4370
60.2.94 A/D Conversion Error Status Clear Register (ADERSCR) 4371
60.2.95 A/D Converter Calibration End Status Register (ADCALENDSR) 4371
60.2.96 A/D Converter Calibration End Status Clear Register (ADCALENDSCR) 4372
60.2.97 A/D Conversion Overflow Error Status Register (ADOVFERSR) 4372
60.2.98 A/D Conversion Overflow Channel Status Register 0 (ADOVFCHSR0) 4373
60.2.99 A/D Conversion Overflow Channel Status Register 1 (ADOVFCHSR1) 4373
60.2.100 Extended Analog A/D Conversion Overflow Status Register (ADOVFEXSR) 4374
60.2.101 A/D Conversion Overflow Error Status Clear Register (ADOVFERSCR) 4375
60.2.102 A/D Conversion Overflow Channel Status Clear Register 0 (ADOVFCHSCR0) 4376
60.2.103 A/D Conversion Overflow Channel Status Clear Register 1 (ADOVFCHSCR1) 4376
60.2.104 Extended Analog A/D Conversion Overflow Status Clear Register (ADOVFEXSCR) 4377
60.2.105 FIFO Control Register (ADFIFOCR) 4378
60.2.106 FIFO Interrupt Control Register (ADFIFOINTCR) 4379

60.2.107 FIFO Interrupt Generation Level Register 0 (ADFIFOINTLR0) 4379
60.2.108 FIFO Interrupt Generation Level Register 1 (ADFIFOINTLR1) 4380
60.2.109 FIFO Interrupt Generation Level Register 2 (ADFIFOINTLR2) 4381
60.2.110 FIFO Interrupt Generation Level Register 3 (ADFIFOINTLR3) 4382
60.2.111 FIFO Interrupt Generation Level Register 4 (ADFIFOINTLR4) 4383
60.2.112 FIFO Interrupt Generation Level Register 5 (ADFIFOINTLR5) 4384
60.2.113 FIFO Status Register 0 (ADFIFOSR0) 4385
60.2.114 FIFO Status Register 1 (ADFIFOSR1) 4385
60.2.115 FIFO Status Register 2 (ADFIFOSR2) 4386
60.2.116 FIFO Status Register 3 (ADFIFOSR3) 4386
60.2.117 FIFO Status Register 4 (ADFIFOSR4) 4387
60.2.118 FIFO Status Register 5 (ADFIFOSR5) 4387
60.2.119 FIFO Data Clear Register (ADFIFODCR) 4388
60.2.120 FIFO Error Status Register (ADFIFOERSR) 4389
60.2.121 FIFO Error Status Clear Register (ADFIFOERSCR) 4390
60.2.122 A/D Data Register n (ADDRn) (n = 0 to 35) 4391
60.2.123 A/D Extended Analog Data Register n (ADEXDRn) (n = 0 to 2, 4 to 6, 8, 9, 16 to 18) 4392
60.2.124 FIFO Data Register n (ADFIFODRn) (n = 0 to 11) 4394
60.3 Operation 4395
60.3.1 A/D Conversion Clock 4395
60.3.2 A/D Converter Operation Mode 4395
60.3.2.1 SAR Mode 4395
60.3.2.2 Oversampling Mode 4395
60.3.2.3 Hybrid Mode 4396
60.3.3 Single-Ended Input and Differential Input 4396
60.3.4 Analog Channel 4397
60.3.5 Virtual Channel 4397
60.3.6 Scan Group 4398
60.3.7 Scan Mode 4399
60.3.7.1 Single Scan Mode 4399
60.3.7.2 Continuous Scan Mode 4399
60.3.7.3 Background Continuous Scan Mode 4400
60.3.7.4 Same Channel Continuous Scan Mode 4400
60.3.7.5 Fixed Channels Continuous Scan Mode 4400
60.3.8 Example of the Scanning Operation 4402
60.3.8.1 SAR Mode – Single Scan Mode 4402
60.3.8.2 SAR Mode – Continuous Scan Mode 4403
60.3.8.3 Oversampling Mode – Single Scan Mode 4404
60.3.8.4 Oversampling Mode – Continuous Scan Mode 4405
60.3.8.5 Oversampling Mode – Same Channel Continuous Scan Mode 4406

60.3.8.6 Hybrid Mode – Single Scan Mode 4407
60.3.8.7 Hybrid Mode – Continuous Scan Mode 4408
60.3.8.8 Hybrid Mode – Background Continuous Scan Mode 4410
60.3.8.9 Hybrid Mode – Fixed Channels Continuous Scan Mode 4412
60.3.9 Self-Calibration 4414
60.3.9.1 Conditions under Which Self-Calibration is Required 4414
60.3.9.2 Self-Calibration Procedure 4415
60.3.9.3 Restrictions on Self-Calibration 4416
60.3.10 Analog Input Channel 4417
60.3.11 Extended Analog Function 4417
60.3.12 Self-Diagnosis Function 4417
60.3.12.1 Self-Diagnosis 4417
60.3.12.2 Self-Diagnosis Mode 4418
60.3.12.3 Notes on Self-Diagnosis Function 4419
60.3.13 Internal Reference Voltage 4419
60.3.14 Temperature Sensor 4419
60.3.15 D/A Converter 4419
60.3.16 VBATT 1/6 Voltage Monitoring Output 4420
60.3.17 Channel-Dedicated Sample-and-hold Circuit 4420
60.3.17.1 Configuration of Channel-Dedicated Sample-and-Hold Circuit 4420
60.3.17.2 Operation in SAR Mode with Channel-Dedicated Sample-and-Hold Circuit 4422
60.3.17.3 Operation in Hybrid Mode with Channel-Dedicated Sample-and-Hold Circuit 4432
60.3.17.4 Restrictions on Channel-Dedicated Sample-and-Hold Circuit 4439
60.3.18 Disconnection Detection Assist Function 4441
60.3.19 Group Priority Operation 4444
60.3.19.1 Group Priority Operation in SAR Mode – Single Scan Mode 4444
60.3.19.2 Group Priority Operation in SAR Mode – Continuous Scan Mode 4446
60.3.19.3 Restrictions on Group Priority Operation 4450
60.3.20 Synchronous Operation 4451
60.3.20.1 Synchronous Operation Examples 4451
60.3.20.2 Restrictions on Synchronous Operation 4453
60.3.21 A/D Conversion Operation Monitor Function 4454
60.4 A/D Conversion Data 4455
60.4.1 Internal Data Processing Flow 4455
60.4.2 Digital Filter Function 4456
60.4.2.1 Configuration and Characteristics 4456
60.4.2.2 Operation of Digital Filter Function 4457
60.4.3 Calibration and Adjustment 4458
60.4.3.1 Gain Error and Offset Error Calibration 4458
60.4.3.2 User’s Gain Adjustment 4458
60.4.3.3 User’s Offset Adjustment 4460

60.4.4 A/D-Converted Value Addition/Averaging Function 4462
60.4.5 Limiter Clip Function 4463
60.4.6 Data Formatting process 4464
60.4.6.1 Signed/Unsigned Data Process 4464
60.4.6.2 Data Rounding Process 4464
60.4.7 Data Format 4465
60.4.8 Compare Match Function 4471
60.4.8.1 Compare Match 4471
60.4.8.2 Composite Compare Match 4472
60.4.9 Data Registers 4474
60.4.10 FIFO Function 4474
60.4.10.1 Operation When Writing A/D Conversion Data to FIFO 4475
60.4.10.2 Operation When Reading A/D Conversion Data from FIFO 4475
60.4.10.3 FIFO Data Read Request and Overflow 4475
60.4.10.4 Clearing FIFO Data 4475
60.4.10.5 Clearing FIFO Data by Starting/Resuming Scanning 4475
60.4.10.6 Usage Notes on FIFO 4476
60.4.11 A/D Conversion Data Output Decimation 4477
60.4.12 A/D Conversion Data Error Detection 4478
60.5 Start and Stop Control of A/D Conversion 4479
60.5.1 Software Trigger 4479
60.5.2 Peripheral Module Triggers 4479
60.5.2.1 ELC Trigger 4479
60.5.2.2 GPT Trigger 4480
60.5.2.3 External Trigger 4480
60.5.3 Trigger Delay 4482
60.5.4 Force Stops the A/D Conversion Operation 4482
60.5.4.1 Forced Stop Procedure 4482
60.5.4.2 Waiting Time after Disabling Trigger Input for Forced Stop Processing 4482
60.6 Error Detection 4484
60.6.1 A/D Converter Error 4484
60.6.2 A/D Conversion Overflow 4484
60.6.3 FIFO Overflow 4485
60.7 Procedure for Setting up and Changing 4486
60.7.1 Initial Setup Procedure 4486
60.7.2 Procedure for Changing ADCLK Settings 4486
60.7.3 Procedure for Changing the Settings of the A/D Converter 4488
60.7.4 Procedure for the A/D Converter Entering to and Returning from the Software Standby Mode 4489
60.8 Interrupt Sources 4490
60.9 Scan Conversion Time 4494

60.9.1 Scan Start Processing Time 4494
60.9.2 Conversion Processing Time 4496
60.9.3 Scan End Processing Time 4500
60.10 Usage Notes 4502
60.10.1 Prohibition of Changing the Operation Settings During A/D Conversion Operation 4502
60.10.2 Usage Notes on Forced Stop of A/D Conversion 4502
60.10.3 Usage Notes on A/D Data Registers 4502
60.10.4 Settings for the Module-Stop Function 4503
60.10.5 Settings for the Sleep Function 4503
60.10.6 Restrictions on Entering and Releasing the Low-Power States 4503
60.10.7 Notes on Board Design 4503
60.10.8 Notes on Synchronous Operation 4505
60.10.9 Notes on Channel-Dedicated Sample-and-Hold Circuit 4505
60.10.10 Restrictions on Analog Channel Shared Among Multiple A/D Converters 4506
60.10.11 Notes on A/D Conversion Start Trigger 4506
60.10.12 Notes on Self-Calibration 4506
60.10.13 Notes on Group Priority Operation 4506
60.10.14 Restrictions on SAR Mode 4506
60.10.15 Restrictions on Oversampling Mode 4506
60.10.16 Restrictions on Hybrid Mode 4507
60.10.17 Restrictions on the High Accuracy Mode 4508
60.10.18 Restrictions on Composite Compare Match 4508
60.10.19 Estimating the Sampling Error and Sampling Time 4509
60.10.20 Restriction on A/D Conversion Overflow in Single-Ended Input Mode 4511
61. 12-Bit D/A Converter (DAC12R) 4512
61.1 Overview 4512
61.2 Register Descriptions 4514
61.2.1 D/A Data Register (DADR) 4514
61.2.2 D/A Control Register 0 (DACR0) 4515
61.2.3 D/A Control Register 1 (DACR1) 4517
61.2.4 D/A Control Register 2 (DACR2) 4518
61.3 Operation 4519
61.3.1 D/A Conversion 4519
61.4 Linked Operation with the Use of the Event Link Function 4522
61.4.1 Action in Response to Receiving an Event Signal 4522
61.4.2 Usage Notes on Event Link Operation 4522
61.5 Usage Notes 4523
61.5.1 Module Stop Function Setting 4523
61.5.2 Operation of the 12-Bit D/A Converter in Module Stop State 4523
61.5.3 Operation of the 12-Bit D/A Converter in Software Standby Mode or Deep Software Standby Mode 4523

REVISION HISTORY 4893

600-MHz 32-bit RX MCU, on-chip double-precision floating-point coprocessor, 3604 CoreMark, arithmetic unit for trigonometric functions, up to 1-MB code MRAM (supporting the dual bank function), 1.5-MB SRAM, Ethernet MAC unit compliant with IEEE 802.3, SD/MMC host interface, expanded serial peripheral interfaces, various communications interfaces including CAN FD, 16-bit A/D converters, RTC, encryption functions, serial sound interfaces

Features

■ 32-bit RXv3e CPU core

- Maximum operating frequency: 600 MHz
  Capable of 3604 CoreMark performance in operation at 600 MHz
- 64-bit double-precision IEEE-754 floating point
- A collective register bank save function is available.
- Supports memory-protection units (MPUs)
- JTAG, SWD, and FINE (one-line) debugging interfaces
- Supports the Protect Zone function
- Instruction cache and data cache: 32 Kbytes each; support for ECC
- Two local RAMs: 128 Kbytes each; support for ECC

■ Low-power design and architecture

- Operation from a single 1.62- to 3.63-V supply
- The RTC and backup registers are capable of operation from a battery power supply.
- Seven low power consumption modes

■ On-chip user extra MRAM

- 128 Kbytes (switchable to operate as MTJ-OTP memory)
- User code is programmable by on-board or off-board programming.
- Capable of holding the user boot program, data, etc.

■ On-chip code MRAM

- Devices with up to 1 Mbyte are available.
- No wait cycles when the prefetch buffer is hit
- Supports reading at 100 MHz
- User code is programmable by on-board or off-board programming.
- Programming as a background operation (BGO)
- A dual-bank structure allows swapping the start-up bank.

■ On-chip data MRAM

- 48 Kbytes; programmable up to 100,000 times
- Programming as a background operation (BGO)

■ On-chip SRAM

- 1.5 Mbytes; support for ECC and reading at 150 MHz

■ Data transfer

- Eight DMA controllers (DMACs), DTCA, two EXDMA controllers (EXDMACs), Ethernet DMAC (GWCA), and two XSPIs serving as target modules

■ Reset and supply management

- Power-on reset (POR)
- Programmable voltage detection (PVD)
- Core voltage monitoring (CVM)
- Temperature monitoring reset
- Backup area reset
- Reset output function

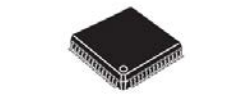
■ Clock functions

- Main clock oscillator for an 8- to 48-MHz external resonator
- Sub-clock oscillator for a 32.768-kHz crystal resonator
- Two PLL circuits
- 8-MHz MOCO, HOCO with 16, 18, 20, 32, or 48 MHz selectable, and 32.768-kHz LOCO
- Clock output function

■ Realtime clock

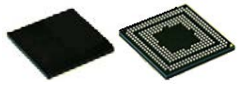
- Adjustment functions (for 30 seconds, leap year, and time error)
- Realtime clock counting and binary counting modes are selectable.
- Time capture in response to event-signal input

■ Independent watchdog timer



- Operation at 16.384 kHz. Operation in deep software standby mode 1 is possible.

■ Useful functions for IEC60730 compliance



- Oscillation stop detection (MOSC, SOSC), clock frequency accuracy measurement circuits, CRCA, IWDTa, DOCA, self-diagnosis and disconnection detection assist functions for the A/D converters, etc.
- Register write protection function protects important registers against overwriting.

■ External address space

- Buses for high-speed data transfer (max. operating frequency of 80 MHz)
- 8 CS areas with 8-, 16-, or 32-bit bus space selectable per area
- Independent SDRAM area (128 Mbytes) and XSPI areas (1 Gbyte)

PLQP0176KJ-A 24 × 24 mm, 0.5-mm pitch
PLQP0144KA-B 20 × 20 mm, 0.5-mm pitch
PLQP0100KP-A 14 × 14 mm, 0.5-mm pitch

PLBG0320GD-A 17 × 17 mm, 0.8-mm pitch
PLBG0224GE-A 13 × 13 mm, 0.8-mm pitch
PLBG0176GG-A 13 × 13 mm, 0.8-mm pitch

■ Various communications interfaces

- One Ethernet MAC unit with a single port, compliant with IEEE 802.3
- One high-speed USB 2.0 port for host/function, OTG controller, or BC 1.2, with on-chip PHY layer
- One full-speed USB 2.0 port for host/function or OTG controller, with on-chip PHY layer
- Three CAN FD modules compliant with the specifications of ISO 11898-1:2015
- 13 RSCIs with 16-byte transmission and reception FIFO buffers
  The serial communications mode can be selected from among asynchronous, clock synchronous, smart card interface, simple SPI, simple I^2C, and extended serial.
  Communications in Manchester code available, support for HBS functionality
- Two I^2C-bus interfaces for transfer at up to 3.4 Mbps
- I3C bus interface for transfer at up to 12 Mbps in SDR mode
- Three RSPIAs with single I/O for transmission and reception at up to 50 Mbps
- Parallel data capture unit (PDC) for the CMOS camera interface
- SD/MMC host interface with a 1- or 4-bit SD bus for use with SD memory or SDIO
- Two SSIEs for various audio formats such as I^2S
- Two XSPIs for transfer at up to 266 MT/s, switchable between controller and target, support for 1-, 2-, 4-, and 8-bit protocols and decryption on the fly (DOTF)
- PDM-IF connectable with an external microphone

■ Up to 26 extended-function timers

- 16 32-bit general PWM timers (GPTWs), two 8-bit timers (TMRs) with 2 channels per unit, two 16-bit CMTs with 2 channels per unit, two 32-bit compare match timers W (CMTWs) with a single channel per unit

■ Three 16-bit A/D converters

- Up to 36 analog input channels
- Self-diagnosis, detection of analog input disconnection

■ Two 12-bit D/A converters

■ Temperature sensor for measuring temperature within the chip

■ Arithmetic unit for trigonometric functions

■ Two phase-counting interfaces

■ Security features

- Renesas Secure IP (RSIP-E50D) (true-random number generator (TRNG), AES, ChaCha20-Poly1305, RSA, ECC, SHA-512, SHA3-512, and 128-bit unique ID)
- Zeroization
- Device lifecycle management
- Support for decryption on the fly (DOTF)
- Secure boot
- Detection of tampering
- The security attribute is specifiable per pin.
- Protect Zone function

■ Up to 197 pins for general I/O ports

- 5-V tolerance, open drain, input pull-up, switchable driving ability
- Software configurable 32-bit programmable I/O port

■ Operating temperature range

- Tj = –40 to +125°C

1. Overview

1.1 Outline of Specifications

Table 1.1 lists the specifications in outline, and Table 1.2 give a comparison of the functions of products in different packages.
Table 1.1 is an outline of maximum specifications, and the peripheral modules and the number of channels of the modules differ depending on the number of pins on the package. For details, refer to Table 1.2, Comparison of Functions for Different Packages.

Table 1.1 Outline of Specifications (1/10)

Classification	Module/Function	Description
CPU	CPU	• Maximum operating frequency: 600 MHz • 32-bit RX CPU (RXv3e) • Minimum instruction execution time: One instruction per state (cycle of the system clock) • Address space: 4-Gbyte linear • Protect Zone: Three worlds (non-secure, secure, and root) • Register set of the CPU General purpose: Sixteen 32-bit registers Control: Fourteen 32-bit registers Accumulator: Two 72-bit registers • 117 instructions Instructions installed as standard: 111 Basic instructions: 77 Single-precision floating-point operation instructions: 11 DSP instructions: 23 Instructions for register bank save function: 2 Protect Zone instructions: 4 • Addressing modes: 11 • Data arrangement Instructions: Little endian Data: Selectable as little endian or big endian • On-chip 32-bit multiplier: 32 × 32 → 64 bits • On-chip divider: 32 / 32 → 32 bits • Barrel shifter: 32 bits • Instruction cache and data cache: 32 Kbytes each • Accelerator for branch instruction processing: 272 bytes
	FPU	• Single-precision floating-point numbers (32 bits) • Data types and floating-point exceptions in conformance with the IEEE754 standard
	Double-precision floating point coprocessor	• Double-precision floating-point register set Double-precision floating-point data registers: 16, each with 64-bit width Double-precision floating-point control registers: Four, each with 32-bit width • Double-precision floating-point processing instructions: 21 • Notifying the interrupt controller of double-precision floating-point exceptions
	Register bank save function	• Fast collective saving and restoration of the values of CPU registers • Sixteen save register banks are incorporated in each of the root world, secure world, and non-secure world.

Table 1.1 Outline of Specifications (2/10)

Classification	Module/Function	Description
Memory	Code MRAM	• Capacity: 512 Kbytes/1 Mbyte • On-board programming: Five types • A dual-bank structure allows programming during reading or exchanging the start-up areas
	Data MRAM	• Capacity: 48 Kbytes • Programming: 100,000 times
	User extra MRAM	• Capacity: 128 Kbytes • On-board programming: Five types • Switchable to operate as MTJ-OTP
	Unique ID	• 128-bit unique ID for each device of this product family
	RAM	• Capacity: 1.5 Mbytes • Error-correcting code (ECC), single-error correcting and double-error detecting code (SEC-DED)
	Local RAM	• Capacity: 128 Kbytes × 2 • Up to 600 MHz, no-wait access • Error-correcting code (ECC), single-error correcting and double-error detecting code (SEC-DED)
Operating modes		• Operating modes by the mode-setting pins at the time of release from the reset state Single-chip mode Boot mode (SCI interface) Boot mode (USB interface) Boot mode (FINE interface) Boot mode (JTAG interface) Boot mode (SWD interface) • Selection of operating mode by register setting Single-chip mode • Endian selectable
Clocks	Clock generation circuit	• Main clock oscillator, sub-clock oscillator, low-speed/middle-speed/high-speed on-chip oscillator, and PLL frequency synthesizer (two circuits) • The peripheral module clocks can be set to frequencies above that of the system clock. • Main-clock oscillation stoppage detection • Sub-clock oscillation stoppage detection • Separate frequency-division and multiplication settings for the CPU clock (CPUCLK0), system clock (ICLK), MRAM code bus clock (MRICLK), MRAM peripheral clock (MRPCLK), peripheral module clocks (PCLKA, PCLKB, PCLKD, PCLKE), and external bus clock (BCLK) The CPU and local RAM run in synchronization with CPUCLK0: Up to 600 MHz The MRAM bus and code MRAM run in synchronization with MRICLK: Up to 300 MHz The data MRAM runs in synchronization with MRPCLK: Up to 150 MHz The RAM and other bus masters run in synchronization with the system clock (ICLK): Up to 300 MHz Peripheral modules of CRCA, DOCA, RSPIA, RSCI, ESWM, GPTW, HRPWM, POEG, ADC16H, CANFDG, CANFD, RSIP, RI3C, RIICHS, and USBHS run in synchronization with PCLKA, which operates at up to 150 MHz. Other peripheral modules run in synchronization with PCLKB: Up to 75 MHz The counter reference clock for the GPTW runs in synchronization with PCLKD: Up to 150 MHz The CANFDRAM runs in synchronization with PCLKE: Up to 300 MHz Devices connected to the external bus run in synchronization with BCLK: Up to 150 MHz • The high-speed on-chip oscillator (HOCO) can be obtained through frequency-multiplication of the PLL1 or PLL2 reference clock • External clock input frequency for the main clock oscillator: Up to 48 MHz • External clock input frequency for the sub-clock oscillator: 32.768 kHz • Clock output function

Table 1.1 Outline of Specifications (3/10)

Classification	Module/Function	Description
Resets		Sixteen types of reset • RES# pin reset: Triggered when the RES# pin is driven low. • Power-on reset: Triggered when the RES# pin is driven high and VCC rises above specific levels. • Core voltage monitoring reset: Triggered when the core voltage falls below or rises above specific levels. • Voltage-monitoring 0 reset: Triggered when VCC falls below specific levels. • Voltage-monitoring 1, 2, 4, and 5 resets: Triggered when VCC falls below or rises above specific levels. • Temperature-monitoring reset: Triggered due to the detection of temperatures outside the specified range. • Deep software standby reset: Triggered in response to an interrupt to trigger release from deep software standby. • Independent watchdog timer reset: Triggered when the independent watchdog timer underflows, or a refresh error occurs. • Watchdog timer reset: Triggered when the watchdog timer underflows, or a refresh error occurs. • Software reset: Triggered by register setting. • Bus error reset: Triggered in response to an illicit address or size error • Common memory error reset: Triggered in response to an ECC error in the RAM • Local memory error reset: Triggered in response to an ECC error in the CPU cache or local RAM Reset output is available.
Power-on reset		• If the RES# pin is at the high level when power is supplied, an internal reset is generated. After VCC has exceeded the voltage detection level and the specified period has elapsed, the reset is cancelled.
Programmable voltage detection circuit (PVD)		Monitors the voltage being input to the VCC pins and generates an internal reset or interrupt. • Voltage detection circuit 0 Capable of generating an internal reset The option-setting memory can be used to select enabling or disabling of the reset. Voltage detection level: Selectable from seven different levels (2.85 V, 2.58 V, 2.15 V, 2.00 V, 1.90 V, 1.80 V, 1.67 V) • Voltage detection circuits 1, 2, 4 and 5 Voltage detection level: Selectable from twelve different levels (3.14 V, 3.10 V, 3.08 V, 2.85 V, 2.83 V, 2.80 V, 2.62 V, 2.33 V, 1.90 V, 1.86 V, 1.74 V, 1.71 V) Digital filtering (1/2, 1/4, 1/8, and 1/16 LOCO frequency) Capable of generating an internal reset • Two types of timing are selectable for release from reset An internal interrupt can be requested only from voltage detection circuits 1 and 2. • Detection of voltage rising above and falling below thresholds is selectable. • Maskable or non-maskable interrupt is selectable Voltage detection monitoring Event linking
Low power consumption	Low power consumption function	• Module stop function • Seven low power consumption modes Sleep mode, deep sleep mode, software standby modes 1 and 2, and deep software standby modes 1 to 3
	Battery backup function	• When the voltage on the VCC pin drops below a certain point, battery power from the VBATT pin is supplied to the backup power area. • Backup power area: sub clock oscillator real-time clock backup register Tamper detection • Detection of voltage drop in the backup power area

Table 1.1 Outline of Specifications (4/10)

Classification	Module/Function	Description
Interrupt	Interrupt controller (ICUM)	• Number of interrupt vectors: 256 • External interrupts: 32 (pins IRQ0 to IRQ31) • Software interrupts: 2 sources • Non-maskable interrupts: 13 sources • 32 levels specifiable for the order of priority • Method of interrupt source selection: The interrupt vectors consist of 256 vectors (128 sources are fixed. The remaining 128 vectors are selected from among the other 342 sources.)
External bus extension		• The external address space can be divided into eight areas (CS0 to CS7), each with independent control of access settings. Capacity of each area: 16 Mbytes (CS0 to CS7) A chip-select signal (CS0# to CS7#) can be output for each area. Each area is specifiable as an 8-, 16-, or 32-bit bus space. The data arrangement in each area is selectable as little or big endian (only for data). • SDRAM interface connectable • Bus format: Separate bus, multiplex bus • Wait control • Write buffer facility • Connection for a memory device compliant with the expanded serial peripheral interface (xSPI) is possible (JEDEC Standards JESD 251, JESD 251-1, and JESD 252).
DMA	DMA controller (DMACAa)	• 8 channels • Four transfer modes: Normal transfer, repeat transfer, block transfer, and repeat block transfer • Request sources: Software trigger and interrupt requests from peripheral functions
	EXDMA controller (EXDMACAa)	• 2 channels • Four transfer modes: Normal transfer, repeat transfer, block transfer, and repeat block transfer • Request sources: Software trigger, external interrupts, and interrupt requests from peripheral functions
	Data transfer controller (DTCA)	• Three transfer modes: Normal transfer, repeat transfer, and block transfer • Request sources: External interrupts and interrupt requests from peripheral functions • Sequence transfer
I/O ports	Programmable I/O ports	• I/O ports for the 320-pin LFBGA I/O pins: 197 Input pins: 3 Pull-up resistors: 198 Open-drain outputs: 197 5-V tolerant pins: 16 • I/O ports for the 224-pin LFBGA I/O pins: 159 Input pins: 3 Pull-up resistors: 160 Open-drain outputs: 159 5-V tolerant pins: 16 • I/O ports for the 176-pin LFBGA and 176-pin LFQFP I/O pins: 120 Input pins: 3 Pull-up resistors: 121 Open-drain outputs: 120 5-V tolerant pins: 16 • I/O ports for the 144-pin LFQFP I/O pins: 100 Input pins: 3 Pull-up resistors: 101 Open-drain outputs: 100 5-V tolerant pins: 16 • I/O ports for the 100-pin LFQFP I/O pins: 72 Input pins: 3 Pull-up resistors: 73 Open-drain outputs: 72 5-V tolerant pins: 9

Table 1.1 Outline of Specifications (5/10)

Classification	Module/Function	Description
I/O ports	Software configurable 32-bit programmable I/O port (PIO)	• Of the 64 port pins, up to 32 can be selected for simultaneous use. • Input or output can be enabled, and for outputs, the high or low level can be specified through register settings.
Event link controller (ELC)		• Event signals such as interrupt request signals can be interlinked with the operation of functions such as timer counting, eliminating the need for intervention by the CPU to control the functions. • 377 internal event signals can be freely combined for interlinked operation with connected functions. • Event signals from peripheral modules can be used to change the states of output pins (of ports B, C, D, and E). • Changes in the states of pins (of ports B, C, D, and E) being used as inputs can be interlinked with the operation of peripheral modules.
Timers	General PWM timer (GPTW)	• 32 bits × 16 channels (GPTW0 to GPTW15) • Counting up or down (sawtooth-wave), counting up and down (triangle-wave) selectable for all channels • Clock sources independently selectable for each channel • 2 input/output pins per channel • 2 output compare/input capture registers per channel • For the 2 output compare/input capture registers of each channel, 4 registers are provided as buffer registers and are capable of operating as comparison registers when buffering is not in use. • In output compare operation, buffer switching can be at crests or troughs, enabling the generation of laterally asymmetrically PWM waveforms. • Registers for setting up frame intervals on each channel (with capability for generating interrupts on overflow or underflow) • Generation of dead times in PWM operation • Generation of highly accurate PWM waveforms with duty cycles close to the settings for values in the vicinity of duty 0% and 100%. • In output compare operation, settings of the comparison registers are immediately reflected, and the generation of PWM waveforms with secured dead times is possible. • Switching the direction of counting during operations in the triangle-wave PWM mode is possible. • The counter can be synchronously started, stopped, cleared, or have its direction of counting switched in any channel. • The counter can be started, stopped, cleared, or have its direction of counting switched, incremented, or decremented in response to up to eight ELC events. • The counter can be started, stopped, cleared, or have its direction of counting switched, incremented, or decremented in response to detecting a state transition in one event input signal while another input signal is at a particular level. • The counter can be started, stopped, cleared, or have its direction of counting switched, incremented, or decremented in response to up to four external triggers. • Disabling of output on detection of a dead time error or a short-circuit among output pins is possible. • Using a timer to generate a trigger signal to start A/D conversion is possible. The trigger signal can be output to the external pin is possible. • Output of events, such as compare-matches from A to F, overflow, and underflow, to the ELC is possible. • The noise filter of input capture is available. • Cycle counting • Measurement of the pulse width of the input signal • Output of the result of a logical operation on the output signal from one channel and that from another channel is possible. • Synchronous counter setting/counter clearing/input capture among channels • The timer-linked synchronization signal output function enables synchronous operation between channels synchronized with the timer period, and synchronous operation with other IPs synchronized with the timer period. • GTIOCnA/GTIOCnB pin input/output polarity inversion
	High resolution PWM waveform generation circuit (HRPWMb)	• Finely adjusting a PWM waveform generated by GPTW0 to GPTW3 with a minimum resolution of approximately 49 ps is possible.

Table 1.1 Outline of Specifications (6/10)

Classification	Module/Function	Description
Timers	GPTW port output enable (POEGd)	Various types of request to stop output from general PWM timers (GPTWs) are available. • Stopping output in response to detecting the input level on the GTETRGx pin • Stopping output in response to an output stopping signal from the GPTW • Stopping output in response to detecting the stopping of oscillation, or to requests by software • Stopping output in response to detecting the input level or an edge on the POEG pin
	8-bit timer (TMRa)	• (8 bits × 2 channels) × 2 units • Select from among seven internal clock signals (PCLKB/1, PCLKB/2, PCLKB/8, PCLKB/32, PCLKB/64, PCLKB/1024, PCLKB/8192) and one external clock signal • Capable of output of pulse trains with desired duty cycles or of PWM signals • The 2 channels of each unit can be cascaded to create a 16-bit timer • Capable of generating baud-rate clocks for RSCI • Event linking by the ELC
	Compare match timer (CMT)	• (16 bits × 2 channels) × 2 units • Select from among four internal clock signals (PCLKB/8, PCLKB/32, PCLKB/128, PCLKB/512)
	Compare match timer W (CMTW)	• (32 bits × 1 channel) × 2 units • Compare-match, input-capture input, and output-comparison output are available. • Select from among four internal clock signals (PCLKB/8, PCLKB/32, PCLKB/128, PCLKB/512) • Interrupt requests can be output in response to compare-match, input-capture, and output-comparison events. • Event linking by the ELC
	Realtime clock (RTCBb)*1	• Clock sources: Low-speed on-chip oscillator, sub-clock • Selection of the 32-bit binary count in time count/second unit possible • Clock and calendar functions • Interrupt sources: Alarm interrupt, periodic interrupt, and carry interrupt • Battery backup operation • Time-capture facility for three values • Event linking by the ELC
	Watchdog timer (WDTA)	• 14 bits × 1 channel • Select from among 6 counter-input clock signals (PCLKB/4, PCLKB/64, PCLKB/128, PCLKB/512, PCLKB/2048, PCLKB/8192) • Event linking by the ELC
	Independent watchdog timer (IWDTa)	• 14 bits × 1 channel • Counter-input clock: Low-speed on-chip oscillator (IWDT-dedicated clock) • Dedicated clock/1, dedicated clock/16, dedicated clock/32, dedicated clock/64, dedicated clock/128, dedicated clock/256 • Window function: The positions where the window starts and ends are specifiable (the window defines the timing with which refreshing is enabled and disabled). • Event linking by the ELC • Operation in the deep software standby mode 1 is possible.
Communications functions	Ethernet module (ESWM)	• One channel (one port) • Transfer at 10, 100, or 1000 Mbps • Full- and half-duplex modes • Detection of Magic Packets™*2 or output of a “Wake-On-LAN” signal (WOL) • Management frame transmission/reception with PHY-LSI compliant with the following specifications: MII (Media-Independent Interface), RMII (Reduced Media-Independent Interface), GMII (Gigabit Media-Independent Interface), and RGMII (Reduced Gigabit Media-Independent Interface) • Support for MII MAC-to-MAC connection • Two gPTP channels

Table 1.1 Outline of Specifications (7/10)

Classification	Module/Function	Description
Communications functions	USB 2.0 full-speed host/function module (USBf)	• Includes a USB device controller (UDC) and transceiver for USB 2.0 FS • One port • Compliant with the USB 2.0 specification • Transfer rate: Full speed (12 Mbps), low speed (1.5 Mbps) (host only) • Both self-powered mode and bus-powered mode are supported • On-the-Go (OTG) operation is possible (low-speed is not supported) • Incorporates 2 Kbytes of RAM as a transfer buffer • External pull-up and pull-down resistors are not required
	USB 2.0 high-speed host/function module (USBHS)	• Includes a USB device controller (UDC) and transceiver for USB 2.0 HS • One port (320-pin/224-pin/176-pin products only) • Compliant with the USB 2.0 specification • Transfer rate: High speed (480 Mbps), full speed (12 Mbps), low speed (1.5 Mbps) (host only) • Both self-powered mode and bus-powered mode are supported • On-the-Go (OTG) operation is possible (low-speed is not supported) • Compliant with Battery Charging Specification Revision 1.2 (BC1.2) • Incorporates 8.5 Kbytes of RAM as a transfer buffer • External pull-up and pull-down resistors are not required
	Serial communications interface (RSCI)	• 13 channels • Serial communications modes: Asynchronous, clock synchronous, and smart-card interface • Multi-processor function • On-chip baud rate generator allows selection of the desired bit rate • Choice of LSB-first or MSB-first transfer • Start-bit detection: Level or edge detection is selectable. • Simple I^2C • Simple SPI • 9-bit transfer mode • Bit rate modulation • Double-speed mode • Average transfer rate clock can be input from TMR timers • Event linking by the ELC • Supports the serial communications protocol, which contains the start frame and information frame • Supports the LIN format • Data can be transmitted or received in sequence by the 16-byte FIFO buffers of the transmission and reception unit • Manchester encoding is supported. • RSCI has some home bus system (HBS) functionality. • Data match detection • Adjustment of the timing of sampling of the RXD signals
	I3C bus interface (RI3C)	• Single channel (I^2C/I3C) • I^2C protocol mode Communication formats: I^2C-bus format/SMBus format Supports the multi-master Max. transfer rate: 3.4 Mbps • I3C protocol mode Communication protocols: SDR mode, Legacy I^2C message support Supports the multi-master Max. transfer rate: 12 Mbps • Event linking by the ELC
	High-speed I^2C-bus interface (RIICHS)	• Two channels (I^2C only) • I^2C-bus interface Communication formats: I^2C-bus format/SMBus format Supports the multi-master Max. transfer rate: 3.4 Mbps

Table 1.1 Outline of Specifications (8/10)

Classification	Module/Function	Description
Communications functions	CAN FD module with gateway functionality (CANFDG)	• 2 channels • Compliance with the ISO11898-1:2015 specification (standard frame and extended frame) • Gateway function • Message buffers 32 receive message buffers 16 transmit message buffers per channel Four transmit queues per channel • FIFO Eight receive FIFOs Six common FIFOs
	CAN FD module (CANFD)	• 1 channel • Compliance with the ISO11898-1:2015 specification (standard frame and extended frame) • Message buffers 16 receive message buffers Four transmit message buffers One transmit queue • FIFO Tow receive FIFOs One common FIFO
	Serial peripheral interface (RSPIA)	• 3 channels • RSPI transfer facility Using the MOSI (master out, slave in), MISO (master in, slave out), SSL (slave select), and RSPCK (RSPI clock) signals enables serial transfer through SPI operation (four lines) or clock-synchronous operation (three lines) Capable of handling serial transfer as a master or slave • Data formats Switching between MSB first and LSB first The number of bits in each transfer can be changed to any number of bits from 8 to 16, 20, 24, or 32 bits. 128-bit buffers for transmission and reception Up to four frames can be transmitted or received in a single transfer operation (with each frame having up to 32 bits) Transmit/receive data can be swapped in byte units • Buffered structure The transmitter and receiver each have four-stage 32-bit FIFO buffers to enable continuous transmission and reception. • RSPCK can be stopped with the receive buffer full for master reception. • Event linking by the ELC • Communications protocol: RSPIA supports the Texas Instruments Synchronous Serial Protocol (TI SSP).
	Expanded serial peripheral interface (XSPI)	• 2 units (switchable between controller and target) • Compliant with xSPI (JEDEC Standards JESD 251, JESD 251-1, and JESD 252) • 1-bit, 2-bit, 4-bit, and 8-bit protocols supported • Supports Octal SPI in the JESD 251 Profile 1.0, and HyperBus™ (HyperRAM™ and HyperFlash™) in the JESD 251 Profile 2.0. • Supports decryption on the fly (DOTF) • Maximum operating rate as a controller: 266 MT/s (133-MHz clock) • Maximum operating rate as a target: 200 MT/s (100-MHz clock)
Serial sound interface (SSIE)		• 2 channels • Full-duplex transmission (for both channel 0 and channel 1) • Various types of serial audio formatting are supported. • Master and slave operations are supported. • The bit-clock frequency is selectable from among 13 frequencies (1/1, 1/2, 1/4, 1/6, 1/8, 1/12, 1/16, 1/24, 1/32, 1/48, 1/64, 1/96, or 1/128). • Data formats with 8, 16, 18, 20, 22, 24, and 32 bits are supported. • 32-stage FIFO buffers for transmission and reception • Stopping or not stopping the SSILRCK signal on stopping of data transmission is selectable. • Clock signal from a GPTW is selectable.

Table 1.1 Outline of Specifications (9/10)

Classification	Module/Function	Description
SD/MMC host interface (SDHIc)		• 1 channel • SD bus interface One interface for SD memory and I/O cards (supporting 1- and 4-bit SD buses) Compatible with the SD, SDHC, and SDXC formats • MMC bus interface Data buses: Support for 1-, 4-, and 8-bit MMC buses • Interrupt requests: Card access interrupt, SDIO access interrupt, card detection interrupt, interrupt of SD buffer access • DMA transfer requests: SD_BUF write and SD_BUF read • Support for card detection and write protection
Arithmetic unit for trigonometric functions (TFUv2)		• Calculation of sine, cosine, arctangent, and hypotenuse Simultaneous calculation of sine and cosine Simultaneous calculation of arctangent and hypotenuse
Parallel data capture unit (PDC)		• 1 channel • Acquisition of synchronization through external 8-bit horizontal and vertical synchronization signals • Setting of the image size when clipping of the output for a one-frame image is required
Pulse-density modulation interface (PDM-IF)		• 1 channel • Connectable with an external microphone • 1-bit digital input data can be converted to 20- or 16-bit data. • Four filters: Sinc filter, high-pass filter, correction filter, and half-band decimation filter • Incorporates an internal buffer
Phase-counting interface (PCIF)		• Two units • Outputs ABZ-phase waveforms similar to incremental encoder outputs • Carrier-cycle event input from the ELC
16-bit A/D converter (ADC16H)		• Three units • Hybrid architecture that combines successive comparison and delta-sigma modulation • Up to 16-bit resolution (switchable between 16, 14, 12, and 10 bits) • High-speed conversion: 0.16 µs at the 50-MHz A/D conversion clock • Self-calibration • Extended analog functions: Self-diagnostic function, temperature sensor, internal reference voltage, VBATT voltage, D/A converter • Channel-dedicated sample-and-hold function (3 channels only in unit 0) • Supports single-ended and differential inputs
12-bit D/A converter (DAC12R)		• 2 channels • 12-bit resolution • Output voltage: 0.2 V to AVCC0 – 0.2 V (buffered output), 0 V to AVCC0 (unbuffered output) • Buffered output or unbuffered output can be selected. • Event linking by the ELC
Temperature sensor		• 1 channel • Relative precision: ± 1°C • The voltage of the temperature is converted into a digital value by the 16-bit A/D converter. • Detection of abnormally high and low temperatures
Safety	Memory-protection unit (MPU)	• Protection area: Eight areas (max.) can be specified in the range from 0000 0000h to FFFF FFFFh. • Minimum protection unit: 32 bytes • Reading from, writing to, and enabling the execution access can be specified for each area. • An access exception occurs when the detected access is not in the permitted area.
	Register write protection function	• Protects important registers from being overwritten for in case a program runs out of control.

Table 1.1 Outline of Specifications (10/10)

Classification	Module/Function	Description
Safety	CRC calculator (CRCA)	• Generation of CRC codes for 8-/32-bit data 8-bit data Selectable from the following three polynomials $X^8 + X^2 + X + 1$, $X^{16} + X^{15} + X^2 + 1$, $X^{16} + X^{12} + X^5 + 1$ 32-bit data Selectable from the following two polynomials $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$, $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ • Generation of CRC codes for use with LSB-first or MSB-first communications is selectable
	Main clock oscillation stop detection	• Main clock oscillation stop detection: Available
	Sub clock oscillation stop detection	• Sub clock oscillation stop detection: Available
	Clock frequency accuracy measurement circuit (CAC)	• Three units • Monitors the clock output from the main clock oscillator, sub-clock oscillator, low-, middle-, and high-speed on-chip oscillators, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, PLL2R, and PCLKB, and generates interrupts when the setting range is exceeded.
	Data operation circuit (DOCA)	• This handles the comparison, addition, subtraction, comparison in terms of which is larger or smaller, or window comparison of 32-bit values.
Security	Security function	• Protect Zone function Security state of the CPU: Secure or non-secure Access to the secure area is only possible through the CPU when it is in the secure state. • Privilege control • Device lifecycle management • Configurable range for access by the debugger at the debug authentication level • Secure key injection • Secure multi-function pin controller • Secure boot • Secure factory programming • The RSIP can be used for data confidentiality and protection against tampering with data. 256-bit hardware unique key (HUK) 128-bit unique ID OEM boot loader version Key data for use with circuits for decryption on the fly (DOTFs) Protection against SPA or DPA
	Decryption on the fly (DOTF)	Decrypt encrypted content stored in external memory in real time.
Encryption function	Renesas Secure IP (RSIP-E50D)	• Common key encryption: AES, ChaCha20-Poly1305 • Public key encryption: RSA, ECC • Hash value generation: SHA-512, SHA3-512 • TRNG (true-random number generator) : 128-bit
Operating frequency		Up to 600 MHz
Power supply voltage		VCC = VCC2 = 1.62 to 3.63 V VCC_USB = VCC_USBHS = AVCC_USBHS = 1.62 to 3.63 V AVCC0 = 1.62 to 3.63 V, 1.62 ≤ VREFH0 ≤ AVCC0 V_{BATT} = 1.62 to 3.63 V The level of each power supply voltage can independently be set. Connect the VCC_DCDC pin to VCC or VSS in accord with the power-supply mode.
Junction temperature		'4' version: –40 to +125°C
Package		320-pin LFBGA (PLBG0320GD-A) 224-pin LFBGA (PLBG0224GE-A) 176-pin LFBGA (PLBG0176GG-A) 176-pin LFQFP (PLQP0176KJ-A) 144-pin LFQFP (PLQP0144KA-B) 100-pin LFQFP (PLQP0100KP-A)
On-chip debugging system		• JTAG, SWD, and FINE interfaces

Note 1. When the realtime clock is not used, initialize the registers in the time clock according to description in section 30.6.8, Initialization Procedure When the Realtime Clock is Not to be Used.

Note 2. Magic Packet™ is a registered trademark of Advanced Micro Devices, Inc.

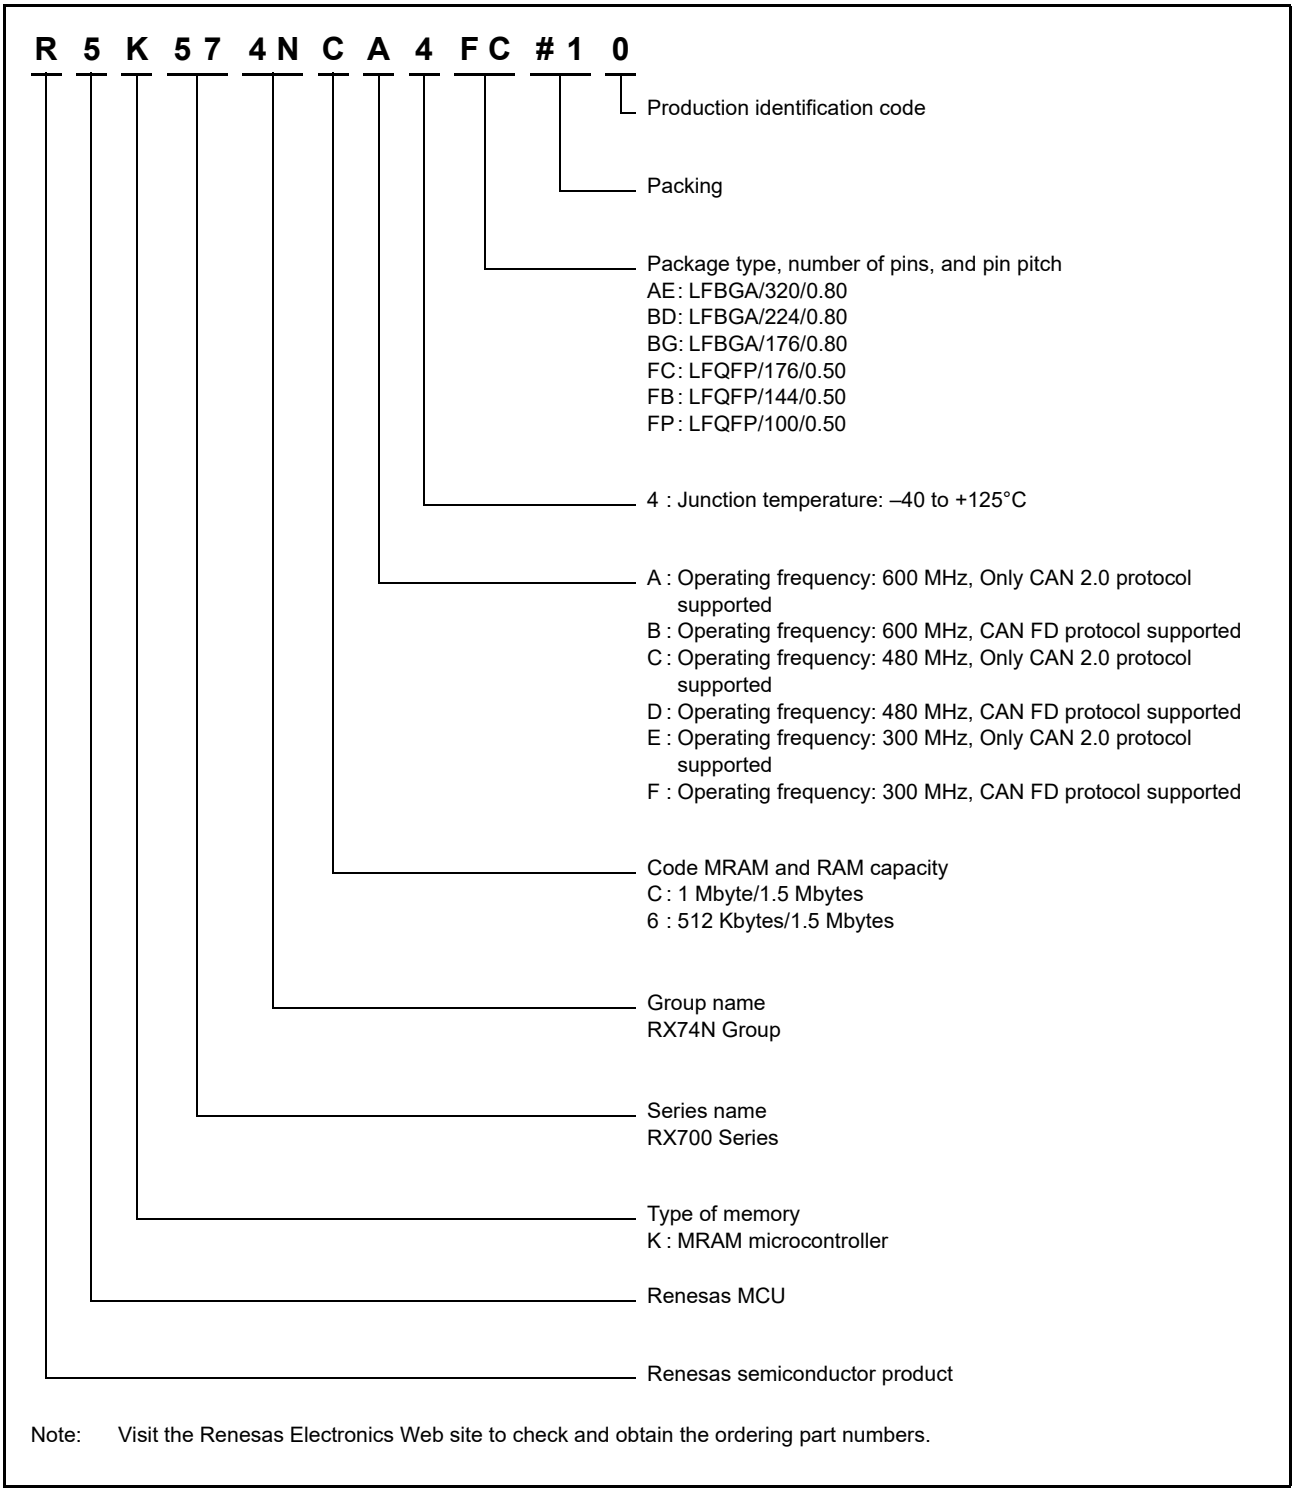
Note 1. Products with this part number support only CAN 2.0 protocol.



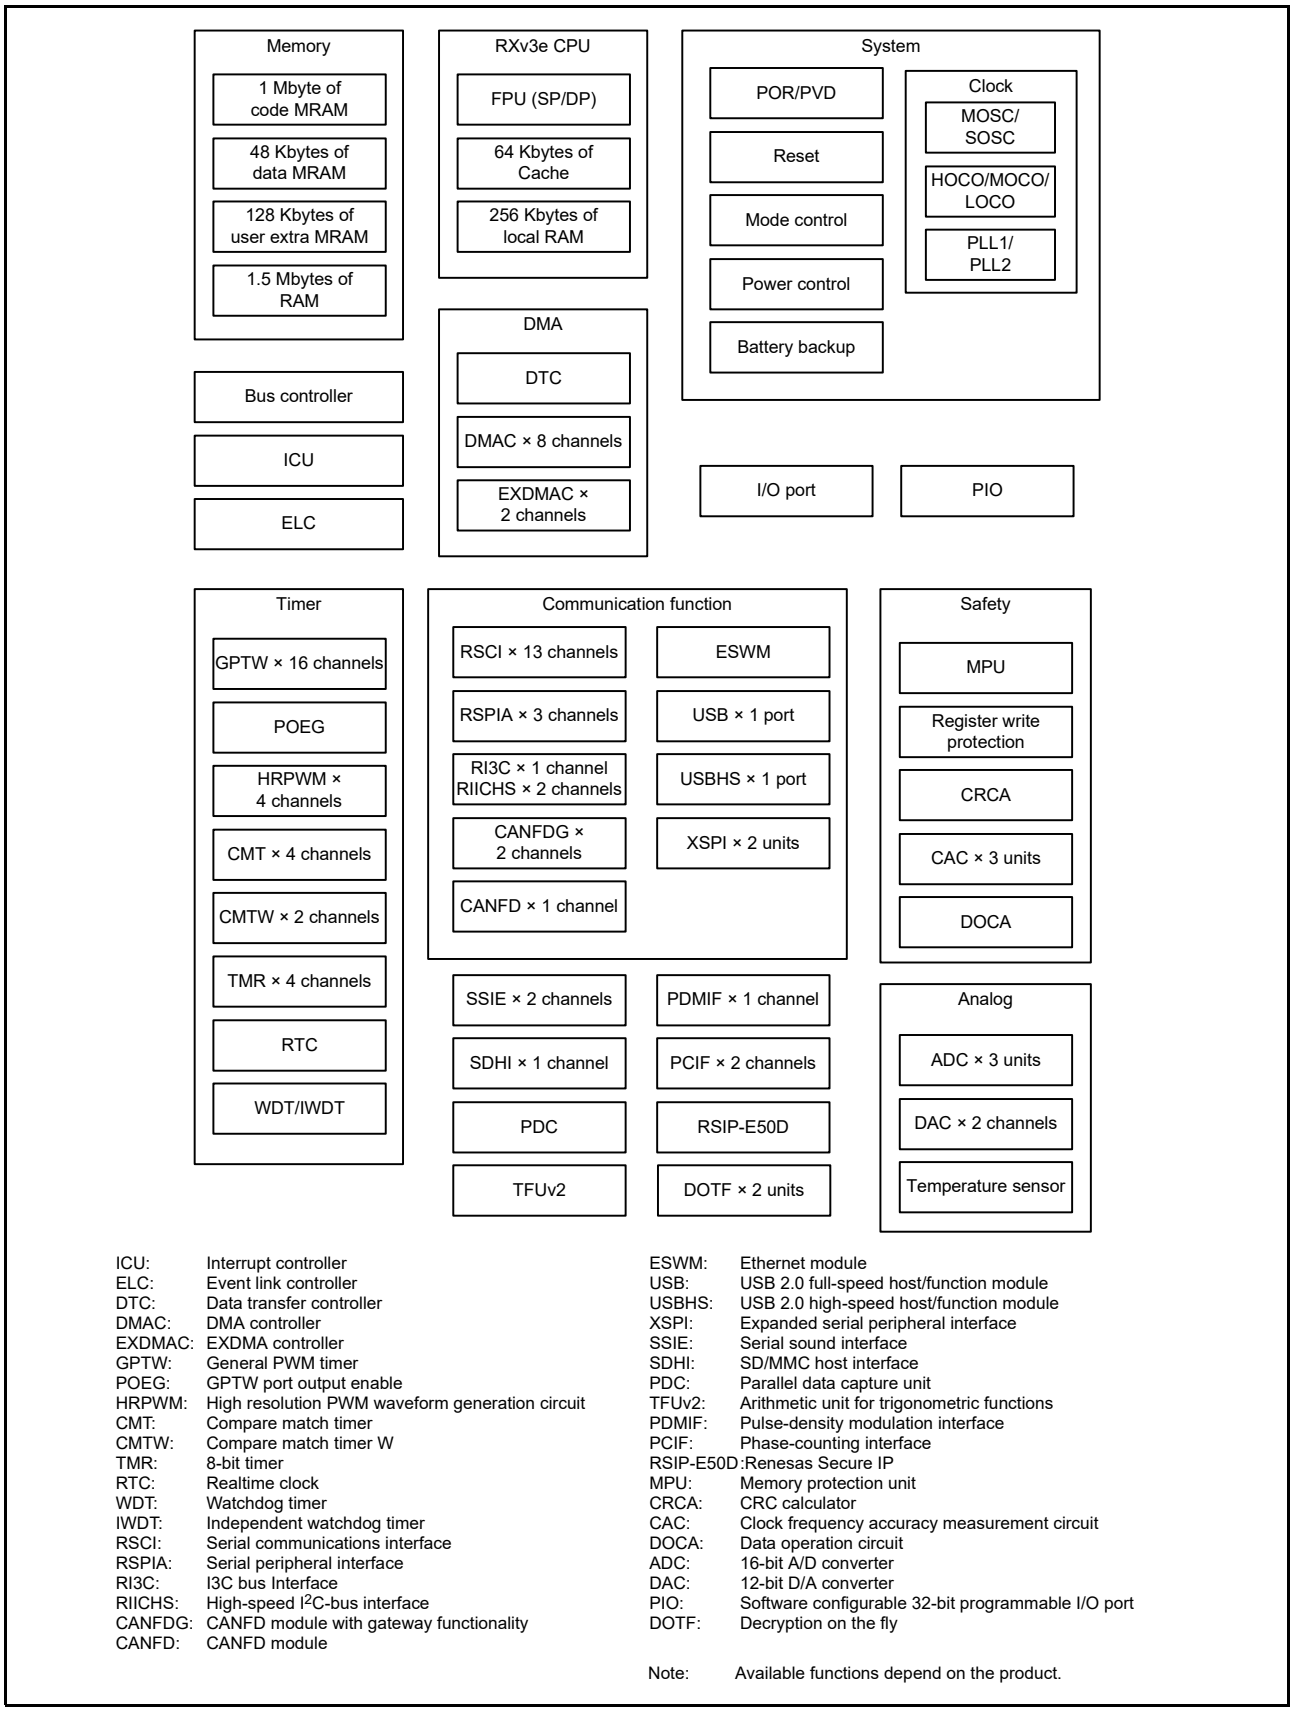


Figure 1.1 How to Read the Product Part Number

1.3 Block Diagram

Figure 1.2 shows a block diagram.

ICU: Interrupt controller
ELC: Event link controller
DTC: Data transfer controller
DMAC: DMA controller
EXDMAC: EXDMA controller
GPTW: General PWM timer
POEG: GPTW port output enable
HRPWM: High resolution PWM waveform generation circuit
CMT: Compare match timer
CMTW: Compare match timer W
TMR: 8-bit timer
RTC: Realtime clock
WDT: Watchdog timer
IWDT: Independent watchdog timer
RSCI: Serial communications interface
RSPIA: Serial peripheral interface
RI3C: I3C bus Interface
RIICHS: High-speed I^2C-bus interface
CANFDG: CANFD module with gateway functionality
CANFD: CANFD module

ESWM: Ethernet module
USB: USB 2.0 full-speed host/function module
USBHS: USB 2.0 high-speed host/function module
XSPI: Expanded serial peripheral interface
SSIE: Serial sound interface
SDHI: SD/MMC host interface
PDC: Parallel data capture unit
TFUv2: Arithmetic unit for trigonometric functions
PDMIF: Pulse-density modulation interface
PCIF: Phase-counting interface
RSIP-E50D: Renesas Secure IP
MPU: Memory protection unit
CRCA: CRC calculator
CAC: Clock frequency accuracy measurement circuit
DOCA: Data operation circuit
ADC: 16-bit A/D converter
DAC: 12-bit D/A converter
PIO: Software configurable 32-bit programmable I/O port
DOTF: Decryption on the fly

Note: Available functions depend on the product.

Figure 1.2 Block Diagram

1.4 Pin Functions

Table 1.4 lists the pin functions.

Table 1.4 Pin Functions (1/7)

Classifications	Pin Name	I/O	Description
Digital power supply	VCC	Input	Power supply pin. Connect this pin to the system power supply. Connect the pin to VSS via a 0.1-μF multilayer ceramic capacitor. The capacitor should be placed close to the pin.
	VCC2	Input	Power supply pin. Connect this pin to the system power supply. Connect the pin to VSS via a 0.1-μF multilayer ceramic capacitor. The capacitor should be placed close to the pin.
	VCL	Input	The pin setting depends on the power-supply mode. For details, see section 66, Internal Voltage Regulator.
	VSS	Input	Ground pin. Connect it to the system power supply (0 V).
	VBATT	Input	Backup power pin
Switching regulator	VCC_DCDC	Input	Power supply pin of the switching regulator
	VLO	Output	Output pin of the switching regulator Connect this pin to an external inductor and capacitor.
	VSS_DCDC	Input	Ground pin of the switching regulator
Clock	XTAL	Output	Input/output pins for a crystal resonator. An external clock signal can be input through the EXTAL pin.
	EXTAL	Input	
	EBCLK	Output	Outputs the external bus clock for external devices.
	SDCLK	Output	Outputs the SDRAM-dedicated clock.
	XCOUT	Output	Input/output pins for the sub-clock oscillator. Connect a crystal resonator between XCOUT and XCIN.
	XCIN	Input	
	EXCIN	Input	External sub-clock input pin
	CLKOUT	Output	Clock output pin.
Clock frequency accuracy measurement	CACREF	Input	Reference clock input pin for the clock frequency accuracy measurement circuit
Operating mode control	MD	Input	Input pin for setting the operating mode. The signal level on this pin must not be changed during operation.
System control	RES#/RSTOUT#	I/O	Reset signal input pin. This MCU enters the reset state when this signal goes low.
On-chip emulator	FINED	I/O	FINE interface pin
	TMS	Input	On-chip emulator or boundary scan pins.
	TDI	Input	
	TCK	Input	
	TDO	Output	
	SWDIO	I/O	Serial wire debugging data input/output pin
	SWCLK	Input	Serial wire clock pin
Address bus	A0 to A23	Output	Output pins for the address
Data bus	D0 to D31	I/O	Input and output pins for the bidirectional data bus
Multiplexed bus	A0/D0 to A15/D15	I/O	Address/data multiplexed bus

Table 1.4 Pin Functions (2/7)

Classifications	Pin Name	I/O	Description
Bus control	RD#	Output	Strobe signal which indicates that reading from the external bus interface space is in progress
	WR#	Output	Strobe signal which indicates that writing to the external bus interface space is in progress, in 1-write strobe mode
	WR0# to WR3#	Output	Strobe signals which indicate that either group of data bus pins (D7 to D0, D15 to D8, D23 to D16 and D31 to D24) is valid in writing to the external bus interface space, in byte strobe mode
	BC0# to BC3#	Output	Strobe signals which indicate that either group of data bus pins (D7 to D0, D15 to D8, D23 to D16 and D31 to D24) is valid in access to the external bus interface space, in 1-write strobe mode
	ALE	Output	Address latch signal when address/data multiplexed bus is selected
	WAIT#	Input	Input pin for wait request signals in access to the external space
	CS0# to CS7#	Output	Select signals for CS areas
	BREQ#	Input	External bus request signal from an external device
	BACK#	Output	External bus acknowledge signal from the MCU
SDRAM interface	CKE	Output	SDRAM clock enable signal
	SDCS#	Output	SDRAM chip select signal
	RAS#	Output	SDRAM row address strobe signal
	CAS#	Output	SDRAM column address strobe signal
	WE#	Output	SDRAM write enable pin
	DQM0 to DQM3	Output	SDRAM I/O data mask enable signals
Interrupt	NMI	Input	Non-maskable interrupt request pin
	IRQ0 to IRQ31, IRQ0-DS to IRQ31-DS	Input	Maskable interrupt request pins
General PWM timer	GTETRGA, GTETRGB, GTETRGC, GTETRGD	Input	Input pins for the external trigger signals
	GTIOC0A to GTIOC15A, GTIOC0B to GTIOC15B	I/O	Input capture input/output compare output/PWM output pins
	GTCPPO0 to GTCPPO15	Output	PWM synchronous output
	GTIU, GTIV, GTIW	Input	Hall sensor input pins
	GTOUUP	Output	3-phase PWM output for BLDC motor control (positive U-phase)
	GTOULO	Output	3-phase PWM output for BLDC motor control (negative U-phase)
	GTOVUP	Output	3-phase PWM output for BLDC motor control (positive V-phase)
	GTOVLO	Output	3-phase PWM output for BLDC motor control (negative V-phase)
	GTOWUP	Output	3-phase PWM output for BLDC motor control (positive W-phase)
	GTOWLO	Output	3-phase PWM output for BLDC motor control (negative W-phase)
	GTADSM0, GTADSM1	Output	Output pins for monitoring A/D conversion start requests.
GPTW port output enable	POEGA, POEGB, POEGC, POEGD	Input	Input pins for request signals to place GPTW outputs in the high-impedance state
8-bit timer	TMO0 to TMO3	Output	Compare match output pins
	TMCI0 to TMCI3	Input	Input pins for external clocks to be input to the counter
	TMRI0 to TMRI3	Input	Input pins for the counter reset
Compare match timer W	TIC0 to TIC3	Input	Input pins for CMTW
	TOC0 to TOC3	Output	Output pins for CMTW

Table 1.4 Pin Functions (3/7)

Classifications	Pin Name	I/O	Description
Serial communications interface	• Asynchronous mode/clock synchronous mode		
	SCK000 to SCK012	I/O	Input/output pins for the clock
	RXD000 to RXD012	Input	Input pins for received data
	TXD000 to TXD012	Output	Output pins for transmitted data
	CTS000# to CTS012#	Input	Input pins for controlling the start of transmission and reception
	RTS000# to RTS012#	Output	Output pins for controlling the start of transmission and reception
	DE000 to DE012	Output	Output pins for controlling the RS-485 driver
	• Simple I^2C mode		
	SSCL000 to SSCL012	I/O	Input/output pins for the I^2C clock
	SSDA000 to SSDA012	I/O	Input/output pins for the I^2C data
	• Simple SPI mode		
	SCK000 to SCK012	I/O	Input/output pins for the clock
	SMISO000 to SMISO012	I/O	Input/output pins for slave transmission of data
	SMOSI000 to SMOSI012	I/O	Input/output pins for master transmission of data
	SS000# to SS012#	Input	Chip-select input pins
	• HBS support mode		
	RXD000 to RXD012	Input	Input pins for received data
	TXDA000 to TXDA012	Output	Output pins for transmitted data
	TXDB000 to TXDB012		
I3C bus interface	SCL00	I/O	Input/output pins for clocks
	SDA00	I/O	Input/output pins for data
High-speed I^2C-bus interface	SCLHS1, SCLHS2	I/O	Input/output pins for clocks
	SDAHS1, SDAHS2	I/O	Input/output pins for data
Ethernet module	• RMII mode		
	RMII0_REF50CK	Input	50-MHz reference clocks. These pins input reference signals for transmission/reception timing in RMII mode.
	RMII0_CRS_DV	Input	These pins indicate that there are carrier detection signals and valid receive data on RMIIn_RXD1 and RMIIn_RXD0 in RMII mode.
	RMII0_TXD0, RMII0_TXD1	Output	2-bit transmit data in RMII mode
	RMII0_RXD0, RMII0_RXD1	Input	2-bit receive data in RMII mode
	RMII0_TX_EN	Output	Output pin for data transmit enable signal in RMII mode
	RMII0_RX_ER	Input	These pins indicate an error has occurred during reception of data in RMII mode.
	• RGMII mode		
	RGMII0_TXC	Output	Transmission clock signals in RGMII mode
	RGMII0_RXC	Input	Reception clock signals in RGMII mode
	RGMII0_TX_CTL	Output	Control of transmission in RGMII mode
	RGMII0_TXD0 to RGMII0_TXD3	Output	4-bit transmission data in RGMII mode
	RGMII0_RX_CTL	Input	Control of reception in RGMII mode

Table 1.4 Pin Functions (4/7)

Classifications	Pin Name	I/O	Description
Ethernet module	RGMII0_RXD0 to RGMII0_RXD3	Input	4-bit reception data in RGMII mode
	• GMII/MII mode		
	ET0_GTX_CLK	Output	1000-Mbps transmission clock pin
	ET0_CRS	Input	Carrier detection/data reception enable pins
	ET0_RX_DV	Input	These pins indicate that there are valid receive data.
	ET0_TXD0 to ET0_TXD7	Output	8 bits of GMII transmit data/4 bits of MII transmit data
	ET0_RXD0 to ET0_RXD7	Input	8 bits of GMII receive data/4 bits of MII receive data
	ET0_TX_EN	Output	Transmit enable pins.
	ET0_TX_ER	Output	Transmit error pins. These pins function as signals notifying the PHY-LSI of an error during transmission.
	ET0_RX_ER	Input	Receive error pins. These pins function as signals to recognize an error during reception.
	ET0_TX_CLK	I/O	100-Mbps/10-Mbps transmission clock pins (input for MII, output for MAC-to-MAC connection)
	ET0_RX_CLK	Input	Receive clock pins.
	ET0_COL	Input	Input collision detection signals.
	• Common		
	ET0_LINKSTA	Input	Input link status from the PHY-LSI.
	ET0_INT	Input	Input for an interrupt signal from PHY-LSI
	ET0_WOL	Output	Signals indicating receipt of Magic Packet.
	ET0_MDC	Output	Output reference clock signals for information transfer via ETn_MDIO.
	ET0_MDIO	I/O	Input or output bidirectional signals for exchange of management information between this MCU and the PHY-LSI.
	GPTP_CAPTURE0, GPTP_CAPTURE1	Input	Media clock capture input
	GPTP_MATCH0, GPTP_MATCH1	Output	Media clock recovery output
	GPTP0_PPS	Output	PPS signals
	GPTP_PTPOUT0, GPTP_PTPOUT1	Output	PTP pulse generation signals
	ETHPHYCLK	Output	Clock output pin for PHY clock input
USB 2.0 host/function module	VCC_USB, VCC_USBHS	Input	Power supply pins
	VSS_USB, VSS_USBHS	Input	Ground pins
	AVCC_USBHS	Input	Analog voltage supply pin for USBHS
	AVSS_USBHS	Input	Analog ground pin for USBHS
	USBHS_RREF	I/O	Reference voltage supply pin for USBHS
	USB0_DP, USBHS_DP	I/O	Input or output USB transceiver D+ data.
	USB0_DM, USBHS_DM	I/O	Input or output USB transceiver D- data.
	USB0_EXICEN, USBHS_EXICEN	Output	Connect to the OTG power IC.
	USB0_ID, USBHS_ID	Input	Connect to the OTG power IC.
	USB0_VBUSEN, USBHS_VBUSEN	Output	USB VBUS power enable pins

Table 1.4 Pin Functions (5/7)

Classifications	Pin Name	I/O	Description
USB 2.0 host/function module	USB0_OVRCURA/ USB0_OVRCURB, USBHS_OVRCURA/ USBHS_OVRCURB, USB0_OVRCURA-DS/ USB0_OVRCURB-DS, USBHS_OVRCURA-DS/ USBHS_OVRCURB-DS	Input	USB overcurrent pins
	USB0_VBUS, USBHS_VBUS, USB0_VBUS-DS, USBHS_VBUS-DS	Input	USB cable connection/disconnection detection input pin
CANFD module	CRX0, CRX1, CRX2	Input	CAN input pins
	CTX0, CTX1, CTX2	Output	CAN output pins
Serial peripheral interface	RSPCK0 to RSPCK2	I/O	Clock input/output pins
	MOSI0 to MOSI2	I/O	Input or output data output from the master
	MISO0 to MISO2	I/O	Input or output data output from the slave
	SSL00, SSL10, SSL20	I/O	Input or output pins for slave selection
	SSL01 to SSL03, SSL11 to SSL13, SSL21 to SSL23	Output	Output pins for slave selection
Expanded serial peripheral interface	XSPI0_CK, XSPI1_CK	I/O	Clock input/output pins (output in the controller mode; input in the target mode)
	XSPI0_CKN#, XSPI1_CKN#	Output	Inverted clock output (output in the controller mode; N/A in the target mode)
	XSPI0_CS0#, XSPI0_CS1#, XSPI1_CS0#, XSPI1_CS1#	I/O	Chip select signals (output in the controller mode; input in the target mode)
	XSPI0_DS, XSPI1_DS	I/O	Read data strobe/write data mask signal
	XSPI0_IO0 to XSPI0_IO7, XSPI1_IO0 to XSPI1_IO7	I/O	Data input/output pins
	XSPI0_RESET0#, XSPI0_RESET1#, XSPI1_RESET0#, XSPI1_RESET1#	I/O	Signals from the controller device to reset the target device (output in the controller mode; input in the target mode)
	XSPI0_ECS0#, XSPI0_ECS1#, XSPI1_ECS0#, XSPI1_ECS1#	Input	Signals that indicate the state of error correction in the target device
	XSPI0_INT0#, XSPI1_INT0#	I/O	Interrupt signals from the target device (input in the controller mode; output in the target mode)
	XSPI0_INT1#, XSPI1_INT1#	Input	Interrupt signals from the target device (input in the controller mode; N/A in the target mode)
	XSPI0_RSTO0#, XSPI1_RSTO0#	I/O	Signals from the target device to reset the controller device (input in the controller mode; output in the target mode)
	XSPI0_RSTO1#, XSPI1_RSTO1#	Input	Signals from the target device to reset the controller device (input in the controller mode; N/A in the target mode)
	XSPI0_WP0#, XSPI0_WP1#, XSPI1_WP0#, XSPI1_WP1#	Output	Signals to control protection of the target device against writing by the controller device
Serial sound interface	SSIBCK0, SSIBCK1	I/O	SSIE serial bit-clock pins
	SSILRCK0, SSILRCK1	I/O	LR clock
	SSITXD0, SSITXD1	Output	Serial data output pins
	SSIRXD0, SSIRXD1	Input	Serial data input pins
	AUDIO_CLK	Input	External clock pin for audio (input for an oversampling clock)

Table 1.4 Pin Functions (6/7)

Classifications	Pin Name	I/O	Description
SD/MMC host interface	SD0_CLK	Output	SD clock output pin
	SD0_CMD	I/O	SD command output or response input signal pin
	SD0_DAT0 to SD0_DAT7	I/O	SD/MMC data bus pins
	SD0_CD	Input	SD card detection pin
	SD0_WP	Input	SD write-protect signal
Parallel data capture unit	PIXCLK	Input	Image transfer clock pin
	VSYNC	Input	Vertical synchronization signal pin
	HSYNC	Input	Horizontal synchronization signal pin
	PIXD0 to PIXD7	Input	8-bit image data pins
	PCKO	Output	Output pin for dot clock
Pulse-density modulation interface	PDMCLK0	Output	Output pin for the clock
	PDMDAT0	Input	Input pin for data
Phase-counting interface	PCINA0, PCINA1	Input	A-phase input pins
	PCINB0, PCINB1	Input	B-phase input pins
	PCINZ0, PCINZ1	Input	Z-phase input pins
	PCOUTA0, PCOUTA1	Output	A-phase output pins
	PCOUTB0, PCOUTB1	Output	B-phase output pins
	PCOUTZ0, PCOUTZ1	Output	Z-phase output pins
Realtime clock	RTCOUT	Output	Output pin for 1-Hz/64-Hz clock
	RTCIC0 to RTCIC2	Input	Time capture event input pins
Battery backup	TAMPI0 to TAMPI2	Input	Input pins for detecting tampering
16-bit A/D converter	AN000 to AN035	Input	Input pins for the analog signals to be processed by the A/D converter
	ADTRG0# to ADTRG2#	Input	Input pins for the external trigger signals that start the A/D conversion
	ADST0 to ADST2	Output	Scan period monitor output
	ADCNV0 to ADCNV2	Output	Successive approximation period monitor output
	ADSYNC	Output	Synchronous A/D conversion start signal monitor output
12-bit D/A converter	DA0, DA1	Output	Output pins for the analog signals to be processed by the D/A converter
Analog power supply	AVCC0	Input	Analog power supply pin for the 16-bit A/D converter, and analog power supply and reference voltage pin for the D/A converter.
	AVSS0	Input	Analog ground pin for the 16-bit A/D converter, and analog ground and reference ground pin for the D/A converter
	VREFH0	Input	Analog reference voltage supply pin for the 16-bit A/D converter
	VREFL0	Input	Analog reference ground pin for the 16-bit A/D converter
	VREFH00 to VREFH02*1	Input	Analog reference voltage supply pin for the 16-bit A/D converter
	VREFL00 to VREFL02*1	Input	Analog reference ground pin for the 16-bit A/D converter
Software Configurable 32-Bit Programmable I/O Port	PIO_000 to PIO_063	I/O	Pins composing the software configured general-purpose I/O port

Table 1.4 Pin Functions (7/7)

Classifications	Pin Name	I/O	Description
I/O ports	P000 to P015	I/O	16-bit input/output pins
	P100 to P115	I/O	16-bit input/output pins
	P200 to P215	I/O	16-bit input/output pins
	P300 to P312, P315	I/O	14-bit input/output pins (P305, P308, P309: input pin)
	P400 to P415	I/O	16-bit input/output pins
	P500 to P515	I/O	16-bit input/output pins
	P600 to P607	I/O	8-bit input/output pins
	P700 to P715	I/O	16-bit input/output pins
	P800 to P807	I/O	8-bit input/output pins
	P900 to P907	I/O	8-bit input/output pins
	PA00 to PA07	I/O	8-bit input/output pins
	PB00 to PB07	I/O	8-bit input/output pins
	PC00 to PC07	I/O	8-bit input/output pins
	PD00 to PD07	I/O	8-bit input/output pins
	PE00 to PE07	I/O	8-bit input/output pins
	PF00 to PF09	I/O	10-bit input/output pins
	PG00 to PG15	I/O	16-bit input/output pins

Note: Note the following points regarding pin names. For details, refer to section 1.6, List of Pin and Pin Functions.
- Suffixes such as “-A” or “-B” appended to pin names indicate pin group identifiers. Electrical characteristics were evaluated per pin group. AC electrical characteristics are only guaranteed when pins within the same group are used together.
- When a pin function has “-DS” appended to its name, it can also be used as a trigger for release from deep software standby mode.

Note 1. This pin is only present in 320-pin products.

1.5 Pin Assignments

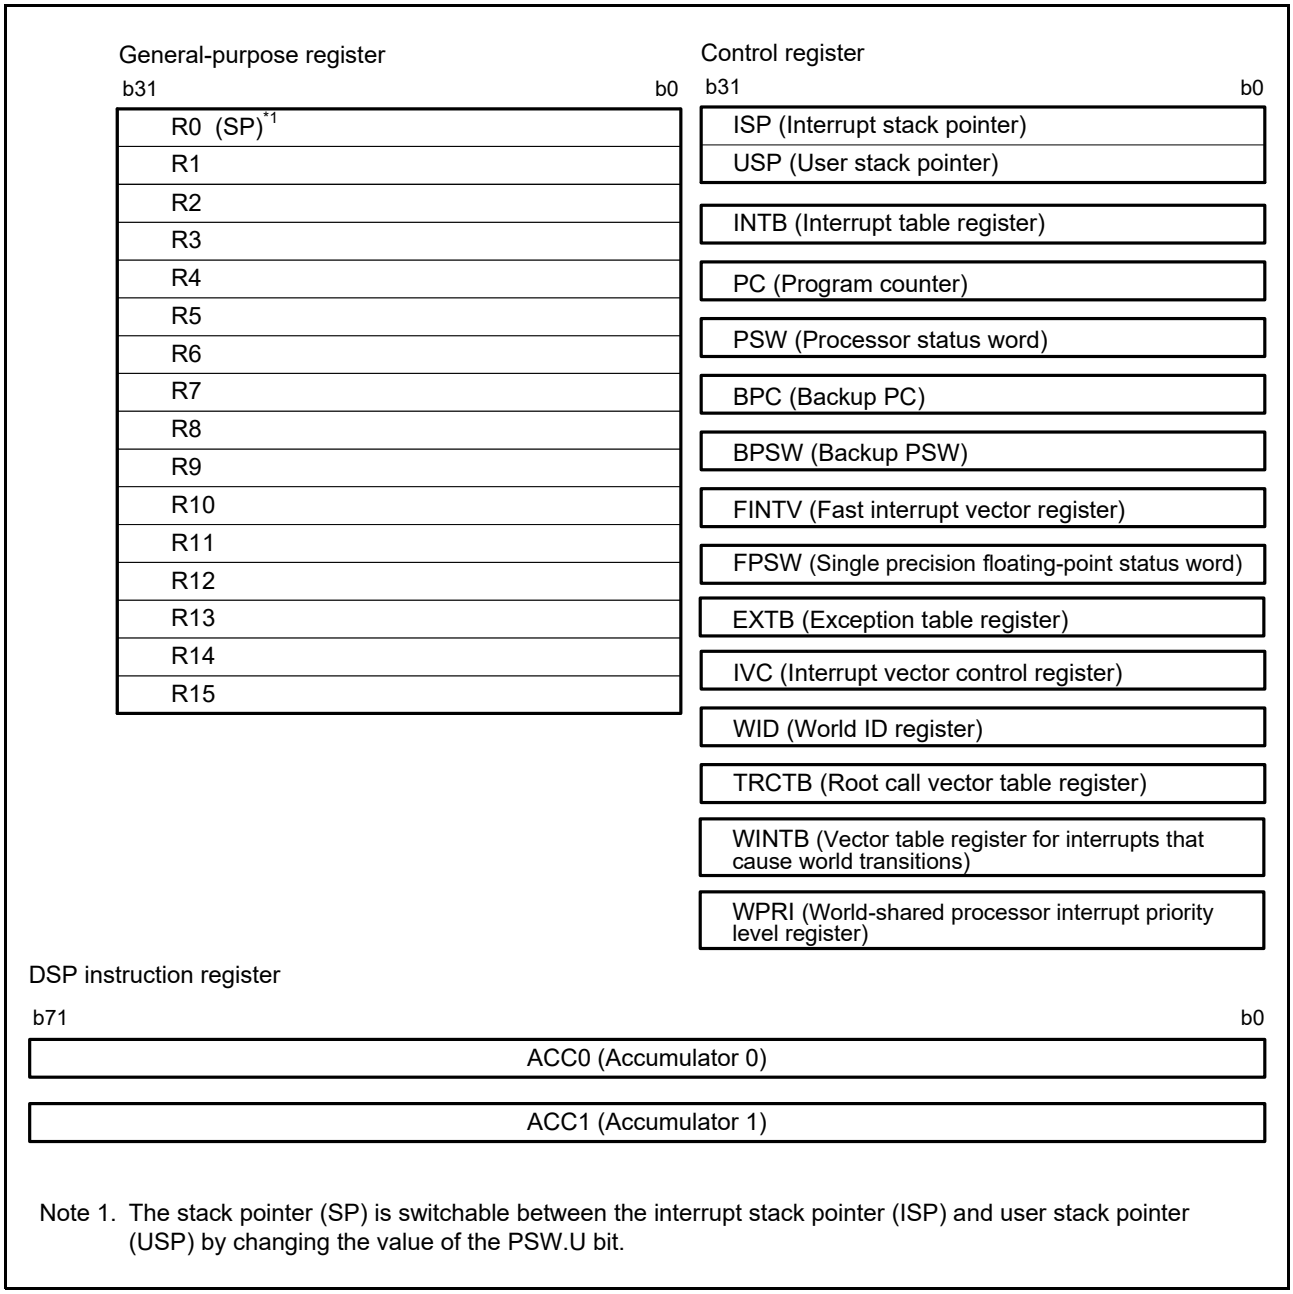
2. CPU

The RXv3e CPU is based on the RXv3e instruction set architecture. The architecture is based on the addition of a security function as an expansion to the architecture for the RXv3 CPU.
The RXv3e instruction set architecture (RXv3e) provides upward compatibility with the RXv3 instruction set architecture (RXv3), the RXv2 instruction set architecture (RXv2), and the RXv1 instruction set architecture (RXv1).

- Protect Zone
  The RXv3e CPU is equipped with Protect Zone technology. This is used to define and manage the security states of the CPU core, and supports the partitioning of software execution environments in terms of these security states.
- Adoption of variable-length instruction format
  The CPU has short formats for frequently used instructions, facilitating the development of programs that are efficient in terms of taking up less memory.
- Powerful instruction set
  DSP instructions and floating-point operation instructions realize high-speed arithmetic processing.
- Versatile addressing modes
  The CPU has versatile addressing modes, with register-register operations, register-memory operations, and bitwise operations included. Data transfer between memory locations is also possible.

2.1 Features



- Minimum instruction execution time: One clock cycle
- Address space: 4-Gbyte linear addresses
- Protect Zone: Three “worlds” (non-secure, secure, and root)
- Register set of the CPU
  General purpose: Sixteen 32-bit registers
  Control: Fifteen 32-bit registers
  Accumulator: Two 72-bit registers
- Variable-length instruction format (lengths from one to eight bytes)
- 117 instructions
  Standard provided instructions: 111
  Basic instructions: 77
  Single-precision floating point instructions: 11
  DSP instructions: 23
  Instructions for register bank save function: 2
  Protect Zone instructions: 4
- Processor modes
  Supervisor mode and user mode
- Vector tables
  Exception vector table, interrupt vector table, root call vector table, and world transition interrupt vector table
- Memory protection unit
- Data arrangement
  Selectable as little endian or big endian
- Register bank save function
- On-chip double-precision floating point coprocessor
  Double-precision floating-point processing instructions: 21
- Instruction cache and data cache
  Instruction cache: 32 Kbytes (4-way set associative cache)

Data cache: 32 Kbytes (4-way set associative cache)

- Branch instruction processing accelerator
  Accelerator for MRAM and LRAM: 272 bytes (Fully associative cache)
- Local SRAM (LRAM)
  128 Kbytes × 2 units

2.2 Register Set of the CPU

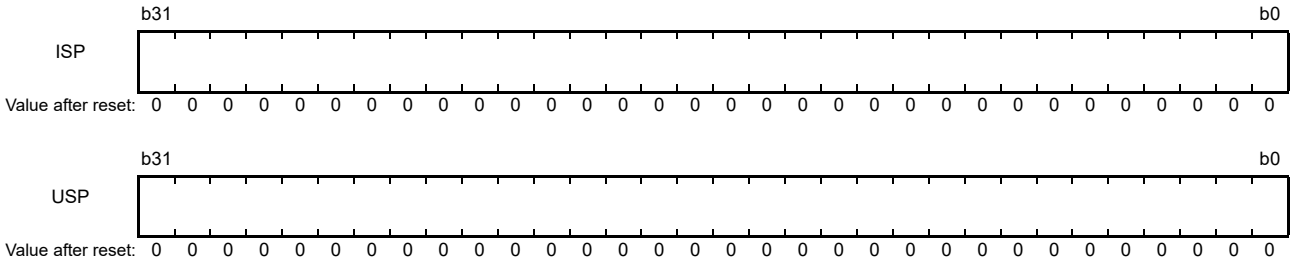
The CPU has sixteen general-purpose registers, fifteen control registers, and two accumulators used for DSP instructions.

Note 1. The stack pointer (SP) is switchable between the interrupt stack pointer (ISP) and user stack pointer (USP) by changing the value of the PSW.U bit.

Figure 2.1 Register Set of the CPU

2.2.1 General-Purpose Registers (R0 to R15)

This CPU has sixteen 32-bit general-purpose registers (R0 to R15). R0 to R15 can be used as data registers or address registers.
R0, a general-purpose register, also functions as the stack pointer (SP).
The stack pointer is switched to operate as the interrupt stack pointer (ISP) or user stack pointer (USP) by the value of the stack pointer select bit (U) in the processor status word (PSW).

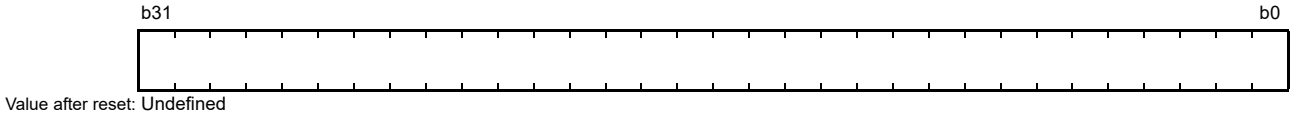


2.2.2 Control Registers

The CPU has sixteen control registers: fifteen are accessible through dedicated instructions.

- Interrupt stack pointer (ISP)*1
- User stack pointer (USP)
- Interrupt table register (INTB)*1
- Program counter (PC)
- Processor status word (PSW)
- Backup PC (BPC)*1
- Backup PSW (BPSW)*1
- Fast interrupt vector register (FINTV)
- Single-precision floating-point status word (FPSW)
- Exception table register (EXTB)*1
- Interrupt vector control register (IVC)*1
- World ID register (WID)
- Root call vector table register (TRCTB)
- Vector table register for interrupts that cause world transitions (WINTB)
- World-shared processor interrupt priority level register (WPRI)

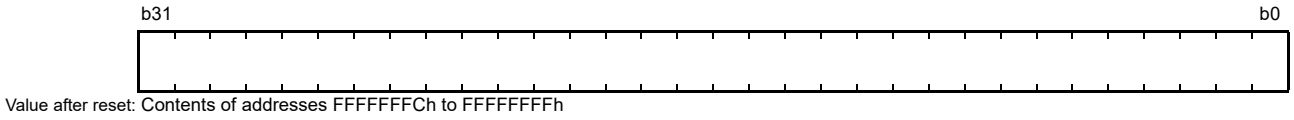
Note 1. This control register is actually implemented as three registers to support the Protect Zone function. Where this is required, the three registers are distinguished by postfixes appended to the register names, specifically _TR for the root world register, _S for the secure world register, and _NS for the non-secure world register.



2.2.2.1 Interrupt Stack Pointer (ISP)/User Stack Pointer (USP)

The stack pointer (SP) can be either of two types, the interrupt stack pointer (ISP) or the user stack pointer (USP). Whether the stack pointer operates as the ISP or USP depends on the value of the stack pointer select bit (U) in the processor status word (PSW).
The ISP is actually implemented as the following three registers to support the Protect Zone function.

- For the root world: ISP_TR (only accessible in the root world)
- For the secure world: ISP_S (only accessible in the secure world or root world)
- For the non-secure world: IPS_NS (only accessible in the non-secure world or root world)



2.2.2.2 Interrupt Table Register (INTB)

The interrupt table register (INTB) specifies the address where the interrupt vector table starts. This register is actually implemented as the following three registers to support the Protect Zone function.

- For the root world: INTB_TR (only accessible in the root world)
- For the secure world: INTB_S (only accessible in the secure world or root world)
- For the non-secure world: INTB_NS (only accessible in the non-secure world or root world)

2.2.2.3 Program Counter (PC)

The program counter (PC) indicates the address of the instruction being executed.

2.2.2.4 Processor Status Word (PSW)

b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. In user mode, writing to the IPL[4:0], PM, U, and I bits by an MVTC or a POPC instruction is ignored. Writing to the IPL[4:0] bits by an MVTIPL instruction generates a privileged instruction exception.
Note 2. In supervisor mode, writing to the PM bit by an MVTC or a POPC instruction is ignored, but writing to the other bits is possible.
Note 3. Switching from supervisor mode to user mode requires execution of an RTE instruction after having set the PSW.PM bit saved on the stack to 1 or executing an RTFI instruction after having set the BPSW.PM bit to 1.
Note 4. Writing to the IPL[4:0] bits in response to an MVTC, POPC, or MVTIPL instruction in the non-secure world always causes clearing of the IPL[4] bit (to 0).
Executing an RTE or RTFI instruction in the non-secure world also always causes clearing of the IPL[4] bit (to 0).

The processor status word (PSW) indicates the results of instruction execution or the state of the CPU.

C Flag (Carry Flag)

This flag retains the state of the bit after a carry, borrow, or shift-out has occurred.

Z Flag (Zero Flag)

This flag is set to 1 if the result of an operation is 0; otherwise its value is set to 0.

S Flag (Sign Flag)

This flag is set to 1 if the result of an operation is negative; otherwise its value is set to 0.

O Flag (Overflow Flag)

This flag is set to 1 if the result of an operation overflows; otherwise its value is set to 0.

I Bit (Interrupt Enable)

This bit enables interrupt requests. When an exception is accepted, the value of this bit becomes 0. Even if the value of

this bit is 0, an interrupt request will only be accepted in the non-secure world when the conditions of both the setting of the NSIC bit in the interrupt vector control register (IVC) and the priority level of the requested interrupt are met as listed in Table 2.1.

Table 2.1 Conditions of Interrupt Acceptance

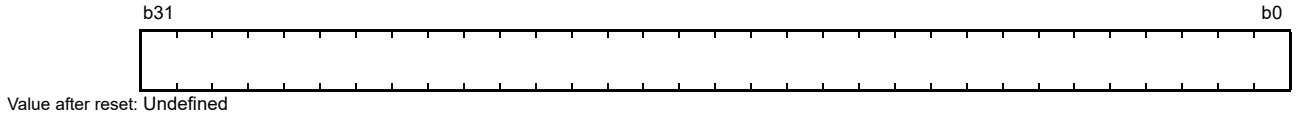
Current World	I bit	IVC.NSIC	IPR	Enabling or Disabling of Interrupts
Root or secure	0	—	—	Disabled
	1	—	—	Enabled
Non-secure	0	0	—	Disabled
		1	Less than 16	Disabled
			16 or greater	Enabled
	1	—	—	Enabled

IPR: The priority level of a requested interrupt

U Bit (Stack Pointer Select)

This bit specifies the stack pointer as either the ISP or USP. When an exception request is accepted, this bit is set to 0. When the processor mode is switched from supervisor mode to user mode, this bit is set to 1.

PM Bit (Processor Mode Select)



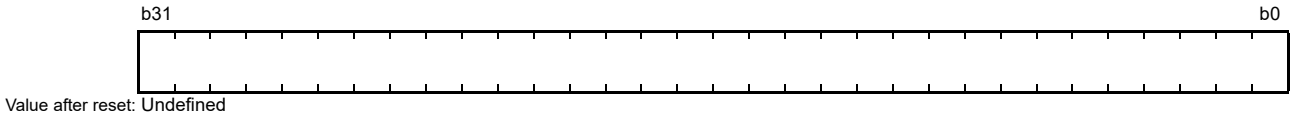
This bit specifies the processor mode. When an exception is accepted, the value of this bit becomes 0.

IPL[4:0] Bits (Processor Interrupt Priority Level)

The IPL[4:0] bits specify the processor interrupt priority level in the root world or secure world as one of 32 levels from 0 to 31, wherein priority level 0 is the lowest and priority level 31 the highest. In the non-secure world, the level is specified as one of 16 levels from 0 to 15, wherein level 0 is the lowest and level 15 the highest. Priority level 16 or a higher level cannot be specified in the non-secure world.

When the priority level of a requested interrupt is higher than the processor interrupt priority level specified in these bits, the interrupt is enabled. Setting the IPL[4:0] bits to level 31 (1Fh) in the root world or secure world disables all interrupt requests. In the non-secure world, setting the IPL[4:0] bits to level 15 (0Fh) disables all interrupt requests for the non-secure world. The IPL[4:0] bits are set to level 31 (1Fh) when a non-maskable interrupt for the root world or secure world is generated. The IPL[4:0] bits are set to level 15 (0Fh) when a non-maskable interrupt for the non-secure world is generated while execution is in progress in the non-secure world. When interrupts in general are generated, the bits are set to the priority levels of accepted interrupts.

2.2.2.5 Backup PC (BPC)



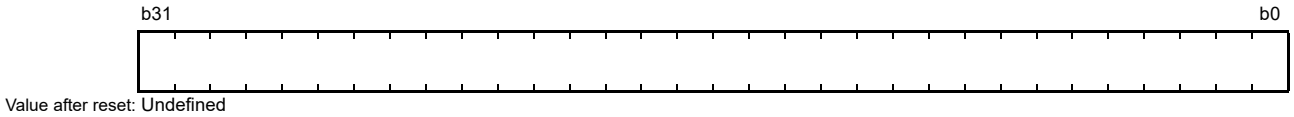
Value after reset: Undefined

The backup PC (BPC) is provided to speed up response to interrupts.

After a fast interrupt has been generated, the contents of the program counter (PC) are saved in the BPC register. This register is actually implemented as the following three registers to support the Protect Zone function.

- For the root world: BPC_TR (only accessible in the root world)
- For the secure world: BPC_S (only accessible in the secure world or root world)
- For the non-secure world: BPC_NS (only accessible in the non-secure world or root world)

2.2.2.6 Backup PSW (BPSW)



The backup PSW (BPSW) is provided to speed up response to interrupts.

After a fast interrupt has been generated, the contents of the processor status word (PSW) are saved in the BPSW. The allocation of bits in the BPSW corresponds to that in the PSW. This register is actually implemented as the following three registers to support the Protect Zone function.

- For the root world: BPSW_TR (only accessible in the root world)
- For the secure world: BPSW_S (only accessible in the secure world or root world)
- For the non-secure world: BPSW_NS (only accessible in the non-secure world or root world)

In the case of an attempt to write a value to bit 28 in BPSW_NS, 0 is written to the bit.

2.2.2.7 Fast Interrupt Vector Register (FINTV)

The fast interrupt vector register (FINTV) is provided to speed up response to interrupts.

The FINTV register specifies a branch destination address when a fast interrupt has been generated. This register is only accessible in the root world.

2.2.2.8 Single-Precision Floating-Point Status Word (FPSW)

b31	FS	Single-Precision Floating-Point Error Summary Flag	This bit reflects the logical OR of the FU, FZ, FO, and FV flags.	R

Note 1. Writing 0 to the bit clears it. Writing 1 to the bit does not affect its value.
Note 2. Positive denormalized numbers are treated as +0, negative denormalized numbers as –0.
Note 3. When the EV bit is set to 0, the FV flag is enabled.
Note 4. When the EO bit is set to 0, the FO flag is enabled.
Note 5. When the EZ bit is set to 0, the FZ flag is enabled.
Note 6. When the EU bit is set to 0, the FU flag is enabled.
Note 7. When the EX bit is set to 0, the FX flag is enabled.
Note 8. Once the bit has been set to 1, this value is retained until it is set to 0 by software.

The single-precision floating-point status word (FPSW) indicates the results of single-precision floating-point arithmetic operations.
When the corresponding exception handling enable bits (Ej) are set to enable processing of the exceptions (Ej = 1), the Cj flags can be used by the exception handling routine to identify the source of that exception. If handling of an exception is masked (Ej = 0), the Fj flag can be used to check for the generation of the exception at the end of a sequence of processing. The Fj flags operate in an accumulative fashion (j = X, U, Z, O, or V).

RM[1:0] Bits (Single-Precision Floating-Point Rounding-Mode Setting)

These bits specify the single-precision floating-point rounding-mode.

Explanation of Single-Precision Floating-Point Rounding Modes

- Rounding towards the nearest value (the default behavior): An inexact result is rounded to the available value that is closest to the result of a hypothetical calculation with infinite precision. If two available values are equally close, rounding is to the even alternative.
- Rounding towards 0: An inexact result is rounded to the smallest available absolute value, i.e. in the direction of zero (simple truncation).
- Rounding towards +∞: An inexact result is rounded to the nearest available value in the direction of positive infinity.
- Rounding towards –∞: An inexact result is rounded to the nearest available value in the direction of negative infinity.

(1) Rounding to the nearest value is specified as the default mode and returns the most accurate value.
(2) Modes such as rounding towards 0, rounding towards +∞, and rounding towards –∞ are used to ensure precision when interval arithmetic is employed.

CV Flag (Invalid Operation Cause Flag), CO Flag (Overflow Cause Flag), CZ Flag (Division-by-Zero Cause Flag), CU Flag (Underflow Cause Flag), CX Flag (Inexact Cause Flag), and CE Flag (Unimplemented Processing Cause Flag)

Single-precision floating-point exceptions include the five specified in the IEEE754 standard, namely overflow, underflow, inexact, division-by-zero, and invalid operation. For a further single-precision floating-point exception that is generated upon detection of unimplemented processing, the corresponding flag (CE) is set to 1.

- If an exception or processing that is not implemented is not encountered in the execution of a single-precision floating-point arithmetic instruction, the corresponding flags become 0.
- When 0 is written to the bit by the MVTC and POPC instructions, the bit is set to 0; the bit retains the previous value when 1 is written by the instruction.

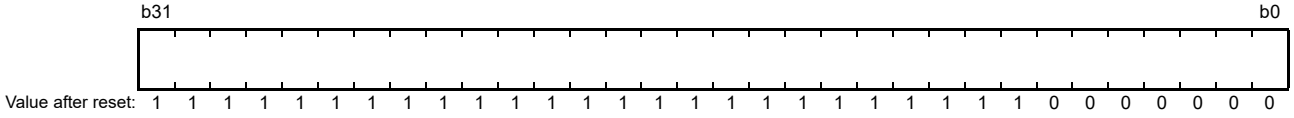
DN Bit (0 Flush Bit of Denormalized Number)

When this bit is set to 0, a denormalized number is handled as a denormalized number. When this bit is set to 1, a denormalized number is handled as 0.

EV Bit (Invalid Operation Exception Enable), EO Bit (Overflow Exception Enable), EZ Bit (Division-by-Zero Exception Enable), EU Bit (Underflow Exception Enable), and EX Bit (Inexact Exception Enable)

When any of five single-precision floating-point exceptions specified in the IEEE754 standard is generated by the single-precision floating-point operation instruction, the bit decides whether the CPU will start handling the exception. When the bit is set to 0, the exception handling is masked; when the bit is set to 1, the exception handling is enabled.

FV Flag (Invalid Operation Flag), FO Flag (Overflow Flag), FZ Flag (Division-by-Zero Flag), FU Flag (Underflow Flag), and FX Flag (Inexact Flag)



While the exception handling enable bit (Ej) is 0 (exception handling is masked), if any of five single-precision floating-point exceptions specified in the IEEE754 standard is generated, the corresponding bit is set to 1.

- When Ej is 1 (exception handling is enabled), the value of the flag remains.
- When the corresponding flag is set to 1, it remains 1 until it is set to 0 by software (accumulation flag).

FS Flag (Single-Precision Floating-Point Error Summary Flag)

This bit reflects the logical OR of the FU, FZ, FO, and FV flags.

2.2.2.9 Exception Table Register (EXTB)

The exception table register (EXTB) specifies the address where the exception vector table starts. This register is actually implemented as the following three registers to support the Protect Zone function.

- For the root world: EXTB_TR (only accessible in the root world)
- For the secure world: EXTB_S (only accessible in the secure world or root world)
- For the non-secure world: EXTB_NS (only accessible in the non-secure world or root world)

The initial value depends on the world.

- EXTB_TR, EXTB_S: FFFF FF80h
- EXTB_NS: 7FFF FF80h

2.2.2.10 Interrupt Vector Control Register (IVC)

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	BWINM[7:0]	Backup Interrupt Source Number for World Transition	These bits hold the source number of an interrupt accepted through the world-transition acceptance method.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	UIR[1:0]	Software Interrupt Restriction	These bits control the range of interrupt numbers that can be specified as the operand in an INT instruction to be executed in user mode. A number outside this range being specified as the operand will cause a privileged instruction exception. In supervisor mode, a number from 0 to 255 can be specified as the operand regardless of the setting in these bits. • For INT #imm:8 b17 b16 0 0: A number from 0 to 255 can be specified. 0 1: A number from 0 to 15 can be specified. 1 x: Setting prohibited • For INT Rs b17 b16 0 0: A number from 0 to 255 can be specified. 0 1: Software interrupts cannot be executed. 1 x: Setting prohibited	R/W
b23 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24	NSIC	Non-secure Interrupt Enable Control	This bit controls the function of the PSW.I bit in the non-secure world. 0: Interrupts are disabled while the PSW.I bit is 0. 1: Interrupts up to priority level 15 are disabled while the PSW.I bit is 0.	R/W *1
b27 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b28	EXCSE	Secure Exception Detection during Hardware Pre-processing	This bit is set if a secure exception occurs during hardware pre-processing. 0: A secure exception has not occurred during hardware pre-processing. 1: A secure exception has occurred during hardware pre-processing.	R/W *1
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. In the IVC_NS and IVC_S registers, this bit is always read as 0.

This register is actually implemented as the following three registers to support the Protect Zone function.

- For the root world: IVC_TR (only accessible in the root world)
- For the secure world: IVC_S (only accessible in the secure world or root world)
- For the non-secure world: IVC_NS (only accessible in the non-secure world or root world)

These actual registers are only modifiable during execution in supervisor mode while in the root world.

BWINM[7:0] Bits (Backup Interrupt Source Number for World Transition)

When an interrupt accepted through the world-transition acceptance method is generated, the vector number in the

interrupt vector table is stored in the IVC_TR.BWINM[7:0] bits and in the IVC.BWINM[7:0] bits in the destination world of the interrupt. The same value is written to the BWINM[7:0] bits of both the IVC_TR register and IVC register in the destination world for the transition (that is, the IVC_S.BWINM[7:0] bits in the secure world or the IVC_NS.BWINM[7:0] bits in the non-secure world).

UIR[1:0] Bits (Software Interrupt Restriction)

These bits are used to restrict the interrupt numbers that can be specified as the operand in an INT instruction to be executed in user mode. This setting is ignored in supervisor mode.

NSIC Bit (Non-secure Interrupt Enable Control)

This bit is used to control the function of the PSW.I bit for interrupts with a priority level 16 or higher in the non-secure world. When the NSIC bit is set to 1, interrupts with a priority level of 16 or higher are accepted regardless of the setting of the PSW.I bit. Interrupts with a priority level up to 15 are only accepted while the setting of the PSW.I bit is 1.
When the NSIC bit is set to 0, interrupts, whatever their priority level, are only accepted while the PSW.I bit is 1.

EXCSE Bit (Secure Exception Detection during Hardware Pre-processing)

This bit indicates that a secure exception has been detected during hardware pre-processing.
If a secure exception occurs during hardware pre-processing, the pre-processing is aborted and the secure exception is accepted. In this case, execution cannot be returned from the processing of the secure exception by using the TRRTE instruction. This bit can be used to identify such situations.

2.2.2.11 World ID Register (WID)

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	BWI	—	—	—	—	—	—	—	—	—	—	—	—	—	BITW[1:0]

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

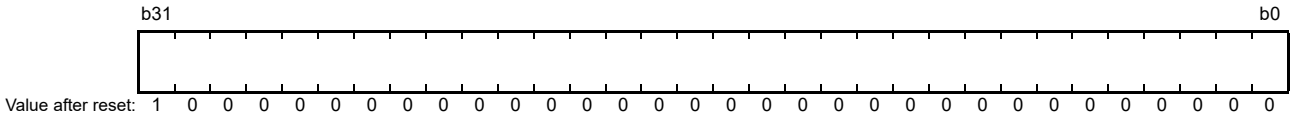
Bit	Symbol	Bit Name	Description	R/W
b1, b0	WID[1:0]	World ID	These bits hold the ID of the world in which execution is currently in progress.	R
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	BWID[1:0]	Backup World ID	These bits hold the world ID that was saved as the backup in a transition to root world.	R/W*1
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	BITW[1:0]	Backup Destination World ID	These bits hold the destination world ID for a backup interrupt (with world-transition acceptance) or non-maskable interrupt (with world-transition acceptance).	R
b30 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	BWI	Backup Interrupt Enable for Source World of Transition	This bit holds the value of the interrupt enable bit (PSW.I) specified in the source world of a transition for an unconditional trap (with world-transition acceptance).	R

Note 1. The bit is read as 0 during execution in the secure world or non-secure world.

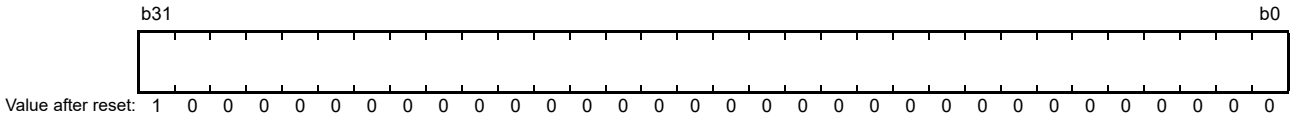
The following world IDs are defined.



00: Root world

01: Secure world

10: Non-secure world



This register is only modifiable during execution in supervisor mode while in the root world. It is read-only during execution in the secure world or non-secure world.

2.2.2.12 Root Call Vector Table Register (TRCTB)

Use the root call vector table register (TRCTB) to specify the first address of the root call vector table to be used for unconditional traps accepted through the world-transition acceptance method. The initial value of this register is 8000 0000h. This register is only accessible during execution in supervisor mode while in the root world.

2.2.2.13 Vector Table Register for Interrupts that Cause World Transitions (WINTB)

Use the vector table register for interrupts that cause world transitions (WINTB) to specify the first address of the vector table for interrupts that cause world transitions to be used for interrupts accepted through the world-transition acceptance method. The initial value of this register is 8000 0000h. This register is only accessible during execution in supervisor mode while in the root world.

2.2.2.14 World-Shared Processor Interrupt Priority Level Register (WPRI)

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	WIPL[4:0]					—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b28 to b24	WIPL[4:0]	World-Shared Processor Interrupt Priority Level	b28 b24 0 0 0 0 0: Priority level 0 (lowest) 0 0 0 0 1: Priority level 1 0 0 0 1 0: Priority level 2 0 0 0 1 1: Priority level 3 0 0 1 0 0: Priority level 4 0 0 1 0 1: Priority level 5 0 0 1 1 0: Priority level 6 0 0 1 1 1: Priority level 7 0 1 0 0 0: Priority level 8 0 1 0 0 1: Priority level 9 0 1 0 1 0: Priority level 10 0 1 0 1 1: Priority level 11 0 1 1 0 0: Priority level 12 0 1 1 0 1: Priority level 13 0 1 1 1 0: Priority level 14 0 1 1 1 1: Priority level 15 (non-secure, highest) 1 0 0 0 0: Priority level 16 1 0 0 0 1: Priority level 17 1 0 0 1 0: Priority level 18 1 0 0 1 1: Priority level 19 1 0 1 0 0: Priority level 20 1 0 1 0 1: Priority level 21 1 0 1 1 0: Priority level 22 1 0 1 1 1: Priority level 23 1 1 0 0 0: Priority level 24 1 1 0 0 1: Priority level 25 1 1 0 1 0: Priority level 26 1 1 0 1 1: Priority level 27 1 1 1 0 0: Priority level 28 1 1 1 0 1: Priority level 29 1 1 1 1 0: Priority level 30 1 1 1 1 1: Priority level 31 (secure/root, highest)	R/W
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R

This register is only readable and writable in the secure or root world.
This register is only writable in supervisor mode.

WIPL[4:0] Bits (World-Shared Processor Interrupt Priority Level)

The WIPL[4:0] bits specify the world-shared processor interrupt priority level as one of 32 levels from 0 to 31, wherein priority level 0 is the lowest and priority level 31 the highest.
When the priority level of a requested interrupt is higher than the current processor interrupt priority level specified in PSW.IPL[4:0] and higher than the world-shared processor interrupt priority level specified in WPRI.WIPL[4:0], the interrupt is enabled.

2.2.3 Accumulator

The accumulator (ACC0 or ACC1) is a 72-bit register used for DSP instructions. The accumulator is handled as a 96-bit register for reading and writing. At this time, when bits 95 to 72 of the accumulator are read, the value where the value of bit 71 is sign extended is read. Writing to bits 95 to 72 of the accumulator is ignored. ACC0 is also used for the multiply and multiply-and-accumulate instructions; EMUL, EMULU, FMUL, MUL, and RMPA, in which case the prior value in ACC0 is modified by execution of the instruction.

Use the MVTACGU, MVTACHI, and MVTACLO instructions for writing to the accumulator. The MVTACGU, MVTACHI, and MVTACLO instructions write data to the guard bits (bits 95 to 64), the higher-order 32 bits (bits 63 to 32), and the lower-order 32 bits (bits 31 to 0), respectively.

Use the MVFACGU, MVFACHI, MVFACMI, and MVFACLO instructions for reading data from the accumulator. The MVFACGU, MVFACHI, MVFACMI, and MVFACLO instructions read data from the guard bits (bits 95 to 64), higher-order 32 bits (bits 63 to 32), the middle 32 bits (bits 47 to 16), and the lower-order 32 bits (bits 31 to 0), respectively.

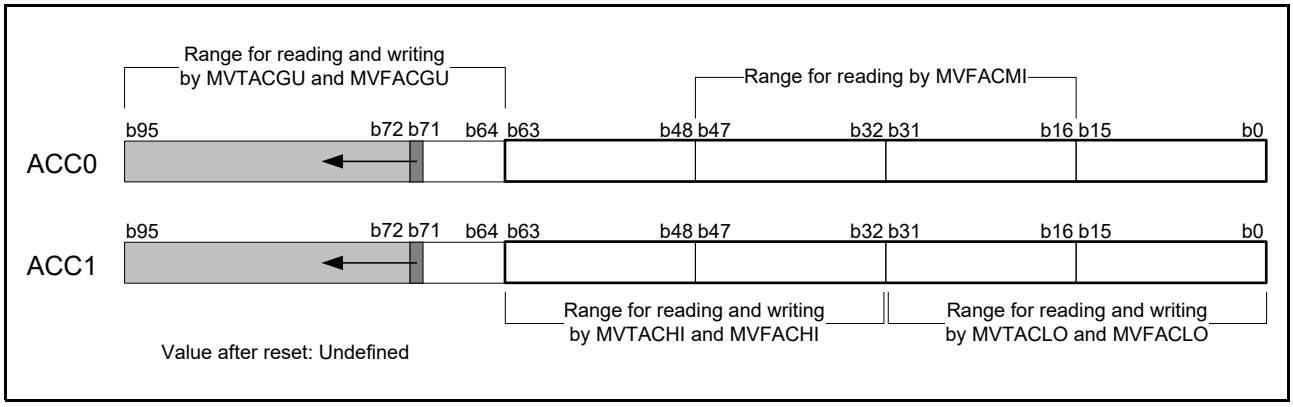

Figure 2.2 Accumulator

Note: When bits 95 to 72 of the accumulator are read, the value is the sign-extended value of bit 71. Writing to this area is ignored.

2.3 Processor Mode

The CPU supports two processor modes, supervisor and user. These processor modes and the memory protection function enable the realization of a hierarchical CPU resource protection and memory protection mechanism. Each processor mode imposes a level on rights of access to memory and the instructions that can be executed. Supervisor mode carries greater rights than user mode. The initial state after a reset is supervisor mode.

2.3.1 Supervisor Mode

In supervisor mode, all CPU resources that are allowed in the world in which execution is in progress are accessible and all instructions that are allowed in the world in which execution is in progress can be executed. However, writing to the processor mode select bit (PM) in the processor status word (PSW) by executing an MVTC or a POPC instruction will be ignored. For details on how to write to the PM bit, refer to section 2.2.2.4, Processor Status Word (PSW).

2.3.2 User Mode

In user mode, write access to the CPU resources listed below is restricted. The restriction applies to any instruction capable of write access.

- Some bits (bits IPL[4:0], PM, U, and I) in the processor status word (PSW)
- Interrupt stack pointer (ISP)
- Interrupt table register (INTB)
- Backup PSW (BPSW)
- Backup PC (BPC)
- Fast interrupt vector register (FINTV)
- Exception table register (EXTB)
- Interrupt vector control register (IVC)
- World ID register (WID)
- Root call vector table register (TRCTB)
- Vector table register for interrupts that cause world transitions (WINTB)
- World-shared processor interrupt priority level register (WPRI)

2.3.3 Privileged Instruction

Privileged instructions can only be executed in supervisor mode. Executing a privileged instruction in user mode produces a privileged instruction exception. Privileged instructions include the RTFI, MVTIPL, RTE, WAIT, TRCALL, TRMVFC, TRMVTC, TRRTE, SAVE, and RSTR instructions. If the INT instruction is executed in user mode with a number outside the specified allowable range, a privileged instruction exception occurs. For details, see the description of the IVC.UIR bit.

2.3.4 Switching Between Processor Modes

Manipulating the processor mode select bit (PM) in the processor status word (PSW) switches the processor mode. However, rewriting to the PM bit by executing an MVTC, TRMVTC, or POPC instruction is prohibited. Switch the processor mode by following the procedures described below.

(1) Switching from user mode to supervisor mode

After an exception has been generated, the PSW.PM bit is set to 0 and the CPU switches to supervisor mode. The hardware pre-processing is executed in supervisor mode. The state of the processor mode before the exception was generated is retained in the PSW.PM bit that is saved on the stack.

(2) Switching from supervisor mode to user mode

Executing an RTE or TRRTE instruction when the value of the PSW.PM bit that has been saved on the stack is 1 or an RTFI instruction when the value of the PSW.PM bit that has been saved in the backup PSW (BPSW) is 1 causes a transition to user mode. In the transition to user mode, the value of the stack pointer designation bit (the PSW.U bit) becomes 1.

2.4 Data Types

The CPU can handle four types of data: integer, single-precision floating-point number, bit, and string.
For details, refer to RX Family RXv3e Instruction Set Architecture User's Manual: Software.

2.4.1 Integer

An integer can be signed or unsigned. For signed integers, negative values are represented by two's complements.

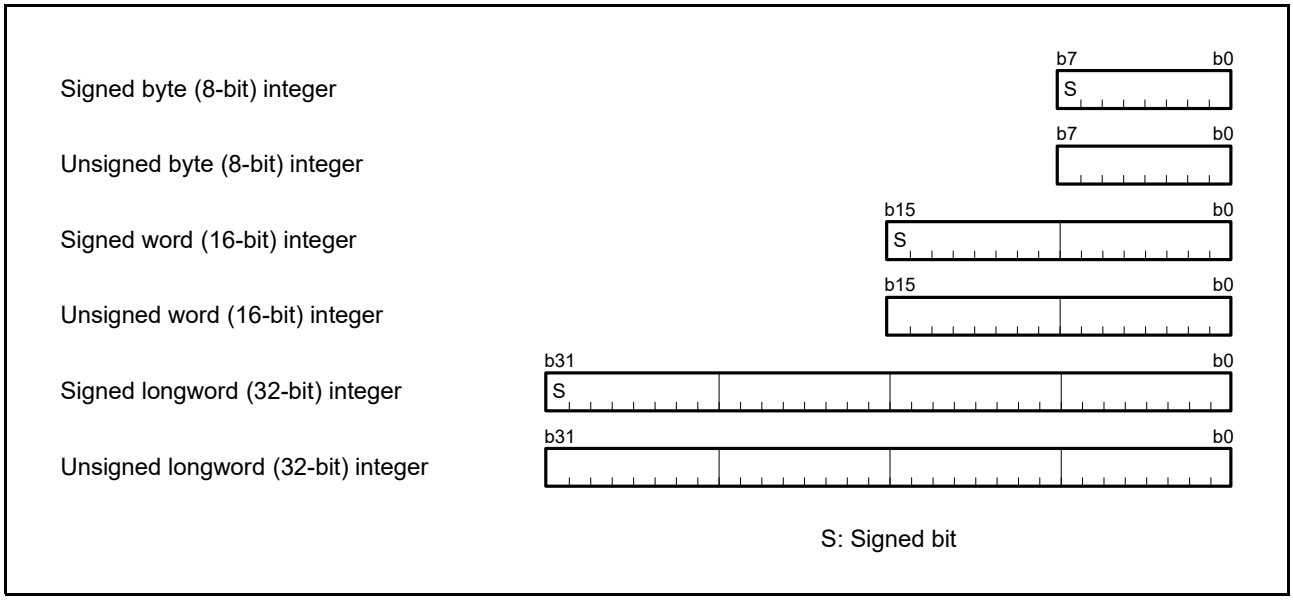

Figure 2.3 Integer

2.4.2 Single-Precision Floating-Point Numbers

The single-precision floating-point number is compliant with that specified in the IEEE754 standard; operands of this type can be used in eleven single-precision floating-point operation instructions: FADD, FCMP, FDIV, FMUL, FSQRT, FSUB, FTOI, FTOU, ITOF, ROUND, and UTOF.

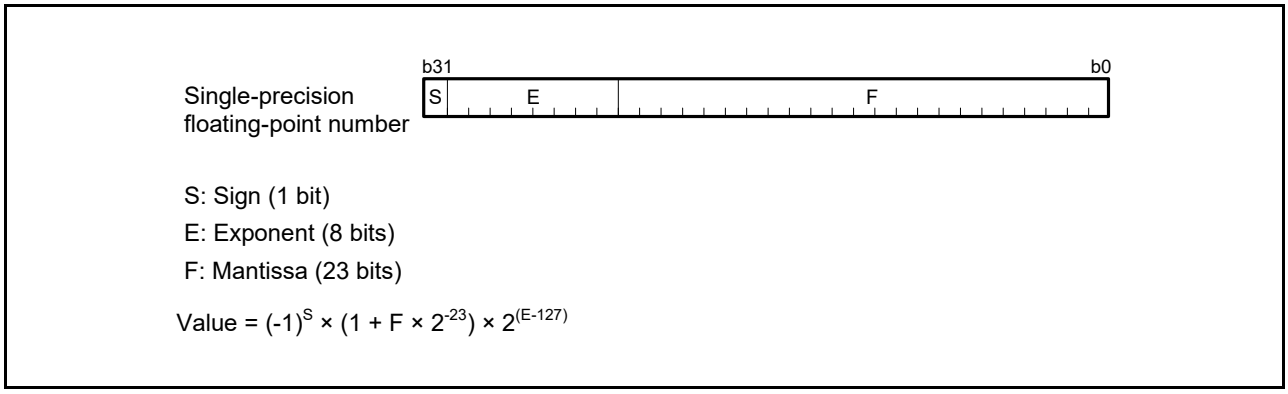

Figure 2.4 Single-Precision Floating-Point Number

The single-precision floating-point number can represent the values listed below.

- 0 < E < 255 (normal numbers)
- E = 0 and F = 0 (signed zero)
- E = 0 and F > 0 (denormalized numbers)*1
- E = 255 and F = 0 (infinity)
- E = 255 and F > 0 (NaN: Not-a-Number)

Note 1. The number is treated as 0 when the FPSW.DN bit is 1. When the DN bit is 0, an unimplemented processing exception is generated.

2.4.3 Bitwise Operations

Five bit-manipulation instructions are provided for bitwise operations: BCLR, BM*Cnd*, BNOT, BSET, and BTST.
A bit in a register is specified as the destination register and a bit number in the range from 31 to 0.
A bit in memory is specified as the destination address and a bit number from 7 to 0. The addressing modes available to specify addresses are register indirect and register relative.

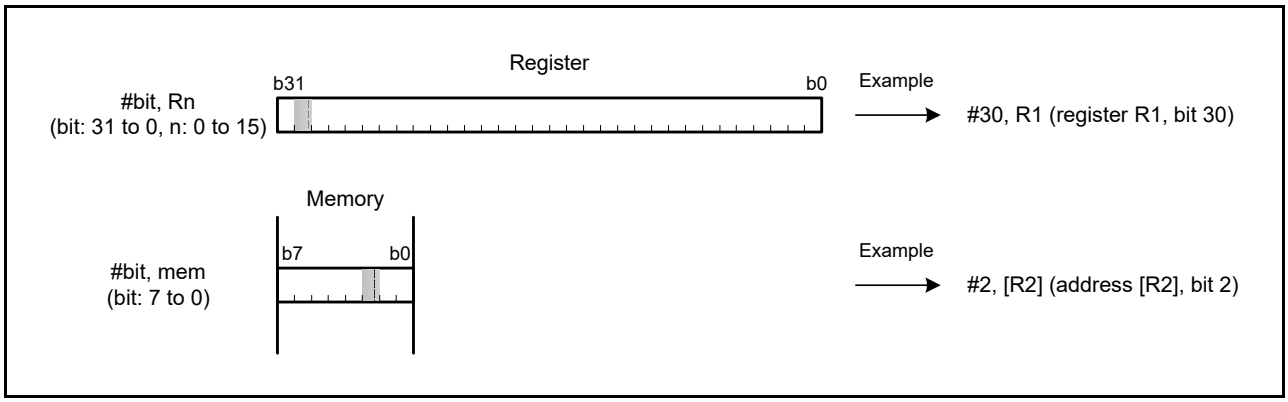

Figure 2.5 Bit

2.4.4 Strings

The string data type consists of an arbitrary number of consecutive byte (8-bit), word (16-bit), or longword (32-bit) units. Seven string manipulation instructions are provided for use with strings: SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, and SWHILE.

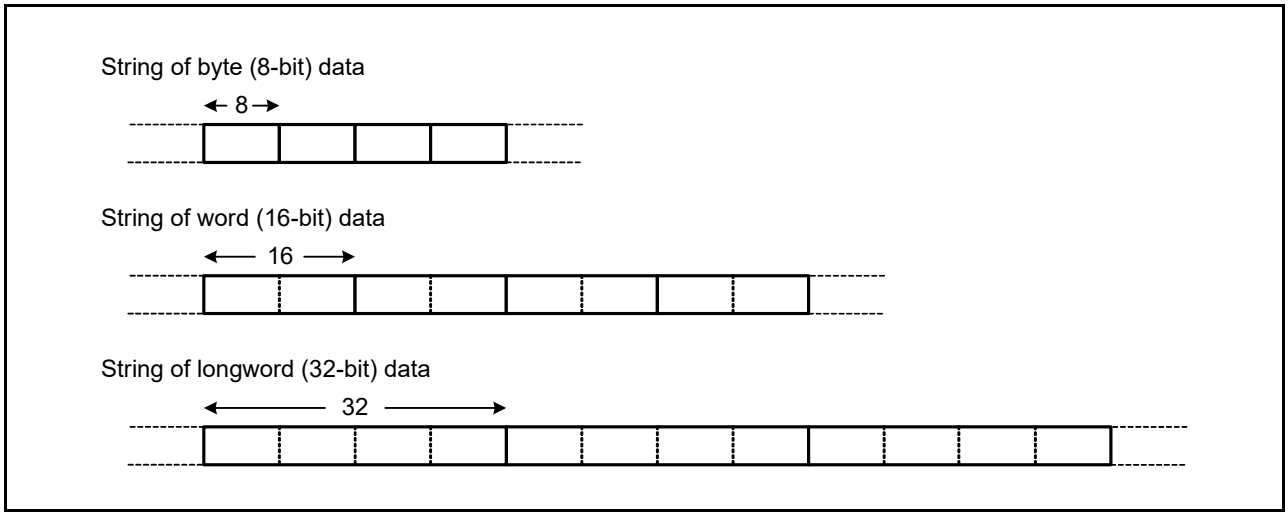

Figure 2.6 String

2.5 Endian

For the CPU, instructions are little endian, but the treatment of data is selectable as little or big endian.

2.5.1 Switching the Endian

As arrangements of bytes, this MCU supports both big endian, where the higher-order byte (MSB) is at location 0, and little endian, where the lower-order byte (LSB) is at location 0.
For details on the endian setting, see section 3, Operating Modes.
Operations for access differ according to the endian setting and, depending on the instruction, whether 8-, 16- or 32-bit access has been selected. Operations for access in the various possible cases are described in Table 2.2 to Table 2.13.
In the tables,

LL indicates bits D7 to D0 of the general-purpose register,
LH indicates bits D15 to D8 of the general-purpose register,
HL indicates bits D23 to D16 of the general-purpose register, and
HH indicates bits D31 to D24 of the general-purpose register.

	D31 to D24	D23 to D16	D15 to D8	D7 to D0
General purpose register: Rm	HH	HL	LH	LL

2.5.2 Access to I/O Registers

The addresses of I/O registers are fixed, and this is regardless of whether the setting is for little endian or big endian. Accordingly, changes to the endian do not affect access to I/O registers. For the arrangements of I/O registers, refer to the descriptions of registers in the relevant sections.

2.5.3 Notes on Access to I/O Registers

Ensure that access to I/O registers is in accord with the following rules.

- With I/O registers for which a bus width of eight bits is indicated, use instructions having operands of the same width (eight bits). That is, access these registers by using instructions with .B as the size specifier (.size), or with .B or .UB as the size-extension specifier (.memex).
- With I/O registers for which a bus width of 16 bits is indicated, use instructions having operands of the same width (16 bits). That is, access these registers by using instructions with .W as the size specifier (.size), or with .W or .UW as the size-extension specifier (.memex).
- With I/O registers for which a bus width of 32 bits is indicated, use instructions having operands of the same width (32 bits). That is, access these registers by using instructions with .L as the size specifier (.size), or with .L size-extension specifier (.memex).

2.5.4 Data Arrangement

2.5.4.1 Data Arrangement in Registers

Figure 2.7 shows the relation between the sizes of registers and bit numbers.

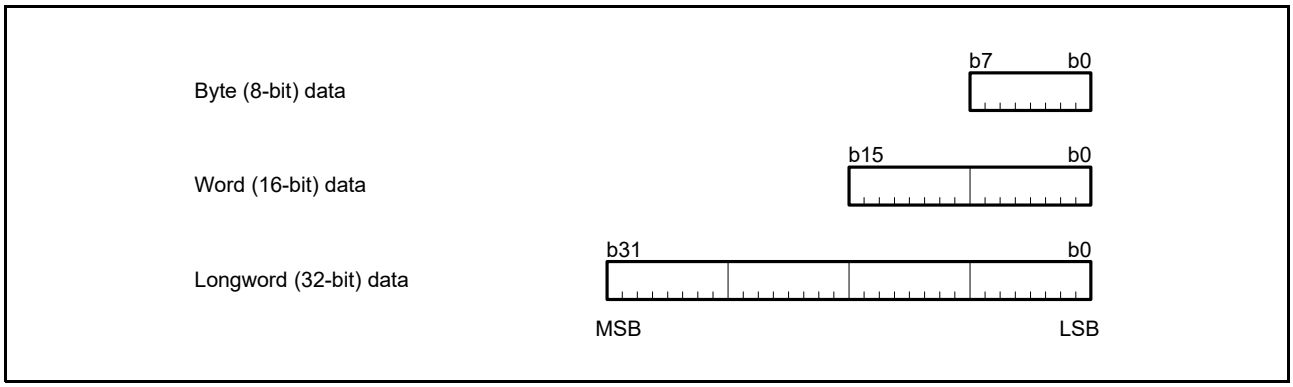

Figure 2.7 Data Arrangement in Registers

2.5.4.2 Data Arrangement in Memory

Data in memory have three sizes: byte (8-bit), word (16-bit), and longword (32-bit). The data arrangement is selectable as little endian or big endian. Figure 2.8 shows the arrangement of data in memory.

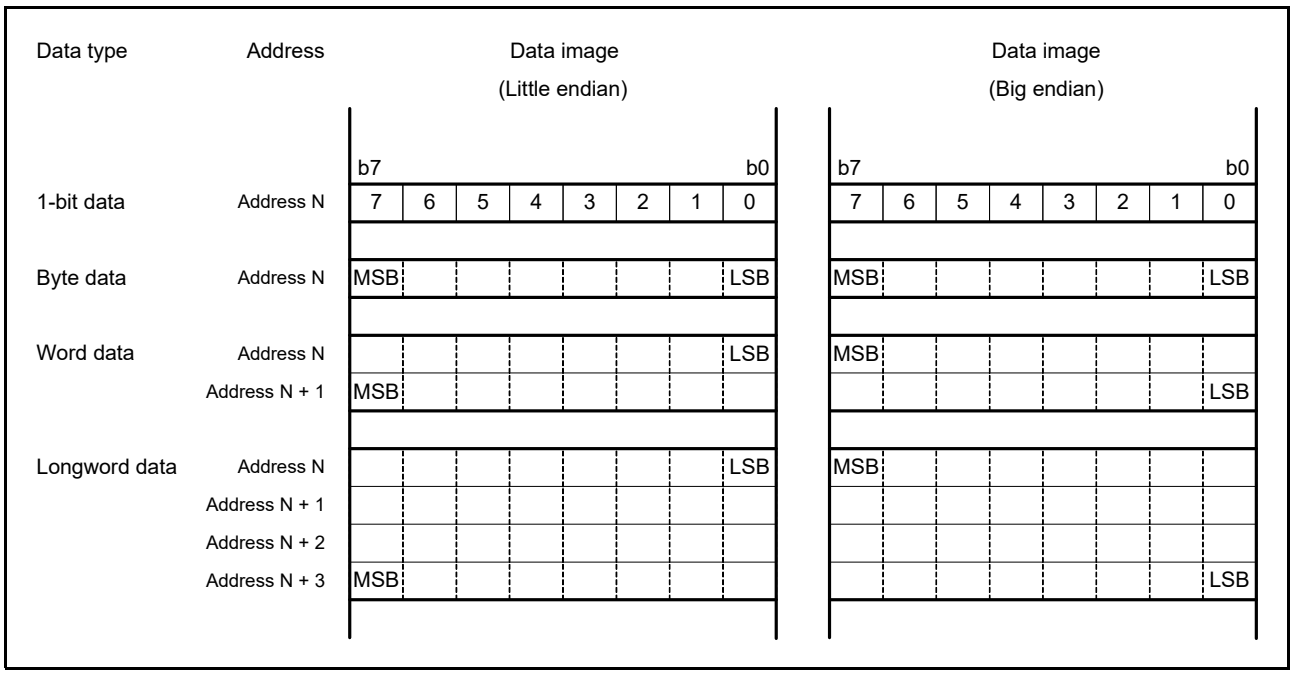

Figure 2.8 Data Arrangement in Memory

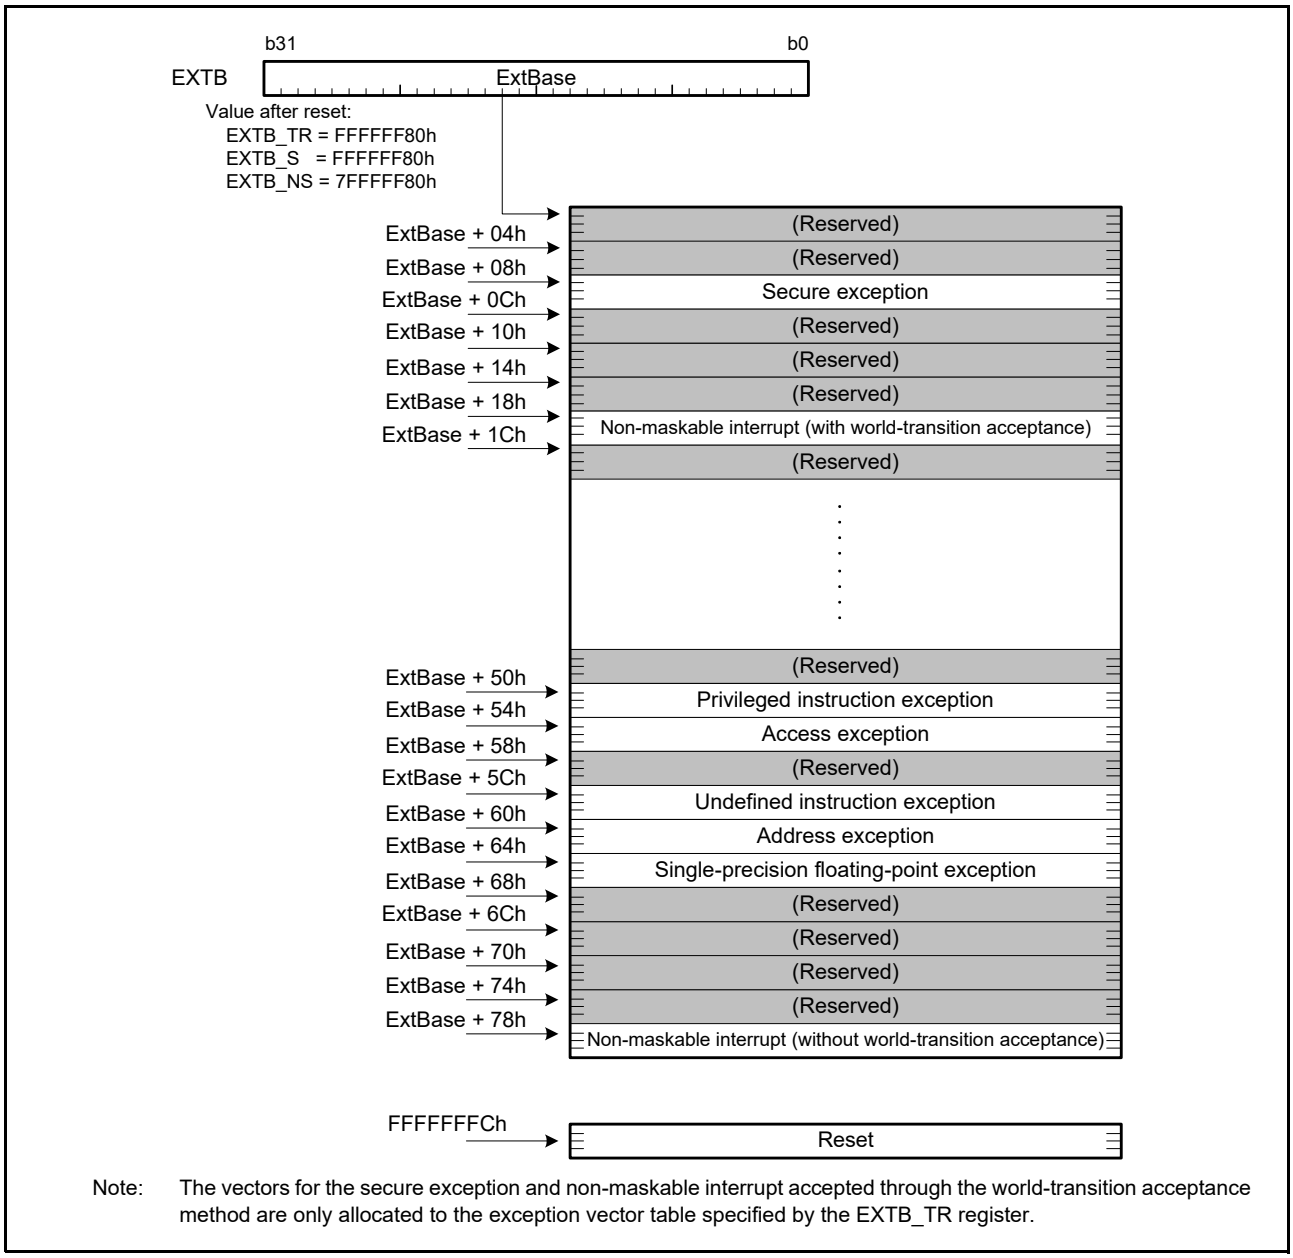
2.5.5 Notes on the Allocation of Instruction Codes

The allocation of instruction codes to an external address space where the endian differs from that of the chip is prohibited. If the instruction codes are allocated to the external address space, they must be allocated to areas where the endian setting is the same as that for the chip.



2.6 Vector Tables

There are four types of vector tables: exception vector table, interrupt vector table, root call vector table, and vector table for interrupt that cause world transitions. Each vector in the vector table consists of four bytes and specifies the address where the corresponding exception handling routine starts.

2.6.1 Exception Vector Table

In the exception vector table, the individual vectors for the secure exceptions, non-maskable interrupt (with world-transition acceptance), privileged instruction exception, access exception, address exception, undefined instruction exception, single-precision floating-point exception, and non-maskable interrupt (with normal acceptance) are allocated to the 124-byte area where the value indicated by the exception table register (EXTB) is used as the starting address (ExtBase). The reset vector is always allocated to FFFFFFFCh, regardless of the value of the exception vector table register.

Figure 2.9 shows the exception vector table.

Note: The vectors for the secure exception and non-maskable interrupt accepted through the world-transition acceptance method are only allocated to the exception vector table specified by the EXTB_TR register.

Figure 2.9 Exception Vector Table

2.6.2 Interrupt Vector Table

The address where the interrupt vector table is placed can be adjusted. The table is a 1,024-byte region that contains all vectors for unconditional traps and interrupts and starts at the address (IntBase) specified in the interrupt table register (INTB). Figure 2.10 shows the interrupt vector table.

Each vector in the interrupt vector table has a vector number from 0 to 255. Vector numbers from 0 to 255 are assigned for the INT instruction, which generates an unconditional trap, and the vector corresponding to the INT instruction number is read from the vector table. Vector number 0 is assigned for the BRK instruction and the vector is always read from the entry with vector number 0 in the table. In addition, fixed vector numbers (0 to 255) are assigned to the individual interrupt sources and the assigned numbers vary with the product type. For more on interrupt vector numbers, see section 15.3.1, Interrupt Vector Table.

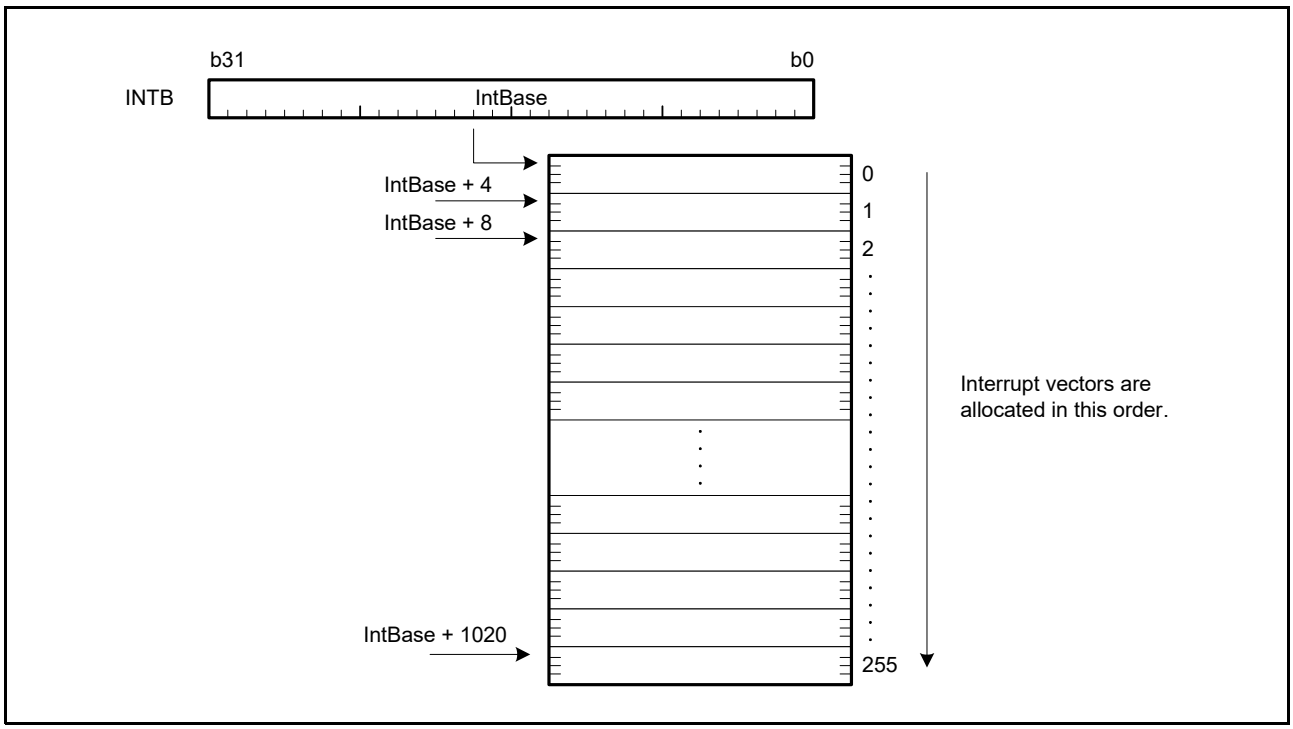


Figure 2.10 Interrupt Vector Table

2.6.3 Root Call Vector Table

The root call vector table is a 1024-byte region starting at the address (TRCallBase) specified in the root call vector table register (TRCTB). Each vector called by the TRCALL instruction is assigned to this vector table. Figure 2.11 shows the root call vector table.

Each vector in the root call vector table has a vector number from 0 to 255. Vector numbers 0 to 255 are assigned for the TRCALL instruction and the vector corresponding to the number specified in the operand of the instruction is read from the vector table.

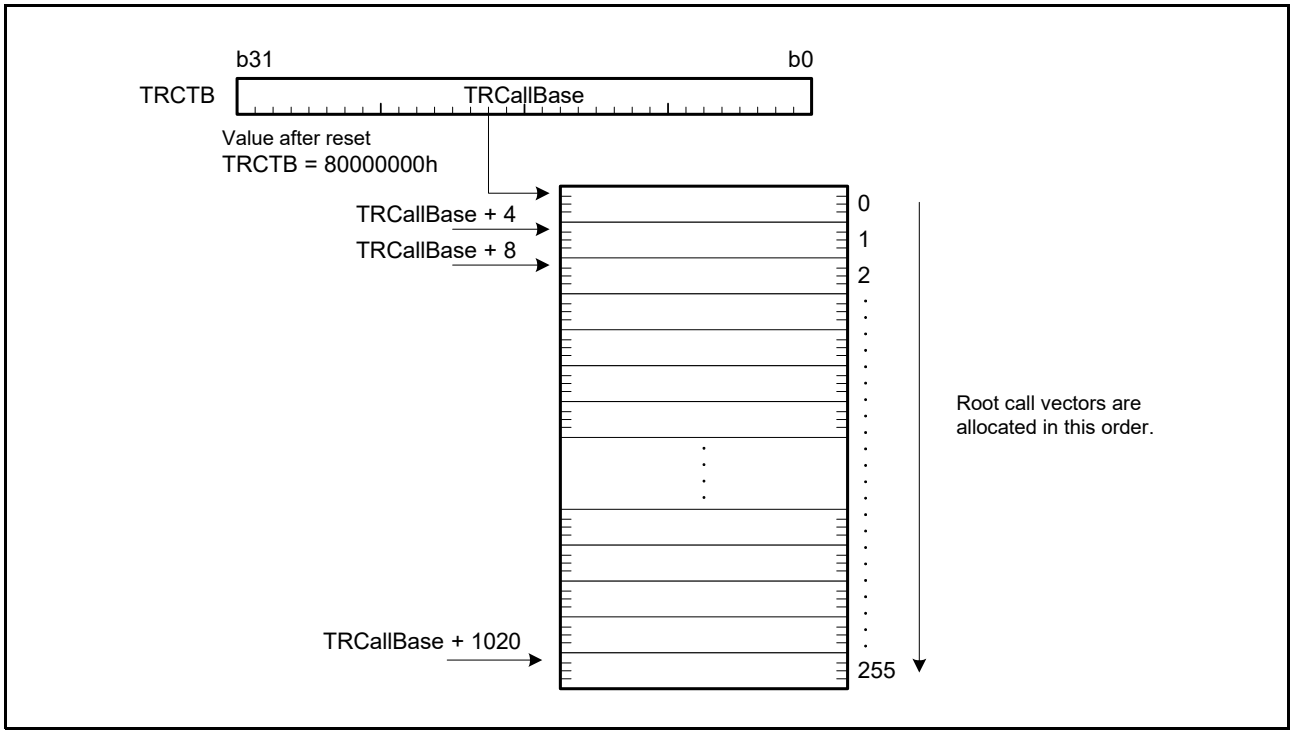

Figure 2.11 Root Call Vector Table

2.6.4 Vector Table for Interrupts that Cause World Transitions

The vector table for interrupts that cause world transition is a 12-byte region starting at the address (WIntBase) specified in the vector table register for interrupts that cause world transitions (WINTB). The individual vectors for the interrupts accepted through the world-transition acceptance method are allocated to this vector table. Figure 2.12 shows the vector table for interrupts that cause world transitions.

Each vector in this vector table has a vector number from 0 to 2. The vector number corresponds to the ID of the destination world for the interrupt accepted through the world-transition acceptance method.

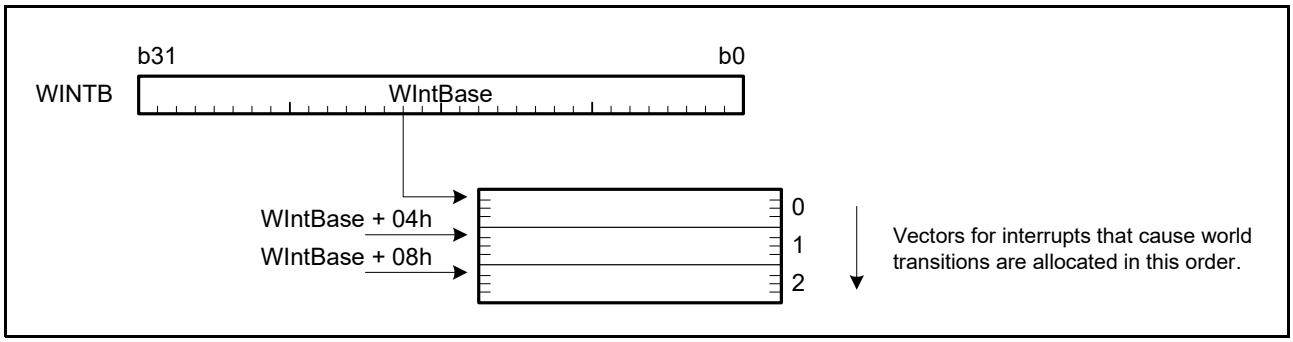

Figure 2.12 Vector Table for Interrupts that Cause World Transitions

2.7 Register Bank Save Function

The CPU has dedicated register-saving banks and functionality for using them for the fast saving and restoring of the values of CPU registers (see Figure 2.13). The register-saving banks enable the fast collective saving at the start of the exception handling routine and fast collective restoring of register values at the end of the exception handling routine. The register-saving banks are only accessible by the SAVE and RSTR instructions, and are independent of the 4-Gbyte address space. Each of the multiple banks is used to save and restore the values of the following CPU registers: all general purpose registers except R0, the USP, FPSW, and accumulators (ACC0, ACC1). Values in the register-saving banks are undefined after a reset.

A unique number (bank number) is allocated to each register-saving bank.

The MCU has 16 save register banks per world, to which the bank numbers 0 to 15 are assigned.

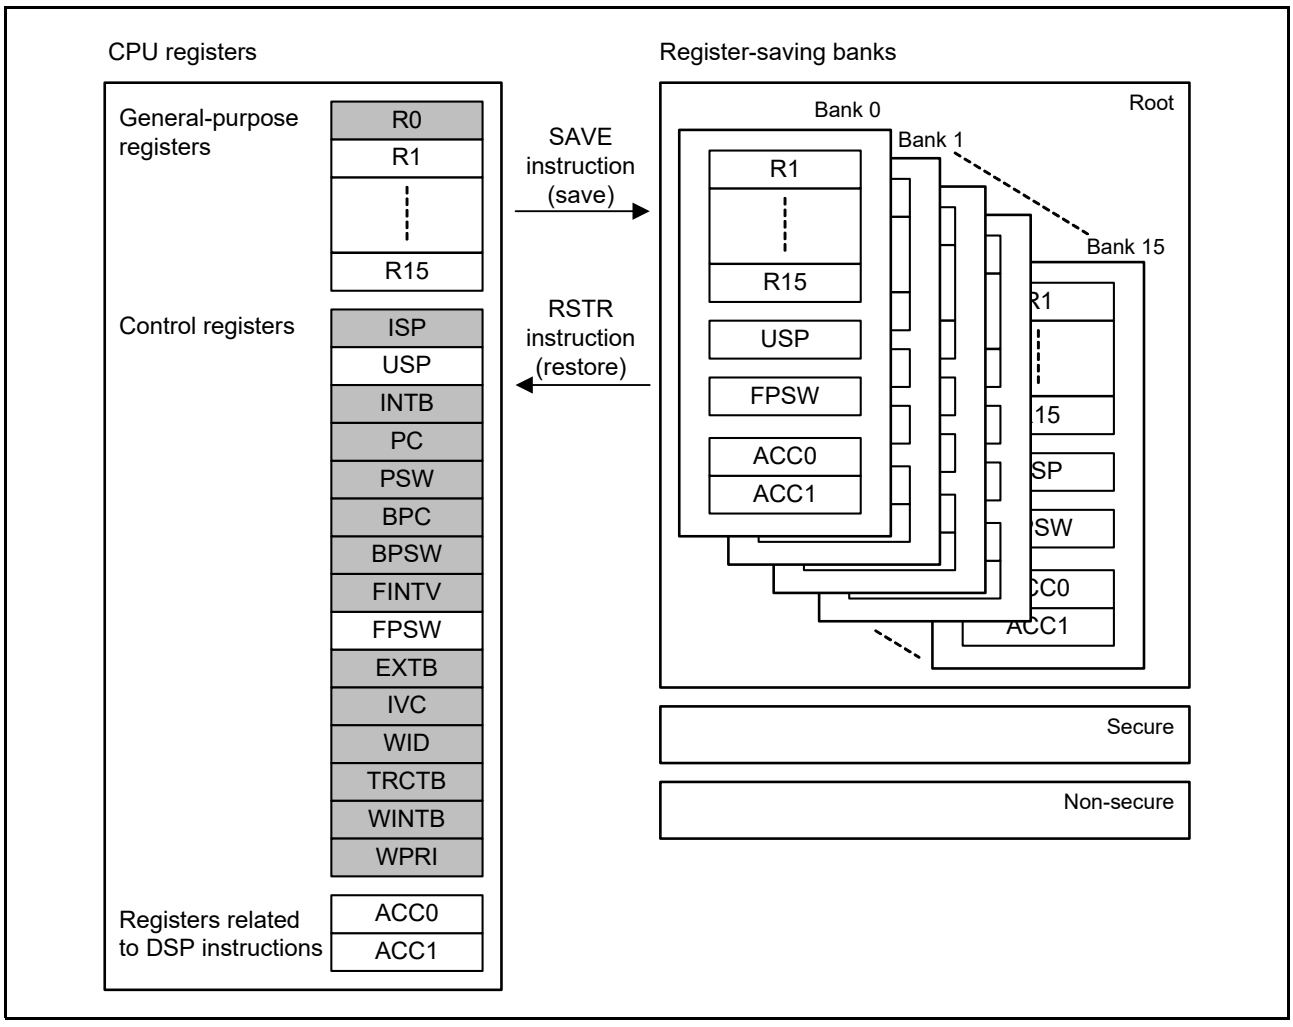

Figure 2.13 Register-Saving Banks

Each world has its own register-saving bank. There is a TR register-saving bank for root, an S register-saving bank for secure, and an NS register-saving bank for non-secure. The register-saving bank corresponding to the world in which the SAVE or RSTR instruction was executed is used.

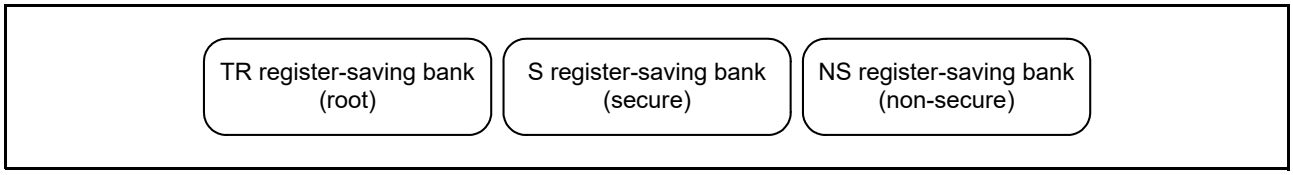

Figure 2.14 Configuration of Register-Saving Banks to Support the Protect Zone Function

2.8 Double-Precision Floating-Point Coprocessor

The double-precision floating-point coprocessor operates as a coprocessor of the CPU, and executes double-precision floating-point processing instructions. Using the double-precision floating-point coprocessor considerably accelerates the processing of double-precision floating point arithmetic.

2.8.1 Features

- Double-precision floating-point register set
  Double-precision floating-point data registers: Sixteen 64-bit registers
  Double-precision floating-point control registers: Four 32-bit registers
- Double-precision floating-point processing instructions: 21
- Notifying the interrupt controller of double-precision floating-point exceptions

2.8.2 Double-Precision Floating-Point Register Set

The double-precision floating-point coprocessor consists of 16 double-precision floating-point data registers and 4 double-precision floating-point control registers.

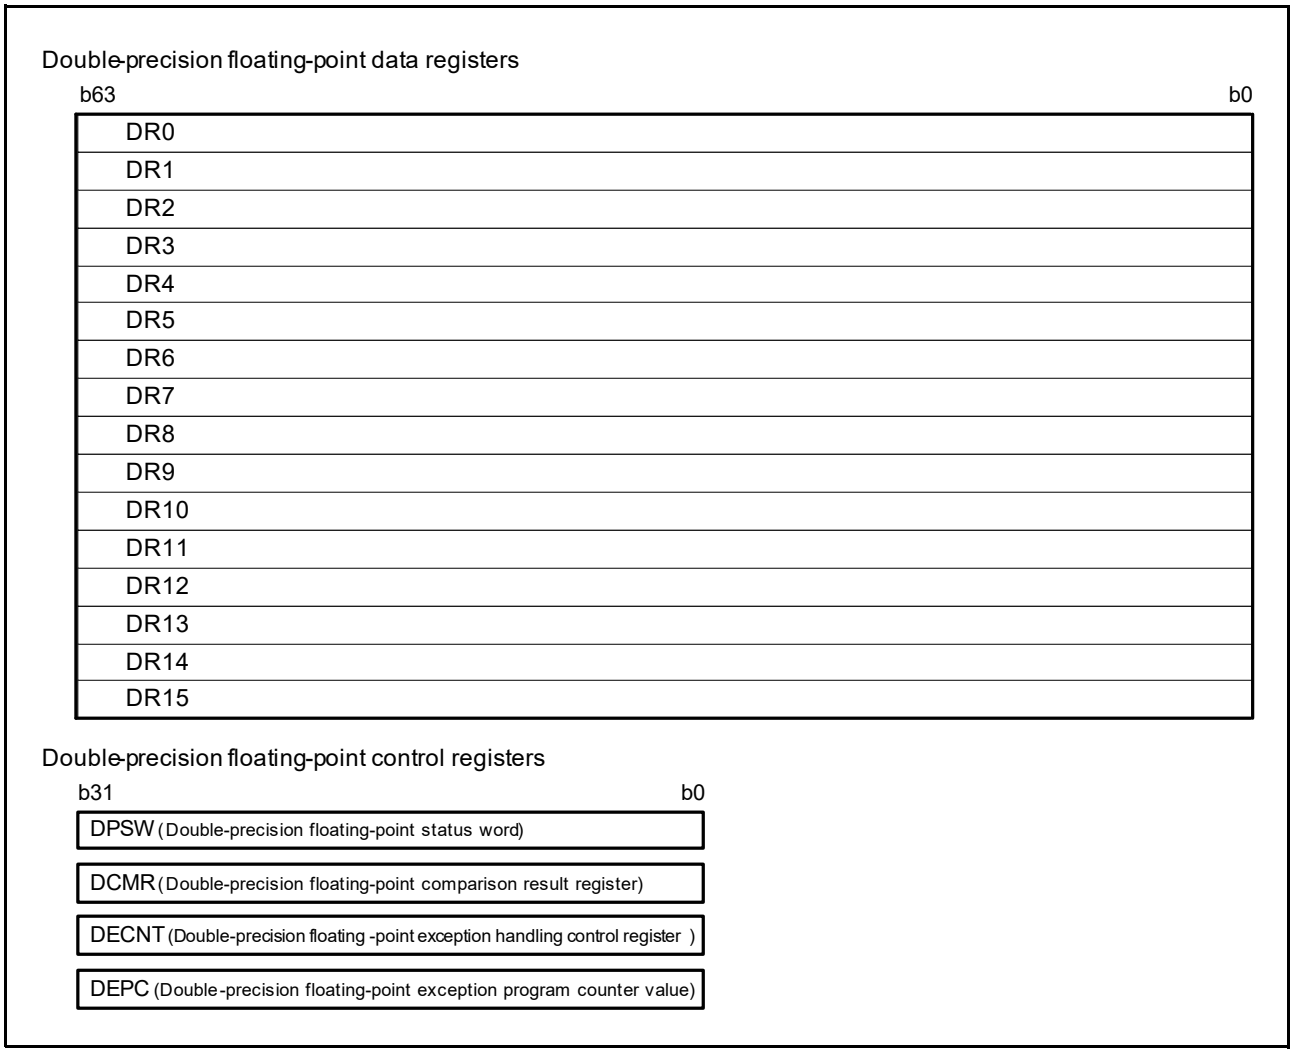

Figure 2.15 Double-Precision Floating-Point Register Set

2.8.2.1 Double-Precision Floating-Point Data Registers (DR0 to DR15)

16 double-precision floating-point data registers with 64-bit width are provided (DR0 to DR15). To specify 32-bit values, use the upper 32 bits (DRH0 to DRH15) or lower 32 bits (DRL0 to DRL15) as separate units.

2.8.2.2 Double-Precision Floating-Point Control Registers

Four double-precision floating-point control registers are provided.

- Double-precision floating-point status word (DPSW)
- Double-precision floating-point comparison result register (DCMR)
- Double-precision floating-point exception handling control register (DECNT)
- Double-precision floating-point exception program counter (DEPC)

Bit	Symbol	Bit Name	Description	R/W
b31	DFS	Double-Precision Floating-Point Error Summary Flag	This bit reflects the logical OR of the DFU, DFZ, DFO, and DFV flags.	R

Note 1. When 0 is written to the bit, the setting of the bit will be 0; the bit retains the previous value in response to the writing of 1.
Note 2. Positive denormalized numbers are treated as +0, negative denormalized numbers as –0.
Note 3. When the DEV bit is set to 0, the DFV flag is enabled.
Note 4. When the DEO bit is set to 0, the DFO flag is enabled.
Note 5. When the DEZ bit is set to 0, the DFZ flag is enabled.
Note 6. When the DEU bit is set to 0, the DFU flag is enabled.
Note 7. When the DEX bit is set to 0, the DFX flag is enabled.
Note 8. Once the bit has been set to 1, this value is retained until it is set to 0 by software.

The double-precision floating-point status word (DPSW) indicates the results of double-precision floating-point arithmetic operations.
When the corresponding exception handling enable bits (DEj) are set to enable processing of the exceptions (DEj = 1), the DCj flags can be used by the exception handling routine (the interrupt handling routine with the double-precision floating-point exception as its source) to identify the source of that exception. If handling of an exception is masked (DEj = 0), the DFj flag can be used to check for the generation of the exception at the end of a sequence of processing. The DFj flags operate in an accumulative fashion (j =X, U, Z, O, or V).
The single-precision floating-point status word (FPSW) is neither referred to nor updated in double-precision floating-point arithmetic operations.

DRM[1:0] Bits (Double-Precision Floating-Point Rounding-Mode Setting)

These bits specify the double-precision floating-point rounding-mode.

Explanation of Double-Precision Floating-Point Rounding Modes

- Rounding to the nearest value (the default behavior): An inexact result is rounded to the available value that is closest to the result of a hypothetical calculation with infinite precision. If two available values are equally close, rounding is to the even alternative.
- Rounding towards 0: An inexact result is rounded to the smallest available absolute value; i.e., in the direction of zero (simple truncation).
- Rounding towards +∞: An inexact result is rounded to the nearest available value in the direction of positive infinity.
- Rounding towards –∞: An inexact result is rounded to the nearest available value in the direction of negative infinity.

(1) Rounding to the nearest value is specified as the default mode and returns the most accurate value.
(2) Modes such as rounding towards 0, rounding towards +∞, and rounding towards –∞ are used to ensure precision when interval arithmetic is employed.

DCV Flag (Invalid Operation Cause Flag), DCO Flag (Overflow Cause Flag), DCZ Flag (Division-by-Zero Cause Flag), DCU Flag (Underflow Cause Flag), DCX Flag (Inexact Cause Flag), and DCE Flag (Unimplemented Processing Cause Flag)

Double-precision floating-point exceptions include the five specified in the IEEE754 standard, namely overflow, underflow, inexact, division-by-zero, and invalid operation. For a further double-precision floating-point exception that is generated upon detection of unimplemented processing, the corresponding flag (DCE) is set to 1.

- If an exception or processing that is not implemented is not encountered in the execution of a double-precision floating-point arithmetic instruction other than DABS or DNEG, the corresponding flags become 0.
- When 0 is written to the bit, the setting of the bit will be 0; the bit retains the previous value in response to the writing of 1.

DDN Bit (0 Flush Bit of Denormalized Number)

When this bit is set to 0, a denormalized number is handled as a denormalized number.
When this bit is set to 1, a denormalized number is handled as 0.

DEV Bit (Invalid Operation Exception Enable), DEO Bit (Overflow Exception Enable), DEZ Bit (Division-by-Zero Exception Enable), DEU Bit (Underflow Exception Enable), and DEX Bit (Inexact Exception Enable)

When any of the five floating-point exceptions specified in the IEEE754 standard is generated in the execution of a double-precision floating-point operation instructions, these bits determine whether the CPU will start handling the exception (interrupt information will be held by setting the DECNT.EHS bit and an interrupt request will be sent to the interrupt controller).

When the bit corresponding to an exception is 0, the DECNT.EHS bit is not set to 1. When the bit corresponding to an exception is 1, the DECNT.EHS bit is set to 1. However, if the DECNT.EHM bit is 0, the DECNT.EHS bit will not be set to 1 regardless of the value of the bit corresponding to the exception.

DFV Flag (Invalid Operation Flag), DFO Flag (Overflow Flag), DFZ Flag (Division-by-Zero Flag), DFU Flag (Underflow Flag), and DFX Flag (Inexact Flag)

While the exception handling enable bit (DEj) is 0 (exception handling is masked), if any of five floating-point exceptions specified in the IEEE754 standard is generated, the corresponding bit is set to 1.

- When DEj is 1 (exception handling is enabled), the value of the flag remains.
- When the corresponding flag is set to 1, it remains 1 until it is set to 0 by software (Accumulation flag).

DFS Flag (Double-Precision Floating-Point Error Summary Flag)

This bit reflects the logical OR of the DFU, DFZ, DFO, and DFV flags.

The value of this register is not updated when the EHM and EHS bits in the DECNT register are 1.

(2) Double-Precision Floating-Point Comparison Result Register (DCMR)

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RES	Double-Precision Floating-Point Compare Instruction Result Flag	0: Condition for comparison was not satisfied. 1: Condition for comparison was satisfied.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

(3) Double-Precision Floating-Point Exception Handling Control Register (DECNT)

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EHS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EHM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EHM	Double-Precision Floating-Point Exception Information Saving Mode	0: Mode in which information on the sources of exceptions is not saved. Information on the generation of double-precision floating-point exceptions is not saved when they occur. No interrupt request is sent to the interrupt controller. 1: Mode in which information on the generation of exceptions is saved. When a double-precision floating-point exception is generated and an interrupt request is sent to the interrupt controller, the EHS bit is changed to 1 to save information at the time the exception was generated, and the interrupt request is sent to the interrupt controller.	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	EHS	Double-Precision Floating-Point Exception Information Saving Status	0: Exception information is not being saved. 1: Exception information is being saved. Updating of the following registers stops when the EHM and EHS bits are 1, and interrupts due to double-precision floating-point exceptions do not occur. • Double-precision floating-point status word • Double-precision floating-point exception program counter In addition, an interrupt request is sent to the interrupt controller. Writing 0 to this bit releases the information recorded at the time the exception was generated from the retained state.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

(4) Double-Precision Floating-Point Exception Program Counter (DEPC)

	b31	b0
Value after reset:	Undefined	

When a double-precision floating-point exception is generated and the corresponding DEX, DEU, DEZ, DEO, or DEV bit of the DPSW is 1, the value of the program counter for the instruction that has caused the most recent double-precision floating-point exception is saved in this register. This register is read-only. The value of this register is not updated when the value of the DECNT.EHS bit is 1 while that of the DECNT.EHM bit is also 1.

2.8.3 Data Types (for the Double-Precision Floating-Point Coprocessor)

The double-precision floating-point coprocessor can handle double-precision floating-point numbers.
In addition, it can handle single-precision floating-point numbers with the DTOF and FTOD instructions, and 32-bit integers with the DROUND, DTOI, DTOU, ITOD and UTOD instructions.
For single-precision floating-point numbers, refer to section 2.4.2, Single-Precision Floating-Point Numbers, and for 32-bit integers, refer to section 2.4.1, Integer.

2.8.3.1 Double-Precision Floating-Point Numbers

The double-precision floating-point number is compliant with that specified in the IEEE754 standard. Operands of this type can be used in fifteen double-precision floating-point arithmetic instructions: DABS, DADD, DCMPcm, DDIV, DMUL, DNEG, DROUND, DSUB, DSQRT, DTOF, DTOI, DTOU, FTOD, ITOD, and UTOD.

Figure 2.16 Double-Precision Floating-Point Number

The double-precision floating-point number can represent the values listed below.
0 < E < 2047 (normal numbers)
E = 0 and F = 0 (signed zero)
E = 0 and F > 0 (denormalized numbers)*1
E = 2047 and F = 0 (infinity (∞))
E = 2047 and F > 0 (Not-a-Number (NaN))
Note 1. The number is treated as 0 when the DPSW.DDN bit is 1. When the DDN bit is 0, an unimplemented processing exception is generated.

2.8.4 Data Arrangement (for the Double-Precision Floating-Point Coprocessor)

The double-precision floating-point coprocessor can handle 32-bit and 64-bit values.
For 32-bit values, refer to section 2.5.4, Data Arrangement, and section 2.5.1, Switching the Endian.

2.8.4.1 Arrangement of Data in the Double-Precision Floating-Point Registers

Figure 2.17 shows the relationship between the sizes of registers DR0 to DR15 and the bit numbers.

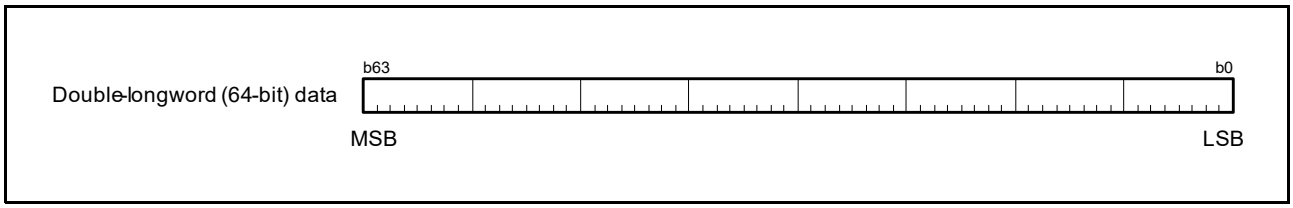

Figure 2.17 Data Arrangement in Registers

2.8.4.2 Arrangement of Data for Double-Precision Floating-Point Numbers in Memory

A double-precision floating-point number is always represented as a double-longword (64 bits) in memory. The data arrangement is selectable as little endian or big endian. Figure 2.18 shows the arrangement of data in memory.

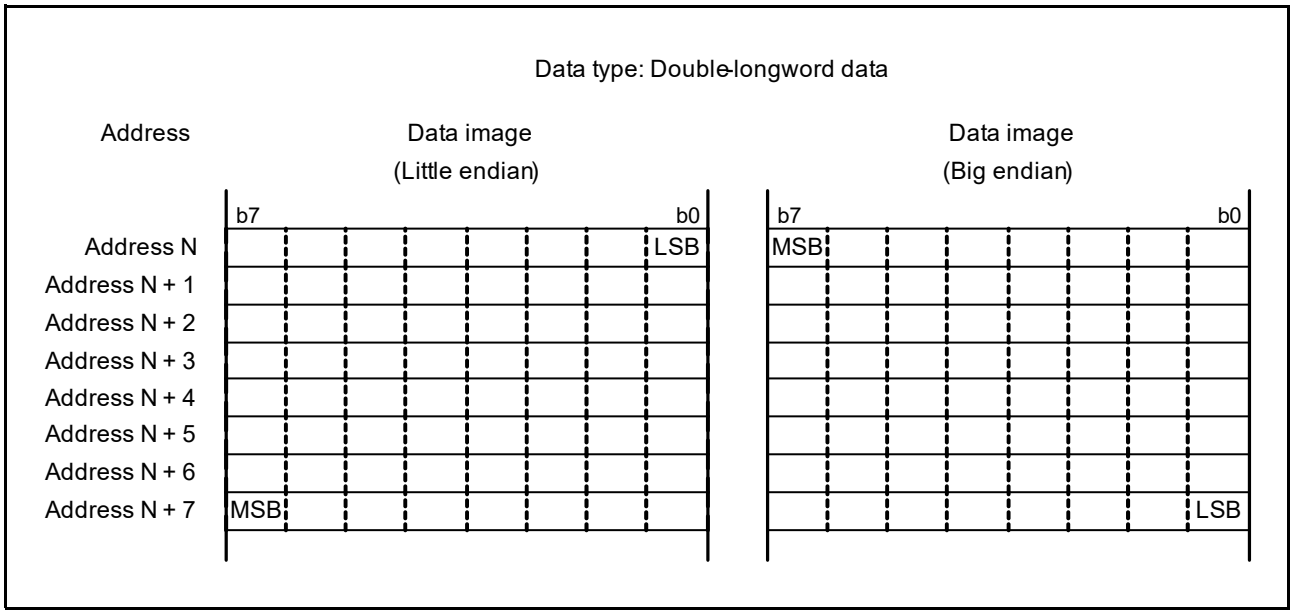

Figure 2.18 Data Arrangement in Memory

2.8.5 Switching the Endian (for the Double-Precision Floating-Point Coprocessor)

The operation in access with 64-bit values by double-precision floating-point processing instructions depends on the endian setting. Table 2.14 to Table 2.17 show operations in access for each endian and in the cases of reading and writing.

Address exceptions are generated in response to 64-bit access to addresses that are not on 32-bit boundaries.

In the tables,

LLL indicates bits D7 to D0 of the double-precision floating-point data registers,
LLH indicates bits D15 to D8 of the double-precision floating-point data registers,
LHL indicates bits D23 to D16 of the double-precision floating-point data registers,
LHH indicates bits D31 to D24 of the double-precision floating-point data registers,
HLL indicates bits D39 to D32 of the double-precision floating-point data registers,
HLH indicates bits D47 to D40 of the double-precision floating-point data registers,
HHL indicates bits D55 to D48 of the double-precision floating-point data registers, and
HHH indicates bits D63 to D56 of the double-precision floating-point data registers.

Double-precision floating-point data register: DRm	D63 to D56	D55 to D48	D47 to D40	D39 to D32
	HHH	HHL	HLH	HLL
	D31 to D24	**D23 to D16**	**D15 to D8**	**D7 to D0**
	LHH	LHL	LLH	LLL

2.9 Acceleration Functions

This MCU has two caches, one each for instructions and data, a branch instruction processing accelerator, and local SRAM (LRAM) for acceleration of processing. All are capable of operating at the same frequency as that of the CPU core.

2.9.1 Features

- Instruction cache and data cache
  Instruction cache: 32 Kbytes (4-way set associative cache)
  Data cache: 32 Kbytes (4-way set associative cache)
- Branch instruction processing accelerator
  Accelerator for MRAM and LRAM: 272 bytes (Fully associative cache)
- Local SRAM (LRAM)
  128 Kbytes × 2 units

Table 2.18 lists the features of the caches, Table 2.19 lists the features of the branch instruction processing accelerator, and Table 2.20 lists the features of the LRAM.

Table 2.18 Features of the Caches

Item	Instruction Cache	Data Cache
Capacity	32 Kbytes	32 Kbytes
Mapping	4-way set associative cache	4-way set associative cache
Line size	256 bits (32 bytes)	256 bits (32 bytes)
Number of entries	256 entries/way	256 entries/way
Write mode	—	Write-through or write-back non-write-allocate/write-allocate
Update Method	LRU	LRU
Error detection method	ECC Data: 1-bit error correction, 2-bit error detection Tag: 1-bit error detection, 2-bit error detection	ECC Data: 1-bit error correction, 2-bit error detection Tag: 1-bit error detection, 2-bit error detection

Table 2.19 Features of the Branch Instruction Processing Accelerator

Item	Description
Capacity	272 bytes (256 bytes for branch Instructions and 16 bytes for RTS instruction)
Mapping	Fully associative cache
Line size	128 bits (One line consists of two 64-bit data fields allocated on 64-bit boundaries.)
Number of entries	16 entries for branch Instructions and 1 entry for RTS instruction
Update Method	LRU
Caching areas	MRAM: 7F00 0000h to 7FFF FFFFh, FF00 0000h to FFFF FFFFh LRAM: 0000 0000h to 00FF FFFFh, 8000 0000h to 80FF FFFFh

Table 2.20 Features of the Local SRAM (LRAM)

Item	LRAM0/1
Capacity	128 Kbytes
Error detection method	ECC 1-bit error correction, 2-bit error detection

2.9.2 Block Diagrams

Figure 2.19 shows the relationship between the caches, branch instruction processing accelerator, and LRAM units.

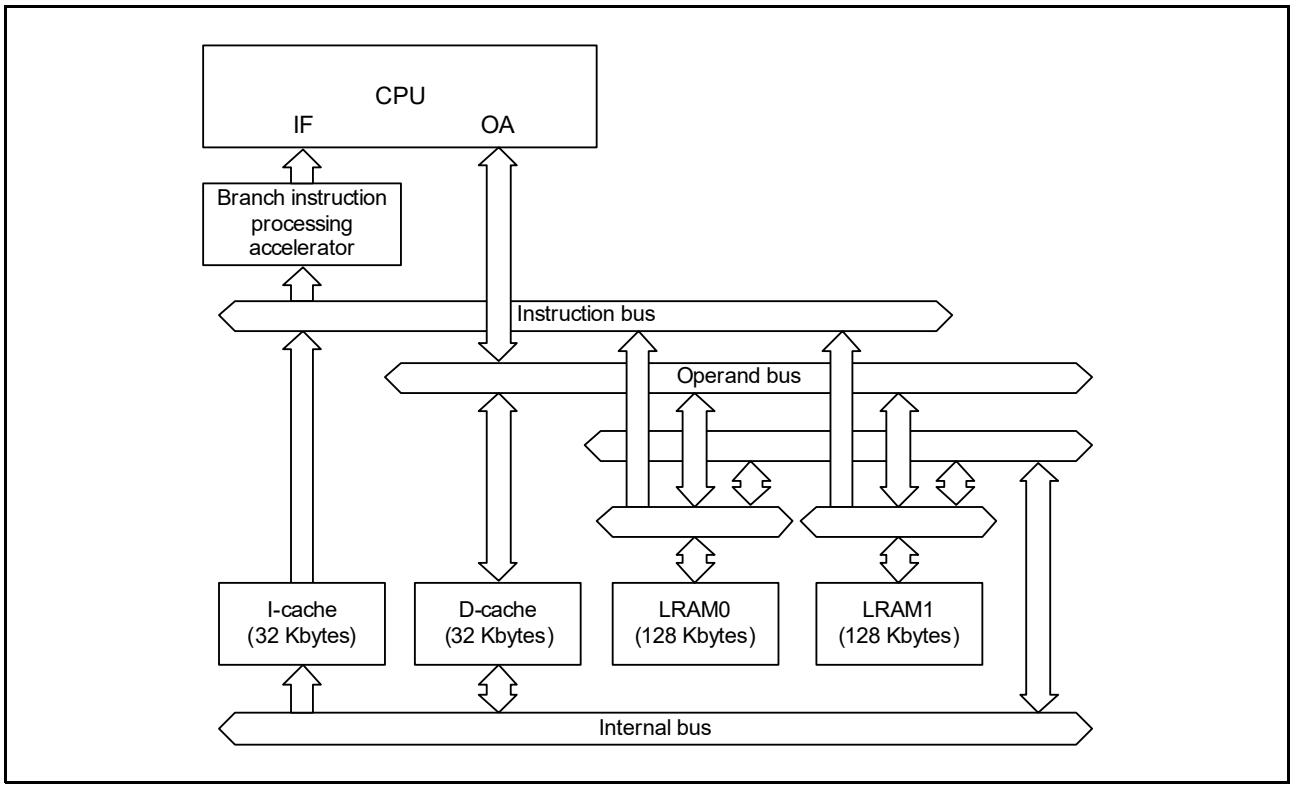

Figure 2.19 Relationship between the Caches, Branch Instruction Accelerator, and LRAM Units

Figure 2.20 shows the structure of the caches.

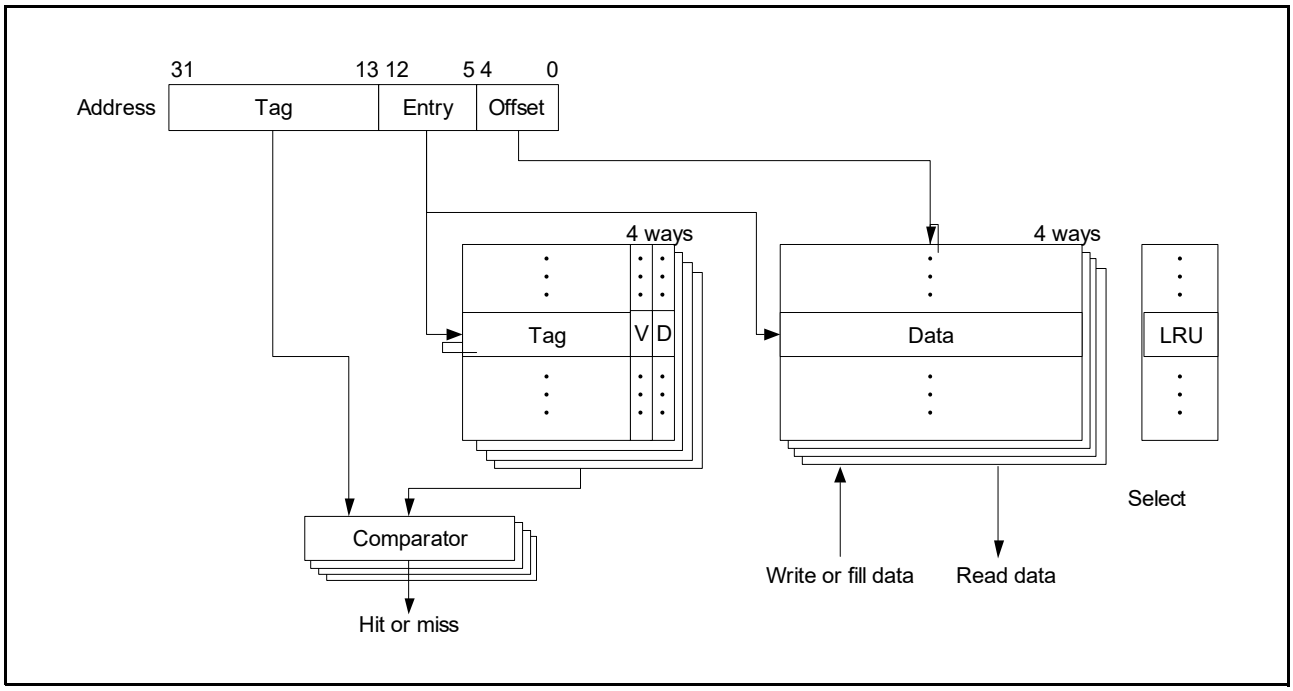

Figure 2.20 Internal Structure of the Caches

- Tag
  Each tag field holds cached address bits 31 to 13. It also holds the ECC code for the 32-bit value consisting of address bits 31 to 13, V bit, and 0-extension bits. The tag fields are cleared by a cache flush.
- V
  Each cache line has a valid (V) bit. This indicates that the valid data has been stored in the cache line. The tag fields are cleared by a cache flush.
- D
  Each cache line has a dirty (D) bit. This indicates that the valid data value stored in the cache line has changed from the initial value and the value needs to be written back through the internal bus. Note that the instruction cache does not have D bits.
- Data
  Each data field consists of 256 bits per cache line. It also holds the ECC codes for every 32-bit unit.
- LRU
  The LRU (least recently used) field indicates the next cache line to be replaced.
- Comparator
  The comparator judges whether the target data value for access is stored in any cache line. When the V bit is set and the target address matches the address stored in the tag field, the access is judged to be a cache hit. Otherwise, the access is judged to be a cache miss. Note that if an ECC error is found in the tag while the access has been judged as a hit, the operation is handled as a miss.

Figure 2.21 shows the structure of the branch instruction processing accelerator.

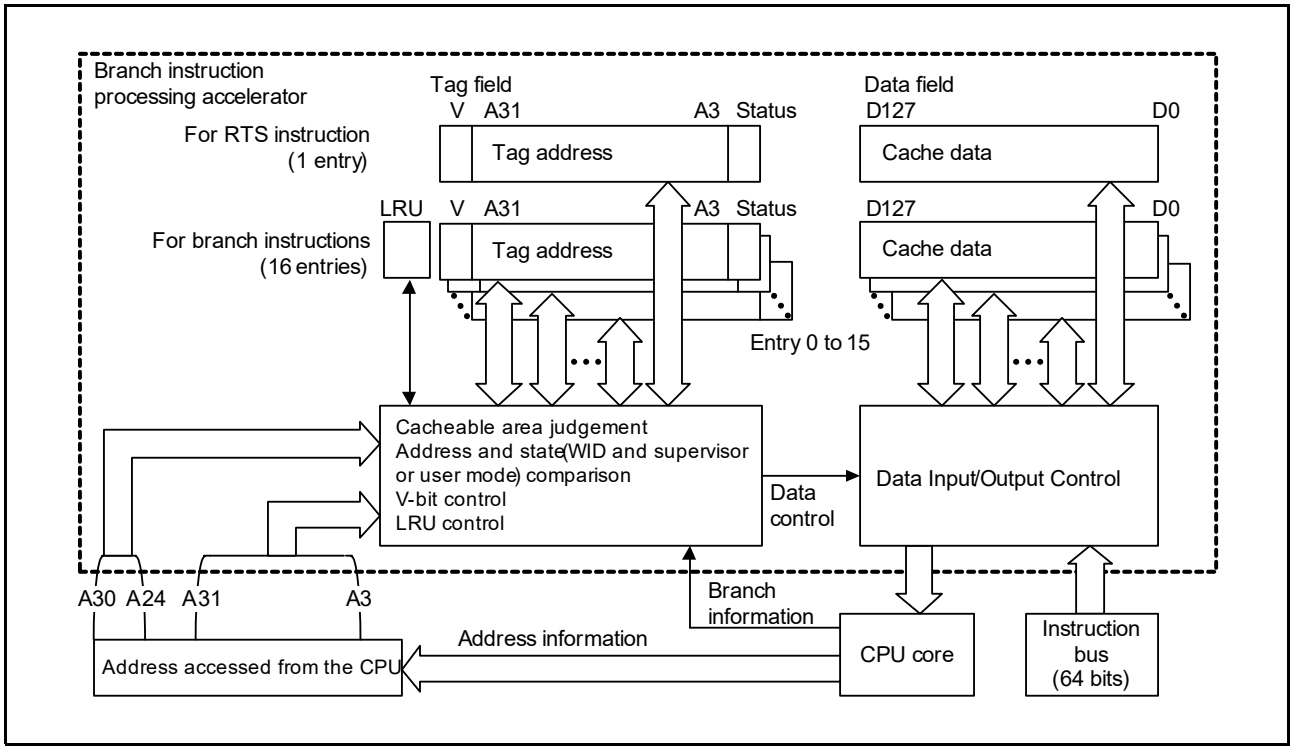

Figure 2.21 Internal Structure of the Branch Instruction Processing Accelerator

2.9.3 Cache Control Registers

The cache has the following fourteen control registers.

- Cache security attribute register (CACHESAR)
- Instruction cache control register (IFCACTL)
- Instruction cache flush control register (IFCAFCT)
- Instruction cache error detection status register (IFCAEDST)
- Instruction cache test access address register (IFCATAA)*1
- Instruction cache test access data register (IFCATAD)*1
- Data cache control register (OACACTL)
- Data cache flush control register (OACAFCT)
- Data cache write attribute register (OACAWTA)
- Data cache error detection status register (OACAEDST)
- Data cache test access address register (OACATAA)*1
- Data cache test access data register (OACATAD)*1
- Operation settings after cache error detection register (CAOAD)
- Cache protection register (CAPRCR)

Note 1. The register can be used in testing of the ECC decoder for function safety.

2.9.3.1 Cache Security Attribute Register (CACHESAR)

Address(es): CPSCU.CACHESAR 8701 8500h, CPSCU_NS.CACHESAR 0701 8500h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	CACHEESA	—	CACHESA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CACHESA	Security Attribute Setting for Control Registers	0: Secure 1: Non-secure	R/W
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b2	CACHEESA	Security Attribute Setting for Error Registers	0: Secure 1: Non-secure	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

This register is write-protected by the PRCR_S.PRC4 bit. It is only writable from secure world.

CACHESA Bit (Security Attribute Setting for Control Registers)

This bit is used to specify the security attribute for the control registers. The following lists the applicable registers.
IFCACTL, IFCAEDST, OACACTL, OACAWTA, OACAEDST

CACHEESA Bit (Security Attribute Setting for Error Registers)

This bit is used to specify the security attribute for the error registers. The following lists the applicable registers.
CAOAD, CAPRCR

To make secure program or secure data cacheable, set the CACHESA and CACHEESA bits to 0 (secure).

2.9.3.2 Instruction Cache Control Register (IFCACTL)

Address(es): CACHE.IFCACTL 8101 0000h, CACHE_NS.IFCACTL 0101 0000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	FL	—	—	—	—	—	—	—	EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	EN	Instruction Cache Enable	0: The instruction cache is disabled. 1: The instruction cache is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	FL	Instruction Cache Flush	0: No effect 1: The instruction cache is flushed: that is, all lines are invalidated. This bit has the same function as that of the IFCAFCT.FL bit.	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

EN Bit (Instruction Cache Enable)

This bit is used to enable or disable the instruction cache. When the instruction cache is enabled, whether to cache the fetched instruction depends on the cache attribute of the CPU access. Refer to the related descriptions in the section on the MPU.

FL Bit (Instruction Cache Flush)

Refer to the description of the IFCAFCT.FL bit for details.

2.9.3.3 Instruction Cache Flush Control Register (IFCAFCT)

Address(es): CACHE.IFCAFCT 8101 0004h, CACHE_NS.IFCAFCT 0101 0004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FL	Instruction Cache Flush	0: No effect 1: The instruction cache is flushed: that is, all lines are invalidated.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

FL Bit (Instruction Cache Flush)

Writing 1 to this bit starts flushing of the instruction cache (invalidating the contents of the cache). This bit is automatically cleared upon completion of the flush. Do not write to this bit or the IFCAFCT register before automatic clearing of this bit.

2.9.3.4 Instruction Cache Error Detection Status Register (IFCAEDST)

Address(es): CACHE.IFCAEDST 8101 0010h, CACHE_NS.IFCAEDST 0101 0010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	EST2	—	ESTC	ESD2	ESD1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESD1	Instruction Cache 1-bit ECC Error Flag*1	This flag indicates that a 1-bit ECC error has been detected during reading from a data field in the instruction cache. 0: A 1-bit ECC error has not been detected. 1: A 1-bit ECC error has been detected and the error has been corrected.	R/W
b1	ESD2	Instruction Cache 2-bit ECC Error Flag*1	This flag indicates that a 2-bit ECC error has been detected during reading from a data field in the instruction cache. 0: A 2-bit ECC error has not been detected. 1: A 2-bit ECC error has been detected.	R/W
b2	ESTC	Instruction Cache Tag Clean Line Invalidate Flag*1	This flag indicates that a clean line has been invalidated due to the detection of a 1-bit ECC error during reading from a tag field in the instruction cache. 0: A clean line has not been invalidated. 1: A clean line has been invalidated.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	EST2	Instruction Cache Tag 2-bit ECC Error Flag*1	This flag indicates that a 2-bit ECC error has been detected during reading from a tag field in the instruction cache. 0: A 2-bit ECC error has not been detected. 1: A 2-bit ECC error has been detected.	R/W
b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. The write value should be 0. Writing 0 will clear the flag.

ESD1 Flag (Instruction Cache 1-bit ECC Error Flag)

This flag indicates whether a 1-bit ECC error has been detected during reading from a data field in the instruction cache. The flag can be cleared by writing 0 to it. This flag is also cleared by a reset other than a bus error reset or a memory error reset. If an error occurs at the same time as clearing of the flag, the flag is cleared and the error is ignored.

ESD2 Flag (Instruction Cache 2-bit ECC Error Flag)

This flag indicates whether a 2-bit ECC error has been detected during reading from a data field in the instruction cache. The flag can be cleared by writing 0 to it. This flag is also cleared by a reset other than a bus error reset or a memory error reset. If an error occurs at the same time as clearing of the flag, the flag is cleared and the error is ignored.

ESTC Flag (Instruction Cache Tag Clean Line Invalidate Flag)

This flag indicates whether a line has been invalidated due to the detection of a 1-bit ECC error during reading from a tag field in the instruction cache. The flag can be cleared by writing 0 to it. This flag is also cleared by a reset other than a bus error reset or a memory error reset. If an error occurs at the same time as clearing of the flag, the flag is cleared and

the error is ignored.

EST2 Flag (Instruction Cache Tag 2-bit ECC Error Flag)

This flag indicates whether a 2-bit ECC error has been detected during reading from a tag field in the instruction cache. The flag can be cleared by writing 0 to it. This flag is also cleared by a reset other than a bus error reset or a memory error reset. If an error occurs at the same time as clearing of the flag, the flag is cleared and the error is ignored.

2.9.3.5 Instruction Cache Test Access Address Register (IFCATAA)

Address(es): CACHE.IFCATAA 8101 0014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	WAY[1:0]		—	—	—	—	—	—	RW	—	—	—	—	TARGET[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	ENTRY[7:0]								OFFSET[2:0]			—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4 to b2	OFFSET[2:0]	Address Offset	Specify the value of bits 4 to 2 of the address for test access to the instruction cache; these bits indicate the value of the three high-order bits of the cache offset for use in testing. This setting is valid for the reading and writing of cache data or ECC codes.	R/W
b12 to b5	ENTRY[7:0]	Address Entry	Specify the value of bits 12 to 5 of the address for test access to the instruction cache; these bits indicate the cache entry for use in testing.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b18 to b16	TARGET[2:0]	Target of Test Access	Specify the target of test access to the instruction cache. The type of access can be selected by the RW bit. b18 b16 0 0 0: Reading or writing of cache data 0 0 1: Reading or writing of ECC codes 0 1 0: Reading or writing of the tag field and V bit 0 1 1: Reading or writing of the LRU 1 0 0: Reading or writing of ECC code for the address in the tag field Settings other than above are prohibited.	R/W
b22 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23	RW	Read/Write Select	Select the type of access (read or write) to the target of testing. 0: Read 1: Write	R/W
b29 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31, b30	WAY[1:0]	Address Way	Specify the value of bits 31 and 30 of the address for test access to the instruction cache; these bits indicate the cache way for use in testing. This setting is valid for the reading and writing of cache data, ECC codes, or tag values. The setting is ignored in reading and writing of the LRU value.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register should be accessed in 32-bit units.

When the type of test access is “write”, write to the IFCATAD register before writing to the IFCATAA register. When the type of test access is “read”, read the IFCATAD register after writing to the IFCATAA register. Use the procedure in Table 2.21 for reading and the procedure in Table 2.22 for writing.

Table 2.21 Procedure of Reading

1	Write 0 (reading) to the IFCATAA.RW bit and set the other bits to values that suite the test.
2	Read the IFCATAA register and check the value that is read.
3	Read the IFCATAD register.

Table 2.22 Procedure of Writing

1	Write a value to the IFCATAD register.
2	Write 1 (writing) to the IFCATAA.RW bit and set the other bits to values that suit the test.

OFFSET[2:0] Bits (Address Offset)
ENTRY[7:0] Bits (Address Entry)
WAY[1:0] Bits (Address Way)

Specify the address for test access to the instruction cache.

Table 2.23 Relationship between the TARGET[2:0], WAY[1:0], ENTRY[7:0], and OFFSET[2:0] Bits

TARGET[2:0]	WAY[1:0]	ENTRY[7:0]	OFFSET[2:0]
000b (Cache data)	Valid	Valid	Valid
001b (ECC code)	Valid	Valid	Valid
010b (TAG and V bits)	Valid	Valid	Invalid
011b (LRU)	Invalid	Valid	Invalid
100b (TAG ECC code)	Valid	Valid	Invalid

TARGET[2:0] Bits (Target of Test Access)

Specify the target of test access to the instruction cache.

RW Bit (Read/Write Select)

Select the type of access (read or write) to the target of testing.

2.9.3.6 Instruction Cache Test Access Data Register (IFCATAD_DATA, IFCATAD_ECC, IFCATAD_TAG, IFCATAD_LRU, IFCATAD_TAGECC)

The valid bits and their functions depend on the setting of the IFCATAA.TARGET[2:0] bits.

- IFCATAA.TARGET[2:0] bits = 000b (Cache data)

Address(es): CACHE.IFCATAD_DATA 8101 0018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DATA[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	DATA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	DATA[31:0]	Cache Data	These bits hold the cache data that have been read or are to be written in test access to the instruction cache.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

DATA[31:0] Bits (Cache Data)

These bits hold the cache data that have been read or are to be written in test access to the instruction cache. Before access to this register, disable the instruction cache by setting the IFCACTL.EN bit to 0. If updating of the IFCATAD register by test read access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

- IFCATAA.TARGET[2:0] bits = 001b (ECC code)

Address(es): CACHE.IFCATAD_ECC 8101 0018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	ECC[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	ECC[6:0]	ECC Code	These bits hold the ECC code that has been read or is to be written in test access to the instruction cache.	R/W
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

ECC[6:0] Bits (ECC Code)

These bits hold the ECC code that has been read or is to be written in test access to the instruction cache. Before access to this register, disable the instruction cache by setting the IFCACTL.EN bit to 0. If updating of the IFCATAD register by

test read access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

- IFCATAA.TARGET[2:0] bits = 010b (TAG and V bits)

Address(es): CACHE.IFCATAD_TAG 8101 0018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TAG[18:3]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	V	Valid	This bit holds the value of the valid bit that has been read or is to be written in test access to the instruction cache.	R/W
b12 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b13	TAG[18:0]	TAG Data	These bits hold the value of the TAG[31:13] bits that has been read or is to be written in test access to the instruction cache.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

V Bit (Valid)

This bit holds the value of the valid bit that has been read or is to be written in test access to the instruction cache. Before access to this register, disable the instruction cache by setting the IFCACTL.EN bit to 0. If updating of the IFCATAD register by test read access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

TAG[18:0] Bits (TAG Data)

These bits hold the value of the TAG[31:13] bits that has been read or is to be written in test access to the instruction cache. Before access to this register, disable the instruction cache by setting the IFCACTL.EN bit to 0. If updating of the IFCATAD register by test read access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

- IFCATAA.TARGET[2:0] bits = 011b (LRU)

Address(es): CACHE.IFCATAD_LRU 8101 0018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	TAG ECC[6:0]	TAG ECC Code	These bits hold the ECC code for the tag that has been read or is to be written in test access to the instruction cache.	R/W
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

TAG ECC[6:0] Bits (TAG ECC Code)

These bits hold the ECC code for the tag that has been read or is to be written in test access to the instruction cache. Before access to this register, disable the instruction cache by setting the IFCACTL.EN bit to 0. If updating of the IFCATAD register by test read access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

2.9.3.7 Data Cache Control Register (OACACTL)

Address(es): CACHE.OACACTL 8101 0040h, CACHE_NS.OACACTL 0101 0040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	WB	FL	—	—	—	—	—	—	—	EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	EN	Data Cache Enable	0: The data cache is disabled. 1: The data cache is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	FL	Data Cache Flush	0: No effect 1: The data cache is flushed: that is, all lines are invalidated. This bit has the same function as that of the OACAFCT.FL bit.	R/W
b9	WB	Data Cache Write-back	0: No effect 1: The contents of the data cache are written back to memory. This bit has the same function as that of the OACAFCT.WB bit.	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

EN Bit (Data Cache Enable)

This bit is used to enable or disable the data cache. When the data cache is enabled, whether to cache data depends on the cache attribute of the CPU access. Refer to the related descriptions in the section on the MPU.

FL Bit (Data Cache Flush)

Refer to the description of the OACAFCT.FL bit for details.

WB Bit (Data Cache Write-back)

Refer to the description of the OACAFCT.WB bit for details.

2.9.3.8 Data Cache Flush Control Register (OACAFCT)

Address(es): CACHE.OACAFCT 8101 0044h, CACHE_NS.OACAFCT 0101 0044h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WB	FL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FL	Data Cache Flush	0: No effect 1: The data cache is flushed: that is, all lines are invalidated.	R/W
b1	WB	Data Cache Write-back	0: No effect 1: The contents of the data cache are written back to memory.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When the OACAFCT.FL bit is set to 1 while the OACAWTA.WT bit is 0, the cache is flushed and data are written back to memory.

FL Bit (Data Cache Flush)

Writing 1 to this bit starts flushing of the data cache (invalidating the contents of the cache). This bit is automatically cleared upon completion of the flush. Do not write to this bit before automatic clearing of this bit.

WB Bit (Data Cache Write-back)

Writing 1 to this bit writes the contents of the data cache back to memory. This bit is automatically cleared upon completion of writing back. Do not write to this bit before automatic clearing of this bit.

2.9.3.9 Data Cache Write Attribute Register (OACAWTA)

Address(es): CACHE.OACAWTA 8101 004Ch, CACHE_NS.OACAWTA 0101 004Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WA	WT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	WT	Data Cache Write-through Setting	0: Whether the data cache is set to the write-through mode or write-back mode depends on the cache attribute. 1: The data cache is set to the write-through mode.	R/W
b1	WA	Data Cache Write Allocation Setting	0: The write allocation mode is disabled. 1: Whether the write allocation mode is enabled or disabled depends on the cache attribute.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

WT Bit (Data Cache Write-through Setting)

This bit is used to specify the method for writing data from the data cache to memory. Before modifying this setting, set the OACACTL.EN bit to 0 to disable the data cache. For details of the cache attributes, refer to the section on the MPU.

WA Bit (Data Cache Write Allocation Setting)

This bit is used to specify the write allocation mode for the data cache. Before modifying this setting, set the OACACTL.EN bit to 0 to disable the data cache. For details of the cache attributes, refer to the section on the MPU.

2.9.3.10 Data Cache Error Detection Status Register (OACAEDST)

Address(es): CACHE.OACAEDST 8101 0050h, CACHE_NS.OACAEDST 0101 0050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	EST2	ESTD	ESTC	ESD2	ESD1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESD1	Data Cache 1-Bit ECC Error Flag *1	This flag indicates that a 1-bit ECC error has been detected during reading from a data field in the data cache. 0: A 1-bit ECC error has not been detected. 1: A 1-bit ECC error has been detected and the error correction has been executed.	R/W
b1	ESD2	Data Cache 2-Bit ECC Error Flag *1	This flag indicates that a 2-bit ECC error has been detected during reading from a data field in the data cache. 0: A 2-bit ECC error has not been detected. 1: A 2-bit ECC error has been detected.	R/W
b2	ESTC	Data Cache Tag Clean Line Invalidate Flag*1	This flag indicates that a clean line has been invalidated due to the detection of a 1-bit ECC error during reading from a tag field in the data cache. 0: A 1-bit ECC error has not been detected. 1: A 1-bit ECC error has been detected and a clean line has been invalidated.	R/W
b3	ESTD	Data Cache Tag Dirty Line Invalidate Flag*1	This flag indicates that a dirty line has been invalidated due to the detection of a 1-bit ECC error during reading from a tag field in the data cache. 0: A 1-bit ECC error has not been detected. 1: A 1-bit ECC error has been detected and a dirty line has been invalidated.	R/W
b4	EST2	Data Cache Tag 2-Bit ECC Error Flag*1	This flag indicates that a 2-bit ECC error has been detected during reading from a tag field in the data cache. 0: A 2-bit ECC error has not been detected. 1: A 2-bit ECC error has been detected.	R/W
b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. The write value should be 0. Writing 0 will clear the flag.

ESD1 Flag (Data Cache 1-Bit ECC Error Flag)

This flag indicates whether a 1-bit ECC error has been detected during reading from a data field in the data cache. The flag can be cleared by writing 0 to it. This flag is also cleared by a reset other than a bus error reset or a memory error reset. If an error occurs at the same time as clearing of the flag, the flag is cleared and the error is ignored.

ESD2 Flag (Data Cache 2-Bit ECC Error Flag)

This flag indicates whether a 2-bit ECC error has been detected during reading from a data field in the data cache. The flag can be cleared by writing 0 to it. This flag is also cleared by a reset other than a bus error reset or a memory error reset. If an error occurs at the same time as clearing of the flag, the flag is cleared and the error is ignored.

ESTC Flag (Data Cache Tag Clean Line Invalidate Flag)

This flag indicates whether a clean line has been invalidated due to the detection of a 1-bit ECC error during reading from a tag field in the data cache.
The flag can be cleared by writing 0 to it. This flag is also cleared by a reset other than a bus error reset or a memory error reset. If an error occurs at the same time as clearing of the flag, the flag is cleared and the error is ignored.

ESTD Flag (Data Cache Tag Dirty Line Invalidate Flag)

This flag indicates whether a dirty line has been invalidated due to the detection of a 1-bit ECC error during reading from a tag field in the data cache.
The flag can be cleared by writing 0 to it. This flag is also cleared by a reset other than a bus error reset or a memory error reset. If an error occurs at the same time as clearing of the flag, the flag is cleared and the error is ignored. If the ESTD bit is 1, the dirty line is invalidated without writing its contents back to memory.

EST2 Flag (Data Cache Tag 2-Bit ECC Error Flag)

This flag indicates whether a 2-bit ECC error has been detected during reading from a tag field in the data cache.
The flag can be cleared by writing 0 to it. This flag is also cleared by a reset other than a bus error reset or a memory error reset. If an error occurs at the same time as clearing of the flag, the flag is cleared and the error is ignored.

2.9.3.11 Data Cache Test Access Address Register (OACATAA)

Address(es): CACHE.OACATAA 8101 0054h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	WAY[1:0]		—	—	—	—	—	—	RW	—	—	—	—	TARGET[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	ENTRY[7:0]								OFFSET[2:0]			—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4 to b2	OFFSET[2:0]	Address Offset	Specify the value of bits 4 to 2 of the address for test access to the data cache; these bits indicate the value of the three high-order bits of the cache offset for use in testing. This setting is valid for the reading and writing of cache data or ECC codes.	R/W
b12 to b5	ENTRY[7:0]	Address Entry	Specify the value of bits 12 to 5 of the address for test access to the data cache; these bits indicate the cache entry for use in testing.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b18 to b16	TARGET[2:0]	Target of Test Access	Specify the target of test access to the data cache. The type of access can be selected by the RW bit. b18 b16 0 0 0: Reading or writing of cache data 0 0 1: Reading or writing of ECC codes in the DATA field 0 1 0: Reading or writing of the tag field, D and V bits 0 1 1: Reading or writing of the LRU 1 0 0: Reading or writing of ECC code for the address in the tag field Settings other than above are prohibited.	R/W
b22 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23	RW	Read/Write Select	Select the type of access (read or write) to the target of testing. 0: Read 1: Write	R/W
b29 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31, b30	WAY[1:0]	Address Way	Specify the value of bits 31 and 30 of the address for test access to the data cache; these bits indicate the cache way for use in testing. This setting is valid for the reading and writing of cache data, ECC codes, or tag values. The setting is ignored in reading and writing of the LRU value.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register should be accessed in 32-bit units.

When the type of test access is “write”, write to the OACATAD register before writing to the OACATAA register. When the type of test access is “read”, read the OACATAD register after writing to the OACATAA register. Use the procedure in Table 2.24 for reading and the procedure in Table 2.25 for writing.

Table 2.24 Procedure of Reading

1	Write 0 (reading) to the OACATAA.RW bit and set the other bits to values that suit the test.
2	Read the OACATAA register and check the value that is read.
3	Read the OACATAD register.

Table 2.25 Procedure of Writing

1	Write a value to the OACATAD register.
2	Write 1 (writing) to the OACATAA.RW bit and set the other bits to values that suit the test.

OFFSET[2:0] Bits (Address Offset)
ENTRY[7:0] Bits (Address Entry)
WAY[1:0] Bits (Address Way)

Specify the address for test access to the data cache.

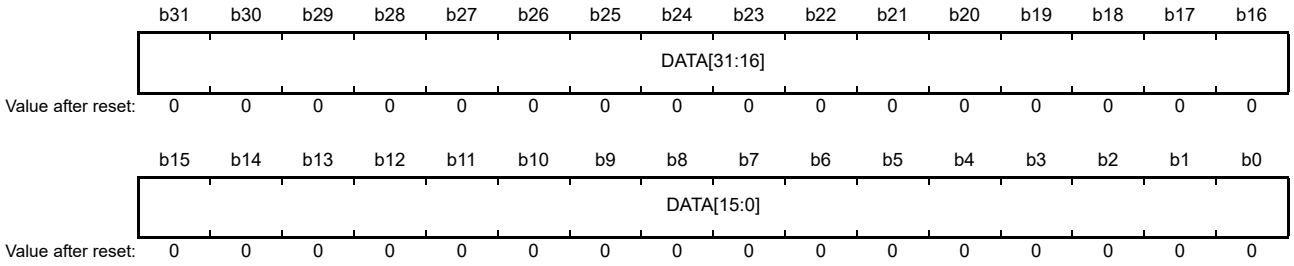
Table 2.26 Relationship between the TARGET[2:0], WAY[1:0], ENTRY[7:0], and OFFSET[2:0] Bits

TARGET[2:0]	WAY[1:0]	ENTRY[7:0]	OFFSET[2:0]
000b (Cache data)	Valid	Valid	Valid
001b (ECC code)	Valid	Valid	Valid
010b (TAG, V, and D bits)	Valid	Valid	Invalid
011b (LRU)	Invalid	Valid	Invalid
100b (TAG ECC code)	Valid	Valid	Invalid

TARGET[2:0] Bits (Target of Test Access)

Specify the target of test access to the data cache.

RW Bit (Read/Write Select)



Select the type of access (read or write) to the target of testing.

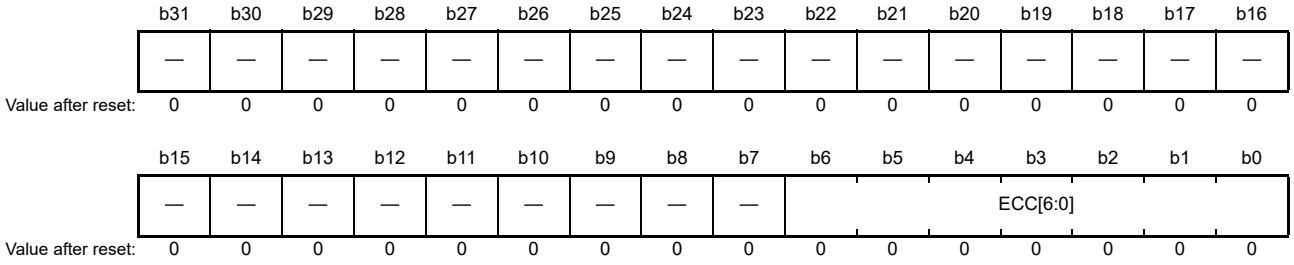
2.9.3.12 Data Cache Test Access Data Register (OACATAD_DATA, OACATAD_ECC, OACATAD_TAG, OACATAD_LRU, OACATAD_TAGECC)

The valid bits and their functions depend on the setting of the OACATAA.TARGET[2:0] bits.

- OACATAA.TARGET[2:0] bits = 000b (Cache data)

Address(es): CACHE.OACATAD_DATA 8101 0058h

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	DATA[31:0]	Cache Data	These bits hold the cache data that have been read or are to be written in test access to the data cache.	R/W



Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

DATA[31:0] Bits (Cache Data)

These bits hold the cache data that have been read or are to be written in test access to the data cache. Before access to this register, disable the data cache by setting the OACACTL.EN bit to 0. If updating of the OACATAD register by test read access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

- OACATAA.TARGET[2:0] bits = 001b (ECC code)

Address(es): CACHE.OACATAD_ECC 8101 0058h

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	ECC[6:0]	ECC Code	These bits hold the ECC code that has been read or is to be written in test access to the data cache.	R/W
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

ECC[6:0] Bits (ECC Code)

These bits hold the ECC code that has been read or is to be written in test access to the data cache. Before access to this register, disable the data cache by setting the OACACTL.EN bit to 0. If updating of the OACATAD register by test read

access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

- OACATAA.TARGET[2:0] bits = 010b (TAG, V, D bit)

Address(es): CACHE.OACATAD_TAG 8101 0058h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TAG[18:3]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TAG[2:0]			—	—	—	—	—	—	—	—	—	—	—	V	D
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	D	Dirty	This bit holds the value of the dirty bit that has been read or is to be written in test access to the data cache.	R/W
b1	V	Valid	This bit holds the value of the valid bit that has been read or is to be written in test access to the data cache.	R/W
b12 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b13	TAG[18:0]	TAG Data	These bits hold the value of the TAG[31:13] bits that has been read or is to be written in test access to the data cache.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

D Bit (Dirty)

This bit holds the value of the dirty bit that has been read or is to be written in test access to the data cache. Before access to this register, disable the data cache by setting the OACACTL.EN bit to 0. If updating of the OACATAD register by test read access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

V Bit (Valid)

This bit holds the value of the valid bit that has been read or is to be written in test access to the data cache. Before access to this register, disable the data cache by setting the OACACTL.EN bit to 0. If updating of the OACATAD register by test read access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

TAG[18:0] Bits (TAG Data)

These bits hold the value of the TAG[31:13] bits that has been read or is to be written in test access to the data cache. Before access to this register, disable the data cache by setting the OACACTL.EN bit to 0. If updating of the OACATAD register by test read access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

- OACATAA.TARGET[2:0] bits = 011b (LRU)

Address(es): CACHE.OACATAD_LRU 8101 0058h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	LRU[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	LRU[4:0]	LRU	These bits hold the value of the LRU that has been read or is to be written in test access to the data cache.	R/W
b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

LRU[4:0] Bits (LRU)

These bits hold the value of the LRU that has been read or is to be written in test access to the data cache. Before access to this register, disable the data cache by setting the OACACTL.EN bit to 0. If updating of the OACATAD register by test read access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

- OACATAA.TARGET[2:0] bits = 100b (TAG ECC code)

Address(es): CACHE.OACATAD_TAGECC 8101 0058h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	TAG ECC[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	TAG ECC[6:0]	TAG ECC Code	These bits hold the ECC code for the tag that has been read or is to be written in test access to the data cache.	R/W
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

TAG ECC[6:0] Bits (TAG ECC Code)

These bits hold the ECC code for the address in the tag field in test access to the data cache. Before access to this register, disable the data cache by setting the OACACTL.EN bit to 0. If updating of the OACATAD register by test read access and writing to the register occur simultaneously, updating of the register is ignored and writing to the register proceeds.

2.9.3.13 Operation Settings After Cache Error Detection Register (CAOAD)

Address(es): CACHE.CAOAD 8101 0200h, CACHE_NS.CAOAD 0101 0200h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	E1STSEN	ECCMOD1	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OAD	Setting of Operation after Cache Error Detection	0: Interrupt 1: Reset	R/W
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	ECCMOD1	ECC Error Correction Enable	0: ECC error correction is disabled. 1: ECC error correction is enabled.	R/W
b4	E1STSEN	Non-fatal ECC Error Information Updating Enable	0: The flags to indicate non-fatal ECC errors are not updated. 1: The flags to indicate non-fatal ECC errors are updated.	R/W
b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

OAD Bit (Setting of Operation after Cache Error Detection)

This bit is used to specify the operation after the detection of an ECC error.

ECCMOD1 Bit (ECC Error Correction Enable)

This bit is used to enable the detection and correction of ECC errors. Only modify this setting while cache operations are stopped.

E1STSEN Bit (Non-fatal ECC Error Information Updating Enable)

This bit is used to enable or disable updating of the status flags for non-fatal ECC errors (IFCAEDST.ESD1, IFCAEDST.ESTC, OACAEDST.ESD1, and OACAEDST.ESTC flags). While this bit is 0, the error status flags are not updated and the operation specified to follow error detection does not proceed regardless of the setting of the OAD bit in this register.

2.9.3.14 Cache Protection Register (CAPRCR)

Address(es): CACHE.CAPRCR 8101 0204h, CACHE_NS.CAPRCR 0101 0204h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	KW[6:0]							PRCR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PRCR	CAOAD Register Write Control	0: Writing to the CAOAD register is disabled. 1: Writing to the CAOAD register is enabled.	R/W
b7 to b1	KW[6:0]	Write Keyword	Modification of the CAOAD register setting is enabled or disabled. Before modifying the CAOAD register setting, write 1111000b to these bits.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

While the KW[6:0] bits are 1111000b, writing 1 to the PRCR bit is enabled. The KW[6:0] bits are always read as 0000000b. The CAOAD register is the only target of write-protection by this means. Once the PRCR bit is set to 1, writing to the CAOAD register is enabled until the PRCR bit is set to 0.

2.9.4 Branch Instruction Processing Accelerator Registers

The branch instruction processing accelerator has the following control registers.

- Branch instruction processing accelerator security attribute register (IFUSAR)
- Branch instruction processing accelerator enable register (CPUBAEN)
- Branch instruction processing accelerator invalidation setting register (CPUBAINV)

2.9.4.1 Branch Instruction Processing Accelerator Security Attribute Register (IFUSAR)

Address(es): CPSCU.IFUSAR 8701 8144h, CPSCU_NS.IFUSAR 0701 8144h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IFUSA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IFUSA	Security Attribute	0: Secure 1: Non-secure	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

This register is used to configure the security attribute of the CPUBAEN and CPUBAINV registers. This register is write-protected by the PRCR_S.PRC4 bit.

2.9.4.2 Branch Instruction Processing Accelerator Enable Register (CPUBAEN)

Address(es): CPU_CTRL.CPUBAEN 8100 0100h, CPU_CTRL_NS.CPUBAEN 0100 0100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BAEN	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	BAEN	Enable	0: The branch instruction processing accelerator is disabled. 1: The branch instruction processing accelerator is enabled (initial value)	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

This register is used to enable both the entries for branch instructions and the entry for the RTS instruction in the branch instruction accelerator. Writing 0 to the BAEN bit stops the branch instruction processing accelerator.

2.9.4.3 Branch Instruction Processing Accelerator Invalidation Setting Register (CPUBAINV)

Address(es): CPU_CTRL.CPUBAINV 8100 0104h, CPU_CTRL_NS.CPUBAINV 0100 0104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BAIV	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	BAIV	Invalidation	0: Invalidation processing does not proceed. 1: The contents of the branch instruction processing accelerator are invalidated.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

This register is used to invalidate the contents of both the entries for branch instructions and the entry for the RTS instruction in the branch instruction processing accelerator. The entries are invalid immediately after a reset. Modifying the settings of the SAU or MPU also automatically invalidates the entries, so invalidation by using this register is not required. However, the entries are not automatically invalidated after overwriting an instruction in the MRAM or LRAM or modifying security settings other than those in the SAU, so use this register to invalidate the entries in such cases.

2.9.5 Local SRAM (LRAM) Control Registers

The LRAM has the following seven control registers.

- LRAM security attribute setting register (LRMSAR)
- LRAMn boundary address setting register (LRMSABARn)
- LRAM protection control register (LRMPRCR)*1
- LRAMn control register (LRMCRn)
- LRAM error flag register (LRMESR)
- LRAM error flag clear register (LRMESCLR)
- LRAMn error address register m (LRMEARnm)

Note 1. This register is actually implemented as two registers to support the Protect Zone function. Where this is required, the two registers are distinguished by postfixes appended to the register names, specifically _S for the secure world register and _NS for the non-secure world register.

2.9.5.1 LRAM Security Attribute Setting Register (LRMSAR)

Address(es): CPSCU.LRMSAR 8701 8504h, CPSCU_NS.LRMSAR 0701 8504h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LRMSA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LRMSA	Security Attribute	0: Secure 1: Non-secure	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

This register is write-protected by the PRCR_S.PRC4 bit.

This register controls two types of register: the LRMCRn registers and LRMESCLR register. When secure programs or secure data are to be allocated to the LRAM, set the LRMSA bit to 0 to select secure attribute.

2.9.5.2 LRAMn Boundary Address Setting Register (LRMSABARn) (n = 0, 1)

Address(es): CPSCU.LRMSABAR0 8701 8508h, CPSCU.LRMSABAR1 8701 850Ch,
CPSCU_NS.LRMSABAR0 0701 8508h, CPSCU_NS.LRMSABAR1 0701 850Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	LRMSABA[5:3]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LRMSABA[2:0]			—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b12 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b18 to b13	LRMSABA[5:0]	Security Attribute Boundary Address	First address of non-secure area	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

This register is write-protected by the PRCR_S.PRC4 bit.

This register is used to specify the address of the boundary between secure area and non-secure area in each LRAM unit. Specify the address where non-secure area starts in the LRMSABA[5:0] bits.

When the boundary address LRMSABA[5:0] = 000000b, the entire LRAMn becomes a non-secure area. When LRMSABA[5:0] ≥ 010000b, the entire LRAMn becomes a secure area. Since the initial value of LRMSABA[5:0] is 111111b, the entire LRAMn after a reset becomes a secure area.

Table 2.27 Address Map and Accessibility in LRAM0

Master	Address as Seen from the Master	Secure Setting in the LRAM	Access
CPU (secure)	0000 0000h to 0000 0000h + LRMSABAR0 –1	Secure	Access violation
	0000 0000h + LRMSABAR0 to 0001 FFFFh	Non-secure	Available
	8000 0000h to 8000 0000h + LRMSABAR0 –1	Secure	Available
	8000 0000h + LRMSABAR0 to 8001 FFFFh	Non-secure	Access violation
CPU (non-secure)	0000 0000h to 0000 0000h + LRMSABAR0 –1	Secure	Access violation
	0000 0000h + LRMSABAR0 to 0001 FFFFh	Non-secure	Available
	8000 0000h to 8000 0000h + LRMSABAR0 –1	Secure	Access violation
	8000 0000h + LRMSABAR0 to 8001 FFFFh	Non-secure	Access violation
Bus master (secure)	0280 0000h to 0280 0000h + LRMSABAR0 –1	Secure	Access violation
	0280 0000h + LRMSABAR0 to 0281 FFFFh	Non-secure	Available
	8280 0000h to 8280 0000h + LRMSABAR0 –1	Secure	Available
	8280 0000h + LRMSABAR0 to 8281 FFFFh	Non-secure	Access violation
Bus master (non-secure)	0280 0000h to 0280 0000h + LRMSABAR0 –1	Secure	Access violation
	0280 0000h + LRMSABAR0 to 0281 FFFFh	Non-secure	Available
	8280 0000h to 8280 0000h + LRMSABAR0 –1	Secure	Access violation
	8280 0000h + LRMSABAR0 to 8281 FFFFh	Non-secure	Access violation

Table 2.28 Address Map and Accessibility in LRAM1

Master	Address as Seen from the Master	Secure Setting in the LRAM	Access
CPU (secure)	0002 0000h to 0002 0000h + LRMSABAR1 –1	Secure	Access violation
	0002 0000h + LRMSABAR1 to 0003 FFFFh	Non-secure	Available
	8002 0000h to 8002 0000h + LRMSABAR1 –1	Secure	Available
	8002 0000h + LRMSABAR1 to 8003 FFFFh	Non-secure	Access violation
CPU (non-secure)	0002 0000h to 0002 0000h + LRMSABAR1 –1	Secure	Access violation
	0002 0000h + LRMSABAR1 to 0003 FFFFh	Non-secure	Available
	8002 0000h to 8002 0000h + LRMSABAR1 –1	Secure	Access violation
	8002 0000h + LRMSABAR1 to 8003 FFFFh	Non-secure	Access violation
Bus master (secure)	0282 0000h to 0282 0000h + LRMSABAR1 –1	Secure	Access violation
	0282 0000h + LRMSABAR1 to 0283 FFFFh	Non-secure	Available
	8282 0000h to 8282 0000h + LRMSABAR1 –1	Secure	Available
	8282 0000h + LRMSABAR1 to 8283 FFFFh	Non-secure	Access violation
Bus master (non-secure)	0282 0000h to 0282 0000h + LRMSABAR1 –1	Secure	Access violation
	0282 0000h + LRMSABAR1 to 0283 FFFFh	Non-secure	Available
	8282 0000h to 8282 0000h + LRMSABAR1 –1	Secure	Access violation
	8282 0000h + LRMSABAR1 to 8283 FFFFh	Non-secure	Access violation

2.9.5.3 LRAM Protection Control Register for Secure Applications (LRMPRCR_S), LRAM Protection Control Register for Non-Secure Applications (LRMPRCR_NS)

Address(es): LRAM.LRMPRCR_S 8101 0800h, LRAM_NS.LRMPRCR_NS 0101 0804h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KW[7:0]								—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PR	LRMCRn Register Write Control	0: Writing to the LRMCRn register is disabled. 1: Writing to the LRMCRn register is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KW[7:0]	Write Keyword	Keyword bits for use in protection against writing to the PR bit	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be accessed in 32-bit units.

The two LRMPRCR registers are present, each for secure application developers (LRAMPRCR_S) and non-secure application developers (LRAMPRCR_NS). Setting the LRMSAR.LRMSA bit to 0 enables the LRAMPRCR_S register, and setting the LRMSAR.LRMSA bit to 1 enables the LRAMPRCR_NS register. The LRAMPRCR_S register is only accessible by secure transactions, and the LRAMPRCR_NS register is only accessible by non-secure transactions. Attempted access to these registers by using an unauthorized type of transaction causes a Protect Zone access error.
The LRAM control register (LRMCRn) is the only target of write-protection by this means. Once the PR bit is set to 1, writing to the LRMCRn register is enabled until the PR bit is set to 0. When writing to the PR bit, write 10100101b to the KW[7:0] bits at the same time. If another value is written to the KW[7:0] bits, the value of the PR bit will not be changed. The KW[7:0] bits are always read as 00000000b.

2.9.5.4 LRAMn Control Register (LRMCRn) (n = 0, 1)

Address(es): LRAM.LRMCR0 8101 0810h, LRAM.LRMCR1 8101 0814h,
LRAM_NS.LRMCR0 0101 0810h, LRAM_NS.LRMCR1 0101 0814h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TSTBYP	—	—	E1STSEN	ECCMOD[1:0]		—	OAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OAD	Setting of Operation after Error Detection	0: Interrupt 1: Reset	R/W
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3, b2	ECCMOD[1:0]	ECC Operation Mode Select	b3 b2 0 0: ECC function is disabled. 0 1: Setting prohibited 1 0: ECC function is enabled, but without error checking. 1 1: ECC function is enabled, and with error checking.	R/W
b4	E1STSEN	1-Bit ECC Error Information Update Enable	0: Information on 1-bit ECC errors is not updated. 1: Information on 1-bit ECC errors is updated.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TSTBYP	ECC Bypass Enable	0: ECC function is not bypassed. 1: ECC function is bypassed.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to this register while access to the LRAM is in progress.

OAD Bit (Setting of Operation after Error Detection)

This bit is used to specify the operation after the detection of an ECC error.

ECCMOD[1:0] Bits (ECC Operation Mode Select)

These bits are used to select the function for detecting and correcting ECC errors.

E1STSEN Bit (1-Bit ECC Error Information Update Enable)

This bit is used to enable or disable updating of the status flags for 1-bit ECC errors (the ERR01 and ERR11 bits in the LRMESR register). Even if a 1-bit ECC error has been corrected, the operation specified to follow error detection does not proceed regardless of the setting of the OAD bit in this register while the E1STSEN bit is 0.

TSTBYP Bit (ECC Bypass Enable)

While the ECCMOD[1:0] bits are 00b (disabling the ECC function), this bit is used to enable direct access to the ECC codes by bypassing the ECC function. The length of the ECC code for 32 bits of data is seven bits. When the TSTBYP bit is 1, bits 0 to 6 of the data that are read hold the ECC code and bits 7 to 31 hold an undefined value. Bits 0 to 6 of the written data are written to the ECC area at the specified address for writing to the LRAM. Bits 7 to 31 of the written data are ignored.

2.9.5.5 LRAM Error Flag Register (LRMESR)

Address(es): LRAM.LRMESR 8101 0840h, LRAM_NS.LRMESR 0101 0840h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	ERR12	ERR11	ERR02	ERR01
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ERR01	LRAM0 1-bit ECC Error Flag	0: A 1-bit ECC error has not occurred. 1: A 1-bit ECC error has occurred.	R
b1	ERR02	LRAM0 2-bit ECC Error Flag	0: A 2-bit ECC error has not occurred. 1: A 2-bit ECC error has occurred.	R
b2	ERR11	LRAM1 1-bit ECC Error Flag	0: A 1-bit ECC error has not occurred. 1: A 1-bit ECC error has occurred.	R
b3	ERR12	LRAM1 2-bit ECC Error Flag	0: A 2-bit ECC error has not occurred. 1: A 2-bit ECC error has occurred.	R
b31 to b4	—	Reserved	These bits are read as 0	R

ERRn1 Flag (LRAMn 1-bit ECC Error Flag) (n = 0, 1)

This flag indicates whether a 1-bit ECC error has occurred. While the ECC function with error checking is enabled and updating of the information on 1-bit errors is enabled, the ERRn1 bit is set to 1 when a 1-bit error is detected. In addition, a reset or an interrupt request is generated according to the setting of the LRMCRn.OAD bit.

ERRn2 Flag (LRAMn 2-bit ECC Error Flag) (n = 0, 1)

This flag indicates whether a 2-bit ECC error has occurred. While the ECC function with error checking is enabled, the ERRn2 bit is set to 1 when a 2-bit error is detected. In addition, a reset or an interrupt request is generated according to the setting of the LRMCRn.OAD bit.

2.9.5.6 LRAM Error Flag Clear Register (LRMESCLR)

Address(es): LRAM.LRMESCLR 8101 0848h, LRAM_NS.LRMESCLR 0101 0848h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	CLR12	CLR11	CLR02	CLR01
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CLR01	LRAM0 1-bit ECC Error Flag Clear	This bit is read as 0. Writing 1 to this bit clears the LRMESR.ERR01 flag and the LRMEAR01.EAR[14:0] bits. Writing 0 is ignored.	R/W
b1	CLR02	LRAM0 2-bit ECC Error Flag Clear	This bit is read as 0. Writing 1 to this bit clears the LRMESR.ERR02 flag and the LRMEAR02.EAR[14:0] bits. Writing 0 is ignored.	R/W
b2	CLR11	LRAM1 1-bit ECC Error Flag Clear	This bit is read as 0. Writing 1 to this bit clears the LRMESR.ERR11 flag and the LRMEAR11.EAR[14:0] bits. Writing 0 is ignored.	R/W
b3	CLR12	LRAM1 2-bit ECC Error Flag Clear	This bit is read as 0. Writing 1 to this bit clears the LRMESR.ERR12 flag and the LRMEAR12.EAR[14:0] bits. Writing 0 is ignored.	R/W
b31 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

This register is used to clear the flags in the LRMESR register and the values in the LRMEARnm registers (n = 0, 1; m = 1, 2). Writing 1 to a bit clears the corresponding flag and register to 0.

2.9.5.7 LRAMn Error Address Register m (LRMEARnm) (n = 0, 1) (m = 1, 2)

Address(es): LRAM.LRMEAR01 8101 0850h, LRAM.LRMEAR02 8101 0854h, LRAM.LRMEAR11 8101 0858h, LRAM.LRMEAR12 8101 085Ch, LRAM_NS.LRMEAR01 0101 0850h, LRAM_NS.LRMEAR02 0101 0854h, LRAM_NS.LRMEAR11 0101 0858h, LRAM_NS.LRMEAR12 0101 085Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EAR[14]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EAR[13:0]														—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16 to b2	EAR[14:0]	Error Address	These are the upper 15 bits of the LRAM offset address, corresponding to bits 16 through 2 of the address. If an ECC occurs, the address of the error is stored in these bits.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The error address to be stored in the LRAM error address register is obtained from the address as seen from the CPU in the ways stated in Table 2.29.

Table 2.29 Calculation of Error Addresses (m = 1, 2)

Bus Master	LRAM0 or LRAM1	Address Calculation Expression
CPU	LRAM0	0000 0000h + LRMEAR0m
		8000 0000h + LRMEAR0m
	LRAM1	0002 0000h + LRMEAR1m
		8002 0000h + LRMEAR1m
Bus master	LRAM0	0280 0000h + LRMEAR0m
		8280 0000h + LRMEAR0m
	LRAM1	0282 0000h + LRMEAR1m
		8282 0000h + LRMEAR1m

LRMEAR01 and LRMEAR11 Registers

The addresses where 1-bit ECC errors were detected are stored in these registers. Each register holds the address of the first error to have been generated.

Table 2.30 Relationship between the 1-bit ECC Error Address Registers and the Bits for Clearing the Registers

LRAM0 or LRAM1	Register	Bit for Clearing the Register
LRAM0	LRMEAR01	LRMESCLR.CLR01 bit
LRAM1	LRMEAR11	LRMESCLR.CLR11 bit

LRMEAR02 and LRMEAR12 Registers

The addresses where 2-bit ECC errors were detected are stored in these registers. Each register holds the address of the first error to have been generated.

Table 2.31 Relationship between the 2-bit ECC Error Address Registers and the Bits for Clearing the Registers

LRAM0 or LRAM1	Register	Bit for Clearing the Register
LRAM0	LRMEAR02	LRMESCLR.CLR02 bit
LRAM1	LRMEAR12	LRMESCLR.CLR12 bit

2.9.6 Operations of Caches

2.9.6.1 Basic Operation of Caches

A cache operates when the following conditions are satisfied.

1. The cache is enabled, that is, the EN bit in the corresponding one of the IFCACTL and OACACTL registers is set to 1.
2. The access from the CPU is to a cacheable area (an area for which caching is enabled by the MPU).

A cache hit or miss is judged through comparison of the address requested by the CPU and the addresses stored in the tag fields.

Read miss	When the address requested by the CPU does not match the address in a tag field, the cache reads one line of data from memory, stores the data in the cache, and returns the requested data to the CPU.
Read hit	When the address requested by the CPU matches the address in a tag field, the cache reads the requested data from the data field in the cache and returns the data to the CPU. Therefore, no cycles of waiting are required when the cache is hit.
Write miss	When the address requested by the CPU does not match the address in a tag field, the cache writes data to memory. If the write allocation mode is specified (the OACAWTA.WA bit is set to 1) and the target area has the write allocation attribute, the cache reads one line of data from memory and stores the data in the cache. For the cache attributes with respect to access by the CPU, refer to the section on the MPU.
Write hit	When the address requested by the CPU matches the address in a tag field, the cache writes the data to itself. If the write-through mode is specified (the OACAWTA.WT bit is set to 1) or the target area has the write-through attribute, the cache also writes the data to memory. If the write-through mode is not specified (the OACAWTA.WT bit is set to 0) and the target area has the write-back attribute, the cache sets the dirty bit of the tag corresponding to the written data field. For the cache attributes with respect to access by the CPU, refer to the section on the MPU.

2.9.6.2 Cache Flush

To flush a cache, write 1 to the FL bit in the corresponding one of the IFCAFCT and OACAFCT registers or the FL bit in the corresponding one of the IFCACTL and OACACTL registers. Flushing a cache clears the valid (V) bit, dirty bit (D) bit, and tag address in each tag field. The ECC code for each tag address is initialized to the code generated for a value of 0. Note that the cache data are not cleared.

In the case of access to the same address but with different cache attributes, the contents of the cache must be written back and flushed before any data or instruction access proceeds with changed cache attributes at the target address. While the OACAWTA.WT bit is 1, however, the write-back operation is not required. Here, “same address” refers to addresses that correspond to the same cache line, based on the cache line size. For the cache attributes with respect to access by the CPU, refer to the section on the MPU.

2.9.6.3 LRU and Replace

The caches use the LRU (replacing the least recently used data) algorithm as the strategy for updating the cache. After CPU access is judged to be a cache hit or miss, the data in the caches are updated in order from that to which reference has not been made for the longest period.

2.9.6.4 Interrupt Source

The detection of an ECC error (local memory error) in a cache serves as a source for interrupt generation. Whether to generate a reset request or an interrupt request can be selected by the CAOAD.OAD bit. In the case of an interrupt, the interrupt is generated when at least one of the error flags in the IFCAEDST or OACAEDST register is set to 1 and continues to be generated until all error flags in the IFCAEDST and OACAEDST register are cleared.

2.9.6.5 Bus Error

Responses to bus errors from the bus slave are as shown in Table 2.32.

Table 2.32 Ways of Responding to Bus Errors

No.	State of Cache	Ways of Responding to Bus Errors
1	Cache off	The cache will return a bus error to the CPU.
2	Non-cacheable access	The cache will return a bus error to the CPU.
3	Cache fill	The cache will return a bus error to the CPU. A line that includes an error will not be registered in the cache memory.
4	Write hit	The cache will not return a bus error to the CPU.
5	Write miss	The cache will not return a bus error to the CPU.

2.9.7 Operations of the Branch Instruction Processing Accelerator

2.9.7.1 Judgment of Hit or Miss and Registration of Data

When the CPU executes a branch to an area that is in the scope of caching, the branch instruction processing accelerator searches for the destination address of the branch in the tag fields of the accelerator entries for branch instructions and the entry for the RTS instruction. If the result of the search is a hit*1, the data for that address are transferred to the CPU. If the result is a miss, the instruction at the branch destination is fetched, the destination address of the branch and the CPU state (the current mode (user or supervisor mode) and current world) are registered in the tag field, and one line (128 bits)*2 of data that include the instruction at the branch destination are registered in the data field. In addition, if the branch instruction is a branch to a subroutine (BSR instruction or JSR instruction), one line (128 bits)*2 of data that include the instruction that follows the branch instruction are registered in the accelerator entry for the RTS instruction regardless of the results of the search.

Note 1. The destination address of the branch and the CPU state (the current mode (user or supervisor mode) and WID) matching the contents of a tag is judged to be a hit.
Note 2. One line consists of two 64-bit data values placed on 64-bit boundaries.

2.9.7.2 Algorithm for Replacement

If all entries contain valid data when data are to be registered in the branch instruction processing accelerator, data are replaced according to the LRU algorithm.

2.9.7.3 Invalidation through the Branch Instruction Processing Accelerator Invalidation Setting Register

Use the branch instruction processing accelerator invalidation setting register (CPUBAINV) to invalidate the contents of the branch instruction processing accelerator. This invalidates all lines in the accelerator.

2.9.8 Operations of LRAM

2.9.8.1 Interrupt Source

The detection of an ECC error (local memory error) in the LRAM serves as a source for interrupt generation. Whether to generate a reset request or an interrupt request can be selected by the LRMCRn.OAD bit (n = 0 or 1). In the case of an interrupt, the interrupt is generated when at least one of the error flags in the LRMESR register is set to 1 and continues to be generated until all error flags in the LRMESR register are cleared. The source of the generated error can be checked by the LRMESR register.

2.9.8.2 Security Function

The registers for the LRAM and each of the LRAM units can be protected against non-secure or secure transactions through the use of the security attribute. If the security attribute of the LRAM registers is secure or that of an LRAM unit is secure, the security function prevents access by non-secure transactions by detecting a security error in response, thus protecting the registers and LRAM from non-secure access. If the security attribute of the LRAM registers is non-secure or that of an LRAM unit is non-secure, the security function prevents access by secure transactions by detecting a security error in response, thus protecting the registers and LRAM from secure access. A security attribute setting for the LRAM registers applies in common to the LRMCRn and LRMESCLR registers. In contrast, separate security attribute settings apply to the LRAM0 and LRAM1 areas, that is, each of the areas can separately be set as secure or non-secure. Table 2.33 lists the details of this. If an attempt at access fails due to the security function, an error response will be generated.

Table 2.33 Correspondence of Security Attributes to Accessibility

Security Attribute of LRAM Registers or LRAM Units	Security Attribute of Transactions	Write Access	Read Access
Secure	Secure	Enabled	Enabled
	Non-secure	Protected (not accessible)	Protected (not accessible)
Non-secure	Secure	Protected (not accessible)	Protected (not accessible)
	Non-secure	Enabled	Enabled

2.9.9 ECC

The cache and local RAM (LRAM) have ECC functionality.

2.9.9.1 ECC Function

The respective ECC functions can be enabled or disabled through the register bits listed in Table 2.34. The ECC function is disabled in the initial state. The type of ECC checking is SEC-DED (single (1-bit) error correction and double (2-bit) error detection) for the cache data and local RAM or SED-DED (single error detection and double error detection) for the cache tags. When the ECC function is enabled, a 7-bit ECC code is generated from each 32 bits of data and written to the cache, cache tag, or LRAM. If an ECC error is detected in access to a cache tag, the line is invalidated and handling of the access is as a cache miss. An error in a clean line can be corrected by filling the cache line again but an error in a dirty line cannot be restored to the correct state because data cannot be written back.

Table 2.34 ECC Function

Target Memory	Target Register Bit	Function
Cache	CAOAD.ECCMOD1 bit	0: ECC function is disabled
		1: ECC function is enabled
LRAM	LRMCRn.ECCMOD[1:0] bits	00: ECC function is disabled
		01: Setting prohibited
		10: ECC function is enabled without error checking
		11: ECC function is enabled with error checking

Table 2.35 shows the processing after an error while the ECC function is enabled. If a 1-bit or 2-bit error is present while the ECC function is disabled, the error is neither detected nor corrected. Before using the ECC function for the LRAM, initial writing to the LRAM area to be used in 32-bit units or initial writing with the ECC function enabled and error checking disabled is required.

Table 2.35 Processing after an Error

Target Memory	Processing after a 1-Bit Error	Processing after a 2-Bit Error
Cache*1	The error is corrected. When the CAOAD.E1STSEN bit is 1, the ESD1 bit in the corresponding one of the IFCAEDST or OACAEDST registers is set to 1.	The error is detected but not corrected. The ESD2 bit of the corresponding one of the IFCAEDST or OACAEDST registers is set to 1.
LRAM	• When the LRMCRn.ECCMOD[1:0] bits is 10b: The error is corrected. The LRMESR.ERRn1 bit is not updated. • When the LRMCRn.ECCMOD[1:0] bits is 11b: The error is corrected. When the LRMCRn.E1STSEN bit is 1, the LRMESR.ERRn1 bit is set to 1.	• When theLRMCRn.ECCMOD[1:0] bits is 10b: The error is neither detected nor corrected. • When the LRMCRn.ECCMOD[1:0] bits is 11b: The error is detected but not corrected. The LRMESR.ERRn2 bit is set to 1.

Note 1. When an ECC error is detected in the data field of a cache, only error correction and error status setting proceed but the cache is not invalidated. This differs from the processing after an ECC error in the tag field.

2.9.9.2 Methods of Testing the ECC Decoder Circuits for the Caches

The ECC circuits for the caches have diagnostic circuits that allow users to detect failures by testing the decoder circuits along the paths for reading cache tags and cache data. For the data cache, the ECC decoder circuits consist of one for each way for the cache tags, two for each way in the path for CPU reading of cache data, and two in the write-back path for cache data, for a total of 14. The instruction cache does not have decoders for the write-back path, so the total number is 12. In the ECC decoder test for cache data, conduct tests along the CPU read path (see section 2.9.9.2, (1)) and along the write-back path (see section 2.9.9.2, (2)). In the ECC decoder test for cache tags, conduct tests on all of ways 0 to 3 for the tags with the same flow of testing as for the CPU read path. The ECC decoders for some cache data are shared among ways 0 to 3, so testing the ECC decoders is possible without conducting tests on all ways.

(1) CPU Read Path Test

Table 2.36 lists the steps in the flow of testing for the ECC decoders and the ECC decoders for tags when the CPU reads data from a cache. There are 12 ECC decoders, so repeat the steps from (1) to (13) listed in Table 2.36 for each of the instruction cache and data cache, in accordance with Table 2.37.

Table 2.36 Flow of Testing when the CPU Reads Data from a Cache (1/2)

Step Number	Test Flow Details
(0)	When a cache is in use, disable the cache according to the procedure in section 2.13.2, Points to Note on Cache Operations before starting on the main flow below.
(1)	Initialize four ways of the target lines in the memory. To initialize one line, write data to the addresses with OFFSET = 00h to 1Fh. To initialize the data for way 1, write to the line at “address 0 + different tag address”. Initialize the data for ways 2 and 3 in the same way as well. Example: Address 0 = 2100 0000h Address 0 + different tag 1 = 2101 0000h Address 0 + different tag 2 = 2102 0000h Address 0 + different tag 3 = 2103 0000h
(2)	Enable the ECC. The ECC is enabled by writing 0000 0018h to the CAOAD register after writing 0000 00F1h to the CAPRCR register.
(3)	Enable the cache and wait for flushing to complete. [For the instruction cache] After writing 0000 0101h to the IFCACTL register, wait until the IFCAFCT register becomes 0. [For the data cache] After writing 0000 0101h to the OACACTL register, wait until the OACAFCT register becomes 0.
(4)	Have the CPU perform read access to fill the lines of way 0 in the cache.
(5)	Have the CPU perform read access to fill the lines of ways 1 to 3 in the cache.
(6)	Disable the cache and ECC. [For the instruction cache] The cache and ECC are disabled by writing 0000 0000h to the IFCACTL register and 0000 0000h to the CAOAD register. [For the data cache] The cache and ECC are disabled by writing 0000 0000h to the OACACTL register and 0000 0000h to the CAOAD register.
(7)	Read data from the cache memory to the test access data register. [For the instruction cache] By writing to the IFCATAA register, read data from the cache memory to the IFCATAD register. Before proceeding to the next step, read the IFCATAA register to confirm that it reflects the written data.*1 [For the data cache] By writing to the OACATAA register, read data from the cache memory to the OACATAD register. Before proceeding to the next step, read the OACATAA register to confirm that it reflects the written data.*1

Table 2.36 Flow of Testing when the CPU Reads Data from a Cache (2/2)

Step Number	Test Flow Details
(8)	Write data that have been changed by one bit to the test access data register. [For the instruction cache] Write data that have been changed by one bit to the IFCATAD register. When testing 2-bit ECC error detection, write the value of IFCATAD with two bits inverted. [For the data cache] Write data that have been changed by one bit to the OACATAD register. When testing 2-bit ECC error detection, write the value of OACATAD with two bits inverted.
(9)	Write the address for test access and data to the cache memory. [For the instruction cache] Write the contents of the IFCATAD register to the cache memory by writing to the IFCATAA register. [For the data cache] Write the contents of the OACATAD register to the cache memory by writing to the OACATAA register.
(10)	Enable the cache and ECC. [For the instruction cache] Write 0000 0018h to the CAOAD register to enable the ECC, and then write 0000 0001h to the IFCACTL register to enable the cache. [For the data cache] Write 0000 0018h to the CAOAD register to enable the ECC, and then write 0000 0001h to the OACACTL register to enable the cache.
(11)	Have the CPU read the target address. When testing way 1, have the CPU read “address 0 + different tag 1”. When testing way 2, have the CPU read “address 0 + different tag 2”. When testing way 3, have the CPU read “address 0 + different tag 3”.
(12)	Read the error detection status register to confirm that the register bits indicate the expected error state. [For the instruction cache] When testing 1-bit ECC error correction, check that the data read have been corrected. In each test, confirm that the value of the IFCAEDST register is the corresponding value in Table 2.38. [For the data cache] When testing 1-bit ECC error correction, check that the data read have been corrected. In each test, confirm that the value of the OACAEDST register is the corresponding value in Table 2.38.
(13)	Clear the error state. [For the instruction cache] The error state can be cleared by writing 0000 0000h to the IFCAEDST register. [For the data cache] The error state can be cleared by writing 0000 0000h to the OACAEDST register.

Note 1. When the CPU writes to the I/O registers, it executes subsequent instructions without waiting for completion of the writing. Regarding the specific method of waiting for reflection of the results of preceding instructions, see (2) Notes on Writing to I/O Registers of section 5, I/O Registers.

Table 2.37 Example Settings of the IFCATAA and OACATAA Registers

No.	Target Decoder for Testing	IFCATAA and OACATAA Registers Settings
1	ECC decoder for tags of way 0	WAY[1:0] = 00b, TARGET[2:0] = 010b or 100b
2	ECC decoder for tags of way 1	WAY[1:0] = 01b, TARGET[2:0] = 010b or 100b
3	ECC decoder for tags of way 2	WAY[1:0] = 10b, TARGET[2:0] = 010b or 100b
4	ECC decoder for tags of way 3	WAY[1:0] = 11b, TARGET[2:0] = 010b or 100b
5	ECC decoder for data of way 0 (offset higher-order part [63:32])	WAY[1:0] = 00b, TARGET[2:0] = 000b or 001b OFFSET[2:0] = 001b
6	ECC decoder for data of way 0 (offset lower-order part [31:0])	WAY[1:0] = 00b, TARGET[2:0] = 000b or 001b OFFSET[2:0] = 000b
7	ECC decoder for data of way 1 (offset higher-order part [63:32])	WAY[1:0] = 01b, TARGET[2:0] = 000b or 001b OFFSET[2:0] = 001b
8	ECC decoder for data of way 1 (offset lower-order part [31:0])	WAY[1:0] = 01b, TARGET[2:0] = 000b or 001b OFFSET[2:0] = 000b
9	ECC decoder for data of way 2 (offset higher-order part [63:32])	WAY[1:0] = 10b, TARGET[2:0] = 000b or 001b OFFSET[2:0] = 001b
10	ECC decoder for data of way 2 (offset lower-order part [31:0])	WAY[1:0] = 10b, TARGET[2:0] = 000b or 001b OFFSET[2:0] = 000b
11	ECC decoder for data of way 3 (offset higher-order part [63:32])	WAY[1:0] = 11b, TARGET[2:0] = 000b or 001b OFFSET[2:0] = 001b
12	ECC decoder for data of way 3 (offset lower-order part [31:0])	WAY[1:0] = 11b, TARGET[2:0] = 000b or 001b OFFSET[2:0] = 000b

Note: Set RW = 0 (reading) for step (7) and RW = 1 (writing) for step (9).

Table 2.38 Read Data Confirmation Values for Step (12)

Target	Error	IFCAEDST and OACAEDST Registers Settings
Data	1-bit ECC error	0000 0001h
	2-bit ECC error	0000 0002h
Data ECC	1-bit ECC error	0000 0001h
	2-bit ECC error	0000 0002h
Tag	1-bit ECC error	0000 0004h
	2-bit ECC error	0000 0010h
Tag ECC	1-bit ECC error	0000 0004h
	2-bit ECC error	0000 0010h

(2) Write-back Path Test

Table 2.39 shows the flow for testing of the ECC decoders at the time of write-back. The ECC decoders for the write-back path are only provided for the data cache. There are two decoders for the write-back path, which are the offset higher-order and lower-order decoders along the cache data path, so select way 0 (Nos. 5 and 6) from Table 2.37 in steps (7) and (9) and repeat the steps from (1) to (15) twice.

Table 2.39 Flow of Testing when the CPU Writes to the Data Cache (in the Case of Way 0*1)

Step Number	Test Flow Details
(0)	When a cache is in use, disable the cache according to the procedure in section 2.13.2, Points to Note on Cache Operations before starting on the main flow below.
	The steps from (1) to (9) are the same as those for the CPU read path test.
(10)	Replace the D bit of the cache tag with 1. Step 1: Set the OACATAA register according to the settings in Table 2.40 (RW = 0). Step 2: Read the OACATAA register to confirm that it reflects the written data.*2 Step 3: Obtain the logical OR of the OACATAD register value and 00000001h, write it to the OACATAD register, and confirm that result of writing is reflected. Step 4: Set the OACATAA register according to the settings in Table 2.40 (RW = 1). To conduct a test along a path other than that for way 0, see Nos. 7 to 12 in Table 2.37.
(11)	Make the LRU setting for the cache such that “the oldest is way 0”. Set the OACATAD and OACATAA registers according to the settings in Table 2.41. To conduct a test along a path other than that for way 0, see Table 2.42.
(12)	Enable the cache and ECC. Write 0000 0018h to the CAOAD register to enable the ECC, and then write 0000 0001h to the OACACTL register to enable the cache.
(13)	Have the CPU read from an address not registered in the cache to generate a cache miss. The different tag (not in cache) is a tag address different from the address of the way used in step (1). Example: address 0 + different tag (not in cache) = 2110 0000h
(14)	Check the write-back data. When testing the response to 1-bit ECC errors, check that the data read from address 0 again (the write-back value) has been corrected. When testing the response to 2-bit ECC errors, check that the data read from address 0 again (the write-back value) has not been corrected. Read the error detection status register (OACAEDST) to check that its value is the one for the corresponding type of error as listed in Table 2.43.
(15)	Clear the error state. The error state can be cleared by writing 0000 0000h to the OACAEDST register.

Note 1. The case of way 0 is given as an example. The same testing is also possible along the paths for ways 1 to 3.
Note 2. When the CPU writes to the I/O registers, it executes subsequent instructions without waiting for completion of the writing. Regarding the specific method of waiting for reflection of the results of preceding instructions, see (2) Notes on Writing to I/O Registers of section 5, I/O Registers.

Table 2.40 OACATAA Register Settings (in the Case of Way 0)

No.	Target Decoder for Testing	OACATAA Register Settings
1	ECC decoder for write-back (offset higher-order part)	WAY[1:0] = 00b, TARGET[2:0] = 010b OFFSET[2:0] = 001b
2	ECC decoder for write-back (offset lower-order part)	WAY[1:0] = 00b, TARGET[2:0] = 010b OFFSET[2:0] = 000b

Table 2.41 OACATAD and OACATAA Registers Settings (in the Case of Way 0)

No.	Target Decoder for Testing	OACATAD Register Setting	OACATAA Register Settings
1	ECC decoder for write-back (offset higher-order part)	0000 0014h	WAY[1:0] = 00b, TARGET[2:0] = 011b OFFSET[2:0] = 001b, RW = 1b
2	ECC decoder for write-back (offset lower-order part)	0000 0014h	WAY[1:0] = 00b, TARGET[2:0] = 011b OFFSET[2:0] = 000b, RW = 1b

Table 2.42 OACATAD Register Settings According to the Selected Way

	Way0	Way1	Way2	Way3
OACATAA.WAY	00b	01b	10b	11b
OACATAD	0000 0014h	0000 0009h	0000 001Eh	0000 0013h

Table 2.43 Read Data Confirmation Values for Step (14)

Target	Error	OACAEDST Register Setting
Data	1-bit ECC error	0000 0001h
	2-bit ECC error	0000 0002h
Data ECC	1-bit ECC error	0000 0001h
	2-bit ECC error	0000 0002h

2.9.9.3 Methods of Testing the ECC Decoder Circuits for the LRAM

The decoder circuits in the ECC of the LRAM allow users to detect failures through the flow described in Table 2.44.

Table 2.44 Flow of Testing the ECC Decoder Circuits for the LRAM

Step Number	Test Flow Details
(1)	Confirm that the operation of the preceding instruction is completed.*1
(2)	Write 0000 A501h to the LRMPRCR register to enable writing to the LRAM-related registers.
(3)	Write 0000 0008h to the LRMCRn register to enable the ECC function without error checking and disable the ECC bypass function.
(4)	Confirm that the operation of the preceding instruction is completed.*1
(5)	Write 4 bytes of data to the target address for testing. 7-bit ECC code is automatically updated.
(6)	Confirm that the operation of the preceding instruction is completed.*1
(7)	Write 0000 0080h to the LRMCRn register to disable the ECC function and enable the ECC bypass function.
(8)	Confirm that the operation of the preceding instruction is completed.*1
(9)	Read the target address for testing to obtain a 7-bit ECC code.
(10)	To generate an ECC 1-bit or 2-bit error, invert one or two bits of the data that were read in step (9) and write the data back to the target address.
(11)	Confirm that the operation of the preceding instruction is completed.*1
(12)	Write 0000 001Ch to the LRMCRn register to enable the ECC function with error checking, set 1-bit ECC error information updating to “enabled”, and disable the ECC bypass function.
(13)	Confirm that the operation of the preceding instruction is completed.*1
(14)	Read the target address for testing.
(15)	Confirm that the operation of the preceding instruction is completed.*1
(16)	Confirm the generation of ECC errors with LRMESR.

Note 1. When the CPU writes to the I/O registers, it executes subsequent instructions without waiting for completion of the writing. Regarding the specific method of waiting for reflection of the results of preceding instructions, see (2) Notes on Writing to I/O Registers of section 5, I/O Registers.

2.10 CPU Control Registers

2.10.1 CPU Function Lock Control Register (CPULOCKCR)

Address(es): CPU_CTRL.CPULOCKCR 8100 0000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LCKSAU	LCKSMPU
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LCKSMPU	Secure MPU Registers Write Disable	0: Writing to the target registers is enabled. 1: Writing to the target registers is disabled.	R/W*1
b1	LCKSAU	SAU Registers Write Disable	0: Writing to the target registers is enabled. 1: Writing to the target registers is disabled.	R/W*1
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Only writing 1 to this bit is valid. Writing 0 to the bit when it is 1 does not clear it.

LCKSMPU Bit (Secure MPU Registers Write Disable)

Setting this bit to 1 disables writing to the MPU registers in the secure world through the CPU or debugger. This applies to the following MPU registers in the secure world:

MPU.RSPAGEn, MPU.REPAGEn, MPU.MPEN, MPU.MPBAC, MPU.MPECLR, MPU.MPESTS, MPU.MPDEA, MPU.MPSA, MPU.MPOPS, MPU.MPOPI, MPU.MHITI, MPU.MHITD

LCKSAU Bit (SAU Registers Write Disable)

Setting this bit to 1 disables writing to the registers in the security attribute unit (SAU). This applies to the following registers listed in section 56, Security Features:

SAU.AAS, SAU.SESTS, SAU.SECLR, SAU.SEA

2.10.2 CPU Non-secure Function Lock Control Register (CPULOCKCRNS)

Address(es): CPU_CTRL_NS.CPULOCKCRNS 0100 0004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LCKNSMPU
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LCKNSMPU	Non-secure MPU Registers Write Disable	0: Writing to the target registers is enabled. 1: Writing to the target registers is disabled.	R/W*1
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Only writing 1 to this bit is valid. Writing 0 to the bit when it is 1 does not clear it.

LCKNSMPU Bit (Non-secure MPU Registers Write Disable)

Setting this bit to 1 disables writing to the MPU registers in the non-secure world through the CPU or debugger. This applies to the following MPU registers in the non-secure world:

MPU_NS.RSPAGEn, MPU_NS.REPAGEn, MPU_NS.MPEN, MPU_NS.MPBAC, MPU_NS.MPECLR, MPU_NS.MPESTS, MPU_NS.MPDEA, MPU_NS.MPSA, MPU_NS.MPOPS, MPU_NS.MPOPI, MPU_NS.MHITI, MPU_NS.MHITD

2.11 Operation of Instructions

2.11.1 Restrictions on RMPA and String-Manipulation Instructions

2.11.1.1 Transfer Size and Data Prefetching

The RMPA instruction and the string-manipulation instructions (SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, and SWHILE instructions) transfer data in longword units to speed up the reading of data from and writing of data to the memory. If the last of the data to be processed is less than a longword, data transfer proceeds with the sizes described below:

- RMPA, SSTR, SUNTIL, and SWHILE instructions: Size specified by the size specifier
- SCMPU, SMOVB, SMOVF, and SMOVU instructions: Byte

Additionally, in the above processing, the RMPA instruction and the string-manipulation instructions other than the SSTR instruction (that is, the SCMPU, SMOVB, SMOVF, SMOVU, SUNTIL, and SWHILE instructions) prefetch data when reading data from the memory. Data is prefetched from the prefetching start position with three bytes as the upper limit. The prefetching start positions of each operation are shown below.

- RMPA instruction: The multiplicand address specified by R1, and the multiplier address specified by R2
- SCMPU instruction: The source address specified by R1 for comparison, and the destination address specified by R2 for comparison
- SUNTIL and SWHILE instructions: The destination address specified by R1 for comparison
- SMOVB, SMOVF, and SMOVU instructions: The source address specified by R2 for transfer

2.11.1.2 Access to the External Address Space

Although the external address space has a per-area ending-switching facility (only for data), the allocation of data to be handled by RMPA or string-manipulation instructions (SCMPU, SMOVB, SMOVF, SMOVU,SSTR, SUNTIL, and SWHILE instructions) to an area where the endian differs from that of the chip is prohibited, and operation is not guaranteed if this restriction is not observed. If data to be handled by RMPA or string-manipulation instructions are allocated to the external address space, they must be allocated to areas where the endian setting is the same as that for the chip.

2.11.1.3 Access to I/O Registers

The allocation of data to be handled by RMPA or string-manipulation instructions (SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, and SWHILE instructions) to I/O registers is prohibited, and operation is not guaranteed if this restriction is not observed.

2.12 Numbers of Cycles

2.12.1 Instructions and Numbers of Cycles

Table 2.45 to Table 2.53 show the numbers of cycles in operation of each instruction. The listed numbers of cycles for access to memory are the numbers of cycles during no-wait access. The operands in the table below indicate the following meanings.

#IMM: Immediate
flag: bit, flag
Rs, Rs2, Rd, Rd2, Ri, Rb: General-purpose register
As, Ad: Accumulator
CR: Control register
dsp: displacement
pcdsp: displacement

Table 2.45 Numbers of Cycles for Arithmetic/logic Instructions

Instruction	Mnemonic (indicates the common operation when the size is omitted)	Numbers of Cycles
Arithmetic/logic instructions (register-register, immediate-register)	• {ABS, NEG, NOT} “Rd”/“Rs, Rd” • {ADC, MAX, MIN, ROTL, ROTR} “#IMM, Rd”/“Rs, Rd” • ADD “#IMM, Rd”/“Rs, Rd”/“#IMM, Rs, Rd”/“Rs, Rs2, Rd” • {AND, MUL, OR, SUB, XOR} “#IMM, Rd”/“Rs, Rd”/“Rs, Rs2, Rd” • {CMP, TST} “#IMM, Rs”/“Rs, Rs2” • NOP • {ROLC, RORC, SAT} “Rd” • SBB “Rs, Rd” • {SHAR, SHLL, SHLR} “#IMM, Rd”/“Rs, Rd”/“#IMM, Rs, Rd”	1
	• DIV “#IMM, Rd”/“Rs, Rd”	3 to 20*1
	• DIVU “#IMM, Rd”/“Rs, Rd”	2 to 18*1
	• {EMUL, EMULU} “#IMM, Rd”/“Rs, Rd”	2
	• SATR	3
Arithmetic/logic instructions (memory source operand)	• {ADC, ADD, AND, MAX, MIN, MUL, OR, SBB, SUB, XOR} “[Rs], Rd”/“dsp[Rs], Rd” • {CMP, TST} “[Rs], Rs2”/“dsp[Rs], Rs2”	3
	• DIV “[Rs], Rd / dsp[Rs], Rd”	5 to 22*1
	• DIVU“[Rs], Rd / dsp[Rs], Rd”	4 to 20*1
	• {EMUL, EMULU} “[Rs], Rd”/“dsp[Rs], Rd”	4
	• RMPA.B	6+7×floor(n/4)+4×(n%4) n: Number of processed bytes*2
	• RMPA.W	6+5×floor(n/2)+4×(n%2) n: Number of processed words*2
	• RMPA.L	6+4n n: Number of processed longwords

Note 1. The number of cycles for the dividing instruction varies according to the divisor and dividend.
Note 2. floor (x): Maximum integer that is smaller than x.

Table 2.46 Numbers of Cycles for Transfer Instructions

Instruction	Mnemonic (indicates the common operation when the size is omitted)	Numbers of Cycles
Transfer instructions (register-register, immediate-register)	• MOV “#IMM, Rd”/“Rs, Rd” • {MOVU, REVL, REVW} “Rs, Rd” • SC*Cnd* “Rd” • {STNZ, STZ} “#IMM, Rd”/ “Rs, Rd”	1
	• XCHG “Rs, Rd”	2
Transfer instructions (load operation)	• {MOV, MOVU} “[Rs], Rd”/“dsp[Rs], Rd”/“[Rs+], Rd”/“[-Rs], Rd”/“[Ri, Rb], Rd” • MOVLI “[Rs], Rd” • POP “Rd”	Throughput: 1 Latency: 2*1
	• POPC “CR”	Throughput: 3 Latency: 4*1
	• POPM “Rd-Rd2”	Throughput: n Latency: n+1 n: Number of registers*1, *2
Transfer instructions (store operation)	• MOV “Rs, [Rd]”/“Rs, dsp[Rd]”/“Rs, [Rd+]”/“Rs, [-Rd]”/“Rs, [Ri, Rb]”/“#IMM, dsp[Rd]”/“#IMM, [Rd]” • PUSH “Rs” • PUSHC “CR” • SC*Cnd* “[Rd]”/“dsp[Rd]” • MOVCO “Rs, [Rd]”	1
	• PUSHM “Rs-Rs2”	n n: Number of registers*3
Transfer instructions (memory-register)	• XCHG “[Rs], Rd”/“dsp[Rs], Rd”	2
Transfer instructions (memory-memory)	• MOV “[Rs], [Rd]”/“dsp[Rs], [Rd]”/“[Rs], dsp[Rd]”/“dsp[Rs], dsp[Rd]” • PUSH “[Rs]”/“dsp[Rs]”	3
Transfer instructions (bit field)	• {BFMOV, BFMOVZ} “#IMM, #IMM, #IMM, R, R”	1

Note 1. When the load data is used by the subsequent instruction, the number of cycles described as “latency” is counted as the number of cycles for the memory load instruction. For the cycles other than the memory load instruction, the number of cycles described as “throughput” is counted.

Note 2. The POPM instruction is converted into multiple load operations. The processing is the same as the one for the load operations of the MOV instruction repeated for the number of specified registers.

Note 3. The PUSHM instruction is converted into multiple store operations. The processing is the same as the one for the store operations of the MOV instruction repeated for the number of specified registers.

Table 2.47 Numbers of Cycles for Bit Manipulation Instructions

Instruction	Mnemonic (indicates the common operation when the size is omitted)	Numbers of Cycles
Bit manipulation instructions (register)	• {BCLR, BNOT, BSET} “#IMM, Rd”/“Rs, Rd” • BM*Cnd* “#IMM, Rd” • BTST “#IMM, Rs”/“Rs, Rs2”	1
Bit manipulation instructions (memory source operand)	• {BCLR, BNOT, BSET} “#IMM, [Rd]”/“#IMM, dsp[Rd]”/“Rs, [Rd]”/“Rs, dsp[Rd]” • BM*Cnd* “#IMM, [Rd]”/“#IMM, dsp[Rd]” • BTST “#IMM, [Rs]”/“#IMM, dsp[Rs]”/“Rs, [Rs2]”/“Rs, dsp[Rs2]”	3

Table 2.48 Numbers of Cycles for Branch Instructions

Instruction	Mnemonic (indicates the common operation when the size is omitted)	Numbers of Cycles
Branch instructions	• B*Cnd* “pcdsp” • {BRA, BSR} “pcdsp”/“Rs” • {JMP, JSR} “Rs”	Branch taken: 3 Branch not taken: 1
	• {RTE, TRRTE}	6
	• RTFI	3
	• RTS	5
	• RTSD “#IMM”	5
	• RTSD “#IMM, Rd-Rd2”	Throughput: n<5?5:1+n Latency: n<4?5:2+n n: Number of registers*1

?: Conditional operator

Note 1. When the load data is used by the subsequent instruction, the number of cycles described as “latency” is counted as the number of cycles for the memory load instruction. For the cycles other than the memory load instruction, the number of cycles described as “throughput” is counted.

Table 2.49 Numbers of Cycles for Single-Precision Floating-Point Operation Instructions

Instruction	Mnemonic (indicates the common operation when the size is omitted)	Numbers of Cycles
Single-precision floating-point operation instructions (register-register, immediate-register)	• {FADD, FSUB} “#IMM, Rd”/ “Rs, Rd”/ “Rs, Rs2, Rd”	2
	• FCMP “#IMM, Rs”/“Rs, Rs2”	1
	• FDIV “#IMM, Rd”/“Rs, Rd”	16
	• FMUL “#IMM, Rd”/ “Rs, Rd” / “Rs, Rs2, Rd”	2
	• FSQRT “Rs, Rd”	16
	• {FTOI, ROUND, ITOF} “Rs, Rd”	2
	• {FTOU, UTOF} “Rs, Rd”	2
Single-precision floating-point operation instructions (memory source operand)	• {FADD, FSUB} “[Rs], Rd”/“dsp[Rs], Rd”	4
	• FCMP “[Rs], Rs2”/“dsp[Rs], Rs2”	3
	• FDIV “[Rs], Rd”/“dsp[Rs], Rd”	18
	• FMUL “[Rs], Rd”/“dsp[Rs], Rd”	4
	• FSQRT “[Rs], Rd”/“dsp[Rs], Rd”	18
	• {FTOI, ROUND, ITOF} “[Rs], Rd”/“dsp[Rs], Rd”	4
	• {FTOU, UTOF} “[Rs], Rd”/“dsp[Rs], Rd”	4

Table 2.50 Numbers of Cycles for DSP Instructions

Instruction	Mnemonic (indicates the common operation when the size is omitted)	Numbers of Cycles
DSP instructions	• {EMULA, EMACA, EMSBA, MULLH, MULHI, MULLO, MACLH, MACHI, MACLO, MSBLH, MSBHI, MSBLO}“Rs, Rs2, Ad” • {MVFACHI, MVFACMI, MVFACLO, MVFACGU} “#IMM, As, Rd” • {MVTACHI, MVTACLO, MVTACGU} “Rs, Ad” • {RDACW, RDACL, RACW, RACL} “#IMM, Ad”	1

Table 2.51 Numbers of Cycles for String Manipulation Instructions

Instruction	Mnemonic (indicates the common operation when the size is omitted)	Numbers of Cycles
String manipulation instructions*1	• SCMPU	2+4×floor(n/4)+4×(n%4) n: Number of compared bytes*2
	• SMOVB	n>3?6+3×floor(n/4)+3×(n%4):2+3n n: Number of transferred bytes*2
	• SMOVF, SMOVU	2+3×floor(n/4)+3×(n%4) n: Number of transferred bytes*2
	• SSTR.B	2+floor(n/4)+n%4 n: Number of transferred bytes*2
	• SSTR.W	2+floor(n/2)+n%2 n: Number of transferred words*2
	• SSTR.L	2+n n: Number of transferred longwords
	• SUNTIL.B, SWHILE.B	3+3×floor(n/4)+3×(n%4) n: Number of compared bytes*2
	• SUNTIL.W, SWHILE.W	3+3×floor(n/2)+3×(n%2) n: Number of compared words*2
	• SUNTIL.L, SWHILE.L	3+3×n n: Number of compared longwords

?: Conditional operator

Note 1. Each of the SCMPU, SMOVU, SWHILE, and SUNTIL instructions ends the execution regardless of the specified cycles if the end condition is satisfied during execution.
Note 2. floor (x): Maximum integer less than or equal to x.

Table 2.52 Numbers of Cycles for System Manipulation Instructions

Instruction	Mnemonic (indicates the common operation when the size is omitted)	Numbers of Cycles
System manipulation instructions	• {CLRPSW, SETPSW}“flag” • MVTC “#IMM, CR”/“Rs, CR” • MVFC “CR, Rd” • MVTIPL “#IMM”	1
	• TRMVTC “#IMM, CR”/“Rs, CR”	3
	• TRMVFC “CR, Rd”	2
	• RTE	6
	• RTFI	3

Table 2.53 Numbers of Cycles for Instructions for Register Bank Save Function

Instruction	Mnemonic (indicates the common operation when the size is omitted)	Numbers of Cycles
Instructions for register bank save function	• SAVE “#IMM”/“R”	1
	• RSTR “#IMM”/“R”	3 to 6

2.12.2 Instructions and Numbers of Cycles (for the Double-Precision Floating-Point Coprocessor)

Table 2.54 shows the numbers of cycles for the double-precision floating-point related instructions. The listed numbers of cycles for access to memory are the numbers of cycles during no-wait access. The operands in the table below indicate the following meanings.

#IMM: Immediate
Rs, Rd: General-purpose register
dsp: displacement
DRs, DRs2, DRd, DRd2: Double-precision floating-point data register
DRHs, DRHd: Upper 32 bits in the double-precision floating-point data register
DRLs, DRLd: Lower 32 bits in the double-precision floating-point data register
DCRs, DCRs2, DCRd, DCRd2: Double-precision floating-point control register

Table 2.54 Numbers of Cycles for the Double-Precision Floating-Point Related Instructions

Instruction	Mnemonic (indicates the common operation when the size is omitted)	Numbers of Cycles
Double-precision floating-point processing instructions	• {DADD, DSUB} “DRs, DRs2, DRd”	4*1
	• {DABS, DNEG} “DRs, DRd”	1
	• DCMPcm “DRs, DRs2”	4*1
	• DDIV “DRs, DRs2, DRd”	33*1
	• DMUL “DRs, DRs2, DRd”	5*1
	• DSQRT “DRs, DRd”	33*1
	• {DTOF, DTOI, DTOU, DROUND} “DRs, DRd”	4*1
	• {FTOD, ITOD, UTOD} “Rs, DRd”	4*1
Double-precision floating-point data transfer instructions	• DMOV “Rs, DRHd”/ “Rs, DRLd” / “DRHs, Rd” / “DRLs, Rd” / “DRs, DRd”/“#IMM, DRHd”/ “#IMM, DRLd”	1
	• DMOV “DRs, [Rd]”/ “DRs, dsp[Rd]”	1
	• DMOV “[Rs], DRd”/ “dsp[Rs], DRd”	Throughput: 1 Latency: 2*2
	• DPUSHM “DRs-DRs2” / “DCRs-DCRs2”	n n: Number of registers*4
	• DPOPM “DRd-DRd2” / “DCRd-DCRd2”	Throughput: n Latency: n + 1 n: Number of registers*2, *3
	• MVFDC “DCRs, Rd”	1
	• MVFDR	1
	• MVTDC “Rs, DCRd”	1

Note 1. The numbers of cycles for reference to the results of arithmetic operations by double-precision floating-point data transfer instructions and the DABS and DNEG instructions are the listed numbers of cycles plus 1.
Note 2. When the load data is used by the subsequent instruction, the number of cycles described as “latency” is counted as the number of cycles for the memory load instruction. For the cycles other than the memory load instruction, the number of cycles described as “throughput” is counted.
Note 3. The DPOPM instruction is converted into multiple load operations. The processing is the same as the one for the load operations of the DMOV instruction repeated for the number of specified registers.
Note 4. The DPUSHM instruction is converted into multiple store operations. The processing is the same as the one for the store operations of the DMOV instruction repeated for the number of specified registers.

2.12.3 Numbers of Cycles for Response to Interrupts

Table 2.55 lists the numbers of cycles taken by processing for response to interrupts.

Table 2.55 Numbers of Cycles for Response to Interrupts

Type of Interrupt Request/Details of Processing	Fast Interrupt	Other Interrupts
ICU Judgment of priority order	2 cycles (ICLK)	
CPU Numbers of cycles from notification to acceptance of the interrupt request	N cycles (CPUCLK0) (varies with the instruction being executed at the time the interrupt was received)	
CPU Pre-processing by hardware Saving the current PC and PSW values in RAM (or in control registers in the case of the fast interrupt) Reading of the vector Branching to the start of the exception handling routine	4 cycles (CPUCLK0)	6 cycles (CPUCLK0)

Times calculated from the values in Table 2.55 will be applicable when access to memory from the CPU is processed with no waiting. This MCU has a LRAM that allows no-wait access and cache memory. Numbers of cycles for response to interrupts can be minimized by placing program code, vectors and the stack in LRAM. In addition, by setting it to a cacheable area when placing it in MRAM or SRAM, the number of interrupt response cycles will be minimized if there is a cache hit. Place the addresses where the exception handling routine start on 8-byte boundaries.
For information on the numbers of cycles from notification to acceptance of the interrupt request, indicated by N in the table above, see Table 2.45 to Table 2.54.
The timing of interrupt acceptance depends on the execution state of the instruction. For more information on this, see section 14.3.1, Timing of Acceptance and Saved PC Value.

2.12.4 Numbers of Cycles of Waiting

Access to the LRAM usually requires no cycles of waiting. However, the following cases do require waiting.

(1) Cycles of waiting are generated when the LRAM is written in 8- or 16-bit units while the ECC function is enabled (the ECCMOD1 bit in the corresponding LRMCRn register is 1 (n = 0 or 1).

(2) In cases of contention between access by the CPU and access by another bus master, the CPU takes priority and the bus interface of the LRAM causes the other bus master to wait for the number of cycles required for the completion of access by the CPU.

(3) If access by the CPU or another bus master to the LRAM leads to a security violation, the LRAM returns an AHB error and this is accompanied by the insertion of cycles of waiting.

2.13 Usage Notes

2.13.1 Notes on Self-Diagnosis of the RAM for the Register-Saving Banks

The register-saving banks in this MCU are configured of RAM. As the register-saving banks are equipped with a buffer, data may be read from the buffer rather than from the memory cells of the RAM when the same address is to be read by a RSTR instruction after a write operation by the SAVE instruction. When running self-diagnosis of the RAM in the register-saving banks, confirm that the data have actually been written to the memory by following the procedure below so that data will not be read from the buffer.

(1) Write data to the bank targeted for diagnosis with the SAVE instruction.
(2) Write data to a bank different from the bank in the procedure (1) with the SAVE instruction.
(3) Read the data from the bank in the procedure (1) with the RSTR instruction.

2.13.2 Points to Note on Cache Operations

If a cache is disabled by the EN bit of the IFCACTL or OACACTL register or a reset is applied, the contents of the cache are not automatically flushed. If valid data remain in the cache while the cache is disabled, a mismatch will occur between the contents of the cache and memory. Use the following procedures to enable and disable the caches.

(1) Disabling the instruction cache

1. Set the IFCACTL register to 0000 0100h to specify disabling and start flushing of the cache.
2. Wait until the IFCAFCT.FL bit becomes 0 to ensure that flushing has been completed.
   The cache is disabled after this.

Note: Make sure that the setting of the IFCAFCT.FL bit is 0 before starting the above procedure.

(2) Enabling the instruction cache after a reset

1. Set the IFCACTL register to 0000 0101h to specify enabling and start flushing of the cache.
2. Wait until the IFCAFCT.FL bit becomes 0 to ensure that flushing has been completed.
   The cache is enabled after this. The cache is automatically flushed in response to the initial write access to the IFCACTL or IFCAFCT register after a reset.

(3) Enabling the instruction cache after it has been disabled

1. Check that the IFCAFCT.FL bit is 0, that is, flushing has been completed.
2. Set the IFCACTL register to 0000 0001h to enable the cache.

(4) Disabling the data cache

1. Set the OACACTL register to 0000 0100h (write-back is disabled) or 0000 0300h (write-back is enabled) to specify disabling and start flushing of the cache.
2. Wait until the OACAFCT register becomes 0000 0000h to ensure that the write-back and flush operations have been completed. The cache is disabled after this.

Note: Make sure that the setting of the OACAFCT.FL bit is 0 before starting the above procedure.

(5) Enabling the data cache after a reset

1. Set the OACACTL register to 0000 0101h to specify enabling and start flushing of the cache.
2. Wait until the OACAFCT.FL bit becomes 0 to ensure that flushing has been completed.
   The cache is enabled after this. The cache is automatically flushed in response to the initial write access to the OACACTL or OACAFCT register after a reset. Even if the WB bit is set to 1 at the same time as the write access to either register, write-back does not proceed.

(6) Enabling the data cache after it has been disabled

1. Check that the OACAFCT register is 0000 0000h, that is, the write-back and flush operations have been completed.
2. Set the OACACTL register to 0000 0001h to enable the cache.

2.13.3 Note on Cache Coherency

Software is required to guarantee coherency between the caches and external memory or on-chip SRAM. When multiple bus masters (for example, the CPU and DMAC) share an area in the scope of a cache, flush and write back the cache contents as required.

2.13.4 Note on Cache Flush and Write-Back

When using the CPU to start a flush or write-back of the contents of a cache in the CPU, check that the corresponding one among the IACAFCT.FL bit, the OACAFCT.WB bit, and the OACAFCT.FL bit has become 0 to confirm the completion of the flush or write-back operation. Do not use a bus master other than the CPU to start a flush or write-back operation for a cache in the CPU. After the flush or write-back processing has begun, that processing takes priority over access by the CPU.

2.13.5 Note on Testing LRAM Memory Cells

As the LRAM units each have a write buffer, data may be read from the write buffer rather than the LRAM memory cells if a value is written to an address and then read from the same address. When testing LRAM memory cells by writing data and then reading the written data, use the procedure stated in Table 2.56 to avoid reading from the write buffer.

Table 2.56 Procedure of Testing LRAM Memory Cells

(1)	Write any value to the target address of testing.
(2)	In the same LRAM unit, write any value to an address which is at least four locations away from that in (1).
(3)	Read data from the address to which writing proceeded in (1).

2.13.6 Notes on Modifying Instruction Codes

Either of the following procedures is required when modifying instruction codes in memory.

- When caching is enabled and the area corresponding to the modification is cacheable, the procedure is as follows.
  - After completing the write operation, make the data cache write back to memory by writing 1 to the OACAFCT.WB bit.
  - Before executing the modified instruction, invalidate the instruction cache by writing 1 to the IFCAFCT.FL bit.
- When the branch instruction processing accelerator is enabled and the area corresponding to the modification is cacheable, the procedure is as follows.
  - Before executing the modified instruction, invalidate the branch instruction processing accelerator by writing 1 to the CPUBAINV.BAIV bit.

Before executing the modified instruction code, verify that the data have actually been written and can be read correctly by reading back the last of the data to have been written.

3. Operating Modes

3.1 Operating Mode Types and Selection

The operating mode is selectable in either of the following ways.

- Level on the mode-setting pin (MD) on release from a reset (RES# pin reset or power-on reset)
- Control by software following release from the reset state

Table 3.1 shows the relationships between the level on the mode-setting pin and the operating mode to be selected. For details on each of the operating modes, refer to section 3.3, Details of Operating Modes. Operation starts with the on-chip code MRAM enabled, regardless of the mode in which operation started.

Table 3.1 Selection of Operating Modes by the Mode-Setting Pin on Release from the Reset State

Mode-Setting Pin		SYSCR0 Initial State
MD	Operating Mode	ROME
High*1, *2	Single-chip mode, boot mode (JTAG/SWD interface)*4	1 (On-chip code MRAM enabled)
Low*1	Boot mode (SCI/USB interface)	
Low → High*3	Boot mode (FINE interface)	

Note 1. Transitions of the operating mode proceed during the waiting time after RES# release or the power-on reset time. Do not change the input level on the MD pin during any of those periods. For details about the waiting time after RES# release and the power-on reset time, refer to section 67, Electrical Characteristics.
Note 2. After the chip starts in single-chip mode, the MD pin can also be used as a general-purpose I/O port pin or P315.
Note 3. This is controlled by the serial programmer or emulator.
Note 4. When a request to transit to boot mode is input from the JTAG or SWD interface while a reset is being applied through the RES# pin, the chip starts up in boot mode through the JTAG or SWD interface.

Table 3.2 gives a list of the operating mode settings that can be made with system control register 0 (SYSCR0).

Table 3.2 Selection of Operating Modes by Register Setting

SYSCR0	
ROME	Operating Mode
0*1	Single-chip mode (On-chip code MRAM disabled)
1	Single-chip mode (On-chip code MRAM enabled)

Note 1. Once the ROME bit is set to 0, it cannot be reverted to 1.

The endian is selectable in single-chip mode. Endian is selected by the endian selection bits (MDE[2:0]) in the endian select register (MDE). Table 3.3 lists the correspondence between the setting and endian. For details on selection of endian, refer to section 7.2.4, Endian Select Register (MDE). In boot mode, little endian is always selected regardless of the setting of the MDE[2:0] bits.

Table 3.3 Selection of Endian

MDE	
Setting of the MDE[2:0] Bits	Selected Endian
000b	Big endian
111b	Little endian

3.2 Register Descriptions

3.2.1 System Control Register 0 (SYSCR0)

Address(es): SYSC.SYSCR0 8701 9006h, SYSC_NS.SYSCR0 0701 9006h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	ROME
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	ROME	On-Chip Code MRAM Enable	0: The on-chip code MRAM is disabled. 1: The on-chip code MRAM is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	SYSCR0 Key Code	These bits control permission and prohibition of writing to the SYSCR0 register. To modify the SYSCR0 register, write 5Ah to the eight higher-order bits and the desired value to the eight lower-order bits as a 16-bit unit.	R/(W)*1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Values written are not retained.

ROME Bit (On-Chip Code MRAM Enable)

The ROME bit enables or disables the on-chip code MRAM.

Once set to 0, it cannot be reverted to 1.

A 0 should not be written to this bit while a program is being executed from the on-chip code MRAM. After writing a 0 to this bit, be sure to disable the on-chip code MRAM by changing the ROME bit to 0 before proceeding with further processing. When the setting of the ROME bit is 0, access to the CS0 area of the external address space is enabled.

3.2.2 Operating Mode Security Attribution Register (MDSAR)

Address(es): SYSC.MDSAR 8701 93D4h, SYSC_NS.MDSAR 0701 93D4h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	NONSEC8	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	NONSEC8	Security Attribution	0: Secure 1: Non-secure	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

NONSEC8 Bit (Security Attribution)

The NONSEC8 bit is used to set the security attributes for the SYSCR0 register.

3.3 Details of Operating Modes

3.3.1 Single-Chip Mode

In single-chip mode, all I/O port pins are available for use as input or output port pins, inputs or outputs for peripheral functions, or as interrupt inputs.
The chip starts up in single-chip mode if the chip is released from the reset state while the signal on the MD pin is fixed to the high level. The on-chip code MRAM is enabled (SYSCR0.ROME bit = 1) at this time. The on-chip code MRAM can be disabled by software (by clearing the SYSCR0.ROME bit to 0), but it cannot be re-enabled (by setting the SYSCR0.ROME bit to 1) once this is done. When the setting of the ROME bit is 0, access to the CS0 area of the external address space is enabled.

3.3.2 Boot Mode (SCI Interface)

The on-chip MRAM modifying program (boot program) stored in a dedicated area within the MCU runs in this mode. On-chip MRAM units (code MRAM and data MRAM) can be modified from outside the MCU by using a universal asynchronous receiver/transmitter (SCI1). For details, refer to section 65, MRAM.
The chip starts up in boot mode (SCI interface) if the chip is released from the reset state while the signal on the MD pin is fixed to the low level.

3.3.3 Boot Mode (USB Interface)

The on-chip MRAM modifying program (boot program) stored in a dedicated area within the MCU runs in this mode. On-chip MRAM units (code MRAM and data MRAM) can be modified from outside the MCU by using the USB. For details, refer to section 65, MRAM.
The chip starts up in boot mode (USB interface) if the chip is released from the reset state while the signal on the MD pin is fixed to the low level.

3.3.4 Boot Mode (JTAG/SWD Interface)

The on-chip MRAM modifying program (boot program) stored in a dedicated area within the MCU runs in this mode. On-chip MRAM units (code MRAM and data MRAM) can be modified from outside the MCU by using the JTAG interface or SWD interface. For details, refer to section 65, MRAM.
When the MD pin is being driven high and a request to transit to boot mode is input from the JTAG or SWD interface while a reset is being applied through the RES# pin, the chip starts up in boot mode through the JTAG or SWD interface.

3.3.5 Boot Mode (FINE Interface)

The on-chip MRAM modifying program (boot program) stored in a dedicated area within the MCU runs in this mode. On-chip MRAM units (code MRAM and data MRAM) can be modified from outside the MCU by using a FINE connection. For details, refer to section 65, MRAM.
The chip starts up in boot mode (FINE interface) if the chip is released from the reset state while the signal on the MD pin is fixed to the low level and then driven high within 20 to 100 ms after that.

3.4 Transitions of Operating Modes

3.4.1 Operating Mode Transitions Determined by the Mode-Setting Pin

Figure 3.1 shows operating mode transitions determined by the settings of the MD pin.

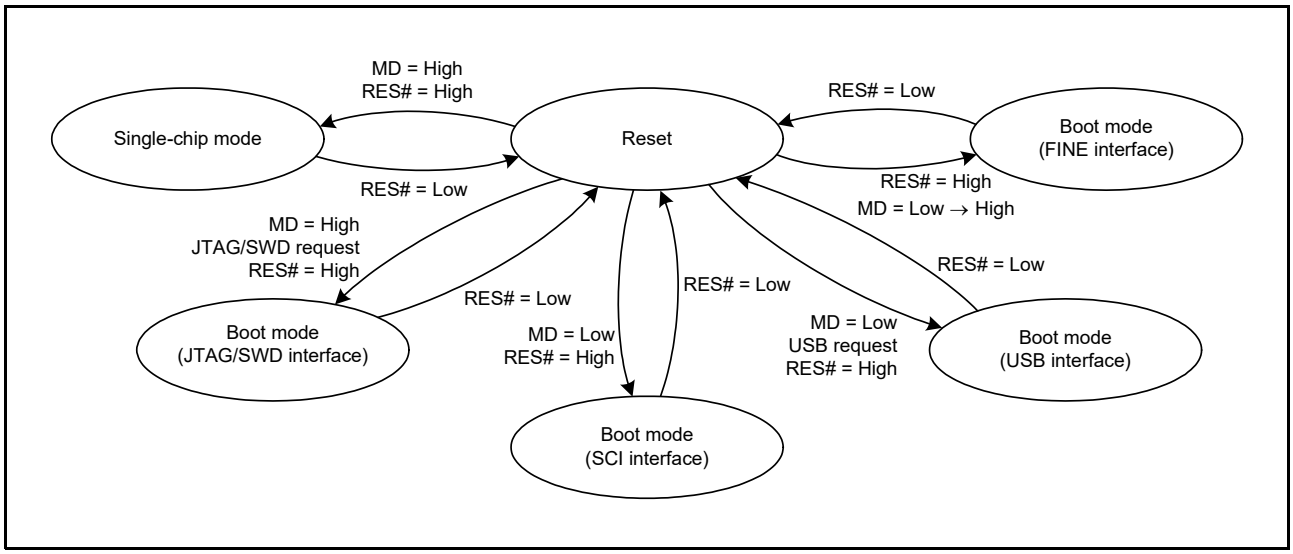


Figure 3.1 Level on the Mode-Setting Pin and Operating Mode

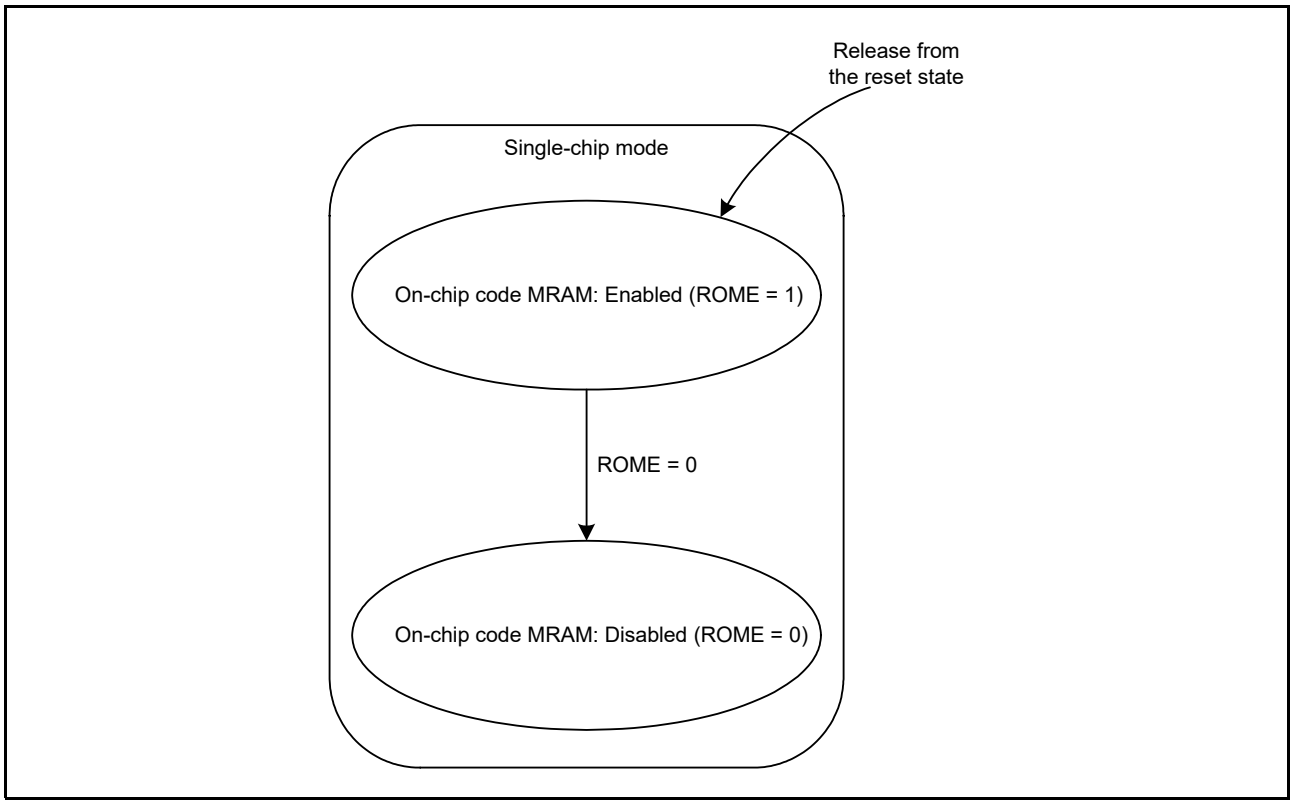
3.4.2 Operating Mode Transitions According to Register Setting

Figure 3.2 shows operating mode transitions according to the setting of the ROME bit in the SYSCR0 register.



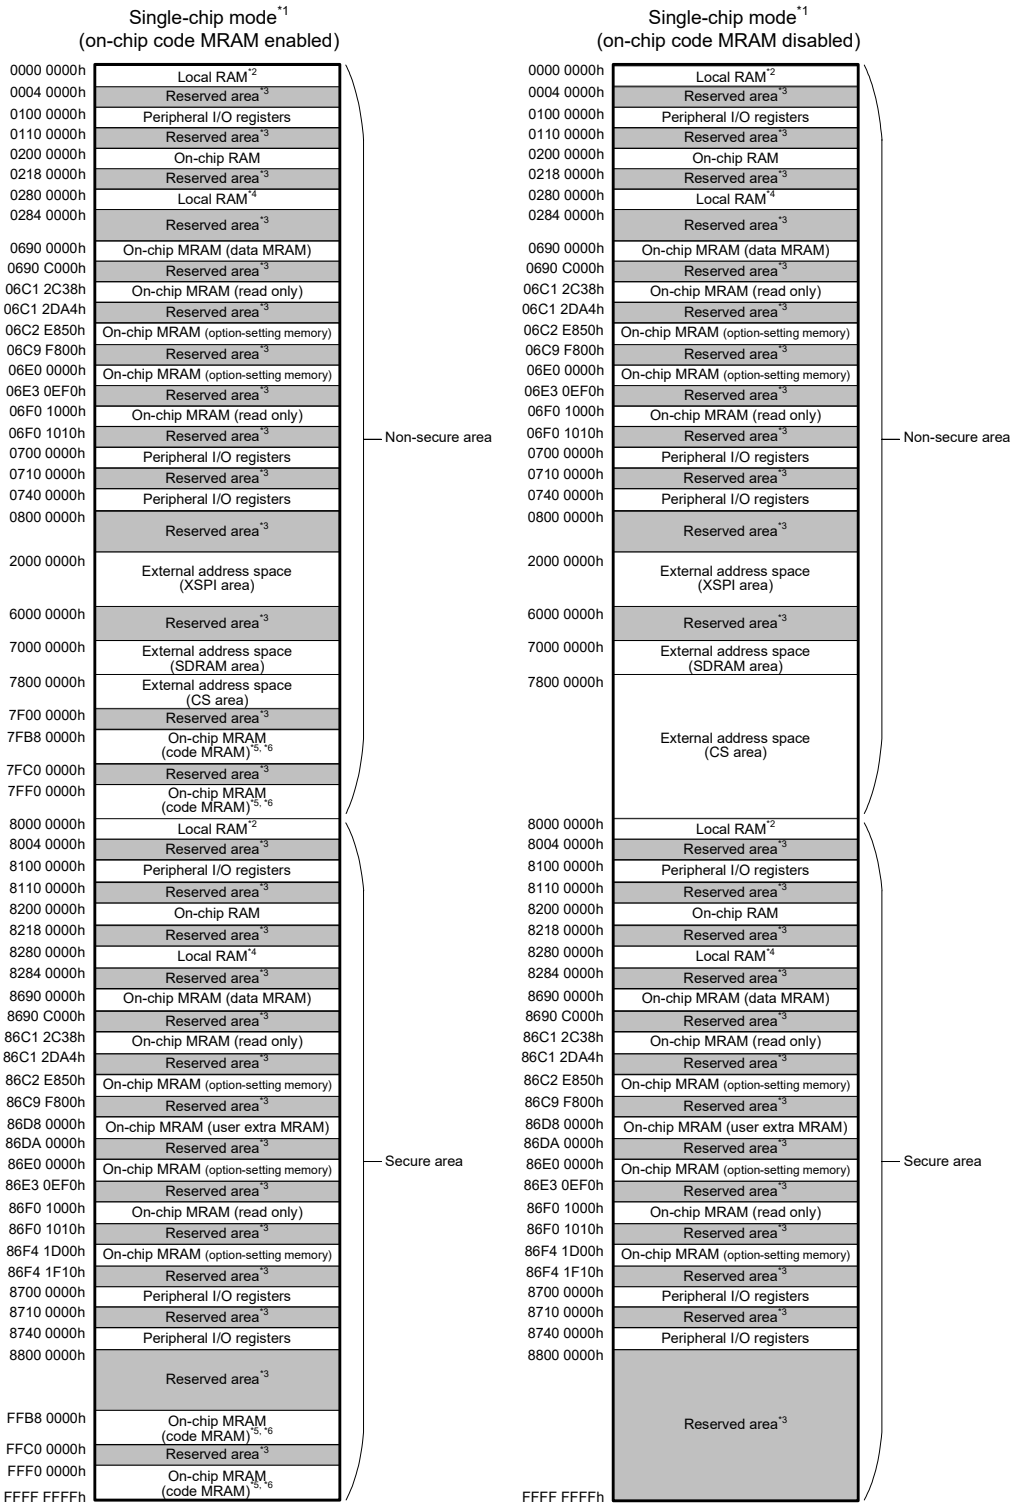


Figure 3.2 Setting of SYSCR0.ROME Bit and Operating Modes

4. Address Space

4.1 Address Space

This MCU has a 4-Gbyte address space, consisting of the range of addresses from 0000 0000h to FFFF FFFFh. That is, linear access to an address space of up to 4 Gbytes is possible, and this contains both program and data areas.
The address space is divided into Secure area (addresses 8000 0000h to FFFF FFFFh) and Non-secure area (addresses 0000 0000h to 7FFF FFFFh).
For details on the security attributes, refer to section 56, Security Features.

Figure 4.1 shows the memory maps in the respective operating modes. Accessible areas will differ according to the operating mode and states of control bits.

Note 1. The address space in boot mode is the same as the address space in single-chip mode.
Note 2. The address to the left applies when access is from the CPU.
Note 3. Reserved areas should not be accessed.
Note 4. The address to the left applies when access is from a bus master other than the CPU.
Note 5. The on-chip MRAM (code MRAM) can be used in linear mode, where the user area forms a single area, or in dual mode, where the user area is divided into two banks. For details, refer to section 65, MRAM.
Note 6. The capacities of the MRAM differ depending on the products. For details, refer to Table 4.1, Capacities of the MRAM (Secure Area) and Table 4.2, Capacities of the MRAM (Non-secure Area).

Figure 4.1 Memory Map in Each Operating Mode

Table 4.1 Capacities of the MRAM (Secure Area)

Code MRAM			Data MRAM		On-Chip RAM	
	Address					
Capacity	Linear mode	Dual mode (BANKSEL.BANKSWP[2:0] = 111b)	Capacity	Address	Capacity	Address
1 Mbyte	FFF0 0000h to FFFF FFFFh	bank 1: FFB8 0000h to FFBF FFFFh	48 Kbytes	8690 0000h to 8690 BFFFh	1.5 Mbytes	8200 0000h to 8217 FFFFh
		bank 0: FFF8 0000h to FFFF FFFFh				
512 Kbytes	FFF8 0000h to FFFF FFFFh	bank 1: FFBC 0000h to FFBF FFFFh	48 Kbytes	8690 0000h to 8690 BFFFh	1.5 Mbytes	8200 0000h to 8217 FFFFh
		bank 0: FFFC 0000h to FFFF FFFFh				

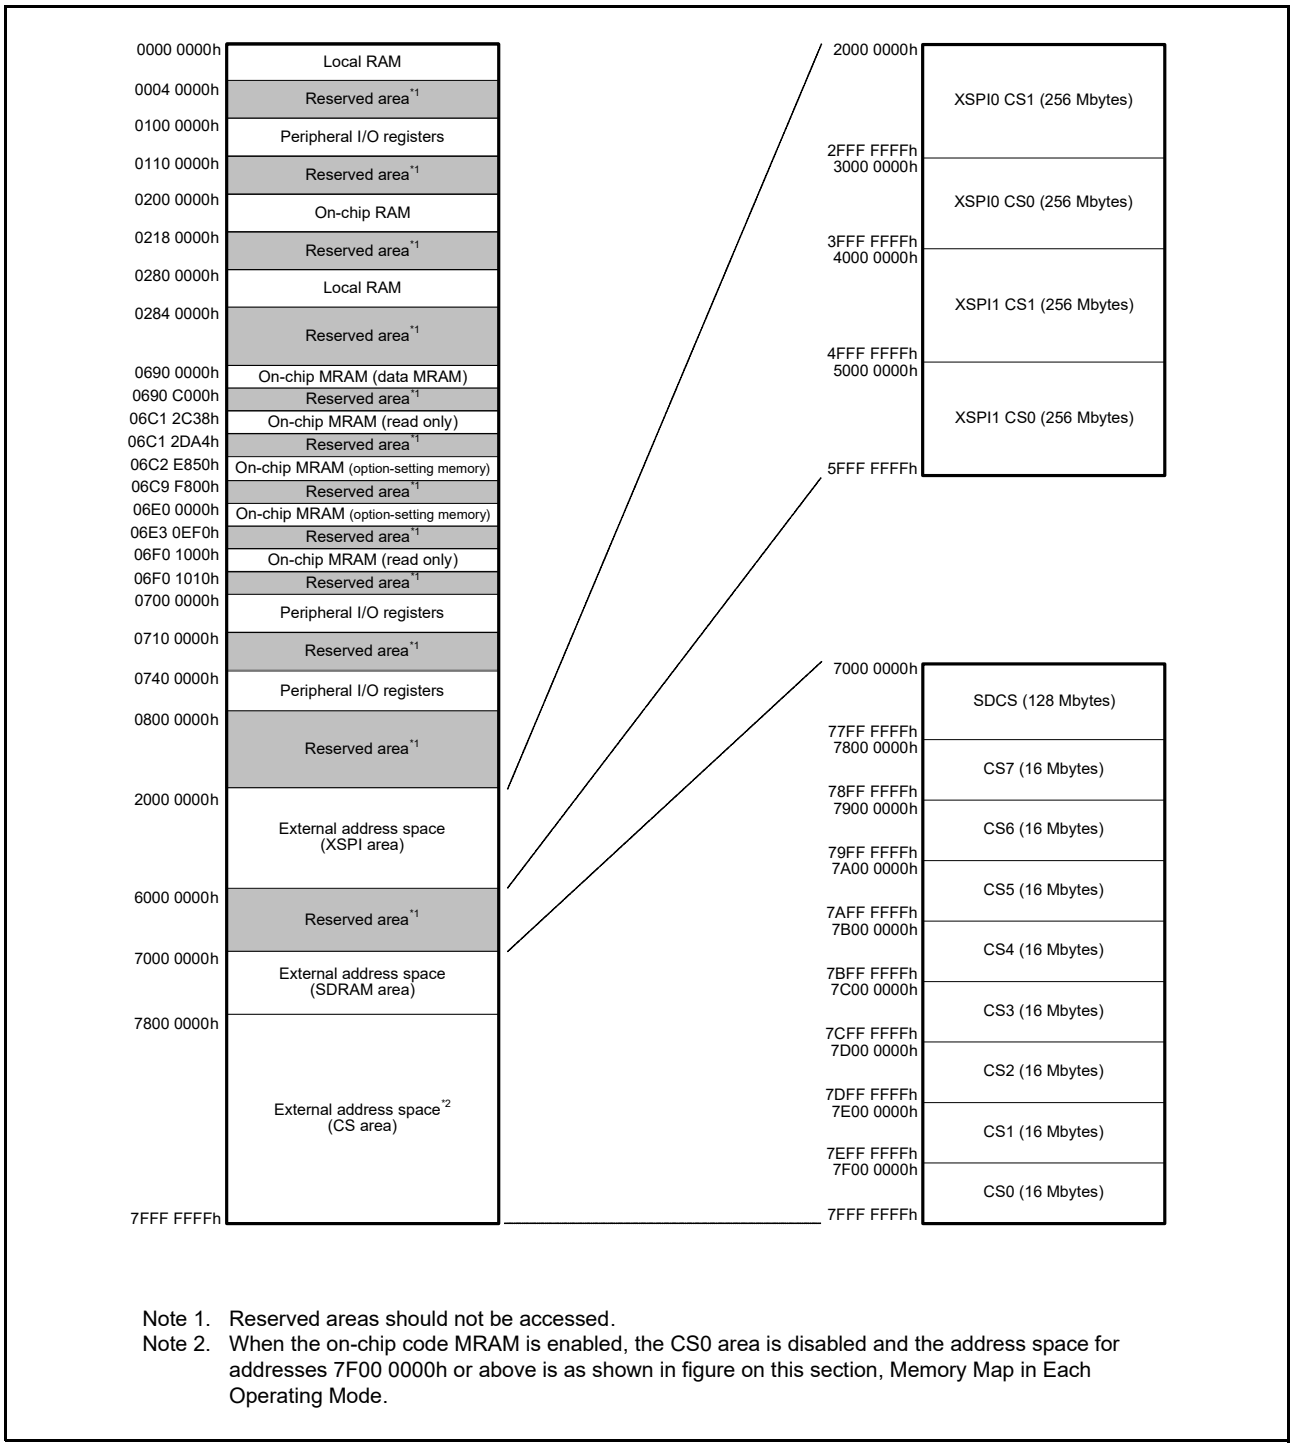

Table 4.2 Capacities of the MRAM (Non-secure Area)

Code MRAM			Data MRAM		On-Chip RAM	
	Address					
Capacity	Linear mode	Dual mode (BANKSEL.BANKSWP[2:0] = 111b)	Capacity	Address	Capacity	Address
1 Mbyte	7FF0 0000h to 7FFF FFFFh	bank 1: 7FB8 0000h to 7FBF FFFFh	48 Kbytes	0690 0000h to 0690 BFFFh	1.5 Mbytes	0200 0000h to 0217 FFFFh
		bank 0: 7FF8 0000h to 7FFF FFFFh				
512 Kbytes	7FF8 0000h to FFFF FFFFh	bank 1: 7FBC 0000h to 7FBF FFFFh	48 Kbytes	0690 0000h to 0690 BFFFh	1.5 Mbytes	0200 0000h to 0217 FFFFh
		bank 0: 7FFC 0000h to 7FFF FFFFh				

4.2 External Address Space

The external address space is divided into CS areas (CS0 to CS7), an SDRAM area (SDCS), and XSPI areas (XSPImCS0, XSPImCS1) (m = 0, 1). The CS areas are divided into up to eight areas (CS0 to CS7), each corresponding to the CSn# signal output from a CSn# (n = 0 to 7) pin. The XSPI area can be divided into up to four XSPI areas (XSPImCS0, XSPImCS1), each corresponding to an XSPIm_CSn# signal output from an XSPIm_CSn# pin (m = 0, 1, n = 0, 1).

Figure 4.2 shows the address ranges corresponding to the individual CS areas (CS0 to CS7), SDRAM area (SDCS), and XSPI areas (XSPImCS0, XSPImCS1) (m = 0, 1) when the on-chip code MRAM is disabled.

Note 1. Reserved areas should not be accessed.
Note 2. When the on-chip code MRAM is enabled, the CS0 area is disabled and the address space for addresses 7F00 0000h or above is as shown in figure on this section, Memory Map in Each Operating Mode.

Figure 4.2 Correspondence between External Address Spaces and CS Areas (On-Chip Code MRAM Disabled)

5. I/O Registers

The coverage of registers in this section is a summary of information on the on-chip I/O registers that have multiple access sizes. For the other on-chip registers, see the respective sections. The information is given in the form described below. Notes on writing to registers are also given at the end.

(1) I/O Register Addresses (Address Order)

- Registers are listed from the lower allocation addresses.
- Registers are classified according to module symbols.
- Within the internal I/O register area, addresses not stated in the descriptions of registers in each section are reserved. Do not access these addresses; otherwise, the operation in access to the corresponding bits and other subsequent operations cannot be guaranteed.

(2) Notes on Writing to I/O Registers

When writing to an I/O register, the CPU starts executing the subsequent instruction before completing I/O register write. This may cause the subsequent instruction to be executed before the post-update I/O register value is reflected on the operation.
As described in the following examples, special care is required for the cases in which the subsequent instruction must be executed after the post-update I/O register value is actually reflected.

[Examples of cases requiring special care]

- The subsequent instruction must be executed while an interrupt request is disabled with the IENj bit in IERm of the ICU (interrupt request enable bit) set to 0.
- A WAIT instruction is executed immediately after the preprocessing for causing a transition to the low power consumption state.

In the above cases, after writing to an I/O register, wait until the write operation is completed using the following procedure and then execute the subsequent instruction.

(a) Write to an I/O register.
(b) Read the value from the I/O register to a general register.
(c) Execute the operation using the value read.
(d) Execute the subsequent instruction.

[Instruction examples]

- Byte-size I/O registers

```
MOV.L  #SFR_ADDR, R1
MOV.B  #SFR_DATA, [R1]
CMP    [R1].UB, R1
;; Next process
```

- Word-size I/O registers

```
MOV.L  #SFR_ADDR, R1
MOV.W  #SFR_DATA, [R1]
CMP    [R1].W, R1
;; Next process
```

- Longword-size I/O registers

```
MOV.L  #SFR_ADDR, R1
MOV.L  #SFR_DATA, [R1]
CMP    [R1].L, R1
;; Next process
```

If multiple registers are written to and a subsequent instruction should be executed after the write operations are entirely completed, only read the I/O register that was last written to and execute the operation using the value; it is not necessary to read or execute operation for all the registers that were written to.

(3) Notes on Sleep Mode and Mode Transitions

Writing to the registers related to system control (indicated by 'SYSC' in the addresses of registers in each section) while in sleep mode, deep sleep mode, or during mode transitions is prohibited.

(4) Restrictions in Relation to RMPA and String-Manipulation Instructions

The allocation of data to be handled by RMPA or string-manipulation instructions to I/O registers is prohibited, and operation is not guaranteed if this restriction is not observed.

5.1 I/O Register Addresses (Address Order)

Table 5.1 List of I/O Registers (Address Order) (1/11)

Secure Address	Module Symbol	Register Name	Register Symbol	Number of Bits	Access Size*1
8741 0004h	CRC	CRC Data Input Register	CRCDIR	32	8, 32
8741 0008h	CRC	CRC Data Output Register	CRCDOR	32	8, 16, 32
8741 100Ch	DOC	DOC Data Input Register	DODIR	32	16, 32
8741 1010h	DOC	DOC Data Setting Register 0	DODSR0	32	16, 32
8741 1014h	DOC	DOC Data Setting Register 1	DODSR1	32	16, 32
8745 1014h	USBHS	CFIFO Port Register	CFIFO	32	8, 16, 32
8745 1018h	USBHS	D0FIFO Port Register	D0FIFO	32	8, 16, 32
8745 101Ch	USBHS	D1FIFO Port Register	D1FIFO	32	8, 16, 32
8745 8000h	RSCI0	Receive Data Register	RDR	32	8, 16, 32
8745 8004h	RSCI0	Transmit Data Register	TDR	32	8, 16, 32
8745 8100h	RSCI1	Receive Data Register	RDR	32	8, 16, 32
8745 8104h	RSCI1	Transmit Data Register	TDR	32	8, 16, 32
8745 8200h	RSCI2	Receive Data Register	RDR	32	8, 16, 32
8745 8204h	RSCI2	Transmit Data Register	TDR	32	8, 16, 32
8745 8300h	RSCI3	Receive Data Register	RDR	32	8, 16, 32
8745 8304h	RSCI3	Transmit Data Register	TDR	32	8, 16, 32
8745 8400h	RSCI4	Receive Data Register	RDR	32	8, 16, 32
8745 8404h	RSCI4	Transmit Data Register	TDR	32	8, 16, 32
8745 8500h	RSCI5	Receive Data Register	RDR	32	8, 16, 32
8745 8504h	RSCI5	Transmit Data Register	TDR	32	8, 16, 32
8745 8600h	RSCI6	Receive Data Register	RDR	32	8, 16, 32
8745 8604h	RSCI6	Transmit Data Register	TDR	32	8, 16, 32
8745 8700h	RSCI7	Receive Data Register	RDR	32	8, 16, 32
8745 8704h	RSCI7	Transmit Data Register	TDR	32	8, 16, 32
8745 8800h	RSCI8	Receive Data Register	RDR	32	8, 16, 32
8745 8804h	RSCI8	Transmit Data Register	TDR	32	8, 16, 32
8745 8900h	RSCI9	Receive Data Register	RDR	32	8, 16, 32
8745 8904h	RSCI9	Transmit Data Register	TDR	32	8, 16, 32
8745 8A00h	RSCI10	Receive Data Register	RDR	32	8, 16, 32
8745 8A04h	RSCI10	Transmit Data Register	TDR	32	8, 16, 32
8745 8B00h	RSCI11	Receive Data Register	RDR	32	8, 16, 32
8745 8B04h	RSCI11	Transmit Data Register	TDR	32	8, 16, 32
8745 8C00h	RSCI12	Receive Data Register	RDR	32	8, 16, 32
8745 8C04h	RSCI12	Transmit Data Register	TDR	32	8, 16, 32
8745 C000h	RSPIA0	RSPI Data Register	SPDR	32	8, 16, 32
8745 C100h	RSPIA1	RSPI Data Register	SPDR	32	8, 16, 32
8745 C200h	RSPIA2	RSPI Data Register	SPDR	32	8, 16, 32
8745 F158h	RI3C0	Transmit/Receive Data Register	ICDR	32	8, 32
8745 F558h	RIICHS1	Transmit/Receive Data Register	ICDR	32	8, 32
8745 F958h	RIICHS2	Transmit/Receive Data Register	ICDR	32	8, 32
8747 0520h to 8747 056Bh	CANFD	Receive FIFO 0	RFB0	608	8, 16, 32
8747 056Ch to 8747 05B7h	CANFD	Receive FIFO 1	RFB1	608	8, 16, 32
8747 05B8h to 8747 0603h	CANFD	Common FIFO 0	CFB0	608	8, 16, 32

Table 5.1 List of I/O Registers (Address Order) (2/11)

Secure Address	Module Symbol	Register Name	Register Symbol	Number of Bits	Access Size*1
8747 0604h to 8747 064Fh	CANFD	Transmit Message Buffer 0	TMB0	608	8, 16, 32
8747 0650h to 8747 069Bh	CANFD	Transmit Message Buffer 1	TMB1	608	8, 16, 32
8747 069Ch to 8747 06E7h	CANFD	Transmit Message Buffer 2	TMB2	608	8, 16, 32
8747 06E8h to 8747 0733h	CANFD	Transmit Message Buffer 3	TMB3	608	8, 16, 32
8747 0920h to 8747 096Bh	CANFD	Receive Message Buffer 0	RMB0	608	8, 16, 32
8747 096Ch to 8747 09B7h	CANFD	Receive Message Buffer 1	RMB1	608	8, 16, 32
8747 09B8h to 8747 0A03h	CANFD	Receive Message Buffer 2	RMB2	608	8, 16, 32
8747 0A04h to 8747 0A4Fh	CANFD	Receive Message Buffer 3	RMB3	608	8, 16, 32
8747 0A50h to 8747 0A9Bh	CANFD	Receive Message Buffer 4	RMB4	608	8, 16, 32
8747 0A9Ch to 8747 0AE7h	CANFD	Receive Message Buffer 5	RMB5	608	8, 16, 32
8747 0AE8h to 8747 0B33h	CANFD	Receive Message Buffer 6	RMB6	608	8, 16, 32
8747 0B34h to 8747 0B7Fh	CANFD	Receive Message Buffer 7	RMB7	608	8, 16, 32
8747 0D20h to 8747 0D6Bh	CANFD	Receive Message Buffer 8	RMB8	608	8, 16, 32
8747 0D6Ch to 8747 0DB7h	CANFD	Receive Message Buffer 9	RMB9	608	8, 16, 32
8747 0DB8h to 8747 0E03h	CANFD	Receive Message Buffer 10	RMB10	608	8, 16, 32
8747 0E04h to 8747 0E4Fh	CANFD	Receive Message Buffer 11	RMB11	608	8, 16, 32
8747 0E50h to 8747 0E9Bh	CANFD	Receive Message Buffer 12	RMB12	608	8, 16, 32
8747 0E9Ch to 8747 0EE7h	CANFD	Receive Message Buffer 13	RMB13	608	8, 16, 32
8747 0EE8h to 8747 0F33h	CANFD	Receive Message Buffer 14	RMB14	608	8, 16, 32
8747 0F34h to 8747 0F7Fh	CANFD	Receive Message Buffer 15	RMB15	608	8, 16, 32
8748 2000h to 8748 204Bh	CANFDG0	Receive Message Buffer 0	RMB0	608	8, 16, 32
8748 2080h to 8748 20CBh	CANFDG0	Receive Message Buffer 1	RMB1	608	8, 16, 32
8748 2100h to 8748 214Bh	CANFDG0	Receive Message Buffer 2	RMB2	608	8, 16, 32
8748 2180h to 8748 21CBh	CANFDG0	Receive Message Buffer 3	RMB3	608	8, 16, 32
8748 2200h to 8748 224Bh	CANFDG0	Receive Message Buffer 4	RMB4	608	8, 16, 32
8748 2280h to 8748 22CBh	CANFDG0	Receive Message Buffer 5	RMB5	608	8, 16, 32
8748 2300h to 8748 234Bh	CANFDG0	Receive Message Buffer 6	RMB6	608	8, 16, 32
8748 2380h to 8748 23CBh	CANFDG0	Receive Message Buffer 7	RMB7	608	8, 16, 32
8748 2400h to 8748 244Bh	CANFDG0	Receive Message Buffer 8	RMB8	608	8, 16, 32
8748 2480h to 8748 24CBh	CANFDG0	Receive Message Buffer 9	RMB9	608	8, 16, 32

Table 5.1 List of I/O Registers (Address Order) (3/11)

Secure Address	Module Symbol	Register Name	Register Symbol	Number of Bits	Access Size*1
8748 2500h to 8748 254Bh	CANFDG0	Receive Message Buffer 10	RMB10	608	8, 16, 32
8748 2580h to 8748 25CBh	CANFDG0	Receive Message Buffer 11	RMB11	608	8, 16, 32
8748 2600h to 8748 264Bh	CANFDG0	Receive Message Buffer 12	RMB12	608	8, 16, 32
8748 2680h to 8748 26CBh	CANFDG0	Receive Message Buffer 13	RMB13	608	8, 16, 32
8748 2700h to 8748 274Bh	CANFDG0	Receive Message Buffer 14	RMB14	608	8, 16, 32
8748 2780h to 8748 27CBh	CANFDG0	Receive Message Buffer 15	RMB15	608	8, 16, 32
8748 2800h to 8748 284Bh	CANFDG0	Receive Message Buffer 16	RMB16	608	8, 16, 32
8748 2880h to 8748 28CBh	CANFDG0	Receive Message Buffer 17	RMB17	608	8, 16, 32
8748 2900h to 8748 294Bh	CANFDG0	Receive Message Buffer 18	RMB18	608	8, 16, 32
8748 2980h to 8748 29CBh	CANFDG0	Receive Message Buffer 19	RMB19	608	8, 16, 32
8748 2A00h to 8748 2A4Bh	CANFDG0	Receive Message Buffer 20	RMB20	608	8, 16, 32
8748 2A80h to 8748 2ACBh	CANFDG0	Receive Message Buffer 21	RMB21	608	8, 16, 32
8748 2B00h to 8748 2B4Bh	CANFDG0	Receive Message Buffer 22	RMB22	608	8, 16, 32
8748 2B80h to 8748 2BCBh	CANFDG0	Receive Message Buffer 23	RMB23	608	8, 16, 32
8748 2C00h to 8748 2C4Bh	CANFDG0	Receive Message Buffer 24	RMB24	608	8, 16, 32
8748 2C80h to 8748 2CCBh	CANFDG0	Receive Message Buffer 25	RMB25	608	8, 16, 32
8748 2D00h to 8748 2D4Bh	CANFDG0	Receive Message Buffer 26	RMB26	608	8, 16, 32
8748 2D80h to 8748 2DCBh	CANFDG0	Receive Message Buffer 27	RMB27	608	8, 16, 32
8748 2E00h to 8748 2E4Bh	CANFDG0	Receive Message Buffer 28	RMB28	608	8, 16, 32
8748 2E80h to 8748 2ECBh	CANFDG0	Receive Message Buffer 29	RMB29	608	8, 16, 32
8748 2F00h to 8748 2F4Bh	CANFDG0	Receive Message Buffer 30	RMB30	608	8, 16, 32
8748 2F80h to 8748 2FCBh	CANFDG0	Receive Message Buffer 31	RMB31	608	8, 16, 32
8748 6000h to 8748 604Bh	CANFDG0	Receive FIFO 0	RFB0	608	8, 16, 32
8748 6080h to 8748 60CBh	CANFDG0	Receive FIFO 1	RFB1	608	8, 16, 32
8748 6100h to 8748 614Bh	CANFDG0	Receive FIFO 2	RFB2	608	8, 16, 32
8748 6180h to 8748 61CBh	CANFDG0	Receive FIFO 3	RFB3	608	8, 16, 32
8748 6200h to 8748 624Bh	CANFDG0	Receive FIFO 4	RFB4	608	8, 16, 32
8748 6280h to 8748 62CBh	CANFDG0	Receive FIFO 5	RFB5	608	8, 16, 32
8748 6300h to 8748 634Bh	CANFDG0	Receive FIFO 6	RFB6	608	8, 16, 32
8748 6380h to 8748 63CBh	CANFDG0	Receive FIFO 7	RFB7	608	8, 16, 32

Table 5.1 List of I/O Registers (Address Order) (4/11)

Secure Address	Module Symbol	Register Name	Register Symbol	Number of Bits	Access Size*1
8748 6400h to 8748 644Bh	CANFDG0	Common FIFO 0	CFB0	608	8, 16, 32
8748 6480h to 8748 64CBh	CANFDG0	Common FIFO 1	CFB1	608	8, 16, 32
8748 6500h to 8748 654Bh	CANFDG0	Common FIFO 2	CFB2	608	8, 16, 32
8748 6580h to 8748 65CBh	CANFDG0	Common FIFO 3	CFB3	608	8, 16, 32
8748 6600h to 8748 664Bh	CANFDG0	Common FIFO 4	CFB4	608	8, 16, 32
8748 6680h to 8748 66CBh	CANFDG0	Common FIFO 5	CFB5	608	8, 16, 32
8749 0000h to 8749 004Bh	CANFDG0	Transmit Message Buffer 0	TMB0	608	8, 16, 32
8749 0080h to 8749 00CBh	CANFDG0	Transmit Message Buffer 1	TMB1	608	8, 16, 32
8749 0100h to 8749 014Bh	CANFDG0	Transmit Message Buffer 2	TMB2	608	8, 16, 32
8749 0180h to 8749 01CBh	CANFDG0	Transmit Message Buffer 3	TMB3	608	8, 16, 32
8749 0200h to 8749 024Bh	CANFDG0	Transmit Message Buffer 4	TMB4	608	8, 16, 32
8749 0280h to 8749 02CBh	CANFDG0	Transmit Message Buffer 5	TMB5	608	8, 16, 32
8749 0300h to 8749 034Bh	CANFDG0	Transmit Message Buffer 6	TMB6	608	8, 16, 32

87C0 0D70h	PFS	Port Security Attribute Setting Register	PGSAR	16	8, 16

Note 1. The table above only lists the addresses of registers with the Secure attribute and multiple access sizes. Note that registers with the Non-secure attribute have different addresses from those listed in the table, but the same access sizes.

6. Resets

6.1 Overview

This MCU supports the following 16 types of reset.
It also has functionality for controlling (enabling or disabling) reset generation by using registers which are only accessible by a secure program.
Table 6.1 lists the names and sources of the resets.

Table 6.1 Names and Sources of Resets

Reset Name	Source
RES# pin reset	Voltage input to the RES# pin is driven low.
Power-on reset	VCC rises (voltage used in monitoring: VPOR)*1
Voltage monitoring 0 reset	VCC falls (voltage used in monitoring: Vdet0)*1
Voltage monitoring 1 reset	VCC falls (voltage used in monitoring: Vdet1)*1 VCC rises (voltage used in monitoring: Vdet1)*1
Voltage monitoring 2 reset	VCC falls (voltage used in monitoring: Vdet2)*1 VCC rises (voltage used in monitoring: Vdet2)*1
Voltage monitoring 4 reset	VCC falls (voltage used in monitoring: Vdet4)*1 VCC rises (voltage used in monitoring: Vdet4)*1
Voltage monitoring 5 reset	VCC falls (voltage used in monitoring: Vdet5)*1 VCC rises (voltage used in monitoring: Vdet5)*1
Core voltage monitoring reset	VDD falls (voltage used in monitoring: Vdet_VDDL)*1 VDD rises (voltage used in monitoring: Vdet_VDDH)*1
Temperature monitoring reset	Detection of a temperature beyond the specified range
Independent watchdog timer reset	Independent watchdog timer underflow or refresh error
Watchdog timer reset	Watchdog timer underflow or refresh error
Bus error reset	Bus error
Common memory error reset	ECC error in the RAM
Local memory error reset	ECC error in the CPU cache or local RAM
Deep software standby reset	Release from deep software standby mode by an interrupt
Software reset	Register setting

Note 1. For details on the voltages for use in monitoring (VPOR, Vdet0, Vdet1, Vdet2, Vdet4, Vdet5, Vdet_VDDL, and Vdet_VDDH), see section 8, Programmable Voltage Detection Circuit (PVD) and section 67, Electrical Characteristics.

When the OFS1.RODIS bit is set to 0, an internal reset signal can be output on the RES# pin. When this output occurs, the MCU is also initialized by an RES# pin reset. This function is called the reset output function. For details, see section 6.3.15, Reset Output Function.
Table 6.2 lists the reset sources for which reset output is possible.

Table 6.2 Reset Sources for which Reset Output is Possible

Reset Source	Reset Output
RES# pin reset	Not possible
Power-on reset	Not possible
Voltage monitoring 0 reset	Possible
Voltage monitoring 1 reset	Possible
Voltage monitoring 2 reset	Possible
Voltage monitoring 4 reset	Possible
Voltage monitoring 5 reset	Possible
Core voltage monitoring reset	— *1
Temperature monitoring reset	Possible
Independent watchdog timer reset	Possible
Watchdog timer reset	Possible
Bus error reset	Possible
Common memory error reset	Possible
Local memory error reset	Possible
Deep software standby reset	Not possible
Software reset	Possible

Note 1. When a core voltage monitoring reset occurs, it is propagated within the MCU so the MCU will be initialized, but the reset output is not guaranteed. The reset output not having proceeded can be identified by the RSTSR3.CVMRF flag being set, while the reset output having proceeded can be identified by the ROUTSR2.ROCVMRF flag being set.

The internal state is initialized by a reset, which also sets the pins to their initial states. Table 6.3, Table 6.4, Table 6.5, and Table 6.6 list the targets for initialization according to the type of reset.

Table 6.3 Targets for Initialization According to Type of Reset (Reset Detect Flags 1) (1/2)

Target for Initialization	Reset Source								
	RES# Pin Reset	Power-On Reset	Voltage Monitoring 0 Reset	Core Voltage Monitoring Reset	Voltage Monitoring 4 Reset	Voltage Monitoring 5 Reset	Temperature Monitoring Reset	Independent Watchdog Timer Reset	Watchdog Timer Reset
Power-on reset detect flag (RSTSR0.PORF)	✓	—	—	—	—	—	—	—	—
Voltage monitoring 0 reset detect flag (RSTSR0.PVD0RF)	✓	✓	—	—	—	—	—	—	—
Core voltage monitoring reset detect flag (RSTSR3.CVMRF)	✓	✓	✓	—	—	—	—	—	—
Temperature monitoring reset detect flag (RSTSR3.TEMPRF)	✓	✓	✓	—	—	—	—	—	—
Independent watchdog timer reset detect flag (RSTSR1.IWDTRF)	✓	✓	✓	✓	✓	✓	✓	—	—
Watchdog timer reset detect flag (RSTSR1.WDT0RF)	✓	✓	✓	✓	✓	✓	✓	—	—
Voltage monitoring 1 reset detect flag (RSTSR0.PVD1RF)	✓	✓	✓	✓	✓	✓	✓	—	—
Voltage monitoring 2 reset detect flag (RSTSR0.PVD2RF)	✓	✓	✓	✓	✓	✓	✓	—	—
Voltage monitoring 4 reset detect flag (RSTSR0.PVD4RF)	✓	✓	✓	—	—	—	—	—	—
Voltage monitoring 5 reset detect flag (RSTSR0.PVD5RF)	✓	✓	✓	—	—	—	—	—	—
Software reset detect flag (RSTSR1.SWRF)	✓	✓	✓	✓	✓	✓	✓	—	—
Bus error reset detect flag (RSTSR1.BUSRF)	✓	✓	✓	✓	✓	✓	✓	—	—
Common memory error reset detect flag (RSTSR1.CMRF)	✓	✓	✓	✓	✓	✓	✓	—	—
Local memory error reset detect flag (RSTSR1.LM0RF)	✓	✓	✓	✓	✓	✓	✓	—	—
Deep software standby reset detect flag (RSTSR0.DPSRSTF)	✓	✓	✓	✓	✓	✓	✓	—	—
Cold start/warm start determination flag (RSTSR2.CWSF)	—	✓	—	—	—	—	—	—	—
Voltage monitoring 0 reset detect flag (ROUTSR0.ROPVD0RF)	—	✓	—	—	—	—	—	—	—

System reset mask control registers	SYRSTMSK0, SYRSTMSK2	—	—	—	—	—	—	—	—	—
Power shut-off control registers	PDRAMSCR0, PDRAMSCR2	—	—	—	—	—	—	✓	✓	✓
Other than the above		✓	✓	✓	✓	✓	✓	✓	✓	✓

✓: Initialized to 0, —: Not changed

Note 1. Some control bits are initialized by any reset. For details on the target control bits, see section 30, Realtime Clock (RTCBb).
Note 2. Depends on the setting of DPSBYCR.IOKEEP.
Note 3. Only initialized by a backup area reset. For details, see section 12.3.2, Power-Down Detector.

The sub-clock oscillator and LOCO are selectable as the clock source for the RTC. Table 6.7 and Table 6.8 list the states of the sub-clock oscillator and LOCO when a reset occurs.

Table 6.7 States of Sub-Clock Oscillator when Reset Occurs

		Backup Area Reset	All Resets
Sub-clock oscillator	Enabled or disabled	Initialized to “disabled”	Maintains the state that was selected before a reset
	Driving ability	Initialized to the standard driving ability	

Table 6.8 States of LOCO when Reset Occurs

		Reset Source	
		Power-On Reset, Voltage Monitoring 0/4/5 Reset, Core Voltage Monitoring Reset, Temperature Monitoring Reset, Deep Software Standby 2/3 Reset	Others
LOCO	Enabled or disabled	Initialized to “enabled”	
	Oscillation accuracy*1	Initialized (to the accuracy of ±15% before adjustment by the LOCOUTCR register)	Maintains the accuracy adjusted by the LOCOUTCR register

Note 1. Note that if the LOCO adjusted by the LOCOUTCR register is selected as the RTC clock source, the LOCO oscillation accuracy is initialized by a power-on reset, voltage monitoring 0/4/5 reset, core voltage monitoring reset, temperature monitoring reset, or deep software standby 2/3 reset.

On release from the reset state, reset exception handling will start. For the reset exception handling, see section 14, Exception Handling.
Table 6.9 lists the I/O pins related to the reset.

Table 6.9 I/O Pins Related to Reset

Pin Name	I/O	Function
RES# / RSTOUT#	I/O	Reset pin

6.2 Register Descriptions

6.2.1 Reset Security Attribute Register (RSTSAR)

Address(es): SYSC.RSTSAR 8701 93C4h, SYSC_NS.RSTSAR 0701 93C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	NONSEC5	—	NONSEC3	NONSEC2	NONSEC1	NONSEC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	NONSEC0	Non-Secure Attribute 0	Target registers: RSTSR0, ROUTSR0 0: Secure 1: Non-secure	R/W
b1	NONSEC1	Non-Secure Attribute 1	Target registers: RSTSR1, ROUTSR1 0: Secure 1: Non-secure	R/W
b2	NONSEC2	Non-Secure Attribute 2	Target register: RSTSR2 0: Secure 1: Non-secure	R/W
b3	NONSEC3	Non-Secure Attribute 3	Target registers: RSTSR3, ROUTSR2 0: Secure 1: Non-secure	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	NONSEC5	Non-Secure Attribute 5	Target register: SWRR 0: Secure 1: Non-secure	R/W
b31 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is only writable from the secure world. An attempt at writing to it from the non-secure world will be ignored, but does not cause a protect zone access error. The register can be read from either world.

NONSEC0 Bit (Non-Secure Attribute 0)

This bit controls the security attribute of the RSTSR0 and ROUTSR0 registers.

NONSEC1 Bit (Non-Secure Attribute 1)

This bit controls the security attribute of the RSTSR1 and ROUTSR1 registers.

NONSEC2 Bit (Non-Secure Attribute 2)

This bit controls the security attribute of the RSTSR2 register.

NONSEC3 Bit (Non-Secure Attribute 3)

This bit controls the security attribute of the RSTSR3 and ROUTSR2 registers.

NONSEC5 Bit (Non-Secure Attribute 5)

This bit controls the security attribute of the SWRR register.

6.2.2 Reset Status Register 0 (RSTSR0)

Address(es): SYSC.RSTSR0 8701 9A40h, SYSC_NS.RSTSR0 0701 9A40h

	b7	b6	b5	b4	b3	b2	b1	b0
	DPSRSTF	PVD5RF	PVD4RF	—	PVD2RF	PVD1RF	PVD0RF	PORF
Value after reset:	x*1	x*1	x*1	0	x*1	x*1	x*1	x*1

Bit	Symbol	Bit Name	Description	R/W
b0	PORF	Power-On Reset Detect Flag	0: Power-on reset not detected 1: Power-on reset detected	R/W*2
b1	PVD0RF	Voltage Monitoring 0 Reset Detect Flag	0: Voltage monitoring 0 reset not detected 1: Voltage monitoring 0 reset detected	R/W*2
b2	PVD1RF	Voltage Monitoring 1 Reset Detect Flag	0: Voltage monitoring 1 reset not detected 1: Voltage monitoring 1 reset detected	R/W*2
b3	PVD2RF	Voltage Monitoring 2 Reset Detect Flag	0: Voltage monitoring 2 reset not detected 1: Voltage monitoring 2 reset detected	R/W*2
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	PVD4RF	Voltage Monitoring 4 Reset Detect Flag	0: Voltage monitoring 4 reset not detected 1: Voltage monitoring 4 reset detected	R/W*2
b6	PVD5RF	Voltage Monitoring 5 Reset Detect Flag	0: Voltage monitoring 5 reset not detected 1: Voltage monitoring 5 reset detected	R/W*2
b7	DPSRSTF	Deep Software Standby Reset Detect Flag	0: Request for release from deep software standby mode by an interrupt or reset*3 not generated 1: Request for release from deep software standby mode by an interrupt or reset*3 generated	R/W*2

Note: If this register is allocated to the secure world, it is only accessible from the secure world. In this case, an attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.
If this register is allocated to the non-secure world, it is only accessible from the non-secure world. In this case, an attempt at access to it from the secure world will be ignored, and will cause a protect zone access error.
Note 1. The value after reset depends on the source of the reset.
Note 2. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 to it after reading 1.
Note 3. Independent watchdog timer reset, voltage monitoring 1 reset, or voltage monitoring 2 reset

If the reset output function is enabled by OFS, read b1 to b6 of the ROUTSR0 register instead of b1 to b6 of the RSTSR0 register to identify the source of the reset.

PORF Flag (Power-On Reset Detect Flag)

The PORF flag indicates that a power-on reset has occurred.

[Setting condition]

- When a power-on reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the PORF flag after it was read as 1

PVD0RF Flag (Voltage Monitoring 0 Reset Detect Flag)

The PVD0RF flag indicates that a voltage monitoring 0 reset has occurred.

[Setting condition]

- When a voltage monitoring 0 reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the PVD0RF flag after it was read as 1

PVD1RF Flag (Voltage Monitoring 1 Reset Detect Flag)

The PVD1RF flag indicates that a voltage monitoring 1 reset has occurred.

[Setting condition]

- When a voltage monitoring 1 reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the PVD1RF flag after it was read as 1

PVD2RF Flag (Voltage Monitoring 2 Reset Detect Flag)

The PVD2RF flag indicates that a voltage monitoring 2 reset has occurred.

[Setting condition]

- When a voltage monitoring 2 reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the PVD2RF flag after it was read as 1

PVD4RF Flag (Voltage Monitoring 4 Reset Detect Flag)

The PVD4RF flag indicates that a voltage monitoring 4 reset has occurred.

[Setting condition]

- When a voltage monitoring 4 reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the PVD4RF flag after it was read as 1

PVD5RF Flag (Voltage Monitoring 5 Reset Detect Flag)

The PVD5RF flag indicates that a voltage monitoring 5 reset has occurred.

[Setting condition]

- When a voltage monitoring 5 reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the PVD5RF flag after it was read as 1

DPSRSTF Flag (Deep Software Standby Reset Detect Flag)

The DPSRSTF flag indicates that deep software standby mode has been released by an external or internal interrupt, and that an internal reset (deep software standby reset) has occurred at the time of exception generation from deep software standby mode.

[Setting condition]

- When deep software standby mode is released by an external or an internal interrupt. For details, see section 11, Low Power Consumption.

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the DPSRSTF flag after it was read as 1

6.2.3 Reset Status Register 1 (RSTSR1)

Address(es): SYSC.RSTSR1 8701 90C0h, SYSC_NS.RSTSR1 0701 90C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	CMRF	—	—	—	BUSRF	—	—	—	—	LM0RF	—	—	SWRF	WDT0RF	IWDTRF
Value after reset:	0	x*1	0	0	0	x*1	0	0	0	0	x*1	0	0	x*1	x*1	x*1

Bit	Symbol	Bit Name	Description	R/W
b0	IWDTRF	Independent Watchdog Timer Reset Detect Flag	0: Independent watchdog timer reset not detected 1: Independent watchdog timer reset detected	R/W*2
b1	WDT0RF	Watchdog Timer Reset Detect Flag	0: Watchdog timer reset not detected 1: Watchdog timer reset detected	R/W*2
b2	SWRF	Software Reset Detect Flag	0: Software reset not detected 1: Software reset detected	R/W*2
b4, b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	LM0RF	Local Memory Error Reset Detect Flag	0: Local memory error reset not detected 1: Local memory error reset detected	R/W*2
b9 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b10	BUSRF	Bus Error Reset Detect Flag	0: Bus error reset not detected 1: Bus error reset detected	R/W*2
b13 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	CMRF	Common Memory Error Reset Detect Flag	0: Common memory error reset not detected 1: Common memory error reset detected	R/W*2
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: If this register is allocated to the secure world, it is only accessible from the secure world. In this case, an attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.
If this register is allocated to the non-secure world, it is only accessible from the non-secure world. In this case, an attempt at access to it from the secure world will be ignored, and will cause a protect zone access error.
Note 1. The value after reset depends on the source of the reset.
Note 2. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 to it after reading 1.

If the reset output function is enabled by OFS, read the ROUTSR1 register instead of the RSTSR1 register to identify the source of the reset.

IWDTRF Flag (Independent Watchdog Timer Reset Detect Flag)

The IWDTRF flag indicates that an independent watchdog timer reset has occurred.
[Setting condition]

- When an independent watchdog timer reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the IWDTRF flag after it was read as 1

WDT0RF Flag (Watchdog Timer Reset Detect Flag)

The WDT0RF flag indicates that a watchdog timer reset has occurred.
[Setting condition]

- When a watchdog timer reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the WDT0RF flag after it was read as 1

SWRF Flag (Software Reset Detect Flag)

The SWRF flag indicates that a software reset has occurred.
[Setting condition]

- When a software reset occurs.

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the SWRF flag after it was read as 1

LM0RF Flag (Local Memory Error Reset Detect Flag)

The LM0RF flag indicates that a local memory error reset (ECC error in the CPU cache or local RAM) has occurred.
[Setting condition]

- When a local memory error reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the LM0RF flag after it was read as 1

BUSRF Flag (Bus Error Reset Detect Flag)

The BUSRF flag indicates that a bus error reset (master security attribute unit error, master MPU error, illegal address error, protect zone filter error, slave bus error, or bufferable write error) has occurred.
[Setting condition]

- When a bus error reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the BUSRF flag after it was read as 1

CMRF Flag (Common Memory Error Reset Detect Flag)

The CMRF flag indicates that a common memory error reset (ECC error in the SRAM) has occurred.
[Setting condition]

- When a common memory error reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the CMRF flag after it was read as 1

6.2.4 Reset Status Register 2 (RSTSR2)

Address(es): SYSC.RSTSR2 8701 9A44h, SYSC_NS.RSTSR2 0701 9A44h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CWSF
Value after reset:	0	0	0	0	0	0	0	x*1

Bit	Symbol	Bit Name	Description	R/W
b0	CWSF	Cold/Warm Start Determination Flag	0: Cold start 1: Warm start	R/W*2
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: If this register is allocated to the secure world, it is only accessible from the secure world. In this case, an attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.
If this register is allocated to the non-secure world, it is only accessible from the non-secure world. In this case, an attempt at access to it from the secure world will be ignored, and will cause a protect zone access error.
Note 1. The value after reset depends on the source of the reset.
Note 2. Only 1 can be written to clear the flag.

The RSTSR2 register determines whether a power-on reset has caused the reset processing (cold start) or the reset signal being input during operation has caused the reset processing (warm start).

CWSF Flag (Cold/Warm Start Determination Flag)

The CWSF flag indicates the type of reset processing (cold start or warm start). The CWSF flag is initialized by a power-on reset. It is not initialized by a RES# pin reset.

[Setting condition]

- When 1 is written by software. Writing 0 to the CWSF flag does not clear it to 0.

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs

6.2.5 Reset Status Register 3 (RSTSR3)

Address(es): SYSC.RSTSR3 8701 9A48h, SYSC_NS.RSTSR3 0701 9A48h

	b7	b6	b5	b4	b3	b2	b1	b0
	TEMPRF	—	—	—	—	—	—	CVMRF
Value after reset:	x*1	0	0	0	0	0	0	x*1

Bit	Symbol	Bit Name	Description	R/W
b0	CVMRF	Core Voltage Monitoring Reset Detect Flag	0: Core voltage monitoring reset not detected 1: Core voltage monitoring reset detected	R/W*2
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TEMPRF	Temperature Monitoring Reset Detect Flag	0: Temperature monitoring reset not detected 1: Temperature monitoring reset detected	R/W*2

Note: If this register is allocated to the secure world, it is only accessible from the secure world. In this case, an attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.
If this register is allocated to the non-secure world, it is only accessible from the non-secure world. In this case, an attempt at access to it from the secure world will be ignored, and will cause a protect zone access error.
Note 1. The value after reset depends on the source of the reset.
Note 2. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 to it after reading 1.

If the reset output function is enabled by OFS, read the ROUTSR2 register instead of the RSTSR3 register to identify the source of the reset.

CVMRF Flag (Core Voltage Monitoring Reset Detect Flag)

The CVMRF flag indicates that a core voltage monitoring reset has occurred.
[Setting condition]

- When a core voltage monitoring reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the CVMRF flag after it was read as 1

TEMPRF Flag (Temperature Monitoring Reset Detect Flag)

The TEMPRF flag indicates that a temperature monitoring reset has occurred.
[Setting condition]

- When a temperature monitoring reset occurs

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the TEMPRF flag after it was read as 1

6.2.6 System Reset Mask Control Register 0 (SYRSTMSK0)

Address(es): SYSC.SYRSTMSK0 8701 9AD0h

	b7	b6	b5	b4	b3	b2	b1	b0
	BUSMASK	CMMASK	LM0MASK	—	—	SWMASK	WDT0MASK	IWDTMASK
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IWDTMASK	Independent Watchdog Timer Reset Mask	0: Reset generation enabled 1: Reset generation disabled	R/W
b1	WDT0MASK	Watchdog Timer Reset Mask	0: Reset generation enabled 1: Reset generation disabled	R/W
b2	SWMASK	Software Reset Mask	0: Reset generation enabled 1: Reset generation disabled	R/W
b4, b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	LM0MASK	Local Memory Error Reset Mask	0: Reset generation enabled 1: Reset generation disabled	R/W
b6	CMMASK	Common Memory Error Reset Mask	0: Reset generation enabled 1: Reset generation disabled	R/W
b7	BUSMASK	Bus Error Reset Mask	0: Reset generation enabled 1: Reset generation disabled	R/W

Note: This register is only accessible from the secure world. An attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.
Note: Set the PRCR_S.PRC5 bit to 1 (enabling writing) before changing the value of this register.

The SYRSTMSK0 register controls generation of a reset.
The value of the IWDTMASK bit cannot be changed while the independent watchdog timer is operating. The value of the WDT0MASK bit cannot be changed while the watchdog timer is operating.

6.2.7 System Reset Mask Control Register 2 (SYRSTMSK2)

Address(es): SYSC.SYRSTMSK2 8701 9AD8h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PVD2MASK	PVD1MASK
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PVD1MASK	Voltage Monitoring 1 Reset Mask	0: Reset generation enabled 1: Reset generation disabled	R/W
b1	PVD2MASK	Voltage Monitoring 2 Reset Mask	0: Reset generation enabled 1: Reset generation disabled	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is only accessible from the secure world. An attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.

Note: Set the PRCR_S.PRC5 bit to 1 (enabling writing) before changing the value of this register.

The SYRSTMSK2 register controls generation of a reset.

6.2.8 Temperature Monitoring Reset Control Register (TEMPRCR)

Address(es): SYSC.TEMPRCR 8701 9ADCh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	TSNKEEP	CMPEN	TSNEN	TEMPREN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TEMPREN	Temperature Monitoring Reset Enable	This bit selects enabling or disabling in combination with the TSNKEEP bit. TSNKEEP TEMPREN 0 0: Temperature monitoring reset disabled 0 1: Setting prohibited 1 0: Setting prohibited 1 1: Temperature monitoring reset enabled	R/W
b1	TSNEN	Temperature Sensor Enable	0: Temperature sensor disabled 1: Temperature sensor enabled	R/W
b2	CMPEN	Comparator Enable	0: Comparator disabled 1: Comparator enabled	R/W
b3	TSNKEEP	Temperature Sensor Setting	This bit selects enabling or disabling in combination with the TEMPREN bit. For details of the function, see the description of the TEMPREN bit.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is only accessible from the secure world. An attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.

Note: Set the PRCR_S.PRC5 bit to 1 (enabling writing) before changing the value of this register.

6.2.9 Temperature Monitoring Reset Lock Register (TEMPRLR)

Address(es): SYSC.TEMPRLR 8701 9AE0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	LOCK
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	LOCK	Temperature Monitoring Reset Control Register Lock	0: The TEMPRCR register can be written. 1: The TEMPRCR register cannot be written.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is only accessible from the secure world. An attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.
Note: Set the PRCR_S.PRC5 bit to 1 (enabling writing) before changing the value of this register.
Note: This register only accepts write access twice following a reset. If you need to write to the TEMPRLR register three or more times, reset the device before writing to the register again.

6.2.10 Reset Output Status Register 0 (ROUTSR0)

Address(es): SYSC.ROUTSR0 8701 9B78h, SYSC_NS.ROUTSR0 0701 9B78h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	ROPVD5RF	ROPVD4RF	—	ROPVD2RF	ROPVD1RF	ROPVD0RF	—
Value after reset:	0	x*1	x*1	0	x*1	x*1	x*1	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	ROPVD0RF	Voltage Monitoring 0 Reset Detect Flag	0: Voltage monitoring 0 reset not detected 1: Voltage monitoring 0 reset detected	R/W*2
b2	ROPVD1RF	Voltage Monitoring 1 Reset Detect Flag	0: Voltage monitoring 1 reset not detected 1: Voltage monitoring 1 reset detected	R/W*2
b3	ROPVD2RF	Voltage Monitoring 2 Reset Detect Flag	0: Voltage monitoring 2 reset not detected 1: Voltage monitoring 2 reset detected	R/W*2
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	ROPVD4RF	Voltage Monitoring 4 Reset Detect Flag	0: Voltage monitoring 4 reset not detected 1: Voltage monitoring 4 reset detected	R/W*2
b6	ROPVD5RF	Voltage Monitoring 5 Reset Detect Flag	0: Voltage monitoring 5 reset not detected 1: Voltage monitoring 5 reset detected	R/W*2
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note: If this register is allocated to the secure world, it is only accessible from the secure world. In this case, an attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.
If this register is allocated to the non-secure world, it is only accessible from the non-secure world. In this case, an attempt at access to it from the secure world will be ignored, and will cause a protect zone access error.
Note 1. The value after reset depends on the source of the reset.
Note 2. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 to it after reading 1.

If the reset output function is enabled by OFS, read the RSTSR0 register instead of the ROUTSR0 register to identify the source of the reset.

ROPVD0RF Flag (Voltage Monitoring 0 Reset Detect Flag)

The ROPVD0RF flag indicates that a voltage monitoring 0 reset has occurred.
[Setting condition]

- When a voltage monitoring 0 reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROPVD0RF flag after it was read as 1

ROPVD1RF Flag (Voltage Monitoring 1 Reset Detect Flag)

The ROPVD1RF flag indicates that a voltage monitoring 1 reset has occurred.
[Setting condition]

- When a voltage monitoring 1 reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROPVD1RF flag after it was read as 1

ROPVD2RF Flag (Voltage Monitoring 2 Reset Detect Flag)

The ROPVD2RF flag indicates that a voltage monitoring 2 reset has occurred.
[Setting condition]

- When a voltage monitoring 2 reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROPVD2RF flag after it was read as 1

ROPVD4RF Flag (Voltage Monitoring 4 Reset Detect Flag)

The ROPVD4RF flag indicates that a voltage monitoring 4 reset has occurred.
[Setting condition]

- When a voltage monitoring 4 reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROPVD4RF flag after it was read as 1

ROPVD5RF Flag (Voltage Monitoring 5 Reset Detect Flag)

The ROPVD5RF flag indicates that a voltage monitoring 5 reset has occurred.
[Setting condition]

- When a voltage monitoring 5 reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROPVD5RF flag after it was read as 1

6.2.11 Reset Output Status Register 1 (ROUTSR1)

Address(es): SYSC.ROUTSR1 8701 9B7Ch, SYSC_NS.ROUTSR1 0701 9B7Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	ROCMRF	—	—	—	ROBUSRF	—	—	—	—	ROLM0RF	—	—	ROSWRF	ROWDT0RF	ROIWDTRF
Value after reset:	0	x*1	0	0	0	x*1	0	0	0	0	x*1	0	0	x*1	x*1	x*1

Bit	Symbol	Bit Name	Description	R/W
b0	ROIWDTRF	Independent Watchdog Timer Reset Detect Flag	0: Independent watchdog timer reset not detected 1: Independent watchdog timer reset detected	R/W*2
b1	ROWDT0RF	Watchdog Timer Reset Detect Flag	0: Watchdog timer reset not detected 1: Watchdog timer reset detected	R/W*2
b2	ROSWRF	Software Reset Detect Flag	0: Software reset not detected 1: Software reset detected	R/W*2
b4, b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	ROLM0RF	Local Memory Error Reset Detect Flag	0: Local memory error reset not detected 1: Local memory error reset detected	R/W*2
b9 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b10	ROBUSRF	Bus Error Reset Detect Flag	0: Bus error reset not detected 1: Bus error reset detected	R/W*2
b13 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	ROCMRF	Common Memory Error Reset Detect Flag	0: Common memory error reset not detected 1: Common memory error reset detected	R/W*2
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: If this register is allocated to the secure world, it is only accessible from the secure world. In this case, an attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.
If this register is allocated to the non-secure world, it is only accessible from the non-secure world. In this case, an attempt at access to it from the secure world will be ignored, and will cause a protect zone access error.

Note 1. The value after reset depends on the source of the reset.

Note 2. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 to it after reading 1.

If the reset output function is enabled by OFS, read the RSTSR1 register instead of the ROUTSR1 register to identify the source of the reset.

ROIWDTRF Flag (Independent Watchdog Timer Reset Detect Flag)

The ROIWDTRF flag indicates that an independent watchdog timer reset has occurred.

[Setting condition]

- When an independent watchdog timer reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROIWDTRF flag after it was read as 1

ROWDT0RF Flag (Watchdog Timer Reset Detect Flag)

The ROWDT0RF flag indicates that a watchdog timer reset has occurred.
[Setting condition]

- When a watchdog timer reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROWDT0RF flag after it was read as 1

ROSWRF Flag (Software Reset Detect Flag)

The ROSWRF flag indicates that a software reset has occurred.
[Setting condition]

- When a software reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROSWRF flag after it was read as 1

ROLM0RF Flag (Local Memory Error Reset Detect Flag)

The ROLM0RF flag indicates that a local memory error reset (ECC error in the CPU cache or local RAM) has occurred.
[Setting condition]

- When a local memory error reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROLM0RF flag after it was read as 1

ROBUSRF Flag (Bus Error Reset Detect Flag)

The ROBUSRF flag indicates that a bus error reset (master security attribute unit error, master MPU error, illegal address error, protect zone filter error, slave bus error, or bufferable write error) has occurred.
[Setting condition]

- When a bus error reset occurs while the reset output function is enabled (OFS1.RODIS = 0).

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROBUSRF flag after it was read as 1

ROCMRF Flag (Common Memory Error Reset Detect Flag)

The ROCMRF flag indicates that a common memory error reset (ECC error in the SRAM) has occurred.
[Setting condition]

- When a common memory error reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROCMRF flag after it was read as 1

6.2.12 Reset Output Status Register 2 (ROUTSR2)

Address(es): SYSC.ROUTSR2 8701 9B80h, SYSC_NS.ROUTSR2 0701 9B80h

	b7	b6	b5	b4	b3	b2	b1	b0
	ROTEMPRF	—	—	—	—	—	—	ROCVMRF
Value after reset:	x*1	0	0	0	0	0	0	x*1

Bit	Symbol	Bit Name	Description	R/W
b0	ROCVMRF	Core Voltage Monitoring Reset Detect Flag	0: Core voltage monitoring reset not detected 1: Core voltage monitoring reset detected	R/W*2
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	ROTEMPRF	Temperature Monitoring Reset Detect Flag	0: Temperature monitoring reset not detected 1: Temperature monitoring reset detected	R/W*2

Note: If this register is allocated to the secure world, it is only accessible from the secure world. In this case, an attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.
If this register is allocated to the non-secure world, it is only accessible from the non-secure world. In this case, an attempt at access to it from the secure world will be ignored, and will cause a protect zone access error.
Note 1. The value after reset depends on the source of the reset.
Note 2. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 to it after reading 1.

If the reset output function is enabled by OFS, read the RSTSR3 register instead of the ROUTSR2 register to identify the source of the reset.

ROCVMRF Flag (Core Voltage Monitoring Reset Detect Flag)

The ROCVMRF flag indicates that a core voltage monitoring reset has occurred.
[Setting condition]

- When a core voltage monitoring reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROCVMRF flag after it was read as 1

ROTEMPRF Flag (Temperature Monitoring Reset Detect Flag)

The ROTEMPRF flag indicates that a temperature monitoring reset has occurred.
[Setting condition]

- When a temperature monitoring reset occurs while the reset output function is enabled (OFS1.RODIS = 0)

[Clearing conditions]

- When a reset listed in Table 6.3 and Table 6.4 occurs
- When 0 is written to the ROTEMPRF flag after it was read as 1

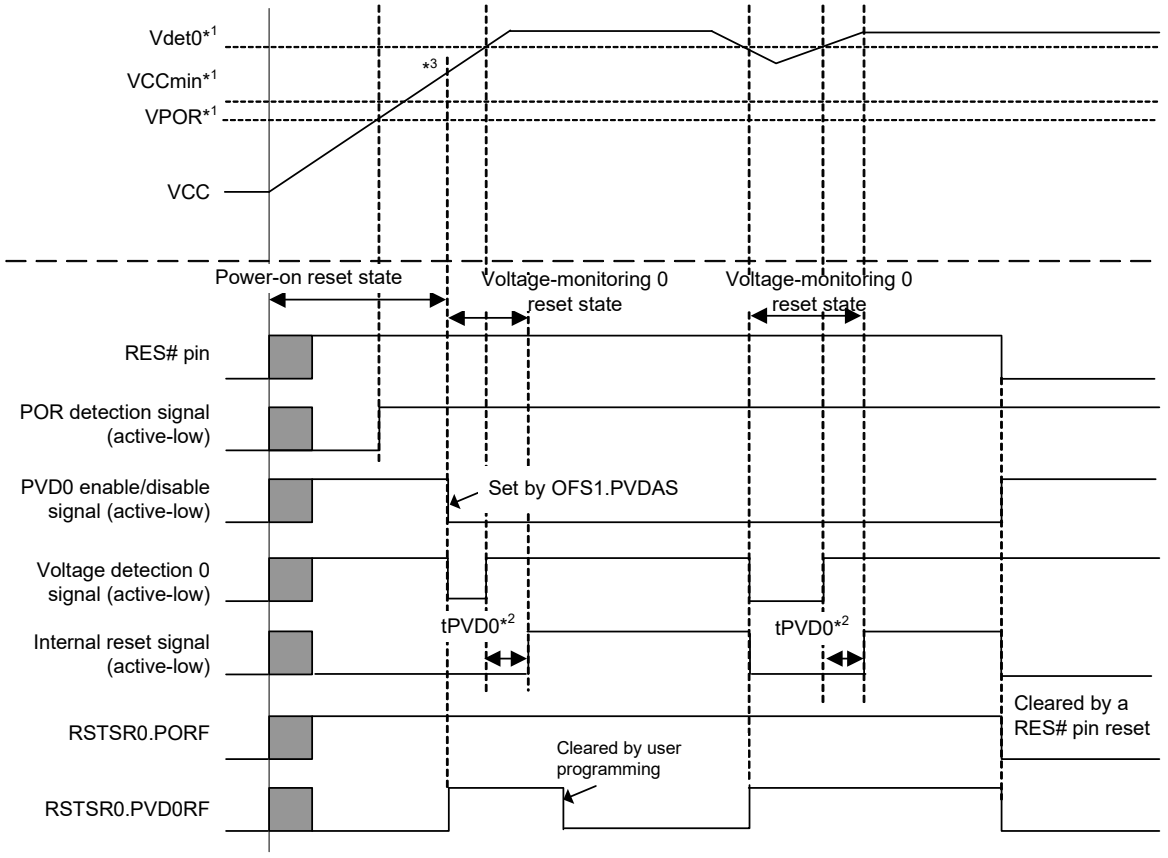
6.2.13 Software Reset Register (SWRR)

Address(es): SYSC.SWRR 8701 90B0h, SYSC_NS.SWRR 0701 90B0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SWRR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	SWRR[15:0]	Software Reset	Writing A501h to these bits resets the MCU. When read, they are read as 0000h.	R/W

Note: If this register is allocated to the secure world, it is only accessible from the secure world. In this case, an attempt at access to it from the non-secure world will be ignored, and will cause a protect zone access error.
If this register is allocated to the non-secure world, it is only accessible from the non-secure world. In this case, an attempt at access to it from the secure world will be ignored, and will cause a protect zone access error.



6.3 Operation

6.3.1 RES# Pin Reset

This is a reset generated by the RES# pin. When the RES# pin is driven to the low level, all the processing in progress is aborted and the MCU enters a reset state. In order to unfailingly reset the MCU, the RES# pin should be held low for the specified power supply stabilization time at power-on.
After the RES# pin is driven to the high from the low level, the device is released from the internal reset state after the wait time following RES# de-assertion (tRESWT) has elapsed, and the CPU starts reset exception handling.
For details, see section 67, Electrical Characteristics.

6.3.2 Power-On Reset and Voltage Monitoring 0 Reset

A power-on reset is an internal reset generated by the power-on reset circuit. If the RES# pin is at the high level when power is supplied, a power-on reset is generated.
When VCC exceeds VPOR, the device is released from the internal reset state after the specified period (power-on reset time) has elapsed, and the CPU starts reset exception handling. The power-on reset time is a period for stabilization of power supply and stable operation of the MCU.
When a power-on reset occurs, the RSTSR0.PORF flag is set to 1. The PORF flag is initialized by a RES# pin reset.
Power-on resets are generated by two types of voltage detection circuit, respectively referred to as power-on reset circuits 1 and 2 (POR1 and POR2). The VCC ramp-up rate after power is supplied determines the timing of release from a power-on reset. Specifically, if VCC rises slowly following the supply of power, POR1 determines the timing of release from the power-on reset state. On the other hand, if VCC rises rapidly, POR2 is the determinant. See Figure 67.138, Power-on Reset Timing in section 67, Electrical Characteristics, for details.
A voltage monitoring 0 reset is an internal reset generated by the voltage monitoring circuit. If the voltage detection 0 circuit start bit (PVDAS) of option function select register 1 (OFS1) is 0 (enabling the voltage monitoring 0 reset after a reset) and VCC falls to or below Vdet0, the RSTSR0.PVD0RF flag becomes 1 and the voltage detection circuit generates a voltage monitoring 0 reset. When a voltage monitoring 0 reset is to be used, set the OFS1.PVDAS bit to 0.
When VCC exceeds Vdet0, the device is released from the internal reset state after the voltage monitoring 0 reset time (tPVD0) has elapsed, and the CPU starts reset exception handling. The voltage detection level for Vdet0 can be changed by the setting of the VDSEL[2:0] bits in option function select register 1 (OFS1).
Figure 6.1 shows an example of the operation of the power-on reset and voltage monitoring 0 reset.
For details on the voltage monitoring 0 reset, see section 8, Programmable Voltage Detection Circuit (PVD).

Note . For details on the electrical characteristics, see section 67, Electrical Characteristics.
Note 1. Vdet0 is the detection level for the voltage monitoring 0 reset, VPOR is the detection level for the power-on reset, and VCCmin is the minimum guaranteed voltage of the MCU.
Note 2. tPVD0 is the period of the voltage monitoring 0 reset.
Note 3. At power-on, VCC should rise to or above the minimum guaranteed voltage before release from the power-on reset state.

Figure 6.1 Example of Operation at the Time of Power-On Reset and Voltage Monitoring 0 Reset

6.3.3 Voltage Monitoring 1, 2, 4 and 5 Resets

These are internal resets generated by the voltage monitoring circuit.

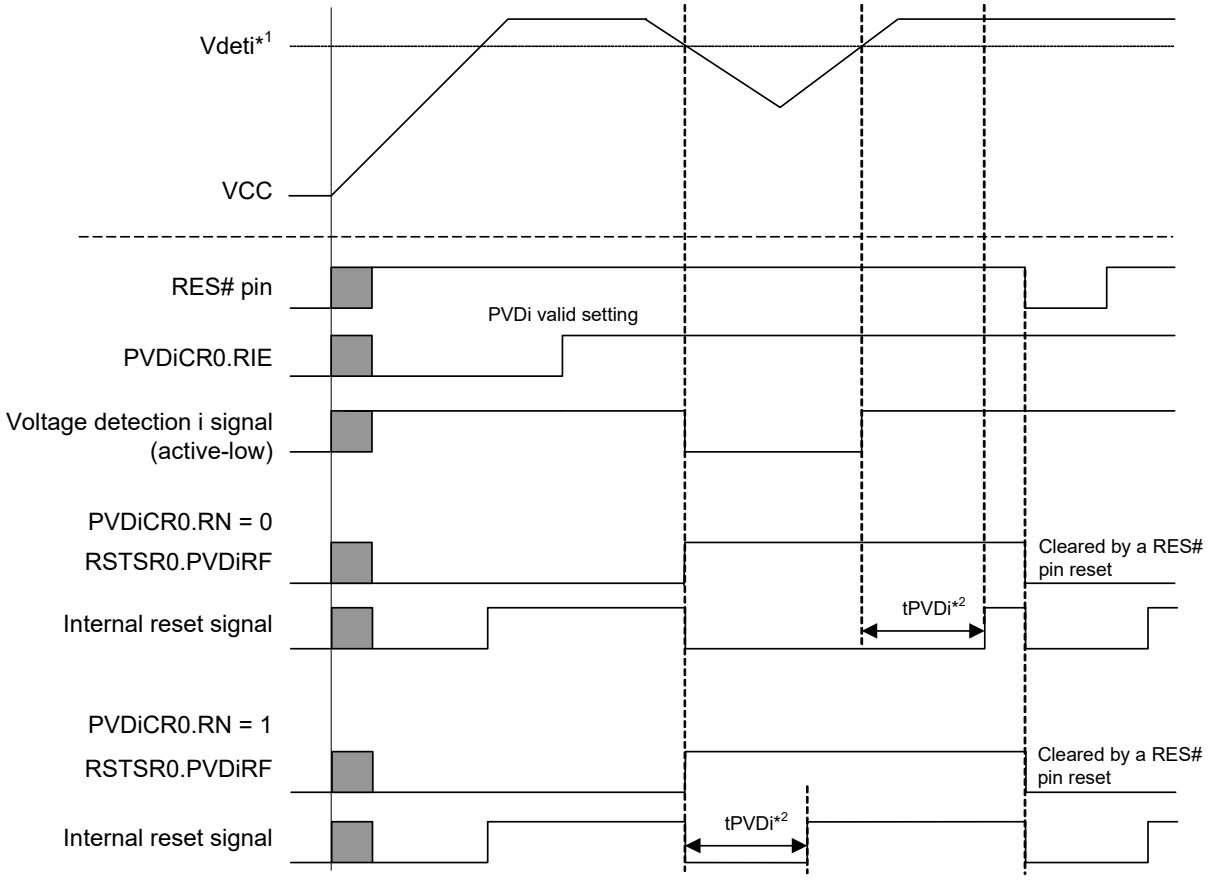
(1) When PVDiFCR.RHSEL = 0 and PVDjFCR.RHSEL = 0 (i = 1, 2; j = 4, 5)

If VCC falls to or below Vdet1 while the voltage monitoring 1 interrupt/reset enable bit (RIE) of voltage monitoring 1 circuit control register 0 (PVD1CR0) is 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the voltage monitoring 1 circuit mode select bit (RI) is 1 (selecting generation of a reset in response to detection of a low voltage), the RSTSR0.PVD1RF flag is set to 1 and the voltage detection circuit generates a voltage monitoring 1 reset. Likewise, if VCC falls to or below Vdet2 while the voltage monitoring 2 interrupt/reset enable bit (RIE) of voltage monitoring 2 circuit control register 0 (PVD2CR0) is 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the voltage monitoring 2 circuit mode select bit (RI) is 1 (selecting generation of a reset in response to detection of a low voltage), the RSTSR0.PVD2RF flag is set to 1 and the voltage detection circuit generates a voltage monitoring 2 reset.

The timing of release from the voltage monitoring 1 reset state is selectable by using the voltage monitoring 1 reset negate select bit (RN) of the PVD1CR0 register. When the PVD1CR0.RN bit is 0, the device is released from the internal reset state following the voltage monitoring 1 reset time (tPVD1) having elapsed after VCC has fallen to or below Vdet1 and then exceeded Vdet1, and the CPU starts reset exception handling.

When the PVD1CR0.RN bit is 1, the device is released from the internal reset state following the voltage monitoring 1 reset time (tPVD1) having elapsed after VCC has fallen to or below Vdet1, and the CPU starts reset exception handling. Likewise, the timing of release from the voltage monitoring 2 reset state is selectable by the setting of the voltage monitoring 2 reset negate select bit (RN) in the PVD2CR0 register.

If VCC falls to or below Vdet4 while the voltage monitoring 4 reset enable bit (RE) of voltage monitoring 4 circuit control register 0 (PVD4CR0) is 1 (enabling generation of a reset by the voltage detection circuit), the RSTSR0.PVD4RF flag is set to 1 and the voltage detection circuit generates a voltage monitoring 4 reset.



The device is released from the internal reset state following the voltage monitoring 1 reset time (tPVD4) having elapsed after VCC has fallen to or below Vdet4 and then exceeded Vdet4, and the CPU starts reset exception handling.

If VCC falls to or below Vdet5 while the voltage monitoring 5 reset enable bit (RE) of voltage monitoring 5 circuit control register 0 (PVD5CR0) is 1 (enabling generation of a reset by the voltage detection circuit), the RSTSR0.PVD5RF flag is set to 1 and the voltage detection circuit generates a voltage monitoring 5 reset.

The device is released from the internal reset state following the voltage monitoring 5 reset time (tPVD5) having elapsed after VCC has fallen to or below Vdet5 and then exceeded Vdet5, and the CPU starts reset exception handling.

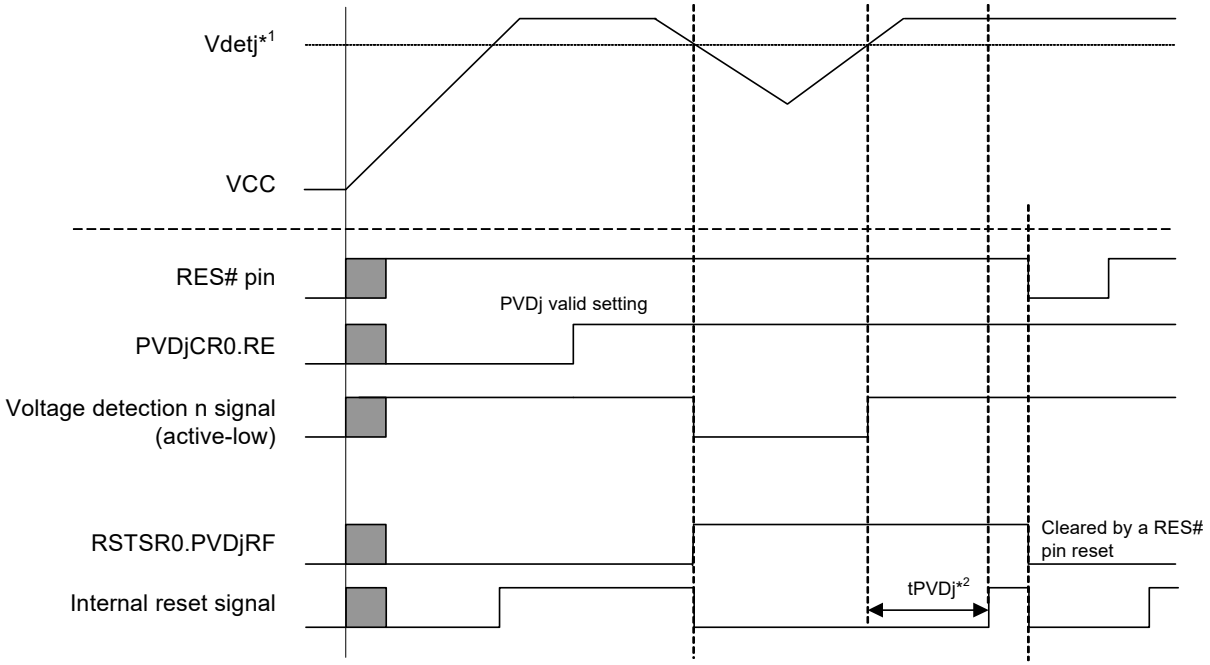


Figure 6.2 shows an example of the operation of the voltage monitoring 1 and 2 resets. Figure 6.3 shows an example of the operation of the voltage monitoring 4 and 5 resets.

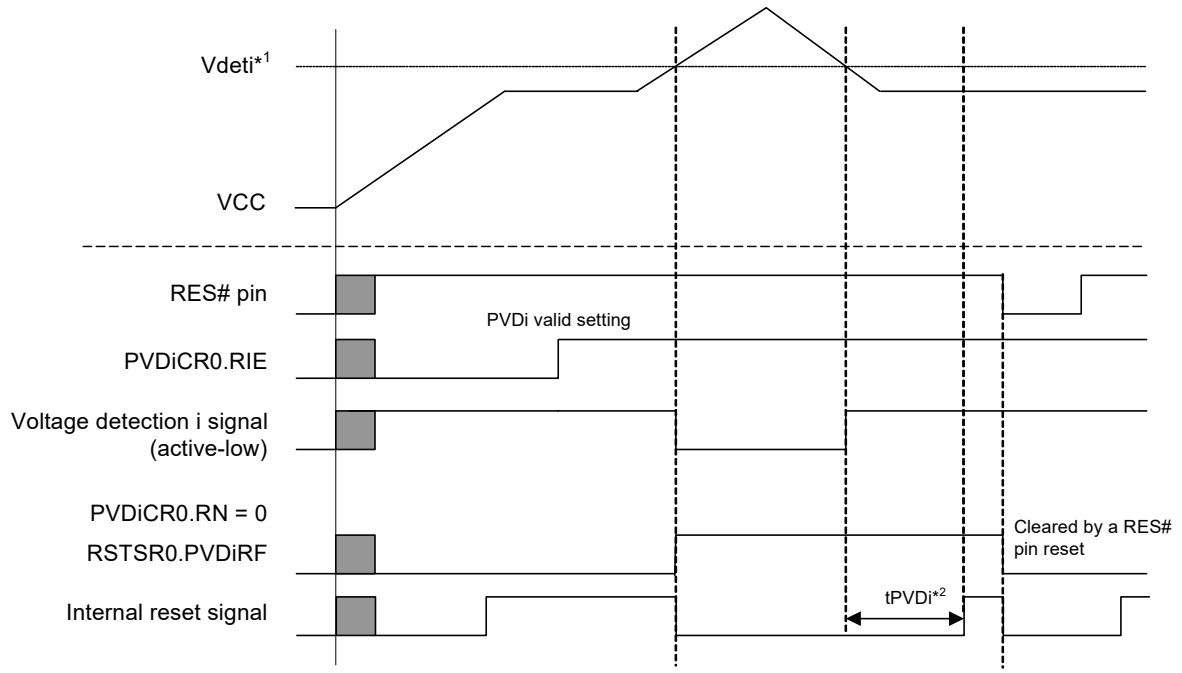
For details on the voltage monitoring 1, 2, 4, and 5 resets, see section 8, Programmable Voltage Detection Circuit (PVD).

Note . For details on the electrical characteristics, see section 67, Electrical Characteristics.
Note 1. Vdeti is the detection level for the voltage monitoring 1 or 2 reset. (i = 1, 2)
Note 2. tPVDi is the period of the voltage monitoring 1 or 2 reset. (i = 1, 2)

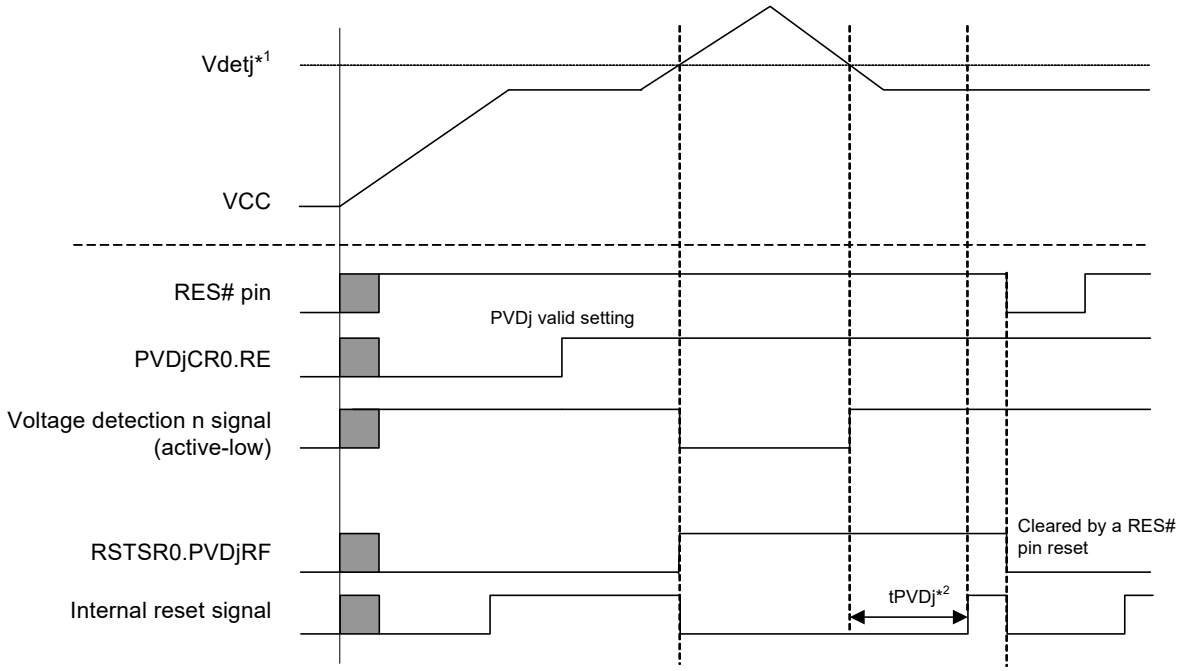
Figure 6.2 Example of Operation of Voltage Monitoring 1 and 2 Resets (RHSEL = 0)



Note . For details on the electrical characteristics, see section 67, Electrical Characteristics.
Note 1. Vdetj is the detection level for the voltage monitoring 4 or 5 reset. (j = 4, 5)
Note 2. tPVDj is the period of the voltage monitoring 4 or 5 reset. (j = 4, 5)

Figure 6.3 Example of Operation of Voltage Monitoring 4 and 5 Resets (RHSEL = 0)

(2) When PVDiFCR.RHSEL = 1 and PVDjFCR.RHSEL = 1 (i = 1, 2; j = 4, 5)

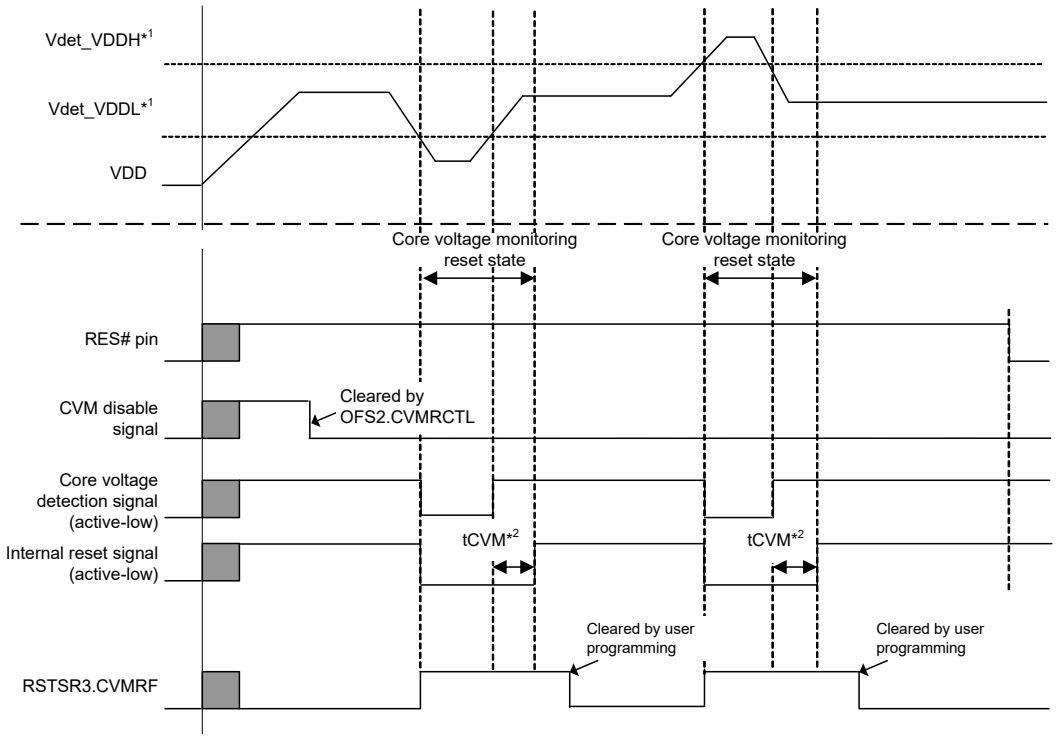


If VCC rises to or above Vdet1 while the voltage monitoring 1 interrupt/reset enable bit (RIE) of voltage monitoring 1 circuit control register 0 (PVD1CR0) is 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the voltage monitoring 1 circuit mode select bit (RI) is 1 (selecting generation of a reset in response to detection of a low voltage), the RSTSR0.PVD1RF flag is set to 1 and the voltage detection circuit generates a voltage monitoring 1 reset.
The device is released from the internal reset state following the voltage monitoring 1 reset time (tPVD1) having elapsed after VCC has risen to or above Vdet1 and then fallen below Vdet1, and the CPU starts reset exception handling.
If VCC rises to or above Vdet2 while the voltage monitoring 2 interrupt/reset enable bit (RIE) of voltage monitoring 2 circuit control register 0 (PVD2CR0) is 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the voltage monitoring 2 circuit mode select bit (RI) is 1 (selecting generation of a reset in response to detection of a low voltage), the RSTSR0.PVD2RF flag is set to 1 and the voltage detection circuit generates a voltage monitoring 2 reset.
The device is released from the internal reset state following the voltage monitoring 2 reset time (tPVD2) having elapsed after VCC has risen to or above Vdet2 and then fallen below Vdet2, and the CPU starts reset exception handling.
If VCC rises to or above Vdet4 while the voltage monitoring 4 reset enable bit (RE) of voltage monitoring 4 circuit control register 0 (PVD4CR0) is 1 (enabling generation of a reset by the voltage detection circuit), the RSTSR0.PVD4RF flag is set to 1 and the voltage detection circuit generates a voltage monitoring 4 reset.
The device is released from the internal reset state following the voltage monitoring 4 reset time (tPVD4) having elapsed after VCC has risen to or above Vdet4 and then fallen below Vdet4, and the CPU starts reset exception handling.
If VCC rises to or above Vdet5 while the voltage monitoring 5 reset enable bit (RE) of voltage monitoring 5 circuit control register 0 (PVD5CR0) is 1 (enabling generation of a reset by the voltage detection circuit), the RSTSR0.PVD5RF flag is set to 1 and the voltage detection circuit generates a voltage monitoring 5 reset.
The device is released from the internal reset state following the voltage monitoring 5 reset time (tPVD5) having elapsed after VCC has risen to or above Vdet5 and then fallen below Vdet5, and the CPU starts reset exception handling.

Figure 6.4 shows an example of the operation of the voltage monitoring 1 and 2 resets. Figure 6.5 shows an example of the operation of the voltage monitoring 4 and 5 resets.

Note . For details on the electrical characteristics, see section 67, Electrical Characteristics.
Note 1. Vdeti is the detection level for the voltage monitoring 1 or 2 reset. (i = 1, 2)
Note 2. tPVDi is the period of the voltage monitoring 1 or 2 reset. (i = 1, 2)

Figure 6.4 Example of Operation of Voltage Monitoring 1 and 2 Resets (RHSEL = 1)



Note . For details on the electrical characteristics, see section 67, Electrical Characteristics.
Note 1. Vdetj is the detection level for the voltage monitoring 4 or 5 reset. (j = 4, 5)
Note 2. tPVDj is the period of the voltage monitoring 4 or 5 reset. (j = 4, 5)

Figure 6.5 Example of Operation of Voltage Monitoring 4 and 5 Resets (RHSEL = 1)

6.3.4 Core Voltage Monitoring Reset

A core voltage monitoring reset is an internal reset generated by the core voltage monitoring circuit.
If VDD falls below Vdet_VDDL or exceeds Vdet_VDDH while the OFS2.CVMRCTL bit is 0 (enabling the core voltage monitoring reset after a reset), the RSTSR3.CVMRF flag is set to 1 and the core voltage detection circuit generates a core voltage monitoring reset.
After that, if VDD falls between Vdet_VDDL and Vdet_VDDH, the device is released from the internal reset state following the core voltage monitoring reset time (tCVM) having elapsed, and the CPU starts reset exception handling.
The core voltage monitoring reset function does not operate during deep software standby mode.
If the RES# pin reset signal is asserted while a core voltage monitoring reset is being issued, the core voltage monitoring reset is not negated.
If a core voltage monitoring reset occurs, the values of the IO registers, SRAM, and backup registers are not guaranteed; whether they are retained depends on the response time until generation of the reset.
Figure 6.6 shows an example of the operation of the core voltage monitoring reset.

Note 1. For details on the electrical characteristics, see section 67, Electrical Characteristics.
Note 2. tCVM is the period of the core voltage monitoring reset.

Figure 6.6 Example of Operation of Core Voltage Monitoring Reset

6.3.5 Deep Software Standby Reset

This is an internal reset generated on release from deep software standby mode by an interrupt.
When a trigger for release from deep software standby mode is generated, a deep software standby reset is generated. This then causes release from the deep software standby reset state after the recovery time following release from deep software standby mode (tDSBY) has elapsed. Release from deep software standby mode also proceeds at the same time.
After release from deep software standby mode, the device is released from the internal reset state after the wait time following release from deep software standby mode (tDSBYWT) has elapsed, and the CPU starts reset exception handling.
For details on the deep software standby reset, see section 11, Low Power Consumption.

6.3.6 Independent Watchdog Timer Reset

This is an internal reset generated by the independent watchdog timer.
Output of the independent watchdog timer reset from the independent watchdog timer can be selected by the setting of the IWDT reset control register (IWDTRCR) or option function select register 0 (OFS0).
When output of the independent watchdog timer reset is selected, an independent watchdog timer reset is generated if the independent watchdog timer underflows, or if data is written when refresh operation is disabled. After generation of an independent watchdog timer reset, the device is released from the internal reset state after the internal reset time (tRESW2) has elapsed, and the CPU starts reset exception handling.
For details on the independent watchdog timer reset, see section 32, Independent Watchdog Timer (IWDTa).

6.3.7 Watchdog Timer Reset

This is an internal reset generated by the watchdog timer.
Output of the watchdog timer reset from the watchdog timer can be selected by the setting of the WDT reset control register (WDTRCR) or option function select register 0 (OFS0).
When output of the watchdog timer reset is selected, a watchdog timer reset is generated if the watchdog timer underflows, or if data is written while refresh operation is disabled. After generation of a watchdog timer reset, the device is released from the internal reset state after the internal reset time (tRESW2) has elapsed, and the CPU starts reset exception handling.
For details on the watchdog timer reset, see section 31, Watchdog Timer (WDTA).

6.3.8 Software Reset

This is an internal reset generated by the software reset circuit.
When A501h is written to the SWRR register, a software reset is generated. After generation of a software reset, the device is released from the internal reset state after the internal reset time (tRESW2) has elapsed, and the CPU starts reset exception handling.

6.3.9 Bus Error Reset

This is an internal reset generated by buses.
It is a consolidated reset generated by buses and is configured of the following reset:

- Bus error reset (master security attribute unit error, master MPU error, Illegal address error, protect zone filter error, slave bus error, bufferable write error)

Output of the bus error reset can be selected by the MSAOAD.OAD, MMPUOAD.OAD, BUSOAD.ILERROAD, BUSOAD.SLERROAD, or BUSOAD.BWERROAD bit.
After generation of a bus error reset, the device is released from the internal reset state after the internal reset time (tRESW2) has elapsed, and the CPU starts reset exception handling.
For details on the bus error reset, see section 16, Buses. Determination of a bus error as the source of reset generation is similar to determination of a bus error as the source of interrupt generation. See section 15, Interrupt Controller (ICUM).

6.3.10 Common Memory Error Reset

This is an internal reset generated by SRAMs.
It is a consolidated reset generated by SRAMs and is configured of the following reset:

- Common memory error reset (ECC error in the SRAM)

Output of the memory error reset (ECC error in the SRAM) can be selected by the SRAMCR0.OAD or SRAMCR1.OAD bit.
After generation of a common memory error reset, the device is released from the internal reset state after the internal reset time (tRESW2) has elapsed, and the CPU starts reset exception handling.
For details on the common memory error reset, see section 64, SRAM. Determination of a common memory error as the source of reset generation is similar to determination of a common memory error as the source of interrupt generation. See section 15, Interrupt Controller (ICUM).

6.3.11 Local Memory Error Reset

This is an internal reset generated by CPU caches or local RAMs.
It is a consolidated reset generated by CPU caches or local RAMs and is configured of the following reset:

- Local memory error reset (ECC error in the CPU cache or local RAM)

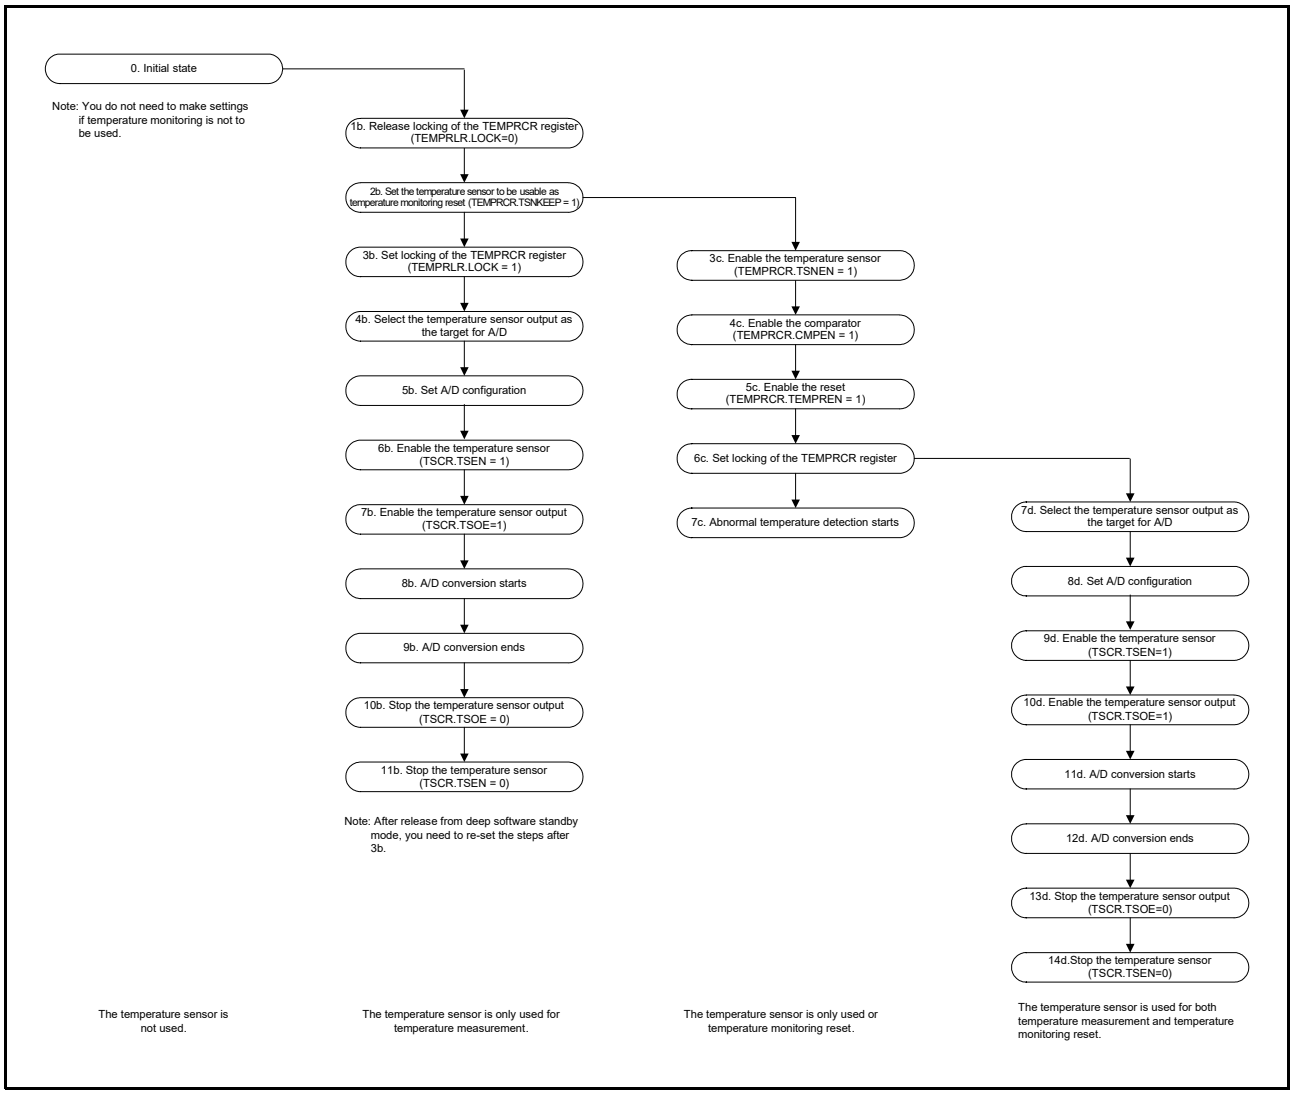
Output of the local memory error reset can be selected by the CAOAD.OAD, LRMCR0.OAD, or LRMCR1.OAD bit.
After generation of a local memory error reset, the device is released from the internal reset state after the internal reset time (tRESW2) has elapsed, and the CPU starts reset exception handling.
For details on the local memory error reset, see section 2, CPU. Determination of a local memory error as the source of reset generation is similar to determination of a local memory error as the source of interrupt generation. See section 15, Interrupt Controller (ICUM).

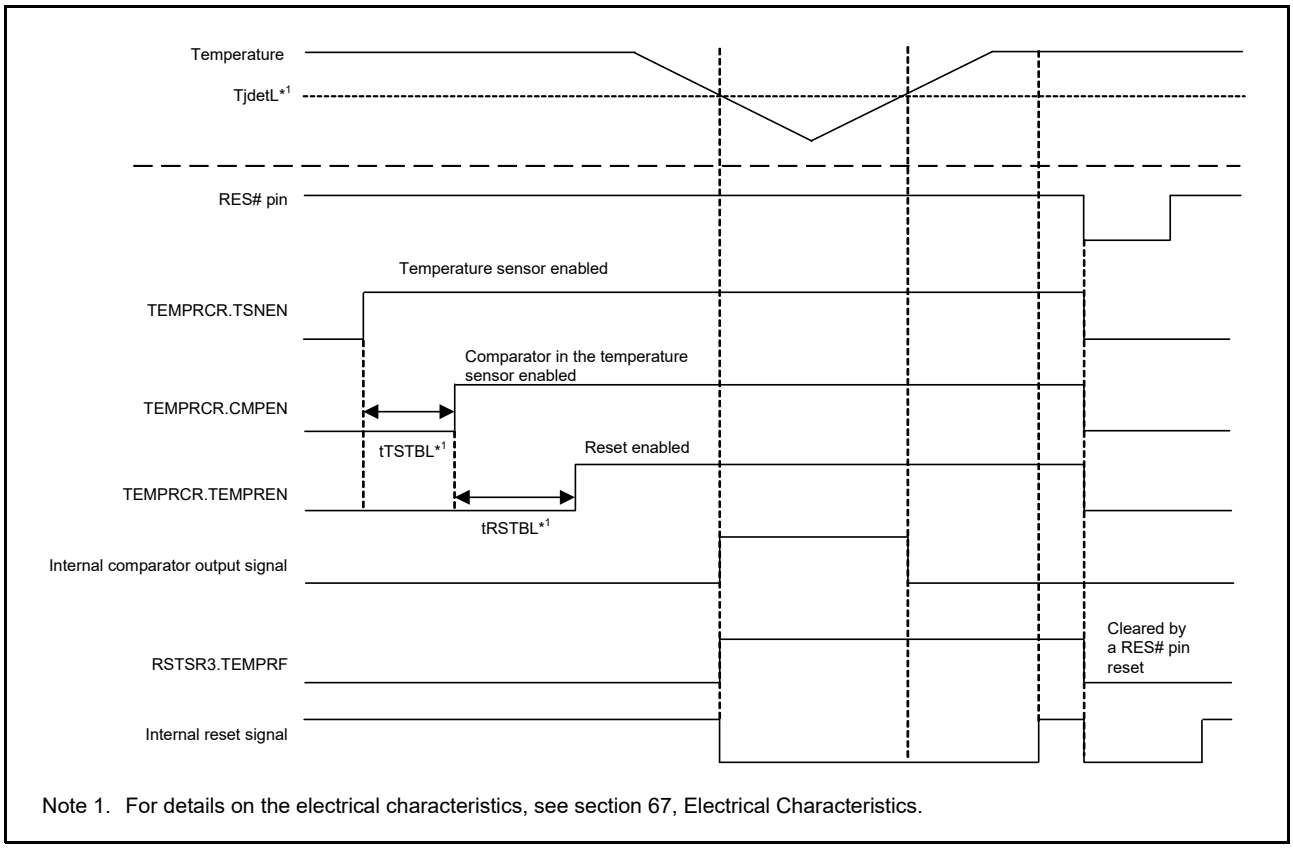
6.3.12 Temperature Monitoring Reset

This is an internal reset generated by the temperature sensor.

The temperature sensor detects the ambient temperature of the surrounding environment of the MCU. If it detects a temperature outside the specified range, a temperature monitoring reset is generated.

Figure 6.7 shows the procedure for setting the temperature sensor to enable the temperature monitoring reset function. If the temperature sensor is operating and the temperature monitoring reset function is enabled, temperature monitoring (abnormal temperature detection) proceeds. Figure 6.8 and Figure 6.9 show examples of the operation of the temperature monitoring reset for abnormally low and high temperatures, respectively.





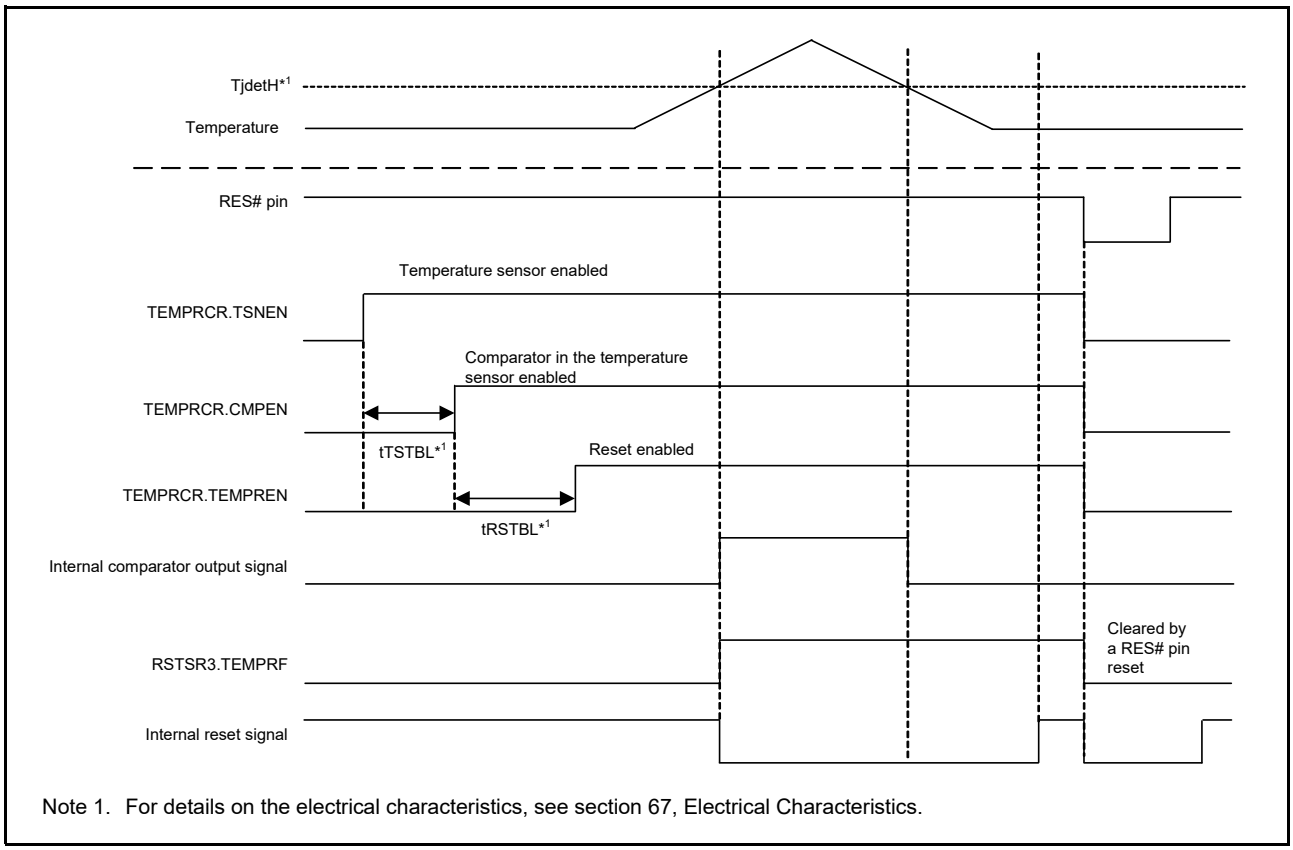


Figure 6.7 Temperature Sensor Setting Procedure

Note 1. For details on the electrical characteristics, see section 67, Electrical Characteristics.

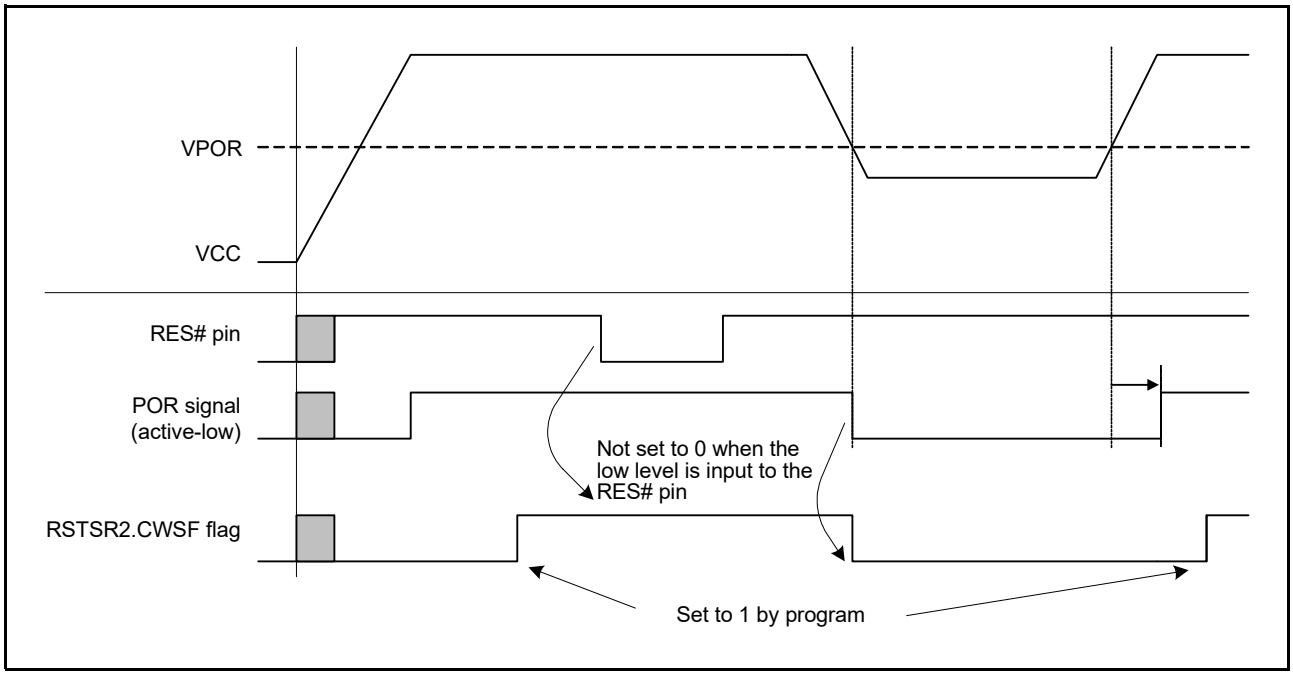
Figure 6.8 Example of Operation of Temperature Monitoring Reset (Abnormally Low Temperature Detection)

Note 1. For details on the electrical characteristics, see section 67, Electrical Characteristics.

Figure 6.9 Example of Operation of Temperature Monitoring Reset (Abnormally High Temperature Detection)

6.3.13 Determination of Cold/Warm Start

The RSTSR2.CWSF flag allows determining whether a power-on reset has caused the reset processing (cold start) or the reset signal being input during operation has caused the reset processing (warm start).
The RSTSR2.CWSF flag is set to 0 when a power-on reset occurs (cold start). Otherwise, the flag is not set to 0. The flag is set to 1 when 1 is written to it. The flag does not change when 0 is written to it.
Figure 6.10 shows an example of the operation of cold/warm start determination.



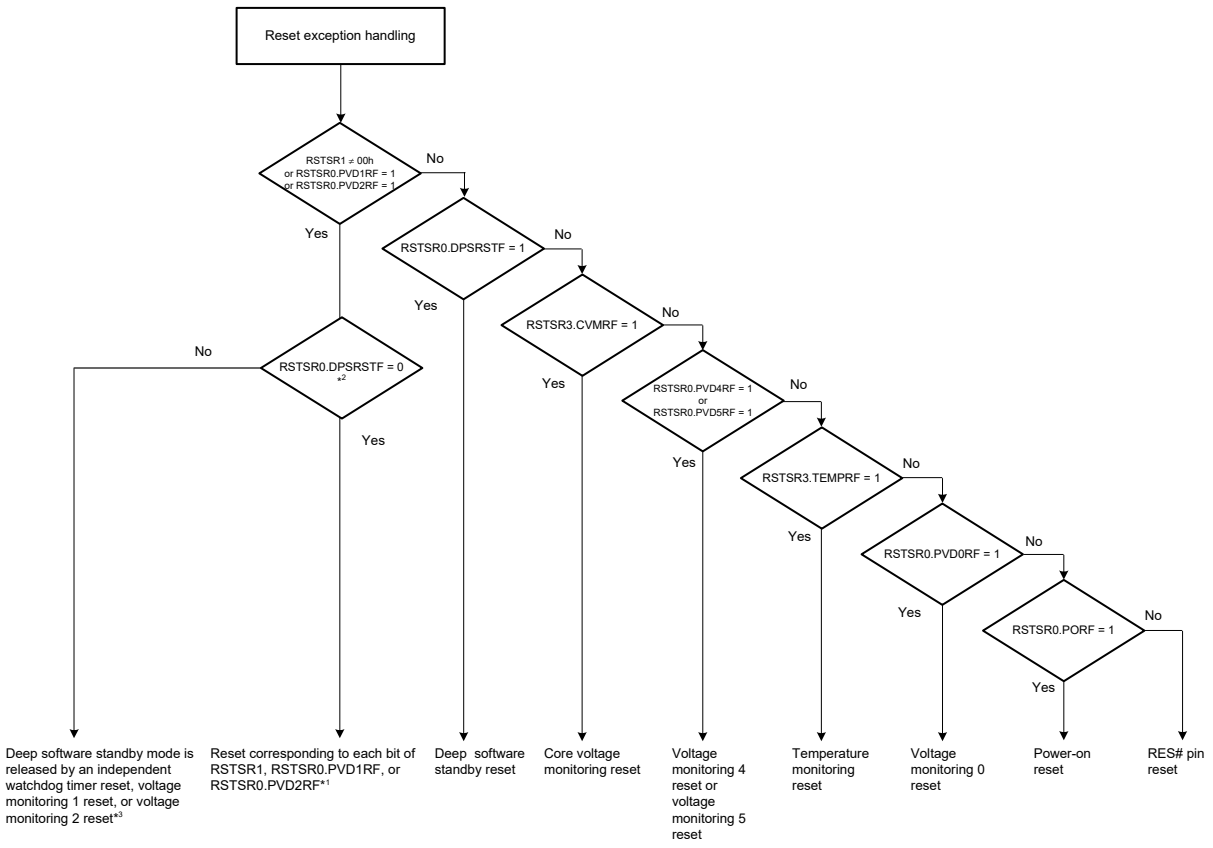


Figure 6.10 Example of Operation of Cold/Warm Start Determination

6.3.14 Determining the Source of Reset Generation

Reading of the RSTSR0, RSTSR1, and RSTSR3 registers can identify the type of reset which led to the reset exception handling.

Figure 6.11 shows an example flowchart to determine the source of reset generation.

Note 1. If any combination of resets corresponding to bits among the RSTSR1, RSTSR0.PVD1RF, and RSTSR0.PVD2RF flags occurred simultaneously, all reset flags for which the reset source condition occurred become 1.

Note 2. After checking that RSTSR1 ≠ 00h, RSTSR0.PVD1RF = 1, or RSTSR0.PVD2RF = 1, check RSTSR0.DPSRSTF to determine whether release from deep software standby mode occurred.

Note 3. Clear the reset status register (RSTSR0, RSTSR1, RSTSR2, RSTSR3) before a transition to deep software standby mode. If the reset flag is not cleared, the recovery source cannot be correctly identified.

Figure 6.11 Example Flowchart to Determine the Source of Reset Generation

6.3.15 Reset Output Function

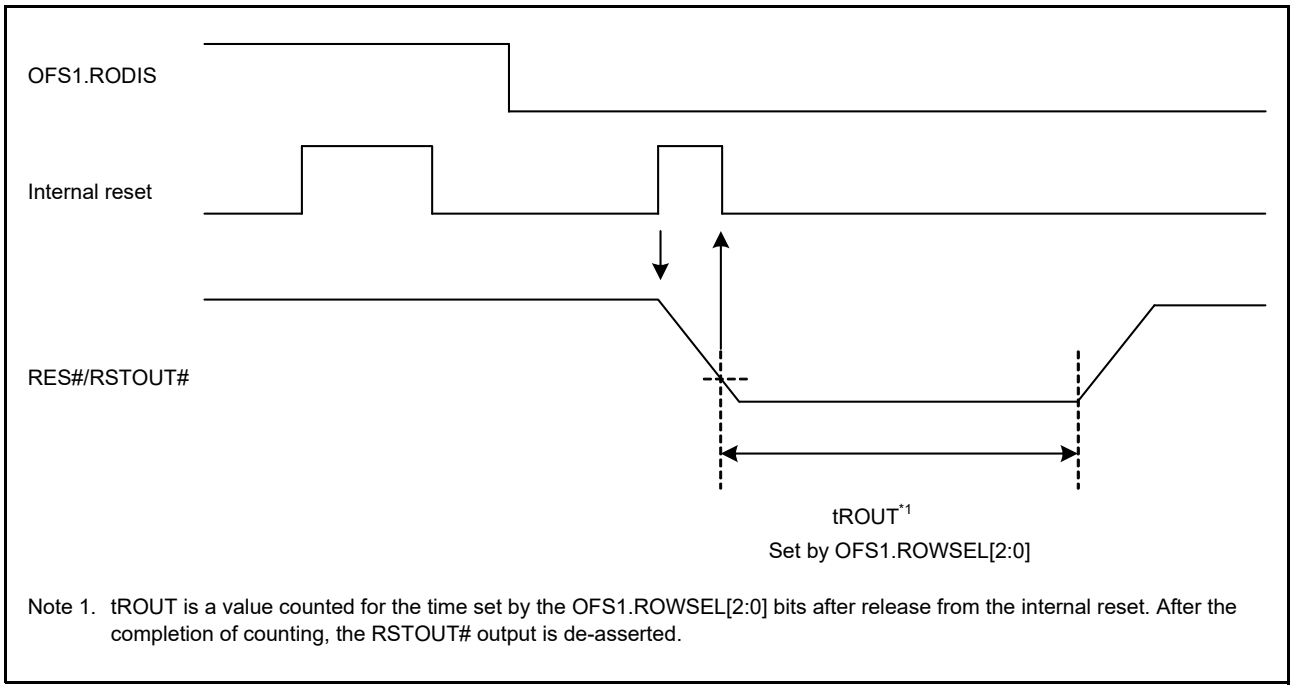
Reset output is a function for notifying external devices of the internal reset state. The output pin function (RSTOUT#) is multiplexed with the RES# input pin function, and the low level is output at the time of a reset when the reset output function is enabled.

The output of an internal reset to the RSTOUT# pin as a reset output is itself recognized as if it were a reset input on the RES# pin. At this time, the reset control registers and reset source are initialized by the backflow from the reset output being handled as if it were a reset input on the RES# pin, so the internal reset cannot continue to be issued even if the MCU still satisfies the condition for having issued the reset. However, the core voltage monitoring reset is an exception because it can continue to be issued.

Disabling of the reset output function is selectable by the setting of the RODIS bit of option function select register 1 (OFS1). The width of the reset output pulse is selectable by the setting of the ROWSEL[2:0] bits of option function select register 1 (OFS1).

OFS1.ROWSEL[2:0] = 000b: 0.25 ms or above
OFS1.ROWSEL[2:0] = 100b: 0.5 ms or above
OFS1.ROWSEL[2:0] = 101b: 1 ms or above
OFS1.ROWSEL[2:0] = 110b: 5 ms or above
OFS1.ROWSEL[2:0] = 111b: 10 ms or above

When an internal reset is output as a reset output, the reset flags of the RSTSR0 register other than the RSTSR0.PORF and RSTSR0.DPSRSTF flags, and the RSTSR1 register and RSTSR3 register are initialized by the reset output. Therefore, to determine the reset source when the reset output function is enabled, read the RSTSR0.PORF and RSTSR0.DPSRSTF flags and the ROUTSR0, ROUTSR1, and ROUTSR2 registers.



After having determined the reset source, clear all bits of the RSTSR0, RSTSR1, RSTSR2, RSTSR3, ROUTSR0, ROUTSR1, and ROUTSR2 registers in preparation for generation of the next reset.

Table 6.10 shows the relationship between the reset output function settings and the reset source determination flags.

Table 6.10 Relationship between Reset Output Function Settings and Reset Source Determination Flags

		Reset Output Determination Flag	
		Reset Output Function Enabled (OFS1.RODIS = 0)	Reset Output Function Disabled (OFS1.RODIS = 1)
Reset source	Power-on reset	—	RSTSR0.PORF
	Voltage monitoring 0 reset	ROUTSR0.ROPVD0RF	RSTSR0.PVD0RF
	Voltage monitoring 1 reset	ROUTSR0.ROPVD1RF	RSTSR0.PVD1RF
	Voltage monitoring 2 reset	ROUTSR0.ROPVD2RF	RSTSR0.PVD2RF
	Voltage monitoring 4 reset	ROUTSR0.ROPVD4RF	RSTSR0.PVD4RF
	Voltage monitoring 5 reset	ROUTSR0.ROPVD5RF	RSTSR0.PVD5RF
	Deep software standby reset	—	RSTSR0.DPSRSTF
	Independent watchdog timer reset	ROUTSR1.ROIWDTRF	RSTSR1.IWDTRF
	Watchdog timer reset	ROUTSR1.ROWDT0RF	RSTSR1.WDT0RF
	Software reset	ROUTSR1.ROSWRF	RSTSR1.SWRF
	Local memory error reset	ROUTSR1.ROLM0RF	RSTSR1.LM0RF
	Bus error reset	ROUTSR1.ROBUSRF	RSTSR1.BUSRF
	Common memory error reset	ROUTSR1.ROCMRF	RSTSR1.CMRF
	Core voltage monitoring reset	ROUTSR2.ROCVMRF	RSTSR3.CVMRF
	Temperature monitoring reset	ROUTSR2.ROTEMPRF	RSTSR3.TEMPRF

Figure 6.12 shows an example of the operation of the reset output. For details of tROUT, see section 67, Electrical Characteristics.

Note 1. tROUT is a value counted for the time set by the OFS1.ROWSEL[2:0] bits after release from the internal reset. After the completion of counting, the RSTOUT# output is de-asserted.

Figure 6.12 Example of Operation of Reset Output

Figure 6.13 is a block diagram of the reset output.

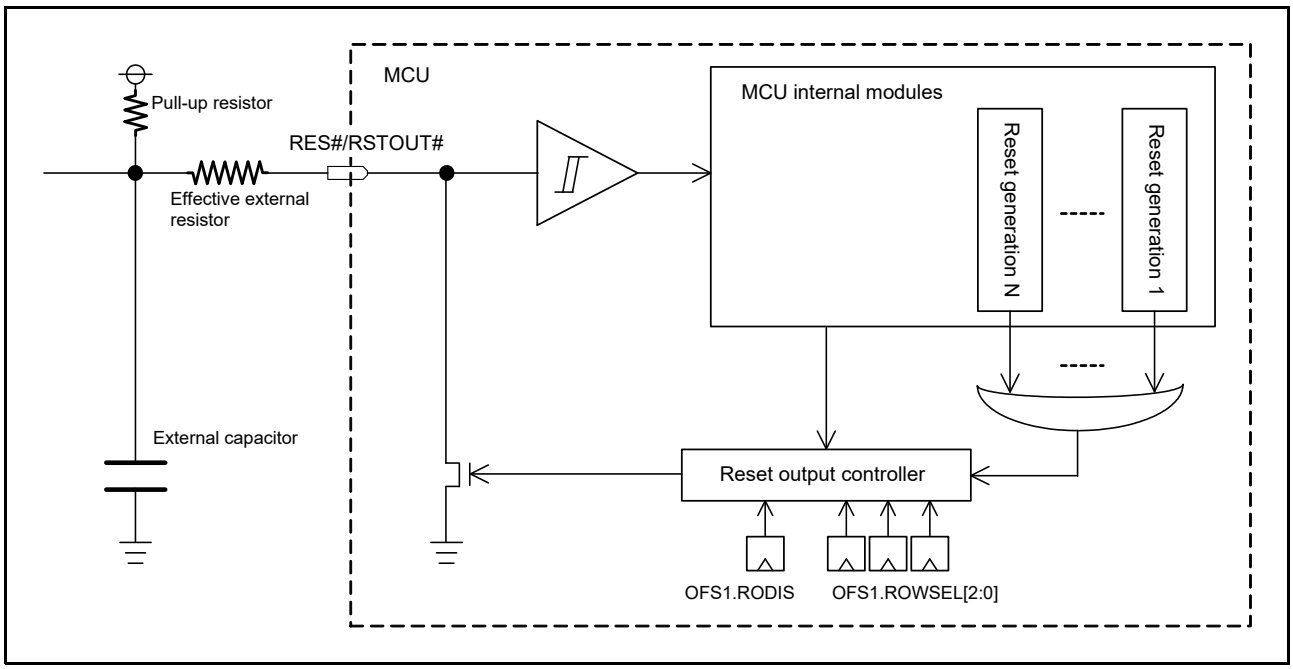


Figure 6.13 Block Diagram of Reset Output

6.4 Protection from Reset Control by a Non-Secure Program

Generation of resets from some of the reset sources is controllable. The settings of the bits of the SYRSTMSK0 and SYRSTMSK2 registers control (enable or disable) generation of resets from those sources. These registers are only accessible from a secure program.

A reset from a source that is disabled is still generated but is not propagated to the MCU. Also, the corresponding reset flags in the RSTSR0 and RSTSR1 registers are not set.

The controllable reset sources are as follows.

- Independent watchdog timer reset
- Watchdog timer reset
- Common memory error reset
- Local memory error reset
- Bus error reset
- Voltage monitoring 1 reset
- Voltage monitoring 2 reset
- Software reset

7. Option-Setting Memory (OFSM)

7.1 Overview

The option-setting memory is a set of registers used to determine the state of the MCU after a reset. The option-setting memory is allocated to the configuration setting area in the extra MRAM area.
Table 7.1 and Table 7.2 show the registers in the option-setting memory area.

Table 7.1 Option-Setting Memory (Extra MRAM Area)

Address	Register Name	Security Attribute*1
06C4 EC60h	Bank Select Register for Non-Secure Application (BANKSEL_NS)	Non-secure
06C4 EC70h	Block Select Register for Non-Secure Application (BLSEL_NS)	Non-secure
06C9 F480h	Data MRAM Block Protect Register 0 for Non-Secure Application (BPSD0_NS)	Non-secure
06C9 F500h to 06C9 F50Ch	Block Swap Setting Register n for Non-Secure Application (BLKSWPn_NS) (n = 0 to 3)	Non-secure
06C9 F600h to 06C9 F63Ch, 06C9 F700h to 06C9 F71Ch	Block Protect Register n for Non-Secure Application (BPSn_NS) (n = 0 to 15, 64 to 71)	Non-secure
86C2 E850h	Bank Mode Select Register (DUALSEL)	Secure
86C2 E870h	Start-Up Area Setting Register (SAS)	Secure
86C2 E874h	Start-Up Area Setting Register 2 (SAS2)	Secure
86C2 E9B0h	Bank Select Register for Secure Application (BANKSEL_S)	Secure
86C2 E9C0h	Block Select Register for Secure Application (BLSEL_S)	Secure
86C2 E9E0h	BANKSEL Attribute Select Register (BANKSEL_SEL)	Secure
86C2 E9F0h	BLSEL Attribute Select Register (BLSEL_SEL)	Secure
86C9 F050h	MRAM Security Attribute Boundary Register (MRAMSABR)	Secure
86C9 F080h	Data MRAM Block Protect Register 0 for Secure Application (BPSD0_S)	Secure
86C9 F100h to 86C9 F10Ch	Block Swap Setting Register n for Secure Application (BLKSWPn_S) (n = 0 to 3)	Secure
86C9 F200h to 86C9 F23Ch, 86C9 F300h to 86C9 F31Ch	Block Protect Register n for Secure Application (BPSn_S) (n = 0 to 15, 64 to 71)	Secure

Note 1. Only secure application developers can set values in registers with the security attribute secure.

Table 7.2 Option-Setting Memory (OTP Area in Extra MRAM) (1/2)

Address	Register Name	Memory Type	Security Attribute*1
06E2 0810h	Non-Secure Switchable OTP Memory Type Setting Register (SOTPMS_NS)	OTP	Non-secure

86F4 1E40h to 86F4 1E5Ch	Anti-Rollback Counter 2 for Non-Secure Application [i] (ARCNS2[i]) (i = 0 to 7)	OTP	Secure
86F4 1E60h to 86F4 1E7Ch	Anti-Rollback Counter 3 for Non-Secure Application [i] (ARCNS3[i]) (i = 0 to 7)	OTP	Secure
86F4 1E00h to 86F4 1E7Ch	Anti-Rollback Counter for Non-Secure Application [i] (ARCNS[i]) (i = 0 to 31)	OTP	Secure
86F4 1F00h, 86F4 1F04h	Anti-Rollback Counter for OEM Boot Loader [i] (ARCOEMBL[i]) (i = 0, 1)	OTP	Secure

Note 1. Only secure application developers can set values in registers with the security attribute secure.

7.2 Register Descriptions

7.2.1 Secure Switchable OTP Memory Type Setting Register (SOTPMS_S), Non-Secure Switchable OTP Memory Type Setting Register (SOTPMS_NS)

Address(es): OFSM.SOTPMS_S 86E1 0610h, OFSM_NS.SOTPMS_NS 06E2 0810h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOTPMS
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b0	SOTPMS	Switchable OTP Memory Type Select	0: Memory type of the switchable OTP is OTP. 1: Memory type of the switchable OTP is MRAM.	R
b31 to b1	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

SOTPMS Bit (Switchable OTP Memory Type Select)

This bit specifies the memory type for the registers located in the switchable OTP area (06E2 0820h to 06E2 087Fh, 86E1 0620h to 86E1 06EFh, and 86E1 0710h to 86E1 07FFh).

After setting this bit to 0, set the values for the registers in the switchable OTP area again.

7.2.2 Option Function Select Register 0 (OFS0)

Address(es): OFSM.OFS0 86E1 0640h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	WDT0SLCSTP	—	WDT0RSTIRQS	WDT0RPSS[1:0]		WDT0RPES[1:0]		WDT0CKS[3:0]				WDT0TOPS[1:0]		WDT0STRT	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	IWDTSLCSTP	—	IWDTRSTIRQS	IWDTRPSS[1:0]		IWDTRPES[1:0]		IWDTCKS[3:0]				IWDTTOPS[1:0]		IWDTSTRT	—
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	When reading, this bit returns the value written by the user. The write value should be 1.	R
b1	IWDTSTRT	IWDT Start Mode Select	0: IWDT is automatically started after a reset (auto-start mode). 1: IWDT is halted after a reset (register start mode).	R
b3, b2	IWDTTOPS[1:0]	IWDT Timeout Period Select	b3 b2 0 0: 128 cycles (007Fh) 0 1: 512 cycles (01FFh) 1 0: 1024 cycles (03FFh) 1 1: 2048 cycles (07FFh)	R
b7 to b4	IWDTCKS[3:0]	IWDT Clock Division Ratio Select	b7 b4 0 0 0 0: No division 0 0 1 0: Divide-by-16 0 0 1 1: Divide-by-32 0 1 0 0: Divide-by-64 1 1 1 1: Divide-by-128 0 1 0 1: Divide-by-256 Settings other than above are prohibited.	R
b9, b8	IWDTRPES[1:0]	IWDT Window End Position Select	b9 b8 0 0: 75% 0 1: 50% 1 0: 25% 1 1: 0% (window end position is not specified.)	R
b11, b10	IWDTRPSS[1:0]	IWDT Window Start Position Select	b11 b10 0 0: 25% 0 1: 50% 1 0: 75% 1 1: 100% (window start position is not specified.)	R
b12	IWDTRSTIRQS	IWDT Reset Interrupt Request Select	0: Non-maskable interrupt request or maskable interrupt request is output. 1: Reset signal is output.	R
b13	—	Reserved	When reading, this bit returns the value written by the user. The write value should be 1.	R
b14	IWDTSLCSTP	IWDT Sleep Mode Count Stop Control	0: Counter continues counting even in sleep mode, deep sleep mode, software standby mode, or deep software standby mode 1. 1: Counter stops when entering sleep mode, deep sleep mode, software standby mode, or deep software standby mode 1.	R
b16, b15	—	Reserved	When reading, this bit returns the value written by the user. The write value should be 1.	R
b17	WDT0STRT	WDT Start Mode Select	0: WDT is automatically started after a reset (auto-start mode) 1: WDT is halted after a reset (register start mode)	R

Bit	Symbol	Bit Name	Description	R/W
b19, b18	WDT0TOPS[1:0]	WDT Timeout Period Select	b19 b18 0 0: 1024 cycles (03FFh) 0 1: 4096 cycles (0FFFh) 1 0: 8192 cycles (1FFFh) 1 1: 16384 cycles (3FFFh)	R
b23 to b20	WDT0CKS[3:0]	WDT Clock Division Ratio Select	b23 b20 0 0 0 1: Divide-by-4 0 1 0 0: Divide-by-64 1 1 1 1: Divide-by-128 0 1 1 0: Divide-by-512 0 1 1 1: Divide-by-2048 1 0 0 0: Divide-by-8192 Settings other than above are prohibited.	R
b25, b24	WDT0RPES[1:0]	WDT Window End Position Select	b25 b24 0 0: 75% 0 1: 50% 1 0: 25% 1 1: 0% (window end position is not specified.)	R
b27, b26	WDT0RPSS[1:0]	WDT Window Start Position Select	b27 b26 0 0: 25% 0 1: 50% 1 0: 75% 1 1: 100% (window start position is not specified.)	R
b28	WDT0RSTIRQS	WDT Reset Interrupt Request Select	0: Non-maskable interrupt request or maskable interrupt request is output. 1: Reset signal is output.	R
b29	—	Reserved	When reading, this bit returns the value written by the user. The write value should be 1.	R
b30	WDT0SLCSTP	WDT Sleep Mode Count Stop Control	0: Counter continues counting even in sleep mode or deep sleep mode. 1: Counter stops when entering sleep mode or deep sleep mode.	R
b31	—	Reserved	When reading, this bit returns the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value. Once the memory type is set to OTP, it is not possible to change a bit that was set to 0 back to 1.

The OFS0 register specifies the operation of the independent watchdog timer (IWDT) and the watchdog timer (WDT) after a reset.

IWDTSTRT Bit (IWDT Start Mode Select)

This bit selects the IWDT start mode after a reset (register start mode or auto-start mode). When auto-start mode is selected, the OFS0 register setting is reflected in each IWDT register.

IWDTTOPS[1:0] Bits (IWDT Timeout Period Select)

These bits specify the timeout period (time until the counter underflows) in cycles of the divided clock set by the IWDTCKS[3:0] bits. 128, 512, 1024, or 2048 cycles can be selected. The time until underflow after a refresh (number of IWDTCLK cycles) is determined by the combination of the IWDTCKS[3:0] and IWDTTOPS[1:0] bits.
For details, refer to section 32, Independent Watchdog Timer (IWDTa).

IWDTCKS[3:0] Bits (IWDT Clock Division Ratio Select)

These bits select the division ratio of the prescaler that divides IWDTCLK from among divided-by 1, 16, 32, 64, 128, and 256. In combination with the setting of the IWDTTOPS[1:0] bits, the IWDT count period can be set within the range of 128 to 524,288 cycles of the IWDTCLK.
For details, refer to section 32, Independent Watchdog Timer (IWDTa).

IWDTRPES[1:0] Bits (IWDT Window End Position Select)

These bits select the window end position of the counter from 75%, 50%, 25%, or 0% of the count period. It is 100% at when the count starts, and 0% when an underflow occurs. Select a value smaller than the window start position for the window end position. If a value larger than the window start position is selected, the setting of this bit becomes invalid (= 0%).

The counter values for the window start and end positions set by the IWDTRPSS[1:0] and IWDTRPES[1:0] bits depend on the setting of the IWDTTOPS[1:0] bits.

For details, refer to section 32, Independent Watchdog Timer (IWDTa).

IWDTRPSS[1:0] Bits (IWDT Window Start Position Select)

These bits select the window start position of the counter from 100%, 75%, 50%, or 25% of the count period. It is 100% at when the count starts, and 0% when an underflow occurs. The period from the window start position to the window end position is the refresh-permitted period and the other periods are the refresh-prohibited periods.

For details, refer to section 32, Independent Watchdog Timer (IWDTa).

IWDTRSTIRQS Bit (IWDT Reset Interrupt Request Select)

This bit selects the action to be taken when an underflow or refresh error occurs. An independent watchdog timer reset or an interrupt request (non-maskable or maskable) can be selected.

For details, refer to section 32, Independent Watchdog Timer (IWDTa).

IWDTSLCSTP Bit (IWDT Sleep Mode Count Stop Control)

This bit specifies whether to stop the IWDT counting when entering sleep mode, deep sleep mode, software standby mode, or deep software standby mode 1.

For details, refer to section 32, Independent Watchdog Timer (IWDTa).

WDT0STRT Bit (WDT Start Mode Select)

This bit selects the WDT start mode after a reset (register start mode or auto-start mode). When auto-start mode is selected, the OFS0 register setting is reflected in each WDT register.

WDT0TOPS[1:0] Bits (WDT Timeout Period Select)

These bits specify the timeout period (time until the counter underflows) in cycles of the divided clock set by the WDT0CKS[3:0] bits. 1024, 4096, 8192, or 16384 cycles can be selected. The time until underflow after a refresh (number of PCLKB cycles) is determined by the combination of the WDT0CKS[3:0] and WDT0TOPS[1:0] bits.

For details, refer to section 31, Watchdog Timer (WDTA).

WDT0CKS[3:0] Bits (WDT Clock Division Ratio Select)

These bits select the division ratio of the prescaler that divides PCLKB from among divided-by 4, 64, 128, 512, 2048, and 8192. In combination with the setting of the WDT0TOPS[1:0] bits, the WDT count period can be set within the range of 4096 to 134,217,728 cycles of the PCLKB.

For details, refer to section 31, Watchdog Timer (WDTA).

WDT0RPES[1:0] Bits (WDT Window End Position Select)

These bits select the window end position of the counter from 75%, 50%, 25%, or 0% of the count period. It is 100% at when the count starts, and 0% when an underflow occurs. Select a value smaller than the window start position for the window end position. If a value larger than the window start position is selected, the setting of this bit becomes invalid (= 0%).

The counter values for the window start and end positions set by the WDT0RPSS[1:0] and WDT0RPES[1:0] bits depend on the setting of the WDT0TOPS[1:0] bits.

For details, refer to section 31, Watchdog Timer (WDTA).

WDT0RPSS[1:0] Bits (WDT Window Start Position Select)

These bits select the window start position of the counter from 100%, 75%, 50%, or 25% of the count period. It is 100% at when the count starts, and 0% when an underflow occurs. The period from the window start position to the window end position is the refresh-permitted period and the other periods are the refresh-prohibited periods.
For details, refer to section 31, Watchdog Timer (WDTA).

WDT0RSTIRQS Bit (WDT Reset Interrupt Request Select)

This bit selects the action to be taken when an underflow or refresh error occurs. A watchdog timer reset or an interrupt request (non-maskable or maskable) can be selected.
For details, refer to section 31, Watchdog Timer (WDTA).

WDT0SLCSTP Bit (WDT Sleep Mode Count Stop Control)

This bit specifies whether to stop the WDT counting when entering sleep mode or deep sleep mode.
For details, refer to section 31, Watchdog Timer (WDTA).

7.2.3 Option Function Select Register 2 (OFS2)

Address(es): OFSM.OFS2 86E1 0644h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CVMRCTL	—
	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	When reading, this bit returns the value written by the user. The write value should be 1.	R
b1	CVMRCTL	Core Voltage Monitoring Reset Control	0: Core voltage monitoring reset is enabled after a reset. 1: Core voltage monitoring reset is disabled after a reset.	R
b31 to b2	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value. Once the memory type is set to OTP, it is not possible to change a bit that was set to 0 back to 1.

The OFS2 register controls the internal core voltage of the MCU.

CVMRCTL Bit (Core Voltage Monitoring Reset Control)

This bit selects whether the core voltage monitoring reset is enabled or disabled after a reset.

7.2.4 Endian Select Register (MDE)

Address(es): OFSM.MDE 86E1 064Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	MDE[2:0]		
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	MDE[2:0]	Endian Select	b2 b0 0 0 0: Big endian 1 1 1: Little endian Settings other than above are prohibited.	R
b31 to b3	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value. Once the memory type is set to OTP, it is not possible to change a bit that was set to 0 back to 1.

The MDE register selects the endian for the CPU.

MDE[2:0] Bits (Endian Select)

These bits select little endian or big endian for the CPU.

7.2.5 Bank Mode Select Register (DUALSEL)

Address(es): OFSM.DUALSEL 86C2 E850h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	BANKMD[2:0]		
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	BANKMD[2:0]	Bank Mode Select	b2 b0 0 0 0: Dual mode 1 1 1: Linear mode Settings other than above are prohibited.	R
b31 to b3	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value.

The DUALSEL register selects the bank mode in the dual bank function of the code MRAM.

BANKMD[2:0] Bits (Bank Mode Select)

These bits select the bank mode in the dual bank function of the code MRAM.

7.2.6 Bank Select Register for Secure Application (BANKSEL_S), Bank Select Register for Non-Secure Application (BANKSEL_NS)

Address(es): OFSM.BANKSEL_S 86C2 E9B0h, OFSM_NS.BANKSEL_NS 06C4 EC60h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	BANKSWP[2:0]		
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	BANKSWP[2:0]	Startup Bank Switch	b2 b0 0 0 0: Set Bank 1 as the startup bank.*2 1 1 1: Set Bank 0 as the startup bank.*2 Settings other than above are prohibited.	R
b31 to b3	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value.
Note 2. A startup bank is a bank located at address 7FFF FFFFh in the non-secure area and at address FFFF FFFFh in the secure area.

The BANKSEL register selects the program startup bank when the code MRAM is in dual mode. There are two registers: one for secure application developers (BANKSEL_S) and one for non-secure application developers (BANKSEL_NS). Which setting is used is specified by the BANKSEL_SEL register.

BANKSWP[2:0] Bits (Startup Bank Switch)

These bits select whether to start the program from Bank 0 or Bank 1 of the code MRAM when the code MRAM is in dual mode.
The setting of these bits is invalid in linear mode.

7.2.7 BANKSEL Attribute Select Register (BANKSEL_SEL)

Address(es): OFSM.BANKSEL_SEL 86C2 E9E0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	BANKSWP_SEL[2:0]		
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	BANKSWP_SEL[2:0]	BANKSWP Attribute Select	b2 b0 0 0 0: The value set in the BANKSEL_S.BANKSWP[2:0] bits is selected. 1 1 1: The value set in the BANKSEL_NS.BANKSWP[2:0] bits is selected. Settings other than above are prohibited.	R
b31 to b3	—	Reserved	When reading, these bits return the value written by the user. The write value should be 0.	R

Note 1. The value for a blank product is 0000 0000h. After setting a value, this register will retain the set value.

The BANKSEL_SEL register selects whether the settings in the BANKSEL_S register or the BANKSEL_NS register are enabled.

BANKSWP_SEL[2:0] Bits (BANKSWP Attribute Select)

These bits are used to select whether the startup bank switch is configured by the non-secure application developer or the secure application developer.

7.2.8 Block Select Register for Secure Application (BLSEL_S), Block Select Register for Non-Secure Application (BLSEL_NS)

Address(es): OFSM.BLSEL_S 86C2 E9C0h, OFSM_NS.BLSEL_NS 06C4 EC70h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BLSWAREA
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b0	BLSWAREA	Block Swap Area Select	0: Enable block swapping for half of the entire code MRAM area. 1: Enable block swapping for a quarter of the entire code MRAM area.	R
b31 to b1	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value.

The BLSEL register specifies the target area for the block swap function when the code MRAM is in linear mode. There are two registers: one for secure application developers (BLSEL_S) and one for non-secure application developers (BLSEL_NS). Which setting is used is specified by the BLSEL_SEL register.

BLSWAREA Bit (Block Swap Area Select)

This bit selects whether to enable block swapping of the code MRAM at half or a quarter of the total capacity. Table 7.3 lists the addresses subject to block swapping. Depending on the setting of this bit, 8-Kbytes blocks can be swapped between swap area 0 and swap area 1 on a block-by-block basis.
The setting of this bit is invalid in dual mode.

Table 7.3 Block Swap Area

Code MRAM Size	BLSWAREA bit	Block Swap Area (Offset Address)	Swap Area 0 (Offset Address)	Swap Area 1 (Offset Address)
1 Mbyte	0	F0 0000h to F7 FFFFh	F0 0000h to F3 FFFFh	F4 0000h to F7 FFFFh
	1	F0 0000h to F3 FFFFh	F0 0000h to F1 FFFFh	F2 0000h to F3 FFFFh
512 Kbytes	0	F8 0000h to FB FFFFh	F8 0000h to F9 FFFFh	FA 0000h to FB FFFFh
	1	F8 0000h to F9 FFFFh	F8 0000h to F8 FFFFh	F9 0000h to F9 FFFFh

7.2.9 BLSEL Attribute Select Register (BLSEL_SEL)

Address(es): OFSM.BLSEL_SEL 86C2 E9F0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BLSWAREA_SEL
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b0	BLSWAREA_SEL	BLSWAREA Attribute Select	0: The value set in the BLSEL_S.BLSWAREA bit is selected. 1: The value set in the BLSEL_NS.BLSWAREA bit is selected.	R
b31 to b1	—	Reserved	When reading, these bits return the value written by the user. The write value should be 0.	R

Note 1. The value for a blank product is 0000 0000h. After setting a value, this register will retain the set value.

The BLSEL_SEL register selects whether the BLSEL_S register setting or the BLSEL_NS register setting is to be used.

BLSWAREA_SEL Bit (BLSWAREA Attribute Select)

This bit is used to select whether the size of the block swap area is configured by the non-secure application developer or the secure application developer.

7.2.10 Block Swap Setting Register n for Secure Application (BLKSWPn_S) (n = 0 to 3), Block Swap Setting Register n for Non-Secure Application (BLKSWPn_NS) (n = 0 to 3)

Address(es): OFSM.BLKSWP0_S 86C9 F100h to OFSM.BLKSWP3_S 86C9 F10Ch,
OFSM_NS.BLKSWP0_NS 06C9 F500h to OFSM_NS.BLKSWP3_NS 06C9 F50Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SWP7[3:0]				SWP6[3:0]				SWP5[3:0]				SWP4[3:0]			
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SWP3[3:0]				SWP2[3:0]				SWP1[3:0]				SWP0[3:0]			
Value after reset:	The value set by the user*1															

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value.

This register is used to enable or disable block swapping.

SWPi[3:0] Bits (Swap i) (i = 0 to 7)

These bits specify whether to swap the corresponding address blocks. Setting them to 0000b swaps the corresponding address blocks, while setting them to 1111b reverts them to their original state. No other values are permitted.
The address blocks corresponding to each set of bits are shown in Table 7.4 through Table 7.7.

Table 7.4 Corresponding Address Blocks for Each Set of Bits (Code MRAM Size: 1 Mbyte, the BLSEL.BLSWAREA bit is 0)

Register	Bits	Address Blocks to Be Swapped (Offset Address)
BLKSWP0	SWP0[3:0]	F7 E000h to F7 FFFFh and F3 E000h to F3 FFFFh
	SWP1[3:0]	F7 C000h to F7 DFFFh and F3 C000h to F3 DFFFh

	:	:
	SWP7[3:0]	F9 0000h to F9 1FFFh and F8 0000h to F8 1FFFh

7.2.11 Start-Up Area Setting Register (SAS)

Address(es): OFSM.SAS 86C2 E870h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	BTSIZE[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b29 to b0	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b31, b30	BTSIZE[1:0]	Start-Up Area Size Setting	b31 b30 0 0: Setting prohibited. 0 1: 32 Kbytes 1 0: 16 Kbytes 1 1: 8 Kbytes	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value.

The SAS register specifies the size of start-up area 0 and start-up area 1, which are subject to the start-up program protection function.

BTSIZE[1:0] Bits (Start-Up Area Size Setting)

These bits specify the size of the area subject to the start-up program protection function.
The setting value of these bits and the address of each start-up area are shown in Table 7.8.

Table 7.8 Addresses of Start-Up Area 0 and 1

BTSIZE[1:0] Bits	SAS2.BTFLG Bit	Start-Up Area 0	Start-Up Area 1
11b	1	FFFF E000h to FFFF FFFFh	FFFF C000h to FFFF DFFFh
	0	FFFF C000h to FFFF DFFFh	FFFF E000h to FFFF FFFFh
10b	1	FFFF C000h to FFFF FFFFh	FFFF 8000h to FFFF BFFFh
	0	FFFF 8000h to FFFF BFFFh	FFFF C000h to FFFF FFFFh
01b	1	FFFF 8000h to FFFF FFFFh	FFFF 0000h to FFFF 7FFFh
	0	FFFF 0000h to FFFF 7FFFh	FFFF 8000h to FFFF FFFFh

7.2.12 Start-Up Area Setting Register 2 (SAS2)

Address(es): OFSM.SAS2 86C2 E874h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	BTFLG	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b30 to b0	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b31	BTFLG	Start-Up Area Select	0: Start-up area 1 is placed on the FFFF FFFFh side (start-up area is swapped). 1: Start-up area 0 is placed on the FFFF FFFFh side (start-up area is not swapped).	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value.

The SAS2 register selects the start-up area used by the start-up program protection function.

BTFLG Bit (Start-Up Area Select)

This bit sets whether or not to switch the start-up area using the start-up program protection function. Program this bit to 1 when using dual mode (DUALSEL.BANKMD[2:0] = 000b)

Refer to section 65.9.3, Startup Program Protection for details.

7.2.13 Option Function Select Register 1 for Secure Application (OFS1_S), Option Function Select Register 1 for Non-Secure Application (OFS1_NS)

Address(es): OFSM.OFS1_S 86E1 07A0h, OFSM_NS.OFS1_NS 06E2 0850h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	RODIS	ROWSEL[2:0]			—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	HOCOFRQ0[2:0]			HOCO EN	—	—	DSBYL PSEL	—	PVDAS	VDSEL[2:0]		
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	VDSEL[2:0]	Voltage Detection 0 Level Select	b2 b0 0 0 0: 2.85 V 0 0 1: 2.58 V 0 1 0: 2.15 V 0 1 1: 2.00 V 1 0 0: 1.90 V 1 0 1: 1.80 V 1 1 0: 1.67 V Settings other than above are prohibited when the PVDAS bit is set to 0.	R
b3	PVDAS	Voltage Detection 0 Circuit Start	0: Voltage monitoring 0 reset is enabled after a reset. 1: Voltage monitoring 0 reset is disabled after a reset.	R
b4	—	Reserved	When reading, this bit returns the value written by the user. The write value should be 1.	R
b5	DSBYLPSEL	Deep Software Standby Mode Power Reduction	Setting this bit to 0 further reduces power consumption during deep software standby modes 1 and 2.	R
b7, b6	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b8	HOCOEN	HOCO Oscillation Enable	0: HOCO oscillation is enabled after a reset. 1: HOCO oscillation is disabled after a reset.	R
b11 to b9	HOCOFRQ0[2:0]	HOCO Frequency Setting	b11 b9 0 0 0: 16 MHz 0 0 1: 18 MHz 0 1 0: 20 MHz 1 0 0: 32 MHz 1 1 1: 48 MHz Settings other than above are prohibited.	R
b27 to b12	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b30 to b28	ROWSEL[2:0]	Reset Output Pulse Width Select	b30 b28 0 0 0: 0.25 ms 1 0 0: 0.5 ms 1 0 1: 1 ms 1 1 0: 5 ms 1 1 1: 10 ms Settings other than above are prohibited.?	R
b31	RODIS	Reset Output Enable	0: Reset output function is enabled. 1: Reset output function is disabled.	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value. Once the memory type is set to OTP, it is not possible to change a bit that was set to 0 back to 1.

The OFS1 register specifies the operation of the voltage detection 0 circuit, the high-speed on-chip oscillator, and the reset output function. There are two registers: one for secure application developers (OFS1_S) and one for non-secure

application developers (OFS1_NS). Which setting is used is specified by the OFS1_SEL register.

VDSEL[2:0] Bits (Voltage Detection 0 Level Select)

These bits select the voltage detection level of the voltage detection 0 circuit.

PVDAS Bit (Voltage Detection 0 Circuit Start)

This bit selects whether the voltage monitoring 0 reset is enabled or disabled after a reset.

DSBYLPSEL Bit (Deep Software Standby Mode Power Reduction)

This bit controls power consumption during deep software standby mode 1 and 2.
When this bit is set to 0, PVD0 is used for voltage detection in the battery backup function during deep software standby mode 1 or 2. When this bit is set to 1, a dedicated voltage detector is used for voltage detection in the battery backup function during deep software standby mode 1 or 2.

HOCOEN Bit (HOCO Oscillation Enable)

This bit selects whether the HOCO oscillation is enabled or disabled after a reset.
Setting this bit to 0 allows the HOCO oscillation to start before the CPU starts operating, reducing the oscillation stabilization wait time.
Note that even if this bit is set to 0, the system clock source is not switched to HOCO. To switch the system clock source, set the clock source select bits (SCKSCR.CKSEL[2:0]).

HOCOFRQ0[2:0] Bits (HOCO Frequency Setting)

These bits select the oscillation frequency of HOCO after a reset.

ROWSEL[2:0] Bits (Reset Output Pulse Width Select)

These bits select the minimum value of the pulse width when reset is output.

RODIS Bit (Reset Output Enable)

This bit selects whether to enable or disable the reset output function. When this bit is set to 0, the reset output function is enabled and the internal reset signal of the MCU is output from the RES# pin.

7.2.14 OFS1 Attribute Select Register (OFS1_SEL)

Address(es): OFSM.OFS1_SEL 86E1 07D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	RODIS_SEL	ROWSEL_SEL[2:0]			—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	HOCOFRQ0_SEL[2:0]			HOCOEN_SEL	—	—	DSBYLPSEL_SEL	—	PVDAS_SEL	VDSEL_SEL[2:0]		
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	VDSEL_SEL[2:0]	VDSEL Attribute Select	b2 b0 0 0 0: The value set in the OFS1_S.VDSEL[2:0] bits is selected. 1 1 1: The value set in the OFS1_NS.VDSEL[2:0] bits is selected. Settings other than above are prohibited.	R
b3	PVDAS_SEL	PVDAS Attribute Select	0: The value set in the OFS1_S.PVDAS bit is selected. 1: The value set in the OFS1_NS.PVDAS bit is selected.	R
b4	—	Reserved	When reading, this bit returns the value written by the user. The write value should be 1.	R
b5	DSBYLPSEL_SEL	DSBYLPSEL Attribute Select	0: The value set in the OFS1_S.DSBYLPSEL bit is selected. 1: The value set in the OFS1_NS.DSBYLPSEL bit is selected.	R
b7, b6	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b8	HOCOEN_SEL	HOCOEN Attribute Select	0: The value set in the OFS1_S.HOCOEN bit is selected. 1: The value set in the OFS1_NS.HOCOEN bit is selected.	R
b11 to b9	HOCOFRQ0_SEL[2:0]	HOCOFREQ0 Attribute Select	b11 b9 0 0 0: The value set in the OFS1_S.HOCOFRQ0[2:0] bits is selected. 1 1 1: The value set in the OFS1_NS.HOCOFRQ0[2:0] bits is selected. Settings other than above are prohibited.	R
b27 to b12	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b30 to b28	ROWSEL_SEL[2:0]	ROWSEL Attribute Select	0: The value set in the OFS1_S.ROWSEL[2:0] bits is selected. 1: The value set in the OFS1_NS.ROWSEL[2:0] bits is selected.	R
b31	RODIS_SEL	RODIS Attribute Select	0: The value set in the OFS1_S.RODIS bit is selected. 1: The value set in the OFS1_NS.RODIS bit is selected.	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value. Once the memory type is set to OTP, it is not possible to change a bit that was set to 0 back to 1.

The OFS1_SEL register selects whether the OFS1_S register setting or the OFS1_NS register setting is to be used. When a bit is set to 0 in this register, the setting of the corresponding bit in the OFS1_S register is used, and when a bit is set to 1 in this register, the setting of the corresponding bit in the OFS1_NS register is used.

7.2.15 MRAM Security Attribute Boundary Register (MRAMSABR)

Address(es): OFSM.MRAMSABR 86C9 F050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	MRDSAB[4:0]					—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MRCSAB[8:0]									—	—	—	—	—
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b13 to b5	MRCSAB[8:0]	Code MRAM Security Attribute Boundary Setting	• In linear mode When the setting value is n, the address (100 0000h – n × 8000h) (offset address) serves as the boundary of the security attributes. The area starting from this address is the secure area, and the area preceding this address is the non-secure area. Example: 000h: Address 100 0000h is the security attribute boundary (the entire area is non-secure). 001h: Address FF 8000h is the security attribute boundary. 002h: Address FF 0000h is the security attribute boundary. 010h: Address F8 0000h is the security attribute boundary (the entire area is secure in 512-Kbyte products). 01Fh: Address F0 8000h is the security attribute boundary. 020h: Address F0 0000h is the security attribute boundary (the entire area is secure in 1-Mbyte products). 1FFh: The entire area is secure. • In dual mode In addition to the above, the address (C0 0000h – n × 8000h) (offset address) also serves as the boundary for security attributes.	R
b23 to b14	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b28 to b24	MRDSAB[4:0]	Data MRAM Security Attribute Boundary Setting	When the setting value is n, the address (90 0000h + n × 800h) (offset address) serves as the boundary of the security attributes. The area preceding this address is the secure area, and the area following this address is the non-secure area. Example: 00h: Address 90 0000h is the security attribute boundary (the entire area is non-secure). 01h: Address 90 0800h is the security attribute boundary. 17h: Address 90 B800h is the security attribute boundary. 18h: Address 90 C000h is the security attribute boundary (the entire area is secure). 1Fh: The entire area is secure.	R
b31 to b29	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value.

This register is used to configure the security attribute boundary for MRAM.

MRCSAB[8:0] Bit (Code MRAM Security Attribute Boundary Setting)

These bits are used to configure the security attribute boundary of the code MRAM in 32-Kbyte units.

When the set value is n, the offset address “100 0000h – n × 8000h” serves as the boundary between the secure and non-secure areas.
For example, in the product with 1 Mbyte of code MRAM and in linear mode:
When n = 001h, addresses FFFF 8000h to FFFF FFFFh are the secure area, and addresses 7FF0 0000h to 7FFF 7FFFh are the non-secure area.
When n = 01Fh, addresses FFF0 8000h to FFFF FFFFh are the secure area, and addresses 7FF0 0000h to 7FF0 7FFFh are the non-secure area.
When n = 000h, the entire area is non-secure, and when n ≥ 020h, the entire area is secure.
In dual mode, the boundary moves by 32 Kbytes for both bank 0 and bank 1.

MRDSAB[4:0] Bit (Data MRAM Security Attribute Boundary Setting)

These bits are used to configure the security attribute boundary of the data MRAM in 2-Kbyte units.
When the set value is n, the offset address “0690 0000h + n × 800h” serves as the boundary between the secure and non-secure areas.
For example:
When n = 01h, addresses F690 0000h to F690 07FFh are the secure area, and addresses 7690 0800h to 7690 BFFFh are the non-secure area.
When n = 17h, addresses F690 0000h to F690 B7FFh are the secure area, and addresses 7690 B800h to 7690 BFFFh are the non-secure area.
When n = 00h, the entire area is non-secure, and when n ≥ 18h, the entire area is secure.

Note: Note that the relationship between setting value and increase or decrease of address differs between code MRAM and data MRAM.

7.2.16 Block Protect Register n for Secure Application (BPSn_S) (n = 0 to 15, 64 to 71), Block Protect Register n for Non-Secure Application (BPSn_NS) (n = 0 to 15, 64 to 71)

Address(es): OFSM.BPS0_S 86C9 F200h to OFSM.BPS15_S 86C9 F23Ch, OFSM.BPS64_S 86C9 F300h to OFSM.BPS71_S 86C9 F31Ch, OFSM_NS.BPS0_NS 06C9 F600h to OFSM_NS.BPS15_NS 06C9 F63Ch, OFSM_NS.BPS64_NS 06C9 F700h to OFSM_NS.BPS71_NS 06C9 F71Ch

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	The value set by the user*1														

b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
BP3[3:0]				BP2[3:0]				BP1[3:0]				BP0[3:0]			
Value after reset:	The value set by the user*1														

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	BP0[3:0]	Block Protect 0	0: The corresponding address block is protected. 1: The corresponding address block is unprotected.	R
b7 to b4	BP1[3:0]	Block Protect 1		R
b11 to b8	BP2[3:0]	Block Protect 2		R
b15 to b12	BP3[3:0]	Block Protect 3		R
b19 to b16	BP4[3:0]	Block Protect 4		R
b23 to b20	BP5[3:0]	Block Protect 5		R
b27 to b24	BP6[3:0]	Block Protect 6		R
b31 to b28	BP7[3:0]	Block Protect 7		R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value.

The BPSn register enables or disables block protection for code MRAM. There are 24 registers each for secure application developers (BPSn_S) and non-secure application developers (BPSn_NS).
Block protection can protect code MRAM in 8-Kbyte units. Use the BPSn_S registers to protect address blocks placed in the secure area of code MRAM, and use the BPSn_NS registers to protect address blocks placed in the non-secure area.

BPi[3:0] Bits (Block Protect i)

Each set of bits corresponds to an 8-Kbyte address block in code MRAM. The address block (offset address) corresponding to the bits is calculated using the following formula.

100 0000h – (n × 8 + i +1) × 2000h to FF FFFFh – (n × 8 + i) × 2000h

Setting these bits to 0000b protects the corresponding address block, preventing it from programming. Setting them to 1111b removes the protection. No other values are permitted.
To disable block protection using this register, set the MRAM.MRCBPROTNS.BPCN bit or the MRAM.MRCBPROTS.BPCN bit to 1.
Refer to section 65, MRAM for details.

Table 7.9 Corresponding Address Block for Each Set of Bits

Register	Bits	Corresponding Address Block (Offset Address)	Register	Bits	Corresponding Address Block (Offset Address)
BPS0	BP0[3:0]	FF E000h to FF FFFFh	BPS64	BP0[3:0]	BF E000h to BF FFFFh

b23	BP23	Block Protect 23		R
b31 to b24	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. After setting a value, this register will retain the set value.

The BPSD0 register enables or disables block protection for data MRAM. There are registers for secure application developers (BPSD0_S) and non-secure application developers (BPSD0_NS).
Block protection for data MRAM can be performed in 2-Kbyte units. Use the BPSD0_S register to protect address blocks placed in the secure area of data MRAM, and use the BPSD0_NS register to protect address blocks placed in the non-secure area.

BPi[3:0] Bits (Block Protect i)

Each bit corresponds to a 2-Kbyte address block in data MRAM. The address block (offset address) corresponding to the bit is calculated using the following formula.

90 0000h + i × 800h to 90 07FFh + i × 800h

Setting this bit to 0 protects the corresponding address block, preventing it from programming. Setting it to 1 removes the protection.

For details, refer to section 65, MRAM.

7.2.18 Permanent Block Protect Register m for Secure Application (PBPSm_S) (m = 0 to 3, 16, 17), Permanent Block Protect Register m for Non-Secure Application (PBPSm_NS) (m = 0 to 3, 16, 17)

Address(es): OFSM.PBPS0_S 86E1 0A00h to OFSM.PBPS3_S 86E1 0A0Ch, OFSM.PBPS16_S 86E1 0A40h, OFSM.PBPS17_S 86E1 0A44h, OFSM_NS.PBPS0_NS 06E2 0C00h to OFSM_NS.PBPS3_NS 06E2 0C0Ch, OFSM_NS.PBPS16_NS 06E2 0C40h, OFSM_NS.PBPS17_NS 06E2 0C44h

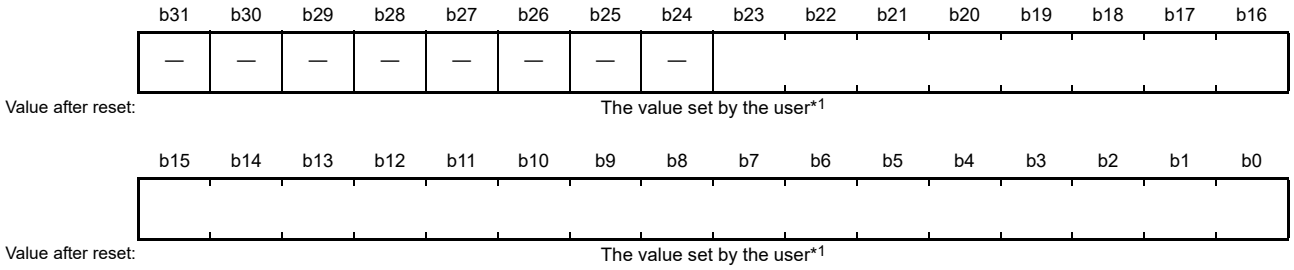
	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	The value set by the user*1															

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

PBPSm register is used to prohibit rewriting of the BPSn register. There are six registers each for secure application developers (PBPSm_S) and non-secure application developers (PBPSm_NS). Protect the BPSn_S registers with the PBPSm_S registers, and the BPSn_NS registers with the PBPSm_NS registers.
Each bit of the PBPSm register corresponds to the BPSn.BPi[3:0] bits*1. For example, bit 0 of the PBPS0 register can prohibit rewriting of the BPS0.BP0[3:0] bits, and bit 0 of the PBPS1 register can prohibit rewriting of the BPS4.BP0[3:0] bits.

Note 1. The BPSn.BPi[3:0] bits correspond to bit j of the PBPSm register can be calculated by the following formula:
n = int ((m × 32 + j) / 8) = 4m + int (j / 8)
i = (m × 32 + j) % 8 = j % 8



Each bit of the PBPSm register can be set to 0 only when the corresponding BPSn.BPi[3:0] bits are 0000b. Once a bit in the PBPSm register is set to 0, it can never be set back to 1, thus permanently protecting an address block in the code MRAM.
For details, refer to section 65, MRAM.

Table 7.10 Relationship Between the Bits in the PBPSm Register and the BPSn.BPi[3:0] Bits

Bit j of the PBPSm Register	Corresponding BPSn.BPi[3:0] Bits	Description
1	1111b	Program to addresses 100 0000h – (n × 8 + i +1) × 2000h to FF FFFFh – (n × 8 + i) × 2000h is enabled.
	0000b	Program to addresses 100 0000h – (n × 8 + i +1) × 2000h to FF FFFFh – (n × 8 + i) × 2000h is disabled.
0	0000b	Program to addresses 100 0000h – (n × 8 + i +1) × 2000h to FF FFFFh – (n × 8 + i) × 2000h is permanently disabled.

7.2.19 Data MRAM Permanent Block Protect Register 0 for Secure Application (PBPSD0_S), Data MRAM Permanent Block Protect Register 0 for Non-Secure Application (PBPSD0_NS)

Address(es): OFSM.PBPSD0_S 86E1 0A80h, OFSM_NS.PBPSD0_NS 06E2 0C80h

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

PBPSD0 register is used to prohibit rewriting of the BPSD0 register. There are registers for secure application developers (PBPSD0_S) and non-secure application developers (PBPSD0_NS). Bits 24 to 31 are reserved and should be set to 1. Protect the BPSD0_S registers with the PBPSD0_S registers, and the BPSD0_NS registers with the PBPSD0_NS registers.

Each bit of the PBPSD0 register corresponds one-to-one with a bit of the BPSD0 register.

Each bit of the PBPSD0 register can be set to 0 only when the corresponding bit in the BPSD0 register is 0. Once a bit in the PBPSD0 register is set to 0, it can never be set back to 1, thus permanently protecting an address block in the data MRAM.

For details, refer to section 65, MRAM.

7.2.20 Secure MRAM Option Setting Memory Protect Register n (MOFSPSn_S) (n = 0 to 3)

Address(es): OFSM.MOFSPS0_S 86E3 0E60h to OFSM.MOFSPS3_S 86E3 0E6Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	The value set by the user*1															

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The MOFSPSn_S register disables programming of registers with the secure attribute within the option setting memory listed in Table 7.1.
Each bit of the MOFSPSn_S register corresponds to each register (including reserved areas) at addresses 86C2 E820h to 86C2 E9FCh. For example, bit 12 of the MOFSPS0_S register corresponds to the DUALSEL register, bit 20 of the MOFSPS0_S register corresponds to the SAS register, and bit 20 of the MOFSPS3_S register corresponds to the BLSEL_SEL register. Bits 24 to 31 of the MOFSPS3_S register are reserved bits.
When each bit is set to 0, the corresponding register cannot be programmed permanently.
For details, refer to section 65, MRAM.

7.2.21 Non-secure MRAM Option Setting Memory Protect Register 0 (MOFSPS0_NS)

Address(es): OFSM_NS.MOFSPS0_NS 06E3 0EE0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	The value set by the user*1															

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The MOFSPS0_NS register disables programming of registers with the non-secure attribute within the option setting memory listed in Table 7.1.
Each bit of the MOFSPS0_NS register corresponds to each register (including reserved areas) at addresses 06C4 EC20h to 06C4 EC7Ch. Bit 16 of the MOFSPS0_NS register corresponds to the BANKSEL_NS register, and bit 20 of the MOFSPS0_NS register corresponds to the BLSEL_NS register. Bits 24 to 31 of the MOFSPS0_NS register are reserved bits.
When each bit is set to 0, the corresponding register cannot be programmed permanently.
For details, refer to section 65, MRAM.

7.2.22 Secure Switchable OTP Option Setting Memory Protect Register n (SOFSPSn_S) (n = 0 to 3)

Address(es): OFSM.SOFSPS0_S 86E3 0E00h to OFSM.SOFSPS3_S 86E3 0E0Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	The value set by the user*1															

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The SOFSPSn_S register disables programming of switchable-OTP registers with the secure attribute within the option setting memory listed in Table 7.2.
Each bit of the SOFSPSn_S register corresponds to each register (including reserved areas) at addresses 86E1 0620h to 86E1 07FCh. For example, bit 8 of the SOFSPS0_S register corresponds to the OFS0 register, and bit 0 of the SOFSPS3_S register corresponds to the OFS1_S register. Bits 20 to 27 of the SOFSPS1_S register and bits 24 to 31 of the SOFSPS3_S register are reserved bits.
When each bit is set to 0, the corresponding register cannot be programmed permanently.
For details, refer to section 65, MRAM.

7.2.23 Non-secure Switchable OTP Option Setting Memory Protect Register 0 (SOFSPS0_NS)

Address(es): OFSM_NS.SOFSPS0_NS 06E3 0E80h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	The value set by the user*1															

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The SOFSPS0_NS register disables programming of switchable-OTP registers with the non-secure attribute within the option setting memory listed in Table 7.2.
Each bit of the SOFSPS0_NS register corresponds to each register (including reserved areas) at addresses 06E2 0820h to 06E2 087Ch. Bit 12 of the SOFSPS0_NS register corresponds to the OFS1_NS register. Bits 24 to 31 of the SOFSPS0_NS register are reserved bits.
When each bit is set to 0, the corresponding register cannot be programmed permanently.
For details, refer to section 65, MRAM.

7.2.24 FSBL Control Register 0 (FSBLCTRL0)

Address(es): OFSM.FSBLCTRL0 86E0 0400h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	—	—	—	—	FSBLCLK[2:0]			FSBLSKIPDS[2:0]			FSBLSKIPSW[2:0]			FSBLEN[2:0]		
	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	FSBLEN[2:0]	FSBL Enable	b2 b0 0 0 0: FSBL is enabled. 1 1 1: FSBL is disabled. Settings other than above are prohibited.	R
b5 to b3	FSBLSKIPSW[2:0]	FSBL Skip Enable for Software Reset	b5 b3 0 0 0: Skip FSBL at software reset 1 1 1: Reboot from FSBL even at software reset Settings other than above are prohibited.	R
b8 to b6	FSBLSKIPDS[2:0]	FSBL Skip Enable for Deep Software Standby Reset	b8 b6 0 0 0: Skip FSBL at deep software standby reset 1 1 1: Reboot from FSBL even at deep software standby reset Settings other than above are prohibited.	R
b11 to b9	FSBLCLK[2:0]	FSBL Operating Clock Frequency Select	b11 b9 0 0 0: CPUCLK0 is set to 150 MHz. 0 0 1: CPUCLK0 is set to 200 MHz. 0 1 0: CPUCLK0 is set to 300 MHz. Settings other than above are prohibited. Refer to Table 7.11 for the other clock frequencies.	R
b31 to b12	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The FSBLCTRL0 register specifies the operation of the first-stage boot loader (FSBL).

FSBLEN[2:0] Bits (FSBL Enable)

These bits select whether to boot from FSBL after a reset is released.
When these bits are set to 111b, the system boots from the user extra MRAM area or the code MRAM.

FSBLSKIPSW[2:0] Bits (FSBL Skip Enable for Software Reset)

These bits select whether to reboot from FSBL or skip the FSBL after a software reset. These bits are valid only when the FSBLEN[2:0] bits are set to 000b.

FSBLSKIPDS[2:0] Bits (FSBL Skip Enable for Deep Software Standby Reset)

These bits select whether to reboot from FSBL or skip the FSBL after a deep software standby reset. These bits are valid only when the FSBLEN[2:0] bits are set to 000b.

FSBLCLK[2:0] Bits (FSBL Operating Clock Frequency Select)

These bits select the operating clock frequency when FSBL is being executed. These bits are valid only when the FSBLEN[2:0] bits are set to 000b. Table 7.11 lists the system clock frequencies for each setting value.

Table 7.11 Relationship Between the FSBLCLK[2:0] Bit Setting and System Clock Frequencies

	FSBLCLK[2:0] Bits		
System Clock	**000b**	**001b**	**010b**
CPUCLK0	150 MHz	200 MHz	300 MHz
ICLK	150 MHz	200 MHz	300 MHz
MRICLK	150 MHz	200 MHz	300 MHz
MRPCLK	75 MHz	100 MHz	150 MHz
PCLKA	150 MHz	100 MHz	150 MHz
PCLKB	75 MHz	50 MHz	75 MHz

7.2.25 FSBL Control Register 1 (FSBLCTRL1)

Address(es): OFSM.FSBLCTRL1 86E0 0404h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FSBLEXMD[1:0]	
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b1, b0	FSBLEXMD[1:0]	FSBL Execution Mode	b1 b0 0 0: CRC validation, no measurement report 0 1: CRC validation, measurement report 1 0: HMAC authentication, no measurement report 1 1: HMAC authentication, measurement report	R
b31 to b2	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The FSBLCTRL1 register specifies the operation when the first-stage boot loader (FSBL) verifies the integrity of the OEM boot loader (OEM_BL).

FSBLEXMD[1:0] Bits (FSBL Execution Mode)

These bits select whether FSBL validates the integrity of the OEM_BL by checking the CRC value or by performing HMAC authentication. These bits also specify whether to generate a measurement report during the verification.

7.2.26 FSBL Control Register 2 (FSBLCTRL2)

Address(es): OFSM.FSBLCTRL2 86E0 0408h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	PORTGN[4:0]					PORTPN[3:0]			
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	PORTPN[3:0]	FSBL Error Notification Pin Select*2	b3 b0 0 0 0 0: Pm00 pin 0 0 0 1: Pm01 pin : : 1 1 1 1: Pm15 pin	R
b8 to b4	PORTGN[4:0]	FSBL Error Notification Port Select*3	b8 b4 0 0 0 0 0: PORT0 0 0 0 0 1: PORT1 : : 1 0 0 0 0: PORTG Settings other than above are prohibited.	R
b31 to b9	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.
Note 2. Do not select a non-existent pin.
Note 3. Do not select a non-existent port.

The FSBLCTRL2 register selects the pin to output an error if an error occurs during execution of the first-stage boot loader (FSBL) or if the integrity of the OEM boot loader (OEM_BL) cannot be verified. To use this function, set the selected pin to the general output port.

PORTPN[3:0] Bits (FSBL Error Notification Pin Select)

These bits specify the “n” of the Pmn pin.

PORTGN[4:0] Bits (FSBL Error Notification Port Select)

These bits specify the “m” of the Pmn pin.

7.2.27 Code Certificate 0 Start Address Register n (SACC0n) (n = 0 to 3)

Address(es): OFSM.SACC00 86E0 0420h, OFSM.SACC01 86E0 0440h, OFSM.SACC02 86E0 0460h, OFSM.SACC03 86E0 0480h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	The value set by the user*1															

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The SACC0n register specifies the start address of the area where the code certificate is stored when startup area 0 is used.
This register is in the OTP area and cannot be rewritten. It should be used in order from SACC00 to SACC03. FSBL searches for a non-blank register in order from SACC03 to SACC00 and uses the first one found as a valid register.

7.2.28 Code Certificate 1 Start Address Register n (SACC1n) (n = 0 to 3)

Address(es): OFSM.SACC10 86E0 0430h, OFSM.SACC11 86E0 0450h, OFSM.SACC12 86E0 0470h, OFSM.SACC13 86E0 0490h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	The value set by the user*1															

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The SACC1n register specifies the start address of the area where the code certificate is stored when startup area 1 is used.
This register is in the OTP area and cannot be rewritten. It should be used in order from SACC10 to SACC13. FSBL searches for a non-blank register in order from SACC13 to SACC10 and uses the first one found as a valid register.

7.2.29 Measurement Report Start Address Register (SAMR)

Address(es): OFSM.SAMR 86E0 0414h

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The SAMR register specifies the start address of the area that stores the measurement report generated when the first-stage boot loader (FSBL) is executed.
Specify an address in SRAM for this register. The size of the measurement report is 68 bytes.

7.2.30 OEM_ROOT_PK Revoke Register (REVOKE)

Address(es): OFSM.REVOKE 86E3 0E10h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	REVOKE3	REVOKE2	REVOKE1	REVOKE0
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b0	REVOKE0	OEM_ROOT_PK0 Revoke	0: OEM_ROOT_PK0 is revoked. 1: OEM_ROOT_PK0 is enabled.	R
b1	REVOKE1	OEM_ROOT_PK1 Revoke	0: OEM_ROOT_PK1 is revoked. 1: OEM_ROOT_PK1 is enabled.	R
b2	REVOKE2	OEM_ROOT_PK2 Revoke	0: OEM_ROOT_PK2 is revoked. 1: OEM_ROOT_PK2 is enabled.	R
b3	REVOKE3	OEM_ROOT_PK3 Revoke	0: OEM_ROOT_PK3 is revoked. 1: OEM_ROOT_PK3 is enabled.	R
b31 to b4	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The REVOKE register is used to revoke public root key (OEM_ROOT_PK) for the public key certificate of the OEM boot loader.
When revoking the key, revoke it in order starting from OEM_ROOT_PK3. FSBL searches for non-zero bits starting from the REVOKE3 bit, and uses the key corresponding to the first bit found.

REVOKEn Bit (OEM_ROOT_PKn Revoke) (n = 0 to 3)

This bit is used to revoke the HOEMRTPKn register.
When this bit is set to 0, 0000 0000h can be read from the corresponding HOEMRTPKn[i] registers (i = 0 to 11).

7.2.31 OEM_ROOT_PKn Hash Register [i] (HOEMRTPKn[i]) (n = 0 to 3; i = 0 to 11)

Address(es): OFSM.HOEMRTPK0[0] 86E0 0000h to OFSM.HOEMRTPK0[11] 86E0 002Ch,
OFSM.HOEMRTPK1[0] 86E0 0030h to OFSM.HOEMRTPK1[11] 86E0 005Ch,
OFSM.HOEMRTPK2[0] 86E0 0060h to OFSM.HOEMRTPK2[11] 86E0 008Ch,
OFSM.HOEMRTPK3[0] 86E0 0090h to OFSM.HOEMRTPK3[11] 86E0 00BCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	The value set by the user*1															

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The HOEMRTPKn register is a 48-byte register used to store the hash value of the public root key (OEM_ROOT_PK) for the OEM boot loader public key certificate.
This register can only be written to by the boot program.

7.2.32 HUK Zeroization Register (ZHUK)

Address(es): OFSM.ZHUK 86E3 0E20h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	ZHUKEN3	ZHUKEN2	ZHUKEN1	ZHUKEN0
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b0	ZHUKEN0	Tamper 0 Zeroization Enable*2	0: Zeroize HUK when tamper 0 event is detected 1: Do not zeroize HUK when tamper 0 event is detected	R
b1	ZHUKEN1	Tamper 1 Zeroization Enable*2	0: Zeroize HUK when tamper 1 event is detected 1: Do not zeroize HUK when tamper 1 event is detected	R
b2	ZHUKEN2	Tamper 2 Zeroization Enable*2	0: Zeroize HUK when tamper 2 event is detected 1: Do not zeroize HUK when tamper 2 event is detected	R
b3	ZHUKEN3	MREZC Zeroization Enable	0: Zeroization of HUK by the MREZC register is enabled. 1: Zeroization of HUK by the MREZC register is disabled.	R
b31 to b4	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

Note 2. Set the ZHUKENn bit to the inverted value of the SYSC.TAMPCR2.ZHUKEn bit (n = 0 to 2) (Refer to section 12, Battery Backup Function (VBATTBa)). For example, when the ZHUKEN2 to ZHUKEN0 bits are 101b, set the SYSC.TAMPCR2.ZHUKE2 to ZHUKE0 bits to 010b.

The ZHUK register is used to specify whether to zeroize the hardware unique key (HUK) when a tamper event is detected or when zeroization is requested by the MREZC register.

ZHUKENn Bit (Tamper n Zeroization Enable) (n = 0 to 2)

This bit selects whether to zeroize the hardware unique key (HUK) when a tamper event is detected.
When this bit is set to 0, set the SYSC.TAMPCR2.ZHUKEn bit to 1 (zeroize HUK on tamper n event).

ZHUKEN3 Bit (MREZC Zeroization Enable)

This bit enables/disables zeroization of the hardware unique key (HUK) by writing 3C07h to the MRAM.MREZC register.

7.2.33 Anti-Rollback Counter Setting Register (ARCCS)

Address(es): OFSM.ARCCS 86E3 0E30h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	ARCMD[1:0]		—	—	—	—	—	—	CNFARCNS[1:0]	
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b17, b16	CNFARCNS[1:0]	ARCNS Counter Configuration Select	b17 b16 0 0: The ARCNS counter is configured as four 256-bit counters. 0 1: The ARCNS counter is configured as single 1024-bit counter. 1 0: Setting prohibited. 1 1: The ARCNS counter is disabled.	R
b23 to b18	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b25, b24	ARCMD[1:0]	ARC Usage Mode Select	b25 b24 0 0: Mode 2 (ARCS usage mode) 0 1: Mode 1 (ARCOEMBL usage mode) 1 0: Setting prohibited. 1 1: All anti-rollback counters are not used.	R
b31 to b26	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

The ARCCS register is used to set the anti-rollback counter (ARC).

CNFARCNS[1:0] Bits (ARCNS Counter Configuration Select)

These bits are used to enable/disable the anti-rollback counter for non-secure application (ARCNS) and to select the counter configuration.

When these bit are set to 00b, the ARCNS is divided into four 256-bit counters (ARCNS0 to ARCNS3). When these bits are set to 01b, the ARCNS operates as a 1024-bit counter.

When these bit are set to 11b, the ARCNS is disabled. Do not issue the increment counter command or read counter command to the ARCNS.

ARCMD[1:0] Bits (ARC Usage Mode Select)

These bits are used to select the anti-rollback counter for use in version management by the boot program.

Set these bits to 01b when the OEM boot loader is to be used to validate the application program. Set them to 00b when the first-stage boot loader (FSBL) is to be used to validate the application program.

If they are set to 11b, the anti-rollback counters are not incremented even if the increment counter command is issued.

7.2.34 Anti-Rollback Counter for Secure Application [i] (ARCS[i]) (i = 0 to 31)

Address(es): OFSM.ARCS[0] 86F4 1D00h to OFSM.ARCS[31] 86F4 1D7Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	The value set by the user*1															

Note 1. The value for a blank product is 0000 0000h. When an increment counter command is issued, the least significant bit set to 0 becomes 1. Once a bit is set to 1, it cannot be set back to 0.

The ARCS register is a 1024-bit anti-rollback counter for secure application. The most significant 32 bits are stored in the ARCS[31] register, and the least significant 32 bits are stored in the ARCS[0] register.
When an increment counter command is issued to the ARCS register, the least significant bit set to 0 is set to 1. After all bits are set to 1, the value does not change even if an increment counter command is issued.

7.2.35 Anti-Rollback Counter n for Non-Secure Application [i] (ARCNSn[i]) (n = 0 to 3, i = 0 to 7)

Address(es): OFSM.ARCNS0[0] 86F4 1E00h to OFSM.ARCNS0[7] 86F4 1E1Ch,
OFSM.ARCNS1[0] 86F4 1E20h to OFSM.ARCNS1[7] 86F4 1E3Ch,
OFSM.ARCNS2[0] 86F4 1E40h to OFSM.ARCNS2[7] 86F4 1E5Ch,
OFSM.ARCNS3[0] 86F4 1E60h to OFSM.ARCNS3[7] 86F4 1E7Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	The value set by the user*1															

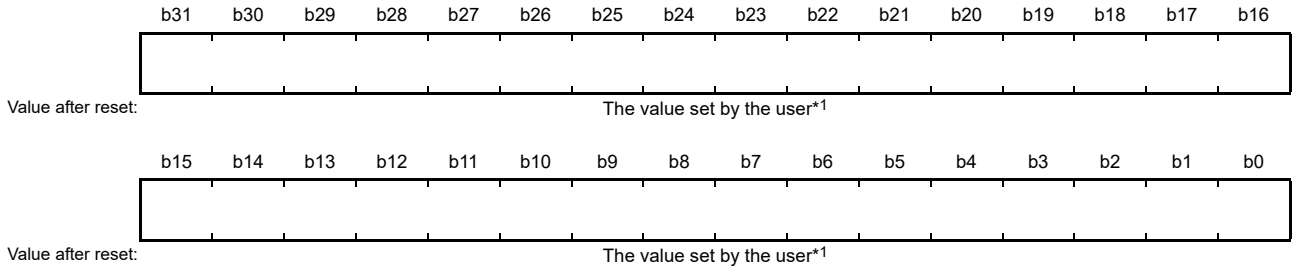
	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	The value set by the user*1															

Note 1. The value for a blank product is 0000 0000h. When an increment counter command is issued, the least significant bit set to 0 becomes 1. Once a bit is set to 1, it cannot be set back to 0.

The ARCNSn registers are 256-bit anti-rollback counters for non-secure applications. This configuration is enabled when the ARCCS.CNFARCNS[1:0] bits are set to 00b. The most significant 32 bits are stored in the ARCNS[7] register, and the least significant 32 bits are stored in the ARCNS[0] register.
When an increment counter command is issued to the ARCNSn register, the least significant bit set to 0 is set to 1. After all bits are set to 1, the value does not change even if an increment counter command is issued.

7.2.36 Anti-Rollback Counter for Non-Secure Application [i] (ARCNS[i]) (i = 0 to 31)

Address(es): OFSM.ARCNS[0] 86F4 1E00h to OFSM.ARCNS[31] 86F4 1E7Ch



Note 1. The value for a blank product is 0000 0000h. When an increment counter command is issued, the least significant bit set to 0 becomes 1. Once a bit is set to 1, it cannot be set back to 0.

The ARCNS registers are 1024-bit anti-rollback counters for non-secure applications. This configuration is enabled when the ARCCS.CNFARCNS[1:0] bits are set to 01b. The most significant 32 bits are stored in the ARCNS[31] register, and the least significant 32 bits are stored in the ARCNS[0] register.
When an increment counter command is issued to the ARCNS register, the least significant bit set to 0 is set to 1. After all bits are set to 1, the value does not change even if an increment counter command is issued.

7.2.37 Anti-Rollback Counter for OEM Boot Loader [i] (ARCOEMBL[i]) (i = 0, 1)

Address(es): OFSM.ARCOEMBL[0] 86F4 1F00h, OFSM.ARCOEMBL[1] 86F4 1F04h

Note 1. The value for a blank product is 0000 0000h. When an increment counter command is issued, the least significant bit set to 0 becomes 1. Once a bit is set to 1, it cannot be set back to 0.

The ARCOEMBL register is a 64-bit anti-rollback counter for OEM boot loader. The upper 32 bits are stored in the ARCOEMBL[1] register, and the lower 32 bits are stored in the ARCOEMBL[0] register.
When an increment counter command is issued to the ARCOEMBL register, the least significant bit set to 0 is set to 1. After all bits are set to 1, the value does not change even if an increment counter command is issued.

7.2.38 User Extra MRAM Configuration Register (UMRECR)

Address(es): OFSM.UMRECR 86E3 0E50h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DCDCCTL
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	UMREEN	—	—	—	—	—	—	—	UMREMS
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b0	UMREMS	User Extra MRAM Area Memory Type Select	0: Memory type of the user extra MRAM area is OTP. 1: Memory type of the user extra MRAM area is MRAM.	R
b7 to b1	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b8	UMREEN	User Extra MRAM Enable	0: Execute a program in the user extra MRAM area 1: Do not execute a program in the user extra MRAM area	R
b15 to b9	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R
b16	DCDCCTL	DC-DC Converter Control	0: DC-DC converter is disabled after a reset (External VDD mode). 1: DC-DC converter is enabled after a reset.	R
b31 to b17	—	Reserved	When reading, these bits return the value written by the user. The write value should be 1.	R

Note 1. The value for a blank product is FFFF FFFFh. A bit programmed to 0 becomes 0. Once a bit is set to 0, it cannot be set back to 1.

UMREMS Bit (User Extra MRAM Area Memory Type Select)

This bit selects the memory type of the user extra MRAM area from either MRAM or OTP. When 1 (MRAM) is selected, the user extra MRAM area can be rewritten any number of times within the range specified in the electrical characteristics. When 0 (OTP) is selected, the user extra MRAM area can be programmed only once and cannot be rewritten after it has been written once.

UMREEN Bit (User Extra MRAM Enable)

This bit selects whether to execute the program in the user extra MRAM area when a reset is released.
When the FSBLEN[2:0] bits are 111b and this bit is 0, the system boots from the user extra MRAM. When the FSBLEN[2:0] bits are 111b and this bit is 1, the system boots from the code MRAM.

DCDCCTL Bit (DC-DC Converter Control)

This bit selects whether to operate the DC-DC converter after a reset.
When this bit is set to 1, the MCU starts up in DC-DC mode after a reset. When this bit is set to 0 the MCU starts up in external VDD mode after a reset.

7.3 Setting the Option-Setting Memory

7.3.1 Allocation of Data in the Option-Setting Memory

Data for programming in the option-setting memory should be allocated to the addresses shown in Table 7.1 and Table 7.2. The method of data allocation (source code syntax) differs depending on the compiler. Refer to the compiler manual for details.

7.3.2 Programming to Option-Setting Memory

To write the data allocated above into the option-setting memory, use one of the following methods.

(1) Rewriting by Self-Programming

Use the configuration setting command to write data to the option-setting memory in the extra MRAM area (refer to Table 7.1). Use the program command to write data to registers except the HOEMRTPKn register (n = 0 to 3) and the anti-rollback counter in the option-setting memory of the OTP area (refer to Table 7.2).
The anti-rollback counter can only be updated by the increment counter command.
For details of the configuration setting command, program command, and increment counter command, refer to section 65, MRAM.

(2) Rewriting by Serial Programmer or Emulator

The specific procedure varies depending on the tool used. For details, refer to the instruction manual of the tool used.
This MCU provides the following two setting procedures.

- The data allocated as described in section 7.3.1 above is taken from the object file or Motorola S-format file generated by the compiler and programmed into the MCU.
- Set values directly into each register using the tool's GUI interface.

7.3.3 Security Attributes of Option-Setting Memory

The option-setting memory contains registers with secure attribute and registers with non-secure attribute (refer to Table 7.1 and Table 7.2).
Registers with secure attribute can only be read from a secure application. Attempting to read from a non-secure application will result in a Protect Zone access error. Registers with non-secure attribute can be read from any application.
The conditions for rewriting the option setting memory vary depending on the rewriting method.

(1) Rewriting by Self-Programming

Registers with secure attribute can only be rewritten from a secure application. Issuing a commands from a non-secure application will result in a Protect Zone access error. Registers with the non-secure attribute can be rewritten from any application.

(2) Rewriting by Serial Programmer or Emulator

Rewriting registers with secure attribute requires Secure Application Developer privileges (Authentication Level 2 (AL2)); rewriting registers with non-secure attribute requires Non-secure Application Developer or higher privileges (Authentication Level 1 or 2 (AL1 or AL2)).

7.3.4 Registers with Selectable Security Attributes for Each Bit

There are three sets of registers in the option-setting memory, consisting of three registers for non-secure, secure, and attribute selection, as shown below.

- Bank select register (BANKSEL_NS, BANKSEL_S, BANKSEL_SEL)
- Block select register (BLSEL_NS, BLSEL_S, BLSEL_SEL)
- Option function select register 1 (OFS1_NS, OFS1_S, OFS1_SEL)

These registers can be selected to use the setting for non-secure or secure for each bit.
As shown in the example in Figure 7.1, when a bit in the attribute select register is set to 0, the corresponding bit in the secure register is used, and when set to 1, the corresponding bit in the non-secure register is used.
For example, in the case of the OFS1 register, if the reset output and HOCO settings are to be controlled from the non-secure application and the PVD0 setting from the secure application, the OFS1_SEL register must be set to F000 0F00h.

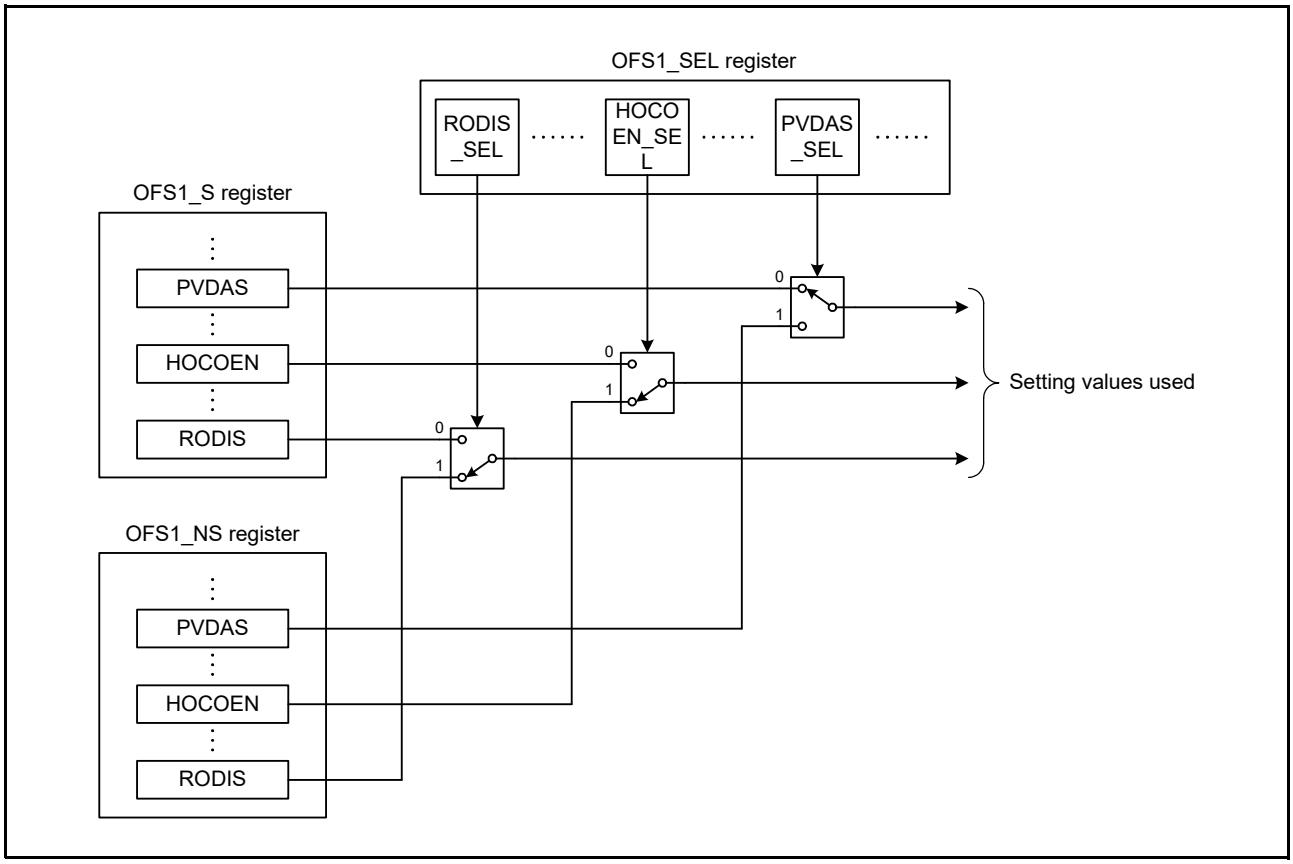


Figure 7.1 Selection of applied value

7.3.5 Reflection Timing of the Setting Value

When the SAS, BPS_NS, BPS_S, PBPS_NS, and PBPS_S registers are rewritten, the set values are immediately reflected in each circuit. When other registers are rewritten, the set values are reflected after the MCU is reset.

7.4 Usage Note

7.4.1 Set Value for Reserved Area

(1) Attribute select register area (86C2 E9E0h to 86C2 E9FFh)

When issuing a program command to the reserved registers or reserved bits in this area, write 0000 0000h or 0, respectively. If 1 is programmed, subsequent operation is not guaranteed.

(2) Areas other than the above

When issuing a program command to the reserved registers or reserved bits in this area, write FFFF FFFFh or 1, respectively. If 0 is programmed, subsequent operation is not guaranteed.

7.4.2 Notes on the First-Stage Boot Loader (FSBL)

Setting the FSBLCTRL0.FSBLEN[2:0] bits to 000b causes FSBL to be executed after the system reset is released. At this time, setting the FSBLSKIPSW[2:0] and the FSBLSKIPDS[2:0] bits to 000b allows the FSBL to skip execution after software reset and deep software standby reset, respectively.
However, after a software reset or deep software standby reset, if any reset detection flag other than the software reset detection flag and the deep software standby reset detection flag is set to 1, the FSBL is executed without being skipped.
When using this function, be sure to clear the RSTSR0, RSTSR1, and RSTSR3 registers before executing a software reset or before transitioning to deep software standby mode.

8. Programmable Voltage Detection Circuit (PVD)

8.1 Overview

The programmable voltage detection (PVD) module monitors the voltage input to the VCC pin. The detection levels are selectable by software.
The PVD module consists of several voltage detectors which measure the voltage being input to the VCC pin. Detection of a change in the input voltage on the VCC pin can be set with various voltage thresholds by registers of the PVD module.
Each of the voltage detectors has an associated voltage monitoring circuit. The voltage monitoring registers can set the PVD to trigger an interrupt, event link output, or reset when the threshold is exceeded.
Table 8.1 lists the specifications of the PVD module. Figure 8.1 is a block diagram of the voltage monitoring 0 reset circuit. Figure 8.2 and Figure 8.3 are block diagrams of the voltage monitoring m interrupt/reset circuit (m = 1, 2) and the voltage monitoring n reset circuit (n = 4, 5), respectively.
Each PVD circuit consists of a low voltage detector (LVD) and a high voltage detector (HVD). The LVD detects VCC falling below the voltage threshold, and the HVD detects VCC rising above the voltage threshold.
The PVDn circuits are implemented for security and their available functions are limited in comparison with those of the PVDm circuits.
The PVDn circuits have a register locking function for security.

A separate voltage detector for the core voltage is also implemented. It monitors the voltage input to VDD and the detection level is predefined in hardware.
The voltage detector for the core voltage has a corresponding voltage monitoring circuit. The voltage monitoring circuit for the core voltage can generate a reset (core voltage monitoring reset) when the core voltage crosses respective thresholds to become less than Vdet_VDDL or to exceed Vdet_VDDH.
The core voltage monitoring reset (CVMR) function is enabled when OFS2.CVMRCTL = 0.

Table 8.1 PVD Specifications (1/2)

Item		Programmable Voltage Monitoring 0	Programmable Voltage Monitoring m (m = 1, 2)	Programmable Voltage Monitoring n (n = 4, 5)
Voltage monitoring	Monitored voltage	VCC	VCC	VCC
	Detection event	Vdet0 > VCC	Voltage rises or falls past Vdetm	Voltage rises or falls past Vdetn
	Detection voltage	Vdet0 is selectable from among 7 different levels by using the OFS1.VDSEL[2:0] bits	Vdetm is selectable from among 12 different levels by using the PVDmCMPCR.PVDLVL[4:0] bits	Vdetn is selectable from among 12 different levels by using the PVDnCMPCR.PVDLVL[4:0] bits
	Monitoring flag	None	PVDmSR.MON flag: Monitors whether voltage is higher or lower than Vdetm	None
			PVDmSR.DET flag: Vdetm crossing detection	

Table 8.1 PVD Specifications (2/2)

Item		Programmable Voltage Monitoring 0	Programmable Voltage Monitoring m (m = 1, 2)	Programmable Voltage Monitoring n (n = 4, 5)
Process upon voltage detection	Reset	Voltage monitoring 0 reset	Voltage monitoring m reset	Voltage monitoring n reset
		Reset when Vdet0 > VCC CPU operation restarts after the specified time with VCC > Vdet0	Reset condition selectable: Reset when Vdetm > VCC (LVD) or Vdetm < VCC (HVD) CPU restart timing selectable: after the specified time with LVD or HVD	Reset condition selectable: Reset when Vdetn > VCC (LVD) or Vdetn < VCC (HVD)
	Interrupt	None	Voltage monitoring m interrupt	None
			Non-maskable interrupt or maskable interrupt selectable	
			Interrupt request issued in response to either or both LVD and HVD	
Digital filter	Enable/Disable switching	Digital filter function not available	Available	Available
	Sampling time	—	1/s LOCO frequency × 2 (s: 2, 4, 8, 16)	1/s LOCO frequency × 2 (s: 2, 4, 8, 16)
Event linking		None	Output of event signals on detection of Vdetm crossings	None
Register locking function		None	None	PVDLR register

Table 8.2 CVM Specifications

Item		Core Voltage Monitoring
Voltage monitoring	Monitored voltage	VDD
	Detection event	Voltage falls past Vdet_VDDL Voltage rises past Vdet_VDDH
	Detection voltage	Predetermined level*1
Process upon voltage detection	Reset	Core voltage monitoring reset*2
		Reset when Vdet_VDDL > VDD or Vdet_VDDH < VDD CPU operation restarts after the specified time with Vdet_VDDL ≤ VDD ≤ Vdet_VDDH

Note 1. This refers to Vdet_VDDL and Vdet_VDDH.
Note 2. For the core voltage monitoring reset, see section 6, Resets.

Bit	Symbol	Bit Name	Description	R/W
b0	NONSEC0	PVD1 Security Attribute Setting	Target registers: Registers for PVD1 0: Secure 1: Non-secure	R/W
b1	NONSEC1	PVD2 Security Attribute Setting	Target registers: Registers for PVD2 0: Secure 1: Non-secure	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.
Note: Set the PRCR.PRC4 bit to 1 (enabling writing) before writing to this register.

This register controls the secure attribute of PVD registers.

NONSEC0 Bit (PVD1 Security Attribute Setting)

This bit controls the security attribute of the PVD1CMPCR, PVD1CR0, PVD1CR1, PVD1SR, and PVD1FCR registers.

NONSEC1 Bit (PVD2 Security Attribute Setting)

This bit controls the security attribute of the PVD2CMPCR, PVD2CR0, PVD2CR1, PVD2SR, and PVD2FCR registers.

8.2.2 Voltage Monitoring m Comparator Control Register (PVDmCMPCR) (m = 1, 2)

Address(es): SYSC.PVD1CMPCR 8701 9A58h, SYSC.PVD2CMPCR 8701 9A5Ch,
SYSC_NS.PVD1CMPCR 0701 9A58h, SYSC_NS.PVD2CMPCR 0701 9A5Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	PVDE	—	—	PVDLVL[4:0]				
Value after reset:	0	0	0	0	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	PVDLVL[4:0]	Voltage Detection m Level Select	b4 b0 0 0 1 0 0: 3.14 V (Vdetm_4) 0 0 1 0 1: 3.10 V (Vdetm_5) 0 0 1 1 0: 3.08 V (Vdetm_6) 0 0 1 1 1: 2.85 V (Vdetm_7) 0 1 0 0 0: 2.83 V (Vdetm_8) 0 1 0 0 1: 2.80 V (Vdetm_9) 0 1 0 1 0: 2.62 V (Vdetm_10) 0 1 0 1 1: 2.33 V (Vdetm_11) 0 1 1 0 0: 1.90 V (Vdetm_12) 0 1 1 0 1: 1.86 V (Vdetm_13) 0 1 1 1 0: 1.74 V (Vdetm_14) 0 1 1 1 1: 1.71 V (Vdetm_15) Others: Setting prohibited These are standard voltage levels at voltage drop. For the standard voltage levels at voltage rise, see section 67, Electrical Characteristics.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	PVDE	Voltage Detection m Enable	0: Voltage detection m circuit disabled 1: Voltage detection m circuit enabled	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC3 bit to 1 (enabling writing) before writing to this register.

PVDLVL[4:0] Bits (Voltage Detection m Level Select)

These bits can only be changed when all PVDmCMPCR.PVDE bits and all PVDnCMPCR.PVDE bits are 0. Do not set more than one among PVD1, PVD2, PVD4, and PVD5 to the same detection voltage.
Do not change these bits and the PVDmCMPCR.PVDE bit at the same time.

PVDE Bit (Voltage Detection m Enable)

When using the voltage detection m interrupt/reset or PVDmSR.MON flag, set this bit to 1. The voltage detection m circuit starts when td(E-A) has elapsed after the value of this bit has been changed from 0 to 1.
This bit can only be changed when the PVDmCR0.CMPE bit is 0.
When using the voltage detection m circuit in deep software standby mode, do not allow a transition to deep software standby mode 3.

8.2.3 Voltage Monitoring n Comparator Control Register (PVDnCMPCR) (n = 4, 5)

Address(es): SYSC.PVD4CMPCR 8701 9A64h, SYSC.PVD5CMPCR 8701 9A68h

	b7	b6	b5	b4	b3	b2	b1	b0
	PVDE	—	—	PVDLVL[4:0]				
Value after reset:	0	0	0	0	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	PVDLVL[4:0]	Voltage Detection n Level Select	b4 b0 0 0 1 0 0: 3.14 V (Vdetm_4) 0 0 1 0 1: 3.10 V (Vdetm_5) 0 0 1 1 0: 3.08 V (Vdetm_6) 0 0 1 1 1: 2.85 V (Vdetm_7) 0 1 0 0 0: 2.83 V (Vdetm_8) 0 1 0 0 1: 2.80 V (Vdetm_9) 0 1 0 1 0: 2.62 V (Vdetm_10) 0 1 0 1 1: 2.33 V (Vdetm_11) 0 1 1 0 0: 1.90 V (Vdetm_12) 0 1 1 0 1: 1.86 V (Vdetm_13) 0 1 1 1 0: 1.74 V (Vdetm_14) 0 1 1 1 1: 1.71 V (Vdetm_15) Others: Setting prohibited These are standard voltage levels at voltage drop. For the standard voltage levels at voltage rise, see section 67, Electrical Characteristics.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	PVDE	Voltage Detection n Enable	0: Voltage detection n circuit disabled 1: Voltage detection n circuit enabled	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC3 bit to 1 (enabling writing) before writing to this register.

PVDLVL[4:0] Bits (Voltage Detection n Level Select)

These bits can only be changed when all PVDmCMPCR.PVDE bits and all PVDnCMPCR.PVDE bits are 0. Do not set more than one among PVD1, PVD2, PVD4, and PVD5 to the same detection voltage.
Do not change these bits and the PVDnCMPCR.PVDE bit at the same time.

PVDE Bit (Voltage Detection n Enable)

When using the voltage detection n reset, set this bit to 1. The voltage detection n circuit starts when td(E-A) has elapsed after the value of this bit has been changed from 0 to 1.
This bit can only be changed when the PVDnCR0.CMPE bit is 0.
When using the voltage detection n circuit in deep software standby mode, do not allow a transition to deep software standby mode 3.

8.2.4 Voltage Monitoring m Circuit Control Register 0 (PVDmCR0) (m = 1, 2)

Address(es): SYSC.PVD1CR0 8701 9A70h, SYSC.PVD2CR0 8701 9A74h,
SYSC_NS.PVD1CR0 0701 9A70h, SYSC_NS.PVD2CR0 0701 9A74h

	b7	b6	b5	b4	b3	b2	b1	b0
	RN	RI	FSAMP[1:0]		—	CMPE	DFDIS	RIE
Value after reset:	1	0	0	0	x	0	1	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	RIE	Voltage Monitoring m Interrupt/ Reset Enable	0: Disabled 1: Enabled	R/W
b1	DFDIS	Voltage Monitoring m Digital Filter Disable	0: Digital filter enabled 1: Digital filter disabled	R/W
b2	CMPE	Voltage Monitoring m Circuit Comparison Result Output Enable	0: Voltage monitoring m circuit comparison result output disabled 1: Voltage monitoring m circuit comparison result output enabled	R/W
b3	—	Reserved	The read value is undefined. The write value should be 1.	R/W
b5, b4	FSAMP[1:0]	Sampling Clock Select	b5 b4 0 0: 1/2 LOCO frequency 0 1: 1/4 LOCO frequency 1 0: 1/8 LOCO frequency 1 1: 1/16 LOCO frequency	R/W
b6	RI	Voltage Monitoring m Circuit Mode Select	(1) When PVDmFCR.RHSEL = 0 0: Voltage monitoring m interrupt is generated whenever the voltage crosses Vdetm. 1: Voltage monitoring m reset is generated when the voltage crosses Vdetm while falling. (2) When PVDmFCR.RHSEL = 1 0: Setting prohibited 1: Voltage monitoring m reset is generated whenever the voltage crosses Vdetm while rising	R/W
b7	RN	Voltage Monitoring m Reset Negate Select	(1) When PVDmFCR.RHSEL = 0 0: Negation follows a stabilization time (tPVDm) after VCC > Vdetm is detected. 1: Negation follows a stabilization time (tPVDm) after assertion of the PVDm reset. (2) When PVDmFCR.RHSEL = 1 0: Negation follows a stabilization time (tPVDm) after VCC < Vdetm is detected. 1: Setting prohibited	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC3 bit to 1 (enabling writing) before writing to this register.

RIE Bit (Voltage Monitoring m Interrupt/Reset Enable)

The RIE bit enables or disables the corresponding voltage monitoring interrupt and voltage monitoring m reset. Ensure that neither the voltage monitoring m interrupt nor voltage monitoring m reset is generated during programming of the MRAM.

DFDIS Bit (Voltage Monitoring m Digital Filter Disable)

The DFDIS bit enables or disables the digital filter. When the DFDIS bit is 0 (digital filter enabled), set the LOCOCR.LCSTP bit to 0 (the LOCO is operating). When using the voltage monitoring m circuit in software standby or

deep software standby mode, set the DFDIS bit to 1 (digital filter disabled).

FSAMP[1:0] Bits (Sampling Clock Select)

The FSAMP[1:0] bits can only be modified when the PVDmCR0.DFDIS bit is 1 (digital filter disabled).
Do not modify the FSAMP[1:0] bits when the PVDmCR0.DFDIS bit is 0 (digital filter enabled).

RI Bit (Voltage Monitoring m Circuit Mode Select)

When the PVDmCR0.RI bit is 1 (voltage monitoring m reset selected), a transition to deep software standby mode 2 or 3 is not possible. In this case, the device makes the transition to deep software standby mode 1. To allow a transition to deep software standby mode 2 or 3, set the PVDmCR0.RI bit to 0 (voltage monitoring m interrupt selected).

RN Bit (Voltage Monitoring m Reset Negate Select)

- When PVDmFCR.RHSEL = 0

When setting the RN bit to 1 (negation follows a stabilization time after assertion of the PVDm reset signal), set the LOCOCR.LCSTP bit to 0 (the LOCO is operating). Furthermore, if a transition to software standby or deep software standby mode is to be made, the only possible value for the RN bit is 0 (negation follows a stabilization time after VCC > Vdetm is detected). Do not set the RN bit to 1 when this is the case.

- When PVDmFCR.RHSEL = 1

Do not set the RN bit to 1.

8.2.5 Voltage Monitoring n Circuit Control Register 0 (PVDnCR0) (n = 4, 5)

Address(es): SYSC.PVD4CR0 8701 9A7Ch, SYSC.PVD5CR0 8701 9A80h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	FSAMP[1:0]		—	CMPE	DFDIS	RE
Value after reset:	0	1	0	0	x	0	1	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	RE	Voltage Monitoring n Reset Enable	0: Disabled 1: Enabled	R/W
b1	DFDIS	Voltage Monitoring n Digital Filter Disable	0: Digital filter enabled 1: Digital filter disabled	R/W
b2	CMPE	Voltage Monitoring n Circuit Comparison Result Output Enable	0: Voltage monitoring n circuit comparison result output disabled 1: Voltage monitoring n circuit comparison result output enabled	R/W
b3	—	Reserved	The read value is undefined. The write value should be 1.	R/W
b5, b4	FSAMP[1:0]	Sampling Clock Select	b5 b4 0 0: 1/2 LOCO frequency 0 1: 1/4 LOCO frequency 1 0: 1/8 LOCO frequency 1 1: 1/16 LOCO frequency	R/W
b6	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC3 bit to 1 (enabling writing) before writing to this register.

RE Bit (Voltage Monitoring n Reset Enable)

The RE bit enables or disables the corresponding voltage monitoring n reset. Ensure that the voltage monitoring n reset is not generated during programming of the MRAM.

DFDIS Bit (Voltage Monitoring n Digital Filter Disable)

The DFDIS bit enables or disables the digital filter. When the DFDIS bit is 0 (digital filter enabled), set the LOCOCR.LCSTP bit to 0 (the LOCO is operating). When using the voltage monitoring n circuit in software standby or deep software standby mode, set the DFDIS bit to 1 (digital filter disabled).

FSAMP[1:0] Bits (Sampling Clock Select)

The FSAMP[1:0] bits can only be modified when the PVDnCR0.DFDIS bit is 1 (digital filter disabled).
Do not modify the FSAMP[1:0] bits when the PVDnCR0.DFDIS bit is 0 (digital filter enabled).

8.2.6 Voltage Monitoring m Circuit Control Register 1 (PVDmCR1) (m = 1, 2)

Address(es): SYSC.PVD1CR1 8701 90E0h, SYSC.PVD2CR1 8701 90E2h, SYSC_NS.PVD1CR1 0701 90E0h, SYSC_NS.PVD2CR1 0701 90E2h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	IRQSEL	IDTSEL[1:0]	
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b1, b0	IDTSEL[1:0]	Voltage Monitoring m Interrupt Generation Condition Select	(1) When PVDmFCR.RHSEL = 0 0 0: An interrupt is generated when VCC ≥ Vdetm (rise) is detected. 0 1: An interrupt is generated when VCC < Vdetm (drop) is detected. 1 0: An interrupt is generated when a voltage drop or rise is detected. 1 1: Settings prohibited (2) When PVDmFCR.RHSEL = 1 These bits are not applied.	R/W
b2	IRQSEL	Voltage Monitoring m Interrupt Type Select	0: Non-maskable interrupt 1: Maskable interrupt*1	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC3 bit to 1 (enabling writing) before writing to this register.

Note 1. When enabling maskable interrupts, do not change the value of the NMIER.PVDmEN bit in the ICU from the reset state.

8.2.7 Voltage Monitoring m Circuit Status Register (PVDmSR) (m = 1, 2)

Address(es): SYSC.PVD1SR 8701 90E1h, SYSC.PVD2SR 8701 90E3h, SYSC_NS.PVD1SR 0701 90E1h, SYSC_NS.PVD2SR 0701 90E3h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	MON	DET
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	DET	Voltage Monitoring m Voltage Change Detection Flag*1	(1) When PVDmFCR.RHSEL = 0 0: Undetected 1: Vdetm crossing is detected. (2) When PVDmFCR.RHSEL = 1 This bit is not applied.	R/W
b1	MON	Voltage Monitoring m Signal Monitor Flag	(1) When PVDmFCR.RHSEL = 0 0: VCC ≤ Vdetm 1: VCC > Vdetm or MON is disabled. (2) When PVDmFCR.RHSEL = 1 This bit is not applied.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC3 bit to 1 (enabling writing) before writing to this register.
Note 1. Only 0 can be written to this bit. After writing 0 to this bit, two cycles of the system clock (ICLK) are taken until the bit is read as 0.

DET Flag (Voltage Monitoring m Voltage Change Detection Flag)

The DET flag is enabled when the PVDmCMPCR.PVDE bit is 1 (voltage detection m circuit enabled) and the PVDmCR0.CMPE bit is 1 (voltage monitoring m circuit comparison result output enabled).
When setting the DET flag to 0, make sure that the PVDmCR0.RIE bit is set to 0 (voltage monitoring m interrupt/reset disabled).
When setting the RIE bit to 1 again after setting it to 0, wait for at least two cycles of PCLKB. Depending on the number of cycles of PCLKB defined for read access to I/O registers, at least two cycles of PCLKB may have to be secured as waiting time.

MON Flag (Voltage Monitoring m Signal Monitor Flag)

The MON flag is enabled when the PVDmCMPCR.PVDE bit is 1 (voltage detection m circuit enabled) and the PVDmCR0.CMPE bit is 1 (voltage monitoring m circuit comparison result output enabled).

8.2.8 Voltage Monitoring m Function Control Register (PVDmFCR) (m = 1, 2)

Address(es): SYSC.PVD1FCR 8701 9B20h, SYSC.PVD2FCR 8701 9B24h,
SYSC_NS.PVD1FCR 0701 9B20h, SYSC_NS.PVD2FCR 0701 9B24h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RHSEL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RHSEL	Rising Hysteresis Select	0: Hysteresis level for VCC drop detection selected 1: Hysteresis level for VCC rise detection selected	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The PVDmFCR.RHSEL bit can only be changed when all PVDmCMPCR.PVDE bits and all PVDnCMPCR.PVDE bits are 0.

RHSEL Bit (Rising Hysteresis Select)

When RHSEL = 0 for VCC drop detection, the hysteresis level is set above the detection voltage set by the PVDLVL[4:0] bits. When RHSEL = 1 for VCC rise detection, the hysteresis level is set under the detection voltage set by the PVDLVL[4:0] bits. For details of the hysteresis level of the PVD, see section 67, Electrical Characteristics.
If a PVD reset generated by VCC drop detection is required, set the RHSEL bit to 0.
If a PVD reset generated by VCC rise detection is required, set the RHSEL bit to 1.
When PVDmCR0.RI = 0, do not set the RHSEL bit to 1.
When PVDmCR0.RN = 1, do not set the RHSEL bit to 1.

8.2.9 Voltage Monitoring n Function Control Register (PVDnFCR) (n = 4, 5)

Address(es): SYSC.PVD4FCR 8701 9B2Ch, SYSC.PVD5FCR 8701 9B30h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RHSEL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RHSEL	Rising Hysteresis Select	0: Hysteresis level for VCC drop detection selected 1: Hysteresis level for VCC rise detection selected	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

The PVDnFCR.RHSEL bit can only be changed when all PVDmCMPCR.PVDE bits and all PVDnCMPCR.PVDE bits are 0.

RHSEL Bit (Rising Hysteresis Select)

When RHSEL = 0 for VCC drop detection, the hysteresis level is set above the detection voltage set by the PVDLVL[4:0] bits. When RHSEL = 1 for VCC rise detection, the hysteresis level is set under the detection voltage set by the PVDLVL[4:0] bits. For details of the hysteresis level of the PVD, see section 67, Electrical Characteristics.
If a PVD reset generated by VCC drop detection is required, set the RHSEL bit to 0.
If a PVD reset generated by VCC rise detection is required, set the RHSEL bit to 1.

8.2.10 Voltage Monitoring Lock Register (PVDLR)

Address(es): SYSC.PVDLR 8701 9B34h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	LOCK
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	LOCK	Lock Control	0: The control registers of PVD4 and PVD5 are writable 1: The control registers of PVD4 and PVD5 are not writable	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

LOCK Bit (Lock Control)

The initial value of the LOCK bit is 1. When the LOCK bit is 1, the control registers of PVD4 and PVD5 are not writable. 0 can be written to the LOCK bit only once after the LOCK bit has been initialized by a reset that initializes the LOCK bit (POR, RES# pin reset, voltage monitoring 0 reset (PVD0 reset)). The control registers of PVD4 and PVD5 are only writable in this state.

After that, writing either value to the LOCK bit causes its value to be fixed to 1 and the control registers of PVD4 and PVD5 become unwritable. The control registers of PVD4 and PVD5 are PVD4CMPCR, PVD5CMPCR, PVD4CR0, PVD5CR0, PVD4FCR, and PVD5FCR.

8.3 VCC Input Voltage Monitoring

8.3.1 Monitoring Vdet0

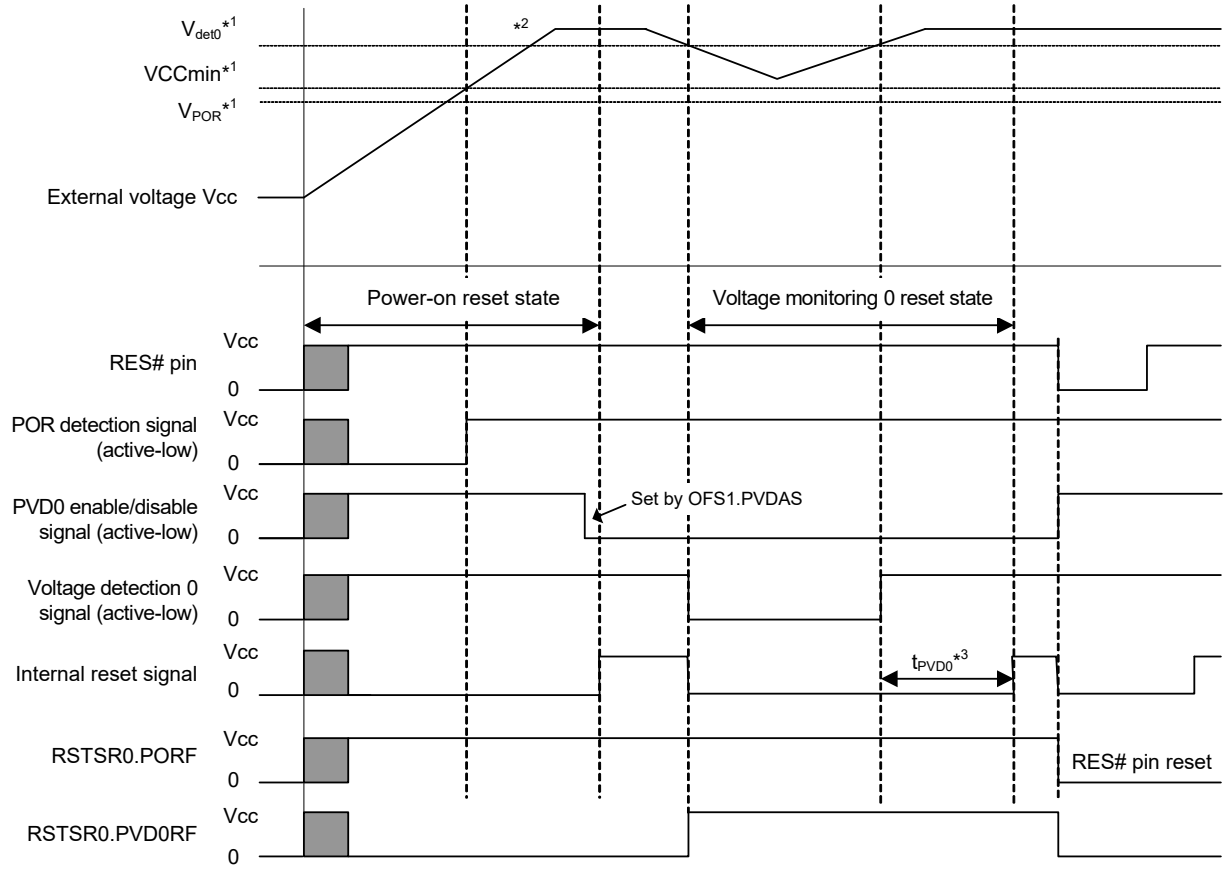
The results of comparison by voltage monitoring 0 cannot be read.

8.3.2 Monitoring Vdetm

Table 8.3 lists the procedures for setting up monitoring against Vdetm. After the settings are completed, the results of comparison by voltage monitoring m can be monitored by using the PVDmSR.MON flag.

Table 8.3 Procedures for Setting up Monitoring against Vdetm

Step		Monitoring the Results of Comparison by Voltage Monitoring m
Setting the voltage detection m circuit	1	Set PVDmCMPCR.PVDE = 0 (disabling the voltage detection m circuit). (Disable the voltage detection m circuit before writing to the PVDmCMPCR.PVDLVL[4:0] bits.)
	2	Select the detection voltage by setting the PVDmCMPCR.PVDLVL[4:0] bits.
	3	Set PVDmCMPCR.PVDE = 1 (enabling the voltage detection m circuit).
	4	Wait for at least td(E-A).*1
Setting the digital filter*2	5	Select the sampling clock for the digital filter by setting the PVDmCR0.FSAMP[1:0] bits.
	6	Set PVDmCR0.DFDIS = 0 (enabling the digital filter).
	7	Wait for at least 2s + 3 cycles of the LOCO (where s = 2, 4, 8, 16, and the sampling clock for the digital filter is the LOCO frequency-divided by s).
Enabling output	8	Set PVDmCR0.CMPE = 1 (enabling output of the results of comparison by voltage monitoring m).



Note 1. Steps 5 to 7 can be performed during the waiting time of step 4.
Note 2. Steps 5 to 7 are not required if the digital filter is not in use.

When changing the settings of PVDm again after setting PVDm according to the procedure in Table 8.3, set the PVDmCR0.CMPE bit to 0 first, and then set PVDm again according to the procedure in Table 8.3.
When changing the PVDmCMPCR.PVDLVL[4:0] bits, follow the description in section 8.2.2, Voltage Monitoring m Comparator Control Register (PVDmCMPCR) (m = 1, 2).

8.4 Voltage Monitoring 0 Reset

When using a voltage monitoring 0 reset, clear the OFS1.PVDAS bit to 0 (enabling the voltage monitoring 0 reset after a reset).

Figure 8.4 shows an example of the operation of the voltage monitoring 0 reset.

Note . For details on the electrical characteristics, see section 67, Electrical Characteristics.
Note 1. Vdet0 is the detection level for the voltage monitoring 0 reset, VCCmin is the minimum guaranteed voltage of the MCU, and VPOR is the detection level for the power-on reset.
Note 2. At power-on, VCC should rise to or above the minimum guaranteed voltage before release from the POR reset state.
Note 3. tPVD0 is the period until release from the voltage monitoring 0 reset.

Figure 8.4 Example of Operation of Voltage Monitoring 0 Reset

8.5 Voltage Monitoring m Interrupt and Voltage Monitoring m Reset (m = 1, 2)

An interrupt or reset can be generated in response to the results of comparison by the voltage detection m circuit. Table 8.4 lists the procedures for setting bits related to the voltage monitoring m interrupt and voltage monitoring m reset to run voltage monitoring. Table 8.5 lists the procedure for setting bits related to the voltage monitoring m interrupt and voltage monitoring m reset to stop voltage monitoring. Figure 8.5 shows an example of the operation of the voltage monitoring m interrupt. For the operation of the voltage monitoring m reset, see Figure 6.2 in section 6, Resets. Furthermore, when using the voltage monitoring m circuit in software standby or deep software standby mode, make settings for the voltage monitoring m circuit according to the following procedures.

(1) Setting in software standby mode

- Disable the digital filter (PVDmCR0.DFDIS = 1).
- When PVDmFCR.RHSEL = 0
  After VCC > Vdetm is detected, negate the voltage monitoring m reset signal (PVDmCR0.RN = 0) following a stabilization time.

(2) Settings in deep software standby mode

- Disable the digital filter (PVDmCR0.DFDIS = 1).
- Enable the voltage monitoring m interrupt (PVDmCR0.RI = 0). When the voltage monitoring m reset is enabled (PVDmCR0.RI = 1), a transition to deep software standby mode 2 or 3 is not possible, and the device makes the transition to software standby mode 1.
- During deep software standby mode 3, the voltage monitoring m circuit is stopped. When using the voltage monitoring m circuit in deep software standby mode, do not allow a transition to deep software standby mode 3.

Table 8.4 Procedures for Setting Bits Related to the Voltage Monitoring m Interrupt and Voltage Monitoring m Reset to Run Voltage Monitoring

Step		Voltage Monitoring m Interrupt (Voltage Monitoring m ELC Event Output)	Voltage Monitoring m Reset
Setting the voltage detection m circuit	1	Set PVDmCMPCR.PVDE = 0 (disabling the voltage detection m circuit). (Disable the voltage detection m circuit before writing to the PVDmCMPCR.PVDLVL[4:0] and PVDmFCR.RHSEL bits.)	
	2	Select the detection voltage by setting the PVDmCMPCR.PVDLVL[4:0] bits.	
	3	—	Select the type of reset condition by setting the PVDmFCR.RHSEL bit.
	4	Set PVDmCMPCR.PVDE = 1 (enabling the voltage detection m circuit).	
	5	Wait for at least td(E-A).*1	
Setting the digital filter*2	6	Select the sampling clock for the digital filter by setting the PVDmCR0.FSAMP[1:0] bits.	
	7	Set PVDmCR0.DFDIS = 0 (enabling the digital filter).	
	8	Wait for at least 2s + 3 cycles of the LOCO (where s = 2, 4, 8, 16, and the sampling clock for the digital filter is the LOCO frequency-divided by s)*4	
Setting the voltage monitoring m interrupt or reset	9	Set PVDmCR0.RI = 0 (voltage monitoring m interrupt).	• Set PVDmCR0.RI = 1 (voltage monitoring m reset). • Select the type of reset negation by setting the PVDmCR0.RN bit.
	10	• Select the timing of interrupt requests by setting the PVDmCR1.IDTSEL[1:0] bits. • Select the type of interrupt by setting the PVDmCR1.IRQSEL bit.	—
Enabling output	11	Set PVDmSR.DET = 0.	—
	12	Set PVDmCR0.RIE = 1 (enabling the voltage monitoring m interrupt or reset).*3	
	13	Set PVDmCR0.CMPE = 1 (enabling output of the results of comparison by voltage monitoring m).	

Note 1. Steps 6 to 12 can be performed during the waiting time of step 5.
Note 2. Steps 6 to 8 are not required if the digital filter is not in use.
Note 3. Step 12 is not required if only the ELC event signal is to be output.
Note 4. Steps 9 to 12 can be performed during the waiting time of step 8.

When changing the settings of PVDm again after setting PVDm according to the procedure in Table 8.4, stop PVDm according to the procedure in Table 8.5, and then set PVDm again according to the procedure in Table 8.4.
When changing the PVDmCMPCR.PVDLVL[4:0] bits, follow the description in section 8.2.2, Voltage Monitoring m Comparator Control Register (PVDmCMPCR) (m = 1, 2).
When changing the PVDmFCR.RHSEL bit, follow the description in section 8.2.8, Voltage Monitoring m Function Control Register (PVDmFCR) (m = 1, 2).

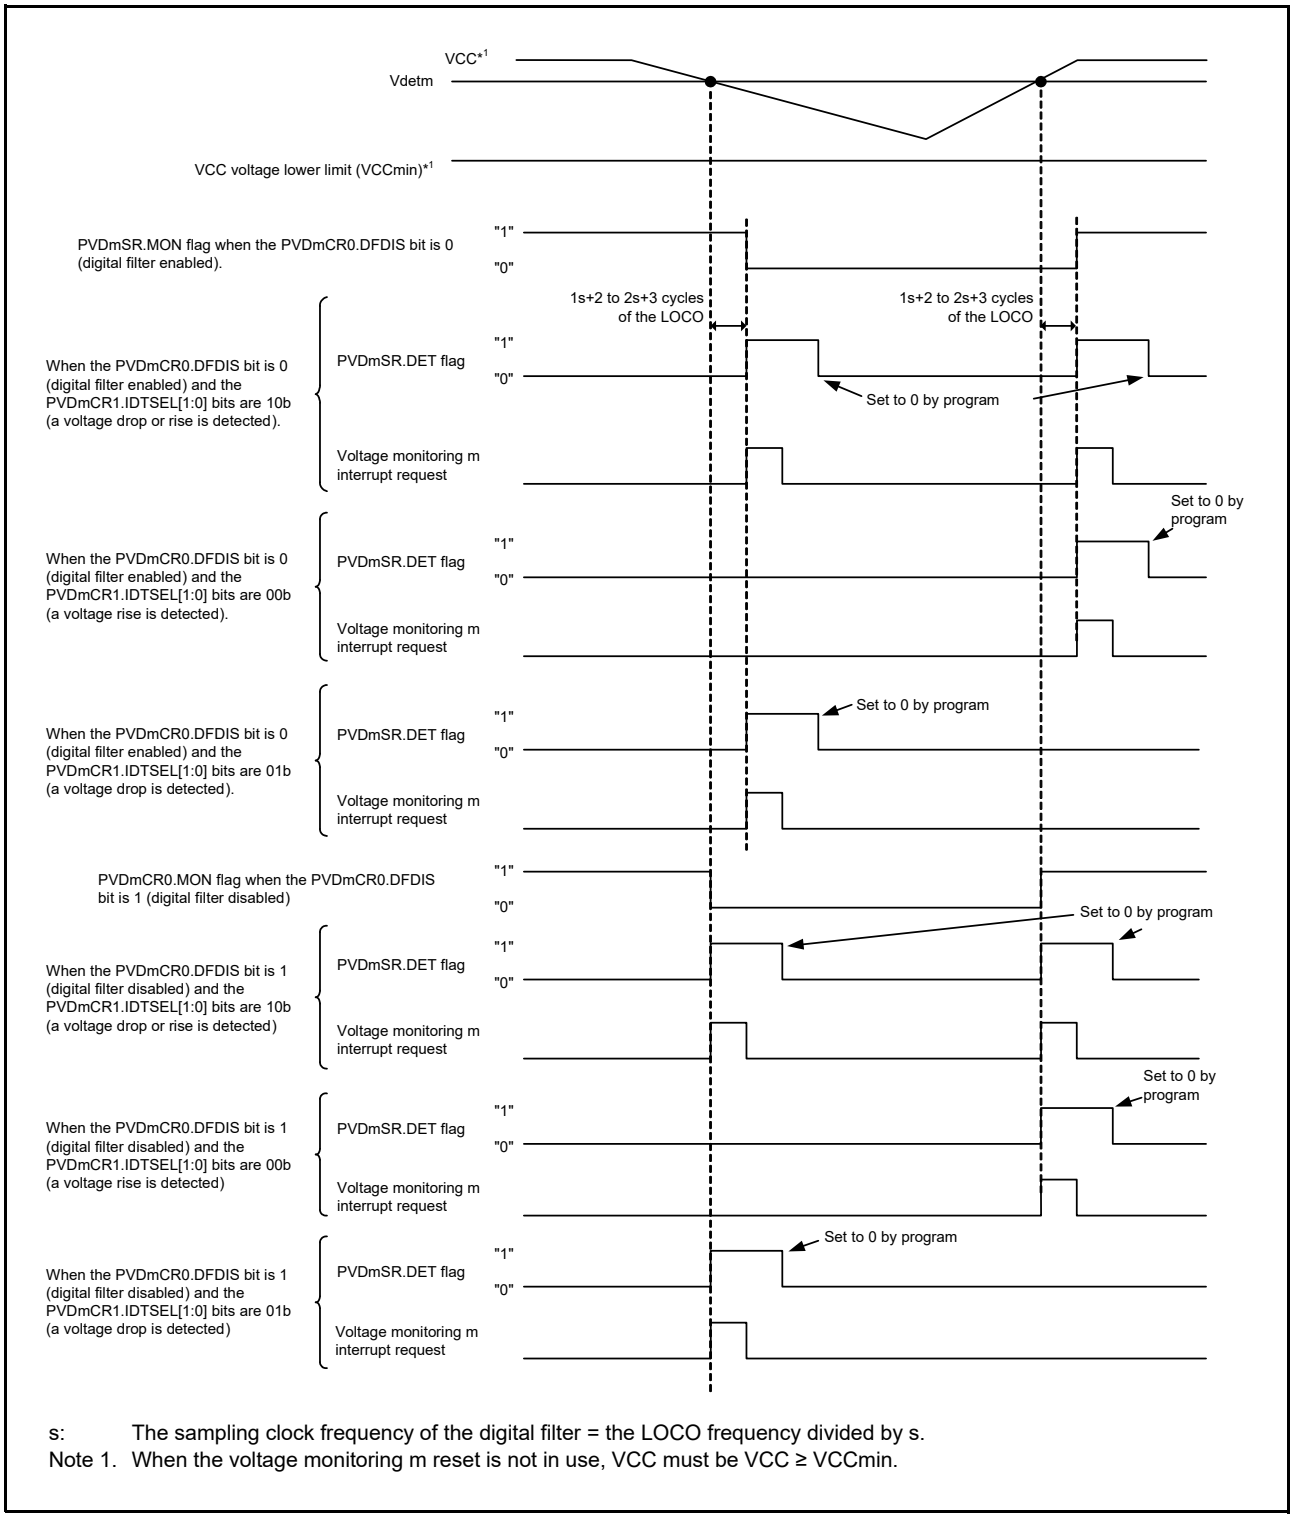


Table 8.5 Procedures for Setting Bits Related to the Voltage Monitoring m Interrupt and Voltage Monitoring m Reset to Stop Voltage Monitoring

Step		Voltage Monitoring m Interrupt (Voltage Monitoring m ELC Event Output), Voltage Monitoring m Reset
Stopping enabling of output	1	Set PVDmCR0.CMPE = 0 (disabling output of the results of comparison by voltage monitoring m).
	2	Wait for at least 2s + 3 cycles of the LOCO (where s = 2, 4, 8, 16, and the sampling clock for the digital filter is the LOCO frequency-divided by s).*1
	3	Set PVDmCR0.RIE = 0 (disabling the voltage monitoring m interrupt or reset).*3
Stopping the digital filter	4	Set PVDmCR0.DFDIS = 1 (disabling the digital filter).*1, *2
Stopping the voltage detection m circuit	5	Set PVDmCMPCR.PVDE = 0 (disabling the voltage detection m circuit).

Note 1. Steps 2 and 4 are not required if the digital filter is not in use.
Note 2. To disable the digital filter from its enabled state and then re-enable it, disable it and wait for at least two cycles of the LOCO before re-enabling it.
Note 3. Step 3 is not required if only the ELC event signal is to be output.

If the voltage monitoring m interrupt or voltage monitoring m reset setting is to be made again after it has been used and stopped once, the following steps in the procedures for stopping and making the setting can be omitted depending on the condition.

- Setting or stopping the voltage detection m circuit is not required if the setting for the voltage detection m circuit is not to be changed.
- Setting or stopping the digital filter is not required if the setting for the digital filter is not to be changed.
- Setting the voltage monitoring m interrupt or voltage monitoring m reset is not required if the setting for the voltage monitoring m interrupt or reset is not to be changed.

s: The sampling clock frequency of the digital filter = the LOCO frequency divided by s.

Note 1. When the voltage monitoring m reset is not in use, VCC must be VCC ≥ VCCmin.

Figure 8.5 Example of Operation of Voltage Monitoring m Interrupt

8.6 Voltage Monitoring n Reset (n = 4, 5)

A reset can be generated in response to the results of comparison by the voltage detection n circuit.
Table 8.6 lists the procedures for setting bits related to the voltage monitoring n reset to run voltage monitoring, and Table 8.7 lists the procedure for setting bits related to the voltage monitoring n reset to stop voltage monitoring. For the operation of the voltage monitoring n reset, see Figure 6.3 in section 6, Resets.
Furthermore, when using the voltage monitoring n circuit in software standby or deep software standby mode, make settings for the voltage monitoring n circuit according to the following procedures.

(1) Setting in software standby mode

- Disable the digital filter (PVDnCR0.DFDIS = 1).

(2) Settings in deep software standby mode

- Disable the digital filter (PVDnCR0.DFDIS = 1).
- During deep software standby mode 3, the voltage monitoring n circuit is stopped. When using the voltage monitoring n circuit in deep software standby mode, do not allow a transition to deep software standby mode 3.

Table 8.6 Procedures for Setting Bits Related to the Voltage Monitoring n Reset to Run Voltage Monitoring

Step		Voltage Monitoring n Reset
Setting the voltage detection n circuit	1	Set PVDnCMPCR.PVDE = 0 (disabling the voltage detection n circuit). (Disable the voltage detection n circuit before writing to the PVDnCMPCR.PVDLVL[4:0] and PVDnFCR.RHSEL bits.)
	2	Select the detection voltage by setting the PVDnCMPCR.PVDLVL[4:0] bits.
	3	Select the type of reset condition by setting the PVDnFCR.RHSEL bit.
	4	Set PVDnCMPCR.PVDE = 1 (enabling the voltage detection n circuit).
	5	Wait for at least td(E-A).*1
Setting the digital filter*2	6	Select the sampling clock for the digital filter by setting the PVDnCR0.FSAMP[1:0] bits.
	7	Set PVDnCR0.DFDIS = 0 (enabling the digital filter).
	8	Wait for at least 2s + 3 cycles of the LOCO (where s = 2, 4, 8, 16, and the sampling clock for the digital filter is the LOCO frequency-divided by s)*3
Enabling output	9	Set PVDnCR0.RE = 1 (enabling the voltage monitoring n reset).*3
	10	Set PVDnCR0.CMPE = 1 (enabling output of the results of comparison by voltage monitoring n).

Note 1. Steps 6 to 10 can be performed during the waiting time of step 5.
Note 2. Steps 6 to 8 are not required if the digital filter is not in use.
Note 3. Step 9 can be performed during the waiting time of step 8.

When changing the settings of PVDn again after setting PVDn according to the procedure in Table 8.6, stop PVDn according to the procedure in Table 8.7, and then set PVDn again according to the procedure in Table 8.6.
When changing the PVDnCMPCR.PVDLVL[4:0] bits, follow the description in section 8.2.3, Voltage Monitoring n Comparator Control Register (PVDnCMPCR) (n = 4, 5).
When changing the PVDnFCR.RHSEL bit, follow the description in section 8.2.9, Voltage Monitoring n Function Control Register (PVDnFCR) (n = 4, 5).

Table 8.7 Procedures for Setting Bits Related to the Voltage Monitoring n Reset to Stop Voltage Monitoring

Step		Voltage Monitoring n Reset
Stopping enabling of output	1	Set PVDnCR0.CMPE = 0 (disabling output of the results of comparison by voltage monitoring n).
	2	Wait for at least 2s + 3 cycles of the LOCO (where s = 2, 4, 8, 16, and the sampling clock for the digital filter is the LOCO frequency-divided by s).*1
	3	Set PVDnCR0.RE = 0 (disabling the voltage monitoring n reset).
Stopping the digital filter	4	Set PVDnCR0.DFDIS = 1 (disabling the digital filter).*1, *2
Stopping the voltage detection m circuit	5	Set PVDmCMPCR.PVDE = 0 (disabling the voltage detection m circuit).

Note 1. Steps 2 and 4 are not required if the digital filter is not in use.
Note 2. To disable the digital filter from its enabled state and then re-enable it, disable it and wait for at least two cycles of the LOCO before re-enabling it.

If the voltage monitoring n reset setting is to be made again after it has been used and stopped once, the following steps in the procedures for stopping and making the setting can be omitted depending on the condition.

- Setting or stopping the voltage detection n circuit is not required if the setting for the voltage detection n circuit is not to be changed.
- Setting or stopping the digital filter is not required if the setting for the digital filter is not to be changed.
- Setting the voltage monitoring n reset is not required if the setting for the voltage monitoring n reset is not to be changed.

8.7 Event Link Output

The PVD can output event signals to the event link controller (ELC).

- Vdetm crossing detection event output

The PVD outputs an event signal upon detection of a Vdetm crossing while a voltage detection m circuit is enabled and output of the results of comparison by the voltage monitoring m circuit is enabled (m = 1, 2).

To enable the event link output function of the PVD, enable the PVD event link function on the ELC side after making the setting to enable the PVD. To stop the event link output function of the PVD, disable the PVD event link function on the ELC side before making the setting to stop the PVD.

8.7.1 Interrupt Handling and Event Linking

Each PVD has an enable bit that controls enabling or disabling of the voltage monitoring 1 and 2 interrupts, respectively. When the corresponding interrupt source condition is generated, the interrupt signal is output to the CPU if the interrupt enable bit is set to “enable”.
When handled as an event link output signal, on the other hand, the signal is output to the other module via the ELC as an event signal upon generation of the interrupt source condition regardless of the value of the interrupt enable bit.
The voltage monitoring m interrupt signal can be output in software standby mode, deep software standby mode 1, and deep software standby mode 2. In these modes, the event signals for the ELC are output as follows:

- If a Vdetm crossing is detected while the device is in software standby mode, an event signal for the ELC is not output because a clock signal is not supplied in software standby mode. However, the Vdetm crossing detection flag is retained, so when the clock supply is resumed on return from software standby mode, the event signal for the ELC is output according to the state of the Vdetm crossing detection flag.

- If a Vdetm crossing is detected while the device is in deep software standby mode, an event signal for the ELC is not output.

9. Clock Generation Circuit

9.1 Overview

This MCU incorporates a clock generation circuit.
Table 9.1 and Table 9.2 list the specifications of the clock generation circuit. Figure 9.1 shows a block diagram of the clock generation circuit and Table 9.3 lists the I/O pins.

Table 9.1 Specifications of the Clock Generation Circuit (Clock Sources)

Clock Source	Description	Specifications
Main clock oscillator (MOSC)	Resonator frequency	8 MHz to 48 MHz
	External clock input frequency	Up to 48 MHz
	Connectable resonator or additional circuit: Ceramic resonator or crystal resonator Pins for connection: EXTAL and XTAL	Available
	Driving capacity switching	Available
	Oscillation stop detection function	Available
Sub-clock oscillator (SOSC)	Resonator frequency	32.768 kHz
	Connectable resonator or additional circuit: Crystal resonator Pins for connection: XCIN and XCOUT	Available
	External clock input	Available
	Driving capacity switching	Available
	Oscillation stop detection function	Available
PLL1 circuit PLL2 circuit	Input clock source	MOSC or HOCO
	Input clock frequency division ratio	Selectable from division by 1 to division by 3
	Input clock frequency	8 MHz to 48 MHz
	Input clock frequency (after input frequency division)	8 MHz to 24 MHz
	Frequency multiplication ratio	Selectable from 40 to 300 (Fractional part: 0, 0.33, 0.50, or 0.66)
	VCO frequency	960 MHz to 2400 MHz
	Number of output clocks	Three different clocks are output.
	PLL output clock P	60 to 600 MHz (PLL1)*1, 60 to 500 MHz (PLL2)*2 (Output frequency division ratio: 2, 3, 4, 6, 8, or 16)
	PLL output clock Q	106.6 to 500 MHz*3 (Output frequency division ratio: 2, 3, 4, 5, 6, 8, or 9)
	PLL output clock R	106.6 to 500 MHz (Output frequency division ratio: 2, 3, 4, 5, 6, 8, or 9)
High-speed on-chip oscillator (HOCO)	Oscillation frequency	16, 18, 20, 32, or 48 MHz
	Frequency locked loop (FLL) function	Available
	User trimming	Available
Middle-speed on-chip oscillator (MOCO)	Oscillation frequency	8 MHz
	User trimming	Available
Low-speed on-chip oscillator (LOCO)	Oscillation frequency	32.768 kHz
	User trimming	Available
External clock input for JTAG (TCK)	Input clock frequency	Up to 25 MHz
External clock input for SWD (SWCLK)	Input clock frequency	Up to 25 MHz

Note 1. The specification of the maximum frequency varies depending on the part number.

- R5K574NxA4xx and R5K574NxB4xx: 60 to 600 MHz
- R5K574NxC4xx and R5K574NxD4xx: 60 to 480 MHz
  In DCDC mode, set the VSCR.VSCM[2:0] bits to select VSCR_2. In external VDD mode, use this device within voltage range 2.
- R5K574NxE4xx and R5K574NxF4xx: 60 to 300 MHz
  In DCDC mode or LDO mode, set the VSCR.VSCM[2:0] bits to select VSCR_2. In external VDD mode, use this device within voltage range 2.

Note 2. The specification of the maximum frequency varies depending on the part number.
- R5K574NxA4xx, R5K574NxB4xx, R5K574NxC4xx, and R5K574NxD4xx: 60 to 500 MHz
- R5K574NxE4xx and R5K574NxF4xx: 60 to 300 MHz

Note 3. The specification of the maximum frequency varies depending on the part number.
- R5K574NxA4xx, R5K574NxB4xx, R5K574NxC4xx, and R5K574NxD4xx: 106.6 MHz to 500 MHz
- R5K574NxE4xx and R5K574NxF4xx: 106.6 MHz to 300 MHz

Table 9.2 Specifications of the Clock Generation Circuit (Internal Clocks) (1/3)

Item	Clock Source	Maximum Frequency of Clock Source	Destination of Clock Supply	Specifications
CPU clock (CPUCLK0)	MOSC, SOSC, HOCO, MOCO, or PLL1P	600 MHz*2	CPU	Up to 600 MHz*1 Division ratio: 1, 2, 3, 4, 6, 8, 12, 16, 24, 32, or 64
MRAM code bus clock (MRICLK)	MOSC, SOSC, HOCO, MOCO, or PLL1P	600 MHz*2	Code MRAM and MRAM code bus	Up to 300 MHz Division ratio: 1, 2, 3, 4, 6, 8, 12, 16, 24, 32, or 64
MRAM peripheral bus clock (MRPCLK)	MOSC, SOSC, HOCO, MOCO, or PLL1P	600 MHz*2	Extra MRAM and MRAM peripheral bus	Up to 150 MHz Division ratio: 1, 2, 3, 4, 6, 8, 12, 16, 24, 32, or 64
System clock (ICLK)	MOSC, SOSC, HOCO, MOCO, or PLL1P	600 MHz*2	DMAC, EXDMAC, DTC, SRAM, system bus, I/O ports, and ICU	Up to 300 MHz Division ratio: 1, 2, 3, 4, 6, 8, 12, 16, 24, 32, or 64
Peripheral module clock A (PCLKA)	MOSC, SOSC, HOCO, MOCO, or PLL1P	600 MHz*2	High-speed peripheral bus (ESWM, USBHS, RSCI, RI3C, RIICHS, CANFDG, CANFD, RSPIA, CRC, DOC, ADC16H, RSIP-E50D, GPTW, HRPWM, and POEG) and DOTF operating clock	Up to 150 MHz Division ratio: 1, 2, 3, 4, 6, 8, 12, 16, 24, 32, or 64
Peripheral module clock B (PCLKB)	MOSC, SOSC, HOCO, MOCO, or PLL1P	600 MHz*2	Low-speed peripheral bus (CAC, ELC, RTC, WDT, IWDT, USB, SSIE, SDHI, TEMPS, XSPI, DOTF, DAC12R, PDMIF, PDC, PCIF, CMT, CMTW, TMR, and PIO)	Up to 75 MHz Division ratio: 1, 2, 3, 4, 6, 8, 12, 16, 24, 32, or 64
Peripheral module clock C (PCLKC)	MOSC, SOSC, HOCO, MOCO, or PLL1P	600 MHz*2	Not used	Up to 75 MHz Division ratio: 1, 2, 3, 4, 6, 8, 12, 16, 24, 32, or 64
Peripheral module clock D (PCLKD)	MOSC, SOSC, HOCO, MOCO, or PLL1P	600 MHz*2	Peripheral module (GPTW count clock)	Up to 150 MHz Division ratio: 1, 2, 3, 4, 6, 8, 12, 16, 24, 32, or 64
Peripheral module clock E (PCLKE)	MOSC, SOSC, HOCO, MOCO, or PLL1P	600 MHz*2	Peripheral module (CANFDG message buffer RAM, CANFDG acceptance filter RAM, CANFD message buffer RAM)	Up to 300 MHz Division ratio: 1, 2, 3, 4, 6, 8, 12, 16, 24, 32, or 64
External bus clock (BCLK)	MOSC, SOSC, HOCO, MOCO, or PLL1P	600 MHz*2	External bus	Up to 150 MHz Division ratio: 1, 2, 3, 4, 6, 8, 12, 16, 24, 32, or 64
Asynchronous external bus clock (BCLKA)	MOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz*3	External bus	Up to 133 MHz Division ratio: 1, 2, 4, 6, 8, 10, 16, or 32
EBCLK pin output (EBCLK)	BCLK, 1/2 BCLK, or BCLKA	—	EBCLK pin	Up to 100 MHz Division ratio: 1 or 2
SDRAM clock (SDCLK)	BCLK or BCLKA	—	SDCLK pin, external bus for SDRAM	Up to 133 MHz

Table 9.2 Specifications of the Clock Generation Circuit (Internal Clocks) (2/3)

Item	Clock Source	Maximum Frequency of Clock Source	Destination of Clock Supply	Specifications
SCI clock (SCICLK)	MOSC, SOSC, HOCO, MOCO, LOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz*3	RSCI	Up to 120 MHz Division ratio: 1, 2, 3, 4, 5, 6, 8, 10, 16, or 32
SPI clock (SPICLK)	MOSC, SOSC, HOCO, MOCO, LOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz*3	RSPIA	Up to 100 MHz Division ratio: 1, 2, 3, 4, 5, 6, 8, 10, 16, or 32
XSPI clock (XSPICLK)	MOSC, SOSC, HOCO, MOCO, LOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz*3	XSPI	Up to 266 MHz Division ratio: 1, 2, 3, 4, 5, 6, 8, 10, 16, or 32
Divided XSPI clock (XSPIDIVCLK)	1/2 XSPICLK	—	XSPI	Up to 133 MHz
CANFD core clock (CANFDCLK)	MOSC, SOSC, HOCO, MOCO, LOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz*3	CANFD and CANFDG	Up to 80 MHz Division ratio: 1, 2, 3, 4, 5, 6, 8, 10, 16, or 32
ADC clock (ADCCLK)	MOSC, SOSC, HOCO, MOCO, LOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz*3	ADC16H	Up to 60 MHz Division ratio: 1, 2, 4, 6, 8, 10, 16, or 32
GPT clock (GPTCLK)	MOSC, HOCO, MOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz*3	GPTW, ADC16H, HRPWM, and PCIF	Up to 200 MHz Division ratio: 1, 2, 3, 4, 5, 6, 8, 10, 16, or 32
USB clock (USBCLK)	MOSC, HOCO, MOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz*3	USB and USBHS	48 MHz Division ratio: 1, 2, 3, 4, 5, 6, 8, 10, 16, or 32
USBHS-PHY clock (USB60CLK)	MOSC, HOCO, MOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz*3	USBHS	60 MHz Division ratio: 1, 2, 3, 4, 5, 6, 8, 10, 16, or 32
I3C clock (I3CCLK)	MOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz*3	RI3C and RIICHS	Up to 100 MHz Division ratio: 1, 2, 3, 4, 5, 6, 8, 10, 16, or 32
ESWM clock (ESWCLK)	MOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz	ESWM	Up to 250 MHz Division ratio: 1, 2, 4, 6, 8, 10, 16, or 32
ESWM-PHY clock (ESWPHYCLK)	MOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz	ESWM	100, 200, or 500 MHz Division ratio: 1, 2, 4, 6, 8, 10, 16, or 32
Ethernet-PHY clock (ETHPHYCLK)	MOSC, MOCO, PLL1P, PLL1Q, PLL1R, PLL2P, PLL2Q, or PLL2R	500 MHz*3	ETHPHYCLK pin	25 or 50 MHz Division ratio: 1, 2, 4, 6, 8, 10, 16, or 32
Clock or buzzer output (CLKOUT)	MOSC, SOSC, HOCO, MOCO, LOCO, ICLK, PLL1P, PLL1Q, PLL2P, or PLL2Q	300 MHz	CLKOUT pin	Up to 48 MHz Division ratio: 1, 2, 4, 8, 16, 32, 64, or 128
MOSC clock for USBHS (USBMCLK)	MOSC	—	USBHS	12, 20, 24, or 48 MHz Not divided
CANFD main clock (CANFDMCLK)	MOSC	—	CANFD and CANFDG	8 MHz to 48 MHz Not divided

Table 9.2 Specifications of the Clock Generation Circuit (Internal Clocks) (3/3)

Item	Clock Source	Maximum Frequency of Clock Source	Destination of Clock Supply	Specifications
PDMIF clock (PDMIFCLK)	MOCO	—	PDMIF	8 MHz Not divided
CAC main clock (CACMCLK)	MOSC	—	CAC	Up to 48 MHz Not divided
CAC sub-clock (CACSCLK)	SOSC	—	CAC	32.768 kHz Not divided
CAC HOCO clock (CACHCLK)	HOCO	—	CAC	16, 18, 20, 32, or 48 MHz Not divided
CAC MOCO clock (CACMOCLK)	MOCO	—	CAC	8 MHz Not divided
CAC LOCO clock (CACLCLK)	LOCO	—	CAC	32.768 kHz Not divided
CAC PLL1P clock (CACPL1PCLK)	PLL1P	—	CAC	Up to 37.5 MHz Divided by 16
CAC PLL1Q clock (CACPL1QCLK)	PLL1Q	—	CAC	Up to 31.25 MHz Divided by 16
CACPLL1R clock (CACPL1RCLK)	PLL1R	—	CAC	Up to 31.25 MHz Divided by 16
CACPLL2P clock (CACPL2PCLK)	PLL2P	—	CAC	Up to 31.25 MHz Divided by 16
CACPLL2Q clock (CACPL2QCLK)	PLL2Q	—	CAC	Up to 31.25 MHz Divided by 16
CACPLL2R clock (CACPL2RCLK)	PLL2R	—	CAC	Up to 31.25 MHz Divided by 16
RTC LOCO clock (RTCLCLK)	LOCO	—	RTC	32.768 kHz Not divided
RTC sub-clock (RTCSCLK)	SOSC	—	RTC	32.768 kHz Not divided
IWDT clock (IWDTCLK)	LOCO divided by 2	—	IWDT	16.384 kHz Not divided
JTAG clock (JTAGTCK)	TCK	—	JTAG	Up to 25 MHz Not divided
Serial wire clock (SWCLK)	TCK	—	OCD	Up to 25 MHz Not divided

Note: Restrictions on clock frequency settings:
CPUCLK0 ≥ ICLK, MRICLK ≥ ICLK, CPUCLK0 ≥ MRICLK, ICLK ≥ MRPCLK, ICLK ≥ PLKA ≥ PCLKB, ICLK ≥ BCLK, GPTCLK ≥ PCLKA, PCLKD ≥ PCLKA ≥ PCLKB
Restrictions on clock frequency ratios (N: integer up to 64):
CPUCLK0:ICLK = N:1, MRICLK:ICLK = N:1, CPUCLK0:MRICLK = N:1, ICLK:MRPCLK = N:1, ICLK:BCLK = N:1, ICLK:PCLKA = N:1, ICLK:PCLKB = N:1, ICLK:PCLKC = N:1 or 1:N, ICLK:PCLKD = N:1 or 1:N, ICLK:PCLKE = N:1 or 1:N
When one clock is set to division by 3, 6, 12, or 24, do not set the other clocks to division by 2, 4, 8, 16, 32, or 64 by the SCKDIVCR and SCKDIVCR2 registers.

Note: Set each clock within the allowable frequency range shown in the Specifications column in the table.
The guaranteed frequency range for the HOCO differs between when the FLL function is used and when it is not used (see section 67, Electrical Characteristics).
Take special care when the PLL clock source is set to the HOCO. Set the PLL multiplication ratio so that the resultant frequency is in the allowable frequency range even if the maximum value of the guaranteed frequency range for the HOCO is reached.
In addition, when the PLL clock source is set to the HOCO, select the SRAM and MRAM wait cycles carefully (see section 64, SRAM, and section 65, MRAM).
For SRAM, determine the setting value based on whether the SRAM access frequency exceeds 150 MHz when the maximum value of the guaranteed frequency range for the HOCO is reached.
For MRAM, specify the MRAM access frequency value when the maximum value of the guaranteed frequency range for the

HOCO is reached.

Note 1. The specification of the maximum frequency varies depending on the part number.
- R5K574NxA4xx and R5K574NxB4xx: 600 MHz
- R5K574NxC4xx and R5K574NxD4xx: 480 MHz
  In DCDC mode, set the VSCR.VSCM[2:0] bits to select VSCR_2. In external VDD mode, use this device within voltage range 2.
- R5K574NxE4xx and R5K574NxF4xx: 300 MHz
  In DCDC mode or LDO mode, set the VSCR.VSCM[2:0] bits to select VSCR_2. In external VDD mode, use this device within voltage range 2.

Note 2. The maximum frequency of clock source varies depending on the part number.
- R5K574NxA4xx and R5K574NxB4xx: 600 MHz
- R5K574NxC4xx and R5K574NxD4xx: 480 MHz
  In DCDC mode, set the VSCR.VSCM[2:0] bits to select VSCR_2. In external VDD mode, use this device within voltage range 2.
- R5K574NxE4xx and R5K574NxF4xx: 300 MHz
  In DCDC mode or LDO mode, set the VSCR.VSCM[2:0] bits to select VSCR_2. In external VDD mode, use this device within voltage range 2.

Note 3. The maximum frequency of clock source varies depending on the part number.
- R5K574NxA4xx, R5K574NxB4xx, R5K574NxC4xx, and R5K574NxD4xx: 500 MHz
- R5K574NxE4xx and R5K574NxF4xx: 300 MHz

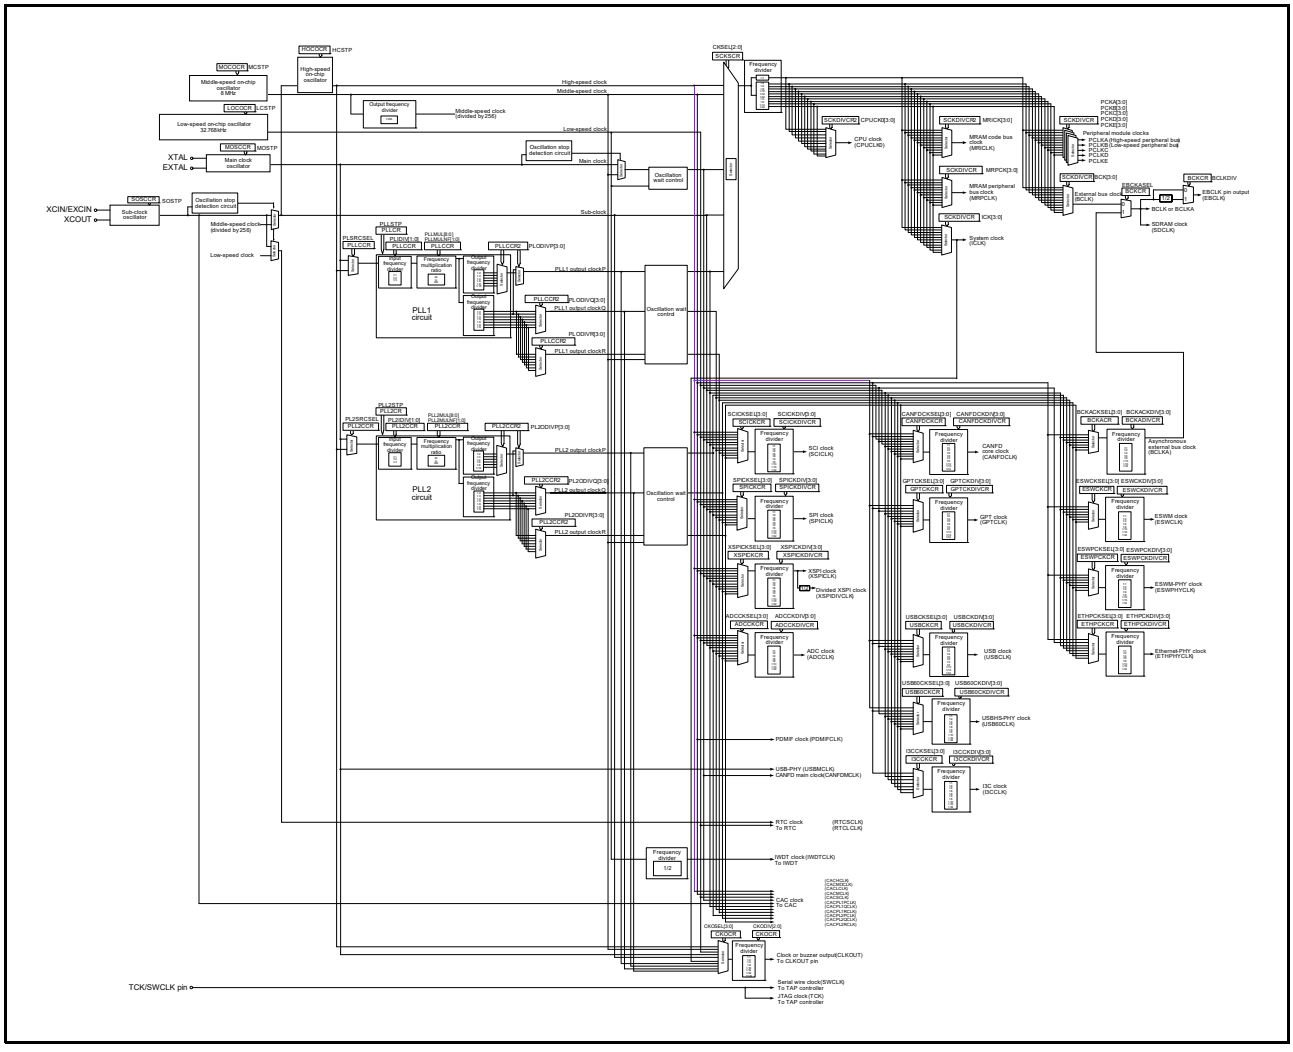

Figure 9.1 Block Diagram of Clock Generation Circuit

Table 9.3 lists the input/output pins of the clock generation circuit.

Table 9.3 Input/Output Pins of the Clock Generation Circuit

Pin Name	I/O	Description
XTAL	Output	These pins are used to connect a ceramic resonator or a crystal resonator. The EXTAL pin can also be used to input an external clock. For details, see section 9.3.2, Inputting an External Clock.
EXTAL	Input	
XCIN/EXCIN	Input	These pins are used to connect a 32.768-kHz crystal resonator. The XCIN pin can also be used to input an external clock. For details, see section 9.4.3, Input of an External Clock.
XCOUT	Output	
TCK/SWCLK	Input	This pin is used to input the clock for the JTAG and SWD.
EBCLK	Output	This pin is used to supply external devices with the external bus clock (EBCLK).
SDCLK	Output	This pin is used to supply external devices with the SDRAM clock (SDCLK).
CLKOUT	Output	This pin is used to output the CLKOUT clock or buzzer signal.

9.2 Register Descriptions

9.2.1 Clock Generation Function Security Attribute Register (CGFSAR)

Address(es): SYSC.CGFSAR 8701 93C0h, SYSC_NS.CGFSAR 0701 93C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

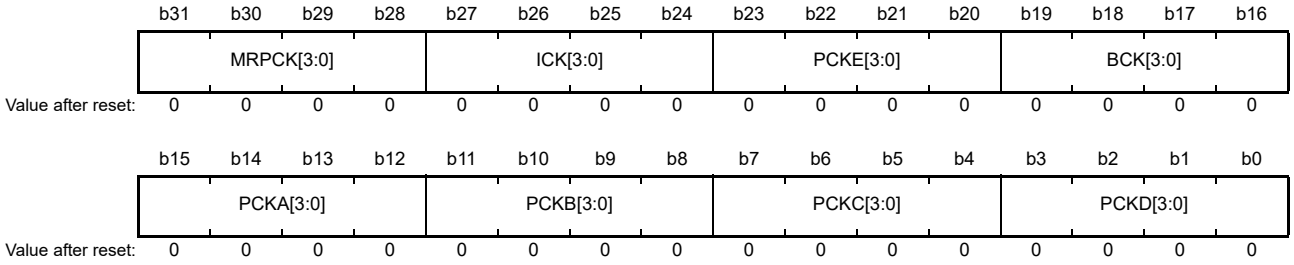
Bit	Symbol	Bit Name	Description	R/W
b0	NONSEC00	System Clock Attribute Setting	Target: SCKDIVCR, SCKDIVCR2, SCKSCR 0: Secure 1: Non-secure	R/W
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b2	NONSEC02	HOCO Attribute Setting	Target: HOCOCR, HOCOCR2, FLLCR1, FLLCR2, HOCOUTCR, HOCOSCR 0: Secure 1: Non-secure	R/W
b3	NONSEC03	MOCO Attribute Setting	Target: MOCOCR, MOCOUTCR, MOCOSCR 0: Secure 1: Non-secure	R/W
b4	NONSEC04	LOCO Attribute Setting	Target: LOCOCR, LOCOUTCR 0: Secure 1: Non-secure	R/W
b5	NONSEC05	Main Clock Attribute Setting	Target: MOSCCR, MOSCWTCR, MOMCR, MOSCSCR 0: Secure 1: Non-secure	R/W
b6	NONSEC06	Oscillation Stop Detection-Related Register Attribute Setting	Target: OSTDCR, OSTDSR 0: Secure 1: Non-secure	R/W
b7	NONSEC07	Sub-Clock Attribute Setting	Target: SOSCCR, SOMCR 0: Secure 1: Non-secure	R/W
b8	NONSEC08	PLL1 Clock Attribute Setting	Target: PLLCCR, PLLCCR2, PLLCR 0: Secure 1: Non-secure	R/W
b9	NONSEC09	PLL2 Clock Attribute Setting	Target: PLL2CCR, PLL2CCR2, PLL2CR 0: Secure 1: Non-secure	R/W
b10	NONSEC10	Sub-Clock Stop Detection-Related Register Attribute Setting	Target: SOSTDCR, SOSTDSR 0: Secure 1: Non-secure	R/W
b11	NONSEC11	Clock Output Attribute Setting	Target: CKOCR 0: Secure 1: Non-secure	R/W
b12	NONSEC12	External Bus Clock Attribute Setting	Target: BCKCR, EBCKOCR 0: Secure 1: Non-secure	R/W
b13	NONSEC13	SDRAM Clock Attribute Setting	Target: SDCKOCR 0: Secure 1: Non-secure	R/W



Bit	Symbol	Bit Name	Description	R/W
b14	NONSEC14	Asynchronous External Bus Clock Attribute Setting	Target: BCKADIVCR, BCKACR 0: Secure 1: Non-secure	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b16	NONSEC16	USB Clock Attribute Setting	Target: USBCKDIVCR, USBCKCR 0: Secure 1: Non-secure	R/W
b17	NONSEC17	XSPI Clock Attribute Setting	Target: XSPICKDIVCR, XSPICKCR 0: Secure 1: Non-secure	R/W
b18	NONSEC18	CANFD Clock Attribute Setting	Target: CANFDCKDIVCR, CANFDCKCR 0: Secure 1: Non-secure	R/W
b19	NONSEC19	USBHS-PHY Clock Attribute Setting	Target: USB60CKDIVCR, USB60CKCR 0: Secure 1: Non-secure	R/W
b20	NONSEC20	I3C Clock Attribute Setting	Target: I3CCKDIVCR, I3CCKCR 0: Secure 1: Non-secure	R/W
b21	NONSEC21	SCI Clock Attribute Setting	Target: SCICKDIVCR, SCICKCR 0: Secure 1: Non-secure	R/W
b22	NONSEC22	SPI Clock Attribute Setting	Target: SPICKDIVCR, SPICKCR 0: Secure 1: Non-secure	R/W
b23	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b24	NONSEC24	ADC Clock Attribute Setting	Target: ADCCKDIVCR, ADCCKCR 0: Secure 1: Non-secure	R/W
b25	NONSEC25	GPT Clock Attribute Setting	Target: GPTCKDIVCR, GPTCKCR 0: Secure 1: Non-secure	R/W
b26	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b27	NONSEC27	ESWM-PHY Clock Attribute Setting	Target: ESWCKDIVCR, ESWCKCR, ESWPCKDIVCR, ESWPCKCR 0: Secure 1: Non-secure	R/W
b28	NONSEC28	Ethernet-PHY Clock Attribute Setting	Target: ETHPCKDIVCR, ETHPCKCR 0: Secure 1: Non-secure	R/W
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.
Note: Set the PRCR.PRC4 bit to 1 (write enabled) before changing the value of this register.

The CGFSAR register is used to control the security attribute of the clock generation function registers.

9.2.2 System Clock Frequency Division Control Register (SCKDIVCR)

Address(es): SYSC.SCKDIVCR 8701 9020h,
SYSC_NS.SCKDIVCR 0701 9020h

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	PCKD[3:0]	Peripheral Module Clock D (PCLKD) Select*1	b3 b0 0 0 0 0: Division by 1 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 8 0 1 0 0: Division by 16 0 1 0 1: Division by 32 0 1 1 0: Division by 64 1 0 0 0: Division by 3 1 0 0 1: Division by 6 1 0 1 0: Division by 12 1 0 1 1: Division by 24 Settings other than those listed above are prohibited.	R/W
b7 to b4	PCKC[3:0]	Peripheral Module Clock C (PCLKC) Select*2	b7 b4 0 0 0 0: Division by 1 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 8 0 1 0 0: Division by 16 0 1 0 1: Division by 32 0 1 1 0: Division by 64 1 0 0 0: Division by 3 1 0 0 1: Division by 6 1 0 1 0: Division by 12 1 0 1 1: Division by 24 Settings other than those listed above are prohibited.	R/W

R/W
b23 to b20	PCKE[3:0]	Peripheral Module Clock E (PCLKE) Select*1, *5	b23 b20 0 0 0 0: Division by 1 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 8 0 1 0 0: Division by 16 0 1 0 1: Division by 32 0 1 1 0: Division by 64 1 0 0 0: Division by 3 1 0 0 1: Division by 6 1 0 1 0: Division by 12 1 0 1 1: Division by 24 Settings other than those listed above are prohibited.	R/W
b27 to b24	ICK[3:0]	System Clock (ICLK) Select *1, *3, *4, *6, *7, *8, *9	b27 b24 0 0 0 0: Division by 1 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 8 0 1 0 0: Division by 16 0 1 0 1: Division by 32 0 1 1 0: Division by 64 1 0 0 0: Division by 3 1 0 0 1: Division by 6 1 0 1 0: Division by 12 1 0 1 1: Division by 24 Settings other than those listed above are prohibited.	R/W
b31 to b28	MRPCK[3:0]	MRAM Peripheral Bus Clock (MRPCLK) Select*7, *10	b31 b28 0 0 0 0: Division by 1 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 8 0 1 0 0: Division by 16 0 1 0 1: Division by 32 0 1 1 0: Division by 64 1 0 0 0: Division by 3 1 0 0 1: Division by 6 1 0 1 0: Division by 12 1 0 1 1: Division by 24 Settings other than those listed above are prohibited.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

Note: Restrictions on clock frequency settings:
CPUCLK0 ≥ ICLK, MRICLK ≥ ICLK, CPUCLK0 ≥ MRICLK, ICLK ≥ MRPCLK, ICLK ≥ PCLKA ≥ PCLKB, ICLK ≥ BCLK, GPTCLK ≥ PCLKA, PCLKD ≥ PCLKA ≥ PCLKB
Restrictions on clock frequency ratios (N: integer up to 64):
CPUCLK0:ICLK = N:1, MRICLK:ICLK = N:1, CPUCLK0:MRICLK = N:1, ICLK:MRPCLK = N:1, ICLK:BCLK = N:1, ICLK:PCLKA = N:1, ICLK:PCLKB = N:1, ICLK:PCLKC = N:1 or 1:N, ICLK:PCLKD = N:1 or 1:N, ICLK:PCLKE = N:1 or 1:N
When one clock is set to division by 3, 6, 12, or 24, do not set the other clocks to division by 2, 4, 8, 16, 32, or 64 by the SCKDIVCR and SCKDIVCR2 registers.

Note 1. The following condition should be satisfied between the frequencies of the system clock (ICLK) and peripheral module clocks (PCLKD, PCLKE).
ICLK:PCLKD or PCLKE = N:1 (N: integer)

Note 2. Set the PCKC[3:0] bits to the same value as the PCKB[3:0] bits.

Note 3. The following condition should be satisfied between the frequencies of the system clock (ICLK) and peripheral module clocks (PCLKA, PCLKB).
ICLK:PCLKA or PCLKB = N:1(N: integer)

Note 4. When using ESWM, set the PCLKA frequency to be less than the ICLK frequency.

Note 5. When using CANFD or CANFDG, set the PCLKE frequency to twice the PCLKA frequency.

Note 6. The following condition should be satisfied between the frequencies of the system clock (ICLK) and external bus clock (BCLK).
ICLK:BCLK = N:1 (N: integer)

Note 7. The following condition should be satisfied between the frequencies of the system clock (ICLK) and MRAM peripheral bus clock (MRPCLK).
ICLK:MRPCLK = N:1 (N: integer)

Note 8. The following condition should be satisfied between the frequencies of the CPU clock (CPUCLK0) and system clock (ICLK).
CPUCLK0:ICLK = N:1 (N: integer)

Note 9. The following conditions should be satisfied between the frequencies of the MRAM code bus clock (MRICLK), CPU clock (CPUCLK0), and system clock (ICLK).
MRICLK:ICLK = N:1 (N: integer), CPUCLK0:MRICLK = N:1 (N: integer)

Note 10. The frequency of the MRAM peripheral bus clock (MRPCLK) is limited by the setting of the extra MRAM frequency notifications register (MREFREQ). See section 65, MRAM.

The SCKDIVCR register is used to select the frequencies of the system clock (ICLK), peripheral module clocks (PCLKA, PCLKB, PCLKC, PCLKD, and PCLKE), MRAM peripheral bus clock (MRPCLK), and external bus clock (BCLK).

9.2.3 System Clock Frequency Division Control Register 2 (SCKDIVCR2)

Address(es): SYSC.SCKDIVCR2 8701 9024h,
SYSC_NS.SCKDIVCR2 0701 9024h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MRICK[3:0]				—	—	—	—	—	—	—	—	CPUCK0[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	CPUCK0[3:0]	CPU Clock (CPUCLK0) Select*1	b3 b0 0 0 0 0: Division by 1 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 8 0 1 0 0: Division by 16 0 1 0 1: Division by 32 0 1 1 0: Division by 64 1 0 0 0: Division by 3 1 0 0 1: Division by 6 1 0 1 0: Division by 12 1 0 1 1: Division by 24 Settings other than those listed above are prohibited.	R/W
b11 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b12	MRICK[3:0]	MRAM Code Bus Clock (MRICLK) Select*2, *3	b15 b12 0 0 0 0: Division by 1 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 8 0 1 0 0: Division by 16 0 1 0 1: Division by 32 0 1 1 0: Division by 64 1 0 0 0: Division by 3 1 0 0 1: Division by 6 1 0 1 0: Division by 12 1 0 1 1: Division by 24 Settings other than those listed above are prohibited.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Restrictions on clock frequency settings:
CPUCLK0 ≥ ICLK, MRICLK ≥ ICLK, CPUCLK0 ≥ MRICLK, ICLK ≥ MRPCLK, ICLK ≥ PCLKA ≥ PCLKB, ICLK ≥ BCLK, GPTCLK ≥ PCLKA, PCLKD ≥ PCLKA ≥ PCLKB
Restrictions on clock frequency ratios (N: integer up to 64):
CPUCLK0:ICLK = N:1, MRICLK:ICLK = N:1, CPUCLK0:MRICLK = N:1, ICLK:MRPCLK = N:1, ICLK:BCLK = N:1, ICLK:PCLKA = N:1, ICLK:PCLKB = N:1, ICLK:PCLKC = N:1 or 1:N, ICLK:PCLKD = N:1 or 1:N, ICLK:PCLKE = N:1 or 1:N
When one clock is set to division by 3, 6, 12, or 24, do not set the other clocks to division by 2, 4, 8, 16, 32, or 64 by the SCKDIVCR and SCKDIVCR2 registers.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

Note 1. The following condition should be satisfied between the frequencies of the CPU clock (CPUCLK0) and system clock (ICLK).
CPUCLK0:ICLK = N:1 (N: integer)

Note 2. The following conditions should be satisfied between the frequencies of the MRAM code bus clock (MRICLK), CPU clock (CPUCLK0), and system clock (ICLK).
MRICLK:ICLK = N:1 (N: integer), CPUCLK0:MRICLK = N:1 (N: integer)

Note 3. The frequency of the MRAM code bus clock (MRICLK) is limited by the setting of the code MRAM frequency notifications register (MRCFREQ). See section 65, MRAM.

The SCKDIVCR2 register is used to select the frequencies of the CPU clock (CPUCLK0) and MRAM code bus clock (MRICLK).

9.2.4 System Register Access Status Register (SYRACCR)

Address(es): SYSC.SYRACCR 8701 90CCh,
SYSC_NS.SYRACCR 0701 90CCh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	BUSY
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BUSY	Access Ready State Monitoring Flag	0: Ready for read/write access 1: Writing in progress	R
b7 to b1	—	Reserved	These bits are read as 0.	R

The SYRACCR register is used to monitor whether the target registers can be accessed.
The target registers are LOCOCR and LOCOUTCR.

BUSY Flag (Access Ready State Monitoring Flag)

When this flag is 0, the target registers can be accessed.
Confirm that this flag is 0 before accessing the target registers.
When this flag is 1, the write access to one of the target registers is in progress. In this state, further writing to one of the target registers is ignored and the values read from the target registers are not guaranteed.

9.2.5 System Clock Source Control Register (SCKSCR)

Address(es): SYSC.SCKSCR 8701 9026h,
SYSC_NS.SCKSCR 0701 9026h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	CKSEL[2:0]		
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CKSEL[2:0]	Clock Source Select	b2 b0 0 0 0: High-speed on-chip oscillator (HOCO) 0 0 1: Middle-speed on-chip oscillator (MOCO) (initial value) 0 1 0: Setting prohibited 0 1 1: Main clock oscillator (MOSC) 1 0 0: Sub-clock oscillator (SOSC) 1 0 1: PLL1 output clock P (PLL1P) 1 1 0: Setting prohibited 1 1 1: Setting prohibited	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The SCKSCR register is used to select the clock source for the system clock.

CKSEL[2:0] Bits (Clock Source Select)

These bits select the source of the following clocks.

- CPU clock (CPUCLK0)
- MRAM code bus clock (MRICLK)
- MRAM peripheral bus clock (MRPCLK)
- System clock (ICLK)
- Peripheral module clocks (PCLKA, PCLKB, PCLKC, PCLKD, and PCLKE)
- External bus clock (BCLK)
- SDRAM clock (SDCLK)

Switching to a stopped clock source is prohibited.
The operating state of each clock source is controlled not only by the clock oscillator enable settings but also by the operating states of other functions and the operating mode. Some clock sources might be forcibly stopped depending on the operating mode.
Check the operating and stop conditions of each clock source and the operation state of clock sources in each operating mode, and do not select the clock source to be stopped in SCKSCR. Switch clock sources only when no interrupts from the WDT/IWDT are occurring.

9.2.6 PLL Clock Control Register (PLLCCR)

Address(es): SYSC.PLLCCR 8701 90ACh,
SYSC_NS.PLLCCR 0701 90ACh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PLLMUL[8]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PLLMUL[7:0]								PLLMULNF[1:0]		—	PLSRCSEL	—	—	PLIDIV[1:0]	
Value after reset:	0	0	1	0	0	1	1	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PLIDIV[1:0]	PLL1 Input Frequency Division Ratio Select*1	b1 b0 0 0: Division by 1 0 1: Division by 2 1 0: Division by 3 Settings other than those listed above are prohibited.	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	PLSRCSEL	PLL1 Clock Source Select	0: Main clock oscillator 1: HOCO*2	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7, b6	PLLMULNF[1:0]	PLL1 Frequency Multiplication Fractional Ratio Select*3	b7 b6 0 0: 0.00 (initial value) 0 1: 0.33 (1/3) 1 0: 0.66 (2/3) 1 1: 0.50 (1/2)	R/W
b16 to b8	PLLMUL[8:0]	PLL1 Frequency Multiplication Ratio Select*3	27h: × 40 (initial value) 28h: × 41 29h: × 42 : 12Ah: × 299 12Bh: × 300 Settings other than those listed above are prohibited.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

Note 1. The PLIDIV[1:0] bits set the frequency division ratio of the input clock source for the PLL1 circuit. Set these bits so that the input frequency (after division of the input frequency) is within the range of the specifications shown in Table 9.1, Specifications of the Clock Generation Circuit (Clock Sources).

Note 2. Enable the FLL function when using USBCLK.

Note 3. The PLLMUL[8:0] and PLLMULNF[1:0] bits set the frequency multiplication ratio of the PLL1 circuit. Set these bits so that the VCO frequency is within the range of the specifications shown in Table 9.1, Specifications of the Clock Generation Circuit (Clock Sources).

The PLLCCR register is used to set the operation of the PLL1 circuit.

Writing to this register is prohibited while the PLLCR.PLLSTP bit is 0 (PLL1 is operating).

9.2.7 PLL Clock Control Register 2 (PLLCCR2)

Address(es): SYSC.PLLCCR2 8701 904Ch,
SYSC_NS.PLLCCR2 0701 904Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	PLODIVR[3:0]				PLODIVQ[3:0]				PLODIVP[3:0]			
Value after reset:	0	0	0	0	0	1	0	1	0	1	0	1	0	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	PLODIVP[3:0]	PLL1 Output Frequency Division Ratio Select for Output Clock P*1	b3 b0 0 0 0 1: Division by 2 0 0 1 0: Division by 3 0 0 1 1: Division by 4 0 1 0 1: Division by 6 (initial value) 0 1 1 1: Division by 8 1 1 1 1: Division by 16 Settings other than those listed above are prohibited.	R/W
b7 to b4	PLODIVQ[3:0]	PLL1 Output Frequency Division Ratio Select for Output Clock Q*1	b7 b4 0 0 0 1: Division by 2 0 0 1 0: Division by 3 0 0 1 1: Division by 4 0 1 0 0: Division by 5 0 1 0 1: Division by 6 (initial value) 0 1 1 1: Division by 8 1 0 0 0: Division by 9 Settings other than those listed above are prohibited.	R/W
b11 to b8	PLODIVR[3:0]	PLL1 Output Frequency Division Ratio Select for Output Clock R*1	b11 b8 0 0 0 1: Division by 2 0 0 1 0: Division by 3 0 0 1 1: Division by 4 0 1 0 0: Division by 5 0 1 0 1: Division by 6 (initial value) 0 1 1 1: Division by 8 1 0 0 0: Division by 9 Settings other than those listed above are prohibited.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

Note 1. The PLODIVn[3:0] bits set the output frequency division ratio of each output clock n in the PLL1 circuit. Set these bits so that PLL1 output clock n is within the range of the specifications shown in Table 9.1, Specifications of the Clock Generation Circuit (Clock Sources). (n = P, Q, or R)

The PLLCCR2 register is used to set the operation of the PLL1 circuit. Writing to this register is prohibited while the PLLCR.PLLSTP bit is 0 (PLL1 is operating).

Even if only one of the PLL1 output clocks P, Q, and R is used, PLLCCR2 must be set so that the frequency of PLL1 output clock n is within the range of the specifications shown in Table 9.1, Specifications of the Clock Generation Circuit (Clock Sources). (n = P, Q, or R)

9.2.8 PLL Control Register (PLLCR)

Address(es): SYSC.PLLCR 8701 902Ah,
SYSC_NS.PLLCR 0701 902Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	PLLSTP
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	PLLSTP	PLL1 Stop Control	0: PLL1 is started. 1: PLL1 is stopped.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The PLLCR register is used to control the operation of the PLL1 circuit.

PLLSTP Bit (PLL1 Stop Control)

This bit starts or stops the operation of the PLL1 circuit.
The PLL1 clock source is selectable as the main clock oscillator and HOCO.
Selecting the main clock oscillator as the PLL1 clock source by the PLLCCR.PLSRCSEL bit requires setting of the main clock oscillator wait control register (MOSCWTCR).
After the value of the PLLSTP bit has been changed to 0, confirm that the OSCSF.PLLSF flag has been set to 1 before starting to use the PLL1 clock. That is, PLL1 requires a certain amount of time for oscillation to become stable after it starts operation. A certain amount of time is also required for oscillation to stop after the PLL1 operation is stopped.
In addition, note the following when starting or stopping PLL1 by the PLLSTP bit.

- After stopping PLL1, confirm that the OSCSF.PLLSF flag is 0 before restarting PLL1.
- Confirm that PLL1 is operating and that the OSCSF.PLLSF flag is 1 before stopping PLL1.
- Regardless of whether PLL1 is selected as the system clock source, confirm that the OSCSF.PLLSF flag is 1 before executing a WAIT instruction to place the MCU in software standby or deep software standby mode after the PLL1 operation is started.
- Confirm that the OSCSF.PLLSF flag is 0 before executing a WAIT instruction to place the MCU in software standby or deep software standby mode after the PLL1 operation is stopped.

Writing 1 to the PLLSTP bit is prohibited while SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL1 output clock P (PLL1P)).
Confirm the following conditions before writing 0 to the PLLSTP bit.

- When PLL1 source clock = MOSC: MOSCCR.MOSTP = 0 (MOSC is operating)
- When PLL1 source clock = HOCO: HOCOCR.HCSTP = 0 (HOCO is operating)

9.2.9 PLL2 Clock Control Register (PLL2CCR)

Address(es): SYSC.PLL2CCR 8701 90C8h,
SYSC_NS.PLL2CCR 0701 90C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PLL2MUL[8]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	1	0	0	1	1	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PL2IDIV[1:0]	PLL2 Input Frequency Division Ratio Select*1	b1 b0 0 0: Division by 1 (initial value) 0 1: Division by 2 1 0: Division by 3 Settings other than those listed above are prohibited.	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	PL2SRCSEL	PLL2 Clock Source Select	0: Main clock oscillator 1: HOCO*2	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7, b6	PLL2MULNF[1:0]	PLL2 Frequency Multiplication Fractional Ratio Select*3	b7 b6 0 0: 0.00 (initial value) 0 1: 0.33 (1/3) 1 0: 0.66 (2/3) 1 1: 0.50 (1/2)	R/W
b16 to b8	PLL2MUL[8:0]	PLL2 Frequency Multiplication Ratio Select*3	27h: × 40 (initial value) 28h: × 41 29h: × 42 : 12Ah: × 299 12Bh: × 300 Settings other than those listed above are prohibited.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note 1. The PL2IDIV[1:0] bits set the frequency division ratio of the input clock source for the PLL2 circuit. Set these bits so that the input frequency (after division of the input frequency) is within the range of the specifications shown in Table 9.1, Specifications of the Clock Generation Circuit (Clock Sources).
Note 2. Be sure to enable the FLL function when using USBCLK.
Note 3. The PLL2MUL[8:0] and PLL2MULNF[1:0] bits set the frequency multiplication ratio of the PLL2 circuit. Set these bits so that the VCO frequency is within the range of the specifications shown in Table 9.1, Specifications of the Clock Generation Circuit (Clock Sources).

The PLL2CCR register is used to set the operation of the PLL2 circuit.
Writing to this register is prohibited while the PLL2CR.PLL2STP bit is 0 (PLL2 is operating).

9.2.10 PLL2 Clock Control Register 2 (PLL2CCR2)

Address(es): SYSC.PLL2CCR2 8701 904Eh,
SYSC_NS.PLL2CCR2 0701 904Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	PL2ODIVR[3:0]				PL2ODIVQ[3:0]				PL2ODIVP[3:0]			
Value after reset:	0	0	0	0	0	1	0	1	0	1	0	1	0	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	PL2ODIVP[3:0]	PLL2 Output Frequency Division Ratio Select for Output Clock P*1	b3 b0 0 0 0 1: Division by 2 0 0 1 0: Division by 3 0 0 1 1: Division by 4 0 1 0 1: Division by 6 (initial value) 0 1 1 1: Division by 8 1 1 1 1: Division by 16 Settings other than those listed above are prohibited.	R/W
b7 to b4	PL2ODIVQ[3:0]	PLL2 Output Frequency Division Ratio Select for Output Clock Q*1	b7 b4 0 0 0 1: Division by 2 0 0 1 0: Division by 3 0 0 1 1: Division by 4 0 1 0 0: Division by 5 0 1 0 1: Division by 6 (initial value) 0 1 1 1: Division by 8 1 0 0 0: Division by 9 Settings other than those listed above are prohibited.	R/W
b11 to b8	PL2ODIVR[3:0]	PLL2 Output Frequency Division Ratio Select for Output Clock R*1	b11 b8 0 0 0 1: Division by 2 0 0 1 0: Division by 3 0 0 1 1: Division by 4 0 1 0 0: Division by 5 0 1 0 1: Division by 6 (initial value) 0 1 1 1: Division by 8 1 0 0 0: Division by 9 Settings other than those listed above are prohibited.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

Note 1. The PLODIVn[3:0] bits set the output frequency division ratio of each output clock n in the PLL2 circuit. Set these bits so that PLL2 output clock n is within the range of the specifications shown in Table 9.1, Specifications of the Clock Generation Circuit (Clock Sources). (n = P, Q, or R)

The PLL2CCR2 register is used to set the operation of the PLL2 circuit. Writing to this register is prohibited while the PLL2CR.PLL2STP bit is 0 (PLL2 is operating).

Even if only one of the PLL2 output clocks P, Q, and R is used, PLL2CCR2 must be set so that the frequency of PLL2 output clock n is within the range of the specifications shown in Table 9.1, Specifications of the Clock Generation Circuit (Clock Sources). (n = P, Q, or R)

9.2.11 PLL2 Control Register (PLL2CR)

Address(es): SYSC.PLL2CR 8701 904Ah,
SYSC_NS.PLL2CR 0701 904Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	PLL2STP
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	PLL2STP	PLL2 Stop Control	0: PLL2 is started. 1: PLL2 is stopped.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The PLL2CR register is used to control the operation of the PLL2 circuit.

PLL2STP Bit (PLL2 Stop Control)

This bit starts or stops the operation of the PLL2 circuit.
The PLL2 clock source is selectable as the main clock oscillator and HOCO.
Selecting the main clock oscillator as the PLL2 clock source by the PLL2CCR.PL2SRCSEL bit requires setting of the main clock oscillator wait control register (MOSCWTCR).
After the value of the PLL2STP bit has been changed to 0, confirm that the OSCSF.PLL2SF flag has been set to 1 before starting to use the PLL2 clock. That is, PLL2 requires a certain amount of time for stabilization after it starts operation. A certain amount of time is also required for oscillation to stop after the PLL2 operation is stopped.
In addition, note the following when starting or stopping PLL2 by the PLL2STP bit.

- After stopping PLL2, confirm that the OSCSF.PLL2SF flag is 0 before restarting PLL2.
- Confirm that PLL2 is operating and that the OSCSF.PLL2SF flag is 1 before stopping PLL2.
- Confirm that the OSCSF.PLL2SF flag is 1 before executing a WAIT instruction to place the MCU in software standby or deep software standby mode after the PLL2 operation is started.
- Confirm that the OSCSF.PLL2SF flag is 0 before executing a WAIT instruction to place the MCU in software standby or deep software standby mode after the PLL2 operation is stopped.

Confirm the following conditions before writing 0 to the PLL2STP bit.

- When PLL2 source clock = MOSC: MOSCCR.MOSTP = 0 (MOSC is operating)
- When PLL2 source clock = HOCO: HOCOCR.HCSTP = 0 (HOCO is operating)

9.2.12 External Bus Clock Control Register (BCKCR)

Address(es): SYSC.BCKCR 8701 9030h,
SYSC_NS.BCKCR 0701 9030h

	b7	b6	b5	b4	b3	b2	b1	b0
	EBCKASEL	—	—	—	—	—	—	BCLKDIV
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BCLKDIV	EBCLK Pin Output Select	0: The clock selected by the EBCKASEL bit is output without change. 1: The clock selected by the EBCKASEL bit is divided by 2 before it is output.	R/W
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	EBCKASEL	External Bus Asynchronous Source Select*1	0: Synchronous (BCLK) 1: Asynchronous (BCLKA)	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note 1. Before changing this bit, set BCKACR.BCKACKSREQ = 1 and then change the value while BCKACR.BCKACKSRDY = 1.

The BCKCR register is used to control the external bus clocks.
When the asynchronous clock (BCLKA) is selected for the external bus clock, the setting of the BCKACR register is also required. For details, see section 9.2.61, Asynchronous External Bus Clock Control Register (BCKACR).

BCLKDIV Bit (EBCLK Pin Output Select)

This bit selects the clock for output from the EBCLK pin.
Either the clock specified by the EBCKASEL bit or that clock with its frequency divided by two can be selected.
Set the BCLKDIV bit to 0 when BCLKA is selected by setting the EBCKASEL bit to 1.

EBCKASEL Bit (External Bus Asynchronous Source Select)

This bit selects the clock source for external bus, EBCLK, and SDCLK. Either BCLK or BCLKA can be selected, with division ratios set by the SCKDIVCR.BCK[2:0] bits and the BCKADIVCR.BCKACKDIV[3:0] bits, respectively.

9.2.13 Main Clock Oscillator Control Register (MOSCCR)

Address(es): SYSC.MOSCCR 8701 9032h,
SYSC_NS.MOSCCR 0701 9032h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	MOSTP
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	MOSTP	Main Clock Oscillator Stop	0: The main clock oscillator is started (operating).*1 1: The main clock oscillator is stopped.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Set the MOMCR register before setting the MOSTP bit to 0.

The MOSCCR register is used to control the main clock oscillator.

MOSTP Bit (Main Clock Oscillator Stop)

This bit starts or stops the operation of the main clock oscillator.
After the value of this bit has been changed, read the bit and check that the value has been updated before executing subsequent instructions.
To use the main clock oscillator, set the main clock oscillator mode oscillation control register (MOMCR) and the main clock oscillator wait control register (MOSCWTCR) before setting the MOSTP bit to 0.
After the value of the MOSTP bit has been changed to 0, confirm that the OSCSF.MOSCSF flag has been set to 1 before starting to use the main clock oscillator. That is, the main clock oscillator requires a certain amount of time for oscillation to become stable after it is set to start operation. A certain amount of time is also required for oscillation to stop after the main clock oscillator operation is stopped. In addition, note the following when starting or stopping operation.

- After stopping the main clock oscillator, confirm that the OSCSF.MOSCSF flag is 0 before restarting the main clock oscillator.
- Confirm that the main clock oscillator is operating and that the OSCSF.MOSCSF flag is 1 before stopping the main clock oscillator.
- Regardless of whether the main clock oscillator is selected as the system clock source, confirm that the OSCSF.MOSCSF flag is 1 before executing a WAIT instruction to place the MCU in software standby or deep software standby mode.
- Confirm that the OSCSF.MOSCSF flag is 0 before executing a WAIT instruction to place the MCU in software standby or deep software standby mode after the main clock oscillator operation is stopped.

Writing 1 to the MOSTP bit is prohibited under any of the following conditions.

- SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC)
- PLLCCR.PLSRCSEL = 0 (PLL1 clock source = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL1P)
- PLLCCR.PLSRCSEL = 0 (PLL1 clock source = MOSC) and PLLCR.PLLSTP = 0 (PLL1 is operating)
- PLL2CCR.PL2SRCSEL = 0 (PLL2 clock source = MOSC) and PLL2CR.PLL2STP = 0 (PLL2 is operating)

9.2.14 Sub-Clock Oscillator Control Register (SOSCCR)

Address(es): SYSC.SOSCCR 8701 9C00h,
SYSC_NS.SOSCCR 0701 9C00h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SOSTP
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	SOSTP	Sub-Clock Oscillator Stop	0: The sub-clock oscillator is started (operating).*1 1: The sub-clock oscillator is stopped.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note 1. Set the SOMCR register before setting the SOSTP bit to 0.

The SOSCCR register is used to control the sub-clock oscillator.
This register is only initialized by the backup domain reset.

SOSTP Bit (Sub-Clock Oscillator Stop)

This bit starts or stops the operation of the sub-clock oscillator. After the value of this bit has been changed, read the bit and check that the value has been updated before executing subsequent instructions.
To use the sub-clock oscillator, set the sub-clock oscillator mode control register (SOMCR) before setting the SOSTP bit to 0.
When the external clock input is to be used, set the SOMCR.SOSEL bit to 1 to select the external clock input, wait for 50 µs, and then set the SOSTP bit to 0.
Note the following when starting or stopping operation.

- After stopping the sub-clock oscillator, allow a stop interval of at least five cycles of the SOSC clock before restarting the oscillator.
- After setting the SOSTP bit to 0, use the sub-clock only after the sub-clock oscillation stabilization wait time ($t_{SUBOSCWT}$) has elapsed.
- Regardless of whether the sub-clock oscillator is selected as the system clock source, confirm that oscillation of the sub-clock is stable before executing a WAIT instruction to place the MCU in software standby or deep software standby mode.
- Wait for at least three cycles of the SOSC clock before executing a WAIT instruction to place the MCU in software standby or deep software standby mode after the sub-clock oscillator operation is stopped.

Writing 1 to the SOSTP bit is prohibited under the following condition.

- SCKSCR.CKSEL[2:0] = 100b (system clock source = SOSC).

9.2.15 Low-Speed On-Chip Oscillator Control Register (LOCOCR)

Address(es): SYSC.LOCOCR 8701 9400h,
SYSC_NS.LOCOCR 0701 9400h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	LCSTP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LCSTP	LOCO Stop	0: The LOCO is started (operating). 1: The LOCO is stopped.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note: Confirm that the SYRACCR.BUSY bit is 0 before accessing the LOCOCR register. If SYRACCR.BUSY is 1, write access is ignored and the read value is not guaranteed.

The LOCOCR register is used to control the LOCO.

LCSTP Bit (LOCO Stop)

This bit starts or stops the operation of the LOCO.

After the value of this bit has been changed, read the bit and check that the value has been updated before executing subsequent instructions.

There are restrictions on the operation and stopping of the LOCO. For details, see section 9.5, Low-Speed On-Chip Oscillator (LOCO).

9.2.16 High-Speed On-Chip Oscillator Control Register (HOCOCR)

Address(es): SYSC.HOCOCR 8701 9036h,
SYSC_NS.HOCOCR 0701 9036h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	HCSTP
Value after reset:	0	0	0	0	0	0	0	0/1*1

Bit	Symbol	Bit Name	Description	R/W
b0	HCSTP	HOCO Stop	0: The HOCO is started (operating).*2, *3 1: The HOCO is stopped.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note 1. The value of the HCSTP bit after a reset is 0 when the OFS1.HOCOEN bit is 0. It is 1 when the OFS1.HOCOEN bit is 1.
Note 2. When the HOCO is used (HCSTP = 0), set the OFS1.HOCOFRQ0[2:0] bits to an optimal value.
Note 3. The value of the OFS1.HOCOFRQ0[2:0] bits is automatically transferred to the HOCOCR2.HCFRQ0[2:0] bits after a reset, therefore, the HOCO frequency can be changed by setting the HOCOCR2.HCFRQ0[2:0] bits.

The HOCOCR register is used to control the HOCO.

HCSTP Bit (HOCO Stop)

This bit starts or stops the operation of the HOCO.
After the value of this bit has been changed to 0 to start the HOCO, confirm that the OSCSF.HOCOSF flag has been set to 1 before starting to use the HOCO clock. When the OFS1.HOCOEN bit is 0, confirm that the OSCSF.HOCOSF flag is also set to 1 before using the HOCO clock. That is, the HOCO requires a certain amount of time for oscillation to become stable after it is set to start operation. A certain amount of wait time is also required for oscillation to stop after the HOCO clock is set to stop.
Note the following when starting or stopping operation.

- After stopping the HOCO clock, wait for at least the HOCO stop width time and confirm that the OSCSF.HOCOSF flag is 0 before restarting the HOCO clock. For the HOCO stop width time, see section 67, Electrical Characteristics.
- Confirm that the HOCO clock is operating and that the OSCSF.HOCOSF flag is 1 before stopping the HOCO.
- Regardless of whether the HOCO clock is selected as the system clock, confirm that the HOCO clock is stable before executing a WAIT instruction to place the MCU in software standby or deep software standby mode.
- Confirm that the OSCSF.HOCOSF flag is 0 before executing a WAIT instruction to place the MCU in software standby or deep software standby mode after the HOCO operation is stopped.

Writing 1 to the HCSTP bit is prohibited under any of the following conditions.

- SCKSCR.CKSEL[2:0] = 000b (system clock source = HOCO)
- PLLCCR.PLSRCSEL = 1 (PLL1 clock source = HOCO) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL1P)
- PLLCCR.PLSRCSEL = 1 (PLL1 clock source = HOCO) and PLLCR.PLLSTP = 0 (PLL1 is operating)
- PLL2CCR.PL2SRCSEL = 1 (PLL2 clock source = HOCO) and PLL2CR.PLL2STP = 0 (PLL2 is operating)

9.2.17 High-Speed On-Chip Oscillator Control Register 2 (HOCOCR2)

Address(es): SYSC.HOCOCR2 8701 9037h,
SYSC_NS.HOCOCR2 0701 9037h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	HCFRQ0[2:0]		
Value after reset:	0	0	0	0	0	0/1*1	0/1*1	0/1*1

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	HCFRQ0[2:0]	HOCO Frequency Setting 0	b2 b0 0 0 0: 16 MHz 0 0 1: 18 MHz 0 1 0: 20 MHz 1 0 0: 32 MHz 1 1 1: 48 MHz Settings other than above are prohibited.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note 1. The value after a reset depends on the setting of the OFS1.HOCOFRQ0[2:0] bits.

The HOCOCR2 register is used to control the HOCO clock.
Writing to the HOCOCR2 register is prohibited when the HOCOCR.HCSTP bit is 0 (making the HOCO run).

HCFRQ0[2:0] Bits (HOCO Frequency Setting 0)

These bits select the frequency of the HOCO.

9.2.18 Middle-Speed On-Chip Oscillator Control Register (MOCOCR)

Address(es): SYSC.MOCOCR 8701 9038h,
SYSC_NS.MOCOCR 0701 9038h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	MCSTP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MCSTP	MOCO Stop	0: The MOCO is started (operating). 1: The MOCO is stopped.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The MOCOCR register is used to control the MOCO.

MCSTP Bit (MOCO Stop)

This bit starts or stops the operation of the MOCO.

After the value of this bit has been changed, read the bit and check that the value has been updated before executing subsequent instructions.

There are restrictions on MOCO operation conditions, MOCO stop conditions, and the setting of the MCSTP bit. For details, see section 9.6, Middle-Speed On-Chip Oscillator (MOCO).

9.2.19 FLL Control Register 1 (FLLCR1)

Address(es): SYSC.FLLCR1 8701 9039h,
SYSC_NS.FLLCR1 0701 9039h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	FLLEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FLLEN	FLL Enable	0: The FLL function is disabled. 1: The FLL function is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Stop the HOCO (HOCOCR.HCSTP = 1) before modifying the FLLCR1.FLLEN bit.
Note: The sub-clock oscillator needs to be operating and its oscillation needs to be stable while FLL is enabled (FLLCR1.FLLEN = 1).
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The FLLCR1 register controls the frequency correction function (frequency locked loop (FLL) function) of the HOCO.

FLLEN Bit (FLL Enable)

This bit enables or disables the FLL function of the HOCO.

The accuracy of clock frequency is guaranteed after FLL has become stable. Stabilization of FLL can be checked through measurement of the frequency by the clock frequency accuracy measurement circuit (CAC) after stabilization of the HOCO.

The FLL function needs to be disabled by setting the FLLEN bit to 0 before placing the MCU in software standby mode. Table 9.4 shows sample procedures for setting the FLL function in some situations.

Table 9.4 Procedures for Setting the FLL Function (1/2)

Procedure		Operation
After release from the reset state or deep software standby mode	1	Start (After release from the reset state or deep software standby mode)
	2	Set the multiplication ratio for FLL (FLLCR2.FLLCNTL[10:0]).
	3	Enable FLL (FLLCR1.FLLEN = 1).*1
	4	Enable the HOCO (HOCOCR.HCSTP = 0).
	5	Wait until FLL has become stable (tFLLWT).
	6	Check that the HOCO has become stable (OSCSF.HOCOSF = 1).
	7	End (The HOCO can be used.)
Transition to or release from software standby mode	1	Start (FLL is being used.)
	2	Stop the HOCO (HOCOCR.HCSTP = 1).*2
	3	Disable FLL (FLLCR1.FLLEN = 0).
	4	Execute a WAIT instruction.
	5	Software standby mode
	6	Release from software standby mode
	7	Enable FLL (FLLCR1.FLLEN = 1).

Table 9.4 Procedures for Setting the FLL Function (2/2)

Procedure		Operation
Transition to or release from software standby mode	8	Enable the HOCO (HOCOCR.HCSTP = 0).
	9	Wait until FLL has become stable (tFLLWT).
	10	Check that the HOCO has become stable (OSCSF.HOCOSF = 1).
	11	End (The HOCO can be used.)

Note 1. Enable the FLL function while oscillation of the SOSC is stable.
Note 2. If the HOCO is used as the source of the system clock or PLL clocks, change the source to a different clock before stopping the HOCO.

9.2.20 FLL Control Register 2 (FLLCR2)

Address(es): SYSC.FLLCR2 8701 903Ah,
SYSC_NS.FLLCR2 0701 903Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	FLLCNTL[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	FLLCNTL[10:0]	FLL Multiplication Control	Set these bits to 1E8h when the OFS1.HOCOFRQ0[2:0] bits are set to 000b (16 MHz) or 100b (32 MHz). Set to 225h when the OFS1.HOCOFRQ0[2:0] bits are set to 001b (18 MHz). Set to 262h when the OFS1.HOCOFRQ0[2:0] bits are set to 010b (20 MHz). Set to 1E8h when the OFS1.HOCOFRQ0[2:0] bits are set to 111b (48 MHz). Settings other than those listed above are prohibited.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note: The value of the OFS1.HOCOFRQ0[2:0] bits is automatically transferred to the HOCOCR2.HCFRQ0[2:0] bits after a reset, therefore, the HOCO frequency can be changed by setting the HOCOCR2.HCFRQ0[2:0] bits.

The FLLCR2 register controls the FLL function of the HOCO.

FLLCNTL[10:0] Bits (FLL Multiplication Control)

These bits select the frequency multiplication ratio of the FLL reference clock.
Set these bits before enabling the FLL function (FLLCR1.FLLEN = 1).

9.2.21 Oscillation Stabilization Flag Register (OSCSF)

Address(es): SYSC.OSCSF 8701 903Ch,
SYSC_NS.OSCSF 0701 903Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	PLL2SF	PLLSF	—	MOSCSF	—	—	HOCOSF
Value after reset:	0	0	0	0	0	0	0	0/1*1

Bit	Symbol	Bit Name	Description	R/W
b0	HOCOSF	HOCO Clock Oscillation Stabilization Flag	0: The HOCO clock is stopped or oscillation of the clock has not yet become stable. 1: Oscillation of the HOCO clock is stable and the clock is available for use as the system clock source.	R
b2, b1	—	Reserved	These bits are read as 0.	R
b3	MOSCSF	Main Clock Oscillation Stabilization Flag	0: The main clock oscillator is stopped or oscillation of the clock has not yet become stable*2 1: Oscillation of the main clock oscillator is stable and the clock is available for use as the system clock source.	R
b4	—	Reserved	This bit is read as 0.	R
b5	PLLSF	PLL1 Clock Oscillation Stabilization Flag	0: The PLL1 clock is stopped or oscillation of the clock has not yet become stable 1: Oscillation of the PLL1 clock is stable and the clock is available for use as the system clock source.	R
b6	PLL2SF	PLL2 Clock Oscillation Stabilization Flag	0: The PLL2 clock is stopped or oscillation of the clock has not yet become stable 1: Oscillation of the PLL2 clock is stable.	R
b7	—	Reserved	This bit is read as 0.	R

Note 1. The value after a reset depends on the setting of the OFS1.HOCOEN bit.
When OFS1.HOCOEN = 1 (HOCO is stopped), the value of HOCOSF after a reset is 0.
When OFS1.HOCOEN = 0 (HOCO is operating), the HOCOSF bit is set to 0 immediately after release from a reset but its value is set to 1 after the HOCO oscillation stabilization wait time has elapsed.

Note 2. This is true when an appropriate value is set in the main clock oscillator wait control register (MOSCWTCR). If the value (wait time) set in the register is not sufficient, the oscillation stabilization flag is set to 1 and supply of the clock signal to the internal circuits starts before oscillation has become stable.

This register is not controlled by the CGFSAR register.
The OSCSF register contains flags to indicate the states of operation of the counters in the oscillation stabilization wait circuits for the individual oscillators. The counters measure the wait times until the output clocks of the individual oscillators are supplied to the internal circuits after oscillation starts. Each oscillation stabilization flag being set to 1 indicates that the corresponding clock supply is stable and can be used in the related circuits.

HOCOSF Flag (HOCO Clock Oscillation Stabilization Flag)

This flag indicates the state of operation of the counter that measures the wait time for the high-speed on-chip clock oscillator (HOCO).
When the OFS1.HOCOEN bit is set to 0, confirm that the OSCSF.HOCOSF flag is set to 1 before using the HOCO clock.
[Setting condition]

- After the HOCOCR.HCSTP bit is set to 0, the HOCOSF flag is set to 1 after the fluctuation of the HOCO clock has fallen within a range of ±10%.

Note: To use the clock in the frequency fluctuation range specified in the electrical characteristics, wait until the oscillation stabilization wait time specified in the electrical characteristics has elapsed. (For details, see section 67, Electrical Characteristics).

Note: When the HOCOCR.HCSTP bit is set to 0, the HOCO clock is supplied to the MCU internal circuits regardless of the value of the HOCOSF flag.

[Clearing condition]

- The flag is cleared after oscillation of the HOCO has been stopped by setting the HOCOCR.HCSTP bit to 1 while the HOCO is operating.

Note: Even if the OFS1.HOCOEN bit has been set to 0, confirm that the OSCSF.HOCOSF flag is set to 1 before starting the use of the HOCO clock.

MOSCSF Flag (Main Clock Oscillation Stabilization Flag)

This flag indicates the state of operation of the counter that measures the wait time for the main clock oscillator.

[Setting condition]

- After the MOSCCR.MOSTP bit is set to 0 while the main clock oscillator is stopped, the MOSCSF flag is set after the number of LOCO clock cycles corresponding to the setting of the MOSCWTCR register has been counted and supply of the main clock in the MCU has started.

[Clearing condition]

- The flag is cleared when deactivation of the main clock oscillator is completed after the MOSCCR.MOSTP bit is set to 1 while the main clock oscillator is operating.

PLLSF Flag (PLL1 Clock Oscillation Stabilization Flag)

This flag indicates the oscillation stabilization status for the PLL1.

[Setting condition]

- After the PLLCR.PLLSTP bit is set to 0 while PLL1 is stopped, supply of the PLL1 clock begins after the clock has become stable.
  If oscillation of the clock source for PLL1 selected by the PLLCCR.PLSRCSEL bit is not stable when the PLLSTP bit is set to 0, wait until the clock becomes stable after oscillation of the clock source has become stable.

[Clearing condition]

- The flag is cleared when deactivation of PLL1 is completed after the PLLCR.PLLSTP bit is set to 1 while PLL1 is operating.

PLL2SF Flag (PLL2 Clock Oscillation Stabilization Flag)

This flag indicates the oscillation stabilization status for the PLL2.

[Setting condition]

- After the PLL2CR.PLL2STP bit is set to 0 while PLL2 is stopped, supply of the PLL2 clock begins after the clock has become stable.
  If oscillation of the clock source for PLL2 selected by the PLL2CCR.PL2SRCSEL bit is not stable when the PLL2STP bit is set to 0, wait until the clock becomes stable after oscillation of the clock source has become stable.

[Clearing condition]

- The flag is cleared when deactivation of PLL2 is completed after the PLL2CR.PLL2STP bit is set to 1 while PLL2 is operating.

9.2.22 Oscillator Monitor Register (OSCMONR)

Address(es): SYSC.OSCMONR 8701 9043h,
SYSC_NS.OSCMONR 0701 9043h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	LOCOMON	MOCOMON	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0.	R
b1	MOCOMON	MOCO Operation Monitoring Flag	0: The MOCO is set to operate. 1: The MOCO is set to stop.	R
b2	LOCOMON	LOCO Operation Monitoring Flag	0: The LOCO is set to operate. 1: The LOCO is set to stop.	R
b7 to b3	—	Reserved	These bits are read as 0.	R

This register is not controlled by the CGFSAR register.

MOCOMON Flag (MOCO Operation Monitoring Flag)

This flag indicates whether the MOCO is set to operate or stop.

[Clearing condition]

- The flag is cleared when the MOCO operating conditions are satisfied. For details, see section 9.6.1, MOCO Operating Conditions.

[Setting condition]

- The flag is set when the MOCO stop conditions are satisfied. For details, see section 9.6.2, MOCO Stop Conditions.

LOCOMON Flag (LOCO Operation Monitoring Flag)

This flag indicates whether the LOCO is set to operate or stop.

[Clearing condition]

- The flag is cleared when the LOCO operating conditions are satisfied. For details, see section 9.5.1, LOCO Operating Conditions.

[Setting condition]

- The flag is set when the LOCO stop conditions are satisfied. For details, see section 9.5.2, LOCO Stop Conditions.

9.2.23 Oscillation Stop Detection Control Register (OSTDCR)

Address(es): SYSC.OSTDCR 8701 9040h,
SYSC_NS.OSTDCR 0701 9040h

	b7	b6	b5	b4	b3	b2	b1	b0
	OSTDE	—	—	—	—	—	—	OSTDIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OSTDIE	Oscillation Stop Detection Interrupt Enable	0: The oscillation stop detection interrupt is disabled. Oscillation stop detection is not reported to the POEG. 1: The oscillation stop detection interrupt is enabled. Oscillation stop detection is reported to the POEG.	R/W
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	OSTDE	Oscillation Stop Detection Function Enable	0: The oscillation stop detection function is disabled. 1: The oscillation stop detection function is enabled.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The OSTDCR register is used to enable the main clock oscillation stop detection function.

OSTDIE Bit (Oscillation Stop Detection Interrupt Enable)

This bit enables or disables the main clock oscillation stop detection function interrupt. It also controls whether main clock oscillation stop detection is reported to the POEG.
If the oscillation stop detection flag in the oscillation stop detection status register (OSTDSR.OSTDF) requires clearing, do this after clearing the OSTDIE bit to 0. Wait for at least two cycles of PCLKB before setting the OSTDIE bit to 1 again. By reading an I/O register whose access time is defined with the number of PCLKB cycles, a wait time of at least two PCLKB cycles can be secured.

OSTDE Bit (Oscillation Stop Detection Function Enable)

This bit enables or disables the oscillation stop detection function for the main clock.
Setting the OSTDE bit to 1 (enabled) changes the MOCO stop bit (MOCOCR.MCSTP) to 0 and the MOCO starts operation.
The MOCO clock cannot be stopped while the main clock oscillation stop detection function is enabled; writing 1 to the MOCOCR.MCSTP bit to stop the MOCO has no effect.
Writing 0 to the OSTDE bit has no effect while the oscillation stop detection flag of the oscillation stop detection status register (OSTDSR.OSTDF) is 1 (stopping of main clock oscillation has been detected).

9.2.24 Oscillation Stop Detection Status Register (OSTDSR)

Address(es): SYSC.OSTDSR 8701 9041h,
SYSC_NS.OSTDSR 0701 9041h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	OSTDF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OSTDF	Oscillation Stop Detection Flag	0: Stopping of main clock oscillation has not been detected. 1: Stopping of main clock oscillation has been detected.	R/W*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note 1. Only 0 can be written. This flag can be cleared by reading 1 from it and then writing 0.

The OSTDSR register indicates the detection of stopping of the main clock oscillator.

OSTDF Flag (Oscillation Stop Detection Flag)

This flag indicates the state of the main clock oscillator. When this flag is 1, it indicates that stopping of main clock oscillation has been detected. Once stopping of oscillation is detected, the OSTDF flag is not set to 0 even though main clock oscillation is restarted. The flag can be cleared to 0 by reading 1 from it and then writing 0.
At least three ICLK cycles of wait time are necessary until the OSTDF flag is read as 0 after 0 is written to it.
If the OSTDF flag is cleared to 0 while main clock oscillation is stopped, the flag becomes 0 and then returns to 1.

The OSTDF flag cannot be set to 0 under either of the following conditions.

- SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC)
- PLLCCR.PLSRCSEL = 0 (PLL1 clock source = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL1P)

The OSTDF flag should be set to 0 after the clock source is switched to a source other than the main clock oscillator or PLL1P.
[Setting condition]

- The flag is set when main clock oscillation is stopped while the OSTDCR.OSTDE bit is 1 (oscillation stop detection function is enabled).

[Clearing condition]

- The flag is cleared when 1 is read and then 0 is written while neither of the following conditions is satisfied.
  - SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC)
  - PLLCCR.PLSRCSEL = 0 (PLL1 clock source = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL1P)

9.2.25 Sub-Clock Oscillation Stop Detection Control Register (SOSTDCR)

Address(es): SYSC.SOSTDCR 8701 9C04h,
SYSC_NS.SOSTDCR 0701 9C04h

	b7	b6	b5	b4	b3	b2	b1	b0
	SOSTDE	—	—	—	—	—	—	SOSTDIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SOSTDIE	Sub-Clock Oscillation Stop Detection Interrupt Enable	0: The oscillation stop detection interrupt is disabled. 1: The oscillation stop detection interrupt is enabled.	R/W
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	SOSTDE	Sub-Clock Oscillation Stop Detection Function Enable	0: The oscillation stop detection function is disabled. 1: The oscillation stop detection function is enabled.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The SOSTDCR register is used to enable the sub-clock oscillation stop detection function.
This register is only initialized by the backup domain reset.

SOSTDIE Bit (Sub-Clock Oscillation Stop Detection Interrupt Enable)

This bit enables or disables the sub-clock oscillation stop detection function interrupt.
If the sub-clock oscillation stop detection flag in the sub-clock oscillation stop detection status register (SOSTDSR.SOSTDF) requires clearing, do this after clearing the SOSTDIE bit to 0. Confirm that the SOSTDF flag has been cleared before setting the SOSTDIE bit to 1 again.

SOSTDE Bit (Sub-Clock Oscillation Stop Detection Function Enable)

This bit enables or disables the sub-clock oscillation stop detection function.
When the SOSTDE bit is set to 1 (enabled), the MOCO stop bit (MOCOCR.MCSTP) and LOCO stop bit (LOCOCR.LCSTP) are set to 0, and the MOCO and LOCO start operating.
Except in deep software standby mode and battery backup mode, the MOCO cannot be stopped while the sub-clock oscillation stop detection function is enabled. The LOCO cannot be stopped while the sub-clock oscillation stop detection function is enabled. Writing 1 to the MOCOCR.MCSTP bit or LOCOCR.LCSTP bit has no effect while the sub-clock oscillation stop detection function is enabled.
Writing 0 to the SOSTDE bit has no effect while the sub-clock oscillation stop detection flag of the sub-clock oscillation stop detection status register (SOSTDSR.SOSTDF) is 1 (stopping of sub-clock oscillation has been detected).
To enable the sub-clock oscillation stop detection function, set the SOSTDCR.SOSTDE bit to 1 and then clear the SOSTDSR.SOSTDF flag to 0. Here, after setting the SOSTDCR.SOSTDE bit to 1, wait for the sub-clock oscillation stop detection circuit start-up wait time (t_{sosdup}) to elapse before clearing the SOSTDSR.SOSTDF flag. For the SOSTDSR register, see section 9.2.26, Sub-Clock Oscillation Stop Detection Status Register (SOSTDSR).
Set the system clock to other clock sources than the sub-clock oscillator before enabling the sub-clock oscillation stop detection function.
Set this bit only once. After it has been set to 1, setting it to 0 is prohibited.

9.2.26 Sub-Clock Oscillation Stop Detection Status Register (SOSTDSR)

Address(es): SYSC.SOSTDSR 8701 9C05h,
SYSC_NS.SOSTDSR 0701 9C05h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SOSTDF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SOSTDF	Sub-Clock Oscillation Stop Detection Flag	0: Stopping of sub-clock oscillation has not been detected. 1: Stopping of sub-clock oscillation has been detected.	R/W*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note 1. Only 0 can be written. This flag can be cleared by reading 1 from it and then writing 0.

The SOSTDSR register indicates the detection of stopping of the sub-clock oscillator.
This register is only initialized by the backup domain reset.

SOSTDF Flag (Sub-Clock Oscillation Stop Detection Flag)

This flag indicates the state of the sub-clock oscillator. When this flag is 1, it indicates that stopping of sub-clock oscillation has been detected.
Once stopping of oscillation is detected, the SOSTDF flag is not set to 0 even though sub-clock oscillation is restarted.
The flag can be cleared to 0 by reading 1 from it and then writing 0.
At least 3 PCLKB cycles of wait time are necessary until the SOSTDF flag is read as 0 after 0 is written to it.
If the SOSTDF flag is cleared to 0 while the sub-clock oscillation is stopped, the flag is immediately set to 1.
The SOSTDF flag cannot be set to 0 under the following condition.

- SCKSCR.CKSEL[2:0] = 100 (system clock source = SOSC)

[Setting condition]

- The flag is set when sub-clock oscillation is stopped while the SOSTDCR.SOSTDE bit is 1 (oscillation stop detection function is enabled).

[Clearing condition]

- The flag is cleared when 1 is read and then 0 is written while the value of the SCKSCR.CKSEL[2:0] bits is not 100b (system clock source = SOSC).

9.2.27 Main Clock Oscillator Wait Control Register (MOSCWTCR)

Address(es): SYSC.MOSCWTCR 8701 90A2h,
SYSC_NS.MOSCWTCR 0701 90A2h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	MSTS[3:0]			
Value after reset:	0	0	0	0	0	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	MSTS[3:0]	Main Clock Oscillator Stabilization Wait Time Setting	b3 b0 0 0 0 0: Wait time = 3 cycles (11.4 µs) 0 0 0 1: Wait time = 35 cycles (133.5 µs) 0 0 1 0: Wait time = 67 cycles (255.6 µs) 0 0 1 1: Wait time = 131 cycles (499.7 µs) 0 1 0 0: Wait time = 259 cycles (988.0 µs) 0 1 0 1: Wait time = 547 cycles (2086.6 µs) (initial value) 0 1 1 0: Wait time = 1059 cycles (4039.8 µs) 0 1 1 1: Wait time = 2147 cycles (8190.2 µs) 1 0 0 0: Wait time = 4291 cycles (16368.9 µs) 1 0 0 1: Wait time = 8163 cycles (31139.4 µs) Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

MSTS[3:0] Bits (Main Clock Oscillator Stabilization Wait Time Setting)

These bits specify the oscillation stabilization wait time for the main clock oscillator.

Set the main clock oscillation stabilization time to at least the stabilization time recommended by the manufacturer of the resonator. When an external input clock is used as the main clock, set these bits to 0000b because the oscillation stabilization time is not required.

The wait time set in these bits is counted by using the following equation.

1 cycle (µs) = 1/(fLOCO (MHz) × 8) = 1/(0.032768 × 8) = 3.81 µs (min.)

While waiting for the main clock oscillator to stabilize (when the MOSCCR.MOSTP bit is 0 and the OSCSF.MOSCSF flag is 0), the LOCO clock operates regardless of the value of the LOCOCR.LCSTP bit. After the specified wait time has elapsed, supply of the main clock starts in the MCU and the OSCSF.MOSCSF flag is set to 1. If the specified wait time is short, supply of the main clock starts before oscillation of the clock becomes stable.

Only rewrite the MOSCWTCR register when the MOSCCR.MOSTP bit is 1 and the OSCSF.MOSCSF flag is 0. Do not rewrite this register under any other conditions.

9.2.28 Main Clock Oscillator Mode Oscillation Control Register (MOMCR)

Address(es): SYSC.MOMCR 8701 9A50h,
SYSC_NS.MOMCR 0701 9A50h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	MOSEL	—	—	MODRV0[2:0]			—
Value after reset:	0	0	0	1	1	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3 to b1	MODRV0[2:0]	Main Clock Oscillator Driving Capacity Switching	b3 b1 0 0 0: 8 MHz 0 1 1: 8 MHz to 24 MHz 1 0 1: 8 MHz to 48 MHz (initial value) Settings other than those listed above are prohibited.	R/W
b4	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	MOSEL	Main Clock Oscillator Switching	0: Resonator 1: External clock input	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: The EXTAL and XTAL pins can be used as port pins. In the initial state, the pins are set as port pins.
Note: Set the MOSCCR.MOSTP bit to 1 (MOSC is stopped) before changing the value of this register.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

MODRV0[2:0] Bits (Main Clock Oscillator Driving Capacity Switching)

These bits switch the driving capacity of the main clock oscillator. These bits should normally be set to 101b. To reduce power consumption, set these bits to an appropriate value according to the frequency of the oscillator or resonator used. See section 67, Electrical Characteristics for current consumption.

MOSEL Bit (Main Clock Oscillator Switching)

This bit switches the source for the main clock oscillator.
For details, see section 9.3, Main Clock Oscillator.

9.2.29 Sub-Clock Oscillator Mode Control Register (SOMCR)

Address(es): SYSC.SOMCR 8701 9C01h,
SYSC_NS.SOMCR 0701 9C01h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	SOSEL	—	—	—	—	SODRV[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SODRV[1:0]	Sub-Clock Oscillator Driving Capacity Switching	b1 b0 0 0: Standard (12.5 pF) 0 1: Low-power mode 1 (9 pF) 1 0: Low-power mode 2 (7 pF) 1 1: Setting prohibited	R/W
b5 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	SOSEL	Sub-Clock Oscillator Switching	0: Resonator 1: External clock input	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The SOMCR register must be modified when the SOSCCR.SOSTP bit is 1 (SOSC is stopped). This register is only initialized by the backup domain reset.

SODRV[1:0] Bits (Sub-Clock Oscillator Driving Capacity Switching)

These bits switch the driving capacity of the sub-clock oscillator.

SOSEL Bit (Sub-Clock Oscillator Switching)

This bit switches the oscillation source for the sub-clock oscillator.

For details, see section 9.4, Sub-Clock Oscillator.

9.2.30 Clock Output Control Register (CKOCR)

Address(es): SYSC.CKOCR 8701 903Eh,
SYSC_NS.CKOCR 0701 903Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	CKOEN	CKODIV[2:0]			CKOSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	CKOSEL[3:0]	Clock Output Source Select	b3 b0 0 0 0 0: HOCO 0 0 0 1: MOCO (initial value) 0 0 1 0: LOCO 0 0 1 1: MOSC 0 1 0 0: SOSC 0 1 0 1: ICLK 1 0 0 0: PLL1P 1 1 0 1: PLL2P 1 1 1 0: PLL1Q 1 1 1 1: PLL2Q Settings other than those listed above are prohibited.	R/W
b6 to b4	CKODIV[2:0]	Clock Output Frequency Division Ratio	b6 b4 0 0 0: Division by 1 0 0 1: Division by 2 0 1 0: Division by 4 0 1 1: Division by 8 1 0 0: Division by 16 1 0 1: Division by 32 1 1 0: Division by 64 1 1 1: Division by 128	R/W
b7	CKOEN	Clock Output Enable	0: Clock output is disabled. 1: Clock output is enabled.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

CKOSEL[3:0] Bits (Clock Output Source Select)

These bits select the source of the clock to be output from the CLKOUT pin. Set the CKOEN bit to 0 before changing the clock source.

CKODIV[2:0] Bits (Clock Output Frequency Division Ratio)

The CKODIV[2:0] bits set the frequency division ratio of the clock selected by the CKOSEL[3:0] bits. Set the CKOEN bit to 0 before changing the division ratio. Set these bits so that the frequency of the clock output from the CLKOUT pin is within the range of the electrical characteristics. For details, see section 67, Electrical Characteristics.

CKOEN Bit (Clock Output Enable)

The CKOEN bit enables or disables output from the CLKOUT pin.

Setting the bit to 1 leads to output of the selected clock. Setting the bit to 0 drives the output to the low level.

Confirm that the source clock for the output clock selected by the CKOSEL[3:0] bits is stable before changing the value of this bit. Otherwise, a glitch may be generated in the output.

To stop output from the CLKOUT pin in software standby mode or deep software standby mode, set this bit to 0 before entering the mode.

9.2.31 External Bus Clock Output Control Register (EBCKOCR)

Address(es): SYSC.EBCKOCR 8701 9052h,
SYSC_NS.EBCKOCR 0701 9052h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	EBCKOEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	EBCKOEN	EBCLK Pin Output Control	0: Output from the EBCLK pin is disabled and the pin is fixed to the high level. 1: Output from the EBCLK pin is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

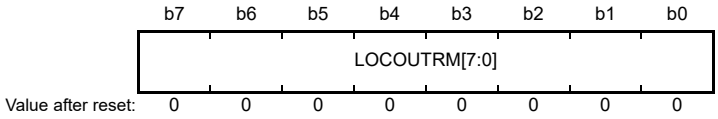
Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

9.2.32 SDRAM Clock Output Control Register (SDCKOCR)

Address(es): SYSC.SDCKOCR 8701 9053h,
SYSC_NS.SDCKOCR 0701 9053h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SDCKOEN
Value after reset:	0	0	0	0	0	0	0	0



Bit	Symbol	Bit Name	Description	R/W
b0	SDCKOEN	SDCLK Pin Output Control	0: Output from the SDCLK pin is disabled and the pin is fixed to the high level. 1: Output from the SDCLK pin is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

9.2.33 LOCO User Trimming Control Register (LOCOUTCR)

Address(es): SYSC.LOCOUTCR 8701 9402h,
SYSC_NS.LOCOUTCR 0701 9402h

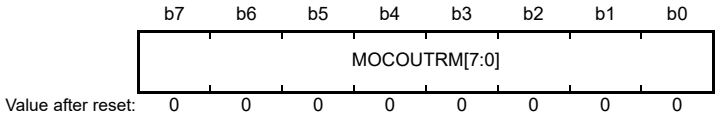
Bit	Symbol	Bit Name	Description	R/W
b7 to b0	LOCOUTRM[7:0]	LOCO User Trimming	80h: –128 81h: –127 : FFh: –1 00h: Center code 01h: +1 : 7Eh: +126 7Fh: +127	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

Note: Confirm that the SYRACCR.BUSY bit is 0 before accessing the LOCOUTCR register. If SYRACCR.BUSY is 1, write access is ignored and the read value is not guaranteed.

Note: MCU operation is not guaranteed if the LOCOUTCR register is set to a value that causes the LOCO frequency to be outside the specification range.



Note: A certain amount of time is required for the frequency to become stable after the value of the LOCOUTCR register is changed. This is the same amount of time as the oscillation stabilization time after operation begins.

The value of the LOCOUTCR register is added to the original LOCO trimming data.

Do not change the LOCOUTCR value while the RTC is operating.

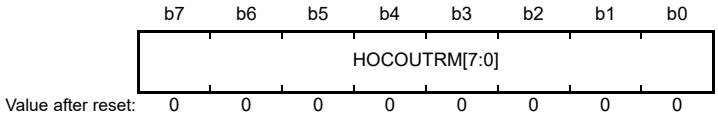
9.2.34 MOCO User Trimming Control Register (MOCOUTCR)

Address(es): SYSC.MOCOUTCR 8701 9061h,
SYSC_NS.MOCOUTCR 0701 9061h

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	MOCOUTRM[7:0]	MOCO User Trimming	80h: –128 81h: –127 : FFh: –1 00h: Center code 01h: +1 : 7Eh: +126 7Fh: +127	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.



Note: MCU operation is not guaranteed if the MOCOUTCR register is set to a value that causes the MOCO frequency to be outside the specification range.

Note: A certain amount of time is required for the frequency to become stable after the value of the MOCOUTCR register is changed. This is the same amount of time as the oscillation stabilization time after operation begins.

The value of the MOCOUTCR register is added to the original MOCO trimming data.

9.2.35 HOCO User Trimming Control Register (HOCOUTCR)

Address(es): SYSC.HOCOUTCR 8701 9062h,
SYSC_NS.HOCOUTCR 0701 9062h

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	HOCOUTRM[7:0]	HOCO User Trimming	80h: –128 81h: –127 : FFh: –1 00h: Center code 01h: +1 : 7Eh: +126 7Fh: +127	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

Note: MCU operation is not guaranteed if the HOCOUTCR register is set to a value that causes the HOCO frequency to be outside the specification range.

Note: A certain amount of time is required for the frequency to become stable after the value of the HOCOUTCR register is changed. This is the same amount of time as the oscillation stabilization time after operation begins.

Note: Set this register to 00h when the FLL function is enabled (FLLCR1.FLLEN = 1).

The value of the HOCOUTCR register is added to the original HOCO trimming data.

9.2.36 Main Clock Oscillator Standby Control Register (MOSCSCR)

Address(es): SYSC.MOSCSCR 8701 907Ch,
SYSC_NS.MOSCSCR 0701 907Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	MOSCSOKP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MOSCSOKP	Main Clock Oscillator Standby Oscillation Keep Select	0: Disabled 1: Enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

Change the value of the MOSCSCR register while the MOSCCR.MOSTP bit is 1 (MOSC is stopped).

MOSCSOKP Bit (Main Clock Oscillator Standby Oscillation Keep Select)

This bit controls whether the main clock oscillator continues oscillation or stops in software standby mode.

If this bit is 0 (disabled) and the MOSCCR.MOSTP bit is 0 (MOSC is operating), the main clock oscillator stops in software standby mode.

If this bit is 1 (enabled) and the MOSCCR.MOSTP bit is 0 (MOSC is operating), the main clock oscillator keeps oscillating in software standby mode.

If the MOSCCR.MOSTP bit is 1 (MOSC is stopped), the main clock oscillator stops in software standby mode regardless of the setting of the MOSCSOKP bit.

9.2.37 High-Speed On-Chip Oscillator Standby Control Register (HOCOSCR)

Address(es): SYSC.HOCOSCR 8701 907Dh,
SYSC_NS.HOCOSCR 0701 907Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	HOCOSOKP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	HOCOSOKP	HOCO Standby Oscillation Keep Select	0: Disabled 1: Enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

HOCOSOKP Bit (HOCO Standby Oscillation Keep Select)

This bit controls whether the HOCO continues oscillation or stops in software standby mode.

If this bit is 0 (disabled) and the HOCOCR.HCSTP bit is 0 (HOCO is operating), the HOCO stops in software standby mode.

If this bit is 1 (enabled) and the HOCOCR.HCSTP bit is 0 (HOCO is operating), the HOCO keeps oscillating in software standby mode.

If the HOCOCR.HCSTP bit is 1 (HOCO is stopped), the HOCO stops in software standby mode regardless of the setting of the HOCOSOKP bit.

9.2.38 Middle-Speed On-Chip Oscillator Standby Control Register (MOCOSCR)

Address(es): SYSC.MOCOSCR 8701 9084h,
SYSC_NS.MOCOSCR 0701 9084h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	MOCOSOKP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MOCOSOKP	MOCO Standby Oscillation Keep Select	0: Disabled 1: Enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

MOCOSOKP Bit (MOCO Standby Oscillation Keep Select)

This bit controls the MOCO so that it keeps oscillating in software standby mode.

If this bit is 0 (disabled) and the MOCOCR.MCSTP bit is 0 (MOCO is operating), the MOCO stops in software standby mode.

If this bit is 1 (enabled) and the MOCOCR.MCSTP bit is 0 (MOCO is operating), the MOCO keeps oscillating in software standby mode.

9.2.39 USB Clock Frequency Division Control Register (USBCKDIVCR)

Address(es): SYSC.USBCKDIVCR 8701 906Ch,
SYSC_NS.USBCKDIVCR 0701 906Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	USBCKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	USBCKDIV[3:0]	USB Clock (USBCLK) Frequency Division Ratio Select	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 0 1: Division by 3 0 1 1 0: Division by 5 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The USBCKDIVCR register is used to control the USB clock (USBCLK).

USBCKDIV[3:0] Bits (USB Clock (USBCLK) Frequency Division Ratio Select)

These bits select the frequency of USBCLK. Change the value of these bits while the USBCKCR.USBCKSRDY flag is 1.

When switching the division ratio setting from 1/n (n ≠ 1), set MSTPCRB.MSTPB11 = 1, and MSTPCRB.MSTPB12 = 1 before setting USBCKCR.USBCKSREQ = 1.

9.2.40 XSPI Clock Frequency Division Control Register (XSPICKDIVCR)

Address(es): SYSC.XSPICKDIVCR 8701 906Dh,
SYSC_NS.XSPICKDIVCR 0701 906Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	XSPICKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	XSPICKDIV[3:0]	XSPI Clock (XSPICLK) Frequency Division Ratio Select	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 0 1: Division by 3 0 1 1 0: Division by 5 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The XSPICKDIVCR register is used to control the XSPI clock (XSPICLK).

XSPICKDIV[3:0] Bits (XSPI Clock (XSPICLK) Frequency Division Ratio Select)

These bits select the frequency of XSPICLK. Change the value of these bits while the XSPICKCR.XSPICKSRDY flag is 1.

When switching the division ratio setting from 1/n (n ≠ 1), set MSTPCRB.MSTPB16 = 1 and MSTPCRB.MSTPB17 = 1 before setting XSPICKCR.XSPICKSREQ = 1.

9.2.41 CANFD Core Clock Frequency Division Control Register (CANFDCKDIVCR)

Address(es): SYSC.CANFDCKDIVCR 8701 906Eh,
SYSC_NS.CANFDCKDIVCR 0701 906Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	CANFDCKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	CANFDCKDIV[3:0]	CANFD Core Clock (CANFDCLK) Frequency Division Ratio Select	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 0 1: Division by 3 0 1 1 0: Division by 5 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The CANFDCKDIVCR register is used to control the CANFD core clock (CANFDCLK).

CANFDCKDIV[3:0] Bits (CANFD Core Clock (CANFDCLK) Frequency Division Ratio Select)

These bits select the frequency of CANFDCLK. Change the value of these bits while the CANFDCKCR.CANFDCKSRDY flag is 1.

When switching the division ratio setting from 1/n (n ≠ 1), set MSTPCRC.MSTPC25 = 1 and MSTPCRC.MSTPC27 = 1 before setting CANFDCKCR.CANFDCKSREQ = 1.

9.2.42 USBHS-PHY Clock Frequency Division Control Register (USB60CKDIVCR)

Address(es): SYSC.USB60CKDIVCR 8701 906Fh,
SYSC_NS.USB60CKDIVCR 0701 906Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	USB60CKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	USB60CKDIV[3:0]	USBHS-PHY Clock (USB60CLK) Frequency Division Ratio Select	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 0 1: Division by 3 0 1 1 0: Division by 5 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The USB60CKDIVCR register is used to control the USBHS-PHY clock (USB60CLK).

USB60CKDIV[3:0] Bits (USBHS-PHY Clock (USB60CLK) Frequency Division Ratio Select)

These bits select the frequency of USB60CLK. Change the value of these bits while the USB60CKCR.USB60CKSRDY flag is 1.

When switching the division ratio setting from 1/n (n ≠ 1), set MSTPCRB.MSTPB12 = 1 before setting USB60CKCR.USB60CKSREQ = 1.

9.2.43 I3C Clock Frequency Division Control Register (I3CCKDIVCR)

Address(es): SYSC.I3CCKDIVCR 8701 9070h,
SYSC_NS.I3CCKDIVCR 0701 9070h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	I3CCKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	I3CCKDIV[3:0]	I3C Clock (I3CCLK) Frequency Division Ratio Select*1	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 0 1: Division by 3 0 1 1 0: Division by 5 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note 1. Make sure that the frequency of I3CCLK does not exceed twice the frequency of PCLKA.

The I3CCKDIVCR register is used to control the I3C clock (I3CCLK).

I3CCKDIV[3:0] Bits (I3C Clock (I3CCLK) Frequency Division Ratio Select)

These bits select the frequency of I3CCLK. Change the value of these bits while the I3CCKCR.I3CCKSRDY flag is 1. When switching the division ratio setting from 1/n (n ≠ 1), set MSTPCRB.MSTPB4 = 1, MSTPCRB.MSTPB7 = 1, and MSTPCRB.MSTPB8 = 1 before setting I3CCKCR.I3CCKSREQ = 1.

9.2.44 USB Clock Control Register (USBCKCR)

Address(es): SYSC.USBCKCR 8701 9074h,
SYSC_NS.USBCKCR 0701 9074h

	b7	b6	b5	b4	b3	b2	b1	b0
	USBCKSRDY	USBCKSREQ	—	—	USBCKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	USBCKSEL[3:0]	USB Clock (USBCLK) Source Select	b3 b0 0 0 0 0: HOCO 0 0 0 1: MOCO (initial value) 0 0 1 1: Main clock oscillator 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	USBCKSREQ	USB Clock (USBCLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	USBCKSRDY	USB Clock (USBCLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The USBCKCR register is used to control the USB clock (USBCLK).
When switching the clock source, stable output of the clock should be ensured before and after switching. To change the values of the USBCKDIVCR.USBCKDIV[3:0] and USBCKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to the MSTPCRB.MSTPB11 and MSTPCRB.MSTPB12 bits only when switching the division ratio setting from 1/n ($n \neq 1$).
2. Wait for two USBCLK only when switching the division ratio setting from 1/n ($n \neq 1$).
3. Write 1 to the USBCKSREQ bit.
4. Poll the USBCKSRDY flag until it is read as 1.
   While the USBCKSRDY flag is 1, USBCLK is not output.
5. Set the USBCKDIVCR.USBCKDIV[3:0] and USBCKSEL[3:0] bits.
6. Write 0 to the USBCKSREQ bit.
7. Poll the USBCKSRDY flag until it is read as 0.
8. When the USBCKSRDY flag becomes 0, clock switching is complete and output of USBCLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while USBCKSREQ = 0 and USBCKSRDY = 0.

USBCKSEL[3:0] Bits (USB Clock (USBCLK) Source Select)

These bits select the source of USBCLK. Change the value of these bits while the USBCKSRDY flag is 1.
Do not stop the oscillator selected by these bits unless the MOCO is selected.

USBCKSREQ Bit (USB Clock (USBCLK) Switching Request)

This bit selects whether to request switching of USBCLK.

USBCKSRDY Flag (USB Clock (USBCLK) Switching Ready State Flag)

This flag indicates whether switching of USBCLK is possible. While this flag is 1, USBCLK is not output.

9.2.45 XSPI Clock Control Register (XSPICKCR)

Address(es): SYSC.XSPICKCR 8701 9075h,
SYSC_NS.XSPICKCR 0701 9075h

	b7	b6	b5	b4	b3	b2	b1	b0
	XSPICKSRDY	XSPICKSREQ	—	—	XSPICKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	XSPICKSEL[3:0]	XSPI Clock (XSPICLK) Source Select	b3 b0 0 0 0 0: HOCO 0 0 0 1: MOCO (initial value) 0 0 1 0: LOCO 0 0 1 1: Main clock oscillator 0 1 0 0: Sub-clock oscillator 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	XSPICKSREQ	XSPI Clock (XSPICLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	XSPICKSRDY	XSPI Clock (XSPICLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The XSPICKCR register is used to control the XSPI clock (XSPICLK).

When switching the clock source, stable output of the clock should be ensured before and after switching.

To change the values of the XSPICKDIVCR.XSPICKDIV[3:0] and XSPICKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to MSTPCRB.MSTPB16 and MSTPCRB.MSTPB17 only when switching the division ratio setting from 1/n (n ≠ 1).
2. Check that both the MSTPCRB.MSTPB16 bit and MSTPCRB.MSTPB17 bit are read as 1 and then wait for two XSPICLK only when switching the frequency division ratio setting from 1/n (n ≠ 1).
3. Write 1 to the XSPICKSREQ bit.
4. Poll the XSPICKSRDY flag until it is read as 1.
   While the XSPICKSRDY flag is 1, XSPICLK is not output.
5. Set the XSPICKDIVCR.XSPICKDIV[3:0] and XSPICKSEL[3:0] bits.
6. Write 0 to the XSPICKSREQ bit.
7. Poll the XSPICKSRDY flag until it is read as 0.
8. When the XSPICKSRDY flag becomes 0, clock switching is complete and output of XSPICLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while XSPICKSREQ = 0 and XSPICKSRDY = 0.

XSPICKSEL[3:0] Bits (XSPI Clock (XSPICLK) Source Select)

These bits select the source of XSPICLK. Change the value of these bits while the XSPICKSRDY flag is 1.
Do not stop the oscillator selected by these bits unless the MOCO is selected.

XSPICKSREQ Bit (XSPI Clock (XSPICLK) Switching Request)

This bit selects whether to request switching of XSPICLK.

XSPICKSRDY Flag (XSPI Clock (XSPICLK) Switching Ready State Flag)

This flag indicates whether switching of XSPICLK is possible. While this flag is 1, XSPICLK is not output.

9.2.46 CANFD Core Clock Control Register (CANFDCKCR)

Address(es): SYSC.CANFDCKCR 8701 9076h,
SYSC_NS.CANFDCKCR 0701 9076h

	b7	b6	b5	b4	b3	b2	b1	b0
	CANFDCKSRDY	CANFDCKSREQ	—	—	CANFDCKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	CANFDCKSEL[3:0]	CANFD Core Clock (CANFDCLK) Source Select	b3 b0 0 0 0 0: HOCO 0 0 0 1: MOCO (initial value) 0 0 1 0: LOCO 0 0 1 1: Main clock oscillator 0 1 0 0: Sub-clock oscillator 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	CANFDCKSREQ	CANFD Core Clock (CANFDCLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	CANFDCKSRDY	CANFD Core Clock (CANFDCLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The CANFDCKCR register is used to control the CANFD core clock (CANFDCLK).

When switching the clock source, stable output of the clock should be ensured before and after switching. To change the values of the CANFDCKDIVCR.CANFDCKDIV[3:0] and CANFDCKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to the MSTPCRC.MSTPC25 and MSTPCRC.MSTPC27 bits only when switching the division ratio setting from 1/n (n ≠ 1).
2. Wait for two CANFDCLK only when switching the division ratio setting from 1/n (n ≠ 1).
3. Write 1 to the CANFDCKSREQ bit.
4. Poll the CANFDCKSRDY flag until it is read as 1.
   While the CANFDCKSRDY flag is 1, CANFDCLK is not output.
5. Set the CANFDCKDIVCR.CANFDCKDIV[3:0] and CANFDCKSEL[3:0] bits.
6. Write 0 to the CANFDCKSREQ bit.
7. Poll the CANFDCKSRDY flag until it is read as 0.
8. When the CANFDCKSRDY flag becomes 0, clock switching is complete and output of CANFDCLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while CANFDCKSREQ = 0 and CANFDCKSRDY = 0.

CANFDCKSEL[3:0] Bits (CANFD Core Clock (CANFDCLK) Source Select)

These bits select the source of CANFDCLK. Change the value of these bits while the CANFDCKSRDY flag is 1. Do not stop the oscillator selected by these bits unless the MOCO is selected.

CANFDCKSREQ Bit (CANFD Core Clock (CANFDCLK) Switching Request)

This bit selects whether to request switching of CANFDCLK.

CANFDCKSRDY Flag (CANFD Core Clock (CANFDCLK) Switching Ready State Flag)

This flag indicates whether switching of CANFDCLK is possible. While this flag is 1, CANFDCLK is not output.

9.2.47 USBHS-PHY Clock Control Register (USB60CKCR)

Address(es): SYSC.USB60CKCR 8701 9077h,
SYSC_NS.USB60CKCR 0701 9077h

	b7	b6	b5	b4	b3	b2	b1	b0
	USB60CKSRDY	USB60CKSREQ	—	—	USB60CKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	USB60CKSEL[3:0]	USBHS-PHY Clock (USB60CLK) Source Select	b3 b0 0 0 0 0: HOCO 0 0 0 1: MOCO (initial value) 0 0 1 1: Main clock oscillator 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	USB60CKSREQ	USBHS-PHY Clock (USB60CLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	USB60CKSRDY	USBHS-PHY Clock (USB60CLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The USB60CKCR register is used to control the USBHS-PHY clock (USB60CLK).
When switching the clock source, stable output of the clock should be ensured before and after switching.
To change the values of the USB60CKDIVCR.USB60CKDIV[3:0] and USB60CKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to the MSTPCRB.MSTPB12 bit only when switching the division ratio setting from 1/n (n ≠ 1).
2. Wait for two USB60CLK only when switching the division ratio setting from 1/n (n ≠ 1).
3. Write 1 to the USB60CKSREQ bit.
4. Poll the USB60CKSRDY flag until it is read as 1.
   While the USB60CKSRDY flag is 1, USB60CLK is not output.
5. Set the USB60CKDIVCR.USB60CKDIV[3:0] and USB60CKSEL[3:0] bits.
6. Write 0 to the USB60CKSREQ bit.
7. Poll the USB60CKSRDY flag until it is read as 0.
8. When the USB60CKSRDY flag becomes 0, clock switching is complete and output of USB60CLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while USB60CKSREQ = 0 and USB60CKSRDY = 0.

USB60CKSEL[3:0] Bits (USBHS-PHY Clock (USB60CLK) Source Select)

These bits select the source of USB60CLK. Change the value of these bits while the USB60CKSRDY flag is 1.

Do not stop the oscillator selected by these bits unless the MOCO is selected.

USB60CKSREQ Bit (USBHS-PHY Clock (USB60CLK) Switching Request)

This bit selects whether to request switching of USB60CLK.

USB60CKSRDY Flag (USBHS-PHY Clock (USB60CLK) Switching Ready State Flag)

This flag indicates whether switching of USB60CLK is possible. While this flag is 1, USB60CLK is not output.

9.2.48 I3C Clock Control Register (I3CCKCR)

Address(es): SYSC.I3CCKCR 8701 9078h,
SYSC_NS.I3CCKCR 0701 9078h

	b7	b6	b5	b4	b3	b2	b1	b0
	I3CCK SRDY	I3CCK SREQ	—	—	I3CCKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	I3CCKSEL[3:0]	I3C Clock (I3CCLK) Source Select	b3 b0 0 0 0 1: MOCO (initial value) 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	I3CCKSREQ	I3C Clock (I3CCLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	I3CCKSRDY	I3C Clock (I3CCLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The I3CCKCR register is used to control the I3C clock (I3CCLK).
When switching the clock source, stable output of the clock should be ensured before and after switching.
To change the values of the I3CCKDIVCR.I3CCKDIV[3:0] and I3CCKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to the MSTPCRB.MSTPB4, MSTPCRB.MSTPB7, and MSTPCRB.MSTPB8 bits only when switching the division ratio setting from 1/n (n ≠ 1).
2. Wait for two I3CCLK only when switching the division ratio setting from 1/n (n ≠ 1).
3. Write 1 to the I3CCKSREQ bit.
4. Poll the I3CCKSRDY flag until it is read as 1.
   While the I3CCKSRDY flag is 1, I3CCLK is not output.
5. Set the I3CCKDIVCR.I3CCKDIV[3:0] and I3CCKSEL[3:0] bits.
6. Write 0 to the I3CCKSREQ bit.
7. Poll the I3CCKSRDY flag until it is read as 0.
8. When the I3CCKSRDY flag becomes 0, clock switching is complete and output of I3CCLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while I3CCKSREQ = 0 and I3CCKSRDY = 0.

I3CCKSEL[3:0] Bits (I3C Clock (I3CCLK) Source Select)

These bits select the source of I3CCLK. Change the value of these bits while the I3CCKSRDY flag is 1.
Do not stop the oscillator selected by these bits unless the MOCO is selected.

I3CCKSREQ Bit (I3C Clock (I3CCLK) Switching Request)

This bit selects whether to request switching of I3CCLK.

I3CCKSRDY Flag (I3C Clock (I3CCLK) Switching Ready State Flag)

This flag indicates whether switching of I3CCLK is possible. While this flag is 1, I3CCLK is not output.

9.2.49 SCI Clock Frequency Division Control Register (SCICKDIVCR)

Address(es): SYSC.SCICKDIVCR 8701 9054h,
SYSC_NS.SCICKDIVCR 0701 9054h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SCICKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	SCICKDIV[3:0]	SCI Clock (SCICLK) Frequency Division Ratio Select	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 0 1: Division by 3 0 1 1 0: Division by 5 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The SCICKDIVCR register is used to control the SCI clock (SCICLK).

SCICKDIV[3:0] Bits (SCI Clock (SCICLK) Frequency Division Ratio Select)

These bits select the frequency of SCICLK. Change the value of these bits while the SCICKCR.CKSRDY flag is 1. When switching the division ratio setting from 1/n (n ≠ 1), set the MSTPCRB.MSTPB0 bit and all of the MSTPCRB.MSTPB20 bit to the MSTPCRB.MSTPB31 bit to 1 before setting SCICKCR.SCICKSREQ = 1.

9.2.50 SPI Clock Frequency Division Control Register (SPICKDIVCR)

Address(es): SYSC.SPICKDIVCR 8701 9056h,
SYSC_NS.SPICKDIVCR 0701 9056h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SPICKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	SPICKDIV[3:0]	SPI Clock (SPICLK) Frequency Division Ratio Select	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 0 1: Division by 3 0 1 1 0: Division by 5 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The SPICKDIVCR register is used to control the SPI clock (SPICLK).

SPICKDIV[3:0] Bits (SPI Clock (SPICLK) Frequency Division Ratio Select)

These bits select the frequency of SPICLK. Change the value of these bits while the SPICKCR.CKSRDY flag is 1. When switching the division ratio setting from 1/n (n ≠ 1), set MSTPCRB.MSTPB18 = 1, MSTPCRB.MSTPB19 = 1, and MSTPCRC.MSTPC23 = 1 before setting SPICKCR.SPICKSREQ = 1.

9.2.51 ADC Clock Frequency Division Control Register (ADCCKDIVCR)

Address(es): SYSC.ADCCKDIVCR 8701 905Ah,
SYSC_NS.ADCCKDIVCR 0701 905Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	ADCCKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ADCCKDIV[3:0]	ADC Clock (ADCCLK) Frequency Division Ratio Select	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The ADCCKDIVCR register is used to control the ADC clock (ADCCLK).

ADCCKDIV[3:0] Bits (ADC Clock (ADCCLK) Frequency Division Ratio Select)

These bits select the frequency of ADCCLK. Change the value of these bits while the ADCCKCR.ADCCKSRDY flag is 1.

When switching the division ratio setting from 1/n ($n \neq 1$), set MSTPCRD.MSTPD21 = 1 before setting ADCCKCR.ADCCKSREQ = 1.

9.2.52 GPT Clock Frequency Division Control Register (GPTCKDIVCR)

Address(es): SYSC.GPTCKDIVCR 8701 905Ch,
SYSC_NS.GPTCKDIVCR 0701 905Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	GPTCKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	GPTCKDIV[3:0]	GPT Clock (GPTCLK) Frequency Division Ratio Select	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 0 1: Division by 3*1 0 1 1 0: Division by 5*1 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note 1. Do not set when GPTCLK is used for ADC16H or HRPWM.

The GPTCKDIVCR register is used to control the GPT clock (GPTCLK).

GPTCKDIV[3:0] Bits (GPT Clock (GPTCLK) Frequency Division Ratio Select)

These bits select the frequency of GPTCLK. Change the value of these bits while the GPTCKCR.GPTCKSRDY flag is 1.

When switching the division ratio setting from 1/n (n ≠ 1), set MSTPCRE.MSTPE31 = 1 before setting GPTCKCR.GPTCKSREQ = 1.

9.2.53 SCI Clock Control Register (SCICKCR)

Address(es): SYSC.SCICKCR 8701 9055h,
SYSC_NS.SCICKCR 0701 9055h

	b7	b6	b5	b4	b3	b2	b1	b0
	SCICKSRDY	SCICKSREQ	—	—	SCICKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	SCICKSEL[3:0]	SCI Clock (SCICLK) Source Select	b3 b0 0 0 0 0: HOCO 0 0 0 1: MOCO (initial value) 0 0 1 0: LOCO 0 0 1 1: Main clock oscillator 0 1 0 0: Sub-clock oscillator 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	SCICKSREQ	SCI Clock (SCICLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	SCICKSRDY	SCI Clock (SCICLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The SCICKCR register is used to control the SCI clock (SCICLK).

When switching the clock source, stable output of the clock should be ensured before and after switching. To change the values of the SCICKDIVCR.SCICKDIV[3:0] and SCICKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to the MSTPCRB.MSTPB0 bit and all of the MSTPCRB.MSTPB20 bit to the MSTPCRB.MSTPB31 bit only when switching the division ratio setting from 1/n ($n \neq 1$).
2. Wait for two SCICLK only when switching the division ratio setting from 1/n ($n \neq 1$).
3. Write 1 to the SCICKSREQ bit.
4. Poll the SCICKSRDY flag until it is read as 1.
   While the SCICKSRDY flag is 1, SCICLK is not output.
5. Set the SCICKDIVCR.SCICKDIV[3:0] and SCICKSEL[3:0] bits.
6. Write 0 to the SCICKSREQ bit.
7. Poll the SCICKSRDY flag until it is read as 0.
8. When the SCICKSRDY flag becomes 0, clock switching is complete and output of SCICLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while SCICKSREQ = 0 and SCICKSRDY = 0.

SCICKSEL[3:0] Bits (SCI Clock (SCICLK) Source Select)

These bits select the source of SCICLK. Change the value of these bits while the SCICKSRDY flag is 1.
Do not stop the oscillator selected by these bits unless the MOCO is selected.

SCICKSREQ Bit (SCI Clock (SCICLK) Switching Request)

This bit selects whether to request switching of SCICLK.

SCICKSRDY Flag (SCI Clock (SCICLK) Switching Ready State Flag)

This flag indicates whether switching of SCICLK is possible. While this flag is 1, SCICLK is not output.

9.2.54 SPI Clock Control Register (SPICKCR)

Address(es): SYSC.SPICKCR 8701 9057h,
SYSC_NS.SPICKCR 0701 9057h

	b7	b6	b5	b4	b3	b2	b1	b0
	SPICK SRDY	SPICK SREQ	—	—	SPICKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	SPICKSEL[3:0]	SPI Clock (SPICLK) Source Select	b3 b0 0 0 0 0: HOCO 0 0 0 1: MOCO (initial value) 0 0 1 0: LOCO 0 0 1 1: Main clock oscillator 0 1 0 0: Sub-clock oscillator 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	SPICKSREQ	SPI Clock (SPICLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	SPICKSRDY	SPI Clock (SPICLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The SPICKCR register is used to control the SPI clock (SPICLK).

When switching the clock source, stable output of the clock should be ensured before and after switching. To change the values of the SPICKDIVCR.SPICKDIV[3:0] and SPICKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to the MSTPCRB.MSTPB18, MSTPCRB.MSTPB19, and MSTPCRC.MSTPC23 bits only when switching the division ratio setting from 1/n (n ≠ 1).
2. Wait for two SPICLK only when switching the division ratio setting from 1/n (n ≠ 1).
3. Write 1 to the SPICKSREQ bit.
4. Poll the SPICKSRDY flag until it is read as 1.
   While the SPICKSRDY flag is 1, SPICLK is not output.
5. Set the SPICKDIVCR.SPICKDIV[3:0] and SPICKSEL[3:0] bits.
6. Write 0 to the SPICKSREQ bit.
7. Poll the SPICKSRDY flag until it is read as 0.
8. When the SPICKSRDY flag becomes 0, clock switching is complete and output of SPICLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while SPICKSREQ = 0 and SPICKSRDY = 0.

SPICKSEL[3:0] Bits (SPI Clock (SPICLK) Source Select)

These bits select the source of SPICLK. Change the value of these bits while the SPICKSRDY flag is 1.
Do not stop the oscillator selected by these bits unless the MOCO is selected.

SPICKSREQ Bit (SPI Clock (SPICLK) Switching Request)

This bit selects whether to request switching of SPICLK.

SPICKSRDY Flag (SPI Clock (SPICLK) Switching Ready State Flag)

This flag indicates whether switching of SPICLK is possible.
While the SPICKSRDY flag is 1, SPICLK is not output.

9.2.55 ADC Clock Control Register (ADCCKCR)

Address(es): SYSC.ADCCKCR 8701 905Bh,
SYSC_NS.ADCCKCR 0701 905Bh

	b7	b6	b5	b4	b3	b2	b1	b0
	ADCCKSRDY	ADCCKSREQ	—	—	ADCCKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ADCCKSEL[3:0]	ADC Clock (ADCCLK) Source Select	b3 b0 0 0 0 0: HOCO 0 0 0 1: MOCO (initial value) 0 0 1 0: LOCO 0 0 1 1: Main clock oscillator 0 1 0 0: Sub-clock oscillator 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	ADCCKSREQ	ADC Clock (ADCCLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	ADCCKSRDY	ADC Clock (ADCCLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The ADCCKCR register is used to control the ADC clock (ADCCLK).

When switching the clock source, stable output of the clock should be ensured before and after switching.

To change the values of the ADCCKDIVCR.ADCCKDIV[3:0] and ADCCKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to the MSTPCRD.MSTPD21 bit only when switching the division ratio setting from 1/n ($n \neq 1$).
2. Wait for two ADCCLK only when switching the division ratio setting from 1/n ($n \neq 1$).
3. Write 1 to the ADCCKSREQ bit.
4. Poll the ADCCKSRDY flag until it is read as 1.
   While the ADCCKSRDY flag is 1, ADCCLK is not output.
5. Set the ADCCKDIVCR.ADCCKDIV[3:0] and ADCCKSEL[3:0] bits.
6. Write 0 to the ADCCKSREQ bit.
7. Poll the ADCCKSRDY flag until it is read as 0.
8. When the ADCCKSRDY flag becomes 0, clock switching is complete and output of ADCCLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while ADCCKSREQ = 0 and ADCCKSRDY = 0.

ADCCKSEL[3:0] Bits (ADC Clock (ADCCLK) Source Select)

These bits select the source of ADCCLK.
Change the value of these bits while the ADCCKSRDY flag is 1.
Do not stop the oscillator selected by these bits unless the MOCO is selected.

ADCCKSREQ Bit (ADC Clock (ADCCLK) Switching Request)

This bit selects whether to request switching of ADCCLK.

ADCCKSRDY Flag (ADC Clock (ADCCLK) Switching Ready State Flag)

This flag indicates whether switching of ADCCLK is possible.
While the ADCCKSRDY flag is 1, ADCCLK is not output.

9.2.56 GPT Clock Control Register (GPTCKCR)

Address(es): SYSC.GPTCKCR 8701 905Dh,
SYSC_NS.GPTCKCR 0701 905Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	GPTCKSRDY	GPTCKSREQ	—	—	GPTCKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	GPTCKSEL[3:0]	GPT Clock (GPTCLK) Source Select	b3 b0 0 0 0 0: HOCO 0 0 0 1: MOCO (initial value) 0 0 1 1: Main clock oscillator 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	GPTCKSREQ	GPT Clock (GPTCLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	GPTCKSRDY	GPT Clock (GPTCLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The GPTCKCR register is used to control the GPT clock (GPTCLK).
When switching the clock source, stable output of the clock should be ensured before and after switching.
To change the values of the GPTCKDIVCR.GPTCKDIV[3:0] and GPTCKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to the MSTPCRE.MSTPE31 bit only when switching the division ratio setting from 1/n (n ≠ 1).
2. Wait for two GPTCLK only when switching the division ratio setting from 1/n (n ≠ 1).
3. Write 1 to the GPTCKSREQ bit.
4. Poll the GPTCKSRDY flag until it is read as 1.
   While the GPTCKSRDY flag is 1, GPTCLK is not output.
5. Set the GPTCKDIVCR.GPTCKDIV[3:0] and GPTCKSEL[3:0] bits.
6. Write 0 to the GPTCKSREQ bit.
7. Poll the GPTCKSRDY flag until it is read as 0.
8. When the GPTCKSRDY flag becomes 0, clock switching is complete and output of GPTCLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while GPTCKSREQ = 0 and GPTCKSRDY = 0.

GPTCKSEL[3:0] Bits (GPT Clock (GPTCLK) Source Select)

These bits select the source of GPTCLK. Change the value of these bits while the GPTCKSRDY flag is 1.
Do not stop the oscillator selected by these bits unless the MOCO is selected.

GPTCKSREQ Bit (GPT Clock (GPTCLK) Switching Request)

This bit selects whether to request switching of GPTCLK.

GPTCKSRDY Flag (GPT Clock (GPTCLK) Switching Ready State Flag)

This flag indicates whether switching of GPTCLK is possible. While this flag is 1, GPTCLK is not output.

9.2.57 Asynchronous External Bus Clock Frequency Division Control Register (BCKADIVCR)

Address(es): SYSC.BCKADIVCR 8701 90D4h,
SYSC_NS.BCKADIVCR 0701 90D4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	BCKACKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	BCKACKDIV[3:0]	Asynchronous External Bus Clock (BCLKA) Frequency Division Ratio Select	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The BCKADIVCR register is used to control the asynchronous external bus clock (BCLKA).

BCKACKDIV[3:0] Bits (Asynchronous External Bus Clock (BCLKA) Frequency Division Ratio Select)

These bits select the frequency of BCLKA. Change the value of these bits while the BCKACR.BCKACKSRDY flag is 1.

When switching the division ratio setting from 1/n (n ≠ 1), set EBCKOCR.EBCKOEN = 0 and SDCKOCR.SDCKOEN = 0 before setting BCKACR.BCKACKSREQ = 1. In addition, set BCKCR.EBCKASEL = 0 to select the synchronous (BCLK) side before switching the division ratio.

9.2.58 ESWM Clock Frequency Division Control Register (ESWCKDIVCR)

Address(es): SYSC.ESWCKDIVCR 8701 90D5h,
SYSC_NS.ESWCKDIVCR 0701 90D5h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	ESWCKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ESWCKDIV[3:0]	ESWM Clock (ESWCLK) Frequency Division Ratio Select *1	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.
Note 1. When using ESWM, set the ESWCLK frequency to satisfy the following relationship:
PCLKA < ESWCLK ≤ ICLK × 1.5

The ESWCKDIVCR register is used to control the ESWM clock (ESWCLK).

ESWCKDIV[3:0] Bits (ESWM Clock (ESWCLK) Frequency Division Ratio Select)

These bits select the frequency of ESWCLK. Change the value of these bits while the ESWCKCR.ESWCKSRDY flag is 1.

When switching the division ratio setting from 1/n (n ≠ 1), set MSTPCRC.MSTPC30 = 1 before setting ESWCKCR.ESWCKSREQ = 1.

9.2.59 ESWM-PHY Clock Frequency Division Control Register (ESWPCKDIVCR)

Address(es): SYSC.ESWPCKDIVCR 8701 90D6h,
SYSC_NS.ESWPCKDIVCR 0701 90D6h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	ESWPCKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ESWPCKDIV[3:0]	ESWM-PHY Clock (ESWPHYCLK) Frequency Division Ratio Select	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The ESWPCKDIVCR register is used to control the ESWM-PHY clock (ESWPHYCLK).

ESWPCKDIV[3:0] Bits (ESWM-PHY Clock (ESWPHYCLK) Frequency Division Ratio Select)

These bits select the frequency of ESWPHYCLK. Change the value of these bits while the ESWPCKCR.ESWPCKSRDY flag is 1.

When switching the division ratio setting from 1/n (n ≠ 1), set MSTPCRC.MSTPC30 = 1 before setting ESWPCKCR.ESWPCKSREQ = 1.

9.2.60 Ethernet-PHY Clock Frequency Division Control Register (ETHPCKDIVCR)

Address(es): SYSC.ETHPCKDIVCR 8701 90D8h,
SYSC_NS.ETHPCKDIVCR 0701 90D8h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	ETHPCKDIV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ETHPCKDIV[3:0]	Ethernet-PHY Clock (ETHPHYCLK) Frequency Division Ratio Select	b3 b0 0 0 0 0: Division by 1 (initial value) 0 0 0 1: Division by 2 0 0 1 0: Division by 4 0 0 1 1: Division by 6 0 1 0 0: Division by 8 0 1 1 1: Division by 10 1 0 0 0: Division by 16 1 0 0 1: Division by 32 Settings other than those listed above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The ETHPCKDIVCR register is used to control the Ethernet-PHY clock (ETHPHYCLK).

ETHPCKDIV[3:0] Bits (Ethernet-PHY Clock (ETHPHYCLK) Frequency Division Ratio Select)

These bits select the frequency of ETHPHYCLK. Change the value of these bits while the ETHPCKCR.ETHPCKSRDY flag is 1.

When switching the division ratio setting from 1/n ($n \neq 1$), set MSTPCRC.MSTPC28 = 1 before setting ETHPCKCR.ETHPCKSREQ = 1.

9.2.61 Asynchronous External Bus Clock Control Register (BCKACR)

Address(es): SYSC.BCKACR 8701 90DAh,
SYSC_NS.BCKACR 0701 90DAh

	b7	b6	b5	b4	b3	b2	b1	b0
	BCKACKSRDY	BCKACKSREQ	—	—	BCKACKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	BCKACKSEL[3:0]	Asynchronous External Bus Clock (BCLKA) Source Select	b3 b0 0 0 0 1: MOCO (initial value) 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	BCKACKSREQ	Asynchronous External Bus Clock (BCLKA) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	BCKACKSRDY	Asynchronous External Bus Clock (BCLKA) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The BCKACR register is used to control the asynchronous external bus clock (BCLKA).
When switching the clock source, stable output of the clock should be ensured before and after switching.
To change the values of the BCKADIVCR.BCKACKDIV[3:0] and BCKACKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 0 to the EBCKOCR.EBCKOEN and SDCKOCR.SDCKOEN bits only when switching the division ratio setting from 1/n (n ≠ 1).
2. Write 1 to the BCKACKSREQ bit.
3. Poll the BCKACKSRDY flag until it is read as 1.
   While the BCKACKSRDY flag is 1, BCLKA is not output.
4. Write 0 to the BCKCR.EBCKASEL bit only when switching the division ratio setting from 1/n (n ≠ 1).
5. Set the BCKCR.BCLKDIV, BCKCR.EBCKASEL, BCKADIVCR.BCKACKDIV[3:0], and BCKACKSEL[3:0] bits.
6. Write 0 to the BCKACKSREQ bit.
7. Poll the BCKACKSRDY flag until it is read as 0.
8. When the BCKACKSRDY flag becomes 0, clock switching is complete and output of BCLKA begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while BCKACKSREQ = 0 and BCKACKSRDY = 0.

BCKACKSEL[3:0] Bits (Asynchronous External Bus Clock (BCLKA) Source Select)

These bits select the source of BCLKA. Change the value of these bits while the BCKACKSRDY flag is 1.
Do not stop the oscillator selected by these bits unless the MOCO is selected.

BCKACKSREQ Bit (Asynchronous External Bus Clock (BCLKA) Switching Request)

This bit selects whether to request switching of BCLKA.

BCKACKSRDY Flag (Asynchronous External Bus Clock (BCLKA) Switching Ready State Flag)

This flag indicates whether switching of BCLKA is possible. While this flag is 1, BCLKA is not output.

9.2.62 ESWM Clock Control Register (ESWCKCR)

Address(es): SYSC.ESWCKCR 8701 90DBh,
SYSC_NS.ESWCKCR 0701 90DBh

	b7	b6	b5	b4	b3	b2	b1	b0
	ESWCKSRDY	ESWCKSREQ	—	—	ESWCKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ESWCKSEL[3:0]	ESWM Clock (ESWCLK) Source Select	b3 b0 0 0 0 1: MOCO (initial value) 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	ESWCKSREQ	ESWM Clock (ESWCLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	ESWCKSRDY	ESWM Clock (ESWCLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The ESWCKCR register is used to control the ESWM clock (ESWCLK).
When switching the clock source, stable output of the clock should be ensured before and after switching.
To change the values of the ESWCKDIVCR.ESWCKDIV[3:0] and ESWCKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to the MSTPCRC.MSTPC30 bit only when switching the division ratio setting from 1/n (n ≠ 1).
2. Wait for two ESWCLK only when switching the division ratio setting from 1/n (n ≠ 1).
3. Write 1 to the ESWCKSREQ bit.
4. Poll the ESWCKSRDY flag until it is read as 1.
   While the ESWCKSRDY flag is 1, ESWCLK is not output.
5. Set the ESWCKDIVCR.ESWCKDIV[3:0] and ESWCKSEL[3:0] bits.
6. Write 0 to the ESWCKSREQ bit.
7. Poll the ESWCKSRDY flag until it is read as 0.
8. When the ESWCKSRDY flag becomes 0, clock switching is complete and output of ESWCLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while ESWCKSREQ = 0 and ESWCKSRDY = 0.

ESWCKSEL[3:0] Bits (ESWM Clock (ESWCLK) Source Select)

These bits select the source of ESWCLK. Change the value of these bits while the ESWCKSRDY flag is 1.
Do not stop the oscillator selected by these bits unless the MOCO is selected.

ESWCKSREQ Bit (ESWM Clock (ESWCLK) Switching Request)

This bit selects whether to request switching of ESWCLK.

ESWCKSRDY Flag (ESWM Clock (ESWCLK) Switching Ready State Flag)

This flag indicates whether switching of ESWCLK is possible. While this flag is 1, ESWCLK is not output.

9.2.63 ESWM-PHY Clock Control Register (ESWPCKCR)

Address(es): SYSC.ESWPCKCR 8701 90DCh,
SYSC_NS.ESWPCKCR 0701 90DCh

	b7	b6	b5	b4	b3	b2	b1	b0
	ESWPCKSRDY	ESWPCKSREQ	—	—	ESWPCKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ESWPCKSEL[3:0]	ESWM-PHY Clock (ESWPHYCLK) Source Select	b3 b0 0 0 0 1: MOCO (initial value) 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	ESWPCKSREQ	ESWM-PHY Clock (ESWPHYCLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	ESWPCKSRDY	ESWM-PHY Clock (ESWPHYCLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The ESWPCKCR register is used to control the ESWM-PHY clock (ESWPHYCLK).
When switching the clock source, stable output of the clock should be ensured before and after switching.
To change the values of the ESWPCKDIVCR.ESWPCKDIV[3:0] and ESWPCKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to the MSTPCRC.MSTPC30 bit only when switching the division ratio setting from 1/n (n ≠ 1).
2. Wait for two ESWPHYCLK only when switching the division ratio setting from 1/n (n ≠ 1).
3. Write 1 to the ESWPCKSREQ bit.
4. Poll the ESWPCKSRDY flag until it is read as 1.
   While the ESWPCKSRDY flag is 1, ESWPHYCLK is not output.
5. Set the ESWPCKDIVCR.ESWPCKDIV[3:0] and ESWPCKSEL[3:0] bits.
6. Write 0 to the ESWPCKSREQ bit.
7. Poll the ESWPCKSRDY flag until it is read as 0.
8. When the ESWPCKSRDY flag becomes 0, clock switching is complete and output of ESWPHYCLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while ESWPCKSREQ = 0 and ESWPCKSRDY = 0.

ESWPCKSEL[3:0] Bits (ESWM-PHY Clock (ESWPHYCLK) Source Select)

These bits select the source of ESWPHYCLK. Change the value of these bits while the ESWPCKSRDY flag is 1.
Do not stop the oscillator selected by these bits unless the MOCO is selected.

ESWPCKSREQ Bit (ESWM-PHY Clock (ESWPHYCLK) Switching Request)

This bit selects whether to request switching of ESWPHYCLK.

ESWPCKSRDY Flag (ESWM-PHY Clock (ESWPHYCLK) Switching Ready State Flag)

This flag indicates whether switching of ESWPHYCLK is possible. While this flag is 1, ESWPHYCLK is not output.

9.2.64 Ethernet-PHY Clock Control Register (ETHPCKCR)

Address(es): SYSC.ETHPCKCR 8701 90DEh,
SYSC_NS.ETHPCKCR 0701 90DEh

	b7	b6	b5	b4	b3	b2	b1	b0
	ETHPCKSRDY	ETHPCKSREQ	—	—	ETHPCKSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ETHPCKSEL[3:0]	Ethernet-PHY Clock (ETHPHYCLK) Source Select	b3 b0 0 0 0 1: MOCO (initial value) 0 0 1 1: Main clock oscillator 0 1 0 1: PLL1P 0 1 1 0: PLL2P 0 1 1 1: PLL1Q 1 0 0 0: PLL1R 1 0 0 1: PLL2Q 1 0 1 0: PLL2R Settings other than those listed above are prohibited.	R/W
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	ETHPCKSREQ	Ethernet-PHY Clock (ETHPHYCLK) Switching Request	0: No request. 1: Switching is requested.	R/W
b7	ETHPCKSRDY	Ethernet-PHY Clock (ETHPHYCLK) Switching Ready State Flag	0: Switching is not possible. 1: Switching is possible.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before changing the value of this register.

The ETHPCKCR register is used to control the Ethernet-PHY clock (ETHPHYCLK).
When switching the clock source, stable output of the clock should be ensured before and after switching.
To change the values of the ETHPCKDIVCR.ETHPCKDIV[3:0] and ETHPCKSEL[3:0] bits, use the following procedure.

Procedure for switching the clock

1. Write 1 to the MSTPCRC.MSTPC28 bit only when switching the division ratio setting from 1/n (n ≠ 1).
2. Wait for two ETHPHYCLK only when switching the division ratio setting from 1/n (n ≠ 1).
3. Write 1 to the ETHPCKSREQ bit.
4. Poll the ETHPCKSRDY flag until it is read as 1.
   While the ETHPCKSRDY flag is 1, ETHPHYCLK is not output.
5. Set the ETHPCKDIVCR.ETHPCKDIV[3:0] and ETHPCKSEL[3:0] bits.
6. Write 0 to the ETHPCKSREQ bit.
7. Poll the ETHPCKSRDY flag until it is read as 0.
8. When the ETHPCKSRDY flag becomes 0, clock switching is complete and output of ETHPHYCLK begins.

When the MCU is to be placed in software standby or deep software standby mode, do not execute a WAIT instruction during clock switching. Execute a WAIT instruction while ETHPCKSREQ = 0 and ETHPCKSRDY = 0.

ETHPCKSEL[3:0] Bits (Ethernet-PHY Clock (ETHPHYCLK) Source Select)

These bits select the source of ETHPHYCLK. Change the value of these bits while the ETHPCKSRDY flag is 1.
Do not stop the oscillator selected by these bits unless the MOCO is selected.

ETHPCKSREQ Bit (Ethernet-PHY Clock (ETHPHYCLK) Switching Request)

This bit selects whether to request switching of ETHPHYCLK.

ETHPCKSRDY Flag (Ethernet-PHY Clock (ETHPHYCLK) Switching Ready State Flag)

This flag indicates whether switching of ETHPHYCLK is possible. While this flag is 1, ETHPHYCLK is not output.

9.3 Main Clock Oscillator

To supply a clock signal to the main clock oscillator, use either of the following methods:

- Connect a resonator.
- Connect the input of an external clock signal.

9.3.1 Connecting a Resonator

Figure 9.2 shows an example of connecting a resonator. A damping resistor (Rd) should be inserted, if required.
Since the resistor value varies depending on the resonator and oscillation driving capacity, use a value recommended by the resonator manufacturer. If the addition of an external feedback resistor (Rf) is directed by the resonator manufacturer, follow that direction and insert an Rf resistor between the EXTAL and XTAL pins.
When connecting a resonator to supply the clock, the frequency of the resonator should be in the frequency range of the resonator for the main clock oscillator, as shown in Table 9.1.

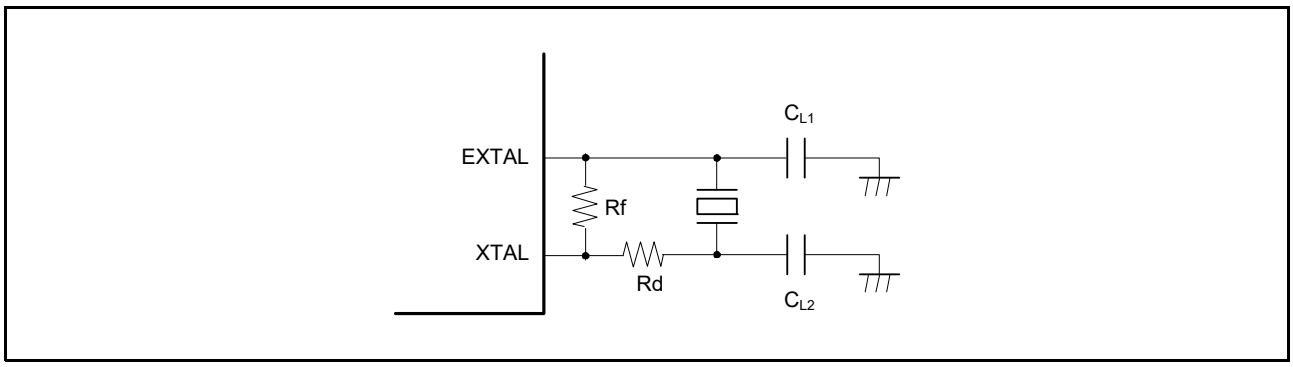


Figure 9.2 Example of Connecting a Resonator

Figure 9.3 shows an equivalent circuit of the resonator.

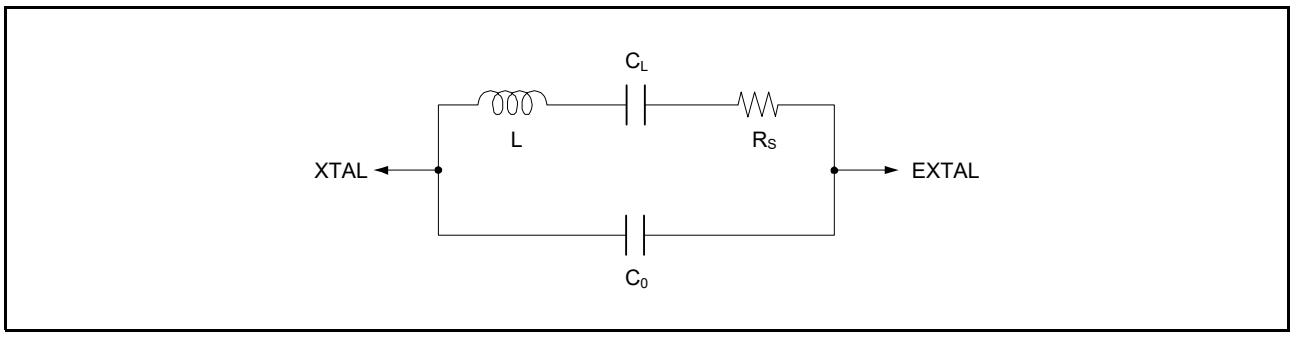

Figure 9.3 Equivalent Circuit of the Resonator

9.3.2 Inputting an External Clock

Figure 9.4 shows an example of connecting an external clock input. To operate the oscillator with an external clock signal, set the MOMCR.MOSEL bit to 1. The XTAL pin is put in the high-impedance state.

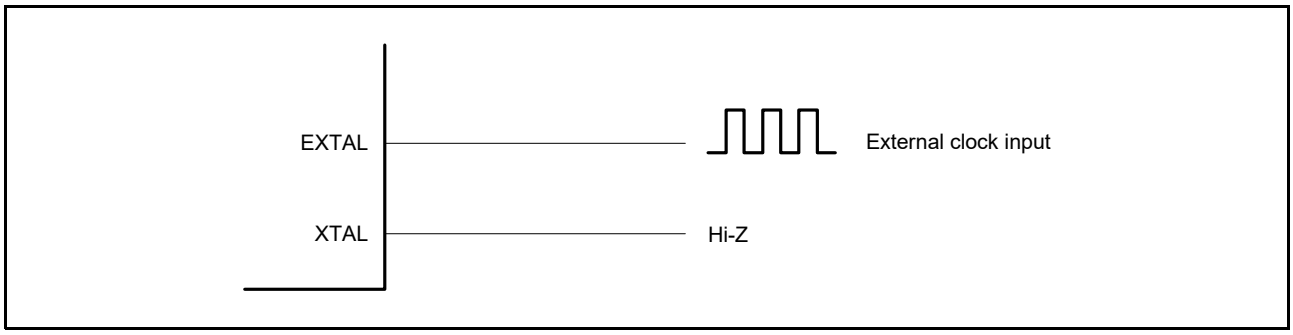

Figure 9.4 Example of Connecting an External Clock

9.3.3 Note on the External Clock Input

The frequency of the external clock input can only be changed when the main clock oscillator is stopped. Do not change the frequency of the external clock input when the setting of the main clock oscillator stop bit (MOSCCR.MOSTP) is 0.

9.3.4 Notes on Oscillation Keeping in Software Standby Mode

By using the oscillation keep function of the main clock oscillator in software standby mode, the oscillation stabilization wait time of the main clock oscillator after release from software standby mode can be shortened.
If the MCU is placed in software standby mode when the MOSCSCR.MOSCSOKP bit is 1 (enabled) and the main clock oscillator is operating, the main clock oscillator will keep oscillating in software standby mode. When the MCU is released from software standby mode in this state, the main clock can be used without requiring any oscillation stabilization wait time.
When using the oscillation keep function, confirm that the setting value is written to the register before the MCU is placed in software standby mode.
However, even if the oscillation keep function is enabled, the clock supply to the system and peripheral modules is stopped in software standby mode.

9.4 Sub-Clock Oscillator

To supply a clock signal to the sub-clock oscillator, use either of the following methods:

- Connect a resonator.
- Connect the input of an external clock signal.

9.4.1 Connecting a 32.768-kHz Crystal Resonator

To supply a clock to the sub-clock oscillator, connect a 32.768-kHz crystal resonator, as shown in Figure 9.5. A damping resistor (Rd) should be inserted, if required. Since the resistor value varies depending on the resonator and oscillation driving capacity, use a value recommended by the resonator manufacturer. If the addition of an external feedback resistor (Rf) is directed by the resonator manufacturer, follow that direction and insert an Rf resistor between the XCIN and XCOUT pins. When connecting a resonator to supply the clock, the frequency of the resonator should be in the frequency range of the resonator for the sub-clock oscillator, as shown in Table 9.1.

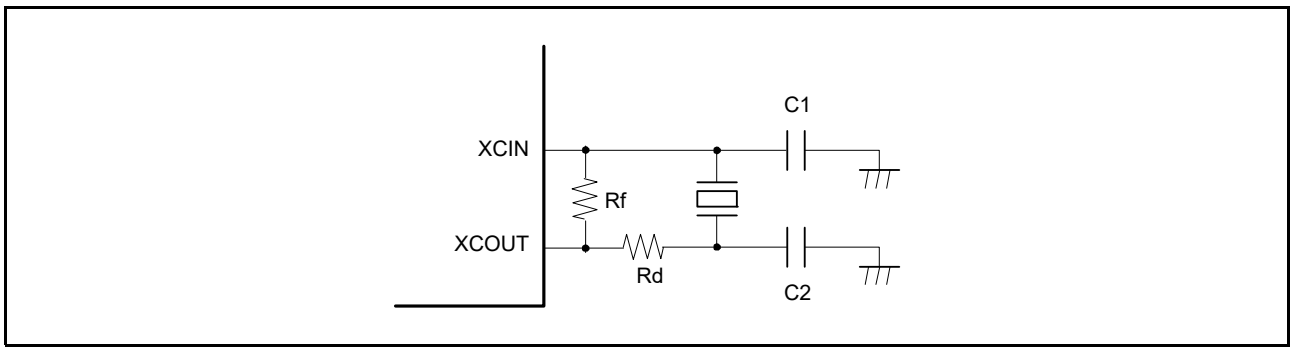

Figure 9.5 Example of Connecting a 32.768-kHz Crystal Resonator

Figure 9.6 shows an equivalent circuit of the 32.768-kHz crystal resonator.

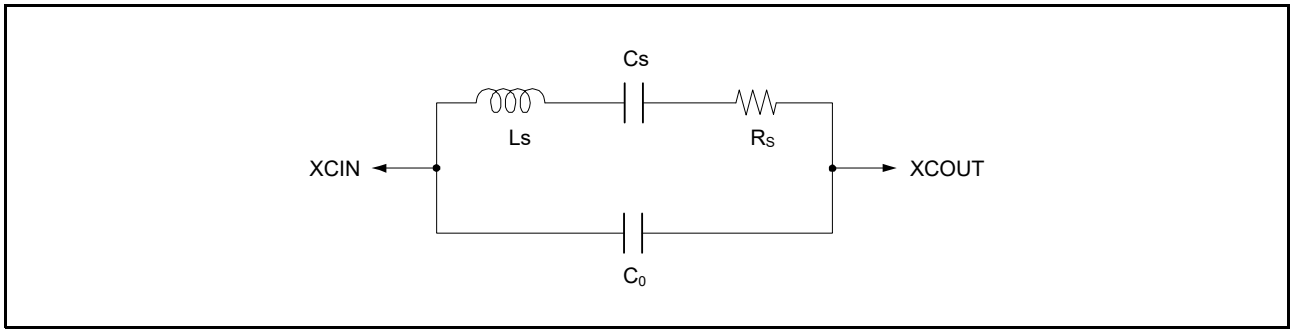

Figure 9.6 Equivalent Circuit of the 32.768-kHz Crystal Resonator

9.4.2 Handling of Pins when the Sub-Clock Oscillator is Not in Use

For handling of pins when the sub-clock is not in use, see section 22.5, Handling of Unused Pins.

9.4.3 Input of an External Clock

In the external clock input mode, apply the external clock to the XCIN pin. See section 22.6.10, Note on Using the Sub-Clock Oscillator.

9.5 Low-Speed On-Chip Oscillator (LOCO)

The low-speed on-chip oscillator (LOCO) is an internal oscillator that supplies a low-speed clock.

9.5.1 LOCO Operating Conditions

There are restrictions on LOCO operation settings. For details, see section 9.5.3, Restrictions on LOCO Operation and Stopping.
The LOCO oscillates when any of the following conditions is met.

[LOCO operating conditions]

- The LOCO is set to start operation in the LOCOCR register (LOCOCR.LCSTP bit is 0).
- The IWDT is set to auto start mode. (OFS0.IWDTSTRT bit is 0).*1
- The IWDT is set to register start mode (OFS0.IWDTSTRT bit is 1) and counting is started.*2
- While waiting for the oscillation stabilization of the main clock oscillator (while the MOSCCR.MOSTP bit is 0 and the OSCSF.MOSCSF bit is 0)*3
- The SOSC oscillation stop detection function is enabled (SOSTDCR.SOSTDE bit is 1).

Note 1. When the IWDT is set to auto start mode, regardless of the setting of the OFS0.IWDTSLCSTP bit, the LOCO continues to oscillate. After that, even if the MCU is placed in CPU sleep mode or CPU deep sleep mode, the LOCO continues to oscillate.
Note 2. When the IWDT is set to register start mode, regardless of the setting of the IWDTCSTPR.SLCSTP bit, the LOCO continues to oscillate once the IWDT starts counting. After that, even if the MCU is placed in CPU sleep mode or CPU deep sleep mode, the LOCO continues to oscillate.
Note 3. Even if the main clock oscillator is set to external clock input mode, the LOCO operates because the oscillation stabilization wait circuit operates when the main clock oscillator starts operating.

9.5.2 LOCO Stop Conditions

There are restrictions on LOCO stop settings. For details, see section 9.5.3, Restrictions on LOCO Operation and Stopping.
The LOCO can be stopped by setting the LCSTP bit of the LOCOCR register to the stop setting (LOCOCR.LCSTP = 1). However, even if the LCSTP bit is set to the stop setting, the LOCO may not stop according to the operating state of the IWDT and oscillator.
The LOCO can be stopped when all of the following conditions are met.

[LOCO stop conditions]

- The LOCO is set to stop operation in the LOCOCR register (LOCOCR.LCSTP bit is 1).
- The IWDT has not started counting or the IWDT was stopped by a transition to software standby mode 1 or 2 or deep software standby mode 1 during counting by the IWDT while the OFS0.IWDTSTPCTL bit is set to 1 or the IWDT.IWDTCSTPR.SLCSTP bit is set to 1.*1
- The main clock oscillator is stopped or main clock oscillation is stable (MOSCCR.MOSTP bit is 1, or MOSCCR.MOSTP bit is 0 and OSCSF.MOSCSF bit is 1).
- When the SOSC oscillation stop detection function is set to disabled (SOSTDCR.SOSTDE bit is 0).

Note 1. The operating state of the IWDT does not affect the LOCO operation in deep software standby mode 2 or 3.

9.5.3 Restrictions on LOCO Operation and Stopping

After setting the LOCOCR.LCSTP bit to 0 to start the LOCO, only use the LOCO clock after the LOCO clock oscillation stabilization wait time (tLOCOWT) has elapsed. A fixed oscillation stabilization wait time is required after setting the LOCO to start operation. A fixed wait time for the oscillation to stop is also required.

The following restrictions apply when starting and stopping operation:

- After stopping the LOCO, read the OSCMONR.LOCOMON flag to make sure that the LOCO is stopped, and then set the operation.
- Confirm that LOCO clock oscillation is stable before stopping the LOCO.
- Confirm that LOCO clock oscillation is stable before executing a WAIT instruction to place the MCU in software standby mode or deep software standby mode.
- When placing the MCU in software standby mode or deep software standby mode after setting the LOCO to stop, read the OSCMONR.LOCOMON flag to make sure that the LOCO is stopped, and then execute a WAIT instruction.

The LOCO clock is used to measure the oscillation stabilization wait time of the main clock oscillator. While the main clock oscillator is waiting for oscillation stabilization, the LOCO oscillates regardless of the setting of the LCSTP bit. At this time, it is necessary to prevent conflicts between the LOCO being stopped (or started) by the LCSTP bit and the LOCO oscillating during the oscillation stabilization wait time of the main clock oscillator (or the LOCO clock being stopped after oscillation stabilization of the main clock). Therefore, do not change the LOCOCR.LCSTP bit during the period from three LOCO clock cycles before setting the main clock oscillator to start until confirming stabilization of the main clock oscillator with the oscillation stabilization flag in the OSCSF register.
When using the IWDT in register start mode (OFS0.IWDTSTRT = 1), set the LOCO to operate (LOCOCR.LCSTP = 0) before IWDT counting starts, and use the IWDT after LOCO oscillation has stabilized.
When using the IWDT in register start mode, do not change the LOCOCR.LCSTP bit during the period from three LOCO clock cycles before IWDT counting starts until confirming the start of IWDT counting.
When negation of the voltage-monitoring m reset is selected or digital filtering is used in programmable voltage detection (PVDm) (m = 1, 2, 4, or 5), set the LOCO to start operation (LOCOCR.LCSTP = 0) before enabling PVDm, and use PVDm only after the LOCO oscillation has stabilized. When voltage monitor m reset negation is selected (PVDmCR0.RN = 1) or when the digital filter is used (PVDmCR0.DFDIS = 1), do not write 1 to the LOCOCR.LCSTP bit (LOCO stop) (m = 1, 2, 4, or 5).

9.6 Middle-Speed On-Chip Oscillator (MOCO)

The middle-speed on-chip oscillator (MOCO) is an internal oscillator that supplies a middle-speed clock.

9.6.1 MOCO Operating Conditions

There are restrictions on MOCO operation settings. For details, see section 9.6.3, Restrictions on MOCO Operation and Stopping.
The MOCO oscillates when any of the following conditions is met.

[MOCO operating conditions]

- The MOCO is set to start operation in the MOCOCR register (MOCOCR.MCSTP = 0).
- While waiting for the HOCO oscillation stabilization (while the OFS1.HOCOEN bit is 0 or the HOCOCR.HCSTP bit is 0, and the OSCSF.HOCOSF bit is 0)
- While waiting for the PLL1 oscillation stabilization (while the PLLCR.PLLSTP bit is 0 and the OSCSF.PLLSF bit is 0)
- While waiting for the PLL2 oscillation stabilization (while the PLL2CR.PLL2STP bit is 0 and the OSCSF.PLL2SF bit is 0)
- The MOSC oscillation stop detection function is enabled (OSTDCR.OSTDE bit is 1).
- The SOSC oscillation stop detection function is enabled (SOSTDCR.SOSTDE bit is 1).

Note: The MOCO is stopped in software standby mode or deep software standby mode.

9.6.2 MOCO Stop Conditions

There are restrictions on MOCO stop settings. For details, see section 9.6.3, Restrictions on MOCO Operation and Stopping.
There are two methods to stop the MOCO: stop the MOCO by placing the MCU in a low power consumption mode or stop the MOCO by using the MOCOCR register.

(1) MOCO stop conditions related to low power consumption modes

The MOCO stops when the MCU is placed in either of the following low power consumption modes:

- Software standby mode (MOCOSCR.MOCOSOKP = 0)
- Deep software standby mode

(2) MOCO stop conditions related to the MOCOCR register

When the MOCO is to be stopped using the MOCOCR register, even if the MCSTP bit is set to stop (MOCOCR.MCSTP bit is 1), the MOCO may not stop depending on the operating state of the system.
The MOCO can be stopped when all of the following conditions are met.

[MOCO stop conditions]

- The MOCO is set to stop operation in the MOCOCR register (MOCOCR.MCSTP bit is 1).
- The HOCO is stopped or HOCO oscillation is stable (OFS1.HOCOEN bit is 1 and HOCOCR.HCSTP bit is 1, or OSCSF.HOCOSF bit is 1).
- The PLL1 circuit is stopped or PLL1 oscillation is stable (PLLCR.PLLSTP bit is 1 or OSCSF.PLLSF bit is 1).
- The PLL2 circuit is stopped or PLL2 oscillation is stable (PLL2CR.PLL2STP bit is 1 or OSCSF.PLL2SF bit is 1).

- The MOSC oscillation stop detection function is disabled (the OSTDCR.OSTDE bit is set to 0).
- The SOSC oscillation stop detection function is disabled (the SOSTDCR.SOSTDE bit is set to 0).

9.6.3 Restrictions on MOCO Operation and Stopping

After setting the MOCOCR.MCSTP bit to 0 to start the MOCO, only use the MOCO clock after the MOCO clock oscillation stabilization wait time (tMOCOWT) has elapsed. A fixed oscillation stabilization wait time is required after setting the MOCO to start operation. A fixed wait time for the oscillation to stop is also required.

The following restrictions apply when starting and stopping operation:

- After stopping the MOCO, read the OSCMONR.MOCOMON flag to make sure that the MOCO is stopped, and then set the operation.
- Confirm that MOCO oscillation is stable before stopping the MOCO.
- Regardless of whether the MOCO clock is selected as the system clock source, confirm that MOCO oscillation is stable before executing a WAIT instruction to place the MCU in software standby mode or deep software standby mode. If the MOCO is stopped, start operation of the MOCO.
- Regardless of whether the MOCO clock is selected as the system clock source, confirm that MOCO oscillation is stable before executing a WAIT instruction to place the MCU in CPU deep sleep mode. If the MOCO is stopped, start operation of the MOCO.
- Confirm that MOCO oscillation is stable before executing power control for each power domain by software. If the MOCO is stopped, start operation of the MOCO.
- Confirm that MOCO oscillation is stable before programming or erasing MRAM. If the MOCO is stopped, start operation of the MOCO.

Writing 1 to the MCSTP bit is prohibited under the following conditions:

- SCKSCR.CKSEL[2:0] = 001b (system clock source = MOCO)
- Main clock oscillation stop detection is enabled (OSTDCR.OSTDE bit is 1).
- While waiting for HOCO oscillation stabilization (while the OFS1.HOCOEN bit is 0 or the HOCOCR.HCSTP bit is 0, and the OSCSF.HOCOSF bit is 0)
- While waiting for PLL1 oscillation stabilization (while the PLLCR.PLLSTP bit is 0 and the OSCSF.PLLSF bit is 0)
- While waiting for PLL2 oscillation stabilization (while the PLL2CR.PLL2STP bit is 0 and the OSCSF.PLL2SF bit is 0)
- While executing power control for each power domain by software (during power gating control)

The MOCO clock is used to measure the oscillation stabilization wait time of the HOCO, PLL1, or PLL2 clock. While waiting for the HOCO, PLL1, or PLL2 clock oscillation to become stable, the MOCO oscillates regardless of the MOCOCR.MCSTP bit setting. At this time, it is necessary to prevent conflicts between the MOCO being stopped (or started) by the MOCOCR.MCSTP bit and the MOCO oscillating during the HOCO, PLL1, or PLL2 clock oscillation stabilization wait time (or the MOCO clock being stopped after HOCO, PLL1, or PLL2 clock oscillation stabilization). Therefore, do not change the MOCOCR.MCSTP bit during the period from three MOCO clock cycles before setting the HOCO, PLL1, or PLL2 to start until confirming stabilization of the HOCO, PLL1, or PLL2 clock oscillation with the HOCOSF, PLLSF, or PLL2SF flag in the OSCSF register.

9.7 High-Speed On-Chip Oscillator (HOCO)

The high-speed on-chip oscillator (HOCO) is an internal oscillator that supplies a high-speed clock.

9.7.1 Frequency Locked Loop Function

The HOCO supports the frequency locked loop (FLL) function that corrects the frequency accuracy of the HOCO clock using the sub-clock oscillator. When the FLL function is enabled, the frequency accuracy of the HOCO clock can be improved compared to when the FLL function is disabled.
When using the FLL function, oscillation of the sub-clock oscillator must be stable. In addition, the sub-clock oscillator must meet the frequency accuracy specified in the electrical characteristics. (For details, see section 67, Electrical Characteristics.)
When enabling the FLL function and using the HOCO, enable the FLL function in advance and enable the HOCO (HOCOCR.HCTSP = 0) after SOSC oscillation has stabilized.
Set the FLLCR2.FLLCNTL[10:0] bits as follows for each HOCO frequency setting. The HOCO clock will reach the desired frequency after the period of tFLLWT has elapsed following the HOCO becoming enabled.

Table 9.5 FLLCNTL Setting for Each HOCO Frequency Setting

FLLCR2.FLLCNTL[10:0]	OFS1.HOCOFRQ0[2:0]	Target Frequency (FHOCO)
1E8h	000b	16 MHz
225h	001b	18 MHz
262h	010b	20 MHz
1E8h	100b	32 MHz
1E8h	111b	48 MHz

9.7.2 Notes on Oscillation Keeping in Software Standby Mode

By using the oscillation keep function of the HOCO in software standby mode, the HOCO oscillation stabilization wait time after release from software standby mode can be shortened.
To keep the HOCO oscillating in software standby mode, make the following settings:

- Enable the HOCO standby oscillation keep function (set the HOCOSCR.HOCOSOKP bit to 1).
- Set power control for the HOCO in the HOCOLDOCR register.

If the MCU is placed in software standby mode while the HOCO is operating with the above settings, the HOCO will keep oscillating in software standby mode. When the MCU is released from software standby mode in this state, the HOCO clock can be used without any oscillator stabilization wait time.
When using the oscillation keep function, confirm that the setting value is written to the register before the MCU is placed in software standby mode.
However, even if the oscillation keep function is enabled, the clock supply to the system and peripheral modules is stopped in software standby mode.

9.8 PLL Circuits

The PLL circuits are capable of multiplying the frequency of the clock input from an oscillator.
Figure 9.7 shows a block diagram of the PLL1 circuit, and Figure 9.8 shows a block diagram of the PLL2 circuit. The PLL1 and PLL2 circuits have the same circuit configuration. The PLL1 circuit is explained below as an example.
The input clock source selection circuit selects the clock source input to the PLL circuit.
The input clock frequency dividing circuit divides the frequency of the input clock and generates the PLL reference clock.
The frequency control circuit controls the VCO clock to be generated from the PLL reference clock according to the setting of the frequency multiplier. The multiplication ratio is determined by the combination of the PLLMUL and PLLMULNF bits. The PLLMUL bits determine the integer part of the multiplication ratio and the PLLMULNF bits determine the fractional part of the multiplication ratio. For example, if the setting of the PLLMUL bits is 26 and the setting of the PLLMULNF bits is 0.33, the multiplication ratio is 26.33.
The PLL circuit has three output clocks. The output clock frequency dividing circuit divides the VCO clock to generate each PLL clock output. The division ratio for generating each output clock can be set independently with the PLODIVP, PLODIVQ, and PLODIVR bits.
The PLL input clock frequency, PLL reference clock frequency, VCO clock frequency, and each output clock frequency must be within the specified ranges in section 67, Electrical Characteristics.
The PLL frequency setting can only be changed when the PLL circuit is stopped. Do not change the PLL frequency setting when the PLL stop control bit (PLLSTP) is 0.

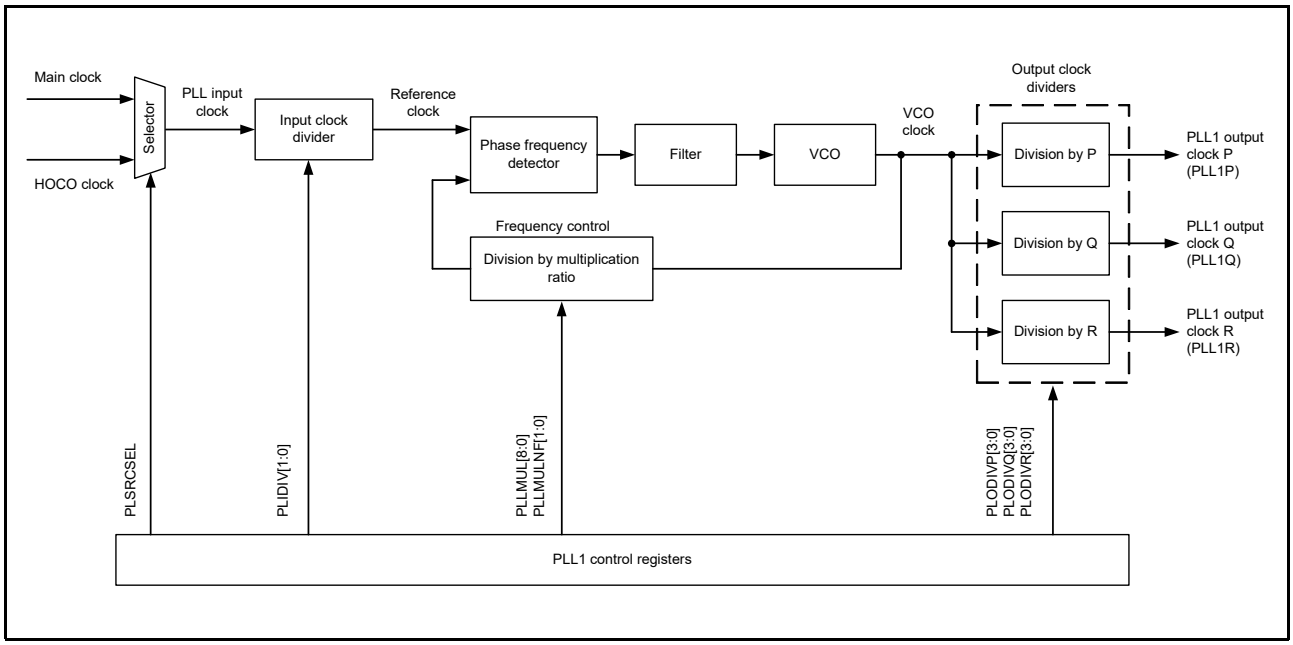

Figure 9.7 Block Diagram of the PLL1 Circuit

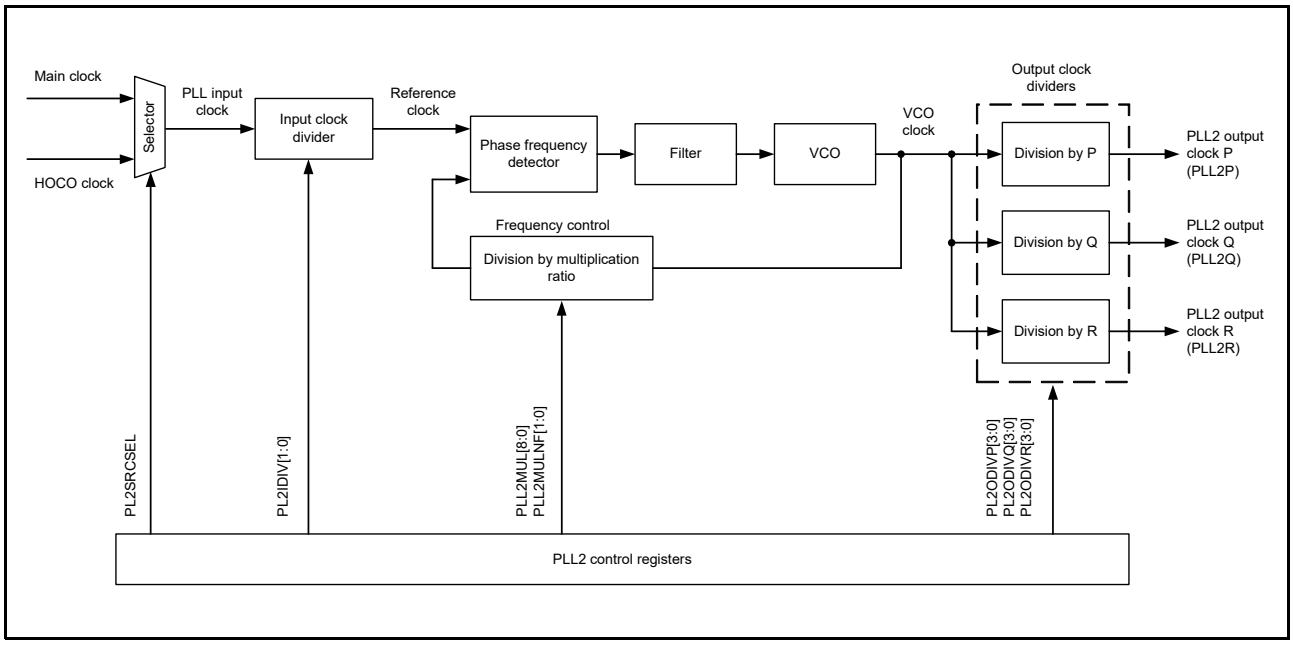

Figure 9.8 Block Diagram of the PLL2 Circuit

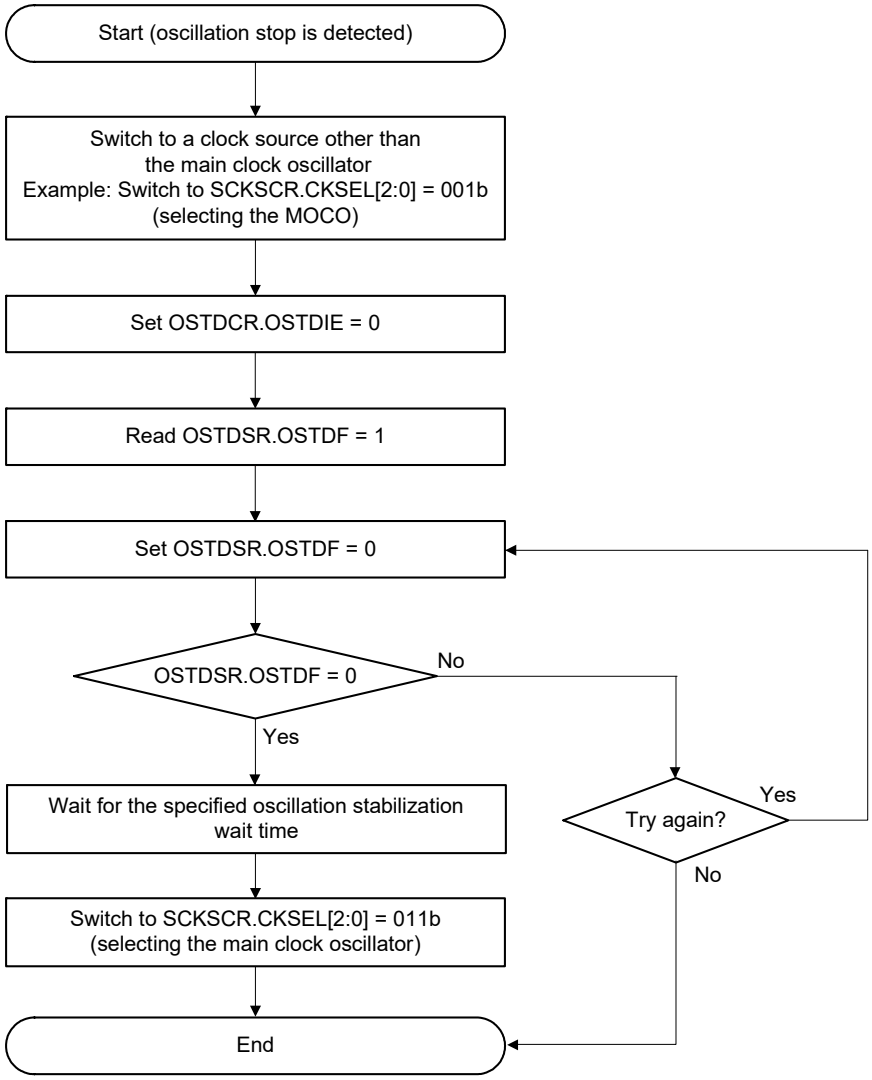
9.9 Oscillation Stop Detection Function

9.9.1 Main Clock Oscillation Stop Detection and Operation after Detection

The main clock oscillation stop detection function is used to detect stopping of the main clock oscillator. When an oscillation stop is detected, the system clock source is switched as follows:

- If an oscillation stop is detected when SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC), the system clock source is switched to the MOCO clock.
- If an oscillation stop is detected when PLLCCR.PLSRCSEL = 0 (PLL1 source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL1P), the system clock source remains to be the PLL1 clock. The frequency becomes the free-running value and the setting of the SCKSCR.CKSEL[2:0] bits does not change.



An oscillation stop detection interrupt request can be generated when an oscillation stop is detected. In addition, the general PWM timer (GPTW) output can be forced to the stop state on detection.
Stopping of the main clock oscillator is detected when the input clock of the oscillation stop detection circuit remains low or high for a certain period, for example, when a malfunction occurs in the main clock oscillator. See section 67, Electrical Characteristics.
Switching between the main clock and MOCO clock or between the PLL1 clock and PLL1 free-running clock is controlled by the oscillation stop detection flag (OSTDSR.OSTDF).
The OSTDF flag controls the switched clock as follows:

- When SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC)
  - When the OSTDF flag changes from 0 to 1, the clock source switches to the MOCO clock.
  - When the OSTDF flag changes from 1 to 0, the clock source switches back to MOSC.
- When PLLCCR.PLSRCSEL = 0 (PLL1 source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL1P)
  - When the OSTDF flag changes from 0 to 1, the clock source switches to the PLL1 free-running oscillation clock.
  - When the OSTDF flag changes from 1 to 0, the clock source switches back to the PLL1 clock.

To switch the clock source to the main clock or PLL1 clock again after detection of an oscillation stop, set the CKSEL[2:0] bits to a clock source other than the main clock or PLL1 clock and clear the OSTDF flag to 0. After that, check that the OSTDF flag is not 1, and then set the CKSEL[2:0] bits to the main clock or PLL1 clock after the specified oscillation stabilization wait time has elapsed.
After release from the reset state, the main clock oscillator is stopped and the main clock oscillation stop detection function is disabled. To enable the main clock oscillation stop detection function, activate the main clock oscillator and write 1 to the oscillation stop detection function enable bit (OSTDCR.OSTDE) after the specified oscillation stabilization wait time has elapsed.
The main clock oscillation stop detection function detects when the main clock oscillator is stopped by an external cause.
The main clock oscillation stop detection function switches the following clocks to the MOCO clock (when the system clock source is MOSC).

- All clocks that can be selected as the MOSC clock, except for CLKOUT and the clock source of PLL
- The system clock (ICLK) frequency during MOCO operation (when the system clock source is MOSC) is specified by the MOCO oscillation frequency and the division ratio set by the system clock select bits (SCKDIVCR.ICK[3:0]).

Example of returning when setting CKSEL[2:0] = 011b (selecting the main clock oscillator) after an oscillation stop has been detected

Note: On return from the oscillation-stopped state, the factor responsible for stopping the main clock oscillation circuit must be removed from the user system to allow oscillation to resume.

Figure 9.9 Flow for Recovery from Detecting Stopping of the Main Clock Oscillator

9.9.2 Main Clock Oscillation Stop Detection Interrupts

A main clock oscillation stop detection interrupt (OSTDI) is generated when the oscillation stop detection flag (OSTDSR.OSTDF) is 1 and the oscillation stop detection interrupt enable bit in the oscillation stop detection control register (OSTDCR.OSTDIE) is 1 (enabled). At this time, the GPTW port output enable (POEG) is notified that the main clock oscillator has stopped. On accepting the notification, the POEG sets the oscillation stop detection flag in the POEG group x setting register (POEGGx.OSTPF) (x = A to D) to 1.
After the oscillation stop has been detected, wait for at least 10 clock cycles of PCLKB before writing to the POEGGn.OSTPF flag. When the OSTDSR.OSTDF flag requires clearing, do so after setting the oscillation stop detection interrupt enable bit in the oscillation stop detection control register (OSTDCR.OSTDIE) to 0. Wait for at least two clock cycles of PCLKB before setting the OSTDCR.OSTDIE bit to 1 again. A waiting time longer than two cycles of PCLKB may have to be secured, depending on the number of cycles required to read a given I/O register.
Main clock oscillation stop detection interrupts are non-maskable interrupts. Since non-maskable interrupts are disabled in the initial state after release from the reset state, enable non-maskable interrupts through software before using main clock oscillation stop detection interrupts. For details, see section 15, Interrupt Controller (ICUM).

9.9.3 Sub-Clock Oscillation Stop Detection and Operation after Detection

The sub-clock oscillation stop detection function is used to detect stopping of the sub-clock oscillator. When an oscillation stop is detected, the system clock source is switched as follows:

- If an oscillation stop is detected when SCKSCR.CKSEL[2:0] = 100b (system clock source = SOSC), the system clock source is switched to the MOCO/256 clock.

An oscillation stop detection interrupt request can be generated when an oscillation stop is detected.
Stopping of the sub-clock oscillator is detected when the input clock of the oscillation stop detection circuit remains low or high for a certain period, for example, when a malfunction occurs in the sub-clock oscillator. See section 67, Electrical Characteristics.
Switching between the sub-clock and MOCO/256 clock is controlled by the sub-clock oscillation stop detection flag (SOSTDSR.SOSTDF).
The SOSTDF flag controls the switched clock as follows:

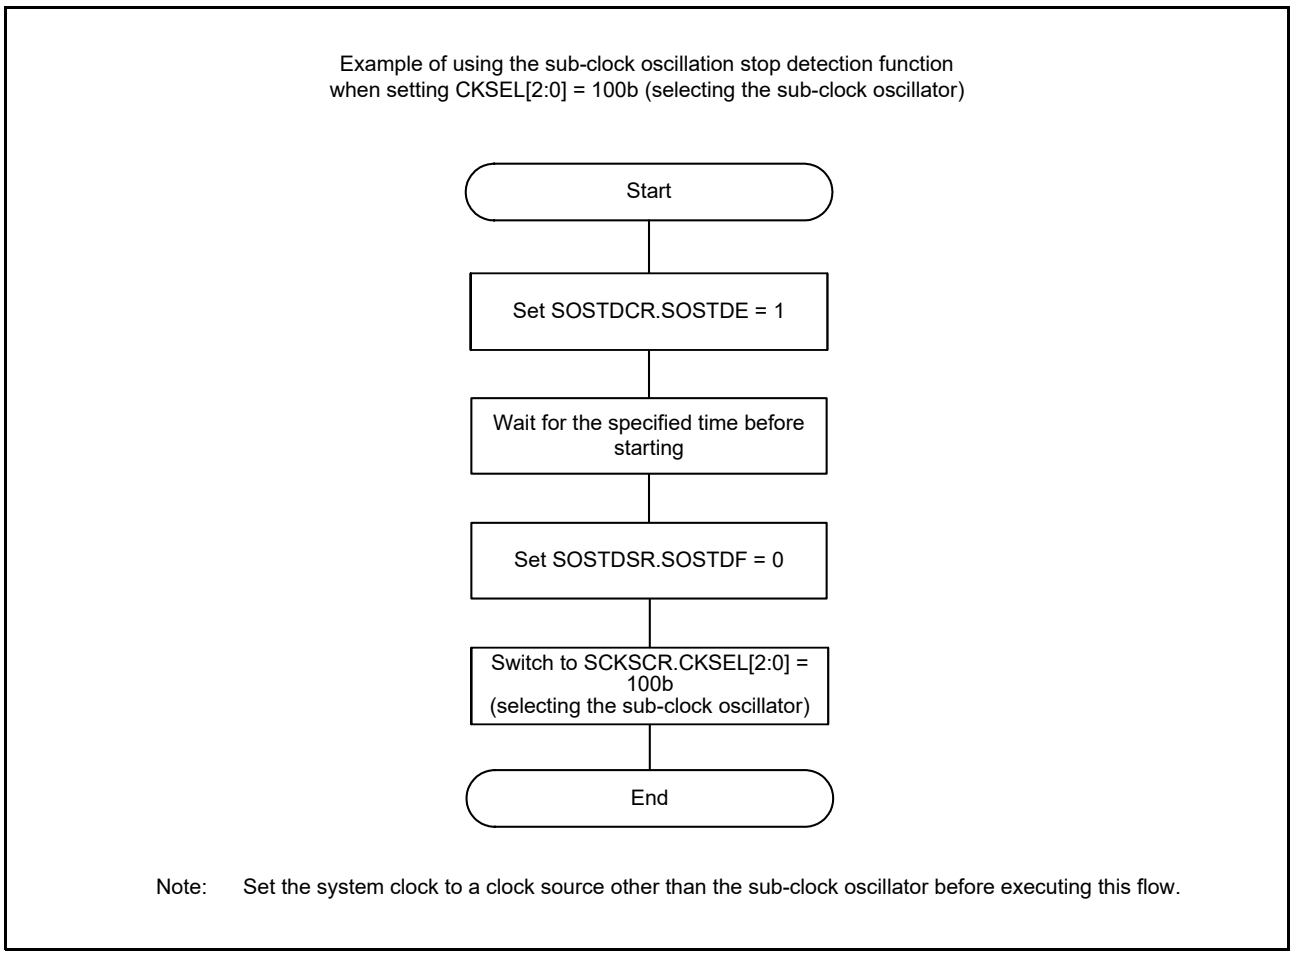
- When SCKSCR.CKSEL[2:0] = 100b (system clock source = SOSC)
  - When the SOSTDF flag changes from 0 to 1, the clock source switches to the MOCO/256 clock.
  - When the SOSTDF flag changes from 1 to 0, the clock source switches back to SOSC.

To switch the clock source to the sub-clock again after detection of an oscillation stop, set the CKSEL[2:0] bits to a clock source other than the sub-clock and clear the SOSTDF flag to 0. After that, check that the SOSTDF flag is not 1, and then set the CKSEL[2:0] bits to the sub-clock after the specified oscillation stabilization wait time has elapsed.

After release from the backup area reset, the sub-clock oscillator is stopped and the sub-clock oscillation stop detection function is disabled.
To enable the sub-clock oscillation stop detection function, activate the sub-clock oscillator and write 1 to the sub-clock oscillation stop detection function enable bit (SOSTDCR.SOSTDE) after the specified oscillation stabilization wait time has elapsed.
After that, clear the sub-clock oscillation stop detection flag (SOSTDSR.SOSTDF) to 0 after the sub-clock oscillation stop detection circuit operation start wait time (t_{sosdup}) has elapsed.
When selecting the sub-clock for the system clock, complete the above settings before switching.
The sub-clock oscillation stop detection function detects when the sub-clock oscillator is stopped by an external cause.
The sub-clock oscillation stop detection function switches the following clocks to the MOCO/256 clock.

- The input clock of all modules that can select the SOSC clock as the input clock, except for RTCSCLK and CACSCLK

- The system clock (ICLK) frequency during MOCO/256 operation is specified by the MOCO oscillation frequency and the division ratio set by the system clock select bits (SCKDIVCR.ICK[3:0]).
- When stopping of the sub-clock is detected, RTCSCLK is switched to the LOCO clock.
- Even when stopping of the sub-clock is detected, CACSCLK is not switched to another clock.



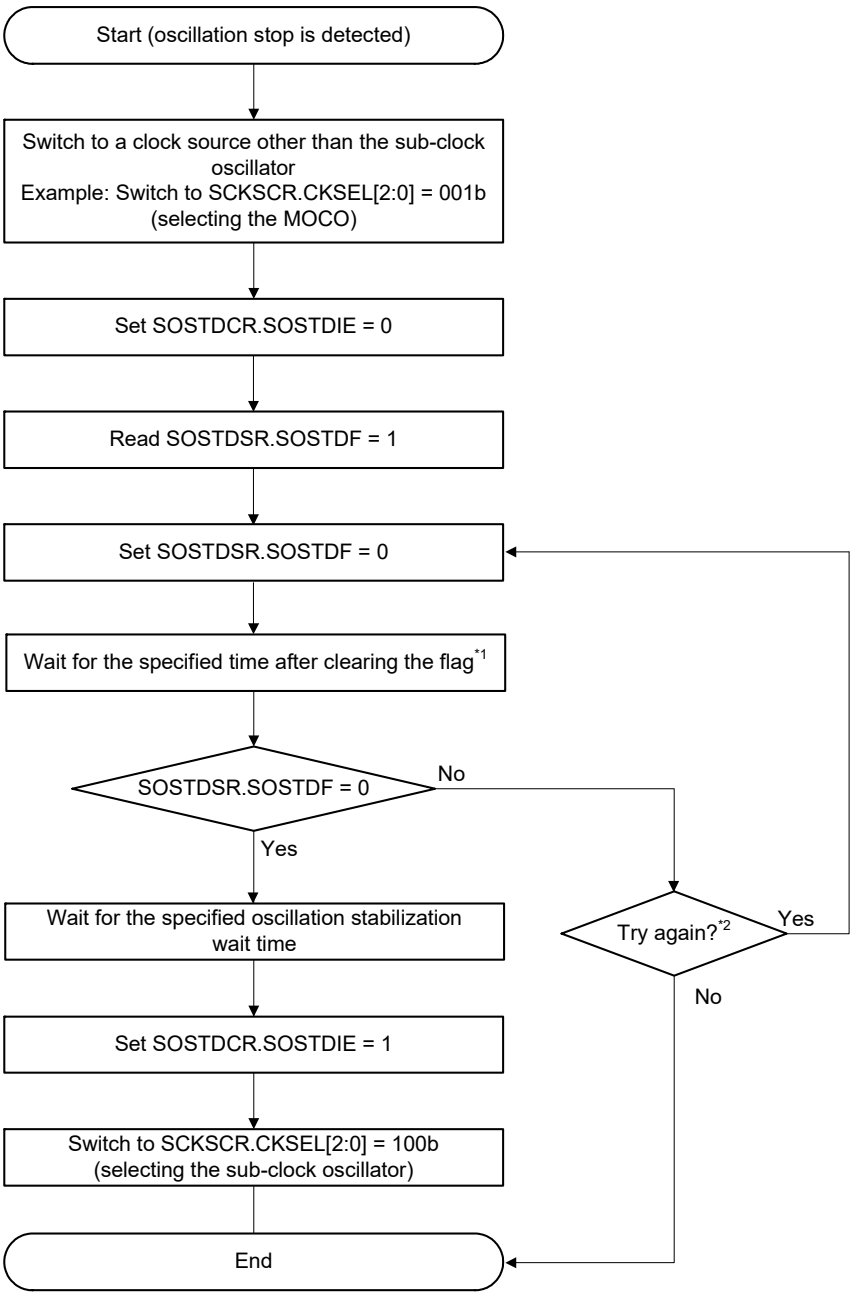


Figure 9.10 Operation Flow of the Sub-Clock Oscillation Stop Detection Function

Example of returning when setting CKSEL[2:0] = 100b (selecting the sub-clock oscillator) after an oscillation stop has been detected

Note: On return from the oscillation-stopped state, the factor responsible for stopping the sub-clock oscillation circuit must be removed from the user system to allow oscillation to resume.
Note 1. If the SOSTDSR.SOSTDF flag is cleared, wait for at least 1.5 µs before reading the next SOSTDSR.SOSTDF flag.
Note 2. Retry at least once.

Figure 9.11 Flow for Recovery from Detecting Stopping of the Sub-Clock Oscillator

9.9.4 Sub-Clock Oscillation Stop Detection Interrupts

A sub-clock oscillation stop detection interrupt (SOSTDI) is generated when the sub-clock oscillation stop detection flag (SOSTDSR.SOSTDF) is 1 and the sub-clock oscillation stop detection interrupt enable bit in the sub-clock oscillation stop detection control register (SOSTDCR.SOSTDIE) is 1 (enabled).

When the SOSTDF flag requires clearing, after setting the sub-clock oscillation stop detection interrupt enable bit in the sub-clock oscillation stop detection control register (SOSTDCR.SOSTDIE) to 0, clear the SOSTDF flag before setting the SOSTDIE bit to 1.

9.10 Internal Clocks

The clock sources for the internal clock signals are as follows:

- Main clock oscillator
- Sub-clock oscillator
- HOCO clock
- MOCO clock
- LOCO clock
- PLL1 clock (PLL1P, PLL1Q, PLL1R)
- PLL2 clock (PLL2P, PLL2Q, PLL2R)
- External clock input for JTAG
- External clock input for SWD

The following internal clocks are produced from these clock sources.

- Operating clock for the CPU: CPU clock (CPUCLK0)
- Operating clock for the CPU, DMAC, EXDMAC, DTC, SRAM, system bus, I/O ports, and ICU: System clock (ICLK)
- Operating clocks of the code MRAM and MRAM code bus: MRAM code bus clock (MRICLK)
- Operating clocks of peripheral modules: Peripheral module clocks (PCLKA, PCLKB, PCLKC, PCLKD, and PCLKE)
- Operating clocks of the extra MRAM and MRAM peripheral bus: MRAM peripheral bus clock (MRPCLK)
- Clocks for the external bus controller and external pin output: External bus clock (BCLK, EBCLK)
- Clock for the external bus controller and external pin output for the SDRAM: SDRAM clock (SDCLK)
- Operating clock for the RSCI: SCI clock (SCICLK)
- Operating clock for the RSPIA: SPI clock (SPICLK)
- Operating clock for the XSPI: XSPI clock (XSPICLK, XSPIDIVCLK)
- Operating clock for the CANFD and CANFDG: CANFD core clock (CANFDCLK)
- Operating clock for the USB and USBHS: USB clock (USBCLK)
- Operating clock for the USBHS: USBHS-PHY clock (USB60CLK)
- Operating clock for the ADC16H: ADC clock (ADCCLK)
- Operating clock for the GPTW, PCIF, and ADC16H: GPT clock (GPTCLK)
- Operating clock for the RI3C and RIICHS: I3C clock (I3CCLK)
- Clock for the external bus controller (asynchronous) and clock for output through an external pin: Asynchronous external bus clocks (BCLKA, EBCLK)
- Operating clock for ESWM: ESWM clock (ESWCLK)
- Operating clock for ESWM-PHY: ESWM-PHY clock (ESWPHYCLK)
- Operating clock for the ETHPHYCLK pin output: Ethernet-PHY clock (ETHPHYCLK)
- Clock for external pin output: Clock/Buzzer output (CLKOUT)
- Operating clock for the USBHS: MOSC clock for USBHS (USBMCLK)
- Operating clock for the CANFD and CANFDG: CANFD main clock (CANFDMCLK)
- Operating clock for the CAC: CAC clock (CACCLK)
- Operating clock for the RTC: RTC LOCO clock (RTCLCLK) and RTC sub-clock (RTCSCLK)
- Operating clock for the PDMIF: PDMIF clock (PDMIFCLK)
- Operating clock for the IWDT: IWDT clock (IWDTCLK)
- Operating clock for the JTAG: JTAG clock (JTAGTCK)

For details on the registers used to set the frequencies of the internal clocks, see section 9.10.4, System Clock (ICLK) to section 9.10.28, JTAG Clock.
If the value of any of these bits is changed, subsequent operation is performed at the frequency determined by the new value.

9.10.1 CPU Clock (CPUCLK0)

The CPU clock (CPUCLK0) is the operating clock for the CPU. The frequency is specified by the following bits.

- CPUCK0[3:0] bits in SCKDIVCR2
- CKSEL[2:0] bits in SCKSCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0] bits in PLLCCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.2 MRAM Code Bus Clock (MRICLK)

The MRAM code bus clock (MRICLK) is the operating clock for the code MRAM and the MRAM code bus. The frequency is specified by the following bits.

- MRICK[3:0] bits in SCKDIVCR2
- CKSEL[2:0] bits in SCKSCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0] bits in PLLCCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.3 MRAM Peripheral Bus Clock (MRPCLK)

The MRAM peripheral bus clock (MRPCLK) is the operating clock for extra MRAM and MRAM peripheral bus. The frequency is specified by the following bits.

- MRPCK[3:0] bits in SCKDIVCR
- CKSEL[2:0] bits in SCKSCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0] bits in PLLCCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.4 System Clock (ICLK)

The system clock (ICLK) is the operating clock for the DMAC, EXDMAC, DTC, MRAM, SRAM, system bus, I/O ports, and ICU. The frequency is specified by the following bits.

- ICK[3:0] bits in SCKDIVCR
- CKSEL[2:0] bits in SCKSCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0] bits in PLLCCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

When the ICLK clock source is switched, the duration of the ICLK clock cycle becomes longer while the clock sources are switched. See Figure 9.12 and Figure 9.13.

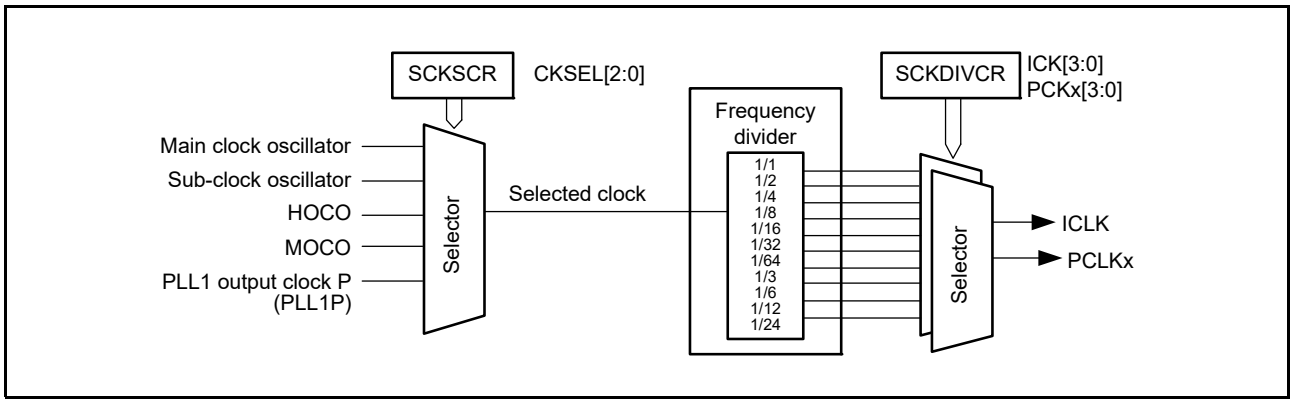

Figure 9.12 Block Diagram of Clock Source Selectors

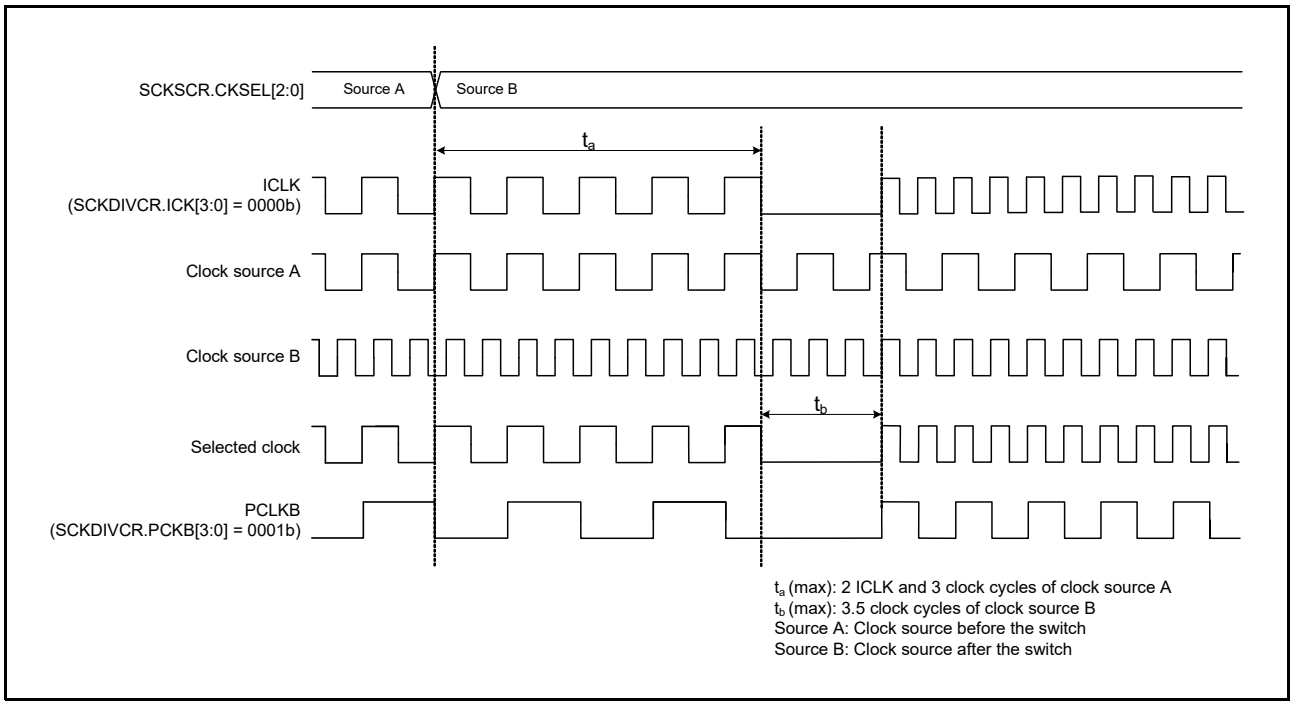

Figure 9.13 Timing of Clock Source Switching

9.10.5 Peripheral Module Clock (PCLKA, PCLKB, PCLKC, PCLKD, PCLKE)

The peripheral module clocks (PCLKA, PCLKB, PCLKC, PCLKD, and PCLKE) are the operating clocks for use by peripheral modules.
The frequency of the given clock is specified by the following bits.

- PCKA[3:0], PCKB[3:0], PCKC[3:0], PCKD[3:0], and PCKE[3:0] bits in SCKDIVCR
- CKSEL[2:0] bits in SCKSCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0] bits in PLLCCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

When the clock source of the peripheral module clock is switched, the duration of the peripheral module clock cycle becomes longer while the clock sources are switched. See Figure 9.12 and Figure 9.13.

9.10.6 External Bus Clock (BCLK, EBCLK)

The external bus clock (BCLK) is the operating clock for the external bus controller. It is also output externally from the EBCLK pin to the external bus.
BCLK can be output from the EBCLK pin by setting the EBCKOCR.EBCKOEN bit to 1 and the P801PFS.PSEL[6:0] bits to 0111101b. The value of the P801PFS.PSEL[6:0] bits can be changed to 0111101b only when the EBCKOCR.EBCKOEN bit is 0.
BCLK can be selected by setting the BCKCR.EBCKASEL bit to 0.
When the BCKCR.BCLKDIV bit is set to 1, the BCLK clock divided by 2 is output from the EBCLK pin. The frequency is specified by the following bits.

- BCK[3:0] bits in SCKDIVCR
- CKSEL[2:0] bits in SCKSCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0] bits in PLLCCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

A frequency higher than the system clock (ICLK) should not be set for BCLK.

9.10.7 SDRAM Clock (SDCLK)

The SDRAM clock (SDCLK) is the operating clock for the external bus controller. It is output externally from the SDCLK pin to SDRAM that is connected to the external bus.
To output SDCLK from the SDCLK pin, set the SDCKOCR.SDCKOEN bit to 1 and the P700PFS.PSEL[6:0] bits to 0111101b (SDCLK output is enabled). The value of the P700PFS.PSEL[6:0] bits can be changed to 0111101b only when the SDCKOCR.SDCKOEN bit is 0. The frequency is specified by the following bits.

- BCK[3:0] bits in SCKDIVCR
- CKSEL[2:0] bits in SCKSCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR

- PLODIVP[3:0] bits in PLLCCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

A frequency higher than the system clock (ICLK) should not be set for SDCLK.

9.10.8 SCI Clock (SCICLK)

The SCI clock (SCICLK) is the operating clock for the RSCI. The frequency is specified by the following bits.

- SCICKDIV[3:0] bits in SCICKDIVCR
- SCICKSEL[3:0] bits in SCICKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.9 SPI Clock (SPICLK)

The SPI clock (SPICLK) is the operating clock for the RSPIA. The frequency is specified by the following bits.

- SPICKDIV[3:0] bits in SPICKDIVCR
- SPICKSEL[3:0] bits in SPICKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.10 XSPI Clock (XSPICLK, XSPIDIVCLK)

The XSPI clock (XSPICLK) is the operating clock for the XSPI. The frequency is specified by the following bits.

- XSPICKDIV[3:0] bits in XSPICKDIVCR
- XSPICKSEL[3:0] bits in XSPICKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

XSPICLK divided by 2 is always output for XSPIDIVCLK.

9.10.11 CANFD Core Clock (CANFDCLK)

The CANFD core clock (CANFDCLK) is the operating clock for the CANFD and CANFDG. The frequency is specified by the following bits.

- CANFDCKDIV[3:0] bits in CANFDCKDIVCR
- CANFDCKSEL[3:0] bits in CANFDCKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.12 USB Clock (USBCLK)

The USB clock (USBCLK) is the operating clock for the USB and USBHS.
A 48-MHz clock must be supplied when using the USB module or when using the USBHS module in classic-only mode (CL-only mode). USBCLK does not need to be supplied except for when using the USBHS in CL-only mode.
The frequency is specified by the following bits.

- USBCKDIV[3:0] bits in USBCKDIVCR
- USBCKSEL[3:0] bits in USBCKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.13 USBHS-PHY Clock (USB60CLK)

The USBHS-PHY clock (USB60CLK) is the operating clock for the USBHS. A 60-MHz clock must be supplied when using the USBHS in CL-only mode. USB60CLK does not need to be supplied except for when using the USBHS in CL-only mode.
The frequency is specified by the following bits.

- USB60CKDIV[3:0] bits in USB60CKDIVCR
- USB60CKSEL[3:0] bits in USB60CKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2

- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.14 MOSC Clock for USBHS (USBMCLK)

The MOSC clock for USBHS (USBMCLK) is the operating clock for the USBHS module when it is used in modes other than CL-only mode. USBMCLK does not need to be supplied when using the USBHS module in CL-only mode.
The USBMCLK frequency is 12, 20, 24, or 48 MHz, and it is supplied from the main clock oscillator.

9.10.15 ADC Clock (ADCCLK)

The ADC clock (ADCCLK) is the operating clock for the ADC16H. The frequency is specified by the following bits.

- ADCCKDIV[3:0] bits in ADCCKDIVCR
- ADCCKSEL[3:0] bits in ADCCKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.16 GPT Clock (GPTCLK)

The GPT clock (GPTCLK) is the operating clock for the GPTW, PCIF, and ADC16H. The frequency is specified by the following bits.

- GPTCKDIV[3:0] bits in GPTCKDIVCR
- GPTCKSEL[3:0] bits in GPTCKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.17 I3C Clock (I3CCLK)

The I3C clock (I3CCLK) is the operating clock for the RI3C and RIICHS. The frequency is specified by the follwing bits.

- I3CCKDIV[3:0] bits in I3CCKDIVCR
- I3CCKSEL[3:0] bits in I3CCKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.18 Asynchronous External Bus Clock (BCLKA, EBCLK)

The asynchronous external bus clock (BCLKA) is used as the operating clock for the external bus controller. It is also output externally from the EBCLK pin on the external bus.
BCLKA can be output from the EBCLK pin by setting the EBCKOCR.EBCKOEN bit to 1 and the P801PFS.PSEL[6:0] bits to 0111101b. Change the value of the P801PFS.PSEL[6:0] bits to 0111101b only while the EBCKOCR.EBCKOEN bit is 0.
BCLKA can be selected by setting the BCKCR.EBCKASEL bit to 1. When BCLKA is selected, set the BCKCR.BCLKDIV bit to 0. The frequency is specified by the following bits.

- BCKACKDIV[3:0] bits in BCKADIVCR
- BCKACKSEL[3:0] bits in BCKACR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.19 ESWM Clock (ESWCLK)

The ESWM clock (ESWCLK) is the operating clock for the ESWM. The frequency is specified by the following bits.

- ESWCKDIV[3:0] bits in ESWCKDIVCR
- ESWCKSEL[3:0] bits in ESWCKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset,

therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.20 ESWM-PHY Clock (ESWPHYCLK)

The ESWM-PHY clock (ESWPHYCLK) is the operating clock for the ESWM. The frequency is specified by the following bits.

- ESWPCKDIV[3:0] bits in ESWPCKDIVCR
- ESWPCKSEL[3:0] bits in ESWPCKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.21 Ethernet-PHY Clock (ETHPHYCLK)

The Ethernet-PHY clock (ETHPHYCLK) is the clock for the ETHPHYCLK pin output. The frequency is specified by the following bits.

- ETHPCKDIV[3:0] bits in ETHPCKDIVCR
- ETHPCKSEL[3:0] bits in ETHPCKCR
- PLLMUL[8:0], PLLMULNF[1:0], and PLIDIV[1:0] bits in PLLCCR
- PLODIVP[3:0], PLODIVQ[3:0], and PLODIVR[3:0] bits in PLLCCR2
- PLL2MUL[8:0], PLL2MULNF[1:0], and PL2IDIV[1:0] bits in PLL2CCR
- PL2ODIVP[3:0], PL2ODIVQ[3:0], and PL2ODIVR[3:0] bits in PLL2CCR2
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.22 CANFD Main Clock (CANFDMCLK)

The CANFD main clock (CANFDMCLK) is the operating clock for the CANFD and CANFDG. CANFDMCLK is generated by the main clock oscillator.

9.10.23 CAC Clock (CACCLK)

The CAC clock (CACCLK) is the operating clock for the CAC.CACCLK includes the following clocks.

- CAC main clock (CACMCLK) that is generated by the main clock oscillator
- CAC sub-clock (CACSCLK) that is generated by the sub-clock oscillator
- CAC HOCO clock (CACHCLK) that is generated by the HOCO
- CAC MOCO clock (CACMOCLK) that is generated by the MOCO
- CAC LOCO clock (CACLCLK) that is generated by the LOCO
- CAC PLL1P clock (CACPL1PCLK) that is generated from the PLL1P clock of PLL1
- CAC PLL1Q clock (CACPL1QCLK) that is generated from the PLL1Q clock of PLL1

- CAC PLL1R clock (CACPL1RCLK) that is generated from the PLL1R clock of PLL1
- CAC PLL2P clock (CACPL2PCLK) that is generated from the PLL2P clock of PLL2
- CAC PLL2Q clock (CACPL2QCLK) that is generated from the PLL2Q clock of PLL2
- CAC PLL2R clock (CACPL2RCLK) that is generated from the PLL2R clock of PLL2

9.10.24 RTC Clock (RTCSCLK, RTCLCLK)

The RTC clock (RTCSCLK, RTCLCLK) is the operating clock for the RTC.
RTCSCLK is generated by the sub-clock oscillator, and RTCLCLK is generated by the LOCO.

9.10.25 IWDT Clock (IWDTCLK)

The IWDT clock (IWDTCLK) is the operating clock for the IWDT.
IWDTCLK is internally generated by the LOCO which always divides the clock by 2.

9.10.26 PDMIF Clock (PDMIFCLK)

The PDMIF clock (PDMIFCLK) is the operating clock for the PDMIF.
PDMIFCLK is generated by the MOCO.

9.10.27 External Pin Output Clock (CLKOUT)

CLKOUT is output externally from the CLKOUT pin for the clock output or buzzer output. CLKOUT is output to the CLKOUT pin when the CKOCR.CKOEN bit is set to 1. The value of the CKODIV[2:0] or CKOSEL[3:0] bits can be changed only when the CKOCR.CKOEN bit is 0.
The frequency is specified by the following bits.

- CKODIV[2:0] and CKOSEL[3:0] bits in CKOCR
- HOCOFRQ0[2:0] bits in OFS1 and HCFRQ0[2:0] bits in HOCOCR2*1

Note 1. The value of OFS1.HOCOFRQ0[2:0] bits is automatically transferred to HOCOCR2.HCFRQ0[2:0] bits after reset, therefore HOCO frequency can also be specified by HOCOCR2.HCFRQ0[2:0] bits.

9.10.28 JTAG Clock

The JTAG clock (JTAGTCK) is the clock for the JTAG. JTAGTCK is generated from the JTAG external clock (TCK).

9.11 Clock Setting

9.11.1 Setting the System Clock

9.11.1.1 Initial Settings of the System Clock

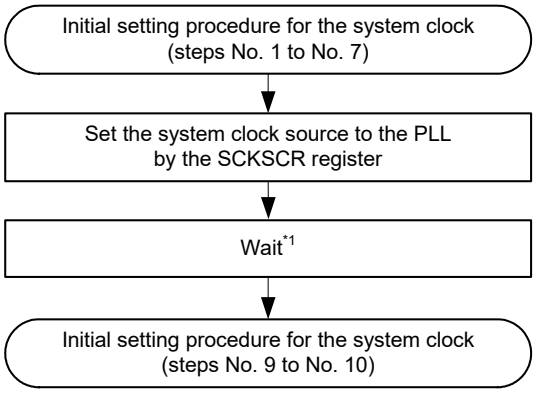

Table 9.6 shows an example of the procedure for making initial settings of the system clock.

Table 9.6 Example of the Procedure for Making Initial Settings of the System Clock (After Release from the Reset State or Deep Software Standby Mode)

No.	Step	Description
1	Start	After release from the reset state or deep software standby mode (MOCO is selected as the system clock source)
2	Cancel write protection for registers	Set the PRC0 bit in the PRCR register to 1.
3	Set the clock source to oscillate	Set the clock source that is switched to be the system clock source to start oscillation.
4	Set wait cycles for MRAM and SRAM	Set the number of wait cycles for access to MRAM and SRAM according to the operating frequency after the system clock (ICLK), MRICLK, and MRPCLK have been set. For details, see section 64, SRAM and section 65, MRAM.
5	Set voltage scaling	Set an appropriate target voltage of VDD according to the frequency of each clocks after switching the system clock. For details, see section 11, Low Power Consumption.
6	Set the internal clock frequency division ratios	Set the internal clock frequency division ratios with the SCKDIVCR and SCKDIVCR2 registers.
7	Set the external bus clock output or SDRAM clock output*1	Set the EBCLK pin output with the BCKCR register. Set the SDCLK pin output with the SDCKOCR register.
8	Switch the system clock source	Switch the system clock source with the SCKSCR register. Before switching the system clock source, make sure that oscillation of the clock source is stable.
9	Set write protection for registers	Set the PRC0 bit in the PRCR register to 0.
10	End	Setup of the system clock is complete.

Note 1. This setting is not required when the external bus or SDRAM is not used.

When PLL1 is selected as the system clock source, an additional step is required at step No. 8. This additional step is shown in Figure 9.14. It is recommended to use software to measure the wait time. Be sure to consider the worst-case conditions to ensure that the required wait time elapses. If an interrupt is unavoidably generated during the wait time, wait again after return from the interrupt.

Note 1. 30 µs is in DCDC mode, 10 µs in External VDD mode. No wait time is required in LDO mode.

Figure 9.14 Additional Flow of Initial System Clock Setting When PLL1 is Selected for the System Clock Source (Assuming All Module Stop Bits are Initial Value)

9.11.1.2 Setting the System Clock to Increase the Frequency

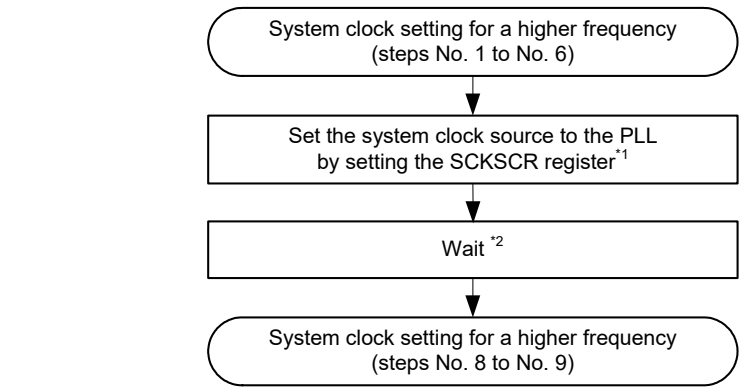

Table 9.7 shows an example of the procedure for making settings to change the current system clock frequency to a higher frequency.

Table 9.7 Example of the Procedure for Making Settings to Increase the Current System Clock Frequency

No.	Step	Description
1	Start	
2	Cancel write protection for registers	Set the PRC0 bit in the PRCR register to 1.
3	Set the clock source to oscillate	Set the clock source that is switched to be the system clock source to start oscillation.*1
4	Set wait cycles for MRAM and SRAM	Set the number of wait cycles for access to MRAM and SRAM according to the operating frequency after the system clock (ICLK), MRICLK, and MRPCLK have been set. For details, see section 64, SRAM and section 65, MRAM.
5	Set voltage scaling	Set an appropriate target voltage of VDD according to the frequency of each clocks after switching the system clock. For details, see section 11, Low Power Consumption.
6	Set the internal clock frequency division ratios	Set the internal clock frequency division ratios with the SCKDIVCR and SCKDIVCR2 registers.
7	Switch the system clock source*2	Switch the system clock source with the SCKSCR register. Before switching the system clock source, make sure that oscillation of the clock source is stable.
8	Set write protection for registers	Set the PRC0 bit in the PRCR register to 0.
9	End	The frequency of the system clock becomes higher.

Note 1. To change the frequency of the PLL selected as the system clock source, it is necessary to change the system clock source to another clock source, stop the PLL, and then change the PLL setting.
Note 2. This setting is not required when the system clock source is not changed.

When PLL1 is selected as the system clock source, an additional step is required at step No. 7. This additional step is shown in Figure 9.15. It is recommended to use software to measure the wait time. Be sure to consider the worst-case conditions to ensure that the required wait time elapses. If an interrupt is unavoidably generated during the wait time, wait again after return from the interrupt.

Note 1. Do not set the SCKSCR register when the PLL is already selected.
Note 2. 30 µs is in DCDC mode, 10 µs in External VDD mode. No wait time is required in LDO mode.

Figure 9.15 Additional Flow for Setting the System Clock (When Using a PLL for the System Clock Source and CPUCLK0 and Increasing the Frequency)

9.11.1.3 Setting the System Clock to Decrease the Frequency

Table 9.8 shows an example of the procedure for making settings to change the current system clock frequency to a lower frequency.

Table 9.8 Example of the Procedure for Making Settings to Decrease the Current System Clock Frequency

No.	Step	Description
1	Start	
2	Cancel write protection for registers	Set the PRC0 bit in the PRCR register to 1.
3	Set the clock source to oscillate*1	Set the clock source that is switched to be the system clock source to start oscillation.*2
4	Set the internal clock frequency division ratios	Make the following settings so that the frequency does not exceed the range of the electrical characteristics when the system clock source is switched in the next step. • Set the internal clock frequency division ratios to be greater than the current division ratio. • Set the internal clock frequency division ratios so that the frequency after the switchover of the system clock source is lower than the current frequency.*1
5	Switch the system clock source*1	Switch the system clock source with the SCKSCR register. Before switching the system clock source, make sure that oscillation of the clock source is stable.
6	Re-set the internal clock frequency division ratios	Re-set the internal clock frequency division ratios with the SCKDIVCR and SCKDIVCR2 registers, according to the frequency after the system clock source has been switched.
7	Set voltage scaling	Set an appropriate target voltage of VDD according to the frequency of each clocks after switching the system clock. For details, see section 11, Low Power Consumption.
8	Set wait cycles for MRAM and SRAM	Set an access wait cycle count for MRAM and SRAM according to the frequency at which it operates after the system clock (ICLK), MRICLK, and MRPCLK have been set. For details, see section 64, SRAM and section 65, MRAM.
9	Set write protection for registers	Set the PRC0 bit in the PRCR register to 0.
10	End	The frequency of the system clock becomes lower.

Note 1. This setting is not required when the system clock source is not changed.
Note 2. To change the frequency of the PLL selected as the system clock source, it is necessary to change the system clock source to another clock source, stop the PLL, and then change the PLL setting.

When the PLL1 is selected as the system clock source before switching the system clock source, additional procedure is required before procedure No.4. This additional step is shown in Figure 9.16. It is recommended to use software to measure the wait time. Be sure to consider the worst-case conditions to ensure that the required wait time elapses. If an interrupt is unavoidably generated during the wait time, wait again after return from the interrupt.

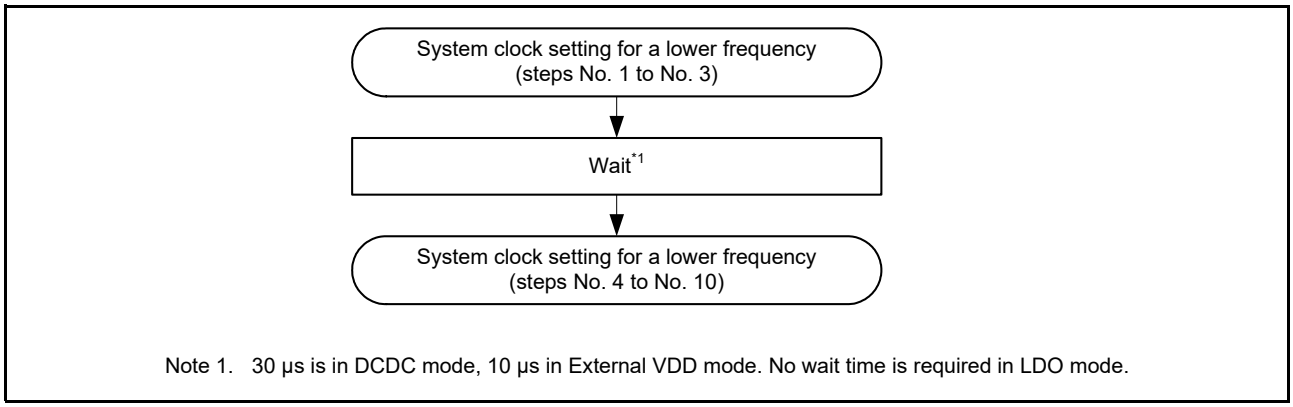

Figure 9.16 Additional Flow for Setting the System Clock (When Using a PLL for the System Clock Source and CPUCLK0 and Decreasing the Frequency)

9.11.2 Setting Peripheral Module-Dedicated Clocks

The procedures for setting peripheral module-dedicated clocks are described. The target clocks are SCICLK, SPICLK, XSPICLK, CANFDCLK, USBCLK, USB60CLK, ADCCLK, GPTCLK, I3CCLK, BCLKA, ESWCLK, ESWPHYCLK, and ETHPHYCLK.

9.11.2.1 Initial Settings of a Peripheral Module-Dedicated Clock

Table 9.9 shows an example of the procedure for making initial settings of a peripheral module-dedicated clock.

Table 9.9 Example of the Procedure for Making Initial Settings of a Peripheral Module-Dedicated Clock (After Release from the Reset State or Deep Software Standby Mode)

No.	Step	Description
1	Start	After release from the reset state or deep software standby mode (MOCO is selected as the system clock source)
2	Cancel write protection for registers	Set the PRC0 bit in the PRCR register to 1.
3	Set the CKSREQ bit to 1 and wait for the CKSRDY flag to be set	Write 1 to the CKSREQ bit in each CKCR register. Carry out polling until the CKSRDY flag in each CKCR register is read as 1. When the CKSRDY flag becomes 1, the clock supply is stopped.
4	Set the clock source to oscillate	Set the clock source that is switched to be the system clock source to start oscillation.
5	Set the clock frequency division ratio and switch the clock source	Write the setting value to the CKDIV[3:0] bits in each CKDIVCR register. Write the setting value to the CKSEL[3:0] bits in each CKCR register.
6	Set the CKSREQ bit to 0 and wait for the CKSRDY flag to be cleared	Write 0 to the CKSREQ bit in each CKCR register. Carry out polling until the CKSRDY flag in each CKCR register is read as 0. When the CKSRDY flag becomes 0, the clock supply is started.
7	Cancel the module stop control	Cancel the module stop control in the MSTPCRn register (n = A to F) and supply the clock to the peripheral module.
8	Set write protection for registers	Set the PRC0 bit in the PRCR register to 0.
9	End	Setup of the clock is complete. After that, set the peripheral module.

9.11.2.2 Changing the Clock Source of a Peripheral Module-Dedicated Clock

Table 9.10 shows an example of the procedure for changing the settings when switching the clock source of a peripheral module-dedicated clock.

Table 9.10 Example of the Procedure for Changing the Settings When Switching the Clock Source of a Peripheral Module-Dedicated Clock

No.	Step	Description
1	Start	The operating clock for the peripheral module is being used.
2	Stop the peripheral module	Stop the operation of the peripheral module whose operating clock is to be changed.
3	Cancel write protection for registers	Set the PRC0 bit in the PRCR register to 1.
4	Set the CKSREQ bit to 1 and wait for the CKSRDY flag to be set	Write 1 to the CKSREQ bit in each CKCR register. Carry out polling until the CKSRDY flag in each CKCR register is read as 1. When the CKSRDY flag becomes 1, the clock supply is stopped.
5	Set the clock source to oscillate	Set the clock source that is switched to be the system clock source to start oscillation.
6	Set the clock frequency division ratio and switch the clock source	Write the setting value to the CKDIV[3:0] bits in each CKDIVCR register. Write the setting value to the CKSEL[3:0] bits in each CKCR register.
7	Set the CKSREQ bit to 0 and wait for the CKSRDY flag to be cleared	Write 0 to the CKSREQ bit in each CKCR register. Carry out polling until the CKSRDY flag in each CKCR register is read as 0. When the CKSRDY flag becomes 0, the clock supply is started.
8	Set write protection for registers	Set the PRC0 bit in the PRCR register to 0.
9	Restart the peripheral module	After the settings of the operating clock have been changed, in accordance with those settings, change the settings of the peripheral module. After that, restart the operation of the peripheral module.
10	End	Setup of the clock is complete.

9.11.2.3 Changing the Division Ratio of a Peripheral Module-Dedicated Clock

Table 9.11 shows an example of the procedure for changing the settings when switching the division ratio of a peripheral module-dedicated clock.

Table 9.11 Example of the Procedure for Changing the Settings When Switching the Division Ratio of a Peripheral Module-Dedicated Clock (No Change in the Clock Source)

No.	Step	Description
1	Start	The operating clock for the peripheral module is being used.
2	Stop the peripheral module	Stop the operation of the peripheral module whose operating clock is to be changed.
3	Cancel write protection for registers	Set the PRC0 bit in the PRCR register to 1.
4	Set the clock frequency division ratio	Write the setting value to the CKDIV[3:0] bits in each CKDIVCR register.
5	Set write protection for registers	Set the PRC0 bit in the PRCR register to 0.
6	Restart the peripheral module	After the settings of the operating clock have been changed, in accordance with those settings, change the settings of the peripheral module. After that, restart the operation of the peripheral module.
7	End	Setup of the clock is complete.

9.11.3 Setting the Main Clock Oscillator

Table 9.12 shows an example of the procedure for making initial settings of the main clock oscillator.

Table 9.12 Example of the Procedure for Making Initial Settings of the Main Clock Oscillator (After Release from the Reset State or Deep Software Standby Mode)

No.	Step	Description
1	Start	The main clock oscillator is stopped after release from the reset state or deep software standby mode.
2	Cancel write protection for registers	Set the PRC0 bit in the PRCR register to 1.
3	Set the mode of the main clock oscillator	Set the following main clock oscillator mode with the MOMCR register. • Resonator or clock input • Driving capacity
4	Set the oscillation stabilization wait time	Set the oscillation stabilization wait time of the main clock oscillator in the MOSCWTCR register.
5	Set oscillation keeping in software standby mode	Set the MOSCSCR register if the main clock oscillator keeps oscillating in software standby mode.
6	Set the main clock oscillator to operate	Set the main clock oscillator to start oscillating with the MOSCCR register.
7	Wait for main clock oscillation to become stable	Carry out polling until the MOSCSF flag in the OSCSF register is read as 1 (oscillation is stable).
8	Set write protection for registers	Set the PRC0 bit in the PRCR register to 0.
9	End	Setup of the main clock oscillator is complete. The main clock is available.

9.11.4 Setting the Sub-Clock Oscillator

Table 9.13 shows an example of the procedure for making initial settings of the sub-clock oscillator.

Table 9.13 Example of the Procedure for Making Initial Settings of the Sub-Clock Oscillator (After Release from the Backup Domain Reset State)

No.	Step	Description
1	Start	The sub-clock oscillator is stopped after release from the backup domain reset state.
2	Cancel write protection for registers	Set the PRC0 bit in the PRCR register to 1.
3	Set the mode of the sub-clock oscillator	Set the following sub-clock oscillator mode with the SOMCR register. • Resonator or clock input • Driving capacity
4	Set the sub-clock oscillator to operate	Set the sub-clock oscillator to start oscillating with the SOSCCR register.
5	Wait for sub-clock oscillation to become stable	Wait for the oscillation stabilization wait time of the sub-clock (tSUBOSCWT) to elapse. For the oscillation stabilization wait time of the sub-clock, see section 67, Electrical Characteristics.
6	Set write protection for registers	Set the PRC0 bit in the PRCR register to 0.
7	End	Setup of the sub-clock oscillator is complete. The sub-clock is available.

9.11.5 Setting the High-Speed On-Chip Oscillator

9.11.5.1 Initial Settings of the HOCO Clock

Table 9.14 shows an example of the procedure for making initial settings of the HOCO.

Table 9.14 Example of the Procedure for Making Initial Settings of the HOCO (After Release from the Reset State or Deep Software Standby Mode) (OFS1.HOCOEN = 1, without the FLL Function)

No.	Step	Description
1	Start	The HOCO is stopped after release from the reset state or deep software standby mode when the OFS1.HOCOEN bit is 1.
2	Cancel write protection for registers	Set the PRC0 and PRC1 bits in the PRCR register to 1.
3	Check the HOCO power supply*1	Confirm that the following bit in the HOCOLDOCR register is set as shown. • LDOSTP bit is 0 (LDO is enabled)
4	Set the HOCO frequency	Set the HOCO frequency with the HOCOCR2 register.
5	Set oscillation keeping in software standby mode	Set the following if the HOCO keeps oscillating in software standby mode. • HOCOSOKP bit in the HOCOSCR register • SKEEP bit in the HOCOLDOCR register
6	Set the HOCO to operate	Set the HOCO to start oscillating with the HOCOCR register.
7	Wait for HOCO clock oscillation to become stable	Carry out polling until the HOCOSF flag in the OSCSF register is read as 1 (oscillation is stable).
8	Set write protection for registers	Set the PRC0 and PRC1 bits in the PRCR register to 0.
9	End	Setup of the HOCO is complete. The HOCO clock is available.

Note 1. When the HOCOLDOCR.LDOSTP bit is 1, do not operate the HOCO. If the HOCOLDOCR.LDOSTP bit is switched from 1 to 0, it is necessary to wait until the HOCO power supply has stabilized. For the wait time required until the HOCO power supply becomes stable, see section 67, Electrical Characteristics.

9.11.5.2 Setting the HOCO by the FLL Function

Table 9.15 shows an example of the procedure for making initial settings of the HOCO using the FLL function.
Table 9.16 shows the flow for setting the FLL function when placing the MCU in software standby mode and releasing the MCU from software standby mode.

Table 9.15 Example of the Procedure for Making Initial Settings of the HOCO Using the FLL Function (After Release from the Reset State or Deep Software Standby Mode) (OFS1.HOCOEN = 1)

No.	Step	Description
1	Start	The HOCO is stopped after release from the reset state or deep software standby mode when the OFS1.HOCOEN bit is 1.
2	Cancel write protection for registers	Set the PRC0 and PRC1 bits in the PRCR register to 1.
3	Check the HOCO power supply*1	Confirm that the following bit in the HOCOLDOCR register is set as shown. • LDOSTP bit is 0 (LDO is enabled)
4	Set the HOCO frequency	Set the HOCO frequency with the HOCOCR2 register.
5	Enable the FLL function*2	Set FLL multiplication control with the FLLCR2 register. Set the FLL function to be enabled with the FLLCR1 register.
6	Set the HOCO to operate	Set the HOCO to start oscillating with the HOCOCR register.
7	Wait for HOCO clock oscillation to become stable	Carry out polling until the HOCOSF flag in the OSCSF register is read as 1 (oscillation is stable).
8	Wait for FLL stabilization	Wait for the FLL stabilization wait time (tFLLWT) to elapse or wait until the frequency accuracy being stable can be confirmed by measuring the HOCO clock.
9	Check the HOCO stabilization	Check that the HOCOSF flag in the OSCSF register is read as 1.
10	Set write protection for registers	Set the PRC0 and PRC1 bits in the PRCR register to 0.
11	End	Setup of the HOCO is complete. The HOCO clock is available.

Note 1. When the HOCOLDOCR.LDOSTP bit is 1, do not operate the HOCO. If the HOCOLDOCR.LDOSTP bit is switched from 1 to 0, it is necessary to wait until the HOCO power supply has stabilized. For the wait time required until the HOCO power supply becomes stable, see section 67, Electrical Characteristics.
Note 2. The sub-clock oscillator must be oscillating stably.

Table 9.16 Flow for Setting the FLL Function at a Transition to Software Standby Mode and Release from Software Standby Mode

No.	Step	Description
1	Start	The HOCO is operating with the FLL function enabled.
2	Cancel write protection for registers	Set the PRC0 and PRC1 bits in the PRCR register to 1.
3	Stop the HOCO*1	Stop the HOCO with the HOCOCR register.
4	Disable the FLL function	Set the FLL function to be disabled with the FLLCR1 register.
5	WAIT instruction*2	The MCU is placed in software standby mode by the WAIT instruction.
6	Software standby mode*2	The MCU is in software standby mode.
7	Release from software standby mode*2	Release the MCU from software standby mode.
8	Enable the FLL function*3	Set FLL multiplication control with the FLLCR2 register. Set the FLL function to be enabled with the FLLCR1 register.
9	Set the HOCO to operate	Set the HOCO to start oscillating with the HOCOCR register.
10	Wait for FLL stabilization	Wait for the FLL stabilization wait time (tFLLWT) to elapse or wait until the frequency accuracy being stable can be confirmed by measuring the HOCO clock at CAC.
11	Check the HOCO stabilization	Check that the HOCOSF flag in the OSCSF register is read as 1.
12	Set write protection for registers	Set the PRC0 and PRC1 bits in the PRCR register to 0.
13	End	The HOCO clock is available.

Note 1. If the HOCO is used as the system clock source or the clock source of PLL, these clock sources must be changed to another clock before the HOCO is stopped.
Note 2. For details on software standby mode, see section 11, Low Power Consumption.
Note 3. The sub-clock oscillator must be oscillating stably.

9.11.6 Setting PLL Circuits

9.11.6.1 Initial Settings of a PLL Clock

Table 9.17 shows an example of the procedure for making initial settings of a PLL.

Table 9.17 Example of the Procedure for Making Initial Settings of a PLL (After Release from the Reset State or Deep Software Standby Mode) (PLL1 or PLL2)

No.	Step	Description
1	Start	PLL1 is stopped after release from the reset state or deep software standby mode. PLL2 is stopped after release from the reset state or deep software standby mode.
2	Cancel write protection for registers	Set the PRC0 and PRC1 bits in the PRCR register to 1.
3	Check the PLL power supply PLL*1	[PLL1] Confirm that the following bit in the PLL1LDOCR register is set as shown. • LDOSTP bit is 0 (LDO is enabled) [PLL2] Confirm that the following bit in the PLL2LDOCR register is set as shown. • LDOSTP bit is 0 (LDO is enabled)
4	Set the PLL	[PLL1] Make the following PLL1 settings with the PLLCCR and PLLCCR2 registers. [PLL2] Make the following PLL2 settings with the PLL2CCR and PLL2CCR2 registers. [Setting items] • PLL input frequency division ratio • PLL clock source • Frequency multiplication ratio • Frequency multiplication fractional ratio • PLL output frequency division ratio (P/Q/R)
5	Set the PLL to operate	[PLL1] Set PLL1 to start oscillating with the PLLCR register. [PLL2] Set PLL2 to start oscillating with the PLL2CR register.
6	Wait for PLL clock oscillation to become stable	[PLL1] Carry out polling until the PLLSF flag in the OSCSF register is read as 1 (oscillation is stable). [PLL2] Carry out polling until the PLL2SF flag in the OSCSF register is read as 1 (oscillation is stable).
7	Set write protection for registers	Set the PRC0 and PRC1 bits in the PRCR register to 0.
8	End	Setup of the PLL1 or PLL2 is complete. [PLL1] The PLL1P, PLL1Q, or PLL1R clock is available. [PLL2] The PLL2P, PLL2Q, or PLL2R clock is available.

Note 1. When the PLL1LDOCR.LDOSTP bit is 1, do not operate PLL1. If the PLL1LDOCR.LDOSTP bit is switched from 1 to 0, it is necessary to wait until the PLL1 power supply has stabilized. For the wait time required until the PLL1 power supply becomes stable, see section 67, Electrical Characteristics.
When the PLL2LDOCR.LDOSTP bit is 1, do not operate PLL2. If the PLL2LDOCR.LDOSTP bit is switched from 1 to 0, it is necessary to wait until the PLL2 power supply has stabilized. For the wait time required until the PLL2 power supply becomes stable, see section 67, Electrical Characteristics.

9.11.6.2 Changing the PLL Settings

Table 9.18 shows an example of the procedure for changing the PLL settings.

Table 9.18 Example of the Procedure for Changing the PLL Settings (PLL1 or PLL2)

No.	Step	Description
1	Start	PLL1 is oscillating and the PLL1 clocks (PLL1P, PLL1Q, and PLL1R) are being used. PLL2 is oscillating and the PLL2 clocks (PLL2P, PLL2Q, and PLL2R) are being used.
2	Cancel write protection for registers	Set the PRC0 and PRC1*1 bits in the PRCR register to 1.
3	Stop the PLL*1	[PLL1] Stop PLL1 with the PLLCR register. [PLL2] Stop PLL2 with the PLL2CR register.
4	Change the PLL settings	[PLL1] Make the following PLL1 settings with the PLLCCR and PLLCCR2 registers. [PLL2] Make the following PLL2 settings with the PLL2CCR and PLL2CCR2 registers. [Setting items] • PLL input frequency division ratio • PLL clock source • Frequency multiplication ratio • Frequency multiplication fractional ratio • PLL output frequency division ratio (P/Q/R)
5	Set the PLL to operate	[PLL1] Set PLL1 to start oscillating with the PLLCR register. [PLL2] Set PLL2 to start oscillating with the PLL2CR register.
6	Wait for PLL clock oscillation to become stable	[PLL1] Carry out polling until the PLLSF flag in the OSCSF register is read as 1 (oscillation is stable). [PLL2] Carry out polling until the PLL2SF flag in the OSCSF register is read as 1 (oscillation is stable)
7	Set write protection for registers	Set the PRC0 and PRC1*1 bits in the PRCR register to 0.
8	End	Setup of the PLL1 or PLL2 is complete. [PLL1] The PLL1P, PLL1Q, or PLL1R clock is available. [PLL2] The PLL2P, PLL2Q, or PLL2R clock is available.

Note 1. If the PLL1P clock is used as the system clock source, the system clock source must be changed to another clock source before PLL1 is stopped.

9.12 Usage Notes

9.12.1 Notes on the Clock Generation Circuit

The frequency of the following clocks supplied to each module changes according to the settings of the SCKDIVCR and SCKDIVCR2 registers.

- CPU clock (CPUCLK0)
- MRAM code bus clock (MRICLK)
- System clock (ICLK)
- Peripheral module clock (PCLKA, PCLKB, PCLKC, PCLKD, PCLKE)
- MRAM peripheral bus clock (MRPCLK)
- External bus clock (BCLK)

Each frequency must meet the following conditions.

- Each frequency must be selected within the operation guaranteed range of the operating frequency (f) that is specified in the AC characteristics. See section 67, Electrical Characteristics.
- Each clock must be set according to Table 9.2.
- Do not change the clock frequency during external bus accesses. Furthermore, when an external bus access is to start after the clock frequency has been changed, make sure to start the external bus access after confirming that the frequency change has been completed.

To ensure correct processing after changing the clock frequency, first write to the relevant clock control register to change the frequency, then read the register value to confirm the change, and finally execute the subsequent processing.

9.12.2 Restrictions on a Resonator

Since resonator characteristics relate closely to the user's board design, adequate evaluation is required before use. For an example of connecting a resonator, see Figure 9.5. The circuit constants for a resonator vary depending on the resonator to be used and the stray capacitance of the circuit on which it is to be mounted. Therefore, the circuit constants should always be determined in consultation with the resonator manufacturer. The voltage to be applied to resonator connection pins must not exceed the absolute maximum rating.

9.12.3 Notes on Board Design

When using a crystal resonator, place the resonator and load capacitors as close to the XTAL and EXTAL pins as possible. Signal lines should be routed away from the oscillation circuit as shown in Figure 9.17 to prevent electromagnetic induction from causing abnormal oscillation. Figure 9.17 shows a case in which the main clock oscillator is used. For a case in which the sub-clock oscillator is used, the figure will be the same as Figure 9.17.

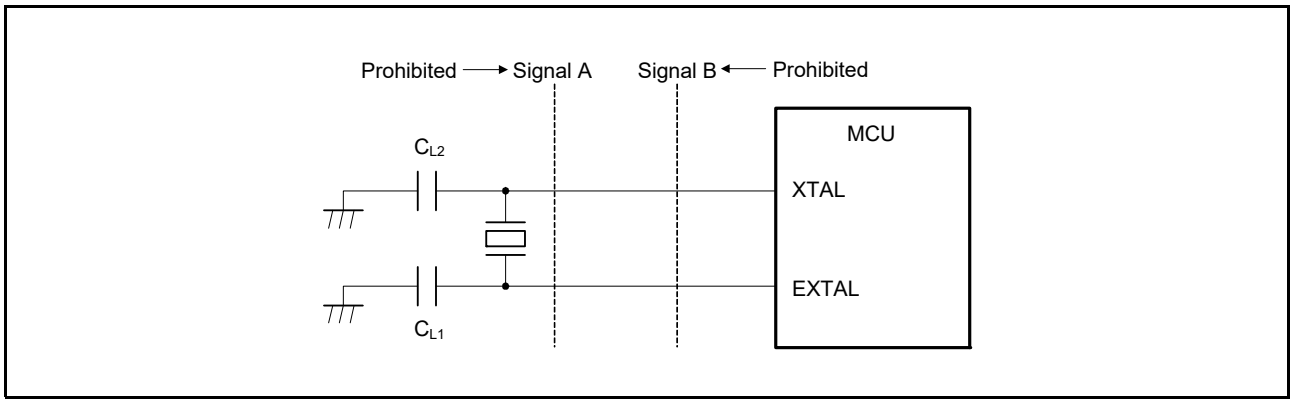

Figure 9.17 Selecting Signal Paths in Oscillation Circuit Board Design

9.12.4 Notes on Resonator Connection Pins

When the main clock is not used, the EXTAL and XTAL pins can be used as general ports. When these pins are used as general ports, the main clock must be stopped (MOSCCR.MOSTP bit should be set to 1).
When the sub-clock is not used, the XCIN and XCOUT pins can be used as general ports. When these pins are used as general ports, the sub-clock must be stopped (SOSCCR.SOSTP bit should be set to 1).

9.12.5 Notes on Using the Sub-Clock Oscillator

The output of the P306 (EXTAL) and P307 (XTAL) pins may affect the oscillation of the sub-clock oscillator.
If the sub-clock oscillator is used, design the board so as not to affect oscillation. When using the P306 (EXTAL) and P307 (XTAL) pins as output pins while using the sub-clock oscillator, setting the P306PFS.DSCR[3:0] and P307PFS.DSCR[3:0] bits to 0000b or 0001b is strongly recommended.
In addition, when using the P306 (EXTAL) and P307 (XTAL) pins as output pins while using the sub-clock oscillator in a low-power mode (SOMCR.SODRV[1:0] = 01b or 10b), setting the P306PFS.DSCR[3:0] and P307PFS.DSCR[3:0] bits to 0000b is recommended.

9.12.6 Notes on the Reset Conditions of the SOSC and LOCO

The RTC is not initialized by any reset source.
The SOSC and LOCO can be selected as the clock source of the RTC. Table 9.19 and Table 9.20 show the states of the SOSC and LOCO when a reset occurs.

Table 9.19 State of the SOSC at a Reset

		Reset Source	
		Backup Area Reset	**Others**
SOSC	Enabled/Disabled	Initialized	The state before the reset is retained.
	Driving capacity	Initialized	The state before the reset is retained.

Table 9.20 State of the LOCO at a Reset

		Reset Source	
		Power-On Reset, Voltage-Monitoring 0, 4, or 5 Reset, Core Voltage Monitoring Reset, or Deep Software Standby 2 or 3 Reset	**Others**
LOCO	Enabled/Disabled	Initialized	
	Oscillation accuracy*1	Initialized to the accuracy before trimming by the LOCOUTCR register (accuracy: ±15%)	The accuracy that was trimmed by the LOCOUTCR register is kept.

Note 1. If the LOCO frequency trimmed by the LOCOUTCR register is selected as the RTC clock source, note that the oscillation accuracy of the LOCO will be initialized by a power-on reset, voltage-monitoring 0, 4, or 5 reset, core voltage monitoring reset, or deep software standby 2 or 3 reset.

After release from the reset state, the reset exception handling starts.
For details on the reset exception handling, see section 6, Resets.

10. Clock Frequency Accuracy Measurement Circuit (CAC)

This MCU incorporates three units of clock frequency accuracy measurement circuits (CAC0 to CAC2).
The CAC counts pulses of the clock to be measured (measurement target clock) within the time generated by the clock to be used as a measurement reference (measurement reference clock), and determines the accuracy depending on whether the number of pulses is within the allowable range.
When measurement is completed or the number of pulses within the time generated by the measurement reference clock is not within the allowable range, an interrupt request is generated.

10.1 Overview

Table 10.1 lists the specifications of the CAC and Figure 10.1 shows a block diagram of the CAC.

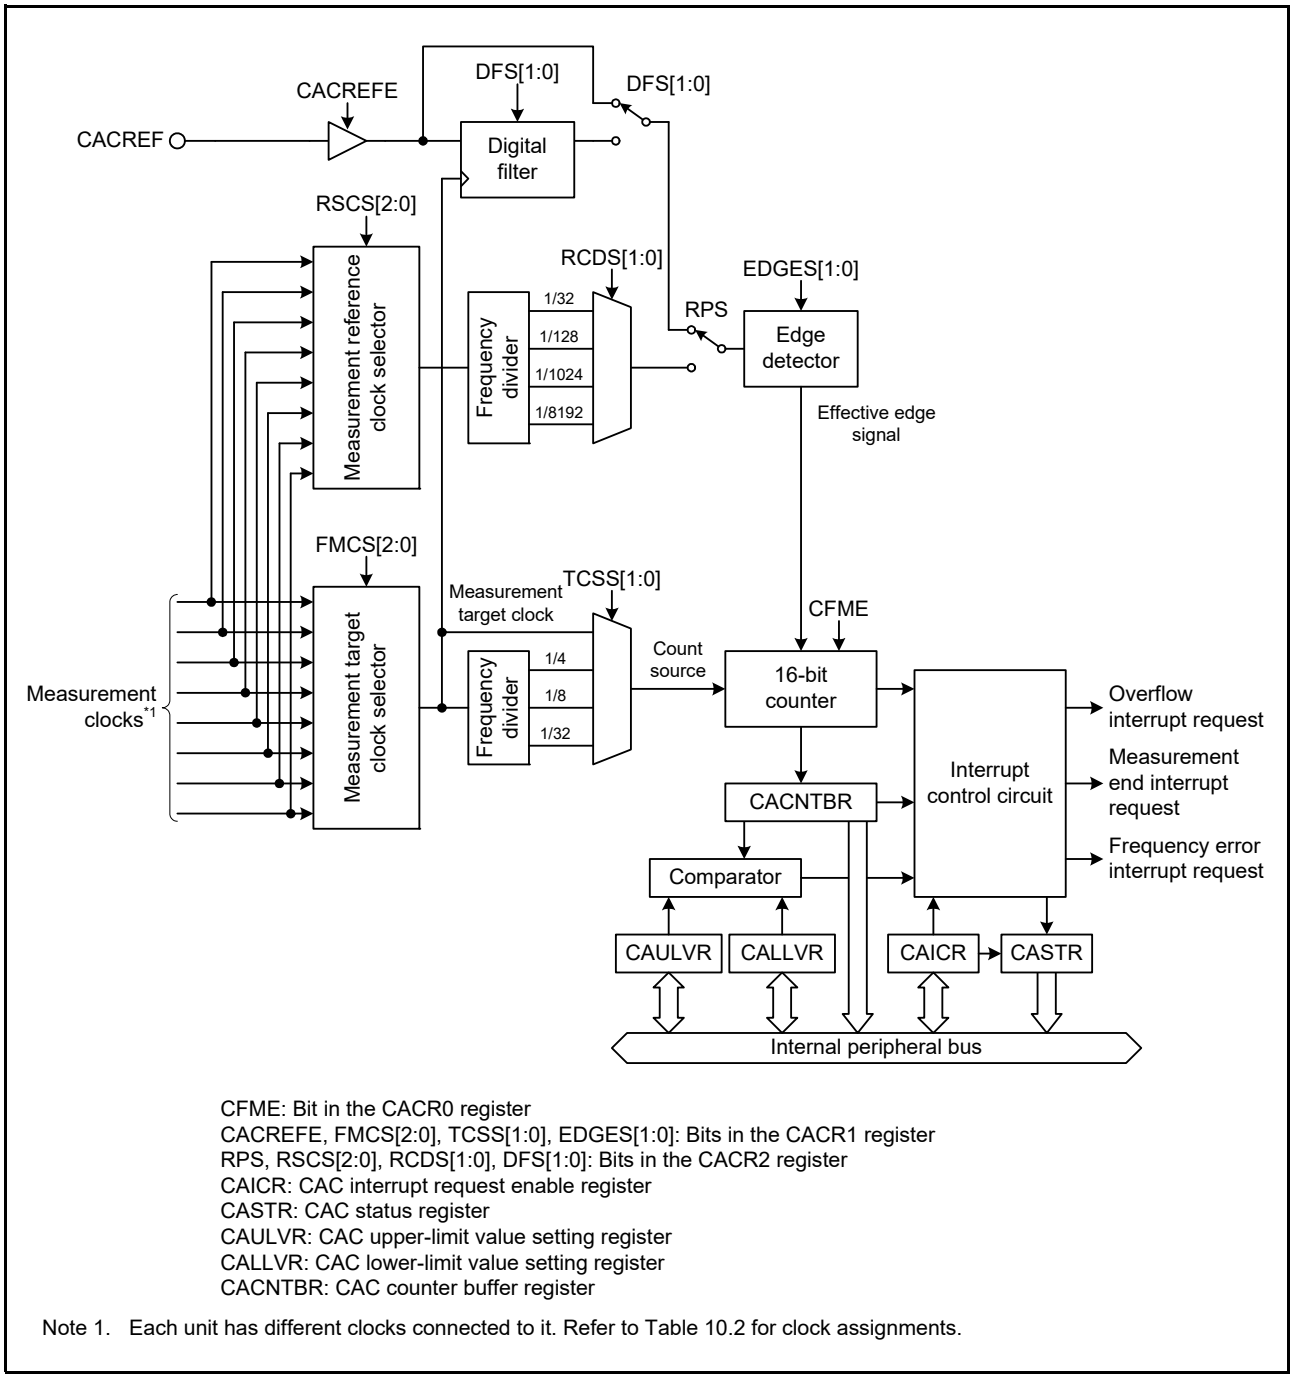

Table 10.1 CAC Specifications

Item	Description
Measurement target clocks*1	The frequency of the following clocks can be measured. • Main clock • Sub-clock • HOCO clock • MOCO clock • LOCO clock • Peripheral module clock B (PCLKB) • PLL1 output clock P/Q/R (divided by 16) • PLL2 output clock P/Q/R (divided by 16)
Measurement reference clocks*1	• External clock input to the CACREF pin • Main clock • Sub-clock • HOCO clock • MOCO clock • LOCO clock • Peripheral module clock B (PCLKB) • PLL1 output clock P/Q/R (divided by 16) • PLL2 output clock P/Q/R (divided by 16)
Selectable function	Digital filter function
Interrupt sources	• Measurement end interrupt • Frequency error interrupt • Overflow interrupt
Low power consumption function	Module stop state can be set.
Protect Zone filter	Security attribute can be set.*2

Note 1. Each unit has different clocks connected to it. Refer to Table 10.2 for clock assignments.
Note 2. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Table 10.2 Clocks Connected to Each Unit

Unit 0	Unit 1	Unit 2
Main clock	Main clock	Main clock
Sub-clock	HOCO clock	HOCO clock
HOCO clock	MOCO clock	MOCO clock
MOCO clock	Peripheral module clock B (PCLKB)	Peripheral module clock B (PCLKB)
LOCO clock	PLL1 output clock P (divided by 16)	PLL2 output clock P (divided by 16)
Peripheral module clock B (PCLKB)	PLL1 output clock Q (divided by 16)	PLL2 output clock Q (divided by 16)
	PLL1 output clock R (divided by 16)	PLL2 output clock R (divided by 16)

CFME: Bit in the CACR0 register
CACREFE, FMCS[2:0], TCSS[1:0], EDGES[1:0]: Bits in the CACR1 register
RPS, RSCS[2:0], RCDS[1:0], DFS[1:0]: Bits in the CACR2 register
CAICR: CAC interrupt request enable register
CASTR: CAC status register
CAULVR: CAC upper-limit value setting register
CALLVR: CAC lower-limit value setting register
CACNTBR: CAC counter buffer register

Note 1. Each unit has different clocks connected to it. Refer to Table 10.2 for clock assignments.

Figure 10.1 CAC Block Diagram

Table 10.3 shows the pin configuration of the CAC.

Table 10.3 Pin Configuration of CAC

Pin Name	I/O	Function
CACREF	Input	Measurement reference clock input pin

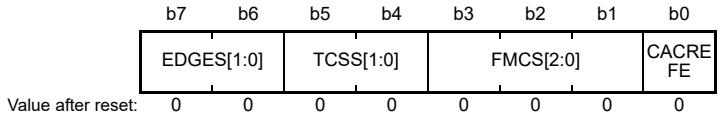
10.2 Register Descriptions

10.2.1 CAC Control Register 0 (CACR0)

Address(es): CAC0.CACR0 8780 2400h, CAC1.CACR0 8780 2480h, CAC2.CACR0 8780 2500h, CAC0_NS.CACR0 0780 2400h, CAC1_NS.CACR0 0780 2480h, CAC2_NS.CACR0 0780 2500h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CFME
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CFME	Clock Frequency Measurement Enable	0: Clock frequency measurement is disabled. 1: Clock frequency measurement is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W



CFME Bit (Clock Frequency Measurement Enable)

This bit specifies whether clock frequency measurement is enabled or disabled.

When rewriting this bit, more time is required than other bits for the new value to be reflected in the register. Further write access to this bit are ignored until the current write access is reflected in the register. Read the bit to confirm that the rewrite has been reflected in the register.

10.2.2 CAC Control Register 1 (CACR1)

Address(es): CAC0.CACR1 8780 2401h, CAC1.CACR1 8780 2481h, CAC2.CACR1 8780 2501h, CAC0_NS.CACR1 0780 2401h, CAC1_NS.CACR1 0780 2481h, CAC2_NS.CACR1 0780 2501h

Bit	Symbol	Bit Name	Description	R/W
b0	CACREFE	CACREF Pin Input Enable	0: CACREF pin input is disabled. 1: CACREF pin input is enabled.	R/W
b3 to b1	FMCS[2:0]	Measurement Target Clock Select	• Unit 0 b3 b1 0 0 0: Main clock 0 0 1: Sub-clock 0 1 0: HOCO clock 0 1 1: MOCO clock 1 0 0: LOCO clock 1 0 1: Peripheral module clock B (PCLKB) Settings other than above are prohibited. • Unit 1 b3 b1 0 0 0: Main clock 0 0 1: PLL1 output clock P (divided by 16) 0 1 0: HOCO clock 0 1 1: MOCO clock 1 0 0: PLL1 output clock Q (divided by 16) 1 0 1: Peripheral module clock B (PCLKB) 1 1 0: PLL1 output clock R (divided by 16) 1 1 1: Setting prohibited. • Unit 2 b3 b1 0 0 0: Main clock 0 0 1: PLL2 output clock P (divided by 16) 0 1 0: HOCO clock 0 1 1: MOCO clock 1 0 0: PLL2 output clock Q (divided by 16) 1 0 1: Peripheral module clock B (PCLKB) 1 1 0: PLL2 output clock R (divided by 16) 1 1 1: Setting prohibited.	R/W
b5, b4	TCSS[1:0]	Timer Count Source Select	b5 b4 0 0: No division 0 1: ×1/4 clock 1 0: ×1/8 clock 1 1: ×1/32 clock	R/W
b7, b6	EDGES[1:0]	Valid Edge Select	b7 b6 0 0: Rising edge 0 1: Falling edge 1 0: Both rising and falling edges 1 1: Setting prohibited	R/W

Note: Set the CACR1 register when the CACR0.CFME bit is 0.

CACREFE Bit (CACREF Pin Input Enable)

This bit specifies whether the CACREF pin input is enabled or disabled.

FMCS[2:0]Bits (Measurement Target Clock Select)

These bits select the measurement target clock whose frequency is to be measured.

TCSS[1:0] Bits (Timer Count Source Select)

These bits select the count source for the clock frequency accuracy measurement circuit.

EDGES[1:0]Bits (Valid Edge Select)

These bits select the valid edge for the reference signal.

10.2.3 CAC Control Register 2 (CACR2)

Address(es): CAC0.CACR2 8780 2402h, CAC1.CACR2 8780 2482h, CAC2.CACR2 8780 2502h, CAC0_NS.CACR2 0780 2402h, CAC1_NS.CACR2 0780 2482h, CAC2_NS.CACR2 0780 2502h

	b7	b6	b5	b4	b3	b2	b1	b0
	DFS[1:0]		RCDS[1:0]		RSCS[2:0]			RPS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RPS	Reference Signal Select	0: CACREF pin input 1: Internal clock (internally generated signal)	R/W
b3 to b1	RSCS[2:0]	Measurement Reference Clock Select	• Unit 0 b3 b1 0 0 0: Main clock 0 0 1: Sub-clock 0 1 0: HOCO clock 0 1 1: MOCO clock 1 0 0: LOCO clock 1 0 1: Peripheral module clock B (PCLKB) Settings other than above are prohibited. • Unit 1 b3 b1 0 0 0: Main clock 0 0 1: PLL1 output clock P (divided by 16) 0 1 0: HOCO clock 0 1 1: MOCO clock 1 0 0: PLL1 output clock Q (divided by 16) 1 0 1: Peripheral module clock B (PCLKB) 1 1 0: PLL1 output clock R (divided by 16) 1 1 1: Setting prohibited. • Unit 2 b3 b1 0 0 0: Main clock 0 0 1: PLL2 output clock P (divided by 16) 0 1 0: HOCO clock 0 1 1: MOCO clock 1 0 0: PLL2 output clock Q (divided by 16) 1 0 1: Peripheral module clock B (PCLKB) 1 1 0: PLL2 output clock R (divided by 16) 1 1 1: Setting prohibited.	R/W
b5, b4	RCDS[1:0]	Measurement Reference Clock Frequency Division Ration Select	b5 b4 0 0: ×1/32 clock 0 1: ×1/128 clock 1 0: ×1/1024 clock 1 1: ×1/8192 clock	R/W
b7, b6	DFS[1:0]	Digital Filter Select	b7 b6 0 0: Digital filtering is disabled. 0 1: The sampling clock for the digital filter is the measurement target clock. 1 0: The sampling clock for the digital filter is the measurement target clock divided by 4. 1 1: The sampling clock for the digital filter is the measurement target clock divided by 16.	R/W

Note: Set the CACR2 register when the CACR0.CFME bit is 0.

RPS Bit (Reference Signal Select)

This bit selects whether to use the CACREF pin input or an internal clock (internally generated signal) as the reference signal.

RSCS[2:0]Bits (Measurement Reference Clock Select)

These bits select the clock source for generating the measurement reference clock.

RCDS[1:0]Bits (Measurement Reference Clock Frequency Division Ration Select)

These bits select the frequency division ratio of the measurement reference clock.

DFS[1:0]Bits (Digital Filter Select)

The setting of these bits enables or disables the digital filter and selects its sampling clock.

10.2.4 CAC Interrupt Request Enable Register (CAICR)

Address(es): CAC0.CAICR 8780 2403h, CAC1.CAICR 8780 2483h, CAC2.CAICR 8780 2503h, CAC0_NS.CAICR 0780 2403h, CAC1_NS.CAICR 0780 2483h, CAC2_NS.CAICR 0780 2503h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	OVFFCL	MENDFCL	FERRFCL	—	OVFIE	MENDIE	FERRIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FERRIE	Frequency Error Interrupt Request Enable	0: Frequency error interrupt request is disabled. 1: Frequency error interrupt request is enabled.	R/W
b1	MENDIE	Measurement End Interrupt Request Enable	0: Measurement end interrupt request is disabled. 1: Measurement end interrupt request is enabled.	R/W
b2	OVFIE	Overflow Interrupt Request Enable	0: Overflow interrupt request is disabled. 1: Overflow interrupt request is enabled.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	FERRFCL	FERRF Clear	When 1 is written to this bit, the CASTR.FERRF flag is cleared. This bit is read as 0.	R/W
b5	MENDFCL	MENDF Clear	When 1 is written to this bit, the CASTR.MENDF flag is cleared. This bit is read as 0.	R/W
b6	OVFFCL	OVFF Clear	When 1 is written to this bit, the CASTR.OVFF flag is cleared. This bit is read as 0.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

FERRIE Bit (Frequency Error Interrupt Request Enable)

This bit specifies whether the frequency error interrupt request is enabled or disabled.

MENDIE Bit (Measurement End Interrupt Request Enable)

This bit specifies whether the measurement end interrupt request is enabled or disabled.

OVFIE Bit (Overflow Interrupt Request Enable)

This bit specifies whether the overflow interrupt request is enabled or disabled.

FERRFCL Bit (FERRF Clear)

Setting this bit to 1 clears the CASTR.FERRF flag.

MENDFCL Bit (MENDF Clear)

Setting this bit to 1 clears the CASTR.MENDF flag.

OVFFCL Bit (OVFF Clear)

Setting this bit to 1 clears the CASTR.OVFF flag.

10.2.5 CAC Status Register (CASTR)

Address(es): CAC0.CASTR 8780 2404h, CAC1.CASTR 8780 2484h, CAC2.CASTR 8780 2504h, CAC0_NS.CASTR 0780 2404h, CAC1_NS.CASTR 0780 2484h, CAC2_NS.CASTR 0780 2504h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	OVFF	MENDF	FERRF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FERRF	Frequency Error Flag	0: The clock frequency is within the range corresponding to the settings. 1: The clock frequency has deviated beyond the range corresponding to the settings (frequency error).	R
b1	MENDF	Measurement End Flag	0: Measurement is in progress. 1: Measurement has ended.	R
b2	OVFF	Overflow Flag	0: The counter has not overflowed. 1: The counter has overflowed.	R
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

FERRF Flag (Frequency Error Flag)

This flag indicates deviation of the clock frequency from the set value (frequency error).

[Setting condition]

- The clock frequency is outside of the setting range.

[Clearing condition]

- 1 is written to the CAICR.FERRFCL bit.

MENDF Flag (Measurement End Flag)

This flag indicates the end of measurement.

[Setting condition]

- Measurement has finished.

[Clearing condition]

- 1 is written to the CAICR.MENDFCL bit.

OVFF Flag (Overflow Flag)

This flag indicates that the counter has overflowed.

[Setting condition]

- The counter has overflowed.

[Clearing condition]

- 1 is written to the CAICR.OVFFCL bit.

10.2.6 CAC Upper-Limit Value Setting Register (CAULVR)

Address(es): CAC0.CAULVR 8780 2406h, CAC1.CAULVR 8780 2486h, CAC2.CAULVR 8780 2506h, CAC0_NS.CAULVR 0780 2406h, CAC1_NS.CAULVR 0780 2486h, CAC2_NS.CAULVR 0780 2506h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CAULVR register is a 16-bit readable/writable register that specifies the upper-limit value of the counter used for measuring the frequency. When the frequency rises above the value specified in this register, a frequency error is detected.

Write to this register when the CACR0.CFME bit is 0.

The counter value held in the CACNTBR register can vary with the difference between the phases of the digital filter and edge-detection circuit on the one hand and the signal on the CACREF pin on the other, so ensure that this setting allows an adequate margin.

10.2.7 CAC Lower-Limit Value Setting Register (CALLVR)

Address(es): CAC0.CALLVR 8780 2408h, CAC1.CALLVR 8780 2488h, CAC2.CALLVR 8780 2508h, CAC0_NS.CALLVR 0780 2408h, CAC1_NS.CALLVR 0780 2488h, CAC2_NS.CALLVR 0780 2508h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CALLVR register is a 16-bit readable/writable register that specifies the lower-limit value of the counter used for measuring the frequency. When the frequency falls below the value specified in this register, a frequency error is detected.

Write to this register when the CACR0.CFME bit is 0.

The counter value held in the CACNTBR register can vary with the difference between the phases of the digital filter and edge-detection circuit on the one hand and the signal on the CACREF pin on the other, so ensure that this setting allows an adequate margin.

10.2.8 CAC Counter Buffer Register (CACNTBR)

Address(es): CAC0.CACNTBR 8780 240Ah, CAC1.CACNTBR 8780 248Ah, CAC2.CACNTBR 8780 250Ah, CAC0_NS.CACNTBR 0780 240Ah, CAC1_NS.CACNTBR 0780 248Ah, CAC2_NS.CACNTBR 0780 250Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CACNTBR register is a 16-bit read-only register that retains the counter value at the time a valid reference signal edge is input.

10.3 Operation

10.3.1 Measuring Clock Frequency

The clock frequency accuracy measurement circuit measures the clock frequency using the CACREF pin input or the internal clock as a reference. Figure 10.2 shows an operating example of the clock frequency accuracy measurement circuit.

The clock frequency accuracy measurement circuit operates as shown below when measuring the clock frequency.

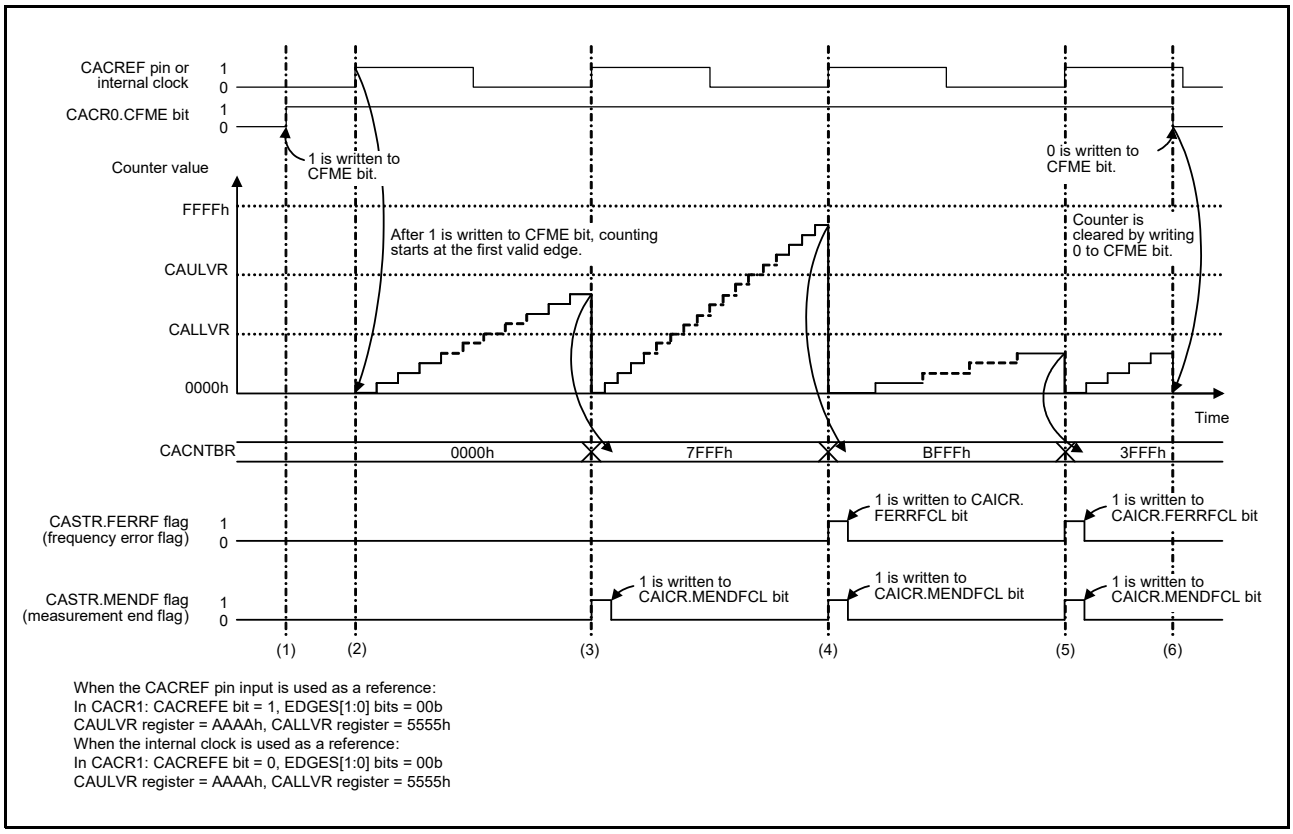


Figure 10.2 Operating Example of Clock Frequency Accuracy Measurement Circuit

(1) When the CACREF pin input is used as a reference (the CACR1.CACREFE bit = 1), clock frequency measurement is enabled by writing 1 to the CACR0.CFME bit while the CACR2.RPS bit is 0 and the CACR1.CACREFE bit is 1. On the other hand, when the internal clock is used as a reference (the CACR1.CACREFE bit = 0), clock frequency measurement is enabled by writing 1 to the CACR0.CFME bit while the CACR2.RPS bit is 1.

(2) When the CACREF pin input is used as a reference, the timer starts up-counting if the valid edge selected by the CACR1.EDGES[1:0] bits is input from the CACREF pin after 1 is written to the CFME bit. The valid edge is a rising edge (the CACR1.EDGES[1:0] bits = 00b) in Figure 10.2.
When the internal clock is used as a reference, the timer starts up-counting if the valid edge selected by the CACR1.EDGES[1:0] bits is input based on the clock source selected by the CACR2.RSCS[2:0] bits after 1 is written to the CFME bit. The valid edge is a rising edge (the CACR1.EDGES[1:0] bits = 00b) in Figure 10.2.

(3) When the next valid edge is input, the counter value is transferred in the CACNTBR register and compared with the values of the CAULVR and CALLVR registers. If the formula CALLVR ≤ CACNTBR ≤ CAULVR is satisfied, only the CASTR.MENDF flag is set to 1 because the clock frequency is correct. If the CAICR.MENDIE bit is 1, a measurement end interrupt is generated.

(4) When the next valid edge is input, the counter value is transferred in the CACNTBR register and compared with the values of the CAULVR and CALLVR registers. In the case of CACNTBR > CAULVR, the CASTR.FERRF flag is set to 1 because the clock frequency is erroneous. If the CAICR.FERRIE bit is 1, a frequency error interrupt is

generated. Also, the CASTR.MENDF flag is set to 1. If the CAICR.MENDIE bit is 1, a measurement end interrupt is generated.

(5) When the next valid edge is input, the counter value is transferred in the CACNTBR register and compared with the values of the CAULVR and CALLVR registers. In the case of CACNTBR < CALLVR, the CASTR.FERRF flag is set to 1 because the clock frequency is erroneous. If the CAICR.FERRIE bit is 1, a frequency error interrupt is generated. Also, the CASTR.MENDF flag is set to 1. If the CAICR.MENDIE bit is 1, a measurement end interrupt is generated.

(6) While the CACR0.CFME bit is 1, the counter value is transferred in the CACNTBR register and compared with the values of the CAULVR and CALLVR registers every time a valid edge is input. Writing 0 to the CACR0.CFME bit clears the counter and stops up-counting.

10.3.2 Digital Filtering of Signals on the CACREF Pin

The CACREF pin has a digital filter. Levels on the target pin for sampling are conveyed to the internal circuitry after matching three consecutive times at the selected sampling interval and the same level continues to be conveyed internally until the level on the pin again matches three consecutive times.

Enabling and disabling of the digital filter and its sampling clock are selectable.

The counter value transferred in the CACNTBR register may be in error by up to one cycle of the sampling clock due to the difference between the phases of the digital filter and the signal input to the CACREF pin.

When a frequency dividing clock is selected as a count source, the counter value error is obtained by the following formula:

Counter value error = (One cycle of the count source) / (One cycle of the sampling clock)

10.4 Interrupt Requests

The CAC generates three types of interrupt request: frequency error interrupt, measurement end interrupt, and overflow interrupt. When an interrupt source is generated, the corresponding status flag becomes 1. Table 10.4 lists details on the interrupt requests of the clock frequency accuracy measurement circuit.

Table 10.4 Interrupt Requests of Clock Frequency Accuracy Measurement Circuit

Interrupt Request	Interrupt Enable Bit	Status Flag	Interrupt Source
Frequency error interrupt	CAICR.FERRIE	CASTR.FERRF	The result of comparing CACNTBR to CAULVR and CALLVR is either CACNTBR > CAULVR or CACNTBR < CALLVR.
Measurement end interrupt	CAICR.MENDIE	CASTR.MENDF	A valid edge is input from the CACREF pin. Note however that a measurement end interrupt does not occur at the first valid edge after writing 1 to the CACR0.CFME bit.
Overflow interrupt	CAICR.OVFIE	CASTR.OVFF	The counter has overflowed.

10.5 Usage Notes

10.5.1 Module Stop Function Setting

CAC operation can be disabled or enabled using module stop control register C (MSTPCRC). The initial setting is for the CAC to be halted. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

11. Low Power Consumption

11.1 Overview

This MCU has several functions for reducing power consumption, including switching of clock signals to reduce power consumption, EBCLK output control, SDCLK output control, stopping modules, power gating control, and transitions to low power consumption modes.

Table 11.1 lists the specifications of low power consumption functions. Table 11.2 to Table 11.4 list the conditions to shift to low power consumption modes, states of the CPU and peripheral modules, and the method for release from each mode. After a reset, this MCU enters the normal program execution state, but modules except for the DMAC, DTC, and RAM do not operate.

Table 11.1 Specifications of Low Power Consumption Functions

Item	Specification
Reducing power consumption by switching clock signals	The frequency division ratio is settable independently for the CPU clock (CPUCLK0), system clock (ICLK), peripheral module clock (PCLKA, PCLKB, PCLKD, PCLKE), external bus clock (BCLK), MRAM code bus clock (MRICLK), and MRAM peripheral bus clock (MRPCLK).*1
EBCLK output control function	BCLK output or high-level output can be selected.*1
SDCLK output control function	SDCLK output or high-level output can be selected.*1
Module-stop function	Functions can be stopped independently for each peripheral module.
Power gating control function	The power state can be controlled for each power domain. • Control the ON/OFF state of each power domain. • Control the retention of specific circuits during power gating.
Transition to the low power consumption state	• Transition to a low power consumption mode in which the CPU, peripheral modules, or oscillators are stopped is enabled.
Processor low power consumption modes	• CPU sleep mode • CPU deep sleep mode
Low power consumption modes	• Software standby mode 1, 2*2 • Deep software standby mode 1, 2, 3*2

Note 1. For details, see section 9, Clock Generation Circuit.
Note 2. This mode is not supported in external VDD mode.

Table 11.2 Entering and Exiting Processor Low Power Consumption Modes and Operating States in Each Mode

Item	CPU Sleep Mode	CPU Deep Sleep Mode
Transition condition	When the following conditions are satisfied while the LPSCR.LPMD[3:0] bits are 0h and the CLPCR.DEEPSLEEP bit is 0: • The WAIT instruction is executed • The CPU is unable to accept a valid interrupt request*1 (including a request before a transition to CPU sleep mode is complete after execution of the WAIT instruction).	When the following conditions are satisfied while the LPSCR.LPMD[3:0] bits are 0h and the CLPCR.DEEPSLEEP bit is 1: • The WAIT instruction is executed • The CPU is unable to accept a valid interrupt request*1 (including a request before a transition to CPU sleep mode is complete after execution of the WAIT instruction).
Method for release from each mode	Interrupt	Interrupt
	Reset	Reset
State after release by an interrupt	Program execution state (interrupt processing)	Program execution state (interrupt processing)
State after release by a reset	Reset state	Reset state
CPU	Stopped (retained)	Stopped (retained)*2
TFU	Operation possible	Stopped (retained)*2
DMA controller (DMAC)	Operation possible	Operation possible
Data transfer controller (DTC)	Operation possible	Operation possible
Watchdog timer (WDT)	Operation possible*3	Operation possible*3
Independent watchdog timer (IWDT)	Operation possible*4	Operation possible*4
Other peripheral modules	Operation possible	Operation possible

Note: “Operation possible” means that operation or stopping can be controlled by setting the control register.
“Stopped (retained)” means that internal register values are retained and internal operations are suspended.

Note 1. “Valid interrupt request” refers to any interrupt or exception that is not masked by the priority level of a current exception or the priority level specified by the IPRr register.

Note 2. The power is turned off.

Note 3. In WDT auto-start mode, operation or stopping can be selected by setting the WDT sleep mode count stop control bit (OFS0.WDT0SLCSTP) in option function select register 0. In WDT register start mode, operation or stopping can be selected by setting the sleep mode count stop control bit (WDTCSTPR.SLCSTP) in the WDT count stop control register.

Note 4. In IWDT auto-start mode, operation or stopping can be selected by setting the IWDT sleep mode count stop control bit (OFS0.IWDTSLCSTP) in option function select register 0. In IWDT register start mode, operation or stopping can be selected by setting the sleep mode count stop control bit (IWDTCSTPR.SLCSTP) in the IWDT count stop control register.

Table 11.3 Entering and Exiting Low Power Consumption Modes and Operating States in Each Mode (1/2)

Item	Software Standby Mode (SSTBY)		Deep Software Standby Mode (DSTBY)		
	SSTBY 1	**SSTBY 2**	**DSTBY 1**	**DSTBY 2**	**DSTBY 3**
Transition condition	When the following conditions are satisfied while the LPSCR.LPMD[3:0] bits are 4h and the CLPCR.DEEPSLEEP bit is 1: • The WAIT instruction is executed • The CPU is unable to accept a valid interrupt request*1 (including a request before a transition to software standby mode 1 is complete after execution of the WAIT instruction).	When the following conditions are satisfied while the LPSCR.LPMD[3:0] bits are 5h and the CLPCR.DEEPSLEEP bit is 1: • The WAIT instruction is executed • The CPU is unable to accept a valid interrupt request*1 (including a request before a transition to software standby mode 2 is complete after execution of the WAIT instruction).	When the following conditions are satisfied while the LPSCR.LPMD[3:0] bits are 8h, the CLPCR.DEEPSLEEP bit is 1, and the DCCR.DSTBYCON bit is 1: • The WAIT instruction is executed • The CPU is unable to accept a valid interrupt request*1 (including a request before a transition to deep software standby mode 1 is complete after execution of the WAIT instruction).	When the following conditions are satisfied while the LPSCR.LPMD[3:0] bits are 9h, the CLPCR.DEEPSLEEP bit is 1, and the DCCR.DSTBYCON bit is 1: • The WAIT instruction is executed • The CPU is unable to accept a valid interrupt request*1 (including a request before a transition to deep software standby mode 2 is complete after execution of the WAIT instruction).	When the following conditions are satisfied while the LPSCR.LPMD[3:0] bits are Ah, the CLPCR.DEEPSLEEP bit is 1, and the DCCR.DSTBYCON bit is 1: • The WAIT instruction is executed • The CPU is unable to accept a valid interrupt request*1 (including a request before a transition to deep software standby mode 3 is complete after execution of the WAIT instruction).
Method for release from each mode	Interrupts shown in Table 11.4		Interrupts shown in Table 11.4		
	Reset		Reset		
State after release by an interrupt	Program execution state		Reset state		
State after release by a reset	Reset state		Reset state		
Main clock oscillator	Operation possible*2		Stopped		
Sub-clock oscillator	Operation possible		Operation possible		
High-speed on-chip oscillator	Operation possible*3		Stopped		
Middle-speed on-chip oscillator	Operation possible*4		Stopped		
Low-speed on-chip oscillator	Operation possible*5, *6		Operation possible *5, *6	Operation possible*6	
PLL1	Stopped		Stopped		
PLL2	Stopped		Stopped		
Main clock oscillator stop detection function	Operation possible*7		Stopped		
Sub-clock oscillator stop detection function	Operation possible		Operation possible		
Clock/buzzer output function	Operation possible*8		Stopped (undefined)		
External bus (EBCLK)	Stopped (retained)		Stopped (retained)		
CPU	Stopped (retained)		Stopped (undefined)		
Local RAM (SRAM)	Stopped (retained/undefined)*9		Stopped (undefined)		
User SRAM	Stopped (retained/undefined)*10		Stopped (undefined)		
Backup register	Stopped (retained)		Stopped (retained)		
MRAM	Stopped (retained)		Stopped (retained)		
Independent watchdog timer (IWDT)	Operation possible*11		Operation possible *11	Stopped (undefined)	

Table 11.3 Entering and Exiting Low Power Consumption Modes and Operating States in Each Mode (2/2)

Item	Software Standby Mode (SSTBY)		Deep Software Standby Mode (DSTBY)		
	SSTBY 1	SSTBY 2	DSTBY 1	DSTBY 2	DSTBY 3
Ethernet module (ESWM)	Stopped (retained)*12	Stopped (undefined)	Stopped (undefined)		
USB 2.0 full-speed host/function module (USB)	Stopped (retained)*13		Stopped (retained) *13	Stopped (undefined)	
USB 2.0 high-speed host/function module (USBHS)	Stopped (retained)*14		Stopped (retained) *14	Stopped (undefined)

Programmable voltage detection circuit (PVD)	Operation possible		Operation possible*23	Operation possible*23	Stopped (undefined)*23
VCC voltage drop detection circuit dedicated to VBATT	Operation possible		Operation possible*24	Operation possible*24	Stopped (undefined)
Power-on reset circuit	Enabled		Enabled	Enabled	Enabled*25
CVM reset circuit	Operation possible		Stopped	Stopped	Stopped
Other peripheral modules	Stopped (retained)		Stopped (undefined)		
I/O ports	Retained*26		Retained*26		

Note: “Operation possible” means that operation or stopping can be controlled by setting the control register.
“Stopped (retained)” means that operation is suspended and after recovery from a low power consumption mode, the internal state before the transition to that mode is retained.
“Stopped (undefined)” means that power to the internal circuitry is turned off and after recovery from a low power consumption mode, the internal state is initialized.

Note 1. “Valid interrupt request” refers to any interrupt or exception that is not masked by the priority level of a current exception or the priority level specified by the IPRr register.

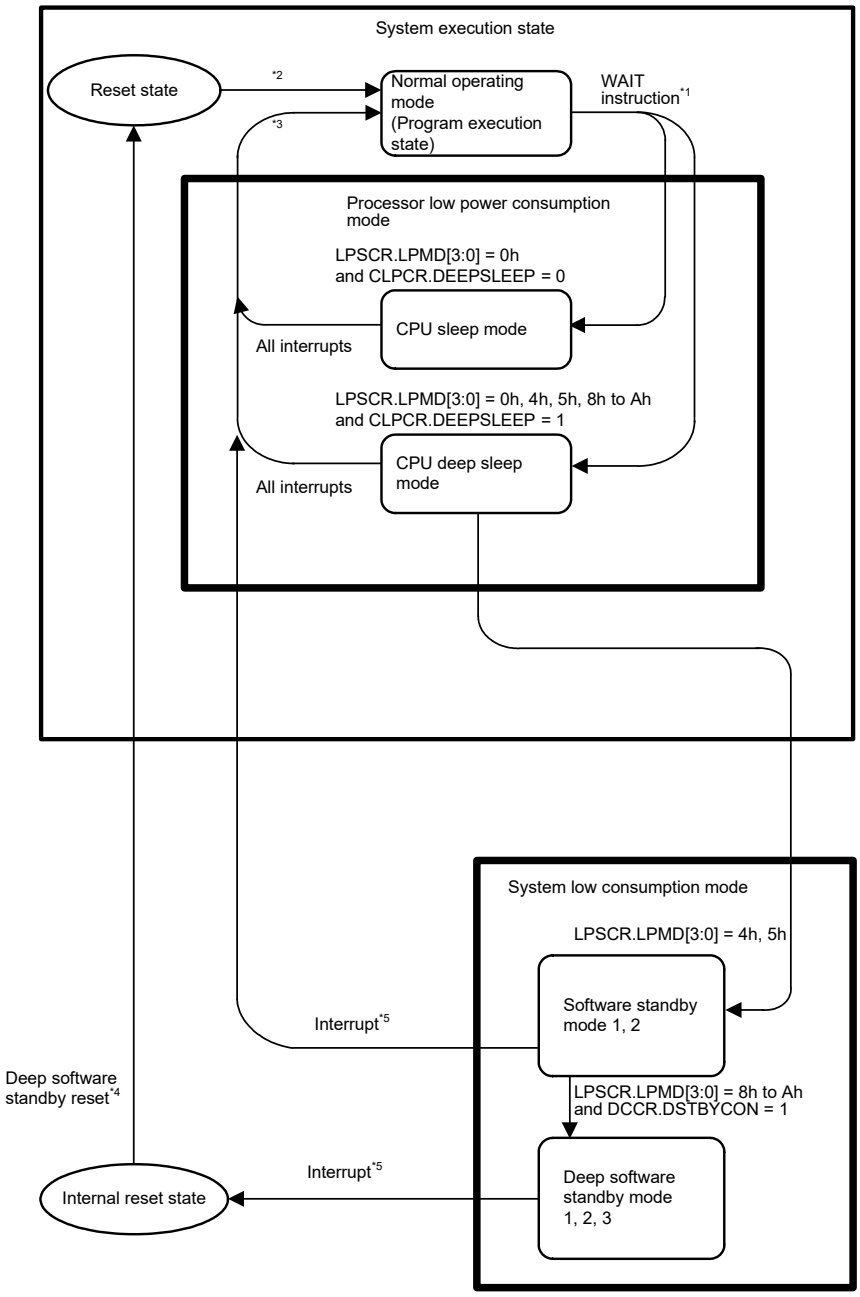
Note 2. If MOSCSCR.MOSCSOKP is set to 1 while the MOSC is oscillating, the MOSC continues to oscillate during software standby mode.

Note 3. If MOSCSCR.MOSCSOKP is set to 1 while the HOCO is oscillating, the HOCO continues to oscillate during software standby mode.

Note 4. Operation or stopping can be selected by setting the MOCOSCR.MOCOSOKP bit.

Note 5. This oscillator can be made to operate or stop by the setting of the LOCOCR.LCSTP bit. However, the oscillator continues to operate regardless of the LCSTP setting in either of the following cases.

- When the IWDT is set for counting operation in IWDT auto-start mode and the IWDT sleep mode count stop control bit in option function select register 0 (OFS0.IWDTSLCSTP) is set to 0
- When the IWDT is set for counting operation in IWDT register start mode and the sleep mode count stop control bit in the IWDT count stop control register (IWDTCSTPR.SLCSTP) is set to 0



Note 6. This oscillator operates when the sub-clock oscillation stop detection function is enabled (SOSTDCR.SOSTDE = 1).
Note 7. Operation or stopping can be selected by setting the MOSCSCR.MOSCSOKP bit.
Note 8. Operation is possible only when the clock output source select bits (CKOCR.CKOSEL[2:0]) are set to 010b (LOCO) or 100b (SOSC). Stopped when the bits are set to a value other than 010b (LOCO) and 100b (SOSC).
Note 9. A retained or undefined state can be selected by setting the PDRAMSCR2.RKEEP0 bit.
Note 10. A retained or undefined state can be selected by setting the PDRAMSCR0.RKEEPn (n = 0 to 11) bit.
Note 11. In IWDT auto-start mode, operation or stopping can be selected by setting the IWDT sleep mode count stop control bit (OFS0.IWDTSLCSTP) in option function select register 0. In IWDT register start mode, operation or stopping can be selected by setting the sleep mode count stop control bit (IWDTCSTPR.SLCSTP) in the IWDT count stop control register.
Note 12. The state of RAM for ESWM is undefined.
Note 13. Only the resume detection is available. The contents of the FIFO buffer are undefined.
Note 14. Only the resume detection is available. The contents of the FIFO buffer are undefined.
Note 15. The contents of the acceptance filter list RAM and message buffer RAM are undefined.
Note 16. The contents of the message buffer RAM are undefined.
Note 17. The state of the SD buffer is undefined.
Note 18. Only the wakeup function is available.
Note 19. Only the wakeup function is available.
Note 20. The D/A output is retained if D/A conversion is enabled.
Note 21. Only the temperature monitoring reset is available.
Note 22. Only the audio detection interrupt is available.
Note 23. When using the PVD, do not set the LPSCR.LPMD[3:0] bits to Ah (deep software standby mode 3).
Note 24. When the MCU transitions to deep software standby mode 1 or 2 with OFS1.PVDAS = 0 and OFS1.DSBYLPSEL = 0, the battery power switch is controlled by voltage monitor 0, which consumes less power than the VCC voltage drop detection circuit dedicated to VBATT. When the MCU transitions to deep software standby mode 1 or 2 with OFS1.DSBYLPSEL = 1, the battery power switch is controlled by the VCC voltage drop detection circuit dedicated to VBATT. For details, see section 12, Battery Backup Function (VBATTBa) and section 67, Electrical Characteristics.
Note 25. In deep software standby mode 3, the PVD circuit is stopped.
Note 26. Whether the address bus and bus control signals (CS0# to CS7#, RD#, WR0# to WR3#, WR#, BC0# to BC3#, ALE, BACK#, CKE, SDCS#, RAS#, CAS#, WE#, DQM0 to DQM3) are placed in the high-impedance or the output state is retained can be specified by the SBYCR.OPE bit.

Table 11.4 Interrupts That Can Cause Release from Software Standby Mode and Deep Software Standby Mode

Source of interrupt request	Interrupt Source	Name	Software Standby Mode		Deep Software Standby Mode		
			SSTBY1	SSTBY2	DSTBY1	DSTBY2	DSTBY3
ICU	NMI pin	NMI	Possible	Possible	Possible	Possible	Possible
ICU	External pin	IRQn (n = 0 to 31)	Possible	Possible	Impossible	Impossible	Impossible
		IRQn-DS (n = 0 to 31)	Possible	Possible	Possible	Possible	Possible
PVD	Voltage monitoring m (m = 1, 2)	PVDm (m = 1, 2)	Possible	Possible	Possible	Possible	Impossible
IWDT	IWDT underflow	IWUNI	Possible	Possible	Possible	Impossible	Impossible
USB0	USB0 suspend/resume	USBR*1	Possible	Possible	Possible*2	Impossible	Impossible
USBHS	USBHS suspend/resume	USBHSR*3	Possible	Possible	Possible*2	Impossible	Impossible
RTC	RTC alarm	ALM	Possible	Possible	Possible	Possible	Possible
	RTC periodic	PRD	Possible	Possible	Possible	Possible	Possible
RIICHS1	Wake-up	WUI	Possible	Possible	Impossible	Impossible	Impossible
RIICHS2	Wake-up	WUI	Possible	Possible	Impossible	Impossible	Impossible
RI3C0	Wake-up	WUI	Possible	Possible	Impossible	Impossible	Impossible

Note 1. For details on USBR, see Table 40.14, USB Interrupts and section 40.3.1.5, Release from Deep Software Standby Mode 1 Due to USB Suspend/Resume Interrupts.
Note 2. To comply with USB 2.0 when using resume interrupts, it is necessary to consider the oscillator stabilization time.
Note 3. For details on USBHSR, see Table 41.17, USBHS Interrupt Sources and section 41.3.18, Release from Deep Software Standby Mode 1 in Response to the USBHS Resume Interrupt.

Figure 11.1 shows the transitions between low power consumption modes.
For details, see section 11.6, Low Power Consumption Modes.

Note 1. If an interrupt that causes release of the MCU from CPU sleep mode or CPU deep sleep mode is accepted during the transition to CPU sleep mode or CPU deep sleep mode, the MCU will return to normal operating mode instead of entering CPU sleep mode or CPU deep sleep mode.
If an interrupt that causes release of the MCU from CPU sleep mode or CPU deep sleep mode is received during the transition to software standby mode, the MCU will return to normal operating mode instead of entering software standby mode.
Note 2. The MOCO is the source of the operating clock following a transition from the reset state to normal operating mode.
Note 3. When a transition from CPU sleep mode, CPU deep sleep mode or software standby mode to normal mode occurs because of an interrupt, the clock source is the same as before entering each low power consumption mode.
Note 4. If, after transitioning to deep software standby mode, an interrupt request that acts as a releasing source is generated, an internal reset (deep software standby reset) occurs for a certain period of time after the mode transition is complete. The system then transitions to normal mode upon release from the internal reset state, and executes the reset exception processing with the MOCO clock as the operating clock source.
Note 5. For interrupts that act as a releasing source for each low power consumption mode, see Table 11.4.

Figure 11.1 Transitions between Low Power Consumption Modes

11.2 Register Descriptions

11.2.1 Low Power Consumption Mode Security Attribution Register (LPMSAR)

b31 to b22	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The LPMSAR register is used to set the security attribute of each low power consumption mode register.

NONSEC1 Bit (Security Attribution 1)

This bit sets the security attribute of the LPSCR register.

NONSEC2 Bit (Security Attribution 2)

This bit sets the security attribute of the SBYCR, SSCR1, and SVSCR registers.

NONSEC4 Bit (Security Attribution 4)

This bit sets the security attribute of the VSCR register.

NONSEC8 Bit (Security Attribution 8)

This bit sets the security attribute of the DPSBYCR and DCCR registers.

NONSEC16 Bit (Security Attribution 16)

This bit sets the security attribute of the LDOECR register.

NONSEC17 Bit (Security Attribution 17)

This bit sets the security attribute of the HOCOLDOCR register.

NONSEC18 Bit (Security Attribution 18)

This bit sets the security attribute of the PLL1LDOCR register.

NONSEC19 Bit (Security Attribution 19)

This bit sets the security attribute of the PLL2LDOCR register.

NONSEC21 Bit (Security Attribution 21)

This bit sets the security attribute of the LVOCR and MWMCR registers.
For details about the LVOCR register, see section 22.3.17, Low-Voltage Operating Characteristics Control Register (LVOCR). For details about the MWMCR register, see section 65.5.52, MRAM-OTP Write Mode Control Register (MWMCR).

11.2.2 Power Gating Security Attribution Register (PGCSAR)

Address(es): SYSC.PGCSAR 8701 93D8h, SYSC_NS.PGCSAR 0701 93D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	NONSEC0	Security Attribution 0	Target register: PGSCR 0: Secure 1: Non-secure	R/W
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	NONSEC3	Security Attribution 3	Target register: PSSTCR2 0: Secure 1: Non-secure	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	NONSEC5	Security Attribution 5	Target register: PSSTCR4 0: Secure 1: Non-secure	R/W
b6	NONSEC6	Security Attribution 6	Target register: PSSTCR5, PDCTRESWM 0: Secure 1: Non-secure	R/W
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The PGCSAR register is used to set the security attribute of each power gating register.

NONSEC0 Bit (Security Attribution 0)

This bit sets the security attribute of the PGSCR register.

NONSEC3 Bit (Security Attribution 3)

This bit sets the security attribute of the PSSTCR2 register.

NONSEC5 Bit (Security Attribution 5)

This bit sets the security attribute of the PSSTCR4 register.

NONSEC6 Bit (Security Attribution 6)

This bit sets the security attribute of the PSSTCR5 and PDCTRESWM registers.

11.2.3 Deep Software Standby Interrupt Source Security Attribution Register (DPFSAR)

b19	DPFSA19	Deep Software Standby Interrupt Source Security Attribution 19	Target register: DPSIER2.DRTCAIE, DPSIFR2.DRTCAIF Target source: RTC alarm 0: Secure 1: Non-secure	R/W

Bit	Symbol	Bit Name	Description	R/W
b20	DPFSA20	Deep Software Standby Interrupt Source Security Attribution 20	Target register: DPSIER2.DNMIE, DPSIFR2.DNMIF, DPSIEGR2.DNMIEG Target source: NMI pin 0: Secure 1: Non-secure	R/W
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24	DPFSA24	Deep Software Standby Interrupt Source Security Attribution 24	Target register: DPSIER3.DUSBFSIE, DPSIFR3.DUSBFSIF Target source: USB0 suspend/resume 0: Secure 1: Non-secure	R/W
b25	DPFSA25	Deep Software Standby Interrupt Source Security Attribution 25	Target register: DPSIER3.DUSBHSIE, DPSIFR3.DUSBHSIF Target source: USBHS suspend/resume 0: Secure 1: Non-secure	R/W
b28 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b29	DPFSA29	Deep Software Standby Interrupt Source Security Attribution 29	Target register: DPSIER3.DIWDTIE, DPSIFR3.DIWDTIF Target source: IWDT underflow 0: Secure 1: Non-secure	R/W
b30	DPFSA30	Deep Software Standby Interrupt Source Security Attribution 30	Target register: DPSIER3.DSOSTDIE, DPSIFR3.DSOSTDIF Target source: Sub-clock oscillator stop detection 0: Secure 1: Non-secure	R/W
b31	DPFSA31	Deep Software Standby Interrupt Source Security Attribution 31	Target register: DPSIER3.DVBATTADIE, DPSIFR3.DVBATTADIF Target source: Tamper detection 0: Secure 1: Non-secure	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The DPFSAR register is used to set the security attribute of each deep software standby interrupt source control register.

DPFSAn Bit (Deep Software Standby Interrupt Source Security Attribution n) (n = 0 to 7)

This bit sets the security attribute of the DPSIER0.DIRQnE, DPSIFR0.DIRQnF, and DPSIEGR0.DIRQnEG bits.
The target source is the IRQn-DS pin.

DPFSAn Bit (Deep Software Standby Interrupt Source Security Attribution n) (n = 8 to 15)

This bit sets the security attribute of the DPSIER1.DIRQnE, DPSIFR1.DIRQnF, and DPSIEGR1.DIRQnEG bits.
The target source is the IRQn-DS pin.

DPFSA16 Bit (Deep Software Standby Interrupt Source Security Attribution 16)

This bit sets the security attribute of the DPSIER2.DPVD1IE, DPSIFR2.DPVD1IF, and DPSIEGR2.DPVD1EG bits.
The target source is PVD1.

DPFSA17 Bit (Deep Software Standby Interrupt Source Security Attribution 17)

This bit sets the security attribute of the DPSIER2.DPVD2IE, DPSIFR2.DPVD2IF, and DPSIEGR2.DPVD2EG bits.
The target source is PVD2.

DPFSA18 Bit (Deep Software Standby Interrupt Source Security Attribution 18)

This bit sets the security attribute of the DPSIER2.DRTCIIE and DPSIFR2.DRTCIIF bits.
The target source is the RTC interval.

DPFSA19 Bit (Deep Software Standby Interrupt Source Security Attribution 19)

This bit sets the security attribute of the DPSIER2.DRTCAIE and DPSIFR2.DRTCAIF bits.
The target source is the RTC alarm.

DPFSA20 Bit (Deep Software Standby Interrupt Source Security Attribution 20)

This bit sets the security attribute of the DPSIER2.DNMIE, DPSIFR2.DNMIF, and DPSIEGR2.DNMIEG bits.
The target source is the NMI pin.

DPFSA24 Bit (Deep Software Standby Interrupt Source Security Attribution 24)

This bit sets the security attribute of the DPSIER3.DUSBFSIE and DPSIFR3.DUSBFSIF bits.
The target source is USB0 suspend/resume.

DPFSA25 Bit (Deep Software Standby Interrupt Source Security Attribution 25)

This bit sets the security attribute of the DPSIER3.DUSBHSIE and DPSIFR3.DUSBHSIF bits.
The target source is USBHS suspend/resume.

DPFSA29 Bit (Deep Software Standby Interrupt Source Security Attribution 29)

This bit sets the security attribute of the DPSIER3.DIWDTIE and DPSIFR3.DIWDTIF bits.
The target source is IWDT underflow.

DPFSA30 Bit (Deep Software Standby Interrupt Source Security Attribution 30)

This bit sets the security attribute of the DPSIER3.DSOSTDIE and DPSIFR3.DSOSTDIF bits.
The target source is oscillation stop detection in the sub-clock oscillator.

DPFSA31 Bit (Deep Software Standby Interrupt Source Security Attribution 31)

This bit sets the security attribute of the DPSIER3.DVBATTADIE and DPSIFR3.DVBATTADIF bits.
The target source is tamper detection.

11.2.4 Deep Software Standby Interrupt Source Security Attribution Register 1 (DPFSAR1)

b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The DPFSAR1 register is used to set the security attribute of each deep software standby interrupt source control register.

DPFSAn Bit (Deep Software Standby Interrupt Source Security Attribution n) (n = 0 to 7)

This bit sets the security attribute of the DPSIER4.DIRQmE, DPSIFR4.DIRQmF, and DPSIEGR3.DIRQmEG bits. The target source is the IRQm-DS pin. (m = 16 to 23)

DPFSAn Bit (Deep Software Standby Interrupt Source Security Attribution n) (n = 8 to 15)

This bit sets the security attribute of the DPSIER5.DIRQmE, DPSIFR5.DIRQmF, and DPSIEGR4.DIRQmEG bits. The target source is the IRQm-DS pin. (m = 24 to 31)

11.2.5 RAM Standby Control Security Attribution Register (RSCSAR)

b11	RSCSA11	RAM Standby Control Security Attribution 11	Target register: PDRAMSCR0.RKEEP11 0: Secure 1: Non-secure	R/W
b23 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24	RSCSA24	RAM Standby Control Security Attribution 24	Target register: PDRAMSCR2.RKEEP0 0: Secure 1: Non-secure	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The RSCSAR register is used to set the security attribute of each standby control register for the SRAM power domain.

RSCSAn Bit (RAM Standby Control Security Attribution n) (n = 0 to 11)

This bit sets the security attribute of the PDRAMSCR0.RKEEPn bit.

RSCSA24 Bit (RAM Standby Control Security Attribution 24)

This bit sets the security attribute of the PDRAMSCR2.RKEEP0 bit.

11.2.6 Module Stop Control Register A (MSTPCRA)

Address(es): MSTP.MSTPCRA 8780 3000h, MSTP_NS.MSTPCRA 0780 3000h

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MSTPA1	MSTPA0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MSTPA0	SRAM0 Module Stop*1	Target module: SRAM0 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b1	MSTPA1	SRAM1 Module Stop*1	Target module: SRAM1 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b21 to b2	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b22	MSTPA22	DMA Controller and Data Transfer Controller Module Stop*2	Target module: DMAC, DTC 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b28 to b23	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b29	MSTPA29	EXDMA Controller Module Stop*3	Target module: EXDMAC 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b31 to b30	—	Reserved	These bits are read as 1. The write value should be 1.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. After changing the value of this bit, confirm that the value has actually been updated before executing subsequent instructions.

Note 2. When rewriting the MSTPA22 bit from 0 to 1, disable the DMAC and DTC before setting the MSTPA22 bit.

Note 3. When rewriting the MSTPA29 bit from 0 to 1, disable the EXDMAC before setting the MSTPA29 bit.

11.2.7 Module Stop Control Register B (MSTPCRB)

b31	MSTPB31	Serial Communication Interface 0 Module Stop*1	Target module: RSCI0 0: Release from the module-stop state 1: Transition to the module-stop state	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. The MSTPBi bit must be rewritten while the oscillation of the clock controlled by this bit is stabilized. For entering software standby mode after writing a new value to the MSTPBi bit, wait for two cycles of the SCI clock (SCICLK) to elapse after writing the new value, and then execute the WAIT instruction (i = 0, 20 to 31).

Note 2. The MSTPBi bit must be rewritten while the oscillation of the clock controlled by this bit is stabilized. For entering software standby mode after writing a new value to the MSTPBi bit, wait for two cycles of the I3C clock (I3CCLK) to elapse after writing the new value, and then execute the WAIT instruction (i = 4, 7, 8).

Note 3. The MSTPBi bit must be rewritten while the oscillation of the clock controlled by this bit is stabilized. For entering software standby mode after writing a new value to the MSTPBi bit, wait for two cycles of the USB clock (USBCLK) to elapse after writing the new value, and then execute the WAIT instruction (i = 11, 12).

Note 4. The MSTPBi bit must be rewritten while the oscillation of the clock controlled by this bit is stabilized. For entering software standby mode after writing a new value to the MSTPBi bit, wait for two cycles of the XSPI clock (XSPICLK) to elapse after writing the new value, and then execute the WAIT instruction (i = 16, 17). After changing the value of this bit, confirm that the value has actually been updated before executing subsequent instructions.

Note 5. The MSTPBi bit must be rewritten while the oscillation of the clock controlled by this bit is stabilized. For entering software standby mode after writing a new value to the MSTPBi bit, wait for two cycles of the SPI clock (SPICLK) to elapse after writing the new value, and then execute the WAIT instruction (i = 18, 19).

b24	MSTPC24	Pulse-Density Modulation Interface Module Stop*3	Target module: PDMIF 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b25	MSTPC25	CAN FD Module with Gateway Functionality Module Stop*4	Target module: CANFDG 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b26	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b27	MSTPC27	CAN FD Module Stop*4	Target module: CANFD 0: Release from the module-stop state 1: Transition to the module-stop state	R/W

Bit	Symbol	Bit Name	Description	R/W
b28	MSTPC28	Ethernet-PHY Clock Module Stop*5	Target module: ETHPHYCLK 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b29	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b30	MSTPC30	Ethernet Module Stop*6	Target module: ESWM 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b31	MSTPC31	Renesas Secure IP Module Stop	Target module: RSIP-E50D 0: Release from the module-stop state 1: Transition to the module-stop state	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. The MSTPC0 bit must be rewritten while the oscillation of the clock to be controlled by this bit is stabilized. To place the MCU in software standby mode after writing a new value to this bit, wait for 2 cycles of the slowest clock among the clocks output by the oscillators to elapse after writing the new value, and then execute the WAIT instruction.

Note 2. The MSTPC23 bit must be rewritten while the oscillation of the clock controlled by this bit is stabilized. To place the MCU in software standby mode after writing a new value to the MSTPC23 bit, wait for two cycles of the SPI clock (SPICLK) to elapse after writing the new value, and then execute the WAIT instruction.

Note 3. The MSTPC24 bit must be rewritten while the oscillation of the clock controlled by this bit is stabilized. To place the MCU in software standby mode after writing a new value to the MSTPC24 bit, wait for two cycles of the PDMIF clock (PDMIFCLK) to elapse after writing the new value, and then execute the WAIT instruction.

Note 4. The MSTPCi bit must be rewritten while the oscillation of the clock controlled by this bit is stabilized. To place the MCU in software standby mode after writing a new value to the MSTPCi bit, wait for two cycles of the CANFD clock (CANFDCLK) to elapse after writing the new value, and then execute the WAIT instruction (i = 25, 27).

Note 5. The MSTPC28 bit must be rewritten while the oscillation of the clock controlled by this bit is stabilized. To place the MCU in software standby mode after writing a new value to the MSTPC28 bit, wait for two cycles of the Ethernet-PHY clock (ETHPHYCLK) to elapse after writing the new value, and then execute the WAIT instruction.

Note 6. The MSTPC30 bit must be rewritten while the oscillation of the clock controlled by this bit is stabilized. To place the MCU in software standby mode after writing a new value to the MSTPC30 bit, wait for two cycles of the ESWM clock (ESWCLK) and two cycles of the ESWM-PHY clock (ESWPHYCLK) to elapse after writing the new value and then execute the WAIT instruction.

11.2.9 Module Stop Control Register D (MSTPCRD)

Address(es): MSTP.MSTPCRD 8780 300Ch, MSTP_NS.MSTPCRD 0780 300Ch

Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b6	MSTPF6	8-Bit Timer 3, 2 (Unit 1) Module Stop	Target module: TMR2, TMR3 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b7	MSTPF7	8-Bit Timer 1, 0 (Unit 0) Module Stop	Target module: TMR0, TMR1 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b11 to b8	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b12	MSTPF12	Compare Match Timer W (Unit 1) Module Stop	Target module: CMTW1 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b13	MSTPF13	Compare Match Timer W (Unit 0) Module Stop	Target module: CMTW0 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b14	MSTPF14	Compare Match Timer (Unit 1) Module Stop	Target module: CMT unit 1 (CMT2, CMT3) 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b15	MSTPF15	Compare Match Timer (Unit 0) Module Stop	Target module: CMT unit 0 (CMT0, CMT1) 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b16	MSTPF16	Software Configurable 32-Bit Programmable I/O Port Module Stop	Target module: PIO 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b29 to b17	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b30	MSTPF30	Phase Counting Interface 1 Module Stop	Target module: PCIF1 0: Release from the module-stop state 1: Transition to the module-stop state	R/W
b31	MSTPF31	Phase Counting Interface 0 Module Stop	Target module: PCIF0 0: Release from the module-stop state 1: Transition to the module-stop state	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

11.2.12 Power Gating Shift Control Register (PGSCR)

Address(es): SYSC.PGSCR 8701 9104h, SYSC_NS.PGSCR 0701 9104h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	PGS
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	PGS	Power Gating Shift Timing	0: Power gating control for all domains is started simultaneously. 1: Power gating control for the individual domains is started sequentially.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

PGS Bit (Power Gating Shift Timing)

The PGS bit is used to specify the timing to start power gating for the domains. Set this bit to 0 before placing the MCU in software standby mode or deep software standby mode.

11.2.13 Power Switch Control Start Time Control Register n (PSSTCRn) (n = 2, 4, 5)

Address(es): SYSC.PSSTCR2 8701 9214h, SYSC.PSSTCR4 8701 9218h, SYSC.PSSTCR5 8701 921Ah,
SYSC_NS.PSSTCR2 0701 9214h, SYSC_NS.PSSTCR4 0701 9218h, SYSC_NS.PSSTCR5 0701 921Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	PSST[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b12 to b0	PSST[12:0]	Power Switch Control Start Time	Set the time to start power switch control while PGSCR.PGS = 0. Set these bits to 00B0h. Other settings are prohibited.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

11.2.14 ESWM Power Domain Control Register (PDCTRESWM)

Address(es): SYSC.PDCTRESWM 8701 9118h, SYSC_NS.PDCTRESWM 0701 9118h

	b7	b6	b5	b4	b3	b2	b1	b0
	PDPGSF	PDCSF	—	—	—	—	—	PDDE
Value after reset:	1	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	PDDE	Power Control Enable	0: The target domain is turned on 1: The target domain is turned off	R/W
b5 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	PDCSF	Power Transition State Flag	0: Transition is completed. 1: Transition is in progress.	R
b7	PDPGSF	Power Status Flag	0: The target power domain is turned on and not gated. 1: The target power domain is turned off and gated.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The PDCTRESWM register is used to control the power to the ESWM power domain.
For constraints related to this register, see not only this section but also section 11.5.1, Power Gating Control Using the Power Domain Control Register.

PDDE Bit (Power Control Enable)

The PDDE bit controls the power to the target power domain. Before changing the PDDE bit from 0 to 1, confirm that both the PDCSF and PDPGSF bits are 0.
Also, before changing the PDDE bit from 1 to 0, confirm that the PDCSF bit is 0 and the PDPGSF bit is 1.

PDCSF Flag (Power Transition State Flag)

The PDCSF flag indicates whether a change to the power state of the target power domain is in progress.

PDPGSF Flag (Power Status Flag)

The PDPGSF flag indicates whether the power to the target power domain is on or off.

11.2.15 SRAM Power Domain Standby Control Register 0 (PDRAMSCR0)

Address(es): SYSC.PDRAMSCR0 8701 9140h, SYSC_NS.PDRAMSCR0 0701 9140h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b9	RKEEP9			R/W
b10	RKEEP10			R/W
b11	RKEEP11			R/W
b14 to b12	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

The PDRAMSCR0 register is used to control the target memory in software standby mode.

RKEEPn Bit (RAM Retention) (n = 0 to 11)

The RKEEPn bit controls whether to retain the contents of the target memory in software standby mode.
Table 11.5 shows the relationship between each bit and the target memory.

Table 11.5 Relationship Between Each Bit and the Target Memory (1/2)

Bit in the PDRAMSCR0 Register	Target Memory	
RKEEP0	SRAM0	8200 0000h to 8201 FFFFh (Secure area) 0200 0000h to 0201 FFFFh (Non-secure area)
RKEEP1	SRAM0	8202 0000h to 8203 FFFFh (Secure area) 0202 0000h to 0203 FFFFh (Non-secure area)
RKEEP2	SRAM0	8204 0000h to 8205 FFFFh (Secure area) 0204 0000h to 0205 FFFFh (Non-secure area)
RKEEP3	SRAM0	8206 0000h to 8207 FFFFh (Secure area) 0206 0000h to 0207 FFFFh (Non-secure area)
RKEEP4	SRAM0	8208 0000h to 8209 FFFFh (Secure area) 0208 0000h to 0209 FFFFh (Non-secure area)
RKEEP5	SRAM0	820A 0000h to 820B FFFFh (Secure area) 020A 0000h to 020B FFFFh (Non-secure area)

Table 11.5 Relationship Between Each Bit and the Target Memory (2/2)

Bit in the PDRAMSCR0 Register	Target Memory	
RKEEP6	SRAM0	820C 0000h to 820D FFFFh (Secure area) 020C 0000h to 020D FFFFh (Non-secure area)
RKEEP7	SRAM0	820E 0000h to 820F FFFFh (Secure area) 020E 0000h to 020F FFFFh (Non-secure area)
RKEEP8	SRAM1	8210 0000h to 8211 FFFFh (Secure area) 0210 0000h to 0211 FFFFh (Non-secure area)
RKEEP9	SRAM1	8212 0000 to 8213 FFFFh (Secure area) 0212 0000 to 0213 FFFFh (Non-secure area)
RKEEP10	SRAM1	8214 0000 to 8215 FFFFh (Secure area) 0214 0000 to 0215 FFFFh (Non-secure area)
RKEEP11	SRAM1	8216 0000h to 8217 FFFFh (Secure area) 0216 0000h to 0217 FFFFh (Non-secure area)

11.2.16 SRAM Power Domain Standby Control Register 2 (PDRAMSCR2)

Address(es): SYSC.PDRAMSCR2 8701 9143h, SYSC_NS.PDRAMSCR2 0701 9143h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RKEEP0
Value after reset:	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	RKEEP0	RAM Retention(Local RAM)	0: When entering the software standby mode, the contents of the target RAM are not retained 1: When entering the software standby mode, the contents of the target RAM are retained	R/W
b1	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

The PDRAMSCR2 register is used to control the target memory in software standby mode.

RKEEP0 Bit (RAM Retention)

The RKEEP0 bit controls whether to retain the contents of the local RAM in software standby mode.

11.2.17 Standby Control Register (SBYCR)

Address(es): SYSC.SBYCR 8701 900Ch, SYSC_NS.SBYCR 0701 900Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	OPE	—	—	—	—	—	—
Value after reset:	0	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	OPE	Output Port Enable	0: In software standby mode or deep software standby mode, the address bus and bus control signals are set to the high-impedance state 1: In software standby mode or deep software standby mode, the address bus and bus control signals retain the output state	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The SBYCR register is used to control the bus signal output in software standby mode and deep software standby mode.

OPE Bit (Output Port Enable)

The OPE bit specifies whether to retain the output of the address bus and bus control signals (CS0# to CS7#, RD#, WR0# to WR3#, WR#, BC0# to BC3#, ALE, BACK#, CKE, SDCS#, RAS#, CAS#, WE#, and DQM0 to DQM3), or to set the output to the high-impedance state in software standby mode or deep software standby mode.

11.2.18 Software Standby Control Register 1 (SSCR1)

Address(es): SYSC.SSCR1 8701 9A98h, SYSC_NS.SSCR1 0701 9A98h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SS2LP[1:0]		—	SS2FR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SS2FR	Software Standby 2 Fast Return	0: When returning from software standby mode 2, the fast return function is disabled 1: When returning from software standby mode 2, fast return function is enabled	R/W
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3, b2	SS2LP[1:0]	Software Standby 2 Low Power Select	b3 b2 0 0: SS2LP_0 (default mode) 0 1: SS2LP_1 (low power setting 1) Other settings are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

SS2FR Bit (Software Standby 2 Fast Return)

The SS2FR bit controls the time required to return from software standby mode 2 when the SS2LP[0] bit is 1.
When the SS2LP[1:0] bits are set to 01b (SS2LP_1), setting the SS2FR bit to 1 shortens the time required to return from software standby mode 2. Setting this bit to 1 is recommended. The only effect of setting this bit to 0 is extending the time to return from software standby mode 2. For details on the time to return, see section 67, Electrical Characteristics.
When the SS2LP[1:0] bits are set to 00b, the SS2FR bit setting is invalid.

SS2LP[1:0] Bit (Software Standby 2 Low Power Select)

The SS2LP[1:0] bits control the current consumption in software standby mode 2. Setting these bits to 01b (SS2LP_1) reduces the current consumption in software standby mode 2 relative to that when the bits are set to 00b (SS2LP_0). Since the time to return from software standby mode 2 becomes longer, setting the SS2FR bit to 1 is recommended. For details on the current consumption and time to return, see section 67, Electrical Characteristics.

11.2.19 Low Power Consumption State Control Register (LPSCR)

Address(es): SYSC.LPSCR 8701 9A90h, SYSC_NS.LPSCR 0701 9A90h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	LPMD[3:0]			
Value after reset:	0	0	0	0	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	LPMD[3:0]	Low Power Consumption Mode Setting	0h: Software standby mode/deep software standby mode is disabled 4h: Software standby mode 1 5h: Software standby mode 2 8h: Deep software standby mode 1 9h: Deep software standby mode 2 Ah: Deep software standby mode 3 Other settings are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The LPSCR register is used to control the transition destination of low power consumption mode.
The LPSCR register is not initialized by the internal reset signal (deep software standby reset signal) that is the source for release from deep software standby mode. For details, see section 6, Resets.

LPMD[3:0] Bits (Low Power Consumption Mode Setting)

The LPMD[3:0] bits indicate the destination of low power consumption mode. Actual low power consumption mode transition is executed by the WAIT instruction in the CPU.
The transition of software standby mode and deep software standby mode does not occur unless each WAIT instruction is executed in the CPU.
When an interrupt has initiated release from the low power consumption mode, the value of the LPMD[3:0] bits remains the same as before the transition. Writing 0 to this bit clears the bit itself.
Depending on the settings of bits in related registers, the transition to the low power consumption mode specified by the LPMD[3:0] bits may not proceed. For details, see Table 11.7.
While the MENTRYR.MENTRY bit is 1, the selection of software standby mode or deep software standby mode is ineffective. Even if the value of the LPMD[3:0] bits is any of 4h, 5h, or 8h to Ah, the MCU is placed in CPU deep sleep mode in response to the execution of a WAIT instruction.
While the OFS0.IWDTSLCSTP bit is 0 (counting continues), the selection of deep software standby mode 2 or 3 is ineffective. Even if the value of the LPMD[3:0] bits is any of 9h or Ah, the MCU is placed in deep software standby mode 1 in response to the execution of the WAIT instruction.
While the IWDTCSTPR.SLCSTP bit is 0 (counting continues), the selection of deep software standby mode 2 or 3 is ineffective. Even if the value of the LPMD[3:0] bits is any of 9h or Ah, the MCU is placed in deep software standby mode 1 in response to the execution of the WAIT instruction.
While the voltage monitor n (n = 1, 2) reset is enabled (PVDnCR0.RI = 1), the selection of deep software standby mode 2 or 3 is ineffective. Even if the value of the LPMD[3:0] bits is any of 9h or Ah, the MCU is placed in deep software standby mode 1 in response to the execution of the WAIT instruction.
If at least one of the PVDnCR0.RE (n = 4, 5) bis is 1, both of the PVDnCR0.RI (n = 1, 2) bits are 0, and stopping the counting operation of the IWDT in a low power consumption mode is specified (the OFS0.IWDTSLCSTP bit is 1 in auto-start mode or the IWDTCSTPR.SLCSTP bit is 1 in register start mode), the selection of deep software standby

mode 3 will be ineffective. Even if the value of the LPMD[3:0] bits is Ah, the MCU is placed in deep software standby mode 2 in response to the execution of the WAIT instruction.

11.2.20 Deep Software Standby Control Register (DPSBYCR)

Address(es): SYSC.DPSBYCR 8701 9A00h, SYSC_NS.DPSBYCR 0701 9A00h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	IOKEEP	—	—	DCSSMODE[1:0]		LDOSSMODE[1:0]	
Value after reset:	0	0	0	1	0	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b1, b0	LDOSSMODE[1:0]	LDO Soft Start Mode	Select the return time from deep software standby mode in LDO mode b1 b0 0 0: Setting prohibited 0 1: LDOSSMODE_1 1 0: LDOSSMODE_2 1 1: LDOSSMODE_3	R/W
b3, b2	DCSSMODE[1:0]	DCDC Soft Start Mode	Select the return time from deep software standby mode in DCDC mode b3 b2 0 0: Setting prohibited 0 1: DCSSMODE_1 1 0: DCSSMODE_2 1 1: DCSSMODE_3	R/W
b4	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	IOKEEP	I/O Port Retention	0: Upon release from deep software standby mode, the I/O ports, and D/A output are in the reset state 1: Upon release from deep software standby mode, the I/O ports, and D/A output are in the same state as in the deep software standby mode	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The DPSBYCR register is used to control the deep software standby mode.
The DPSBYCR register is not initialized by the internal reset signal (deep software standby reset signal) that is the source for release from deep software standby mode. For details, see section 6, Resets.

LDOSSMODE[1:0] Bits (LDO Soft Start Mode)

The LDOSSMODE[1:0] bits are used to select the time required to return from deep software standby mode in LDO mode. Increasing the time to return reduces the inrush current. For details on the time to return and inrush current, see section 67, Electrical Characteristics.

DCSSMODE[1:0] Bits (DCDC Soft Start Mode)

The DCSSMODE[1:0] bits are used to select the time required to return from deep software standby mode in DCDC mode. Increasing the time to return reduces the inrush current. For details on the time to return and inrush current, see section 67, Electrical Characteristics.

IOKEEP Bit (I/O Port Retention)

In deep software standby mode, I/O ports, and D/A output keep the same states as in the software standby mode. The IOKEEP bit determines whether the state of the I/O ports, and D/A output should be reset after release from deep software standby mode.

11.2.21 Deep Software Standby Interrupt Enable Register 0 (DPSIER0)

Address(es): SYSC.DPSIER0 8701 9A08h, SYSC_NS.DPSIER0 0701 9A08h

	b7	b6	b5	b4	b3	b2	b1	b0
	DIRQ7E	DIRQ6E	DIRQ5E	DIRQ4E	DIRQ3E	DIRQ2E	DIRQ1E	DIRQ0E
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DIRQ0E	IRQ0-DS Pin Enable	0: Release from deep software standby mode by the IRQ0-DS pin is disabled 1: Release from deep software standby mode by the IRQ0-DS pin is enabled	R/W
b1	DIRQ1E	IRQ1-DS Pin Enable	0: Release from deep software standby mode by the IRQ1-DS pin is disabled 1: Release from deep software standby mode by the IRQ1-DS pin is enabled	R/W
b2	DIRQ2E	IRQ2-DS Pin Enable	0: Release from deep software standby mode by the IRQ2-DS pin is disabled 1: Release from deep software standby mode by the IRQ2-DS pin is enabled	R/W
b3	DIRQ3E	IRQ3-DS Pin Enable	0: Release from deep software standby mode by the IRQ3-DS pin is disabled 1: Release from deep software standby mode by the IRQ3-DS pin is enabled	R/W
b4	DIRQ4E	IRQ4-DS Pin Enable	0: Release from deep software standby mode by the IRQ4-DS pin is disabled 1: Release from deep software standby mode by the IRQ4-DS pin is enabled	R/W
b5	DIRQ5E	IRQ5-DS Pin Enable	0: Release from deep software standby mode by the IRQ5-DS pin is disabled 1: Release from deep software standby mode by the IRQ5-DS pin is enabled	R/W
b6	DIRQ6E	IRQ6-DS Pin Enable	0: Release from deep software standby mode by the IRQ6-DS pin is disabled 1: Release from deep software standby mode by the IRQ6-DS pin is enabled	R/W
b7	DIRQ7E	IRQ7-DS Pin Enable	0: Release from deep software standby mode by the IRQ7-DS pin is disabled 1: Release from deep software standby mode by the IRQ7-DS pin is enabled	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

The DPSIER0 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

After the setting of the DPSIER0 register is modified, an edge may be internally generated depending on the state of the pin, resulting in the DPSIFR0 register being set to 1. Therefore, the DPSIFR0 register should be set to 0 before a transition to deep software standby mode.

For the sources of interrupts that cause release of the MCU from each type of deep software standby mode, see Table 11.4.

11.2.22 Deep Software Standby Interrupt Enable Register 1 (DPSIER1)

Address(es): SYSC.DPSIER1 8701 9A0Ch, SYSC_NS.DPSIER1 0701 9A0Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	DIRQ15E	DIRQ14E	DIRQ13E	DIRQ12E	DIRQ11E	DIRQ10E	DIRQ9E	DIRQ8E
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DIRQ8E	IRQ8-DS Pin Enable	0: Release from deep software standby mode by the IRQ8-DS pin is disabled 1: Release from deep software standby mode by the IRQ8-DS pin is enabled	R/W
b1	DIRQ9E	IRQ9-DS Pin Enable	0: Release from deep software standby mode by the IRQ9-DS pin is disabled 1: Release from deep software standby mode by the IRQ9-DS pin is enabled	R/W
b2	DIRQ10E	IRQ10-DS Pin Enable	0: Release from deep software standby mode by the IRQ10-DS pin is disabled 1: Release from deep software standby mode by the IRQ10-DS pin is enabled	R/W
b3	DIRQ11E	IRQ11-DS Pin Enable	0: Release from deep software standby mode by the IRQ11-DS pin is disabled 1: Release from deep software standby mode by the IRQ11-DS pin is enabled	R/W
b4	DIRQ12E	IRQ12-DS Pin Enable	0: Release from deep software standby mode by the IRQ12-DS pin is disabled 1: Release from deep software standby mode by the IRQ12-DS pin is enabled	R/W
b5	DIRQ13E	IRQ13-DS Pin Enable	0: Release from deep software standby mode by the IRQ13-DS pin is disabled 1: Release from deep software standby mode by the IRQ13-DS pin is enabled	R/W
b6	DIRQ14E	IRQ14-DS Pin Enable	0: Release from deep software standby mode by the IRQ14-DS pin is disabled 1: Release from deep software standby mode by the IRQ14-DS pin is enabled	R/W
b7	DIRQ15E	IRQ15-DS Pin Enable	0: Release from deep software standby mode by the IRQ15-DS pin is disabled 1: Release from deep software standby mode by the IRQ15-DS pin is enabled	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

The DPSIER1 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

After the setting of the DPSIER1 register is modified, an edge may be internally generated depending on the state of the pin, resulting in the DPSIFR1 register being set to 1. Therefore, the DPSIFR1 register should be set to 0 before a transition to deep software standby mode.

For the sources of interrupts that cause release of the MCU from each type of deep software standby mode, see Table 11.4.

11.2.23 Deep Software Standby Interrupt Enable Register 2 (DPSIER2)

Address(es): SYSC.DPSIER2 8701 9A10h, SYSC_NS.DPSIER2 0701 9A10h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DNMIE	DRTCAIE	DRTCIIE	DPVD2IE	DPVD1IE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DPVD1IE	PVD1 Deep Software Standby Release Signal Enable	0: Release from deep software standby mode by PVD1 is disabled 1: Release from deep software standby mode by PVD1 is enabled	R/W
b1	DPVD2IE	PVD2 Deep Software Standby Release Signal Enable	0: Release from deep software standby mode by PVD2 is disabled 1: Release from deep software standby mode by PVD2 is enabled	R/W
b2	DRTCIIE	RTC Periodic interrupt Deep Software Standby Release Signal Enable	0: Release from deep software standby mode by the RTC periodic interrupt signal is disabled 1: Release from deep software standby mode by the RTC periodic interrupt signal is enabled	R/W
b3	DRTCAIE	RTC Alarm Interrupt Deep Software Standby Release Signal Enable	0: Release from deep software standby mode by the RTC alarm interrupt signal is disabled 1: Release from deep software standby mode by the RTC alarm interrupt signal is enabled	R/W
b4	DNMIE	NMI Pin Deep Software Standby Release Signal Enable	0: Release from deep software standby mode by the NMI pin is disabled 1: Release from deep software standby mode by the NMI pin is enabled	R/W*1
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. 1 can be written only once. Once 1 is written to this bit, subsequent write accesses are disabled.

The DPSIER2 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

After the setting of the DPSIER2 register is modified, an edge may be internally generated depending on the state of the pin, resulting in the DPSIFR2 register being set to 1. Therefore, the DPSIFR2 register should be set to 0 before a transition to deep software standby mode.

For the sources of interrupts that cause release of the MCU from each type of deep software standby mode, see Table 11.4.

11.2.24 Deep Software Standby Interrupt Enable Register 3 (DPSIER3)

Address(es): SYSC.DPSIER3 8701 9A14h, SYSC_NS.DPSIER3 0701 9A14h

	b7	b6	b5	b4	b3	b2	b1	b0
	DVBATTADIE	DSOSTDIE	DIWDTIE	—	—	—	DUSBHSIE	DUSBFSIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DUSBFSIE	USB0 Suspend/Resume Deep Software Standby Release Signal Enable	0: Release from deep software standby mode by the USBFS suspend/resume is disabled 1: Release from deep software standby mode by the USBFS suspend/resume is enabled	R/W
b1	DUSBHSIE	USBHS Suspend/Resume Deep Software Standby Release Signal Enable	0: Release from deep software standby mode by the USBHS suspend/resume is disabled 1: Release from deep software standby mode by the USBHS suspend/resume is enabled	R/W
b4 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	DIWDTIE	IWDT Underflow Deep Software Standby Release Signal Enable	0: Release from deep software standby mode by an IWDT underflow is disabled 1: Release from deep software standby mode by an IWDT underflow is enabled	R/W
b6	DSOSTDIE	Sub-Clock Oscillation Stop Detection Deep Software Standby Release Signal Enable	0: Release from deep software standby mode by sub-clock oscillation stop detection is disabled 1: Release from deep software standby mode by sub-clock oscillation stop detection is enabled	R/W
b7	DVBATTADIE	VBATT Tamper Detection Deep Software Standby Release Signal Enable	0: Release from deep software standby mode by VBATT tamper detection is disabled 1: Release from deep software standby mode by VBATT tamper detection is enabled	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

The DPSIER3 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

After the setting of the DPSIER3 register is modified, an edge may be internally generated depending on the state of the pin, resulting in the DPSIFR3 register being set to 1. Therefore, the DPSIFR3 register should be set to 0 before a transition to deep software standby mode.

For the sources of interrupts that cause release of the MCU from each type of deep software standby mode, see Table 11.4.

11.2.25 Deep Software Standby Interrupt Enable Register 4 (DPSIER4)

Address(es): SYSC.DPSIER4 8701 9B40h, SYSC_NS.DPSIER4 0701 9B40h

	b7	b6	b5	b4	b3	b2	b1	b0
	DIRQ23E	DIRQ22E	DIRQ21E	DIRQ20E	DIRQ19E	DIRQ18E	DIRQ17E	DIRQ16E
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DIRQ16E	IRQ16-DS Pin Enable	0: Release from deep software standby mode by the IRQ16-DS pin is disabled 1: Release from deep software standby mode by the IRQ16-DS pin is enabled	R/W
b1	DIRQ17E	IRQ17-DS Pin Enable	0: Release from deep software standby mode by the IRQ17-DS pin is disabled 1: Release from deep software standby mode by the IRQ17-DS pin is enabled	R/W
b2	DIRQ18E	IRQ18-DS Pin Enable	0: Release from deep software standby mode by the IRQ18-DS pin is disabled 1: Release from deep software standby mode by the IRQ18-DS pin is enabled	R/W
b3	DIRQ19E	IRQ19-DS Pin Enable	0: Release from deep software standby mode by the IRQ19-DS pin is disabled 1: Release from deep software standby mode by the IRQ19-DS pin is enabled	R/W
b4	DIRQ20E	IRQ20-DS Pin Enable	0: Release from deep software standby mode by the IRQ20-DS pin is disabled 1: Release from deep software standby mode by the IRQ20-DS pin is enabled	R/W
b5	DIRQ21E	IRQ21-DS Pin Enable	0: Release from deep software standby mode by the IRQ21-DS pin is disabled 1: Release from deep software standby mode by the IRQ21-DS pin is enabled	R/W
b6	DIRQ22E	IRQ22-DS Pin Enable	0: Release from deep software standby mode by the IRQ22-DS pin is disabled 1: Release from deep software standby mode by the IRQ22-DS pin is enabled	R/W
b7	DIRQ23E	IRQ23-DS Pin Enable	0: Release from deep software standby mode by the IRQ23-DS pin is disabled 1: Release from deep software standby mode by the IRQ23-DS pin is enabled	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

The DPSIER4 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

After the setting of the DPSIER4 register is modified, an edge may be internally generated depending on the state of the pin, resulting in the DPSIFR4 register being set to 1. Therefore, the DPSIFR4 register should be set to 0 before a transition to deep software standby mode.

For the sources of interrupts that cause release of the MCU from each type of deep software standby mode, see Table 11.4.

11.2.26 Deep Software Standby Interrupt Enable Register 5 (DPSIER5)

Address(es): SYSC.DPSIER5 8701 9B44h, SYSC_NS.DPSIER5 0701 9B44h

	b7	b6	b5	b4	b3	b2	b1	b0
	DIRQ31E	DIRQ30E	DIRQ29E	DIRQ28E	DIRQ27E	DIRQ26E	DIRQ25E	DIRQ24E
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DIRQ24E	IRQ24-DS Pin Enable	0: Release from deep software standby mode by the IRQ24-DS pin is disabled 1: Release from deep software standby mode by the IRQ24-DS pin is enabled	R/W
b1	DIRQ25E	IRQ25-DS Pin Enable	0: Release from deep software standby mode by the IRQ25-DS pin is disabled 1: Release from deep software standby mode by the IRQ25-DS pin is enabled	R/W
b2	DIRQ26E	IRQ26-DS Pin Enable	0: Release from deep software standby mode by the IRQ26-DS pin is disabled 1: Release from deep software standby mode by the IRQ26-DS pin is enabled	R/W
b3	DIRQ27E	IRQ27-DS Pin Enable	0: Release from deep software standby mode by the IRQ27-DS pin is disabled 1: Release from deep software standby mode by the IRQ27-DS pin is enabled	R/W
b4	DIRQ28E	IRQ28-DS Pin Enable	0: Release from deep software standby mode by the IRQ28-DS pin is disabled 1: Release from deep software standby mode by the IRQ28-DS pin is enabled	R/W
b5	DIRQ29E	IRQ29-DS Pin Enable	0: Release from deep software standby mode by the IRQ29-DS pin is disabled 1: Release from deep software standby mode by the IRQ29-DS pin is enabled	R/W
b6	DIRQ30E	IRQ30-DS Pin Enable	0: Release from deep software standby mode by the IRQ30-DS pin is disabled 1: Release from deep software standby mode by the IRQ30-DS pin is enabled	R/W
b7	DIRQ31E	IRQ31-DS Pin Enable	0: Release from deep software standby mode by the IRQ31-DS pin is disabled 1: Release from deep software standby mode by the IRQ31-DS pin is enabled	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

The DPSIER5 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

After the setting of the DPSIER5 register is modified, an edge may be internally generated depending on the state of the pin, resulting in the DPSIFR5 register being set to 1. Therefore, the DPSIFR5 register should be set to 0 before a transition to deep software standby mode.

For the sources of interrupts that cause release of the MCU from each type of deep software standby mode, see Table 11.4.

11.2.27 Deep Software Standby Interrupt Flag Register 0 (DPSIFR0)

Address(es): SYSC.DPSIFR0 8701 9A18h, SYSC_NS.DPSIFR0 0701 9A18h

	b7	b6	b5	b4	b3	b2	b1	b0
	DIRQ7F	DIRQ6F	DIRQ5F	DIRQ4F	DIRQ3F	DIRQ2F	DIRQ1F	DIRQ0F
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DIRQ0F	IRQ0-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ0-DS pin 1: Request for release is generated on the IRQ0-DS pin	R/W*1
b1	DIRQ1F	IRQ1-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ1-DS pin 1: Request for release is generated on the IRQ1-DS pin	R/W*1
b2	DIRQ2F	IRQ2-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ2-DS pin 1: Request for release is generated on the IRQ2-DS pin	R/W*1
b3	DIRQ3F	IRQ3-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ3-DS pin 1: Request for release is generated on the IRQ3-DS pin	R/W*1
b4	DIRQ4F	IRQ4-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ4-DS pin 1: Request for release is generated on the IRQ4-DS pin	R/W*1
b5	DIRQ5F	IRQ5-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ5-DS pin 1: Request for release is generated on the IRQ5-DS pin	R/W*1
b6	DIRQ6F	IRQ6-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ6-DS pin 1: Request for release is generated on the IRQ6-DS pin	R/W*1
b7	DIRQ7F	IRQ7-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ7-DS pin 1: Request for release is generated on the IRQ7-DS pin	R/W*1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 after 1 is read.

Each flag is set to 1 when a request for release specified by the DPSIEGR0 register is generated.
This flag may be set to 1 when a request for release is generated in any mode (not only deep software standby mode). It may also be set to 1 by modifying the setting of the DPSIER0 register. Therefore, a transition to deep software standby mode should be made after the DPSIFR0 register is cleared to 00h.
To clear the DPSIFR0 register to 00h after modifying it, wait for at least six PCLKB cycles, read the DPSIFR0 register, and then write 0 to it. Six or more PCLKB cycles can be secured, for example, by reading the DPSIER0 register.
The DPSIFR0 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

DIRQnF Flag (IRQn-DS Pin Deep Software Standby Release Flag) (n = 0 to 7)

The DIRQnF flag indicates that a request for release has been generated on the IRQn-DS pin.
[Setting condition]

- A request for release is generated on the IRQn-DS pin specified by the DPSIEGR0 register

[Clearing condition]

- Writing 0 to each flag after 1 is read

11.2.28 Deep Software Standby Interrupt Flag Register 1 (DPSIFR1)

Address(es): SYSC.DPSIFR1 8701 9A1Ch, SYSC_NS.DPSIFR1 0701 9A1Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	DIRQ15F	DIRQ14F	DIRQ13F	DIRQ12F	DIRQ11F	DIRQ10F	DIRQ9F	DIRQ8F
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DIRQ8F	IRQ8-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ8-DS pin 1: Request for release is generated on the IRQ8-DS pin	R/W*1
b1	DIRQ9F	IRQ9-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ9-DS pin 1: Request for release is generated on the IRQ9-DS pin	R/W*1
b2	DIRQ10F	IRQ10-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ10-DS pin 1: Request for release is generated on the IRQ10-DS pin	R/W*1
b3	DIRQ11F	IRQ11-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ11-DS pin 1: Request for release is generated on the IRQ11-DS pin	R/W*1
b4	DIRQ12F	IRQ12-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ12-DS pin 1: Request for release is generated on the IRQ12-DS pin	R/W*1
b5	DIRQ13F	IRQ13-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ13-DS pin 1: Request for release is generated on the IRQ13-DS pin	R/W*1
b6	DIRQ14F	IRQ14-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ14-DS pin 1: Request for release is generated on the IRQ14-DS pin	R/W*1
b7	DIRQ15F	IRQ15-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ15-DS pin 1: Request for release is generated on the IRQ15-DS pin	R/W*1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 after 1 is read.

Each flag is set to 1 when a request for release specified by the DPSIEGR1 register is generated.
This flag may be set to 1 when a request for release is generated in any mode (not only deep software standby mode). It may also be set to 1 by modifying the setting of the DPSIER1 register. Therefore, a transition to deep software standby mode should be made after the DPSIFR1 register is cleared to 00h.
To clear the DPSIFR1 register to 00h after modifying it, wait for at least six PCLKB cycles, read the DPSIFR1 register, and then write 0 to it. Six or more PCLKB cycles can be secured, for example, by reading the DPSIER1 register.
The DPSIFR1 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

DIRQnF Flag (IRQn-DS Pin Deep Software Standby Release Flag) (n = 8 to 15)

The DIRQnF flag indicates that a request for release has been generated on the IRQn-DS pin.
[Setting condition]

- A request for release is generated on the IRQn-DS pin specified by the DPSIEGR1 register

[Clearing condition]

- Writing 0 to each flag after 1 is read

11.2.29 Deep Software Standby Interrupt Flag Register 2 (DPSIFR2)

Address(es): SYSC.DPSIFR2 8701 9A20h, SYSC_NS.DPSIFR2 0701 9A20h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DNMIF	DRTCAIF	DRTCIIF	DPVD2IF	DPVD1IF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DPVD1IF	PVD1 Deep Software Standby Release Flag	0: Request for release by PVD1 is not generated 1: Request for release by PVD1 is generated	R/W*1
b1	DPVD2IF	PVD2 Deep Software Standby Release Flag	0: Request for release by PVD2 is not generated 1: Request for release by PVD2 is generated	R/W*1
b2	DRTCIIF	RTC Periodic Interrupt Deep Software Standby Release Flag	0: Request for release by the RTC periodic interrupt signal is not generated 1: Request for release by the RTC periodic interrupt signal is generated	R/W*1
b3	DRTCAIF	RTC Alarm Interrupt Deep Software Standby Release Flag	0: Request for release by the RTC alarm interrupt signal is not generated 1: Request for release by the RTC alarm interrupt signal is generated	R/W*1
b4	DNMIF	NMI Pin Deep Software Standby Release Flag	0: Request for release is not generated on the NMI pin 1: Request for release is generated on the NMI pin	R/W*1
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 after 1 is read.

The PVDm deep software standby release flag (m = 1, 2) and NMI pin deep software standby release flag are set to 1 when the request for release corresponding to that specified in the DPSIEGR2 register is generated. The RTC periodic interrupt deep software standby release flag and RTC alarm interrupt deep software standby release flag are also set to 1 when the corresponding request for release is generated.

This flag may be set to 1 when a request for release is generated in any mode (not only deep software standby mode). It may also be set to 1 by modifying the setting of the DPSIER2 register. Therefore, a transition to deep software standby mode should be made after the DPSIFR2 register is cleared to 00h.

To clear the DPSIFR2 register to 00h after modifying it, wait for at least six PCLKB cycles, read the DPSIFR2 register, and then write 0 to it. Six or more PCLKB cycles can be secured, for example, by reading the DPSIER2 register.

The DPSIFR2 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

DPVDmIF Flag (PVDm Deep Software Standby Release Flag) (m = 1, 2)

The DPVDmIF flag indicates that a request for release by the voltage monitor m signal has been generated.

[Setting condition]

- A request for release is generated by the voltage monitor m signal that is selected in the DPSIEGR2 register

[Clearing condition]

- Writing 0 to each flag after 1 is read

DRTCIIF Flag (RTC Periodic Interrupt Deep Software Standby Release Flag)

This flag indicates that a request for release by the RTC interval interrupt signal has been generated.

[Setting condition]

- A request for release by the RTC periodic interrupt signal is generated

[Clearing condition]

- Writing 0 to each flag after 1 is read

DRTCAIF Flag (RTC Alarm Interrupt Deep Software Standby Release Flag)

This flag indicates that a request for release by the RTC alarm interrupt signal has been generated.

[Setting condition]

- A request for release by the RTC alarm interrupt signal is generated

[Clearing condition]

- Writing 0 to each flag after 1 is read

DNMIF Flag (NMI Pin Deep Software Standby Release Flag)

This flag indicates that a request for release has been generated on the NMI pin.

[Setting condition]

- A request for release is generated on the NMI pin specified by the DPSIEGR2 register

[Clearing condition]

- Writing 0 to each flag after 1 is read

11.2.30 Deep Software Standby Interrupt Flag Register 3 (DPSIFR3)

Address(es): SYSC.DPSIFR3 8701 9A24h, SYSC_NS.DPSIFR3 0701 9A24h

	b7	b6	b5	b4	b3	b2	b1	b0
	DVBATTADIF	DSOSTDIF	DIWDTIF	—	—	—	DUSBHSIF	DUSBFSIF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DUSBFSIF	USB0 Suspend/Resume Deep Software Standby Release Flag	0: Request for release by the USB suspend/resume is not generated 1: Request for release by the USB suspend/resume is generated	R/W*1
b1	DUSBHSIF	USBHS Suspend/Resume Deep Software Standby Release Flag	0: Request for release by the USBHS suspend/resume is not generated 1: Request for release by the USBHS suspend/resume is generated	R/W*1
b4 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	DIWDTIF	IWDT Underflow Deep Software Standby Release Flag	0: Request for release by an IWDT underflow is not generated 1: Request for release by an IWDT underflow is generated	R/W*1
b6	DSOSTDIF	Sub-Clock Oscillation Stop Detection Deep Software Standby Release Flag	0: Request for release by sub-clock oscillation stop detection is not generated 1: Request for release by sub-clock oscillation stop detection is generated	R/W*1
b7	DVBATTADIF	VBATT Tamper Detection Deep Software Standby Release Flag	0: Request for release by VBATT tamper detection is not generated 1: Request for release by VBATT tamper detection is generated	R/W*1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 after 1 is read.

Each flag is set to 1 when the corresponding request for release is generated.
This flag may be set to 1 when a request for release is generated in any mode (not only deep software standby mode). It may also be set to 1 by modifying the setting of the DPSIER3 register. Therefore, a transition to deep software standby mode should be made after the DPSIFR3 register is cleared to 00h.
To clear the DPSIER3 register to 00h after modifying it, wait for at least six PCLKB cycles, read the DPSIER3 register, and then write 0 to it. Six or more PCLKB cycles can be secured, for example, by reading the DPSIER3 register.
The DPSIFR3 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

DUSBFSIF Flag (USB0 Suspend/Resume Deep Software Standby Release Flag)

This flag indicates that a request for release by the USB0 suspend/resume has been generated.
The DUSBFSIF flag is a flag for USB0.
[Setting condition]

- A request for release by the USB0 suspend/resume is generated

[Clearing condition]

- Writing 0 after 1 is read

DUSBHSIF Flag (USBHS Suspend/Resume Deep Software Standby Release Flag)

This flag indicates that a request for release by the USBHS suspend/resume has been generated.
The DUSBHSIF flag is a flag for USBHS.
[Setting condition]

- A request for release by the USBHS suspend/resume is generated

[Clearing condition]

- Writing 0 after 1 is read

DIWDTIF Flag (IWDT Underflow Deep Software Standby Release Flag)

This flag indicates that a request for release by an IWDT underflow has been generated.
[Setting condition]

- A request for release by the IWDT is generated

[Clearing condition]

- Writing 0 after 1 is read

DSOSTDIF Flag (Sub-Clock Oscillation Stop Detection Deep Software Standby Release Flag)

This flag indicates that a request for release by sub-clock oscillation stop detection has been generated.
[Setting condition]

- A request for release by the SOSTD is generated

[Clearing condition]

- Writing 0 after 1 is read

DVBATTADIF Flag (VBATT Tamper Detection Deep Software Standby Release Flag)

This flag indicates that a request for release by the VBATT tamper detection has been generated.
[Setting condition]

- A request for release by the VBATT tamper detection is generated

[Clearing condition]

- Writing 0 after 1 is read

11.2.31 Deep Software Standby Interrupt Flag Register 4 (DPSIFR4)

Address(es): SYSC.DPSIFR4 8701 9B48h, SYSC_NS.DPSIFR4 0701 9B48h

	b7	b6	b5	b4	b3	b2	b1	b0
	DIRQ23F	DIRQ22F	DIRQ21F	DIRQ20F	DIRQ19F	DIRQ18F	DIRQ17F	DIRQ16F
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DIRQ16F	IRQ16-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ16-DS pin 1: Request for release is generated on the IRQ16-DS pin	R/W*1
b1	DIRQ17F	IRQ17-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ17-DS pin 1: Request for release is generated on the IRQ17-DS pin	R/W*1
b2	DIRQ18F	IRQ18-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ18-DS pin 1: Request for release is generated on the IRQ18-DS pin	R/W*1
b3	DIRQ19F	IRQ19-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ19-DS pin 1: Request for release is generated on the IRQ19-DS pin	R/W*1
b4	DIRQ20F	IRQ20-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ20-DS pin 1: Request for release is generated on the IRQ20-DS pin	R/W*1
b5	DIRQ21F	IRQ21-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ21-DS pin 1: Request for release is generated on the IRQ21-DS pin	R/W*1
b6	DIRQ22F	IRQ22-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ22-DS pin 1: Request for release is generated on the IRQ22-DS pin	R/W*1
b7	DIRQ23F	IRQ23-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ23-DS pin 1: Request for release is generated on the IRQ23-DS pin	R/W*1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 after 1 is read.

Each flag is set to 1 when a request for release specified by the DPSIEGR3 register is generated.
This flag may be set to 1 when a request for release is generated in any mode (not only deep software standby mode). It may also be set to 1 by modifying the setting of the DPSIER4 register. Therefore, a transition to deep software standby mode should be made after the DPSIFR4 register is cleared to 00h.
To clear the DPSIER4 register to 00h after modifying it, wait for at least six PCLKB cycles, read the DPSIFR4 register, and then write 0 to it. Six or more PCLKB cycles can be secured, for example, by reading the DPSIER4 register.
The DPSIFR4 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

DIRQnF Flag (IRQn-DS Pin Deep Software Standby Release Flag) (n = 16 to 23)

The DIRQnF flag indicates that a request for release has been generated on the IRQn-DS pin.
[Setting condition]

- A request for release is generated on the IRQn-DS pin specified by the DPSIEGR3 register

[Clearing condition]

- Writing 0 to each flag after 1 is read

11.2.32 Deep Software Standby Interrupt Flag Register 5 (DPSIFR5)

Address(es): SYSC.DPSIFR5 8701 9B4Ch, SYSC_NS.DPSIFR5 0701 9B4Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	DIRQ31F	DIRQ30F	DIRQ29F	DIRQ28F	DIRQ27F	DIRQ26F	DIRQ25F	DIRQ24F
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DIRQ24F	IRQ24-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ24-DS pin 1: Request for release is generated on the IRQ24-DS pin	R/W*1
b1	DIRQ25F	IRQ25-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ25-DS pin 1: Request for release is generated on the IRQ25-DS pin	R/W*1
b2	DIRQ26F	IRQ26-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ26-DS pin 1: Request for release is generated on the IRQ26-DS pin	R/W*1
b3	DIRQ27F	IRQ27-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ27-DS pin 1: Request for release is generated on the IRQ27-DS pin	R/W*1
b4	DIRQ28F	IRQ28-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ28-DS pin 1: Request for release is generated on the IRQ28-DS pin	R/W*1
b5	DIRQ29F	IRQ29-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ29-DS pin 1: Request for release is generated on the IRQ29-DS pin	R/W*1
b6	DIRQ30F	IRQ30-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ30-DS pin 1: Request for release is generated on the IRQ30-DS pin	R/W*1
b7	DIRQ31F	IRQ31-DS Pin Deep Software Standby Release Flag	0: Request for release is not generated on the IRQ31-DS pin 1: Request for release is generated on the IRQ31-DS pin	R/W*1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. Only 0 can be written to clear the flag. The flag must be cleared by writing 0 after 1 is read.

Each flag is set to 1 when a request for release specified by the DPSIEGR4 register is generated.
This flag may be set to 1 when a request for release is generated in any mode (not only deep software standby mode). It may also be set to 1 by modifying the setting of the DPSIER5 register. Therefore, a transition to deep software standby mode should be made after the DPSIFR5 register is cleared to 00h.
To clear the DPSIER5 register to 00h after modifying it, wait for at least six PCLKB cycles, read the DPSIER5 register, and then write 0 to it. Six or more PCLKB cycles can be secured, for example, by reading the DPSIER5 register.
The DPSIFR5 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

DIRQnF Flag (IRQn-DS Pin Deep Software Standby Release Flag) (n = 24 to 31)

The DIRQnF flag indicates that a request for release has been generated on the IRQn-DS pin.
[Setting condition]

- A request for release is generated on the IRQn-DS pin specified by the DPSIEGR4 register

[Clearing condition]

- Writing 0 to each flag after 1 is read

11.2.33 Deep Software Standby Interrupt Edge Register 0 (DPSIEGR0)

Address(es): SYSC.DPSIEGR0 8701 9A28h, SYSC_NS.DPSIEGR0 0701 9A28h

	b7	b6	b5	b4	b3	b2	b1	b0
	DIRQ7EG	DIRQ6EG	DIRQ5EG	DIRQ4EG	DIRQ3EG	DIRQ2EG	DIRQ1EG	DIRQ0EG
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DIRQ0EG	IRQ0-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b1	DIRQ1EG	IRQ1-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b2	DIRQ2EG	IRQ2-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b3	DIRQ3EG	IRQ3-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b4	DIRQ4EG	IRQ4-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W

b3	DIRQ11EG	IRQ11-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b4	DIRQ12EG	IRQ12-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b5	DIRQ13EG	IRQ13-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b6	DIRQ14EG	IRQ14-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b7	DIRQ15EG	IRQ15-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

The DPSIEGR1 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

11.2.35 Deep Software Standby Interrupt Edge Register 2 (DPSIEGR2)

Address(es): SYSC.DPSIEGR2 8701 9A30h, SYSC_NS.DPSIEGR2 0701 9A30h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DNMIEG	—	—	DPVD2EG	DPVD1EG
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DPVD1EG	PVD1 Edge Select	0: A request for release is generated when VCC < Vdet1 (fall) is detected 1: A request for release is generated when VCC ≥ Vdet1 (rise) is detected	R/W
b1	DPVD2EG	PVD2 Edge Select	0: A request for release is generated when VCC < Vdet2 (fall) is detected 1: A request for release is generated when VCC ≥ Vdet2 (rise) is detected	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	DNMIEG	NMI Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

The DPSIEGR2 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

11.2.36 Deep Software Standby Interrupt Edge Register 3 (DPSIEGR3)

Address(es): SYSC.DPSIEGR3 8701 9A34h, SYSC_NS.DPSIEGR3 0701 9A34h

	b7	b6	b5	b4	b3	b2	b1	b0
	DIRQ23EG	DIRQ22EG	DIRQ21EG	DIRQ20EG	DIRQ19EG	DIRQ18EG	DIRQ17EG	DIRQ16EG
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DIRQ16EG	IRQ16-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b1	DIRQ17EG	IRQ17-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b2	DIRQ18EG	IRQ18-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b3	DIRQ19EG	IRQ19-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b4	DIRQ20EG	IRQ20-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b5	DIRQ21EG	IRQ21-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b6	DIRQ22EG	IRQ22-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b7	DIRQ23EG	IRQ23-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

The DPSIEGR3 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

11.2.37 Deep Software Standby Interrupt Edge Register 4 (DPSIEGR4)

Address(es): SYSC.DPSIEGR4 8701 9B50h, SYSC_NS.DPSIEGR4 0701 9B50h

	b7	b6	b5	b4	b3	b2	b1	b0
	DIRQ31EG	DIRQ30EG	DIRQ29EG	DIRQ28EG	DIRQ27EG	DIRQ26EG	DIRQ25EG	DIRQ24EG
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DIRQ24EG	IRQ24-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b1	DIRQ25EG	IRQ25-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b2	DIRQ26EG	IRQ26-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b3	DIRQ27EG	IRQ27-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b4	DIRQ28EG	IRQ28-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b5	DIRQ29EG	IRQ29-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b6	DIRQ30EG	IRQ30-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W
b7	DIRQ31EG	IRQ31-DS Pin Edge Select	0: A request for release is generated at a falling edge 1: A request for release is generated at a rising edge	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

The DPSIEGR4 register is not initialized by the internal reset signal that is the source for release from deep software standby mode. For details, see section 6, Resets.

11.2.38 PLL1-LDO Control Register (PLL1LDOCR)

Address(es): SYSC.PLL1LDOCR 8701 9B04h, SYSC_NS.PLL1LDOCR 0701 9B04h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SKEEP	LDOSTP
Value after reset:	0	0	0	0	0	x	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LDOSTP	LDO Stop	0: PLL1-LDO is enabled 1: PLL1-LDO is stopped	R/W
b1	SKEEP	STBY Retention	0: PLL1-LDO is stopped during software standby mode 2 1: During software standby mode 2, the PLL1-LDO state before software standby mode 2 is retained	R/W
b2	—	Reserved	The read value is undefined.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

The PLL1LDOCR register is used to control the dedicated LDO for PLL1 (PLL1-LDO).

LDOSTP Bit (LDO Stop)

This bit controls switching of the PLL1-LDO on and off. After setting this bit to 1, do not set it to 0 for at least 1 µs. This bit can only be set to 0 after 1 µs has elapsed since it was set to 1.
If this bit is changed from 1 to 0, it takes 25 µs for the power supply to stabilize.
Allow the power supply to become stable before making this PLL1 setting.

SKEEP Bit (STBY Retention)

This bit controls the PLL1-LDO state during software standby mode 2. When PLL1-LDO operation stops in software standby mode 2, power consumption in software standby mode 2 can be reduced.

11.2.39 PLL2-LDO Control Register (PLL2LDOCR)

Address(es): SYSC.PLL2LDOCR 8701 9B08h, SYSC_NS.PLL2LDOCR 0701 9B08h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SKEEP	LDOSTP
Value after reset:	0	0	0	0	0	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	LDOSTP	LDO Stop	0: PLL2-LDO is enabled 1: PLL2-LDO is stopped	R/W
b1	SKEEP	STBY Retention	0: PLL2-LDO is stopped during software standby mode 2 1: During software standby mode 2, the PLL2-LDO state before software standby mode 2 is retained	R/W
b2	—	Reserved	The read value is undefined.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

The PLL2LDOCR register is used to control the dedicated LDO for PLL2 (PLL2-LDO).

LDOSTP Bit (LDO Stop)

This bit controls switching of the PLL2-LDO on and off. After setting this bit to 1, do not set it to 0 for at least 1 µs. This bit can only be set to 0 after 1 µs has elapsed since it was set to 1.
If this bit is changed from 1 to 0, it takes 25 µs for the power supply to stabilize.
Allow the power supply to become stable before making this PLL2 setting.

SKEEP Bit (STBY Retention)

This bit controls the PLL2-LDO state during software standby mode. If the PLL2-LDO operation is stopped during software standby mode, the power consumption during software standby mode can be reduced.

11.2.40 HOCO/LDO Control Register (HOCOLDOCR)

Address(es): SYSC.HOCOLDOCR 8701 9B0Ch, SYSC_NS.HOCOLDOCR 0701 9B0Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SKEEP	LDOSTP
Value after reset:	0	0	0	0	0	x	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LDOSTP	LDO Stop	0: HOCO-LDO is enabled 1: HOCO-LDO is stopped	R/W
b1	SKEEP	STBY Retention	0: HOCO-LDO is stopped during software standby mode 2 1: During software standby mode 2, the HOCO-LDO state before software standby mode 2 is retained	R/W
b2	—	Reserved	The read value is undefined.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

The HOCOLDOCR register is used to control the dedicated LDO for HOCO (HOCO-LDO).

LDOSTP Bit (LDO Stop)

This bit controls switching of the HOCO-LDO on and off. After setting this bit to 1, do not set it to 0 for at least 2 µs.
This bit can only be set to 0 after 2 µs has elapsed since it was set to 1.
If this bit is changed from 1 to 0, it takes 5 µs for the power supply to stabilize.
Allow the power supply to become stable before making this HOCO setting.

SKEEP Bit (STBY Retention)

This bit controls the HOCO-LDO state during software standby mode 2. When HOCO-LDO operation stops in software standby mode 2, power consumption in software standby mode 2 can be reduced.

11.2.41 Voltage Scaling Control Register (VSCR)

Address(es): SYSC.VSCR 8701 9014h, SYSC_NS.VSCR 0701 9014h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	VSCMTSF	—	VSCM[2:0]		
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	VSCM[2:0]	Voltage Scaling Control Mode	Set the VDD target voltage. b2 b0 0 0 1: VSCR_1 0 1 0: VSCR_2 (initial value) Settings other than the above are prohibited.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	VSCMTSF	Voltage Scaling Control Mode Transition Status Flag	• Read 0: Transition completed 1: During transition • Write Write 0	R
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

The VSCR register is used to control voltage scaling processing.

VSCM[2:0] Bits (Voltage Scaling Control Mode)

The VSCM bits set the VDD target voltage for voltage scaling processing. See section 67, Electrical Characteristics, for details on the VDD target voltage.

VSCMTSF Flag (Voltage Scaling Control Mode Transition Status Flag)

The VSCMTSF flag indicates the status when voltage scaling control processing is being executed. When a write attempt is made to change the voltage scaling mode, the VSCMTSF flag is set to 1. This flag is set to 0 when the voltage scaling control mode change is complete. Before performing the subsequent operation, make sure that the VSCMTSF flag is set to 0 (voltage scaling control mode transition processing is complete).

11.2.42 SSTBY Voltage Scaling Control Register (SVSCR)

Address(es): SYSC.SVSCR 8701 9A9Ch, SYSC_NS.SVSCR 0701 9A9Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SVSCM[2:0]		
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SVSCM[2:0]	SSTBY Voltage Scaling Control Mode	Set the VDD target voltage in SSTBY2. b2 b0 0 0 1: SVSCR_1 0 1 0: SVSCR_2 (initial value) 0 1 1: SVSCR_3 1 0 0: SVSCR_4 1 0 1: SVSCR_5 Settings other than the above are prohibited.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

The SVSCR register is used to control the voltage scaling processing in software standby mode 2.

SVSCM[2:0] Bits (SSTBY Voltage Scaling Control Mode)

The SVSCM bits set the VDD target voltage for voltage scaling processing in SSTBY2. See section 67, Electrical Characteristics, for details on the VDD target voltage.

When the SVSCM bit is set to SVSCR_1 and the value of the SSCR1.SS2LP[1:0] bits is 01b, transition to SSTBY2 mode is prohibited. When SVSCR_3, SVSCR_4, or SVSCR_5 is set, interrupt sources that can cause a return from SSTBY2 are limited to NMI and IRQ.

When using XSPI, setting SVSCR_4, or SVSCR_5 and transitioning to SSTBY2 is prohibited.

11.2.43 LDO Efficiency Control Register (LDOECR)

Address(es): SYSC.LDOECR 8701 9AF4h, SYSC_NS.LDOECR 0701 9AF4h

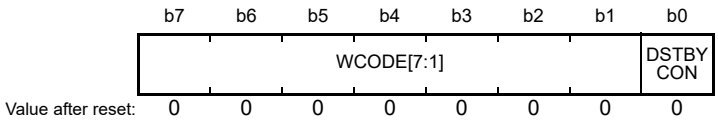
	b7	b6	b5	b4	b3	b2	b1	b0
	EFUPTSF	—	—	—	—	—	—	EFUPE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	EFUPE	LDO Efficiency Improvement Enable	0: LDO efficiency improvement function is disabled 1: LDO efficiency improvement function is enabled	R/W
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	EFUPTSF	LDO Efficiency Improvement Transition Status Flag	0: Transition completed 1: During transition	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

The LDOECR register is used to control enabling or disabling of the LDO efficiency improvement function in LDO mode.

EFUPE Bit (LDO Efficiency Improvement Enable)



This bit is used to improve the power efficiency of the LDO. In general, setting this bit to 1 is recommended. However, the power efficiency deteriorates when the VCC voltage is low. Consult the graph of the voltage dependence of the current consumption when the LDO efficiency improvement function is enabled in section 67, Electrical Characteristics, to determine whether or not to use this function.
Do not place the MCU in software standby mode or deep software standby mode when the EFUPE bit is 1. Set the EFUPE bit to 0 and wait for the EFUPTSF flag to become 0 before proceeding to place the MCU in software standby mode or deep software standby mode.

EFUPTSF Flag (LDO Efficiency Improvement Transition Status Flag)

The EFUPTSF flag is used to indicate the status of the LDO efficiency improvement function enable/disable processing. Do not write to the EFUPE bit when this flag is set to 1.

11.2.44 DSTBY Condition Control Register (DCCR)

Address(es): SYSC.DCCR 8701 9AB8h, SYSC_NS.DCCR 0701 9AB8h

Bit	Symbol	Bit Name	Description	R/W
b0	DSTBYCON	DSTBY Control	0: Transition to deep software standby mode is disabled 1: Transition to deep software standby mode is enabled	R/W
b7 to b1	WCODE[7:1]	Write Code	1010010: Writing 1 to DSTBYCON is enabled Other than above: Writing 0 to DSTBYCON is enabled	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

To set the DSTBYCON bit to 1, write 10100101b to the WCODE[7:1] bits.
If any value other than 10100101b is written to the WCODE[7:1] bits, the DSTBYCON bit will be set to 0.

DSTBYCON Bit (DSTBY Control)

After setting the LPSCR.LPMD[3:0] bits, set the DSTBYCON bit to 1 immediately before executing the deep software standby transition with the WAIT instruction.
Note that the DSTBYCON bit is automatically set to 0 when returning from deep software standby mode. For this reason, when transitioning back to deep software standby mode, set the DSTBYCON bit to 1 immediately before executing the WAIT instruction.

11.2.45 CPU Low Power Control Register (CLPCR)

Address(es): LPM.CLPCR 8700 6BFCh, LPM_NS.CLPCR 0700 6BFCh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	DEEPSLEEP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DEEPSLEEP	Deep Sleep Select	0: Transition to CPU sleep mode with WAIT instruction 1: Transition to CPU deep sleep mode with WAIT instruction	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

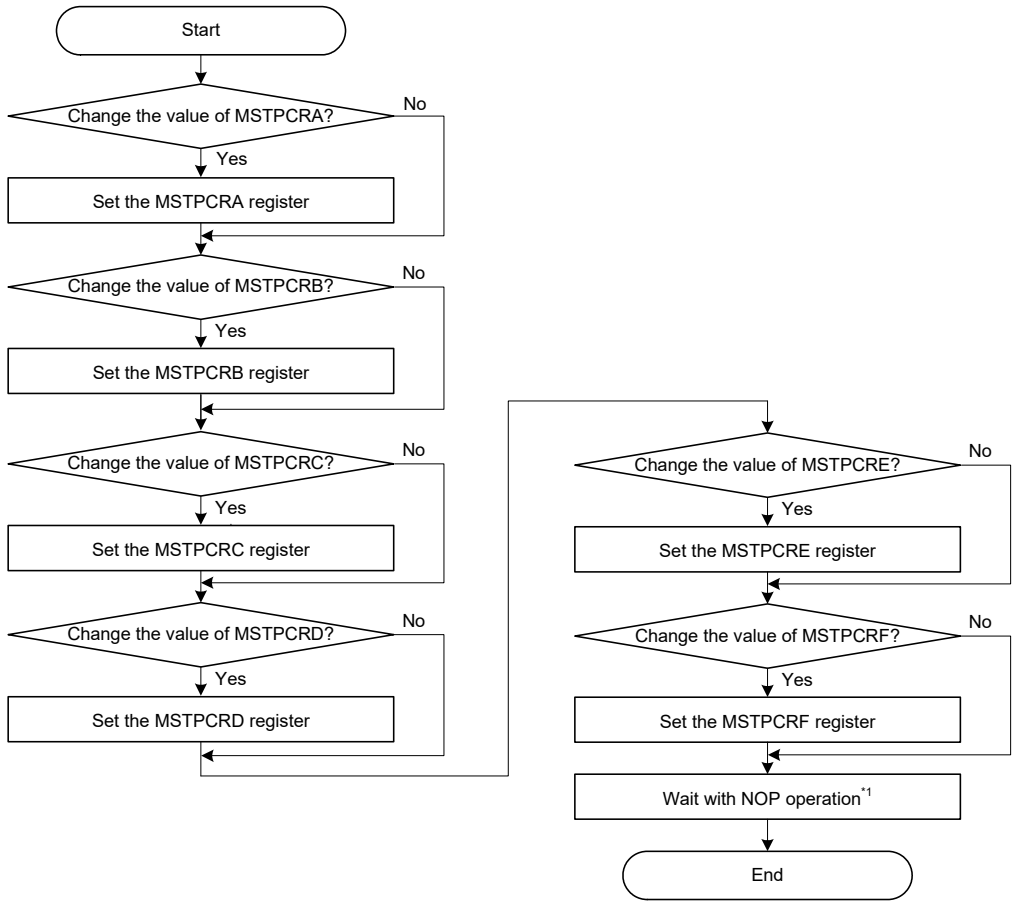
The security attribute of this register is set with the ICUSARC.SACLPCR0 bit.

DEEPSLEEP Bit (Deep Sleep Select)

This bit selects the low power mode for the CPU.

When 0, the MCU enters CPU sleep mode with the WAIT instruction.

When 1, the MCU enters CPU deep sleep mode with the WAIT instruction.



When transitioning to software standby mode or deep software standby mode, set this bit to 1.

11.3 Reducing Power Consumption by Switching Clock Signals

When the SCKDIVCR and SCKDIVCR2 registers are set, the clock frequency changes.
For details, see section 9, Clock Generation Circuit.

11.4 Module-Stop Function

The module-stop function can be set for each on-chip peripheral module.
When the MSTPmi bit (m = A to F; i = 31 to 0) in registers MSTPCRA to MSTPCRF is set to 1, the specified module stops operating and enters the module-stop state, but the CPU continues to operate independently. When the corresponding MSTPmi bit is set to 0, the module is released from the module-stop state and restarts operating at the end of the bus cycle. The internal states of modules are retained in the module-stop state.
After release from a reset, all modules except for the DMAC, DTC, EXDMAC, and RAM are placed in the module-stop state. Do not access a module while the corresponding MSTPmi bit is 1. Read data, write data, and module operation are not guaranteed. Also, do not set the MSTPmi bit to 1 while accessing the corresponding module.
If the CPUCLK0 is faster than the ICLK maximum frequency in the electrical characteristics, after the MSTPmi bit is changed, a wait time should be provided according to the flow shown in Figure 11.2. It is recommended to use software to measure the wait time. Be sure to consider the worst-case conditions to ensure that the required wait time elapses. If an interrupt is unavoidably generated during the wait time, retry the measurement after return from the interrupt.

Note 1. This is required to take up 30 µs in DCDC mode and 10 µs in external VDD mode. No waiting time is required in LDO mode.

Figure 11.2 Setting Flow of Module Stop Control Registers in Case of CPUCLK0 is Higher than the ICLK Maximum Frequency in Electrical Characteristics

11.5 Power Gating Control

The MCU supports the power gating function of the power domains.
Users can individually control the power on/off of divided power domains.
In the power-gated state, power to the domain is switched off and the domain is placed in the same state as indicated by the items listed under SSTBY2 in Table 11.3.

11.5.1 Power Gating Control Using the Power Domain Control Register

Table 11.6 shows the relationship between the PDCTR register and the target power domain.
When the PDCTR register is set, power gating control is executed. Be sure to set the MOCOCR.MCSTP bit to 0 (MOCO operation) to use the power gating function.
Do not place the MCU in CPU deep sleep mode, software standby mode, or deep software standby mode while power domain control through the PDCTRESWM register is in use (PDCTRESWM.PDCSF = 1).

Table 11.6 Relationship Between the PDCTR Register and the Target Power Domain

Control Register				Target Power Domain Name	Target Module
Register Name	PDDE	PDCSF	PDPGSF		
PDCTRESWM	Available	Available	Available	ESWM Domain	ESWM

Example of power gating control procedure
(1) Power Off with the PDCTRESWM.PDDE Bit*1
Step 1: Make sure that the target domain is not undergoing a power gating process.
- Confirm that PDCTRESWM.PDCSF = 0.
Step 2: Set the module stop control register so that the module stops.
- Write 1 to the MSTPCRC.MSTPC30 bit.
Step 3: Set the PDCTRESWM.PDDE bit and start power control.
- Write 1 to the PDCTRESWM.PDDE bit.
Step 4: Confirm that the power gating control is complete and that the target power domain is powered off.
- Confirm that PDCTRESWM.PDCSF = 0 and PDCTRESWM.PDPGSF = 1.

(2) Power On with the PDCTRESWM.PDDE Bit*1
Step 1: Make sure that the target domain is not undergoing a power gating process.
- Confirm that PDCTRESWM.PDCSF = 0.
Step 2: Set the PDCTRESWM.PDDE bit and start power control.
- Write 1 to the PDCTRESWM.PDDE bit.
Step 3: Confirm that the power gating control is complete and that the target power domain is powered on.
- Confirm that PDCTRESWM.PDCSF = 0 and PDCTRESWM.PDPGSF = 0.
Step 4: Set the module stop control register so that the module operates.
- Write 0 to the MSTPCRC.MSTPC30 bit.

Note 1. Do not change the PDCTRESWM register when the PDCTRESWM.PDCSF flag is set to 1 (power gating control processing in progress).

11.6 Low Power Consumption Modes

11.6.1 CPU Sleep Mode/CPU Deep Sleep Mode

This MCU has two low power consumption modes for the CPU: CPU sleep mode and CPU deep sleep mode. The mode is selected by the CLPCR.DEEPSLEEP bit. In CPU deep sleep mode, power to the CPU is switched off, lengthening the time to return from the mode but reducing power consumption more sharply. For details, see section 67, Electrical Characteristics. Aside from those points, operations in relation to CPU sleep mode and CPU deep sleep mode are the same.

11.6.1.1 Transition to CPU Sleep Mode or CPU Deep Sleep Mode

When the WAIT instruction is executed with the LPSCR.LPMD[3:0] bits set to 0h and the CLPCR.DEEPSLEEP bit set to 0, the MCU enters CPU sleep mode. When the WAIT instruction is executed with the LPSCR.LPMD[3:0] bits set to 0h and the CLPCR.DEEPSLEEP bit set to 1, the MCU enters CPU deep sleep mode. Set the MOCOCR.MCSTP bit to 0 (MOCO operation) before switching to either mode. In these modes, the CPU stops operating but the contents of its internal registers are retained. Other peripheral functions do not stop.

Counting by the IWDT stops if the MCU enters CPU sleep mode or CPU deep sleep mode while the IWDT is being used in auto-start mode and the OFS0.IWDTSLCSTP bit is 1 (stopping counting by the IWDT at transitions to CPU sleep mode or CPU deep sleep mode).
In the same way, counting by the IWDT stops if the MCU enters CPU sleep mode or CPU deep sleep mode while the IWDT is being used in register start mode and the SLCSTP bit in the IWDTCSTPR register is 1 (stopping counting by the IWDT at transitions to CPU sleep mode or CPU deep sleep mode).

Counting by the IWDT continues even if the MCU enters CPU sleep mode or CPU deep sleep mode while the IWDT is used in auto-start mode and the OFS0.IWDTSLCSTP bit is 0 (counting by the IWDT continues through transitions to CPU deep sleep mode or CPU deep sleep mode).
In the same way, counting by the IWDT continues even if the MCU enters CPU sleep mode or CPU deep sleep mode while the IWDT is being used in register start mode and the SLCSTP bit in the IWDTCSTPR register is 0 (counting by IWDT continues through transitions to CPU sleep mode or CPU deep sleep mode).

Counting by the WDT stops if the MCU enters CPU sleep mode or CPU deep sleep mode while the WDT is being used in auto-start mode and the OFS0.WDT0SLCSTP bit is 1 (stopping counting by the WDT at transitions to CPU sleep mode or CPU deep sleep mode). In the same way, counting by the WDT stops if the MCU enters CPU sleep mode or CPU deep sleep mode while the WDT is being used in register start mode and the SLCSTP bit in the WDTCSTPR register is 1 (stopping counting by the WDT at transitions to CPU sleep mode or CPU deep sleep mode).

Counting by the WDT continues even if the MCU enters CPU sleep mode or CPU deep sleep mode while the WDT is used in auto-start mode and the OFS0.WDT0SLCSTP bit is 0 (counting by the WDT continues through transitions to CPU deep sleep mode or CPU deep sleep mode). In the same way, counting by the WDT continues even if the MCU enters CPU sleep mode or CPU deep sleep mode while the WDT is being used in register start mode and the SLCSTP bit in the WDTCSTPR register is 0 (counting by WDT continues through transitions to CPU sleep mode or CPU deep sleep mode).

11.6.1.2 Release from CPU Sleep Mode/CPU Deep Sleep Mode

The MCU is released from CPU sleep mode or CPU deep sleep mode by resets or interrupts due to the following sources:

- Interrupt
- Reset:
  - RES# pin reset
  - Power-on reset
  - Voltage monitoring 0 reset
  - Independent watchdog timer reset
  - Watchdog timer reset
  - Voltage monitoring m reset (m = 1, 2, 4, 5)
  - Common memory error reset
  - Bus error reset
  - Core voltage monitoring reset
  - Temperature-monitoring reset
  - Local memory error reset

When resets or interrupts due to these sources are generated, operation of this MCU is as indicated under the corresponding heading below.

(1) Release triggered by an interrupt signal

Generation of an interrupt request releases the MCU from CPU sleep mode or CPU deep sleep mode and the MCU starts handling for the given interrupt.

(2) Release due to a reset on the RES# pin

When the RES# pin is driven low, the MCU enters the reset state. Keep the RES# pin at the low level for the period specified in section 67, Electrical Characteristics. When the RES# pin is driven high after the specified time period, the CPU starts reset exception handling.

(3) Release due to an IWDT reset

Generation of an internal reset due to an IWDT underflow releases the MCU from CPU sleep mode or CPU deep sleep mode and the MCU starts reset exception handling. However, since the IWDT is stopped in CPU sleep mode and CPU deep sleep mode under the following conditions, it will not generate an internal reset to release the MCU from CPU sleep mode or CPU deep sleep mode.

- OFS0.IWDTSTRT = 0 (auto-start mode) and OFS0.IWDTSLCSTP = 1
- OFS0.IWDTSTRT = 1 (register start mode) and IWDTCSTPR.SLCSTP = 1

(4) Release due to a WDT reset

Generation of an internal reset due to a WDT underflow releases the MCU from CPU sleep mode or CPU deep sleep mode and the MCU starts reset exception handling. However, since the WDT is stopped in CPU sleep mode and CPU deep sleep mode under the following conditions, it will not generate an internal reset to release the MCU from CPU sleep mode or CPU deep sleep mode.

- OFS0.WDT0STRT = 0 (auto-start mode) and OFS0.WDT0SLCSTP = 1
- OFS0.WDT0STRT = 1 (register start mode) and WDTCSTPR.SLCSTP = 1

(5) Release due to other resets in CPU sleep mode or CPU deep sleep mode

The MCU is released from CPU sleep mode or CPU deep sleep mode by any other reset and it starts reset exception handling.

Note: For details on the settings of interrupts, see section 15, Interrupt Controller (ICUM).

11.6.2 Software Standby Mode

11.6.2.1 Transitioning to Software Standby Mode

When the WAIT instruction is executed with the LPSCR.LPMD[3:0] bits set to 4h or 5h and the CLPCR.DEEPSLEEP bit set to 1, the MCU enters software standby mode 1 or 2 according to the setting in the LPSCR.LPMD[3:0] bits. Be sure to set the MOCOCR.MCSTP bit to 0 (MOCO operation) before executing the WAIT instruction to place the MCU in this mode.

In software standby mode 1 or 2, the CPU, most of the on-chip peripheral functions and most of the oscillators stop*1. However, the contents of the CPU internal registers, RAM data, and the states of on-chip peripheral functions and the I/O ports are retained.
Software standby mode 1 or 2 allows significant reduction in power consumption because most oscillators stop in this mode. Table 11.3 shows the status of each on-chip peripheral function and oscillator.
In addition, setting the SSCR1.SS2LP[1:0] bits to 01b (low power setting 1) can further reduce power consumption in software standby mode 2. For details, see section 11.2.18, Software Standby Control Register 1 (SSCR1).

Note 1. The state of the oscillators depends on the setting of the control register for each oscillator. For details, see section 9, Clock Generation Circuit.

The status of address bus and bus control signals in software standby mode can be selected by SBYCR.OPE bit.
The SBYCR.OPE bit specifies whether the address bus and bus control signals are placed in the high-impedance state or retain the output in software standby mode.

Set the DMAST.DMST bit, DTCST.DTCST bit, and EDMAST.DMST bit to 0 before executing the WAIT instruction.

Counting by IWDT stops when the MCU enters software standby mode while the IWDT is in auto-start mode and the OFS0.IWDTSLCSTP bit is 1 (stopping counting by the IWDT at transitions to software standby mode). Similarly, counting by IWDT stops when the MCU enters software standby mode while the IWDT is in register start mode and the SLCSTP bit in the IWDTCSTPR register is 1 (stopping counting by the IWDT at transitions to software standby mode).

Counting by IWDT continues even when the MCU enters software standby mode while the IWDT is in auto-start mode and the OFS0.IWDTSLCSTP bit is 0 (counting by IWDT continues through transitions to software standby mode). Similarly, counting by IWDT continues even when the MCU enters software standby mode while the IWDT is in register start mode and the SLCSTP bit in the IWDTCSTPR register is 0 (counting by IWDT continues through transitions to software standby mode).

WDT stops counting when the MCU enters software standby mode 1 or 2 because the PCLK stops.

Do not place the MCU in software standby mode while MRAM is being programmed. In order to switch to software standby mode in this situation, wait until the programming procedure is complete and then execute the WAIT instruction.

Do not place the MCU in software standby mode while MRAM configuration update transfer control is in progress. In order to switch to software standby mode in this situation, wait until the configuration update transfer control is complete and then execute the WAIT instruction.

Do not place the MCU in software standby mode 1 or 2 while the LDO efficiency improvement function is enabled (LDOECR.EFUPE = 1). To set the LDOECR.EFUPE bit to 0 to switch to this mode, wait until the LDOECR.EFUPTSF flag becomes 0 before starting the transition.

In external VDD mode, do not put the MCU into software standby mode 1 or 2.

Depending on the register bit settings, the MCU may not transition to the low power mode set by the LPSCR.LPMD[3:0] bits.
Table 11.7 shows the relationship between the settings of the register bits that affect the transition to low power consumption mode, the settings of the LPSCR.LPMD[3:0] bits, and the low power consumption mode to which the transition occurs.

Table 11.7 Relationship Between the Settings of the Register Bits That Affect the Transition to Low Power Consumption Mode, Settings of the LPSCR.LPMD[3:0] Bits, and Low Power Consumption Mode to Which the Transition Occurs

		LPSCR.LPMD[3:0] Bit Setting (When the WAIT Instruction Is Executed with CLPCR.DEEPSLEEP = 1)				
		4h (SSTBY1)	5h (SSTBY2)	8h (DSTBY1)	9h (DSTBY2)	Ah (DSTBY3)
Bit setting that affects the transition to low power consumption mode	MENTRYR.MENTRY = 1	CPU deep sleep mode	CPU deep sleep mode	CPU deep sleep mode	CPU deep sleep mode	CPU deep sleep mode
	OFS0.IWDTSLCSTP = 0 (in auto-start mode)	No effect (software standby 1)	No effect (software standby 2)	No effect (deep software standby 1)	Deep software standby 1	Deep software standby 1
	IWDTCSTPR.SLCSTP = 0 (in register start mode)	No effect (software standby 1)	No effect (software standby 2)	No effect (deep software standby 1)	Deep software standby 1	Deep software standby 1
	PVD1CR0.RI = 1	No effect (software standby 1)	No effect (software standby 2)	No effect (deep software standby 1)	Deep software standby 1	Deep software standby 1
	PVD2CR0.RI = 1	No effect (software standby 1)	No effect (software standby 2)	No effect (deep software standby 1)	Deep software standby 1	Deep software standby 1
	PVD4CR0.RE = 1	No effect (software standby 1)	No effect (software standby 2)	No effect (deep software standby 1)	No effect (deep software standby 2)	Deep software standby 2
	PVD5CR0.RE = 1	No effect (software standby 1)	No effect (software standby 2)	No effect (deep software standby 1)	No effect (deep software standby 2)	Deep software standby 2

Note: If multiple bit settings that affect low power consumption mode transition are set, the higher priority conditions in Table 11.7 take precedence. For example, if LPSCR.LPMD[3:0] = Ah and PVD1CR0.RI = 1 and PVD4CR0.RE = 1, the low-power mode that is transitioned to is deep software standby 1.

11.6.2.2 Release from Software Standby Mode

The MCU is released from software standby mode 1 or 2 by any of the interrupts listed in Table 11.4, a RES# pin reset, a power-on reset, a voltage monitoring reset, a core voltage monitoring reset, a reset caused by an IWDT underflow, or a temperature monitoring reset.
Upon release from software standby mode, the oscillators that were running before a transition to the mode restart operation. After the operation of all these oscillators has become stable, the MCU returns from software standby to normal operating mode.

(1) Release triggered by an interrupt signal

When an interrupt request (see Table 11.4) is generated, each oscillator that was operating before transitioning to software standby mode resumes operation. After all these oscillators have been stabilized, the MCU returns from software standby mode to normal mode and starts interrupt processing.
When release from software standby mode is initiated by an interrupt, each power domain returns to the same power state as the state before entering the software standby state.

(2) Release due to a reset on the RES# pin

When the RES# pin is set to low, the MCU transitions to the reset state, and the oscillator that was in the operating state by default starts oscillating. Be sure to keep the RES# pin low for the time period specified in section 67, Electrical Characteristics. When the RES# pin is driven high after the specified time period, the CPU starts the reset exception processing.

(3) Release due to a power-on reset

The MCU is released from software standby mode by a power-on reset and it starts the reset exception processing.

(4) Release due to a voltage monitoring reset

The MCU is released from software standby mode by a voltage monitoring reset by the voltage detection circuit and it starts the reset exception processing.

(5) Release due to an IWDT reset

When an internal reset is generated due to an IWDT underflow, the MCU is released from software standby mode and it starts reset exception processing. However, under the following conditions, the IWDT stops in software standby mode, and an internal reset to initiate a release from software standby mode is not generated.

- OFS0.IWDTSTRT = 0 (auto-start mode) and OFS0.IWDTSLCSTP = 1
- OFS0.IWDTSTRT = 1 (register start mode) and IWDTCSTPR.SLCSTP = 1

(6) Release due to a core voltage monitoring reset

The MCU is released from software standby mode by a core voltage monitoring reset (CVMR) and it starts the reset exception processing.

(7) Release due to a temperature monitoring reset

The MCU is released from software standby mode by a temperature monitoring reset and it then starts reset exception handling.

11.6.2.3 Example of Software Standby Mode Application

Figure 11.3 shows an example where a transition to software standby mode is made at the falling edge of the IRQn (n = 0 to 31) pin, and release from software standby mode is initiated at the rising edge of the IRQn pin.
In this example, an IRQn interrupt is accepted with the IRQCRi.IRQMD[1:0] (i = 0 to 31) bits of the ICU set to 00b (falling edge), and then the IRQCRi.IRQMD[1:0] bits are set to 01b (rising edge). Furthermore, if MOCO is not operating, MOCOCR.MCSTP must be set to 0 (MOCO operation). Next, after the LPSCR.LPMD[3:0] bits are set to 4h and the CLPCR.DEEPSLEEP bit set to 1, the WAIT instruction is executed.
Thus, a transition to software standby mode 1 is made. After that, release from software standby mode 1 is initiated at the rising edge of the IRQn pin.
To return from software standby mode, settings of the ICU are also necessary. For details, see section 15, Interrupt Controller (ICUM). Figure 11.3 The oscillation stabilization time in is specified in section 67, Electrical Characteristics.

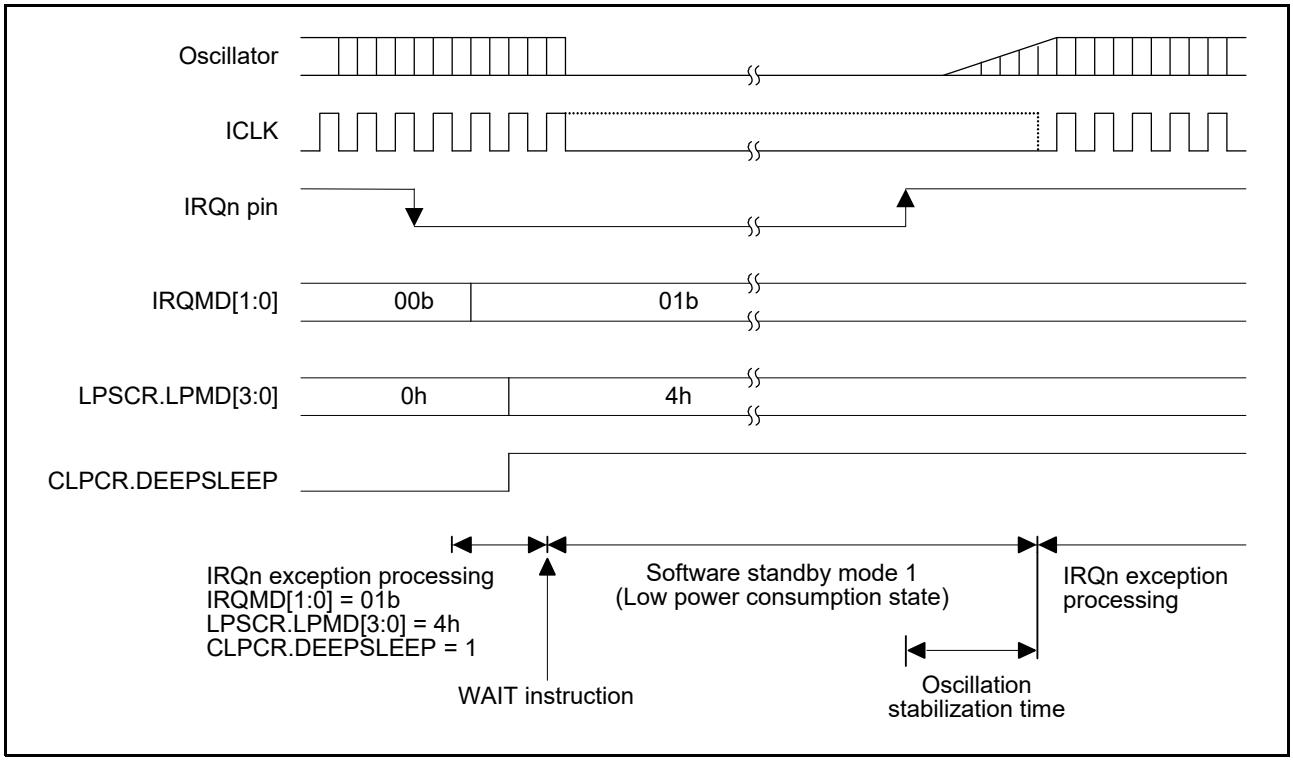


Figure 11.3 Example of Software Standby Mode Application

11.6.3 Deep Software Standby Mode

11.6.3.1 Transition to Deep Software Standby Mode

When the WAIT instruction is executed with the LPSCR.LPMD[3:0] bits set to 8h, 9h or Ah, the CLPCR.DEEPSLEEP bit set to 1 and the DCCR.DSTBYCON bit set to 1, the MCU enters deep software standby mode 1, 2 or 3 according to the setting in the LPSCR.LPMD[3:0] bits. Before executing the WAIT instruction to transition to this mode, the MOCOCR.MCSTP bit must be set to 0 (MOCO operation).

In these modes, almost all of the CPU, on-chip peripheral functions, SRAM, and oscillators are stopped. Furthermore, since the internal power supply to these inactive modules is stopped, power consumption is remarkably reduced. The contents of all the registers of the CPU and specific internal peripheral modules become undefined. For details, see Table 11.3.

When the battery backup function is in use in deep software standby mode 1 or 2, setting OFS1.PVDAS = 0 and OFS1.DSBYLPSEL = 0 further reduces power consumption in the deep software standby mode because the power switch is controlled by the voltage detection 0 circuit (PVD0), which consumes less power than the voltage detection circuit in the battery backup function. In deep software standby mode 2, the supply of internal power to the USB0 resume detection unit, USBHS resume detection unit, and IWDT is also stopped, further reducing power consumption. In deep software standby mode 3, the PVD is also stopped, even further reducing power consumption. For details, see section 67, Electrical Characteristics.

Set the DMAST.DMST bit, DTCST.DTCST bit, and EDMAST.DMST bit to 0 and then execute the WAIT instruction.

Depending on the settings of bits in related registers, the transition to the deep software standby mode specified by the LPSCR.LPMD[3:0] bits may not proceed. Table 11.7 lists the relationships between the register bit settings that may affect transitions to the low power consumption modes, the LPSCR.LPMD[3:0] bit settings, and the low power consumption mode to which the transition proceeds.

When the MCU is placed in deep software standby mode 2 or 3 while the IWDT is in auto-start mode and the OFS0.IWDTSLCSTP bit is 1, the IWDT clock (IWDTCLK) stops and the power supply to the IWDT is turned off. Counting by the IWDT thus also stops.

When the IWDT is in auto-start mode and the OFS0.IWDTSLCSTP bit is 0, the MCU enters deep software standby mode 1 instead of deep software standby mode 2 or 3, regardless of the setting in the LPSCR.LPMD[3:0] bits.

When the IWDT is in register start mode and the IWDTCSTPR.SLCSTP is 0, the MCU enters deep software standby mode 1 instead of deep software standby mode 2 or 3, regardless of the setting in the LPSCR.LPMD[3:0] bits.

If one of the PVDnCR0.RI (n = 1, 2) bits is set to 1 (voltage monitoring n reset selected), the MCU enters deep software standby mode 1 instead of entering deep software standby mode 2 or 3 regardless of the setting of the LPSCR.LPMD[3:0] bits.

If both of the PVDnCR0.RI (n = 1, 2) bits are set to 0, at least one of the PVDnCR0.RE (n = 4, 5) bits is set to 1, and stopping the counting operation of the IWDT in a low power consumption mode is specified (the OFS0.IWDTSLCSTP bit is 1 in auto-start mode or the IWDTCSTPR.SLCSTP bit is 1 in register start mode), the MCU enters deep software standby mode 2 instead of deep software standby mode 3 regardless of the setting of the LPSCR.LPMD[3:0] bits.

The states of the I/O port pins are the same as those in software standby mode.

Do not place the MCU in deep software standby mode while MRAM is being programmed. In order to switch to deep software standby mode in this situation, wait until the programming procedure is complete and then execute the WAIT instruction.

Do not place the MCU in deep software standby mode while MRAM configuration update transfer control is in progress. In order to switch to deep software standby mode in this situation, wait until the configuration update transfer control is complete and then execute the WAIT instruction.

Do not place the MCU in deep software standby mode in LDO mode with LDOECR.EFUPE = 1. To set the LDOECR.EFUPE bit to 0 to switch to this mode, wait until the LDOECR.EFUPTSF flag becomes 0 before starting the transition.

In external VDD mode, do not put the MCU into deep software standby mode.

11.6.3.2 Release from Deep Software Standby Mode

Release from deep software standby mode is initiated by any of the interrupts shown in Table 11.4, an RES# pin reset, a power-on reset, a voltage monitoring reset, a reset caused by an IWDT underflow, or a temperature monitoring reset.

(1) Release triggered by an interrupt signal

Release from deep software standby mode is controlled by registers DPSIERn (n = 0 to 5) and DPSIFRn (n = 0 to 5). When a deep software standby release interrupt is generated, the corresponding flag in the DPSIFRn register is set to 1. At this time, if release from deep software standby mode by the interrupt is enabled in the DPSIERn register, release from deep software standby mode proceeds. Rising edge or falling edge can be selected by the DPSIEGRn register (n = 0 to 4). The interrupts for which an edge can be selected are NMIs, IRQ0-DS to IRQ31-DS, voltage monitoring n (n = 1, 2) interrupts. When a request for release from deep software standby mode is generated, the internal power is supplied and MOCO starts oscillating, and then an internal reset (deep software standby reset) is generated for the entire MCU.
The stable MOCO clock is then supplied to the entire MCU, which is released from the deep software standby reset. Then, the MCU starts reset exception processing.
When release from deep software standby mode is triggered by an external interrupt pin or internal interrupt signal, the RSTSR0.DPSRSTF flag is set to 1.

(2) Release due to a reset on the RES# pin

When the RES# pin is driven low, the MCU is released from deep software standby mode and enters a reset state. Make sure to keep RES# pin low for the time period specified in the section of Electrical Specifications. When the RES# pin is driven high after the specified time period, the CPU starts the reset exception processing.

(3) Release due to a power-on reset

The MCU is released from deep software standby mode by a power-on reset and it starts the reset exception processing.

(4) Release due to a voltage monitoring 0 reset

The MCU is released from deep software standby mode by a voltage monitoring 0 reset from the voltage detection circuit and it starts the reset exception processing.

(5) Release due to a voltage monitoring n reset (n = 1, 2)

The MCU is released from deep software standby mode 1 or 2 by a voltage monitoring n reset (n = 1, 2) from the voltage detection circuit and it starts the reset exception processing.
A voltage monitoring n reset (n = 1, 2) from the voltage detection circuit causes the MCU to be released from deep software standby mode 1 or 2 and the MCU starts the reset exception processing.

(6) Release due to an IWDT reset

An IWDT reset (internal reset due to an underflow of the IWDT) leads to release from deep software standby mode 1 and the MCU starts the reset exception processing. However, under the following conditions, the IWDT stops in deep software standby mode 1, and an IWDT reset to initiate a release from deep software standby mode 1 is not generated.

- OFS0.IWDTSTRT = 0 (auto-start mode) and OFS0.IWDTSLCSTP = 1
- OFS0.IWDTSTRT = 1 (register start mode) and IWDTCSTPR.SLCSTP = 1

(7) Release due to a temperature monitoring reset

The MCU is released from deep software standby mode by a temperature monitoring reset and it then starts reset exception handling.

11.6.3.3 Pin States at the Time of Release from Deep Software Standby Mode

In deep software standby mode, the I/O ports remain in the same state as before transitioning to deep software standby mode. The MCU is initialized by an internal reset generated on release from deep software standby mode. Upon release from deep software standby mode, reset exception processing starts immediately.
Whether to initialize the I/O ports or to retain the I/O port states as before transition to deep software standby mode can be selected by the DPSBYCR.IOKEEP bit.

- When the DPSBYCR.IOKEEP bit = 0

I/O ports are initialized by an internal reset generated on release from deep software standby mode.

- When the DPSBYCR.IOKEEP bit = 1

Although the MCU is initialized by an internal reset generated on release from deep software standby mode, I/O ports remain in the same state as before transitioning to deep software standby mode. At this time, the I/O port states remain unchanged as before transition to deep software standby mode even if settings of I/O ports or peripheral modules are made. Then, the retained I/O port states are released by setting the DPSBYCR.IOKEEP bit to 0, and the MCU operates according to the internal state.
The DPSBYCR.IOKEEP bit is not initialized by the internal reset signal (deep software standby reset signal) that is the source for release from deep software standby mode.

11.6.3.4 Example of Deep Software Standby Mode Application

Figure 11.4 shows an example where a transition to deep software standby mode is made at the falling edge of the IRQn-DS pin, and release from deep software standby mode is initiated at the rising edge of the IRQn-DS pin. In this example, an IRQn interrupt is accepted with the IRQCRi.IRQMD[1:0] bits of the ICU set to 00b (falling edge). If MOCO is not operating, the MOCOCR.MCSTP bit must be set to 0 (MOCO operation). After that, the DPSIEGRy.DIRQnEG (y = 0, 1, 4, 5; n = 0 to 31) bit is set to 1 (rising edge), the LPSCR.LPMD[3:0] bits are set to 8h, 9h or AH, the CLPCR.DEEPSLEEP bit is set to 1, the DCCR.DSTBYCON bit is set to 1, and then the WAIT instruction is executed. Thus, a transition to deep software standby mode is made. After that, release from deep software standby mode is initiated at the rising edge of the IRQn-DS pin.

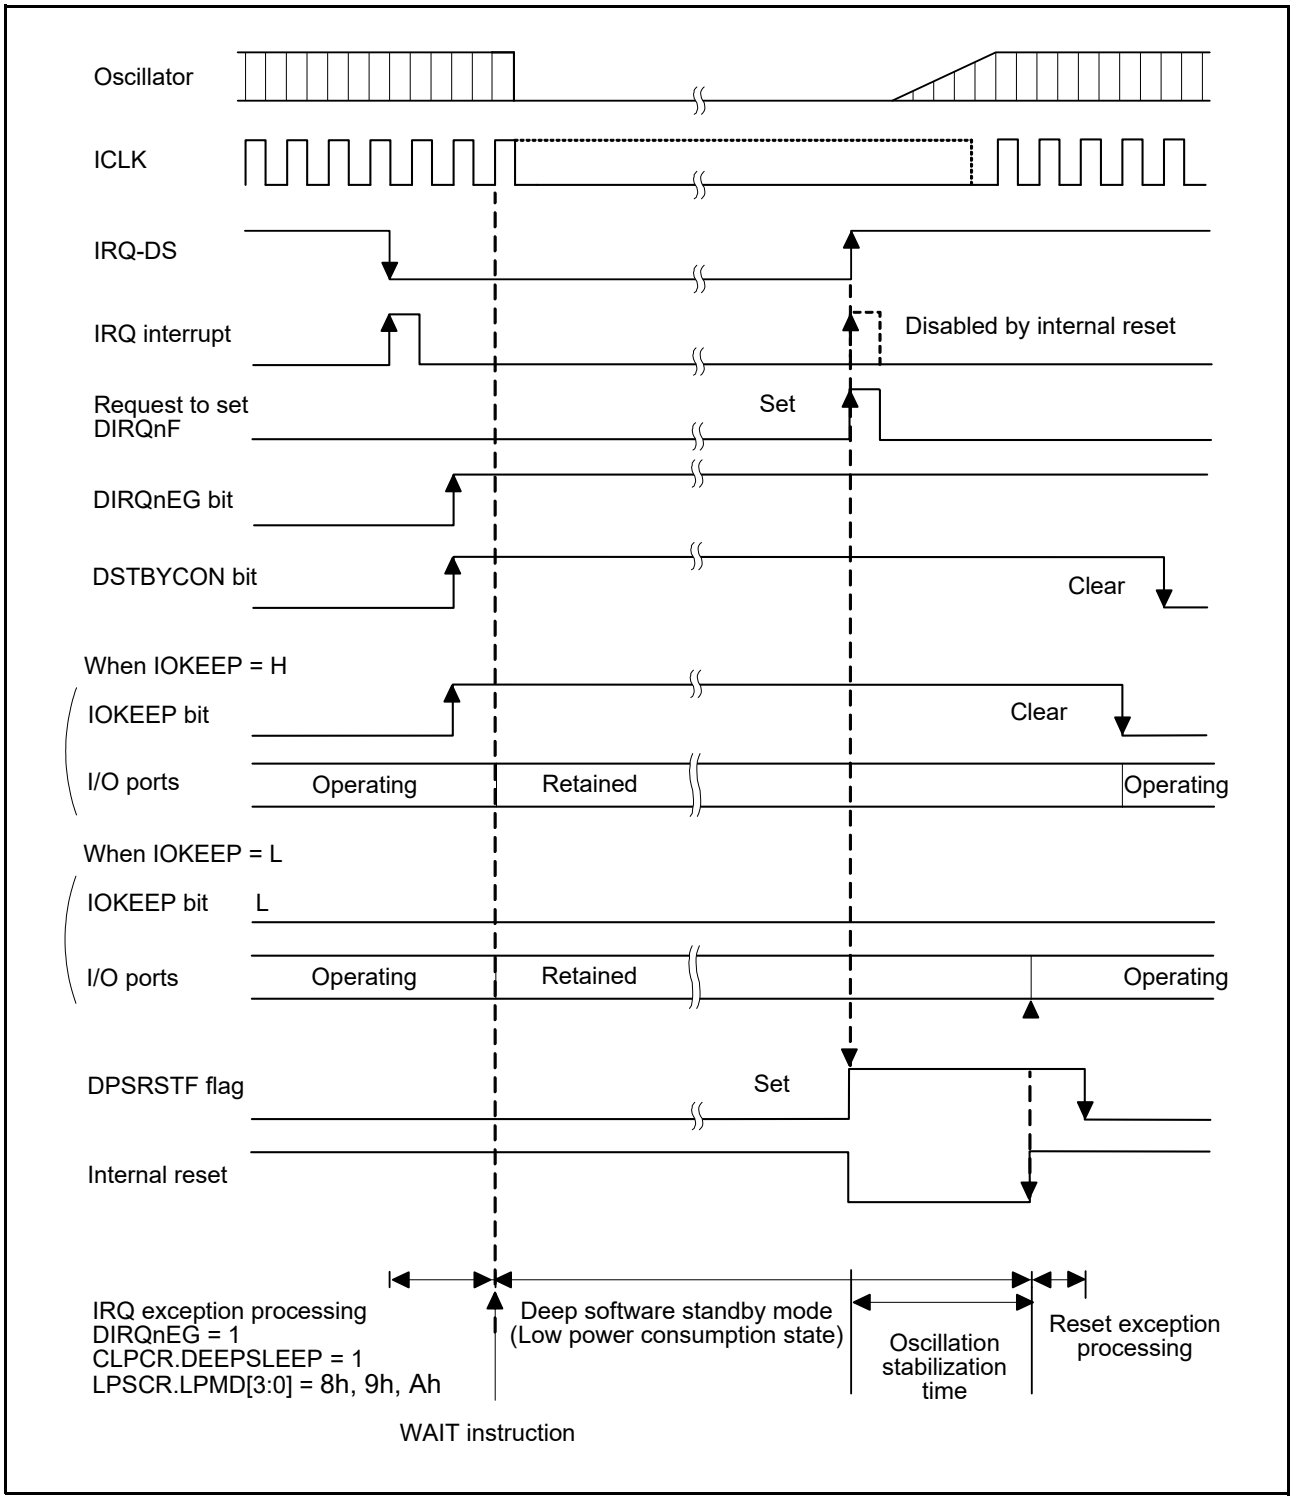

Figure 11.4 Example of Deep Software Standby Mode Application

11.6.3.5 Flowchart to Use Deep Software Standby Mode

Figure 11.5 shows an example of a flowchart to use deep software standby mode. In this example, the RSTSR0.DPSRSTF flag of the reset function is read after the reset exception processing to determine whether a reset was generated by the RES# pin or by release from deep software standby mode. In the case of a reset by the RES# pin, a transition to deep software standby mode is made after the required register settings have been made. In the case of a reset by release from deep software standby mode, the DPSBYCR.IOKEEP bit is set to 0 after the I/O port settings have been made.

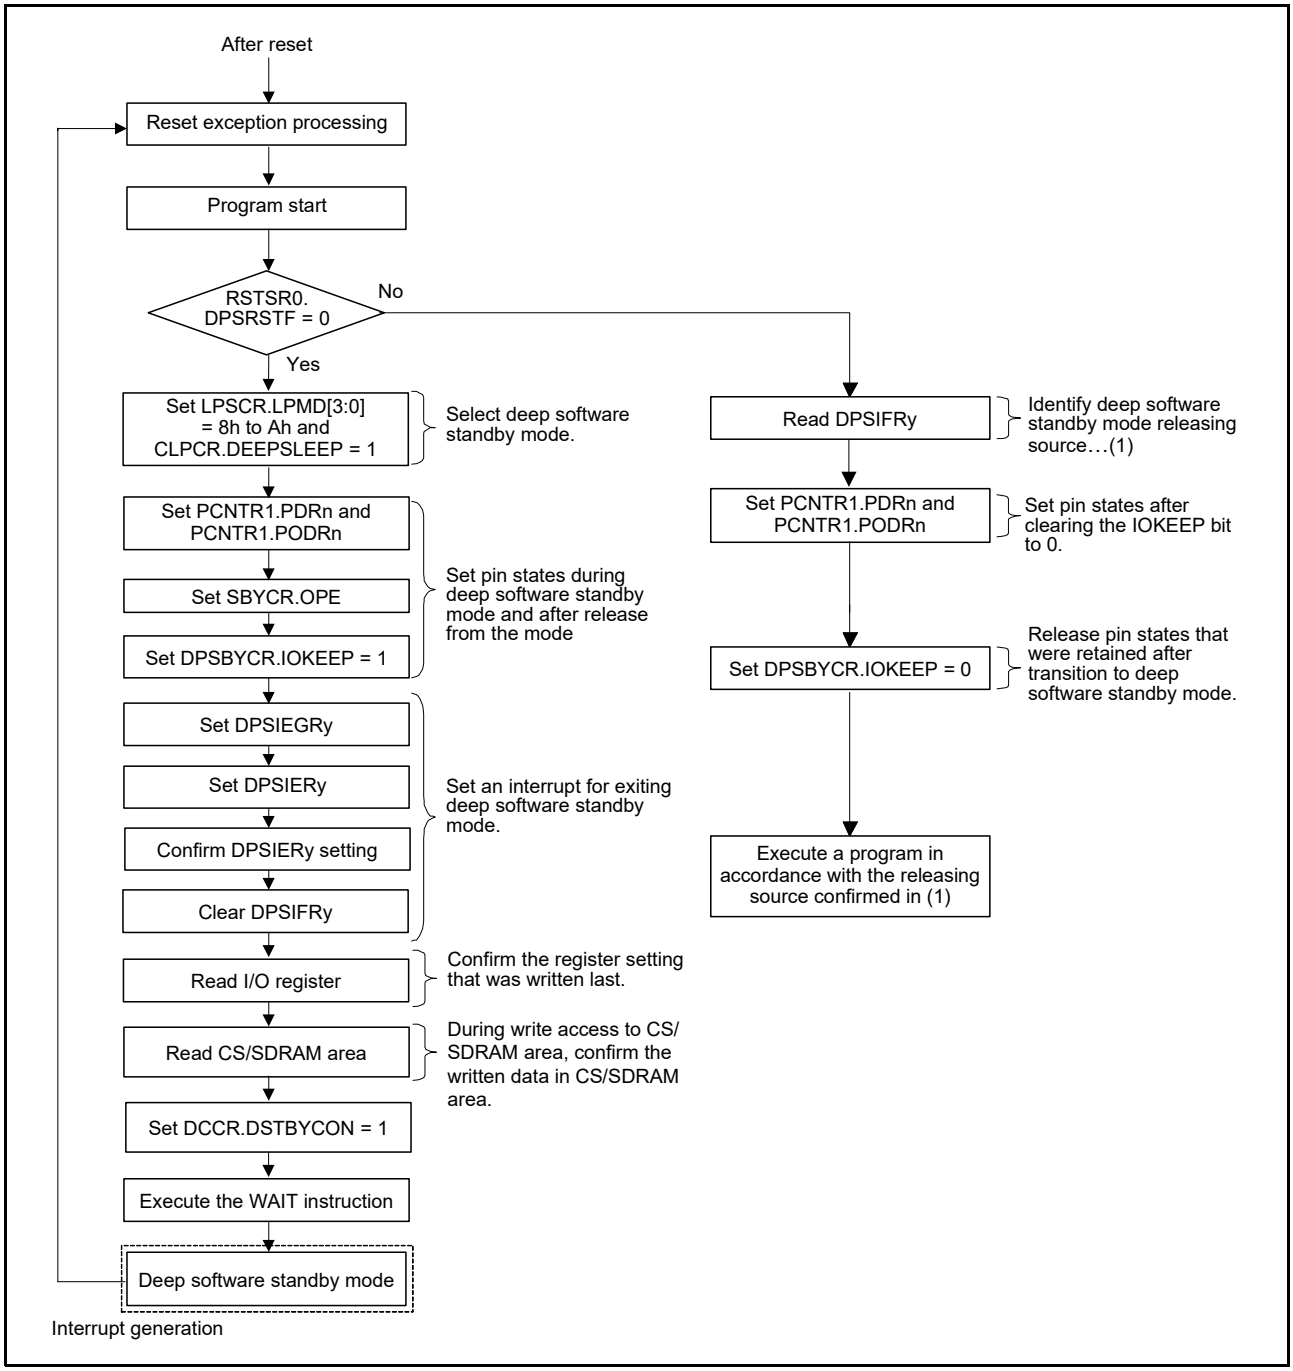

Figure 11.5 Example of Flowchart to Use Deep Software Standby Mode

11.7 Voltage Scaling Control

The MCU supports voltage scaling (DVFS) control for low-power or high-performance operation. Figure 11.6 shows the transitions of DVFS control.

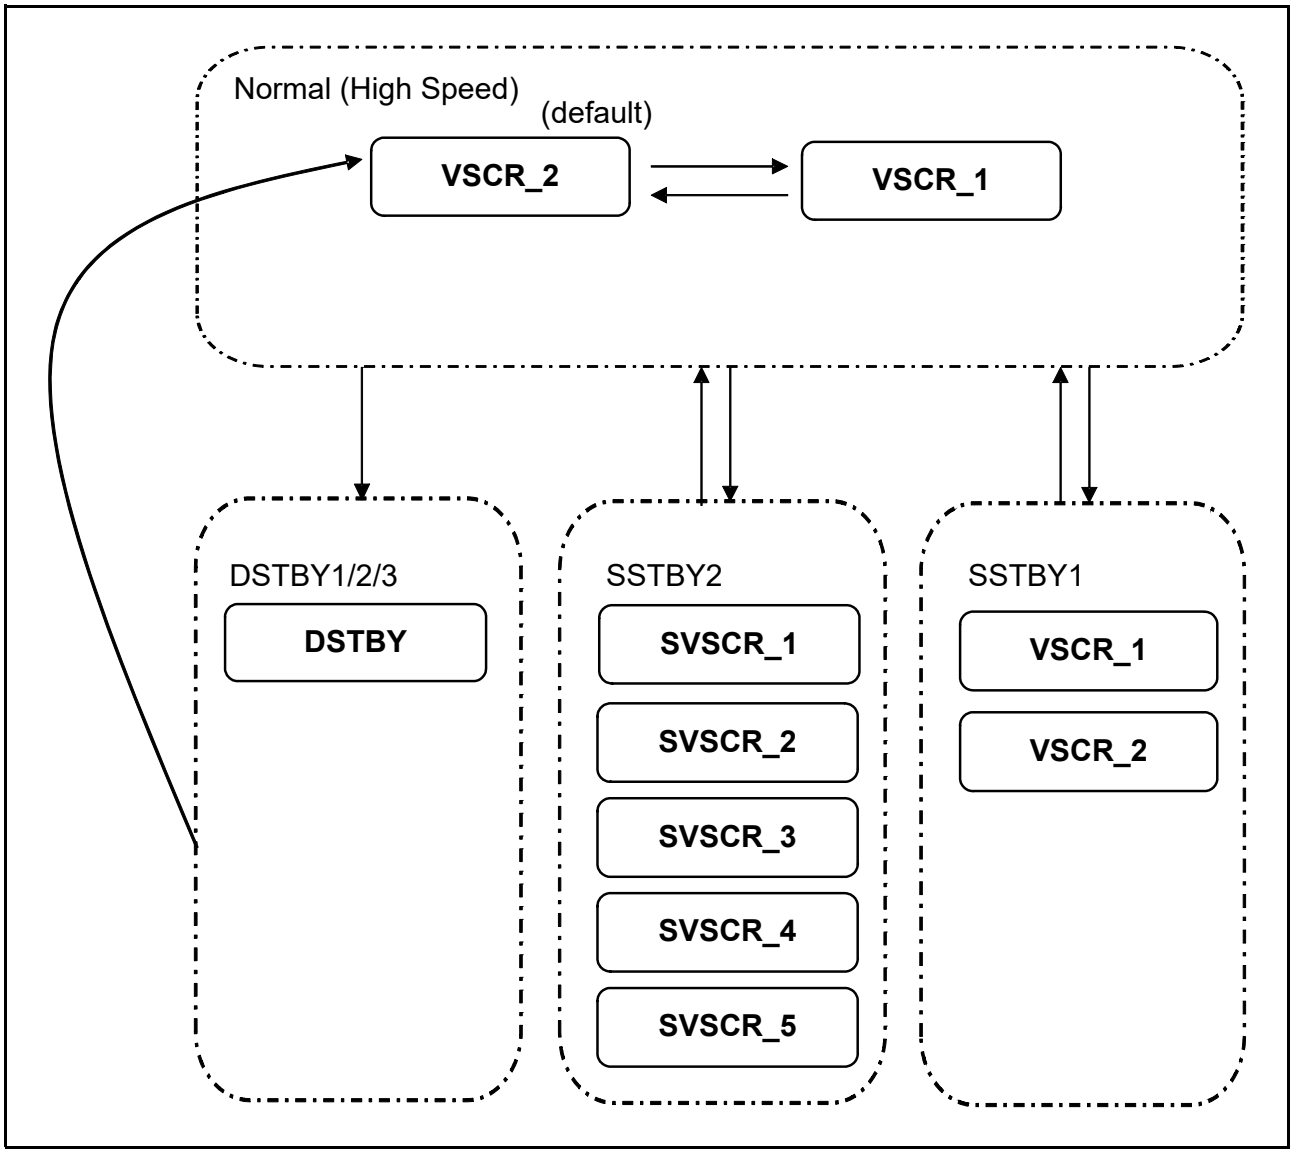

Figure 11.6 Voltage Scaling (DVFS) Control for Low Power Consumption and High Performance Operation

<Normal operating mode>

Make sure that the operating conditions (frequency range) before and after switching VDD in normal mode are always within the specified range. Switch the voltage so that each clock does not exceed the maximum frequency indicated in section 67, Electrical Characteristics.

The following is an example of the VDD switching procedure:

(1) Switching from VSCR_2 to VSCR_1

1. Set the VSCR.VSCM[2:0] bits to 001b.
2. Confirm that the VSCR.VSCMTSF flag is set to 0.
3. Set SCKDIVCR and SCKDIVCR2 to the desired values.

(2) Switching from VSCR_1 to VSCR_2

1. Set SCKDIVCR and SCKDIVCR2 to the desired values.
2. Set the VSCR.VSCM[2:0] bits to 010b.
3. Confirm that the VSCR.VSCMTSF flag is set to 0.

(3) If the PLL Settings Must Be Changed When Changing VDD

1. Change the clock source to one other than PLL.
2. Stop the PLL.
3. Change the PLL settings.
4. Set the VSCR.VSCM[2:0] bits to the desired values.
5. Confirm that the VSCR.VSCMTSF flag is set to 0.
6. Enable the PLL.
7. Wait for the PLL to stabilize.
8. Change the clock source to PLL.

<Software standby mode 1>

- A transition to and return from SSTBY1 are possible even if the VSCR.VSCM[2:0] bits are set to a value other than the default in normal operating mode.
- In SSTBY1, the setting of the VSCR.VSCM[2:0] bits is maintained, and the setting is retained and remains effective upon return from SSTBY1.

<Software standby mode 2>

- A transition to and return from SSTBY2 are possible even if the VSCR.VSCM[2:0] bits are set to a value other than the default in normal operating mode.
  The value of the SVSCR.SVSCM[2:0] bits becomes effective in SSTBY2. Prior setup of these bits is required. The value of the VSCR.VSCM[2:0] bits is retained and remains effective upon return from SSTBY2.
- With the SVSCR.SVSCM[2:0] bits are set to 001b and the SSCR1.SS2LP[1:0] bits are set to 01b, transition to SSTBY2 is prohibited.

<Deep software standby mode 1, 2, 3>

- A transition to and return from DSTBY are possible even if the VSCR.VSCM[2:0] bits are set to a value other than the default in normal operating mode.
- The VSCR.VSCM[2:0] bits are reset to the initial value upon return from DSTBY.

11.8 Usage Notes

11.8.1 Register Access

(1) Do not write to the following registers under any of the following conditions.

<Register>

- All registers whose peripheral function name is SYSC

<Conditions>

- MENTRYR.MENTRY = 1 (MRAM is being programmed)
- VSCR.VSCMTSF = 1 (during transition of voltage scaling control mode)
- Timing in the range from execution of the WAIT instruction until the return to normal operating mode

(2) Do not write to the following registers by the DTC or DMAC.

- MSTPCRA, MSTPCRB, MSTPCRC, MSTPCRD, MSTPCRE, MSTPCRF

(3) When the PRCR.PRC1 bit is 0, write access to the following registers is invalid.

- PGSCR, PSSTCRn, PDRAMSCRn, SBYCR, SSCR1, LPSCR, DPSBYCR, DPSIERn, DPSIFRn, DPSIEGRn, PLL1LDOCR, PLL2LDOCR, HOCOLDOCR, LVOCR, VSCR, SVSCR, MWMCR, LDOECR, DCCR

(4) When the PRCR.PRC4 bit is 0, write access to the following registers is invalid.

- LPMSAR, PGCSAR, DPFSAR, DPFSAR1, RSCSAR

11.8.2 I/O Port States

I/O port states are retained in software standby mode and deep software standby mode. Therefore, the current consumption is not reduced while output signals are held high.

11.8.3 Module-Stop State of DMAC and DTC

Before setting the MSTPCRA.MSTPA22 bit to 1, set the DMAST.DMST bit of the DMAC and the DTCST.DTCST bit of the DTC to 0. For details, see section 18, DMA Controller (DMACAa) and section 20, Data Transfer Controller (DTCA). Before setting the MSTPCRA.MSTPA29 bit to 1, set the EDMAST.DMST bit of the EXDMAC to 0. For details, see section 19, EXDMA Controller (EXDMACAa).

11.8.4 On-Chip Peripheral Module Interrupts

These interrupts do not operate in the module-stop state. Therefore, if the module-stop state is entered after an interrupt request is generated, a CPU interrupt source or a DMAC or DTC activating source cannot be cleared. For this reason, disable interrupts before entering the module-stop state.

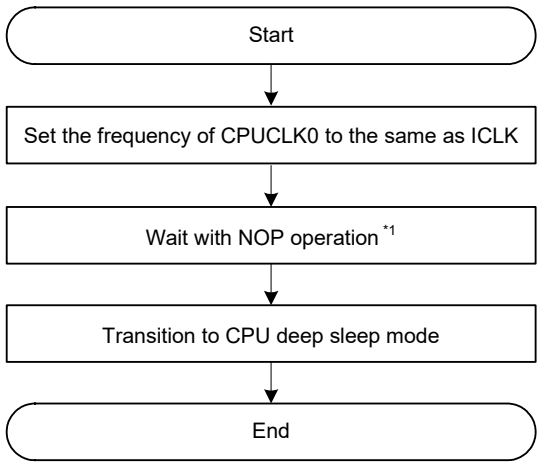
11.8.5 Input Buffer Control by the DIRQnE Bit (n = 0 to 31)

Setting the DPSIERy.DIRQnE (y = 0, 1, 4, 5; n = 0 to 31) bit to 1 enables the input buffer of the IRQ0-DS to IRQ31-DS pins. Note that, although inputs to these pins are sent to the DPSIFRy.DIRQnF (y = 0, 1, 4, 5; n = 0 to 31) bit, they are not sent to the interrupt controller, peripheral modules, and I/O ports.

11.8.6 Timing of the WAIT Instruction

It is possible for the WAIT instruction to be executed before I/O register and CS/SDRAM area writes are complete, in which case operation may not be as intended. This can happen if the WAIT instruction is executed immediately after a write to an I/O register and CS/SDRAM area. To avoid this problem, it is advisable to read back the register and CS/SDRAM area that were written to confirm that the write has completed.

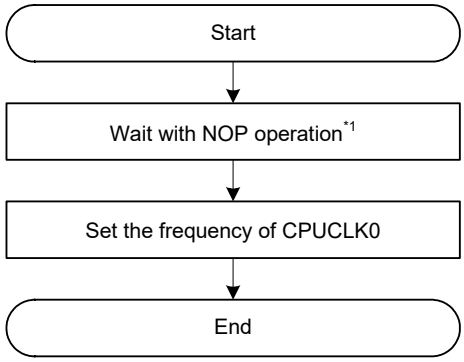
11.8.7 Writing to the WDT/IWDT Registers by the DMAC or DTC



Do not write to the registers in the WDT or IWDT by the DMAC or DTC while the WDT or IWDT is stopped in processor low power consumption mode.

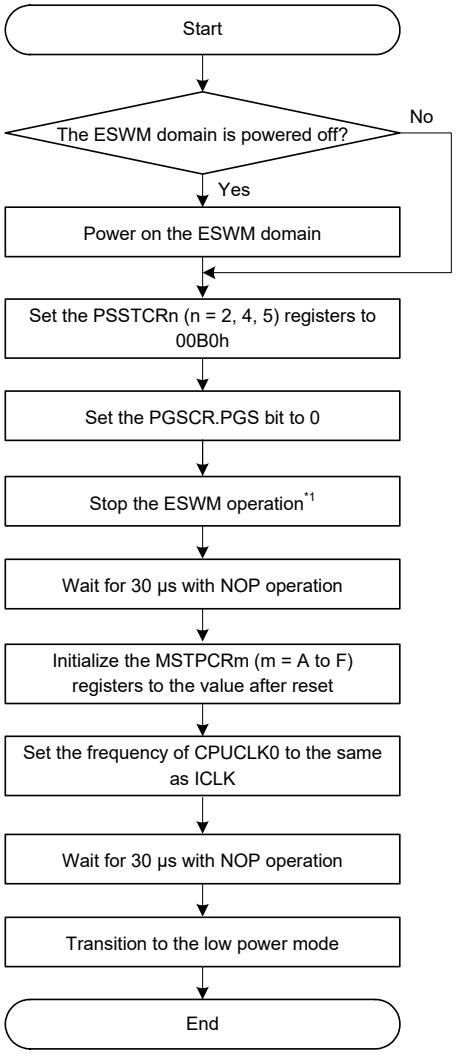
11.8.8 Timing of Writing to the Module Stop Bits

Access to an I/O register of a module may proceed before writing to the module stop bit that controls the module is complete. In such a case, access to the I/O register may lead to unintended behavior. To avoid this problem, read the module stop bit to confirm that the write operation is complete before proceeding with access to an I/O register.



11.8.9 Notes on Transition to and Return from Low Power Modes

A transition to or return from a low power mode requires a specific procedure.
Figure 11.7 to Figure 11.10 show the flows of these procedures. The use of software to measure the stated waiting times is recommended. Consider worst-case scenarios to ensure that the required waiting times have elapsed. If an unavoidable interrupt occurs during a waiting time, measure the waiting time again after execution returns from handling of the interrupt.



Note 1. This is required to take up 30 µs in DCDC mode and 10 µs in external VDD mode. No waiting time is required in LDO mode.

Figure 11.7 Flow for the Transition to CPU Deep Sleep Mode

Note 1. This is required to take up 30 µs in DCDC mode and 10 µs in external VDD mode. No waiting time is required in LDO mode.

Figure 11.8 Flow for Return from CPU Deep Sleep Mode (Assuming that CPUCLK0 and ICLK are Running at the Same Frequency upon Return).

Note 1. For how to stop the operation of the module, refer to the usage notes in section 33, Ethernet Module.

Figure 11.9 Flow for Transition to Software Standby Mode and Deep Software Standby Mode 1, 2, or 3

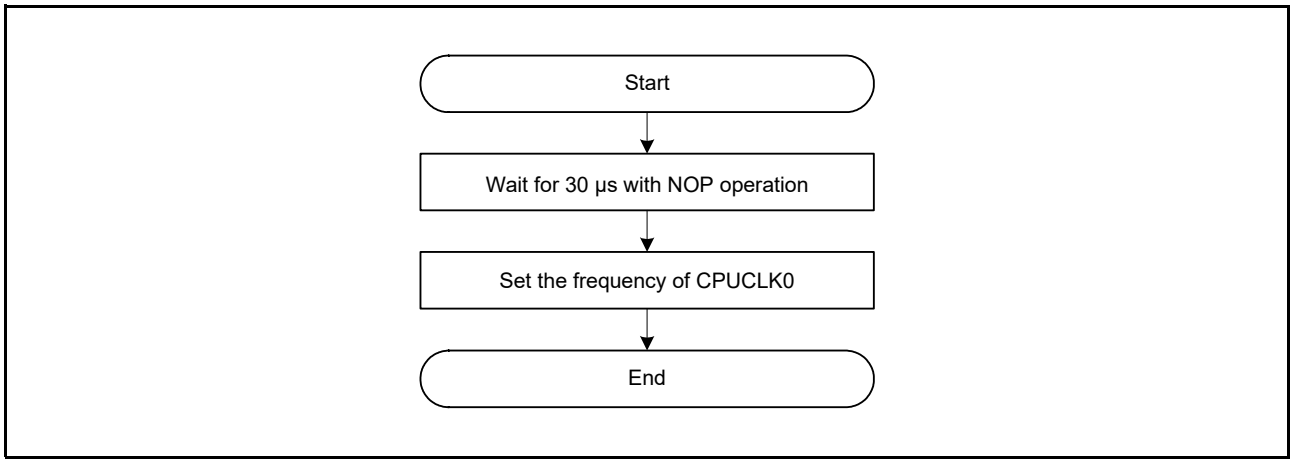


Figure 11.10 Flow for Return from Software Standby Mode (Assuming CPUCLK0 and ICLK are Running at the Same Frequency upon Return).

12. Battery Backup Function (VBATTBa)

12.1 Overview

Backup power supplied by a battery can keep the realtime clock (RTC) operating and retain the important data while the VCC power is turned off. The tamper detection function can be used to erase the backed-up data in cases where an intrusion to the system has been detected.

Table 12.1 lists the specifications of the VBATT module, Figure 12.1 is a block diagram, and Table 12.2 lists the I/O pins of the VBATT module.

Table 12.1 VBATT Specifications

Item	Description
Scope of backup	All modules in the backup domain • Backup registers • Sub-clock oscillator • Low-speed on-chip oscillator (LOCO) • Power-down detector • Tamper detector • Realtime clock (RTC)
Backup registers	128 bytes • The backup registers can be immediately erased in response to the detection of physical tampering.
Battery voltage measurement function	1/6 of the voltage applied to the VBATT pin can be measured by the A/D converter.
Backup domain power-down detection	A backup domain reset signal is generated when the supply voltage for the backup domain has fallen below V_{PDR}.
Tamper event detection	When the tamper detector has detected an intrusion to the system, it indicates this by setting a flag and, if this is selected, generating an interrupt. • Each tamper event can acquire a timestamp upon detection of a tamper event. • Three tamper input pins (TAMPI0 to TAMPI2) • Noise filter (sampling rate: 32.768 kHz or 64 to 1 Hz; passes signal transitions in response to three consecutive samples with the same level) • Capable of triggering wakeup from deep software standby mode • The backup registers can be immediately erased upon detection of a tamper event. • The hardware unique key (HUK) can be zeroized upon detection of a tamper event.
Protect Zone filter	Security attribute can be set for each register.

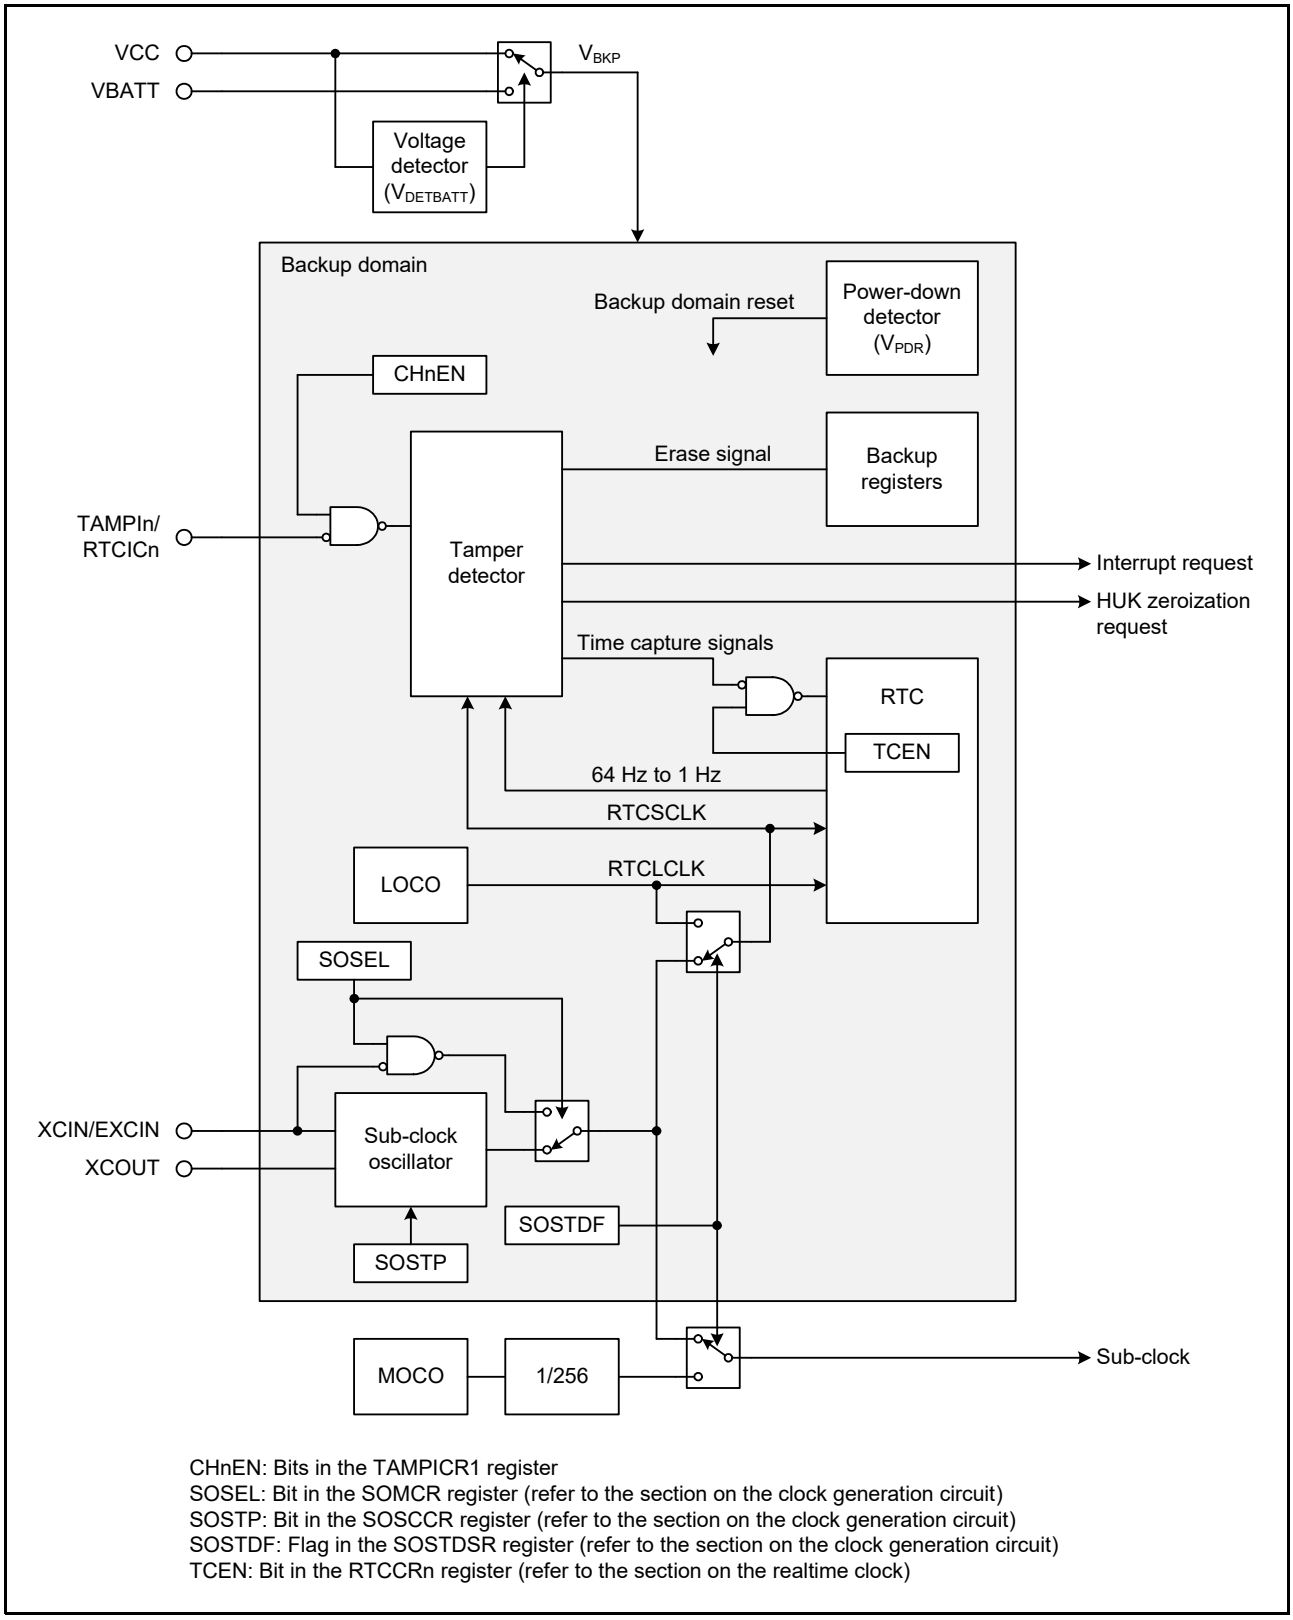

Figure 12.1 Block Diagram of VBATT (n = 0 to 2)

Table 12.2 VBATT Input/Output Pins

Pin Name	I/O	Function
VCC	Input	Power-supply pin
VBATT	Input	Pin for backup battery (power-supply pin)
XCIN	Input	Pins for a crystal for the sub-clock Connect a 32.768-kHz crystal to these pins.
XCOUT	Output	
EXCIN	Input	Clock input pin for an external sub-clock oscillator
TAMPI0 to TAMPI2	Input	Tamper input pins
RTCIC0 to RTCIC2	Input	Time capture event input pins for RTC

12.2 Register Descriptions

Registers in the battery backup function (VBATT) can only be initialized by the backup domain reset except for some registers*1. Resets generated by other sources such as the RES# pin or software will not affect these registers.

Note 1. Registers VBSAR, BKRSABR, VBATTMCR, and VBATTCR1

12.2.1 VBATT Security Attribution Register (VBSAR)

Address(es): SYSC.VBSAR 8701 93D0h, SYSC_NS.VBSAR 0701 93D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	SATAM PICR3	SATAM PCR2	SATAM PD	SAVBA TT	SATAM PI	SABKR CR	SAVBA TTMCR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SAVBATTMCR	VBATTMCR Security Attribution	0: Secure 1: Non-secure	R/W
b1	SABKRCR	BKRCR Security Attribution		R/W
b2	SATAMPI	Tamper Input Security Attribution		R/W
b3	SAVBATT	Battery Backup Security Attribution		R/W
b4	SATAMPD	Tamper Detection Security Attribution		R/W
b5	SATAMPCR2	TAMPCR2 Security Attribution		R/W
b6	SATAMPICR3	TAMPICR3 Security Attribution		R/W
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.
Note: This register is write-protected by the SYSC.PRCR_S.PRC4 bit.

This register is used to set the security attributes for the registers in the battery backup function.

SAVBATTMCR Bit (VBATTMCR Security Attribution)

This bit is used to set the security attribute of the VBATTMCR register.

SABKRCR Bit (BKRCR Security Attribution)

This bit is used to set the security attribute of the BKRCR register.

SATAMPI Bit (Tamper Input Security Attribution)

This bit is used to set the security attributes of the tamper/RTCIC input related registers (TAMPICR1, TAMPICR2, TAMPIMR).

SAVBATT Bit (Battery Backup Security Attribution)

This bit is used to set the security attributes of the battery backup related registers (VBATTCR1, VBATTCR2, BKPSR).

SATAMPD Bit (Tamper Detection Security Attribution)

This bit is used to set the security attributes of the tamper detector related registers (TAMPSR, TAMPCR, TCECR).

SATAMPCR2 Bit (TAMPCR2 Security Attribution)

This bit is used to set the security attribute of the TAMPCR2 register.

SATAMPICR3 Bit (TAMPICR3 Security Attribution)

This bit is used to set the security attribute of the TAMPICR3 register.

12.2.2 Backup Register Security Attribute Boundary Register (BKRSABR)

Address(es): SYSC.BKRSABR 8701 93B0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	0	0	0	0	0

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR_S.PRC4 bit.

The BKRSABR register is used to specify the boundary for dividing the backup registers (BKRn) into Secure and Non-secure areas.
Set the lower 16 bits of the boundary address in this register. There are five possible values: 9D00h, 9D20h, 9D40h, 9D60h, and 9D80h. The set offset address and the area above it have the Non-secure attribute. For example, if 9D40h is set in this register, addresses 8701 9D00h to 8701 9D3Fh become the Secure area and addresses 0701 9D40h to 0701 9D7Fh become the Non-secure area. If 9D00h is set in this register, the entire area becomes Non-secure area, and if 9D80h is set, the entire area becomes Secure area.

12.2.3 Battery Voltage Measurement Function Control Register (VBATTMCR)

Address(es): SYSC.VBATTMCR 8701 9A84h, SYSC_NS.VBATTMCR 0701 9A84h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	VBATTME
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	VBATTME	VBATT Voltage Measurement Enable	0: VBATT voltage measurement is disabled. 1: VBATT voltage measurement is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC3 bit.
Note: This register can be initialized by all resets except the backup domain reset.

The VBATTMCR register is used to control the battery voltage measurement function.

VBATTME Bit (VBATT Voltage Measurement Enable)

This bit is used to measure the voltage input from the VBATT pin with the A/D converter.
After setting this bit to 1, wait for the output voltage to stabilize (t_{MONWT}) before starting A/D conversion. The voltage of VBATT pin is six times of the measurement result.
After completing the measurement, set this bit to 0.

12.2.4 Battery Backup Function Control Register 1 (VBATTCR1)

Address(es): SYSC.VBATTCR1 8701 9A88h, SYSC_NS.VBATTCR1 0701 9A88h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	PSWDIS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PSWDIS	Power Switch Disable	0: The power switches are enabled. 1: The power switches are disabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC1 bit.
Note: This register can be initialized by all resets except the backup domain reset and deep software standby reset.

The VBATTCR1 register is used to control the battery backup function.

PSWDIS Bit (Power Switch Disable)

This bit is used to disable the switches to supply power from the VBATT pin when the main power from the VCC pin is turned off. When this bit is set to 1, the battery backup function is also disabled, and the VBATTCR2.VDETE bit should also be set to 0.

When changing this bit from 1 to 0, make sure that the VDETE bit is set to 0. After setting this bit to 0, wait for the voltage detector to stabilize (t_{DETWT}) before setting the VDETE bit to 1.

12.2.5 Battery Backup Function Control Register 2 (VBATTCR2)

Address(es): SYSC.VBATTCR2 8701 9C45h, SYSC_NS.VBATTCR2 0701 9C45h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	VDETE	—	VDETSEL[2:0]		
Value after reset:	0	0	0	0	0	1	1	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	VDETSEL[2:0]	Detection Voltage Select	b2 b0 0 0 0: 2.80 V 0 0 1: 2.53 V 0 1 0: 2.10 V 0 1 1: 1.95 V 1 0 0: 1.85 V 1 0 1: 1.75 V Settings other than above are prohibited.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	VDETE	Voltage Detection Enable	0: The voltage detector is disabled. 1: The voltage detector is enabled.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC1 bit.
Note: This register can only be initialized by the backup domain reset. It is not affected by the MCU reset.

The VBATTCR2 register is used to control the battery backup function.

VDETSEL[2:0] Bits (Detection Voltage Select)

These bits are used to select the $V_{DETBATT}$ voltage. Set these bits while the VDETE bit is 0.
The $V_{DETBATT}$ voltage should be lower than the voltage detection 0 level (V_{det0}) and higher than the power-on reset voltage (V_{POR}).

VDETE Bit (Voltage Detection Enable)

This bit is used to enable the voltage detector in the battery backup function.
After setting the VDETSEL[2:0] bits, wait for the voltage detector to stabilize (t_{DETWT}) before setting this bit to 1.

12.2.6 Backup Domain Power Status Register (BKPSR)

Address(es): SYSC.BKPSR 8701 9C46h, SYSC_NS.BKPSR 0701 9C46h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	PSMF	PDRMF	—	—	—	PDDF
Value after reset:	0	0	x	x	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	PDDF	Power-Down Detected Flag	0: The voltage for the backup domain has not fallen below V_{PDR}. 1: The voltage for the backup domain has fallen below V_{PDR}.	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	PDRMF	Backup Domain Reset Monitor Flag	0: The backup domain reset signal is asserted. 1: The backup domain reset signal is negated.	R
b5	PSMF	Power Switch Monitor Flag	0: Power for the backup domain is supplied from the VBATT pin (VCC < $V_{DETBATT}$) 1: Power for the backup domain is supplied from the VCC pin (VCC ≥ $V_{DETBATT}$)	R
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC1 bit.
Note: This register can only be initialized by the backup domain reset. It is not affected by the MCU reset.

The BKPSR register indicates the state of the backup domain power supply.

PDDF Flag (Power-Down Detected Flag)

The PDDF flag indicates that the supply voltage for the backup domain has fallen below V_{PDR} and a backup domain reset was generated.

[Setting condition]

- The voltage supplied to the backup domain falling below V_{PDR}.

[Clearing conditions]

- 0 being written to the PDDF flag.

PDRMF Flag (Backup Domain Reset Monitor Flag)

The PDRMF flag indicates the status of the backup domain reset signal. When this flag is 0, the registers in the backup domain are being reset. Wait until this flag becomes 1 before accessing the registers.

PSMF Flag (Power Switch Monitor Flag)

The PSMF flag indicates the state of the power switch (result of comparison between VCC and $V_{DETBATT}$).

12.2.7 Tamper Status Register (TAMPSR)

Address(es): SYSC.TAMPSR 8701 9C48h, SYSC_NS.TAMPSR 0701 9C48h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	TAMP2F	TAMP1F	TAMP0F
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TAMP0F	Tamper 0 Event Detection Flag	0: Tamper 0 event has not been detected. 1: Tamper 0 event has been detected.	R/(W) *1
b1	TAMP1F	Tamper 1 Event Detection Flag	0: Tamper 1 event has not been detected. 1: Tamper 1 event has been detected.	R/(W) *1
b2	TAMP2F	Tamper 2 Event Detection Flag	0: Tamper 2 event has not been detected. 1: Tamper 2 event has been detected.	R/(W) *1
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC1 bit.
Note: This register can only be initialized by the backup domain reset. It is not affected by the MCU reset.
Note 1. Only 0 can be written to this bit, to clear the flag. To clear this flag, confirm that its value is 1 and then write 0 to it.

The TAMPSR register indicates the detection status of the tamper events.

TAMPnF Flag (Tamper n Event Detection Flag) (n = 0 to 2)

Each TAMPnF flag indicates that a trigger (an effective edge) was input to the TAMPIn pin. The trigger is selected by the TAMPICR2.CHnTRG bit.

[Setting condition]

- The trigger set by the TAMPICR2.CHnTRG bit being detected on the TAMPIn pin.

[Clearing conditions]

- 0 being written to the TAMPnF flag after having confirmed that its value is 1.

12.2.8 Tamper Control Register (TAMPCR)

Address(es): SYSC.TAMPCR 8701 9C49h, SYSC_NS.TAMPCR 0701 9C49h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	TAMP2EE	TAMP1EE	TAMP0EE	—	TAMP2IE	TAMP1IE	TAMP0IE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TAMP0IE	Tamper 0 Event Detection Interrupt Enable	0: Tamper 0 event detection interrupt is disabled. 1: Tamper 0 event detection interrupt is enabled.	R/W
b1	TAMP1IE	Tamper 1 Event Detection Interrupt Enable	0: Tamper 1 event detection interrupt is disabled. 1: Tamper 1 event detection interrupt is enabled.	R/W
b2	TAMP2IE	Tamper 2 Event Detection Interrupt Enable	0: Tamper 2 event detection interrupt is disabled. 1: Tamper 2 event detection interrupt is enabled.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	TAMP0EE	Tamper 0 Erase Enable	0: Backup registers are not erased in response to a tamper 0 event. 1: Backup registers are erased in response to a tamper 0 event.	R/W
b5	TAMP1EE	Tamper 1 Erase Enable	0: Backup registers are not erased in response to a tamper 1 event. 1: Backup registers are erased in response to a tamper 1 event.	R/W
b6	TAMP2EE	Tamper 2 Erase Enable	0: Backup registers are not erased in response to a tamper 2 event. 1: Backup registers are erased in response to a tamper 2 event.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC1 bit.
Note: This register can only be initialized by the backup domain reset. It is not affected by the MCU reset.

The TAMPCR register controls operations in response to the detection of tampering.

TAMPnIE Bit (Tamper n Event Detection Interrupt Enable) (n = 0 to 2)

The TAMPnIE bit enables or disables the tamper n event detection interrupt.

TAMPnEE Bit (Tamper n Erase Enable) (n = 0 to 2)

The TAMPnEE bit selects whether the backup registers should be or should not be erased in response to a tamper n event.

12.2.9 Tamper Control Register 2 (TAMPCR2)

Address(es): SYSC.TAMPCR2 8701 9C54h, SYSC_NS.TAMPCR2 0701 9C54h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	ZHUKE2	ZHUKE1	ZHUKE0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ZHUKE0	Tamper 0 Zeroization Request Enable	0: HUK zeroization request triggered by tamper 0 event detection is disabled. 1: HUK zeroization request triggered by tamper 0 event detection is enabled.	R/W
b1	ZHUKE1	Tamper 1 Zeroization Request Enable	0: HUK zeroization request triggered by tamper 1 event detection is disabled. 1: HUK zeroization request triggered by tamper 1 event detection is enabled.	R/W
b2	ZHUKE2	Tamper 2 Zeroization Request Enable	0: HUK zeroization request triggered by tamper 2 event detection is disabled. 1: HUK zeroization request triggered by tamper 2 event detection is enabled.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC1 bit.
Note: This register can only be initialized by the backup domain reset. It is not affected by the MCU reset.

The TAMPCR2 register controls operations in response to the detection of tampering.

ZHUKEn Bit (Tamper n Zeroization Request Enable) (n = 0 to 2)

The ZHUKEn bit enables or disables the zeroization request for the hardware unique key (HUK) when a tamper event is detected.

12.2.10 Time Capture Event Control Register (TCECR)

Address(es): SYSC.TCECR 8701 9C4Ah, SYSC_NS.TCECR 0701 9C4Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	TCE2S	TCE1S	TCE0S
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TCE0S	Time Capture Event 0 Source Select	0: Input signal from the RTCIC0 pin 1: Tamper 0 event	R/W
b1	TCE1S	Time Capture Event 1 Source Select	0: Input signal from the RTCIC1 pin 1: Tamper 1 event	R/W
b2	TCE2S	Time Capture Event 2 Source Select	0: Input signal from the RTCIC2 pin 1: Tamper 2 event	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC1 bit.
Note: This register can only be initialized by the backup domain reset. It is not affected by the MCU reset.

The TCECR register selects the sources for time capture events of the RTC.

TCEnS Bit (Time Capture Event n Source Select) (n = 0 to 2)

The TCEnS bit selects the source of time capture event n for the RTC.
When this bit is set to 0, a signal input to the RTCICn pin is input to the RTC. Selection of this setting is recommended when tamper event detection is not to be used.
When this bit is set to 1, the tamper n event detection signal is input to the RTC. Selection of this setting is recommended when a tamper event is to cause a timestamp to be recorded.

12.2.11 Tamper/RTCIC Input Control Register 1 (TAMPICR1)

Address(es): SYSC.TAMPICR1 8701 9C4Ch, SYSC_NS.TAMPICR1 0701 9C4Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	CH2EN	CH1EN	CH0EN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CH0EN	Channel 0 Input Enable	0: The TAMPI0/RTCIC0 signal input is disabled. 1: The TAMPI0/RTCIC0 signal input is enabled.	R/W
b1	CH1EN	Channel 1 Input Enable	0: The TAMPI1/RTCIC1 signal input is disabled. 1: The TAMPI1/RTCIC1 signal input is enabled.	R/W
b2	CH2EN	Channel 2 Input Enable	0: The TAMPI2/RTCIC2 signal input is disabled. 1: The TAMPI2/RTCIC2 signal input is enabled.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC1 bit.
Note: This register can only be initialized by the backup domain reset. It is not affected by the MCU reset.

The TAMPICR1 register enables or disables input from the TAMPIn/RTCICn pins (n = 0 to 2).

CHnEN Bit (Channel n Input Enable) (n = 0 to 2)

The CHnEN bit enables or disables the input from the TAMPIn/RTCICn pin.

Set each bit to 1 not only if tamper events are to be detected but also if the RTC time capture function is to be used. After setting this bit to 1, it requires up to 50 µs for the output from the input buffer to stabilize. Wait at least 50 µs before using the TAMPIn/RTCICn signal.

12.2.12 Tamper/RTCIC Input Control Register 2 (TAMPICR2)

Address(es): SYSC.TAMPICR2 8701 9C4Dh, SYSC_NS.TAMPICR2 0701 9C4Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	CH2TRG	CH1TRG	CH0TRG	—	CH2NFE	CH1NFE	CH0NFE
Value after reset:	0	1	1	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CH0NFE	Channel 0 Noise Filter Enable	0: Noise filter for the TAMPI0/RTCIC0 pin is disabled. 1: Noise filter for the TAMPI0/RTCIC0 pin is enabled.	R/W
b1	CH1NFE	Channel 1 Noise Filter Enable	0: Noise filter for the TAMPI1/RTCIC1 pin is disabled. 1: Noise filter for the TAMPI1/RTCIC1 pin is enabled.	R/W
b2	CH2NFE	Channel 2 Noise Filter Enable	0: Noise filter for the TAMPI2/RTCIC2 pin is disabled. 1: Noise filter for the TAMPI2/RTCIC2 pin is enabled.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	CH0TRG	Channel 0 Trigger Select	Select the trigger for tamper 0 event detection. 0: A falling edge of the input on the TAMPI0 pin 1: A rising edge of the input on the TAMPI0 pin	R/W
b5	CH1TRG	Channel 1 Trigger Select	Select the trigger for tamper 1 event detection. 0: A falling edge of the input on the TAMPI1 pin 1: A rising edge of the input on the TAMPI1 pin	R/W
b6	CH2TRG	Channel 2 Trigger Select	Select the trigger for tamper 2 event detection. 0: A falling edge of the input on the TAMPI2 pin 1: A rising edge of the input on the TAMPI2 pin	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC1 bit.
Note: This register can only be initialized by the backup domain reset. It is not affected by the MCU reset.

The TAMPICR2 register is used to enable or disable the noise filters for the TAMPIn/RTCICn pins (n = 0 to 2) and select the triggers for tamper event detection.

CHnNFE Bit (Channel n Noise Filter Enable) (n = 0 to 2)

The CHnNFE bit enables or disables the noise filter for the TAMPIn/RTCICn pin. When tamper n event detection is not to be used, set the bit to 0.

Five cycles of the clock selected by the TAMPICR3.NFCS[2:0] bits are necessary for the output of the noise filter to become stable after this bit has been set to 1.

CHnTRG Bit (Channel n Trigger Select) (n = 0 to 2)

The CHnTRG bit is used to select the effective edge for the input signal from the TAMPIn pin for use as a trigger of tamper event detection.

12.2.13 Tamper/RTCIC Input Control Register 3 (TAMPICR3)

Address(es): SYSC.TAMPICR3 8701 9C50h, SYSC_NS.TAMPICR3 0701 9C50h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	NFCS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	NFCS[2:0]	Noise Filter Clock Select	b2 b0 0 0 0: 32.768 kHz 0 0 1: 64 Hz 0 1 0: 32 Hz 0 1 1: 16 Hz 1 0 0: 8 Hz 1 0 1: 4 Hz 1 1 0: 2 Hz 1 1 1: 1 Hz	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC1 bit.
Note: This register can only be initialized by the backup domain reset. It is not affected by the MCU reset.

The TAMPICR3 register is used to control the noise filters for the TAMPIn/RTCICn pins (n = 0 to 2).

NFCS[2:0] Bits (Noise Filter Clock Select)

The NFCS[2:0] bits are used to select the sampling frequency of the noise filters. When setting a value other than 000b, set the RTC.RCR2.START bit to 1.
Set these bits while the TAMPICR2.CHnNFE bits are all 0 (n = 0 to 2).

12.2.14 Tamper/RTCIC Input Monitoring Register (TAMPIMR)

Address(es): SYSC.TAMPIMR 8701 9C4Eh, SYSC_NS.TAMPIMR 0701 9C4Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	CH2LVL	CH1LVL	CH0LVL
Value after reset:	0	0	0	0	0	x	x	x

Bit	Symbol	Bit Name	Description	R/W
b0	CH0LVL	Channel 0 Level Monitoring Flag	0: The low level is being input on the TAMPI0 pin. 1: The high level is being input on the TAMPI0 pin.	R
b1	CH1LVL	Channel 1 Level Monitoring Flag	0: The low level is being input on the TAMPI1 pin. 1: The high level is being input on the TAMPI1 pin.	R
b2	CH2LVL	Channel 2 Level Monitoring Flag	0: The low level is being input on the TAMPI2 pin. 1: The high level is being input on the TAMPI2 pin.	R
b7 to b3	—	Reserved	These bits are read as 0.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: This register can only be initialized by the backup domain reset. It is not affected by the MCU reset.

The TAMPIMR register is used to monitor the input levels on the TAMPIn pins (n = 0 to 2).

CHnLVL Flag (Channel n Level Monitoring Flag) (n = 0 to 2)

Each CHnLVL flag indicates the input level on an TAMPIn pin.

12.2.15 Backup Register Control Register (BKRCR)

Address(es): SYSC.BKRCR 8701 9C40h, SYSC_NS.BKRCR 0701 9C40h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	BKRAE	—	—	—
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	BKRAE	Backup Register Access Enable	0: Access to the BKRn registers is disabled. 1: Access to the BKRn registers is enabled.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register is write-protected by the SYSC.PRCR.PRC1 bit.
Note: This register is only initialized when switching to battery backup mode or by a power-on reset. During battery backup mode, the BKRAE bit is reset to 1, but the internal state retains the value set before entering battery backup mode.

The BKRCR register is used to control access to the backup registers.

BKRAE Bit (Backup Register Access Enable)

This bit enables access to the BKRn registers. When reading from or writing to the BKRn registers, wait at least 500 ns after setting this bit to 1. After access to the BKRn registers is no longer required, set this bit to 0. If the mode is switched to battery backup mode with this bit remains 1, the contents of the BKRn registers are not guaranteed.

12.2.16 Backup Register n (BKRn) (n = 0 to 127)

Address(es): SYSC.BKR0 8701 9D00h to SYSC.BKR127 8701 9D7Fh, SYSC_NS.BKR0 0701 9D00h to SYSC_NS.BKR127 0701 9D7Fh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

Note: When these registers are set to the secure attribute, they are accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When these registers are set to the non-secure attribute, they are accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: These registers are write-protected by the SYSC.PRCR.PRC1 bit.
Note: These registers can only be initialized by the backup domain reset. They are not affected by the MCU reset.

The contents of the BKRn registers are retained even in the battery backup mode.
The BKRn registers can be erased when a tamper event is detected.

12.3 Operation

12.3.1 Battery Backup Function

This function is used to retain the operations of the modules in the backup domain by supplying power from the VBATT pin (battery backup mode) while the main power supply is turned off.
If the VCC voltage falls below $V_{DETBATT}$, the backup domain power supply is automatically switched to VBATT. When the VCC voltage rises back to $V_{DETBATT}$, the backup domain power supply is automatically switched back to VCC.
When the battery backup function is to be used, enable the voltage monitor 0 reset.
Figure 12.2 shows the structure of the power switches and Figure 12.3 shows switching of the power supply for the backup domain.

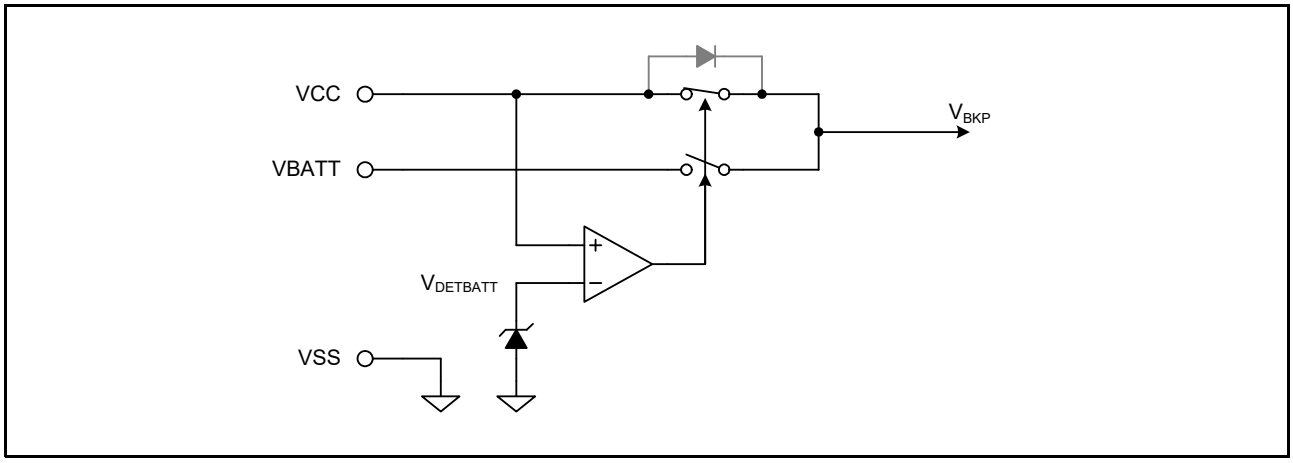

Figure 12.2 Power Switches

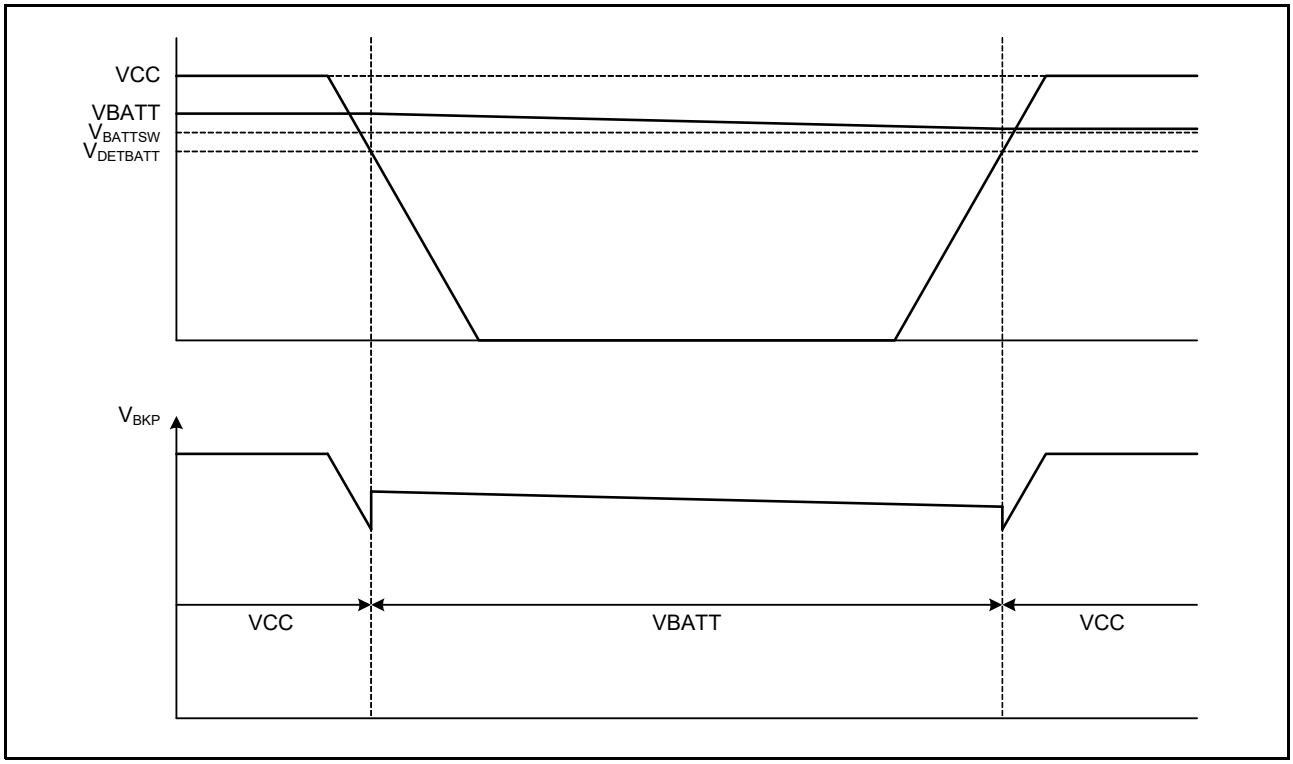

Figure 12.3 Switching of the Power Supply for the Backup Domain

Setting the OFSM.OFS1.DSBYLPSEL bit to 0 can further reduce the power consumption during deep software standby mode 1 or 2. When the DSBYLPSEL bit is set to 0, the voltage detector in the battery backup function does not operate

during deep software standby mode 1 or 2, and instead the voltage detection 0 circuit (PVD0) controls the power supply switch. In this case, the detection voltage changes from $V_{DETBATT}$ to V_{det0}. Set the V_{det0} voltage using the OFSM.OFS1.VDSEL[2:0] bits.

The following modules are in the backup domain.

- Sub-clock oscillator
- Low-speed on-chip oscillator (LOCO)
- Power-down detector
- Backup registers
- Tamper detector
- RTC

The VBATT pin only supplies power for the following pins in the battery backup mode.

- The XCIN and XCOUT pins for a crystal resonator
- The EXCIN pin for an external crystal oscillator
- The TAMPI0, TAMPI1, and TAMPI2 pins for tamper event detection

When using the battery backup function, configure each register according to the procedure shown in Figure 12.4 after a power-on reset.

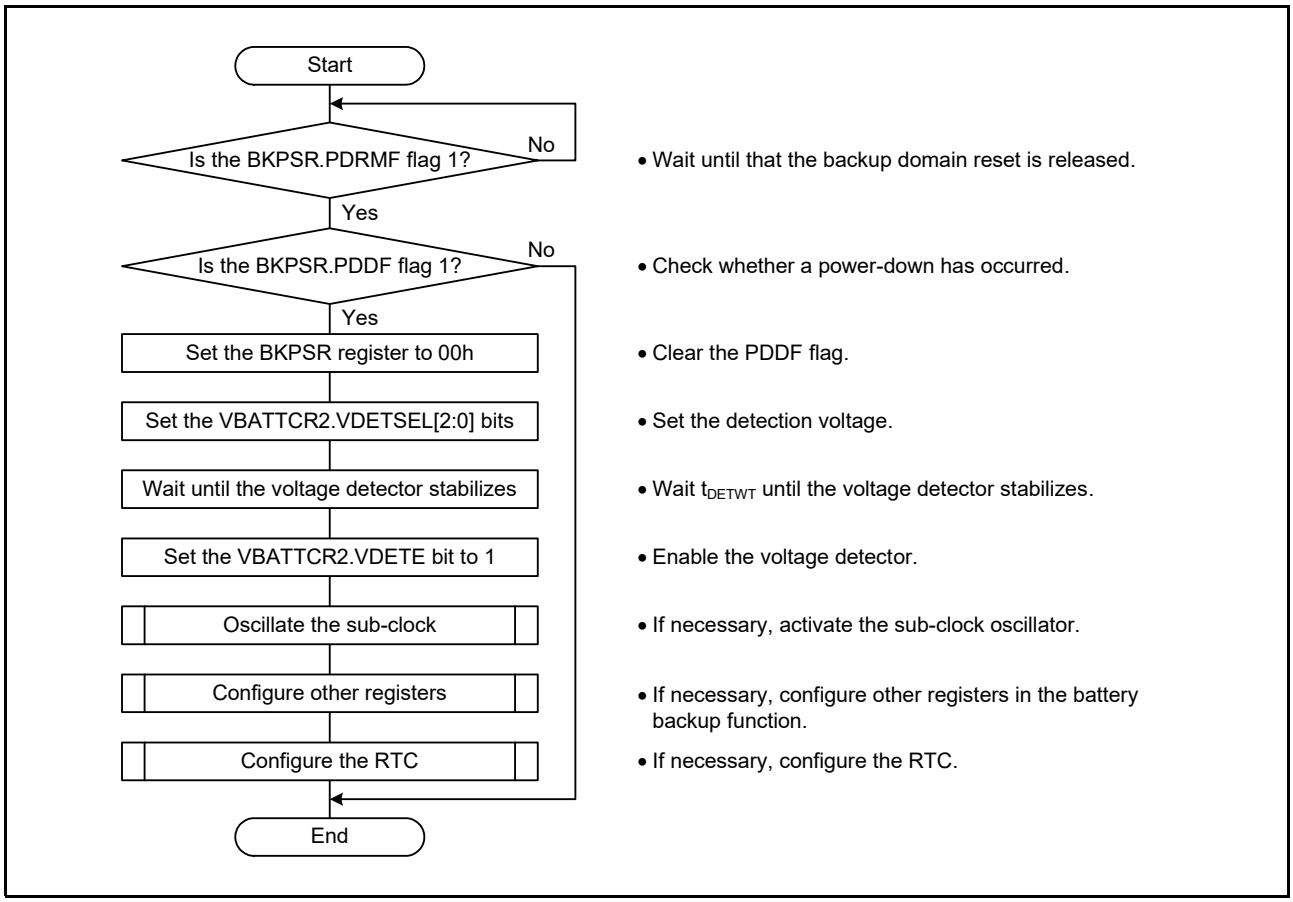

Figure 12.4 Example of the Configuration Flow after Power-On Reset

12.3.2 Power-Down Detector

This module monitors the supply voltage to the backup domain (V_{BKP}) and generates a backup domain reset signal. Specifically, the backup domain reset signal is asserted when the V_{BKP} voltage falls below $V_{PDR(BKP)}$. When the V_{BKP} voltage rises above $V_{PDR(BKP)}$, the reset signal is negated.

A backup domain reset only affects the registers described in this chapter and the SOSCCR, SOSTDCR, SOSTDSR, and SOMCR registers described in the chapter on the clock generation circuit. However, the reset does not affect the registers and counters in the RTC.

The value of the BKPSR.PDDF flag is 1 when a backup domain reset had been generated. If the BKPSR.PDDF flag is 1, set all registers in the backup domain again.

Figure 12.5 shows the structure of the power-down detector and Figure 12.6 shows its operation.

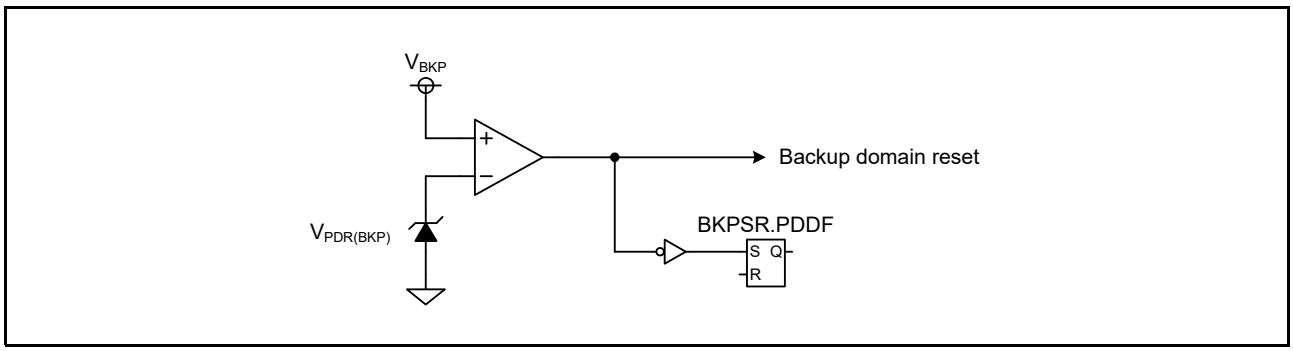

Figure 12.5 Structure of the Power-Down Detector

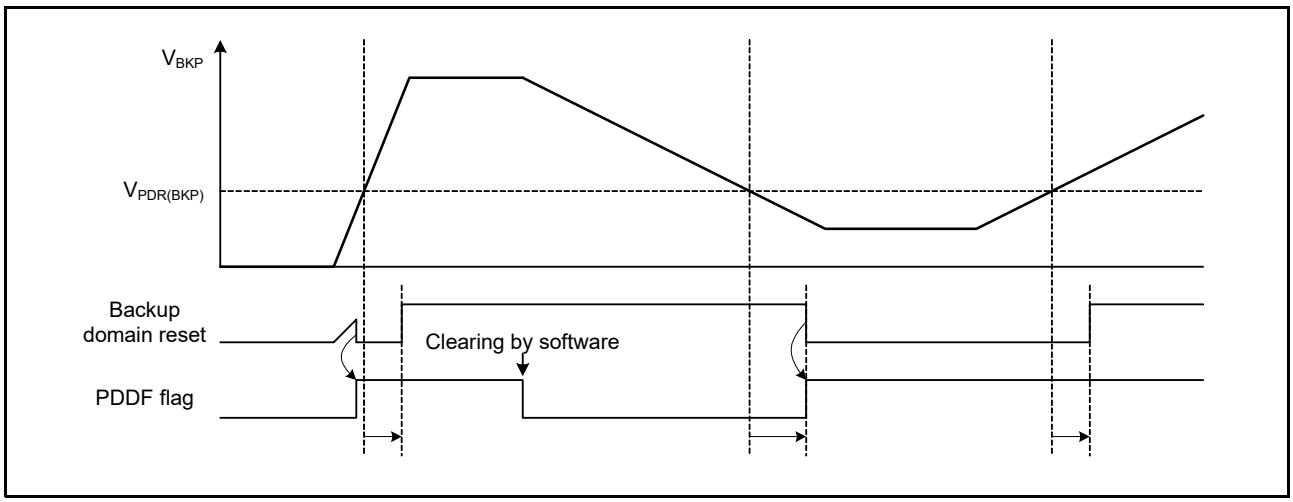

Figure 12.6 Backup Domain Reset Signal

12.3.3 Backup Registers

This MCU has 128 bytes of backup registers (BKRn (n = 0 to 127)) to save data that should not be lost even if the VCC power supply is lost.

Protection for the BKRn registers becomes effective 250 ns after the BKRCR.BKRAE bit is set to 0. To transition to deep software standby mode after saving data to the BKRn registers, set the BKRAE bit to 0, wait at least 250 ns, and then execute the WAIT instruction.

When the TAMPSR.TAMPnF flag is set to 1 while the TAMPCR.TAMPnEE bit is 1 (Backup registers are erased in response to a tamper n event), erasing the backup registers begins (n = 0 to 2). To stop erasing the backup registers, wait at least 100 ns after the TAMPnF flag is set to 1, then set the TAMPnEE bit or the TAMPnF flag to 0. Wait at least 500 ns before accessing the backup registers again.

12.3.4 Tamper Detector

This MCU has three tamper pins (TAMPI0 to TAMPI2) which remain functional in the battery backup mode and can detect physical intrusions.
The tamper inputs can be configured for rising or falling edge detection and with or without noise filtering.
The following operations can be selected in response to the detection of tampering.

- Generating an interrupt request
- Erasing the backup registers
- Zeroization of a hardware unique key (HUK)
- Generating RTC timestamp events

Figure 12.7 is a block diagram of the tamper detector.

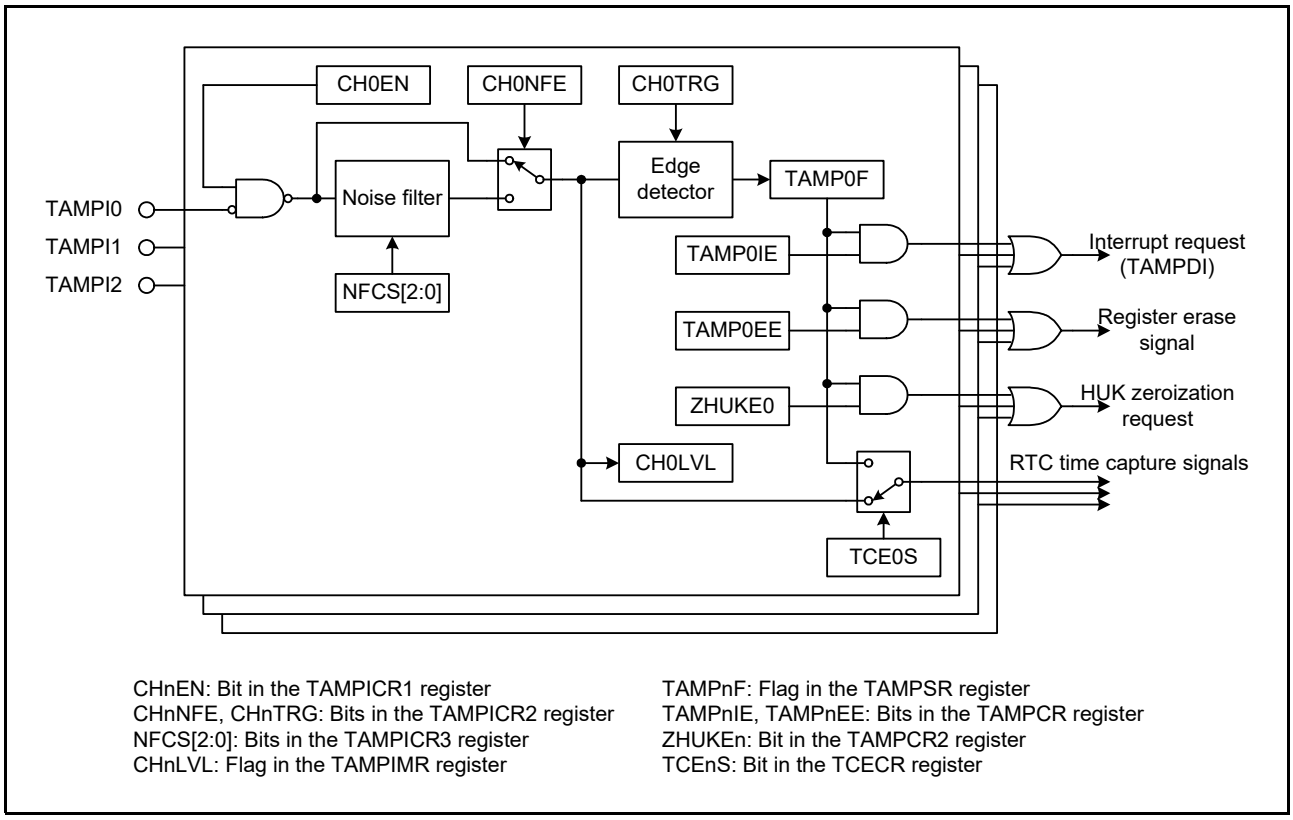

Figure 12.7 Tamper detector (n = 0 to 2)

If the value of the TAMPICR1.CHnEN bit or the CHnNFE or CHnTRG bit in the TAMPICR2 register is changed, a TAMPSR.TAMPnF flag may become 1 (n = 0 to 2). Set the TAMPnIE and TAMPnEE bits in the TAMPCR register and the TAMPCR2.ZHUKEn bit to 0 before setting these bits. Clear the TAMPnF flags after setting these bits.
The TAMPIMR.CHnLVL flags are for monitoring the levels being input on the TAMPIn pins.
When an effective edge is detected in any of the channels, the corresponding TAMPnF flag becomes 1. If the TAMPnIE bit is 1 at this point, the TAMPDI interrupt is generated. If the TAMPnEE bit is 1, the backup registers are erased to 00h. If the ZHUKEn bit is 1, the HUK zeroization request is output.
Setting the TCECR.TCEnS bit to 1 enables the time capture function of the RTC to record a timestamp when a tamper event is detected. For details on the time capture function, refer to section 30, Realtime Clock (RTCBb).

Figure 12.8 shows the setting flow when using the tamper detector.

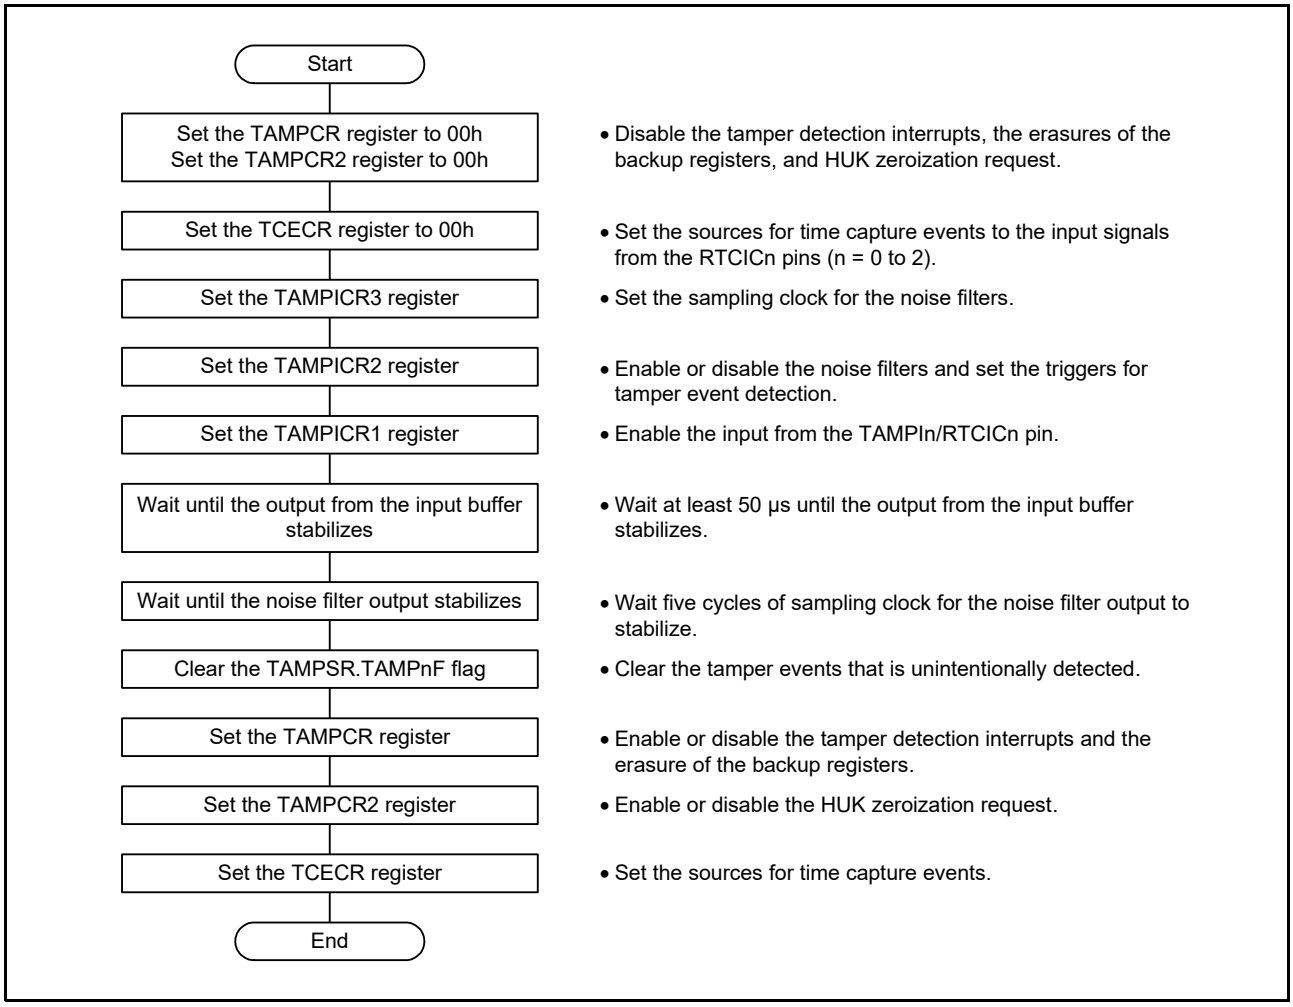

Figure 12.8 Setting Flow for Tamper Detector

12.4 Interrupt

The VBATT has the three interrupt sources listed in Table 12.3.

Table 12.3 VBATT Interrupt Sources

Name	Symbol	Interrupt Source	Interrupt Flag	Interrupt Enable Bit
Tamper event detection interrupt	TAMPDI	Tamper 0 event detection	TAMP0F	TAMP0IE
		Tamper 1 event detection	TAMP1F	TAMP1IE
		Tamper 2 event detection	TAMP2F	TAMP2IE

12.5 Usage Notes

12.5.1 Voltage Monitor 0 Reset

When the battery backup function is to be used, enable the voltage monitor 0 reset (OFSM.OFS1.PVDAS bit = 0).

12.5.2 When the Battery Backup Function is Not to be Used

If the battery backup function is not to be used, externally connect the VBATT pin to the VCC pin. Also, set the VBATTCR1.PSWDIS bit to 1 and the VBATTCR2.VDETE bit to 0.
With this configuration, a backup domain reset may not be generated in cases such as when the VCC voltage drops and then recovers immediately. Initialize the registers using the procedure shown in Figure 12.9.

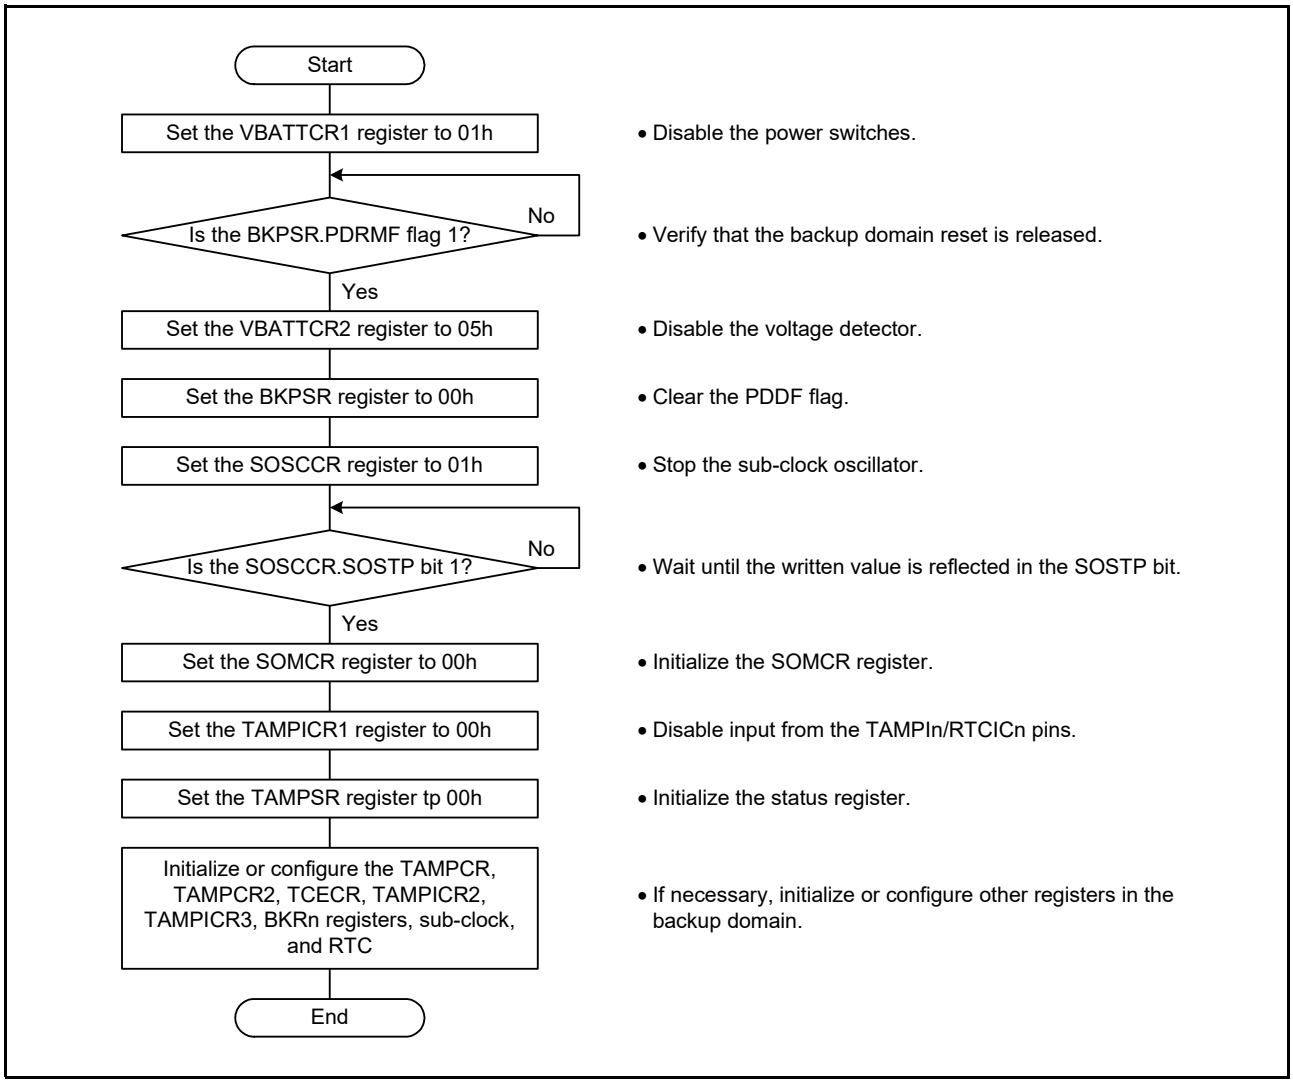

Figure 12.9 Example of Register Initialization Flow

12.5.3 Current Injection Flowing into the VBATT Pin

During operation in the battery backup mode, the voltage of the VCC pin being higher than V_{BATT} may inject a current into the VBATT pin through the parasitic diode connected to the power switch (refer to Figure 12.2). If the power supply or battery connected to the VBATT pin cannot support this current injection, it is recommended that an external low-drop diode be connected between this power supply and the VBATT pin.

13. Register Write Protection Function

The register write protection function protects the specified registers from being overwritten in case a program runs out of control. The registers to be protected can be specified by using the protect registers (PRCR_S and PRCR_NS).
The PRCR_S register is used to protect the registers set as Secure, and the PRCR_NS register is used to protect the registers set as Non-secure. For the sake of descriptions in this section, these two registers are collectively referred to as the PRCR registers.
Table 13.1 lists the association between the PRCR register and the registers to be protected.

Table 13.1 Association between PRCR Register and Registers to be Protected

PRCR	Register to be Protected
PRC0	• Registers related to the clock generation circuit: SCKDIVCR, SCKDIVCR2, SCKSCR, PLLCCR, PLLCR, BCKCR, MOSCCR, HOCOCR, HOCOCR2, MOCOCR, FLLCR1, FLLCR2, CKOCR, OSTDCR, OSTDSR, SOSTDCR, SOSTDSR, PLL2CCR, PLL2CR, PLLCCR2, PLL2CCR2, EBCKOCR, SDCKOCR, SCICKDIVCR, SCICKCR, SPICKDIVCR, SPICKCR, ADCCKDIVCR, ADCCKCR, GPTCKDIVCR, GPTCKCR, BCKADIVCR, ESWCKDIVCR, ESWPCKDIVCR, ETHPCKDIVCR, BCKACR, ESWCKCR, ESWPCKCR, ETHPCKCR, MOCOUTCR, HOCOUTCR, USBCKDIVCR, XSPICKDIVCR, CANFDCKDIVCR, USB60CKDIVCR, I3CCKDIVCR, USBCKCR, XSPICKCR, CANFDCKCR, USB60CKCR, I3CCKCR, MOSCSCR, HOCOSCR, MOCOSCR, MOSCWTCR, LOCOCR, LOCOUTCR, MOMCR, SOSCCR, SOMCR
PRC1	• Registers related to the operating modes: SYSCR0 • Registers related to the low power consumption functions: PGSCR, PSSTCR2, PSSTCR4, PSSTCR5, PDCTRESWM, PDRAMSCR0, PDRAMSCR2, SBYCR, SSCR1, LPSCR, DPSBYCR, DPSIERn (n = 0 to 5), DPSIFRn (n = 0 to 5), DPSIEGRn (n = 0 to 4), PLL1LDOCR, PLL2LDOCR, HOCOLDOCR, LVOCR, VSCR, SVSCR, MWMCR, LDOECR, DCCR • Registers related to the battery backup function: BKRCR, TAMPICR1, BKRn (n = 0 to 127), VBATTCR1, VBATTCR2, BKPSR, TAMPSR, TAMPCR, TCECR, TAMPICR2, TAMPCR2, TAMPICR3 • Software reset register: SWRR
PRC3	• Registers related to the PVD: PVD1CMPCR, PVD2CMPCR, PVD4CMPCR, PVD5CMPCR, PVD1CR0, PVD2CR0, PVD4CR0, PVD5CR0, PVD1CR1, PVD1SR, PVD2CR1, PVD2SR, PVD1FCR, PVD2FCR, PVD4FCR, PVD5FCR, PVDLR, VBATTMCR
PRC4*1	• Registers related to the security function: ELCSARx (x = A to D), PSARx (x = B to F), MSSAR, PmSAR (m = 0 to 9 or A to G), CACHESAR, IFUSR, LRMSAR, LRMSABARx (x = 0, 1), ICUSARx (x = A to D), ICU0SARx (x = 0 to 7), TEVTRCR, ICUNSACR, PRTZCR, BUSSARx (x = A to C), MMPUSARB, DMACCHSAR, DMACSAR, EXDMACCHSAR, EXDMACSAR, DTCSAR, SRAMSABARx (x = 0, 1), SRAMSAR, MSAR, CGFSAR, RSTSAR, LPMSAR, PVDSAR, VBSAR, DPFSAR, DPFSAR1, RSCSAR, PGCSAR, BKRSABR
PRC5*1	• Registers related to the resets: SYRSTMSK0, SYRSTMSK2, TEMPRCR, TEMPRLR

Note 1. This bit is only present in the PRCR_S register.

13.1 Register Descriptions

13.1.1 Protect Register (PRCR_S)

Address(es): SYSC.PRCR_S 8701 93FAh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PRKEY[7:0]								—	—	PRC5	PRC4	PRC3	—	PRC1	PRC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PRC0	Protect Bit 0	Enables writing to the registers related to the clock generation circuit. 0: Write disabled 1: Write enabled	R/W
b1	PRC1	Protect Bit 1	Enables writing to the registers related to operating modes, low power consumption, battery backup, and software reset. 0: Write disabled 1: Write enabled	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	PRC3	Protect Bit 3	Enables writing to the registers related to the PVD. 0: Write disabled 1: Write enabled	R/W
b4	PRC4	Protect Bit 4	Enables writing to the registers related to the security function. 0: Write disabled 1: Write enabled	R/W
b5	PRC5	Protect Bit 5	Enables writing to the registers related to the resets. 0: Write disabled 1: Write enabled	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	PRKEY[7:0]	PRC Key Code	These bits control permission and prohibition of writing to the PRCR_S register. To modify the PRCR_S register, write A5h to the eight higher-order bits and the desired value to the eight lower-order bits as a 16-bit unit.	R/(W)*1

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Written values are not retained. These bits are read as 00h.

The PRCR_S register is used to protect the registers set as Secure.

PRCi Bits (Protect Bit i) (i = 0, 1, 3, 4, 5)

These bits enable or disable writing to the corresponding registers to be protected.
Setting the PRCi bits to 1 and 0 enables and disables writing to the corresponding registers to be protected, respectively.
In case of successive write access to the PRCR_S register and to registers controlled by the PRCR_S register, the registers under control of the PRC4 bit may not reflect a change in the PRC4 bit. Avoid successive write access, or after having written a new value to the PRC4 bit, read the PRCR_S register before writing to the registers under control of the PRC4 bit.

13.1.2 Protect Register (PRCR_NS)

Address(es): SYSC_NS.PRCR_NS 0701 93FEh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PRKEY[7:0]								—	—	—	—	PRC3	—	PRC1	PRC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PRC0	Protect Bit 0	Enables writing to the registers related to the clock generation circuit. 0: Write disabled 1: Write enabled	R/W
b1	PRC1	Protect Bit 1	Enables writing to the registers related to operating modes, low power consumption, battery backup, and software reset. 0: Write disabled 1: Write enabled	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	PRC3	Protect Bit 3	Enables writing to the registers related to the PVD. 0: Write disabled 1: Write enabled	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	PRKEY[7:0]	PRC Key Code	These bits control permission and prohibition of writing to the PRCR_NS register. To modify the PRCR_NS register, write A5h to the eight higher-order bits and the desired value to the eight lower-order bits as a 16-bit unit.	R/(W)*1

Note: This register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Written values are not retained. These bits are read as 00h.

The PRCR_NS register is used to protect the registers set as Non-secure.

PRCi Bits (Protect Bit i) (i = 0, 1, 3)

These bits enable or disable writing to the corresponding registers to be protected.
Setting the PRCi bits to 1 and 0 enables and disables writing to the corresponding registers to be protected, respectively.

14. Exception Handling

14.1 Exception Events

During the execution of a program by the CPU, the occurrence of a certain event may cause execution of the program to be suspended and execution of another program to be started. Such events are called exception events. The RXv3e CPU supports ten types of exception. The types of exception events are shown in Figure 14.1. The occurrence of an exception causes the processor mode to shift to supervisor mode.

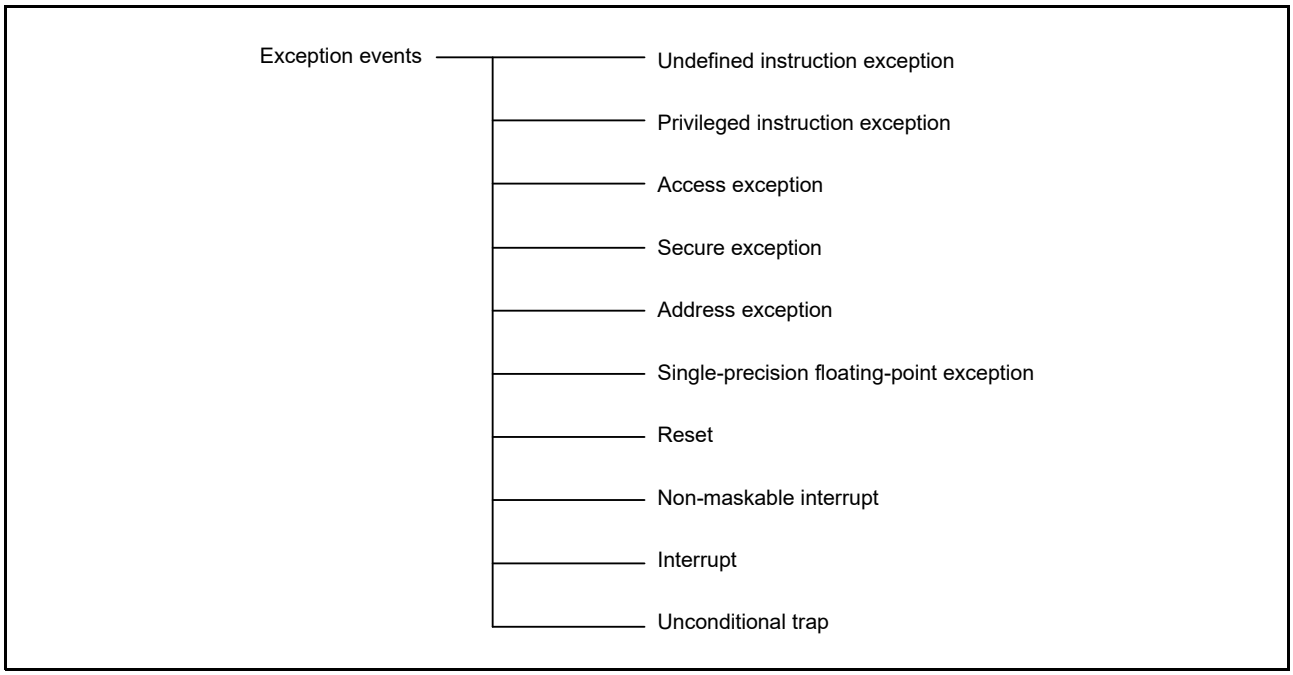

Figure 14.1 Types of Exception Events

14.1.1 Undefined Instruction Exception

An undefined instruction exception occurs when execution of an undefined instruction (an instruction not implemented) is detected. This exception also occurs in the case of an attempt to execute an instruction that is exclusively for use in the root world (TRMVTC, TRMVFC, or TRRTE) from outside the root world.

14.1.2 Privileged Instruction Exception

A privileged instruction exception occurs when execution of a privileged instruction is detected in user mode. Privileged instructions can be executed only in supervisor mode.

14.1.3 Access Exception

An access exception occurs when the memory protection unit detects an error in memory access by the CPU. If the error is due to instruction fetching, an instruction access exception occurs, and if the error is due to operand access, an operand access exception occurs.

14.1.4 Secure Exception

A secure exception occurs when a security violation is detected in memory access by the CPU. If an error occurs due to an instruction fetch, an instruction secure exception occurs, and if an error occurs due to an operand access, an operand secure exception occurs.
The CPU core is placed in the root world on generation of a secure exception.
Even when a security violation is detected in memory access, the CPU may not generate a secure exception. This depends on the location and timing of the detection.

14.1.5 Address Exception

An address exception is generated in response to 64-bit operand access to an address that is not multiples of four.

14.1.6 Single-Precision Floating-Point Exception

A single-precision floating-point exception is generated when any of the five exceptions specified in the IEEE 754 standard, namely overflow, underflow, inexact, division-by-zero, or invalid operation, or an attempt to use processing that is not implemented, is detected upon execution of a single-precision floating-point operation instruction. Exception handling by the CPU only proceeds when any among the EX, EU, EZ, EO, or EV bits in the FPSW, which corresponding to the five types of exception, is set to 1.

14.1.7 Reset

A reset is generated by input of a reset signal to the CPU. This has the highest priority of any exception and is always accepted.

14.1.8 Non-Maskable Interrupt

Input of the non-maskable interrupt signal to the CPU generates a non-maskable interrupt. This interrupt is assumed to be used when a fatal problem with the system is judged to have arisen. In such cases, use it under the condition that return to the original program being executed when the exception was generated will not proceed after the exception handling routine. In addition, unless a Flat-Project is in use, returning to the original program being executed when the exception was generated is not possible.
Non-maskable interrupts are accepted independently of the type of the world that is currently in use.
The behavior upon acceptance of a non-maskable interrupt is divided into the following two cases according to the situation at the time of acceptance.

	Situation on Acceptance of a Non-Maskable Interrupt	World Transition
Normal acceptance	The ID of the destination world for a non-maskable interrupt is the same as the ID of the current world.	No world transition
World-transition acceptance	The ID of the destination world for a non-maskable interrupt is different from the ID of the current world.	Transition to the root world occurs

In the case of normal acceptance, a transition from the current world to another world does not occur.
In the case of world-transition acceptance, a transition to the root world occurs. After that, a transition to the destination world of the non-maskable interrupt is produced by software running in the root world.

14.1.9 Interrupt

An interrupt is generated by the input of an interrupt signal to the CPU. A fast interrupt can be selected as the interrupt with the highest priority. In the case of the fast interrupt, hardware pre-processing and hardware post-processing are handled fast. The priority level of the fast interrupt is 31 (the highest).

An interrupt can only be accepted when the conditions in the table below are met. The conditions for acceptance depend on the current world.

Table 14.1 Conditions of Interrupt Acceptance

Current World		
Root	**Secure**	**Non-secure**
• ITW is root and • PSW.I is 1 and • (PSW.IPL < IPR) and • (WPRI.WIPL < IPR)	• PSW.I is 1 and • (PSW.IPL < IPR) and • (WPRI.WIPL < IPR)	• PSW.I is 1 and • (PSW.IPL < IPR) and • (WPRI.WIPL < IPR) However, when the IVC.NSIC bit is 1, an interrupt will even be accepted under the following condition in addition to the above conditions. • (15 < IPR) and • (WPRI.WIPL < IPR)

IPR: The priority level of a requested interrupt
ITW: The destination world ID for a requested interrupt

The behavior upon acceptance of an interrupt is divided into the following two cases according to the situation at the time of acceptance.

	Situation on Acceptance of Interrupt	World Transition
Normal acceptance	The ID of the destination world for an interrupt is the same as the ID of the current world.	No world transition
World-transition acceptance	The ID of the destination world for an interrupt is different from the ID of the current world.	Transition to the root world occurs

In the case of normal acceptance, a transition from the current world to another world does not occur. In the case of world-transition acceptance, a transition to the root world occurs. After that, a transition to the destination world of the interrupt is produced by software running in the root world. Interrupt priority levels 1 to 31 can be used for interrupts having root or secure as the destination world. Interrupt priority levels 1 to 15 can be used for interrupts having non-secure as the destination world. Fast interrupts are only usable in Flat-Projects.

14.1.10 Unconditional Trap

An unconditional trap is generated when the INT, BRK, or TRCALL instruction is executed. The behavior upon acceptance depends on the instruction and is divided into the following two cases.

	Instructions	World Transition
Normal acceptance	INT, BRK	No world transition
World-transition acceptance	TRCALL	Transition to the root world occurs

14.2 Exception Handling Procedure

Exception handling procedures are of two types. In one, the exception event is processed without world transitions. In the other, the exception event is processed with world transitions.
Table 14.2 shows which exception events generate world transitions.

Table 14.2 Exception Events and World Transition

Exception Event	Presence of World Transitions
Undefined instruction exception	No world transitions
Privileged instruction exception	No world transitions
Access exception	No world transitions
Secure exception	World transitions
Address exception	No world transitions
Single-precision floating-point exception	No world transitions
Reset	— (always causes a transition to the root world)
Non-maskable interrupt (with normal acceptance)	No world transitions
Non-maskable interrupt (with world-transition acceptance)	World transitions
Interrupt (with normal acceptance)	No world transitions
Interrupt (with world-transition acceptance)	World transitions
Unconditional trap (with normal acceptance)	No world transitions
Unconditional trap (with world-transition acceptance)	World transitions

14.2.1 Exception Handling Procedure without World Transitions

In the exception handling, part of the processing is handled automatically by hardware and part of it is handled by a program (exception handling routine) that has been written by the user. Figure 14.2 shows the processing procedure when an exception other than a reset is accepted.

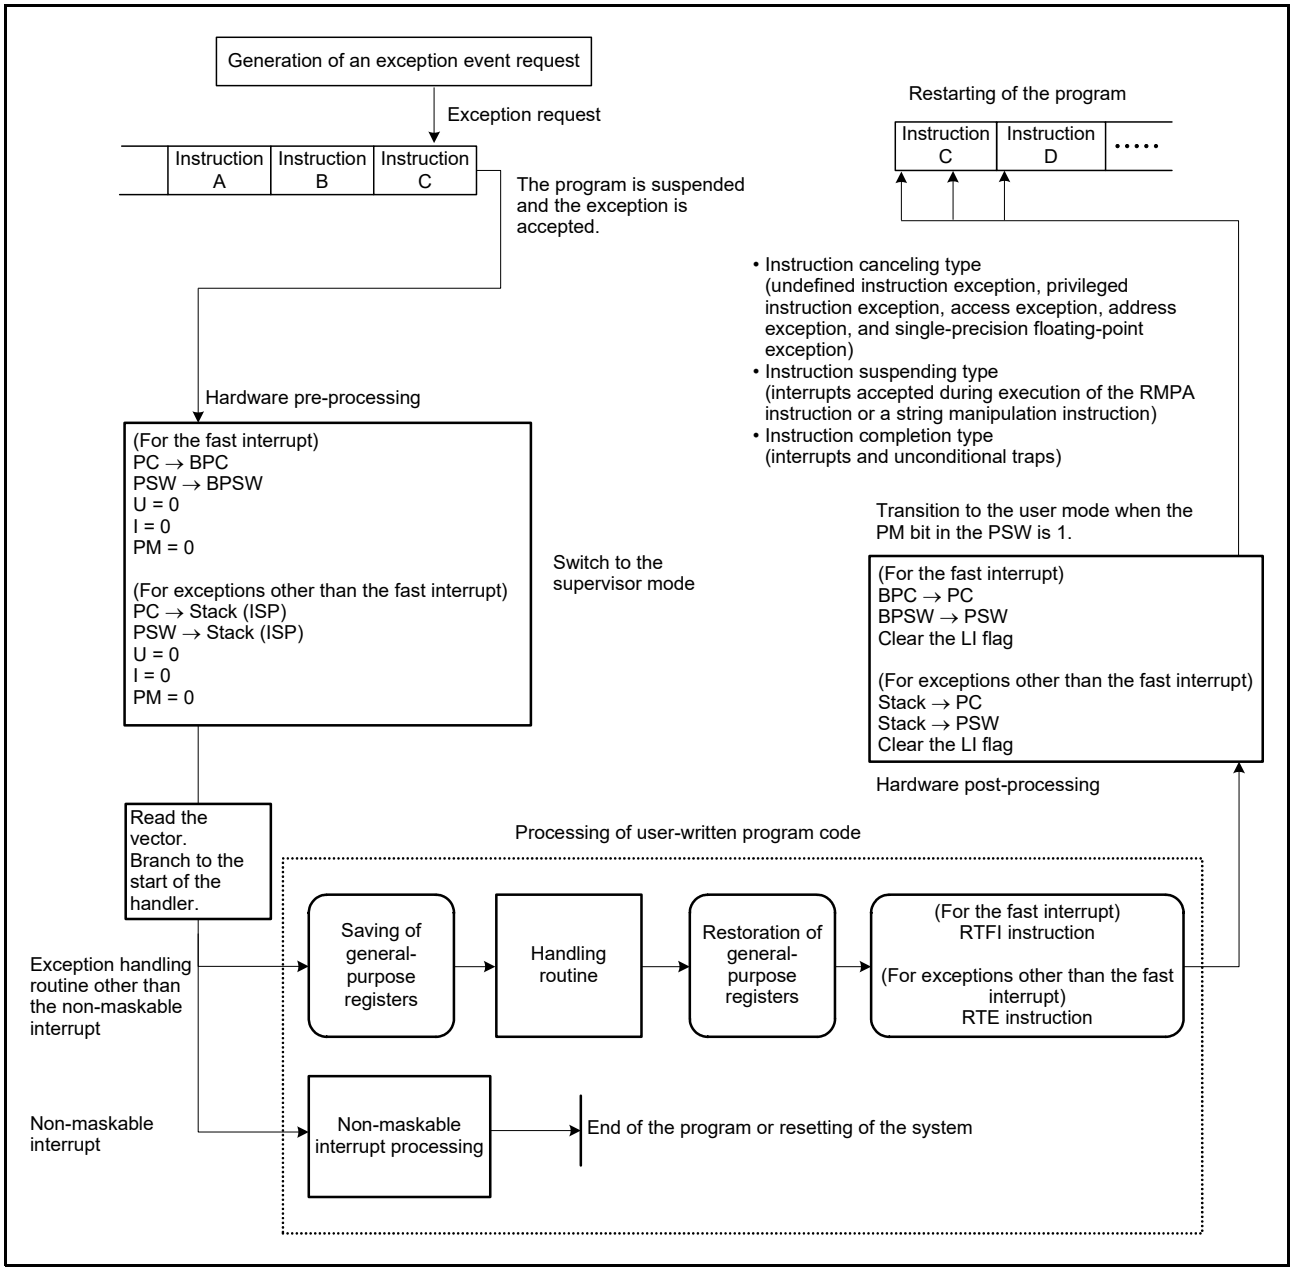

Figure 14.2 Outline of Exception Handling Procedure without World Transitions

When an exception is accepted, hardware processing by the RXv3e CPU is followed by access to the vector to acquire the address of the branch destination. In the vector, a vector address is allocated to each exception, and the branch destination address of the exception handling routine is written to each vector address.

Hardware pre-processing by the RXv3e CPU handles saving of the values of the program counter (PC) and processor status word (PSW). In the case of the fast interrupt, the values of the PC and PSW are saved in the backup PC (BPC) and the backup PSW (BPSW), respectively. In the case of exceptions other than the fast interrupt, the values of the PC and PSW are saved on the stack. The values of general purpose registers and control registers other than the PC and PSW that are to be used within an exception handling routine must be saved by the user program at the start of the exception

handling routine.
At the end of exception handling routine, after the restoration of registers saved by the user, the RTE instruction is executed to return from the exception handling routine to the original program. For return from the fast interrupt, the RTFI instruction is used instead. In the case of the non-maskable interrupt, end the program or reset the system without returning to the original program.
Hardware post-processing by the RXv3e CPU handles restoration of the contents of the PC and PSW. In the case of the fast interrupt, the values of the BPC and BPSW are restored to the PC and PSW, respectively. In the case of other exceptions, the values are restored from the stack to the PC and PSW.
The stack or the register-saving bank can be used to save and restore the general-purpose and other registers at the start and end of an exception handling routine.
Saving to and restoring from the register-saving bank is executed by using the SAVE and RSTR instructions. To save and restore a register that is not within the scope of saving or restoring by the SAVE and RSTR instructions, use the PUSH and POP instructions for saving to and restoring from the stack.
Using the register-saving bank is usually faster than using the stack, except when the number of registers that require saving and restoring in transitions to and from an exception-handling routine is extremely small.

14.2.2 Exception Handling Procedure with World Transitions

An exception handling procedure has a part that is automatically processed by hardware and parts that are processed by user-created programs (processing programs to be executed in the root world, processing programs to be executed in the destination world of the exception event, and exception handling routines). Figure 14.3 shows an exception handling procedure that includes world transitions.

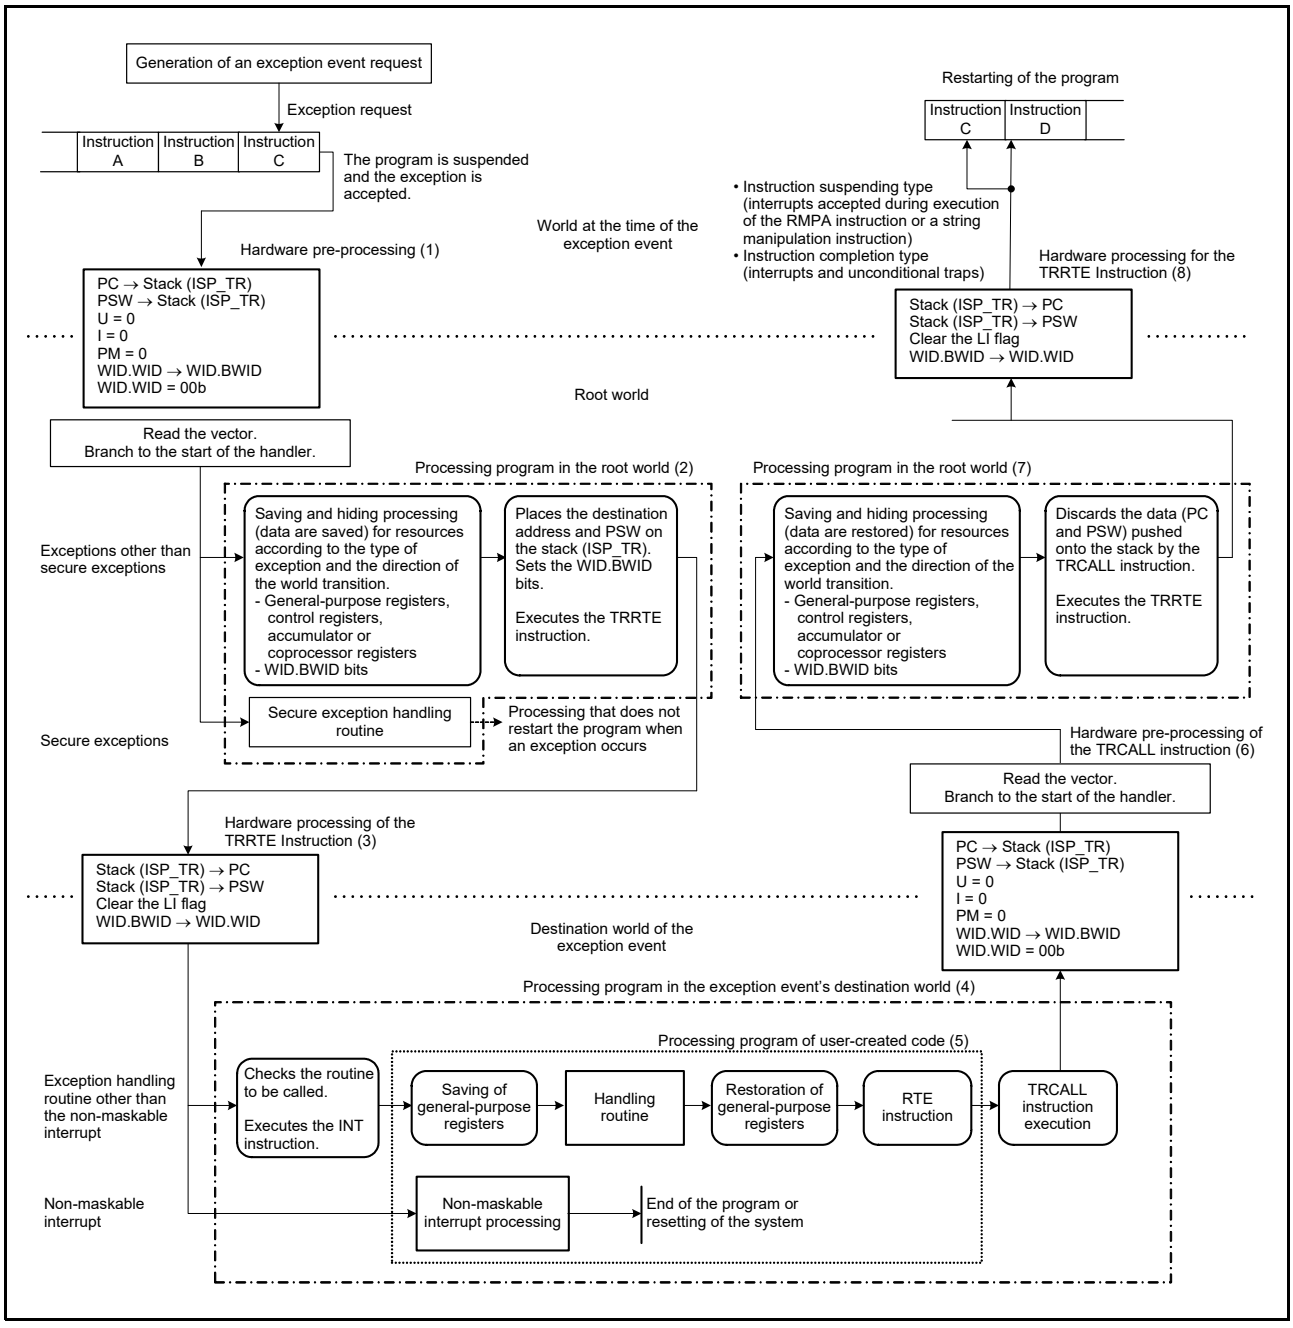

Figure 14.3 Outline of Exception Handling Procedure with World Transitions

When an exception that includes world transitions is accepted, the CPU performs hardware pre-processing (1) and access to the vector table, then obtains the branch destination address. A vector address is assigned to the vector for each exception, and the branch destination address to the processing program in the root world (2) is written to that address. In hardware preprocessing by the CPU (1), the values of the PC and PSW are placed on the stack (ISP_TR). Also, the value of the WID.WID bits is saved in the WID.BWID bits, and a transition is made to the root world with the WID.WID bits set to 0.

In the processing program in the root world (2), the flow of processing depends on whether the exception is secure (in other words, processing of the original program will not resume on return) or not (in other words, processing of the original program in the original world resumes after the exception handling routine in another world has been run via the root world). In the case of a secure exception, after appropriate processing by the secure exception handling routine in the root world, the program is terminated or a jump is made to processing that does not involve resuming processing by the program at the time the exception occurred. In the case of an exception other than a secure exception, consider the type of the exception and the direction of world transitions due to that exception, and perform processing to save or hide resources required by the system (general-purpose registers, control registers, and accumulator or coprocessor registers). After that, set the WID.BWID bits to match the destination world, place the start address and PSW of the processing program in the exception event's destination world (4) on the stack (ISP_TR), and execute the TRRTE instruction.
The hardware processing of the TRRTE instruction (3) causes a transition to the processing program in the exception event's destination world (4).
With the processing program in the exception event's destination world (4), if the interrupt is not non-maskable, the INT instruction is used to cause a transition to processing of the user-created code (5). In processing an interrupt, the value of the IVC register is used as an argument of the INT instruction. Programming in this manner in the destination world of the exception event enables (5) to be used in common with cases that involve no world transitions (this method is shown here as an example of a processing procedure, but can also be used to make a common program except for the processing to save and restore the general-purpose registers). After that, execute the TRCALL instruction to execute the processing program in the root world (7).
In the hardware pre-processing of the TRCALL instruction (6), the values of the PC and PSW are placed on the stack (ISP_TR). Also, the value of the WID.WID bits is saved in the WID.BWID bits, and a transition is made to the root world with the WID.WID bits set to 0.
The processing program in the root world (7), after restoring the resources saved in (2), including the value of the WID.BWID bits, and discarding the PC and PSW that were pushed onto the stack (ISP_TR) by the immediately preceding TRCALL instruction, executes the TRRTE instruction.
The hardware processing of the TRRTE instruction (8) causes a transition to the location for resuming processing by the program at the point where the exception was accepted.

The flow of the processing procedure is explained above, but the processing program in the root world ((2) or (7)), should also run checking according to the current security requirements, such as whether the world from which the TRCALL instruction was called is appropriate, or whether there are any inconsistencies in the number of world transitions going back and forth.

14.3 Acceptance of Exception Events

When an exception occurs, the CPU suspends the execution of the program and processing branches to the exception handling routine.

14.3.1 Timing of Acceptance and Saved PC Value

Table 14.3 lists the timing of acceptance and the program counter (PC) value to be saved for each exception event. For interrupts, non-maskable interrupts, and unconditional traps, the behavior shown in the table below will not change regardless of whether the exception is accepted through world-transition acceptance or normal acceptance.

Table 14.3 Timing of Acceptance and Saved PC Value

Exception		Type of Handling	Timing of Acceptance	Value Saved in the BPC/on the Stack
Undefined instruction exception		Instruction canceling type	During instruction execution	PC value of the instruction that generated the exception
Privileged instruction exception		Instruction canceling type	During instruction execution	PC value of the instruction that generated the exception
Access exception		Instruction canceling type	During instruction execution	PC value of the instruction that generated the exception
Secure exception		Instruction canceling type	During instruction execution	PC value of the instruction that generated the exception
Address exception		Instruction canceling type	During instruction execution	PC value of the instruction that generated the exception
Single-precision floating-point exception		Instruction canceling type	During instruction execution	PC value of the instruction that generated the exception
Reset		Instruction abandonment type	Any machine cycle	None
Non-maskable interrupt	During execution of the RMPA, SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, and SWHILE instructions	Instruction suspending type	During instruction execution	PC value of the instruction being executed
	Other than above	Instruction completion type	At the next break between instructions	PC value of the next instruction
Interrupt	During execution of the RMPA, SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, and SWHILE instructions	Instruction suspending type	During instruction execution	PC value of the instruction being executed
	Other than above	Instruction completion type	At the next break between instructions	PC value of the next instruction
Unconditional trap		Instruction completion type	At the next break between instructions	PC value of the next instruction

14.3.2 Vector and Location for Saving the PC and PSW

The vector for each type of exception and the location for saving the contents of the program counter (PC) and processor status word (PSW) are listed in Table 14.4 and Table 14.5. The addresses where the exception vector table and interrupt vector table start must be set. For details, see section 2.6, Vector Tables.

Table 14.4 Vector and Location for Saving the PC and PSW for an Exception without World Transitions

Exception		Vector	Location for Saving the PC and PSW
Undefined instruction exception		Exception vector table in the current world	Stack in the current world
Privileged instruction exception		Exception vector table in the current world	Stack in the current world
Access exception		Exception vector table in the current world	Stack in the current world
Address exception		Exception vector table in the current world	Stack in the current world
Single-precision floating-point exception		Exception vector table in the current world	Stack in the current world
Reset		FFFF FFFCh	Nowhere
Non-maskable interrupt		Exception vector table in the current world	Stack in the current world
Interrupt	Fast interrupt	FINTV	BPC and BPSW in the root world
	Other than above	Interrupt vector table in the current world	Stack in the current world
Unconditional trap		Interrupt vector table in the current world	Stack in the current world

Table 14.5 Vector and Location for Saving the PC and PSW for an Exception with World Transitions

Exception		Vector	Location for Saving the PC and PSW
Non-maskable interrupt		Exception vector table in the root world (EXTB_TR)	Stack in the root world (ISP_TR)
Interrupts	Fast interrupt	—	—
	Other than above	Vector table for interrupts that cause world transitions (WINTB)	Stack in the root world (ISP_TR)
Secure exception		Exception vector table in the root world (EXTB_TR)	Stack in the root world (ISP_TR)
Unconditional trap		Root call vector table (TRCTB)	Stack in the root world (ISP_TR)

14.4 Hardware Processing for Accepting and Returning from Exceptions

This section describes the hardware processing for accepting and returning from exceptions other than a reset.

14.4.1 Hardware Processing for Accepting and Returning from Exceptions Not Involving World Transitions

(1) Hardware Pre-Processing for Accepting an Exception

(a) Saving PSW

- For a fast interrupt
  PSW → BPSW
- For exceptions other than a fast interrupt
  PSW → Stack

Note: The FPSW is not saved by the hardware pre-processing. If single-precision floating-point operation instructions are used within an exception-handling routine, the user must save the FPSW on the stack within the exception-handling routine.

(b) Updating PM, U, and I Bits in PSW

I: Set to 0
U: Set to 0
PM: Set to 0

(c) Saving PC

- For a fast interrupt
  PC → BPC
- For exceptions other than a fast interrupt
  PC → Stack

(d) Setting Branch Destination Address of Exception Handling Routine in PC

Processing is shifted to the exception handling routine by acquiring the vector corresponding to the exception and then branching accordingly.

(2) Hardware Post-Processing for Execution of RTE and RTFI Instructions

(a) Restoring PSW

- For a fast interrupt
  BPSW → PSW
- For exceptions other than a fast interrupt
  Stack → PSW

(b) Restoring PC

- For a fast interrupt
  BPC → PC
- For exceptions other than a fast interrupt
  Stack → PC

(c) Clearing the LI flag

14.4.2 Hardware Processing for Accepting and Returning from Exceptions Involving World Transitions

(1) Hardware Pre-Processing for Accepting an Exception

(a) Saving WID

WID.WID → WID.BWID

(b) Updating the WID

WID.WID: Cleared to 00b

(c) Saving the PSW

PSW → Stack (ISP_TR)

(d) Updating the PM, U, and I bits in the PSW

I: Cleared to 0
U: Cleared to 0
PM: Cleared to 0

(e) Saving the PC

PC → Stack (ISP_TR)

(f) Setting the branch-destination address of the exception handling routine in the PC

Processing is shifted to the exception handling routine by acquiring the vector corresponding to the exception and branching accordingly.

(2) Hardware post-processing for executing TRRTE instruction

(a) Restoring the WID

WID.BWID → WID.WID

(b) Restoring the PSW

Stack (ISP_TR) → PSW

(c) Restoring the PC

Stack (ISP_TR) → PC

(d) Clearing the LI flag

14.5 Hardware Pre-Processing

The hardware pre-processing from reception of each exception request to execution of the associated exception handling routine are explained below.

14.5.1 Undefined Instruction Exception

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. The value of the program counter (PC) is saved on the stack (ISP).
4. The vector is fetched from the address obtained by the value of EXTB + 0000 005Ch.
5. The fetched vector is set to the PC and processing branches to the exception handling routine.

14.5.2 Privileged Instruction Exception

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. The value of the program counter (PC) is saved on the stack (ISP).
4. The vector is fetched from the address obtained by the value of EXTB + 0000 0050h.
5. The fetched vector is set to the PC and processing branches to the exception handling routine.

14.5.3 Access Exception

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. The value of the program counter (PC) is saved on the stack (ISP).
4. The vector is fetched from the address obtained by the value of EXTB + 0000 0054h.
5. The fetched vector is set to the PC and processing branches to the exception handling routine.

14.5.4 Secure Exception

1. The value of the WID.WID bits is saved to the WID.BWID bits.
2. The WID.WID bits are set to 0 and a transition is made to the root world.
3. The value of the processor status word (PSW) is saved on the stack (ISP_TR).
4. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in the PSW are cleared to 0.
5. The value of the program counter (PC) is saved on the stack (ISP_TR).
6. The vector is fetched from the value of EXTB + address 0000 0008h.
7. The PC is set to the fetched address and processing branches to the start of the exception handling routine.

14.5.5 Address Exceptions

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. The value of the program counter (PC) is saved on the stack (ISP).
4. The vector is fetched from the address obtained by the value of EXTB + 0000 0060h.
5. The fetched vector is set to the PC and processing branches to the exception handling routine.

14.5.6 Single-Precision Floating-Point Exceptions

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. The value of the program counter (PC) is saved on the stack (ISP).
4. The vector is fetched from the address obtained by the value of EXTB + 0000 0064h.
5. The fetched vector is set to the PC and processing branches to the exception handling routine.

14.5.7 Reset

1. The control registers are initialized.
2. The vector is fetched from address FFFF FFFCh.
3. The fetched vector is set to the PC.

14.5.8 Non-Maskable Interrupts (with Normal Acceptance)

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. If the interrupt was generated during the execution of an RMPA, SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, or SWHILE instruction, the value of the program counter (PC) for that instruction is saved on the stack (ISP). For other instructions, the PC value of the next instruction is saved.
4. The processor interrupt priority level bits (IPL[4:0]) in PSW are set to 0Fh if the current instruction is being executed in the non-secure world; if not, they are set to 1Fh.
5. The vector is fetched from the address obtained by the value of EXTB + 0000 0078h.
6. The fetched vector is set to the PC and processing branches to the exception handling routine.

14.5.9 Non-Maskable Interrupts (with World-Transition Acceptance)

1. The value in WID.WID is saved to WID.BWID.
2. Set WID.WID to 0 and transition to the root world.
3. The destination world ID of the non-maskable interrupt is stored in the WID.BITW bits.
4. The value of the processor status word (PSW) is saved on the stack (ISP_TR).
5. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in the PSW are cleared to 0.
6. If the interrupt was generated during the execution of an RMPA, SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, or SWHILE instruction, the value of the program counter (PC) for that instruction is saved on the stack (ISP_TR). For other instructions, the PC value of the next instruction is saved.
7. The processor interrupt priority level bits (IPL[4:0]) in the PSW are set to 1Fh.
8. The vector is fetched from the value of EXTB + address 0000 0018h.
9. The PC is set to the fetched address and processing branches to the start of the exception handling routine.

14.5.10 Interrupts (with Normal Acceptance)

1. The value of the processor status word (PSW) is saved on the stack (ISP) or, for the fast interrupt, in the backup PSW (BPSW).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. If the interrupt was generated during the execution of an RMPA, SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, or SWHILE instruction, the value of the program counter (PC) for that instruction is saved. For other instructions, the PC value of the next instruction is saved on the stack (ISP). Saving of the PC is in the backup PC (BPC) for fast interrupts.
4. The processor interrupt priority level bits (IPL[4:0]) in PSW indicate the interrupt priority level of the interrupt.
5. The vector for an interrupt source other than the fast interrupt is fetched from the interrupt vector table. For the fast interrupt, the address is fetched from the fast interrupt vector register (FINTV).
6. The fetched vector is set to the PC and processing branches to the exception handling routine.

14.5.11 Interrupts (with World-Transition Acceptance)

1. The value in WID.WID is saved to WID.BWID.
2. Set WID.WID to 0 and transition to the root world.
3. The destination world ID of the interrupt is stored in the WID.BITW bits.
4. The interrupt source number is stored in the IVC.BWINM bits in the root world and in the destination world of the interrupt.
5. The value of the processor status word (PSW) is saved on the stack (ISP_TR).
6. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in the PSW are cleared to 0.
7. If the interrupt was generated during the execution of an RMPA, SCMPU, SMOVB, SMOVF, SMOVU, SSTR, SUNTIL, or SWHILE instruction, the value of the program counter (PC) for that instruction is saved on the stack (ISP_TR). For other instructions, the PC value of the next instruction is saved.
8. The interrupt priority level of the accepted interrupt is set in the processor interrupt priority level bits (IPL[4:0]) in the PSW.
9. The vector corresponding to the destination world of the interrupt is fetched from the vector table for the interrupt that caused the world transition.
10. The PC is set to the fetched address and processing branches to the start of the exception handling routine.

14.5.12 Unconditional Trap (with Normal Acceptance)

1. The value of the processor status word (PSW) is saved on the stack (ISP).
2. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in PSW are set to 0.
3. The value of the program counter (PC) for the next instruction is saved on the stack (ISP).
4. For the INT instruction, the value at the vector corresponding to the INT instruction number is fetched from the interrupt vector table.
   For the BRK instruction, the value at the vector from the start address is fetched from the interrupt vector table.
5. The fetched vector is set to the PC and processing branches to the exception handling routine.

14.5.13 Unconditional Trap (with World-Transition Acceptance)

1. The value in WID.WID is saved to WID.BWID.
2. Set WID.WID to 0 and transition to the root world.
3. The value of the PSW.I bit is stored in the WID.BWI bit.
4. The value of the processor status word (PSW) is saved on the stack (ISP_TR).
5. The processor mode select bit (PM), the stack pointer select bit (U), and the interrupt enable bit (I) in the PSW are cleared to 0.
6. The value of the program counter (PC) for the next instruction is saved on the stack (ISP_TR).
7. The vector corresponding to the TRCALL instruction number is fetched from the root call vector table.
8. The PC is set to the fetched address and processing branches to the start of the exception handling routine.

14.6 Return from Exception Handling Routine

Executing the instruction listed in Table 14.6 at the end of the corresponding exception handling routine leads to restoration of the values of the program counter (PC) and processor status word (PSW) that were saved on the stack or in the backup PC (BPC) or the backup PSW (BPSW) by the hardware preprocessing.

Table 14.6 Return from Exception Handling Routine

Exception		Instruction for Return
Undefined instruction exception		RTE
Privileged instruction exception		RTE
Access exception		RTE
Secure exception		TRRTE*1
Address exception		RTE
Single-precision floating-point exception		RTE
Reset		Return is impossible
Non-maskable interrupt (normal acceptance)		RTE*2
Non-maskable interrupt (world-transition acceptance)		TRRTE*2
Interrupts (normal acceptance)	Fast interrupt	RTFI
	Other than above	RTE
Interrupts (world-transition acceptance)	Fast interrupt	—
	Other than above	TRRTE
Unconditional trap (normal acceptance)		RTE
Unconditional trap (world-transition acceptance)		TRRTE

Note 1. Returning to the original program is not possible.
Note 2. Returning to the original program is not recommended. If the destination world of the non-maskable interrupt is secure or non-secure, returning to the original program is in any case not possible.

14.7 Priority of Exception Events

The priority of exception events is listed in Table 14.7. When multiple exceptions are generated at the same time, the exception with the highest priority is accepted first.

Table 14.7 Priority of Exception Events

Priority		Exception Event
High	1	Reset
▲	2	Non-maskable interrupt

14.8 Exception Generated in Coprocessor

This section describes exceptions generated in the coprocessor and handling of them.

14.8.1 Double-Precision Floating-Point Exceptions

Double-precision floating-point exceptions are generated when any of the five exceptions specified in the IEEE 754 standard, namely overflow, underflow, inexact, division-by-zero, or invalid operation, or an attempt to use processing that is not implemented, is detected upon execution of a double-precision floating-point operation instruction. When a double-precision floating-point exception is generated, an interrupt request is sent to the interrupt controller according to the settings (the DEX, DEU, DEZ, DEO, and DEV bits of the DPSW corresponding to the five exceptions, and the EHM bit of DECNT) without the CPU performing exception handling.
For the vector numbers allocated to the interrupt controller, refer to section 15, Interrupt Controller (ICUM).

15. Interrupt Controller (ICUM)

15.1 Overview

The interrupt controller (ICU) controls various interrupt requests from the peripheral modules and the IRQi pin (i = 0 to 31), and generates an interrupt request to the CPU and a transfer request to the DTC and DMAC.
Table 15.1 lists the ICU specifications, and Figure 15.1 shows a block diagram of the interrupt controller.

Table 15.1 ICU Specifications (1/2)

Item		Description
Interrupts	Peripheral interrupts	Interrupts from peripheral modules • Interrupt detection method: Edge detection/level detection (fixed for each interrupt source) • Group interrupt: Multiple interrupt sources are grouped together and treated as an interrupt source.*1 • Group IL0 and Group IL1 interrupts: Interrupt sources of memories and coprocessors that use ICLK as the operating clock • Group BL0 and Group BL1 interrupts: Interrupt sources of peripheral modules that use PCLKB as the operating clock • Group AL0 to Group AL6 interrupts: Interrupt sources of peripheral modules that use PCLKA as the operating clock • Software configurable interrupts: Any of the interrupt sources for peripheral modules can be assigned to interrupt vector numbers 128 to 255.
	External pin interrupt	Interrupt by the input signal to the IRQi pin (i = 0 to 31) • Interrupt detection method: Detection of low level, falling edge, rising edge, rising and falling edges One of these detection methods can be set for each source. • Digital noise filter can be used to remove noise.
	Software interrupt	• Interrupt request can be generated by writing to a register. • Two interrupt sources
	Interrupt priority	Priority level can be set with interrupt source priority register r (IPRr) (r = 000 to 255).
	Fast interrupt function*2	Fast interrupt response due to the use of internal CPU resources instead of a stack. This function can be used for only one interrupt source.
	DTC/DMAC control	Interrupt sources can be used to start the DTC and DMAC.*3
	EXDMAC control	Any two of the interrupt sources assigned to software configurable interrupts can be used to start EXDMAC0 and EXDMAC1, respectively.
Non-maskable interrupts *4, *5	NMI pin interrupt	Interrupt by the input signal to the NMI pin • Interrupt detection: Falling edge/rising edge • Digital noise filter can be used to remove noise.
	Main clock oscillation stop detection interrupt	This interrupt occurs when the main clock oscillator stop is detected.
	Sub-clock oscillation stop detection interrupt	This interrupt occurs when the sub-clock oscillator stop is detected.
	WDT underflow/refresh error interrupt	This interrupt occurs when the watchdog timer (WDT) underflows or a refresh error occurs.
	IWDT underflow/refresh error interrupt	This interrupt occurs when the independent watchdog timer (IWDT) underflows or a refresh error occurs.
	Voltage monitoring 1 interrupt	Interrupt from voltage detection circuit 1 (PVD1)
	Voltage monitoring 2 interrupt	Interrupt from voltage detection circuit 2 (PVD2)
	Double-precision floating-point exceptions	Exceptions from double-precision floating-point coprocessor
	Bus error interrupt	This interrupt occurs when a bus error occurs.
	Common memory error interrupt	This interrupt occurs when an ECC error occurs in SRAM0 or SRAM1.
	Local memory error interrupt	This interrupt occurs when an ECC error occurs in the cache memory or LRAM in the CPU.

Table 15.1 ICU Specifications (2/2)

Item		Description
Non-maskable interrupts *4, *5	Code MRAM read access error interrupt	This interrupt occurs when an read access error occurs in the code area of MRAM.
	Extra MRAM read access error interrupt	This interrupt occurs when an read access error occurs in the extra area of MRAM.

Note 1. Groups to which no interrupt source is assigned are reserved. Also, there is no register corresponding to that group.
Note 2. Fast interrupt can be used when the PRTZCR.PRTZC bit is 0.
Note 3. For the DTC and DMAC triggers, refer to Table 15.6, Interrupt Vector Table.
Note 4. Once non-maskable interrupts are enabled, they cannot be disabled.
Note 5. Non-maskable interrupts, except NMI pin interrupt, can be used as maskable interrupts. When using for maskable interrupts, do not change the NMIER register value from the value after reset. To enable the voltage monitoring 1 interrupt, set the PVD1CR1.IRQSEL bit to 1, and to enable the voltage monitoring 2 interrupt, set the PVD2CR1.IRQSEL bit to 1.

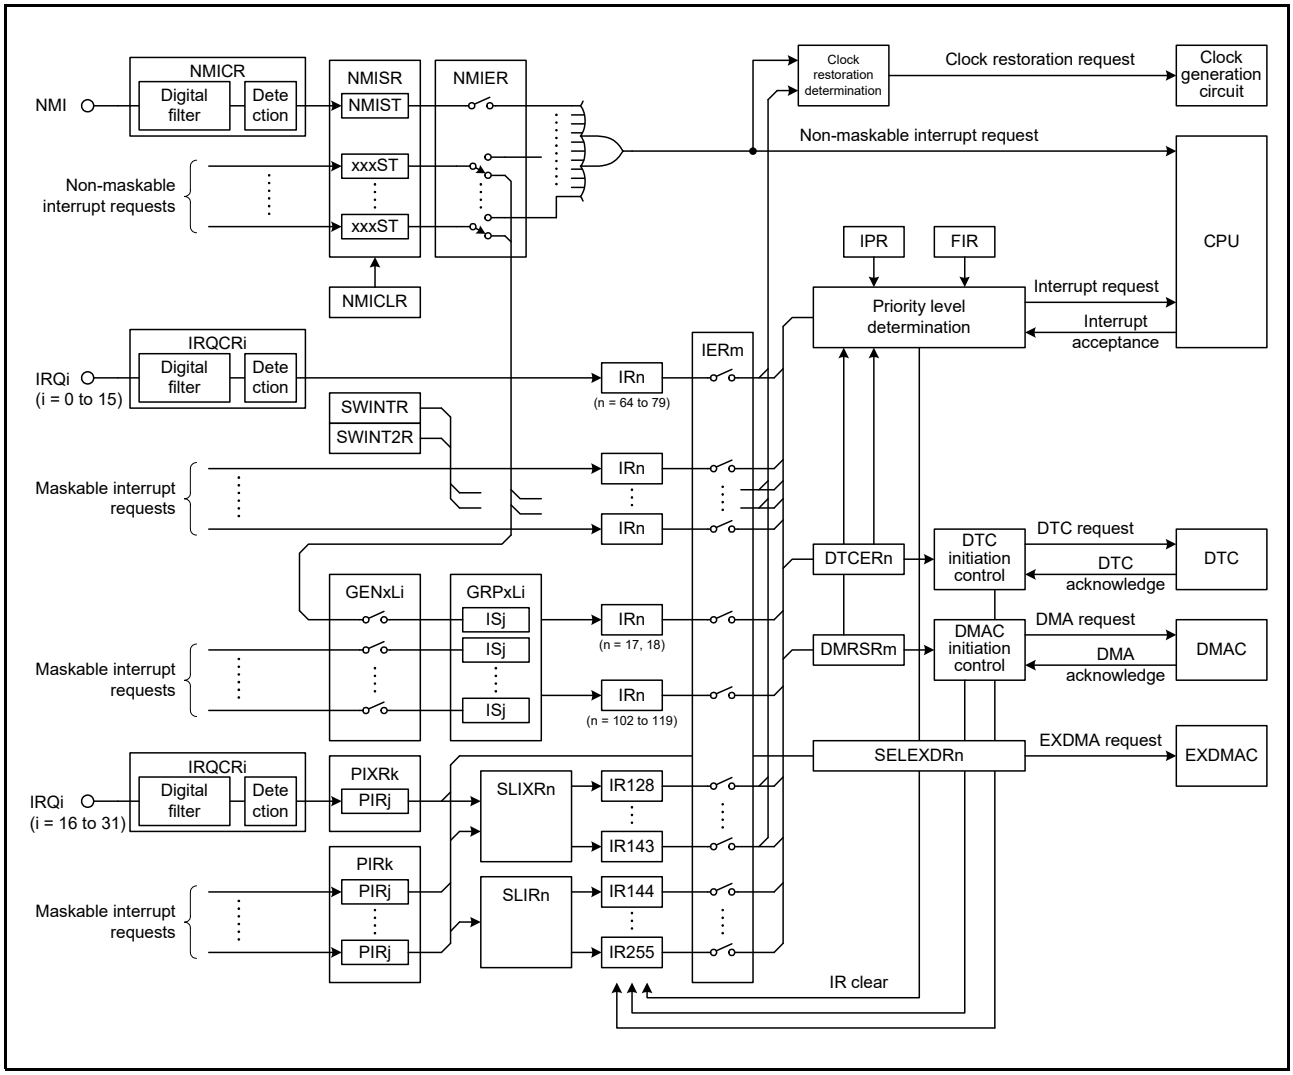

Figure 15.1 Block Diagram of the ICU

Table 15.2 lists I/O pins used for the ICU.

Table 15.2 ICU I/O Pins

Pin Name	I/O	Description
NMI	Input	Non-maskable interrupt request pin
IRQ0 to IRQ31	Input	External interrupt request pins

15.2 Register Descriptions

15.2.1 Interrupt Request Register n (IRn) (n = 16 to 255)

Address(es): ICU.IR16 8700 6010h to ICU.IR255 8700 60FFh, ICU_NS.IR16 0700 6010h to ICU_NS.IR255 0700 60FFh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	IR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IR	Interrupt Status Flag	0: No interrupt request is generated. 1: An interrupt request is generated.	R/(W) *1
b7 to b1	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. For an edge detection interrupt source, only 0 can be written to this bit; do not write 1.
For a level detection interrupt source, neither 0 nor 1 can be written.

The IRn register indicates whether an interrupt request has been generated.

This register is provided for each interrupt vector number, and n matches the interrupt vector number.

For the correspondence between interrupt sources and interrupt vector numbers, refer to Table 15.6, Interrupt Vector Table.

IR Flag (Interrupt Status Flag)

The IR flag is a status flag indicating whether an interrupt request has been generated. This flag becomes 1 when an interrupt request is generated. To detect an interrupt request, set the interrupt enable bit of the peripheral module to enable output of the interrupt request.

An interrupt request can be detected by edge detection or level detection. For interrupts from peripheral modules, the detection method (edge detection or level detection) is determined depending on the source. Refer to Table 15.6, Interrupt Vector Table for details on the detection method for each source. For interrupts from the IRQi pin (i = 0 to 31), edge detection or level detection can be selected by setting the IRQCRi.IRQMD[1:0] bits.

The interrupt status flag for group interrupts is the ISj flag (j = 0 to 31) in the group interrupt request register (GRPIL0, GRPIL1, GRPBL0, GRPBL1, and GRPAL0 to GRPAL6). When any of the ISj flags becomes 1, the IRn.IR flag corresponding to each group interrupt becomes 1. Group interrupts are detected by level detection.

Refer to section 15.4.4, Group Interrupts for details on group interrupts.

(1) Edge detection

This flag becomes 1 under the following condition:

- The IR flag becomes 1 when an interrupt request for peripheral interrupts or external pin interrupts is generated. For interrupt requests for peripheral modules, refer to the corresponding sections.

This flag becomes 0 under any of the following conditions:

- The IR flag becomes 0 when the interrupt request destination accepts an interrupt request.
- The IR flag becomes 0 by writing 0 to the IR flag. Note that when the interrupt request destination is the DTC or DMAC, do not write 0 to the IR flag.

(2) Level detection

This flag becomes 1 under any of the following conditions:

- The IR flag is 1 while an interrupt request for peripheral interrupts or external pin interrupts is generated. For interrupt requests for peripheral modules, refer to the corresponding sections.
- For group interrupts, the IR flag becomes 1 when the ISj flag in the group interrupt request register (GRPIL0, GRPIL1, GRPBL0, GRPBL1, and GRPAL0 to GRPAL6) is 1 (interrupt request is generated) while the ENj bit in the group interrupt request enable register (GENIL0, GENIL1, GENBL0, GENBL1, and GENAL0 to GENAL6) is 1 (enabled) (j = 0 to 31).

This flag becomes 0 under any of the following conditions:

- The IR flag becomes 0 by clearing output of the peripheral module interrupt request. The IR flag does not become 0 when the interrupt request destination accepts the interrupt request. For interrupt requests for peripheral modules, refer to the corresponding sections.
- For group interrupts, the IR flag becomes 0 when the ENj bit in the group interrupt request enable register is 0 (disabled) or when the ISj flag in the group interrupt request register is 0 (interrupt request is not generated).

When level detection is selected for detecting external pin interrupts, set the input level of the IRQi pin to high (i = 0 to 31) to cancel the external pin interrupt that has occurred. When level detection is selected, do not write to the IR flag.

15.2.2 Interrupt Request Enable Register m (IERm) (m = 2 to 31)

Address(es): ICU.IER2 8700 6202h to ICU.IER31 8700 621Fh, ICU_NS.IER2 0700 6202h to ICU_NS.IER31 0700 621Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	IEN7	IEN6	IEN5	IEN4	IEN3	IEN2	IEN1	IEN0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IEN0	Interrupt Request Enable 0	0: Interrupt request is disabled. 1: Interrupt request is enabled.	R/W
b1	IEN1	Interrupt Request Enable 1		R/W
b2	IEN2	Interrupt Request Enable 2		R/W
b3	IEN3	Interrupt Request Enable 3		R/W
b4	IEN4	Interrupt Request Enable 4		R/W
b5	IEN5	Interrupt Request Enable 5		R/W
b6	IEN6	Interrupt Request Enable 6		R/W
b7	IEN7	Interrupt Request Enable 7		R/W

Note: The security attributes for this register can be set for each bit.
When a bit is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When a bit is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note: When the interrupt source of the interrupt vector number is reserved, set the corresponding bit to 0. The read value is 0.

The IERm register enables or disables output of the interrupt request to the interrupt request destination.

IENj Bit (Interrupt Request Enable j) (j = 0 to 7)

When the IENj bit is 1, an interrupt request is output to the destination. When the IENj bit is 0, an interrupt request is not output to the destination.

The IRn.IR flag (n = 16 to 255) is not affected by the IENj bit setting. Even when the IENj bit is 0, the IR flag changes according to the conditions described in section 15.2.1, Interrupt Request Register n (IRn) (n = 16 to 255).

The IERm.IENj bit is provided for each interrupt vector number.

Refer to Table 15.6, Interrupt Vector Table for the correspondence between interrupt sources and the IERm.IENj bit.

Note that m and j can be calculated by the following formula:

m = quotient when n divided by 8

j = remainder when n divided by 8

Refer to section 15.7.3.1, Interrupt Request Destination Setting Procedure for the procedure to set the IERm.IENj bit to select the interrupt request destination.

15.2.3 Interrupt Source Priority Register r (IPRr) (r = 0 to 255)

Address(es): ICU.IPR0 8700 6300h to ICU.IPR255 8700 63FFh, ICU_NS.IPR0 0700 6300h to ICU_NS.IPR255 0700 63FFh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	IPR[4:0]				
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	IPR[4:0]	Interrupt Priority Level Select	b4 b0 0 0 0 0 0: Level 0 (interrupt disabled)*1 0 0 0 0 1: Level 1 0 0 0 1 0: Level 2 0 0 0 1 1: Level 3 : : 0 1 1 0 1: Level 13 0 1 1 1 0: Level 14 0 1 1 1 1: Level 15 (highest level in Non-secure)*2 1 0 0 0 0: Level 16 1 0 0 0 1: Level 17 1 0 0 1 0: Level 18 : : 1 1 1 0 0: Level 28 1 1 1 0 1: Level 29 1 1 1 1 0: Level 30 1 1 1 1 1: Level 31 (highest level)	R/W
b7 to b5	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. For an interrupt source of a fast interrupt, even when the IPR[4:0] bits are set to level 0, the priority level is level 31.
Note 2. The interrupt sources from the non-secure world should be set in the range of level 0 to level 15.

The IPRr register sets the interrupt priority level of an interrupt source that is assigned to the corresponding interrupt vector number.

IPR[4:0] Bits (Interrupt Priority Level Select)

The IPR[4:0] bits select the interrupt priority level of the corresponding interrupt source.
The priority level selected by the IPR[4:0] bits is used for only determining the priority level of interrupt requests to the CPU. It does not affect transfer requests to the DTC and DMAC.
The CPU accepts only interrupt requests that have the higher priority level than the processor interrupt priority level indicated by the PSW.IPL[4:0] bits.
When multiple interrupt requests are concurrently generated, the priority levels selected by the corresponding IPR[4:0] bits are compared. When multiple interrupt requests that have the same priority level are concurrently generated, the interrupt request that has the smallest interrupt vector number has priority.
Write to this register while the corresponding IERm.IENj bit is 0 (interrupt request is disabled) (m = 2 to 31; j = 0 to 7).
Refer to Table 15.6, Interrupt Vector Table for the correspondence between interrupt vectors and the IPRr register.
Note that r matches the vector number when the interrupt vector number is 32 or greater.

15.2.4 Fast Interrupt Set Register (FIR)

Address(es): ICU.FIR 8700 62F0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FIEN	—	—	—	—	—	—	—	FVCT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	FVCT[7:0]	Fast Interrupt Vector Number	Set the vector number of an interrupt source that is assigned to a fast interrupt.	R/W
b14 to b8	—	Reserved	The read value is 0. The write value should be 0.	R/W
b15	FIEN	Fast Interrupt Enable*1	0: Fast interrupt is disabled 1: Fast interrupt is enabled	R/W

Note 1. When the PRTZCR.PRTZC bit is 1, the fast interrupt cannot be used. Do not set this bit to 1 when the PRTZCR.PRTZC bit is set to 1.

The FIR register sets an interrupt source that is handled as the fast interrupt.
The fast interrupt is enabled only when the destination is the CPU. When the destination is the DTC or DMAC, the DTC or DMA transfer request is not affected by setting the interrupt vector number as the fast interrupt.
Write to this register while the corresponding IERm.IENj bit is 0 (m = 2 to 31; j = 0 to 7).
Refer to section 15.9, Fast interrupt for details on the fast interrupt.

FVCT[7:0] Bits (Fast Interrupt Vector Number)

The FVCT[7:0] bits set the interrupt vector number of an interrupt source for the fast interrupt.
Refer to Table 15.6, Interrupt Vector Table for interrupt vector numbers that can be set in the FVCT[7:0] bits. Do not set an interrupt vector number that is reserved.

FIEN Bit (Fast Interrupt Enable)

The FIEN bit enables the fast interrupt to be used.
When the FIEN bit is 1, the interrupt source that is assigned to the interrupt vector number set by the FVCT[7:0] bits is handled as the fast interrupt.
When an interrupt request of the interrupt vector number set by the FVCT[7:0] bits is generated to the CPU while the FIEN bit is 1, an interrupt request is output to the CPU as the fast interrupt regardless of the IPRr register setting (r = 000 to 255). Note that the IPRr register setting is required when using the fast interrupt to exit software standby mode. Refer to section 15.10.2, Exiting Software Standby Mode for details.

15.2.5 Software Interrupt Generation Register (SWINTR)

Address(es): ICU.SWINTR 8700 62E0h, ICU_NS.SWINTR 0700 62E0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SWINT
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SWINT	Software Interrupt Generation	The read value is 0. When writing 1 to this bit, a software interrupt request is generated. Writing 0 to this bit has no effect.	R/W
b7 to b1	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The SWINTR register controls generation of a software interrupt request.

SWINT Bit (Software Interrupt Generation)

When the SWINT bit is set to 1, a software interrupt request (SWINT) is generated, and the IR27.IR flag becomes 1. A software interrupt request (SWINT) can be set as a DTC trigger, but it cannot be set as a DMAC trigger.

15.2.6 Software Interrupt 2 Generation Register (SWINT2R)

Address(es): ICU.SWINT2R 8700 62E1h, ICU_NS.SWINT2R 0700 62E1h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SWINT2
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SWINT2	Software Interrupt 2 Generation	The read value is 0. When writing 1 to this bit, a software interrupt request 2 is generated. Writing 0 to this bit has no effect.	R/W
b7 to b1	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The SWINT2R register controls generation of software interrupt request 2.

SWINT2 Bit (Software Interrupt 2 Generation)

When the SWINT2 bit is set to 1, software interrupt request 2 (SWINT2) is generated, and the IR26.IR flag becomes 1. Software interrupt request 2 (SWINT2) can be set as the DTC trigger, but it cannot be set as the DMAC trigger.

15.2.7 DTC Transfer Request Enable Register n (DTCERn) (n = 26 to 255)

Address(es): ICU.DTCER26 8700 611Ah to ICU.DTCER255 8700 61FFh, ICU_NS.DTCER26 0700 611Ah to ICU_NS.DTCER255 0700 61FFh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	DTCE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DTCE	DTC Transfer Request Enable	0: The corresponding interrupt source is selected as an interrupt request to the CPU or as the DMAC trigger. 1: The corresponding interrupt source is selected as the DTC trigger.	R/W
b7 to b1	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The DTCERn register selects the interrupt source corresponding to interrupt vector number n as the DTC trigger.
Do not set the same interrupt source for both the DTC trigger and DMAC trigger. Refer to Table 15.6, Interrupt Vector Table for the correspondence between interrupt sources and interrupt vector numbers and interrupt sources that can be used as the DTC trigger.

DTCE Bit (DTC Transfer Request Enable)

When the DTCE bit is set to 1, the corresponding interrupt source is selected as the DTC trigger.
This bit becomes 1 under the following condition:

- 1 is written to the DTCE bit

This bit becomes 0 under any of the following conditions:

- The specified number of transfers is completed (for the chain transfer, the number of transfers for the last chain transfer is completed)
- 0 is written to the DTCE bit

15.2.8 DMAC Trigger Select Register m (DMRSRm) (m = 0 to 7)

Address(es): ICU.DMRSR0 8700 6400h, ICU.DMRSR1 8700 6404h, ICU.DMRSR2 8700 6408h, ICU.DMRSR3 8700 640Ch, ICU.DMRSR4 8700 6410h, ICU.DMRSR5 8700 6414h, ICU.DMRSR6 8700 6418h, ICU.DMRSR7 8700 641Ch, ICU_NS.DMRSR0 0700 6400h, ICU_NS.DMRSR1 0700 6404h, ICU_NS.DMRSR2 0700 6408h, ICU_NS.DMRSR3 0700 640Ch, ICU_NS.DMRSR4 0700 6410h, ICU_NS.DMRSR5 0700 6414h, ICU_NS.DMRSR6 0700 6418h, ICU_NS.DMRSR7 0700 641Ch

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	—	These bits set the interrupt vector number of the interrupt source as the DMAC trigger.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, the behavior changes depending on the trusted event route setting.
When the trusted event route is disabled, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
When the trusted event route is enabled, it can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The DMRSRm register sets an interrupt source as the DMACm trigger.

Do not set the same vector number for multiple DMRSRm registers. Do not set the same interrupt source for both the DTC trigger and DMAC trigger. Otherwise, the operation is not guaranteed.

Set the interrupt vector number of an interrupt source used as the DMAC trigger in the DMRSRm register. Do not set vector numbers of interrupt sources that cannot be used as the DMAC trigger.

Refer to Table 15.6, Interrupt Vector Table for interrupt vector numbers of interrupt sources.

Write the DMRSRm register while the DMACm.DMCNT.DTE bit is 0.

15.2.9 IRQi Pin Interrupt Control Register (IRQCRi) (i = 0 to 31)

Address(es): ICU.IRQCR0 8700 6C20h to ICU.IRQCR31 8700 6C3Fh, ICU_NS.IRQCR0 0700 6C20h to ICU_NS.IRQCR31 0700 6C3Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	FLTEN	FCLKSEL[2:0]			—	FLTMD	IRQMD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	IRQMD[1:0]	IRQ Detection Select	b1 b0 0 0: Falling edge 0 1: Rising edge 1 0: Rising and falling edges 1 1: Low level	R/W
b2	FLTMD	IRQ Digital Noise Filter Operation Mode Select	0: Detects 3 consecutive levels match 1: Detects 4 consecutive levels match	R/W
b3	—	Reserved	The read value is 0. The write value should be 0.	R/W
b6 to b4	FCLKSEL[2:0]	IRQ Digital Noise Filter Sampling Clock Select	b6 b4 0 0 0: PCLKB 0 0 1: PCLKB/8 0 1 0: PCLKB/32 0 1 1: PCLKB/64 1 0 0: PCLKB/128 1 0 1: PCLKB/4 1 1 0: PCLKB/16 1 1 1: Setting prohibited	R/W
b7	FLTEN	IRQ Digital Noise Filter Enable	0: Digital noise filter is disabled. 1: Digital noise filter is enabled.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The IRQCRi register selects the detection method and the digital noise filter operation for external pin interrupts.
Write to this register while the corresponding IERm.IENj bit is 0 (m = 2 to 31; j = 0 to 7). After writing to this register, set the IRn.IR flag to 0, and then set the IENj bit to 1 (n = 16 to 255). Note that setting the IR flag to 0 is not required when changing the detection method to level detection.

IRQMD[1:0] Bits (IRQ Detection Select)

The IRQMD[1:0] bits set the detection method for the IRQi pin interrupt (i = 0 to 31).
Refer to section 15.7.4, Setting the External Pin Interrupt for the procedure to set the external pin interrupts.

FLTEN Bit (IRQ Digital Noise Filter Enable)

This bit is used to enable the digital noise filter for the IRQi pin.
When this bit is 1, the signal input to the IRQi pin is sampled with the clock set by the FCLKSEL[2:0] bits. When the sampled signal level does not match for the number of consecutive times specified by the FLTMD bit, the input signal is removed.
Refer to section 15.7.6, Digital Noise Filter for details on the digital noise filter.

15.2.10 Non-Maskable Interrupt Status Register (NMISR)

Address(es): ICU.NMISR 8700 6580h, ICU_NS.NMISR 0700 6580h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The NMISR register indicates whether a non-maskable interrupt request has occurred.

Each flag in the NMISR register is not affected by the setting of the corresponding bit in the NMIER register.

In the non-maskable interrupt handler, read the NMISR register to check if the other non-maskable interrupt has

occurred. Confirm that all the status flags are 0 before exiting the interrupt handler.

IWDTST Flag (IWDT Underflow/Refresh Error Status Flag)

The IWDTST flag indicates whether an IWDT underflow/refresh error interrupt request is generated.

This flag becomes 1 under the following condition:

- An IWDT underflow/refresh error interrupt occurs while the IWDTRCR.RSTIRQS bit is 0.

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.IWDTCLR bit.

WDTST Flag (WDT Underflow/Refresh Error Status Flag)

The WDTST flag indicates whether an WDT underflow/refresh error interrupt request is generated.

This flag becomes 1 under the following condition:

- A WDT underflow/refresh error interrupt occurs while the WDTRCR.RSTIRQS bit is 0.

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.WDTCLR bit.

PVD1ST Flag (Voltage Monitoring 1 Interrupt Status Flag)

The PVD1ST flag indicates whether a voltage monitoring 1 interrupt request is generated.

This flag becomes 1 under the following condition:

- A voltage monitoring 1 interrupt occurs while the PVD1CR1.IRQSEL bit is 0.

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.PVD1CLR bit.

PVD2ST Flag (Voltage Monitoring 2 Interrupt Status Flag)

The PVD2ST flag indicates whether a voltage monitoring 2 interrupt request is generated.

This flag becomes 1 under the following condition:

- A voltage monitoring 2 interrupt occurs while the PVD2CR1.IRQSEL bit is 0.

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.PVD2CLR bit.

SOSTST Flag (Sub-Clock Oscillation Stop Detection Interrupt Status Flag)

The SOSTST flag indicates whether an oscillation stop detection interrupt request has been generated in the sub-clock oscillator.

This flag becomes 1 under the following condition:

- An oscillation stop detection interrupt occurs in the sub-clock oscillator.

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.SOSTCLR bit

OSTST Flag (Main Clock Oscillation Stop Detection Interrupt Status Flag)

The OSTST flag indicates whether an oscillation stop detection interrupt request has been generated in the main clock oscillator.

This flag becomes 1 under the following condition:

- An oscillation stop detection interrupt occurs in the main clock oscillator.

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.OSTCLR bit

NMIST Flag (NMI Pin Interrupt Status Flag)

The NMIST flag indicates whether an NMI pin interrupt request has been generated.

This flag becomes 1 under the following condition:

- An edge set in the NMICR.NMIMD bit is input to the NMI pin.

This flag becomes 0 under the following condition:

- 1 is written to the NMICLR.NMICLR bit.

BUSST Flag (Bus Error Interrupt Status Flag)

The BUSST flag indicates whether an bus error interrupt request is generated.

This flag becomes 1 under the following condition:

- A bus error interrupt occurs.

This flag becomes 0 under the following condition:

- When all sources which set the BUSST flag to 1 are cleared.

CMST Flag (Common Memory Error Interrupt Status Flag)

The CMST flag indicates whether a common memory error interrupt request is generated.

This flag becomes 1 under the following condition:

- An ECC error occurs in the common memory.

This flag becomes 0 under the following condition:

- When all sources which set the CMST flag to 1 are cleared.

LMST Flag (Local Memory Error Interrupt Status Flag)

The LMST flag indicates whether a local memory error interrupt request is generated.

This flag becomes 1 under the following condition:

- An ECC error occurs in the local memory.

This flag becomes 0 under the following condition:

- When all sources which set the LMST flag to 1 are cleared.

DPFPUST Flag (Double-Precision Floating-Point Exception Status Flag)

The DPFPUST flag indicates whether an double-precision floating-point exception is generated by double-precision floating-point coprocessor.

This flag becomes 1 under the following condition:

- A double-precision floating-point exception occurs.

This flag becomes 0 under the following condition:

- When all sources which set the DPFPUST flag to 1 are cleared.

MRCRDST Flag (Code MRAM Read Access Error Interrupt Status Flag)

The MRCRDST flag indicates whether a read access error interrupt has occurred in the code area of the MRAM.

This flag becomes 1 under the following condition:

- An ECC error has occurred in the code area of the MRAM.

This flag becomes 0 under the following condition:

- When all sources which set the MRCRDST flag to 1 are cleared.

MRERDST Flag (Extra MRAM Read Access Error Interrupt Status Flag)

The MRERDST flag indicates whether a read access error interrupt has occurred in the extra area of the MRAM.

This flag becomes 1 under the following condition:

- An ECC error has occurred in the extra area of the MRAM.

This flag becomes 0 under the following condition:

- When all sources which set the MRERDST flag to 1 are cleared.

15.2.11 Non-Maskable Interrupt Enable Register (NMIER)

Address(es): ICU.NMIER 8700 6584h, ICU_NS.NMIER 0700 6584h

b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. When this interrupt is to be used as a maskable interrupt, leave this bit set to 0.

Note 2. Once this bit is set to 1, it cannot be set to 0 by software.

The NMIER register enables and disables generation of non-maskable interrupt requests. When each bit is 1, the corresponding interrupt source is used as a non-maskable interrupt.

IWDTEN Bit (IWDT Underflow/Refresh Error Enable)

The IWDTEN bit enables and disables generation of a non-maskable interrupt by the IWDT underflow/refresh error interrupt.

WDTEN Bit (WDT Underflow/Refresh Error Enable)

The WDTEN bit enables and disables generation of a non-maskable interrupt by the WDT underflow/refresh error interrupt.

PVD1EN Bit (Voltage Monitoring 1 Interrupt Enable)

The PVD1EN bit enables and disables generation of a non-maskable interrupt by the voltage monitoring 1 interrupt.

PVD2EN Bit (Voltage Monitoring 2 Interrupt Enable)

The PVD2EN bit enables and disables generation of a non-maskable interrupt by the voltage monitoring 2 interrupt.

SOSTEN Bit (Sub-Clock Oscillation Stop Detection Interrupt Enable)

The SOSTEN bit enables and disables generation of a non-maskable interrupt by the oscillation stop detection interrupt of the sub-clock oscillator.

OSTEN Bit (Main Clock Oscillation Stop Detection Interrupt Enable)

The OSTEN bit enables and disables generation of a non-maskable interrupt by the oscillation stop detection interrupt of the main clock oscillator.

NMIEN Bit (NMI Pin Interrupt Enable)

The NMIEN bit enables and disables using the NMI pin interrupt.

BUSEN Bit (Bus Error Interrupt Enable)

The BUSEN bit enables and disables generation of a non-maskable interrupt by the bus error interrupt.

CMEN Bit (Common Memory Error Interrupt Enable)

The CMEN bit enables and disables generation of a non-maskable interrupt by the common memory error interrupt.

LMEN Bit (Local Memory Error Interrupt Enable)

The LMEN bit enables and disables generation of a non-maskable interrupt by the local memory error interrupt.

DPFPUEN Bit (Double-Precision Floating-Point Exception Enable)

The DPFPUEN bit enables and disables generation of a non-maskable interrupt by the double-precision floating-point exception from double-precision floating-point coprocessor.

MRCRDEN Bit (Code MRAM Read Access Error Interrupt Enable)

The MRCRDEN bit enables and disables generation of a non-maskable interrupt by the read access error interrupt of code MRAM.

MRERDEN Bit (Local MRAM Read Access Error Interrupt Enable)

The MRERDEN bit enables and disables generation of a non-maskable interrupt by the read access error interrupt of extra MRAM.

15.2.12 Non-Maskable Interrupt Status Clear Register (NMICLR)

Address(es): ICU.NMICLR 8700 6588h, ICU_NS.NMICLR 0700 6588h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IWDTCLR	IWDT Clear	The read value is 0. When 1 is written to this bit, the NMISR.IWDTST flag becomes 0. Writing 0 to this bit has no effect.	R/(W)
b1	WDTCLR	WDT Clear	The read value is 0. When 1 is written to this bit, the NMISR.WDTST flag becomes 0. Writing 0 to this bit has no effect.	R/(W)
b2	PVD1CLR	PVD1 Clear	The read value is 0. When 1 is written to this bit, the NMISR.PVD1ST flag becomes 0. Writing 0 to this bit has no effect.	R/(W)
b3	PVD2CLR	PVD2 Clear	The read value is 0. When 1 is written to this bit, the NMISR.PVD2ST flag becomes 0. Writing 0 to this bit has no effect.	R/(W)
b4	—	Reserved	The read value is 0. The write value should be 0.	R/W
b5	SOSTCLR	SOST Clear	The read value is 0. When 1 is written to this bit, the NMISR.SOSTST flag becomes 0. Writing 0 to this bit has no effect.	R/(W)
b6	OSTCLR	OST Clear	The read value is 0. When 1 is written to this bit, the NMISR.OSTST flag becomes 0. Writing 0 to this bit has no effect.	R/(W)
b7	NMICLR	NMI Clear	The read value is 0. When 1 is written to this bit, the NMISR.NMIST flag becomes 0. Writing 0 to this bit has no effect.	R/(W)
b31 to b8	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The NMICLR register clears each flag in the NMISR register.

When writing 1 to a bit in this register, the corresponding status flag becomes 0.

15.2.13 NMI Pin Interrupt Control Register (NMICR)

Address(es): ICU.NMICR 8700 6C0Ch, ICU_NS.NMICR 0700 6C0Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	NFLTEN	NFCLKSEL[2:0]			—	NFLTMD	—	NMIMD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	NMIMD	NMI Detection Select	0: Falling edge 1: Rising edge	R/W
b1	—	Reserved	The read value is 0. The write value should be 0.	R/W
b2	NFLTMD	NMI Digital Noise Filter Operation Mode Select	0: Detects 3 consecutive levels match 1: Detects 4 consecutive levels match	R/W
b3	—	Reserved	The read value is 0. The write value should be 0.	R/W
b6 to b4	NFCLKSEL[2:0]	NMI Digital Noise Filter Sampling Clock	b6 b4 0 0 0: PCLKB 0 0 1: PCLKB/8 0 1 0: PCLKB/32 0 1 1: PCLKB/64 1 0 0: PCLKB/128 1 0 1: PCLKB/4 1 1 0: PCLKB/16 1 1 1: Setting prohibited	R/W
b7	NFLTEN	NMI Digital Noise Filter Enable	0: Digital noise filter is disabled. 1: Digital noise filter is enabled.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The NMICR register selects a detection method for the NMI pin interrupt.
Write to the NMICR register while the NMIER.NMIEN bit is 0.

NMIMD Bit (NMI Detection Select)

This bit sets the detection method for the NMI pin interrupt.

NFLTEN Bit (NMI Digital Noise Filter Enable)

This bit is used to enable the digital noise filter for the NMI pin.
When this bit is 1, the signal input to the NMI pin is sampled with the clock set by the NFCLKSEL[2:0] bits. When the sampled signal level does not match for the number of consecutive times specified by the NFLTMD bit, the input signal is removed.
Refer to section 15.7.6, Digital Noise Filter for details on the digital noise filter.

15.2.14 Group ILi Non-Secure Interrupt Request Register (GRPILi_NS) (i = 0, 1), Group BLi Non-Secure Interrupt Request Register (GRPBLi_NS) (i = 0, 1), Group ALi Non-Secure Interrupt Request Register (GRPALi_NS) (i = 0 to 6)

Address(es): ICU_NS.GRPIL0_NS 0700 6540h, ICU_NS.GRPIL1_NS 0700 6544h, ICU_NS.GRPBL0_NS 0700 6600h, ICU_NS.GRPBL1_NS 0700 6604h, ICU_NS.GRPAL0_NS 0700 6700h, ICU_NS.GRPAL1_NS 0700 6704h, ICU_NS.GRPAL2_NS 0700 6708h, ICU_NS.GRPAL3_NS 0700 670Ch, ICU_NS.GRPAL4_NS 0700 6710h, ICU_NS.GRPAL5_NS 0700 6714h, ICU_NS.GRPAL6_NS 0700 6718h

b31	IS31	Interrupt Status Flag 31		R

Note: This register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access

error is generated.

These registers indicate the status of each interrupt request from peripherals allocated to the non-secure world among the group interrupt sources.
The GRPILi_NS register (i = 0, 1) contains the statuses of interrupt sources that are detected by level detection and use ICLK as the operating clock.
The GRPBLi_NS register (i = 0, 1) contains the statuses of interrupt sources that are detected by level detection and use PCLKB as the operating clock.
The GRPALi_NS register (i = 0 to 6) contains the statuses of interrupt sources that are detected by level detection and use PCLKA as the operating clock.
These registers are collectively referred to as the “group interrupt request register”.
Refer to section 15.4.4, Group Interrupts for details on group interrupts.

ISj Flag (Interrupt Status Flag j) (j = 0 to 31)

The ISj flag indicates the status of interrupt sources from peripherals allocated to the non-secure world among the interrupt sources assigned to group interrupts.
The ISj flag becomes 1 only when the corresponding ENj bit in the group interrupt request enable register (GENIL0_NS, GENIL1_NS, GENBL0_NS, GENBL1_NS, and GENAL0_NS to GENAL6_NS) is 1 and the attribute of corresponding interrupt is non-secure. When any of the ISj flags becomes 1, the IRn.IR flag corresponding to the group interrupt becomes 1 (n = 16 to 255).
This flag becomes 1 under the following condition:

- This flag becomes 1 while the corresponding peripheral module interrupt request is generated when the corresponding ENj bit in the group interrupt request enable register is 1.

This flag becomes 0 under any of the following conditions:

- This flag becomes 0 when the corresponding peripheral module interrupt request is cleared.
- This flag becomes 0 when the corresponding ENj bit in the group interrupt request enable register is set to 0.

15.2.15 Group ILi Secure Interrupt Request Register (GRPILi_S) (i = 0, 1), Group BLi Secure Interrupt Request Register (GRPBLi_S) (i = 0, 1), Group ALi Secure Interrupt Request Register (GRPALi_S) (i = 0 to 6)

Address(es): ICU.GRPIL0_S 8700 6550h, ICU.GRPIL1_S 8700 6554h, ICU.GRPBL0_S 8700 6640h, ICU.GRPBL1_S 8700 6644h, ICU.GRPAL0_S 8700 6740h, ICU.GRPAL1_S 8700 6744h, ICU.GRPAL2_S 8700 6748h, ICU.GRPAL3_S 8700 674Ch, ICU.GRPAL4_S 8700 6750h, ICU.GRPAL5_S 8700 6754h, ICU.GRPAL6_S 8700 6758h

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access

error is generated.

These registers indicate the status of each interrupt request from peripherals allocated to the secure world among the group interrupt sources.
The GRPILi_S register (i = 0, 1) contains the statuses of interrupt sources that are detected by level detection and use ICLK as the operating clock.
The GRPBLi_S register (i = 0, 1) contains the statuses of interrupt sources that are detected by level detection and use PCLKB as the operating clock.
The GRPALi_S register (i = 0 to 6) contains the statuses of interrupt sources that are detected by level detection and use PCLKA as the operating clock.
These registers are collectively referred to as the “group interrupt request register”.
Refer to section 15.4.4, Group Interrupts for details on group interrupts.

ISj Flag (Interrupt Status Flag j) (j = 0 to 31)

The ISj flag indicates the status of interrupt sources from peripherals allocated to the secure world among the interrupt sources assigned to group interrupts.
The ISj flag becomes 1 only when the corresponding ENj bit in the group interrupt request enable register (GENIL0_S, GENIL1_S, GENBL0_S, GENBL1_S, and GENAL0_S to GENAL6_S) is 1 and the attribute of corresponding interrupt is secure. When any of the ISj flags becomes 1, the IRn.IR flag corresponding to the group interrupt becomes 1 (n = 16 to 255).
This flag becomes 1 under the following condition:

- This flag becomes 1 while the corresponding peripheral module interrupt request is generated when the corresponding ENj bit in the group interrupt request enable register is 1.

This flag becomes 0 under any of the following conditions:

- This flag becomes 0 when the corresponding peripheral module interrupt request is cleared.
- This flag becomes 0 when the corresponding ENj bit in the group interrupt request enable register is set to 0.

15.2.16 Group ILi Non-Secure Interrupt Request Enable Register (GENILi_NS) (i = 0, 1), Group BLi Non-Secure Interrupt Request Enable Register (GENBLi_NS) (i = 0, 1), Group ALi Non-Secure Interrupt Request Enable Register (GENALi_NS) (i = 0 to 6)

b31	EN31	Interrupt Request Enable 31		R/W

Note: This register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: When a bit has no corresponding interrupt source (bit is reserved), set the bit to 0.

These registers select whether the ISj flag in the group interrupt request register is set to 1 when each interrupt request for group interrupt sources is generated from a peripheral allocated to the non-secure world. These registers are collectively referred to as the “group interrupt request enable register”.
Registers GENIL0_NS, GENIL1_NS, GENBL0_NS, GENBL1_NS, and GENAL0_NS to GENAL6_NS control the ISj flag in registers GRPIL0_NS, GRPIL1_NS, GRPBL0_NS, GRPBL1_NS, and GRPAL0_NS to GRPAL6_NS, respectively.
Refer to section 15.4.4, Group Interrupts for details on group interrupts.

ENj Bits (Interrupt Request Enable j) (j = 0 to 31)

The ENj bits select whether the corresponding ISj flag in the group interrupt request register is set to 1 when an interrupt request assigned to group interrupts is generated.
When a peripheral module interrupt request is generated while the ENj bit is 1, the corresponding ISj flag in the group interrupt request register (GRPIL0_NS, GRPIL1_NS, GRPBL0_NS, GRPBL1_NS, and GRPAL0_NS to GRPAL6_NS) becomes 1. When the ENj bit is 0, the ISj flag does not become 1.
The setting of this bit is invalid for interrupt sources from peripherals allocated to the secure world.
When the ENj bit is set to 0, the ISj flag becomes 0.

15.2.17 Group ILi Secure Interrupt Request Enable Register (GENILi_S) (i = 0, 1), Group BLi Secure Interrupt Request Enable Register (GENBLi_S) (i = 0, 1), Group ALi Secure Interrupt Request Enable Register (GENALi_S) (i = 0 to 6)

Address(es): ICU.GENIL0_S 8700 6570h, ICU.GENIL1_S 8700 6574h, ICU.GENBL0_S 8700 66C0h, ICU.GENBL1_S 8700 66C4h, ICU.GENAL0_S 8700 67C0h, ICU.GENAL1_S 8700 67C4h, ICU.GENAL2_S 8700 67C8h, ICU.GENAL3_S 8700 67CCh, ICU.GENAL4_S 8700 67D0h, ICU.GENAL5_S 8700 67D4h, ICU.GENAL6_S 8700 67D8h

b31	EN31	Interrupt Request Enable 31		R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

Note: When a bit has no corresponding interrupt source (bit is reserved), set the bit to 0.

These registers select whether the ISj flag in the group interrupt request register is set to 1 when each interrupt request for group interrupt sources is generated from a peripheral allocated to the secure world. These registers are collectively referred to as the “group interrupt request enable register”.
Registers GENIL0_S, GENIL1_S, GENBL0_S, GENBL1_S, and GENAL0_S to GENAL6_S control the ISj flag in registers GRPIL0_S, GRPIL1_S, GRPBL0_S, GRPBL1_S, and GRPAL0_S to GRPAL6_S, respectively.
Refer to section 15.4.4, Group Interrupts for details on group interrupts.

ENj Bits (Interrupt Request Enable j) (j = 0 to 31)

The ENj bits select whether the corresponding ISj flag in the group interrupt request register is set to 1 when an interrupt request assigned to group interrupts is generated.
When a peripheral module interrupt request is generated while the ENj bit is 1, the corresponding ISj flag in the group interrupt request register (GRPIL0_S, GRPIL1_S, GRPBL0_S, GRPBL1_S, and GRPAL0_S to GRPAL6_S) becomes 1.
When the ENj bit is 0, the ISj flag does not become 1.
The setting of this bit is invalid for interrupt sources from peripherals allocated to the non-secure world.
When the ENj bit is set to 0, the ISj flag becomes 0.

15.2.18 Software Configurable Interrupt Request Register Xk (PIXRk) (k = 0, 1)

Address(es): ICU.PIXR0 8700 6520h, ICU.PIXR1 8700 6521h, ICU_NS.PIXR0 0700 6520h, ICU_NS.PIXR1 0700 6521h

	b7	b6	b5	b4	b3	b2	b1	b0
	PIR7	PIR6	PIR5	PIR4	PIR3	PIR2	PIR1	PIR0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIR0	Software Configurable Interrupt Status Flag 0	When reading 0: Interrupt is not requested. 1: Interrupt is requested. When writing *1, *2 0: Ignored. 1: The software configurable interrupt status flag is cleared.	R/W
b1	PIR1	Software Configurable Interrupt Status Flag 1		R/W
b2	PIR2	Software Configurable Interrupt Status Flag 2		R/W
b3	PIR3	Software Configurable Interrupt Status Flag 3		R/W
b4	PIR4	Software Configurable Interrupt Status Flag 4		R/W
b5	PIR5	Software Configurable Interrupt Status Flag 5		R/W
b6	PIR6	Software Configurable Interrupt Status Flag 6		R/W
b7	PIR7	Software Configurable Interrupt Status Flag 7		R/W

Note: The security attributes for this register can be set for each bit.
When a bit is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When a bit is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. Writing to this register is only valid when any of the edge detection is selected by IRQCRi.IRQMD[1:0] bits. When the level detection is selected, writing to this register is ignored.

Note 2. Do not use bit manipulation instructions. If a bit manipulation instruction is used, multiple status flags may be cleared. Write 1 only to the flag to be cleared and write 0 to the other flags (write to this register in 8-bit units).

These registers are used for polling of interrupt requests of external pin interrupts (IRQi pin interrupts (i = 16 to 31)) that is assigned to software configurable interrupt by software. The IRQ16 to IRQ23 pins correspond to the PIXR0.PIR0 to PIR7 flags, and the IRQ24 to IRQ31 pins correspond to the PIXR1.PIR0 to PIR7 flags, respectively. When “3FFh” (external pin interrupt) is set in the SLIXRn register, use the corresponding IRn.IR flag for polling (n = 128 to 143).

PIRj Flag (Software Configurable Interrupt Status Flag j) (j = 0 to 7)

When an interrupt request of external pin interrupt assigned to software configurable interrupt is generated, the corresponding PIRj flag becomes 1 regardless of whether “3FFh” is set in the SLIXRn register.
Although the PIRj flag does not become 0 after the interrupt request is accepted by the destination (CPU, DTC, DMAC), generation of interrupt requests is not affected.
When using the PIRj flag for polling at edge detection, set the PIRj flag to 0 by writing 1 to the flag in advance.
This flag becomes 1 under the following condition:

- When an interrupt request is generated when edge detection is selected
- When low is input to the IRQi pin when level detection is selected

This flag becomes 0 under the following condition:

- When 1 is written to the PIXRk.PIRj flag when edge detection is selected
- When high is input to the IRQi pin when level detection is selected

15.2.19 Software Configurable Interrupt Request Register k (PIRk) (k = 0 to 127)

Address(es): ICU.PIR0 8700 6800h to ICU.PIR127 8700 687Fh, ICU_NS.PIR0 0700 6800h to ICU_NS.PIR127 0700 687Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	PIR7	PIR6	PIR5	PIR4	PIR3	PIR2	PIR1	PIR0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PIR0	Software Configurable Interrupt Status Flag 0	When reading 0: Interrupt is not requested. 1: Interrupt is requested. When writing *1 0: Ignored. 1: The software configurable interrupt B status flag is cleared.	R/W
b1	PIR1	Software Configurable Interrupt Status Flag 1		R/W
b2	PIR2	Software Configurable Interrupt Status Flag 2		R/W
b3	PIR3	Software Configurable Interrupt Status Flag 3		R/W
b4	PIR4	Software Configurable Interrupt Status Flag 4		R/W
b5	PIR5	Software Configurable Interrupt Status Flag 5		R/W
b6	PIR6	Software Configurable Interrupt Status Flag 6		R/W
b7	PIR7	Software Configurable Interrupt Status Flag 7		R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
To allow access by the non-secure transaction, set the CPSCU.ICUNSACR.NSACE bit to 1.

Note 1. Do not use bit manipulation instructions. If a bit manipulation instruction is used, multiple status flags may be cleared. Write 1 only to the flag to be cleared and write 0 to the other flags (write to this register in 8-bit units).

The PIRk register is used for polling of interrupt requests of interrupt sources that is assigned to software configurable interrupt by software. For an interrupt request of software configurable interrupt set in the SLIXRn or SLIRn register, use the corresponding IRn.IR flag for polling (n = 128 to 255).
Refer to Table 15.3, Interrupt Sources for Software Configurable Interrupt for correspondence between interrupt source numbers and interrupt sources for software configurable interrupt.

PIRj Flag (Software Configurable Interrupt Status Flag j) (j = 0 to 7)

When an interrupt request of interrupt sources assigned to software configurable interrupt is generated, the corresponding PIRk.PIRj flag becomes 1 regardless of whether the interrupt source is selected in the SLIXRn or SLIRn register.
Although the PIRj flag does not become 0 after the interrupt request is accepted by the destination (CPU, DTC, DMAC), generation of interrupt requests is not affected.
When using the PIRj flag for polling, set the PIRj flag to 0 by writing 1 to the flag in advance.
This flag becomes 1 under the following condition:

- An interrupt request is generated

This flag becomes 0 under the following condition:

- 1 is written to the PIRk.PIRj flag

15.2.20 Software Configurable Interrupt Source Select Register Xn (SLIXRn) (n = 128 to 143)

Address(es): ICU.SLIXR128 8700 6900h to ICU.SLIXR143 8700 691Eh, ICU_NS.SLIXR128 0700 6900h to ICU_NS.SLIXR143 0700 691Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	—	000h: No interrupt source selected. 001h: Interrupt source number 1 002h: Interrupt source number 2 : : 3FDh: Interrupt source number 1021 3FEh: Interrupt source number 1022 3FFh: External pin interrupt (IRQi pin interrupt (i = n – 112)) Settings other than above are prohibited.	R/W*1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, the behavior changes depending on the trusted event route setting.
When the trusted event route is disabled, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
When the trusted event route is enabled, it can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

Note 1. Writing to these bits is ignored while the SLIPRCR.WPRC bit is set to 1.

The SLIXRn register is used to assign interrupt sources assigned to software configurable interrupt, or external pin interrupts (IRQ16 pin interrupt to IRQ31 pin interrupt) to interrupt vector numbers 128 to 143.

Table 15.3, Interrupt Sources for Software Configurable Interrupt lists interrupt sources assigned to software configurable interrupt. Set the SLIXRn register to an interrupt source number that is not reserved. When 000h are set, no interrupt source is assigned to interrupt vector number n. When 3FFh are set, the IRQ16 to IRQ31 pin interrupts are assigned to interrupt vector numbers 128 to 143, respectively.

Do not assign the same interrupt source to multiple registers from registers SLIXRn and SLIRn.

Some interrupt sources can be used to start the DTC or DMAC. Refer to Table 15.3, Interrupt Sources for Software Configurable Interrupt for details on which sources can be used to start the DTC or DMAC.

Refer to section 15.7.7, Setting Software Configurable Interrupts for the procedure to set software configurable interrupts.

15.2.21 Software Configurable Interrupt Source Select Register n (SLIRn) (n = 144 to 255)

Address(es): ICU.SLIR144 8700 6920h to ICU.SLIR255 8700 69FEh, ICU_NS.SLIR144 0700 6920h to ICU_NS.SLIR255 0700 69FEh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	—	000h: No interrupt source selected. 001h: Interrupt source number 1 002h: Interrupt source number 2 : : 3FDh: Interrupt source number 1021 3FEh: Interrupt source number 1022 3FFh: No interrupt source selected. Settings other than above are prohibited.	R/W*1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, the behavior changes depending on the trusted event route setting.
When the trusted event route is disabled, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
When the trusted event route is enabled, it can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

Note 1. Writing to these bits is ignored while the SLIPRCR.WPRC bit is set to 1.

The SLIRn register is used to assign interrupt vector numbers 144 to 255 to interrupt sources for software configurable interrupt.

Table 15.3, Interrupt Sources for Software Configurable Interrupt lists interrupt sources for software configurable interrupt. Set the SLIRn register to an interrupt source number that is not reserved. When 000h or 3FFh are set, no interrupt source is assigned to interrupt vector number n.

Do not assign the same interrupt source to multiple registers from registers SLIXRn and SLIRn.

Some interrupt sources can be used to start the DTC or DMAC. Refer to Table 15.3, Interrupt Sources for Software Configurable Interrupt for details on which sources can be used to start the DTC or DMAC.

Refer to section 15.7.7, Setting Software Configurable Interrupts for the procedure to set software configurable interrupts.

Table 15.3 Interrupt Sources for Software Configurable Interrupt (1/10)

Interrupt Source No.	Interrupt Request Source	Name	Start the DTC	Start the DMAC	Interrupt Status Flag
0	None	No interrupt selected (initial value)	N/A	N/A	—

822		CCMPUM4 (composite condition compare unmatch 4)	✓	✓	PIR102.PIR6
823		CCMPUM5 (composite condition compare unmatch 5)	✓	✓	PIR102.PIR7
824		CCMPUM6 (composite condition compare unmatch 6)	✓	✓	PIR103.PIR0
825		CCMPUM7 (composite condition compare unmatch 7)	✓	✓	PIR103.PIR1
826 to 1022	Reserved	—	N/A	N/A	PIR103.PIR2 to PIR127.PIR6
1023	Reserved	External pin interrupt/No interrupt selected*1	N/A	N/A	PIR127.PIR7

Note 1. “External pin interrupt” for the SLIXRn register, and “no interrupt selected” for the SLIRn register.

15.2.22 EXDMAC Trigger Select Register n (SELEXDRn) (n = 0, 1)

Address(es): ICU.SELEXDR0 8700 6C40h, ICU.SELEXDR1 8700 6C44h, ICU_NS.SELEXDR0 0700 6C40h, ICU_NS.SELEXDR1 0700 6C44h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	SLIRQ[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SLI[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	SLI[15:0]	Interrupt Source Select	000h: No interrupt source selected. 001h: Interrupt source number 1 002h: Interrupt source number 2 : : 3FDh: Interrupt source number 1021 3FEh: Interrupt source number 1022 3FFh: External pin interrupt (selected by the SLIRQ[4:0]bit) Settings other than above are prohibited.	R/W
b20 to b16	SLIRQ[4:0]	External Pin Interrupt Select*1	00h: IRQ0 pin interrupt 01h: IRQ1 pin interrupt 02h: IRQ2 pin interrupt : : 1Eh: IRQ30 pin interrupt 1Fh: IRQ31 pin interrupt	R/W
b31 to b21	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Set a value other than 11b in the IRQCRi.IRQMD[1:0] bits corresponding to the selected IRQi pin.

The SELEXDRn register selects an interrupt source assigned to software configurable interrupt, or an external pin interrupt (IRQ0 pin interrupt to IRQ31 pin interrupt) as the EXDMAC trigger.

Table 15.3, Interrupt Sources for Software Configurable Interrupt lists interrupt sources assigned to software configurable interrupt. Set the SELEXDRn register to an interrupt source number that is not reserved. When 000h is set, the EXDMAC cannot be triggered by an interrupt.

15.2.23 Non-Secure Software Configurable Interrupt Source Select Register Write Protect Register (SLIPRCR_NS)

Address(es): ICU_NS.SLIPRCR_NS 0700 6A00h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	WPRC
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	WPRC	Software Configurable Interrupt Source Select Register Write Protect	0: Write enabled. 1: Write disabled.	R/(W) *1
b7 to b1	—	Reserved	The read value is 0. The write value should be 0.	R

Note: This register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Once this bit is set to 1, it cannot be set to 0 by software.

The SLIPRCR_NS register protects registers that control assignment of software configurable interrupts from being written to. This register protects registers with the non-secure attribute.

WPRC Bit (Software Configurable Interrupt Source Select Register Write Protect)

The WPRC bit disables writing to the SLIXRn and SLIRn registers with the non-secure attribute.

Once this bit is set to 1, it cannot be set to 0 by software.

After assigning software configurable interrupts, confirm that the WPRC bit is 1 before the corresponding interrupt request is generated. Refer to section 15.7.7, Setting Software Configurable Interrupts for the procedure to set software configurable interrupts.

15.2.24 Secure Software Configurable Interrupt Source Select Register Write Protect Register (SLIPRCR_S)

Address(es): ICU.SLIPRCR_S 8700 6A04h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	WPRC
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	WPRC	Software Configurable Interrupt Source Select Register Write Protect	0: Write enabled. 1: Write disabled.	R/(W) *1
b7 to b1	—	Reserved	The read value is 0. The write value should be 0.	R

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Once this bit is set to 1, it cannot be set to 0 by software.

The SLIPRCR_S register protects registers that control assignment of software configurable interrupts from being written to. This register protects registers with the secure attribute.

WPRC Bit (Software Configurable Interrupt Source Select Register Write Protect)

The WPRC bit disables writing to the SLIXRn and SLIRn registers with the secure attribute.

Once this bit is set to 1, it cannot be set to 0 by software.

After assigning software configurable interrupts, confirm that the WPRC bit is 1 before the corresponding interrupt request is generated. Refer to section 15.7.7, Setting Software Configurable Interrupts for the procedure to set software configurable interrupts.

15.2.25 ICU Security Attribution Register A (ICUSARA)

Address(es): CPSCU.ICUSARA 8701 8040h, CPSCU_NS.ICUSARA 0701 8040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b9	SAIRQCR9	IRQCR9 Security Attribution		R/W
b10	SAIRQCR10	IRQCR10 Security Attribution		R/W
b11	SAIRQCR11	IRQCR11 Security Attribution		R/W
b12	SAIRQCR12	IRQCR12 Security Attribution		R/W
b13	SAIRQCR13	IRQCR13 Security Attribution		R/W
b14	SAIRQCR14	IRQCR14 Security Attribution		R/W
b15	SAIRQCR15	IRQCR15 Security Attribution		R/W
b16	SAIRQCR16	IRQCR16 and PIXR0.PIR0 Security Attribution		R/W
b17	SAIRQCR17	IRQCR17 and PIXR0.PIR1 Security Attribution		R/W
b18	SAIRQCR18	IRQCR18 and PIXR0.PIR2 Security Attribution		R/W
b19	SAIRQCR19	IRQCR19 and PIXR0.PIR3 Security Attribution		R/W
b20	SAIRQCR20	IRQCR20 and PIXR0.PIR4 Security Attribution		R/W
b21	SAIRQCR21	IRQCR21 and PIXR0.PIR5 Security Attribution		R/W
b22	SAIRQCR22	IRQCR22 and PIXR0.PIR6 Security Attribution		R/W
b23	SAIRQCR23	IRQCR23 and PIXR0.PIR7 Security Attribution		R/W
b24	SAIRQCR24	IRQCR24 and PIXR1.PIR0 Security Attribution		R/W
b25	SAIRQCR25	IRQCR25 and PIXR1.PIR1 Security Attribution		R/W
b26	SAIRQCR26	IRQCR26 and PIXR1.PIR2 Security Attribution		R/W
b27	SAIRQCR27	IRQCR27 and PIXR1.PIR3 Security Attribution		R/W
b28	SAIRQCR28	IRQCR28 and PIXR1.PIR4 Security Attribution		R/W
b29	SAIRQCR29	IRQCR29 and PIXR1.PIR5 Security Attribution		R/W
b30	SAIRQCR30	IRQCR30 and PIXR1.PIR6 Security Attribution		R/W
b31	SAIRQCR31	IRQCR31 and PIXR1.PIR7 Security Attribution		R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

This register is used to set the security attributes for the IRQCR0 to IRQCR31 registers, the PIXR0.PIR0 to PIR7 bits, and the PIXR1.PIR0 to PIR7 bits.

15.2.26 ICU Security Attribution Register B (ICUSARB)

Address(es): CPSCU.ICUSARB 8701 8044h, CPSCU_NS.ICUSARB 0701 8044h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SANMI0	SANMICR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SANMICR	NMICR Security Attribution	0: Secure 1: Non-secure	R/W
b1	SANMI0	Non-Maskable Interrupt Security Attribution 0		R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

This register is used to set the security attributes for the NMICR, NMISR, NMIER, and NMICLR registers.

SANMICR Bit (NMICR Security Attribution)

This bit is used to set the security attribute of the NMICR register.

SANMI0 Bit (Non-Maskable Interrupt Security Attribution 0)

This bit is used to set the security attributes of the NMISR, NMIER, and NMICLR registers.

15.2.27 ICU Security Attribution Register C (ICUSARC)

Address(es): CPSCU.ICUSARC 8701 8048h, CPSCU_NS.ICUSARC 0701 8048h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SACLPCR0	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	SACLPCR0	CLPCR Security Attribution 0	0: Secure 1: Non-secure	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

This register is used to set the security attributes for the CLPCR register.

SACLPCR0 Bit (CLPCR Security Attribution 0)

This bit is used to set the security attribute of the LPM.CLPCR register. Refer to section 11, Low Power Consumption for details on the CLPCR register.

15.2.28 ICU Security Attribution Register D (ICUSARD)

Address(es): CPSCU.ICUSARD 8701 804Ch, CPSCU_NS.ICUSARD 0701 804Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SADPFPU	Double-Precision Floating-Point Exception Security Attribution	0: Secure 1: Non-secure	R/W
b1	SALM	Local Memory Error Interrupt Security Attribution		R/W
b2	SACM	Common Memory Error Interrupt Security Attribution		R/W
b3	SAHLDTO	External Bus Hold Timeout Interrupt Security Attribution		R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	SAMCEE	Code MRAM ECC Error Interrupt Security Attribution	0: Secure 1: Non-secure	R/W
b9	SAMEEE	Extra MRAM ECC Error Interrupt Security Attribution		R/W
b10	SAMCWE	Code MRAM Write Error Interrupt Security Attribution		R/W
b11	SAMDWE	Data MRAM Write Error Interrupt Security Attribution		R/W
b12	SAMEWE	Extra MRAM Write Error Interrupt Security Attribution		R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

This register is used to set the security attributes for the interrupt sources assigned to the group IL0.

15.2.29 ICU Security Attribution Register 0 (ICU0SAR0)

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

Note: Leave the bits corresponding to the vector numbers marked as “Reserved” in Table 15.6 set to 0.

Note 1. Set this bit to 0.
Note 2. Set this bit to 1.

The ICU0SAR0 register configures the security attributes of registers and bits associated with vector numbers 0 to 31. Refer to Table 15.6, Interrupt Vector Table for the correspondence between interrupt vector numbers and registers. Table 15.4 lists the targets controlled by each bit.

Table 15.4 Targets controlled by each bit

Bit	Targets to Be Controlled
SAIR0	IPR0 register
SAIR1	IPR1 register
SAIR2	IPR2 register
SAIR3	IPR3 register
SAIR4	IPR4 register
SAIR5	IPR5 register
SAIR6	IPR6 register
SAIR7	IPR7 register
SAIR8	IPR8 register
SAIR9 to SAIR15	None
SAIR16	IR16 register, IER2.IEN0 bit
SAIR17	IR17 register, IER2.IEN1 bit
SAIR18	IR18 register, IER2.IEN2 bit
SAIR19	IR19 register, IER2.IEN3 bit, IPR19 register
SAIR20	IR20 register, IER2.IEN4 bit, IPR20 register
SAIR21 to SAIR25	None
SAIR26	IR26 register, IER3.IEN2 bit, DTCER26 register, SWINT2R register
SAIR27	IR27 register, IER3.IEN3 bit, DTCER27 register, SWINTR register
SAIR28	IR28 register, IER3.IEN4 bit, DTCER28 register
SAIR29	IR29 register, IER3.IEN5 bit, DTCER29 register
SAIR30	IR30 register, IER3.IEN6 bit, DTCER30 register
SAIR31	IR31 register, IER3.IEN7 bit, DTCER31 register

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

Note: Leave the bits corresponding to the vector numbers marked as “Reserved” in Table 15.6 set to 0.

The ICU0SAR1 register configures the security attributes of registers and bits associated with vector numbers 32 to 63. Refer to Table 15.6, Interrupt Vector Table for the correspondence between interrupt vector numbers and registers.

SAIRn Bit (IRn Security Attribution) (n = 32 to 63)

This bit configures the security attribute of the IRn register, the IERm.IENj bit (m = n / 8; j = n % 8), the IPRn register, and the DTCERn register.

Example:

When “n” is 32: the IR32 register, the IER4.IEN0 bit, the IPR32 register, and the DTCER32 register

When “n” is 63: the IR63 register, the IER7.IEN7 bit, the IPR63 register, and the DTCER63 register

15.2.31 ICU Security Attribution Register 2 (ICU0SAR2)

b31	SAIR95	IR95 Security Attribution		R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

Note: Leave the bits corresponding to the vector numbers marked as “Reserved” in Table 15.6 set to 0.

The ICU0SAR2 register configures the security attributes of registers and bits associated with vector numbers 64 to 95. Refer to Table 15.6, Interrupt Vector Table for the correspondence between interrupt vector numbers and registers.

SAIRn Bit (IRn Security Attribution) (n = 64 to 95)

This bit configures the security attribute of the IRn register, the IERm.IENj bit (m = n / 8; j = n % 8), the IPRn register, and the DTCERn register.

Example:

When “n” is 64: the IR64 register, the IER8.IEN0 bit, the IPR64 register, and the DTCER64 register

When “n” is 95: the IR95 register, the IER11.IEN7 bit, the IPR95 register, and the DTCER95 register

15.2.32 ICU Security Attribution Register 3 (ICU0SAR3)

b29	SAIR125	IR125 Security Attribution		R/W
b30	SAIR126	IR126 Security Attribution		R/W
b31	SAIR127	IR127 Security Attribution		R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

Note: Leave the bits corresponding to the vector numbers marked as “Reserved” in Table 15.6 set to 0.

Note 1. Set this bit to 0.
Note 2. Set this bit to 1.

The ICU0SAR3 register configures the security attributes of registers and bits associated with vector numbers 96 to 127. Refer to Table 15.6, Interrupt Vector Table for the correspondence between interrupt vector numbers and registers.

SAIRn Bit (IRn Security Attribution) (n = 96 to 127)

This bit configures the security attribute of the IRn register, the IERm.IENj bit (m = n / 8; j = n % 8), the IPRn register, and the DTCERn register.

Example:

When “n” is 96: the IR96 register, the IER12.IEN0 bit, the IPR96 register, and the DTCER96 register

When “n” is 127: the IR127 register, the IER15.IEN7 bit, the IPR127 register, and the DTCER127 register

15.2.33 ICU Security Attribution Register 4 (ICU0SAR4)

b30	SAIR158	IR158 Security Attribution		R/W
b31	SAIR159	IR159 Security Attribution		R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The ICU0SAR4 register configures the security attributes of registers and bits associated with vector numbers 128 to 159. Refer to Table 15.6, Interrupt Vector Table for the correspondence between interrupt vector numbers and registers.

SAIRn Bit (IRn Security Attribution) (n = 128 to 143)

This bit configures the security attribute of the IRn register, the IERm.IENj bit (m = n / 8; j = n % 8), the IPRn register, the DTCERn register, and the SLIXRn register.

Example:

When “n” is 128: the IR128 register, the IER16.IEN0 bit, the IPR128 register, the DTCER128 register, and the SLIXR128 register

When “n” is 143: the IR143 register, the IER17.IEN7 bit, the IPR143 register, the DTCER143 register, and the SLIXR143 register

SAIRn Bit (IRn Security Attribution) (n = 144 to 159)

This bit configures the security attribute of the IRn register, the IERm.IENj bit (m = n / 8; j = n % 8), the IPRn register, the DTCERn register, and the SLIRn register.

Example:

When “n” is 144: the IR144 register, the IER18.IEN0 bit, the IPR144 register, the DTCER144 register, and the SLIR144 register

When “n” is 159: the IR159 register, the IER19.IEN7 bit, the IPR159 register, the DTCER159 register, and the SLIR159 register

b31	SAIR191	IR191 Security Attribution		R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The ICU0SAR5 register configures the security attributes of registers and bits associated with vector numbers 160 to 191. Refer to Table 15.6, Interrupt Vector Table for the correspondence between interrupt vector numbers and registers.

SAIRn Bit (IRn Security Attribution) (n = 160 to 191)

This bit configures the security attribute of the IRn register, the IERm.IENj bit (m = n / 8; j = n % 8), the IPRn register, the DTCERn register, and the SLIRn register.

Example:

When “n” is 160: the IR160 register, the IER20.IEN0 bit, the IPR160 register, the DTCER160 register, and the SLIR160 register

When “n” is 191: the IR191 register, the IER23.IEN7 bit, the IPR191 register, the DTCER191 register, and the SLIR191 register

15.2.35 ICU Security Attribution Register 6 (ICU0SAR6)

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The ICU0SAR6 register configures the security attributes of registers and bits associated with vector numbers 192 to 223. Refer to Table 15.6, Interrupt Vector Table for the correspondence between interrupt vector numbers and registers.

SAIRn Bit (IRn Security Attribution) (n = 192 to 223)

This bit configures the security attribute of the IRn register, the IERm.IENj bit (m = n / 8; j = n % 8), the IPRn register, the DTCERn register, and the SLIRn register.

Example:

When “n” is 192: the IR192 register, the IER24.IEN0 bit, the IPR192 register, the DTCER192 register, and the SLIR192 register

When “n” is 223: the IR223 register, the IER27.IEN7 bit, the IPR223 register, the DTCER223 register, and the SLIR223 register

15.2.36 ICU Security Attribution Register 7 (ICU0SAR7)

b30	SAIR254	IR254 Security Attribution		R/W
b31	SAIR255	IR255 Security Attribution		R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The ICU0SAR7 register configures the security attributes of registers and bits associated with vector numbers 224 to 255. Refer to Table 15.6, Interrupt Vector Table for the correspondence between interrupt vector numbers and registers.

SAIRn Bit (IRn Security Attribution) (n = 224 to 255)

This bit configures the security attribute of the IRn register, the IERm.IENj bit (m = n / 8; j = n % 8), the IPRn register, the DTCERn register, and the SLIRn register.

Example:

When “n” is 224: the IR224 register, the IER28.IEN0 bit, the IPR224 register, the DTCER224 register, and the SLIR224 register

When “n” is 255: the IR255 register, the IER31.IEN7 bit, the IPR255 register, the DTCER255 register, and the SLIR255 register

15.2.37 Trusted Event Route Control Register (TEVTRCR)

Address(es): CPSCU.TEVTRCR 8701 8600h, CPSCU_NS.TEVTRCR 0701 8600h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TEVTE	ELC Trusted Event Route Control	0: Trusted event route is disabled. 1: Trusted event route is enabled.	R/W
b1	TEVTEICU0	ICU Trusted Event Route Control 0		R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

Note: This register is write-protected by the SYSC.PRCR.PRC4 bit.

This register is used to provide special attributes regarding the security attributes for some registers in the ELC and ICU. When the security attribute of the target register is configured as non-secure and the trusted event route is enabled, writing by the non-secure transaction is disabled and reading/writing by the secure transaction is enabled.

TEVTE Bit (ELC Trusted Event Route Control)

This bit controls the trusted event route for the ELC.ELSRn registers.

TEVTEICU0 Bit (ICU Trusted Event Route Control 0)

This bit controls the trusted event route for the DMRSRm, SLIXRn, and SLIRn registers.

15.2.38 ICU Non-Secure Access Control Register (ICUNSACR)

Address(es): CPSCU.ICUNSACR 8701 8604h, CPSCU_NS.ICUNSACR 0701 8604h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	NSACE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	NSACE	PIRk Register Non-Secure Access Enable	0: Disabled. 1: Enabled.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.
Note: This register is write-protected by the SYSC.PRCR.PRC4 bit.

This register is used to provide special attributes for the PIRk registers (k = 0 to 127).

NSACE Bit (PIRk Register Non-Secure Access Enable)

This bit enables reading from or writing to the PIRk registers by the non-secure transaction.

15.2.39 Protect Zone Interrupt Control Register (PRTZCR)

Address(es): CPSCU.PRTZCR 8701 8620h, CPSCU_NS.PRTZCR 0701 8620h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PRTZC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PRTZC	Protect Zone Control	0: The destination for all interrupts is fixed as the root world. 1: The destination for each interrupt can be selected as either the secure world or the non-secure world.*1	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.
Note: This register is write-protected by the SYSC.PRCR.PRC4 bit.
Note 1. The destination for each maskable interrupt can be selected by the corresponding SAIRn bit in the ICU0SARm registers, while the destination for non-maskable interrupts can be selected by the ICUSARB.SANMI0 bit (n = interrupt vector number; m = 0 to 7).

This register controls the operation of the ICU according to the Protect Zone setting.

PRTZC Bit (Protect Zone Control)

This bit is used to direct the ICU whether or not to operate according to the settings of the Protect Zone feature of the CPU. Set this bit to 0 when a program is only to run in the root world, and to 1 when a program that utilizes the concept of worlds within the Protect Zone is to be run.
Table 15.5 lists the setting of this bit and the operation of the ICU.

Table 15.5 PRTZC Bit Setting and ICU Operation

Item	PRTZC = 0	PRTZC = 1	
		Secure interrupt	Non-secure interrupt
Fast interrupt	Enabled	Disabled	
Interrupt destination	Fixed to Root world	Secure world	Non-secure world
Interrupt priority level	0 to 31	0 to 31	0 to 15

15.3 Vector Table

There are two types of exceptions detected by the ICU: maskable interrupts (hereinafter referred to as “interrupts”) and non-maskable interrupts.
When the CPU accepts an interrupt or non-maskable interrupt, it acquires a 4-byte vector address from the vector table.

15.3.1 Interrupt Vector Table

The vector table that is used for maskable interrupts is called the interrupt vector table.
The interrupt vector table is allocated to a 1024-byte area (4 bytes × 256 sources) beginning with the address set in the INTB register in the CPU. Set the INTB register before enabling interrupts. Set a multiple of 4 in the INTB register.
An unconditional trap is generated when the INT or BRK instruction is executed. Interrupt vectors for unconditional traps use the same area as the interrupt vector table. The BRK instruction is assigned to interrupt vector number 0. The INT instruction is assigned to the interrupt vector number corresponding to the value set as the operand (0 to 255).
Table 15.6 lists details of the interrupt vectors. Details of the headings in Table 15.6 are listed below.

Heading	Description
Interrupt request generated by	Name of the source that generates the interrupt request (module symbol)
Name	Name of the interrupt source (symbol)
Vector no.	Interrupt vector number
Vector address offset	Offset from the address set in the INTB register
Interrupt detection method	“Edge” indicates that the interrupt is detected by edge detection. “Level” indicates that the interrupt is detected by level detection.
CPU interrupt	Interrupt source indicated by “✓” can be used as an interrupt source to the CPU.
Start the DTC	Interrupt source indicated by “✓” can be used as the DTC trigger.
Start the DMAC	Interrupt source indicated by “✓” can be used as the DMAC trigger.
Exit from SSBY	Interrupt source indicated by “✓” can be used as a source to exit software standby mode.
IER	Name of the bit in the IER register corresponding to the interrupt vector number
IPR	Name of the IPR register corresponding to the interrupt source
DTCER	Name of the DTCER register corresponding to the DTC trigger

Note: This table lists the interrupt vectors for the maximum specification. The interrupt vectors for individual products correspond to the functions listed in Table 1.2. For details, refer to Table 1.2, Comparison of Functions for Different Packages.
Note 1. For the group interrupt sources, refer to Table 15.8, Group Interrupt Requests.
Note 2. This is the case where the corresponding non-maskable interrupt enable bit is set to 0 (disabled).
Note 3. For the software configurable interrupt sources, refer to Table 15.3, Interrupt Sources for Software Configurable Interrupt. Note that some interrupt sources cannot start the DTC, DMAC, or EXDMAC.‘
Note 4. Only external pin interrupts can be used as a source to exit software standby mode.

15.3.2 Fast Interrupt Vector Area

The interrupt set as the fast interrupt uses the FINTV register in the CPU. Set the FINTV register before enabling the fast interrupt.

15.3.3 Non-maskable Interrupt Vector Area

Non-maskable interrupts use the vector area in the exception vector table.
The exception vector table is allocated to the 128-byte area (4 bytes × 32 sources) beginning with the address set in the EXTB register in the CPU. Set the EXTB register before enabling non-maskable interrupts. Set a multiple of 4 in the EXTB register.

15.4 Types of Interrupts

Interrupts are divided into maskable interrupts and non-maskable interrupts. Maskable interrupts can be masked by the PSW.I bit or IPL[4:0] bits of the processor status word in the CPU. Non-maskable interrupts can be accepted by the CPU regardless of those bits. While interrupt sources assigned to vector numbers 0 to 127 are fixed, an interrupt source assigned to each vector number from 128 to 255 (software configurable interrupt) can be selected from multiple sources. Note that maskable interrupts are referred to as interrupts in this chapter.
Figure 15.2 shows types of interrupts.

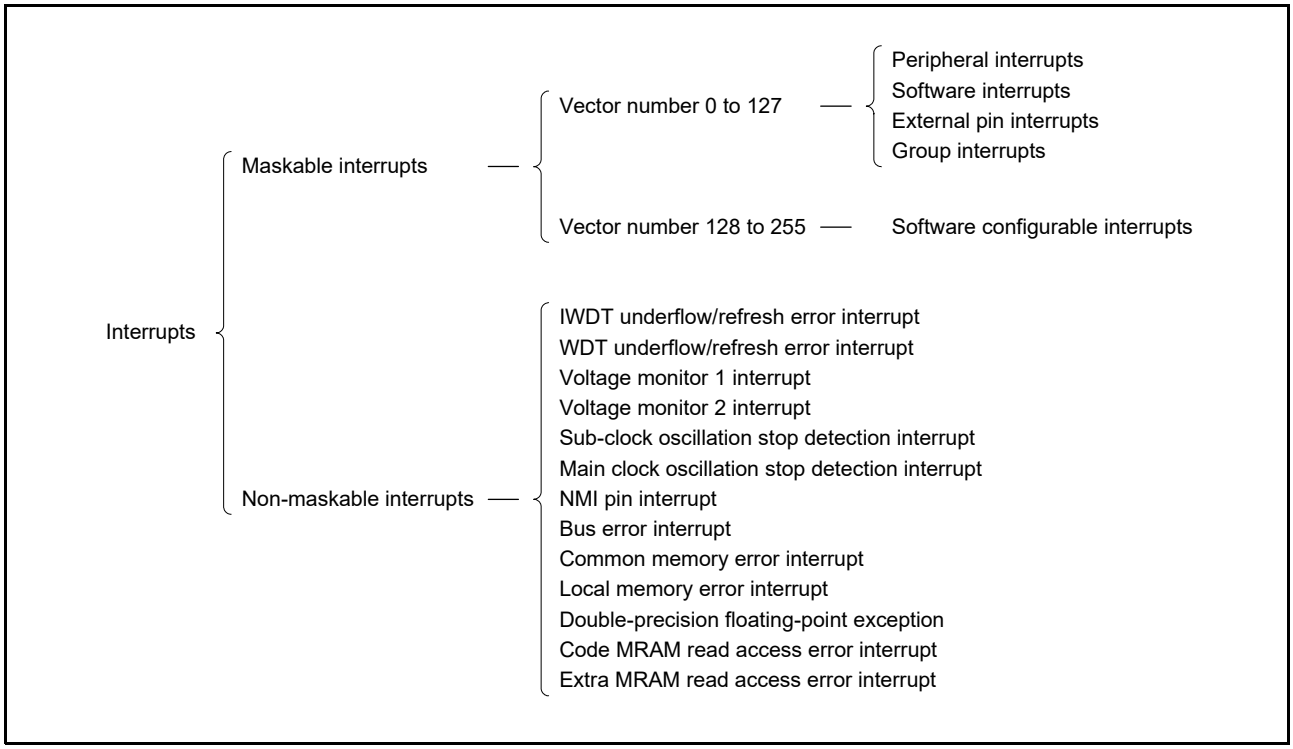

Figure 15.2 Types of Interrupts

15.4.1 Peripheral Interrupts

Peripheral interrupt is generated by peripherals. Peripheral interrupts sources assigned to vector numbers 0 to 127 cannot be assigned to the software configurable interrupts. Refer to section 15.4.5, Software Configurable Interrupts for details on software configurable interrupts.

15.4.2 Software Interrupts

When the SWINTR.SWINT bit and SWINT2R.SWINT2 bit are set to 1, the SWINT interrupt and SWINT2 interrupt occur, respectively.

15.4.3 External Pin Interrupt

An external pin interrupt is generated by signals input to the IRQi pin (i = 0 to 31). Refer to section 15.7.4, Setting the External Pin Interrupt for the procedure to set the external pin interrupt.

15.4.4 Group Interrupts

Multiple peripheral interrupt requests (up to 32 requests) are grouped together as one interrupt request. Interrupts are grouped depending on the peripheral operating clock (ICLK, PCLKB, or PCLKA) and the security attribute.

(1) Types of Group Interrupts

Table 15.7 lists types of group interrupts.

Table 15.7 Types of Group Interrupts

Interrupt Vector Number	Interrupt Name	Group Interrupt Source	
		Peripheral operating clock	Security attribute
17	GROUPIL0_S	ICLK	Secure
18	GROUPIL0_NS		Non-secure
19	GROUPIL1_S		Secure
20	GROUPIL1_NS		Non-secure
102	GROUPBL0_S	PCLKB	Secure
103	GROUPBL1_S		
104	GROUPAL0_S	PCLKA	
105	GROUPAL1_S		
106	GROUPAL2_S		
107	GROUPAL3_S		
108	GROUPAL4_S		
109	GROUPAL5_S		
110	GROUPAL6_S		
111	GROUPBL0_NS	PCLKB	Non-secure
112	GROUPBL1_NS		
113	GROUPAL0_NS	PCLKA	
114	GROUPAL1_NS		
115	GROUPAL2_NS		
116	GROUPAL3_NS		
117	GROUPAL4_NS		
118	GROUPAL5_NS		
119	GROUPAL6_NS		

(2) Configuration of Group Interrupts

When an interrupt request is generated while the corresponding ENj bit in the group interrupt request enable register (GENIL0, GENIL1, GENBL0, GENBL1, and GENAL0 to GENAL6*1) is 1, the ISj flag in the group interrupt request register (GRPIL0, GRPIL1, GRPBL0, GRPBL1, and GRPAL0 to GRPAL6*1) becomes 1 (j = 0 to 31).

Note 1. There is no register in the group to which no interrupt source is assigned.

Figure 15.3 shows the configuration of group interrupts.

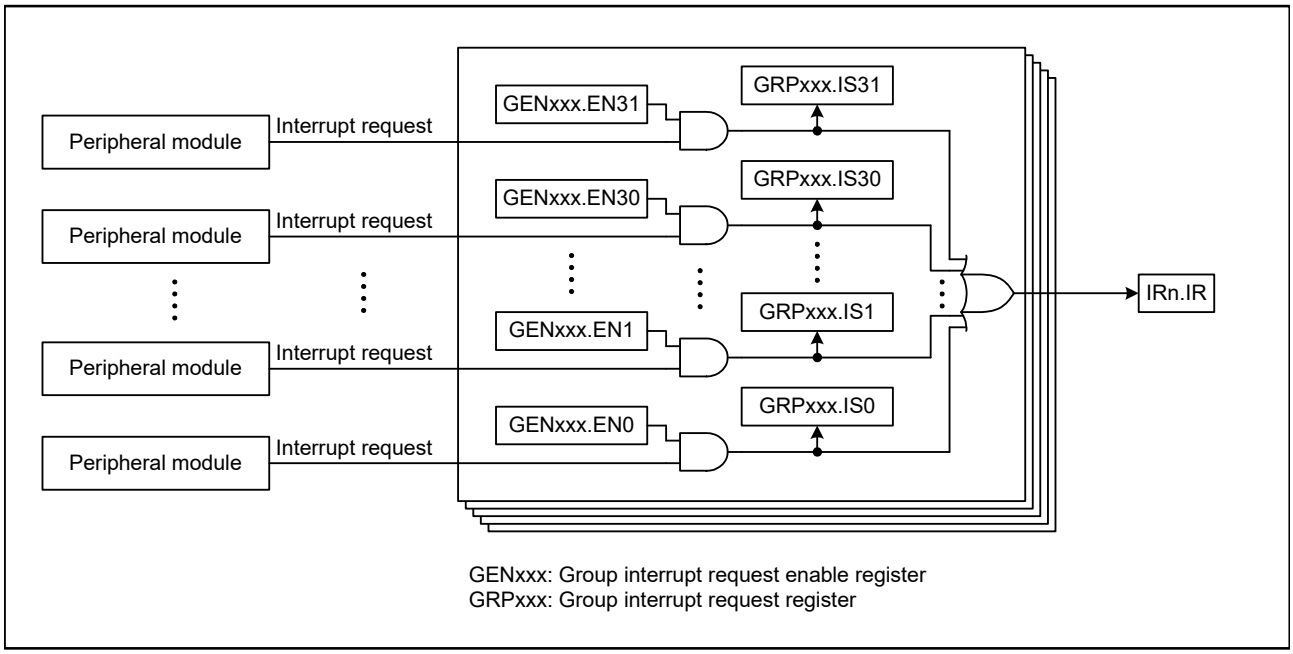

Figure 15.3 Group Interrupt Configuration (n = 17 to 20, 102 to 119)

(3) Group Interrupt Sources

Table 15.8 lists peripheral interrupt sources that are assigned to group interrupts.

Table 15.8 Group Interrupt Requests (1/5)

Group	No.	Interrupt Request Source	Name	Interrupt Request Enable Bit	Interrupt Status Flag	Vector No. (IRn.IR)
IL0	0	DPFPU	DPFPUEX (double-precision floating-point exception)	GENIL0.EN0	GRPIL0.IS0	17 or 18
	1	LM0	ERR (local memory error)	GENIL0.EN1	GRPIL0.IS1	
	2	CM	ERR (common memory error)	GENIL0.EN2	GRPIL0.IS2	
	3	BUS	HLDTO (external bus hold timeout)	GENIL0.EN3	GRPIL0.IS3	
	4 to 7	Reserved	—	—	—	
	8	MRAM	MRCRDI (code MRAM ECC error)	GENIL0.EN8	GRPIL0.IS8	
	9		MRERDI (extra MRAM ECC error)	GENIL0.EN9	GRPIL0.IS9	
	10		MRCPRI (code MRAM access error)	GENIL0.EN10	GRPIL0.IS10	
	11		MRDPRI (data MRAM access error)	GENIL0.EN11	GRPIL0.IS11	
	12		MREPRI (extra MRAM access error)	GENIL0.EN12	GRPIL0.IS12	
	13 to 31	Reserved	—	—	—	
IL1	0 to 31	Reserved	—	—	—	19 or 20
BL0	0	SDHI	CDETI (card detection interrupt)	GENBL0.EN0	GRPBL0.IS0	102 or 111
	1		CACI (card access interrupt)	GENBL0.EN1	GRPBL0.IS1	
	2		SDACI (SDIO access interrupt)	GENBL0.EN2	GRPBL0.IS2	
	3	XSPI0	CMP (complete interrupt)	GENBL0.EN3	GRPBL0.IS3	
	4		ERR (error interrupt)	GENBL0.EN4	GRPBL0.IS4	
	5	XSPI1	CMP (complete interrupt)	GENBL0.EN5	GRPBL0.IS5	
	6		ERR (error interrupt)	GENBL0.EN6	GRPBL0.IS6	
	7	SSIE0	SSIF0 (status interrupt)	GENBL0.EN7	GRPBL0.IS7	
	8	SSIE1	SSIF1 (status interrupt)	GENBL0.EN8	GRPBL0.IS8	
	9	PDC	PCFEI (frame end interrupt)	GENBL0.EN9	GRPBL0.IS9	
	10		PCERI (error interrupt)	GENBL0.EN10	GRPBL0.IS10	
	11	PDMIF	ERR0 (error interrupt)	GENBL0.EN11	GRPBL0.IS11	
	12 to 31	Reserved	—	—	—	
BL1	0	CAC0	FERRI (frequency error)	GENBL1.EN0	GRPBL1.IS0	103 or 112
	1		MENDI (measurement end)	GENBL1.EN1	GRPBL1.IS1	
	2		OVFI (overflow interrupt)	GENBL1.EN2	GRPBL1.IS2	
	3	CAC1	FERRI (frequency error)	GENBL1.EN3	GRPBL1.IS3	
	4		MENDI (measurement end)	GENBL1.EN4	GRPBL1.IS4	
	5		OVFI (overflow interrupt)	GENBL1.EN5	GRPBL1.IS5	
	6	CAC2	FERRI (frequency error)	GENBL1.EN6	GRPBL1.IS6	
	7		MENDI (measurement end)	GENBL1.EN7	GRPBL1.IS7	
	8		OVFI (overflow interrupt)	GENBL1.EN8	GRPBL1.IS8	
	9 to 31	Reserved	—	—	—	

Table 15.8 Group Interrupt Requests (2/5)

Group	No.	Interrupt Request Source	Name	Interrupt Request Enable Bit	Interrupt Status Flag	Vector No. (IRn.IR)
AL0	0	RSCI0	TEI (transmission end/condition generated)	GENAL0.EN0	GRPAL0.IS0	104 or 113
	1		ERI (receive error)	GENAL0.EN1	GRPAL0.IS1	
	2		BFD (break field detect)	GENAL0.EN2	GRPAL0.IS2	
	3	RSCI1	TEI (transmission end/condition generated)	GENAL0.EN3	GRPAL0.IS3

15.4.5 Software Configurable Interrupts

An interrupt source assigned to each interrupt vector number from 128 to 255 can be selected from multiple sources. Refer to Table 15.3, Interrupt Sources for Software Configurable Interrupt for interrupt sources that can be assigned to software configurable interrupt. Figure 15.4 shows the software configurable interrupt configuration.

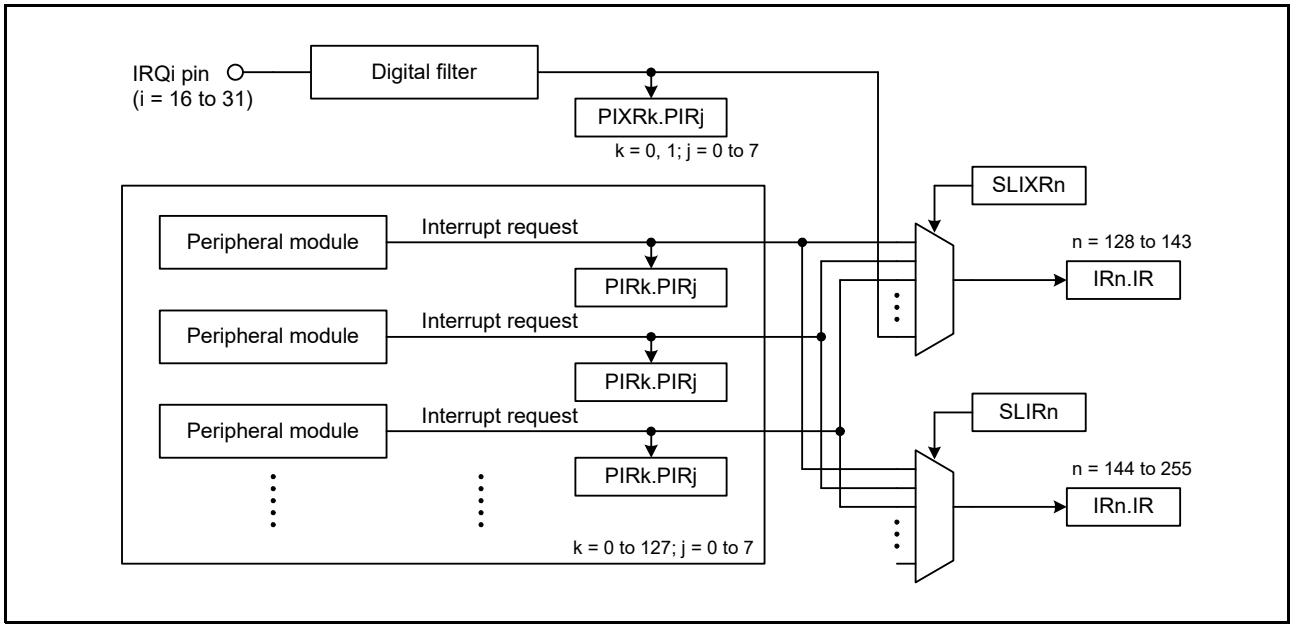

Figure 15.4 Software Configurable Interrupt Configuration

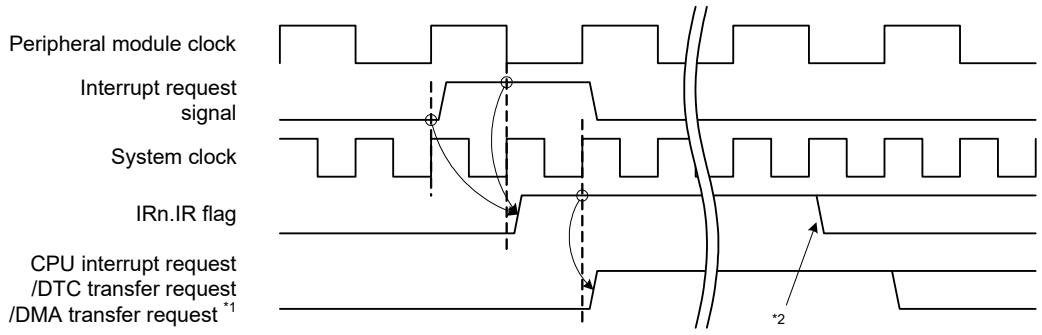
15.4.6 Non-Maskable Interrupts

Non-maskable interrupts include the 13-types of interrupts listed in Table 15.9.

Table 15.9 Types of Non-Maskable Interrupts

Name	Description
IWDT underflow/refresh error interrupt	Underflow or refresh error has occurred in IWDT.
WDT underflow/refresh error interrupt	Underflow or refresh error has occurred in WDT.
Voltage monitoring 1 interrupt	The interrupt generation condition set in PVD1 has been met.
Voltage monitoring 2 interrupt	The interrupt generation condition set in PVD2 has been met.
Sub-clock oscillation stop detection interrupt	The sub-clock oscillator has stopped oscillating.
Main clock oscillation stop detection interrupt	The main clock oscillator has stopped oscillating.
NMI pin interrupt	The specified edge is input from the NMI pin.
Bus error interrupt	Bus error has occurred.
Common memory error interrupt	An ECC error has occurred in SRAM0 or SRAM1.
Local memory error interrupt	An ECC error has occurred in CPU cache or LRAM.
Double-precision floating-point exception	An exception has occurred in the double-precision floating-point coprocessor.
Code MRAM read access error interrupt	An ECC error has occurred in the code area of MRAM.
Extra MRAM read access error interrupt	An ECC error has occurred in the extra area of MRAM.



Non-maskable interrupts have the highest priority in all interrupts, including the fast interrupt, so are accepted regardless of the settings of the PSW.I bit (interrupt enable) and IPL[4:0] bits (processor interrupt priority level) in the CPU.
The NMISR register can be used to confirm whether a non-maskable interrupt is generated.
Only the CPU can be selected as the interrupt request destination of non-maskable interrupt. The DTC and DMAC cannot be selected.

15.5 Interrupt Detection

Level detection or edge detection can be used for detecting an interrupt request.
For interrupt requests from the peripherals, edge detection or level detection is fixed for each interrupt source. For interrupt requests of the external pin interrupt, edge detection or level detection can be selected with the IRQCRi.IRQMD[1:0] bits (i = 0 to 31).
Refer to Table 15.6, Interrupt Vector Table for the method to detect each interrupt request.
All interrupt requests by interrupt sources assigned to the group interrupts are level-detected, and the group interrupts themselves (GROUPIL0, GROUPIL1, GROUPBL0, GROUPBL1, and GROUPAL0 to GROUPAL6) are also level-detected.
Refer to section 15.4.4, Group Interrupts for group interrupts. Refer to section 15.5.3, Interrupt Detection for Group Interrupts for interrupt requests of group interrupts.

15.5.1 Edge Detection

Figure 15.5 shows the operation of the IRn.IR flag at edge detection (n = 26 to 255).
The IRn.IR flag becomes 1 when the rising edge of the interrupt request signal is detected. Then, the IRn.IR flag does not become 0 by disabling the interrupt request of the peripheral module. When the CPU accepts the interrupt request or the DTC/DMAC accepts the transfer request, the IRn.IR flag automatically becomes 0. It is not required to set the IRn.IR flag to 0 by software. Refer to Table 15.10, Operations When Starting the DTC/DMAC for details on clearing the IRn.IR flag by DTC/DMAC.
For the external pin interrupts of interrupt vector number 64 to 79, software configurable interrupts of interrupt vector number 128 to 143 with external pin interrupts selected, and interrupt sources of interrupt vector number 80 to 95, the timing when the IRn.IR flag becomes 1 after an interrupt signal occurs is different from the other interrupts. For the external pin interrupts, the timing is delayed for internal delay plus two cycles of PCLKB after a signal is input to the IRQ pin (i = 0 to 31). For interrupts of interrupt vector number 80 to 95, the timing is delayed for two cycles of PCLKB.

Note 1. A CPU interrupt request, DTC transfer request, or DMA transfer request is generated. Refer to section 15.7.3.1, Interrupt Request Destination Setting Procedure.
Note 2. For a CPU interrupt request, the IRn.IR flag becomes 0 when the CPU accepts an interrupt request. For the timing for a DTC transfer request or DMA transfer request, refer to Table 15.10, Operations When Starting the DTC/DMAC.

Figure 15.5 IRn.IR Flag Operation for Interrupts Detected by Edge Detection

(1) Detecting Consecutive Interrupt Request Signals

When interrupt request signals occur every cycle, the latter interrupt signal cannot be detected. To accept consecutive interrupt request signals, the interval of at least two cycles of the system clock or peripheral module clock, whichever is lower, is required between interrupt signals. Figure 15.6 shows the interval for accepting consecutive interrupt request signals.

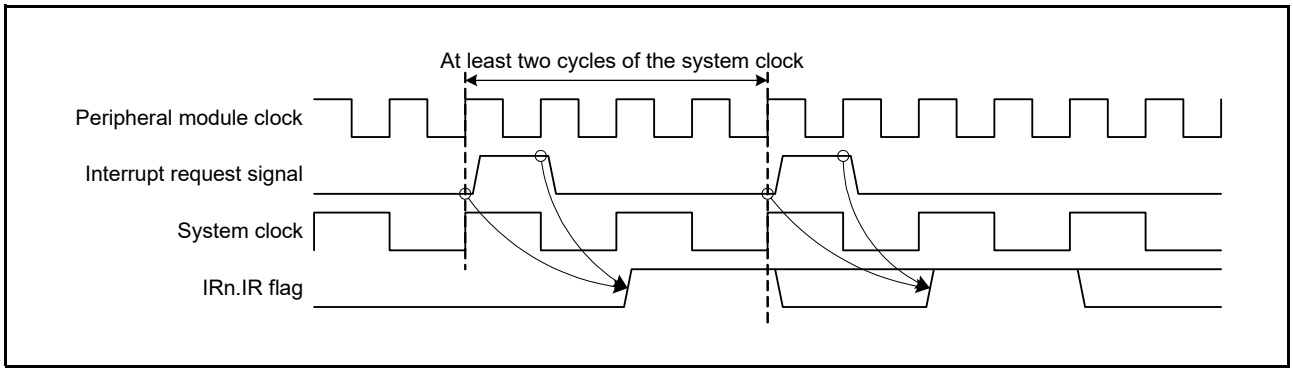


Figure 15.6 Accepting Consecutive Interrupt Signals (when the system clock frequency is lower than the peripheral clock frequency)

When an interrupt request is generated again while the IRn.IR flag is 1, the interrupt request is ignored (n = 26 to 255). However, for transmit interrupt requests, receive interrupt requests, and buffer access interrupt requests of the RSCI, RI3C, RIICHS, RSPIA, SSIE, SDHI, and PDC, when an interrupt request occurs while the IRn.IR flag is 1, the interrupt request is retained in the module. After the IRn.IR flag becomes 0, the IRn.IR flag is set to 1 again by the retained request. Refer to the descriptions for interrupts in each chapter of peripheral modules for details.
Figure 15.7 shows the timing when the IRn.IR flag is set again.

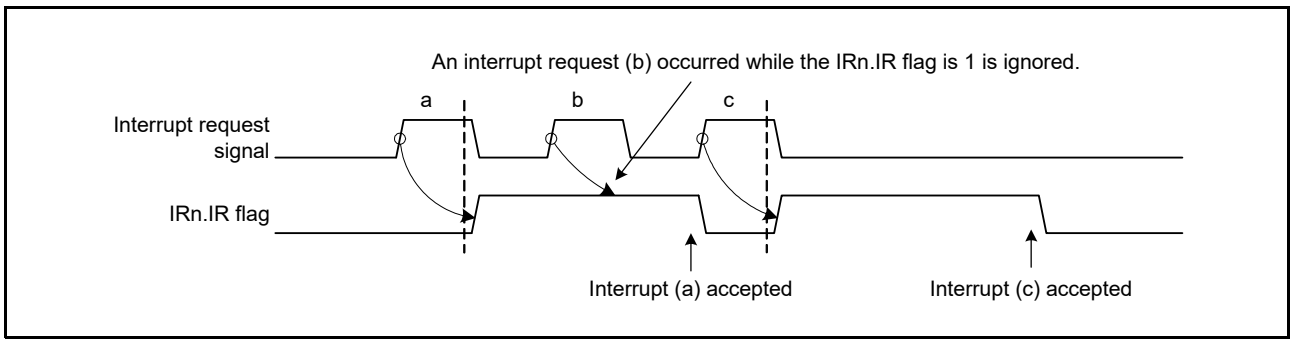

Figure 15.7 Timing to Set the IRn.IR Flag Again

(2) Relation between the IRn.IR flag and Interrupt Request Enable Bits

After the IRn.IR flag becomes 1, the IRn.IR flag does not become 0 even when an interrupt request enable bit in the corresponding peripheral module is set to 0.

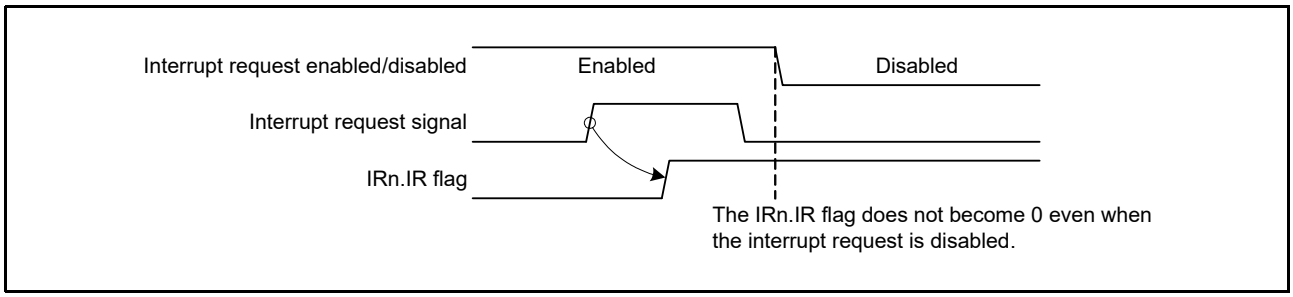

Figure 15.8 Relation Between Disabling the Interrupt Request and the IRn.IR Flag

15.5.2 Level Detection

Figure 15.9 shows operation of the interrupt request signal and the IRn.IR flag for level detection (n = 16 to 124). The IRn.IR flag is 1 while the interrupt request signal is 1. To set the IRn.IR flag to 0, set the corresponding interrupt request signal of the peripheral module to 0. Set the corresponding interrupt status flag of the peripheral module to 0 and wait for the time until the value is reflected in the IRn.IR flag before exiting the interrupt handler. Refer to (2) Notes on Writing to I/O Registers in section 5, I/O Registers for details on waiting for the reflection.

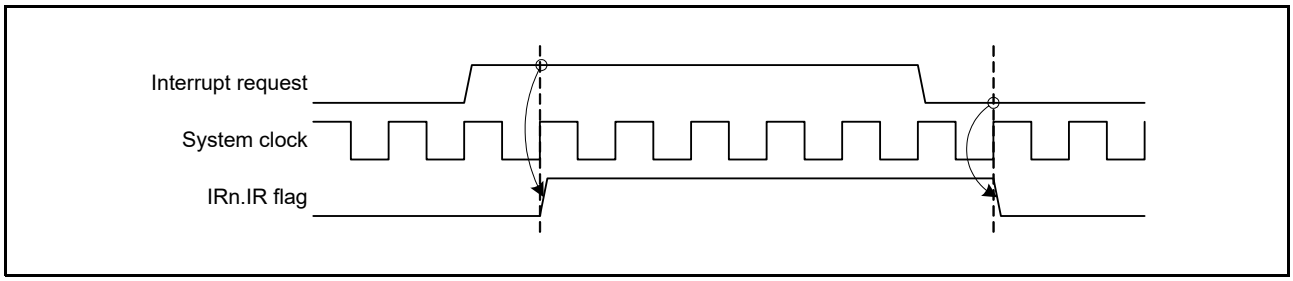

Figure 15.9 IRn.IR Flag Operation for Level Detection

Figure 15.10 shows an example of the procedure to handle interrupts for level detection.

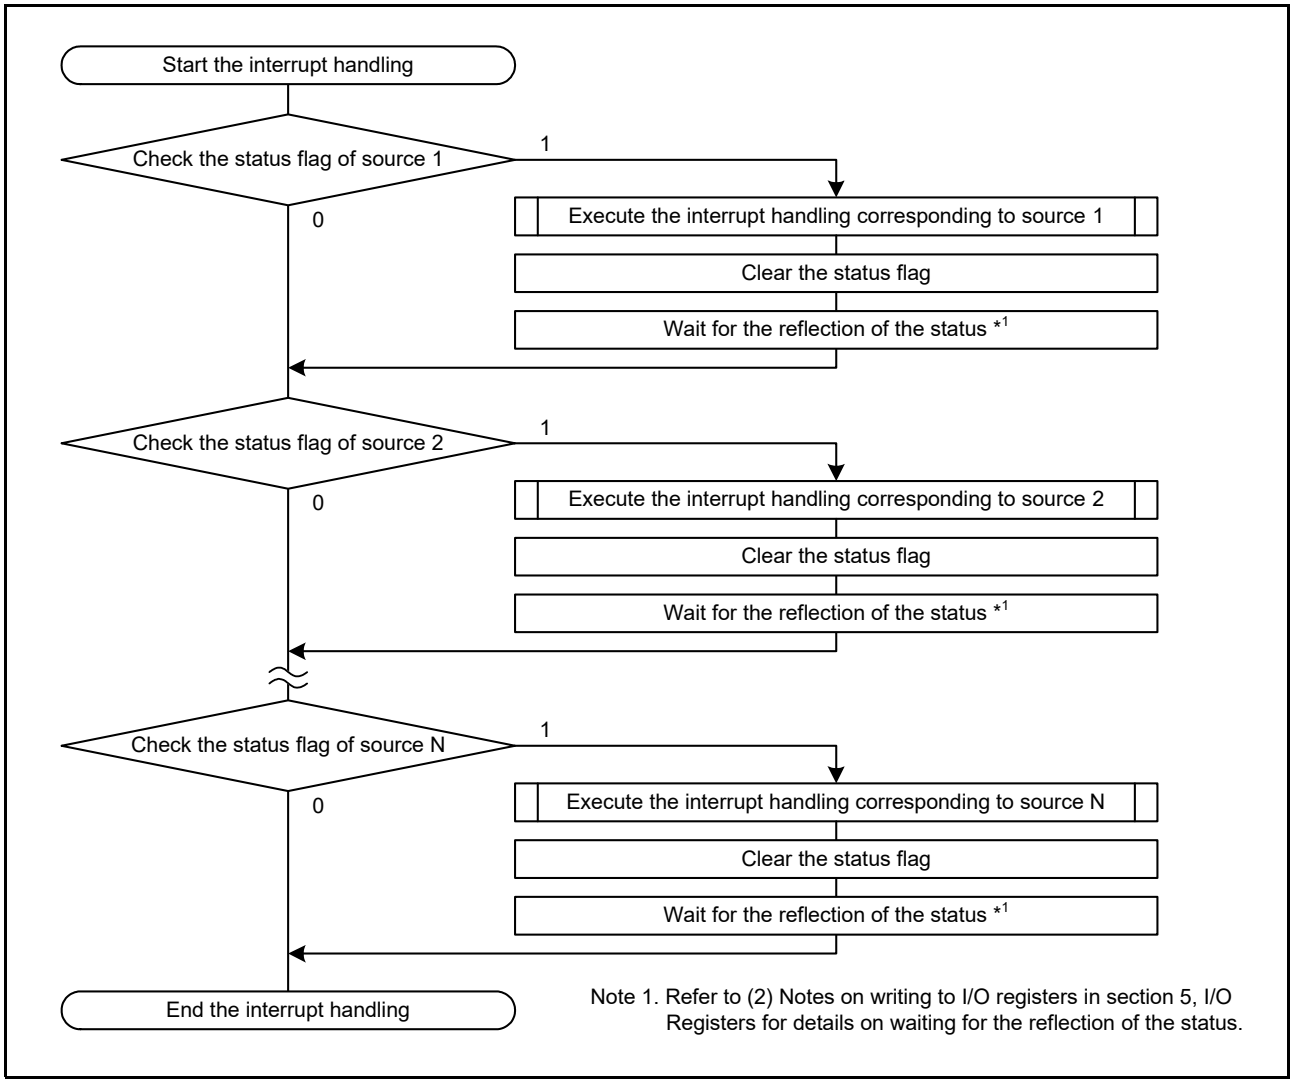

Figure 15.10 Example of Level Detection Interrupt Handling Procedure (N indicates the number of status flags)

15.5.3 Interrupt Detection for Group Interrupts

Groups IL0, IL1, BL0, BL1, and AL0 to AL6 includes interrupt sources that are detected by level detection.
The IR17.IR to IR20.IR, and IR102.IR to IR119.IR flags corresponding to the group interrupts change under the same conditions as level detection.
When an interrupt signal becomes 1 while the corresponding ENj bit in the GENIL0, GENIL1, GENBL0, GENBL1, or GENAL0 to GENAL6 register is 1, the ISj flag in the GRPIL0, GRPIL1, GRPBL0, GRPBL1, or GRPAL0 to GRPAL6 register and the IRn.IR flag become 1 (j = 0 to 31). Then, the ISj flag in the GRPIL0, GRPIL1, GRPBL0, GRPBL1, or GRPAL0 to GRPAL6 register and IRn.IR flag becomes 0 when the corresponding interrupt request signal becomes 0.
Also, when the ENj bit in the GENIL0, GENIL1, GENBL0, GENBL1, or GENAL0 to GENAL6 register is set to 0, the corresponding ISj flag in the GRPIL0, GRPIL1, GRPBL0, GRPBL1, or GRPAL0 to GRPAL6 register and IRn.IR flag become 0.
Figure 15.11 shows an operation example of group interrupts using level detection. Figure 15.12 shows an example of operation when interrupt requests are generated by multiple interrupt sources in the same group.

Note: • There is no register in the group to which no interrupt source is assigned.

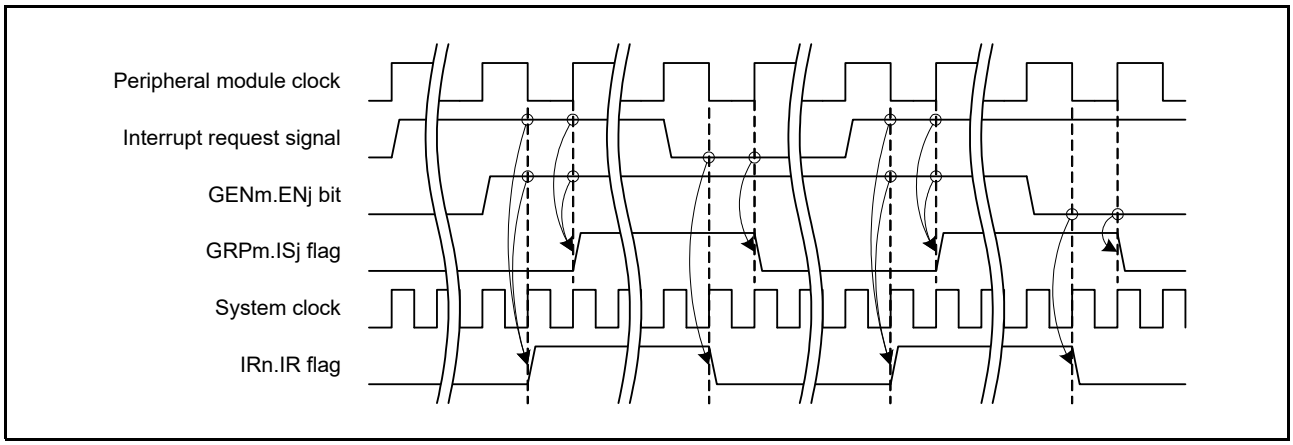

Figure 15.11 Operation Example of Group Interrupt Using Level Detection (m = IL0, IL1, BL0, BL1, and AL0 to AL6)

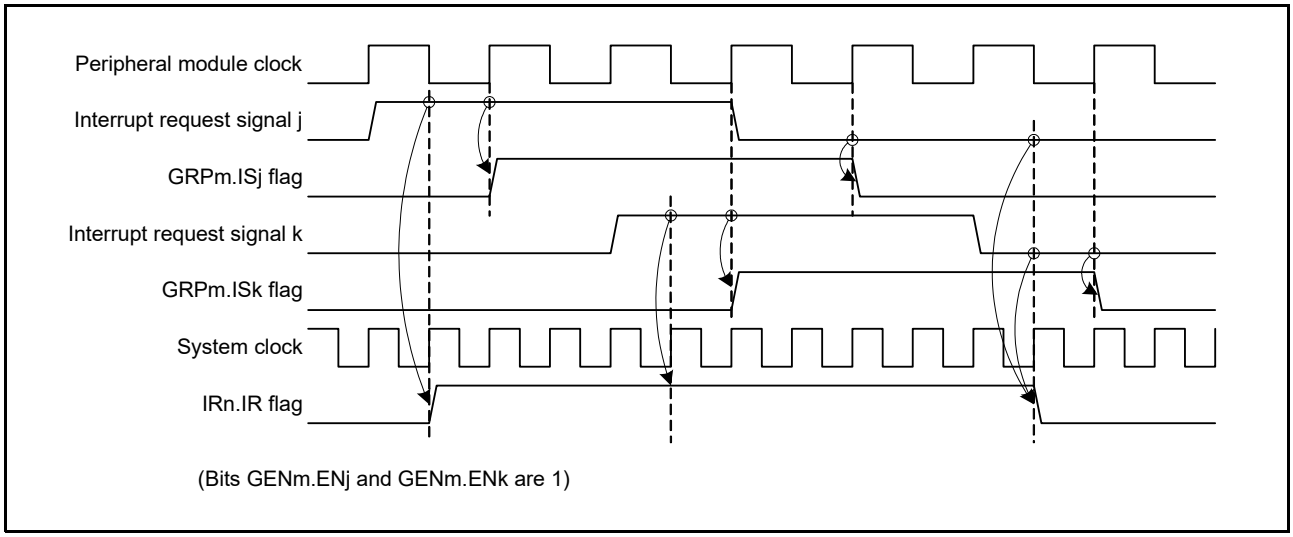

Figure 15.12 Operation Example When Multiple Interrupt Requests are Generated in the Same Group (m = IL0, IL1, BL0, BL1, and AL0 to AL6)

Figure 15.13 shows the procedure to handle group interrupts for level detection.

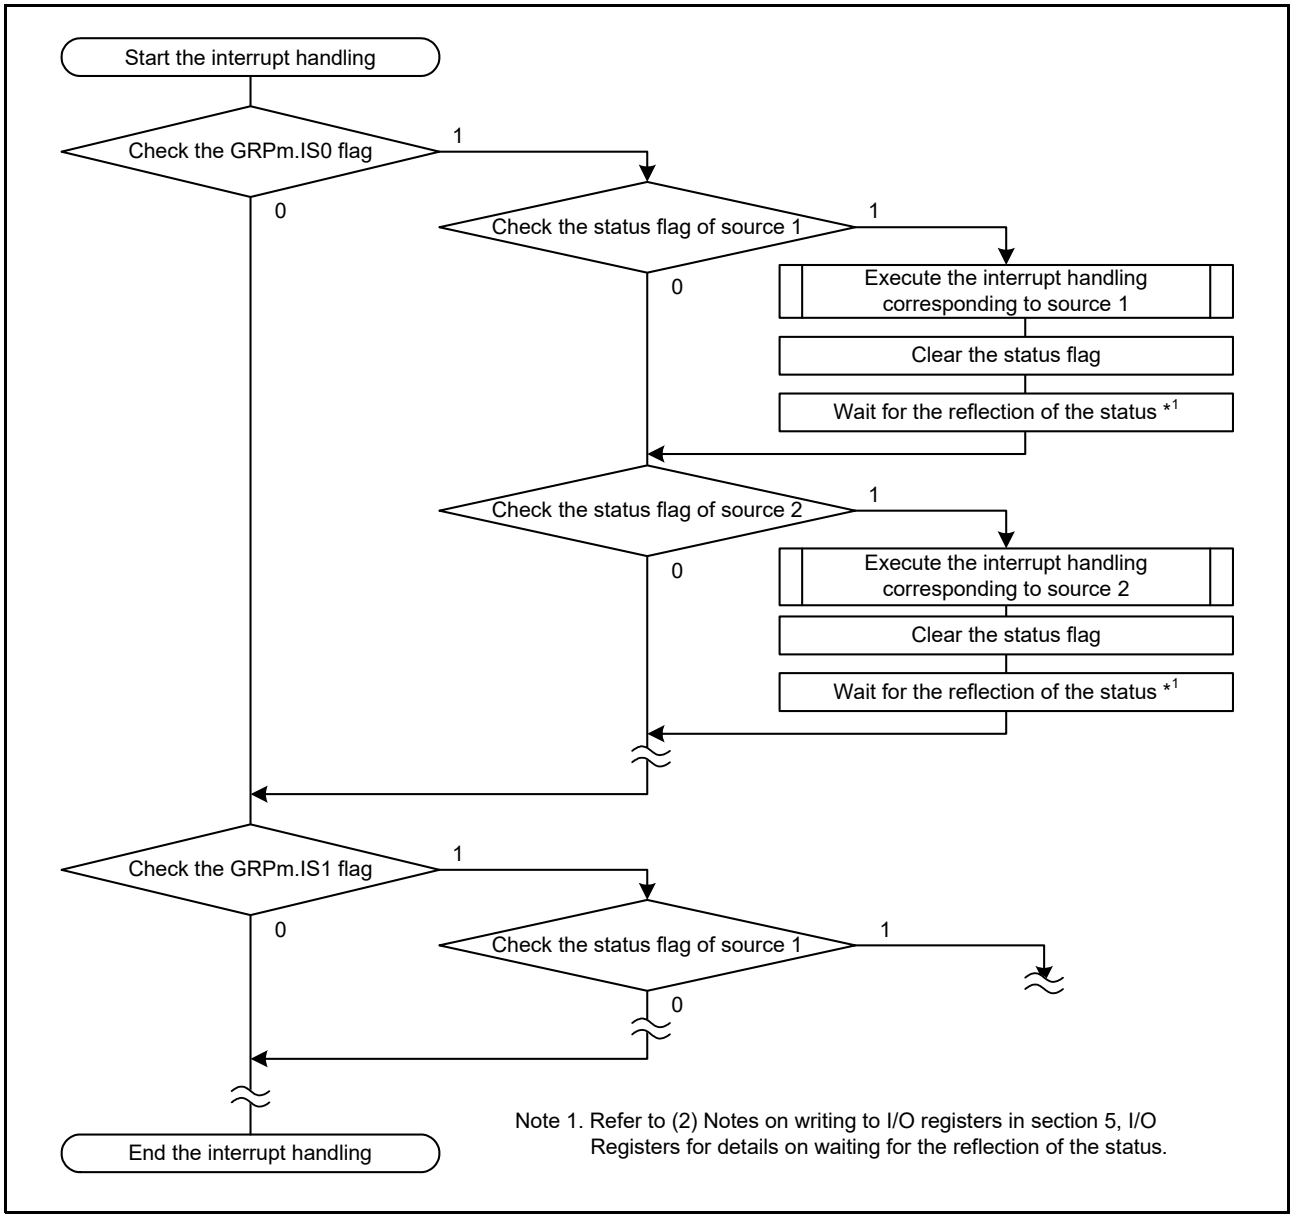

Figure 15.13 Example of Group Interrupt Handling Procedure for Level Detection (m = IL0, IL1, BL0, BL1, and AL0 to AL6)

15.5.4 Interrupt Detection for Software Configurable Interrupts

Interrupt sources and interrupt requests for software configurable interrupts are detected by edge detection.
Figure 15.14 shows an operation example of the interrupt request and interrupt status flag for software configurable interrupts.

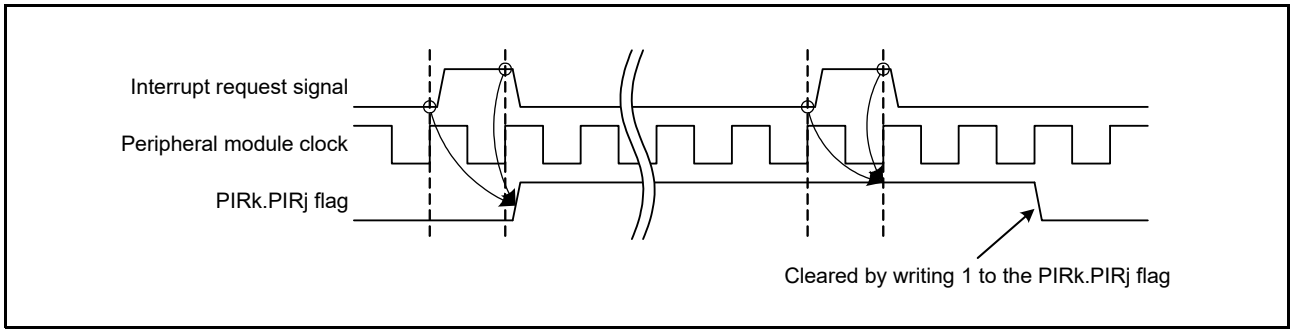

Figure 15.14 Operation Example of the Interrupt Request and Interrupt Status Flag for Software Configurable Interrupts

15.6 Determining Priority of Interrupt Requests

The ICU determines the priority for each interrupt request destination. The priority for each interrupt request destination is determined as follows.

(1) Determining Priority when the CPU is the Interrupt Request Destination

A source selected for the fast interrupt has the highest priority. Next to the fast interrupt, the priority is determined by the IPRr.IPR[4:0] bit value, and an interrupt source with a larger value has priority (r = 000 to 255). If multiple sources has the same IPRr.IPR[4:0] bit value, the priority is determined by the interrupt vector number, and the source with the smaller number has priority.

(2) Determining Priority when the DTC is the Interrupt Request Destination

The IPRr.IPR[4:0] bits have no effect (r = 000 to 255). The priority is determined by only the interrupt vector number, and an interrupt source with a smaller number has priority.

(3) Determining Priority when the DMAC is the Interrupt Request Destination

The IPRr.IPR[4:0] bits have no effect. The priority is determined by the DMAC channel number. Refer to section 18, DMA Controller (DMACAa) for details on the DMAC channel priority.

15.7 Interrupt Setting Procedure

15.7.1 Enabling Interrupt Requests

The following describes the procedure to enable interrupt requests.

(1) Set the interrupt request enable bit of the peripheral modules to enable output of the interrupt request.
(2) For group interrupts, set the corresponding ENj bit in the group interrupt request enable register to 1 to enable output of the interrupt request to the ISj flag in the group interrupt request register (j = 0 to 31).
(3) Set the corresponding IERm.IENj bit to 1 to enable output of the interrupt request to the interrupt request destination (m = 2 to 31; j = 0 to 7).

After the above procedure is completed, when a peripheral interrupt occurs, the IRn.IR flag corresponding to the interrupt source becomes 1 (n = 16 to 255).
For group interrupts, the ISj flag in the group interrupt request register becomes 1, the IRn.IR flag corresponding to the group becomes 1, and an interrupt request is output to the interrupt request destination.
When the IERm.IENj bit is 0, the interrupt request corresponding to the interrupt source is not output to the interrupt request destination.

15.7.2 Disabling Interrupt Requests

The following describes the procedure to disable interrupt requests.

(1) Set the corresponding IERm.IENj bit to 0 (m = 2 to 31; j = 0 to 7).
(2) For group interrupts, set the corresponding ENj bit in the group interrupt request enable register to 0 to disable output of the interrupt request to the ISj flag in the group interrupt request register (j = 0 to 31).
(3) Set the interrupt request enable bit of the peripheral modules to disable output of the interrupt request. Read the register that has been set to confirm that the value is reflected.
(4) As needed, read the IRn.IR flag or set the IR flag to 0.*1
For group interrupts, confirm that the ISj flag in the group interrupt request register is 0 or set the ISj flag to 0.

Note 1. When disabling the transmit interrupt request, receive interrupt request, or buffer access interrupt requests of the RSCI, RI3C, RIICHS, RSPIA, SSIE, SDHI, or PDC, set the IRn.IR flag to 0 according to the above procedure. Refer to the description of interrupts in the corresponding section of peripheral modules for details.

15.7.3 Selecting Interrupt Request Destination

15.7.3.1 Interrupt Request Destination Setting Procedure

The destination of an interrupt request can be selected from the CPU, DTC, or DMAC for each interrupt source. Destinations that can be selected differ depending on the interrupt source. Refer to Table 15.6, Interrupt Vector Table for details on the destinations. Do not select a destination that is not indicated as "✓" in Table 15.6.
When set the external pin interrupt as the DTC or DMAC trigger, set the IRQCRi.IRQMD[1:0] bits to select edge detection (i = 0 to 31).
The following describes the procedure to select a destination of an interrupt request.

(1) Setting Interrupt Sources as the DMAC trigger

Perform the following settings while the IERm.IENj bit is 0 of the interrupt source that is selected as the DMAC trigger (m = 2 to 31; j = 0 to 7).

(1) Set the interrupt vector number of the interrupt source used as the DMAC trigger in the DMRSRm register corresponding to the DMAC channel (m = DMAC channel number).*1
(2) Set the DMTMD.DCTG[1:0] bits corresponding to the DMAC channel to 01b in order to select the peripheral interrupt or external pin interrupt as the DMAC trigger.
(3) Set the DMCNT.DTE bit corresponding to the DMAC channel to 1.

After the above settings are completed, set the corresponding IERm.IENj bit to 1.
Also, set the DMAST.DMST bit to 1 before or after the above settings.
Refer to section 18.3.9, Activating the DMAC in section 18, DMA Controller (DMACAa) for the procedure to set the DMAC.

(2) Setting Interrupt Sources as the DTC trigger

Perform the following setting while the IERm.IENj bit of the interrupt source that is selected as the DTC trigger is 0.

(1) Set the DTCERn.DTCE bit corresponding to the interrupt vector number n used for the DTC trigger to 1 (n = 26 to 255).*1

After the above setting is completed, set the IERm.IENj bit to 1.
Also set the DTCST.DTCST bit to 1 before or after the above settings.
Refer to section 20.5, DTC Setting Procedure in section 20, Data Transfer Controller (DTCA) for the procedure to set the DTC.

Note 1. Do not set the same interrupt source as DTC and DMAC triggers. Also, do not set the same interrupt source as triggers of multiple DMAC channels.

(3) Setting Interrupt Sources for the CPU

When an interrupt source is not selected as the DTC or DMAC trigger, the interrupt request is output to the CPU.
Set the IERm.IENj bit to 1 while the interrupt source is not selected as a DTC or DMAC trigger.

15.7.3.2 Operations When the DTC/DMAC Selected

Table 15.10 lists operations when the DTC or DMAC is set as an interrupt request destination.

Table 15.10 Operations When Starting the DTC/DMAC

Interrupt Request Destination	DISEL *1	Number of Remaining Transfers	Operation per Request	IR Flag Clear Timing *2	Interrupt Request Destination after Transfer
DTC *3	1	≠ 0	DTC transfer → CPU interrupt	Cleared when the CPU accepts an interrupt request.	DTC
		= 0	DTC transfer → CPU interrupt	Cleared when the CPU accepts an interrupt request.	CPU (DTCERn.DTCE bit becomes 0)
	0	≠ 0	DTC transfer	Cleared when the DTC starts data transfer.	DTC
		= 0	DTC transfer → CPU interrupt *4	Cleared when the CPU accepts an interrupt request. *4	CPU (DTCERn.DTCE bit becomes 0)
DMAC	1	≠ 0	DMA transfer → CPU interrupt	Cleared when the CPU accepts an interrupt request.	DMAC
		= 0	DMA transfer → CPU interrupt	Cleared when the CPU accepts an interrupt request.	CPU (DMACm.DMCNT.DTE bit becomes 0)
	0	≠ 0	DMA transfer	Cleared when the DMAC starts data transfer.	DMAC
		= 0	DMA transfer *4	Cleared when the DMAC starts data transfer. *4	CPU (DMACm.DMCNT.DTE bit becomes 0)

Note 1. For the DTC, set the DTC.MRB.DISEL bit; For the DMAC, set the DMACm.DMCSL.DISEL bit.
Note 2. When the IRn.IR flag is 1, an interrupt request (DTC or DMA transfer request) that is generated again is ignored.
Note 3. For chain transfer, the DTC transfer continues until the chain transfer ends. After chain transfer ends, whether a CPU interrupt occurs, the IRn.IR flag clear timing, and the interrupt request destination differ depending on the DISEL bit value the number of remaining transfers. For the chain transfer, refer to Table 20.4, Chain Transfer Conditions in section 20, Data Transfer Controller (DTCA).
Note 4. When the DISEL bit is 0 and the number of remaining transfers is 0, operations in the DTC and DMAC are different.

15.7.3.3 Changing the Interrupt Request Destination

Set the IERm.IENj bit to 0 before changing the interrupt request destination (m = 2 to 31; j = 0 to 7).

(1) When the current interrupt request destination is the DMAC

To change interrupt request destinations or change the DMAC trigger to another interrupt source while the DMA transfer is not completed (DMCNT.DTE bit is not cleared) after the procedure described in (1) Setting Interrupt Sources as the DMAC trigger of section 15.7.3.1, Interrupt Request Destination Setting Procedure, follow the procedure below.

(1) Set the IERm.IENj bit of both the current and new triggers to 0.
(2) Check the DMAC transfer status. If transfer is not completed, wait until the completion of transfer.
(3) Perform the procedure described in 15.7.3.1 Interrupt Request Destination Setting Procedure.

(2) When the current interrupt request destination is the DTC

To change interrupt request destinations or change the DTC transfer information while the DTC transfer is not completed (the DTCERn.DTCE bit is not cleared) after the procedure described in (2) Setting Interrupt Sources as the DTC trigger of section 15.7.3.1, Interrupt Request Destination Setting Procedure, follow the procedure below (n = 26 to 255).

(1) Set the IERm.IENj bit of both the current and new triggers to 0 (m = 2 to 31; j = 0 to 7).
(2) Check the DTC transfer status. If transfer is not completed, wait until the completion of transfer.
(3) Perform the procedure described in 15.7.3.1 Interrupt Request Destination Setting Procedure.

15.7.4 Setting the External Pin Interrupt

The following describes the procedure to use the external pin interrupt.

(1) Set the IERm.IENj bit corresponding to the IRQi pin to 0 (interrupt request is disabled) (m = 2 to 31; j = 0 to 7; i = 0 to 31).
(2) Set the IRQCRi.FLTEN bit to 0 (digital noise filter is disabled).
(3) Set the IRQCRi.FCLKSEL[2:0] bits to select the sampling clock and FLTMD bit to select the operating mode of the digital noise filter.
(4) Set the I/O port and confirm the setting.
(5) Set the IRQCRi.IRQMD[1:0] bits to select the detection method.
(6) When edge detection is selected, set the corresponding IRn.IR flag to 0 (n = 16 to 255).
(7) Set the IRQCRi.FLTEN bit to 1 (digital noise filter is enabled).
(8) To select the DTC as the interrupt request destination, set the DTCERn.DTCE bit. To select the DMAC as the interrupt request destination, set the DMRSRm register. When neither the DTCERn.DTCE bit nor the DMRSRm register is set, the interrupt request is sent to the CPU (m = DMAC channel number; n = 26 to 255).
(9) Set the corresponding IERm.IENj bit to 1 (interrupt request is enabled).

15.7.5 Setting Non-Maskable Interrupts

After reset, non-maskable interrupts are disabled. To use non-maskable interrupts, follow the procedure below.

(1) Set the stack pointer (SP).
(2) When using the NMI pin, set the NMICR.NFLTEN bit to 0 (digital noise filter is disabled).
(3) When using the NMI pin, set the NMICR.NFCLKSEL[2:0] bits to select the sampling clock and NFLTMD bit to select the operating mode of the digital noise filter.
(4) When using the NMI pin, set the NMICR.NMIMD bit to select the edge for detection.
(5) When using the NMI pin, write 1 to the NMICLR.NMICLR bit to set the NMISR.NMIST flag to 0.
(6) When using the NMI pin, set the NMICR.NFLTEN bit to 1 (digital noise filter is enabled).
(7) To enable generation of the non-maskable interrupt, set the bit in the NMIER register corresponding to the used interrupt source to 1.

Once a bit in the NMIER register is set to 1 (enabled), the bit cannot be rewritten so it cannot be set to 0 (disabled). To disable a non-maskable interrupt that has been enabled, reset the MCU.
Refer to section 14, Exception Handling for details on the flow of non-maskable interrupt handling.
The NMIST, OSTST, SOSTST, PVD2ST, PVD1ST, WDTST, and IWDTST flags in the NMISR register become 0 by writing 1 to the corresponding bit in the NMICLR register.
Confirm that all flags in the NMISR register are 0 before exiting the interrupt handler of non-maskable interrupts.
Non-maskable interrupts, excluding the NMI pin interrupt, can be used as a maskable interrupt. When using as a maskable interrupt, do not change the NMIER register value from the value after reset. In addition, set the PVD1CR1.IRQSEL bit and PVD2CR1.IRQSEL bit to 1 when using voltage monitoring 1 interrupt and voltage monitoring 2 interrupt as a maskable interrupt.

15.7.6 Digital Noise Filter

Noise included in signals input to pins IRQi and NMI can be reduced by enabling the digital noise filter (i = 0 to 31). The digital noise filter samples signals input to pins using the sampling clock (PCLKB, PCLKB/4, PCLKB/8, PCLKB/16, PCLKB/32, PCLKB/64, or PCLKB/128) for the digital noise filter, and passes the input signal only when three or four consecutive sampled signals are the same level.

When using the digital noise filter for the IRQi pin, refer to section 15.7.4, Setting the External Pin Interrupt to set the associated registers. When using the digital noise filter for the NMI pin, refer to section 15.7.5, Setting Non-Maskable Interrupts to set the associated registers.

When the external pin interrupt or the NMI pin interrupt is used as a source to exit software standby mode, the digital noise filter cannot be used. Set the IRQCRi.FLTEN bit or NMICR.NFLTEN bit to 0 before entering software standby mode. To enable the digital noise filter again, set the IRQCRi.FLTEN bit or NMICR.NFLTEN bit to 1.

When changing the digital noise filter settings, also set the IRQCRi.FLTEN bit or NMICR.NFLTEN bit to 0.

Figure 15.15 shows an example of digital noise filter operation.

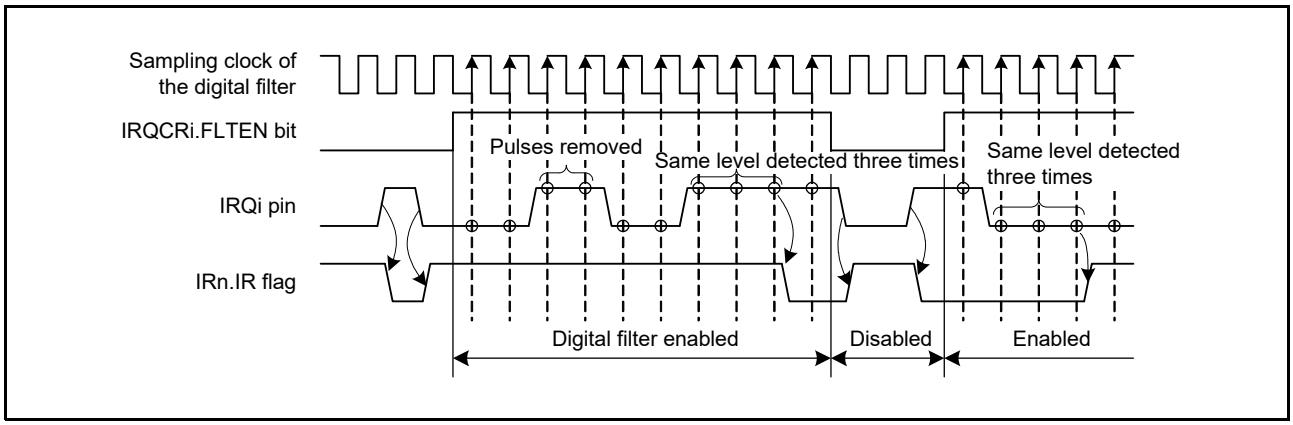

Figure 15.15 Digital Noise Filter Operation Example (when the IRQCRi.IRQMD[1:0] bits are 11b (low level))

15.7.7 Setting Software Configurable Interrupts

The following describes the procedure to assign interrupt sources to software configurable interrupts.

(1) Set the corresponding IERm.IENj bit to 0 (m = 2 to 31; j = 0 to 7). This setting is not required when the value does not change from the value after reset.
(2) Set the interrupt source number in the SLIXRn (n = 128 to 143) or SLIRn (n = 144 to 255) register. The source number for the external pin interrupt is 255. For the source numbers for other interrupts, refer to Table 15.3, Interrupt Sources for Software Configurable Interrupt.
(3) Set the SLIPRCR.WPRC or SLIPRCR_NS.WPRC bit to 1.*1
(4) Confirm that the WPRC bit set in (3) is 1.*1
(5) Select the interrupt request destination from the CPU, DTC, or DMAC. Refer to section 15.7.3.1, Interrupt Request Destination Setting Procedure for details on the setting procedure.
(6) Write 0 to the IRn.IR flag (n = 128 to 255).
(7) Set the IERm.IENj bit to 1.

Note 1. When not using write protection, this setting is not required.

15.7.7.1 Polling for Software Configurable Interrupts

When polling an interrupt request by reading the PIXRk.PIRj flag (k = 0, 1; j = 0 to 7) or the PIRk.PIRj flag (k = 0 to 127; j = 0 to 7), follow the procedure below.

(1) Set the external pin or peripheral interrupt used.
(2) Clear the PIXRk.PIRj*1 or PIRk.PIRj flag for polling by writing 1 to the flag.*2
(3) Enable output of the peripheral interrupt request.
(4) As needed, read the PIXRk.PIRj or PIRk.PIRj flag to check the value.
(5) When clearing the PIXRk.PIRj*1 or PIRk.PIRj flag, write 1 to the targeted flag.*2
(6) As needed, repeat step (4) and (5).

Note 1. Only when any of the edge detection is selected by IRQCRi.IRQMD[1:0] bits
Note 2. Do not use bit manipulation instructions. Multiple status flags may be cleared if a bit manipulation instruction is used. To clear a flag, write the PIRk register in 8-bit units as follows: set the flag that is to be cleared to 1 and set the other flags to 0.

15.8 Multiple Interrupt

To enable another interrupt while processing an interrupt (multiple interrupt), set the PSW.I bit to 1 (interrupt enabled) in the interrupt handler of an accepted interrupt.
The PSW.IPL[4:0] bits in the interrupt handler are the same value as the priority level of the accepted interrupt request. In this case, when an interrupt request with the higher priority level than the PSW.IPL[4:0] bit value is generated, the interrupt request is accepted.
The PSW.I bit can be rewritten only in supervisor mode. Since the PSW.PM bit becomes 0 (supervisor mode is selected) when an interrupt is accepted, the PSW.I bit can be rewritten in the interrupt handler.

15.9 Fast interrupt

The fast interrupt is an interrupt that the CPU can respond to fast. Only one interrupt source can be assigned to the fast interrupt. The fast interrupt can be used when the PRTZCR.PRTZC bit is 0.
The priority level of the fast interrupt is 31 (highest) regardless of the IPRr.IPR[4:0] bit setting (r = 000 to 255). Also, the fast interrupt has higher priority than the other interrupt sources of which the priority level is 31. Note that the fast interrupt cannot be accepted when the PSW.IPL[4:0] bits are 11111b (priority level 31).
To assign an interrupt source to the fast interrupt, set the FIR.FVCT[7:0] bits to select the vector number of the interrupt source, and set the FIR.FIEN bit to 1 (fast interrupt is enabled).
The fast interrupt is enabled only when the CPU is selected as the interrupt request destination. When the DTC or DMAC is selected as the destination, the fast interrupt is disabled.
Refer to section 2, CPU and section 14, Exception Handling for details on the fast interrupt.

15.10 Exiting Low Power Consumption State

Interrupts can be used for exiting sleep mode, deep sleep mode, and software standby mode.
Refer to section 11, Low Power Consumption for details. This section describes the procedure to set an interrupt source for exiting each low power consumption mode.
Refer to section 11.6.3, Deep Software Standby Mode for details on exiting deep software standby mode.

15.10.1 Exiting Sleep Mode or Deep Sleep Mode

Non-maskable interrupts and all interrupt sources can be used for exiting sleep mode. The following conditions must be satisfied.

(1) Non-maskable interrupts

- Generation of the interrupt that is used for exiting is enabled in the NMIER register.

(2) Interrupts

- The CPU is selected as the interrupt request destination.
- The interrupt request is enabled by the IERm.IENj bit (m = 2 to 31; j = 0 to 7).
- The priority level is higher than the PSW.IPL[4:0] bit value in the CPU.
- For group interrupts, the interrupt request is enabled by the corresponding ENj bit in the group interrupt request enable register (GENIL0, GENIL1, GENBL0, GENBL1, and GENAL0 to GENAL6) (j = 0 to 31).

15.10.2 Exiting Software Standby Mode

Non-maskable interrupts and interrupt sources that have a "✓" in the Exit from SSBY column in Table 15.6, Interrupt Vector Table can be used for exiting software standby mode. The conditions below must be satisfied.

(1) Non-maskable interrupts

- Generation of the interrupt that is used for exiting is enabled in the NMIER register.
- When using the NMI pin interrupt, the digital noise filter is disabled.

(2) Interrupts

- The interrupt source can be used for exiting software standby mode.
- The CPU is selected as the interrupt request destination.
- The interrupt request is enabled by the IERm.IENj bit (m = 2 to 31; j = 0 to 7).
- The priority level is higher than the PSW.IPL[4:0] bit value in the CPU.
  When using the fast interrupt, set not only the FIR register but also the corresponding IPRr.IPR[4:0] bits (r = 000 to 255). Set the IPRr.IPR[4:0] bits to a higher level than the PSW.IPL[4:0] bit value in the CPU.
- When using the external pin interrupt, the digital noise filter of the IRQi pin used is disabled.

Refer to section 15.7.6, Digital Noise Filter for details on the procedure to set the digital noise filter.

15.11 Usage Notes

15.11.1 Notes on the WAIT instruction When Using the Non-Maskable Interrupt

Confirm that all status flags in the NMISR register are 0 before executing the WAIT instruction.

15.11.2 Interrupt Requests in Software Standby Mode

When an interrupt request occurs in software standby mode but the interrupt source is not set as a source for exiting software standby mode, the request is held in the ICU. The request is handled after exiting by another interrupt source. Note that the interrupt request for the external pin interrupt is not held.

15.11.3 Notes on Bus Error during DTC/DMA Transfer

If a bus error occurs during DTC/DMA transfer, clear the corresponding IRn.IR flag by software. Also, set the corresponding DTCERn or DMRSRm register to 00h to prevent the same DTC/DMA transfer from being initiated again.

16. Buses

16.1 Overview

In this section, the EDMAC indicates the Ethernet CPU agent (GWCA) of the Ethernet module (ESWM), and SPI0M and SPI1M indicate XSPI0 and XSPI1 serving as target modules, respectively. Table 16.1 lists the bus specifications, Figure 16.1 shows the system bus configuration, and Table 16.3 lists the addresses assigned for each bus.

Table 16.1 Bus Specifications

Bus Master/Bus Slave	Sync clock	Description
Classification: Bus masters		
CPU0IFBI	CPUCLK0	Connected to the CPU0IF AHB Interface
CPU0OABI	CPUCLK0	Connected to the CPU0OA AHB Interface
DMAC/DTC0BI	ICLK	Connected to the DMAC/DTC0 Interface
EXDMACBI	ICLK	Connected to the EXDMAC Interface
EDMACBI	ICLK	Connected to EDMAC Interface
SPI0MBI	ICLK	Connected to the SPI0 Master (SPI0M) AXI Interface
SPI1MBI	ICLK	Connected to the SPI1 Master (SPI1M) AXI Interface
Classification: Bus slaves		
MRC0BI	MRICLK	Connected to the code MRAM bank 0 (MRC0)
MRC1BI	MRICLK	Connected to the code MRAM bank 1 (MRC1)
MRE0BI	MRPCLK	Connected to the extra MRAM
LRAM0BI	CPUCLK0	Connected to the LRAM0 AHB Interface
LRAM1BI	CPUCLK0	Connected to the LRAM1 AHB Interface
S0BI	ICLK	Connected to the SRAM0
S1BI	ICLK	Connected to the SRAM1
ECBI	BCLK	Connected to the external devices (External Memory Interface)
XSPI0BI	ICLK	Connected to the XSPI0 controller (External Memory Interface)
XSPI1BI	ICLK	Connected to the XSPI1 controller (External Memory Interface)
PBBI	PCLKB	Connected to peripheral modules synchronizes with PCLKB
PABI	PCLKA	Connected to peripheral modules synchronizes with PCLKA
PIBI	ICLK	Connected to peripheral modules synchronizes with ICLK
PS0BI	ICLK	Connected to ICU0 controller Connected to DMAC/DTC0 controller
PC0BI	CPUCLK0	Connected to peripheral system modules. (TFU, MPU, CPU controller, and CPU0-cache controller)
PSBI	ICLK	Connected to peripheral system modules. (CSC/SDRAM, SRAM, Bus controller, EXDMAC, and Security attribution controller)
	MRPCLK	Connected to peripheral system module. (MRAM controller)
	PCLKB	Connected to peripheral system module. (System controller)

Note: CPU0IFBI: CPU0 IF AHB interface
CPU0OABI: CPU0 OA AHB interface
DMAC/DTC0BI: DMAC/DTC0 bus interface
EXDMACBI: EXDMAC bus interface
EDMACBI: EDMAC bus interface
SPI0MBI: SPI0 master bus interface
SPI1MBI: SPI1 master bus interface
MRC0BI: MRC0 bus interface
MRC1BI: MRC1 bus interface
MRE0BI: MRE0 bus interface
LRAM0BI: LRAM0 AHB interface
LRAM1BI: LRAM1 AHB interface

S0BI: SRAM0 bus interface
S1BI: SRAM1 bus interface
ECBI: External memory CSC and SDRAM bus interface
XSPI0BI: External memory XSPI0 controller bus interface
XSPI1BI: External memory XSPI1 controller bus interface
PBBI: Peripheral bus interface synchronized with PCLKB
PABI: Peripheral bus interface synchronized with PCLKA
PIBI: Peripheral bus interface synchronized with ICLK
PS0BI: ICU0, DMAC/DTC0 controller bus interface
PC0BI: CPU peripheral system bus interface
PSBI: Peripheral system bus interface

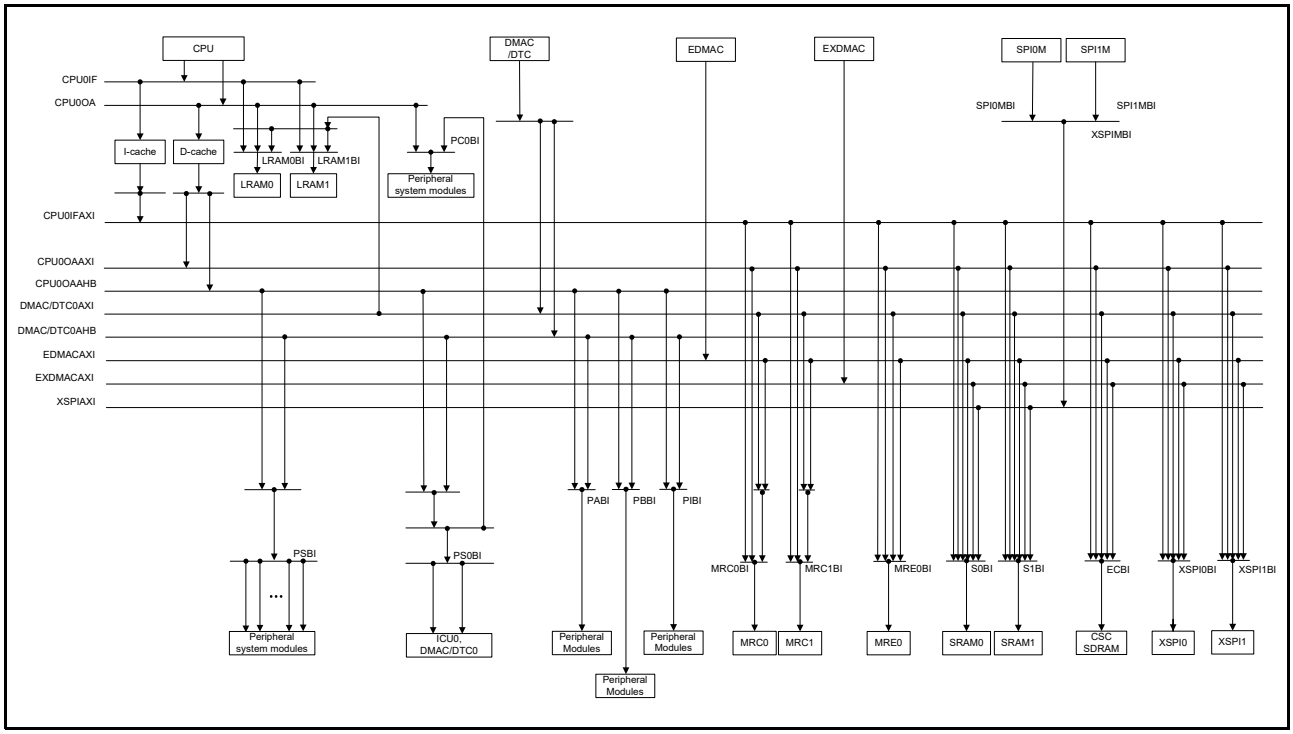

Figure 16.1 System Bus Connection

Table 16.2 System Bus Access Path

		Master					
	Name	**CPU0IFBI*1**	**CPU0OABI**	**DMAC/DTC0BI**	**EXDMACBI**	**EDMACBI**	**SPI0MBI/SPI1MBI**

	XSPI0BI/XSPI1BI	T	T	T	T	T	F

T : The Master can access slaves
F : The master cannot access slaves
Note 1. CPU0IFBI is read-only master
Note 2. Read-only

Table 16.3 Address Assigned to Each Slave

Address	Bus Interface	Area
0000 0000h to 0001 FFFFh (Non-secure) 8000 0000h to 8001 FFFFh (Secure)	LRAM0BI	LRAM0 (Area when accessed by the CPU)
0002 0000h to 0003 FFFFh (Non-secure) 8002 0000h to 8003 FFFFh (Secure)	LRAM1BI	LRAM1 (Area when accessed by the CPU)
0100 0000h to 010F FFFFh (Non-secure) 8100 0000h to 810F FFFFh (Secure)	PC0BI	TFU, CPU0-cache, LRAM, MPU controller
0200 0000h to 020F FFFFh (Non-secure) 8200 0000h to 820F FFFFh (Secure)	SRAM0BI	SRAM0
0210 0000h to 0217 FFFFh (Non-secure) 8210 0000h to 8217 FFFFh (Secure)	SRAM1BI	SRAM1
0280 0000h to 0281 FFFFh (Non-secure) 8280 0000h to 8281 FFFFh (Secure)	LRAM0BI	LRAM0 (Area when accessed by a bus master other than the CPU)
0282 0000h to 0283 FFFFh (Non-secure) 8282 0000h to 8283 FFFFh (Secure)	LRAM1BI	LRAM1 (Area when accessed by a bus master other than the CPU)
0600 0000h to 06FF FFFFh (Non-secure) 8600 0000h to 86FF FFFFh (Secure)	MRE0BI	MRE0
0700 0000h to 0700 FFFFh (Non-secure) 8700 0000h to 8700 FFFFh (Secure)	PS0BI	ICU0, DMAC0, DTC0
0701 0000h to 070F FFFFh (Non-secure) 8701 0000h to 870F FFFFh (Secure)	PSBI	System controller, MRAM, CPSCU, BUS, EXBUS, EXDMAC, SRAM controller
0740 0000h to 077F FFFFh (Non-secure) 8740 0000h to 877F FFFFh (Secure)	PABI	Peripheral modules synchronized to PCLKA
0780 0000h to 07BF FFFFh (Non-secure) 8780 0000h to 87BF FFFFh (Secure)	PBBI	Peripheral modules synchronized to PCLKB
07C0 0000h to 07FF FFFFh (Non-secure) 87C0 0000h to 87FF FFFFh (Secure)	PIBI	Peripheral modules synchronized to ICLK
2000 0000h to 3FFF FFFFh (Non-secure)	XSPI0BI	XSPI0 controller
4000 0000h to 5FFF FFFFh (Non-secure)	XSPI1BI	XSPI1 controller
7000 0000h to 77FF FFFFh (Non-secure)	ECBI	SDRAM controller
7800 0000h to 7EFF FFFFh (Non-secure)	ECBI	CS1 to CS7 controller
7F00 0000h to 7FFF FFFFh (Non-secure)*1 FF00 0000h to FFFF FFFFh (Secure)	MRC0BI/MRC1BI	MRC0/MRC1
7F00 0000h to 7FFF FFFFh (Non-secure)*2	ECBI	CS0 controller

Note 1. MRAM (MRC0/MRC1) is not allocated when the on-chip code MRAM is disabled.
Note 2. CS0 is allocated when the on-chip code MRAM is disabled.

16.2 Description of Buses

16.2.1 Arbitration

Except for PC0BI, LRAM0BI, LRAM1BI, and XSPIMBI, for arbitration between masters, fixed-priority and round-robin methods can be selected. For details, refer to section 16.3.27, Bus Slave Arbitration Control Register 0 (BUSSABT0MRE0BI, BUSSABT0S0BI, BUSSABT0S1BI, BUSSABT0ECBI, BUSSABT0XSPI0BI, BUSSABT0XSPI1BI, BUSSABT0PBBI, BUSSABT0PABI, BUSSABT0PIBI, BUSSABT0PSBI, BUSSABT0PS0BI), and section 16.3.28, Bus Slave Arbitration Control Register 1 (BUSSABT1MRC0BI, BUSSABT1MRC1BI).
Table 16.4 lists the priority of PC0BI, LRAM0BI, LRAM1BI, and XSPIMBI.

Table 16.4 Priority of PC0BI, LRAM0BI, LRAM1BI, and XSPIMBI

Bus Interface	Priority*1
PC0BI	CPU0OA <-> (CPU0OAAHB or DMAC0)
LRAM0BI	CPU0OA > CPU0IF > DMAC0
LRAM1BI	CPU0OA > CPU0IF > DMAC0
XSPIMBI	SPI0M > SPI1M

Note 1. > : Indicates that the left side has higher priority.
<-> : Indicates round-robin.

16.2.2 External Bus

The external bus controller arbitrates bus access requests in the external address space from CPU0IFBI, CPU0OABI, DMAC/DTC0BI, EXDMACBI, SPI0MBI, SPI1MBI, and EDMACBI. For details about the priority and arbitration method for each master, refer to section 16.2.1, Arbitration.
The bus system provides an external space for XSPI (XSPI0BI/XSPI1BI). For details, refer to section 48, Expanded Serial Peripheral Interface (XSPI).
Table 16.5 lists the external bus specifications and Table 16.6 lists the input/output pins.
The external bus controller transfers data between the AXI master and the external bus via a FIFO.
For external address space accesses, the FIFO captures the bus access request and releases the internal bus before the external bus access is completed, allowing the internal bus to begin the next bus access. However, if the FIFO is full and the next access is an access to external address space, it will wait until the previous external bus operation is completed. Figure 16.2 shows an example of operation when the FIFO function is used. When this function is used, if the next operation after access to an external device is to access a peripheral module, the peripheral module access is executed in parallel without waiting for the completion of the external device access.

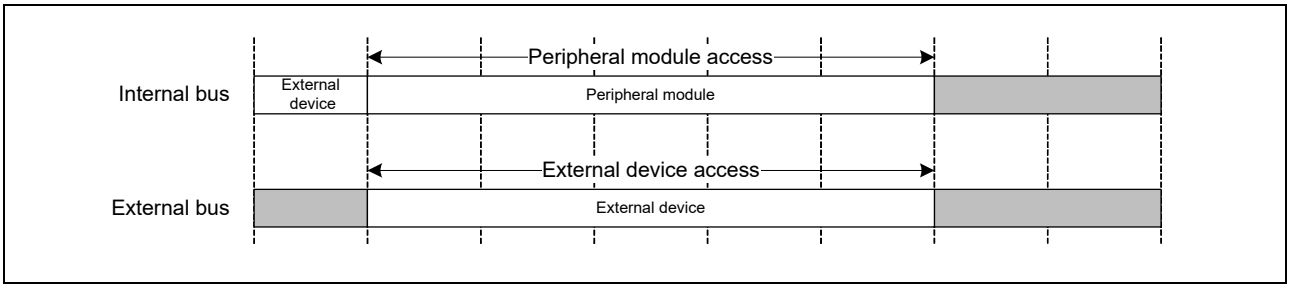

Figure 16.2 Example operation when using the FIFO function

Table 16.5 Specifications of the External Bus

Parameter	Description
External address space	• An external address space is divided into eight CS areas (CS0 to CS7) and the SDRAM area (SDCS) for management. • Chip select signals can be output for each area. • Bus width can be set for each area. Separate bus: An 8, 16, or 32-bit bus space is selectable. Address/data multiplexed bus: An 8 or 16-bit bus space is selectable. • Endian mode can be specified for each area. • Big endian mode has the following restrictions. See section 16.2.5.1, Restriction on Endian.
CS area controller	• Recovery cycles can be inserted. Read recovery: Up to 15 cycles Write recovery: Up to 15 cycles • Cycle wait function: Wait for up to 31 cycles (page access: up to 7 cycles) • Wait control can be used to set up the following. Timing of assertion and negation for chip-select signals (CS0# to CS7#) The timing of assertion of the read signal (RD#) and write signals (WR0#/WR# to WR3#) The timing with which data output starts and ends • Write access mode: Single write strobe mode/byte strobe mode Separate bus or address/data multiplexed bus can be set for each area.
SDRAM area controller	• Multiplexing output of row address/column address (8, 9, 10, or 11 bits) • Self-refresh and auto-refresh selectable • CAS latency can be specified from one to three cycles
FIFO	FIFO stages : 16 for read data / write data
Frequency	• The CS area controller (CSC) operates in synchronization with the external bus clock (BCLK)*1 • The frequency of the EBCLK pin output is the same as BCLK by default. Half of the BCLK cycles can be supplied by setting the EBCLK Pin Output Select bit, BCKCR.BCLKDIV, in the External Bus Clock Control Register. For more information, see section 9, Clock Generation Circuit. • The SDRAM area controller (SDRAMC) operates in synchronization with the SDRAM clock (SDCLK).*1

Note 1. The EBCLK and the SDCLK should be operated with the same frequency when the SDRAM is in use.

Table 16.6 Pin Configuration of the External Bus (1/2)

Pin Name	I/O	Related Functions	Description
EBCLK, SDCLK*1	Output	CSC, SDRAMC	Clock output pins
A23 to A0*2	Output	CSC, SDRAMC	Address output pins
D31 to D0	I/O	CSC, SDRAMC	Data input/output pins • D31 to D0 pins are enabled when the 32-bit bus space is specified. • D15 to D0 pins are enabled when the 16-bit bus space is specified. • D7 to D0 pins are enabled when the 8-bit bus space is specified.
BC0#	Output	CSC	• A strobe signal; (the BC0# signal being at the low level) during access to an external address space in single write strobe mode indicates that D7 to D0 are valid, active-low. • When an 8-bit bus space is specified, this output pin is always held low regardless of write access mode.
BC1#	Output	CSC	• A strobe signal; (the BC1# signal being at the low level) during access to an external address space in single write strobe mode indicates that D15 to D8 are valid, active-low. • This pin is not used when the 8-bit bus space is specified.
BC2#	Output	CSC	• A strobe signal; (the BC2# signal being at the low level) during access to an external address space in single write strobe mode indicates that D23 to D16 are valid, active-low. • This pin is not used when the 8- or 16-bit bus space is specified.
BC3#	Output	CSC	• A strobe signal; (the BC3# signal being at the low level) during access to an external address space in single write strobe mode indicates that D31 to D24 are valid, active-low. • This pin is not used when the 8- or 16-bit bus space is specified.
CS0#*3	Output	CSC	A chip select signal for area 0 (CS0), active-low
CS1#*3	Output	CSC	A chip select signal for area 1 (CS1), active-low
CS2#*3	Output	CSC	A chip select signal for area 2 (CS2), active-low
CS3#*3	Output	CSC	A chip select signal for area 3 (CS3), active-low
CS4#	Output	CSC	A chip select signal for area 4 (CS4), active-low
CS5#	Output	CSC	A chip select signal for area 5 (CS5), active-low
CS6#	Output	CSC	A chip select signal for area 6 (CS6), active-low
CS7#	Output	CSC	A chip select signal for area 7 (CS7), active-low
RD#	Output	CSC	A strobe signal indicating that reading from an external address space (CS0 to CS7) is in progress, active-low.
WR0#/WR#*4	Output	CSC	• WR0# signal is a strobe signal indicates that (the WR0# signal being at the low level) writing to an external address space is in progress in byte strobe mode, and D7 to D0 are valid, active-low. • WR# signal is a strobe signal that indicates writing to an external address space is in progress in single write strobe mode, active-low. • When an 8-bit bus space is specified, this output pin is held low during a write access regardless of write access mode.
WR1#	Output	CSC	• A strobe signal; (the WR1# signal being at the low level) during writing to an external address space in byte strobe mode indicates that D15 to D8 are valid, active-low. • This signal is invalid in single write strobe mode. • This pin is not used when the 8-bit bus space is specified.
WR2#	Output	CSC	• A strobe signal; (the WR2# signal being at the low level) during writing to an external address space in byte strobe mode indicates that D23 to D16 are valid, active-low. • This signal is invalid in single write strobe mode. • This pin is not used when the 8- or 16-bit bus space is specified.

Table 16.6 Pin Configuration of the External Bus (2/2)

Pin Name	I/O	Related Functions	Description
WR3#	Output	CSC	• A strobe signal; (the WR3# signal being at the low level) during writing to an external address space in byte strobe mode indicates that D31 to D24 are valid, active-low. • This signal is invalid in single write strobe mode. • This pin is not used when the 8- or 16-bit bus space is specified.
ALE	Output	CSC	Address latch signal when address/data multiplexed bus is selected.
WAIT#	Input	CSC	A wait request signal when accessing the external address space (CS0 to CS7), active-low.
BREQ#	Input	CSC/SDRAM	External bus hold request, active-low
BACK#	Output	CSC/SDRAM	External bus hold accepted, active-low
CKE	Output	SDRAMC	SDRAM clock enable signal
SDCS#	Output	SDRAMC	SDRAM chip select signal, active-low.
RAS#	Output	SDRAMC	SDRAM low address strobe signal, active-low.
CAS#	Output	SDRAMC	SDRAM column address strobe signal, active-low.
WE#	Output	SDRAMC	SDRAM write enable signal, active-low.
DQM0	Output	SDRAMC	SDRAM I/O data mask enable signal for D7 to D0
DQM1	Output	SDRAMC	SDRAM I/O data mask enable signal for D15 to D8
DQM2	Output	SDRAMC	SDRAM I/O data mask enable signal for D23 to D16
DQM3	Output	SDRAMC	SDRAM I/O data mask enable signal for D31 to D24

Note 1. The EBCLK and SDCLK pin functions are shared by the CS region controller (CSC) and the SDRAM region controller (SDRAMC).
When using the CSC and the SDRAMC simultaneously, the SDCLK pin function is valid.

Note 2. The A23 to A0 pin functions are shared by the CSC and the SDRAMC.
When using the CSC only:
The A0 and BC0# pin functions share the same pin, and either becomes valid according to the area, with the function being A0 in byte strobe mode and BC0# in single-write strobe mode.
Setting the 8-bit external bus width is prohibited in single-write strobe mode.
When using the SDRAMC only:
The A15 to A0 pin functions are valid.
The A0 and DQM1 pin functions share the same pin, and either pin function becomes valid according to the external bus width. When selecting 8-bit bus width, the pin function is A0. When selecting 16-bit bus width, the pin function is DQM1.
When using the CSC and the SDRAMC simultaneously:
The A23 to A16 pin functions are valid for CSC. The A15 to A0 pin functions are shared by the CSC and the SDRAMC. In the SDRAMC functions, the A0 and the DQM1 pin functions work as described.
In the CSC functions, the A0 and the BC0# pin function works as described.

Note 3. The CS0# to CS3# (CSC) and SDRAMC pin functions share the same pin. When using the CSC and the SDRAMC simultaneously, the CS0# to CS3# pin functions are invalid.

Note 4. The WR0# signal and WR# signal are identical. The WR0# signal is referred to as WR# in single-write strobe mode.

16.2.3 Parallel Operation

Parallel operation is possible when different bus-master modules are requesting access to different slave modules. For example, if the CPU is fetching an instruction from code MRAM, the DMAC is able to handle transfer between a peripheral module and the external memory interface at the same time.
Figure 16.3 shows an example of parallel operations. In this example, the CPU uses CPUMAXIBI to access MRC0BI. Furthermore, the DMAC/DTC simultaneously accesses the peripheral bus or the external bus during access to MRC0BI by the CPU.

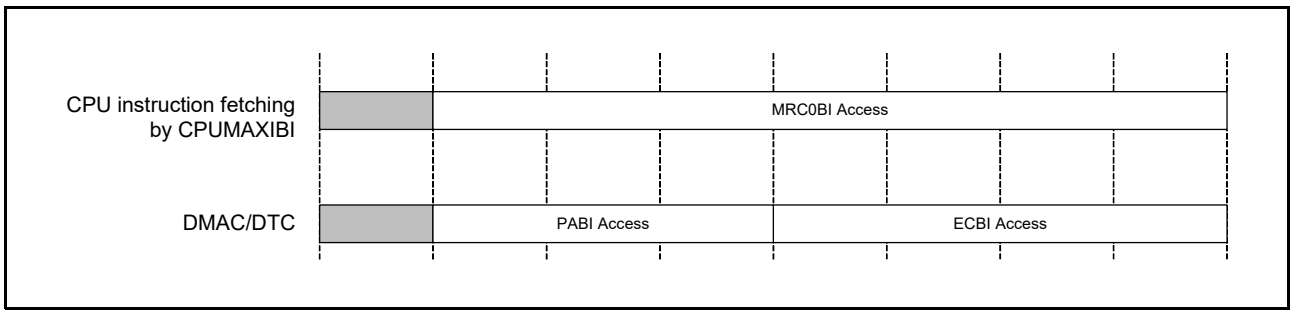

Figure 16.3 Example of Parallel Operations

16.2.4 Bus Settings

Set up the external bus with the following registers.

- Mode settings :
  CSn Mode Register (CSnMOD)
  CSn Wait Control Register 1 (CSnWCR1)
  CSn Wait Control Register 2 (CSnWCR2)
  CSn Control Register (CSnCR)
  CSn Recovery Cycle Setting Register (CSnREC)
  CS Recovery Cycle Insertion Enable Register (CSRECEN)
- I/O port assignments :
  PmnPFS.PMR = 1 and PmnPFS.PSEL[6:0] = 3Dh or 3Eh
- Frequency of the external bus clock (BCLK) and SDRAM clock (SDCLK) :
  SCKDIVCR register.

For details on PmnPFS, refer to section 22, I/O Ports. For details on SCKDIVCR, refer to section 9, Clock Generation Circuit.

16.2.5 Restrictions

16.2.5.1 Restriction on Endian

The following restrictions apply to areas where the endian setting for each area is different from that for the chip:

- No instruction code can be allocated in the area. The instruction code should be allocated to the external space whose endian setting is the same as that for the chip.
- When allocating data to be handled by the RMPA instruction or a string-manipulation instruction to an external space, be sure to allocate the data to an area with the same endian as that set for the chip. Also, do not allocate data to be handled by the RMPA instruction or a string-manipulation instruction to an I/O register.
- Set the endian for the area not to be cached. If data in an area that differs from the endian setting of the chip is registered in the cache, it will not operate properly. For information on caching settings, see section 17, Memory-Protection Unit (MPU).
- 64-bit access is not possible. When performing 64-bit access from a master other than CPU0IF, access an area whose endian setting is the same as that for the chip.
- Unaligned access is not possible. When performing unaligned access, access an area whose endian setting is the same as that for the chip.
- Do not access from EDMAC.

In addition, an XSPI is fixed to little endian. Accordingly, if the chip is set as big endian, data cannot be written correctly in unaligned access.

16.2.5.2 Bufferable Write

In bufferable writes, as shown below, the write response does not return from the endpoint of the write access, but from an intermediate point on the bus.

1. CPU0OA accesses any area.
2. DMAC0 accesses PABI, PBBI, PIBI, PSBI, PS0BI, PC0BI, LRAM0BI, and LRAM1IB.

If an access violation occurs due to a bufferable write, no error response is returned to the bus master, but an interrupt or reset request is issued depending on the setting of the BUSOAD register. For details, refer to 16.8.2 Operations When a Bus Error Occurs.

16.2.5.3 Notes on the Timing of Writing Completion

In writing to the MRC0BI or MRC1BI, regardless of whether the write operation is or is not bufferable, the write response is returned from the write buffer for use with the MRAM, not from the MRAM itself.
In writing to the ECBI, regardless of whether the write operation is or is not bufferable, the write response is returned from the CS area controller (CSC) or the SDRAM area controller (SDRAMC) when writing to a CS area or SDRAM starts.

16.3 Register Descriptions

16.3.1 Bus Security Attribution Register A (BUSSARA)

Address(es): CPSCU.BUSSARA 8701 8100h,
CPSCU_NS.BUSSARA 0701 8100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BUSSA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BUSSA0	Bus Security Attribution A0	0: Secure 1: Non-secure	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

BUSSA0 Bit (Bus Security Attribution A0)

This bit specifies the security attributes for arbitration and throughput control register. The target registers are as follows:

- BUSSABT0MRE0BI, BUSSABT0S0BI, BUSSABT0S1BI, BUSSABT0ECBI, BUSSABT0XSPI0BI, BUSSABT0XSPI1BI, BUSSABT0PBBI, BUSSABT0PABI, BUSSABT0PIBI, BUSSABT0PSBI, BUSSABT0PS0BI, BUSSABT1MRC0BI, BUSSABT1MRC1BI

16.3.2 Bus Security Attribution Register B (BUSSARB)

Address(es): CPSCU.BUSSARB 8701 8104h,
CPSCU_NS.BUSSARB 0701 8104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BUSSB0	Bus Security Attribution B0	0: Secure 1: Non-secure	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

BUSSB0 Bit (Bus Security Attribution B0)

This bit specifies the security attributes of registers related to bus errors. The target registers are as follows:

- BUSERRCLRx, MBWERRCLR, BUSOAD, BUSOADPT, BUSINTENx
  x = CPU0IF, CPU0OA, DMAC0, EXDMAC, EDMAC, XSPI0, XSPI1

16.3.3 Bus Security Attribution Register C (BUSSARC)

Address(es): CPSCU.BUSSARC 8701 8110h,
CPSCU_NS.BUSSARC 0701 8110h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BUSSC0	Bus Security Attribution C0	0: Secure 1: Non-secure	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

BUSSC0 Bit (Bus Security Attribution C0)

This bit specifies the security attribute of the bus (SDRAMC/CSC) control register. The target registers are as follows:

- CSnCR (n = 0 to 7), CSnREC (n = 0 to 7), CSRECEN, CSnMOD (n = 0 to 7), CSnWCR1 (n = 0 to 7), CSnWCR2 (n = 0 to 7), SDCCR, SDCMOD, SDAMOD, SDSELF, SDRFCR, SDRFEN, SDICR, SDIR, SDADR, SDTR, SDMOD, SDSR, EXBERR, EXBEREN, EXBECLR, EXBAD, EXHLDEN

16.3.4 CSn Control Register (CSnCR) (n = 0 to 7)

Address(es): BUS.CS0CR 8701 D802h,
BUS_NS.CS0CR 0701 D802h

Address(es): BUS.CS1CR 8701 D812h, BUS.CS2CR 8701 D822h, BUS.CS3CR 8701 D832h, BUS.CS4CR 8701 D842h, BUS.CS5CR 8701 D852h, BUS.CS6CR 8701 D862h, BUS.CS7CR 8701 D872h,
BUS_NS.CS1CR 0701 D812h, BUS_NS.CS2CR 0701 D822h, BUS_NS.CS3CR 0701 D832h, BUS_NS.CS4CR 0701 D842h, BUS_NS.CS5CR 0701 D852h, BUS_NS.CS6CR 0701 D862h, BUS_NS.CS7CR 0701 D872h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	MPXEN	—	—	—	EMODE	—	—	BSIZE[1:0]		—	—	—	EXENB
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	EXENB	Operation Enable	0: Operation is disabled 1: Operation is enabled	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5, b4	BSIZE[1:0]	External Bus Width Select	b5 b4 0 0: A 16-bit bus space is selected 0 1: A 32-bit bus space is selected 1 0: An 8-bit bus space is selected 1 1: Setting prohibited	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	EMODE	Endian Mode	0: Endian of area n is the same as the endian of operating mode. 1: Endian of area n is not the endian of operating mode.	R/W
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	MPXEN	Address/Data Multiplexed I/O Interface Select	0: Separate bus interface is selected for area n. 1: Address/data multiplexed I/O interface is selected for area n.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the CSnCR register while access to the CSn area is in progress.

EXENB Bit (Operation Enable)

This bit enables operation of the associated CS area. On MCU reset, operation is enabled (EXENB = 1) only for area 0. Operation in other areas is disabled (EXENB = 0). Attempts to access disabled areas have no effect.
When the CSC and SDRAMC are in use at the same time, EBCLK and SDCLK must operate at the same frequency.

BSIZE[1:0] Bits (External Bus Width Select)

These bits specify the data bus width of each area.
The data bus width of area 0 (CS0) after a reset depends on the setting of the bus width in operating mode.
When the address/data multiplexed I/O interface is selected with the MPXEN bit, setting other than 8- and 16-bit bus spaces is prohibited. If set, the operation cannot be guaranteed.

EMODE Bit (Endian Mode)

This bit specifies the endian of each area. For details, refer to section 16.2.5.1, Restriction on Endian.

MPXEN Bit (Address/Data Multiplexed I/O Interface Select)

This bit specifies separate bus interface or address/data multiplexed I/O interface of each area.

16.3.5 CSn Recovery Cycle Register (CSnREC) (n = 0 to 7)

Address(es): BUS.CS0REC 8701 D80Ah, BUS.CS1REC 8701 D81Ah, BUS.CS2REC 8701 D82Ah, BUS.CS3REC 8701 D83Ah, BUS.CS4REC 8701 D84Ah, BUS.CS5REC 8701 D85Ah, BUS.CS6REC 8701 D86Ah, BUS.CS7REC 8701 D87Ah, BUS_NS.CS0REC 0701 D80Ah, BUS_NS.CS1REC 0701 D81Ah, BUS_NS.CS2REC 0701 D82Ah, BUS_NS.CS3REC 0701 D83Ah, BUS_NS.CS4REC 0701 D84Ah, BUS_NS.CS5REC 0701 D85Ah, BUS_NS.CS6REC 0701 D86Ah, BUS_NS.CS7REC 0701 D87Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	WRCV[3:0]				—	—	—	—	RRCV[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	RRCV[3:0]	Read Recovery	b3 b0 0 0 0 0: No recovery cycle is inserted. 0 0 0 1: 1 recovery cycle is inserted. 0 0 1 0: 2 recovery cycles are inserted. 0 0 1 1: 3 recovery cycles are inserted. 0 1 0 0: 4 recovery cycles are inserted. 0 1 0 1: 5 recovery cycles are inserted. 0 1 1 0: 6 recovery cycles are inserted. 0 1 1 1: 7 recovery cycles are inserted. 1 0 0 0: 8 recovery cycles are inserted. 1 0 0 1: 9 recovery cycles are inserted. 1 0 1 0: 10 recovery cycles are inserted. 1 0 1 1: 11 recovery cycles are inserted. 1 1 0 0: 12 recovery cycles are inserted. 1 1 0 1: 13 recovery cycles are inserted. 1 1 1 0: 14 recovery cycles are inserted. 1 1 1 1: 15 recovery cycles are inserted.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11 to b8	WRCV[3:0]	Write Recovery	b11 b8 0 0 0 0: No recovery cycle is inserted. 0 0 0 1: 1 recovery cycle is inserted. 0 0 1 0: 2 recovery cycles are inserted. 0 0 1 1: 3 recovery cycles are inserted. 0 1 0 0: 4 recovery cycles are inserted. 0 1 0 1: 5 recovery cycles are inserted. 0 1 1 0: 6 recovery cycles are inserted. 0 1 1 1: 7 recovery cycles are inserted. 1 0 0 0: 8 recovery cycles are inserted. 1 0 0 1: 9 recovery cycles are inserted. 1 0 1 0: 10 recovery cycles are inserted. 1 0 1 1: 11 recovery cycles are inserted. 1 1 0 0: 12 recovery cycles are inserted. 1 1 0 1: 13 recovery cycles are inserted. 1 1 1 0: 14 recovery cycles are inserted. 1 1 1 1: 15 recovery cycles are inserted.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the CSnREC register while access to the CSn area is in progress.

When the preceding bus access is a separate bus access, CSnREC is valid when the recovery cycle insertion is enabled with the separate bus recovery cycle insertion enable bit (RCVENi (i = 0 to 7)) in CSRECEN. When the preceding bus access is an address/data multiplexed bus access, CSnREC is valid when the recovery cycle insertion is enabled with the multiplexed bus recovery cycle insertion enable bit (RCVENMj (j = 0 to 7)) in CSRECEN. For details, refer to section 16.5.4, Insertion of Recovery Cycles.

RRCV[3:0] Bits (Read Recovery)

These bits specify the number of recovery cycles to be inserted after a read access to the external bus for CSn (n = 0 to 7). When the recovery cycle insertion is enabled and a value except 0000b is written to these bits, 1 to 15 recovery cycles are inserted in the following cases.

- After a read access to the external bus, a read access is made to the external bus in the same area.
- After a read access to the external bus, a read access is made to the external bus in a different area.
- After a read access to the external bus, a write access is made to the external bus in the same area.
- After a read access to the external bus, a write access is made to the external bus in a different area.

WRCV[3:0] Bits (Write Recovery)

These bits specify the number of recovery cycles to be inserted after a write access to the external bus for CSn (n = 0 to 7). When the recovery cycle insertion is enabled and a value except 0000b is written to these bits, 1 to 15 recovery cycles are inserted in the following cases.

- After a write access to the external bus, a read access is made to the external bus in the same area.
- After a write access to the external bus, a read access is made to the external bus in a different area.
- After a write access to the external bus, a write access is made to the external bus in the same area.
- After a write access to the external bus, a write access is made to the external bus in a different area.

16.3.6 CS Recovery Cycle Insertion Enable Register (CSRECEN)

Address(es): BUS.CSRECEN 8701 D880h,
BUS_NS.CSRECEN 0701 D880h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b12	RCVENM4	Multiplexed Bus Recovery Cycle Insertion Enable 4	0: Recovery cycle insertion is disabled. 1: Recovery cycle insertion is enabled.	R/W
b13	RCVENM5	Multiplexed Bus Recovery Cycle Insertion Enable 5	0: Recovery cycle insertion is disabled. 1: Recovery cycle insertion is enabled.	R/W
b14	RCVENM6	Multiplexed Bus Recovery Cycle Insertion Enable 6	0: Recovery cycle insertion is disabled. 1: Recovery cycle insertion is enabled.	R/W
b15	RCVENM7	Multiplexed Bus Recovery Cycle Insertion Enable 7	0: Recovery cycle insertion is disabled. 1: Recovery cycle insertion is enabled.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the CSRECEN register while access to the CSn area is in progress. For more information on insertion recovery cycles, refer to section 16.6.3, Insertion of Recovery Cycles.

RCVENi Bit (Separate Bus Recovery Cycle Insertion Enable i) (i = 0 to 7)

This bit enables or disables the insertion of read or write recovery cycles when, after a read or write access to the external bus, a read or write access is made to the external bus in the same or different area.

RCVENMj Bit (Multiplexed Bus Recovery Cycle Insertion Enable j) (j = 0 to 7)

This bit enables or disables the insertion of read or write recovery cycles when, after a read or write access to the external bus, a read or write access is made to the external bus in the same or different area.

Table 16.7 Access type associations with the RCVENn bits

Access Type	External Address Space	Insertion of Recovery Cycles	Corresponding Bits (Separate/Multiplexed)
Read access after read access	Same area	Recovery cycles specified by the RRCV[3:0] bits are inserted for the priority access area.	RCVEN0/RCVENM0
	Different area	Recovery cycles specified by the RRCV[3:0] bits are inserted for the priority access area.	RCVEN1/RCVENM1
Write access after read access	Same area	Recovery cycles specified by the RRCV[3:0] bits are inserted for the priority access area.	RCVEN2/RCVENM2
	Different area	Recovery cycles specified by the RRCV[3:0] bits are inserted for the priority access area.	RCVEN3/RCVENM3
Read access after write access	Same area	Recovery cycles specified by the WRCV[3:0] bits are inserted for the priority access area.	RCVEN4/RCVENM4
	Different area	Recovery cycles specified by the WRCV[3:0] bits are inserted for the priority access area.	RCVEN5/RCVENM5
Write access after write access	Same area	Recovery cycles specified by the WRCV[3:0] bits are inserted for the priority access area.	RCVEN6/RCVENM6
	Different area	Recovery cycles specified by the WRCV[3:0] bits are inserted for the priority access area.	RCVEN7/RCVENM7

16.3.7 CSn Mode Register (CSnMOD) (n = 0 to 7)

Address(es): BUS.CS0MOD 8701 D002h, BUS.CS1MOD 8701 D012h, BUS.CS2MOD 8701 D022h, BUS.CS3MOD 8701 D032h, BUS.CS4MOD 8701 D042h, BUS.CS5MOD 8701 D052h, BUS.CS6MOD 8701 D062h, BUS.CS7MOD 8701 D072h, BUS_NS.CS0MOD 0701 D002h, BUS_NS.CS1MOD 0701 D012h, BUS_NS.CS2MOD 0701 D022h, BUS_NS.CS3MOD 0701 D032h, BUS_NS.CS4MOD 0701 D042h, BUS_NS.CS5MOD 0701 D052h, BUS_NS.CS6MOD 0701 D062h, BUS_NS.CS7MOD 0701 D072h

Bit	Symbol	Bit Name	Description	R/W
b0	WRMOD	Write Access Mode Select	0: Byte strobe mode 1: Single write strobe mode	R/W
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	EWENB	External Wait Enable	0: External wait is disabled 1: External wait is enabled	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	PRENB	Page Read Access Enable	0: Page read access is disabled 1: Page read access is enabled	R/W
b9	PWENB	Page Write Access Enable	0: Page write access is disabled 1: Page write access is enabled	R/W
b14 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	PRMOD	Page Read Access Mode Select	0: Normal access compatible mode 1: External data read continuous assertion mode	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the CSnMOD register while access to the CSn area is in progress.

WRMOD Bit (Write Access Mode Select)

This bit selects a write access operating mode.
Writing 0 to this bit selects byte strobe mode where data write operation is controlled by the WRn# (n = 0 to 3) signal corresponding to the respective byte positions.
Writing 1 to this bit selects single write strobe mode where data write operation is controlled by the BCn# (n = 0 to 3) signal and the WR# signal corresponding to respective byte positions.

Note: In single write strobe mode, the external bus width must not be set to 8 bits.

Table 16.8 Control Signals for Write Access Mode

Mode	Pin Name							
Write Access Mode	WR3#	WR2#	WR1#	WR0#/ WR#	BC3#	BC2#	BC1#	BC0#
Byte strobe mode	✓	✓	✓	✓ (WR0#)	—	—	—	—
Single write strobe mode	—	—	—	✓ (WR#)	✓	✓	✓	✓

✓: Enabled, —: Disabled

EWENB Bit (External Wait Enable)

This bit enables or disables external wait.
Writing 0 to this bit disables the WAIT# signal.

Writing 1 to this bit selects external wait and allows control of the number of waits in each cycle with the WAIT# signal. In this state, wait cycles are inserted while the WAIT# signal is at the low level.

PRENB Bit (Page Read Access Enable)

This bit enables or disables page read accesses.

Note: When the address/data multiplexed I/O interface is selected with the CSnCR.MPXEN bit, this bit should not be set to enable page read accesses. Page read accesses are not supported in the address/data multiplexed I/O interface.

PWENB Bit (Page Write Access Enable)

This bit enables or disables page write accesses.

Note: When the address/data multiplexed I/O interface is selected with the CSnCR.MPXEN bit, this bit should not be set to enable page write accesses. Page write accesses are not supported in the address/data multiplexed I/O interface.

PRMOD Bit (Page Read Access Mode Select)

This bit selects a page read access operating mode.
Writing 0 to this bit selects normal access compatible mode where the RD# signal is negated and RD assert wait is inserted each time a piece of data is read. However, when there is no RD assert wait, the RD# signal is negated only in the final transfer of the external bus access.
Writing 1 to this bit selects external data read continuous assertion mode where RD assert wait is inserted and the RD# signal is continuously asserted during this time period.

16.3.8 CSn Wait Control Register 1 (CSnWCR1) (n = 0 to 7)

Address(es): BUS.CS0WCR1 8701 D004h, BUS.CS1WCR1 8701 D014h, BUS.CS2WCR1 8701 D024h, BUS.CS3WCR1 8701 D034h, BUS.CS4WCR1 8701 D044h, BUS.CS5WCR1 8701 D054h, BUS.CS6WCR1 8701 D064h, BUS.CS7WCR1 8701 D074h, BUS_NS.CS0WCR1 0701 D004h, BUS_NS.CS1WCR1 0701 D014h, BUS_NS.CS2WCR1 0701 D024h, BUS_NS.CS3WCR1 0701 D034h, BUS_NS.CS4WCR1 0701 D044h, BUS_NS.CS5WCR1 0701 D054h, BUS_NS.CS6WCR1 0701 D064h, BUS_NS.CS7WCR1 0701 D074h

R/W
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. The CSPWWAIT[2:0] value is valid only when the CSnMOD.PWENB bit is set to 1.

Note 2. The CSPRWAIT[2:0] value is valid only when the CSnMOD.PRENB bit is set to 1.

Do not write to the CSnWCR1 register while access to the CSn area is in progress.
Set each of these bits within a range of the restrictions described in section 16.5.6 (1) Limitations on Using Separate Bus Interface or section 16.5.6 (2) Limitations on Using Address/Data Multiplexed Bus Interface, according to the bus interface used.

CSPWWAIT[2:0] Bits (Page Write Cycle Wait Select)

These bits specify the number of wait cycles to be inserted into the second and subsequent accesses during a page write cycle. This setting is enabled when the CSnMOD.PWENB bit is set to 1.

Note: Be sure to satisfy 1 ≤ CSnWCR2.WDON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSPWWAIT[2:0] value and CSnWCR2.CSON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSPWWAIT[2:0] value.

CSPRWAIT[2:0] Bits (Page Read Cycle Wait Select)

These bits specify the number of wait cycles to be inserted into the second and subsequent accesses during a page read cycle. This setting is enabled when the CSnMOD.PRENB bit is set to 1.

Note: Be sure to satisfy CSnWCR2.CSON[2:0] value ≤ CSnWCR2.RDON[2:0] value ≤ CSnWCR1.CSPRWAIT[2:0] value.

CSWWAIT[4:0] Bits (Normal Write Cycle Wait Select)

These bits specify the number of wait cycles to be inserted into the first access during a normal write cycle or page write cycle.

Note: Be sure to satisfy 1 ≤ CSnWCR2.WDON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSWWAIT[4:0] value and CSnWCR2.CSON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSWWAIT[4:0] value.

CSRWAIT[4:0] Bits (Normal Read Cycle Wait Select)

These bits specify the number of wait cycles to be inserted into the first access during a normal read cycle or page read cycle.

Note: Be sure to satisfy CSnWCR2.CSON[2:0] value ≤ CSnWCR2.RDON[2:0] value ≤ CSnWCR1.CSRWAIT[4:0] value.

16.3.9 CSn Wait Control Register 2 (CSnWCR2) (n = 0 to 7)

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the CSnWCR2 register while access to the CSn area is in progress.
Set each of these bits within a range of the restrictions described in section 16.5.6 (1) Limitations on Using Separate Bus Interface or section 16.5.6 (2) Limitations on Using Address/Data Multiplexed Bus Interface, according to the bus interface used.

CSROFF[2:0] Bits (Read-Access CS Extension Cycle Select)

These bits specify the number of wait cycles to be inserted in a time period from the end of a wait cycle (RD# signal negated) until the CSn# signal (n = 0 to 7) is negated in read access mode.

CSWOFF[2:0] Bits (Write-Access CS Extension Cycle Select)

These bits specify the number of wait cycles to be inserted in a time period from the end of a wait cycle (WRn# signal (n = 0 to 3) negated) until the CSn# signal (n = 0 to 7) is negated in write access mode.

Note: Be sure to satisfy CSnWCR2.WDOFF[2:0] value ≤ CSnWCR2.CSWOFF[2:0] value.

WDOFF[2:0] Bits (Write Data Output Extension Cycle Select)

These bits specify the number of wait cycles to be inserted in a time period from the end of a wait cycle (WRn# signal (n = 0 to 3) negated) until the write data output is completed in write access mode.

Note: Be sure to satisfy CSnWCR2.WDOFF[2:0] value ≤ CSnWCR2.CSWOFF[2:0] value.

AWAIT[1:0] Bits (Address Cycle Wait Select)

These bits specify the number of wait cycles to be inserted into an address output cycle with the address/data multiplexed I/O interface.

Note: CSnWCR2.CSON[2:0] value ≤ CSnWCR2.AWAIT[1:0] value
For read access, satisfy CSnWCR2.AWAIT[1:0] value + 2 ≤ CSnWCR2.RDON[2:0] value ≤ CSnWCR1.CSRWAIT[4:0] value.
For write access, satisfy CSnWCR2.AWAIT[1:0] value + 2 ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSWWAIT[4:0] value and CSnWCR2.AWAIT[1:0] value + 2 ≤ CSnWCR2.WDON[2:0] value ≤ CSnWCR1.CSWWAIT[4:0] value.

RDON[2:0] Bits (RD Assert Wait Select)

These bits specify the number of wait cycles to be inserted before the RD# signal is asserted.

Note: For normal read access, satisfy CSnWCR2.CSON[2:0] value ≤ CSnWCR2.RDON[2:0] value ≤ CSnWCR1.CSRWAIT[4:0] value.
For page read access, satisfy CSnWCR2.CSON[2:0] value ≤ CSnWCR2.RDON[2:0] value ≤ CSnWCR1.CSPRWAIT[2:0] value.
When the address/data multiplexed I/O interface is selected, satisfy CSnWCR2.AWAIT[1:0] value + 2 ≤ CSnWCR2.RDON[2:0] value ≤ CSnWCR1.CSRWAIT[4:0] value.

WRON[2:0] Bits (WR Assert Wait Select)

These bits specify the number of wait cycles to be inserted before the WRn# signal (n = 0 to 3)) is asserted.

Note: For normal write access, satisfy 1 ≤ CSnWCR2.WDON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSWWAIT[4:0] value and CSnWCR2.CSON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSWWAIT[4:0] value.
For page write access, satisfy 1 ≤ CSnWCR2.WDON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSPWWAIT[2:0] value and CSnWCR2.CSON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSPWWAIT[2:0] value.
When the address/data multiplexed I/O interface is selected, satisfy CSnWCR2.AWAIT[1:0] value + 2 ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSWWAIT[4:0] value.

WDON[2:0] Bits (Write Data Output Wait Select)

These bits specify the number of wait cycles to be inserted before the write data is output.

Note: For normal write access, satisfy 1 ≤ CSnWCR2.WDON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSWWAIT[4:0] value.
For page write access, satisfy 1 ≤ CSnWCR2.WDON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSPWWAIT[2:0] value.
When the address/data multiplexed I/O interface is selected, satisfy CSnWCR2.AWAIT[1:0] value + 2 ≤ CSnWCR2.WDON[2:0] value ≤ CSnWCR1.CSWWAIT[4:0] value.

CSON[2:0] Bits (CS Assert Wait Select)

These bits specify the number of wait cycles to be inserted before the CSn# signal (n = 0 to 7) is asserted.

Note: For normal read access, satisfy CSnWCR2.CSON[2:0] value ≤ CSnWCR2.RDON[2:0] value ≤ CSnWCR1.CSRWAIT[4:0] value.
For page read access, satisfy CSnWCR2.CSON[2:0] value ≤ CSnWCR2.RDON[2:0] value ≤ CSnWCR1.CSPRWAIT[2:0] value.
For normal write access, satisfy CSnWCR2.CSON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSWWAIT[4:0] value.
For page write access, satisfy CSnWCR2.CSON[2:0] value ≤ CSnWCR2.WRON[2:0] value ≤ CSnWCR1.CSPWWAIT[2:0] value.

When the address/data multiplexed I/O interface is selected, satisfy CSnWCR2.CSON[2:0] value ≤ CSnWCR2.AWAIT[1:0] value.

16.3.10 SDC Control Register (SDCCR)

Address(es): BUS.SDCCR 8701 DC00h,
BUS_NS.SDCCR 0701 DC00h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	BSIZE[1:0]		—	—	—	EXENB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	EXENB	Operation Enable	0: Operation is disabled 1: Operation is enabled	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5, b4	BSIZE[1:0]	SDRAM Bus Width Select	b5 b4 0 0: A 16-bit bus space is selected 0 1: A 32-bit bus space is selected 1 0: An 8-bit bus space is selected 1 1: Setting prohibited	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the SDCCR register while an SDRAM area is being accessed.

EXENB Bit (Operation Enable)

This bit enables or disables the operation of the SDRAM address space. After reset, this bit is set to 0 (operation disabled). Attempts to access disabled areas have no effect.
When the CSC and SDRAMC are in use at the same time, EBCLK and SDCLK must operate at the same frequency.

BSIZE[1:0] Bits (SDRAM Bus Width Select)

These bits specify the data bus width for the corresponding area.

16.3.11 SDC Mode Register (SDCMOD)

Address(es): BUS.SDCMOD 8701 DC01h,
BUS_NS.SDCMOD 0701 DC01h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	EMODE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	EMODE	Endian Mode	0: Endian of SDRAM address space is the same as the endian of operating mode. 1: Endian of SDRAM address space is not the endian of operating mode.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Writing to this register is possible only once after reset is released when SDCCR.EXENB = 0. Write access more than once is prohibited. If write access is performed more than once, the SDRAM access operation is not guaranteed.

EMODE Bit (Endian Mode)

This bit specifies the endian of the SDRAM address space. For details, re1fer to section 16.2.5.1, Restriction on Endian

16.3.12 SDRAM Access Mode Register (SDAMOD)

Address(es): BUS.SDAMOD 8701 DC02h,
BUS_NS.SDAMOD 0701 DC02h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	BE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BE	Continuous Access Enable	0: Continuous access is disabled 1: Continuous access is enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Set SDAMOD while the conditions listed in Table 16.18, Limitations at the Time of Normal Access, are satisfied. The operation is not guaranteed if this register is set while these conditions are not satisfied.

BE Bit (Continuous Access Enable)

This bit enables or disables continuous access to the SDRAM access space.

16.3.13 SDRAM Self-Refresh Control Register (SDSELF)

Address(es): BUS.SDSELF 8701 DC10h,
BUS_NS.SDSELF 0701 DC10h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SFEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SFEN	SDRAM Self-Refresh Enable	0: Self-refresh is disabled 1: Self-refresh is enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Set SDSELF while the conditions listed in Table 16.18, Limitations at the Time of Normal Access, are satisfied. The operation is not guaranteed if this register is set while these conditions are not satisfied.

SFEN Bit (SDRAM Self-Refresh Enable)

This bit controls self-refresh operation. Setting this bit to 1 performs auto-refresh cycle operation, after which self-refresh operation begins. Setting this bit to 0 ends self-refresh operation, and auto-refresh operation resumes afterwards. If this bit is set to 1, the value written to this bit is reflected when self-refresh operation starts. If this bit is set to 0, the value written to this bit is reflected after the end of self-refresh operation.

16.3.14 SDRAM Refresh Control Register (SDRFCR)

Address(es): BUS.SDRFCR 8701 DC14h,
BUS_NS.SDRFCR 0701 DC14h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	REFW[3:0]				RFC[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	RFC[11:0]	Auto-Refresh Request Interval Setting	b11 b0 0 0 0 0 0 0 0 0 0 0 0 0: Setting prohibited 0 0 0 0 0 0 0 0 0 0 0 1: 2 cycles 0 0 0 0 0 0 0 0 0 0 1 0: 3 cycles : 1 1 1 1 1 1 1 1 1 1 1 1: 4096 cycles	R/W
b15 to b12	REFW[3:0]	Auto-Refresh Cycle/ Self-Refresh Clearing Cycle Count Setting	b15 b12 0 0 0 0: 1 cycle 0 0 0 1: 2 cycles 0 0 1 0: 3 cycles 0 0 1 1: 4 cycles 0 1 0 0: 5 cycles 0 1 0 1: 6 cycles 0 1 1 0: 7 cycles 0 1 1 1: 8 cycles 1 0 0 0: 9 cycles 1 0 0 1: 10 cycles 1 0 1 0: 11 cycles 1 0 1 1: 12 cycles 1 1 0 0: 13 cycles 1 1 0 1: 14 cycles 1 1 1 0: 15 cycles 1 1 1 1: 16 cycles	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

RFC[11:0] Bits (Auto-Refresh Request Interval Setting)

These bits specify the auto-refresh request interval. These bits can be written to at any time, regardless of the state of the auto-refresh operation enable (RFEN) bit in SDRFEN. If auto-refresh is enabled, the value written to these bits is reflected after the end of auto-refresh cycles. The refresh counter operates in SDCLK.

REFW[3:0] Bits (Auto-Refresh Cycle/ Self-Refresh Clearing Cycle Count Setting)

These bits specify the number of auto-refresh cycles and the number of self-refresh clearing cycles. These bits can be written to at any time, regardless of the state of the auto-refresh operation enable (RFEN) bit in SDRFEN. If an auto-refresh cycle is in progress, the value written to these bits while auto-refresh is enabled takes effect after the cycle completes.

Note: Auto-refresh requests are not accepted while SDRAM is being accessed; they must wait until the access completes, so the auto-refresh interval may become enlarged in some cases. Set the RFC[11:0] bits to an auto-refresh request interval value that satisfies the auto-refresh interval specification of the SDRAM being used. Furthermore, make sure to set the auto-refresh request interval to a duration longer than the auto-refresh cycle. Note that the auto-refresh interval cannot be automatically adjusted when the frequency is changed during operation; in this case, perform self-refresh operation and set the auto-refresh interval appropriate for the frequency again.

16.3.14.1 Auto-Refresh Request Interval and RFC Set Value

SDRAMC (SDRAM area controller) includes a 12-bit refresh counter that generates auto-refresh requests at fixed intervals. The following equation is used to calculate the set value for the RFC[11:0] bits from the auto-refresh request interval.

RFC = (Auto-refresh request interval / SDCLK cycle) – 1

Note: Auto-refresh requests are not accepted while SDRAM is being accessed; they must wait until the access completes. However, the counter value is updated regardless of whether or not the request was accepted. If two or more auto-refresh requests are generated while SDRAM is being accessed, the second and subsequent requests are ignored.

16.3.15 SDRAM Auto-Refresh Control Register (SDRFEN)

Address(es): BUS.SDRFEN 8701 DC16h,
BUS_NS.SDRFEN 0701 DC16h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RFEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFEN	Auto-Refresh Operation Enable	0: Auto-refresh operation is disabled 1: Auto-refresh operation is enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

RFEN Bit (Auto-Refresh Operation Enable)

The RFEN bit enables auto-refresh operation. If auto-refresh is required, set the RFEN bit to 1 before accessing the SDRAM.

When the RFEN bit is set to 0 when auto-refresh is enabled, the RFEN bit becomes 0 after the auto-refresh cycle ends, and auto-refresh operation stops. The interval at which refresh requests are generated is determined by the value of the auto-refresh request interval setting bits (RFC[11:0]) in the SDRAM Refresh Control Register (SDRFCR).

16.3.16 SDRAM Initialization Sequence Control Register (SDICR)

Address(es): BUS.SDICR 8701 DC20h,
BUS_NS.SDICR 0701 DC20h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	INIRQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	INIRQ	Initialization Sequence Start	0: Invalid 1: Initialization sequence starts	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Writing to this register is possible only once after release from the reset state. Operation is not guaranteed after write access more than once is attempted.

INIRQ Bit (Initialization Sequence Start)

Setting this bit to 1 causes the SDRAM initialization sequence to start and automatically sets the initialization status bit (INIST) in the SDRAM status register (SDSR) to 1. The INIST bit is cleared automatically after the initialization sequence ends.
The value written to the INIRQ bit is not retained.
Please initialize the SDRAM according to the procedure in section 16.6.11.1, SDRAMC Access Procedure.

Note: Set the INIRQ bit to start the SDRAM initialization sequence while the conditions listed in Table 16.18, Limitations at the Time of Normal Access, are satisfied. The operation is not guaranteed if this bit is set while these conditions are not satisfied.

16.3.17 SDRAM Initialization Register (SDIR)

Address(es): BUS.SDIR 8701 DC24h,
BUS_NS.SDIR 0701 DC24h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	PRC[2:0]			ARFC[3:0]				ARFI[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ARFI[3:0]	Initialization Auto-Refresh Interval	b3 b0 0 0 0 0: 3 cycles 0 0 0 1: 4 cycles 0 0 1 0: 5 cycles 0 0 1 1: 6 cycles 0 1 0 0: 7 cycles 0 1 0 1: 8 cycles 0 1 1 0: 9 cycles 0 1 1 1: 10 cycles 1 0 0 0: 11 cycles 1 0 0 1: 12 cycles 1 0 1 0: 13 cycles 1 0 1 1: 14 cycles 1 1 0 0: 15 cycles 1 1 0 1: 16 cycles 1 1 1 0: 17 cycles 1 1 1 1: 18 cycles	R/W
b7 to b4	ARFC[3:0]	Initialization Auto-Refresh Count	b7 b4 0 0 0 0: Setting prohibited 0 0 0 1: 1 time 0 0 1 0: 2 times 0 0 1 1: 3 times 0 1 0 0: 4 times 0 1 0 1: 5 times 0 1 1 0: 6 times 0 1 1 1: 7 times 1 0 0 0: 8 times 1 0 0 1: 9 times 1 0 1 0: 10 times 1 0 1 1: 11 times 1 1 0 0: 12 times 1 1 0 1: 13 times 1 1 1 0: 14 times 1 1 1 1: 15 times	R/W
b10 to b8	PRC[2:0]	Initialization Precharge Cycle Count	b10 b8 0 0 0: 3 cycles 0 0 1: 4 cycles 0 1 0: 5 cycles 0 1 1: 6 cycles 1 0 0: 7 cycles 1 0 1: 8 cycles 1 1 0: 9 cycles 1 1 1: 10 cycles	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

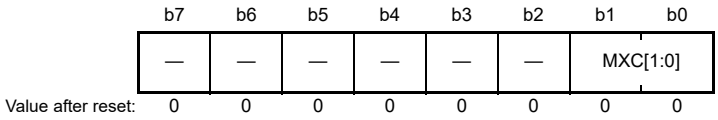
Writing to this register is possible only once after release from the reset state. Operation is not guaranteed after write access more than once is attempted.

ARFI[3:0] Bits (Initialization Auto-Refresh Interval)

These bits specify the interval at which auto-refresh commands are issued in the SDRAM initialization sequence.

ARFC[3:0] Bits (Initialization Auto-Refresh Count)

These bits specify the number of times auto-refresh is to be performed in the SDRAM initialization sequence.



PRC[2:0] Bits (Initialization Precharge Cycle Count)

These bits specify the number of precharge cycles in the SDRAM initialization sequence.

Note: Make settings that satisfy the specifications of the connected SDRAM before starting the initialization sequence.

16.3.18 SDRAM Address Register (SDADR)

Address(es): BUS.SDADR 8701 DC40h,
BUS_NS.SDADR 0701 DC40h

Bit	Symbol	Bit Name	Description	R/W
b1, b0	MXC[1:0]	Address Multiplex Select	b1 b0 0 0: 8-bit shift 0 1: 9-bit shift 1 0: 10-bit shift 1 1: 11-bit shift	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Set SDADR while the conditions listed in Table 16.18, Limitations at the Time of Normal Access, are satisfied. The operation is not guaranteed if this bit is set while these conditions are not satisfied.

MXC[1:0] Bits (Address Multiplex Select)

These bits select the size of the shift toward the lower half of the row address in row address/column address multiplexing.
For details, refer to Table 16.25, Address Multiplexing.

16.3.19 SDRAM Timing Register (SDTR)

Address(es): BUS.SDTR 8701 DC44h,
BUS_NS.SDTR 0701 DC44h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	RAI[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	RCD[1:0]		RP[2:0]			WR	—	—	—	—	—	CL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CL[2:0]	SDRAMC Column Latency	b2 b0 0 0 0: Setting prohibited 0 0 1: 1 cycle 0 1 0: 2 cycles 0 1 1: 3 cycles Settings other than above are prohibited.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	WR	Write Recovery Interval	0: 1 cycle 1: 2 cycles	R/W
b11 to b9	RP[2:0]	Row Precharge Interval	b11 b9 0 0 0: 1 cycle 0 0 1: 2 cycles 0 1 0: 3 cycles 0 1 1: 4 cycles 1 0 0: 5 cycles 1 0 1: 6 cycles 1 1 0: 7 cycles 1 1 1: 8 cycles	R/W
b13, b12	RCD[1:0]	Row Column Latency	b13b12 0 0: 1 cycle 0 1: 2 cycles 1 0: 3 cycles 1 1: 4 cycles	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b18 to b16	RAI[2:0]	Row Active Interval	b18 b16 0 0 0: 1 cycle 0 0 1: 2 cycles 0 1 0: 3 cycles 0 1 1: 4 cycles 1 0 0: 5 cycles 1 0 1: 6 cycles 1 1 0: 7 cycles 1 1 1: Setting prohibited	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

When the SDCCR.EXENB bit is set to 1, if a write access is made, the write is ignored.

The SDTR register specifies the timing for read and write accesses to SDRAM. For details, refer to section 16.6.11.3, Timing Register Settings and Access Timing.

Set the SDTR register while the conditions listed in Table 16.18, Limitations at the Time of Normal Access, are satisfied. The operation is not guaranteed if this bit is set while these conditions are not satisfied.

Writing to this register is possible only once after release from the reset state. Operation is not guaranteed after write access more than once is attempted.

CL[2:0] Bits (SDRAMC Column Latency)

These bits specify the column latency of the SDRAM controller. This setting only affects the latency setting on the SDRAM controller side. To specify the column latency for externally connected SDRAM, use the SDRAM mode register (SDMOD).

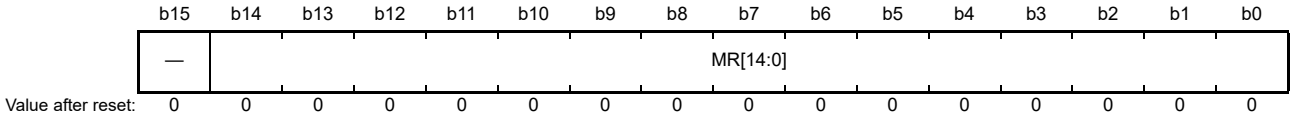
WR Bit (Write Recovery Interval)

This bit specifies the interval that must elapse between the SDRAM write command (WRIT) and deactivation (PALL).

RP[2:0] Bits (Row Precharge Interval)

These bits specify the minimum number of cycles that must elapse between the SDRAM deactivation command (PALL) and the next valid command.

RCD[1:0] Bits (Row Column Latency)



These bits specify the row-column latency of the SDRAM.

RAI[2:0] Bits (Row Active Interval)

These bits specify the minimum interval that must elapse between the SDRAM row activation command (ACTV) and deactivation (PALL). The value specified by these bits should be less than or equal to the sum of the row-column latency (RCD[1:0]) and column latency (CL[2:0]) settings.

16.3.20 SDRAM Mode Register (SDMOD)

Address(es): BUS.SDMOD 8701 DC48h,
BUS_NS.SDMOD 0701 DC48h

Bit	Symbol	Bit Name	Description	R/W
b14 to b0	MR[14:0]	Mode Register Setting	Writing to these bits: Mode register set command is issued	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The SDMOD register specifies the value to be written to the SDRAM mode register. Writing to this register causes a mode register set command to be issued automatically to SDRAM. Set the SDMOD register while the conditions listed in Table 16.18, Limitations at the Time of Normal Access, are satisfied. The operation is not guaranteed if this register is set while these conditions are not satisfied.
Writing to this register is possible only once after release from the reset state. Operation is not guaranteed after write access more than once is attempted.

MR[14:0] Bits (Mode Register Setting)

Writing to these bits causes a mode register set command to be issued to SDRAM. The setting of the MR[14:0] bits is output to the lower bits of the address. For details, refer to section 16.6.9, Setting Mode Register.
Please write the mode register according to the procedure in section 16.6.11.1, SDRAMC Access Procedure.

Note: The following points should be kept in mind regarding SDMOD settings.
- Make sure to set a burst length of 1 for SDRAM. Operation cannot be guaranteed with settings other than burst length 1.
- The SDRAM column latency must match the setting of the SDRAMC column latency setting bits (CL[2:0]) in the SDRAM timing register (SDTR). Operation cannot be guaranteed if the latency settings do not agree.
- Whenever writing is to proceed, confirm that all of the status bits (SDSR.SRFST, INIST, and MRSST) in the SDRAM status register are 0 beforehand.

16.3.21 SDRAM Status Register (SDSR)

Address(es): BUS.SDSR 8701 DC50h,
BUS_NS.SDSR 0701 DC50h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SRFST	INIST	—	—	MRSST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MRSST	Mode Register Setting Status	0: Mode register setting not in progress 1: Mode register setting in progress	R
b2, b1	—	Reserved	These bits are read as 0.	R
b3	INIST	Initialization Status	0: Initialization sequence not in progress 1: Initialization sequence in progress	R
b4	SRFST	Self-Refresh Transition/Recovery Status	0: Transition/recovery not in progress 1: Transition/recovery in progress	R
b7 to b5	—	Reserved	These bits are read as 0.	R

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

MRSST Bit (Mode Register Setting Status)

When set to 1, this bit indicates that SDRAM mode register setting is in progress.

INIST Bit (Initialization Status)

When set to 1, this bit indicates that the SDRAM initialization sequence is in progress.

SRFST Bit (Self-Refresh Transition/Recovery Status)

When set to 1, this bit indicates that a transition to or recovery from self-refresh operation is in progress for SDRAM. “Transition to or recovery from self-refresh operation in progress” refers to the interval from the point at which the bits listed in Table 16.9 are written until the corresponding commands are issued.

Note: Execution of a self-refresh, an initialization sequence, or mode register setting may only be performed when all the status bits are 0. Do not rewrite the registers (bits) listed in Table 16.9 when any of the status bits (SRFST, INIST, MRSST) is set to 1.

Table 16.9 List of Registers and Bits Requiring Checking Status Bits

Function	Register	Bits
Self-refresh	SDSELF	SFEN
Initialization sequence	SDICR	INIRQ
Mode register setting	SDMOD	MR[14:0]

16.3.22 EXBUS Error Status Register (EXBERR)

Address(es): BUS.EXBERR 8701 D8A0h,
BUS_NS.EXBERR 0701 D8A0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	BCAN	HLDTO	TO
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TO	External Wait Timeout Error Status Flag	0: No external wait timeout has occurred 1: An external wait timeout has occurred	R
b1	HLDTO	External Bus Hold Timeout Error Status Flag	0: No external bus hold timeout error has occurred 1: An external bus hold timeout error has occurred	R
b2	BCAN	Bus Access Cancel Error Status Flag	0: No bus access cancel has occurred 1: Bus access cancel has occurred	R
b7 to b3	—	Reserved	These bits are read as 0.	R

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

In this register, if there are no errors, the error flag for the first error detected is set to 1. However, if a BCAN error is detected when the HLDTO flag is 1, the BCAN flag will be 1. To enable error detection, clear all error flags and confirm that all flags are 0.

TO Flag (External Wait Timeout Error Status Flag)

The TO flag indicates that a timeout error due to the WAIT# signal has occurred.
If a bus access to the CS area does not finish within 768 external bus clock (BCLK) cycles after the bus access starts, the TO flag becomes 1. Writing 1 to the EXBECLR.TOCLR bit sets the EXBERR.TO flag to 0.
For more information about timeout errors, refer to section 16.8.4, Timeout.

HLDTO Flag (External Bus Hold Timeout Error Status Flag)

The HLDTO flag indicates that an external bus hold timeout error has occurred.
The HLDTO flag is set to 1 when the LOW period of both the BREQ# and BACK# signals is equal to or greater than 768 external bus clock cycles. Writing 1 to the EXBECLR.HLDTOCLR bit sets the EXBERR.HLDTO flag to 0.
For more information about external bus hold timeouts, refer to section 16.8.4, Timeout.

BCAN Flag (Bus Access Cancel Error Status Flag)

When any of the following events occur, the BCAN flag becomes 1, an error response is returned to the bus master, and a slave bus error occurs:

- The CSnCR.EXENB bit is 0 and the CSn area is accessed (n = 0 to 7)
- The SDCCR.EXENB bit is 0 and the SDRAM area is accessed
- The HLDTO flag is 1 and the CSn area or SDRAM area is accessed (n = 0 to 7)

Writing 1 to the EXBECLR.BCANCLR bit sets the EXBERR.BCAN flag to 0.

16.3.23 EXBUS Error Enable Register (EXBEREN)

Address(es): BUS.EXBEREN 8701 D8A4h,
BUS_NS.EXBEREN 0701 D8A4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TOEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TOEN	External Bus Timeout Detection Enable*1, *2	0: External bus timeout detection is disabled. 1: External bus timeout detection is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. When detection is disabled (the TOEN bit is set to 0), bus access can cause the bus to freeze.

Note 2. Do not set the TOEN bit to 0 (bus timeout detection disabled) while timeout errors are being detected.

For timeout errors, refer to section 16.8.4, Timeout.

16.3.24 EXBUS Error Status Clear Register (EXBECLR)

Address(es): BUS.EXBECLR 8701 D8A8h,
BUS_NS.EXBECLR 0701 D8A8h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	BCANCLR	HLDTOCLR	TOCLR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TOCLR	External Bus Wait Timeout Error Status Clear	0: No effect 1: Clears the EXBERR.TO flag	R/W
b1	HLDTOCLR	External Bus Hold Timeout Error Status Clear	0: No effect 1: Clears the EXBERR.HLDTO flag	R/W
b2	BCANCLR	Bus Access Cancel Error Status Clear	0: No effect 1: Clears the EXBERR.BCAN flag	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

TOCLR Bit (External Bus Wait Timeout Error Status Clear)

Writing 1 to this bit clears the EXBERR.TO flag. Before writing 1 to this bit, release the WAIT# signal assertion.
Writing 0 to this bit has no effect. This bit returns 0.
For information on timeout errors, refer to 16.8.4 Timeout.

HLDTOCLR Bit (External Bus Hold Timeout Error Status Clear)

Writing 1 to this bit clears the EXBERR.HLDTO flag. Before writing 1 to this bit, release the BREQ# signal assertion.
Writing 0 to this bit has no effect. This bit returns 0.
For information on timeout errors, refer to 16.8.4 Timeout.

BCANCLR Bit (Bus Access Cancel Error Status Clear)

Writing 1 to this bit clears the EXBERR.BCAN flag. Before writing 1 to this bit, release the BREQ# signal assertion.
Writing 0 to this bit has no effect. This bit returns 0.

16.3.25 EXBUS Error Address Register (EXBEAD)

Address(es): BUS.EXBEAD 8701 D8ACh,
BUS_NS.EXBEAD 0701 D8ACh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	EADDR[12:0]													—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b18 to b0	—	Reserved	These bits are read as 0.	R
b31 to b19	EADDR[12:0]	EXBUS Error Address	These bits indicate the 13 higher-order bits (bits 31 to 19) of the address corresponding to the bus-access error.	R

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

This register indicates the address of the bus access that corresponds to an error flag that is set to 1 in the EXBERR register.

If a new error occurs when either the TO or BCAN flag in the EXBERR register is 1, the address is not retained. Writing to this register has no effect. When all flags in the EXBERR register are 0, the EXBEAD register is read as 0.

For more information about timeout errors, refer to section 16.8.4, Timeout.

16.3.26 EXBUS Hold Enable Register (EXHLDEN)

Address(es): BUS.EXHLDEN 8701 D8B4h,
BUS_NS.EXHLDEN 0701 D8B4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	HLDEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	HLDEN	External bus hold enable	0: External bus hold function is disabled. 1: External bus hold function is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

HLDEN Bit (External bus hold enable)

Setting this bit to 1 enables the external bus hold function.

Do not set this bit to 0 while the external bus is held.

For details, refer to section 16.7, External Bus Hold.

16.3.27 Bus Slave Arbitration Control Register 0 (BUSSABT0MRE0BI, BUSSABT0S0BI, BUSSABT0S1BI, BUSSABT0ECBI, BUSSABT0XSPI0BI, BUSSABT0XSPI1BI, BUSSABT0PBBI, BUSSABT0PABI, BUSSABT0PIBI, BUSSABT0PSBI, BUSSABT0PS0BI)

Address(es): BUS.BUSSABT0MRE0BI 8701 E210h, BUS.BUSSABT0S0BI 8701 E220h, BUS.BUSSABT0S1BI 8701 E228h, BUS.BUSSABT0ECBI 8701 E250h, BUS.BUSSABT0XSPI0BI 8701 E258h, BUS.BUSSABT0XSPI1BI 8701 E260h, BUS.BUSSABT0PBBI 8701 E278h, BUS.BUSSABT0PABI 8701 E280h, BUS.BUSSABT0PIBI 8701 E288h, BUS.BUSSABT0PSBI 8701 E290h, BUS.BUSSABT0PS0BI 8701 E298h, BUS_NS.BUSSABT0MRE0BI 8701 E210h, BUS_NS.BUSSABT0S0BI 8701 E220h, BUS_NS.BUSSABT0S1BI 8701 E228h, BUS_NS.BUSSABT0ECBI 8701 E250h, BUS_NS.BUSSABT0XSPI0BI 8701 E258h, BUS_NS.BUSSABT0XSPI1BI 8701 E260h, BUS_NS.BUSSABT0PBBI 8701 E278h, BUS_NS.BUSSABT0PABI 8701 E280h, BUS_NS.BUSSABT0PIBI 8701 E288h, BUS_NS.BUSSABT0PSBI 8701 E290h, BUS_NS.BUSSABT0PS0BI 8701 E298h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ARBS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ARBS	Arbitration Select for Each Slave Bus Interface	0: Fixed priority 1: Round-robin	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

ARBS Bit (Arbitration Select for Each Slave Bus Interface)

This bit specifies the priority order among the bus masters connected to each bus interface. For fixed priority, refer to Table 16.10. For round-robin priority, refer to Table 16.11.

Table 16.10 Bus Priorities with Fixed-Priority Arbitration (ARBS = 0)

Bus Slave Arbitration Control Register	Bus Interface	Priority*1
BUSSABT0MRE0BI	MRE0BI	EDMAC > DMAC0 > CPU0OA > CPU0IF
BUSSABT0SnBI (n = 0, 1)	S0BI, S1BI	EDMAC > EXDMAC > DMAC0 > CPU0OA > CPU0IF > XSPIM
BUSSABT0ECBI BUSSABT0XSPI0BI BUSSABT0XSPI1BI	ECBI XSPI0BI XSPI1BI	EDMAC > EXDMAC > DMAC0 > CPU0OA > CPU0IF
BUSSABT0PBBI BUSSABT0PABI BUSSABT0PIBI BUSSABT0PSBI BUSSABT0PS0BI	PBBI PABI PIBI PSBI PS0BI	DMAC0 (W > R) > CPU0OA

Note 1. > : Indicates that the left side has higher priority.

Table 16.11 Bus Priorities with Round-Robin Arbitration (ARBS = 1)

Bus Slave Arbitration Control Register	Bus Interface	Priority*1
BUSSABT0MRE0BI	MRE0BI	EDMAC <-> DMAC0 <-> CPU0OA <-> CPU0IF

Note 1. <-> : Indicates round-robin.

16.3.28 Bus Slave Arbitration Control Register 1 (BUSSABT1MRC0BI, BUSSABT1MRC1BI)

Address(es): BUS.BUSSABT1MRC0BI 8701 E200h, BUS.BUSSABT1MRC1BI 8701 E208h, BUS_NS.BUSSABT1MRC0BI 0701 E200h, BUS_NS.BUSSABT1MRC1BI 0701 E208h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ARBS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	ARBS[1:0]	Arbitration Select for Each Slave Bus Interface	b1 b0 0 0: Fixed priority 0 1: Setting prohibited 1 0: Combination of round-robin and fixed priority 1 1: Round-robin	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

ARBS[1:0] Bits (Arbitration Select for Each Slave Bus Interface)

These bits specify the priority order among the bus masters connected to each bus interface. For the priority of each setting, see Table 16.12, Table 16.13, and Table 16.14.

Table 16.12 Bus Priorities with Fixed-Priority Arbitration (ARBS[1:0] = 00b)

Bus Slave Arbitration Control Register	Slave Bus Interface	Priority*1
BUSSABT1MRC0BI BUSSABT1MRC1BI	MRC0BI MRC1BI	EDMAC > DMAC0 > CPU0OA > CPU0IF

Note 1. > : Indicates that the left side has higher priority.

Table 16.13 Bus Priorities with Combination of Round-Robin and Fixed Priority Arbitration (ARBS[1:0] = 10b)

Bus Slave Arbitration Control Register	Slave Bus Interface	Priority*1
BUSSABT1MRC0BI BUSSABT1MRC1BI	MRC0BI MRC1BI	(EDMAC <-> DMAC0) > CPU0OA > CPU0IF

Note 1. <-> : Indicates round-robin.
> : Indicates that the left side has higher priority.

Table 16.14 Bus Priorities with Round-Robin Arbitration (ARBS[1:0] = 11b)

Bus Slave Arbitration Control Register	Slave Bus Interface	Priority*1
BUSSABT1MRC0BI BUSSABT1MRC1BI	MRC0BI MRC1BI	(EDMAC <-> DMAC0) <-> CPU0OA <-> CPU0IF

Note 1. <-> : Indicates round-robin.

16.3.29 Bus Error Status Register (BUSERRSTATCPU0IF, BUSERRSTATCPU0OA, BUSERRSTATDMAC0, BUSERRSTATEXDMAC, BUSERRSTATEDMAC, BUSERRSTATXSPI0, BUSERRSTATXSPI1)

Address(es): BUS.BUSERRSTATCPU0IF 8701 E800h, BUS.BUSERRSTATCPU0OA 8701 E810h, BUS.BUSERRSTATDMAC0 8701 E880h, BUS.BUSERRSTATEXDMAC 8701 E890h, BUS.BUSERRSTATEDMAC 8701 E8A0h, BUS.BUSERRSTATXSPI0 8701 E8B0h, BUS.BUSERRSTATXSPI1 8701 E8C0h,
BUS_NS.BUSERRSTATCPU0IF 0701 E800h, BUS_NS.BUSERRSTATCPU0OA 0701 E810h, BUS_NS.BUSERRSTATDMAC0 0701 E880h, BUS_NS.BUSERRSTATEXDMAC 0701 E890h, BUS_NS.BUSERRSTATEDMAC 0701 E8A0h, BUS_NS.BUSERRSTATXSPI0 0701 E8B0h, BUS_NS.BUSERRSTATXSPI1 0701 E8C0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MSERRSTAT	ILERRSTAT	MMERRSTAT	—	—	SLERRSTAT
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SLERRSTAT	Slave Bus Error Status	0: No error occurred. 1: Error occurred.	R
b2, b1	—	Reserved	These bits are read as 0.	R
b3	MMERRSTAT	Bus Master MPU Error Status	0: No error occurred. 1: Error occurred.	R
b4	ILERRSTAT	Illegal Address Access Error Status	0: No error occurred. 1: Error occurred.	R
b5	MSERRSTAT	Master Security Attribution Unit Error Status	0: No error occurred. 1: Error occurred.	R
b7, b6	—	Reserved	These bits are read as 0.	R

This register is cleared by any reset other than a bus error reset, common memory error reset, or local memory error reset.
If multiple bus errors occur simultaneously, the STAT bit of the highest priority error will be 1.
The priority order is as follows (> : indicates that the left side has higher priority):

Master security attribute unit error > Slave bus error, Protect Zone access error > Bus master MPU error > Invalid address access error

MSERRSTAT, ILERRSTAT, MMERRSTAT, and SLERRSTAT flags are not updated if any of them are set to 1.

SLERRSTAT Flag (Slave Bus Error Status)

When a slave error or Protect Zone access error occurs on the bus, the BUSERRSTATx.SLERRSTAT flag becomes 1.
[Clearing condition]

- Set the BUSERRCLRx.SLERRSTAT bit to 1.

A slave error is an error that occurs in the slave, such as a timeout.
For violations when using a debugger, the SLERRSTAT bit is not set.
For more information about slave errors that occur on the bus, refer to section 16.8, Bus Error Monitoring Section.
x = CPU0IF, CPU0OA, DMAC0, EXDMAC, EDMAC, XSPI0, XSPI1

MMERRSTAT Flag (Bus Master MPU Error Status)

When a bus master MPU error occurs on the bus, the BUSERRSTATx.MMERRSTAT flag becomes 1.
[Clearing condition]

- Set the BUSERRCLRx.MMERRCLR bit to 1.

For more information about master MPU errors that occur on the bus, refer to section 17, Memory-Protection Unit

(MPU).

ILERRSTAT Flag (Illegal Address Access Error Status)

When an illegal address access error occurs on the bus or a write access occurs to MRE0BI, the BUSERRSTATx.ILERRSTAT flag becomes 1.
[Clearing condition]

- Set the BUSERRCLRx.ILERRCLR bit to 1.

The ILERRSTAT flag is not set if a violation occurs while using a debugger.
For details about illegal address access errors that occur on the bus, refer to 16.8 Bus Error Monitoring Section.

MSERRSTAT Flag (Master Security Attribution Unit Error Status)

When a master security attribute error occurs on the bus, the BUSERRSTATx.MSERRSTAT flag becomes 1.
[Clearing condition]

- Set the BUSERRCLRx.MSERRCLR bit to 1.

For details on master security attribute errors that occur on the bus, refer to 16.8 Bus Error Monitoring Section.

Table 16.15 Associations between Bus Types and Registers

n	Bus Master	Bus Error Status Register	Bus Error Clear Register	Bus Error Interrupt Enable Register
0	CPU0IF	BUSERRSTATCPU0IF	BUSERRCLRCPU0IF	BUSINTENCPU0IF
1	CPU0OA	BUSERRSTATCPU0OA	BUSERRCLRCPU0OA	BUSINTENCPU0OA
8	DMAC0	BUSERRSTATDMAC0	BUSERRCLRDMAC0	BUSINTENDMAC0
9	EXDMAC	BUSERRSTATEXDMAC	BUSERRCLREXDMAC	BUSINTENEXDMAC
10	EDMAC	BUSERRSTATEDMAC	BUSERRCLREDMAC	BUSINTENEDMAC
11	XSPI0	BUSERRSTATXSPI0	BUSERRCLRXSPI0	BUSINTENXSPI0
12	XSPI1	BUSERRSTATXSPI1	BUSERRCLRXSPI1	BUSINTENXSPI1

16.3.30 Bus Error Clear Register (BUSERRCLRCPU0IF, BUSERRCLRCPU0OA, BUSERRCLRDMAC0, BUSERRCLREXDMAC, BUSERRCLREDMAC, BUSERRCLRXSPI0, BUSERRCLRXSPI1)

Address(es): BUS.BUSERRCLRCPU0IF 8701 E804h, BUS.BUSERRCLRCPU0OA 8701 E814h, BUS.BUSERRCLRDMAC0 8701 E884h, BUS.BUSERRCLREXDMAC 8701 E894h, BUS.BUSERRCLREDMAC 8701 E8A4h, BUS.BUSERRCLRXSPI0 8701 E8B4h, BUS.BUSERRCLRXSPI1 8701 E8C4h,
BUS_NS.BUSERRCLRCPU0IF 0701 E804h, BUS_NS.BUSERRCLRCPU0OA 0701 E814h, BUS_NS.BUSERRCLRDMAC0 0701 E884h, BUS_NS.BUSERRCLREXDMAC 0701 E894h, BUS_NS.BUSERRCLREDMAC 0701 E8A4h, BUS_NS.BUSERRCLRXSPI0 0701 E8B4h, BUS_NS.BUSERRCLRXSPI1 0701 E8C4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MSERRCLR	ILERRCLR	MMERRCLR	—	—	SLERRCLR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SLERRCLR	Slave Bus Error Clear	Writing 1 to this bit clears the BUSERRSTATx.SLERRSTAT flag.	R/(W) *1
b2 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	MMERRCLR	Bus Master MPU Error Clear	Writing 1 to this bit clears the BUSERRSTATx.MMERRSTAT flag.	R/(W) *1
b4	ILERRCLR	Illegal Address Access Error Clear	Writing 1 to this bit clears the BUSERRSTATx.ILERRSTAT flag.	R/(W) *1
b5	MSERRCLR	Master Security Attribution Unit Error Clear	Writing 1 to this bit clears the BUSERRSTATx.MSERRSTAT flag.	R/(W) *1
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

x = CPU0IF, CPU0OA, DMAC0, EXDMAC, EDMAC, XSPI0, XSPI1

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Only 1 can be written to this bit. This bit is read as 0. Writing 0 has no effect.

When writing 1 to the error clear bit in the Bus Error Clear Register for each bus, stop the bus access that causes an error in the target bus master.

SLERRCLR Bit (Slave Bus Error Clear)

Writing 1 to this bit clears the BUSERRSTATx.SLERRSTAT flag. This bit is read as 0.

MMERRCLR Bit (Bus Master MPU Error Clear)

Writing 1 to this bit clears the BUSERRSTATx.MMERRSTAT flag. This bit is read as 0.

ILERRCLR Bit (Illegal Address Access Error Clear)

Writing 1 to this bit clears the BUSERRSTATx.ILERRSTAT flag. This bit is read as 0.

MSERRCLR Bit (Master Security Attribution Unit Error Clear)

Writing 1 to this bit clears the BUSERRSTATx.MSERRSTAT flag. This bit is read as 0.

16.3.31 Bus Operation after Detection Register (BUSOAD)

Address(es): BUS.BUSOAD 8701 E000h,
BUS_NS.BUSOAD 0701 E000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	BWERROAD	SLERROAD	ILERROAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ILERROAD	Illegal Address Access Error Operation After Detection	0: Interrupt 1: Reset	R/W
b1	SLERROAD	Slave Bus Error Operation After Detection	0: Interrupt 1: Reset	R/W
b2	BWERROAD	Bufferable Write Error Operation After Detection	0: Interrupt 1: Reset	R/W
b15 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: When an error occurs during an unexpected access from the CPU while the operation bit after each error detection or the BUSINTENx.EN bit is set to 1, a system reset request may be generated.
(x = CPU0IF, CPU0OA, DMAC0, EXDMAC, EDMAC, XSPI0, XSPI1)

ILERROAD Bit (Illegal Address Access Error Operation After Detection)

This bit specifies the operation to be taken when the illegal address access error is detected.
If this bit is 0 and BUSINTENx.EN = 1, an error response is returned and interrupt request is generated. If this bit is 1 and BUSINTENx.EN = 1, error response is returned and reset request is generated.
x = CPU0IF, CPU0OA, DMAC0, EXDMAC, EDMAC, XSPI0, XSPI1

SLERROAD Bit (Slave Bus Error Operation After Detection)

This bit specifies the operation to be taken when the slave bus error is detected.
If this bit is 0 and BUSINTENx.EN = 1, an error response is returned and interrupt request is generated. If this bit is 1 and BUSINTENx.EN = 1, error response is returned and reset request is generated.

BWERROAD Bit (Bufferable Write Error Operation After Detection)

This bit specifies the operation to be taken when the bufferable write error is detected.
If this bit is 0 and BUSINTENx.EN = 1, an error response is returned and interrupt request is generated. If this bit is 1 and BUSINTENx.EN = 1, error response is returned and reset request is generated.
In addition, interrupts due to bus errors (including bufferable errors) can also be used as non-maskable interrupts. For details, refer to the NMIER register specifications in section 15, Interrupt Controller (ICUM)

16.3.32 Bus Operation after Detection Protect Register (BUSOADPT)

Address(es): BUS.BUSOADPT 8701 E004h,
BUS_NS.BUSOADPT 0701 E004h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	PROTECT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PROTECT	Protection of Register	0: Writing to the BUSOAD register is enabled. 1: Writing to the BUSOAD register is disabled. Reading is possible.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Enable or disable writing to the PROTECT bit	W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

PROTECT Bit (Protection of Register)

This bit enables or disables writing to the associated registers to be protected.

This bit controls the following registers:

- BUSOAD

When the PROTECT bit is set simultaneously, write A5h to the KEY[7:0] bits by accessing them in 16-bit units.

KEY[7:0] Bits (Key Code)

The KEY[7:0] bits enable or disable writing to the PROTECT bit. When writing to the PROTECT bit simultaneously, write A5h to the KEY[7:0] bits. When other values are written to the KEY[7:0] bits, the PROTECT bit is not updated. The KEY[7:0] bits are always read as 00h.

16.3.33 Master Bufferable Write Error Status Register (MBWERRSTAT)

Address(es): BUS.MBWERRSTAT 8701 EB00h,
BUS_NS.MBWERRSTAT 0701 EB00h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	MBWERR19	MBWERR18	MBWERR17	MBWERR16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	MBWERR8	—	—	—	—	—	—	—	MBWERR0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MBWERR0	Master Bufferable Write Error 0 Flag	0: No bufferable write error occurred 1: Bufferable write error occurred	R
b7 to b1	—	Reserved	These bits are read as 0.	R
b8	MBWERR8	Master Bufferable Write Error 8 Flag	0: No bufferable write error occurred 1: Bufferable write error occurred	R
b15 to b9	—	Reserved	These bits are read as 0.	R
b16	MBWERR16	Master Bufferable Write Error 16 Flag	0: No bufferable write error occurred 1: Bufferable write error occurred	R
b17	MBWERR17	Master Bufferable Write Error 17 Flag	0: No bufferable write error occurred 1: Bufferable write error occurred	R
b18	MBWERR18	Master Bufferable Write Error 18 Flag	0: No bufferable write error occurred 1: Bufferable write error occurred	R
b19	MBWERR19	Master Bufferable Write Error 19 Flag	0: No bufferable write error occurred 1: Bufferable write error occurred	R
b31 to b20	—	Reserved	These bits are read as 0.	R

Note: This register is cleared by reset other than bus error reset, common memory error reset, and local memory error reset.

MBWERRn Flag (Master Bufferable Write Error n Flag) (n = 0, 8, 16 to 19)

When bufferable write access error has occurred, the MBWERRSTAT.MBWERRn flag is set to 1.

[Clearing condition]

- Set the MBWERRCLR.MBWECLRn bit to 1.

Table 16.16 lists the registers associated with each bus master type.

Table 16.16 Associations between Bus Master Types and Bits

Bus Master type	Master Bufferable Write Error Status Flag	Master Bufferable Write Error Clear Bit
CPU0OA	MBWERR0	MBWECLR0
DMAC/DTC0	MBWERR8	MBWECLR8
EXDMAC	MBWERR16	MBWECLR16
EDMAC	MBWERR17	MBWECLR17
XSPI0	MBWERR18	MBWECLR18
XSPI1	MBWERR19	MBWECLR19

16.3.34 Master Bufferable Write Error Clear Register (MBWERRCLR)

Address(es): BUS.MBWERRCLR 8701 EB08h,
BUS_NS.MBWERRCLR 0701 EB08h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	MBWECLR19	MBWECLR18	MBWECLR17	MBWECLR16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	MBWECLR8	—	—	—	—	—	—	—	MBWECLR0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MBWECLR0	Master Bufferable Write Error 0 Flag Clear	Writing 1 to this bit clears the MBWERSTAT.MBWERR0 flag.	R/(W)*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	MBWECLR8	Master Bufferable Write Error 8 Flag Clear	Writing 1 to this bit clears the MBWERSTAT.MBWERR8 flag.	R/(W)*1
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	MBWECLR16	Master Bufferable Write Error 16 Flag Clear	Writing 1 to this bit clears the MBWERSTAT.MBWERR16 flag.	R/(W)*1
b17	MBWECLR17	Master Bufferable Write Error 17 Flag Clear	Writing 1 to this bit clears the MBWERSTAT.MBWERR17 flag.	R/(W)*1
b18	MBWECLR18	Master Bufferable Write Error 18 Flag Clear	Writing 1 to this bit clears the MBWERSTAT.MBWERR18 flag.	R/(W)*1
b19	MBWECLR19	Master Bufferable Write Error 19 Flag Clear	Writing 1 to this bit clears the MBWERSTAT.MBWERR19 flag.	R/(W)*1
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Only 1 can be written to this bit. This bit is read as 0. Writing 0 has no effect.

MBWECLRn Bit (Master Bufferable Write Error n Flag Clear) (n = 0, 8, 16 to 19)

Writing 1 to this bit clears the MBWERRSTAT.MBWERRn flag.

This bit is read as 0.

Bit	Symbol	Bit Name	Description	R/W
b0	EN	Bus Error Interrupt Request Enable	0: Disabled 1: Enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

When writing 1 to the BUSINTENx.EN bit, stop the bus access that causes an error in the target bus master.
x = CPU0IF, CPU0OA, DMAC0, EXDMAC, EDMAC, XSPI0, XSPI1

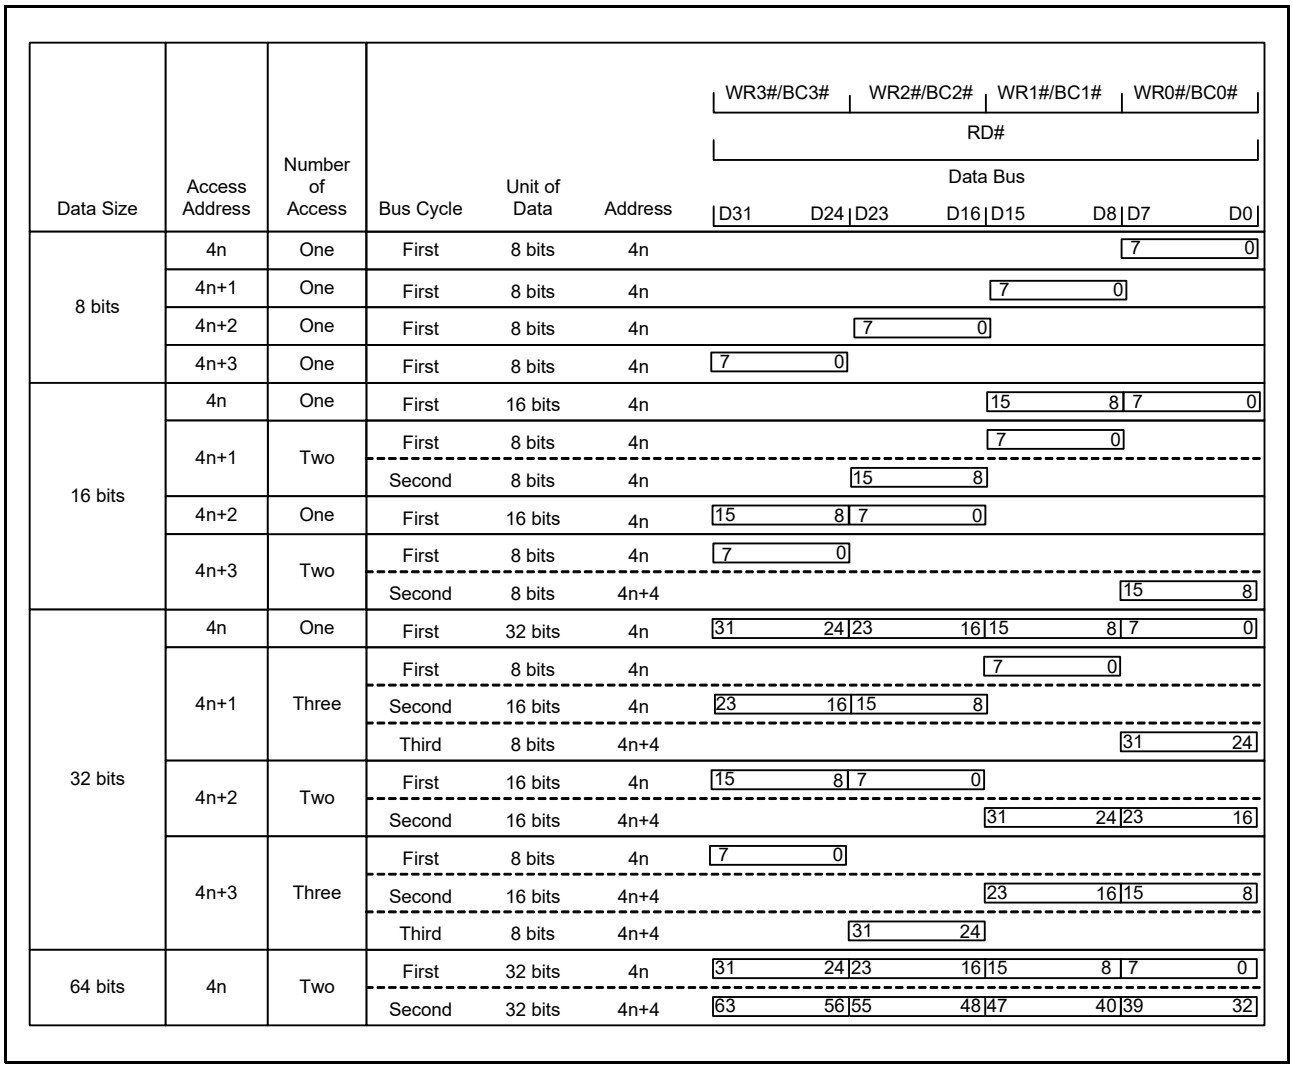
EN Bit (Bus Error Interrupt Request Enable)

To output a bus error interrupt request to the ICU due to an error except for a master bufferable write error, select the interrupt in the BUSOAD setting corresponding to each error, and enable the interrupt request with this bit. The setting of this bit does not depend on the issuance of a bus error interrupt request due to a master bufferable write error.

16.4 Endian and Data Alignment

The external bus has a data-alignment function to control which byte of the data bus (D31 to D24, D23 to D16, D15 to D8, or D7 to D0) is used according to the bus specifications of the area to be accessed (8-bit, 16-bit, or 32-bit bus space), data size, and endian format when accessing the external address space (the CS and SDRAM areas).

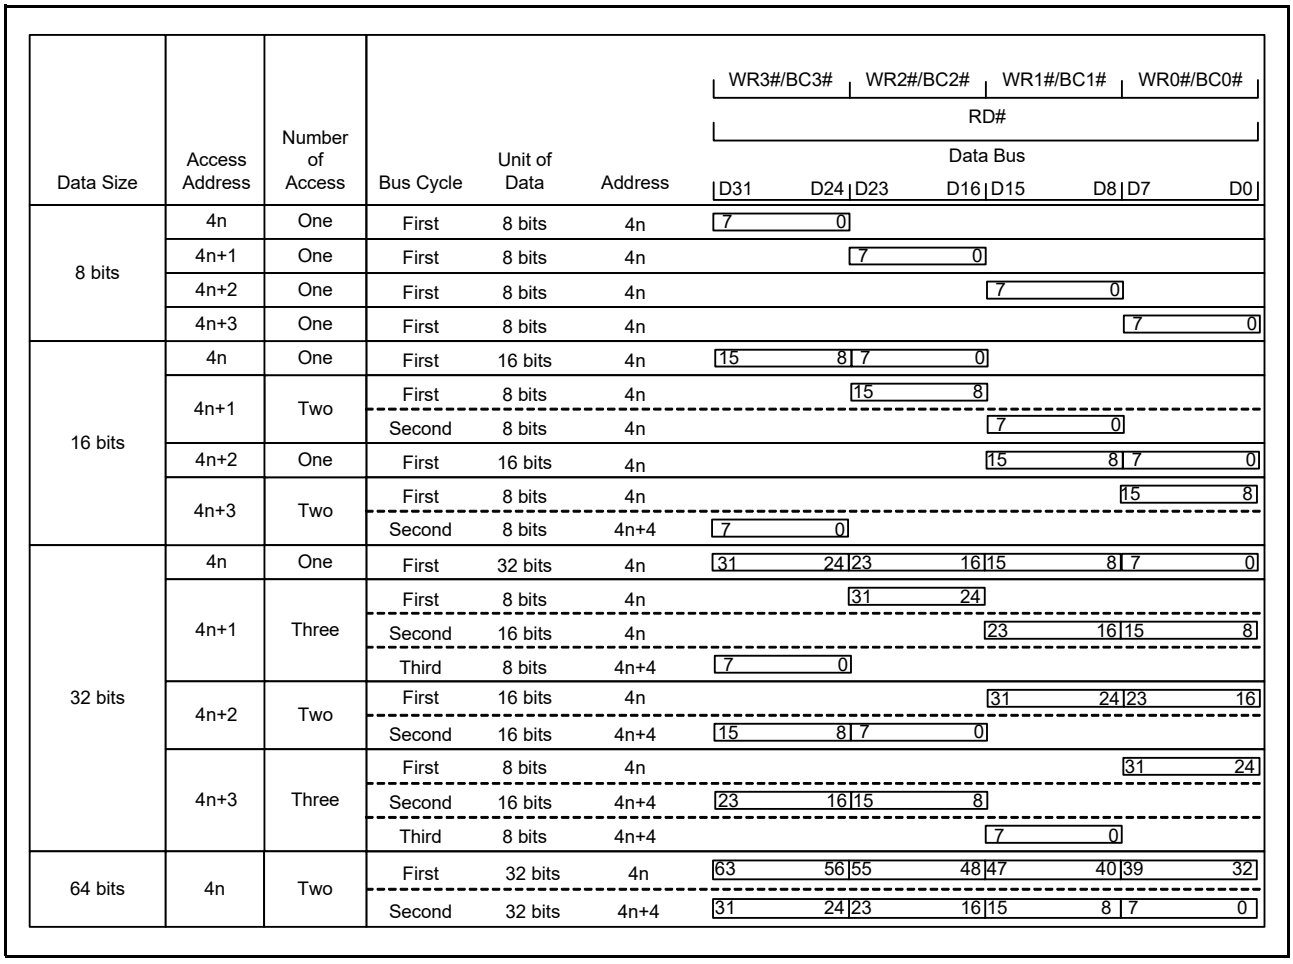
16.4.1 Data Alignment Control for CS Area



(1) 32-Bit Bus Space

When a 32-bit width is selected for a bus space by the BSIZE[1:0] bits in CSnCR, the address buses A23 to A2 are enabled to output address signals in units of 32 bits, and the address buses A1 and A0 are disabled (always output the low level).

When byte strobe mode is selected (the WRMOD bit = 0 in CSnMOD), the WR0# to WR3# pins are enabled. The BC0# to BC3# pins are not used.



When single write strobe mode is selected (the WRMOD bit = 1 in CSnMOD), only the WR0# pin is enabled and always outputs the low level during write access, regardless of the data size. Here, the WR1# to WR3# pins are invalid (always output the high level). The valid byte position is indicated by the BC0# to BC3# pins.

In 32-bit bus space, the valid positions of data external to the chip and of control signals differ according to whether the endian is big or little.

Data Size	Access Address	Number of Access	Bus Cycle	Unit of Data	Address

Figure 16.5 Data Alignment (Big Endian) in 32-Bit Bus Space

(2) 16-Bit Bus Space

When a 16-bit width is selected for a bus space by the BSIZE[1:0] bits in CSnCR, the address buses A23 to A1 are enabled to output address signals in units of 16 bits, and the address bus A0 is disabled (always output the low level).
When byte strobe mode is selected (CSnMOD.WRMOD = 0), the WR0# and WR1# pins are enabled, and the WR2# and WR3# pins are disabled (fixed high). The BC0# to BC3# pins are not used.
When single write strobe mode is selected (CSnMOD.WRMOD = 1), only the WR0# pin is enabled and always outputs the low level during write access, regardless of the data size. Here, the WR1# to WR3# pins are invalid (always output the high level). The valid byte position is indicated by the BC0# and BC1# pins.
In 16-bit bus space, the valid positions of data external to the chip and of control signals differ according to whether the endian is big or little. See Figure 16.6 and Figure 16.7.
In 16-bit bus space, page access can occur in access to data in 32-bit units. Specifically, page access can occur when an access does not spread over a 32-bit boundary and causes no change in BC0# and BC1# signals. The situations in which page access occurs are indicated by the letter (p) in Figure 16.6 and Figure 16.7.

(p): Page access (only when page access is enabled with the CSnMOD.PRENB and PWENB bits)

Figure 16.7 Data Alignment (Big Endian) in 16-Bit Bus Space

(3) 8-Bit Bus Space

When an 8-bit bus space is selected by the CSnCR.BSIZE[1:0] bits, the address buses A23 to A0 are enabled to output address signals in byte units.

In 8-bit bus space, only the WR0# pin is valid regardless of write access mode, and always outputs the low level during write access. The WR1# to WR3# pins and the BC0# to BC3# pins are not used.

In 8-bit bus space, page access can occur in access to data in 16-, 32- or 64-bit units. Specifically, page access can occur when an access does not spread over a 32-bit boundary. The situations in which page access occurs are indicated by the letter (p) in Figure 16.8 and Figure 16.9.

In 8-bit bus space, the valid positions of data external to the chip are D7 to D0 and WR0# is used as the control signal, regardless of the endian mode.

Data Size	Access Address	Number of Access	Bus Cycle	Unit of Data	Address		WR1#/BC1# WR0#/BC0# RD# Data Bus D15 D8 D7 D0

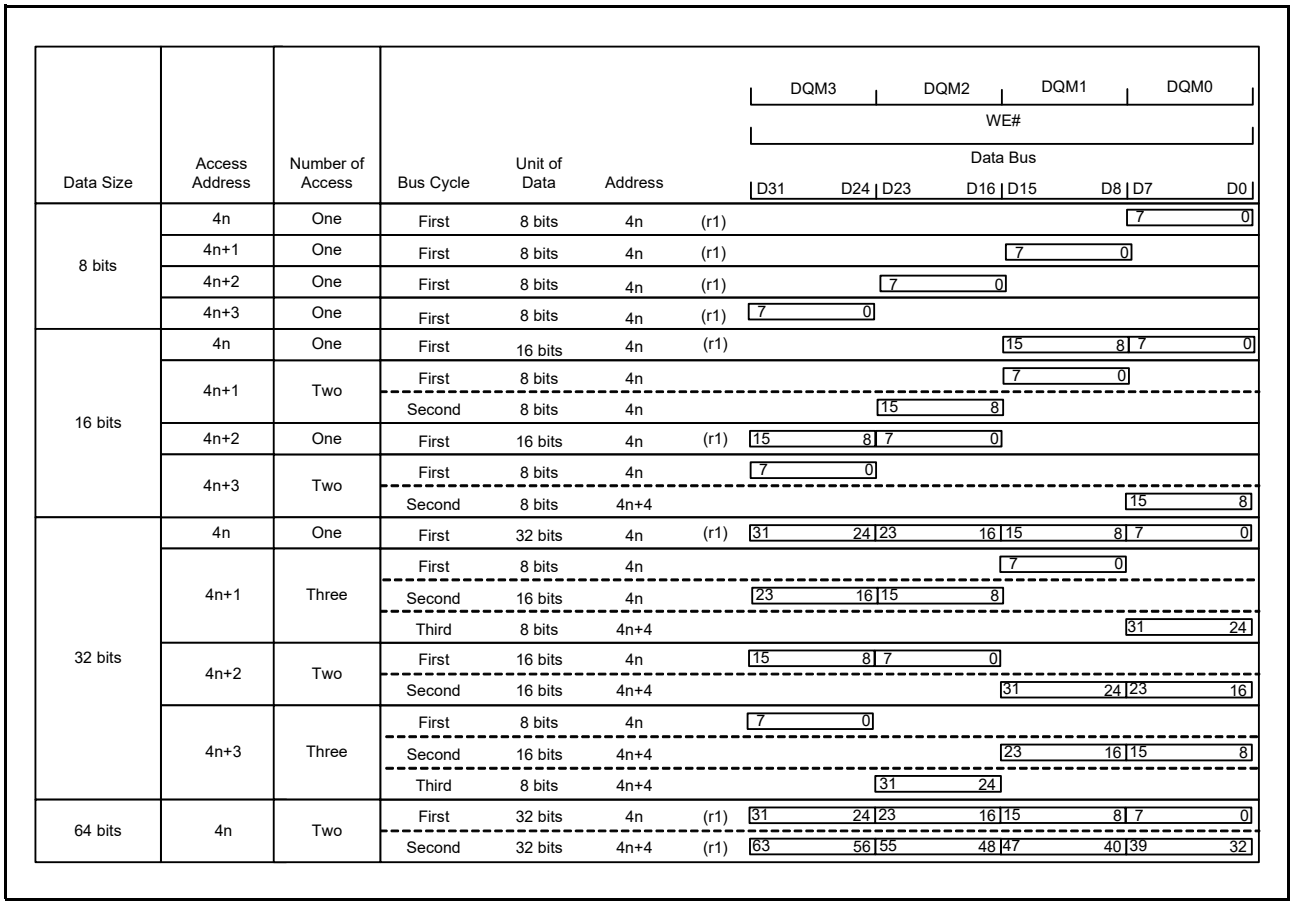
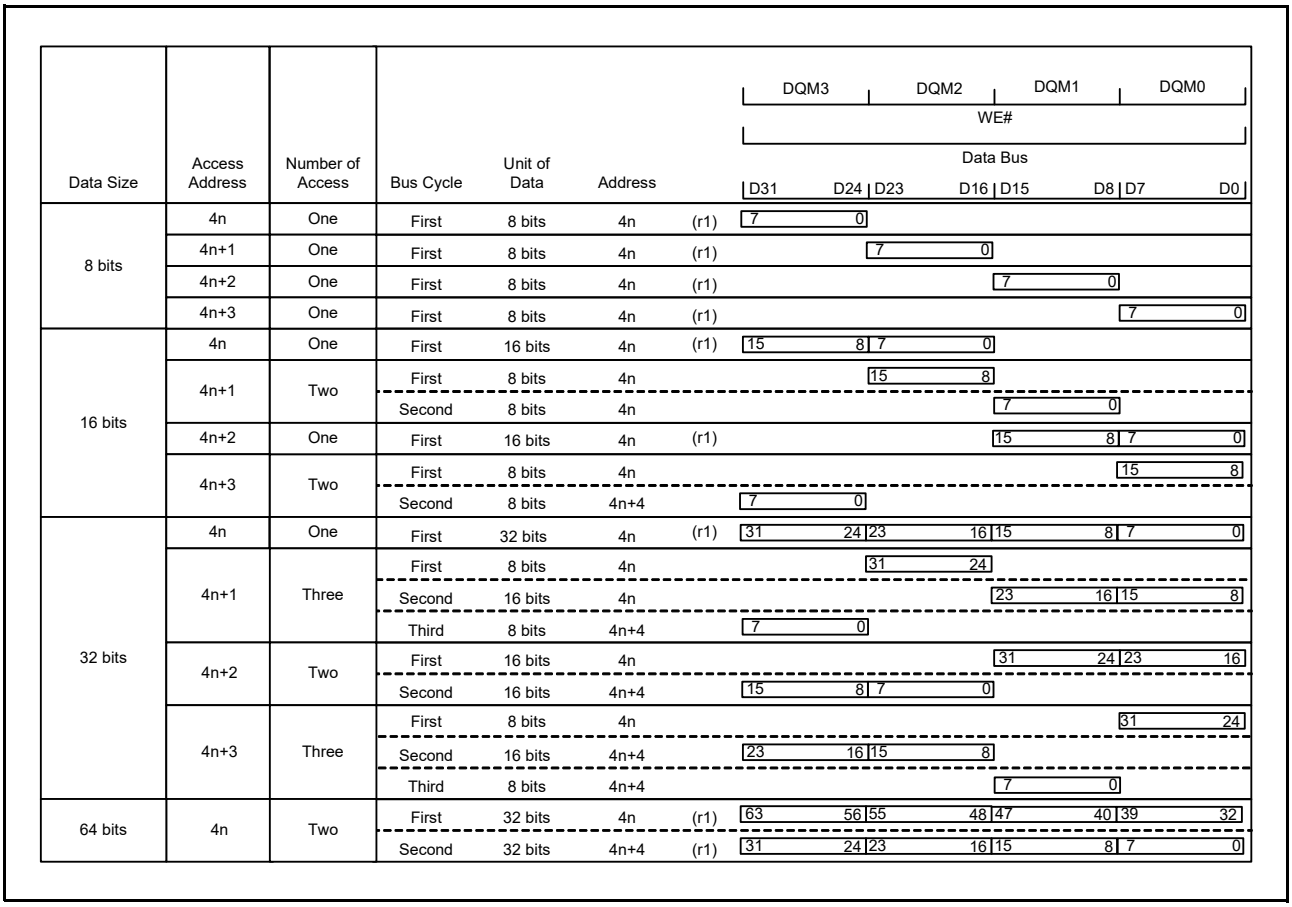
Figure 16.9 Data Alignment (Big Endian) in 8-Bit Bus Space



16.4.2 Data Alignment Control for SDRAM Area

(1) 32-Bit Bus Space

When a 32-bit width is selected for a bus space by the SDCCR.BSIZE[1:0] bits, the address buses A26 to A2 are enabled to output address signals in units of 32 bits, and the address buses A1 and A0 are disabled (always output the low level). The valid byte position is indicated by DQM0 to DQM3 signals. The external data is accessed using the D31 to D24, D23 to D16, D15 to D8, and D7 to D0 pins. Data widths that can be handled in a single cycle of access are 8, 16 and 32 bits.



In 32-bit bus space, the valid positions of data external to the chip and of SDRAM control signals (DQM0 to DQM3) differ according to whether the endian is big or little. Figure 16.10 and Figure 16.11 show data alignment control when the endian is little and big, respectively.

When the conditions indicated by (r1) in Figure 16.10 and Figure 16.11 are satisfied while the SDAMOD.BE bit is set to 1, the SDRAM area controller continues the access without reasserting the same row address, enabling consecutive rounds of memory accesses to the SDRAM.

Data Size	Access Address	Number of Access	Bus Cycle	Unit of Data	Address	
8 bits	4n	One	First	8 bits	4n	(r1)
	4n+1	One	First	8 bits	4n	(r1)

			Second	32 bits	4n+4	(r1)

Figure 16.11 Data Alignment (Big Endian) in 32-Bit Bus Space of SDRAM Area

(2) 16-Bit Bus Space

When a 16-bit width is selected for a bus space by the SDCCR.BSIZE[1:0] bits, the address buses A26 to A1 are enabled to output address signals in units of 16 bits, and the address buses A0 is disabled (always output the low level). The valid byte position is indicated by DQM0 and DQM1 signals.

In 16-bit bus space, the external data is accessed using the D15 to D8 and D7 to D0 pins and DQM0 and DQM1 control signals. Data widths that can be handled in a single cycle of access are 8 and 16 bits.

When the conditions indicated by (r1) in Figure 16.12 and Figure 16.13 are satisfied while the SDAMOD.BE bit is set to 1, the SDRAM area controller continues the access without reasserting the same row address, enabling consecutive rounds of memory accesses to the SDRAM.

The valid positions of control signals and data outside the MCU depend on the endian order. For details, see Figure 16.12 and Figure 16.13.

Data Size	Access Address	Number of Access	Bus Cycle	Unit of Data	Address		DQM1 / DQM0 / WE# / Data Bus (D15 D8 D7 D0)

Figure 16.13 Data Alignment (Big Endian) in 16-Bit Bus Space of SDRAM Area

(3) 8-Bit Bus Space

When an 8-bit width is selected for a bus space by the SDCCR.BSIZE[1:0] bits, the address buses A26 to A0 are enabled to output address signals in units of 8 bits.
In 8-bit bus space, the external data is accessed using the D7 to D0 pins and DQM0 control signal. Eight-bit data can be accessed at a time; 16-bit data is accessed with two 8-bit accesses, and 32-bit data is accessed with four 8-bit accesses.
When the conditions indicated by (r1) in Figure 16.14 and Figure 16.15 are satisfied while the SDAMOD.BE bit is set to 1, the SDRAM area controller continues the access without reasserting the same row address, enabling consecutive rounds of memory accesses to the SDRAM.
The valid positions of control signals and data outside the MCU depend on the endian order. For details, see Figure 16.14 and Figure 16.15.

Figure 16.15 Data Alignment (Big Endian) in 8-Bit Bus Space of SDRAM Area

16.5 Operation of CS Area Controller

16.5.1 Separate Bus

The various periods in the timing charts are described below.
The CS area controller (CSC) operates in synchronization with the external bus clock (BCLK). The operation cycles, such as wait cycles specified with the CSC register, are counted on BCLK. In the following description, frequencies of BCLK and EBCLK pin output are the same, unless otherwise noted.
Access via the external bus starts at the same point as the output of a rising edge on the EBCLK pin. However, if the external bus clock (BCLK) and the output on the EBCLK pin are at different frequencies so that a single request from a bus master for transfer leads to two or more rounds of access via the external bus, the wait settings may cause the start of access for the second and subsequent rounds to coincide with the falling edge of the output on the EBCLK pin (refer to Figure 16.18 to Figure 16.27). If recovery cycles are inserted for bus access, the setting for the number of recovery cycles may also cause the start of access for the second and subsequent rounds to coincide with the falling edge of the output on the EBCLK pin (refer to Figure 16.45).

(a) Tw1 to Twn (Clock Cycles of Waiting for a Normal Read Cycle or Normal Write Cycle)

The period Tw1 to Twn is made up of the number of clock cycles between the start of access via the external bus clock and one cycle before the strobe signal is valid. The number of cycles are selectable within the range from zero to 31. The respective wait settings determine the timing of the assertion of the CSn#, RD#, and WRn# signals during this period. Specifically, the periods of waiting are controlled by the following bits in CSn wait control register 2 (CSnWCR2).

- the CS assert wait select bits (CSON[2:0])
- the RD assert wait select bits (RDON[2:0])
- the WR assert wait select bits (WRON[2:0])
- the write data output wait select bits (WDON[2:0])

The number of clock cycles for each of these periods of waiting is selectable as a value from zero to seven counted from the start of external bus access. Selectable numbers of cycles are also within the overall number of clock cycles of waiting for reading or writing.

(b) Tend (Clock Cycle where the Strobe Signal is Valid)

Tend is the next clock cycle after completion of the period of waiting for a normal cycle of reading or writing or for a cycle of page reading or page writing. If each wait select bit for a normal cycle of reading or writing or for a cycle of page reading or page writing is zero, the clock cycle where bus access starts is the clock cycle where the strobe signal is valid. The RD# and WRn# signals are negated in the next clock cycle after the cycle where the strobe signal is valid. In the case of read access, the clock cycle where the strobe signal is valid becomes the clock cycle where the data to be read are sampled.
If an external wait is enabled, the wait signal is sampled at the time of the cycle where the strobe signal is valid. The bus cycle is extended if the wait signal is at the low level. The bus cycle is completed in the next clock cycle if the wait signal is at the high level. Tend indicates the cycle where sampling of the wait signal starts.
After the first cycle where the strobe signal is valid during page access, second and subsequent page access operations (see (e) Tpw1 to Tpwn (Page-Read Cycle Wait or Page-Write Cycle Wait)) start in the next cycle except in cases of write access where a setting (other than zero) for write-data output extension clock cycles (see (d) Tdw1 to Tdwn (Write-Data Output Extension Clock Cycles)) has been made. If the setting for the RD or WR assertion wait is a value other than zero, the RD# and WRn# signals are negated in the next clock cycle. If the setting is zero, assertion continues. Furthermore, the CSn# signal continues to be asserted rather than being negated.

(c) Tn1 to Tnm (Clock Cycles of CS Extension)

In the case of normal access, Tn1 to Tnm represent the clock cycles of the period following the cycle where the strobe signal is valid (Tend) up to negation of the CSn# signal. For read or write access, the timing of negation can be controlled by the read-access CS extension cycle select bits (CSROFF[2:0]) and the write-access CS extension cycle select bits (CSWOFF[2:0]) in the CSn wait control register 2 (CSnWCR2), respectively.
The number of cycles are counted from the cycle following the cycle where the strobe signal is valid.
In the case of page access, Tn1 to Tnm represent the clock cycles of the period for the cycle following the last cycle where the strobe signal is valid up to negation of the CSn# signal.
For write access, setting the write data output extension cycle select bits (WDOFF[2:0]) controls extension of the period where the address and output data are valid.

(d) Tdw1 to Tdwn (Write-Data Output Extension Clock Cycles)

For write access, if the setting for write-data output extension wait is a value other than zero, clock cycles of write-data output extension are inserted from the cycle that follows the cycle where the strobe signal is valid (Tend).
In the case of normal access, this is inserted within the period of clock cycles of CS extension (see (c) Tn1 to Tnm (Clock Cycles of CS Extension)).
In the case of page access, this is inserted within the period of the cycle where the strobe signal is valid and subsequent page access or within the period of clock cycles of CS extension (see (c) Tn1 to Tnm (Clock Cycles of CS Extension)). Valid address and data output are extended over this period, and the WRn# signal is negated.

(e) Tpw1 to Tpwn (Page-Read Cycle Wait or Page-Write Cycle Wait)

For the second and subsequent bus cycles during page access, the values for a page-read cycle wait or page-write cycle wait are used instead of the settings for a normal read or write cycle wait. Setting the WR assert wait select bits becomes enabled in the same way as for the first round of access. How the setting for RD assertion controls operation depends on the setting for page-read access mode (the PRMOD bit in CSnMOD) as described below.

CSnMOD.PRMOD = 0: A wait until RD assertion is inserted in the same way as for the first round of access, and the RD# signal is negated.
CSnMOD.PRMOD = 1: Although a wait until RD assertion is inserted in the same way as for normal-access compatibility mode, the RD# signal continues to be asserted over this period.

(f) Tr1 to Trn (Recovery Cycles)

Recovery cycles can be inserted from the point where a bus cycle is completed (CSn# signal negation). The number of recovery cycles can be controlled by the setting of the read recovery (RRCV) or write recovery (WRCV) bits in the CSn recovery cycle register (CSnREC). Both numbers of recovery cycles are counted from the end of a bus cycle (CSn# negation) and can be selected from 0 to 15 cycles. For details on recovery cycles, refer to section 16.5.4, Insertion of Recovery Cycles.

(1) Normal Access

When the PRENB and PWENB bits in the CSnMOD register are set to 0 to disable page-read and page-write access, respectively, all bus accesses will take the form of normal access operations.
Even when the PRENB and PWENB bits are set to 1 to enable page-read and page-write access, respectively, bus access other than page access will take the form of normal access operations.
Figure 16.16 to Figure 16.18 show the normal access operations.

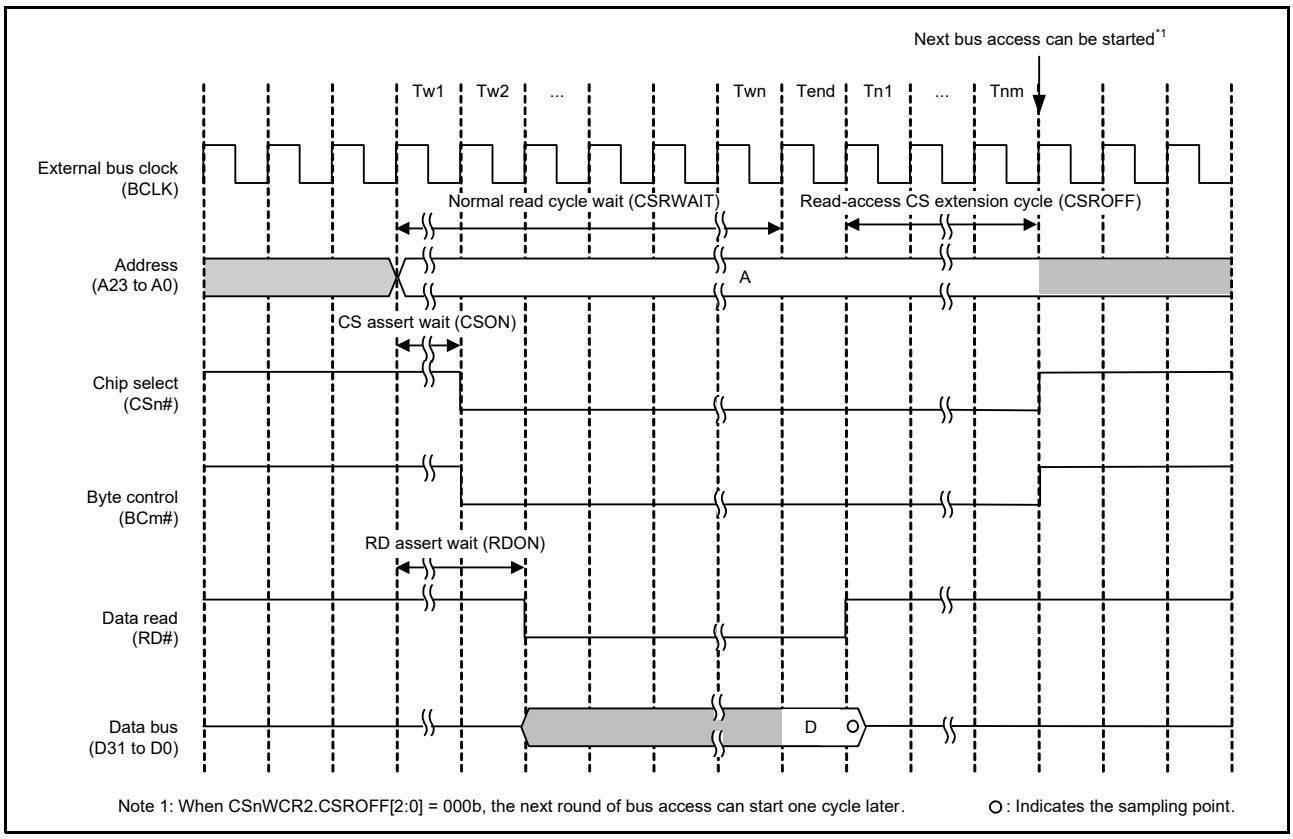

Figure 16.16 Bus Timing (Normal-Read Operation) (n = 0 to 7, m = 0 to 3)

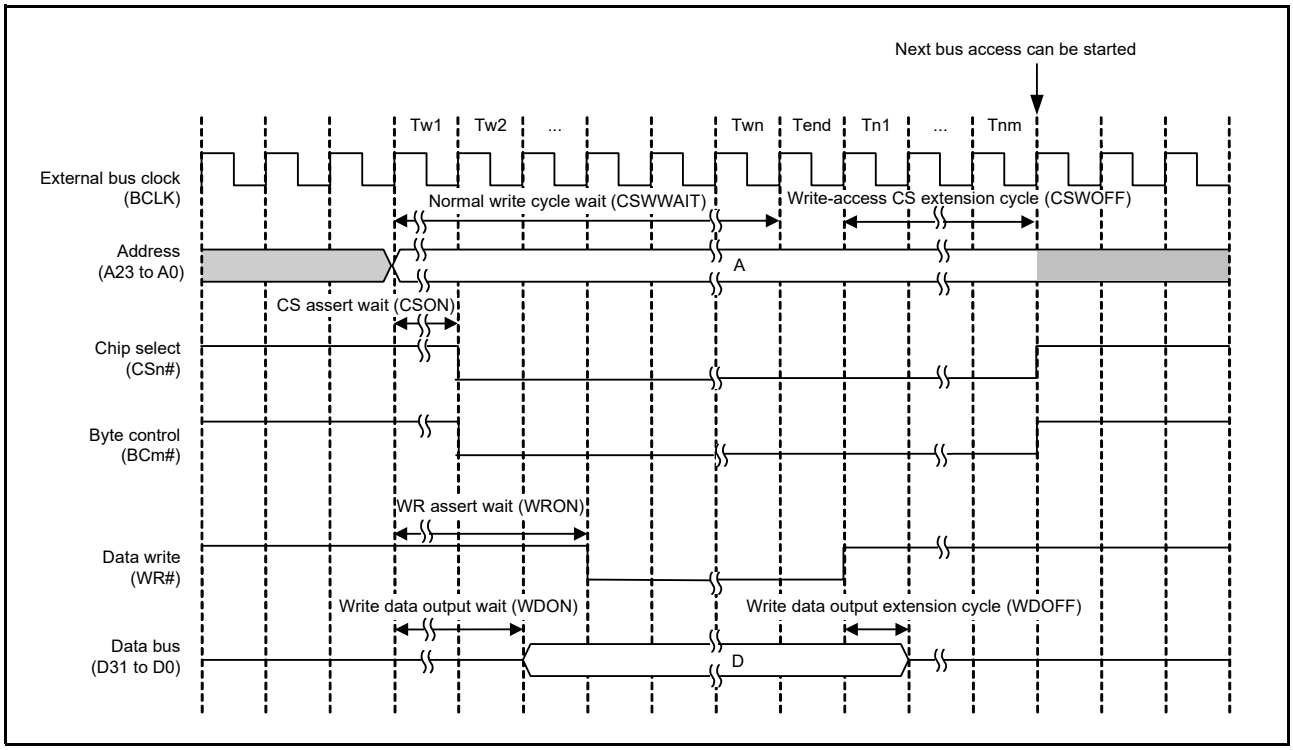

Figure 16.17 Bus Timing (Normal-Write Operation, Single Write Strobe Mode) (n = 0 to 7, m = 0 to 3)

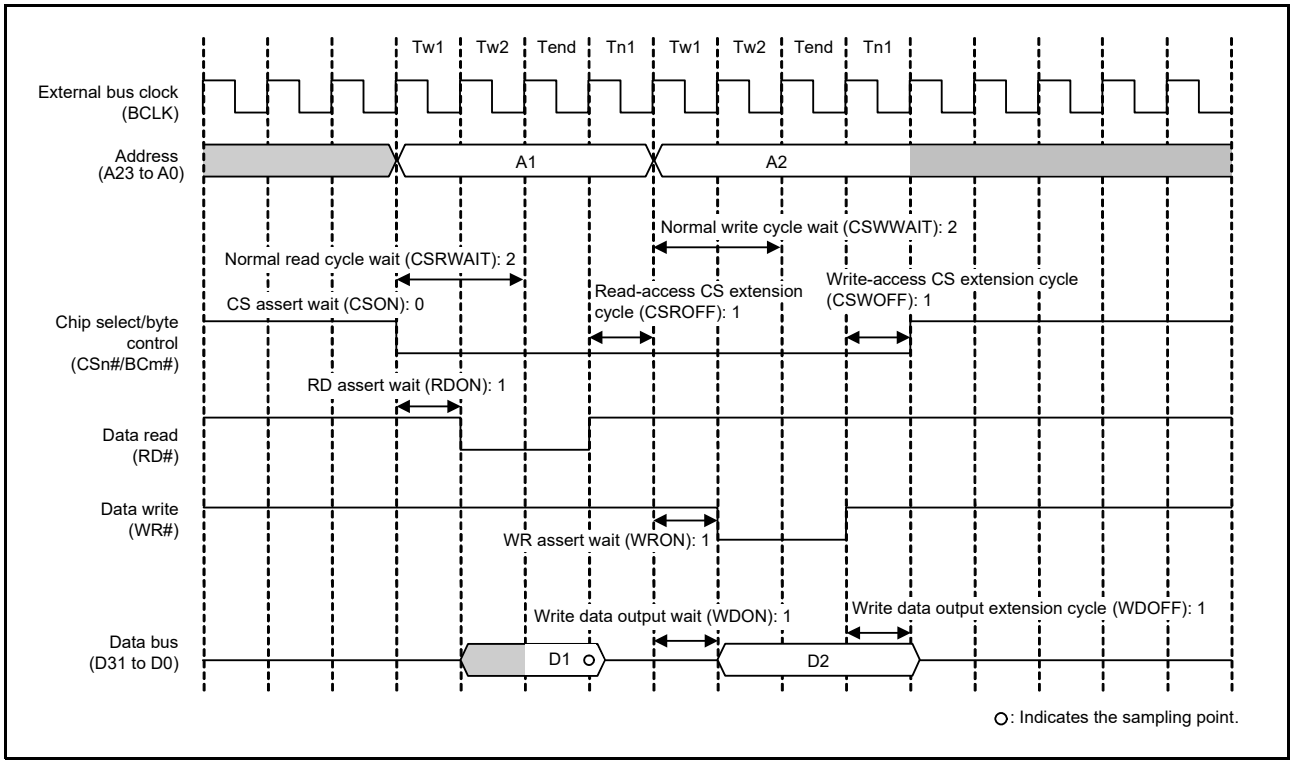

Figure 16.18 Example of Normal Access Operation (Read/Write) (n = 0 to 7, m = 0 to 3)

When two or more rounds of external bus access are required in response to a single request for transfer from a bus master, normal access operations (steps (a) Tw1 to Twn (Clock Cycles of Waiting for a Normal Read Cycle or Normal Write Cycle) to (d) Tdw1 to Tdwn (Write-Data Output Extension Clock Cycles)) are repeated. Figure 16.19 and Figure 16.20 show examples of operations when two rounds of bus access are generated in response to a single request for transfer. If the recovery cycle insertion condition is satisfied, recovery cycles (step (f) Tr1 to Trn (Recovery Cycles)) are also inserted in the second and subsequent external bus accesses (refer to Figure 16.43). The values of the wait control registers are example settings. In practice, set the register bits according to the specifications of connected devices.

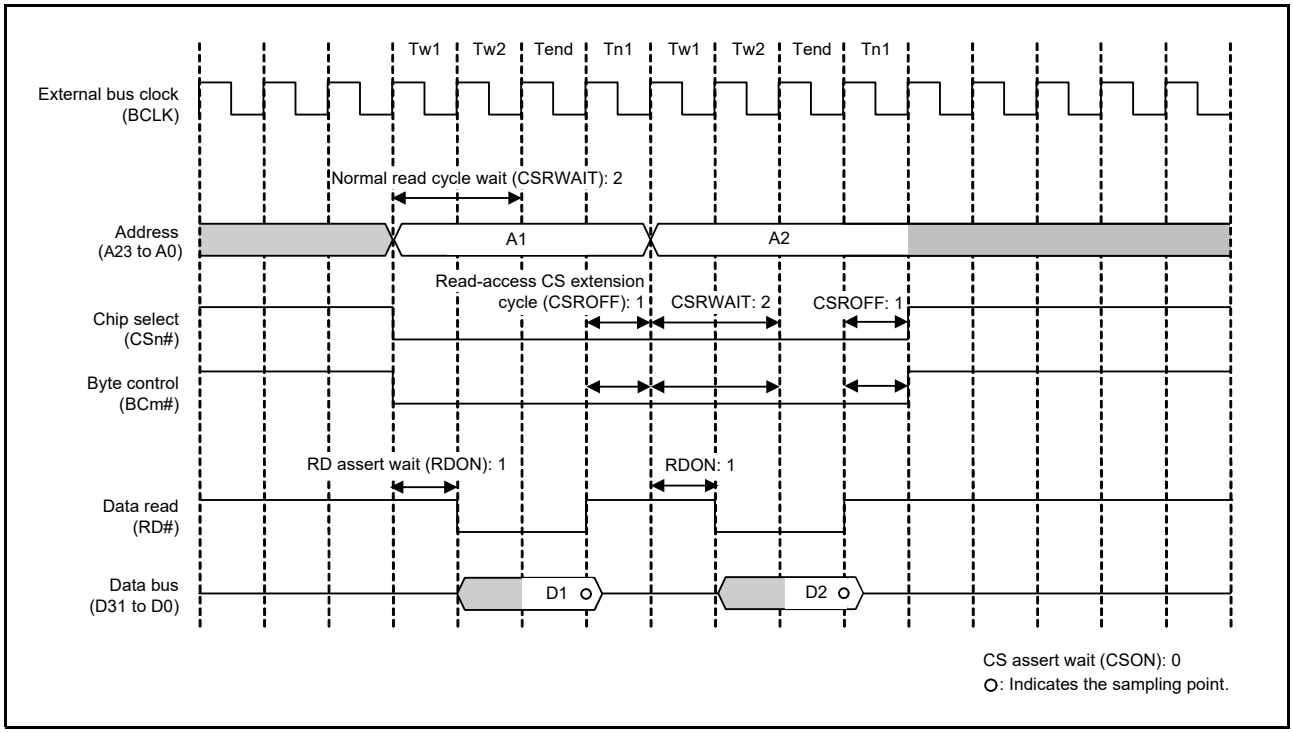

Figure 16.19 Example of Normal-Read Operation (when Two Rounds of Bus Access are Generated in Response to a Single Request for Transfer) (n = 0 to 7, m = 0 to 3)

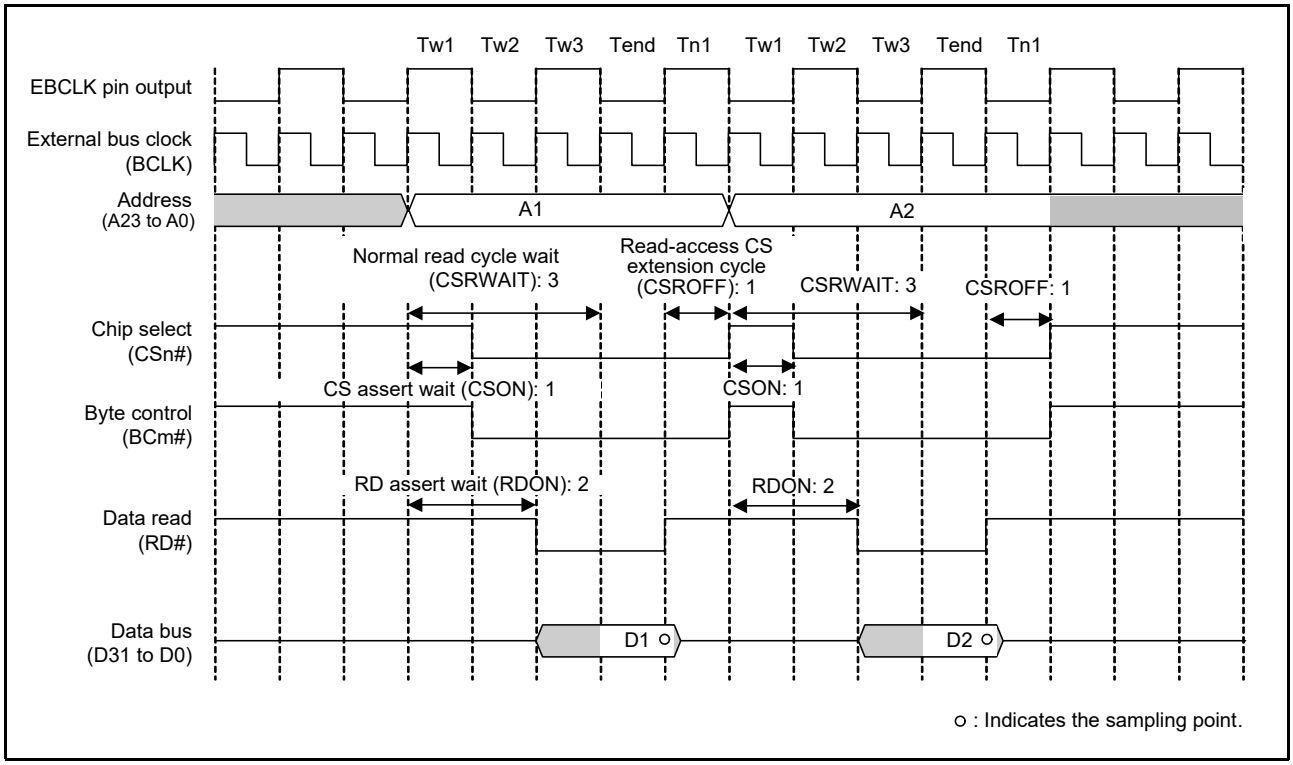

Figure 16.26 Example of Normal-Read Operation (when 1/2 BCLK is Selected with the EBCLK Pin Output Select Bit and Two Rounds of Bus Access are Generated in Response to a Single Request for Transfer) (n = 0 to 7, m = 0 to 3)

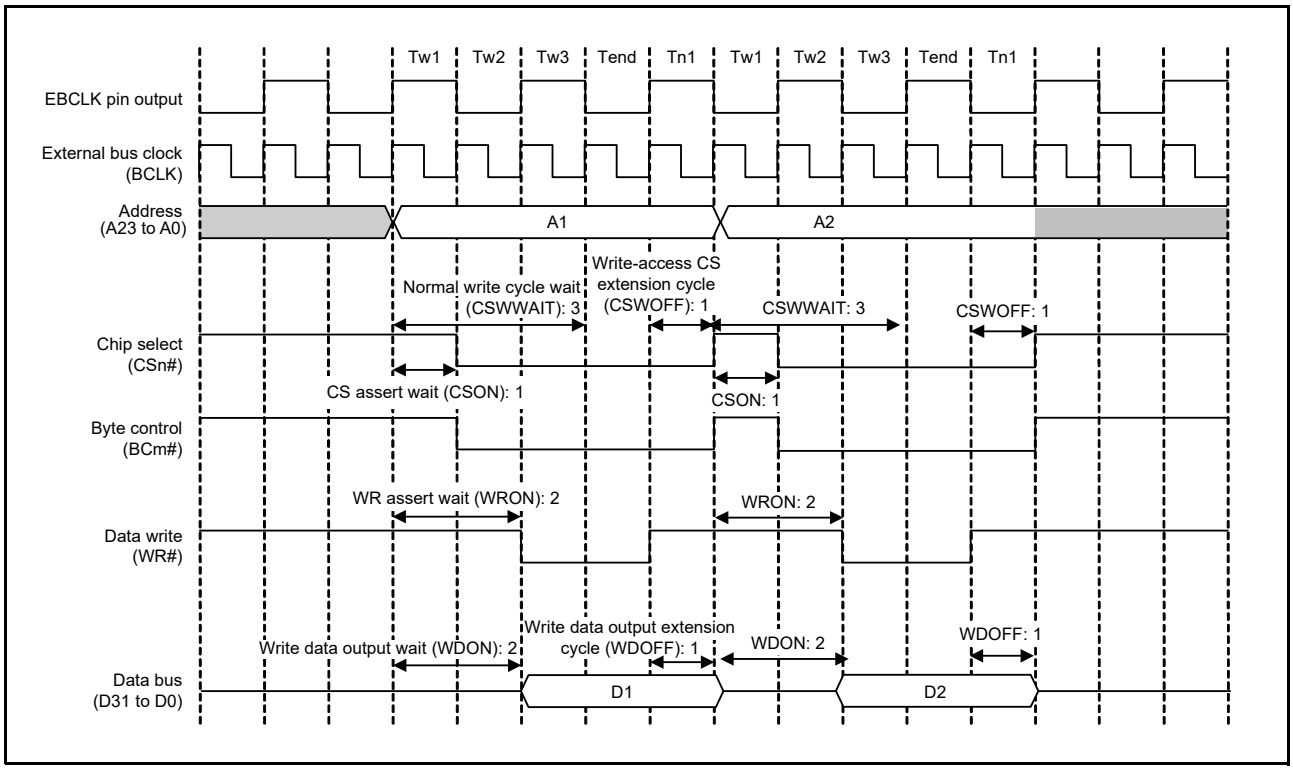

Figure 16.27 Example of Normal-Write Operation (when 1/2 BCLK is Selected with the EBCLK Pin Output Select Bit and Two Rounds of Bus Access are Generated in Response to a Single Request for Transfer) (n = 0 to 7, m = 0 to 3)

(2) Page Access

When the PRENB and PWENB bits in CSnMOD are set to 1 to enable page-read and page-write access, respectively, the bus access for page access operations becomes page reading and writing. Specifically, page access can occur when two or more rounds of external bus access are required for a single transfer request from the bus master. However, normal access is made when the split accesses are not aligned or the access spreads over the 32-bit boundary. Refer to Figure 16.6 to Figure 16.9 for the conditions under which page access occurs.
Figure 16.28 and Figure 16.29 show examples of page access operations.

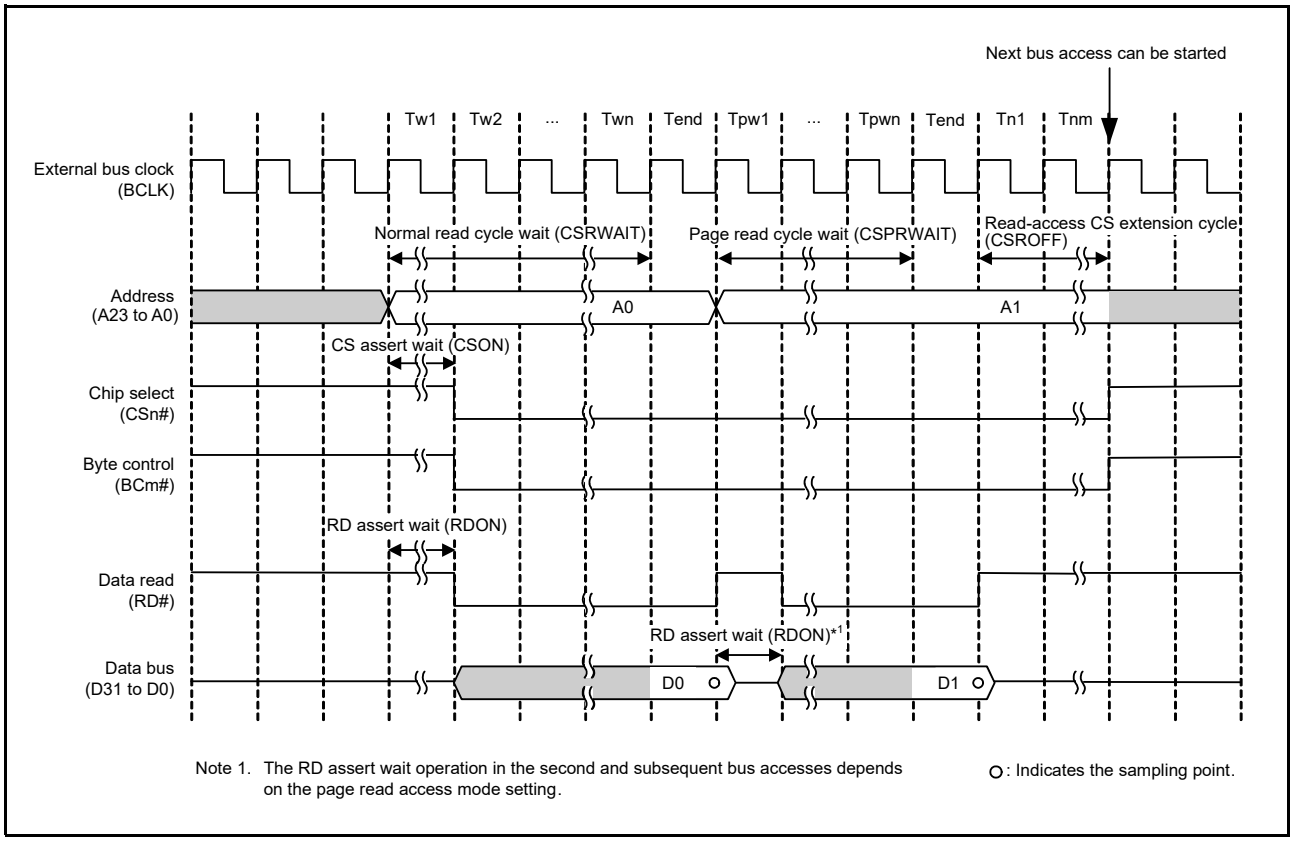

Figure 16.28 Page-Read Access Timing (n = 0 to 7, m = 0 to 3)

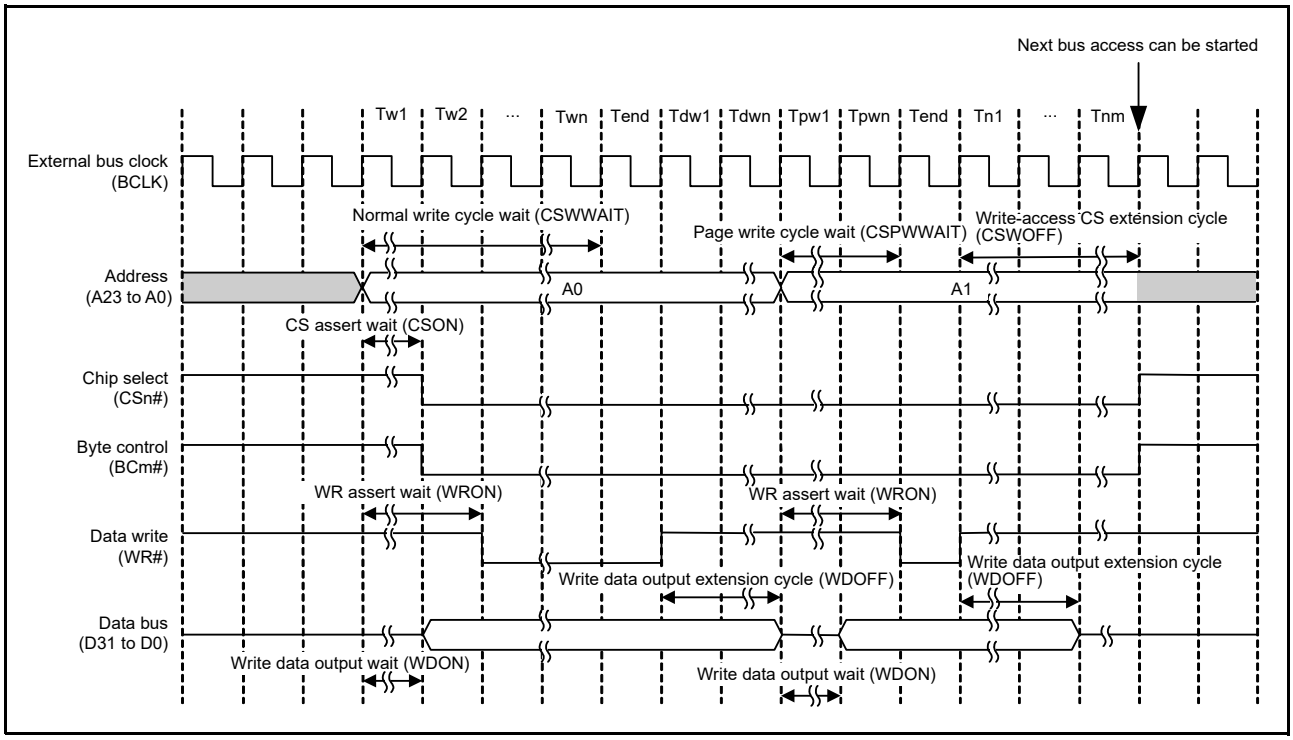

Figure 16.29 Page-Write Access Timing (n = 0 to 7, m = 0 to 3)

Figure 16.30 and Figure 16.31 show examples of operations for access to a 16-bit bus space in 32 bits. The values of the wait control registers are example settings. In practice, the register settings will correspond to the specifications of connected devices.

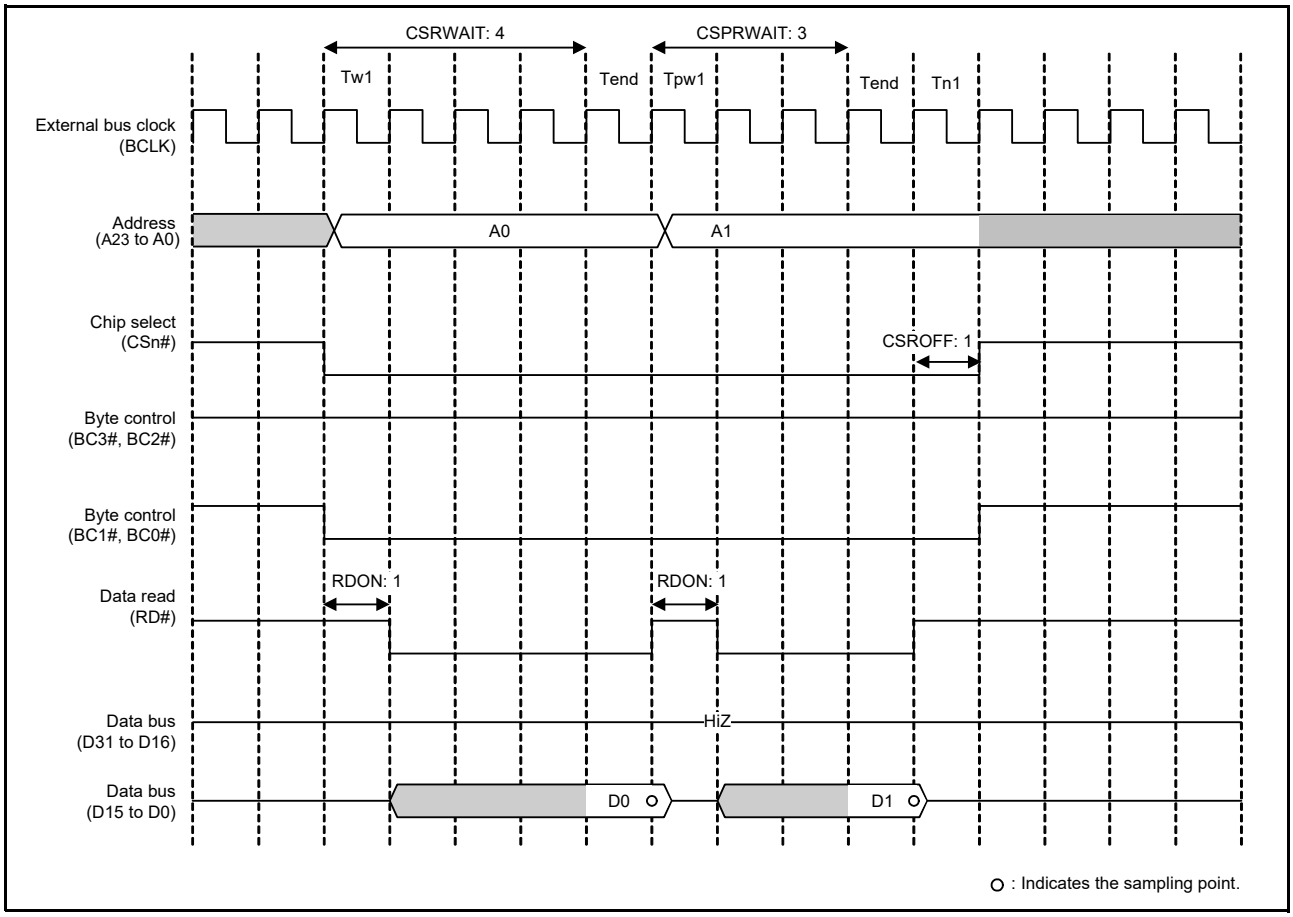

Figure 16.30 Example of Page-Read Access Operation (when 16-Bit Bus Space is Accessed in 32 Bits) (n = 0 to 7)

16.5.2 Address/Data Multiplexed Bus

When the address/data multiplexed I/O interface select bit (MPXEN) in CSnCR is set to 1, addresses and data can be multiplexing input/output to/from the D15 to D0 pins in the corresponding area. Using this function enables direct connection of this MCU to peripheral LSIs requiring address/data multiplexing. When 8-bit width is selected with the BSIZE[1:0] bits in CSnCR, D7 to D0 are multiplexed with A7 to A0. When 16-bit width is selected, D15 to D0 are multiplexed with A15 to A0. In the address/data multiplexed I/O space, accesses are controlled with the ALE, RD#, WRn#, and BCn# signals.
Byte strobe mode or single-write strobe mode is selectable in the same way as for a separate bus. However, with regard to the BCn# signals within the address cycle, the byte-control signal is output for the data being read or written.
During the address/data multiplexed I/O space access, after the number of wait cycles specified by the address cycle wait select bits (AWAIT[1:0]) in CSnWCR2 is inserted in the address output cycle, data access is performed.

- Ta1 to Tan (Address Cycle Wait)

The period Ta1 to Tan is valid only when the address/data multiplexed I/O space is specified. This period is made up of the number of clock cycles between the start of external bus access and one cycle before the address latch (ALE) signal is negated. The number of cycles is selectable within the range from zero to three. Addresses are output until the next cycle of ALE signal negation (address cycle). The timing of ALE signal is the same as that of CS# assertion. After the address cycle, a data cycle is started. CSnWCR1 and CSnWCR2 should be set so that an address cycle and a data cycle do not overlap.
Page access to the address/data multiplexed I/O space is invalid. When the PRENB or PWENB bit in CSnMOD is set to 1 to enable page-read or page-write access, these settings are ignored and normal read or write operation is performed.

Figure 16.34 to Figure 16.36 show examples of operations with the address/data multiplexed I/O interface.

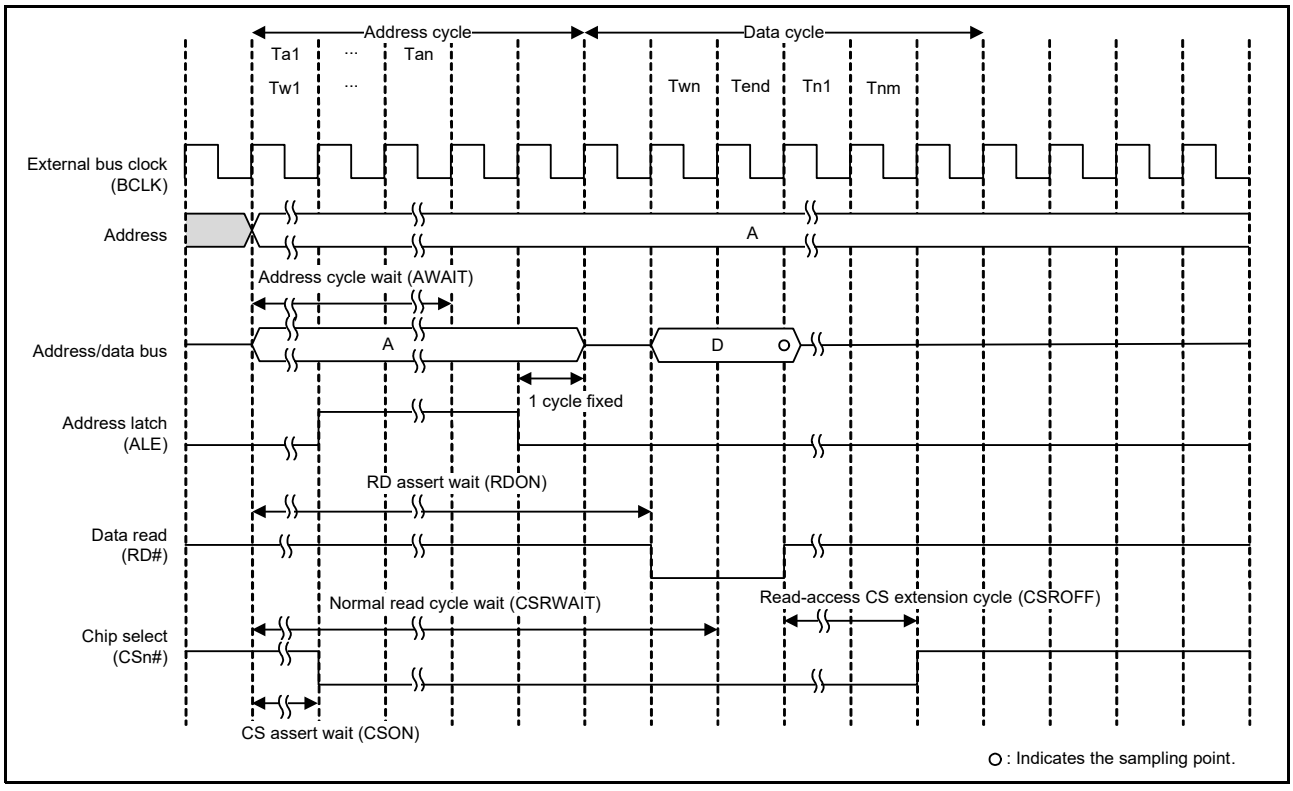

Figure 16.34 Example of Read Access Operation with Address/Data Multiplexed I/O Interface (n = 0 to 7)

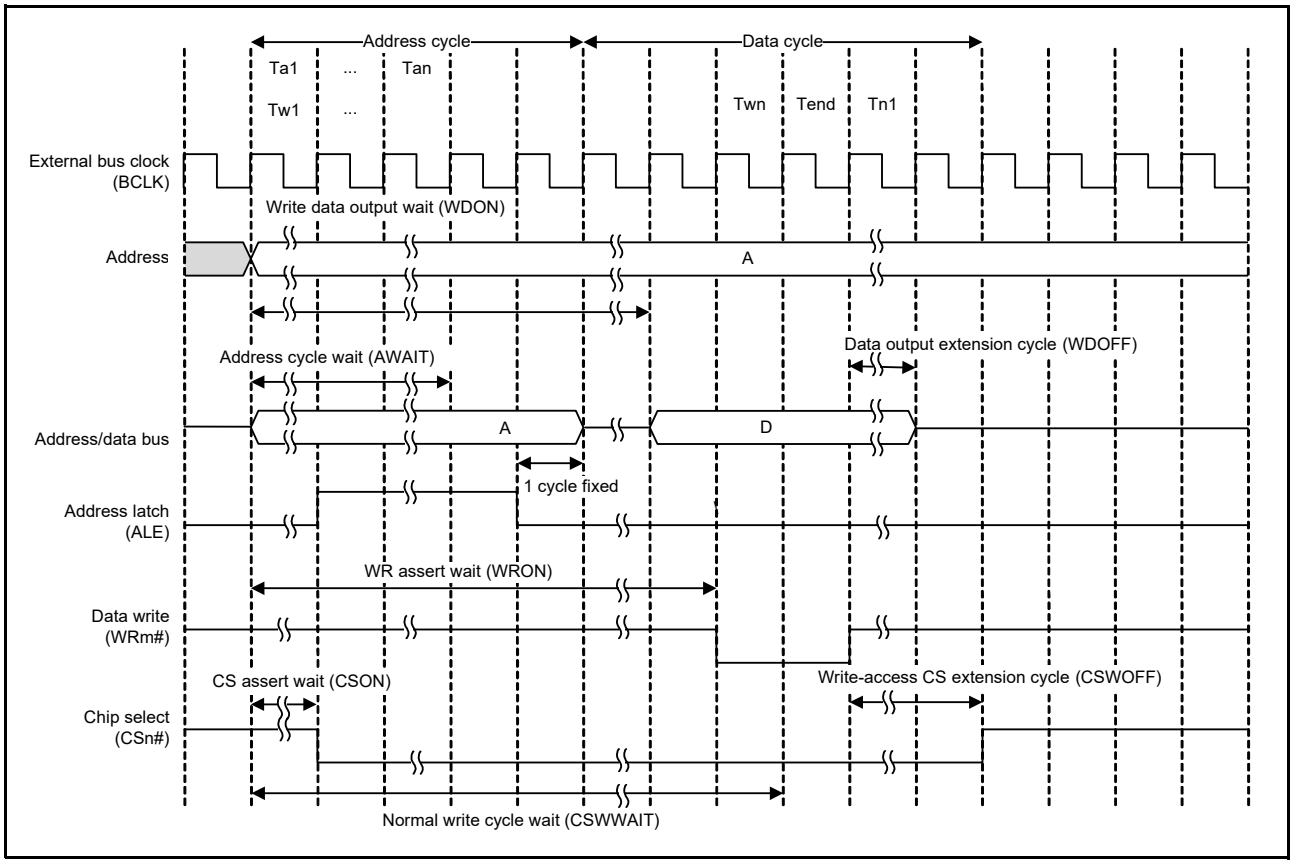

Figure 16.35 Example of Write Access Operation with Address/Data Multiplexed I/O Interface (n = 0 to 7; m = 0, 1)

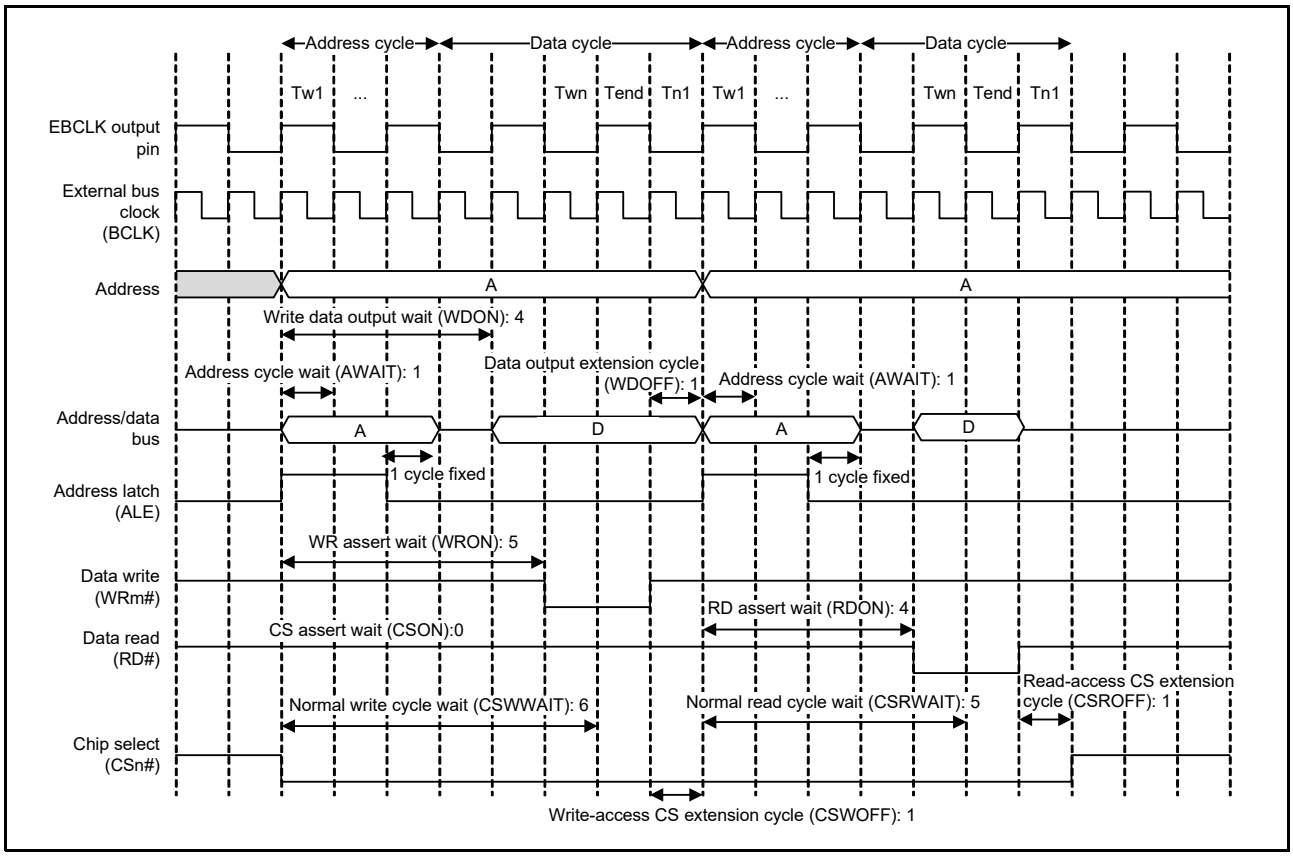

Figure 16.36 Example of Bus Timing with Address/Data Multiplexed I/O Interface (n = 0 to 7; m = 0, 1)

16.5.3 External Wait Function

Wait cycles can be extended by the WAIT# signal over the length of normal access cycle wait (specified by the CSRWAIT[4:0] and CSWWAIT[4:0] bits in CSnWCR1) and page access cycle wait (specified by the CSPRWAIT[2:0] and CSPWWAIT[2:0] bits in CSnWCR1).
When external wait is enabled (the EWENB bit = 1 in CSnMOD), wait cycles are inserted while the WAIT# signal is held low. When external wait is disabled (the EWENB bit = 0 in CSnMOD), the WAIT# signal has no effect.
All wait cycles specified in CSnWCR1 are inserted independently of the WAIT# signal.

(1) Normal Access

Sampling of the WAIT# signal begins upon completion of the wait cycle (Tend) specified in CSnWCR1. The bus cycle is extended while the WAIT# signal is held low. The wait cycle ends (Tend) at the next cycle after the WAIT# signal becomes high.

(2) Page Access

The first access operation is the same as the normal access operation. Sampling of the WAIT# signal begins upon completion of the wait cycle (Tend) specified in the CSnWCR1 register. The bus cycle is extended while the WAIT# signal is held low. The wait cycle ends (Tend) at the next cycle after the WAIT# signal becomes high.
With respect to the second and subsequent accesses, sampling of the WAIT# signal begins upon completion of the wait cycle of the page access (Tend). The wait cycle of the page access is extended while the WAIT# signal is held low, and ends (Tend) at the next cycle after the WAIT# signal becomes high.
Figure 16.37 to Figure 16.40 show examples of external wait insertion timing with the separate bus interface.

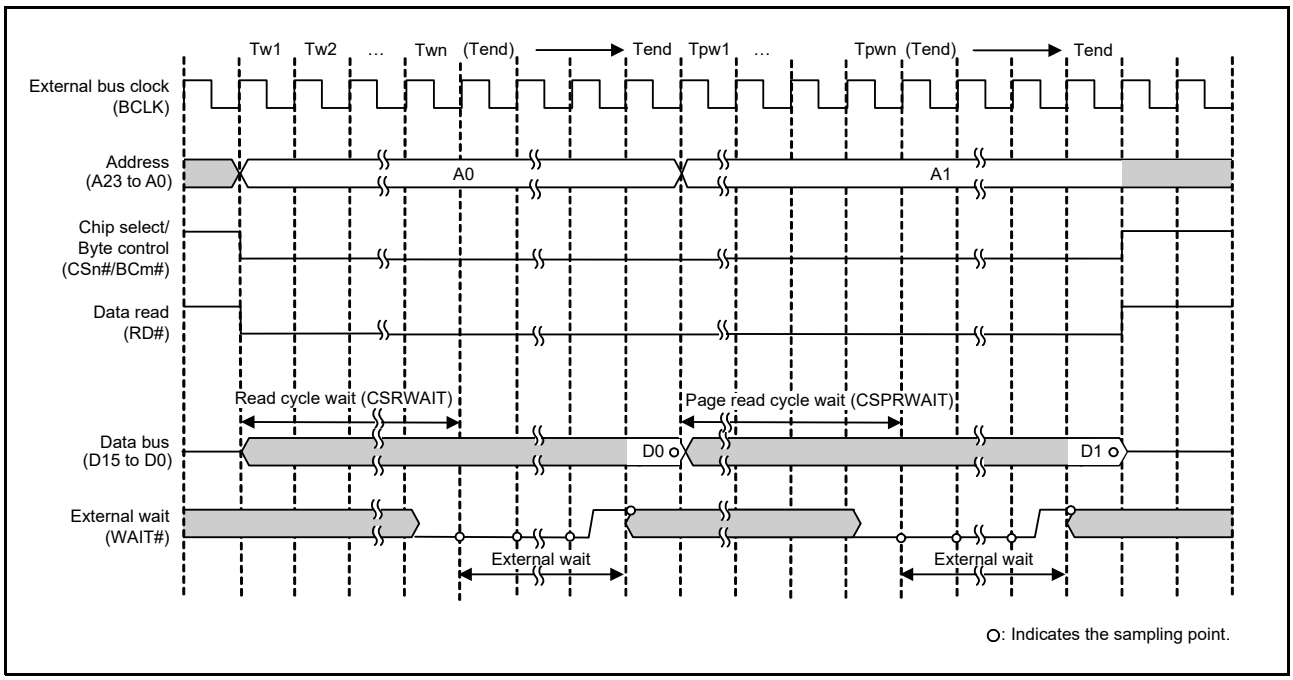

Figure 16.37 Example of External Wait Timing (Page-Read Access to 16-Bit Bus Space, when 1/1 BCLK is Selected with the EBCLK Pin Output Select Bit) (n = 0 to 7; m = 0, 1)

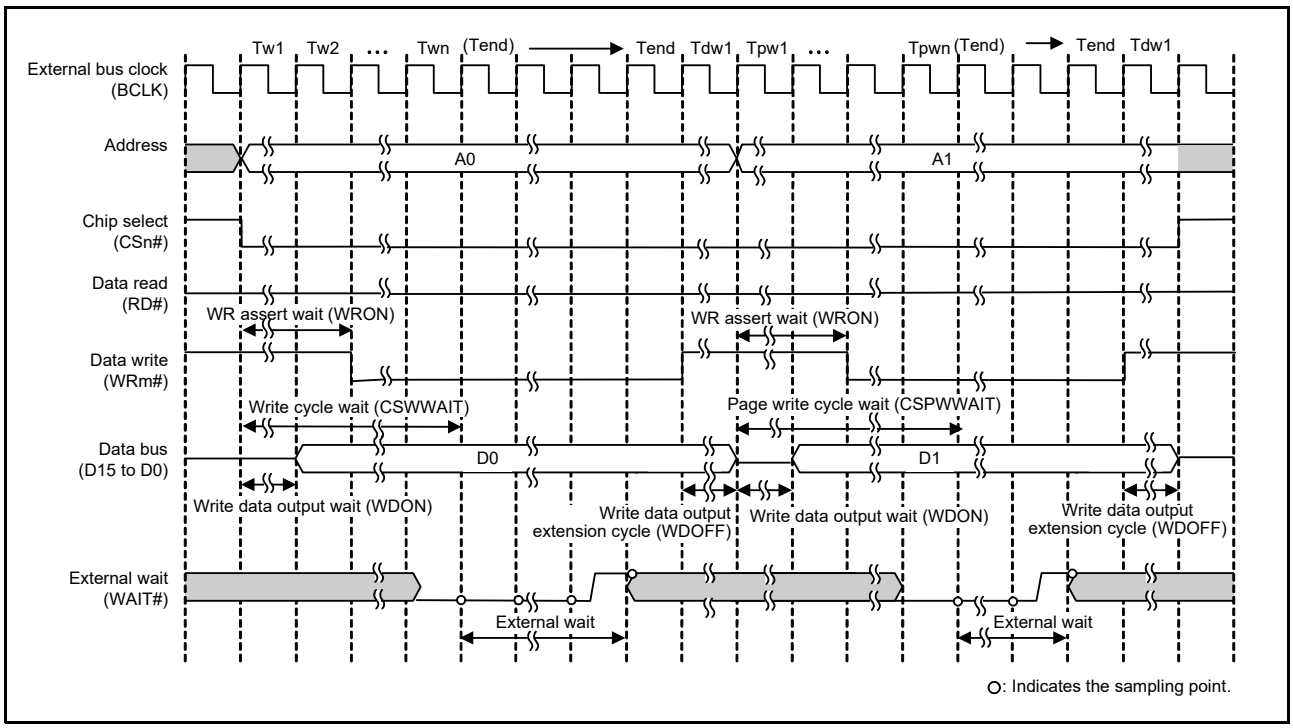

Figure 16.39 Example of External Wait Timing (Page-Write Access to 16-Bit Bus Space in Byte Strobe Mode, when 1/1 BCLK is Selected with the EBCLK Pin Output Select Bit) (n = 0 to 7; m = 0, 1)

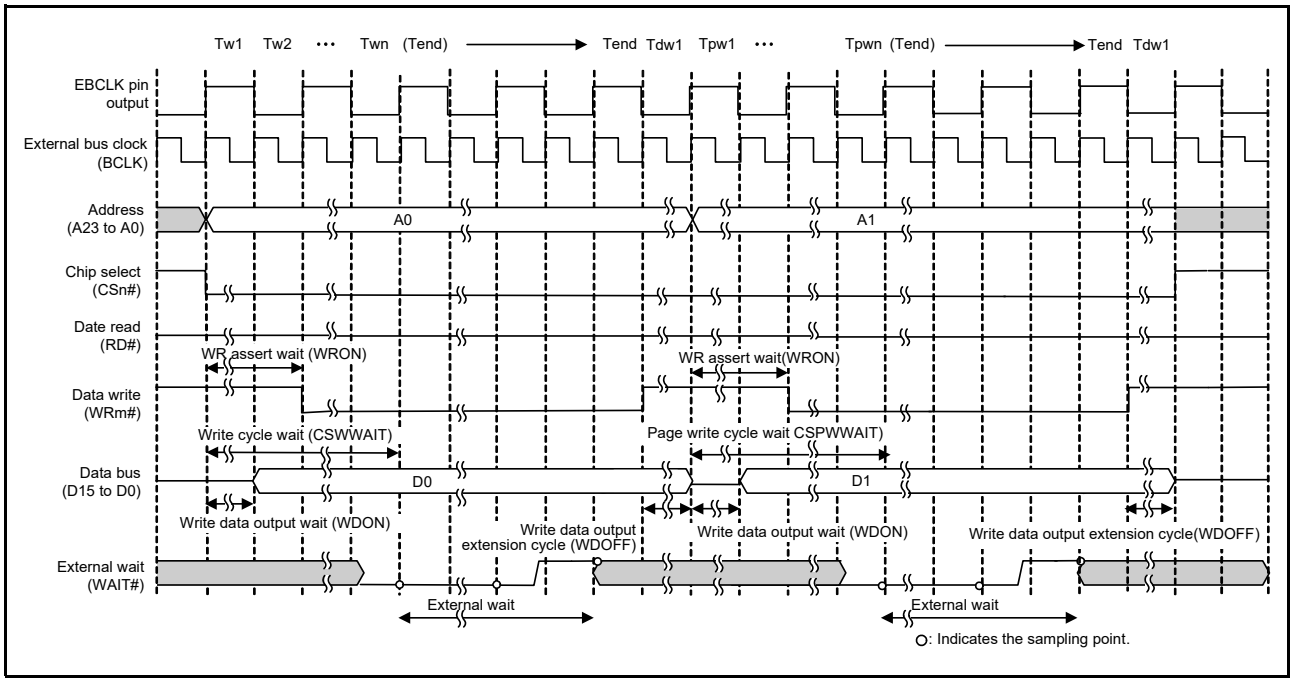

Figure 16.40 Example of External Wait Timing (Page-Write Access to 16-Bit Bus Space in Byte Strobe Mode, when 1/2 BCLK is Selected with the EBCLK Pin Output Select Bit) (n = 0 to 7; m = 0, 1)

(3) Address/Data Multiplexed I/O Interface

In a data cycle with the address/data multiplexed I/O interface, programmed waits and pin waits using the WAIT# pin can be inserted in the same way as that with the separate bus interface.
Address cycles are not affected by the wait control settings. Figure 16.41 shows an example of external wait insertion timing with the address/data multiplexed I/O interface.

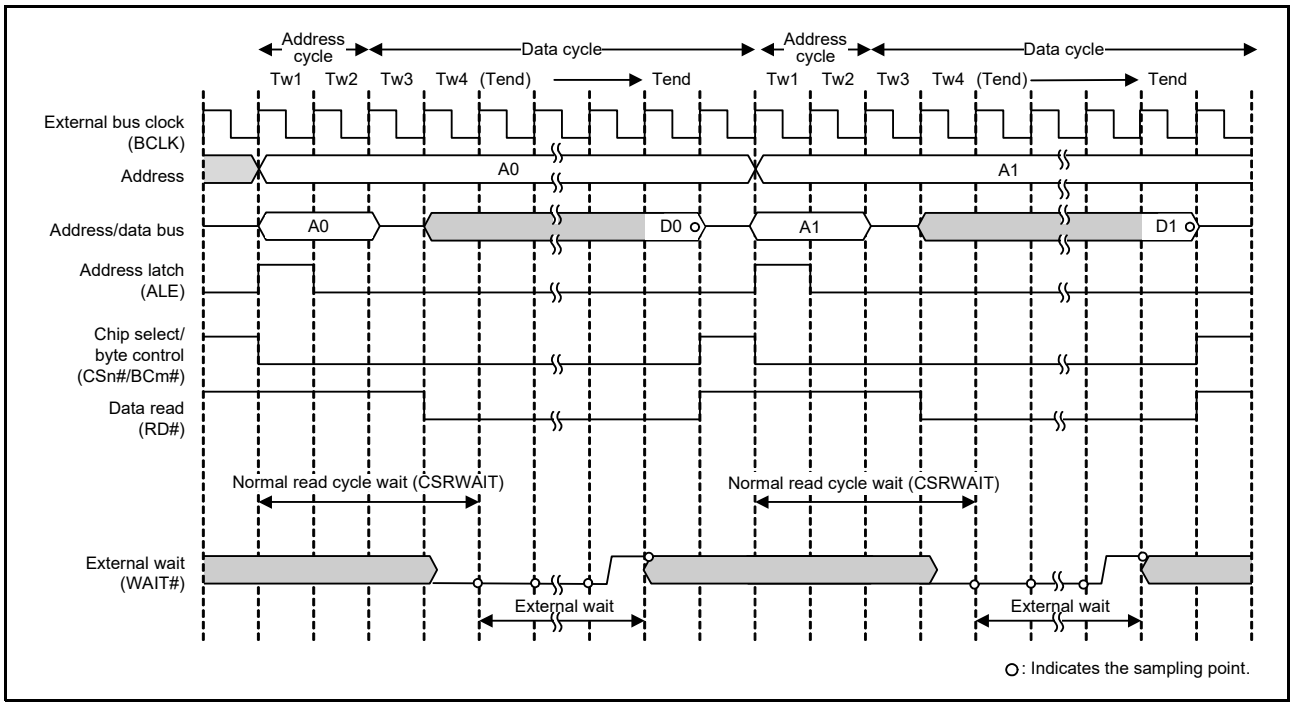

Figure 16.41 Example of External Wait Insertion Timing with Address/Data Multiplexed I/O Interface (n = 0 to 7; m = 0, 1)

16.5.4 Insertion of Recovery Cycles

Recovery cycles can be inserted between consecutive rounds of external bus access by setting the recovery cycle insertion enable bit in CSRECEN to 1.
The number of recovery cycles to be inserted after read cycles and write cycles can be separately set for each area using CSnREC. When the preceding bus cycle is a write access, the number of write recovery cycles should be set with the WRCV[3:0] bits for the area. When the preceding bus cycle is a read access, the number of read recovery cycles should be set with the RRCV[3:0] bits for the area. For example, when CS1 read access occurs after CS0 read access, the number of recovery cycles to be inserted between them is set by the RRCV[3:0] bits in CS0REC.
Recovery cycles can be inserted on any of the following eight conditions. The recovery cycle insertion can be enabled or disabled with the RCVENi (i = 0 to 7) in CSRECEN when the preceding bus access is a separate bus access, and with RCVENMj (j = 0 to 7) when the preceding bus access is an address/data multiplexed bus access.

- After a read access to the external bus, a read access is made to the external bus in the same area.
- After a read access to the external bus, a read access is made to the external bus in a different area.
- After a read access to the external bus, a write access is made to the external bus in the same area.
- After a read access to the external bus, a write access is made to the external bus in a different area.
- After a write access to the external bus, a read access is made to the external bus in the same area.
- After a write access to the external bus, a read access is made to the external bus in a different area.
- After a write access to the external bus, a write access is made to the external bus in the same area.
- After a write access to the external bus, a write access is made to the external bus in a different area.

The recovery cycle starts at the end of the preceding bus cycle, i.e. when the CSn# signal (n = 0 to 7) is negated. A high-level period of the CSn# signal is inserted for the specified recovery cycle period starting from this point.
The CSn# signal for the next round of bus access is asserted immediately after the end of recovery cycles in the fastest case. Even if the next request for access to an external address space is generated during the recovery period, the next round of access over the external bus will start immediately after the end of recovery cycles.
When two or more external bus access cycles are required for a single transfer request from a bus master and the recovery cycle insertion condition is satisfied, recovery cycles are also inserted between these bus access cycles. However, when page read access is enabled (CSnMOD.PRENB = 1) or page write access is enabled (CSnMOD.PWENB = 1), recovery cycles are not inserted except after the last bus access cycle of the transfer even if the recovery cycle insertion condition is satisfied (see Figure 16.44).
Similarly, during normal accesses with page access enabled, recovery cycles are not inserted between bus access cycles but inserted only after the last bus access cycle of the transfer.
With the address/data multiplexed I/O interface, when the recovery cycle insertion condition is satisfied, recovery cycles are inserted between bus access cycles regardless of the page access enable setting.

Figure 16.42 to Figure 16.44 show examples of recovery cycle insertion with the separate bus interface.

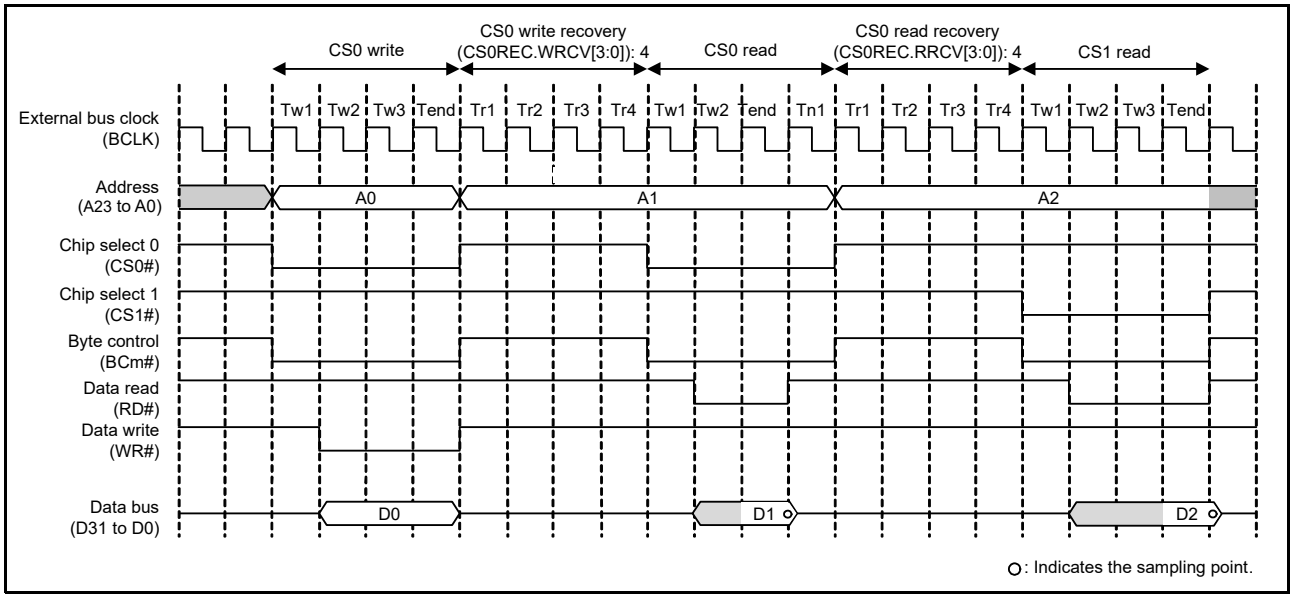

Figure 16.42 Example of Recovery Cycle Insertion with Separate Bus Interface (m = 0 to 3)

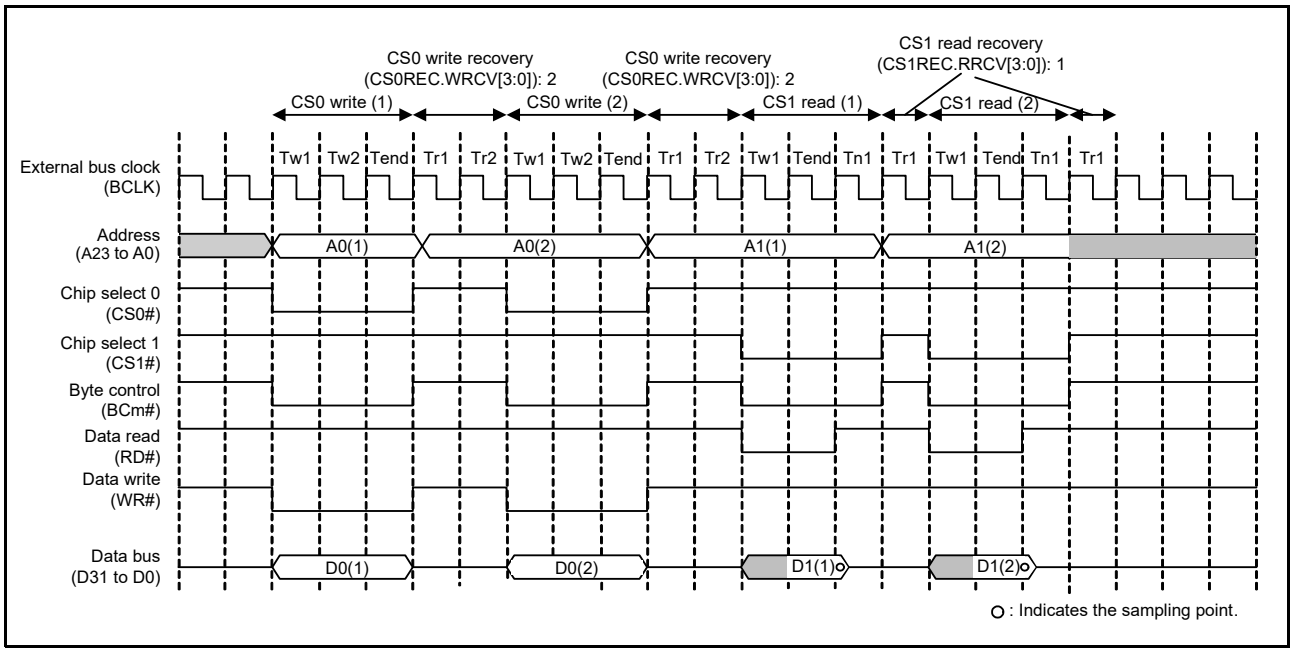

Figure 16.43 Example of Recovery Cycle Insertion When a Bus Access is Split (with Separate Bus Interface, Normal Access) (m = 0 to 3)

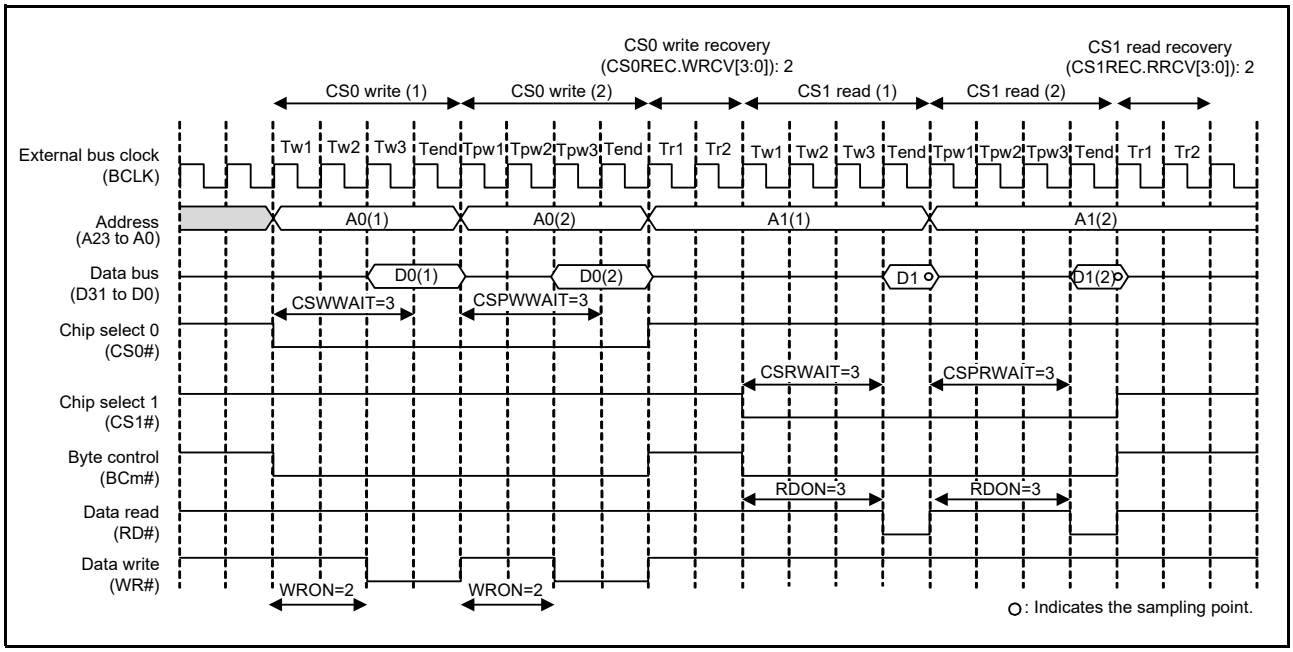

Figure 16.44 Example of Recovery Cycle Insertion When a Bus Access is Split (with Separate Bus Interface, Page Access) (m = 0 to 3)

Figure 16.45 shows examples of operations when the EBCLK pin output selection bits are set for frequency-division of BCLK by 2.

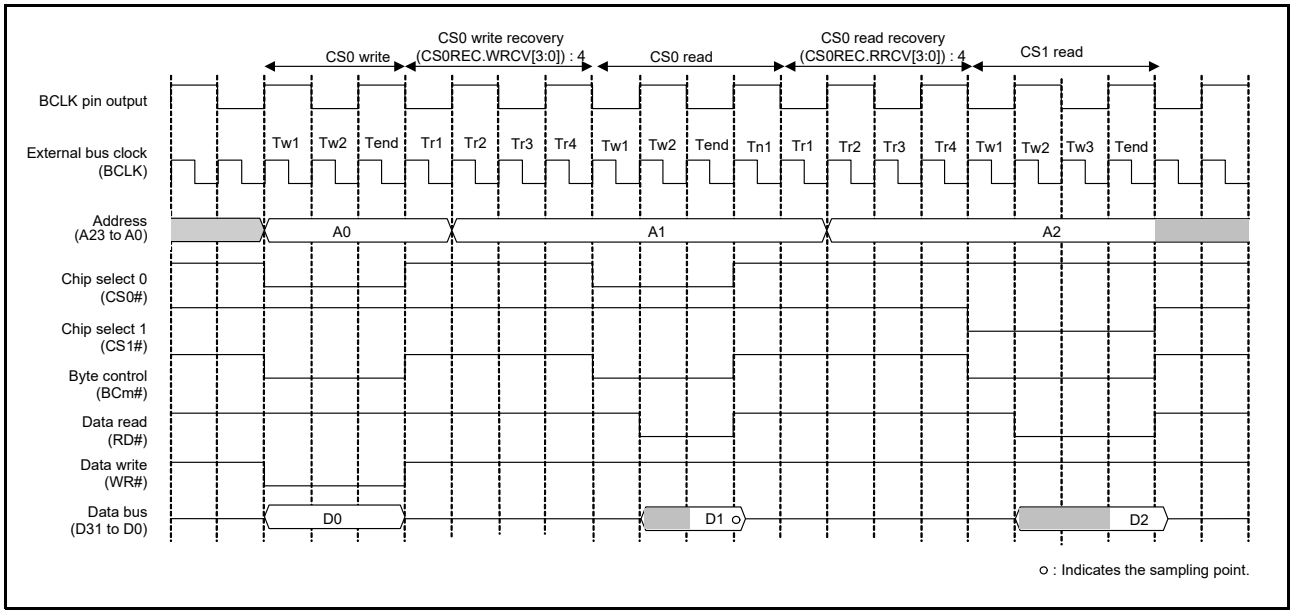

Figure 16.45 Example of Operation for Recovery Cycles when the EBCLK Pin Output Selection Bits are Set for Frequency-Division of BCLK by 2 (for the Case of Normal Access through a Separate Bus Interface) (m = 0 to 3)

With the address/data multiplexed I/O interface, recovery cycles are inserted in the same way as that with the separate bus interface. Figure 16.46 and Figure 16.47 show examples of recovery cycle insertion with the address/data multiplexed I/O interface.

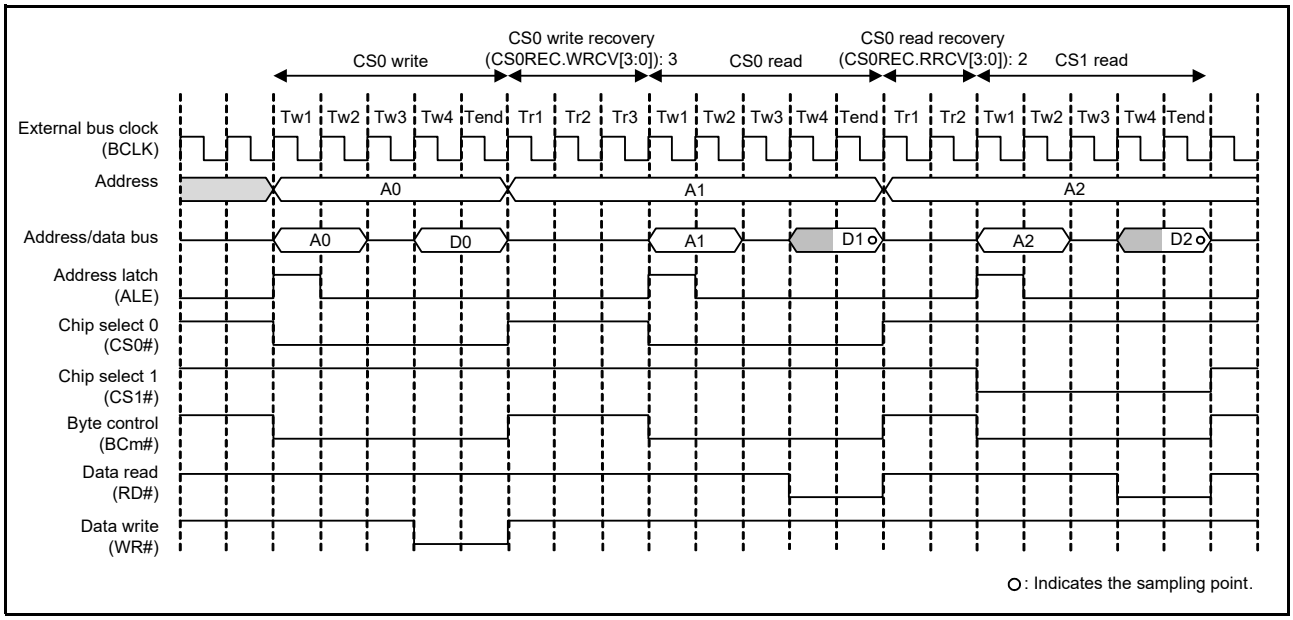

Figure 16.46 Example of Recovery Cycle Insertion with Address/Data Multiplexed I/O Interface (m = 0, 1)

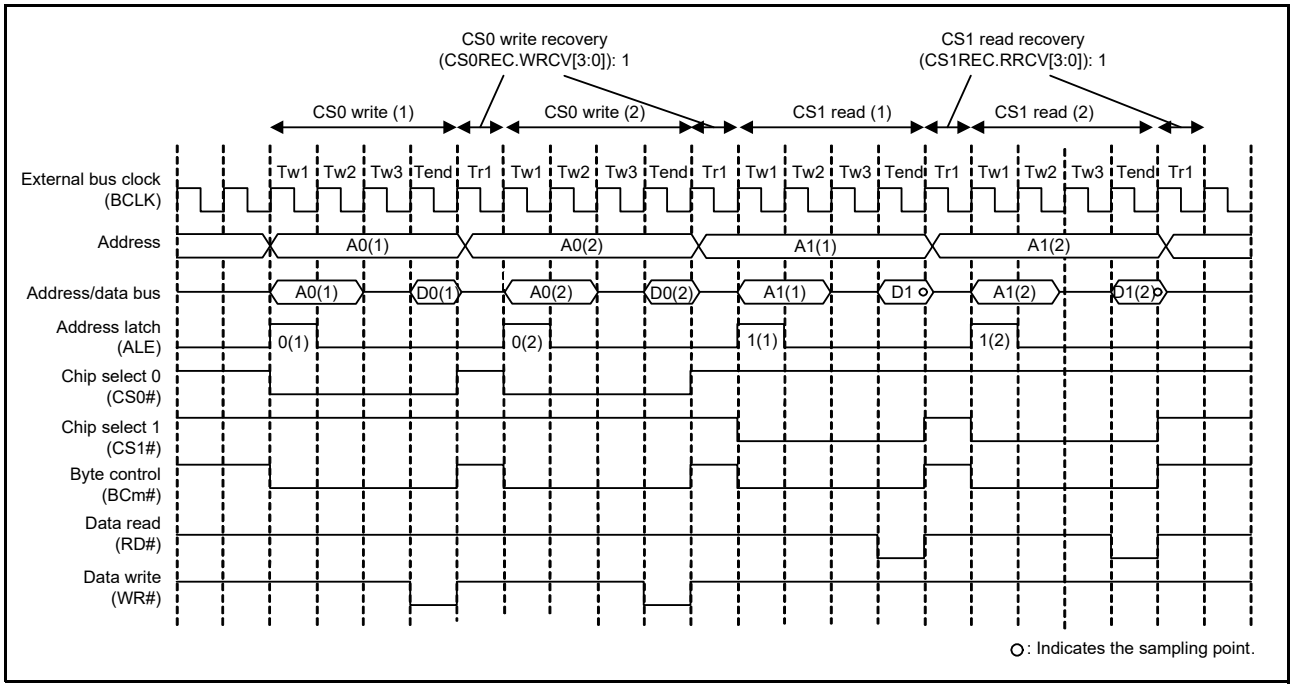

Figure 16.47 Example of Recovery Cycle Insertion When a Bus Access is Split with Address/Data Multiplexed I/O Interface (m = 0, 1)

16.5.5 No Access State

When no external address space is accessed, CSn#, BCn#, WRn#, and RD# signals are high, ALE signal is low, and D31 to D0 are in the high-impedance state.

16.5.6 Limitations

(1) Limitations on Using Separate Bus Interface

Limitations that apply to various bits of CSn wait control register 1 (CSnWCR1) and CSn wait control register 2 (CSnWCR2) at the times of normal and page accesses are listed in Table 16.17.
Even if the setting of the page-read access enable bit in the CSn mode register or the page-write access enable bit in the CSn mode register selects permission (CSnMOD.PRENB = 1 or CSnMOD.PWENB = 1), the first round of access for page access and the access that does not fall within the scope of page access are normal access operation, and thus limitations on normal access must be satisfied.

Table 16.17 Limitations at the Time of Normal and Page Access

Limitations at the Time of Normal Access		Limitations at the Time of Page Access	
Reading	**Writing**	**Reading**	**Writing**
CSON[2:0] ≤ CSRWAIT RDON[2:0] ≤ CSRWAIT CSON[2:0] ≤ RDON	1 ≤ WDON[2:0] CSON[2:0] ≤ CSWWAIT WRON[2:0] ≤ CSWWAIT WDON[2:0] ≤ CSWWAIT WDOFF[2:0] ≤ CSWOFF WDON[2:0] ≤ WRON CSON[2:0] ≤ WRON	CSON[2:0] ≤ CSPRWAIT RDON[2:0] ≤ CSPRWAIT CSON[2:0] ≤ RDON	1 ≤ WDON[2:0] CSON[2:0] ≤ CSPWWAIT WRON[2:0] ≤ CSPWWAIT WDON[2:0] ≤ CSPWWAIT WDOFF[2:0] ≤ CSWOFF WDON[2:0] ≤ WRON CSON[2:0] ≤ WRON

Note: When two or more external bus access cycles are required for a single transfer request from a bus master and the recovery cycle insertion condition is satisfied with page read access enabled (CSnMOD.PRENB = 1) or page write access enabled (CSnMOD.PWENB = 1), recovery cycles are not inserted between bus access cycles but inserted only after the last bus access cycle of the transfer.

(2) Limitations on Using Address/Data Multiplexed Bus Interface

In the address/data multiplexed I/O space, page accesses are invalid. If a page access setting is specified, the setting is ignored and the normal read or write operation is performed.
When the address/data multiplexed I/O interface is set, the BSIZE[1:0] bits in CSnCR should not be set to other than 8- and 16-bit bus spaces. If set, the operation cannot be guaranteed.

Table 16.18 Limitations at the Time of Normal Access

Limitations at the Time of Normal Access	
Reading	**Writing**
CSON[2:0] ≤ CSRWAIT RDON[2:0] ≤ CSRWAIT CSON[2:0] ≤ RDON AWAIT[1:0] + 2 ≤ RDON CSON[2:0] ≤ AWAIT	CSON[2:0] ≤ CSWWAIT WRON[2:0] ≤ CSWWAIT WDON[2:0] ≤ CSWWAIT WDOFF[2:0] ≤ CSWOFF WDON[2:0] ≤ WRON CSON[2:0] ≤ WRON AWAIT[1:0] + 2 ≤ WRON AWAIT[1:0] + 2 ≤ WDON CSON[2:0] ≤ AWAIT

(3) Limitation when a Pin is Multiplexed between A0 and BC0# Functions

When the A0 and BC0# pin functions share the same pin, setting the single write strobe mode is prohibited in the 8-bit bus space; otherwise the operation is not guaranteed.

(4) Limitations when 1/2 BCLK is Selected with EBCLK Pin Output Select Bit

When 1/2 BCLK is selected through the EBCLK pin output select bit, the external bus access cycle starts at the rising edge of the EBCLK pin output. However, when two or more external bus access cycles are generated for a single transfer request from a bus master, the second or subsequent external bus access cycle may start at the falling edge of the EBCLK pin output depending on the wait cycle settings. Make appropriate register settings according to the specifications of the device to be connected.

(5) Restriction on Instruction Code

The instruction code should be fixed to little endian. For details, refer to section 16.2.5.1, Restriction on Endian.

16.6 SDRAM Area Controller Operation

The following sections describe how the SDRAM area controller (SDRAMC) is enabled and the SDRAM bus width is set, which is followed by the description of SDRAMC operations including read, write, auto-refresh, self-refresh, initialization sequence, and mode register setting.

16.6.1 Enabling/Disabling SDRAM Access and Setting SDRAM Bus Width

SDRAM access can be enabled or disabled using the SDC control register (SDCCR). The SDRAM bus width can also be set using SDCCR. Even when the operation of the SDRAM address space is disabled, refresh operation is available as long as self-refresh or auto-refresh operation is enabled.

16.6.2 No Access State

When no external address space is accessed, SDCS#, WE#, RAS#, and CAS# signals are high.

16.6.3 Insertion of Recovery Cycles

When access to the SDRAM area follows access to the CS area, data recovery cycles are inserted for the CS area controller (CSC). If the number of recovery cycles for the CSC is 0, the ACT command for the next SDRAM access is issued immediately after negation of CSn# signal at the earliest. If the number of recovery cycles are not 0, the ACT command is issued two cycles after the specified recovery cycle period elapsed after negation of CSn# signal at the earliest. Since no data conflicts can occur during access to the SDRAM area, there is no need to set data recovery cycles for the SDRAM (fixed to zero cycle).

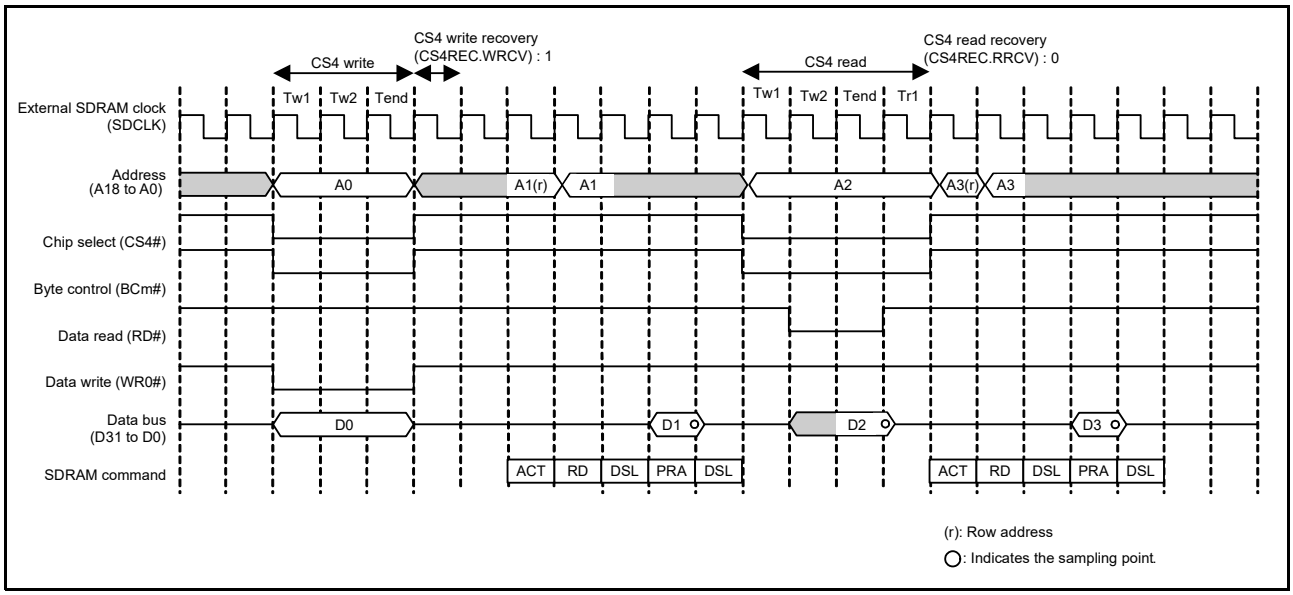

Figure 16.48 Example of Recovery Timing (for SDRAM Access)

16.6.4 SDRAM Commands

The SDRAMC issues a command for each bus cycle to control SDRAM. Commands are defined by combination of SDCS#, RAS#, CAS#, WE#, CKE, and other signals. Table 16.19 lists the commands issued by the SDRAMC.

Table 16.19 List of SDRAMC Commands

Name	Abbreviation	Command	SDCS#	RAS#	CAS#	WE#	CKE	
							n-1	n
DESL	DSL	Device deselect	H	x	x	x	H	x
ACTV	ACT	Bank active	L	L	H	H	H	x
READ	RD	Read	L	H	L	H	H	x
WRIT	WRI	Write	L	H	L	L	H	x
PALL	PRA	All bank precharge	L	L	H	L	H	x
REF	RFA	Auto-refresh	L	L	L	H	H	x
MRS	MRS	Mode register set	L	L	L	L	H	x
SELF	RFS	Self-refresh entry	L	L	L	H	H	L
SELFX	RFX	Self-refresh end	H	x	x	x	L	H

Note: H: High level, L: Low level, x: Don't care. (High level or low level)
n: Command issue cycle, n-1: One cycle before the command is issued.

16.6.5 Conditions for Setting SDRAMC Registers

SDRAMC registers should be modified only when all the corresponding conditions are satisfied as listed in Table 16.20.

Table 16.20 Conditions for Register Modification

Function/Operation	Registers	Conditions
Self-refresh	SDSELF*1	• SDRAM access is disabled. (SDCCR.EXENB = 0*2) • Auto-refresh operation is enabled. (SDRFEN.RFEN = 1)
Auto-refresh	SDRFCR	Self-refresh operation is disabled. (SDSELF.SFEN = 0)
	SDRFEN	• SDRAM access is disabled. (SDCCR.EXENB = 0*2) • Self-refresh operation is disabled. (SDSELF.SFEN = 0)
Initialization sequence	SDIR*1	The SDICR has not been set yet, and the same conditions as SDICR modification should be satisfied.
	SDICR*1	• SDRAM access is disabled. (SDCCR.EXENB = 0*2) • Auto-refresh operation is disabled. (SDRFEN.RFEN = 0) • Self-refresh operation is disabled. (SDSELF.SFEN = 0)
Address register	SDADR	• SDRAM access is disabled. (SDCCR.EXENB = 0*2) • Auto-refresh operation is disabled. (SDRFEN.RFEN = 0) • Self-refresh operation is disabled. (SDSELF.SFEN = 0)
Timing register	SDTR	• During self-refresh operation (SDSELF.SFEN = 1) or • SDRAM access is disabled. (SDCCR.EXENB = 0*2) • Auto-refresh operation is disabled. (SDRFEN.RFEN = 0) • Self-refresh operation is disabled. (SDSELF.SFEN = 0)
Mode register	SDMOD*1	• SDRAM access is disabled. (SDCCR.EXENB = 0*2) • Self-refresh operation is disabled. (SDSELF.SFEN = 0)
SDRAM Access Mode Register	SDAMOD	• SDRAM access is disabled. (SDCCR.EXENB = 0*2) • Auto-refresh operation is disabled. (SDRFEN.RFEN = 0) • Self-refresh operation is disabled. (SDSELF.SFEN = 0)

Note 1. Before modification, confirm that all the status bits in SDSR are 0.
Note 2. After writing 0 to the EXENB bit, confirm that the EXENB bit is set to 0.

16.6.6 Self-Refresh

Transition to or recovery from self-refresh mode can be controlled using the SDRAM self-refresh control register (SDSELF). Immediately before transition to self-refresh mode, auto-refresh operation is performed. In self-refresh mode, the CKE signal is low. Immediately after recovery from self-refresh mode, the auto-refresh cycle is started.
Figure 16.49 and Figure 16.50 show timing examples of transition to self-refresh mode and recovery from self-refresh mode, respectively.

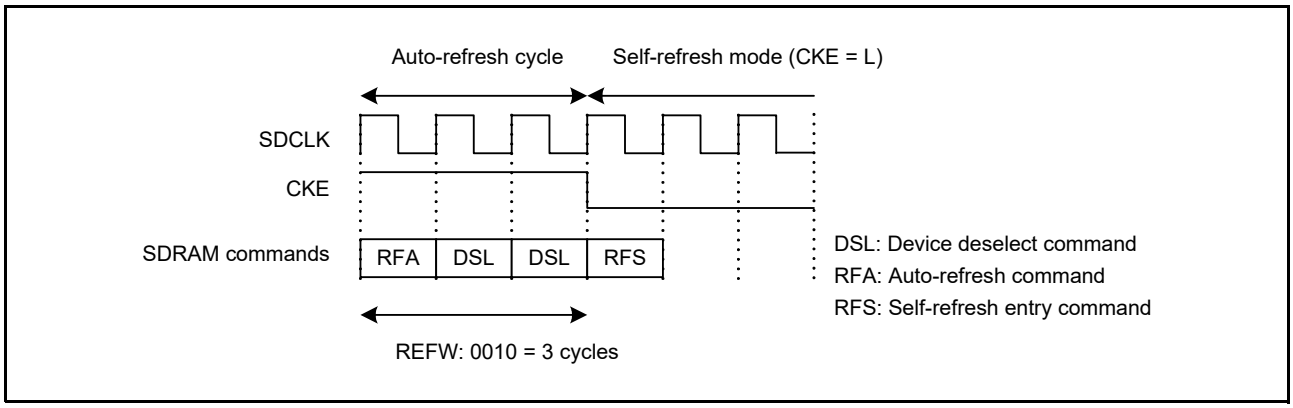

Figure 16.49 Timing Example of Transition to Self-Refresh Mode (when SDRFCR.REFW[3:0] = 0010b: 3 Cycles)

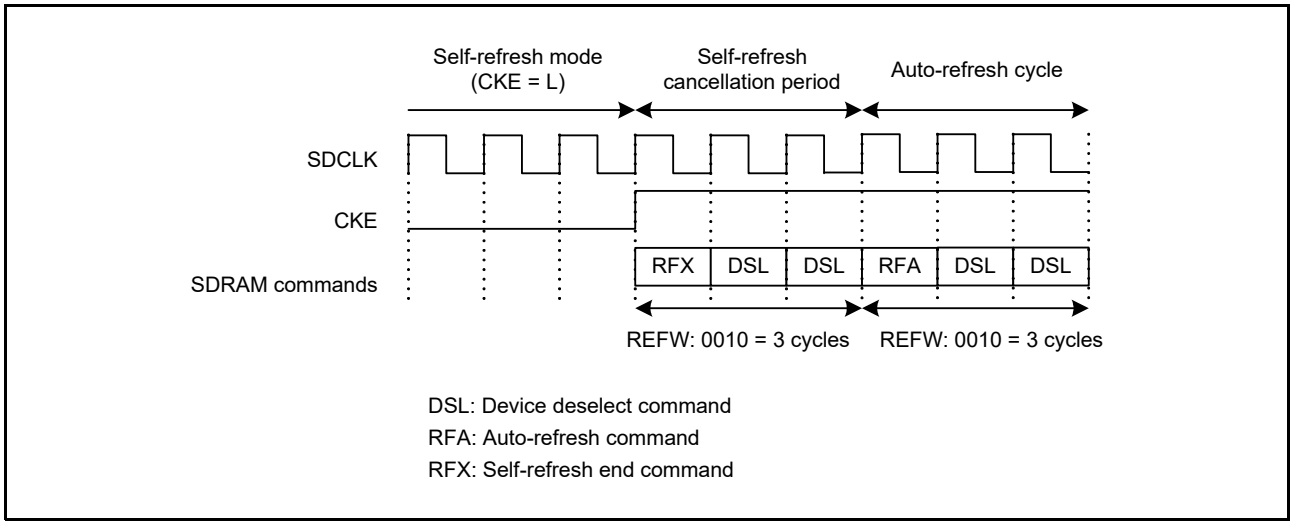

Figure 16.50 Timing Example of Recovery from Self-Refresh Mode

(1) Self-Refresh in Software Standby Mode

When causing transition to self-refresh mode in software standby mode, first cause transition to self-refresh mode according to the procedure shown in section 16.6.11.2, Procedure for Transition to and Recovery from Self-Refresh Mode, and then make settings to cause transition to software standby mode. In software standby mode, set the output port enable bit (OPE) in the standby control register (SBYCR) to 1 to hold the output state of the address bus and bus control signals.
After canceling software standby mode, follow the procedure shown in section 16.6.11.2, Procedure for Transition to and Recovery from Self-Refresh Mode. For details of transition and cancellation of software standby mode, refer to section 11, Low Power Consumption.

(2) Self-Refresh in Deep Software Standby Mode

Transition to deep software standby mode is performed via software standby mode. On transition to deep software standby mode from software standby mode, the state of pins remains unchanged. Therefore, transition to self-refresh mode in deep software standby mode can be made according to the same procedure as that in software standby mode. In deep software standby mode, however, additional setting is necessary to cause transition to self-refresh mode; it is necessary to set the I/O port keep bit (IOKEEP) in the deep software standby control register (DPSBYCR) to 1.
Since the SDRAMC is internally reset by an internal reset signal when deep software standby mode is canceled, the SDRAM control registers need to be set again. After canceling deep software standby mode, follow the procedure shown below to cancel self-refresh mode. Figure 16.51 shows self-refresh timing in deep software standby mode.
For details of transition and cancellation of deep software standby mode, refer to section 11, Low Power Consumption.

1. Set DPSBYCR.IOKEEP to 1 to keep the CKE signal output low in deep software standby mode.
2. Start clock supply to SDRAMC.
3. Set the SDRAM control registers (SDCMOD, SDADR, and SDTR) again, which have been initialized by an internal reset upon transition to deep software standby mode.
4. Enable auto-refresh operation (RFEN bit in SDRFEN = 1).
5. Check that all the status bits in SDSR are set to 0 and set the SFEN bit in SDSELF to 1 to set self-refresh mode again.
6. Modify port settings for the SDRAM interface.
7. Set the SDCKOEN bit in SDCKOCR to 1 to start clock supply to the SDRAM via the SDCLK pin.
8. Check that all the status bits in SDSR are set to 0 and set the SFEN bit in SDSELF to 0 to cancel self-refresh mode.

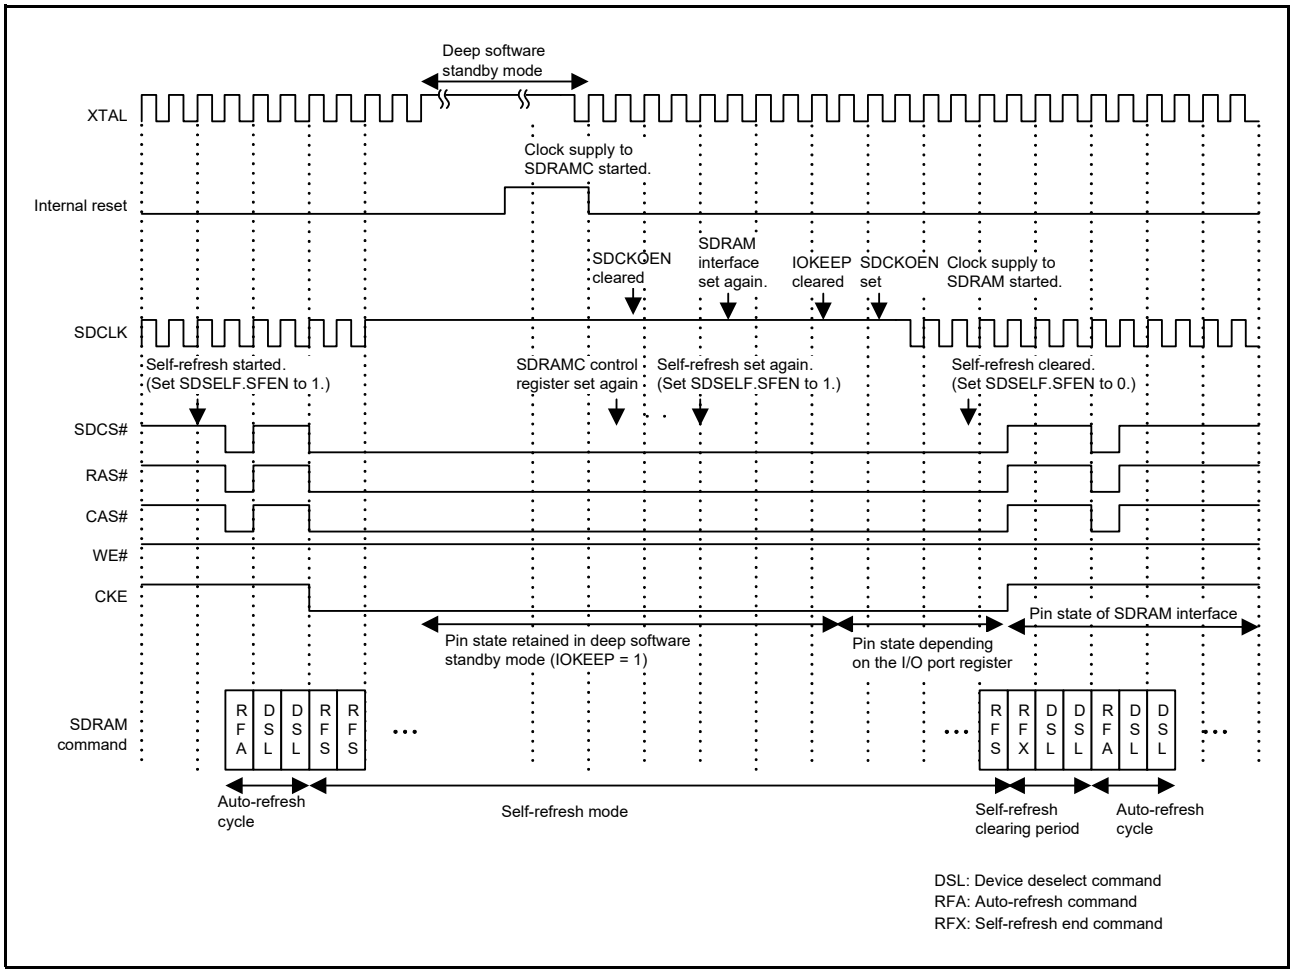

Figure 16.51 Timing Example of Self-Refresh Cycle (in Deep Software Standby Mode)

16.6.7 Auto-Refresh

The auto-refresh cycle can be started by setting the auto-refresh operation enable bit (RFEN) in the SDRAM auto-refresh control register (SDRFEN) to 1. Once the cycle is started, refresh requests are generated at fixed intervals determined by the refresh counter to start the auto-refresh cycle. However, since refresh requests are not accepted during read/write access, the auto-refresh cycle may be suspended.

If an SDRAM access and a refresh request are generated at the same time, the refresh request takes precedence. A CS area access and a refresh request can be made at the same if the SDCS#, RAS#, CAS#, WE#, and CKE signals, which are necessary for issuing the refresh command, are exclusively provided for SDRAM access.

The refresh counter is halted during self-refresh operation. After recovery from self-refresh mode, the auto-refresh cycle is started and the counter value is reset thus resuming the counter operation.

Figure 16.52 shows an example of the timing of an auto-refresh cycle.

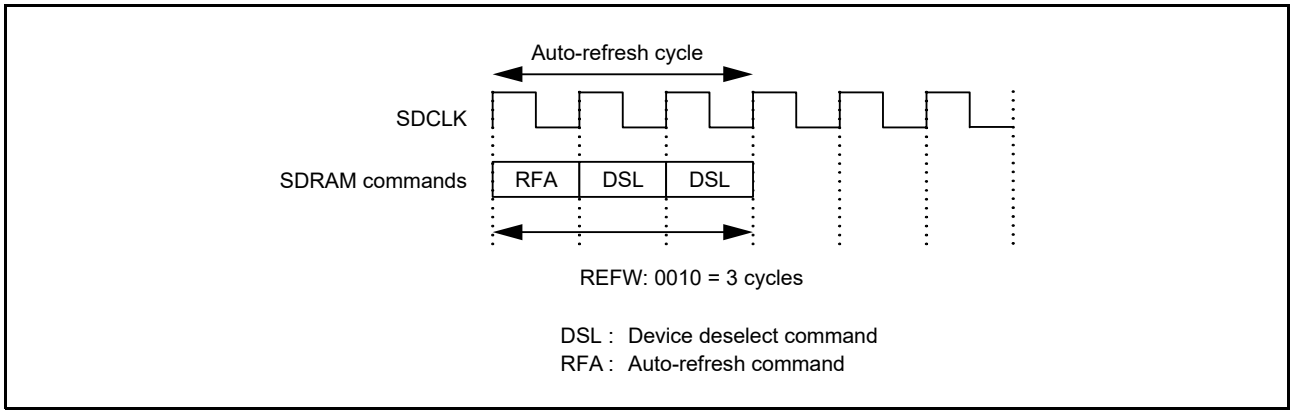

Figure 16.52 Timing Example of Auto-Refresh Cycle (1)

Figure 16.53 and Figure 16.54 show examples of operation when an auto-refresh request is generated during single access and continuous access, respectively.

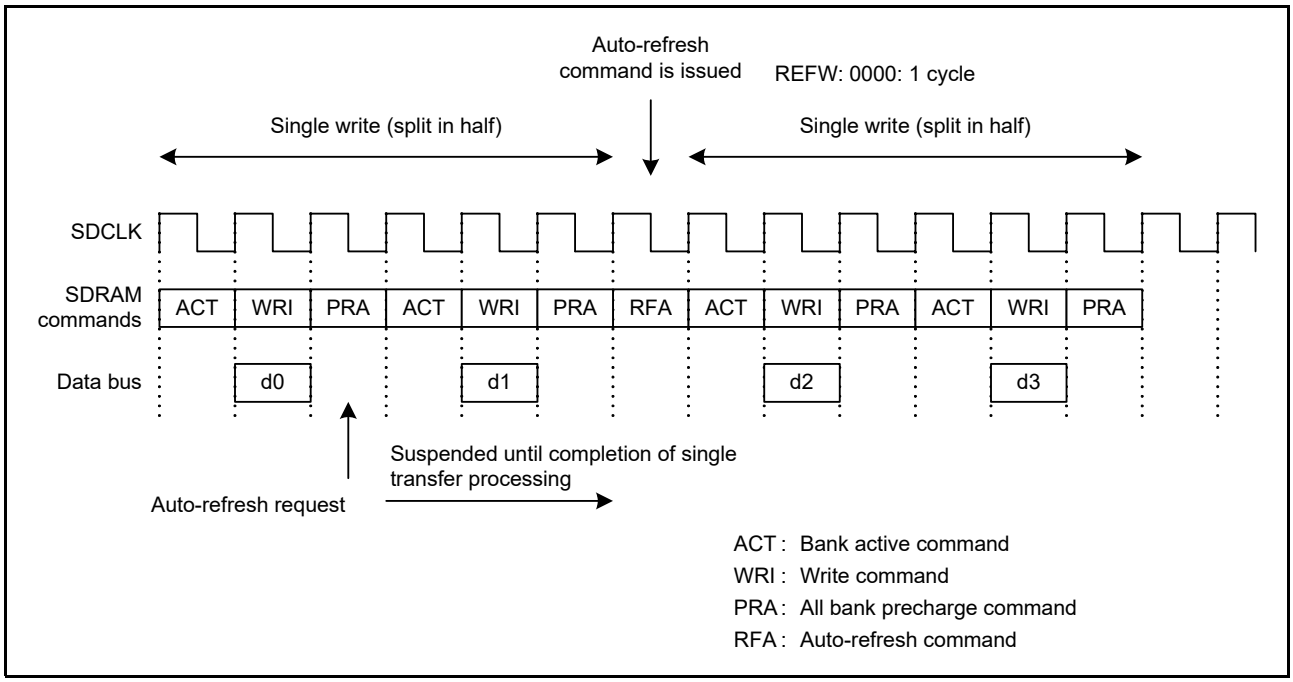

Figure 16.53 Timing Example of Auto-Refresh Cycle (2) (Auto-Refresh Request is Made during Single Access)

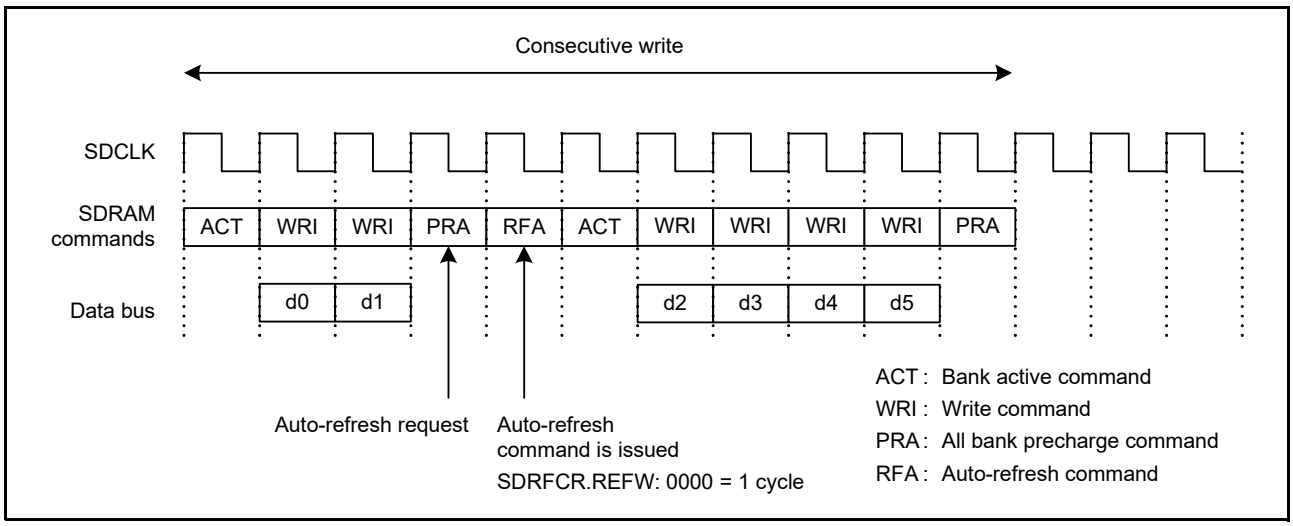

Figure 16.54 Timing Example of Auto-Refresh Cycle (3) (Auto-Refresh Request is Made during Continuous Access)

16.6.8 Initialization Sequencer

The SDRAMC has a sequencer to issue SDRAM initialization commands. After a reset, the initialization sequence must be activated; the operation is not guaranteed if the SDRAM is not initialized.

The SDRAM initialization sequencer issues an all-bank-precharge command followed by auto-refresh commands n times (n = 1 to 15). The SDRAM initialization sequence timing can be set using the SDRAM initialization register (SDIR). The SDRAM initialization sequence can be activated using the SDRAM initialization sequence control register (SDICR). These registers should be set only when the conditions listed in Table 16.20, Conditions for Register Modification.

Figure 16.55 shows a timing example of the SDRAM initialization sequence. When the ARFC[3:0] bits in SDIR are set so that auto-refresh operation is performed two or more times, auto-refresh cycles are repeated in the initialization sequence accordingly.

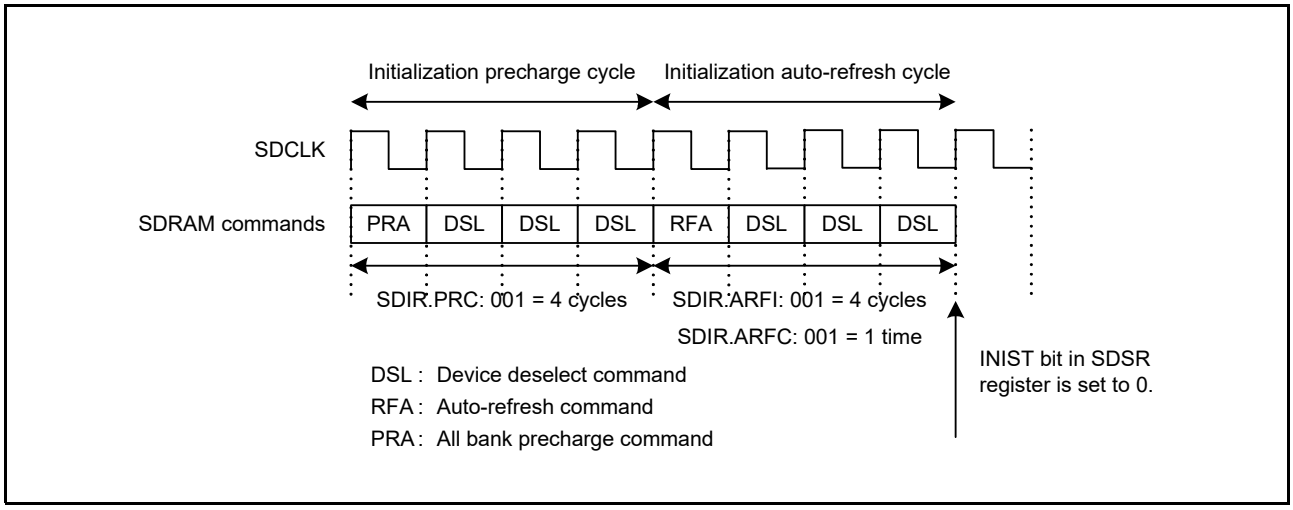

Figure 16.55 Timing Example of SDRAM Initialization Sequence

16.6.9 Setting Mode Register

Setting the SDRAM mode register (SDMOD) allows the mode register set command to be issued to SDRAM and the value set in the MR[14:0] bits in SDMOD to be output to the lower bits of the address; specifically, to the A14 to A0 for 8-bit bus width, A15 to A1 for 16-bit bus width, and A16 to A2 for 32-bit bus width. Therefore, set the SDCCR.BSIZE[1:0] bits before setting the mode register, to determine the data bus width of the SDRAM.
Figure 16.56 shows the mode register setting timing.

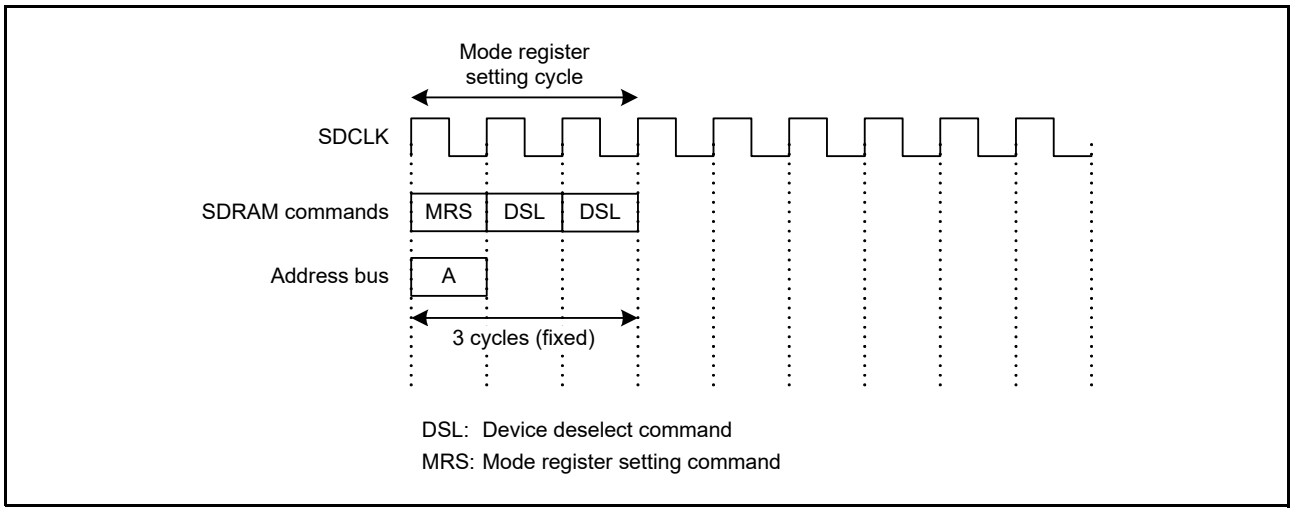

Figure 16.56 Mode Register Setting Timing

16.6.10 Read/Write Access

The SDRAMC controls read/write access in the following two modes.

- Single access mode: the row address is output each time data is accessed
- Consecutive access mode: when the same row address is accessed consecutively, only the column address is changed after the row address is output, enabling quick data access.

Consecutive SDRAM access is enabled by setting the continuous access enable bit (BE) in SDRAM access mode register (SDAMOD) to 1.

If the transfer from the bus master has a burst length of 2 or more and the transfer data size is less than or equal to the external bus width, consecutive access will occur.

(1) Single Access

Figure 16.57 shows timing examples for single read and single write. The specific access timing depends on the SDRAM timing register (SDTR) settings. For details, refer to section 16.6.11.3, Timing Register Settings and Access Timing.

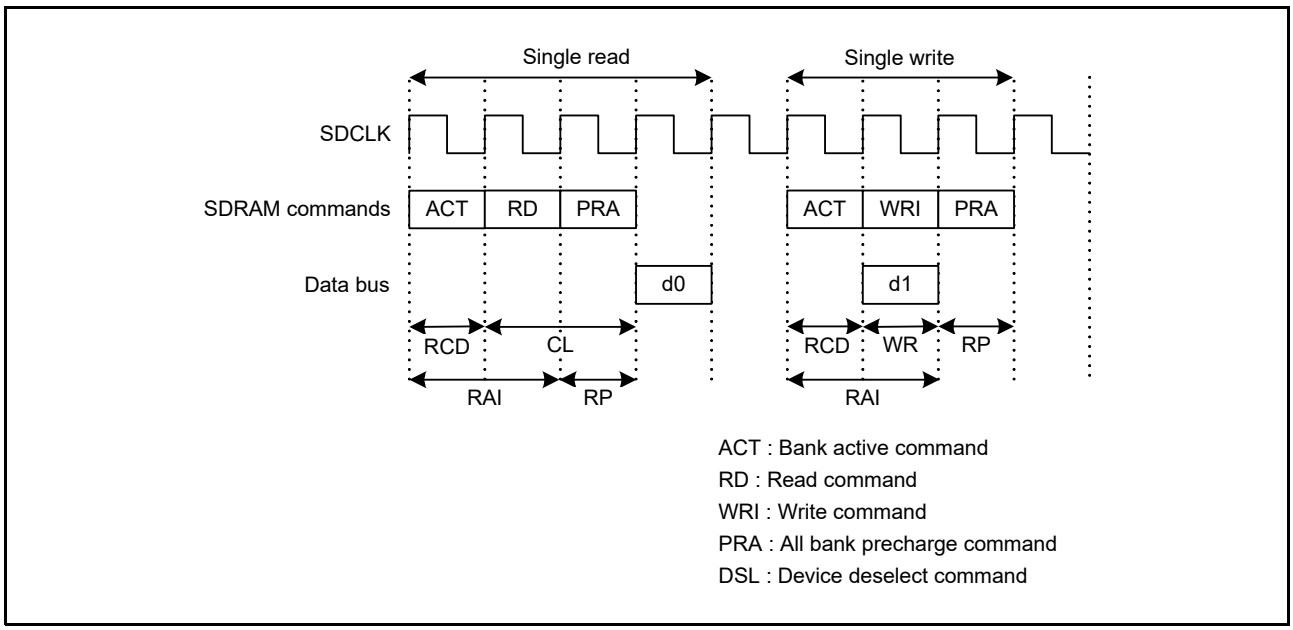

Figure 16.57 Timing Example of Single Read / Write

(2) Consecutive Access

Figure 16.58 show timing examples of consecutive read and consecutive write for four data, respectively.
When the SDRAM row address changes during transfer, the pertinent row is automatically deactivated, and then activated.
The specific access timing depends on the SDRAM timing register (SDTR) settings. For details, refer to section 16.6.11.3, Timing Register Settings and Access Timing.

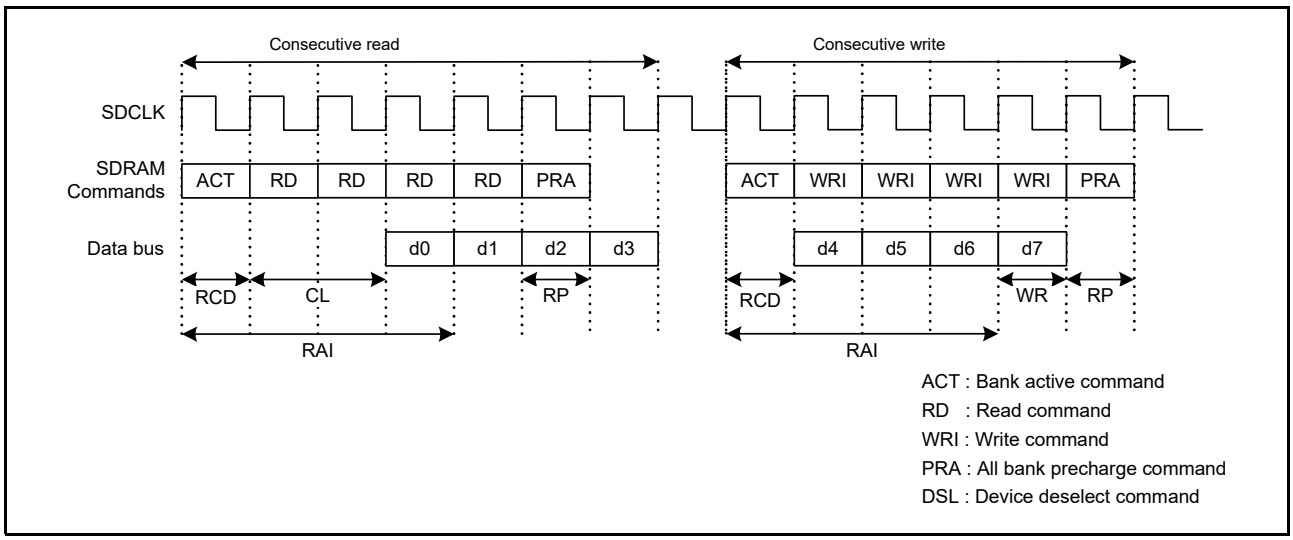

Figure 16.58 Timing Example of Consecutive Read / Write

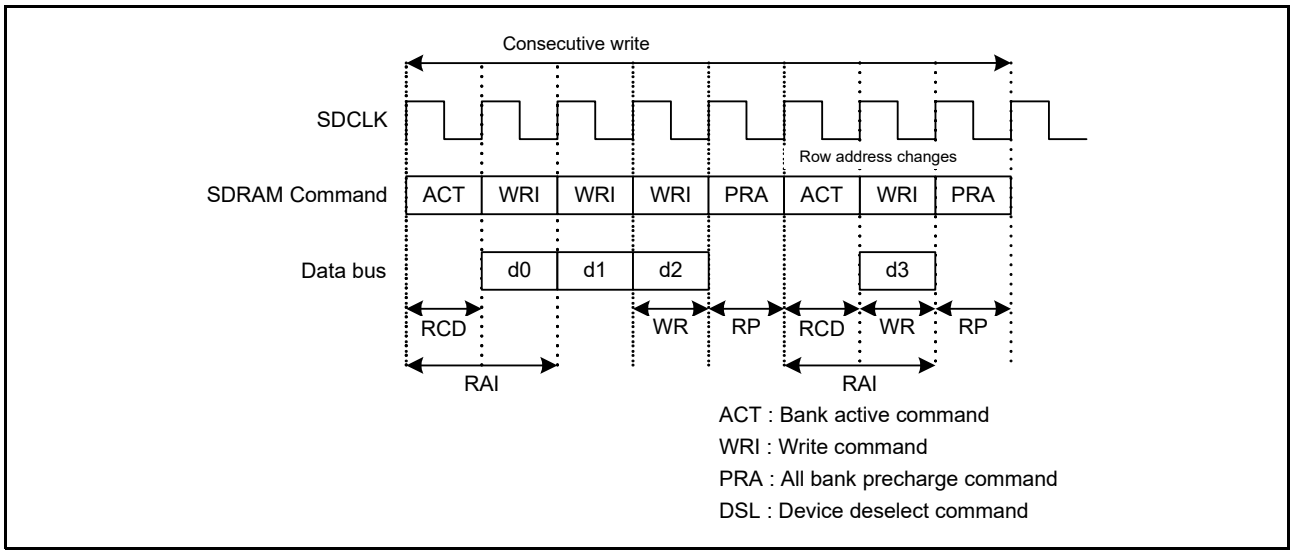
Figure 16.59 shows a timing example of consecutive write in which the row address changes.



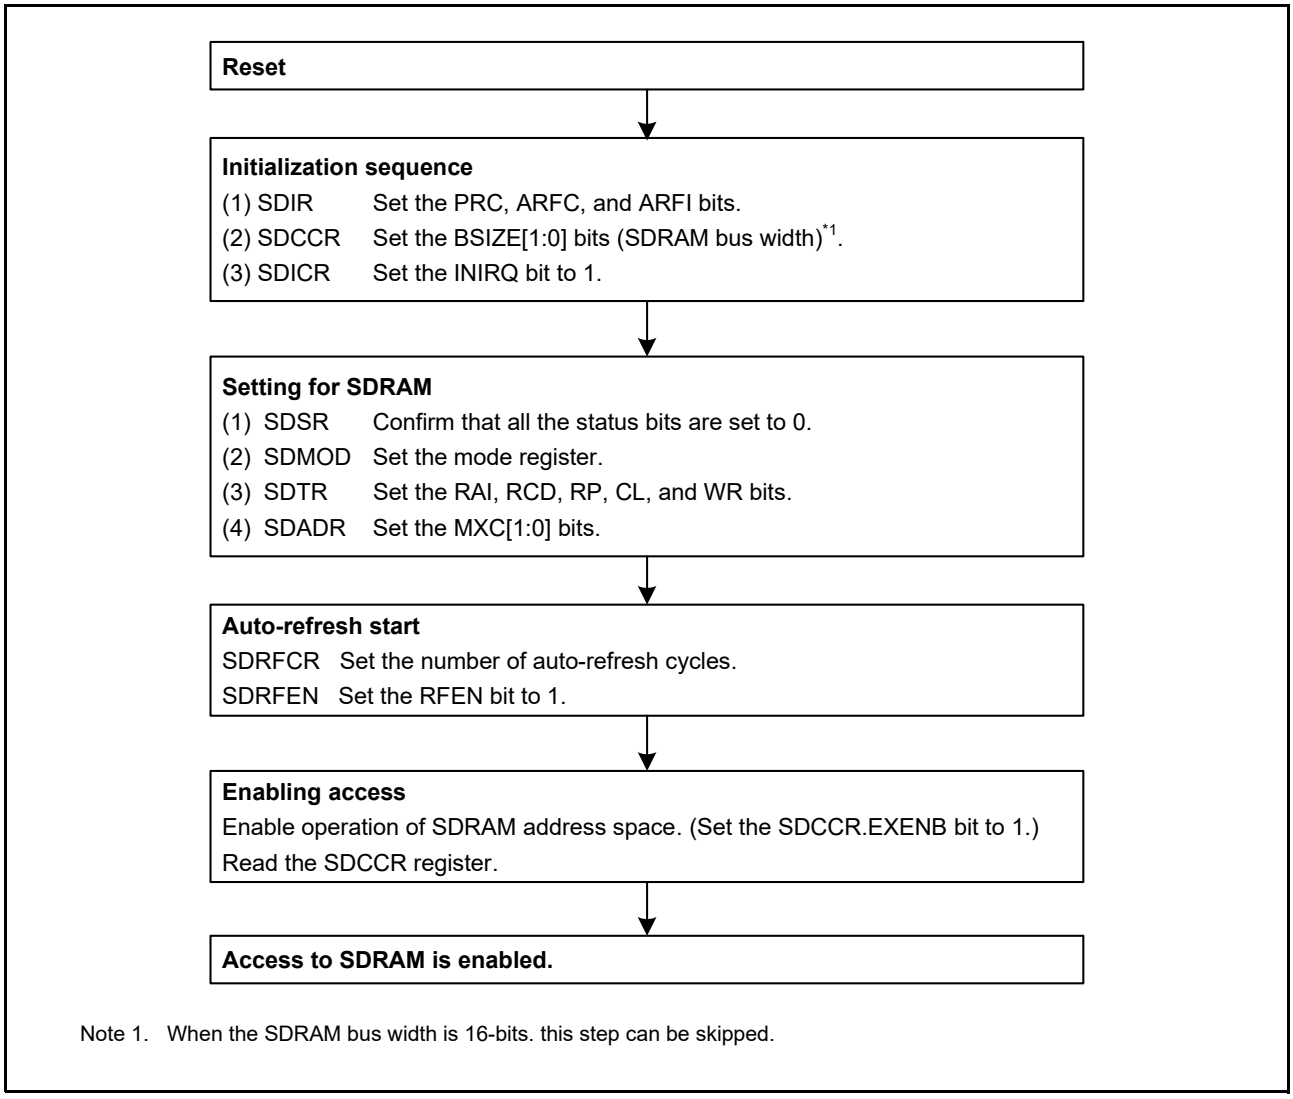


Figure 16.59 Timing Example of Consecutive Write in which the Row Address Changes

16.6.11 SDRAMC Setting Examples

This section describes the SDRAMC setting procedure, timing register setting examples, and procedure for transition to and recovery from self-refresh mode.

16.6.11.1 SDRAMC Access Procedure

Figure 16.60 shows the SDRAMC setting procedure.

Note 1. When the SDRAM bus width is 16-bits. this step can be skipped.

Figure 16.60 SDRAMC Setting Procedure

16.6.11.2 Procedure for Transition to and Recovery from Self-Refresh Mode

Figure 16.61 shows the procedure for transition to and recovery from self-refresh mode.

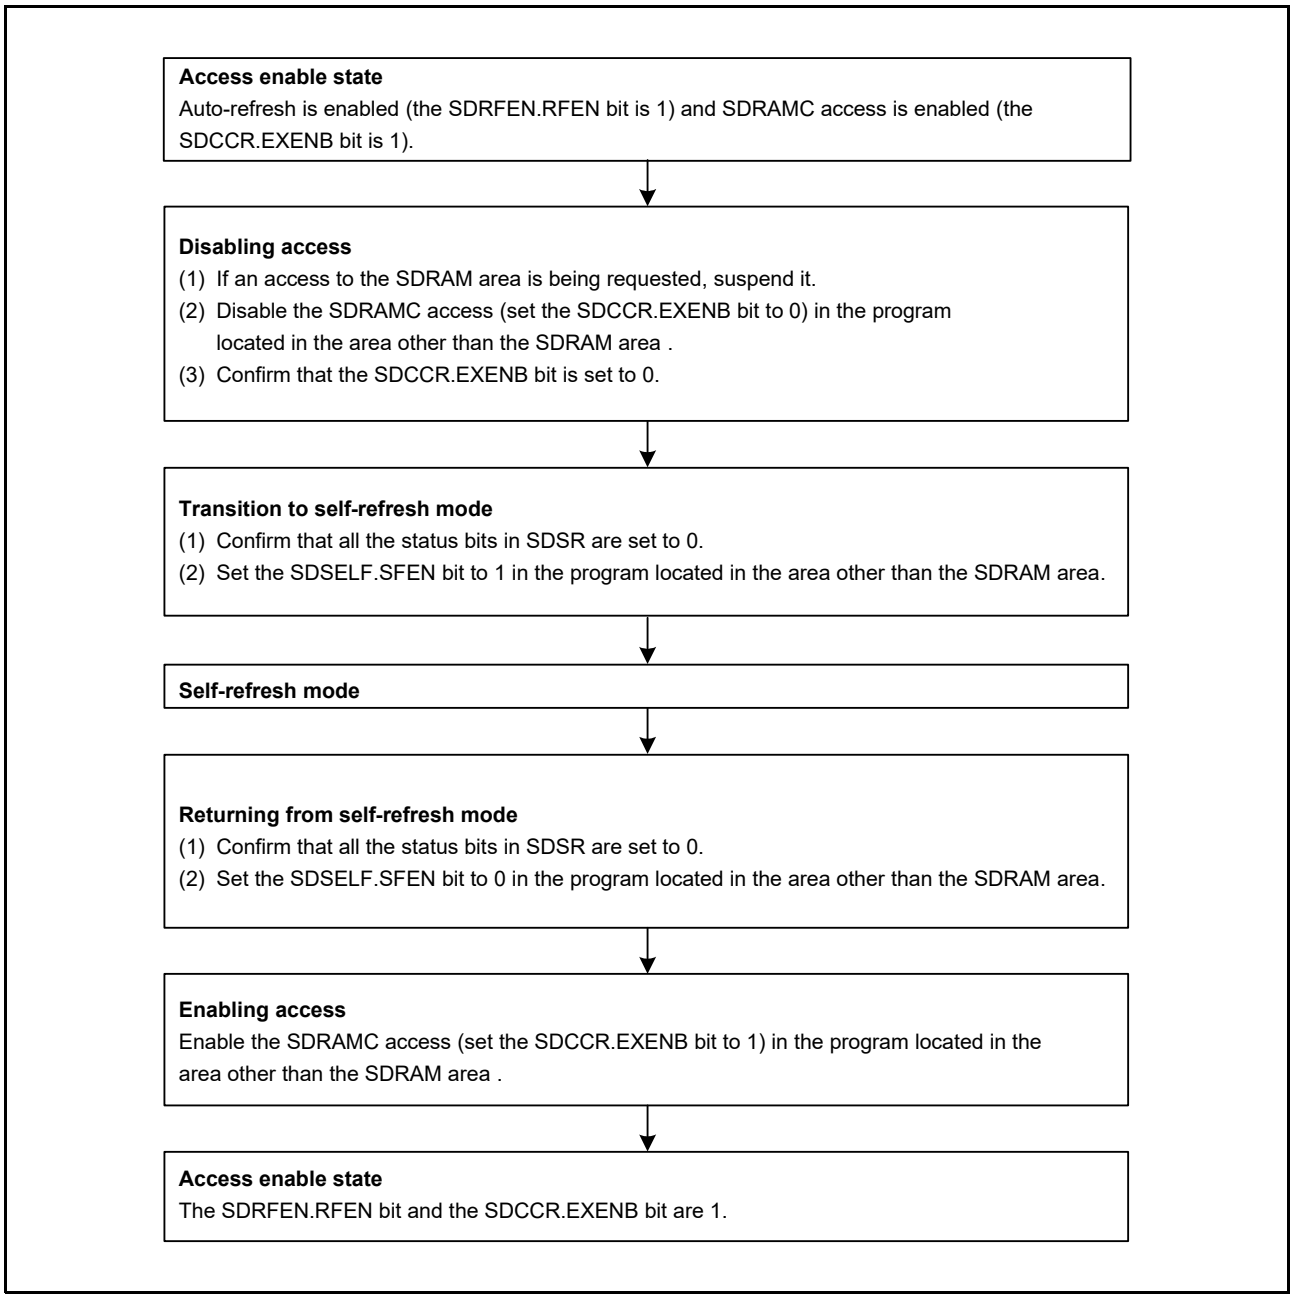

Figure 16.61 Procedure for Transition to and Recovery from Self-Refresh Mode

Note: Transition to and recovery from self-refresh mode requires SDRAM access to be disabled. Accordingly, transition to and recovery from self-refresh mode cannot be made during SDRAM access. The instructions in Figure 16.62 should be followed in programming.
- Before making transition to self-refresh mode, disable the access to the SDRAM area.
- During transition to self-refresh mode, self-refresh operation, and recovery from self-refresh mode, do not allow any operand access or instruction fetch (including prefetch) to the SDRAM area to be generated.

Figure 16.62 shows the procedure for transition to and recovery from self-refresh mode in deep software standby mode.

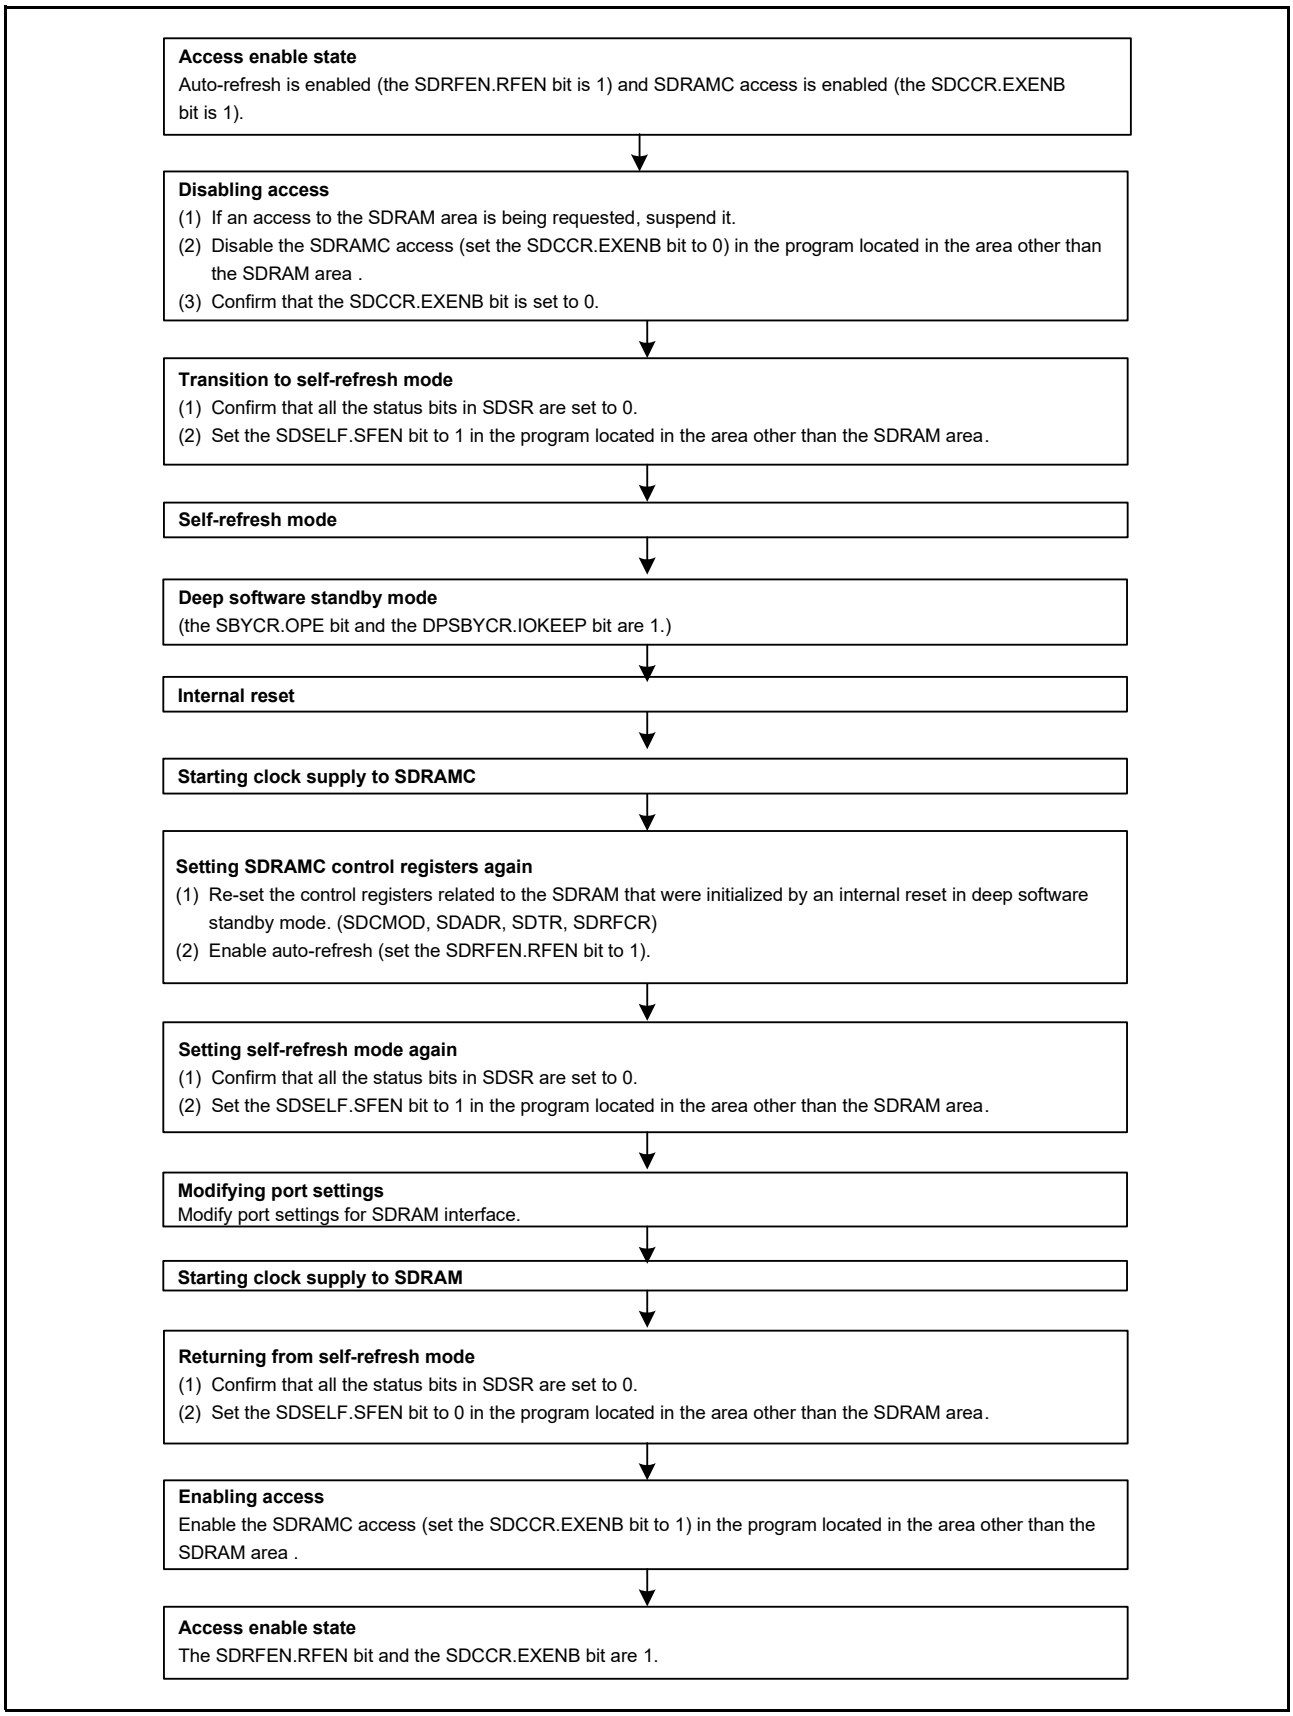

Figure 16.62 Procedure for Transition to and Recovery from Self-Refresh Mode in Deep Software Standby Mode

16.6.11.3 Timing Register Settings and Access Timing

This section describes the relationship between the read/write timing and the settings of the SDRAM timing register (SDTR).

(1) Single Read Timing Examples

Figure 16.63 to Figure 16.67 show the relationship between the single read timing and the SDTR register settings. Table 16.21 lists the correspondence between the figures and the SDTR register settings.
During read access, the next bus access is enabled two cycles after the read data becomes valid at the earliest. However, if two or more accesses occur for one transfer request, the next bus access is enabled one cycle after the read data becomes valid at the earliest, as shown in Figure 16.67.

Table 16.21 Correspondence between Target Figures and SDTR Register Settings (Single Read Timing)

Figure No.	RAI[2:0] Settings	Number of Cycles	RCD[1:0] Settings	Number of Cycles	RP[2:0] Settings	Number of Cycles	CL[2:0] Settings	Number of Cycles

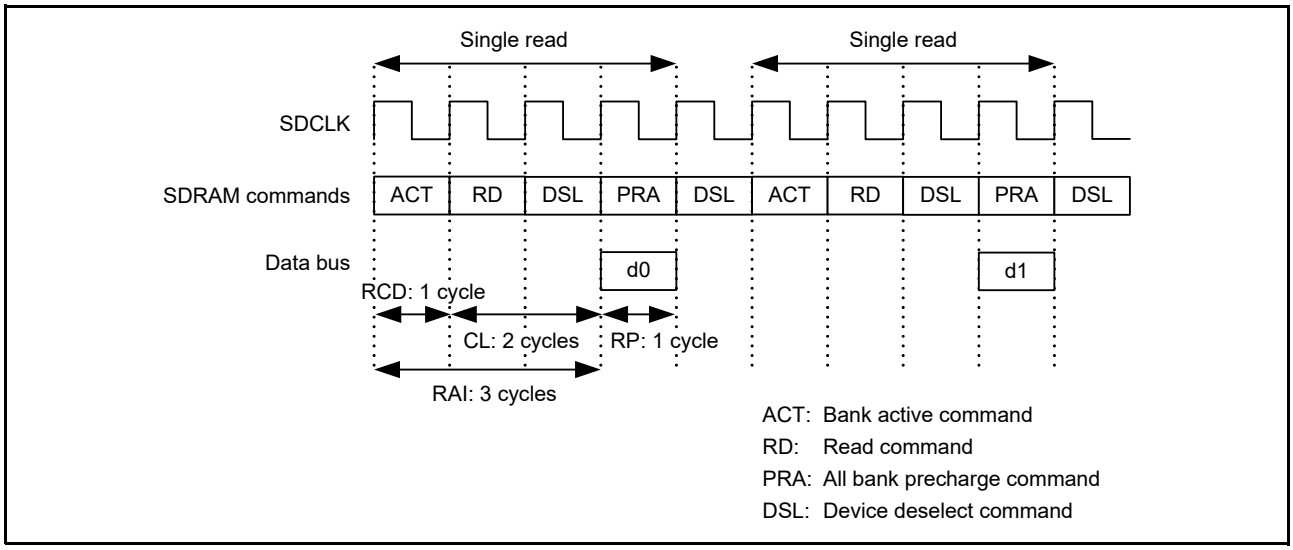

Figure 16.66 Timing Example of Single Read (4)

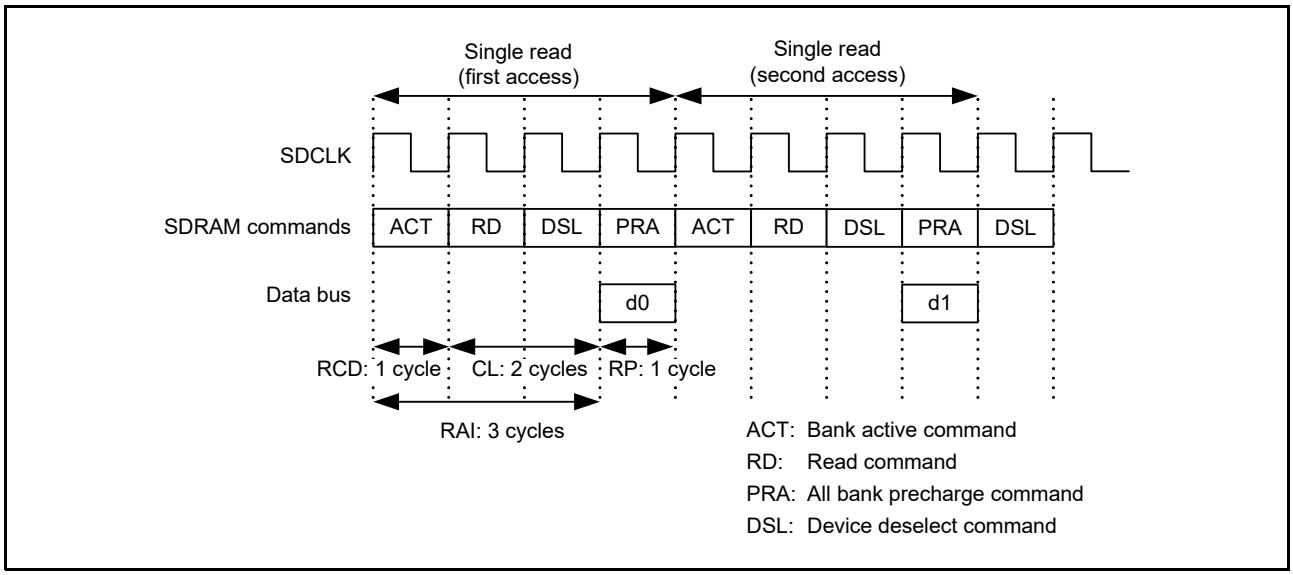

Figure 16.67 Timing Example of Single Read (5) (Two Bus Accesses Occur for One Transfer Request)

(2) Single Write Timing Examples

Figure 16.68 to Figure 16.72 show the relationship between the single write timing and the SDTR register settings. Table 16.22 lists the correspondence between the figures and the SDTR register settings.
During write access, the next bus access is enabled two cycles after an all-bank-precharge command (PRA) is issued at the earliest. However, if two or more accesses occur for one transfer request, the next bus access is enabled one cycle after the PRA is issued at the earliest, as shown in Figure 16.72.

Table 16.22 Correspondence between Target Figures and SDTR Register Settings (Single Write Timing)

16.6.12 Address Multiplexing

In the SDRAM space, row and column addresses are multiplexed. The size of the shift in a row address should be specified for address multiplexing by the address multiplex select bits (SDADR.MXC[1:0]) in the SDRAM address register (SDADR). Moreover, in the SDRAM space, the address precharge select command (precharge-sel) is output to the upper bits of column addresses. Table 16.25 lists the relationship between the SDADR.MXC[1:0] settings and the shift amount.

Table 16.25 Address Multiplexing

MXC [1:0]	Shift Amount	Data Bus Width	Address	Address Pins External to the Microcomputer																		
				A18	A17	A16	A15	A14	A13	A12	A11	A10	A9	A8	A7	A6	A5	A4	A3	A2	A1	A0

Figure 16.84 SDRAM Connection Example (256-Mbit × 1, with 16-Bit Bus)

16.6.14 Restrictions

(1) Prohibition of Access that Spans Areas of Address Space

Single access that spans multiple areas of the address space is prohibited, and operation of such an access is not guaranteed. Setting must be made so that two areas are not accessed at the same time by a single 16-bit or 32-bit access.

(2) Low Power Consumption State

In software standby mode and deep software standby mode, auto-refresh operation is not available since the clock supply to SDRAMC is stopped. To retain the data in the SDRAM when the SDRAM is externally connected, use the self-refresh function. For the procedure for transition to and recovery from self-refresh mode, refer to section 16.6.6, Self-Refresh.

(3) Setting the SDRAM Timing Register

Set the RAI[2:0] bits in the SDRAM timing register (SDTR) to a value less than or equal to the sum of the row column latency (SDTR.RCD[1:0]) and column latency (SDTR.CL[2:0]) settings. Operation is not guaranteed if this condition is not satisfied.

(4) Restriction on the Placement of Instruction Codes

Do not allocate an instruction code to an area with an endian different from that set for the chip. When allocating an instruction code to an external space, be sure to allocate it to an area with the same endian as that set for the chip.
For details, refer to section 16.2.5.1, Restriction on Endian.

(5) Consecutive-Access Mode

When the SDAMOD.BE bit is set to 1 (continuous access mode), setting the SDTR.CL[2:0] bits to 1 is prohibited. If set, operation is not guaranteed.

16.7 External Bus Hold

When the EXHLDEN.HLDEN bit is 1, the external bus can be held by the BREQ# pin.
When the EXHLDEN.HLDEN bit is 1 and the BREQ# pin goes low, the external bus controller puts the external bus into a hold state. When the transition to the external bus hold state is complete, the BACK# pin goes low to notify that the external bus has been released.
When the BREQ# pin goes high, the external bus controller puts the BACK# pin high to release the bus hold state.

Note: The SDRAM cannot be refreshed during an external bus hold state. When using an external bus hold, take into consideration the SDRAM refresh interval.
Note: After the BREQ# pin goes low, do not set the BREQ# pin to high before the BACK# pin goes low.
Note: After the BREQ# pin goes high, do not set the BREQ# pin to low before the BACK# pin goes high.
Note: Set the EXHLDEN.HLDEN bit to 0 before entering the software standby mode or deep software standby mode.

16.8 Bus Error Monitoring Section

The bus error monitoring section monitors the individual areas for bus errors, and when a bus error occurs, the error is indicated to the bus master.

16.8.1 Types of Bus Error

The following types of errors can occur on each bus:

- Master security attribution unit error
- Bus master MPU error
- Illegal address access
- Protect Zone access error
- Bus error transmitted from each slave module

Table 16.29 shows the address ranges that cause an illegal address access error when accessed. The reserved areas in the slave do not cause an illegal address access error. For information about the bus master MPU, refer to section 17, Memory-Protection Unit (MPU).
If an instruction fetch causes an illegal address access error, a Protect Zone access error, or a bus error sent from each slave IP, and the instruction code at the time the error occurred is executed by the CPU, an instruction secure exception occurs in the CPU.

16.8.2 Operations When a Bus Error Occurs

If an access violation occurs due to these bufferable writes, an error response may not be returned to the bus master. If a bufferable write error that does not return an error response is detected, the access is blocked and the flag corresponding to the location where the error occurred in the MBWERRSTAT register is set to 1. In addition, an interrupt request or reset request is generated according to the setting of the BUSOAD.BWERROAD bit. The MBWERRSTAT register is retained until it is cleared by a reset other than a bus error reset or memory error reset or by the MBWERRCLR register, so it can be checked in the interrupt handler or after a reset.
Bufferable write errors may occur in the following cases:

1. CPU0OA accesses an illegal address area.
2. CPU0OA accesses an accessible area and a slave bus error or Protect Zone access error occurs.
3. DMAC0 accesses PABI, PBBI, PIBI, PSBI, PS0BI, PC0BI, LRAM0BI, or LRAM1BI and a slave error or Protect Zone access error occurs.

Table 16.26 Bus Error Notice Method for Bufferable Write Access

Operation Settings after Error Detection	All Masters
BUSOAD.BWERROAD = 0 (Interrupt)	BUSERR.IRQ
BUSOAD.BWERROAD = 1 (Reset)	Reset

If a bus error occurs due to an access other than a bufferable write, the error access is blocked and the error operation determined by the bus master and the operation setting after error detection for that error is performed. Table 16.27 shows the operation setting after error detection corresponding to each error. Table 16.28 shows the notification method when a bus error occurs during non-bufferable write.

- When the operation setting for error detection corresponding to each error is interrupt
  An error response is returned to the bus master, and if BUSINTENx.EN = 1, an interrupt request is generated. To generate an interrupt request, set BUSINTENx.EN to 1. Interrupts due to bus errors (including bufferable errors) can be used as non-maskable interrupts (NMI). For details, refer to the ICU.NMIER register specifications.

- When the operation setting for error detection corresponding to each error is reset
  An error response is returned to the bus master and a reset request is generated.
  x = CPU0IF, CPU0OA, DMAC0, EXDMAC, EDMAC, XSPI0, XSPI1

Table 16.27 OAD Bit (Operation after Detection Bit) for Each Error

Error Type	Operation after Detection Bit
MSAU error	MSAOAD.OAD
MPU error	MMPUOAD.OAD
Illegal access error	BUSOAD.ILERROAD
Slave bus error	BUSOAD.SLERROAD
Protect Zone access error	BUSOAD.SLERROAD

Table 16.28 Bus Error Notice Method for Non-Bufferable Write Access

Operation Settings after Error Detection	All Masters
BUSOAD.ILERROAD = 0 (Interrupt)	BUSERR.IRQ
BUSOAD.SLERROAD = 0 (Interrupt)	
BUSOAD.ILERROAD = 1 (Reset)	Reset
BUSOAD.SLERROAD = 1 (Reset)	

Note: DMAC/DTC0, EDMAC, EXDMAC, and XSPI0/XSPI1 can issue an interrupt when they receive an error response. This non-maskable interrupt is output to the ICU and sent from the ICU to the CPU.

Figure 16.85 shows the operation setting flow when an error is detected after a reset. Bus masters must be stopped while setting this register.

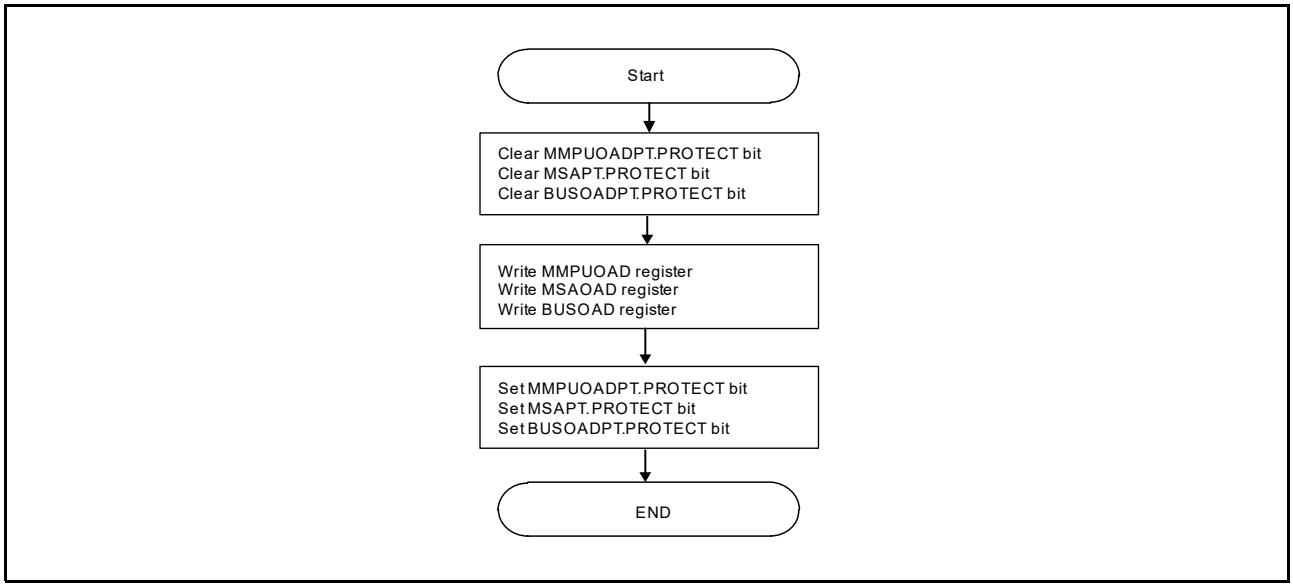

Figure 16.85 Operation Setting Flow when an Error is Detected after a Reset

For details on the MMPUOADPT and MMPUOAD registers, refer to section 17, Memory-Protection Unit (MPU). For details on the MSAPT and MSAOAD registers, refer to section 56, Security Features.

(1) Master Security Attribution Unit Error

When the master security attribute unit (MSAU) detects a master security attribution unit error, it returns an error response to the master that caused the error and the value of the BUSERRSTATx.MSERRSTAT flag corresponding to that master becomes 1. If the value of the BUSINTENx.EN bit is 1, either a bus error interrupt request or reset request is also generated according to the setting of the MSAOAD.OAD bit. The values of the flags in the BUSERRSTATx registers are retained until they are cleared by a reset other than a bus error reset request or common memory error reset request, or by writing to the corresponding bits of the BUSERRCLRx registers. Accordingly, the values of the flags can be checked within the interrupt handler or after a reset. An interrupt request is only generated in response to the first master security attribution unit error to be generated following a reset or clearing of the BUSERRSTATx.MSERRSTAT flag by the corresponding BUSERRCLRx.MSERRCLR bit.
x = CPU0IF, CPU0OA, DMAC0, EXDMAC, EDMAC, XSPI0, XSPI1

(2) Bus Master MPU Error

When the bus master MPU detects a bus master MPU error, it returns an error response to the master that caused the error and the value of the BUSERRSTATx.MMERRSTAT flag corresponding to that master becomes 1. If the value of the BUSINTENx.EN bit is 1, either a bus error interrupt request or reset request is also generated according to the setting of the MMPUOAD.OAD bit. The values of the flags in the BUSERRSTATx registers are retained until they are cleared by a reset other than a bus error reset request or common memory error reset request, or by writing to the corresponding bits of the BUSERRCLRx registers. Accordingly, the values of the flags can be checked within the interrupt handler or after a reset. An interrupt request is only generated in response to the first bus master MPU error to be generated following a reset or clearing of the BUSERRSTATx.MMERRSTAT flag by the corresponding BUSERRCLRx.MMERRCLR bit.

(3) Illegal Address Access Error

Meeting any of the conditions listed in section 16.8.3, Conditions Leading to Illegal Address Access Errors, leads to an illegal address access error, for which an error response is returned to the master that caused the error, and the value of the BUSERRSTATx.ILERRSTAT flag corresponding to that master becomes 1. If the value of the BUSINTENx.EN bit is 1, either a bus error interrupt request or reset request is also generated according to the setting of the BUSOAD.ILERROAD bit. The values of the flags in the BUSERRSTATx registers are retained until they are cleared by a reset other than a bus error reset request or common memory error reset request, or by writing to the corresponding bits of the BUSERRCLRx registers. Accordingly, the values of the flags can be checked within the interrupt handler or after a reset. An interrupt request is only generated in response to the first illegal address access error to be generated following a reset or clearing of the BUSERRSTATx.ILERRSTAT flag by the corresponding BUSERRCLRx.ILERRCLR bit.

(4) Protect Zone Access Error

When a Protect Zone access error is detected, an error response is returned to the master that caused the error and the value of the BUSERRSTATx.SLERRSTAT flag corresponding to that master becomes 1. If the value of the BUSINTENx.EN bit is 1, either a bus error interrupt request or reset request is also generated according to the setting of the BUSOAD.SLERROAD bit. The values of the flags in the BUSERRSTATx registers are retained until they are cleared by a reset other than a bus error reset request or common memory error reset request, or by writing to the corresponding bits of the BUSERRCLRx registers. Accordingly, the values of the flags can be checked within the interrupt handler or after a reset. An interrupt request is only generated in response to the first slave error or Protect Zone access error to be generated following a reset or clearing of the BUSERRSTATx.SLERRSTAT flag by the corresponding BUSERRCLRx.SLERRCLR bit.

(5) Slave Bus Error

When a bus error is detected in the destination module for bus access, an error response is returned to the master that caused the error and the value of the BUSERRSTATx.SLERRSTAT flag corresponding to that master becomes 1. If the value of the BUSINTENx.EN bit is 1, either a bus error interrupt request or reset request is also generated according to the setting of the BUSOAD.SLERROAD bit. The values of the flags in the BUSERRSTATx registers are retained until they are cleared by a reset other than a bus error reset request or common memory error reset request, or by writing to the corresponding bits of the BUSERRCLRx registers. Accordingly, the values of the flags can be checked within the interrupt handler or after a reset. An interrupt request is only generated in response to the first slave error or Protect Zone access error to be generated following a reset or clearing of the BUSERRSTATx.SLERRSTAT flag by the corresponding BUSERRCLRx.SLERRCLR bit.

16.8.3 Conditions Leading to Illegal Address Access Errors

Table 16.29 lists illegal address access error by bus access occurs in the address space.

Note 1. When CPU0IF and CPU0OA cause an illegal address access error, it may be set as a slave bus error in the bus error status register.

16.8.4 Timeout

16.8.4.1 Peripheral Bus

As for some peripheral modules, a timeout error can occur in the module-stop function. When there is no response from the slave for a certain period of time, a timeout error is detected.

16.8.4.2 External Bus Access Wait with WAIT# Signal

When the external bus timeout detection enable bit (EXBEREN.TOEN) is set to 1, it is possible to detect an external bus access wait timeout error caused by the WAIT# signal.
When the EXBEREN.TOEN bit is 1 and the wait time for external bus access caused by the WAIT# signal exceeds 768 BCLK cycles, a timeout error occurs and the EXBERR.TO flag is set to 1.
Once a timeout error occurs, accesses from the bus master are rejected for 256 BCLK cycles. If multiple external bus accesses are generated with a single request from the bus master during the transfer, the bus accesses cannot be stopped by a timeout. At this time, timeout errors may occur repeatedly.
When a timeout error occurs, do not write to the CSnCR.EXENB bit or the SDCCR.EXENB bit.

16.8.4.3 External Bus Hold with BREQ# and BACK# Signals

When the external bus timeout detection enable bit (EXBEREN.TOEN) is set to 1, it is possible to detect an external bus hold timeout error caused by the BREQ# and BACK# signals.
When the EXBEREN.TOEN bit is 1 and the external bus hold time caused by the BREQ# and BACK# signals exceeds 768 BCLK cycles, a timeout error occurs and the EXBERR.HLDTO flag is set to 1.
Any access to the external bus from 256 BCLK cycles after an external bus hold timeout error has been detected until the BREQ# signal is negated is treated as a slave error.
When a timeout error occurs, do not write to the CSnCR.EXENB bit or the SDCCR.EXENB bit.

17. Memory-Protection Unit (MPU)

17.1 Overview

This MCU has three memory-protection units: two for the CPU (CPU MPUs) and one for the xSPI bus masters (bus master MPU).
Table 17.1 lists the specifications of the memory-protection units, Table 17.2 lists the memory-protection error detection operations.

Table 17.1 Specifications of Memory Protection (1 / 2)

Specification		Description
CPU MPU	Region to be covered by memory protection and processor mode	0000 0000h to FFFF FFFFh (in user mode) No memory protection applies in supervisor mode and only the cache attribute settings are effective.
	Number of regions	8
	Page size (smallest unit of protection)	32 bytes
	Specifying addresses of individual regions	Setting the page numbers where regions start and end
	Setting to make memory protection effective or ineffective in individual regions	A V (valid) bit in each region-n end page number register (REPAGEn) makes the settings effective or ineffective for the corresponding region (n = 0 to 7).
	Access control information settings for individual regions	Instruction execution: Permission to execute Operand access: Permission to read, permission to write
	Cache attribute information settings for individual regions	Set cache attributes for individual regions. Instruction access: Not cached Instruction cached Data access: Not cached Cached (write-through) Cached (write-back)
	Start of memory-protection operations	After the memory-protection unit has been enabled, access monitoring starting up with the transition to user mode.
	Memory-protection error processing	Generation of access exceptions
	Addresses where memory-protection errors are generated	Address in instruction execution: The PC value is preserved on the stack. Address in operand access: The address is stored in the data memory-protection error address register (MPDEA).
	Determining the reasons for memory-protection errors	The memory-protection error status register (MPESTS) holds indicators of the reason.
	Background region access control settings	Access control information can be set for the background region (the whole address space).
	Background region cache settings	Caches can be set for the background region (the whole address space).
	Processing where regions overlap	If region settings overlap for an address and the access control information for these regions is different, the information is handled as the logical OR of each bit setting. As a result, permission is given priority in access control. The information for the cache attribute is also handled in the same way, as the logical OR of the settings.

Table 17.1 Specifications of Memory Protection (2 / 2)

Specification		Description
Bus master MPU	Memory protection (except for the CPU)	Memory protection function for the bus master ・ xSPI0: 4 regions ・ xSPI1: 4 regions
	Protected region	0000 0000h to FFFF FFFFh
	Number of regions	xSPI0: 4 regions; xSPI1: 4 regions
	Specifying addresses of individual regions	The start/end addresses of individual regions can be set.
	Memory protection permission/prohibition setting for individual regions	Setting for permission or prohibition for the relevant region
	Access control settings for individual regions	Permitting writing or reading
	Error detection operation	Reset or error response
	Register protection	Protection against illegal writing

Table 17.2 Memory-Protection Error Detection Operations

Type	Access Permission Setting	Minimum Unit for Boundary Address Setting	Error Response for Error Notification	Bus Access at Error Detection	Whether Error Access Information is Held
CPU MPU	Read access Write access Execution	32 bytes	Supported	Illegal write access Illegal read access	Held
Bus master MPU	Read access Write access	xSPI0/1: 4 Kbytes	Supported	Write access is ignored For read access, the value read is 0	Held

17.2 CPU MPU

17.2.1 Overview of CPU MPU

The RXv3e CPU incorporates two memory-protection units (MPUs), one for secure access and the other for non-secure access, which check the addresses accessed by the CPU over the whole address space (0000 0000h to FFFF FFFFh). The secure MPU checks the addresses for secure access, and the non-secure MPU checks the addresses for non-secure access. For secure access and non-secure access, see section 56, Security Features.

Up to eight regions can be set for each of the secure and non-secure MPUs, and access is permitted or prohibited in accord with the access control information for each region. If an access outside the set regions is detected, a memory-protection error occurs by default.

The access control information for each region corresponds to permitting reading, permitting writing, and permitting execution. This access control information is effective when the processor mode of the CPU is user mode. Memory protection is not applied when the CPU is in supervisor mode.

Cache attributes for instruction access and data access are set for each region. The cache attribute settings are effective in supervisor mode as well as in user mode.

The registers of the memory-protection units are only accessible from the CPU. Access to the MPU for the secure world is only possible through the CPU when it is in the secure state. Access to the MPU in the non-secure world is possible through the CPU whether it is in either the non-secure or secure state.

Figure 17.1 is a block diagram of a CPU MPU.

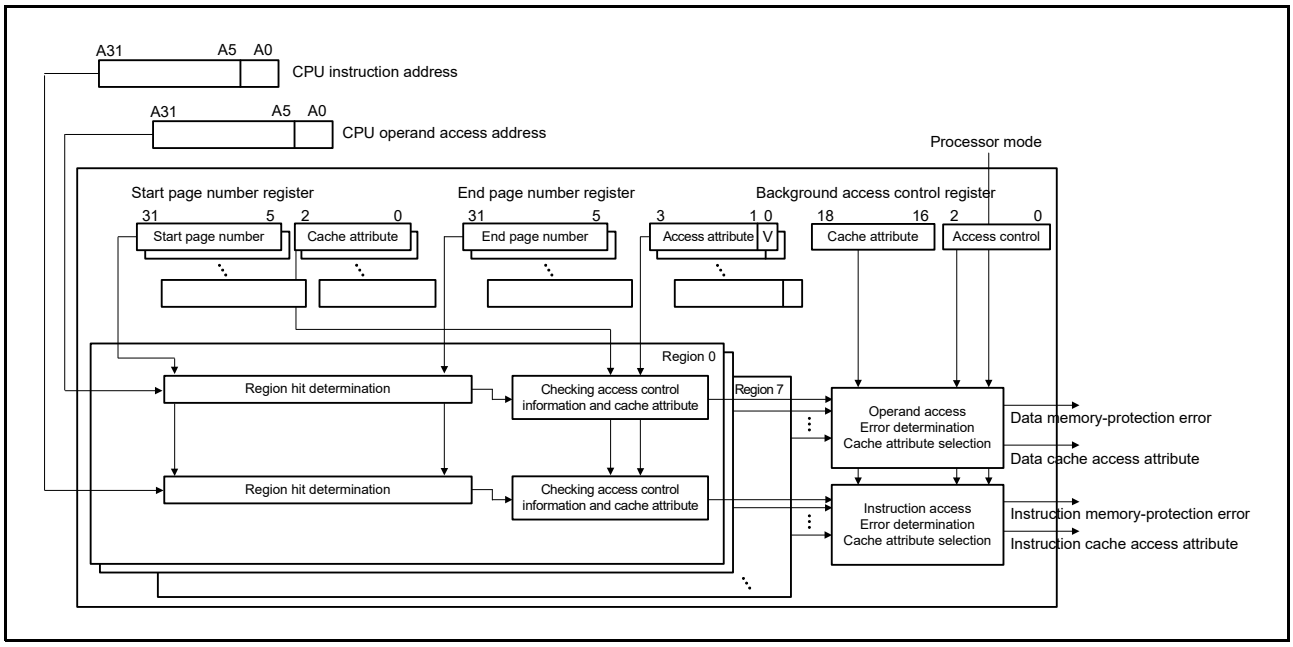

Figure 17.1 Block Diagram of CPU MPU

17.2.1.1 Types of Access Control

There are three types of access control: controlling permission for instruction execution, permission for the reading of operands, and permission for the writing of operands. Detection of a violation of any of these forms of access control only proceeds for a program in user mode. A violation is not detected for a program in supervisor mode.

17.2.1.2 Access Control Regions

Up to eight regions for access control can be defined. The range of each access control region is set by the region-n start page number registers (RSPAGEn) and region-n end page number registers (REPAGEn) (n = 0 to 7).
The minimum unit for access control is the “page”, by which the address space is divided into 32-byte units. The 27 higher-order bits ([31:5]) of the address [31:0] bits correspond to the page number.
The REPAGEn register specifies the access control information for each region and whether the settings for the region are validated or not.

17.2.1.3 Cache Attribute

For each access control region, the cache attribute can be set as “instruction not cached” or “instruction cached” for instruction access, and as “data not cached”, “data cached (write-through)”, or “data cached (write-back)” for data access.
However, for the IO registers region, “instruction not cached” and “data not cached” are selected regardless of the setting. As for the allocation of caches, read allocation proceeds in the case of “data cached (write-through)”, and write allocation and read allocation proceed in the case of “data cached (write-back)”.

17.2.1.4 Background Region

“Background region” refers to the whole address space (0000 0000h to FFFF FFFFh). The access control information for the background region is set by the MPBAC.UBAC bits. Unlike the eight access control regions, the access control information for the background region is effective as long as memory protection is enabled (the MPEN.MPEN bit is 1). The cache settings for the background region are set by using the MPBAC.DCA and MPBAC.ICA bits. These settings are effective even while memory protection is disabled (the MPEN.MPEN bit is 0).

17.2.1.5 Overlap between Regions

In cases of overlap between multiple regions, the access control information becomes the logical OR of the access control bits for the overlapping regions (including the background region), with permission given priority. In the same way as for the access control information, overlapping settings for the cache attribute are also handled as the logical OR of the settings. Accordingly, the order of priority is “cache enabled” > “cache disabled” for instruction access, and “cache enabled (write-back) > “cache enabled (write-through)” > “cache disabled” for data access. In the case of the cache attribute, the background region setting is not included in the logical OR to obtain the applicable setting.

17.2.1.6 Instructions and Data that Span Regions

Operations in response to the detection of memory-protection errors when instructions or data span regions for which different access control settings and cache settings have been made are undefined. Ensure that instructions and data do not span regions for which different access control settings and cache settings have been made.

17.2.2 Register Descriptions of CPU MPU

17.2.2.1 Region-n Start Page Number Register (RSPAGEn) (n = 0 to 7)

Address(es): MPU.RSPAGE0 8100 0800h, MPU.RSPAGE1 8100 0808h, MPU.RSPAGE2 8100 0810h, MPU.RSPAGE3 8100 0818h, MPU.RSPAGE4 8100 0820h, MPU.RSPAGE5 8100 0828h, MPU.RSPAGE6 8100 0830h, MPU.RSPAGE7 8100 0838h, MPU_NS.RSPAGE0 0100 0800h, MPU_NS.RSPAGE1 0100 0808h, MPU_NS.RSPAGE2 0100 0810h, MPU_NS.RSPAGE3 0100 0818h, MPU_NS.RSPAGE4 0100 0820h, MPU_NS.RSPAGE5 0100 0828h, MPU_NS.RSPAGE6 0100 0830h, MPU_NS.RSPAGE7 0100 0838h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1, b0	DCA[1:0]	Data Cache Attribute Setting	b1 b0 0 0: Data not cached 0 1: Data cached (write-through) 1 0: Setting prohibited 1 1: Data cached (write-back)	R/W
b2	ICA	Instruction Cache Attribute Setting	0: Instruction not cached 1: Instruction cached	R/W
b4, b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b5	RSPN[26:0]	Region Start Page Number	Region-start page number information for use in region determination	R/W

DCA[1:0] Bits (Data Cache Attribute Setting)

These bits set the data cache attribute. These bits are valid in both user mode and supervisor mode.

ICA Bit (Instruction Cache Attribute Setting)

This bit sets the instruction cache attribute. This bit is valid in both user mode and supervisor mode.

RSPN[26:0] Bits (Region Start Page Number)

These bits set the region-start page number.

17.2.2.2 Region-n End Page Number Register (REPAGEn) (n = 0 to 7)

Address(es): MPU.REPAGE0 8100 0804h, MPU.REPAGE1 8100 080Ch, MPU.REPAGE2 8100 0814h, MPU.REPAGE3 8100 081Ch, MPU.REPAGE4 8100 0824h, MPU.REPAGE5 8100 082Ch, MPU.REPAGE6 8100 0834h, MPU.REPAGE7 8100 083Ch, MPU_NS.REPAGE0 0100 0804h, MPU_NS.REPAGE1 0100 080Ch, MPU_NS.REPAGE2 0100 0814h, MPU_NS.REPAGE3 0100 081Ch, MPU_NS.REPAGE4 0100 0824h, MPU_NS.REPAGE5 0100 082Ch, MPU_NS.REPAGE6 0100 0834h, MPU_NS.REPAGE7 0100 083Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	REPN[26:11]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	REPN[10:0]											—	UAC[2:0]			V
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	V	Valid	0: Region setting invalid 1: Region setting valid	R/W
b3 to b1	UAC[2:0]	Access Control in User Mode	b3 0: Reading prohibited 1: Reading permitted b2 0: Writing prohibited 1: Writing permitted b1 0: Execution prohibited 1: Execution permitted	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b31 to b5	REPN[26:0]	Region-End Page Number	Region-end page number information for use in region determination	R/W

V Bit (Valid)

This bit selects whether the corresponding region settings are to be valid or invalid. The setting of this bit determines validation or invalidation of both the memory protection and cache attribute setting functions.
This bit is set to 0 when the region invalidation operation register (MPOPI) invalidates all access control regions.

UAC[2:0] Bits (Access Control in User Mode)

These bits set access control in user mode.

REPN[26:0] Bits (Region-End Page Number)

These bits set the region-end page number. Set a value greater than or equal to the start page number of the corresponding region. The page specified by the region-end page number is also part of the target region for memory protection.

17.2.2.3 Memory-Protection Enable Register (MPEN)

Address(es): MPU.MPEN 8100 0900h,
MPU_NS.MPEN 0100 0900h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MPEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MPEN	Memory-Protection Enable	0: Memory protection disabled 1: Memory protection enabled	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

MPEN Bit (Memory-Protection Enable)

This bit enables or disables memory protection.

After 1 is written to this bit, address checking for memory protection by the CPU starts upon execution of a branch instruction (RTE or RTFI) that shifts operation to user mode.

17.2.2.4 Background Access Control Register (MPBAC)

Address(es): MPU.MPBAC 8100 0904h,
MPU_NS.MPBAC 0100 0904h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	ICA	DCA[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	UBAC[2:0]			—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3 to b1	UBAC[2:0]	Background Access Control in User Mode	b3 0: Reading prohibited 1: Reading permitted b2 0: Writing prohibited 1: Writing permitted b1 0: Execution prohibited 1: Execution permitted	R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	DCA[1:0]	Data Cache Attribute Setting	b17 b16 0 0: Data not cached 0 1: Data cached (write-through) 1 0: Setting prohibited 1 1: Data cached (write-back)	R/W
b18	ICA	Instruction Cache Attribute Setting	0: Instruction not cached 1: Instruction cached	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

UBAC[2:0] Bits (Background Access Control in User Mode)

These bits set background access control in user mode.

DCA[1:0] Bits (Data Cache Attribute Setting)

These bits set the background data cache attribute.

The setting of these bits is effective even while memory protection is disabled (MPEN = 0).

ICA Bit (Instruction Cache Attribute Setting)

These bits set the background instruction cache attribute. The setting of these bits is effective even while memory protection is disabled (MPEN = 0).

17.2.2.5 Memory-Protection Error Status Clear Register (MPECLR)

Address(es): MPU.MPECLR 8100 0908h,
MPU_NS.MPECLR 0100 0908h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CLR	Error Status Clear	[Reading] 0: Fixed for reading [Writing] 0: Nothing is done. 1: The MPESTS.DRW, DMPER, and IMPER bits are set to 0.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CLR Bit (Error Status Clear)

This bit clears the data read/write bit (DRW), data memory-protection error generation bit (DMPER), and instruction memory-protection error generation bit (IMPER) in the memory-protection error status register (MPESTS) to 0.

17.2.2.6 Memory-Protection Error Status Register (MPESTS)

Address(es): MPU.MPESTS 8100 090Ch,
MPU_NS.MPESTS 0100 090Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	DRW	DMPER	IMPER
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IMPER	Instruction Memory-Protection Error Generation Flag	0: No instruction memory-protection error occurred 1: Instruction memory-protection error occurred	R
b1	DMPER	Data Memory-Protection Error Generation Flag	0: No data memory-protection error occurred 1: Data memory-protection error occurred	R
b2	DRW	Data Read/Write Flag	0: Data read 1: Data write	R
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

IMPER Flag (Instruction Memory-Protection Error Generation Flag)

This flag indicates the state of memory-protection error generation by instruction execution.
It is only cleared to 0 by setting the error status clear bit (CLR) of the memory-protection error status clear register (MPECLR) to 1.

DMPER Flag (Data Memory-Protection Error Generation Flag)

This flag indicates the state of memory-protection error generation by operand access.
It is only cleared to 0 by setting the error status clear bit (CLR) of the memory-protection error status clear register (MPECLR) to 1.

DRW Flag (Data Read/Write Flag)

This flag indicates the read/write attribute for operand access that led to a memory-protection error. This flag is only valid while the DMPER bit is 1.
It is only cleared to 0 by setting the error status clear bit (CLR) of the memory-protection error status clear register (MPECLR) to 1.

17.2.2.7 Data Memory-Protection Error Address Register (MPDEA)

Address(es): MPU.MPDEA 8100 0914h,
MPU_NS.MPDEA 0100 0914h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DEA[31:16]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	DEA[31:0]	Data Memory-Protection Error Address	Data memory-protection error address	R

DEA[31:0] Bits (Data Memory-Protection Error Address)

These bits hold the address where a memory-protection error occurred due to operand access.

17.2.2.8 Region Search Address Register (MPSA)

Address(es): MPU.MPSA 8100 0920h,
MPU_NS.MPSA 0100 0920h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SA[31:16]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SA[15:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	SA[31:0]	Region Search Address	Address for region search	R/W

SA[31:0] Bits (Region Search Address)

These bits specify the address for use in comparison with region-start addresses in the region-n start page number registers (RSPAGEn) and region-end addresses in the region-n end page number registers (REPAGEn) in a region search operation.

17.2.2.9 Region Search Operation Register (MPOPS)

Address(es): MPU.MPOPS 8100 0924h,
MPU_NS.MPOPS 0100 0924h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	S	Regions Search Operation	[Reading] 0: Fixed for reading [Writing] 0: Nothing is done. 1: A region search operation proceeds.	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

S Bit (Regions Search Operation)

Setting this bit to 1 makes the memory-protection unit perform a region search operation. The address specified in the region search address register (MPSA) is compared with the address information for individual regions to search for a hitting region.

The result of searching is stored in the data-hit region bits (HITD[7:0]) of the data-hit region register (MHITD). Moreover, the logical OR of the respective access control bits for hitting regions is stored in the data-hit region access control bits in user mode (UHACD[2:0]).

17.2.2.10 Region Invalidation Operation Register (MPOPI)

Address(es): MPU.MPOPI 8100 0926h,
MPU_NS.MPOPI 0100 0926h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	INV	Region Invalidation Start	[Reading] 0: Fixed for reading [Writing] 0: Nothing is done. 1: All access control regions are invalidated.	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

INV Bit (Region Invalidation Start)

Setting this bit to 1 clears the valid bits (V) in all of the region-n end page number registers (REPAGEn) to 0. After a REPAGEn.V bit is set to 0, all settings other than the access control settings for the background region are invalidated.

17.2.2.11 Instruction-Hit Region Register (MHITI)

Address(es): MPU.MHITI 8100 0928h,
MPU_NS.MHITI 0100 0928h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	—	—	—	—	—	—	—	UHACI[2:0]			—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3 to b1	UHACI[2:0]	Instruction-Hit Region Access Control in User Mode	b3 0: Reading prohibited 1: Reading permitted b2 0: Writing prohibited 1: Writing permitted b1 0: Execution prohibited 1: Execution permitted	R
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	HITI[7:0]	Instruction-Hit Region	When the instruction memory-protection error generation bit (MPESTS.IMPER) = 1, [b23:b16] = 0000 0000b indicates that attempted access to the background region led to an instruction memory-protection error. Other than the above b23 0: No instruction memory-protection error in region 7 1: Instruction memory-protection error in region 7 b22 0: No instruction memory-protection error in region 6 1: Instruction memory-protection error in region 6 b21 0: No instruction memory-protection error in region 5 1: Instruction memory-protection error in region 5 b20 0: No instruction memory-protection error in region 4 1: Instruction memory-protection error in region 4 b19 0: No instruction memory-protection error in region 3 1: Instruction memory-protection error in region 3 b18 0: No instruction memory-protection error in region 2 1: Instruction memory-protection error in region 2 b17 0: No instruction memory-protection error in region 1 1: Instruction memory-protection error in region 1 b16 0: No instruction memory-protection error in region 0 1: Instruction memory-protection error in region 0	R
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

UHACI[2:0] Bits (Instruction-Hit Region Access Control in User Mode)

These bits hold the access control bits in user mode (REPAGEn.UAC[2:0]) for the region where an instruction memory-protection error occurred.

When an error occurred in overlapping regions, the value held here is the logical OR of the access control bits in user mode for the corresponding regions (including the background region).

HITI[7:0] Bits (Instruction-Hit Region)

These bits indicate the region where an instruction memory-protection error occurred. They are set to 0000 0000b in response to the generation of an instruction memory-protection error in the background region.

17.2.2.12 Data-Hit Region Register (MHITD)

Address(es): MPU.MHITD 8100 092Ch,
MPU_NS.MHITD 0100 092Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3 to b1	UHACD[2:0]	Data-Hit Region Access Control in User Mode	b3 0: Reading prohibited 1: Reading permitted b2 0: Writing prohibited 1: Writing permitted b1 0: Execution prohibited 1: Execution permitted	R
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	HITD[7:0]	Data-Hit Region	When the data memory-protection error generation bit (MPESTS.DMPER) = 1, [b23:b16] = 0000 0000b indicates that attempted access to the background region led to a data memory-protection error. Other than the above b23 0: No data memory-protection error or no search hit in region 7 1: A data memory-protection error or a search hit in region 7 b22 0: No data memory-protection error or no search hit in region 6 1: A data memory-protection error or a search hit in region 6 b21 0: No data memory-protection error or no search hit in region 5 1: A data memory-protection error or a search hit in region 5 b20 0: No data memory-protection error or no search hit in region 4 1: A data memory-protection error or a search hit in region 4 b19 0: No data memory-protection error or no search hit in region 3 1: A data memory-protection error or a search hit in region 3 b18 0: No data memory-protection error or no search hit in region 2 1: A data memory-protection error or a search hit in region 2 b17 0: No data memory-protection error or no search hit in region 1 1: A data memory-protection error or a search hit in region 1 b16 0: No data memory-protection error or no search hit in region 0 1: A data memory-protection error or a search hit in region 0	R
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

UHACD[2:0] Bits (Data-Hit Region Access Control in User Mode)

These bits hold the access control bits in user mode (REPAGEn.UAC[2:0]) for the region where a data memory-protection error occurred or the region that was hit in a region search.
When an error occurred in overlapping regions or a region was hit in a region search, the value held here is the logical OR of the access control bits in user mode for the corresponding regions (including the background region).

HITD[7:0] Bits (Data-Hit Region)

These bits indicate the region where a data memory-protection error occurred or the region that was hit in a region search. These bits are set to 0000 0000b when a data memory-protection error occurred in the background region.

Note: If access to a register of the memory-protection unit in user mode causes a data memory-protection error, the value of this register is set to 0000 0000h.

17.2.3 Functions of CPU MPU

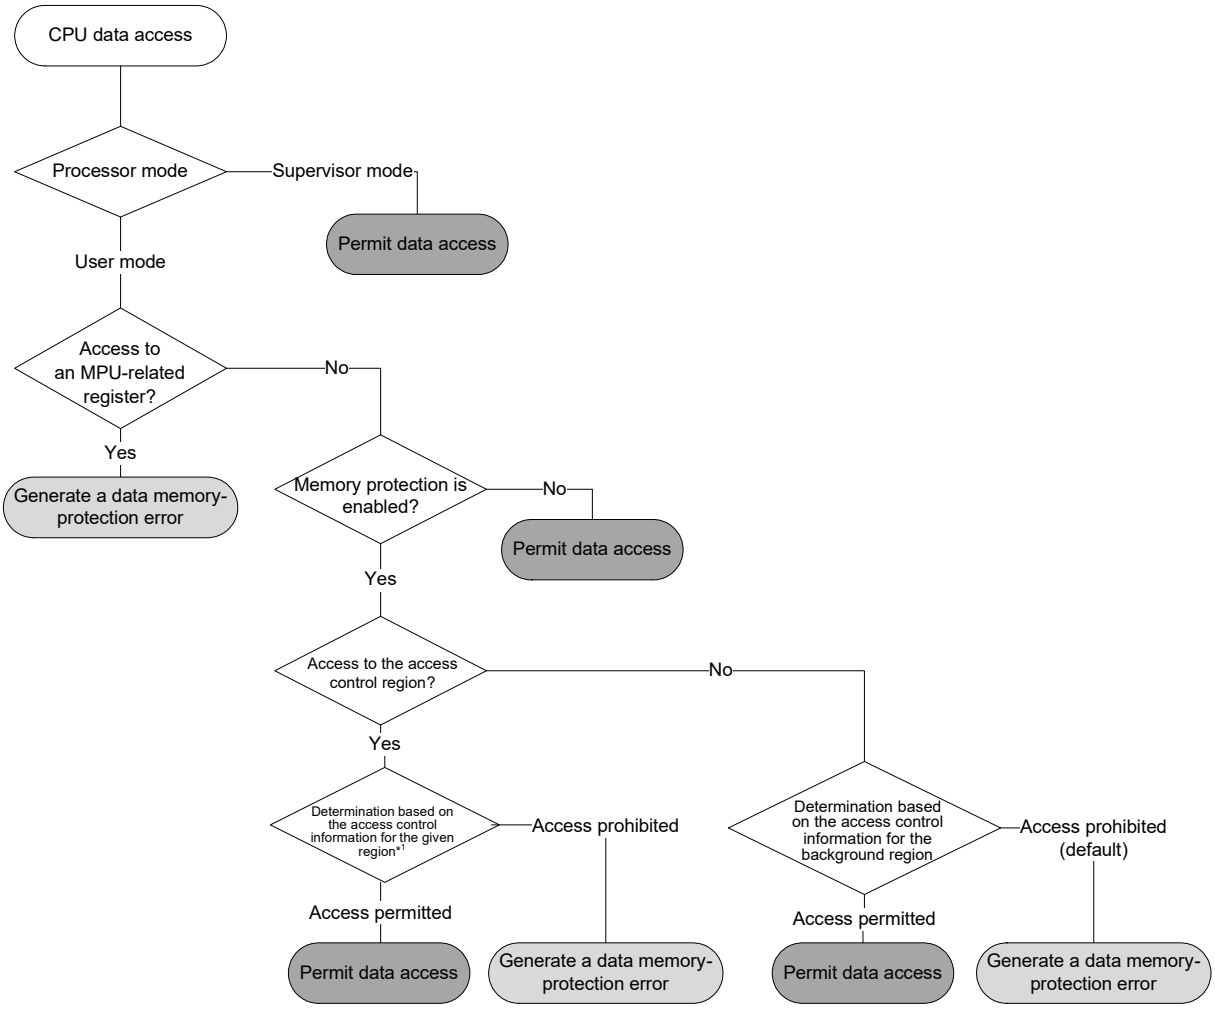
17.2.3.1 Memory Protection Function

Memory protection monitors whether or not access by programs running in user mode violates the access control settings, in accord with the access control information set for the individual access control regions and the background region. When the memory-protection unit detects an access control violation (memory-protection error), it notifies the CPU of this information, and the CPU starts access-exception processing.
Memory protection is enabled by setting the memory-protection enable bit (MPEN) of the memory-protection enable register (MPEN) to 1.
An instruction memory-protection error occurs on detection of a violation in terms of executing an instruction, and a data memory-protection error occurs on detection of a violation in terms of reading or writing for operand access. When a data memory-protection error occurs, the operand access that caused the access control violation does not proceed.

17.2.3.2 Cache Attribute Setting Function

The cache attribute setting function is for setting the cache attribute for each region.
The cache attribute setting function is enabled by setting the memory-protection enable bit (MPEN) of the memory-protection enable register (MPEN) to 1.
When this bit is 0 or the corresponding region does not exist, the cache attribute set in the background access control register (MPBAC.DCA/ICA) is used.

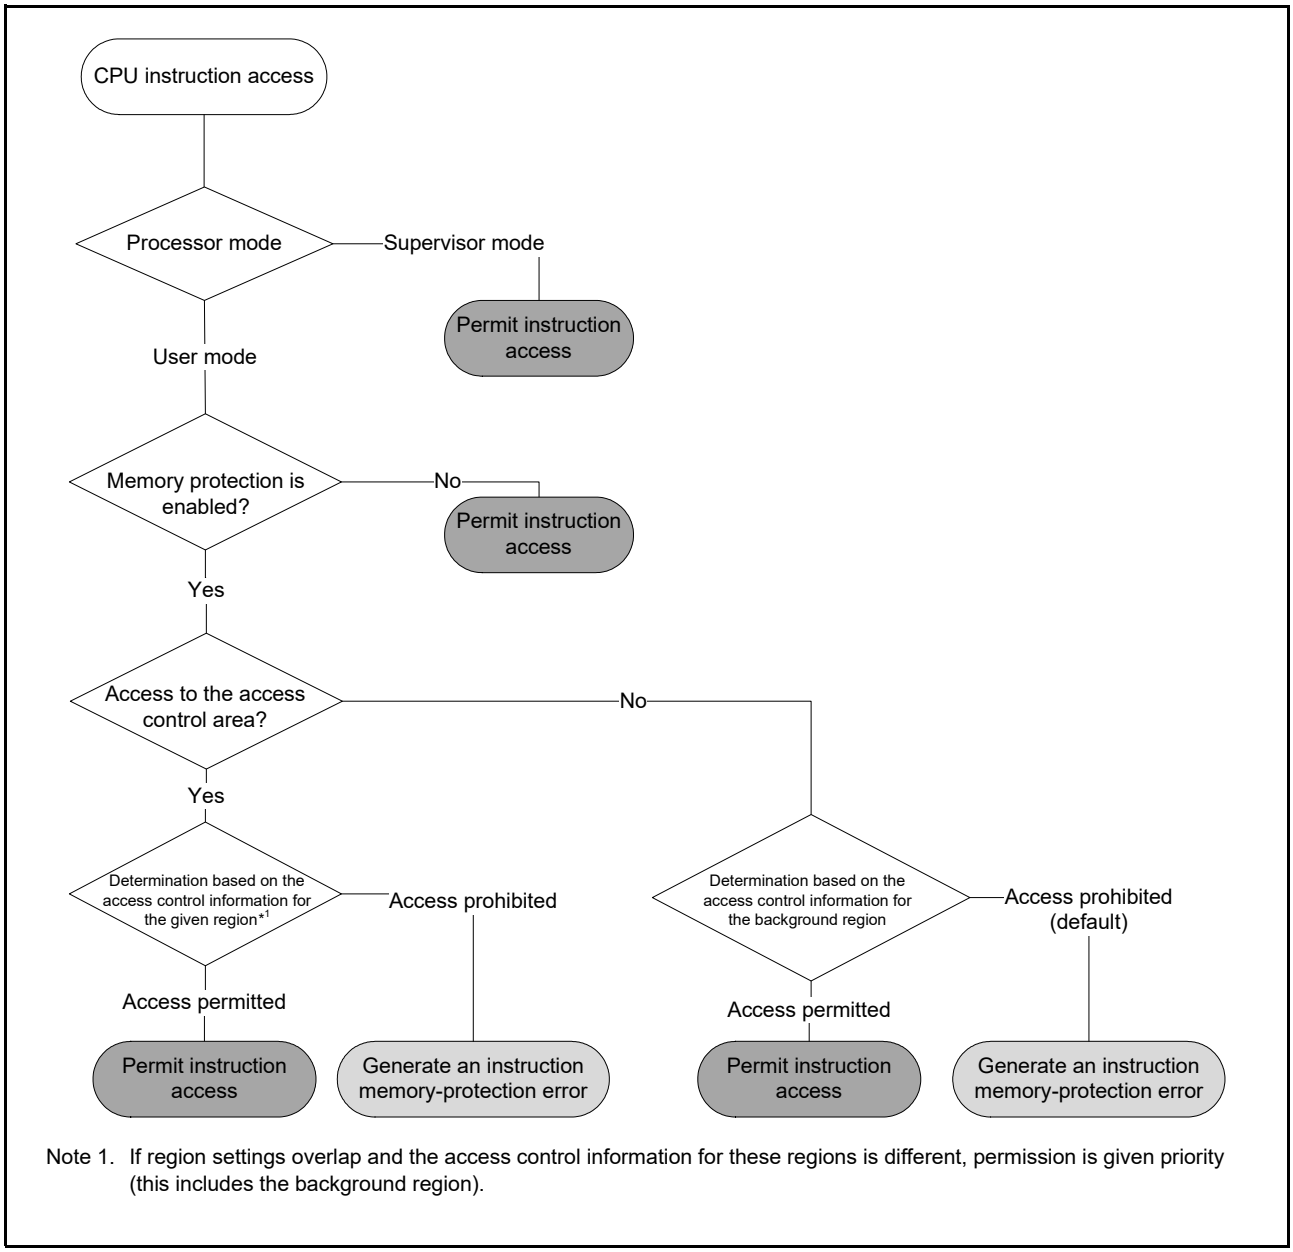
17.2.3.3 Region Search



Region search is a function to search for the region among the eight access control regions in which a certain address was hit and the access control information (execution permitted, reading permitted, and writing permitted) settings for that address.
When the region search operation bit (S) of the region search operation register (MPOPS) is set to 1, the address specified in the region search address register (MPSA) is compared with the addresses for the individual regions. After a region search is executed, the data-hit region register (MHITD) indicates the logical OR of the access control information for the region which was “hit” and for the other regions.
Region search cannot be used to check on the cache attribute.

17.2.3.4 Protection of Registers Related to the Memory-Protection Unit

Registers related to the memory-protection unit are not accessible through means of access other than operand access by the CPU (i.e. by instruction fetching or DMA). These registers are only accessible in supervisor mode. Attempted access to them in user mode through operand access by the CPU leads to a data memory-protection error regardless of whether or not memory protection is in effect at the given location.



17.2.3.5 Flow for Determining Access by the Memory Protection Function

Figure 17.2 shows the flow for determining data access and Figure 17.3 shows the flow for determining instruction access.

Note 1. If region settings overlap and the access control information for these regions is different, permission is given priority (this includes the background region).

Figure 17.2 Flow for Determining Data Access

Note 1. If region settings overlap and the access control information for these regions is different, permission is given priority (this includes the background region).

Figure 17.3 Flow for Determining Instruction Access

17.2.3.6 Flow for Determining the Cache Attributes

Regardless of the type of MPU, it determines the cache attributes through the flow below, as well as handling the access determination.

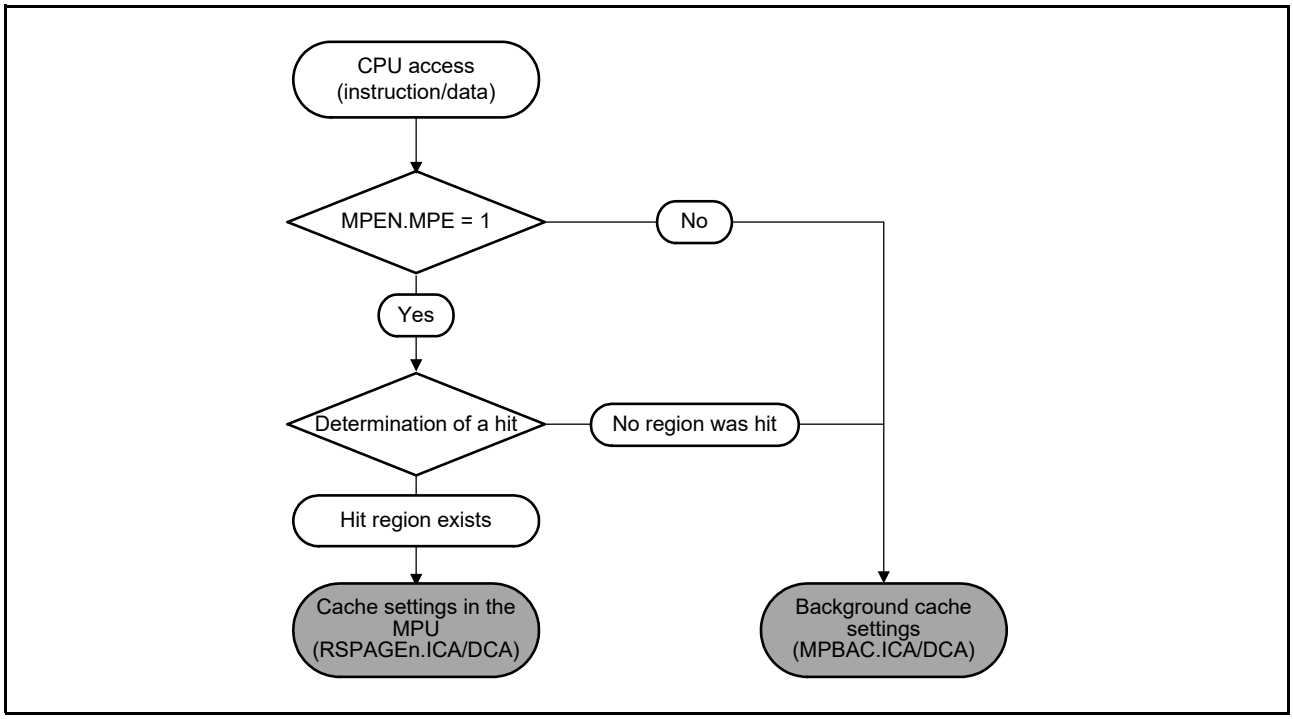


Figure 17.4 Flow for Determining the Cache Attributes

17.2.4 Procedures for Using the Memory Protection Function

17.2.4.1 Setting the Access Control Information and Cache Attributes

The access control information for the individual regions is set in supervisor mode.
Up to eight access control regions are set by using the region-n start page number registers (RSPAGEn) and region-n end page number registers (REPAGEn) (n = 0 to 7).
The background access control region is set by using the background access control register (MPBAC).

17.2.4.2 Enabling the Memory Protection and Cache Attribute Setting Functions

Set the memory-protection enable bit (MPEN) of the memory-protection enable (MPEN) register to 1 in supervisor mode. However, the background cache settings are effective even when MPEN = 0

17.2.4.3 Transition to User Mode

After modifying the settings of the registers related to the memory-protection unit, read any of these registers and check that the settings have been made before the transition to user mode. Either of the methods below can be used for the transition from supervisor mode to user mode.

- Set the processor mode setting bit (PM) of the processor status word (PSW) saved on the stack area to 1 (the setting for user mode) and then execute an RTE instruction.
- Set the PM bit of the backup PSW (BPSW) to 1 and then execute an RTFI instruction.

Note: Writing to the PSW.PM bit by an MVTC or POPC instruction has no effect. Use an RTE or RTFI instruction to change the value of the PSW.PM bit.

The memory-protection unit starts checking the addresses for the CPU's instruction execution and operand access following a transition to user mode.

17.2.4.4 Modifying the Cache Attributes

The cache attributes are effective even in supervisor mode. Therefore, when modifying the cache attributes, that is; when modifying the attributes for a given region, enabling or disabling the MPU and the attributes for a given region, or modifying a background attribute; although the modified settings will in general be reflected from the next access for both data access and instruction access, this also depends on the state of the pipeline, so reflection of the modified settings from execution of the next instruction is not guaranteed.
By executing a branch instruction, reflection of the settings after the modification of cache attributes is guaranteed from the destination of the branch instruction. In addition, proceed with a write-back from the cache and cache invalidation processing as required.

Modify cache attributes either while the cache is disabled or by following the procedure below.

Procedure for modifying cache attributes while the cache is enabled:

In this procedure, we define region X as the area for which the cache attributes change before and after modifying the attributes, and region Y as the area for which they do not change.

1. Place the code for modifying cache attributes in region Y in advance. At this time, make sure that not only the instruction that modifies the cache attributes but also the 32 bytes that follow the instruction are placed within region Y, in consideration of instruction prefetching.
2. Execute the code placed in region Y to modify the cache attributes of region X. Proceed with a write-back from the cache and cache invalidation processing as required.

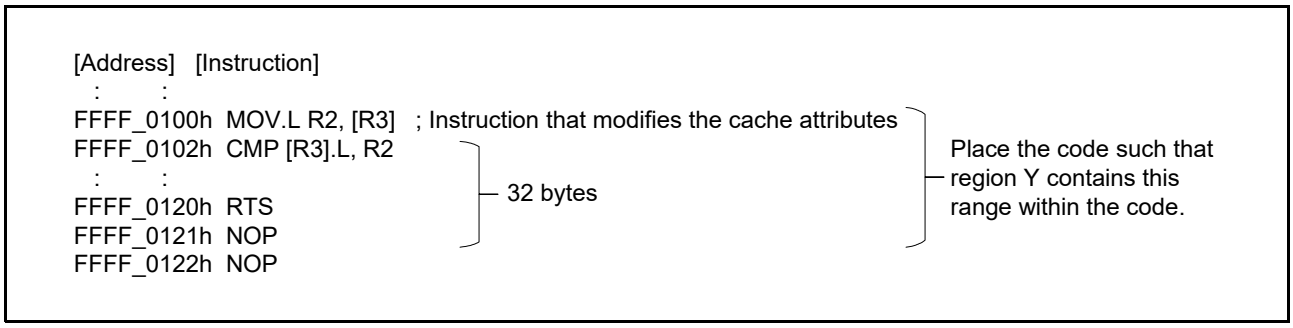

Figure 17.5 Depiction of Placing the Code for Modifying the Cache Attributes in Region Y

17.2.4.5 Processing in Response to a Memory-Protection Error

The CPU starts access exception processing on detection of an access control violation (memory-protection error). For details of the CPU operation for access exception processing, see section 14, Exception Handling.
Check the instruction memory-protection error generation bit (IMPER) and data memory-protection error generation bit (DMPER) in the memory-protection error status register (MPESTS) in the exception processing routine to determine which type of error occurred, instruction memory-protection error or data memory-protection error.
After confirming the type of error, clear the MPESTS register by writing 1 to the error status clear bit (CLR) in the memory-protection error status clear register (MPECLR).

(1) When a data memory-protection error occurs

The address of the instruction that caused a memory-protection error is saved on the stack by the access exception processing by the CPU. Furthermore, the operand access address where a memory-protection error occurred is stored in the data memory-protection error address register (MPDEA), and the region information that caused a memory-protection error is stored in the data-hit region register (MHITD).

- When access to valid regions 0 to 7 violates access control

The data-hit region bits (MHITD.HITD[7:0]) corresponding to the number of the region where the error occurred is set to 1. The logical OR of the access control information for the region where the error occurred is set in the data-hit region access control bits in user mode (MHITD.UHACD[2:0]).

- When access to valid regions 0 to 7 is outside the regions and access control for the background region is violated

The data-hit region bits (MHITD.HITD[7:0]) are set to 0000 0000b. The access control information for the background region is set in the data-hit region access control bits in user mode (MHITD.UHACD[2:0]).

By referring to this information, processing such as identifying the sources of errors can proceed.

(2) When an instruction memory-protection error occurs

The address of the instruction that caused a memory-protection error is saved on the stack by the access exception processing by the CPU. Furthermore, the information for the region where the error occurred is stored in the instruction-hit region register (MHITI).

- When access to valid regions 0 to 7 violates access control

The instruction-hit region bits (MHITI.HITI[7:0]) corresponding to the number of the region where the error occurred is set to 1. The logical OR of the access control information for the region where the error occurred is set in the instruction-hit region access control bits in user mode (MHITI.UHACI[2:0]).

- When access to valid regions 0 to 7 is outside the regions and access control for the background region is violated

The instruction-hit region bits (MHITI.HITI[7:0]) are set to 0000 0000b. The access control information for the background region is set in the instruction-hit region access control bits in user mode (MHITI.UHACI[2:0]).

(3) When an CPU access error occurs

The address of the instruction executed by the CPU that caused an access exception is saved on the stack by the access exception processing by the CPU. The registers of the memory protection function are not changed.

17.3 Bus Master MPU

17.3.1 Overview of Bus Master MPU

The bus master MPU monitors addresses accessed by the bus master over the whole address space (0000 0000h to FFFF FFFFh). The access monitoring information can be set as follows:

- xSPI0: 4 regions
- xSPI1: 4 regions

The bus master MPU monitors access to individual regions based on these settings.
In the case of access to a region protected by the bus master MPU or access that crosses the boundary of a permitted MPU region in a burst access, the bus master MPU returns an error response.
Regarding error access, see section 17.3.2.1, Master Memory-Protection Unit Security Attribute Register B (MMPUSARB) and section 16.8.2, Operations When a Bus Error Occurs in section 16, Buses.

17.3.2 Register Descriptions of Bus Master MPU

17.3.2.1 Master Memory-Protection Unit Security Attribute Register B (MMPUSARB)

Address(es): CPSCU.MMPUSARB 8701 8134h,
CPSCU_NS.MMPUSARB 0701 8134h

Bit	Symbol	Description	R/W
b31 to b0	n/a	Region end address register for xSPI Region end address (for use in region determination) The MPU region end address must be set in the range from 0000 0FFFh to FFFF FFFF FFFFh. Writing to bits 0 to 11 will be ignored. These bits are read as 1.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MMPUSXSPImn (m = 0, 1; n = 0 to 3) register specifies the end address where the region ends.
This register must be read or written in 32-bit units. It is neither readable nor writable in 8-bit or 16-bit units. If it is read or written in 8-bit or 16-bit units, the operation is not guaranteed.

17.3.2.4 MMPU Access Control Register for xSPI (MMPUACXSPImn) (m = 0, 1, n = 0 to 3)

Address(es): BUSMPU.MMPUACXSPI00 8701 1400h, BUSMPU.MMPUACXSPI01 8701 1410h, BUSMPU.MMPUACXSPI02 8701 1420h, BUSMPU.MMPUACXSPI03 8701 1430h, BUSMPU.MMPUACXSPI10 8701 1600h, BUSMPU.MMPUACXSPI11 8701 1610h, BUSMPU.MMPUACXSPI12 8701 1620h, BUSMPU.MMPUACXSPI13 8701 1630h, BUSMPU_NS.MMPUACXSPI00 0701 1400h, BUSMPU_NS.MMPUACXSPI01 0701 1410h, BUSMPU_NS.MMPUACXSPI02 0701 1420h, BUSMPU_NS.MMPUACXSPI03 0701 1430h, BUSMPU_NS.MMPUACXSPI10 0701 1600h, BUSMPU_NS.MMPUACXSPI11 0701 1610h, BUSMPU_NS.MMPUACXSPI12 0701 1620h, BUSMPU_NS.MMPUACXSPI13 0701 1630h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	WP	RP	ENABLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ENABLE	Region Enable	0: XSPI region mn unit disabled 1: XSPI region mn unit enabled	R/W
b1	RP	Read Protect	0: Reading permitted 1: Protected against reading	R/W
b2	WP	Write Protect	0: Writing permitted 1: Protected against writing	R/W
b15 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

ENABLE Bit (Region Enable)

This bit enables or disables the xSPImn (m = 0, 1; n = 0 to 3) region.
When the ENABLE bit is set to 1, the RP and WP bits are enabled for permission or prohibition of access to the region set by the MMPUSXSPImn and MMPUEXSPImn registers.
When the ENABLE bit is set to 0, access to the xSPI0 region is handled as being outside the region.

RP Bit (Read Protect)

This bit enables or disables read protection for the xSPImn (m = 0, 1; n = 0 to 3) region.
This bit can be used when the ENABLE bit is set to 1.

WP Bit (Write Protect)

This bit enables or disables write protection for the xSPImn (m = 0, 1; n = 0 to 3) region.
This bit can be used when the ENABLE bit is set to 1.

17.3.2.5 MMPU Enable Register for xSPI (MMPUENXSPIm) (m = 0, 1)

Address(es): BUSMPU.MMPUENXSPI0 8701 1300h, BUSMPU.MMPUENXSPI1 8701 1500h,
BUSMPU_NS.MMPUENXSPI0 0701 1300h, BUSMPU_NS.MMPUENXSPI1 0701 1500h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	ENABLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ENABLE	xSPI Bus Master MPU Enable	0: xSPI bus master MPU disabled 1: xSPI bus master MPU enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits permit or prohibit writing to the ENABLE bit.	W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: This register must be written in 16-bit units. Reading or writing to the register in 8-bit units is prohibited. If it is read or written in 8-bit units, the operation is not guaranteed.

ENABLE Bit (xSPI Bus Master MPU Enable)

This bit enables or disables the bus master MPU function of each master group.

When the ENABLE bit is set to 1, the MMPUACXSPImn (m = 0, 1; n = 0 to 3) register can be used.

When the ENABLE bit is set to 0, the MMPUACXSPImn (m = 0, 1; n = 0 to 3) register cannot be used for all regions.

The bus master MPU function of each master group sets the ENABLE bit.

When setting the ENABLE bit, write A5h to the KEY[7:0] bits at the same time.

KEY[7:0] Bits (Key Code)

These bits permit or prohibit writing to the ENABLE bit.

When writing to the ENABLE bit, write A5h to the KEY[7:0] bits at the same time.

If a value other than A5h is written to the KEY[7:0] bits, the ENABLE bit is not updated. The KEY[7:0] bits are always read as 00h.

17.3.2.6 MMPU Enable Protect Register for xSPI (MMPUENPTXSPIm) (m = 0, 1)

Address(es): BUSMPU.MMPUENPTXSPI0 8701 1304h, BUSMPU.MMPUENPTXSPI1 8701 1504h, BUSMPU_NS.MMPUENPTXSPI0 0701 1304h, BUSMPU_NS.MMPUENPTXSPI1 0701 1504h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	PROTECT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PROTECT	Write Protect	0: The MMPUENXSPI register is writable. 1: The MMPUENXSPI register is write-protected. The register is readable.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits permit or prohibit writing to the PROTECT bit.	W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: This register must be written in 16-bit units. Reading or writing to the register in 8-bit units is prohibited. If it is read or written in 8-bit units, the operation is not guaranteed.

PROTECT Bit (Write Protect)

This bit controls protection of the MMPUENXSPIm (m = 0, 1) register.

When setting the PROTECT bit, write A5h to the KEY[7:0] bits at the same time.

KEY[7:0] Bits (Key Code)

These bits permit or prohibit writing to the PROTECT bit.

When writing to the PROTECT bit, write A5h to the KEY[7:0] bits at the same time.

If a value other than A5h is written to the KEY[7:0] bits, the PROTECT bit is not updated. The KEY[7:0] bits are always read as 00h.

17.3.2.7 MMPU Region Protect Register for xSPI (MMPURPTXSPIm) (m = 0, 1)

Address(es): BUSMPU.MMPURPTXSPI0 8701 1308h, BUSMPU.MMPURPTXSPI1 8701 1508h, BUSMPU_NS.MMPURPTXSPI0 0701 1308h, BUSMPU_NS.MMPURPTXSPI1 0701 1508h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	PROTECT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PROTECT	Write Protect	0: The bus master MPU register for xSPI is writable. 1: The bus master MPU register for xSPI is write-protected. The register is readable.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits permit or prohibit writing to the PROTECT bit.	W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: This register must be written in 16-bit units. Reading or writing to the register in 8-bit units is prohibited. If it is read or written in 8-bit units, the operation is not guaranteed.

PROTECT Bit (Write Protect)

This bit permits or prohibits writing to the registers associated with protection.
The MMPURPTXSPIm.PROTECT (m = 0, 1) bit controls the following registers.

- MMPUSXSPImn (m = 0, 1; n = 0 to 3)
- MMPUEXSPImn (m = 0, 1; n = 0 to 3)
- MMPUACXSPImn (m = 0, 1; n = 0 to 3)

When writing to the PROTECT bit, write A5h to the KEY[7:0] bits at the same time in an overall 16-bit unit.

KEY[7:0] Bits (Key Code)

These bits permit or prohibit writing to the PROTECT bit.
When writing to the PROTECT bit, write A5h to the KEY[7:0] bits at the same time.
If a value other than A5h is written to the KEY[7:0] bits, the PROTECT bit is not updated. The KEY[7:0] bits are always read as 00h.

17.3.2.8 MMPU Post-Detection Operation Register (MMPUOAD)

Address(es): BUSMPU.MMPUOAD 8701 0000h,
BUSMPU_NS.MMPUOAD 0701 0000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OAD	Post-Detection Operation Select	0: Interrupt request 1: Reset request	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits permit or prohibit writing to the OAD bit.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: This register must be written in 16-bit units. Reading or writing to the register in 8-bit units is prohibited. If it is read or written in 8-bit units, the operation is not guaranteed.

OAD Bit (Post-Detection Operation Select)

This bit specifies operation when an access violation is detected.

When the OAD bit is 0, an error response is returned, and an interrupt request is generated when BUSINTEN<Master Name>.EN = 1. For details, see section 16.3.35, Bus Error Interrupt Enable Register (BUSINTENCPU0IF, BUSINTENCPU0OA, BUSINTENDMAC0, BUSINTENEXDMAC, BUSINTENEDMAC, BUSINTENXSPI0, BUSINTENXSPI1).

An interrupt caused by a bus error can be used as an NMI. For details, refer to the specification of the ICU.NMIER register.

When the OAD bit is 1, a reset request is generated.

When writing to the OAD bit, write A5h to the KEY[7:0] bits at the same time in an overall 16-bit unit.

KEY[7:0] Bit (Key Code)

These bits permit or prohibit writing to the OAD bit. When writing to the OAD bit, write A5h to the KEY[7:0] bits at the same time. If any other value is written, the OAD bit is not updated.

The KEY[7:0] bits are always read as 00h.

17.3.2.9 MMPU Post-Detection Operation Protect Register (MMPUOADPT)

Address(es): BUSMPU.MMPUOADPT 8701 0004h,
BUSMPU_NS.MMPUOADPT 0701 0004h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	PROTECT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PROTECT	Write Protect	0: The MMPUOAD register is writable. 1: The MMPUOAD register is write-protected. The register is readable.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits permit or prohibit writing to the PROTECT bit.	W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: This register must be written in 16-bit units. Reading or writing to the register in 8-bit units is prohibited. If it is read or written in 8-bit units, the operation is not guaranteed.

PROTECT Bit (Write Protect)

This bit permits or prohibits writing to the registers associated with protection.
The MMPUOADPT.PROTECT bit controls the following register.

- MMPUOAD

When writing to the PROTECT bit, write A5h to the KEY[7:0] bits at the same time in an overall 16-bit unit.

KEY[7:0] Bits (Key Code)

These bits permit or prohibit writing to the PROTECT bit. When writing to the PROTECT bit, write A5h to the KEY[7:0] bits at the same time. If any other value is written, the PROTECT bit is not updated. The KEY[7:0] bits are always read as 00h.

17.3.3 Functions of Bus Master MPU

17.3.3.1 Bus Master Memory Protection

The bus master MPU monitors memory access by using the control setting made individually to the access control region. Access to a region protected by the bus master MPU causes the MPU to generate a memory-protection error. “Bus master MPU” refers to either MPU in the master group of xSPI0 and xSPI1. The memory protection function checks the bus addresses of the bus master group and blocks illegal access through the bus master group to a region protected by a bus master MPU. The region setting registers for the xSPI bus master MPU can be configured for secure masters and non-secure masters by using the PSCU.PSARB register. The MPU region settings while the setting of the PSCU.PSARB.PSARBn bit (n = 16, 17) is 0 only apply to access by secure masters. The MPU region settings while the setting of the given bit is 1 only apply to access by non-secure masters.

The bus master MPU permits access and execution for all regions after a reset. If MMPUENXXXX.ENABLE is 1 and there is no MPU region setting for the corresponding bus master, all regions are protected. (XXXX = Master Group name)

Figure 17.6 shows access permission or protection in the case of overlapping bus master MPU regions. Access control for the overlapping regions is as follows.

- The region is handled as a protected region when output of one or more region units is a protected region.
- The region is handled as a protected region when output of all region units is outside the regions.
- Other cases are handled as permitted regions.

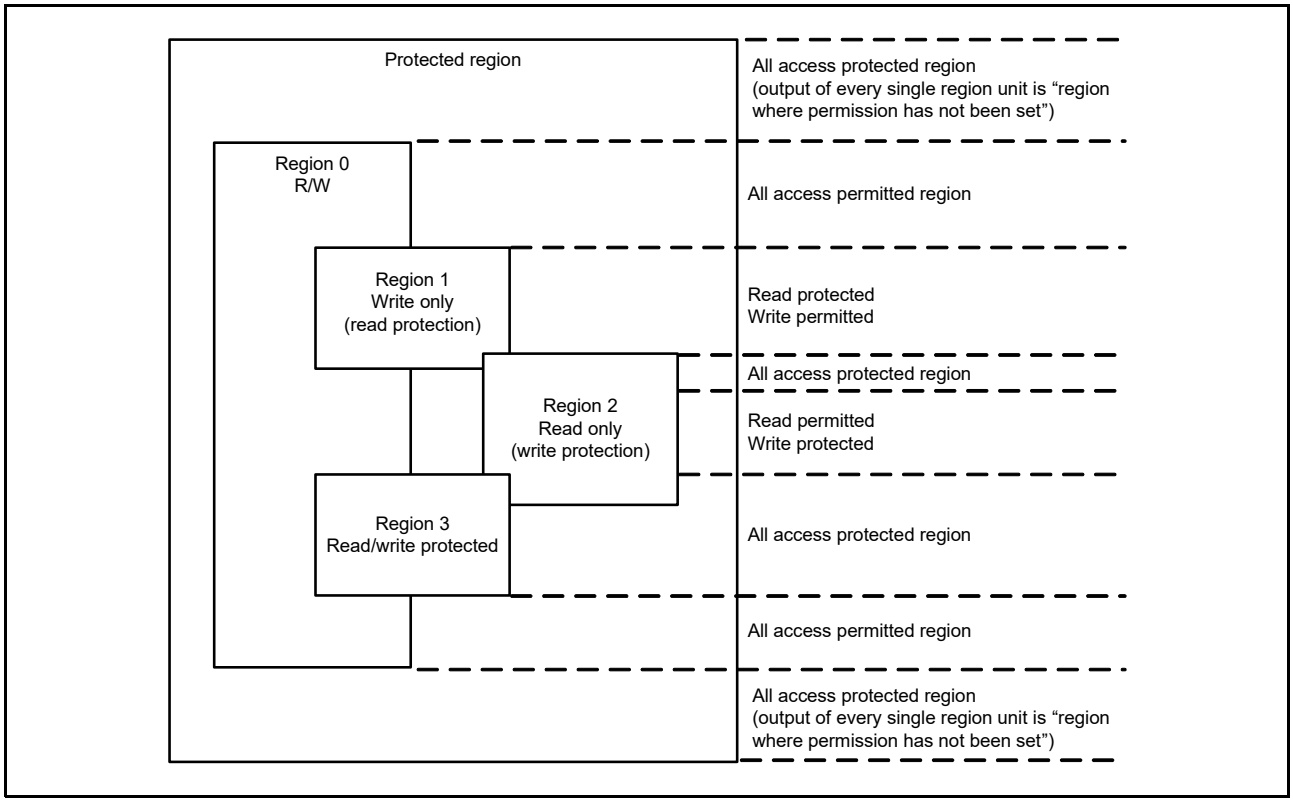

Figure 17.6 Access Permission or Protection in the Case of Overlapping Bus Master MPU Regions

Figure 17.7 shows the flow for setting the registers after a reset. While making these register settings, stop each bus master except for the CPU.

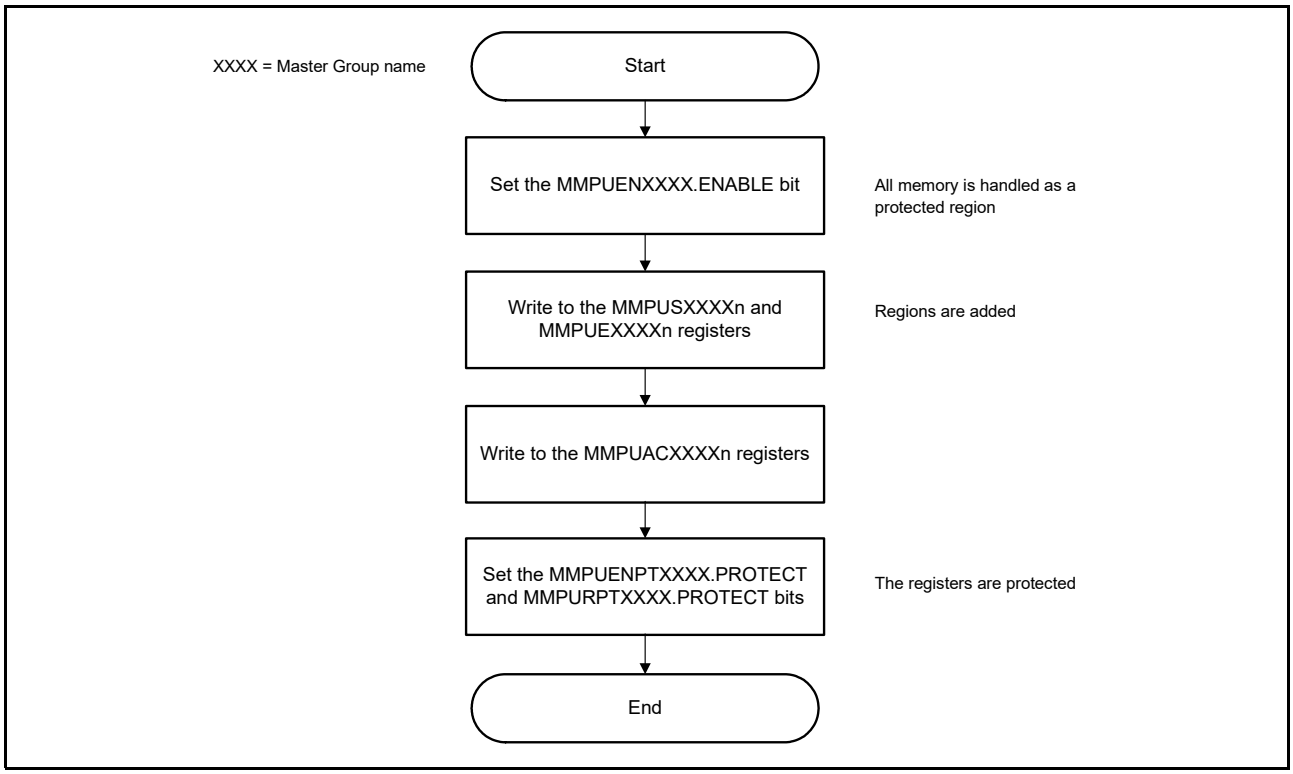

Figure 17.7 Flow for Setting Registers after Reset

Figure 17.8 shows the flow for setting the registers to add regions. While making these register settings, stop each bus master except for the CPU.

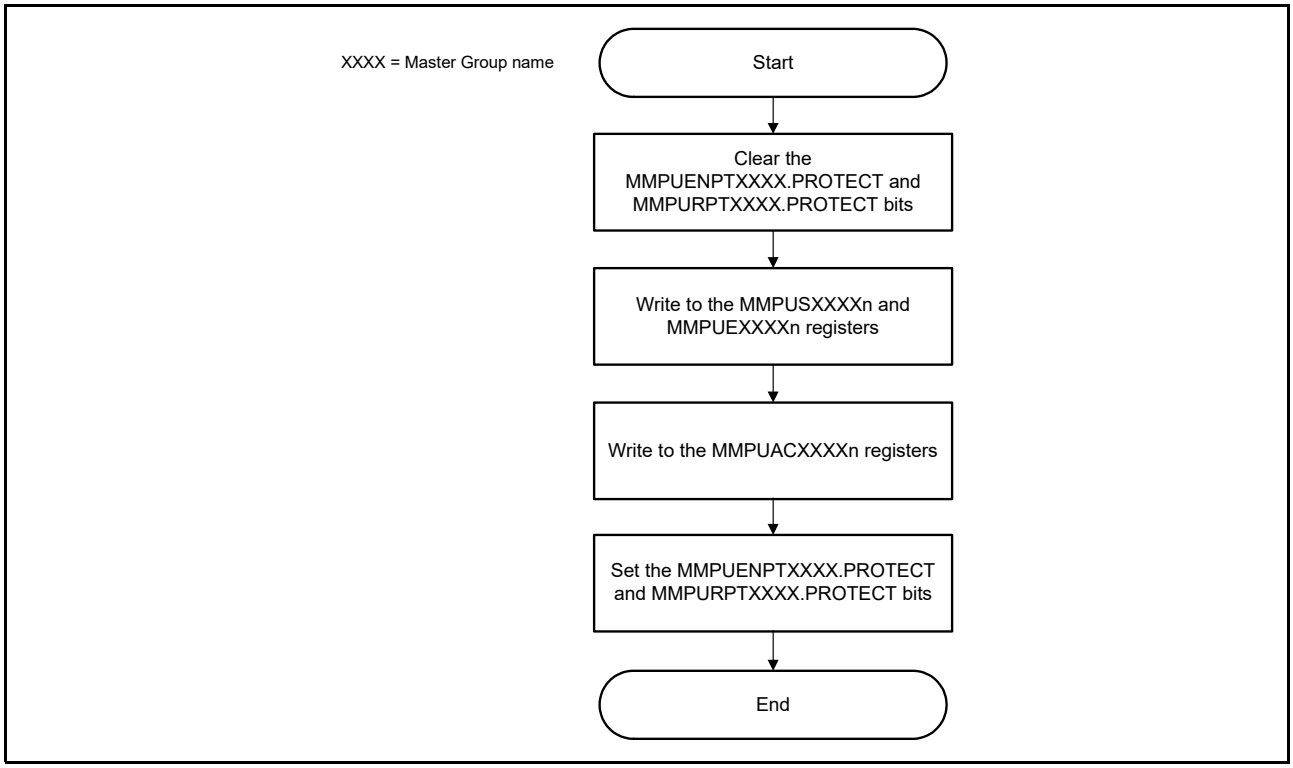

Figure 17.8 Flow for Setting Registers for Region Addition

17.3.3.2 Register Protection

The registers related to the bus master MPU can be protected by using the PROTECT bits as listed in Table 17.3.

Table 17.3 PROTECT Bits and Target Registers for Protection

PROTECT Bit	Target Registers for Protection
MMPUENPTXSPIm.PROTECT	MMPUENXSPI m (m = 0, 1)
MMPURPTXSPIm.PROTECT	MMPUSXSPImn (m = 0, 1; n = 0 to 3) MMPUEXSPImn (m = 0, 1; n = 0 to 3) MMPUACXSPImn (m = 0, 1; n = 0 to 3)
MMPUOADPT.PROTECT	MMPUOAD

17.3.3.3 Memory-Protection Error

The bus master MPU generates an error on detection of access to the protected region.
Set the MMPUOAD.OAD bit to select whether the error is reported as an interrupt or reset.
For details of the bus master MPU error, see section 16.8.2, Operations When a Bus Error Occurs.
The state of the interrupt is indicated in ICU.IR16.IR. For details, see section 15, Interrupt Controller (ICUM).
The state of the reset is indicated in SYSC.RSTSR1.BUSRF. For details, see section 6, Resets.
An interrupt caused by a bus error can be used as an NMI. For details, refer to the specification of the ICU.NMIER register.

18. DMA Controller (DMACAa)

This MCU incorporates an 8-channel direct memory access controller (DMAC). The DMAC is a module to transfer data without the CPU. When a transfer request is generated, the DMAC transfers data stored at the transfer source address to the transfer destination address.

18.1 Overview

Table 18.1 lists the specifications of the DMAC, and Figure 18.1 shows a block diagram of the DMAC.

Table 18.1 Specifications of DMAC (1/2)

Item		Description DMAC
Number of channels		8 (DMACm (m = 0 to 7))
Transfer space		4 Gbytes (0000 0000h to FFFF FFFFh excluding reserved areas)
Maximum transfer volume		64M data (Maximum number of transfers in block transfer mode: 1024 data × 65536 blocks)
DMA trigger source		• Trigger source selectable for each channel Software trigger Interrupt requests from peripheral modules or trigger input to external interrupt input pins*1
Channel priority		Selectable from fixed priority or round-robin • Fixed priority: Channel 0 > channel 1 > channel 2 > channel 3... > channel 7 > DTC (channel 0: Highest) • Round-robin
Transfer data	Single data	Bit length: 8, 16, 32, 64 bits
	Block size	Number of data: 1 to 1024
Transfer mode	Normal transfer mode	• One data transfer by one DMA transfer request • Free running function (setting in which total number of data transfers is not specified) settable
	Repeat transfer mode	• One data transfer by one DMA transfer request • Program returns to the transfer start address on completion of the repeat size of data transfer specified for the transfer source or destination. • Maximum settable repeat size: 1024 • Free running function settable
	Block transfer mode	• One block data transfer by one DMA transfer request • Maximum settable block size: 1024 data • Free running function settable
	Repeat-block transfer mode	• One block data transfer by one DMA transfer request • Maximum settable block size: 1024 data • Block transfer can be repeated • Maximum settable repeat size: 64K • Free running function settable
Selective functions	Extended repeat area function	• Function in which data can be transferred by repeating the address values in the specified range with the upper bit values in the transfer address register fixed • Area of 2 bytes to 128 Mbytes separately settable as extended repeat area for transfer source and destination
Processing on DMA transfer error		• When DMA transfer error occurs, the transfer that caused the error is stopped • For clearing requests to the registers for trigger source in the ICU, clearing targets are selectable for each channel or all channels.
CPU interrupt source (DMACnI (n = 0 to 3, 74))	Transfer end interrupt	Generated on completion of transferring data volume specified by the transfer counter.
	Transfer escape end interrupt	• Generated when the repeat size of data transfer is completed. • Generated when the source address extended repeat area overflows. • Generated when the destination address extended repeat area overflows.
Event link function		An event link request is generated after each data transfer (for block transfer, after each block is transferred).
Power consumption reduction function		Module-stop state can be set.

Table 18.1 Specifications of DMAC (2/2)

Item	Description
	DMAC
Protect Zone Filter	Security can be set for each channel.

Note 1. For details on DMAC trigger sources, see Table 15.6, Interrupt Vector Table, Table 15.3, Interrupt Sources for Software Configurable Interrupt in section 15, Interrupt Controller (ICUM).

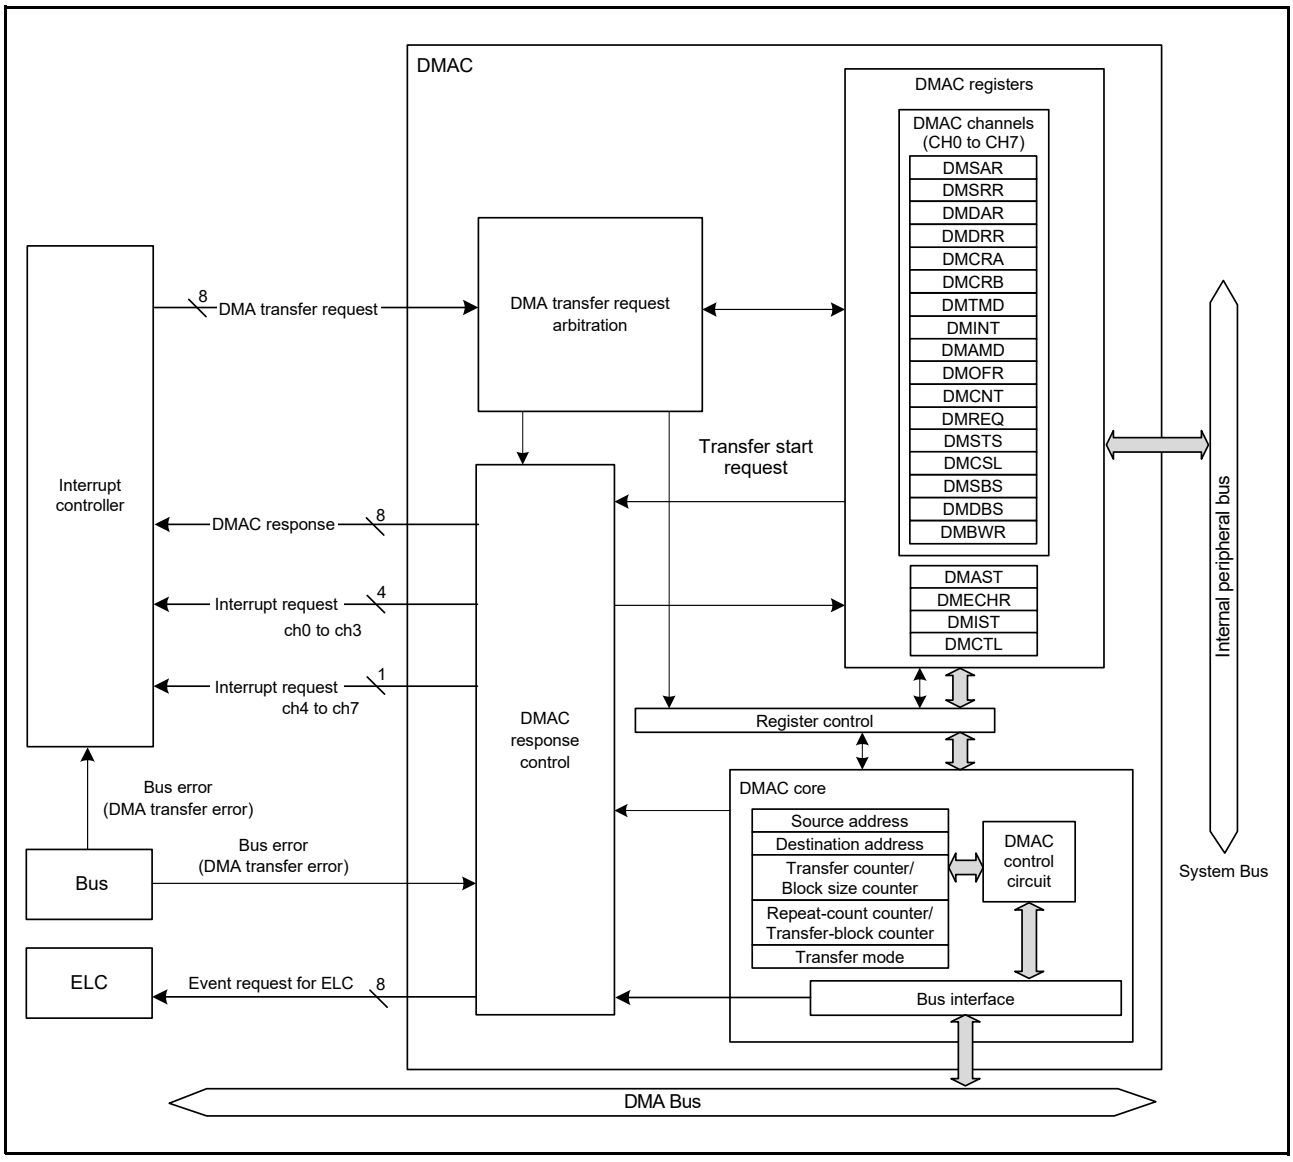

Figure 18.1 Block Diagram of DMAC

18.2 Register Descriptions

Security attribution can be set for each register and is used to determine whether the target register is a secure register or a non-secure register. The attribution can be set by the DMACCHSAR register.

18.2.1 DMAC Channel Security Attribution Register (DMACCHSAR)

Address(es): CPSCU.DMACCHSAR 8701 81A0h, CPSCU_NS.DMACCHSAR 0701 81A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	SADMAC7	SADMAC6	SADMAC5	SADMAC4	SADMAC3	SADMAC2	SADMAC1	SADMAC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SADMAC0	Security Attributes of Output and Registers for DMAC Channel 0 Select	0: Secure 1: Non-secure	R/W
b1	SADMAC1	Security Attributes of Output and Registers for DMAC Channel 1 Select	0: Secure 1: Non-secure	R/W
b2	SADMAC2	Security Attributes of Output and Registers for DMAC Channel 2 Select	0: Secure 1: Non-secure	R/W
b3	SADMAC3	Security Attributes of Output and Registers for DMAC Channel 3 Select	0: Secure 1: Non-secure	R/W
b4	SADMAC4	Security Attributes of Output and Registers for DMAC Channel 4 Select	0: Secure 1: Non-secure	R/W
b5	SADMAC5	Security Attributes of Output and Registers for DMAC Channel 5 Select	0: Secure 1: Non-secure	R/W
b6	SADMAC6	Security Attributes of Output and Registers for DMAC Channel 6 Select	0: Secure 1: Non-secure	R/W
b7	SADMAC7	Security Attributes of Output and Registers for DMAC Channel 7 Select	0: Secure 1: Non-secure	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

SADMACn Bits (Security Attributes of Output and Registers for DMAC Channel n Select) (n = 0 to 7)

Each bit specifies the security attribute of the register for a DMAC Channel n. For details, see section 18.3.13, Channel Security. Set the same security attribute to the four bits, SADMAC4 to SADMAC7. The target registers are ICU.DMRSRm, DMIST, DMSAR, DMSRR, DMDAR, DMDRR, DMCRA, DMCRB, DMTMD, DMINT, DMAMD, DMOFR, DMCNT, DMREQ, DMSTS, DMCSL, DMSBS, DMDBS, DMBWR, and DMIST.

18.2.2 DMA Controller Security Attribution Register (DMACSAR)

Address(es): CPSCU.DMACSAR 8701 8034h, CPSCU_NS.DMACSAR 0701 8034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMASTSA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DMASTSA0	DMAST Security Attribution Setting 0	0: Secure 1: Non-secure	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

For DMAC, security attribution is set for each channel. However, security attribution of the DMAST and DMCTL registers is set by this register.

DMASTSA0 Bit (DMAST Security Attribution Setting 0)

The DMASTSA0 bit specifies security attribution of the DMAST and DMCTL registers.

18.2.3 DMA Source Address Register (DMSAR)

Address(es): DMAC0.DMSAR 8700 7000h, DMAC1.DMSAR 8700 7040h, DMAC2.DMSAR 8700 7080h, DMAC3.DMSAR 8700 70C0h, DMAC4.DMSAR 8700 7100h, DMAC5.DMSAR 8700 7140h, DMAC6.DMSAR 8700 7180h, DMAC7.DMSAR 8700 71C0h, DMAC0_NS.DMSAR 0700 7000h, DMAC1_NS.DMSAR 0700 7040h, DMAC2_NS.DMSAR 0700 7080h, DMAC3_NS.DMSAR 0700 70C0h, DMAC4_NS.DMSAR 0700 7100h, DMAC5_NS.DMSAR 0700 7140h, DMAC6_NS.DMSAR 0700 7180h, DMAC7_NS.DMSAR 0700 71C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Description	Setting Range	R/W
b31 to b0	Specifies the transfer source start address	0000 0000h to FFFF FFFFh (4 Gbytes)	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

18.2.4 DMA Source Reload Address Register (DMSRR)

Address(es): DMAC0.DMSRR 8700 7020h, DMAC1.DMSRR 8700 7060h, DMAC2.DMSRR 8700 70A0h, DMAC3.DMSRR 8700 70E0h, DMAC4.DMSRR 8700 7120h, DMAC5.DMSRR 8700 7160h, DMAC6.DMSRR 8700 71A0h, DMAC7.DMSRR 8700 71E0h, DMAC0_NS.DMSRR 0700 7020h, DMAC1_NS.DMSRR 0700 7060h, DMAC2_NS.DMSRR 0700 70A0h, DMAC3_NS.DMSRR 0700 70E0h, DMAC4_NS.DMSRR 0700 7120h, DMAC5_NS.DMSRR 0700 7160h, DMAC6_NS.DMSRR 0700 71A0h, DMAC7_NS.DMSRR 0700 71E0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Description	Setting Range	R/W
b31 to b0	Specifies the transfer source reload address	0000 0000h to FFFF FFFFh (4 Gbytes)	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

DMSRR register is used to specify the DMA transfer source start and reload addresses in repeat-block transfer mode. Set the same value to DMSRR register as that of DMSAR register. For details on the repeat-block transfer mode operation, see section (4), Repeat-Block Transfer Mode. In normal transfer mode, repeat transfer mode and block transfer mode, DMSRR register is not used. The setting is invalid.
Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

18.2.5 DMA Destination Address Register (DMDAR)

Address(es): DMAC0.DMDAR 8700 7004h, DMAC1.DMDAR 8700 7044h, DMAC2.DMDAR 8700 7084h, DMAC3.DMDAR 8700 70C4h, DMAC4.DMDAR 8700 7104h, DMAC5.DMDAR 8700 7144h, DMAC6.DMDAR 8700 7184h, DMAC7.DMDAR 8700 71C4h, DMAC0_NS.DMDAR 0700 7004h, DMAC1_NS.DMDAR 0700 7044h, DMAC2_NS.DMDAR 0700 7084h, DMAC3_NS.DMDAR 0700 70C4h, DMAC4_NS.DMDAR 0700 7104h, DMAC5_NS.DMDAR 0700 7144h, DMAC6_NS.DMDAR 0700 7184h, DMAC7_NS.DMDAR 0700 71C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Description	Setting Range	R/W
b31 to b0	Specifies the transfer destination start address	0000 0000h to FFFF FFFFh (4 Gbytes)	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

18.2.6 DMA Destination Reload Address Register (DMDRR)

Address(es): DMAC0.DMDRR 8700 7024h, DMAC1.DMDRR 8700 7064h, DMAC2.DMDRR 8700 70A4h, DMAC3.DMDRR 8700 70E4h, DMAC4.DMDRR 8700 7124h, DMAC5.DMDRR 8700 7164h, DMAC6.DMDRR 8700 71A4h, DMAC7.DMDRR 8700 71E4h, DMAC0_NS.DMDRR 0700 7024h, DMAC1_NS.DMDRR 0700 7064h, DMAC2_NS.DMDRR 0700 70A4h, DMAC3_NS.DMDRR 0700 70E4h, DMAC4_NS.DMDRR 0700 7124h, DMAC5_NS.DMDRR 0700 7164h, DMAC6_NS.DMDRR 0700 71A4h, DMAC7_NS.DMDRR 0700 71E4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Description	Setting Range	R/W
b31 to b0	Specifies the transfer destination reload address	0000 0000h to FFFF FFFFh (4 Gbytes)	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

DMDRR register is used to specify the DMA transfer destination start and reload addresses in repeat-block transfer mode. Set the same value to DMDRR register as that of DMDAR register. For details on the repeat-block transfer mode operation, see section (4), Repeat-Block Transfer Mode. In normal transfer mode, repeat transfer mode and block transfer mode, DMDRR register is not used. The setting is invalid.
Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

18.2.7 DMA Transfer Count Register (DMCRA)

Address(es): DMAC0.DMCRA 8700 7008h, DMAC1.DMCRA 8700 7048h, DMAC2.DMCRA 8700 7088h, DMAC3.DMCRA 8700 70C8h, DMAC4.DMCRA 8700 7108h, DMAC5.DMCRA 8700 7148h, DMAC6.DMCRA 8700 7188h, DMAC7.DMCRA 8700 71C8h, DMAC0_NS.DMCRA 0700 7008h, DMAC1_NS.DMCRA 0700 7048h, DMAC2_NS.DMCRA 0700 7088h, DMAC3_NS.DMCRA 0700 70C8h, DMAC4_NS.DMCRA 0700 7108h, DMAC5_NS.DMCRA 0700 7148h, DMAC6_NS.DMCRA 0700 7188h, DMAC7_NS.DMCRA 0700 71C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	DMCRAH[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DMCRAL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DMCRAL[15:0]	Lower Bits of Transfer Count	Specifies the number of transfer operations	R/W
b25 to b16	DMCRAH[9:0]	Upper Bits of Transfer Count		R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: Set the same value for DMCRAH[9:0] and DMCRAL[15:0] bits in repeat transfer mode, block transfer mode, and repeat-block transfer mode. Bits 15 to 10 are fixed to 0 in repeat transfer mode and block transfer mode.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

(1) Normal Transfer Mode (DMTMD.MD[1:0] Bits = 00b)

The DMCRAL[15:0] bits function as a 16-bit transfer counter. The number of transfer operations is one when the setting is 0001h, and 65535 when it is FFFFh. The value is decremented by one each time data is transferred. When the setting is 0000h, no specific number of transfer operations is set; data transfer is performed with the transfer counter stopped (free-running function). Free running function is not selected by DMTMD.TKP bit in normal transfer mode. The DMCRAH[9:0] bits are not used in normal transfer mode. Write 000h to the DMCRAH[9:0] bits.

(2) Repeat Transfer Mode (DMTMD.MD[1:0] Bits = 01b)

The DMCRAH[9:0] bits specify the repeat size and the DMCRAL[15:0] bits function as a 10-bit transfer counter. The number of transfer operations is one when the setting is 001h, 1023 when it is 3FFh, and 1024 when it is 000h. In repeat transfer mode, a value in the range of 000h to 3FFh can be set for the DMCRAH[9:0] and DMCRAL[15:0] bits. Setting bits 15 to 10 in the DMCRAL[15:0] bits is invalid. Write 0 to these bits. The value in the DMCRAL[15:0] bits is decremented by one each time data is transferred until it reaches 000h, at which the value in the DMCRAH[9:0] bits is loaded into the DMCRAL[15:0] bits.

(3) Block Transfer Mode (DMTMD.MD[1:0] Bits = 10b)

The DMCRAH[9:0] bits specify the block size and the DMCRAL[15:0] bits function as a 10-bit block size counter. The block size is one when the setting is 001h, 1023 when it is 3FFh, and 1024 when it is 000h. In block transfer mode, a value in the range of 000h to 3FFh can be set for the DMCRAH[9:0] and DMCRAL[15:0] bits. Setting bits 15 to 10 in the DMCRAL[15:0] bits is invalid. Write 0 to these bits. The value in the DMCRAL[15:0] bits is decremented by one each time data is transferred until it reaches 000h, at which the value in the DMCRAH[9:0] bits is loaded into the

DMCRAL[15:0] bits.

(4) Repeat-Block Transfer Mode (DMTMD.MD[1:0] Bits = 11b)

The DMCRAH[9:0] bits specify the block size and the DMCRAL[15:0] bits function as a 10-bit block size counter. The block size is one when the setting is 001h, 1023 when it is 3FFh, and 1024 when it is 000h. In repeat-block transfer mode, a value in the range of 000h to 3FFh can be set for the DMCRAH[9:0] and DMCRAL[15:0] bits. Setting bits 15 to 10 in the DMCRAL[15:0] bits is invalid. Write 0 to these bits. The value in the DMCRAL[15:0] bits is decremented by one each time data is transferred until it reaches 000h, at which the value in the DMCRAH[9:0] bits is loaded into the DMCRAL[15:0] bits.

18.2.8 DMA Block Transfer Count Register (DMCRB)

Address(es): DMAC0.DMCRB 8700 700Ch, DMAC1.DMCRB 8700 704Ch, DMAC2.DMCRB 8700 708Ch, DMAC3.DMCRB 8700 70CCh, DMAC4.DMCRB 8700 710Ch, DMAC5.DMCRB 8700 714Ch, DMAC6.DMCRB 8700 718Ch, DMAC7.DMCRB 8700 71CCh, DMAC0_NS.DMCRB 0700 700Ch, DMAC1_NS.DMCRB 0700 704Ch, DMAC2_NS.DMCRB 0700 708Ch, DMAC3_NS.DMCRB 0700 70CCh, DMAC4_NS.DMCRB 0700 710Ch, DMAC5_NS.DMCRB 0700 714Ch, DMAC6_NS.DMCRB 0700 718Ch, DMAC7_NS.DMCRB 0700 71CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DMCRBH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DMCRBL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DMCRBL[15:0]	Lower Bits of Block Transfer Count	Counts the number of block, repeat or repeat-block transfer operations	R/W
b31 to b16	DMCRBH[15:0]	Upper Bits of Block Transfer Count		R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Set the same value for DMCRBH[15:0] and DMCRBL[15:0] bits in repeat transfer mode, block transfer mode, and repeat-block transfer mode. DMCRBH[15:0] and DMCRBL[15:0] bits specifies and counts, respectively, the number of transfer operations in block, repeat, and repeat-block transfer mode. The number of transfer operations is one when the setting is 0001h, 65535 when it is FFFFh, and 65536 when it is 0000h. In repeat transfer mode, the value is decremented by one when the final data of one repeat size is transferred. In block transfer mode and repeat-block transfer mode, the value is decremented by one when the final block data is transferred. In normal transfer mode, do not use the DMCRB register because the setting is invalid. When DMTMD.TKP bit is 1 and the final data of one repeat size or one block size is transferred, DMCRBL[15:0] bits reloads the value of DMCRBH[15:0] bits automatically.
Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

18.2.9 DMA Transfer Mode Register (DMTMD)

Address(es): DMAC0.DMTMD 8700 7010h, DMAC1.DMTMD 8700 7050h, DMAC2.DMTMD 8700 7090h, DMAC3.DMTMD 8700 70D0h, DMAC4.DMTMD 8700 7110h, DMAC5.DMTMD 8700 7150h, DMAC6.DMTMD 8700 7190h, DMAC7.DMTMD 8700 71D0h, DMAC0_NS.DMTMD 0700 7010h, DMAC1_NS.DMTMD 0700 7050h, DMAC2_NS.DMTMD 0700 7090h, DMAC3_NS.DMTMD 0700 70D0h, DMAC4_NS.DMTMD 0700 7110h, DMAC5_NS.DMTMD 0700 7150h, DMAC6_NS.DMTMD 0700 7190h, DMAC7_NS.DMTMD 0700 71D0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MD[1:0]		DTS[1:0]		—	TKP	SZ[1:0]		—	—	—	—	—	—	DCTG[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	DCTG[1:0]	Transfer Request Source Select	b1 b0 0 0: Software 0 1: Interrupts*1 from peripheral modules or external interrupt input pins 1 0: Setting prohibited 1 1: Setting prohibited	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	SZ[1:0]	Data Transfer Size	b9 b8 0 0: 8 bits 0 1: 16 bits 1 0: 32 bits 1 1: 64 bits	R/W
b10	TKP	Transfer Keeping	0: Transfer is stopped by completion of specified total number of transfer operations. 1: Transfer is not stopped by completion of specified total number of transfer operations (free-running).	R/W
b11	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b13, b12	DTS[1:0]	Repeat Area Select	b13 b12 0 0: The destination is specified as the repeat area or block area. 0 1: The source is specified as the repeat area or block area. 1 0: The repeat area or block area is not specified. 1 1: Setting prohibited	R/W
b15, b14	MD[1:0]	Transfer Mode Select	b15 b14 0 0: Normal transfer 0 1: Repeat transfer 1 0: Block transfer 1 1: Repeat-block transfer	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. DMAC trigger source is selected using the ICU.DMRSRm registers. For details on DMAC trigger sources, see Table 15.6, Interrupt Vector Table, Table 15.3, Interrupt Sources for Software Configurable Interrupt in section 15, Interrupt Controller (ICUM).

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

DTS[1:0] Bits (Repeat Area Select)

DTS[1:0] bits select either the source or destination as the repeat area in repeat or block transfer mode. In normal or repeat-block transfer mode, setting these bits is invalid.

TKP Bit (Transfer Keeping)

TKP bit selects either stopping transfer or keeping transfer by completion of specified total number of transfer operations in repeat, block or repeat-block transfer mode. In normal transfer mode, setting this bit is invalid.

18.2.10 DMA Interrupt Setting Register (DMINT)

Address(es): DMAC0.DMINT 8700 7013h, DMAC1.DMINT 8700 7053h, DMAC2.DMINT 8700 7093h, DMAC3.DMINT 8700 70D3h, DMAC4.DMINT 8700 7113h, DMAC5.DMINT 8700 7153h, DMAC6.DMINT 8700 7193h, DMAC7.DMINT 8700 71D3h, DMAC0_NS.DMINT 0700 7013h, DMAC1_NS.DMINT 0700 7053h, DMAC2_NS.DMINT 0700 7093h, DMAC3_NS.DMINT 0700 70D3h, DMAC4_NS.DMINT 0700 7113h, DMAC5_NS.DMINT 0700 7153h, DMAC6_NS.DMINT 0700 7193h, DMAC7_NS.DMINT 0700 71D3h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DTIE	ESIE	RPTIE	SARIE	DARIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DARIE	Destination Address Extended Repeat Area Overflow Interrupt Enable	0: Disables an interrupt request for an extended repeat area overflow on the destination address 1: Enables an interrupt request for an extended repeat area overflow on the destination address	R/W
b1	SARIE	Source Address Extended Repeat Area Overflow Interrupt Enable	0: Disables an interrupt request for an extended repeat area overflow on the source address 1: Enables an interrupt request for an extended repeat area overflow on the source address	R/W
b2	RPTIE	Repeat Size End Interrupt Enable	0: Disables the repeat size end interrupt request. 1: Enables the repeat size end interrupt request.	R/W
b3	ESIE	Transfer Escape End Interrupt Enable	0: Disables the transfer escape end interrupt request. 1: Enables the transfer escape end interrupt request.	R/W
b4	DTIE	Transfer End Interrupt Enable	0: Disables the transfer end interrupt request. 1: Enables the transfer end interrupt request.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

DARIE Bit (Destination Address Extended Repeat Area Overflow Interrupt Enable)

When an extended repeat area overflow on the destination address occurs while this bit is set to 1, the DMCNT.DTE bit is set to 0. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that an interrupt due to an extended repeat area overflow on the destination address is requested. When block transfer mode is used with the extended repeat area function, an interrupt is requested when transfer of each single-block size of data is completed. When you set 1 in the DMCNT.DTE bit of the channel for which a transfer has been stopped, the transfer is resumed from the state when the transfer is stopped. When the extended repeat area is not specified for the destination address, this bit is ignored. When you use repeat-block transfer mode, do not set this bit to 1.

SARIE Bit (Source Address Extended Repeat Area Overflow Interrupt Enable)

When an extended repeat area overflow on the source address occurs while this bit is set to 1, the DMCNT.DTE bit is set to 0. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that an interrupt due to an extended repeat area overflow on the source address is requested. When block transfer mode is used with the extended repeat area function, an interrupt is requested when transfer of each single-block size of data is completed. When you set 1 in the DMCNT.DTE bit of the channel for which a transfer has been stopped, the transfer is resumed from the state when the transfer is stopped. When the extended repeat area is not specified for the source address, this bit is ignored. When you use repeat-block transfer mode, do not set this bit to 1.

RPTIE Bit (Repeat Size End Interrupt Enable)

When this bit is set to 1 in repeat transfer mode, the DMCNT.DTE bit is set to 0 when transfer of each single-repeat size of data is completed. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that the repeat size end interrupt request has been generated. The repeat size end interrupt request can be generated even when the DMTMD.DTS[1:0] bits are 10b (= repeat area or block area is not specified). When this bit is set to 1 in block transfer mode, the DMCNT.DTE bit is set to 0 when transfer of each single-block size of data is completed in the same way as repeat transfer mode. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that the repeat size end interrupt request has been generated. The repeat size end interrupt request can be generated even when the DMTMD.DTS[1:0] bits are 10b (= repeat area or block area is not specified). When you use repeat-block transfer mode, do not set this bit to 1.

ESIE Bit (Transfer Escape End Interrupt Enable)

This bit enables or disables the transfer escape end interrupt requests (repeat size end interrupt request and interrupt requests for extended repeat area overflows on the source and destination addresses) that are generated during DMA transfer. The transfer escape end interrupt is generated when the DMSTS.ESIF flag is set to 1 with this bit set to 1. The transfer escape end interrupt is cleared by setting this bit or the DMSTS.ESIF flag to 0.

DTIE Bit (Transfer End Interrupt Enable)

This bit enables or disables the transfer end interrupt request to be generated on completion of a specified number of data transfers. The transfer end interrupt is generated when the DMSTS.DTIF flag is set to 1 with this bit set to 1. The transfer end interrupt is cleared by setting this bit or the DMSTS.DTIF flag to 0.

18.2.11 DMA Address Mode Register (DMAMD)

Address(es): DMAC0.DMAMD 8700 7014h, DMAC1.DMAMD 8700 7054h, DMAC2.DMAMD 8700 7094h, DMAC3.DMAMD 8700 70D4h, DMAC4.DMAMD 8700 7114h, DMAC5.DMAMD 8700 7154h, DMAC6.DMAMD 8700 7194h, DMAC7.DMAMD 8700 71D4h, DMAC0_NS.DMAMD 0700 7014h, DMAC1_NS.DMAMD 0700 7054h, DMAC2_NS.DMAMD 0700 7094h, DMAC3_NS.DMAMD 0700 70D4h, DMAC4_NS.DMAMD 0700 7114h, DMAC5_NS.DMAMD 0700 7154h, DMAC6_NS.DMAMD 0700 7194h, DMAC7_NS.DMAMD 0700 71D4h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SM[1:0]		SADR	SARA[4:0]					DM[1:0]		DADR	DARA[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	DARA[4:0]	Destination Address Extended Repeat Area Setting	Specifies the extended repeat area on the destination address. For details on the settings, see Table 18.2.	R/W
b5	DADR	Destination Address Update Setting after Reload	0: Only reloading. 1: Add index after reloading.	R/W
b7, b6	DM[1:0]	Destination Address Update Mode Select	b7 b6 0 0: Destination address is fixed. 0 1: Offset addition 1 0: Destination address is incremented. 1 1: Destination address is decremented.	R/W
b12 to b8	SARA[4:0]	Source Address Extended Repeat Area Setting	Specifies the extended repeat area on the source address. For details on the settings, see Table 18.2.	R/W
b13	SADR	Source Address Update Setting after Reload	0: Only reloading. 1: Add index after reloading.	R/W
b15, b14	SM[1:0]	Source Address Update Mode Select	b15 b14 0 0: Source address is fixed. 0 1: Offset addition 1 0: Source address is incremented. 1 1: Source address is decremented.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

DARA[4:0] Bits (Destination Address Extended Repeat Area Setting)

These bits specify the extended repeat area on the destination address. The extended repeat area function is realized by updating the specified lower address bits with the remaining upper address bits fixed. The size of the extended repeat area can be any power of two between 2 bytes and 128 Mbytes. That is, the interval between settings is any power of two. When the lower address overflows the extended repeat area by address increment, the start address of the extended repeat area is set. Similarly, when the lower address underflows the extended repeat area by address decrement, the end address of the extended repeat area is set. When the repeat area or block area is specified as a transfer destination, do not specify the extended repeat area on the destination address. When repeat transfer or block transfer is selected, and when DMTMD.DTS[1:0] = 00b (the transfer destination is specified as the repeat area or block area), write 00000b in the DARA[4:0] bits. In repeat-block transfer mode, write 00000b in the DARA[4:0] bits. An interrupt can be requested when an overflow or underflow occurs in the extended repeat area with the DMINT.DARIE bit set to 1. Table 18.2 lists the settings and the corresponding extended repeat areas.

Note: When setting the extended repeat area, set the lowest bit or lower bits of DMDAR as follows according to the setting of DMTMD.SZ[1:0].
When DMTMD.SZ[1:0] = 01b (16 bits), set DMDAR[0] to 0b.

When DMTMD.SZ[1:0] = 10b (32 bits), set DMDAR[1:0] to 00b.
When DMTMD.SZ[1:0] = 11b (64 bits), set DMDAR[2:0] to 000b.

DADR Bit (Destination Address Update Setting after Reload)

In repeat-block transfer mode, this bit specifies the behavior of DMDAR register after reloading the value of DMDRR register. When this bit is set to 1, an index value ((DMDBSH – DMDBSL) × transfer data size) is added to DMDAR register after reloading the value of DMDRR register. When this bit is set to 0, DMDAR register only reloads DMDRR register. This behavior is described in Table 18.13. In normal, repeat or block transfer mode, this bit is ignored.

DM[1:0] Bits (Destination Address Update Mode Select)

These bits select the mode of updating the destination address. When increment is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, 10b, and 11b, the destination address is incremented by 1, 2, 4, and 8, respectively. When decrement is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, 10b, and 11b, the destination address is decremented by 1, 2, 4, and 8, respectively. When offset addition is selected, the offset specified by the DMOFR register is added to the address.

SARA[4:0] Bits (Source Address Extended Repeat Area Setting)

These bits specify the extended repeat area on the source address. The extended repeat area function is realized by updating the specified lower address bits with the remaining upper address bits fixed. The size of the extended repeat area can be any power of two between 2 bytes and 128 Mbytes. When the lower address overflows the extended repeat area by address increment, the start address of the extended repeat area is set. Similarly, when the lower address underflows the extended repeat area by address decrement, the end address of the extended repeat area is set. When the repeat area or block area is specified as a transfer source, do not specify the extended repeat area on the source address. When repeat transfer or block transfer is selected, and when DMTMD.DTS[1:0] = 01b (the transfer source is specified as the repeat area or block area), write 00000b in the SARA[4:0] bits. In repeat-block transfer mode, write 00000b in the SARA[4:0] bits. An interrupt can be requested when an overflow or underflow occurs in the extended repeat area with the DMINT.SARIE bit set to 1. Table 18.2 lists the settings and the corresponding extended repeat areas.

Note: When setting the extended repeat area, set the lowest bit or lower bits of DMSAR as follows according to the setting of DMTMD.SZ[1:0].
When DMTMD.SZ[1:0] = 01b (16 bits), set DMSAR[0] to 0b.
When DMTMD.SZ[1:0] = 10b (32 bits), set DMSAR[1:0] to 00b.
When DMTMD.SZ[1:0] = 11b (64 bits), set DMSAR[2:0] to 000b.

SADR Bit (Source Address Update Setting after Reload)

In repeat-block transfer mode, this bit specifies the behavior of DMSAR register after reloading the value of DMSRR register. When this bit is set to 1, an index value ((DMSBSH – DMSBSL) × transfer data size) is added to DMSAR register after reloading the value of DMSRR register. When this bit is set to 0, DMSAR register only reloads DMSRR register. This behavior is described in Table 18.12. In normal, repeat or block transfer mode, this bit is ignored.

SM[1:0] Bits (Source Address Update Mode Select)

These bits select the mode of updating the source address. When increment is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, 10b, and 11b, the source address is incremented by 1, 2, 4, and 8, respectively. When decrement is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, 10b, and 11b, the source address is decremented by 1, 2, 4, and 8, respectively. When offset addition is selected, the offset specified by the DMOFR register is added to the address.

Table 18.2 Settings and Corresponding Extended Repeat Areas

SARA[4:0] or DARA[4:0]	Extended Repeat Area
00000b	Not specified
00001b	2 bytes specified as extended repeat area by the lower 1 bit of the address
00010b	4 bytes specified as extended repeat area by the lower 2 bits of the address
00011b	8 bytes specified as extended repeat area by the lower 3 bits of the address
00100b	16 bytes specified as extended repeat area by the lower 4 bits of the address
00101b	32 bytes specified as extended repeat area by the lower 5 bits of the address
00110b	64 bytes specified as extended repeat area by the lower 6 bits of the address
00111b	128 bytes specified as extended repeat area by the lower 7 bits of the address
01000b	256 bytes specified as extended repeat area by the lower 8 bits of the address
01001b	512 bytes specified as extended repeat area by the lower 9 bits of the address
01010b	1 Kbyte specified as extended repeat area by the lower 10 bits of the address
01011b	2 Kbytes specified as extended repeat area by the lower 11 bits of the address
01100b	4 Kbytes specified as extended repeat area by the lower 12 bits of the address
01101b	8 Kbytes specified as extended repeat area by the lower 13 bits of the address
01110b	16 Kbytes specified as extended repeat area by the lower 14 bits of the address
01111b	32 Kbytes specified as extended repeat area by the lower 15 bits of the address
10000b	64 Kbytes specified as extended repeat area by the lower 16 bits of the address
10001b	128 Kbytes specified as extended repeat area by the lower 17 bits of the address
10010b	256 Kbytes specified as extended repeat area by the lower 18 bits of the address
10011b	512 Kbytes specified as extended repeat area by the lower 19 bits of the address
10100b	1 Mbyte specified as extended repeat area by the lower 20 bits of the address
10101b	2 Mbytes specified as extended repeat area by the lower 21 bits of the address
10110b	4 Mbytes specified as extended repeat area by the lower 22 bits of the address
10111b	8 Mbytes specified as extended repeat area by the lower 23 bits of the address
11000b	16 Mbytes specified as extended repeat area by the lower 24 bits of the address
11001b	32 Mbytes specified as extended repeat area by the lower 25 bits of the address
11010b	64 Mbytes specified as extended repeat area by the lower 26 bits of the address
11011b	128 Mbytes specified as extended repeat area by the lower 27 bits of the address
11100b to 11111b	Setting prohibited.

18.2.12 DMA Offset Register (DMOFR)

Address(es): DMAC0.DMOFR 8700 7018h, DMAC1.DMOFR 8700 7058h, DMAC2.DMOFR 8700 7098h, DMAC3.DMOFR 8700 70D8h, DMAC4.DMOFR 8700 7118h, DMAC5.DMOFR 8700 7158h, DMAC6.DMOFR 8700 7198h, DMAC7.DMOFR 8700 71D8h, DMAC0_NS.DMOFR 0700 7018h, DMAC1_NS.DMOFR 0700 7058h, DMAC2_NS.DMOFR 0700 7098h, DMAC3_NS.DMOFR 0700 70D8h, DMAC4_NS.DMOFR 0700 7118h, DMAC5_NS.DMOFR 0700 7158h, DMAC6_NS.DMOFR 0700 7198h, DMAC7_NS.DMOFR 0700 71D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Description	Setting Range	R/W
b31 to b0	Specifies the offset when offset addition is selected as the address update mode for transfer source or destination.	0000 0000h to 00FF FFFFh (0 bytes to (16 M – 1) bytes) FF00 0000h to FFFF FFFFh (–16 Mbytes to –1 byte)	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

Setting bits 31 to 25 is invalid; a value of bit 24 is extended to bits 31 to 25. Reading DMOFR register returns the extended value. In repeat-block transfer mode, the offset cannot be specified by DMOFR register when offset addition is selected, write 0000 0000h to DMOFR register.

18.2.13 DMA Transfer Enable Register (DMCNT)

Address(es): DMAC0.DMCNT 8700 701Ch, DMAC1.DMCNT 8700 705Ch, DMAC2.DMCNT 8700 709Ch, DMAC3.DMCNT 8700 70DCh, DMAC4.DMCNT 8700 711Ch, DMAC5.DMCNT 8700 715Ch, DMAC6.DMCNT 8700 719Ch, DMAC7.DMCNT 8700 71DCh, DMAC0_NS.DMCNT 0700 701Ch, DMAC1_NS.DMCNT 0700 705Ch, DMAC2_NS.DMCNT 0700 709Ch, DMAC3_NS.DMCNT 0700 70DCh, DMAC4_NS.DMCNT 0700 711Ch, DMAC5_NS.DMCNT 0700 715Ch, DMAC6_NS.DMCNT 0700 719Ch, DMAC7_NS.DMCNT 0700 71DCh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	DTE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DTE	DMA Transfer Enable	0: Disables DMA transfer. 1: Enables DMA transfer.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

DTE Bit (DMA Transfer Enable)

When the DMAST.DMST bit is set to 1 (DMAC activation is enabled) and this bit is set to 1 (DMA transfer is enabled), DMA transfer can be started for the corresponding channel. If the DTE bit is cleared during DMA transfer, no transfer requests for the corresponding channel will be accepted after the transfer ends.

[Setting condition]

- 1 is written to this bit.

[Clearing conditions]

- 0 is written to this bit.
- The specified total volume of data transfer is completed.
- The DMA transfer is stopped by the repeat size end interrupt.
- The DMA transfer is stopped by the extended repeat area overflow interrupt.
- The DMA transfer is stopped due to the occurrence of an access error. For details, see section 18.5, Processing on DMA Transfer Error.

18.2.14 DMA Software Start Register (DMREQ)

Address(es): DMAC0.DMREQ 8700 701Dh, DMAC1.DMREQ 8700 705Dh, DMAC2.DMREQ 8700 709Dh, DMAC3.DMREQ 8700 70DDh, DMAC4.DMREQ 8700 711Dh, DMAC5.DMREQ 8700 715Dh, DMAC6.DMREQ 8700 719Dh, DMAC7.DMREQ 8700 71DDh, DMAC0_NS.DMREQ 0700 701Dh, DMAC1_NS.DMREQ 0700 705Dh, DMAC2_NS.DMREQ 0700 709Dh, DMAC3_NS.DMREQ 0700 70DDh, DMAC4_NS.DMREQ 0700 711Dh, DMAC5_NS.DMREQ 0700 715Dh, DMAC6_NS.DMREQ 0700 719Dh, DMAC7_NS.DMREQ 0700 71DDh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	CLRS	—	—	—	SWREQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SWREQ	DMA Software Start	Writing 1 to this bit triggers the generation of a DMA transfer request, and DMA transfer is started in response to the request	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	CLRS	DMA Software Start Bit Auto Clear Setting	0: SWREQ bit is cleared after DMA transfer is started by software. 1: SWREQ bit is not cleared after DMA transfer is started by software.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

SWREQ Bit (DMA Software Start)

When 1 is written to this bit, a DMA transfer request is generated. After DMA transfer is started in response to the request, this bit is set to 0 if the CLRS bit is set to 0. This bit is not set to 0 while the CLRS bit is set to 1. In this case, a DMA transfer request can be issued again after completion of a transfer. Note that, however, setting this bit is valid and DMA transfer by software is enabled only when the DMTMD.DCTG[1:0] bits are set to 00b (DMAC trigger source is software). Setting this bit is invalid when the DMTMD.DCTG[1:0] bits are set to a value other than 00b. To start DMA transfer by software with the CLRS bit being 0, ensure that the SWREQ bit is 0, and then write 1 to the SWREQ bit.

[Setting condition]

- 1 is written to this bit.

[Clearing conditions]

- The DMA transfer request by software is accepted and DMA transfer is started while the CLRS bit is set to 0 (the SWREQ bit is cleared after DMA transfer is started by software).
- The DMA transfer is stopped due to the occurrence of an access error. See section 18.5, Processing on DMA Transfer Error.
- 0 is written to this bit.

CLRS Bit (DMA Software Start Bit Auto Clear Setting)

This bit specifies whether to clear the SWREQ bit to 0 after DMA transfer is started in response to the DMA transfer request generated by setting the SWREQ bit to 1. With this bit set to 0, the SWREQ bit is set to 0 after DMA transfer is started. With this bit set to 1, the SWREQ bit is not set to 0. In this case, a DMA transfer request can be issued again after completion of a transfer.

18.2.15 DMA Status Register (DMSTS)

Address(es): DMAC0.DMSTS 8700 701Eh, DMAC1.DMSTS 8700 705Eh, DMAC2.DMSTS 8700 709Eh, DMAC3.DMSTS 8700 70DEh, DMAC4.DMSTS 8700 711Eh, DMAC5.DMSTS 8700 715Eh, DMAC6.DMSTS 8700 719Eh, DMAC7.DMSTS 8700 71DEh, DMAC0_NS.DMSTS 0700 701Eh, DMAC1_NS.DMSTS 0700 705Eh, DMAC2_NS.DMSTS 0700 709Eh, DMAC3_NS.DMSTS 0700 70DEh, DMAC4_NS.DMSTS 0700 711Eh, DMAC5_NS.DMSTS 0700 715Eh, DMAC6_NS.DMSTS 0700 719Eh, DMAC7_NS.DMSTS 0700 71DEh

	b7	b6	b5	b4	b3	b2	b1	b0
	ACT	—	—	DTIF	—	—	—	ESIF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESIF	Transfer Escape End Interrupt Flag	0: A transfer escape end interrupt has not been generated. 1: A transfer escape end interrupt has been generated.	R/W*1
b3 to b1	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R
b4	DTIF	Transfer End Interrupt Flag	0: A transfer end interrupt has not been generated. 1: A transfer end interrupt has been generated.	R/W*1
b6, b5	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R
b7	ACT	DMA Active Flag	0: DMAC operation is suspended. 1: DMAC is operating.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Only 0 can be written to clear the flag.

ESIF Flag (Transfer Escape End Interrupt Flag)

This flag indicates that the transfer escape end interrupt has been generated.

[Setting conditions]

- Transfer of each single-repeat size of data is completed in repeat transfer mode with the DMINT.RPTIE bit set to 1.
- Transfer of each single-block size of data is completed in block transfer mode with the DMINT.RPTIE bit set to 1.
- An extended repeat area overflow on the source address occurs while the DMINT.SARIE bit is set to 1 and the DMAMD.SARA[4:0] bits are set to a value other than 00000b (extended repeat area is specified on the transfer source address).
- An extended repeat area overflow on the destination address occurs while the DMINT.DARIE bit is set to 1 and the DMAMD.DARA[4:0] bits are set to a value other than 00000b (extended repeat area is specified on the transfer destination address).

[Clearing conditions]

- 0 is written to this bit.
- 1 is written to the DMCNT.DTE bit.

DTIF Flag (Transfer End Interrupt Flag)

This flag indicates that the transfer end interrupt has been generated.

[Setting conditions]

- The specified number of unit-transfers is completed in normal transfer mode (the value of the DMCRAL[15:0] bits has become 0000h on completion of transfer).
- The specified number of repeat transfer operations is completed in repeat transfer mode (the value of the DMCRBL[15:0] bits has become 0000h on completion of transfer (DMTMD.TKP = 0), or the DMCRBL[15:0] bits reload the value of the DMCRBH[15:0] bits (DMTMD.TKP = 1)).

- The specified number of blocks has been transferred in block transfer mode (the value of the DMCRBL[15:0] bits has become 0000h on completion of transfer (DMTMD.TKP = 0), or the DMCRBL[15:0] bits have been reloaded with the value of the DMCRBH[15:0] bits (DMTMD.TKP = 1)).
- The specified number of blocks has been transferred in repeat-block transfer mode (the value of the DMCRBL[15:0] bits has become 0000h on completion of transfer (DMTMD.TKP = 0), or the DMCRBL[15:0] bits have been reloaded with the value of the DMCRBH[15:0] bits (DMTMD.TKP = 1)).

[Clearing conditions]

- 0 is written to this bit.
- 1 is written to the DMCNT.DTE bit.

ACT Flag (DMA Active Flag)

This flag indicates whether the DMAC is in the idle or active state.

[Setting condition]

- The DMAC starts data transfer.

[Clearing condition]

- The data transfer in response to one transfer request is completed.

18.2.16 DMAC Trigger Source Flag Control Register (DMCSL)

Address(es): DMAC0.DMCSL 8700 701Fh, DMAC1.DMCSL 8700 705Fh, DMAC2.DMCSL 8700 709Fh, DMAC3.DMCSL 8700 70DFh, DMAC4.DMCSL 8700 711Fh, DMAC5.DMCSL 8700 715Fh, DMAC6.DMCSL 8700 719Fh, DMAC7.DMCSL 8700 71DFh, DMAC0_NS.DMCSL 0700 701Fh, DMAC1_NS.DMCSL 0700 705Fh, DMAC2_NS.DMCSL 0700 709Fh, DMAC3_NS.DMCSL 0700 70DFh, DMAC4_NS.DMCSL 0700 711Fh, DMAC5_NS.DMCSL 0700 715Fh, DMAC6_NS.DMCSL 0700 719Fh, DMAC7_NS.DMCSL 0700 71DFh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	DISEL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DISEL	Interrupt Select	0: At the beginning of transfer, clear the interrupt status flag of the trigger source to 0. 1: At the end of transfer, the interrupt status flag of the trigger source issues an interrupt to the CPU.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

DISEL Bit (Interrupt Select)

This bit selects whether the interrupt status flag of the trigger source is set to 0 or issues an interrupt request to the CPU, at the beginning of DMA transfer. When DMTMD.DCTG[1:0] = 00b (activation by software), the setting of the DISEL bit does not affect the operation.

18.2.17 DMA Source Buffer Size Register (DMSBS)

Address(es): DMAC0.DMSBS 8700 7028h, DMAC1.DMSBS 8700 7068h, DMAC2.DMSBS 8700 70A8h, DMAC3.DMSBS 8700 70E8h, DMAC4.DMSBS 8700 7128h, DMAC5.DMSBS 8700 7168h, DMAC6.DMSBS 8700 71A8h, DMAC7.DMSBS 8700 71E8h, DMAC0_NS.DMSBS 0700 7028h, DMAC1_NS.DMSBS 0700 7068h, DMAC2_NS.DMSBS 0700 70A8h, DMAC3_NS.DMSBS 0700 70E8h, DMAC4_NS.DMSBS 0700 7128h, DMAC5_NS.DMSBS 0700 7168h, DMAC6_NS.DMSBS 0700 71A8h, DMAC7_NS.DMSBS 0700 71E8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DMSBSH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DMSBSL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DMSBSL[15:0]	Lower Bits of Source Buffer Size	Functions as data transfer counter in repeat-block transfer mode	R/W
b31 to b16	DMSBSH[15:0]	Upper Bits of Source Buffer Size	Specifies the repeat-area size in repeat-block transfer mode	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.
Set the same value for the DMSBSH[15:0] and DMSBSL[15:0] bits in repeat-block transfer mode. Write 00000000h to the DMSBS register in normal, repeat and block transfer mode. The DMSBSH[15:0] bits specify buffer size and the DMSBSL[15:0] bits function as a 16-bit buffer size counter in repeat-block transfer mode. In repeat-block transfer mode, source repeat area is specified by the DMSBSH[15:0] bits. When address update mode is incremented address or decremented address, this register means the numbers of data of whole buffer. When address update mode is offset addition, this register means the numbers of data of an individual buffer. In offset addition, setting the DMSBSH[15:0] and DMSBSL[15:0] bits to 0000h is prohibited. When final data of one buffer size is transferred, the DMSBSL[15:0] bits reload value of the DMSBSH[15:0] bits. When address update mode is fixed address, this register is ignored. Table 18.3 lists the setting values of Source Buffer Size Register corresponding to Transfer Data Size in Source Address Update Mode.

Table 18.3 Available Setting for DMSBS Register in Repeat-Block Transfer Mode

Source Address Update Mode (DMAMD.SM)	Transfer Data Size (DMTMD.SZ)	Available Setting for DMSBSH[15:0] and DMSBSL[15:0] Bits
Source address is fixed. (SM = 00b)	Don't care	0000h (DMSBS is not used)
Offset addition (SM = 01b)	8 bits (SZ = 00b)	0001h to FFFFh (1 to 65535)
	16 bits (SZ = 01b)	0001h to 7FFFh (1 to 32767)
	32 bits (SZ = 10b)	0001h to 3FFFh (1 to 16383)
	64 bits (SZ = 11b)	0001h to 1FFFh (1 to 8191)
Source address is incremented or decremented. (SM = 1xb)	Don't care	0000h (infinite) 0001h to FFFFh (1 to 65535)

18.2.18 DMA Destination Buffer Size Register (DMDBS)

Address(es): DMAC0.DMDBS 8700 702Ch, DMAC1.DMDBS 8700 706Ch, DMAC2.DMDBS 8700 70ACh, DMAC3.DMDBS 8700 70ECh, DMAC4.DMDBS 8700 712Ch, DMAC5.DMDBS 8700 716Ch, DMAC6.DMDBS 8700 71ACh, DMAC7.DMDBS 8700 71ECh, DMAC0_NS.DMDBS 0700 702Ch, DMAC1_NS.DMDBS 0700 706Ch, DMAC2_NS.DMDBS 0700 70ACh, DMAC3_NS.DMDBS 0700 70ECh, DMAC4_NS.DMDBS 0700 712Ch, DMAC5_NS.DMDBS 0700 716Ch, DMAC6_NS.DMDBS 0700 71ACh, DMAC7_NS.DMDBS 0700 71ECh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DMDBSH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DMDBSL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DMDBSL[15:0]	Lower Bits of Destination Buffer Size	Functions as data transfer counter in repeat-block transfer mode	R/W
b31 to b16	DMDBSH[15:0]	Upper Bits of Destination Buffer Size	Specifies the repeat-area size in repeat-block transfer mode	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.
Set the same value for the DMDBSH[15:0] and DMDBSL[15:0] bits in repeat-block transfer mode. Write 00000000h to the DMDBS register in normal, repeat and block transfer mode. The DMDBSH[15:0] bits specify buffer size and the DMDBSL[15:0] bits function as a 16-bit buffer size counter in repeat-block transfer mode. In repeat-block transfer mode, destination repeat area is specified by the DMDBSH[15:0] bits. When address update mode is incremented address or decremented address, this register means the numbers of data of whole buffer. When address update mode is offset addition, this register means the numbers of data of an individual buffer. In offset addition, setting the DMDBSH[15:0] and DMDBSL[15:0] bits to 0000h is prohibited. When final data of one buffer size is transferred, the DMDBSL[15:0] bits reload value of the DMDBSH[15:0] bits. When address update mode is fixed address, this register is ignored. Table 18.4 lists the setting values of Destination Buffer Size Register corresponding to Transfer Data Size in Destination Address Update Mode.

Table 18.4 Available Setting for DMDBS Register in Repeat-Block Transfer Mode

Destination Address Update Mode (DMAMD.DM)	Transfer Data Size (DMTMD.SZ)	Available Setting for DMDBSH[15:0] and DMDBSL[15:0] Bits
Destination address is fixed. (DM = 00b)	Don't care	0000h (DMDBS is not used)
Offset addition (DM = 01b)	8 bits (SZ = 00b)	0001h to FFFFh (1 to 65535)
	16 bits (SZ = 01b)	0001h to 7FFFh (1 to 32767)
	32 bits (SZ = 10b)	0001h to 3FFFh (1 to 16383)
	64 bits (SZ = 11b)	0001h to 1FFFh (1 to 8191)
Destination address is incremented or decremented. (DM = 1xb)	Don't care	0000h (infinite) 0001h to FFFFh (1 to 65535)

18.2.19 DMA Bufferable Write Enable Register (DMBWR)

Address(es): DMAC0.DMBWR 8700 7030h, DMAC1.DMBWR 8700 7070h, DMAC2.DMBWR 8700 70B0h, DMAC3.DMBWR 8700 70F0h, DMAC4.DMBWR 8700 7130h, DMAC5.DMBWR 8700 7170h, DMAC6.DMBWR 8700 71B0h, DMAC7.DMBWR 8700 71F0h, DMAC0_NS.DMBWR 0700 7030h, DMAC1_NS.DMBWR 0700 7070h, DMAC2_NS.DMBWR 0700 70B0h, DMAC3_NS.DMBWR 0700 70F0h, DMAC4_NS.DMBWR 0700 7130h, DMAC5_NS.DMBWR 0700 7170h, DMAC6_NS.DMBWR 0700 71B0h, DMAC7_NS.DMBWR 0700 71F0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	BWE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BWE	Bufferable Write Enable	0: Writing to bufferable areas bypasses the write buffers. 1: Writing to bufferable areas proceeds through the write buffers.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

BWE Bit (Bufferable Write Enable)

This bit enables or disables buffered writing to bufferable areas. When the setting of this bit is 1 (enabling use of the buffers), even if the write access by the DMAC is completed, the actual write operation might not have been finished. The DMAC treats writing as complete once it has written to a write buffer, even though writing to the destination may not yet be finished. For details, see section 16.2.5.2, Bufferable Write and section 16.2.5.3, Notes on the Timing of Writing Completion. If an error occurs during writing to a slave that is capable of supporting buffered write operations, this is detected as a buffered write error, triggering an interrupt or reset. However, the DMA transfer does not stop at such times.

18.2.20 DMAC Module Start Register (DMAST)

Address(es): DMAC.DMAST 8700 7800h,
DMAC_NS.DMAST 0700 7800h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	DMST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DMST	DMAC Module Start	0: DMAC module stop 1: DMAC module start	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

DMST Bit (DMAC Module Start)

When this bit is set to 1, DMAC is ready to accept transfer requests for all channels. When 1 is written to the DMCNT.DTE bit (DMA transfer is enabled) of multiple channels and then this bit is set to 1 (DMAC module start), the corresponding multiple channels can be placed in the transfer request acceptable state at the same time. When the DMST bit is set to 0 during DMA transfer, DMA transfer is suspended after completion of the current data transfer corresponding to a single transfer request. DMA transfer can be resumed by setting the DMST bit to 1 again.

[Setting condition]

- 1 is written to this bit.

[Clearing condition]

- 0 is written to this bit.

18.2.21 DMAC Error Channel Register (DMECHR)

Address(es): DMAC.DMECHR 8700 7840h, DMAC_NS.DMECHR 0700 7840h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMESTA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DMERRW	—	—	—	DMECHSAM	—	—	—	—	DMECH[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	DMECH[3:0]	DMAC Error Channel Flag	Indicates the channel number causing the error 0000: Error occurred on channel 0 0001: Error occurred on channel 1 0010: Error occurred on channel 2 : : 0111: Error occurred on channel 7	R
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	DMECHSAM	DMAC Error Channel Security Attribution Monitor Flag	Indicates the security attribution of a channel causing the error 0: Secure channel 1: Non-secure channel	R
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R
b12	DMERRW	DMAC Error Access Read/Write Attribute Flag	Indicates the read/write attribute of the error access 0: Read access 1: Write access	R
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	DMESTA	DMAC Error Status Flag	0: No DMA transfer error occurred 1: DMA transfer error occurred	R/W*1
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Writing to the DMESTA flag depends on the value of the DMECHSAM flag.

When reading this register, it can be accessed from both secure and non-secure access. When writing this register, it depends on the value of the DMECHR.DMECHSAM flag.

- When the value of the DMECHR.DMECHSAM flag is 1, it can be accessed from secure and non-secure access.
- When the value of the DMECHR.DMECHSAM flag is 0, it can be accessed from secure. An error is returned when write access is performed in a non-secure access.

This register is cleared by a reset. On debugging a program, select an interrupt instead of a reset in the corresponding bits of the registers listed in the interrupt/reset selection column of Table 18.20 in section 18.6.2, Transfer Error Interrupt.

DMECH[3:0] Flag (DMAC Error Channel Flag)

When a transfer error due to DMA transfer occurs, this flag stores the channel number of the DMAC that was violated. When reset was selected in BUSMPU.MMPUOAD.OAD and BUS.MSAOAD.OAD bits, this register is also reset. Select NMI when you want to debug the program.

[Setting condition]

- A DMA transfer error occurs while the DMESTA flag is 0.

[Clearing condition]

- 1 is written to the DMESTA flag.

DMECHSAM Flag (DMAC Error Channel Security Attribution Monitor Flag)

When a transfer error due to DMA transfer occurs, this flag indicates the security attribution of the violating DMAC channel. When reset was selected in BUSMPU.MMPUOAD.OAD and BUS.MSAOAD.OAD bits, this register is also reset. Select NMI when you want to debug the program.

[Setting condition]

- A DMA transfer error occurs while the DMESTA flag is 0.

[Clearing condition]

- 1 is written to DMESTA flag.

DMERRW Flag (DMAC Error Access Read/Write Attribute Flag)

Indicates the read/write attribute of the error access.

[Setting condition]

- A DMA transfer error occurs during write access to the on-chip memory or registers of other modules.

[Clearing condition]

- 1 is written to the DMESTA flag.

DMESTA Flag (DMAC Error Status Flag)

Indicates whether or not a DMA transfer error occurred. DMECH[3:0] bits, DMECHSAM bit, DMESTA flag are cleared by writing 1 to DMESTA flag. Writing 0 to DMESTA flag is ignored. When reset was selected in BUSMPU.MMPUOAD.OAD and BUS.MSAOAD.OAD bits, this register is also reset. Select NMI when you want to debug the program.

[Setting condition]

- A DMA transfer error occurs.

[Clearing condition]

- 1 is written to the DMESTA flag.

Note: When DMECHSAM = 1, it can be cleared in the secure state and non-secure state. When DMECHSAM = 0, it cannot be cleared in the non-secure state.

18.2.22 DMAC74 Interrupt Status Monitor Register (DMIST)

Address(es): DMAC.DMIST 8700 7804h,
DMAC_NS.DMIST 0700 7804h

	b7	b6	b5	b4	b3	b2	b1	b0
	DMIS7	DMIS6	DMIS5	DMIS4	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R
b4	DMIS4	DMAC4 Interrupt Status Flag	0: DMAC4 interrupt is not requested. 1: DMAC4 interrupt is requested.	R
b5	DMIS5	DMAC5 Interrupt Status Flag	0: DMAC5 interrupt is not requested. 1: DMAC5 interrupt is requested.	R
b6	DMIS6	DMAC6 Interrupt Status Flag	0: DMAC6 interrupt is not requested. 1: DMAC6 interrupt is requested.	R
b7	DMIS7	DMAC7 Interrupt Status Flag	0: DMAC7 interrupt is not requested. 1: DMAC7 interrupt is requested.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: The security attribute depends on the setting of the DMACCHSAR.SADMAC4 bit.

DMISm Flag (DMACm Interrupt Status Flag) (m = 4 to 7)

This flag monitors the DMACm interrupt request. Writing to this flag will be ignored. While the DMACm.DMINT.DTIE bit is 1 and the DMACm.DMSTS.DTIF flag is 1, or the DMACm.DMINT.ESIE bit is 1 and the DMACm.DMSTS.ESIF flag is 1, the DMIST.DMISm flag is set to 1.

18.2.23 DMAC Control Register (DMCTL)

Address(es): DMAC.DMCTL 8700 7810h,
DMAC_NS.DMCTL 0700 7810h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	ERCH	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PR	Priority Control Select	0: Fixed priority 1: Round-robin	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	ERCH	Clear Channel Select	0: Target channel only 1: All channels	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Do not write to the register for a given channel while either the DMSTS.ACT flag is 1 (DMA transfer in progress) or the DMCNT.DTE bit is 1 (enabling DMA transfer) for the same channel.

PR Bit (Priority Control Select)

When the DMCTL.PR bit is set to 0, arbitration is performed in the fixed priority mode of channel 0 > channel 1 > channel 2 > channel 3 …> channel 7 (channel 0: highest priority) > DTC and DMA transfer is started. When the DMCTL.PR bit is set to 1, arbitration is performed in the round-robin mode and DMA transfer is started.

ERCH Bit (Clear Channel Select)

When the DMCTL.ERCH bit is set to 0, the ICU clears all bits of the target channel of DMRSRm register (m = 0 to 7) by the error response during transfer. DMRSRm register (m = 0 to 7) other than the target channel is not cleared. When the DMCTL.ERCH bit is set to 1, the ICU clears all bits of all channels of DMRSRm register (m = 0 to 7) by the error response during transfer.

18.3 Operation

18.3.1 Transfer Mode

(1) Normal Transfer Mode

In normal transfer mode, one data is transferred by one transfer request. A maximum of 65535 can be set as the number of transfer operations using the DMCRAL[15:0] bits. When these bits are set to 0000h, no specific number of transfer operations is set; data transfer is performed with the transfer counter stopped (free-running function). Setting the DMCRB register is invalid in normal transfer mode. Except in free-running mode, a transfer end interrupt request can be generated after completion of the specified number of transfer operations. Table 18.5 lists the register update operation in normal transfer mode, and Figure 18.2 shows an operation example in normal transfer mode.

Table 18.5 Register Update Operation in Normal Transfer Mode

Register	Function	Update Operation after Completion of a Transfer by One Transfer Request
DMSAR	Transfer source address	Increment/decrement/fixed/offset addition
DMDAR	Transfer destination address	Increment/decrement/fixed/offset addition
DMCRA.DMCRAL[15:0]	Transfer counter	Decremented by one/not updated (in free-running function)
DMCRA.DMCRAH[9:0]	—	Not updated (Not used in normal transfer mode)
DMCRB	—	Not updated (Not used in normal transfer mode)

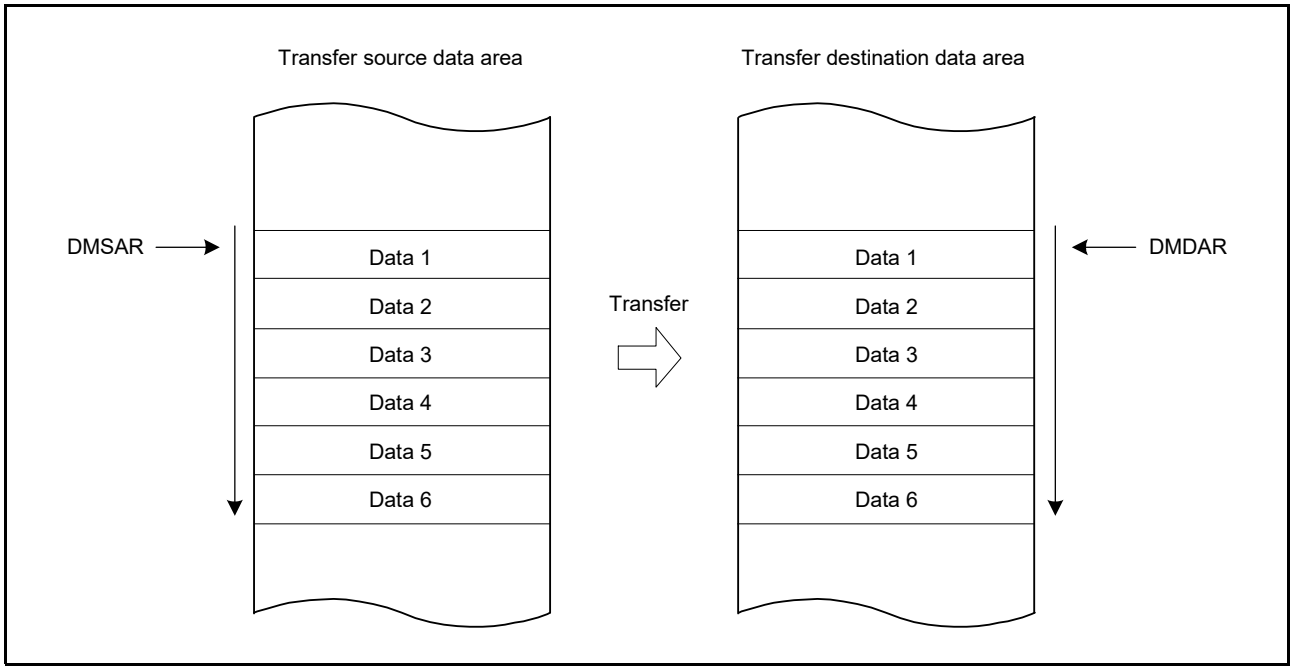

Figure 18.2 Operation Example in Normal Transfer Mode

(2) Repeat Transfer Mode

In repeat transfer mode, one data is transferred by one transfer request. A maximum of 1K data can be set as a total repeat transfer size using the DMCRA register. A maximum of 64K can be set as the number of repeat transfer operations using the DMCRB register; therefore, a maximum of 64M data (1K data × 64K counts of repeat transfer operations) can be set as a total data transfer size. Either the transfer source or transfer destination can be specified as a repeat area. When transfer of the repeat size data is completed, the address of the specified repeat area (DMSAR or DMDAR) returns to the transfer start address. When data of the specified repeat size has all been transferred in repeat transfer mode, DMA transfer can be stopped and the repeat size end interrupt can be requested. DMA transfer can be resumed by writing 1 to the DMCNT.DTE bit in the repeat size end interrupt handling. A transfer end interrupt request can be generated after completion of the specified number of repeat transfer operations. Table 18.6 lists the register update operation in repeat transfer mode, and Figure 18.3 shows an operation example in repeat transfer mode.

Table 18.6 Register Update Operation in Repeat Transfer Mode

Register	Function	Update Operation after Completion of a Transfer by One Transfer Request	
		When the DMCRA.DMCRAL[15:0] bits are not 1	When the DMCRA.DMCRAL[15:0] bits are 1 (Transfer of the Last Data in Repeat Size)
DMSAR	Transfer source address	Increment/decrement/fixed/ offset addition	• DMTMD.DTS[1:0] = 00b Increment/decrement/fixed/offset addition • DMTMD.DTS[1:0] = 01b Initial value of DMSAR • DMTMD.DTS[1:0] = 10b Increment/decrement/fixed/offset addition
DMDAR	Transfer destination address	Increment/decrement/fixed/ offset addition	• DMTMD.DTS[1:0] = 00b Initial value of DMDAR • DMTMD.DTS[1:0] = 01b Increment/decrement/fixed/offset addition • DMTMD.DTS[1:0] = 10b Increment/decrement/fixed/offset addition

DMCRB.DMCRBL [15:0]	Count of repeat transfer operations	Not updated	Decremented by one

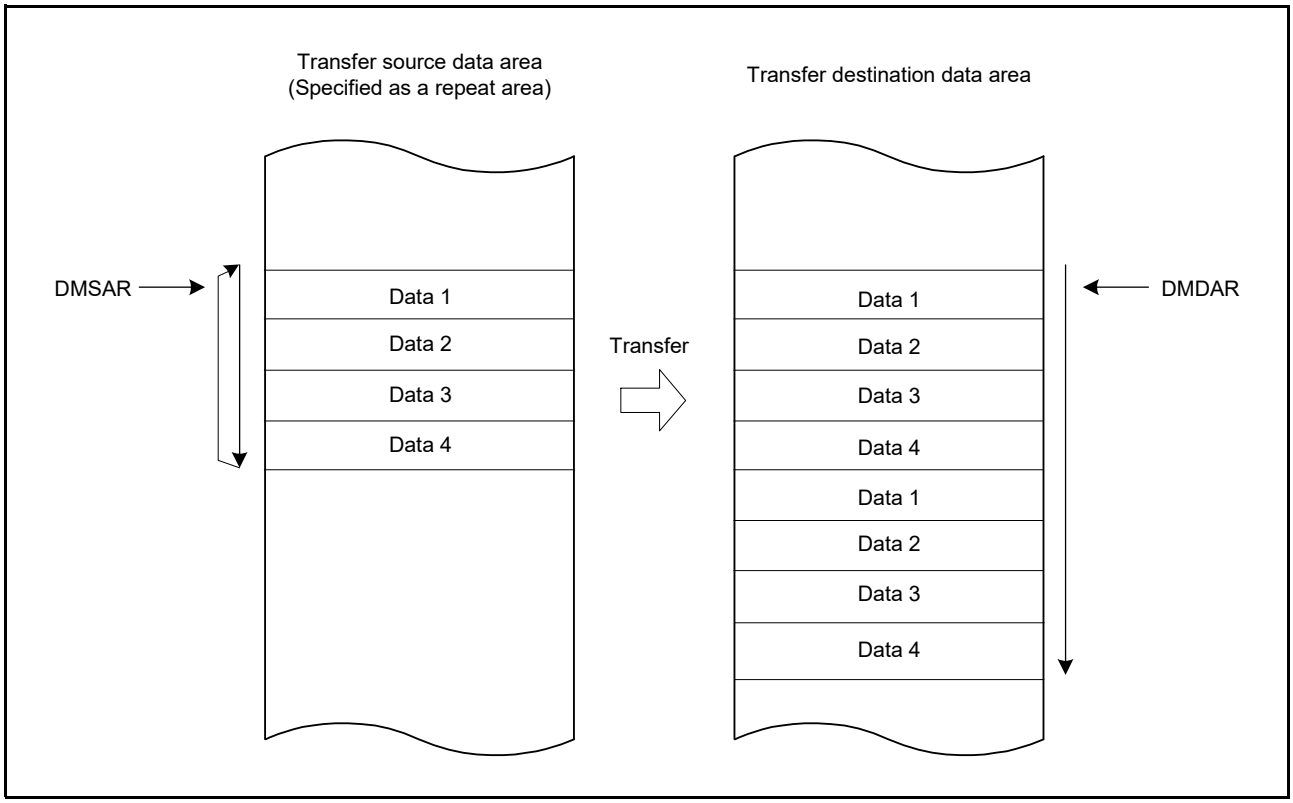

Figure 18.3 Operation Example in Repeat Transfer Mode

(3) Block Transfer Mode

In block transfer mode, a single block data is transferred by one transfer request. A maximum of 1K data can be set as a total block transfer size using the DMCRA register. A maximum of 64K can be set as the number of block transfer operations using the DMCRB register; therefore, a maximum of 64M data (1K data × 64K counts of block transfer operations) can be set as a total data transfer size. Either the transfer source or transfer destination can be specified as a block area. When transfer of a single block data is completed, the address of the specified block area (DMSAR or DMDAR) returns to the transfer start address. When a single block data has all been transferred in block transfer mode, DMA transfer can be stopped and the repeat size end interrupt can be requested. DMA transfer can be resumed by writing 1 to the DMCNT.DTE bit in the repeat size end interrupt handling. Transfer end interrupt request can be generated after completion of the specified number of block transfer operations. Table 18.7 lists the register update operation in block transfer mode, and Figure 18.4 shows an operation example in block transfer mode.

Table 18.7 Register Update Operation in Block Transfer Mode

Register	Function	Update Operation after Completion of Single-Block Transfer by One Transfer Request
DMSAR	Transfer source address	• DMTMD.DTS[1:0] = 00b Increment/decrement/fixed/offset addition • DMTMD.DTS[1:0] = 01b Initial value of DMSAR • DMTMD.DTS[1:0] = 10b Increment/decrement/fixed/offset addition
DMDAR	Transfer destination address	• DMTMD.DTS[1:0] = 00b Initial value of DMDAR • DMTMD.DTS[1:0] = 01b Increment/decrement/fixed/offset addition • DMTMD.DTS[1:0] = 10b Increment/decrement/fixed/offset addition
DMCRA.DMCRAH[9:0]	Block size	Not updated
DMCRA.DMCRAL[15:0]	Transfer count	DMCRA.DMCRAH[9:0]
DMCRB.DMCRBH[15:0]	Number of block transfer operations	Not updated
DMCRB.DMCRBL[15:0]	Count of block transfer operations	Decremented by one

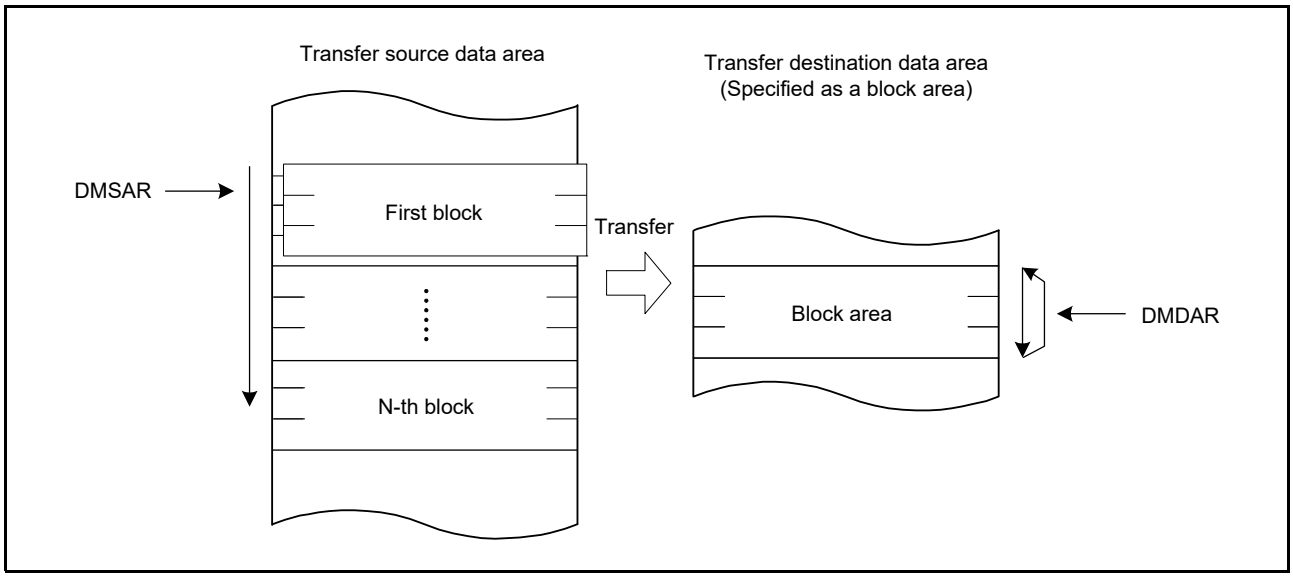

Figure 18.4 Operation Example in Block Transfer Mode

(4) Repeat-Block Transfer Mode

Repeat-block transfer is the operation mode with the following functions added to the block transfer function.
Repeat function: Added function (ring buffer) to repeat specified address area.
Offset function: Multiple areas with offset can be specified within one block transfer.
The repeat function and the offset function can be used for both the transfer source and the transfer destination of repeat-block transfer. Figure 18.5 shows an example of adding a repeat function to the transfer destination. Figure 18.6 shows repeat-block transfer with an offset to the transfer destination. In repeat-block transfer mode, a single block data is transferred by one transfer request. A maximum of 1K data can be set as a total block transfer size using DMCRA register. A maximum of 64K can be set as the number of block transfer operations using DMCRB register; therefore, a maximum of 64M data (1K data × 64K counts of block transfer operations) can be set as a total data transfer size. Generation of a transfer end interrupt request after completion of the specified number of block-transfer operations is selectable.

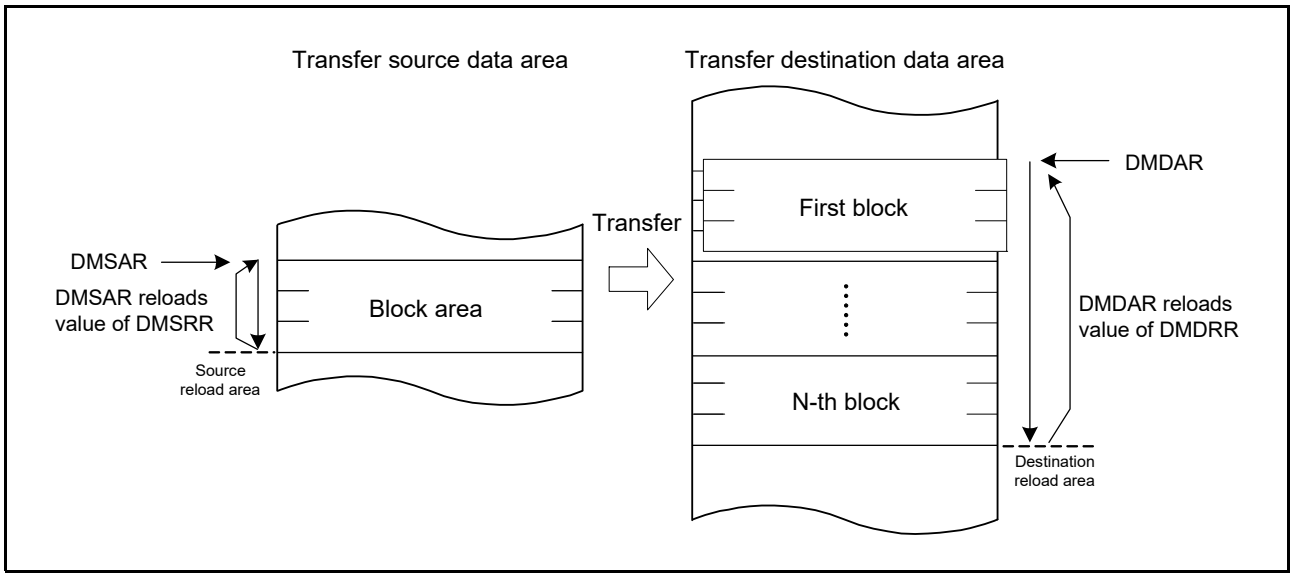

Figure 18.5 Operation Example in Repeat-Block Transfer Mode

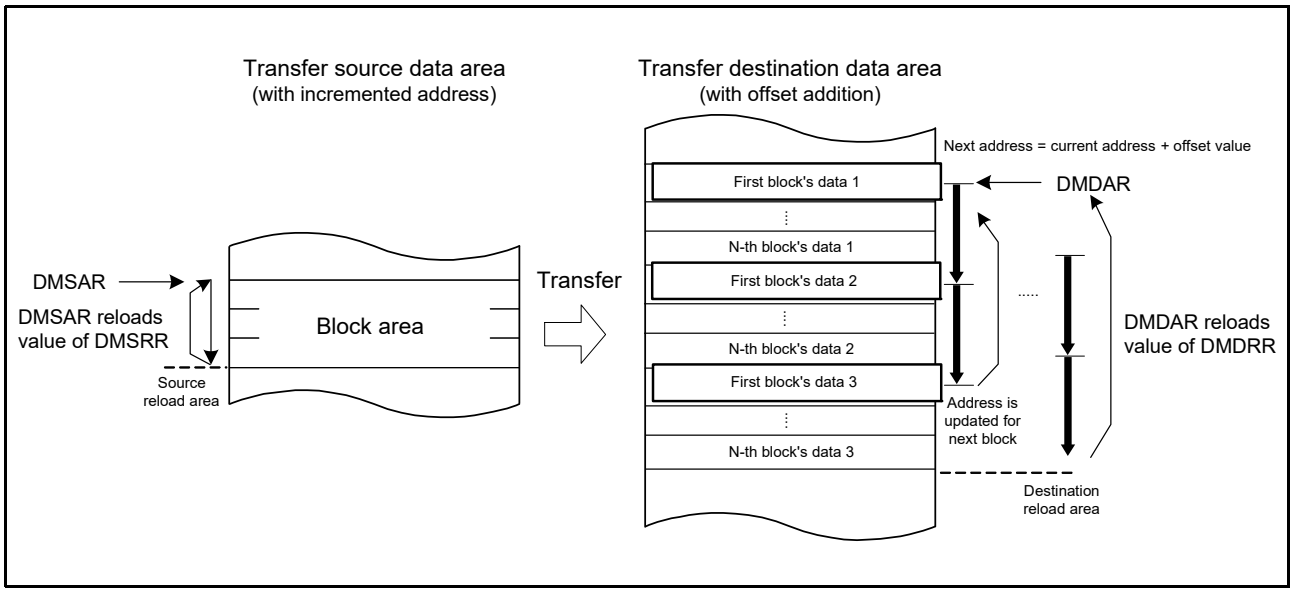

Figure 18.6 Operation Example in Repeat-Block Transfer Mode with Offset Addition

Table 18.8 to Table 18.13 list the register update operations in repeat-block transfer mode.

For more information about address update operation in repeat-block transfer mode, see section 18.3.5, Address-Update Function in Repeat-Block Transfer Mode.

18.3.2 Extended Repeat Area Function

The DMAC supports a function to specify the extended repeat areas on the transfer source and destination addresses. With the extended repeat areas set, the address registers repeatedly indicate the addresses of the specified extended repeat areas. The extended repeat areas can be specified separately to the transfer source address register (DMSAR) and transfer destination address register (DMDAR). The extended repeat area on the source address is specified by the DMAMD.SARA[4:0] bits. The extended repeat area on the destination address is specified by the DMAMD.DARA[4:0] bits. The size can be specified separately for the source and destination sides. However, the area (of transfer source or transfer destination) which is specified as the repeat area or block area should not be specified as the extended repeat area. When the address register value reaches the end address of the extended repeat area and the extended repeat area overflows, DMA transfer is stopped and an interrupt due to an extended repeat area overflow can be requested. When an overflow occurs in the extended repeat area on the transfer source while the DMINT.SARIE bit is set to 1, the DMSTS.ESIF flag is set to 1 and the DMCNT.DTE bit is set to 0 to stop DMA transfer. At this time, if the DMINT.ESIE bit is set to 1, an interrupt due to an extended repeat area overflow is requested. When the DMINT.DARIE bit is set to 1, the destination address register becomes a target to apply the function. DMA transfer can be resumed by writing 1 to the DMCNT.DTE bit in the interrupt handling. Figure 18.7 shows an example of the extended repeat area operation.

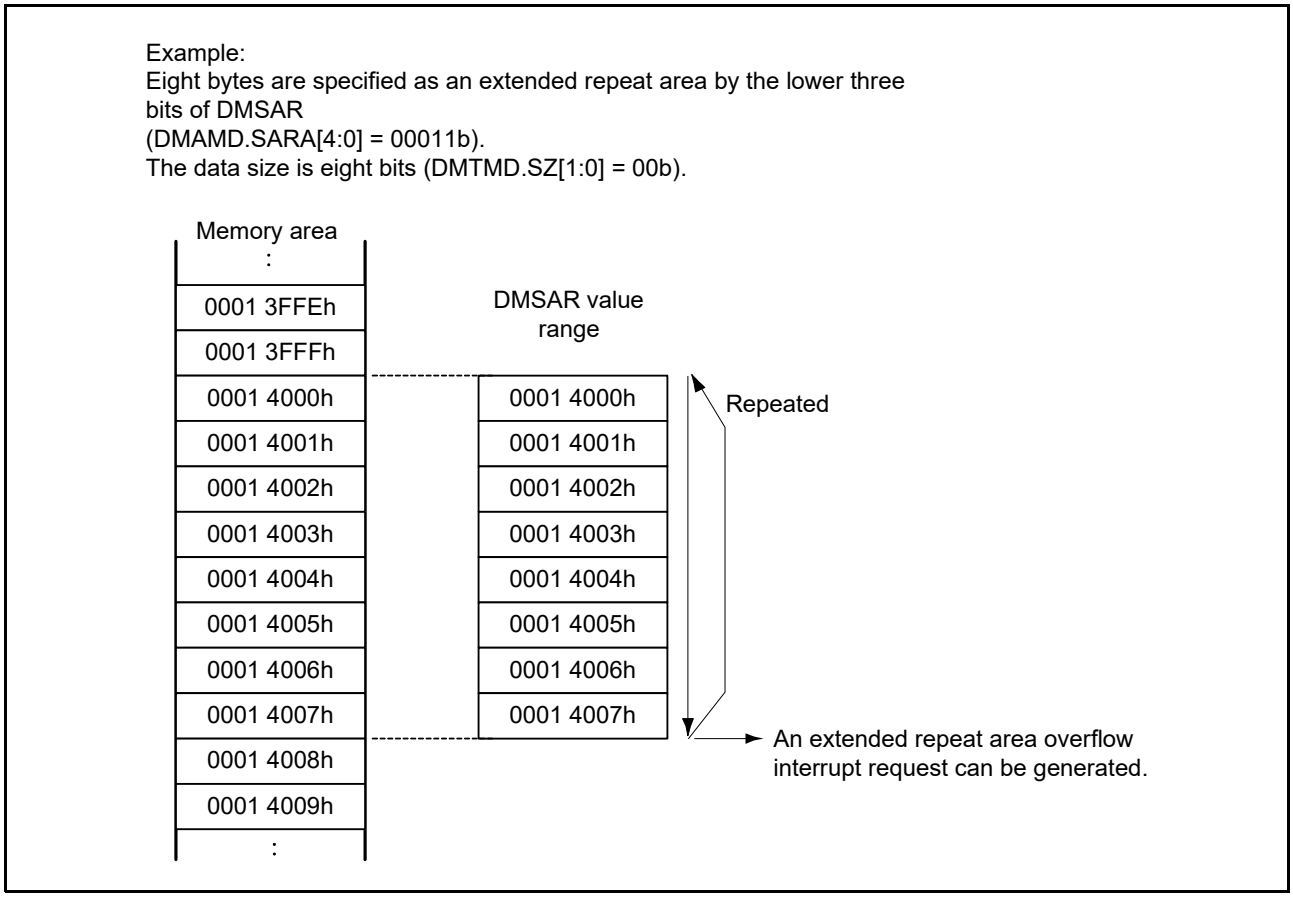

Figure 18.7 Example of Extended Repeat Area Operation

When an interrupt due to an extended repeat area overflow is used in block transfer mode, the following should be taken into consideration. When a transfer is stopped by an interrupt due to an extended repeat area overflow, the address register must be set so that the block size is a power of 2 or the block size boundary is aligned with the extended repeat area boundary. When an overflow on the extended repeat area occurs during a transfer of one block, the interrupt due to the overflow is suspended until transfer of the block is completed, and the transfer overruns. Figure 18.8 shows an example when the extended repeat area function is used in block transfer mode.

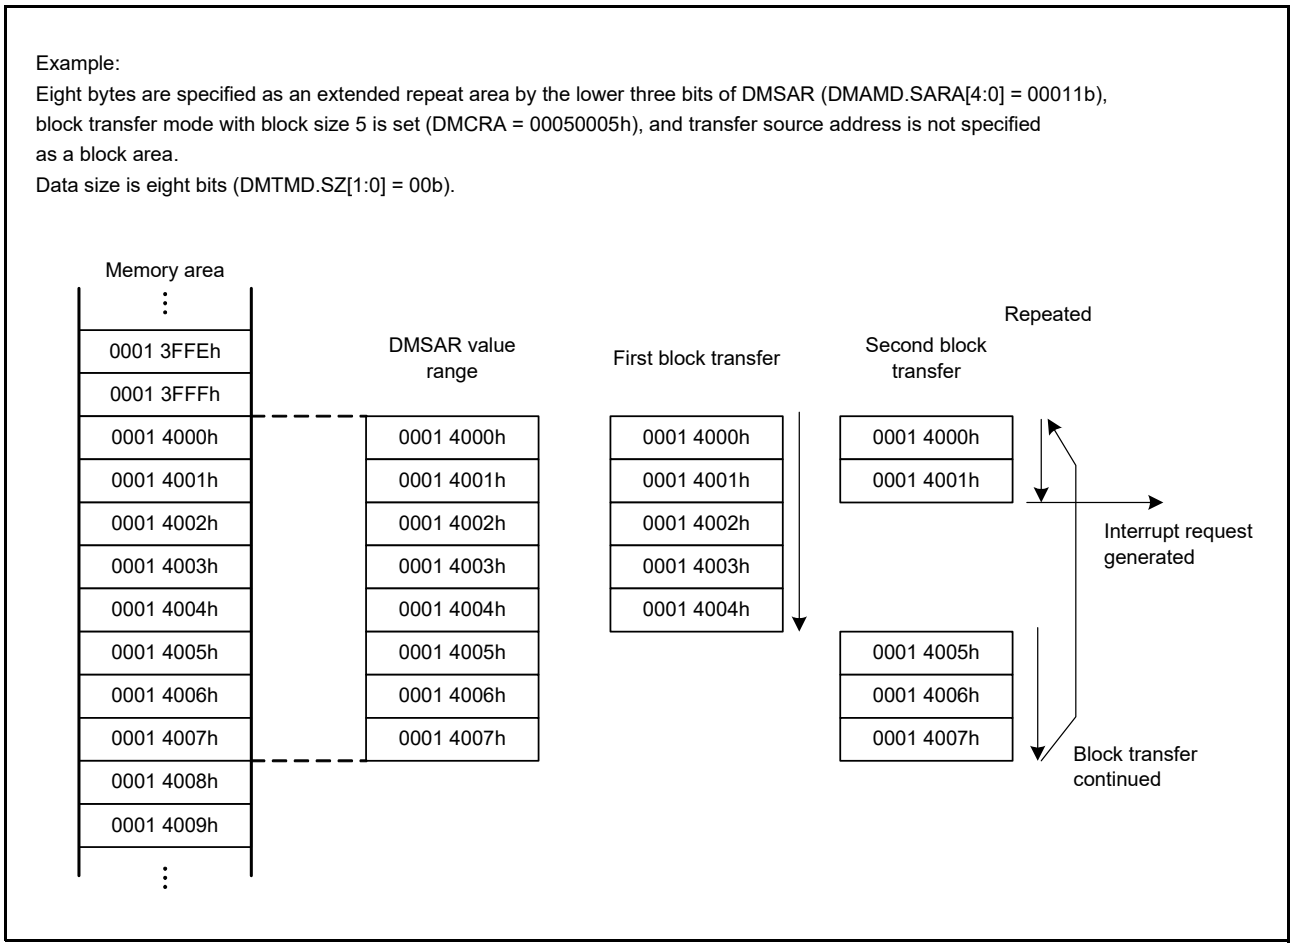

Figure 18.8 Example of Extended Repeat Area Function in Block Transfer Mode

18.3.3 Free-Running Function

The DMAC supports free-running function. This function allows to transfer repeatedly without reconfiguring in interrupt handler.

(1) In Normal Transfer Mode

In normal transfer mode, when DMCRA.DMCRAL[15:0] bits are set to 0000h, no specific number of transfer operations is set; data transfer is performed with the transfer counter stopped. For more information, see section 18.3.1, Transfer Mode.

(2) In Other Transfer Modes

In repeat, block and repeat-block transfer mode, the DMAC supports free-running function using the DMTMD.TKP bit. If the DMTMD.TKP bit is set to 1, the transfer is not stopped by completion of specified total number of transfer operations and the value of the DMCRBH[9:0] bits is reloaded repeatedly. Figure 18.9 shows an example of block transfer operation without free-running function.

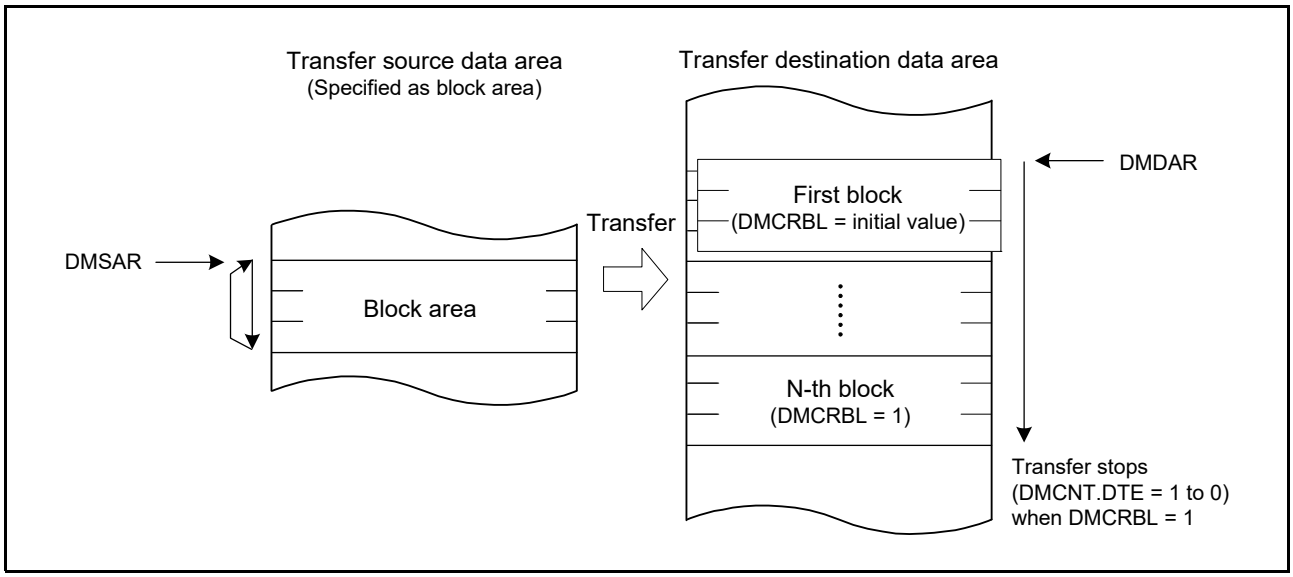

Figure 18.9 Operation in Block Transfer Mode with DMTMD.TKP = 0

Figure 18.10 shows an example of block transfer operation with free-running function.

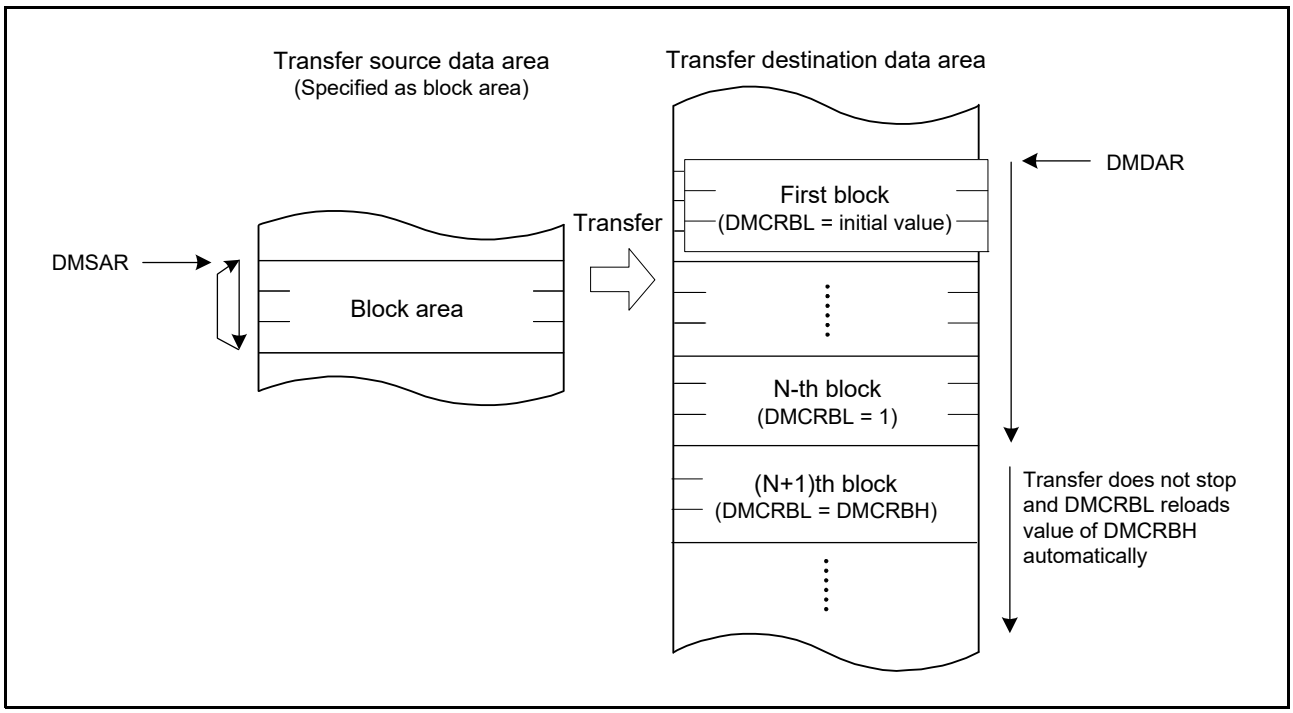

Figure 18.10 Operation in Block Transfer Mode with DMTMD.TKP = 1

18.3.4 Address Update Function using Offset

The source and destination addresses can be updated by fixing, increment, decrement, or offset addition. In normal, repeat and block transfer mode, when the offset addition is selected, the offset specified by the DMA offset register (DMOFR) is added to the address every time the DMAC performs one data transfer. This function realizes a data transfer where addresses are allocated to separated areas. Offset subtraction can also be realized by setting a negative value in DMOFR. In this case, the negative value must be 2's complement. DMSBS or DMDBS register are used instead of DMOFR register in repeat-block transfer mode. For more information, see section (4), Repeat-Block Transfer Mode and section 18.3.5, Address-Update Function in Repeat-Block Transfer Mode. Table 18.14 lists the address update method in each address update mode.

Table 18.14 Address Update Method in Each Address Update Mode

Address Update Mode	Settings of DMAMD.SM[1:0] and DMAMD.DM[1:0] for Address Update Modes	Address Update Method (for Different DMTMD.SZ[1:0] Settings)			
		SZ[1:0] = 00b	SZ[1:0] = 01b	SZ[1:0] = 10b	SZ[1:0] = 11b
Address fixed	00b	Fixed			
Offset addition	01b	+DMOFR*1			
Increment	10b	+1	+2	+4	+8
Decrement	11b	–1	–2	–4	–8

Note 1. When setting a negative value in the DMA offset register, the value must be 2's complement. The 2's complement is obtained by the following formula.
2's complement of a negative offset value = ~ (offset) + 1 (~: Bit inversion)

(1) Basic Transfer Using Offset Addition

Figure 18.11 shows an example of address updating using offset addition.

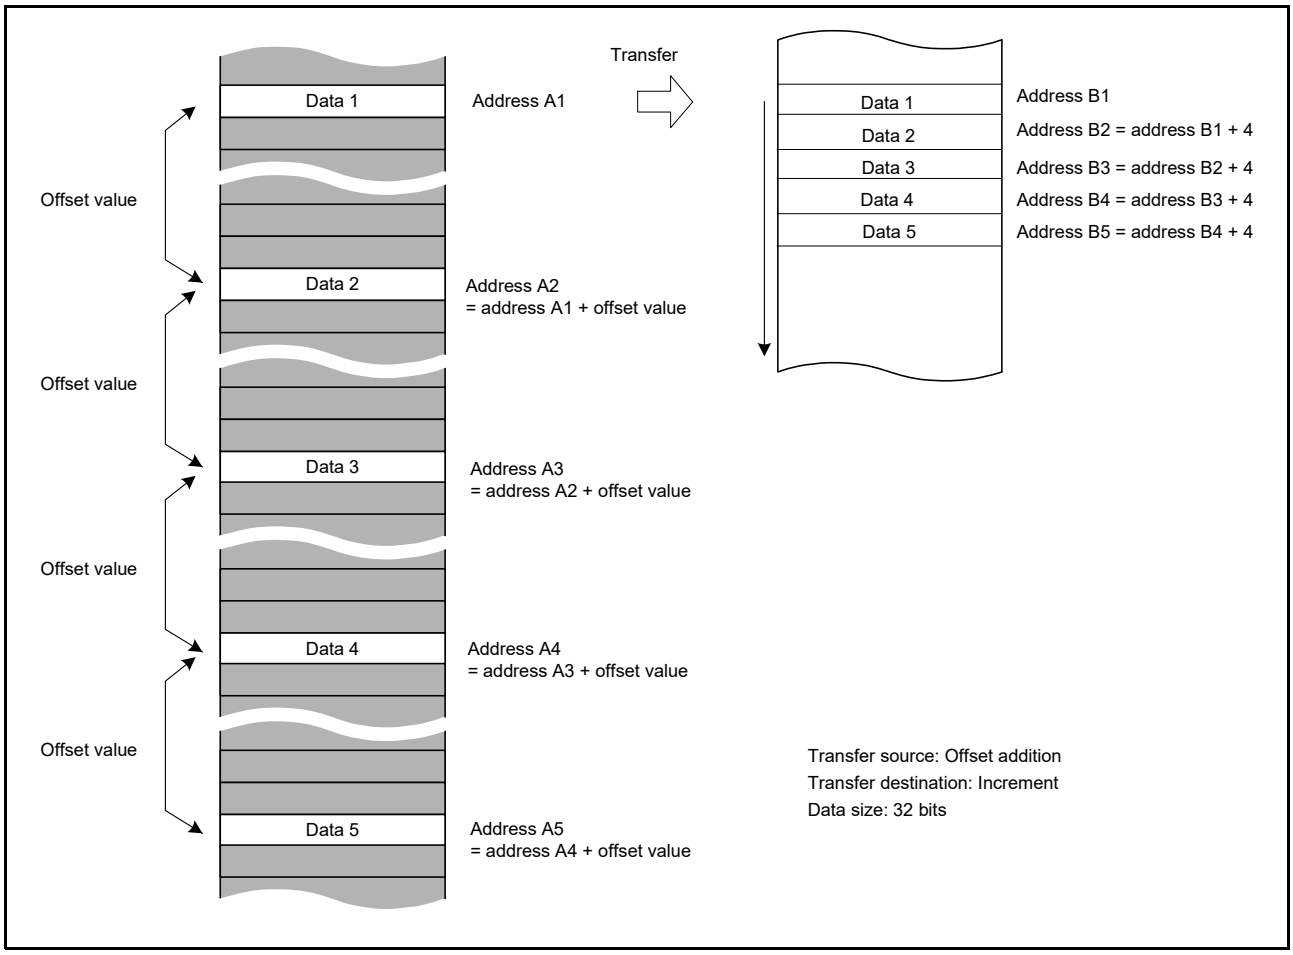

Figure 18.11 Example of Address Updating by Offset Addition

In Figure 18.11, the transfer data is 32 bits long, and offset addition and increment are set as the transfer source address update mode and transfer destination address update mode, respectively. The second and subsequent data is each read from the transfer source address obtained by adding the offset value to the previous address. The data read from the addresses at the specified intervals is written to the continuous locations on the destination.

(2) Example of XY Conversion Using Offset Addition

Figure 18.12 shows the XY conversion using offset addition in repeat transfer mode. Settings are as follows:

- DMAMD.SM[1:0]: Source address update mode select: Offset addition
- DMAMD.DM[1:0]: Destination address update mode select: Destination address is incremented.
- DMTMD.SZ[1:0]: Data transfer size: 32 bits
- DMTMD.MD[1:0]: Transfer mode select: Repeat transfer
- DMTMD.DTS[1:0]: Repeat area select: The source is specified as the repeat area.
- DMOFR: Offset address: 10h
- DMCRA.DMCRAH[9:0]: Repeat size: 4h
- DMINT.RPTIE: The repeat size end interrupt is enabled.

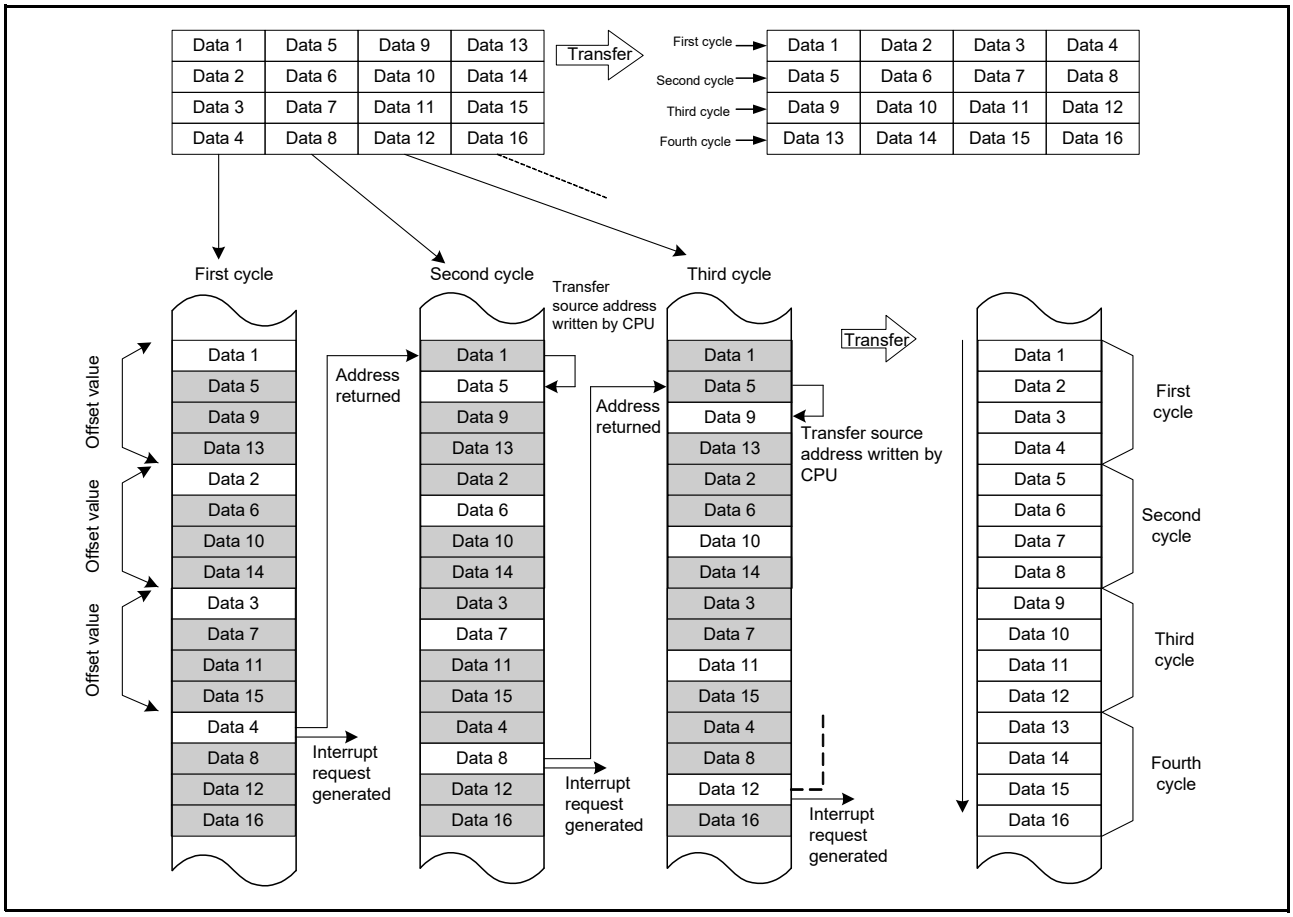

Figure 18.12 XY Conversion Operation Using Offset Addition in Repeat Transfer Mode

When a transfer starts, the offset value is added to the transfer source address every time data is transferred. The transfer data is written to the destination continuous addresses. When data 4 is transferred, which means that the repeat size of transfers is completed, the transfer source address returns to the transfer start address (address of data 1 on the transfer source) and a repeat size end interrupt is requested. While this interrupt stops the transfer temporarily, perform the following.

- DMSAR register: Rewrite the DMA transfer source address to the address of data 5 (with the above example, the data 1 address + 4).
- DMCNT register: Set the DTE bit to 1.

The DMA transfer is resumed from the state when the DMA transfer is stopped. After that, the operations described above are repeated until the transfer source data is transposed to the destination area (XY conversion).

Figure 18.13 shows a flowchart of the XY conversion.

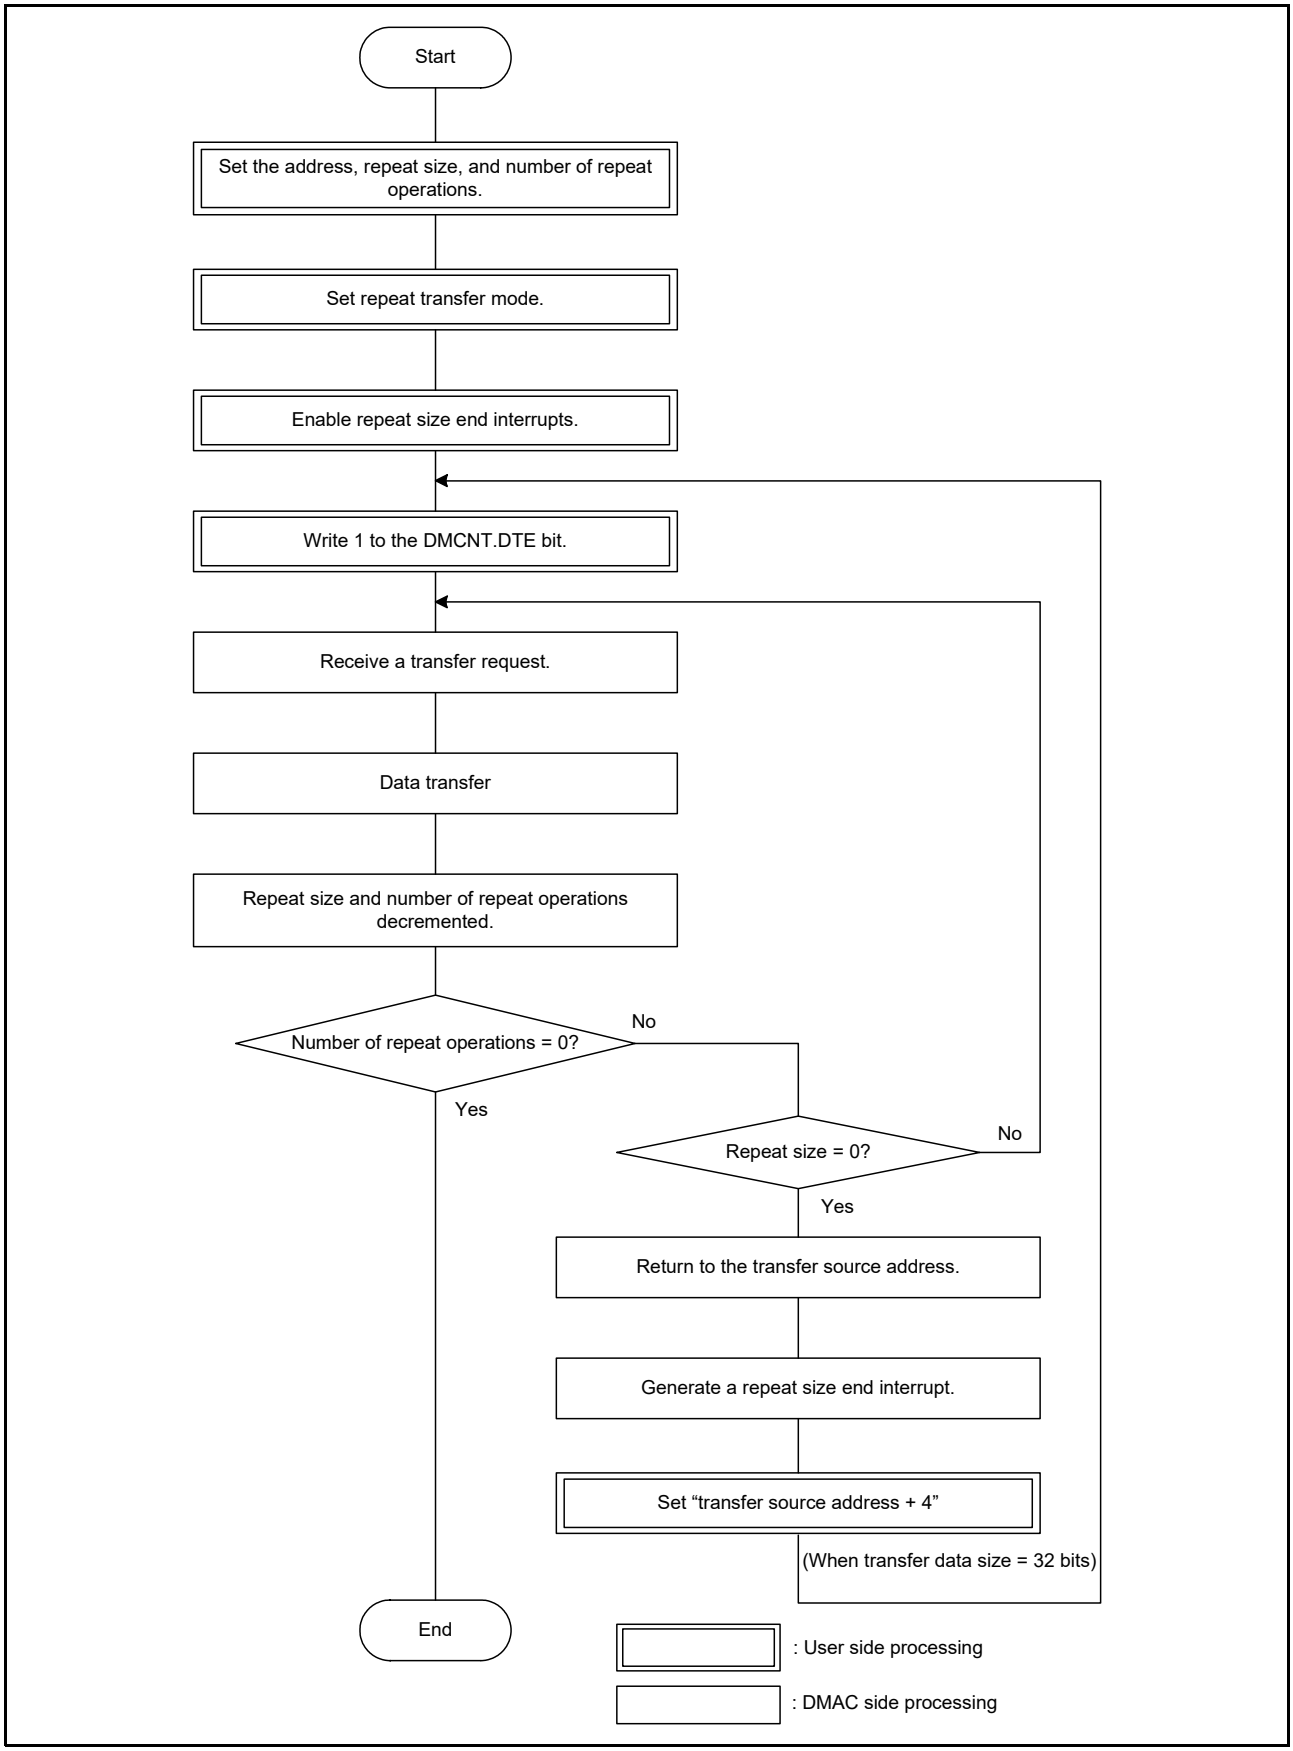

Figure 18.13 XY Conversion Flowchart Using Offset Addition in Repeat Transfer Mode

18.3.5 Address-Update Function in Repeat-Block Transfer Mode

The repeat-block transfer mode is an extension of repeat transfer mode and block transfer mode. However, the detailed behavior in address updating differs from the behavior in the two other modes. This section describes the address-update function in the repeat-block transfer mode.

(1) Fixed Address Mode

When DMAMD.SM[1:0] bits is set to 00b, the address update mode of the source is fixed address. And when DMAMD.DM[1:0] bits is set to 00b, the address update mode of the destination is fixed address. In fixed address, the address is not updated from the initial value of DMSAR and DMDAR registers. If the block size (DMCRA) is larger than 1, the same data will be transferred multiple times for one request. Figure 18.14 shows address update in fixed address.

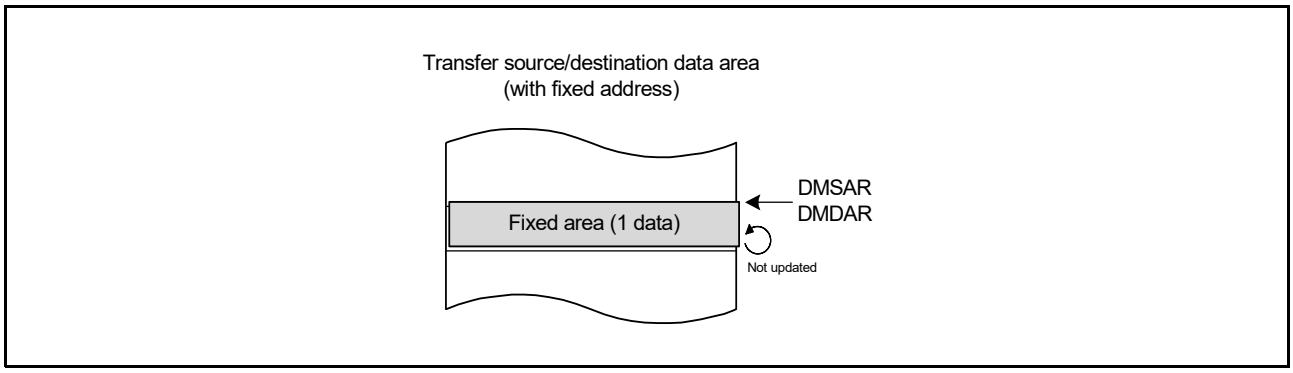

Figure 18.14 Address Update in Fixed Address

(2) Incremental and Decremental Address Mode

When DMAMD.SM[1:0] bits is set to 10b, the address update mode of the source is incremental address. And when DMAMD.DM[1:0] bits is set to 10b, the address update mode of the destination is incremental address. When DMAMD.SM[1:0] bits is set to 11b, the address update mode of the source is decremental address. And when DMAMD.DM[1:0] bits is set to 11b, the address update mode of the destination is decremental address. In these update modes, the address is incremented or decremented according to the setting of DMTMD.SZ[1:0] bits. In these update modes DMSBS and DMDBS registers indicates a reload area. The unit of DMSBS and DMDBS registers is “number of data”. At the start of transfer, DMSBSL and DMDBSL registers, which is the lower 16 bits of DMSBS and DMDBS registers, operates as a down counter and decrements each time one data transfer is performed. When the value becomes 1, DMSAR and DMDAR registers reloads the value of DMSRR and DMDRR registers. Figure 18.15 shows address update in incremental address.

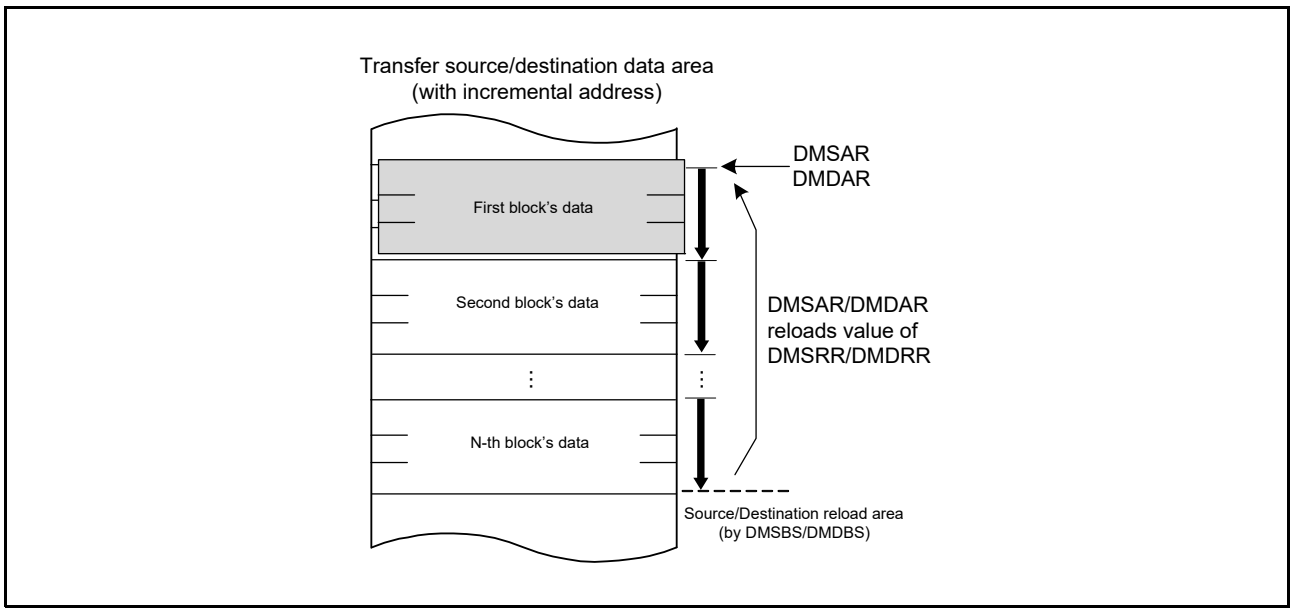

Figure 18.15 Address Update in Incremental Address

(3) Offset Addition Mode

When DMAMD.SM[1:0] bits is set to 01b, the address update mode of the source is offset addition. And when DMAMD.DM[1:0] bits is set to 01b, the address update mode of the destination is offset addition. In offset addition, DMSBS and DMDBS registers indicates reload area and also works as an access offset value. Unlike other transfer modes, DMOFR register is not used in repeat-block transfer mode. In offset addition, the unit of DMSBS and DMDBS registers is the number of blocks. When the transfer starts, DMCRAL[15:0] bits operates as a down counter, DMSAR and DMDAR registers reloads the value of DMSRR and DMDRR registers every time one block is transferred. In addition, DMSBSL[15:0] and DMDBSL[15:0] bits, which is the lower 16 bits of DMSBS and DMDBS registers, also operates as a down counter and decrements every time one block is transferred. When the DMSBS and DMDBS registers value becomes 1, DMSAR and DMDAR registers reloads the value of DMSRR and DMDRR registers. When DMAMD.SADR and DMAMD.DADR registers is set to 0, offset addition operation of the same area is repeated. DMDAR register only reloads DMDRR register. Figure 18.16 shows address update in offset addition with DMAMD.SADR and DMAMD.DADR = 0.

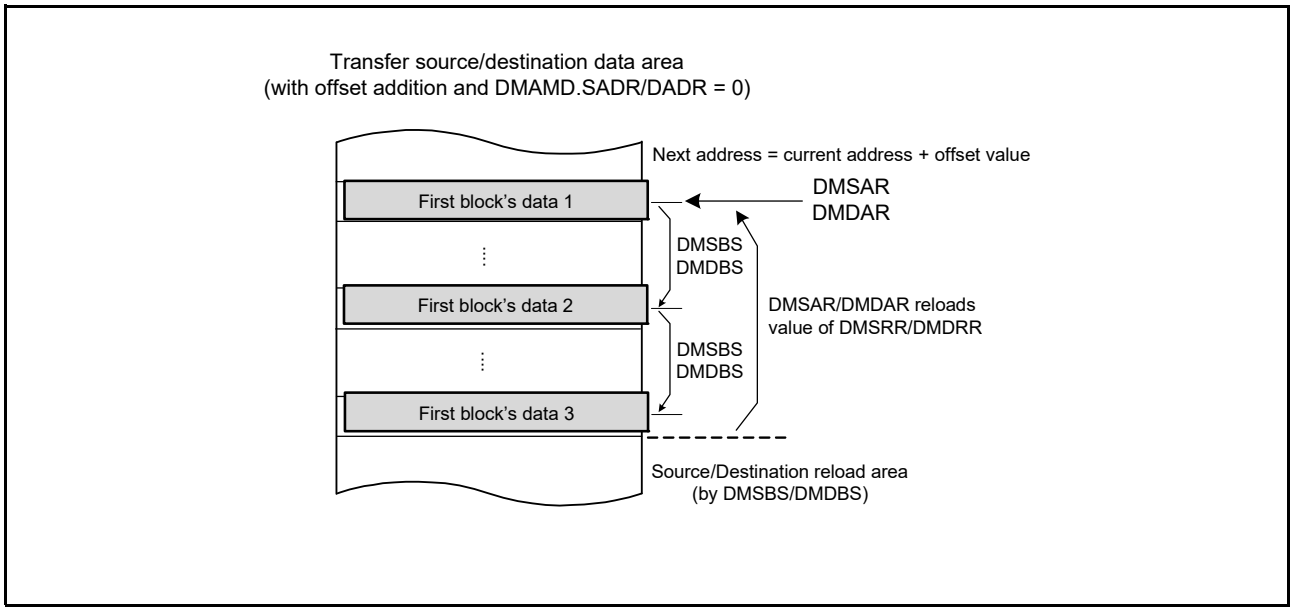

Figure 18.16 Address Update in Offset Addition with DMAMD.SADR and DMAMD.DADR = 0

When DMAMD.SADR and DMAMD.DADR bits is set to 1, the address is incremented by one data unit after DMSRR and DMDRR registers is reloaded by DMCRAL[15:0] = 1. In other words, an index value ((DMDBSH – DMDBSL) × transfer data size) is added to DMDAR after DMDRR is reloaded. This behavior is used to implement multiple ring buffers. Figure 18.17 shows address update in offset addition with DMAMD.SADR and DMAMD.DADR = 1.

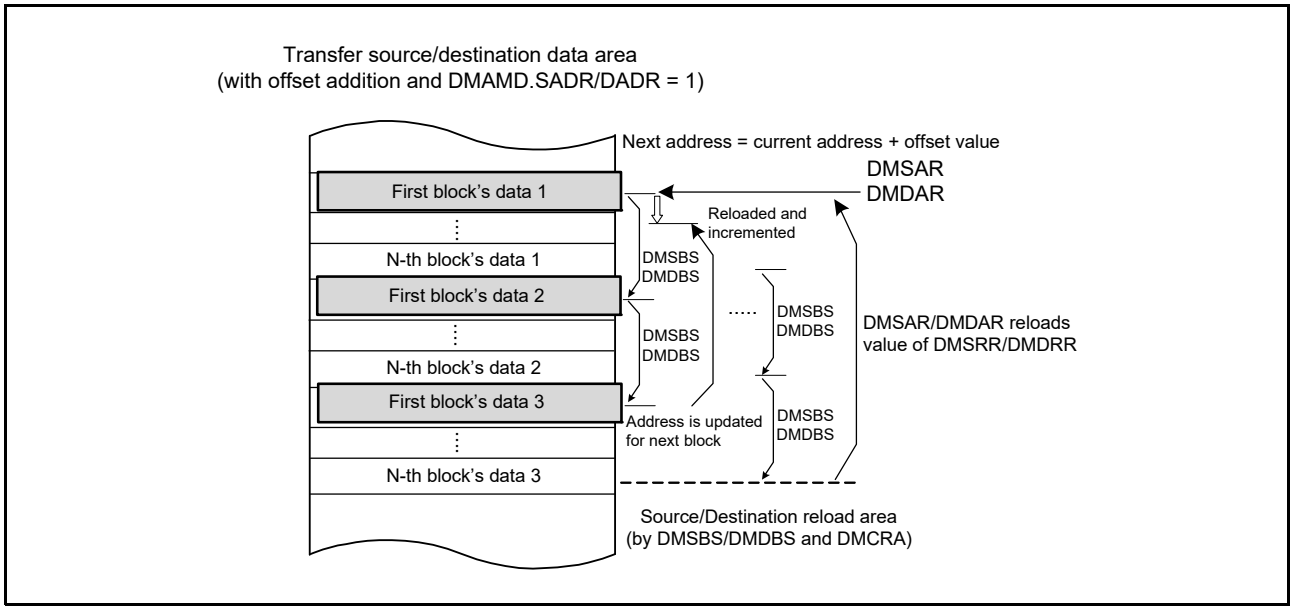

Figure 18.17 Address Update in Offset Addition with DMAMD.SADR and DMAMD.DADR = 1

18.3.6 Example of Using Repeat-Block Transfer Mode

In repeat-block transfer mode, it is possible to realize repeated access to interval data and single or multiple ring buffers by combining the above address update modes. Following sections shows some usage examples.

(1) Use Case Example: Interval Address to Single Ring Buffer

Figure 18.18 shows an example of reading interval ADDRn registers (data register) of ADC module and storing it in single ring buffer. It transfers 2 data every 4 words per 1 request. The value of DMSAR register is incremented by 1 data per 1 request. The following settings enable this: The transfer source is offset addition, DMAMD.SADR = 1, the block size (DMCRA) is 2, and the transfer source offset (DMSBS) is 4. Table 18.15 lists a setting example.

Table 18.15 Setting Example: Interval Address to Single Ring Buffer

Register	Value	Description
DMSAR, DMSRR	8743 A000h	Initial source address
DMDAR, DMDRR	8200 0000h	Initial destination address
DMTMD.SZ[1:0]	10b	Data size is word
DMAMD.SADR	1	Source address update setting after reload: Add index after reloading
DMAMD.SM[1:0]	01b	Source update mode is offset addition
DMAMD.DM[1:0]	10b	Destination update mode is increment
DMCRAH[9:0], DMCRAL[15:0]	2	Transfer block size
DMSBSH[15:0], DMSBSL[15:0]	4	Source whole buffer size (unit is ‘blocks’) and Source access offset (unit is ‘data’)
DMDBSH[15:0], DMDBSL[15:0]	N × 2 (DMCRA)	Destination buffer size (unit is ‘data’)

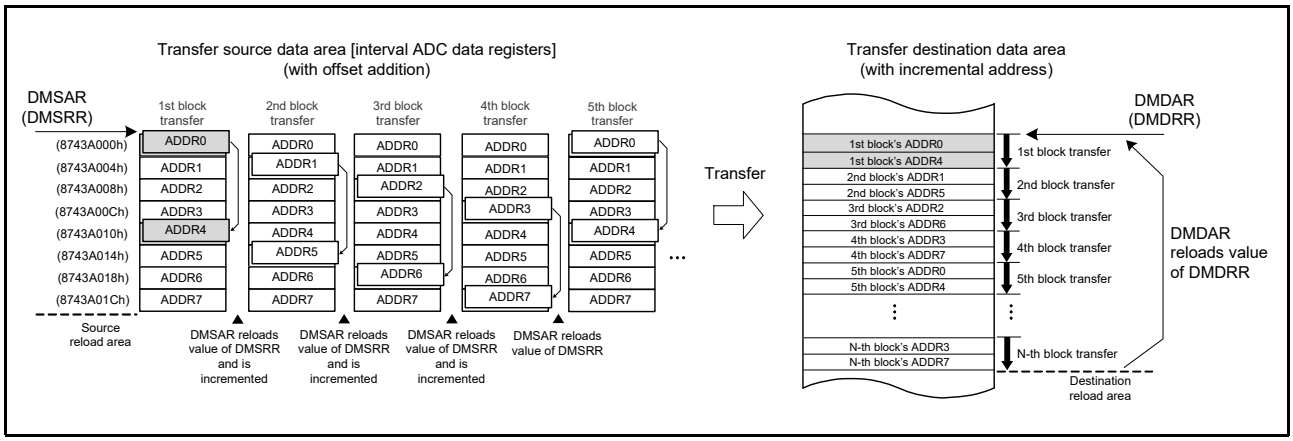

Figure 18.18 Use Case Example: Interval Address to Single Ring Buffer

(2) Use Case Example: Single Block to Multiple Ring Buffer

Figure 18.19 shows an example of storing the continuous ADDRn registers (data register) of ADC module individually in multiple ring buffers. In this example, a ring buffer in which only the first element (ADDR0) in a single block is arranged in transfer order is created at the destination. Also, in the next area, a ring buffer in which only the second element (ADDR1) is arranged in transfer order is created at the destination. In the following case, a ring buffer of length N defined by DMDBS register is created. The number of data elements in the block is 3, which is defined by DMCRA register. Table 18.16 lists a setting example.

Table 18.16 Setting Example: Single Block to Multiple Ring Buffer

Register	Value	Description
DMSAR, DMSRR	8743 A000h	Initial source address
DMDAR, DMDRR	8200 0000h	Initial destination address
DMTMD.SZ[1:0]	10b	Data size is word
DMAMD.SADR	0	Source address update setting after reload: Only reloading
DMAMD.DADR	1	Destination address update setting after reload: Add index after reloading
DMAMD.SM[1:0]	10b	Source update mode is increment
DMAMD.DM[1:0]	10b	Destination update mode is increment
DMCRAH[9:0], DMCRAL[15:0]	3	Transfer block size
DMSBSH[15:0], DMSBSL[15:0]	3	Source buffer size (unit is ‘data’)
DMDBSH[15:0], DMDBSL[15:0]	N	Destination whole buffer size (unit is ‘blocks’) and Destination access offset (unit is ‘data’)

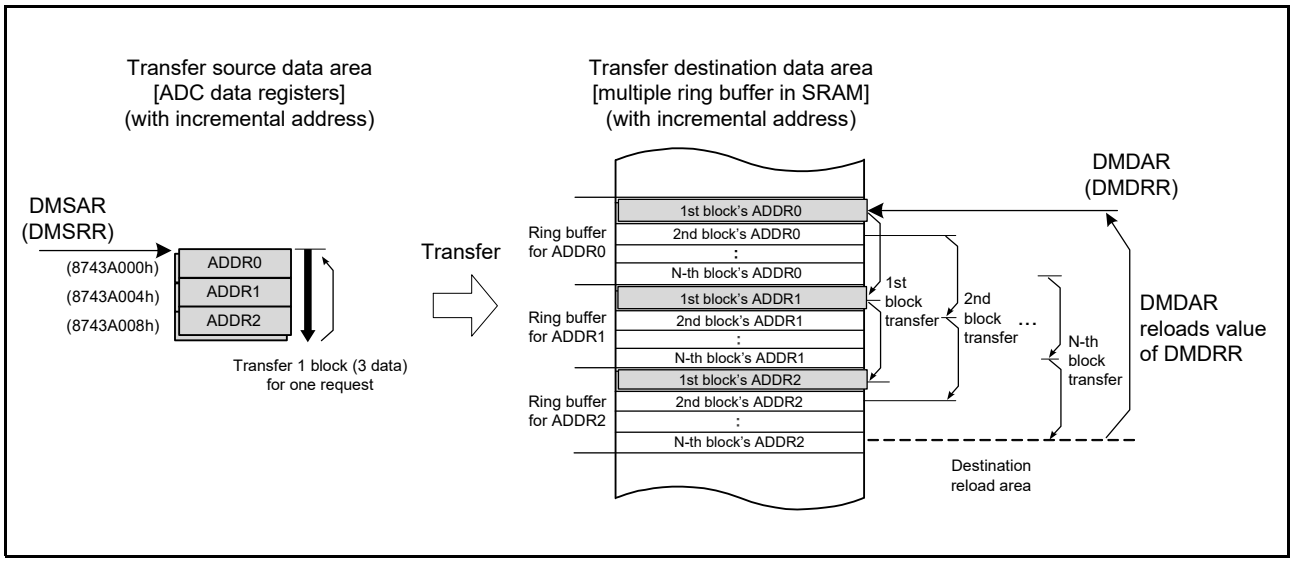

Figure 18.19 Use Case Example: Single Block to Multiple Ring Buffer

18.3.7 Trigger Sources

Software, the interrupt requests from the peripheral modules, and the external interrupt requests can be specified as the DMAC trigger sources. Setting the DMTMD.DCTG[1:0] bits selects the trigger source.

(1) Trigger by Software

When DMA transfer is started by software, follow below procedure.

1. Set the DMTMD.DCTG[1:0] bits to 00b.
2. Set the DMCNT.DTE bit to 1 (DMA transfer is enabled).
3. Set the DMAST.DMST bit set to 1 (DMAC activation enabled).
4. Set the DMREQ.SWREQ bit to 1 (DMA requested).

When the DMAC is activated by software while the DMREQ.CLRS bit is 0, the DMREQ.SWREQ bit is cleared to 0 after data transfer is started in response to a DMA transfer request. When the DMAC is activated by software while the CLRS bit is 1, the SWREQ bit is not cleared to 0 after data transfer is started. In this case, a DMA transfer request is issued again after completion of a transfer.

(2) Trigger by Interrupt Request

You can specify interrupt requests from on-chip peripheral modules and external interrupt requests as DMAC trigger sources. The trigger sources can be selected individually for each channel in the ICU.DMRSRm register (m = 0 to 7). To start DMA transfer through an interrupt request from an on-chip peripheral module or an external interrupt request, follow the procedures as indicated below.

1. Set the ICU.DMRSRm register (m = 0 to 7) bits to the event number, and then clear the corresponding IR flag.
2. Set the DMTMD.DCTG[1:0] bits to 01b (interrupts from the peripheral modules and the external interrupt pins).
3. Set the DMCNT.DTE bit to 1 (enable DMA transfer).
4. Set the DMAST.DMST bit to 1 (DMAC activation enabled).
5. Set the IERi.IENj bit to 0 so that the corresponding interrupt is enabled.

For interrupt requests specified as DMAC trigger sources, see Table 15.6, Interrupt Vector Table, Table 15.3, Interrupt Sources for Software Configurable Interrupt in section 15, Interrupt Controller (ICUM).

18.3.8 Operation Timing

Figure 18.20 and Figure 18.21 show DMAC operation timing examples.

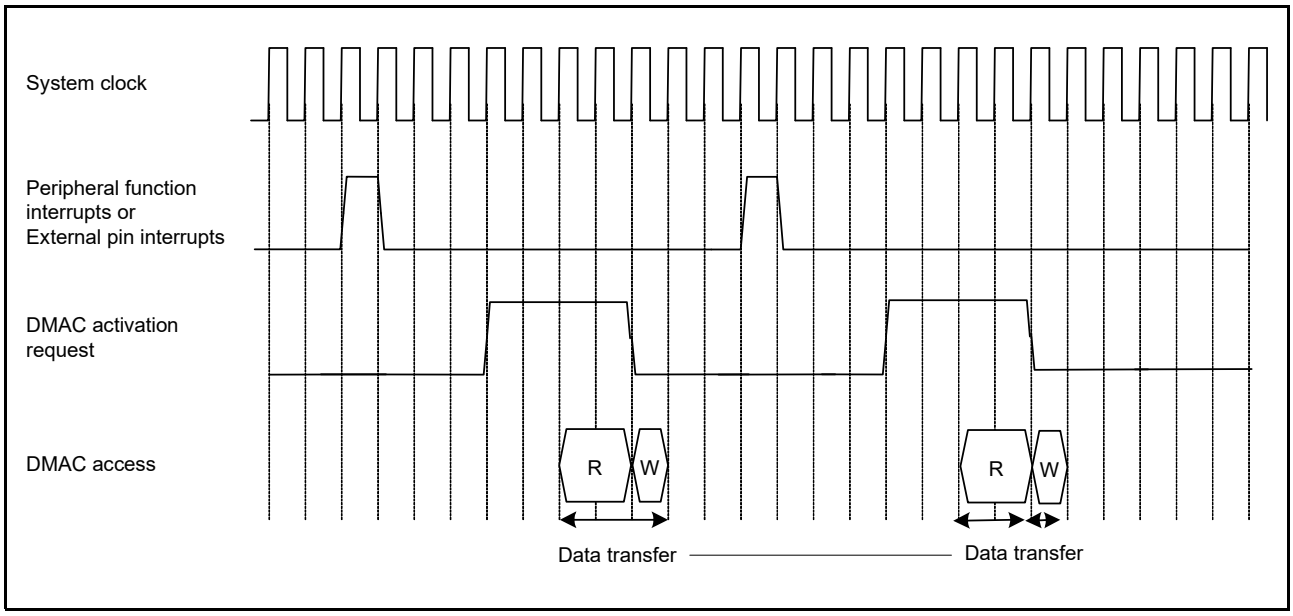

Figure 18.20 DMAC Operation Timing Example (1) (Trigger by Interrupt from Peripheral Module/External Interrupt Input Pin, Normal Transfer Mode, Repeat Transfer Mode)

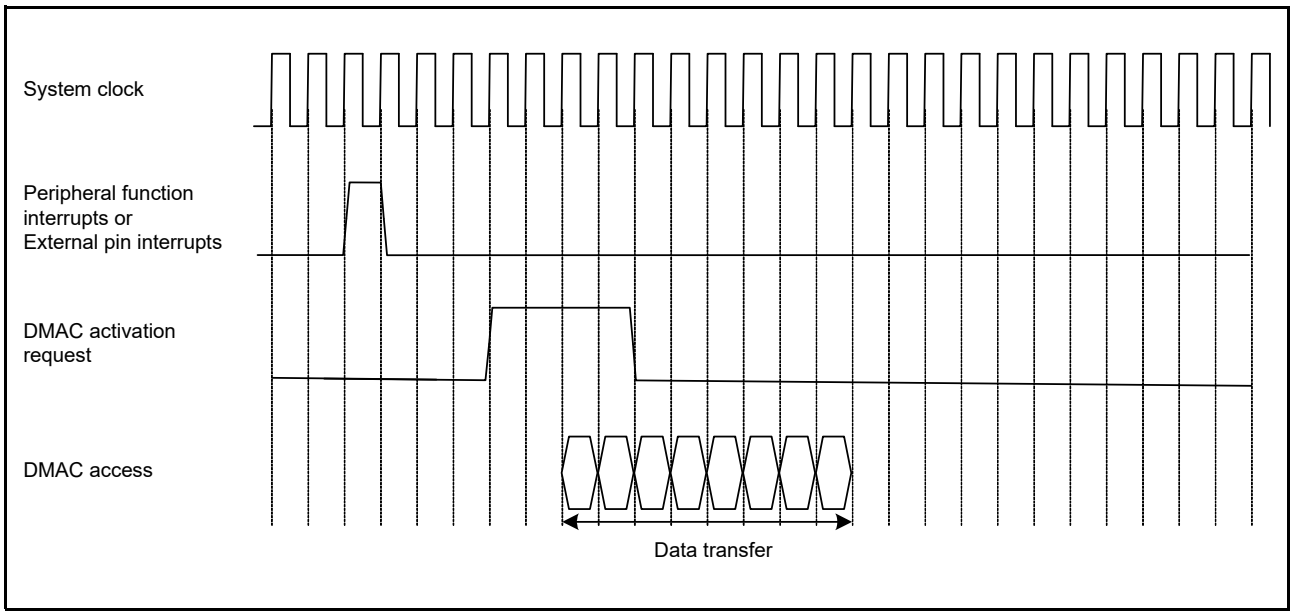

Figure 18.21 DMAC Operation Timing Example (2) (Trigger by Interrupt from Peripheral Module/External Interrupt Input Pin, Block Transfer Mode, Block Size = 4)

18.3.9 Activating the DMAC

Table 18.17 lists the register setting procedure of normal, repeat and block transfer mode and Table 18.18 lists register setting procedure of repeat-block transfer mode.

Table 18.17 Register Setting Procedure of Normal Transfer Mode, Repeat Transfer Mode and Block Transfer Mode

No.	Step Name	Description
1	Disable the peripheral function as the DMAC trigger source.	To use peripheral function interrupts as DMAC trigger sources. Disable the control register for the peripheral function.
2	Disable the IRQn pin as the DMAC trigger source.	To use external pin interrupts as DMAC trigger sources.
3	Clear the ICU.IERi.IENj bit corresponding to the interrupt vector number for the DMAC trigger	Disable the interrupt trigger for the DMAC
4	Clear the DMCNT.DTE bit to 0	Disable DMA transfer.
5	Set the interrupt source as a DMAC trigger source to the DMRSRm register by using the Interrupt Controller Unit	To use internal peripheral interrupts or external pin interrupts as DMAC trigger sources. Enable the interrupt bit for the trigger source. Set the DMAC trigger source.
6	Set the peripheral module as a DMAC trigger source	To use peripheral function interrupt as a DMAC trigger source. Set the control register for the peripheral function.
7	Set the IRQn pin function by using the Interrupt Controller Unit.	To use external pin interrupt as a DMAC trigger source. Set the IRQn pin function by using the Interrupt Controller Unit.
8	Set the DMAMD.DM[1:0] bits Set the DMAMD.SM[1:0] bits Set the DMAMD.DARA[4:0] bits Set the DMAMD.SARA[4:0] bits	Set the Destination address update mode select bits Set the Source address update mode select bits Set the Destination address extended repeat area setting bits Set the Source address extended repeat area setting bits
9	Set the DMTMD.DCTG[1:0] bits Set the DMTMD.SZ[1:0] bits Set the DMTMD.DTS[1:0] bits Set the DMTMD.MD[1:0] bits Set the DMTMD.TKP bit	Set the Transfer request source select bits Set the Data transfer size bits Set the Repeat area select bits Set the Transfer mode select bits Set the Transfer keeping bit
10	Set the DMSAR register Set the DMDAR register Set the DMCRA register	Set the transfer source start address. Set the transfer destination start address. Set the number of transfer operations.
11	Set the DMCRB register	To use block transfer mode or repeat transfer mode. Set the number of block transfer operations.
12	Set the DMOFR register	To use the address update function with offset. Set the offset value.
13	Set the DMINT.DTIE bit to 1	To use the transfer end interrupts. Enable the transfer end interrupts.
